Step 3. Finally, we can conclude that $\boldsymbol{\zeta} \in \boldsymbol{H}_\times^{\min\{\sigma^- - \frac{1}{2}, \sigma^+ - \frac{1}{2}, \frac{1}{2}\}}(\mathrm{div}_\Gamma, \Gamma)$. On a polyhedron we can take for granted that either $\sigma^- < 1$ or $\sigma^+ < 1$. This gives us

$$\boldsymbol{\zeta} \in \boldsymbol{H}_\times^{\min\{\sigma^-, \sigma^+\} - \frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma).$$

Besides, we have already seen that $\mathbf{p} = \mathsf{M}\boldsymbol{\zeta} \in \boldsymbol{H}_\times^{\min\{\alpha,1\}}(\mathrm{div}_\Gamma, \Gamma)$.

Now we can employ the best approximation estimates for div_Γ-conforming elements from Lemma 5.1 and Theorem 5.4 and get quantitative asymptotic convergence estimates.

THEOREM 6.3. *If we rely on $\boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$-conforming boundary elements for the discretization of both $\boldsymbol{\zeta}$ and $\mathbf{p}$, we are guaranteed to get*

$$\|\boldsymbol{\zeta} - \boldsymbol{\zeta}_h\|_{\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)} + \|\mathbf{p} - \mathbf{p}_h\|_{\boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)} \leq C(h^{\min\{\sigma^+, \sigma^-\}} + h^{\min\{\alpha,1\}}),$$

with a constant $C > 0$ independent of the meshwidth h, but may depend upon the wave number k.

REMARK 7. *Since we are solving an indirect boundary integral equation, it is not surprising that the convergence is limited by singularities of both the interior and the exterior Maxwell problem. On the other hand, the main observation is that one can always have $\alpha > 1$ since it is enough to split nonconvex faces into convex ones. Thus, the rate of convergence is not affected by the introduction of the auxiliary unknown $\mathbf{p}$; i.e., $\mathbf{p}$ is always much more regular than the primal unknown $\boldsymbol{\zeta}$.*

REMARK 8. *The above estimate relies on global regularity of the exact solutions. However, we know that $\boldsymbol{\zeta}$ is a combination of traces of Maxwell solutions. Besides, $\mathbf{p}$ emerges as patched-together solutions of Dirichlet boundary value problems for Δ_Γ on the flat faces. In both cases, results on singularities of solutions of boundary value problems on nonsmooth domains reveal much detail about the behavior of $\boldsymbol{\zeta}$ and $\mathbf{p}$ close to edges and corners. We can make use of this knowledge in order to obtain significantly faster convergence on meshes that feature algebraically graded refinement towards the edges of Γ [2, 11]. In this case, making use again of the regularity of $\mathbf{p}$, one might need only to "resolve" the singularities of $\boldsymbol{\zeta}$ by mesh grading. The use of different meshes, on which $\boldsymbol{\zeta}$ and $\mathbf{p}$ are approximated, seems to be advisable in this case; cf. Remark* 3.

ERROR ESTIMATES TO SMOOTH SOLUTIONS OF RUNGE–KUTTA DISCONTINUOUS GALERKIN METHODS FOR SCALAR CONSERVATION LAWS*

QIANG ZHANG† AND CHI-WANG SHU‡

Abstract. In this paper we study the error estimates to sufficiently smooth solutions of scalar conservation laws for Runge–Kutta discontinuous Galerkin (RKDG) methods, where the time discretization is the second order explicit total variation diminishing (TVD) Runge–Kutta method. Error estimates for the $\mathbb{P}^1$ (piecewise linear) elements are obtained under the usual CFL condition $\tau \le \gamma h$ for general nonlinear conservation laws in one dimension and for linear conservation laws in multiple space dimensions, where h and τ are the maximum element lengths and time steps, respectively, and the positive constant γ is independent of h and τ. However, error estimates for higher order $\mathbb{P}^k (k \ge 2)$ elements need a more restrictive time step $\tau \le \gamma h^{4/3}$. We remark that this stronger condition is indeed necessary, as the method is linearly unstable under the usual CFL condition $\tau \le \gamma h$ for the $\mathbb{P}^k$ elements of degree $k \ge 2$. Error estimates of $O(h^{k+1/2} + \tau^2)$ are obtained for general monotone numerical fluxes, and optimal error estimates of $O(h^{k+1} + \tau^2)$ are obtained for upwind numerical fluxes.

Key words. discontinuous Galerkin, finite element, total variation diminishing Runge–Kutta method, error estimates

1. Introduction.

In this paper, we present error estimates for the Runge–Kutta discontinuous Galerkin (RKDG) methods with smooth solutions of scalar conservation laws:

$$\partial_t u + \sum_{i=1}^{d} \partial_{x_i} f_i(u) = 0, \quad (x,t) \in \Omega \times (0, T^\star), \tag{1.1a}$$

$$u(t=0) = u_0, \quad x \in \Omega; \tag{1.1b}$$

here $x = (x_1, \ldots, x_d)$ and $f(u) = (f_1(u), \ldots, f_d(u))$. We do not pay attention to boundary conditions in this paper; hence the solution is considered to be either periodic or compactly supported. For simplicity of presentation, in most cases we will only give detailed analysis for the one-dimensional case; i.e., $\Omega = I = (0,1)$ is the unit interval. We will, however, point out any differences, both in the analysis and in the results, for the multidimensional cases. We assume that the flux $f(u)$ is smooth in the variable u; for example, $f \in C^3$ is enough. The analysis in this paper is for *smooth* solutions of (1.1). Discontinuous solutions with shocks are not considered.

The so-called RKDG method is introduced and developed by Cockburn and Shu [9, 8, 10], Cockburn, Lin, and Shu [7], and Cockburn, Hou, and Shu [6] for nonlinear

hyperbolic conservation laws, which uses DG discretization in space and combines it with an explicit total variation diminishing (TVD) Runge–Kutta time-marching algorithm [21]. In this paper, we concentrate on a second order TVD Runge–Kutta time discretization given in [21]. In practice, the third order TVD Runge–Kutta time discretization given in [21] is more popular, because of its higher order accuracy in time and better linear stability properties. However, the extension of the results in this paper to this third order TVD Runge–Kutta time discretization case is highly nontrivial, and this is still being investigated as an ongoing project.

In this paper, with the second order TVD Runge–Kutta time discretization and for $\mathbb{P}^k$ element space of piecewise kth degree polynomials, the a priori estimate in the usual $L^2(I)$-norm of the form

$$||u(t^n) - u_h^n||_{L^2(I)} \le C(h^{k+\sigma} + \tau^2), \quad \text{for any } t^n = n\tau \le T^\star, \tag{1.2}$$

is obtained, with $\sigma = 1/2$ for arbitrary monotone numerical fluxes and $\sigma = 1$ for the one-dimensional nonlinear case and for multidimensional tensor product ($\mathbb{P}^k$ replaced by $\mathbb{Q}^k$, the tensor product of one-dimensional degree k piecewise polynomials, in rectangular elements) linear cases when upwind numerical fluxes are used in the scheme. Here u_h^n denotes the numerical solution at the nth time level. The error estimates (1.2) for the $\mathbb{P}^1$ (piecewise linear) elements are obtained under the usual CFL condition $\tau \le \gamma h$ for general nonlinear conservation laws in one dimension and for linear conservation laws in multiple space dimensions, where h and τ are the maximum element lengths and time steps, respectively, and the positive constant γ is independent of h and τ. For the $\mathbb{P}^k$ elements with degree $k \ge 2$, a more restrictive time-step condition $\tau \le \gamma h^{4/3}$ is needed for the error estimates. We remark that this stronger condition is indeed necessary as the method is linearly unstable under the usual CFL condition $\tau \le \gamma h$ for the $\mathbb{P}^k$ elements of degree $k \ge 2$; see [12]. Here the positive constant C in (1.2) is independent of n, h, τ, and the numerical solution.

We now mention related results on error estimates of the DG methods in the literature. For smooth solutions of linear conservation laws, optimal a priori error estimates ($O(h^{k+1})$ for one-dimensional and some multidimensional cases and $O(h^{k+\frac{1}{2}})$ for other cases) have been given for the steady state solution or for a fully DG discretization by using space-time finite element spaces in, e.g., [17], [20], and [15], with the optimality in the general cases being proven in [19], and for the semidiscrete (continuous in time) DG method in [11]. For nonsmooth solutions of nonlinear conservation laws, Jiang and Shu [14] have proven a cell entropy inequality for the semidiscrete DG method for the square entropy, which implies that the numerical solutions, *if convergent*, will converge to an entropy solution of (1.1). Also, for nonsmooth solutions of nonlinear conservation laws, Cockburn et al. have proven an error estimate of order $O(h^{1/4})$ in the $L^1(\Omega)$-norm for the $\mathbb{P}^0$ (piecewise constant) finite element space, which is then a monotone finite volume scheme, and for higher order $\mathbb{P}^k$ elements but with additional "shock capturing" terms added to the method; see, e.g., [4]. Their result can be improved to $O(h^{1/2})$ if a uniform upper bound for the total variation can be found, which is the case for the explicit Lax–Friedrichs scheme defined on equilateral triangles [5]. Recently, there have also been works on the a posteriori error estimates; for example, see Adjerid et al. [1]. We have not attempted to address a posteriori error estimates in this paper.

We note that, unlike the semidiscrete or space-time DG methods, to the best of our knowledge there have been no high order error estimates for the RKDG methods in the literature up to now, even for linear problems. The results in this paper are thus

the first attempt to obtain optimal error estimates for the smooth solutions of RKDG methods. The main difficulty of the error estimates is the hybriding of a finite element spatial discretization with an explicit Runge–Kutta time stepping. For finite difference methods, such error estimates are typically obtained by combining local truncation error estimates with stability for linear PDEs and by using Strang's technique [22], which uses linear stability plus dissipation of the scheme and the smoothness of the solution to obtain error estimates for nonlinear PDEs. Unfortunately, such techniques rely heavily on the local truncation error being the same order as the global error, and hence they cannot be easily applied here to obtain optimal error estimates, because the DG spatial discretization, when viewed as a finite difference approximation, has a local truncation error which is lower order than the global error, which is the so-called supraconvergence phenomenon [16, 24]. The main techniques we use in this paper are Taylor expansion and energy estimates as in [23], which considers linear continuous finite elements and obtains error estimates under the rather restrictive time-step condition $\tau \le \gamma h^{4/3}$. We consider DG rather than continuous finite elements and are able to remove this restriction and replace it by the more natural condition $\tau \le \gamma h$ for linear finite elements. We would like to mention that the DG method is more complicated to analyze than the continuous finite element methods in this context, due to the extra interelement boundary terms. We would also like to mention in particular that the a priori assumption about the numerical solution is subtle, which plays an important role in the proof for the nonlinear cases; see section 5.

An overview of this paper is as follows. In section 2 we present the RKDG method with the second order TVD Runge–Kutta time discretization for the considered problem (1.1). In section 3 we introduce an important quantity related to the numerical flux and present the convergence theorem. In section 4, we derive the error equations of the RKDG scheme and a key lemma for the error estimates. We then prove the main result for general monotone numerical fluxes and for upwind numerical fluxes in section 5. Some of the more technical proofs of several lemmas are collected in the appendix.

2. RKDG method. We follow [8] and define the RKDG method for the problem (1.1) in one space dimension. The multidimensional case is similar. For each partition of the interval $I = (0,1)$, $\{x_{j+\frac{1}{2}}\}_{j=0}^{N}$, we set $I_j = (x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}})$, and $h_j = x_{j+\frac{1}{2}} - x_{j-\frac{1}{2}}$ for $j = 1, \dots, N$; we denote the quantity $\max_{1\le j\le N} h_j$ by h. For a given time step τ (which could actually change from step to step but is taken as a constant with respect to the time level n for simplicity), the solution of the scheme is denoted by $u_h^n(x) = u_h(x, n\tau)$, which belongs to the finite element space

$$V_h = V_h^k = \{\, v \in L^1(0,1) : v|_{I_j} \in \mathbb{P}^k(I_j), j = 1, \dots, N \,\}, \tag{2.1}$$

where $\mathbb{P}^k(I_j)$ denotes the space of polynomials in I_j of degree at most k. Note that the functions in V_h are allowed to have discontinuities across element interfaces.

In what follows, we will consider the standard L^2-projection of a function $p \in L^2(0,1)$ into the finite element space V_h, denoted by $\mathbb{P}_h p$, which is defined as the unique function in V_h such that

$$\int_0^1 (\mathbb{P}_h p(x) - p(x)) v_h(x)\, dx = 0 \quad \forall v_h \in V_h. \tag{2.2}$$

For notational convenience we would like to introduce the following operator related to the discontinuous Galerkin spatial discretization. For any functions $p, q \in$

$L^2(0,1)$, denote

$$\mathcal{H}_j(p,q) = \int_{I_j} f(p)\partial_x q(x)\,dx - \widehat{h}(p)_{j+\frac{1}{2}} q(x^-_{j+\frac{1}{2}}) + \widehat{h}(p)_{j-\frac{1}{2}} q(x^+_{j-\frac{1}{2}}), \tag{2.3}$$

where $\widehat{h}(p)_{j+1/2} \equiv \widehat{h}(p^-_{j+1/2}, p^+_{j+1/2})$ is a given monotone numerical flux that depends on the two values of the function p at the discontinuity point $x_{j+1/2}$, namely $p^\pm_{j+1/2} = p(x^\pm_{j+1/2})$. The numerical flux $\widehat{h}(a,b)$ satisfies the following conditions:

(a) It is locally Lipschitz continuous, so it is bounded in any bounded interval.
(b) It is consistent with the flux $f(p)$, i.e., $\widehat{h}(p,p) = f(p)$.
(c) It is a nondecreasing function of its first argument and a nonincreasing function of its second argument.

The best-known examples of monotone numerical fluxes are the Godunov flux, the Engquist–Osher flux, the Lax–Friedrichs flux, etc. For more details, see, for example, [18]. We use the usual notation $[p] = p^+ - p^-$ and $\bar{p} = (p^+ + p^-)/2$ to denote the jump and mean of the function p on each boundary point, respectively.

The approximate solution in V_h from time $n\tau$ to $(n+1)\tau$ given by the RKDG method with the second order TVD Runge–Kutta time discretization is defined as follows: find $w^n_h \equiv w^n_h(x) \in V_h$ and $u^{n+1}_h \equiv u^{n+1}_h(x) \in V_h$ such that, for any $v_h \equiv v_h(x) \in \mathbb{P}^k(I_j)$ and $1 \le j \le N$,

$$\int_{I_j} w^n_h v_h\,dx = \int_{I_j} u^n_h v_h\,dx + \tau\mathcal{H}_j(u^n_h, v_h), \tag{2.4a}$$

$$\int_{I_j} u^{n+1}_h v_h\,dx = \frac{1}{2}\int_{I_j} u^n_h v_h\,dx + \frac{1}{2}\int_{I_j} w^n_h v_h\,dx + \frac{\tau}{2}\mathcal{H}_j(w^n_h, v_h), \tag{2.4b}$$

with the initial value $u^0_h = \mathbb{P}_h u_0(x)$. This is an explicit time-marching method when a local orthogonal basis is chosen for polynomials on I_j or when a small local mass matrix on I_j is inverted. More details and numerical results of this scheme can be found in, e.g., [3] and [12].

3. The main results. We would like to present the main results on the error estimates in this section. To this end, we will introduce some notation for convenience and define an important quantity measuring the relationship between the numerical flux and the physical flux.

3.1. Notation for different constants. We will adopt the following convention for different constants. These constants may have a different value in each occurrence.

We will denote by C (or accompanied by lower indices) a positive constant independent of h and τ, which may depend on the solution of the considered conservation law (1.1). Especially, to emphasize the nonlinearity of the flux $f(u)$, we will denote by $C_\star$ a positive constant depending solely on the maximum of $|f''|$ or/and $|f'''|$. We remark that $C_\star = 0$ for a linear flux $f = cu$, where c is a constant.

We will denote by ε a small positive constant independent of h, τ, and u, the solution of conservation law (1.1). Meanwhile, by M and $M(\varepsilon)$ we will denote those constants depending only on the small constant ε.

3.2. Modification of the flux. To achieve uniform a priori error estimates for the RKDG method, we make the following customary modification on the flux $f(u)$. Suppose the initial solution $u_0(x)$ lies in $[m_0, M_0]$; then, by the maximum principle, the exact solution $u(x,t)$ is also in this range. Thus there is no harm in modifying the

flux function f on the set $\mathbb{R}\backslash[m_0, M_0]$, since the exact solution to (1.1) stays the same. We would choose the modified flux function $\tilde{f}$ to equal the original flux function f on $[m_0, M_0]$, belong to $C^3(\mathbb{R})$, and satisfy $\tilde{f}'(s) = \tilde{f}''(s) = 0$ for all $s \notin [m_0 - 1, M_0 + 1]$. For notational convenience this modified function is still denoted by f. Therefore, we can assume in this paper that the flux function $f(u)$ itself and up to the third order derivatives are all bounded on $\mathbb{R}$.

3.3. A quantity related to the numerical flux. For a general monotone numerical flux which is consistent with f, we introduce an important quantity $\alpha(\widehat{h}; p)$ to measure the difference between the numerical flux and the physical flux; cf. Harten [13]. The definition is given in the following lemma.

LEMMA 3.1. *For any piecewise smooth function $p \in L^2(0,1)$, on each boundary point we define*

$$\alpha(\widehat{h}; p) \equiv \alpha(\widehat{h}; p^-, p^+) \triangleq \begin{cases} [p]^{-1}(f(\bar{p}) - \widehat{h}(p)) & \text{if } [p] \neq 0, \\ |f'(\bar{p})| & \text{if } [p] = 0, \end{cases} \tag{3.1}$$

where $\widehat{h}(p) \equiv \widehat{h}(p^-, p^+)$ is a monotone numerical flux consistent with the given flux f. Then $\alpha(\widehat{h}; p)$ is nonnegative and bounded for any $(p^-, p^+) \in \mathbb{R}^2$. Moreover, we have

$$\frac{1}{2}|f'(\bar{p})| \leq \alpha(\widehat{h}; p) + C_\star|[p]|, \tag{3.2a}$$

$$-\frac{1}{8}f''(\bar{p})[p] \leq \alpha(\widehat{h}; p) + C_\star|[p]|^2, \tag{3.2b}$$

where the positive constant $C_\star$ depends solely on the maximum of $|f''|$ and/or $|f'''|$.

Proof. Obviously, the first conclusion $\alpha(\widehat{h}; p) \geq 0$ is true, because of the property of a monotone numerical flux or, more generally, an E-flux as defined by Osher [18]:

$$(f(q) - \widehat{h}(p^-, p^+))(p^+ - p^-) \geq 0 \tag{3.3}$$

for all q between p^- and p^+. The Lipschitz continuity of the monotone numerical flux $\widehat{h}$, together with the modification of the flux f, implies the bounded property of $\alpha(\widehat{h}; p)$.

We now prove the inequality (3.2a). If $[p] = 0$, the conclusion is obvious by the definition (3.1). Otherwise, we would like to consider the next two cases to get (3.2a): (i) if $f'(\bar{p}) \geq 0$, then from a simple Taylor expansion up to second order and property (3.3) we have

$$\alpha(\widehat{h}; p) = \frac{1}{[p]}(f(\bar{p}) - f(p^-)) + \frac{1}{[p]}(f(p^-) - \widehat{h}(p)) \geq \frac{1}{2}f'(\bar{p}) - \frac{C_\star}{8}|[p]|;$$

otherwise, (ii) if $f'(\bar{p}) < 0$, there similarly holds that

$$\alpha(\widehat{h}; p) = \frac{1}{[p]}(f(\bar{p}) - f(p^+)) + \frac{1}{[p]}(f(p^+) - \widehat{h}(p)) \geq -\frac{1}{2}f'(\bar{p}) - \frac{C_\star}{8}|[p]|,$$

where the positive constant $C_\star$ is the maximum of $|f''|$. This proves (3.2a). We can also prove the inequality (3.2b) along the same lines, wherein the Taylor expansion up to third order is used. ∎

Remark 3.1. The nonnegative property of the quantity $\alpha(\widehat{h}; p)$ is crucial for obtaining the L^2-stability of the RKDG scheme, especially for the case with the usual CFL condition for piecewise linear elements. Details can be seen in subsection 5.2.

Remark 3.2. Here and in what follows we will refer to the value $\bar{p} = (p^+ + p^-)/2$ as the *reference value* of the function p on each boundary point. It is used in the error analysis for general monotone numerical fluxes. Later on we will introduce another reference value p^* for upwind numerical fluxes; see subsection 5.3.

We would also like to use the following simplified notation. For any functions p and q, we denote

$$\alpha^m(\widehat{h};q)[p]^2 = \sum_{1\le j\le N} \left\{\alpha(\widehat{h};q)_{j+\frac{1}{2}}\right\}^m [p]^2_{j+\frac{1}{2}} \quad (m=1,2,3)$$

if there is no confusion.

3.4. The main results. We are now ready to state the main error estimates of the RKDG scheme (2.4). Detailed proof will be given in subsequent sections for different cases.

THEOREM 3.1 (the main results). *Let u be the exact solution of problem* (1.1)*, which is sufficiently smooth with bounded derivatives, and assume $f \in C^3$. Let u_h be the numerical solution of the RKDG scheme* (2.4) *with the second order TVD Runge–Kutta time discretization, and denote the corresponding numerical error by $e_u^n = u(t^n) - u_h^n$. For regular triangulations of $I = (0,1)$, if the finite element space V_h is of piecewise polynomials of degree $k \ge 1$, then for small enough h there holds the following error estimate:*

$$\max_{0\le n\le N_\tau} ||e_u^n||^2 + \sum_{0\le m<N_\tau} \alpha(\widehat{h};u_h^m)[e_u^m]^2\tau \le C(h^{2k+1}+\tau^4). \tag{3.4a}$$

Moreover, if an upwind numerical flux is used, then for small enough h there holds

$$\max_{0\le n\le N_\tau} ||e_u^n|| \le C(h^{k+1}+\tau^2). \tag{3.4b}$$

These estimates hold for $k \ge 2$ under the restrictive time-step condition $\tau \le \gamma h^{4/3}$ with any given positive constant γ; meanwhile, they hold for $k = 1$ under the usual CFL condition $\tau \le \gamma h$ with a suitable positive CFL number γ which is independent of τ and h. Here $||\cdot||$ is the norm in $L^2(0,1)$, the positive constant C is independent of n, h, τ, and the approximate solution u_h, and $N_\tau = [T^\star/\tau]$.

For the generalization of these results to multiple space dimensions, see the remarks in section 5.

4. Error equations, energy equality, and properties of the finite element spaces. In this section we derive the error equations of the RKDG scheme (2.4) and obtain the important energy equality for the error analysis. At the end of this section, we present some interpolation properties and inverse properties for the finite element spaces that will be used in the error analysis.

4.1. Error equations and energy equality. In order to obtain the error estimate to smooth solutions for the considered RKDG scheme (2.4), we need to first get the error equations. To do this, we follow the idea of Ying [23] and derive the truncation error in time.

LEMMA 4.1. *Assume that the solution u of the conservation law* (1.1) *is sufficiently smooth with bounded derivatives. Let*

$$w(x,t) = u(x,t) + \partial_t u(x,t)\tau; \tag{4.1}$$

then, for any $1 \le j \le N, n < N_\tau$, *and any function* $v(x) \in L^2(I_j)$, *the following equations hold:*

$$\int_{I_j} w(x,t^n)v(x)\,dx = \int_{I_j} u(x,t^n)v(x)\,dx + \tau\mathcal{H}_j(u(x,t^n),v(x)), \tag{4.2a}$$

$$\begin{aligned}\int_{I_j} u(x,t^{n+1})v(x)\,dx &= \frac{1}{2}\int_{I_j} u(x,t^n)v(x)\,dx + \frac{1}{2}\int_{I_j} w(x,t^n)v(x)\,dx \\ &\quad + \frac{\tau}{2}\mathcal{H}_j(w(x,t^n),v(x)) + \int_{I_j} E(x;n)v(x)\,dx,\end{aligned} \tag{4.2b}$$

where $E(x;n) = O(\tau^3)$.

Proof. By the Taylor expansion in time we have

$$u(x,t+\tau) - u(x,t) - \partial_t u(x,t)\frac{\tau}{2} - \partial_t u(x,t+\tau)\frac{\tau}{2} = O(\tau^3).$$

By the conservation law (1.1) and the Taylor expansion, it follows that

$$\begin{aligned}\partial_t u(x,t+\tau) &= -\partial_x f(u(x,t+\tau)) = -\partial_x f(u(x,t) + \partial_t u(x,t)\tau + O(\tau^2)) \\ &= -\partial_x f(u(x,t) + \partial_t u(x,t)\tau) + O(\tau^2) = -\partial_x f(w(x,t)) + O(\tau^2).\end{aligned}$$

We then substitute this into the former equation to get

$$u(x,t+\tau) = \frac{1}{2}u(x,t) + \frac{1}{2}w(x,t) - \partial_x f(w(x,t))\frac{\tau}{2} + O(\tau^3).$$

Therefore

$$\begin{aligned}w(x,t^n) &= u(x,t^n) - \partial_x f(u(x,t^n))\tau, \\ u(x,t^{n+1}) &= \frac{1}{2}u(x,t^n) + \frac{1}{2}w(x,t^n) - \partial_x f(w(x,t^n))\frac{\tau}{2} + O(\tau^3).\end{aligned}$$

The above analysis is the same as that in [23]. We multiply the above two equations by an arbitrary function $v(x)$ and integrate over I_j and get, after a simple integration by parts, their weak formulations, which are the conclusions of this lemma. Note that the consistency of the numerical flux $\widehat{h}(u,u) = f(u)$ and the continuity of the exact solution u is used in the derivation. This completes the proof. ∎

We would like to obtain error estimates for each time step, namely $e_u^n = u(t^n) - u_h^n$ and $e_w^n = w(t^n) - w_h^n$, where for notational convenience the argument x is suppressed. In what follows we will also denote $u^n = u(t^n)$ and $w^n = w(t^n)$.

As is customary in error analysis of finite element methods, we denote $\eta_p = \mathbb{Q}p - p$ and $\xi_p = \mathbb{Q}p - p_h$, where the projection $\mathbb{Q}$ is either the L^2-projection $\mathbb{P}_h$ or the Gauss–Radau projection $\mathbb{R}_h$ to be described in more detail in subsection 4.2. The errors of the RKDG scheme at each time step can then be written as $e_p^n = \xi_p^n - \eta_p^n$, where $p = u$ and w.

It is then easy to get, by Lemma 4.1 and the scheme (2.4), the error equations for the error variables ξ_u^n and ξ_w^n in the following form:

$$\int_{I_j} \xi_w^n v_h\,dx = \int_{I_j} \xi_u^n v_h\,dx + \mathcal{K}_j^n(v_h) \quad \forall v_h(x) \in \mathbb{P}^k(I_j), \tag{4.3a}$$

$$\begin{aligned}\int_{I_j} \xi_u^{n+1} v_h\,dx &= \int_{I_j} \left(\frac{1}{2}\xi_u^n + \frac{1}{2}\xi_w^n\right) v_h\,dx + \frac{1}{2}\mathcal{L}_j^n(v_h) \\ &= \int_{I_j} \xi_u^n v_h\,dx + \frac{1}{2}\mathcal{K}_j^n(v_h) + \frac{1}{2}\mathcal{L}_j^n(v_h) \quad \forall v_h(x) \in \mathbb{P}^k(I_j),\end{aligned} \tag{4.3b}$$

for any $1 \le j \le N$ and $n < N_\tau$, where

(4.3c)

$$\mathcal{K}_j^n(v_h) = \int_{I_j} (\eta_w^n - \eta_u^n) v_h \, dx + \tau \mathcal{H}_j(u^n, v_h) - \tau \mathcal{H}_j(u_h^n, v_h),$$

(4.3d)

$$\mathcal{L}_j^n(v_h) = \int_{I_j} (2\eta_u^{n+1} - \eta_w^n - \eta_u^n + 2E(x;n)) v_h \, dx + \tau \mathcal{H}_j(w^n, v_h) - \tau \mathcal{H}_j(w_h^n, v_h).$$

For notational convenience, we will denote $\mathcal{K}^n(v_h) = \sum_{1 \le j \le N} \mathcal{K}_j^n(v_h)$ and $\mathcal{L}^n(v_h) = \sum_{1 \le j \le N} \mathcal{L}_j^n(v_h)$.

Based on these error equations, we shall use energy estimates to analyze the error of the RKDG scheme with second order TVD Runge–Kutta time marching. By taking the test functions $v_h = \xi_u^n$ in (4.3a) and $v_h = \xi_w^n$ in (4.3b), after a simple calculation we obtain the important energy equality

$$||\xi_u^{n+1}||^2 - ||\xi_u^n||^2 = ||\xi_u^{n+1} - \xi_w^n||^2 + \mathcal{K}^n(\xi_u^n) + \mathcal{L}^n(\xi_w^n). \tag{4.4}$$

In the following sections we shall analyze each term on the right-hand side of this energy equation (4.4) to obtain the error estimates under different degrees of polynomials and different types of numerical fluxes. The key point in this process is to obtain a sharp estimate to the first term $||\xi_u^{n+1} - \xi_w^n||^2$, since the estimates to the other terms, namely $\mathcal{K}^n(\xi_u^n)$ and $\mathcal{L}^n(\xi_w^n)$, are a simple extension of that in the semidiscretized setting (cf. [3]).

4.2. Finite element spaces and projections. In this subsection we would like to introduce two interpolations $\mathbb{Q}p(\cdot, t^n)$ which we mentioned before. One is the standard L^2-projection $\mathbb{P}_h p(\cdot, t^n)$, which has been defined in section 2 and will be used for general monotone fluxes. The other is the Gauss–Radau projection $\mathbb{R}_h p(\cdot, t^n)$, which is defined below and will be used for upwind numerical fluxes.

The Gauss–Radau projection is defined following a standard trick in DG analysis. For functions at time level t^n, the projection actually depends on the exact solution u^n and is defined element by element as follows. If $f'(u^n)$ maintains its sign in element I_j, then the projection in this element is defined by

$$\mathbb{R}_h p(x_{j,\ell}) - p(x_{j,\ell}) = 0, \quad \ell = 0, 1, \ldots, k, \tag{4.5}$$

where the points $x_{j,\ell}$ are the Gauss–Radau quadrature points of the interval I_j; that is, one of the boundary points is within the quadrature points:

$$\begin{array}{ll} \text{(i)} & x_{j,k} = x_{j+\frac{1}{2}} \quad \text{if } f'(u^n) > 0 \text{ on the element } I_j, \\ \text{(ii)} & x_{j,0} = x_{j-\frac{1}{2}} \quad \text{if } f'(u^n) < 0 \text{ on the element } I_j. \end{array} \tag{4.6}$$

Otherwise, in case (iii) when $f'(u^n)$ has at least one zero point in the element I_j, we define $\mathbb{R}_h p(\cdot, t^n) = \mathbb{P}_h p(\cdot, t^n)$ to be the standard L^2-projection.

4.2.1. Interpolation properties. Before we start proving the main results for error estimates, we present some interpolation inequalities for these projections. The usual notation of norms and seminorms in Sobolev spaces will be used.

For both projections mentioned above, it is easy to show (cf. [2])

$$||\eta_p^n|| + h||\eta_p^n||_\infty + h^{\frac{1}{2}}||\eta_p^n||_{\Gamma_h} \le Ch^{k+1} \quad (p = u, w;\ 0 \le n \le N_\tau), \tag{4.7}$$

where the positive constant C, solely depending on u, is independent of n, h, and τ, and Γ_h denotes the set of boundary points of all elements I_j. Moreover, for $0 \le n < N_\tau$ we have that

$$\left| \int_{I_j} (p^n - \mathbb{Q}p^n)\partial_x v_h \, dx \right| \le Ch^{k+1}||v_h||_{I_j} \quad \forall v_h \in \mathbb{P}^k(I_j), \tag{4.8}$$

where p could be u and w, and the positive constant C is independent of h, τ, and v_h. This inequality (4.8) is easy to verify, the constant C depends solely on k and $||p||_{L^\infty(H^{k+2}(I_j))}$ for the Gauss–Radau projection $\mathbb{R}_h$, and $C = 0$ for the L^2-projection $\mathbb{P}_h$. For more details, see, for example, [3].

For the Gauss–Radau projection, it is important to mention that it is an exact collocation at one of the boundary points of each element I_j in cases (i) and (ii). If $f'(u^n) > 0$ on the element I_j (case (i)), we have $\eta_p^n(x_{j+1/2}^-) = 0$; if $f'(u^n) < 0$ on the element I_j (case (ii)), we have $\eta_p^n(x_{j-1/2}^+) = 0$, where p could be u or w.

Noticing the definition (4.1) of w, we can conclude, for both projections, that

$$||\eta_u^{n+1} - \eta_u^n|| + ||\eta_w^n - \eta_u^n|| \le Ch^{k+1}\tau, \quad n < N_\tau, \tag{4.9}$$

where the positive constant C solely depends on $\partial_t u$ and is independent of n, h, and τ. It is easy to get (4.9) for the L^2-projection $\mathbb{P}_h$ since the projection $\mathbb{P}_h$ is linear. For the Gauss–Radau projection $\mathbb{R}_h$ the conclusion (4.9) is valid due to the following observation: Notice that the different interpolation points in the Gauss–Radau projection $\mathbb{R}_h$ depend on the exact solution u^n, not on the numerical solution u_h^n. Hence if an element I_j is in case (iii) at the initial time $t = 0$, namely, there is a point inside I_j such that $f'(u_0) = 0$, then the characteristic line at this point is vertical and the element I_j would be in case (iii) for all future time levels. Since we assume in this paper that the exact solution is smooth, the characteristics will not intersect with each other; hence if a cell I_j is in one of the three cases (i), (ii), or (iii) initially, it will stay in that case for all future time. Therefore, we can easily conclude that the inequality (4.9) holds for the Gauss–Radau projection $\mathbb{R}_h$ as well.

4.2.2. Inverse properties. Finally, we list some inverse properties of the finite element space V_h that will be used in our error analysis. For any $v_h \in V_h$, there exists a positive constant C, independent of v_h and h, such that

$$\text{(i) } ||\partial_x v_h|| \le Ch^{-1}||v_h||; \quad \text{(ii) } ||v_h||_{\Gamma_h} \le Ch^{-1/2}||v_h||; \quad \text{(iii) } ||v_h||_\infty \le Ch^{-1/2}||v_h||.$$

For more details of these inverse properties, we refer the reader to [2].

5. Proof of the main results. In this section we present the main proof of Theorem 3.1, leaving some of the more technical details to the appendix. We shall prove the theorem by analyzing each term on the right-hand side of the energy equation (4.4) for different degrees of polynomials and different types of numerical fluxes. As we have mentioned before, the key point of the analysis is to give a sharp estimate to the first term $||\xi_u^{n+1} - \xi_w^n||$ on the right-hand side of (4.4).

5.1. Some lemmas. In this subsection we collect some lemmas for the estimate to the crucial term $||\xi_u^{n+1} - \xi_w^n||$ for both linear and higher order piecewise polynomials. This term comes from the time discretization of the second order TVD Runge–Kutta method and must be analyzed sharply in order to get global optimal error estimates.

We first consider the difference between the operator $\mathcal{L}^n$ and $\mathcal{K}^n$ at successive stages of the Runge–Kutta time marching. The main technique used is Taylor expansion, with special attention paid to the terms associated with the boundaries of each element. The inequalities (4.7), (4.8), and (4.9) will be used for the projection $\mathbb{Q}$.

By using Taylor expansions on $f(u)$ up to second order, and with some (tedious) manipulations, we can prove the following lemma.

LEMMA 5.1. *Let ε be any given small positive constant. Suppose that the interpolation properties* (4.7), (4.8), *and* (4.9) *are satisfied; then we have, for $n = 0, 1, \ldots, N_\tau - 1$ and any $v_h \in V_h$, that*

$$\begin{aligned}(\mathcal{L}^n - \mathcal{K}^n)(v_h) \le{}& \varepsilon||v_h||^2 + \frac{M(\varepsilon)\tau^2}{h}\alpha^2(\widehat{h}; w_h^n)[\xi_w^n]^2 + \frac{M(\varepsilon)\tau^2}{h}\alpha^2(\widehat{h}; u_h^n)[\xi_u^n]^2 \\ &+ \frac{C_\star\tau^2}{h^2}(||e_u^n||_\infty^2||\xi_u^n||^2 + ||e_w^n||_\infty^2||\xi_w^n||^2) + C\tau^2(||\xi_u^n||^2 + ||\xi_w^n||^2) \\ &+ C(\Xi(n)h^{2k+2}\tau + \tau^6) - \sum_{1\le j\le N}\tau f'(u_j^n)\int_{I_j} v_h\partial_x(\xi_w^n - \xi_u^n)\,dx, \end{aligned} \tag{5.1}$$

where $\Xi(n) = 1 + C_\star h^{-1}||e_u^n||_\infty^2 + C_\star h^{-1}||e_w^n||_\infty^2$, the positive constants C and $C_\star$ are independent of n, h, τ, and the approximate solution u_h, and the positive constant $M(\varepsilon) = O(\varepsilon^{-1})$ depends on ε solely. u_j^n denotes the value of the exact solution at the cell center, $u(x_j, t^n)$.

The rather technical proof of this lemma is left for the appendix. We now use this lemma to get an estimate to $||\xi_u^{n+1} - \xi_w^n||$. The next lemma follows from Lemma 5.1 by choosing suitable test functions v_h and setting the positive constant ε in (5.1) small enough.

LEMMA 5.2. *Suppose that the interpolation properties* (4.7), (4.8), *and* (4.9) *are satisfied; then we have, for any $n = 0, 1, \ldots, N_\tau - 1$,*

$$\begin{aligned}||\xi_u^{n+1} - \xi_w^n||^2 \le{}& C(\Xi(n)h^{2k+2}\tau + \tau^6) + \frac{M\tau^2}{h}\alpha^2(\widehat{h}; w_h^n)[\xi_w^n]^2 + \frac{M\tau^2}{h}\alpha^2(\widehat{h}; u_h^n)[\xi_u^n]^2 \\ &+ \frac{C_\star\tau^2}{h^2}(||e_u^n||_\infty^2||\xi_u^n||^2 + ||e_w^n||_\infty^2||\xi_w^n||^2) + C\tau^2(||\xi_u^n||^2 + ||\xi_w^n||^2) \\ &+ M\sum_{1\le j\le N}\tau^2|f'(u_j^n)|^2\int_{I_j}\{\partial_x(\xi_w^n - \xi_u^n)\}^2\,dx, \end{aligned} \tag{5.2}$$

where the positive constants C and $C_\star$ are independent of n, h, τ, and the approximate solution u_h, and the constant M is solely determined by a suitably given positive constant ε in Lemma 5.1.

Proof. By subtracting the error equation (4.3a) from (4.3b) we have that

$$\int_{I_j}(\xi_u^{n+1} - \xi_w^n)v_h\,dx = \frac{1}{2}(\mathcal{L}_j^n - \mathcal{K}_j^n)(v_h) \quad \forall v_h \in \mathbb{P}^k(I_j), \quad 1 \le j \le N, \tag{5.3}$$

which implies that $||\xi_u^{n+1} - \xi_w^n||^2 = \frac{1}{2}(\mathcal{L}^n - \mathcal{K}^n)(\xi_u^{n+1} - \xi_w^n)$ if the test function in (5.3) is taken as $v_h = \xi_u^{n+1} - \xi_w^n$. Also taking the test function $v_h = \xi_u^{n+1} - \xi_w^n$ in (5.1), and

letting the positive constant ε be small enough, we have that

$$\begin{aligned}||\xi_u^{n+1}-\xi_w^n||^2 \le C(\Xi(n)h^{2k+2}\tau+\tau^6)+\frac{M\tau^2}{h}\alpha^2(\widehat{h};w_h^n)[\xi_w^n]^2+\frac{M\tau^2}{h}\alpha^2(\widehat{h};u_h^n)[\xi_u^n]^2\\ +\frac{C_\star\tau^2}{h^2}(||e_u^n||_\infty^2||\xi_u^n||^2+||e_w^n||_\infty^2||\xi_w^n||^2)+C\tau^2(||\xi_u^n||^2+||\xi_w^n||^2)\\ -M\sum_{1\le j\le N}\tau f'(u_j^n)\int_{I_j}(\xi_u^{n+1}-\xi_w^n)\partial_x(\xi_w^n-\xi_u^n)\,dx,\end{aligned}\tag{5.4}$$

where the positive constant M is determined solely by ε.

We now need only to estimate the last integral term in (5.4). To this end, we take the test function $v_h\in V_h$ in (5.3), defined on each element I_j by $v_h=-\tau f'(u_j^n)\partial_x(\xi_w^n-\xi_u^n)$. Then we have, for $1\le j\le N$, that

$$-\tau f'(u_j^n)\int_{I_j}(\xi_u^{n+1}-\xi_w^n)\partial_x(\xi_w^n-\xi_u^n)\,dx=\frac{1}{2}(\mathcal{L}_j^n-\mathcal{K}_j^n)(-\tau f'(u_j^n)\partial_x(\xi_w^n-\xi_u^n)).$$

Thus we can use Lemma 5.1 to estimate the integral term in (5.4) by taking this test function in (5.1) and using the inverse property (i) and the general CFL condition $\tau\le Ch$ for a fixed constant C independent of h and τ. The proof of this lemma is thus completed by substituting this estimate into the inequality (5.4). ∎

The conclusion (5.2) is the key inequality for obtaining error estimates of the DG scheme with the second order TVD Runge–Kutta time marching, which holds for the finite element space with piecewise polynomials of any degree $k\ge 1$. In the next two subsections, we will use this key estimate to obtain error estimates for general numerical fluxes, i.e., to estimate the first term on the right-hand side of (4.4). We shall pay more attention to estimating sharply the last integral term in (5.2) for either linear or higher order piecewise polynomial finite element spaces.

We follow the same lines of analysis for the operator $(\mathcal{L}^n-\mathcal{K}^n)(v_h)$ in Lemma 5.1, using Taylor expansions of $f(u)$ up to second order and first order, respectively, to prove the following lemma.

LEMMA 5.3. *Let ε be any given small positive constant. Suppose that the interpolation properties* (4.7), (4.8), *and* (4.9) *are satisfied; then we have, for $n=0,1,\dots,N_\tau-1$ and any $v_h\in V_h$, that*

$$\begin{aligned}\mathcal{K}^n(v_h)\le\varepsilon||v_h||^2+\frac{M(\varepsilon)\tau^2}{h}\alpha^2(\widehat{h};u_h^n)[\xi_u^n]^2+\left(\frac{C_\star\tau^2}{h^2}||e_u^n||_\infty^2+C\tau^2\right)||\xi_u^n||^2\\ +(Ch^{-1}+C_\star h^{-1}||e_u^n||_\infty^2)h^{2k+2}\tau-\sum_{1\le j\le N}\tau f'(u_j^n)\int_{I_j}v_h\partial_x\xi_u^n\,dx\end{aligned}\tag{5.5}$$

and

$$\mathcal{K}^n(v_h)\le\varepsilon||v_h||^2+\frac{C\tau^2}{h^2}||\xi_u^n||^2+Ch^{2k}\tau^2,\tag{5.6}$$

where the positive constants C and $C_\star$ are independent of n,h,τ, and the approximate solution u_h, and the positive constant $M(\varepsilon)=O(\varepsilon^{-1})$ depends solely on ε.

Proof. The proof is technical but follows along the same lines as that for Lemma 5.1 and is thus omitted.

COROLLARY 5.1. *Under the assumptions of Lemma* 5.3, *if a general CFL condition $\tau\le Ch$ is satisfied, then we have*

$$||\xi_w^n||\le C||\xi_u^n||+Ch^k\tau\quad(n=0,1,\dots,N_\tau-1),\tag{5.7}$$

where the positive constant C is independent of n, h, τ, and the approximate solution u_h.

Proof. Since it follows from the error equations (4.3a) that $||\xi_w^n - \xi_u^n||^2 = \mathcal{K}^n(\xi_w^n - \xi_u^n)$, we can complete the proof by taking the test function $v_h = \xi_w^n - \xi_u^n$ and setting ε small enough in (5.6). Here the general CFL condition $\tau \le Ch$ is used. ∎

The estimates in Lemma 5.3 hold for any test function $v_h \in V_h$. However, for a special test function $\xi_u^n \in V_h$ we have another estimate to $\mathcal{K}^n(\xi_u^n)$ given in the lemma below, which corresponds to the second term on the right-hand side of the energy equation (4.4). The proof of this lemma will be given in the appendix.

LEMMA 5.4. *Suppose the interpolation properties* (4.7), (4.8), *and* (4.9) *are satisfied; then we have, for $n = 0, 1, \dots, N_\tau - 1$, that*

$$\mathcal{K}^n(\xi_u^n) \le \Phi(u^n)||\xi_u^n||^2\tau - \frac{\tau}{4}\alpha(\widehat{h}; u_h^n)\left[\xi_u^n\right]^2 + (C + C_\star h^{-1}||e_u^n||_\infty^2)h^{2k+1}\tau, \tag{5.8}$$

where $\Phi(u^n) = C + C_\star(||\xi_u^n||_\infty + h^{-1}||e_u^n||_\infty^2)$, and the positive constants C and $C_\star$ are independent of n, h, τ, and the approximate solution u_h.

By a similar analysis we have the following lemma to estimate the last term on the right-hand side of the energy equation (4.4). The proof is omitted.

LEMMA 5.5. *Under the assumptions in Lemma* 5.4, *we have, for* $n = 0, 1, \dots, N_\tau - 1$,

$$\mathcal{L}^n(\xi_w^n) \le \Phi(w^n)||\xi_w^n||^2\tau - \frac{\tau}{4}\alpha(\widehat{h}; w_h^n)\left[\xi_w^n\right]^2 + (C + C_\star h^{-1}||e_w^n||_\infty^2)h^{2k+1}\tau + C\tau^5, \tag{5.9}$$

where $\Phi(w^n) = C + C_\star(||\xi_w^n||_\infty + h^{-1}||e_w^n||_\infty^2)$, and the positive constants C and $C_\star$ are independent of n, h, τ, and the approximate solution u_h.

5.2. Error estimates for general monotone numerical fluxes. In this subsection we will prove Theorem 3.1 for arbitrary monotone numerical fluxes. To emphasize the main idea of the analysis we would like to present in detail the proof for the case of linear polynomials, i.e., the proof for (3.4a) under a suitable CFL condition for $k = 1$. We will then briefly indicate the additional difficulties for higher order piecewise polynomial cases.

To deal with the nonlinearity of the flux $f(u)$ we would like to make an a priori assumption that, for small enough h, there holds

$$||u^n - u_h^n|| \le h. \tag{5.10}$$

This assumption is obviously satisfied for $n = 0$ by $u_h^0 = \mathbb{P}_h u_0(x)$ defined in the DG scheme. We shall later verify the correctness of (5.10) by showing that (5.10) still holds true for $n+1$ if it holds true for a given n. For a linear flux $f = cu$, this a priori assumption is unnecessary.

COROLLARY 5.2. *Suppose that the interpolation property* (4.7) *is satisfied; then the a priori assumption* (5.10) *implies that*

$$||e_p^n||_\infty \le Ch^{\frac{1}{2}} \quad \textit{and} \quad ||\xi_p^n||_\infty \le Ch^{\frac{1}{2}} \quad (p = u, w). \tag{5.11}$$

Proof. This follows from the inverse property (iii) and the inequality (5.7). ∎

To obtain the error estimates shown in Theorem 3.1, we shall give separate estimates to each term on the right-hand side of (4.4). The analyses for $\mathcal{K}(\xi_u^n)$ and $\mathcal{L}(\xi_w^n)$ have been given in Lemma 5.4 and Lemma 5.5. Thus in what follows we will pay

special attention to the estimate of the first term on the right-hand side of (4.4) for linear and higher order piecewise polynomials, respectively. To this end, we need to obtain a sharp estimate to $\max_{1\le j\le N}|f'(u_j^n)|^2\cdot||\partial_x(\xi_w^n-\xi_u^n)||^2$ by virtue of Lemma 5.2, where $||\partial_x(\xi_w^n-\xi_u^n)||^2\triangleq\sum_{1\le j\le N}||\partial_x(\xi_w^n-\xi_u^n)||_{I_j}^2$.

5.2.1. Estimates for the linear polynomials. The inequality (5.5), together with (5.2), gives more information to estimate $||\partial_x(\xi_w^n-\xi_u^n)||$ sharply for piecewise linear polynomials than for higher order polynomials. We start by noting that any function g_h can be written as

$$g_h=\widetilde{g_h}+(g_h-\widetilde{g_h}), \tag{5.12}$$

where $\widetilde{g_h}$ is a piecewise constant function, defined by the corresponding average of g_h on each element I_j, i.e.,

$$\int_{I_j}(g_h-\widetilde{g_h})\,dx=0,\quad 1\le j\le N.$$

In the case when the finite element space V_h is of piecewise linear polynomials, it follows from $\xi_u^n\in V_h$ that its derivative $\partial_x\xi_u^n$ is a constant on each element I_j. Hence we also have, for any function g_h, that

$$\int_{I_j}(g_h-\widetilde{g_h})\partial_x\xi_u^n\,dx=0,\quad 1\le j\le N. \tag{5.13}$$

This property plays a key role in obtaining the estimates under the usual CFL condition. Unfortunately, this property holds only for piecewise linear polynomials, not for piecewise polynomials of higher order.

Let $g_h=\xi_w^n-\xi_u^n$; clearly both g_h and $g_h-\widetilde{g_h}\in V_h$. We remark that $g_h-\widetilde{g_h}\in V_h$ holds only for the DG method, not for the standard conforming finite element methods. After a simple calculation, it is easy to show by (4.3a) and (5.12) that

$$||g_h-\widetilde{g_h}||^2=(g_h,g_h-\widetilde{g_h})=(\xi_w^n-\xi_u^n,g_h-\widetilde{g_h})=\mathcal{K}^n(g_h-\widetilde{g_h}). \tag{5.14}$$

By setting the test function $v_h=g_h-\widetilde{g_h}$ in (5.5) we can see that the last integral term in (5.5) becomes 0. Choosing ε small enough, then we have, by (5.14), that

$$||g_h-\widetilde{g_h}||^2\le\frac{M\tau^2}{h}\alpha^2(\widehat{h};u_h^n)[\xi_u^n]^2+\left(C+\frac{C_\star}{h^2}||e_u^n||_\infty^2\right)||\xi_u^n||^2\tau^2+\Upsilon(n)h^3\tau, \tag{5.15}$$

where $\Upsilon(n)=C+C_\star||e_u^n||_\infty^2$ and the positive constants C and $C_\star$ are independent of n,h,τ, and the numerical solution u_h.

Noticing that for the DG method $\partial_x g_h=\partial_x(g_h-\widetilde{g_h})\in V_h$, we have, by virtue of the inverse property (i), a sharp estimate in the form

$$||\partial_x(\xi_w^n-\xi_u^n)||^2\le\frac{M\tau^2}{h^3}\alpha^2(\widehat{h};u_h^n)[\xi_u^n]^2+\left(\frac{C}{h^2}+\frac{C_\star}{h^4}||e_u^n||_\infty^2\right)||\xi_u^n||^2\tau^2+\Upsilon(n)h\tau. \tag{5.16}$$

To estimate the last integral term in (5.2), we multiply $\max_{1\le j\le N}|f'(u_j^n)|^2$ to both sides of the inequality (5.16) and analyze each term on the right-hand side separately. The first term can be bounded by using the following inequality:

$$\max_{1\le j\le N}|f'(u_j^n)|^2\le 8\max_{1\le j\le N}\alpha^2(\widehat{h};u_h^n)_{j+\frac12}+C_\star||e_u^n||_\infty^2,$$

which results from (3.2a) of Lemma 3.1, together with the smoothness of f and u; however, the other two terms can be bounded easily by using the boundedness of $\max_{1\le j\le N}|f'(u_j^n)|^2$. Thus, the last integral term in (5.2) for piecewise linear polynomials can be bounded by

$$\frac{M\tau^3}{h^3}\max_{1\le j\le N}\alpha^3(\widehat{h};u_h^n)_{j+\frac{1}{2}}\cdot\alpha(\widehat{h};u_h^n)[\xi_u^n]^2\tau+\left(\frac{C\tau^3}{h^2}+\frac{C_\star\tau^3}{h^4}||e_u^n||_\infty^2\right)||\xi_u^n||^2\tau+\Upsilon(n)h\tau^3,$$

where the inverse property (ii) and the boundedness of $\alpha(\widehat{h};u_h^n)$ (see Lemma 3.1) have been used.

We substitute this new estimate, together with (5.7), into (5.2). Then we get the following sharp estimate to the first term on the right-hand side of (4.4) for piecewise linear polynomials in the form

$$\begin{aligned}||\xi_u^{n+1}-\xi_w^n||^2\le{}&C(\Xi(n)h^4\tau+h^3\tau+\tau^6)+\delta_1(n)\alpha(\widehat{h};u_h^n)[\xi_u^n]^2\tau+\delta_2(n)\alpha(\widehat{h};w_h^n)[\xi_w^n]^2\tau\\&+\left\{\frac{C_\star\tau}{h^2}(||e_u^n||_\infty^2+||e_w^n||_\infty^2)+\frac{C_\star\tau^3}{h^4}||e_u^n||_\infty^2+C\tau\right\}||\xi_u^n||^2\tau,\end{aligned}\tag{5.17}$$

under the CFL condition $\tau\le\gamma h$ with a suitable CFL number γ (the exact bound of γ and the fact that it is bounded from below will be discussed later), where the positive constants C and $C_\star$ in (5.17) are independent of n,h,τ, and the approximate solution u_h, and $\Xi(n)=1+C_\star h^{-1}||e_u^n||_\infty^2+C_\star h^{-1}||e_w^n||_\infty^2$ has been defined in (5.1). In the above inequality (5.17),

$$\delta_1(n)=\frac{M\tau}{h}\max_{1\le j\le N}\alpha(\widehat{h};u_h^n)_{j+\frac{1}{2}}+\frac{M\tau^3}{h^3}\max_{1\le j\le N}\alpha^3(\widehat{h};u_h^n)_{j+\frac{1}{2}},\tag{5.18a}$$

$$\delta_2(n)=\frac{M\tau}{h}\max_{1\le j\le N}\alpha(\widehat{h};w_h^n)_{j+\frac{1}{2}},\tag{5.18b}$$

where the positive constant M is solely determined by the fixed constant ε and is independent of n,h,τ, the exact solution u^n, and the numerical solution u_h^n.

Therefore, by combining (5.8), (5.9), and (5.17), together with (5.7), and using the results (5.11) implied by the a priori assumption (5.10), under a suitable CFL condition $\tau\le\gamma h$, finally we obtain, for h small enough, that

$$\begin{aligned}&||\xi_u^{n+1}||^2-||\xi_u^n||^2+\frac{1}{4}\alpha(\widehat{h};u_h^n)[\xi_u^n]^2\tau+\frac{1}{4}\alpha(\widehat{h};w_h^n)[\xi_w^n]^2\tau\\&\le C(||\xi_u^n||^2\tau+h^3\tau+\tau^5)+\delta_1(n)\alpha(\widehat{h};u_h^n)[\xi_u^n]^2\tau+\delta_2(n)\alpha(\widehat{h};w_h^n)[\xi_w^n]^2\tau,\end{aligned}\tag{5.19}$$

where the positive constant C is independent of n,h,τ, and the approximate solution u_h^n.

Since the positive constant M in (5.18) is independent of n,h,τ, and the numerical solution u_h^n, there exist two positive constants r_1 and r_2, independent of n,h, and τ, such that

$$Mr_1+Mr_1^3\le\frac{1}{8}\quad\text{and}\quad Mr_2\le\frac{1}{8}.$$

Here we take r_1 and r_2 as large as possible under these restrictions. Then the time step τ^n for piecewise linear polynomials can be determined by $\tau^n\le\gamma^n h$, where the CFL number γ^n is given by

$$\gamma^n=\min\left\{r_1\left(\max_{1\le j\le N}\alpha(\widehat{h};u_h^n)_{j+\frac{1}{2}}\right)^{-1},r_2\left(\max_{1\le j\le N}\alpha(\widehat{h};w_h^n)_{j+\frac{1}{2}}\right)^{-1}\right\}.\tag{5.20}$$

Since the time step considered in this paper is assumed to be constant for convenience, we would like to write the above CFL condition in the uniform formulation $\tau \le \gamma h$, where the CFL number is taken as $\gamma = \min_{n \le N_\tau} \gamma^n$. We comment on the reason that γ is bounded below from zero in Remark 5.1 below.

Then, under this CFL condition, the inequality (5.19) shows that

$$||\xi_u^{n+1}||^2 - ||\xi_u^n||^2 + \frac{\tau}{8}\alpha(\widehat{h}; u_h^n)[\xi_u^n]^2 + \frac{\tau}{8}\alpha(\widehat{h}; w_h^n)[\xi_w^n]^2 \le C(||\xi_u^n||^2\tau + h^3\tau + \tau^5).$$

By Gronwall's inequality, we can get the following error estimate:

$$||\xi_u^{n+1}||^2 + \sum_{0 \le m \le n} \alpha(\widehat{h}; u_h^m)[\xi_u^m]^2\tau \le C_0 h^3, \quad \text{for any } \ n \le N_\tau, \tag{5.21}$$

where the positive constant C_0 is independent of n, h, τ, and the approximate solution u_h^n. Thus the conclusion (3.4a) for linear piecewise polynomials in Theorem 3.1 follows by triangle inequality and the interpolating property (4.7).

To complete the proof, let us verify the a priori assumption (5.10). If it is satisfied for a certain n, then it follows from (5.21) and the interpolation property (4.7) that

$$||u^{n+1} - u_h^{n+1}|| \le C_0 h^{3/2}.$$

It implies that $||u^{n+1} - u_h^{n+1}|| \le h$ for small enough h and the assumption (5.10) is also true for $n+1$. Thus the given a priori (5.10) is verified, and all of the estimates above based on this a priori (5.10) still hold for $n \le N_\tau$. This completes the proof of (3.4a) for the linear piecewise polynomials and for arbitrary monotone numerical fluxes in Theorem 3.1.

Remark 5.1. We notice that the condition (5.20) is the usual CFL condition for conservation laws. For example, by Lemma 3.1 and (5.11) we know that for any numerical flux $\alpha(\widehat{h}; u_h^n)$ is lower bounded by a constant times the maximum of $|f'|$ for h small enough. For example, the CFL number γ for the linear flux $f = cu$, determined by (5.20), depends solely on $|c|$. This also explains why the CFL constant γ is lower bounded away from zero during mesh refinements.

5.2.2. Estimates for the high order polynomials. As we have mentioned before, the property (5.13) is not true for high order piecewise polynomials. Then we can only get the following estimate to the first term on the right-hand side of (4.4):

$$\begin{aligned} ||\xi_u^{n+1} - \xi_w^n||^2 \le{}& C(\Xi(n)h^{2k+2}\tau + \tau^6) + \frac{M\tau^2}{h}\alpha^2(\widehat{h}; w_h^n)[\xi_w^n]^2 + \frac{M\tau^2}{h}\alpha^2(\widehat{h}; u_h^n)[\xi_u^n]^2 \\ &+ \left\{ \frac{C_\star \tau^2}{h^2}(||e_u^n||_\infty^2 + ||e_w^n||_\infty^2)||\xi_u^n||^2 + C\left(\tau^2 + \frac{\tau^4}{h^4}\right) \right\} ||\xi_u^n||^2 \end{aligned} \tag{5.22}$$

by combining (5.2) and (5.7) and using the inverse properties (i) and (ii). Here the constants C and $C_\star$ are independent of n, h, τ, and the approximate solution u_h, the constant M depends solely on the fixed positive constant ε, and $\Xi(n) = 1 + C_\star h^{-1}||e_u^n||_\infty^2 + C_\star h^{-1}||e_w^n||_\infty^2$ has been defined in (5.1).

Comparing this estimate (5.22) with (5.17), we can see that there is an additional factor τ^4/h^4 in front of the term $||\xi_u^n||^2$ for high order piecewise polynomials. It implies a need for the stronger time-step restriction $\tau \le \gamma h^{\frac{4}{3}}$. For high order ($k \ge 2$) piecewise polynomials, it is justified to have such a stronger time-step restriction because the

scheme (2.4) is linearly unstable under CFL condition $\tau \le \gamma h$ for any fixed $\gamma > 0$; see [12].

The remaining analysis for high order polynomials is almost identical to that for the linear piecewise polynomials, so we omit the details. Finally, under the stronger time-step restriction we also get the conclusion (3.4a).

Remark 5.2. We have only carried out the details of the error estimate for sufficiently smooth solutions of one-dimensional scalar conservation laws. However, for a linear flux $f = cu$ the results of Theorem 3.1 still hold for multidimensional conservation laws, because the a priori assumption (5.10) is unnecessary. Moreover, for d-dimensional general nonlinear problems the above analysis still works if we assume the degree of piecewise polynomials satisfies $k > \frac{1}{2}(d+1)$ to keep the a priori assumption (5.10) valid.

Remark 5.3. The assumption $f \in C^3$ is used in the above estimates. However, for the piecewise high order ($k \ge 2$) polynomials it is enough to assume $f \in C^2$ by using another a priori assumption, $||u^n - u_h^n|| \le h^{3/2}$, and using lower order Taylor expansions. The details of the analysis are omitted since they are very similar to what we have presented above.

5.3. Optimal error estimates for the upwind numerical fluxes. In this subsection we shall study the error estimates for RKDG schemes with upwind numerical fluxes. A numerical flux $\widehat{h}(p)$ is called upwind if it satisfies

$$\widehat{h}(p) = \begin{cases} f(p^-) & \text{if } f'(q) \ge 0 \quad \forall q \in [\min(p^-, p^+), \max(p^-, p^+)], \\ f(p^+) & \text{if } f'(q) < 0 \quad \forall q \in [\min(p^-, p^+), \max(p^-, p^+)]. \end{cases}$$

The best-known examples of upwind numerical fluxes are the Godunov flux, the Engquist–Osher flux, and the Roe flux with an entropy fix. In addition, we assume that, on each boundary point, the quantity $\alpha(\widehat{h}; p)$ for the upwind numerical flux depends on the value $|f'(p)|$ in a *local* interval including $p^{\pm}$; i.e., there are positive constants C and $C_\star$ independent of f and p such that

$$\alpha(\widehat{h}; p) \le C|f'(\bar{p})| + C_\star|[p]|. \tag{5.23}$$

This assumption (5.23), together with (3.2a), demonstrates the approximate equivalence between the quantity $\alpha(\widehat{h}; p)$ and $|f'(\bar{p})|$. It is easy to verify that all of the upwind numerical fluxes mentioned above satisfy this assumption (5.23).

To obtain the optimal error estimates for these upwind numerical fluxes, we will estimate again each term on the right-hand side of the energy equation (4.4), following along the lines of the analysis in subsection 5.2. Most of the analysis is similar to that in subsection 5.2; we thus point out only the main differences. One such difference is that the Gauss–Radau projection $\mathbb{R}_h$, which interpolates at one of the boundary points of each cell, is used here; see subsection 4.2. The other is that a new reference value $p_h^{n,\star}$ ($p_h^n = u_h^n$ or w_h^n) on each boundary point $x_{j+1/2}$ at time $t = t^n$ is introduced, corresponding to the sign of $f'(u^n)$ on the adjacent elements $I_j \cup I_{j+1}$. If $f'(u^n) < 0$ on $I_j \cup I_{j+1}$ (i.e., the wind blows to the left), we take the reference value $p_h^{n,\star} = p_h^{n,+}$; otherwise (i.e., either $f'(u^n)$ is always positive or it has zero point(s) in $I_j \cup I_{j+1}$), we take the reference value $p_h^{n,\star} = p_h^{n,-}$. This replaces the simple reference value $\bar{p}_h^n = \bar{p}_h$, the average of p_h, used for the case of general monotone numerical fluxes in subsection 5.2.

We now state conclusions for each term on the right-hand side of the energy equation (4.4), in parallel to those in subsection 5.2. We shall only present the results

for piecewise linear polynomials as an example, with proofs deferred to the appendix. In what follows we will use the notation $|f'(u^n)|[\xi_u^n]^2 = \sum_{1\le j\le N} |f'(u^n_{j+\frac{1}{2}})|[\xi_u^n]^2_{j+\frac{1}{2}}$, etc.

LEMMA 5.6. *If the Gauss–Radau projection $\mathbb{R}_h$ is used, then we have, for piecewise linear polynomials ($k = 1$),*

$$
\begin{aligned}
||\xi_u^{n+1} - \xi_w^n||^2 \le C\,(\Xi(n)h^4\tau + \tau^6) + \widetilde{\delta}_1(n)|f'(u^n)|[\xi_u^n]^2\tau + \widetilde{\delta}_2(n)|f'(w^n)|[\xi_w^n]^2\tau \\
+ \left\{ \frac{C_\star\tau^2}{h^2}(||e_u^n||_\infty^2 + ||e_w^n||_\infty^2) + \frac{C_\star\tau^4}{h^4}||e_u^n||_\infty^2 + C\tau^2 \right\} ||\xi_u^n||^2,
\end{aligned} \tag{5.24}
$$

under the general CFL condition $\tau \le Ch$, where the positive constants C and $C_\star$ are independent of n, h, τ, and the approximate solution u_h, and

$$
\widetilde{\delta}_1(n) = \frac{M\tau}{h}||f'(u^n)||_\infty + \frac{M\tau^3}{h^3}||f'(u^n)||_\infty^3 \quad \textit{and} \quad \widetilde{\delta}_2(n) = \frac{M\tau}{h}||f'(w^n)||_\infty, \tag{5.25}
$$

with the positive constant M independent of n, h, τ, u, and u_h.

Remark 5.4. For higher order piecewise polynomials, the estimate to the first term on the right-hand side of the energy equation (4.4), namely $||\xi_u^{n+1} - \xi_w^n||^2$, is almost the same as (5.24), except for an additional factor τ^4/h^4 in front of the last term $||\xi_u^n||^2$.

LEMMA 5.7. *If the Gauss–Radau projection $\mathbb{R}_h$ is used, then we have, for piecewise polynomials with any degree $k \ge 1$, that*

$$
\mathcal{K}^n(\xi_u^n) \le \Psi(u^n)||\xi_u^n||^2\tau - \frac{1}{2}|f'(u^n)|[\xi_u^n]^2\tau + (C + C_\star h^{-2}||e_u^n||_\infty^2)h^{2k+2}\tau, \tag{5.26a}
$$

$$
\mathcal{L}^n(\xi_w^n) \le \Psi(w^n)||\xi_w^n||^2\tau - \frac{1}{2}|f'(w^n)|[\xi_w^n]^2\tau + (C + C_\star h^{-2}||e_w^n||_\infty^2)h^{2k+2}\tau + C\tau^5, \tag{5.26b}
$$

where $\Psi(p^n) = C + C_\star(h^{-1}||e_p^n||_\infty + h^{-2}||e_p^n||_\infty^2)$ ($p = u, w$), and the positive constants C and $C_\star$ are independent of n, h, τ, and the approximate solution u_h.

To deal with the nonlinearity of the flux $f(u)$, we would also like to use here an a priori assumption that, for small enough h,

$$
||u^n - u_h^n|| \le h^{3/2}, \tag{5.27}
$$

which implies that $||e_u^n||_\infty \le Ch$ and $||e_w^n||_\infty \le Ch$. It is easy to verify that this a priori assumption is true.

Finally, by combining the above estimates (5.24), (5.26a), and (5.26b), we can use Gronwall's inequality to obtain the optimal error estimates for upwind numerical fluxes under a suitable CFL condition.

For piecewise linear polynomials, the usual CFL condition $\tau \le \gamma h$ is enough, where the CFL number γ can be determined by $\widetilde{\delta}_1(n) \le 1/4$ and $\widetilde{\delta}_2(n) \le 1/4$. The treatment is similar to that shown in subsection 5.2. However, for piecewise higher order polynomials, a stronger restriction on the time step is needed, as an additional factor τ^4/h^4 appears in front of the term $||\xi_u^n||^2$ in (5.24).

This finishes the proof of (3.4b) for upwind numerical fluxes and thus for all results in Theorem 3.1.

6. Appendix: Proof of several lemmas. We collect the rather technical proofs of Lemmas 5.1, 5.4, 5.6, and 5.7 in this appendix. The conclusions of these lemmas are used in the previous sections to prove Theorem 3.1.

6.1. Proof of Lemma 5.1. Denote $\Pi(n) = f(w^n) - f(w_h^n) - f(u^n) + f(u_h^n)$ for x inside each element and $\hat{\Pi}(n) = f(w^n) - \widehat{h}(w_h^n) - f(u^n) + \widehat{h}(u_h^n)$ for x on the boundary points of each element. Then by subtracting (4.3d) from (4.3e), we have, for any $v_h \in V_h$, the following result:

$$\begin{aligned}(\mathcal{L}_j^n - \mathcal{K}_j^n)(v_h) &= 2\int_{I_j} (\eta_u^{n+1} - \eta_w^n + E(x;n))v_h\,dx + \tau\int_{I_j} \Pi(n)\partial_x v_h\,dx \\ &\quad - \tau\hat{\Pi}(n)_{j+\frac{1}{2}} v_h(x_{j+\frac{1}{2}}^-) + \tau\hat{\Pi}(n)_{j-\frac{1}{2}} v_h(x_{j-\frac{1}{2}}^+) \\ &\triangleq \theta_{1,j}(v_h) + \theta_{2,j}(v_h) + \theta_{3,j}(v_h) + \theta_{4,j}(v_h). \end{aligned} \tag{6.1}$$

We denote the sum of $\theta_{i,j}(v_h)$ over all the elements I_j by $\Theta_i(v_h) = \sum_{1\le j\le N} \theta_{i,j}(v_h)$, where $i = 1, 2, 3, 4$.

We shall analyze each term on the right-hand side of (6.1) separately. The main tool used is Taylor expansion.

First, it is easy to show from Young's inequality $ab \le \varepsilon a^2 + b^2/(4\varepsilon)$, together with $E(x,n) = O(\tau^3)$ (see Lemma 4.1) and the approximation property (4.9), that

$$|\Theta_1(v_h)| \le C(h^{2k+2}\tau^2 + \tau^6) + \varepsilon||v_h||^2,$$

where ε is a small positive constant.

To estimate the second term $\Theta_2(v_h)$, we would like to split the term $\Pi(n)$ into five terms by the Taylor expansion and the definition (4.1), i.e.,

$$\begin{aligned}\Pi(n) &= \tau f''_{w,u} u'(t)(\xi_w^n - \eta_w^n) - \frac{1}{2} f''_w (\xi_w^n - \eta_w^n)^2 + \frac{1}{2} f''_u (\xi_u^n - \eta_u^n)^2 \\ &\quad - f'(u^n)(\eta_w^n - \eta_u^n) + f'(u^n)(\xi_w^n - \xi_u^n) \\ &\triangleq R_1 + R_2 + R_3 + R_4 + R_5; \end{aligned} \tag{6.2}$$

here f''_u, f''_w, and $f''_{w,u}$ are the mean values given by $f''_p = f''(\theta_p p^n + (1-\theta_p)p_h^n)$ and $f''_{u,w} = f''(\theta_{u,w} u^n + (1-\theta_{u,w})w^n)$ with $0 \le \theta_p \le 1$ $(p = u, w)$ and $0 \le \theta_{u,w} \le 1$. Thus, we can write, corresponding to each element I_j, the second term $\Theta_2(v_h)$ in the form

$$\theta_{2,j}(v_h) = \sum_{i=1}^5 \int_{I_j} \tau R_k \partial_x v_h\,dx = \sum_{i=1}^5 S_{i,j}(v_h).$$

Denote the sum of $S_{i,j}(v_h)$ over all elements I_j by $S_i(v_h)$; then $\Theta_2(v_h) = \sum_{i=1}^5 S_i(v_h)$. By Young's inequality and the inverse property (i), it is easy to get that

$$\begin{aligned} |S_1(v_h)| &\le \frac{C_\star \tau^4}{h^2}||\xi_w^n - \eta_w^n||^2 + \varepsilon||v_h||^2, \\ |S_2(v_h)| &\le \frac{C_\star \tau^2}{h^2}||e_w^n||_\infty^2||\xi_w^n - \eta_w^n||^2 + \varepsilon||v_h||^2, \\ |S_3(v_h)| &\le \frac{C_\star \tau^2}{h^2}||e_u^n||_\infty^2||\xi_u^n - \eta_u^n||^2 + \varepsilon||v_h||^2, \\ |S_4(v_h)| &\le \frac{C\tau^2}{h^2}||\eta_w^n - \eta_u^n||^2 + \varepsilon||v_h||^2. \end{aligned}$$

The last term $S_5(v_h)$, which is the sum of $S_{5,j}(v_h) = \tau \int_{I_j} f'(u^n)(\xi_w^n - \xi_u^n)\partial_x v_h \, dx$ for $1 \le j \le N$, remains to be estimated later, together with a few other terms.

Now we are going to estimate the last two terms in (6.1), namely $\theta_{3,j}(v_h)$ and $\theta_{4,j}(v_h)$, which are related to the numerical flux on the boundary points of each element I_j. Since their analysis is almost the same, we will only present the details of the estimate to the term $\theta_{3,j}(v_h) = -\tau\hat{\Pi}(n)_{j+\frac{1}{2}} v_h(x^-_{j+\frac{1}{2}})$. To do this, we write $\hat{\Pi}(n)_{j+\frac{1}{2}}$ in the following way:

$$\hat{\Pi}(n) = \underbrace{f(w^n) - f(\bar{w}_h^n)}_{\Lambda_1} \underbrace{-f(u^n) + f(\bar{u}_h^n)}_{\Lambda_2} \underbrace{-f(\bar{u}_h^n) + \widehat{h}(u_h^n)}_{\Lambda_3} \underbrace{+f(\bar{w}_h^n) - \widehat{h}(w_h^n)}_{\Lambda_4}, \tag{6.3}$$

where the subscript $j + 1/2$ is omitted for convenience. As we have done for $\theta_{2,j}(v_h)$, we expand the first two terms, Λ_1 and Λ_2, by Taylor expansion in the form

$$\begin{aligned}\Lambda_1 + \Lambda_2 &= f''_{w,u} u'(t)\tau(\bar{\xi}_w^n - \bar{\eta}_w^n) - \frac{1}{2} f''_w(\bar{\xi}_w^n - \bar{\eta}_w^n)^2 + \frac{1}{2} f''_u(\bar{\xi}_u^n - \bar{\eta}_u^n)^2 \\ &\quad - f'(u^n)(\bar{\eta}_w^n - \bar{\eta}_u^n) + f'(u^n)(\bar{\xi}_w^n - \bar{\xi}_u^n) \\ &\triangleq Q_1 + Q_2 + Q_3 + Q_4 + Q_5, \end{aligned} \tag{6.4}$$

where f''_u, f''_w, and $f''_{w,u}$ are again the mean values. We remark that although we use the same notation here as that in (6.2), this notation may have different mean values. Therefore, we have the following representation for the terms $\theta_{3,j}(v_h)$ and $\theta_{4,j}(v_h)$:

$$\theta_{3,j} = -\tau(Q_1 + \cdots + Q_5 + \Lambda_3 + \Lambda_4)_{j+\frac{1}{2}} v_h(x^-_{j+\frac{1}{2}}) \triangleq (T_{1,j} + \cdots + T_{5,j} + T_{6,j} + T_{7,j})(v_h),$$

$$\theta_{4,j} = +\tau(Q_1 + \cdots + Q_5 + \Lambda_3 + \Lambda_4)_{j-\frac{1}{2}} v_h(x^+_{j-\frac{1}{2}}) \triangleq (\widetilde{T}_{1,j} + \cdots + \widetilde{T}_{5,j} + \widetilde{T}_{6,j} + \widetilde{T}_{7,j})(v_h).$$

Denote the sum of $T_{i,j}(v_h)$ (respectively, $\widetilde{T}_{i,j}(v_h)$) over all elements I_j by $T_i(v_h)$ (respectively, $\widetilde{T}_i(v_h)$). Next we will estimate one by one the terms listed above.

By Young's inequality and the inverse property (ii), it is easy to show that

$$\begin{aligned}|T_1(v_h)| &\le \frac{C_\star \tau^4}{h^2}||\xi_w^n||^2 + \frac{C_\star \tau^4}{h}||\eta_w^n||^2_{\Gamma_h} + \varepsilon||v_h||^2, \\ |T_2(v_h)| &\le \frac{C_\star \tau^2}{h^2}||e_w^n||^2_\infty||\xi_w^n||^2 + \frac{C_\star \tau^2}{h}||e_w^n||^2_\infty||\eta_w^n||^2_{\Gamma_h} + \varepsilon||v_h||^2, \\ |T_3(v_h)| &\le \frac{C_\star \tau^2}{h^2}||e_u^n||^2_\infty||\xi_u^n||^2 + \frac{C_\star \tau^2}{h}||e_u^n||^2_\infty||\eta_u^n||^2_{\Gamma_h} + \varepsilon||v_h||^2, \\ |T_4(v_h)| &\le \frac{C\tau^2}{h}||\eta_w^n - \eta_u^n||^2_{\Gamma_h} + \varepsilon||v_h||^2. \end{aligned}$$

By virtue of the definition of $\alpha(\widehat{h}; u_h^n)$ in Lemma 3.1, we have that

$$\begin{aligned}|\Lambda_3| &= \alpha(\widehat{h}; u_h^n)|[u_h^n]| = \alpha(\widehat{h}; u_h^n)|[u^n - u_h^n]| \le \alpha(\widehat{h}; u_h^n)(|[\xi_u^n]| + |[\eta_u^n]|), \\ |\Lambda_4| &= \alpha(\widehat{h}; w_h^n)|[w_h^n]| = \alpha(\widehat{h}; w_h^n)|[w^n - w_h^n]| \le \alpha(\widehat{h}; w_h^n)(|[\xi_w^n]| + |[\eta_w^n]|). \end{aligned}$$

Then Young's inequality with the inverse property (ii) implies that the terms $T_6(v_h)$ and $T_7(v_h)$ can be bounded in the form

$$\begin{aligned}|T_6(v_h)| &\le \frac{M(\varepsilon)\tau^2}{h}\alpha^2(\widehat{h}; u_h^n)[\xi_u^n]^2 + \frac{C\tau^2}{h}\alpha^2(\widehat{h}; u_h^n)[\eta_u^n]^2 + \varepsilon||v_h||^2, \\ |T_7(v_h)| &\le \frac{M(\varepsilon)\tau^2}{h}\alpha^2(\widehat{h}; w_h^n)[\xi_w^n]^2 + \frac{C\tau^2}{h}\alpha^2(\widehat{h}; w_h^n)[\eta_w^n]^2 + \varepsilon||v_h||^2. \end{aligned}$$

Thus we have estimated each term included in $\Theta_3(v_h)$, except the term $T_5(v_h)$, which is the sum of $T_{5,j}(v_h) = -\tau f'(u^n_{j+1/2})(\bar{\xi}^n_w - \bar{\xi}^n_u)_{j+1/2} v_h(x_{j+1/2})$ over each element I_j. This term will be estimated later, together with a few other terms.

Along the same lines we have almost the same estimate to the term $\Theta_4(v_h)$, except that the term $\widetilde{T}_5(v_h)$, which is the sum of $\tilde{T}_{5,j}(v_h) = \tau f'(u^n_{j-1/2})(\bar{\xi}^n_w - \bar{\xi}^n_u)_{j-1/2} v_h(x_{j-1/2})$ over each element I_j, is also left to be estimated later.

We now have obtained estimates for each term in the difference $(\mathcal{L}^n_j - \mathcal{K}^n_j)(v_h)$, except for three remaining terms, namely $S_5(v_h), T_5(v_h)$, and $\widetilde{T}_5(v_h)$. To estimate them sharply, we would like to consider their sum on each element I_j. After a simple integration by parts, we have that

$$\begin{aligned}
&S_{5,j}(v_h) + T_{5,j}(v_h) + \widetilde{T}_{5,j}(v_h) \\
&= -\tau \int_{I_j} f'(u^n_j) v_h \partial_x (\xi^n_w - \xi^n_u)\, dx - \tau \int_{I_j} \{f'(u^n) - f'(u^n_j)\} v_h \partial_x (\xi^n_w - \xi^n_u)\, dx \\
&\quad - \tau \int_{I_j} \partial_x f'(u^n)(\xi^n_w - \xi^n_u) v_h\, dx - \frac{\tau}{2} f'(u^n_{j+\frac{1}{2}})[\xi^n_w - \xi^n_u]_{j+\frac{1}{2}} v_h(x^-_{j+\frac{1}{2}}) \\
&\quad + \frac{\tau}{2} f'(u^n_{j-\frac{1}{2}})[\xi^n_w - \xi^n_u]_{j-\frac{1}{2}} v_h(x^+_{j-\frac{1}{2}}) \\
&\triangleq G_{1,j}(v_h) + G_{2,j}(v_h) + G_{3,j}(v_h) + G_{4,j}(v_h) + G_{5,j}(v_h), \qquad (6.5)
\end{aligned}$$

where we have introduced the piecewise constant $u^n_j = u((x_{j+1/2} + x_{j-1/2})/2, t^n)$ on each element I_j. Also we denote the sum of $G_{i,j}(v_h)$ over all elements I_j by $G_i(v_h)$, and then

$$S_5(v_h) + T_5(v_h) + \widetilde{T}_5(v_h) = G_1(v_h) + G_2(v_h) + G_3(v_h) + G_4(v_h) + G_5(v_h). \qquad (6.6)$$

In what follows we will estimate each term on the right-hand side of (6.6) separately.

It follows that $|f'(u^n) - f'(u^n_j)| = O(h)$ on each element I_j from the smoothness of the solution u and the flux f. Then by the inverse property (i) and Young's inequality, it is easy to show that

$$|G_2(v_h)| \le C\tau^2 ||\xi^n_w - \xi^n_u||^2 + \varepsilon ||v_h||^2.$$

By Young's inequality we can show that

$$|G_3(v_h)| \le C\tau^2 ||\xi^n_w - \xi^n_u||^2 + \varepsilon ||v_h||^2.$$

For the last two terms on the right-hand side of (6.6) related to the numerical flux, namely $G_4(v_h)$ and $G_5(v_h)$, we need to estimate them more carefully. Our aim is to bound them by the product of $\alpha(\widehat{h}; u^n_h)$ or $\alpha(\widehat{h}; w^n_h)$ and the corresponding jump of ξ^n_u or ξ^n_w across element interfaces.

Since the estimates are very similar, we will only present the analysis to the term $G_4(v_h)$. Dropping the subscript $j + 1/2$ for convenience, we have the following representation:

$$\begin{aligned}
f'(u^n)[\xi^n_w - \xi^n_u] &= f'(w^n)[\xi^n_w] - f'(u^n)[\xi^n_u] + (f'(u^n) - f'(w^n))[\xi^n_w] \\
&= f'(\bar{w}^n_h)[\xi^n_w] - f'(\bar{u}^n_h)[\xi^n_u] + (f'(w^n) - f'(\bar{w}^n_h))[\xi^n_w] \\
&\quad - (f'(u^n) - f'(\bar{u}^n_h))[\xi^n_u] + (f'(u^n) - f'(w^n))[\xi^n_w] \\
&\triangleq \gamma_{1,j} + \gamma_{2,j} + \cdots + \gamma_{5,j}.
\end{aligned}$$

Then we have $G_4(v_h) = \sum_{i=1}^{5} \gamma_i(v_h)$, where $\gamma_i(v_h) = -\frac{\tau}{2} \sum_{1\le j\le N} \gamma_{i,j} v_h(x_{j+1/2})$. We would like to estimate each term separately. We use the conclusion (3.2a) in Lemma 3.1 to analyze the terms $\gamma_1(v_h)$ and $\gamma_2(v_h)$. Finally, by Young's inequality and the inverse property (ii), we have that

$$
\begin{aligned}
|\gamma_1(v_h)| &\le M(\varepsilon)\frac{\tau^2}{h}\alpha^2(\widehat{h}; w_h^n)[\xi_w^n]^2 + \frac{C_\star \tau^2}{h^2}||e_w^n||_\infty^2||\xi_w^n||^2 + \frac{\varepsilon}{5}||v_h||^2,\\
|\gamma_2(v_h)| &\le M(\varepsilon)\frac{\tau^2}{h}\alpha^2(\widehat{h}; u_h^n)[\xi_u^n]^2 + \frac{C_\star \tau^2}{h^2}||e_u^n||_\infty^2||\xi_u^n||^2 + \frac{\varepsilon}{5}||v_h||^2,\\
|\gamma_3(v_h)| &\le \frac{C_\star \tau^2}{h^2}||e_w^n||_\infty^2||\xi_w^n||^2 + \frac{\varepsilon}{5}||v_h||^2,\\
|\gamma_4(v_h)| &\le \frac{C_\star \tau^2}{h^2}||e_u^n||_\infty^2||\xi_u^n||^2 + \frac{\varepsilon}{5}||v_h||^2,\\
|\gamma_5(v_h)| &\le \frac{C_\star \tau^4}{h^2}||\xi_w^n||^2 + \frac{\varepsilon}{5}||v_h||^2.
\end{aligned}
$$

Therefore, we conclude, by summing up the above estimates, that

$$
\begin{aligned}
|G_4(v_h)| \le \varepsilon||v_h||^2 &+ \frac{C_\star \tau^2}{h^2}||e_u^n||_\infty^2||\xi_u^n||^2 + \frac{C_\star \tau^2}{h^2}||e_w^n||_\infty^2||\xi_w^n||^2 + \frac{C_\star \tau^4}{h^2}||\xi_w^n||^2\\
&+ M(\varepsilon)\frac{\tau^2}{h}\alpha^2(\widehat{h}; w_h^n)[\xi_w^n]^2 + M(\varepsilon)\frac{\tau^2}{h}\alpha^2(\widehat{h}; u_h^n)[\xi_u^n]^2,
\end{aligned}
$$

where the positive constant $M(\varepsilon)$ depends on ε solely, and the other positive constants C and $C_\star$ are independent of n, h, τ, and the numerical solution u_h.

Similarly, we can obtain the same estimate for the term $G_5(v_h)$ as that for $G_4(v_h)$.

Note that until now we have not yet analyzed the first term $G_1(v_h)$ in (6.6), which is the sum of $G_{1,j}(v_h) = -\tau \int_{I_j} f'(u_j^n) v_h \partial_x(\xi_w^n - \xi_u^n)\, dx$ over each element I_j. This term is left to be estimated differently for piecewise polynomials of different degrees; see subsection 5.2.

Finally, by collecting all the analysis presented above and using the interpolation property (4.7) and (4.9) and the general CFL condition $\tau \le Ch$, after some simple calculations we finish the proof of Lemma 5.1. ∎

6.2. Proof of Lemma 5.4. Noticing the periodic or zero (compactly supported) boundary conditions, after some simple calculation we have the sum of $\mathcal{K}_j^n(\xi_u^n)$ as follows:

$$
\begin{aligned}
\mathcal{K}^n(\xi_u^n) = (\eta_w^n - \eta_u^n, \xi_u^n) &+ \tau \sum_{1\le j\le N} \int_{I_j} \big(f(u^n) - f(u_h^n)\big)\partial_x \xi_u^n\, dx\\
&+ \tau \sum_{1\le j\le N} \big\{f(u^n) - f(\bar{u}_h^n)\big\}_{j+\frac{1}{2}} \big[\xi_u^n\big]_{j+\frac{1}{2}} + \tau \sum_{1\le j\le N} \big\{f(\bar{u}_h^n) - \widehat{h}(u_h^n)\big\}_{j+\frac{1}{2}} \big[\xi_u^n\big]_{j+\frac{1}{2}}\\
&\triangleq W_1 + W_2 + W_3 + W_4. \qquad (6.7)
\end{aligned}
$$

Note that we refer to $\bar{u}_h^n$ in the terms W_3 and W_4 above as the reference value on each boundary point. We would like to analyze each term on the right-hand side of (6.7) separately.

First, it follows from the interpolation property (4.9) that

$$
W_1 \le Ch^{2k+2}\tau + C\tau||\xi_u^n||^2. \qquad (6.8)
$$

Since the exact solution u^n of conservation laws (1.1) is continuous on each boundary point, we have that $[u_h^n] = -[e_u^n] = [\eta_u^n - \xi_u^n]$. Noticing the definition and boundedness of $\alpha(\widehat{h}; u_h^n)$ (see Lemma 3.1), we can easily show, by Young's inequality and the interpolation property (4.7), that

$$W_4 \le -\frac{3}{4}\alpha(\widehat{h}; u_h^n)[\xi_u^n]^2\tau + C\alpha(\widehat{h}; u_h^n)[\eta_u^n]^2\tau \le -\frac{3}{4}\alpha(\widehat{h}; u_h^n)[\xi_u^n]^2\tau + Ch^{2k+1}\tau. \tag{6.9}$$

To complete the proof of Lemma 5.4, we should pay more attention to the terms W_2 and W_3. Thus we would like to use the following Taylor expansions:

$$\begin{aligned} f(u^n) - f(u_h^n) &= f'(u^n)\xi_u^n - \frac{1}{2}f''(u^n)(\xi_u^n)^2 - f'(u^n)\eta_u^n + f''(u^n)\xi_u^n\eta_u^n \\ &\quad - \frac{1}{2}f''(u^n)(\eta_u^n)^2 - \frac{1}{6}f'''_u(\xi_u^n - \eta_u^n)^3 \triangleq \phi_1 + \cdots + \phi_6, \end{aligned} \tag{6.10a}$$

$$\begin{aligned} f(u^n) - f(\bar{u}_h^n) &= f'(u^n)\bar{\xi}_u^n - \frac{1}{2}f''(u^n)(\bar{\xi}_u^n)^2 - f'(u^n)\bar{\eta}_u^n + f''(u^n)\bar{\xi}_u^n\bar{\eta}_u^n \\ &\quad - \frac{1}{2}f''(u^n)(\bar{\eta}_u^n)^2 - \frac{1}{6}\tilde{f}'''_u(\bar{\xi}_u^n - \bar{\eta}_u^n)^3 \triangleq \psi_1 + \cdots + \psi_6, \end{aligned} \tag{6.10b}$$

where f'''_u and $\tilde{f}'''_u$ are again the mean values. These imply the following representation:

$$W_2 = X_1 + X_2 + \cdots + X_6 \quad \text{and} \quad W_3 = Y_1 + Y_2 + \cdots + \cdots + Y_6,$$

where X_i and Y_i, given by

$$X_i = \tau \sum_{1\le j\le N} \int_{I_j} \phi_i \partial_x \xi_u^n \, dx \quad \text{and} \quad Y_i = \tau \sum_{1\le j\le N} (\psi_i)_{j+\frac{1}{2}} [\xi_u^n]_{j+\frac{1}{2}} \quad (i = 1, 2, \ldots, 6),$$

will be estimated separately later.

It is easy to get, after a simple integration by parts, that

$$X_1 + Y_1 = -\frac{\tau}{2} \sum_{1\le j\le N} \int_{I_j} \partial_x f'(u^n)(\xi_u^n)^2 \, dx \le C||\xi_u^n||^2\tau \tag{6.11a}$$

and

$$X_2 + Y_2 = \frac{\tau}{24} \sum_{1\le j\le N} f''(u^n)_{j+\frac{1}{2}} \left[\xi_u^n\right]_{j+\frac{1}{2}}^3 + \frac{\tau}{6} \sum_{1\le j\le N} \int_{I_j} \partial_x f''(u^n)(\xi_u^n)^3 \, dx.$$

Notice that $f''(u^n)[\xi_u^n] = f''(\bar{u}_h^n)[\eta_h^n] - f''(\bar{u}_h^n)[u_h^n] + f'''[\xi_u^n]e_u^n$ by a simple Taylor expansion, where f''' denotes a mean value of the third derivative of the flux f. It implies, together with (3.2b) of Lemma 3.1 and the interpolation property (4.7), that on each boundary point $x_{j+1/2}$ there holds $\frac{1}{24}f''(u^n)[\xi_u^n] \le \frac{1}{3}\alpha(\widehat{h}; u_h^n) + C_\star(h + ||e_u^n||_\infty^2)$. Thus we have, by virtue of the inverse property (ii), that

$$X_2 + Y_2 \le \frac{1}{3}\alpha(\widehat{h}; u_h^n)[\xi_u^n]^2\tau + C_\star(C + ||\xi_u^n||_\infty + h^{-1}||e_u^n||_\infty^2)||\xi_u^n||^2\tau. \tag{6.11b}$$

As we have shown before, $|f'(u^n) - f'(u_j^n)| = O(h)$ on each element I_j. Then by the inverse property (i), together with the interpolation property (4.7) and (4.8), we have that

$$\begin{aligned} X_3 &\le \tau \sum_{1\le j\le N} \left| \int_{I_j} (f'(u^n) - f'(u_j^n))\eta_u^n \partial_x \xi_u^n \, dx \right| + \tau \sum_{1\le j\le N} \left| f'(u_j^n) \int_{I_j} \eta_u^n \partial_x \xi_u^n \, dx \right| \\ &\le Ch^{2k+2}\tau + C||\xi_u^n||^2\tau. \end{aligned}$$

It follows easily that $|f'(u^n_{j+1/2})| \le 2\alpha(\widehat{h}; u^n_h)_{j+1/2} + C_\star ||e^n_u||_\infty$ for any $1 \le j \le N$ from the conclusion (3.2a) in Lemma 3.1 and the smoothness of u and f. Hence, by Young's inequality and the boundedness of $\alpha(\widehat{h}; u^n_h)$ (see Lemma 3.1), we have that

$$Y_3 \le Ch^{2k+1}\tau + \frac{1}{6}\alpha(\widehat{h}; u^n_h)[\xi^n_u]^2\tau + \frac{C_\star\tau}{h}||e^n_u||^2_\infty ||\xi^n_u||^2.$$

Thus, we have that

$$X_3 + Y_3 \le \frac{1}{6}\alpha(\widehat{h}; u^n_h)[\xi^n_u]^2\tau + (C + C_\star h^{-1}||e^n_u||^2_\infty)||\xi^n_u||^2\tau + Ch^{2k+1}\tau. \tag{6.11c}$$

It is easy to show by Young's inequality and the inverse properties (i) and (ii) that

$$X_4 + Y_4 \le C_\star h^{-1}||\eta^n_u||_\infty ||\xi^n_u||^2\tau \le C_\star ||\xi^n_u||^2\tau, \tag{6.11d}$$

$$X_5 + Y_5 \le C_\star h^{-1}||\eta^n_u||_\infty (||\eta^n_u|| + h^{\frac{1}{2}}||\eta^n_u||_{\Gamma_h})||\xi^n_u||\tau \le C_\star ||\xi^n_u||^2\tau + C_\star h^{2k+2}\tau, \tag{6.11e}$$

$$X_6 + Y_6 \le C_\star h^{-1}||e^n_u||^2_\infty (||\xi^n_u||^2\tau + Ch^{2k+2}\tau). \tag{6.11f}$$

Therefore, by summing up the above estimates about W_2 and W_3, we have that

$$W_2 + W_3 \le \Phi(u^n)||\xi^n_u||^2\tau + \frac{1}{2}\alpha(\widehat{h}; u^n_h)\big[\xi^n_u\big]^2\tau + (C + C_\star h^{-1}||e^n_u||^2_\infty)h^{2k+1}\tau, \tag{6.12}$$

where $\Phi(u^n) = C + C_\star(||\xi^n_u||_\infty + h^{-1}||e^n_u||^2_\infty)$, and the positive constants C and $C_\star$ are independent of n, h, τ, and the numerical solution u_h.

Finally, we collect the above estimates (6.8), (6.12), and (6.9) to complete the proof of Lemma 5.4. ∎

6.3. Proof of Lemma 5.6. The proof of Lemma 5.6 follows the general lines of the proof of Lemmas 5.2 and 5.3, with some modifications. First, we use the assumption (5.23) and the fact that $[u^n_h] = -[e^n_u]$, since u^n is a continuous function, to obtain

$$\alpha(\widehat{h}; u^n_h)_{j+\frac{1}{2}} \le C|f'(u^n_{j+\frac{1}{2}})| + C_\star ||e^n_u||_\infty \tag{6.13}$$

for some positive constants C and $C_\star$ on each boundary point $x_{j+1/2}$. There is a similar inequality for the quantity $\alpha(\widehat{h}; w^n_h)$. We would also like, for the current upwind fluxes, to improve the expression $(Ch^{-1} + C_\star h^{-1}||e^n_u||^2_\infty)h^4\tau$ on the right-hand side of the inequality (5.5) in Lemma 5.3 to $(C + C_\star h^{-1}||e^n_u||^2_\infty)h^4\tau$. This improvement would need a sharp estimate to the term $f(u^n) - \hat{h}(u^n_h)$ on each boundary point, in parallel to the proof of Lemma 5.3. In what follows we will only present the key estimates different from the general treatments for monotone numerical fluxes.

On each boundary point $x_{j+1/2}$, we denote $G^n = f(u^{n,\star}_h) - \widehat{h}(u^n_h)$. Here and in what follows, the subscript $j + 1/2$ is omitted for notational convenience. We then have

$$f(u^n) - \hat{h}(u^n_h) = [f(u^n) - f(u^{n,\star}_h)] + G^n.$$

We would like to estimate the expression above for different cases of the sign variation of $f'(u^n)$ on each $I_j \cup I_{j+1}$.

The estimate to $f(u^n)-f(u_h^{n,\star})$ is similar as before, except for one term resulting from the Taylor expansion, namely $\pi \triangleq -f'(u^n)\eta_u^{n,\star}$, which needs more explanation. If the sign of $f'(u^n)$ is unchanged on $I_j \cup I_{j+1}$, then it is obvious that $\pi = 0$ by the definition of $\mathbb{R}_h$ and the setting of the reference value $u_h^{n,\star}$. Otherwise, if $f'(u^n)$ has at least one zero point on $I_j \cup I_{j+1}$, which implies $f'(u^n_{j+1/2}) = O(h)$, then we have $\pi = O(h^{k+3/2})$ by the interpolating approximate property (4.7). Therefore

$$\left| \sum_{1\le j\le N} \pi_{j+\frac{1}{2}} v_h(x^-_{j+\frac{1}{2}})\tau \right| \le \varepsilon ||v_h||^2 + Ch^{2k+2}\tau^2. \tag{6.14}$$

Next we would like to estimate the second term G^n for different choices of the reference value $u_h^{n,\star}$ on each boundary point $x_{j+1/2}$. Since the analysis for each case is very similar, we will only present here the estimates for the case that $f'(u^n) < 0$ on $I_j \cup I_{j+1}$; i.e., the reference value is $u_h^{n,\star} = u_h^{n,+}$. To estimate G^n for this case, we consider the detailed setting of the upwind numerical flux $\widehat{h}(u_h^n)$, corresponding to the sign variation of $f'(\cdot)$ between $u_h^{n,-}$ and $u_h^{n,+}$. If $f'(\cdot)$ is negative, then it follows from the upwind property of the numerical flux that (a) $G^n = 0$. If $f'(\cdot)$ is positive, then $G^n = f(u_h^{n,+}) - f(u_h^{n,-})$. In this case, there certainly exists a zero point $u^\star$, such that $f'(u^\star) = 0$, in the interval covering the numerical solution $u_h^n(x^{\pm}_{j+\frac{1}{2}})$ and the exact solution u^n on $I_j \cup I_{j+1}$. Thus a simple manipulation shows (b) $|G^n| \le C_\star(h+||e_u^n||_\infty)|[u_h^n]|$. Otherwise, if the sign of $f'(\cdot)$ is changed, we also have the above inequality (b) by the assumption (5.23) for the upwind numerical fluxes. Thus, by summing up the above conclusions, we have

$$|G^n| \le C_\star(h + ||e_u^n||_\infty)|[u_h^n]|. \tag{6.15}$$

Noticing the inverse property (ii) and $[u_h^n] = [\eta_u^n] - [\xi_u^n]$, we thus have

$$\left| \sum_{1\le j\le N} G^n_{j+\frac{1}{2}} v_h(x^-_{j+\frac{1}{2}})\tau \right| \le \frac{C_\star\tau^2}{h^2}(h^2 + ||e_u^n||_\infty^2)(||\xi_u^n||^2 + ||\eta_u^n||^2_{\Gamma_h}) + \varepsilon||v_h||^2. \tag{6.16}$$

The estimates to the other terms are similar as before; thus we omit them here and conclude the proof for Lemma 5.6. □

6.4. Proof of Lemma 5.7. As indicated before, we will again use the reference value $u_h^{n,\star}$ on each boundary point instead of the simple reference value $\bar{u}_h$ used in the proof of Lemma 5.4, for example in the formulation (6.7), and denote the corresponding representation by the same notation. We will analyze again each term on the right-hand side of (6.7) separately.

The estimate to the term W_1 is the same as before. By the inequality (6.15) for upwind numerical fluxes, the term W_4 can be bounded by

$$W_4 \le C_\star(1 + h^{-1}||e_u^n||_\infty)||\xi_u^n||^2\tau + \frac{C_\star\tau}{h}(h^2 + ||e_u^n||_\infty^2)||\eta_u^n||^2_{\Gamma_h}. \tag{6.17}$$

To estimate the terms W_2 and W_3, we follow the proof of Lemma 5.4 and estimate each term in (6.10) with only minor modifications, arising from the replacement of $\bar{u}_h^n, \bar{\xi}_u^n$, and $\bar{\eta}_u^n$ in (6.10b) by $u_h^{n,\star}, \xi_u^{n,\star}$, and $\eta_u^{n,\star}$, respectively. We still denote these terms by X_i and Y_i separately and estimate them one by one.

After a simple integration by parts, it is easy to show that

$$X_1 + Y_1 = -\frac{\tau}{2} \sum_{1\le j\le N} \int_{I_j} \partial_x f'(u^n)(\xi_u^n)^2\, dx - \sum_{1\le j\le N} f'(u^n_{j+\frac12})(\bar\xi_u^n - \xi_u^{n,\star})_{j+\frac12} [\xi_u^n]_{j+\frac12}\tau.$$

If $f'(u^n) < 0$ on $I_j \cup I_{j+1}$, then the reference values are $u_h^{n,\star} = u_h^{n,+}$ and $\xi_u^{n,\star} = \xi_u^{n,+}$, respectively; otherwise, $u_h^{n,\star} = u_h^{n,-}$ and $\xi_u^{n,\star} = \xi_u^{n,-}$. If the sign of $f'(u^n)$ is unchanged on $I_j \cup I_{j+1}$, then it is easy to see that $f'(u^n_{j+1/2})(\bar\xi_u^n - \xi_u^{n,\star})_{j+1/2} = \frac12 |f'(u^n_{j+1/2})|[\xi_u^n]_{j+1/2}$; if the sign of $f(u^n)$ is changed on $I_j \cup I_{j+1}$, then a simple Taylor expansion implies that $|f'(u^n_{j+1/2}) - |f'(u^n_{j+1/2})|| \le C_\star h$, even if $f'(u^n_{j+1/2}) < 0$. Thus we have

$$X_1 + Y_1 \le C_\star ||\xi_u^n||^2 \tau - |f'(u^n)|[\xi_u^n]^2\tau. \tag{6.18a}$$

The inverse properties (i) and (ii) imply the estimate to $X_2 + Y_2$ in the form

$$X_2 + Y_2 \le Ch^{-1}||\xi_u^n||_\infty ||\xi_u^n||^2\tau. \tag{6.18b}$$

Noticing the estimate to the term π (see subsection 6.3), we have, by virtue of the inverse property (ii), that

$$X_3 + Y_3 \le Ch^{2k+2}\tau + C||\xi_u^n||^2\tau. \tag{6.18c}$$

The estimate to the remaining terms are the same as (6.11d), (6.11e), and (6.11f).

Thus, by combining the above inequalities we obtain the estimate (5.26a). Along the same line we can also get (5.26b). Thus we complete the proof of Lemma 5.7. □

A STABILIZED DOMAIN DECOMPOSITION METHOD WITH NONMATCHING GRIDS FOR THE STOKES PROBLEM IN THREE DIMENSIONS*

FAKER BEN BELGACEM†

Abstract. We present and study a nonconforming domain decomposition method for the discretization of the *three-dimensional* Stokes problem in the velocity-pressure formulation. The approximation is based on some local mixed finite elements for nonmatching tetrahedral grids. The aim pursued is a systematic construction of the mortared discrete velocity space, the pressure being not subjected to any matching constraints across the interfaces. Using the bubble stabilization techniques, applied in Brezzi and Marini's paper to the three fields method [*Math. Comp.*, 70 (2001), pp. 911–934], allows us to define an algorithm which is easy to implement. The numerical analysis relies on the pressure-splitting argument of Boland and Nicolaides and allows us to establish an *inf-sup* condition with a constant that does not depend on the mesh size or on the total number of the subdomains. Then, by the Berger–Scott–Strang lemma written down for our saddle point system we derive optimal accuracy results.

Key words. mortar method, nonmatching meshes, bubble stabilization, mixed formulation, *inf-sup* condition, Boland and Nicolaides argument

1. Introduction and the functional framework.

The approximation of the Sobolev space H^1 in *three dimensions* by Lagrangian finite elements based on the concept of domain decomposition with nonmatching grids is a source of difficulties, especially for tetrahedral elements (see [5], [10], [21], [39]). Substantial research originated from the numerical modeling of the "weak continuity" versus the "strong continuity," to prevent numerical locking across the interfaces. Resorting to the nonconforming domain decomposition method is an opportunity for enhancing the numerical simulation of partial differential equations with nonregular coefficients and/or set on nonsmooth domains. The analysis of complex phenomena is often based on large scale numerical simulations using different environments and, then, can take advantage of any affordable tool to easily and efficiently match different meshes. Moreover, the high degree of parallelization achieved by the domain decomposition concept together with the permanent growth of performing iterative substructuring and multigrid procedures to compute nonconforming multidomain solutions (see [3], [2], [21], [47]) are encouraging us to study their extension to the higher dimension.

Among the class of existing multidomain techniques with nonmatching grids, the mortar element method has become very popular (see [8] for a *biography* of the method and its applications). Introduced by Bernardi, Maday, and Patera in [15]—we refer also to the earlier work of [13]—it was improved and widely analyzed for different variational discretizations such as finite elements, spectral elements, and wavelets for the Poisson problem in two dimensions. A nonexhaustive bibliography restricted to the second order elliptic problems is provided by [15], [33], [5], [6], [48], [21], [29],

[17], [18], [19]. The mortar finite element method is successful in three dimensions for hexahedral elements. An appropriate matching of hexahedral Lagrangian elements is described in [5] (see also [11]); the proof of the optimality of this approach and its implementation issues are detailed in [1], [44]. In contrast, when tetrahedral finite elements, which are of a high importance in practice, are employed, enforcing the matching constraints turns out to be more complicated. A suggestion is made in [10] (see also [22], [39] for further comments), where the construction of the matching functions—the Lagrange multipliers of the primal hybrid formulation—across the interfaces is not systematic. Even though the numerical analysis results in an optimal convergence rate for affine tetrahedral finite elements, developing a computing code taking into account this matching is not automatic. For instance, if a refining of the mesh or a remeshing is needed, then the practitioner has to update the reconstruction of the Lagrange multipliers.

An alternative allowing the use of more natural finite element multipliers in such a context is to combine the mortar geometrical features with the functional stabilization techniques used by Brezzi's team. The selected stabilization tool consists of adding to the local affine finite element discretization some boundary bubble functions as in [24] (see also [26], [28], [16]). The main difference is that the support of a bubble function is an entire triangle. This enables us to use piecewise constant Lagrange multipliers which are really easy to handle. The definition of the approximation spaces becomes clear and the implementation gains in facility. The modification proposed here on the bubble stabilization has a *major* impact as *it makes things coherent and conceptually easier* when we are involved with the extension to three dimensions of the nonconforming multidomain algorithms.

The core of this work is to deal with the *stabilized domain decomposition method applied to* the three-dimensional incompressible Stokes system. The local discrete spaces are obtained from some mixed finite elements satisfying the Babuška–Brezzi criterion (see [23], [25]). The global velocity finite element space is enriched by some stabilizing boundary bubble functions in order to enforce the matching conditions across the interfaces while the pressure space is free of any constraints. The verification of the *inf-sup* condition for the global discretization relies on a trick due to Boland and Nicolaides (see [20]). This contribution is an improvement of the results of [34], [7], and [9] (dealing with the two-dimensional mortar element method) since we prove that the constant involved in the *inf-sup* condition does not depend on the size of the meshes or on the total number of the subdomains.

A brief outline of the paper is as follows. Section 3 is a description of the stabilized mortared velocity and pressure finite elements spaces and a presentation of the discrete problem. In section 4 we use the Boland–Nicolaides argument to show an optimal Babuška–Brezzi condition. Section 5 is dedicated to the error estimate of the stabilized approximation and is based on abstract results of the linear saddle point theory.

Notation. We need to set up some notation and to recall some functional tools necessary to our analysis. Let $\Omega \subset \mathbb{R}^3$ be a Lipschitz domain of size $\mathcal{O}(1)$; a generic point of Ω is denoted $\boldsymbol{x}$. The symbol $L^2(\Omega)$ stands for the Lebesgue space. Throughout this work we make a constant use of the standard Sobolev space $H^m(\Omega)$, $m \geq 1$, provided with the norm

$$\|\psi\|_{H^m(\Omega)} = \left(\sum_{0 \leq |\alpha| \leq m} \|\partial^\alpha \psi\|^2_{L^2(\Omega)} \right)^{\frac{1}{2}},$$

where $\alpha = (\alpha_1, \alpha_2, \alpha_3)$ is a multi-index in $\mathbb{N}^3$ and ∂^α represents the corresponding partial derivative ($H^0(\Omega) = L^2(\Omega)$). The fractional order Sobolev space $H^\lambda(\Omega), \lambda \in \mathbb{R}_+ \setminus \mathbb{N}$, is defined by the norm

$$\|\psi\|_{H^\lambda(\Omega)} = \left(\|\psi\|^2_{H^m(\Omega)} + \sum_{|\alpha|=m} \int_\Omega \int_\Omega \frac{(\partial^\alpha \psi(\boldsymbol{x}) - \partial^\alpha \psi(\boldsymbol{y}))^2}{|\boldsymbol{x} - \boldsymbol{y}|^{3+2\theta}} \, d\boldsymbol{x} \, d\boldsymbol{y} \right)^{\frac{1}{2}},$$

where $\lambda = m + \theta$, m is the integer part of λ, and $\theta \in]0, 1[$ is the decimal part (see [4], [37]).

For any portion γ of the boundary $\partial\Omega$, with size $\mathcal{O}(1)$, the Hilbert space $H^{\frac{1}{2}}(\gamma)$ is associated with the norm

$$\|\psi\|_{H^{\frac{1}{2}}(\gamma)} = \left(\|\psi\|^2_{L^2(\gamma)} + \int_\gamma \int_\gamma \frac{(\psi(\boldsymbol{x}) - \psi(\boldsymbol{y}))^2}{|\boldsymbol{x} - \boldsymbol{y}|^3} \, d\Gamma d\Gamma \right)^{\frac{1}{2}}.$$

The symbol $d\Gamma$ denotes the surface measure on $\partial\Omega$. This space may be obtained by a Hilbertian interpolation argument between $H^1(\gamma)$ and $L^2(\gamma)$, i.e., $H^{\frac{1}{2}}(\gamma) = [H^1(\gamma), L^2(\gamma)]_{\frac{1}{2}}$ (see [40]). The space $H^{-\frac{1}{2}}(\gamma)$ stands for the dual space of $H^{\frac{1}{2}}(\gamma)$, and the duality pairing is denoted by $\langle \cdot, \cdot \rangle_{\frac{1}{2},\gamma}$. The special space $H^{\frac{1}{2}}_{00}(\gamma)$ results from the interpolation between $H^1_0(\gamma)$ and $L^2(\gamma)$. Finally, denoting by L a portion of the boundary $\partial\gamma$, then $H^1_0(\gamma, L)$ stands for $\{\psi \in H^1(\gamma), \psi_{|L} = 0\}$ and $H^{\frac{1}{2}}_{00}(\gamma, L) = [H^1_0(\gamma, L), L^2(\gamma)]_{\frac{1}{2}}$.

If a domain Ω is of size $\mathcal{O}(H)$, then $|\Omega| = \mathcal{O}(H^3)$; a more suitable norm contains a certain scaling factor. The local H^1-norms, which will be of permanent use in this paper, are defined by

$$\|\psi\|_{H^1(\Omega)} = (|\psi|^2_{H^1(\Omega)} + H^{-2}\|\psi\|^2_{L^2(\Omega)})^{\frac{1}{2}}.$$

Bold Latin letters like $\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{f}, \ldots$, indicate vector valued functions, while the capital ones (e.g., $\boldsymbol{X}, \boldsymbol{Y}, \boldsymbol{V}, \ldots$) are functional sets involving vector fields.

2. The variational Stokes problem. Let $\boldsymbol{f}$ be a given force in $(L^2(\Omega))^3$. We are interested in the steady Stokes problem with homogeneous Dirichlet boundary conditions which may be viewed as the "worst" case with respect to the analysis we carry out. Indeed, regarding the *inf-sup* condition, in both continuous and discrete levels, it is well known that Dirichlet-type conditions raise more technicalities than any other type of classical boundary conditions (Neumann, Robin, mixed, etc.). Then, the Stokes–Dirichlet system consists of *finding a velocity vector field* $\boldsymbol{u}$ *and a pressure scalar field* p *such that*

$$-\Delta \boldsymbol{u} + \nabla p = \boldsymbol{f} \quad \text{in } \Omega, \tag{2.1}$$

$$\operatorname{div} \boldsymbol{u} = 0 \quad \text{in } \Omega, \tag{2.2}$$

$$\boldsymbol{u} = 0 \quad \text{on } \Gamma. \tag{2.3}$$

The standard mixed variational formulation is based on a Green integration formula and is written as follows: find $(\boldsymbol{u}, p) \in H^1_0(\Omega)^3 \times L^2_0(\Omega)$ such that

$$\int_\Omega \nabla \boldsymbol{u} \cdot \nabla \boldsymbol{v} \, d\boldsymbol{x} + b(\boldsymbol{v}, p) = \int_\Omega \boldsymbol{f} \cdot \boldsymbol{v} \, d\boldsymbol{x} \quad \forall \boldsymbol{v} \in H^1_0(\Omega)^3, \tag{2.4}$$

$$b(\boldsymbol{u}, q) = 0 \quad \forall q \in L^2_0(\Omega). \tag{2.5}$$

The bilinear form $b(\cdot,\cdot)$ defined over $H_0^1(\Omega)^3 \times L_0^2(\Omega)$ is given by

$$b(\boldsymbol{v},q) = -\int_\Omega (\operatorname{div}\boldsymbol{v}) q \, d\boldsymbol{x}. \tag{2.6}$$

As is well known, $b(\cdot,\cdot)$ satisfies an *inf-sup* condition with a positive constant α (see [25], [36]), $\forall q \in L_0^2(\Omega)$:

$$\inf_{q\in L^2(\Omega)} \sup_{\boldsymbol{v}\in H_0^1(\Omega)^3} \frac{b(\boldsymbol{v},q)}{\|\boldsymbol{v}\|_{H^1(\Omega)^3}\|q\|_{L^2(\Omega)}} \geq \alpha. \tag{2.7}$$

Using the saddle point theory of [23] (see also [36], [25]), problem (2.4)–(2.5) is well posed.

PROPOSITION 2.1. *The variational Stokes problem* (2.4)–(2.5) *has a unique solution* $(\boldsymbol{u},p) \in H_0^1(\Omega)^3 \times L_0^2(\Omega)$*, and we also have the stability condition*

$$\|\boldsymbol{u}\|_{H^1(\Omega)^3} + \|p\|_{L^2(\Omega)} \leq C\|\boldsymbol{f}\|_{L^2(\Omega)^3}. \tag{2.8}$$

3. A mixed mortar finite element discretization. The framework of the stabilized domain decomposition algorithm proceeds by breaking up the domain Ω, where the partial differential equation is to be solved, into k^* nonoverlapping subdomains that are assumed to be polygonally shaped for simplicity:

$$\overline{\Omega} = \bigcup_{k=1}^{k^*} \overline{\Omega}_k \quad \text{with } \Omega_k \cap \Omega_\ell = \emptyset \text{ if } k \neq \ell,$$

where Ω_k is a polyhedron with planar polygonal faces. To prevent high technicalities, we shall analyze here only the case of conforming decompositions, meaning that when the subdomains are considered as macroelements, the intersection of two closed subdomains $\overline{\Omega}_k \cap \overline{\Omega}_\ell$ so as the intersection $\partial\Omega \cap \partial\Omega_k$ is either empty, or reduced to a common vertex, to a common edge, or to a common face. When two subdomains Ω_k and Ω_ℓ, $k < \ell$, are adjacent, $\Gamma_{k\ell}$ is the common interface. The unit outward normal of $\partial\Omega_k$ is $\boldsymbol{n}_k$. The index $k\ell$ is meaningless when Ω_k and Ω_ℓ do not share any common face. All the subdomains are assumed to be of comparable size $\mathcal{O}(H)$; that is, the length of any edge of any Ω_k is of order $\mathcal{O}(H)$ and therefore $|\Omega_k| = \mathcal{O}(H^3)$ and $|\Gamma_{k\ell}| = \mathcal{O}(H^2)$.

With each subdomain Ω_k we then associate a triangulation $\mathscr{T}_h^{\Omega_k}$ which is regular in the sense of [31] and made of tetrahedral elements with a maximum size h_k. We set $h = (h_k)_k$ to be the discretization parameter. The trace of $\mathscr{T}_h^{\Omega_k}$ on the boundary $\partial\Omega_k$ results in a regular (two-dimensional) triangulation $\mathscr{T}_h^{\partial\Omega_k}$ made of triangular elements (that are all entire faces of an element of the triangulation of Ω_k). The $\mathscr{T}_h^{\partial\Omega_k}$ is supposed compatible with the faces of Ω_k in the sense that each face $\Gamma_{k\ell}$ inherits from $\mathscr{T}_h^{\partial\Omega_k}$ a triangulation $\mathscr{T}_h^{\Gamma_{k\ell}}$. Note that, since the triangulations on two adjacent subdomains are independent, $\Gamma_{k\ell}$ is provided with two different and independent (two-dimensional) meshes $\mathscr{T}_h^{\Gamma_{k\ell}}$ (the trace of $\mathscr{T}_h^{\partial\Omega_k}$) and $\mathscr{T}_h^{\Gamma_{\ell k}}$ (the trace of $\mathscr{T}_h^{\partial\Omega_\ell}$). For some technical reasons that will appear later, we need to introduce some new notation taken from [14]. For any $T \in \mathscr{T}_h^{\partial\Omega_k}$, the macroelement Δ_T is the union of all elements of $\mathscr{T}_h^{\partial\Omega_k}$ which share at least a corner with T. Due to the regularity of $\mathscr{T}_h^{\partial\Omega_k}$, the number of elements T' contained in Δ_T is bounded by a constant independent of h_k. We assume also that on any face $\Gamma_{k\ell}$ the meshes $\mathscr{T}_h^{\partial\Omega_k}$ (or $\mathscr{T}_h^{\Gamma_{k\ell}}$) and $\mathscr{T}_h^{\partial\Omega_\ell}$ (or $\mathscr{T}_h^{\Gamma_{\ell k}}$) are locally comparable in the sense that (see Figure 3.1)

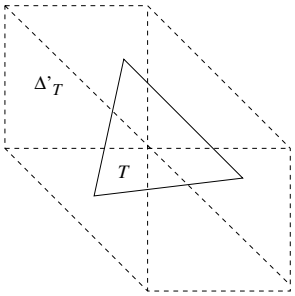

FIG. 3.1. Δ'_T—*dashed lines; for the triangle* T—*solid lines.*

($\mathrm{H_i}$) for any $T \in \mathscr{T}_h^{\partial\Omega_k}$, if Δ'_T is the "minimal" union of all elements of the opposite triangulation $\mathscr{T}_h^{\partial\Omega_\ell}$ such that $T \subset \Delta'_T$, then there exists a constant τ that does not depend on the parameters (h_k, h_ℓ) such that card $\Delta'_T \leq \tau$, where card is the cardinality;

($\mathrm{H_{ii}}$) there exists a constant τ' independent of (h_k, h_ℓ) such that $h_{T'} \leq \tau' h_T$ $\forall T' \in \Delta'_T$.

Remark 3.1. The hypotheses on the meshes $(\mathscr{T}_h^{\partial\Omega_k})_k$ are less stringent than those used in [26], where the authors assumed that these meshes are quasi-uniform and globally comparable, i.e., $\tau h_\ell \leq h_k \leq \tau' h_\ell$. Of course these kinds of meshes satisfy criteria ($\mathrm{H_i}$) and ($\mathrm{H_{ii}}$). Our hypothesis allows the use of some refined meshes—needed in adaptive methods—provided that the "opposite" new elements (in both sides), so to speak, generated by the refining process in both sides of each face $\Gamma_{k\ell}$ are of equivalent sizes so that criterion ($\mathrm{H_{ii}}$) is observed. As a matter of fact, our feeling is similar to that expressed in [26, Remark 1], *"... we believe that the above assumptions are only technical ones, and that the results (and the applicability of the whole method) are valid in more general circumstances."*

The present study is restricted to the configurations where the finite elements approximation of the velocity field within each subdomain is provided by continuous piecewise affine functions. This is the case for the Bercovier–Pironneau $\mathcal{P}_1\mathrm{iso}\mathcal{P}_2/\mathcal{P}1$ element or Arnold–Brezzi–Fortin bubble finite element (see [43], [25]). In order to explain the main ideas of our construction and analysis, we prefer to focus on the second finite element method even though, seemingly, the first one is currently more employed. However, the analysis extends in the same way to the Bercovier–Pironneau elements. For any $\kappa \in \mathscr{T}_h^{\Omega_k}$ and any $r \in \mathbb{N}$, let $\mathcal{P}_r(\kappa)$ stand for the set of polynomials of total degree $\leq r$; $(\boldsymbol{x}_{\kappa,i})_{1\leq i\leq 4}$ are the vertices of κ, and $\lambda_{\kappa,i}$ is the barycentric coordinate associated with $\boldsymbol{x}_{\kappa,i}$. We then define the standard volumic bubble function as

$$\varphi_\kappa(\boldsymbol{x}) = \prod_{i=1}^{4} \lambda_{\kappa,i}(\boldsymbol{x}) \quad \forall \boldsymbol{x} \in \kappa$$

and set $\mathcal{P}_B(\kappa) = \mathcal{P}_1(\kappa) \oplus \mathbb{R}\varphi_\kappa$. Then we introduce the finite dimension vector valued spaces

$$\boldsymbol{Y}_h(\Omega_k) = \{\boldsymbol{v}_h \in \mathscr{C}(\overline{\Omega}_k)^3,\ \forall \kappa \in \mathscr{T}_h^{\Omega_k},\ \boldsymbol{v}_{h|\kappa} \in \mathcal{P}_B(\kappa)^3,\ \boldsymbol{v}_{h,k|\partial\Omega_k\cap\partial\Omega} = 0\}.$$

The notation $\boldsymbol{Y}_h(\partial\Omega_k)$ is used for the space of the functions defined on $\partial\Omega_k$ as the trace of all those in $\boldsymbol{Y}_h(\Omega_k)$.

The purpose is to choose the global velocity finite element approximation that consists of functions whose restriction over each Ω_k belongs to $\boldsymbol{Y}_h(\Omega_k)$. Since the

interface is provided with two independent meshes, the constraint of continuity of the global function over Ω is not compatible with good approximation properties of the discrete space as it would "block" all degrees of freedom over the interfaces $(\Gamma_{k\ell})_{k\ell}$ which results in a numerical locking phenomenon. To avoid this, a nonconforming matching, based on the mortar concept, is proposed in [10] and studied under the assumption that the interfacial meshes $(\mathscr{T}_h^{\Gamma_{k\ell}})_{k\ell}$ are structured and quasi-uniform. Despite the optimality of the results proven therein (see also [22]), the problem with that matching comes from the difficulty of constructing the Lagrange multipliers space. Indeed, for tetrahedral elements this construction is not systematic and may generate some complication for the programming work. The purpose of what follows is to combine the stabilizing techniques with the mortar concept to build-up a comprehensive matching while preserving the optimality to make sure that the method can be easily implemented.

Enforcing the matching conditions for tetrahedral finite elements across a given interface requires deciding which is the mortar side (master side); the other being the nonmortar side (slaved side). For clarity, assume that for any $\Gamma_{k\ell}$, $k<\ell$, the subdomain Ω_k provides the mortar and the subdomain Ω_ℓ the nonmortar. Thus, in $\Gamma_{k\ell}$, we have two grids; when associated with $\mathscr{T}_h^{\Gamma_{k\ell}}$ it is a mortar and if associated with $\mathscr{T}_h^{\Gamma_{\ell k}}$ it is nonmortar. Henceforth, we call $\mathscr{T}_h^{\Gamma_{k\ell}}$, $k<\ell$, the mortar mesh and $\mathscr{T}_h^{\Gamma_{\ell k}}$, $k<\ell$, the nonmortar mesh. The stabilization approach consists of enriching the discrete space $\boldsymbol{Y}_h(\Omega_k)$ by some boundary bubble functions defined on the nonmortar side of each interface $\Gamma_{k\ell}$, $k<\ell$, then endowed with the mesh $\mathscr{T}_h^{\Gamma_{\ell k}}$. Let a triangular element be $(T\in\mathscr{T}_h^{\Gamma_{\ell k}})$, and let $\kappa=\kappa_T$ be the unique tetrahedron of $\mathscr{T}_h^{\Omega_\ell}$ having T as a face. The vertices of κ that are also vertices of T are $\{\boldsymbol{x}_{\kappa,1},\boldsymbol{x}_{\kappa,2},\boldsymbol{x}_{\kappa,3}\}$. The boundary bubble function we need to use is defined by

$$\varphi_T(\boldsymbol{x})=\frac{60}{|T|}\lambda_{\kappa,1}(\boldsymbol{x})\lambda_{\kappa,2}(\boldsymbol{x})\lambda_{\kappa,3}(\boldsymbol{x})\quad\forall\boldsymbol{x}\in\kappa$$

and extended by zero elsewhere. $|T|$ is the surface of T, the modulation coefficient allows $\int_T\varphi_T\,d\Gamma=1$, and we have

$$|T||\varphi_T|^2_{H^1(\kappa_T)}+\|\varphi_T\|^2_{L^2(\kappa_T)}\le c|T|^{-\frac{1}{2}}. \tag{3.1}$$

The local velocities are taken in the stabilized finite dimension vector valued space

$$\boldsymbol{X}_h(\Omega_k)=\boldsymbol{Y}_h(\Omega_k)\oplus\left(\bigoplus_{\substack{T\in\mathscr{T}_h^{\Gamma_{k\ell}}\\ k>\ell}}\mathbb{R}^3\varphi_T\right),$$

and the local discrete pressure space is defined as follows:

$$Q_h(\Omega_k)=\{q_h\in\mathscr{C}(\overline{\Omega}_k),\ \forall\kappa\in\mathscr{T}_h^{\Omega_k},\ q_{h|\kappa}\in\mathcal{P}_1(\kappa)\}.$$

Setting $\tilde{\boldsymbol{X}}_h(\Omega_k)=\boldsymbol{X}_h(\Omega_k)\cap H_0^1(\Omega_k)^3$ and defining $\tilde{Q}_h(\Omega_k)$ as the subspace of $Q_h(\Omega_k)$ involving the null-averaged pressure, it is standard that the family $\{\tilde{\boldsymbol{X}}_h(\Omega_k),\tilde{Q}_h(\Omega_k)\}$ is div-stable; actually this result is issued from the standard div-stability of $(\boldsymbol{Y}_h(\Omega_k)\cap H_0^1(\Omega_k)^3, Q_h(\Omega_k)\cap L_0^2(\Omega))$. This means that the form $b(\cdot,\cdot)$ satisfies a uniform *inf-sup* condition that there exist a constant $\tilde{\alpha}_k>0$ such that for any $q_h\in\tilde{Q}_h(\Omega_k)$ we can

find $\tilde{\boldsymbol{v}}_h \in \tilde{\boldsymbol{X}}_h(\Omega_k)$ that verifies

$$\int_{\Omega_k} (\operatorname{div} \tilde{\boldsymbol{v}}_h) q_h \, d\boldsymbol{x} = \|q_h\|^2_{L^2(\Omega_k)} \qquad \text{and} \qquad \tilde{\alpha}_k \|\tilde{\boldsymbol{v}}_h\|_{H^1(\Omega_k)^3} \leq \|q_h\|_{L^2(\Omega_k)}. \tag{3.2}$$

The constant $\tilde{\alpha}_k$ is independent of h_k and H even though it does depend on the shape of Ω_k—this *inf-sup* condition is derived from a standard statement, proven for a domain with size $\mathcal{O}(1)$ (see [25]), then extended in our context through an appropriate scaling.

Given these local tools, velocities are taken locally in $\boldsymbol{X}_h(\Omega_k)$ and glued together through the interfaces $(\Gamma_{k\ell})_{k\ell}$ by suitable matching conditions. Expressing these conditions requires building some "gluing" functional spaces on the nonmortar side of $\Gamma_{k\ell}$ $(k < \ell)$, then endowed with the triangulation $\mathscr{T}_h^{\Gamma_{\ell k}}$,

$$\boldsymbol{M}_h(\Gamma_{k\ell}) = \{\Psi_h \in L^2(\overline{\Gamma}_{k\ell})^3, \ \forall T \in \mathscr{T}_h^{\Gamma_{\ell k}}, \ \Psi_{h|T} \in \mathcal{P}_0(T)^3\}.$$

By a duality argument, the following estimate holds: $\forall \Psi \in H^{\frac{1}{2}}(\Gamma_{k\ell})$,

$$\inf_{\Psi_h \in \boldsymbol{M}_h(\Gamma_{k\ell})} \|\Psi - \Psi_h\|_{H^{-\frac{1}{2}}(\Gamma_{k\ell})^3} \leq C h_\ell |\Psi|_{H^{\frac{1}{2}}(\Gamma_{k\ell})^3}. \tag{3.3}$$

The purpose of what follows is to use the stabilizing techniques applied to the mortar element method to build-up an easy matching for the velocity. The global velocity approximation space is then given by

$$\boldsymbol{X}_h(\Omega) = \Big\{ \boldsymbol{v}_h = (\boldsymbol{v}_{h,k})_k \in L^2(\Omega)^3 ; \boldsymbol{v}_{h,k} \in \boldsymbol{X}_h(\Omega_k), \, \forall (k,\ell), \, k < \ell, \\ \forall \Psi_h \in \boldsymbol{M}_h(\Gamma_{k\ell}), \int_{\Gamma_{k\ell}} (\boldsymbol{v}_{h,k} - \boldsymbol{v}_{h,\ell}) \cdot \Psi_h \, d\Gamma = 0 \Big\}.$$

Since it is not embedded in $H^1_0(\Omega)^3$, the space $\boldsymbol{X}_h(\Omega)$ is equipped with the Hilbertian broken seminorm (which is actually a norm)

$$\|\boldsymbol{v}_h\|_{\boldsymbol{X}} = \left(\sum_{k=1}^{k^*} |\boldsymbol{v}_{h,k}|^2_{H^1(\Omega_k)^3} \right)^{\frac{1}{2}}.$$

We will denote by C and c generic positive constants. These constants take different values in different occurrences but are always independent of the mesh parameter h and independent of the subdomain size H.

The discretization is nonconforming; nevertheless under assumptions $(\mathrm{H_i})$ and $(\mathrm{H_{ii}})$ the space $\boldsymbol{X}_h(\Omega)$ has suitable approximation properties, the proof of which is postponed to the appendix.

PROPOSITION 3.2. *For any $\boldsymbol{v} \in H^1_0(\Omega)^3$ with $\boldsymbol{v}_k = \boldsymbol{v}_{|\Omega_k} \in H^2(\Omega_k)^3$, it holds that*

$$\inf_{\boldsymbol{v}_h \in \boldsymbol{X}_h(\Omega)} \|\boldsymbol{v} - \boldsymbol{v}_h\|_{\boldsymbol{X}} \leq C \left(\sum_{k=1}^{k^*} h_k^2 |\boldsymbol{v}_k|^2_{H^2(\Omega_k)^3} \right)^{\frac{1}{2}}. \tag{3.4}$$

Remark 3.3. Different choices of the bubble function that leads to the same asymptotic convergence result of Proposition 3.2 are possible. For instance, the function $\varphi_T \in \mathcal{P}_3(\kappa_T)$ can be replaced by a continuous piecewise affine function constructed as follows: the triangle T is broken-up into three smaller ones $(t_{T,i})_{1 \leq i \leq 3}$

sharing the same vertex, the center of T. The tetrahedra determined by the basis $t_{T,i}$ and the internal vertex of κ_T are denoted by $\kappa_{T,i}$; the union of the three resulting tetrahedra $(\kappa_{T,i})_{1\le i\le 3}$ coincides with κ_T. Then, we can choose $\tilde{\varphi}_T$ to be continuous, to vanish on $\partial\kappa_T$, so that $\tilde{\varphi}_{T|\kappa_{T,i}} \in \mathcal{P}_1(\kappa_{T,i})$ and $\int_T \tilde{\varphi}_T \, d\Gamma = 1$. More general bubble functions could be used, provided that their integral on T is one.

Remark 3.4. In the three-dimensional case, a coherent construction of the stabilized finite element space $\boldsymbol{X}_h(\Omega)$ is made possible thanks to the mortaring concept applied to the nonmatching meshes. The original stabilization techniques developed in [24] (see also [26]) for two-dimensional three-field domain decomposition methods with nonmatching grids can hardly be extended to three dimensions. The main reason is that choosing completely independent meshes for $\boldsymbol{X}_h(\Omega)$ and $(\boldsymbol{M}_h(\Gamma_{k\ell}))_{k\ell}$, then merging them for bubble stabilization, would result in a very complicated new mesh with arbitrarily shaped elements that can hardly be used for finite element computations.

The discrete pressure is free of any matching constraints at the interfaces, and the pressure space is defined to be

$$Q_h(\Omega) = \{q_h = (q_{h,k})_k \in L^2_0(\Omega),\ q_{h,k} \in Q_h(\Omega_k)\}.$$

Endowed with the $L^2(\Omega)$-norm, $Q_h(\Omega)$ provides fairly good approximation of regular pressures; that is, the following optimal result holds (see [31]): $\forall q \in L^2_0(\Omega)$ with $q_k = q_{|\Omega_k} \in H^1(\Omega_k)$,

$$\inf_{q_h \in Q_h(\Omega)} \|q - q_h\|_{L^2(\Omega)} \le C \left(\sum_{k=1}^{k^*} h_k^2 |q_k|^2_{H^1(\Omega_k)} \right)^{\frac{1}{2}}. \tag{3.5}$$

Let us stress the fact that only the velocity space is mortared, while the pressure is not subjected to any particular constraints across the interfaces.

We are now in position to formulate and investigate the discrete problem, which consists of *finding* $(\boldsymbol{u}_h, p_h) \in \boldsymbol{X}_h(\Omega) \times Q_h(\Omega)$ *satisfying*

$$a(\boldsymbol{u}_h, \boldsymbol{v}_h) + b(\boldsymbol{v}_h, p_h) = \int_\Omega \boldsymbol{f} \cdot \boldsymbol{v}_h \, d\boldsymbol{x} \quad \forall \boldsymbol{v}_h \in \boldsymbol{X}_h(\Omega), \tag{3.6}$$

$$b(\boldsymbol{u}_h, q_h) = 0 \quad \forall q_h \in Q_h(\Omega), \tag{3.7}$$

where we have set

$$a(\boldsymbol{u}_h, \boldsymbol{v}_h) = \sum_{k=1}^{k^*} \int_{\Omega_k} \nabla \boldsymbol{u}_{h,k} \cdot \nabla \boldsymbol{v}_{h,k} \, d\boldsymbol{x} \quad \forall \boldsymbol{u}_h, \boldsymbol{v}_h \in \boldsymbol{X}_h(\Omega),$$

$$b(\boldsymbol{v}_h, q_h) = -\sum_{k=1}^{k^*} \int_{\Omega_k} (\operatorname{div} \boldsymbol{v}_{h,k}) q_{h,k} \, d\boldsymbol{x} \quad \forall \boldsymbol{v}_h \in \boldsymbol{X}_h(\Omega),\ \forall q_h \in Q_h(\Omega).$$

A notation abuse is made here for $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$ because the expression given here is an extension of (2.6). Deriving existence, uniqueness, and stability results is based on the saddle point theory. The bilinear form $a(\cdot,\cdot)$ is uniformly continuous on $\boldsymbol{X}_h(\Omega)$ and is positive-definite. The main remaining point is the verification of an *inf-sup* condition for $b(\cdot,\cdot)$ on the discrete spaces $\boldsymbol{X}_h(\Omega) \times Q_h(\Omega)$ with a constant that does not depend on h or on the total number k^* of the subdomains. In what follows, the notations C and c (indexed or not by k) are constants that do not depend on the size of the subdomains nor on the mesh size.

4. Boland–Nicolaides argument and the discrete *inf-sup* condition. The core of this work is to state a Babuška–Brezzi *inf-sup* condition on $b(\cdot,\cdot)$ restricted to $\boldsymbol{X}_h(\Omega)\times Q_h(\Omega)$. The proof is based on a tricky decomposition of the pressure space introduced by Boland and Nicolaides (see [20]). This reduces the problem to two simpler ones: the evaluation of the local *inf-sup* constants and the evaluation of a global *inf-sup* constant on reduced spaces. The same idea was used for the mortar element approximation of the Stokes equations for two-dimensional finite elements in [7] and for two- and three-dimensional spectral elements in [9]. The results given therein may be considered partially sharp; it is only proven that the *inf-sup* constant behaves like the local constants, but they do not answer the question of whether this constant grows with the total number k^* of the subdomains or not. Here we provide the answer: *it does not*. As already underlined in [8] for the Poisson problem, this point is of major importance for iterative preconditioned substructuring solvers (see [41], [42], [35]) as the iterations number increases with the *inf-sup* constant. Let us begin by proving an optimal result for $\boldsymbol{X}_h(\Omega)$ and the space of piecewise constant pressures:

$$\check{Q}(\Omega)=\left\{\check{q}=(\check{q}_k)\in\mathbb{R}^{k^*},\ (\check{q},1)_{L^2(\Omega)}=\sum_{k=1}^{k^*}\check{q}_k|\Omega_k|=0\right\}.$$

The main difficulty is inherent to the shape of the subdomains $(\Omega_k)_{1\le k\le k^*}$ which may be pretty complicated. For instance, in the case where the domain is decomposed into tetrahedral or hexahedral subdomains, the proof of the *inf-sup* condition is directly issued from standard conforming mixed finite element results (see [43], [25]). To handle the general case we first need a preliminary result.

LEMMA 4.1. *For any interface $\Gamma_{k\ell}$ $(k<\ell)$ there exists $\boldsymbol{v}_h^{k\ell}\in\boldsymbol{X}_h(\Omega)$ with a support contained in $\overline{\Omega}_k\cup\overline{\Omega}_\ell$ and such that*

$$\|\boldsymbol{v}_h^{k\ell}\|_{\boldsymbol{X}}\le\gamma_{k\ell}H^{-\frac{3}{2}},$$
$$\int_{\Gamma_{k\ell}}\boldsymbol{v}_{h,k}^{k\ell}\cdot\boldsymbol{n}_k\,d\Gamma=-\int_{\Gamma_{k\ell}}\boldsymbol{v}_{h,\ell}^{k\ell}\cdot\boldsymbol{n}_\ell\,d\Gamma=1.$$

The constant $\gamma_{k\ell}$ is independent of H.

Proof. Let $\Gamma_{k\ell}\,(k<\ell)$ be a fixed interface, and assume for a while that $|\Omega_k|\approx|\Omega_k|=\mathcal{O}(1)$. Consider the affine finite element trace space built on the mortar mesh $\mathscr{T}_h^{\Gamma_{k\ell}}$,

$$\boldsymbol{Y}_h(\Gamma_{k\ell})=\{\Phi_h\in\mathscr{C}(\overline{\Gamma}_{k\ell})^3,\ \forall T\in\mathscr{T}_h^{\Gamma_{k\ell}},\ \Phi_{h|T}\in\mathcal{P}_1(T)^3,\ \Phi_{h|\partial\Gamma_{k\ell}}=0\}.$$

Notice that $\prod_{k<\ell}(\boldsymbol{Y}_h(\Gamma_{k\ell}))_{k\ell}$ is the so-called mortar space; we refer to [15] for more details on the mortar terminology. In the same way we construct the space on the nonmortar mesh $\mathscr{T}_h^{\Gamma_{\ell k}}$, which is denoted by $\tilde{\boldsymbol{Y}}_h(\Gamma_{k\ell})$. For conciseness the index $k\ell$ is dropped except for $\Gamma_{k\ell}$ in the remaining part of the proof. If $\tilde{r}_h$ stands for the regularizing Clément operator (see [32] and [14] for the definition and the approximation results) mapping $L^2(\Gamma_{k\ell})^3$ into $\tilde{\boldsymbol{Y}}_h(\Gamma_{k\ell})$, it holds that $\forall\Phi\in H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})$, $\forall T\in\mathscr{T}_h^{\Gamma_{\ell k}}$,

$$\|\Phi-\tilde{r}_h\Phi\|_{L^2(T)}^2\le c|T|^{\frac{1}{2}}|\Phi|^2_{H_*^{\frac{1}{2}}(\Delta_T)},\tag{4.1}$$

$$\|\tilde{r}_h\Phi\|_{L^2(\Gamma_{k\ell})}\le c\|\Phi\|_{L^2(\Gamma_{k\ell})}\qquad\text{and}\qquad|\tilde{r}_h\Phi|_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})}\le c|\Phi|_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})}.\tag{4.2}$$

The space $H_*^{\frac{1}{2}}(\Delta_T)$ coincides with the standard $H^{\frac{1}{2}}(\Delta_T)$ if $\Delta_T \cap \partial\Gamma_{k\ell} = \emptyset$ and is $H_{00}^{\frac{1}{2}}(\Delta_T, \Delta_T \cap \partial\Gamma_{k\ell})$ otherwise. Then, choose $\Phi_h \in \boldsymbol{Y}_h(\Gamma_{k\ell})$ satisfying

$$\int_{\Gamma_{k\ell}} \Phi_h \cdot \boldsymbol{n}_k \, d\Gamma = 1,$$

with $\|\Phi_h\|_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})}$ independent of h. Obviously, such a $\Phi_h^{k\ell}$ exists; moreover, (4.2) implies that $\|\tilde{r}_h\Phi_h\|_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})} \leq C$. We introduce the trivial extensions of Φ_h to $\partial\Omega_k$ and of $(\tilde{r}_h\Phi_h)$ to $\partial\Omega_\ell$ that we still denote $\Phi_h \in \boldsymbol{Y}_h(\partial\Omega_k)$ and $\tilde{r}_h\Phi_h \in \boldsymbol{Y}_h(\partial\Omega_\ell)$. By stable extension (see [14]) we obtain $\boldsymbol{w}_{h,k} \in \boldsymbol{Y}_h(\Omega_k)$ and $\boldsymbol{w}_{h,\ell} \in \boldsymbol{Y}_h(\Omega_\ell)$ that are uniformly bounded:

$$\|\boldsymbol{w}_{h,k}\|_{H^1(\Omega_k)^3} \leq c\|\Phi_h\|_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})}, \tag{4.3}$$

$$\|\boldsymbol{w}_{h,\ell}\|_{H^1(\Omega_\ell)^3} \leq c\|\tilde{r}_h\Phi_h\|_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})} \leq c\|\Phi_h\|_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})}. \tag{4.4}$$

The construction of $\boldsymbol{v}_h$ follows from the correction added to $\boldsymbol{w}_{h,\ell}$,

$$\begin{aligned}\boldsymbol{v}_{h,\ell} &= \boldsymbol{w}_{h,\ell} + \sum_{T \in \mathscr{T}_h^{\Gamma_{k\ell}}} \left(\int_T (\boldsymbol{w}_{h,k} - \boldsymbol{w}_{h,\ell}) \, d\Gamma \right) \varphi_T \\ &= \boldsymbol{w}_{h,\ell} + \sum_{T \in \mathscr{T}_h^{\Gamma_{k\ell}}} \left(\int_T (\Phi_h - \tilde{r}_h\Phi_h) \, d\Gamma \right) \varphi_T,\end{aligned}$$

and we set $\boldsymbol{v}_{h,k} = \boldsymbol{w}_{h,k}$ and $\boldsymbol{v}_h = 0$ outside $\Omega_k \cup \Omega_\ell$. It is readily checked that $\boldsymbol{v}_h \in \boldsymbol{X}_h(\Omega)$ and

$$\int_{\Gamma_{k\ell}} \boldsymbol{v}_{h,k} \cdot \boldsymbol{n}_k \, d\Gamma = \int_{\Gamma_{k\ell}} \Phi_h \cdot \boldsymbol{n}_k \, d\Gamma = -\int_{\Gamma_{k\ell}} \boldsymbol{v}_{h,\ell} \cdot \boldsymbol{n}_\ell \, d\Gamma = 1.$$

What remains to prove is that the added term, henceforth denoted $\boldsymbol{t}_{k\ell}$, is bounded in $H^1(\Omega_\ell)^3$ independently of h_ℓ. Indeed, using (3.1) and (4.1), we have

$$\begin{aligned}|\boldsymbol{t}_{k\ell}|^2_{H^1(\Omega_\ell)^3} &= \sum_{T \in \mathscr{T}_h^{\Gamma_{k\ell}}} \left| \int_T (\Phi_h - \tilde{r}_h\Phi_h) \, d\Gamma \right|^2 |\varphi_T|^2_{H^1(\Omega_\ell)} \\ &\leq c \sum_{T \in \mathscr{T}_h^{\Gamma_{k\ell}}} |T|^{-\frac{3}{2}} \left| \int_T (\Phi_h - \tilde{r}_h\Phi_h) \, d\Gamma \right|^2 \\ &\leq c \sum_{T \in \mathscr{T}_h^{\Gamma_{k\ell}}} |T|^{-\frac{1}{2}} \|\Phi_h - \tilde{r}_h\Phi_h\|^2_{L^2(T)} \\ &\leq c \sum_{T \in \mathscr{T}_h^{\Gamma_{k\ell}}} |\Phi_h|^2_{H_*^{\frac{1}{2}}(\Delta_T)} \leq c|\Phi_h|^2_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})}.\end{aligned}$$

The uniform boundedness of $\boldsymbol{v}_h$ is achieved by (4.2) and is due to the uniform bound if we have a bound for $\|\Phi_h\|_{H_{00}^{\frac{1}{2}}(\Gamma_{k\ell})}$. The more general result of the lemma (i.e., $|\Omega_k| \approx |\Omega_\ell| = \mathcal{O}(H)$) is derived by an easy scaling argument. ∎

Now comes the main result of our study, the div-stability for the reduced family of spaces $(\boldsymbol{X}_h(\Omega), \check{Q}(\Omega))$.

PROPOSITION 4.2. *There exists a constant $\check{\alpha}$ depending neither on the discretization parameter h nor on the size H of the subdomains so that the following* inf-sup *condition holds*:

$$\inf_{\check{q}\in\check{Q}(\Omega)} \sup_{\boldsymbol{v}_h\in\boldsymbol{X}_h(\Omega)} \frac{b(\boldsymbol{v}_h,\check{q})}{\|\boldsymbol{v}_h\|_{\boldsymbol{X}}\|\check{q}\|_{L^2(\Omega)}} \geq \check{\alpha}.$$

Proof. As the *inf-sup* condition is available in the continuous setting (2.7), an equivalent statement of the proposition is to show that for any $\boldsymbol{v} \in H_0^1(\Omega)^3$ there exists $\boldsymbol{v}_h \in \boldsymbol{X}_h(\Omega)$ such that

$$b(\boldsymbol{v}-\boldsymbol{v}_h,\check{q}_h) = 0 \quad \forall \check{q}_h \in \check{Q}(\Omega), \tag{4.5}$$

$$\|\boldsymbol{v}_h\|_{\boldsymbol{X}} \leq \gamma \|\boldsymbol{v}\|_{H^1(\Omega)}, \tag{4.6}$$

where $\gamma > 0$ does not depend on h or H. Then, the constant $\check{\alpha}$ could be taken equal to the quotient $\frac{\alpha}{\gamma}$. Let us set

$$\boldsymbol{v}_h = \sum_{k\ell,\ k<\ell} \left(\int_{\Gamma_{k\ell}} \boldsymbol{v}\cdot\boldsymbol{n}_k \, d\Gamma \right) \boldsymbol{v}_h^{k\ell},$$

where $\boldsymbol{v}_h^{k\ell}$ is provided by Lemma 4.1. Noticing that $\boldsymbol{v}_{h,k|\Gamma_{k\ell}} = \boldsymbol{v}_{h,k|\Gamma_{k\ell}}^{k\ell}$ and $\boldsymbol{v}_{h,\ell|\Gamma_{k\ell}} = \boldsymbol{v}_{h,\ell|\Gamma_{k\ell}}^{k\ell}$, it becomes straightforward that $\forall k\ell$ $(k<\ell)$

$$\int_{\Gamma_{k\ell}} \boldsymbol{v}_{h,k}.\boldsymbol{n}_k \, d\Gamma = \left(\int_{\Gamma_{k\ell}} \boldsymbol{v}\cdot\boldsymbol{n}_k \, d\Gamma \right) \left(\int_{\Gamma_{k\ell}} \boldsymbol{v}_{h,k}^{k\ell}\cdot\boldsymbol{n}_k \, d\Gamma \right) = \int_{\Gamma_{k\ell}} \boldsymbol{v}\cdot\boldsymbol{n}_k \, d\Gamma,$$

$$\int_{\Gamma_{k\ell}} \boldsymbol{v}_{h,\ell}\cdot\boldsymbol{n}_\ell \, d\Gamma = -\int_{\Gamma_{k\ell}} \boldsymbol{v}\cdot\boldsymbol{n}_k \, d\Gamma = \int_{\Gamma_{k\ell}} \boldsymbol{v}\cdot\boldsymbol{n}_\ell \, d\Gamma.$$

This allows us to deduce that $\forall k$ $(1 \leq k \leq k^*)$

$$\int_{\partial\Omega_k} (\boldsymbol{v}-\boldsymbol{v}_{h,k})\cdot\boldsymbol{n}_k \, d\Gamma = 0,$$

and then statement (4.5) is checked by Green's formula. In order to bound $\|\boldsymbol{v}_h\|_{\boldsymbol{X}}$ we make the convention $\boldsymbol{v}_h^{k\ell} = \boldsymbol{v}_h^{\ell k}$; then a scaling argument yields $\forall k$ $(1 \leq k \leq k^*)$

$$\int_{\partial\Omega_k} |\boldsymbol{v}\cdot\boldsymbol{n}_k| \, d\Gamma \leq cH^{\frac{3}{2}} \|\boldsymbol{v}_k\|_{H^1(\Omega_k)^3},$$

which, together with Lemma 4.1, allows the following:

$$\|\boldsymbol{v}_{h,k}\|^2_{H^1(\Omega_k)^3} \leq c_k \sum_{\ell;\ k\ell \text{ is defined}} \|\boldsymbol{v}_{h,k}^{k\ell}\|^2_{H^1(\Omega_k)^3} \left| \int_{\Gamma_{k\ell}} \boldsymbol{v}\cdot\boldsymbol{n}_k \, d\Gamma \right|^2 \leq \gamma_k \|\boldsymbol{v}_k\|^2_{H^1(\Omega_k)^3}.$$

The constant $\gamma_k (= c \max_{k\ell} \gamma_{k\ell})$ is independent of h and of H. This yields the statement (4.6) and achieves the proof with $\gamma = \max_k \gamma_k$. ∎

Remark 4.3. Actually, the constant $\check{\alpha}$ is also independent of k^*, the total number of the subdomains, but it does depend on the shape of $(\Omega_k)_k$ and their distribution (*i.e., nearest neighbor relations*).

Back to the global pressure space $Q_h(\Omega)$, we intend to prove by the Boland–Nicolaides method an optimal *inf-sup* condition between $\boldsymbol{X}_h(\Omega)$ and $Q_h(\Omega)$.

THEOREM 4.4. *There exists a constant α' depending neither on the discretization parameter h nor on the size H of the subdomains so that the following* inf-sup *condition holds*:

$$\inf_{q_h\in Q_h(\Omega)}\ \sup_{\boldsymbol{v}_h\in\boldsymbol{X}_h(\Omega)}\frac{b(\boldsymbol{v}_h,q_h)}{\|\boldsymbol{v}_h\|_{\boldsymbol{X}}\|q_h\|_{L^2(\Omega)}}\geq\alpha'.$$

Proof. Let $q_h=(q_{h,k})_{1\leq k\leq k^*}$ be any function in $Q_h(\Omega)$; it may be decomposed as $\forall k(1\leq k\leq k^*)$,

$$q_{h,k}=\tilde{q}_{h,k}+\check{q}_{h,k},\quad\text{with}\quad\check{q}_{h,k}=\frac{1}{|\Omega_k|}\int_{\Omega_k}q_{h,k}(\boldsymbol{x})\,d\boldsymbol{x}.$$

Since the function $\tilde{q}_{h,k}\in Q_h(\Omega_k)\cap L^2_0(\Omega_k)$, there exists a local velocity field $\tilde{\boldsymbol{v}}_{h,k}\in\tilde{\boldsymbol{X}}_h(\Omega_k)=(\boldsymbol{X}_h(\Omega_k)\cap H^1_0(\Omega_k)^3)$ verifying (3.2). Then, we define the function $\tilde{\boldsymbol{v}}_h=(\tilde{\boldsymbol{v}}_{h,k})_{1\leq k\leq k^*}\in\boldsymbol{X}_h(\Omega)$. Furthermore, by Proposition 4.2 we construct $\check{\boldsymbol{w}}_h\in\boldsymbol{X}_h(\Omega)$ so that

$$b(\check{\boldsymbol{w}}_h,\check{q}_h)=\|\check{q}_h\|^2_{L^2(\Omega)}\qquad\text{and}\qquad\check{\alpha}\|\check{\boldsymbol{w}}_h\|_{\boldsymbol{X}}\leq\|\check{q}_h\|_{L^2(\Omega)}.$$

Next we choose $\check{\boldsymbol{v}}_h=(\check{\boldsymbol{v}}_{h,k})_{1\leq k\leq k^*}$ with $\check{\boldsymbol{v}}_{h,k}=\check{\boldsymbol{w}}_{h,k}+\beta_k\tilde{\boldsymbol{v}}_{h,k}$. The coefficients $(\beta_k)_{1\leq k\leq k^*}$ are computed so that $\{(\operatorname{div}\check{\boldsymbol{v}}_h,\tilde{q}_h)_{L^2(\Omega_k)},(1\leq k\leq k^*)\}$ vanish; thus

$$\beta_k=-\frac{(\operatorname{div}\check{\boldsymbol{w}}_{h,k},\tilde{q}_{h,k})_{L^2(\Omega_k)}}{\|\tilde{q}_{h,k}\|^2_{L^2(\Omega_k)}}.$$

Taking $\boldsymbol{v}_h=\check{\boldsymbol{v}}_h+\tilde{\boldsymbol{v}}_h$, it is readily checked that

$$b(\boldsymbol{v}_h,q_h)=\|\tilde{q}_h\|^2_{L^2(\Omega)}+\|\check{q}_h\|^2_{L^2(\Omega)}=\|q_h\|^2_{L^2(\Omega)},$$

and $\alpha'\|\boldsymbol{v}_h\|_{\boldsymbol{X}}\leq\|q_h\|_{L^2(\Omega)}$, where α' may be chosen so that

$$\alpha'=\frac{1}{2}\min(1,\check{\alpha})\min_{1\leq k\leq k^*}\frac{\tilde{\alpha}_k}{\sqrt{1+\tilde{\alpha}_k^2}}.\qquad\square$$

Remark 4.5. Observe that nowhere in the proof of the *inf-sup* condition were the assumptions ($\mathrm{H_i}$) or ($\mathrm{H_{ii}}$) employed. Theorem 4.4 is then valid for arbitrary meshes.

The immediate consequence is the well posedness of the discrete problem. Indeed, by the saddle point theory we have the following result.

PROPOSITION 4.6. *The discrete problem* (3.6)–(3.7) *has only one solution* $(\boldsymbol{u}_h,p_h)\in\boldsymbol{X}_h(\Omega)\times Q_h(\Omega)$*, and we have*

$$\|\boldsymbol{u}_h\|_{\boldsymbol{X}}+\|p_h\|_{L^2(\Omega)^2}\leq C\|\boldsymbol{f}\|_{L^2(\Omega)^3}.\tag{4.7}$$

5. The final error estimates. In order to perform the numerical analysis and to derive the convergence rate towards the exact solution, we adapt, as is done in [34], the approximation theory of the saddle point problems to our nonconforming discretization. Let us introduce the space

$$\boldsymbol{V}_h(\Omega)=\{\boldsymbol{v}_h\in\boldsymbol{X}_h(\Omega),\ b(\boldsymbol{v}_h,q_h)=0,\ \forall q_h\in Q_h(\Omega)\}.$$

Then we have the abstract error estimate which is considered as an extension of the Berger–Scott–Strang lemma to the Stokes problem (see [12], [34]).

LEMMA 5.1. *We have the following error estimate:*

$$\begin{aligned}&\|\boldsymbol{u}-\boldsymbol{u}_h\|_{\boldsymbol{X}}+\|p-p_h\|_{L^2(\Omega)}\\ &\quad\le C\left(\inf_{\boldsymbol{v}_h\in\boldsymbol{V}_h(\Omega)}\|\boldsymbol{u}-\boldsymbol{v}_h\|_{\boldsymbol{X}}+\inf_{q_h\in Q_h(\Omega)}\|p-q_h\|_{L^2(\Omega)}\right.\\ &\qquad\left.+\sup_{\boldsymbol{w}_h\in\boldsymbol{V}_h(\Omega)}\frac{1}{\|\boldsymbol{w}_h\|_{\boldsymbol{X}}}\sum_{k=1}^{k^*}\langle(\partial_{\boldsymbol{n}_k}\boldsymbol{u}+p),\boldsymbol{w}_{h,k}\rangle_{\frac12,\partial\Omega_k}\right).\end{aligned}\tag{5.1}$$

The first two error terms in (5.1) are known as the approximation error; the third term is the consistency error and is a consequence of the discontinuity of the elements of $\boldsymbol{V}_h(\Omega)$ through the interfaces. The main convergence result on u is given in the following theorem.

THEOREM 5.2. *Assume that the exact solution* $(\boldsymbol{u},p)\in H_0^1(\Omega)^3\times L_0^2(\Omega)$ *satisfies the regularities*

$$\boldsymbol{u}_k=\boldsymbol{u}_{|\Omega_k}\in H^2(\Omega_k)^3,\quad p_k=p_{|\Omega_k}\in H^1(\Omega_k)\quad\forall k\ (1\le k\le k^*);$$

then under the hypotheses ($\mathrm{H_i}$) *and* ($\mathrm{H_{ii}}$) *it holds that*

$$\|\boldsymbol{u}-\boldsymbol{u}_h\|_{\boldsymbol{X}}+\|p-p_h\|_{L^2(\Omega)}\le C\left(\sum_{k=1}^{k^*}h_k^2(|\boldsymbol{u}_k|^2_{H^2(\Omega_k)^3}+|p_k|^2_{H^1(\Omega_k)})\right)^{\frac12}.\tag{5.2}$$

The *inf-sup* condition of Theorem 4.4 is independent of h; techniques used for standard h-finite element approximation work as well. Indeed, the best approximation rate of the velocity $\boldsymbol{u}$ by vector valued functions of $\boldsymbol{V}_h(\Omega)$ is asymptotically equivalent to that provided by the best fit of $\boldsymbol{u}$ by the functions of $\boldsymbol{X}_h(\Omega)$. Under the hypotheses ($\mathrm{H_i}$) and ($\mathrm{H_{ii}}$) this rate is optimal, as given in Proposition 3.2. Moreover, the approximation error is optimal for the pressure (3.5). The only remaining point is to evaluate the consistency error which is handled in a standard way using estimate (3.3) and turns out to be optimal.

LEMMA 5.3. *Under the regularity assumptions of Theorem* 5.2 *it holds that*

$$\begin{aligned}&\sup_{\boldsymbol{w}_h\in\boldsymbol{V}_h(\Omega)}\frac{1}{\|\boldsymbol{w}_h\|_{\boldsymbol{X}}}\sum_{k=1}^{k^*}\langle(\partial_{\boldsymbol{n}_k}\boldsymbol{u}+p\boldsymbol{n}_k),\boldsymbol{w}_{h,k}\rangle_{\frac12,\partial\Omega_k}\\ &\quad\le C\left(\sum_{k=1}^{k^*}h_k^2(|\boldsymbol{u}_k|^2_{H^2(\Omega_k)^3}+|p_k|^2_{H^1(\Omega_k)})\right)^{\frac12}.\end{aligned}$$

Proof. It is clear that $\forall\boldsymbol{v}_h\in\boldsymbol{V}_h(\Omega)$

$$\sum_{k=0}^{k^*}\langle(\partial_{\boldsymbol{n}_k}\boldsymbol{u}+p\boldsymbol{n}_k),\boldsymbol{w}_{h,k}\rangle_{\frac12,\partial\Omega_k}=\sum_{k<\ell}\int_{\Gamma_{k\ell}}(\partial_{\boldsymbol{n}_k}\boldsymbol{u}+p\boldsymbol{n}_k)(\boldsymbol{v}_{h,k}-\boldsymbol{v}_{h,\ell})\,d\Gamma.$$

On account of the definition of $\boldsymbol{X}_h(\Omega)$, which contains $\boldsymbol{V}_h(\Omega)$, we say that $\forall\psi_h\in\boldsymbol{M}_h(\Gamma_{k\ell})$,

$$\int_{\Gamma_{k\ell}}(\partial_{\boldsymbol{n}_k}\boldsymbol{u}+p\boldsymbol{n}_k)(\boldsymbol{v}_{h,k}-\boldsymbol{v}_{h,\ell})\,d\Gamma=\int_{\Gamma_{k\ell}}(\partial_{\boldsymbol{n}_k}\boldsymbol{u}+p\boldsymbol{n}_k-\psi_h)(\boldsymbol{v}_{h,k}-\boldsymbol{v}_{h,\ell})\,d\Gamma.$$

The proof is achieved in a standard way after noticing that Aubin–Nitsche duality yields

$$\inf_{\psi_h \in \boldsymbol{M}_h(\Gamma_{k\ell})} \|\partial_{\boldsymbol{n}_k} \boldsymbol{u} + p\boldsymbol{n}_k - \psi_h\|_{(H^{\frac{1}{2}}(\Gamma_{k\ell})^2)'} \leq C h_\ell (|\boldsymbol{u}_k|_{H^2(\Omega_\ell)^3} + |p_\ell|_{H^1(\Omega_\ell)}). \qquad \square$$

Proof of Theorem 5.2. It is a direct consequence of Lemma 5.1, Proposition 3.2, and Lemma 5.3.

Remark 5.4. It may occur that the solution $(\boldsymbol{u}, p)$ of the problem (2.1)–(2.3) is less regular than assumed in Theorem 5.2. Also, in this case the optimal error estimate holds. For instance, if $(\boldsymbol{u}, p) \in H_0^1(\Omega)^3 \times L^2(\Omega)$ such that $\boldsymbol{u}_k \in H^{1+\lambda_k}(\Omega_k)^3$ and $p_k \in H^{\lambda_k}(\Omega_k)$ with $0 < \lambda_k \leq 1$, we have

$$\|\boldsymbol{u} - \boldsymbol{u}_h\|_{\boldsymbol{X}} + \|p - p_h\|_{L^2(\Omega)} \leq C \left(\sum_{k=1}^{k^*} h_k^{2\lambda_k} (\|\boldsymbol{u}_k\|^2_{H^{1+\lambda_k}(\Omega_k)^3} + \|p_k\|^2_{H^{\lambda_k}(\Omega_k)} + \|\boldsymbol{f}\|^2_{L^2(\Omega_k)^3}) \right)^{\frac{1}{2}}.$$

This convergence rate is proven directly for $\lambda_k > \frac{1}{2}$, following the analysis realized here, and the term $\|\boldsymbol{f}\|_{L^2(\Omega_k)^3}$ may disappear. It is more technical for $\lambda_k \leq \frac{1}{2}$ and is obtained as in [7] by Hilbertian interpolation of the stability estimates (2.8) and (4.7) in one side and from estimate (5.2) in the other side.

Remark 5.5. Using the bubble stabilized domain decomposition approach with higher order mixed $\mathcal{P}_2/\mathcal{P}_1$ Taylor–Hood finite elements also yields the optimal convergence rate (5.2) as long as the local solution $(\boldsymbol{u}_k, p_k)$ belongs to $H^{1+\lambda_k}(\Omega_k)^3 \times H^{\lambda_k}(\Omega_k)$ with $\lambda_k \leq \frac{3}{2}$.

6. Conclusion. For the numerical simulation by domain decomposition procedures of second order elliptic problems, the attempts already made to propose an efficient way to match (incompatible) *three-dimensional tetrahedral* finite element grids are based on a more or less heavy construction of Lagrange multiplier spaces (see [10], [48], [39]). Besides, using the current refining/unrefining processes for adaptivity turns out to be a pain in the neck due to the nonsystematic character of these constructions. Combining the (architectural) mortar features together with the bubble-stabilization techniques, as presented in this paper, allow an easy and systematic numerical modeling of the "*weak continuity*" across the interfaces. The mathematical analysis of the stabilized mortar finite element method highlights the expected optimality. Moreover, the implementation of this algorithm does not seem to be a difficult work! Some tips for the numerical programming are given in Appendix B.

Apart from the extension to three dimensions, this paper allows us to recover the optimality on the *inf-sup* constant for the Stokes system. Indeed, that constant turns out to be independent of h and of k^*, the mesh size and the total number of the subdomains. Earlier works in two dimensions (see [7], [9]) failed to prove that it does not grow with k^*.

Appendix A. The proof of Proposition 3.2. For simplicity, the proof is processed on each component of $\boldsymbol{v}$, henceforth denoted v. Let us associate with u the local (to subdomains) Lagrange interpolants $v_{h,k} = (\mathcal{I}_{h,k} v) \in Y_h(\Omega_k)$; then we have (see [31]) that $\forall k$, $\forall \kappa \in \mathscr{T}_h^{\Omega_k}$,

$$|v - v_{h,k}|_{H^1(\kappa)} + |\kappa|^{-\frac{1}{3}} \|v - v_{h,k}\|_{L^2(\kappa)} \leq C |\kappa|^{\frac{1}{3}} |v|_{H^2(\kappa)}; \tag{A.1}$$

note that $|\kappa|^{\frac{1}{3}} \leq ch_k$. The function $v_h = (v_{h,k})_k$ does not satisfy the matching condition across the interfaces. To cope with this, we have to add to v_h a correction term so as to obtain an approximation of v that belongs to $X_h(\Omega)$. Let us focus on a single face $\Gamma_{k\ell}$, $k < \ell$, which is common to Ω_k and Ω_ℓ with Ω_k the mortar side and Ω_ℓ the nonmortar side. Enforcing the matching across $\Gamma_{k\ell}$ requires the following modification of $v_{h,\ell}$ based on the bubble functions:

$$\tilde{v}_{h,\ell} = v_{h,\ell} + \sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} \left(\int_T (v_{h,k} - v_{h,\ell})\, d\Gamma \right) \varphi_T. \tag{A.2}$$

For convenience we also set $\tilde{v}_{h,k} = v_{h,k}$, $k \neq \ell$. Clearly, $\tilde{v}_h = (\tilde{v}_{h,k})_k$ fulfills the matching across $\Gamma_{k\ell}$. In addition, remark that $\tilde{v}_{h,\ell}$ coincides with the initial $v_{h,\ell}$ on the $\partial\Omega_\ell$ except, of course, the interior of $\Gamma_{k\ell}$. Bearing in mind that this process has to be iterated, this modification will be realized on all the faces; the aforementioned remark is very important and says that the correction made on $\Gamma_{k\ell}$ will not alter the matching on the other faces. The remaining work consists of bounding the correction term of (A.2), henceforth denoted $t_{k\ell}$. In view of (3.1) we have

$$\begin{aligned}
|t_{k\ell}|^2_{H^1(\Omega_\ell)} &= \sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} \left(\int_T (v_{h,k} - v_{h,\ell})\, d\Gamma \right)^2 |\varphi_T|^2_{H^1(\Omega_\ell)} \\
&\leq c \sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{3}{2}} \left(\int_T (v_{h,k} - v_{h,\ell})\, d\Gamma \right)^2 \\
&\leq c \sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}} \|v_{h,k} - v_{h,\ell}\|^2_{L^2(T)} \\
&\leq c \sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}} (\|v - v_{h,\ell}\|^2_{L^2(T)} + \|v - v_{h,k}\|^2_{L^2(T)}).
\end{aligned}$$

The first part of the sum is easily handled. Using (A.1) and the regularity of the mesh $\mathscr{T}_h^{\Gamma_{\ell k}}$ yields

$$\begin{aligned}
\sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}} \|v - v_{h,\ell}\|^2_{L^2(T)} &\leq c \sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}} |T|^{\frac{3}{2}} |v|^2_{H^{\frac{3}{2}}(T)} \\
&\leq Ch_\ell^2 |v|^2_{H^{\frac{3}{2}}(\Gamma_{k\ell})} \leq Ch_\ell^2 |v|^2_{H^2(\Omega_\ell)}.
\end{aligned}$$

Bounding the second part is performed using the technical assumptions on the trace meshes. It holds that

$$\begin{aligned}
\sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}} \|v - v_{h,k}\|^2_{L^2(T)} &\leq \sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}} \|v - v_{h,k}\|^2_{L^2(\Delta'_T)} \\
&\leq \sum_{T \in \mathscr{T}_h^{\Gamma_{\ell k}}} \sum_{T' \subset \Delta'_T} |T|^{-\frac{1}{2}} |T'|^{\frac{3}{2}} |v|^2_{H^{\frac{3}{2}}(T')}.
\end{aligned}$$

By assumption (H_{ii})—local comparison between adjacent meshes—we get

$$\sum_{T\in\mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}}\|v-v_{h,k}\|^2_{L^2(T)} \le c \sum_{T\in\mathscr{T}_h^{\Gamma_{\ell k}}} \sum_{T'\subset\Delta'_T} |T'||v|^2_{H^{\frac{3}{2}}(T')}$$
$$\le ch_k^2 \sum_{T\in\mathscr{T}_h^{\Gamma_{\ell k}}} |v|^2_{H^{\frac{3}{2}}(\Delta'_T)}.$$

Using hypothesis (H_i) yields the final result,

$$\sum_{T\in\mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}}\|v-v_{h,k}\|^2_{L^2(T)} \le ch_k^2|v|^2_{H^{\frac{3}{2}}(\Gamma_{k\ell})} \le Ch_k^2|v|^2_{H^2(\Omega_k)}.$$

Iterating the process on all the remaining faces completes the proof.

Remark A.1. The end of the proof becomes direct when the trace meshes $(\mathscr{T}_h^{\Gamma_{k\ell}})_{k\ell}$ are quasi-uniform and any couple of adjacent meshes are globally comparable (see Remark 3.2). Indeed, we may write that

$$\sum_{T\in\mathscr{T}_h^{\Gamma_{\ell k}}} |T|^{-\frac{1}{2}}\|v-v_{h,k}\|^2_{L^2(T)} \le ch_\ell^{-1} \sum_{T\in\mathscr{T}_h^{\Gamma_{\ell k}}} \|v-v_{h,k}\|^2_{L^2(T)}$$
$$\le ch_\ell^{-1}\|v-v_{h,k}\|^2_{L^2(\Gamma_{k\ell})} \le ch_\ell^{-1}h_k^3|v|^2_{H^{\frac{3}{2}}(\Gamma_{k\ell})}.$$

Appendix B. Some remarks on the implementation. We shall give some hints about the numerical implementation of the stabilized mortar finite element method. The goal we are assigned is to understand the issue of the matching constraints implementation in the algebraic form of the problem. Then we choose, for briefness, to address the Poisson problem consisting of *finding* $u_h \in X_h(\Omega)$ *such that*

$$\sum_{k=1}^{k^*} \int_{\Omega_k} \nabla u_{h,k}\cdot\nabla v_{h,k}\, d\boldsymbol{x} = \int_\Omega f v_h\, d\boldsymbol{x} \quad \forall v_h \in X_h(\Omega). \tag{B.1}$$

The presentation adopted here is pretty similar to that detailed in [27], even though the expository supplied there is based on the primal hybrid framework.

Let $v_h = (v_{h,k})_k$ be an arbitrary function of the approximated space $X_h(\Omega)$; then $v_{h,k}$ is split into

$$v_{h,k} = \tilde{v}_{h,k} + \sum_{k\ell,\ k>\ell} \sum_{T\in\mathscr{T}^{\Gamma_{k\ell}}} \beta_T(v_h)\varphi_T \quad \forall k\ (1\le kk^*),$$

where $\tilde{v}_{h,k} \in Y_h(\Omega_k)$ is piecewise linear and $\beta_T(v_h)$ is a real number for any T. The matching condition allows us to obtain the value of $\beta_T(v_h)$ so as to eliminate it from the variational formulation,

$$\beta_T(v_h) = \int_T (\tilde{v}_{h,\ell} - \tilde{v}_{h,k})\, d\Gamma = \int_T [\tilde{v}_h]_{k\ell}\, d\Gamma, \quad \forall T \in \mathscr{T}_h^{\Gamma_{k\ell}}. \tag{B.2}$$

Plugging it into the Poisson problem (B.1), we obtain a stabilized problem with

$\tilde{u}_h = (\tilde{u}_{h,k}) \in Y_h(\Omega) = \prod_{k=1}^{k^*} Y_h(\Omega_k)$ as the only unknown:

$$\begin{aligned}
&\sum_{k=1}^{k^*} \int_{\Omega_k} \nabla \tilde{u}_{h,k} \cdot \nabla \tilde{v}_{h,k}\, d\boldsymbol{x} + \sum_{k\ell,\, k>\ell} \sum_{T \in \mathscr{T}^{\Gamma_{k\ell}}} |\varphi_T|^2_{H^1(\kappa_T)} \beta_T(u_h)\beta_T(v_h) \\
&\qquad + \sum_{k\ell,\, k>\ell} \sum_{T \in \mathscr{T}^{\Gamma_{k\ell}}} \int_{\kappa_T} (\beta_T(u_h) \nabla \varphi_T \cdot \nabla v_{h,k} + \beta_T(v_h) \nabla u_{h,k} \cdot \nabla \varphi_T)\, d\boldsymbol{x} \\
&\qquad = \int_\Omega f \tilde{v}_h\, d\boldsymbol{x} + \sum_{k\ell, k>\ell} \sum_{T \in \mathscr{T}^{\Gamma_{k\ell}}} \beta_T(v_h) \int_{\kappa_T} f \varphi_T\, d\boldsymbol{x} \quad \forall v_h \in Y_h(\Omega).
\end{aligned}$$

The norm $|\varphi_T|_{H^1(T)}$ can be easily computed by hand. Equation (B.2) and an elementary integration by parts yield the following formulation: *find* $\tilde{u}_h \in Y_h(\Omega)$ *such that*

$$\begin{aligned}
&\sum_{k=1}^{k^*} \int_{\Omega_k} \nabla \tilde{u}_{h,k} \cdot \nabla \tilde{v}_{h,k}\, d\boldsymbol{x} + \sum_{k\ell,\, k>\ell} \sum_{T \in \mathscr{T}^{\Gamma_{k\ell}}} |\varphi_T|^2_{H^1(\kappa_T)} \left(\int_T [\tilde{u}_h]_{k\ell}\, d\Gamma \right) \left(\int_T [\tilde{v}_h]_{k\ell}\, d\Gamma \right) \\
&\qquad - \sum_{k\ell, k>\ell} \sum_{T \in \mathscr{T}^{\Gamma_{k\ell}}} \int_T ([\tilde{u}_h]_{k\ell} \partial_{\boldsymbol{n}} \tilde{v}_{h,k} + \partial_{\boldsymbol{n}} \tilde{u}_{h,k} [\tilde{v}_h]_{k\ell})\, d\Gamma \\
&\qquad = \int_\Omega f \tilde{v}_h\, d\boldsymbol{x} + \sum_{k\ell,\, k>\ell} \sum_{T \in \mathscr{T}^{\Gamma_{k\ell}}} \left(\int_T [\tilde{v}_h]_{k\ell}\, d\Gamma \right) \left(\int_{\kappa_T} f \varphi_T\, d\boldsymbol{x} \right) \quad \forall \tilde{v}_h \in Y_h(\Omega).
\end{aligned}$$

The bilinear form involved in the left-hand side of this variational equation is symmetric. As already indicated in [26], this formulation of the discrete problem (B.1) looks like the Nitsche stabilization introduced in [46] to handle in a variational way the Dirichlet condition. A similar stabilization is also used in [38] in the nonconforming domain decomposition context for the two-dimensional problems.

The most critical point pertains to the evaluation of $\int_T [v_h]_{k\ell}\, d\Gamma$. Indeed, $[v_h]_{k\ell}$ is piecewise linear on the triangle T. An exact computation of this term would be often expensive and sometimes inaccessible, in particular when the trace of the mortar mesh on T results in a complex partition of T. It is then necessary to resort to a numerical integration. The main effect is that the mortar integral matching is not exactly satisfied anymore. So far this difficulty, which has to be solved efficiently in practice, is common to all the domain decomposition methods with nonmatching grids. In [30] and in [45], a high number of numerical experiences realized in reasonable circumstances are discussed, and the authors come to the conclusion that a Gauss integration with a sufficient number of integrating points can be used. However, they recommend use of a different quadrature formula for the evaluation of $\int_T [u_h]_{k\ell}\, d\Gamma$ (the computation should be realized on the mesh $\mathscr{T}_h^{\Gamma_{k\ell}}$) and of $\int_T [v_h]_{k\ell}\, d\Gamma$ (rather $\mathscr{T}_h^{\Gamma_{\ell k}}$ has to be used), which results in a Petrov–Galerkin procedure. Although the symmetry of the system is definitely broken, they claim that this approach does not introduce any numerical instabilities and gives satisfactory results. Our belief is that these trends should be confirmed by numerical tests in three dimensions.

Acknowledgments. The author would like to address his deepest thanks to Y. Maday and C. Bernardi for fruitful discussions and for their help.

ON THE EQUIVALENCE OF SOFT WAVELET SHRINKAGE, TOTAL VARIATION DIFFUSION, TOTAL VARIATION REGULARIZATION, AND SIDEs*

GABRIELE STEIDL†, JOACHIM WEICKERT‡, THOMAS BROX‡, PAVEL MRÁZEK‡, AND MARTIN WELK‡

Abstract. Soft wavelet shrinkage, total variation (TV) diffusion, TV regularization, and a dynamical system called SIDEs are four useful techniques for discontinuity preserving denoising of signals and images. In this paper we investigate under which circumstances these methods are equivalent in the one-dimensional case. First, we prove that Haar wavelet shrinkage on a single scale is equivalent to a single step of space-discrete TV diffusion or regularization of two-pixel pairs. In the translationally invariant case we show that applying cycle spinning to Haar wavelet shrinkage on a single scale can be regarded as an absolutely stable explicit discretization of TV diffusion. We prove that space-discrete TV diffusion and TV regularization are identical and that they are also equivalent to the SIDEs system when a specific force function is chosen. Afterwards, we show that wavelet shrinkage on multiple scales can be regarded as a single step diffusion filtering or regularization of the Laplacian pyramid of the signal. We analyze possibilities to avoid Gibbs-like artifacts for multiscale Haar wavelet shrinkage by scaling the thresholds. Finally, we present experiments where hybrid methods are designed that combine the advantages of wavelets and PDE/variational approaches. These methods are based on iterated shift-invariant wavelet shrinkage at multiple scales with scaled thresholds.

Key words. soft wavelet shrinkage, total variation diffusion, total variation regularization, stabilized inverse diffusion equation

1. Introduction.

Image denoising is a field where one is typically interested in removing noise without sacrificing important structures such as edges. This goal cannot be achieved with linear filters. Consequently, a large variety of nonlinear strategies has been proposed including, among others, wavelet techniques [22, 23, 31], PDEs [2, 37, 41, 47], and variational methods [5, 6, 9, 36].

Although these method classes serve the same purpose, relatively few publications exist where their similarities and differences are juxtaposed and their mutual relations are analyzed. However, such an analysis is highly desirable, since it can help to transfer results from one of these classes to the others. Moreover, a deeper understanding of the differences between these classes might be helpful for designing novel hybrid methods that combine the advantages of the different classes.

The goal of the present paper is to address this problem by analyzing relations between four important representatives of discontinuity-preserving denoising methods:

- wavelet soft thresholding [22],
- space-discrete total variation (TV) diffusion [3, 4],

- discrete TV regularization [40, 1],
- SIDEs, a dynamical system that has been inspired from space-discrete stabilized inverse diffusion equations [38].

Figure 1 gives an illustration of the denoising properties of soft wavelet shrinkage and TV regularization methods. The original image is available from [31]. We observe that the results do not differ very much. Indeed, we shall prove in our paper that all four aforementioned methods are very closely related.

In order to keep things as simple as possible we base our analysis on the one-dimensional (1-D) case. Our basic strategy is to start with the simplest cases for which we can establish equivalence. Afterwards, we extend these results to more general situations. The higher-dimensional case is beyond the scope of the present paper, since it cannot be treated as a straightforward generalization of the 1-D ideas. For some preliminary results in two dimensions, we refer the reader to [34], where diffusion-inspired wavelet shrinkage with improved rotation invariance is introduced.

Our paper is organized as follows. In section 2 we give a very brief description of the general ideas behind wavelet shrinkage, nonlinear diffusion filtering, variational image denoising, and SIDEs. In section 3 we specify these paradigms to the simplest cases where equivalence can be shown. In this section we restrict ourselves to two-pixel signals, soft Haar wavelet shrinkage, TV diffusivity, and its corresponding regularizer. Under these circumstances we prove equivalence between wavelet shrinkage, TV diffusion, and TV regularization. These results are extended in section 4 to the translationally invariant case with N-pixel signals. In the wavelet setting, we use

a Haar wavelet-based technique on a single scale with cycle spinning. We show that it can be regarded as a single iteration of a stabilized explicit scheme for TV diffusion, and we prove that this TV diffusion is equivalent to both TV regularization and SIDEs with an appropriate force function. In section 5 we extend our wavelet results from a single scale to multiple scales. We show that multiple scale Haar wavelet soft shrinkage can be regarded as TV diffusion, TV regularization, or SIDEs applied to a Laplacian pyramid decomposition of the signal. Moreover, we propose and analyze a strategy for avoiding Gibbs-like artifacts by scaling the shrinkage thresholds. In section 6 we present experiments where we compare iterated single-scale filtering with noniterated and iterated multiscale filtering. The paper is concluded with a summary in section 7.

Related work. Recently, a number of interesting connections between wavelet shrinkage of functions, regularization methods, and PDEs has been established. A book by Meyer [33] presents a unified view on wavelets and nonlinear evolutions, and Shen and Strang [43] have included wavelets into the solution of the linear heat equation. Chambolle et al. [13] showed that one may interpret wavelet shrinkage of functions as regularization processes in suitable Besov spaces. In particular, Haar thresholding was considered in [18]. Furthermore, Cohen et al. [17] showed that the space of functions of bounded variation can be "almost" characterized by wavelet expansions. Chambolle and Lucier [15] considered iterated translationally invariant wavelet shrinkage and interpreted it as a nonlinear scale-space, which differs from other scale-spaces by the fact that it is not given in terms of PDEs.

There has also been a rapidly increasing interest in designing hybrid methods using both wavelet shrinkage and TV denoising methods. Durand and Froment [24] proposed to address the problem of pseudo-Gibbs artifacts in wavelet denoising by replacing the thresholded wavelet coefficients by coefficients that minimize the total variation. Their method is also close in spirit to approaches by Chan and Zhou [16], who postprocessed images obtained from wavelet shrinkage by a TV-like regularization technique. Coifman and Sowa [20] used functional minimization with wavelet constraints for postprocessing signals that have been degraded by wavelet thresholding or quantization. Candés and Guo [12] also presented related work, in which they combined ridgelets and curvelets with TV minimization strategies. Recently, Malgouyres [30] proposed a hybrid method that uses both wavelet packets and TV approaches. His experiments showed that it may restore textured regions without introducing ringing artifacts.

Regarding the relations between wavelet shrinkage denoising of discrete signals and TV reduction, not much research has been done so far. One notable exception is a recent paper by Coifman and Sowa [21], where they propose TV diminishing flows that act along the direction of Haar wavelets. Bao and Krim [7] addressed the problem of texture loss in diffusion scale-spaces by incorporating ideas from wavelet analysis. An experimental evaluation of the denoising capabilities of three-dimensional wavelet shrinkage and nonlinear diffusion filters is presented in a paper by Frangakis, Stoschek, and Hegerl [27].

This discussion shows that our paper differs from preceding work by the fact that we investigate conditions under which we can prove equivalence between wavelet shrinkage of discrete signals, space-discrete TV diffusion or regularization, and SIDEs. Some preliminary results in this paper have been presented at conferences [44, 10].

2. The basic methods. The goal of this section is to give a brief introduction to the methods that are considered in this paper: soft Haar wavelet shrinkage, TV diffusion, TV denoising, and SIDEs.

2.1. Wavelet shrinkage. During recent years wavelet methods have proved their use in various signal processing tasks. One of them is discontinuity-preserving denoising. The discrete wavelet transform represents a 1-D signal $f(x)$ in terms of shifted versions of a dilated lowpass scaling function $\varphi(x)$, as well as shifted and dilated versions of a bandpass wavelet function $\psi(x)$. In the case of orthogonal wavelets, this gives

$$f(x) = \sum_{i\in\mathbb{Z}} \langle f, \varphi_i^{j_e}\rangle\, \varphi_i^{j_e}(x) + \sum_{j=-\infty}^{j_e} \sum_{i\in\mathbb{Z}} \langle f, \psi_i^j\rangle\, \psi_i^j(x),$$

where $\psi_i^j(x) := 2^{-j/2}\psi(2^{-j}x - i)$ and where $\langle\cdot,\cdot\rangle$ denotes the inner product in $L_2(\mathbb{R})$. The wavelet representation employs scaling components only at one level j_e, and wavelet components at levels $j \le j_e$ add higher resolution details to the signal.

If the measurements f are corrupted by white Gaussian noise, then this noise is contained to a small amount in all wavelet coefficients $\langle f, \psi_i^j\rangle$, while the original signal is in general determined by few significant wavelet coefficients. Therefore wavelet shrinkage attempts to eliminate noise from the wavelet coefficients by the following three-step procedure:

- *Analysis.* Transform the noisy data f to the wavelet coefficients $d_i^j = \langle f, \psi_i^j\rangle$ and scaling function coefficients $c_i^{j_e} = \langle f, \varphi_i^{j_e}\rangle$.
- *Shrinkage.* Apply a shrinkage function S_τ with a threshold parameter τ related to the variance of the Gaussian noise to the wavelet coefficients, i.e., $S_\tau(d_i^j) = S_\tau(\langle f, \psi_i^j\rangle)$.
- *Synthesis.* Reconstruct the denoised version u of f from the shrunken wavelet coefficients

$$u(x) := \sum_{i\in\mathbb{Z}} \langle f, \varphi_i^{j_e}\rangle\, \varphi_i^{j_e}(x) + \sum_{j=-\infty}^{j_e} \sum_{i\in\mathbb{Z}} S_\tau(\langle f, \psi_i^j\rangle)\, \psi_i^j(x).$$

In the literature a number of different shrinkage functions have been considered. In this paper we focus on one of the most popular strategies, namely Donoho's soft shrinkage [22]. It uses the soft thresholding with threshold parameter $\tau > 0$:

$$S_\tau(x) = \begin{cases} x - \tau \operatorname{sgn}(x) & \text{if} \quad |x| > \tau, \\ 0 & \text{if} \quad |x| \le \tau, \end{cases} \tag{2.1}$$

which shrinks all coefficients towards zero. Other shrinkage functions will be considered in a forthcoming paper.

Furthermore, in this paper we restrict our attention to Haar wavelets. They are well suited for recovering piecewise constant signals with discontinuities. The Haar wavelet $\psi(x)$ and the corresponding scaling function $\varphi(x)$ are given by $\psi(x) := 1_{[0,\frac{1}{2})} - 1_{[\frac{1}{2},1)}$ and $\varphi(x) := 1_{[0,1)}$, where $1_{[a,b)}$ is the characteristic function of $[a,b)$:

$$1_{[a,b)}(x) \;:=\; \begin{cases} 1 & \text{if } x \in [a,b), \\ 0 & \text{else.} \end{cases}$$

Using the so-called two-scale relation of the wavelet and its scaling function, the coefficients c_i^j and d_i^j at higher level j can be computed from the coefficients c_i^{j-1} at lower level $j-1$ and vice versa. This results in fast algorithms for the analysis step

and the synthesis step. For the Haar wavelets, we obtain

$$c_i^j = \frac{c_{2i}^{j-1} + c_{2i+1}^{j-1}}{\sqrt{2}}, \qquad d_i^j = \frac{c_{2i}^{j-1} - c_{2i+1}^{j-1}}{\sqrt{2}}, \tag{2.2}$$

$$c_{2i}^{j-1} = \frac{c_i^j + d_i^j}{\sqrt{2}}, \qquad c_{2i+1}^{j-1} = \frac{c_i^j - d_i^j}{\sqrt{2}}. \tag{2.3}$$

2.2. Diffusion filtering. Let us now consider a function $f(x)$ on some interval $[a, b]$. The basic idea behind nonlinear diffusion filtering is to obtain a family $u(x, t)$ of filtered versions of the signal $f(x)$ as the solution of a suitable diffusion process with $f(x)$ as initial condition and homogeneous Neumann boundary conditions [37]:

$$\begin{aligned} u_t = (g(u_x^2)\, u_x)_x \quad & \text{on } (a, b) \times (0, \infty), \\ u(x, 0) = f(x) \quad & \text{for all } x \in [a, b], \\ u_x(a, t) = u_x(b, t) = 0 \quad & \text{for all } t \in (0, \infty), \end{aligned} \tag{2.4}$$

where subscripts denote partial derivatives, and the diffusion time t is a simplification parameter: larger values correspond to stronger filtering.

The diffusivity $g(u_x^2)$ is a nonnegative function that steers the amount of diffusion. Usually, it is decreasing in u_x^2. This ensures that strong edges are less blurred by the diffusion filter than noise and low-contrast details. In the present paper, we focus on the *TV diffusivity*

$$g(u_x^2) \;:=\; \frac{1}{|u_x|}. \tag{2.5}$$

The resulting *TV diffusion filter* (also called *TV flow*) has a number of interesting properties. It requires no additional parameters (besides t), it is well posed [3, 8, 25], it preserves the shape of some objects [8], and it leads to constant signals in finite time [4].

2.3. Regularization methods. Regularization methods constitute an alternative to diffusion filters when one is interested in a discontinuity-preserving denoising method for a continuous signal $f(x)$ with $x \in [a, b]$. Here the basic idea is to look for the minimizer u of the energy functional

$$E(u; \alpha, f) \;:=\; \int_a^b \Big((u - f)^2 \;+\; \alpha\, \Psi(u_x^2) \Big)\, dx. \tag{2.6}$$

The first term of this functional encourages similarity between the original signal $f(x)$ and its filtered version $u(x)$, while the second term penalizes deviations from smoothness. The increasing function Ψ is called the *penalizer (regularizer)*, and the nonnegative *regularization parameter* α serves as smoothness weight: larger values correspond to a more pronounced filtering.

As is explained in detail in [42], there are strong relations between regularization methods and diffusion filters: A minimizer of (2.6) satisfies necessarily the Euler–Lagrange equation

$$\frac{u - f}{\alpha} \;=\; (\Psi'(u_x^2)\, u_x)_x,$$

with homogeneous Neumann boundary conditions. This equation may be regarded as a fully implicit time discretization of the diffusion equation (2.4) with diffusivity

$g(u_x^2) = \Psi'(u_x^2)$, initial value $f(x)$, and stopping time α. Thus, one would expect that the minimizer of (2.6) *approximates* the diffusion filter (2.4) but is not identical to it.

In the present paper, we are interested in one of the most popular nonlinear regularization methods, namely *TV regularization* [40, 1]. It uses the penalizer $\Psi(u_x^2) := 2\,|u_x|$, which corresponds to the TV diffusivity (2.5). This regularization is well known for its good denoising capabilities and its tendency to create blocky, segmentation-like results. Well-posedness results can be found in [14].

2.4. SIDEs. A SIDE is a dynamical system that has been inspired from a stabilized limiting case of a space-discrete nonlinear diffusion filter [38]. The name SIDE is an acronym for *stabilized inverse diffusion equation*.

Let us consider a discrete signal $f = (f_i)_{i=0}^{N-1}$. Then its SIDE evolution produces a sequence of filtered images $u(t) = (u_i(t))_{i=0}^{N-1}$, with $u(0) = f$. Increasing the time t leads to a consecutive merging of regions. The evolution between two merging events is governed by a dynamical system with a discontinuous right-hand side.

Assume that at some time t_j a pixel with index i belongs to a constant region of size m_{i,t_j}; i.e., there exist $l \geq 1$ and $r \geq 0$ with $m_{i,t_j} = l + r$,

$$u_{i-l+1} = \cdots = u_i = u_{i+1} = \cdots = u_{i+r},$$
$$u_{i-l} \neq u_{i-l+1} \text{ if } i - l \geq 0, \qquad u_{i+r} \neq u_{i+r+1} \text{ if } i + r \leq N - 2.$$

Then the SIDEs algorithm proceeds as follows:

(i) *Initialization*. Start at time $t_0 = 0$ with the trivial segmentation, where each pixel i is regarded as a region of size $m_{i,0} = 1$:

$$u_i(0) = f_i.$$

(ii) *Evolution*. Given a segmentation at time t_j, the signal evolves according to

$$\dot{u}_i = \begin{cases} \frac{1}{m_{i,t_j}} F(u_{i+r+1} - u_{i+r}) & \text{if } i - l = -1, \\ \frac{-1}{m_{i,t_j}} F(u_{i-l+1} - u_{i-l}) & \text{if } i + r = N - 1, \\ \frac{1}{m_{i,t_j}} \left(F(u_{i+r+1} - u_{i+r}) - F(u_{i-l+1} - u_{i-l})\right) & \text{else,} \end{cases} \tag{2.7}$$

where $\dot{u}_i$ denotes the derivative of u_i with respect to t and F is a so-called *force function* that satisfies a number of formal requirements [38]. The first case in (2.7) describes the evolution of the region at the left signal boundary, the second case applies for the right boundary region, and the third case specifies the evolution of all inner regions.

In [38], only the third case has been specified. We have supplemented the other two cases here in order to be able to treat the boundary regions in a proper way as well. The evolution is stopped when two neighboring regions attain equal grey values. This determines the new merging time t_{j+1}.

(iii) *Merging*. Merge the neighboring regions with equal grey values.

(iv) *Loop control*. Stop if all regions are merged to one; else go back to step (ii).

We see that the stabilization in SIDEs is achieved by an additional definition that results in merging neighboring regions when they approach each other. This step is crucial for the performance of SIDEs, as it can be used for reducing the state variables of the dynamical system. The analytical solutions in the following sections will provide further theoretical justification for this region-merging step.

In [38] several theoretical results for SIDEs are proved, including a maximum principle, well-posedness properties, and a finite extinction time.

The dynamic system suggests that for the specific case $m_i = 1$ one may regard a 1-D SIDE as a space discretization of the PDE

$$u_t = (F(u_x))_x$$

with homogeneous Neumann boundary conditions. This is a diffusion equation with flux function F. Since we are specifically interested in the TV case, we do not consider the specific choice in [38] but restrict ourselves to the *TV force function*

$$F(v) := \begin{cases} 1 & \text{if} \quad v > 0, \\ -1 & \text{if} \quad v < 0. \end{cases}$$

Then it is evident that if $m_i = 1$ for all i, TV diffusion is approximated.

3. Two-pixel signals. In this section, we analyze relations between soft wavelet shrinkage, TV diffusion, TV regularization, and SIDEs for the simplest signals, namely discrete signals with only two pixels. We will see that the restriction to two pixels allows us to find analytical solutions for these degenerated nonlinear processes.

3.1. Soft Haar wavelet shrinkage of two-pixel signals. Let us now consider a discrete two-pixel signal $f = (f_0, f_1)$ and study its change under soft Haar wavelet shrinkage. The analysis step produces the coefficients $c = (f_0 + f_1)/\sqrt{2}$ and $d = (f_0 - f_1)/\sqrt{2}$ of the scaling function and the wavelet. For simplicity, we have dropped the sub- and superscripts for c and d. This step is followed by the shrinkage operation $S_\tau(d)$ with the soft shrinkage function (2.1). Then the synthesis step $u_0 = (c + S_\tau(d))/\sqrt{2}$, $u_1 = (c - S_\tau(d))/\sqrt{2}$ gives the final result:

$$u_0 = \begin{cases} f_0 + \frac{\tau}{\sqrt{2}} \operatorname{sgn}(f_1 - f_0) & \text{if} \quad \tau < |f_1 - f_0|/\sqrt{2}, \\ (f_0 + f_1)/2 & \text{else}, \end{cases} \tag{3.1}$$

$$u_1 = \begin{cases} f_1 - \frac{\tau}{\sqrt{2}} \operatorname{sgn}(f_1 - f_0) & \text{if} \quad \tau < |f_1 - f_0|/\sqrt{2}, \\ (f_0 + f_1)/2 & \text{else}. \end{cases} \tag{3.2}$$

This shows that by increasing the shrinkage threshold τ the grey values of both pixels approach each other. For $\tau = |f_1 - f_0|/\sqrt{2}$ they merge, and for larger τ they remain merged.

3.2. TV diffusion of two-pixel signals. Next, we are interested in the space-discrete diffusion of two-pixel signals (f_0, f_1). The homogeneous Neumann boundary conditions are discretized by setting flows over the signal boundary to zero. In this case a space-discrete version of the TV diffusion equation

$$u_t = \left(\frac{u_x}{|u_x|} \right)_x$$

can be written as

$$\dot{u}_0 = \frac{u_1 - u_0}{|u_1 - u_0|}, \qquad \dot{u}_1 = -\frac{u_1 - u_0}{|u_1 - u_0|}, \tag{3.3}$$

with initial conditions $u_0(0) = f_0$ and $u_1(0) = f_1$. Here the dot denotes again temporal differentiation, and the pixel size is set to 1. Setting $w(t) := u_1(t) - u_0(t)$ and

$\eta := f_1 - f_0$, and subtracting $\dot{u}_0$ from $\dot{u}_1$ in (3.3), we obtain the following initial value problem:

$$\dot{w} = -2\,\frac{w}{|w|}, \qquad w(0) = \eta. \tag{3.4}$$

The right-hand side of this differential equation is discontinuous for $w = 0$ and thus requires a generalization of the concept of solution. We say that w is a solution of (3.4) if it is an absolutely continuous function which fulfills

$$\dot{w} = -2\,\mathrm{sgn}\,(w), \qquad w(0) = \eta \tag{3.5}$$

almost everywhere, where

(I) $\mathrm{sgn}\,(w) := 1$ if $w > 0$,
$\mathrm{sgn}\,(w) := -1$ if $w < 0$
and may take any value in $[-1, 1]$ if $w = 0$.

Note that this definition is in agreement with the frequently used concept of differential inclusions for differential equations with discontinuous right-hand sides [26], where absolutely continuous solutions of

$$-\frac{1}{2}\,\dot{w} \in \begin{cases} \{1\} & \text{if } w > 0, \\ \{-1\} & \text{if } w < 0, \\ [-1, 1] & \text{if } w = 0 \end{cases}$$

were considered. The solution of (3.5) can be obtained as follows: If $\eta \neq 0$, then we have by straightforward computation for $t < |\eta|/2$ that $w(t) = \eta - 2\,t\,\mathrm{sgn}\,(\eta)$ and in particular, by continuity of w, that $w(|\eta|/2) = 0$. Assume that $w(t) \neq 0$ for some $t > |\eta|/2$. Let without loss of generality $w(t) > 0$. The opposite assumption $w(t) < 0$ can be handled in the same way. Then $w(t) = -2t + C$, where we get by continuity of w, if t approaches $|\eta|/2$, that $C = |\eta|$ and, consequently, $w(t) = 2(|\eta|/2 - t) < 0$. This contradicts our assumption. Thus $w(t) = 0$ for $t \geq |\eta|/2$. In summary, we obtain the solution

$$w(t) = \begin{cases} \eta \;-\; 2\,t\,\mathrm{sgn}\,(\eta) & \text{if } t < |\eta|/2, \\ 0 & \text{if } t \geq |\eta|/2. \end{cases} \tag{3.6}$$

This equation shows that the grey value difference $w(t) = u_1(t) - u_0(t)$ tends linearly to 0. Both pixels merge at time $t = |f_1 - f_0|/2$ and remain merged afterwards. Thus, already the simple two-pixel model indicates a finite extinction time for TV diffusion. Since $\dot{u}_0 + \dot{u}_1 = 0$ and $u_0(0) + u_1(0) = f_0 + f_1$, we see further that the average grey value is preserved:

$$u_0(t) + u_1(t) = f_0 + f_1 \qquad \forall\, t \geq 0. \tag{3.7}$$

Using (3.6) and (3.7), we obtain the analytical solution

$$u_0(t) = \begin{cases} f_0 \;+\; t\,\mathrm{sgn}\,(f_1 - f_0) & \text{if} \quad t < |f_1 - f_0|/2, \\ (f_0 + f_1)/2 & \text{else}, \end{cases} \tag{3.8}$$

$$u_1(t) = \begin{cases} f_1 \;-\; t\,\mathrm{sgn}\,(f_1 - f_0) & \text{if} \quad t < |f_1 - f_0|/2, \\ (f_0 + f_1)/2 & \text{else}. \end{cases} \tag{3.9}$$

Interestingly, this result is identical to the results (3.1)–(3.2) for soft Haar wavelet shrinkage if one identifies the diffusion time t with the threshold parameter $\tau = \sqrt{2}t$.

3.3. TV regularization of two-pixel signals. Let us now turn our attention to the regularization framework. Again we are interested only in the two-pixel model (f_0, f_1). We consider a space-discrete variant of (2.6) with a TV penalizer:

$$E(u_0, u_1; \alpha, f) \;=\; (f_0 - u_0)^2 + (f_1 - u_1)^2 + 2\alpha\,|u_1 - u_0|. \tag{3.10}$$

Straightforward computation results in the following minimizer of (3.10):

$$u_0 = \begin{cases} f_0 \;+\; \alpha\,\mathrm{sgn}\,(f_1 - f_0) & \text{if} \quad \alpha < |f_1 - f_0|/2, \\ (f_0 + f_1)/2 & \text{else,} \end{cases}$$

$$u_1 = \begin{cases} f_1 \;-\; \alpha\,\mathrm{sgn}\,(f_1 - f_0) & \text{if} \quad \alpha < |f_1 - f_0|/2, \\ (f_0 + f_1)/2 & \text{else.} \end{cases}$$

This result coincides with the outcome of a single Haar wavelet shrinkage step with shrinkage parameter $\tau = \sqrt{2}\,\alpha$. Moreover, it is identical to TV diffusion if one replaces the diffusion time t by the regularization parameter α. Thus, all three methods are equivalent by setting $\tau = \sqrt{2}\,t = \sqrt{2}\,\alpha$. It is remarkable that TV diffusion and TV regularization give identical evolutions in the two-pixel case. From the considerations in section 2.3 one would expect only that the processes approximate each other. In section 4.3 we will investigate if this equivalence also holds in the general space-discrete case with N pixels.

3.4. SIDEs for two-pixel signals. If we consider the SIDE evolution of a two-pixel signal (f_0, f_1), we obtain for the case of a TV force function the dynamical system

$$\dot{u}_0 = \frac{u_1 - u_0}{|u_1 - u_0|}, \qquad \dot{u}_1 = -\frac{u_1 - u_0}{|u_1 - u_0|},$$

with initial conditions $u_0(0) = f_0$ and $u_1(0) = f_1$.

This is the same evolution as in the TV diffusion case. Hence, its solution is given by (3.8)–(3.9), and there is a finite merging time $t = |f_1 - f_0|/2$.

4. *N*-pixel signals. So far we have focused on the two-pixel case. Let us now investigate which of the equivalences carry over to the general 1-D case with N pixels. To this end we will consider shift invariant wavelet shrinkage on a single scale, show that it performs a numerical approximation to TV diffusion, prove the equivalence of space-discrete TV diffusion and discrete TV regularization by deriving analytical solutions of both processes, and show that this solution coincides with SIDEs with TV force functions.

4.1. Shift invariant wavelet shrinkage on a single scale. Let us first reconsider the soft Haar wavelet shrinkage on a single scale with N pixels, where N is even. Figure 2 illustrates this computation as the two-channel filter bank. As usual we apply the z-transform notation $f(z) = \sum_{i=0}^{N-1} f_i z^{-i}$. Then $\boxed{H_i(z)}$ $(i = 0, 1)$ denotes the convolution of f with the lowpass filter $(i = 0)$ and the highpass filter $(i = 1)$, i.e., $f(z)H_i(z)$, $\boxed{2\downarrow}$ and $\boxed{2\uparrow}$ downsampling and upsampling by 2, respectively, and the circle soft thresholding by S_τ. Finally, $\bullet$ signifies addition.

The use of Haar wavelets creates a natural decomposition of the signal into two-pixel pairs of type (f_{2j}, f_{2j+1}) $(j = 0, \ldots, N/2-1)$. This two-pixel clustering, however, also causes a lack of translation invariance which may be responsible for visual artifacts. One method to improve the quality of the denoised signal considerably is to

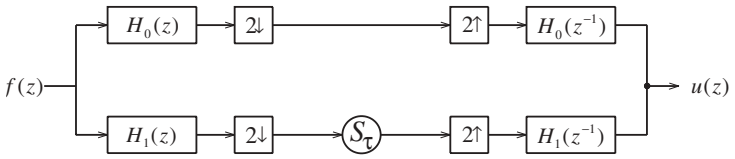

FIG. 2. *Two-channel filter bank with* $H_0(z) = \frac{1+z}{\sqrt{2}}$ *and* $H_1(z) = \frac{1-z}{\sqrt{2}}$.

"average out" the translation dependence. This method was termed *cycle spinning* by Coifman and Donoho [19]. For a single wavelet decomposition step, the basic idea of cycle spinning on a single scale reads as follows:

(a) perform wavelet shrinkage (3.1), (3.2) on successive pairs of the original signal;
(b) shift the signal one pixel to the right;
perform wavelet shrinkage on successive pairs of the shifted signal;
shift the resulting signal one pixel back to the left;
(c) average both results.

The shifting process requires the incorporation of boundary conditions for f. Again we mirror the signal f at its ends. Steps (a)–(c) are equivalent to denoising the signal using a nonsubsampled filter bank. More sophisticated material on oversampled filter banks, corresponding wavelet frames, and undecimated wavelet transforms can be found in [31].

4.2. Equivalence to a numerical scheme for TV diffusion. We have seen that, in order to improve the performance of wavelet shrinkage and to make wavelet-based denoising translationally invariant, cycle spinning can be used. Since there is an equivalence between Haar wavelet shrinkage and TV diffusion in the two-pixel case, it would be natural to ask if there is a TV diffusion scheme equivalent to translationally invariant soft Haar wavelet shrinkage on a single level. This leads us to an interesting novel scheme for TV diffusion.

Derivation of the scheme. We have been able to derive an analytical solution for TV diffusion in the two-pixel case. We can use this two-pixel solution to create a numerical scheme for N pixels. In order to derive such a scheme for some time step size $\triangle t$, we proceed in three steps that are inspired by the cycle spinning technique:

(a) perform TV diffusion with step size $2\triangle t$ on all pixel pairs (u_{2j}, u_{2j+1});
(b) perform TV diffusion with step size $2\triangle t$ on all pixel pairs (u_{2j-1}, u_{2j});
(c) average both results.

Obviously, one step of this iterative scheme is equivalent to a translationally invariant Haar wavelet shrinkage with threshold $\tau = 2\sqrt{2}\triangle t$ on a single level. So let us investigate this scheme in more detail.

At iteration level k, we assume that our signal is given by $(u_i^k)_{i=0}^{N-1}$. We denote the resulting signal of step (a) by $(v_i^{k+1})_{i=0}^{N-1}$ and the spatial grid size by h. From our analysis of the two-pixel situation, it follows that v_i in some even pixel $i = 2j$ is given by

$$v_i^{k+1} = \frac{u_i^k + u_{i+1}^k}{2} - \begin{cases} \max\left(\frac{u_{i+1}^k - u_i^k}{2} - \frac{2\triangle t}{h}, 0\right) & \text{if } u_{i+1}^k \geq u_i^k, \\ \min\left(\frac{u_{i+1}^k - u_i^k}{2} + \frac{2\triangle t}{h}, 0\right) & \text{if } u_{i+1}^k < u_i^k. \end{cases} \tag{4.1}$$

To simplify the notation, we assume only in this subsection instead of the third agreement in (I) that $\operatorname{sgn}(0) := 0$. It is not difficult to see that (4.1) can be rewritten

as

$$v_i^{k+1} \;=\; u_i^k + \frac{2\triangle t}{h}\,\mathrm{sgn}\,(u_{i+1}^k - u_i^k)\,\min\left(1,\,\frac{h}{4\triangle t}|u_{i+1}^k - u_i^k|\right). \tag{4.2}$$

Step (b) leads to a resulting signal $(w_i^{k+1})_{i=0}^{N-1}$. For $i = 2j$ it is given by

$$w_i^{k+1} \;=\; u_i^k - \frac{2\triangle t}{h}\,\mathrm{sgn}\,(u_i^k - u_{i-1}^k)\,\min\left(1,\,\frac{h}{4\triangle t}|u_i^k - u_{i-1}^k|\right). \tag{4.3}$$

Thus, the averaging step (c) gives the final scheme for TV diffusion:

$$\begin{aligned} u_i^{k+1} \;=\; u_i^k &+ \frac{\triangle t}{h}\,\mathrm{sgn}\,(u_{i+1}^k - u_i^k)\,\min\left(1,\,\frac{h}{4\triangle t}|u_{i+1}^k - u_i^k|\right) \\ &- \frac{\triangle t}{h}\,\mathrm{sgn}\,(u_i^k - u_{i-1}^k)\,\min\left(1,\,\frac{h}{4\triangle t}|u_i^k - u_{i-1}^k|\right). \end{aligned} \tag{4.4}$$

The same scheme can also be derived if i is odd, since the construction (a)–(c) in this subsection ensures that the result is translationally invariant. Hence it holds for every inner pixel $i \in \{1, \ldots, N-2\}$. It is even valid for the boundary pixels $i = 0$ and $i = N-1$ if we realize the homogeneous Neumann boundary conditions by introducing dummy values $u_{-1}^k := u_0^k$ and $u_N^k := u_{N-1}^k$.

Stability. Let us now investigate the stability properties of the explicit finite difference scheme (4.2). Since (4.2) satisfies

$$\min(u_i^k, u_{i+1}^k) \;\le\; v_i^{k+1} \;\le\; \max(u_i^k, u_{i+1}^k)$$

and (4.3) fulfills the estimate

$$\min(u_{i-1}^k, u_i^k) \;\le\; w_i^{k+1} \;\le\; \max(u_{i-1}^k, u_i^k),$$

we can conclude that

$$\min(u_{i-1}^k, u_i^k, u_{i+1}^k) \;\le\; u_i^{k+1} \;\le\; \max(u_{i-1}^k, u_i^k, u_{i+1}^k).$$

With the initial condition $u_j^0 = f_j$ for $j = 0, \ldots, N-1$, it follows that the two-pixel scheme (4.2) satisfies the discrete maximum-minimum principle

$$\min_j f_j \;\le\; u_i^{k+1} \;\le\; \max_j f_j$$

for all pixels $i \in \{0, \ldots, N-1\}$, all iteration levels $k = 0, 1, 2, \ldots$, and all time step sizes $\triangle t > 0$. In particular, this shows that the scheme is absolutely stable in the maximum norm.

We may regard (4.4) as a stabilization of the naive explicit scheme

$$u_i^{k+1} \;=\; u_i^k + \frac{\triangle t}{h}\,\mathrm{sgn}\,(u_{i+1}^k - u_i^k) - \frac{\triangle t}{h}\,\mathrm{sgn}\,(u_i^k - u_{i-1}^k), \tag{4.5}$$

which becomes unstable for arbitrary small time steps if neighboring values become arbitrarily close.

Consistency. The absolute stability in scheme (4.4) is at the expense that its consistency is no longer unconditional. This effect is typical for absolutely stable explicit schemes; see, for example, the DuFort–Frankel scheme for linear diffusion. In

our case, (4.4) is an $O(\triangle t + h^2)$ approximation to the continuous TV diffusion for $\triangle t \leq \frac{h}{4} \min\left(|u_{i+1}^k - u_i^k|, |u_i^k - u_{i-1}^k|\right)$, since it coincides with scheme (4.5) then. For larger time step sizes, the scheme performs averaging within the neighborhood of each pixel. By using small time step sizes, these averaging effects appear only in regions that are already almost flat such that the difference from real TV diffusion becomes invisible. This two-pixel scheme may be regarded as an alternative to classical finite difference schemes that are based on the regularized TV flow

$$u_t = \left(\frac{u_x}{\sqrt{\epsilon^2 + u_x^2}} \right)_x . \tag{4.6}$$

The ϵ-regularization is necessary for making the diffusivity bounded. It has an effect similar to the deviation from consistency in the two-pixel scheme (4.4): For small $|u_x|$, a PDE is approximated that differs from TV diffusion and has better stability properties. Indeed, in section 6 we shall see that both schemes give very similar results.

Related schemes. The idea to split up a diffusion process into pairwise interactions has also proved to be fruitful in other fields. In the context of fluid dynamic problems, related schemes have been formulated by Richardson, Ferrell, and Long [39]. These authors, however, use multiplicative splittings; i.e., they first compute the diffusion of the pairs of type (u_{2j}, u_{2j+1}), which is then used as the initial state for the subsequent diffusion of the shifted pairs. In a general nonlinear setting, such a scheme is not translationally invariant. Our approach computes the diffusion of the pairs and the shifted pairs in parallel and averages afterwards. This additive splitting guarantees translation invariance. The splitting into two-pixel interactions distinguishes scheme (4.4) from other additive operator splittings [29, 48]. They use directional splittings along the coordinate axis.

4.3. Equivalence of space-discrete TV diffusion and discrete TV regularization. The equivalence of TV diffusion and TV regularization in the two-pixel case gives rise to the question of whether this equivalence also holds in the N-pixel situation. In order to prove this, we now show that both processes have the same analytical solutions.

4.3.1. Space-discrete TV diffusion. We consider the following dynamical system designed to describe space-discrete TV flow on a 1-D signal with N pixels:

$$\begin{aligned} \dot{u}_0 &= \operatorname{sgn}(u_1 - u_0), \\ \dot{u}_i &= \operatorname{sgn}(u_{i+1} - u_i) - \operatorname{sgn}(u_i - u_{i-1}) \qquad (i = 1, \ldots, N-2), \\ \dot{u}_{N-1} &= -\operatorname{sgn}(u_{N-1} - u_{N-2}), \\ u(0) &= f. \end{aligned} \tag{4.7}$$

In the following, we further set $u_{-1} := u_0$ and $u_N := u_{N-1}$. Since the right-hand side of this system is discontinuous, we need again a more detailed specification of when a system of functions is said to satisfy these differential equations. A vector-valued function u is said to fulfill the system (4.7) over the time interval $[0, T]$ if the following holds true:

(II) u is an absolutely continuous vector-valued function which satisfies (4.7) almost everywhere, where sgn is defined by (I) in subsection 3.2.

(III) If $\dot{u}_i(t)$ and $\dot{u}_{i+1}(t)$ exist for the same t, and $u_{i+1}(t) = u_i(t)$ holds, then the expression $\operatorname{sgn}(u_{i+1}(t) - u_i(t))$ occurring in both the right-hand sides for $\dot{u}_i(t)$ and $\dot{u}_{i+1}(t)$ must take the same value in both equations.

With this notation we can establish the following results.

PROPOSITION 4.1 (properties of space-discrete TV diffusion). *The system* (4.7) *has a unique solution* $u(t)$ *in the sense of* (II) *and* (III). *This solution has the following properties:*

(i) Finite extinction time. *There exists a finite time* $T \geq 0$ *such that for all* $t \geq T$ *the signal becomes constant:*

$$u_i(t) = \frac{1}{N} \sum_{k=0}^{N-1} f_k \qquad \text{for all } \; i = 0, \ldots, N-1. \tag{4.8}$$

(ii) Finite number of merging events. *There exists a finite sequence* $0 = t_0 < t_1 < \cdots < t_{n-1} < t_n = T$ *such that the interval* $[0, T)$ *splits into subintervals* $[t_j, t_{j+1})$ *with the property that for all* $i = 0, \ldots, N-2$ *either* $u_i(t) = u_{i+1}(t)$ *or* $u_i(t) \neq u_{i+1}(t)$ *throughout* $[t_j, t_{j+1})$. *The absolute difference between neighboring pixels does not become larger for increasing* $t \in [t_j, t_{j+1})$.

(iii) Analytical solution. *In each of the subintervals* $[t_j, t_{j+1})$ *constant regions of* $u(t)$ *evolve linearly:*

For a fixed index i *let us consider a constant region given by*

$$\begin{gathered} u_{i-l+1} = \cdots = u_i = u_{i+1} = \cdots = u_{i+r} \qquad (l \geq 1, r \geq 0), \\ u_{i-l} \neq u_{i-l+1} \;\text{ if } i - l \geq 0, \qquad u_{i+r} \neq u_{i+r+1} \;\text{ if } i + r \leq N-1 \end{gathered} \tag{4.9}$$

for all $t \in [t_j, t_{j+1})$. *We call* (4.9) *a region of size* $m_{i,t_j} = l + r$. *For* $t \in [t_j, t_{j+1})$ *let* $\triangle t = t - t_j$. *Then* $u_i(t)$ *is given by*

$$u_i(t) = u_i(t_j) + \mu_{i,t_j} \frac{2 \triangle t}{m_{i,t_j}},$$

where μ_{i,t_j} *reflects the relation between the region containing* u_i *and its neighboring regions. It is given as follows:*

For inner regions (i.e., $i - l \geq 0$ *and* $i + r \leq N - 1$*) we have*

$$\mu_{i,t_j} = \begin{cases} 0 & \text{if } \; (u_{i-l}, u_i, u_{i+r+1}) \text{ is strictly monotonic}, \\ 1 & \text{if } \; u_i \text{ is minimal in } (u_{i-l}, u_i, u_{i+r+1}), \\ -1 & \text{if } \; u_i \text{ is maximal in } (u_{i-l}, u_i, u_{i+r+1}), \end{cases} \tag{4.10}$$

and in the boundary case ($i - l + 1 = 0$ *or* $i + r = N - 1$*) the evolution is half as fast:*

$$\mu_{i,t_j} = \begin{cases} 0 & \text{if } \; m = N, \\ \frac{1}{2} & \text{if } \; u_i \text{ is minimal in } (u_{i-l}, u_i, u_{i+r+1}), \\ -\frac{1}{2} & \text{if } \; u_i \text{ is maximal in } (u_{i-l}, u_i, u_{i+r+1}). \end{cases} \tag{4.11}$$

Proof. Let u be a solution of (4.7). We show that u is uniquely determined and satisfies the rules (i)–(iii). Our proof proceeds in four steps.

Step 1. If $\dot{u}(t)$ exists at a fixed time t and $u_i(t)$ lies at this time in some region

$$\begin{gathered} u_{i-l+1}(t) = \cdots = u_i(t) = \cdots = u_{i+r}(t) \qquad (l \geq 1, r \geq 0), \\ u_{i-l}(t) \neq u_{i-l+1}(t) \;\text{ if } i - l \geq 0, \qquad u_{i+r}(t) \neq u_{i+r+1}(t) \;\text{ if } i + r \leq N-1 \end{gathered}$$

of size $m_{i,t}$, then it follows by (4.7) and (III) in the nonboundary case $i - l \geq 0$ and $i + r \leq N - 1$ that

$$u_i(t) \;=\; \frac{1}{m_{i,t}} \sum_{k=-l+1}^{r} u_{i+k}(t),$$

and therefore

$$\dot{u}_i(t) = \frac{1}{m_{i,t}} \sum_{k=-l+1}^{r} \dot{u}_{i+k}(t) = \frac{1}{m_{i,t}} \left(\operatorname{sgn}(u_{i+r+1}(t) - u_i(t)) - \operatorname{sgn}(u_i(t) - u_{i-l}(t))\right)$$

$$= \mu_{i,t} \frac{2}{m_{i,t}}, \tag{4.12}$$

where $\mu_{i,t}$ describes the relation between the region containing u_i and its neighbors at time t as in (4.10). In the boundary case $i - l + 1 = 0$ or $i + r = N - 1$ we follow the same lines and obtain (4.12) with $\mu_{i,t}$ defined by (4.11).

Step 2. Let $\dot{u}(t)$ exist in some small interval (τ_0, τ_1), and assume that $u_i(t) \neq u_{i+1}(t)$ for some $i \in \{0, \dots, N-2\}$ and all $t \in (\tau_0, \tau_1)$. By continuity of u we may assume that $u_i(t) < u_{i+1}(t)$ throughout (τ_0, τ_1). The opposite case $u_i(t) > u_{i+1}(t)$ can be handled in the same way. Then we obtain by (4.12) and the definition of $\mu_{i,t}$ for all $t \in (\tau_0, \tau_1)$ that

$$\dot{u}_i(t) \geq 0 \quad \text{if} \quad i - l \geq 0, \tag{4.13}$$

$$\dot{u}_i(t) > 0 \quad \text{if} \quad i - l + 1 = 0, \tag{4.14}$$

$$\dot{u}_{i+1}(t) \leq 0 \quad \text{if} \quad i + r \leq N - 2, \tag{4.15}$$

$$\dot{u}_{i+1}(t) < 0 \quad \text{if} \quad i + r = N - 1. \tag{4.16}$$

Set $w(t) := u_{i+1}(t) - u_i(t)$. Then the mean value theorem yields

$$w(\tau_1) - w(\tau_0) = (\tau_1 - \tau_0)\, \dot{w}(t^*)$$

for some $t^* \in (\tau_0, \tau_1)$, and we get by (4.13)–(4.16) that

$$w(\tau_1) - w(\tau_0) \leq 0$$

with strict inequality in the boundary case. Consequently, the difference between pixels cannot become larger in the considered interval. In particular, by continuity of u, pixels cannot be split. Once merged they stay merged.

Step 3. Now we start at time $t_0 = 0$. Let t_1 be the largest time such that $\dot{u}(t)$ exists and no merging of regions appears in $(0, t_1)$. Then, for all $i \in \{0, \dots, N-1\}$, a function u_i is in the same region with the same relations to its neighboring regions throughout $[0, t_1)$. Thus, we conclude by (4.12) that

$$\dot{u}_i(t) = \mu_{i,0} \frac{2}{m_{i,0}} \qquad (t \in (0, t_1))$$

and, consequently,

$$u_i(t) = \mu_{i,0} \frac{2t}{m_{i,0}} + C_{i,0} = f_i + \mu_{i,0} \frac{2t}{m_{i,0}} \qquad (t \in [0, t_1]),$$

where the last equality follows by continuity of u_i if t approaches 0.

Step 4. We are now in the position to analyze the entire chain of merging events successively.

Next, we consider the largest interval (t_1, t_2) without merging events in the same way, where we take the initial setting $u(t_1)$ into account instead of f. Then we obtain

$$u_i(t) = \mu_{i,t_1} \frac{2t}{m_{i,t_1}} + C_{i,t_1},$$

where, by continuity of u_i, $u_i(t_1) = \mu_{i,t_1} \frac{2t_1}{m_{i,t_1}} + C_{i,t_1}$ and, consequently,

$$u_i(t) = u_i(t_1) + \mu_{i,t_1} \frac{2(t-t_1)}{m_{i,t_1}}.$$

Now we can continue in the same way by considering $[t_2, t_3)$ and so on. Since we have only a finite number N of pixels and some of these pixels merge at the points t_j, the process stops after a finite number of n steps with output (4.8). Conversely, it is easy to check that a function u with (i)–(iii) is a solution of the system (4.7). This completes the proof of the proposition. □

4.3.2. Discrete TV regularization. Next, we will prove that discrete TV regularization satisfies the same rules as space-discrete TV diffusion. For given initial data $f = (f_0, \dots, f_{N-1})$ discrete TV regularization consists of constructing the minimizer $u(\alpha) = \min_u E(u; \alpha, f)$ of the functional

$$E(u; \alpha, f) = \sum_{i=0}^{N-1} \left((u_i - f_i)^2 + 2\alpha |u_{i+1} - u_i| \right), \tag{4.17}$$

where we suppose again Neumann boundary conditions $u_{-1} = u_0$ and $u_N = u_{N-1}$.

For a fixed regularization parameter $\alpha \geq 0$, the minimizer of (4.17) is uniquely determined since $E(u; \alpha, f)$ is strictly convex in $u_0, \dots, u_{N-1}$. Further, $E(u, \alpha; f)$ is a continuous function in $u_0, \dots, u_{N-1}, \alpha$. Consequently, $u(\alpha)$ is a (componentwise) continuous function in α.

The following proposition implies, together with Proposition 4.1, the equivalence of space-discrete TV diffusion and discrete TV regularization.

PROPOSITION 4.2 (properties of discrete TV regularization). *The minimizing function $u(\alpha)$ of (4.17) is uniquely determined by the following rules:*

(i) Finite extinction parameter. *There exists a finite $A \geq 0$ such that for all $\alpha \geq A$ the signal becomes constant:*

$$u_i(\alpha) = \frac{1}{N} \sum_{k=0}^{N-1} f_k \qquad \text{for all } i = 0, \dots, N-1.$$

(ii) Finite number of merging events. *There exists a finite sequence $0 = a_0 < a_1 < \cdots < a_{n-1} < a_n = A$ such that the interval $[0, A)$ splits into subintervals $[a_j, a_{j+1})$ with the property that for all $i = 0, \dots, N-2$ either $u_i(\alpha) = u_{i+1}(\alpha)$ or $u_i(\alpha) \neq u_{i+1}(\alpha)$ throughout $[a_j, a_{j+1})$. The absolute difference between neighboring pixels does not become larger for increasing $\alpha \in [a_j, a_{j+1})$.*

(iii) Analytical solution. *In each of the subintervals $[a_j, a_{j+1})$ constant regions of $u(\alpha)$ evolve linearly:*

For a fixed index i let us consider a constant region given by

$$u_{i-l+1} = \cdots = u_i = u_{i+1} = \cdots = u_{i+r} \qquad (l \geq 1, r \geq 0), \tag{4.18}$$

$$u_{i-l} \neq u_{i-l+1} \text{ if } i - l \geq 0, \qquad u_{i+r} \neq u_{i+r+1} \text{ if } i + r \leq N-2 \tag{4.19}$$

for all $\alpha \in [a_j, a_{j+1})$. We call (4.18) a region of size $m_{i,a_j} = l + r$. For $\alpha \in [a_j, a_{j+1})$ let $\triangle\alpha = \alpha - a_j$. Then $u_i(\alpha)$ is given by

$$u_i(\alpha) = u_i(a_j) + \mu_{i,a_j} \frac{2\triangle\alpha}{m_{i,a_j}},$$

where μ_{i,a_j} reflects the relation between the region containing u_i and its neighboring regions. It is given as follows:

For inner regions (i.e., $i-l \geq 0$ and $i+r \leq N-2$) we have

$$\mu_{i,a_j} = \begin{cases} 0 & \text{if } (u_{i-l}, u_i, u_{i+r+1}) \text{ is strictly monotonic,} \\ 1 & \text{if } u_i \text{ is minimal in } (u_{i-l}, u_i, u_{i+r+1}), \\ -1 & \text{if } u_i \text{ is maximal in } (u_{i-l}, u_i, u_{i+r+1}), \end{cases} \tag{4.20}$$

and in the boundary case ($i-l+1=0$ or $i+r=N-1$) the evolution is half as fast:

$$\mu_{i,a_j} = \begin{cases} 0 & \text{if } m = N, \\ \frac{1}{2} & \text{if } u_i \text{ is minimal in } (u_{i-l}, u_i, u_{i+r+1}), \\ -\frac{1}{2} & \text{if } u_i \text{ is maximal in } (u_{i-l}, u_i, u_{i+r+1}). \end{cases} \tag{4.21}$$

Proof. A proof that is in complete analogy with our proof for the TV diffusion case is presented in [10, 45]. □

Similar results have also been established in a different way by Strong [46] for the case of continuous TV regularization methods with step functions as initializations. It should be noted that TV regularization by using the taut-string algorithm was also considered by Mammen and van de Geer [32]; see also [28].

4.4. Equivalence to SIDEs with TV force functions. In section 2.4 we have seen that 1-D SIDEs with region size 1 and TV force function are identical to space-discrete TV diffusion. Moreover, in section 4.3 we have derived analytical solutions of space-discrete TV diffusion and discrete TV regularization that show the same merging behavior as SIDEs with TV force functions. Consequently, 1-D SIDEs can be interpreted as an exact solution of space-discrete TV diffusion or regularization in general.

This also confirms that the merging steps in the SIDE evolution are much more than a heuristic stabilization that speeds up the evolution: They are a natural consequence of the degenerated diffusivities that are unbounded in 0. Last but not least, our considerations can be regarded as a theoretical justification of region merging in terms of variational and PDE-based techniques.

5. Multiple scales. So far we have considered only soft wavelet shrinkage on a single scale. In almost all practical applications, however, wavelet shrinkage is performed on multiple scales. In this section, we interpret *multiscale* soft shrinkage with Haar wavelets as the application of nonlinear TV-based diffusion to two-pixel groups of *hierarchical* signals. First, we consider the standard situation without shift invariance; then we discuss the shift-invariant case. Finally, we address a frequent problem that occurs with wavelet shrinkage on multiple scales: the presence of Gibbs-like artifacts. We analyze ways to circumvent this phenomenon by using scale-dependent thresholds.

Throughout this section we deal with signals of length $N = 2^n$ ($n \in \mathbb{N}$).

5.1. Standard case without shift invariance. Haar wavelet shrinkage on two scales is described by the filter bank in Figure 3. To obtain more than two scales we further split up the upper branch of the inner filter bank and so on until we arrive at scale $n = \log_2 N$, where the successive downsampling by 2 results in a one-pixel signal.

Next, we briefly recall the concept of *Gaussian* and *Laplacian pyramids* [11] with respect to the Haar filters. The Gaussian pyramid we are interested in is the sequence

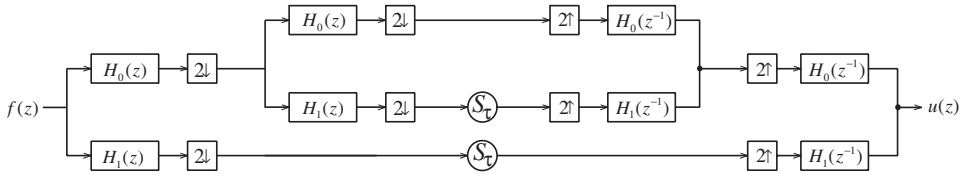

FIG. 3. *Two scales of Haar wavelet shrinkage with* $H_0(z) = \frac{1+z}{\sqrt{2}}$ *and* $H_1(z) = \frac{1-z}{\sqrt{2}}$.

of H_0-smoothed and downsampled versions of an initial signal f given by

$$f = f^{(0)} \longrightarrow f^{(1)} = Rf \longrightarrow \cdots \longrightarrow f^{(n)} = R^n f,$$

where R denotes the operator for H_0-smoothing and subsequent downsampling by 2, i.e.,

$$f_i^{(j+1)} = \big(Rf^{(j)}\big)_i = \big(f_{2i}^{(j)} + f_{2i+1}^{(j)}\big)/\sqrt{2} \qquad (j = 0, \ldots, n-1;\ i = 0, \ldots, N/2^{j+1} - 1).$$

Let $Pf^{(j)}$ denote the prolongated version of $f^{(j)}$ given by

$$\big(Pf^{(j)}\big)_{2i} = \big(Pf^{(j)}\big)_{2i+1} = f_i^{(j)}/\sqrt{2} \qquad (j = 1, \ldots, n;\ i = 0, \ldots, N/2^j - 1). \tag{5.1}$$

Then the corresponding Laplacian pyramid is the sequence

$$f - Pf^{(1)} \longrightarrow f^{(1)} - Pf^{(2)} \longrightarrow \cdots \longrightarrow f^{(n-1)} - Pf^{(n)} \longrightarrow f^{(n)}.$$

By

$$f^{(j)} = Pf^{(j+1)} + \big(f^{(j)} - Pf^{(j+1)}\big) \qquad (j = n-1, \ldots, 0)$$

we can reconstruct f from its Laplacian pyramid.

Let diff_t denote the operator of nonlinear diffusion with TV diffusivity and stopping time t applied to the successive two-pixel parts of a signal. By subsection 3.2 we know that diff_t performs like a single wavelet shrinkage step with soft threshold parameter $\tau = \sqrt{2}t$. In other words, the result of the filter bank in Figure 2 is $u = \mathrm{diff}_t(f)$. Further, we see that the upper branch of this filter bank produces $Pf^{(1)}$ so that the lower branch must produce $\mathrm{diff}_t(f) - Pf^{(1)}$. By (5.1) and (3.1) it is easy to check that the nonlinear operator diff_t fulfills $\mathrm{diff}_t(f) - Pf^{(1)} = \mathrm{diff}_t\big(f - Pf^{(1)}\big)$. Thus, one wavelet shrinkage step is given by $u = Pf^{(1)} + \mathrm{diff}_t\big(f - Pf^{(1)}\big)$. Now the multiscale Haar wavelet shrinkage up to scale n can be described by successive application of diff_t to the Laplacian pyramid:

$$u^{(n)} = f^{(n)}, \tag{5.2}$$

$$u^{(j)} = Pu^{(j+1)} + \mathrm{diff}_t\big(f^{(j)} - Pf^{(j+1)}\big) \qquad (j = n-1, \ldots, 0). \tag{5.3}$$

The result of the multiscale wavelet shrinkage is $u = u^{(0)}$.

5.2. Shift-invariant case. Now we consider translation-invariant multiscale wavelet shrinkage. In the multiscale setting we apply cycle spinning over the range of all N shifts of f. The filter bank which corresponds to two scales of translation-invariant Haar wavelet shrinkage is shown in Figure 4. Note that the inner filter bank uses z^2 instead of z in H_i $(i = 0, 1)$. In general we have to replace z by $z^{2^{j-1}}$ at

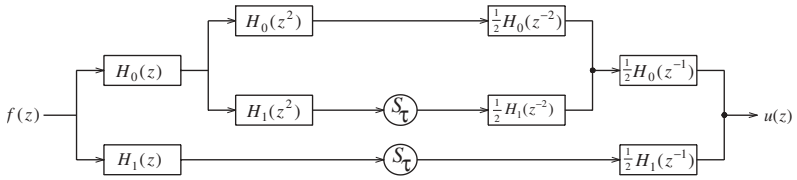

FIG. 4. *Two scales of shift-invariant Haar wavelet shrinkage with* $H_0(z) = \frac{1+z}{\sqrt{2}}$ *and* $H_1(z) = \frac{1-z}{\sqrt{2}}$.

scale j. While ordinary wavelet shrinkage requires $O(N)$ arithmetic operations, its translation-invariant version needs $O(N \log_2 N)$ arithmetic operations.

In subsection 4.2 we have deduced a numerical scheme for TV diffusion. Each iteration is given by (4.4). This coincides with a single translation-invariant Haar wavelet shrinkage step with threshold $\tau = 2\sqrt{2}t$. Using our operator diff. and the operator S, which shifts a signal one pixel to the right, the result u of the single-scale translation-invariant filter bank is given by

$$u = \frac{1}{2}\left(\mathrm{diff}_{2t}(f) + S^{-1}\mathrm{diff}_{2t}(Sf)\right).$$

Now the multiscale translation-invariant Haar wavelet shrinkage can be interpreted as application of diff. to a multiple Laplacian pyramid. We define a multiple Gaussian pyramid by

$$f^{(0,0)} \to \left(f^{(1,0)}, f^{(1,1)}\right) \to \left(f^{(2,0)}, f^{(2,1)}, f^{(2,2)}, f^{(2,3)}\right) \to \cdots \to \left(f^{(n,0)}, \ldots, f^{(n,2^n-1)}\right),$$

where $f = f^{(0,0)}$. Here $f^{(j,k)}$ is obtained by successive application of the operators R and RS on f as follows: Let 0 denote the application of R and 1 the application of RS; then these operators are applied to f in the order of the binary representation $(k_{j-1}, \ldots, k_0)_2$ of k, where we start from the left. For example, we get $f^{(2,1)} = f^{(2,(0,1)_2)} = RS\,Rf$ and $f^{(2,2)} = f^{(2,(1,0)_2)} = R\,RSf$. Then the multiple Laplacian pyramid is given by

$$\begin{aligned}&\left(f^{(0,0)} - Pf^{(1,0)}, Sf^{(0,0)} - Pf^{(1,1)}\right)\\ &\longrightarrow \left(f^{(1,0)} - Pf^{(2,0)}, Sf^{(1,0)} - Pf^{(2,1)}, f^{(1,1)} - Pf^{(2,2)}, Sf^{(1,1)} - Pf^{(2,3)}\right) \longrightarrow \cdots \longrightarrow\\ &\left(f^{(n,0)}, \ldots, f^{(n,2^n-1)}\right),\end{aligned}$$

and the translation-invariant version of (5.2)–(5.3) can be obtained from this multiple Laplacian pyramid by

$$\begin{aligned}u^{(n,k)} &= f^{(n,k)} \qquad (k = 0, \ldots, 2^n - 1),\\ u^{(j,k)} &= \frac{1}{2}\Big(Pu^{(j+1,2k)} + \mathrm{diff}_{2t}(f^{(j,k)} - Pf^{(j+1,2k)})\\ &\qquad + S^{-1}\left(Pu^{(j+1,2k+1)} + \mathrm{diff}_{2t}(Sf^{(j,k)} - Pf^{(j+1,2k+1)})\right)\Big)\end{aligned}$$

for $j = n-1, \ldots, 0$; $k = 0, \ldots, 2^j - 1$. The result is $u = u^{(0,0)}$.

5.3. Scale-dependent thresholds. Cycle spinning techniques can be used to make wavelet shrinkage not only translationally invariant, but they can also reduce artifacts. However, it is still possible that oscillatory (Gibbs-like) artifacts appear if

multiple scales are used. We want to demonstrate that the use of the scale-dependent thresholds

$$\tau_j = \tau/\sqrt{2}^{j-1} \qquad (j = 1, \dots, n) \tag{5.4}$$

suppresses oscillations in the shrinkage process.

In this subsection, we consider signals $f = (f_0, \dots, f_{N-1})$ with periodic boundary conditions. Note that mirror boundary conditions can easily be transferred into periodic ones by doubling the signal. The decimated Haar wavelet shrinkage with full n-scale decomposition and thresholds (5.4) consists of three operations. It starts with the linear transform (2.2) of f yielding the wavelet coefficients $(c^n, d^n, d^{n-1}, \dots, d^1)$, where $d^j := (d_0^j, \dots, d_{N/2^j-1}^j)$. The wavelet coefficients then undergo the soft wavelet thresholding $s_i^j := S_{\tau_j}(d_i^j)$ $(j = 1, \dots, n;\ i = 0, \dots, N/2^j - 1)$ followed by the inverse linear transform (2.3) of $(c^n, s^n, s^{n-1}, \dots, s^1)$ which gives the denoised signal $u(\tau)$. In particular we have $u(0) = f$. Note that by the semigroup property $S_{\tau+\tilde{\tau}}(x) = S_{\tilde{\tau}}\,(S_\tau(x))$ of our shrinkage function (2.1) the signal $u(K\tau)$ obtained by one n-scale wavelet shrinkage cycle with threshold $K\tau$ coincides with the signal which results from K times repeating one n-scale wavelet shrinkage cycle with smaller threshold τ. Of course, this is no longer true for the translation-invariant wavelet transform. In our examples in the next section we will consider iterated translation-invariant Haar wavelet shrinkage with small thresholds τ.

Since oscillatory (Gibbs-like) artifacts are characterized by the emergence of new local extrema, we study the behavior of local extrema of the signal under the shrinkage process. We call u_i an *extremal pixel* if either $u_{i-1} < u_i$, $u_i > u_{i+1}$ or $u_{i-1} > u_i$, $u_i < u_{i+1}$.

First, we consider the dynamics of "infinitesimal translation-invariant soft Haar wavelet shrinkage," i.e., the speed at which pixels of the signal evolve with respect to the threshold $\tau \in [0, T]$ in the limit case $T \to 0$.

PROPOSITION 5.1 (suppression of Gibbs-like artifacts by scaled thresholds). *Under infinitesimal translation-invariant soft Haar wavelet shrinkage, an extremal pixel f_i evolves as follows:*

(i) *The value of the extremal pixel decreases, i.e., $\dot{u}_i < 0$, if it is a maximum and increases, i.e., $\dot{u}_i > 0$, if it is a minimum. Here the dot denotes differentiation with respect to τ.*

(ii) *The absolute value of the difference of the extremal pixel to each of its two neighbors decreases; i.e., $\dot{u}_i - \dot{u}_{i\pm1} < 0$ for a maximum and $\dot{u}_i - \dot{u}_{i\pm1} > 0$ for a minimum.*

Statement (i) *holds also for the decimated Haar wavelet shrinkage, while statement* (ii) *cannot be established in that setting.*

Proof. For the decimated Haar wavelet shrinkage with full n-scale decomposition and thresholds (5.4) it is easy to check that the resulting signal $\tilde{u}_i$ is given by

$$\tilde{u}_i = \mu + \sum_{j=1}^{n} 2^{-j/2} \varepsilon_j(i) s^j_{\lfloor i/2^j \rfloor},$$

where $\lfloor x \rfloor$ denotes the largest integer $\le x$. Moreover, $\mu := \frac{1}{N} \sum_{i=0}^{N-1} f_i$ is the average value, and

$$\varepsilon_j(i) := \begin{cases} 1 & \text{if } \lfloor i/2^{j-1} \rfloor \text{ is even,} \\ -1 & \text{if } \lfloor i/2^{j-1} \rfloor \text{ is odd.} \end{cases}$$

For the translation-invariant Haar wavelet shrinkage, the sum on the right-hand side of this equation is replaced by the average of N sums of the same kind containing the back-shifted shrunken wavelet coefficients of N forward-shifted initial signals, i.e.,

$$u_i = \mu + \frac{1}{N}\sum_{\nu=0}^{N-1}\sum_{j=1}^{n} 2^{-j/2}\varepsilon_j(i+\nu)s^j_{\lfloor (i+\nu)/2^j\rfloor,\nu}, \tag{5.5}$$

where $s^j_{i,\nu}$ denotes the ith coefficient of the jth level of the ν-shifted initial signal, and the coefficients are treated $N/2^j$-periodic with respect to i. Of course, some coefficients coincide for different ν; more precisely,

$$s^j_{\lfloor (i+\nu)/2^j\rfloor,\nu} = s^j_{\lfloor (i+\nu+r2^j)/2^j\rfloor,\nu+r2^j} \qquad (\nu = 0,\dots,2^j-1; \quad r = 0,\dots,N/2^j-1).$$

This equation allows us to rewrite (5.5) as

$$\begin{aligned} u_i &= \mu + \frac{1}{2\sqrt{2}}\left(\varepsilon_1(i)s^1_{\lfloor i/2\rfloor,0} + \varepsilon_1(i+1)s^1_{\lfloor (i+1)/2\rfloor,1}\right) \\ &\quad + \frac{1}{N}\sum_{j=2}^{n} 2^{-j/2}\sum_{\nu=0}^{2^j-1}\sum_{r=0}^{N/2^j-1}\varepsilon_j(i+\nu+r2^j)s^j_{\lfloor (i+\nu+r2^j)/2^j\rfloor,\nu+r2^j} \\ &= \mu + \frac{s_{i,+}-s_{i,-}}{2\sqrt{2}} + \sum_{j=2}^{n} 2^{-3j/2}\sum_{\nu=0}^{2^j-1}\varepsilon_j(i+\nu)s^j_{\lfloor (i+\nu)/2^j\rfloor,\nu}, \end{aligned}$$

where $s_{i,+} := S_\tau(d_{i,+}) = S_\tau\big((f_i - f_{i+1})/\sqrt{2}\big)$ and $s_{i,-} := S_\tau(d_{i,-}) = S_\tau\big((f_{i-1} - f_i)/\sqrt{2}\big)$. Now the evolution of u_i under infinitesimal soft wavelet shrinkage is described by

$$\dot{u}_i = \frac{\dot{s}_{i,+}-\dot{s}_{i,-}}{2\sqrt{2}} + \sum_{j=2}^{n} 2^{-3j/2}\sum_{\nu=0}^{2^j-1}\varepsilon_j(i+\nu)\dot{s}^j_{\lfloor (i+\nu)/2^j\rfloor,\nu}, \tag{5.6}$$

where

$$\dot{s}^j_{\cdot} = \frac{\mathrm{d}S_{\tau_j}(d^j_{\cdot})}{\mathrm{d}\tau_j}\cdot\frac{\mathrm{d}\tau_j}{\mathrm{d}\tau} = \frac{-\operatorname{sgn}(d^j_{\cdot})}{\sqrt{2}^{j-1}}.$$

Inserting this into (5.6), we obtain

$$\dot{u}_i = \frac{-\operatorname{sgn}(d_{i,+}) + \operatorname{sgn}(d_{i,-})}{2\sqrt{2}} - A_i, \tag{5.7}$$

where

$$A_i := \sqrt{2}\sum_{j=2}^{n} 4^{-j}\sum_{\nu=0}^{2^j-1}\varepsilon_j(i+\nu)\operatorname{sgn}\left(d^j_{\lfloor (i+\nu))/2^j\rfloor,\nu}\right).$$

By the triangle inequality we can estimate

$$|A_i| \le \sqrt{2}\sum_{j=2}^{n} 2^{-j} < \frac{1}{\sqrt{2}}. \tag{5.8}$$

If f_i is an extremal pixel, then we have that $\operatorname{sgn}(d_{i,+}) = -\operatorname{sgn}(d_{i,-}) = 1$ for a maximum and -1 for a minimum. This implies by (5.7) and (5.8) that

$$\operatorname{sgn}(\dot{u}_i) = -\operatorname{sgn}(d_{i,+}), \tag{5.9}$$

proving statement (i) of the proposition.

By subtracting from (5.7) its counterpart for pixel u_{i+1}, we obtain by $d_{i,+} = d_{i+1,-}$ that

$$\dot{u}_i - \dot{u}_{i+1} = \frac{\operatorname{sgn}(d_{i,-}) - 2\operatorname{sgn}(d_{i,+}) + \operatorname{sgn}(d_{i+1,+})}{2\sqrt{2}} - (A_i - A_{i+1}). \tag{5.10}$$

In

$$\begin{aligned} &A_i - A_{i+1} \\ &= \sqrt{2}\sum_{j=2}^{n} 4^{-j} \sum_{\nu=0}^{2^j-1} \left(\varepsilon_j(i+\nu)\operatorname{sgn}\left(d^j_{\lfloor (i+\nu)/2^j \rfloor,\nu}\right) - \varepsilon_j(i+1+\nu)\operatorname{sgn}\left(d^j_{\lfloor (i+1+\nu)/2^j \rfloor,\nu}\right)\right) \end{aligned}$$

the values in the inner brackets cancel except for the two indices $\nu = \nu_k^j \in \{0,\dots,2^j - 1\}$ $(k = 0, 1)$ with $\nu_k^j + 1 + i \equiv 0 \bmod 2^{j-1}$. For these indices the signs of $\varepsilon_j(i + \nu_k)$ and $\varepsilon_j(i+1+\nu_k)$ are opposite. Consequently, for each j, the inner sum contains only four summands, and we can estimate

$$|A_i - A_{i+1}| \le \sqrt{2}\sum_{j=2}^{n} 4^{-j} \cdot 4 < \frac{\sqrt{2}}{3}. \tag{5.11}$$

By inserting this into (5.10), it becomes clear that for an extremal pixel f_i we get

$$\operatorname{sgn}(\dot{u}_i - \dot{u}_{i+1}) = -\operatorname{sgn}(d_{i,+}). \tag{5.12}$$

We have therefore proven that the difference of an extremal pixel to its right neighbor decreases under infinitesimal soft wavelet shrinkage. Analogous considerations apply to the left neighbor, which completes the proof of (ii). □

It follows particularly from Proposition 5.1 that under iterated infinitesimal soft wavelet shrinkage no oscillatory (Gibbs-like) artifacts can appear. Any artifact of this type would include at least one local extremum evolving from a flat region which would, for continuity, have to grow over a finite time interval in contradiction to Proposition 5.1.

It should be noted that a single step of infinitesimal shrinkage does not effectively change the signal any more since $T \to 0$. To investigate true changes of the signal by the shrinkage procedure, one has to consider iterated shrinkage. Summing up τ over all iteration steps, a "total evolution time" t is obtained; for fixed t, the number of iteration steps tends to infinity as τ goes to zero. Infinitesimal translation-invariant soft Haar wavelet shrinkage thus becomes a dynamic process parametrized by t, and Proposition 5.1 describes its behavior at a single point of time.

Of course, this analysis can be extended to a time interval. Then one has to take care of the discontinuity of sgn at 0. Similarly, as in the proof of Proposition 4.1, this can be done by splitting the time axis into intervals in which no sign changes of wavelet coefficients occur. However, since once-merged pixels can split again in the process considered here, sgn(0) will in most cases occur only in discrete time points.

Now we turn to consider finite-size shrinkage steps τ. The ideas used in the proof of Proposition 5.1 can also be applied to analyze soft wavelet shrinkage with finite threshold τ by simply replacing the derivatives $\dot{u}_i$, $\dot{s}^j_{i,\nu}$ by differences $\Delta u_i := u_i(\tau) - u_i(0)$ and $\Delta s^j_{i,\nu} := s^j_{i,\nu} - d^j_{i,\nu}$, respectively. Then we obtain instead of (5.7) that

$$\Delta u_i = \frac{(s_{i,+} - d_{i,+}) - (s_{i,-} - d_{i,-})}{2\sqrt{2}} + A_i,$$

where

$$A_i = \sum_{j=2}^{n} 2^{-3j/2} \sum_{\nu=0}^{2^j-1} \varepsilon_j(i+\nu) \Delta s^j_{\lfloor (i+\nu)/2^j \rfloor, \nu}.$$

By (5.4) and (2.1) we obtain instead of (5.8) the estimate

$$|A_i| \le \tau\sqrt{2} \sum_{j=2}^{n} 2^{-j} < \frac{\tau}{\sqrt{2}}.$$

However, the implication from inequality (5.8) to (5.9) can be transferred only if $|d_{i,+}| \ge \tau$ and $|d_{i,-}| \ge \tau$. Similarly, we conclude instead of (5.10) that

$$\Delta u_i - \Delta u_{i+1} = \frac{-\Delta s_{i,-} + 2\Delta s_{i,+} - \Delta s_{i+1,+}}{2\sqrt{2}} + (A_i - A_{i+1}) \tag{5.13}$$

and estimate the latter difference by

$$|A_i - A_{i+1}| \le \tau\sqrt{2} \sum_{j=2}^{n} 4^{-j}\, 4 < \frac{\tau\sqrt{2}}{3}. \tag{5.14}$$

However, the conclusion from (5.11) to (5.12) can be transferred only if $|\Delta s_{i,-} - 2\Delta s_{i,+} + \Delta s_{i+1,+}| \ge 4\tau/3$. The latter holds true if (but not only if) $|d_{i,+}| \ge \tau$ and $|d_{i,-}| \ge \tau$, i.e., if $f_i - f_{i\pm1} \ge \sqrt{2}\tau$. In this case we obtain by (5.13), (5.14), and their counterparts for the left neighbors of f_i that

$$-\frac{\tau\sqrt{2}}{3} \le u_i(\tau) - u_{i\pm1}(\tau) \le f_i - f_{i\pm1} - \frac{\tau\sqrt{2}}{6}$$

if f_i is a maximum. Analogous inequalities hold true if f_i is a minimum. We can therefore state the following corollary.

COROLLARY 5.2 (behavior of extrema under Haar wavelet shrinkage). *Under translation-invariant soft Haar wavelet shrinkage with thresholds* (5.4) *an extremal pixel f_i, which differs at least by $\sqrt{2}\tau$ from each of its neighbors, evolves as follows:*

(i) *The value of the extremal pixel decreases, i.e., $\Delta u_i < 0$, if it is a maximum and increases, i.e., $\Delta u_i > 0$, if it is a minimum.*

(ii) *The absolute value of the difference of the extremal pixel to each of its two neighbors decreases; in particular, one has $\Delta u_i - \Delta u_{i\pm1} < 0$ for a maximum and $\Delta u_i - \Delta u_{i\pm1} > 0$ for a minimum.*

It can be shown by examples that each of the statements (i) and (ii) of the corollary can be violated if the extremal pixel f_i differs from its neighbors by not more than $\sqrt{2}\tau$. In summary, it follows that Gibbs-like artifacts can in principle still occur under finite-size steps of soft Haar wavelet shrinkage but are restricted in amplitude.

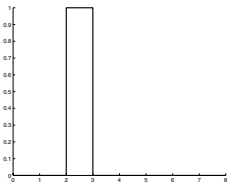

FIG. 5. *Test signal with $N = 8$ pixels.*

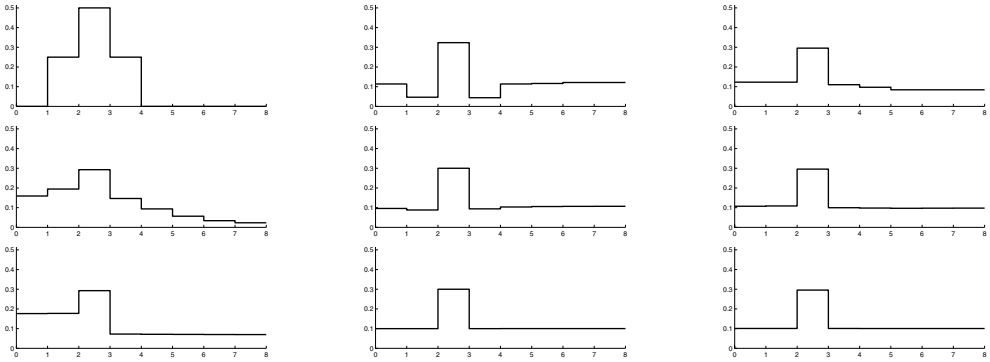

FIG. 6. *$K = 1, 20, 1000$ iterations (top to bottom) of translation-invariant soft Haar wavelet shrinkage with thresholds τ/K applied to the signal in Figure 5. Left column: single-scale wavelet shrinkage with $\tau = 1$. Center column: multiscale wavelet shrinkage ($m = 4$) with uniform threshold $\tau = 0.48$ on all scales. Right column: multiscale wavelet shrinkage ($m = 4$) with $\tau = 0.585$ and scale-adapted thresholds according to* (5.4).

6. Experiments. In this section we illustrate the interplay of iterations and multiscale soft Haar wavelet shrinkage by two examples. As in the previous section we consider initial signals $f = (f_0, \ldots, f_{N-1})$, where $N = 2^n$ is a power of 2. Furthermore, we restrict our attention to reflecting (Neumann) boundary conditions. Then we can perform multiscale wavelet shrinkage up to some assigned scale $m \leq n$.

We start with a simple example which demonstrates the influence of the interplay between iterations and multiscale wavelet shrinkage on Gibbs-like artifacts and its relation to TV diffusion. We consider the initial signal in Figure 5 and apply iterated translation-invariant single-scale and multiscale soft Haar wavelet shrinkage with various threshold parameters. The resulting signals are presented in Figure 6.

Consider the left column of Figure 6. In subsection 4.2 we have shown that translation-invariant soft Haar wavelet shrinkage corresponds to a stable numerical scheme for TV diffusion which represents real TV diffusion if the shrinkage parameter τ is small enough. The first row demonstrates the local effect of the single-scale wavelet shrinkage with threshold $\tau = 1$. The K-times iterated processes with thresholds $\tau = 1/K$ in the second and third rows spread the information globally over the signal. For $K = 1000$, the scheme is a very good approximation to TV diffusion.

The middle and the right columns of Figure 6 deal with multiscale wavelet shrinkage which does not fully correspond to TV diffusion. Already a single iteration results in global effects here. Iterating the multiplescale wavelet shrinkage flattens homogeneous regions, as desired also in TV diffusion. In the middle column, we can observe Gibbs-like phenomena. In the right column, they are avoided by scaling the thresholds.

In our second example we are concerned with the initial signal in Figure 7 ob-

tained using the *WaveLab* package [31]. Figure 8 presents the denoised signal, where the parameter of each method (threshold value or number of iterations) was chosen to optimize the signal-to-noise ratio on the output. We have applied the following techniques:

A. 1 level, regularized TV scheme (4.6) with $\epsilon = \frac{0.04}{2\sqrt{2}}$, iterated with $\tau = \frac{0.01}{2\sqrt{2}}$, $K = 53707$ iterations.

B. 1 level, two-pixel scheme (4.4), iterated with $\tau = 0.01$, $K = 53707$ iterations.

C. 13 levels, 1 iteration, uniform threshold $\tau = 37.4$.

D. 13 levels, iterated, $\tau = 0.01$, $K = 3244$ iterations.

E. 13 levels, 1 iteration, scaled thresholds, $\tau = 92.6$.

F. 13 levels, iterated, $\tau = 0.01$, $K = 7800$ iterations.

The best restoration results in terms of the signal-to-noise ratio are obtained using the regularized TV diffusion scheme (A, SNR=24.6dB), iterated single-scale wavelet shrinkage (B, SNR=24.5dB), or the iterated n-scale wavelet shrinkage with adapted thresholds (F, SNR=24.3dB). Although these methods are not exactly equivalent, they reveal a high level of visual similarity and provide a good piecewise constant approximation to the original signal. The single step multiscale wavelet shrinkage with scale-adapted threshold (E, SNR=21.9dB) performs slightly worse. The single step and iterated multiscale wavelet shrinkage techniques with a uniform threshold on all scales (C, SNR=18.3dB and D, SNR=21.3dB, respectively) are less satisfactory, also visually.

These experiments show that TV denoising outperforms many soft wavelet shrinkage strategies. On the other hand, this is at the expense of a relatively high numerical effort. In order to make wavelets competitive, the shrinkage should be shift invariant, iterative, and use multiple scales with scaled thresholds. In those cases where it is possible to reduce the number of iterations without severe quality degradations, one obtains a hybrid method that combines the speed of multiscale wavelet techniques with the quality of variational or PDE-based denoising methods. For more experiments on multiscale ideas versus iterations we refer the reader to [35].

7. Summary. The goal of the present paper was to investigate under which conditions one can prove equivalence between four discontinuity preserving denoising techniques in the 1-D case: soft wavelet thresholding, TV diffusion, TV regularization, and SIDEs. Starting from a simple two-pixel case we were able to derive analytical solutions. These two-pixel solutions have been used for the following purposes:

- They establish equivalence between soft Haar wavelet shrinkage with threshold parameter τ and TV diffusion of two-pixel signal pairs with diffusion time $t = \tau/\sqrt{2}$.
- They prove also equivalence to TV regularization of two-pixel pairs with regularization parameter $\alpha = \tau/\sqrt{2}$.
- They conjecture equivalence of space-discrete TV diffusion and discrete TV regularization for general N-pixel signals. This conjecture has been proven in subsection 4.3.
- They prove that space-discrete TV diffusion and discrete TV regularization are also equivalent to a SIDE evolution with a TV-based force function. This gives a sound theoretical justification for the heuristically introduced evolution rules for SIDEs.
- They design a novel numerical scheme for TV diffusion of N-pixel signals. It is based on an additive operator splitting into two-pixel interactions where analytical solutions exist for arbitrary large time step sizes. Thus, the numerical scheme is

explicit and absolutely stable.

We showed that wavelet shrinkage on multiple scales can also be regarded as two-pixel TV diffusion or regularization on the Laplacian pyramid of the signal. On the wavelet side, our experiments show that one can improve the denoising performance by rescaling the thresholds for each wavelet level and by iterating the translation-invariant wavelet shrinkage. On the PDE side, it is possible to achieve a speed-up without significant quality deterioration by using iterated multiple scales instead of iterated single-scale denoising. Thus, the resulting hybrid methods combine the advantages of wavelet and PDE-based denoising.

In our future work we intend to consider more advanced wavelet methods (other shrinkage functions, different wavelets) and to analyze the multidimensional case. In two dimensions, first results on diffusion-inspired wavelet shrinkage with improved rotation invariance are presented in [34]. We will also consider extensions of the numerical two-pixel schemes for TV diffusion.

Acknowledgment. Joachim Weickert thanks Stephen Keeling (Graz, Austria) for interesting discussions on two-pixel signals.

A FINITE ELEMENT TECHNIQUE FOR SOLVING FIRST-ORDER PDEs IN L^P*

J. L. GUERMOND†

Abstract. An approximation technique for solving first-order PDEs in $L^p(\Omega)$, $1 \leq p < +\infty$, is proposed. The method is a generalization of the least-squares method to non-Hilbertian settings. A priori and a posteriori error estimates are proven. Numerical tests in $L^1(\Omega)$ show that this type of technique can handle discontinuities without resorting to limiting procedures.

Key words. finite elements, least-squares, first-order PDEs, nonsmooth optimization

1. Introduction.

Given a linear, first-order PDE in a domain $\Omega \subset \mathbb{R}^d$,

$$Lu = f, \tag{1.1}$$

with suitable boundary conditions, the objective of this paper is to present an approximation technique that can handle right-hand sides in $L^1(\Omega)$ and, more generally, right-hand sides in $L^p(\Omega)$, $1 \leq p < +\infty$.

1.1. Introductory comments.

The number of attempts at approximating (1.1) directly in $L^1(\Omega)$ seem to be extremely few (see the series of papers by Lavery [29, 30, 28] and the iteratively reweighted least-squares method of Jiang [23] and [24, Chap. 9]) or seem to have encountered some theoretical difficulties (see [32]). This is in sharp contrast with the fact that an enormous amount of work has been dedicated to the study of first-order PDEs and their various nonlinear generalizations in $L^1(\Omega)$. The main difficulty is that when expressed directly in $L^1(\Omega)$ the discrete problems consist in minimizing nondifferentiable functionals; see, e.g., [23]. The lack of theory and of practical popular algorithms for minimizing this type of functional is responsible for the general preference of authors to seek an approximate solution in the $L^2(\Omega)$ framework where differentiability rules, and the force of habit has made this point of view an undisputed paradigm. The goal of the present work is to show that, as claimed in Jiang [23], when the right-hand side is really so rough as to not be in $L^2(\Omega)$ but in $L^1(\Omega)$ only or when the coefficients of the differential operator are so rough that the solution is only meaningful in $L^1(\Omega)$, then it really pays off to approximate the solution to (1.1) directly in $L^1(\Omega)$. In this case, the discontinuities of the solution are captured as sharply as the grid permits without resorting to adaptive refinement, and numerical tests reveal that the method is not plagued by spurious over- or undershootings. Contrary to standard stabilized $L^2(\Omega)$-based techniques, the direct $L^1(\Omega)$ approximation does not require additional ad hoc tunable coefficients or limiting procedures (see, e.g., Galerkin least-squares techniques [16, 25, 26], discontinuous

Galerkin methods [31, 17], bubble stabilization [13, 3, 14], or subgrid stabilization [20, 21, 15]).

The paper is organized as follows. In section 2, we introduce an abstract problem, together with its discrete counterpart, and we give an abstract convergence result. We reformulate this result in the $L^p(\Omega)$ setting in section 3, and we describe an algorithm for computing the approximate solution in this setting. We illustrate numerically the method in section 4, where we solve transport equations and advection-diffusion equations in mixed form in $L^1(\Omega)$. We record conclusions in section 5.

1.2. Notation. Let Ω be an open, bounded, connected Lipschitz domain in $\mathbb{R}^d$. We denote by $|\Omega|$ the measure of Ω. For every Lebesgue measurable function $v : \Omega \longrightarrow \mathbb{R}^m$, $m \geq 1$, we denote by $v \cdot w$ the Euclidean scalar product in $\mathbb{R}^m$. For $1 \leq p < +\infty$, we denote by $\|v\|_{\ell^p}$ the discrete ℓ^p-norm of v, i.e., $\|v\|_{\ell^p} = (\sum_{1\leq i\leq m} v_i^p)^{\frac{1}{p}}$. As usual, we denote by $L^p(\Omega)^m$ the real Banach space of $\mathbb{R}^m$-valued functions whose pth power is Lebesgue integrable, i.e., $\|v\|_{L^p(\Omega)^m} = (\int_\Omega \|v(x)\|_{\ell^p}^p dx)^{\frac{1}{p}}$. $W^{1,p}(\Omega)$ is the space of functions in $L^p(\Omega)$ whose partial derivatives in the distributional sense can be identified with functions in $L^p(\Omega)$. $L^\infty(\Omega)$ is the real Banach space of essentially bounded functions. Hereafter we identify the dual of $L^1(\Omega)$ with $L^\infty(\Omega)$.

Considering two real numbers A, B, we shall use the expression $A \lesssim B$ to say that there exists a generic positive constant c, independent of the discretization parameters, such that (s.t.) $A \leq cB$.

2. An abstract problem.

2.1. The continuous setting. Let E and F be two Banach spaces with norms $\|\cdot\|_E$ and $\|\cdot\|_F$, respectively. Let $L : E \longrightarrow F$ be a bounded linear operator, i.e., $L \in \mathcal{L}(E;F)$. We denote by $L^* : F' \longrightarrow E'$ its adjoint, where E' and F' are the duals of E and F, respectively. We assume also that L is bijective. Let us recall the following important consequence of Banach's closed range theorem and open mapping theorem (see, e.g., [12, p. 29] or [36, p. 205]).

LEMMA 2.1. *An operator $L \in \mathcal{L}(E;F)$ is bijective if and only if there is a constant $\alpha > 0$ s.t.*

$$\forall u \in E, \quad \alpha\|u\|_E \leq \|Lu\|_F, \tag{2.1}$$

$$\forall f' \in F', \quad (L^* f' = 0) \Rightarrow (f' = 0). \tag{2.2}$$

We want to solve the following problem: For $f \in F$,

$$\begin{cases} \text{find } u \in E \text{ s.t.} \\ Lu = f \quad \text{in } F. \end{cases} \tag{2.3}$$

This problem is well-posed, and (2.1) yields the following stability property:

$$\|u\|_E \leq \frac{1}{\alpha}\|f\|_F.$$

Let us now introduce an alternative formulation of problem (2.3). Let us define the functional $J : E \longrightarrow \mathbb{R}$ s.t. $J(v) = \|Lv - f\|_F$, and consider the following problem:

$$\begin{cases} \text{Find } u \in E \text{ s.t.} \\ J(u) \leq J(v) \quad \forall v \in E. \end{cases} \tag{2.4}$$

It is clear that problems (2.4) and (2.3) are equivalent in the sense that they have the same unique solution.

To gain more insight on the nature of problem (2.4), let us consider the case where F is a Hilbert space.

PROPOSITION 2.1. *If F is a Hilbert space (equipped with the scalar product $(v,w)_F = \frac{1}{2}(\|v+w\|_F^2 - \|v\|_F^2 - \|w\|_F^2)$), the solution to* (2.4) *is also the unique solution to the following problem:*

$$\begin{cases} \text{Find } u \in E \text{ s.t.} \\ (Lu, Lv)_F = (f, Lv)_F \quad \forall v \in E. \end{cases} \tag{2.5}$$

Proof. J and J^2 have the same minimum, J^2 is clearly differentiable, and (2.5) is the first-order condition for optimality. Owing to (2.1), the bilinear form $(Lu, Lv)_F$ is continuous and coercive, and $(f, Lv)_F$ is continuous; hence, existence and uniqueness of the solution are easy consequences of the Lax–Milgram theorem. ∎

Actually, (2.5) is the so-called least-squares formulation of (2.3), and it can also be interpreted as the Galerkin formulation of the problem

$$L^*Lu = L^*f.$$

Hence, (2.4) is a simple generalization of the least-squares method to non-Hilbertian settings.

2.2. The discrete setting. We now look for an approximate solution to (2.4). Let $(E_h)_{h>0}$ be a sequence of finite-dimensional spaces s.t. $E_h \subset E$. We assume that the sequence of spaces $(E_h)_{h>0}$ has some interpolation properties; that is, we assume that there is a dense normed subspace $W \subset E$ and a function $\epsilon(h)$, continuous at zero with $\epsilon(0) = 0$, s.t.

$$\forall v \in W, \quad \inf_{v_h \in E_h} \|v - v_h\|_E \lesssim \epsilon(h)\|v\|_W. \tag{2.6}$$

The discrete counterpart to (2.4) is as follows:

$$\begin{cases} \text{Find } u_h \in E_h \text{ s.t.} \\ J(u_h) = \min\limits_{v_h \in E_h} J(v_h). \end{cases} \tag{2.7}$$

The main result of this paper is stated in the following theorem.

THEOREM 2.1. (i) *Problem* (2.7) *has at least one global minimizer.*

(ii) *There are no local minimizers.*

(iii) *All minimizers satisfy the following stability property:*

$$\|u_h\|_E \lesssim \|f\|_F. \tag{2.8}$$

(iv) *All minimizers satisfy the a priori error bound*

$$\|u - u_h\|_E \lesssim \min_{v_h \in E_h} \|u - v_h\|_E, \tag{2.9}$$

and the following a posteriori error estimate holds:

$$\|u - u_h\|_E \lesssim \|f - Lu_h\|_F. \tag{2.10}$$

Proof. (i) Let $K_h \subset E_h$ be the ball of radius $\frac{2}{\alpha}\|f\|_F$ centered at 0. It is clear that

$$\inf_{v_h \in E_h} J((v_h) = \min\left(\inf_{v_h \in E_h \setminus K_h} J(v_h), \inf_{v_h \in K_h} J(v_h)\right).$$

But for all $v_h \in E_h \setminus K_h$ (i.e., $\|v_h\|_E > \frac{2}{\alpha}\|f\|_F$) we have

$$\begin{aligned} J(v_h) &\geq \|Lv_h\|_F - \|f\|_F \\ &\geq \alpha\|v_h\|_E - \|f\|_F \\ &> \|f\|_F \\ &> J(0), \end{aligned}$$

where we have used the stability condition (2.1). Since $0 \in K_h$, we infer that

$$\inf_{v_h \in E_h \setminus K_h} J(v_h) > J(0) \geq \inf_{v_h \in K_h} J(v_h).$$

That is to say,

$$\inf_{v_h \in E_h} J(v_h) = \inf_{v_h \in K_h} J(v_h).$$

As a result, the existence of a global minimizer is a simple consequence of the fact that J is continuous and K_h is compact (since E_h is finite-dimensional).

(ii) The functional $J(v_h) = \|Lu_h - f\|_F$ is obviously convex; hence, local minimizers of (2.7) are necessarily global.

(iii) From (i) we infer that any minimizer u_h is in K_h; hence, $\|u_h\|_E \lesssim \|f\|_F$.

(iv) The stability condition (2.1) yields

$$\begin{aligned} \alpha\|u - u_h\|_E &\leq \|Lu - Lu_h\|_F \\ &= \|f - Lu_h\|_F \\ &= \min_{v_h \in E_h} \|f - Lv_h\|_F \\ &= \min_{v_h \in E_h} \|Lu - Lv_h\|_F \\ &\leq \|L\|_{\mathcal{L}(E;F)} \min_{v_h \in E_h} \|u - v_h\|_E. \end{aligned}$$

The proof is complete. ∎

Remark 2.1. Note that the question of the uniqueness of u_h is open. Actually, it may happen that u_h is not unique. To gain some insight on this problem, let us consider $D = \{(x_1, x_2) \in \mathbb{R}^2 \,|\, x_1 + x_2 \geq 1\}$, $x_0 = (0, 0)$, and let us define S to be the set of points in D that minimize the ℓ^1-distance to x_0. A simple calculation shows $S = \{(x_1, x_2) \in \mathbb{R}^2 \,|\, x_1 + x_2 = 1,\, x_1 \geq 0,\, x_2 \geq 0\}$; that is, even though the functional and D are convex, the solution to this minimization problem is not unique. Of course, uniqueness would have been guaranteed if we had considered the Euclidean (Hilbertian) distance.

Now, using a standard density argument, we deduce the following corollary.

COROLLARY 2.1. *Under the hypotheses of Theorem* 2.1 *and* (2.6) *we have*

$$\lim_{h \to 0} \|u - u_h\|_E = 0, \tag{2.11}$$

and if $u \in W$*, the following a priori error estimate holds:*

$$\|u - u_h\|_E \lesssim \epsilon(h)\|u\|_W. \tag{2.12}$$

Remark 2.2.

(i) Note that the a priori error estimate (2.12) is optimal since it is bounded by the interpolation error up to a constant.

(ii) Note that the price paid for the approximation optimality when $F = L^1(\Omega)$ is the loss of differentiability. More precisely, the functional $J(v_h) = \|Lu_h - f\|_{L^1(\Omega)}$ is not differentiable; hence, no first-order optimality condition can be written. To better appreciate the difficulty we face here, think of the following two functionals: $\phi(x) = x^2$ and $\psi(x) = |x|$. It is clear that the minimum of ϕ is reached at x_0 when $\phi'(x_0) = 2x_0 = 0$, whereas no nice first-order optimality condition can be written for ψ except for the awkward statement that 0 is in the subdifferential of $\psi(x_0)$, i.e., $0 \in \partial\psi(x_0)$. We describe an algorithm in section 3.6 to solve this difficulty. ∎

3. The $L^p(\Omega)$ setting. We show in this section how the above abstract result can be reformulated in the $L^p(\Omega)$ setting for first-order PDEs.

3.1. Formulation of the problem. In the context of first-order PDEs, F is usually a space $L^p(\Omega)^m$, $1 \le p < \infty$ (or possibly a closed subspace of $L^p(\Omega)^m$), and E is the domain of an unbounded linear operator

$$L : D(L) = E \subset L^p(\Omega)^m \longrightarrow L^p(\Omega)^m = F$$

whose graph is closed in $L^p(\Omega)^m \times L^p(\Omega)^m$ and whose domain $D(L)$ is dense in $L^p(\Omega)^m$ so that when the vector space $E = D(L)$ is equipped with the graph norm $\|v\|_E = (\|v\|^p_{L^p(\Omega)^m} + \|Lv\|^p_{L^p(\Omega)^m})^{\frac{1}{p}}$ it becomes a Banach space.

In this setting, the abstract problem (2.3) is interpreted as follows: For $f \in L^p(\Omega)^m$,

$$\begin{cases} \text{find } u \in E \text{ s.t.} \\ Lu = f \quad \text{ in } L^p(\Omega)^m. \end{cases} \tag{3.1}$$

Owing to the Riesz representation theorem, which permits us to identify the dual of $L^p(\Omega)^m$ with $L^{p'}(\Omega)^m$, where $\frac{1}{p} + \frac{1}{p'} = 1$, this problem can be alternatively put into the following form:

$$\begin{cases} \text{Find } u \in E \text{ s.t.} \\ \displaystyle\int_\Omega \phi \cdot Lu = \int_\Omega f \cdot \phi \quad \forall \phi \in L^{p'}(\Omega)^m. \end{cases} \tag{3.2}$$

3.1.1. Example 1: Advection-reaction. Let us consider an advection-reaction problem. Let $\boldsymbol{\beta}$ be a smooth vector field in $\mathbb{R}^d$, say $\boldsymbol{\beta} \in L^\infty(\Omega)^d$ and $\nabla\cdot\boldsymbol{\beta} \in L^\infty(\Omega)$, and set

$$\partial\Omega^- = \{x \in \partial\Omega \mid \boldsymbol{\beta}(x) \cdot \mathbf{n}(\mathbf{x}) < \mathbf{0}\},$$
$$\partial\Omega^+ = \{x \in \partial\Omega \mid \boldsymbol{\beta}(x) \cdot \mathbf{n}(\mathbf{x}) > \mathbf{0}\}.$$

$\partial\Omega^-$ is the inflow boundary, $\partial\Omega^+$ is the outflow boundary, and $\mathbf{n}(\mathbf{x})$ is the unit exterior normal to $\partial\Omega$ at $x \in \partial\Omega$. It may happen that these two subsets of $\partial\Omega$ are empty if $\boldsymbol{\beta}$ is s.t. $\boldsymbol{\beta} \cdot \mathbf{n}(\mathbf{x}) = \mathbf{0}$ for all $x \in \partial\Omega$. Let μ be a function in $L^\infty(\Omega)$, and assume that there is a constant $\mu_0 > 0$ so that

$$\mu(x) \ge \mu_0 > 0 \quad \text{a.e. } x \text{ in } \Omega. \tag{3.3}$$

We introduce the differential operator

$$L(u) = \mu u + \nabla\cdot(u\boldsymbol{\beta}),$$

with domain

$$E = D(L) = \{w \in L^1(\Omega);\ \nabla\cdot(w\boldsymbol{\beta}) \in L^1(\Omega);\ \boldsymbol{\beta}\cdot\mathbf{n}|_{\partial\Omega^-} = 0\} \subset L^1(\Omega) = F.$$

It can be shown that L is an isomorphism from E to F; i.e., (2.1) and (2.2) hold.

Remark 3.1. If $\mu = 0$, the hypothesis (3.3) is not satisfied. Nevertheless, L is still an isomorphism if $\boldsymbol{\beta}$ is a smooth filling field, i.e., if for almost every x in Ω there is a characteristic of $\boldsymbol{\beta}$ that starts from x and reaches $\partial\Omega^-$ in finite time. The reader is referred to Azerad and Pousin [1] for other details on this problem.

3.1.2. Example 2: The Darcy equation. Let Ω be a porous medium characterized by the permeability tensor $\mathbf{K}(\mathbf{x})$. This tensor is assumed to be symmetric positive definite, and its smallest and largest eigenvalues are assumed to be bounded from below and from above uniformly in Ω. We consider the following problem:

$$\begin{cases} \mathbf{K^{-1}}\cdot\mathbf{u} + \nabla\mathbf{p} = \mathbf{f}, \\ \nabla\cdot\mathbf{u} + \alpha\mathbf{p} = \mathbf{g}, \\ p_{|\partial\Omega} = 0. \end{cases} \tag{3.4}$$

This problem is known as the Darcy problem. It is also the mixed form of the Poisson problem. Nonlinear versions of (3.4) play important roles in underground storage problems, hydrogeology, and the petroleum industry. It is very often coupled with a transport equation for the concentration of a chemical species or a phase fraction.

To formulate (3.4) in the $L^p(\Omega)$ setting, we introduce some definitions:

$$\begin{aligned} X &= \{\mathbf{v} \in \mathbf{L^p(\Omega)^d};\ \nabla\cdot\mathbf{v} \in \mathbf{L^p(\Omega)}\}, \\ \|\mathbf{v}\|_{\mathbf{X}} &= (\|\mathbf{v}\|^{\mathbf{p}}_{\mathbf{L^p(\Omega)^d}} + \|\nabla\cdot\mathbf{v}\|^{\mathbf{p}}_{\mathbf{L^p(\Omega)}})^{\frac{1}{\mathbf{p}}}, \\ Y &= \{q \in L^p(\Omega);\ \nabla q \in L^p(\Omega)^d,\ q_{|\partial\Omega} = 0\}, \\ \|q\|_Y &= \|q\|_{W^{1,p}(\Omega)} = (\|q\|^p_{L^p(\Omega)} + \|\nabla q\|^p_{L^p(\Omega)^d})^{\frac{1}{p}}. \end{aligned}$$

X and Y are Banach spaces. We set $E = X \times Y$ and $F = L^p(\Omega)^d \times L^p(\Omega)$, which we equip with the norms $\|(\mathbf{v},\mathbf{q})\|_{\mathbf{E}} = (\|\mathbf{v}\|^{\mathbf{p}}_{\mathbf{X}} + \|\mathbf{q}\|^{\mathbf{p}}_{\mathbf{Y}})^{\frac{1}{\mathbf{p}}}$ and $\|(\mathbf{v},\mathbf{q})\|_{\mathbf{F}} = (\|\mathbf{v}\|^{\mathbf{p}}_{\mathbf{L^p(\Omega)^d}} + \|\mathbf{q}\|^{\mathbf{p}}_{\mathbf{L^p(\Omega)}})^{\frac{1}{\mathbf{p}}}$, respectively. We now define the operator

$$\begin{aligned} &L : E \longrightarrow F, \\ &(\mathbf{v},\mathbf{q}) \longmapsto (\mathbf{K^{-1}}\mathbf{v} + \nabla\mathbf{q}, \nabla\cdot\mathbf{v} + \alpha\mathbf{q}). \end{aligned}$$

L is clearly continuous, and it can be shown that it is an isomorphism if $\alpha \geq 0$, for $1 < p < +\infty$, and if $\alpha > 0$ for $p = 1$ (see, e.g., [6, 11, 34]).

3.2. Friedrichs's systems. The above two examples are particular cases of Friedrichs's symmetric systems; see [19]. Most of what is said hereafter generalizes to this broad class of PDEs.

3.3. The discrete setting. Henceforth, we assume that F is a closed subspace of $L^p(\Omega)^m$. We assume also that we are given a sequence of regular finite element meshes $(\mathcal{T}_h)_{h>0}$ covering the domain Ω. With each mesh we associate a finite-dimensional space $E_h \subset E$ having some interpolation properties; that is, there is a dense normed subspace of smooth functions $W \subset E$ and a continuous function $\epsilon(h)$ with $\epsilon(0) = 0$ s.t. (2.6) holds. For $\mathbb{P}_k$ or $\mathbb{Q}_k$ Lagrange finite elements, we have $\epsilon(h) = h^k$, where h is the meshsize.

3.4. A brief review of some standard techniques. One of the standard ways of approximating (3.2) without invoking a minimization principle like (2.7) is the Galerkin technique. This method consists in replacing the solution space, E, and the test space, $L^{p'}(\Omega)^m$, by the same discrete space E_h as follows:

$$\begin{cases} \text{Find } u_h \in E_h \text{ s.t.} \\ \displaystyle\int_\Omega \phi_h \cdot Lu_h = \int_\Omega \phi_h \cdot f \quad \forall \phi_h \in E_h. \end{cases} \tag{3.5}$$

Note that using the same space for testing the equation and approximating the solution guarantees that the corresponding linear system has as many equations as unknowns. Even though it often happens that the discrete solution is unique, (3.5) does not yield stability in the E-norm in general. To better appreciate this point, let us consider the scalar problem $u' = f$ with $u(0) = 0$ in the one-dimensional (1D) domain $\Omega =]0,1[$, where we assume $f \in L^2(\Omega)$. For $N \in \mathbb{N}^\star$, let us set $h = 1/N$ and $x_i = ih$ for $i \in \{0, 1, \ldots, N\}$. We define

$$E_h = \{v_h \in \mathcal{C}^0(\overline{\Omega});\ v_{h|[x_i,x_{i+1}]} \in \mathbb{P}_1,\ 0 \le i \le N-1;\ v_h(0) = 0\}. \tag{3.6}$$

It is clear that $E_h \subset E = \{v \in H^1(\Omega);\ v(0) = 0\}$. The discrete Galerkin formulation of the problem is as follows:

$$\begin{cases} \text{Find } u_h \text{ in } E_h \text{ s.t.} \\ \displaystyle\int_0^1 v_h u_h' = \int_0^1 v_h f \qquad \forall v_h \in E_h, \end{cases} \tag{3.7}$$

and its stability constant (i.e., the counterpart of α in (2.1)) is

$$\alpha_h := \inf_{u_h \in E_h} \sup_{v_h \in E_h} \frac{\int_0^1 u_h' v_h}{\|u_h\|_{H^1(\Omega)} \|v_h\|_{L^2(\Omega)}}.$$

The following negative result can be proved.

THEOREM 3.1. *There are two constants $c_1 > 0$ and $c_2 > 0$, independent of h, s.t.*

$$c_1 h \le \alpha_h \le c_2 h.$$

Proof. See, e.g., Ern and Guermond [18, pp. 197–199]. ∎

In other words, the stability constant for the approximate problem (3.7) goes to zero as the mesh is refined. This result is the main reason for the failure of the Galerkin technique to work properly for first-order PDEs in general.

An interesting alternative to the Galerkin formulation consists in the least-squares formulation. The origins of the least-squares technique can be traced back to Gauss (*Theoria Motus Corporum Coelestium* (1809)). As early papers in the numerical analysis literature we cite the series of papers by Bramble and Schatz [9, 10] published in 1970. Since then, it has been applied to a wide variety of problems (see, e.g., [2, 33, 24]). This method is clearly optimal in the $L^2(\Omega)$-graph norm, but it performs poorly when the source term is not in $L^2(\Omega)$ but in $L^1(\Omega)$ only or the boundary data are discontinuous (see the numerical tests in section 4).

The list of alternative techniques for solving (3.2) is quite long, and it is out of the question to make this list exhaustive, but among the most popular ones is the so-called Galerkin least-squares method [16, 25], which combines the accuracy of the Galerkin

method and the stability properties of the least-squares method. Other methods of interest are those based on discontinuous interpolation spaces (e.g., discontinuous Galerkin methods [31, 17]), on bubble functions (e.g., residual free bubble methods [13, 3, 14]), or on a hierarchical decomposition of the approximation space (e.g., subgrid stabilization [20, 21, 15] or spectral viscosity [35]). Although all these methods are quite efficient in general, they cannot cope with discontinuities and boundary layers without resorting to shock-capturing and nonlinear limiting techniques [26, 22] since they are all L^2-based; i.e., they rely on a priori L^2 estimates.

3.5. The discrete problem and regularization. Upon setting $J(v) = \|Lv - f\|_{L^p(\Omega)^m}$, the minimization problem we would like to solve is to find u_h in E_h such that $J(u_h) = \min_{v_h \in E_h} J(v_h)$. Actually, since $\mathbb{R}^+ \ni x \longmapsto x^p$ is an increasing function, an equivalent reformulation consists of setting

$$\mathcal{J}(v) = \|Lv - f\|^p_{L^p(\Omega)^m}$$

and considering the following problem:

$$\begin{cases} \text{Find } u_h \in E_h \text{ s.t.} \\ \mathcal{J}(u_h) = \min\limits_{v_h \in E_h} \mathcal{J}(v_h). \end{cases} \tag{3.8}$$

To handle this possibly nondifferentiable minimization problem by means of standard gradient techniques, we propose to regularize it as follows. Let us define $\varepsilon > 0$ and introduce

$$\varphi_\varepsilon(r) = r^2(r+\varepsilon)^{p-2}. \tag{3.9}$$

Then we regularize $\mathbb{R}^m \ni x \longmapsto \|x\|^p_{\ell^p}$ by replacing this function by

$$\psi_\varepsilon(x) = \sum_{i=1}^m \varphi_\varepsilon(|x_i|). \tag{3.10}$$

Upon denoting by $\mathrm{sg}(t)$ the sign function (i.e., $\mathrm{sg}(t) = t/|t|$ if $t \neq 0$ and $\mathrm{sg}(0) = 0$), we have

$$\forall v \in \mathbb{R}^m, \quad D\psi_\varepsilon(x) \cdot v = \sum_{i=1}^m \varphi'_\varepsilon(|x_i|)\mathrm{sg}(x_i)v_i, \tag{3.11}$$

$$\forall v, w \in \mathbb{R}^m, \quad w \cdot D^2\psi_\varepsilon(x) \cdot v = \sum_{i=1}^m \varphi''_\varepsilon(|x_i|)v_i w_i. \tag{3.12}$$

Note that φ''_ε is a decreasing function on $\mathbb{R}^+$ if $1 \le p \le 2$, and it is an increasing function if $p \ge 2$. More precisely, we have the following:

$$\text{if } 1 \le p \le 2, \quad \exists c > 0 \ \forall a > 0, \ \forall r \in [0,a], \quad c\,a^{p-2} \le \varphi''_\varepsilon(r) \le 2\,\varepsilon^{p-2}, \tag{3.13}$$

$$\text{if } 2 \le p, \quad \exists c > 0 \ \forall a > 0, \ \forall r \in [0,a], \quad 2\,\varepsilon^{p-2} \le \varphi''_\varepsilon(r) \le c\,a^{p-2}. \tag{3.14}$$

This, in turn, implies the following property:

$$\text{if } 1 \le p \le 2 \quad \begin{cases} \forall y \in \mathbb{R}^m, & c\,\|y\|^{p-2}_{\ell^\infty}\,\|y\|^2_{\ell^2} \le y \cdot D^2\psi_\varepsilon(x) \cdot y, \\ \forall y, z \in \mathbb{R}^m, & |z \cdot D^2\psi_\varepsilon(x) \cdot y| \le 2\,\varepsilon^{p-2}\,\|z\|_{\ell^2}\|y\|_{\ell^2}, \end{cases} \tag{3.15}$$

and an obvious similar property holds if $p \ge 2$.

Now we introduce the regularized functional

$$\mathcal{J}_\varepsilon(v_h) = \int_\Omega \psi_\varepsilon(Lu_h - f), \tag{3.16}$$

and we define u_h^ε to be a solution to the following minimization problem:

$$\begin{cases} \text{Find } u_h^\varepsilon \in E_h \text{ s.t.} \\ \mathcal{J}_\varepsilon(u_h^\varepsilon) = \min\limits_{v_h \in E_h} \mathcal{J}_\varepsilon(v_h). \end{cases} \tag{3.17}$$

It is clear that, owing to the regularization, $\mathcal{J}_\varepsilon$ is differentiable (in the Fréchet sense), and the first-order optimality condition for (3.17) is

$$\int_\Omega D\psi_\varepsilon(Lu_h^\varepsilon - f) \cdot Lv_h = 0 \quad \forall v_h \in E_h.$$

The algorithm that we propose in the next section consists in obtaining a solution to (3.8) as a limit of a sequence $(u_h^\varepsilon)_{\varepsilon>0}$ as $\varepsilon \to 0$.

Now we give a series of lemmas clarifying the stability of u_h^ε with respect to the data, the uniqueness of u_h^ε, the convergence of the sequence $(u_h^\varepsilon)_{\varepsilon>0}$ as $\varepsilon \to 0$, and, finally, the convergence of the sequence $(u_h^\varepsilon)_{\varepsilon>0,h>0}$ as both ε and h go to zero.

LEMMA 3.1. *Solutions to* (3.17) *satisfy the following stability estimate:*

$$\alpha \|u_h^\varepsilon\|_E \le \|f\|_{L^p(\Omega)^m} + (m\,\varepsilon^p|\Omega| + 2\|\psi_\varepsilon(f)\|_{L^1(\Omega)})^{\frac{1}{p}}.$$

Proof. Owing to the definition of φ_ε, it is clear that for all $g \in L^p(\Omega)^m$,

$$1 \le i \le m, \qquad \frac{1}{2}\int_{\{|g_i|\ge\varepsilon\}} |g_i|^p \le \int_\Omega \varphi_\varepsilon(|g_i|).$$

As a result,

$$\int_\Omega |g_i|^p = \int_{\{|g_i|<\varepsilon\}} |g_i|^p + \int_{\{|g_i|\ge\varepsilon\}} |g_i|^p \le \varepsilon^p|\Omega| + 2\int_\Omega \varphi_\varepsilon(|g_i|)$$

and

$$\int_\Omega \|g\|_{\ell^p}^p \le m\,\varepsilon^p|\Omega| + 2\int_\Omega \psi_\varepsilon(g).$$

Hence,

$$\int_\Omega \|Lu_h^\varepsilon - f\|_{\ell^p}^p \le m\,\varepsilon^p|\Omega| + 2\int_\Omega \psi_\varepsilon(Lu_h^\varepsilon - f) \le m\,\varepsilon^p|\Omega| + 2\int_\Omega \psi_\varepsilon(f).$$

The triangle inequality, together with (2.1), yields the result. ∎

LEMMA 3.2. *If $f \in L^\infty(\Omega)^m$, there is a unique function u_h^ε minimizing $\mathcal{J}_\varepsilon$.*

Proof. Let u_h^1 and u_h^2 be two functions in E_h. We have

$$\begin{aligned} D\mathcal{J}_\varepsilon(u_h^1)(v_h) - D\mathcal{J}_\varepsilon(u_h^2)(v_h) &= \int_\Omega [D\psi_\varepsilon(Lu_h^1 - f) - D\psi_\varepsilon(Lu_h^2 - f)] \cdot Lv_h \\ &= \int_\Omega L(u_h^1 - u_h^2) \cdot \int_0^1 D^2\psi_\varepsilon(R(s))ds \cdot Lv_h, \end{aligned}$$

where $R(s) = L(su_h^1 + (1-s)u_h^2) - f$. Now using $v_h = u_h^1 - u_h^2$ as a test function and making use of (3.15), we infer that

$$(D\mathcal{J}_\varepsilon(u_h^1) - D\mathcal{J}_\varepsilon(u_h^2))(u_h^1 - u_h^2) \geq \int_\Omega \alpha_\varepsilon(u_h^1, u_h^2, f)\|L(u_h^1 - u_h^2)\|_{\ell^2}^2,$$

where $\alpha_\varepsilon(u_h^1, u_h^2, f) = c \inf_{0\leq s\leq 1} \min(\|R(s)\|_{\ell^\infty}^{p-2})$ if $1 \leq p \leq 2$ and $\alpha_\varepsilon(u_h^1, u_h^2, f) = 2\varepsilon^{p-2}$ if $p \geq 2$.

If u_h^1 and u_h^2 both minimize $\mathcal{J}_\varepsilon$, then, owing to inverse inequalities, both of these functions are bounded. Since f is also assumed to be bounded, we necessarily have $\|Lu_h^i - f\|_{L^\infty(\Omega)^m} < +\infty$, $i = 1, 2$; that is to say, ess $\inf_\Omega \alpha_\varepsilon(u_h^1, u_h^2, f) > 0$ and

$$0 \geq \operatorname*{ess\,inf}_\Omega \alpha_\varepsilon(u_h^1, u_h^2, f) \int_\Omega \|L(u_h^1 - u_h^2)\|_{\ell^2}^2,$$

which yields $u_h^1 = u_h^2$ since L is injective. ∎

Since E_h is finite-dimensional (hence locally compact), a first consequence of Lemma 3.1 is that, up to a subsequence, $(u_h^\varepsilon)_{\varepsilon>0}$ converges to some u_h^0 in E_h.

LEMMA 3.3. *Every limit u_h^0 of $(u_h^\varepsilon)_{\varepsilon>0}$, up to a subsequence, is a solution to the unregularized minimization problem* (3.8).

Proof. First, let us observe that

$$\forall p \geq 1,\ \forall x \in \mathbb{R}, \qquad |\varphi_\varepsilon(|x|) - |x|^p| \leq (2+p)2^p\,\varepsilon\,(|x|^{p-1} + \varepsilon^{p-1}).$$

As a result, for all $x \in E$, we have

$$\begin{aligned}|\mathcal{J}_\varepsilon(x) - \mathcal{J}(x)| &\leq (2+p)2^p\,\varepsilon \int_\Omega \left(\sum_{i=1}^m |L_i x - f_i|^{p-1} + \varepsilon^{p-1}\right) \\ &\leq (2+p)2^p\,\varepsilon\,(m\,\varepsilon^{p-1}|\Omega| + m^{\frac{1}{p}}|\Omega|^{\frac{1}{p}}\mathcal{J}(x)^{\frac{p-1}{p}}).\end{aligned} \tag{3.18}$$

Furthermore, for all x^1 and x^2 in E, we have

$$|\mathcal{J}(x^1)^{\frac{1}{p}} - \mathcal{J}(x^2)^{\frac{1}{p}}| = |\|Lx^1 - f\|_F - \|Lx^2 - f\|_F| \leq \|L\|\,\|x^1 - x^2\|_E.$$

Combining these two results, we infer that if $x^\varepsilon \to x^0$ in E, then $\mathcal{J}_\varepsilon(x^\varepsilon) \to \mathcal{J}(x^0)$. Then we have

$$\mathcal{J}(u_h^0) = \lim_{\varepsilon\to 0} \mathcal{J}_\varepsilon(u_h^\varepsilon) = \lim_{\varepsilon\to 0} \min_{v_h\in E_h} \mathcal{J}_\varepsilon(v_h) = \min_{v_h\in E_h} \mathcal{J}(v_h),$$

which means that u_h^0 minimizes $\mathcal{J}$ in E_h. ∎

LEMMA 3.4. *Every solution to problem* (3.17) *is such that*

$$\|u - u_h^\varepsilon\|_E \lesssim \left(\varepsilon\,c(\|f\|_F) + \min_{v_h\in E_h} \|u - v_h\|_E^p\right)^{\frac{1}{p}},$$

where $c(\cdot)$ is a continuous function.

Proof. Owing to Lemma 3.1 and (3.18), we infer that

$$\begin{aligned}0 \leq \mathcal{J}(u_h^\varepsilon) - \mathcal{J}(u_h) &\leq \mathcal{J}(u_h^\varepsilon) - \mathcal{J}_\varepsilon(u_h^\varepsilon) + \mathcal{J}_\varepsilon(u_h^\varepsilon) - \mathcal{J}_\varepsilon(u_h) \\ &\quad + \mathcal{J}_\varepsilon(u_h) - \mathcal{J}(u_h) \\ &\leq \mathcal{J}(u_h^\varepsilon) - \mathcal{J}_\varepsilon(u_h^\varepsilon) + \mathcal{J}_\varepsilon(u_h) - \mathcal{J}(u_h) \\ &\lesssim \varepsilon\left(\varepsilon^{p-1} + \mathcal{J}(u_h^\varepsilon)^{\frac{p-1}{p}} + \mathcal{J}(u_h)^{\frac{p-1}{p}}\right) \\ &\lesssim \varepsilon\,c(\|f\|_F).\end{aligned}$$

Hence,

$$\begin{aligned}\|u-u_h^\varepsilon\|_E^p &\lesssim \|f-Lu_h^\varepsilon\|_F^p = \mathcal{J}(u_h^\varepsilon)-\mathcal{J}(u_h)+\mathcal{J}(u_h)\\ &\lesssim \varepsilon\, c(\|f\|_F)+\min_{v_h\in E_h}\|u-v_h\|_E^p.\end{aligned}$$

The proof is complete. ∎

Remark 3.2. Lemma 3.4 guarantees that if $\varepsilon^{1/p}$ is smaller than the interpolation error, then u_h^ε is as good an approximation of u as u_h. Note also that the smaller the p the smaller the error induced by regularization, and regularization is needed only if $1\le p<2$.

3.6. A simple algorithm for solving (3.8). We now present a simple algorithm for solving (3.8). The main idea is to set a sequence of regularization parameters $(\varepsilon^k)_{k\ge 0}$ tending to zero (or some numerically acceptable threshold) as k grows and then, for each parameter ε^k, to find a reasonable approximation of the minimizer of $\mathcal{J}_\varepsilon$ using Newton's algorithm and starting from the approximate minimizer evaluated at step $k-1$. More precisely, the algorithm we propose is as follows:

Step 1: Initialize ε^0 (say, $\varepsilon^0\sim h$) and compute some initial guess u_h^0 (use a crude $L^2(\Omega)$-stabilized technique; for instance, add a Laplace perturbation to the equation and evaluate the Galerkin solution, or evaluate the least-squares solution).

Step 2: Iterate on index k, starting from $k=0$.

Step 3$_k$: Set $u_h^{k,0}=u_h^k$.

Step 4$_k$: Iterate on index l, starting from $l=0$.

Step 5$_{k,l}$: Evaluate the gradient and the Hessian of $\mathcal{J}_{\varepsilon^k}(u_h^{k,l})$ as follows:

$$D\mathcal{J}_{\varepsilon^k}(u_h^{k,l})(v_h)=\int_\Omega D\psi_{\varepsilon^k}(Lu_h^{k,l}-f)\cdot Lv_h, \tag{3.19}$$

$$D^2\mathcal{J}_{\varepsilon^k}(u_h^{k,l})(v_h,w_h)=\int_\Omega Lw_h\cdot D^2\psi_{\varepsilon^k}(Lu_h^{k,l}-f)\cdot Lv_h. \tag{3.20}$$

Step 6$_{k,l}$: Deduce a descent direction, d_h, by solving the following problem:

$$\begin{cases}\text{Find } d_h\in X_h \text{ s.t.}\\ D^2\mathcal{J}_{\varepsilon^k}(u_h^{k,l})(v_h,d_h)=D\mathcal{J}_{\varepsilon^k}(u_h^{k,l})(v_h)\quad \forall v_h\in X_h.\end{cases} \tag{3.21}$$

Note that $D^2\psi_{\varepsilon^k}>0$; hence, in addition to being symmetric, the bilinear form $D^2\mathcal{J}_{\varepsilon^k}(u_h^{k,l})(v_h,w_h)$ is always positive definite; that is, (3.21) has always a unique solution.

Step 7$_{k,l}$: Make a line search of the minimum of $\mathcal{J}$ along the direction d_h. Call the corresponding solution $u_h^{k,l+1}$.

Step 8$_{k,l}$: If $\|u_h^{k,l+1}-u_h^{k,l}\|_E^p$ is smaller than ε^k, set $u_h^{k+1}=u_h^{k,l+1}$ and exit the l loop; otherwise continue iterations on l.

Step 9$_k$: If ε^k is smaller than some fixed tolerance, exit the k loop; otherwise divide ε^k by some fixed constant, say $\frac{3}{2}$, call the result ε^{k+1}, and continue iterations on k.

Step 10: Stop.

Remark 3.3.

(i) Note that at Step 7 the line search minimizes $\mathcal{J}$; hence, the algorithm always makes $\mathcal{J}$ decrease.

(ii) Note that in the above algorithm ε is not a tunable coefficient; i.e., this coefficient cannot be compared to any stabilizing parameter usually introduced by L^2-based stabilizing techniques (e.g., GaLS, residual free bubbles, subgrid viscosity, etc.). The sequence $(\varepsilon^k)_{k\geq 0}$ is meant to accelerate the convergence process, and it goes to zero as the number of iterations grows.

(iii) Note that the cost of one loop of the algorithm above is that of evaluating the Hessian and solving for the descent direction; however, (3.21) does not need to be solved very accurately. The computational cost per loop is identical to that of an approximate Galerkin solve. Hence, the total cost of the algorithm is that of an approximate Galerkin solve times the number of loops. In the examples reported below, the number of loops required to reach a reasonable convergence criterion was between 10 to 25 when using $u_h^0 = 0$. It is very likely that this crude algorithm is not optimal, and further research is needed to improve on this aspect of the problem. One can imagine, for instance, embedding the above algorithm within a multigrid strategy and/or some adaptive refinement strategy.

(iv) Using a stabilized L^2-based technique to compute u_h^0 significantly shortens the number of iterations in the above algorithm. In this context minimizing the residual in L^1 could be viewed as postprocessing for the L^2-based method.

(v) The above regularization-based iterative algorithm has some similarities with the so-called iteratively reweighted least-squares method of Jiang [24, Chap. 9].

(vi) When the operator L is nonlinear, the above algorithm still holds, provided formulas (3.19) and (3.20) defining the gradient and the Hessian of $\mathcal{J}_{\varepsilon^k}(u_h^{k,l})$ are modified accordingly. In this context, solving the problem in any $L^p(\Omega)$ does not cost more than solving the problem in the standard $L^2(\Omega)$ setting.

4. Numerical results. We report in this section on results of numerical tests meant to assess the theoretical a priori error estimates derived above and to illustrate the performance of the method when dealing with nonsmooth data and nonlinear problems. Unless stated explicitly otherwise, all the numerical tests reported herein have been performed in $L^1(\Omega)$.

4.1. Convergence tests.

4.1.1. A transport equation. We consider the two-dimensional (2D) domain $\Omega =]0,1[^2$ and the transport equation

$$\partial_x u = f, \quad u|_{x=0} = u_0, \tag{4.1}$$

with smooth data

$$f(x,y) = 2\pi\cos(2\pi(x+y)), \quad u_0(y) = \sin(2\pi y),$$

s.t. the exact solution is

$$u = \sin(2\pi(x+y)).$$

We approximate the solution using piecewise linear and piecewise quadratic triangular elements on unstructured Delaunay meshes. We compute the approximate solution of (4.1) in $L^1(\Omega)$. For the $\mathbb{P}_1$ solution we use meshes s.t. $\frac{1}{10} \leq h \leq \frac{1}{100}$, and for the $\mathbb{P}_2$ solution we take h in the range $\frac{1}{5} \leq h \leq \frac{1}{60}$. All the integrals are evaluated by using the 3 Gauss points quadrature rule for the $\mathbb{P}_1$ solution and the 7 Gauss points

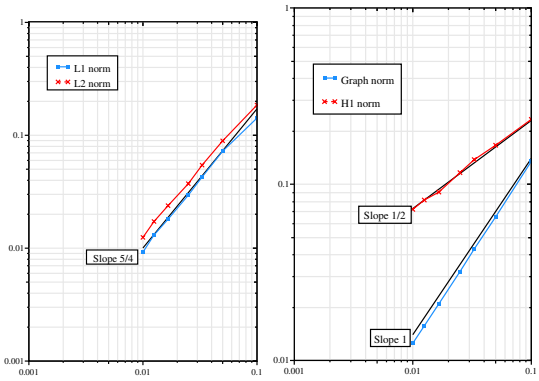

FIG. 1. *Convergence tests for $\mathbb{P}_1$ approximation. Left: Error in the L^1-norm and L^2-norm vs. the meshsize. Right: Error in the $L^1(\Omega)$-graph norm and H^1-norm vs. the meshsize.*

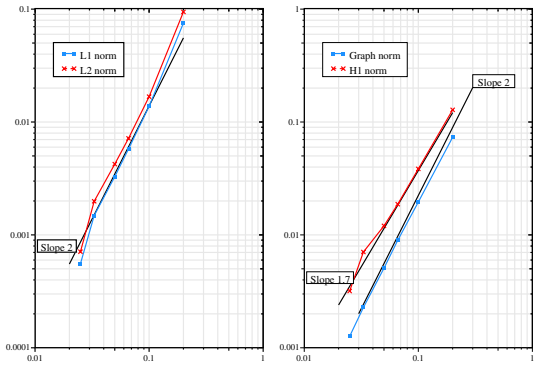

FIG. 2. *Convergence tests for $\mathbb{P}_2$ approximation. Left: Error in the L^1-norm and L^2-norm vs. the meshsize. Right: Error in the $L^1(\Omega)$-graph norm and H^1-norm vs. the meshsize.*

quadrature rule for the $\mathbb{P}_2$ solution. We evaluate the errors in the L^1-norm, the L^2-norm, the $L^1(\Omega)$-graph norm, and the H^1-norm. The results for the $\mathbb{P}_1$ approximation are displayed in Figure 1, and those for the $\mathbb{P}_2$ approximation are shown in Figure 2.

We note that the a priori error estimate (2.12) in the $L^1(\Omega)$-graph norm is fully confirmed: the slope is of order one with $\mathbb{P}_1$ finite elements and of order two with $\mathbb{P}_2$ finite elements. The error in the H^1-norm is of order $\frac{1}{2}$ for the $\mathbb{P}_1$ approximation and of order 1.7 for the $\mathbb{P}_2$ approximation. The fact that the convergence orders in the $L^1(\Omega)$-graph norm and the H^1-norm are different confirms that the method performs as expected and that it does not introduce excessive artificial cross-wind diffusion. The convergence rates of the error in the L^1-norm and the $L^2(\Omega)$-norm are slightly better than first-order in the $\mathbb{P}_1$ case and better than second-order in the $\mathbb{P}_2$ case. Note, however, that in both cases the rates are suboptimal. This result is not surprising since transport equations have no regularizing effects; that is, the Nitsche–Aubin duality argument that holds for elliptic equations does not hold here.

4.2. An elliptic operator. We now test the method on the Laplace operator. We use again $\Omega =]0,1[^2$. We solve

$$-\nabla^2 p = f, \quad p|_{\partial\Omega} = p_0,$$

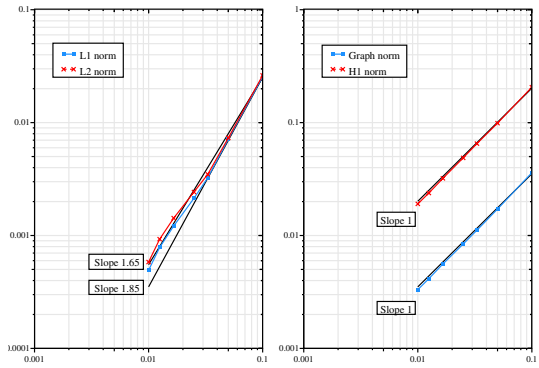

FIG. 3. *Convergence tests for $\mathbb{P}_1$ approximation of the Laplace operator. Left: Error in the L^1-norm and L^2-norm vs. the meshsize. Right: Error in the $L^1(\Omega)$-graph norm and H^1-norm vs. the meshsize.*

with the data being s.t. $p = x + 2y + \sin(2\pi x)\cos(2\pi y)$ is the exact solution.

The problem is rewritten in its first-order form (3.4) and solved in this form. We approximate the solution in $L^1(\Omega)$ using $\mathbb{P}_1$ finite elements on unstructured Delaunay meshes with $\frac{1}{10} \leq h \leq \frac{1}{100}$. For each mesh we measure the error in the $L^1(\Omega)$-norm, the $L^2(\Omega)$-norm, the $W^{1,1}(\Omega)$-norm, and the $H^1(\Omega)$-norm. The results are reported in Figure 3. We observe that the rate of convergence in the $W^{1,1}(\Omega)$-norm and in the $H^1(\Omega)$-norm are of first order; that is, they are optimal. Note that the error in the $W^{1,1}(\Omega)$-norm is almost eight times lower than that in the $H^1(\Omega)$-norm. For the $L^1(\Omega)$-norm there is not a clear rate, but we observe that the numerical results are bracketed by two lines of slope 1.65 and 1.85. Hence, the convergence is not second-order, but it is close to second-order. A similar conclusion holds for the convergence rate in the $L^2(\Omega)$-norm.

4.3. Transport equation with shock-like solutions. To illustrate the performance of the method when dealing with nonsmooth data, we consider again the 2D rectangular domain $\Omega =]0,1[^2$, and we solve the transport equation

$$\partial_x u = f, \quad u|_{x=0} = u_0, \tag{4.2}$$

with the two source terms

$$f_1(x,y) = \tfrac{1}{2\gamma}\Big[1 - \tanh^2\big(\tfrac{x-0.5}{\gamma}\big)\Big],$$
$$f_2(x,y) = \tfrac{1}{2\gamma}\Big[1 - \tanh^2\big(\tfrac{x-0.5(y+0.5)}{\gamma}\big)\Big],$$

for which the respective solutions are

$$u_1(x,y) = \tfrac{1}{2}\Big[1 + \tanh\big(\tfrac{x-0.5}{\gamma}\big)\Big],$$
$$u_2(x,y) = \tfrac{1}{2}\Big[1 + \tanh\big(\tfrac{x-0.5(y+0.5)}{\gamma}\big)\Big],$$

where $\gamma > 0$ is a small parameter. The source terms f_1 and f_2 are approximations of Dirac measures supported by the segments $x = \frac{1}{2}$ and $x - \frac{1}{2}(y - \frac{1}{2})$, respectively. These data mimic shock-like solutions.

To emphasize the capability of the method to perform well on unrefined and unstructured meshes, we show in Figure 4 the approximate solutions calculated on a

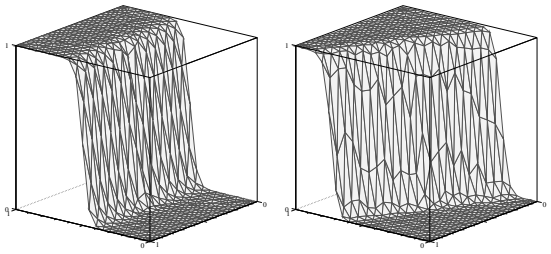

FIG. 4. *Piecewise linear L^1 approximations for test cases* (4.2). *Left: source term f_1; right: source term f_2.*

Delaunay mesh composed of 932 triangles of meshsize $h = \frac{1}{20}$. The parameter γ in the definition of the source terms is chosen to be $\gamma = h$ to guarantee that the inexact numerical integrations of the residuals are accurate enough.

Note that the solutions do not exhibit spurious over- or undershootings.

4.4. Transport equation with shear-layer-like solutions. In this section, we compare the performance of the method with that of the least-squares method on a transport equation with discontinuous boundary data.

4.4.1. 1D transport. We consider the 2D rectangular domain

$$\Omega =]0.2, 0.8[\times]0, 2[,$$

and we solve the following transport equation:

$$\partial_x u = 0, \quad u|_{x=0} = \begin{cases} 1 & \text{if } y \geq 0.5, \\ 0 & \text{otherwise.} \end{cases} \tag{4.3}$$

The exact solution is

$$u(x, y) = \begin{cases} 1 & \text{if } y \geq 0.5, \\ 0 & \text{otherwise.} \end{cases}$$

We perform the calculations on a Delaunay mesh with $h = \frac{1}{40}$. Due to the interpolation process, the boundary data is regularized for $0.475 \leq y \leq 0.525$.

We evaluate the least-squares solution (i.e., the $L^2(\Omega)$ approximation) and the $L^1(\Omega)$ approximation. The results are shown in Figure 5. The $L^1(\Omega)$ solution is shown at the top of the figure, and the $L^2(\Omega)$ one is shown at the bottom. For each solution we show contour lines in the left panels of the figure. Note that for both solutions there is some smearing in the transverse direction at the onset of the flow. This is due to the fact that the mesh is not aligned with the flow and the boundary data has been interpolated. In the right panels we show the projection of the graph of each solution onto the plane $x = 0$. It is clear that the least-squares solution is significantly more smeared than the $L^1(\Omega)$ one. The least-squares solution also exhibits over- and undershootings; i.e., it does not satisfy the maximum principle.

4.4.2. Curved transport. We consider the half disk

$$\Omega = \{(x, y);\ \sqrt{x^2 + y^2} < 1;\ y > 0\},$$

and let us set $\partial\Omega^- = \{-1 < x < 0;\ y = 0\}$. We want to solve the following transport problem:

$$\mathbf{v} \cdot \nabla u = 0, \quad u|_{\partial\Omega^-} = \begin{cases} 1 & \text{if } -1 < x < -0.74, \\ 0 & \text{if } -0.74 < x < 0, \end{cases} \tag{4.4}$$

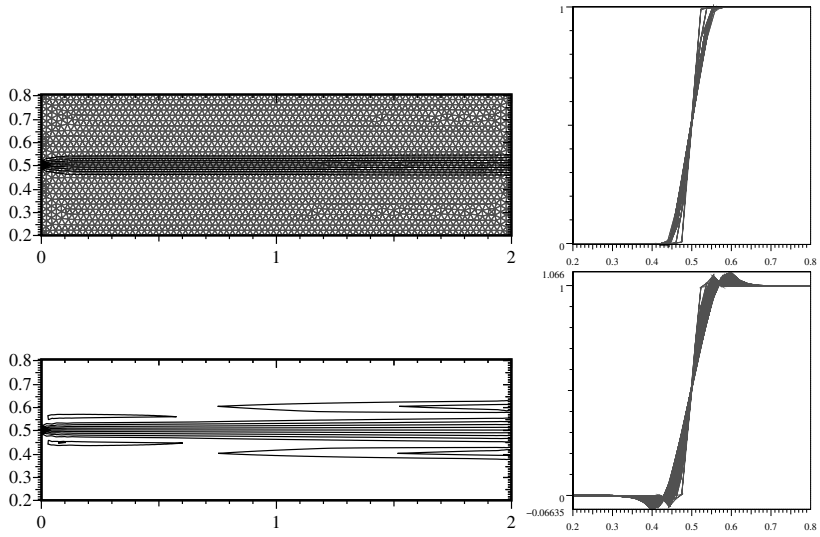

FIG. 5. *Advection equation* (4.3). *Top:* $L^1(\Omega)$ *solution and mesh; bottom:* $L^2(\Omega)$ *solution.*

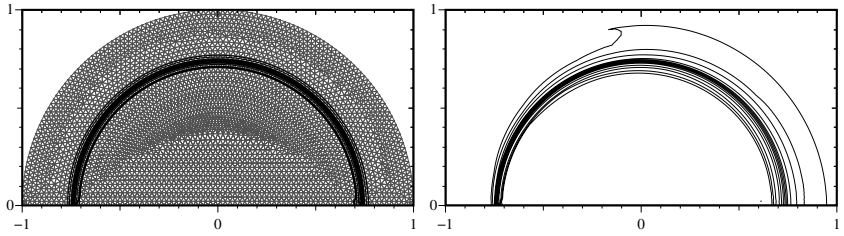

FIG. 6. *Advection equation* (4.4). *Left:* $L^1(\Omega)$ *solution with mesh; right:* $L^2(\Omega)$ *solution.*

with the curved flow field $\mathbf{v}(\mathbf{x}, \mathbf{y}) = (\sin\theta, -\cos\theta)$, where θ is the polar angle; i.e., $\theta = \arctan(y/x) \in [0, \pi[$ with the convention $\arctan(\pm\infty) = \pi/2$. The exact solution is

$$u(x, y) = \begin{cases} 1 & \text{if } \sqrt{x^2 + y^2} > 0.74, \\ 0 & \text{otherwise.} \end{cases}$$

We perform the calculations on a Delaunay mesh with $h = \frac{1}{40}$. Due to the interpolation process, the boundary condition is regularized for $-0.765 \le x \le -0.715$.

Contour lines of the $L^1(\Omega)$ and $L^2(\Omega)$ solutions are shown in Figure 6. We show about 13 contour lines for each solution. The $L^1(\Omega)$ solution is shown in the left panel of the figure, and the $L^2(\Omega)$ one is shown in the right panel. For both solutions there is some smearing in the transverse direction at the onset of the flow due to misalignment of the flow with the mesh and the interpolation of the data. It is clear, once again, that the least-squares solution is significantly more smeared than the $L^1(\Omega)$ solution and exhibits over- and undershootings.

Remark 4.1. The two test cases considered above show that for a given mesh the $L^1(\Omega)$ solution has better qualitative properties than the standard $L^2(\Omega)$ solution. In particular, discontinuities are less smeared by the L^1 approximation technique. We observe also that the $L^1(\Omega)$ solution satisfies the maximum principle. This numerical observation has yet to be fully explained mathematically.

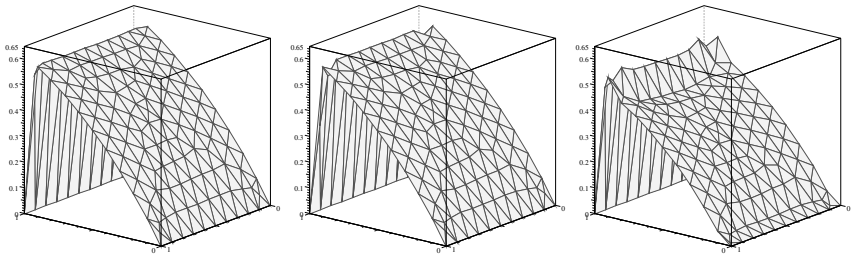

FIG. 7. *Advection equation* (4.5)*, Case* 1*,* $\nu = 0.02$*. Left:* $\mathbb{P}_1$ *Lagrange interpolate of the exact solution; center,* $L^1(\Omega)$ *solution; right,* $L^2(\Omega)$ *solution.*

Remark 4.2. Of course, if the meshes are adapted to the flow, results much sharper than those shown here can be easily obtained. We do not show these results here, for our objective in the present paper is rather to compare the performance of the $L^1(\Omega)$ and $L^2(\Omega)$ methods on arbitrary meshes than to show that each method can produce sharp results on adapted meshes.

4.5. Advection-diffusion equation. We conclude this series of tests on linear equations by solving an advection-diffusion equation in the vanishing viscosity regime.

For the sake of simplicity, we consider again the rectangular domain $\Omega =]0,1[^2$, and we denote

$$\partial\Omega_D = \{(x,y) \in \partial\Omega;\ x = 0 \text{ or } x = 1\},$$
$$\partial\Omega_N = \{(x,y) \in \partial\Omega;\ y = 0 \text{ or } y = 1\}.$$

We want to solve

$$\begin{cases} \alpha p + \boldsymbol{\beta} \cdot \nabla p + \sqrt{\nu}\, \nabla \cdot \mathbf{u} = \mathbf{f}, \\ \sqrt{\nu}\, \nabla p + \mathbf{u} = \mathbf{0}, \\ p_{|\partial\Omega_D} = p_D, \quad \mathbf{u} \cdot \mathbf{n}_{|\partial\boldsymbol{\Omega}_\mathbf{N}} = \mathbf{0}. \end{cases} \tag{4.5}$$

We set $\boldsymbol{\beta} = (1,0)$ s.t. the exact solution can be evaluated exactly.

4.5.1. Case 1. $\boldsymbol{\alpha \neq 0}$**.** We set

$$\alpha = 1, \quad f = 1, \quad p_D = 0. \tag{4.6}$$

The exact solution is

$$p(x,y) = \tfrac{1}{\alpha} + \mu^+ e^{\lambda^+ x} + \mu^- e^{\lambda^- x},$$
$$\lambda^{\pm} = \tfrac{-1 \pm \sqrt{1+4\alpha\nu}}{-2\nu}, \quad \mu^+ = -\tfrac{1}{\alpha} \tfrac{e^{\lambda^-} - 1}{e^{\lambda^-} - e^{\lambda^+}}, \quad \mu^- = -\tfrac{1}{\alpha} \tfrac{e^{\lambda^+} - 1}{e^{\lambda^+} - e^{\lambda^-}}. \tag{4.7}$$

We choose $\nu = 0.02$. We compute the $L^1(\Omega)$ and the least-squares approximations on a coarse grid with $h = \frac{1}{10}$. To the best of our knowledge, no finite element method is capable of producing a reasonable approximation to this problem with these parameters ($|\boldsymbol{\beta}|h/\nu = 5$) without resorting to some stabilization and/or nonlinear limiting technique. The results are shown in Figure 7. The $\mathbb{P}_1$ Lagrange interpolate of the exact solution is shown in the leftmost panel of the figure, the L^1 solution is in the center panel, and the least-squares solution is in the rightmost panel.

It is clear that the least-squares solution is far from the exact solution, whereas the L^1 one is a good approximation, considering the very low number of degrees of freedom used.

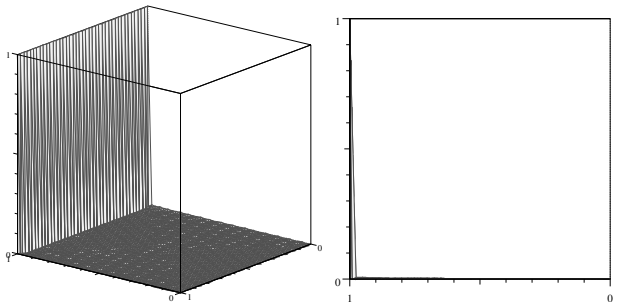

FIG. 8. *Advection equation* (4.5) *with* $\nu = 0.00125$, *Case* 2. *Left: side view of the graph of the approximate solution. Right: projection onto plane* $y = 0$ *of the graph of the approximate solution.*

4.5.2. Case 2. Now we set $\alpha = 0$. We choose the following data:

$$f = 0, \quad p_D = \begin{cases} 0 & \text{if } x = 0, \\ 1 & \text{if } x = 1. \end{cases} \tag{4.8}$$

The exact solution is

$$p(x, y) = \frac{e^{x/\nu} - 1}{e^{1/\nu} - 1}. \tag{4.9}$$

This case is frequently used in the literature to test the capability of numerical methods to solve advection-diffusion equations with dominant advection.

We set $\nu = 0.00125$, and we compute the $L^1(\Omega)$ solution on a grid of meshsize $h = \frac{1}{40}$. The result is shown in Figure 8.

It is clear that, within the capability of the mesh, the boundary layer is well-captured and the solution is not plagued by spurious oscillations.

4.6. Viscosity solutions of first-order PDEs. A striking property of the L^1 approximation technique is that it seemingly can select viscosity solutions of first-order PDEs (i.e., in the sense of Bardos, Leroux, and Nédélec [5] and Kružkov [27]).

4.6.1. Notion of viscosity solution. To illustrate this phenomenon, let Ω be a bounded domain of $\mathbb{R}^d$ with a smooth boundary. Let $\alpha > 0$, and let $\boldsymbol{\beta}$ be a vector field s.t. $\beta_i \in \mathcal{C}^1(\overline{\Omega})$, $1 \le i \le d$. Let u_0 be a smooth function on $\partial\Omega$, say $u_0 \in \mathcal{C}^2(\partial\Omega)$, and let $f \in W^{1,1}(\Omega)$. Following Bardos, Leroux, and Nédélec, [5], we say that u is a viscosity solution of

$$\alpha u + \nabla \cdot (\boldsymbol{\beta} u) = f, \quad u|_{\partial\Omega} = u_0, \tag{4.10}$$

if $u \in \mathrm{BV}(\Omega)$, u solves the PDE, and u satisfies the boundary condition in the following sense:

$$\int_{\partial\Omega} (\boldsymbol{\beta} \cdot \mathbf{n})(\mathbf{u} - \mathbf{k})(\mathrm{sg}(\mathbf{u} - \mathbf{k}) - \mathrm{sg}(\mathbf{u_0} - \mathbf{k})) \ge \mathbf{0} \quad \forall \mathbf{k} \in \mathbb{R}, \tag{4.11}$$

where $\mathrm{sg}(t)$ is the sign of t if $t \neq 0$ and $\mathrm{sg}(0) = 0$. In the present linear case, the boundary condition amounts to enforcing $u = u_0$ on $\partial\Omega^- = \{\mathbf{x} \in \partial\boldsymbol{\Omega} \,|\, \mathbf{x} \cdot \mathbf{n} < \mathbf{0}\}$. The interest of (4.11) is that it generalizes easily to nonlinear equations, whereas the notion of inflow and outflow boundary condition does not, since for nonlinear problems the inflow or outflow status of the boundary may depend on the solution

itself. For instance, if the linear term $\boldsymbol{\beta} u$ is replaced by $F(u, \mathbf{x})$, then the boundary condition $u|_{\partial\Omega} = u_0$ has to be understood in the sense

$$\int_{\partial\Omega} (F(u, \mathbf{x}) - \mathbf{F}(\mathbf{k}, \mathbf{x})) \cdot \mathbf{n}(\mathrm{sg}(\mathbf{u} - \mathbf{k}) - \mathrm{sg}(\mathbf{u_0} - \mathbf{k})) \geq \mathbf{0} \quad \forall \mathbf{k} \in \mathbb{R}. \tag{4.12}$$

Using arguments similar to those in [5] and [4], it is possible to prove that (4.10) has a unique viscosity solution, provided α is large enough. The bulk of the argument consists of proving that the solution to the following problem,

$$\alpha u_\epsilon + \nabla \cdot (\boldsymbol{\beta} u_\epsilon) - \epsilon \nabla^2 u_\epsilon = f, \quad u_\epsilon|_{\partial\Omega} = u_0, \tag{4.13}$$

converges in $\mathrm{BV}(\Omega)$ and the limit is the so-called viscosity solution; i.e., the limit satisfies the PDE in (4.10) and (4.11).

Despite the appearance, the problem (4.10) is not purely formal. It is typically this type of problem that arises when one tries to approximate (4.13) on meshes which are not refined enough. More precisely, when $\epsilon/h^2 \ll 1/h$ the second-order term in (4.13) is completely dominated by the first-order one, and solving (4.13) numerically amounts to trying to solve (4.10), where the boundary condition is understood in the classical sense instead of (4.11).

Once this point is understood, it becomes clear that the least-squares technique cannot work properly on the advection-diffusion equation (4.13) if the mesh is not refined enough.

PROPOSITION 4.1. *The H^1-conformal approximate least-squares solution to the linear problem* (4.13) *(written in mixed form) may not converge to the viscosity solution as $h \to 0$.*

Proof. As we want to build a counterexample, let us restrict ourselves to the 1D viewpoint, and let us take $\Omega =]0, 1[$, $\boldsymbol{\beta} = 1$, $u_0 = 0$, $\alpha = 1$, and $f = 1$. Let $E_h \subset H_0^1(\Omega)$ be a finite-dimensional finite element space. Thanks to crude a priori estimates in $L^2(\Omega)$ and standard inverse inequalities, it is clear that the least-squares approximation to (4.15) converges to the solution of the following problem as $\epsilon \to 0$:

$$\int_0^1 (u_h + u_h')(v_h + v_h') = \int_0^1 (v_h + v_h') \quad \forall v_h \in E_h.$$

Since test functions in E_h satisfy $v_h(0) = v_h(1) = 0$, we obtain

$$\int_0^1 (u_h + u_h')(v_h + v_h') = \int_0^1 v_h \quad \forall v_h \in E_h.$$

Then it is clear that, when $h \to 0$, the solution to the above problem converges in $H_0^1(]0, 1[)$ to the solution of the following PDE:

$$w - w'' = 1, \quad w(0) = w(1) = 0,$$

which is obviously different from the viscosity solution which solves

$$u + u' = 1, \quad u(0) = 0.$$

This completes the proof. ∎

This example shows that for a given mesh the L^2-based least-squares approximation technique does not select the right limit of (4.15) as $\epsilon \to 0$. The situation is quite different in $L^1(\Omega)$. For reasons not yet clear, numerical tests, reported in the next section, show that the solution that minimizes the L^1 distance is a reasonable approximation of the viscosity solution.

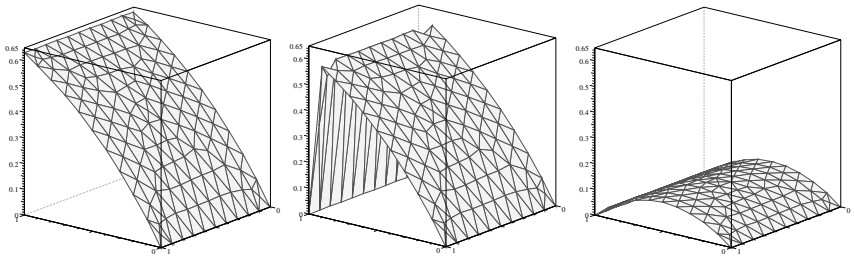

FIG. 9. *Viscosity solution to* (4.14). *Left:* $\mathbb{P}_1$ *Lagrange interpolate of the exact solution; center,* $L^1(\Omega)$ *solution; right,* $L^2(\Omega)$ *solution.*

4.6.2. Numerical experiments. let us consider the 2D rectangular domain $\Omega =]0,1[^2$ with $\partial\Omega_D = \{x = 0\} \cup \{x = 1\}$ and $\partial\Omega_N = \{y = 0\} \cup \{y = 1\}$. We want to solve the following scalar problem:

$$\alpha u + \partial_x u = f, \quad u|_{\partial\Omega_D} = u_0. \tag{4.14}$$

Of course, this problem is not well-posed in the standard sense since the outflow boundary condition is overspecified, but this problem is meaningful in the viscosity sense as defined above. Let E_h be a H^1-conformal finite element space s.t. for all v_h in E_h, $v_h|_{\partial\Omega_D} = 0$. It is clear that approximating the regularized problem

$$\alpha u_\epsilon + \partial_x u_\epsilon - \epsilon\nabla^2 u_\epsilon = f, \quad u_\epsilon|_{\partial\Omega_D} = u_0, \quad \partial_y u_\epsilon|_{\partial\Omega_N} = 0, \tag{4.15}$$

and taking the limit $\epsilon \to 0$, h being fixed, is equivalent to approximating (4.14) in E_h (recall that in E_h the Dirichlet boundary condition is enforced in the standard sense).

Let us set

$$\alpha = 1, \quad f = 1, \quad u_0 = 0. \tag{4.16}$$

We solve (4.14) in $L^1(\Omega)$ and in $L^2(\Omega)$, respectively, using continuous $\mathbb{P}_1$ finite elements and (3.8). To emphasize the capabilities of the L^1 approximation technique, we restrict ourselves to a very coarse mesh, $h = 1/10$. The results are shown in Figure 9.

In the left panel we show the $\mathbb{P}_1$ Lagrange interpolate of the viscosity solution, in the center panel we show the L^1 solution, and in the right panel we show the least-squares solution. Considering the mesh used, the $L^1(\Omega)$ approximation is a reasonable approximation, whereas the least-squares solution is completely wrong (thus confirming Proposition 4.1). Convergence tests, not reported here, show that the $L^1(\Omega)$ approximate solution converges in the $L^1(\Omega)$-norm to the viscosity solution as $h \to 0$.

Contrary to what it seems, the two horn-like spikes observable on the graph of the L^1 solution are not overshootings. These are perspective effects induced by the fact that the two corresponding $\mathbb{P}_1$-nodes are not aligned with the others. This is made clear by looking at the xz-projection of the graph of the L^1 solution shown in Figure 10.

Given that the least-squares method, together with its many variants, is a central part for the stabilization of the Galerkin technique (see, e.g., [16, 25, 26]), the above example gives new reasons why the Galerkin least-squares method cannot generally cope properly with shocks and boundary layers without the help of shock-capturing terms [26, 22].

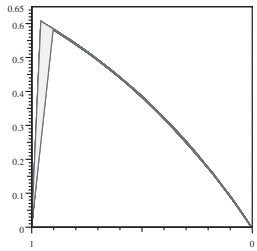

FIG. 10. *Projection in the xz-plane of the graph of the L^1 solutions in Figure 9.*

4.7. The Burgers equation. To finish this series of tests we propose to solve the Burgers-like equation

$$\nabla\cdot\left(\left(\boldsymbol{\beta}+\frac{u}{2}\frac{\mathbf{x}-\mathbf{x_0}}{\|\mathbf{x}-\mathbf{x_0}\|_{\ell^2}^{\mathbf{2}}}\right)u\right)=0,\quad u|_{\partial\Omega_1}=1,\quad u|_{\partial\Omega_0}=0, \tag{4.17}$$

in the following 2D domain:

$$\Omega=]0,1[^2\setminus\{\|\mathbf{x_0}-\mathbf{x}\|_{\ell^2}\leq\mathbf{0.2}\},$$

where $\partial\Omega_1=\{\|\mathbf{x_0}-\mathbf{x}\|_{\ell^2}=\mathbf{0.2}\}$, $\partial\Omega_0=\{x=0\}$, $\mathbf{x_0}=(\mathbf{0.5},\mathbf{0.5})$, and $\boldsymbol{\beta}=(v_0,0)$ with $v_0\geq 0$. This form of the Burgers equation retains the simplicity of its 1D counterpart and allows for more realistic 2D numerical tests.

We select an entropy solution to this problem by taking the limit as $t\to+\infty$ of the solution to the time-dependent version of (4.17), using as initial data the solution to the following problem:

$$\nabla^2 u_0=0,\quad u_0|_{\partial\Omega_1}=1,\quad u_0|_{\partial\Omega_0}=0,\quad \partial_n u_0|_{\partial\Omega_N}=0,$$

where $\partial\Omega_N$ is the complement of $\partial\Omega_0\cup\partial\Omega_1$.

The L^1 approximation is computed iteratively by solving the time-dependent problem, using the implicit Euler time-stepping. We test two configurations, $v_0=6$ and $v_0=4/3$, henceforth referred to as case 1 and case 2, respectively. To assess the accuracy of the method and its sensitivity to mesh refinement, we first do the computation on a uniform grid, $h=1/40$; then we redo it on a somewhat adapted grid with $1/10\leq h\leq 1/100$.

The results for case 1 are shown in Figure 11. We show the contour lines of the solution. Essentially, the exact solution consists of two regions where u is either equal to 1 or equal to 0, and these two regions are separated by a shock. Note that there is no shock in the upstream region and the $u=0$ solution reaches the cylinder. This means that the boundary condition $u|_{\partial\Omega_1}=1$ is satisfied in the entropy sense as defined in (4.12). We observe that the numerical solution satisfies the maximum principle and the contour lines are concentrated in the shock region. In this case the shock spreads over 2 to 3 elements; the reason for this is that the shock is almost aligned with the flow. This phenomenon is comparable to the smearing observed in the transport problem described in section 4.4. Smearing of oblique shocks is a common feature of techniques dealing with shocks. Note that the position of the shock does not change significantly as the mesh is refined, thus demonstrating that the coarse uniform mesh predicts quite well the position of the shock in question.

The contour lines of the numerical solution to case 2 are shown in Figure 12. Once more, the numerical solution is not plagued by spurious over- or undershootings. The

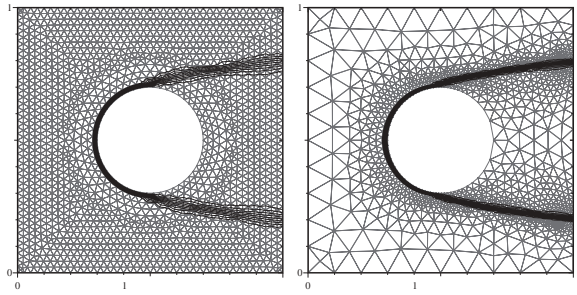

FIG. 11. *The Burgers equation with* $v_0 = 6$. *Contour lines of the solution. Left: uniform mesh* $h = 1/40$*; right: nonuniform mesh* $1/10 \leq h \leq 1/100$.

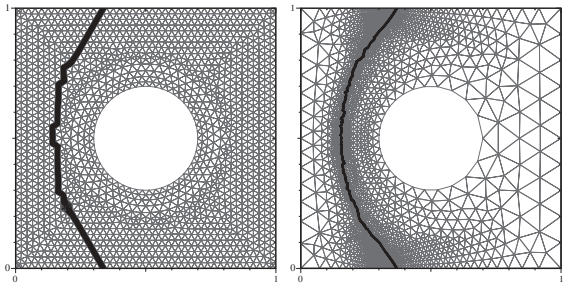

FIG. 12. *The Burgers equation with* $v_0 = 4/3$. *Contour lines of the solution. Left: uniform mesh* $h = 1/40$*; right: nonuniform mesh* $1/10 \leq h \leq 1/100$.

shock is almost perpendicular to the incoming flow; as a result, there is no smearing. The shock is a.e. contained within one element only.

The two above examples show that the L^1 technique is capable of selecting the entropy solution of Burgers-like equations. Moreover, the L^1 solution seems to satisfy a maximum principle. These two numerical observations are still to be understood and possibly proved mathematically.

5. Concluding remarks. One of the objectives driving the present work is to show that for solving first-order PDEs supplemented with nonsmooth data the ongoing debate pitting methods based on continuous interpolation against those based on discontinuous ones (e.g., H^1-conformal Galerkin vs. discontinuous Galerkin) is possibly pointless, insofar as the analysis is usually restricted to the $L^2(\Omega)$ setting. In the present paper, we have tried to promote the idea that working in a functional setting that provides for the right stability properties is as important as debating on the nature of the approximation (interpolation) space. Once the required stability property is guaranteed by the functional setting, the only requirement set for the discrete space is that it possesses good interpolation properties. As an illustration of this point of view, we have shown that, when working in $L^1(\Omega)$, the often despised continuous $\mathbb{P}_1$ finite element is capable of accurately approximating shocks, shear-layers, and boundary layers.

For reasons not yet completely clear, it seems that the $L^1(\Omega)$ approximation technique is capable of selecting viscosity solutions of first-order PDEs [5, 27] without resorting to any artificial artifact and/or tuning parameter, though this conjecture has yet to be substantiated mathematically.

All that has been said in this paper can be extended to spaces that are more exotic than the L^p's. For instance, we could consider Besov spaces or Radon measures, provided the corresponding norms can be computed efficiently in the discrete space E_h. While these spaces may provide better interpolation or approximation properties, they would require the use of wavelet bases or other hierarchical approximation spaces (for researches going in this direction, we refer the reader to, e.g., [7, 8]).

The generalization of the present work to evolution equations and conservation laws is under investigation and will be reported in a forthcoming paper.

FINITE ELEMENT APPROXIMATION OF A PHASE FIELD MODEL FOR VOID ELECTROMIGRATION*

JOHN W. BARRETT†, ROBERT NÜRNBERG†, AND VANESSA STYLES‡

Abstract. We consider a fully practical finite element approximation of the nonlinear degenerate parabolic system

$$\gamma\,\tfrac{\partial u}{\partial t} - \nabla.(\,b(u)\,\nabla[w+\alpha\,\phi]\,) = 0\,, \quad w = -\gamma\,\Delta u + \gamma^{-1}\,\Psi'(u)\,, \quad \nabla.(\,c(u)\,\nabla\phi) = 0$$

subject to an initial condition $u^0(\cdot) \in [-1,1]$ on u and flux boundary conditions on all three equations. Here $\gamma \in \mathbb{R}_{>0}$, $\alpha \in \mathbb{R}_{\geq 0}$, Ψ is a nonsmooth double well potential, and $c(u) := 1+u$, $b(u) := 1-u^2$ are degenerate coefficients. The degeneracy in b restricts $u(\cdot,\cdot) \in [-1,1]$. The above, in the limit $\gamma \to 0$, models the evolution of voids by surface diffusion in an electrically conducting solid. In addition to showing stability bounds for our approximation, we prove convergence, and hence existence of a solution to this nonlinear degenerate parabolic system in two space dimensions. Furthermore, an iterative scheme for solving the resulting nonlinear discrete system is introduced and analyzed. Finally, some numerical experiments are presented.

Key words. void electromigration, surface diffusion, phase field model, diffuse interface model, degenerate Cahn–Hilliard equation, fourth order degenerate parabolic system, finite elements, convergence analysis

1. Introduction.

Interconnect lines on microelectronic circuits usually contain small voids or cracks due to the extreme thermal stress that they are exposed to when cooled to room temperature during the production process. The applied electric field and interfacial tension cause surface diffusion; that is, atoms diffuse from one part of the void boundary to another. The void effectively "drifts" through the conductor, changing its shape as it does so. If the void becomes large enough to sever a line, it causes an open circuit. As producers try to reduce the dimensions of microchips further and further, these circuit failures become more and more frequent. Hence there is great interest in understanding the mechanism that leads to this phenomenon known as void electromigration. For further details, see, e.g., [28, 12] and the references therein. As the height of interconnect lines are extremely thin compared to the dimensions of the base, voids fully penetrate in this vertical direction. Hence a two dimensional model in the plane suffices.

Let $\Omega := (-L_1, L_1) \times (-L_2, L_2)$ be the rectangular domain in $\mathbb{R}^2$, representing the interconnect line, with boundary $\partial\Omega$. At any time $t \in [0,T]$, let the region occupied by the void be $\Omega^-(t) \subset\subset \Omega$ with boundary $\Gamma(t)$. Then the electric field in the conducting region, $\Omega^+(t) := \Omega \setminus \overline{\Omega^-(t)}$, is $E = -\nabla\phi$, where the potential ϕ at any time $t \in [0,T]$

satisfies

$$\Delta\phi = 0 \quad \text{in } \Omega^+(t), \qquad \tfrac{\partial\phi}{\partial\nu_{\Gamma(t)}} = 0 \quad \text{on } \Gamma(t)\,, \tag{1.1a}$$

$$\tfrac{\partial\phi}{\partial\nu} = 0 \quad \text{on } \partial_1\Omega, \qquad 2\,\tfrac{\partial\phi}{\partial\nu} + \phi = g^{\pm} := x_1 \pm 2 \quad \text{on } \partial_2^{\pm}\Omega\,, \tag{1.1b}$$

$\nu_{\Gamma(t)}$ being the unit normal to $\Gamma(t)$ pointing into $\Omega^-(t)$. In the above $\partial\Omega = \partial_1\Omega \cup \partial_2\Omega$, where $\partial_1\Omega \cap \partial_2\Omega = \emptyset$ and

$$\partial_2\Omega = \partial_2^-\Omega \cup \partial_2^+\Omega \quad \text{with} \quad \partial_2^{\pm}\Omega := \{\pm L_1\} \times [-L_2, L_2]\,,$$

and ν is the outward unit normal to $\partial\Omega$; see the sketch below. Hence $\partial_1\Omega$ is the insulated boundary of Ω, while the Robin boundary conditions on the ends $\partial_2^{\pm}\Omega$ model a uniform parallel electric field, $\phi \approx x_1$, as $L_1 \to \infty$. We note that one could alternatively model this with either (a) the Dirichlet condition $\phi = x_1$ or (b) the Neumann condition $\frac{\partial\phi}{\partial\nu} = \pm 1$ on $\partial_2^{\pm}\Omega$. However, in deriving energy bounds it is convenient to have a Robin condition; see (1.8) below. The motion of the void boundary, $\Gamma(t)$, then evolves according to the law

$$V = -\Delta_s\,[\,\alpha_1\,\kappa - \alpha_2\,\phi\,] \qquad \text{on } \Gamma(t)\,, \tag{1.2}$$

where V is the velocity of $\Gamma(t)$ in the direction of $\nu_{\Gamma(t)}$, Δ_s is the surface Laplacian $\equiv \frac{\partial^2}{\partial s^2}$, s being arc-length, and κ is the curvature of $\Gamma(t)$ (positive where $\Omega^-(t)$ is convex). Here $\alpha_1 \in \mathbb{R}_{>0}$ and, without loss of generality (see, e.g., [12, p. 101]), $\alpha_2 \in \mathbb{R}_{\geq 0}$ are given parameters depending on the conductor. The first term on the right-hand side of (1.2) is surface diffusion due to interfacial tension, which models atoms moving around the boundary to positions of large curvature, whereas the second term is surface diffusion due to the electric field. The void electromigration model is then the coupled system (1.1a), (1.1b) and (1.2).

If $\alpha_2 = 0$, then a local existence result for the motion (1.2) can be found in [14]. Moreover, they showed that a global solution exists if the initial curve, $\Gamma(0)$, is close to a circle and that it converges to a circle. For $\alpha_2 \geq 0$, the motion preserves the area enclosed by the closed curve $\Gamma(t)$ since

$$\tfrac{d}{dt}\,[\underline{m}(\Omega^-(t))] = -\int_{\Gamma(t)} V\,\mathrm{d}s = 0\,,$$

where $\underline{m}(D)$ is the measure of a domain D. In addition, for $\alpha_2 = 0$ this motion decreases the length of the interface since

$$\tfrac{d}{dt}\,[\underline{m}(\Gamma(t))] = -\int_{\Gamma(t)} V\,\kappa\,\mathrm{d}s = -\alpha_1 \int_{\Gamma(t)} [\tfrac{\partial\kappa}{\partial s}]^2\,\mathrm{d}s \leq 0\,.$$

A circular void moving at a constant speed is a solution of (1.1a), (1.1b) and (1.2) in the case of an infinite conductor: that is, for any $\alpha_i \in \mathbb{R}_{\geq 0}$, $R \in \mathbb{R}_{>0}$, and $z = (z_1, z_2) \in \mathbb{R}^2$,

$$\Gamma(t) := \{x \in \mathbb{R}^2 : (x_1 - z_1(t))^2 + (x_2 - z_2)^2 = R^2\}, \qquad z_1(t) := z_1 + \tfrac{2\,\alpha_2}{R}\,t, \tag{1.3a}$$

where the corresponding electric potential

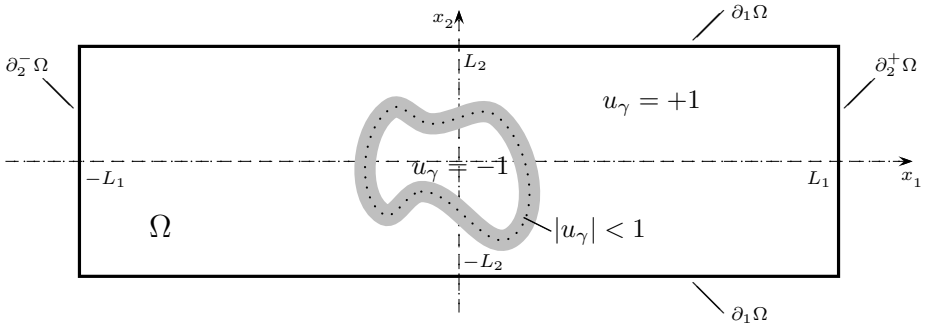
$$\phi(x,t) = [x_1 - z_1(t)]\left(1 + \tfrac{R^2}{(x_1 - z_1(t))^2 + (x_2 - z_2)^2}\right) \tag{1.3b}$$

solves (1.1a), (1.1b) and (1.2) with

(1.3c)
Ω in (1.1a) replaced by $\mathbb{R}^2$ and (1.1b) replaced by $\nabla\phi \to (1,0)^T$ as $|x| \to \infty$.

Observe that (1.2) reduces to $V = -\frac{2\,\alpha_2}{R^2}\,[x_1 - z_1(t)]$ on $\Gamma(t)$. The explicit solution (1.3a), (1.3b) was first noted in [18].

A number of authors (see, e.g., [9, 19, 28]) have considered a direct finite element approximation of (1.1a), (1.1b) and (1.2). This involves the explicit tracking of the approximate void boundary, the approximation of surface derivatives on it, and the remeshing of the approximation to $\Omega^+(t)$ in order to approximate ϕ. This direct approach breaks down at singularities, where there is a change in topology of the interface due to either the breakup or the coalescence of voids. In this paper we will consider a diffuse interface/phase field model of the original "sharp interface" void electromigration model (1.1a), (1.1b) and (1.2). The advantage of a phase field method is that the interface is implicitly embedded and is not tracked explicitly. Moreover, this approach can cope with the voids changing topology. One should also note that the phase field approach carries across unchanged to the three dimensional problem.



We introduce the interfacial parameter $\gamma \in \mathbb{R}_{>0}$ and the conserved order parameter $u_\gamma(\cdot,t) \in \mathcal{K} := [-1,1] \subset \mathbb{R}$, where at any time $t \in [0,T]$ $u_\gamma(\cdot,t) = -1$ denotes the void and $u_\gamma(\cdot,t) = +1$ denotes the conductor, while the void boundary is approximated by the $u_\gamma(\cdot,t) = 0$ contour line inside the $|u_\gamma(\cdot,t)| < 1$ interfacial region. We introduce also the chemical potential $w_\gamma(\cdot,t)$ and the electric potential $\phi_\gamma(\cdot,t)$. The sharp interface model, (1.1a), (1.1b) and (1.2), is then approximated by the following nonlinear degenerate parabolic system:

(P_γ) Find functions $u_\gamma : \Omega \times [0,T] \to \mathcal{K}$ and w_γ, $\phi_\gamma : \Omega \times [0,T] \to \mathbb{R}$ such that

(1.4a) $\gamma\,\frac{\partial u_\gamma}{\partial t} - \nabla.(\,b(u_\gamma)\,\nabla[w_\gamma + \alpha\,\phi_\gamma]\,) = 0 \quad \text{in } \Omega_T := \Omega \times (0,T],$

(1.4b) $w_\gamma = -\gamma\,\Delta u_\gamma + \gamma^{-1}\,\Psi'(u_\gamma) \quad \text{in } \Omega_T, \text{ where } |u_\gamma| < 1,$

(1.4c) $u_\gamma(x,0) = u_\gamma^0(x) \in \mathcal{K} \qquad \forall\, x \in \Omega,$

(1.4d) $\frac{\partial u_\gamma}{\partial \nu} = b(u_\gamma)\,\frac{\partial[w_\gamma + \alpha\,\phi_\gamma]}{\partial \nu} = 0 \quad \text{on } \partial\Omega \times (0,T]\,,$

(1.4e) $\nabla.(\,c(u_\gamma)\,\nabla\phi_\gamma) = 0 \quad \text{in } \Omega_T,$

(1.4f) $c(u_\gamma)\,\frac{\partial \phi_\gamma}{\partial \nu} = 0 \text{ on } \partial_1\Omega \times (0,T],\ c(u_\gamma)\,\frac{\partial \phi_\gamma}{\partial \nu} + \phi_\gamma = g^\pm \text{ on } \partial_2^\pm\Omega \times (0,T]\,.$

In (1.4a)–(1.4f), $\gamma > 0$ and $\alpha \geq 0$ are given constants and

$$\Psi(s) := \begin{cases} \frac{1}{2}\left(1 - s^2\right) & \text{if } s \in \mathcal{K}, \\ \infty & \text{if } s \notin \mathcal{K} \end{cases} \tag{1.5}$$

is an obstacle-free energy which restricts $u_\gamma(\cdot,\cdot) \in \mathcal{K}$. In addition, we define the degenerate diffusion coefficients

$$c(s) := 1 + s, \qquad b(s) := 1 - s^2 = c(s)\, c(-s) \qquad \forall\ s \in \mathcal{K}. \tag{1.6}$$

If $\alpha = 0$, then (1.4a)–(1.4d) collapses to (Q_γ), the degenerate Cahn–Hilliard equation. Existence of a solution to (Q_γ), which is a fourth order degenerate parabolic equation for u_γ as $b(u_\gamma)$ can take on zero values, can be found in [13]. Degenerate parabolic equations of higher order exhibit some new characteristic features which are fundamentally different from those for second order degenerate parabolic equations. The key point is that there is no maximum or comparison principle for parabolic equations of higher order. This drastically complicates the analysis since a lot of results which are known for second order equations are proven with the help of comparison techniques. Related to this is the fact that there is no uniqueness result known for (Q_γ). Although there is no comparison principle, one of the main features of (Q_γ) is the fact that one can show existence of a solution with $|u_\gamma| \leq 1$ if given initial data $|u_\gamma^0| \leq 1$. This is in contrast to linear parabolic equations of fourth order.

Moreover, it is shown in [10] by using the techniques of formal asymptotic expansions that the zero level sets of u_γ, the solution to (Q_γ) for a fixed $\gamma > 0$, converge as $\gamma \to 0$ to an interface, $\Gamma(t)$, evolving according to the geometric motion (1.2) with $\alpha_1 = \frac{\pi^2}{16}$ and $\alpha_2 = 0$. Furthermore, on the zero level sets of u_γ the chemical potential w_γ tends to $-\frac{\pi}{4}\kappa$, where κ is the curvature of the limiting interface $\Gamma(t)$. This limiting motion of surface diffusion is a purely local geometric motion for the interface and is in contrast to the nonlocal Mullins–Sekerka motion, which is the limiting motion of (Q_γ) with a constant diffusion term b in place of the degenerate b, (1.6). It is a straightforward matter to extend the technique of formal asymptotic expansions in [10] for (Q_γ) to (P_γ), and one obtains that the zero level sets of u_γ, the solution to (P_γ) for a fixed $\gamma > 0$, converge as $\gamma \to 0$ to an interface, $\Gamma(t)$, evolving according to the modified motion (1.2) with $\alpha_1 = \frac{\pi^2}{16}$ and $\alpha_2 = \frac{\pi\,\alpha}{4}$; see [23] for details. Hence the limiting sharp interface motion of (P_γ) is the void electromigration model, (1.1a), (1.1b) and (1.2), for a suitable choice of α and on rescaling time. Note that (1.4e), (1.4f) with the choice (1.6) is the natural diffuse interface approximation of (1.1a), (1.1b). We remark that for both (P_γ) and (Q_γ) the formal asymptotics yield that the interface thickness is approximately $\gamma\,\pi$.

A phase field approximation of (1.1a), (1.1b) and (1.2), which is very similar to (P_γ), has been considered in [8]. The only difference is in the choice of mobility $b(s) = b_0 \in \mathbb{R}_{>0}$ for $|s| < 1$ and $b(s) = 0$ otherwise. An alternative phase field approximation of (1.1a), (1.1b) and (1.2), where the diffusion coefficient b is nondegenerate and depends on $|\nabla u|^2$ as opposed to u itself, is considered in [22, 21]. Finally, an alternative fixed mesh approximation of (1.1a), (1.1b) and (1.2) is considered in [20] and in [25]. Both are based on a local level set approach to approximate (1.2) and, for $\alpha > 0$, a modified immersed interface method for approximating (1.1a), (1.1b). The former requires approximating fourth order partial differential equations for the scalar level set variable.

We should stress that there is no analysis of any of the above numerical approaches to (1.1a), (1.1b) and (1.2). In this paper we introduce and analyze a finite element

approximation of the degenerate phase field model (P_γ), which approximates the sharp interface motion (1.1a), (1.1b) and (1.2) in the limit $\gamma \to 0$. There is very little work on the numerical analysis of degenerate parabolic equations of fourth order: for work on the thin film equation see [2, 29, 17]; for thin film flows in the presence of surfactants see [5]; and for work on degenerate Cahn–Hilliard systems see [3, 4, 1]. In all of these papers, although stability bounds were proved in space dimensions $d = 1$ and 2, the main convergence result was restricted to one space dimension. However, recently Grün [16] has proved convergence in two space dimensions of a finite element approximation to the thin film equation. This approach was extended in [7] to prove convergence in two space dimensions of a finite element approximation to the thin film equation in the presence of surfactants and repulsive van der Waals forces. It is the aim of this paper to adapt the techniques in [3, 4, 16] to propose and prove convergence of a finite element approximation of (P_γ), and hence prove existence of a solution to (P_γ).

The basic ingredients of our approach are some key energy estimates. First, we relate F to c and G to b by the identities

$$c(s)\,F''(s) = 1 \qquad \text{and} \qquad b(s)\,G''(s) = 1\,. \tag{1.7}$$

Knowing c and b (recall (1.6)), the above identities determine F and G up to a linear term. Furthermore, we have that F and G are convex. As the analysis in this paper is for a fixed γ, for the remainder of this paper we drop the γ subscripts in (P_γ) for notational convenience. One can then derive formally the following energy estimates for (P). Testing (1.4e) with ϕ yields that

$$\int_\Omega c(u)\,|\nabla\phi|^2\,\mathrm{d}x + \tfrac{1}{2}\int_{\partial_2\Omega}\phi^2\,\mathrm{d}s \le \tfrac{1}{2}\int_{\partial_2\Omega} g^2\,\mathrm{d}s\,, \tag{1.8}$$

where $g := g^\pm \equiv \pm(2 + L_1)$ on $\partial_2^\pm\Omega$. Testing (1.4e) with $F'(u)$ and noting (1.7) and (1.8) yield that

$$\left|\int_\Omega \nabla\phi\,.\,\nabla u\,\mathrm{d}x\right| = \left|\int_\Omega c(u)\nabla\phi\,.\,\nabla[F'(u)]\,\mathrm{d}x\right| \le 2\left[\int_{\partial_2\Omega} g^2\,\mathrm{d}s\right]^{\frac{1}{2}}\left[\int_{\partial_2\Omega}[F'(u)]^2\,\mathrm{d}s\right]^{\frac{1}{2}}. \tag{1.9}$$

Testing (1.4a) with w and (1.4b) with $\frac{\partial u}{\partial t}$, combining and noting (1.6) and (1.8) yields that

$$\begin{aligned}\tfrac{\mathrm{d}}{\mathrm{d}t}\int_\Omega\left[\tfrac{1}{2}\,\gamma\,|\nabla u|^2 + \gamma^{-1}\,\Psi(u)\right]\mathrm{d}x + \tfrac{1}{2}\,\gamma^{-1}\int_\Omega b(u)\,|\nabla w|^2\,\mathrm{d}x&\\ \le \tfrac{1}{2}\,\alpha^2\,\gamma^{-1}\int_\Omega b(u)\,|\nabla\phi|^2\,\mathrm{d}x \le \alpha^2\,\gamma^{-1}\int_\Omega c(u)\,|\nabla\phi|^2\,\mathrm{d}x&\\ \le \tfrac{1}{2}\,\alpha^2\,\gamma^{-1}\int_{\partial_2\Omega} g^2\,\mathrm{d}s\,.&\end{aligned} \tag{1.10}$$

Testing (1.4a) with $G'(u)$ and (1.4b) with $-\Delta u$, combining and noting (1.7), (1.5), and (1.9) yields that

$$\begin{aligned}\gamma\,\tfrac{\mathrm{d}}{\mathrm{d}t}\int_\Omega G(u)\,\mathrm{d}x + \gamma\int_\Omega|\Delta u|^2\,\mathrm{d}x \le \int_\Omega\nabla(\gamma^{-1}\,u - \alpha\,\phi)\,.\,\nabla u\,\mathrm{d}x&\\ \le \gamma^{-1}\int_\Omega|\nabla u|^2\,\mathrm{d}x + 2\,\alpha\left[\int_{\partial_2\Omega} g^2\,\mathrm{d}s\right]^{\frac{1}{2}}\left[\int_{\partial_2\Omega}[F'(u)]^2\,\mathrm{d}s\right]^{\frac{1}{2}}.&\end{aligned} \tag{1.11}$$

It is the goal of this paper to derive a finite element approximation of (P) that is consistent with the energy estimates (1.8)–(1.11). Following [3], we impose the $|\cdot| \leq 1$ constraint of the discrete approximation to u as a constraint and require equation (1.4b) only where $|u| < 1$. In addition, in order to derive a discrete analogue of the energy estimates (1.9) and (1.11) we adapt a technique introduced in [29, 17] for deriving a discrete entropy bound for the thin film equation.

This paper is organized as follows. In section 2 we formulate a fully practical finite element approximation of the degenerate system (P) and derive discrete analogues of the energy estimates (1.8)–(1.11). In section 3 we prove convergence, and hence existence of a solution to the system (P) in two space dimensions. In section 4 we introduce and prove convergence of a "Gauss–Seidel-type" iterative scheme for solving the nonlinear discrete system for the approximations of u and w at each time level. Finally, in section 5 we present some numerical experiments.

Notation and auxiliary results. For $D \subset \mathbb{R}^d$, $d = 1$ or 2, we adopt the standard notation for Sobolev spaces, denoting the norm of $W^{m,q}(D)$ ($m \in \mathbb{N}$, $q \in [1, \infty]$) by $\|\cdot\|_{m,q,D}$ and the seminorm by $|\cdot|_{m,q,D}$. We extend these norms and seminorms in the natural way to the corresponding spaces of vector and matrix valued functions. For $q = 2$, $W^{m,2}(D)$ will be denoted by $H^m(D)$ with the associated norm and seminorm written, respectively, as $\|\cdot\|_{m,D}$ and $|\cdot|_{m,D}$. For notational convenience, we drop the domain subscript on the above norms and seminorms in the case $D \equiv \Omega$. Throughout, $(\cdot, \cdot)$ denotes the standard L^2 inner product over Ω. In addition, we define

$$\fint \eta := \tfrac{1}{\mathcal{L}^2(\Omega)}\,(\eta, 1) \qquad \forall\ \eta \in L^1(\Omega)\,.$$

For later purposes, we recall the following compactness results. Let X, Y, and Z be Banach spaces with a compact embedding $X \hookrightarrow Y$ and a continuous embedding $Y \hookrightarrow Z$. Then the embeddings

$$\{\, \eta \in L^2(0,T;X) : \tfrac{\partial \eta}{\partial t} \in L^2(0,T;Z) \,\} \hookrightarrow L^2(0,T;Y) \tag{1.12a}$$

and

$$\{\, \eta \in L^\infty(0,T;X) : \tfrac{\partial \eta}{\partial t} \in L^2(0,T;Z) \,\} \hookrightarrow C([0,T];Y) \tag{1.12b}$$

are compact, and a generalized version of (1.12a), where the time derivative is replaced by a time translation, holds. That is, any bounded and closed subset E of $L^2(0,T;X)$ with

$$\lim_{\theta \to 0} \left\{ \sup_{\eta \in E} \|\eta(\cdot, \cdot + \theta) - \eta(\cdot, \cdot)\|_{L^2(0,T-\theta;Z)} \right\} = 0 \tag{1.12c}$$

is compact in $L^2(0,T;Y)$; see [26].

It is convenient to introduce the "inverse Laplacian" operator $\mathcal{G} : Y \to Z$ such that

$$(\nabla[\mathcal{G}z], \nabla\eta) = \langle z, \eta \rangle \qquad \forall\ \eta \in H^1(\Omega), \tag{1.13}$$

where $Y := \left\{ z \in (H^1(\Omega))' : \langle z, 1 \rangle = 0 \right\}$ and $Z := \{ z \in H^1(\Omega) : (z, 1) = 0 \}$. Here and throughout, $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $(H^1(\Omega))'$ and $H^1(\Omega)$. The well

posedness of $\mathcal{G}$ follows from the generalized Lax–Milgram theorem and the Poincaré inequality

$$|\eta|_0 \leq C\,(\,|\eta|_1 + |(\eta,1)|\,) \qquad \forall\ \eta \in H^1(\Omega). \tag{1.14}$$

We note also for future reference Young's inequality

$$r\,s \leq \tfrac{\theta}{2}\,r^2 + \tfrac{1}{2\theta}\,s^2 \qquad \forall\ r,s \in \mathbb{R},\ \theta \in \mathbb{R}_{>0}\,. \tag{1.15}$$

Throughout, C denotes a generic constant independent of h, τ, and ε, the mesh and temporal discretization parameters, and the regularization parameter. In addition, $C(a_1,\ldots,a_I)$ denotes a constant depending on the arguments $\{a_i\}_{i=1}^I$. Furthermore, $\cdot^{(\star)}$ denotes an expression with or without the superscript $\star$. Finally, we define for any $s \in \mathbb{R}$

$$[s]_- := \min\{s,0\}, \quad [s]_+ := \max\{s,0\}, \quad [s]_{\mathcal{K}} := \max\{-1,\min\{s,1\}\}, \tag{1.16a}$$

and

$$\lfloor s \rfloor\ := \max\{z \in \mathbb{Z} : z \leq s\}. \tag{1.16b}$$

2. Finite element approximation. We consider the finite element approximation of (P) under the following assumptions on the mesh:

(A) Let Ω be a rectangular domain. Let $\{\mathcal{T}^h\}_{h>0}$ be a quasi-uniform family of partitionings of Ω into disjoint open simplices σ with $h_\sigma := \operatorname{diam}(\sigma)$ and $h := \max_{\sigma\in\mathcal{T}^h} h_\sigma$ so that $\overline{\Omega} = \cup_{\sigma\in\mathcal{T}^h}\overline{\sigma}$. In addition, it is assumed that all simplices $\sigma \in \mathcal{T}^h$ are right-angled.

We note that the right-angled simplices assumption is not a severe constraint, as there exist adaptive finite element codes that satisfy this requirement; see, e.g., [24].

Associated with $\mathcal{T}^h$ is the finite element space

$$S^h := \{\chi \in C(\overline{\Omega}) : \chi\,|_\sigma \ \text{ is linear } \forall\ \sigma \in \mathcal{T}^h\} \subset H^1(\Omega).$$

We introduce also

$$K^h := \{\chi \in S^h : |\chi| \leq 1 \text{ in } \Omega\} \subset K := \{\eta \in H^1(\Omega) : |\eta| \leq 1 \text{ a.e. in } \Omega\}\,.$$

Let J be the set of nodes of $\mathcal{T}^h$ and $\{p_j\}_{j\in J}$ the coordinates of these nodes. Let $\{\chi_j\}_{j\in J}$ be the standard basis functions for S^h; that is, $\chi_j \in S^h$ and $\chi_j(p_i) = \delta_{ij}$ for all $i,j \in J$. The right angle constraint on the partitioning is required for our approximations of $b(\cdot)$ and $c(\cdot)$ (see (2.12a), (2.12b) and (2.9a), (2.9b) below), but one consequence is that

$$\int_\sigma \nabla\chi_i\,.\,\nabla\chi_j\,\mathrm{d}x \leq 0, \qquad i \neq j \qquad \forall\ \sigma \in \mathcal{T}^h. \tag{2.1}$$

We introduce $\pi^h : C(\overline{\Omega}) \to S^h$, the interpolation operator, such that $(\pi^h\eta)(p_j) = \eta(p_j)$ for all $j \in J$. A discrete semi-inner product on $C(\overline{\Omega})$ is then defined by

$$(\eta_1,\eta_2)^h := \int_\Omega \pi^h(\eta_1(x)\,\eta_2(x))\,\mathrm{d}x = \sum_{j\in J} m_j\,\eta_1(p_j)\,\eta_2(p_j), \tag{2.2}$$

where $m_j := (1, \chi_j) > 0$. The induced discrete seminorm is then

$$|\eta|_h := [\,(\eta,\eta)^h\,]^{\frac{1}{2}} = \left(\int_\Omega \pi^h[\eta^2]\,\mathrm{d}x\right)^{\frac{1}{2}} \qquad \forall\ \eta \in C(\overline{\Omega}). \tag{2.3}$$

We introduce also the L^2 projection $Q^h : L^2(\Omega) \to S^h$ defined by

$$(Q^h\eta, \chi)^h = (\eta, \chi) \qquad \forall\ \chi \in S^h. \tag{2.4}$$

On recalling (1.6) and (1.7), we then define functions F and G such that $c(u)\,\nabla[F'(u)] = \nabla u$ and $b(u)\,\nabla[G'(u)] = \nabla u$; that is,

$$F''(s) = \tfrac{1}{c(s)} = \tfrac{1}{1+s} \quad \text{and} \quad G''(s) = \tfrac{1}{b(s)} = \tfrac{1}{c(s)\,c(-s)} = \tfrac{1}{1-s^2}\,. \tag{2.5}$$

We take F, $G \in C^\infty(-1,1)$ such that

$$F(s) = (1+s)\,\log(\tfrac{1+s}{2}) + (1-s) \qquad \text{and} \qquad G(s) = \tfrac{1}{2}\,[F(s) + F(-s)]\,; \tag{2.6}$$

and, for computational purposes, we replace F, G for any $\varepsilon \in (0,1)$ by the regularized functions F_ε, $G_\varepsilon : \mathbb{R} \to \mathbb{R}$ such that

$$F_\varepsilon(s) := \begin{cases} F(\varepsilon-1) + (s-\varepsilon+1)\,F'(\varepsilon-1) + \frac{(s-\varepsilon+1)^2}{2}\,F''(\varepsilon-1), & s \le \varepsilon-1, \\ F(s), & s \ge \varepsilon-1, \end{cases}$$

$$G_\varepsilon(s) := \tfrac{1}{2}\,[F_\varepsilon(s) + F_\varepsilon(-s)]\,. \tag{2.7}$$

Hence F_ε, $G_\varepsilon \in C^{2,1}(\mathbb{R})$ with the first two derivatives of F_ε given by

$$F_\varepsilon'(s) := \begin{cases} F'(\varepsilon-1) + (s-\varepsilon+1)\,F''(\varepsilon-1), & s \le \varepsilon-1, \\ F'(s), & s \ge \varepsilon-1, \end{cases}$$

$$\text{and} \quad F_\varepsilon''(s) := \begin{cases} F''(\varepsilon-1), & s \le \varepsilon-1, \\ F''(s), & s \ge \varepsilon-1\,, \end{cases}$$

respectively. We note for later purposes that for all $s \in \mathcal{K}$

$$\tfrac{1}{2} \le F_\varepsilon''(s) \le \varepsilon^{-1}, \qquad \tfrac{1}{2}\,F_\varepsilon''(s) \le G_\varepsilon''(s) \le [\varepsilon\,(2-\varepsilon)]^{-1} \le \varepsilon^{-1}\,; \tag{2.8a}$$

and for all $s_1, s_2 \in \mathcal{K}$ with $s_1 \ne s_2$

$$\tfrac{1}{2}\,\frac{F_\varepsilon'(s_1) - F_\varepsilon'(s_2)}{s_1 - s_2} \le \frac{G_\varepsilon'(s_1) - G_\varepsilon'(s_2)}{s_1 - s_2}\,. \tag{2.8b}$$

Similarly to the approach in [29, 17], we introduce $\Lambda_\varepsilon : S^h \to [L^\infty(\Omega)]^{2\times 2}$ such that for all $z^h \in S^h$ and a.e. in Ω

$$\Lambda_\varepsilon(z^h) \text{ is symmetric and positive semidefinite,} \tag{2.9a}$$

$$\Lambda_\varepsilon(z^h)\,\nabla\pi^h[F_\varepsilon'(z^h)] = \nabla z^h. \tag{2.9b}$$

We now give the construction of Λ_ε. Let $\{e_i\}_{i=1}^2$ be the orthonormal vectors in $\mathbb{R}^2$ such that the jth component of e_i is δ_{ij}, $i, j = 1 \to 2$. Given nonzero constants β_i, $i = 1 \to 2$, let $\widehat{\sigma}(\{\beta_i\}_{i=1}^2)$ be the reference open simplex in $\mathbb{R}^2$ with vertices $\{\widehat{p}_i\}_{i=0}^2$, where $\widehat{p}_0$ is the origin and $\widehat{p}_i = \beta_i\,e_i$, $i = 1 \to 2$. Given a $\sigma \in \mathcal{T}^h$ with vertices $\{p_{j_i}\}_{i=0}^2$ such that p_{j_0} is the right-angled vertex, then there exists a rotation matrix R_σ and

nonzero constants $\{\beta_i\}_{i=1}^2$ such that the mapping $\mathcal{R}_\sigma : \widehat{x} \in \mathbb{R}^2 \to p_{j_0} + R_\sigma \widehat{x} \in \mathbb{R}^2$ maps the vertex $\widehat{p}_i$ to p_{j_i}, $i = 0 \to 2$, and hence $\widehat{\sigma} \equiv \widehat{\sigma}(\{\beta_i\}_{i=1}^2)$ to σ. For any $z^h \in S^h$, we then set

$$\Lambda_\varepsilon(z^h)\,|_\sigma := R_\sigma\, \widehat{\Lambda}_\varepsilon(\widehat{z}^h)\,|_{\widehat{\sigma}}\, R_\sigma^T, \tag{2.10}$$

where $\widehat{z}^h(\widehat{x}) \equiv z^h(\mathcal{R}_\sigma \widehat{x})$ for all $\widehat{x} \in \overline{\widehat{\sigma}}$ and $\widehat{\Lambda}_\varepsilon(\widehat{z}^h)\,|_{\widehat{\sigma}}$ is the 2×2 diagonal matrix with diagonal entries, where $k = 1 \to 2$:

(2.11)
$$[\widehat{\Lambda}_\varepsilon(\widehat{z}^h)\,|_{\widehat{\sigma}}]_{kk} := \begin{cases} \frac{\widehat{z}^h(\widehat{p}_k) - \widehat{z}^h(\widehat{p}_0)}{F_\varepsilon'(\widehat{z}^h(\widehat{p}_k)) - F_\varepsilon'(\widehat{z}^h(\widehat{p}_0))} \equiv \frac{z^h(p_{j_k}) - z^h(p_{j_0})}{F_\varepsilon'(z^h(p_{j_k})) - F_\varepsilon'(z^h(p_{j_0}))} & \text{if } z^h(p_{j_k}) \neq z^h(p_{j_0}), \\ \frac{1}{F_\varepsilon''(\widehat{z}^h(\widehat{p}_0))} \equiv \frac{1}{F_\varepsilon''(z^h(p_{j_0}))} & \text{if } z^h(p_{j_k}) = z^h(p_{j_0}). \end{cases}$$

As $R_\sigma^T \equiv R_\sigma^{-1}$, $\nabla z^h \equiv R_\sigma\, \widehat{\nabla} \widehat{z}^h$, where $x \equiv (x_1, x_2)^T$, $\nabla \equiv (\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2})^T$, $\widehat{x} \equiv (\widehat{x}_1, \widehat{x}_2)^T$, and $\widehat{\nabla} \equiv (\frac{\partial}{\partial \widehat{x}_1}, \frac{\partial}{\partial \widehat{x}_2})^T$, it easily follows that $\Lambda_\varepsilon(z^h)$ constructed in (2.10) and (2.11) satisfies (2.9a), (2.9b). It is this construction that requires the right angle constraint on the partitioning $\mathcal{T}^h$. In a similar fashion we introduce $\Xi_\varepsilon : S^h \to [L^\infty(\Omega)]^{2\times 2}$ such that for all $z^h \in S^h$ and a.e. in Ω

$$\Xi_\varepsilon(z^h) \text{ is symmetric and positive semidefinite,} \tag{2.12a}$$

$$\Xi_\varepsilon(z^h)\, \nabla \pi^h [G_\varepsilon'(z^h)] = \nabla z^h. \tag{2.12b}$$

We extend the construction (2.10)–(2.11) for Λ_ε to Ξ_ε.

In addition to $\mathcal{T}^h$, let $0 = t_0 < t_1 < \cdots < t_{N-1} < t_N = T$ be a partitioning of $[0, T]$ into possibly variable time steps $\tau_n := t_n - t_{n-1}$, $n = 1 \to N$. We set $\tau := \max_{n=1\to N} \tau_n$. For any given $\varepsilon \in (0, 1)$, we then consider the following fully practical finite element approximation of (P):

($\mathrm{P}_\varepsilon^{h,\tau}$) For $n \geq 1$ find $\{\Phi_\varepsilon^n, U_\varepsilon^n, W_\varepsilon^n\} \in S^h \times K^h \times S^h$ such that

$$(\Lambda_\varepsilon(U_\varepsilon^{n-1})\, \nabla \Phi_\varepsilon^n, \nabla \chi) + \int_{\partial_2 \Omega} \Phi_\varepsilon^n\, \chi \,\mathrm{d}s = \int_{\partial_2 \Omega} g\, \chi \,\mathrm{d}s \qquad \forall\ \chi \in S^h, \tag{2.13a}$$

$$\gamma \left(\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}, \chi \right)^h + (\Xi_\varepsilon(U_\varepsilon^{n-1})\, \nabla [W_\varepsilon^n + \alpha\, \Phi_\varepsilon^n], \nabla \chi) = 0 \qquad \forall\ \chi \in S^h, \tag{2.13b}$$

$$\gamma\, (\nabla U_\varepsilon^n, \nabla [\chi - U_\varepsilon^n]) \geq (W_\varepsilon^n + \gamma^{-1}\, U_\varepsilon^{n-1}, \chi - U_\varepsilon^n)^h \qquad \forall\ \chi \in K^h, \tag{2.13c}$$

where g is as in (1.8) and $U_\varepsilon^0 \in K^h$ is an approximation of $u^0 \in K$, e.g., $U_\varepsilon^0 \equiv Q^h u^0$ or $U_\varepsilon^0 \equiv \pi^h u^0$, if $u^0 \in C(\overline{\Omega})$.

Remark 2.1. We note that in the case $\alpha = 0$, (2.13b), (2.13c) collapses to an approximation of the degenerate Cahn–Hilliard equation, (1.4a)–(1.4d) with $\alpha = 0$, discussed in the multicomponent context in [4, pp. 731–734].

Below we recall some well-known results concerning S^h for any $\sigma \in \mathcal{T}^h$, $\chi, z^h \in S^h$, $m \in \{0, 1\}$, $p \in [1, \infty]$, and $q \in (2, \infty]$:

$$|\chi|_{1,\sigma} \leq C\, h_\sigma^{-1}\, |\chi|_{0,\sigma}\,; \tag{2.14}$$

$$|\chi|_{m,r,\sigma} \leq C\, h_\sigma^{-2\,(\frac{1}{p} - \frac{1}{r})}\, |\chi|_{m,p,\sigma} \qquad \text{for any } r \in [p, \infty]\,; \tag{2.15}$$

$$|(I - \pi^h)\eta|_m \leq C\, h^{2-m}\, |\eta|_2 \qquad \forall\ \eta \in H^2(\Omega)\,; \tag{2.16}$$

$$|(I - \pi^h)\eta|_{m,q} \leq C\, h^{1-m}\, |\eta|_{1,q} \qquad \forall\ \eta \in W^{1,q}(\Omega)\,; \tag{2.17}$$

$$\int_\sigma \chi^2 \,\mathrm{d}x \leq \int_\sigma \pi^h[\chi^2] \,\mathrm{d}x \leq 4 \int_\sigma \chi^2 \,\mathrm{d}x\,; \tag{2.18}$$

$$|(\chi, z^h) - (\chi, z^h)^h| \leq |(I - \pi^h)(\chi\, z^h)|_{0,1} \leq C\, h^{1+m}\, |\chi|_m\, |z^h|_1\,. \tag{2.19}$$

It follows from (2.4) that

$$(Q^h\eta)(p_j) = \frac{(\eta,\chi_j)}{(1,\chi_j)} \quad \forall\, j \in J \quad \Longrightarrow \quad |Q^h\eta|_{0,\infty} \leq |\eta|_{0,\infty} \quad \forall\, \eta \in L^\infty(\Omega). \tag{2.20}$$

Finally, as we have a quasi-uniform family of partitionings, it holds that

$$|(I - Q^h)\eta|_m \leq C\, h^{1-m}\, |\eta|_1 \qquad \forall\, \eta \in H^1(\Omega). \tag{2.21}$$

We define $Z^h := \{z^h \in S^h : (z^h, 1) = 0\} \subset Y^h := \{z \in C(\overline{\Omega}) : (z,1)^h = 0\}$. Then, similarly to (1.13), we introduce $\mathcal{G}^h : Y^h \to Z^h$ such that

$$(\nabla[\mathcal{G}^h z], \nabla\chi) = (z,\chi)^h \qquad \forall\, \chi \in S^h\,. \tag{2.22}$$

We introduce the "discrete Laplacian" operator $\Delta^h : S^h \to Z^h$ such that

$$(\Delta^h z^h, \chi)^h = -(\nabla z^h, \nabla\chi) \qquad \forall\, \chi \in S^h. \tag{2.23}$$

We note for future reference, as we have a quasi-uniform family of partitionings and as Ω is convex, that for all $z^h \in S^h$

$$|z^h|_{1,s} \leq C\, |\Delta^h z^h|_0 \quad \text{for any } s \in (1,\infty)\,; \tag{2.24}$$

see, for example, [6, Lemma 3.1].

We introduce, for all $\varepsilon \in (0,1)$, $c_\varepsilon : \mathcal{K} \to [\varepsilon, 2]$ and $b_\varepsilon : \mathcal{K} \to [\varepsilon\,(2-\varepsilon), 1]$, defined, on recalling (2.5), (2.7), (2.8a), and (1.16a), by

$$c_\varepsilon(s) := \ [c(s) - \varepsilon]_+ + \varepsilon = \tfrac{1}{F''_\varepsilon(s)} \geq \tfrac{1}{F''(s)} = c(s)\,, \tag{2.25a}$$

$$b_\varepsilon(s) := 2\, \tfrac{c_\varepsilon(s)\, c_\varepsilon(-s)}{c_\varepsilon(s) + c_\varepsilon(-s)} = \tfrac{1}{G''_\varepsilon(s)} \geq \tfrac{1}{G''(s)} = b(s)\,. \tag{2.25b}$$

LEMMA 2.2. *Let the assumptions* (A) *hold. Then for any given $\varepsilon \in (0,1)$ the functions Λ_ε, $\Xi_\varepsilon : S^h \to [L^\infty(\Omega)]^{2\times 2}$ satisfy for all $z^h \in K^h$, for all $\xi \in \mathbb{R}^2$, and for all $\sigma \in \mathcal{T}^h$*

$$\varepsilon\, \xi^T\xi \leq \min_{x\in\overline{\sigma}} c_\varepsilon(z^h(x))\, \xi^T\xi \leq \ \xi^T\, \Lambda_\varepsilon(z^h)\,|_\sigma\, \xi \leq \max_{x\in\overline{\sigma}} c_\varepsilon(z^h(x))\, \xi^T\xi \leq 2\, \xi^T\xi\,, \tag{2.26a}$$

$$\varepsilon\,(2-\varepsilon)\, \xi^T\xi \leq \min_{x\in\overline{\sigma}} b_\varepsilon(z^h(x))\, \xi^T\xi \leq \ \xi^T\, \Xi_\varepsilon(z^h)\,|_\sigma\, \xi \leq \max_{x\in\overline{\sigma}} b_\varepsilon(z^h(x))\, \xi^T\xi \leq \xi^T\xi\,, \tag{2.26b}$$

$$\xi^T\, \Xi_\varepsilon(z^h)\,|_\sigma\, \xi \leq 2\, \xi^T\, \Lambda_\varepsilon(z^h)\,|_\sigma\, \xi\,. \tag{2.26c}$$

Proof. The desired results (2.26a)–(2.26c) follow from the construction of Λ_ε and Ξ_ε; cf. (2.10) and (2.11), (2.25a), (2.25b), and (2.8a), (2.8b). ∎

LEMMA 2.3. *Let the assumptions* (A) *hold, and let $\|\cdot\|$ denote the spectral norm on $\mathbb{R}^{2\times 2}$. Then for any given $\varepsilon \in (0,1)$ the functions $\Lambda_\varepsilon : S^h \to [L^\infty(\Omega)]^{2\times 2}$ and $\Xi_\varepsilon : S^h \to [L^\infty(\Omega)]^{2\times 2}$ are such that for all $z^h \in K^h$ and for all $\sigma \in \mathcal{T}^h$*

$$\max_{x\in\sigma} \|\{\Lambda_\varepsilon(z^h) - c_\varepsilon(z^h)\, \mathcal{I}\}(x)\| \leq h_\sigma\, |\nabla[c_\varepsilon(z^h)]\,|_{0,\infty,\sigma} \leq h_\sigma\, |\nabla z^h\,|_\sigma\,|\,, \tag{2.27a}$$

$$\max_{x\in\sigma} \|\{\Xi_\varepsilon(z^h) - b_\varepsilon(z^h)\, \mathcal{I}\}(x)\| \leq h_\sigma\, |\nabla[b_\varepsilon(z^h)]\,|_{0,\infty,\sigma} \leq 2\, h_\sigma\, |\nabla z^h\,|_\sigma\,|\,, \tag{2.27b}$$

where $\mathcal{I}$ is the 2×2 identity matrix.

Proof. Adopting the notation of (2.10), we have from (2.11), (2.25a), (1.6), and the Lipschitz continuity of c_ε that

$$\begin{aligned}\max_{x\in\sigma}\|\{\Lambda_\varepsilon(z^h)-c_\varepsilon(z^h)\,\mathcal{I}\}(x)\| &= \max_{\widehat{x}\in\widehat{\sigma}}\|\{\widehat{\Lambda}_\varepsilon(\widehat{z}^h)-c_\varepsilon(\widehat{z}^h)\,\mathcal{I}\}(\widehat{x})\|\\ &= \max_{\widehat{x}\in\widehat{\sigma}}\max_{k=1\to 2}|\,[\widehat{\Lambda}_\varepsilon(\widehat{z}^h)]_{kk}-c_\varepsilon(\widehat{z}^h)(\widehat{x})\,|\le h_\sigma\,|\widehat{\nabla}[c_\varepsilon(\widehat{z}^h)]\,|_{0,\infty,\widehat{\sigma}}\\ &= h_\sigma\,|\nabla[c_\varepsilon(z^h)]\,|_{0,\infty,\sigma}\le h_\sigma\,|\nabla z^h\,|_\sigma\,|,\end{aligned}$$

where we have noted that $[\widehat{\Lambda}_\varepsilon(\widehat{z}^h)\,|_{\widehat{\sigma}}\,]_{kk}=c_\varepsilon(\widehat{z}^h(\widehat{\xi}^{(k)}))\equiv c_\varepsilon(z^h(\xi^{(k)}))$ with $\xi^{(k)}\equiv\mathcal{R}_\sigma\widehat{\xi}^{(k)}\in\overline{\sigma}$ for some point $\widehat{\xi}^{(k)}\in\overline{\widehat{\sigma}}$. Hence we obtain the desired result (2.27a). The desired result (2.27b) follows similarly to the above on noting the Lipschitz continuity of b_ε; see (2.25b). ∎

LEMMA 2.4. *Let the assumptions* (A) *hold and* $U_\varepsilon^{n-1}\in K^h$. *Then for all* $\varepsilon\in(0,1)$ *and for all* h, $\tau_n>0$ *there exists a solution* $\{\Phi_\varepsilon^n,U_\varepsilon^n,W_\varepsilon^n\}$ *to the* n*th step of* $(\mathrm{P}_\varepsilon^{h,\tau})$ *with* $\fint U_\varepsilon^n=\fint U_\varepsilon^{n-1}$. $\{\Phi_\varepsilon^n,U_\varepsilon^n\}$ *is unique. In addition,* W_ε^n *is unique if there exists* $j\in J$ *such that* $U_\varepsilon^n(p_j)\in(-1,1)$. *Moreover, it holds that*

$$(\Lambda_\varepsilon(U_\varepsilon^{n-1})\,\nabla\Phi_\varepsilon^n,\nabla\Phi_\varepsilon^n)+\tfrac12\,|\Phi_\varepsilon^n|^2_{0,\partial_2\Omega}\le\tfrac12\,|g|^2_{0,\partial_2\Omega},\tag{2.28}$$

$$|(\nabla\Phi_\varepsilon^n,\nabla U_\varepsilon^{n-1})|\le 2\,|g|_{0,\partial_2\Omega}\,|\pi^h[F_\varepsilon'(U_\varepsilon^{n-1})]|_{0,\partial_2\Omega},\tag{2.29}$$

and

$$\begin{aligned}&\mathcal{E}(U_\varepsilon^n)+\tfrac12\big[\,\gamma\,|U_\varepsilon^n-U_\varepsilon^{n-1}|_1^2+\gamma^{-1}\,|U_\varepsilon^n-U_\varepsilon^{n-1}|_h^2\,\big]\\ &\quad+\tfrac12\,\gamma^{-1}\,\tau_n\,|\,[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac12}\,\nabla W_\varepsilon^n|_0^2\le\mathcal{E}(U_\varepsilon^{n-1})+\tfrac12\,\alpha^2\,\gamma^{-1}\,\tau_n\,|g|^2_{0,\partial_2\Omega}\,,\end{aligned}\tag{2.30a}$$

where

$$\mathcal{E}(U_\varepsilon^n):=\tfrac12\,[\,\gamma\,|U_\varepsilon^n|_1^2-\gamma^{-1}\,|U_\varepsilon^n|_h^2\,]\,.\tag{2.30b}$$

Furthermore, it holds that

$$\begin{aligned}&\gamma\,(G_\varepsilon(U_\varepsilon^n)-G_\varepsilon(U_\varepsilon^{n-1}),1)^h+\gamma\,\tau_n\,|\Delta^h U_\varepsilon^n|_h^2\le\varepsilon^{-1}\,\gamma\,|U_\varepsilon^n-U_\varepsilon^{n-1}|_h^2\\ &\qquad+\tau_n\,(\nabla W_\varepsilon^n,\nabla[U_\varepsilon^n-U_\varepsilon^{n-1}]\,)+\tau_n\,(\nabla[\gamma^{-1}\,U_\varepsilon^n-\alpha\,\Phi_\varepsilon^n],\nabla U_\varepsilon^{n-1})\,.\end{aligned}\tag{2.31}$$

Proof. Given $U_\varepsilon^{n-1}\in K^h$, it follows immediately from (2.26a) and a Friedrich inequality that there exists a unique solution $\Phi_\varepsilon^n\in S^h$ to (2.13a). In order to prove existence of a solution $\{U_\varepsilon^n,W_\varepsilon^n\}\in K^h\times S^h$ to (2.13b), (2.13c), we introduce, similarly to (2.22), for $q^h\in K^h$ the discrete anisotropic Green's operator $\mathcal{G}_{q^h}^h:Z^h\to Z^h$ such that

$$(\Xi_\varepsilon(q^h)\,\nabla[\mathcal{G}_{q^h}^h z^h],\nabla\chi)=(z^h,\chi)^h\qquad\forall\ \chi\in S^h.\tag{2.32}$$

It follows immediately from (2.26b) and (1.14) that $\mathcal{G}_{q^h}^h$ is well-posed. It follows from (2.13b) and (2.32) that

$$W_\varepsilon^n\equiv-\alpha\,\Phi_\varepsilon^n-\gamma\,\mathcal{G}^h_{U_\varepsilon^{n-1}}\Big[\tfrac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}\Big]+\lambda^n,\tag{2.33}$$

where $\lambda^n\in\mathbb{R}$ is a constant. Hence (2.13b), (2.13c) can be restated as follows: Find $U_\varepsilon^n\in K^h(U_\varepsilon^{n-1}):=\{\chi\in K^h:\chi-U_\varepsilon^{n-1}\in Z^h\}$ and a Lagrange multiplier $\lambda^n\in\mathbb{R}$

such that for all $\chi \in K^h$

$$\gamma \left[(\nabla U_\varepsilon^n, \nabla(\chi - U_\varepsilon^n)) + \left(\mathcal{G}^h_{U_\varepsilon^{n-1}} \left[\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n} \right], \chi - U_\varepsilon^n \right)^h \right] \geq (\gamma^{-1}\, U_\varepsilon^{n-1} - \alpha\, \Phi_\varepsilon^n + \lambda^n, \chi - U_\varepsilon^n)^h. \tag{2.34}$$

It follows from (2.34) that $U_\varepsilon^n \in K^h(U_\varepsilon^{n-1})$ is such that for all $\chi \in K^h(U_\varepsilon^{n-1})$

$$\gamma \left[(\nabla U_\varepsilon^n, \nabla(\chi - U_\varepsilon^n)) + \left(\mathcal{G}^h_{U_\varepsilon^{n-1}} \left[\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n} \right], \chi - U_\varepsilon^n \right)^h \right] \geq (\gamma^{-1} U_\varepsilon^{n-1} - \alpha \Phi_\varepsilon^n, \chi - U_\varepsilon^n)^h. \tag{2.35}$$

There exists a unique $U_\varepsilon^n \in K^h(U_\varepsilon^{n-1})$ solving (2.35) since, on noting (2.32), this is the Euler–Lagrange variational inequality of the strictly convex minimization problem

$$\min_{z^h \in K^h(U_\varepsilon^{n-1})} \left\{ \tfrac{\gamma}{2} |z^h|_1^2 + \tfrac{\gamma}{2\,\tau_n} |[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac12}\, \nabla \mathcal{G}^h_{U_\varepsilon^{n-1}}(z^h - U_\varepsilon^{n-1})|_0^2 - (\gamma^{-1}\, U_\varepsilon^{n-1} - \alpha\, \Phi_\varepsilon^n, z^h)^h \right\}.$$

Existence of the Lagrange multiplier λ^n in (2.34) then follows from standard optimization theory; see, e.g., [11]. Therefore we have existence of a solution $\{U_\varepsilon^n, W_\varepsilon^n\} \in K^h \times S^h$ to (2.13b), (2.13c). If $|U_\varepsilon^n(p_j)| < 1$ for some $j \in J$, then $\pi^h[1 - (U_\varepsilon^n)^2] \not\equiv 0$ and choosing $\chi \equiv U_\varepsilon^n \pm \delta \pi^h[1 - (U_\varepsilon^n)^2]$ in (2.34) for $\delta > 0$ sufficiently small yields uniqueness of λ^n and, on noting (2.33), uniqueness of W_ε. Furthermore, choosing $\chi \equiv 1$ in (2.13b) yields $\fint U_\varepsilon^n = \fint U_\varepsilon^{n-1}$.

The bound (2.28) follows immediately from choosing $\chi \equiv \Phi_\varepsilon^n$ in (2.13a) and applying (1.15). Choosing $\chi \equiv \pi^h[F_\varepsilon'(U_\varepsilon^{n-1})]$ in (2.13a) and noting (2.9b) and (2.28) yield that

$$|(\nabla \Phi_\varepsilon^n, \nabla U_\varepsilon^{n-1})| = \left| \int_{\partial_2\Omega} (g - \Phi_\varepsilon^n)\, \pi^h[F_\varepsilon'(U_\varepsilon^{n-1})]\, \mathrm{d}s \right| \leq 2\, |g|_{0,\partial_2\Omega}\, |\pi^h[F_\varepsilon'(U_\varepsilon^{n-1})]|_{0,\partial_2\Omega},$$

and hence the desired result (2.29). Choosing $\chi \equiv W_\varepsilon^n$ in (2.13b) and $\chi \equiv U_\varepsilon^{n-1}$ in (2.13c) yields that

$$\gamma\, (U_\varepsilon^n - U_\varepsilon^{n-1}, W_\varepsilon^n)^h + \tau_n\, (\Xi_\varepsilon(U_\varepsilon^{n-1})\, \nabla[W_\varepsilon^n + \alpha\, \Phi_\varepsilon^n], \nabla W_\varepsilon^n) = 0, \tag{2.36a}$$

$$\gamma\, (\nabla U_\varepsilon^n, \nabla[U_\varepsilon^{n-1} - U_\varepsilon^n]) \geq (W_\varepsilon^n + \gamma^{-1}\, U_\varepsilon^{n-1}, U_\varepsilon^{n-1} - U_\varepsilon^n)^h. \tag{2.36b}$$

On noting the elementary identity

$$2\, r\, (r - s) = (r^2 - s^2) + (r - s)^2 \qquad \forall\ r, s \in \mathbb{R},$$

it follows from (2.36a), (2.36b), (2.30b), (1.15), and (2.26c) that

$$\begin{aligned} &\mathcal{E}(U_\varepsilon^n) + \tfrac12 \left[\gamma\, |U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2 + \gamma^{-1}\, |U_\varepsilon^n - U_\varepsilon^{n-1}|_h^2 \right] + \gamma^{-1}\, \tau_n\, |\, [\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac12}\, \nabla W_\varepsilon^n|_0^2 \\ &\quad \leq \mathcal{E}(U_\varepsilon^{n-1}) - \alpha\, \gamma^{-1}\, \tau_n\, (\Xi_\varepsilon(U_\varepsilon^{n-1})\, \nabla \Phi_\varepsilon^n, \nabla W_\varepsilon^n) \\ &\quad \leq \mathcal{E}(U_\varepsilon^{n-1}) + \gamma^{-1}\, \tfrac{\tau_n}{2} \left[|\, [\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac12}\, |\nabla W_\varepsilon^n|_0^2 + 2\, \alpha^2\, |\, [\Lambda_\varepsilon(U_\varepsilon^{n-1})]^{\frac12}\, \nabla \Phi_\varepsilon^n|_0^2 \right]. \end{aligned} \tag{2.37}$$

Hence the desired result (2.30a) follows from (2.37) and (2.28).

Choosing $\chi \equiv \pi^h[G'_\varepsilon(U_\varepsilon^{n-1})]$ in (2.13b) and noting (2.12b) yield that

$$\gamma\,(U_\varepsilon^n - U_\varepsilon^{n-1}, G'_\varepsilon(U_\varepsilon^{n-1}))^h + \tau_n\,(\nabla[W_\varepsilon^n + \alpha\,\Phi_\varepsilon^n], \nabla U_\varepsilon^{n-1}) = 0\,. \tag{2.38}$$

We now apply an argument similar to that in [4, Theorem 2.3]. From (2.13c) we have for all $j \in J$ on choosing $\chi \equiv U_\varepsilon^n + \delta\,\chi_j$, $U_\varepsilon^n \pm \delta\,\chi_j$, $U_\varepsilon^n - \delta\,\chi_j \in K^h$, respectively, for $\delta > 0$ sufficiently small, that

$$\gamma\,(\nabla U_\varepsilon^n, \nabla\chi_j) - (W_\varepsilon^n + \gamma^{-1}\,U_\varepsilon^{n-1}, \chi_j)^h \begin{cases} \geq 0 \\ = 0 \\ \leq 0 \end{cases} \quad \text{if} \quad U_\varepsilon^n(p_j) \quad \begin{cases} = -1 \\ \in (-1,1) \\ = 1 \end{cases}\,. \tag{2.39}$$

From (2.23), (2.2), and (2.1) it follows for all $j \in J$ that

$$U_\varepsilon^n(p_j) = \pm 1 \implies \pm U_\varepsilon^n(p_j) \geq \pm U_\varepsilon^n(p_i) \qquad \forall\, i \in J \implies \pm\,\Delta^h U_\varepsilon^n(p_j) \leq 0. \tag{2.40}$$

Combining (2.39) and (2.40) and noting (2.23) and (2.3) yield

$$\begin{aligned} \gamma\,|\Delta^h U_\varepsilon^n|_h^2 = -\gamma\,(\nabla U_\varepsilon^n, \nabla(\Delta^h U_\varepsilon^n)\,) &\leq -(W_\varepsilon^n + \gamma^{-1}\,U_\varepsilon^{n-1}, \Delta^h U_\varepsilon^n)^h \\ &= (\nabla[W_\varepsilon^n + \gamma^{-1}\,U_\varepsilon^{n-1}], \nabla U_\varepsilon^n). \end{aligned} \tag{2.41}$$

It follows from (2.38), (2.8a), and (2.41) that

$$\begin{aligned} &\gamma(G_\varepsilon(U_\varepsilon^n) - G_\varepsilon(U_\varepsilon^{n-1}), 1)^h + \gamma\tau_n|\Delta^h U_\varepsilon^n|_h^2 \\ &\quad\leq \gamma(U_\varepsilon^n - U_\varepsilon^{n-1}, G'_\varepsilon(U_\varepsilon^n))^h + \tau_n(\nabla[W_\varepsilon^n + \gamma^{-1}U_\varepsilon^{n-1}], \nabla U_\varepsilon^n) \\ &\quad\leq \gamma(U_\varepsilon^n - U_\varepsilon^{n-1}, G'_\varepsilon(U_\varepsilon^n) - G'_\varepsilon(U_\varepsilon^{n-1}))^h + \tau_n(\nabla W_\varepsilon^n, \nabla[U_\varepsilon^n - U_\varepsilon^{n-1}]) \\ &\qquad\qquad + \tau_n(\nabla[\gamma^{-1}U_\varepsilon^n - \alpha\Phi_\varepsilon^n], \nabla U_\varepsilon^{n-1}) \\ &\quad\leq \varepsilon^{-1}\gamma|U_\varepsilon^n - U_\varepsilon^{n-1}|_h^2 + \tau_n[(\nabla W_\varepsilon^n, \nabla[U_\varepsilon^n - U_\varepsilon^{n-1}]) + (\nabla[\gamma^{-1}U_\varepsilon^n - \alpha\Phi_\varepsilon^n], \nabla U_\varepsilon^{n-1})], \end{aligned}$$

and hence the desired result (2.31). ∎

Remark 2.5. We note that (2.28)–(2.31) are the discrete analogues of the energy estimates (1.8)–(1.11), respectively.

THEOREM 2.6. *Let the assumptions* (A) *hold and* $U_\varepsilon^0 \in K^h$. *Then for all* $\varepsilon \in (0,1)$, *for all* $h > 0$, *and for all time partitions* $\{\tau_n\}_{n=1}^N$, *the solution* $\{\Phi_\varepsilon^n, U_\varepsilon^n, W_\varepsilon^n\}_{n=1}^N$ *to* $(\mathrm{P}_\varepsilon^{h,\tau})$ *is such that* $\fint U_\varepsilon^n = \fint U_\varepsilon^0$, $n = 1 \to N$, *and*

$$\begin{aligned} &\gamma \max_{n=1\to N} \|U_\varepsilon^n\|_1^2 + \sum_{n=1}^N \left[\,\gamma\,|U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2 + \gamma^{-1}\,|U_\varepsilon^n - U_\varepsilon^{n-1}|_0^2\,\right] \\ &\quad + \gamma^{-1}\sum_{n=1}^N \tau_n\,|\,[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac12}\,\nabla W_\varepsilon^n|_0^2 \leq C\left[\,\gamma\,\|U_\varepsilon^0\|_1^2 + \gamma^{-1}\,(1 + T\,|g|_{0,\partial_2\Omega}^2)\,\right]. \end{aligned} \tag{2.42}$$

In addition,

$$\gamma \sum_{n=1}^{N} \tau_n \left| \mathcal{G}\left[\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}\right]\right|_1^2 + \gamma\, \tau^{-\frac{1}{2}} \sum_{n=1}^{N} |U_\varepsilon^n - U_\varepsilon^{n-1}|_0^2$$
$$\leq C\left[\, \gamma\, \|U_\varepsilon^0\|_1^2 + \gamma^{-1}\,(1 + T\,|g|_{0,\partial_2\Omega}^2)\,\right] \tag{2.43}$$

and
$$\gamma \max_{n=1\to N} (G_\varepsilon(U_\varepsilon^n), 1)^h + \gamma \sum_{n=1}^{N} \tau_n\, |\Delta^h U_\varepsilon^n|_h^2$$
$$\leq \gamma\,(G_\varepsilon(U_\varepsilon^0), 1)^h + \alpha^2 \sum_{n=1}^{N} \tau_n\, |\pi^h[F_\varepsilon'(U_\varepsilon^{n-1})]|_{0,\partial_2\Omega}^2$$
$$+ C(T)\,[\,1 + \gamma^{-2} + \varepsilon^{-1}\tau^{\frac{1}{2}}\,]\,\left[\,\gamma\,\|U_\varepsilon^0\|_1^2 + \gamma^{-1}\,(1 + T\,|g|_{0,\partial_2\Omega}^2)\,\right]. \tag{2.44}$$

Proof. Summing (2.30a) from $n = 1 \to k$ yields for any $k \leq N$ that

$$\mathcal{E}(U_\varepsilon^k) + \tfrac{1}{2} \sum_{n=1}^{k} \left[\gamma\, |U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2 + \gamma^{-1}\, |U_\varepsilon^n - U_\varepsilon^{n-1}|_h^2\,\right]$$
$$+ \tfrac{1}{2}\,\gamma^{-1} \sum_{n=1}^{k} \tau_n\, |\,[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac{1}{2}}\, \nabla W_\varepsilon^n|_0^2 \leq \mathcal{E}(U_\varepsilon^0) + \tfrac{1}{2}\,\alpha^2\,\gamma^{-1}\, t_k\, |g|_{0,\partial_2\Omega}^2\,. \tag{2.45}$$

The desired result (2.42) then follows from (2.45), (2.30b), (2.3), (2.18), and the fact that $U_\varepsilon^n \in K^h$, $n = 0 \to N$.

From (1.13), (2.4), (2.13b), (2.26b), (2.26c), and (2.21) we obtain for any $\eta \in H^1(\Omega)$ that

$$\gamma\left(\nabla \mathcal{G}[\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}], \nabla\eta\right) = \gamma\left(\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}, \eta\right) = \gamma\left(\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}, Q^h\eta\right)^h$$
$$= -(\Xi_\varepsilon(U_\varepsilon^{n-1})\,\nabla[W_\varepsilon^n + \alpha\,\Phi_\varepsilon^n], \nabla[Q^h\eta])$$
$$\leq \left[\, |[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla W_\varepsilon^n|_0 + \alpha\,|[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla\Phi_\varepsilon^n|_0\,\right] |Q^h\eta|_1$$
$$\leq C\left[\, |[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla W_\varepsilon^n|_0 + \alpha\,|[\Lambda_\varepsilon(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla\Phi_\varepsilon^n|_0\,\right] |\eta|_1\,. \tag{2.46}$$

The first bound in (2.43) then follows from (2.46), (2.28), and (2.42). Moreover, we have from (1.13) that

$$\sum_{n=1}^{N} |U_\varepsilon^n - U_\varepsilon^{n-1}|_0^2 \leq \tau^{\frac{1}{2}} \left[\sum_{n=1}^{N} |U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2\right]^{\frac{1}{2}} \left[\sum_{n=1}^{N} \tau_n \left|\mathcal{G}[\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}]\right|_1^2\right]^{\frac{1}{2}}.$$

The second bound in (2.43) then follows from the first and (2.42). Finally, summing (2.31) from $n = 1 \to k$ and noting (2.3), (2.18), and (2.26b) yield for any $k \leq N$ that

$$\gamma\,(G_\varepsilon(U_\varepsilon^k), 1)^h + \gamma \sum_{n=1}^{k} \tau_n\, |\Delta^h U_\varepsilon^n|_h^2 \leq \gamma\,(G_\varepsilon(U_\varepsilon^0), 1)^h$$
$$+ \sum_{n=1}^{k} \left[\, 4\,\varepsilon^{-1}\,\gamma\,|U_\varepsilon^n - U_\varepsilon^{n-1}|_0^2 + \alpha\,\tau_n\,|(\nabla\Phi_\varepsilon^n, \nabla U_\varepsilon^{n-1})|\,\right] + \gamma^{-1}\, t_k \max_{n=0\to k} \|U_\varepsilon^n\|_1^2$$
$$+ \left[\varepsilon^{-1} \sum_{n=1}^{k} \tau_n\, |\,[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac{1}{2}}\,\nabla W_\varepsilon^n|_0^2\right]^{\frac{1}{2}} \left[\sum_{n=1}^{k} \tau_n\, |U_\varepsilon^n - U_\varepsilon^{n-1}|_1^2\right]^{\frac{1}{2}}. \tag{2.47}$$

The desired result (2.44) then follows from (2.47), (2.29), (1.15), (2.42), and (2.43). ∎

LEMMA 2.7. *Let $u^0 \in K$ and the assumptions* (A) *hold. On choosing either $U_\varepsilon^0 \equiv Q^h u^0$ or, if $u^0 \in W^{1,p}(\Omega)$ with $p > 2$, $U_\varepsilon^0 \equiv \pi^h u^0$, it follows that $U_\varepsilon^0 \in K^h$ is such that for all $h > 0$*

$$\|U_\varepsilon^0\|_1^2 + (G_\varepsilon(U_\varepsilon^0), 1)^h \leq C. \tag{2.48}$$

Proof. The desired result (2.48) follows immediately from (2.20), (2.21), (2.17), (2.7), and (2.6). ∎

Remark 2.8. As an alternative to the approximation $(\mathrm{P}_\varepsilon^{h,\tau})$ of (P) one could consider $(\overline{\mathrm{P}}_\varepsilon^{h,\tau})$, which is the same as $(\mathrm{P}_\varepsilon^{h,\tau})$ but with $\Lambda_\varepsilon(U_\varepsilon^{n-1})$ in (2.13a) replaced by $\Lambda_\varepsilon(U_\varepsilon^n)$ and $\Xi_\varepsilon(U_\varepsilon^{n-1})$ in (2.13b) replaced by $\Xi_\varepsilon(U_\varepsilon^n)$. This is more in line with the approximation of the thin film equation in [17]. This has the advantage that to prove the key energy bound (2.44) one can choose $\chi \equiv \pi^h[F_\varepsilon'(U_\varepsilon^n)]$ and $\chi \equiv \pi^h[G_\varepsilon'(U_\varepsilon^n)]$ in the modified versions of (2.13a) and (2.13b), respectively. This would simplify the proof of (2.44) and in particular remove the term $\varepsilon^{-1}\tau^{\frac{1}{2}}$ on the right-hand side. The presence of this term for our chosen scheme $(\mathrm{P}_\varepsilon^{h,\tau})$ leads to the constraint $\tau \leq C\,\varepsilon^2$ for our convergence results; see Lemma 3.1. However, the scheme $(\overline{\mathrm{P}}_\varepsilon^{h,\tau})$ has the severe disadvantage that the well posedness and computation of $\{\Phi_\varepsilon^n, U_\varepsilon^n, W_\varepsilon^n\}$ is nontrivial, since they are coupled in a highly nonlinear system of equations.

Remark 2.9. Also in line with the approximation of the thin film equation in [17], one could remove the inequality constraint in (2.13c) for either of the approximations in Remark 2.8. In particular, it follows from (2.7) that

$$\varepsilon^{-1}\,(|s| - (1-\varepsilon))^2 \leq 4\,G_\varepsilon(s) \qquad \forall\ |s| \geq 1-\varepsilon. \tag{2.49}$$

On combining (2.49) with the energy bound (2.44), which still holds, one has control, in terms of ε, on the overshoot of U_ε^n from $\mathcal{K}$ in $|\cdot|_h$. As the inequality constraint in (2.13c) does not lead to any theoretical or computational complications, we prefer to impose it so one can clearly identify the three computational regions: conductor $U_\varepsilon^n = +1$, interface $|U_\varepsilon^n| < 1$, and void $U_\varepsilon^n = -1$.

Remark 2.10. The approximation $(\mathrm{P}_\varepsilon^{h,\tau})$ of (P) and all the variants mentioned in Remarks 2.8 and 2.9 require solving for $\{\Phi_\varepsilon^n, U_\varepsilon^n, W_\varepsilon^n\}$ over the whole domain Ω, due to the nondegeneracy of $\Lambda_\varepsilon(\cdot)$ and $\Xi_\varepsilon(\cdot)$; see (2.26a), (2.26b). For computational speed it would be more convenient to solve for Φ_ε^n just in the conductor and interfacial regions, $U_\varepsilon^{n-1} > -1$, and for $\{U_\varepsilon^n, W_\varepsilon^n\}$ just in the interfacial region, $|U_\varepsilon^{n-1}| < 1$. With this in mind, and adopting the notation (2.10) and (2.11), we introduce $\widetilde{\Lambda}_\varepsilon, \widetilde{\Xi}_\varepsilon : S^h \to [L^\infty(\Omega)]^{2\times 2}$ such that $\widetilde{\Lambda}_\varepsilon(z^h)\,|_\sigma := R_\sigma \widehat{\Lambda}_\varepsilon^\star(\widehat{z}^h)\,|_{\widehat{\sigma}}\ R_\sigma^T$ and $\widetilde{\Xi}_\varepsilon(z^h)\,|_\sigma := R_\sigma \widehat{\Xi}_\varepsilon^\star(\widehat{z}^h)\,|_{\widehat{\sigma}}\ R_\sigma^T$, where

$$[\widehat{\Lambda}_\varepsilon^\star(\widehat{z}^h)\,|_{\widehat{\sigma}}]_{kk} := \begin{cases} 0 & \text{if } \widehat{z}^h(\widehat{p}_k) = \widehat{z}^h(\widehat{p}_0) = -1, \\ [\widehat{\Lambda}_\varepsilon(\widehat{z}^h)\,|_{\widehat{\sigma}}]_{kk} & \text{otherwise;} \end{cases}$$

$$\text{and} \quad [\widehat{\Xi}_\varepsilon^\star(\widehat{z}^h)\,|_{\widehat{\sigma}}]_{kk} := \begin{cases} 0 & \text{if } \widehat{z}^h(\widehat{p}_k) = \widehat{z}^h(\widehat{p}_0) = \pm 1, \\ [\widehat{\Xi}_\varepsilon(\widehat{z}^h)\,|_{\widehat{\sigma}}]_{kk} & \text{otherwise.} \end{cases}$$

We note that the key identities, $\Lambda_\varepsilon(z^h)$ in (2.9a), (2.9b) replaced by $\widetilde{\Lambda}_\varepsilon(z^h)$ and $\Xi_\varepsilon(z^h)$ in (2.12a), (2.12b) replaced by $\widetilde{\Xi}_\varepsilon(z^h)$, still hold. We then introduce the approximation $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ of (P), which is the same as $(\mathrm{P}_\varepsilon^{h,\tau})$ but with $\Lambda_\varepsilon(U_\varepsilon^{n-1})$ in (2.13a) replaced by $\widetilde{\Lambda}_\varepsilon(U_\varepsilon^{n-1})$ and $\Xi_\varepsilon(U_\varepsilon^{n-1})$ in (2.13b) replaced by $\widetilde{\Xi}_\varepsilon(U_\varepsilon^{n-1})$. As $\widetilde{\Lambda}_\varepsilon(\cdot)$ and $\widetilde{\Xi}_\varepsilon(\cdot)$ are

now degenerate, existence of a solution $\{\Phi_\varepsilon^n, U_\varepsilon^n, W_\varepsilon^n\}$ to $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ does not appear to be trivial. However, this can easily be established by splitting the nodes into passive and active sets; see, e.g., [3]. Moreover, one can show that U_ε^n is unique, $\Phi_\varepsilon^n(p_j)$ is unique if $(\widetilde{\Lambda}_\varepsilon(U_\varepsilon^{n-1}), \chi_j) > 0$, and $W_\varepsilon^n(p_j)$ is unique if $(\widetilde{\Xi}_\varepsilon(U_\varepsilon^{n-1}), \chi_j) > 0$. Furthermore, one can establish analogues of the energy estimates (2.42) and (2.43). Unfortunately, it does not appear possible to establish an analogue of the key energy estimate (2.44) for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$.

3. Convergence. Let

$$U_\varepsilon(t) := \tfrac{t-t_{n-1}}{\tau_n}\, U_\varepsilon^n + \tfrac{t_n-t}{\tau_n}\, U_\varepsilon^{n-1}, \qquad t \in [t_{n-1}, t_n], \quad n \geq 1, \tag{3.1a}$$

$$U_\varepsilon^+(t) := U_\varepsilon^n, \qquad U_\varepsilon^-(t) := U_\varepsilon^{n-1}, \qquad t \in (t_{n-1}, t_n], \qquad n \geq 1. \tag{3.1b}$$

We note for future reference that

$$U_\varepsilon - U_\varepsilon^\pm = (t - t_n^\pm)\, \tfrac{\partial U_\varepsilon}{\partial t}, \qquad t \in (t_{n-1}, t_n), \quad n \geq 1, \tag{3.2}$$

where $t_n^+ := t_n$ and $t_n^- := t_{n-1}$. We introduce also

$$\bar\tau(t) := \tau_n, \qquad t \in (t_{n-1}, t_n], \quad n \geq 1. \tag{3.3}$$

Using the above notation and introducing analogous notation for W_ε^+ and Φ_ε^+, $(\mathrm{P}_\varepsilon^{h,\tau})$ can be restated as follows: Find $\{\Phi_\varepsilon^+, U_\varepsilon, W_\varepsilon^+\} \in L^\infty(0,T;S^h) \times C([0,T];K^h) \times L^\infty(0,T;S^h)$ such that for all $\chi \in L^\infty(0,T;S^h)$ and $z^h \in L^\infty(0,T;K^h)$

$$\int_0^T (\Lambda_\varepsilon(U_\varepsilon^-)\, \nabla\Phi_\varepsilon^+, \nabla\chi)\, \mathrm{d}t + \int_0^T \int_{\partial_2\Omega} \Phi_\varepsilon^+\, \chi\, \mathrm{d}s\, \mathrm{d}t = \int_0^T \int_{\partial_2\Omega} g\, \chi\, \mathrm{d}s\, \mathrm{d}t, \tag{3.4a}$$

$$\int_0^T \Big[\gamma\, \big(\tfrac{\partial U_\varepsilon}{\partial t}, \chi\big)^h + (\Xi_\varepsilon(U_\varepsilon^-)\, \nabla[W_\varepsilon^+ + \alpha\, \Phi_\varepsilon^+], \nabla\chi)\Big]\, \mathrm{d}t = 0, \tag{3.4b}$$

$$\gamma \int_0^T (\nabla U_\varepsilon^+, \nabla[z^h - U_\varepsilon^+])\, \mathrm{d}t \geq \int_0^T (W_\varepsilon^+ + \gamma^{-1}\, U_\varepsilon^-, z^h - U_\varepsilon^+)^h\, \mathrm{d}t. \tag{3.4c}$$

LEMMA 3.1. *Let $u^0 \in K$ with $\fint u^0 \in (-1,1)$. Let $\{\mathcal{T}^h, U_\varepsilon^0, \{\tau_n\}_{n=1}^N, \varepsilon\}_{h>0}$ be such that*

(i) *either $U_\varepsilon^0 \equiv Q^h u^0$ or $U_\varepsilon^0 \equiv \pi^h u^0$ if $u^0 \in W^{1,p}(\Omega)$ with $p > 2$;*
(ii) *Ω and $\{\mathcal{T}^h\}_{h>0}$ fulfill assumptions* (A)*, $\varepsilon \in (0,1)$ with $\varepsilon \to 0$ as $h \to 0$, and $\tau_n \leq C\, \tau_{n-1} \leq C\, \varepsilon^2$, $n = 2 \to N$.*

Then there exists a subsequence of $\{\Phi_\varepsilon^+, U_\varepsilon, W_\varepsilon^+\}_h$, where $\{\Phi_\varepsilon^+, U_\varepsilon, W_\varepsilon^+\}$ solve $(\mathrm{P}_\varepsilon^{h,\tau})$, and a function

$$u \in L^\infty(0,T;K) \cap H^1(0,T;(H^1(\Omega))') \tag{3.5}$$

with $u(\cdot,0) = u^0(\cdot)$ in $L^2(\Omega)$ and $\fint u(\cdot,t) = \fint u^0$ for a.a. $t \in (0,T)$ such that as $h \to 0$

$$U_\varepsilon,\ U_\varepsilon^\pm \to u \qquad \text{weak-}* \text{ in } L^\infty(0,T;H^1(\Omega)), \tag{3.6a}$$

$$\mathcal{G}\tfrac{\partial U_\varepsilon}{\partial t} \to \mathcal{G}\tfrac{\partial u}{\partial t} \qquad \text{weakly in } L^2(0,T;H^1(\Omega)), \tag{3.6b}$$

$$U_\varepsilon,\ U_\varepsilon^\pm \to u \qquad \text{strongly in } L^2(0,T;L^s(\Omega)), \tag{3.7a}$$

$$\Xi_\varepsilon(U_\varepsilon^-) \to b(u)\, \mathcal{I} \qquad \text{strongly in } L^2(0,T;L^s(\Omega)), \tag{3.7b}$$

$$\Lambda_\varepsilon(U_\varepsilon^-) \to c(u)\, \mathcal{I} \qquad \text{strongly in } L^2(0,T;L^s(\Omega)) \tag{3.7c}$$

for all $s \in [2,\infty)$. *If, in addition,* $u^0 \in H^2(\Omega)$ *with* $\frac{\partial u^0}{\partial \nu} = 0$ *on* $\partial\Omega$, $U_\varepsilon^0 \equiv \pi^h u^0$, *and*

$$\alpha^2 \int_0^T |\pi^h [F_\varepsilon'(U_\varepsilon^-)]|^2_{0,\partial_2\Omega} \,\mathrm{d}t \le C, \tag{3.8}$$

then u, *in addition to* (3.5), *satisfies*

$$u \in L^2(0,T;H^2(\Omega)) \tag{3.9}$$

and there exists a subsequence of $\{\Phi_\varepsilon^+, U_\varepsilon, W_\varepsilon^+\}_h$ *satisfying* (3.6a), (3.6b), (3.7a)–(3.7c) *and as* $h \to 0$

$$\Delta^h U_\varepsilon,\ \Delta^h U_\varepsilon^\pm \to \Delta u \qquad \text{weakly in } L^2(\Omega_T), \tag{3.10a}$$

$$U_\varepsilon,\ U_\varepsilon^\pm \to u \qquad \text{weakly in } L^2(0,T;W^{1,s}(\Omega)) \quad \text{for any } s \in [2,\infty), \tag{3.10b}$$

$$U_\varepsilon \to u \qquad \text{strongly in } L^2(0,T;C^{0,\beta}(\overline{\Omega})) \quad \text{for any } \beta \in (0,1). \tag{3.10c}$$

Proof. Noting the definitions (3.1a), (3.1b) and (3.3), the bounds in (2.28), (2.42), and (2.43), together with (1.14), (2.48) and our assumption (i), imply that

$$\begin{aligned} &\| [\Lambda_\varepsilon(U_\varepsilon^-)]^{\frac12} \nabla \Phi_\varepsilon^+ \|^2_{L^2(\Omega_T)} + \|\Phi_\varepsilon^+\|^2_{L^2(0,T;L^2(\partial_2\Omega))} + \|U_\varepsilon^{(\pm)}\|^2_{L^\infty(0,T;H^1(\Omega))} \\ &\quad + \|\bar\tau^{\frac12} \tfrac{\partial U_\varepsilon}{\partial t}\|^2_{L^2(0,T;H^1(\Omega))} + \| [\Xi_\varepsilon(U_\varepsilon^-)]^{\frac12} \nabla W_\varepsilon^+ \|^2_{L^2(\Omega_T)} + \|\mathcal{G} \tfrac{\partial U_\varepsilon}{\partial t}\|^2_{L^2(0,T;H^1(\Omega))} \\ &\quad + \tau^{-\frac12} \|\bar\tau^{\frac12} \tfrac{\partial U_\varepsilon}{\partial t}\|^2_{L^2(\Omega_T)} \le C. \end{aligned} \tag{3.11}$$

Furthermore, we deduce from (3.2) and (3.11) that

$$\|U_\varepsilon - U_\varepsilon^\pm\|^2_{L^2(0,T;H^1(\Omega))} \le \|\bar\tau \tfrac{\partial U_\varepsilon}{\partial t}\|^2_{L^2(0,T;H^1(\Omega))} \le C\,\tau\,. \tag{3.12}$$

Hence on noting (3.11), (3.12), $U_\varepsilon(\cdot,t) \in K^h$, and (1.12a) we can choose a subsequence $\{\Phi_\varepsilon^+, U_\varepsilon, W_\varepsilon^+\}_h$ such that the convergence results (3.5), (3.6a), (3.6b), and (3.7a) hold. Then (3.5) and Theorem 2.6 yield, on noting (1.12b), assumption (i), (2.21), and (2.17), that the subsequence satisfies the additional initial and integral conditions.

We now prove (3.7b). We have that

$$\begin{aligned} \|b(u)\,\mathcal{I} - \Xi_\varepsilon(U_\varepsilon^-)\|_{L^2(0,T;L^s(\Omega))} &\le \|b(u) - b(U_\varepsilon^-)\|_{L^2(0,T;L^s(\Omega))} \\ &\quad + \|b(U_\varepsilon^-) - b_\varepsilon(U_\varepsilon^-)\|_{L^2(0,T;L^s(\Omega))} + \|b_\varepsilon(U_\varepsilon^-)\,\mathcal{I} - \Xi_\varepsilon(U_\varepsilon^-)\|_{L^2(0,T;L^s(\Omega))}. \end{aligned} \tag{3.13}$$

Noting the Lipschitz continuity of b on $\mathcal{K}$, (2.27b), (2.15), and (3.11), we have that

$$\begin{aligned} &\|b(u) - b(U_\varepsilon^-)\|_{L^2(0,T;L^s(\Omega))} + \|b_\varepsilon(U_\varepsilon^-)\,\mathcal{I} - \Xi_\varepsilon(U_\varepsilon^-)\|_{L^2(0,T;L^s(\Omega))} \\ &\qquad \le 2\,\|u - U_\varepsilon^-\|_{L^2(0,T;L^s(\Omega))} + C\,h^{\frac{2}{s}}\,\|\nabla U_\varepsilon^-\|_{L^2(\Omega_T)} \\ &\qquad \le 2\,\|u - U_\varepsilon^-\|_{L^2(0,T;L^s(\Omega))} + C\,h^{\frac{2}{s}}. \end{aligned} \tag{3.14}$$

It follows from (2.25b) and (1.6) that

$$\|b(U_\varepsilon^-) - b_\varepsilon(U_\varepsilon^-)\|_{L^2(0,T;L^s(\Omega))} \le C\,b_\varepsilon(1) \le C\,\varepsilon\,. \tag{3.15}$$

Combining (3.13), (3.14), (3.15) and noting (3.7a) and our assumption (ii) on ε yield the desired result (3.7b). A similar argument to the above yields the desired result (3.7c).

We now prove the results (3.10a)–(3.10c). It follows from (2.3), (2.18), (2.23), (2.16), our assumptions on u^0, and (2.14) that

$$\begin{aligned}|\Delta^h U_\varepsilon^0|_0^2 &= |\Delta^h(\pi^h u^0)|_0^2 \leq |\Delta^h(\pi^h u^0)|_h^2 = -(\nabla(\pi^h u^0), \nabla(\Delta^h(\pi^h u^0)))\\ &= -(\nabla u^0, \nabla(\Delta^h(\pi^h u^0))) + (\nabla(I-\pi^h)u^0, \nabla(\Delta^h(\pi^h u^0)))\\ &\leq |\Delta u^0|_0\, |\Delta^h(\pi^h u^0)|_0 + C\, h\, |u^0|_2\, |\nabla(\Delta^h(\pi^h u^0))|_0 \leq C\, |u^0|_2^2 \leq C. \end{aligned} \tag{3.16}$$

Moreover, (2.44), (2.48), (3.16), (2.3), (2.18), (3.1a), (3.1b), and our assumption (ii) on $\{\tau_n\}_{n=1}^N$ yield that

$$\|\Delta^h U_\varepsilon^{(\pm)}\|_{L^2(\Omega_T)} \leq C\,. \tag{3.17}$$

From (3.17), (2.23), (2.17), (2.19), (3.11), and (3.6a) we have for any $\eta \in L^2(0,T; W^{1,q}(\Omega))$, $q > 2$, that

$$\begin{aligned}\int_0^T (\Delta^h U_\varepsilon^{(\pm)}, \eta)\,\mathrm{d}t &= \int_0^T (\Delta^h U_\varepsilon^{(\pm)}, (I-\pi^h)\eta)\,\mathrm{d}t\\ &\quad + \int_0^T \Big[\,(\Delta^h U_\varepsilon^{(\pm)}, \pi^h\,\eta) - (\Delta^h U_\varepsilon^{(\pm)}, \pi^h\,\eta)^h\,\Big]\,\mathrm{d}t\\ &\quad + \int_0^T (\nabla U_\varepsilon^{(\pm)}, \nabla(I-\pi^h)\eta)\,\mathrm{d}t - \int_0^T (\nabla U_\varepsilon^{(\pm)}, \nabla\eta)\,\mathrm{d}t\\ &\to -\int_0^T (\nabla u, \nabla\eta)\,\mathrm{d}t \qquad \text{as } h \to 0\,. \end{aligned} \tag{3.18}$$

Combining (3.17), (3.18), and the denseness of $L^2(0,T;W^{1,q}(\Omega))$ in $L^2(\Omega_T)$ yields (3.10a) and, in particular, $\Delta u \in L^2(\Omega_T)$. This, together with elliptic regularity, as Ω is a rectangle, and (3.5), proves (3.9). Furthermore, it follows from (3.10a) and (2.24) that (3.10b) holds on extracting a further subsequence. Finally, (3.10c) follows from (3.10b), (3.6b), (1.12a), and the compact embedding $W^{1,s}(\Omega) \hookrightarrow C^{0,\beta}(\overline{\Omega})$. ∎

Remark 3.2. The conditions $u^0 \in H^2(\Omega)$ with $\frac{\partial u^0}{\partial \nu} = 0$ on $\partial\Omega$ for the results (3.10a)–(3.10c) can be replaced by a restriction on τ_1 in terms of h (see [7, Lemma 3.1]), but they are not particularly restrictive. The assumption (3.8) holds if $U_\varepsilon(x,t) = 1$ for all $x \in \partial_2\Omega$ and $t \in [0,T]$, and this condition held in all our numerical experiments, provided $u^0 = 1$ on $\partial_2\Omega$ and either L_1 is chosen sufficiently large or T is chosen sufficiently small. This can be made rigorous for the approximation $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ (see Remark 2.10), as the degeneracy of $\widetilde{\Xi}_\varepsilon$ leads to finite speed of propagation of the numerical interfacial region; at each time level it can move locally at most one mesh point; see [3].

In addition to the above lemma, we need the following two lemmas in order to prove our main result, Theorem 3.6 below.

LEMMA 3.3. *Let all the assumptions of Lemma* 3.1 *hold. If, in addition,* $\tau_n = \tau$, $n = 1 \to N$, *then*

$$\int_0^{T-\theta} |U_\varepsilon^\pm(t+\theta) - U_\varepsilon^\pm(t)|_0^2\,\mathrm{d}t \leq C\,\theta \qquad \forall\ \theta \in (0,T). \tag{3.19}$$

Moreover, it holds that the subsequence of $\{\Phi_\varepsilon^+, U_\varepsilon, W_\varepsilon^+\}_h$ *in Lemma* 3.1 *is such that for any* $\beta \in (0,1)$

$$U_\varepsilon^\pm \to u \qquad \textit{strongly in } L^2(0,T;C^{0,\beta}(\overline{\Omega})) \qquad \textit{as } h \to 0; \tag{3.20a}$$

and, on extracting a further subsequence, it holds for a.a. $t \in (0,T)$ *that*

$$U_\varepsilon^\pm(\cdot,t) \to u(\cdot,t) \qquad \text{strongly in } C^{0,\beta}(\overline{\Omega}) \qquad \text{as } h \to 0. \tag{3.20b}$$

Proof. The proof is similar to the proofs in [16, Lemmas 7.1 and 8.8]; see also [7, Lemma 3.2]. It follows from (2.13b) for $m = 0 \to N-l$, $l \in \{1,\dots,N\}$ fixed, that

$$\begin{aligned} &\gamma \sum_{n=m+1}^{m+l} \tau_n \left(\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}, U_\varepsilon^{m+l} - U_\varepsilon^m\right)^h \\ &\qquad = -\sum_{n=m+1}^{m+l} \tau_n \left(\Xi_\varepsilon(U_\varepsilon^{n-1})\, \nabla[W_\varepsilon^n + \alpha\, \Phi_\varepsilon^n], \nabla(U_\varepsilon^{m+l} - U_\varepsilon^m)\right). \end{aligned} \tag{3.21}$$

Similarly to (2.46), we obtain from (3.21) and (2.26b), (2.26c) that

$$\gamma\, |U_\varepsilon^{m+l} - U_\varepsilon^m|_h^2 \le \sum_{n=m+1}^{m+l} \tau_n\, a_n\, |U_\varepsilon^{m+l} - U_\varepsilon^m|_1 = \sum_{k=1}^{l} \tau_{m+k}\, a_{m+k}\, |U_\varepsilon^{m+l} - U_\varepsilon^m|_1, \tag{3.22}$$

where $a_n := |[\Xi_\varepsilon(U_\varepsilon^{n-1})]^{\frac12}\, \nabla W_\varepsilon^n|_0 + 2^{\frac12}\, \alpha\, |[\Lambda_\varepsilon(U_\varepsilon^{n-1})]^{\frac12}\, \nabla \Phi_\varepsilon^n|_0$. Summing (3.22) for $m = 0 \to N-l$ and using the uniform time step assumption yield on noting (2.28), (2.42), and (2.48) that

$$\begin{aligned} \gamma \sum_{m=0}^{N-l} \tau\, |U_\varepsilon^{m+l} - U_\varepsilon^m|_h^2 &\le \sum_{k=1}^{l} \tau \sum_{m=0}^{N-l} \tau\, a_{m+k}\, |U_\varepsilon^{m+l} - U_\varepsilon^m|_1 \\ &\le \sum_{k=1}^{l} \tau \left[\sum_{m=0}^{N-l} \tau\, a_{m+k}^2\right]^{\frac12} \left[\sum_{m=0}^{N-l} \tau\, |U_\varepsilon^{m+l} - U_\varepsilon^m|_1^2\right]^{\frac12} \le C\, l\, \tau. \end{aligned} \tag{3.23}$$

Combining (3.23), (2.3), (2.18), and (3.1b) yields (3.19) for $\theta = l\,\tau$. For arbitrary $\theta \in (0,T)$ with $\theta = \mu\,\tau$, $\mu \in (0,N)$, we argue as follows. On recalling (1.16b), let $l = \lfloor \mu \rfloor$, $\vartheta = \mu - \lfloor \mu \rfloor \in [0,1)$ and $m \in \{0,\dots,N-l\}$ be such that $t \in (m\,\tau, (m+1)\,\tau]$. Hence

$$U_\varepsilon^\pm(t + \mu\,\tau) = \begin{cases} U_\varepsilon^\pm(t + l\,\tau) & \text{if } \ t \in (m\,\tau, m\,\tau + (1-\vartheta)\,\tau], \\ U_\varepsilon^\pm(t + (l+1)\,\tau) & \text{if } \ t \in (m\,\tau + (1-\vartheta)\,\tau, (m+1)\,\tau], \end{cases}$$

and we obtain on noting (3.23) that

$$\begin{aligned} &\gamma \int_0^{T-\mu\,\tau} |U_\varepsilon^\pm(t + \mu\,\tau) - U_\varepsilon^\pm(t)|_h^2 \,\mathrm{d}t \\ &\qquad \le \tau\,(1-\vartheta) \sum_{m=0}^{N-l} |U_\varepsilon^{m+l} - U_\varepsilon^m|_h^2 + \tau\,\vartheta \sum_{m=0}^{N-l-1} |U_\varepsilon^{m+l+1} - U_\varepsilon^m|_h^2 \\ &\qquad \le C\,[(1-\vartheta)\,l + \vartheta\,(l+1)]\,\tau = C\,\mu\,\tau. \end{aligned} \tag{3.24}$$

Combining (3.24), (2.3), and (2.18) yields (3.19) for all $\theta \in (0,T)$. It follows from (3.10b) and (3.19), on noting (1.12c) and the compact embedding $W^{1,s}(\Omega) \hookrightarrow C^{0,\beta}(\overline{\Omega})$, that (3.20a) holds. Finally, the desired result (3.20b) follows immediately from (3.20a). ∎

From (3.11), (2.26a), (2.26b), (2.25a), (2.25b), (1.6), and (3.20b) we see that we can only control $\nabla\Phi_\varepsilon^+$ and ∇W_ε^+ on the sets where $\Lambda_\varepsilon(U_\varepsilon^-)$ and $\Xi_\varepsilon(U_\varepsilon^-)$ are bounded below independently of ε, and hence h on noting (ii), i.e., on the sets where $u > -1$ and $|u| < 1$, respectively. Therefore in order to construct the appropriate limits as $h \to 0$, we introduce the following open subsets of $\overline{\Omega}$. For any $\delta \in (0,1)$, we define for a.a. $t \in (0,T)$

$$B_\delta(t) := \{\, x \in \overline{\Omega} : |u(x,t)| < 1-\delta \,\} \subset D_\delta(t) := \{\, x \in \overline{\Omega} : -1+\delta < u(x,t) \,\}\,. \tag{3.25}$$

From (3.20b) we have that there exist positive constants $C_x(t)$ such that

$$|u(y,t) - u(z,t)| \le C_x(t)\,|y-z|^\beta \qquad \forall\ y,\ z \in \overline{\Omega} \quad \text{for a.a. } t \in (0,T). \tag{3.26}$$

As $\fint u(\cdot,t) = \fint u^0 \in (-1,1)$ for a.a. $t \in (0,T)$, it follows that there exists a $\delta_0 \in (0, 1 - |\fint u^0|\,)$ such that $D_{\delta_0}(t) \supset B_{\delta_0}(t) \not\equiv \emptyset$ for a.a. $t \in (0,T)$. It immediately follows from (3.25) and (3.26) for a.a. $t \in (0,T)$ and for any δ_1, $\delta_2 \in (0,\delta_0)$ with $\delta_1 > \delta_2$ that

$$\begin{aligned} &\text{either} \quad y \in B_{\delta_1}(t) \text{ and } z \in \partial B_{\delta_2}(t) \quad \text{or} \quad y \in D_{\delta_1}(t) \text{ and } z \in \partial D_{\delta_2}(t) \quad \text{with } z \notin \partial\Omega \\ &\quad \Longrightarrow \qquad C_x(t)\,|y-z|^\beta \ge u(y,t) - u(z,t) > (\delta_1 - \delta_2), \end{aligned}$$

where $\partial B_\delta(t)$ and $\partial D_\delta(t)$ are the boundaries of $B_\delta(t)$ and $D_\delta(t)$, respectively. This implies that for a.a. $t \in (0,T)$ and any $\delta \in (0,\delta_0)$ there exists an $h_0(\delta,t)$ such that for all $h \le h_0(\delta,t)$ there exist collections of simplices $\mathcal{T}^h_{B,\delta}(t) \subset \mathcal{T}^h_{D,\delta}(t) \subset \mathcal{T}^h$ such that

$$B_\delta(t) \subset B^h_\delta(t) := \cup_{\sigma\in\mathcal{T}^h_{B,\delta}(t)}\,\overline{\sigma} \subset B_{\frac{\delta}{2}}(t)\,, \qquad D_\delta(t) \subset D^h_\delta(t) := \cup_{\sigma\in\mathcal{T}^h_{D,\delta}(t)}\,\overline{\sigma} \subset D_{\frac{\delta}{2}}(t)\,. \tag{3.27}$$

Clearly, we have from (3.25) that

$$\delta_2 < \delta_1 < \delta_0 \qquad \Longrightarrow \qquad h_0(\delta_2,t) \le h_0(\delta_1,t)\,.$$

For a.a. $t \in (0,T)$ and any fixed $\delta \in (0,\widehat{\delta}_0)$, where $\widehat{\delta}_0 := \min\{\delta_0, \frac{1}{2}\}$, it follows from (3.25), (3.20b), and our assumption (ii) of Lemma 3.1 that there exists an $\widehat{h}_0(\delta,t) \le h_0(\delta,t)$ such that for $h \le \widehat{h}_0(\delta,t)$

$$1 - 2\,\delta \le |U_\varepsilon^\pm(x,t)| \quad \forall\ x \notin B_\delta(t), \quad |U_\varepsilon^\pm(x,t)| \le 1 - \tfrac{\delta}{2} \qquad \forall\ x \in B_\delta(t)\,, \tag{3.28a}$$

$$U_\varepsilon^\pm(x,t) \le -1 + 2\,\delta \quad \forall\ x \notin D_\delta(t), \qquad -1 + \tfrac{\delta}{2} \le U_\varepsilon^\pm(x,t) \quad \forall\ x \in D_\delta(t), \tag{3.28b}$$

and

$$\varepsilon \leq \delta\,. \tag{3.29}$$

LEMMA 3.4. *Let all the assumptions of Lemma* 3.3 *hold. Then for a.a.* $t \in (0,T)$ *there exist functions*

$$\phi(\cdot,t) \in H^1_{loc}(\{u(\cdot,t) > -1\}),\ \ w(\cdot,t) \equiv -\gamma\,\Delta u(\cdot,t) - \gamma^{-1}\,u(\cdot,t) \in H^1_{loc}(\{|u(\cdot,t)| < 1\}), \tag{3.30}$$

where $\{u(\cdot,t) > -1\} := \{x \in \Omega : u(x,t) > -1\}$ *and* $\{|u(\cdot,t)| < 1\} := \{x \in \Omega : |u(x,t)| < 1\}$. *Moreover, on assuming that*

$$u(x,t) = 1 \qquad \forall\ x \in \partial_2\Omega, \quad \text{for a.a. } t \in (0,T)\,, \tag{3.31}$$

and extracting a further subsequence from the subsequence $\{\Phi^+_\varepsilon, U_\varepsilon, W^+_\varepsilon\}_h$ *in Lemma* 3.3, *it holds as* $h \to 0$ *that*

$$\Phi^+_\varepsilon \to \phi \qquad \text{weakly in } L^2(0,T;L^2(\partial_2\Omega))\,, \tag{3.32a}$$

$$\Lambda_\varepsilon(U^-_\varepsilon)\,\nabla\Phi^+_\varepsilon \to \mathcal{H}_{\{u>-1\}}\,c(u)\,\nabla\phi \qquad \text{weakly in } L^2(\Omega_T), \tag{3.32b}$$

$$\Xi_\varepsilon(U^-_\varepsilon)\,\nabla\Phi^+_\varepsilon \to \mathcal{H}_{\{|u|<1\}}\,b(u)\,\nabla\phi \qquad \text{weakly in } L^2(\Omega_T), \tag{3.32c}$$

$$\Xi_\varepsilon(U^-_\varepsilon)\,\nabla W^+_\varepsilon \to \mathcal{H}_{\{|u|<1\}}\,b(u)\,\nabla w \qquad \text{weakly in } L^2(\Omega_T), \tag{3.32d}$$

where $\mathcal{H}_{\{u>-1\}}$ *and* $\mathcal{H}_{\{|u|<1\}}$ *are the characteristic functions of the sets* $\{u > -1\} := \{(x,t) \in \Omega_T : u(x,t) > -1\}$ *and* $\{|u| < 1\} := \{(x,t) \in \Omega_T : |u(x,t)| < 1\}$, *respectively.*

Proof. It follows from (3.11) and (2.26a)–(2.26c) that

$$\|\Lambda_\varepsilon(U^-_\varepsilon)\nabla\Phi^+_\varepsilon\|^2_{L^2(\Omega_T)} + \|\Xi_\varepsilon(U^-_\varepsilon)\nabla\Phi^+_\varepsilon\|^2_{L^2(\Omega_T)} + \|\Xi_\varepsilon(U^-_\varepsilon)\nabla W^+_\varepsilon\|^2_{L^2(\Omega_T)} \leq C. \tag{3.33}$$

Hence (3.33) implies that there exist functions $\underline{z}_i \in L^2(\Omega_T)$, $i = 1 \to 3$, and, on extracting a further subsequence from the subsequence $\{\Phi^+_\varepsilon, U_\varepsilon, W^+_\varepsilon\}_h$ in Lemma 3.3, it holds as $h \to 0$ that

$$\Lambda_\varepsilon(U^-_\varepsilon)\nabla\Phi^+_\varepsilon \to \underline{z}_1\,,\ \Xi_\varepsilon(U^-_\varepsilon)\nabla\Phi^+_\varepsilon \to \underline{z}_2\,,\ \Xi_\varepsilon(U^-_\varepsilon)\nabla W^+_\varepsilon \to \underline{z}_3 \quad \text{weakly in } L^2(\Omega_T)\,. \tag{3.34}$$

We now identify the functions $\underline{z}_i$.

First, we consider a fixed $\delta \in (0, \delta_0)$. It follows from (1.6), (2.25a), (2.25b), (2.26a), (2.26b), (3.28a), (3.28b), and (3.11) that for a.a. $t \in (0,T)$ and for all $h \leq \widehat{h}_0(\delta, t)$

$$\begin{aligned}
\tfrac{\delta}{2}\,|\nabla\Phi_\varepsilon^+(\cdot,t)|^2_{0,D_\delta(t)} &= c(-1+\tfrac{\delta}{2})\,|\nabla\Phi_\varepsilon^+(\cdot,t)|^2_{0,D_\delta(t)} \\
&\leq c_\varepsilon(-1+\tfrac{\delta}{2})\,|\nabla\Phi_\varepsilon^+(\cdot,t)|^2_{0,D_\delta(t)} \\
&\leq |\,(\,[\Lambda_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla\Phi_\varepsilon^+)(\cdot,t)|^2_0 \leq C(t)\,, \qquad (3.35a)\\
\delta\,(1-\tfrac{\delta}{4})\,|\nabla W_\varepsilon^+(\cdot,t)|^2_{0,B_\delta(t)} &= b(1-\tfrac{\delta}{2})\,|\nabla W_\varepsilon^+(\cdot,t)|^2_{0,B_\delta(t)} \\
&\leq b_\varepsilon(1-\tfrac{\delta}{2})\,|\nabla W_\varepsilon^+(\cdot,t)|^2_{0,B_\delta(t)} \\
&\leq |\,(\,[\Xi_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla W_\varepsilon^+)(\cdot,t)|^2_0 \leq C(t)\,. \qquad (3.35b)
\end{aligned}$$

From (3.35a), (3.35b), (3.27), (2.26a)–(2.26c), (3.28a), (3.28b), and (3.29) we have for a.a. $t \in (0,T)$ and for all $h \leq \widehat{h}_0(\delta,t)$

$$\begin{aligned}
&|\,(\Lambda_\varepsilon(U_\varepsilon^-)\,\nabla\Phi_\varepsilon^+)(\cdot,t)|^2_{0,\Omega\setminus D_\delta(t)} \\
&\qquad\leq \max_{x\in\Omega\setminus D_{2\delta}(t)} c_\varepsilon(U_\varepsilon^-(x))\,|\,(\,[\Lambda_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla\Phi_\varepsilon^+)(\cdot,t)|^2_{0,\Omega\setminus D_\delta(t)} \\
&\qquad\leq C(t)\,c_\varepsilon(-1+4\,\delta) \leq C(t)\,\max\{4\delta,\varepsilon\} \leq C(t)\,\delta\,, \qquad (3.36a)\\
&|\,(\Xi_\varepsilon(U_\varepsilon^-)\,\nabla\Phi_\varepsilon^+)(\cdot,t)|^2_{0,\Omega\setminus B_\delta(t)} \\
&\qquad\leq \max_{x\in\Omega\setminus B_{2\delta}(t)} 2\,b_\varepsilon(U_\varepsilon^-(x))\,|\,(\,[\Lambda_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla\Phi_\varepsilon^+)(\cdot,t)|^2_{0,\Omega\setminus B_\delta(t)} \\
&\qquad\leq C(t)\,b_\varepsilon(1-4\,\delta) \leq C(t)\,\max\{4\delta,\varepsilon\} \leq C(t)\,\delta\,, \qquad (3.36b)\\
&|\,(\Xi_\varepsilon(U_\varepsilon^-)\,\nabla W_\varepsilon^+)(\cdot,t)|^2_{0,\Omega\setminus B_\delta(t)} \\
&\qquad\leq \max_{x\in\Omega\setminus B_{2\delta}(t)} b_\varepsilon(U_\varepsilon^-(x))\,|\,(\,[\Xi_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla W_\varepsilon^+)(\cdot,t)|^2_{0,\Omega\setminus B_\delta(t)} \\
&\qquad\leq C(t)\,b_\varepsilon(1-4\,\delta) \leq C(t)\,\delta\,. \qquad (3.36c)
\end{aligned}$$

From (3.35a) and appealing to the de Rham theorem (see, e.g., [27, p. 10]), we have that there exists a function $\phi \in L^2_{loc}(D_\delta(t))$ with $\nabla\phi \in L^2(D_\delta(t))$ and, on extracting a further subsequence, such that for a.a. $t \in (0,T)$

$$\nabla\Phi_\varepsilon^+(\cdot,t) \to \nabla\phi(\cdot,t) \quad \text{weakly in } L^2(D_\delta(t)) \quad \text{as } h \to 0. \qquad (3.37)$$

In order to show (3.32a) we proceed as follows. On recalling (3.20b) and (3.31) we define open sets $D_L^\pm(t) \subset D_\delta(t)$ with Lipschitz boundaries $\partial D_L^\pm(t)$ such that $\partial_2^\pm\Omega \subset \partial D_L^\pm(t)$. Since $D_L^\pm(t)$ is a Lipschitz domain, Friedrich's inequality, (3.11), and a corresponding $D_L^\pm(t)$ version of (3.35a) yield that for a.a. $t \in (0,T)$ and for all $h \leq \widehat{h}_0(\delta,t)$

$$\|\Phi_\varepsilon^+(\cdot,t)\|^2_{1,D_L^\pm(t)} \leq C(t)\,[\,|\nabla\Phi_\varepsilon^+(\cdot,t)|^2_{0,D_L^\pm(t)} + |\Phi_\varepsilon^+(\cdot,t)|^2_{0,\partial_2^\pm\Omega}\,] \leq C(t)\,. \qquad (3.38)$$

Combining (3.38) and (3.37) yields that

$$\Phi_\varepsilon^+(\cdot,t) \to \phi(\cdot,t) \quad \text{weakly in } H^1(D_L^\pm(t)) \quad \text{as } h \to 0. \qquad (3.39)$$

Then we define the following elliptic operators $\mathcal{F}^\pm : L^2(\partial_2^\pm\Omega) \to H^1(D_L^\pm(t))$:

$$\int_{D_L^\pm(t)} \left[\nabla[\mathcal{F}^\pm z].\nabla\eta + [\mathcal{F}^\pm z]\,\eta\right]\,\mathrm{d}x = \int_{\partial_2^\pm\Omega} z\,\eta\,\mathrm{d}s \qquad \forall\ \eta \in H^1(D_L^\pm(t)).$$

On noting that $\partial_2^\pm\Omega \subset \partial D_L^\pm(t)$, we have from (3.37) and (3.39) for a.a. $t \in (0,T)$ and any $\eta \in L^2(\partial_2^\pm\Omega)$ that

$$\int_{\partial_2^\pm\Omega} \Phi_\varepsilon^+(\cdot,t)\,\eta\,\mathrm{d}s = \int_{D_L^\pm(t)} \left[\nabla\Phi_\varepsilon^+(\cdot,t).\nabla[\mathcal{F}^\pm\eta] + \Phi_\varepsilon^+(\cdot,t)\,\mathcal{F}^\pm\eta\right]\,\mathrm{d}x$$

$$\to \int_{D_L^\pm(t)} \left[\nabla\phi(\cdot,t).\nabla[\mathcal{F}^\pm\eta] + \phi(\cdot,t)\,\mathcal{F}^\pm\eta\right]\,\mathrm{d}x = \int_{\partial_2^\pm\Omega} \phi(\cdot,t)\,\eta\,\mathrm{d}s\,. \tag{3.40}$$

Combining (3.11) and (3.40) yields the desired result (3.32a).

On noting (3.17) we have for a.a. $t \in (0,T)$ that

$$|\Delta^h U_\varepsilon^+(\cdot,t)|_0 \le C(t)\,.$$

Similarly to (3.18) this yields for a.a. $t \in (0,T)$ that as $h \to 0$

$$\Delta^h U_\varepsilon^+(\cdot,t) \to \Delta u(\cdot,t) \qquad \text{weakly in } L^2(\Omega). \tag{3.41}$$

Combining (2.39), (2.23), (3.1b), (3.28a), and (3.27) yields for a.a. $t \in (0,T)$, and for all $h \le \widehat{h}_0(\frac{\delta}{2},t)$ that

$$W_\varepsilon^+(\cdot,t) \equiv -\gamma\,\Delta^h U_\varepsilon^+(\cdot,t) - \gamma^{-1}\,U_\varepsilon^-(\cdot,t) \qquad \text{on } B_\delta(t)\,. \tag{3.42}$$

It follows from (3.42), (3.41), and (3.20b) for a.a. $t \in (0,T)$ that as $h \to 0$

$$W_\varepsilon^+(\cdot,t) \to -\gamma\,\Delta u(\cdot,t) - \gamma^{-1}\,u(\cdot,t) \quad \text{weakly in } L^2(B_\delta(t)).$$

This, together with (3.35b), yields

$$W_\varepsilon^+(\cdot,t) \to w(\cdot,t) \quad \text{weakly in } H^1(B_\delta(t)). \tag{3.43}$$

Combining (3.34), (3.37), (3.43), and (3.7b), (3.7c) yields for a.a. $t \in (0,T)$ that as $h \to 0$

$$(\Lambda_\varepsilon(U_\varepsilon^-)\nabla\Phi_\varepsilon^+)(\cdot,t) \to c(u(\cdot,t))\,\nabla\phi(\cdot,t) \qquad \text{weakly in } L^2(D_\delta(t)), \tag{3.44a}$$

$$(\Xi_\varepsilon(U_\varepsilon^-)\nabla\Phi_\varepsilon^+)(\cdot,t) \to b(u(\cdot,t))\,\nabla\phi(\cdot,t) \qquad \text{weakly in } L^2(B_\delta(t)), \tag{3.44b}$$

$$(\Xi_\varepsilon(U_\varepsilon^-)\nabla W_\varepsilon^+)(\cdot,t) \to b(u(\cdot,t))\,\nabla w(\cdot,t) \qquad \text{weakly in } L^2(B_\delta(t)). \tag{3.44c}$$

Repeating (3.35a), (3.35b)–(3.37) and (3.42)–(3.44a)–(3.44c) for all $\delta \in (0,\widehat{\delta}_0)$ yields, on recalling (3.20b), that (3.30) holds and, on noting (3.36a)–(3.36c) and (3.34), the desired results (3.32b)–(3.32d). ∎

Remark 3.5. The assumption (3.31) is similar to the assumption (3.8); see Remark 3.2.

THEOREM 3.6. *Let the assumptions of Lemma* 3.4 *hold. Then there exists a subsequence of* $\{\Phi_\varepsilon^+, U_\varepsilon, W_\varepsilon^+\}_h$, *where* $\{\Phi_\varepsilon^+, U_\varepsilon, W_\varepsilon^+\}$ *solve* $(\mathrm{P}_\varepsilon^{h,\tau})$, *and functions* $\{\phi,u,w\}$ *satisfying* (3.5), (3.9), *and* (3.30). *In addition, as* $h \to 0$ *the following hold:* (3.6a), (3.6b), (3.7a)–(3.7c), (3.10a)–(3.10c), (3.20a), (3.20b) *for* a.a. $t \in (0,T)$, *and* (3.32a)–(3.32d). *Furthermore, we have that* $\{\phi,u,w\}$ *fulfill* $u(\cdot,0) = u^0(\cdot)$ *in* $L^2(\Omega)$ *and satisfy for all* $\eta \in L^2(0,T;H^1(\Omega))$

$$\int_{\{u>-1\}} c(u)\,\nabla\phi\,.\,\nabla\eta\,\mathrm{d}x\,\mathrm{d}t + \int_0^T \int_{\partial_2\Omega} \phi\,\eta\,\mathrm{d}s\,\mathrm{d}t = \int_0^T \int_{\partial_2\Omega} g\,\eta\,\mathrm{d}s\,\mathrm{d}t\,, \tag{3.45a}$$

$$\gamma \int_0^T \langle \tfrac{\partial u}{\partial t}, \eta\rangle\,\mathrm{d}t + \int_{\{|u|<1\}} b(u)\,\nabla\left[w + \alpha\,\phi\right]\,.\,\nabla\eta\,\mathrm{d}x\,\mathrm{d}t = 0\,, \tag{3.45b}$$

where $w(\cdot,t) \equiv -\gamma\,\Delta u(\cdot,t) - \gamma^{-1}u(\cdot,t)$ *on the set* $\{|u(\cdot,t)| < 1\}$ *for a.a.* $t \in (0,T)$.

Proof. For any $\eta \in H^1(0,T;H^2(\Omega))$ we choose $\chi \equiv \pi^h \eta$ in (3.4a), (3.4b) and now analyze the subsequent terms. First, (2.19), the embedding $H^1(0,T;X) \hookrightarrow C([0,T];X)$, (3.11), and (2.16) yield that

$$\begin{aligned}
&\left| \int_0^T \left[\left(\tfrac{\partial U_\varepsilon}{\partial t}, \pi^h \eta\right)^h - \left(\tfrac{\partial U_\varepsilon}{\partial t}, \pi^h \eta\right) \right] \mathrm{d}t \right| \\
&\quad = \left| - \int_0^T \left(U_\varepsilon, \tfrac{\partial (\pi^h \eta)}{\partial t} \right)^h \mathrm{d}t + (U_\varepsilon(\cdot,T), \pi^h \eta(\cdot,T))^h - (U_\varepsilon(\cdot,0), \pi^h \eta(\cdot,0))^h \right. \\
&\qquad \left. + \int_0^T \left(U_\varepsilon, \tfrac{\partial (\pi^h \eta)}{\partial t} \right) \mathrm{d}t - (U_\varepsilon(\cdot,T), \pi^h \eta(\cdot,T)) + (U_\varepsilon(\cdot,0), \pi^h \eta(\cdot,0)) \right| \\
&\quad \le C\, h\, \|U_\varepsilon\|_{L^\infty(0,T;L^2(\Omega))}\, \|\pi^h \eta\|_{H^1(0,T;H^1(\Omega))} \le C\, h\, \|\eta\|_{H^1(0,T;H^2(\Omega))}. \qquad (3.46)
\end{aligned}$$

Furthermore, it follows from (1.13), (3.11), and (2.16) that

$$\begin{aligned}
\left| \int_0^T \left(\tfrac{\partial U_\varepsilon}{\partial t}, (I - \pi^h)\eta \right) \mathrm{d}t \right| &\le C\, \|\mathcal{G} \tfrac{\partial U_\varepsilon}{\partial t}\|_{L^2(0,T;H^1(\Omega))}\, \|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\le C\, h\, \|\eta\|_{L^2(0,T;H^2(\Omega))}. \qquad (3.47)
\end{aligned}$$

Combining (3.46), (3.47), and (3.6b) yields that

$$\int_0^T \left(\tfrac{\partial U_\varepsilon}{\partial t}, \pi^h \eta \right)^h \mathrm{d}t \to \int_0^T \langle \tfrac{\partial u}{\partial t}, \eta \rangle \, \mathrm{d}t \quad \text{as } h \to 0. \qquad (3.48)$$

Moreover, it holds on noting (3.11), g as in (1.8), a trace inequality, and (2.16) that

$$\begin{aligned}
&\left| \int_0^T \int_{\partial_2 \Omega} (\Phi_\varepsilon^+ - g)\, (I - \pi^h)\eta \, \mathrm{d}s \, \mathrm{d}t \right| \\
&\quad \le \left[\|\Phi_\varepsilon^+\|_{L^2(0,T;L^2(\partial_2\Omega))} + \|g\|_{L^2(0,T;L^2(\partial_2\Omega))} \right] \|(I-\pi^h)\eta\|_{L^2(0,T;L^2(\partial_2\Omega))} \\
&\quad \le C\, \|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))} \le C\, h\, \|\eta\|_{L^2(0,T;H^2(\Omega))}. \qquad (3.49)
\end{aligned}$$

In view of (2.26a)–(2.26c), (3.11), and (2.16) we deduce that

$$\begin{aligned}
&\left| \int_0^T (\Xi_\varepsilon(U_\varepsilon^-)\, \nabla W_\varepsilon^+, \nabla (I - \pi^h)\eta) \, \mathrm{d}t \right| \\
&\qquad \le \|\Xi_\varepsilon(U_\varepsilon^-)\, \nabla W_\varepsilon^+\|_{L^2(\Omega_T)}\, \|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad \le \|[\Xi_\varepsilon(U_\varepsilon^-)]^{\frac{1}{2}}\, \nabla W_\varepsilon^+\|_{L^2(\Omega_T)}\, \|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad \le C\, h\, \|\eta\|_{L^2(0,T;H^2(\Omega))} \qquad (3.50a)
\end{aligned}$$

and, similarly,

$$\begin{aligned}
&\left| \int_0^T (\Lambda_\varepsilon(U_\varepsilon^-)\, \nabla \Phi_\varepsilon^+, \nabla (I - \pi^h)\eta) \, \mathrm{d}t \right| + \left| \int_0^T (\Xi_\varepsilon(U_\varepsilon^-)\, \nabla \Phi_\varepsilon^+, \nabla (I - \pi^h)\eta) \, \mathrm{d}t \right| \\
&\qquad \le C\, \|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))} \le C\, h\, \|\eta\|_{L^2(0,T;H^2(\Omega))}. \qquad (3.50b)
\end{aligned}$$

It follows from (3.50a), (3.50b) and (3.32b)–(3.32d) that as $h \to 0$

$$\int_0^T (\Lambda_\varepsilon(U_\varepsilon^-)\nabla\Phi_\varepsilon^+, \nabla(\pi^h\eta))\,\mathrm{d}t \to \int_{\{u>-1\}} c(u)\,\nabla\phi.\nabla\eta\,\mathrm{d}x\,\mathrm{d}t, \tag{3.51a}$$

$$\int_0^T (\Xi_\varepsilon(U_\varepsilon^-)\,\nabla\Phi_\varepsilon^+, \nabla(\pi^h\eta))\,\mathrm{d}t \to \int_{\{|u|<1\}} b(u)\,\nabla\phi.\nabla\eta\,\mathrm{d}x\,\mathrm{d}t, \tag{3.51b}$$

$$\int_0^T (\Xi_\varepsilon(U_\varepsilon^-)\,\nabla W_\varepsilon^+, \nabla(\pi^h\eta))\,\mathrm{d}t \to \int_{\{|u|<1\}} b(u)\,\nabla w.\nabla\eta\,\mathrm{d}x\,\mathrm{d}t. \tag{3.51c}$$

Combining (3.4a), (3.4b), (3.48), (3.49), (3.32a), (3.51a)–(3.51c), and the denseness of $H^1(0,T;\,H^2(\Omega))$ in $L^2(0,T;H^1(\Omega))$ yields the desired results (3.45a), (3.45b), on recalling (3.5) and (3.30). ∎

Remark 3.7. We note that it is possible to prove rigorously that the formally derived energy estimates (1.8), (1.10), and (1.11) are satisfied by the weak solution $\{\phi, u, w\}$. Using the techniques of the proof of Lemma 3.4, it is straightforward to derive from (3.11) and (3.7b), (3.7c) that as $h \to 0$

(3.52a)
$$[\Lambda_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla\Phi_\varepsilon^+ \to \underline{z}_1 \quad \text{weakly in } L^2(\Omega_T), \quad \text{with } \underline{z}_1 \equiv [c(u)]^{\frac12}\,\nabla\phi \text{ on } \{u>-1\};$$

(3.52b)
$$[\Xi_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla W_\varepsilon^+ \to \underline{z}_2 \quad \text{weakly in } L^2(\Omega_T), \quad \text{with } \underline{z}_2 \equiv [b(u)]^{\frac12}\,\nabla w \text{ on } \{|u|<1\}.$$

Combining (3.52a), (3.32a), and (2.28) then yields that

$$\begin{aligned}&\int_{\{u>-1\}} c(u)\,|\nabla\phi|^2\,\mathrm{d}x\,\mathrm{d}t + \tfrac12\int_0^T |\phi|^2_{0,\partial_2\Omega}\,\mathrm{d}t\\ &\le \liminf_{h\to0}\left\{\int_0^T |\,[\Lambda_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla\Phi_\varepsilon^+|_0^2\,\mathrm{d}t + \tfrac12\int_0^T |\Phi_\varepsilon^+|^2_{0,\partial_2\Omega}\,\mathrm{d}t\right\} \le \tfrac12\int_0^T |g|^2_{0,\partial_2\Omega}\,\mathrm{d}t\,.\end{aligned} \tag{3.53}$$

Similarly, it follows from (3.52b), (3.6a), (3.20b), (2.30a), and (2.16) that for a.a. $t \in (0,T)$

$$\begin{aligned}&\mathcal{E}(u(t)) + \gamma^{-1}\int_0^t \int_{\{|u(\cdot,\bar t)|<1\}} b(u)\,|\nabla w|^2\,\mathrm{d}x\,\mathrm{d}\bar t\\ &\qquad\le \liminf_{h\to0}\left\{\mathcal{E}(U_\varepsilon^+(t)) + \gamma^{-1}\int_0^t |\,[\Xi_\varepsilon(U_\varepsilon^-)]^{\frac12}\,\nabla W_\varepsilon^+|_0^2\,\mathrm{d}\bar t\right\}\\ &\qquad\le \lim_{h\to0}\mathcal{E}(U_\varepsilon^0) + \tfrac12\,\alpha^2\,\gamma^{-1}\,t\,|g|^2_{0,\partial_2\Omega} = \mathcal{E}(u^0) + \tfrac12\,\alpha^2\,\gamma^{-1}\,t\,|g|^2_{0,\partial_2\Omega}\,.\end{aligned} \tag{3.54}$$

We note that (3.53) and (3.54) correspond to the earlier formally derived energy estimates (1.8) and (1.10).

For the formally derived entropy estimate (1.11) we can argue as follows. First, it follows from (3.20b), (2.7), and assumption (ii) of Lemma 3.1 that for a.a. $t \in (0,T)$ as $h \to 0$

$$\begin{aligned}&|\,(G(u(\cdot,t)) - G_\varepsilon(U_\varepsilon^+(\cdot,t)),1)^h\,|\\ &\le |\,(G(u(\cdot,t)) - G(U_\varepsilon^+(\cdot,t)),1)^h\,| + |\,(G(U_\varepsilon^+(\cdot,t)) - G_\varepsilon(U_\varepsilon^+(\cdot,t)),1)^h\,| \;\to 0\,.\end{aligned} \tag{3.55}$$

Combining the convexity of G, (3.10a), (2.18), (2.44), (3.8), (3.55), (2.16), and assumption (ii) of Lemma 3.1 yields for a.a. $t \in (0,T)$ that

$$\begin{aligned}
\gamma\,(G(u(\cdot,t)),1) + \gamma \int_0^t |\Delta\, u|_0^2 \,\mathrm{d}\bar{t} &\le \gamma\,(G(u(\cdot,t)),1)^h + \gamma \int_0^t |\Delta\, u|_0^2 \,\mathrm{d}\bar{t} \\
&\le \lim_{h\to 0} \left\{ \gamma\,(G_\varepsilon(U_\varepsilon^+(\cdot,t)),1)^h + \gamma\,|\,(G(u(\cdot,t)) - G_\varepsilon(U_\varepsilon^+(\cdot,t)),1)^h\,| \,\right\} \\
&\quad + \gamma \liminf_{h\to 0} \int_0^t |\Delta^h\, U_\varepsilon^+|_h^2 \,\mathrm{d}\bar{t} \\
&\le \lim_{h\to 0} \{ \gamma\,(G_\varepsilon(U_\varepsilon^0),1)^h + \gamma\,|\,(G(u(\cdot,t)) - G_\varepsilon(U_\varepsilon^+(\cdot,t)),1)^h\,| \\
&\qquad + C(T)\,[1+\gamma^{-2}+\varepsilon^{-1}\,\tau^{\frac{1}{2}}\,]\,[\,\gamma\,\|U_\varepsilon^0\|_1^2 + \gamma^{-1}\,(1+T\,|g|_{0,\partial_2\Omega}^2)\,]\} \\
&= \gamma\,(G(u^0),1) + C(T)\,[1+\gamma^{-2}]\,[\,\gamma\,\|u^0\|_1^2 + \gamma^{-1}(\,1+T\,|g|_{0,\partial_2\Omega}^2)\,]\,.
\end{aligned}$$

This clearly corresponds to the formally derived estimate (1.11).

Remark 3.8. For our main convergence result, Theorem 3.6, we choose $U_\varepsilon^0 \equiv \pi^h u^0$. Therefore we require only the quasi-uniformity assumption in order to obtain (a) (2.43) via (2.46) and (2.21) and (b) (3.10b) via (3.10a) and (2.24). However, in case (a) we can replace the quasi uniformity with the far milder assumption that $\{\mathcal{T}^h\}_{h>0}$ is a regular partitioning at the expense of a minimum constraint on the uniform time step, similar to the argument in [2]. On recalling (1.13) and (2.22) it is easily established from $\{\mathcal{T}^h\}_{h>0}$ being a regular partitioning, elliptic regularity, as Ω is a rectangle, (1.14), and (2.19) that

$$\|(\mathcal{G}-\mathcal{G}^h)z^h\|_1 \le C\,h\,|z^h|_0 \qquad \forall\ z^h \in Z^h\,. \tag{3.56}$$

Then choosing $\chi \equiv \mathcal{G}^h \frac{\partial U_\varepsilon}{\partial t}$ in (2.13b) we obtain, similarly to (2.46), that

$$\|\mathcal{G}^h \tfrac{\partial U_\varepsilon}{\partial t}\|_{L^2(0,T;H^1(\Omega))} \le C. \tag{3.57}$$

Combining (3.56), (3.57) and noting (3.11), it follows that

$$\begin{aligned}
\|\mathcal{G}\tfrac{\partial U_\varepsilon}{\partial t}\|_{L^2(0,T;H^1(\Omega))} &\le \|(\mathcal{G}-\mathcal{G}^h)\tfrac{\partial U_\varepsilon}{\partial t}\|_{L^2(0,T;H^1(\Omega))} + \|\mathcal{G}^h \tfrac{\partial U_\varepsilon}{\partial t}\|_{L^2(0,T;H^1(\Omega))} \\
&\le C\,h\,\|\tfrac{\partial U_\varepsilon}{\partial t}\|_{L^2(\Omega_T)} + C \le C\,(\tau^{-\frac{1}{4}}\,h+1) \le C
\end{aligned}$$

if the mild time-step constraint $C\,h^4 \le \tau$ is satisfied. As for case (b), the obtained result $\|U_\varepsilon\|_{L^2(0,T;H^2(\Omega))} \le C$ is more than we need. For our main convergence result we really need only $\|U_\varepsilon\|_{L^2(0,T;W^{1,s}(\Omega))} \le C$, $s>2$. However, it does not appear possible to derive this bound without using the stronger result and the quasi-uniformity assumption.

4. Solution of the discrete system. We now discuss algorithms for solving the resulting system of algebraic equations for $\{\Phi_\varepsilon^n, U_\varepsilon^n, W_\varepsilon^n\}$ arising at each time level from the approximation ($\mathrm{P}_\varepsilon^{h,\tau}$). As (2.13a) in ($\mathrm{P}_\varepsilon^{h,\tau}$) is independent of $\{U_\varepsilon^n, W_\varepsilon^n\}$, we solve it first to obtain Φ_ε^n and then solve (2.13b), (2.13c) for $\{U_\varepsilon^n, W_\varepsilon^n\}$. Solving (2.13a) is straightforward, as it is linear.

Adopting the obvious notation, the system (2.13b), (2.13c) can be rewritten as follows: Find $\{\underline{U}_\varepsilon^n, \underline{W}_\varepsilon^n\} \in \mathcal{K}^{\mathcal{J}} \times \mathbb{R}^{\mathcal{J}}$ such that

$$\gamma\,M\,\underline{U}_\varepsilon^n + \tau_n\,A^{n-1}\,\underline{W}_\varepsilon^n = \underline{r}, \tag{4.1a}$$

$$\gamma\,(\underline{V}-\underline{U}_\varepsilon^n)^T\,B\,\underline{U}_\varepsilon^n - (\underline{V}-\underline{U}_\varepsilon^n)^T\,M\,\underline{W}_\varepsilon^n \ge (\underline{V}-\underline{U}_\varepsilon^n)^T\,\underline{s} \qquad \forall\ \underline{V} \in \mathcal{K}^{\mathcal{J}}, \tag{4.1b}$$

where M, B, and A^{n-1} are symmetric $\mathcal{J}\times\mathcal{J}$ matrices, $\mathcal{J}:=\#J$, with entries

$$M_{ij}:=(\chi_i,\chi_j)^h,\qquad B_{ij}:=(\nabla\chi_i,\nabla\chi_j),\qquad A^{n-1}_{ij}:=(\Xi_\varepsilon(U^{n-1}_\varepsilon)\,\nabla\chi_i,\nabla\chi_j)$$

$$\text{and}\qquad \underline{r}:=\gamma\,M\,\underline{U}^{n-1}_\varepsilon-\alpha\,\tau_n\,A^{n-1}\,\underline{\Phi}^n_\varepsilon\in\mathbb{R}^{\mathcal{J}},\qquad \underline{s}:=\gamma^{-1}\,M\,\underline{U}^{n-1}_\varepsilon\in\mathbb{R}^{\mathcal{J}}. \tag{4.2}$$

Let $A^{n-1}\equiv A_D-A_L-A_L^T$, with A_L and A_D being the lower triangular and diagonal parts of the matrix A^{n-1}, and similarly for B. We use this formulation in constructing our "Gauss–Seidel-type" iterative method to solve (2.13b), (2.13c).

Given $\{U^{n,0}_\varepsilon,W^{n,0}_\varepsilon\}\in K^h\times S^h$, for $k\geq 1$ find $\{U^{n,k}_\varepsilon,W^{n,k}_\varepsilon\}\in K^h\times S^h$ such that

$$\gamma\,M\,\underline{U}^{n,k}_\varepsilon+\tau_n\,(A_D-A_L)\,\underline{W}^{n,k}_\varepsilon=\underline{r}+\tau_n\,A_L^T\,\underline{W}^{n,k-1}_\varepsilon, \tag{4.3a}$$

$$(\underline{V}-\underline{U}^{n,k}_\varepsilon)^T\,(\gamma\,(B_D-B_L)\,\underline{U}^{n,k}_\varepsilon-M\,\underline{W}^{n,k}_\varepsilon)\geq(\underline{V}-\underline{U}^{n,k}_\varepsilon)^T\,(\underline{s}+\gamma\,B_L^T\,\underline{U}^{n,k-1}_\varepsilon)\qquad\forall\ \underline{V}\in\mathcal{K}^{\mathcal{J}}. \tag{4.3b}$$

A similar iterative method is used in [15] to solve a related linear system. They prove convergence of this approach for their linear system by analyzing the eigenvalues of the resultant iteration matrix. Below, we prove convergence of (4.3a), (4.3b) for our nonlinear system (2.13b), (2.13c) using an energy method.

THEOREM 4.1. *Let the assumptions* (A) *hold. Then for* $\{U^{n,0}_\varepsilon,W^{n,0}_\varepsilon\}\in K^h\times S^h$ *the sequence* $\{U^{n,k}_\varepsilon,W^{n,k}_\varepsilon\}_{k\geq0}$ *generated by the algorithm* (4.3a), (4.3b) *satisfies*

$$\|U^n_\varepsilon-U^{n,k}_\varepsilon\|_1\to0\quad\textit{and}\quad\int_\Omega\Xi_\varepsilon(U^{n-1}_\varepsilon)\,|\nabla(W^n_\varepsilon-W^{n,k}_\varepsilon)|^2\,\mathrm{d}x\to0\quad\textit{as } k\to\infty. \tag{4.4}$$

Proof. Let $\underline{Y}^{n,k}:=\underline{U}^n_\varepsilon-\underline{U}^{n,k}_\varepsilon$ and $\underline{Z}^{n,k}:=\underline{W}^n_\varepsilon-\underline{W}^{n,k}_\varepsilon$. Now subtracting (4.3a) from (4.1a) and testing the resulting equation with $\underline{Z}^{n,k}$ yield

$$\gamma\,[\underline{Z}^{n,k}]^T\,M\,\underline{Y}^{n,k}+\tau_n\,[\underline{Z}^{n,k}]^T\,(A_D-A_L)\,\underline{Z}^{n,k}=\tau_n\,[\underline{Z}^{n,k}]^T\,A_L^T\,\underline{Z}^{n,k-1}. \tag{4.5}$$

Choosing $\underline{V}\equiv\underline{U}^{n,k}_\varepsilon$ in (4.1b) and $\underline{V}\equiv\underline{U}^n_\varepsilon$ in (4.3b) yields

$$-\gamma\,[\underline{Y}^{n,k}]^T\,(B_D-B_L)\,\underline{Y}^{n,k}+[\underline{Y}^{n,k}]^T\,M\,\underline{Z}^{n,k}\geq-\gamma\,[\underline{Y}^{n,k}]^T\,B_L^T\,\underline{Y}^{n,k-1}. \tag{4.6}$$

Combining (4.5) and (4.6) yields that

$$\begin{aligned}&\gamma^2\,[\underline{Y}^{n,k}]^T\,(B_D-B_L)\,\underline{Y}^{n,k}+\tau_n\,[\underline{Z}^{n,k}]^T\,(A_D-A_L)\,\underline{Z}^{n,k}\\&\qquad\leq\gamma^2\,[\underline{Y}^{n,k}]^T\,B_L^T\,\underline{Y}^{n,k-1}+\tau_n\,[\underline{Z}^{n,k}]^T\,A_L^T\,\underline{Z}^{n,k-1}.\end{aligned} \tag{4.7}$$

We now split the diagonal matrix $A_D:=A_{D_1}+A_{D_2}$, where $(A_{D_1})_{ii}:=-\sum_{j=1}^{i-1}A_{ij}$ and $(A_{D_2})_{ii}:=-\sum_{j=i+1}^{\mathcal{J}}A_{ij}=A_{ii}-(A_{D_1})_{ii}$. Then we have that

$$\begin{aligned}[\underline{Z}^{n,k}]^T\,A_L^T\,\underline{Z}^{n,k-1}&=\sum_{i=1}^{\mathcal{J}}Z^{n,k}_i\sum_{j=1}^{\mathcal{J}}(A_L^T)_{ij}\,Z^{n,k-1}_j\\&\leq\tfrac12\sum_{i=1}^{\mathcal{J}}\sum_{j=1}^{\mathcal{J}}(A_L)_{ji}\,[(Z^{n,k}_i)^2+(Z^{n,k-1}_j)^2]\\&\leq\tfrac12\sum_{i=1}^{\mathcal{J}}(A_{D_2})_{ii}\,(Z^{n,k}_i)^2+\tfrac12\sum_{j=1}^{\mathcal{J}}(A_{D_1})_{jj}\,(Z^{n,k-1}_j)^2.\end{aligned} \tag{4.8}$$

Combining (4.7), (4.8), and a similar argument for B yields that

$$\tfrac{\gamma^2}{2}\,[\underline{Y}^{n,k}]^T B\,\underline{Y}^{n,k} + \tfrac{\gamma^2}{2}\,[\underline{Y}^{n,k}]^T B_{D_1}\,\underline{Y}^{n,k} + \tfrac{\tau_n}{2}\,[\underline{Z}^{n,k}]^T A^{n-1}\,\underline{Z}^{n,k} + \tfrac{\tau_n}{2}\,[\underline{Z}^{n,k}]^T A_{D_1}\,\underline{Z}^{n,k}$$

(4.9)

$$\leq \tfrac{\gamma^2}{2}\,[\underline{Y}^{n,k-1}]^T B_{D_1}\,\underline{Y}^{n,k-1} + \tfrac{\tau_n}{2}\,[\underline{Z}^{n,k-1}]^T A_{D_1}\,\underline{Z}^{n,k-1}.$$

Therefore, we have that $\{\, \frac{\gamma^2}{2}\,[\underline{Y}^{n,k}]^T\, B_{D_1}\,\underline{Y}^{n,k} + \frac{\tau_n}{2}\,[\underline{Z}^{n,k}]^T\, A_{D_1}\,\underline{Z}^{n,k}\,\}_{k\geq 0}$ is a decreasing sequence. Since it is bounded below the sequence has a limit. Combining this and (4.9) yields

(4.10)

$$|U_\varepsilon^n - U_\varepsilon^{n,k}|_1 \to 0 \quad \text{and} \quad \int_\Omega \Xi_\varepsilon(U_\varepsilon^{n-1})\,|\nabla(W_\varepsilon^n - W_\varepsilon^{n,k})|^2\,\mathrm{d}x \to 0 \quad \text{as } k\to\infty.$$

Furthermore, multiplying (4.3a) with $\underline{1}^T := (1,\dots,1)$, noting that $A^{n-1}\,\underline{1} = \underline{0}$, and recalling the splitting of A^{n-1} yields that

$$\begin{aligned}\gamma\,(U_\varepsilon^{n,k} - U_\varepsilon^{n-1}, 1)^h &= \tau_n\,\underline{1}^T A_L^T\,(\underline{W}_\varepsilon^{n,k-1} - \underline{W}_\varepsilon^{n,k}) = \tau_n\,\underline{1}^T A_{D_1}\,(\underline{W}_\varepsilon^{n,k} - \underline{W}_\varepsilon^{n,k-1})\\ &= \tau_n\,\underline{1}^T A_{D_1}\,\underline{Z}^{n,k-1} - \tau_n\,\underline{1}^T A_{D_1}\,\underline{Z}^{n,k} \quad \to\ 0\,,\end{aligned} \tag{4.11}$$

where we have again used the fact that $\{\,\tau_n\,[\underline{Z}^{n,k}]^T\,A_{D_1}\,\underline{Z}^{n,k}\,\}_{k\geq 0}$ has a limit. Combining (4.10), (4.11), (2.3), and (2.18) yields the desired result (4.4). ∎

Remark 4.2. We note that (4.3a), (4.3b) can be solved explicitly for $j = 1 \to \mathcal{J}$. In particular, let $\widehat{\underline{r}} := \underline{r} + \tau_n\,(A_L\,\underline{W}_\varepsilon^{n,k} + A_L^T\,\underline{W}_\varepsilon^{n,k-1})$ and $\widehat{\underline{s}} := \underline{s} + \gamma\,(B_L\,\underline{U}_\varepsilon^{n,k} + B_L^T\,\underline{U}_\varepsilon^{n,k-1})$. Then, on recalling (1.16a), we set for $j = 1 \to \mathcal{J}$

$$[\underline{U}_\varepsilon^{n,k}]_j = \left[\frac{M_{jj}\,\widehat{\underline{r}}_j + \tau_n\,A_{jj}^{n-1}\,\widehat{\underline{s}}_j}{\gamma\,[M_{jj}]^2 + \tau_n\,\gamma\,A_{jj}^{n-1}\,B_{jj}}\right]_{\mathcal{K}} \quad \text{and} \quad [\underline{W}_\varepsilon^{n,k}]_j = \frac{\widehat{\underline{r}}_j - \gamma\,M_{jj}\,[\underline{U}_\varepsilon^{n,k}]_j}{\tau_n\,A_{jj}^{n-1}}. \tag{4.12}$$

Remark 4.3. Although we have no convergence proof, in practice an overrelaxed version of (4.3a), (4.3b) performed better. To this end we replace (4.12) for a given $\omega \geq 1$ with

$$\begin{aligned}[\underline{U}_\varepsilon^{n,k}]_j &= \left[\omega\,\frac{M_{jj}\,\widehat{\underline{r}}_j - \tau_n\,A_{jj}^{n-1}\,\widehat{\underline{s}}_j}{\gamma\,[M_{jj}]^2 + \tau_n\,\gamma\,A_{jj}^{n-1}\,B_{jj}} + (1-\omega)\,[\underline{U}_\varepsilon^{n,k-1}]_j\right]_{\mathcal{K}}\\ \text{and} \quad [\underline{W}_\varepsilon^{n,k}]_j &= \frac{\widehat{\underline{r}}_j - \gamma\,M_{jj}\,[\underline{U}_\varepsilon^{n,k}]_j}{\tau_n\,A_{jj}^{n-1}}\,.\end{aligned} \tag{4.13}$$

5. Numerical results. In order to define the initial shape of the void we introduce the following function. Given $z \in \mathbb{R}^2$, $a \in \mathbb{R}^2$ with $\min\{a_1, a_2\} = 1$ and $R \in \mathbb{R}_{>0}$ we define

$$v(z,a,R;\,x) := \begin{cases} -1, & r(x) \leq R - \frac{\gamma\,\pi}{2},\\ \sin(\frac{r(x)-R}{\gamma}), & |r(x) - R| < \frac{\gamma\,\pi}{2}\,,\\ 1, & r(x) \geq R + \frac{\gamma\,\pi}{2}, \end{cases} \tag{5.1}$$

where $r(x) := ((\frac{x_1-z_1}{a_1})^2 + (\frac{x_2-z_2}{a_2})^2)^{\frac{1}{2}}$. Equation (5.1) represents a void with the shape of an ellipse with semiaxes $a_1 R$ and $a_2 R$. In line with the asymptotics of the phase field approach (see section 1), the interfacial thickness is not less than $\gamma\,\pi$. For the initial data u^0 to (P) we chose either (i) one ellipse or (ii) two ellipses; that is,

(5.2)

$$\text{(i)}\quad u^0(x) = v(z,a,R;\,x) \qquad \text{or} \quad \text{(ii)}\quad u^0(x) = v(z,a,R;\,x) + v(\tilde{z},\tilde{a},\widetilde{R};\,x) - 1\,.$$

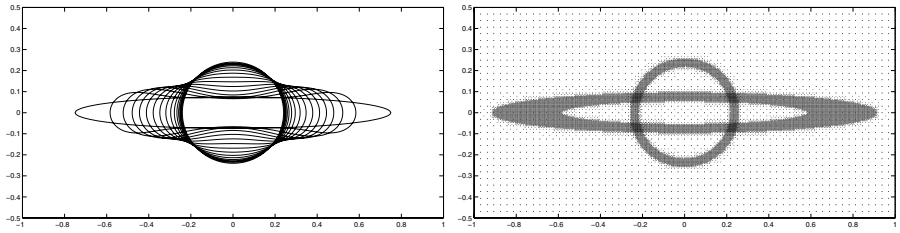


FIG. 1. *($\alpha = 0$). Zero level sets for solution $U_\varepsilon(x,t)$ of $(\mathrm{P}_\varepsilon^{h,\tau})$ at times $t = 0, 2\times10^{-4}, \ldots, 3\times10^{-3}, T = 10^{-2}$ and adaptive mesh for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ at times $t = 0, T$.*

In all the experiments below, the parameters above were chosen so that these ellipses lie in the interior of Ω; and hence the resulting u^0 satisfies all the assumptions of Lemma 3.1.

To solve for $(\mathrm{P}_\varepsilon^{h,\tau})$, the given domain $\Omega = (-L_1, L_1) \times (-L_2, L_2)$ was partitioned uniformly into right-angled isosceles triangles. Throughout, we chose the number of triangles such that there were at least approximately 6 mesh points across the interface in each direction; that is, $8(\frac{h}{\sqrt{2}}) \leq \gamma\,\pi$.

For the iterative algorithm (4.3a), (4.3b) we set, for $n \geq 1$, $\{U_\varepsilon^{n,0}, W_\varepsilon^{n,0}\} \equiv \{U_\varepsilon^{n-1}, W_\varepsilon^{n-1}\}$, where $U_\varepsilon^0 \equiv \pi^h u^0$ and $W_\varepsilon^0 \equiv -\gamma\,\Delta^h U_\varepsilon^0 - \gamma^{-1}\,U_\varepsilon^0$, and adopted the stopping criterion

$$|U_\varepsilon^{n,k} - U_\varepsilon^{n,k-1}|_{0,\infty} < tol,$$

with $tol = 10^{-7}$. Furthermore, we set $\{U_\varepsilon^n, W_\varepsilon^n\} \equiv \{\pi^h[p_{\mathcal{K}}^{tol}(U_\varepsilon^{n,k})], W_\varepsilon^{n,k}\}$, where

$$p_{\mathcal{K}}^{tol}(s) := \begin{cases} -1 & s \leq -1 + tol, \\ s & |s| < 1 - tol, \\ 1 & s \geq 1 - tol. \end{cases}$$

Our first experiment is for $\alpha = 0$ and shows the evolution of an ellipse to a circle due to surface diffusion. We chose the following parameters for $(\mathrm{P}_\varepsilon^{h,\tau})$: $L_1 = 1$, $L_2 = 0.5$, $\gamma = \frac{1}{16\pi}$, $\alpha = 0$, $T = 10^{-2}$, $\tau_n = \tau = 8\times10^{-7}$, $\varepsilon = 10^{-5}$. For the initial profile we chose (5.2)(i) with $z = (0,0)$, $a = (10,1)$, and $R = 0.075$ and used $\omega = 1.4$ for the iterative algorithm (4.13). We used a uniform 128×128 triangulation for each of the two unit squares. In Figure 1 we plot the zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 2\times10^{-4}, \ldots, 3\times10^{-3}, T$. We note the very good agreement with the direct finite element approximation of the sharp interface problem, (1.1a), (1.1b) and (1.2), in [28, Figure 3]. We repeated the above experiment for the scheme $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ (see Remark 2.10) and obtained graphically indistinguishable results. However, the scheme $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ was 2.2 times faster than solving the original approximation $(\mathrm{P}_\varepsilon^{h,\tau})$. Moreover, for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ one knows a priori that $U_\varepsilon^n(p_j) = U_\varepsilon^{n-1}(p_j)$ for all $j \in J$ with $(\widetilde{\Xi}_\varepsilon(U_\varepsilon^{n-1}), \chi_j) = 0$, the so-called passive nodes. A natural approach to utilize this fact is to use a fine mesh in the "interfacial region" only, while employing a coarser mesh elsewhere. We note that for $\alpha = 0$ this is equivalent to using a uniform fine mesh. However, for the above experiment the described adaptive mesh approach was 4.4 times faster than solving $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ on a uniform mesh. Hence, overall to solve for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ took 10% of the time it took to solve $(\mathrm{P}_\varepsilon^{h,\tau})$. Hence for all the remaining computations we used an adaptive mesh to solve for the approximation $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$.

We should note that for $\alpha > 0$ the adaptive mesh approach is not equivalent to solving $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ on a uniform mesh, since in the former case not all the active nodes with respect to $\widetilde{\Lambda}_\varepsilon(U_\varepsilon^{n-1})$, as opposed to $\widetilde{\Xi}_\varepsilon(U_\varepsilon^{n-1})$, are represented on the fine mesh. Hence the respective solutions Φ_ε^n can differ slightly in the interfacial region, yielding different solutions U_ε^n. But the electric potential is not rapidly varying away from the interfacial region, and hence is well approximated by the coarse mesh, so there is no need for the more costly fine mesh. Furthermore, we obtained virtually identical results in test runs, and hence we are satisfied that these differences are negligible.

In order to implement the desired mesh we used the adaptive finite element code Albert 1.0; see [24]. The code uses bisectioning, and its reversal, for refining and coarsening, respectively. Hence starting with an initial right-angled isosceles triangulation yields similar triangles throughout. We now describe our mesh refinement strategy for the physically relevant case of $L_1 \geq L_2$ and further assume without loss of generality that L_1 is an integer multiple of L_2.

Given the two parameters $N_c < N_f$ we set $h_c := \frac{2^{\frac{3}{2}} L_2}{N_c}$ and $h_f := \frac{2^{\frac{3}{2}} L_2}{N_f}$, respectively. Throughout, we choose our initial triangulation $\widetilde{\mathcal{T}}^0$ to be a uniform partitioning of Ω into triangles σ of diameter $h_\sigma = h_f$ and fix the parameters $\delta_f = tol \times 10^{-1}$ and $\delta_c = tol \times 10^{-3}$. Then, for $n \geq 1$, given U_ε^{n-1} and a triangulation $\widetilde{\mathcal{T}}^{n-1}$, a triangle $\sigma \in \widetilde{\mathcal{T}}^{n-1}$ is marked for refinement if it, or one of its neighboring elements, satisfies

$$\eta_\sigma := \left| \min_{x \in \overline{\sigma}} |U_\varepsilon^{n-1}(x)| - 1 \right| > \delta_f .$$

If a triangle that is marked for refinement satisfies $h_\sigma > h_f$, it is refined into two smaller triangles via a bisectioning of its longest edge. A triangle σ is marked for coarsening if it satisfies $h_\sigma < h_c$ and $\eta_\sigma < \delta_c$. A triangle that is marked for coarsening is coarsened only if all its neighboring elements are marked for coarsening as well. This cycle is repeated until no triangle has been refined or coarsened. We note that the maximum number of cycles is $\frac{N_f}{N_c}$. However, apart from the case $n = 1$ the number of cycles required will be 1, due to the fact that the region of active nodes can advance one mesh point per time step only; see Remark 3.2. The above process ensures that all active nodes are always within the fine part of the adaptive mesh.

For the remaining experiments we adopted the following strategy. Given a $\gamma > 0$ we chose N_f such that there were at least approximately 6 mesh points across the interface, set $N_c := \frac{1}{8} N_f$, and chose a suitable time step size τ. As the numerical interfacial region can only advance by one mesh point per time step one has to choose τ sufficiently small so that $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$ is capable of approximating the speed of propagation of the void; cf. [3, section 5.1]. On obtaining the desired experiment's solutions for these discretization parameters we halved γ, halved h_f, and quartered τ, while keeping $\varepsilon = 10^{-5}$ fixed throughout. In almost all instances we repeated the above procedure until the solutions for two consecutive choices of γ were graphically indistinguishable. Here we report on the converged experiments.

First, we repeated the previous experiment for $\alpha = 0$ for a smaller $\gamma = \frac{1}{32\pi}$, using a finer mesh. In particular, we chose the following parameters for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$: $L_1 = 1$, $L_2 = 0.5$, $T = 10^{-2}$, $\tau_n = \tau = 2 \times 10^{-7}$. For the initial profile we chose (5.2)(i) with $z = (0, 0)$, $a = (10, 1)$, and $R = 0.075$ and used $\omega = 1.5$ for the iterative algorithm (4.13). The refinement parameters were $N_f = 256$ and $N_c = 32$. The obtained results were virtually identical to the ones from our earlier computations; see Figure 1. On the right-hand side of this figure we plot the vertices of the adaptive mesh for the latter experiment at times $t = 0, T$.

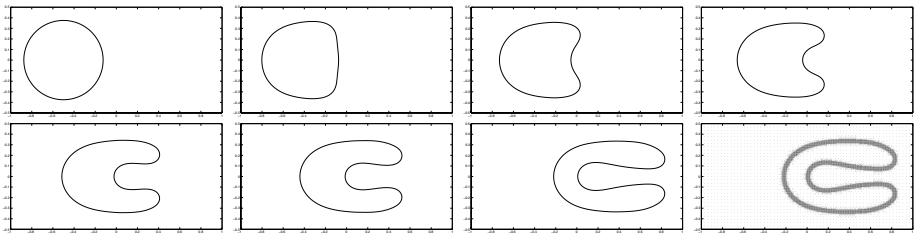

FIG. 2. *($\alpha \approx 114\,\pi$). Zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 4\times10^{-5}, 8\times10^{-5}, 1.2\times10^{-4}, 2\times10^{-4}, 2.4\times10^{-4}, T = 3.6\times10^{-4}$ and adaptive mesh at time $t = T$.*

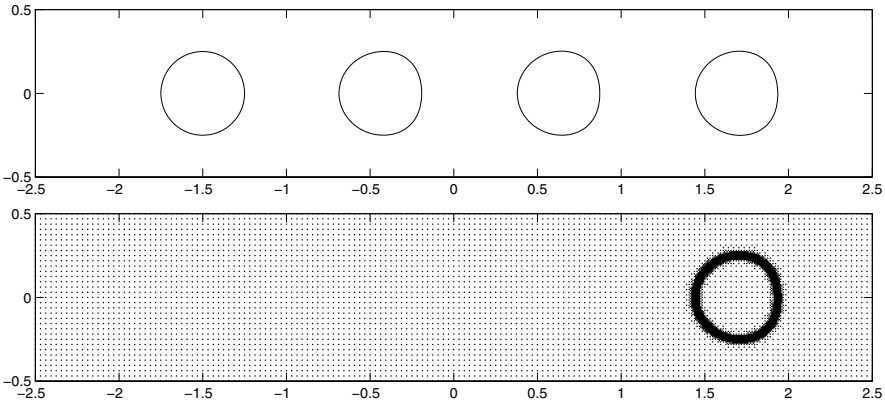

FIG. 3. *($\alpha = 40\,\pi$). Zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 1.25\times10^{-3}, \dots, T = 3.75\times10^{-3}$ and adaptive mesh at time $t = T$.*

In our first experiment for $\alpha > 0$ we chose the radius of the initially circular void to be relatively large compared to the width of the conductor, $2\,L_2$, in correspondence to [9, Figure 4]. We used the following parameters for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$: $L_1 = 1$, $L_2 = 0.5$, $\gamma = \frac{1}{32\pi}$, $\alpha = \frac{1024}{9}\,\pi \approx 114\,\pi$, $T = 3.6\times10^{-4}$, $\tau_n = \tau = 10^{-7}$. As initial data we chose (5.2)(i) with $z = (-0.5, 0)$, $a = (1, 1)$, and $R = 0.375$ and used $\omega = 1.9$ for the iterative algorithm (4.13). The refinement parameters were $N_f = 256$ and $N_c = 32$. In Figure 2 we plot the zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 4\times10^{-5}, 8\times10^{-5}, 1.2\times10^{-4}, 2\times10^{-4}, 2.4\times10^{-4}, T$ and the vertices of the adaptive mesh at time $t = T$. We note the good agreement with the direct finite element approximation of the sharp interface problem, (1.1a), (1.1b) and (1.2), in [9, Figure 4].

The next experiment corresponds to [20, Figure 5] and [28, Figure 6]. We chose the following parameters for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$: $L_1 = 2.5$, $L_2 = 0.5$, $\gamma = \frac{1}{32\pi}$, $\alpha = 40\,\pi$, $T = 3.75\times10^{-3}$, $\tau_n = \tau = 6\times10^{-7}$. As initial data we chose (5.2)(i) with $z = (-1.5, 0)$, $a = (1, 1)$, and $R = 0.25$ and used $\omega = 1.9$ for the iterative algorithm (4.13). The refinement parameters were $N_f = 256$ and $N_c = 32$. In Figure 3 we plot the zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 1.25\times10^{-3}, \dots, T$ and the vertices of the adaptive mesh at time $t = T$. One can observe that the circular void, with a slightly flattened front, stably propagates through the conductor.

However, for larger α this is no longer the case. We repeated the above experiment for $\alpha = 120\,\pi$ in correspondence to [28, Figure 7]. In particular, we chose $L_1 = 2.5$, $L_2 = 0.5$, $\gamma = \frac{1}{64\pi}$, $\alpha = 120\,\pi$, $T = 1.184\times10^{-3}$, $\tau_n = \tau = 5\times10^{-8}$. We used the same initial data as in Figure 3 and chose $\omega = 1$ for the iterative algorithm (4.13). The

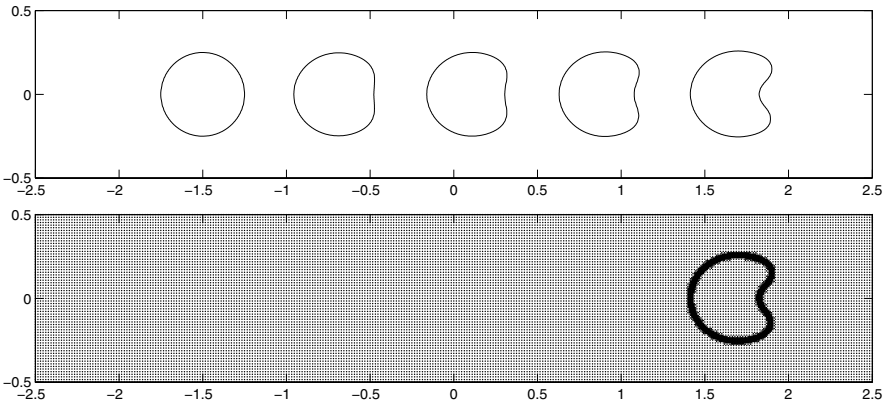

FIG. 4. *($\alpha = 120\,\pi$). Zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 3\times10^{-4}, \ldots, T = 1.184\times10^{-3}$ and adaptive mesh at time $t = T$.*

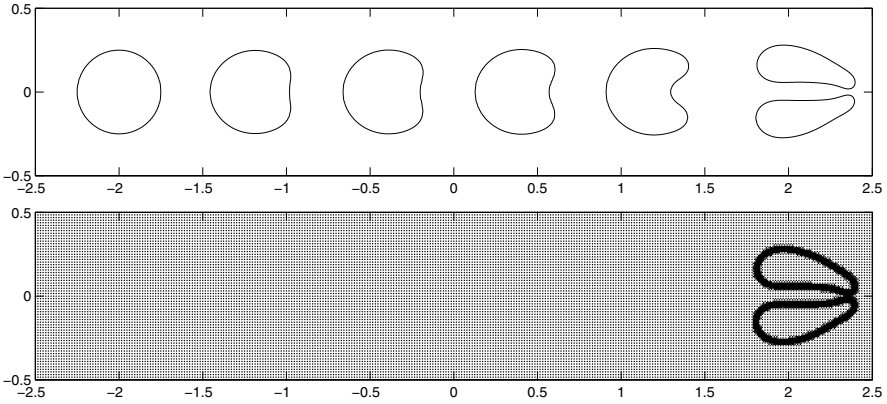

FIG. 5. *($\alpha = 120\,\pi$). Zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 3\times10^{-4}, \ldots, T = 1.5\times10^{-3}$ and adaptive mesh at time $t = T$.*

refinement parameters were $N_f = 512$ and $N_c = 64$. In Figure 4 we plot the zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 2.96\times10^{-4}, \ldots, T$ and the vertices of the adaptive mesh at time $t = T$. We repeated the last experiment with the same parameters but started with the initial void more to the left and integrated for a longer time; in particular, we set $z = (-2, 0)$ and $T = 1.5\times10^{-3}$. This allows the void to further change its shape; see Figure 5. The above three experiments are very sensitive to the choice of γ and τ. Although our results show similarities with the cited ones, there is no strong agreement between these different types of simulations.

The next experiment corresponds to [20, Figure 9]. We chose the following parameters for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$: $L_1 = 0.5$, $L_2 = 0.5$, $\gamma = \frac{1}{32\pi}$, $\alpha = 12\,\pi$, $T = 1.5\times10^{-4}$, $\tau_n = \tau = 2\times10^{-7}$. As initial data we chose (5.2)(ii) with $z = (-0.15, 0)$, $a = (1.12, 1.6)$, $R = 0.125$, $\tilde{z} = (0.15, 0)$, $\tilde{a} = (0.96, 1.92)$, and $\widetilde{R} = 0.125$ and used $\omega = 1.8$ for the iterative algorithm (4.13). The refinement parameters were $N_f = 256$ and $N_c = 32$. In Figure 6 we plot the zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 3.04\times10^{-5}, 3.8\times10^{-5}, 4.56\times10^{-5}, T$ and the vertices of the adaptive mesh at time $t = T$. We note that the time the two ellipses are merging is sensitive to the choice of γ.

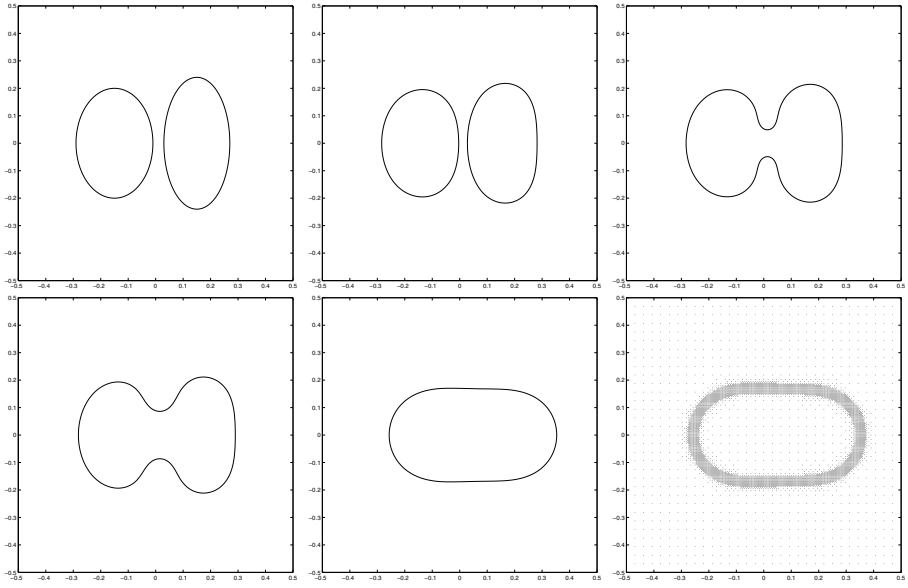

FIG. 6. *($\alpha = 12\,\pi$). Zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 3.04\times10^{-5}, 3.8\times10^{-5}, 4.56\times10^{-5}, T = 1.5\times10^{-4}$ and adaptive mesh at time $t = T$.*

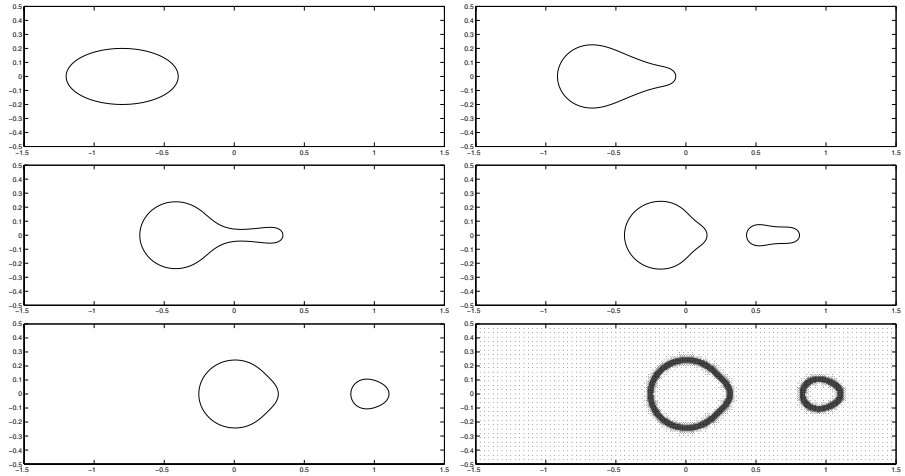

FIG. 7. *($\alpha = 120\,\pi$). Zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 8.75\times10^{-5}, 1.75\times10^{-4}, 2.625\times10^{-4}, T = 3.32\times10^{-4}$ and adaptive mesh at time $t = T$.*

The next experiment corresponds to [20, Figure 11]. We chose the following parameters for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$: $L_1 = 1.5$, $L_2 = 0.5$, $\gamma = \frac{1}{32\pi}$, $\alpha = 120\,\pi$, $T = 3.32\times10^{-4}$, $\tau_n = \tau = 2.5\times10^{-8}$. As initial data we chose (5.2)(i) with $z = (-0.8, 0)$, $a = (2, 1)$, and $R = 0.2$ and used $\omega = 1.3$ for the iterative algorithm (4.13). The refinement parameters were $N_f = 256$ and $N_c = 32$. In Figure 7 we plot the zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 8.75\times10^{-5}, 1.75\times10^{-4}, 2.625\times10^{-4}, T$ and the vertices of the adaptive mesh at time $t = T$.

Our final experiment corresponds to [20, Figure 10]. We chose the following parameters for $(\widetilde{\mathrm{P}}_\varepsilon^{h,\tau})$: $L_1 = 1.5$, $L_2 = 0.5$, $\gamma = \frac{1}{32\pi}$, $\alpha = 64\,\pi$, $T = 7.91\times10^{-4}$,

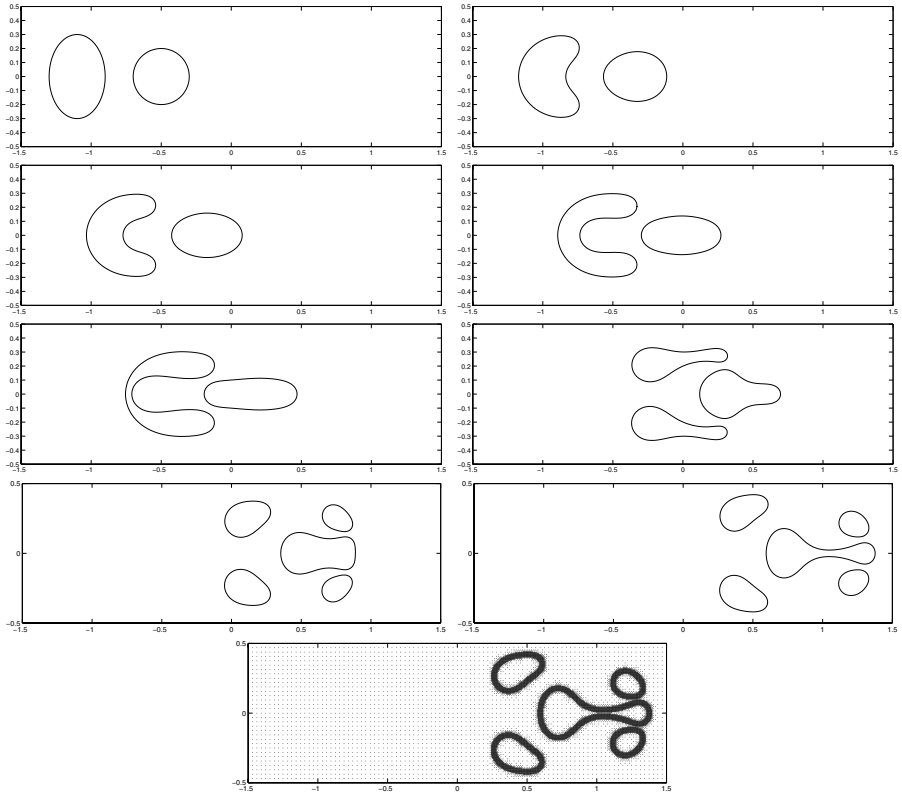

FIG. 8. *($\alpha = 64\,\pi$). Zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 1.13\times10^{-4}, \ldots, T = 7.91\times10^{-4}$ and adaptive mesh at time $t = T$.*

$\tau_n = \tau = 2.5\times10^{-8}$. As initial data we chose (5.2)(ii) with $z = (-1.1, 0)$, $a = (1, 1.5)$, $R = 0.2$, $\tilde{z} = (-0.5, 0)$, $\tilde{a} = (1, 1)$, and $\widetilde{R} = 0.2$ and used $\omega = 1.3$ for the iterative algorithm (4.13). The refinement parameters were $N_f = 256$ and $N_c = 32$. In Figure 8 we plot the zero level sets for $U_\varepsilon(x,t)$ at times $t = 0, 1.13\times10^{-4}, \ldots, T$ and the vertices of the adaptive mesh at time $t = T$. We note that for the last two experiments there is good agreement for different values of γ but only partial agreement with the cited results in [20]. However, one should note that the fixed mesh for their level set approach of the sharp interface model, (1.1a), (1.1b) and (1.2), is rather coarse.

SURFACE DIFFUSION OF GRAPHS: VARIATIONAL FORMULATION, ERROR ANALYSIS, AND SIMULATION*

EBERHARD BÄNSCH†, PEDRO MORIN‡, AND RICARDO H. NOCHETTO§

Abstract. Surface diffusion is a (fourth-order highly nonlinear) geometric driven motion of a surface with normal velocity proportional to the surface Laplacian of mean curvature. We present a novel variational formulation for graphs and derive a priori error estimates for a time-continuous finite element discretization. We also introduce a semi-implicit time discretization and a Schur complement approach to solve the resulting fully discrete, linear systems. After computational verification of the orders of convergence for polynomial degrees 1 and 2, we show several simulations in one dimension and two dimensions with and without forcing which explore the smoothing effect of surface diffusion, as well as the onset of singularities in finite time, such as infinite slopes and cracks.

Key words. surface diffusion, fourth-order parabolic problem, finite elements, a priori error estimates, Schur complement, smoothing effect

1. Introduction.

Controlling morphological changes in stressed epitaxial films is of paramount importance in materials science. The film may be thought of as subjected to mechanical stresses to model its misfit with the crystalline structure of the substrate. This in turn causes a plastic deformation of the free surface of the film, a morphological instability of the free surface which may eventually lead to crack formation and fracture. The simplest model couples surface diffusion of the free surface with linear elasticity in the bulk [1, 6, 13, 14, 15, 18, 19, 20]. Investigating this complicated nonlinear dynamics requires effective and reliable computational tools.

This paper studies the *geometric* motion law of *surface diffusion* with given forcing but without elasticity. The dynamics of the free surface $\Gamma(t)$ is thus governed by the (highly nonlinear) fourth-order geometric PDE

$$V = -\Delta_S(\kappa + f), \tag{1.1}$$

where V is the normal velocity of $\Gamma(t)$, κ is its mean curvature, and Δ_S is the Laplace–Beltrami operator on $\Gamma(t)$. In this reduced model f is given, whereas in the full model f corresponds to the elastic energy density of the bulk $\Omega(t)$ restricted to $\Gamma(t)$. Our goal is to present novel variational formulations and finite element methods for (1.1), which may be viewed as building blocks towards solving the fully coupled system.

We study the *graph* case in this paper and the *parametric* case in [3]. From now on we assume that $\Omega \subseteq \mathbb{R}^d$ $(d \geq 1)$ is a fixed domain and $\Gamma(t) := \{(x, u(t,x)) \mid x \in \Omega\} \subseteq \mathbb{R}^{d+1}$ is the free surface for $0 \leq t \leq T$ described by the unknown function u. If $Q = Q(u) = \sqrt{1 + |\nabla u|^2}$ denotes the elementary surface area, then the unit normal ν to $\Gamma(t)$, its mean curvature κ, and the normal velocity V of $\Gamma(t)$ can be expressed as follows:

$$\nu = \frac{1}{Q}(-\nabla u, 1)^T, \qquad \kappa = \nabla \cdot \left(\frac{\nabla u}{Q}\right), \qquad V = \frac{\partial_t u}{Q}.$$

Therefore, (1.1) can be written as the following system of second-order nonlinear PDEs:

$$\frac{\partial_t u}{Q} = -\Delta_S(\kappa + f), \qquad \kappa = \nabla \cdot \left(\frac{\nabla u}{Q}\right), \tag{1.2}$$

for (u, κ). Once completed with initial and boundary conditions, this system constitutes our starting point. Issues about existence, uniqueness, and regularity are not yet settled, not even for the graph formulation; we refer the reader to [12] for local existence for closed surfaces, as well as global existence and exponential asymptotic behavior for solutions close to a sphere. It is known, however, that the graph property may be lost in finite time [11], an intriguing situation corroborated by simulations in section 7.3.

We introduce in section 2 a new variational formulation with several crucial stability properties. Using C^0 finite elements of any degree $k \geq 1$, we obtain a space discretization in section 3 with solutions (u_h, κ_h) and show corresponding stability properties. After deriving a number of auxiliary results for the semidiscrete scheme in section 4, we use them to prove the quasi-optimal estimate in section 5 for the errors $e_u = u - u_h$ and $e_\kappa = \kappa - \kappa_h$:

$$\sup_{t\in[0,T]} \left(\|e_u\|^2_{L^2(\Omega)} + \int_{\Gamma_h(t)} |\nabla_S e_u|^2 \right) + \int_0^T \left(\|e_\kappa\|^2_{L^2(\Omega)} + \int_{\Gamma_h(t)} |\nabla_S e_\kappa|^2 \right) \leq C\, h^{2k}. \tag{1.3}$$

Here $C > 0$ depends on the regularity of u and κ, $k \geq 1$ is the polynomial degree, and h is the mesh size. It is worth comparing our results with the existing literature. A space-time finite element method for *axially symmetric* surfaces is presented by Coleman, Falk, and Moakher in [7], along with several stability properties and very interesting dynamics, some not predicted by linearized stability. More recently, Deckelnick, Dziuk, and Elliott provided an error analysis [9] for the axially symmetric case. Our formulation, discretization, and analysis differ from those in [7, 9].

In section 6 we introduce a *semi-implicit* time discretization in the spirit of Deckelnick and Dziuk [8] and Dziuk [10]. This leads to a sequence of surfaces Γ^n and *linear* elliptic PDEs on them. We derive again several crucial stability properties and discuss a Schur complement approach for doing effective numerical linear algebra. Finally, we show a number of numerical experiments in section 7. Their purpose is twofold: first, we computationally verify the rate (1.3) for $k = 1, 2$, and, second, we explore the nonlinear regime of (1.1) via simulation. In fact, we examine the regularizing effect of surface diffusion, as well as whether (1.1) is capable of forming singularities. They manifest themselves as vertical slopes $|\nabla u| = \infty$ for $f = 0$ and cracks for $f \neq 0$ of a special form. We display results for both $d = 1, 2$ computed with the finite element toolbox ALBERT [17, 16].

2. Variational formulation. In this section we write (1.2) in weak form. We start with some notation and basic formulas.

2.1. Elementary differential geometry. Let $v, w : \Omega \to \mathbb{R}$ be (smooth) functions. Since the area element is given by Q, then

$$\int_\Gamma v = \int_\Omega v\, Q;$$

in particular, the area $A(t)$ of $\Gamma(t)$ reads $A(t) = \int_\Omega Q$ at time t. If $\tilde{v}$ is the trivial extension of v to $\mathbb{R}^{d+1}$, namely, $\tilde{v}(x_1, \dots, x_{d+1}) := v(x_1, \dots, x_d)$, then the *tangential* gradient ∇_S is given by

$$\nabla_S v = \nabla_{d+1}\tilde{v} - \nabla_{d+1}\tilde{v} \cdot \nu\, \nu,$$

where ∇_{d+1} denotes the gradient in $\mathbb{R}^{d+1}$. Since $\nabla_{d+1}\tilde{v} = (\nabla v^T, 0)^T$, we readily get

$$\nabla_S v \cdot \nabla_S w = \nabla v \cdot \nabla w - \frac{1}{Q^2} \nabla v \cdot \nabla u\ \nabla w \cdot \nabla u.$$

Note that there is also an intrinsic definition of ∇_S. If $\gamma = \partial\Gamma$ indicates the boundary of Γ, then this expression, together with integration by parts, yields

$$\begin{aligned} -\int_\Gamma \Delta_S v\, w + \int_\gamma \underline{\partial}_{\nu_\gamma} v\, w &= \int_\Gamma \nabla_S v \cdot \nabla_S w = \int_\Omega \nabla_S v \cdot \nabla_S w\, Q \\ &= \int_\Omega \left(\nabla v \cdot \nabla w\, Q - \frac{\nabla v \cdot \nabla u\, \nabla w \cdot \nabla u}{Q} \right). \end{aligned} \tag{2.1}$$

Here ν_γ denotes the intrinsic outer unit normal of Γ at γ, given by $\nu_\gamma = \nu_\Gamma \wedge \tau_\gamma$ with τ_γ the tangential unit vector of γ with the appropriate sign for $\Gamma \subseteq \mathbb{R}^3$.

2.2. Boundary conditions and function spaces. Let $L^p(\Omega)$, $1 \le p \le \infty$, be the usual space of Lebesgue measurable functions with norm $\|v\|_p := (\int_\Omega |v|^p)^{1/p}$. By $\langle \cdot, \cdot \rangle$ we denote the L^2 inner product $\langle v, w \rangle := \int_\Omega vw$ for $v, w \in L^2(\Omega)$. We indicate with $H^{m,p}(\Omega)$ the Sobolev space of functions in $L^p(\Omega)$ with mth weak derivatives also in $L^p(\Omega)$ equipped with the norm $\|v\|_{m,p} := (\sum_{|\alpha| \le m} \int_\Omega |\partial_\alpha v|^p)^{1/p}$ and $H^m := H^{m,2}$. Furthermore, $\mathring{H}^1(\Omega)^p$ is the subspace of functions in $H^{1,p}$ with vanishing boundary values in the sense of traces.

Finally, for a time interval $[0, T]$ and a function space V we define the parabolic spaces $L^p(V)$ of V-valued functions that are measurable in time with $\|v\|_{L^p(V)} := (\int_0^T \|v(t)\|_V^p dt)^{1/p} < \infty$.

To simplify the notation we will write $\|v\|_\infty = \|v\|_{L^\infty(L^\infty)}$. This ambiguity of notation will not lead to confusion.

We now discuss boundary conditions and corresponding function spaces $\mathcal{X}$.

Periodic boundary condition. Let $\Omega = \Pi_{i=1}^d (0, X_i)$ be a parallelogram. If $u(t, x + X_i e_i) = u(t, x), \kappa(t, x + X_i e_i) = \kappa(t, x)$ for all $x \in \partial\Omega$ and $1 \le i \le d$, then

$$\mathcal{X} := \{ v \in H^1(\Omega) \mid v(x + X_i e_i) = v(x) \quad \text{for } x \in \partial\Omega,\ 1 \le i \le d \}.$$

Neumann boundary condition. If $\nu_\gamma \cdot \nabla_S u(t, x) = \nu_\gamma \cdot \nabla_S \kappa(t, x) = 0$ for $x \in \partial\Omega$, then $\mathcal{X} := H^1(\Omega)$.

Dirichlet boundary condition. If $u(t, x) = \kappa(t, x) = 0$ for $x \in \partial\Omega$, then $\mathcal{X} := \mathring{H}^1(\Omega)$.

2.3. Weak form. We are now in a position to introduce two bilinear forms in (v, w) and state the variational formulation of (1.2). Let

$$\boldsymbol{a}(u; v, w) := \int_\Omega \left(\nabla v \cdot \nabla w \, Q - \frac{\nabla v \cdot \nabla u \, \nabla w \cdot \nabla u}{Q} \right), \tag{2.2}$$

$$\tilde{\boldsymbol{a}}(u; v, w) := \int_\Omega \frac{\nabla v \cdot \nabla w}{Q}. \tag{2.3}$$

LEMMA 2.1 (equivalence). *Let $u \in C^1([0,T]; C^4(\bar\Omega))$, let $\kappa \in C^0([0,T]; C^2(\bar\Omega))$, and let $\mathcal{X}$ be as defined in section 2.2. Then (u, κ) is a solution of (1.2) with initial value u_0 and boundary conditions as in section 2.2 iff $u(t)$, $\kappa(t) \in \mathcal{X}$ for all $t \in [0,T]$, $u(0,\cdot) = u_0$, and*

$$\langle \partial_t u, \psi \rangle - \boldsymbol{a}(u; \kappa, \psi) = \boldsymbol{a}(u; f, \psi) \qquad \forall \psi \in \mathcal{X}, \tag{2.4}$$

$$\langle \kappa, \varphi \rangle + \tilde{\boldsymbol{a}}(u; u, \varphi) = 0 \qquad \forall \varphi \in \mathcal{X}. \tag{2.5}$$

Proof. Multiply the first equation in (1.2) by ψ, integrate over Γ, and use formula (2.1). Observe that the boundary term vanishes because of the choice of function space $\mathcal{X}$. Equation (2.5) follows similarly from the second equation in (1.2) integrating by parts over Ω. ∎

Remark 2.2 (mean curvature flow). In contrast to the mean curvature flow, for which a divergence formulation reads [8, 10]

$$\int_\Omega \frac{\partial_t u \, v}{Q} + \tilde{\boldsymbol{a}}(u; u, v) = 0 \qquad \forall\, v \in \mathcal{X},$$

we do not have the factor $\frac{1}{Q}$ in the parabolic term.

Remark 2.3 (comparing $\boldsymbol{a}$ and $\tilde{\boldsymbol{a}}$). The forms $\boldsymbol{a}$ and $\tilde{\boldsymbol{a}}$ are symmetric and nonnegative. If $d = 1$, they coincide; i.e., $\boldsymbol{a}(u; \cdot, \cdot) = \tilde{\boldsymbol{a}}(u; \cdot, \cdot)$. If $d > 1$, instead,

$$\boldsymbol{a}(u; v, u) = \tilde{\boldsymbol{a}}(u; v, u) \qquad \forall\, v \in \mathcal{X}$$

because $Q(1 - \frac{|\nabla u|^2}{Q^2}) = \frac{1}{Q}$. Similarly,

$$\boldsymbol{a}(u; v, v) = \int_\Gamma \nabla_S v \cdot \nabla_S v = \int_\Omega \left(|\nabla v|^2 Q - \frac{|\nabla v \cdot \nabla u|^2}{Q} \right) \geq \int_\Omega \frac{|\nabla v|^2}{Q} = \tilde{\boldsymbol{a}}(u; v, v).$$

Remark 2.4 (equivalent forms of $\boldsymbol{a}$). Let $\zeta := \frac{\nabla u}{|\nabla u|}$ be a unit vector in the direction of ∇u, provided that $\nabla u \neq 0$, and be arbitrary otherwise. Let $(\chi_i)_{i=1}^{d-1}$ be a complementary orthonormal set perpendicular to ζ. A simple calculation then yields

$$\boldsymbol{a}(u; v, w) = \int_\Omega \left(\frac{\nabla v \cdot \zeta \, \nabla w \cdot \zeta}{Q} + Q \sum_{i=1}^{d-1} \nabla v \cdot \chi_i \, \nabla w \cdot \chi_i \right) \quad \forall v, w \in \mathcal{X}. \tag{2.6}$$

Another equivalent form is obtained using $\otimes$ to denote the tensor product in $\mathbb{R}^d$:

$$\boldsymbol{a}(u; v, w) = \int_\Omega \nabla v^T \left(Q\, I - \frac{\nabla u \otimes \nabla u}{Q} \right) \nabla w; \tag{2.7}$$

here I denotes the identity matrix in $\mathbb{R}^d$.

Remark 2.5 (volume conservation and area decrease). If the function $v = 1 \in \mathcal{X}$, then (2.4) yields $0 = \langle \partial_t u, 1\rangle = \frac{d}{dt}\int_\Omega u$, which is the formula for conservation of volume. On the other hand, if the forcing term $f \equiv 0$, then the area of $\Gamma(t)$ is decreasing regardless of boundary conditions (see Lemma 2.6). Both of these properties will also hold true for the semidiscrete and fully discrete formulations of section 3 and section 6.

With the help of the above variational form of the equations, we are in a position to prove a stability result for the continuous solution.

LEMMA 2.6 (continuous stability). *Let (u, κ) be a solution of* (1.2) *fulfilling the assumptions of Lemma* 2.1, *and let $A(t)$ denote the area of $\Gamma(t)$. There are two constants, $C_1 = C_1(\Omega)$ and $C_2 = C_2\big(\|\nabla f\|_\infty, A(0)\big)$, such that*

$$\sup_{t\in[0,T]} \|u(t)\|_2^2 + \int_0^T \|\kappa\|_2^2 \le \|u(0)\|_2^2 + C_1 \int_0^T \|\nabla f\|_2,$$

$$\sup_{t\in[0,T]} A(t) + \int_0^T \boldsymbol{a}(u;\kappa,\kappa) \le C_2.$$

Moreover, if $f \equiv 0$, then the function $A(t)$ is decreasing (strictly provided that $\Delta_S \kappa \not\equiv 0$).

Proof. We omit the proof because it is the same as that of Proposition 3.2. ∎

3. Space discretization. Let $(\mathcal{T}_h)_{h>0}$ be a family of (possibly graded) shape regular triangulations of Ω, with h being the largest size of elements in $\mathcal{T}_h$. We fix $k \in \mathbb{N}$ and denote by $\mathcal{X}_h \subseteq \mathcal{X}$ the subspace of continuous finite elements of polynomial degree k with appropriate boundary conditions. Let $I_h : \mathcal{X} \cap C^0(\bar\Omega) \to \mathcal{X}_h$ be an interpolation operator fulfilling

$$\|I_h v - v\|_p + h\|\nabla(I_h - v)\|_p \le C\, h^{k+1}\|v\|_{k+1,p} \tag{3.1}$$

for $1 \le p \le \infty$ and $v \in H^{k+1,p}(\Omega)$ [5]. We will not need an inverse estimate for the error analysis and thus do not require quasi uniformity of the underlying meshes.

DEFINITION 3.1 (semidiscrete solution). *A pair u_h, κ_h with $u_h \in C^1([0,T], \mathcal{X}_h)$, $\kappa_h \in C^0([0,T]; \mathcal{X}_h)$ is called a* semidiscrete solution *of* (1.2) *if $u_h(0,\cdot) = I_h u_0$ and*

$$\langle \partial_t u_h, \psi_h\rangle - \boldsymbol{a}(u_h;\kappa_h,\psi_h) = \boldsymbol{a}(u_h; f, \psi_h) \qquad \forall \psi_h \in \mathcal{X}_h, \tag{3.2}$$

$$\langle \kappa_h, \varphi_h\rangle + \tilde{\boldsymbol{a}}(u_h; u_h, \varphi_h) = 0 \qquad \forall \varphi_h \in \mathcal{X}_h. \tag{3.3}$$

From now on we consider $d \ge 2$; the analysis for $d = 1$ is just a simplified version of this case. We recall from Remark 2.4 that $\{\zeta, \chi_1, \dots, \chi_{d-1}\}$ is a set of orthonormal vectors for which (2.6) holds. If $\{\zeta_h, \chi_{h,1}, \dots, \chi_{h,d-1}\}$ denotes likewise a semidiscrete orthonormal set and $Q_h = Q(u_h)$, then

$$\boldsymbol{a}(u_h; v, w) = \int_\Omega \left(\frac{\nabla v\cdot\zeta_h\, \nabla w\cdot\zeta_h}{Q_h} + \sum_{i=1}^{d-1} \nabla v\cdot\chi_{h,i}\, \nabla w\cdot\chi_{h,i}\, Q_h \right). \tag{3.4}$$

PROPOSITION 3.2 (semidiscrete stability). *Let (u_h, κ_h) be a semidiscrete solution in the sense of Definition* 3.1, *and let $A_h(t) := \int_\Omega Q_h$ denote the area of the surface $\Gamma_h(t) := \{(x, u_h(t,x)) \,|\, x \in \Omega\}$. There are two constants, $C_1 = C_1(\Omega)$ and*

$C_2 = C_2\big(\|\nabla f\|_\infty, A_h(0)\big)$, such that

$$\sup_{t\in[0,T]} \|u_h(t)\|_2^2 + \int_0^T \|\kappa_h\|_2^2 \le \|u_h(0)\|_2^2 + C_1 \int_0^T \|\nabla f\|_2, \tag{3.5}$$

$$\sup_{t\in[0,T]} A_h(t) + \int_0^T \boldsymbol{a}(u_h;\kappa_h,\kappa_h) \le C_2. \tag{3.6}$$

Moreover, if $f \equiv 0$, the function $A_h(t)$ is decreasing (strictly if $\boldsymbol{a}(u_h;\kappa_h,\kappa_h) > 0$).

Proof. First, choose $\psi_h := u_h$, $\varphi_h := \kappa_h$ as test functions in (3.2) and (3.3), respectively. In view of Remark 2.3, we get

$$\langle \partial_t u_h, u_h\rangle + \langle \kappa_h, \kappa_h\rangle + \underbrace{\tilde{\boldsymbol{a}}(u_h;u_h,\kappa_h) - \boldsymbol{a}(u_h;\kappa_h,u_h)}_{=0} = \boldsymbol{a}(u_h;f,u_h),$$

and, since $|\nabla u_h|/Q_h \le 1$,

$$\boldsymbol{a}(u_h;f,u_h) = \tilde{\boldsymbol{a}}(u_h;f,u_h) = \int_\Omega \frac{\nabla f\cdot\nabla u_h}{Q_h} \le \|\nabla f\|_2 \left(\int_\Omega \frac{|\nabla u_h|^2}{Q_h^2}\right)^{1/2} \le C_1\|\nabla f\|_2.$$

Integrating in time gives (3.5). We next set $\psi_h := -\kappa_h$, $\varphi_h := \partial_t u_h$ to derive

$$\underbrace{-\langle \partial_t u_h, \kappa_h\rangle + \langle \kappa_h, \partial_t u_h\rangle}_{=0} + \boldsymbol{a}(u_h;\kappa_h,\kappa_h) + \tilde{\boldsymbol{a}}(u_h;u_h,\partial_t u_h) = -\boldsymbol{a}(u_h;f,\kappa_h).$$

Observing that

$$\tilde{\boldsymbol{a}}(u_h;u_h,\partial_t u_h) = \int_\Omega \frac{\nabla u_h\cdot\nabla\partial_t u_h}{Q_h} = \frac{d}{dt}\int_\Omega Q_h = \frac{d}{dt}A_h(t), \tag{3.7}$$

we get

$$\frac{d}{dt}A_h(t) + \boldsymbol{a}(u_h;\kappa_h,\kappa_h) = -\boldsymbol{a}(u_h;f,\kappa_h),$$

which implies that $A_h(t)$ is decreasing, provided that $f \equiv 0$. To prove (3.6) for $f \not\equiv 0$, we have to bound $\boldsymbol{a}(u_h;f,\kappa_h)$. Making use of (3.4), we obtain

$$\begin{aligned}
\boldsymbol{a}(u_h;f,\kappa_h) &= \int_\Omega \left(\frac{\nabla f\cdot\zeta_h\,\nabla\kappa_h\cdot\zeta_h}{Q_h} + \sum_{i=1}^{d-1} \nabla f\cdot\chi_{h,i}\,\nabla\kappa_h\cdot\chi_{h,i}\,Q_h\right)\\
&\le \|\nabla f\|_\infty \int_\Omega \left(\frac{|\nabla\kappa_h\cdot\zeta_h|}{Q_h} + \sum_{i=1}^{d-1} |\nabla\kappa_h\cdot\chi_{h,i}|\,Q_h\right)\\
&\le \|\nabla f\|_\infty \left(\frac{|\Omega|}{4\epsilon} + \epsilon\int_\Omega \left(\frac{|\nabla\kappa_h\cdot\zeta_h|^2}{Q_h} + \sum_{i=1}^{d-1} |\nabla\kappa_h\cdot\chi_{h,i}|^2 Q_h\right) + \frac{\int_\Omega Q_h}{4\epsilon}\right)\\
&= \|\nabla f\|_\infty \Big(C_\epsilon + \epsilon\,\boldsymbol{a}(u_h;\kappa_h,\kappa_h) + C_\epsilon A_h(t)\Big),
\end{aligned}$$

where we have used that $Q_h \ge 1$. Choosing ϵ sufficiently small, a Gronwall argument finally yields (3.6). ∎

COROLLARY 3.3 (global existence of semidiscrete solution). *For $h > 0$ and $T > 0$ there is a unique semidiscrete solution (u_h, κ_h) fulfilling* (3.2) *and* (3.3).

Proof. Observing that (3.2)–(3.3) is equivalent to a system of ODEs with a locally Lipschitz right-hand side, we get a local in time existence of the semidiscrete solution. Using the above stability estimate, this solution can be extended to the time interval $[0,T]$ by standard arguments. Uniqueness follows from the local Lipschitz continuity of the right-hand side. ∎

4. Auxiliary estimates. In this section we present some auxiliary lemmas and results that will be instrumental in deriving the error estimates. Since they will be used several times and might be of independent interest, we present them separately.

We start by introducing the following notation:

$$e_u := u - u_h, \qquad e_\kappa := \kappa - \kappa_h, \qquad N_h := \int_\Omega |\nu - \nu_h|^2 Q_h.$$

LEMMA 4.1 (basic geometric formulas). *Using the notation introduced above, the following inequalities hold:*

$$\left|\frac{1}{Q} - \frac{1}{Q_h}\right| \le |\nu - \nu_h|, \qquad |Q - Q_h| \le Q Q_h |\nu - \nu_h|, \tag{4.1}$$

and

$$\left|\frac{\nabla u \otimes \nabla u}{Q} - \frac{\nabla u_h \otimes \nabla u_h}{Q_h}\right| \le 3\, Q\, Q_h\, |\nu - \nu_h|. \tag{4.2}$$

Proof. Recalling that $\nu = \frac{1}{Q}(\nabla u, -1)^T$ and $\nu_h = \frac{1}{Q_h}(\nabla u_h, -1)^T$, the inequalities in (4.1) are immediate. To prove (4.2), let us introduce the notation $z := \frac{\nabla u}{Q}$ and $z_h := \frac{\nabla u_h}{Q_h}$, and observe that

$$\begin{aligned}\frac{\nabla u \otimes \nabla u}{Q} - \frac{\nabla u_h \otimes \nabla u_h}{Q_h} &= z \otimes z\, Q - z_h \otimes z_h\, Q_h \\ &= (z - z_h) \otimes z\, Q + z_h \otimes z\, (Q - Q_h) + z_h \otimes (z - z_h)\, Q_h.\end{aligned}$$

Therefore, the triangle inequality and the fact that $|z - z_h| \le |\nu - \nu_h|$ yield (4.2). ∎

The following lemma is crucial for our error analysis and provides a coercivity estimate for $\tilde{\boldsymbol{a}}$. The estimate is the same as the one that appears in the error analysis for mean curvature flow and is due to Deckelnick and Dziuk [8] and Dziuk [10]. Even though its proof can be found in [8, p. 347], we sketch it here for completeness.

LEMMA 4.2 (coercivity of $\tilde{\boldsymbol{a}}$). *The following estimate holds true:*

$$\tilde{\boldsymbol{a}}(u; u, \partial_t e_u) - \tilde{\boldsymbol{a}}(u_h; u_h, \partial_t e_u) \ge \frac{1}{2}\frac{d}{dt} N_h(t) - \|\nabla \partial_t u(t)\|_\infty N_h(t).$$

Proof. We start with two geometric relations which follow by simple calculation:

$$1 - \frac{1 + \nabla u \cdot \nabla u_h}{Q Q_h} = \frac{1}{2}\big|\nu - \nu_h\big|^2, \quad \left|\left(\frac{1}{Q} - \frac{1}{Q_h}\right)\left(\frac{\nabla u}{Q} - \frac{\nabla u_h}{Q_h}\right)\right| \le \frac{1}{2}\big|\nu - \nu_h\big|^2. \tag{4.3}$$

We now use the first equality in (4.3) to realize that

$$\begin{aligned}\frac{1}{2}\partial_t\big(|\nu-\nu_h|^2Q_h\big) &= \partial_t\left(\left(1-\frac{1+\nabla u\cdot\nabla u_h}{QQ_h}\right)Q_h\right)\\ &= \frac{\nabla u_h\cdot\nabla\partial_t u_h}{Q_h}+\frac{\nabla u\cdot\nabla\partial_t u}{Q^3}\big(1+\nabla u\cdot\nabla u_h\big)\\ &\quad -\frac{1}{Q}\big(\nabla u_h\cdot\nabla\partial_t u+\nabla u\cdot\nabla\partial_t u_h\big),\end{aligned}$$

and, upon adding and subtracting $\frac{\nabla u_h\cdot\partial_t\nabla u}{Q_h}$ and reordering terms, we find out that

$$\begin{aligned}\frac{1}{2}\partial_t\big(|\nu-\nu_h|^2Q_h\big) &= \left(\frac{\nabla u}{Q}-\frac{\nabla u_h}{Q_h}\right)\cdot\nabla\partial_t(u-u_h)\\ &\quad -\partial_t\nabla u\cdot\left(\frac{\nabla u}{Q}-\frac{\nabla u_h}{Q_h}+\frac{\nabla u_h}{Q}-\frac{1+\nabla u\cdot\nabla u_h}{Q^2}\frac{\nabla u}{Q}\right).\end{aligned}$$

We next integrate over Ω, use the definition of N_h, and add and subtract $\nabla\partial_t u\cdot\nabla u\frac{Q_h}{Q^2}$ to obtain

$$\begin{aligned}\tilde{\boldsymbol{a}}(u;u,\partial_t e_u)-\tilde{\boldsymbol{a}}(u_h;u_h,\partial_t e_u) &= \int_\Omega\left(\frac{\nabla u}{Q}-\frac{\nabla u_h}{Q_h}\right)\cdot\nabla\partial_t(u-u_h)\\ &= \frac{1}{2}\frac{d}{dt}\int_\Omega|\nu-\nu_h|^2Q_h\\ &\quad +\int_\Omega\partial_t\nabla u\cdot\left(\frac{\nabla u}{Q}-\frac{\nabla u_h}{Q_h}\right)\left(\frac{1}{Q_h}-\frac{1}{Q}\right)Q_h\\ &\quad +\int_\Omega\partial_t\nabla u\cdot\frac{\nabla u}{Q^2}\left(1-\frac{1+\nabla u\cdot\nabla u_h}{QQ_h}\right)Q_h\\ &\geq \frac{1}{2}\frac{d}{dt}N_h(t)-\|\nabla\partial_t u(t)\|_\infty N_h(t),\end{aligned}$$

where we have employed both estimates (4.3). This finally concludes the proof. ∎

The following two lemmas are consistency estimates for the bilinear forms $\boldsymbol{a}$ and $\tilde{\boldsymbol{a}}$, respectively.

LEMMA 4.3 (consistency estimate for $\boldsymbol{a}$). *For every $\epsilon>0$ there exists a constant $C=C(\epsilon,\|\nabla\kappa\|_\infty,\|Q\|_\infty,\|\nabla f\|_\infty)>0$ such that*

$$|\boldsymbol{a}(u;\kappa,w)-\boldsymbol{a}(u_h;\kappa_h,w)| \;\leq\; \epsilon\,\boldsymbol{a}(u_h;e_\kappa,e_\kappa)\;+\;C\,\|\nabla w\|_\infty^2\;+\;N_h(t)\quad\forall w\in\mathcal{X}.$$

Proof. We first add and subtract the term $\boldsymbol{a}(u_h;\kappa,w)$ to obtain

$$\boldsymbol{a}(u;\kappa,w)-\boldsymbol{a}(u_h;\kappa_h,w)=\boldsymbol{a}(u_h;\kappa-\kappa_h,w)+\big(\boldsymbol{a}(u;\kappa,w)-\boldsymbol{a}(u_h;\kappa,w)\big)=:(I)+(II)$$

and analyze (I) and (II) separately. By the Cauchy–Schwarz inequality,

$$(I)\leq\epsilon\,\boldsymbol{a}(u_h;e_\kappa,e_\kappa)+\frac{1}{4\epsilon}\boldsymbol{a}(u_h;w,w),$$

and, using the definition (2.2) of $\boldsymbol{a}(u_h;\cdot,\cdot)$, we get

$$\boldsymbol{a}(u_h;w,w)=\int_\Omega|\nabla w|^2Q_h-\frac{1}{Q_h}|\nabla w\cdot\nabla u_h|^2\leq\int_\Omega|\nabla w|^2Q_h\leq\|\nabla w\|_\infty^2A_h(t).$$

Therefore,

$$(I) \le \epsilon\, \boldsymbol{a}(u_h; e_\kappa, e_\kappa) + \frac{1}{4\epsilon}\|\nabla w\|_\infty^2 A_h(t).$$

We now turn to estimate (II). Using the equivalent form (2.7) for $\boldsymbol{a}$, we have

$$(II) = \int_\Omega \nabla\kappa^T \left((Q - Q_h)I - \left(\frac{\nabla u \otimes \nabla u}{Q} - \frac{\nabla u_h \otimes \nabla u_h}{Q_h} \right) \right) \nabla w.$$

By (4.1) and (4.2), the integrand in (II) is bounded by $4\,Q\,Q_h\,|\nabla\kappa|\,|\nabla w|\,|\nu - \nu_h|$, which by the Cauchy–Schwarz inequality gives

$$\begin{aligned}(II) &\le 4\int_\Omega Q^2 |\nabla\kappa|^2 |\nabla w|^2 Q_h + \int_\Omega |\nu - \nu_h|^2 Q_h \\ &\le 4\|Q\|_\infty^2 \|\nabla\kappa\|_\infty^2 \|\nabla w\|_\infty^2 A_h(t) + N_h(t).\end{aligned}$$

Since $A_h(t) \le C$ from (3.6), the bounds for (I) and (II) yield the assertion. ∎

LEMMA 4.4 (consistency estimate for $\tilde{\boldsymbol{a}}$). *For every $\epsilon > 0$ we have*

$$|\tilde{\boldsymbol{a}}(u; u, w) - \tilde{\boldsymbol{a}}(u_h; u_h, w)| \le \epsilon \tilde{\boldsymbol{a}}(u_h; w, w) + \frac{1}{4\epsilon} N_h(t) \quad \forall w \in \mathcal{X}.$$

Proof. Using the definition (2.3) of $\tilde{\boldsymbol{a}}$ and the Cauchy–Schwarz inequality, we get

$$\begin{aligned}|\tilde{\boldsymbol{a}}(u; u, w) - \tilde{\boldsymbol{a}}(u_h; u_h, w)| &\le \int_\Omega \left| \frac{\nabla u}{Q} - \frac{\nabla u_h}{Q_h} \right| |\nabla w| \le \int_\Omega |\nu - \nu_h|\,|\nabla w| \\ &\le \epsilon \int_\Omega \frac{|\nabla w|^2}{Q_h} + \frac{1}{4\epsilon} N_h(t) = \epsilon\, \tilde{\boldsymbol{a}}(u_h; w, w) + \frac{1}{4\epsilon} N_h(t),\end{aligned}$$

which is the desired estimate. ∎

The following lemma establishes another consistency estimate for $\boldsymbol{a}$, this time provided that solely the *nonlinear* part of $\boldsymbol{a}$ changes.

LEMMA 4.5. *There exists a constant $C = C(\|Q\|_\infty) > 0$ such that for every $\epsilon > 0$*

$$|\boldsymbol{a}(u; v, w) - \boldsymbol{a}(u_h; v, w)| \le \epsilon\, \boldsymbol{a}(u_h; w, w) + \frac{C}{\epsilon}\|\nabla v\|_\infty^2 N_h(t) \qquad \forall v, w \in \mathcal{X}.$$

Proof. With $R := \|Q\|_\infty$, we consider the following disjoint splitting of Ω: $\Omega = \Omega^+ \cup \Omega^-$ with $\Omega^+ := \{x \in \Omega \,|\, Q_h(x) > 2R\}$ and $\Omega^- := \{x \in \Omega \,|\, Q_h(x) \le 2R\}$.

We first estimate the integrand of $\boldsymbol{a}(u; \cdot, \cdot) - \boldsymbol{a}(u_h; \cdot, \cdot)$ in the case $x \in \Omega^-$. According to (2.7), we consider this integrand written in the form

$$\nabla v^T \left((Q - Q_h)I - \left(\frac{\nabla u \otimes \nabla u}{Q} - \frac{\nabla u_h \otimes \nabla u_h}{Q_h} \right) \right) \nabla w =: (I).$$

Since $Q_h(x) \le 2R$ for $x \in \Omega^-$, in view of (4.1) and (4.2) we have

$$\begin{aligned}(I) &\le 4|\nabla v|\,|\nabla w|\,Q\,Q_h|\nu - \nu_h| \le 8R^2 |\nabla v| \frac{|\nabla w|}{\sqrt{Q_h}} |\nu - \nu_h| \sqrt{Q_h} \\ &\le \epsilon \frac{|\nabla w|^2}{Q_h} + 16 \frac{R^4}{\epsilon} \|\nabla v\|_\infty^2 |\nu - \nu_h|^2 Q_h.\end{aligned}$$

To analyze the case $x \in \Omega^+$, we choose ζ, ζ_h, χ_i, $\chi_{h,i}$ as in Remark 2.4. Since $Q(x) \le R$ and $Q_h(x) > 2R$ we have

$$|\nu - \nu_h| \ge \frac{1}{Q} - \frac{1}{Q_h} \ge \frac{1}{2R} \quad \text{and} \quad |\zeta - \zeta_h|\,, |\chi_i - \chi_{h,i}| \le 2 \le 4R|\nu - \nu_h|. \tag{4.4}$$

Consider the integrand in the form (2.6):

$$\underbrace{\left(\frac{\nabla v\cdot\zeta\,\nabla w\cdot\zeta}{Q} - \frac{\nabla v\cdot\zeta_h\,\nabla w\cdot\zeta_h}{Q_h}\right)}_{(II)} + \sum_{i=1}^{d-1} \underbrace{\nabla w^T\big(\chi_i\otimes\chi_i\,Q - \chi_{h,i}\otimes\chi_{h,i}\,Q_h\big)\nabla v}_{(III)_i}.$$

Since $R \ge 1$, we have for (II)

$$\begin{aligned}
(II) &= \nabla v^T\left(\frac{\zeta\otimes\zeta}{Q} - \frac{\zeta_h\otimes\zeta_h}{Q_h}\right)\nabla w \\
&= \nabla v^T\left[(\zeta-\zeta_h)\otimes\zeta\frac{1}{Q} + \zeta_h\otimes\zeta\left(\frac{1}{Q}-\frac{1}{Q_h}\right) + \zeta_h\otimes(\zeta-\zeta_h)\frac{1}{Q_h}\right]\nabla w \\
&\le C\,R\,|\nabla v|\,|\nabla w|\,|\nu-\nu_h| \le \frac{C^2\,R^2}{4\epsilon}\|\nabla v\|_\infty^2\,|\nu-\nu_h|^2 Q_h + \epsilon\frac{|\nabla w|^2}{Q_h}.
\end{aligned}$$

For $(III)_i$, instead, we proceed as follows with the aid of (4.1):

$$\begin{aligned}
(III)_i &= \nabla w^T\Big((\chi_i-\chi_{h,i})\otimes\chi_i\,Q + \chi_{h,i}\otimes\chi_i\,(Q-Q_h) + \chi_{h,i}\otimes(\chi_i-\chi_{h,i})Q_h\Big)\nabla v \\
&\le 4\,R^2\,|\nu-\nu_h|\,|\nabla v|\,|\nabla w| + 5R\,|\nu-\nu_h|Q_h|\chi_{h,i}\cdot\nabla w|\,|\nabla v| \\
&\le \epsilon\frac{|\nabla w|^2}{Q_h} + \epsilon|\nabla w\cdot\chi_{h,i}|^2 Q_h + \frac{CR^4}{\epsilon}\|\nabla v\|_\infty^2|\nu-\nu_h|^2 Q_h.
\end{aligned}$$

Collecting the estimates for both cases, $x \in \Omega^-$ and $x \in \Omega^+$, integrating over Ω, and recalling (2.6), we obtain the assertion after relabeling ϵ. ∎

Using Lemma 4.5 we obtain a coercivity estimate for $\boldsymbol{a}$.

COROLLARY 4.6 (coercivity of $\boldsymbol{a}$). *There exists $C = C(\|Q\|_\infty) > 0$ such that*

$$\boldsymbol{a}(u;\kappa,e_\kappa) - \boldsymbol{a}(u_h;\kappa_h,e_\kappa) \ge \frac{1}{2}\boldsymbol{a}(u_h;e_\kappa,e_\kappa) - C\|\nabla\kappa\|_\infty^2 N_h(t).$$

Proof. Adding and subtracting $\boldsymbol{a}(u_h;\kappa,e_\kappa)$, and using Lemma 4.5 with $\epsilon = 1/2$, we readily obtain the desired estimate. ∎

LEMMA 4.7 (coercivity of $N_h(t)$). *There exists $C = C(\|Q\|_\infty)$ such that*

$$\boldsymbol{a}(u_h;e_u,e_u) \le C N_h(t).$$

Proof. In light of Remark 2.4, we can write

$$\boldsymbol{a}(u_h;e_u,e_u) = \int_\Omega \underbrace{\frac{|\nabla e_u\cdot\zeta_h|^2}{Q_h}}_{(I)} + \sum_{i=1}^{d-1}\int_\Omega \underbrace{|\nabla e_u\cdot\chi_{h,i}|^2 Q_h}_{(II)_i}.$$

By virtue of (4.1), (I) satisfies

$$\begin{aligned}
(I) &\le \frac{|\nabla e_u|^2}{Q_h} = \frac{|\nabla u - \nabla u_h|^2}{Q_h} \le \frac{|\nu Q - \nu_h Q_h|^2}{Q_h} \\
&\le \frac{|\nu(Q-Q_h) + (\nu-\nu_h)Q_h|^2}{Q_h}Q_h \le 4\|Q\|_\infty^2\,Q_h|\nu-\nu_h|^2.
\end{aligned} \tag{4.5}$$

To treat the integrand $(II)_i$ we again split Ω into Ω^- and Ω^+, as in Lemma 4.5. Consider first $x \in \Omega^-$, namely, $Q_h(x) \le 2R$ with $R := \|Q(t)\|_\infty$. As in (4.5), we get

$$|\nabla e_u \cdot \chi_{h,i}|^2 Q_h \le 4R^2 \frac{|\nabla e_u|^2}{Q_h} \le 16 \|Q\|_\infty^4 Q_h |\nu - \nu_h|^2.$$

Now we consider $Q_h(x) > 2R$. Since $\nabla u_h \cdot \chi_{h,i} = 0$, it follows from (4.4) that

$$\nabla e_u \cdot \chi_{h,i} = \nabla(u - u_h) \cdot \chi_{h,i} = \nabla u \cdot \chi_{h,i} \le |\nabla u| \le 2\, R\, \|\nabla u\|_\infty |\nu - \nu_h|,$$

whence

$$|\nabla e_u \cdot \chi_{h,i}|^2 Q_h \le 4 \|Q\|_\infty^4 |\nu - \nu_h|^2 Q_h.$$

The desired estimate then follows by integration over Ω. ∎

5. A priori error analysis. In this section we prove the main theoretical result of this article, which can be stated as follows.

THEOREM 5.1. *Let (u_h, κ_h) be the semidiscrete solution of Definition* 3.1*, and let $e_u := u - u_h$, $e_\kappa := \kappa - \kappa_h$. There exists a constant C depending on $\|\nabla f\|_\infty$, $\|\partial_t u\|_{L^2(H^{k+1}(\Omega))}$, $\|\partial_t \nabla u\|_\infty$, $\|\kappa\|_{L^2(H^{k+1}(\Omega))}$, $\|\partial_t \kappa\|_{L^2(H^k(\Omega))}$, and $\|\nabla \kappa\|_\infty$ such that*

$$\sup_{t\in[0,T]} \left(\|e_u(t)\|_2^2 + \int_{\Gamma_h(t)} |\nabla_S e_u|^2 \right) + \int_0^T \left(\|e_\kappa\|_2^2 + \int_{\Gamma_h(t)} |\nabla_S e_\kappa|^2 \right) \le C\, h^{2k}.$$

The proof of Theorem 5.1 is a consequence of two estimates, the strong and the weak estimates, derived from the error equations (5.1) and (5.2) below by choosing appropriate test functions.

Remark 5.2 (H^1 estimate). The estimate for $\nabla_S e_u$ might seem surprising at first sight since direct H^1 estimates are unavailable for minimal surfaces for dimension $d > 2$. It is thus worth stressing that, instead of the usual H^1 norm, we have an integral over the discrete surface $\Gamma_h(t)$ which involves the tangential gradient ∇_S. In its derivation, we exploit parabolicity to prove first an estimate for $N_h(t)$ and then use Lemma 4.7 (see section 5.1).

Remark 5.3 (regularity). The required regularity of (u, κ) in Theorem 5.1 might appear inconsistent with that of Ω for polynomial degree $k > 1$. In fact, we have assumed that Ω can be partitioned exactly into finite elements but not that Ω is polyhedral (see section 3). This would thus entail the use of isoparametric elements for $k > 1$, but still $\Omega = \Omega_h$ might fail to hold. Accounting for the effect of $\Omega \ne \Omega_h$ is mostly a technical issue and is, therefore, omitted in the subsequent discussion, which is already rather technical.

5.1. Proof of Theorem 5.1. Subtracting (3.2) and (3.3) from (2.4) and (2.5), respectively, we get the following error equations:

$$\langle \partial_t e_u, \psi_h \rangle - (\boldsymbol{a}(u; \kappa, \psi_h) - \boldsymbol{a}(u_h; \kappa_h, \psi_h)) = \boldsymbol{a}(u; f, \psi_h) - \boldsymbol{a}(u_h; f, \psi_h), \tag{5.1}$$

$$\langle e_\kappa, \varphi_h \rangle + (\tilde{\boldsymbol{a}}(u; u, \varphi_h) - \tilde{\boldsymbol{a}}(u_h; u_h, \varphi_h)) = 0 \tag{5.2}$$

for all $\psi_h, \varphi_h \in \mathcal{X}_h$. The strong and weak estimates below are formulated in terms of the following interpolation errors, which can be bounded via (3.1):

$$\rho_u := u - I_h u, \qquad \rho_\kappa := \kappa - I_h \kappa_h. \tag{5.3}$$

The strong estimate of section 5.2 reads as follows: *For all $\epsilon > 0$ there exists a constant C_0 depending only on $\|\nabla f\|_\infty, \|\nabla\kappa\|_\infty, \|\partial_t\nabla u\|_\infty$, and ϵ such that for $t \in [0,T]$*

$$
\begin{aligned}
N_h(t) + \int_0^t \boldsymbol{a}(u_h; e_\kappa, e_\kappa) &\le N_h(0) + C_0 \int_0^t \Big(N_h + \|e_u\|_2^2 \Big) \\
&+ 2\epsilon \left(\|e_u(t)\|_2^2 + \int_0^t \|e_\kappa\|_2^2 \right) \\
&+ \frac{1}{2\epsilon} \|\rho_\kappa(t)\|_2^2 + \|e_u(0)\|_2^2 + \|\rho_\kappa(0)\|_2^2 \\
&+ C_0 \int_0^t \Big(\|\nabla\rho_\kappa\|_\infty^2 + \|\partial_t\nabla\rho_u\|_2^2 + \|\partial_t\rho_u\|_2^2 + \|\partial_t\rho_\kappa\|_2^2 \Big).
\end{aligned} \tag{5.4}
$$

It is clear that to close the argument we need separate control on the term multiplied by ϵ of the right-hand side of (5.4). This is provided by the weak estimate of section 5.3, which reads as follows: *There exist constants C_1, C_2 depending on $\|\nabla f\|_\infty$ and $\|Q\|_\infty$ such that for $t \in [0,T]$ we have*

$$
\begin{aligned}
\frac{1}{2}\|e_u(t)\|_2^2 + \int_0^t \|e_\kappa\|_2^2 &\le \frac{1}{2}\|e_u(0)\|_2^2 + \int_0^t \|e_u\|_2^2 \\
&+ C_1 \int_0^t N_h + \frac{1}{2}\int_0^t \boldsymbol{a}(u_h; e_\kappa, e_\kappa) \\
&+ \int_0^t \Big(\|\nabla\rho_\kappa\|_2^2 + \|\rho_\kappa\|_2^2 + \|\partial_t\rho_u\|_2^2 \Big) \\
&+ 2\|\rho_u(t)\|_2^2 + C_2 \int_0^t \|\nabla\rho_u\|_\infty^2.
\end{aligned} \tag{5.5}
$$

To prove Theorem 5.1 we add (5.4) and (5.5) and then choose $\epsilon = 1/8$ to eliminate $\|e_u(t)\|_2^2 + \int_0^t \|e_\kappa\|_2^2$ from the right-hand side. Employing a Gronwall argument, we can also remove $\int_0^t \big(N_h(s) + \|e_u\|_2^2\big)$ from the right-hand side at the expense of an exponential depending on C_0, C_1, and T. Finally, Lemma 4.7, in conjunction with $\boldsymbol{a}(u_h; v, v) = \int_{\Gamma_h} \nabla_S v \cdot \nabla_S v$, yields the left-hand side of the asserted estimate. Its right-hand side and underlying a priori regularity result from applying (3.1) to the terms involving ρ_κ, ρ_u defined in (3.1).

5.2. Strong estimate (5.4). To prove (5.4), we choose the discrete functions

$$
\begin{aligned}
-\psi_h &:= I_h\kappa - \kappa_h = (\kappa - \kappa_h) + (I_h\kappa - \kappa) = e_\kappa - \rho_\kappa \in \mathcal{X}_h, \\
\varphi_h &:= \partial_t(I_h u - u_h) = \partial_t e_u - \partial_t\rho_u \in \mathcal{X}_h.
\end{aligned}
$$

Adding (5.1) and (5.2), and invoking Lemma 4.2 and Corollary 4.6, we get

$$
\begin{aligned}
\frac{1}{2}\frac{d}{dt}N_h(t) &+ \frac{1}{2}\boldsymbol{a}(u_h; e_\kappa, e_\kappa) - C\, N_h(t) \\
&\le \boldsymbol{a}(u; \kappa, e_\kappa) - \boldsymbol{a}(u_h; \kappa_h, e_\kappa) + \tilde{\boldsymbol{a}}(u; u, \partial_t e_u) - \tilde{\boldsymbol{a}}(u_h; u_h, \partial_t e_u) \\
&= \big(\boldsymbol{a}(u; \kappa, \rho_\kappa) - \boldsymbol{a}(u_h; \kappa_h, \rho_\kappa)\big) - \big(\boldsymbol{a}(u; f, e_\kappa - \rho_\kappa) - \boldsymbol{a}(u_h; f, e_\kappa - \rho_\kappa)\big) \\
&\quad + \big(\tilde{\boldsymbol{a}}(u; u, \partial_t\rho_u) - \tilde{\boldsymbol{a}}(u_h; u_h, \partial_t\rho_u)\big) - \langle \partial_t e_u, \rho_\kappa\rangle + \langle e_\kappa, \partial_t\rho_u\rangle \\
&=: (I) + (II) + (III) + (IV) + (V),
\end{aligned}
$$

with C depending only on $\|\partial_t \nabla u\|_\infty$, $\|\nabla \kappa\|_\infty$, and $\|Q\|_\infty$. We now proceed to estimate each term on the right-hand side separately.

By Lemma 4.3, there is a constant $C = C(\epsilon, \|\nabla\kappa\|_\infty, \|Q\|_\infty, \|\nabla f\|_\infty)$ such that

$$\big|(I)\big| \le \epsilon\, \boldsymbol{a}(u_h; e_\kappa, e_\kappa) + C\|\nabla \rho_\kappa\|_\infty^2 + N_h(t).$$

Using Lemma 4.4 with $\epsilon = 1$, we obtain

$$\big|(III)\big| \le \tilde{\boldsymbol{a}}(u_h; \partial_t \rho_u, \partial_t \rho_u) + N_h(t) \le \|\nabla \partial_t \rho_u\|_2^2 + N_h(t).$$

For any $t \in [0,T]$ we integrate (IV) by parts on $[0,t]$, thereby obtaining

$$\begin{aligned}\int_0^t (IV) &= \langle e_u(0), \rho_\kappa(0)\rangle - \langle e_u(t), \rho_\kappa(t)\rangle + \int_0^t \langle e_u, \partial_t \rho_\kappa\rangle \\ &\le \frac{1}{2}\|e_u(0)\|_2^2 + \frac{1}{2}\|\rho_\kappa(0)\|_2^2 + \frac{\epsilon}{2}\|e_u(t)\|_2^2 + \frac{1}{2\epsilon}\|\rho_\kappa(t)\|_2^2 + \frac{1}{2}\int_0^t \Big(\|e_u\|_2^2 + \|\partial_t \rho_\kappa\|_2^2\Big).\end{aligned}$$

For (V) we readily have

$$|(V)| \le \frac{\epsilon}{2}\|e_\kappa\|_2^2 + \frac{1}{2\epsilon}\|\partial_t \rho_u\|_2^2.$$

We decompose (II) into discretization and interpolation errors as follows:

$$-(II) = \underbrace{\big(\boldsymbol{a}(u; f, e_\kappa) - \boldsymbol{a}(u_h; f, e_\kappa)\big)}_{(II)_e} - \underbrace{\big(\boldsymbol{a}(u; f, \rho_\kappa) - \boldsymbol{a}(u_h; f, \rho_\kappa)\big)}_{(II)_\rho}. \tag{5.6}$$

In light of Lemma 4.5, there is a constant $C = C(\|Q\|_\infty)$ such that

$$\big|(II)_e\big| \le \frac{1}{4}\,\boldsymbol{a}(u_h; e_\kappa, e_\kappa) + C\|\nabla f\|_\infty^2 N_h(t).$$

Using Lemma 4.1 and (3.6), we find a constant $C = C(\|\nabla f\|_\infty, \|Q\|_\infty, A_h(0))$ such that

$$\begin{aligned}\big|(II)_\rho\big| &= \left|\int_\Omega \nabla f^T \left((Q - Q_h)I - \left(\frac{\nabla u \otimes \nabla u}{Q} - \frac{\nabla u_h \otimes \nabla u_h}{Q_h}\right)\right)\nabla \rho_\kappa\right| \\ &\le 4\int_\Omega |\nabla f|\,|\nabla \rho_\kappa|\,Q\,Q_h\,|\nu - \nu_h| \\ &\le 4\|\nabla f\|_\infty^2 \|\nabla \rho_\kappa\|_\infty^2 \|Q\|_\infty^2 \int_\Omega Q_h + \int_\Omega |\nu - \nu_h|^2 Q_h \\ &\le C\|\nabla \rho_\kappa\|_\infty^2 A_h(t) + N_h(t) \le C\|\nabla \rho_\kappa\|_\infty^2 + N_h(t).\end{aligned}$$

Finally, collecting the above estimates for (I) to (V), subtracting $\frac{1}{4}\,\boldsymbol{a}(u_h; e_\kappa, e_\kappa)$, and integrating in time from 0 to $t \in [0,T]$, we arrive at (5.4).

5.3. Weak estimate (5.5). To prove (5.5), we choose the discrete functions

$$\begin{aligned}\psi_h &:= I_h u - u_h = e_u - \rho_u \in \mathcal{X}_h, \\ \varphi_h &:= I_h \kappa - \kappa_h = e_\kappa - \rho_\kappa \in \mathcal{X}_h.\end{aligned}$$

Adding the error equations (5.1) and (5.2), we obtain

(5.7)
$$\begin{aligned}\langle \partial_t e_u, e_u\rangle + \langle e_\kappa, e_\kappa\rangle \;=\; & \big(\boldsymbol{a}(u;\kappa,e_u) - \boldsymbol{a}(u_h;\kappa_h,e_u)\big) - \big(\tilde{\boldsymbol{a}}(u;u,e_\kappa) - \tilde{\boldsymbol{a}}(u_h;u_h,e_\kappa)\big)\\ & + \langle \partial_t e_u, \rho_u\rangle - \big(\boldsymbol{a}(u;\kappa,\rho_u) - \boldsymbol{a}(u_h;\kappa_h,\rho_u)\big)\\ & + \big(\boldsymbol{a}(u;f,e_u-\rho_u) - \boldsymbol{a}(u_h;f,e_u-\rho_u)\big) + \langle e_\kappa,\rho_\kappa\rangle\\ & + \big(\tilde{\boldsymbol{a}}(u;u,\rho_\kappa) - \tilde{\boldsymbol{a}}(u_h;u_h,\rho_\kappa)\big)\\ =:\; & (I)+\cdots+(VII).\end{aligned}$$

We proceed now to bound each term from (I) to (VII) separately.

Adding and subtracting $\boldsymbol{a}(u_h;\kappa,e_u)$ to (I), and employing Lemma 4.5 with $\epsilon=\frac{1}{6}$, we readily have

$$\begin{aligned}|(I)| &\le |\boldsymbol{a}(u;\kappa,e_u)-\boldsymbol{a}(u_h;\kappa,e_u)| + |\boldsymbol{a}(u_h;e_\kappa,e_u)|\\ &\le C\|\nabla\kappa\|_\infty^2 N_h(t) + \frac{5}{2}\,\boldsymbol{a}(u_h;e_u,e_u) + \frac{1}{6}\,\boldsymbol{a}(u_h;e_\kappa,e_\kappa).\end{aligned}$$

Consequently, Lemma 4.7 yields the following bound with $C=C(\|\nabla\kappa\|_\infty,\|Q\|_\infty)$:

$$\big|(I)\big| \le C N_h(t) + \frac{1}{6}\,\boldsymbol{a}(u_h;e_\kappa,e_\kappa).$$

Making use of Lemma 4.4 and Remark 2.3, we readily deduce (using $\epsilon=\frac{1}{6}$)

$$\big|(II)\big| \le \frac{1}{6}\,\tilde{\boldsymbol{a}}(u_h;e_\kappa,e_\kappa) + \frac{3}{2}N_h(t) \le \frac{1}{6}\,\boldsymbol{a}(u_h;e_\kappa,e_\kappa) + \frac{3}{2}N_h(t),$$

as well as (using $\epsilon=\frac{1}{2}$)

$$\big|(VII)\big| \le \frac{1}{2}\tilde{\boldsymbol{a}}(u_h;\rho_\kappa,\rho_\kappa) + \frac{1}{2}N_h(t) \le \frac{1}{2}\|\nabla\rho_\kappa\|_2^2 + \frac{1}{2}N_h(t).$$

Using Lemma 4.3 with $\epsilon=\frac{1}{6}$ we find a constant $C=C(\|\nabla\kappa\|_\infty,\|Q\|_\infty,\|\nabla f\|_\infty)$ such that

$$\big|(IV)\big| \le \frac{1}{6}\,\boldsymbol{a}(u_h;e_\kappa,e_\kappa) + N_h(t) + C\|\nabla\rho_u\|_\infty^2.$$

For (VI), we obviously have $\big|(VI)\big| \le \frac{1}{2}\|e_\kappa\|_2^2 + \frac{1}{2}\|\rho_\kappa\|_2^2$. For (III), instead, we integrate by parts on $[0,t]$ for any $t\in[0,T]$ to obtain

$$\begin{aligned}\int_0^t (III) &= \langle e_u(t),\rho_u(t)\rangle - \langle e_u(0),\rho_u(0)\rangle - \int_0^t \langle e_u,\partial_t\rho_u\rangle\\ &\le \frac{1}{4}\,\|e_u(t)\|_2^2 + \|\rho_u(t)\|_2^2 + \frac{1}{2}\int_0^t \Big(\|e_u\|_2^2 + \|\partial_t\rho_u\|_2^2\Big).\end{aligned}$$

It remains to bound (V), which involves the right-hand side f. Applying Lemma 4.5 (with $\epsilon=1$) and Lemma 4.7, we obtain

$$\big|\boldsymbol{a}(u;f,e_u) - \boldsymbol{a}(u_h;f,e_u)\big| \le C\|\nabla f\|_\infty^2 N_h(t) + \boldsymbol{a}(u_h;e_u,e_u) \le C N_h(t),$$

with $C=C(\|\nabla f\|_\infty,\|Q\|_\infty)$. Since $\boldsymbol{a}(u;f,\rho_u)-\boldsymbol{a}(u_h;f,\rho_u)$ is similar to $(II)_\rho$ in (5.6), we likewise deduce

$$\big|\boldsymbol{a}(u;f,\rho_u) - \boldsymbol{a}(u_h;f,\rho_u)\big| \le C\|\nabla\rho_u\|_\infty^2 A_h(t) + N_h(t) \le C\|\nabla\rho_u\|_\infty^2 + N_h(t),$$

whence, for C depending on $\|\nabla f\|_\infty$ and $\|Q\|_\infty$, we end up with

$$\big|(V)\big| \le C\|\nabla \rho_u\|_\infty^2 + CN_h(t).$$

Inserting the above bounds for (I) to (VII) back into (5.7) and integrating from 0 to t, we finally obtain the desired estimate (5.5).

6. Full discretization. In this section we introduce the fully discrete scheme actually used in simulations, along with the linear algebra approach to its solution.

6.1. Definition and properties. To discretize in time we subdivide the time interval into $t_0 = 0 < t_1 < \cdots < t_N = T$ and set $\tau_n := t_{n+1} - t_n$. We define the notion of *semi-implicit* fully discrete problem as follows: Set $u_h^0 = u_h(0)$ and for $n = 0, 1, \ldots, N-1$ determine u_h^{n+1}, $\kappa_h^{n+1} \in \mathcal{X}_h$ by

$$\langle u_h^{n+1}, \psi_h\rangle - \tau_n \boldsymbol{a}(u_h^n; \kappa_h^{n+1}, \psi_h) = \tau_n \boldsymbol{a}(u_h^n; f^n, \psi_h) + \langle u_h^n, \psi_h\rangle \qquad \forall \psi_h \in \mathcal{X}_h, \tag{6.1}$$

$$\langle \kappa_h^{n+1}, \varphi_h\rangle + \tilde{\boldsymbol{a}}(u_h^n; u_h^{n+1}, \varphi_h) = 0 \qquad \forall \varphi_h \in \mathcal{X}_h, \tag{6.2}$$

with $f^n := f(t_n)$. Existence and uniqueness of solutions u_h^n, κ_h^n follow from the considerations in section 6.2.

We now establish a stability estimate analogous to (3.6) in Lemma 2.6.

THEOREM 6.1 (fully discrete stability). *Let $(u_h^n, \kappa_h^n)_{n=0}^N$ be a solution of the fully discrete equations* (6.1) *and* (6.2)*, and let $A_h^n := \int_\Omega Q(u_h^n)$ denote the area of the surface $\Gamma_h^n := \{(x, u_h^n(x)) \mid x \in \Omega\}$. There exists $C = C(\|\nabla f\|_\infty, A_h^0)$ such that*

$$\sup_{1\le n\le N} A_h^n + \sum_{n=1}^N \tau_n \int_{\Gamma_h^{n-1}} |\nabla_S \kappa_h^n|^2 \le C. \tag{6.3}$$

Moreover, if $f \equiv 0$, A_h^n is a decreasing sequence (strictly if $\boldsymbol{a}(u_h^{n-1}; \kappa_h^n, \kappa_h^n) > 0$).

Proof. Choose as test functions $-\kappa_h^{n+1}$ and $(u_h^{n+1} - u_h^n)$ in (6.1) and (6.2), respectively, and add both equations. One readily gets

$$\tau_n \boldsymbol{a}(u_h^n; \kappa_h^{n+1}, \kappa_h^{n+1}) + \int_\Omega \frac{\nabla u_h^{n+1} \cdot \nabla (u_h^{n+1} - u_h^n)}{Q(u_h^n)} = -\tau_n \boldsymbol{a}(u_h^n; f^n, \kappa_h^{n+1}). \tag{6.4}$$

The next step consists of finding a discrete counterpart of (3.7). Observing that

$$|a| - |b| \le \frac{a \cdot (a-b)}{|b|} \qquad \forall a, b \in \mathbb{R}^{d+1}$$

and setting $a := (\nabla u_h^{n+1}, 1)^T$, $b := (\nabla u_h^n, 1)^T$, we obtain

$$Q(u_h^{n+1}) - Q(u_h^n) \le \frac{\nabla u_h^{n+1} \cdot \nabla (u_h^{n+1} - u_h^n)}{Q(u_h^n)}.$$

Inserting this into (6.4) gives $A_h^{n+1} \le A_h^n$ if $f \equiv 0$. To prove (6.3) for $f \not\equiv 0$, we have to bound the right-hand side in (6.4). This can be done similarly to (3.5), obtaining

$$|\boldsymbol{a}(u_h^n; f^n, \kappa_h^{n+1})| \le C(1 + A_h^n) \; + \; \epsilon\, \boldsymbol{a}(u_h^n; \kappa_h^{n+1}, \kappa_h^{n+1}),$$

with $C = C(\epsilon, \|\nabla f\|_\infty)$. Multiplying by τ_n, choosing ϵ sufficiently small, summing up over all n, and using a discrete Gronwall argument, the result follows. ∎

6.2. Schur complement strategy. Let $\mathcal{X}_h = \operatorname{span}\{\varphi_j\} \subseteq \mathcal{X}$ with the usual nodal basis functions φ_j and the corresponding nodal space $\underline{\mathbf{X}}$. Then, for the time instant t_{n+1}, the fully discrete system of equations can be rewritten as

$$\begin{bmatrix} \tilde{A} & M \\ M^T & -\tau_n A \end{bmatrix} \begin{bmatrix} \underline{U}^{n+1} \\ \underline{K}^{n+1} \end{bmatrix} = \begin{bmatrix} 0 \\ M^T \underline{U}^n + \tau_n \underline{F}^n \end{bmatrix}, \tag{6.5}$$

where $\underline{U}^n$, $\underline{K}^n$ denote the vector of nodal values for u_h^n, κ_h^n, respectively,

$$u_h^n = \sum_j \underline{U}_j^n \, \varphi_j, \qquad \kappa_h^n = \sum_j \underline{K}_j^n \, \varphi_j,$$

the vector $\underline{F}^n$ is given by $\underline{F}_j^n = \boldsymbol{a}(u_h^n; f^n, \varphi_j)$, and the matrices M, A, $\tilde{A}$ are given by

$$M_{i,j} = \langle \varphi_j, \varphi_i \rangle, \qquad A_{i,j} = \boldsymbol{a}(u_h^n; \varphi_j, \varphi_i), \qquad \tilde{A}_{i,j} = \tilde{\boldsymbol{a}}(u_h^n; \varphi_j, \varphi_i).$$

Notice that the matrices A and $\tilde{A}$ depend on u_h^n and thus have to be reassembled in every time step.

To derive a Schur complement formulation, we have to distinguish between the various boundary conditions (see section 2.2).

Dirichlet boundary conditions. In this case, since $\mathcal{X} := \mathring{H}^1(\Omega)$, the matrix $\tilde{A}$ is invertible, and a Schur complement for $\underline{K}^{n+1}$ is thus given by

$$\begin{aligned} \left(M^T \tilde{A}^{-1} M \; + \; \tau_n A \right) \underline{K}^{n+1} &= -M^T \underline{U}^n - \tau_n \underline{F}^n, \\ \tilde{A} \, \underline{U}^{n+1} &= -M \, \underline{K}^{n+1}. \end{aligned}$$

This system is decoupled and uniquely solvable for both $\underline{K}^{n+1}$ and $\underline{U}^{n+1}$.

Periodic and Neumann boundary conditions. This case is a bit more involved because constant functions are in $\mathcal{X}_h$, whence $\tilde{A}$ has a kernel $\ker(\tilde{A}) = \operatorname{span}\{\underline{1}\}$.

Let $\underline{\mathbf{V}}, \underline{\mathbf{W}} \subseteq \underline{\mathbf{X}}$ be the spaces of nodal values for $\underline{U}^{n+1}$ defined by

$$\underline{\mathbf{V}} := \{\underline{V} \mid \underline{1} \cdot MV = 0\}, \qquad \underline{\mathbf{W}} := \{\underline{V} \mid \underline{1} \cdot \underline{V} = 0\} = \operatorname{span}\{\underline{1}\}^{\perp}.$$

Multiplying the first equation in (6.5) by $\underline{1}$, we see that $\underline{1} \cdot M\underline{K}^{n+1} = 0$, which means that $\underline{K}^{n+1} \in \underline{\mathbf{V}}$. Let P be the orthogonal projection onto $\operatorname{span}\{\underline{1}\}$ with respect to the Euclidean inner product in $\mathbb{R}^I$, with $I = \dim \underline{\mathbf{X}}$. If $S := (\tilde{A}_{|\underline{\mathbf{W}}})^{-1}$, then

$$SM\underline{K}^{n+1} = -S\tilde{A}\underline{U}^{n+1} = -(Id - P)\underline{U}^{n+1} = -\underline{U}^{n+1} + P\underline{U}^{n+1},$$

or $\underline{U}^{n+1} = -SM\underline{K}^{n+1} + P\underline{U}^{n+1}$. Consequently, using the second equation in (6.5),

$$(M^T SM + \tau_n A) \, \underline{K}^{n+1} - M^T P \, \underline{U}^{n+1} = -M^T \underline{U}^n - \tau_n \underline{F}^n. \tag{6.6}$$

Now let $\Pi := Id - \frac{M^T \underline{1} \otimes M^T \underline{1}}{|M^T \underline{1}|^2}$ be the orthogonal projection onto $\underline{\mathbf{V}}$. Applying Π to both sides of (6.6) and using that $\Pi M P \underline{U}^{n+1} = 0$ and $\Pi \underline{K}^{n+1} = \underline{K}^{n+1}$, we arrive at

$$\Pi(M^T SM + \tau_n A)\Pi \, \underline{K}^{n+1} = -\Pi(M^T \underline{U}^n + \tau_n \underline{F}^n). \tag{6.7}$$

The matrix $\Pi(M^T SM + \tau_n A)\Pi$ is symmetric and positive definite in $\underline{\mathbf{V}}$, and thus (6.7) is uniquely solvable for $\underline{K}^{n+1}$ in $\underline{\mathbf{V}}$. Finally, $\underline{U}^{n+1}$ is uniquely determined by

$$\tilde{A} \, \underline{U}^{n+1} = -M \, \underline{K}^{n+1}, \qquad \underline{1} \cdot M^T \underline{U}^{n+1} = \underline{1} \cdot M^T \underline{U}^n. \tag{6.8}$$

Note that the last equation is the conservation of volume $\int_\Omega (U^{n+1} - U^n) = 0$ written in matrix-vector form; compare with Remark 2.5.

7. Numerical experiments. The purpose of this section is to document via several experiments the performance of the discretization scheme proposed in this article. We open this section with some comments about the implementation of the algorithm within the flexible adaptive finite element toolbox ALBERT [16, 17]. We continue with a verification of the experimental orders of convergence (EOCs) achieved by the method with different polynomial degrees and relations between time step τ and mesh size h. We next illustrate the smoothing effect of surface diffusion (case $f = 0$), and we finally present simulations driven by a forcing term which exhibit singularity formation in finite time in both one dimension and two dimensions (case $f \neq 0$).

7.1. Implementation. The matrices of section 6 were assembled using the standard assembling tools of ALBERT, and the solution to the linear systems (6.7)–(6.8) was obtained by a conjugate gradient method.

For the assembling of the linear systems, quadrature rules exact for polynomials of degree $2k$ were used, where k is the degree of the finite element. For computing the errors versus the exact solution, quadratures of order $2k + 2$ were used.

For all the experiments presented in this article, domains with periodic boundary conditions were considered. Experiments with other boundary conditions were also carried out and will be shown elsewhere. The results were similar.

7.2. EOCs. To test the performance of the discretization scheme we consider the domain $\Omega = (-1, 1) \times (-1, 1) \subset \mathbb{R}^2$ with the exact solution

$$u(x, y, t) = 1 + 0.1 \sin(\pi x) \sin(2\pi y) \cos(\pi t) \qquad \forall\, t \in [0, 1].$$

The exact curvature $\kappa = \nabla \cdot \left(\frac{\nabla u}{Q}\right)$ and right-hand side $F = \partial_t u - Q\Delta_S \kappa$ were obtained using the symbolic capabilities of Mathematica. The finite element method of section 6 is used to compute (u_h, κ_h), and a comparison with (u, κ) is presented in Tables 7.1–7.4. They display the errors

$$\mathrm{err}_\nu := \sup_{0\le t\le T} \left(\int_\Omega |\nu - \nu_h|^2 Q_h \right)^{1/2}, \qquad \mathrm{err}_u := \sup_{0\le t\le T} \boldsymbol{a}(u_h; e_u, e_u)^{1/2},$$

$$\mathrm{err}_\kappa := \left(\int_0^T \boldsymbol{a}(u_h; e_\kappa, e_\kappa) \right)^{1/2}, \quad \mathrm{err}_{u,2} := \sup_{0\le t\le T} \|e_u\|_2, \quad \mathrm{err}_{\kappa,2} := \left(\int_0^T \|e_\kappa\|_2^2 \right)^{1/2}$$

for different values of h and τ along with the EOCs. Given two meshes with mesh sizes H, h and errors err_H, err_h, respectively, the EOC is determined according to

$$\mathrm{EOC} = \frac{\log(\mathrm{err}_H/\mathrm{err}_h)}{\log(H/h)},$$

which gives the computational exponent k in the expression $\mathrm{err}_h \cong Ch^k$.

In Table 7.1 we show the results obtained using *linear* elements and a time step $\tau = h$. Even though τ seems to be large as compared to h, the convergence rate is still linear, and no instabilities arise. This is not so surprising if we recall that the fully discrete system is *unconditionally* stable (see Theorem 6.1). In order to verify the error analysis in section 5 for the *semidiscretization in space*, we also compute the EOCs for smaller values of τ, namely $\tau = 0.1h$ and $\tau = h^2$; see Tables 7.2 and 7.3. Here again, we observe that the EOCs are at least 1. Moreover, as one would expect, the errors measured in $L^2(\Omega)$ norms are approximately of second order, provided

that $\tau = h^2$; this is not predicted by our theory though. For $\tau = h, 0.1h$ we do not recover second-order errors because the time discretization error—expected to be of first order—dominates the space error in $L^2(\Omega)$ norms.

To further verify experimentally the error estimates of section 5, which are valid for any polynomial degree, we also compute the EOCs for *quadratic* elements. Table 7.4 displays the results obtained with quadratics and $\tau = h^2$. The EOCs are about 2 in all the error norms, as predicted by theory, including those in $L^2(\Omega)$. In fact, the latter cannot exhibit EOCs close to 3 due to the choice of the time step $\tau = h^2$.

7.3. Smoothing effect in one dimension: Case $f \equiv 0$. In this section we present experimental results in $\Omega = (-1, 1)$ concerning the behavior of the discrete solution when $f \equiv 0$ and $u_0(x) = 1 + \delta(x)$ is a perturbation of the stationary solution $u \equiv 1$.

Superposition of sines. We consider the perturbation

$$\delta(x) = 0.1 \sin(\pi x) + 0.3 \sin(16\,\pi x), \tag{7.1}$$

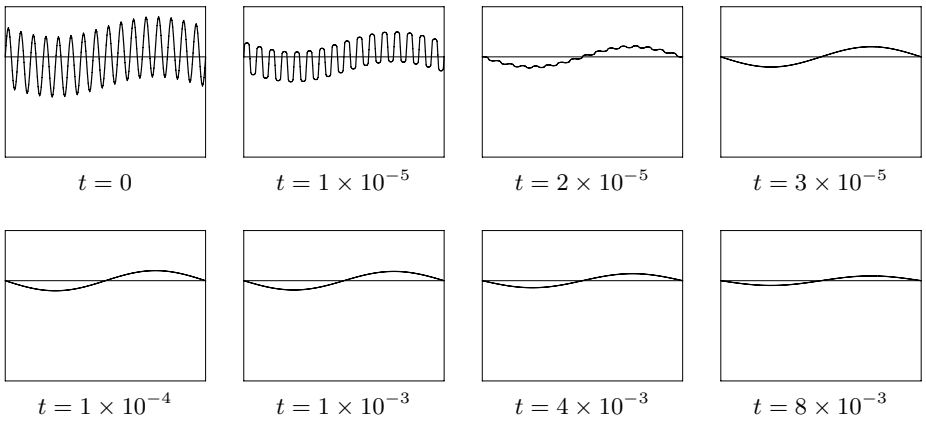

FIG. 7.1. *Solutions for* $f \equiv 0$ *and* $u_0(x) = 1 + 0.1\sin(\pi x) + 0.3\sin(16\pi x)$ *at various instants* t. *In all the plots, the* x*-axis ranges from* -1 *to* 1, *and the* y*-axis ranges from* 0 *to* 1.5.

which results from the superposition of two frequencies. We compute the approximate solution with linear elements and parameters $h = 1/128$, $\tau = 10^{-6}$. This choice of discretization parameters is necessary to reflect the intrinsic time scale for this example. Figure 7.1 depicts the solution for different time instants and shows that high frequencies are rapidly damped, whereas the amplitude of low frequency waves decays *very* slowly. To quantify the difference in the time scales it is worth noting that the time elapsed between the first and the last plot of the first row of Figure 7.1 is 3×10^{-5}, whereas that of the second row is almost 10^{-2}, a difference of three orders of magnitude. This is related to the fourth-order operator of surface diffusion.

Nonnegative perturbation. Let the perturbation be $\delta(x) = 0.3\,\delta_0(0.15x)$, with

$$\delta_0(x) = \min(1, \max(0, 2 - |x|)), \tag{7.2}$$

which is nonnegative and rather singular for this fourth-order flow because of its kinks (see Figure 7.2). We compute the approximate solution with linear elements and parameters $h = 1/128$, $\tau = 10^{-6}$. Figure 7.2 displays the solution for different time instants and confirms the strong smoothing effect of surface diffusion alluded to before. Another important feature that can be visualized in Figure 7.2 is the lack of maximum principle for this equation: we start with a function $u_0 \geq 1$ and, after the first time step, there are already points x with $u(x) < 1$. This is consistent with the fourth-order structure of the operator. It is also worth observing that the spectrum of u_0 is rather full due to the kinks and that high and low frequencies have drastically different decay rates.

Steep perturbation. This example shows that global in time existence may not be expected for a classical solution of (1.1), thereby revealing some limitations of the graph formulation. For $K = 1 + \frac{\sqrt{5}}{2}$, we take the perturbation $\delta(x) = 0.3\delta_0(0.15x)$, with

$$\delta_0(x) = \begin{cases} -K + (1+K)|x| & \text{if } |x| < 1, \\ 2 - |x| & \text{if } 1 \leq |x| < 2, \\ 0 & \text{otherwise.} \end{cases} \tag{7.3}$$

δ is steep, and its mean value vanishes (see Figure 7.3). We compute the approximate solution with linear elements and parameters $h = 1/128$, $\tau = 10^{-7}$. The most impor-

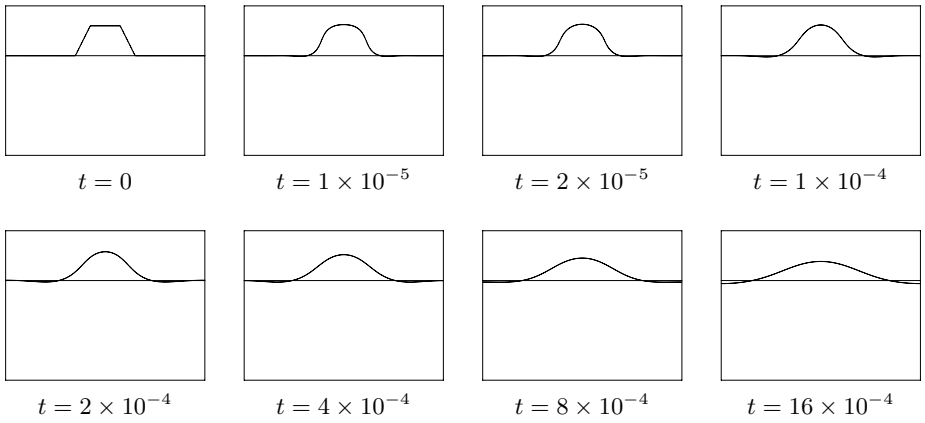

FIG. 7.2. *Solutions for $f \equiv 0$ and $u_0(x) = 1 + \delta(x)$, with $\delta(x)$ a positive perturbation at various times t. In all the plots, the x-axis ranges from -1 to 1, and the y-axis ranges from 0 to 1.5.*

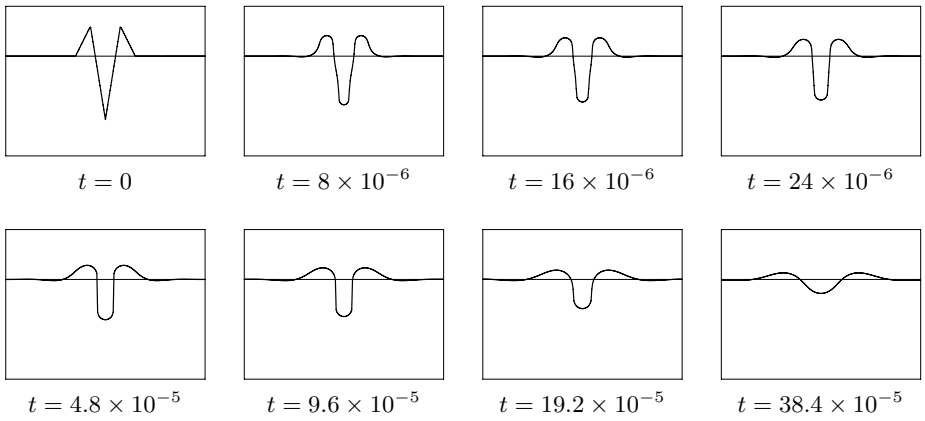

FIG. 7.3. *Solutions for $f \equiv 0$ and $u_0(x) = 1 + \delta(x)$ at various times t, with a steep perturbation $\delta(x)$. In all the plots, the x-axis ranges from -1 to 1, and the y-axis ranges from 0 to 1.5.*

tant features of δ are its steep slope, together with a big jump of the first derivative around $x = 0$. As can be seen in Figure 7.3, the slope seems to become vertical around $t = 4.8 \times 10^{-5}$, which indicates that the classical solution might cease to exist in finite time; in contrast, the *discrete* solution exists globally in time (see section 3). We stress that the lack of smoothness of u_0 plays a secondary role since starting with the (smooth) solution $u(t)$ for some small $t > 0$ would yield the same evolution.

To investigate the formation of singularities in finite time, we use the parametric formulation of [2, 3] with the same initial data; for more examples and details about the discretization for parametric surfaces, we refer the reader to [2, 3]. Since the parametric formulation works for *closed* curves and surfaces, we thus embed the graph of u_0 into a closed curve (see Figure 7.4, top left). For the time scale of Figure 7.3, the effect of this extension is negligible. Figure 7.4 displays a sequence of solutions obtained for the same eight time instants as in Figure 7.3. We see that the parametric evolution by surface diffusion tends to form a *mushroom* starting with this initial condition. Therefore, we conclude that the *continuous* solution will cease to be the graph of a function in finite time; i.e., the exact solution to the graph formulation of

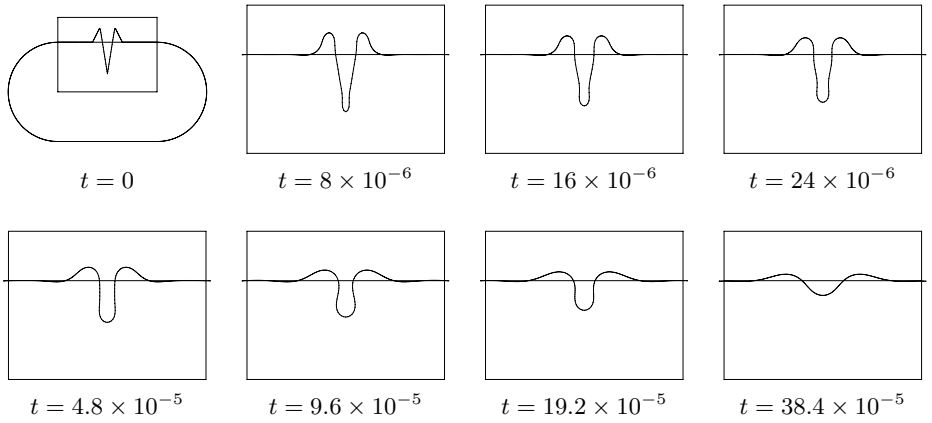

FIG. 7.4. *Solutions obtained with a discretization for parametric curves from* $[2, 3]$ *at the same times as in Figure* 7.3. *In all the plots, the rectangles in thin lines are* $[-1, 1] \times [0, 1.5]$.

surface diffusion exists only *locally* in time for certain initial conditions. To assess the range of validity of the graph formulation, namely, to be able to detect blow-up, time and space adaptivity might be relevant. It is worth noticing the striking similarity of the solutions obtained with both methods. Even though the parametric solution develops a mushroom at $t = 9.6 \times 10^{-5}$, and thus the solution to the graph formulation is questionable thereon, they still exhibit an excellent quantitative agreement for $t > 9.6 \times 10^{-5}$ (compare the last two plots of Figures 7.4 and 7.3).

7.4. Smoothing effect in two dimensions: Case $f \equiv 0$. In this section we present experimental results in $\Omega = (-1, 1) \times (-1, 1)$ concerning the behavior of the discrete solution when $f \equiv 0$ and $u_0(x) = 1 + \delta(x)$ is a perturbation of the solution $u \equiv 1$.

Positive perturbation. We consider a positive perturbation as depicted in Figure 7.5 and compute the approximate solution with linear elements and parameters $h = 1/16$, $\tau = 10^{-6}$. Figure 7.5 displays the solution for different time instants. We observe, as in the one-dimensional case, a strong smoothing effect much faster for high frequencies than for low frequencies, as well as the solution becoming less than 1 (lack of maximum principle).

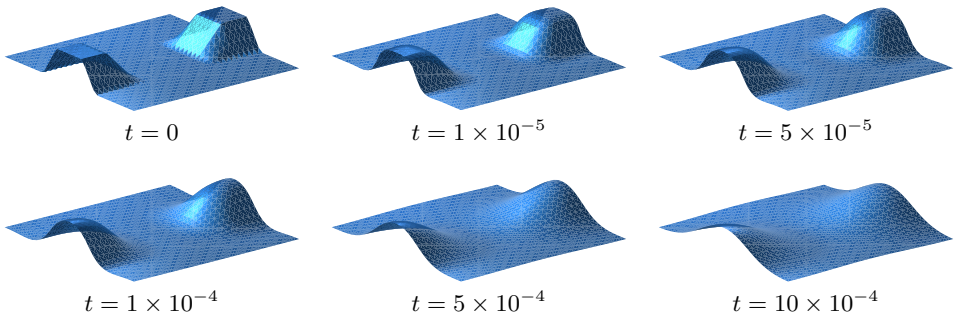

FIG. 7.5. *Solutions for* $f \equiv 0$ *and* $u_0(x) = 1 + \delta(x)$ *at various time instants, with* $\delta(x)$ *a positive perturbation touching the periodic boundary.*

7.5. Crack formation in one dimension: Case $f = -C/u$. We study here the effect of a prescribed forcing of the form $f = -C/u$, which is motivated by the following stationary situation in one dimension and corresponding linearized stability analysis. The nonlinear evolution undergoes two distinct regimes: coarsening and crack formation. We define the latter as the instance when the height u becomes zero at one or more points.

Equilibrium shape of deformable solids. Following [4], we consider a two-dimensional thin solid occupying the domain $\{(x, y) : -1 \le x \le 1\,,\ 0 \le y \le u(x)\}$ and undergoing a plastic deformation due to competition of elastic effects and surface tension with volume constraint $\int_{-1}^{1} u = 2$. The solid is to adjust its shape in order to minimize the following energy:

$$\mathcal{I}(u, v, \lambda) := \int_{-1}^{1} \sqrt{1 + |u_x|^2} + \frac{1}{2} \int_{-1}^{1} u|v_x|^2 - \lambda \left(\int_{-1}^{1} u - 2 \right), \tag{7.4}$$

where $u(x)$ describes the free surface of the film, $v(x)$ is the displacement of the solid, and λ is a Lagrange multiplier associated with the volume constraint. Hence, the first term in (7.4) corresponds to surface tension, whereas the second one is the elastic energy, provided that the displacement v solely depends on the horizontal variable x. Upon variational differentiation with respect to u, v, and λ, the Euler–Lagrange equations turn out to be

$$-\left(\frac{u_x}{\sqrt{1 + |u_x|^2}} \right)_x + \frac{1}{2}|v_x|^2 - \lambda = 0, \qquad (uv_x)_x = 0, \qquad \int_{-1}^{1} u = 2.$$

This immediately yields $v_x = \frac{C}{u}$, whence the equation for u reads

$$-\left(\frac{u_x}{\sqrt{1 + |u_x|^2}} \right)_x + \frac{C}{u^2} - \lambda = 0.$$

Linearized stability analysis. Since $u \equiv 1$ is a solution of (1.1), then a perturbation w of u evolves for a short time according to the linearized PDE around u:

$$\partial_t w = -\Delta(\Delta w + f'(u)w),$$

where $f(u) = -C/u^\gamma$ from the previous discussion, with $\gamma > 0$. Taking an ansatz $w = e^{\mu t} e^{i\pi k x}$ periodic in $(-1, 1)$, we obtain the spectral relation

$$\mu = -(\pi k)^4 + C\gamma(\pi k)^2. \tag{7.5}$$

This implies that $\mu > 0$, provided that $(\pi k)^2 < C\gamma$, whence low frequency perturbations grow and the rest decay for a short time (*linear regime*).

In the simulations below, we make the simplest choice $\gamma = 1$ and take $C = 50$. Our goal is to explore the long-time behavior of (1.1) not predicted by (7.5) (*nonlinear regime*). We discretize the nonlinear forcing term $f(u)$ explicitly, namely, $f_{n+1} = -I_h(C/u_h^n)$, and use linear finite elements with parameters $h = 1/128$, $\tau = 10^{-5}$.

Superposition of sines. We consider the sinusoidal perturbation of (7.1). Figure 7.6 displays the solution at different time instants and shows that high frequencies are rapidly damped, whereas the low frequencies slowly lead to a crack formation. This is consistent with the linearized stability analysis (7.5), according to which the frequency $k = 1$ is the only unstable mode.

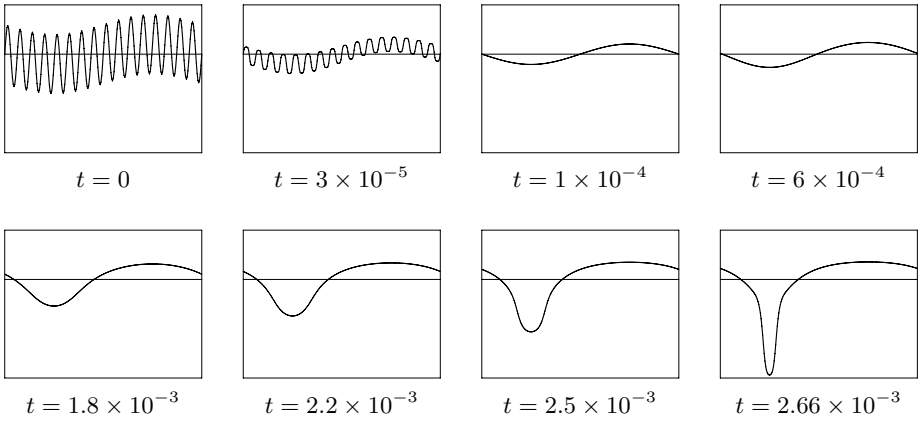

FIG. 7.6. *Solutions for* $f = -50/u$ *and* $u_0(x) = 1 + 0.1\sin(\pi x) + 0.3\sin(16\pi x)$ *at various time instants. In all the plots, the* x*-axis ranges from* -1 *to* 1*, and the* y*-axis ranges from* 0 *to* 1.5.

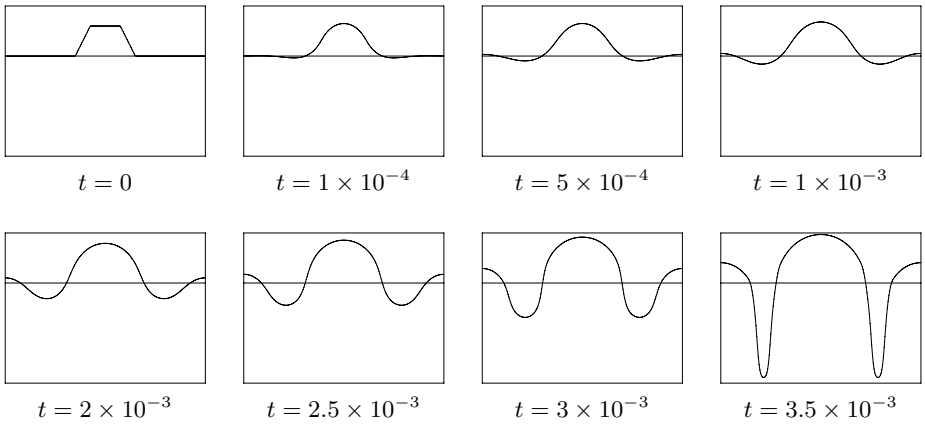

FIG. 7.7. *Solutions for* $f = -50/u$ *and* $u_0(x) = 1 + \delta(x)$ *at various time instants, with* $\delta(x)$ *the positive perturbation of* (7.2)*. In all the plots, the* x*-axis ranges from* -1 *to* 1*, and the* y*-axis ranges from* 0 *to* 1.5.

Positive perturbation. We consider the perturbation δ of (7.2) and display the results in Figure 7.7, which shows an evolution towards crack formation in finite time.

Small perturbation. We consider a perturbation $\delta(x) = 0.1\delta_0(0.02x)$, with δ_0 given in (7.3). Simulations are depicted in Figure 7.8, which shows that by $t = 2 \times 10^{-5}$ the solution is smoothed out. It seems that we have reached a constant equilibrium for a relatively long time $t \cong 7.5 \times 10^{-3}$ (*metastable state*). Then an instability grows, and a fracture starts to form. The latter develops rather fast.

In order to shed light on the actual evolution during the transition between the fast smoothing of the perturbation and the crack development, we show in Figure 7.9 the solution at some time instants between 2×10^{-5} and 7.5×10^{-3}, with the y-axis ranging between 0.998 and 1.001. Even though $u(t)$ looks constant to the eye in Figure 7.8 for t in this interval, a magnification of the y-axis shows that this is not the case: some long waves survive the smoothing effect, and at some point their amplitudes start to increase.

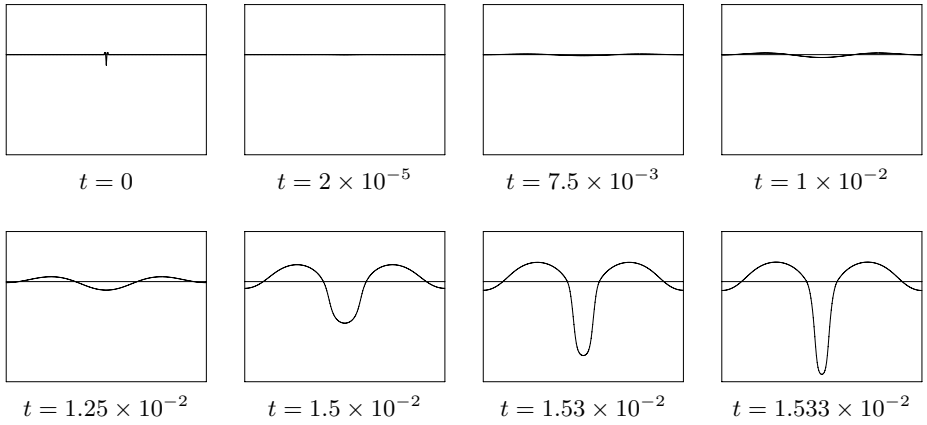

FIG. 7.8. *Solutions for $f = -50/u$ and $u_0(x) = 1 + \delta(x)$ at various time instants, with $\delta(x)$ a small Lipschitz perturbation. In all the plots, the x-axis ranges from -1 to 1, and the y-axis ranges from 0 to 1.5.*

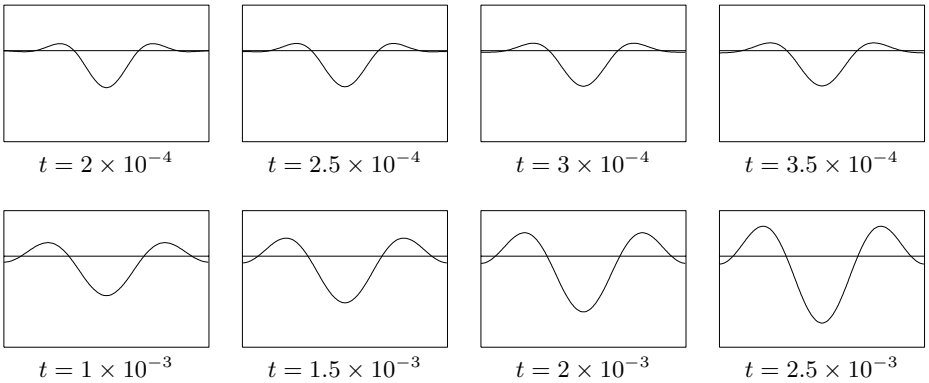

FIG. 7.9. *Solutions for $f = -50/u$ and $u_0(x) = 1 + \delta(x)$ at various time instants between $t = 2 \times 10^{-5}$ and $t = 7.5 \times 10^{-3}$, with the small perturbation of Figure 7.8. In all the plots, the x-axis ranges from -1 to 1, and the y-axis ranges from 0.998 to 1.001.*

Figure 7.10 displays the Fourier modes of $u(t)$ at times $t = 0, 10^{-5}, 10^{-2}, 3 \times 10^{-2}$. We observe that all the modes except the first two decrease immediately, whereas the first two modes increase. This is consistent with the prediction (7.5) of linearized stability because $k^2\pi^2 < 50$ implies $k \leq 2$.

Other simulations, also with forcing $f = -50/u$, do not corroborate this apparent consistency with the linearized stability analysis. We observe that, for a fixed *high* frequency, the solution either develops a crack or tends to the steady solution $u = 1$, depending on the *size* of the perturbation; for instance, if $u_0(x) = 1 + \alpha \sin(4\pi x)$, then a crack forms for $\alpha \geq 0.2375$, thus violating the prediction $k^2\pi^2 < 50$ of (7.5). On the other hand, for a low frequency, the solution always develops a crack regardless of the magnitude of perturbation; for instance, if $u_0(x) = 1 + \alpha \sin(\pi x)$, then a crack forms for all $\alpha \in [0.001, 0.5]$ tested. These simulations will be reported elsewhere. We also refer the reader to [7, 9], where simulations under the assumption of axial symmetry, but without forcing, are performed and singularities are observed as well, which do not conform to the linearized stability analysis either.

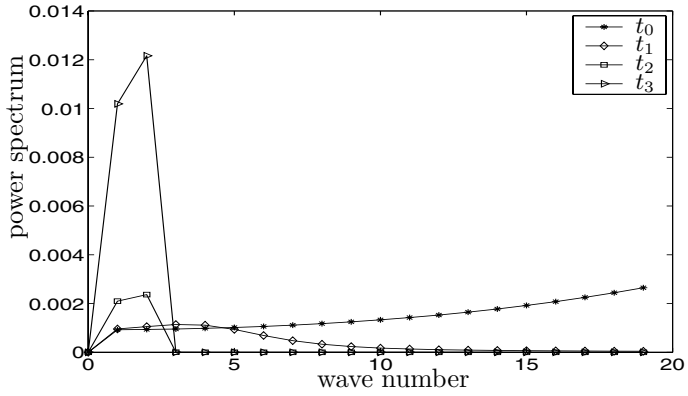

FIG. 7.10. *Power spectrum for the solutions with* $f = -50/u$ *and* $u_0(x) = 1 + \delta(x)$*, with the perturbation* δ *of Figure* 7.8*. The time instants are* $t_0 = 0$*,* $t_1 = 10^{-5}$*,* $t_2 = 10^{-2}$*, and* $t_3 = 3 \times 10^{-2}$*.*

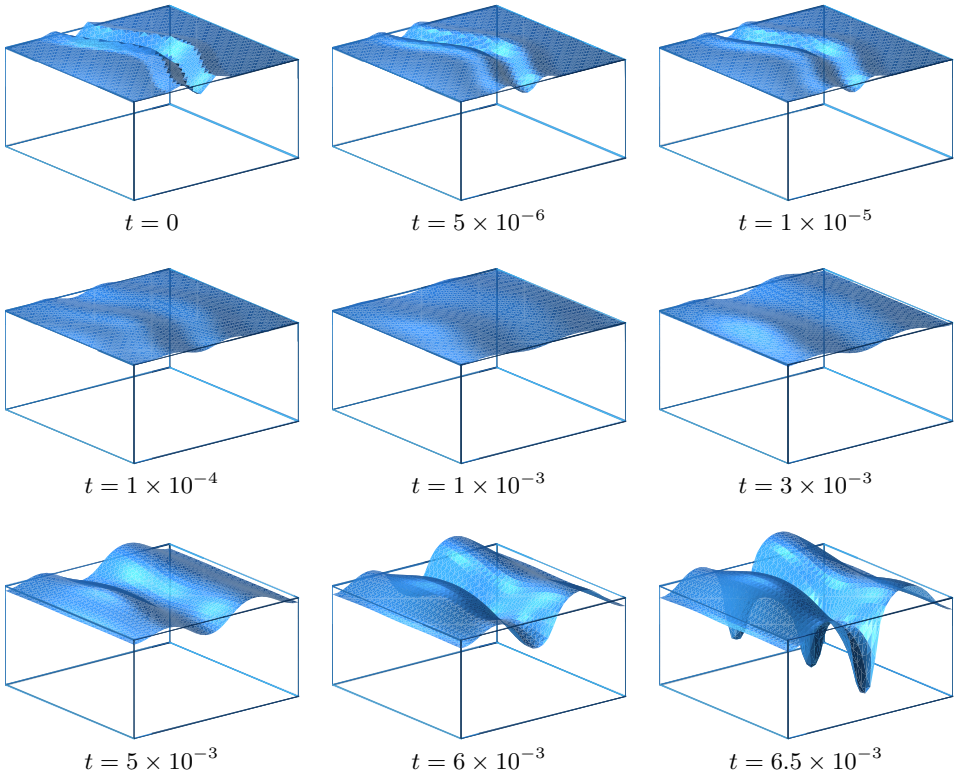

FIG. 7.11. *Solutions for* $f = -50/u$ *and* $u_0(x) = 1 + \delta(x)$ *at various time instants, with* $\delta(x)$ *a small perturbation across* $y = \cos x$*.*

7.6. Crack formation in two dimensions: Case $f = -C/u$. We conclude this section with the evolution of two-dimensional surfaces immersed in $\mathbb{R}^3$. We consider again the initial surface to be $u_0 = 1 + \delta$, where δ is a perturbation similar to that of Figure 7.3. First, we choose such δ across the periodic curve $y = \cos x$ (see Figure 7.11) and, finally, across the circle $x^2 + y^2 = 1/4$ centered at the ori-

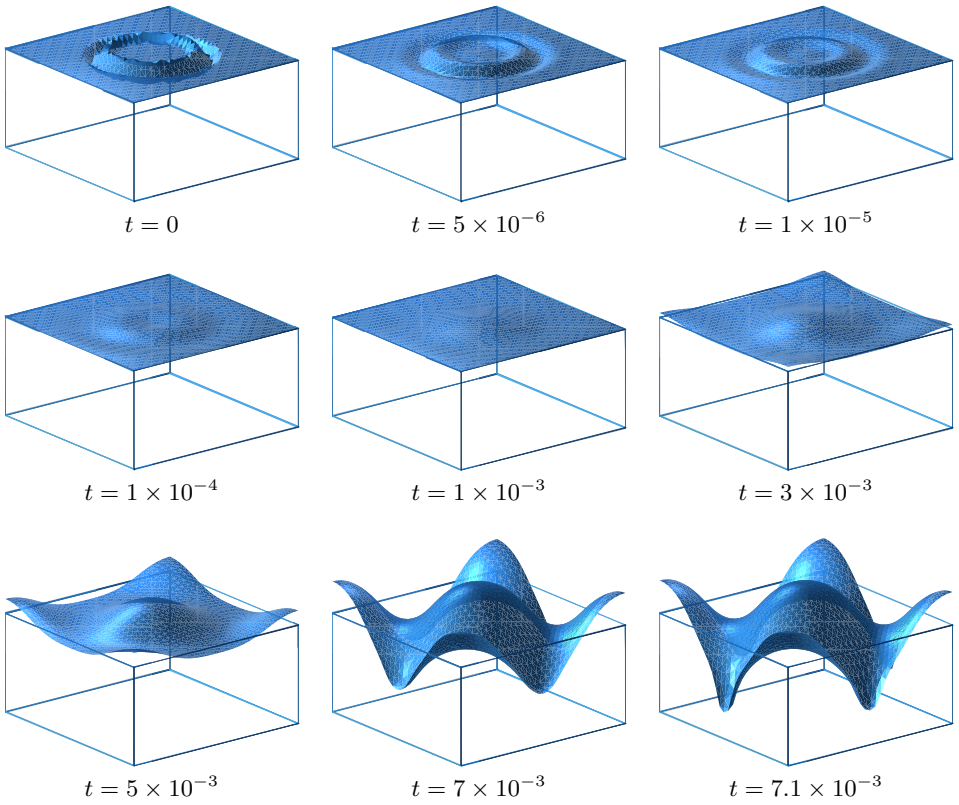

FIG. 7.12. *Solutions for* $f = -50/u$ *and* $u_0(x) = 1 + \delta(x)$ *at various time instants, with* $\delta(x)$ *a small perturbation across* $x^2 + y^2 = 1/4$.

gin (see Figure 7.12). We compute with linear elements and parameters $h = 1/16$, $\tau = 10^{-6}$.

We observe first a smoothing effect followed by crack formation. The latter seems to occur at isolated points rather than at lines, as illustrated in Figures 7.11 and 7.12. This happens even for one-dimensional profiles in two dimensions: point singularities seem to be preferred by this evolution.

Acknowledgments. We would like to thank J. Colin and M. Grinfeld, who originated our interest in surface diffusion, and F. Haußer for discovering (and fixing) a bug in our code.

GALERKIN FINITE ELEMENT APPROXIMATIONS OF STOCHASTIC ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS*

IVO BABUŠKA†, RAÚL TEMPONE†, AND GEORGIOS E. ZOURARIS‡

Abstract. We describe and analyze two numerical methods for a linear elliptic problem with stochastic coefficients and homogeneous Dirichlet boundary conditions. Here the aim of the computations is to approximate statistical moments of the solution, and, in particular, we give a priori error estimates for the computation of the expected value of the solution. The first method generates independent identically distributed approximations of the solution by sampling the coefficients of the equation and using a standard Galerkin finite element variational formulation. The Monte Carlo method then uses these approximations to compute corresponding sample averages. The second method is based on a finite dimensional approximation of the stochastic coefficients, turning the original stochastic problem into a deterministic parametric elliptic problem. A Galerkin finite element method, of either the h- or p-version, then approximates the corresponding deterministic solution, yielding approximations of the desired statistics. We present a priori error estimates and include a comparison of the computational work required by each numerical approximation to achieve a given accuracy. This comparison suggests intuitive conditions for an optimal selection of the numerical approximation.

Key words. stochastic elliptic equation, perturbation estimates, Karhunen–Loève expansion, finite elements, Monte Carlo method, $k \times h$-version, $p \times h$-version, expected value, error estimates

1. Introduction.

Due to the great development in computational resources and scientific computing techniques, more mathematical models can be solved efficiently. Ideally, this artillery could be used to solve many classical partial differential equations, the mathematical models we shall focus on here, to high accuracy. However, in many cases, the information available to solve a given problem is far from complete and is in general very limited. This is the case when solving a partial differential equation whose coefficients depend on material properties that are known to some accuracy. The same may occur with its boundary conditions and even with the geometry of its domain; see, for example, the works [5, 4]. Naturally, since the current engineering trends are going toward more reliance on computational predictions, the need for assessing the level of accuracy in the results grows accordingly. More than ever, the goal then becomes to represent and propagate uncertainties from the available data to the desired result through our partial differential equation. By uncertainty we mean either intrinsic variability of physical quantities or simply lack of knowledge about some physical behavior; cf. [38]. If variability is interpreted as randomness,

then naturally we can apply probability theory. To be fruitful, probability theory requires considerable empirical information about the random quantities in question, usually in the form of probability distributions or their statistical moments. On the other hand, if the only available information comes in the form of some bounds for the uncertain variables, the description and analysis of uncertainty may be based on other methods, such as convexity methods; cf. [8, 18]. This approach is closely related to the so-called worst case scenario.

This work addresses elliptic partial differential equations with stochastic coefficients, with applications to physical phenomena, e.g., random vibrations, seismic activity, oil reservoir management, and composite materials; see [2, 17, 19, 22, 27, 28, 30, 39, 43] and the references therein. Solving a stochastic partial differential equation entails finding the joint probability distribution of the solution, which is a hard problem. In practice we shall usually be satisfied with much less, namely, the computation of some moments, e.g., the expected value of the solution, or some probability related to a given event, e.g., the probability of some eventual failure; cf. [26, 34]. Although the results presented in this paper can be generalized to linear elliptic stochastic partial differential equations we now focus our study on the standard model problem, a second order linear elliptic equation with homogeneous Dirichlet boundary conditions.

Let D be a convex bounded polygonal domain in $\mathbb{R}^d$ and $(\Omega, \mathcal{F}, P)$ be a complete probability space. Here Ω is the set of outcomes, $\mathcal{F} \subset 2^\Omega$ is the σ-algebra of events, and $P : \mathcal{F} \to [0,1]$ is a probability measure. Consider the following stochastic linear elliptic boundary value problem: find a stochastic function, $u : \Omega \times \overline{D} \to \mathbb{R}$, such that P-a.e. in Ω, or, in other words, almost surely (a.s.), the following equation holds:

$$\begin{aligned} -\nabla \cdot (a(\omega,\cdot)\nabla u(\omega,\cdot)) &= f(\omega,\cdot) \quad \text{on } D, \\ u(\omega,\cdot) &= 0 \quad \text{on } \partial D. \end{aligned} \tag{1.1}$$

Here $a, f : \Omega \times D \to \mathbb{R}$ are stochastic functions with continuous and bounded covariance functions. If we denote by $B(D)$ the Borel σ-algebra generated by the open subsets of D, then a, f are assumed measurable with the σ-algebra $(\mathcal{F} \otimes B(D))$. In what follows we shall assume that a is bounded and uniformly coercive, i.e.,

$$\exists\, a_{\min}, a_{\max} \in (0, +\infty) : \quad P\big(\omega \in \Omega :\ a(\omega,x) \in [a_{\min}, a_{\max}] \quad \forall x \in \overline{D}\big) = 1. \tag{1.2}$$

To ensure regularity of the solution u we assume also that a has a uniformly bounded and continuous first derivative; i.e., there exists a real deterministic constant C such that

$$P\big(\omega \in \Omega :\ a(\omega,\cdot) \in C^1(\overline{D}) \ \text{ and } \ \max_{\overline{D}} |\nabla_x a(\omega,\cdot)| < C\big) = 1 \tag{1.3}$$

and that the right-hand side in (1.1) satisfies

$$\int_\Omega \int_D f^2(\omega,x)dx\, dP(\omega) < +\infty, \ \text{ which implies } \ \int_D f^2(\omega,x)dx < +\infty \text{ a.s.} \tag{1.4}$$

Depending on the structure of the noise that drives an elliptic partial stochastic differential equation, there are different numerical approximations. For example, when the size of the noise is relatively small, a Neumann expansion around the mean value of the elliptic operator in (1.1) is a popular approach. It requires only the solution of standard deterministic partial differential equations, the number of them being equal to the number of terms in the expansion. Equivalently, a Taylor expansion of the solution around its mean value with respect to the noise yields the same result. Similarly, the work [30] uses formal Taylor expansions up to second order of the solution but does not study their convergence properties. Recently, the work [3] proposed a perturbation method with successive approximations. It also proves that uniform coercivity of the diffusion is sufficient for the convergence of the perturbation method.

When only the load f is stochastic, it is also possible to derive deterministic equations for the statistical moments of the solution. This case was analyzed in [1, 32] and more recently in the work [40], where a new method to solve these equations with optimal complexity is presented.

On the other hand, the works by Deb [14], Deb, Babuška, and Oden [15], Ghanem and Red-Horse [21], and Ghanem and Spanos [22] address the general case where all the coefficients are stochastic. Both approaches transform the original stochastic problem into a deterministic one with a large dimensional parameter, and they differ in the choice of the approximating functional spaces. The works [14, 15] use finite elements to approximate the noise dependence of the solution, while [21, 22] use a formal expansion in terms of Hermite polynomials. The approximation error in the approach [14, 15] can then be bounded in terms of deterministic quantities, as described in this work. After finishing this paper the authors became aware of the work [9], which developed a related error analysis for elliptic stochastic differential equations. The work [9] gives approximation error estimates for functionals of the solution, while our work focuses on error estimates for the strong approximation of the statistical moments of the solution. Besides, we use the Karhunen–Loève expansion and characterize the regularity of the solution, yielding, e.g., exponential rates of convergence; cf. section 6. On the other hand, the analysis in [9] uses the regularity of the computed functional together with estimates in negative spaces for the approximation error in the solution of the stochastic partial differential equation. This negative estimate can in principle accommodate rough solutions; however, they require H^2 spatial regularity, an assumption that is not clearly fulfilled by rough solutions.

Monte Carlo methods are both general and simple to code, and they are naturally suited for parallelization. They generate a set of independent identically distributed (iid) approximations of the solution by sampling the coefficients of the equation, using a spatial discretization of the partial differential equation, e.g., by a Galerkin finite element method. Then using these approximations we can compute corresponding sample averages of the desired statistics. Monte Carlo methods have a rate of convergence that may be considered slow, but its computational work grows only like a polynomial with respect to the number of random variables present in the problem. It is worth mentioning that in particular cases their convergence can be accelerated by variance reduction techniques; see [29]. The convergence rate of the Monte Carlo method is interpreted in the probability sense, and a practical estimate of its error needs an a posteriori estimate of the variance of the sampled random variable, which in turn requires an a priori bound on higher statistical moments; cf. the Berry-Essen theorem in [16]. Besides this, if the probability density of a random variable is smooth,

the convergence rate of the Monte Carlo method for the approximation of its expected value can be improved; cf. [35, 45]. Quasi-Monte Carlo methods (see [12, 41, 42]) offer a way to get a better convergence rate than the Monte Carlo method, although this advantage seems to deteriorate in general when the number of random variables present in the problem becomes large.

Another way to provide a notion of stochastic partial differential equations is based on the Wick product and the Wiener chaos expansion; see [27] and [46]. This approach yields solutions in Kondratiev spaces of stochastic distributions that are based on a different interpretation of (1.1); the solutions proposed in [27] and [46] are not the same as those arising from (2.1). The choice between (2.1) and [27] is a modeling decision, based on the physical situation under study. For example, with the Wick product we have $E[a \diamond u] = E[a]E[u]$, regardless of the correlation between a and u, whereas this is in general not true with the usual product. A numerical approximation for Wick stochastic linear elliptic partial differential equations is studied in [44], yielding a priori convergence rates.

This work studies the case of stochastic linear elliptic partial differential equations with random diffusion and load coefficients, stating and proving conditions for existence and uniqueness of solutions; for example, to obtain a meaningful numerical solution for (1.1) its diffusion coefficient should be uniformly coercive. Besides, it compares a Monte Carlo Galerkin method with the stochastic Galerkin finite element method introduced in [14] and introduces a related p-version, developing a priori error estimates for each case. A priori error estimates are useful to characterize the convergence, and ultimately they provide information to compare the number of operations required by numerical methods. The conclusion for now is that if the noise is described by a small number of random parameters or if the accuracy requirement is sufficiently strict, then a stochastic Galerkin method is preferred; otherwise, a Monte Carlo Galerkin method still seems to be the best choice; see section 8. It is worth mentioning that the development of numerical methods for stochastic differential equations is still very much ongoing, and better numerical methods are expected to appear.

2. Theoretical aspects of the continuous problem.

2.1. Notation and function spaces. Let d be a positive integer and D be an open, connected, bounded, and convex subset of $\mathbb{R}^d$ with polygonal boundary ∂D. Denote the volume of D by $|D| \equiv \int_D 1dx$. For a nonnegative integer s and $1 \leq p \leq +\infty$, let $W^{s,q}(D)$ be the Sobolev space of functions having generalized derivatives up to order s in the space $L^q(D)$. Using the standard multi-index notation, $\alpha = (\alpha_1, \ldots, \alpha_d)$ is a d-tuple of nonnegative integers, and the length of α is given by $|\alpha| = \sum_{i=1}^d \alpha_i$. The standard Sobolev norm of $v \in W^{s,q}(D)$ will be denoted by $\|v\|_{W^{s,q}(D)}$, $1 \leq q \leq +\infty$. Whenever $q = 2$, we shall use the notation $H^s(D)$ instead of $W^{s,2}(D)$. As usual, the function space $H_0^1(D)$ is the subspace of $H^1(D)$ consisting of functions which vanish at the boundary of D in the sense of trace, equipped with the norm $\|v\|_{H_0^1(D)} = \{\int_D |\nabla v|^2 \, dx\}^{1/2}$. Whenever $s = 0$ we shall keep the notation with $L^q(D)$ instead of $W^{0,q}(D)$. For the sake of generality, sometimes we shall let H be a Hilbert space with inner product $(\cdot, \cdot)_H$. In that case we shall also denote the dual space of H, H', that contains linear bounded functionals, $\mathcal{L} : H \to \mathbb{R}$, and is endowed with the operator norm $\|\mathcal{L}\|_{H'} = \sup_{0 \neq v \in H} \frac{\mathcal{L}(v)}{\|v\|_H}$.

Since stochastic functions intrinsically have different structure with respect to ω and with respect to x, the analysis of numerical approximations requires tensor

spaces. Let H_1, H_2 be Hilbert spaces. The tensor space $H_1 \otimes H_2$ is the completion of formal sums $u(y,x) = \sum_{i=1,\dots,n} v_i(y)w_i(x)$, $\{v_i\} \subset H_1$, $\{w_i\} \subset H_2$, with respect to the inner product $(u,\hat{u})_{H_1\otimes H_2} = \sum_{i,j}(v_i,\hat{v}_j)_{H_1}(w_i,\hat{w}_j)_{H_2}$. For example, let us consider two domains, $y \in \Gamma, x \in D$, and the tensor space $L^2(\Gamma)\otimes H^1(D)$, with tensor inner product

$$(u,\hat{u})_{L^2(\Gamma)\otimes H^1(D)} = \int_\Gamma \left(\int_D u(y,x)\hat{u}(y,x)dx \right) dy + \int_\Gamma \left(\int_D \nabla_x u(y,x) \cdot \nabla_x \hat{u}(y,x)dx \right) dy.$$

Thus, if $u \in L^2(\Gamma) \otimes H^k(D)$, then $u(y,\cdot) \in H^k(D)$ a.e. on Γ and $u(\cdot,x) \in L^2(\Gamma)$ a.e. on D. Moreover, we have the isomorphism $L^2(\Gamma) \otimes H^k(D) \simeq L^2(\Gamma; H^k(D)) \simeq H^k(D; L^2(\Gamma))$ with the definitions

$$L^2(\Gamma; H^k(D)) = \left\{ v : \Gamma \times D \to \mathbb{R} \mid v \text{ is strongly measurable and } \int_\Gamma \|v(y,\cdot)\|^2_{H^k(D)} < +\infty \right\},$$

$$H^k(D; L^2(\Gamma)) = \Bigg\{ v : \Gamma \times D \to \mathbb{R} \mid v \text{ is strongly measurable and } \forall |\alpha| \le k \ \exists\, \partial^\alpha v \in L^2(\Gamma)\otimes L^2(D) \text{ with } \int_\Gamma \int_D \partial_\alpha v(y,x)\varphi(y,x)dxdy = (-1)^{|\alpha|} \int_\Gamma \int_D v(y,x)\partial_\alpha \varphi(y,x)dxdy \quad \forall \varphi \in C_0^\infty(\Gamma \times D) \Bigg\}.$$

Similar constructions can be done for the tensor product of Banach spaces, although the norm for the tensor space used to obtain the completion of the formal sums has to be defined explicitly on each case. Here the Banach space $C(\Gamma; H)$ comprises all continuous functions $u : \Gamma \to H$ with the norm $\|u\|_{C(\Gamma;H)} \equiv \sup_{y\in\Gamma} \|u(y)\|_H$. Similar definitions apply to the spaces $C^k(\Gamma; H)$, $k = 1, \dots$; cf. [20, p. 285].

Let Y be an $\mathbb{R}^N$-valued random variable in $(\Omega, \mathcal{F}, P)$. If $Y \in L^1_P(\Omega)$, we denote its expected value by $E[Y] = \int_\Omega Y(\omega)dP(\omega) = \int_{\mathbb{R}^N} y \, d\mu_Y(y)$, where μ_Y is the distribution measure for Y, defined for the Borel sets $\tilde{b} \in B(\mathbb{R}^N)$ by $\mu_Y(\tilde{b}) \equiv P(Y^{-1}(\tilde{b}))$. If μ_Y is absolutely continuous with respect to the Lebesgue measure, then there exists a density function $\rho_Y : \mathbb{R} \to [0, +\infty)$ such that $E[Y] = \int_{\mathbb{R}^N} y \, \rho_Y(y)dy$. Analogously, whenever $Y_i \in L^2_P(\Omega)$ for $i = 1, \dots, d$, the covariance matrix of Y, $Cov[Y] \in \mathbb{R}^{d\times d}$, is defined by $Cov[Y](i,j) = Cov(Y_i, Y_j) = E[(Y_i - E[Y_i])(Y_j - E[Y_j])]$, $i, j = 1, \dots, d$. Besides this, whenever $u(\omega, x)$ is a stochastic process the positive semidefinite function $Cov[u](x_1, x_2) = Cov[u(x_1), u(x_2)] = Cov[u(x_2), u(x_1)]$ is the covariance function of the stochastic process u.

To introduce the notion of stochastic Sobolev spaces we first recall the definition of stochastic weak derivatives. Let $v \in L^2_P(\Omega) \otimes L^2(D)$; then the α stochastic weak derivative of v, $w = \partial_\alpha v \in L^2_P(\Omega) \otimes L^2(D)$, satisfies $\int_D v(\omega,x)\partial^\alpha \phi(x)dx = (-1)^{|\alpha|} \int_D w(\omega,x)\phi(x)dx \, \forall \phi \in C_0^\infty(D)$ a.s.

We shall work with stochastic Sobolev spaces $\widetilde{W}^{s,q}(D) = L^q_P(\Omega, W^{s,q}(D))$ containing stochastic functions, $v : \Omega \times D \to \mathbb{R}$, that are measurable with respect to the

product σ-algebra $\mathcal{F} \otimes B(D)$ and equipped with the averaged norms $\|v\|_{\widetilde{W}^{s,q}(D)} = (E[\|v\|^q_{W^{s,q}(D)}])^{1/q} = (E[\sum_{|\alpha|\le s} \int_D |\partial^\alpha v|^q dx])^{1/q}$, $1 \le q < +\infty$, and $\|v\|_{\widetilde{W}^{s,\infty}(D)} = \max_{|\alpha|\le s} \left(\text{ ess } \sup_{\Omega\times D} |\partial^\alpha v| \right)$. Observe that if $v \in \widetilde{W}^{s,q}(D)$, then $v(\omega,\cdot) \in W^{s,q}(D)$ a.s. and $\partial^\alpha v(\cdot,x) \in L^q_P(\Omega)$ a.e. on D for $|\alpha| \le s$. Whenever $q = 2$, the above space is a Hilbert space, i.e., $\widetilde{W}^{s,2}(D) = \widetilde{H}^s(D) \simeq L^2_P(\Omega) \otimes H^s(D)$.

2.2. Existence and uniqueness for the solution of a linear stochastic elliptic problem. Let us consider the tensor product Hilbert space $H = \widetilde{H}^1_0(D) \simeq L^2_P(\Omega; H^1_0(D))$ endowed with the inner product $(v,u)_H \equiv E[\int_D \nabla v \cdot \nabla u dx]$.

Define the bilinear form, $\mathcal{B} : H \times H \to \mathbb{R}$, by $\mathcal{B}(v,w) \equiv E[\int_D a \nabla v \cdot \nabla w dx] \, \forall v, w \in H$. The standard assumption (1.2) yields both the continuity and the coercivity of $\mathcal{B}$; i.e., $|\mathcal{B}(v,w)| \le a_{max} \|v\|_H \|w\|_H \, \forall v, w \in H$, and $a_{min}\|v\|^2_H \le \mathcal{B}(v,v) \, \forall v \in H$. A direct application of the Lax–Milgram lemma (cf. [11]) implies the existence and uniqueness for the solution to the following variational formulation: find $u \in H$ such that

$$\mathcal{B}(u,v) = \mathcal{L}(v) \quad \forall v \in H. \tag{2.1}$$

Here $\mathcal{L}(v) \equiv E[\int_D f v dx] \, \forall v \in H$ defines a bounded linear functional since the random field f satisfies (1.4). Since the domain D is convex and bounded and assumptions (1.2), (1.3) on the diffusion a hold, the theory of elliptic regularity (cf. [20]) implies that the solution of (1.1) satisfies $u(\omega,\cdot) \in H^2(D) \cap H^1_0(D)$ a.s. Moreover, standard arguments from measure theory show that the solution to (2.1) also solves (1.1). The formulation (2.1), together with assumption (2.1) on finite dimensional noise, gives the basis for the stochastic Galerkin finite element method (SGFEM) introduced in sections 5 and 6, while formulation (1.1) is the basis for the Monte Carlo Galerkin finite element method (MCGFEM), discussed in section 4.

2.3. Continuity with respect to the coefficients a and f. Since the coefficients a and f are not known exactly, in the next proposition we consider a perturbed weak formulation and estimate the size of the corresponding perturbation in the solution. The proof uses standard estimates and is included in [6].

PROPOSITION 2.1. *Let $(H, (\cdot,\cdot)_H)$ be a Hilbert space. Consider two symmetric bilinear forms $\mathcal{B}, \widehat{\mathcal{B}} : H \times H \to \mathbb{R}$ that are H-coercive and bounded; i.e., there exist real constants $0 < a_{min} \le a_{max}$ such that*

$$a_{min} \|v\|^2_H \le \min\{\mathcal{B}(v,v), \widehat{\mathcal{B}}(v,v)\} \quad \forall v \in H \tag{2.2}$$

and

$$\max\{|\mathcal{B}(v,w)|, |\widehat{\mathcal{B}}(v,w)|\} \le a_{max} \|v\|_H \|w\|_H \quad \forall v, w \in H. \tag{2.3}$$

Consider two bounded linear functionals, $\mathcal{L}, \hat{\mathcal{L}} \in H'$, and let u,$\hat{u} \in H$ be the solutions of the problems

$$\begin{aligned} \mathcal{B}(u,v) &= \mathcal{L}(v) \quad \forall v \in H, \\ \hat{\mathcal{B}}(\hat{u},v) &= \hat{\mathcal{L}}(v) \quad \forall v \in H. \end{aligned}$$

If, in addition, we know that there exist Banach spaces, V_1,V_2, and positive constants, C,γ', such that $u \in V_2 \subseteq H \subset V_1$, $\|\cdot\|_{V_1} \le C\|\cdot\|_H$, and

$$|(\hat{\mathcal{B}} - \mathcal{B})(w,v)| \le \gamma' \|w\|_{V_1} \|v\|_{V_2} \quad \forall w \in H, \ v \in V_2, \tag{2.4}$$

then

$$\|u-\hat{u}\|_H \leq \frac{1}{a_{min}}(\|\mathcal{L}-\hat{\mathcal{L}}\|_{H'} + C\gamma'\|u\|_{V_2}). \tag{2.5}$$

Next we consider a perturbation of (2.1). A direct application of Proposition 2.1 yields the following estimate.

COROLLARY 2.1. *Let* $1 < p < +\infty$ *with* $1/p+1/q = 1$. *Consider the Hilbert space* $H = \widetilde{H}_0^1(D)$ *and perturbed coefficients,* $\hat{a}, \hat{f}$, *satisfying* $0 < a_{min} \leq \hat{a} \leq a_{max} < \infty$, $(P\otimes dx)$ *a.e. on* $D\times\Omega, \hat{f} \in \widetilde{L}^2(D)$. *Let* u *and* $\hat{u}$ *solve* $E[\int_D \hat{a}\nabla\hat{u}\cdot\nabla v dx] = E[\int_D \hat{f}v dx]$ $\forall v \in H, E[\int_D a\nabla u\cdot\nabla v dx] = E[\int_D fv dx]\,\forall v \in H$. *Besides this, assume that the solution* u *belongs to the stochastic Sobolev space* $\widetilde{W}^{1,2q}(D)$. *Then*

$$\|u-\hat{u}\|_{\widetilde{H}_0^1(D)} \leq \tfrac{1}{a_{min}}(C_D\|\hat{f}-f\|_{\widetilde{L}^2(D)} + \|a-\hat{a}\|_{\widetilde{L}^{2p}(D)}\|u\|_{\widetilde{W}^{1,2q}(D)}),$$

with $C_D > 0$ *being the Poincaré constant for the domain* D; *i.e.,* $\|v\|_{L^2(D)} \leq C_D$ $\|v\|_{H_0^1(D)}\forall v \in H_0^1(D)$.

Proof. Take $V_1 = \widetilde{H}_0^1(D)$ and $V_2 = \widetilde{W}^{1,2q}(D)$. In order to apply (2.5) it is enough to bound the difference of bilinear forms

$$\begin{aligned}
&\left|E\left[\int_D (a-\hat{a})\nabla u\cdot\nabla v dx\right]\right| \\
&\leq \left(E\left[\int_D (a-\hat{a})^2|\nabla u|^2 dx\right]\right)^{1/2}\left(E\left[\int_D |\nabla v|^2 dx\right]\right)^{1/2} \\
&\leq \left(E\left[\int_D (a-\hat{a})^{2p} dx\right]\right)^{1/2p}\left(E\left[\int_D |\nabla u|^{2q} dx\right]\right)^{1/2q}\left(E\left[\int_D |\nabla v|^2 dx\right]\right)^{1/2}. \qquad \square
\end{aligned}$$

2.4. Karhunen–Loève expansions and finite dimensional noise. Here we recall the Karhunen–Loève expansion, a suitable tool for the approximation of stochastic processes. Consider a stochastic process a with continuous covariance function $Cov[a] : \overline{D}\times\overline{D} \to \mathbb{R}$. Besides this, let $\{(\lambda_n, b_n)\}_{n=1}^{\infty}$ denote the sequence of eigenpairs associated with the compact self-adjoint operator that maps

$$f \in L^2(D) \mapsto \int_D Cov[a](x,\cdot)f(x)dx \in L^2(D).$$

Its nonnegative eigenvalues, $\sqrt{\int_{D\times D}(Cov[a](x_1,x_2))^2 dx_1\, dx_2} \geq \lambda_1 \geq \lambda_2 \geq \cdots \geq 0$, satisfy $\sum_{n=1}^{+\infty}\lambda_n = \int_D Var[a](x)dx$. The corresponding eigenfunctions are orthonormal, i.e., $\int_D b_i(x)b_j(x)dx = \delta_{ij}$. The truncated Karhunen–Loève expansion of the stochastic process a (cf. [33]) is

$$a_N(\omega,x) = E[a](x) + \sum_{n=1}^{N}\sqrt{\lambda_n}b_n(x)Y_n(\omega),$$

where the real random variables, $\{Y_n\}_{n=1}^{\infty}$, are mutually uncorrelated and have mean zero and unit variance. These random variables are uniquely determined by $Y_n(\omega) = \frac{1}{\sqrt{\lambda_n}}\int_D(a(\omega,x) - E[a](x))b_n(x)dx$ for $\lambda_n > 0$. Then, by Mercer's theorem (cf. [37, p. 245]), we have

$$\sup_{x\in D} E[(a-a_N)^2](x) = \sup_{x\in D}\sum_{n=N+1}^{+\infty}\lambda_n b_n^2(x) \to 0 \ \text{ as } \ N\to\infty.$$

If, in addition,

- the images $Y_n(\Omega)$, $n = 1, \ldots$, are uniformly bounded in $\mathbb{R}$,
- the eigenfunctions b_n are smooth, which is the case when the covariance function is smooth,
- and the eigenpairs have at least the decay $\sqrt{\lambda_n}\|b_n\|_{L^\infty(D)} = \mathcal{O}(\frac{1}{1+n^s})$ for some $s > 1$,

then $\|a - a_N\|_{\widetilde{L}^\infty(D)} \to 0$. Notice that for larger values of the decay exponent s we can also obtain the convergence of higher spatial derivatives of a_N in $\widetilde{L}^\infty(D)$. The last two conditions can be readily verified once the covariance function of a is known. However, observe that it is also necessary to verify the uniform coercivity of a_N, which depends on the probability distributions of Y_n, $n = 1, \ldots$.

In many problems the source of the randomness can be approximated using just a small number of mutually uncorrelated, sometimes mutually independent, random variables. Take, for example, the case of a truncated Karhunen–Loève expansion described previously.

Assumption 2.1 (finite dimensional noise). Whenever we apply some numerical method to solve (1.1) we assume that the coefficients used in the computations, $a, f : \Omega \times D \to \mathbb{R}$, are finite Karhunen–Loève expansions; i.e., $a(\omega, x) = E[a](x) + \sum_{n=1}^{N} \sqrt{\lambda_n} b_n(x) Y_n(\omega)$ and $f(\omega, x) = E[f](x) + \sum_{n=1}^{N} \sqrt{\hat{\lambda}_n} \hat{b}_n(x) Y_n(\omega)$, where $\{Y_n\}_{n=1}^{N}$ are real random variables with mean value zero and unit variance, are uncorrelated, and have images, $\Gamma_n \equiv Y_n(\Omega)$, that are bounded intervals in $\mathbb{R}$ for $n = 1, \ldots, N$. Moreover, we assume that each Y_n has a density function $\rho_n : \Gamma_n \to \mathbb{R}^+$ for $n = 1, \ldots, N$.

In what follows we use the notation $\rho(y)\ \forall y \in \Gamma$ for the joint probability density of $(Y_1, \ldots, Y_N)$ and $\Gamma \equiv \prod_{n=1}^{N} \Gamma_n \subset \mathbb{R}^N$ for the support of such probability density.

After making Assumption 2.1, we have by the Doob–Dynkin lemma (cf. [36]) that u, the solution corresponding to the stochastic partial differential equation (1.1), can be described by just a finite number of random variables, i.e., $u(\omega, x) = u(Y_1(\omega), \ldots, Y_N(\omega), x)$. The number N has to be large enough so that the approximation error is sufficiently small. Now the goal is to approximate the function $u(y, x)$. In addition, the stochastic variational formulation (2.1) has a deterministic equivalent in the following: find $u \in L^2_\rho(\Gamma) \otimes H^1_0(D)$ such that

$$\begin{aligned} &\int_\Gamma \rho(y) \int_D a(y,x) \nabla u(y,x) \cdot \nabla v(y,x) dx dy \\ &\quad = \int_\Gamma \rho(y) \int_D f(y,x) v(y,x) dx dy \quad \forall\ v \in L^2_\rho(\Gamma) \otimes H^1_0(D). \end{aligned} \tag{2.6}$$

In this work the gradient notation, ∇, always means differentiation with respect to $x \in D$ only, unless otherwise stated. The corresponding strong formulation for (2.6) is an elliptic partial differential equation with an N-dimensional parameter, i.e.,

$$\begin{aligned} -\nabla \cdot (a(y,x)\ \nabla u(y,x)) &= f(y,x) \quad \forall (y,x) \in \Gamma \times D, \\ u(y,x) &= 0 \qquad\quad \forall (y,x) \in \Gamma \times \partial D. \end{aligned} \tag{2.7}$$

Making Assumption 2.1 is a crucial step, turning the original stochastic elliptic equation (1.1) into a deterministic parametric elliptic one and allowing the use of finite element and finite difference techniques to approximate the solution of the resulting deterministic problem.

Truncation of the outcomes set, Γ. For the sake of efficiency, it may be useful to compute the solution of (2.7) in a subdomain with strictly positive probability, $\Gamma_0 \subset \Gamma$. Besides, we assume the probability density of Y to be strictly positive in Γ_0. In that case, we approximate the function

$$E[u(Y,\cdot)\ 1_{\{Y\in\Gamma_0\}}] = E[u(Y,\cdot)|Y\in\Gamma_0]\ \ P(Y\in\Gamma_0)$$

instead of the original $E[u]$. If $\bar{u}$ is an approximation of u in Γ_0, then we have the splitting

(2.8)
$$\begin{aligned}&\|E[u(Y,\cdot)] - E[\bar{u}(Y,\cdot)\ 1_{\{Y\in\Gamma_0\}}]\|\\ &\qquad \le \|E[u(Y,\cdot)] - E[u(Y,\cdot)\ 1_{\{Y\in\Gamma_0\}}]\| + \|E[u(Y,\cdot)-\bar{u}(Y,\cdot)|Y\in\Gamma_0]\|P(Y\in\Gamma_0).\end{aligned}$$

Property 2.1 below gives a simple estimate for the first error contribution, which is related to the truncation of Γ. The second error contribution in (2.8) is the discretization error, and it will be analyzed for each numerical approximation separately; see sections 4, 5, and 6. In those sections we shall simplify the notation by writing $\Gamma = \Gamma_0$ and work with the corresponding conditional probability space.

PROPERTY 2.1. *Let u be the solution of the problem* (2.7); *then there exists a constant C such that*

$$\big\|E[u(Y,\cdot)]-E[u(Y,\cdot)\ 1_{\{Y\in\Gamma\}}]\big\|_{H_0^1(D)} \le C\sqrt{P(Y\notin\Gamma_0)}\ \|f\|_{L^2_\rho(\Gamma\setminus\Gamma_0)\otimes L^2(D)}. \tag{2.9}$$

3. The finite element spaces. In this section, we define tensor product finite element spaces on the set $\Gamma\times D$, which we will use to construct approximations of the solution of the parametric boundary value problem (2.7), stating their approximation properties.

3.1. Finite element spaces on the spatial set $D\subset\mathbb{R}^d$: h-version. Consider a family of finite element approximation spaces, $X_h^d \subset H_0^1(D)$, consisting of piecewise linear continuous functions on conforming triangulations (of simplices), $\mathcal{T}_h^d$, of the convex polyhedral domain, $D\subset\mathbb{R}^d$, with a maximum mesh spacing parameter $h>0$. We will always assume that the triangulations are nondegenerate (sometimes also called regular); cf., [11, p. 106]. Then (cf. [11, 13]) the finite element spaces X_h^d satisfy a standard approximation estimate, namely, that for all $v\in H^2(D)\cap H_0^1(D)$

$$\min_{\chi\in X_h^d}\|v-\chi\|_{H_0^1(D)} \le C\,h\,\|v\|_{H^2(D)}, \tag{3.1}$$

where $C>0$ is a constant independent of v and h.

3.2. Tensor product finite element spaces on the outcomes set $\Gamma\subset\mathbb{R}^N$: k-version. Let $\Gamma=\prod_{n=1}^N\Gamma_n$ be as in subsection 2.4. Consider a partition of Γ consisting of a finite number of disjoint $\mathbb{R}^N$-boxes, $\gamma=\prod_{n=1}^N(a_n^\gamma,b_n^\gamma)$, with $(a_n^\gamma,b_n^\gamma)\subset\Gamma_n$ for $n=1,\dots,N$. The mesh spacing parameters, $k_n>0$, are defined by $k_n\equiv\max_\gamma|b_n^\gamma-a_n^\gamma|$ for $1\le n\le N$. For every nonnegative integer multi-index $q=(q_1,\dots,q_N)$ consider the finite element approximation space of (discontinuous) piecewise polynomials with degree at most q_n on each direction y_n, $Y_k^q\subset L^2(\Gamma)$. Thus, if $\varphi\in Y_k^q$, its restriction to each of the partition boxes satisfies $\varphi|_\gamma\in\operatorname{span}\big(\prod_{n=1}^N y_n^{\alpha_n}:\ \alpha_n\in\mathbb{N}\text{ and }\alpha_n\le q_n,\quad n=1,\dots,N\big)$. It is easy to verify

that the finite element spaces Y_k^q have the following approximation property: for all $v \in H^{q+1}(\Gamma)$,

$$\min_{\varphi \in Y_k^q} \|v - \varphi\|_{L^2(\Gamma)} \le \sum_{n=1}^{N} \left(\frac{k_n}{2}\right)^{q_n+1} \frac{\|\partial_{y_n}^{q_n+1} v\|_{L^2(\Gamma)}}{(q_n+1)!}. \tag{3.2}$$

3.3. Tensor product finite element spaces on $\Gamma \times D$: $k \times h$-version. Here we will discuss some approximation properties of the following tensor product finite element spaces:

(3.3)

$$Y_k^q \otimes X_h^d \equiv \left\{\psi = \psi(y,x) \in L^2(\Gamma \times D) : \psi \in \operatorname{span}\big(\varphi(y)\,\chi(x) : \varphi \in Y_k^q,\, \chi \in X_h^d\big)\right\}$$

with X_h^d and Y_k^q as in subsections 3.1 and 3.2.

For later use we recall the definition of the standard L^2-projection operators $\Pi_k^q : L^2(\Gamma) \to Y_k^q$ by

$$(\Pi_k^q w - w, \varphi)_{L^2(\Gamma)} = 0 \quad \forall \varphi \in Y_k^q, \quad \forall w \in L^2(\Gamma) \tag{3.4}$$

and the H_0^1-projection operator $\mathcal{R}_h : H_0^1(D) \to X_h^d$ by

$$(\nabla(\mathcal{R}_h v - v), \nabla\chi)_{L^2(D)} = 0 \quad \forall \chi \in X_h^d, \quad \forall v \in H_0^1(D). \tag{3.5}$$

Estimates (3.1) and (3.2) imply

$$\begin{aligned} \|v - \mathcal{R}_h v\|_{H_0^1(D)} &\le C\,h\,\|v\|_{H^2(D)}, \\ \|w - \Pi_k^q w\|_{L^2(\Gamma)} &\le \sum_{n=1}^{N} \left(\frac{k_n}{2}\right)^{q_n+1} \frac{\|\partial_{y_n}^{q_n+1} w\|_{L^2(\Gamma)}}{(q_n+1)!} \end{aligned} \tag{3.6}$$

for all $v \in H^2(D) \cap H_0^1(D)$ and $w \in H^{q+1}(\Gamma)$. We now state an approximation property for the tensor product finite element spaces defined in (3.3) which is a direct implication of the approximation properties of the spaces Y_k^q and X_h^d.

PROPOSITION 3.1. *There exists a constant $C > 0$ independent of h, N, q, and k such that*

$$\begin{aligned} &\inf_{\psi \in Y_k^q \otimes X_h^d} \|v - \psi\|_{L^2(\Gamma; H_0^1(D))} \\ &\qquad \le C \left\{ h\,\|v\|_{L^2(\Gamma; H^2(D))} + \sum_{n=1}^{N} \left(\frac{k_n}{2}\right)^{q_n+1} \frac{\|\partial_{y_n}^{q_n+1} v\|_{L^2(\Gamma; H_0^1(D))}}{(q_n+1)!} \right\} \end{aligned} \tag{3.7}$$

for all $v \in C^{q+1}(\Gamma; H^2(D) \cap H_0^1(D))$.

Proof. Since $\Pi_k^q(\mathcal{R}_h v) \in Y_k^q \otimes X_h^d$, using (3.6) we obtain

$$\begin{aligned} \inf_{\psi \in Y_k^q \otimes X_h^d} \|v - \psi\|_{L^2(\Gamma; H_0^1(D))} &\le \|v - \Pi_k^q(\mathcal{R}_h v)\|_{L^2(\Gamma; H_0^1(D))} \\ &\le \|v - \mathcal{R}_h v\|_{L^2(\Gamma; H_0^1(D))} \\ &\quad + \|\mathcal{R}_h v - \Pi_k^q(\mathcal{R}_h v)\|_{L^2(\Gamma; H_0^1(D))} \\ &\le C\,h\,\|v\|_{L^2(\Gamma; H^2(D))} \\ &\quad + \|\mathcal{R}_h v - \Pi_k^q(\mathcal{R}_h v)\|_{L^2(\Gamma; H_0^1(D))}. \end{aligned} \tag{3.8}$$

Applying the estimate (3.2) and using the boundedness of $\mathcal{R}_h$ in $H_0^1(D)$ yield

$$\begin{aligned}\|\mathcal{R}_h v - \Pi_k^q(\mathcal{R}_h v)\|_{L^2(\Gamma;H_0^1(D))} &\leq \|v - \Pi_k^q v\|_{L^2(\Gamma;H_0^1(D))} \\ &\leq \sum_{n=1}^{N} \left(\frac{k_n}{2}\right)^{q_n+1} \frac{\|\partial_{y_n}^{q_n+1} v\|_{L^2(\Gamma;H_0^1(D))}}{(q_n+1)!}.\end{aligned}$$

The estimate (3.7) follows, combining (3.8) with the last estimate. ∎

3.4. Tensor product finite element spaces on $\Gamma \times D$: $p \times h$-version. This approximation space is in fact a particular case of the $k \times h$-version with no k partition of Γ, i.e., $k_n = |\Gamma_n|$, $n = 1, \ldots, N$. Instead, only the polynomial degree is increased. Here the multi-index $p = (p_1, \ldots, p_N)$ plays the role of the q from section 3.3, and we use the tensor finite element space $Z^p = \bigotimes_{n=1}^N Z_n^{p_n}$, where the one dimensional global polynomial subspaces, $Z_n^{p_n}$, are defined by $Z_n^{p_n} = \{v : \Gamma_n \to \mathbb{R} : v \in \text{span}(y^s, s = 0, \ldots, p_n)\}, n = 1, \ldots, N$.

4. Monte Carlo Galerkin finite element method. In this section we describe the use of the standard Monte Carlo Galerkin finite element method (MCGFEM) to construct approximations of the expected value of the solution.

Formulation of the MCGFEM.

• Give a number of realizations, M, a piecewise linear finite element space on D, X_h^d, as defined in subsection 3.1.

• For each $j = 1, \ldots, M$, sample iid realizations of the diffusion $a(\omega_j, \cdot)$ and the load $f(\omega_j, \cdot)$, based on realizations of $\{Y_n\}_{n=1}^N$, and find a corresponding approximation $u_h(\omega_j, \cdot) \in X_h^d$ such that

$$(a(\omega_j, \cdot)\nabla u_h(\omega_j, \cdot), \nabla\chi)_{L^2(D)} = (f(\omega_j, \cdot), \chi)_{L^2(D)} \quad \forall \chi \in X_h^d. \tag{4.1}$$

• Finally, use the sample average $\frac{1}{M}\sum_{j=1}^M u_h(\omega_j; \cdot)$ to approximate $E[u]$. ∎

Here we consider only the case where X_h^d is the same for all realizations; i.e., the spatial triangulation is deterministic. The computational error naturally separates into two parts:

$$E[u] - \frac{1}{M}\sum_{j=1}^{M} u_h(\omega_j, \cdot) = \big(E[u] - E[u_h]\big) + \left(E[u_h] - \frac{1}{M}\sum_{j=1}^{M} u_h(\omega_j, \cdot)\right) \equiv \mathcal{E}_h + \mathcal{E}_S. \tag{4.2}$$

The size of the spatial triangulation controls the space discretization error $\mathcal{E}_h$, while the number of realizations, M of u_h, controls the statistical error $\mathcal{E}_S$.

To study the behavior of the statistical error, let us first consider the random variable $\|\mathcal{E}_S\|_{H_0^1(D)}$ which, due to the independence of the realizations $u_h(\omega_j, \cdot)$, $j = 1, \ldots, M$, satisfies the estimate

$$M\ E\big[\|\mathcal{E}_S\|_{H_0^1(D)}^2\big] \leq \|u_h\|_{\widetilde{H}_0^1(D)}^2 \leq \left(\frac{C_D}{a_{min}}\right)^2 \|f\|_{\widetilde{L}^2(D)}^2, \tag{4.3}$$

and a similar result also holds in $L^2(D)$. Then, thanks to (4.3) we have that, for either $H = L^2(D)$ or $H = H_0^1(D)$, the statistical error $\|\mathcal{E}_S\|_H$ tends a.s. to zero as we increase the number of realizations; i.e., we have the following.

PROPOSITION 4.1. *Suppose that there exists a constant $C > 0$ independent of M and h such that the statistical error in H norm satisfies*

$$M\ E[\|\mathcal{E}_S\|_H^2] \le C \quad \forall M, h. \tag{4.4}$$

Then, taking the number of realizations, M_k, increasingly from the set $\{2^k : k \in \mathbb{N}\}$, we have, for any $\alpha \in (0, 1/2)$ and any choice of mesh size h, $\lim_{M_k\to\infty} {M_k}^{\alpha}\|\mathcal{E}_S\|_H = 0$ a.s.

Proof. Let $\epsilon > 0$. Then (4.4) and Markov's inequality give

$$P((M_k)^{\alpha}\|\mathcal{E}_S\|_H > \epsilon) \le \frac{E[(M_k)^{2\alpha}\|\mathcal{E}_S\|_H^2]}{\epsilon^2} \le \frac{C}{\epsilon^2 (M_k)^{1-2\alpha}}.$$

Thus, for $\alpha \in (0, 1/2)$ we have

$$\sum_{k=1}^{\infty} P(M_k^{\alpha}\|\mathcal{E}_S\|_H > \epsilon) \le \frac{C}{\epsilon^2}\sum_{k=1}^{\infty}\frac{1}{M_k^{1-2\alpha}} \le \frac{C}{\epsilon^2}\sum_{k=1}^{\infty}\frac{1}{(2^{1-2\alpha})^k} < \infty,$$

which, together with the Borel–Cantelli lemma, finishes the proof. ∎

Under the same assumptions as in Proposition 4.1 we have that for any given $\epsilon > 0$ there exists a constant $C > 0$ independent of ϵ, M, and h such that

$$P\left(\|\mathcal{E}_S\|_H > \frac{\epsilon}{\sqrt{M}}\right) \le \frac{C}{\epsilon^2}. \tag{4.5}$$

Thus, within a given confidence level we have the usual convergence rate for the Monte Carlo method, which is independent of the mesh size h. Next we present error estimates for the space discretization error, namely, we have the following.

PROPOSITION 4.2 (spatial discretization error estimates). *There holds*

$$h\|u - u_h\|_{H_0^1(D)} + \|u - u_h\|_{L^2(D)} \le C\, h^2 \|f\|_{L^2(D)} \quad a.s.,$$
$$h\|E[u] - E[u_h]\|_{H_0^1(D)} + \|E[u] - E[u_h]\|_{L^2(D)} \le C h^2 E[\|f\|_{L^2(D)}^2]^{1/2}.$$

The results from Proposition 4.2 and estimate (4.5) will be used in section 8 to compare the MCGFEM with other discretizations for (1.1).

5. Stochastic Galerkin finite element method: $k \times h$-version. This section defines and analyzes the $k \times h$-version of the stochastic Galerkin finite element method ($k \times h$-SGFEM) which, via a Galerkin variational formulation, yields approximations, $u_{kh} \in Y_k^q \otimes X_h^d$, of the solution u of the parametric elliptic boundary value problem (2.7).

Formulation of the $k \times h$-SGFEM. Denote by $q = (q_1, \ldots, q_N) \in \mathbb{N}^N$ a multi-index, and let Γ be a bounded box in $\mathbb{R}^N$. The $k \times h$-SGFEM approximation is the tensor product, $u_{kh} \in Y_k^q \otimes X_h^d$, such that

$$(u_{kh}, \psi)_E \equiv \int_\Gamma \rho\, \left(a\, \nabla u_{kh}, \nabla\psi\right)_{L^2(D)}\, dy = \int_\Gamma \rho\, \left(f, \psi\right)_{L^2(D)}\, dy \quad \forall\, \psi \in Y_k^q \otimes X_h^d. \tag{5.1}$$

Recall that $\rho : \Gamma \to (0, +\infty)$ is the density function of the vector-valued random variable $Y : \Omega \to \Gamma \subset \mathbb{R}^N$. Hence, the assumption (1.2) on the random function $a(\omega, x) \equiv a(Y(\omega), x)$ reads

$$a(y, x) \in [a_{\min}, a_{\max}] \quad \forall (y, x) \in \overline{\Gamma \times D}. \tag{5.2}$$

Although the analysis can be generalized [6], we now focus on the practical case where both a and f are truncated Karhunen–Loève expansions. Later, section 7 discusses how to compute efficiently u_{kh}, the solution of (5.1), by a double orthogonal polynomials technique. By Lemma 4.1 in [31], the solution u of (2.7) satisfies $u \in C^\infty(\Gamma; H^2(D) \cap H_0^1(D))$. Use (5.2) and (2.7) to obtain

$$\|u(y,\cdot)\|_{H_0^1(D)} \leq \tfrac{C_D}{a_{\min}} \|f(y,\cdot)\|_{L^2(D)} \quad \forall y \in \Gamma, \tag{5.3}$$

where C_D is the constant of the Poincaré–Friedrichs inequality on D. Also, elliptic regularity yields

$$\|u(y,\cdot)\|_{H^2(D)} \leq C_{0,B} \|f(y,\cdot)\|_{L^2(D)} \quad \forall y \in \Gamma, \tag{5.4}$$

where $C_{0,B}$ is a constant which depends on D and $\|a\|_{L^\infty(\Gamma;W^{1,\infty}(D))}$. Finally, take derivatives with respect to y_n in (2.7), proceed as in the derivation of (5.3), and follow an inductive argument arriving at

$$\frac{\|\partial_{y_n}^{q_n+1} u(y,\cdot)\|_{H_0^1(D)}}{(q_n+1)!} \leq (r_n)^{q_n} \frac{C_D}{a_{min}} \big(\|\partial_{y_n} f(y,\cdot)\|_{L^2(D)} + r_n \|f(y,\cdot)\|_{L^2(D)}\big), \quad q_n \geq 0, \tag{5.5}$$

with $r_n \equiv \sqrt{\lambda_n}\|\frac{b_n}{a}\|_{L^\infty(\Gamma\times D)}$, and $n = 1, \ldots, N$. As a consequence of (3.7), (5.4), and (5.5) we have an a priori error estimate for the $k \times h$-SGFEM in the energy norm.

PROPOSITION 5.1. *Let u be the solution of the problem* (2.7) *and $u_{kh} \in Y_k^q \otimes X_h^d$ be the $k \times h$-SGFEM approximations of u defined in* (5.1). *If $\rho \in L^\infty(\Gamma)$ and $f \neq 0$, then*

$$\begin{aligned} &\frac{\|u - u_{kh}\|_E}{\sqrt{\|a\,\rho\|_{L^\infty(\Gamma\times D)}}\|f\|_{L^2(\Gamma;L^2(D))}} \\ &\qquad \leq Ch + \frac{C_D}{a_{min}} \sum_{n=1}^{N} \frac{k_n}{2} \left(\frac{k_n r_n}{2}\right)^{q_n} \left(\frac{\|\partial_{y_n} f\|_{L^2(\Gamma;L^2(D))}}{\|f\|_{L^2(\Gamma;L^2(D))}} + r_n\right), \end{aligned} \tag{5.6}$$

where the constant C depends on D and a and is independent of q, k, h, and u.

The next step is to use Proposition 5.1 together with a duality technique to estimate the $H_0^1(D)$ and $L^2(D)$ errors in the approximation of the expected value of $u(Y,\cdot)$.

THEOREM 5.1. *Let u be the solution of the problem* (2.7) *and $u_{kh} \in Y_k^q \otimes X_h^d$ be the $k \times h$-SGFEM approximations of u defined in* (5.1). *If $\rho \in L^\infty(\Gamma)$, then for $\ell = 0, 1$ we have*

$$\frac{\big\|E[u(Y,\cdot)] - E[u_{kh}(Y,\cdot)]\big\|_{H^\ell(D)}}{\|a\,\rho\|_{L^\infty(\Gamma\times D)}} \leq C \left(h^{2-\ell} + \sum_{n=1}^{N} \left(\frac{k_n}{2}\right)^{2-\ell} \left(\frac{k_n r_n}{2}\right)^{(2-\ell)q_n}\right). \tag{5.7}$$

The constant C depends on D, f, and a, and it is independent of k, q, and h.

Proof. The case $\ell = 1$ follows directly from Proposition 5.1, so we now prove the case $\ell = 0$. Denote $e \equiv u - u_{kh}$ and use the auxiliary function $\hat{u}$ that solves

$$\begin{aligned} -\nabla_{x^\bullet}(a(y,\cdot)\,\nabla\hat{u}(y,\cdot)) &= E[e](\cdot) \ \text{ in } \ D, \\ \hat{u}(y,\cdot) &= 0 \ \text{ on } \ \partial D. \end{aligned} \tag{5.8}$$

Then (5.4) reads

$$\|\hat{u}(y,\cdot)\|_{H^2(D)} \le C_{0,B}\,\|E[e]\|_{L^2(D)} \quad \forall y \in \Gamma, \tag{5.9}$$

and, since $E[e]$ is independent of y, the estimate (5.5) for the problem (5.8) reads

$$\frac{\|\partial_{y_n}^{q_n+1}\hat{u}(y,\cdot)\|_{H_0^1(D)}}{(q_n+1)!} \le (r_n)^{q_n+1}\frac{C_D}{a_{min}}\|E[e]\|_{L^2(D)} \quad \forall y \in \Gamma. \tag{5.10}$$

Now use Galerkin orthogonality, together with (5.8), to obtain

$$\int_\Gamma \rho\,(E[e],e)_{L^2(D)}\,dy = \int_\Gamma \rho\,\big(a\nabla e, \nabla(\hat{u}-\psi)\big)_{L^2(D)}\,dy \quad \forall \psi \in Y_k^q \otimes X_h^d,$$

which yields, by the Cauchy–Schwarz inequality,

$$\|E[e]\|_{L^2(D)}^2 \le \widetilde{B}_1\,\widetilde{B}_2, \tag{5.11}$$

with

$$\widetilde{B}_1 \equiv \left(\int_\Gamma \rho\,\|\sqrt{a}\,\nabla e\|_{L^2(D)}^2\,dy\right)^{\frac{1}{2}}$$

and

$$\widetilde{B}_2 \equiv \inf_{\psi \in Y_k^q \otimes X_h^d}\left(\int_\Gamma \rho\,\|\sqrt{a}\,\nabla(\hat{u}-\psi)\|_{L^2(D)}^2\,dy\right)^{\frac{1}{2}}.$$

Next observe that $\widetilde{B}_1$ can be bounded using (5.6). Finally, use (3.7), (5.9), and (5.10) to bound $\widetilde{B}_2$ as follows:

(5.12)

$$\begin{aligned}\widetilde{B}_2 &\le C\,\|a\,\rho\|_{L^\infty(\Gamma\times D)}^{\frac{1}{2}}\left\{h\,\|\hat{u}\|_{L^2(\Gamma;H^2(D))} + \sum_{n=1}^{N}\left(\frac{k_n}{2}\right)^{q_n+1}\frac{\|\partial_{y_n}^{q_n+1}\hat{u}\|_{L^2(\Gamma;H_0^1(D))}}{(q_n+1)!}\right\}\\ &\le C\,\|a\,\rho\|_{L^\infty(\Gamma;L^\infty(D))}^{\frac{1}{2}}\left(h + \frac{C_D}{a_{min}}\sum_{n=1}^{N}\left(\frac{r_n\,k_n}{2}\right)^{q_n+1}\right)\|E[e]\|_{L^2(D)}.\end{aligned}$$

Combining (5.11), (5.6), and (5.12), the estimate (5.7) follows. ∎

The estimates given in Proposition 5.1 and Theorem 5.1 give the optimal order of convergence with respect to k but are not optimal with respect to q. They can be improved by the analysis given in section 6, yielding exponential convergence with respect to q without the need to decrease k.

6. Stochastic Galerkin finite element method: $p \times h$-version. The goal of this section is to analyze the $p \times h$-version of the SGFEM method, which does not refine the set Γ. This method yields an exponential rate of convergence with respect to p, the degree of the polynomials used for approximation; cf. Theorem 6.2. The application of the p-version in the y-direction is motivated by the fact that u is analytic with respect to $y \in \Gamma$; cf. Lemma 6.1. The basic assumption for this section is the following.

Assumption 6.1. Let $\hat{\Gamma}_n \equiv \prod_{1\le j\le N, j\neq n} \Gamma_j$, and let $\hat{y}_n$ be an arbitrary element of $\hat{\Gamma}_n$. Then for each $\hat{y}_n \in \hat{\Gamma}_n$ let $\tilde{a}_n(\hat{y}_n) \equiv \min_{x\in D}\{E[a](x) + \sum_{1\le j\le N, j\neq n} \sqrt{\lambda_j} b_j(x) y_j\}$, and assume a slightly stronger uniform coercivity requirement; i.e., there exists a constant $\nu > 0$, independent of N, such that

$$\tilde{a}_n(\hat{y}_n) - \sqrt{\lambda_n}\|b_n\|_{L^\infty(D)} \max_{y\in\Gamma_n} |y| \ge \nu > 0 \quad \forall \hat{y}_n \in \hat{\Gamma}_n. \qquad \square$$

Observe that with the above construction we have $0 < \nu \le a_{min}$.

$p \times h$-version of the SGFEM method. The $p \times h$-version SGFEM approximation is the tensor product $u_h^p \in Z^p \otimes X_h^d$ (cf. section 3.4) that satisfies

$$(u_h^p, \chi)_E \equiv \int_\Gamma \rho \left(a \nabla u_h^p, \nabla \chi\right)_{L^2(D)} dy = \int_\Gamma \rho \left(f, \chi\right)_{L^2(D)} dy \quad \forall\, \chi \in Z^p \otimes X_h^d. \tag{6.1}$$

6.1. Error estimates. A first step in the analysis of the $p \times h$-version is to study the energy error, i.e., to consider

$$\begin{aligned}\|u - u_h^p\|_E &\le \sqrt{\|\rho a\|_{L^\infty(\Gamma\times D)}} \min_{v\in Z^p\otimes X_h^d} \|u - v\|_{L^2(\Gamma)\otimes H_0^1(D)} \\ &\le \sqrt{\|\rho a\|_{L^\infty(\Gamma\times D)}} \Big\{ \min_{v\in Z^p\otimes H_0^1(D)} \|u - v\|_{L^2(\Gamma)\otimes H_0^1(D)} \\ &\qquad + \min_{v\in L^2(\Gamma)\otimes X_h^d} \|u - v\|_{L^2(\Gamma)\otimes H_0^1(D)} \Big\}.\end{aligned}$$

This bound splits the error into an $L^2(\Gamma)$ approximation error and a standard $H_0^1(D)$ FEM approximation error. The rest of this section studies the first one, since for the second we can apply the results from Proposition 3.1 together with a density argument. The minimizer

$$\|u - u^p\|_{L^2(\Gamma)\otimes H_0^1(D)} = \min_{v\in Z^p\otimes H_0^1(D)} \|u - v\|_{L^2(\Gamma)\otimes H_0^1(D)}$$

is the projection $u^p = (\Pi_1 \dots \Pi_N)u$ with $\Pi_n : L^2(\Gamma) \otimes H_0^1(D) \to L^2(\Gamma) \otimes H_0^1(D)$ being the natural extension of the L^2 projection $\bar{\Pi}_n : L^2(\Gamma_n) \to Z_n^{p_n}$, so the difference $u - u^p$ splits into $u - u^p = (1 - \Pi_1)u + \dots + (\Pi_1 \dots \Pi_{N-1})(1 - \Pi_N)u$. In addition, the boundedness of the projections Π_n, $n = 1, \dots, N$, yields

$$\|u - u^p\|_{L^2(\Gamma)\otimes H_0^1(D)} \le \sum_{n=1}^N \|(1 - \Pi_n)u\|_{L^2(\Gamma)\otimes H_0^1(D)}. \tag{6.2}$$

Without loss of generality we now estimate the first term on the right-hand side of (6.2), since the other terms have a completely similar behavior. Moreover, since

$$\|(1 - \Pi_1)u\|^2_{L^2(\Gamma)\otimes H_0^1(D)} = \int_{\hat{\Gamma}_1} \left(\int_{\Gamma_1} \|(1 - \Pi_1)u(y_1, \hat{y}_1, \cdot)\|^2_{H_0^1(D)} dy_1 \right) d\hat{y}_1$$

it is enough to estimate

$$(E_1)^2(\hat{y}_1) \equiv \int_{\Gamma_1} \|(1 - \Pi_1)u(y_1, \hat{y}_1, \cdot)\|^2_{H_0^1(D)} dy_1, \tag{6.3}$$

and thus our analysis requires only one dimensional arguments in the y-direction. Let $\Gamma_1 = (y_{min}, y_{max})$, and consider the map $\Psi : [-1,1] \to H_0^1(D)$ defined by

$$\Psi(t) = u(y_1(t), \hat{y}_1, \cdot) \in H_0^1(D)$$

with the affine transformation, $y_1 : [-1,1] \to \Gamma_1$, $y_1(t) \equiv \left(\frac{y_{max}+y_{min}}{2}\right) + \left(\frac{y_{max}-y_{min}}{2}\right)\ t$. In the upcoming estimate of the quantities $\|d_n\|_{H_0^1(D)}$, to be proved in Lemma 6.2, we need to consider a continuation of Ψ to the complex plane, namely, the following.

LEMMA 6.1 (complex continuation). *The function $\Psi : [-1,1] \to H_0^1(D)$ can be analytically extended to the complex domain.*

Proof. Let $t_0 \in (-1,1)$. We shall prove that the real function Ψ can be represented as a power series for $|t - t_0| < r_{t_0}$ for some $r_{t_0} > 0$. Since Ψ depends linearly on f, let us assume that $f(y,x) = f(x)$ only, without loss of generality. Let $y(t) = (y_1(t), \hat{y}_1)$, and consider the formal series

$$u_F(t) \equiv \sum_{j=0}^{+\infty} \left(\frac{|\Gamma_1|(t-t_0)}{2}\right)^j u_j,$$

with $u_j \in H_0^1(D)$ satisfying

$$\int_D a(y(t_0), \cdot)\nabla u_0 \cdot \nabla v = \int_D fv \quad \forall v \in H_0^1(D) \tag{6.4}$$

and, for $j \geq 0$,

$$\int_D a(y(t_0), \cdot)\nabla u_{j+1} \cdot \nabla v = -\int_D \sqrt{\lambda_1} b_1 \nabla u_j \cdot \nabla v \quad \forall v \in H_0^1(D). \tag{6.5}$$

This construction implies $\|u_j\|_{H_0^1(D)} \leq (\sqrt{\lambda_1}\|\frac{b_1}{a(y(t_0),\cdot)}\|_{L^\infty(D)})^j \frac{C_D\|f\|_{L^2(D)}}{a_{min}}$, $j \geq 1$, and then

$$\|u_F\|_{H_0^1(D)} \leq \frac{C_D\|f\|_{L^2(D)}}{a_{min}} \frac{1}{1-q} < \infty$$

for $q \equiv \frac{|t-t_0||\Gamma_1|\sqrt{\lambda_1}}{2}\|\frac{b_1}{a(y(t_0),\cdot)}\|_{L^\infty(D)} < 1$. Thus, for any $t_0 \in (-1,1)$ and $|t - t_0| < r_{t_0} \equiv \frac{2}{|\Gamma_1|\sqrt{\lambda_1}\left\|\frac{b_1}{a(y(t_0),\cdot)}\right\|_{L^\infty(D)}}$, the function u_F can be represented as a power series in $t - t_0$. At the same time, we have the equality $u_F(t) = \Psi(t)$ for $t \in (-1,1)$ since both functions solve the linear elliptic equation

$$\begin{array}{ll} -\nabla \cdot (a(y(t),x)\ \nabla u(y(t),x)) = f(x) & \forall x \in D, \\ u(y(t),x) = 0 & \forall x \in \partial D, \end{array}$$

which has a unique solution. Then u_F is the analytic continuation of Ψ, and the proof is complete. ∎

Remark 6.1. Consider the natural extension of the real variable t to the complex variable η. Observe that $\Psi(\eta)$ from Lemma 6.1 solves

$$\begin{array}{ll} -\nabla \cdot (a(y(\eta),x)\ \nabla \Psi(\eta,x)) = f(x) & \forall x \in D, \\ \Psi(\eta,x) = 0 & \forall x \in \partial D. \end{array} \tag{6.6}$$

Following [24], we use the Legendre polynomials to prove approximation estimates for the $p \times h$-version of the SGFEM. Since the Legendre polynomials

$$p_n(t) \equiv \frac{1}{2^n n!}\frac{d^n}{dt^n}((t^2-1)^n),\ n = 0, 1, \ldots,$$

are orthogonal with respect to the $L^2(-1,1)$ inner product we have the error representation

$$(E_1)^2(\hat{y}_1) = \frac{|\Gamma_1|}{2}\sum_{n=p_1+1}^{+\infty}\frac{2}{2n+1}\|d_n\|^2_{H_0^1(D)} \tag{6.7}$$

with the corresponding Fourier coefficients

$$d_n \equiv \frac{2n+1}{2}\int_{-1}^{1}\Psi(t)p_n(t)dt \in H_0^1(D).$$

Therefore, to obtain an estimate for E_1 we shall study the convergence of the tail series in (6.7).

NOTATION 6.1. *For each $\hat{y}_1 \in \hat{\Gamma}_1$, consider the natural extension of the variable t to the complex η and introduce the real function, $\mathcal{A} : \mathbb{C} \to \mathbb{R}$:*

$$\begin{aligned}\mathcal{A}(\eta) &\equiv \min_{x\in D}\ \mathrm{Re}\{a(y_1(\eta), \hat{y}_1, x)\}\\ &= \min_{x\in D}[a(0, \hat{y}_1, x) + y_1(\mathrm{Re}\{\eta\})\sqrt{\lambda_1}b_1(x)],\end{aligned}$$

with $\mathrm{Re}\{\eta\}$ *being the real part of* $\eta \in \mathbb{C}$. *Whenever* $\mathcal{A}(\eta) \neq 0$, *the extended function* Ψ, *the solution of* (6.6), *satisfies the bound*

$$\|\Psi(\eta)\|_{H_0^1(D)} \leq C_D\frac{\|f(y_1(\eta), \hat{y}_1, \cdot)\|_{L^2(D)}}{\mathcal{A}(\eta)}, \tag{6.8}$$

with C_D *being the Poincaré constant for the domain* D. *Besides this, observe that*

$$\mathcal{A}(\eta) \geq \tilde{a}_1(\hat{y}_1) - |y_1(\mathrm{Re}\{\eta\})|\ \sqrt{\lambda_1}\|b_1\|_{L^\infty(D)}. \tag{6.9}$$

We are now ready to estimate the Fourier coefficients in (6.7).

LEMMA 6.2. *Let* $\tau \in (0,1)$. *Under Assumption* 6.1 *there exists a positive constant* $\theta_f(\hat{y}_1, \tau) > 0$ *such that*

$$\|d_n\|_{H_0^1(D)} \leq \frac{C_D\ \ \theta_f\ \ (2n+1)}{\tau\,\nu\,2^n}\int_{-1}^{1}\left(\frac{1-t^2}{t+1+\delta}\right)^n dt,$$

with $0 < \delta = \frac{2(1-\tau)\nu}{|\Gamma_1|\sqrt{\lambda_1}\|b_1\|_{L^\infty(D)}}$.

Proof. Consider

$$d_n = \frac{2n+1}{2}\int_{-1}^{1}\Psi(t)p_n(t)dt = \frac{(2n+1)(-1)^n}{n!\ \ 2^{n+1}}\int_{-1}^{1}\frac{d^n}{dt^n}\Psi(t)(1-t^2)^n dt.$$

Use the analytic continuation of the real function Ψ to the complex domain as in Lemma 6.1. The application of Cauchy's formula gives

$$\frac{d^n}{dt^n}\Psi(t) = \frac{n!\big(-1\big)^n}{2\pi i}\int_{\gamma_t}\frac{\Psi(\eta)}{(\eta-t)^{n+1}}d\eta,$$

where γ_t is a positively oriented closed circumference with the center at the real point $t \in (-1,1)$, with radius $R(t)$, and such that all singularities from Ψ are exterior to γ_t. Estimate (6.8) implies

$$\begin{aligned}\left\| \frac{d^n}{dt^n}\Psi(t) \right\|_{H_0^1(D)} &\leq \frac{C_D \ n!}{2\pi} \int_{\gamma_t} \frac{\|f(y_1(\eta), \hat{y}_1, \cdot)\|_{L^2(D)}}{\mathcal{A}(\eta)|\eta - t|^{n+1}} |d\eta| \\ &\leq \frac{C_D \ n!}{2\pi} \left(\sup_{\eta \in \gamma_t} \|f(y_1(\eta), \hat{y}_1, \cdot)\|_{L^2(D)} \right) \int_{\gamma_t} \frac{|d\eta|}{\mathcal{A}(\eta)|\eta - t|^{n+1}} \\ &\leq \frac{C_D \ n!}{(R(t))^n} \left(\sup_{\eta \in \gamma_t} \|f(y_1(\eta), \hat{y}_1, \cdot)\|_{L^2(D)} \right) \sup_{\eta \in \gamma_t} \frac{1}{\mathcal{A}(\eta)}. \end{aligned} \tag{6.10}$$

Let

$$\theta_f \equiv \sup_{t \in [-1,1]} \sup_{\eta \in \gamma_t} \|f(y_1(\eta), \hat{y}_1, \cdot)\|_{L^2(D)};$$

then estimate (6.10) implies

$$\|d_n\|_{H_0^1(D)} \leq \frac{(2n+1) C_D \theta_f}{2^{n+1}} \int_{-1}^{1} \left(\frac{1}{\inf_{\eta \in \gamma_t} \mathcal{A}(\eta)} \right) \left(\frac{1 - t^2}{R(t)} \right)^n dt. \tag{6.11}$$

Let $\tau \in (0,1)$. We want to choose $R(t)$ such that

$$\inf_{t \in [-1,1]} \inf_{\eta \in \gamma_t} \mathcal{A}(\eta) \geq \tau \nu. \tag{6.12}$$

Since Assumption 6.1 holds, then (6.12) is satisfied taking $R(t) = 1 - |t| + \delta$, with $\delta = \frac{2(1-\tau)\nu}{|\Gamma_1|\sqrt{\lambda_1}\|b_1\|_{L^\infty(D)}}$. Finally, the proof concludes by combining (6.11)–(6.12) and the definition of $R(t)$. ∎

Now we use a result from [24], namely, that we have the following.

LEMMA 6.3 (integral estimate). *Let $\xi < -1$, and define*

$$r \equiv \frac{1}{|\xi| + \sqrt{\xi^2 - 1}}, \ 0 < r < 1.$$

Then there holds

$$(-1)^n \int_{-1}^{1} \left(\frac{t^2 - 1}{t + \xi} \right)^n dt = (2r)^n 2^{n+1} \frac{n!}{(2n+1)!!} \Phi_{n,0}(r^2),$$

where $\Phi_{n,0}(r^2)$ is the Gauss hypergeometric function. Moreover, we have

$$\Phi_{n,0}(r^2) = \sqrt{1 - r^2} + \mathcal{O}\left(\frac{1}{n^{1/3}} \right)$$

uniformly with respect to $0 < r < 1$.

Finally, we can state the estimate for the size of the series in (6.7).

LEMMA 6.4. *Let $\tau \in (0,1)$. Under Assumption 6.1 there exists a positive constant $\theta_f > 0$ such that*

$$(E_1)(\hat{y}_1) \leq \frac{C_D \theta_f \sqrt{|\Gamma_1|}}{\tau \tilde{a}_1} \left(\sqrt{1 - r^2} + \mathcal{O}\left(\frac{1}{(p_1)^{1/3}} \right) \right) \sqrt{\pi} \ \ \frac{r^{p_1+1}}{\sqrt{1 - r^2}},$$

with $r \equiv \frac{1}{|\xi|+\sqrt{\xi^2-1}}, 0 < r < 1$, *and* $\xi < -(1 + \frac{2(1-\tau)\nu}{|\Gamma_1|\sqrt{\lambda_1}\|b_1\|_{L^\infty(D)}})$.

Proof. Use Lemmas 6.2 and 6.3, together with the asymptotic equivalence $\frac{(2n)!!}{(2n-1)!!} \sim \sqrt{\frac{\pi n}{2}}, n \to \infty$, yielding

$$\|d_n\|_{H_0^1(D)} \leq \frac{2C_D\theta_f}{\tau\tilde{a}_1}\sqrt{\frac{\pi n}{2}} \quad \left(\sqrt{1-r^2} + \mathcal{O}\left(\frac{1}{n^{1/3}}\right)\right) r^n.$$

Then use the result to estimate the tail of the series:

$$(E_1)^2(\hat{y}_1) = \frac{|\Gamma_1|}{2} \sum_{n=p_1+1}^{+\infty} \frac{2}{2n+1}\|d_n\|^2_{H_0^1(D)}. \qquad \square$$

The main result of this section, namely the exponential convergence with respect to the multi-index p as in [24], follows from the above lemmas; i.e., we have the following.

THEOREM 6.2. *Let* $\tau \in (0,1)$ *and* u *be the solution of* (2.6), $u \in L^2(\Gamma) \otimes H_0^1(D)$, *which is analytic with respect to* y, *onto the subspace* $Z^p \otimes H_0^1(D)$. *Under Assumption* 6.1 *there exist positive constants,* $0 < C, C_f$, *such that*

$$\begin{aligned} E_p &\equiv \min_{v \in Z^p \otimes H_0^1(D)} \|u - v\|_{L^2(\Gamma)\otimes H_0^1(D)} \\ &\leq \frac{C_D C_f}{\tau\nu}\sqrt{\pi|\Gamma|}\sum_{n=1}^{N}\left(1 + \frac{1}{\sqrt{1-r_n^2}}\mathcal{O}\left(\frac{1}{(p_n)^{1/3}}\right)\right)(r_n)^{p_n+1}, \end{aligned} \tag{6.13}$$

with $0 < r_n \equiv \frac{1}{|\xi_n|+\sqrt{\xi_n^2-1}} < 1$, *and* $\xi_n < -(1 + \frac{2(1-\tau)\nu}{|\Gamma_n|\sqrt{\lambda_n}\|b_n\|_{L^\infty(D)}})$ *for* $n = 1, \ldots, N$.

Similarly, as in the $k \times h$-version (cf. (5.7)), the p-version has a convergence result for the approximation to the expected value of the solution.

THEOREM 6.3. *With the same assumptions as in Theorem* 6.2 *and for* $\ell = 0, 1$, *we have*

$$\|E[u - u_h^p]\|_{H^\ell(D)} \leq \quad C\left(h^{2-\ell} + \frac{1}{\tau}\sum_{n=1}^{N}(r_n)^{(2-\ell)(p_n+1)}\right),$$

with $0 < r_n < 1$ *as in Theorem* 6.2 *and* $C > 0$ *independent of* h, p_n, *and* r_n.

The proof of the previous theorem uses Theorem 6.2 and is completely similar to the proof of Theorem 5.1.

Remark 6.2. Whenever the coefficients a and f are independent the constants θ_f from Lemma 6.2, C_f from Theorem 6.2, and C from Theorem 6.3 do not depend on N.

7. Double orthogonal polynomials. Here we explain the idea of double orthogonal polynomials, used by various authors in different contexts; see, e.g., [47] to compute efficiently the solution of the $k \times h$-version and the $p \times h$-version studied in sections 5 and 6, respectively. The idea is to use a special basis to decouple the system in the y-direction, yielding just a number of uncoupled systems, each one with the size and structure of one Monte Carlo realization of (4.1). The double orthogonal polynomials are able to perform the decoupling whenever the random variables in the Karhunen–Loève expansion of $a, Y_n, n = 1, \ldots, N$, are independent.

Without loss of generality we focus on the p-version, i.e., find $u_h^p \in Z^p \otimes X_h^d$ such that

$$\begin{aligned}\int_\Gamma \rho(y)(a(y,\cdot)\nabla u_h^p(y,\cdot), \nabla v(y,\cdot))_{L^2(D)}dy \\ = \int_\Gamma \rho(y)(f(y,\cdot), v(y,\cdot))_{L^2(D)}dy \quad \forall v \in Z^p \otimes X_h^d.\end{aligned} \tag{7.1}$$

Let $\{\psi_j(y)\}$ be a basis of the subspace $Z^p \subset L^2(\Gamma)$ and $\{\varphi_i(x)\}$ be a basis of the subspace $X_h^d \subset H_0^1(D)$. Write the approximate solution as

$$u_h^p(y,x) = \sum_{j,i} u_{ij}\psi_j(y)\varphi_i(x) \tag{7.2}$$

and use test functions $v(y,x) = \psi_k(y)\varphi_\ell(x)$ to find the coefficients u_{ij}. Then (7.1) gives

$$\begin{aligned}\sum_{j,i}\left(\int_\Gamma \rho(y)\psi_k(y)\psi_j(y)(a(y,\cdot)\nabla\varphi_i, \nabla\varphi_\ell)_{L^2(D)}dy\right)u_{ij} \\ = \int_\Gamma \rho(y)\psi_k(y)(f(y,\cdot),\varphi_\ell)_{L^2(D)}dy \quad \forall k,\ell,\end{aligned}$$

which can be rewritten as

$$\sum_{j,i}\left(\int_\Gamma \rho(y)\psi_k(y)\psi_j(y)K_{i,\ell}(y)dy\right)u_{ij} = \int_\Gamma \rho(y)\psi_k(y)f_\ell(y)dy \quad \forall k,\ell,$$

with $K_{i,\ell}(y) \equiv (a(y,\cdot)\nabla\varphi_i, \nabla\varphi_\ell)_{L^2(D)}$ and $f_\ell(y) \equiv (f(y,\cdot),\varphi_\ell)_{L^2(D)}$. If the diffusion coefficient, a, is a truncated Karhunen–Loève expansion, $a(y,x) = E[a](x) + \sum_{n=1}^N b_n(x)y_n$, and by the independence of the $Y_n, n = 1,\dots,N$, we have a corresponding "Karhunen–Loève" expression for the stiffness matrix $K_{i,\ell}(y) \equiv \int_D (E[a](x) + \sum_{n=1}^N b_n(x)y_n)\nabla\varphi_i(x)\cdot\nabla\varphi_\ell(x)dx = K_{i,\ell}^0 + \sum_{n=1}^N y_n K_{i,\ell}^n$ with deterministic coefficients $K_{i,\ell}^0 \equiv (E[a]\nabla\varphi_i, \nabla\varphi_\ell)_{L^2(D)}$ and $K_{i,\ell}^n \equiv (b_n\nabla\varphi_i, \nabla\varphi_\ell)_{L^2(D)}$. By the same token we have

$$\begin{aligned}\int_\Gamma \rho(y)\psi_k(y)\psi_j(y)K_{i,\ell}(y)dy = K_{i,\ell}^0\int_\Gamma \rho(y)\psi_k(y)\psi_j(y)dy \\ + \sum_{n=1}^N K_{i,\ell}^n \int_\Gamma y_n\rho(y)\psi_k(y)\psi_j(y)dy.\end{aligned}$$

Since $\psi_k \in Z^p$, with multi-index $p = (p_1,\dots,p_N)$, it is enough to take it as the product $\psi_k(y) = \prod_{r=1}^N \psi_{kr}(y_r)$, where $\psi_{kr}\colon \Gamma_r \to \mathbb{R}$ is a basis function of the subspace

$$Z^{p_r} = \operatorname{span}[1, y, \dots, y^{p_r}] = \operatorname{span}[\psi_{hr} : h = 1,\dots,p_r+1].$$

Keeping this choice of ψ_k in mind,

$$\begin{aligned}\int_\Gamma \rho(y)\psi_k(y)\psi_j(y)K_{i,\ell}(y)dy = K_{i,\ell}^0\int_\Gamma \prod_{m=1}^N \rho_m(y_m)\psi_{km}(y_m)\psi_{jm}(y_m)dy \\ + \sum_{n=1}^N K_{i,\ell}^n \int_\Gamma y_n \prod_{m=1}^N \rho_m(y_m)\psi_{km}(y_m)\psi_{jm}(y_m)dy.\end{aligned}$$

Now, for every set Γ_n, $n = 1, \ldots, N$, choose the polynomials, $\psi_j(y) = \prod_{n=1}^{N} \psi_{jn}(y_n)$, to be biorthogonal; i.e., for $n = 1, \ldots, N$ they must satisfy

$$\begin{aligned} \int_{\Gamma_n} \rho_n(z)\psi_{kn}(z)\psi_{jn}(z)dz &= \delta_{kj}, \\ \int_{\Gamma_n} z\rho_n(z)\psi_{kn}(z)\psi_{jn}(z)dz &= c_{kn}\delta_{kj}. \end{aligned} \tag{7.3}$$

To find the polynomials ψ_k we have to solve N eigenproblems, each of them with size $(1 + p_n)$. The computational work required by these eigenproblems is negligible with respect to the one required to solve for u_{ij}; cf. [23, section 8.7.2]. The orthogonality properties (7.3) for ψ_k imply the decoupling $\int_\Gamma \rho\psi_k\psi_j dy = \delta_{kj}, \int_\Gamma y_n\rho\psi_k\psi_j dy = c_{kn}\delta_{kj}$. By means of this decoupling we now conclude that

$$\begin{aligned} &\sum_{j,i} \left(\int_\Gamma \rho(y)\psi_k(y)\psi_j(y)K_{i,\ell}(y)dy \right) \\ &\quad = K^0_{i,\ell} \int_\Gamma \rho(y)\psi_k(y)\psi_j(y)dy + \sum_{n=1}^{N} K^n_{i,\ell} \int_\Gamma y_n\rho(y)\psi_k(y)\psi_j(y)dy \\ &\quad = \left(K^0_{i,\ell} + \sum_{n=1}^{N} c_{kn} \;\; K^n_{i,\ell} \right) \delta_{kj}. \end{aligned}$$

The structure of the linear system that determines u_{ij} now becomes block diagonal, with each block being coercive and with the sparsity structure identical to one deterministic FEM stiffness matrix, i.e.,

$$\begin{bmatrix} \left(K^0 + \sum\limits_{n=1}^{N} c_{1n}\, K^n \right) & 0 & \cdots & 0 \\ 0 & \left(K^0 + \sum\limits_{n=1}^{N} c_{2n}\, K^n \right) & \cdots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & \cdots & 0 & \left(K^0 + \sum\limits_{n=1}^{N} c_{Nn}\, K^n \right) \end{bmatrix}.$$

Observe that as a consequence of the uniform coercivity assumption, each of the diagonal blocks in the system above is symmetric and strictly positive definite. The conclusion is that the computational work to find the coefficients u_{ij} in (7.2) is the same as the one needed to compute $\prod_{i=1}^{N}(1 + p_i)$ Monte Carlo realizations of u_h defined in (4.1), but the accuracies of these methods may differ. Section 8 studies this issue.

8. Asymptotical efficiency comparisons. In this section we compare the asymptotical numerical complexity for the Monte Carlo Galerkin finite element method (cf. section 4) with the stochastic Galerkin finite element method introduced in sections 5 and 6. The quantity of interest, i.e., the goal of the computation, is the expected value of the solution, $E[u]$, and its approximation is studied in both the $L^2(D)$ and the $H^1_0(D)$ sense. In all the cases, the spatial discretization is done by piecewise linear finite elements on globally quasi-uniform meshes. For the $k \times h$-SGFEM the Γ partitions are also assumed to be globally quasi-uniform. Besides this, the diffusion function a is assumed to be a truncated Karhunen–Loève expansion with independent random variables $Y_n,\ n = 1, \ldots, N$.

8.1. MCGFEM versus $k \times h$-SGFEM. Here we consider the computational work to achieve a given accuracy bounded by a positive constant TOL for both the MCGFEM and the $k \times h$-SGFEM methods. This optimal computational work indicates under which circumstances one method may be best suited. When using the MCGFEM method to approximate the solution of (1.1) in $H_0^1(D)$ the error becomes, applying Proposition 4.2 together with (4.5), that given a confidence level, $0 < c_0 < 1$, there exists a constant $C > 0$ depending only on c_0 such that

$$P\left(\left\|E[u] - \frac{1}{M}\sum_{j=1}^{M} u_h(\cdot;\omega_j)\right\|_{H_0^1(D)} \leq C\left(h + \frac{1}{\sqrt{M}}\right)\right) \geq c_0. \tag{8.1}$$

Then in the sense of (8.1) we write $E_{MCGFEM} = O(h) + O(1/\sqrt{M})$. The corresponding computational work for the MCGFEM method is $Work_{MCGFEM} = O((1/h^d)^r + 1/h^d)M$, where the parameter $1 \leq r \leq 3$ relates to the computational effort devoted to solve one linear system with n unknowns, $O(n^r)$. From now on we continue the discussion with the optimal $r = 1$ that can be achieved by means of the multigrid method; cf. [10]. Thus, choosing h and M to minimize the computational work for a given desired level of accuracy TOL > 0 yields the optimal work

$$Work^*_{MCGFEM} = O(\mathrm{TOL}^{-(2+d)}). \tag{8.2}$$

On the other hand, if we apply a $k \times h$-SGFEM with piecewise polynomials of order q in the y-direction, the computational error in $H_0^1(D)$ norm is (cf. Theorem 5.1)

$$E_{SGFEM} = O(h) + O(k^{q+1}),$$

and the corresponding computational work for the $k \times h$-version is

$$Work_{SGFEM} = O(h^{-d}(1+q)^N k^{-N}).$$

Here N is the number of terms in the truncated Karhunen–Loève expansion of the coefficients a and f and k is the discretization parameter in the y-direction. Similarly as before, we can compute the optimal work for the $k \times h$-SGFEM method, yielding

$$Work^*_{SGFEM} = O((1+q)^N \mathrm{TOL}^{-\frac{N}{q+1}} \mathrm{TOL}^{-d}).$$

Therefore, a $k \times h$-version SGFEM is likely to be preferred whenever TOL is sufficiently small and $N/2 < 1 + q$; i.e., if the number of terms in the Karhunen–Loève expansion of a is large, then the degree of approximation in the y-direction, q, has to become correspondingly large. We summarize the comparison results in Table 1, where we also include corresponding results from the $p \times h$-version, to be derived in subsection 8.2. Similarly, if we are interested in controlling the difference $\|E[u] - E[u_h]\|_{L^2(D)}$, the application of (4.2) and Proposition 4.2 for the MCGFEM method and Theorem 5.1 on the convergence of the $k \times h$-SGFEM method imply the results shown in Table 2. In this case $k \times h$-SGFEM is likely to be preferred whenever $N/4 < (q+1)$ and TOL is sufficiently small. In addition, the comparison tells us that to be able to be competitive with the Monte Carlo method when the number of relevant terms in the Karhunen–Loève expansion is not so small, an optimal method should have a high order of approximation and should avoid as much as possible the coupling between the different components of the numerical solution to preserve computational efficiency. The approach proposed by Ghanem and Spanos [22] based on

TABLE 1
Approximation of the function $E[u]$ in $H_0^1(D)$. Asymptotical numerical complexity for the MCGFEM and SGFEM methods.

	MCGFEM	$k \times h$-version SGFEM	$p \times h$-version SGFEM
$Work$	M/h^d	$\frac{(1+q)^N}{h^d k^N}$	$\frac{(1+p)^N}{h^d}$
$H_0^1(D)$ $Error$	$h + \frac{1}{\sqrt{M}}$	$h + \quad k^{q+1}$	$h + r^{(p+1)}$
$H_0^1(D)$ $Work^*$	$\mathrm{TOL}^{-(2+d)}$	$\mathrm{TOL}^{-\frac{N}{q+1}}\mathrm{TOL}^{-d}$	$(\log_r(\mathrm{TOL}))^N\mathrm{TOL}^{-d}$

TABLE 2
Approximation of the function $E[u]$ in $L^2(D)$. Asymptotical numerical complexity for the MCGFEM and SGFEM methods.

	MCGFEM	$k \times h$-version SGFEM	$p \times h$-version SGFEM
$Work$	M/h^d	$\frac{(1+q)^N}{h^d k^N}$	$\frac{(1+p)^N}{h^d}$
$L^2(D)$ $Error$	$h^2 + \frac{1}{\sqrt{M}}$	$h^2 + k^{2(q+1)}$	$h^2 + r^{2(p+1)}$
$L^2(D)$ $Work^*$	$\mathrm{TOL}^{-(2+d/2)}$	$(\mathrm{TOL})^{-\frac{N}{2(q+1)}}\ \mathrm{TOL}^{-d/2}$	$(\log_r(\mathrm{TOL}))^N\mathrm{TOL}^{-d/2}$

orthogonal polynomials has, whenever the approximate diffusion satisfies (1.2), a high order of approximation but introduces coupling between the different components of the numerical solution. The uncoupling can be achieved for linear equations using double orthogonal polynomials; see the description in section 7. With this motivation, section 6 studies the convergence of the $p \times h$-SGFEM.

8.2. MCGFEM versus $p \times h$-SGFEM. Here we consider the computational work to achieve a given accuracy for both the $p \times h$-version of SGFEM defined in (6.1) and the MCGFEM method for the approximation of $E[u]$ defined in section 4; i.e., we are interested in controlling the difference $\|E[u] - E[u_h^p]\|_{L^2(D)}$ or $\|E[u] - \frac{1}{M}\sum_{j=1}^M u_h(\cdot;\omega_j)\|_{L^2(D)}$, respectively. This computational work indicates under which circumstances one method may be better suited than the other. Besides this, let us assume that we use in our computations a piecewise linear FEM space in D. When using the MCGFEM method to approximate the expected value of the solution of (1.1), we have the optimal work required to achieve a given desired level of accuracy $\mathrm{TOL} > 0$ (cf. (8.2)):

$$Work^*_{MCGFEM} = O(1/\mathrm{TOL}^{2+\frac{d}{2}}).$$

On the other hand, if we apply a $p \times h$-version of the SGFEM, with $p_i = p,\ i = 1, \ldots, N$, the computational error is (cf. Theorem 6.3)

$$E_{SGFEM} = O(h^2) + O(r^{2(p+1)}), \quad 0 < r < 1,$$

and the corresponding computational work is (cf. section 7)

$$Work_{SGFEM} = O\left(\frac{(1+p)^N}{h^d}\right).$$

Recall that N is the number of terms in the truncated Karhunen–Loève expansion of the coefficients a and f, and k is the discretization parameter in the y-direction. As

before, we can compute the optimal work for the SGFEM method, yielding

$$Work^*_{SGFEM} \leq O((\log_r(\mathrm{TOL}))^N \mathrm{TOL}^{-\frac{d}{2}})$$

and the asymptotical comparison

$$\lim_{\mathrm{TOL}\to 0} \frac{Work^*_{SGFEM}}{Work^*_{MCGFEM}} = \lim_{\mathrm{TOL}\to 0} (\log_r(\mathrm{TOL}))^N \mathrm{TOL}^2 = 0.$$

Therefore, for sufficiently strict accuracy requirements, i.e., sufficiently small TOL, in the computation of $E[u]$, SGFEM requires less computational effort than MCGFEM. The work of Bahvalov and its subsequent extensions (cf. [7, 25, 45, 35]) generalize the standard Monte Carlo method, taking advantage of the available integrand's smoothness and yielding a faster order of convergence. The optimal work of such a method is for our case, i.e., the approximation of $E[u]$ in $L^2(D)$, $\mathcal{O}(C(N)\mathrm{TOL}^{-\frac{1}{1/2+q/N}}\mathrm{TOL}^{-d/2})$, where it is assumed that the integrand u has bounded derivatives up to order q with respect to y and the integral is done in the N-dimensional unit cube.

The result on the computational work of the $p \times h$-version of the SGFEM presented in this work is then related to the case $q = \infty$, since u is analytic with respect to y. This analyticity allows the exponential convergence with respect to p; cf. Theorem 6.3.

Notice that we discussed only the optimal asymptotical computational work required by both methods, but in practice the constants involved in the asymptotic approximations make these comparisons just indicative and not conclusive. In addition, we have studied only the case where the integrals $\int_{\Gamma_i} \rho_i y^k dy$ can be computed exactly for $k = 0, 1, \ldots$, and not considered the more general case where quadrature rules are needed to approximate such integrals. For further information we refer the reader to [6].

LEAST-SQUARES METHODS FOR LINEAR ELASTICITY*

ZHIQIANG CAI† AND GERHARD STARKE‡

Abstract. This paper develops least-squares methods for the solution of linear elastic problems in both two and three dimensions. Our main approach is defined by simply applying the L^2 norm least-squares principle to a stress-displacement system: the constitutive and the equilibrium equations. It is shown that the homogeneous least-squares functional is elliptic and continuous in the $H(\mathrm{div};\Omega)^d \times H^1(\Omega)^d$ norm. This immediately implies optimal error estimates for finite element subspaces of $H(\mathrm{div};\Omega)^d \times H^1(\Omega)^d$. It admits optimal multigrid solution methods as well if Raviart–Thomas finite element spaces are used to approximate the stress tensor. Our method does not degrade when the material properties approach the incompressible limit. Least-squares methods that impose boundary conditions weakly and use an inverse norm are also considered. Numerical results for a benchmark test problem of planar elasticity are included in order to illustrate the robustness of our method in the incompressible limit.

Key words. least-squares method, mixed finite element method, linear elasticity, incompressible limit

1. Introduction.

The primitive physical equations for linear elastic problems are the constitutive equation, which expresses a relation between the stress and strain tensors, and the equilibrium equation. This first-order partial differential system is called the stress-displacement formulation. Substituting the stress into the equilibrium equation leads to a second-order elliptic partial differential system called the pure displacement formulation. However, the stress-displacement formulation is preferable to the pure displacement formulation for some important practical problems, e.g., modeling of nearly incompressible or incompressible materials and modeling of plastic materials where the elimination of the stress tensor is difficult. In addition, the stress is usually a physical quantity of primary interest. It can be obtained in the pure displacement method by differentiating displacement, but this degrades the order of the approximation.

A mixed finite element method is based on the weak form of the stress-displacement formulation, and it requires a stable combination of finite element spaces to approximate these variables. Unlike mixed methods for second-order scalar elliptic boundary value problems, stress-displacement finite elements are extremely difficult to construct. This is caused by the symmetry constraint of the stress tensor. Recently, Arnold and Winther in [3] constructed a family of stable conforming elements in two dimensions on a triangular tessellation. Their simplest element has 21 stress and 3 displacement degrees of freedom per triangle. The local degrees of freedom are reduced to 12 for the stress and 3 for the displacement for a stable nonconforming element in [4]. For previous work on mixed methods for linear elasticity, see [3] and

references therein. Like scalar elliptic problems, mixed methods lead to saddle-point problems. Many solution methods that work well for symmetric and positive definite problems cannot be applied directly. Although substantial progress in solution methods for saddle-point problems has been achieved, these problems may still be difficult and expensive to solve.

In recent years there has been increasing interest in the use of least-squares principles for numerical approximations of partial differential equations and systems (see, e.g., the survey paper [6], the monograph [18], and references therein). Their advantages over the usual mixed finite element discretizations include that the choice of finite element spaces is not subject to the stability condition (see, e.g., [9]), that the resulting algebraic equations can be solved efficiently by standard multigrid methods or preconditioned by well-known techniques, and that the value of a least-squares functional provides a free, sharp, and practical a posteriori error indicator which can be used efficiently in a local refinement process. For linear elasticity, in particular, least-squares methods have an additional edge over mixed methods in that the known stable mixed elements are very limited and they have a large number of degrees of freedom. In [11], Cai, Manteuffel, McCormick, and Parter proposed a two-stage least-squares approach that first solves for the displacement gradient and then solves for the displacement itself (if desired). Physical quantities such as the strain, the stress, and the rotation are then simple linear combinations of the displacement gradient. At the first stage, it has four (nine) variables in two (three) dimensions, compared to five (nine) variables for the stress-displacement formulation. One drawback of this approach is its requirement of sufficient smoothness on the original problem if using standard continuous finite element approximations. Another approach was proposed by engineers in [19] based on a displacement-stress-rotation formulation; it has the same drawback as that of [11]. In addition, it introduces extra variables (the rotation): one (three) variable in two (three) dimensions. For other least-squares approaches in the engineering literature in solid mechanics, see references in [19].

In contrast to these approaches, our aim is to develop a least-squares approach that does not have the above-mentioned drawbacks, and that computes the stress and the displacement directly. Thus it would be easier to extend this method to applications such as nonlinear elasticity, plasticity, etc. The stress components are physical quantities of primary interest in many practical applications including coupling of elastic deformation with fluid flow models. The method to be developed in this paper is based on the primitive physical equations of linear elasticity: the stress-displacement formulation, *without introducing any new variables or any new equations*. Applying the L^2 norm least-squares principle to this first-order system with an appropriately scaled constitutive equation, we develop a least-squares formulation for linear elasticity. It is shown that the homogeneous least-squares functional is elliptic and continuous in the $H(\mathrm{div};\Omega)$ norm for the stress and in the H^1 norm for the displacement uniformly with respect to material constants. This immediately implies optimal error estimates for finite element subspaces of $H(\mathrm{div};\,\Omega)^d \times H^1(\Omega)^d$. It also admits optimal multigrid solution methods if Raviart–Thomas finite element spaces (see, e.g., [9]) are used to approximate the stress tensor. Both discretization accuracy and multigrid convergence rate of the method do not degrade when the material properties approach the incompressible limit. As usual, the evaluation of the least-squares functional on each element is a practical and sharp a posteriori error indicator for adaptive mesh refinements. The practical performance of the resulting

adaptive strategy will be tested numerically for a common benchmark problem of linear elasticity in the final section of this paper.

The method here is closely related to our previous work in [12, 10]. The main difference is the scale in the constitutive equation. The homogeneous least-squares functionals in [12, 10] are equivalent to the $H(\mathrm{div};\Omega)$ norm for the stress and the *energy* norm for the displacement. This means that the least-squares variational problems in [12, 10] do not apply for incompressible materials and require effective discretizations and efficient solvers for the pure displacement problem when materials are nearly incompressible. These tasks remain difficult and expensive although some progress has been achieved (see, e.g., [8] and references therein).

For completeness, we study an inverse norm least-squares functional and show that its homogeneous form is equivalent to the $L^2(\Omega)^{d\times d}\times H^1(\Omega)^d$ norm for the stress and the displacement. This functional can be used to develop a discrete inverse norm least-squares method (see, e.g., [7]). For some applications, it is convenient to impose boundary conditions weakly by adding boundary functionals. Such a functional is also studied in this paper. See [21] for how to use these types of functionals to develop a computationally feasible numerical method.

An outline of the paper is as follows. The stress-displacement formulation for the linear elastic problem is introduced in section 2, along with some notation, the pure displacement formulation, and some regularity estimates. Section 3 develops the least-squares functionals based on the stress-displacement formulation and establishes their ellipticity and continuity. Section 4 discusses finite element approximations. Section 5 studies a least-squares functional with boundary terms that enforces boundary conditions weakly. Finally, numerical results for a benchmark test problem of linear elasticity are presented in section 6.

1.1. Notation. We use the standard notation and definitions for the Sobolev spaces $H^s(\Omega)^d$ and $H^s(\partial\Omega)^d$ for $s\geq 0$; the standard associated inner products are denoted by $(\cdot,\cdot)_{s,\Omega}$ and $(\cdot,\cdot)_{s,\partial\Omega}$, and their respective norms are denoted by $\|\cdot\|_{s,\Omega}$ and $\|\cdot\|_{s,\partial\Omega}$. (We suppress the superscript d because their dependence on dimension will be clear by context. We also omit the subscript Ω from the inner product and norm designation when there is no risk of confusion.) For $s=0$, $H^s(\Omega)^d$ coincides with $L^2(\Omega)^d$. In this case, the inner product and norm will be denoted by $\|\cdot\|$ and $(\cdot,\cdot)$, respectively. Set $H^1_D(\Omega):=\{q\in H^1(\Omega)\,:\,q=0 \text{ on } \Gamma_D\}$. We use $H_D^{-1}(\Omega)$ and $H^{-\frac{1}{2}}(\partial\Omega)$ to denote the dual of $H^1_D(\Omega)$ and $H^{\frac{1}{2}}(\partial\Omega)$ with norms defined by

$$\|\phi\|_{-1,\,D}=\sup_{0\neq\psi\in H^1_D(\Omega)}\frac{(\phi,\,\psi)}{\|\psi\|_1}\quad\text{and}\quad\|\phi\|_{-1/2,\,\partial\Omega}=\sup_{0\neq\psi\in H^{\frac{1}{2}}(\partial\Omega)}\frac{(\phi,\,\psi)}{\|\psi\|_{1/2,\partial\Omega}}.$$

Denote the product space $H_D^{-1}(\Omega)^d=\prod_{i=1}^d H_D^{-1}(\Omega)$ with the standard product norm. Set

$$H(\mathrm{div};\Omega)=\{\mathbf{v}\in L^2(\Omega)^2\,:\,\nabla\cdot\mathbf{v}\in L^2(\Omega)\},$$

which is a Hilbert space under the norm

$$\|\mathbf{v}\|_{H(\mathrm{div};\,\Omega)}=\left(\|\mathbf{v}\|^2+\|\nabla\cdot\mathbf{v}\|^2\right)^{\frac{1}{2}}.$$

2. Linear elasticity and preliminaries. Let Ω be a bounded, open, connected subset of $\Re^d$ ($d=2$ or 3) with a Lipschitz continuous boundary $\partial\Omega$. Denote $\mathbf{n}=(n_1,\,\ldots\,,n_d)^t$ as the outward unit vector normal to the boundary. We partition the

boundary of the domain Ω into two open subsets Γ_D and Γ_N such that $\partial\Omega = \bar{\Gamma}_D \cup \bar{\Gamma}_N$ and $\Gamma_D \cap \Gamma_N = \emptyset$. For simplicity, we assume that Γ_D is not empty (i.e., mes $(\Gamma_D) \neq 0$). Our approaches proposed in this paper can be easily extended to the pure traction problem ($\Gamma_D = \emptyset$) by excluding the space of infinitesimal rigid motions.

Let $\mathbf{f} = (f_1, \ldots, f_d)^t$ be a given body force defined on Ω. The linear elastic problem consists of finding a displacement field $\mathbf{u} = (u_1, \ldots, u_d)^t$ and a stress tensor $\boldsymbol{\sigma} = \big(\sigma_{ij}\big)_{d\times d}$ that satisfy the equilibrium equation

$$\sum_{j=1}^{d} \frac{\partial \sigma_{ij}}{\partial x_j} + f_i = 0 \quad \text{for } i = 1, \ldots, d \tag{2.1}$$

and boundary conditions

$$\mathbf{u} = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \sum_{j=1}^{d} \sigma_{ij}\, n_j = 0 \quad \text{on } \Gamma_N \quad \text{for } i = 1, \ldots, d. \tag{2.2}$$

For simplicity, here we assume that the boundary conditions are homogeneous.

Denote $\boldsymbol{\epsilon}(\mathbf{u}) = (\epsilon_{ij}(\mathbf{u}))_{d\times d}$ as the linearized strain tensor, where

$$\epsilon_{ij}(\mathbf{u}) = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right).$$

The constitutive law expresses a relation between the stress and the strain tensors:

$$\boldsymbol{\sigma} = \mathcal{C}\,\boldsymbol{\epsilon}(\mathbf{u}) \quad \text{or} \quad \boldsymbol{\epsilon}(\mathbf{u}) = \mathcal{A}\,\boldsymbol{\sigma}, \tag{2.3}$$

where $\mathcal{C}$ and $\mathcal{A}$ are the elasticity and the compliance tensors of fourth order, respectively. Denote by tr the trace operator

$$\mathrm{tr}\big(\boldsymbol{\epsilon}(\mathbf{u})\big) = \epsilon_{11}(\mathbf{u}) + \cdots + \epsilon_{dd}(\mathbf{u}) = \nabla \cdot \mathbf{u},$$

where $\nabla\cdot$ stands for the divergence operator. For an isotropic elastic material, the elasticity tensor has the following simple expression:

$$\mathcal{C}\,\boldsymbol{\epsilon}(\mathbf{u}) = \lambda\,\mathrm{tr}\big(\boldsymbol{\epsilon}(\mathbf{u})\big)\boldsymbol{\delta} + 2\mu\,\epsilon(\mathbf{u}), \tag{2.4}$$

where $\boldsymbol{\delta} = (\delta_{ij})_{d\times d}$ is the identity tensor, and positive constants λ and μ are the Lamé constants such that $\mu \in [\mu_1, \mu_2]$ with $0 < \mu_1 < \mu_2$ and $\lambda \in (0, \infty)$. Materials are said to be nearly incompressible or incompressible when λ is very large or infinite, respectively. Note that both the stress and the strain tensors are symmetric. Such symmetry of the stress stems from the conservation of angular momentum.

For a second-order tensor $\boldsymbol{\tau} = (\tau_{ij})_{d\times d}$, define its divergence and normal by

$$\nabla \cdot \boldsymbol{\tau} = \begin{pmatrix} \partial\tau_{11}/\partial x_1 + \cdots + \partial\tau_{1d}/\partial x_d \\ \vdots \\ \partial\tau_{d1}/\partial x_1 + \cdots + \partial\tau_{dd}/\partial x_d \end{pmatrix} \quad \text{and} \quad \mathbf{n}\cdot\boldsymbol{\tau} = \begin{pmatrix} n_1\tau_{11} + \cdots + n_d\tau_{1d} \\ \vdots \\ n_1\tau_{d1} + \cdots + n_d\tau_{dd} \end{pmatrix},$$

respectively. That is, the divergence and normal operators apply to each row of the tensor. Then the stress-displacement system in (2.3), (2.1), and (2.2) may be rewritten in the compact form

$$\begin{cases} \boldsymbol{\sigma} - \mathcal{C}\,\boldsymbol{\epsilon}(\mathbf{u}) &= \mathbf{0} & \text{in} \quad \Omega, \\ \nabla\cdot\boldsymbol{\sigma} &= -\mathbf{f} & \text{in} \quad \Omega \end{cases} \tag{2.5}$$

with the boundary conditions

$$\mathbf{u} = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot \boldsymbol{\sigma} = \mathbf{0} \quad \text{on } \Gamma_N. \tag{2.6}$$

There are three approaches to treating this first-order partial differential system. One is to substitute the stress into the equilibrium equation to get the pure displacement formulation in (2.7). Numerical methods based on this formulation are not desirable for accurate approximations of the stress and for some important practical problems such as the modeling of nearly incompressible or incompressible or plastic materials. Another approach is to find the unique saddle point $(\boldsymbol{\sigma}, \mathbf{u}) \in H_N^S(\text{div}; \Omega)^d \times L^2(\Omega)^d$ of the Hellinger–Reissner functional

$$\mathcal{J}(\boldsymbol{\tau}, \mathbf{v}) = \frac{1}{2}(\mathcal{A}\boldsymbol{\tau}, \boldsymbol{\tau}) + (\nabla \cdot \boldsymbol{\tau} + \mathbf{f}, \mathbf{v}).$$

Here $H_N^S(\text{div}; \Omega)^d$ denotes the space of square-integrable symmetric tensors with square-integrable divergence and homogeneous normal on Γ_N. Equivalently, $(\boldsymbol{\sigma}, \mathbf{u})$ satisfies the following weak formulation:

$$(\mathcal{A}\boldsymbol{\sigma}, \boldsymbol{\tau}) + (\mathbf{u}, \nabla \cdot \boldsymbol{\tau}) + (\nabla \cdot \boldsymbol{\sigma}, \mathbf{v}) = (-\mathbf{f}, \mathbf{v}) \quad \forall\, (\boldsymbol{\tau}, \mathbf{v}) \in H_N^S(\text{div}; \Omega)^d \times L^2(\Omega)^d.$$

Numerical methods based on this formulation require a stable combination of finite element spaces to approximate the stress and the displacement. Known stable mixed elements are very limited and have a large number of degrees of freedom. In addition, the resulting indefinite algebraic system is still difficult and expensive to solve. In this paper, we study the third approach based on the least-squares principle that automatically stabilizes the stress-displacement system (see section 3).

We complete this section by deriving the pure displacement formulation and describing some regularity estimates. To this end, eliminating the stress in system (2.5)–(2.6) yields the pure displacement formulation which satisfies the following second-order elliptic partial differential system:

$$\begin{cases} 2\mu \nabla \cdot \boldsymbol{\epsilon}(\mathbf{u}) + \lambda \nabla(\nabla \cdot \mathbf{u}) &= -\mathbf{f} \quad \text{in} \quad \Omega, \\ \mathbf{u} &= \mathbf{0} \quad \text{on} \quad \Gamma_D, \\ \mathbf{n} \cdot (2\mu\, \boldsymbol{\epsilon}(\mathbf{u}) + \lambda\, (\nabla \cdot \mathbf{u})\, \boldsymbol{\delta}) &= \mathbf{0} \quad \text{on} \quad \Gamma_N, \end{cases} \tag{2.7}$$

where ∇ stands for the gradient operator. The energy norm associated with the above problem is defined as follows:

$$|||\mathbf{v}||| = \left(2\mu\, \|\boldsymbol{\epsilon}(\mathbf{v})\|^2 + \lambda\, \|\nabla \cdot \mathbf{v}\|^2\right)^{\frac{1}{2}}. \tag{2.8}$$

By using Korn's inequality (see [14]),

$$\|\mathbf{v}\|_1 \le C\, \|\boldsymbol{\epsilon}(\mathbf{v})\| \quad \forall\, \mathbf{v} \in H_D^1(\Omega)^d, \tag{2.9}$$

the energy norm is equivalent to the H^1 norm for a fixed λ. In this paper, we use C with or without subscripts to denote a generic positive constant, possibly different at different occurrences, which is independent of the Lamé constant λ and the mesh size h introduced in section 4 but may depend on the domain Ω. Note that one could scale the variables and the right-hand side accordingly so that μ is equal to one. We will frequently use the term *uniform* in reference to a relation to mean that it holds independent of λ and h.

The weak form of boundary value problem (2.7) has a unique solution $\mathbf{u} \in H_D^1(\Omega)^d$ for any $\mathbf{f} \in H_D^{-1}(\Omega)^d$ (see [14]). Moreover, the solution satisfies the following H^1-regularity estimate (see, e.g., [8, 14]):

$$\|\mathbf{u}\|_1 + \lambda \|\nabla \cdot \mathbf{u}\| \leq C \|\mathbf{f}\|_{-1,D}. \tag{2.10}$$

Furthermore, if the domain Ω is convex or its boundary is $C^{1,1}$ and if either Γ_D or Γ_N is empty, then the H^2-regularity estimate

$$\|\mathbf{u}\|_2 + \lambda \|\nabla \cdot \mathbf{u}\|_1 \leq C \|\mathbf{f}\| \tag{2.11}$$

holds. Both the regularity estimates in (2.10) and (2.11) suggest that the divergence of the displacement has a different scale from the displacement itself for large λ.

3. Least-squares variational formulation. In this section, we first discuss an appropriate stress-displacement formulation and then consider the corresponding least-squares functionals based on such a first-order system. Our primary objective here is to establish continuity and ellipticity of these least-squares functionals in the appropriate Hilbert spaces.

It is convenient to view $d \times d$-matrices as d^2-vectors and vice versa. For example, view $(\sigma_{ij})_{d\times d}$ as $(\boldsymbol{\sigma}_1, \ldots, \boldsymbol{\sigma}_d)^t$, where $\boldsymbol{\sigma}_j = (\sigma_{j1}, \ldots, \sigma_{jd})$ is the jth row of $(\sigma_{ij})_{d\times d}$ for $j = 1, \ldots, d$. Let

$$\mathbf{b} = \begin{cases} (1,\,0,\,0,\,1)^t & d = 2, \\ (1,\,0,\,0,\,0,\,1,\,0,\,0,\,0,\,1)^t & d = 3, \end{cases}$$

which may be viewed as the $d \times d$ identity matrix $I_{d\times d}$ or the identity tensor $\boldsymbol{\delta}$. Thus,

$$\operatorname{tr} \boldsymbol{\sigma} = \operatorname{tr} (\sigma_{ij})_{d\times d} = \sum_{i=1}^{d} \sigma_{ii} = \mathbf{b}^t \begin{pmatrix} \boldsymbol{\sigma}_1^t \\ \vdots \\ \boldsymbol{\sigma}_d^t \end{pmatrix} = \mathbf{b}^t \boldsymbol{\sigma}.$$

By viewing a $d \times d$-matrix as a d^2-vector, we can then write the fourth-order elasticity tensor as $d^2 \times d^2$-matrix

$$\mathcal{C} = \lambda\, \mathbf{b}\mathbf{b}^t + 2\mu\, I.$$

It is clear that $\mathcal{C}$ is symmetric and that $\mathcal{C}$ is positive definite for finite λ. The compliance tensor has the form

$$\mathcal{A} = \frac{1}{2\mu} \left(I - \frac{\lambda}{d\lambda + 2\mu} \mathbf{b}\mathbf{b}^t \right). \tag{3.1}$$

Note that $\mathcal{A} = \mathcal{C}^{-1}$ for finite λ. When the λ approaches ∞, the elasticity tensor blows up and the compliance tensor tends to

$$\frac{1}{2\mu} \left(I - \frac{1}{d}\, \mathbf{b}\mathbf{b}^t \right) \equiv \frac{1}{2\mu}\, \mathbf{dev}, \tag{3.2}$$

which is not invertible. For any tensor $\boldsymbol{\tau}$, $\mathbf{dev}\boldsymbol{\tau} = \boldsymbol{\tau} - \frac{1}{d}\,(\operatorname{tr}\boldsymbol{\tau})\boldsymbol{\delta}$ is the deviatoric part of $\boldsymbol{\tau}$. Hence, for nearly incompressible or incompressible materials, it is preferable to use the following strain and stress relation:

$$\boldsymbol{\epsilon}(\mathbf{u}) = \mathcal{A}\, \boldsymbol{\sigma} = \frac{1}{2\mu} \left(\boldsymbol{\sigma} - \frac{\lambda}{d\lambda + 2\mu} (\operatorname{tr} \boldsymbol{\sigma}) \boldsymbol{\delta} \right). \tag{3.3}$$

Now, the first-order system for the stress and the displacement of linear elasticity is as follows:

$$\left\{\begin{array}{rcll} \mathcal{A}\,\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u}) &=& \mathbf{0} & \text{in} \quad \Omega, \\ \nabla\cdot\boldsymbol{\sigma} + \mathbf{f} &=& \mathbf{0} & \text{in} \quad \Omega \end{array}\right. \tag{3.4}$$

with boundary conditions (2.6), where $\mathcal{A}$ is given in (3.1).

It is important to note that the stress is symmetric; i.e.,

$$\boldsymbol{\sigma} - \boldsymbol{\sigma}^t = \mathbf{0}, \tag{3.5}$$

where $\boldsymbol{\sigma}^t$ denotes the transpose of $\boldsymbol{\sigma}$ as a $d\times d$-matrix. One can impose this symmetry condition either in the solution space (in a strong sense) or in the equation (in a weak sense). In [12], we augment (3.5) with the stress-displacement system so that our least-squares methods have freedom to treat it either strongly or weakly depending on discretization and solution methods. In [10], we show that the symmetry constraint of the stress is enforced at the continuous level even without the term $\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^t\|^2$ in the least-squares functionals. This is because for any $\boldsymbol{\tau}\in L^2(\Omega)^{d\times d}$ and any $\mathbf{v}\in H^1(\Omega)^d$, we have

$$\|\boldsymbol{\tau} - \boldsymbol{\tau}^t\| \le C\,\|\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})\|. \tag{3.6}$$

Thus, $\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v}) = 0$ implies that $\boldsymbol{\tau}$ is symmetric. Therefore, we will apply the least-squares principle to first-order system (3.4) without augmenting (3.5). Inequality (3.6) follows from the symmetry of $\boldsymbol{\epsilon}(\mathbf{v})$, (3.1), and the triangle inequality that

$$\begin{aligned} \|\boldsymbol{\tau} - \boldsymbol{\tau}^t\| &= 2\mu \left\| \left(\frac{1}{2\mu}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})\right) - \left(\frac{1}{2\mu}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})\right)^t \right\| \\ &= 2\mu\,\|\,(\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})) - (\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v}))^t\,\| \le 4\mu\,\|\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})\|. \end{aligned}$$

Before defining least-squares functionals, let us first describe solution spaces. If $\Gamma_N = \emptyset$, then $\int_\Omega \nabla\cdot\mathbf{u}\,dx = \int_{\partial\Omega}\mathbf{n}\cdot\mathbf{u}\,ds = 0$, which implies

$$\int_\Omega \operatorname{tr}\boldsymbol{\sigma}\,dx = 0.$$

Therefore, we are at liberty to impose such a condition for the stress $\boldsymbol{\sigma}$. Let

$$\mathbf{X} = \left\{\begin{array}{ll} H(\mathrm{div};\,\Omega)^d & \text{if } \Gamma_N \neq \emptyset, \\ \{\boldsymbol{\tau}\in H(\mathrm{div};\,\Omega)^d \mid \int_\Omega \operatorname{tr}\boldsymbol{\sigma}\,dx = 0\} & \text{otherwise,} \end{array}\right.$$

and denote its subspace by

$$\mathbf{X}_N = \{\boldsymbol{\tau}\in\mathbf{X} \,:\, \mathbf{n}\cdot\boldsymbol{\tau} = \mathbf{0} \ \text{ on } \ \Gamma_N\}.$$

Let

$$\mathcal{V}_B = \mathbf{X}_N \times H^1_D(\Omega)^d.$$

For $\mathbf{f}\in L^2(\Omega)^d$, we define the following least-squares functionals:

$$G_{-1}(\boldsymbol{\sigma},\,\mathbf{u}\,;\,\mathbf{f}) = \|\mathcal{A}\,\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla\cdot\boldsymbol{\sigma} + \mathbf{f}\|^2_{-1,D} \tag{3.7}$$

and

$$G(\boldsymbol{\sigma}, \mathbf{u}; \mathbf{f}) = \|\mathcal{A}\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla \cdot \boldsymbol{\sigma} + \mathbf{f}\|^2 \tag{3.8}$$

for $(\boldsymbol{\sigma}, \mathbf{u}) \in \mathcal{V}_B$. Least-squares variational problems for the stress-displacement of linear elasticity are then to minimize the above least-squares functionals over $\mathcal{V}_B$. In this paper, we concentrate on the least-squares problem based on the L^2 norm functional in (3.8): find $(\boldsymbol{\sigma}, \mathbf{u}) \in \mathcal{V}_B$ such that

$$G(\boldsymbol{\sigma}, \mathbf{u}; \mathbf{f}) = \inf_{(\boldsymbol{\tau}, \mathbf{v}) \in \mathcal{V}_B} G(\boldsymbol{\tau}, \mathbf{v}; \mathbf{f}). \tag{3.9}$$

Note that the inverse norm functional in (3.7) can be used to develop a discrete inverse norm least-squares method (see [7]) as well.

REMARK 3.1. *Since the minimum of the quadratic functional $G(\boldsymbol{\sigma}, \mathbf{u}; \mathbf{f})$ is zero, by* (3.6) *the symmetry of the stress tensor is guaranteed by the first term of the functional, i.e., the constitutive equation.*

REMARK 3.2. *The least-squares functionals defined in* (3.7) *and* (3.8) *differ from those in* [12, 10] *mainly in the first term with an extra weight of $\mathcal{C}^{-\frac{1}{2}}$. More precisely, the first term of the functionals in* [12, 10] *is $\|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\sigma} - \mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{u})\|^2$. Note that $\|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{u})\|^2 = \lambda \|\nabla \mathbf{u}\|^2 + 2\mu \|\boldsymbol{\epsilon}(\mathbf{u})\|^2$. This means that the least-squares variational problems in* [12, 10] *do not apply for incompressible materials and require effective discretizations and efficient solvers for the pure displacement problem when materials are nearly incompressible.*

Below we establish uniform continuity and ellipticity (i.e., equivalence) of the homogeneous functionals $G_{-1}(\boldsymbol{\tau}, \mathbf{v}; \mathbf{0})$ and $G(\boldsymbol{\tau}, \mathbf{v}; \mathbf{0})$ in terms of the respective functionals $M_{-1}(\boldsymbol{\tau}, \mathbf{v})$ and $M(\boldsymbol{\tau}, \mathbf{v})$ defined on $\mathcal{V}_B$ by

$$M_{-1}(\boldsymbol{\tau}, \mathbf{v}) = \|\boldsymbol{\epsilon}(\mathbf{v})\|^2 + \|\boldsymbol{\tau}\|^2$$

and

$$M(\boldsymbol{\tau}, \mathbf{v}) = \|\boldsymbol{\epsilon}(\mathbf{v})\|^2 + \|\boldsymbol{\tau}\|^2 + \|\nabla \cdot \boldsymbol{\tau}\|^2.$$

To do so, we need the following fundamental inequality on the trace of $\mathbf{X}_N$:

$$\|\operatorname{tr} \boldsymbol{\tau}\| \le C \left(\sqrt{(\mathcal{A}\boldsymbol{\tau}, \boldsymbol{\tau})} + \|\nabla \cdot \boldsymbol{\tau}\|_{-1,D} \right) \quad \forall\, \boldsymbol{\tau} \in \mathbf{X}_N, \tag{3.10}$$

where C is a positive constant independent of λ. This inequality should be a classic result. But the only references that we know for its proof are [1] for two dimensions and Dirichlet boundary conditions (i.e., $d = 2$ and $\Gamma_N = \emptyset$) and [12] for both two and three dimensions and general boundary conditions. Note that

$$\begin{aligned} (\mathcal{A}\boldsymbol{\tau}, \boldsymbol{\tau}) &= \frac{1}{2\mu} \left(\|\boldsymbol{\tau}\|^2 - \frac{\lambda}{d\lambda + 2\mu} \|\operatorname{tr} \boldsymbol{\tau}\|^2 \right) \\ &= \frac{1}{2\mu} \|\mathbf{dev}\, \boldsymbol{\tau}\|^2 + \frac{1}{d(d\lambda + 2\mu)} \|\operatorname{tr} \boldsymbol{\tau}\|^2, \end{aligned} \tag{3.11}$$

where $\mathbf{dev}\, \boldsymbol{\tau}$ and $\operatorname{tr} \boldsymbol{\tau}$ are the respective deviatoric and volumetric parts of $\boldsymbol{\tau}$. It is then obvious that the divergence term in (3.10) is necessary to bound the L^2 norm of the trace. From the definition of the inverse norm and the Cauchy–Schwarz inequality, we have that

$$\|\nabla \cdot \boldsymbol{\tau}\|_{-1,\,D} \le \|\boldsymbol{\tau}\|. \tag{3.12}$$

By (3.10), (3.11), and (3.12) it is easy to see that

$$\|\boldsymbol{\tau}\|_a \equiv \left((\mathcal{A}\,\boldsymbol{\tau},\,\boldsymbol{\tau}) + \|\nabla\cdot\boldsymbol{\tau}\|^2_{-1,\,D}\right)^{\frac{1}{2}}$$

is equivalent to the L^2 norm; i.e., there exists a positive constant C independent of λ such that

$$\frac{1}{C}\,\|\boldsymbol{\tau}\|^2 \le \|\boldsymbol{\tau}\|_a^2 \le C\,\|\boldsymbol{\tau}\|^2 \quad \forall\ \boldsymbol{\tau}\in\mathbf{X}_N. \tag{3.13}$$

THEOREM 3.1. *The homogeneous functionals $G_{-1}(\boldsymbol{\tau},\,\mathbf{v};\,\mathbf{0})$ and $G(\boldsymbol{\tau},\,\mathbf{v};\,\mathbf{0})$ are uniformly equivalent to the functionals $M_{-1}(\boldsymbol{\tau},\,\mathbf{v})$ and $M(\boldsymbol{\tau},\,\mathbf{v})$, respectively; i.e., there exist positive constants C_1 and C_2, independent of λ, such that*

$$\frac{1}{C_1}\,M_{-1}(\boldsymbol{\tau},\,\mathbf{v}) \le G_{-1}(\boldsymbol{\tau},\,\mathbf{v}\,;\,\mathbf{0}) \le C_1\,M_{-1}(\boldsymbol{\tau},\,\mathbf{v}) \tag{3.14}$$

and

$$\frac{1}{C_2}\,M(\boldsymbol{\tau},\,\mathbf{v}) \le G(\boldsymbol{\tau},\,\mathbf{v}\,;\,\mathbf{0}) \le C_2\,M(\boldsymbol{\tau},\,\mathbf{v}) \tag{3.15}$$

hold for all $(\boldsymbol{\tau},\,\mathbf{v})\in\mathcal{V}_B$.

Proof. It follows from (3.1) that

$$\begin{aligned}\|\mathcal{A}\,\boldsymbol{\tau}\|^2 &= \left(\frac{1}{2\mu}\right)^2\left(\|\boldsymbol{\tau}\|^2 - \frac{2\lambda}{d\lambda+2\mu}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2 + d\left(\frac{\lambda}{d\lambda+2\mu}\right)^2\|\mathrm{tr}\,\boldsymbol{\tau}\|^2\right)\\ &= \left(\frac{1}{2\mu}\right)^2\left(\|\boldsymbol{\tau}\|^2 - \frac{\lambda\,(d\lambda+4\mu)}{(d\lambda+2\mu)^2}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2\right) \le \left(\frac{1}{2\mu}\right)^2\|\boldsymbol{\tau}\|^2.\end{aligned}$$

Thus, $\mathcal{A}\,\boldsymbol{\tau}$ is bounded above by $\boldsymbol{\tau}$ in the L^2 norm:

$$\|\mathcal{A}\,\boldsymbol{\tau}\| \le \frac{1}{2\mu}\,\|\boldsymbol{\tau}\|. \tag{3.16}$$

The upper bounds in both (3.14) and (3.15) follow easily from the triangle inequality, (3.16), and (3.12). To show the validity of the lower bound in (3.14), we first prove that $\boldsymbol{\tau}$ in the L^2 norm is bounded above by the homogeneous functional:

$$\|\boldsymbol{\tau}\|^2 \le C\,G_{-1}(\boldsymbol{\tau},\,\mathbf{v}\,;\mathbf{0}) \quad \forall\ (\boldsymbol{\tau},\,\mathbf{v})\in\mathcal{V}_B. \tag{3.17}$$

To this end, by the triangle inequality and (3.16) we have

$$\|\boldsymbol{\epsilon}(\mathbf{v})\| \le \|\boldsymbol{\epsilon}(\mathbf{v}) - \mathcal{A}\,\boldsymbol{\tau}\| + \|\mathcal{A}\,\boldsymbol{\tau}\| \le \|\boldsymbol{\epsilon}(\mathbf{v}) - \mathcal{A}\,\boldsymbol{\tau}\| + \frac{1}{2\mu}\,\|\boldsymbol{\tau}\|. \tag{3.18}$$

Since $\boldsymbol{\epsilon}(\mathbf{v}) = \frac{1}{2}\,(\nabla\mathbf{v} + (\nabla\mathbf{v})^t)$ is symmetric, then integration by parts; the triangle, Cauchy–Schwarz, and Korn inequalities; and (3.6) give

$$\begin{aligned}|(\boldsymbol{\tau},\,\boldsymbol{\epsilon}(\mathbf{v}))| &= \left|(\boldsymbol{\tau},\,\nabla\mathbf{v}) - \left(\frac{\boldsymbol{\tau}-\boldsymbol{\tau}^t}{2},\,\nabla\mathbf{v}\right)\right| = \left|(\nabla\cdot\boldsymbol{\tau},\,\mathbf{v}) + \left(\frac{\boldsymbol{\tau}-\boldsymbol{\tau}^t}{2},\,\nabla\mathbf{v}\right)\right|\\ &\le \left(\|\nabla\cdot\boldsymbol{\tau}\|_{-1,\,D} + \left\|\frac{\boldsymbol{\tau}-\boldsymbol{\tau}^t}{2}\right\|\right)\,\|\mathbf{v}\|_1\\ &\le C\,\left(\|\nabla\cdot\boldsymbol{\tau}\|_{-1,\,D} + \|\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})\|\right)\,\|\boldsymbol{\epsilon}(\mathbf{v})\|,\end{aligned}$$

which, together with (3.18), implies that

$$|(\boldsymbol{\tau},\, \boldsymbol{\epsilon}(\mathbf{v}))| \le C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0}) + C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0})^{\frac{1}{2}}\, \|\boldsymbol{\tau}\|, \tag{3.19}$$

where $G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0})^{\frac{1}{2}}$ denotes the square root of $G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0})$. Now, it follows from the Cauchy–Schwarz inequality, (3.19), and (3.13) that

$$\begin{aligned}(\mathcal{A}\,\boldsymbol{\tau},\, \boldsymbol{\tau}) &= (\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v}),\, \boldsymbol{\tau}) + (\boldsymbol{\epsilon}(\mathbf{v}),\, \boldsymbol{\tau}) \\ &\le \|\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})\|\, \|\boldsymbol{\tau}\| + C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0}) + C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0})^{\frac{1}{2}}\, \|\boldsymbol{\tau}\| \\ &\le C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0}) + C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0})^{\frac{1}{2}}\, \left((\mathcal{A}\,\boldsymbol{\tau},\, \boldsymbol{\tau}) + \|\nabla\cdot\boldsymbol{\tau}\|^2_{-1,\,D}\right)^{\frac{1}{2}} \\ &\le C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0}) + C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0})^{\frac{1}{2}}\, (\mathcal{A}\,\boldsymbol{\tau},\, \boldsymbol{\tau})^{\frac{1}{2}}.\end{aligned}$$

Hence,

$$(\mathcal{A}\,\boldsymbol{\tau},\, \boldsymbol{\tau}) \le C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0}),$$

which, together with (3.13), implies the validity of (3.17). With (3.18) and (3.17), it is then easy to see that $\|\boldsymbol{\epsilon}(\mathbf{v})\|^2$ is also bounded above by the homogeneous functional $G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\mathbf{0})$. This completes the proof of the lower bound in (3.14). Since

$$G_{-1}(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{0}) \le G(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{0}) \quad \text{and} \quad \|\nabla\cdot\boldsymbol{\tau}\|^2 \le G(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{0}),$$

then the lower bound in (3.15) follows from (3.14). The proof of the theorem is therefore completed. ∎

4. Finite element approximation. We approximate the minimum of the least-squares functional $G(\boldsymbol{\sigma}, \mathbf{u}; \mathbf{f})$ in (3.9) using a Rayleigh–Ritz type finite element method. For convenience, we use two-dimensional terminology ($d = 2$). Assuming that the domain Ω is a polygon, let $\mathcal{T}_h$ be a triangulation of Ω with triangular elements of size $\mathcal{O}(h)$ that is regular (see [13]). We restrict ourselves to triangular elements for convenience because extension to either rectangular or a combination of triangular and rectangular elements is straightforward.

Since the homogeneous functional $G(\boldsymbol{\sigma},\, \mathbf{u}\,;\mathbf{0})$ is equivalent to the $H(\mathrm{div};\, \Omega)$ norm for the stress and the H^1 norm for the displacement by Theorem 3.1 and Korn's inequality (2.9), it is then natural to approximate the stress (each row) by the standard $H(\mathrm{div};\, \Omega)$ conforming Raviart–Thomas space of order k (see [20]) and the standard (conforming) continuous piecewise polynomials of degree $k+1$ for the displacement:

$$\Sigma_h^k = \{\boldsymbol{\tau} \in \mathbf{X}_N \,:\, \boldsymbol{\tau}|_K \in RT_k(K)^2 \;\forall\, K \in \mathcal{T}_h\} \subset \mathbf{X}_N, \tag{4.1}$$

$$V_h^k = \{\mathbf{v} \in C^0(\Omega)^2 \,:\, \mathbf{v}|_K \in P_k(K)^2 \;\forall\, K \in \mathcal{T}_h,\; \mathbf{v} = \mathbf{0} \text{ on } \Gamma_D\} \subset H^1_D(\Omega)^2, \tag{4.2}$$

where $RT_k(K)$ is local Raviart–Thomas space of order k defined by

$$RT_k(K) = P_k(K)^2 + \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} P_k(K),$$

and $P_k(K)$ is the space of polynomials of degree k on triangle K. These spaces have the following approximation properties: if $k \ge 0$ is an integer and $l \in (0,\, k+1]$, then

$$\inf_{\boldsymbol{\tau}\in\Sigma_h^k} \|\boldsymbol{\sigma} - \boldsymbol{\tau}\|_{H(\mathrm{div};\,\Omega)} \le C\, h^l\, (\|\boldsymbol{\sigma}\|_l + \|\nabla\cdot\boldsymbol{\sigma}\|_l) \tag{4.3}$$

for $\boldsymbol{\sigma} \in H^l(\Omega)^{2\times 2} \cap \mathbf{X}_N$ with $\nabla \cdot \boldsymbol{\sigma} \in H^l(\Omega)^2$, and

$$\inf_{\mathbf{u}\in V_h^{k+1}} \|\mathbf{u}-\mathbf{v}\|_1 \le C\, h^l\, \|\mathbf{u}\|_{l+1} \tag{4.4}$$

for $\mathbf{u} \in H^{l+1}(\Omega)^2 \cap H_D^1(\Omega)^2$.

The finite element approximation for minimizing $G(\boldsymbol{\sigma}, \mathbf{u}; \mathbf{f})$ in (3.9) on $\mathcal{V}_B$ becomes: find $(\boldsymbol{\sigma}_h, \mathbf{u}_h) \in \Sigma_h^k \times V_h^{k+1}$ such that

$$G(\boldsymbol{\sigma}_h, \mathbf{u}_h; \mathbf{f}) = \min_{(\boldsymbol{\tau}, \mathbf{v})\in \Sigma_h^k \times V_h^{k+1}} G(\boldsymbol{\tau}, \mathbf{v}; \mathbf{f}). \tag{4.5}$$

By Theorem 3.1, (2.9), and the fact that $\Sigma_h^k \times V_h^{k+1}$ is a subspace of $\mathcal{V}_B$, we conclude that (4.5) has a unique solution and is equivalent to the weak form: find $(\boldsymbol{\sigma}_h, \mathbf{u}_h) \in \Sigma_h^k \times V_h^{k+1}$ such that

$$\mathcal{F}(\boldsymbol{\sigma}_h, \mathbf{u}_h; \boldsymbol{\tau}, \mathbf{v}) = (-\mathbf{f}, \nabla \cdot \boldsymbol{\tau}) \quad \forall\ (\boldsymbol{\tau}, \mathbf{v}) \in \Sigma_h^k \times V_h^{k+1}, \tag{4.6}$$

where the bilinear form $\mathcal{F}(\cdot\,;\,\cdot)$ has the form of

$$\mathcal{F}(\boldsymbol{\sigma}_h, \mathbf{u}_h; \boldsymbol{\tau}, \mathbf{v}) = (\mathcal{A}\,\boldsymbol{\sigma}_h - \boldsymbol{\epsilon}(\mathbf{u}_h), \mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})) + (\nabla \cdot \boldsymbol{\sigma}_h, \nabla \cdot \boldsymbol{\tau}).$$

Moreover, the error $(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h)$ satisfies the orthogonality property

$$\mathcal{F}(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h; \boldsymbol{\tau}, \mathbf{v}) = 0 \quad \forall\ (\boldsymbol{\tau}, \mathbf{v}) \in \Sigma_h^k \times V_h^{k+1}. \tag{4.7}$$

THEOREM 4.1. *Assume that the solution,* $(\boldsymbol{\sigma}, \mathbf{u})$*, of* (3.9) *is in* $H^l(\Omega)^{2\times 2} \times H^{l+1}(\Omega)^2$ *and that the divergence of the stress,* $\nabla \cdot \boldsymbol{\sigma}$*, is in* $H^l(\Omega)^2$*. Let* $k+1$ *be the smallest integer greater than or equal to* l*. Then with* $(\boldsymbol{\sigma}_h, \mathbf{u}_h) \in \Sigma_h^k \times V_h^{k+1}$*, the following error estimate holds:*

$$\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_{H(\mathrm{div};\,\Omega)} + \|\mathbf{u} - \mathbf{u}_h\|_1 \le C\, h^l(\|\boldsymbol{\sigma}\|_l + \|\nabla \cdot \boldsymbol{\sigma}\|_l + \|\mathbf{u}\|_{l+1}). \tag{4.8}$$

Proof. The proof is a simple consequence of the orthogonality property (4.7) and the approximation properties (4.3) and (4.4) of the finite element spaces $\Sigma_h^k \times V_h^{k+1}$. ∎

Theorem 3.1 indicates that the bilinear form $\mathcal{F}(\cdot\,;\,\cdot)$ is elliptic and continuous with respect to the $H(\mathrm{div};\,\Omega)$ norm for the stress and the H^1 norm for the displacement. It is then well known that multigrid methods applied to the resulting discrete system (4.6) are optimally convergent (see, e.g., [16, 2, 17, 23]).

It is obvious that the finite element approximation in (4.5) does not preserve the symmetry of the stress. But the finite element approximation of the stress is approximately symmetric. Moreover, one can obtain symmetric stress approximation with the same accuracy as $\boldsymbol{\sigma}_h$ by simply computing

$$\tilde{\boldsymbol{\sigma}}_h = \frac{1}{2}\left(\boldsymbol{\sigma}_h + \boldsymbol{\sigma}_h^t\right). \tag{4.9}$$

It should also be noted that many mixed finite element approaches commonly used produce stress approximations which do not satisfy symmetry exactly (cf. [9, sect. VII.2]).

COROLLARY 4.2. *Under the assumptions of Theorem* 4.1*, we have that*

$$\|\boldsymbol{\sigma}_h - \boldsymbol{\sigma}_h^t\| \le C\, h^l\, (\|\boldsymbol{\sigma}\|_l + \|\nabla \cdot \boldsymbol{\sigma}\|_l + \|\mathbf{u}\|_{l+1}) \tag{4.10}$$

and that

$$\|\boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h\| \le C\, h^l \left(\|\boldsymbol{\sigma}\|_l + \|\nabla \cdot \boldsymbol{\sigma}\|_l + \|\mathbf{u}\|_{l+1}\right). \tag{4.11}$$

Proof. Since the stress $\boldsymbol{\sigma}$ is symmetric, by the triangle inequality we have that

$$\|\boldsymbol{\sigma}_h - \boldsymbol{\sigma}_h^t\| = \|(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h) - (\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)^t\| \le 2\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|$$

and that

$$\|\boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h\| = \left\|\frac{1}{2}(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h) + \frac{1}{2}(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)^t\right\| \le \|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|.$$

Now, (4.10) and (4.11) follow from the error bound in (4.8). ∎

Nevertheless, there may be a possible reluctance in the engineering community to accept nonsymmetric stress approximation since the symmetry is due to the conservation of angular momentum. In order to directly preserve the symmetry of finite element approximations to the stress tensor, one may enforce the symmetry constraint in the finite element approximation space. To this end, let $\mathbf{X}_N^s$ denote the symmetric stress space,

$$\mathbf{X}_N^s = \{\boldsymbol{\tau} \in \mathbf{X}_N \,|\, \boldsymbol{\tau}^t = \boldsymbol{\tau} \text{ in } \Omega\}.$$

A simple and obvious choice is to use continuous piecewise polynomials of degree k for each component of the symmetric stress:

$$\Sigma_h^{k,s} = \{\boldsymbol{\tau} \in C^0(\Omega)^{2\times 2} \cap \mathbf{X}_N^s \,:\, \boldsymbol{\tau}|_K \in P_k(K)^{2\times 2}\ \forall\, K \in \mathcal{T}_h\} \subset \mathbf{X}_N^s. \tag{4.12}$$

This space has the following approximation property: if $k \ge 1$ is an integer and $l \in (0,\, k]$, then

$$\inf_{\boldsymbol{\tau} \in \Sigma_h^{k,s}} \|\boldsymbol{\sigma} - \boldsymbol{\tau}\|_{H(\mathrm{div};\,\Omega)} \le C\, h^l\, \|\boldsymbol{\sigma}\|_{l+1} \tag{4.13}$$

for $\boldsymbol{\sigma} \in H^{l+1}(\Omega)^2 \cap \mathbf{X}_N$. Now, the least-squares finite element approximation problem is to minimize G over $\Sigma_h^{k,s} \times V_h^k$: find $(\boldsymbol{\sigma}_h,\, \mathbf{u}_h) \in \Sigma_h^{k,s} \times V_h^k$ such that

$$G(\boldsymbol{\sigma}_h,\, \mathbf{u}_h\,;\, \mathbf{f}) = \inf_{(\boldsymbol{\tau},\, \mathbf{v}) \in \Sigma_h^{k,s} \times V_h^k} G(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{f}). \tag{4.14}$$

It is easy to see that (4.14) has a unique solution $(\boldsymbol{\sigma}_h,\, \mathbf{u}_h)$, that $\boldsymbol{\sigma}_h$ is symmetric, and that $\boldsymbol{\sigma}_h$ has the following error bound:

$$\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_{H(\mathrm{div};\,\Omega)} + \|\mathbf{u} - \mathbf{u}_h\|_1 \le C\, h^l \left(\|\boldsymbol{\sigma}\|_{l+1} + \|\mathbf{u}\|_{l+1}\right) \tag{4.15}$$

if the solution, $(\boldsymbol{\sigma},\, \mathbf{u})$, of (3.9) is in $H^{l+1}(\Omega)^{2\times 2} \times H^{l+1}(\Omega)^2$. Note that this estimate is not optimal in the regularity of the displacement. Nevertheless, the nodal elements $\Sigma_h^{k,s}$ have many fewer local average degrees of freedom than the Raviart–Thomas elements Σ_h^k. Developing a better finite element space of the symmetric stress will be a topic of our further study.

5. Weakly imposed boundary conditions. In previous sections, boundary conditions are imposed in the solution space. This leads to least-squares finite element approximations that are much more accurate on the boundary than in the interior of the domain. In the context of the least-squares method, it is natural to treat boundary conditions weakly through boundary functionals. For many applications, this is also convenient. In this section, we study a least-squares functional with boundary terms minimized over a solution space free of boundary conditions. We focus on establishing continuity and ellipticity of this functional here. See [21] for the development of computable finite element approximations and the corresponding iterative solvers based on this functional.

Assume the following nonhomogeneous boundary conditions:

$$\mathbf{u} = \mathbf{g} \ \text{ on } \ \Gamma_D \quad \text{and} \quad \mathbf{n}\cdot\boldsymbol{\sigma} = \mathbf{h} \ \text{ on } \ \Gamma_N. \tag{5.1}$$

Let

$$\mathcal{V} = \mathbf{X} \times H^1(\Omega)^d,$$

and for $\mathbf{g} \in H^{1/2}(\Gamma_D)$ and $\mathbf{h} \in H^{-1/2}(\Gamma_N)$ define the least-squares functional as follows:

$$\begin{aligned}\tilde{G}(\boldsymbol{\sigma},\, \mathbf{u}; \mathbf{f}, \mathbf{g}, \mathbf{h}) = {} & \|\mathcal{A}\,\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla\cdot\boldsymbol{\sigma} + \mathbf{f}\|^2 \\ & + \|\mathbf{u} - \mathbf{g}\|^2_{\frac{1}{2},\,\Gamma_D} + \|\mathbf{n}\cdot\boldsymbol{\sigma} - \mathbf{h}\|^2_{-\frac{1}{2},\,\Gamma_N}\end{aligned} \tag{5.2}$$

for $(\boldsymbol{\sigma},\, \mathbf{u}) \in \mathcal{V}$. The least-squares variational problem is then to minimize $\tilde{G}$ over $\mathcal{V}$: find $(\boldsymbol{\sigma},\, \mathbf{u}) \in \mathcal{V}$ such that

$$\tilde{G}(\boldsymbol{\sigma},\, \mathbf{u}\,;\, \mathbf{f},\, \mathbf{g},\, \mathbf{h}) = \inf_{(\boldsymbol{\tau},\,\mathbf{v})\in\mathcal{V}} \tilde{G}(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{f},\, \mathbf{g},\, \mathbf{h}). \tag{5.3}$$

To establish the continuity and ellipticity of the homogeneous least-squares functional $\tilde{G}(\mathbf{u},\, \boldsymbol{\sigma}\,;\, \mathbf{0},\, \mathbf{0},\, \mathbf{0})$ in $\mathcal{V}$, we need the trace inequalities (see [15])

$$\begin{aligned}&\|u\|_{\frac{1}{2},\,\partial\Omega} \le \|u\|_1 && \forall\ u \in H^1(\Omega),\\ &\|\mathbf{n}\cdot\mathbf{v}\|_{-\frac{1}{2},\,\partial\Omega} \le \|\mathbf{v}\|_{H(\mathrm{div};\,\Omega)} && \forall\ \mathbf{v} \in H(\mathrm{div};\,\Omega)\end{aligned}$$

and the generalized Korn inequality

$$\|\mathbf{v}\|_1 \le C\,(\|\boldsymbol{\epsilon}(\mathbf{v})\| + \|\mathbf{v}\|_{0,\,\Gamma_D}) \quad \forall\ \mathbf{v} \in H^1(\Omega)^d. \tag{5.4}$$

THEOREM 5.1. *The homogeneous functional $\tilde{G}(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{0},\, \mathbf{0},\, \mathbf{0})$ is uniformly equivalent to the functional $M(\mathbf{v},\, \boldsymbol{\tau})$; i.e., there exists a positive constant C independent of λ such that*

$$\frac{1}{C}\, M(\boldsymbol{\tau},\, \mathbf{v}) \le \tilde{G}(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{0},\mathbf{0},\mathbf{0}) \le C\, M(\boldsymbol{\tau},\, \mathbf{v}) \tag{5.5}$$

holds for all $(\boldsymbol{\tau},\, \mathbf{v}) \in \mathcal{V}$.

Proof. The upper bound in (5.5) follows easily from the triangle inequality, (3.16), and trace inequalities. The proof of the lower bound in (5.5) is the same as that for Theorem 3.1 except the proof on the upper bound of $|(\boldsymbol{\tau},\, \boldsymbol{\epsilon}(\mathbf{v}))|$. This is because $\mathbf{v}$

and $\mathbf{n} \cdot \boldsymbol{\tau}$ do not satisfy any boundary conditions and our new functional has extra boundary terms. Therefore, it suffices to show that

$$|(\boldsymbol{\tau},\, \boldsymbol{\epsilon}(\mathbf{v}))| \le C\, \tilde{G}(\boldsymbol{\tau},\, \mathbf{v}\,; \mathbf{0}, \mathbf{0}, \mathbf{0}) + C\, \tilde{G}(\boldsymbol{\tau},\, \mathbf{v}\,; \mathbf{0}, \mathbf{0}, \mathbf{0})^{\frac{1}{2}}\, \|\boldsymbol{\tau}\|. \tag{5.6}$$

To this end, the triangle, Cauchy–Schwarz, and generalized Korn inequalities give

$$\begin{aligned}
\left| \int_{\partial\Omega} \mathbf{v} \cdot \big(\mathbf{n} \cdot \boldsymbol{\tau}\big)\, ds \right| &= \left| \int_{\Gamma_D} \mathbf{v} \cdot \big(\mathbf{n} \cdot \boldsymbol{\tau}\big)\, ds + \int_{\Gamma_N} \mathbf{v} \cdot \big(\mathbf{n} \cdot \boldsymbol{\tau}\big)\, ds \right| \\
&\le \|\mathbf{v}\|_{\frac{1}{2},\,\Gamma_D}\, \|\mathbf{n} \cdot \boldsymbol{\tau}\|_{-\frac{1}{2},\,\Gamma_D} + \|\mathbf{v}\|_{\frac{1}{2},\,\Gamma_N}\, \|\mathbf{n} \cdot \boldsymbol{\tau}\|_{-\frac{1}{2},\,\Gamma_N} \\
&\le \|\mathbf{v}\|_{\frac{1}{2},\,\Gamma_D}\, \|\boldsymbol{\tau}\|_{H(\mathrm{div};\,\Omega)} + \|\mathbf{v}\|_1\, \|\mathbf{n} \cdot \boldsymbol{\tau}\|_{-\frac{1}{2},\,\Gamma_N}.
\end{aligned}$$

Now, it follows from the symmetry of $\boldsymbol{\epsilon}(\mathbf{v})$; integration by parts; the triangle, Cauchy–Schwarz, and generalized Korn inequalities; and (3.6) that

$$\begin{aligned}
|(\boldsymbol{\tau},\, \boldsymbol{\epsilon}(\mathbf{v}))| &= \left| (\boldsymbol{\tau},\, \nabla\mathbf{v}) - \left(\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2},\, \nabla\mathbf{v} \right) \right| \\
&= \left| (\nabla \cdot \boldsymbol{\tau},\, \mathbf{v}) - \int_{\partial\Omega} \mathbf{v} \cdot \big(\mathbf{n} \cdot \boldsymbol{\tau}\big)\, ds + \left(\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2},\, \nabla\mathbf{v} \right) \right| \\
&\le \left(\|\nabla \cdot \boldsymbol{\tau}\| + \left\| \frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2} \right\| \right) \|\mathbf{v}\|_1 + \|\mathbf{v}\|_{\frac{1}{2},\,\Gamma_D}\, \|\boldsymbol{\tau}\|_{H(\mathrm{div};\,\Omega)} + \|\mathbf{v}\|_1\, \|\mathbf{n} \cdot \boldsymbol{\tau}\|_{-\frac{1}{2},\,\Gamma_N} \\
&\le C \left(\|\nabla \cdot \boldsymbol{\tau}\| + \|\mathcal{A}\,\boldsymbol{\tau} - \boldsymbol{\epsilon}(\mathbf{v})\| + \|\mathbf{n} \cdot \boldsymbol{\tau}\|_{-\frac{1}{2},\,\Gamma_N} \right) \left(\|\boldsymbol{\epsilon}(\mathbf{v})\| + \|\boldsymbol{\tau}\| \right) + \|\mathbf{v}\|_{\frac{1}{2},\,\Gamma_D}\, \|\nabla \cdot \boldsymbol{\tau}\|,
\end{aligned}$$

which, together with (3.18), implies (5.6) and, hence, the theorem. ∎

6. Numerical results. In this section, numerical results for a benchmark problem of linear elasticity taken from [22] are presented. The problem to be considered is given by a quadratic membrane of elastic isotropic material with a circular hole in the center. Traction forces act on the upper and lower edges of the strip. Because of the symmetry of the domain, it suffices to discretize only a fourth of the total geometry. The computational domain is then given by

$$\Omega = \{\mathbf{x} \in \Re^2 : 0 < x_1 < 10, 0 < x_2 < 10, x_1^2 + x_2^2 > 1\}$$

(see Figure 6.1). The boundary conditions on the top edge of the computational domain ($x_2 = 10,\ 0 < x_1 < 10$) are set to $\boldsymbol{\sigma} \cdot \mathbf{n} = 4.5$, the boundary conditions on the bottom ($x_2 = 0,\ 1 < x_1 < 10$) are set to $(\sigma_{11}, \sigma_{12}) \cdot \mathbf{n} = 0,\ u_2 = 0$ (symmetry condition), and, finally, the boundary conditions on the left ($x_1 = 0,\ 1 < x_2 < 10$) are given by $u_1 = 0$, $(\sigma_{21}, \sigma_{22}) \cdot \mathbf{n} = 0$ (symmetry condition). The material parameters are $E = 206900$ for Young's modulus and $\nu = 0.29$ for Poisson's ratio, and their relation with the Lamé constants is given by

$$\lambda = \frac{E\,\nu}{(1+\nu)(1-2\nu)} \quad \text{and} \quad \mu = \frac{E}{2(1+\nu)}.$$

Obviously, the definition of the functional in (3.8) implies

$$G(\boldsymbol{\sigma}_h, \mathbf{u}_h; \mathbf{f}) = \sum_{K \in \mathcal{T}_h} \left(\|\mathcal{A}\,\boldsymbol{\sigma}_h - \boldsymbol{\epsilon}(\mathbf{u}_h)\|_{0,K}^2 + \|\nabla \cdot \boldsymbol{\sigma}_h + \mathbf{f}\|_{0,K}^2 \right) =: \sum_{K \in \mathcal{T}_h} G_K(\boldsymbol{\sigma}_h, \mathbf{u}_h; \mathbf{f})\,.$$

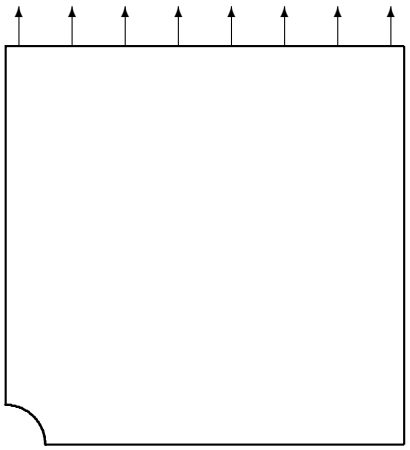

FIG. 6.1. *Computational domain and boundary conditions.*

$l = 6$	4384	43532	17844	3.51e-5	13.8771
$l = 7$	8678	86190	35302	9.20e-6	13.8912
$l = 8$	17152	170398	69730	2.59e-6	13.8884

Due to the equivalence (3.15), the local contributions $G_K(\boldsymbol{\sigma}_h, \mathbf{u}_h; \mathbf{f})$ to the least-squares functional constitute an a posteriori error estimator to be used for adaptive refinement (cf. [5]). The results in Table 6.1 are computed on a sequence of adaptively refined meshes based on this error estimator. In each refinement step those triangles with the largest values of $G_K(\boldsymbol{\sigma}_h, \mathbf{u}_h; \mathbf{f})$ (roughly 25 percent) were refined regularly (by dividing each into four congruent subtriangles). The Raviart–Thomas spaces of order one for the stress approximation are coupled with standard quadratic conforming elements for the displacement ($\Sigma_h^1 \times V_h^2$ in the terminology of section 4).

Table 6.1 provides a strong indication that the minimum of the functional is inversely proportional to the square of the number of degrees of freedom:

$$\mathcal{F}_h(\boldsymbol{\sigma}_h, \mathbf{u}_h) \sim \frac{1}{(\dim\, \Sigma_h^1 + \dim\, V_h^2)^2}\,.$$

This is the optimal asymptotic convergence rate achievable with piecewise quadratic finite elements. Of particular interest in this example is the stress component σ_{22} at the point $(1, 0)$. The size of this stress component is responsible for failure of the

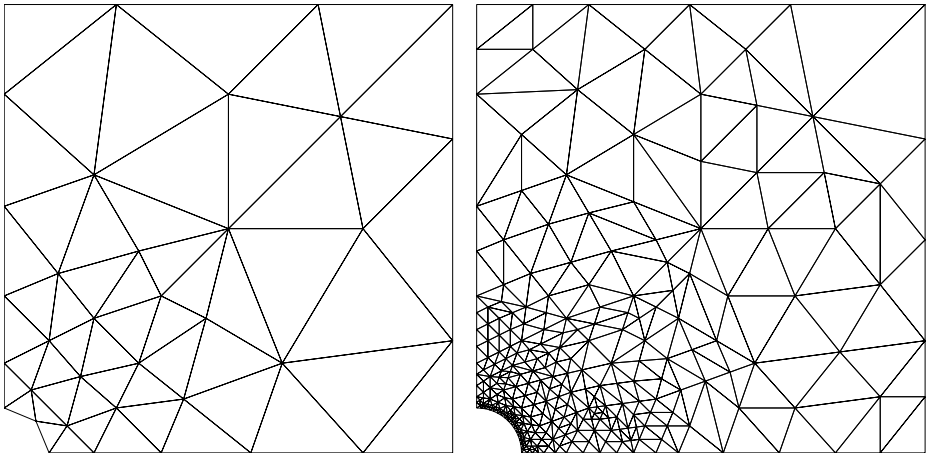

FIG. 6.2. *Initial triangulation and result after three adaptive refinement steps.*

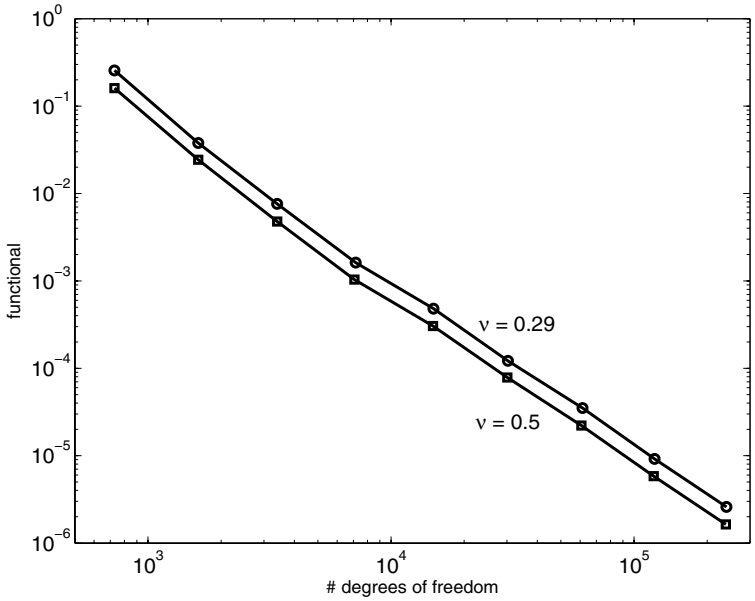

FIG. 6.3. *Adaptive finite element approximation for* $k = 1$ *(*$\nu = 0.29, 0.5$*).*

material at this point. For $\nu = 0.29$ the value of $\sigma_{22}(1,0) = 13.8873$ is given in [22] for a reference solution computed by a polynomial approximation of high degree. The corresponding column in Table 6.1 shows the convergence of the solutions obtained with our least-squares approach to that reference value as the mesh is refined. The initial triangulation and the result of three adaptive refinement steps are shown in Figure 6.2.

The robustness with respect to the incompressible limit can be seen in the doubly logarithmic convergence graphs in Figure 6.3. In addition to the numbers of Table 6.1, the results for the incompressible limit ($\nu = 0.5$) are shown in Figure 6.3.

LEAST-SQUARES METHODS FOR INCOMPRESSIBLE NEWTONIAN FLUID FLOW: LINEAR STATIONARY PROBLEMS*

ZHIQIANG CAI†, BARRY LEE‡, AND PING WANG§

Abstract. This paper develops and analyzes two least-squares methods for the numerical solution of linear, stationary incompressible Newtonian fluid flow in two and three dimensions. Both approaches use the L^2 norm to define least-squares functionals. One is based on the stress-velocity formulation (see section 3.2), and it applies to general boundary conditions. The other is based on an equivalent formulation for the *pseudostress* and velocity (see section 4.2), and it applies to pure velocity Dirichlet boundary conditions. The velocity gradient and vorticity can be obtained algebraically from this new tensor variable. It is shown that the homogeneous least-squares functionals are elliptic and continuous in the $H(\mathrm{div};\Omega)^d \times H^1(\Omega)^d$ norm. This immediately implies optimal error estimates for conforming finite element approximations. As well, it admits optimal multigrid solution methods if Raviart–Thomas finite element spaces are used to approximate the stress or the pseudostress tensor.

Key words. least-squares method, mixed finite element method, Navier–Stokes, Stokes, incompressible Newtonian flow

1. Introduction.

For incompressible Newtonian fluid flow with homogeneous density, the primitive physical equations are the conservation of momentum and the constitutive law. The constitutive law relates the stress tensor to the deformation rate tensor and pressure, and it states the incompressibility condition. It is a first-order partial differential system for the physical variables stress, velocity, and pressure. By differentiating and eliminating the stress, one obtains the well-known second-order incompressible Navier–Stokes equations in the velocity-pressure formulation. A tremendous amount of computational research has been done on this second-order partial differential system (see, e.g, mathematical books [17, 18]), but these equations may still be one of the most challenging problems in computational fluid mechanics and computational mathematics.

In recent years there has been substantial interest in the use of least-squares principles for the numerical approximation of Newtonian fluid flow problems (see, e.g., the survey paper [5], the monograph [21], and references therein). In particular, there are many research articles in both the mathematics and engineering communities on least-squares methods for the stationary Stokes equations (see [5]). Specifically, least-squares methods based on five first-order partial differential systems have been proposed, analyzed, implemented, and tested. These five first-order systems are formulations for variables (i) velocity, vorticity, and pressure [5, 21], (ii) velocity, pres-

sure, and "stress" [4], (iii) velocity, velocity gradient, and pressure [11], (iv) velocity, velocity gradient, and pressure with additional constraints [11], and (v) constrained velocity gradient and pressure [15]. The new "stress" variable in (ii) is actually the deformation rate tensor and not the physical stress. Least-squares methods based on the first three formulations employ either discrete inverse norms (see [10, 7]) or mesh-weighted L^2 norms (see [3]) in order to achieve optimal finite element approximations. The inverse norm approach is very expensive due to its discrete inverse norm evaluations, and fast multigrid solvers are still a missing ingredient for the mesh-weighted L^2 norm approaches. If the original problem is sufficiently smooth, methods based on the last two formulations are equivalent to the H^1 norm. Such equivalence implies optimal finite element approximations and optimal convergence of multigrid solvers. But the smoothness requirement is restrictive.

A common feature of all these formulations is that they do not involve the primitive physical equations. Based on the velocity-pressure formulation of the Stokes equations, they are derived by introducing new variables such as vorticity in (i), "stress" in (ii), velocity gradient in (iii) and (iv), and constrained velocity gradient in (v). Some of these new variables have physical meanings, but they are not original physical quantities of interest.

The first objective of this paper is to develop a new least-squares method that does not have the above mentioned drawbacks and that computes the original physical quantities directly. For linear, stationary problems of incompressible Newtonian fluid flow, our least-squares method is based directly on the primitive first-order partial differential system: the stress-velocity-pressure formulation, without introducing any new variables nor any new equations. We define the least-squares functional by applying a L^2 norm least-squares principle to this first-order system. It is shown that the homogeneous least-squares functional is elliptic and continuous in the $H(\mathrm{div};\,\Omega)^d$ norm for the stress, the $H^1(\Omega)^d$ norm for the velocity, and the L^2 norm for the pressure. This immediately implies optimal error estimates for conforming finite element approximations in $H(\mathrm{div};\,\Omega)^d \times H^1(\Omega)^d \times L^2(\Omega)$. It also admits optimal multigrid solution methods if Raviart–Thomas finite element spaces are used to approximate the stress tensor. Both discretization accuracy and multigrid convergence rates are uniform in the viscosity parameter.

Since the pressure can be represented in terms of the normal stress and since the stress is an independent variable in the first-order system, the pressure can be eliminated from the first-order system. By replacing the pressure with the normal stress, we derive the stress-velocity formulation for incompressible Newtonian fluid flow. We can then define the corresponding least-squares method and show identical numerical properties to those of the stress-velocity-pressure formulation, since the stress-velocity formulation is a special case of the stress-velocity-pressure formulation. It is important to note that, mathematically, the stress-velocity formulation for linear, stationary problems of incompressible Newtonian fluid flow is the limiting case of the stress-displacement formulation for elastic problems when $2\mu = \nu$. This indicates that this paper, together with [14], develops a unified least-squares approach for both elastic solids and incompressible Newtonian fluids with respect to spatial discretization and fast solution solvers, even though the variables and materials have different physical meanings. Hence, our method can be extended to problems coupling elastic deformation with fluid flow.

Many applications in incompressible Newtonian fluid flow do not have traction boundary conditions. It is then not necessary to use the stress as an independent

variable. This is especially true because the stress does not contain any information on the vorticity that is a physical quantity of great interest in fluid mechanics. Thus, for pure velocity Dirichlet boundary conditions, we define a new independent variable, *pseudostress*, in terms of the velocity gradient and pressure, and then derive an equivalent first-order system containing the pseudostress and velocity. The pressure, the velocity gradient, and, hence, the vorticity are expressed in terms of the pseudostress. The L^2 norm least-squares functional based on this first-order system is again shown to be elliptic and continuous in the $H(\mathrm{div};\,\Omega)^d \times H^1(\Omega)^d$ norm. Hence, Raviart–Thomas finite elements for the pseudostress and standard continuous piecewise polynomials for the velocity yield optimal approximation, and the resulting algebraic equations can be solved with optimal multigrid methods.

For completeness, we also study inverse norm least-squares functionals and show that their homogeneous forms are elliptic and continuous in appropriate Hilbert spaces. These functionals can be used to develop discrete inverse norm least-squares methods (see, e.g., [6]). Also, for many applications, it is convenient to impose boundary conditions weakly through boundary functionals. Such functionals are also studied in this paper (see section 4.5). (See [23] for the computational feasibility of methods based on these types of functionals.)

Least-squares methods developed in this paper for linear, stationary problems can be easily extended to nonlinear incompressible Newtonian flows, at least in principle. One can simply include an appropriate form of the nonlinear convection term in the residual of the momentum equations. Possible choices for this form can (1) involve only the velocity or (2) involve the (pseudo-) stress which replaces the velocity gradient. Mathematical analysis for least-squares methods applied to nonlinear problems is much more difficult, but it still can be established using the abstract theory of [9]. Formulations of our methods can be easily extended to incompressible non-Newtonian flows as well: only a simple modification is needed in the constitutive equation.

An outline of the paper is as follows. In section 2, the stress-velocity-pressure formulation for incompressible Newtonian fluid flow problems and the corresponding linear, stationary problems are introduced, as well as some notation and the Stokes equations. In section 3, least-squares functionals based on the stress-velocity-pressure and stress-velocity formulations are developed, their ellipticity and continuity are established, and finite element approximations and multigrid solvers are discussed. In section 4, least-squares methods for pure Dirichlet boundary conditions are developed.

1.1. Notation. We use the standard notation and definitions for the Sobolev spaces $H^s(\Omega)^d$ and $H^s(\partial\Omega)^d$ for $s \geq 0$. The standard associated inner products are denoted by $(\cdot,\,\cdot)_{s,\Omega}$ and $(\cdot,\,\cdot)_{s,\partial\Omega}$, and their respective norms are denoted by $\|\cdot\|_{s,\Omega}$ and $\|\cdot\|_{s,\partial\Omega}$. (We suppress the superscript d because the dependence on dimension will be clear by context. We also omit the subscript Ω from the inner product and norm designation when there is no risk of confusion.) For $s = 0$, $H^s(\Omega)^d$ coincides with $L^2(\Omega)^d$. In this case, the inner product and norm will be denoted by $\|\cdot\|$ and $(\cdot,\,\cdot)$, respectively. Set $H^1_D(\Omega) := \{q \in H^1(\Omega) \,:\, q = 0 \text{ on } \Gamma_D\}$. We denote the duals of $H^1_D(\Omega)$ and $H^{\frac{1}{2}}(\partial\Omega)$ by $H_D^{-1}(\Omega)$ and $H^{-\frac{1}{2}}(\partial\Omega)$ with norms defined by

$$\|\phi\|_{-1,\,D} = \sup_{0\neq\psi\in H^1_D(\Omega)} \frac{(\phi,\,\psi)}{\|\psi\|_1} \quad \text{and} \quad \|\phi\|_{-1/2,\,\partial\Omega} = \sup_{0\neq\psi\in H^{\frac{1}{2}}(\partial\Omega)} \frac{(\phi,\,\psi)}{\|\psi\|_{1/2,\partial\Omega}}.$$

When $D = \partial\Omega$, we denote the dual of $H^1_0(\Omega) = H^1_D(\Omega)$ and its norm by $H_0^{-1}(\Omega)$ and $\|\cdot\|_{-1,\,0}$, respectively. When D is empty, the dual of $H^1(\Omega)$ and its norm are

denoted by the respective $H^{-1}(\Omega)$ and $\|\cdot\|_{-1}$. Also, we denote the product space $\prod_{i=1}^{d} H_D^{-1}(\Omega)$ with the standard product norm by $H_D^{-1}(\Omega)^d$. Finally, set

$$H(\mathrm{div};\Omega) = \{\mathbf{v} \in L^2(\Omega)^2 \,:\, \nabla\cdot\mathbf{v} \in L^2(\Omega)\},$$

which is a Hilbert space under the norm

$$\|\mathbf{v}\|_{H(\mathrm{div};\,\Omega)} = \left(\|\mathbf{v}\|^2 + \|\nabla\cdot\mathbf{v}\|^2\right)^{\frac{1}{2}},$$

and define the subspace

$$H_N(\mathrm{div};\Omega) = \{\mathbf{v} \in H(\mathrm{div};\Omega) \,:\, \mathbf{n}\cdot\mathbf{v} = 0\}.$$

2. Mathematical equations for incompressible Newtonian fluid flow. Let Ω be a bounded, open, connected subset of $\Re^d$ ($d = 2$ or 3) with a Lipschitz continuous boundary $\partial\Omega$. Denote the outward unit vector normal to the boundary by $\mathbf{n} = (n_1, \ldots, n_d)^t$. We partition the boundary of Ω into two open subsets Γ_D and Γ_N such that $\partial\Omega = \bar{\Gamma}_D \cup \bar{\Gamma}_N$ and $\Gamma_D \cap \Gamma_N = \emptyset$. For simplicity, we will assume that Γ_D is not empty (i.e., $\mathrm{mes}\,(\Gamma_D) \neq 0$).

For a second-order tensor $\boldsymbol{\tau} = (\tau_{ij})_{d\times d}$, define its divergence and normal by

$$\nabla\cdot\boldsymbol{\tau} = \begin{pmatrix} \partial\tau_{11}/\partial x_1 + \cdots + \partial\tau_{1d}/\partial x_d \\ \vdots \\ \partial\tau_{d1}/\partial x_1 + \cdots + \partial\tau_{dd}/\partial x_d \end{pmatrix} \quad \text{and} \quad \mathbf{n}\cdot\boldsymbol{\tau} = \begin{pmatrix} n_1\tau_{11} + \cdots + n_d\tau_{1d} \\ \vdots \\ n_1\tau_{d1} + \cdots + n_d\tau_{dd} \end{pmatrix},$$

respectively. That is, the divergence and normal operators apply to each row of the tensor. Also denote the matrix trace operator by tr:

$$\mathrm{tr}\,\boldsymbol{\tau} = \tau_{11} + \cdots + \tau_{dd}.$$

Let $\mathbf{f} = (f_1, \ldots, f_d)^t$ be a given external body force defined in Ω and $\mathbf{g} = (g_1, \ldots, g_d)^t$ be a given external surface traction applied on Γ_N. Let $\mathbf{u}(\mathbf{x}, t) = (u_1, \ldots, u_d)^t$ be the velocity vector field of a particle of fluid that is moving through $\mathbf{x}$ at time t, and let $\boldsymbol{\sigma} = (\sigma_{ij})_{d\times d}$ be the stress tensor field. Without loss of generality, we assume that the homogeneous density is one. Then conservation of momentum implies both symmetry of the stress tensor and the local relation

$$\left\{ \begin{array}{rcll} \frac{D\mathbf{u}}{Dt} - \nabla\cdot\boldsymbol{\sigma} &=& \mathbf{f} & \text{in} \quad \Omega, \\ \mathbf{n}\cdot\boldsymbol{\sigma} &=& \mathbf{g} & \text{on} \quad \Gamma_N, \end{array} \right. \tag{2.1}$$

where $\frac{D}{Dt}$ is the material derivative

$$\frac{D}{Dt} = \frac{\partial}{\partial t} + \mathbf{u}\cdot\nabla = \frac{\partial}{\partial t} + \sum_{i=1}^{d} u_i \frac{\partial}{\partial x_i}.$$

In this paper, we restrict ourselves to linear, stationary problems, i.e., problems where the momentum equation in (2.1) is of the form

$$-\nabla\cdot\boldsymbol{\sigma} = \mathbf{f}. \tag{2.2}$$

Let ν be the viscosity parameter, p the pressure, and

$$\boldsymbol{\epsilon}(\mathbf{u}) = \frac{1}{2}\left(\nabla\,\mathbf{u} + (\nabla\,\mathbf{u})^t\right)$$

the deformation rate tensor, where $\nabla \mathbf{u}$ is the velocity gradient tensor with entries $(\nabla \mathbf{u})_{ij} = \partial u_i / \partial x_j$. Then the constitutive law for incompressible Newtonian fluids is

$$\begin{cases} \boldsymbol{\sigma} &= \nu\, \boldsymbol{\epsilon}(\mathbf{u}) - p\, I & \text{in} \quad \Omega, \\ \nabla \cdot \mathbf{u} &= 0 & \text{in} \quad \Omega. \end{cases} \tag{2.3}$$

The second equation in (2.3) is the incompressibility condition. Without loss of generality, we assume that $\nu = 1$, since otherwise $\mathbf{u}$ can be rescaled to $\nu\, \mathbf{u}$. Now, combining (2.2) and (2.3), we have the stress-velocity-pressure formulation for incompressible Newtonian fluid flow:

$$\begin{cases} -\nabla \cdot \boldsymbol{\sigma} &= \mathbf{f} & \text{in} \quad \Omega, \\ \boldsymbol{\sigma} + p\, I - \boldsymbol{\epsilon}(\mathbf{u}) &= \mathbf{0} & \text{in} \quad \Omega, \\ \nabla \cdot \mathbf{u} &= 0 & \text{in} \quad \Omega. \end{cases} \tag{2.4}$$

Differentiating and eliminating the stress in the above system leads to the well-known incompressible Stokes equations:

$$\begin{cases} -\nabla \cdot \boldsymbol{\epsilon}(\mathbf{u}) + \nabla p &= \mathbf{f} & \text{in} \quad \Omega, \\ \nabla \cdot \mathbf{u} &= 0 & \text{in} \quad \Omega. \end{cases} \tag{2.5}$$

3. General boundary conditions. For simplicity, we assume that the boundary conditions are homogeneous:

$$\mathbf{u} = \mathbf{0} \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot \boldsymbol{\sigma} = \mathbf{0} \quad \text{on } \Gamma_N. \tag{3.1}$$

When Γ_N is nonempty, because of the traction boundary condition, it is natural and necessary to have the stress be the independent variable. Hence, we study least-squares functionals based on formulations for stress-velocity-pressure (section 3.1) and for stress-velocity (section 3.2). Our primary goal in this section is to establish continuity and ellipticity for these least-squares functionals in appropriate Hilbert spaces. The least-squares finite element method based on the stress-velocity formulation is described in section 3.3.

3.1. Least-squares functionals based on the stress-velocity-pressure formulation. The first-order system (2.4), together with boundary conditions (3.1), is the stress-velocity-pressure formulation for linear, stationary incompressible Newtonian flow. Taking the trace of the second equation in (2.4) and using the fact that

$$\operatorname{tr} \boldsymbol{\epsilon}(\mathbf{u}) = \nabla \cdot \mathbf{u} = 0,$$

we have the following important relation between the pressure and normal stress:

$$\operatorname{tr} \boldsymbol{\sigma} + d\, p = 0. \tag{3.2}$$

Before defining least-squares functionals, let us first describe solution spaces. When $\Gamma_D = \partial\Omega$, Stokes system (2.5) and (3.1) have a unique solution, provided that

$$\int_\Omega p\, dx = 0. \tag{3.3}$$

Together with (3.2), this implies

$$\int_\Omega \mathrm{tr}\boldsymbol{\sigma}\, dx = 0.$$

Therefore, we are at liberty to impose these conditions on the stress and pressure. Thus, define the spaces

$$\mathbf{X}_N = \begin{cases} H_N(\mathrm{div};\,\Omega)^d & \text{if } \Gamma_N \neq \emptyset, \\ \mathbf{X}_0 \equiv \left\{ \boldsymbol{\tau} \in H(\mathrm{div};\,\Omega)^d \mid \displaystyle\int_\Omega \mathrm{tr}\,\boldsymbol{\tau}\, dx = 0 \right\} & \text{otherwise} \end{cases}$$

and

$$L^2_N(\Omega) = \begin{cases} L^2(\Omega) & \text{if } \Gamma_N \neq \emptyset, \\ L^2_0(\Omega) = \left\{ q \in L^2(\Omega) \mid \displaystyle\int_\Omega q\, dx = 0 \right\} & \text{otherwise.} \end{cases}$$

Then for $\mathbf{f} \in L^2(\Omega)^d$ we define the following least-squares functionals:

$$G_{-1}(\boldsymbol{\sigma},\, \mathbf{u},\, p\,;\, \mathbf{f}) = \|\nabla\cdot\boldsymbol{\sigma} + \mathbf{f}\|^2_{-1,D} + \|\boldsymbol{\sigma} + p\,I - \boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla\cdot\mathbf{u}\|^2 \tag{3.4}$$

and

$$G(\boldsymbol{\sigma},\, \mathbf{u},\, p\,;\, \mathbf{f}) = \|\nabla\cdot\boldsymbol{\sigma} + \mathbf{f}\|^2 + \|\boldsymbol{\sigma} + p\,I - \boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla\cdot\mathbf{u}\|^2 \tag{3.5}$$

for $(\boldsymbol{\sigma},\, \mathbf{u},\, p) \in \mathcal{V} \equiv \mathbf{X}_N \times H^1_D(\Omega)^d \times L^2_N(\Omega)$. We will first establish uniform boundedness and ellipticity (i.e., equivalence) of the homogeneous functionals $G_{-1}(\boldsymbol{\tau},\, \mathbf{v},\, q\,;\, \mathbf{0})$ and $G(\boldsymbol{\tau},\, \mathbf{v},\, q\,;\, \mathbf{0})$ in terms of the respective functionals $M_{-1}(\boldsymbol{\tau},\, \mathbf{v},\, q)$ and $M(\boldsymbol{\tau},\, \mathbf{v},\, q)$ defined on $\mathcal{V}$ by

$$M_{-1}(\boldsymbol{\tau},\, \mathbf{v},\, q) = \|\mathbf{v}\|^2_1 + \|q\|^2 + \|\boldsymbol{\tau}\|^2$$

and

$$M(\boldsymbol{\tau},\, \mathbf{v},\, q) = \|\mathbf{v}\|^2_1 + \|q\|^2 + \|\boldsymbol{\tau}\|^2 + \|\nabla\cdot\boldsymbol{\tau}\|^2.$$

To accomplish this, let $\mathcal{A}_\lambda : R^{d\times d} \longrightarrow R^{d\times d}$ be a linear map defined by

$$\mathcal{A}_\lambda\,\boldsymbol{\tau} = \boldsymbol{\tau} - \frac{\lambda}{d\lambda + 2\mu}(\mathrm{tr}\,\boldsymbol{\tau})\,I \quad \forall\ \boldsymbol{\tau} \in R^{d\times d}.$$

The $\mathcal{A}_\lambda$ is the compliance tensor of fourth order, a terminology from elasticity. Parameters λ and μ are material constants for both solids and fluids. We will use the following fundamental inequality for the trace of $\mathbf{X}_N$:

$$\|\mathrm{tr}\,\boldsymbol{\tau}\| \le C\left(\sqrt{(\mathcal{A}_\lambda\,\boldsymbol{\tau},\, \boldsymbol{\tau})} + \|\nabla\cdot\boldsymbol{\tau}\|_{-1,D}\right) \quad \forall\ \boldsymbol{\tau} \in \mathbf{X}_N, \tag{3.6}$$

where C is a positive constant independent of λ. This inequality was proved in [1] for two dimensions and Dirichlet boundary conditions (i.e., $d = 2$ and $\Gamma_N = \emptyset$) and in [13] for both two and three dimensions and general boundary conditions. When λ approaches ∞, the limit of the linear map $\mathcal{A}_\lambda$ is

$$\mathcal{A}_\infty\,\boldsymbol{\tau} = \boldsymbol{\tau} - \frac{1}{d}\,(\mathrm{tr}\,\boldsymbol{\tau})\,I \ :\ R^{d\times d} \longrightarrow R^{d\times d}.$$

Note that $\mathcal{A}_\infty$ is not an invertible map. A simple calculation gives

$$\begin{cases} (\mathcal{A}_\infty\,\boldsymbol{\tau},\,\boldsymbol{\tau}) = \|\boldsymbol{\tau}\|^2 - \frac{1}{d}\,\|\mathrm{tr}\,\boldsymbol{\tau}\|^2 = \|\mathcal{A}_\infty\,\boldsymbol{\tau}\|^2, \\ (\mathcal{A}_\lambda\,\boldsymbol{\tau},\,\boldsymbol{\tau}) = \|\boldsymbol{\tau}\|^2 - \frac{\lambda}{d\lambda+2\mu}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2 = \|\mathcal{A}_\infty\,\boldsymbol{\tau}\|^2 + \frac{2\mu}{d(d\lambda+2\mu)}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2. \end{cases} \tag{3.7}$$

Since the constant in (3.6) is independent of λ, taking the limit of (3.6) as $\lambda \to \infty$ and using the first equation in (3.7) we obtain

$$\|\mathrm{tr}\,\boldsymbol{\tau}\| \le C\,(\|\mathcal{A}_\infty\,\boldsymbol{\tau}\| + \|\nabla\cdot\boldsymbol{\tau}\|_{-1,D}) \quad \forall\ \boldsymbol{\tau} \in \mathbf{X}_N. \tag{3.8}$$

Let $\|\boldsymbol{\tau}\|_a \equiv \left(\|\mathcal{A}_\infty\,\boldsymbol{\tau}\|^2 + \|\nabla\cdot\boldsymbol{\tau}\|^2_{-1,\,D}\right)^{\frac{1}{2}}$; then $\|\boldsymbol{\tau}\|_a$ is equivalent to the L^2 norm.

LEMMA 3.1. *There exists a positive constant C such that*

$$\frac{1}{C}\|\boldsymbol{\tau}\|^2 \le \|\boldsymbol{\tau}\|_a^2 \le C\,\|\boldsymbol{\tau}\|^2 \quad \forall\ \boldsymbol{\tau} \in \mathbf{X}_N. \tag{3.9}$$

Proof. From the definition of the inverse norm and the Cauchy–Schwarz inequality, we have that

$$\|\nabla\cdot\boldsymbol{\tau}\|_{-1,\,D} \le \|\boldsymbol{\tau}\|. \tag{3.10}$$

Equation (3.9) follows easily from (3.7), (3.8), and (3.10). ∎

Now we are ready to establish equivalence between functionals G_{-1} and M_{-1} and equivalence between functionals G and M.

THEOREM 3.2. *The homogeneous functionals $G_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\,\mathbf{0})$ and $G(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\,\mathbf{0})$ are uniformly equivalent to the functionals $M_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q)$ and $M(\boldsymbol{\tau},\,\mathbf{v},\,q)$, respectively; i.e., there exist positive constants C_1 and C_2 such that*

$$\frac{1}{C_1}M_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q) \le G_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\,\mathbf{0}) \le C_1 M_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q) \tag{3.11}$$

and

$$\frac{1}{C_2}M(\boldsymbol{\tau},\,\mathbf{v},\,q) \le G(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\,\mathbf{0}) \le C_2 M(\boldsymbol{\tau},\,\mathbf{v},\,q) \tag{3.12}$$

hold for all $(\boldsymbol{\tau},\,\mathbf{v},\,q) \in \mathcal{V}$.

Proof. The upper bounds in both (3.11) and (3.12) follow easily from the triangle inequality and (3.10).

To show the validity of the lower bound in (3.11), we first note that

$$\begin{aligned} \|\boldsymbol{\tau} - \boldsymbol{\tau}^t\| &= \|\,(\boldsymbol{\tau} + q\,I - \boldsymbol{\epsilon}(\mathbf{v})) - (\boldsymbol{\tau} + q\,I - \boldsymbol{\epsilon}(\mathbf{v}))^t\,\| \\ &\le 2\,\|\boldsymbol{\tau} + q\,I - \boldsymbol{\epsilon}(\mathbf{v})\|. \end{aligned}$$

We used symmetry of I and $\boldsymbol{\epsilon}(\mathbf{v})$ and the triangle inequality above. Now integration by parts and the Cauchy–Schwarz and Korn inequalities lead to

$$\begin{aligned} |(\boldsymbol{\tau},\,\boldsymbol{\epsilon}(\mathbf{v}))| &= \left|\left(\frac{\boldsymbol{\tau}+\boldsymbol{\tau}^t}{2},\,\boldsymbol{\epsilon}(\mathbf{v})\right)\right| = \left|\left(\frac{\boldsymbol{\tau}+\boldsymbol{\tau}^t}{2},\,\nabla\,\mathbf{v}\right)\right| \\ &= \left|(\boldsymbol{\tau},\,\nabla\mathbf{v}) - \left(\frac{\boldsymbol{\tau}-\boldsymbol{\tau}^t}{2},\,\nabla\mathbf{v}\right)\right| = \left|(-\nabla\cdot\boldsymbol{\tau},\,\mathbf{v}) - \left(\frac{\boldsymbol{\tau}-\boldsymbol{\tau}^t}{2},\,\nabla\mathbf{v}\right)\right| \\ &\le \|\nabla\cdot\boldsymbol{\tau}\|_{-1,\,D}\,\|\mathbf{v}\|_1 + \|\boldsymbol{\tau} + q\,I - \boldsymbol{\epsilon}(\mathbf{v})\|\,\|\nabla\,\mathbf{v}\| \\ &\le C\,(\|\nabla\cdot\boldsymbol{\tau}\|_{-1,\,D} + \|\boldsymbol{\tau} + q\,I - \boldsymbol{\epsilon}(\mathbf{v})\|)\,\|\boldsymbol{\epsilon}(\mathbf{v})\| \\ &\le C\,G_{-1}^{\frac{1}{2}}(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\mathbf{0})\,\|\boldsymbol{\epsilon}(\mathbf{v})\|, \end{aligned} \tag{3.13}$$

where $G_{-1}^{\frac{1}{2}}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0})$ denotes the square root of $G_{-1}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0})$. To bound the deformation rate tensor $\boldsymbol{\epsilon}(\mathbf{v})$, it follows from the fact that

$$(q\, I, \boldsymbol{\epsilon}(\mathbf{v})) = (q, \nabla \cdot \mathbf{v}),$$

the Cauchy–Schwarz inequality, and (3.13) that

$$\begin{aligned}
\|\boldsymbol{\epsilon}(\mathbf{v})\|^2 &= (\boldsymbol{\epsilon}(\mathbf{v}) - \boldsymbol{\tau} - q\, I, \boldsymbol{\epsilon}(\mathbf{v})) + (\boldsymbol{\tau}, \boldsymbol{\epsilon}(\mathbf{v})) + (q, \nabla \cdot \mathbf{v}) \\
&\le \|\boldsymbol{\epsilon}(\mathbf{v}) - \boldsymbol{\tau} - q\, I\|\, \|\boldsymbol{\epsilon}(\mathbf{v})\| + C\, G_{-1}^{\frac{1}{2}}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0})\, \|\boldsymbol{\epsilon}(\mathbf{v})\| + \|q\|\, \|\nabla \cdot \mathbf{v}\| \\
&\le \|\boldsymbol{\epsilon}(\mathbf{v}) - \boldsymbol{\tau} - q\, I\|^2 + C\, G_{-1}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + \frac{1}{2}\, \|\boldsymbol{\epsilon}(\mathbf{v})\|^2 + \|q\|\, \|\nabla \cdot \mathbf{v}\|.
\end{aligned}$$

This implies that

$$\|\boldsymbol{\epsilon}(\mathbf{v})\|^2 \le C\, G_{-1}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + 2\, \|q\|\, \|\nabla \cdot \mathbf{v}\|. \tag{3.14}$$

Now to bound $\|q\|$ in (3.14), since $\operatorname{tr}\, (\boldsymbol{\tau} + q\, I - \boldsymbol{\epsilon}(\mathbf{v})) = \operatorname{tr} \boldsymbol{\tau} + d\, q - \nabla \cdot \mathbf{v}$, we have

$$\|\operatorname{tr} \boldsymbol{\tau} + d\, q - \nabla \cdot \mathbf{v}\| \le d\, \|\boldsymbol{\tau} + q\, I - \boldsymbol{\epsilon}(\mathbf{v})\|.$$

It then follows from the triangle inequality that

$$\begin{aligned}
\|q\| &\le \frac{1}{d}\, (\|\operatorname{tr} \boldsymbol{\tau} + d\, q - \nabla \cdot \mathbf{v}\| + \|\operatorname{tr} \boldsymbol{\tau}\| + \|\nabla \cdot \mathbf{v}\|) \\
&\le d\, G_{-1}^{\frac{1}{2}}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + \|\operatorname{tr} \boldsymbol{\tau}\|. \qquad (3.15)
\end{aligned}$$

Next, we bound $\|\operatorname{tr} \boldsymbol{\tau}\|$ above by the homogeneous functional and the L^2 norm of the deformation rate tensor. To do so, we first establish a similar upper bound for $\|\mathcal{A}_\infty \boldsymbol{\tau}\|$. Note that $\mathcal{A}_\infty^2 = \mathcal{A}_\infty$ and that $(q\, I, \mathcal{A}_\infty \boldsymbol{\tau}) = 0$. These identities and the Cauchy–Schwarz inequality lead to

$$\begin{aligned}
\|\mathcal{A}_\infty \boldsymbol{\tau}\|^2 &= (\boldsymbol{\tau}, \mathcal{A}_\infty \boldsymbol{\tau}) = (\boldsymbol{\tau} + q\, I - \boldsymbol{\epsilon}(\mathbf{v}), \mathcal{A}_\infty \boldsymbol{\tau}) + (\boldsymbol{\epsilon}(\mathbf{v}), \mathcal{A}_\infty \boldsymbol{\tau}) \\
&\le (\|\boldsymbol{\tau} + q\, I - \boldsymbol{\epsilon}(\mathbf{v})\| + \|\boldsymbol{\epsilon}(\mathbf{v})\|)\, \|\mathcal{A}_\infty \boldsymbol{\tau}\|,
\end{aligned}$$

which implies that

$$\|\mathcal{A}_\infty \boldsymbol{\tau}\| \le \|\boldsymbol{\tau} + q\, I - \boldsymbol{\epsilon}(\mathbf{v})\| + \|\boldsymbol{\epsilon}(\mathbf{v})\|. \tag{3.16}$$

Together with (3.9), inequality (3.16) yields

$$\begin{aligned}
\|\operatorname{tr} \boldsymbol{\tau}\| \le \|\boldsymbol{\tau}\| &\le C\, (\|\mathcal{A}_\infty \boldsymbol{\tau}\| + \|\nabla \cdot \boldsymbol{\tau}\|_{-1,D}) \\
&\le C\, (\|\boldsymbol{\tau} + q\, I - \boldsymbol{\epsilon}(\mathbf{v})\| + \|\boldsymbol{\epsilon}(\mathbf{v})\| + \|\nabla \cdot \boldsymbol{\tau}\|_{-1,D}) \\
&\le C\, \left(G_{-1}^{\frac{1}{2}}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + \|\boldsymbol{\epsilon}(\mathbf{v})\|\right). \qquad (3.17)
\end{aligned}$$

Now, combining upper bounds in (3.14), (3.15), and (3.17) and using the Cauchy–Schwarz inequality, we have

$$\begin{aligned}
\|\boldsymbol{\epsilon}(\mathbf{v})\|^2 &\le C\, G_{-1}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + \left(d\, G_{-1}^{\frac{1}{2}}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + \|\operatorname{tr} \boldsymbol{\tau}\|\right)\, \|\nabla \cdot \mathbf{v}\| \\
&\le C\, G_{-1}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + C\, \left(G_{-1}^{\frac{1}{2}}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + \|\boldsymbol{\epsilon}(\mathbf{v})\|\right)\, \|\nabla \cdot \mathbf{v}\| \\
&\le C\, G_{-1}(\boldsymbol{\tau}, \mathbf{v}, q; \mathbf{0}) + C\, \|\boldsymbol{\epsilon}(\mathbf{v})\|\, \|\nabla \cdot \mathbf{v}\|.
\end{aligned}$$

Hence,

$$\|\boldsymbol{\epsilon}(\mathbf{v})\|^2 \le C\, G_{-1}(\boldsymbol{\tau},\, \mathbf{v},\, q\,;\mathbf{0}),$$

which, together with (3.17), (3.15), and (3.9), implies that both $\|\boldsymbol{\tau}\|^2$ and $\|q\|^2$ are also bounded above by the homogeneous functional $G_{-1}(\boldsymbol{\tau},\, \mathbf{v},\, q\,;\mathbf{0})$. This completes the proof of the lower bound in (3.11). Since

$$G_{-1}(\boldsymbol{\tau},\, \mathbf{v},\, q\,;\, \mathbf{0}) \le G(\boldsymbol{\tau},\, \mathbf{v},\, q\,;\, \mathbf{0}) \quad \text{and} \quad \|\nabla\cdot\boldsymbol{\tau}\|^2 \le G(\boldsymbol{\tau},\, \mathbf{v},\, q\,;\, \mathbf{0}),$$

then the lower bound in (3.12) follows from (3.11). The proof of the theorem is therefore completed. ∎

3.2. Least-squares functionals based on the stress-velocity formulation. In this section, we derive the stress-velocity formulation by using relation (3.2) to eliminate the pressure. We then define least-squares functionals based on this formulation and establish their ellipticity and continuity.

Assume that the first equation in (2.3) holds. Then it is easy to see that (3.2) is equivalent to the incompressible condition, the second equation in (2.3). Relation (3.2) says that the pressure is the negative of the arithmetic average of the normal stress. Since the stress is a variable in our first-order system, using (3.2) we eliminate the pressure in the first equation of (2.3) to obtain the following constitutive equation:

$$\mathcal{A}_\infty\,\boldsymbol{\sigma} = \boldsymbol{\sigma} - \frac{1}{d}(\operatorname{tr}\boldsymbol{\sigma})\, I = \boldsymbol{\epsilon}(\mathbf{u}) \quad \text{in} \quad \Omega. \tag{3.18}$$

Note that taking the trace of this equation yields the incompressible condition. This and the momentum equation define the stress-velocity formulation for incompressible Newtonian fluid flow problems. In particular, for linear stationary problems, we have

$$\begin{cases} \mathcal{A}_\infty\,\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u}) &=& \mathbf{0} & \text{in} \quad \Omega, \\ \nabla\cdot\boldsymbol{\sigma} + \mathbf{f} &=& \mathbf{0} & \text{in} \quad \Omega, \end{cases} \tag{3.19}$$

with boundary conditions (3.1). Let

$$\tilde{\mathcal{V}} = \mathbf{X}_N \times H^1_D(\Omega)^d.$$

For $\mathbf{f} \in L^2(\Omega)^d$, we define the following least-squares functionals:

$$\tilde{G}_{-1}(\boldsymbol{\sigma},\, \mathbf{u}\,;\, \mathbf{f}) = \|\mathcal{A}_\infty\,\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla\cdot\boldsymbol{\sigma} + \mathbf{f}\|^2_{-1,D} \tag{3.20}$$

and

$$\tilde{G}(\boldsymbol{\sigma},\, \mathbf{u}\,;\, \mathbf{f}) = \|\mathcal{A}_\infty\,\boldsymbol{\sigma} - \boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla\cdot\boldsymbol{\sigma} + \mathbf{f}\|^2 \tag{3.21}$$

for $(\boldsymbol{\sigma},\, \mathbf{u}) \in \tilde{\mathcal{V}}$. We also define the norm functionals

$$\tilde{M}_{-1}(\boldsymbol{\tau},\, \mathbf{v}) = \|\mathbf{v}\|_1^2 + \|\boldsymbol{\tau}\|^2$$

and

$$\tilde{M}(\boldsymbol{\tau},\, \mathbf{v}) = \|\mathbf{v}\|_1^2 + \|\boldsymbol{\tau}\|^2 + \|\nabla\cdot\boldsymbol{\tau}\|^2.$$

THEOREM 3.3. *The homogeneous functionals* $\tilde{G}_{-1}(\boldsymbol{\tau}, \mathbf{v}; \mathbf{0})$ *and* $\tilde{G}(\boldsymbol{\tau}, \mathbf{v}; \mathbf{0})$ *are uniformly equivalent to the functionals* $\tilde{M}_{-1}(\boldsymbol{\tau}, \mathbf{v})$ *and* $\tilde{M}(\boldsymbol{\tau}, \mathbf{v})$*, respectively; i.e., there exist positive constants* C_1 *and* C_2 *such that*

$$\frac{1}{C_1}\,\tilde{M}_{-1}(\boldsymbol{\tau}, \mathbf{v}) \le \tilde{G}_{-1}(\boldsymbol{\tau}, \mathbf{v}\,; \mathbf{0}) \le C_1\,\tilde{M}_{-1}(\boldsymbol{\tau}, \mathbf{v}) \tag{3.22}$$

and

$$\frac{1}{C_2}\,\tilde{M}(\boldsymbol{\tau}, \mathbf{v}) \le \tilde{G}(\boldsymbol{\tau}, \mathbf{v}\,; \mathbf{0}) \le C_2\,\tilde{M}(\boldsymbol{\tau}, \mathbf{v}) \tag{3.23}$$

hold for all $(\boldsymbol{\tau}, \mathbf{v}) \in \tilde{\mathcal{V}}$.

Proof. Since $\|\mathrm{tr}\,\boldsymbol{\tau}\| \le d\,\|\boldsymbol{\tau}\|$, Theorem 3.2 with the choice of $q = -\mathrm{tr}\,\boldsymbol{\tau}/d$ yields the upper bounds in both (3.22) and (3.23) and the following lower bounds:

$$\tilde{M}_{-1}(\boldsymbol{\tau}, \mathbf{v}) \le C\,\left(\tilde{G}_{-1}(\boldsymbol{\tau}, \mathbf{v}\,; \mathbf{0}) + \|\nabla \cdot \mathbf{v}\|^2\right)$$

and

$$\tilde{M}(\boldsymbol{\tau}, \mathbf{v}) \le C\,\left(\tilde{G}(\boldsymbol{\tau}, \mathbf{v}\,; \mathbf{0}) + \|\nabla \cdot \mathbf{v}\|^2\right).$$

Now the lower bounds in both (3.22) and (3.23) are a direct consequence of the bound

$$\|\nabla \cdot \mathbf{v}\| = \|\mathrm{tr}\,(\boldsymbol{\epsilon}(\mathbf{v}) - \mathcal{A}_\infty\,\boldsymbol{\tau})\| \le d\,\|\boldsymbol{\epsilon}(\mathbf{v}) - \mathcal{A}_\infty\,\boldsymbol{\tau}\|. \qquad \square$$

3.3. Least-squares finite element methods. In this section, we restrict our attention to the least-squares method based on the L^2 norm least-squares functional $\tilde{G}$ for the stress-velocity formulation, although the method developed in this section can be developed in the same manner for the stress-velocity-pressure formulation, and discrete inverse norm methods can be developed for the inverse norm functionals (see [6]). In fact, it seems that the least-squares method based on the stress-velocity formulation may be preferable since it does not involve the pressure and, more importantly, since it has mathematical structure similar to that of linear elasticity. Consequently, we develop a unified numerical approach for both linear elasticity and linear, stationary incompressible Newtonian flows. The pressure, if desired, can be recovered using (3.2).

The variational problem corresponding to the L^2 norm least-squares functional for the stress-velocity formulation is to minimize functional (3.21) over $\tilde{\mathcal{V}}$, that is, to find $(\boldsymbol{\sigma}, \mathbf{u}) \in \tilde{\mathcal{V}}$ such that

$$\tilde{G}(\boldsymbol{\sigma}, \mathbf{u}\,; \mathbf{f}) = \inf_{(\boldsymbol{\tau}, \mathbf{v}) \in \tilde{\mathcal{V}}} \tilde{G}(\boldsymbol{\tau}, \mathbf{v}\,; \mathbf{f}). \tag{3.24}$$

By Theorem 3.3, we can conclude that (3.24) has a unique solution.

Now (3.24) very much resembles the variational problem for the least-squares formulation of linear elasticity developed in [14]. In particular, the elasticity least-squares problem for limiting case $\lambda \to \infty$ is precisely (3.24). In [14], optimal accuracy for the least-squares finite element approximations and optimal multigrid convergence rates for solving the resulting algebraic equations are established to be uniform in λ. This indicates that using the finite elements in [14] to discretize the least-squares problem in (3.24) will give optimal accuracy, and multigrid methods with optimal

complexity can be used to solve the resulting algebraic equations. For completeness, we describe these finite elements and their approximation properties and comment on multigrid methods for solving the resulting algebraic systems. For simplicity, we take the two-dimensional case ($d = 2$).

Assuming that the domain Ω is polygonal, let $\mathcal{T}_h$ be a regular triangulation of Ω (see [16]) with triangular elements of size $\mathcal{O}(h)$. Let $P_k(K)$ be the space of polynomials of degree k on triangle K, and denote the local Raviart–Thomas space of order k on K:

$$RT_k(K) = P_k(K)^2 + \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} P_k(K).$$

Then the standard $H(\mathrm{div};\,\Omega)$ conforming Raviart–Thomas space of order k [22] and the standard (conforming) continuous piecewise polynomials of degree $k+1$ are defined, respectively, by

$$\Sigma_h^k = \{\boldsymbol{\tau} \in \mathbf{X}_N \,:\, \boldsymbol{\tau}|_K \in RT_k(K)^2 \;\forall\, K \in \mathcal{T}_h\} \subset \mathbf{X}_N, \tag{3.25}$$

$$V_h^{k+1} = \{\mathbf{v} \in C^0(\Omega)^2 \,:\, \mathbf{v}|_K \in P_{k+1}(K)^2 \;\forall\, K \in \mathcal{T}_h,\ \mathbf{v} = \mathbf{0} \text{ on } \Gamma_D\} \subset H_D^1(\Omega)^2. \tag{3.26}$$

Space Σ_h^k is used to approximate the stress, and space V_h^{k+1} is used to approximate the velocity. These spaces have the following approximation properties: let $k \geq 0$ be an integer, and let $l \in (0,\, k+1]$:

$$\inf_{\boldsymbol{\tau} \in \Sigma_h^k} \|\boldsymbol{\sigma} - \boldsymbol{\tau}\|_{H(\mathrm{div};\,\Omega)} \leq C\, h^l \left(\|\boldsymbol{\sigma}\|_l + \|\nabla \cdot \boldsymbol{\sigma}\|_l\right) \tag{3.27}$$

for $\boldsymbol{\sigma} \in H^l(\Omega)^{2\times 2} \cap \mathbf{X}_N$ with $\nabla \cdot \boldsymbol{\sigma} \in H^l(\Omega)^2$ and

$$\inf_{\mathbf{u} \in V_h^{k+1}} \|\mathbf{u} - \mathbf{v}\|_1 \leq C\, h^l\, \|\mathbf{u}\|_{l+1} \tag{3.28}$$

for $\mathbf{u} \in H^{l+1}(\Omega)^2 \cap H_D^1(\Omega)^2$. Based on the smoothness of $\boldsymbol{\sigma}$ and $\mathbf{u}$, we will choose $k+1$ to be the smallest integer greater than or equal to l.

The finite element discretization of our stress-velocity least-squares variational problem is as follows: find $(\boldsymbol{\sigma}^h,\, \mathbf{u}^h) \in \Sigma_h^k \times V_h^{k+1}$ such that

$$\tilde{G}(\boldsymbol{\sigma}^h,\, \mathbf{u}^h;\, \mathbf{f}) = \min_{(\boldsymbol{\tau},\, \mathbf{v}) \in \Sigma_h^k \times V_h^{k+1}} \tilde{G}(\boldsymbol{\tau},\, \mathbf{v};\, \mathbf{f}). \tag{3.29}$$

By Theorem 3.3 and the fact that $\Sigma_h^k \times V_h^{k+1}$ is a subspace of $\tilde{\mathcal{V}}$, (3.29) has a unique solution. As proved in [14], we have the following error estimations.

THEOREM 3.4. *Assume that the solution* $(\boldsymbol{\sigma},\, \mathbf{u})$ *of* (3.24) *is in* $H^l(\Omega)^{2\times 2} \times H^{l+1}(\Omega)^2$ *and that the divergence of the stress* $\nabla \cdot \boldsymbol{\sigma}$ *is in* $H^l(\Omega)^2$. *Let* $k+1$ *be the smallest integer greater than or equal to* l. *Then with* $(\boldsymbol{\sigma}^h,\, \mathbf{u}^h) \in \Sigma_h^k \times V_h^{k+1}$ *denoting the solution to* (3.29), *the following error estimate holds:*

$$\|\boldsymbol{\sigma} - \boldsymbol{\sigma}^h\|_{H(\mathrm{div};\,\Omega)} + \|\mathbf{u} - \mathbf{u}^h\|_1 \leq C\, h^l \left(\|\boldsymbol{\sigma}\|_l + \|\nabla \cdot \boldsymbol{\sigma}\|_l + \|\mathbf{u}\|_{l+1}\right). \tag{3.30}$$

As for the pressure, it can be recovered algebraically using (3.2):

$$p^h = -\frac{1}{d} \operatorname{tr} \boldsymbol{\sigma}^h. \tag{3.31}$$

It follows from (3.2), (3.31), the triangle inequality, and Theorem 3.4 that

$$\|p - p^h\| = \frac{1}{d}\|\mathrm{tr}\,(\boldsymbol{\sigma} - \boldsymbol{\sigma}^h)\| \le \|\boldsymbol{\sigma} - \boldsymbol{\sigma}^h\| \le C\,h^l. \tag{3.32}$$

Remark. Theorem 3.3 states that the homogeneous functional $\tilde{G}(\boldsymbol{\tau}, \mathbf{v}; \mathbf{0})$ is equivalent to the $H(\mathrm{div}; \Omega)$ norm for the tensor variable and the H^1 norm for the vector variable. It is then well known that multigrid methods applied to discrete linear system (3.29) have optimal convergence properties (see, e.g., [19, 2, 12, 20, 24]).

4. Pure Dirichlet boundary conditions. Many applications in incompressible Newtonian fluid flow are not posed under traction boundary conditions. It is then not necessary to use the stress as the independent variable. In fact, the stress and the deformation rate tensor may not be the variables of choice, especially if the vorticity is needed. This is because the vorticity is the skew-symmetric part of the velocity gradient, and thus the stress and deformation rate tensor do not contain information on the vorticity. For this reason, in this section we develop a least-squares method involving variables that can recover the velocity gradient and vorticity without differentiation. This least-squares method will use the finite element spaces described in section 3.3.

For simplicity, we assume the homogeneous Dirichlet boundary condition

$$\mathbf{u} = \mathbf{0} \quad \text{on } \partial\Omega. \tag{4.1}$$

4.1. First-order systems. Whereas the vorticity is the skew-symmetric part of the velocity gradient, the deformation rate tensor $\boldsymbol{\epsilon}(\mathbf{u})$ is the symmetric part of the velocity gradient. From the second equation of first-order system (2.4), it is then not possible to algebraically obtain the vorticity from the stress tensor. To accomplish this, a new variable must be introduced in place of the stress. This new variable should be chosen such that the resulting least-squares functionals have properties similar to G_{-1} and G ($\tilde{G}_{-1}$ and $\tilde{G}$) and such that both the stress and vorticity can be algebraically obtained from this variable. Insight into designing this new variable can be obtained by noting that for incompressible fluids the divergence of $(\nabla\mathbf{u})^t$ vanishes:

$$\nabla\cdot(\nabla\mathbf{u})^t = \nabla\cdot\begin{pmatrix} \partial_1 u_1 & \cdots & \partial_1 u_d \\ \vdots & \vdots & \vdots \\ \partial_d u_1 & \cdots & \partial_d u_d \end{pmatrix} = \nabla\,(\nabla\cdot\mathbf{u}) = \mathbf{0}. \tag{4.2}$$

Specifically, defining the new independent tensor variable, the pseudostress, to be

$$\tilde{\boldsymbol{\sigma}} = \frac{1}{2}\,\nabla\,\mathbf{u} - p\,I, \tag{4.3}$$

then

$$\boldsymbol{\sigma} = \tilde{\boldsymbol{\sigma}} + \frac{1}{2}\,(\nabla\,\mathbf{u})^t, \tag{4.4}$$

and so by (4.2) we have

$$\nabla\cdot\tilde{\boldsymbol{\sigma}} = \nabla\cdot\boldsymbol{\sigma}. \tag{4.5}$$

Moreover, using the incompressibility of $\mathbf{u}$, we have

$$\mathrm{tr}\,\tilde{\boldsymbol{\sigma}} = \mathrm{tr}\,\boldsymbol{\sigma} = -d\,p. \tag{4.6}$$

The pseudostress is not symmetric and probably not a primitive physical quantity. However, the resulting first-order system is

$$\left\{\begin{array}{rcll} -\nabla\cdot\tilde{\boldsymbol{\sigma}} &=& \mathbf{f} & \text{in } \Omega,\\ \tilde{\boldsymbol{\sigma}} + p\,I - \frac{1}{2}\nabla\mathbf{u} &=& \mathbf{0} & \text{in } \Omega,\\ \nabla\cdot\mathbf{u} &=& 0 & \text{in } \Omega, \end{array}\right. \tag{4.7}$$

which is essentially equivalent to (2.4). Differentiating and eliminating $\tilde{\boldsymbol{\sigma}}$ in (4.7) leads to the incompressible Stokes equations:

$$\left\{\begin{array}{rcll} -\frac{1}{2}\Delta\mathbf{u} + \nabla p &=& \mathbf{f} & \text{in } \Omega,\\ \nabla\cdot\mathbf{u} &=& 0 & \text{in } \Omega. \end{array}\right. \tag{4.8}$$

4.2. Least-squares functionals. For $\mathbf{f}\in L^2(\Omega)^d$, we define the following least-squares functionals based on first-order system (4.7):

$$F_{-1}(\tilde{\boldsymbol{\sigma}},\,\mathbf{u},\,p\,;\,\mathbf{f}) = \|\nabla\cdot\tilde{\boldsymbol{\sigma}}+\mathbf{f}\|^2_{-1,0} + \left\|\tilde{\boldsymbol{\sigma}} + p\,I - \frac{1}{2}\nabla\mathbf{u}\right\|^2 + \|\nabla\cdot\mathbf{u}\|^2 \tag{4.9}$$

and

$$F(\tilde{\boldsymbol{\sigma}},\,\mathbf{u},\,p\,;\,\mathbf{f}) = \|\nabla\cdot\tilde{\boldsymbol{\sigma}}+\mathbf{f}\|^2 + \left\|\tilde{\boldsymbol{\sigma}} + p\,I - \frac{1}{2}\nabla\mathbf{u}\right\|^2 + \|\nabla\cdot\mathbf{u}\|^2 \tag{4.10}$$

for $(\tilde{\boldsymbol{\sigma}},\,\mathbf{u},\,p)\in\mathcal{V}_0\equiv\mathbf{X}_0\times H^1_0(\Omega)^d\times L^2_0(\Omega)$.

THEOREM 4.1. *The homogeneous functionals $F_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\,\mathbf{0})$ and $F(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\,\mathbf{0})$ are uniformly equivalent to the functionals $M_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q)$ and $M(\boldsymbol{\tau},\,\mathbf{v},\,q)$, respectively; i.e., there exist positive constants C_1 and C_2 such that*

$$\frac{1}{C_1}M_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q) \le F_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\,\mathbf{0}) \le C_1 M_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q) \tag{4.11}$$

and

$$\frac{1}{C_2}M(\boldsymbol{\tau},\,\mathbf{v},\,q) \le F(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\,\mathbf{0}) \le C_2 M(\boldsymbol{\tau},\,\mathbf{v},\,q) \tag{4.12}$$

hold for all $(\boldsymbol{\tau},\,\mathbf{v},\,q)\in\mathcal{V}_0$.

Proof. The theorem can be proved in a similar manner as in Theorem 3.2. Actually, the key inequality

$$\|\nabla\mathbf{v}\|^2 \le C\,F_{-1}(\boldsymbol{\tau},\,\mathbf{v},\,q\,;\mathbf{0}) + C\,\|q\|\,\|\nabla\cdot\mathbf{v}\|, \tag{4.13}$$

which is similar to inequality (3.14), can be established easily: integration by parts and the Cauchy–Schwarz inequality lead to

$$\begin{aligned}\frac{1}{2}\|\nabla\mathbf{v}\|^2 &= \left(\frac{1}{2}\nabla\mathbf{v} - \boldsymbol{\tau} - q\,I,\,\nabla\mathbf{v}\right) - (\nabla\cdot\boldsymbol{\tau},\,\mathbf{v}) + (q,\,\nabla\cdot\mathbf{v})\\ &\le \left\|\frac{1}{2}\nabla\mathbf{v} - \boldsymbol{\tau} - q\,I\right\|\,\|\nabla\mathbf{v}\| + \|\nabla\cdot\boldsymbol{\tau}\|_{-1,0}\,\|\mathbf{v}\|_1 + \|q\|\,\|\nabla\cdot\mathbf{v}\|.\end{aligned}$$

Now (4.13) follows from the Poincaré and ϵ inequalities. ∎

As in section 3.2, we can derive the following first-order system without the pressure:

$$\left\{\begin{array}{rcll} \mathcal{A}_\infty\,\tilde{\boldsymbol{\sigma}} - \frac{1}{2}\,\nabla\,\mathbf{u} &=& \mathbf{0} & \text{in} \quad \Omega, \\ \nabla\cdot\,\tilde{\boldsymbol{\sigma}} + \mathbf{f} &=& \mathbf{0} & \text{in} \quad \Omega. \end{array}\right. \tag{4.14}$$

The corresponding least-squares functionals are

$$\tilde{F}_{-1}(\tilde{\boldsymbol{\sigma}},\,\mathbf{u}\,;\,\mathbf{f}) = \left\|\mathcal{A}_\infty\,\tilde{\boldsymbol{\sigma}} - \frac{1}{2}\,\nabla\,\mathbf{u}\right\|^2 + \|\nabla\cdot\,\tilde{\boldsymbol{\sigma}} + \mathbf{f}\|^2_{-1,0} \tag{4.15}$$

and

$$\tilde{F}(\tilde{\boldsymbol{\sigma}},\,\mathbf{u}\,;\,\mathbf{f}) = \left\|\mathcal{A}_\infty\,\tilde{\boldsymbol{\sigma}} - \frac{1}{2}\,\nabla\,\mathbf{u}\right\|^2 + \|\nabla\cdot\,\tilde{\boldsymbol{\sigma}} + \mathbf{f}\|^2 \tag{4.16}$$

for $(\tilde{\boldsymbol{\sigma}},\,\mathbf{u}) \in \tilde{\mathcal{V}}_0 \equiv \mathbf{X}_0 \times H^1_0(\Omega)^d$.

THEOREM 4.2. *The homogeneous functionals $\tilde{F}_{-1}(\boldsymbol{\tau},\,\mathbf{v};\,\mathbf{0})$ and $\tilde{F}(\boldsymbol{\tau},\,\mathbf{v};\,\mathbf{0})$ are uniformly equivalent to the functionals $\tilde{M}_{-1}(\boldsymbol{\tau},\,\mathbf{v})$ and $\tilde{M}(\boldsymbol{\tau},\,\mathbf{v})$, respectively; i.e., there exist positive constants C_1 and C_2 such that*

$$\frac{1}{C_1}\,\tilde{M}_{-1}(\boldsymbol{\tau},\,\mathbf{v}) \le \tilde{F}_{-1}(\boldsymbol{\tau},\,\mathbf{v}\,;\,\mathbf{0}) \le C_1\,\tilde{M}_{-1}(\boldsymbol{\tau},\,\mathbf{v}) \tag{4.17}$$

and

$$\frac{1}{C_2}\,\tilde{M}(\boldsymbol{\tau},\,\mathbf{v}) \le \tilde{F}(\boldsymbol{\tau},\,\mathbf{v}\,;\,\mathbf{0}) \le C_2\,\tilde{M}(\boldsymbol{\tau},\,\mathbf{v}) \tag{4.18}$$

hold for all $(\boldsymbol{\tau},\,\mathbf{v}) \in \tilde{\mathcal{V}}_0$.

Proof. The theorem can be shown in a similar fashion as in Theorem 3.3. ∎

Remark. The mixed variational problem based on (4.14) is to find $(\tilde{\boldsymbol{\sigma}},\,\mathbf{u}) \in \mathbf{X}_0 \times L^2_0(\Omega)^d$ such that

$$\left\{\begin{array}{lcll} (\mathcal{A}_\infty\,\tilde{\boldsymbol{\sigma}},\,\boldsymbol{\tau}) + \frac{1}{2}(\mathbf{u},\,\nabla\cdot\,\boldsymbol{\tau}) &=& \mathbf{0} & \forall\ \boldsymbol{\tau} \in \mathbf{X}_0, \\ (\nabla\cdot\,\tilde{\boldsymbol{\sigma}},\,\mathbf{v}) &=& -(\mathbf{f},\,\mathbf{v}) & \forall\ \mathbf{v} \in L^2(\Omega)^d. \end{array}\right. \tag{4.19}$$

It is easy to see that (4.19) is essentially a vector version of the mixed formulation for the second-order elliptic problems. Therefore, any stable pair of finite elements for the second-order elliptic problems (see [8]) is also a stable approximation for (4.19). This will be studied in a forthcoming paper.

4.3. Least-squares finite element methods. The variational problem for the L^2 norm least-squares formulation of (4.14) is to minimize least-squares functional (4.16) over $\tilde{\mathcal{V}}_0$, that is, to find $(\tilde{\boldsymbol{\sigma}},\,\mathbf{u}) \in \tilde{\mathcal{V}}_0$ such that

$$\tilde{F}(\tilde{\boldsymbol{\sigma}},\,\mathbf{u}\,;\,\mathbf{f}) = \inf_{(\boldsymbol{\tau},\,\mathbf{v})\in\tilde{\mathcal{V}}_0} \tilde{F}(\boldsymbol{\tau},\,\mathbf{v}\,;\,\mathbf{f}). \tag{4.20}$$

By Theorem 4.2, (4.20) has a unique solution. The discrete finite element problem is to find $(\tilde{\boldsymbol{\sigma}}^h,\,\mathbf{u}^h) \in \Sigma^k_h \times V^{k+1}_h$ such that

$$\tilde{F}(\tilde{\boldsymbol{\sigma}}^h,\,\mathbf{u}^h;\,\mathbf{f}) = \min_{(\boldsymbol{\tau},\,\mathbf{v})\in\Sigma^k_h\times V^{k+1}_h} \tilde{F}(\boldsymbol{\tau},\,\mathbf{v};\,\mathbf{f}). \tag{4.21}$$

Since $\Sigma_h^k \times V_h^{k+1}$ is a subspace of $\tilde{\mathcal{V}}_0$ ($\Gamma_D = \partial\Omega$ and $\Gamma_N = \emptyset$), by Theorem 4.2, (4.21) has a unique solution. We have the following error estimate for the finite element approximation.

THEOREM 4.3. *Assume that the solution* $(\tilde{\boldsymbol{\sigma}}, \mathbf{u})$ *of* (4.20) *is in* $H^l(\Omega)^{2\times 2} \times H^{l+1}(\Omega)^2$ *and that* $\nabla \cdot \tilde{\boldsymbol{\sigma}}$ *is in* $H^l(\Omega)^2$. *Let* $k+1$ *be the smallest integer greater than or equal to* l. *Then with* $(\tilde{\boldsymbol{\sigma}}^h, \mathbf{u}^h) \in \Sigma_h^k \times V_h^{k+1}$ *denoting the solution to* (4.21), *the following error estimate holds:*

$$\|\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^h\|_{H(\mathrm{div};\,\Omega)} + \|\mathbf{u} - \mathbf{u}^h\|_1 \le C\, h^l \left(\|\tilde{\boldsymbol{\sigma}}\|_l + \|\nabla \cdot \tilde{\boldsymbol{\sigma}}\|_l + \|\mathbf{u}\|_{l+1}\right). \tag{4.22}$$

4.4. Computation of pressure, stress, and vorticity. Physical quantities such as pressure, stress, and vorticity can be approximated in terms of $\tilde{\boldsymbol{\sigma}}^h$. For the pressure, (4.6) gives

$$p = -\frac{1}{d} \operatorname{tr} \tilde{\boldsymbol{\sigma}}. \tag{4.23}$$

For the stress, note that the first equation in (4.14) gives

$$\nabla \mathbf{u} = 2\, \mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}}. \tag{4.24}$$

This, together with (4.4), implies

$$\boldsymbol{\sigma} = \tilde{\boldsymbol{\sigma}} + \frac{1}{2} (\nabla \mathbf{u})^t = \tilde{\boldsymbol{\sigma}} + (\mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}})^t = \mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}} + \tilde{\boldsymbol{\sigma}}^t. \tag{4.25}$$

For the vorticity $\boldsymbol{\omega} = \nabla \times \mathbf{u}$, it can be expressed in terms of the entries of the skew-symmetric part of the velocity gradient and, hence, the pseudostress $\tilde{\boldsymbol{\sigma}}$. More precisely, letting $\mathbf{s} = \frac{1}{2} (\nabla \mathbf{u} - (\nabla \mathbf{u})^t)$, the definition of the curl operator gives

$$\boldsymbol{\omega} = \begin{cases} 2 s_{21}(\mathbf{u}) & \text{if } d = 2, \\ 2(s_{32}(\mathbf{u}),\, s_{13}(\mathbf{u}),\, s_{21}(\mathbf{u}))^t & \text{if } d = 3. \end{cases}$$

Then by (4.24) we have

$$\mathbf{s}(\mathbf{u}) = \mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}} - (\mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}})^t = \tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^t$$

and, hence,

$$\boldsymbol{\omega} = 2 \begin{cases} \tilde{\sigma}_{21} - \tilde{\sigma}_{12} & \text{if } d = 2, \\ (\tilde{\sigma}_{32} - \tilde{\sigma}_{23},\, \tilde{\sigma}_{13} - \tilde{\sigma}_{31},\, \tilde{\sigma}_{21} - \tilde{\sigma}_{12})^t & \text{if } d = 3. \end{cases} \tag{4.26}$$

Equations (4.23), (4.25), and (4.26) suggest that we can approximate the pressure, stress, and vorticity as

$$p^h = -\frac{1}{d} \operatorname{tr} \tilde{\boldsymbol{\sigma}}^h, \qquad \boldsymbol{\sigma}^h = \mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}}^h + (\tilde{\boldsymbol{\sigma}}^h)^t,$$

$$\boldsymbol{\omega}_h = 2 \begin{cases} \tilde{\sigma}_{21}^h - \tilde{\sigma}_{12}^h & \text{if } d = 2, \\ (\tilde{\sigma}_{32}^h - \tilde{\sigma}_{23}^h,\, \tilde{\sigma}_{13}^h - \tilde{\sigma}_{31}^h,\, \tilde{\sigma}_{21}^h - \tilde{\sigma}_{12}^h)^t & \text{if } d = 3. \end{cases}$$

From (4.23), (4.25), (4.26), the triangle inequality, and Theorem 4.3, we have the following error estimates:

$$\|p - p^h\| = \frac{1}{d} \|\mathrm{tr}(\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^h)\| \le C\, h^l,$$

$$\|\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^h\| = \|\mathcal{A}_\infty(\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^h) + (\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^h)^t\| \le C\, h^l,$$

$$\|\boldsymbol{\omega} - \boldsymbol{\omega}^h\| \le C\, \|\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^h\| \le C\, h^l.$$

4.5. Weakly imposed boundary conditions. In the previous sections, boundary conditions were imposed on the solution spaces. This leads to least-squares finite element approximations that are more accurate on the boundary than in the interior of the domain. In the context of least-squares methods, it is natural to treat boundary conditions weakly through boundary functionals. This is also convenient for many applications.

As an example of least-squares boundary functionals, we describe a least-squares functional with boundary terms for first-order system (4.14):

$$\tilde{F}_b(\tilde{\boldsymbol{\sigma}},\, \mathbf{u}\,;\, \mathbf{f}) = \left\| \mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}} - \frac{1}{2}\, \nabla\, \mathbf{u} \right\|^2 + \|\nabla \cdot \tilde{\boldsymbol{\sigma}} + \mathbf{f}\|^2 + \|\mathbf{u}\|^2_{\frac{1}{2},\partial\Omega}. \tag{4.27}$$

The least-squares variational problem is to minimize this functional over a solution space free of imposed boundary conditions: find $(\tilde{\boldsymbol{\sigma}},\, \mathbf{u}) \in \tilde{\mathcal{V}}_b \equiv \mathbf{X}_0 \times H^1(\Omega)^d$ such that

$$\tilde{F}_b(\tilde{\boldsymbol{\sigma}},\, \mathbf{u}\,;\, \mathbf{f}) = \inf_{(\boldsymbol{\tau},\, \mathbf{v}) \in \tilde{\mathcal{V}}_b} \tilde{F}_b(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{f}). \tag{4.28}$$

Using techniques in this paper and in the proof of Theorem 5.1 in [14], we can show that there exists a positive constant C such that

$$\frac{1}{C}\, \tilde{M}(\boldsymbol{\tau},\, \mathbf{v}) \le \tilde{F}_b(\boldsymbol{\tau},\, \mathbf{v}\,;\, \mathbf{0}) \le C\, \tilde{M}(\boldsymbol{\tau},\, \mathbf{v}) \tag{4.29}$$

for all $(\boldsymbol{\tau},\, \mathbf{v}) \in \tilde{\mathcal{V}}_b$. To develop computable finite element methods and the corresponding iterative solvers based on this functional, see [23].

4.6. Relation to existing least-squares methods. There are many existing least-squares methods for the Stokes equations. Since the pseudostress $\tilde{\boldsymbol{\sigma}}$ involves the velocity gradient and the pressure, our approach has some similarities with the methods in [11, 15]. In [11], the velocity gradient is introduced as an independent variable; two additional (consistent) constraints (vanishing trace and curl of the velocity gradient) are added to the original system; the variables of the least-squares method are the velocity, velocity gradient, and pressure; and the homogeneous L^2 norm least-squares functional is elliptic and continuous in $(H(\mathrm{div};\, \Omega)^d \cap H(\mathbf{curl}\,;\, \Omega)^d) \times H^1(\Omega)^d \times H^1(\Omega)$, where $H(\mathbf{curl}\,;\, \Omega)$ is the Hilbert space consisting of square-integrable vectors whose curls are also square-integrable. In [15], a constrained velocity gradient (the velocity gradient satisfying the incompressibility condition) is introduced as an independent variable; the least-squares method is based on the div-curl system of the constraint velocity gradient and the pressure; and the homogeneous functional is elliptic and continuous in $(H(\mathrm{div};\, \Omega)^d \cap H(\mathbf{curl}\,;\, \Omega)^d) \times H^1(\Omega)$. Both methods require sufficient smoothness for the original problem, and, hence, their applicability is very limited.

As a side remark, we comment that the div-curl least-squares method can be developed for our formulations. To see this, applying the curl operator to the first equation of (4.14) leads to the following div-curl system:

$$\begin{cases} \nabla \times (\mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}}) &=& \mathbf{0} & \text{in} & \Omega, \\ \nabla \cdot\, \tilde{\boldsymbol{\sigma}} + \mathbf{f} &=& \mathbf{0} & \text{in} & \Omega, \end{cases} \tag{4.30}$$

with boundary conditions $\mathbf{n} \times (\mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}}) = \mathbf{n} \times \nabla\, \mathbf{u} = \mathbf{0}$ on $\partial\Omega$. The corresponding least-squares functionals are defined as

$$\bar{F}_{-1}(\tilde{\boldsymbol{\sigma}};\, \mathbf{f}) = \|\nabla \times (\mathcal{A}_\infty\, \tilde{\boldsymbol{\sigma}})\,\|^2_{-1,0} + \|\nabla \cdot \tilde{\boldsymbol{\sigma}} + \mathbf{f}\|^2_{-1} \tag{4.31}$$

and

$$\bar{F}(\tilde{\boldsymbol{\sigma}}; \mathbf{f}) = \|\nabla \times (\mathcal{A}_\infty \tilde{\boldsymbol{\sigma}})\|^2 + \|\nabla \cdot \tilde{\boldsymbol{\sigma}} + \mathbf{f}\|^2. \tag{4.32}$$

These div-curl approaches will be studied in a forthcoming paper.

APPROXIMATIONS OF VERY WEAK SOLUTIONS TO BOUNDARY-VALUE PROBLEMS*

MARTIN BERGGREN†

Abstract. Standard weak solutions to the Poisson problem on a bounded domain have square-integrable derivatives, which limits the admissible regularity of inhomogeneous data. The concept of solution may be further weakened in order to define solutions when data is rough, such as for inhomogeneous Dirichlet data that is only square-integrable over the boundary. Such very weak solutions satisfy a nonstandard variational form $(u, v) = G(v)$. A Galerkin approximation combined with an approximation of the right-hand side G defines a finite-element approximation of the very weak solution. Applying conforming linear elements leads to a discrete solution equivalent to the text-book finite-element solution to the Poisson problem in which the boundary data is approximated by L^2-projections. The L^2 convergence rate of the discrete solution is $O(h^s)$ for some $s \in (0, 1/2)$ that depends on the shape of the domain, assuming a polygonal (two-dimensional) or polyhedral (three-dimensional) domain without slits and (only) square-integrable boundary data.

Key words. finite-element methods, very weak solution, transposition, rough data

1. Introduction.

Applications such as optimal control, inverse problems, and shape optimization sometimes call for boundary data that are rougher than the theory for elliptic or parabolic boundary-value problems routinely assumes. This note addresses numerical issues in the presence of rough boundary data.

We restrict the discussion to a simple case, the Poisson equation with inhomogeneous Dirichlet conditions,

$$-\Delta u = f \qquad \text{in } \Omega, \tag{1a}$$

$$u = g \qquad \text{on } \Gamma, \tag{1b}$$

where Ω is a bounded domain in $\mathbb{R}^2$ or $\mathbb{R}^3$, Γ the domain boundary, and f and g are given data. Integration by parts yields that smooth solutions to (1) satisfy

$$\int_\Omega \nabla u \cdot \nabla v \, dx = \int_\Omega f v \, dx \tag{2}$$

for each smooth v vanishing on Γ. The "standard" weak solution to (1), the basis for finite-element discretizations, satisfies variational expression (2) with u and v being elements in certain subspaces of $H^1(\Omega)$, the Sobolev space of order one.

Which type of boundary data g makes sense to specify in (1)? The answer depends on which type of functions we accept as being solutions. For standard weak solutions, it is necessary that g can be extended continuously into a function in $H^1(\Omega)$. Such extensions are not always possible—there are even continuous functions g on the

†Department of Information Technology, Uppsala University, Box 337, SE-751 05 Uppsala, Sweden (Martin.Berggren@it.uu.se).

boundary Γ that do not extend continuously. The situation is even worse for nonsmooth data. For instance, no function with jump discontinuities on the boundary can be extended continuously into a function in $H^1(\Omega)$.

However, even weaker solutions to system (1) than the standard weak solution relax the requirements on g. Integrating (2) by parts once more reveals that solutions to (1) satisfy

$$-\int_\Omega u\,\Delta v\,dx = -\int_\Gamma g\frac{\partial v}{\partial n}\,d\Gamma + \int_\Omega f v\,dx \tag{3}$$

for each smooth v vanishing on Γ. The boundary integral on the right-hand side of expression (3) now makes sense for g being merely square-integrable, as long as the normal derivative of v is also square-integrable on the boundary. Variational expression (3)—in a version made precise in section 4—is the basis for defining very weak solutions to the Poisson equation with boundary data being no more than square-integrable. Compared to the variational form (2), the nonstandard variational form (3) relaxes the regularity requirement on u and g at the price of higher regularity requirements on v, a particular example of the method of *transposition*, treated in great generality in the classic three-volume treatise of Lions and Magenes [15].

This note considers a numerical approximation based on the *Lions-type* variational expression (3) and proves optimal-order convergence rates for linear, conforming elements. To the best of my knowledge, this approach to discretizing problems with rough boundary data has not previously been reported in the literature. Previous analysis of problems with rough data has concerned other discretization approaches.

Babuška [1] defines weak solutions using a generalized Lax–Milgram lemma, a version that would apply, for instance, to the form (3) in the case of full elliptic regularity and a smooth boundary. (Because of lack of regularity, we cannot directly use his method here.) He considers finite-element approximations of the Poisson problem based on the standard variational form (2) with homogeneous boundary data and proves error bounds that cover also very weak solutions such as Green's functions.

French and King [8] analyze a parabolic initial–boundary-value problem for convex domains in $\mathbb{R}^2$. Using temporal averaging combined with spatial L^2-projections for the boundary data, they prove error estimates for a standard finite-element approximation in space, combined with the backward Euler scheme in time, of a very weak solution to the parabolic problem.

In the context of an optimal-control problem for a second-order elliptic equation on convex domains in $\mathbb{R}^2$, French and King [7] introduce a standard finite-element approximation and show that it converges to the very weak solution defined by transposition. Another contribution in this direction is by Bramble and King [2]. They consider elliptic problems on smooth, curved domains in $\mathbb{R}^2$, and their error estimates hold also for rough boundary data.

In all articles cited above, $L^2(\Gamma)$-projections approximate the rough boundary data, which allows the use of the standard variational form (2). In contrast, this article uses the Lions-type variational form (3) as the basis for discretization. Thus, the variational form in the discretization is identical to the one used to define the (very) weak solution, and projection of the data is not needed. Nonetheless, a perhaps surprising result of this article (Theorem 5.2) is that the discrete solution obtained with the current approach is *equivalent* to the standard finite-element approximation combined with $L^2(\Gamma)$-projections of the inhomogeneous data. This observation removes

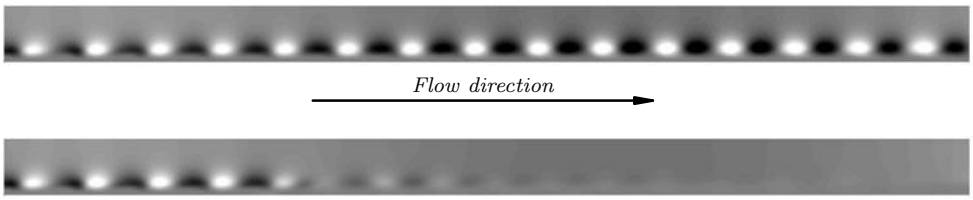

FIG. 1. *Wall-normal velocity disturbance levels depicting Tollmien–Schlichting waves in a boundary layer over a flat plate. The lower picture shows the result after applying boundary control at a portion of the wall.*

some of the arbitrariness of the standard method with data projections, showing its equivalence with a systematic scheme based on the Lions-type variational form.

Another difference from previous work is that the analysis below covers both two and three space dimensions with polygonal or polyhedral boundaries, without assuming convexity of the domain. The analysis in the articles cited above is restricted to two dimensions and assumes convex, polygonal domains.

Solutions as weak as the ones considered here have interest beyond mathematical curiosity. Applications in which very weak solutions appear naturally are *boundary control* and *inverse* problems [4, 9, 14]. The rest of the presentation starts with a short outline of this background in section 2. Section 3 reviews some fundamentals, notation, and the approximation properties that are needed, setting the stage for a more precise description in section 4 of the Poisson-equation solution based on transposition. Section 5 introduces a finite-element approximation of the very weak solution, proving convergence rates and equivalence with the "standard" approximation with projection of the data.

2. Background. Scientific and technical reasons prompt the need for *controlling* the behavior of solutions to partial differential equations, for instance through boundary action. In fluid-dynamics applications, the object is typically to manage the evolution of disturbances. Figure 1 depicts a boundary layer with evolving *Tollmien–Schlichting* waves, the most unstable disturbance according to linear stability theory. The pictures are snapshots from numerical solutions of the unsteady, incompressible Navier–Stokes equations in three space dimensions. A suitable blowing and suction at a portion of the lower boundary dramatically damps the disturbances, as shown in the lower picture of Figure 1. Chevalier et al. [4] report details of this and several similar computations. The blowing and suction is the numerical solution to a nonlinear optimization problem that minimizes the disturbances in the domain over a space of admissible controls. The admissible controls are boundary conditions with no more regularity a priori than being square-integrable functions on a portion of the lower boundary and during a finite time interval. This is a weaker regularity requirement on the boundary condition than needed for weak solutions of the Navier–Stokes equations.

The same regularity concern is an issue also for simpler problems that are easier to analyze. Consider, for instance, the following *inverse problem* for the Poisson equation (1). Given a function z defined in a subdomain $\omega \subset \Omega$, find the boundary condition g that yields $u = z$ in ω. Thinking of (1) as a model for steady heat conduction in a homogeneous, isotropic solid, the inverse problem consists of estimating the temperature g on the boundary given measurements in the interior (in ω).

The inverse problem above is only solvable for a very restricted class of *targets* z. Perhaps the easiest way of getting around this restriction is to solve a linear least-squares problem and minimize the *objective function*

$$J(g) = \frac{\epsilon}{2}\int_\Gamma g^2\,d\Gamma + \frac{1}{2}\int_\omega (u-z)^2\,dx,$$

where $\epsilon > 0$ is a (Tikhonov) regularization parameter, included to prevent g from becoming unbounded. The classical exposition of optimal control problems of this sort is the book by Lions [14]. A newer review by Glowinski and Lions [9] covers also numerical aspects.

To minimize J among all $g \in L^2(\Gamma)$, u needs to be well defined and square-integrable for each $g \in L^2(\Gamma)$. However, the standard variational form (2) of the Poisson equation requires also the derivatives of u to be elements in $L^2(\Omega)$, a property that does not hold for all $g \in L^2(\Omega)$. Including also derivatives (possibly fractional) of g along the boundary in the regularization term of J fixes this problem. However, the derivatives of g complicate a numerical solution of the control problem and introduce an extra *smoothing*, which may be unwanted, of the g that minimizes J.

There are also other reasons to prefer L^2 norms. For instance, for studies of stability and transition in fluid mechanics, the customary measure of the "size" of velocity quantities is expressed as L^2-like norms, because of the connection to the kinetic energy of the fluid (Schmid and Henningson [16]).

3. Preliminaries.

3.1. Notation, function spaces. Consider an open, bounded, and connected domain Ω in $\mathbb{R}^2$ or $\mathbb{R}^3$ with a Lipschitz boundary Γ; that is, the boundary is locally the graph of a Lipschitz function (for details see Definition 1.2.1.1 in Grisvard [11], for instance). We denote by $H^s(\Omega)$ the Sobolev space of order s on Ω. When s is a nonnegative integer, $H^s(\Omega)$ is the space in which each function and all its (weak) partial derivatives up to order s are square-integrable over Ω. We use the convention $H^0(\Omega) = L^2(\Omega)$ and $H^0(\Gamma) = L^2(\Gamma)$. Introducing a norm containing integrals over the domain, as in Definition 1.2.1 in Grisvard [12], generalizes the definition of $H^s(\Omega)$ to any real positive s. An alternative generalization uses interpolation of Hilbert spaces, as in section 2 of Chapter 1 in Lions and Magenes [15, Volume 1]. Brenner and Scott [3, Theorem 12.2.7] provide a proof that the spaces generated in these two ways are equivalent when the boundary is Lipschitz.

The *trace* γv of a function $v \in H^s(\Omega)$ generalizes to Sobolev spaces the *restriction* $v|_\Gamma$ of a smooth function v to the boundary. Unfortunately, the presence of "edges" and "corners" on a nonsmooth boundary complicates the trace concept compared to the case when the boundary is smooth. Nevertheless, it follows from Theorem 1.5.1.2 in Grisvard [11] that for $s \in (1/2, 1]$, each function v in $H^s(\Omega)$ has a well-defined trace γv in the Sobolev space $H^{s-1/2}(\Gamma)$, and that there exists a $C > 0$ such that

$$\|\gamma v\|_{s-1/2,\Gamma} \le C\|v\|_s \qquad \forall v \in H^s(\Omega). \tag{4}$$

Expression (4) uses the notation $\|\cdot\|_{s,\Gamma}$ for norms on $H^s(\Gamma)$. Analogously to $H^s(\Omega)$, integrals over the Lipschitz boundary Γ define a norm on $H^s(\Gamma)$ as long as $s \in [0, 1]$ (section 1.3.3 in Grisvard [11]). Restricting the domain of integration, we may also define norms $\|\cdot\|_{s,\Gamma_i}$ on open subsets Γ_i of Γ.

The closure of $C_0^\infty(\Omega)$, the infinitely differentiable functions with compact support in Ω, with respect to the norm in $H^s(\Omega)$ forms a subspace denoted $H_0^s(\Omega)$. In

particular it holds that

$$H_0^1(\Omega) = \left\{ v \mid v \in H^1(\Omega), \gamma v = 0 \right\};$$

that is, $H_0^1(\Omega)$ is the subspace of functions in $H^1(\Omega)$ with zero trace.

Negative norms are defined by

$$\|v\|_{-s} = \sup_{w \in H_0^s(\Omega)\setminus\{0\}} \frac{1}{\|w\|_s} \int_\Omega vw \, dx, \qquad s > 0. \tag{5}$$

This norm can be used to define $H^{-s}(\Omega)$, a space of distributions on Ω strictly larger than $L^2(\Omega)$ (for instance, the space $H^{-1}(\Omega)$ can then be identified with the dual space of $H_0^1(\Omega)$). However, we will need the norm (5) only for estimates of functions $v \in L^2(\Omega)$.

The "dual" to definition (5),

$$\|w\|_s = \sup_{v \in L^2(\Omega))\setminus\{0\}} \frac{1}{\|v\|_{-s}} \int_\Omega vw \, dx, \tag{6}$$

holds for any $w \in H_0^s(\Omega)$. Yosida [18, Chapter III, section 10] provides a detailed proof for $s = 1$, but the arguments are unchanged for any $s > 0$. From definition (6) one immediately obtains the Cauchy–Schwarz-like inequality

$$\int_\Omega vw \, dx \leq \|v\|_{-s} \|w\|_s. \tag{7}$$

Similarly,

$$\|g\|_{-s,\Gamma_i} = \sup_{h \in H_0^s(\Gamma_i)\setminus\{0\}} \frac{1}{\|h\|_{s,\Gamma_i}} \int_{\Gamma_i} gh \, d\Gamma \tag{8}$$

defines negative norms on open subsets Γ_i of Γ. Again, we will apply this norm only on functions $g \in L^2(\Gamma_i)$. Let $g \in L^2(\Gamma)$ and $h \in C_0^\infty(\Gamma_i) \setminus \{0\}$ be given. Extending h by zero on $\Gamma \setminus \Gamma_i$, we see that

$$\frac{1}{\|h\|_{s,\Gamma_i}} \int_{\Gamma_i} gh \, d\Gamma = \frac{1}{\|h\|_{s,\Gamma}} \int_\Gamma gh \, d\Gamma.$$

Noting that the extended h is in $H_0^s(\Gamma_i)$ as well as in $H_0^s(\Gamma)$, and taking supremum, it follows that

$$\|g\|_{-s,\Gamma_i} \leq \|g\|_{-s,\Gamma}. \tag{9}$$

Throughout the following, C denotes a positive constant, independent of the choice of functions and, later, of the mesh parameter h. However, adhering to a customary abuse of notation, the actual value of C may change, even within the same chain of inequalities.

3.2. Regularity of the Poisson problem with homogeneous boundary conditions. Let Ω be a polyhedral domain in $\mathbb{R}^3$ or a polygonal domain in $\mathbb{R}^2$. We require the domain to be Lipschitz, which excludes domains with slits. Given $v \in L^2(\Omega)$, there is a unique $z \in H_0^1(\Omega)$ such that

$$\int_\Omega \nabla z \cdot \nabla w \, dx = \int_\Omega vw \, dx \qquad \forall w \in H_0^1(\Omega). \tag{10}$$

The regularity properties of solutions to (10) are crucial in the development below. In fact, the possibility of defining the very weak solutions is a *consequence* of the fact that the regularity is better than merely $z \in H_0^1(\Omega)$.

Indeed, if the boundary is smooth, the additional regularity $z \in H^2(\Omega)$ holds. This is still true for polygonal or polyhedral boundaries if the domain is convex. The regularity is reduced, however, in the vicinity of nonconvex portions of polygonal or polyhedral boundaries. Grisvard [12] proves precise regularity results (Theorem 2.4.3 for the two-dimensional case and Corollary 2.6.7 for the three-dimensional case), stating that there exists an $\epsilon \in (0, 1/2]$, which depends on the shape of the domain, such that solutions to (10) are actually in $H^{3/2+\epsilon}(\Omega)$. The following estimate will be needed.

THEOREM 3.1. *There exist an* $\epsilon \in (0, 1/2]$ *and a* $C > 0$ *such that the solution* $z \in H_0^1(\Omega)$ *to* (10) *satisfies*

$$\|z\|_{3/2+\epsilon-s} \le C\|v\|_{-s} \qquad \forall v \in L^2(\Omega) \tag{11}$$

for each $s \in [0, 1]$.

Proof. By the regularity result quoted above, the closed-graph theorem yields that there exists an $\epsilon \in (0, 1/2]$ such that

$$\|z\|_{3/2+\epsilon} \le C\|v\|_0 \qquad \forall v \in L^2(\Omega). \tag{12}$$

Using the notation

$$\| \, |\nabla w| \, \|_0^2 = \int_\Omega |\nabla w|^2 \, dx,$$

(10) implies that

$$\frac{1}{\| \, |\nabla w| \, \|_0} \int_\Omega \nabla z \cdot \nabla w \, dx = \frac{1}{\| \, |\nabla w| \, \|_0} \int_\Omega vw \, dx$$

for each nonzero $w \in H_0^1(\Omega)$. Taking the supremum yields that

$$\begin{aligned} \|z\|_{1/2+\epsilon} &\le C\|z\|_1 \le C\| \, |\nabla z| \, \|_0 \\ &= C \sup_{w \in H_0^1(\Omega)\setminus\{0\}} \frac{1}{\| \, |\nabla w| \, \|_0} \int_\Omega \nabla z \cdot \nabla w \, dx \\ &= C \sup_{w \in H_0^1(\Omega)\setminus\{0\}} \frac{1}{\| \, |\nabla w| \, \|_0} \int_\Omega vw \, dx \le C\|v\|_{-1} \qquad \forall v \in L^2(\Omega), \end{aligned} \tag{13}$$

where the second and the last inequality follow from the fact that the seminorm $\| \, |\nabla z| \, \|_0$ is equivalent to $\|z\|_1$ for $z \in H_0^1(\Omega)$. Estimates (12) and (13) imply that the linear mapping $v \mapsto z$ is bounded from $L^2(\Omega)$ into $H^{3/2+\epsilon}$ as well as from H^{-1} into $H^{1/2+\epsilon}(\Omega)$. Estimate (11) then follows by operator interpolation of the mapping $v \mapsto z$. ∎

We will also need expressions for the *boundary flux* associated with the solution z to (10) and the regularity properties of the boundary flux. Let us first assume full elliptic regularity, that is, $z \in H^2(\Omega) \cap H_0^1(\Omega)$. Integration by parts of the product $-\phi\Delta z$ then yields that the boundary flux $\partial z/\partial n$ satisfies

$$-\int_\Gamma \frac{\partial z}{\partial n} \phi \, d\Gamma = \int_\Omega v\phi \, dx - \int_\Omega \nabla z \cdot \nabla \phi \, dx \qquad \forall \phi \in H^1(\Omega). \tag{14}$$

If, moreover, the boundary is smooth, the boundary flux is an element in $H^{1/2}(\Gamma)$. On polyhedral boundaries, however, the discontinuity of boundary normals complicates the definition of boundary-flux spaces. Nevertheless, the integration-by-parts property (14) holds also for Lipschitz domains in $\mathbb{R}^n$ as long as $z \in H^2(\Omega) \cap H_0^1(\Omega)$; it follows from Proposition 5.1.6 in Brenner and Scott [3], for instance. The following theorem proves a similar expression for less regular z.

THEOREM 3.2. *There are an $\epsilon \in (0, 1/2]$ and a $C > 0$ such that, associated with any $v \in L^2(\Omega)$ and corresponding solution $z \in H_0^1(\Omega)$ to (10), there exists a unique $\lambda \in L^2(\Gamma)$ satisfying*

$$-\int_\Gamma \lambda\phi \, d\Gamma = \int_\Omega v\phi \, dx - \int_\Omega \nabla z \cdot \nabla\phi \, dx \qquad \forall \phi \in H^1(\Omega) \tag{15}$$

and the estimates

$$\begin{aligned} \|\lambda\|_{0,\Gamma} &\le C\|v\|_0, \\ \|\lambda\|_{\epsilon-s,\Gamma_i} &\le C\|v\|_{-s} \qquad \text{for } i = 1, \dots, I \text{ and } \forall s \in [0, \epsilon). \end{aligned} \tag{16}$$

Proof. By assumption, the boundary of Ω can be written $\Gamma = \cup_{i=1}^I \overline{\Gamma}_i$, where each (open and bounded) Γ_i is a planar polygon or a line segment embedded in $\mathbb{R}^3$ and $\mathbb{R}^2$, respectively. Let n_i denote the (constant) outward-directed unit normal associated with each polygonal surface (or line segment) Γ_i. By Theorem 3.1, we know that there is an $\epsilon \in (0, 1/2]$ such that, for each $v \in L^2(\Omega)$ supplied to (10), the solution satisfies $z \in H^{3/2+\epsilon-s}$ $\forall s \in [0, 1]$. Differentiation is a continuous operator from $H^\alpha(\Omega)$ into $H^{\alpha-1}(\Omega)$ as long as $\alpha \neq 1/2$ [11, Theorem 1.4.4.6]. Thus, for each $i = 1, \dots, I$,

$$\frac{\partial z}{\partial n_i} = n_i \cdot \nabla z$$

resides in $H^{1/2+\epsilon-s}(\Omega)$ since $3/2 + \epsilon - s \neq 1/2$ for any $\epsilon \in (0, 1/2]$ and $s \in [0, 1]$. By further restricting s, we can apply the trace theorem for Lipschitz boundaries (Grisvard [11, Theorem 1.5.1.2]) to obtain the bounds, for $s \in [0, \epsilon)$, $i = 1, \dots, I$,

$$\left\| \frac{\partial z}{\partial n_i} \right\|_{\epsilon-s,\Gamma} \le C \left\| \frac{\partial z}{\partial n_i} \right\|_{1/2+\epsilon-s} \le C \, \|z\|_{3/2+\epsilon-s} \,, \tag{17}$$

where the second inequality follows from the above-mentioned continuity of differentiation.

Now, for $i = 1, \dots, I$, we define $\lambda_i \in L^2(\Gamma)$ as

$$\lambda_i = \begin{cases} \dfrac{\partial z}{\partial n_i} & \text{on } \Gamma_i, \\ 0 & \text{on } \Gamma \setminus \Gamma_i, \end{cases}$$

and $\lambda \in L^2(\Gamma)$ as

$$\lambda = \sum_{i=1}^I \lambda_i. \tag{18}$$

The definition of λ, together with inequality (17) and Theorem 3.1, yields estimate (16).

Noting that λ in effect is a weak representation for $\partial z/\partial n$, we will prove the integration-by-parts formula (15) by approximating z by smooth functions. Indeed, since $C_0^\infty(\Omega)$ is dense in $H^{3/2+\epsilon}(\Omega)\cap H_0^1(\Omega)$, there exists a sequence $\{\zeta_n\}_{n=1}^\infty \subset C_0^\infty(\Omega)$ such that

$$\zeta_n \to z \qquad \text{in } H^{3/2+\epsilon}(\Omega) \tag{19}$$

as $n \to \infty$. It follows from inequality (17) that

$$\frac{\partial \zeta_n}{\partial n_i} \to \lambda_i \qquad \text{in } L^2(\Gamma_i) \tag{20}$$

as $n \to \infty$.

Forming $-\Delta\zeta_n$, multiplying by $w \in H_0^1(\Omega)$, integrating by parts, and noting that strong convergence in $H^{3/2+\epsilon}(\Omega) \cap H_0^1(\Omega)$ implies convergence in $H_0^1(\Omega)$, it follows from (19) and (10) that

$$\begin{aligned} \int_\Omega w(-\Delta\zeta_n)\,dx &= \int_\Omega \nabla w \cdot \nabla\zeta_n\,dx \to \int_\Omega \nabla w \cdot \nabla z\,dx \\ &= \int_\Omega wv\,dx \qquad \forall w \in H_0^1(\Omega) \end{aligned} \tag{21}$$

as $n \to \infty$. Since $H_0^1(\Omega)$ is dense in $L^2(\Omega)$, expression (21) yields that

$$-\Delta\zeta_n \to v \text{ weakly in } L^2(\Omega). \tag{22}$$

Let $\phi \in H^1(\Omega)$. Integration by parts yields

$$\begin{aligned} \int_\Omega \phi(-\Delta\zeta_n)\,dx &= -\int_\Gamma \frac{\partial\zeta_n}{\partial n}\phi\,d\Gamma + \int_\Omega \nabla\phi\cdot\nabla\zeta_n\,dx \\ &= -\sum_{i=1}^I \int_{\Gamma_i} \frac{\partial\zeta_n}{\partial n_i}\phi\,d\Gamma + \int_\Omega \nabla\phi\cdot\nabla\zeta_n\,dx. \end{aligned} \tag{23}$$

Letting $n \to \infty$, it follows from (18), (20), (21), and (22) that expression (23) converges to

$$\int_\Omega \phi v\,dx = -\int_\Gamma \lambda\phi\,d\Gamma + \int_\Omega \nabla\phi\cdot\nabla z\,dx,$$

which proves that the λ defined in expression (18) satisfies expression (15). Finally, since λ depends linearly on $v \in L^2(\Omega)$, estimate (16) also provides uniqueness of λ for each given $v \in L^2(\Omega)$. ∎

3.3. Approximation properties. Let us now triangulate the polygonal or polyhedral domain Ω and introduce a mesh parameter $h > 0$ that characterizes the triangulation. We assume nondegenerate meshes [3, Def. 4.4.13]; that is, there is a limit to how "thin" the tetrahedral may become as the mesh is refined. Denote by V^h the space of continuous functions that are linear on each triangle or tetrahedron in the mesh, and denote by V_0^h the subspace of functions in V^h vanishing on Γ. We have $V^h \subset H^1(\Omega)$ and $V_0^h \subset H_0^1(\Omega)$. The restriction to Γ of functions in V^h is denoted γV^h. We also define M^h as the space of all functions $v^h \in V^h$ that vanish at each mesh point in the strict interior of the domain. We have that $V^h = M^h \oplus V_0^h$; that

is, each function in V^h is the sum of unique functions in M^h and V_0^h. Also note that each function $g_h \in \gamma V^h$ uniquely extends to a function $\widehat{g}_h \in M^h$ that equals g_h at the boundary but vanishes at all nodes in Ω. This extension property is useful when solving inhomogeneous boundary-value problems: Given an approximation $g_h \in \gamma V^h$ of the boundary data g, extend g_h to $\widehat{g}_h \in M^h$, write the solution $u_h \in V_h$ as $u_h = u_{h,0} + \widehat{g}_h$, where $u_{h,0} \in V_0^h$, and solve for $u_{h,0}$.

An interpolation operator Π_h from $H^s(\Omega)$ into V^h characterizes the approximation properties of V^h. If $s > d/2$, where d is the space dimension, it follows from the Sobolev embeddings that Π_h can simply be chosen as the linear interpolator of function values at the nodes of the triangulation. However, we need to consider small values of s, so pointwise values may not be well defined. It is therefore appropriate to choose the Scott and Zhang interpolator [17], which uses a local averaging to generate nodal values. This interpolator yields optimal-order estimates, and the averaging is constructed to preserve piecewise-polynomial boundary conditions, a property that Lemma 5.3 exploits.

The following approximation properties hold for V^h: There exists a constant $C > 0$ such that, for all $h > 0$,

$$\|v - \Pi_h v\|_1 \leq Ch^s \|v\|_{1+s} \qquad \forall v \in H^{1+s}(\Omega),\ s \in [0,1], \tag{24a}$$

$$\|v - \Pi_h v\|_0 \leq Ch^s \|v\|_s \qquad \forall v \in H^s(\Omega),\ s \in [0,2]. \tag{24b}$$

Standard textbooks, such as Ciarlet [5], prove these properties for integral values of s. Scott and Zhang [17] supply a proof for the particular case of the above-mentioned Π_h. Operator-interpolation arguments, discussed by Brenner and Scott [3, Chapter 12], for instance, extend the estimates to intermediate real numbers s.

We also need to approximate functions defined on the boundary. Recall that the domain is polyhedral or polygonal, so $\Gamma = \cup_{i=1}^I \overline{\Gamma}_i$, where each Γ_i is an open planar polygon or an open line segment that does not overlap any other Γ_i. The space $\gamma_i V^h$ of traces of function in V^h on Γ_i is a space of continuous, piecewise-linear functions on the triangles (or intervals) of Γ_i. We may thus define an interpolation operator $\Pi_h^{\gamma_i}$ from $H^s(\Gamma_i)$ into $\gamma_i V^h$ with properties analogous to Π_h,

$$\|g - \Pi_h^{\gamma_i} g\|_{0,\Gamma_i} \leq Ch^s \|g\|_{s,\Gamma_i} \qquad \forall g \in H^s(\Gamma_i),\ s \in [0,2]. \tag{25}$$

Another type of approximation in V^h, γV^h, and $\gamma_i V^h$ are the *L^2-projections*, that is, the functions $P_h v \in V^h$, $P_h^\gamma g \in \gamma V^h$, and $P_h^{\gamma_i} g \in \gamma_i V^h$ satisfying

$$\int_\Omega P_h v\, w_h \, dx = \int_\Omega v w_h \, dx \qquad \forall w_h \in V^h, \tag{26a}$$

$$\int_\Gamma P_h^\gamma g\, \varphi_h \, d\Gamma = \int_\Gamma g \varphi_h \, d\Gamma \qquad \forall \varphi_h \in \gamma V^h, \tag{26b}$$

$$\int_{\Gamma_i} P_h^{\gamma_i} g\, \varphi_h \, d\Gamma = \int_{\Gamma_i} g \varphi_h \, d\Gamma \qquad \forall \varphi_h \in \gamma_i V^h,\ i = 1, \ldots, I, \tag{26c}$$

which are well defined for each $v \in L^2(\Omega)$ and $g \in L^2(\Gamma)$. The L^2-projections produce the discrete functions that minimize the L^2 error.

For any $g \in L^2(\Gamma_i)$ and $\psi \in H_0^s(\Gamma_i)$, we have

$$\begin{aligned}(27)\quad \int_{\Gamma_i} (g - P_h^{\gamma_i} g)\psi \, d\Gamma &= \int_{\Gamma_i} (g - P_h^{\gamma_i} g)(\psi - P_h^{\gamma_i}\psi)\, d\Gamma \\ &\le \|g - P_h^{\gamma_i} g\|_{0,\Gamma_i} \|\psi - P_h^{\gamma_i}\psi\|_{0,\Gamma_i} \le \|g - \Pi_h^{\gamma_i} g\|_{0,\Gamma_i} \|\psi - \Pi_h^{\gamma_i}\psi\|_{0,\Gamma_i} \\ &\le C\|g\|_{0,\Gamma_i} h^s \|\psi\|_{s,\Gamma_i} \quad \forall s \in [0,2],\end{aligned}$$

where the first equality follows from definition (26c), the second inequality from the fact that the $L^2(\Gamma_i)$-projection is optimal, and the third from estimate (25). Dividing expression (27) by $\|\psi\|_{s,\Gamma_i}$ and taking the supremum over all $\psi \in H_0^s(\Gamma_i) \setminus \{0\}$ yields, by definition (5),

$$\|g - P_h^{\gamma_i} g\|_{-s,\Gamma_i} \le C h^s \|g\|_{0,\Gamma_i} \qquad \forall s \in [0,2]. \tag{28}$$

We will also need the inverse estimate

$$\|v_h\|_{s,\Gamma} \le C h^{-s} \|v_h\|_{0,\Gamma}, \qquad s \in [0,1]. \tag{29}$$

In contrast to an approximation estimate like (25), the inverse estimate requires quasi-uniform mesh refinements [3, Definition 4.4.13]. That is, the quotient between the largest and smallest diameter of any triangle or line segment should stay uniformly bounded as the mesh is refined. Brenner and Scott [3, Theorem 4.5.11], for instance, prove inverse estimates for integral s and domains in $\mathbb{R}^n$. Local bi-Lipschitz change of variables, partition of unity, and operator interpolation extend these estimates to estimate (29).

4. The variational form. We will make precise the idea of a solution to the Poisson equation based on the Lions-type variational expression (3). Let us define a linear form $G : L^2(\Omega) \to \mathbb{R}$ by the following procedure.

1. Given an element $v \in L^2(\Omega)$, find $z \in H_0^1(\Omega)$ such that

$$\int_\Omega \nabla z \cdot \nabla w \, dx = \int_\Omega v w \, dx \qquad \forall w \in H_0^1(\Omega). \tag{30}$$

2. From v and z, find $\lambda \in L^2(\Gamma)$ such that

$$-\int_\Gamma \lambda \phi \, d\Gamma = \int_\Omega v\phi \, dx - \int_\Omega \nabla z \cdot \nabla \phi \, dx \qquad \forall \phi \in H^1(\Omega). \tag{31}$$

3. Set, for given $g \in L^2(\Gamma)$ and $f \in L^2(\Omega)$, uniquely associated with each G,

$$G(v) = -\int_\Gamma g\lambda \, d\Gamma + \int_\Omega f z \, dx. \tag{32}$$

THEOREM 4.1. *The form G is a bounded linear functional on $L^2(\Omega)$.*

Proof. From Theorem 3.2 it follows that λ and the boundary integral involved in the definition of G are well defined for each $g \in L^2(\Gamma)$. The form G is linear in v since λ and z are linear in v. From (30) follows the estimate

$$\|z\|_1 \le C\|v\|_{-1}. \tag{33}$$

Thus,

$$\begin{aligned}(34)\quad |G(v)| &\le \|g\|_{0,\Gamma} \|\lambda\|_{0,\Gamma} + \|f\|_{-1}\|z\|_1 \le C\left(\|g\|_{0,\Gamma}\|\lambda\|_{0,\Gamma} + \|f\|_{-1}\|v\|_{-1}\right) \\ &\le C(\|g\|_{0,\Gamma} + \|f\|_0)\|v\|_0,\end{aligned}$$

where estimates (7), (33), and (16) are used in the first, second, and third inequality, respectively. ∎

By Theorem 4.1 and Riesz representation, the following problem thus has a unique solution:

$$\begin{aligned} &\text{Find } u \in L^2(\Omega) \text{ such that} \\ &\int_\Omega uv\,dx = G(v) \qquad \forall v \in L^2(\Omega). \end{aligned} \tag{35}$$

Problem (35) defines a weak solution to the Poisson problem (1), in which the boundary data g needs only to be square-integrable. The price to pay for the reduced regularity requirement on g is that $u \notin H^1(\Omega)$ in general and that the meaning of boundary condition $u = g$ will be weak; it will be satisfied only in a distributional sense acute a la Theorem 6.5 in Chapter 2 of Lions and Magenes [15, Volume 1].

Similar to solutions to (10), solutions to problem (35) have higher regularity than asked for.

THEOREM 4.2. *For each $f \in L^2(\Omega)$ and $g \in L^2(\partial\Omega)$ associated with definition* (32) *of G, there exists an $\epsilon \in (0, 1/2]$ so that the solution to problem* (35) *resides in $H^s(\Omega)$ for each $s \in [0, \epsilon)$.*

Proof. First, note that $H_0^s(\Omega) = H^s(\Omega)$ for $s \in (0, 1/2]$, which follows from the fact that $C_0^\infty(\Omega)$ is dense in $H^s(\Omega)$ for $s \in (0, 1/2]$ [11, Theorem 1.4.2.4]. This equivalence allows the use of expression (6) to estimate $\|u\|_s$.

To estimate the boundary-integral term in the definition (32) of G, write the $L^2(\Gamma)$-norm of λ as a sum over contributions from each polygonal surface and utilize estimate (16) in Theorem 3.2. It then follows that there exists an $\epsilon \in (0, 1/2]$ such that, for each $s \in [0, \epsilon)$,

$$\begin{aligned} \left(\int_\Gamma g\lambda\,d\Gamma\right)^2 &\le \|\lambda\|_{0,\Gamma}^2 \|g\|_{0,\Gamma}^2 = \sum_{i=1}^I \|\lambda\|_{0,\Gamma_i}^2 \|g\|_{0,\Gamma}^2 \\ &\le C \sum_{i=1}^I \|\lambda\|_{\epsilon-s,\Gamma_i}^2 \|g\|_{0,\Gamma}^2 \le C\|v\|_{-s}^2 \|g\|_{0,\Gamma}^2 \qquad \forall v \in L^2(\Omega). \end{aligned} \tag{36}$$

We also estimate the second integral in the definition (32) of G as

$$\int_\Omega fz\,dx \le \|f\|_{-1}\|z\|_1 \le \|f\|_{-1}\|z\|_{3/2+\epsilon} \le C\|f\|_{-1}\|v\|_{-s} \quad \forall v \in L^2(\Omega), \tag{37}$$

where the last inequality follows from Theorem 3.1. Equation (35), the definition (32) of G, and estimates (36) and (37) yield that, for some $\epsilon \in (0, 1/2]$,

$$\int_\Omega uv\,dx \le C\|v\|_{-s}(\|g\|_{0,\Gamma} + \|f\|_{-1}) \qquad \forall v \in L^2(\Omega),\ \forall s \in [0, \epsilon). \tag{38}$$

Dividing expression (38) by $\|v\|_{-s}$, taking the supremum over all $v \in L^2(\Omega) \setminus \{0\}$, and using property (6) yields the conclusion. ∎

5. Numerical approximations. Recall the standard Galerkin approximation of the Poisson problem with inhomogeneous boundary data: If $g_h \in \gamma V_h$ approximates the boundary data, we solve the problem:

$$\begin{aligned} &\text{Find } u_h \in V^h \text{ such that } u_h|_\Gamma = g_h \text{ and} \\ &\int_\Omega \nabla u_h \cdot \nabla v_h\,dx = \int_\Omega fv_h\,dx \qquad \forall v_h \in V_0^h. \end{aligned} \tag{39}$$

The error in this approximation depends on how the boundary data is approximated. For *homogeneous* boundary data, $g_h = 0$, standard error estimates and the regularity according to Theorem 3.1 yield that there exists an $\epsilon \in (0, 1/2]$ such that

$$\|u_h - u\|_1 \leq Ch^{1/2+\epsilon}\|f\|_0, \tag{40}$$

where the estimate holds for $\epsilon = 1/2$ when the domain is convex.

Since $V^h \subset L^2(\Omega)$, we can apply a Galerkin approximation to problem (35):

$$\begin{aligned} &\text{Find } \widetilde{u}_h \in V^h \text{ such that} \\ &\int_\Omega \widetilde{u}_h v_h \, dx = G(v_h) \qquad \forall v_h \in V^h. \end{aligned} \tag{41}$$

Subtracting (35) with $v = v_h$ from (41), we obtain

$$\int_\Omega (\widetilde{u}_h - u) v_h \, dx = 0 \qquad \forall v_h \in V^h,$$

implying that the Galerkin approximation is optimal in $L^2(\Omega)$,

$$\|\widetilde{u}_h - u\|_0 = \inf_{v_h \in V^h} \|u - v_h\|_0 \leq \|u - \Pi_h u\|. \tag{42}$$

Approximation (41) is useless as a numerical method, however, since to compute $G(v_h)$, we need the exact solutions z and λ to problems (30) and (31) for each $v_h \in V^h$. A natural alternative is to use numerical approximations z_h and λ_h instead, which pertains to a modification of G—a so-called variational crime. For this, define the linear form $G_h : L^2(\Omega) \to \mathbb{R}$ as follows:

1. Given $v \in L^2(\Omega)$, find $z_h \in V_0^h$ such that

$$\int_\Omega \nabla z_h \cdot \nabla w_h \, dx = \int_\Omega v w_h \, dx \qquad \forall w_h \in V_0^h. \tag{43}$$

2. From v and z_h, compute $\lambda_h \in \gamma V^h$ such that

$$-\int_\Gamma \lambda_h \phi_h \, d\Gamma = \int_\Omega v \phi_h \, dx - \int_\Omega \nabla z_h \cdot \nabla \phi_h \, dx \qquad \forall \phi_h \in M^h. \tag{44}$$

3. Set, given $g \in L^2(\Gamma)$ and $f \in L^2(\Omega)$,

$$G_h(v) = -\int_\Gamma g \lambda_h \, d\Gamma + \int_\Omega f z_h \, dx. \tag{45}$$

A second approximation to (35) is as follows:

$$\begin{aligned} &\text{Find } u_h \in V^h \text{ such that} \\ &\int_\Omega u_h v_h \, dx = G_h(v_h) \qquad \forall v_h \in V^h. \end{aligned} \tag{46}$$

At first glance, approximation (46) appears unreasonably costly to implement, since the computation of each component of the vector $G_h(v_h)$ requires the solution of (43) and (44)! However, a remarkable property of approximation (46), shown in Theorem 5.2, is its equivalence to the standard Galerkin approximation (39), provided that the $L^2(\Gamma)$ projection is used to approximate the inhomogeneous boundary

conditions. Thus, in practical computations, approximation (46) can be implemented as a standard Galerkin approximation combined with L^2-projections of the boundary data. The equivalence of Theorem 5.2 is a consequence of the properties of the mapping $v_h \mapsto (z_h, \lambda_h)$ involved in the definition of G_h.

LEMMA 5.1. *The mapping $v_h \mapsto (z_h, \lambda_h)$, defined by solving* (43) *and* (44)*, is bijective as a mapping $V^h \to V_0^h \times \gamma V^h$. Moreover, the functions v_h, z_h, and λ_h satisfy*

$$\int_\Omega v_h \psi_h \, dx = -\int_\Gamma \lambda_h \psi_h \, d\Gamma + \int_\Omega \nabla z_h \cdot \nabla \psi_h \, dx \qquad \forall \psi_h \in V^h. \tag{47}$$

Proof. Let $v_h \in V^h$ be given, and let $z_h \in V_0^h$ and $\lambda_h \in \gamma V^h$ be the unique solutions to (43) and (44) for $v = v_h$.

Expression (43) with $v = v_h$ can be written

$$0 = \int_\Omega v_h w_h \, dx - \int_\Omega \nabla z_h \cdot \nabla w_h \, dx \qquad \forall w_h \in V_0^h. \tag{48}$$

Adding (48) to (44) with $v = v_h$ yields

$$-\int_\Gamma \lambda_h \phi_h \, d\Gamma = \int_\Omega v_h(\phi_h + w_h) \, dx - \int_\Omega \nabla z_h \cdot \nabla(\phi_h + w_h) \, dx \tag{49}$$

for each $\phi_h \in M^h$ and each $w_h \in V_0^h$. Since $V^h = V_0^h \oplus M^h$, and since functions in V_0^h vanish on Γ, it follows that v_h, z_h, and λ_h are related through expression (47).

Conversely, let $z_h \in V_0^h$ and $\lambda_h \in \gamma V^h$ be given. Expression (47) defines an equation for v_h corresponding to a square linear system with a positive-definite matrix. Equation (47) thus has a unique solution $v_h \in V^h$. The mapping $v_h \mapsto (z_h, \lambda_h)$ is thus bijective, since the mapping itself as well as its inverse are one-to-one. ∎

With the aid of the mapping of Lemma 5.1, we can transfer between the "new" approximation (46) and the traditional (39), as follows.

THEOREM 5.2. *The function $u_h \in V^h$ is a solution to problem* (46) *if and only if*

$$u_h \in V^h \text{ such that}$$

$$\int_\Omega \nabla u_h \cdot \nabla z_h \, dx = \int_\Omega f z_h \, dx \qquad \forall z_h \in V_0^h, \tag{50a}$$

$$u_h = P_h^\gamma g \qquad \text{on } \Gamma, \tag{50b}$$

where $P_h^\gamma g$ is the $L^2(\Gamma)$-projection of g on γV^h, that is,

$$P_h^\gamma g \in \gamma V^h \text{ such that}$$

$$\int_\Gamma P_h^\gamma g \, r_h \, d\Gamma = \int_\Gamma g \, r_h \, d\Gamma \qquad \forall r_h \in \gamma V^h. \tag{51}$$

Proof. (i) Let u_h be the solution to problem (50). Let $v_h \in V^h$ be given, and compute $z_h \in V_0^h$ and $\lambda_h \in \gamma V^h$ by solving (43) and (44) with $v = v_h$. By Lemma 5.1, v_h, z_h, and λ_h are related through the expression

$$-\int_\Gamma \lambda_h \psi_h \, d\Gamma + \int_\Omega \nabla z_h \cdot \nabla \psi_h \, dx = \int_\Omega v_h \psi_h \, dx \qquad \forall \psi_h \in V^h.$$

Choosing $\psi_h = u_h$, it follows that

$$-\int_\Gamma \lambda_h u_h \, d\Gamma + \int_\Omega \nabla z_h \cdot \nabla u_h \, dx = \int_\Omega v_h u_h \, dx. \tag{52}$$

Using (50a) to replace the second term in expression (52), we obtain

$$\begin{aligned} \int_\Omega u_h v_h \, dx &= -\int_\Gamma \lambda_h u_h \, d\Gamma + \int_\Omega f z_h \, dx = -\int_\Gamma \lambda_h \, P_h^\gamma g \, d\Gamma + \int_\Omega f z_h \, dx \\ &= -\int_\Gamma \lambda_h g \, d\Gamma + \int_\Omega f z_h \, dx = G_h(v_h), \end{aligned} \tag{53}$$

where we have used (50b) in the second equality, definition (51) of $P_h^\gamma g$ in the third, and definition (45) of G_h in the fourth equality. Since $v_h \in V^h$ was arbitrary, we have shown that if u_h solves (50), it also solves (46).

(ii) Conversely, let u_h be the solution of problem (46), and let $\lambda_h \in \gamma V^h$ and $z_h \in V_0^h$ be given. By Lemma 5.1, there is a unique $v_h \in V^h$ satisfying

$$\int_\Omega v_h \psi_h \, dx = -\int_\Gamma \lambda_h \psi_h \, d\Gamma + \int_\Omega \nabla z_h \cdot \nabla \psi_h \, dx \qquad \forall \psi_h \in V^h. \tag{54}$$

Choosing $\psi_h = u_h$, we find

$$-\int_\Gamma \lambda_h u_h \, d\Gamma + \int_\Omega \nabla z_h \cdot \nabla u_h \, dx = \int_\Omega v_h u_h \, dx. \tag{55}$$

Since u_h is a solution of problem (46), the right-hand side of expression (55) satisfies

$$\int_\Omega v_h u_h \, dx = -\int_\Gamma g \widehat{\lambda}_h \, d\Gamma + \int_\Omega f \widehat{z}_h \, dx, \tag{56}$$

where $\widehat{z}_h$ and $\widehat{\lambda}_h$ are the solutions to (43) and (44) with $v = v_h$. However, since by Lemma 5.1, $\widehat{z}_h$ and $\widehat{\lambda}_h$ are uniquely defined by v_h, we have $\widehat{z}_h = z_h$ and $\widehat{\lambda}_h = \lambda_h$. Substituting expression (56) into expression (55), we obtain

$$\begin{aligned} \int_\Omega \nabla u_h \cdot \nabla z_h \, dx &= \int_\Gamma \lambda_h (u_h - g) \, d\Gamma + \int_\Omega f z_h \, dx \\ &= \int_\Gamma \lambda_h (u_h - P_h^\gamma g) \, d\Gamma + \int_\Omega f z_h \, dx, \end{aligned}$$

where in the last equality we introduce $P_h^\gamma g \in \gamma V^h$ as the solution of (51). Since the choices of z_h and λ_h were arbitrary, it follows that both (50a) and the boundary condition (50b) must be satisfied. □

The difference between problems (41) and (46) lies in the use of an approximated linear form G_h in problem (46). It is therefore crucial to analyze the error that the use of G_h introduces. Lemma 5.4, which estimates $(G - G_h)$, needs the following discrete extension result.

LEMMA 5.3. *There exists a $C > 0$, independent of $h > 0$, such that for each $g_h \in \gamma V^h$, a $u_h \in V^h$ exists satisfying $u_h|_\Gamma = g_h$ and*

$$\|u_h\|_1 \le C \|g_h\|_{1/2,\Gamma}.$$

Proof. Let $g_h \in \gamma V^h$ be given. The functions in γV^h are continuous and piecewise linear on the boundary, so $\gamma V^h \subset H^{1/2}(\Gamma)$ (in fact, $\gamma V^h \subset H^1(\Gamma)$). By Theorem 1.5.1.3 of Grisvard [11], the trace map $\gamma : H^1(\Omega) \to H^{1/2}(\Omega)$ has a right continuous inverse E. The Scott and Zhang interpolator Π_h, discussed in section 3.3, continuously maps functions in $H^1(\Omega)$ into V^h. Composing Π_h and E, we define $u_h \in V^h$ such that $u_h = \Pi_h E g_h$. Note that $\gamma u_h = g_h$ since the Scott and Zhang interpolator preserves piecewise-polynomial boundary conditions. Moreover, since both E and Π_h are continuous, we find that

$$\|u_h\|_1 \leq C\|g_h\|_{1/2,\Gamma}. \qquad \square$$

Remark 1. Similar results are reported in the estimate (5.5) of Scott and Zhang [17] and in Lemma 11 of Gunzburger and Hou [13].

LEMMA 5.4. *Assume a quasi-uniform triangulation, characterized by the mesh parameter h, of the polyhedral (or polygonal) domain Ω having a Lipschitz boundary. There are an $\epsilon \in (0, 1/2]$ and a $C > 0$ such that, given $g \in L^2(\Gamma)$ and $f \in L^2(\Omega)$, the linear forms G and G_h, defined in expressions* (32) *and* (45)*, satisfy, for each $h > 0$,*

$$(G - G_h)(v) \leq C\left(h^\epsilon \|g\|_{0,\Gamma} + h^{1/2+\epsilon}\|f\|_{-1}\right)\|v\|_0 \qquad \forall v \in L^2(\Omega).$$

Proof. Let $v \in L^2(\Omega)$ be given, and let z and λ be the solutions to (30) and (31) associated with the given v. Likewise, let z_h and λ_h be the solutions to (43) and (44) associated with v. By definitions (32) and (45), we find that

$$\begin{aligned}(G - G_h)(v) &= -\int_\Gamma g(\lambda - \lambda_h)\,d\Gamma + \int_\Omega f(z - z_h)\,dx \\ &= -\int_\Gamma (\lambda - \lambda_h)P_h^\gamma g\,d\Gamma - \int_\Gamma \lambda(g - P_h^\gamma g)\,d\Gamma + \int_\Omega f(z - z_h)\,dx,\end{aligned} \tag{57}$$

introducing $P_h^\gamma g$, the $L^2(\Gamma)$ projection of g on γV^h, defined as in (26b).

We will estimate each of the terms in the right-hand side of expression (57), starting with the first. Let $\varphi_h \in \gamma V^h$ be given. Choose $\phi_h \in V_h$ so that $\phi_h|_\Gamma = \varphi_h$ and so that the estimate of Lemma 5.3 is satisfied. From (31) and (44) it follows that

$$\begin{aligned}-\int_\Gamma (\lambda - \lambda_h)\,\varphi_h\,d\Gamma &= -\int_\Omega \nabla(z - z_h)\cdot\nabla\phi_h\,dx \\ &\leq \|z_h - z\|_1\|\phi_h\|_1 \leq C\|z_h - z\|_1\|\varphi_h\|_{1/2,\Gamma} \\ &\leq C\|z_h - z\|_1\, h^{-1/2}\|\varphi_h\|_{0,\Gamma} \leq Ch^{1/2+\epsilon}\|v\|_0\, h^{-1/2}\|\varphi_h\|_{0,\Gamma} \\ &= Ch^\epsilon\|v\|_0\|\varphi_h\|_{0,\Gamma},\end{aligned} \tag{58}$$

where the second inequality follows from Lemma 5.3 and the third from inverse estimates (29) (the inverse estimate needs the assumption of quasi-uniform mesh refinements); expression (40) yields the existence of an $\epsilon \in (0, 1/2]$ such that the fourth inequality holds.

Next we estimate the second term in the right-hand side of expression (57) as

follows:

$$\begin{aligned}\int_\Gamma \lambda(g - P_h^\gamma g)\,d\Gamma &= \sum_{i=1}^I \int_{\Gamma_i} \lambda(g - P_h^\gamma g)\,d\Gamma \le \sum_{i=1}^I \|\lambda\|_{\epsilon,\Gamma_i}\|g - P_h^\gamma g\|_{-\epsilon,\Gamma_i} \\ &\le C\|v\|_0 \sum_{i=1}^I \|g - P_h^\gamma g\|_{-\epsilon,\Gamma_i} \le C\|v\|_0\|g - P_h^\gamma g\|_{-\epsilon,\Gamma} \\ &\le Ch^\epsilon \|v\|_0\|g\|_{0,\Gamma},\end{aligned} \tag{59}$$

where the second, third, and fourth inequalities use estimates (16), (9), and (28), respectively. The third term in the right-hand side of expression (57) is estimated by expression (40),

$$\int_\Omega f(z - z_h)\,dx \le \|f\|_{-1}\|z - z_h\|_1 \le Ch^{1/2+\epsilon}\|f\|_{-1}\|v\|_0. \tag{60}$$

Substituting estimates (58) (with $\varphi_h = P_h^\gamma g$), (59), and (60) into expression (57) yields the required estimate

$$\begin{aligned}(G - G_h)(v) &\le C\left(h^\epsilon \|P_h^\gamma g\|_{0,\Gamma} + h^\epsilon\|g\|_{0,\Gamma} + h^{1/2+\epsilon}\|f\|_{-1}\right)\|v\|_0 \\ &\le C\left(h^\epsilon\|g\|_{0,\Gamma} + h^{1/2+\epsilon}\|f\|_{-1}\right)\|v\|_0,\end{aligned}$$

where in the second inequality we have used the bound $\|P_h^\gamma g\|_{0,\Gamma} \le \|g\|_{0,\Gamma}$ that holds for an L^2-projection. ∎

The final result of this article is that the solution to (46) converges to the solution of (35) at a rate that depends, through ϵ, on the shape of the domain, where $\epsilon = 1/2$ corresponds to a convex domain.

THEOREM 5.5. *Assume a quasi-uniform triangulation, characterized by the mesh parameter h, of the polyhedral (or polygonal) domain Ω having a Lipschitz boundary. There are an $\epsilon \in (0, 1/2]$ and a $C > 0$ such that, given $g \in L^2(\Gamma)$ and $f \in L^2(\Omega)$, the solutions u and u_h to problems* (35) *and* (46) *satisfy, for each $h > 0$,*

$$\|u - u_h\|_0 \le C\left(h^s\|u\|_s + h^\epsilon\|g\|_{0,\Gamma} + h^{1/2+\epsilon}\|f\|_{-1}\right)$$

for each $s \in [0, \epsilon)$.

Proof. The solution error may be decomposed as $u - u_h = (u - \widetilde{u}_h) + (\widetilde{u}_h - u_h)$, where $\widetilde{u}$ is the solution to problem (41). Thus,

$$\|u - u_h\|_0 \le \|u - \widetilde{u}_h\| + \|\widetilde{u}_h - u_h\|. \tag{61}$$

By estimate (42), approximation property (24b), and Theorem (4.2), there exists an $\epsilon \in (0, 1/2]$ so that

$$\|u - \widetilde{u}_h\|_0 \le Ch^s\|u\|_s \qquad \forall s \in [0, \epsilon). \tag{62}$$

Equations (41) and (46) yield that

$$\int_\Omega (\widetilde{u}_h - u_h)v_h\,dx = G(v_h) - G_h(v_h) \qquad \forall v_h \in V^h,$$

so choosing $v_h = \widetilde{u}_h - u_h$ means that

$$\|\widetilde{u}_h - u_h\|_0^2 = (G - G_h)(\widetilde{u}_h - u_h). \tag{63}$$

Using Lemma 5.4 in expression (63) implies that

$$\|\widetilde{u}_h - u_h\|_0 \leq C \left(h^{\epsilon} \|g\|_{0,\Gamma} + h^{1/2+\epsilon} \|f\|_{-1} \right). \tag{64}$$

Substituting estimates (62) and (64) into expression (61) provides the required estimate. ∎

Remark 2. Theorem 5.5 only provides convergence rates for boundary data in $L^2(\Gamma)$. By the equivalence proven in Theorem 5.2, smoother data will improve the convergence rate, since error estimates for the standard approach then apply. Fix, Gunzburger, and Peterson [6], French and King [7, 8], and Bramble and King [2] prove various error estimates that apply for smoother data.

Acknowledgments. I am grateful to my former advisor Roland Glowinski, who once told his surprised student that the ordinary finite-element approximation converges, although in a weaker sense, also for rough data. This comment sparked an interest, eventually leading to the investigations reported here. For careful readings of the manuscript, which uncovered many issues in need of improvement, I owe much to Ridgway Scott. I also thank Max Gunzburger, Steven Hou, and Christer Kiselman for helpful discussions.

INTEGRATION OF PERTURBED INITIAL VALUE PROBLEMS THROUGH REDUCTION THEORY*

JESÚS PALACIÁN†

Abstract. We propose a method to integrate an initial value problem formed by the differential equations of a perturbed dynamical system plus the initial condition. The approach consists of several steps. First of all, if the original system does not enjoy a continuous symmetry, it is transformed up to a certain order of approximation M into an equivalent but equivariant one after truncation at order M. Second, this new symmetry allows us to define a reduction map which produces in its whole phase space a splitting of the transformed equations. Specifically, the latter system is decoupled into two subsystems, also initial value problems, one of them defined in the orbit space associated with the reduction and the other linear in its coordinates. As a third step the reduced subsystems are analytically resolved or numerically integrated using standard methods. Finally, the solution of the original system is recovered by inverting back the reduction map and thereafter the analytic transformations. We apply our procedure to three examples.

Key words. initial value problems, Lie transformations, generalized normal forms, reduced equations, invariant theory, orbit spaces, Lie groups, semianalytic integration, numerical simulation

1. Introduction.

The goal of this paper is the analysis of initial value problems composed by ordinary differential equations (ODEs) of the type

$$D\boldsymbol{x}(t) = \sum_{i=0}^{L} \frac{\varepsilon^i}{i!} \boldsymbol{F}_i(\boldsymbol{x}(t)), \tag{1.1}$$

where $t \in I \subseteq \boldsymbol{R}$ stands for the independent variable, $\boldsymbol{x} \in \boldsymbol{R}^m$, ε is a small parameter, and, for each $0 \leq i \leq L$, $\boldsymbol{F}_i$ represents a smooth vector field with m components defined in an open set $\Omega \subseteq \boldsymbol{R}^m$. Symbol D represents a differential operator, and thus $D\boldsymbol{\eta}(s) = d\boldsymbol{\eta}/ds$; see, for instance, [20]. The initial condition we add is written as $\boldsymbol{x}(t_0) = \boldsymbol{x}_0 \in \boldsymbol{R}^m$, with $t_0 \in I$. Since L can be understood as the degree reached by the Taylor series of a certain smooth vector field with respect to ε, it could be infinity, at least formally speaking.

In the context of perturbation theory, systems modeled by an ODE such as (1.1) are called perturbed dynamical systems; see, for example, [34]. Indeed, these equations are formed by the sum of a principal part $\boldsymbol{F}_0$ plus a small and regular perturbation. Our purpose is to give a methodology for the analytical or numerical approximation of system (1.1) with adequate initial values, taking advantage of previous manipulations of the equations.

First of all, the initial value problem is converted into a simpler one, called a generalized normal form, by means of formal changes of variables: "generalized" meaning that we extend the standard approach for smooth vector fields based on simplifications through normal forms in a sense that will be specified later on and "simpler" indicating

that in the process of the transformation we introduce a formal (continuous) symmetry in the equations; in other words, we make the transformed system equivariant.

Afterwards, we define a reduction map and make use of a decomposition lemma (or splitting lemma) so that the transformed vector field can be split into two subsystems defined in two different invariant spaces. One of the subsystems, the so-called reduced system, contains the fundamental dynamics of the original system and is defined in a quotient space (called an orbit space; see [1, 35, 21, 13, 7]), whereas the other is a system of linear differential equations with time-dependent coefficients and is defined in a Lie group. Actually, the reduction can be performed thanks to the formal symmetry introduced through the normal form approach.

As the initial vector $\boldsymbol{x}(t_0)$ is also transformed using the change of coordinates, we build two initial value problems, one defined in the orbit space and the other on the Lie group. More precisely, the initial value problem defined in the orbit space is a differential system of equations with constraints among the unknowns. These restrictions appear in the reduction process as a result of constructing the orbit space.

Once we write the subsystems in the appropriate coordinates we have to solve both differential equations with analytical—if possible—or numerical methods. Note that in some cases the reduction is so drastic that we can arrive at two initial value problems that can be solved straightforwardly by means of quadratures, as we shall see in the first and second examples of section 4.

The solution of the original initial value problem is recovered through two steps. First, we shall pass from the vector-valued solutions obtained in the orbit space and in the Lie group to the extended normal form system solving a system of smooth equations (in many cases algebraic equations, as we shall discuss later). Second, the solution of the departure system will be determined by using the inverse change of coordinates.

Our implementation uses Lie transformations for differential equations. The method was introduced by Kamel [27] and Henrard [25]; see also the basic paper by Deprit [15] for Hamiltonian systems. The advantage of working with Lie transformations is that the computations are done in an ascendent way (starting at first order, e.g., with terms factored by ε), arriving at the desired order, say M, where the changes of coordinates—direct and inverse changes—can be obtained explicitly. This feature is in contrast to other techniques based on near-identity transformations such as the classical Poincaré method [43] or the Krylov, Bogoliubov, and Mitropolsky theory of averaging [29, 5], as these procedures provide the formula in mixed coordinates (the original and the transformed ones), and so an inversion of the resulting series is needed. Note, however, that the Lie transformations of Kamel, Henrard, and Deprit and the theory of averaging are based on and inspired by the work of Poincaré.

Here we use the setting given by Meyer [34] through his general perturbation theorem. At this point we emphasize that our procedure is global in the sense that we do not use local expansions around equilibrium points. Nevertheless, the convergence of the transformations is not discussed through the paper, though it is well known that generally transformations based on normal form techniques diverge. Basically, in the setting of smooth vector fields a convergent transformation can be guaranteed if there is a nontrivial local one-parameter group of symmetries; see [10, 52] and the recent book by Cicogna and Gaeta [9]. For polynomial vector fields and the Poincaré–Dulac normal form approach, strong hypotheses of the eigenvalues of the linear part are used to obtain convergence of normal forms. In this framework it is worth mentioning the works by Poincaré [42], Siegel [47], Markhashov [31], and Bryuno [6].

The connection of the general perturbation theorem with the reduction of a dynamical system through the introduction of symmetries has been given for polynomial vector fields in [40]; see also a previous paper by Cicogna and Gaeta [8] dealing with a simpler version. Here we enlarge those studies, considering smooth vector fields and reduction techniques for the case that the Lie group related to the formal symmetry introduced is finitely generated, as we shall detail in section 3. The extension to nonpolynomial vector fields is justified by the use of reduction techniques from the point of view of global analysis of dynamical systems. As examples of global analysis of dynamical sytems based on normal forms of nonpolynomial vector fields we mention the case of perturbed Keplerian systems; see Deprit [16], Cushman [12], Barrio and Palacián [4] and the references therein. Note that in these cases the authors deal with normal forms avoiding collision trajectories, and therefore the perturbations of the two-body problem are smooth functions (but are, in general, nonpolynomial).

Possible fields of application of our approach for perturbed differential equations are classic and quantum mechanics and astrodynamics. The different versions of the n-body problem (general setting or restricted n-body problems; see, for instance, [48]), the motion of artificial satellites around a planet taking into account the gravity potential of the planet (which depends on its shape) [11], or the orbital motion of the Moon [17] are examples of very complex problems to be treated numerically. In classical and quantum mechanics we cite the examples of motion of electrons under the influence of electrical or magnetic fields [18] and the case of ion traps modeled by resonant Hamiltonians with n degrees of freedom [22]. However, generically in these problems, poor numerical approximations are obtained. There are various reasons for this; we mention two: (i) usually very long time spans are required in the simulations; (ii) an initial value problem can depend on external parameters and the corresponding solutions when fixing different values of the parameters and can be very sensitive with respect to them. In this case, a numerical method often exhibits a blind behavior and is not useful for dealing with the solution of the problem. Other sources of problems when dealing with numerical methods are related to the involved expressions defining the original vector field; on other occasions the system of differential equations has a high dimension, and it leads to using very expensive methods from a computational point of view. Finally, if the equations to be resolved are expected to present a chaotic behavior, a numerical treatment can yield unsatisfactory results.

A common idea present in many perturbed ODEs of mechanics [29, 5, 44] is that these problems can be dramatically simplified due to the fact that they are formulated in such a way that some of the variables are angles which oscillate very rapidly in comparison with other angles. Terms of the equation related to the "fast" angles are called short-period terms, whereas terms related to the "slow" ones are called long-period terms. However, short- and long-period terms appear coupled in most applications. If one is interested in the solution of a problem for a long time—for instance to extract information about the numerical stability of some trajectories—a typical approach consists in converting the original equation into an equivalent one but "eliminating" the fast angles up to a certain order (with an appropriate change of coordinates). Thus, one arrives at a simplified problem which can be studied using long steps of time. This is the theory (or the method) of averaging in its modern version formulated by Krylov, Bogoliubov, and Mitropolsky. Using these techniques, Laskar [30] has analyzed the stability of the solar system for a time interval of 10^9 years; see also the review paper by Marmi [32]. A rigorous analysis of artificial satellites orbiting at low altitude has to take into account the oblateness of the Earth

and the atmospheric friction. In [28] a numerical ODE-solver is proposed based on previous averaging of the initial equations. A semianalytical theory [3, 4] has been applied to simplify the original problem, transforming it into another one whose terms are only of long-period type. Hence, the simplified system is numerically solved using a Runge–Kutta method of order eight due to Dormand and Prince and equipped with variable stepsize and continuous output [23].

Nevertheless, to our knowledge, the approach described above has not been followed by the community of applied mathematicians. Besides, the simplification of a system through formal changes of variables can be generalized with the aim of considering not only the case of angular variables but other types of coordinates. This is, consequently, better formulated by the use of reduction to the orbit space (see the seminal paper by Michel [35] and the recent book by Chossat and Lauterbach [7]) but adding the equation in the Lie group. In section 3 we shall show that the averaging method is a particular case of the reduction method we use. Indeed, the variables "eliminated" are the coordinates of the Lie group; therefore, to recover all the departure variables, one needs to solve the linear system of equations in the Lie group.

In this respect the splitting lemma (that is, our splitting decomposition of the transformed equations), together with the relation of the transformed system with the original one, is the essential tool to achieve the solution of the initial ODE via normal forms. In [37] the standard treatment of building formal symmetries of smooth vector fields is extended with the aim of constructing some invariant manifolds of the original ODE using Lie transformations, invariant theory, and reduction techniques. However, the integration of a certain initial value problem such as (1.1) using splitting decompositions is also new.

It can happen that the integration—numerical or analytical—of the corresponding systems in the orbit space and in the Lie group becomes a difficult task. This feature can be caused because the constraints defining the orbit space are involved expressions or due to the fact that the differential system in the orbit space is of high dimension; note that the number of variables in the orbit space can be bigger than the number of original coordinates. Under those circumstances our approach is not recommended, and one must resort to numerical integrations. However, on many interesting occasions, the use of Lie transformations and the subsequent reduction simplify the problem enormously, as we will see in section 4.

The paper has five sections. Section 2 contains the required setting for the generalized normal form formalism. Section 3 contains the central part of the paper and is devoted to the solution of the reduced equations and to describe how one can obtain the solution of the original system. We start this section concretely by describing the geometrical aspects of the reduction after the application of generalized normal forms, dealing with the invariants related to the symmetry introduced by the Lie transformations. We continue showing how the reduced phase spaces are constructed and how the original differential equation is decomposed into the corresponding systems. After that we relate the reduction techniques used with the integration of initial value problems related to such equations. In section 4 we illustrate the technique with three examples. Finally, in section 5 the conclusions of our work are outlined.

2. Analytic reduction.

2.1. Lie transformations for vector fields. Meyer's approach to the calculation of formal symmetries employs Lie transformations and is based on previous work by Kamel [27] and Henrard [25]. In [34], Meyer presents a Lie transformation

treatment in the context of tensor fields. We start by recalling the method applied to smooth vector fields.

Let us consider the differential system

$$D\boldsymbol{x}(t) = \boldsymbol{F}_0(\boldsymbol{x}(t)) + \sum_{i=1}^{\infty} \frac{\varepsilon^i}{i!} \boldsymbol{F}_i(\boldsymbol{x}(t)), \tag{2.1}$$

where t represents the time variable, $\boldsymbol{x} \in \boldsymbol{R}^m$, and ε stands for a dimensionless small parameter. The vector field $\boldsymbol{F}_i$, for $i \geq 0$, has m components, which are analytic functions in $\boldsymbol{x}$, and we truncate the series (2.1) at order L; then $\boldsymbol{F}_i \equiv 0$ for $i > L$. We define by $[\cdot, \cdot]$ the Lie bracket of two vector fields $\boldsymbol{g}_1(\boldsymbol{x})$ and $\boldsymbol{g}_2(\boldsymbol{x})$ in $\boldsymbol{R}^m$, that is, $[\boldsymbol{g}_1, \boldsymbol{g}_2] = D\boldsymbol{g}_1(\boldsymbol{x})\boldsymbol{g}_2 - D\boldsymbol{g}_2(\boldsymbol{x})\boldsymbol{g}_1$.

Let us describe the typical algorithm of Lie transformations for ODEs. A smooth vector field (2.1) depending on a small parameter ε is transformed into another vector field

$$D\boldsymbol{y}(t) = \boldsymbol{G}_0(\boldsymbol{y}(t)) + \sum_{i=1}^{\infty} \frac{\varepsilon^i}{i!} \boldsymbol{G}_i(\boldsymbol{y}(t)), \tag{2.2}$$

where $\boldsymbol{G}_0(\boldsymbol{y}(t)) \equiv \boldsymbol{F}_0(\boldsymbol{x}(t))$, through a generating function

$$\boldsymbol{W}(\boldsymbol{x}; \varepsilon) = \sum_{i=0}^{\infty} \frac{\varepsilon^i}{i!} \boldsymbol{W}_{i+1}(\boldsymbol{x}),$$

following the recursive formula

$$\boldsymbol{F}_i^{(j)} = \boldsymbol{F}_{i+1}^{(j-1)} + \sum_{k=0}^{i} \binom{i}{k} \big[\boldsymbol{F}_{i-k}^{(j-1)}, \boldsymbol{W}_{k+1}\big], \tag{2.3}$$

with $i \geq 0$, $j \geq 1$. Besides, $\boldsymbol{F}_i^{(0)} \equiv \boldsymbol{F}_i$ and $\boldsymbol{F}_0^{(i)} \equiv \boldsymbol{G}_i$ for all $i \geq 0$.

Note that $\boldsymbol{W}(\boldsymbol{x}; \varepsilon)$ is conserved under the transformation, and thus it can also be expressed as $\boldsymbol{W}(\boldsymbol{y}; \varepsilon)$, that is, $\boldsymbol{W}(\boldsymbol{x}; \varepsilon) \equiv \boldsymbol{W}(\boldsymbol{y}; \varepsilon)$. Hence, (2.3) yields the partial differential identity

$$\mathcal{L}_{\boldsymbol{F}_0}(\boldsymbol{W}_i) + \boldsymbol{G}_i = \widetilde{\boldsymbol{F}}_i, \tag{2.4}$$

where $\widetilde{\boldsymbol{F}}_i$ collects all the terms known from the previous orders plus $\boldsymbol{F}_i$. In this identity, called the homology equation, $\boldsymbol{W}_i$ and $\boldsymbol{G}_i$ are determined according to the specific requirements of the Lie transformation one performs. Besides, $\mathcal{L}_{\boldsymbol{F}_0}$ denotes the Lie operator associated with the Lie bracket of two vector functions, i.e., given two vector fields $\boldsymbol{g}_1$ and $\boldsymbol{g}_2$: $\mathcal{L}_{\boldsymbol{g}_1}(\boldsymbol{g}_2) = [\boldsymbol{g}_2, \boldsymbol{g}_1]$.

The transformation $\boldsymbol{x} = \boldsymbol{X}(\boldsymbol{y}; \varepsilon)$ relates the "old" variables $\boldsymbol{x}$ with the "new" ones $\boldsymbol{y}$ and is a near-identity change of coordinates. The direct change is given by

$$\boldsymbol{x} = \boldsymbol{y} + \sum_{i=1}^{\infty} \frac{\varepsilon^i}{i!} \boldsymbol{y}_0^{(i)}. \tag{2.5}$$

Vectors $\boldsymbol{y}_0^{(i)}$, $i \geq 1$, are calculated recursively with the aid of

$$\boldsymbol{y}_i^{(j)} = \boldsymbol{y}_{i+1}^{(j-1)} + \sum_{k=0}^{i} \binom{i}{k} \big(\boldsymbol{y}_k^{(j-1)}, \boldsymbol{W}_{i+1-k}\big), \tag{2.6}$$

with $i \geq 0$, $j \geq 1$, and $\boldsymbol{y}_i^{(0)} \equiv \mathbf{0}$ for $i \geq 1$, $\boldsymbol{y}_0^{(0)} \equiv \boldsymbol{y}$, and each $\boldsymbol{W}_{i+1-k}$ is written in terms of $\boldsymbol{y}$. Besides, given two vector fields $\boldsymbol{g}_1(\boldsymbol{y})$ and $\boldsymbol{g}_2(\boldsymbol{y})$, the operator $(\boldsymbol{g}_1, \boldsymbol{g}_2)$ is computed as $D\boldsymbol{g}_1(\boldsymbol{y})\boldsymbol{g}_2$. Consequently, (2.5) gives the set of coordinates $\boldsymbol{x}$ in terms of $\boldsymbol{y}$ with the use of the generating function $\boldsymbol{W}$.

Similar formulae can be used to obtain the inverse transformation $\boldsymbol{y} = \boldsymbol{Y}(\boldsymbol{x}; \varepsilon)$, which explicitly reads as

$$\boldsymbol{y} = \boldsymbol{x} + \sum_{i=1}^{\infty} \frac{\varepsilon^i}{i!} \boldsymbol{x}_i^{(0)}. \tag{2.7}$$

Now $\boldsymbol{x}_0^{(0)} \equiv \boldsymbol{x}$, and for $i \geq 1$ vectors $\boldsymbol{x}_i^{(0)}$ are calculated recursively by means of

$$\boldsymbol{x}_i^{(j)} = \boldsymbol{x}_{i-1}^{(j+1)} + \sum_{k=0}^{i-1} \binom{i-1}{k} (\boldsymbol{x}_{i-k-1}^{(j)}, \boldsymbol{W}_{k+1}), \tag{2.8}$$

with $i \geq 1$, $j \geq 0$. This time $\boldsymbol{x}_0^{(i)} \equiv \mathbf{0}$ for $i \geq 1$, the Jacobians appearing in the operators of (2.8) are computed with respect to $\boldsymbol{x}$, and $\boldsymbol{W}_{k+1}$ is also written in $\boldsymbol{x}$.

Formulae (2.5) and (2.6) can be used to transform any function expressed in the old coordinates $\boldsymbol{x}$, say $\boldsymbol{P}(\boldsymbol{x}; \varepsilon) = \sum_{i=0}^{\ell} (\varepsilon^i / i!) \boldsymbol{P}_i(\boldsymbol{x})$, as a function of the new variables $\boldsymbol{y}$, after identifying each $\boldsymbol{P}_i(\boldsymbol{x})$ with $\boldsymbol{y}_i^{(0)}$ (and replacing in the identification $\boldsymbol{x}$ by $\boldsymbol{y}$). The result is the function $\boldsymbol{P}$ in terms of $\boldsymbol{y}$. In a similar fashion, (2.7) and (2.8) should be used to transform any function written in terms of $\boldsymbol{y}$ as a function of the coordinates $\boldsymbol{x}$.

2.2. Generalized normal forms. The above method is formal in the sense that the convergence of the various series is not discussed. Moreover, the series diverge in many applications. However, the first orders of the transformed system can give interesting information, and the process can be stopped at a certain order M. It means that these terms of the series are useful to construct both the transformed vector field and the generating function since they are unaffected by the divergent character of the whole process. Now we are ready to build formal symmetries for vector fields using Lie transformations.

THEOREM 2.1 (generalized normal forms). *Let $M \geq 1$ be given, let $\{\mathcal{P}_i\}_{i=0}^{M}$, $\{\mathcal{Q}_i\}_{i=1}^{M}$, and $\{\mathcal{R}_i\}_{i=1}^{M}$ be sequences of vector spaces of smooth vector fields in $\boldsymbol{x} \in \boldsymbol{R}^m$ defined in a common domain Ω in $\boldsymbol{R}^m$, and let $\boldsymbol{T} \equiv \boldsymbol{T}(\boldsymbol{x})$ be a vector field in some $\{\mathcal{P}_i\}_{i=0}^{M}$ with the following properties:*

(i) $\mathcal{Q}_i \subseteq \mathcal{P}_i$, $i = 1, \ldots, M$;
(ii) $\boldsymbol{F}_i \in \mathcal{P}_i$, $i = 0, 1, \ldots, M$;
(iii) *for any $\boldsymbol{D} \in \mathcal{P}_i$ and any $\boldsymbol{K} \in \mathcal{R}_j$ one has $[\boldsymbol{D}, \boldsymbol{K}] \subseteq \mathcal{P}_{i+j}$ for all $i + j = 1, \ldots, M$;*
(iv) *for any $\boldsymbol{D} \in \mathcal{P}_i$, $i = 1, \ldots, M$, one can find $\boldsymbol{E} \in \mathcal{Q}_i$ and $\boldsymbol{K} \in \mathcal{R}_i$ such that*

$$\boldsymbol{E} = \boldsymbol{D} + [\boldsymbol{F}_0, \boldsymbol{K}] \qquad \text{and} \qquad [\boldsymbol{E}, \boldsymbol{T}] = \mathbf{0}.$$

Then there is a smooth vector field $\boldsymbol{W}$,

$$\boldsymbol{W}(\boldsymbol{x}; \varepsilon) = \sum_{i=0}^{M-1} \frac{\varepsilon^i}{i!} \boldsymbol{W}_{i+1}(\boldsymbol{x}),$$

with $\boldsymbol{W}_i \in \mathcal{R}_i$, $i = 1, \ldots, M$, *such that the change of variables* $\boldsymbol{x} = \boldsymbol{X}(\boldsymbol{y}; \varepsilon)$ *is the general solution of the initial value problem*

$$\begin{aligned} D\boldsymbol{x}(\varepsilon) &= D_1 \boldsymbol{W}(\boldsymbol{x}; \varepsilon), \\ \boldsymbol{x}(0) &= \boldsymbol{y}, \end{aligned}$$

and transforms the convergent vector field

$$\boldsymbol{F}(\boldsymbol{x}; \varepsilon) = \sum_{i=0}^{\infty} \frac{\varepsilon^i}{i!} \boldsymbol{F}_i(\boldsymbol{x})$$

to the convergent vector field

$$\boldsymbol{G}(\boldsymbol{y}; \varepsilon) = \sum_{i=0}^{M} \frac{\varepsilon^i}{i!} \boldsymbol{G}_i(\boldsymbol{y}) + \mathcal{O}(\varepsilon^{M+1}),$$

with $\boldsymbol{G}_i \in \mathcal{Q}_i$ *and* $[\boldsymbol{G}_i, \boldsymbol{T}] = \boldsymbol{0}$, $i = 1, \ldots, M$. *Besides, if* $[\boldsymbol{F}_0, \boldsymbol{T}] = \boldsymbol{0}$, *then* $\boldsymbol{T} \equiv \boldsymbol{T}(\boldsymbol{y})$ *is a formal symmetry of* $\boldsymbol{G}$.

Proof. It appears in [40]. Note that we are requiring that functions $\boldsymbol{E} \in \mathcal{Q}_i$ satisfy $[\boldsymbol{E}, \boldsymbol{T}] = \boldsymbol{0}$. In the above $D_1 \boldsymbol{W}(\boldsymbol{x}; \varepsilon)$ stands for the derivatives of $\boldsymbol{W}$ with respect to $\boldsymbol{x}$, that is, the Jacobian. In general, $D_i \boldsymbol{\eta}(\boldsymbol{u}_1, \ldots, \boldsymbol{u}_\ell)$ refers to $d\boldsymbol{\eta}/d\boldsymbol{u}_i$, if $i \in \{1, \ldots, \ell\}$, whereas $D_j \boldsymbol{\omega}(\boldsymbol{s}) = d\boldsymbol{\omega}/ds_j$, using Bourbaki notation [20]. □

If we drop the remainder of $\boldsymbol{G}$ and make $M \to +\infty$, the resulting formal expansion does not converge, in general, as further and deep conditions on the vector field $\boldsymbol{F}$ and on the change of coordinates of the Lie transformation should be added; see, for example, [10, 52].

The number of possible normal forms of $\boldsymbol{F}$ one calculates depends on the different Lie transformations one can execute or, in other words, on the independent symmetries $\boldsymbol{T}$ of $\boldsymbol{F}_0$ selected in order to apply Theorem 2.1. This is in contrast to the usual approach of normal forms in which one chooses $\boldsymbol{T}$ to be $\boldsymbol{F}_0$ or, in the polynomial setting, the semisimple part of $\boldsymbol{F}_0$. However, we allow $\boldsymbol{T}$ to be any symmetry of $\boldsymbol{F}_0$. Hence, the vector field $\boldsymbol{G}$ is called a generalized normal form of $\boldsymbol{F}$; see also [38, 40].

Next, we can determine a formal continuous symmetry of the original system by going back to the departure system. Specifically, we compute $\boldsymbol{T}^*(\boldsymbol{x}; \varepsilon)$ as

$$\boldsymbol{T}^*(\boldsymbol{x}; \varepsilon) = \boldsymbol{T}(\boldsymbol{x}) + \sum_{i=1}^{M} \frac{\varepsilon^i}{i!} \boldsymbol{T}(\boldsymbol{x})_i^{(0)}, \tag{2.9}$$

where $\boldsymbol{T}(\boldsymbol{x})_i^{(0)}$ are calculated using

$$\boldsymbol{T}(\boldsymbol{x})_i^{(j)} = \boldsymbol{T}(\boldsymbol{x})_{i-1}^{(j+1)} + \sum_{k=0}^{i-1} \binom{i-1}{k} (\boldsymbol{T}(\boldsymbol{x})_{i-k-1}^{(j)}, \boldsymbol{W}_{k+1}), \tag{2.10}$$

with $i \geq 1$ and $j \geq 0$. Now $\boldsymbol{T}(\boldsymbol{x})_0^{(0)} \equiv \boldsymbol{T}(\boldsymbol{x})$ and, for $i \geq 1$, $\boldsymbol{T}(\boldsymbol{x})_0^{(i)} \equiv \boldsymbol{0}$. Then $\boldsymbol{T}^*(\boldsymbol{x}; \varepsilon)$ is an asymptotic symmetry of $\boldsymbol{F}$, i.e., $[\boldsymbol{F}, \boldsymbol{T}^*] = \mathcal{O}(\varepsilon^{M+1})$.

We have to note that given a vector field $\boldsymbol{T}$ with $[\boldsymbol{F}_0, \boldsymbol{T}] = \boldsymbol{0}$ it is not always possible in practice to solve the homology equation (2.4) due to the difficulties in finding out the pair $(\boldsymbol{G}_i, \boldsymbol{W}_i)$ satisfying it. Therefore, on some occasions we will stop the computation of a normal form at the order we had reached without trouble.

Estimates of the error committed by the application of Theorem 2.1 are obtained from the theory developed for the method of averaging. Taking into consideration that $\boldsymbol{y} = \boldsymbol{Y}(\boldsymbol{x};\varepsilon)$ and $\boldsymbol{x} = \boldsymbol{X}(\boldsymbol{y};\varepsilon)$, for a given vector field $\boldsymbol{S}(\boldsymbol{x};\varepsilon)$ we call $\boldsymbol{S}^*(\boldsymbol{x};\varepsilon) = \boldsymbol{S}(\boldsymbol{X}(\boldsymbol{Y}(\boldsymbol{x};\varepsilon);\varepsilon);\varepsilon)$; then one can conclude that by using an adequate norm $\|\boldsymbol{S}^*(\boldsymbol{x};\varepsilon) - \boldsymbol{S}(\boldsymbol{x};\varepsilon)\| = \mathcal{O}(\varepsilon^{M+1})$ on a time scale $1/\varepsilon$; see [44] for details. This remark gives the key to know how accurate we get when computing approximate solutions in (2.1). Using these considerations we shall bound the errors in the first and second examples of section 4.

3. Solution of the original equations.

3.1. Decoupling of the transformed equation. From a geometrical standpoint the consequence of introducing a symmetry by making use of Theorem 2.1 is that the dimension of the phase space where the transformed system is defined—the so-called reduced phase space—is reduced from m to s (s denoting the number of functionally independent first integrals associated with $\boldsymbol{T}(\boldsymbol{y})$). Let us see how this is achieved with some details.

System (2.1) is defined over an open subset of $\boldsymbol{R}^m$. This is the phase space of the dynamical system determined by (2.1). Given $\boldsymbol{T}$, an m-dimensional vector field such that $[\boldsymbol{F}_0, \boldsymbol{T}] = 0$, the application of Theorem 2.1 after truncating at order M leads to a smooth vector field that we denote by $\boldsymbol{H}(\boldsymbol{y};\varepsilon)$:

$$D\boldsymbol{y}(t) = \boldsymbol{H}(\boldsymbol{y};\varepsilon) = \sum_{i=0}^{M} \frac{\varepsilon^i}{i!} \boldsymbol{G}_i(\boldsymbol{y}), \tag{3.1}$$

where $\boldsymbol{H}_0 \equiv \boldsymbol{F}_0$, and each $\boldsymbol{G}_i$ is constructed so that $[\boldsymbol{G}_i, \boldsymbol{T}] = \boldsymbol{0}$ for $1 \leq i \leq M$.

We need to show how the transformation performed in section 2 is effective in the sense that we really simplify the departure system. We took inspiration from the result obtained by Gaeta in [21], adapting it to our requirements. Associated with the one-parameter group of symmetries introduced through the Lie transformation there is an $(m-s)$-dimensional Lie group $G_{\boldsymbol{T}}$ such that $\boldsymbol{H}$ is $G_{\boldsymbol{T}}$-equivariant, that is, fixed $\varepsilon > 0$, for any $\boldsymbol{y} \in \boldsymbol{R}^m$ and any $g \in G_{\boldsymbol{T}}$, and the identity $\boldsymbol{H}(\boldsymbol{y};\varepsilon) = \boldsymbol{H}(g\boldsymbol{y};\varepsilon)$ holds.

In [46] Schwarz generalized a result obtained by Hilbert for polynomial first integrals. Specifically, Schwarz showed that given a compact Lie group $G_{\boldsymbol{T}}$ and any $G_{\boldsymbol{T}}$-equivariant vector field, there is a set of smooth functions defined in a domain $\Omega \subseteq \boldsymbol{R}^m$ (in other words, $\mathcal{C}^\infty(\Omega)$-functions) such that any $G_{\boldsymbol{T}}$-equivariant smooth function defined over Ω can be written as a $\mathcal{C}^\infty(\Omega)$-function of those functions. These functions, designated by $\varphi_i(\boldsymbol{y})$, $i = 1, \ldots, r$ (with $\boldsymbol{y} \in \Omega$), correspond to the r linearly independent first integrals of the system $D\boldsymbol{y}(t) = \boldsymbol{T}(\boldsymbol{y}(t))$, from which s (with $1 \leq s \leq r$) are functionally independent. The requisite of $G_{\boldsymbol{T}}$ to be compact cannot be avoided in order to ensure the existence of a finite number of first integrals. However, we can relax somewhat this hypothesis in three important cases:

(i) When $\boldsymbol{T}$ is a homogeneous linear vector field, we do not care about the compactness of the Lie group. Indeed, a classic theorem by Weitzenböck [53] guarantees that the polynomial invariant algebra of the symmetry $\boldsymbol{T}$ (i.e., the set of all polynomial first integrals associated with $\boldsymbol{T}$), denoted by $I(\boldsymbol{T})$, is finitely generated. The semisimple case was treated by Walcher [50, 51], whereas the extension to nonsemisimple vector fields is treated, for instance, in [14]. In summary, if $\boldsymbol{T}$ is a polynomial vector we can always find a finite number of polynomial first integrals, regardless of the compactness of $G_{\boldsymbol{T}}$. Note that even for a nonpolynomial ODE one could obtain a

nonpolynomial normal form using a polynomial vector field $\boldsymbol{T}$ as the symmetry to be extended in the process. Hence in this case the algebra $I(\boldsymbol{T})$ is also finitely generated.

(ii) If $G_{\boldsymbol{T}}$ is a linearly reductive Lie group, Hilbert proved that $G_{\boldsymbol{T}}$ has a finite number of generators, and therefore $I(\boldsymbol{T})$ is finitely generated. A constructive algorithm to compute the required first integrals of $I(\boldsymbol{T})$ is given by Derksen [19].

(iii) If $G_{\boldsymbol{T}}$ is not compact and (i) and (ii) do not hold we can still apply the Frobenius theorem in the neighborhood of any point $\boldsymbol{y} \in \Omega$, finding out a finite set of linearly independent generators from which s are functionally independent. See Theorem 2.17 of the book by Olver [36] for a derivation of these invariants.

Suppose now that we are in the situation that $G_{\boldsymbol{T}}$ is finitely generated and that we have already determined its generators. The set $\{\varphi_1, \ldots, \varphi_r\}$ has the structure of a ring of scalar fields with the standard product and addition of $\mathcal{C}^\infty$-functions. Denote by ${\mathcal{L}^*}_{\boldsymbol{T}}(z)$ the Lie derivative of a function $z : \Omega \to \boldsymbol{R}$ related to $\boldsymbol{T}$, e.g., ${\mathcal{L}^*}_{\boldsymbol{T}}(z(\boldsymbol{y})) = \langle Dz(\boldsymbol{y}), \boldsymbol{T}\rangle$. So ${\mathcal{L}^*}_{\boldsymbol{T}}(\varphi_i(\boldsymbol{y})) = 0$ for $i \in \{1, \ldots, r\}$. Hence, the φ_i are the linearly independent solutions of the linear partial differential equation ${\mathcal{L}^*}_{\boldsymbol{T}}(\varphi_i(\boldsymbol{x})) = 0$. Note that $s \leq m$, but r can be any value.

We follow now the construction of Walcher [50] but in the context of smooth functions. First, we make $\boldsymbol{\varphi} = (\varphi_1, \ldots, \varphi_r)$ and $\boldsymbol{\vartheta} = (\vartheta_1, \ldots, \vartheta_{m-s})$. Then we consider the map $\varrho_{\boldsymbol{T}}$ over $\boldsymbol{R}^m$ as follows:

$$\begin{aligned} \varrho_{\boldsymbol{T}} : \Omega \subseteq \boldsymbol{R}^m &\longrightarrow \boldsymbol{R}^r, \\ \boldsymbol{y} &\mapsto \boldsymbol{\varphi}(\boldsymbol{y}). \end{aligned}$$

Let $S(\boldsymbol{R}^r)$ be the associative and graded algebra of all $\mathcal{C}^\infty$-maps from $\boldsymbol{R}^r$ to $\boldsymbol{R}$, and let $J = \{\gamma \in S(\boldsymbol{R}^r) : \gamma(\boldsymbol{\varphi}(\boldsymbol{y})) = 0 \text{ for all } \boldsymbol{y} \in \Omega\}$; then J is a prime ideal in $S(\boldsymbol{R}^r)$ because for $\gamma_1, \gamma_2 \in S(\boldsymbol{R}^r)$ and $\gamma_1 \cdot \gamma_2 \in J$ one has $\gamma_1(\boldsymbol{\varphi}(\boldsymbol{y})) \cdot \gamma_2(\boldsymbol{\varphi}(\boldsymbol{y})) = 0$ for all $\boldsymbol{y} \in \Omega$. Let $Y = \{\boldsymbol{y} \in \Omega : \gamma(\boldsymbol{y}) = 0 \text{ for all } \gamma \in J\}$ be an irreducible variety. It is clear that $\varrho_{\boldsymbol{T}}(\Omega) \subseteq Y$ and $\dim Y = s$ (that is, the maximum number of functionally independent $\mathcal{C}^\infty(\Omega)$-functions on Y), and the rank of $D\varrho_{\boldsymbol{T}}(\boldsymbol{y})$ is equal to s at most points of Ω.

Next, we define the reduction map as the surjective map

$$\begin{aligned} \pi_{\boldsymbol{T}} : \Omega \subseteq \boldsymbol{R}^m &\longrightarrow Y, \\ \boldsymbol{y} &\mapsto \boldsymbol{\varphi}(\boldsymbol{y}). \end{aligned}$$

By construction, the map $\pi_{\boldsymbol{T}}$ is a solution-preserving map from the equivariant vector field $\boldsymbol{H}(\boldsymbol{y}; \varepsilon)$ to a differential equation defined in the reduced space (or reduced phase space) Y and reflects the actual reduction process; see the details in [50]. In addition, Y has the structure of a variety (semialgebraic whenever $\boldsymbol{T}$ is of polynomial character) and is defined as a set of (smooth) equalities and inequalities that we call reduced phase space. However, the passage to the space Y must be combined with an additional differential equation in the Lie group $G_{\boldsymbol{T}}$ to make the splitting explicit. We have the following result.

THEOREM 3.1 (splitting lemma). *Given the generalized normal form system* (3.1) *with* $\boldsymbol{H}$ *a smooth function of* $\boldsymbol{y}$ *and* ε *(fixed) defined in* $\Omega \subseteq \boldsymbol{R}^m$ *and with the necessary assumptions on the smooth vector field* $\boldsymbol{T}$ *to make* $G_{\boldsymbol{T}}$ *finitely generated,* $\boldsymbol{H}$

can be transformed into a triangular system as

$$
\begin{aligned}
D\boldsymbol{\varphi}(t) &= \boldsymbol{\alpha}(\boldsymbol{\varphi}(t);\varepsilon) = \sum_{i=0}^{M} \frac{\varepsilon^i}{i!}\boldsymbol{\alpha}_i(\boldsymbol{\varphi}(t)),\\
D\boldsymbol{\vartheta}(t) &= \boldsymbol{\beta}(\boldsymbol{\vartheta}(t),\boldsymbol{\varphi}(t);\varepsilon) = \sum_{i=0}^{M} \frac{\varepsilon^i}{i!}\boldsymbol{\beta}_i(\boldsymbol{\vartheta}(t),\boldsymbol{\varphi}(t)),
\end{aligned}
\tag{3.2}
$$

$\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ being smooth functions obtained constructively from $\boldsymbol{H}$, $\boldsymbol{\varphi}$, and $\boldsymbol{\vartheta}$ and having dimensions r and $m-s$, respectively.

Proof. A similar result is proven in [21], but we propose a different version. (See also [1] for details and the seminal paper by Michel [35].) The reason for the appearance of $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ comes from the fact that they are constructed order by order in powers of ε. The first equation of (3.2) depends exclusively on the φ_i, is called the reduced system, and is defined over $\boldsymbol{R}^r$ (or, using the reduction map $\pi_{\boldsymbol{T}}$, over Y), whereas the second equation of (3.2) is defined in the Lie group $G_{\boldsymbol{T}}$. We use that $D\boldsymbol{\varphi}(t) = D\boldsymbol{\varphi}(\boldsymbol{y})\boldsymbol{H}(\boldsymbol{y};\varepsilon)$ and take into account that the right-hand member of this equation can be expressed completely in terms of $\boldsymbol{\varphi}$, as $\boldsymbol{\alpha}$ is $G_{\boldsymbol{T}}$-invariant. Next, we make the identification

$$
\boldsymbol{\alpha}(\boldsymbol{\varphi};\varepsilon) = D\boldsymbol{\varphi}(\boldsymbol{y})\boldsymbol{H}(\boldsymbol{y};\varepsilon), \quad \text{that is,} \quad \boldsymbol{\alpha}_i(\boldsymbol{\varphi}) = D\boldsymbol{\varphi}(\boldsymbol{y})\boldsymbol{H}_i(\boldsymbol{y}).
$$

For each i, the construction of $\boldsymbol{\beta}_i$ is done with the aid of $\boldsymbol{\alpha}_i$ and $\boldsymbol{H}_i$. It must be performed once the coordinates $\boldsymbol{\vartheta}$ have been calculated as functions of $\boldsymbol{y}$. Now there is no systematic way to encounter the components of $\boldsymbol{\vartheta}$, as it depends on each particular case. The dimensions of the vector fields $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ follow, respectively, from the dimensions of $\boldsymbol{\varphi}$ and $\boldsymbol{\vartheta}$. □

Theorem 3.1 is also called the splitting decomposition. Note that as there is not a unique set of coordinates, there is not a unique function $\boldsymbol{\beta}$. From a qualitative standpoint the relevant part of the normal form is given by the equation on Y. However, the equation on the Lie group must be taken into account if an integration (either analytical or numerical) of (3.1) is needed. In this case, if the solution of the equation involving the φ_i is known, then the solution of the remaining equation on $G_{\boldsymbol{T}}$ can be obtained. In particular for polynomial normal forms, this equation is linear in $\boldsymbol{\vartheta}$. As there are $r-s$ functionally independent relations among the $\varphi_i(\boldsymbol{y})$, these relations are indeed the constraints determining the phase space where the normal form system in Y is defined. Besides, the basic properties of system (3.1) are also reflected in Y. For instance, asymptotic expressions at a certain order M of the analytic integrals of the initial system must be found from the analysis of the normal form in the reduced space. The invariance of some subsets of $\boldsymbol{R}^m$ is formally preserved when passing to the reduced space; see a proof in [50].

Whenever $G_{\boldsymbol{T}}$ is compact the set Y can be identified with the orbit space $\Omega/G_{\boldsymbol{T}}$, and our reduction process coincides with the reduction to the orbit space because in this case the invariants separate orbits; see, for instance, [7]. However, for noncompact Lie groups the variety Y is topologically better behaved than $\Omega/G_{\boldsymbol{T}}$; see [50].

The relation of the procedure described through Theorem 3.1 and the theory of averaging is rather clear; see, for instance, [5, 44]. Indeed, it is easy to see that the passage from the original equation to the system defined in the reduced phase space can be interpreted as an average of the equation over all "angular" variables ϑ_i since the coordinates of the Lie group are absent in Y. (The latter has sense, provided that no small divisor appears in the generating functions; otherwise a partial averaging

is needed; that is, one needs to choose adequately those angles out of the resonance domain; therefore, a different selection of the symmetry of the principal part is used.) However, the way we have followed seems to be more transparent and general, as the reduction process does not depend on the variables we use, and the coordinates of $G_{\boldsymbol{T}}$ do not need to be actual angles; see some examples in [41, 56].

For Hamiltonian systems we can perform symplectic transformations. In this context there is a scalar function associated with the initial vector field $\boldsymbol{F}$. This function is called a Hamiltonian or Hamilton function and is usually denoted by $\mathcal{H}$. If $\mathcal{J}$ designates the skew-symmetric matrix of order $2n$,

$$\mathcal{J} = \begin{pmatrix} 0 & I_n \\ -I_n & 0 \end{pmatrix},$$

one has $\boldsymbol{F} = \mathcal{J} D\mathcal{H}(\boldsymbol{x})$. Moreover, we need to select $\boldsymbol{T}$ (a symmetry of $\boldsymbol{F}_0$) such that it has a Hamiltonian nature. That is, $\boldsymbol{T}$ has to be related to a constant of motion (an integral) that we denote by $\mathcal{T}$ through $\boldsymbol{T} = \mathcal{J} D\mathcal{T}(\boldsymbol{x})$. As $\mathcal{T}$ is constant over the solutions of $\boldsymbol{F}$ one can fix a real value for it, i.e., $\mathcal{T} \equiv c \in I \subseteq \boldsymbol{R}$.

The Lie bracket of two vector fields is replaced by the Poisson bracket of two scalar fields $\mathcal{P}$ and $\mathcal{Q}$; specifically, if $\boldsymbol{x} = (x_1, \ldots, x_{2n})$, the Poisson bracket is defined over an open domain of $\boldsymbol{R}^{2n}$ as the quantity

$$\{\mathcal{P}, \mathcal{Q}\}(\boldsymbol{x}) = \sum_{i=1}^{n} D_i \mathcal{P}(\boldsymbol{x}) D_{i+n} \mathcal{Q}(\boldsymbol{x}) - D_{i+n} \mathcal{P}(\boldsymbol{x}) D_i \mathcal{Q}(\boldsymbol{x}).$$

Note that $(x_1, \ldots, x_n)$ stand for the coordinates, whereas $(x_{n+1}, \ldots, x_{2n})$ refer to their conjugate momenta. Moreover, all computations are carried out in the scalar framework, and the generating function $\boldsymbol{W}$ is related to a scalar $\mathcal{W}$ through $\boldsymbol{W} = \mathcal{J} D\mathcal{W}(\boldsymbol{x})$.

As a consequence, the normal form is by construction a function depending exclusively on $\boldsymbol{q}$ [38]. Thus, the second equation of system (3.2) gets reduced to $D\boldsymbol{p}(t) = \boldsymbol{\beta}(\boldsymbol{q}(t); \varepsilon)$. Observe that the variables $\boldsymbol{q}(t)$ are not canonical; however, the vector field $\boldsymbol{\beta}$ admits a symplectic structure because the generating function is also a Hamiltonian. This time the reduction is done adding an extra step. First of all, Theorem 3.1 is applied, and $\boldsymbol{q}$ and $\boldsymbol{\alpha}$ are calculated. Consequently, if a departure Hamiltonian defines a dynamical system on a $2n$-dimensional phase space, that is, a system of n degrees of freedom, after a symplectic reduction, the resulting Hamiltonian lies on a phase space of dimension s if s is even or of dimension $s-1$ if s is odd. Strictly speaking, there is an infinite number of reduced phase spaces, one for each value of $c \in I \subseteq \boldsymbol{R}$. See [37] for an application to the Hénon and Heiles family of Hamiltonians with two degrees of freedom.

Several reductions of a departure system can be performed successively. Indeed, if $\boldsymbol{T}_1, \ldots, \boldsymbol{T}_k$ correspond to k functionally independent vector fields commuting with the principal part of a dynamical system such as (2.1), it is possible (at least theoretically) to apply up to k different reductions (conversions to normal forms followed by the passage to the corresponding invariants and the splitting decompositions). Thus an originally m-dimensional system ($m \geq 3$) could be reduced to a system of dimension one. We shall see an example of this in section 4.3. However, in practice it is quite unlikely to execute more than one transformation due to the difficulty in solving the homology equation in the Lie transformation.

The coordinates of the orbit space receive also the name of generators of the reduced phase space and are indeed the r linearly independent first integrals related

to $\boldsymbol{T}$. Since the dimension of the quotient space $\Omega/G_{\boldsymbol{T}}$ is s, there are s functionally independent invariants. However, the number r of algebraically independent invariants cannot be obtained in a systematic manner, and it depends on each reduction; that is, it is determined by the choice of the vector field $\boldsymbol{T}$, but $r \geq s$ is always satisfied. There are at least $r - s$ relations involving the φ_i. These relations are used to define the reduced phase space.

The reduced phase space can have singular points. In particular, the reduction is called regular whenever $\Omega/G_{\boldsymbol{T}}$ is a regular manifold [33], whereas if there is a vector $\boldsymbol{x} \in \boldsymbol{R}^m$ such that its isotropy subgroup is nontrivial, the reduced phase space is a manifold with singularities. That reduction is called singular [2]. See details in [37].

If the reduction is symplectic, there is another possibility of introducing singularities in the reduced phase space. After determining the corresponding invariants and computing the reduced (Hamiltonian) equations up to the desired order, the value of $\mathcal{T}$ has to be fixed to a constant $c \in \boldsymbol{R}$. This constant appears as a parameter in the constraints which define the reduced phase spaces. In other words, one has a parametric family of reduced phase spaces with at least one parameter.

Thus, these reduced phase spaces have different numbers of singularities according to the values the parameter c takes. We stress that this situation cannot be detected by analyzing the corresponding isotropy subgroups. A straightforward way of calculating the singularities consists in parametrizing the reduced phase space and computing thereafter its gradient vector. The new singularities are those points where the gradient vanishes.

3.2. Integration of the reduced equations. System (3.2) is solved analytically if the reduction procedure has simplified the original system enough; otherwise one resorts to numerical schemes.

First of all, we need to add to (3.2) the adequate initial conditions. Notice that $\boldsymbol{x}_0$ must be converted into a vector $\boldsymbol{y}_0$. It is done by constructing first the inverse change $(\boldsymbol{x} \to \boldsymbol{y})$ using formula (2.7) and truncating it at order M. Then $\boldsymbol{x}$ is replaced by $\boldsymbol{x}_0$, and one obtains an m-dimensional vector $\boldsymbol{y}_0$. Then, by means of $\pi_{\boldsymbol{T}}$, the vector $\boldsymbol{q}_0$ is calculated, and, finally, $\boldsymbol{p}_0$ is determined from the explicit expressions of the coordinates ϑ_i.

Associated with the system

$$\begin{aligned} D\boldsymbol{q}(t) &= \boldsymbol{\alpha}(\boldsymbol{q}(t);\varepsilon), \\ \boldsymbol{q}(t_0) &= \boldsymbol{q}_0, \end{aligned} \tag{3.3}$$

one has some algebraic constraints among the φ_i, which are responsible for defining the orbit space. The number of relations to take into account is $r - s$ (it is zero in some cases). This makes (3.3) a differential equation with constraints, which must either be solved analytically or integrated using adequate numerical methods (see, for example, [24] for generic systems and [26] for a specific algorithm in the Hamiltonian context). Note that the method chosen to execute the numerical computation must have a global error of a size similar to $\mathcal{O}(\varepsilon^{M+1})$ in order not to lose accuracy obtained with the analytic transformation.

Once the vector $\boldsymbol{q}(t)$ has been determined (either explicitly by analytic means or approximately with numerical tools) we are ready to solve the linear problem

$$\begin{aligned} D\boldsymbol{p}(t) &= \boldsymbol{\beta}(\boldsymbol{p}(t), \boldsymbol{q}(t);\varepsilon), \\ \boldsymbol{p}(t_0) &= \boldsymbol{p}_0. \end{aligned} \tag{3.4}$$

We remark that at this step $\boldsymbol{q}(t)$ is a known function of time. Sometimes system (3.4) is readily solved analytically, for instance in some one-dimensional systems (then one has $s = m - 1$). On other occasions we apply an explicit Runge–Kutta method maintaining the global error such as $\mathcal{O}(\varepsilon^{M+1})$. Thus, we obtain $\boldsymbol{p}(t)$ either analytically or numerically.

Finally, if the reduction process is in the Hamiltonian context one can make use of numerical methods based upon symplectic integrators (see, for instance, [45, 57]) to approximate the reduced equations.

3.3. Going back to the original equations. The recovering of the original ODE is a crucial step that makes our approach different from others based on averaging techniques, since our goal is to provide the (approximate) solution of a certain initial value problem. Thus, we need to pass to the initial set of variables through the inversion of the reduction map and the truncated change of coordinates, as we detail now.

We obtain $\boldsymbol{y}(t)$ from $\boldsymbol{q}(t)$ and $\boldsymbol{p}(t)$. This is achieved by solving a system of equations usually of nonlinear nature. In general, in many applications, the coordinates φ_i and ϑ_i are easily expressible in terms of $\boldsymbol{y}$, and this step is immediate (see, for instance, the examples of [39]). However, it could occur that a Newton (or quasi-Newton) method would be needed to obtain each $y_i(t)$. This would make the whole method rather complicated, and one would probably resort to applying numerical integrations from the very beginning.

From $\boldsymbol{y}(t)$ we make use of the direct change of coordinates given by (2.5) to determine $\boldsymbol{x}(t)$. This is the last step of the entire process.

4. Applications. All the calculations we present in the three examples have been done with the numerical and analytical routines of Mathematica, Version 4.2 [55] on a PowerMac G4. The formulae obtained have been translated to LaTeX using the Mathematica function TeXForm[formulae], so as to avoid mistakes in the transcription process.

4.1. Stiff perturbed ODE in two dimensions. Let the following planar nonlinear perturbed initial value problem be given:

$$\begin{aligned} Dx_1(t) &= -2x_1 + x_2 + \varepsilon(-2x_1^2 + x_2^2),\\ Dx_2(t) &= 998x_1 - 999x_2 + \varepsilon(x_1^2 + x_1x_2 + x_2^2), \end{aligned} \tag{4.1}$$

with $x_1(0) = 1/2$, $x_2(0) = 3/5$, and $\varepsilon = 10^{-4}$. As the eigenvalues of the linear part of (4.1) are $\lambda_1 = -1000$ and $\lambda_2 = -1$, the equation is clearly stiff.

We start by using an analytic method to approximate the solution. First, we make a linear transformation of the original equation so as to diagonalize the linear part of it. This is achieved by defining $y_1 = (-x_1 + x_2)/999$ and $y_2 = (998x_1 + x_2)/999$. The new system, in short $D\boldsymbol{y}(t) = \boldsymbol{f}(\boldsymbol{y};\varepsilon)$, reads as

$$\begin{aligned} Dy_1(t) &= -1000y_1 + \varepsilon(996002y_1^2 + 2000y_1y_2 - y_2^2),\\ Dy_2(t) &= -y_2 + 3\varepsilon(331669y_1^2 + 997y_1y_2 + y_2^2), \end{aligned} \tag{4.2}$$

with initial conditions $y_1(0) = \frac{1}{9990}$ and $y_2(0) = \frac{2498}{4995}$.

Now the linear part of (4.2) can be written as $A\boldsymbol{y}$ with $A = \operatorname{diag}\{-1000, -1\}$ and $\boldsymbol{y} = (y_1, y_2)^t$. We choose now the vector field $\boldsymbol{T}(\boldsymbol{y}) = A\boldsymbol{y}$. Clearly, $\boldsymbol{T}$ represents a symmetry of the linear part because $[A\boldsymbol{y}, \boldsymbol{T}(\boldsymbol{y})] = \boldsymbol{0}$. Our purpose is to extend

this symmetry to higher orders by applying an adequate Lie transformation, passing from $\boldsymbol{y}$ to the new coordinates $\boldsymbol{z} = (z_1, z_2)^t$. Let us denote by $\boldsymbol{w}(\boldsymbol{y}) \equiv \boldsymbol{w}(\boldsymbol{z}) = (w_1(\boldsymbol{z}), w_2(\boldsymbol{z}))^t$ the generating function, by $\boldsymbol{g}(\boldsymbol{z}) = (g_1(\boldsymbol{z}), g_2(\boldsymbol{z}))^t$ the nonlinear part of the resulting equation, and by $\widetilde{\boldsymbol{f}}(\boldsymbol{z}) = (\widetilde{f}_1(\boldsymbol{z}), \widetilde{f}_2(\boldsymbol{z}))^t$ the nonlinear part of (4.2) (without ε and replacing $\boldsymbol{y}$ by $\boldsymbol{z}$). Now the homology equation (2.4) which has to be solved in the unknowns $\boldsymbol{w}$ and $\boldsymbol{g}$ takes the following form:

$$\begin{aligned} 1000w_1(\boldsymbol{z}) - 1000z_1 D_1 w_1(\boldsymbol{z}) - z_2 D_2 w_1(\boldsymbol{z}) &= \widetilde{f}_1(\boldsymbol{z}) - g_1(\boldsymbol{z}), \\ w_2(\boldsymbol{z}) - 1000z_1 D_1 w_2(\boldsymbol{z}) - z_2 D_2 w_2(\boldsymbol{z}) &= \widetilde{f}_2(\boldsymbol{z}) - g_2(\boldsymbol{z}). \end{aligned} \tag{4.3}$$

As $\boldsymbol{g}$ is chosen so that $[\boldsymbol{g}, \boldsymbol{T}(\boldsymbol{z})] = \boldsymbol{0}$, we take $\boldsymbol{g}(\boldsymbol{z}) = (|z_1|^{999/1000} z_2, 0)^t$, and hence the transformed equation after truncation is $D\boldsymbol{z}(t) = \boldsymbol{h}(\boldsymbol{z}; \varepsilon) = A\boldsymbol{z} + \varepsilon \boldsymbol{g}(\boldsymbol{z})$. Observe that due to the trivial form of $\boldsymbol{g}$ we can get the solution of this latter differential equation and deduce from it the solution of $\boldsymbol{y}$ in terms of t. Then we would avoid the passage to the reduced equations and the subsequent study. However, we prefer to continue with the standard treatment in order to show all the steps. The expression for the generating function reads as

$$\begin{aligned} w_1(\boldsymbol{z}) &= -\frac{498001}{500} z_1^2 - 2000 z_1 z_2 - \frac{1}{998} z_2^2 + \frac{1}{1000} |z_1|^{999/1000} z_2 \log |z_1|, \\ w_2(\boldsymbol{z}) &= -\frac{995007}{1999} z_1^2 - \frac{2991}{1000} z_1 z_2 - 3 z_2^2. \end{aligned}$$

This completes the normal form procedure at first order. Note that since the limit of w_1 when z_1 tends to zero is finite, we extend the domain of definition of the generating function and consider also the axis $z_1 = 0$.

The vector spaces $\mathcal{P}_i$ and $\mathcal{R}_i$ are chosen as the spaces of continuous vector fields in $\boldsymbol{R}^2$ whose coefficients are in $\boldsymbol{R}$. For each i, the space $\mathcal{Q}_i$ corresponds to the vector subspace of $\mathcal{P}_i$ for which the Lie bracket $[\boldsymbol{q}, T\boldsymbol{y}] = \boldsymbol{0}$ for any continuous two-dimensional vector field $\boldsymbol{q}$. Of course, if we remove the axis $y_1 = 0$ from our analysis, we can consider all vector spaces smooth functions.

Now we calculate the first integrals and the coordinates of the Lie group arriving at the expressions $\varphi = z_1 z_2^{-1000}$ and $\vartheta = z_2$. Thus $r = s = 1$, and $m - s = 1$. We need to transform the initial conditions $y_1(0)$ and $y_2(0)$ in order to obtain $z_1(0)$ and $z_2(0)$. This is done by means of the inverse Lie transformation (2.7), yielding $\boldsymbol{z} = \boldsymbol{Z}(\boldsymbol{y}; \varepsilon)$, where

$$\begin{aligned} z_1 &= y_1 + \varepsilon \left(\frac{498001}{500} y_1^2 + 2000 y_1 y_2 + \frac{1}{998} y_2^2 - \frac{999}{1000} |y_1|^{999/1000} y_2 \log |y_1| \right), \\ z_2 &= y_2 + \varepsilon \left(\frac{995007}{1999} y_1^2 + \frac{2991}{1000} y_1 y_2 + 3 y_2^2 \right). \end{aligned}$$

Replacing in the latter equation $y_1(0)$ and $y_2(0)$ by their specific values we get $z_1(0) = 1.101382 \times 10^{-4}$ and $z_2(0) = 0.500175$. Now we can obtain the reduced equations together with their initial conditions φ_0 and ϑ_0:

$$D\varphi(t) = \varepsilon |\varphi|^{999/1000}, \qquad \varphi_0 = 8.31439 \times 10^{296} \tag{4.4}$$

and

$$D\vartheta(t) = -\vartheta, \qquad \vartheta_0 = 0.500175. \tag{4.5}$$

Note that (4.4) is defined in $\boldsymbol{R}$, which is indeed the reduced phase space (as $r = s$ there is no constraint for the reduced phase space). The Lie group is also isomorphic to $\boldsymbol{R}$. We are lucky this time and can calculate explicit solutions of φ and ϑ as functions of time. We have that

$$\varphi(t) = \left(|\varphi_0|^{1/1000} + \frac{\varepsilon t}{1000}\right)^{1000}, \qquad \vartheta(t) = \vartheta_0 \exp(-t).$$

Now z_1 and z_2 are directly written as functions of time: $z_1(t) = \varphi(t)\vartheta(t)^{1000}$ and $z_2(t) = \vartheta(t)$. The next step consists in calculating the vector $\boldsymbol{y}$ in terms of $\boldsymbol{z}$, i.e., the direct change $\boldsymbol{y} = \boldsymbol{Y}(\boldsymbol{z};\varepsilon)$. This is done by means of (2.5) arriving at

$$y_1 = z_1 - \varepsilon\left(\frac{498001}{500}z_1^2 + 2000 z_1 z_2 + \frac{1}{998}z_2^2 - \frac{999}{1000}|z_1|^{999/1000} z_2 \log|z_1|\right),$$

$$y_2 = z_2 - \varepsilon\left(\frac{995007}{1999}z_1^2 + \frac{2991}{1000}z_1 z_2 + 3z_2^2\right).$$

Finally, we put the initial variables $\boldsymbol{x}$ in terms of $\boldsymbol{y}$ and arrive at an approximate solution of the stiff problem $\boldsymbol{x}(t)$ up to order $\mathcal{O}(\varepsilon^2)$.

A bound of the error made in the process of the Lie transformation is obtained after computing $\|\boldsymbol{h}(\boldsymbol{z};\varepsilon) - \boldsymbol{f}(\boldsymbol{Y}(\boldsymbol{z};\varepsilon);\varepsilon)\| = \varepsilon^2\|\boldsymbol{e}(\boldsymbol{z})\| + \mathcal{O}(\varepsilon^3)$, where $\|\boldsymbol{e}(\boldsymbol{z})\|^2$ is given by

$$\begin{aligned}\frac{1}{|z_1|^{1/500}}\big\{&z_1^2 z_2^2[0.995505 z_1 + 0.002991 z_2\\ &+(-0.000995505 z_1 - 2.991\times 10^{-6} z_2)\log|z_1|]^2\\ &+[-0.497752 z_1^3 + 0.995003 z_1^2 z_2 - 10^{-6}|z_1|^{999/1000} z_2^2 + 0.001 z_1 z_2^2 - 10^{-6} z_2^3\\ &+(0.000497752 z_1^3 - 0.000994007 z_1^2 z_2 + 10^{-6} z_1 z_2^2 + 1.001\times 10^{-9} z_2^3)\log|z_1|]^2\big\}.\end{aligned}$$

Bounding $\boldsymbol{z}$ such that $\max\{|z_1|, |z_2|\} = 1$ and fixing $\varepsilon = 10^{-4}$ we conclude that $\|\boldsymbol{e}(\boldsymbol{z})\| \leq 1.79177\times 10^{-8}$ is an upper bound of the global error. Finally, using the changes $\boldsymbol{y} = \boldsymbol{Y}(\boldsymbol{z};\varepsilon)$, together with the linear transformation relating $\boldsymbol{y}$ and $\boldsymbol{x}$, we obtain that whenever the variable $\boldsymbol{x}$ is controlled such that $|x_1| \leq 2$ and $|x_2| \leq 1000$, the total error of the computation never exceeds 1.79177×10^{-8} in an approximate time interval $[0, 10^4]$.

Notice that we could have chosen another vector field $\boldsymbol{T}(\boldsymbol{y})$ to make the transformation and construct the reduced equations, for instance $\boldsymbol{T}(\boldsymbol{y}) = (y_1, -y_2)^t$. Then the process would not be the same, and it would lead to a different asymptotic approximation of the original equation.

If we perform a numerical integration of (4.1) in a time interval $[0, 10^4]$ and use a Runge–Kutta–Felhberg embedded scheme of orders 4–5 equipped with dense output, the iteration stops at $t = 367.75$, as the process does not converge. However, using the backward-difference formula [23, 24] with variable order (i.e., a stiff-ODE-solver) there is convergence after 258 steps, obtaining a result which is exact up to 14 or 15 digits, and thus in many cases it is better than our approach. However, varying the initial conditions in the domain defined by $|x_1| \leq 2$ and $|x_2| \leq 1000$, the numerical integration by means of the backward-difference integrator does not converge where the analytical procedure gives satisfactory results.

4.2. Analytical integration of the Lorenz equations. We apply the theory of sections 2 and 3 to the Lorenz system given by

(4.6)
$$Dx_1(t) = 10(x_2 - x_1), \quad Dx_2(t) = 28x_1 - x_2 - x_1x_3, \quad Dx_3(t) = x_1x_2 - \frac{8}{3}x_3,$$

where t represents the time variable. To the latter system we add some initial conditions $\boldsymbol{x}(0) = (1/15, -1/11, 1/10)^t$. Equation (4.6) has been widely analyzed through the literature (see, for instance, the book by Verhulst [49] and the references therein), mainly with regard to its chaotic behavior and the existence of a strange attractor. Our aim now is to apply the method described in section 2 to system (4.6) with the goal of analyzing the Lorenz equations in a vicinity of the origin.

The linear part of (4.6) is given by $A\boldsymbol{x}$, where $\boldsymbol{x} = (x_1, x_2, x_3)^t$ and

$$A = \begin{pmatrix} -10 & 10 & 0 \\ 28 & -1 & 0 \\ 0 & 0 & -8/3 \end{pmatrix},$$

and its eigenvalues are $\lambda_{1,2} = \frac{1}{2}(-11 \pm \sqrt{1201})$ and $\lambda_3 = -8/3$. Now we make the corresponding linear change of variables $\boldsymbol{x} \to \boldsymbol{y}'$ so that A becomes diagonal (we call it A_J) with the eigenvalues in its diagonal. We stretch the variables, say $\boldsymbol{y}' \to \varepsilon\boldsymbol{y}$, so as to introduce a dimensionless small parameter $\varepsilon > 0$. Then the resulting differential equation $D\boldsymbol{y}(t) = \boldsymbol{f}(\boldsymbol{y}; \varepsilon)$ can be considered as a perturbed dynamical system. We look for a symmetry of the linear part $A_J\boldsymbol{y}$. It is achieved by taking $T = \operatorname{diag}\{1, \sqrt{2}, 0\}$, and thus $A_JT = TA_J$ and $[A_J\boldsymbol{y}, T\boldsymbol{y}] = \boldsymbol{0}$. This time $s = r = 1$, $m - s = 2$.

We perform the Lie transformation with the aim of constructing a new set of coordinates $\boldsymbol{z}$ in terms of $\boldsymbol{y}$. Let $\boldsymbol{w}_i(\boldsymbol{y}) \equiv \boldsymbol{w}_i(\boldsymbol{z}) = (w_{1i}(\boldsymbol{z}), w_{2i}(\boldsymbol{z}), w_{3i}(\boldsymbol{z}))^t$ be the generating function at order i, $\boldsymbol{g}_i(\boldsymbol{z}) = (g_{1i}(\boldsymbol{z}), g_{2i}(\boldsymbol{z}), g_{3i}(\boldsymbol{z}))^t$ be the nonlinear part of the transformed equation, and $\widetilde{\boldsymbol{f}}_i(\boldsymbol{z}) = (\widetilde{f}_{1i}(\boldsymbol{z}), \widetilde{f}_{2i}(\boldsymbol{z}), \widetilde{f}_{3i}(\boldsymbol{z}))^t$ be the known part at each order; hence the homology equation (2.4) reads as

$$\frac{8}{3}w_{1i}(\boldsymbol{z}) + n_1z_3D_3w_{1i}(\boldsymbol{z}) - n_2z_2D_2w_{1i}(\boldsymbol{z}) - \frac{8}{3}z_1D_1w_{1i}(\boldsymbol{z}) = \widetilde{f}_{1i}(\boldsymbol{z}) - g_{1i}(\boldsymbol{z}),$$

$$n_2w_{2i}(\boldsymbol{z}) + n_1z_3D_3w_{2i}(\boldsymbol{z}) - n_2z_2D_2w_{2i}(\boldsymbol{z}) - \frac{8}{3}z_1D_1w_{2i}(\boldsymbol{z}) = \widetilde{f}_{2i}(\boldsymbol{z}) - g_{2i}(\boldsymbol{z}),$$

$$-n_1w_{3i}(\boldsymbol{z}) + n_1z_3D_3w_{3i}(\boldsymbol{z}) - n_2z_2D_2w_{3i}(\boldsymbol{z}) - \frac{8}{3}z_1D_1w_{3i}(\boldsymbol{z}) = \widetilde{f}_{3i}(\boldsymbol{z}) - g_{3i}(\boldsymbol{z}),$$

where $n_1 = (-11 + \sqrt{1201})/2$ and $n_2 = (11 + \sqrt{1201})/2$.

We denote by $D\boldsymbol{z}(t) = \boldsymbol{h}(\boldsymbol{z}; \varepsilon)$ the normal form up to order three, and it is given by

(4.7)
$$Dz_1(t) = -\frac{8}{3}z_1 + \varepsilon\frac{(-9+\sqrt{1201})}{56}z_3^2 - \varepsilon^3\frac{238268911748107 + 3427671328157\sqrt{1201}}{3389702400(32622739 + 543621\sqrt{1201})}z_3^4,$$

$$Dz_2(t) = -\frac{11+\sqrt{1201}}{2}z_2 + \varepsilon^2\frac{3(1893759619 - 24165531\sqrt{1201})}{10117320080(25+3\sqrt{1201})}z_3^3,$$

$$Dz_3(t) = \frac{-11+\sqrt{1201}}{2}z_3 + \varepsilon^2\frac{15(1201 - 1689\sqrt{1201})}{134512(25+3\sqrt{1201})}z_3^3.$$

Terms in (4.7) factored by ε form the vector $\boldsymbol{h}_1$, whereas those factored by ε^2 are part of $\boldsymbol{h}_2$, and those factored by ε^3 define $\boldsymbol{h}_3$. Besides, $[\boldsymbol{h}_i, T\boldsymbol{y}] = \mathbf{0}$ for $1 \le i \le 3$. The expressions of $\boldsymbol{w}_1$, $\boldsymbol{w}_2$, and $\boldsymbol{w}_3$ have been calculated using rational arithmetic, but we display an approximation with 10 digits. Thus we obtain the generating function $\boldsymbol{w} = \boldsymbol{w}_1 + \varepsilon \boldsymbol{w}_2 + (\varepsilon^2/2)\boldsymbol{w}_3$:

$$
\begin{aligned}
\boldsymbol{w}(\boldsymbol{z};\varepsilon) = (&0.0181340700 z_2^2 + 0.0385714285 z_2 z_3,\\
&- 0.1082080981 z_1 z_2 - 0.0053011728 z_1 z_3,\\
&- 0.0131559168 z_1 z_2 + 0.1082080981 z_1 z_3)^t\\
&+ \varepsilon(-0.0031438583 z_1 z_2^2 + 0.0008811978 z_1 z_2 z_3 + 0.0087311650 z_1 z_3^2,\\
&\quad - 0.0009063498 z_1^2 z_2 + 0.0017330286 z_2^3 - 0.0013559321 z_1^2 z_3\\
&\quad + 0.0028053572 z_2^2 z_3 + 0.0038427758 z_2 z_3^2,\\
&\quad 0.0024674265 z_1^2 z_2 + 0.0000168333 z_2^3 + 0.0009063498 z_1^2 z_3\\
&\quad - 0.0020552276 z_2^2 z_3 - 0.0032459561 z_2 z_3^2)^t\\
&+ \varepsilon^2(-0.0000795658 z_1^2 z_2^2 + 0.0001163808 z_2^4 + 0.0004142502 z_1^2 z_2 z_3\\
&\quad + 0.0001652742 z_2^3 z_3 - 0.0003707416 z_1^2 z_3^2\\
&\quad - 0.0000956330 z_2^2 z_3^2 - 0.0002239279 z_2 z_3^3,\\
&\quad - 0.0000618375 z_1^3 z_2 + 0.0001945584 z_1 z_2^3 - 0.0000817780 z_1^3 z_3\\
&\quad + 0.0004607450 z_1 z_2^2 z_3 - 0.0004185807 z_1 z_2 z_3^2 + 0.0000749699 z_1 z_3^3,\\
&\quad 0.0001084983 z_1^3 z_2 - 0.0000998823 z_1 z_2^3 + 0.0000618375 z_1^3 z_3\\
&\quad - 0.0004245437 z_1 z_2^2 z_3 - 0.0005441518 z_1 z_2 z_3^2\\
&\quad - 0.0014274482 z_1 z_3^3)^t + \mathcal{O}(\varepsilon^3).
\end{aligned}
$$

The vector spaces $\mathcal{P}_i$ and $\mathcal{R}_i$ coincide and are identified with the homogeneous polynomial spaces of dimension 3 and of degree i with coefficients in $\boldsymbol{R}$. Given an i, the space $\mathcal{Q}_i$ corresponds to the vector subspace of $\mathcal{P}_i$ for which the Lie bracket $[\boldsymbol{q}, T\boldsymbol{y}] = \mathbf{0}$ for any homogeneous polynomial vector $\boldsymbol{q}$ of degree i.

The first integrals associated with $T\boldsymbol{z}$ are the invariant polynomials determined from the partial differential equation $\langle D\varphi(\boldsymbol{z}), T\boldsymbol{z}\rangle = 0$, obtaining $\varphi = z_3$; therefore the coordinates of the Lie group are $\vartheta_1 = z_1$ and $\vartheta_2 = z_2$. The key point to obtain only one invariant—and, consequently, transform the initial system to a simpler one—is the nonexistence of resonant conditions among the entries of T. After computing the normal form up to order three, we pass to the reduced equations, yielding that

$$
D\varphi(t) = \frac{-11 + \sqrt{1201}}{2}\varphi + \frac{15(1201 - 1689\sqrt{1201})}{134512(25 + 3\sqrt{1201})}\varepsilon^2\varphi^3, \tag{4.8}
$$

and

$$
\begin{aligned}
D\vartheta_1(t) &= \frac{-9 + \sqrt{1201}}{56}\varepsilon\varphi^2 - \frac{238268911748107 + 3427671328157\sqrt{1201}}{3389702400(32622739 + 543621\sqrt{1201})}\varepsilon^3\varphi^4 - \frac{8}{3}\vartheta_1,\\
D\vartheta_2(t) &= \frac{3(1893759619 - 24165531\sqrt{1201})}{10117320080(25 + 3\sqrt{1201})}\varepsilon^2\varphi^3 - \frac{11 + \sqrt{1201}}{2}\vartheta_2.
\end{aligned} \tag{4.9}
$$

Observe that if we were interested in calculating some invariant sets of (4.6) through the normal forms, it could be enough to analyze the equilibria of the scalar equation (4.8) defined in $\mathbf{R}$. These critical points are in correspondence with two-dimensional

tori of the original equation which would be approximated using the direct Lie transformation. See [41, 37] for more details.

Solutions of (4.8) and (4.9) are obtained straightforwardly, as φ is first written explicitly as a function of time. Specifically, if $\varphi_0 = \varphi(0)$, we have

(4.10)
$$\varphi(t) = \frac{8\sqrt{8407(416-\sqrt{1201})}\exp\left(\frac{-11+\sqrt{1201}}{2}t\right)\varphi_0}{\sqrt{538048(416-\sqrt{1201})+15(1201-1689\sqrt{1201})\{1-\exp[(-11+\sqrt{1201})t]\}\varepsilon^2\varphi_0^2}}.$$

This expression is inserted in the linear equations (4.9). We rewrite system (4.9) as

$$D\vartheta_1(t) = a(t;\varepsilon) - \frac{8}{3}\vartheta_1, \qquad D\vartheta_2(t) = b(t;\varepsilon) - \frac{11+\sqrt{1201}}{2}\vartheta_2, \tag{4.11}$$

where $a(t;\varepsilon)$ and $b(t;\varepsilon)$ come from (4.9) after substituting φ by its expression given in (4.10). Hence we get

$$\begin{aligned}
\vartheta_1(t) &= \exp\left(-\frac{8}{3}t\right)\left((\vartheta_1)_0 + \int_0^t \exp\left(\frac{8}{3}s\right)a(s;\varepsilon)\,ds\right),\\
\vartheta_2(t) &= \exp\left(-\frac{11+\sqrt{1201}}{2}t\right)\left((\vartheta_2)_0 + \int_0^t \exp\left(\frac{11+\sqrt{1201}}{2}s\right)b(s;\varepsilon)\,ds\right),
\end{aligned} \tag{4.12}$$

the constants $(\vartheta_1)_0$ and $(\vartheta_2)_0$ being, respectively, $\vartheta_1(0)$ and $\vartheta_2(0)$. Note that $z_3(t) = \varphi(t)$, $z_1(t) = \vartheta_1(t)$, and $z_2(t) = \vartheta_2(t)$. Moreover, $\varphi_0 = z_3(0)$, $(\vartheta_1)_0 = z_1(0)$, and $(\vartheta_2)_0 = z_2(0)$. Thus, $\boldsymbol{z}(0)$ is obtained from $\boldsymbol{y}(0)$ using the expression $\boldsymbol{z} = \boldsymbol{Z}(\boldsymbol{y};\varepsilon)$, i.e., the inverse Lie transformation. As the expressions with rational arithmetic are quite involved, we display the corresponding numerical approximations with 10 digits. We have $\boldsymbol{z} = \boldsymbol{Z}(\boldsymbol{y};\varepsilon)$ with

$$\begin{aligned}
z_1 &= y_1 + \varepsilon(-0.0181340700y_2^2 - 0.0385714y_2y_3)\\
&\quad + \varepsilon^2(0.00314386y_1y_2^2 - 0.00873117y_1y_3^2 - 0.000881198y_1y_2y_3)\\
&\quad + \varepsilon^3(-0.000263461y_1^2y_2^2 + 2.06654\times10^{-6}y_2^4 - 0.000133513y_1^2y_2y_3\\
&\qquad + 0.0000146633y_2^3y_3 - 0.000783226y_1^2y_3^2 + 0.0000128441y_2^2y_3^2\\
&\qquad + 0.0000176879y_2y_3^3),\\
z_2 &= y_2 + \varepsilon(0.108208y_1y_2 + 0.00530117y_1y_3)\\
&\quad + \varepsilon^2(0.00090635y_1^2y_2 - 0.00173303y_2^3 + 0.00135593y_1^2y_3\\
&\qquad - 0.00280536y_2^2y_3 - 0.00384278y_2y_3^2)\\
&\quad + \varepsilon^3(0.0000154594y_1^3y_2 + 0.000295189y_1y_2^3 + 0.000182807y_1^3y_3\\
&\qquad - 0.000140385y_1y_2^2y_3 - 0.000605481y_1y_2y_3^2 - 0.0000504421y_1y_3^3),\\
z_3 &= y_3 + \varepsilon(0.0131559y_1y_2 - 0.108208y_1y_3)\\
&\quad + \varepsilon^2(-0.00246743y_1^2y_2 - 0.0000168333y_2^3 - 0.00090635y_1^2y_3\\
&\qquad + 0.00205523y_2^2y_3 + 0.00324596y_2y_3^2)\\
&\quad + \varepsilon^3(0.00022467y_1^3y_2 + 4.6008581025\times10^{-6}y_1y_2^3 - 0.0000154594y_1^3y_3\\
&\qquad - 0.000358644y_1y_2^2y_3 + 0.000191187y_1y_2y_3^2 + 0.00117751y_1y_3^3).
\end{aligned}$$

Now $\boldsymbol{y}$ must be expressed in terms of $\boldsymbol{z}$ so as to obtain the direct change $\boldsymbol{y} = \boldsymbol{Y}(\boldsymbol{z};\varepsilon)$ that we do not write down for reasons of space.

Fixing a value for t we evaluate $\boldsymbol{z}(t)$ with the aid of (4.10) and (4.12) (the initial conditions φ_0, $(\vartheta_1)_0 = z_1(0)$, and $(\vartheta_2)_0 = z_2(0)$ are supposed to be calculated previously). Then we determine $\boldsymbol{y}(t)$ by replacing $\boldsymbol{z}(t)$ in the latter system. Hence, we undo the scaling $\boldsymbol{y}(t) = \boldsymbol{y}'(t)/\varepsilon$, and in the end we get $\boldsymbol{x}(t)$ inverting back the Jordan linear change of variables.

Concerning an estimation of the error we know that

$$\|\boldsymbol{f}(\boldsymbol{y};\varepsilon) - \boldsymbol{h}(\boldsymbol{Z}(\boldsymbol{y};\varepsilon);\varepsilon)\| = \varepsilon^4\|\boldsymbol{e}(\boldsymbol{y})\| + \mathcal{O}(\varepsilon^5),$$

where $\|\boldsymbol{e}(\boldsymbol{y})\|^2$ stands for the quantity

$$\begin{aligned}
&1.75\times 10^{-10}y_1^8(y_2^2+y_3^2)\\
&\quad +10^{-9}y_1^6y_3(-1.806y_2^3-1.744y_2^2y_3+1.277y_2y_3^2-2.705y_3^3)\\
&\quad +10^{-10}y_2^2y_3^2(1.42y_2^6+2.84y_2^5y_3+3.47y_2^4y_3^2+1.95y_2^3y_3^3+2.80y_2y_3^5+3.31y_3^6)\\
&\quad +10^{-8}y_1^4(0.0763y_2^6+0.2359y_2^5y_3+0.4409y_2^4y_3^2+0.5054y_2^3y_3^3+0.04450y_2^2y_3^4\\
&\qquad\qquad -1.0003y_2y_3^5+1.5684y_3^6)\\
&\quad +10^{-9}y_1^2(-0.122y_2^8-0.688y_2^7y_3-1.725y_2^6y_3^2-2.249y_2^5y_3^3-1.083y_2^4y_3^4\\
&\qquad\qquad -1.396y_2^3y_3^5-0.545y_2^2y_3^6+3.645y_2y_3^7+0.389y_3^8).
\end{aligned}$$

We restrict ourselves to a vicinity of the origin of the original system. So we bound $\boldsymbol{y}$ by taking $\max\{|y_1|,|y_2|,|y_3|\} = 10$, and choosing $\varepsilon = 10^{-2}$ we have that the global error of our approach is upper bounded by $\varepsilon^4\|\boldsymbol{e}(\boldsymbol{y})\| \leq 1.33969\times 10^{-7}$ on a time scale of order $t \approx 100$. Then, going back to the variable $\boldsymbol{x}$, the solution of the Lorenz equation is calculated with an error less than 1.33969×10^{-7}, provided that we consider $|x_1| \leq 0.26$, $|x_2| \leq 2.28$, and $|x_3| \leq 1.18$.

Note that the solution of (4.6) is calculated almost explicitly. The only drawback is the determination of $\vartheta_1(t)$ and $\vartheta_2(t)$ since it is impossible to put the integrals appearing in (4.12) in terms of known functions of time. However, it is not hard to obtain an approximation of such integrals using polynomial interpolation or even to evaluate them explicitly for a given value of t by means of a standard algorithm capable of approximating numerically definite integrals maintaining the global error smaller than 10^{-7}.

4.3. Reduction and numerical integration of free particles in three degrees of freedom. Suppose we have the case of a free particle in three degrees of freedom (point mass) whose position is given by the vector $\boldsymbol{x} = (x,y,z)^t$, whereas its corresponding velocity is the vector $\boldsymbol{X} = (X,Y,Z)^t$. If the particle is subject to a weak perturbation, the dynamical system describing this effect is given by the Hamilton function

$$\mathcal{H}(\boldsymbol{x},\boldsymbol{X};\boldsymbol{c}) = \frac{1}{2}(X^2+Y^2+Z^2) + \mathcal{P}(\boldsymbol{x},\boldsymbol{X};\boldsymbol{c}), \tag{4.13}$$

where $\mathcal{P}$ refers to the perturbation and is a generic polynomial in $\boldsymbol{x}$ and $\boldsymbol{X}$ of degree three or higher and $\boldsymbol{c}$ contains some parameter(s) of the problem.

First, we define the symplectic change

$$x = X^*, \qquad y = Y^*, \qquad z = Z^*, \qquad X = x^*, \qquad Y = y^*, \qquad Z = z^*. \tag{4.14}$$

Then, after dropping the asterisks to avoid tedious notation, Hamiltonian (4.13) becomes

$$\mathcal{H}(\boldsymbol{x};\boldsymbol{X};\boldsymbol{c}) = \mathcal{H}_0(\boldsymbol{x}) + \mathcal{P}(\boldsymbol{x},\boldsymbol{X};\boldsymbol{c}) = \frac{1}{2}(x^2+y^2+z^2) + \mathcal{H}_1(\boldsymbol{x},\boldsymbol{X};\boldsymbol{c}), \tag{4.15}$$

where we have identified $\mathcal{P}$ with $\mathcal{H}_1$. By means of the linear change (4.14) the unperturbed part of $\mathcal{H}_0$ is proportional to the square of the distance of the particle to the origin, and we can use the whole $\mathcal{H}_0$ as a sole coordinate. Indeed, we introduce a set of orbital variables $(r, \vartheta, \nu, R, \Theta, N)$—called polar-nodal variables—where r stands for the radial distance from the origin of reference to the particle, ϑ represents the argument of latitude, and ν is the right ascension of the node, whereas R, Θ, and N are the conjugate momenta of r, ϑ, and ν, respectively. Besides, $rR = \langle \boldsymbol{x}, \boldsymbol{X} \rangle$, the action Θ designates the modulus of the angular momentum vector, i.e., $\Theta = \|\boldsymbol{x} \times \boldsymbol{X}\|$, and $N = xY - yX$ stands for the third component of the angular momentum; see more details in [11]. Whittaker [54] demonstrated that the transformation

$$\varrho : (r, \vartheta, \nu, R, \Theta, N) \longrightarrow (x, y, z, X, Y, Z),$$

defined by

$$\begin{array}{ll} x = \bar{x}\cos\nu - \bar{y}\cos I \sin\nu, & X = \bar{X}\cos\nu - \bar{Y}\cos I \sin\nu, \\ y = \bar{x}\sin\nu + \bar{y}\cos I \cos\nu, & Y = \bar{X}\sin\nu + \bar{Y}\cos I \cos\nu, \\ z = \bar{y}\sin I, & Z = \bar{Y}\sin I, \end{array} \tag{4.16}$$

where $\cos I = N/\Theta$ and $\bar{x}$, $\bar{y}$, $\bar{X}$, and $\bar{Y}$ are given through

$$\begin{array}{ll} \bar{x} = r\cos\vartheta, & \bar{X} = R\cos\vartheta - \dfrac{\Theta}{r}\sin\vartheta, \\ \bar{y} = r\sin\vartheta, & \bar{Y} = R\sin\vartheta + \dfrac{\Theta}{r}\cos\vartheta, \end{array} \tag{4.17}$$

is symplectic. We have to take into account that the transformation ϱ is singular for $\Theta = 0$, and $\Theta = |N|$ as I is an angle defined in $(0, \pi)$. Therefore, the domain of validity of the change given by ϱ is the subset of $\boldsymbol{R}^6$ defined by

$$\Delta = [0, +\infty) \times [0, 2\pi) \times [0, 2\pi) \times \boldsymbol{R} \times (0, \infty) \times (-\Theta, \Theta).$$

Let us denote by $\boldsymbol{P_N}$ the set of polar-nodal coordinates. In these variables we have $\mathcal{H}_0 = r^2/2$ and $\mathcal{H}_1(\boldsymbol{x}, \boldsymbol{X}; \boldsymbol{c}) \equiv \mathcal{H}_1(\boldsymbol{P_N}; \boldsymbol{c})$. Every term of $\mathcal{H}_1$ contains powers of r, R, Θ, N, or $(1 - N^2/\Theta^2)^{1/2}$, whereas ϑ and ν appear through sines and cosines of multiples of them. Now the Lie operator associated with $\mathcal{H}_0$ is the nilpotent[1] linear operator

$$\mathcal{L}_{\mathcal{H}_0} = rD_4(\cdot(\boldsymbol{P_N})),$$

and the transformation can be executed readily. In fact, if $\mathcal{W}_i$ designates the scalar generating function at order i, the homology equation which has to be solved at each order is

$$rD_4\mathcal{W}_i(\boldsymbol{P_N}) + \mathcal{K}_i = \widetilde{\mathcal{H}_i}. \tag{4.18}$$

Our goal is to construct a formal change of coordinates $\boldsymbol{P_N} \to \boldsymbol{P_N}'$, that is,

$$(r, \vartheta, \nu, R, \Theta, N) \longrightarrow (r', \vartheta', \nu', R', \Theta', N'),$$

so that Θ' and N' become formal integrals of the transformed Hamiltonian. We drop the primes for the polar-nodal variables to avoid tedious notation. Indeed, since both

[1] Its nilpotent character is analyzed in [39].

Θ and N are integrals of $\mathcal{H}_0$, it could be possible to build a unique transformation such that the new Hamiltonian $\mathcal{K}$ has them as integrals. (Note that the corresponding vector fields $\boldsymbol{T}_1$ and $\boldsymbol{T}_2$ are the constant six-dimensional vectors (respectively, (0,0,0,0,−1,0) and (0,0,0,0,0,−1)).)

Next, one has to bring $\mathcal{H}$ to polar-nodal coordinates by means of the transformations (4.16) and (4.17). Then the homology equation has to be solved, and $\widetilde{\mathcal{H}_i}$ is split as

$$\widetilde{\mathcal{H}_i}(r,\vartheta,\nu,R,\Theta,N)=\widetilde{\mathcal{H}_i}^{*}(r,-,-,R,\Theta,N)+\widetilde{\mathcal{H}_i}^{\#}(r,\vartheta,\nu,R,\Theta,N),$$

where $\widetilde{\mathcal{H}_i}^{*}$ groups all the terms of $\widetilde{\mathcal{H}_i}$ independent of ϑ and of ν. So a term belongs to $\ker(\mathcal{L}_\Theta)\cap\ker(\mathcal{L}_N)$ if and only if it is independent of ϑ and of ν. Hence, $\mathcal{K}_i$ is taken to be $\widetilde{\mathcal{H}_i}^{*}$, and $\mathcal{W}_i$ is obtained by solving the quadrature (4.18). The process can be iterated to any order. After M steps, the transformed Hamiltonian $\mathcal{K}$ is given by

$$\mathcal{K}(r,\vartheta,\nu,R,\Theta,N)=\frac{1}{2}r^2+\varepsilon\mathcal{K}_1(r,R;\Theta,N)+\cdots+\frac{\varepsilon^M}{M!}\mathcal{K}_M(r,R;\Theta,N)+\mathcal{O}(\varepsilon^{M+1}).$$

Dropping the tail to $\mathcal{K}$ and giving the same name to the resulting Hamiltonian, we observe that it is independent of ϑ and of ν. In fact, our Lie transformation can be understood as an average over the angles ϑ and ν. Then Θ and N are integrals of $\mathcal{K}$. In this situation $\mathcal{K}$ defines a Hamiltonian vector field with one degree of freedom in the coordinate r and its momentum R.

Next, as we have introduced the integrals Θ and N, we build the invariants of the group of symmetry associated with them. The Poisson brackets of the terms $\varphi_1=x^2+y^2+z^2$, $\varphi_2=X^2+Y^2+Z^2$, $\varphi_3=xX+yY+zZ$, $\varphi_4=xY-yX$, and $\varphi_5=(xY-yX)^2+(xZ-zX)^2+(yZ-zY)^2$ with respect to Θ and N vanish, and they are related through $\varphi_1\varphi_2=\varphi_3^2+\varphi_5$. Thus, we have $r=5$, $s=4$, and $m-s=2$. However, two of the five differential equations associated with the φ_i are trivial, as Θ and N become constants of motion. Note that the cases excluded in polar-nodal variables, i.e., $\Theta=0$ and $|N|=\Theta$, are recovered with the use of the invariants, as they are polynomials, and thus they define perfectly the reduced phase space. Nevertheless, it is relevant only if one is interested in analyzing the behavior of the whole original system through its normal form.

Now we fix values for Θ and N, that is, $\varphi_4=c_1$, $\varphi_5=c_2\geq 0$, with $|c_1|\leq\sqrt{c_2}$. So $\mathcal{K}$ is transformed into the following Hamilton function in nonsymplectic variables:

$$\mathcal{T}(\varphi_1,\varphi_2,\varphi_3;c_1,c_2)=\frac{1}{2}\varphi_1+\varepsilon\mathcal{T}_1(\varphi_1,\varphi_2,\varphi_3;c_1,c_2)+\cdots+\frac{\varepsilon^M}{M!}\mathcal{T}_M(\varphi_1,\varphi_2,\varphi_3;c_1,c_2).$$

Note that the generators of the phase space satisfy

$$\varphi_1\varphi_2=\varphi_3^2+c_2, \tag{4.19}$$

defining, therefore, a two-dimensional surface with respect to the axes φ_1, φ_2, and φ_3, that is, a hyperbolic paraboloid. In the case $c_2=0$ the surface has a singularity at the origin of the frame defined by φ_1, φ_2, and φ_3. However, it is still possible to analyze this situation in the context of singular reduction. See the images depicted in Figure 4.1.

There still remains the extreme situation $\varphi_1=0$. It implies that $x=y=z\equiv 0$, which forces us to consider $\varphi_3=\varphi_4=\varphi_5\equiv 0$, whereas $\varphi_2\geq 0$. In this case the reduced phase space gets reduced to the straight line.

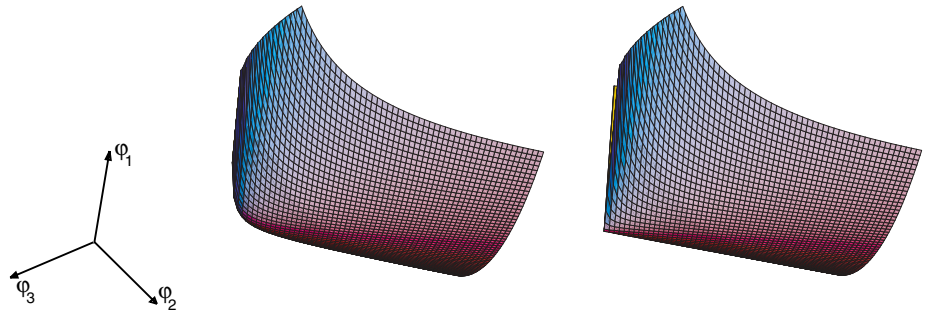

FIG. 4.1. *Reduced phase spaces (orbit spaces) for a Hamiltonian like* $\mathcal{T}(\varphi_1, \varphi_2, \varphi_3)$ *satisfying* (4.19). *The surface on the left is regular and corresponds to the cases* $c_2 \neq 0$. *The surface on the right has a singularity at the origin and is related to* $c_2 = 0$.

As an application of the above paragraphs we take in Hamiltonian (4.15) the perturbation $\mathcal{H}_1 = c\,xyz$, with the constant $c > 0$ being sufficiently small to consider $\mathcal{P}$ a small perturbation of $\mathcal{H}_0$ with small parameter c. Note that with this choice function $\mathcal{H}$ represents a three-degrees-of-freedom Hamilton function in the six-dimensional space spanned by $\boldsymbol{x}$ and $\boldsymbol{X}$.

To simplify the problem by means of coordinate formal transformations, we first need to write xyz in terms of polar-nodal variables. We do it using formulae (4.16) and (4.17). Then we apply the Lie transformation up to order two, i.e., up to an error of size $\mathcal{O}(c^3)$, calculating $\mathcal{K}_1(=0)$, $\mathcal{K}_2$ together with $\mathcal{W}_1$ and $\mathcal{W}_2$.

Hamiltonian $\mathcal{K}$, after truncation, reads as

$$\begin{aligned}\mathcal{K}(r, R; \Theta, N) = \frac{1}{2}r^2 + \frac{c^2}{1536r^8}[&18\Theta^6 \sin^2 I(8 - 12\sin^2 I + 5\sin^4 I)\\ &+ (-8 - 24\sin^2 I + 21\sin^4 I)r^6R^6\\ &+ \Theta^2(-8 - 120\sin^2 I + 105\sin^4 I)r^4R^4\\ &- 6\Theta^4(8 + 16\sin^2 I - 17\sin^4 I + 3\sin^6 I)r^2R^2].\end{aligned}$$

The generating function $\mathcal{W}$ is a finite Fourier series in ϑ and ν whose coefficients are powers of r, R, Θ, and $(1 - N^2/\Theta^2)^{1/2}$. Specifically, it is written as the sum $\mathcal{W}_1 + c\,\mathcal{W}_2$, where $\mathcal{W}_1$ contains 48 terms and $\mathcal{W}_2$ is composed of 200 terms.

The vector spaces $\mathcal{P}_i$ and $\mathcal{R}_i$ are spaces of functions whose terms are rational in r, R, Θ, and $(1 - N^2/\Theta^2)^{1/2}$, whereas the dependence on ϑ and on ν is through sines and cosines. The functions characterizing these spaces are often called Poisson series [17, 16]. However, the spaces $\mathcal{Q}_i$ are purely rational and are indeed the vector subspaces of $\mathcal{P}_i$ which do not contain the trigonometric part of $\mathcal{P}_i$.

The direct and inverse changes of coordinates are also large formulae. More precisely, the passage from the "old" r to the new one is a trigonometric sum in ϑ and ν with 312 terms. The equations of the direct changes for ϑ, ν, R, Θ, and N are also Fourier sums with 579, 454, 336, 340, and 236 terms, respectively. The inverse change contains 338 terms for r, 579 terms for ϑ, 452 for ν, 333 for R, 340 for Θ, and 236 terms for N.

The passage from $\mathcal{K}$ to $\mathcal{T}$ is constructive. Using the identities $rR = \varphi_3$ and

$r^2=\varphi_1$ and fixing $\Theta=\sqrt{c_2}$ and $N=c_1$ we conclude that

$$\begin{aligned}\mathcal{T}(\varphi_1,\varphi_3;\Theta,N)=\frac{1}{2}\varphi_1+\frac{c^2}{1536\varphi_1^4}[&-18c_1^6c_2(5c_2-\varphi_3^2)\\&+18c_1^2c_2(c_2+\varphi_3^2)(c_2^2-4c_2\varphi_3^2-\varphi_3^4)\\&+c_2^2(18c_2^3-60c_2^2\varphi_3^2-23c_2\varphi_3^4-11\varphi_3^6)\\&+3c_1^4(18c_2^3+16c_2^2\varphi_3^2+35c_2\varphi_3^4+7\varphi_3^6)].\end{aligned}$$

Observe that as $\mathcal{T}$ is independent of φ_2—a feature of the perturbation we have chosen—the differential equation in the φ_i contains only two terms, although we can determine φ_2 with the aid of (4.19). Besides, we have to work with trajectories not very close to the origin, as φ_1 appears in the denominator of $\mathcal{T}$. The first equation of (3.2) is determined now taking into account that $Dr(t)=D_4\mathcal{K}(\boldsymbol{P_N})$ and $DR(t)=-D_1\mathcal{K}(\boldsymbol{P_N})$ and then $D\varphi_1(t)=2rD_4\mathcal{K}(\boldsymbol{P_N})$ and $D\varphi_3(t)=RD_4\mathcal{K}(\boldsymbol{P_N})-rD_1\mathcal{K}(\boldsymbol{P_N})$. We obtain

(4.20)
$$\begin{aligned}D\varphi_1(t)&=\frac{c^2\varphi_3}{384c_2^2\varphi_1^3}[18c_1^6c_2-18c_1^2c_2(3c_2+\varphi_3^2)(c_2+3\varphi_3^2)\\&\qquad-c_2^2(60c_2^2+46c_2\varphi_3^2+33\varphi_3^4)+c_1^4(48c_2^2+210c_2\varphi_3^2+63\varphi_3^4)],\\D\varphi_3(t)&=-\varphi_1+\frac{c^2}{192c_2^2\varphi_1^4}[-18c_1^6c_2(5c_2-\varphi_3^2)\\&\qquad+18c_1^2c_2(c_2+\varphi_3^2)(c_2^2-4c_2\varphi_3^2-\varphi_3^4)\\&\qquad+c_2^2(18c_2^3-60c_2^2\varphi_3^2-23c_2\varphi_3^4-11\varphi_3^6)\\&\qquad+3c_1^4(18c_2^3+16c_2^2\varphi_3^2+35c_2\varphi_3^4+7\varphi_3^6)].\end{aligned}$$

The relevant dynamics of (4.13) is reflected in (4.20). However, we are interested in a numerical approximation of the original equation to which we add some initial conditions. We need to find out an numerical solution of (4.20) and to pose the corresponding system in the Lie group.

Now as candidates for coordinates of the Lie group we take ϑ and ν, since they are the angles which have "disappeared" in the analytic transformation. From $D\vartheta(t)=D_5\mathcal{K}(\boldsymbol{P_N})$, $D\nu(t)=D_6\mathcal{K}(\boldsymbol{P_N})$ we arrive at the second equation of (3.2) which is, as expected, independent of ϑ and of ν:

(4.21)
$$\begin{aligned}D\vartheta(t)&=-\frac{c^2}{768c_2^{5/2}\varphi_1^4}[18c_1^6c_2\varphi_3^2-18c_1^2c_2(c_2-\varphi_3^2)^2(2c_2+\varphi_3^2)\\&\qquad+c_2^3(-54c_2^2+120c_2\varphi_3^2+23\varphi_3^4)\\&\qquad+c_1^4(-54c_2^3+105c_2\varphi_3^4+42\varphi_3^6)],\\D\nu(t)&=\frac{c^2c_1}{128c_2^2\varphi_1^4}[9c_1^4c_2(-5c_2+\varphi_3^2)+3c_2(c_2+\varphi_3^2)(c_2^2-4c_2\varphi_3^2-\varphi_3^4)\\&\qquad+c_1^2(18c_2^3+16c_2^2\varphi_3^2+35c_2\varphi_3^4+7\varphi_3^6)].\end{aligned}$$

Observe that once $\varphi_1(t)$ and $\varphi_3(t)$ will be numerically calculated from (4.20), the angles $\vartheta(t)$ and $\nu(t)$ shall be readily determined.

We choose initial conditions for Hamiltonian (4.15), concretely up to 10 digits we put positions $\boldsymbol{x}_0=(-0.0639671104,0,0.0581813272)^t$, and for velocities we write $\boldsymbol{X}_0=(-0.0369885382,-0.1719633719,0.0336429492)^t$. Using (4.16) and (4.17), we

have that $r_0 = 0.086468827$, $\vartheta_0 = 1.5707963267$, $\nu_0 = 1.5707963267$, $R_0 = 0.05$, $\Theta_0 = 0.014869471$, and $N_0 = 0.011$. Fixing the value $c = 10^{-4}$, we obtain $\mathcal{H}_0(\boldsymbol{x}_0) = 0.003738429$, whereas $\mathcal{H}_1(\boldsymbol{x}_0, \boldsymbol{X}_0; c) = 2.139918249 \times 10^{-8}$, and therefore $\mathcal{H}_1$ can be considered as a small perturbation of $\mathcal{H}_0$.

We switch now to polar-nodal variables. First, we need to know the value of the transformed variables, obtained using the inverse Lie change. The transformed initial conditions are given by the six-tuple $(r'_0, \vartheta'_0, \nu'_0, R'_0, \Theta'_0, N'_0) = (0.086469074, 1.570796662, 1.570796248, 0.0500000954, 0.0148695127, 0.0110000280)$. (Now we have recovered the primes for the transformed variables.) Then the initial conditions for system (4.20) are determined, yielding $\varphi_{1_0} = 0.007476900$ and $\varphi_{3_0} = 0.004323461$. Note that the initial conditions for (4.21) are given by ϑ'_0 and ν'_0. Besides, the values for the constants are $c_1 = 0.0110000280$ and $c_2 = 0.0002211024$. Note that $\Theta'(t) = \Theta'_0 \equiv \sqrt{c_2}$ and $N'(t) = N'_0 \equiv c_1$.

System (4.20) has been numerically solved using an Adams–Moulton method and 76 steps in the interval $[0, 15]$. With the approximations $\varphi_1(t)$ and $\varphi_3(t)$ we determine $r'(t) = \sqrt{\phi_1(t)}$ and $R'(t) = \varphi_3(t)/\sqrt{\varphi_1(t)}$. Equation (4.21) is solved obtaining $\vartheta'(t)$ and $\nu'(t)$ for $t \in [0, 15]$, also with the same Adams–Moulton formula and using 108 steps. Next, the passage from the prime polar-nodal variables to the original ones is done after using the direct change of coordinates. Finally, the transformation from the polar-nodal variables to the Cartesian ones is performed with the aid of (4.16) and (4.17). This completes our seminumerical treatment.

Instead of estimating the size of the global error committed with our approach, we have calculated the solution of the initial value problem given by Hamiltonian (4.15) with initial conditions $\boldsymbol{x}_0$ and $\boldsymbol{X}_0$ given above. We have used an Adams–Moulton method, obtaining a solution after 196 steps in the interval $[0, 15]$. Comparison between the fully numerical and seminumerical approaches gives a coincidence of seven digits in the six coordinates for all t in $[0, 15]$. As the value of the Hamiltonian is an invariant of the whole process (as it represents the total energy of the problem), we have compared the value of $\mathcal{H}(\boldsymbol{x}_0, \boldsymbol{X}_0; c)$ with $\mathcal{H}(\boldsymbol{x}(t), \boldsymbol{X}(t); c)$ for $t \in [0, 15]$, obtaining that the difference coincides in at least eight digits. Note that within this approximation our approach behaves better, as the integration of (4.20) and (4.21) is much simpler than the integration of the equation defined through $\mathcal{H}$.

If we enlarge the interval $[0, 15]$, the seminumerical solution begins to become worse. This is explainable from the point of view of the type of solution related to the original unperturbed problem (e.g., (4.13) or (4.15) with $c \equiv 0$). Indeed, if $c = 0$, excepting the radial velocity R, the rest of the polar-nodal variables are constants. Moreover, $R(t) = -r_0 t + R_0$, which means that as t becomes big, the term $|R(t)|$ also increases. Adding now the perturbation $c \neq 0$ it implies that the solution is not bounded while t becomes big. This is an unavoidable feature of the present problem, in contrast to other systems which are formed by a principal equation with bounded solutions to which we attach a small perturbation, as it occurs, for quasi-periodic equations and the elimination of some angular variables (or the time) using averaging procedures.

5. Concluding remarks. This paper outlines a new method for building approximate solutions of initial value problems in the cases where the differential equation is formed by a principal part plus a small regular perturbation. The main features of the technique we present are the following:

- The method is based on the analytic reduction of the original problem by means of the introduction of a formal symmetry through appropriate Lie transformations. After truncating, the reduction process carries out the decoupling of the

transformed original system into two subsystems which are either solved analytically or approximated numerically. We stress that the symmetry properties of the generalized normal form are responsible for allowing the symmetry reduction.

• Compared with the standard numerical routines our approach has the advantage of modifying analytically the initial equation, arriving therefore at a simplified version of it. These transformed systems can sometimes be solved analytically. This leads to a full analytic approximation of the problem with the typical error committed after truncating the normal formal transformation.

• However, if the transformed equations cannot be solved directly, one can still use a numerical algorithm for differential equations with constraints, which involves less computational effort than the solution of the original equations. This is really useful when the dimensions of the two subsystems are small.

• On some occasions the choice of adequate coordinates is crucial to perform the computations, especially those concerning the Lie transformation treatment. Besides, as the splitting of the transformed equation into the two subsystems is usually not apparent, one has to put much care in the determination of the coordinates of the Lie group. Unfortunately, there is no systematic manner for the selection of the variables in which one carries out the Lie transformation, though the coordinates of the orbit space can be obtained constructively.

Acknowledgments. I thank Patricia Yanguas (Universidad Pública de Navarra) for fruitful discussions concerning Lie transformations for vector fields and reduction procedures we shared during the elaboration of the paper. The remarks and suggestions of the anonymous referees have contributed significantly to improve a previous version of the paper.

EFFICIENT SOLVERS FOR SADDLE-POINT PROBLEMS ARISING FROM DOMAIN DECOMPOSITIONS WITH LAGRANGE MULTIPLIERS*

QIYA HU†, ZHONGCI SHI†, AND DEHAO YU†

Abstract. In this paper, we are concerned with the domain decomposition method with Lagrange multipliers for solving three-dimensional elliptic problems with variable coefficients. We shall first introduce a weighted saddle-point problem resulting from this domain decomposition, which can be solved by existing iterative methods. Then we will construct two simple preconditioners, one for the system associated with the displacement variable and the other for the Schur complement system associated with the multiplier variable, that are applicable to various discretization schemes. The new preconditioners possess such local properties that they can be implemented cheaply. We will show that the condition number of the global preconditioned system grows only as the logarithm of the dimension of the local problem associated with an individual substructure and is independent of the large variations of the coefficients across the local interfaces.

Key words. domain decomposition, nonmatching grids, mortar element, Lagrange multiplier, weighted saddle-point problem, preconditioner, condition number

1. Introduction.

In recent years, there has been a fast growing interest in the domain decomposition methods (DDMs) with Lagrange multipliers, which were studied early in [11], [12], [13], and [26]. This kind of DDM has many advantages over the traditional DDMs in applications (cf. [1], [19], [25], [34], and [35]).

It is known that the DDM with Lagrange multipliers results in a saddle-point problem of the displacement variable and the multiplier variable. There exist two different approaches for solving such a saddle-point problem: (1) eliminate the displacement to build an interface equation of the multiplier and solve the interface equation by some PCG method (see [1], [14], [15], [19], [29], and [34]); (2) solve the saddle-point problem itself by some preconditioned iterative method (see [24], [25], and [35]). Each of the approaches has its individual merits: the PCG iteration of the first approach has the optimal convergence, while the interface equation need not be built in the second approach, and so inexact solvers can be applied to both the primal and the Schur complement system (this is important for solving nonlinear problems and problems with variable coefficients). As we know, the displacement corresponds to a singular (positive semidefinite) problem on a floating subdomain. There exist many techniques to deal with such singularity, for example FETI-type methods (see [13], [15], [14], and [24]). The interface equation in a FETI method is always derived in a subspace by using a projection, and the interface equation can be solved by the *projected* PCG method with the Dirichlet preconditioner. The projection is realized by

solving a coarse problem, and each local solver in the preconditioner, which is defined on the boundary of a subdomain, can be implemented by solving a local Dirichlet problem (see [13] and [15] for details).

In the present paper, we consider the second approach mentioned above for solving saddle-point problems and propose a new strategy to handle the singularity. We discuss a general DDM with Lagrange multipliers for three-dimensional elliptic problems with variable coefficients, which allows finite element discretization with nonmatching grids and coupling discretization by the finite element and the spectral element. We will first transform the resulting saddle-point system into another equivalent saddle-point system in which the system corresponding to the displacement is positive definite. Then we construct two new preconditioners for the primal problem corresponding to the displacement and the Schur complement system corresponding to the multiplier, respectively. Each local solver in the preconditioner for the Schur complement is defined on the common face of two neighboring subdomains and can be implemented in a more efficient manner. The new method successfully avoids the action of the projections used in [24] and reduces the cost of computation significantly. It is shown that the global preconditioned system has a nearly optimal condition number, which is independent of the large variations of the coefficient across the local interfaces.

Also, the method can be extended to nonlinear problems with some elliptic properties.

The outline of the remainder of the paper is as follows. We introduce an augmented saddle-point problem in section 2. In section 3, we construct the preconditioners for the saddle-point system and give general convergence results. The main results of the paper will be shown in section 4. In section 5, we discuss various choices of the multiplier space and introduce one class of cheap local solver. Finally, we report some numerical results in section 6.

2. Domain decomposition and the saddle-point problem. This section is devoted to the introduction of the augmented saddle-point problem.

Consider the model problem

$$\begin{cases} -\mathrm{div}(a\nabla u) = f \ \text{ in } \ \Omega, \\ \qquad u = 0 \quad \text{on } \ \partial\Omega, \end{cases} \tag{2.1}$$

where Ω is a bounded, connected Lipschitz domain in $\mathbb{R}^3$ and $a \in L^\infty(\Omega)$ is a positive function.

Let $H_0^1(\Omega)$ denote the standard Sobolev space, and define the bilinear form

$$\mathcal{A}(v,w) = \int_\Omega a\nabla v \cdot \nabla w dx, \quad v, w \in H_0^1(\Omega).$$

Let $(\cdot,\cdot)$ denote the $L^2(\Omega)$ inner product. The weak formulation of (2.1) in $H_0^1(\Omega)$ is then given by the following: find $u \in H_0^1(\Omega)$ such that

$$\mathcal{A}(u,v) = (f,v) \quad \forall v \in H_0^1(\Omega). \tag{2.2}$$

In the following, we define a discrete problem of (2.2) based on nonoverlapping domain decomposition.

Let the domain Ω be decomposed into $\bar{\Omega} = \bigcup_{k=1}^N \bar{\Omega}_k$, which satisfy $\Omega_i \cap \Omega_j = \emptyset$ when $i \neq j$. For simplicity of exposition, we consider only the case of geometrically conforming partitionings of the region into subdomains:

(i) If $\bar{\Omega}_i \cap \bar{\Omega}_j \neq \emptyset$ for some $i \neq j$, then $\Gamma_{ij} = \bar{\Omega}_i \cap \bar{\Omega}_j$ is a face of both Ω_i and Ω_j. Define $\Gamma = \cup \Gamma_{ij}$.

(ii) Each subdomain Ω_k has the same "size" d in the usual way (see [8] and [38]).

As usual, we assume that each Ω_k is a polyhedron. Let $V(\Omega_k)$ be a finite-dimensional space on Ω_k, for example a finite element space or a spectral element space. We assume that $V(\Omega_k) \subset H^1(\Omega_k)$ for each subdomain Ω_k. If $\partial\Omega_k \cap \partial\Omega \neq \emptyset$, we require that all functions in $V(\Omega_k)$ vanish on $\partial\Omega_k \cap \partial\Omega$. Define $V(\Omega) = \prod_{k=1}^N V(\Omega_k)$ and $V(\partial\Omega_k) = V(\Omega_k)|_{\partial\Omega_k}$. In the next section, we will use several additional spaces. For $\Gamma_{ij} \subset \Gamma$, define the *local* trace spaces $V_i(\Gamma_{ij}) = V(\partial\Omega_i)|_{\Gamma_{ij}}$ and $V_j(\Gamma_{ij}) = V(\partial\Omega_j)|_{\Gamma_{ij}}$. Besides, define

$$V_i^0(\Gamma_{ij}) = V_i(\Gamma_{ij}) \cap H_0^1(\Gamma_{ij}) \quad \text{and} \quad V_j^0(\Gamma_{ij}) = V_j(\Gamma_{ij}) \cap H_0^1(\Gamma_{ij}).$$

It is possible that $V_i(\Gamma_{ij}) \neq V_j(\Gamma_{ij})$ and $V_i^0(\Gamma_{ij}) \neq V_j^0(\Gamma_{ij})$, for example for finite element discretization with nonmatching grids or coupling discretization of the finite element and the spectral element.

Let $W(\Gamma_{ij})$ be a given finite-dimensional space on the face Γ_{ij}, which will be chosen as the *local* multiplier space. We assume that the space $W(\Gamma_{ij})$ contains the constant function. There are many ways to define the *local* multiplier space $W(\Gamma_{ij})$, for example the well-known mortar element method (see [6], [4], [22], and section 5 for details). Define $W(\Gamma) = \prod_{\Gamma_{ij} \subset \Gamma} W(\Gamma_{ij})$.

Let $P_{ij} : L^2(\Gamma_{ij}) \to W(\Gamma_{ij})$ be the orthogonal projection with respect to the $L^2(\Gamma_{ij})$ inner product. For $v \in V(\Omega)$, set $v|_{\Omega_k} = v_k$. Define

$$\tilde{V}(\Omega) = \{v \in V(\Omega) : \ P_{ij}(v_i|_{\Gamma_{ij}} - v_j|_{\Gamma_{ij}}) = 0 \text{ for each } \Gamma_{ij} \subset \Gamma\}.$$

Note that we do not require that $\tilde{V}(\Omega) \subset H_0^1(\Omega)$.

Define the *local* bilinear form

$$\mathcal{A}_k(v, w) = \int_{\Omega_k} a \nabla v \cdot \nabla w dx, \quad v, w \in H^1(\Omega_k).$$

The discrete problem of (2.2) is the following: find $\bar{u} \in \tilde{V}(\Omega)$ such that

$$\sum_{k=1}^N \mathcal{A}_k(\bar{u}_k, v_k) = (f, v) \quad \forall v \in \tilde{V}(\Omega). \tag{2.3}$$

We assume that the system (2.3) has a unique solution.

Let $A_k : V(\Omega_k) \to V(\Omega_k)$ be the *local* operator defined by

$$(A_k v, w)_{\Omega_k} = \mathcal{A}_k(v, w), \quad v \in V(\Omega_k) \quad \forall w \in V(\Omega_k).$$

By introducing the *sign* function

$$\sigma_{ij} = \begin{cases} 1, & i < j, \\ -1, & i > j, \end{cases}$$

we define the operator $B_k : V(\Omega_k) \to W(\Gamma)$ as follows:

$$(B_k u)|_{\Gamma_{ij}} = \begin{cases} \sigma_{ij} P_{ij}(u_k|_{\Gamma_{ij}}), & \Gamma_{ij} \subset \partial\Omega_k, \\ 0, & \Gamma_{ij} \not\subset \partial\Omega_k. \end{cases}$$

Define the operators $A : V(\Omega) \to V(\Omega)$ and $B : V(\Omega) \to W(\Gamma)$ by

$$A = \mathrm{diag}(A_1\ A_2 \cdots A_N)$$

and

$$Bv = \sum_{k=1}^{N} B_k v_k, \quad v \in V(\Omega),$$

respectively. Let $\langle \cdot, \cdot \rangle$ denote the $L^2(\Gamma)$ inner product and $B^t : W(\Gamma) \to V(\Omega)$ denote the adjoint of B, which satisfies

$$(B^t \mu, v) = \langle \mu, Bv \rangle \quad \forall \mu \in W(\Gamma),\ v \in V(\Omega).$$

It is easy to see that the space $\tilde{V}(\Omega)$ can be written as

$$\tilde{V}(\Omega) = \{v \in V(\Omega) : Bv = 0\}.$$

Then (2.3) is equivalent to the following saddle-point problem: find $(\bar{u}, \lambda) \in V(\Omega) \times W(\Gamma)$ such that

$$\begin{cases} A\bar{u} + B^t\lambda = f, \\ B\bar{u} = 0. \end{cases} \tag{2.4}$$

Here the unknown λ is called the Lagrange multiplier for the constraint $B\bar{u} = 0$.

Although the operator A is block diagonal, the system (2.4) cannot be solved in the standard way (refer to [26] and [19]). The main difficulty is that each *local* operator A_k corresponding to some internal subdomain Ω_k is singular on $V(\Omega_k)$ (so the *global* operator A is also singular on $V(\Omega)$). To handle this singularity, many existing methods have to consider a subspace of λ and project λ repeatedly into this subspace, which increase the cost of calculation. For example, the paper [24] discussed the preconditioned conjugate residual method for solving the system (2.4) based on this technique.

In the following we propose a new way to deal with such singularity. It is easy to see that

$$\ker(A) \cap \ker(B) = \{0\}, \tag{2.5}$$

and so the operator $A + rB^tB$ is positive definite for any positive number r. Because of this, we may consider the augmented Lagrange multiplier framework

$$\begin{cases} (A + d^{-1}B^tB)\bar{u} + B^t\lambda = f, \\ B\bar{u} = 0, \end{cases} \tag{2.6}$$

which has the same solution as (2.4). A similar method has been discussed in [35], but an additional interface unknown φ was introduced.

The coefficient $a(x)$ has possible large variation from one subdomain to another. To avoid the influence of these large variations, we will consider another augmented Lagrange multiplier formulation instead of (2.6). Let α_k and β_k be the positive constants defined by

$$\alpha_k \le a(x) \le \beta_k \quad \forall x \in \Omega_k,\ (k = 1, \ldots, N). \tag{2.7}$$

Then

$$\alpha_k |v|^2_{1,\Omega_k} \le (A_k v, v)_{\Omega_k} \le \beta_k |v|^2_{1,\Omega_k} \quad \forall \in H^1(\Omega_k). \tag{2.8}$$

For a face $\Gamma_{ij} \subset \Gamma$, define $\alpha_{ij} = \min\{\alpha_i, \alpha_j\}$.

Define the operator $\bar{B}_k : V(\Omega_k) \to W(\Gamma)$,

$$(\bar{B}_k u)|_{\Gamma_{ij}} = \begin{cases} \sigma_{ij} \alpha_{ij}^{\frac{1}{2}} P_{ij}(u_k|_{\Gamma_{ij}}), & \Gamma_{ij} \subset \partial\Omega_k, \\ 0, & \Gamma_{ij} \not\subset \partial\Omega_k, \end{cases}$$

and define $\bar{B} : V(\Omega) \to W(\Gamma)$ by

$$\bar{B}v = \sum_{k=1}^{N} \bar{B}_k v_k, \quad v \in V(\Omega).$$

It is easy to see that $\bar{B}v = 0$ if and only if $Bv = 0$. Thus, the system (2.4) has the same solution with the *weighted* saddle-point problem

$$\begin{cases} (A + d^{-1}\bar{B}^t\bar{B})\bar{u} + B^t\lambda = f, \\ B\bar{u} = 0. \end{cases} \tag{2.9}$$

Note that the operator $A^* = A + d^{-1}\bar{B}^t\bar{B}$ is also symmetric and positive definite on $V(\Omega)$ and generates a sparse stiffness matrix such as A.

Since the operator A^* is not yet block diagonal, it is not practical to eliminate directly the variable $\bar{u}$ in (2.9). Fortunately, many iterative methods have been developed for solving saddle-point problems such as (2.9), for example the inexact Uzawa-type methods (see [2], [9], [20], and [21]), the preconditioned MINRES (i.e., conjugate residual) method (see [30]), and the PCG method based on a positive definite reformulation (see [10]). For all the iterative methods, the projections P and P_R used in [24] need not be introduced (since A^* is positive definite).

In order to illustrate an advantage of the new method, we consider the preconditioned MINRES method for solving the system (2.9). Define

$$M = \begin{pmatrix} A^* & B^t \\ B & 0 \end{pmatrix}, \quad U = \begin{pmatrix} \bar{u} \\ \lambda \end{pmatrix}, \quad F = \begin{pmatrix} f \\ 0 \end{pmatrix}.$$

The system (2.9) can be written as

$$MU = F. \tag{2.10}$$

Let $\bar{A} : V(\Omega) \to V(\Omega)$ be a preconditioner for A^*, and let $\bar{S} : W(\Gamma) \to W(\Gamma)$ be a preconditioner for the Schur complement $\tilde{S} = B\bar{A}^{-1}B^t$. Define the block-diagonal preconditioner $\bar{M}$ for M by

$$\bar{M}^{-1} = \begin{pmatrix} \bar{A}^{-1} & 0 \\ 0 & \bar{S}^{-1} \end{pmatrix}.$$

Then the preconditioned MINRES method for (2.10) is the MINRES method (see [30]) applied to the preconditioned system

$$\bar{M}^{-1}MU = \bar{M}^{-1}F. \tag{2.11}$$

The convergence speed of this method is determined by the condition number $cond(\bar{M}^{-1}M)$, which depends on $cond(\bar{A}^{-1}A^*)$ and $cond(\bar{S}^{-1}\tilde{S})$.

In the next section, we consider the construction of the preconditioners $\bar{A}$ and $\bar{S}$. As we will see, $\bar{A}^{-1}$ has the form $\bar{A}^{-1} = A_0^{-1} + \hat{A}^{-1}$, where A_0 is a coarse solver, and $\hat{A}$ is a block-diagonal operator. Moreover, $\bar{S}$ is also a block-diagonal operator. Thus, the coarse solver needs to be implemented only once at each MINRES iteration for (2.11). For the method proposed in [24], two similar coarse solvers (contained, respectively, in the projections P and P_R) need to be implemented at least twice at each MINRES iteration. Besides, the local solvers in $\bar{S}$ are also cheaper than the existing local solvers.

3. General results. In this section we present the main resuts of this paper. Here we do not involve concrete structures of the spaces $V(\Omega)$ and $W(\Gamma)$.

For convenience, following [38], the symbols $\lesssim$, $\gtrsim$, and $\eqsim$ will be used in the rest of this paper. $x_1 \lesssim y_1,\ x_2 \gtrsim y_2$, and $x_3 \eqsim y_3$ mean that $x_1 \le C_1 y_1,\ x_2 \ge c_2 y_2$, and $c_3 x_3 \le y_3 \le C_3 x_3$ for some constants $C_1,\ c_2,\ c_3$, and C_3 that are independent of the dimensions of the approximate spaces $V(\Omega)$ and $W(\Gamma)$. Define $S = B(A^*)^{-1}B^t$.

We first construct a preconditioner for A^*. To handle the "nonlocal" operator $\bar{B}^t\bar{B}$, we need a *coarse* solver.

Define $V_0 = \ker(A)$, which consists of piecewise constant functions. The natural choice of the coarse solver is the restriction of A^* on V_0. But, for numerical consideration, we can also define the coarse solver $A_0 : V_0 \to V_0$ by

$$(A_0 v_0, w_0) = d \sum_{\Gamma_{ij}} \alpha_{ij}(a_i - a_j)(b_i - b_j), \quad v_0 \in V_0 \quad \forall w_0 \in V_0,$$

where $a_k = v_0|_{\Omega_k}$ and $b_k = w_0|_{\Omega_k}$ (const.). It is easy to see that the *coarse* solver A_0 is positive definite on V_0. The action of A_0^{-1} is very cheap to implement, which is similar to that of the coarse solver in the substructuring preconditioner for *two-dimensional* problems (refer to [7]). Since the space $W(\Gamma_{ij})$ contains the piecewise constant function, we have $P_{ij}(v_{0i}|_{\Gamma_{ij}} - v_{0j}|_{\Gamma_{ij}}) = a_i - a_j$ (const.) for $v_0 \in V_0$. Thus, the operator A_0 is spectrally equivalent to the restriction operator of A^* on V_0. Namely,

$$(A_0 v_0, v_0) \eqsim d^{-1}\langle \bar{B}v_0, \bar{B}v_0\rangle = (A^* v_0, v_0) \quad \forall v_0 \in V_0. \tag{3.1}$$

Note that the coarse solver A_0 is much simpler and cheaper than the one in the classical substructuring method for three-dimensional problems (compare [8]).

Define the (local) solver $\bar{A}_k : V(\Omega_k) \to V(\Omega_k)$ by

$$(\bar{A}_k v, w)_{\Omega_k} = \alpha_k[(\nabla v, \nabla w)_{\Omega_k} + d^{-2}(v, w)_{\Omega_k}], \quad v \in V(\Omega_k) \quad \forall w \in V(\Omega_k).$$

In some applications, we would like to consider an inexact solver for $\bar{A}_k$. Let $\hat{A}_k$ be a symmetric and positive definite operator on $V(\Omega_k)$. Assume that there is a positive number γ_k, which may depend slightly on the dimension of $V(\Omega_k)$, such that

$$(\bar{A}_k v, v)_{\Omega_k} \lesssim (\hat{A}_k v, v)_{\Omega_k} \lesssim \gamma_k (\bar{A}_k v, v)_{\Omega_k} \quad \forall v \in V(\Omega_k). \tag{3.2}$$

Define $\hat{A} = \mathrm{diag}(\hat{A}_1,\ \hat{A}_2, \ldots, \hat{A}_N)$. Let $Q_0 : V(\Omega) \to V_0$ denote the L^2 orthogonal projection. Define $\gamma = \max_{1\le k\le N}(\beta_k/\alpha_k)$ and $\hat{\gamma} = \max_{1\le k\le N}\gamma_k$.

THEOREM 3.1. *Define* $\bar{A}^{-1} = \hat{A}^{-1} + A_0^{-1}Q_0$. *Then*

$$cond(\bar{A}^{-1}A^*) \lesssim \gamma \cdot \hat{\gamma}, \tag{3.3}$$

which is independent of the large variants of $a(x)$ *across the local interfaces* Γ_{ij}.

Remark 3.1. When Ω_k is a regular domain, the action of $\bar{A}_k^{-1}$ can be implemented by FFT, which is much cheaper than that of the exact solver corresponding to A_k. For such Ω_k, we can define $\hat{A}_k = \bar{A}_k$, and so $\gamma_k = 1$. In general, the operator $\hat{A}_k$ can be chosen as the (algebraic) multigrid preconditioner, the hierarchical basis preconditioner, or the ILU preconditioner for $\bar{A}_k$. For the case of the multigrid preconditioner, we have $\gamma_k \lesssim 1$.

We next construct a preconditioner for the Schur complement $\tilde{S}$ or S.

To explain our motivation, we first consider a direct choice of the preconditioner.

Let $B_k^t : W(\Gamma) \to V(\Omega_k)$ be the adjoint of B_k, which is defined by

$$(B_k^t\mu, v)_{\Omega_k} = \langle \mu, B_k v\rangle = \langle \mu, B_k v\rangle_{\partial\Omega_k} \quad \forall \mu \in W(\Gamma),\ v \in V(\Omega_k),$$

and define the operator $R_k : W(\Gamma) \to V(\Omega_k)$ by $R_k = \bar{A}_k^{-1}B_k^t$. Let $I_{ij} : W(\Gamma) \to W(\Gamma_{ij})$ denote the natural restriction operator and $I_{ij}^t : W(\Gamma_{ij}) \to W(\Gamma)$ denote the zero extention operator, which is just the adjoint of I_{ij}.

For a face Γ_{ij}, let $\langle\cdot,\cdot\rangle_{\Gamma_{ij}}$ denote the L^2 inner product on the local interface Γ_{ij}. Define the operator $S_{ij} : W(\Gamma_{ij}) \to W(\Gamma_{ij})$ by

$$\begin{aligned}\langle S_{ij}\lambda_{ij}, \mu_{ij}\rangle_{\Gamma_{ij}} &= (\bar{A}_i R_i I_{ij}^t \lambda_{ij}, R_i I_{ij}^t \mu_{ij})_{\Omega_i} \\ &+ (\bar{A}_j R_j I_{ij}^t \lambda_{ij}, R_j I_{ij}^t \mu_{ij})_{\Omega_j} \quad \forall \mu_{ij} \in W(\Gamma_{ij}).\end{aligned}$$

It can be verified that S_{ij} is spectrally equivalent to the restriction of the operator $\tilde{S}$ (or S) on $W(\Gamma_{ij})$.

By the general framework given in [17], we can define a preconditioner by (refer to [19])

$$\hat{S}^{-1} = \sum_{\Gamma_{ij}} I_{ij}^t S_{ij}^{-1} I_{ij}. \tag{3.4}$$

Since S_{ij} results in a dense stiffness matrix, the action of S_{ij}^{-1} is expensive to implement (when $W(\Gamma_{ij})$ has high dimensions). Because of this, we will construct another preconditioner by replacing S_{ij} with a cheaper local solver.

Throughout this paper, we assume that the local multiplier space $W(\Gamma_{ij})$ is *associated* with the local trace space $V_i(\Gamma_{ij})$ (to distinguish it from $V_j(\Gamma_{ij})$) in the sense that $\dim(W(\Gamma_{ij})) = \dim(V_i^0(\Gamma_{ij}))$ and $W(\Gamma_{ij})$ has a vector space structure similar to that of $V_i^0(\Gamma_{ij})$ (refer to the mortar element method in [6] and [4]). Here we do not require $W(\Gamma_{ij}) \subset V_i(\Gamma_{ij})$. It is also possible that $W(\Gamma_{ij})$ is independent of $V_i(\Gamma_{ij})$ and $V_j(\Gamma_{ij})$ (refer to [19] and [26]).

When the coefficient $a(x)$ has a large variation across the local interface Γ_{ij}, we need a particular choice of the index i. Throughout this paper, we always assume that

H_1: the index i is chosen such that $\alpha_i \le \alpha_j$ (so $\alpha_{ij} = \alpha_i$).

Note that the particular choice of the index i will not influence applications of our method.

Remark 3.2. When $V_i^0(\Gamma_{ij}) = V_j^0(\Gamma_{ij})$ (namely, the meshes on Γ_{ij} are matching), we need not choose a particular index i. If the two local trace spaces on Γ_{ij} have the

relation that either a space is a subspace of another one or a space has much smaller dimension than another one the index i can also be chosen such that $V_i^0(\Gamma_{ij}) \subset V_j^0(\Gamma_{ij})$ or $\dim(V_i^0(\Gamma_{ij})) \ll \dim(V_j^0(\Gamma_{ij}))$. But, for simplicity of exposition, we will not discuss this choice in this paper (refer to [16]).

Let $\|\cdot\|_{1/2,\Gamma_{ij}^0}$ denote the norm on the space $H_{00}^{1/2}(\Gamma_{ij})$ (namely, the norm $\|\cdot\|_{H_{00}^{1/2}(\Gamma_{ij})}$ in [28]). Define the *discrete* dual seminorm $\|\cdot\|_{-*,\Gamma_{ij}}$ by

$$\|\mu\|_{-*,\Gamma_{ij}} = \sup_{v\in V_i^0(\Gamma_{ij})} \frac{|\langle \mu, v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}^0}}, \quad \mu \in W(\Gamma_{ij}).$$

For a face Γ_{ij}, let $n_0(i,j)$ denote the dimension of the space $W(\Gamma_{ij})$. Assume that

H_2: for each face Γ_{ij} there is a number $G(n_0(i,j)) > 1$ such that the inverse estimate holds:

$$\|\mu\|_{0,\Gamma_{ij}} \le G(n_0(i,j))\|\mu\|_{-*,\Gamma_{ij}} \quad \forall \mu \in W(\Gamma). \tag{3.5}$$

Hypothesis H_2 implies that $\|\cdot\|_{-*,\Gamma_{ij}}$ is a norm on $W(\Gamma_{ij})$.

For each face Γ_{ij}, let Λ_{ij} be a symmetric and positive definite operator on $W(\Gamma_{ij})$. As the desired local solver, we hope that Λ_{ij} is spectrally equivalent to S_{ij}. But, for convenience, we assume that

H_3: norm $(\langle \Lambda_{ij}\cdot,\cdot\rangle_{\Gamma_{ij}})^{1/2}$ is spectrally equivalent to dual norm $\alpha_i^{-1/2}\|\cdot\|_{-*,\Gamma_{ij}}$.

Now we define the preconditioner $\bar{S}$ by

$$\bar{S}^{-1} = \sum_{\Gamma_{ij}} I_{ij}^t \Lambda_{ij}^{-1} I_{ij}.$$

To estimate the condition number of the preconditioned system $\bar{S}^{-1}S$, we further assume that

H_4: when $W(\Gamma_{ij}) \not\subset V_i(\Gamma_{ij})$, the inequality holds:

$$G(n_0(i,j)) \cdot \inf_{v_\delta \in V_i(\Gamma_{ij})} \|v - v_\delta\|_{0,\Gamma_{ij}} \lesssim \|v\|_{\frac{1}{2},\Gamma_{ij}} \quad \forall v \in V_j(\Gamma_{ij}). \tag{3.6}$$

Set $G(n) = \max_{\Gamma_{ij}\subset\Gamma} G(n_0(i,j))$.

THEOREM 3.2. *Let conditions* H_1–H_4 *be satisfied. Then we have*

$$cond(\bar{S}^{-1}\tilde{S}) \le C\hat{\gamma}[1 + \log(dG^2(n))]^2 \tag{3.7}$$

and

$$cond(\bar{S}^{-1}S) \le C[1 + \log(dG^2(n))]^2. \tag{3.8}$$

Moreover, the constant C *in* (3.7) *and* (3.8) *can be bounded by* γ^2*, which is independent of the large variations of the coefficient* $a(x)$ *across the local interfaces* Γ_{ij}.

Theorems 3.1 and 3.2 will be proved in the next section. From their proofs, we will see that

$$\lambda_{\min}(\bar{A}^{-1}A^*) \gtrsim \hat{\gamma}^{-1} \quad \text{and} \quad \lambda_{\min}(\bar{S}^{-1}\tilde{S}) \gtrsim \hat{\gamma}^{-1}\gamma^{-1}.$$

Thus, using Lemma 2.1 of [30], together with (3.3) and (3.7), we deduce the following.

COROLLARY. *Let $\bar{M}$ and M be defined as in the last section. Then*

$$cond(\bar{M}^{-1}M \le C\hat{\gamma}[1+\log(dG^2(n))]^2. \tag{3.9}$$

Moreover, the constant C in (3.9) *can be bounded by γ^2, which is independent of the large variations of the coefficient $a(x)$ across the local interfaces Γ_{ij}.*

In section 5, we will estimate the positive number $G(n_0(i,j))$ for different choices of $W(\Gamma_{ij})$. For example, for the finite element discretization we have $G(n_0(i,j)) \lesssim h_i^{-1/2}$, where h_i denotes the diameter of the triangulation on Ω_i. A kind of cheap *local* solver Λ_{ij}^{-1} will also be derived in section 5, which needs only $O(n_0^2(i,j))$ arithmetic operations without any particular requirement to $W(\Gamma_{ij})$.

4. Analyses. This section is devoted to prove the results given in the last section.

4.1. On Theorem 3.1. To prove Theorem 3.1, we need a lemma.

LEMMA 4.1. *The following inequality holds:*

$$d^{-1}(\bar{B}^t\bar{B}v,v) \lesssim (\hat{A}v,v) \quad \forall v \in V(\Omega). \tag{4.1}$$

Proof. As in section 2, we set $v|_{\Omega_k} = v_k$. For any index k, the number of indices l such that $\langle \bar{B}_k v_k, \bar{B}_l v_l\rangle \neq 0$ is independent of N (which equals six at most). Thus,

$$(\bar{B}^t\bar{B}v,v) = \langle \bar{B}v, \bar{B}v\rangle = \left\| \sum_{k=1}^N \bar{B}_k v_k \right\|_{0,\Gamma}^2 \lesssim \sum_{k=1}^N \|\bar{B}_k v_k\|_{0,\Gamma}^2. \tag{4.2}$$

By the definition of the operator $\bar{B}_k$, we have

$$\|\bar{B}_k v_k\|_{0,\Gamma}^2 = \sum_{\Gamma_{kj}\subset\partial\Omega_k} \alpha_{kj}\|P_{kj}(v_k|_{\Gamma_{kj}})\|_{0,\Gamma_{kj}}^2 \le \sum_{\Gamma_{kj}\subset\partial\Omega_k} \alpha_{kj}\|v_k\|_{0,\Gamma_{kj}}^2,$$

which implies that

$$\begin{aligned}\sum_{k=1}^N \|\bar{B}_k v_k\|_{0,\Gamma}^2 &\le \sum_{\Gamma_{ij}} \alpha_{ij}(\|v_i\|_{0,\Gamma_{ij}}^2 + \|v_j\|_{0,\Gamma_{ij}}^2)\\ &\le \sum_{\Gamma_{ij}} (\alpha_i\|v_i\|_{0,\Gamma_{ij}}^2 + \alpha_j\|v_j\|_{0,\Gamma_{ij}}^2)\\ &= \sum_{k=1}^N \alpha_k\|v_k\|_{0,\partial\Omega_k}^2.\end{aligned}$$

Substituting the above inequality into (4.2) and using the trace theorem lead to

$$\begin{aligned}d^{-1}(\bar{B}^t\bar{B}v,v) &\lesssim \sum_{k=1}^N \alpha_k(d^{-1}\|v_k\|_{0,\partial\Omega_k}^2)\\ &\lesssim \sum_{k=1}^N \alpha_k(|v_k|_{1,\Omega_k}^2 + d^{-2}\|v_k\|_{0,\Omega_k}^2) = \sum_{k=1}^N (\bar{A}v_k, v_k)_{\Omega_k},\end{aligned}$$

which, together with (3.2), yields (4.1). ∎

Proof of Theorem 3.1. The inequality (3.3) can be derived by

$$\hat{\gamma}^{-1}(v, A^*v) \lesssim ((\hat{A}^{-1} + A_0^{-1}Q_0)A^*v, A^*v) \lesssim \gamma(v, A^*v) \quad \forall v \in V(\Omega).$$

Consider the space decomposition $V(\Omega) = V_0 + \bar{V}$, with $\bar{V} \subset V(\Omega)$. By the abstract Schwarz theory, we need only to prove that

(a) for any $\varphi_0 \in V_0$ and $\bar{\varphi} \in \bar{V}$, we have

$$(A^*(\varphi_0 + \bar{\varphi}), \varphi_0 + \bar{\varphi}) \lesssim \gamma[(A_0\varphi_0, \varphi_0) + (\hat{A}\bar{\varphi}, \bar{\varphi})]; \tag{4.3}$$

(b) for any $v \in V(\Omega)$, there is a decomposition $v = v_0 + \bar{v}$ with $v_0 \in V_0$ and $\bar{v} \in \bar{V}$ such that

$$(A_0v_0, v_0) + (\hat{A}\bar{v}, \bar{v}) \lesssim \hat{\gamma}(A^*v, v). \tag{4.4}$$

We first prove (a). By the triangle inequality and (3.1), we have

$$\begin{aligned}(A^*(\varphi_0 + \bar{\varphi}), \varphi_0 + \bar{\varphi}) &\le 2[(A^*\varphi_0, \varphi_0) + (A^*\bar{\varphi}, \bar{\varphi})] \\ &\lesssim (A_0\varphi_0, \varphi_0) + (A\bar{\varphi}, \bar{\varphi}) + d^{-1}(\bar{B}^t\bar{B}\bar{\varphi}, \bar{\varphi}).\end{aligned} \tag{4.5}$$

But (2.8) and (3.2) imply that

$$\begin{aligned}(A\bar{\varphi}, \bar{\varphi}) &\le \sum_{k=1}^{N} \beta_k |\bar{\varphi}|^2_{1,\Omega_k} \le \sum_{k=1}^{N} (\beta_k/\alpha_k)(\bar{A}_k(\bar{\varphi}|_{\Omega_k}), \bar{\varphi}|_{\Omega_k})_{\Omega_k} \\ &\lesssim \sum_{k=1}^{N} (\beta_k/\alpha_k)(\hat{A}_k(\bar{\varphi}|_{\Omega_k}), \bar{\varphi}|_{\Omega_k})_{\Omega_k} \le \gamma(\hat{A}\bar{\varphi}, \bar{\varphi}).\end{aligned}$$

Substituting this inequality into (4.5) and using (4.1) yield (4.3).

Now we prove (b). Let $\gamma_{\Omega_k}(v_k)$ denote the average value of v_k on Ω_k. Define $v_0 \in V_0$ as follows: for the internal subdomains Ω_k, define $v_0|_{\Omega_k} = \gamma_{\Omega_k}(v_k)$; otherwise, $v_0|_{\Omega_k} = 0$. Moreover, we define $\bar{v} = v - v_0$. Thus, by Friedrich's inequality, we obtain

$$d^{-2}\alpha_k(\bar{v}_k, \bar{v}_k)_{\Omega_k} = d^{-2}\alpha_k \|v_k - (v_0|_{\Omega_k})\|^2_{0,\Omega_k} \lesssim \alpha_k |v_k|^2_{1,\Omega_k}. \tag{4.6}$$

Using (3.2) and (4.6), we deduce

$$\begin{aligned}(\hat{A}\bar{v}, \bar{v}) &= \sum_{k=1}^{N} (\hat{A}_k\bar{v}_k, \bar{v}_k)_{\Omega_k} \le \sum_{k=1}^{N} \gamma_k(\bar{A}_k\bar{v}_k, \bar{v}_k)_{\Omega_k} \\ &\lesssim \sum_{k=1}^{N} \gamma_k\alpha_k(|\bar{v}_k|^2_{1,\Omega_k} + |v_k|^2_{1,\Omega_k}) = 2\sum_{k=1}^{N} \gamma_k\alpha_k |v_k|^2_{1,\Omega_k}.\end{aligned}$$

This, together with (2.8), leads to

$$(\hat{A}\bar{v}, \bar{v}) \lesssim \hat{\gamma}(A^*v, v). \tag{4.7}$$

On the other hand, we have

$$\begin{aligned}(A_0v_0, v_0) &= (A^*v_0, v_0) = (A^*(v - \bar{v}), v - \bar{v}) \\ &\le 2[(A^*v, v) + (A^*\bar{v}, \bar{v})].\end{aligned} \tag{4.8}$$

It follows by (4.1) and (4.7) that

$$(A^*\bar{v},\bar{v}) \lesssim (\hat{A}\bar{v},\bar{v}) \lesssim \hat{\gamma}(A^*v,v).$$

Substituting the above inequality into (4.8) yields

$$(A_0v_0,v_0) \lesssim \hat{\gamma}(A^*v,v),$$

which, together with (4.7), gives (4.4). ∎

4.2. On Theorem 3.2. In this subsection we prove Theorem 3.2. We consider only the inequality (3.7). The inequality (3.8) can be proved in the same way. To prove (3.7), we need some auxiliary results.

Consider the natural space decomposition $W(\Gamma)=\sum_{\Gamma_{ij}} I_{ij}^t W(\Gamma_{ij})$. The following result can be derived by Theorem 2.1 of [17] (refer to [33]). This result can be regarded as a variant of the abstract Schwarz theory (see [32] and [37]).

LEMMA 4.2. *Assume that the following conditions are satisfied:*

(i) *for each* $\mu \in W(\Gamma)$, *we have*

$$\sum_{\Gamma_{ij}} \langle \Lambda_{ij} I_{ij}\mu, I_{ij}\mu\rangle_{\Gamma_{ij}} \lesssim C_1\hat{\gamma}\langle \tilde{S}\mu,\mu\rangle; \tag{4.9}$$

(ii) *for any* $\phi_{ij} \in W(\Gamma_{ij})$, *we have*

$$\left\langle \tilde{S}\left(\sum_{\Gamma_{ij}} I_{ij}^t\phi_{ij}\right), \sum_{\Gamma_{ij}} I_{ij}^t\phi_{ij}\right\rangle \lesssim C_2[1+\log(dG^2(n))]^2 \sum_{\Gamma_{ij}} \langle \Lambda_{ij}\phi_{ij},\phi_{ij}\rangle_{\Gamma_{ij}}. \tag{4.10}$$

Then the inequality (3.7) *holds with* $C \lesssim C_1C_2$.

The above lemma gives a convenient way to estimate the condition number of the preconditioned Schur complements. To estimate the constants C_1 and C_2 in Lemma 4.2, we need to study carefully a discrete dual norm on the local boundary $\partial\Omega_k$ $(k=1,\dots,N)$.

Define $V(\partial\Omega_k)=V(\Omega_k)|_{\partial\Omega_k}$ and $W(\partial\Omega_k)=W(\Gamma)|_{\partial\Omega_k}$. Let $\|\cdot\|_{-*,\partial\Omega_k}$ be the *discrete* dual norm defined by

$$\|\mu\|_{-*,\partial\Omega_k} = \sup_{v\in V(\partial\Omega_k)} \frac{|\langle \mu,v\rangle_{\partial\Omega_k}|}{\|v\|_{\frac{1}{2},\partial\Omega_k}}, \quad \mu \in W(\partial\Omega_k),$$

with

$$\|v\|_{\frac{1}{2},\partial\Omega_k} = (|v|^2_{\frac{1}{2},\partial\Omega_k} + d^{-1}\|v\|^2_{0,\partial\Omega_k})^{\frac{1}{2}}.$$

For a function $\mu \in W(\Gamma)$, define $\pm\mu \in W(\Gamma)$ by

$$(\pm\mu)|_{\Gamma_{ij}} = \sigma_{ij}(\mu|_{\Gamma_{ij}}) \quad \text{for each } \Gamma_{ij}\subset\Gamma.$$

LEMMA 4.3. *For any index* k, *we have*

$$\beta_k^{-1}\|\pm\mu\|^2_{-*,\partial\Omega_k} \lesssim (\bar{A}_kR_k\mu,R_k\mu)_{\Omega_k} \lesssim \alpha_k^{-1}\|\pm\mu\|^2_{-*,\partial\Omega_k} \quad \forall\mu\in W(\Gamma). \tag{4.11}$$

Proof. We first prove that for any extension $\tilde{v}$ of $v\in V(\partial\Omega_k)$ which satisfies $\tilde{v}\in V(\Omega_k)$ and $\tilde{v}|_{\partial\Omega_k}=v$ we have

$$\langle \mu, B_k\tilde{v}\rangle = \langle \pm\mu, v\rangle_{\partial\Omega_k}. \tag{4.12}$$

In fact, by the definitions of the operator B_k, we deduce

$$\begin{aligned}\langle \mu, B_k\tilde{v}\rangle &= \sum_{\Gamma_{kj}\subset\partial\Omega_k} \langle \mu, \sigma_{kj}P_{kj}(v|_{\Gamma_{kj}})\rangle_{\Gamma_{kj}}\\ &= \sum_{\Gamma_{kj}\subset\partial\Omega_k} \langle \sigma_{kj}(\mu|_{\Gamma_{kj}}), P_{kj}(v|_{\Gamma_{kj}})\rangle_{\Gamma_{kj}}\\ &= \sum_{\Gamma_{kj}\subset\partial\Omega_k} \langle \sigma_{kj}(\mu|_{\Gamma_{kj}}), v\rangle_{\Gamma_{kj}}.\end{aligned}$$

This implies (4.12). Here we have used the fact that $\sigma_{kj}(\mu|_{\Gamma_{kj}}) \in W(\Gamma_{kj})$.

We then prove the second inequality of (4.11).

Since $R_k = \bar{A}_k^{-1}B_k^t$ on $W(\Gamma)$, it follows by (4.12) that

$$\begin{aligned}(\bar{A}_kR_k\mu, R_k\mu)_{\Omega_k} &= (B_k^t\mu, R_k\mu)_{\Omega_k}\\ &= \langle \mu, B_kR_k\mu\rangle = \langle \pm\mu, R_k\mu\rangle_{\partial\Omega_k}.\end{aligned} \tag{4.13}$$

By the Cauchy inequality and the trace theorem, we obtain

$$\begin{aligned}\langle \pm\mu, R_k\mu\rangle_{\partial\Omega_k} &\le \|\pm\mu\|_{-*,\partial\Omega_k}\cdot\|R_k\mu\|_{\frac{1}{2},\partial\Omega_k}\\ &\lesssim \|\pm\mu\|_{-*,\partial\Omega_k}\cdot\|R_k\mu\|_{1,\Omega_k}.\end{aligned} \tag{4.14}$$

Using (4.14) and the equality

$$\alpha_k\|R_k\mu\|_{1,\Omega_k}^2 = (\bar{A}_kR_k\mu, R_k\mu)_{\Omega_k}$$

leads to

$$\langle \pm\mu, R_k\mu\rangle_{\partial\Omega_k} \lesssim \alpha_k^{-\frac{1}{2}}\|\pm\mu\|_{-*,\partial\Omega_k}\cdot((\bar{A}_kR_k\mu, R_k\mu)_{\Omega_k})^{\frac{1}{2}}.$$

Substituting the above inequality into (4.13) yields

$$(\bar{A}_kR_k\mu, R_k\mu)_{\Omega_k} \lesssim \alpha_k^{-1}\|\pm\mu\|_{-*,\partial\Omega_k}^2. \tag{4.15}$$

Now we prove the first inequality of (4.11).

For any $v \in V(\partial\Omega_k)$ there is an extension $\tilde{v} \in V(\Omega_k)$ such that $\tilde{v}|_{\partial\Omega_k} = v$ and

$$\|\tilde{v}\|_{1,\Omega_k} \lesssim \|v\|_{\frac{1}{2},\partial\Omega_k}. \tag{4.16}$$

Using the definition of the operator R_k and the Cauchy inequality yields

$$\begin{aligned}|\langle \mu, B_k\tilde{v}\rangle_{\partial\Omega_k}| &= |(B_k^t\mu, \tilde{v})_{\Omega_k}| = |(\bar{A}_kR_k\mu, \tilde{v})_{\Omega_k}|\\ &\le ((\bar{A}_kR_k\mu, R_k\mu)_{\Omega_k})^{\frac{1}{2}}\cdot((\bar{A}_k\tilde{v}, \tilde{v})_{\Omega_k})^{\frac{1}{2}}.\end{aligned}$$

This, together with (4.16) and the inequality

$$(\bar{A}_k\tilde{v}, \tilde{v})_{\Omega_k} \le \beta_k\|\tilde{v}\|_{1,\Omega_k}^2,$$

leads to

$$|\langle \mu, B_k\tilde{v}\rangle_{\partial\Omega_k}| \lesssim ((\bar{A}_kR_k\mu, R_k\mu)_{\Omega_k})^{\frac{1}{2}}\cdot\beta_k^{\frac{1}{2}}\|v\|_{\frac{1}{2},\partial\Omega_k}.$$

Thus, it follows by (4.12) that

$$\begin{aligned}\|\pm\mu\|_{-*,\partial\Omega_k} &= \sup_{v\in V(\partial\Omega_k)} frac|\langle\mu, B_k\tilde{v}\rangle_{\partial\Omega_k}|\|v\|_{\frac{1}{2},\partial\Omega_k}\\ &\lesssim \beta_k^{\frac{1}{2}}((\bar{A}_k R_k\mu, R_k\mu)_{\Omega_k})^{\frac{1}{2}},\end{aligned}$$

which, together with (4.15), gives the desired result. □

When estimating the constant C_2, some extension results of the discrete dual norm $\|\cdot\|_{-*,\partial\Omega_k}$ will play a key role (refer to [19]). Before proving these results, we give two restriction operators and their properties.

For an open face $\Gamma_{ij}\subset\Gamma$, make a regular and quasi-uniform triangulation with the diameter $h_{ij} = 1/G^2(n_0(i,j))$. Let $\mathcal{N}_{ij}$ and $Z(\Gamma_{ij})$ denote, respectively, the set of the corresponding nodes and the space which consists of continuous piecewise linear polynomials associated with this triangulation. For $v_{ij}\in Z(\Gamma_{ij})$, we define $I^0_{\partial\Gamma_{ij}}v_{ij},\ I^0_{\Gamma_{ij}}v_{ij}\in Z(\Gamma_{ij})$ by

$$I^0_{\partial\Gamma_{ij}}v_{ij}(s) = \begin{cases} v_{ij}(s) & \text{if } s\in\mathcal{N}_{ij}\cap\partial\Gamma_{ij},\\ 0 & \text{if } s\in\mathcal{N}_{ij}\cap\Gamma_{ij}\end{cases}$$

and

$$I^0_{\Gamma_{ij}}v_{ij}(s) = \begin{cases} v_{ij}(s) & \text{if } s\in\mathcal{N}_{ij}\cap\Gamma_{ij},\\ 0 & \text{if } s\in\mathcal{N}_{ij}\cap\partial\Gamma_{ij}.\end{cases}$$

It is easy to see that $v_{ij} = I^0_{\partial\Gamma_{ij}}v_{ij} + I^0_{\Gamma_{ij}}v_{ij}$ on $\bar{\Gamma}_{ij}$.

The following two inequalities can be found in [12] and [38].

LEMMA 4.4. *Let $v_{ij}\in Z(\Gamma_{ij})$. Then*

$$\|I^0_{\Gamma_{ij}}v_{ij}\|_{\frac{1}{2},\Gamma_{ij}} \lesssim [1+\log(d/h_{ij})]\|v_{ij}\|_{\frac{1}{2},\Gamma_{ij}} \tag{4.17}$$

and

$$\|I^0_{\partial\Gamma_{ij}}v_{ij}\|_{0,\partial\Gamma_{ij}} \lesssim [1+\log(d/h_{ij})]^{\frac{1}{2}}\|v_{ij}\|_{\frac{1}{2},\Gamma_{ij}}. \tag{4.18}$$

The following result can be viewed as a variant of the $H^{-\frac{1}{2}}$-extension proved in [18] (see also [19]).

LEMMA 4.5. *Let hypothesis* H_2 *hold. Then, for each $\Gamma_{ij}\subset\Gamma$, we have*

$$\sup_{v\in V_i(\Gamma_{ij})}\frac{|\langle\mu_{ij}, v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} \lesssim [1+\log(dG^2(n_0(i,j)))]\|\mu_{ij}\|_{-*,\Gamma_{ij}} \quad \forall\mu_{ij}\in W(\Gamma_{ij}). \tag{4.19}$$

Proof. For any $v\in V_i(\Gamma_{ij})$, let v_{ij} be the L^2 projection of v on $Z(\Gamma_{ij})$. Then

$$\begin{aligned}|\langle\mu_{ij}, v\rangle_{\Gamma_{ij}}| &\le |\langle\mu_{ij}, v-v_{ij}\rangle_{\Gamma_{ij}}|\\ &\quad + |\langle\mu_{ij}, v_{ij}\rangle_{\Gamma_{ij}}|.\end{aligned} \tag{4.20}$$

It is well known that

$$\|v_{ij}-v\|_{0,\Gamma_{ij}} \le Ch_{ij}^{\frac{1}{2}}\|v\|_{\frac{1}{2},\Gamma_{ij}}.$$

This, together with (3.5), leads to

$$\begin{aligned}|\langle \mu_{ij}, v - v_{ij}\rangle_{\Gamma_{ij}}| &\le \|\mu_{ij}\|_{0,\Gamma_{ij}} \cdot \|v - v_{ij}\|_{0,\Gamma_{ij}} \\ &\lesssim \|\mu_{ij}\|_{0,\Gamma_{ij}} \cdot h_{ij}^{\frac{1}{2}} \|v\|_{\frac{1}{2},\Gamma_{ij}} \\ &\lesssim \|\mu_{ij}\|_{-*,\Gamma_{ij}} \cdot \|v\|_{\frac{1}{2},\Gamma_{ij}}. \end{aligned} \tag{4.21}$$

Here we have used the relation $h_{ij}^{\frac{1}{2}} = 1/G(n_0(i,j))$. Since

$$v_{ij} = I^0_{\Gamma_{ij}} v_{ij} + I^0_{\partial\Gamma_{ij}} v_{ij},$$

we have

$$\begin{aligned}|\langle \mu_{ij}, v_{ij}\rangle_{\Gamma_{ij}}| &\le |\langle \mu_{ij}, I^0_{\Gamma_{ij}} v_{ij}\rangle_{\Gamma_{ij}}| + |\langle \mu_{ij}, I^0_{\partial\Gamma_{ij}} v_{ij}\rangle_{\Gamma_{ij}}| \\ &\le |\langle \mu_{ij}, I^0_{\Gamma_{ij}} v_{ij}\rangle_{\Gamma_{ij}}| + \|\mu_{ij}\|_{0,\Gamma_{ij}} \cdot \|I^0_{\partial\Gamma_{ij}} v_{ij}\|_{0,\Gamma_{ij}} \\ &\le \|\mu_{ij}\|_{-*,\Gamma_{ij}} \cdot \|I^0_{\Gamma_{ij}} v_{ij}\|_{\frac{1}{2},\Gamma_{ij}} \\ &\quad + \|\mu_{ij}\|_{0,\Gamma_{ij}} \cdot h_{ij}^{\frac{1}{2}} \|I^0_{\partial\Gamma_{ij}} v_{ij}\|_{0,\partial\Gamma_{ij}}, \end{aligned} \tag{4.22}$$

where a direct computation is used to bound the term $\|I^0_{\Gamma_{ij}} v_{ij}\|_{\frac{1}{2},\Gamma_{ij}}$ by $h_{ij}^{\frac{1}{2}} \|I^0_{\partial\Gamma_{ij}} v_{ij}\|_{0,\partial\Gamma_{ij}}$ using the discrete L^2 norm. Substituting (4.17), (4.18), and (3.5) into (4.22), we obtain

$$|\langle \mu_{ij}, v_{ij}\rangle_{\Gamma_{ij}}| \lesssim [1 + \log(d/h_{ij})] \|\mu_{ij}\|_{-*,\Gamma_{ij}} \cdot \|v_{ij}\|_{\frac{1}{2},\Gamma_{ij}},$$

which, together with (4.20) and (4.21), yields

$$|\langle \mu_{ij}, v\rangle_{\Gamma_{ij}}| \lesssim [1 + \log(d/h_{ij})] \|\mu_{ij}\|_{-*,\Gamma_{ij}} \cdot \|v\|_{\frac{1}{2},\Gamma_{ij}}.$$

Here we have used the fact

$$\|v_{ij}\|_{\frac{1}{2},\Gamma_{ij}} \lesssim \|v\|_{\frac{1}{2},\Gamma_{ij}}.$$

Therefore, we deduce (4.19) (note that $h_{ij} = 1/G^2(n_0(i,j))$). ∎

LEMMA 4.6. *Let conditions* H_2 *and* H_4 *be satisfied. Then, for each* $\Gamma_{ij} \subset \Gamma$*, we have*

$$\|I^t_{ij} \mu_{ij}\|_{-*,\partial\Omega_i} \lesssim [1 + \log(dG^2(n_0(i,j)))] \|\mu_{ij}\|_{-*,\Gamma_{ij}} \quad \forall \mu_{ij} \in W(\Gamma_{ij}) \tag{4.23}$$

and

$$\|I^t_{ij} \mu_{ij}\|_{-*,\partial\Omega_j} \lesssim [1 + \log(dG^2(n_0(i,j)))] \|\mu_{ij}\|_{-*,\Gamma_{ij}} \quad \forall \mu_{ij} \in W(\Gamma_{ij}). \tag{4.24}$$

Proof. Since

$$\|v\|_{\frac{1}{2},\partial\Omega_i} \ge \|v\|_{\frac{1}{2},\Gamma_{ij}} \quad \forall v \in V_i(\partial\Omega_i),$$

the inequality (4.23) is a direct consequence of (4.19).

Now we consider (4.24). By (4.19), it suffices to prove that

$$\sup_{v \in V_j(\Gamma_{ij})} \frac{|\langle \mu_{ij}, v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} \lesssim \sup_{v \in V_i(\Gamma_{ij})} \frac{|\langle \mu_{ij}, v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} + \|\mu_{ij}\|_{-*,\Gamma_{ij}} \quad \forall \mu_{ij} \in W(\Gamma_{ij}). \tag{4.25}$$

Let $P_{ij}^i : L^2(\Gamma_{ij}) \to V_i(\Gamma_{ij})$ denote the L^2 projection. Then, for any $v \in V_j(\Gamma_{ij})$, we have

$$\frac{|\langle \mu_{ij}, v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} \le \begin{cases} \frac{|\langle \mu_{ij}, P_{ij}^i v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} & \text{if } W(\Gamma_{ij}) \subset V_i(\Gamma_{ij}), \\ \frac{|\langle \mu_{ij}, P_{ij}^i v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} + \frac{|\langle \mu_{ij}, v - P_{ij}^i v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} & \text{if } W(\Gamma_{ij}) \not\subset V_i(\Gamma_{ij}). \end{cases} \tag{4.26}$$

Using the Cauchy inequality and (3.5) yields

$$\begin{aligned} |\langle \mu_{ij}, v - P_{ij}^i v\rangle_{\Gamma_{ij}}| &\le \|\mu_{ij}\|_{0,\Gamma_{ij}} \cdot \|v - P_{ij}^i v\|_{0,\Gamma_{ij}} \\ &\lesssim G(n_0(i,j))\|\mu_{ij}\|_{-*,\Gamma_{ij}} \cdot \inf_{v_\delta \in V_i(\Gamma_{ij})} \|v - v_\delta\|_{0,\Gamma_{ij}}. \end{aligned}$$

Thus, it follows by condition H_4 that

$$\frac{|\langle \mu_{ij}, v - P_{ij}^i v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} \lesssim \|\mu_{ij}\|_{-*,\Gamma_{ij}} \quad (W(\Gamma_{ij}) \not\subset V_i(\Gamma_{ij})). \tag{4.27}$$

Note that $\|v\|_{\frac{1}{2},\Gamma_{ij}} \gtrsim \|P_{ij}^i v\|_{\frac{1}{2},\Gamma_{ij}}$, and using (4.26), together with (4.27), we obtain

$$\sup_{v \in V_j(\Gamma_{ij})} \frac{|\langle \mu_{ij}, v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}}} \lesssim \sup_{v \in V_j(\Gamma_{ij})} \frac{|\langle \mu_{ij}, P_{ij}^i v\rangle_{\Gamma_{ij}}|}{\|P_{ij}^i v\|_{\frac{1}{2},\Gamma_{ij}}} + \|\mu_{ij}\|_{-*,\Gamma_{ij}}.$$

Since $P_{ij}^i v \in V_i(\Gamma_{ij})$, this leads to (4.25). ∎

The following lemma is a direct consequence of the following relations:

$$I_{ij}^t(V_i^0(\Gamma_{ij})) \subset V(\partial\Omega_i) \text{ and } I_{ij}^t(V_j^0(\Gamma_{ij})) \subset V(\partial\Omega_j).$$

LEMMA 4.7. *For each face $\Gamma_{ij} \subset \Gamma$ we have*

$$\|\mu\|_{-*,\Gamma_{ij}} \lesssim \| \pm \mu\|_{-*,\partial\Omega_i} \quad \forall \mu \in W(\Gamma) \tag{4.28}$$

and

$$\sup_{v \in V_j^0(\Gamma_{ij})} \frac{|\langle \mu, v\rangle_{\Gamma_{ij}}|}{\|v\|_{\frac{1}{2},\Gamma_{ij}^0}} \lesssim \| \pm \mu\|_{-*,\partial\Omega_j} \quad \forall \mu \in W(\Gamma). \tag{4.29}$$

For ease of notation, define $S_0 = BA_0^{-1}Q_0B^t$.

LEMMA 4.8. *For $\mu \in W(\Gamma)$, define $\mu_{ij} = I_{ij}\mu \in W(\Gamma_{ij})$. Let assumptions* H_1 *and* H_3 *hold. Then*

$$\langle S_0\mu, \mu\rangle \lesssim [1 + \log(dG^2(n))]^2 \sum_{\Gamma_{ij}} \langle \Lambda_{ij}\mu_{ij}, \mu_{ij}\rangle_{\Gamma_{ij}}. \tag{4.30}$$

Proof. Define $u_0 = A_0^{-1}Q_0B^t\mu$ $(\in V_0)$. Then

$$\begin{aligned} \langle S_0\mu, \mu\rangle &= \langle Bu_0, \mu\rangle = (Q_0B^t\mu, u_0) = (Au_0, u_0) \\ &\eqsim d^{-1}(\bar{B}^t\bar{B}u_0, u_0) = d^{-1}\|\bar{B}u_0\|_{0,\Gamma}^2. \end{aligned} \tag{4.31}$$

In the following we estimate $d^{-1}\|\bar{B}u_0\|_{0,\Gamma}^2$ by using the relation

$$d^{-1}\|\bar{B}u_0\|_{0,\Gamma}^2 \eqsim \langle \mu, Bu_0\rangle. \tag{4.32}$$

From the definitions of V_0, B, and $\bar{B}$, we know that

$$(\bar{B}u_0)|_{\Gamma_{ij}} = \alpha_{ij}^{\frac{1}{2}}(Bu_0)|_{\Gamma_{ij}}$$

is a constant for each Γ_{ij}, which is denoted by a_{ij}^0. Using (4.32) and the Cauchy–Schwarz inequality yields

$$\begin{aligned} d^{-1}\|\bar{B}u_0\|_{0,\Gamma}^2 &\eqsim \sum_{\Gamma_{ij}} a_{ij}^0 \alpha_{ij}^{-\frac{1}{2}} \langle \mu, 1\rangle_{\Gamma_{ij}} \\ &\le \left(\sum_{\Gamma_{ij}} (a_{ij}^0)^2\right)^{\frac{1}{2}} \cdot \left(\sum_{\Gamma_{ij}} \alpha_{ij}^{-1}\langle \mu, 1\rangle_{\Gamma_{ij}}^2\right)^{\frac{1}{2}} \\ &\eqsim d^{-1}\|\bar{B}u_0\|_{0,\Gamma} \cdot \left(\sum_{\Gamma_{ij}} \alpha_{ij}^{-1}\langle \mu, 1\rangle_{\Gamma_{ij}}^2\right)^{\frac{1}{2}}. \end{aligned}$$

Thus,

$$\|\bar{B}u_0\|_{0,\Gamma}^2 \lesssim \sum_{\Gamma_{ij}} \alpha_{ij}^{-1} |\langle \mu, 1\rangle_{\Gamma_{ij}}|^2. \tag{4.33}$$

Since $V(\partial\Omega_i)$ contains the constant function, we have

$$\begin{aligned} |\langle \mu, 1\rangle_{\Gamma_{ij}}| &= |\langle I_{ij}^t \mu_{ij}, 1\rangle_{\partial\Omega_i}| \\ &\le \|I_{ij}^t \mu_{ij}\|_{-*,\partial\Omega_i} \cdot \|1\|_{\frac{1}{2},\partial\Omega_i} \\ &\eqsim d^{\frac{1}{2}} \|I_{ij}^t \mu_{ij}\|_{-*,\partial\Omega_i}. \end{aligned}$$

Substituting the above inequality into (4.33) and using (4.23) lead to

$$d^{-1}\|\bar{B}u_0\|_{0,\Gamma}^2 \lesssim [1 + \log(dG(n))]^2 \sum_{\Gamma_{ij}} \alpha_{ij}^{-1} \|\mu_{ij}\|_{-*,\Gamma_{ij}}^2.$$

Hence, from (4.31) we have

$$\langle S_0\mu, \mu\rangle \lesssim [1 + \log(dG(n))]^2 \sum_{\Gamma_{ij}} \alpha_{ij}^{-1} \|\mu_{ij}\|_{-*,\Gamma_{ij}}^2. \tag{4.34}$$

Note that $\alpha_{ij}^{-1} = \alpha_i^{-1}$ (see assumption H_1), and by (4.34) and the condition H_3 we obtain (4.30). Now we can prove Theorem 3.2 easily.

Proof of Theorem 3.2. By Lemma 4.2, we need only to estimate the constants C_1 and C_2 in (4.9) and (4.10).

For simplicity of exposition, we assume that $\gamma_k \eqsim 1$. It is easy to see that ($\mu \in W(\Gamma)$)

$$\begin{aligned} \langle \tilde{S}\mu, \mu\rangle &= \sum_{k=1}^N \langle B_k \hat{A}_k^{-1} B_k^t \mu, \mu\rangle_{\partial\Omega_k} + \langle BA_0^{-1}Q_0 B^t\mu, \mu\rangle \\ &\eqsim \sum_{k=1}^N (\bar{A}_k^{-1} B_k^t \mu, B_k^t \mu)_{\Omega_k} + \langle S_0\mu, \mu\rangle \\ &= \sum_{k=1}^N (\bar{A}_k R_k \mu, R_k \mu)_{\Omega_k} + \langle S_0\mu, \mu\rangle. \end{aligned} \tag{4.35}$$

We first estimate the constant C_1.

By condition H_3, we have

$$\langle \Lambda_{ij} I_{ij}\mu, I_{ij}\mu\rangle_{\Gamma_{ij}} \lesssim \alpha_i^{-1} \|I_{ij}\mu\|^2_{-*,\Gamma_{ij}}.$$

This, together with Lemmas 4.7 and 4.3, leads to

$$\langle \Lambda_{ij} I_{ij}\mu, I_{ij}\mu\rangle_{\Gamma_{ij}} \lesssim \frac{\beta_i}{\alpha_i}(\bar{A}_i R_i\mu, R_i\mu)_{\Omega_i}.$$

Summing over Γ_{ij} to the above inequality and using (4.35) yield (4.9) with $C_1 \le \max_{1\le k\le N}(\beta_k/\alpha_k) = \gamma$.

We next estimate the constant C_2.

For ease of notation, define $\phi = \sum_{\Gamma_{ij}} I_{ij}^t \phi_{ij}$. Then, from (4.35), we have

$$\begin{aligned}\left\langle \tilde{S}\left(\sum_{\Gamma_{ij}} I_{ij}^t\phi_{ij}\right), \sum_{\Gamma_{ij}} I_{ij}^t\phi_{ij}\right\rangle &= \langle \tilde{S}\phi, \phi\rangle \\ &\eqsim \sum_{k=1}^{N} (\bar{A}_k R_k\phi, R_k\phi)_{\Omega_k} + \langle S_0\phi, \phi\rangle. \end{aligned} \tag{4.36}$$

It follows by Lemma 4.3 that

$$\begin{aligned}(\bar{A}_k R_k\phi, R_k\phi)_{\Omega_k} &\lesssim \alpha_k^{-1} \| \pm \phi\|^2_{-*,\partial\Omega_k} \\ &\lesssim \alpha_k^{-1} \sum_{\Gamma_{kj}\subset\partial\Omega_k} \| \pm I_{kj}^t(\phi|_{\Gamma_{kj}})\|^2_{-*,\partial\Omega_k}.\end{aligned}$$

Substituting the above inequality into (4.36) and noting that $\phi|_{\Gamma_{ij}} = \phi_{ij}$ yield

$$\begin{aligned}\left\langle \tilde{S}\left(\sum_{\Gamma_{ij}} I_{ij}^t\phi_{ij}\right), \sum_{\Gamma_{ij}} I_{ij}^t\phi_{ij}\right\rangle &\lesssim \langle S_0\phi, \phi\rangle \\ + \sum_{\Gamma_{ij}} [\alpha_i^{-1} \|I_{ij}^t\phi_{ij}\|^2_{-*,\partial\Omega_i} &+ \alpha_j^{-1} \|I_{ij}^t\phi_{ij}\|^2_{-*,\partial\Omega_j}].\end{aligned}$$

This, together with Lemma 4.6, leads to

$$\left\langle \tilde{S}\left(\sum_{\Gamma_{ij}} I_{ij}^t\phi_{ij}\right), \sum_{\Gamma_{ij}} I_{ij}^t\phi_{ij}\right\rangle \lesssim \langle S_0\phi, \phi\rangle + [1+\log(dG^2(n))]^2 \sum_{\Gamma_{ij}} \alpha_i^{-1} \|\phi_{ij}\|^2_{-*,\Gamma_{ij}}. \tag{4.37}$$

Thus, Lemma 4.8 and condition H_3 yield (4.10) with $C_2 \le \gamma$. ∎

5. Detailed discussions. In this section, we discuss some details on the preconditioner $\bar{S}$. Theorem 3.2 indicates that the condition number of the preconditioned Schur complements is determined mainly by the positive numbers $G(n_0(i,j))$ in the inverse estimate (3.5). However, the verification of such an inverse estimate depends on the underlying approximate spaces.

5.1. Approximate spaces. As usual, we assume that each Ω_k is a polyhedron. We consider both the finite element space and the spectral element space.

(I) pure finite element discretizations.

With each subdomain Ω_k we associate a regular and quasi-uniform triangulation $\mathcal{T}_k$ made of elements that are either hexahedra or tetrahedra. We denote by h_k the mesh size of $\mathcal{T}_k$; i.e., h_k denotes the maximum diameter of any tetrahedra in the mesh $\mathcal{T}_k$. The triangulations in the subdomains are independent of one other and generally do not match at the interfaces between subdomains. Hence, each interface Γ_{ij} is provided with two different (two-dimensional) meshes $\mathcal{T}_{ij}$ and $\mathcal{T}_{ji}$, which are associated with $\mathcal{T}_i$ and $\mathcal{T}_j$, respectively. Define $V(\Omega_k)$ as the space consisting of continuous piecewise linear functions associated with $\mathcal{T}_k$. For each $\Gamma_{ij} \subset \Gamma$, we choose $\mathcal{T}_{ij}$ or $\mathcal{T}_{ji}$ to define the *local* multiplier space $W(\Gamma_{ij})$; for example, choose $\mathcal{T}_{ij}$. There are many ways to define the local Lagrange multiplier space $W(\Gamma_{ij})$.

For the case of triangulation made of parallelepipeds, the multiplier space $W(\Gamma_{ij})$ can be defined as the tensor product of two one-dimensional multiplier spaces. Thus, we consider only the case where the face Γ_{ij} is meshed with triangular elements.

Case (i). $W(\Gamma_{ij})$ is the *mortar* space (refer to [6], [3], and [4]).

We denote by x_m, $1 \le m \le n(i,j)$, all the nodes on Γ_{ij} associated with the triangulation $\mathcal{T}_{ij}$ and distinguish the internal nodes in Γ_{ij} (numbered from 1 to $n_0(i,j)$) from the boundary notes which belong to $\partial\Gamma_{ij}$ (numbered from $n_0(i,j)+1$ to $n(i,j)$). All these nodes are associated with the shape functions ϕ_m so that each function φ in $W(\Gamma_{ij})$ can be written as

$$\varphi = \sum_{m=1}^{n(i,j)} \varphi(x_m)\phi_m,$$

and each function φ in $V_i^0(\Gamma_{ij})$ can be written as

$$\varphi = \sum_{m=1}^{n_0(i,j)} \varphi(x_m)\phi_m.$$

For a node x_m on $\partial\Gamma_{ij}$ $(n_0(i,j)+1 \le m \le n(i,j))$, only the following two cases are possible: (a) there are $Q(m)$ internal nodes $x_m^l \in \Gamma_{ij}$ such that each x_m^l and x_m are just two end points of an edge of some triangle on Γ_{ij}; (b) all three vertices of the triangle containing x_m are on the boundary of Γ_{ij} (such x_m is a vertex of Γ_{ij}). For case (b), let x_m^l $(l = 1, 2)$ denote the other two vertices of the triangle containing x_m, and set $Q(m) = 2$. Now we choose $Q(m)$ positive numbers a_m^l satisfying

$$\sum_{l=1}^{Q(m)} a_m^l = 1$$

and define

$$\varphi(x_m) = \sum_{l=1}^{Q(m)} a_m^l \varphi(x_m^l).$$

The definition of the space $W(\Gamma_{ij})$ is then

$$W(\Gamma_{ij}) = \left\{ \varphi \in V_i(\Gamma_{ij}) : \forall m,\ n_0(i,j)+1 \le m \le n(i,j),\ \varphi(x_m) = \sum_{l=1}^{Q(m)} a_m^l \varphi(x_m^l) \right\}.$$

It is easy to see that the above space can also be written as

$$W(\Gamma_{ij}) = \left\{ \varphi \in V_i(\Gamma_{ij}) : \varphi = \sum_{m=1}^{n_0(i,j)} \varphi(x_m)\phi_m + \sum_{m=n_0(i,j)+1}^{n(i,j)} \left[\sum_{l=1}^{Q(m)} a_m^l \varphi(x_m^l) \right] \phi_m \right\}.$$

Case (ii). $W(\Gamma_{ij})$ is the *dual basis* space (see [23] and [36]).

We will define a map F_{ij} which takes $V_i^0(\Gamma_{ij})$ to the space of discontinuous functions which are linear when restricted to the triangles of $\mathcal{T}_{ij}$. Let τ be a triangle with vertices $\{y_l,\ l = 1, 2, 3\}$ and v_l denote the value of a function $\varphi \in V_i^0(\Gamma_{ij})$ at y_l. We define F_{ij} by the following rules:

1. If all three vertices of τ are in Γ_{ij}, then we set $F_{ij}\varphi = w$, where w is the linear function with values $w_1 = 3v_1 - v_2 - v_3$, $w_2 = 3v_2 - v_1 - v_3$, and $w_3 = 3v_3 - v_1 - v_2$.

2. If exactly one vertex (say y_1) of τ is on $\partial\Gamma_{ij}$, then we set $w_1 = (v_2 + v_3)/2$, $w_2 = (5v_2 - 3v_3)/2$, and $w_3 = (5v_3 - 3v_2)/2$.

3. If exactly one vertex (say y_1) of τ is in Γ_{ij}, then we set $w_1 = w_2 = w_3 = v_1$.

4. If none of the vertices of τ are in Γ_{ij} then we set $w_1 = w_2 = w_3 = v_l$, where v_l is value of φ at the interior vertex which is closest to the triangle.

Let $\{x_l : l = 1, \ldots, n_0(i,j)\}$ be the nodes in Γ_{ij}. We get a dual basis by defining $\psi_l = F_{ij}\varphi_l$, for $l = 1, \ldots, n_0(i,j)$. In fact, it easily follows from the above definitions that $\{\psi_l : l = 1, \ldots, n_0(i,j)\}$ is linearly independent and satisfies $(\varphi_l, \psi_m) = 0$ whenever $l \neq m$. We define $W(\Gamma_{ij})$ to be the span of $\{\psi_l : l = 1, \ldots, n_0(i,j)\}$. Note that $W(\Gamma_{ij}) \not\subset V_i(\Gamma_{ij})$.

The existence and uniqueness of the solution $\bar{u}$ of (2.3) and the error estimates of $\bar{u}$ have been shown, respectively, in [4] (for Case (i)) and in [23] (for Case (ii)).

(II) coupling spectral and finite element discretization (refer to [5]).

We use spectral discretization on some subdomains, but we use finite element discretization on the other subdomains. Consider an interface Γ_{ij}. Without loss of generality, we assume that $V(\Omega_i)$ is the spectral space of all polynomial functions with degree $\leq n_i$, but $V(\Omega_j)$ is the usual linear finite element space (see (I)).

When $\alpha_i \leq \alpha_j$, we choose the multiplier space $W(\Gamma_{ij})$ as the spectral space of all polynomial functions with degree $\leq n_i - 2$. Otherwise, we choose $W(\Gamma_{ij})$ as a suitable linear finite element space associated with the triangulation $\mathcal{T}_{ji}$ (see [5] for details).

The existence and uniqueness of the solution $\bar{u}$ of (2.3) and the error estimates of $\bar{u}$ have been shown in [5] under suitable assumptions.

Note that for all the cases considered above, we have $\dim(W(\Gamma_{ij})) = \dim(V_i^0(\Gamma_{ij}))$.

5.2. Estimate of the positive numbers $G(n_0(i,j))$. The following result can be derived directly by the definition of $\|\cdot\|_{-*,\Gamma_{ij}}$.

THEOREM 5.1. *Assume that there exists a positive number $E(n_0(i,j))$ such that for any $\mu_{ij} \in W(\Gamma_{ij})$ there is a function $\varphi \in V_i^0(\Gamma_{ij})$ satisfying*

$$|\langle \mu_{ij}, \varphi \rangle_{\Gamma_{ij}}| \geq E(n_0(i,j)) \|\mu_{ij}\|_{0,\Gamma_{ij}} \cdot \|\varphi\|_{0,\Gamma_{ij}}. \tag{5.1}$$

Then

$$G(n_0(i,j)) \leq E_1(n_0(i,j))/E(n_0(i,j)), \tag{5.2}$$

where $E_1(n_0(i,j))$ is defined by the inverse estimate

$$\|v\|_{\frac{1}{2},\Gamma_{ij}^0} \leq E_1(n_0(i,j)) \|v\|_{0,\Gamma_{ij}} \quad \forall v \in V_i^0(\Gamma_{ij}). \tag{5.3}$$

Using Theorem 5.1, we can estimate $G(n_0(i,j))$ for various cases.

PROPOSITION 5.1. *For the two cases in discretization* (I), *we have* $G(n_0(i,j)) \lesssim h_i^{-1/2}$.

Proof. From the standard inverse estimate of the finite element functions, we know that the positive number $E_1(n_0(i,j))$ in (5.3) can be estimated by $E_1(n_0(i,j)) \lesssim h_i^{-1/2}$. We need only to prove the positive number $E(n_0(i,j))$ in (5.1) satisfies $E(n_0(i,j)) \gtrsim 1$.

For Case (ii), this inequality has been shown in [23].

Now we consider Case (i). It has been shown in [4] that the *mortar* projection $\pi_{ij} : L^2(\Gamma_{ij}) \to V_i^0(\Gamma_{ij})$ defined by

$$\int_{\Gamma_{ij}} (\varphi - \pi_{ij}\varphi)\mu ds = 0, \quad \varphi \in L^2(\Gamma_{ij}) \quad \forall \mu \in W(\Gamma_{ij})$$

satisfies the L^2 stability

$$\|\pi_{ij}\varphi\|_{0,\Gamma_{ij}} \lesssim \|\varphi\|_{0,\Gamma_{ij}} \quad \forall \varphi \in L^2(\Gamma_{ij}).$$

Thus,

$$\begin{aligned} &\langle \mu_{ij}, \pi_{ij}\mu_{ij}\rangle_{\Gamma_{ij}} = \langle \mu_{ij}, \mu_{ij}\rangle_{\Gamma_{ij}} \\ &\gtrsim \|\mu_{ij}\|_{0,\Gamma_{ij}} \cdot \|\pi_{ij}\mu_{ij}\|_{0,\Gamma_{ij}}, \end{aligned}$$

which means that the function $\varphi = \pi_{ij}\mu_{ij} \in V_i^0(\Gamma_{ij})$ satisfies (5.1) with $E(n_0(i,j)) \gtrsim 1$. ∎

PROPOSITION 5.2. *For discretization* (II), *we assume that the coupling interface* Γ_{ij} *is affinely equivalent to the reference square. Then* $G(n_0(i,j)) \lesssim (n_i^3/d)^{1/2}$ *(or* $G(n_0(i,j)) \lesssim h_j^{-1/2}$*).*

Proof. From the standard inverse estimate of the spectral element, we know that the positive number $E_1(n_0(i,j))$ in (5.3) can be estimated by $E_1(n_0(i,j)) \lesssim n_i d^{-\frac{1}{2}}$. We need only to prove the positive number $E(n_0(i,j))$ in (5.1) satisfies $E(n_0(i,j)) \gtrsim n_i^{-1/2}$. This inequality can be proved as in Case (i) of Proposition 5.1 by using the inequality (3.2) of [31], which is also true for the current situation. ∎

The following result can be derived by Proposition 5.1 and the approximate property of the finite element space $V_i(\Gamma_{ij})$.

PROPOSITION 5.3. *For Case* (ii) *in discretization* (I), *assumption* H_4 *holds.*

The following proposition is a direct consequence of Proposition 5.2 and the approximate property of the finite element space $V_j^0(\Gamma_{ij})$.

PROPOSITION 5.4. *For discretization* (II), *let the coupling interface* Γ_{ij} *be affinely equivalent to the reference square. We assume that* $h_j n_i^3/d$ *is sufficiently small. Then assumption* H_4 *holds.*

Remark 5.1. From the above discussion, we know that the positive number $G(n)$ in (3.7) and (3.8) can be estimated by

$$G^2(n) \lesssim \begin{cases} h^{-1} & \text{for discretization (I)}, \\ \max\{h^{-1}, \hat{n}^3/d\} & \text{for discretization (II)}. \end{cases}$$

Here, $h = \min h_i$ and $\hat{n} = \max n_i$.

Remark 5.2. We believe that when n_i^3 and $\hat{n}^3$ are replaced by n_i^2 and $\hat{n}^2$, respectively, the results in this section still hold. However, the proof seems complicated.

5.3. On the local solvers. It is clear that the preconditioner $\bar{S}$ is determined by the local solvers Λ_{ij} ($\Gamma_{ij} \subset \Gamma$). When the local multiplier space $W(\Gamma_{ij})$ has low dimension $n_0(i,j)$, the action of the inverse S_{ij}^{-1} can be implemented exactly (which needs $O(n_0^3(i,j))$ arithmetic operations), and Λ_{ij} can be chosen as S_{ij} itself (refer to [18] and [19]). Otherwise, we have to develop a cheaper solver Λ_{ij}, which would be spectrally equivalent to S_{ij} (namely, satisfies assumption H_3). For this purpose, we need an auxiliary result.

Let $Q_{ij} : W(\Gamma_{ij}) \to V_i^0(\Gamma_{ij})$ denote the L^2 projection on $V_i^0(\Gamma_{ij})$, and let $Q_{ij}^t : V_i^0(\Gamma_{ij}) \to W(\Gamma_{ij})$ denote its adjoint with respect to the $L^2(\Gamma_{ij})$ inner product.

THEOREM 5.2. *Let $\hat{\Lambda}_{ij} : V_i^0(\Gamma_{ij}) \to V_i^0(\Gamma_{ij})$ be a symmetric and positive definite operator satisfying $\langle \hat{\Lambda}_{ij}\cdot,\cdot\rangle_{\Gamma_{ij}} \eqsim \|\cdot\|^2_{\frac{1}{2},\Gamma_{ij}^0}$. Define $\Lambda_{ij} = \alpha_i^{-1} Q_{ij}^t \hat{\Lambda}_{ij}^{-1} Q_{ij}$. Then the operator Λ_{ij} satisfies hypothesis* H_3.

Proof. Since there is a positive number $E(n_0(i,j))$ satisfying (5.1) in all cases, it can be verified that the operator $Q_{ij} : W(\Gamma_{ij}) \to V_i^0(\Gamma_{ij})$ is nonsingular. Hence, the operator Λ_{ij} is symmetric and positive definite on $W(\Gamma_{ij})$. It suffices to prove that

$$\|\mu_{ij}\|_{-*,\Gamma_{ij}} \eqsim \langle (\hat{\Lambda}_{ij}^{-1} Q_{ij}\mu_{ij}, Q_{ij}\mu_{ij}\rangle_{\Gamma_{ij}}^{\frac{1}{2}} \quad \forall \mu_{ij} \in W(\Gamma_{ij}). \tag{5.4}$$

Define $v_{ij} = \hat{\Lambda}_{ij}^{-1} Q_{ij}\mu_{ij}$. Since $v_{ij} \in V_i^0(\Gamma_{ij})$, we have from the assumption to $\hat{\Lambda}_{ij}$

$$\begin{aligned}
\|\mu_{ij}\|_{-*,\Gamma_{ij}} &\geq \frac{|\langle \mu_{ij}, v_{ij}\rangle_{\Gamma_{ij}}|}{\|v_{ij}\|_{\frac{1}{2},\Gamma_{ij}^0}} = \frac{|\langle Q_{ij}\mu_{ij}, v_{ij}\rangle_{\Gamma_{ij}}|}{\|v_{ij}\|_{\frac{1}{2},\Gamma_{ij}^0}} \\
&= \langle Q_{ij}\mu_{ij}, \hat{\Lambda}_{ij}^{-1} Q_{ij}\mu_{ij}\rangle_{\Gamma_{ij}}^{\frac{1}{2}} \cdot \frac{\langle \hat{\Lambda}_{ij} v_{ij}, v_{ij}\rangle_{\Gamma_{ij}}^{\frac{1}{2}}}{\|v_{ij}\|_{\frac{1}{2},\Gamma_{ij}^0}} \\
&\gtrsim \langle Q_{ij}\mu_{ij}, \hat{\Lambda}_{ij}^{-1} Q_{ij}\mu_{ij}\rangle_{\Gamma_{ij}}^{\frac{1}{2}} \quad \forall \mu_{ij} \in W(\Gamma_{ij}).
\end{aligned} \tag{5.5}$$

On the other hand, we have for any $v \in V_i^0(\Gamma_{ij})$

$$\begin{aligned}
|\langle \mu_{ij}, v\rangle_{\Gamma_{ij}}| &= |\langle Q_{ij}\mu_{ij}, v\rangle_{\Gamma_{ij}}| \\
&= |\langle \hat{\Lambda}_{ij}^{-\frac{1}{2}} Q_{ij}\mu_{ij}, \hat{\Lambda}_{ij}^{\frac{1}{2}} v\rangle_{\Gamma_{ij}}|.
\end{aligned}$$

Thus, using the Cauchy inequality and the assumption, we deduce

$$\begin{aligned}
|\langle \mu_{ij}, v\rangle_{\Gamma_{ij}}| &\leq \langle \hat{\Lambda}_{ij}^{-1} Q_{ij}\mu_{ij}, Q_{ij}\mu_{ij}\rangle_{\Gamma_{ij}}^{\frac{1}{2}} \cdot \langle \hat{\Lambda}_{ij} v, v\rangle_{\Gamma_{ij}}^{\frac{1}{2}} \\
&\lesssim \langle \hat{\Lambda}_{ij}^{-1} Q_{ij}\mu_{ij}, Q_{ij}\mu_{ij}\rangle_{\Gamma_{ij}}^{\frac{1}{2}} \cdot \|v\|_{\frac{1}{2},\Gamma_{ij}^0}.
\end{aligned} \tag{5.6}$$

By the definition of $\|\cdot\|_{-*,\Gamma_{ij}}$, the inequality (5.6) leads to

$$\|\mu_{ij}\|_{-*,\Gamma_{ij}} \lesssim \langle \hat{\Lambda}_{ij}^{-1} Q_{ij}\mu_{ij}, Q_{ij}\mu_{ij}\rangle_{\Gamma_{ij}}^{\frac{1}{2}} \quad \forall \mu_{ij} \in W(\Gamma_{ij}).$$

This, together with (5.5), yields (5.4). ∎

By Theorem 5.2, we need only to define a suitable operator $\hat{\Lambda}_{ij}$ so that the action of the operator Λ_{ij}^{-1} is cheap to implement.

Remark 5.3. Of course, the operator $\hat{\Lambda}_{ij}$ can be chosen as the positive square root of the discrete Laplace operator (refer to [8] and [38]). But this choice of $\hat{\Lambda}_{ij}$ is not practical for a triangular face Γ_{ij} or spectral element discretization.

We first study the action of $(Q_{ij}^t\hat{\Lambda}_{ij}^{-1}Q_{ij})^{-1}$. For $\mu \in W(\Gamma_{ij})$, set $(Q_{ij}^t\hat{\Lambda}_{ij}^{-1}Q_{ij})^{-1}\mu = \lambda \in W(\Gamma_{ij})$. We need only to explain how to get this λ from $\mu \in W(\Gamma_{ij})$. Since the operator Q_{ij} is nonsingular, we have $(Q_{ij}^t\hat{\Lambda}_{ij}^{-1}Q_{ij})^{-1} = Q_{ij}^{-1}\hat{\Lambda}_{ij}(Q_{ij}^t)^{-1}$. Thus, $Q_{ij}\lambda = \hat{\Lambda}_{ij}(Q_{ij}^t)^{-1}\mu$, which implies that

$$\langle Q_{ij}\lambda, \varphi\rangle_{\Gamma_{ij}} = \langle \hat{\Lambda}_{ij}(Q_{ij}^t)^{-1}\mu, \varphi\rangle_{\Gamma_{ij}} \quad \forall \varphi \in V_i^0(\Gamma_{ij}).$$

Namely,

$$\langle \lambda, \varphi\rangle_{\Gamma_{ij}} = \langle \tilde{\mu}, \hat{\Lambda}_{ij}\varphi\rangle_{\Gamma_{ij}} \quad \forall \varphi \in V_i^0(\Gamma_{ij}). \tag{5.7}$$

Here the function $\tilde{\mu}$ satisfies $Q_{ij}^t\tilde{\mu} = \mu$.

As in section 2, set $\dim(W(\Gamma_{ij})) = n_0(i,j)$. Let $\{\varphi_{ij}^m\}$ and $\{\psi_{ij}^m\}$ $(m = 1, \ldots, n_0(i,j))$ denote a basis of the spaces $V_i^0(\Gamma_{ij})$ and $W(\Gamma_{ij})$, respectively. Then the functions μ and λ can be written as

$$\mu = \sum_m a_m\psi_{ij}^m \quad \text{and} \quad \lambda = \sum_m z_m\psi_{ij}^m,$$

respectively. Define the vectors

$$b_{ij} = (a_1, a_2, \ldots, a_{n_0(i,j)})^t, \quad \chi_{ij} = (z_1, z_2, \ldots, z_{n_0(i,j)})^t.$$

Let K_{ij} and M_{ij} denote the coupling matrix and the mass matrix with the entries $\langle\varphi_{ij}^k, \psi_{ij}^l\rangle_{\Gamma_{ij}}$ and $\langle\psi_{ij}^k, \psi_{ij}^l\rangle_{\Gamma_{ij}}$ $(k,l = 1, \ldots, n_0(i,j))$, respectively. Besides, let N_{ij} denote the stiffness matrix of the operator $\hat{\Lambda}_{ij}$ associated with the basis $\{\varphi_{ij}^m\}$. It can be verified by (5.7) that the vector χ_{ij} is determined by

$$K_{ij}\chi_{ij} = N_{ij}\tilde{b}_{ij}, \tag{5.8}$$

with $\tilde{b}_{ij}$ satisfying

$$K_{ij}^t\tilde{b}_{ij} = M_{ij}b_{ij}. \tag{5.9}$$

The above two equations show the action of the local solver $\Lambda_{ij}^{-1} = \alpha_i(Q_{ij}^t\hat{\Lambda}_{ij}^{-1}Q_{ij})^{-1}$. It follows by (5.8) and (5.9) that the matrix form of Λ_{ij}^{-1} is $\alpha_i K_{ij}^{-1}N_{ij}(K_{ij}^{-1})^t$.

From the viewpoint of computation, we need only to know the matrix N_{ij} instead of the operator $\hat{\Lambda}_{ij}$. In the following, we define an appropriate matrix N_{ij} such that the corresponding operator $\hat{\Lambda}_{ij}$ (for a given basis) satisfies the assumption in Theorem 5.2. Since the linear system (5.8) does not involve the action of N_{ij}^{-1}, we can define N_{ij} in a more direct way. This is the main advantage of our preconditioner over the existing preconditioners.

We first consider discretization (I).

For Case (i), both $\{\varphi_{ij}^m\}$ and $\{\psi_{ij}^n\}$ are chosen as the nodal basis functions, but, for Case (ii), $\{\psi_{ij}^n\}$ is chosen as the dual basis of $\{\varphi_{ij}^m\}$. It is clear that both M_{ij} and K_{ij} are sparse and band matrices. In particular, K_{ij} is a diagonal matrix for Case (ii).

Let $\{x_{ij}^k\}$ denote the nodes associated with the triangulation $\mathcal{T}_{ij}$. Define the operator $\hat{\Lambda}_{ij} : V_i^0(\Gamma_{ij}) \to V_i^0(\Gamma_{ij})$ by

$$\langle \hat{\Lambda}_{ij}\varphi,\psi\rangle_{\Gamma_{ij}} = h_i^4 \sum_{\substack{x_{ij}^m,x_{ij}^n\in\mathcal{T}_{ij}\\ x_{ij}^m\neq x_{ij}^n}} \frac{(\varphi(x_{ij}^m)-\varphi(x_{ij}^n))(\psi(x_{ij}^m)-\psi(x_{ij}^n))}{|x_{ij}^m-x_{ij}^n|^3}$$

$$+ h_i^2 \sum_{x_{ij}^m\in\mathcal{T}_{ij}} \frac{\varphi(x_{ij}^m)\cdot\psi(x_{ij}^m)}{dist(x_{ij}^m,\partial\Gamma_{ij})}, \quad \varphi\in V_i^0(\Gamma_{ij}) \quad \forall\psi\in V_i^0(\Gamma_{ij}). \tag{5.10}$$

In particular, for the nodal basis $\{\varphi_{ij}^k\}$ of $V_i^0(\Gamma_{ij})$, we have

$$\langle \hat{\Lambda}_{ij}\varphi_{ij}^m,\varphi_{ij}^n\rangle_{\Gamma_{ij}} = \begin{cases} \sum_{\substack{x_{ij}^l\in\mathcal{T}_{ij}\\ x_{ij}^l\neq x_{ij}^m}} \frac{h_i^4}{|x_{ij}^l-x_{ij}^m|^3} + \frac{h_i^2}{dist(x_{ij}^m,\partial\Gamma_{ij})} & \text{if } n=m,\\ \frac{-h_i^4}{|x_{ij}^m-x_{ij}^n|^3} & \text{if } n\neq m. \end{cases}$$

This equality gives the entries of the matrix N_{ij}.

If choosing $\psi=\varphi$ in (5.10), then the right-hand side of (5.10) is just the discrete form of the norm $\|\varphi\|^2_{\frac{1}{2},\Gamma_{ij}^0}$ (refer to [38]). Therefore, the operator $\hat{\Lambda}_{ij}$ satisfies the assumption in Theorem 5.2.

Since (refer to [38])

$$\|\varphi\|_{\frac{1}{2},\Gamma_{ij}^0} \eqsim [1+\log(d/h_i)]^{\frac{1}{2}}\|\varphi\|_{\frac{1}{2},\Gamma_{ij}}, \quad \varphi\in V_i^0(\Gamma_{ij}),$$

the matrix N_{ij} can be replaced by $[1+\log(d/h_i)]N_{ij}^0$, where the entries of the matrix N_{ij}^0 are defined by

$$c_{mn}^{ij} = \begin{cases} \sum_{\substack{x_{ij}^l\in\mathcal{T}_{ij}\\ x_{ij}^l\neq x_{ij}^m}} \frac{h_i^4}{|x_{ij}^l-x_{ij}^m|^3} + \frac{h_i^2}{d} & \text{if } n=m,\\ \frac{-h_i^4}{|x_{ij}^m-x_{ij}^n|^3} & \text{if } n\neq m. \end{cases}$$

Remark 5.4. The calculation of the matrix N_{ij} is needed only once before implementing a certain iterative algorithm, so its complexity is much smaller than that of the global iterations. We would like to compare the arithmetic complexity of the local solver Λ_{ij}^{-1} with that of the existing local solvers. Since the matrix K_{ij} is sparse and band, solving χ by (5.8) and (5.9) needs only $O(n_0^2(i,j))$ arithmetic operations. This local solver seems cheaper than all the existing local solvers, including the one in the classical substructuring method (if there is no particular assumption to the triangulation). For example, the action of the local solver in the FETI-type methods is implemented by solving a local Dirichlet problem with $O(n_0^{3/2}(i,j))$ unknown, and so it needs $O(n_0^3(i,j))$ arithmetic operations. We point out that we need not make a particular requirement to the meshes on Γ_{ij} here. This is a very important merit in DDMs for three-dimensional problems. If the meshes on Γ_{ij} have a particular structure, we can decrease the arithmetic operations by defining special operator $\hat{\Lambda}_{ij}$.

Now we consider discretization (II) (on parallelepiped). Without loss of generality, we assume that $\Gamma_{ij}=J^2$ with $J=[-1,1]$. Let $L_k(x)$ denote the Legendre polynomial of degree k ($k=0,\ldots,n_i-1$) defined on J. Define

$$\phi_k(x) = \sqrt{k+\frac{1}{2}}\int_{-1}^{x} L_k(t)dt, \quad k=1,\ldots,n_i-1.$$

It is clear that $\phi_k(-1) = \phi_k(1) = 0$. Let the basis functions of $W(\Gamma_{ij})$ and $V_i^0(\Gamma_{ij})$ be defined by

$$\psi_{mn}(x,y) = L_m(x)L_n(y), \quad m,n = 0,\ldots,n_i-2$$

and

$$\varphi_{mn}(x,y) = \phi_m(x)\phi_n(y), \quad m,n = 1,\ldots,n_i-1,$$

respectively. Let K_0 and M_0 denote the coupling matrix and the mass matrix with the entries $\langle \phi_k, L_l\rangle_J$ $(l = 0,\ldots,n_i-2)$ and $\langle \phi_k,\phi_l\rangle_J$ $(l = 1,\ldots,n_i-1)$, respectively $(k = 1,\ldots,n_i-1)$. It is clear that

$$K_{ij} = K_0 \otimes K_0 \quad \text{and} \quad M_{ij} = M_0 \otimes M_0. \tag{5.11}$$

From the orthogonality of the Legendre polynomial, we infer that K_0 and M_0 are sparse and band matrices with bandwidth ≤ 5. Thus, the matrices K_{ij} and M_{ij} are also sparse and band (with constant bandwidth) by (5.11).

To compute the matrix N_{ij}, we need to investigate the norm $\|\cdot\|^2_{1/2,\Gamma_{ij}^0}$. It can be verified directly that (see Theorem 13.1 of [28])

$$\|v\|^2_{\frac{1}{2},\Gamma_{ij}^0} \eqsim \|\varphi\|^2_{H_{00}^{\frac{1}{2}}(J)}\cdot\|\psi\|^2_{0,J} + \|\varphi\|^2_{0,J}\cdot\|\psi\|^2_{H_{00}^{\frac{1}{2}}(J)}, \quad v(x,y) = \varphi(x)\psi(y) \in V_i^0(\Gamma_{ij}). \tag{5.12}$$

Define

$$V^0(J) = span\{\phi_1,\phi_2,\ldots,\phi_{n_i-1}\}.$$

Let $\Lambda_0 : V^0(J) \to V^0(J)$ be a symmetric and positive definite operator, which satisfies

$$\langle \Lambda_0\phi,\phi\rangle_J \eqsim \|\phi\|^2_{H_{00}^{\frac{1}{2}}(J)} \quad \forall \phi \in V^0(J). \tag{5.13}$$

Define

$$\begin{aligned} &\langle \hat{\Lambda}_{ij} v, w\rangle_{\Gamma_{ij}} = \langle \Lambda_0\varphi^1,\psi^1\rangle_J \cdot \langle \varphi^2,\psi^2\rangle_J + \langle \varphi^1,\psi^1\rangle_J \cdot \langle \Lambda_0\varphi^2,\psi^2\rangle_J, \\ &v(x,y) = \varphi^1(x)\varphi^2(y) \in V^0(J) \quad \forall w(x,y) = \psi^1(x)\psi^2(y) \in V^0(J). \end{aligned} \tag{5.14}$$

It follows by (5.13) and (5.14) that the operator $\hat{\Lambda}_{ij}$ satisfies the assumption in Theorem 5.2. We define the operator Λ_0 by

$$\begin{aligned} \langle \Lambda_0\varphi,\psi\rangle_J &= \int_J\int_J \frac{(\varphi(x)-\varphi(y))(\psi(x)-\psi(y))}{(x-y)^2}dxdy \\ &+ \int_J \frac{\varphi(x)\psi(x)}{dist(x,\partial J)}dx, \quad \varphi \in V^0(J) \quad \forall \psi \in V_0(J), \end{aligned}$$

such that the condition (5.13) is satisfied. In particular, we have

$$\begin{aligned} \langle \Lambda_0\phi_m,\phi_n\rangle_J &= \int_J\int_J \frac{(\phi_m(x)-\phi_m(y))(\phi_n(x)-\phi_n(y))}{(x-y)^2}dxdy \\ &+ \int_J \frac{\phi_m(x)\phi_n(x)}{dist(x,\partial J)}dx, \quad m,n = 1,\ldots,n_i-1. \end{aligned} \tag{5.15}$$

Let N_0 denote the stiffness matrix of the operator Λ_0 associated with the basis $\{\phi_k\}$. From (5.14), we have

$$N_{ij} = N_0 \otimes M_0 + M_0 \otimes N_0. \tag{5.16}$$

The matrix M_0 can be obtained easily, which has only $O(n_i)$ nonzero entries (so the matrix N_{ij} has $O(n_i^3)$ nonzero entries at most).

To calculate the matrix N_0, we need to derive a formula to evaluate the inner product $\langle \Lambda_0 \phi_m, \phi_n \rangle_J$. Define

$$I_{m,n}(k,l) = \int_J \int_J \frac{\int_y^x t^k L_m(t)dt \cdot \int_y^x t^l L_n(t)dt}{(x-y)^2} dxdy,$$
$$k = 0, \ldots, n_i - 1 - m;\ l = 0, \ldots, n_i - 1 - n;\ m, n = 1, \ldots, n_i - 1.$$

Then

$$\int_J \int_J \frac{(\phi_m(x) - \phi_m(y))(\phi_n(x) - \phi_n(y))}{(x-y)^2} dxdy = \sqrt{m + \frac{1}{2}}\sqrt{n + \frac{1}{2}} I_{m,n}(0,0).$$

It is well known that

$$L_{k+1}(x) = \frac{2k+1}{k+1} x L_k(x) - \frac{k}{k+1} L_{k-1}(x), \quad k = 1, \ldots, n_i - 1.$$

Thus, we can obtain the following recurrence formulas ($m, n \geq 2$):

$$I_{1,n}(k,l) = \frac{2n+1}{n+1} I_{1,n-1}(k, l+1) - \frac{n}{n+1} I_{1,n-2}(k,l),$$

$$I_{m,1}(k,l) = \frac{2m+1}{m+1} I_{m-1,1}(k+1, l) - \frac{m}{m+1} I_{m-2,1}(k,l),$$

and

$$I_{m,n}(k,l) = \frac{2m+1}{m+1} \cdot \frac{2n+1}{n+1} I_{m-1,n-1}(k+1, l+1) + \frac{m}{m+1} \cdot \frac{n}{n+1} I_{m-2,n-2}(k,l)$$
$$- \frac{2m+1}{m+1} \cdot \frac{n}{n+1} I_{m-1,n-2}(k+1, l) - \frac{m}{m+1} \cdot \frac{2n+1}{n+1} I_{m-2,n-1}(k, l+1).$$

For any $k, l = 0, \ldots, n_i - 2$, the integration $I_{1,1}(k,l)$ can be evaluated easily. Thus, the integration

$$\int_J \int_J \frac{(\phi_m(x) - \phi_m(y))(\phi_n(x) - \phi_n(y))}{(x-y)^2} dxdy$$

can be evaluated by the above recurrence formulas. In an analogous way, we can evaluate the integration $\int_J \frac{\phi_m(x)\phi_n(x)}{dist(x, \partial J)} dx$, and so we can get the value $\langle \Lambda_0 \phi_m, \phi_n \rangle_J$ by (5.15).

Remark 5.5. For the case of the spectral element, the dimension of the spaces $W(\Gamma_{ij})$ and $V_i^0(\Gamma_{ij})$ are $n_0(i,j) = (n_i - 1)^2$. It is easy to see that the computation of the matrix N_0 needs $O(n_i^4) = O(n_0^2(i,j))$ arithmetic operations. This calculation is needed only once in the preprocessing step and thus is minor to global iterations. From the above discussion, we know that solving χ by (5.8) needs only $O(n_i^3) = O(n_0^{\frac{3}{2}}(i,j))$ arithmetic operations. Note that the number of unknowns corresponding to the subdomain Ω_i is $(n_i + 1)^3$. To our knowledge, there is no literature to discuss the FETI method for spectral element discretization.

6. Numerical experiments. In this section, we apply our newly proposed DDM to solve two elliptic problems: the first one with large jumps in the coefficient across interfaces and the second one with a singular solution.

Consider the elliptic equation of the second order

$$\begin{cases} -\mathrm{div}(a\nabla u) = f & \text{in } \Omega, \\ u = g & \text{on } \partial\Omega, \end{cases} \tag{6.1}$$

where Ω is the unit cube: $\Omega = [0,1]^3$.

Let Ω be decomposed into N equal cubes of size d, with the cubes numbered as Ω_1, $\Omega_2, \ldots, \Omega_N$ in the usual way. The coefficient a is defined by $a(x,y,z) = a_k(1+xyz)$ for $(x,y,z) \in \Omega_k$, where a_k is a constant and will be given below. The functions f and g will be determined by the exact solution of (6.1) with continuous a (i.e., $a_k = 1$). Note that the exact solution with jump a is difficult to construct.

The finite element or the spectral element discretization will be used on each subdomain Ω_k. As demonstrated in section 2, the DDM with Lagrange multipliers results in the augmented saddle-point problem (2.9). The corresponding *algebraic* system will be solved by the Uzawa-type method described by Algorithm 3.1 in [21]. This method needs to compute an approximation $\Psi(\cdot)$ in its inner iteration. For our current examples, the approximation $\Psi(\cdot)$ is generated by a one-step multiplicative Schwarz iteration with solvers $\hat{A}_k$ and a coarse solver A_0, where the optimal relaxation factor is added in the standard way. In the case of finite element discretization, $\hat{A}_k$ is chosen to be the multigrid preconditioner corresponding to $\bar{A}_k$; in the case of spectral element discretization, $\hat{A}_k$ is chosen to be $\bar{A}_k$ itself (since the stiffness matrix of $\bar{A}_k$ has a particular structure). For the outer iteration, we use the preconditioner introduced in subsection 5.3.

To investigate the convergence for jump a, we have to choose a termination criterion carefully, which would not be influenced by possible large jumps. Let $|||\cdot|||$ denote the weighted Euclidean norm with the weights 1 (for the primal vector) and $\{\alpha_{ij}^2\}$ (for the multiplier vectors; refer to section 2).

The initial guess is chosen as the zero vector, and the termination criterion ε is defined to be the (relative) residual norm

$$\varepsilon = |||\mathcal{F} - \mathcal{M}\mathcal{U}_n|||/|||\mathcal{F}|||.$$

Here $\mathcal{M}$, $\mathcal{F}$, and $\mathcal{U}$ denote the algebraic form of M, F, and U, respectively. The iteration terminates when $\varepsilon \le 10^{-5}$.

Example 6.1. In (6.1), the constant a_k is defined by

$$a_k = \begin{cases} 1 & \text{if } k \text{ is odd}, \\ 10^{-5} & \text{if } k \text{ is even}. \end{cases}$$

We take the analytic solution to be $u = e^{xyz}$.

Case (i). Each subdomain Ω_k is divided into small cubes of size h, and the standard Q_1 element is used on Ω_k. The multiplier space on a local interface is spanned by the (two-dimensional) mortar multiplier basis, which is the tensor product of two one-dimensional mortar multiplier bases given in [6].

The numerical results are summarized in Table 1.

This table indicates that the iteration counts depend slightly on the ratio d/h and are almost independent of N or h itself.

Case (ii). We use the same discretization on the subdomains near the boundary $\partial\Omega$ as the one used in Case (i), but with the spectral element discretization on the

TABLE 1
Iteration counts for the case with matching grids.

16	3	44	45
16	5	45	46

inner subdomains. The basis in the spectral space is defined as the tensor product of three one-dimensional Legendre polynomial bases with degree n. The multiplier space is defined as in subsection 5.1.

The iteration counts are given in Table 2.

This table indicates that the iteration counts are indeed determined by $\max\{d/h, n^2\}$ for the coupling discretization.

Example 6.2. In (6.1), we take the analytic solution to be the singular solution $u(x, y, z) = (x + y + z)^{0.2}$.

Since u is singular at the original point, we use the finite element discretization with nonmatching grids. Set $d = 1/4$ $(N = 64)$ or $d = 1/5$ $(N = 125)$, and divide each cube into small cubes with the size h_1, h_2, or h_3 $(h_1 < h_2 < h_3)$. Here the size h_1 is used in the subdomains $\Omega_k \subset [0, d]^3$, the size h_2 in the subdomains $\Omega_k \subset [0, 2d]^3 \backslash [0, d]^3$, and the size h_3 in the subdomains $\Omega_k \subset \Omega \backslash [0, 2d]^3$. Again the standard Q_1 element is used on each cube. The multiplier is chosen as the tensor product of two one-dimensional dual basis multiplier associated with the coarse triangulation on the interface.

We shall compare the performances for the cases with same a_k and different a_k:

Case 1. The constant $a_k \equiv 1$ for all subdomains Ω_k.

Case 2. The constant a_k is defined by

$$a_k = \begin{cases} 10^6 & \text{if } \Omega_k \subset [0, d]^3, \\ 10^3 & \text{if } \Omega_k \subset [0, 2d]^3 \backslash [0, d]^3, \\ 1 & \text{if } \Omega_k \subset \Omega \backslash [0, 2d]^3. \end{cases}$$

The iteration counts are reported in Tables 3 and 4, respectively.

All the numerical results reported in this section clearly demonstrate the efficiency of our method, and this confirms the theoretical results presented in this paper. In particular, we have seen that the iteration counts are not affected by nonmatching grids or jump coefficients.

7. Conclusions. In this paper we have proposed a new DDM with Lagrange multipliers for solving three-dimensional elliptic problems with variable coefficients. For this method, the singularity on floating domains is handled by combining the augmented method and the preconditioning technique. To construct a preconditioner for the Schur complement, we have developed a class of inexact local solver for three important multiplier spaces, which are less expensive than the existing local solvers. Both the theoretical results and the numerical experiments show that our method is

efficient, even if the grids are nonmatching and the coefficient has large variations across local interfaces.

Acknowledgment. The authors wish to thank two anonymous referees for many constructive comments which led to a great improvement of the results and the presentation of the paper.

A RELAXATION SCHEME FOR THE NONLINEAR SCHRÖDINGER EQUATION*

CHRISTOPHE BESSE†

Abstract. In this paper, we present a new numerical scheme for the nonlinear Schrödinger equation. This is a relaxation-type scheme that avoids solving for nonlinear systems and preserves density and energy. We give convergence results for the semidiscretized version of the scheme and perform several numerical experiments.

Key words. nonlinear Schrödinger equation, relaxation method

1. Introduction and statement of the results. We present in this article a semidiscretized numerical scheme for the nonlinear Schrödinger equation defined for $x \in \mathbb{R}^d$ by

$$\begin{cases} iu_t + \Delta u = \lambda |u|^{2\sigma} u, & t > 0, \\ u(x,0) = u_0(x), \end{cases} \tag{1.1}$$

where we set $\lambda \in \mathbb{R}^*$, $\sigma \in \mathbb{N}^*$, and Δ the classical Laplacian operator.

Both density N and energy E are conserved quantities:

$$N(t) = \int_{\mathbb{R}^d} |u|^2(t,x)dx,$$
$$E(t) = \int_{\mathbb{R}^d} \frac{1}{2}|\nabla u|^2 + \frac{\lambda}{2\sigma+2}|u|^{2\sigma+2}dx.$$

Using these conserved quantities, it is well known that the system (1.1) is globally well posed in $H^1(\mathbb{R}^d)$ if $\lambda < 0$, and blow-up may occur if $\lambda > 0$ (see, for example, [11], [7], [12]).

A large number of articles are devoted to the numerical study of this equation using many different time discretizations. The standard cases use schemes of Crank–Nicolson type [9], Runge–Kutta type [3], [1], [2], symplectic type (see, for example, [13], [14]), or splitting type [15], [6]. Recently, Zouraris [16] proved the convergence of scheme developed by [10]. In [4], Bao, Jin, and Markowich use a time-splitting spectral scheme for the more general nonlinear Schrödinger equation (1.2):

$$i\varepsilon u_t + \frac{\varepsilon^2}{2}\Delta u - \mathcal{V}(x)u - f(|u|^2)u = 0, \quad t > 0, \quad x \in \mathbb{R}^d, \tag{1.2}$$

where $\mathcal{V}$ is a given real-valued electrostatic potential and f is a real-valued smooth function. Typically, for $f(\rho) = \delta\rho$ and $\mathcal{V}(x) = |x|^2$, this equation is called the Gross–Pitaevskii equation. In [4], the authors study the behavior of the scheme with respect to the oscillations due to ε. They show that the splitting scheme gives better results than the classical Crank–Nicolson one with respect to ε.

However, only Crank–Nicolson-type schemes succeed in preserving both density and energy. The aim of the present paper is to derive a convergent explicit numerical approximation of (1.1) preserving both conserved quantities.

The scheme is constructed as follows. We rewrite (1.1) as the system of two equations:

$$\left\{ \begin{array}{ll} \phi = |u|^{2\sigma}, \quad t > 0, & \text{(a)} \\ iu_t + \Delta u = \lambda \phi u, \quad t > 0, & \text{(b)} \end{array} \right. \tag{1.3}$$

with $u(x,0) = u_0(x)$.

Let T^* be the existence time of the solution and $T_{\delta t} < T^*$ the computation time. We use N points for the time discretization, thus defining a time step $\delta t = T_{\delta t}/N$. Equations (1.3a) and (1.3b) are discretized at times $t_n = n\delta t$ and $t_{n+\frac{1}{2}} = (n+\frac{1}{2})\delta t$, $n = 1, \ldots, N$, respectively. We define the variables $\phi^{n+\frac{1}{2}}$ and u^{n+1}, which represent the approximations of $|u|^{2\sigma}$ at time $t_{n+\frac{1}{2}}$ and u at time t_{n+1}, respectively. So, we get the semidiscrete-in-time relaxation scheme which reads

$$\left\{ \begin{array}{ll} \dfrac{\phi^{n+\frac{1}{2}} + \phi^{n-\frac{1}{2}}}{2} = |u^n|^{2\sigma}, & \text{(a)} \\ i\dfrac{u^{n+1} - u^n}{\delta t} + \Delta\left(\dfrac{u^{n+1} + u^n}{2}\right) = \lambda\left(\dfrac{u^{n+1} + u^n}{2}\right)\phi^{n+\frac{1}{2}}, & \text{(b)} \end{array} \right. \tag{1.4}$$

with the initial data $u^0(x) = u_0(x)$ and $\phi^{-\frac{1}{2}}(x) = |u^0(x)|^{2\sigma}$. Since only time discretization is involved, the space discretization may be of either finite difference type or finite element type.

Compared to the Crank–Nicolson scheme, which is also based in a time-centering method, this scheme allows us to avoid a costly numerical treatment of the nonlinearity and to preserve the flexibility of spatial discretization choice. On the other hand, we show its capability of conserving the density and energy. There are indications that the order of convergence may be equal to two. We compute in the last section the numerical order p_{num} for different meshes.

The main results of this article are the proof of local existence and uniqueness of a solution in $H^s(\mathbb{R}^d)$, $s > d/2 + 2$, for the scheme (1.4) and its convergence to the solution of (1.1). Moreover, we prove for the case $\sigma = 1$ that density and energy are conserved quantities.

Let us define $u_{\delta t}(t,x) = \sum_{n=0}^{N-1} u^n(x)\mathbf{I}_{[t_n, t_{n+1}[}$ and $\phi_{\delta t}(t,x) = \sum_{n=0}^{N-1} \phi^{n+\frac{1}{2}}(x)\mathbf{I}_{[t_n, t_{n+1}[}$ for $t \in [0, T_{\delta t}]$ and $x \in \mathbb{R}^d$. Then, the results are as follows in Theorem 1.1.

THEOREM 1.1. *Let u_0 belong to $H^s(\mathbb{R}^d)$, $s > d/2 + 2$, and let u be the maximal solution to (1.1) defined in $C^2([0, T^*[; H^s(\mathbb{R}^d))$. Then, there exists a unique maximal solution $(u_{\delta t}, \phi_{\delta t})$ of (1.4) in $L^\infty([0, T_{\delta t}]; (H^s(\mathbb{R}^d))^2)$ which verifies*

$$\sup_{t \in [0, T_{\delta t}]} (\|u_{\delta t}\|_{H^s} + \|\phi_{\delta t}\|_{H^s}) \leq C(T^*, \|u_0\|_{H^s}).$$

If $s > d/2 + 4$, then $\liminf_{\delta t \to 0} T_{\delta t} \geq T^*$ and $\forall T < T^*$, the solution $(u_{\delta t}, \phi_{\delta t})$ to (1.4) converges to $(u, |u|^{2\sigma})$ in $L^\infty([0,T]; (H^s(\mathbb{R}^d))^2)$ as $\delta t \to 0$.

REMARK 1. *In the previous theorem, the solution u is maximal in the sense that if $T^* < \infty$, then $\|u\|_{H^s} \to \infty$ as $t \to T^*$.*

In sections 2 and 3, we prove the local existence of a solution and the convergence of the scheme. We emphasize the main difficulties in proving the theorem and the way to solve them. The scheme is proved to be conservative in section 4. In the last

section, we compute solutions of (1.1) with the relaxation scheme and compare to other schemes and give an estimate of the order of convergence.

An abridged version of this paper as well as the application of this scheme to the Davey–Stewartson system can be found in [5].

2. Local existence and uniqueness of strong solutions. We prove in this section the following proposition.

PROPOSITION 2.1. *Let u_0 belong to $H^s(\mathbb{R}^d)$, $s > d/2+2$, and let u be the maximal solution to* (1.1) *defined in $C^2([0,T^*[;H^s(\mathbb{R}^d))$. Then, there exists a unique maximal solution $(u_{\delta t},\phi_{\delta t})$ of* (1.4) *in $L^\infty([0,T_{\delta t}];(H^s(\mathbb{R}^d))^2)$ which verifies*

$$\sup_{t\in[0,T_{\delta t}]}(\|u_{\delta t}\|_{H^s}+\|\phi_{\delta t}\|_{H^s})\leq C(T^*,\|u_0\|_{H^s}).$$

2.1. Main problems and ideas of the proof. As we stated in the introduction, the relaxation scheme first consists of changing system (1.1) into the system (1.3). Then, both equations in (1.3) are discretized on two staggered time grids.

There are many ways in which we might prove local existence of solutions. Here we detail some solutions.

1. The first idea for proving existence of solutions is to express $\phi^{n+\frac12}$ as a function of $|u^n|^2$ and to plug it into $i\frac{u^{n+1}-u^n}{\delta t}+\Delta(\frac{u^{n+1}+u^n}{2})=\lambda(\frac{u^{n+1}+u^n}{2})\phi^{n+\frac12}$. Unfortunately, the computation of the quantity $\phi^{2p+\frac12}$ for $n=2p$ gives $\phi^{2p+\frac12}=|u_0|^{2\sigma}+\sum_{k=1}^{p}2\delta t\frac{|u^{2k}|^{2\sigma}-|u^{2k-1}|^{2\sigma}}{\delta t}$ (a similar form is obtained for $n=2p+1$). Hence, the term $\phi^{\bullet+\frac12}$ is nothing but the discretization of

$$\phi(t)=|u|^{2\sigma}(0)+\int_0^t\partial_\zeta|u|^{2\sigma}(\zeta)d\zeta. \tag{2.1}$$

Contrary to the continuous evolution equation, where $\phi=|u|^2$, we have a loss of uniformity with respect to time. Hence, we cannot preserve this idea.

2. Another possibility is to consider these equations as a system in which one simultaneously studies the evolution of the two variables ϕ and u. From this, it is possible to use usual fixed point techniques in order to prove the existence and uniqueness of solutions. Thanks to (1.4.a), the discrete derivative of $\phi^{n+1/2}$ is given by $\frac{\phi^{n+\frac12}-\phi^{n-3/2}}{2\delta t}=\frac{|u^n|^{2\sigma}-|u^{n-1}|^{2\sigma}}{\delta t}$. In a sense, the control of the discrete derivative of ϕ depends on the control of the term $\frac{|u^n|^{2\sigma}-|u^{n-1}|^{2\sigma}}{\delta t}$. As $\sigma\in\mathbb{N}^*$ and with the help of (1.4b), we have $\frac{|u^n|^{2\sigma}-|u^{n-1}|^{2\sigma}}{\delta t}=\mathrm{Im}(\Delta(\frac{u^{n+1}+u^n}{2})f(u^{n+1},u^n))$, where f is a function with parameter σ. Therefore, the operator Δ causes a loss of regularity for the time derivative of u, and we have to give up this solution.

3. The two previous demonstrations lead us to control the discrete derivative of u^n. Then, the new idea is to take $v^{n+\frac12}=\frac{u^{n+1}-u^n}{\delta t}$ as a new independent variable. In the continuous framework, this last manipulation amounts to writing

$$\begin{cases}\phi_t=|u|_t^{2\sigma},\\ iu_t+\Delta u=\lambda\phi u,\end{cases} \tag{2.2}$$

and setting $v=u_t$, which is the solution to $iv_t+\Delta v=\lambda(\phi_t u+\phi v)$. Hence, the system

(2.2) reads

$$\text{(2.3)}\qquad \begin{cases} \phi_t = 2\mathrm{Re}(\overline{u}v)(\sigma(|u|^2)^{\sigma-1}) \equiv \Phi_\sigma, \\ iu_t + \Delta u = \lambda\phi u \equiv \lambda U, \\ iv_t + \Delta v = \lambda(2\mathrm{Re}(\overline{u}v)(\sigma(|u|^2)^{\sigma-1})u + \phi v) \equiv \lambda V_\sigma. \end{cases}$$

This system is semilinear and now can be treated easily by a classical fixed point procedure in usual Sobolev spaces. Nevertheless, the discrete case again is slightly more difficult. Indeed, the term $v^{n+\frac{1}{2}}$, which is the discrete equivalent of v, does not propagate through the linear part of the Crank–Nicolson scheme $i\frac{u^{n+1}-u^n}{\delta t} + \Delta(\frac{u^{n+1}+u^n}{2})$ but through $i\frac{v^{n+\frac{3}{2}}-v^{n-\frac{1}{2}}}{2\delta t} + \Delta(\frac{v^{n+\frac{3}{2}}+2v^{n+\frac{1}{2}}+v^{n-\frac{1}{2}}}{4})$, which generates two unitary groups and makes the proof more difficult to handle than in the continuous case.

2.2. Notation. We first denote by $S(t)$ the group associated to the linear Schrödinger equation $iu_t + \Delta u = 0$, $u(0,x) = u_0(x)$. Therefore, we can represent the solution of (1.1) by $u(t,x) = S(t)u_0 - i\int_0^t S(t-\zeta)\lambda|u|^{2\sigma}u(\zeta)d\zeta$.

We introduce also the various operators $A = (1 - i\delta t\frac{\Delta}{2})^{-1}(1 + i\delta t\frac{\Delta}{2})$, $B = (1 - i\delta t\frac{\Delta}{2})^{-1}$, $\Xi^k = (1+A)^{-1}(A^k - (-1)^k)$, and $\mathcal{S}_{\delta t}(t) = \sum_{n=0}^{N-1} A^n(x)\mathbf{I}_{[t_n,t_{n+1}[}$. Then, we have the following lemma.

LEMMA 2.2.

1. *A is a unitary operator on H^s $\forall s$.*
2. *B is a bounded operator on H^s and $\|B\|_s \le 1$.*
3. *$B\Xi^k$ is a bounded operator on H^s and $\|B\Xi^k\|_s \le 1$.*
4. *$\lim_{\delta t\to 0}\mathcal{S}_{\delta t}(t) = \mathcal{S}(t)$ for the strong topology of operators.*
5. *$\lim_{\delta t\to 0} B = 1$.*

Since $\sigma \in \mathbb{N}^*$, $|u^{n+1}|^{2\sigma} - |u^n|^{2\sigma} = (|u^{n+1}|^2 - |u^n|^2)f_\sigma(|u^{n+1}|^2, |u^n|^2)$, where f_σ is a C^1 function. For example, we have $f_1(a,b) \equiv 1$ and $f_2(a,b) \equiv a + b$.

We also set $v^{n+\frac{1}{2}} = \frac{u^{n+1}-u^n}{\delta t}$. Then, we derive from the scheme (1.4) the discrete equivalents of the nonlinearities U, Φ_σ, and V_σ, namely, $U^{n+\frac{1}{2}}$, $\Phi_\sigma^{n+\frac{1}{2}}$, and $V_\sigma^{n+\frac{1}{2}}$:

$$U^{n+\frac{1}{2}} = \phi^{n+\frac{1}{2}}\left(\frac{u^{n+1}+u^n}{2}\right),$$

$$\Phi_\sigma^{n+\frac{1}{2}} = 2\mathrm{Re}\left(v^{n+\frac{1}{2}}\left(\overline{\frac{u^{n+1}+u^n}{2}}\right)\right) f_\sigma(|u^{n+1}|^2, |u^n|^2),$$

$$V_\sigma^{n+\frac{1}{2}} = \left(\frac{\phi^{n+\frac{3}{2}}+\phi^{n-\frac{1}{2}}}{2}\right)\left(\frac{v^{n+\frac{3}{2}}+2v^{n+\frac{1}{2}}+v^{n-\frac{1}{2}}}{4}\right)$$
$$+ 2\mathrm{Re}\left(v^{n+\frac{1}{2}}\left(\overline{\frac{u^{n+1}+u^n}{2}}\right)\right) f_\sigma(|u^{n+1}|^2, |u^n|^2)\left(\frac{u^{n+2}+u^{n+1}+u^n+u^{n-1}}{4}\right).$$

2.3. Proof of Proposition 2.1. The proof is made up of three steps. As stressed above, we need to modify system (1.4) in order to exhibit the equation for $v^{n+\frac{1}{2}}$. The second step consists of solving this new system by a standard fixed point procedure. And, in the last step, we prove that the solution thus obtained is indeed the solution to (1.4).

Step 1: transformation of system (1.4). To begin, let us write (1.4b) at time $t^{n-\frac{3}{2}}$, $n \ge 2$.

We have $i\frac{u^{n-1}-u^{n-2}}{\delta t}+\Delta(\frac{u^{n-1}+u^{n-2}}{2})=\lambda(\frac{u^{n-1}+u^{n-2}}{2})\phi^{n-\frac{3}{2}}$. After subtraction from (1.4b) and division by $2\delta t$, we get

$$
\begin{aligned}
&i\frac{v^{n+\frac{1}{2}}-v^{n-\frac{3}{2}}}{2\delta t}+\Delta\left(\frac{v^{n+\frac{1}{2}}+2v^{n-\frac{1}{2}}+v^{n-\frac{3}{2}}}{4}\right)\\
&\quad=\lambda\left(\frac{\phi^{n+\frac{1}{2}}+\phi^{n-\frac{3}{2}}}{2}\right)\left(\frac{v^{n+\frac{1}{2}}+2v^{n-\frac{1}{2}}+v^{n-\frac{3}{2}}}{4}\right)\\
&\qquad+\lambda\left(\frac{\phi^{n+\frac{1}{2}}-\phi^{n-\frac{3}{2}}}{2\delta t}\right)\left(\frac{u^{n+1}+u^{n}+u^{n-1}+u^{n-2}}{4}\right).
\end{aligned}
$$

Moreover, from (1.4a), the term $\frac{\phi^{n+\frac{1}{2}}-\phi^{n-\frac{3}{2}}}{2\delta t}$ equals $\frac{|u^n|^{2\sigma}-|u^{n-1}|^{2\sigma}}{\delta t}$. This equality together with the definition of f_σ yields

$$
\frac{\phi^{n+\frac{1}{2}}-\phi^{n-\frac{3}{2}}}{2\delta t}=\left(\frac{|u^n|^2-|u^{n-1}|^2}{\delta t}\right)f_\sigma(|u^n|^2,|u^{n-1}|^2).
$$

On the other hand, a simple computation gives $2\mathrm{Re}(v^{n-\frac{1}{2}}(\overline{\frac{u^n+u^{n-1}}{2}}))=\frac{|u^n|^2-|u^{n-1}|^2}{\delta t}$.

Collecting all the previous information, we get the system of equations

$$
\left\{
\begin{aligned}
&\frac{\phi^{n+\frac{3}{2}}-\phi^{n-\frac{1}{2}}}{2\delta t}=\Phi_\sigma^{n+\frac{1}{2}}, && \text{(a)}\\
&i\frac{u^{n+2}-u^{n+1}}{\delta t}+\Delta\left(\frac{u^{n+2}+u^{n+1}}{2}\right)=\lambda U^{n+\frac{3}{2}}, && \text{(b)}\\
&i\frac{v^{n+\frac{3}{2}}-v^{n-\frac{1}{2}}}{2\delta t}+\Delta\left(\frac{v^{n+\frac{3}{2}}+2v^{n+\frac{1}{2}}+v^{n-\frac{1}{2}}}{4}\right)=\lambda V_\sigma^{n+\frac{1}{2}}. && \text{(c)}
\end{aligned}
\right. \tag{2.4}
$$

Step 2: existence and uniqueness of scheme (2.4). This system (2.4) is clearly the discrete equivalent of (2.3). Expressed in this way, the system is semilinear and can be solved by a fixed point procedure in the integral formulation for the vector $(\phi,\, u,\, v)^t$.

Before going any further, we have to define the initial data. We set $u^0(x)=u_0(x)$, $\phi^{-\frac{1}{2}}=\phi^{+\frac{1}{2}}=|u^0|^{2\sigma}$, $v^{-\frac{1}{2}}=\frac{u^0-u^{-1}}{\delta t}$, and $v^{\frac{1}{2}}=\frac{u^1-u^0}{\delta t}$. Also, we define the quantity u^{-1} by

$$
Au^{-1}=(A+1)u^0-u^1.
$$

The choice of u^{-1} is not arbitrary; indeed, it is the only choice that ensures that, for the initial data $v^{\frac{1}{2}}$ and $v^{-\frac{1}{2}}$ defined as above, the solution to $i\frac{v^{n+\frac{3}{2}}-v^{n-\frac{1}{2}}}{2\delta t}+\Delta\frac{v^{n+\frac{3}{2}}+2v^{n+\frac{1}{2}}+v^{n-\frac{1}{2}}}{4}=f^{n+\frac{1}{2}}$ is bounded in $l^\infty(0,N;H^s)$ as soon as $(f^{n+\frac{1}{2}})_n$ is bounded in $l^1(0,N;H^s)$. Obviously, the definitions of $v^{\frac{1}{2}}$ and $v^{-\frac{1}{2}}$ involve the term u^1. However, since $u^1=Au^0-i\delta t\lambda B(\frac{u^1+u^0}{2})\phi^{\frac{1}{2}}$, u^1 exists in $H^s(\mathbb{R}^d)$ (at least for small δt) and is unique.

Now, we transform system (2.4) in order to obtain Duhamel's formula. First, (2.4b) becomes $u^{n+2}=Au^{n+1}-i\lambda\delta tBU^{n+\frac{3}{2}}$, which leads immediately to $u^{n+2}=A^{n+2}u^0-i\lambda\sum_{k=0}^{n+1}\delta tBA^{n+1-k}U^{k+\frac{1}{2}}$. We apply the same transformation to (2.4a). However, for $n=0$, it leads to $\phi^{\frac{3}{2}}=|u_0|^{2\sigma}+2\delta t\Phi^{\frac{1}{2}}$, and for $n=1$, we have

$\phi^{\frac{5}{2}} = |u_0|^{2\sigma} + 2\delta t \Phi^{\frac{3}{2}}$. Therefore, the equation for ϕ will be different according to the evenness of n. Indeed, for $n \geq 0$, we find

$$\begin{aligned}\phi^{n+\frac{3}{2}} &= |u_0|^{2\sigma} + \sum_{k=1}^{[n/2]} 2\delta t \Phi_\sigma^{2k-\frac{1}{2}} \text{ if } n \text{ is odd},\\ \phi^{n+\frac{3}{2}} &= |u_0|^{2\sigma} + \sum_{k=0}^{n/2} 2\delta t \Phi_\sigma^{2k+\frac{1}{2}} \text{ if } n \text{ is even}.\end{aligned}$$

Then, the last component, $v^{n+\frac{3}{2}}$, is governed by

$$v^{n+\frac{3}{2}} - (A-1)v^{n+\frac{1}{2}} - Av^{n-\frac{1}{2}} = -2i\lambda\delta t B V^{n+\frac{1}{2}}.$$

Using the roots of the characteristic equation $r^2 - (A-1)r - A = 0$, the component $v^{n+\frac{3}{2}}$ is

$$\begin{aligned}v^{n+\frac{3}{2}} &= (A+1)^{-1}\Big\{(A^{n+2} - (-1)^{n+2})v^{\frac{1}{2}} + A(A^{n+1} - (-1)^{n+1})v^{-\frac{1}{2}}\\ &\qquad - i\lambda \sum_{k=1}^{n+1} 2\delta t B (A^{n+2-k} - (-1)^{n+2-k}) V_\sigma^{k-\frac{1}{2}}\Big\}\\ &= \Xi^{n+1}(\Xi v^{\frac{1}{2}} + Av^{-\frac{1}{2}}) - i\lambda \sum_{k=0}^{n} 2\delta t\, B\, \Xi^{n+1-k}\, V_\sigma^{k+\frac{1}{2}}.\end{aligned}$$

Collecting all of the above calculations, the system (2.4) reads for $n \geq 0$ as follows:

$$\text{(2.5)}\qquad \begin{cases} \phi^{n+\frac{3}{2}} = \begin{cases} |u_0|^{2\sigma} + \displaystyle\sum_{k=1}^{[n/2]} 2\delta t \Phi_\sigma^{2k-\frac{1}{2}} \text{ if } n \text{ is odd},\\ |u_0|^{2\sigma} + \displaystyle\sum_{k=0}^{n/2} 2\delta t \Phi_\sigma^{2k+\frac{1}{2}} \text{ if } n \text{ is even}, \end{cases}\\ u^{n+2} = A^{n+2}u_0 - i\lambda \displaystyle\sum_{k=0}^{n+1} \delta t\, B\, A^{n+1-k}\, U^{k+\frac{1}{2}},\\ v^{n+\frac{3}{2}} = \Xi^{n+1}(\Xi v^{\frac{1}{2}} + Av^{-\frac{1}{2}}) - i\lambda \displaystyle\sum_{k=0}^{n} 2\delta t\, B\, \Xi^{n+1-k}\, V_\sigma^{k+\frac{1}{2}}. \end{cases}$$

Let us define the sequences

$$\begin{aligned}\mathbf{U}^N &= (u^2, \ldots, u^{N+1}),\\ \Phi^N &= (\phi^{\frac{3}{2}}, \ldots, \phi^{N+\frac{1}{2}}),\\ \mathbf{V}^N &= (v^{\frac{3}{2}}, \ldots, v^{N+\frac{1}{2}}),\\ \widetilde{\mathbf{U}}^N &= (\tilde{u}^2, \ldots, \tilde{u}^{N+1}),\\ \widetilde{\Phi}^N &= (\tilde{\phi}^{\frac{3}{2}}, \ldots, \tilde{\phi}^{N+\frac{1}{2}}),\\ \widetilde{\mathbf{V}}^N &= (\tilde{v}^{\frac{3}{2}}, \ldots, \tilde{v}^{N+\frac{1}{2}}),\end{aligned}$$

and the space $X_N = l^\infty(0, N; H^s(\mathbb{R}^d))$ endowed with the usual norm $\|.\|_{X_N} = \sup_{n\in[0,N]} \|(.)_n\|_s$, where $\|\cdot\|_s$ indicates the norm of $H^s(\mathbb{R}^d)$.

The proof of existence and uniqueness for the previous system consists of showing the existence of a unique fixed point for the map $\mathcal{T}$ defined by

$$\begin{array}{ccc} X_N^3 & \stackrel{\mathcal{T}}{\longrightarrow} & X_N^3, \\ (\widetilde{\mathbf{U}}^N, \widetilde{\Phi}^N, \widetilde{\mathbf{V}}^N) & \longmapsto & (\mathbf{U}^N, \Phi^N, \mathbf{V}^N), \end{array}$$

where, for $n \in [0, N-1]$,

$$\phi^{n+\frac{3}{2}} = \left| \begin{array}{l} |u_0|^{2\sigma} + \displaystyle\sum_{k=1}^{[n/2]} 2\delta t 2\mathrm{Re}\left(\tilde{v}^{2k-\frac{1}{2}} \left(\overline{\frac{\tilde{u}^{2k} + \tilde{u}^{2k-1}}{2}} \right) \right) f_\sigma(|\tilde{u}^{2k}|^2, |\tilde{u}^{2k-1}|^2) \text{ if } n \text{ is odd}, \\ |u_0|^\sigma 2 + \displaystyle\sum_{k=0}^{n/2} 2\delta t 2\mathrm{Re}\left(\tilde{v}^{2k+\frac{1}{2}} \left(\overline{\frac{\tilde{u}^{2k+1} + \tilde{u}^{2k}}{2}} \right) \right) f_\sigma(|\tilde{u}^{2k+1}|^2, |\tilde{u}^{2k}|^2) \text{ if } n \text{ is even}, \end{array} \right.$$

$$u^{n+2} = A^{n+2} u_0 - i\lambda \sum_{k=0}^{n+1} \delta t\, B\, A^{n+1-k} \left(\tilde{\phi}^{k+\frac{1}{2}} \left(\overline{\frac{\tilde{u}^{k+1} + \tilde{u}^k}{2}} \right) \right),$$

$$v^{n+\frac{3}{2}} = \Xi^{n+1} \left(\Xi v^{\frac{1}{2}} + A v^{-\frac{1}{2}} \right)$$

$$-i\lambda \sum_{k=0}^{n} 2\delta t B\, \Xi^{n+1-k} \left(\begin{array}{l} \left(\frac{\tilde{\phi}^{k+\frac{3}{2}} + \tilde{\phi}^{k-\frac{1}{2}}}{2} \right) \left(\frac{\tilde{v}^{k+\frac{3}{2}} + 2\tilde{v}^{k+\frac{1}{2}} + \tilde{v}^{k-\frac{1}{2}}}{4} \right) \\ + 2\mathrm{Re}\left[\tilde{v}^{k+\frac{1}{2}} \left(\frac{\tilde{u}^{k+1} + \tilde{u}^k}{2} \right) \right] f_\sigma(|\tilde{u}^{2k+1}|^2, |\tilde{u}^{2k}|^2) \left(\frac{\tilde{u}^{k+2} + \tilde{u}^{k+1} + \tilde{u}^k + \tilde{u}^{k-1}}{4} \right) \end{array} \right).$$

So that all terms are well defined, we set $\tilde{u}^{-1} = u^{-1}$, $\tilde{u}^0 = u^0$, $\tilde{u}^1 = u^1$, $\tilde{\phi}^{-\frac{1}{2}} = \tilde{\phi}^{\frac{1}{2}} = |u^0|^{2\sigma}$, $\tilde{v}^{-\frac{1}{2}} = v^{-\frac{1}{2}}$, and $\tilde{v}^{\frac{1}{2}} = v^{\frac{1}{2}}$.

Let us define B_R, the ball of X_N^3 centered on 0 with radius R endowed with the usual norm on X_N^3, by

$$B_R = \{(\mathbf{U}^N, \Phi^N, \mathbf{V}^N) \in X_N^3 / \|\mathbf{U}^N\|_{X_N} + \|\Phi^N\|_{X_N} + \|\mathbf{V}^N\|_{X_N} \leq R\}.$$

Then, we show that the application $\mathcal{T}$ sends B_R into B_R with some a priori estimates. Let us make the assumption that $\widetilde{\Phi}^N$, $\widetilde{\mathbf{U}}^N$, and $\widetilde{\mathbf{V}}^N$ belong to X_N.

In the continuous case of nonlinear Schrödinger equation (1.1), $f_\sigma = \sigma(|u|^2)^{\sigma-1}$. In our discrete case, f_σ does not involve the more powerful power of $|u|^2$. As we choose the Sobolev space $H^s(\mathbb{R}^d)$ for $s > d/2 + 2$ and $\sigma \in \mathbb{N}^*$, f_σ belongs to H^s if $u \in H^s$.

Estimate on Φ^N: $\forall n$, $\|\phi^{n+3/2}\|_s \leq \|u^0\|_s^{2\sigma} + c_1 T_{\delta t} \|\widetilde{\mathbf{U}}^N\|_{X_N}^{2\sigma-1} \|\widetilde{\mathbf{V}}^N\|_{X_N}$, with c_1 independent of n and δt.

Estimate on $\mathbf{U}^N$: Lemma 2.2 leads to $\|u^n\|_s \leq \|u^0\|_s + c_2 T_{\delta t} \|\widetilde{\Phi}^N\|_{X_N} \|\widetilde{\mathbf{U}}^N\|_{X_N}$, with c_2 independent of n and δt.

Estimate on $\mathbf{V}^N$: the term $\Xi^{n+1}(\Xi v^{\frac{1}{2}} + A v^{-\frac{1}{2}})$ is not a priori bounded. However, thanks to the definition of u^{-1}, $\Xi^{n+1}(\Xi v^{\frac{1}{2}} + A v^{-\frac{1}{2}}) = A^{n+2} v^{-\frac{1}{2}}$. This term is therefore bounded. Lemma 2.2 yields

$$\|v^{n+\frac{1}{2}}\|_s \leq \|v^{-\frac{1}{2}}\|_s + c_3 T_{\delta t} \left(\|\widetilde{\Phi}^N\|_{X_N} \|\widetilde{\Phi}^N\|_{X_N} + \|\widetilde{\mathbf{V}}^N\|_{X_N} \|\widetilde{\mathbf{U}}^N\|_{X_N}^{2\sigma-1} \right),$$

with c_3 independent of n and δt.

Collecting these three estimates, we finally have

$$\|\mathbf{U}^N\|_{X_N} + \|\Phi^N\|_{X_N} + \|\mathbf{V}^N\|_{X_N} \leq (\|u^0\|_s + \|u^0\|_s^{2\sigma} + \|v^{-\frac{1}{2}}\|_s) + c_4(R)T_{\delta t}.$$

Now, we define R by $\|u^0\|_s + \|u^0\|_s^{2\sigma} + \|v^{-\frac{1}{2}}\|_s = \frac{R}{2}$ and define $T_{\delta t}$ such that $c_6(R)T_{\delta t} \leq \frac{R}{2}$ to ensure that $\mathcal{T}$ maps B_R into itself.

By similar arguments, it is easy to show that $\mathcal{T}$ is a contraction in B_R if $T_{\delta t}$ is small enough. Therefore, $\mathcal{T}$ has a unique fixed point. This last argument shows the existence and uniqueness of the solution to (2.4).

Step 3: equivalence between systems (2.4) and (1.4). Let $(u^{n+1}, v^{n+\frac{1}{2}}, \phi^{n+\frac{1}{2}})$ be the solution of system (2.4). We already know that the couple $(u^{n+1}, \phi^{n+\frac{1}{2}})$ solves (2.4b) at time $t^{n+\frac{1}{2}}$. We have to show that $v^{n+\frac{1}{2}} = \frac{u^{n+1}-u^n}{\delta t}$ and $\frac{\phi^{n+\frac{1}{2}}+\phi^{n-\frac{1}{2}}}{2} = |u^n|^{2\sigma}$. If we rewrite (2.4b) at time $t^{n-\frac{3}{2}}$, we have $i\frac{u^{n-1}-u^{n-2}}{\delta t} + \Delta(\frac{u^{n-1}+u^{n-2}}{2}) = \lambda(\frac{u^{n-1}+u^{n-2}}{2})\phi^{n-\frac{3}{2}}$. We subtract this last equality from (2.4b) at time $t^{n+\frac{1}{2}}$ and divide the result by $2\delta t$. Then, we have

$$\begin{aligned} i\frac{\frac{u^{n+1}-u^n}{\delta t} - \frac{u^{n-1}-u^{n-2}}{\delta t}}{2\delta t} + \Delta\left(\frac{\frac{u^{n+1}-u^n}{\delta t} + 2\frac{u^n-u^{n-1}}{\delta t} + \frac{u^{n-1}-u^{n-2}}{\delta t}}{4}\right) \\ = \lambda\left(\frac{\phi^{n+\frac{1}{2}} - \phi^{n-\frac{3}{2}}}{2\delta t}\right)\left(\frac{u^{n+1}+u^n+u^{n-1}+u^{n-2}}{4}\right) \\ + \lambda\left(\frac{\phi^{n+\frac{1}{2}} + \phi^{n-\frac{3}{2}}}{2}\right)\left(\frac{\frac{u^{n+1}-u^n}{\delta t} + 2\frac{u^n-u^{n-1}}{\delta t} + \frac{u^{n-1}-u^{n-2}}{\delta t}}{4}\right). \end{aligned}$$

This identity is a discrete equivalent of the continuous equation $iu_{tt} + \Delta u_t = \lambda\phi_t u + \lambda\phi u_t$. We know that $\frac{\phi^{n+\frac{1}{2}}-\phi^{n-\frac{3}{2}}}{2\delta t} = 2\mathrm{Re}(v^{n-\frac{1}{2}}(\overline{\frac{u^n+u^{n-1}}{2}}))f_\sigma(|u^n|^2, |u^{n-1}|^2)$. Finally, we get

$$\begin{aligned} i\frac{\frac{u^{n+1}-u^n}{\delta t} - \frac{u^{n-1}-u^{n-2}}{\delta t}}{2\delta t} + \Delta\left(\frac{\frac{u^{n+1}-u^n}{\delta t} + 2\frac{u^n-u^{n-1}}{\delta t} + \frac{u^{n-1}-u^{n-2}}{\delta t}}{4}\right) \\ = \lambda 2\mathrm{Re}\left(v^{n-\frac{1}{2}}\left(\overline{\frac{u^n+u^{n-1}}{2}}\right)\right) f_\sigma(|u^n|^2, |u^{n-1}|^2)\left(\frac{u^{n+1}+u^n+u^{n-1}+u^{n-2}}{4}\right) \\ + \lambda\left(\frac{\phi^{n+\frac{1}{2}} + \phi^{n-\frac{3}{2}}}{2}\right)\left(\frac{\frac{u^{n+1}-u^n}{\delta t} + 2\frac{u^n-u^{n-1}}{\delta t} + \frac{u^{n-1}-u^{n-2}}{\delta t}}{4}\right). \end{aligned}$$

As before, the continuous case reads $iu_{tt} + \Delta u_t = \lambda 2\mathrm{Re}(v\overline{u})u + \lambda\phi u_t$. We set $w^{n+\frac{1}{2}} = v^{n+\frac{1}{2}} - (\frac{u^{n+1}-u^n}{\delta t})$. Then, the subtraction of this last equation from (2.4c) taken at time $t^{n-\frac{1}{2}}$ leads to

$$\begin{aligned} i\frac{w^{n+\frac{1}{2}} - w^{n-\frac{3}{2}}}{2\delta t} + \Delta\left(\frac{w^{n+\frac{1}{2}} + 2w^{n-\frac{1}{2}} + w^{n-\frac{3}{2}}}{4}\right) \\ = \lambda\left(\frac{\phi^{n+\frac{1}{2}} + \phi^{n-\frac{1}{2}}}{2}\right)\left(\frac{w^{n+\frac{1}{2}} + 2w^{n-\frac{1}{2}} + w^{n-\frac{3}{2}}}{4}\right), \end{aligned}$$

with initial data $w^{\frac{1}{2}} = w^{-\frac{1}{2}} = 0$. This is a linear Schrödinger equation with regular potential. So, the only solution is zero. Thus, we have $v^{n+\frac{1}{2}} = \frac{u^{n+1}-u^n}{\delta t}$. Thanks to this equality, we get $\frac{\phi^{k+\frac{1}{2}}-\phi^{k-\frac{3}{2}}}{2\delta t} = \frac{|u^n|^2-|u^{n-1}|^2}{\delta t}$. Summing this last relation for $k \in [0,n]$ yields $\frac{\phi^{n+\frac{1}{2}}+\phi^{n-\frac{1}{2}}}{2} = |u^n|^2$.

The systems (1.4) and (2.4) are equivalent, thus proving Proposition 2.1.

3. Convergence of the relaxation scheme for strong solutions. The result of this section reads as follows.

PROPOSITION 3.1. *Let u be the maximal solution to equation* (1.1) *defined in* $C^2([0,T^*[;H^s(\mathbb{R}^d))$, $s > d/2+4$. *Then, if* $T_{\delta t} = N\delta t$, $\liminf_{\delta t\to 0} T_{\delta t} \geq T^*$ *and* $\forall T < T^*$ *the solution* $(u_{\delta t}, \phi_{\delta t})$ *to* (1.4) *given by Proposition* (2.1) *converges to* $(u, |u|^{2\sigma})$ *in* $L^\infty([0,T];(H^s(\mathbb{R}^d))^2)$ *as* $\delta t \to 0$.

3.1. Ideas and difficulties of the proof. The proof of convergence is done comparing the integral formulation of solutions $(u_{\delta t}, \phi_{\delta t})$ and $(u, |u|^{2\sigma})$. However, for the same reasons as those developed for the proof of Proposition (2.1), we cannot directly show the result of convergence on system (1.4). A priori, we have to work on system (2.4). Since we wish to compare integral formulations of the solutions, we particularly focus on system (2.5).

Duhamel's formula of system (2.3) is given for $x \in \mathbb{R}^d$ and $t > 0$ by

$$\left\{\begin{array}{ll} \phi(x,t) = |u_0(x)|^{2\sigma} + \displaystyle\int_0^t \Phi_\sigma(x,\zeta)d\zeta, & \text{(a)} \\ u(x,t) = S(t)u_0(x) - i\lambda \displaystyle\int_0^t S(t-\zeta)U(x,\zeta)d\zeta, & \text{(b)} \\ v(x,t) = S(t)v(x,t=0) - i\lambda \displaystyle\int_0^t S(t-\zeta)V_\sigma(x,\zeta)d\zeta. & \text{(c)} \end{array}\right. \tag{3.1}$$

Thanks to the consistency of $BA^{n+1-k}U^{k+\frac{1}{2}}$ and $S(t-\zeta)U(x,\zeta)$ (respectively, $\Phi_\sigma^{2k+\frac{1}{2}}$ and Φ_σ), it is quite easy to show convergence of u^{n+2} to $u(x,t)$ (respectively, $\phi^{n+\frac{3}{2}}$ and $\phi(x,t)$).

Therefore, the only difficulty arises from the comparison between $v^{n+\frac{3}{2}}$ and $v(x,t)$. Thanks to the definition of u^{-1}, we have already seen that $\Xi^{n+1}(\Xi v^{\frac{1}{2}} + Av^{-\frac{1}{2}}) = A^{n+2}v^{-\frac{1}{2}}$. Thus, the contribution of the initial datum is easily handled. However, the second part of Duhamel's formula involves the bounded operator $B\Xi^{n+1-k}$ which generates two semigroups according to the evenness of $n+1-k$. Actually,

$$\lim_{\delta t\to 0} \left(B\Xi^{n+1-k}\right)_{n+1-k=2p} = \frac{\exp\left(i\Delta t_{n+1-k}/2\right)-1}{2},$$
$$\lim_{\delta t\to 0} \left(B\Xi^{n+1-k}\right)_{n+1-k=2p+1} = \frac{\exp\left(i\Delta t_{n+1-k}/2\right)+1}{2}.$$

Separately, these two semigroups are different from S. As a consequence, with the current forms of $v^{n+\frac{3}{2}}$ and $v(x,t)$, we cannot prove the convergence.

3.2. Proof of Proposition 3.1. Actually, we have to find another form for the term $\sum_{k=0}^n B\Xi^{n+1-k}V^{k+\frac{1}{2}}$. First, we remark that $\Xi^k = \sum_{l=1}^k (-1)^{l-1}A^{k-l}$. This leads us to write

$$\sum_{k=0}^n 2\delta t B\Xi^{n+1-k}V^{k+\frac{1}{2}} = \sum_{k=0}^n 2\delta t B \sum_{l=1}^{n+1-k} (-1)^{l-1}A^{n+1-k-l}V^{k+\frac{1}{2}}.$$

Finally, by rearranging the previous sums, we get

$$\sum_{k=0}^{n} B\Xi^{n+1-k}V^{k+\frac{1}{2}} = \begin{cases} \displaystyle\sum_{l=0}^{p-1} 2\delta t BA^{2l+1}\left(\sum_{j=0}^{p-l-1}\delta t\frac{V^{2j+\frac{3}{2}}-V^{2j+\frac{1}{2}}}{\delta t}\right) \\ \quad \displaystyle+\sum_{l=0}^{p} 2\delta t BA^{2l}\left(V^{\frac{1}{2}}+\sum_{j=0}^{p-l-1}\delta t\frac{V^{2j+\frac{5}{2}}-V^{2j+\frac{3}{2}}}{\delta t}\right) & \text{if } n=2p, \\ \displaystyle\sum_{l=0}^{p} 2\delta t BA^{2l+1}\left(V^{\frac{1}{2}}+\sum_{j=0}^{p-l-1}\delta t\frac{V^{2j+\frac{5}{2}}-V^{2l+\frac{3}{2}}}{\delta t}\right) \\ \quad \displaystyle+\sum_{l=0}^{p} 2\delta t BA^{2l}\left(\sum_{j=0}^{p-l}\delta t\frac{V^{2j+\frac{3}{2}}-V^{2j+\frac{1}{2}}}{\delta t}\right) & \text{if } n=2p+1. \end{cases}$$

Once more, we observe discrete forms of the time derivative. The continuous equation for $v(x,t)$ may therefore be interpreted as

$$v(x,t) = S(t)v(x,t=0) - i\lambda\int_0^t S(t-s)\int_0^s \partial_\tau V(x,\tau)d\tau ds. \tag{3.2}$$

Unfortunately, $\partial_\tau V$ involves a time derivative of v (denoted by w) and ϕ (denoted by ψ) simultaneously. Therefore, we have to find a discrete system which is equivalent to (1.4) and allows us to control the time derivatives of $v^{n+\frac{3}{2}}$ (defined by $w^{n+1} = \frac{v^{n+\frac{3}{2}}-v^{n+\frac{1}{2}}}{\delta t}$) and $\phi^{n+\frac{3}{2}}$ (defined by $\psi^{n+1} = \frac{\phi^{n+\frac{3}{2}}-\phi^{n+\frac{1}{2}}}{\delta t}$) in order to compare the new formulations of $v^{n+\frac{3}{2}}$ and $v(x,t)$. This new system is proved to be well posed, and Duhamel's formulations for ψ^{n+1} and w^{n+1} read, respectively,

$$\begin{aligned} \psi^n &= \psi^{-1} + \sum_{k=0}^{p} 2\delta t\Psi^{2k}, \quad n=2p+1, \\ \psi^n &= \psi^0 + \sum_{k=1}^{p} 2\delta t\Psi^{2k-1}, \quad n=2p, \end{aligned}$$

and with the convention $D=(1-i\delta t\Delta)^{-1}(1+i\delta t\Delta)$ and $E=(1-i\delta t\Delta)^{-1}$,

$$\begin{aligned} w^n &= D^p w^1 - i\lambda\sum_{k=0}^{p-1} 2\delta t E D^{p-k-1}W^{2(k+1)}, \quad n=2p+1, \\ w^n &= D^p w^0 - i\lambda\sum_{k=0}^{p-1} 2\delta t E D^{p-k-1}W^{2k+1}, \quad n=2p. \end{aligned}$$

The terms Ψ and W denote the nonlinearities involved in Duhamel's formula (see the appendix for the proof and a complete set of notation).

As before, the formulations are different according to the parity of n. However, the proof of convergence is not really influenced by the choice of n. So from now on,

we choose n to be odd. We define for $t \in [t_n, t_{n+1}[$ and $x \in \mathbb{R}^d$

$$\begin{array}{ll} u_{\delta t}(x,t) = u^n(x), & U_{\delta t}(x,t) = U^{n+\frac{1}{2}}(x), \\ \phi_{\delta t}(x,t) = \phi^{n+\frac{1}{2}}(x), & \Phi_{\delta t}(x,t) = \Phi^{n+\frac{1}{2}}(x), \\ v_{\delta t}(x,t) = v^{n+\frac{1}{2}}(x), & V_{\delta t}(x,t) = V^{n+\frac{1}{2}}(x), \\ \psi_{\delta t}(x,t) = \psi^n(x), & \Psi_{\delta t}(x,t) = \Psi^n(x), \\ w_{\delta t}(x,t) = w^n(x), & W_{\delta t}(x,t) = W^n(x). \end{array}$$

Taking $u \in C^2(0,T;H^s(\mathbb{R}^d))$ with $s > d/2+4$, ϕ, $v = u_t$, $\psi = \phi_t$, and $w = u_{tt}$ always belong to $H^s(\mathbb{R}^d)$, and we define the applications $\mathcal{U}_{\delta t}$ and $\mathcal{U}$ as follows:

$$\begin{array}{ccc} (H^s(\mathbb{R}^d))^5 & \xrightarrow{\mathcal{U}_{\delta t}} & (L^\infty(0,T;H^s(\mathbb{R}^d))^5, \\ (u_{\delta t}, \phi_{\delta t}, v_{\delta t}, \psi_{\delta t}, w_{\delta t})(0) & \longmapsto & (u_{\delta t}, \phi_{\delta t}, v_{\delta t}, \psi_{\delta t}, w_{\delta t})(t), \end{array}$$

$$\begin{array}{ccc} (H^s(\mathbb{R}^d))^5 & \xrightarrow{\mathcal{U}} & (L^\infty(0,T;H^s(\mathbb{R}^d))^5, \\ (u, \phi, u_t, \phi_t, u_{tt})(0) & \longmapsto & (u, \phi, u_t, \phi_t, u_{tt})(t). \end{array}$$

In the same way, let us define $\mathcal{F}_{\delta t}$ and $\mathcal{F}$ as the two applications

$$\begin{array}{ccc} (L^\infty(0,T;H^s(\mathbb{R}^d))^5 & \xrightarrow{\mathcal{F}_{\delta t}} & (L^\infty(0,T;H^s(\mathbb{R}^d))^5, \\ (u_{\delta t}, \phi_{\delta t}, v_{\delta t}, \psi_{\delta t}, w_{\delta t}) & \longmapsto & (U_{\delta t}, -i\Phi_{\delta t}, V_{\delta t}, -i\Psi_{\delta t}, W_{\delta t}), \end{array}$$

and

$$\begin{array}{ccc} (L^\infty(0,T;H^s(\mathbb{R}^d))^5, & \xrightarrow{\mathcal{F}} & (L^\infty(0,T;H^s(\mathbb{R}^d))^5, \\ (u, \phi, v, \psi, w) & \longmapsto & (U, -i\Phi, V, -i\Psi, W). \end{array}$$

Finally, we set the operators $\mathcal{B} = (B, I, B, I, E)$, $\mathcal{S}(t) = (S(t), 1, S(t), 1, S(t))$, and for $t \in [t_n, t_{n+1}[$, $\mathcal{S}_{\delta t}(t) = (A^n, 1, A^n, 1, D^{\lfloor n/2 \rfloor})$.

We proceed as in [8] for the proof of convergence. We have to evaluate $\|\mathcal{U}(t) - \mathcal{U}_{\delta t}(t)\|_{(H^s)^5}$ for $t = t_{n+1}$ (we do not replace t by t_{n+1}, in order to simplify the notation). This leads to

(3.3)

$$\begin{aligned} &\left\| \mathcal{S}(t)\mathcal{U}(0) - \mathcal{S}_{\delta t}(t)\mathcal{U}_{\delta t}(0) - i\int_0^t (\mathcal{S}(t-\tau)\mathcal{F}(\mathcal{U})(\tau) - \mathcal{B}\mathcal{S}_{\delta t}(t-\tau)\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\tau))d\tau \right\|_{(H^s)^5} \\ &\quad \le \|(\mathcal{S}(t) - \mathcal{S}_{\delta t}(t))\mathcal{U}(0)\|_{(H^s)^5} + \|\mathcal{S}_{\delta t}(t)(\mathcal{U}(0) - \mathcal{U}_{\delta t}(0))\|_{(H^s)^5} \\ &\qquad + \sum_{k=0}^n \left\| \int_{t_k}^{t_{k+1}} \mathcal{B}\mathcal{S}_{\delta t}(t-t_k)\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\kappa\delta t) - \mathcal{S}(t-\tau)\mathcal{F}(\mathcal{U})(\tau)d\tau \right\|_{(H^s)^5}. \end{aligned}$$

We introduce the variable $\kappa\delta t$ in this inequality in order to insist on the fact that the term $\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\kappa\delta t)$ does not depend on the variable τ. For example, the first component of $\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\kappa\delta t)$ is

$$\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\kappa\delta t) = \phi_{\delta t}(t_{k+\frac{1}{2}}) \left(\frac{u_{\delta t}(t_{k+1}) + u_{\delta t}(t_k)}{2} \right).$$

In order to control the third term in the right-hand side of (3.3), we write each integral as

$$\begin{aligned}\left\|\int_{t_k}^{t_{k+1}} (\mathcal{B}\mathcal{S}_{\delta t}(t-t_k)\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\kappa\delta t) - \mathcal{S}(t-\tau)\mathcal{F}(\mathcal{U})(\tau))d\tau\right\|_{(H^s)^5} \\ \leq \left\|\int_{t_k}^{t_{k+1}} [\mathcal{B}\mathcal{S}_{\delta t}(t-t_k) - \mathcal{S}(t-t_k)]\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\kappa\delta t)d\tau\right\|_{(H^s)^5} \\ + \left\|\int_{t_k}^{t_{k+1}} [\mathcal{S}(t-\tau) - \mathcal{S}(t-t_k)]\mathcal{F}(\mathcal{U})(\tau)d\tau\right\|_{(H^s)^5} \\ + \left\|\int_{t_k}^{t_{k+1}} \mathcal{S}(t-t_k)[\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\kappa\delta t) - \mathcal{F}(\mathcal{U})(\tau)]d\tau\right\|_{(H^s)^5} \\ \equiv I_1^{k,n} + I_2^{k,n} + I_3^{k,n}.\end{aligned}$$

Let $T_1 = N\delta t$. Then, the inequality (3.3) means

$$\begin{aligned}\|\mathcal{U} - \mathcal{U}_{\delta t}\|_{L^\infty([0,T_1],H^s)^5} \leq \|(\mathcal{S} - \mathcal{S}_{\delta t})\mathcal{U}(0)\|_{L^\infty([0,T_1],H^s)^5} \\ + \|\mathcal{S}_{\delta t}(\mathcal{U}(0) - \mathcal{U}_{\delta t}(0))\|_{L^\infty([0,T_1],H^s)^5} \\ + \sup_{n\in[0,N]} \sum_{k=0}^{n} (I_1^{k,n} + I_2^{k,n} + I_3^{k,n}).\end{aligned} \tag{3.4}$$

Thanks to Lemma 2.2, $\mathcal{S}_{\delta t} \longrightarrow \mathcal{S}$ for the strong topology of operators in $(H^s)^5$, and $\mathcal{B} \longrightarrow 1$ in $(H^s)^5$, we have

$$\begin{aligned}\|(\mathcal{S} - \mathcal{S}_{\delta t})\mathcal{U}(0)\|_{L^\infty([0,T_1],H^s)^5} \to 0 \quad \text{as } \delta t \to 0, \\ \sup_{n\in[0,N]} \sum_{k=0}^{n} I_1^{k,n} \to 0 \quad \text{as } \delta t \to 0, \\ \sup_{n\in[0,N]} \sum_{k=0}^{n} I_2^{k,n} \to 0 \quad \text{as } \delta t \to 0.\end{aligned}$$

Since $u \in C^2(0,T;H^s)$, we also have

$$\|\mathcal{S}_{\delta t}(\mathcal{U}(0) - \mathcal{U}_{\delta t}(0))\|_{L^\infty([0,T_1],H^s)^5} \to 0 \quad \text{as } \delta t \to 0.$$

It remains to deal with the term $I_3^{k,n}$. For this, we write, as in [8], $\mathcal{F}(\mathcal{U})(\tau) = \mathcal{F}_{\delta t}(\mathcal{U})(\kappa\delta t) + R_\kappa(\tau)$. Thus,

$$\begin{aligned}I_3^{k,n} \leq \int_{t_k}^{t_{k+1}} \|\mathcal{F}_{\delta t}(\mathcal{U}_{\delta t})(\kappa\delta t) - \mathcal{F}_{\delta t}(\mathcal{U})(\kappa\delta t)\|_{(H^s)^5} + \delta t \sup_{\tau\in[t_k,t_{k+1}]} \|R_\kappa(\tau)\|_{(H^s)^5} \\ \equiv J_k + \delta t G_k(\delta t).\end{aligned}$$

Since $u \in C^2(0,T;H^s)$, we have $\sum_{k=0}^{N} \delta t G_k(\delta t) \to 0$ as $\delta t \to 0$. Thanks to the form of $\mathcal{F}_{\delta t}$, we get

$$J_k \leq \int_{t_k}^{t_{k+1}} C_1 f(\|\mathcal{U}(\kappa\delta t)\|_{(H^s)^5}, \|\mathcal{U}_{\delta t}(\kappa\delta t)\|_{(H^s)^5}) \|\mathcal{U}(\kappa\delta t) - \mathcal{U}_{\delta t}(\kappa\delta t)\|_{(H^s)^5} d\tau,$$

where f is a C^∞ function and C_1 is a constant which is independent of n and δt. Now, referring to uniform estimates of $\mathcal{U}$ and $\mathcal{U}_{\delta t}$ in $[0,T_1]$, we have $J_k \leq$

$C_2\delta t\,\|\mathcal{U}-\mathcal{U}_{\delta t}\|_{L^\infty([0,T_1],H^s)^5}$, with C_2 a constant independent of n and δt. Finally, the inequality (3.4) leads to

$$\|\mathcal{U}-\mathcal{U}_{\delta t}\|_{L^\infty([0,T_1],H^s)^5} \le o(1) + CT_1\,\|\mathcal{U}-\mathcal{U}_{\delta t}\|_{L^\infty([0,T_1],H^s)^5}.$$

Taking $CT_1 < 1$, we get

$$\|\mathcal{U}-\mathcal{U}_{\delta t}\|_{L^\infty([0,T_1],H^s)^5} \le o(1).$$

Applying once more the proof with the initial datum $\mathcal{U}(T_1)$, we get the lower semi-continuity of the existence time $T_{\delta t}$ as $\delta t \to 0$ and the convergence on $[0,T]$ $\forall T < T^*$.

Hence, we have proved Theorem 1.1.

4. Conservation laws. As we recalled in the introduction, (1.1) has two conserved quantities which are the density defined by $\int_{\mathbb{R}^d}|u|^2dx$ and the energy $\int_{\mathbb{R}^d}\frac{1}{2}|\nabla u|^2+\frac{\lambda}{2\sigma+2}|u|^{2\sigma+2}dx$. The minimum requirement for the numerical scheme is to conserve these two quantities. For example, for $\sigma=1$, the Crank–Nicolson scheme (see [9]) has this property, contrary to the split-step scheme (see [15]) which conserves only the density. We show in this section that the relaxation scheme conserves the two quantities, but only for $\sigma=1$.

PROPOSITION 4.1. *Let $(u^n)_n$ and $(\phi^{n-\frac{1}{2}})_n$ be solutions of (1.4) with $\sigma=1$ belonging to $l^\infty([0,N];H^s(\mathbb{R}^d)^2)$, $s>d/2+2$. Then, $\forall n\le N$, we have*

$$\int_{\mathbb{R}^d}|u^n|^2dx = \int_{\mathbb{R}^d}|u^0|^2dx, \tag{4.1}$$

$$\int_{\mathbb{R}^d}\left(|\nabla u^n|^2+\lambda|u^n|^2\phi^{n-\frac{1}{2}}-\lambda\frac{(\phi^{n-\frac{1}{2}})^2}{2}\right)dx = \int_{\mathbb{R}^d}\left(|\nabla u^0|^2+\lambda|u^0|^2\phi^{-\frac{1}{2}}-\lambda\frac{(\phi^{-\frac{1}{2}})^2}{2}\right)dx. \tag{4.2}$$

Moreover, if $(\phi^{n-\frac{1}{2}})_n \in l^\infty([0,N];L^\infty(\mathbb{R}^d))$, then

$$\int_{\mathbb{R}^d}|u^n|^2dx = \int_{\mathbb{R}^d}\phi^{n+\frac{1}{2}}dx. \tag{4.3}$$

REMARK 2.

1. *We remark that $\int_{\mathbb{R}^d}|u^n|^2\phi^{n-\frac{1}{2}}dx = \int_{\mathbb{R}^d}\frac{\phi^{n+\frac{1}{2}}\phi^{n-\frac{1}{2}}}{2}dx+\int_{\mathbb{R}^d}\frac{(\phi^{n-\frac{1}{2}})^2}{2}dx$. Therefore, (4.2) reads*

$$E_0 = \int_{\mathbb{R}^d}\left(|\nabla u^n|^2+\frac{\lambda}{2}\phi^{n+\frac{1}{2}}\phi^{n-\frac{1}{2}}\right)dx = \int_{\mathbb{R}^d}\left(|\nabla u^0|^2+\frac{\lambda}{2}\phi^{\frac{1}{2}}\phi^{-\frac{1}{2}}\right)dx.$$

   Since $\phi^{n+\frac{1}{2}}$ represents $|u^n|^2$, this is the notation that we choose in order to show the conservation of the energy.
2. *Since $\phi^{\frac{1}{2}}=\phi^{-\frac{1}{2}}=|u^0|^2$, $E_0=\int_{\mathbb{R}^d}|\nabla u^0(x)|^2+\frac{\lambda}{2}|u^0(x)|^4dx$.*
3. *In the continuous case, we know that we have to find $\phi=|u|^2$. We do not exactly recover this property in the discrete case; however, (4.3) tells us that this property can be recovered in a weaker formulation.*

Proof.

- Multiplying (1.4b) by $\overline{u^{n+1}+u^n}$, integrating in space, taking the imaginary part, and summing in n, we get (4.1).
- Multiplying (1.4b) by $\overline{\frac{u^{n+1}-u^n}{\delta t}}$, integrating in space, and taking the real part, we get $-\int_{\mathbb{R}^d}\frac{|\nabla u^{n+1}|^2-|\nabla u^n|^2}{2\delta t}dx = \lambda\int_{\mathbb{R}^d}\frac{|u^{n+1}|^2-|u^n|^2}{2\delta t}\phi^{n+\frac{1}{2}}dx$. Summing these

equalities for $n \in [0, N]$ yields

$$-\int_{\mathbb{R}^d} \frac{|\nabla u^{N+1}|^2}{2\delta t} - \frac{|\nabla u^0|^2}{2\delta t} dx = \lambda \sum_{n=0}^{N} \int_{\mathbb{R}^d} \frac{|u^{n+1}|^2 - |u^n|^2}{2\delta t} \phi^{n+\frac{1}{2}} dx. \tag{4.4}$$

Multiplying (1.4a) by $\frac{\phi^{n+\frac{1}{2}} - \phi^{n-\frac{1}{2}}}{\delta t}$, we have $\frac{(\phi^{n+\frac{1}{2}})^2 - (\phi^{n-\frac{1}{2}})^2}{2\delta t} = \frac{|u^n|^2 \phi^{n+\frac{1}{2}} - |u^n|^2 \phi^{n-\frac{1}{2}}}{\delta t}$. Summing again from 0 to N gives

$$\begin{aligned}\frac{(\phi^{N+\frac{1}{2}})^2 - (\phi^{-\frac{1}{2}})^2}{2\delta t} &= \sum_{k=0}^{N} \frac{|u^k|^2 \phi^{k+\frac{1}{2}}}{\delta t} - \sum_{k=0}^{N} \frac{|u^k|^2 \phi^{k-\frac{1}{2}}}{\delta t} \\ &= \sum_{k=0}^{N} \frac{(|u^k|^2 - |u^{k+1}|^2)\phi^{k+\frac{1}{2}}}{\delta t} \\ &\quad + \frac{|u^{N+1}|^2 \phi^{N+\frac{1}{2}}}{\delta t} - \frac{|u^0|^2 \phi^{-\frac{1}{2}}}{\delta t}.\end{aligned}$$

Plugging this last equality into (4.4) yields (4.2).

- Finally, $\int_{\mathbb{R}^d} |u^n|^2 dx = \int_{\mathbb{R}^d} |u^{n-1}|^2 dx$; thus $\int_{\mathbb{R}^d} \frac{\phi^{n+\frac{1}{2}} + \phi^{n-\frac{1}{2}}}{2} dx = \int_{\mathbb{R}^d} \frac{\phi^{n-\frac{1}{2}} + \phi^{n-\frac{3}{2}}}{2} dx$. We therefore obtain $\int_{\mathbb{R}^d} \phi^{n+\frac{1}{2}} dx = \int_{\mathbb{R}^d} \phi^{n-\frac{3}{2}} dx$. As $\int_{\mathbb{R}^d} \phi^{\frac{1}{2}} dx = \int_{\mathbb{R}^d} \phi^{-\frac{1}{2}} dx$, we have $\int_{\mathbb{R}^d} \phi^{n+\frac{1}{2}} dx = \int_{\mathbb{R}^d} \phi^{n-\frac{1}{2}} dx$, which implies (4.3) because $\phi^{-\frac{1}{2}} = |u^0|^2$. □

5. Numerical experiments. We test the relaxation scheme on the nonlinear Schrödinger equation

$$i\frac{\partial u}{\partial t} + \frac{\partial^2 u}{\partial x^2} = -2|u|^2 u,$$

with the initial datum $u(x, 0) = \frac{i \exp(2ik_0 x)}{\cosh(x+2)}$, $x \in \mathbb{R}$. We know the exact solution for this initial datum which is the soliton solution $u_{ex}(x, t) = \frac{i \exp i(2k_0 x + (1-4k_0^2)t)}{\cosh(x+2-4k_0 t)}$.

We want to compute in a first experiment the numerical order p_{num}. Let us define Ω as the computational domain. The numerical order p_{num} is computed by

$$p_{\text{num}} = \frac{1}{\ln n} \ln \left(\sup_t \frac{\|u_{n\delta t} - u_{ex}\|_{L^2(\Omega)}(t)}{\|u_{\delta t} - u_{ex}\|_{L^2(\Omega)}(t)} \right).$$

In order to avoid any numerical reflections due to the boundaries, we take $\Omega = [-50, 50]$ and $k_0 = 0$. Then, the Dirichlet boundary condition is almost verified. We use finite difference approximation for the spatial differential operator $\frac{\partial^2 u}{\partial x^2}$. As we want to identify only the time numerical order, we take a fine mesh with $\delta x = 5.10^{-4}$. The number of points is therefore $N = 200000$.

The full discrete scheme reads

$$\begin{aligned}&\phi_j^{n+\frac{1}{2}} = 2|u_j^n|^2 - \phi^{n-\frac{1}{2}}, \\ &i\frac{u_j^{n+1} - u_j^n}{\delta t} + \frac{u_{j-1}^{n+1} - 2u_j^{n+1} + u_{j+1}^{n+1} + u_{j-1}^n - 2u_j^n + u_{j+1}^n}{2\delta x^2} = \frac{u_j^{n+1} + u_j^n}{2} \phi_j^{n+\frac{1}{2}}, \\ &u_0^{n+1} = 0,\ u_N^{n+1} = 0.\end{aligned}$$

TABLE 5.1
Computation of p_{num}.

Relaxation scheme	7.1s	15.12s
Crank–Nicolson scheme	23.90s	53.32s

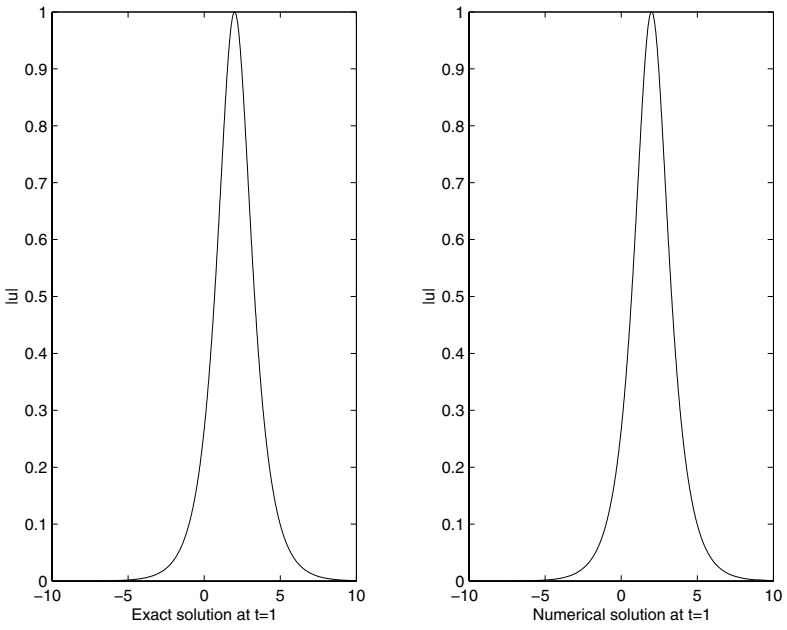

FIG. 5.1. *Comparison between exact and numerical solutions at time* $t = 1$.

The results displayed in Table 5.1 are computed for $\delta t = 10^{-3}$. Then, the order of the relaxation scheme should be two.

In our next experiment, we take $\Omega = [-10, 10]$, $N = 1024$, $\delta t = 10^{-3}$, and the final time $t = 1$. We plot in Figure 5.1 the modulus of the exact and the numerical solutions at $t = 1$. The velocity of the soliton is well preserved as its amplitude. Next, we plot the conserved quantities, namely density (here, equal to 2) and energy (equal to $\frac{11}{3}$), in Figure 5.2. On the one hand, the density is conserved with a precision of 10^{-6} and on the other hand, the energy, which is $\int_{\mathbb{R}} \frac{1}{2}|\nabla u|^2 - \frac{1}{2}|u|^4 dx$, is conserved with a precision of 10^{-2} after 1000 iterations. We plot in Figure 5.3 the numerical error $\|u_{ex} - u_{num}\|_{L^2}$. The result is very accurate. The Crank–Nicolson scheme gives the same results. However, due to the nonlinear step in this scheme, the used cpu time is more important, as we can see in Table 5.2 for different mesh size.

Finally, we experiment with the two-dimensional case. We consider the nonlinear Schrödinger equation $iu_t + \Delta u = -2|u|^2 u$. The computational domain is now $\Omega = [-10, 10] \times [-10, 10]$ and we discretize it with 200×200 points. We take $\delta t = 10^{-2}$,

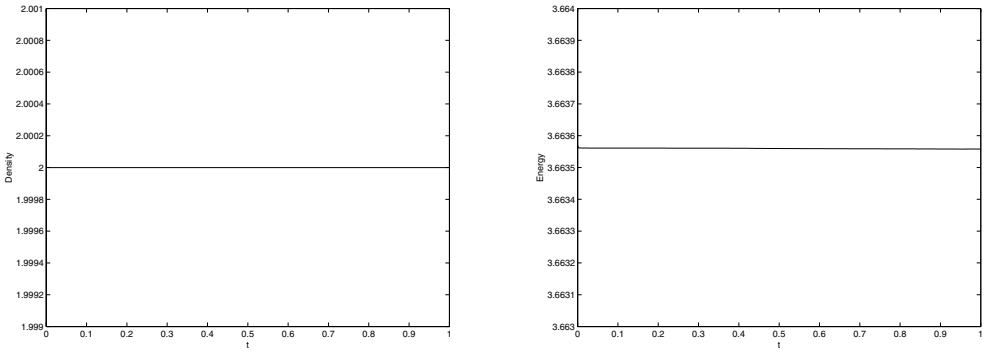

FIG. 5.2. *Density and energy.*

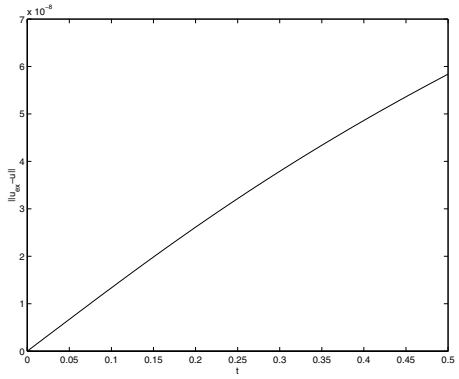

FIG. 5.3. *Error estimate.*

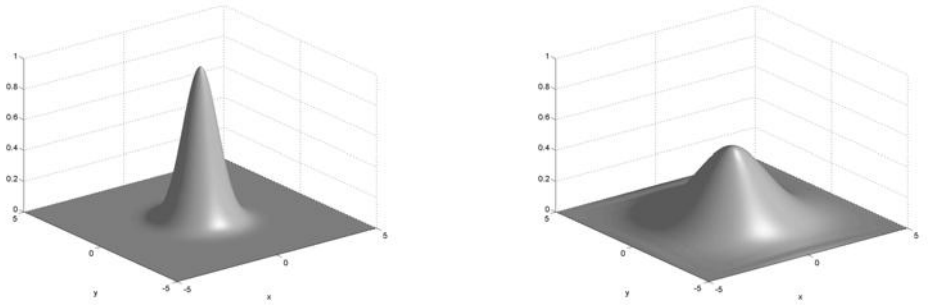

FIG. 5.4. *Initial datum and computed solution at time* $t = 0.5$.

and the final time t is 0.5. The initial datum is $\exp(-x^2 - y^2)$.

The computational time is 166s for the relaxation scheme and 336s for the Crank–Nicolson one. Actually, the nonlinear step involved in the Crank–Nicolson scheme is very costly. At each time step, two or three iterations are necessary in order for the Newton scheme to be convergent. We plot in Figure 5.4 the amplitude of the solution at time $t = 0$ and $t = 0.5$.

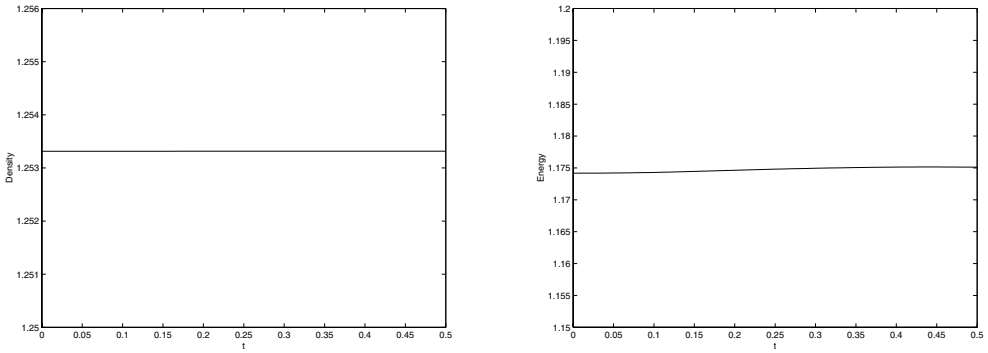

FIG. 5.5. *Density and energy in the two-dimensional case.*

The density and energy are well preserved (see Figure 5.5).

6. Conclusion. We define a new numerical scheme adapted to the nonlinear Schrödinger equation which avoids costly nonlinear computations. We prove local existence of solutions and the convergence of the scheme. Moreover, this scheme conserves the density and the energy quantities. It can be easily adapted to other systems of equations such as the Davey–Stewartson systems, for example.

Appendix. Equivalent system of (2.5). After algebraic calculations on system (2.5), this new system reads

$$\begin{cases} \frac{u^{n+2}-u^{n+1}}{\delta t} - i\Delta\left(\frac{u^{n+2}+u^{n+1}}{2}\right) = -i\lambda U^{n+\frac{3}{2}}, \\ \frac{\phi^{n+\frac{3}{2}}-\phi^{n-\frac{1}{2}}}{2\delta t} = \Phi^{n+\frac{1}{2}}, \\ \frac{v^{n+\frac{3}{2}}-v^{n-\frac{1}{2}}}{2\delta t} - i\Delta\left(\frac{v^{n+\frac{3}{2}}+2v^{n+\frac{1}{2}}+v^{n-\frac{1}{2}}}{4}\right) = -i\lambda V^{n+\frac{1}{2}}, \\ \frac{\psi^{n+1}-\psi^{n-1}}{2\delta t} = \Psi^{n}, \\ \frac{w^{n+1}-w^{n-1}}{2\delta t} - i\Delta\frac{w^{n+1}+w^{n-1}}{2} = -i\lambda W^{n}, \end{cases}$$

with $\psi^{n+1} = \frac{\phi^{n+\frac{3}{2}}-\phi^{n+\frac{1}{2}}}{\delta t}$, $w^{n+1} = \frac{v^{n+\frac{3}{2}}-v^{n+\frac{1}{2}}}{\delta t}$,

$$\begin{aligned} \Psi^n &= 2\mathrm{Re}\left(w^n\,\overline{\tfrac{u^{n+1}+2u^n+u^{n-1}}{4}}\right) + 2\left|\tfrac{v^{n+\frac{1}{2}}+v^{n-\frac{1}{2}}}{2}\right|^2, \\ W^n &= \left(\frac{\psi^{n+1}+\psi^{n-1}}{2}\right)\left(\frac{v^{n+\frac{3}{2}}+3v^{n+\frac{1}{2}}+3v^{n-\frac{1}{2}}+v^{n-\frac{3}{2}}}{8}\right) \\ &\quad + \left(\tfrac{\phi^{n+\frac{3}{2}}+\phi^{n+\frac{1}{2}}+\phi^{n-\frac{1}{2}}+\phi^{n-\frac{3}{2}}}{4}\right)\left(\tfrac{w^{n+1}+2w^n+w^{n-1}}{4}\right) \\ &\quad + 2\left[\mathrm{Re}\left(w^n\left(\overline{\tfrac{u^{n+1}+2u^n+u^{n-1}}{4}}\right)\right)+\left|\tfrac{v^{n+\frac{1}{2}}+v^{n-\frac{1}{2}}}{2}\right|^2\right]\left(\tfrac{u^{n+2}+2u^{n+1}+2u^n+2u^{n-1}+u^{n-2}}{8}\right) \\ &\quad + 2\mathrm{Re}\left(\frac{v^{n+\frac{1}{2}}\,\overline{\frac{u^{n+1}+u^n}{2}}+v^{n-\frac{1}{2}}\,\overline{\frac{u^n+u^{n-1}}{2}}}{2}\right)\left(\tfrac{v^{n+\frac{3}{2}}+v^{n+\frac{1}{2}}+v^{n-\frac{1}{2}}+v^{n-\frac{3}{2}}}{4}\right). \end{aligned}$$

The proof of existence and uniqueness of this new system is similar to that of system (2.4), but is now in $H^s(\mathbb{R}^d)$ with $s > d/2 + 4$ in order to ensure the regularity of w^n. Obviously, we can prove that system (1.4) and this new system are equivalent.

The equivalent continuous version of this system is

$$\begin{cases} u_t - i\Delta u = -i\lambda\phi u, \\ \phi_t = 2\mathrm{Re}(\overline{u}v), \\ v_t - i\Delta v = -i\lambda(2\mathrm{Re}(\overline{u}v)u + \phi v), \\ \psi_t = 2\mathrm{Re}(w\overline{u}) + 2|v|^2, \\ w_t - i\Delta w = -i\lambda(\psi v + \phi w + 2(\mathrm{Re}(w\overline{u} + |v|^2))u + 2\mathrm{Re}(v\overline{u})v), \end{cases}$$

and we can define $\Psi(x,t) = 2\mathrm{Re}(w\overline{u}) + 2|v|^2$ and $W(x,t) = \psi v + \phi w + 2(\mathrm{Re}(w\overline{u} + |v|^2))u + 2\mathrm{Re}(v\overline{u})v$.

Duhamel's formulations for ψ^n and w^n read, respectively,

$$\psi^n = \psi^{-1} + \sum_{k=0}^{p} 2\delta t \Psi^{2k}, \quad n = 2p+1,$$

$$\psi^n = \psi^0 + \sum_{k=1}^{p} 2\delta t \Psi^{2k-1}, \quad n = 2p,$$

and with the convention $D = (1 - i\delta t\Delta)^{-1}(1 + i\delta t\Delta)$ and $E = (1 - i\delta t\Delta)^{-1}$,

$$w^n = D^p w^1 - i\lambda \sum_{k=0}^{p-1} 2\delta t E D^{p-k-1} W^{2(k+1)}, \quad n = 2p+1,$$

$$w^n = D^p w^0 - i\lambda \sum_{k=0}^{p-1} 2\delta t E D^{p-k-1} W^{2k+1}, \quad n = 2p.$$

Acknowledgments. The author gratefully thanks Professor Th. Colin for his help, valuable discussions, and fruitful suggestions. He also would like to thank Professor C.-H. Bruneau for his encouragment and his help.

ON GEOMETRIC INTERPOLATION BY POLYNOMIAL CURVES*

JERNEJ KOZAK† AND EMIL ŽAGAR†

Abstract. In this paper, geometric interpolation by parametric polynomial curves is considered. Discussion is focused on the case where the number of interpolated points is equal to $r+2$, and $n=r$ denotes the degree of the interpolating polynomial curve. The interpolation takes place in $\mathbb{R}^d$ with $d=n$. Even though the problem is nonlinear, simple necessary and sufficient conditions for existence of the solution are stated. These conditions are entirely geometric and do not depend on the asymptotic analysis. Furthermore, they provide an efficient and stable way to the numeric solution of the problem.

Key words. polynomial curve, geometric interpolation, existence, uniqueness, approximation order

AMS subject classifications. 65D05, 65D07

DOI. 10.1137/S0036142903422077

1. Introduction.

Let a sequence of data points

$$\boldsymbol{T}_0, \boldsymbol{T}_1, \ldots, \boldsymbol{T}_{r+1} \in \mathbb{R}^d, \quad \boldsymbol{T}_i \neq \boldsymbol{T}_{i+1}, \tag{1.1}$$

be given. A parametric curve interpolates these points in the geometric sense if the parameter values at which it passes through the points $\boldsymbol{T}_i$ are not prescribed in advance. In the limiting case of the geometric interpolation, if two consecutive points coincide, this scheme leads to the interpolation of a point and a tangent direction at the same parameter value. Further, threefold interpolation at a point also requires the curvature to be known there, etc. The threefold interpolation by cubics in the plane can be traced back to [3], the paper that initiated the study of geometric interpolation. In order to make the proofs of the results simple, only distinct points $\boldsymbol{T}_i$ will be considered in this paper. The extension to the osculatory case will appear elsewhere.

The disadvantage of the geometric approach is obvious. Namely, the problem of finding the interpolatory curve is nonlinear, so the questions of existence, uniqueness, and computation of the solution arise.

However, there are important advantages, too. Free parameter values at which the points $\boldsymbol{T}_i$ are interpolated may raise the approximation order. This fact has been observed in [3] and in many of the subsequent papers. As a bound for the polynomial geometric interpolation, it has been conjectured in [5] that a parametric polynomial curve of degree n in d-dimensional Euclidean space can, in general, interpolate

$$r+2 = n+1+\left\lfloor \frac{n-1}{d-1} \right\rfloor$$

points in $\mathbb{R}^d$ and reach the same approximation order. The conjecture has been proved only for a few particular cases. But perhaps the most important bonus of all is that the geometric approach provides the basis for the G^m continuous spline schemes where

the interpolants do not depend on the local parametrization. This is an important and often-required property in the CAGD applications, and some of the results can be found in [4, 10, 12].

Suppose now that the interpolatory curve is a parametric polynomial curve

$$\boldsymbol{B}_n : [a, b] \to \mathbb{R}^d$$

of degree n. Since linear reparametrization does not change the degree of the polynomial, assumptions $a := 0$ and $b := 1$ can be made. Thus the construction of $\boldsymbol{B}_n$ requires determining t_i,

$$t_0 := 0 < t_1 < t_2 < \cdots < t_r < t_{r+1} := 1, \tag{1.2}$$

such that

$$\boldsymbol{B}_n(t_i) = \boldsymbol{T}_i, \quad i = 0, 1, \ldots, r+1. \tag{1.3}$$

This is the nonlinear part of the problem. Once t_i are known, it is straightforward to obtain the curve $\boldsymbol{B}_n$ in any of the well-known forms, such as Bézier, Newton, or Lagrange.

In order to keep the number of free parameters equal to the number of the unknowns, a Diophantine equation has to be satisfied [4], i.e.,

$$d\,n - (d-1)\,r = d.$$

The case

$$n = r = d \tag{1.4}$$

turns out to be the simplest to handle [6]. Nevertheless, few results can be found in the literature without the assumption that the data points are sufficiently dense and taken from some smooth underlying curve. In the plane case ($d = 2$), some results are included in [10, 8, 9], and in the space case ($d = 3$) they are included in [4].

As it will be shown below, the case $n = r = d$ can be worked out without any asymptotic assumptions. However, if $n > d$, the interpolation problems become much harder to tackle, and the asymptotic approach seems to be necessary [3, 11].

Let us assume (1.4) throughout the paper and simplify the notation of $\boldsymbol{B}_n$ to

$$\boldsymbol{B} := \boldsymbol{B}_n = \boldsymbol{B}_d.$$

The equations that determine the unknowns t_i in this particular case will be worked out in the next section.

The key role in the paper is played by the matrix of data differences,

$$\Delta T := \left(\Delta \boldsymbol{T}_i\right)_{i=0}^{d}, \quad \Delta \boldsymbol{T}_i := \boldsymbol{T}_{i+1} - \boldsymbol{T}_i, \tag{1.5}$$

and by the signs of its minors

$$D_i := \det \left(\Delta \boldsymbol{T}_j\right)_{\substack{j=0 \\ j\neq i}}^{d}, \tag{1.6}$$

i.e., the signs of the volumes of the d-simplexes, based upon the points

$$\boldsymbol{T}_0,\ \boldsymbol{T}_1,\ \ldots,\ \boldsymbol{T}_{i-1},\ \boldsymbol{T}_{i+1} - \Delta \boldsymbol{T}_i,\ \boldsymbol{T}_{i+2} - \Delta \boldsymbol{T}_i,\ \ldots,\ \boldsymbol{T}_{d+1} - \Delta \boldsymbol{T}_i.$$

If the vectors $\Delta \boldsymbol{T}_i$ do not belong to a proper subspace of $\mathbb{R}^d$, the matrix ΔT is of full rank, and the following conclusion can be made.

THEOREM 1.1. *Suppose* rank $\Delta T = d$. *Then the interpolating curve* $\boldsymbol{B}$ *exists if and only if the minors* D_i *are all of the same sign. If* $\boldsymbol{B}$ *exists, it is regular, and the parameter values* $\boldsymbol{t} := (t_i)_{i=1}^d$ *are determined uniquely.*

In the plane case, the signs of the D_i can be identified by certain angles, as has already been observed in [10, 8]. More generally, if the data are convex in the discrete sense, one has

$$\operatorname{sign}(D_0) \;=\; \operatorname{sign}(D_d)\,.$$

The additional requirements of Theorem 1.1 simply guarantee that the data stay convex under the translations

$$\boldsymbol{T}_j \to \boldsymbol{T}_j - \Delta \boldsymbol{T}_i, \quad j = i+1, i+2, \ldots, d, \quad i = 1, 2, \ldots, d-1;$$

i.e., they are not too twisted. Here the sequence of vectors $\boldsymbol{v}_1, \boldsymbol{v}_2, \ldots, \boldsymbol{v}_m$, $\boldsymbol{v}_i \in \mathbb{R}^d$, $m \geq d$, is considered to be convex in the discrete sense if all the volumes of the d-simplexes, i.e.,

$$\det(\boldsymbol{v}_i, \boldsymbol{v}_{i+1}, \ldots, \boldsymbol{v}_{i+d-1}), \quad i = 1, 2, \ldots, m-d+1,$$

are of the same sign.

Let $\mathrm{S}^- : \mathbb{R}^{d+1} \to \{0, 1, \ldots, d\}$ denote the number of strong sign changes in $\boldsymbol{x} := (x_i)_{i=0}^d \in \mathbb{R}^{d+1}$, i.e., the number of actual sign changes in the sequence $x_0, x_1, \ldots, x_d$ with zero terms discarded. Then Theorem 1.1 actually requires that the kernel of ΔT is spanned by

$$\boldsymbol{x} = \left((-1)^i D_i\right)_{i=0}^d,$$

with

$$\mathrm{S}^-(\boldsymbol{x}) = d.$$

This observation can be extended to the case of deficient rank $\Delta T < d$, but then the uniqueness or the regularity of a solution cannot be expected. Still, the following fact can be established.

THEOREM 1.2. *Let* rank $\Delta T < d$. *An interpolating curve* $\boldsymbol{B}$ *of degree* $\leq d$ *can be found if and only if there exists* $\boldsymbol{x} \in \ker \Delta T$ *such that* $\mathrm{S}^-(\boldsymbol{x}) = d$.

In the setup of Theorem 1.2, all regular $\boldsymbol{B}$ will return the same interpolatory curve, considered as a set of points. But the speed of moving along the curve will be different. The additional free parameters should be used to decrease the degree of the interpolating curve if possible. If the obtained lower-degree curve is unique, the proof of Theorem 1.1 can be repeated, and the conclusion that it is regular can also be made. Reduction of the degree is not always possible. As an example, take a cubic curve that interpolates five points in $\mathbb{R}^3$. If the data are lying on a plane, a cubic is still needed, as a quadratic curve can interpolate four planar points in general.

Although the problem of determining the unknowns t_i is nonlinear, there is an efficient and stable way to the numerical solution, given as the following result.

THEOREM 1.3. *Suppose that the requirements of Theorem* 1.1 *are satisfied. The continuation method* [1] *will always compute the numerical solution.*

Practical evidence shows that the best way is to start the continuation method as a one-step method. This step has to be reduced only if in the solution some of the t_is are close together.

2. The equations. Under the assumption (1.4) the system (1.3) can be rewritten as

$$\boldsymbol{B}(t_i) = \boldsymbol{T}_i, \quad i = 0, 1, \ldots, d+1,$$

where the unknowns are (vector) coefficients of the polynomial curve $\boldsymbol{B}$, and scalars $(t_i)_{i=1}^{d}$ have to satisfy (1.2). But the divided difference on arbitrary $d+2$ points maps a polynomial of degree $\leq d$ to zero, so

$$[t_0, t_1, \ldots, t_{d+1}]\boldsymbol{B} = \boldsymbol{0},$$

and $[t_0, t_1, \ldots, t_{d+1}]$ should map the data $\boldsymbol{T}_i$ to zero, too. Since t_i are required to be different, this fact can be written as

$$\sum_{i=0}^{d+1} \frac{1}{\dot{\omega}(t_i)} \boldsymbol{T}_i = \boldsymbol{0}, \quad \omega(t) := \prod_{i=0}^{d+1} (t - t_i), \quad \dot{\omega}(t) := \frac{d\omega}{dt}(t), \tag{2.1}$$

i.e., d scalar equations for d scalar unknowns $t_1, t_2, \ldots, t_d$. The equations (2.1) are the only nonlinear part on the way to the interpolatory curve $\boldsymbol{B}$, and one can efficiently solve them by the continuation method as stated in Theorem 1.3. The final construction of $\boldsymbol{B}$ then follows the function case and is straightforward.

3. The proofs. The assertions in the introduction seem quite simple, but the proofs will take several steps. Here is a brief outline:

1. The system (2.1) will be transformed in a form more suitable for the analysis of the existence and the uniqueness.
2. It will be shown that the existence of a unique solution of the system (2.1) implies that D_i should all be of the same sign (with Lemma 3.1 as part of the proof).
3. Lemma 3.2 will establish the fact that any solution of (2.1) that satisfies (1.2) should be simple, and Lemma 3.3 will ensure that any such solution cannot have t_is arbitrary close.
4. A proof that the system (2.1) has a unique solution for particular data will be outlined in Lemma 3.4.
5. The convex homotopy will help to carry over the conclusions from the particular to the general case in order to complete the proof of Theorem 1.1.
6. The proofs of Theorems 1.2 and 1.3 will complete the section.

Step 1. Let us recall that $[t_0, t_1, \ldots, t_{d+1}]1 = 0$. So the system (2.1) can be rewritten as

$$\sum_{i=0}^{d+1} \frac{1}{\dot{\omega}(t_i)} (\boldsymbol{T}_i - \boldsymbol{T}_0) \;=\; \sum_{i=1}^{d+1} \frac{1}{\dot{\omega}(t_i)} (\boldsymbol{T}_i - \boldsymbol{T}_0) \;=\; \boldsymbol{0} \tag{3.1}$$

or

$$(\boldsymbol{T}_i - \boldsymbol{T}_0)_{i=1}^{d+1} \boldsymbol{\omega} = \boldsymbol{0}, \tag{3.2}$$

where

$$\boldsymbol{\omega} := \left(\frac{1}{\dot{\omega}(t_i)} \right)_{i=1}^{d+1}. \tag{3.3}$$

By inserting $I = U^{-1}U$ between the two factors in (3.2), where

$$U := \begin{pmatrix} 1 & 1 & \dots & 1 \\ 0 & 1 & \dots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{pmatrix} \in \mathbb{R}^{d+1,d+1}, \qquad U^{-1} = \begin{pmatrix} 1 & -1 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{pmatrix},$$

the equations (3.1) become

$$\Delta T\, \boldsymbol{\omega_\Sigma} = \mathbf{0}, \tag{3.4}$$

with

$$\Delta T = (\boldsymbol{T}_i - \boldsymbol{T}_0)_{i=1}^{d+1}\, U^{-1} \in \mathbb{R}^{d,d+1}$$

defined by (1.5), and

$$\boldsymbol{\omega_\Sigma} := U\boldsymbol{\omega} = \left(\sum_{j=i}^{d+1} \frac{1}{\dot\omega(t_j)} \right)_{i=1}^{d+1}. \tag{3.5}$$

If at least one of the determinants D_i defined in (1.6) is different from zero, then ΔT is of full rank d, and the kernel of ΔT is spanned by the vector

$$\big((-1)^{d+1-i}\, D_i\big)_{i=0}^{d}.$$

Since $\boldsymbol{\omega_\Sigma}$ should be proportional to it, the nonlinear system (3.4) becomes

$$\alpha \sum_{j=i}^{d+1} \frac{1}{\dot\omega(t_j)} = (-1)^{d+1-i} D_{i-1}, \quad i = 1, 2, \dots, d+1, \tag{3.6}$$

i.e., $d+1$ scalar equations for $d+1$ unknowns $\alpha, t_1, t_2, \dots, t_d$.

Step 2. The form of the system (3.6) is suitable to proceed with the next part of the proofs. Let $t_0 := 0 < t_1 < \cdots < t_d < t_{d+1} := 1$, and let $\alpha \neq 0$ be a unique solution of the system (3.6). Then

$$D_d = \alpha\, \frac{1}{\dot\omega(t_{d+1})} \neq 0,$$

and $\operatorname{sign}(D_d) = \operatorname{sign}(\alpha)$. Thus

$$\operatorname{sign}(D_{i-1}) \;=\; \operatorname{sign}(\alpha), \quad i = 1, 2, \dots, d,$$

if and only if

$$\mathrm{S}^-(\boldsymbol{\omega_\Sigma}) \;=\; d.$$

This equality will be established with the help of the following lemma.

LEMMA 3.1. *Let p_i, $1 \le i \le d$, be the interpolating polynomial of degree $\le d+1$ that interpolates the data*

$$p_i(t_j) = \begin{cases} 0, & j = 0, 1, \dots, i-1, \\ 1, & j = i, \quad i+1, \dots, d+1, \end{cases}$$

at $d+2$ distinct points $t_0 < t_1 < \cdots < t_{d+1}$. Then p_i is of degree $d+1$, and the sign of its leading coefficient is equal to $(-1)^{d+1-i}$.

Proof. The interpolating conditions imply $p_i \neq \text{const}$; thus $p_i' \neq 0$. By Rolle's theorem, p_i' has at least $i-1$ zeros on (t_0, t_{i-1}) and at least $d-i+1$ zeros on (t_i, t_{d+1}), i.e., at least d zeros on (t_0, t_{d+1}). Since p_i' does not vanish identically, the degree of p_i' is d, and the degree of p_i is $d+1$. Note that p_i' must be increasing on (t_{i-1}, t_i), and $\operatorname{sign}(p_i'(t_i)) = 1$. But then $\operatorname{sign}(p_i'(t_{d+1})) = (-1)^{d+1-i}$. Since the leading coefficient of p_i has to be of the same sign as $p_i'(t_{d+1})$, the lemma has been proved. ∎

Let p_i be the polynomial studied in Lemma 3.1. Its leading coefficient is equal to the divided difference

$$[t_0, t_1, \ldots, t_{d+1}]p_i = \sum_{j=0}^{d+1} \frac{p_i(t_j)}{\dot{\omega}(t_j)} = \sum_{j=i}^{d+1} \frac{1}{\dot{\omega}(t_j)},$$

and the fact

$$\operatorname{sign}\left(\sum_{j=i}^{d+1} \frac{1}{\dot{\omega}(t_j)}\right) = (-1)^{d+1-i}$$

is confirmed by the conclusion of Lemma 3.1. The first part of the proof of Theorem 1.1 is complete.

Step 3. Let us continue with the next step of the proofs. If two consecutive equations in (3.6) are subtracted, the system reads as

$$\frac{\alpha}{\dot{\omega}(t_i)} = (-1)^{d+1-i}(D_{i-1} + D_i), \quad i = 1, 2, \ldots, d+1, \quad D_{d+1} := 0. \tag{3.7}$$

The system (3.7) will have a simple solution if the Jacobian J at that point is non-singular. A straightforward computation gives J as

$$J := J(\boldsymbol{t}, \alpha)\operatorname{diag}\left(\frac{1}{\dot{\omega}(t_i)}\right)_{i=1}^{d+1} A, \tag{3.8}$$

with $A := (a_{ij})_{i,j=1}^{d+1}$, and

$$a_{ij} = \begin{cases} \dfrac{\alpha}{t_i - t_j}, & i \neq j, \quad j < d+1, \\ \displaystyle\sum_{\substack{k=0 \\ k \neq i}}^{d+1} \frac{\alpha}{t_k - t_i}, & i = j, \quad j < d+1, \\ 1, & j = d+1. \end{cases}$$

The suggestions in [7] will help us to prove the following lemma.

LEMMA 3.2. *The determinant of the matrix A is given as*

$$\det A = d!\,\alpha^d\,(t_0 - t_{d+1})\frac{1}{\dot{\omega}(t_0)}.$$

Proof. By definition, $\det A$ is a sum of terms of the form

$$\text{const} \prod_{i \neq j} \frac{1}{t_i - t_j}, \tag{3.9}$$

where the total degree of the denominator, viewed as a polynomial in the variables

$$t_\ell, \quad \ell = 0, 1, \ldots, d+1,$$

is d, but for some terms const could be zero. The terms involving

$$\frac{1}{t_i - t_j} \quad \text{or} \quad \frac{1}{(t_i - t_j)^2}, \quad i, j = 1, 2, \ldots, d+1, \quad i \neq j, \tag{3.10}$$

could not take part in (3.9). To see this, observe that for fixed $i \neq j$, $0 \leq\ i, j \leq d$, only the elements

$$\begin{pmatrix} a_{ii} & a_{ij} \\ a_{ji} & a_{jj} \end{pmatrix} \alpha \begin{pmatrix} \dfrac{1}{t_j - t_i} & \dfrac{1}{t_i - t_j} \\ \dfrac{1}{t_j - t_i} & \dfrac{1}{t_i - t_j} \end{pmatrix} + \text{other terms}$$

in the matrix A are involved. So the contribution of (3.10) to $\det A$ is computed as the determinant of the matrix A where all the other elements in rows i and j and in columns i and j are set to zero. But then all the 2×2 minors obtained from the rows i and j vanish identically, and the Laplace expansion shows that this determinant is equal to zero. A similar argument works for $i = d+1$, $j = 0$, too. But then only the d possible divisors $t_0 - t_i$, $i = 1, 2, \ldots, d$, are left, and $\det A$ has to be of the form

$$\det A = \alpha^d \frac{c}{\prod_{i=1}^{d}(t_0 - t_i)} \alpha^d (t_0 - t_{d+1}) \frac{c}{\dot{\omega}(t_0)},$$

where c is a constant independent of t_i. Since

$$c = \frac{1}{\alpha^d (t_0 - t_{d+1})} \det \big(\operatorname{diag}(t_0 - t_i)_{i=1}^{d+1} A\big),$$

the sequence of limits $t_1 \to t_0, t_2 \to t_0, \ldots, t_d \to t_0$ simplifies c to

$$c = \frac{1}{t_0 - t_{d+1}} \det \begin{pmatrix} 1 & 0 & \cdots & 0 & 0 \\ 1 & 2 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & \cdots & d & 0 \\ -1 & -1 & \cdots & -1 & t_0 - t_{d+1} \end{pmatrix} = d!,$$

and the lemma is proved. □

It is convenient now to describe all the admissible solutions of (3.7) as a set $\mathcal{D}$,

$$\mathcal{D} := \{\boldsymbol{t} = (t_i)_{i=1}^{d} \,|\, 0 := t_0 < t_1 < \cdots < t_d < t_{d+1} := 1\} \times \{\alpha \,|\, \alpha \neq 0\}.$$

The restriction of $\mathcal{D}$ to the case $\alpha > 0$ will be denoted by $\mathcal{D}_+$ and the restriction to the case $\alpha < 0$ by $\mathcal{D}_-$.

LEMMA 3.3. *Let D_i be all positive (negative). The system* (3.7) *cannot have a solution arbitrary close to the boundary $\partial\mathcal{D}_+$ ($\partial\mathcal{D}_-$).*

Proof. Without loss of generality, one can assume that $\operatorname{sign}(\alpha) = \operatorname{sign}(D_i) > 0$. The last equation in (3.7) reads

$$\frac{\alpha}{\dot{\omega}(t_{d+1})} = \frac{\alpha}{(t_{d+1} - t_0)(t_{d+1} - t_1) \cdots (t_{d+1} - t_d)} = D_d. \tag{3.11}$$

Note that

$$t_{d+1} - t_d \le t_{d+1} - t_i \le 1, \quad i = 0, 1, \dots, d,$$

so the inequality

$$(t_{d+1} - t_d)^{d+1} \le \dot{\omega}(t_{d+1}) \le\ t_{d+1} - t_d$$

gives the bounds on α in (3.11) as

$$(t_{d+1} - t_d)^{d+1} \le \frac{\alpha}{D_d} \le\ t_{d+1} - t_d. \tag{3.12}$$

Since $[t_0, t_1, \dots, t_{d+1}]1 = 0$, summing all equations in (3.7) yields

$$\frac{\alpha}{\dot{\omega}(t_0)} = (-1)^{d+1} D_0,$$

and, further, as in (3.12),

$$(t_1 - t_0)^{d+1} \le \frac{\alpha}{D_0} \le\ t_1 - t_0. \tag{3.13}$$

The inequalities (3.12) and (3.13) show that $t_1 - t_0$ and $t_{d+1} - t_d$ should go to zero with α, i.e.,

$$t_1 - t_0 = o(1),\ t_{d+1} - t_d = o(1) \text{ as } \alpha \to 0. \tag{3.14}$$

More generally, with

$$(t_{i+1} - t_i)^{d+1-i} \prod_{j=0}^{i-1} (t_i - t_j) \le (-1)^{d+1-i}\, \dot{\omega}(t_i) \le (t_{i+1} - t_i) \prod_{j=0}^{i-1} (t_i - t_j)$$

one obtains the bounds from the ith equation in (3.7) as

$$(t_{i+1} - t_i)^{d+1-i} \le \frac{\alpha}{(D_{i-1} + D_i) \prod_{j=0}^{i-1} (t_i - t_j)} \le t_{i+1} - t_i, \quad i = 1, 2, \dots, d. \tag{3.15}$$

Let $\alpha \to 0$. The product $\prod_{j=0}^{i-1}(t_i - t_j)$ cannot go faster to zero as α since the right-hand side in (3.15) is bounded by one. So one has either

$$\frac{\alpha}{\prod_{j=0}^{i-1}(t_i - t_j)} = o(1) \text{ as } \alpha \to 0 \tag{3.16}$$

or

$$\frac{\alpha}{\prod_{j=0}^{i-1}(t_i - t_j)} = \text{const as } \alpha \to 0. \tag{3.17}$$

The possibility (3.16) cannot hold for all i since this would, together with (3.14), imply $t_{d+1} \to t_0$, but $t_{d+1} = 1,\ t_0 = 0$, a contradiction. So at least for one i the equation (3.17) holds, and (3.15) further implies that $t_{i+1} - t_i \ge \text{const}$. Suppose that

ℓ, $1 \le \ell \le d$, is the smallest index such that t_ℓ, $t_{\ell+1}$ are separated, i.e., $t_\ell - t_0 = o(1)$ as $\alpha \to 0$, but $t_{\ell+1} - t_\ell = \text{const} > 0$. Then

$$\frac{1}{t_i - t_j} = \frac{1}{t_0 - t_j}\,(1 + \mathcal{O}(t_i - t_0)), \quad i \le \ell < j,$$

and

$$\frac{1}{\dot\omega(t_i)} = \frac{1}{\prod_{\substack{j=0\\ j\neq i}}^{\ell}(t_i - t_j)}\ \frac{1}{\prod_{j=\ell+1}^{d+1}(t_0 - t_j)}\ \left(1 + \sum_{i=0}^{\ell}\mathcal{O}(t_i - t_0)\right), \quad i \le \ell. \tag{3.18}$$

Let

$$w := \prod_{j=\ell+1}^{d+1}(t_j - t_0)\ \ge (t_{\ell+1} - t_\ell)^{d+1-\ell} = \text{const}^{d+1-\ell} > 0.$$

By inserting (3.18) into (3.7), multiplied by w, one computes

$$\frac{\alpha}{\prod_{\substack{j=0\\ j\neq i}}^{\ell}(t_i - t_j)} = (-1)^{\ell-i} w(D_{i-1} + D_i) + \text{ higher-order terms}, \quad i = 0, 1, \ldots, \ell,$$

and the summing of these equations yields

$$\sum_{i=0}^{\ell} \frac{\alpha}{\prod_{\substack{j=0\\ j\neq i}}^{\ell}(t_i - t_j)}[t_0, t_1, \ldots, t_\ell]\alpha = wD_\ell + \text{ higher-order terms}. \tag{3.19}$$

The left-hand side of (3.19) vanishes, since $\ell \ge 1$ and, consequently, $[t_0, t_1, \ldots, t_\ell]\alpha = 0$. On the other hand, the right-hand side is positive if higher-order terms are small enough. This implies that not all of the first $\ell + 1$ equations of (3.7) can be satisfied if $\alpha \ll 1$. So α has to be bounded away from 0, and the equations (3.7) imply that $t_{i+1} - t_i \ge \text{const} > 0$ for all i. The lemma is confirmed. ∎

Step 4. The fourth step of the proofs considers the system (2.1) with a particular set of data points.

LEMMA 3.4. *Let us suppose that the data points* (1.1) *are taken on the polynomial curve* $\boldsymbol{f}(t) := (t^k)_{k=1}^d$ *as*

$$T_i^* := \boldsymbol{f}(\eta_i), \quad i = 0, 1, \ldots, d+1, \tag{3.20}$$

where

$$\eta_0 := 0 < \eta_1 < \cdots < \eta_d < \eta_{d+1} := 1. \tag{3.21}$$

Then the system of nonlinear equations (2.1) *has a unique solution.*

Proof. First, note that the determinants which correspond to the particular data (3.20) are

$$D_i^* := \det\,(\Delta T_i^*)_{\substack{j=0\\ j\neq i}}^{d} \tag{3.22}$$

and can be computed as

$$D_i^* = d! \int_{\eta_0}^{\eta_1} dx_1 \int_{\eta_1}^{\eta_2} dx_2 \ldots \int_{\eta_{i-1}}^{\eta_i} dx_i \int_{\eta_{i+1}}^{\eta_{i+2}} dx_{i+1} \ldots \int_{\eta_d}^{\eta_{d+1}} V(x_1, x_2, \ldots, x_d) dx_d,$$

where

$$V(x_1, x_2, \ldots, x_d) = \prod_{j>i}(x_j - x_i)$$

is the Vandermonde determinant. This implies that $D_i^* > 0$, and rank $\Delta T^* = d$, since η_i are ordered by (3.21). The necessary conditions of Theorem 1.1 are met, and one of the solutions of (2.1) for the particular data is obviously

$$t_i = \eta_i, \quad i = 1, \ldots, d.$$

In order to complete the proof of Theorem 1.1 for these data, it must be shown that this is the only solution that satisfies (1.2). The system in its basic form (2.1) is

$$\sum_{i=0}^{d+1} \frac{\eta_i^\ell}{\dot\omega(t_i)} = 0, \quad \ell = 1, 2, \ldots, d, \tag{3.23}$$

and the identity $[t_0, t_1, \ldots, t_{d+1}]1 = 0$ can always be added. But then (3.23) is reduced to the fact that the vector

$$\left(\frac{1}{\dot\omega(t_i)}\right)_{i=0}^{d+1}$$

should span the kernel of the matrix $M_{\boldsymbol{\eta}}$, where

$$M_{\boldsymbol{z}} := \left(z_i^\ell\right)_{\ell=0;i=0}^{d;d+1}, \quad \boldsymbol{z} = (z_i)_{i=0}^{d+1},$$

since by assumption (3.21) the matrix $M_{\boldsymbol{\eta}}$ is obviously of full rank, i.e., $d+1$. But

$$M_{\boldsymbol{\eta}} \left(\frac{1}{\dot\omega(\eta_i)}\right)_{i=0}^{d+1} \left([\eta_0, \eta_1, \ldots, \eta_{d+1}]_\eta\, \eta^\ell\right)_{\ell=0}^{d} = \mathbf{0}.$$

Thus $(\frac{1}{\dot\omega(\eta_i)})_{i=0}^{d+1}$ spans the kernel of $M_{\boldsymbol{\eta}}$, too, and

$$\begin{aligned}\mathbf{0} = M_{\boldsymbol{\eta}} \left(\frac{1}{\dot\omega(t_i)}\right)_{i=0}^{d+1} &= \operatorname{const} M_{\boldsymbol{\eta}} \left(\frac{1}{\dot\omega(\eta_i)}\right)_{i=0}^{d+1} \\ &= \operatorname{const} M_{\boldsymbol{t}} \left(\frac{1}{\dot\omega(t_i)}\right)_{i=0}^{d+1} = \operatorname{const}_1 M_{\boldsymbol{t}} \left(\frac{1}{\dot\omega(\eta_i)}\right)_{i=0}^{d+1}.\end{aligned}$$

So t_i and η_i are equivalent, and one can simplify further discussion by exchanging the role of the unknowns and the parameters. Thus suppose t_i to be known and η_i to be determined.

The equations (3.23) imply that the values η_i must be equal to the values $p(t_i)$ of some polynomial p of degree $\le d$, and

$$[t_0, t_1, \ldots, t_{d+1}]p^\ell = 0, \quad \ell = 1, 2, \ldots, d. \tag{3.24}$$

It is easy to see that (3.24) does not, in general, determine the polynomial p uniquely, even for small d. Take $d = 3$, and equidistant partition $t_i = \frac{i}{4}$. Then the divided

difference $[t_0, t_1, t_2, t_3, t_4]$ obviously maps to zero the powers $t^\ell,\ \ell = 1, 2, 3$, but also p^ℓ, where

$$p(t) := \frac{1}{3}t(16 - 45t + 32t^2).$$

However, this p does not produce $\eta_i = p(t_i)$ in the order as required in (3.21) since it is not monotone on $[0, 1]$.

Let us proceed to show that for a particular choice of t_i the solution of (3.24) that satisfies (3.21) is unique. Let $0 < h \ll 1$, and

$$t_i = \frac{i}{d}h, \quad i = 1, 2, \ldots, d.$$

Note that $p(0) = 0,\ p(1) = 1$. Thus p can be expressed as follows:

$$p(t) = \sum_{i=1}^{d} c_i t^i, \quad c_d := 1 - \sum_{i=1}^{d-1} c_i,$$

and the first equation of (3.24) is satisfied automatically. Let us recall that the divided difference can also be written as

$$\oint_{\partial\Omega} \frac{f(z)}{\omega(z)}dz = \sum_{i=0}^{d+1} \operatorname{Res}\left(\frac{f}{\omega}; t_i\right) = [t_0, t_1, \ldots, t_{d+1}]f, \quad t_i \in I,$$

if f is analytical on the set $\Omega \subset \mathbb{C},\ I \subset \Omega$. Here, $\operatorname{Res}(g; z)$ denotes the residuum of g at z. Thus (3.24) can be written as

$$\sum_{i=0}^{d+1} \operatorname{Res}\left(\frac{p^\ell}{\omega}; t_i\right) = 0, \quad \ell = 2, 3, \ldots, d. \tag{3.25}$$

The fraction $\frac{p^\ell}{\omega}$ has only isolated singularities in $\mathbb{C}^*$; therefore

$$\sum_{i=0}^{d+1} \operatorname{Res}\left(\frac{p^\ell}{\omega}; t_i\right) + \operatorname{Res}\left(\frac{p^\ell}{\omega}; \infty\right) = 0, \quad \ell = 2, 3, \ldots, d,$$

and the system (3.25) is simplified to

$$\operatorname{Res}\left(\frac{p^\ell}{\omega}; \infty\right) = 0, \quad \ell = 2, 3, \ldots, d. \tag{3.26}$$

The rational function $\frac{1}{\omega}$ expands at ∞ as

$$\frac{1}{\omega(z)} = \frac{1}{z^{d+2}} + \sum_{i=d+3}^{\infty} \frac{1}{z^i}\left(\frac{d+1}{2}h + \mathcal{O}(h^2)\right).$$

Also,

$$p^\ell(z) = \sum_{k=\ell}^{\ell\, d} z^k \sum_{i_1+i_2+\cdots+i_\ell=k} c_{i_1} c_{i_2} \ldots c_{i_\ell}. \tag{3.27}$$

In (3.27), only the terms with $k \geq d+1$ will contribute to the residue. Since $d+1 > \ell$, the system (3.26) reads

$$\sum_{k=d+1}^{\ell\, d} \sum_{i_1+i_2+\cdots+i_\ell=k} c_{i_1} c_{i_2} \dots c_{i_\ell} + \mathcal{O}(h) = 0, \quad \ell = 2, 3, \dots, d. \tag{3.28}$$

But $p^\ell(1) = 1$, and (3.27) simplifies (3.28) to

$$1 - \sum_{k=l}^{d} \sum_{i_1+i_2+\cdots+i_\ell=k} c_{i_1} c_{i_2} \dots c_{i_\ell} + \mathcal{O}(h) = 0, \quad \ell = d, d-1, \dots, 2. \tag{3.29}$$

First, let us consider (3.29) when $h \to 0$. Then the first two equations read as

$$1 - c_1^d = 0 \tag{3.30}$$

and

$$1 - c_1^{d-1} - d c_1^{d-2} c_2 = 0, \tag{3.31}$$

and the rest read as

$$1 - c_1^\ell - \ell c_1^{\ell-1} c_{d-\ell+1} + g_\ell(c_1, c_2, \dots, c_{d-\ell}) = 0, \quad \ell = d-2, d-3, \dots, 2. \tag{3.32}$$

Equation (3.30) implies that $c_1 = 1$ is the only real solution. This is true also for even d, because $c_1 = -1$ implies that p is not monotone. But then (3.31) implies that $c_2 = 0$, and (3.32) implies that $c_i = 0,\ i = 3, 4, \dots, d-1$. A brief look at (3.29) reveals that $g_\ell(c_1, c_2, \dots, c_{d-\ell})$ involves products that include at least two c_i, with $2 \leq i \leq d - \ell$. So the lower triangular nonlinear system (3.30), (3.31), and (3.32) has a nonsingular Jacobian at the limit point $h = 0$, and the limit solution is

$$(c_1, c_2, \dots, c_{d-1}) = (1, 0, \dots, 0).$$

Thus, by the implicit function theorem, there exists $h_0 > 0$ such that for all $h,\ 0 \leq h \leq h_0$, there is a unique monotone solution p of the system (3.24), i.e., $p(t) = t$, independently of h. Consequently, the system (3.6) has a unique solution (3.21) which implies the unique solution of the system (2.1), too. ∎

Step 5. Consider now the general case. Without loss of generality, one may assume that D_i are all positive. Let us join the particular data D_i^*, defined in (3.22), and the general data D_i with a convex homotopy,

$$D_i(\lambda) := (1-\lambda) D_i^* + \lambda D_i > 0, \quad \lambda \in [0, 1].$$

Let

$$\boldsymbol{H}(\boldsymbol{t}, \alpha; \lambda) := \left(\frac{\alpha}{\dot{\omega}(t_i)} \right)_{i=1}^{d+1} - \Big((-1)^{d+1-i} \big(D_{i-1}(\lambda) + D_i(\lambda) \big) \Big)_{i=1}^{d+1}, \quad \lambda \in [0, 1],$$

so that the system (3.7) is simplified to

$$\boldsymbol{H}(\boldsymbol{t}, \alpha; \lambda) = \boldsymbol{0}. \tag{3.33}$$

Note that $D_i(\lambda) = (1-\lambda)\, D_i^* + \lambda\, D_i \geq \min\{D_i^*, D_i\} > 0$. So the system (3.33) satisfies the requirements of Lemma 3.3 for any $\lambda \in [0,1]$. As a consequence, the zeros of $\boldsymbol{H}$ are apart from the boundary $\partial\mathcal{D}_+$ for all $\lambda \in [0,1]$. Let

$$\mathcal{S} := \{(\boldsymbol{t},\alpha) \in \mathcal{D}_+ \,|\, \boldsymbol{H}(\boldsymbol{t},\alpha;\lambda) = 0,\ \lambda \in [0,1]\}$$

be the set of solutions of (3.33) for all $\lambda \in [0,1]$, and let $Co(\mathcal{S}) \supset \mathcal{S}$ be its convex hull. The set $\mathcal{D}_+$ is convex. Thus Lemma 3.3 implies that $Co(\mathcal{S}) \subset \mathcal{D}_+$. But $\mathcal{D}_+$ is an open set, and the compact set $Co(\mathcal{S})$ can be enlarged a little to a compact set $\widetilde{\mathcal{D}}$ with a smooth boundary so that the following relations are satisfied:

$$Co(\mathcal{S}) \subset \widetilde{D} \subset \mathcal{D}_+, \qquad Co(\mathcal{S}) \cap \partial\widetilde{D} = \emptyset.$$

The map $\boldsymbol{H}$ is clearly differentiable on $\widetilde{\mathcal{D}}$ and does not vanish on the boundary $\partial\widetilde{\mathcal{D}}$. But then Brouwer's degree [2, pp. 52–53] of $\boldsymbol{H}$ is invariant for $\lambda \in [0,1]$ on $\widetilde{\mathcal{D}}$. In $\boldsymbol{H}$, only the data depend on λ, and a brief look at the homotopy reveals that its Jacobian is simply $J(\boldsymbol{t},\alpha)$, as given in (3.8). This simplifies Brouwer's degree to

$$\sum_{(\boldsymbol{t},\alpha)\in\widetilde{\mathcal{D}},\, \boldsymbol{H}(\boldsymbol{t},\alpha;\lambda)=0} \operatorname{sign}\big(\det J(\boldsymbol{t},\alpha)\big).$$

By Lemma 3.2, $\det J$ vanishes nowhere in $\mathcal{D}_+ \supset \widetilde{\mathcal{D}}$, and Brouwer's degree is further simplified to

$$\pm\, \#\,\{(\boldsymbol{t},\alpha)\,|\,(\boldsymbol{t},\alpha) \in \widetilde{\mathcal{D}},\ \boldsymbol{H}(\boldsymbol{t},\alpha;\lambda) = 0\},$$

so it provides the exact count of zeros in $\widetilde{\mathcal{D}}$. But by Lemma 3.4 the particular problem $\boldsymbol{H}(\boldsymbol{t},\alpha;0) = 0$ has a unique solution in $\widetilde{\mathcal{D}}$, as do all $\boldsymbol{H}(\boldsymbol{t},\alpha;\lambda) = 0$.

In order to complete the proof of Theorem 1.1, it remains to show that $\boldsymbol{B}$, based upon $\boldsymbol{t}$ that we have just determined, is a regular curve.

Note that $\boldsymbol{B}$ can also be written as

$$\boldsymbol{B} = \sum_{j=0}^{d+1} \boldsymbol{T}_j \ell_j, \qquad \ell_j(t) := \frac{\omega(t)}{(t-t_j)\dot{\omega}(t_j)}.$$

If $\boldsymbol{B}$ is not regular, then

$$\dot{\boldsymbol{B}}(\tilde{t}) = 0 = \Delta T U(\dot{\ell}_i(\tilde{t}))_{i=1}^{d+1}$$

for some $\tilde{t} \in [0,1]$. Since $\ker \Delta T$ is spanned by $\boldsymbol{\omega}_\Sigma = U\boldsymbol{\omega}$, given in (3.5) and (3.3), the vector $\big(\ell_i(\tilde{t})\big)_{i=1}^{d+1}$ should be proportional to $\boldsymbol{\omega}$. But then

$$\dot{\omega}(t_i)\dot{\ell}_i(\tilde{t}) = \left(\frac{\dot{\omega}(\tilde{t})}{\tilde{t}-t_i} - \frac{\omega(\tilde{t})}{(\tilde{t}-t_i)^2}\right) = \text{const}$$

for all $t_i \neq \tilde{t}$, which implies that at least two of t_i are equal, a contradiction that confirms the regularity of the interpolating curve. The proof of Theorem 1.1 is complete.

Step 6. The proof of Theorem 1.3 will precede the proof of Theorem 1.2.

Proof of Theorem 1.3. The conclusion of the theorem follows from Lemma 3.2. Since the Jacobian of $\boldsymbol{H}$ is globally nonsingular it is also nonsingular on the set $\boldsymbol{H}^{-1}(\boldsymbol{0})$; thus $\boldsymbol{0}$ is a regular value of the map $\boldsymbol{H}$. This implies [1, p. 38] that the

convergence of the Euler–Newton method as a continuation method is ensured for a suitable small step-length when the solution curve from the particular system ($\lambda = 0$) to our general one ($\lambda = 1$) is traced. □

Proof of Theorem 1.2. If the interpolating polynomial $\boldsymbol{B}$ exists, then the corresponding $\boldsymbol{\omega_\Sigma} \in \ker \Delta T$, as defined in (3.5), clearly satisfies $\mathrm{S}^-(\boldsymbol{\omega_\Sigma}) = d$. On the other hand, if $\boldsymbol{x} = (x_i)_{i=0}^d \in \ker \Delta T$ can be found such that $\mathrm{S}^-(\boldsymbol{x}) = d$, then x_i may replace the right-hand side $(-1)^{d+1-i} D_i$ in (3.6). The existence part of Theorem 1.1 still carries through, and Theorem 1.2 is proved. □

Let us illustrate the last proof by a simple example. Let data be given on a line in a plane,

$$\boldsymbol{T}_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad \boldsymbol{T}_1 = \frac{1}{3}\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad \boldsymbol{T}_2 = \frac{1}{2}\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad \boldsymbol{T}_3 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}. \tag{3.34}$$

Then

$$\Delta T = \frac{1}{6}\begin{pmatrix} 2 & 1 & 3 \\ 2 & 1 & 3 \end{pmatrix},$$

and rank $\Delta T = 1$. Furthermore, the vector $\boldsymbol{x} \in \ker \Delta T$ such that $\mathrm{S}^-(\boldsymbol{x}) = d = 2$ is given as a parametric family:

$$\boldsymbol{x} = \boldsymbol{x}(\mu) := (\mu, -3 - 2\mu, 1), \qquad \mu > 0.$$

For such an $\boldsymbol{x}$, the system (3.6) has the solution

$$t_1 = t_1(\mu) := \frac{1}{1-\mu}\left(1 - \sqrt{\frac{2\mu(\mu+2)}{3(\mu+1)}}\right), \qquad t_2 = t_2(\mu) := t_1(\mu) + \sqrt{\frac{\mu}{6(\mu+1)(\mu+2)}},$$

and the data (3.34) are interpolated by a quadratically parametrized line

$$\boldsymbol{B} = \phi\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \qquad \phi(t) := \frac{(1-2t_2^2)t - (1-2t_2)t^2}{2t_2(1-t_2)}.$$

Furthermore, the curve $\boldsymbol{B}$ is regular if and only if

$$1 - \frac{1}{\sqrt{2}} \le t_2 \le \frac{1}{\sqrt{2}}, \quad \left(\sqrt{3}-1\right)\left(\sqrt{2}-1\right) \le \mu \le \left(\sqrt{2}+1\right)\left(2+\sqrt{6}\right).$$

There is only one free parameter to decrease the degree of $\boldsymbol{B}$, and $t_2 = t_2(2) = \frac{1}{2}$ reduces the parametrization to the simplest case $\phi(t) = t$. This parametrization is regular since it is a unique solution of degree one of the interpolation problem. This concludes the proofs.

SATURATION OF REGULARIZATION METHODS FOR LINEAR ILL-POSED PROBLEMS IN HILBERT SPACES*

PETER MATHÉ†

Abstract. We prove the saturation of methods for solving linear ill-posed problems in Hilbert spaces for a wide class of regularization methods. It turns out that, under a certain convexity assumption, saturation must necessarily occur. We provide easy to verify assumptions, which allow us to calculate the rate at which saturation occurs.

Key words. saturation, regularization, ill-posed problem

AMS subject classifications. 47A52, 65F22

1. Introduction and problem formulation. We study the numerical solution of operator equations $Ax = y$ under the presence of noise, which means we are given

$$y_\delta = Ax + \delta\xi,$$

where the operator A acts between Hilbert spaces X and Y. Moreover, the noise ξ is assumed to be bounded $\|\xi\| \le 1$. If A acts injectively and has dense range, then the problem of recovering the unknown x from noisy observations y_δ is known to be ill-posed. In this case we are interested in *regularization methods* given by some operator function $\alpha \to g_\alpha(A^*A)$, $0 < \alpha \le a$; i.e., the approximation to $x \in X$ is given by choosing some $\alpha = \alpha(\delta)$ and letting

$$x_{\alpha,\delta} := g_\alpha(A^*A)A^*y_\delta.$$

The most famous method is *Tikhonov–Phillips regularization*, where

$$x_{\alpha,\delta} := (\alpha \mathrm{I} + A^*A)^{-1}A^*y_\delta.$$

The error of any regularization g_α for approximating x, based on observations y_δ, is given by $e(x, g_\alpha, \delta) := \sup_{\|\xi\|\le 1} \|x - g_\alpha(A^*A)A^*y_\delta\|$. For the performance of a given regularization it is interesting to know how sensitive it is with respect to a priori smoothness assumptions. This is captured by the notion of the *qualification* of the regularization: The higher its qualification, the more it is capable of reacting to smoothness assumptions. In this respect, Tikhonov–Phillips regularization is known to have qualification 1; more generally, it can provide the optimal order of accuracy for all concave source conditions within the framework of variable Hilbert scales; see, e.g., [3, 6]. We will not turn to this subject in this paper.

Here we ask for *saturation*, i.e., the maximal smoothness, where a given regularization can provide the best possible order of approximation. This is made precise in section 2. The main result establishes fairly general conditions under which saturation must occur; the core of them is a certain *convexity property*. The saturation phenomenon has been studied several times. We do not recall the history but refer

†Weierstraß Institute for Applied Analysis and Stochastics, Mohrenstraße 39, D–10117 Berlin, Germany (mathe@wias-berlin.de).

the reader to [2], summarizing also the recent [7, 8]. Our attitude is different. Most importantly, the analysis is based on a *geometric concept*, which indicates why saturation occurs. As a side effect, this approach is so general that it covers fairly general regularization methods.

We conclude our study with several examples to exhibit that these conditions are easy to verify in specific situations.

2. Main result. As indicated in section 1 we discuss regularization in the form of

$$x_{\alpha,\delta} := g_\alpha(A^*A)A^*y_\delta.$$

More formally, given any bounded operator $A: X \to Y$, the operator A^*A acts in Y, and we assume it has a norm bound $\|A^*A\| \le a$. By spectral calculus, each bounded (Borel-measurable) function defined on $(0, a]$ taking real values can be assigned a respective function taking nonnegative operators to self-adjoint ones. Therefore we may and do identify g_α with its real-valued function. In terms of real functions g_α the requirements can be expressed as follows.

DEFINITION 2.1 (see [9, 6]). *A family g_α, $0 < \alpha \le a$, of bounded (Borel-measurable) functions is called regularization if there are constants γ_* and γ for which*

$$\sup_{0<\lambda\le a} |1 - \lambda g_\alpha(\lambda)| \le \gamma, \quad 0 < \alpha \le a,$$

and

$$\sup_{0<\lambda\le a} \sqrt{\lambda}\, |g_\alpha(\lambda)| \le \frac{\gamma_*}{\sqrt{\alpha}}, \quad 0 < \alpha \le a. \tag{2.1}$$

The regularization g_α is said to have qualification *ρ, for an increasing function $\rho : (0, a] \to \mathbb{R}_+$, if $\sup_{0<\lambda\le a} |1 - \lambda g_\alpha(\lambda)|\, \rho(\lambda) \le \gamma\rho(\alpha), 0 < \alpha \le a$.*

Remark 1. The above notion of qualification extends the usual one, where the functions ρ are restricted to monomials $\rho(t) := t^\mu$ for $0 < \mu < \infty$. The analysis of regularization methods in this general framework was carried out in [6]. The results of that study are not a prerequisite for the present discussion, but the ideas also rely on geometric concepts.

The main objective in this study is *saturation*, which is made precise as follows.

DEFINITION 2.2. *A family g_α, $0 < \alpha \le a$, is said to have* saturation *ψ, for a certain function $\psi: [0, a] \to \mathbb{R}_+$, if for all $0 \ne x \in X$ there are $\delta(x) > 0$ and a constant $c := c(x) > 0$ such that $\inf_{0<\alpha\le a} \frac{e(x,g_\alpha,\delta)}{\psi(\delta)} \ge c$ for $0 < \delta \le \delta(x)$.*

Remark 2. The above notion is consistent with and formalizes the usual approach. For instance, Theorem 3.1 in [8] may be rephrased as follows: The rate of Tikhonov regularization cannot exceed $\delta^{2/3}$ as $\delta \to 0$, regardless of the choice of regularization parameter and regardless of the actual smoothness of $x \ne 0$.

We shall reprove this result within a general framework.

The main result in this study is as follows.

THEOREM 2.3. *Suppose regularization $\alpha \to g_\alpha$ is chosen such that*

(i) *for some $c > 0$ the following lower bound is valid:*

$$\sup_{0<\lambda\le a} \sqrt{\lambda}\, |g_\alpha(\lambda)| \ge \frac{c}{\sqrt{\alpha}}, \quad 0 < \alpha \le a; \tag{2.2}$$

(ii) *for some increasing function ρ, the regularization has* maximal qualification *ρ; i.e., for all $0 < \lambda \le a$ there is $c := c(\lambda) > 0$ for which*

$$\inf_{0<\alpha\le a} \frac{|1-\lambda g_\alpha(\lambda)|}{\rho(\alpha)} \ge c; \tag{2.3}$$

(iii) *for all $0 < \alpha \le a$ the functions*

$$\lambda \longrightarrow |1-\lambda g_\alpha(\lambda)|^2, \quad 0 < \lambda \le a, \tag{2.4}$$

are convex.

Let $\Theta(t) := \sqrt{t}\rho(t), t > 0$. Then g_α has saturation $\rho\circ\Theta^{-1}$; i.e., there is $c > 0$ for which $\inf_{0<\alpha\le a} \frac{e(x,g_\alpha,\delta)}{\rho(\Theta^{-1}(\delta))} \ge c\|x\|$.

Let us comment on the assumptions. The bound in (2.2) serves as a normalization for the choice of the regularization parameter α and is related to (2.1).

The second assumption (2.3) is related to the qualification. Assumption (2.4) in [7] is a similar condition for the case of saturation of power type.

However, to prove saturation in [7], this assumption has to be accompanied by an additional set ((2.5)–(2.9)) of technical ones. In this paper we clearly indicate a geometric assumption (2.4), which seems to be responsible for saturation.

Last, the function Θ from above actually controls the best possible accuracy under the a priori smoothness assumption related to ρ. So, if the regularization has qualification ρ and the actual smoothness is just or not covered by ρ, then $\delta \to \rho(\Theta^{-1}(\delta))$ yields the best possible accuracy; see [6] for details.

Finally, as seen from the proof, the constant c in the saturation bound depends on x only through the quotient $\|Ax\|/\|x\|$.

The proof is based on the following two lemmas.

LEMMA 2.4. *Let $\rho\colon (0,a] \to \mathbb{R}_+$ be any increasing function. For all $0 < \alpha, \delta \le a$ we have*

$$\max\left\{\rho(\alpha), \delta/\sqrt{\alpha}\right\} \ge \rho(\Theta^{-1}(\delta)). \tag{2.5}$$

Proof. By assumption, the function Θ is increasing, and $\lim_{t\to 0}\Theta(t) = 0$. Therefore, we may let $\beta := \Theta^{-1}(\delta)$. Then (2.5) can be rewritten as

$$\max\left\{\rho(\alpha), \sqrt{\beta/\alpha}\rho(\beta)\right\} \ge \rho(\beta).$$

The latter inequality can easily be verified by distinguishing the two cases $\alpha \le \beta$ and $\alpha > \beta$. ∎

LEMMA 2.5 (Peierls–Bogolyubov [1, Problem IX.8.14]). *Suppose $\varphi : [0,a] \to \mathbb{R}_+$ is bounded measurable such that φ^2 is convex. Then $\|x\|\varphi(\frac{\|Ax\|^2}{\|x\|^2}) \le \|\varphi(A^*A)x\|$.*

Proof. The operator A^*A admits a spectral family $(E_\lambda)_{\lambda\in(0,a]}$ for which

$$\|Ax\|^2 = \langle A^*Ax, x\rangle = \int \lambda d\langle E_\lambda x, x\rangle, \quad x \in X.$$

Because $\int d\langle E_\lambda x, x\rangle = \|x\|^2$ we can use Jensen's inequality to conclude that

$$\begin{aligned}\varphi^2\left(\frac{\|Ax\|^2}{\|x\|^2}\right) &= \varphi^2\left(\frac{1}{\|x\|^2}\int \lambda d\langle E_\lambda x, x\rangle\right)\\ &\le \frac{1}{\|x\|^2}\int \varphi^2(\lambda) d\langle E_\lambda x, x\rangle = \frac{\|\varphi(A^*A)x\|^2}{\|x\|^2}.\end{aligned}$$

The proof is complete. ∎

Remark 3. We note that the above inequality is a special case of an interpolation type inequality, which was established in [4]. For more details we refer the reader to [5].

We are now ready to prove Theorem 2.3.

Proof. For each fixed α and δ we consider the function $\bar{e}\colon X \times Y \to \mathbb{R}_+$, given by

$$(x,\xi) \to \bar{e}(x, g_\alpha, \delta\xi) := \|(\mathrm{I} - g_\alpha(A^*A)A^*A)x - \delta g_\alpha(A^*A)A^*\xi\|. \tag{2.6}$$

Furthermore, we shall exploit the following fact: For any $x, y \in X$ it holds that $\max\{\|x+y\|, \|x-y\|\} \geq \|x\|$. By symmetry, for fixed x we have

$$e(x, g_\alpha, \delta) \geq \max\{\bar{e}(x, g_\alpha, \delta\xi), \bar{e}(x, g_\alpha, -\delta\xi)\} \geq \|(\mathrm{I} - g_\alpha(A^*A)A^*A)x\|.$$

Also, by similar reasoning, for fixed ξ

$$\max\{\bar{e}(x, g_\alpha, \delta\xi), \bar{e}(-x, g_\alpha, \delta\xi)\} \geq \delta\|g_\alpha(A^*A)A^*\xi\|.$$

Since

$$e(x, g_\alpha, \delta) \geq \max_{\|\xi\|\leq 1} \max\{\bar{e}(x, g_\alpha, \delta\xi), \bar{e}(-x, g_\alpha, \delta\xi)\},$$

we arrive at $e(x, g_\alpha, \delta) \geq \max\{\|(\mathrm{I} - g_\alpha(A^*A)A^*A)x\|, \delta\|g_\alpha(A^*A)A^*\colon Y \to X\|\}$. Using the convexity assumption for (2.4) and Lemma 2.5 we deduce with $\bar{\lambda} := \|Ax\|/\|x\|$ that

$$\|(\mathrm{I} - g_\alpha(A^*A)A^*A)x\| \geq \|x\| \left|1 - \bar{\lambda}^2 g_\alpha(\bar{\lambda}^2)\right|.$$

By assumption (2.3), we can find $c > 0$ for which

$$\|(\mathrm{I} - g_\alpha(A^*A)A^*A)x\| \geq c\|x\|\rho(\alpha).$$

Finally, assumption (2.2) allows us to determine $c'(x)$ for which

$$e(x, g_\alpha, \delta) \geq c'(x) \max\left\{\rho(\alpha), \delta/\sqrt{\alpha}\right\}.$$

Applying Lemma 2.4 allows us to complete the proof. ∎

It may not be clear from the very beginning whether ρ from (2.3) exists. This can be clarified under an additional monotonicity assumption. For this purpose it is convenient to introduce the function $r\colon (0,a] \times (0,a] \to \mathbb{R}$ as $r(\alpha,\lambda) := r_\alpha(\lambda) := 1 - \lambda g_\alpha(\lambda)$.

COROLLARY 2.6. *Let regularization g_α be chosen such that* (2.2) *is satisfied. If*

1. *for all α the function $\lambda \to |r_\alpha(\lambda)|^2$ is convex and*
2. *for all λ the function $\alpha \to |r_\alpha(\lambda)|$ is nondecreasing,*

then the function $\alpha \to \rho(\alpha) := \inf_{0<\lambda\leq a} |r_\alpha(\lambda)|$ is nondecreasing and obeys (2.3)*, with constant $c = 1$.*

Thus g_α has saturation at $\rho \circ \Theta^{-1}$, precisely, $e(x, g_\alpha, \delta) \geq \|x\|\rho(\Theta^{-1}(c\delta/\|x\|))$, with c from (2.2).

Proof. We need only to show that ρ is nondecreasing and obeys (2.3) with constant 1. Plainly, for $\alpha < \beta$ we have

$$\begin{aligned}\rho^2(\alpha) \leq \sup_{\xi\leq\beta} \rho^2(\xi) &= \sup_{\xi\leq\beta} \inf_{0<\lambda\leq a} |r_\xi(\lambda)|^2 \\ &\leq \inf_{0<\lambda\leq a} \sup_{\xi\leq\beta} |r_\xi(\lambda)|^2 = \inf_{0<\lambda\leq a} |r_\beta(\lambda)|^2 = \rho^2(\beta).\end{aligned}$$

Moreover, by construction, for all α, λ it holds that $|r_\alpha(\lambda)|/\rho(\alpha) \geq 1$, which allows us to complete the proof. ∎

3. Examples. We close our investigation with several examples. It is easy to see that Examples 1–3 below also obey the assumptions made in Corollary 2.6.

Example 1. Tikhonov regularization $g_\alpha(\lambda) := 1/(\alpha+\lambda)$ obeys the assumptions of the theorem with $\rho(\alpha) = \alpha$. Therefore, for each $x \neq 0$ it holds that $e(x, g_\alpha, \delta) \geq c\delta^{2/3}$, as $\delta \to 0$.

Example 2. n-fold iterated Tikhonov regularization, corresponding to

$$g_\alpha^n(\lambda) := 1/\lambda \left(1 - \left(\frac{\alpha}{\alpha+\lambda}\right)^n\right),$$

allows us to apply the theorem with $\rho(\alpha) = \alpha^n$, since for each λ there is $c'(\lambda)$, where

$$\left(\frac{\alpha}{\alpha+\lambda^2}\right)^n \geq c'\alpha^n.$$

Thus it has maximal qualification $\rho(\alpha) = \alpha^n$, and hence saturation at $\psi(\delta) := \delta^{2n/(2n+1)}$.

It is interesting to see that regularization with infinite qualification in the classical sense may have saturation. We exhibit this in the following example.

Example 3. Landweber iteration $g_\alpha(\lambda) := 1/\lambda \left(1 - (1-\mu\lambda)^{1/\alpha}\right)$, where $\mu < 1/a$ and $1/\alpha \geq 1$, corresponding to the number of iterations greater than or equal to 1, has maximal qualification $\rho_\kappa(\alpha) := \exp(-\kappa/\alpha)$ for some positive κ. Therefore, it can be seen that it has saturation at $\psi(\delta) := \delta(\log(1/\delta))^{1/2\kappa}$.

This example shows that even powerful regularization still may not allow us to regularize very mildly ill-posed problems properly.

If there is no maximal qualification, then the saturation phenomenon need not occur.

Example 4. The spectral cut-off, which is defined as

$$g_\alpha(\lambda) := \begin{cases} 1/\lambda, & \alpha \leq \lambda \leq a, \\ 0, & 0 < \lambda < \alpha, \end{cases}$$

has arbitrary qualification. More specifically, $|1 - \lambda g_\alpha(\lambda)| = 0$, provided that $\alpha < \lambda$. Therefore, there is no maximal qualification in the sense of (2.3). Also, the convexity assumption for (2.4) is violated. Thus, if, for example, the element x has a finite expansion in $u_1, u_2, \ldots$, say of length n, then the spectral cut-off has error of the order δ, which clearly is best possible, if only $\delta \leq s_n$ and $\alpha = a$. This can be seen using the representation of the error as presented in (2.6). We refer the reader to [6] for more details on the behavior of the spectral cut-off.

Acknowledgments. I thank Sergei V. Pereverzev, Kiev, for stimulating discussions on this subject and for reading the manuscript.

Furthermore, I thank an anonymous referee for pointing out the paper [7].

HIGH-ORDER STRONG-STABILITY-PRESERVING RUNGE–KUTTA METHODS WITH DOWNWIND-BIASED SPATIAL DISCRETIZATIONS*

STEVEN J. RUUTH† AND RAYMOND J. SPITERI‡

Abstract. Strong-stability-preserving Runge–Kutta (SSPRK) methods are a specific type of time discretization method that have been widely used for the time evolution of hyperbolic partial differential equations (PDEs). Under a suitable stepsize restriction, these methods share a desirable nonlinear stability property with the underlying PDE, e.g., stability with respect to total variation, the maximum norm, or other convex functionals. This is of particular interest when the solution exhibits shock-like or other nonsmooth behavior. Many results are known for SSPRK methods with nonnegative coefficients. However, it has recently been shown that such methods cannot exist with order greater than 4. In this paper, we give a systematic treatment of explicit SSPRK methods with general (i.e., possibly negative) coefficients up to order 5. In particular, we show how to optimally treat negative coefficients (corresponding to a change in the upwind direction of the spatial discretization) in the context of *effective CFL coefficient* maximization and provide proofs of optimality of some explicit SSPRK methods of orders 1 to 4. We also give the first known explicit fifth-order SSPRK schemes and show their effectiveness in practice versus more well-known fifth-order explicit Runge–Kutta schemes.

Key words. downwinding, strong stability preserving, total variation diminishing, Runge–Kutta methods, high-order accuracy, time discretization

1. Introduction.

Solutions to hyperbolic partial differential equations (PDEs) are commonly approximated by sequentially discretizing the spatial and temporal derivatives. For example, in the method of lines, a discretization of the spatial derivatives of the PDE is carried out to produce a large set of coupled time-dependent ordinary differential equations (ODEs). These ODEs can then be treated by suitable time-stepping techniques such as linear multistep or Runge–Kutta methods.

In the numerical solution of hyperbolic PDEs, difficulties may arise due to the presence of shock waves or other discontinuous behavior. In particular, the numerical solution to such problems often suffers from spurious oscillations or overshoots. This usually represents unphysical behavior, and it is almost always desirable to use a numerical method that suppresses it. One of the first families of such schemes were called *total variation diminishing* (TVD); see [22, 21]. Following more recent work [4], we refer to them as *strong stability preserving* (SSP).

In particular, we are interested in the development, analysis, and optimization of SSP Runge–Kutta (SSPRK) time-stepping methods for the hyperbolic conservation law

$$u_t + f(u)_x = 0 \tag{1.1}$$

subject to appropriate initial conditions. When a SSPRK method with nonnegative coefficients is used it is convenient to consider a semidiscretization of (1.1) in space to yield a large coupled set of ODEs:

$$\dot{U} = F(U). \tag{1.2}$$

More generally, following [22, 21, 3, 4], upwind-biased ($F(U)$) and downwind-biased ($\tilde{F}(U)$) spatial discretizations may be applied in some combination to achieve favorable nonlinear stability properties for a given time-stepping scheme. For simplicity we refer to upwind-biased and downwind-biased spatial discretizations as upwind and downwind spatial discretizations, respectively.

Optimal explicit SSPRK schemes with nonnegative coefficients and where the number of stages s is equal to the order p for $s = p = 1, 2$, and 3 have been known for some time. Gottlieb and Shu [3] showed that no such method exists with nonnegative coefficients when $s = p = 4$. In [25], Spiteri and Ruuth proposed a new class of explicit SSPRK methods with nonnegative coefficients with $s > p$. They gave optimal explicit SSPRK schemes with s stages and orders 1 and 2 (see also [21, 3]), as well as specific schemes for $p = 3$, $s = 4, 5$ and $p = 4$, $s = 5$. The advantage afforded by these high-stage schemes is that the increase in the CFL coefficient allows for a large enough increase in the stable time step to more than offset the increase in computational cost per step. However, in [20] they showed that it was impossible to have an explicit SSPRK method with order greater than 4 with nonnegative coefficients. In this paper, we give a unified treatment of all explicit SSPRK schemes with positive and/or negative coefficients of up to order 5 in terms of the effective CFL coefficient. We find that many of the optimal explicit SSPRK methods under the constraint of nonnegative coefficients are also optimal in terms of the effective CFL coefficient when negative coefficients are allowed. We also present the first fifth-order explicit SSPRK methods.

We remark that explicit fifth-order SSP *multistep* schemes have been successfully constructed [21, 13, 4]. The most efficient scheme of this type that explicitly appears in the literature [21] is

$$\begin{aligned} U^{n+1} = {} & \frac{7}{20}U^n + \frac{3}{10}U^{n-1} + \frac{4}{15}U^{n-2} + \frac{7}{120}U^{n-4} + \frac{1}{40}U^{n-5} + \frac{291201}{108000}F(U^n) \\ & - \frac{198401}{86400}\tilde{F}(U^{n-1}) + \frac{88063}{43200}F(U^{n-2}) - \frac{17969}{43200}\tilde{F}(U^{n-4}) + \frac{73061}{432000}F(U^{n-5}). \end{aligned} \tag{1.3}$$

This six-step scheme involves evaluations of both upwind and downwind operators and has an effective CFL coefficient of 0.065. In this paper we construct explicit SSPRK methods with up to a 325% improvement in the effective CFL coefficient over this scheme. Comparable gains are also shown to arise in practice.

We further note that in this paper we deal with explicit Runge–Kutta methods where the number of stages s can be substantially larger than the order p. These methods are optimized with respect to the effective CFL coefficient, which is a theoretical measure of the stepsize restriction required for nonlinear stability. Although perhaps similar at first glance, this is not in general related to maximizing the area of the (linear) stability region of a Runge–Kutta method; see [3] for a counterexample. For work on the optimization of the linear stability regions of explicit Runge–Kutta methods, we refer the reader to [15] and the references therein.

The remainder of the paper is organized as follows. In section 2 we review some relevant results on SSP schemes as well as define important concepts such as the effective CFL coefficient. In sections 3 and 4 we use analytical as well as numerical techniques to find explicit SSPRK methods up to order 5 with optimal effective CFL coefficients. In section 5 we show the efficiency of the new optimized fifth-order explicit SSPRK methods versus the optimal fifth-order multistep method (1.3) and a commonly used fifth-order explicit Runge–Kutta method. Finally, in section 6 we conclude by summarizing the main findings of the paper.

2. Background on SSP schemes. In this section we give some theoretical background on SSPRK schemes. We begin by recalling the definition of strong stability.

DEFINITION 2.1. *A sequence* $\{U^n\}$ *is said to be* strongly stable *in a given seminorm* $||\cdot||$ *if* $||U^{n+1}|| \le ||U^n||$ *for all* $n \ge 0$.

Strong stability turns out to have an interesting relationship to the more classical concept of *contractivity* (see, e.g., [23, 7, 8]). In this case for equations (1.2) satisfying a one-sided Lipschitz condition, we have that the distance between all exact solutions starting from different initial conditions is nonincreasing in time. It is reasonable to then require the same property of the numerical solution; i.e., $||\tilde{U}^{n+1} - U^{n+1}|| \le ||\tilde{U}^n - U^n||$ for all $n \ge 1$. In classical stability analysis, $\tilde{U}^n$ is usually assumed to be a perturbation of U^n. It is interesting that many of the optimal SSP schemes found in [25] agree with optimal contractive schemes in [8]. In fact, recent work by Ferracina and Spijker [2] for schemes with positive coefficients shows that the stepsize coefficient C (see below) for strong stability is equivalent to the related quantity $R(A, b)$ [8] arising in contractivity studies.

To begin our analysis, assume that upwind spatial discretizations are appropriate, and consider an s-stage, explicit Runge–Kutta method written in the form

$$U^{(0)} = U^n, \tag{2.1a}$$

$$U^{(i)} = \sum_{k=0}^{i-1} (\alpha_{ik} U^{(k)} + \Delta t \beta_{ik} F(U^{(k)})), \qquad i = 1, 2, \ldots, s, \tag{2.1b}$$

$$U^{n+1} = U^{(s)}, \tag{2.1c}$$

where all the $\alpha_{ik} \ge 0$ and $\alpha_{ik} = 0$ only if $\beta_{ik} = 0$ [21].

For consistency, we must have that $\sum_{k=0}^{i-1} \alpha_{ik} = 1$, $i = 1, 2, \ldots, s$. Hence, if both sets of coefficients α_{ik}, β_{ik} are nonnegative, then (2.1) is a convex combination of forward Euler steps with various step sizes $\frac{\beta_{ik}}{\alpha_{ik}} \Delta t$. The strong stability property follows easily from this observation.

The Runge–Kutta scheme (2.1) is not written in standard Butcher array form; however, the representation (2.1) maps uniquely to a Butcher array. On the other hand, written in this form, it is particularly convenient to make use of the following result [22, 4].

THEOREM 2.2. *If the forward Euler method is strongly stable under the CFL restriction* $\Delta t \le \Delta t_{FE}$, *then the Runge–Kutta method* (2.1) *with* $\beta_{ik} \ge 0$ *is SSP, provided*

$$\Delta t \le C \Delta t_{FE},$$

where C *is the CFL coefficient*

$$C \equiv \min_{i,k} \frac{\alpha_{ik}}{\beta_{ik}}.$$

SSPRK schemes with negative coefficients β_{ik} are also possible with the appropriate interpretation. Following the procedure first suggested in [21], whenever $\beta_{ik} < 0$, the operator $\tilde{F}(\cdot)$ is used instead of $F(\cdot)$, where $\tilde{F}(\cdot)$ approximates the same derivatives as $F(\cdot)$ but is assumed to be strongly stable for Euler's method solved *backwards* in time under a suitable time-step restriction. In practice, this corresponds to a change in upwinding direction or, in other words, *downwinding*. This allows the following generalization of Theorem 2.2.

THEOREM 2.3. *Let Euler's method applied forward in time combined with the spatial discretization $F(\cdot)$ be strongly stable under the CFL restriction $\Delta t \le \Delta t_{FE}$. Let Euler's method applied backwards in time combined with the spatial discretization $\tilde{F}(\cdot)$ also be strongly stable under the same CFL restriction $\Delta t \le \Delta t_{FE}$. Then the Runge–Kutta method* (2.1) *is SSP, provided*

$$\Delta t \le C \Delta t_{FE},$$

where C is the CFL coefficient

$$C \equiv \min_{i,k} \frac{\alpha_{ik}}{|\beta_{ik}|}, \tag{2.2}$$

where $\beta_{ik} F(\cdot)$ is replaced by $\beta_{ik} \tilde{F}(\cdot)$ whenever β_{ik} is negative.

We note that the assumptions on strong stability of Euler's method applied forward and backwards in time restrict the theoretical advantages of this result to nondissipative equations such as (1.1).

Irreducible explicit Runge–Kutta methods have one (new) function evaluation per stage. We note that if every coefficient β_{ik} is positive, then the number of stages is trivially equal to the number of function evaluations. However, if both $F(U^{(k)})$ and $\tilde{F}(U^{(k)})$ are required for some k, the Runge–Kutta method (2.1) has more function evaluations[1] than stages. So the first step in creating a fair comparison of the computational cost of a given Runge–Kutta method and in deriving optimal schemes is to consider general methods that allow only one (new) function evaluation per stage. A necessary and sufficient condition for this is that the nonzero coefficients β_{ik} for a given k are all of the same sign. To see this, let $\mathcal{K}_-$ be the set of levels k such that all $\beta_{ik} \le 0$, and we consider

$$\begin{aligned} U^{(0)} &= U^n, \\ U^{(i)} &= \sum_{k=0}^{i-1} \alpha_{ik} U^{(k)} + \Delta t \begin{cases} \beta_{ik} \tilde{F}(U^{(k)})), & k \in \mathcal{K}_-, \\ \beta_{ik} F(U^{(k)})) & \text{otherwise}, \end{cases} \qquad i = 1, 2, \ldots, s-1, \\ U^{n+1} &= U^{(s)}. \end{aligned} \tag{2.3}$$

For the remainder of the paper, we will tacitly assume that the schemes under consideration are of this form. Naturally, schemes that are written combining positive and negative coefficients β_{ik} within a given level k can be augmented with additional stages to be of this form. Thus, without loss of generality, we have that the total

[1]The only difference between $\tilde{F}(\cdot)$ and $F(\cdot)$ is a change in the upwind direction; so $\tilde{F}(\cdot)$ can clearly be computed with the same cost as $F(\cdot)$ [4]. Indeed, recent studies make the assumption that if both $\tilde{F}(U^{(k)})$ and $F(U^{(k)})$ must be computed for some k, the cost, as well as the storage requirements for that k, doubles [3, 4, 25, 17]; i.e., each is given equal weight.

number of evaluations of $F(\cdot)$ and $\tilde{F}(\cdot)$ is identically equal to the number of stages of the method.

We note that this formulation allows one to search for the optimal scheme for a given order and a *given number of stages* (function evaluations). This is a more appropriate description of what should be optimized than has been considered in the literature thus far. For example, searching for the scheme with the largest CFL coefficient (or even effective CFL coefficient, see below) *for a given order* results in the number of stages tending to infinity.

Another advantage to this formulation is that schemes can be represented and implemented in Butcher array form using (3.6) since differences of the form $F(U^{(i)}) - \tilde{F}(U^{(i)})$ do not arise; i.e., the method can be implemented as

$$K_i = \begin{cases} F\left(U^n + \Delta t \sum_{j=1}^{i-1} a_{ij} K_j\right) & \text{if } b_i \geq 0, \\ \tilde{F}\left(U^n + \Delta t \sum_{j=1}^{i-1} a_{ij} K_j\right) & \text{otherwise,} \end{cases} \qquad i = 1, 2, \ldots, s,$$

$$U^{n+1} = U^n + \Delta t \sum_{i=1}^{s} b_i K_i.$$

This form is often desirable for implementing fifth-order schemes because the storage requirements can be reduced. We further remark that the differences $F(U^{(i)}) - \tilde{F}(U^{(i)})$ contribute to artificial dissipation and smearing. For example, this difference is proportional to the discrete Laplacian when first-order upwinding is applied to the linear advection equation. A natural consequence of our formulation is that during optimization these dissipative differences do not arise, leading to schemes with smaller errors and less smearing than would otherwise occur.

In section 5, we compare the computational efficiencies of various Runge–Kutta methods. In order to make a fair comparison of the relative efficiencies of these methods and to derive optimal schemes we make the following definition.

DEFINITION 2.4. *The* effective CFL coefficient C_{eff} *of an SSPRK method is* C/s*, where* C *is the CFL coefficient of the method and* s *is the number of stages (function evaluations) required for one step of the method.*

As conjectured in Shu and Osher [22] and subsequently proven in Gottlieb and Shu [3], the optimal two-stage, order-two explicit SSPRK scheme with nonnegative coefficients is the modified Euler scheme:

$$\begin{aligned} U^{(1)} &= U^n + \Delta t F(U^n), \\ U^{n+1} &= \frac{1}{2} U^n + \frac{1}{2} U^{(1)} + \frac{1}{2} \Delta t F(U^{(1)}). \end{aligned}$$

It has a CFL restriction $\Delta t \leq \Delta t_{FE}$, which implies a CFL coefficient of 1. Henceforth, we will refer to this scheme as SSP(2,2). In general, we adopt the convention of referring to the best (in terms of effective CFL coefficient) known s-stage, order-p explicit SSPRK scheme as SSP(s,p), where s is equal to the total number of function evaluations of $F(\cdot)$ and $\tilde{F}(\cdot)$. In [25] a class of s-stage, order-two explicit SSPRK schemes was given and proved to be optimal with a CFL coefficient of $s - 1$.

Shu and Osher [22] also conjectured that the optimal three-stage, order-three explicit SSPRK scheme with nonnegative coefficients is

$$\begin{aligned} U^{(1)} &= U^n + \Delta t F(U^n), \\ U^{(2)} &= \frac{3}{4}U^n + \frac{1}{4}U^{(1)} + \frac{1}{4}\Delta t F(U^{(1)}), \\ U^{n+1} &= \frac{1}{3}U^n + \frac{2}{3}U^{(2)} + \frac{2}{3}\Delta t F(U^{(2)}), \end{aligned}$$

which has a CFL coefficient of 1 as well. The optimality of this scheme was later proved by Gottlieb and Shu [3]. This scheme is commonly called the *third-order TVD Runge–Kutta scheme*, but we will refer to it as SSP(3,3).

In [20], Ruuth and Spiteri derived a linear bound that can be used to prove that the optimal four-stage, order-three explicit SSPRK scheme with nonnegative coefficients is

$$\begin{aligned} U^{(1)} &= U^n + \frac{1}{2}\Delta t F(U^n), \\ U^{(2)} &= U^{(1)} + \frac{1}{2}\Delta t F(U^{(1)}), \\ U^{(3)} &= \frac{2}{3}U^n + \frac{1}{3}U^{(2)} + \frac{1}{6}\Delta t F(U^{(2)}), \\ U^{n+1} &= U^{(3)} + \frac{1}{2}\Delta t F(U^{(3)}), \end{aligned}$$

which has a CFL coefficient of 2. This observation appears in [25]. Following [25] we will refer to this scheme as SSP(4,3).

Moving on to methods with five stages and order 3 gives a numerically optimized scheme, SSP(5,3), with a CFL coefficient of approximately 2.65. It can be proven that this is also the optimal explicit SSPRK scheme with five stages and order 3 via the following line of reasoning. The CFL coefficient C of SSP(5,3) is equal to the *radius of absolute monotonicity* $R(A, b)$ for linear constant-coefficient problems [7]. Because $C \leq R(A, b)$ [2] and C (and $R(A, b)$) for nonlinear problems cannot exceed that for linear problems, we conclude that SSP(5,3) is the optimal five-stage, third-order explicit SSPRK scheme. A similar line of reasoning can be applied to prove the optimality of SSP(3,3), SSP(4,3), as well as the first- and second-order SSP schemes. Indeed, we have produced schemes of the form SSP(s,3), $s \leq 9$, with CFL coefficients equal to $R(A, b)$ for linear constant-coefficient problems; hence they are also optimal SSP schemes for nonlinear problems. It is worth mentioning, however, that this approach does not seem to be useful for proving the optimality of schemes of order greater than 3.

The main advantage offered by these high-stage schemes is that the additional computational cost incurred per step is more than offset by the increase in stable step size. For example, SSP(4,3) costs 33% more than SSP(3,3) but offers a 100% larger CFL coefficient. Thus for SSP(4,3), $C_{\text{eff}} = 2/4 = 1/2$, whereas for SSP(3,3), $C_{\text{eff}} = 1/3$. This translates into a $(1/2 - 1/3)/1/3 = 50\%$ increase in computational efficiency.

In [3], Gottlieb and Shu proved that it is impossible to have an explicit SSPRK method of order 4 in four stages having only nonnegative coefficients.[2] In section 3.3

[2]We remark that a proof that it is also impossible to have a fourth-order explicit Runge–Kutta method with four stages and $R(A, b) > 0$ appeared earlier and independently of this [8].

we prove the stronger result that it is in fact impossible to obtain an explicit SSPRK method of order 4 with any four (general) function evaluations. In [25] a five-stage, order-four explicit SSPRK scheme with nonnegative coefficients is given. It turns out that this scheme coincides with Kraaijevanger's optimal five-stage, order-four contractive scheme [8, 2]. A further study of explicit SSPRK methods of order 4 and $s = 6, 7, 8$ stages can be found in [24]. For the examples investigated in that paper, it was found that the increased stage number did lead to noteworthy improvements in practical performance. It is also worth mentioning that these high-stage schemes have modest storage requirements.

In [20] it is shown that explicit SSPRK schemes with nonnegative coefficients do not exist with order greater than 4. A similar restriction to orders 4 or less was proven for contractive schemes [8]. This means that the search for explicit schemes of order 5 and higher must involve evaluations of the downwinded operator $\tilde{F}(\cdot)$. In the remainder of the paper we present a unified treatment of explicit SSPRK schemes that use both upwinded and downwinded operators in terms of the effective CFL coefficient and prove the optimality of several lower-order schemes.

In section 4 we give the first fifth-order explicit SSPRK methods, optimized in terms of the effective CFL coefficient. A fifth-order explicit SSPRK method in the form (2.1) was thought to have been found in [22], based on a fifth-order explicit Runge–Kutta scheme on page 143 of [9], which was in turn based on a particular choice from a family of fifth-order explicit Runge–Kutta schemes that appeared in [12]. The family of schemes in question is described by the Butcher tableau

$$
\begin{array}{c|cccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\gamma & \gamma & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{4} & \frac{1}{4} - \frac{1}{32}\gamma^{-1} & \frac{1}{32}\gamma^{-1} & 0 & 0 & 0 & 0 \\
\frac{1}{2} & \frac{1}{2} - 32\sigma - \frac{1}{8}\frac{1-64\sigma}{\gamma} & \frac{1}{8}\frac{1-64\sigma}{\gamma} & 32\sigma & 0 & 0 & 0 \\
\frac{3}{4} & -\frac{9}{16} + 24\sigma - \frac{6\sigma-\frac{3}{16}}{\gamma} & \frac{6\sigma-\frac{3}{16}}{\gamma} & \frac{3}{4} - 24\sigma & \frac{9}{16} & 0 & 0 \\
1 & \frac{11}{7} - \frac{384}{7}\sigma - \frac{1}{7}\frac{\frac{7}{2}-96\sigma}{\gamma} & \frac{1}{7}\frac{\frac{7}{2}-96\sigma}{\gamma} & \frac{384}{7}\sigma & -\frac{12}{7} & \frac{8}{7} & 0 \\
\hline
 & \frac{7}{90} & 0 & \frac{16}{45} & \frac{2}{15} & \frac{16}{45} & \frac{7}{90}
\end{array}
\tag{2.4}
$$

Unfortunately, although this family of explicit Runge–Kutta schemes (2.4) is indeed fifth order, there is an error in the particular member of this family upon which the reported fifth-order explicit SSPRK method was based. This proposed scheme has coefficient matrix A given by

$$
A = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{2} & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{8} & \frac{1}{8} & 0 & 0 & 0 & 0 \\
0 & 0 & \frac{1}{2} & 0 & 0 & 0 \\
0 & -\frac{3}{16} & \frac{3}{8} & \frac{9}{16} & 0 & 0 \\
\frac{1}{7} & \frac{4}{7} & \frac{6}{7} & -\frac{12}{7} & \frac{8}{7} & 0
\end{bmatrix}.
$$

This scheme was meant to correspond to the particular choice of $\sigma = \frac{1}{64}$ and (arbitrary) $\gamma = \frac{1}{2}$. However, it is easily verified that this scheme does not belong to the

family of explicit fifth-order schemes (2.4), differing in the coefficients a_{31} and a_{32}. In fact it is only *second order*; e.g., it is easily seen that the third-order condition $b^T Ac = \frac{1}{6}$ is not satisfied.

3. Optimal SSPRK methods. In this section we prove some optimality results in terms of the effective CFL number for some low-order explicit SSPRK methods ($p = 1, 2, 3$). Optimal schemes for high-order methods ($p = 4, 5$) are determined numerically. We begin by describing the form of the optimization problem solved in all cases. We then prove some existence and optimality results for some explicit SSPRK methods of up to order 4. Section 4 contains some numerical results for the first explicit SSPRK methods of order 5.

3.1. Formulation of the optimization problem. We seek to optimize an s-stage, order-p explicit SSPRK scheme by maximizing its effective CFL coefficient according to Theorem 2.3. That is, we seek the global maximum of the nonlinear programming problem

$$\max_{(\alpha_{ik},\beta_{ik})} \min \frac{\alpha_{ik}}{|\beta_{ik}|}, \tag{3.1}$$

where $\alpha_{ik},\ \beta_{ik},\ k = 0, 1, \ldots, i-1,\ i = 1, 2, \ldots, s$, are real and $0 \le \alpha_{ik} \le 1$. As noted in section 2, we insist that for each k and $i = k+1, k+2, \ldots, s$ that $\beta_{ik} \ge 0$ or $\beta_{ik} \le 0$ to ensure that the number of function evaluations corresponds to the number of stages. The case $\alpha_{ik} = \beta_{ik} = 0$ is defined as `NaN` in the sense that it is not included in the minimization process if it occurs. The objective function (3.1) is also subject to the constraints

$$\sum_{k=0}^{i-1} \alpha_{ik} = 1, \qquad i = 1, 2, \ldots, s, \tag{3.2}$$

$$\sum_{j=1}^{s} b_j \Phi_j(t) = \frac{1}{\gamma(t)}, \quad t \in T_q, \quad q = 1, 2, \ldots, p. \tag{3.3}$$

Here the functions $\Phi_j(t)$ are nonlinear constraints that are polynomial in $\alpha_{ik},\ \beta_{ik}$ and that correspond to the order conditions for a Runge–Kutta method to be of order p (see, e.g., [5]); i.e., T_q stands for the set of all rooted trees of order equal to q. The number of constraints represented by the Runge–Kutta order conditions is equal to

$$\sum_{q=1}^{p} \mathrm{card}(T_q),$$

where $\mathrm{card}(T_q)$ is the cardinality of T_q. Also, we use the notation b_j in the usual sense of the Butcher array representation of a Runge–Kutta method; again this would be a polynomial function of the coefficients α_{ik} and β_{ik}. It can be expected that the particular choice of coefficients $\alpha_{ik},\ \beta_{ik}$ that maximizes the quantity (2.2) for a given Runge–Kutta method will be naturally produced by the solution to this nonlinear programming problem; hence the result will be a sharp estimate of the CFL coefficient.

However, this formulation of the nonlinear programming problem does not lend itself easily to numerical solution; see [25] for further discussion. By introducing a

dummy variable z, the nonlinear programming problem can be reformulated as

$$\max_{(\alpha_{ik},\beta_{ik})} z \tag{3.4a}$$

subject to

$$\alpha_{ik} \geq 0, \tag{3.4b}$$

$$\beta_{k+1,k}, \beta_{k+2,k}, \ldots, \beta_{sk} \geq 0, \tag{3.4c}$$

$$\text{or} \quad \beta_{k+1,k}, \beta_{k+2,k}, \ldots, \beta_{sk} \leq 0, \quad k = 0, \ldots, s-1,$$

$$\sum_{k=0}^{i-1} \alpha_{ik} = 1, \qquad i = 1, 2, \ldots, s, \tag{3.4d}$$

$$\sum_{j=1}^{s} b_j \Phi_j(t) = \frac{1}{\gamma(t)}, \quad t \in T_q, \quad q = 1, 2, \ldots, p, \tag{3.4e}$$

$$\alpha_{ik} - z|\beta_{ik}| \geq 0, \quad k = 0, 1, \ldots, i-1, \ i = 1, 2, \ldots, s. \tag{3.4f}$$

Numerical optimization software may be applied to the reformulated problem (3.4) for various combinations of s and p. In our initial approach we considered using Matlab's Optimization Toolbox but found that it was nontrivial to determine an initial guess to start the nonlinear iteration. Subsequent efforts focused on BARON [26], a deterministic, global optimization software package that uses algorithms of the branch-and-bound type. This approach was found to be superior to Matlab's Optimization Toolbox in the sense that it is faster, gives improved optima, and satisfies active constraints to 15 decimal digits.

In each of the cases $s = 7, 8, 9$ numerically optimal fifth-order SSPRK schemes were found in less than 90 minutes on a (shared) cluster of 96 dual 1.2 GHz Athlon processors with BARON. See [19] for further details on applying BARON to the optimization of SSPRK schemes.

3.2. Optimality of some low-order methods. We now give new results on optimal effective CFL coefficients for some low-order explicit SSPRK methods. Previous results primarily focus on optimizing raw CFL coefficients for methods with nonnegative coefficients. Here we give existence and optimality results in the context of effective CFL coefficients for methods with no sign restriction on their coefficients.

THEOREM 3.1. *For $s = 1, 2, 3, \ldots$, the optimal s-stage explicit SSPRK method of order 1 has effective CFL coefficient 1 and can be represented in the form of SSP$(s, 1)$; i.e.,*

$$\alpha_{ik} = \begin{cases} 1, & k = i-1, \\ 0 & \textit{otherwise}, \end{cases} \qquad \beta_{ik} = \begin{cases} \frac{1}{s}, & k = i-1, \\ 0 & \textit{otherwise}, \end{cases} \qquad i = 1, 2, \ldots, s.$$

Before giving the proof of Theorem 3.1, we introduce the following notation and give two useful lemmas. We find it convenient to write the general s-stage explicit Runge–Kutta method in the following form (cf. [3]):

$$U^{(0)} = U^n, \tag{3.5a}$$

$$U^{(i)} = U^{(0)} + \Delta t \sum_{k=0}^{i-1} \kappa_{ik} \begin{cases} F(U^{(k)}) & \text{if } \kappa_{ik} \geq 0, \\ \tilde{F}(U^{(k)}) & \text{otherwise}, \end{cases} \qquad i = 1, 2, \ldots, s, \tag{3.5b}$$

$$U^{n+1} = U^{(s)}. \tag{3.5c}$$

Using the fact that the β_{ik} at a particular level are all of the same sign, the coefficients κ_{ik} are related to the coefficients $\alpha_{ik},\ \beta_{ik}$ recursively by

$$\kappa_{ik} = \beta_{ik} + \sum_{j=k+1}^{i-1} \alpha_{ij}\kappa_{jk}. \tag{3.6}$$

We remark that the coefficients κ_{ik} can be related to the Butcher array quantities $a_{ik},\ b_k$ by

$$\begin{aligned} a_{ik} &= \kappa_{i-1,k-1}, \qquad k = 1, 2, \ldots, i-1, \quad i = 1, 2, \ldots, s-1, \\ b_k &= \kappa_{s,k-1}, \qquad k = 1, 2, \ldots, s. \end{aligned}$$

It is also important to note that $\operatorname{sgn}(\kappa_{ik}) = \operatorname{sgn}(\beta_{ik})$, motivating the use of (3.5).

LEMMA 3.2. *If a method of the form* (2.1) *with* $\alpha_{ik} \geq 0$ *has a CFL coefficient* $c \geq m > 0$, *then* $0 \leq |\kappa_{ik}| \leq \frac{1}{m}$ *for all* $k = 0, 1, \ldots, i-1,\ i = 1, 2, \ldots, s$.

Proof. From Theorem 2.3, if $c \geq m > 0$, then $\alpha_{ik} \geq m|\beta_{ik}|$ or, equivalently, $|\beta_{ik}| \leq \frac{1}{m}\,\alpha_{ik}$ for all $i,\ k$ such that $\alpha_{ik} \neq 0$.

Now

$$\alpha_{ik} \geq 0, \quad \sum_{k=0}^{i-1} \alpha_{ik} = 1, \quad i = 1, 2, \ldots, s, \quad \Rightarrow \quad \alpha_{ik} \leq 1$$

for all $i,\ k$. Hence, $|\beta_{ik}| \leq \frac{1}{m}$ for all $i,\ k$. In particular, $|\kappa_{10}| = |\beta_{10}| \leq \frac{1}{m}$ for any valid explicit SSPRK method.

We now proceed by induction on stage ℓ of an s-stage method. Assume $|\kappa_{ij}| \leq \frac{1}{m}$ for $j = 0, 1, \ldots, \ell-1;\ i = 1, 2, \ldots, \ell$. (We have just shown that this result holds for $\ell = 1$.) Now consider stage $(\ell+1)$ of a valid explicit SSPRK method; i.e., consider coefficients $\kappa_{\ell+1,k}$ for $k = 0, 1, \ldots, \ell$ with

$$\sum_{k=0}^{\ell} \alpha_{\ell+1,k} = 1.$$

Then, using (3.6),

$$\begin{aligned} |\kappa_{\ell+1,0}| &= \left| \sum_{k=1}^{\ell} \alpha_{\ell+1,k}\kappa_{k0} + \beta_{\ell+1,0} \right| \\ &\leq \sum_{k=1}^{\ell} \alpha_{\ell+1,k}|\kappa_{k0}| + |\beta_{\ell+1,0}| \\ &\leq \frac{1}{m} \sum_{k=1}^{\ell} \alpha_{\ell+1,k} + \frac{1}{m}\,\alpha_{\ell+1,0} \\ &= \frac{1}{m}\,. \end{aligned}$$

Similar arguments can be used to show $|\kappa_{\ell+1,j}| \leq \frac{1}{m}$ for $j = 1, 2, \ldots, \ell$. The lemma now follows by induction. ∎

LEMMA 3.3. *Suppose a consistent s-stage explicit SSPRK method* (2.1) *has coefficients* $\beta_{ik} \le 0$ *at* ℓ *distinct stages; i.e.,* $\beta_{ik} \le 0$ *for all* i *and* $k = k_1, k_2, \ldots, k_\ell$ *with* $0 \le k_1 < k_2 < \cdots < k_\ell \le s-1$. *Then the CFL coefficient* C *of the method satisfies* $C \le s - \ell$.

Proof. Because the method is consistent, we have

$$\sum_{k=0}^{s-1} \kappa_{sk} = 1. \tag{3.7}$$

But by the definition of κ_{ik} it is clear that $\kappa_{sk_1}, \kappa_{sk_2}, \ldots, \kappa_{sk_\ell} \le 0$. Thus

$$\sum_{\substack{k=0 \\ k \ne k_1, k_2, \ldots, k_\ell}}^{s-1} \kappa_{sk} \ge 1. \tag{3.8}$$

The desired result $C \le s - \ell$ now follows immediately from applying Lemma 3.2 to (3.8). ∎

Proof of Theorem 3.1. For nonnegative coefficients $\{\beta_{ik}\}$ the result for the raw CFL coefficient has been shown in [25]. By Lemma 3.3, a method containing any $\beta_{ik} < 0$ must have a CFL coefficient $C \le s - 1 < s$, and thus we must have $C_{\text{eff}} < 1$. This completes the proof. ∎

Remark 1. As noted in [25], despite the increase in the raw CFL coefficient, these first-order methods do not offer a theoretical computational advantage.

THEOREM 3.4. *For* $s = 2, 3, 4, \ldots$, *the optimal s-stage explicit SSPRK method of order* 2 *has effective CFL coefficient* $\frac{s-1}{s}$ *and can be represented in the form of SSP*$(s, 2)$*; i.e.,*

$$\alpha_{ik} = \begin{cases} 1, & k = i-1, \\ 0 & \text{otherwise}, \end{cases} \qquad \beta_{ik} = \begin{cases} \frac{1}{s-1}, & k = i-1, \\ 0 & \text{otherwise}, \end{cases} \qquad i = 1, 2, \ldots, s-1,$$

$$\alpha_{ik} = \begin{cases} \frac{1}{s}, & k = 0, \\ \frac{s-1}{s}, & k = s-1, \\ 0 & \text{otherwise}, \end{cases} \qquad \beta_{ik} = \begin{cases} \frac{1}{s}, & k = s-1, \\ 0 & \text{otherwise}, \end{cases} \qquad i = s.$$

Proof. For nonnegative coefficients $\{\beta_{ik}\}$ the result for the raw CFL coefficient has been shown in [25]. By Lemma 3.3, any consistent, s-stage method with some $\beta_{ik} < 0$ must have a CFL coefficient $C \le s - 1$, and thus we must have $C_{\text{eff}} \le \frac{s-1}{s}$. This completes the proof. ∎

Remark 2. As noted in [25], in this case the theoretical increase in the raw CFL coefficient more than offsets the increased work per step, leading to an overall computational advantage with increasing s. However, the effective CFL coefficient is bounded above by 1.

We now give some specific optimality results for methods of order 3.

THEOREM 3.5. *The optimal three-stage explicit SSPRK method of order* 3 *has effective CFL coefficient* $C_{\text{eff}} = 1/3$, *and an optimal representation is given by SSP*(3,3).

Proof. For nonnegative coefficients $\{\beta_{ik}\}$ the result for the raw CFL coefficient has been shown in [3].

Now suppose we allow $\beta_{ik} < 0$ in an attempt to improve the CFL coefficient. From the third-order condition $b^T Ac = 1/6$, we have $\beta_{10}\beta_{21}\beta_{32} = 1/6 > 0$; so the scheme must have $\beta_{ik} \leq 0$ at exactly two levels. But then we may apply Lemma 3.3 to show that $C \leq 1$, and hence its $C_{\text{eff}} \leq 1/3$. ∎

THEOREM 3.6. *The optimal four-stage explicit SSPRK method of order* 3 *has effective CFL coefficient* $C_{\text{eff}} = 2/3$*, and an optimal representation is given by SSP*(4,3).

Proof. For nonnegative coefficients $\{\beta_{ik}\}$ the result for the raw CFL coefficient has been shown in [25]. By Lemma 3.3 it is clear that $C \leq 2$ if the $\beta_{ik} \leq 0$ at two or more levels. So the only possibility for an improvement in the CFL coefficient over SSP(4,3) is if $\beta_{ik} \leq 0$ at precisely one level. But then by the third-order condition $b^T Ac = 1/6$, one of the following must hold:

$$\begin{aligned}
\kappa_{43}\kappa_{32}\kappa_{21} &\geq 1/6,\\
\kappa_{43}\kappa_{32}\kappa_{20} &\geq 1/6,\\
\kappa_{43}\kappa_{31}\kappa_{10} &\geq 1/6,\\
\kappa_{42}\kappa_{21}\kappa_{10} &\geq 1/6.
\end{aligned}$$

Supposing that the CFL coefficient is greater than 2 in any of these statements leads to a condition of the form $\kappa_{4i}\kappa_{ij}\kappa_{jk} \leq 1/8$, $i = 2, 3$, $1 \leq j \leq i-1$, $0 \leq k \leq j-1$, by Lemma 3.2 and gives rise to a contradiction. Hence the optimal scheme must be SSP(4,3). ∎

3.3. A fourth-order result. In this section we demonstrate that, even allowing negative coefficients β_{ik}, there is no four-stage explicit SSPRK method of order 4. We begin with a lemma.

LEMMA 3.7. *If* $s = p$*, the* β_{ik} *at a particular level* k*, for some* $0 \leq k \leq s-1$*,* $k+1 \leq i \leq s$*, are all of the same sign, i.e.,* $\beta_{ik}\beta_{jk} \geq 0$ *for* $k+1 \leq i, j \leq s$*, and the CFL coefficient is positive, then* $\kappa_{ik} \neq 0$ *for* $k+1 \leq i \leq s$*.*

Proof. From the order conditions, we have $\prod_{i=1}^{p} \beta_{i,i-1} = \frac{1}{p!}$; so each $\beta_{i,i-1} \neq 0, 1 \leq i \leq s$. Since the CFL coefficient is positive, this implies each $\alpha_{i,i-1} > 0, 1 \leq i \leq s$. Expanding κ_{ij} in terms of the α and β coefficients (see, e.g., [3]) it is easily seen that $|\kappa_{ij}| \geq |\beta_{j+1,j} \prod_{k=j+1}^{i-1} \alpha_{k+1,k}| > 0$, proving our result. ∎

We note that Lemma 3.7 is only relevant for $s = p = 1, 2, 3, 4$.[3] In this section, we will, of course, be interested specifically in the case with $s = p = 4$.

In proving the main result of this section, we will make extensive use of the following lemma, which follows immediately from Lemma 3.7 and the definition of the κ_{ij}.

LEMMA 3.8. *If* $s = p$*, the* β_{ik} *at a particular level* k*, for some* $0 \leq k \leq s-1$*,* $k+1 \leq i \leq s$*, are all of the same sign, and the CFL coefficient is positive, then* $\kappa_{ik}, k+1 \leq i \leq s$ *are also all of that same sign and are nonzero.*

We now give the main result of this section.

THEOREM 3.9. *There is no four-stage explicit SSPRK method of order* 4 *with a positive CFL coefficient.*

Proof. General case. We proceed by contradiction. If two parameters u and v are such that $u \neq v$, $u \neq 0$, $u \neq 1/2$, $u \neq 1$, $v \neq 0$, $v \neq 1$, and $6uv - 4(u+v) + 3 \neq 0$,

[3] It is possible to have schemes with $s = p > 4$ for linear, constant-coefficient problems.

then the coefficients $\kappa_{ik} \neq 0$ may be written as functions of u and v [18]:

$$\begin{aligned}
\kappa_{10} &= u, \\
\kappa_{20} &= v - \kappa_{21}, \\
\kappa_{21} &= \frac{v(v-u)}{2u(1-2u)}, \\
\kappa_{30} &= 1 - \kappa_{31} - \kappa_{32}, \\
\kappa_{31} &= \frac{(1-u)[u+v-1-(2v-1)^2]}{2u(v-u)[6uv-4(u+v)+3]}, \\
\kappa_{32} &= \frac{(1-2u)(1-u)(1-v)}{v(v-u)[6uv-4(u+v)+3]}, \\
\kappa_{40} &= \frac{1}{2} + \frac{1-2(u+v)}{12uv}, \\
\kappa_{41} &= \frac{2v-1}{12u(v-u)(1-u)}, \\
\kappa_{42} &= \frac{1-2u}{12v(v-u)(1-v)}, \\
\kappa_{43} &= \frac{1}{2} + \frac{2(u+v)-3}{12(1-u)(1-v)}.
\end{aligned}$$

Similar to [3], there are five possibilities to consider:

1. $u < 0$. If $v < 0$, then $\kappa_{10}\kappa_{40} < 0$. Conversely, if $v > 0$, then $\kappa_{10}\kappa_{20} < 0$. Both results contradict Lemma 3.8.
2. $0 < u < \frac{1}{2}$ and $v < u$.
   $\kappa_{21}\kappa_{41} > 0$ implies that $v < 0$. But this implies $\kappa_{10}\kappa_{20} < 0$, contradicting Lemma 3.8.
3. $0 < u < \frac{1}{2}$ and $v > u$.
   $\kappa_{21}\kappa_{41} > 0$ requires $v > \frac{1}{2}$. $\kappa_{20} > 0$ requires $v < 3u - 4u^2 \leq \frac{9}{16}$. $\kappa_{32}\kappa_{42} > 0$ and $\kappa_{31}\kappa_{41} > 0$ require $u > 2 - 5v + 4v^2$. Since this is a decreasing function of v for $v \leq \frac{9}{16}$, we obtain $u > 2 - 5(3u - 4u^2) + 4(3u - 4u^2)^2$. Rearranging, we find that $0 > 2((2u-1)^2 + 4u^2)(2u-1)^2$, which is impossible.
4. $u > \frac{1}{2}$ and $v < u$. We can only have $\kappa_{32}\kappa_{42} > 0$ in one of two ways:
   (a) $1 - u > 0$ and $6uv - 4(u+v) + 3 > 0$.
   $\kappa_{21}\kappa_{41} > 0$ requires $0 < v < \frac{1}{2}$. Simple calculation yields

$$\kappa_{30} = \frac{(2 - 6u + 4u^2) + (-5 + 15u - 12u^2)v + (4 - 12u + 12u^2)v^2}{2uv(6uv - 4(u+v) + 3)};$$

   hence $\kappa_{30} > 0$ requires

$$\begin{aligned}
A + Bv + Cv^2 \equiv (2 - 6u + 4u^2) \\
&+ (-5 + 15u - 12u^2)v \\
&+ (4 - 12u + 12u^2)v^2 > 0.
\end{aligned}$$

   It is easy to show that when $\frac{1}{2} < u < 1$ we have $A < 0, B < 0$, and

$C > 0$. Thus for $0 < v < \frac{1}{2}$ we have

$$A + Bv + Cv^2 < \max\left(A, A + \frac{1}{2}B + \frac{1}{4}C\right)$$
$$= \max\left(A, \frac{1}{2}(1-2u)(1-u)\right) < 0,$$

resulting in a contradiction.

(b) $1 - u < 0$ and $6uv - 4(u+v) + 3 < 0$.
Suppose $v < 0$. Then $\kappa_{10}\kappa_{20} > 0$ implies $v < -u(4u-3) < -u$, and $\kappa_{21}\kappa_{31} > 0$ implies $u + v - 1 - (2v-1)^2 > 0$. Together these yield a contradiction.
Now suppose $v > 0$. $\kappa_{21}\kappa_{41} > 0$ implies $v > \frac{1}{2}$. $\kappa_{31}\kappa_{41} > 0$ requires $u + v - 1 - (2v-1)^2 < 0$, which implies

$$(1-4v)(1-v) = 4v^2 - 5v + 1 > u - 1 > 0.$$

Given the restrictions on v, this is true only if $v < \frac{1}{4}$, contradicting the requirement that $v > \frac{1}{2}$.

5. $u > \frac{1}{2}$ and $v > u$. $\kappa_{21}\kappa_{41} > 0$ requires $u > 1$. This implies $\kappa_{42} > 0$; so by Lemma 3.8, $\kappa_{32} > 0$. It is now easily seen that $\kappa_{10} > 0$, $\kappa_{21} < 0$, and $\kappa_{43} > 0$. Thus $\kappa_{10}\kappa_{21}\kappa_{32}\kappa_{43} < 0$, contradicting the fourth-order condition $\kappa_{10}\kappa_{21}\kappa_{32}\kappa_{43} = \frac{1}{4!}$.

If $6uv - 4(u+v) + 3 = 0$, $u = 0$, or $v = 0$, then this method is not fourth order [18].

Special cases. There remain three special cases [18, 5].

1. $u = \frac{1}{2},\ v = 0$; $\kappa_{42} = w \neq 0,\ \kappa_{40} = \frac{1}{6} - w,\ \kappa_{41} = \frac{2}{3}$, and $\kappa_{43} = \frac{1}{6}$.
2. $u = v = \frac{1}{2}$; $\kappa_{40} = \frac{1}{6},\ \kappa_{42} = w \neq 0,\ \kappa_{41} = \frac{2}{3} - w$, and $\kappa_{43} = \frac{1}{6}$.
3. $u = 1,\ v = \frac{1}{2}$; $\kappa_{43} = w \neq 0,\ \kappa_{41} = \frac{1}{6} - w,\ \kappa_{40} = \frac{1}{6}$, and $\kappa_{42} = \frac{2}{3}$.

In these cases, κ_{32} is obtained from

$$\kappa_{43}\kappa_{32} = \kappa_{42}(1-v).$$

The remaining coefficients κ_{21} and κ_{31} are then the solutions to the (nonsingular) linear system

$$\kappa_{42}\kappa_{21}uv + \kappa_{43}(\kappa_{31}u + \kappa_{32}v) = \frac{1}{8},$$
$$\kappa_{42}\kappa_{21} + \kappa_{43}\kappa_{31} = \kappa_{41}(1-u).$$

It is easily verified that in each case the κ_{ik} fail to have the same sign at each level whenever negative β_{ik} are considered. ∎

4. Fifth-order explicit SSPRK methods. In this section, we give the results of the numerical optimization procedure outlined in section 3. Examples of optimal explicit SSPRK methods of order 4 and up to eight stages with positive coefficients appear in [24]. We have also constructed optimal explicit SSPRK methods of order 3 and up to nine stages. Here we design the first optimized fifth-order explicit SSPRK methods. No formal proofs of optimality are given; however, the methods described here are the results of extensive numerical testing. We now give the coefficients of the Butcher tableaus for SSP(7,5), SSP(8,5), and SSP(9,5) in Tables 1–3, respectively. The Butcher tableau format is provided because this is the more advantageous format for implementation.

5. Numerical studies. In this section, we study the numerical behavior of our fifth-order schemes and the optimal known fifth-order SSP multistep method (1.3) for a few test problems designed to capture solution features that pose particular difficulties to numerical methods. Our focus here is to illustrate the stability behavior of various fifth-order schemes rather than to provide a detailed accuracy study. If a study of the relative error constants was desired it would be more appropriate to consider systems where the spatial discretization errors are dominated by the time-stepping error. Experiments using the standard implementation of Fehlberg's fifth-order explicit Runge–Kutta method [5] are also included because this method is commonly used in method-of-lines discretizations of hyperbolic conservation laws. We remark that Fehlberg's scheme does not have a positive CFL coefficient in its standard implementation (using only $F(\cdot)$) because SSP methods of order greater than 4 require evaluations of $\tilde{F}(\cdot)$ [20].

We remark that tests using the popular Dormand–Prince scheme [5] gave results very similar to Fehlberg's scheme. For clarity, we do not include these simulations in our plotted results.

5.1. Test problems. There are a variety of solution features in computational fluid dynamics that commonly cause numerical problems. For example, many numerical methods produce significant errors near sonic points (points where the wavespeed equals zero). Upwind methods, in particular, are forced to give sonic points special consideration since the upwind direction changes at sonic points. Shock waves, contact discontinuities, and expansion fans may also lead to a variety of serious problems,

including oscillations, overshoots, and smearing that can spread discontinuities over several cells. In particular, contact discontinuities do not have any physical compression, and thus smearing increases progressively with the number of time steps. Even when approximating smooth solutions, most numerical methods exhibit obvious flaws. For example, many stable numerical methods continuously erode the solution, leading to amplitude and dissipation errors [11].

To investigate the behavior of our time-stepping schemes, we consider three of Laney's five test problems [11]. These three problems involve all of the important flow features identified above: shocks, contacts, expansion fans, sonic points, and smooth solutions. Similar to Laney, we focus on the behavior of the numerical scheme for interior regions rather than boundaries and impose periodic boundary conditions on the domain $[-1,1]$. It is known that sometimes a conventional (and intuitive) treatment of the boundary data (especially in the case of inflow boundary conditions) within the stages of a Runge–Kutta method can lead to a deterioration in the overall accuracy of the integration. We refer the reader to [1] and the references therein for a discussion of this problem and a method for its resolution. The spatial discretization

and the results of three test cases follow.

5.2. Spatial discretization. Similar to [22, 25], we choose finite-difference Shu–Osher methods (ENO) to spatially discretize the equations. These methods are derived using flux reconstruction and have a variety of desirable properties. For example, they naturally extend to an arbitrary order of accuracy in space, and they are independent of the time discretization, thus allowing experimentation with different time discretization methods. Moreover, educational codes are also freely available [11, 10], an attribute which is desirable for standardizing numerical studies. Since we are focusing on fifth-order Runge–Kutta methods we carry out our simulations using a fifth-order spatial discretization. We further note that flux splitting is carried out according to

$$f^+(U) = \frac{1}{2}(f(U) + \alpha^n_{i+1/2}U),$$
$$f^-(U) = \frac{1}{2}(f(U) - \alpha^n_{i+1/2}U),$$

where $\alpha^n_{i+1/2} = \max\{|f'(U^n_{i+1})|, |f'(U^n_i)|\}$. To evaluate $\tilde{F}(\cdot)$ we simply negate the discretization that arises when we apply the Shu–Osher finite difference method to the PDE evolved *backwards in time*[4] (see [21] for further details on the procedure). For further details on the underlying discretization, as well as code for the spatial discretization, see [11, 10].

It is noteworthy that high-order, fully TVD spatial discretization schemes are also available; see Osher and Chakravarthy [16]. In these numerical studies, we choose Shu–Osher spatial discretization schemes rather than TVD schemes because TVD schemes only obtain between first- and second-order accuracy at extrema and they have "been largely superseded by Shu and Osher's class of high-order ENO methods" [11].

It is also noteworthy that recent variations on Shu–Osher methods such as methods based on WENO reconstructions (e.g., [14, 6]) also naturally combine with SSPRK schemes. See [11] for detailed discussions on these and other spatial discretizations appropriate for hyperbolic conservation laws.

5.3. Test case 1: Linear advection of a sinusoid. In this test case, the smooth initial conditions

$$u(x, 0) = -\sin(\pi x)$$

are evolved to time $t = 30$ according to the linear advection equation

$$\frac{\partial u}{\partial t} + \frac{\partial u}{\partial x} = 0$$

using a constant grid spacing of $\Delta x = 1/80$. Because this evolution causes the initial conditions to travel around the periodic domain $[-1, 1]$ exactly 15 times, it is clear that the exact solution is just $u(x, 30) = -\sin(\pi x)$. Test case 1 effectively illustrates the evolution of a smooth solution with no sonic points and is useful for verifying convergence rates for high-order schemes. Moreover, even on completely smooth solutions most numerical methods designed for hyperbolic conservation laws exhibit obvious flaws [11]. This test case is quite helpful for understanding phase and amplitude errors but should not be used to study dispersion because only one frequency is present in the exact solution. It is also informative to contrast these results with those derived for problems involving shocks and other discontinuities.

To quantify the accuracy of the computed solution, we use the logarithm of the l_1 errors, i.e.,

$$\log_{10}\left(\frac{1}{N}\sum_{i=1}^{N}|U_i - u(x_i, 30)|\right),$$

[4] To illustrate the procedure, consider a first-order spatial discretization of $\tilde{F}$ for Burgers's equation. To proceed we need to construct an upwind spatial discretization for Burgers's equation evolved backwards in time, i.e.,

$$u_t = uu_x.$$

Carrying out a first-order upwind discretization with a uniform discretization step size h gives $-\tilde{F}$:

$$-\tilde{F} = \begin{cases} U_j(U_{j+1} - U_j)/h & \text{if } U_j > 0, \\ U_j(U_j - U_{j-1})/h & \text{otherwise,} \end{cases}$$

from which $\tilde{F}$ is trivially obtained.

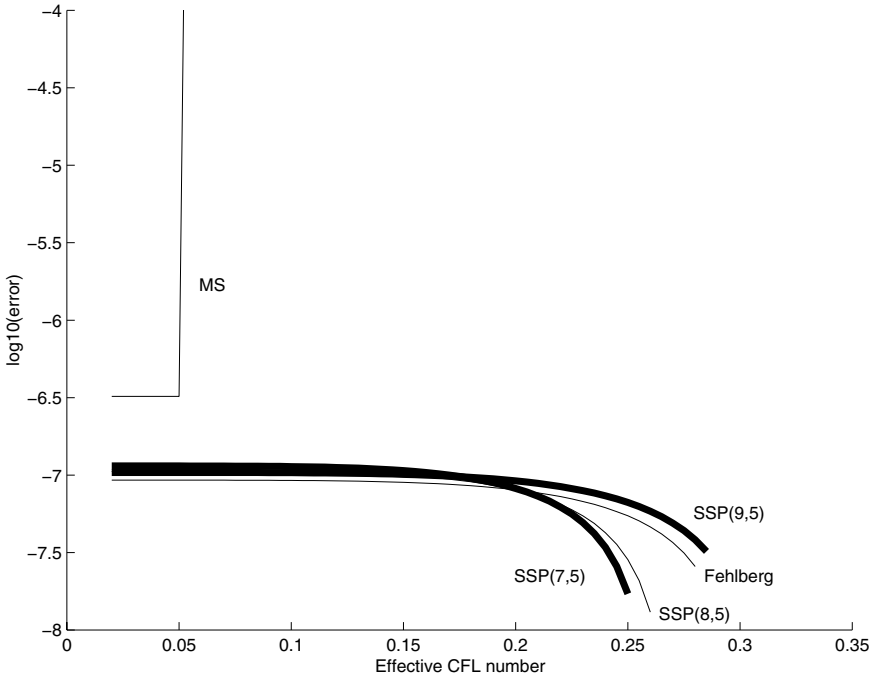

FIG. 1. l_1 *errors as a function of the effective CFL number for test case* 1.

where N is the number of grid points and x_i is the ith grid node. A plot of the error is given in Figure 1. To ensure a fair comparison for methods with a different number of stages, the error is plotted as a function of the effective CFL number[5] rather than the CFL number itself. This implies that for a particular plot the total number of function evaluations at a particular abscissa value will be the same for each scheme. We start calculating errors for an effective CFL number of 0.02 and continue until the numerical method is so unstable that a value of `NaN` is returned; i.e., the scheme has become completely unstable.

In this test example, the main conclusion is that Fehlberg's scheme and our new fifth-order explicit SSPRK schemes all outperform the multistep scheme (1.3) by more than 350%, with SSP(9,5) giving more than a 400% improvement. It is not surprising that Fehlberg's scheme performs well on this *smooth* problem because schemes based purely on a linear stability analysis are expected to perform well. SSP schemes are designed to outperform on problems involving discontinuities in the solution or its derivatives; so in this case there is no reason to expect that schemes derived using a nonlinear stability analysis will necessarily outperform classical schemes based on a linear stability analysis.

5.4. Test case 2: Linear advection of a square wave. In this test case, the discontinuous initial conditions

$$u(x,0) = \begin{cases} 1 & \text{for } |x| < 1/3, \\ 0 & \text{for } 1/3 < |x| \le 1 \end{cases}$$

[5]Similar to the definition of effective CFL coefficient, the *effective CFL number* of an SSPRK method is $\left(\frac{1}{s}\right)\frac{\Delta t}{\Delta x}$, where s is the number of stages required for one step of the method.

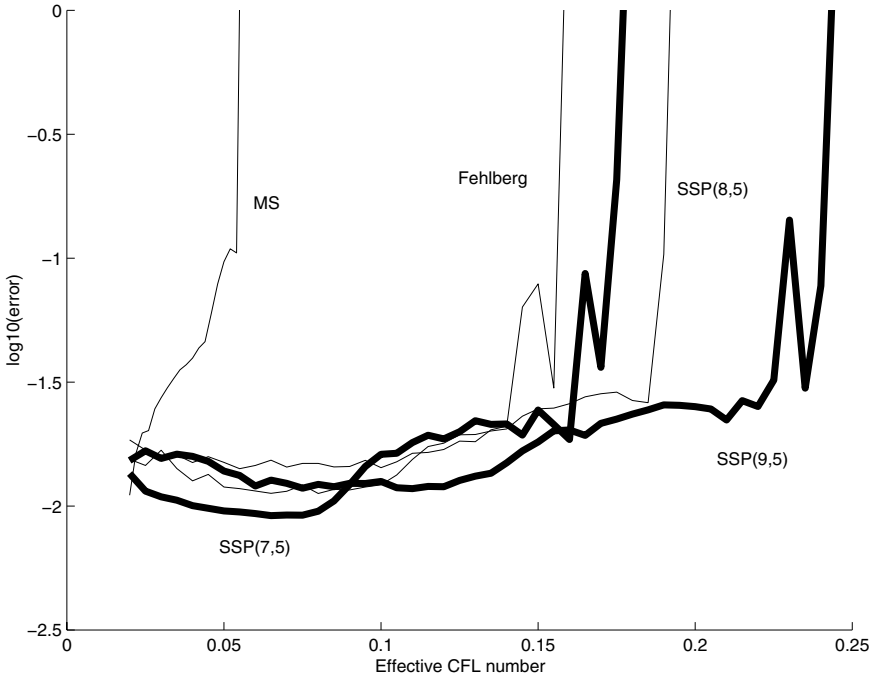

FIG. 2. l_1 *errors as a function of the effective CFL number for test case* 2.

are evolved to time $t = 4$ according to the linear advection equation

$$\frac{\partial u}{\partial t} + \frac{\partial u}{\partial x} = 0$$

using a constant grid spacing of $\Delta x = 1/320$. Because this evolution causes the initial conditions to travel around the periodic domain $[-1, 1]$ exactly two times, it is clear that the exact solution at the final time is just $u(x, 4) = u(x, 0)$. Test case 2 exhibits two jump discontinuities in the solution that correspond to contact discontinuities. This test case nicely illustrates progressive contact smearing and dispersion.

The log of the l_1 errors as a function of the effective CFL number are plotted in Figure 2. Based on these plots, it is immediately clear that a material improvement in stability is obtained using our new fifth-order SSPRK schemes. Indeed, our schemes all outperform the multistep scheme (1.3) by 200% or more, with SSP(9,5) giving a 340% improvement. We also find that our schemes significantly outperform Fehlberg's scheme on this nonsmooth test. In particular, SSP(9,5) gives a 40% improvement over Fehlberg's scheme.

5.5. Test case 3: Evolution of a square wave by Burgers's equation. In this test case, the discontinuous initial conditions

$$u(x, 0) = \begin{cases} 1 & \text{for } |x| < 1/3, \\ -1 & \text{for } 1/3 < |x| \le 1 \end{cases}$$

are evolved to time $t = 0.3$ according to Burgers's equation

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x}\left(\frac{1}{2}u^2\right) = 0$$

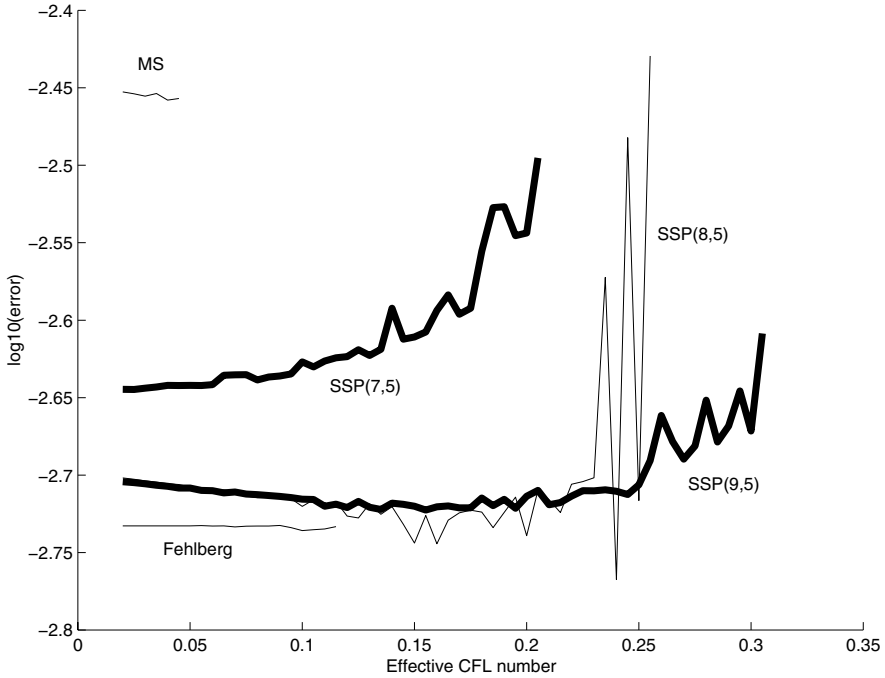

FIG. 3. l_1 *errors as a function of the effective CFL number for test case* 3.

using a constant grid spacing of $\Delta x = 1/320$. In this example, the jump at $x = -1/3$ creates a simple centered expansion fan, and the jump at $x = 1/3$ creates a steady shock. Until the shock and expansion fan intersect (at time $t = 2/3$), the exact solution is

$$u(x,t) = \begin{cases} -1 & \text{for } -\infty < x < b_1, \\ -1 + 2\frac{x-b_1}{b_2-b_1} & \text{for } b_1 < x < b_2, \\ 1 & \text{for } b_2 < x < b_{shock}, \\ -1 & \text{for } b_{shock} < x < \infty, \end{cases}$$

where $b_1 = -1/3 - t$, $b_2 = -1/3 + t$, and $b_{shock} = 1/3$ [11]. Test case 3 is particularly interesting because it illustrates the behaviors near sonic points ($u = 0$) that correspond to an expansion fan and a compressive shock.

The log of the l_1 errors as a function of the effective CFL number are plotted in Figure 3. In this nonlinear test case, we find a dramatic improvement for our new schemes over the multistep scheme (1.3). They all give more than a 350% improvement, with SSP(9,5) giving more than a 575% improvement. We also find that our schemes significantly outperform Fehlberg's scheme on this nonsmooth test. The SSP(9,5) scheme, in particular, gives more than a 150% improvement over Fehlberg's scheme.

6. Conclusions. We have studied high-order SSP explicit Runge–Kutta methods with downwind-biased spatial discretizations. We find that by requiring that the nonzero coefficients β_{ik} for a given k are all of the same sign we obtain a more appropriate description of what should be optimized. This leads to more efficient schemes with less smearing. When the order of the explicit Runge–Kutta method is less than or equal to 4 we prove in a variety of cases that there is no advantage in terms of the

effective CFL coefficient to using downwind-biased spatial discretizations. To achieve explicit SSPRK methods with fifth- or higher-order accuracy, however, downwind-biased discretizations are necessary. This paper provides the first examples of such schemes. We find that these new schemes are much more efficient than existing fifth-order explicit SSP multistep methods (both theoretically and in practice) and handily outperform classical explicit fifth-order schemes on nonsmooth problems. In particular, we found that in our marginally resolved test cases (involving shocks and contact discontinuities) larger time steps and improved efficiency were found as the effective CFL coefficient (and the number of stages) increased. In a well-resolved problem (test case 1), however, the practical performance of SSPRK schemes and classical Runge–Kutta schemes was very similar. This suggests that high-order SSPRK schemes with large effective CFL coefficients have the potential to provide high-order accuracy in smooth regions of the flow while still yielding large stable steps in marginally resolved regions. It is our hope that by providing numerically optimal schemes of this type we will stimulate further numerical studies and comparisons of SSPRK schemes against more classical approaches.

Acknowledgments. The authors thank J. Rusak for his help with the unconstrained global optimization. We also thank S. Gottlieb for interesting discussions on downwind-biased spatial discretizations.

CONTINUOUS M-ESTIMATORS AND THEIR INTERPOLATION BY POLYNOMIALS*

JONG-SHI PANG† AND THOMAS P.-Y. YU‡

Abstract. Replacing the *median* by a general *M-estimator*, we construct in this paper a host of variants of the robust nonlinear pyramid transforms proposed by Donoho and Yu [*SIAM J. Math. Anal.*, 31 (2000) pp. 1030–1061]. Some of these new variants are more amenable to numerical implementations with provable properties when compared to the Donoho–Yu median-based pyramid transforms. At the crux of this generalized construction is the following result: the inverse problem of interpolating a univariate polynomial of degree n with $n+1$ prescribed values for any given continuous M-estimator on $n+1$ nonoverlapping intervals is a well-posed procedure. While the proof of this result is nonconstructive, we study the use of Newton methods for constructing such a polynomial interpolant and report numerical results in some test cases.

1. Introduction.

Donoho and Yu introduced in [3] a family of nonlinear pyramid transforms of signals which is reminiscent of linear biorthogonal wavelet transforms but has the advantage of being robust against non-Gaussian noise. Underlying their construction are the concept of measuring the median values of a signal over intervals at multiple scales and the accurate prediction of fine-scale median values from coarse-scale ones based on polynomial interpolation. The latter polynomial interpolation procedure, shown to be well posed by Goodman and Yu using a nonconstructive argument [6], involves the solution of a *nonsmooth* system of equations for which no existing equation solvers are shown to be convergent.

Instead of directly attacking the computationally challenging median interpolation problem, we introduce in this paper a broad class of "continuous M-estimators" that include the continuous median as a special case. These M-estimators naturally lead to new classes of nonlinear pyramid transforms that extend the original family introduced by Donoho and Yu, which is based on the continuous median. Extending the result of Goodman and Yu, we demonstrate that the interpolation problem of the continuous M-estimators by polynomials is also well posed. With the use of a "smooth kernel," the latter interpolation problem is equivalent to solving a system of differentiable equations, which can be accomplished by, say, a stabilized Newton method that can be demonstrated to be globally and quadratically convergent. In turn, this implies that the pyramid transforms can be implemented using a broad class of robust statistics with the aid of a provably convergent Newton method.

In summary, the main contribution of our work is twofold: first, based on the class of continuous M-estimators, we have significantly broadened the original Donoho–Yu family of nonlinear pyramid transforms; more importantly, a large class of such transforms can be implemented by solving *smooth* systems of nonlinear equations by provably convergent numerical methods.

2. Continuous M-estimators. We begin with a brief review of the median value of a continuous function $f : \mathbb{R} \to \mathbb{R}$ on an interval I and the associated interpolation problem. Specifically, the latter value is defined as

$$\operatorname{med}(f|I) := \arg\min_{m\in\mathbb{R}} \int_I |\, f(t) - m \,|\, dt. \tag{2.1}$$

A key step in the Donoho–Yu proposal for accurately predicting fine-scale medians from coarse-scale ones [3] (see section 5 for more details) requires the inversion of the map

$$M : \Pi_n \to \mathbb{R}^{n+1}, \quad p \mapsto (\operatorname{med}(p|I_i))_{i=0}^n, \tag{2.2}$$

where I_i, $i = 0, \ldots, n$, are nonoverlapping intervals and Π_n is the $(n+1)$-dimensional vector space of polynomials of degree not exceeding n. While this nonlinear map is known to be a homeomorphism [6], implying that M^{-1} exists, computing $M^{-1}(a)$ for a given vector a is nevertheless not an easy task. In general, we have to resort to numerical methods. (In the case of $n = 2$, closed-form formulas for M^{-1} can be found in [3, section 2].) Newton's method applied to the system of nonlinear equations $M(p) = a$ is a prime candidate for this task. Nevertheless, since the map M is not everywhere differentiable, a classical Newton method for smooth systems (such as the ones in [2, 11]) is therefore not applicable. Although there exist provably convergent Newton methods for "semismooth" systems (see [5, Chapters 7 and 8] and the references therein), it is an open problem at this time whether M in (2.2) is semismooth in general.

Partly to broaden the continuous median and partly to alleviate the computational difficulty with inverting the nondifferentiable map M in (2.2), this paper introduces the class of continuous M-estimators defined with respect to triples (K, f, ρ) satisfying the following blanket specifications: (a) K is a solid, compact, connected set whose boundary, denoted ∂K, has measure zero; (b) f is a real-valued continuous function defined on K; and (c) $\rho : \mathbb{R} \to \mathbb{R}_+$ is a convex function with a unique minimizer at zero, and $\rho(0) = 0$. The solidness of K implies that its interior, denoted int K, is nonempty; hence K has positive measure. The convexity of ρ implies its continuity.

Corresponding to such a triple (K, f, ρ), we define the minimand $\theta(\cdot; K, f, \rho) : \mathbb{R} \to \mathbb{R}_+$ and the *continuous M-estimator* $m(f; K, \rho)$ as follows:

$$\begin{aligned} \theta(m; K, f, \rho) &:= \int_K \rho(f(x) - m)\, dx, \quad m \in \mathbb{R}, \\ m(f; K, \rho) &:= \arg\min_{m\in\mathbb{R}} \theta(m; K, f, \rho). \end{aligned}$$

When the pair (K, ρ) is clear from the context, we write $m(f)$ for $m(f; K, \rho)$. Implicit in the above definition of $m(f; K, \rho)$ is the assertion that this is a well-defined quantity (i.e., it exists and is unique); this will be justified in Theorem 2.2. Throughout the paper, we let $C(K)$ denote the set of continuous real-valued functions defined on K.

Before establishing properties of the continuous M-estimator, we give several choices of the convex function ρ. Among these choices all are continuously differentiable except the absolute value function and the third one, which are both piecewise linear. The nomenclature "continuous M-estimator" is coined as a generalization of the well-known robust Huber M-estimator [7], which is recovered from the fourth function.

1. $\rho(t) = |t|^p$ for $p \geq 1$. For $p = 1$, the resulting $m(f; K, \rho)$ is the continuous median of f on K:

$$\operatorname{med}(f|K) = \arg\min_m \int_K |f(x) - m| \, dx,$$

generalizing the case of an interval K. For $p = 2$, the resulting $m(f; K, \rho)$ is the average of f on K:

$$\operatorname{ave}(f|K) = \frac{1}{\operatorname{meas} K} \int_K f(x) \, dx,$$

where "meas" is the abbreviation of "measure."

2. $\rho_\varepsilon(t) = \sqrt{t^2 + \varepsilon^2} - \varepsilon$ for some $\varepsilon > 0$; this function ρ_ε is a strictly convex, C^∞ approximation to the absolute-value function $|\cdot|$. As we will prove in Proposition 4.4, $m(f; K, \rho_\varepsilon)$ converges to $\operatorname{med}(f|K)$ as $\varepsilon \downarrow 0$. Consequently, for $\varepsilon > 0$ sufficiently small, we expect $m(f; K, \rho_\varepsilon)$ to be as robust against outliers as the standard median. (A rigorous quantification of this claim is in the scope of robust statistics, which we will not get into in this paper.)

3. $\rho(t) = \alpha \max(t, 0) + (1 - \alpha) \max(-t, 0)$ for $\alpha \in (0, 1)$. The resulting $m(f; K, \rho)$ measures the continuous α-quantile of the function f over K, i.e., the unique value m, such that

$$\operatorname{meas}\{t \in K : f(t) \geq m\} \leq \alpha \operatorname{meas} K \quad \text{and} \quad \operatorname{meas}\{t \in K : f(t) \leq m\} \leq (1-\alpha)\operatorname{meas} K.$$

4. For a given $c > 0$,

$$\rho(t) = \begin{cases} \frac{1}{2} t^2 & \text{if } |t| \leq c, \\ c|t| - \frac{1}{2} c^2 & \text{if } |t| > c. \end{cases} \tag{2.3}$$

The resulting $m(f; K, \rho)$ is a continuous version of the Huber estimator for discrete empirical data.

2.1. Basic properties. We begin our study of the continuous M-estimator by stating the following result that summarizes several basic properties of the minimand $\theta(\cdot; K, f, \rho)$ and shows in particular that this function inherits many properties of ρ. In the proof of this and other results, we will freely use known properties of convex functions, which can all be found in the classic treatise by Rockafellar [10].

PROPOSITION 2.1. *Let the triple (K, f, ρ) satisfy the blanket assumptions. The following statements hold for the function $\theta := \theta(\cdot; K, \rho, f)$.*

(a) *θ is convex (thus continuous) and coercive on $\mathbb{R}$; coercivity means*

$$\lim_{|m| \to \infty} \theta(m) = \infty.$$

(b) *If ρ is strictly convex, then so is θ.*

(c) *The right and left derivatives of θ are equal to, respectively,*

$$\theta'_+(m) \;:=\; \lim_{h\to 0+} \frac{\varphi(t+h)-\varphi(t)}{h} \;=\; -\int_K \rho'_-(f(x)-m)\,dx,$$

$$\theta'_-(m) \;:=\; \lim_{h\to 0+} \frac{\varphi(t)-\varphi(t-h)}{h} \;=\; -\int_K \rho'_+(f(x)-m)\,dx.$$

(d) *If ρ is k-times continuously differentiable on $\mathbb{R}$ for some $k \geq 1$, then so is θ.*
(e) *If ρ is twice differentiable and $\rho''(t) > 0$ for all $t \in \mathbb{R}$, then so is θ.*
(f) *θ is differentiable at m if and only if the set Ω_m has measure zero, where*

$$\Omega_m := \{\, x \in K : \rho \text{ is not differentiable at } f(x)-m \,\}.$$

Proof. The convexity of θ follows from that of ρ; the coercivity of θ follows from the inequalities

$$\liminf_{|\,m\,|\to\infty} \frac{\theta(m)}{|\,m\,|} \;\geq\; \min(\,\rho(1),\rho(-1)\,) \liminf_{|m|\to\infty} \int_K \frac{|\,f(x)-m\,|}{|\,m\,|}\,dx \;>\; 0.$$

Since K has positive measure, (b) is obvious. To prove (c), let $h \in (0,1]$. We have

$$\frac{\theta(m+h)-\theta(m)}{h} \;=\; \int_K \left[\, \frac{\rho(f(x)-m-h)-\rho(f(x)-m)}{h} \,\right] dx.$$

Since $\rho'_-(t)$ exists for all t, by the compactness of K, it follows that for every $\varepsilon > 0$ there exists $\delta > 0$ such that for all $x \in K$ and all $h \in (0,\delta]$,

$$\left|\, \frac{\rho(f(x)-m-h)-\rho(f(x)-m)}{h} \,\right| \;\leq\; |\,\rho'_-(f(x)-m)\,| + \varepsilon.$$

Since the right-hand side, as a function of x, is clearly integrable on K, it follows by the dominated convergence theorem that

$$\theta'_+(m) \;=\; \int_K -\rho'_-(f(x)-m)\,dx.$$

Similarly, we can establish the desired formula for the left derivative of θ at m. The differentiability of θ in parts (d) and (e) can be proved easily. The positivity of θ'' in part (e) follows from the formula

$$\theta''(m) \;=\; \int_K \rho''(f(x)-m)\,dx. \tag{2.4}$$

Finally, it is clear that if the set Ω_m has measure zero, then

$$\theta'_+(m) \;=\; \theta'_-(m) \;=\; -\int_{\mathcal{D}_m} \rho'(f(x)-m)\,dx,$$

where $\mathcal{D}_m$ is the complement of Ω_m in K. Conversely, suppose that Ω_m has positive measure. Since the set of nondifferentiable points of ρ is countable, it follows that there must exist a $t_0 \in \mathbb{R}$ such that the set

$$\Lambda := \{\, x \in K : f(x)-m = t_0 \,\}$$

has positive measure. Since $\rho'_+(f(x)-m) \geq \rho'_-(f(x)-m)$ for all $x \in K$, it follows that

$$\int_K [\,\rho'_+(f(x)-m) - \rho'_-(f(x)-m)\,]\,dx \;\geq\; (\,\rho'_+(t_0) - \rho'_-(t_0)\,)\,\text{meas}\,\Lambda.$$

Since the right-hand side is positive, it follows that $\theta'_-(m) > \theta'_+(m)$; (f) therefore holds. □

The next result summarizes various properties of the continuous M-estimator $m(f;K,\rho)$. Part (a) asserts the well-definedness of this minimizer and gives its variational characterization; part (b) says that this minimizer must belong to the range $f(\text{int } K)$; part (c) is a technical property that will be used subsequently.

THEOREM 2.2. *Let (K,ρ,f) satisfy the blanket assumptions. The following statements are valid.*

(a) *$m(f;K,\rho)$ exists and is unique; it is the unique scalar $\bar{m}$ satisfying*

$$\int_K \rho'_+(f(x)-\bar{m})\,dx \;\geq\; 0 \;\geq\; \int_K \rho'_-(f(x)-\bar{m})\,dx.$$

(b) *There exists $\bar{x} \in \text{int } K$ such that $f(\bar{x}) = m(f;K,\rho)$.*

(c) *If $m(f) = \min f :=$ minimum value of f on K, then* meas $\{x \in K : f(x) = m(f) = \min f\} > 0$.

Proof. The existence of a global minimizer of $\theta(\cdot;K,\rho,f)$ follows from its convexity (and thus continuity) and its coercivity on $\mathbb{R}$. Moreover, such a global minimizer $\bar{m}$ is characterized by the inclusion $0 \in \partial\theta(\bar{m};K,\rho,f)$, with the latter subgradient equal to the interval

$$\left[-\int_K \rho'_+(f(x)-\bar{m})dx,\; -\int_K \rho'_-(f(x)-\bar{m})dx \right].$$

Thus, except for the uniqueness of the minimizer of $\theta(\cdot;K,\rho,f)$, (a) holds. By way of contradiction, we assume that no $\bar{x} \in \text{int } K$ exists satisfying $\bar{m} = f(\bar{x})$. The function $f(x) - \bar{m}$ then never vanishes on int K. Without loss of generality, we may assume that $f(x) - \bar{m}$ is positive on int K. By convexity of ρ, it follows that $\rho'_-(f(x)-\bar{m})$ is positive on int K, which implies

$$\int_K \rho'_-(f(x)-\bar{m})\,dx \;>\; 0$$

because ∂K has measure zero. The above inequality contradicts the variational characterization of $\bar{m}$. It remains to show the uniqueness of $m(f;K,\rho)$. Suppose there are two distinct minimizers m_1 and m_2. Since $\theta(\cdot;K,\rho,f)$ is convex, $\frac{1}{2}m_1 + \frac{1}{2}m_2$ is also a minimizer. Therefore,

$$\int_K \left[\,\rho(f(x) - m_1/2 - m_2/2) - \tfrac{1}{2}\,\rho(f(x)-m_1) - \tfrac{1}{2}\,\rho(f(x)-m_2)\,\right]\,dx \;=\; 0.$$

Since the integrand on the left-hand side is continuous and nonpositive, it follows that

$$\rho(f(x) - m_1/2 - m_2/2) \;=\; \tfrac{1}{2}\,\rho(f(x)-m_1) + \tfrac{1}{2}\,\rho(f(x)-m_2)$$

for all $x \in K$. By what has been proved above, it follows that there exist $x^1 \neq x^2$ in K such that $f(x^i) = m_i$ for $i = 1,2$. Hence, by the connectedness of K, there exists $x^* \in K$ such that

$$f(x^*) \;=\; \tfrac{1}{2}\,m_1 + \tfrac{1}{2}\,m_2.$$

Since ρ is a nonnegative function, we deduce $\rho(f(x^*) - m_1) = 0 = \rho(f(x^*) - m_2)$, which yields $f(x^*) = m_1 = m_2$, a contradiction. Finally, to prove (c), assume for contradiction that the measure of the set in question is zero. We then have

$$\int_K \rho'_-(f(x) - \min f)\, dx \;=\; \int_{K_+} \rho'_-(f(x) - \min f)\, dx,$$

where $K_+ := \{x \in K : f(x) > \min f = m(f)\}$. By assumption, meas $K_+ =$ meas $K > 0$. Since $\rho'_-(f(x) - \min f) > 0$ on K_+, it follows that

$$\int_K \rho'_-(f(x) - \min f)\, dx \;>\; 0,$$

which contradicts the characterization of $m(f)$ because $\min f = m(f)$ by assumption. □

It is clear that for any constant $c > 0$, $m(f + c) = m(f) + c$. The next result identifies an important monotonicity property of the continuous M-estimator.

THEOREM 2.3. *Let f and g be in $C(K)$ such that $f \geq g$ on K. It holds that $m(f) \geq m(g)$; moreover, strict inequality holds if either* (a) *$f \neq g$, ρ is differentiable, and ρ' is strictly increasing or* (b) *$f > g$ in the interior of K.*

Proof. Assume for contradiction that $m(f) < m(g)$. We have

$$\int_K \rho'_+(g(x) - m(g))\, dx \;\geq\; 0 \;\geq\; \int_K \rho'_-(f(x) - m(f))\, dx.$$

Since ρ'_- is nondecreasing, we deduce

$$\int_K \rho'_-(f(x) - m(f))\, dx \;\geq\; \int_K \rho'_-(g(x) - m(f))\, dx$$

and

$$\int_K \rho'_+(g(x) - m(f))\, dx \;\geq\; \int_K \rho'_+(g(x) - m(g))\, dx.$$

Consequently,

$$\int_K \rho'_+(g(x) - m(f))\, dx \;\geq\; 0 \;\geq\; \int_K \rho'_-(g(x) - m(f))\, dx.$$

By the variational characterization and uniqueness of $m(g)$, it follows that $m(f) = m(g)$, which is a contradiction. If ρ is differentiable, then $m(f)$ and $m(g)$ are the unique scalars m_f and m_g that satisfy the equations

$$\int_K \rho'(f(x) - m(f))\, dx \;=\; 0 \quad \text{and} \quad \int_K \rho'(g(x) - m(g))\, dx \;=\; 0,$$

respectively. If $f \neq g$, then there must exist an open set $\mathcal{O}$ contained in the interior of K such that $f(x) > g(x)$ for all $x \in \mathcal{O}$. If $m(f) = m(g)$, the above characterizations of $m(f)$ and $m(g)$ immediately yield a contradiction, using the fact that $f > g$ on the open set $\mathcal{O} \subset K$. Consequently, strict monotonicity of m (i.e., $m(f) > m(g)$) holds under (a).

Assume (b). Writing $\theta_f := \theta(\cdot; K, \rho, f)$ and $\theta_g := \theta(\cdot; K, \rho, g)$, we divide the remaining proof into six steps.

Step 1. Since $f > g$ in the interior of K, we must have

$$\text{meas}\,\{\,x \in K : g(x) > m(g)\,\} \le \text{meas}\,\{\,x \in K : f(x) > m(g)\,\};$$

the claim is that strict inequality also holds:

$$\text{meas}\,\{x \in K : g(x) > m(g)\} < \text{meas}\,\{x \in K : f(x) > m(g)\}. \tag{2.5}$$

To prove this assertion, we distinguish between two cases (i) $m(g) = \min g$ and (ii) $m(g) > \min g$.

Step 2. Assume that $m(g) = \min g$. Since $\{x \in \text{int } K : f(x) > m(g)\} = \text{int } K$ and meas $\partial K = 0$, it follows that

$$\begin{aligned}
&\text{meas}\,\{\,x \in K : f(x) > m(g)\,\}\\
&\quad = \text{meas}\,\{\,x \in \text{int } K : f(x) > m(g)\,\} = \text{meas int } K = \text{meas } K\\
&\quad = \text{meas}\,\{\,x \in K : g(x) = \min g = m(g)\,\} + \text{meas}\,\{\,x \in K : g(x) > m(g)\,\}\\
&\quad > \text{meas}\,\{\,x \in K : g(x) > m(g)\,\},
\end{aligned}$$

where the last inequality follows from Theorem 2.2(c). Consequently, (2.5) holds in case (i).

Step 3. In case (ii), we have $\min g < m(g)$. Consider the sets

$$E := \{\,x \in K : g(x) \ge m(g)\,\} \quad \text{and} \quad U := \{\,x \in K : f(x) > m(g)\,\}.$$

Since E is contained in the closure of U, we must have meas $U \ge$ meas E. The desired inequality (2.5) follows readily if we can show meas $U >$ meas E. Assume for contradiction that meas $U =$ meas E. It then follows that meas $(U \setminus E) = 0$. But the only way the set $U \setminus E$, which is open in K, has zero measure is when it is empty. This means $U = E$. So $E = U$ is both open and closed in K, which is a connected set. Hence either $E = U = K$ or $E = U = \emptyset$. The former is not possible because $m(g) > \min g$; the latter is not possible because $m(g)$ belongs to the range $g(K)$. This establishes the claim, and thus (2.5) too.

Step 4. Inequality (2.5) implies

$$-\int_K \rho'_{\mp}(f(x) - m(g))\,dx \;<\; -\int_K \rho'_{\mp}(g(x) - m(g))\,dx.$$

Consequently,

$$(\theta_f)'_{\pm}(m(g)) \;<\; (\theta_g)'_{\pm}(m(g)). \tag{2.6}$$

Since $(\theta_f)'_+(m(f)) \ge 0$, to show $m(f) > m(g)$, it suffices to show

$$(\theta_f)'_+(m(g)) \;<\; 0. \tag{2.7}$$

Note that (2.6) is only good enough to imply that $(\theta_f)'_-(m(g)) < 0$, which is weaker than (2.7). If either θ_f or θ_g is differentiable at $m(g)$, then (2.7) follows readily. This is clear in the former case, whereas in the latter case we have $(\theta_f)'_+(m(g)) < (\theta_g)'(m(g)) = 0$.

Step 5. If θ_f and θ_g both fail to be differentiable at $m(g)$, let

$$f_\alpha := \alpha\, f + (1-\alpha)\, g \quad \text{and} \quad \theta_\alpha(m) := \int_K \rho(f_\alpha(x) - m)dx, \quad \alpha \in [0,1].$$

We claim that there exists $\alpha^* \in (0,1)$ such that θ_{α^*} is differentiable at $m(g)$. With this claim established, we can complete the proof as follows. Since $f > f_{\alpha^*} > g$ in the interior of K, together with the result in Step 4 and part (a) proved above, we arrive at $m(f) \geq m(f_{\alpha^*}) > m(g)$. Thus we are left only with the proof of the last claim.

Step 6. Let B be the set of points at which ρ fails to be differentiable. For each $t \in B$ and $\alpha \in (0,1)$, define

$$N_{\alpha,t} := \{\, x \in \text{int } K : f_\alpha(x) - m_g = t \,\}.$$

Note that for fixed $t \in B$ and $\alpha > \alpha'$, the sets $N_{\alpha,t}$ and $N_{\alpha',t}$ are disjoint. Since K has finite measure, for each $t \in B$ and each $n = 1, 2, \ldots$, only a finite number of α satisfies meas $N_{\alpha,t} > 1/n$. Hence the set $\{\alpha \in (0,1) : \text{meas } N_{\alpha,t} > 0\}$ is countable. Since B is countable, it follows that

$$\{\alpha \in (0,1) : \text{meas } N_{\alpha,t} > 0 \text{ for some } t \in B\} = \bigcup_{t \in B} \{\alpha \in (0,1) : \text{meas } N_{\alpha,t} > 0\}$$

is countable. But $(0,1)$ is uncountable, so there exists $\alpha^* \in (0,1)$ such that

$$\begin{aligned} 0 &= \text{meas} \bigcup_{t \in B} N_{\alpha^*,t} = \text{meas } \{\, x \in \text{int } K : f_{\alpha^*}(x) \in B \,\} \\ &= \text{meas } \{\, x \in K : f_{\alpha^*}(x) \in B \,\}. \end{aligned}$$

By part (f) of Proposition 2.1, it follows that θ_{α^*} is differentiable at $m(g)$. □

Remark. It is in general not true that if $f \geq g$ and $f \neq g$, then $m(f) > m(g)$, even if f is almost everywhere strictly greater than g. An example is if f and g are continuous functions defined on an interval I and are both strictly increasing, and $f(x) > g(x)$ except at the midpoint of I. With $\rho = |\cdot|$, it follows that $m(f) = \text{med}(f|I) = f(\text{midpoint of } I) = g(\text{midpoint of } I) = \text{med}(g|I) = m(g)$. □

Part (a) of the next result implies that the continuous M-estimator $m(f)$ is nonexpansive, and thus continuous, in its argument; the second part extends part (b) of Theorem 2.2.

COROLLARY 2.4. *The following two statements hold.*

(a) *The continuous M-estimator m is nonexpansive on $C(K)$; i.e.,*

$$|\, m(f) - m(g) \,| \leq \max_{x \in K} |\, f(x) - g(x) \,| \quad \forall\, f, g \in C(K).$$

(b) *If f and g in $C(K)$ are such that $m(f) = m(g)$, then $x \in \text{int } K$ exists such that $f(x) = g(x)$.*

Proof. Let $\sigma := \max_{x \in K} |f(x) - g(x)|$. We have $g - \sigma \leq f \leq g + \sigma$ on K. An application of the monotonicity of m yields

$$m(g) - \sigma = m(g - \sigma) \leq m(f) \leq m(g + \sigma) = m(g) + \sigma,$$

from which the desired nonexpansiveness of m follows readily.

To prove statement (b), assume for contradiction that $f(x) \neq g(x)$ for all $x \in \text{int } K$. It then follows that either $f > g$ on int K or $f < g$ on int K. Either case yields a contradiction to the assumption that $m(f) = m(g)$ by the strict monotonicity of m. □

The next result asserts a "strong minimizing" property of $m(f; K, \rho)$ associated with a C^2 function ρ with positive second derivatives. A consequence of this property

is that a global a posteriori error bound exists for the continuous M-estimator; see the last inequality in the proposition below.

PROPOSITION 2.5. *Let $f \in C(K)$ and $\rho \in C^2$ be given. If $\rho''(f(x) - m(f))$ does not vanish identically on K, then $\theta''(m(f); K, f, \rho) > 0$. Hence, positive constants c and δ exist such that*

$$|\, m - m(f)\,| \,\le\, \delta \;\Rightarrow\; \theta(m; K, f, \rho) - \theta(m(f); K, f, \rho) \,\ge\, c\,|\, m - m(f)\,|^2 \tag{2.8}$$

and

$$|\, m - m(f)\,| \,>\, \delta \;\Rightarrow\; \theta(m; K, f, \rho) - \theta(m(f); K, f, \rho) \,\ge\, c\,\delta\,|\, m - m(f)\,|. \tag{2.9}$$

Consequently, there exists $\eta > 0$ such that, for all $m \in \mathbb{R}$,

$$\begin{aligned}&|\, m - m(f)\,| \\ &\le\, \eta \max\left\{\, \theta(m; K, f, \rho) - \theta(m(f); K, f, \rho),\, \sqrt{\theta(m; K, f, \rho) - \theta(m(f); K, f, \rho)}\,\right\}.\end{aligned}$$

Proof. Write $\theta := \theta(\cdot; K, f, \rho)$. By part (d) of Proposition 2.1, θ'' exists. Moreover, the expression (2.4) shows that θ'' is nonnegative on $\mathbb{R}$. If $\theta''(m(f)) = 0$, then since f is continuous on K and ρ'' is nonnegative and continuous on $\mathbb{R}$, it follows that $\rho''(f(x) - m(f)) = 0$ for all $x \in K$. But this contradicts the assumption that the latter function does not vanish identically on K. Consequently, $\theta''(m(f)) > 0$.

The existence of δ and c satisfying (2.8) is a standard second-order consequence of the minimizing property of $m(f)$ and of the positivity of $\theta''(m(f); K, f, \rho)$. To prove (2.9), let m be such that $m - m(f) > \delta$. (The proof of the case $m - m(f) < -\delta$ is similar and omitted.) Define $m' := m(f) + \delta$. We then have

$$m' \,=\, \frac{\delta}{m - m(f)}\, m + \frac{m - m(f) - \delta}{m - m(f)}\, m(f),$$

which implies, by convexity of θ,

$$\theta(m') \,\le\, \frac{\delta}{m - m(f)}\, \theta(m) + \frac{m - m(f) - \delta}{m - m(f)}\, \theta(m(f)).$$

Since $\theta(m') \ge \theta(m(f)) + c(m' - m(f))^2 = \theta(m(f)) + c\delta^2$, (2.9) follows readily. The last assertion of the proposition is immediate from (2.8) and (2.9). ∎

3. Interpolation of continuous M-estimators. In this and the next section, we consider the interpolation of the continuous M-estimators of polynomials on given intervals. This section establishes the well-posedness of the interpolation problem using nonconstructive topological arguments, generalizing the main result in [6]. The next section discusses Newton's method for solving the interpolation problem with a smooth ρ.

Denote by Π_n the space of all polynomials of degree $\le n$. Let I be a given closed finite interval. For any nonzero $p \in \Pi_n$ and any $m \in \mathbb{R}$, the set $p^{-1}(m) \cap I$ has at most n elements. Hence, the set

$$\{\, t \in I : \rho \text{ is not differentiable at } p(t) - m \,\}$$

is countable; consequently, by part (f) of Proposition 2.1, the function $\theta(m)$ is differentiable everywhere on $\mathbb{R}$. Hence, for $p \in \Pi_n$ we have

$$\int_I \rho'_{\pm}(p(t) - m(p\,; I, \rho))\, dt \,=\, 0. \tag{3.1}$$

We introduce the map $\mathbf{M}_\rho : \mathbb{R}^{n+1} \to \mathbb{R}^{n+1}$ associated with $n+1$ *nonoverlapping* compact intervals I_i, for $i = 0, \ldots, n$, each with a nonempty interior, where nonoverlapping means $\operatorname{int} I_i \cap \operatorname{int} I_j = \emptyset$ for all $i \neq j$. For each vector $a \in \mathbb{R}^{n+1}$ with components a_i for $i = 0, \ldots, n$, let $\mathbf{M}_\rho(a)$ be the $(n+1)$-vector whose ith component, for $i = 0, \ldots, n$, is equal to $m(p; I_i, \rho)$, where p is the polynomial in Π_n with coefficients a_j; i.e.,

$$p(t) \equiv \sum_{j=0}^{n} a_j \, t^j, \quad t \in \mathbb{R}. \tag{3.2}$$

The goal of this section is to establish the following main result, which immediately implies the *well-posedness* of the interpolation problem of continuous M-estimators: given any values m_i, $i = 0, \ldots, n$, there exists a unique $p \in \Pi_n$ such that $m(p; I_i, \rho) = m_i$ for all i; moreover, such an interpolant p depends continuously on the data m_i.

THEOREM 3.1. *$\mathbf{M}_\rho$ is a homeomorphism from $\mathbb{R}^{n+1}$ onto $\mathbb{R}^{n+1}$.*

Proof. It suffices to show that $\mathbf{M}_\rho$ is continuous, injective, and norm-coercive [8, Theorem 5.3.8]. By Corollary 2.4(a), $\mathbf{M}_\rho$ is Lipschitz continuous. Indeed, for any two vectors a and b in $\mathbb{R}^{n+1}$ with associated polynomials p and q, we have, for every $i = 0, 1, \ldots, n$,

$$| \, m(p; I_i, \rho) - m(q; I_i, \rho) \, | \leq \sup_{t \in I_i} | \, p(t) - q(t) \, | \leq L_i \, \| \, a - b \, \|,$$

where $\| \cdot \|$ denotes the Euclidean norm in $\mathbb{R}^{n+1}$ and $L_i > 0$ is a constant that depends on the interval I_i and is independent of ρ and the vectors a and b. Letting $L = \max_{0 \leq i \leq n} L_i$, we deduce

$$\| \, \mathbf{M}_\rho(a) - \mathbf{M}_\rho(b) \, \| \leq L \, \| \, a - b \, \| \quad \forall \, \rho \text{ and } \quad \forall \, a, b \in \mathbb{R}^{n+1}. \tag{3.3}$$

Note that the Lipschitz constant L is independent of ρ; hence the family of maps $\{\mathbf{M}_\rho : \rho\}$ is *equi-Lipschitz continuous*. Injectivity of $\mathbf{M}_\rho$ follows easily from Corollary 2.4(b): If $p, q \in \Pi_n$ are such that $\mathbf{M}_\rho(p) = \mathbf{M}_\rho(q)$, then there exists, for every $i = 0, \ldots, n$, a point $t_i \in \operatorname{int} I_i$ such that $p(t_i) = q(t_i)$; this implies $p = q$. It remains to show norm-coerciveness; i.e., we need to show that

$$\lim_{\|a\| \to \infty} \| \, \mathbf{M}_\rho(a) \, \| = \infty. \tag{3.4}$$

We divide the remaining proof into several major steps.

Step 1. Define, for any scalar $c > 0$, the function $\rho_c : \mathbb{R} \to \mathbb{R}$ by $\rho_c(t) := \rho(ct)$ for all $t \in \mathbb{R}$. Observe that for any interval I and any function $f \in C(I)$, we have

$$\begin{aligned} m(f; I, \rho) &= \arg\min_m \int_I \rho(f(t) - m) \, dt = \arg\min_m \int_I \rho_c \left(\frac{f(t)}{c} - \frac{m}{c} \right) dt \\ &= c \, m \left(\frac{f}{c}; I, \rho_c \right). \end{aligned}$$

It follows that for a nonzero vector $a \in \mathbb{R}^{n+1}$,

$$\mathbf{M}_\rho(a) = \| \, a \, \| \, \mathbf{M}_{\rho_{\|a\|}} \left(a / \|a\| \right). \tag{3.5}$$

Let S^n denote the unit sphere in $\mathbb{R}^{n+1}$. Clearly, if

$$\inf \{ \, \| \, \mathbf{M}_{\rho_c}(a) \, \| \, : \, c \geq 1, \; a \in S^n \, \} > 0, \tag{3.6}$$

then (3.4) follows. It is clear that (3.6) implies

$$\inf\{\,\|\,\mathbf{M}_{\rho_c}(a)\,\|\,:\,c\,\geq\,1\,\}\,>0\quad\forall\,a\,\in\,S^n. \tag{3.7}$$

Thanks to the compactness of S^n and the equi-Lipschitz continuity of $\{\mathbf{M}_{\rho_c} : c > 0\}$, the converse implication also holds. Indeed, assume that (3.7) holds but (3.6) does not. There exist sequences $\{a^k\} \subset S^n$ and $\{c_k\} \in [1, \infty)$ such that $\mathbf{M}_{\rho_{c_k}}(a^k) \to 0$. Since S^n is compact, we may assume without loss of generality that the sequence $\{a^k\}$ converges to some $a^\infty \in S^n$. By (3.3), we have

$$\|\,\mathbf{M}_{\rho_{c_k}}(a^k) - \mathbf{M}_{\rho_{c_k}}(a^\infty)\,\|\,\leq\,L\,\|\,a^k - a^\infty\,\|\quad\forall\,k.$$

Consequently, it follows that

$$\lim_{k\to\infty}\,\mathbf{M}_{\rho_{c_k}}(a^\infty)\,=\,0,$$

which contradicts (3.7). Hence (3.6) $\Longleftrightarrow$ (3.7).

Step 2. Let $a \in \mathbb{R}^{n+1}$ be an arbitrary nonzero vector, and let $p \in \Pi_n$ be given by (3.2). Since p has no more than n roots and since there are $(n + 1)$ nonoverlapping intervals I_i, it follows that one of two cases must hold:

(i) there exists $j \in \{0, \ldots, n\}$ such that $p > 0$ or $p < 0$ on I_j, or

(ii) $n \geq 1$ and there exists $j \in \{0, \ldots, n-1\}$ such that I_j and I_{j+1} intersect at a common endpoint where p vanishes and $p(x)p(y) < 0$ for all $x \in \text{int } I_j$ and $y \in \text{int } I_{j+1}$.

To see this, note the following special property of a polynomial. Namely, if a polynomial does not change sign and does not vanish in an interval except at one interior point of the interval, then the latter point must be a root of the polynomial of multiplicity at least two. By this property and a straightforward counting argument, one can easily show that if neither of the above two cases hold, then, counting multiplicities, p must have at least $n + 1$ zeros, which is impossible. To complete the proof of the theorem, we show that (3.7) holds in either case (i) or (ii) above.

Step 3. In case (i) there exists $\delta > 0$ such that p or $-p \geq \delta$ on I_j. Since $m(p\,; I_j, \rho_c) = p(t_j)$ for some $t_j \in I_j$, it follows that $\|\mathbf{M}_{\rho_c}(a)\| \geq \delta$ for all $c > 0$.

Step 4. In case (ii) we prove (3.7) by contradiction. If (3.7) fails, then there exists a sequence $\{c_k\}$ in $[1, \infty)$ such that

$$\lim_{k\to\infty}\,m(p\,; I_i, \rho_{c_k})\,=\,0\quad\text{for } i = j \text{ and } j+1.$$

Without loss of generality, we may assume that

$$p\,<\,0 \text{ on int } I_j\quad\text{and}\quad p\,>\,0 \text{ on int } I_{j+1}.$$

For $i = j$, $j + 1$, write $m_{k,i} := m(p\,; I_i, \rho_{c_k})$ and $\theta_{k,i} := \theta(\cdot; I_i, p, \rho_{c_k})$. By part (c) of Theorem 2.2, it follows that $m_{k,j} < 0$ and $m_{k,j+1} > 0$ for all k.

By (3.1), we have the following optimality condition:

$$\int_{I_j}\,\rho'_{\pm}\,(c_k[p(t) - m_{k,j}])\,dt\,=\,0\,=\,\int_{I_{j+1}}\,\rho'_{\pm}\,(c_k[p(t) - m_{k,j+1}])\,dt\quad\forall\,k = 1, 2, \ldots\,. \tag{3.8}$$

Since meas$\{t \in I_i : p(t) = 0\} = 0$, an elementary property of measure gives

$$\lim_{m\uparrow 0}\,\text{meas}\,\{t \in I_j : p(t) \geq m\} = 0 = \lim_{m\downarrow 0}\,\text{meas}\,\{t \in I_{j+1} : p(t) \leq m\}. \tag{3.9}$$

By continuity of p, there exist $\varepsilon > 0$, $\delta > 0$, $J_i \subset I_i$ with meas $J_i \geq \varepsilon$ for $i = j, j+1$ such that $p \leq -\delta$ and $p \geq \delta$ on J_j and J_{j+1}, respectively. Pick k large enough such that $m_{k,j+1} - m_{k,j} < \delta$ (in particular, $-\delta < m_{k,j} < 0$ and $0 < m_{k,j+1} < \delta$),

$$\text{meas } \{t \in I_j : p(t) > m_{k,j}\} < \varepsilon \quad \text{and} \quad \text{meas } \{t \in I_{j+1} : p(t) < m_{k,j+1}\} < \varepsilon.$$

We then have

$$0 = \int_{I_j} (\rho_{c_k})'_+(p(t) - m_{k,j})\, dt = T_1 + T_2 + T_3,$$

where

$$\begin{aligned}
T_1 &:= \int_{\{t:p(t)\leq -\delta\}} (\rho_{c_k})'_+(p(t) - m_{k,j})\, dt \\
&\leq \int_{\{t:p(t)\leq -\delta\}} (\rho_{c_k})'_+(-\delta - m_{k,j})\, dt \leq \varepsilon(\rho_{c_k})'_+(-m_{k,j+1}) \\
T_2 &:= \int_{\{t:-\delta<p(t)<m_{k,j}\}} (\rho_{c_k})'_+(p(t) - m_{k,j})\, dt < 0 \\
T_3 &:= \int_{\{t:p(t)\geq m_{k,j}\}} (\rho_{c_k})'_+(p(t) - m_{k,j})\, dt \\
&\leq \int_{\{t:p(t)>m_{k,j}\}} (\rho_{c_k})'_+(-m_{k,j})\, dt \leq \varepsilon\, (\rho_{c_k})'_+(-m_{k,j}),
\end{aligned}$$

by the monotonicity of $(\rho_{c_k})'_+$. Hence

$$0 < (\rho_{c_k})'_+(-m_{k,j+1}) + (\rho_{c_k})'_+(-m_{k,j}).$$

Similarly, using

$$0 = \int_{I_{j+1}} (\rho_{c_k})'_+(p(t) - m_{k,j+1})\, dt,$$

we can deduce $0 > (\rho_{c_k})'_+(-m_{k,j}) + (\rho_{c_k})'_+(-m_{k,j+1})$, which is a contradiction. ∎

4. Newton's method for interpolation. By Theorem 3.1, the equation

$$\mathbf{M}_\rho(a) = b \tag{4.1}$$

has a unique solution for every vector $b \in \mathbb{R}^{n+1}$; moreover, such a solution depends continuously on b. A natural approach to solve (4.1) is by Newton's method, possibly with a globalization scheme [2]. In order for this method to be directly applicable, we take ρ to be twice continuously differentiable throughout this section. This smoothness assumption allows us to completely bypass the difficulty in dealing with the nonsmoothness of the original median-interpolation problem considered in [3, 6]. Moreover, by the theorem below, if $\rho'' > 0$, then $\mathbf{M}_\rho$ is a diffeomorphism on $\mathbb{R}^{n+1}$; i.e., both $\mathbf{M}_\rho$ and $(\mathbf{M}_\rho)^{-1}$ are differentiable maps. In particular, $\mathbf{M}_\rho$ has a nonsingular Jacobian matrix everywhere on $\mathbb{R}^{n+1}$.

THEOREM 4.1. *Let I_i, $i = 0, \ldots, n$, be $n+1$ nonoverlapping compact intervals, each with a nonempty interior. Let $\rho : \mathbb{R} \to \mathbb{R}$ be a twice continuously differentiable*

function with $\rho'' > 0$ on $\mathbb{R}$. If ρ has a minimizer at zero such that $\rho(0) = 0$, then $\mathbf{M}_\rho$ is a diffeomorphism from $\mathbb{R}^{n+1}$ onto itself.

Proof. For simplicity, we write $\mathbf{M}$ for $\mathbf{M}_\rho$. The positivity of ρ'' implies that ρ is strictly convex on $\mathbb{R}$. Hence, zero is the unique minimizer of ρ. For $i = 0, \ldots, n$, write

$$\theta_i(m, a) := \int_{I_i} \rho\left(\sum_{j=0}^{n} a_j\, t^j - m\right) dt. \tag{4.2}$$

As a function of the two arguments $(m, a) \in \mathbb{R}^{1+(n+1)}$, θ_i is twice continuously differentiable. For any fixed but arbitrary vector $a \in \mathbb{R}^{n+1}$, the continuous M-estimator $\mathbf{M}_i(a)$ is the unique root m of the equation

$$\frac{\partial \theta_i(m, a)}{\partial m} = 0,$$

which is a parametric, nonlinear equation with m as the primary variable and a as the parameter. By Proposition 2.5,

$$\frac{\partial^2 \theta_i(\mathbf{M}_i(a), a)}{\partial m^2} > 0.$$

Therefore, by the implicit-function theorem, it follows that $\mathbf{M}_i$ (and thus $\mathbf{M}$) is a differentiable function on $\mathbb{R}^{n+1}$. We claim that the Jacobian matrix of $\mathbf{M}$ at $a \in \mathbb{R}^{n+1}$, denoted $J\mathbf{M}(a)$, is nonsingular. Note that

$$\frac{\partial \mathbf{M}_i(a)}{\partial a_j} = \left(\frac{\partial^2 \theta_i(\mathbf{M}_i(a), a)}{\partial m^2}\right)^{-1} \left(\frac{\partial^2 \theta_i(\mathbf{M}_i(a), a)}{\partial m\, \partial a_j}\right). \tag{4.3}$$

If $e \in \mathbb{R}^{n+1}$ is such that $J\mathbf{M}(a)e = 0$, then we have

$$\sum_{j=0}^{n} \frac{\partial^2 \theta_i(\mathbf{M}_i(a), a)}{\partial m\, \partial a_j}\, e_j = 0 \quad \forall\, i = 0, \ldots, n.$$

By a direct differentiation, we can see that the above is equivalent to

$$\int_{I_i} \rho''\left(\sum_{\ell=0}^{n} a_\ell\, t^\ell - \mathbf{M}_i(a)\right) q(t)\, dt = 0, \quad i = 0, \ldots, n,$$

where $q(t) \equiv \sum_{j=0}^{n} e_j\, t^j$. Since ρ'' is everywhere positive, it follows that q has at least one zero in int I_i for every $i = 0, \ldots, n$. Consequently, the polynomial $q(t)$, which is of degree n, has $n + 1$ distinct real roots. This is not possible unless $q(t)$ is the zero polynomial. Hence $J\mathbf{M}(a)$ must be nonsingular. This implies that $\mathbf{M}^{-1}$ is differentiable; hence $\mathbf{M}$ is a diffeomorphism on $\mathbb{R}^{n+1}$. □

The condition $\rho'' > 0$ cannot be dispensed with in the above theorem. For example consider $\rho = |\cdot|^p$; then $\rho \in \mathrm{C}^2$ when $p \geq 2$. On the other hand, $\mathbf{M}_{|\cdot|^p}$ is homogeneous of degree 1; i.e.,

$$\mathbf{M}_{|\cdot|^p}(c\, a) = c\, \mathbf{M}_{|\cdot|^p}(a); \quad \text{thus} \quad D_v \mathbf{M}_{|\cdot|^p}(0) = \mathbf{M}_{|\cdot|^p}(v),$$

where D_v denotes the directional derivative operator in the direction v. This implies that $\mathbf{M}_{|\cdot|^p}$ is differentiable at the origin if and only if $\mathbf{M}_{|\cdot|^p}$ is a linear map; but an elementary calculation shows that (unless $n \leq 1$) the latter is true when and only when $p = 2$.

4.1. Method I. With the above preparation, we can formally state a globally convergent Newton method for solving (4.1); see [2, 11]. In essence, this is the damped Newton method that involves two main computational steps in each iteration: the first step is solving the Newton equation

$$\mathbf{M}_\rho(a^k) + J\mathbf{M}_\rho(a^k)\, da^k \;=\; b \tag{4.4}$$

for the direction da^k at the current iterate a^k; the second step is performing an Armijo line search [1, section 1.2, p. 29] on the merit function

$$\phi(a) \;:=\; \tfrac{1}{2}\,(\,\mathbf{M}_\rho(a) - b\,)^T(\,\mathbf{M}_\rho(a) - b\,)$$

at the current iterate along the computed Newton direction. Normally, given scalars σ' and β in $(0, 1)$, the latter line search calls for the determination of the smallest nonnegative integer i satisfying

$$\phi(a^k + \beta^i da^k) - \phi(a^k) \;\le\; \sigma'\,\beta^i\,\nabla\phi(a^k)^T da^k.$$

With the function ϕ on hand and the search direction da^k computed from (4.4), we have

$$\nabla\phi(a^k) \;=\; J\mathbf{M}_\rho(a^k)^T(\,\mathbf{M}_\rho(a^k) - b^k\,),$$

which yields $\nabla\phi(a^k)^T da^k = -2\phi(a^k)$. Noting the latter identity, we formulate the following algorithm.

Newton's Algorithm for Interpolation.

(a) (inputs). Let the function ρ and the $(n+1)$ intervals I_i satisfy the assumptions in Theorem 4.1. Let $b \in \mathbb{R}^{n+1}$ and $a^0 \in \mathbb{R}^{n+1}$ be given. Let σ and β be given scalars in $(0, 1)$. Set $k = 0$.

(b) (solving linear equations). Solve (4.4) for the Newton direction da^k.

(c) (Armijo line search). Let i_k be the smallest nonnegative integer i such that

$$\phi(a^k + \beta^i da^k) \;\le\; (\,1 - \sigma\,\beta^i\,)\,\phi(a^k).$$

Set $\tau_k := \beta^{i_k}$ and $a^{k+1} := a^k + \tau_k da^k$. Let $k \leftarrow k + 1$.

(d) If $\|\mathbf{M}_\rho(a^k) - b\| \le$ tolerance, stop. Otherwise return to step (b). □

While the convergence of Newton's method is well known (cf. [2, Chapter 6] or [5, Chapter 8], e.g.), for completeness we give a sketch of the proof of the following result, omitting some details.

Theorem 4.2. *Under the assumptions of Theorem* 4.1*, the algorithm as described above generates a well-defined sequence* $\{a^k\}$ *that converges Q-superlinearly to the unique solution of* (4.1)*. Moreover,* $i_k = 0$ *for all but finitely many* k*. Finally, if* ρ'' *is Lipschitz continuous on* $\mathbb{R}$*, then the convergence is Q-quadratic.*

Proof. The well-definedness of each search direction da^k is ensured by the nonsingularity of $J\mathbf{M}_\rho(a)$ on $\mathbb{R}^{n+1}$. Since the method is essentially a gradient-related line-search method applied to the unconstrained minimization of the merit function $\phi(a)$, standard results from nonlinear programming, such as [1, Proposition 1.2.1], guarantee that the sequence $\{a^k\}$ is well defined and that every accumulation point of the sequence is a stationary point of ϕ. At least one such point must exist because ϕ has bounded level sets; in turn, the latter is due to the diffeomorphism property of $\mathbf{M}_\rho$. Since $\nabla\phi(a) = J\mathbf{M}_\rho(a)^T(\mathbf{M}_\rho(a) - b)$ and $J\mathbf{M}_\rho(a)$ is a nonsingular matrix for all a, it follows that every accumulation point of the sequence $\{a^k\}$ satisfies (4.1).

Since the latter equation has a unique solution, it follows that $\{a^k\}$ converges to the unique solution of (4.1). Letting a^* be the unique zero of (4.1), we note that $\nabla^2\phi(a^*) = J\mathbf{M}_\rho(a^*)^T J\mathbf{M}_\rho(a^*)$ is positive definite. Therefore, by verifying the well-known Dennis–Moré condition (see [2, equation (6.3.10)]), Theorem 6.3.4 in the latter reference immediately yields the assertion about the ultimate attainment of a unit step size (i.e., $i_k = 0$ for all but finitely many k). This in turn readily implies the quadratic convergence statement. □

4.2. Method II. We present below an alternative formulation of the system of equations (4.1) which results in a total bypass of the evaluation of $\mathbf{M}_\rho(a)$. Nevertheless, we should caution the reader that there is a theoretical difference between the alternative formulation and the original equation (4.1) that will become clear in the following discussion.

Since $\mathbf{M}_i(a) \equiv (\mathbf{M}_\rho)_i(a)$ satisfies $\int_{I_i} \rho'(p(t) - \mathbf{M}_i(a))\,dt = 0$, it is clear that (4.1) is equivalent to

$$\int_{I_i} \rho'\left(\sum_{j=0}^{n} a_j t^j - b_i\right) dt = 0, \quad i = 0, \ldots, n. \tag{4.5}$$

Define the C^1 map $F_\rho := F : \mathbb{R}^{n+1} \to \mathbb{R}^{n+1}$, where $F_i(a)$ is the left-hand side of the above equation. It is useful to clarify the difference between the two functions $\mathbf{M}$ and F in terms of the following function:

$$\psi_i(m, a) := \int_{I_i} \rho'\left(\sum_{j=0}^{n} a_j t^j - m\right) dt = -\frac{\partial \theta_i(m, a)}{\partial m}, \quad (m, a) \in \mathbb{R}^{1+(n+1)},$$

where $\theta_i(m, a)$ is given by (4.2). While $\mathbf{M}_i(a)$ is the (unique) zero of $\psi_i(\cdot, a)$ on $\mathbb{R}$, $F_i(a)$ is the value of $\psi_i(\cdot, a)$ at a given value $b_i \in \mathbb{R}$.

A similar Newton method can be applied to the equation

$$F(a) = 0. \tag{4.6}$$

It is easy to show that

$$\frac{\partial F_i(a)}{\partial a_j} = \left(\frac{\partial^2 \theta_i(b_i, a)}{\partial m\, \partial a_j}\right). \tag{4.7}$$

Under the assumptions of Theorem 4.1, we can show that $JF(a)$ is nonsingular for all $a \in \mathbb{R}^{n+1}$. Thus F is a local homeomorphism everywhere on $\mathbb{R}^{n+1}$. However, unlike $\mathbf{M}$, F is in general *not* a global homeomorphism. In fact, for a function ρ whose derivative ρ' is bounded (e.g., $\rho(t) \equiv \sqrt{t^2 + c} - \sqrt{c}$ for any $c > 0$), it is clear that F has a bounded range and therefore cannot be norm-coercive, and thus it cannot be a global homeomorphism.

In spite of the theoretical difference, Newton's method can be applied to (4.6). Omitting the details, we summarize the two main computational steps in each iteration. At the beginning of each iteration, an iterate $a^k \in \mathbb{R}^{n+1}$ is given. We then solve for da^k in the equation

$$F(a^k) + JF(a^k)\,da^k = 0$$

and next perform an Armijo line search on the merit function

$$\varphi(a) := \tfrac{1}{2} F(a)^T F(a)$$

starting at a^k and moving along the direction da^k. In the resulting scheme, there is no longer a need to evaluate $\mathbf{M}(a^k)$. The convergence of this alternative application of Newton's method is summarized below.

THEOREM 4.3. *Under the assumptions of Theorem* 4.1*, the algorithm as described above generates a well-defined sequence* $\{a^k\}$*. If the level set*

$$L(a^0) := \{ a \in \mathbb{R}^{n+1} : \| F(a) \|_2 \leq \| F(a^0) \|_2 \}$$

is bounded, then $\{a^k\}$ *is bounded, and all other conclusions of Theorem* 4.2 *remain valid.*

Proof. Since the sequence $\{a^k\}$ is contained in the level set $L(a^0)$, the boundedness of $\{a^k\}$ follows from that of the set. The rest of the proof is similar to that of Theorem 4.2. □

In summary, when Newton's method is applied to the two equivalent equations, (4.1) and (4.6), the resulting algorithms differ computationally and theoretically. The computational difference lies in the need to evaluate the continuous M-estimators $\mathbf{M}(a)$ at intermediate polynomials. The theoretical difference lies in the choice of initial iterate a^0. With (4.1), there is no restriction on a^0; with (4.6), a^0 should be such that the level set $L(a^0)$ is bounded.

4.3. Smoothed continuous medians. In addition to producing M-estimators that are of independent interest, the choice of a C^2 function ρ can be used to approximate the continuous median. One such family of "smoothed continuous medians" is obtained by letting

$$\rho_\varepsilon(t) := \sqrt{t^2 + \varepsilon^2} - \varepsilon, \quad t \in \mathbb{R},$$

where ε is a positive scalar presumed to be small. Note that ρ_ε is globally Lipschitz continuous on $\mathbb{R}$ and ρ_ε'' is positive everywhere. Notice that

$$0 \leq |t| - \rho_\varepsilon(t) < \varepsilon \quad \forall\, t \in \mathbb{R}.$$

By the next proposition (which is stated in a general context), the above inequality implies that $\{m(f; I_i, \rho_\varepsilon)\}$ converges to $\mathrm{med}(f|I_i)$, as $\varepsilon \downarrow 0$, for all $f \in C(I_i)$. This limit justifies the use of $m(f; I_i, \rho_\varepsilon)$ as an approximation of the continuous median $\mathrm{med}(f|I_i)$.

PROPOSITION 4.4. *Let* $\rho : \mathbb{R} \to \mathbb{R}_+$ *be a convex function with a unique minimizer at zero such that* $\rho(0) = 0$*. For every* $\varepsilon > 0$*, let* ρ_ε *be a convex function with the same properties as* ρ*. Assume that there exists a constant* $\eta > 0$ *such that, for every* $\varepsilon > 0$ *sufficiently small,*

$$|\rho(t) - \rho_\varepsilon(t)| \leq \eta\, \varepsilon \quad \forall\, t \in \mathbb{R};$$

then, for every $f \in C(K)$*,*

$$\lim_{\varepsilon \downarrow 0} m(f; K, \rho_\varepsilon) = m(f; K, \rho).$$

Proof. For every $\varepsilon > 0$, there exists $x(\varepsilon) \in \mathrm{int}\ K$ such that $m(f; K, \rho_\varepsilon) = f(x(\varepsilon))$. Consequently, it follows that

$$\sup_{\varepsilon > 0} |m(f; K, \rho_\varepsilon)| < \infty.$$

To establish the desired limit, it suffices to show that for every sequence of positive scalars $\{\varepsilon_k\}$ converging to zero, the sequence $\{m(f;K,\rho_{\varepsilon_k})\}$ converges to $m(f;K,\rho)$. In turn, it suffices to show that if

$$\lim_{k(\in\kappa)\to\infty} m(f;K,\rho_{\varepsilon_k}) \,=\, m_\infty,$$

where κ is an infinite subset of $\{1,2,\dots\}$, then

$$\int_K \rho(f(x)-m)\,dx \,\geq\, \int_K \rho(f(x)-m_\infty)\,dx \tag{4.8}$$

for all $m\in\mathbb{R}$. Writing $m_k := m(f;K,\rho_{\varepsilon_k})$, we have, for every k,

$$\int_K \rho_{\varepsilon_k}(f(x)-m)\,dx \,\geq\, \int_K \rho_{\varepsilon_k}(f(x)-m_k)\,dx.$$

For all k sufficiently large, we have

$$\int_K \rho_{\varepsilon_k}(f(x)-m)\,dx \,\leq\, \int_K \rho(f(x)-m)\,dx + \eta\,\varepsilon_k \,\text{meas}\,(K)$$

and

$$\int_K \rho_{\varepsilon_k}(f(x)-m_k)\,dx \,\geq\, \int_K \rho(f(x)-m_k)\,dx - \eta\,\varepsilon_k \,\text{meas}\,(K).$$

Passing to the limit $k(\in\kappa)\to\infty$ readily yields the desired inequality (4.8). □

4.4. Method II applied to interpolation of medians and smoothed medians. We have implemented a MATLAB solver `MEstimatorInterp` that applies Method II in section 4.2 to the M-estimator interpolation problem. We shall report and compare some of the numerical results based on this solver in the next subsection. In the implementation, we evaluate a polynomial using its Lagrange form. Specifically, for a polynomial L_i in Π_n, we write, relative to the interval I_i,

$$L_i(x) \,:=\, \left[\prod_{j=0,j\neq i}^{n} (\,x-x_i\,)\right]\left[\prod_{j=0,j\neq i}^{n} (\,x_j-x_i\,)\right]^{-1}, \quad x_j \,=\, \text{midpoint of } I_j.$$

The numerical result pertains to the following:

(i) `MEstimatorInterp` applied to the smoothed median-interpolation problem. In this case

$$F_i(a) \,=\, \int_{I_i} \rho'\left(\sum_{i=0}^{n} a_i L_i(t) - b_i\right)\,dt, \quad \rho'(t) = \frac{t}{\sqrt{t^2+0.01}}. \tag{4.9}$$

(ii) `MEstimatorInterp` applied to the median-interpolation problem. In this case

$$F_i(a) \,=\, \int_{I_i} \text{sign}\left(\sum_{i=0}^{n} a_i L_i(t) - b_i\right)\,dt. \tag{4.10}$$

Since $\rho = |\cdot|$ does not satisfy assumptions in Theorem 4.3, there is no guarantee that the method would converge.

(iii) `MedianInterp` in [4, section 2.1.4] applied to the median-interpolation problem. Based on a fixed-point iteration, an implementation of this solver, whose convergence has not been established, is freely available in WaveLab 802 at http://www-stat.stanford.edu/~wavelab/.

(iv) Same as (ii), except that the initial guess is chosen to be the fourth iterate computed from the fixed-point method in (iii).

Here are some implementation details:

Initial guess. Except in case (iv), we use the midpoint interpolant of the data $p_0 := \sum_{i=0}^{n} b_i L_i$ as the initial guess. This is motivated by the heuristic

$$\text{med}(p|I) \;\approx\; p(\text{midpoint of } I) \;\approx\; m(p; I, \sqrt{(\cdot)^2 + \varepsilon^2} - \varepsilon).$$

Computing $F(a)$. The integrals (4.9) and (4.10) are computed using `quad()` in Matlab 6.1. This routine is based on a recursive adaptive Simpson quadrature. The tolerance is set to $\texttt{tol} = 10^{-12}$. The evaluations of $\sum_i a_i L_i(t)$ in the integrands of (4.9) and (4.10) are performed using Neville's algorithm.

Computing $JF(a)$. For the computation of the Jacobian of F in the case of (4.9), one can in principle use (4.7), which basically involves an integral with ρ'' appearing in the integrand. This approach, however, turns out to be quite problematic for the purpose of smoothed median interpolation, since in this application $\rho'(x) \approx \text{sign}(x)$ and $\rho''(x) \approx$ the dirac function. Thus we approximate $\partial F_i(a)/\partial a_j$ based on a central divided difference:

$$\frac{\partial F_i(a)}{\partial a_j} \approx \frac{F_i(a + he_j) - F_i(a - he_j)}{2h}, \quad h = 10^{-8} \approx \sqrt{\text{machine precision}}, \tag{4.11}$$

where e_j is the jth vector in the standard basis of $\mathbb{R}^{n+1}$. This bypasses the singularity of ρ'' at zero. The finite difference (4.11) is applicable to the case of the median-interpolation problem; however, we remind the reader that at the time this article is written it is not known whether Method II applied to (4.10) would enjoy any convergence property.

Stopping criterion. We terminate a Newton iteration when the number of steps in a Armijo line search exceeds an upper bound `MAX_LINE_SEARCH` (chosen to be 10 in `MEstimatorInterp`.)

4.5. Numerical experiments.

Experiment I. $n = 4$,$(b_0, b_1, b_2, b_3, b_4) = (-1.2, 1.3, -0.9, 1.0, -0.8)$.

Experiment II. $n = 6$, $(b_0, b_1, b_2, b_3, b_4, b_5, b_6) = (0.05, 0.7, 0.6, -0.25, -0.38, -0.3, -1.5)$.

In both experiments, we take $I_i = [i, i + 1]$. Each of (i)–(iv) in section 4.4 is applied to both datasets above; in the following discussion we label the corresponding subexperiments as I(i)–I(iv) and II(i)–II(iv), respectively. The left panels of Figure 1 depict the error curves $\log(||F(a^k)||)$ versus k; on the right panels we graph the midpoint, median, and smoothed median (with smoothing factor $\varepsilon = 0.1$) interpolants of the data.

While Method II applied to median interpolation converges in Experiment II(ii), the method clearly fails in Experiment I(ii). Nevertheless, the latter failure of convergence is remedied by Experiment I(iv). As mentioned, there is currently no theoretical guarantee that the Newton method with line search applied to the nonsmooth systems in (ii) would enjoy any global (or even local) convergence property. Moreover, one can see from Figure 1(a) and (c) that Newton Method II applied to the nonsmooth median interpolation does not seem to offer fast convergence.

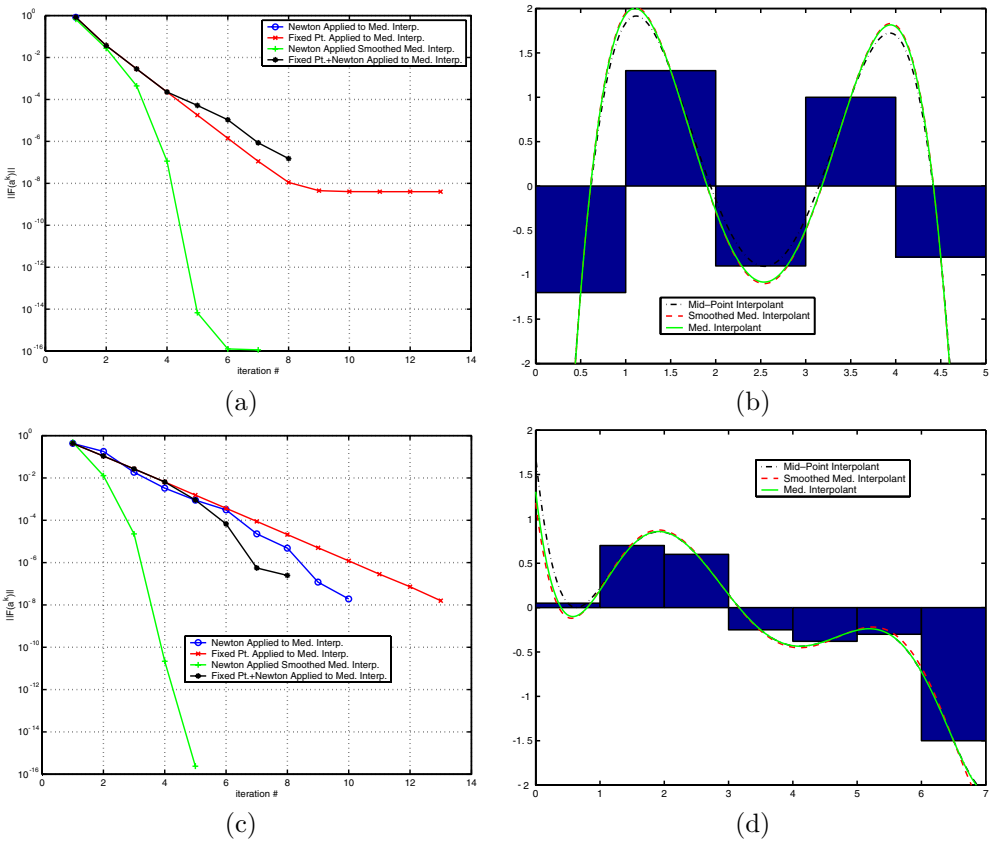

FIG. 1. *Error curves (left) and polynomial interpolants (right).*

On the other hand, Newton Method II applied to the smoothed median-interpolation problem exhibits superlinear convergence in Experiments I(i) and II(i), as expected from Theorem 4.3. As seen from Figure 1(a) and (c), the rates of convergence are noticeably faster than those in Experiment I(iii) and II(iii).

In summary the fixed-point algorithm used in `MedianInterp` for solving the median interpolation problem converges slower than Newton Method II applied to the smoothed median-interpolation problem. The latter method has a provable superlinear convergence property, while the former method has a conjectured linear convergence property. In terms of actual computational speed, one step of Newton iteration in our current implementation of `MEstimatorInterp` is much slower than one step of fixed-point iteration in `MedianInterp`; this is to be expected. Indeed, one can definitely improve the implementation of `MEstimatorInterp`.

During the revision of this article, we received the preprint by Qi [9], who studies the smoothness properties of $\mathbf{M}_\rho$ and F_ρ defined in section 4.1 and 4.2 in the case of the Huber M-Estimator (i.e., when ρ is given by (2.3).) The same article also illustrates a fundamental difficulty in the numerical solution of the median-interpolation problem: specifically, it is shown in section 4 of [9] that $F_{|\cdot|}$, unlike $M_{|\cdot|}$, is in general not even locally Lipschitz. This supports the slow convergence observed empirically in Experiments I(ii),(iv) and II(ii),(iv).

5. Nonlinear pyramid transforms based on M-estimators. Following the same strategy proposed in [3], one can now use the results in this paper to construct new nonlinear pyramid transforms: for a given signal $f : \mathbb{R} \to \mathbb{R}$, one measures the M-estimators of f over dyadic intervals $I_{j,k} = [2^{-j}k, 2^{-j}(k+1)]$, performs coarse-to-fine prediction using local polynomial interpolation, which has been shown to be a well-posed procedure by Theorem 3.1, and then defines the pyramid coefficients based on the errors of such predictions.

Nonlinear subdivision operator. We first define a new class of nonlinear subdivision operators which will serve the purpose of coarse-to-fine prediction. Denote by $l(\mathbb{Z})$ the vector space of all real sequences defined on $\mathbb{Z}$. Let ρ be a convex function with the standard assumptions. Let $L \geq 1$ be an integer. For a given $y \in l(\mathbb{Z})$ and $h > 0$, define $S_{\rho,L;h}(y) \in l(\mathbb{Z})$ as follows.

1. Interpolation: for each $k \in \mathbb{Z}$, let $p_k \in \Pi_{2L}$ be the unique polynomial such that
$$m(p_k; [h(k+l), h(k+l+1)], \rho) = y_{k+l}, \quad l = -L, \dots, L.$$
2. Imputation:
$$\begin{aligned} (S_{\rho,L;h}(y))_{2k} &:= m(p_k; [hk, h(k+1/2)], \rho), \\ (S_{\rho,L;h}(y))_{2k+1} &:= m(p_k; [h(k+1/2), h(k+1)], \rho), \quad k \in \mathbb{Z}. \end{aligned}$$

Since $m(f; K, \rho) = m(f(T\cdot); T^{-1}(K), \rho)$ for any invertible affine map T, the operator $S_{\rho,L;h}$ is independent of the scale parameter h; thus we drop the subscript h and write $S_{\rho,L} : l(\mathbb{Z}) \to l(\mathbb{Z})$. It is worth mentioning that Theorem 3.1 implies that $S_{\rho,L}$ is a bounded operator on $l^\infty(\mathbb{Z})$.

Pyramid transform. For a continuous signal $f : \mathbb{R} \to \mathbb{R}$, a ρ, and an integer $L \geq 1$, we define an M-estimator interpolating pyramid transform of f, denoted by $\textsc{MeIPT}(f; L, \rho)$, as follows.

1. Formation of M-estimators of f over dyadic blocks:
$$m_{j,k} := m(f; I_{j,k}, \rho), \quad j = j_0, j_0+1, \dots, \ k \in \mathbb{Z}.$$
2. Coarse-to-fine prediction: $\widetilde{m}_{j+1} = S_{\rho,L}((m_{j,k})_k)$.
3. Formation of detailed coefficients: $d_{j,k} = m_{j,k} - \widetilde{m}_{j,k}$.

$$\textsc{MeIPT}(f; L, \rho) := \{(m_{0,k})_{k\in\mathbb{Z}}, (d_{1,k})_{k\in\mathbb{Z}}, (d_{2,k})_{k\in\mathbb{Z}}, \dots\}.$$

There is also an inversion process for recovering f from $\textsc{MeIPT}(f; L, \rho)$ based on sequentially reversing the steps above. For this purpose we need also the observation that

$$\lim_{j\to\infty} \left\| f - \sum_{k\in\mathbb{Z}} m(f; I_{j,k}, \rho) 1_{[2^{-j}k, 2^{-j}(k+1))} \right\|_{L^\infty} = 0$$

when f is a bounded continuous function.

For $j = j_0, j_0+1, j_0+2, \ldots,$

1. $f_j := \sum_{k\in\mathbb{Z}} m_{j,k} 1_{[2^{-j}k, 2^{-j}(k+1))}$.
2. Coarse-to-fine prediction: $\widetilde{m}_{j+1} = S_{\rho,L}((m_{j,k})_k)$.
3. Recovery of scale $j+1$ M-estimators of f: $m_{j+1,k} = \widetilde{m}_{j+1,k} + d_{j+1,k}, \quad k \in \mathbb{Z}$.

$$(f_j)_j \to f \text{ uniformly on compact sets.} \tag{5.1}$$

Discussion. In practice, however, one typically recovers an *estimate* of f from a certain *perturbed* version of MeIPT$(f; L, \rho)$; in this case the convergence in (5.1) has to be reexamined, and also the *stability* of MeIPT becomes a very important issue. While these open problems are beyond the scope of the current paper, based on Theorem 3.1 we expect MeIPT to be a decent tool for signal compression. Following the formulation and arguments in [3, Proof of P3, p. 1055], the transform coefficients in MeIPT(f) can be shown to have good *sparsity* when f is piecewise smooth; and the sparsity improves gracefully as the smoothness of f improves. Such a property is attributable to the accurate coarse-to-fine prediction power of the operator $S_{\rho,L}$, thanks to a polynomial exactness property of $S_{\rho,L}$ guaranteed by Theorem 3.1.

Robust pyramid transform based on smoothed medians. Combining the ideas in this and the last section, one can now construct MeIPT based on smoothed continuous medians. Such pyramid transforms had been found experimentally to be as robust against outliers as the median-interpolating pyramid transforms considered in [3]. This is to be expected by virtue of Proposition 4.4.

Acknowledgments. The authors are grateful to Dan Naiman for his discussion in the initial phase of the work. The authors would like to thank two referees for constructive comments on the original version of the paper, which have led to an improvement of the presentation.

ON TIME-DOMAIN SIMULATION OF LOSSLESS TRANSMISSION LINES WITH NONLINEAR TERMINATIONS*

YAO-LIN JIANG†

Abstract. A time-domain approach is presented to solve nonlinear circuits with lossless transmission lines. Mathematically, the circuits are described by a special kind of nonlinear differential-algebraic equations (DAEs) with multiple constant delays. In order to directly compute these delay systems in time-domain, decoupling by waveform relaxation (WR) is applied to the systems. For the relaxation-based method we provide a new convergence proof. Numerical experiments are given to illustrate the novel approach.

Key words. nonlinear circuits, transmission lines, differential-algebraic equations with multiple delays, waveform relaxation, circuit simulation

1. Introduction.

A recent advance in VLSI technology has led to the development of high-speed integrated circuits in which the conductors must be regarded as transmission lines [1, 2]. At low bit rates, the lines may be considered as lossless.

The simulation task is to compute the transient response of a circuit consisting of nonlinear devices interconnected by transmission lines. These lines cause delay of the signals, and if they are terminated in nonlinear devices, they usually cause reflections as well.

In this paper we report a new method to simulate a circuit with lossless transmission lines. The circuit equations are nonlinear differential-algebraic equations (DAEs) with multiple constant delays. In time-domain waveform relaxation (WR) decoupling is applied to the system. The decoupled subsystems are some standard ordinary differential equations (ODEs) and algebraic equations (AEs). The general-purpose circuit simulators can be used to solve the subsystems. WR is a parallel process of computing transient solutions for large systems in time-domain [3, 4, 5, 6, 7]. Recent works on WR convergence for DAEs are reported in [8, 9, 10, 11, 12]. For a standard system of ODEs with usual delay, the papers [13, 14] considered simple WR methods. However, none of the works can be directly applied to this special kind of DAE with multiple delays in simulation of transmission lines. In this paper we provide a detailed proof of the proposed method. Three illustrative examples are also presented.

2. Models of lossless transmission lines.

In general, a transmission line is described by telegrapher's equations. For a lossless transmission line system shown in Figure 1, at time t $(0 \le t \le T_e)$ let $v(x,t)$ and $i(x,t)$ respectively be voltage and

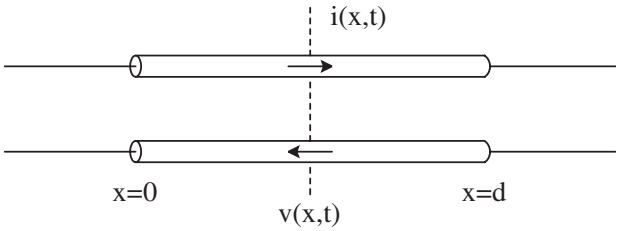

FIG. 1. *A segment of lossless transmission line.*

current at point x $(0 \le x \le d)$. The basic equations are

$$\begin{cases} \dfrac{\partial v(x,t)}{\partial x} = -L\dfrac{\partial i(x,t)}{\partial t}, \\ \dfrac{\partial i(x,t)}{\partial x} = -C\dfrac{\partial v(x,t)}{\partial t}, \end{cases} \tag{1}$$

where L is inductance and C is capacitance for unit length.

Differentiate the first part of (1) with respect to x and the second part of (1) with respect to t, and then combine them to obtain

$$\frac{\partial^2 v(x,t)}{\partial x^2} = LC\frac{\partial^2 v(x,t)}{\partial t^2}. \tag{2}$$

Similarly,

$$\frac{\partial i(x,t)}{\partial x^2} = LC\frac{\partial^2 i(x,t)}{\partial t^2}. \tag{3}$$

Let $LC = 1/\nu^2$, where ν is velocity of signal propagation. The solution of (2) and (3) has the form

$$\begin{cases} v(x,t) = f\left(t - \dfrac{x}{\nu}\right) + g\left(t + \dfrac{x}{\nu}\right), \\ i(x,t) = \dfrac{1}{z_0} f\left(t - \dfrac{x}{\nu}\right) - \dfrac{1}{z_0} g\left(t + \dfrac{x}{\nu}\right), \end{cases} \tag{4}$$

where $z_0 = \sqrt{L/C}$. By (4), we get

$$\begin{cases} f\left(t - \dfrac{x}{\nu}\right) = \dfrac{1}{2}[v(x,t) + z_0 i(x,t)], \\ g\left(t + \dfrac{x}{\nu}\right) = \dfrac{1}{2}[v(x,t) - z_0 i(x,t)]. \end{cases} \tag{5}$$

Let $\tau = \frac{d}{\nu}$, which is the delay of a signal going from $x = 0$ to $x = d$. Now at $x = d$ we have $2v(d,t) = [v(0, t-\tau) + z_0 i(0, t-\tau)] + [v(d,t) - z_0 i(d,t)]$ or

$$v(d,t) = v(0, t-\tau) + z_0 i(0, t-\tau) - z_0 i(d,t). \tag{6}$$

At $x = 0$, we have $2v(0,t) = [v(0,t) + z_0 i(0,t)] + [v(d, t-\tau) - z_0 i(d, t-\tau)]$ or

$$v(0,t) = v(d, t-\tau) - z_0 i(d, t-\tau) + z_0 i(0,t). \tag{7}$$

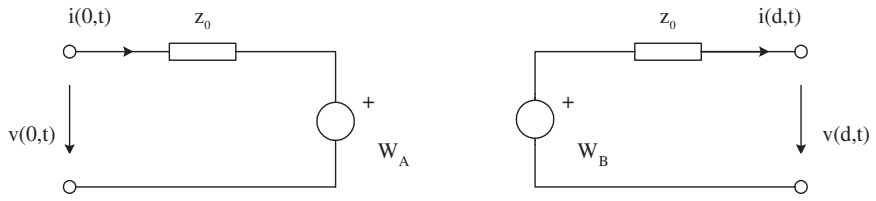

FIG. 2. *Characteristic 2-port of lossless transmission line system.*

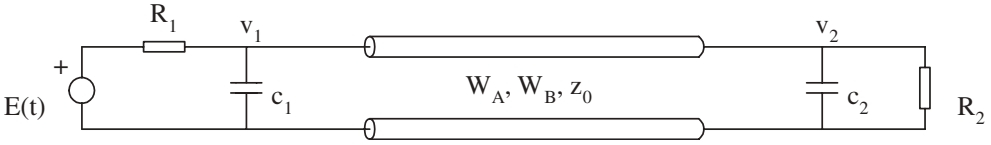

FIG. 3. *A linear circuit with transmission lines.*

Define two quantities

$$\begin{cases} W_A(t-\tau) = v(d,t-\tau) - z_0 i(d,t-\tau), \\ W_B(t-\tau) = v(0,t-\tau) + z_0 i(0,t-\tau). \end{cases} \tag{8}$$

Then (6) and (7) become

$$\begin{cases} v(0,t) = z_0 i(0,t) + W_A(t-\tau), \\ v(d,t) = -z_0 i(d,t) + W_B(t-\tau). \end{cases} \tag{9}$$

By (8) and (9), we have

$$\begin{cases} W_A(t) = 2v(d,t) - W_B(t-\tau), \\ W_B(t) = 2v(0,t) - W_A(t-\tau). \end{cases} \tag{10}$$

The transmission line is therefore characterized by

$$\begin{cases} i(0,t) = \dfrac{1}{z_0} v(0,t) - \dfrac{1}{z_0} - W_A(t-z), \\ 1pti(d,t) = \dfrac{1}{-z_0} v(d,t) + \dfrac{1}{z_0} + W_B(t-z). \end{cases} \tag{11}$$

Its equivalent circuit is shown in Figure 2.

For a linear circuit with the lossless transmission line system given in Figure 3, the circuit equations are

$$\begin{cases} c_1 \dfrac{dv_1(t)}{dt} = \dfrac{E(t)}{R_1} - \left(\dfrac{1}{R_1} + \dfrac{1}{z_0} \right) v_1(t) + \dfrac{1}{z_0} W_A(t-\tau), \\ c_2 \dfrac{dv_2(t)}{dt} = -\left(\dfrac{1}{R_2} + \dfrac{1}{z_0} \right) v_2(t) + \dfrac{1}{z_0} W_B(t-\tau), \\ W_A(t) = 2v_2(t) - W_B(t-\tau), \quad W_B(t) = 2v_1(t) - W_A(t-\tau). \end{cases} \tag{12}$$

Its equivalent circuit is also shown in Figure 4.

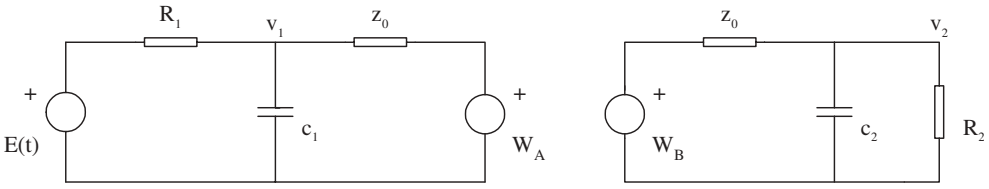

FIG. 4. *An equivalent circuit for a distributed network.*

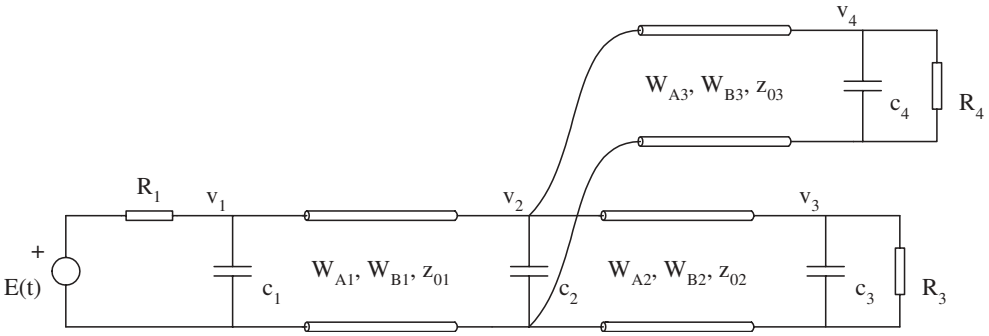

FIG. 5. *A linear circuit with multiple transmission lines.*

Another distributed circuit is given in Figure 5; its circuit equations are described by DAEs with multiple constant delays as follows:

$$
\begin{cases}
c_1\dfrac{dv_1(t)}{dt} = -\left(\dfrac{1}{R_1}+\dfrac{1}{z_{01}}\right)v_1(t) + \dfrac{1}{z_{01}}W_{A1}(t-\tau_1) + \dfrac{E(t)}{R_1}, \\
c_2\dfrac{dv_2(t)}{dt} = -\left(\dfrac{1}{z_{01}}+\dfrac{1}{z_{02}}+\dfrac{1}{z_{03}}\right)v_2(t) + \dfrac{1}{z_{01}}W_{B1}(t-\tau_1) + \dfrac{1}{z_{02}}W_{A2}(t-\tau_2) \\
\qquad\qquad + \dfrac{1}{z_{03}}W_{A3}(t-\tau_3), \\
c_3\dfrac{dv_3(t)}{dt} = -\left(\dfrac{1}{R_3}+\dfrac{1}{z_{02}}\right)v_3(t) + \dfrac{1}{z_{02}}W_{B2}(t-\tau_2), \\
c_4\dfrac{dv_4(t)}{dt} = -\left(\dfrac{1}{R_4}+\dfrac{1}{z_{03}}\right)v_4(t) + \dfrac{1}{z_{03}}W_{B3}(t-\tau_3), \\
W_{A1}(t) = 2v_2(t) - W_{B1}(t-\tau_1), \quad W_{B1}(t) = 2v_1(t) - W_{A1}(t-\tau_1), \\
W_{A2}(t) = 2v_3(t) - W_{B2}(t-\tau_2), \quad W_{B2}(t) = 2v_2(t) - W_{A2}(t-\tau_2), \\
W_{A3}(t) = 2v_4(t) - W_{B3}(t-\tau_3), \quad W_{B3}(t) = 2v_2(t) - W_{A3}(t-\tau_3).
\end{cases}
\tag{13}
$$

The systems of (12) and (13) have no standard form of ODEs with finite delays as studied in [13, 14]. To clearly understand this point, we may see the case of (12).

First, from the algebraic part of (12) we know that

$$
\begin{aligned}
W_A(t) &= 2v_2(t) - W_B(t-\tau) \\
&= 2v_2(t) - 2v_1(t-\tau) + W_A(t-2\tau)
\end{aligned}
\tag{14}
$$

and

$$
\begin{aligned}
W_B(t) &= 2v_1(t) - W_A(t-\tau) \\
&= 2v_1(t) - 2v_2(t-\tau) + W_B(t-2\tau).
\end{aligned}
\tag{15}
$$

Since $W_A(t)$ and $W_B(t)$ are defined on $[-\tau, T_e]$, where $\tau < +\infty$, we cannot rewrite (12) as a system of ODEs with delay. If the functions in (12) are defined on $(-\infty, T_e]$, by (14) and (15), $W_A(t-\tau)$ and $W_B(t-\tau)$ can be expressed as

$$W_A(t-\tau) = 2\sum_{j=1}^{\infty}[v_2(t-(2j-1)\tau) - v_1(t-2j\tau)] \tag{16}$$

and

$$W_B(t-\tau) = 2\sum_{j=1}^{\infty}[v_1(t-(2j-1)\tau) - v_2(t-2j\tau)]. \tag{17}$$

Substituting (16) and (17) into the differential part of (12), we have

$$\begin{cases} c_1\dfrac{dv_1(t)}{dt} = \dfrac{E(t)}{R_1} - \left(\dfrac{1}{R_1}+\dfrac{1}{z_0}\right)v_1(t) + \dfrac{2}{z_0}\displaystyle\sum_{j=1}^{\infty}[v_2(t-(2j-1)\tau) - v_1(t-2j\tau)], \\ c_2\dfrac{dv_2(t)}{dt} = -\left(\dfrac{1}{R_2}+\dfrac{1}{z_0}\right)v_2(t) + \dfrac{2}{z_0}\displaystyle\sum_{j=1}^{\infty}[v_1(t-(2j-1)\tau) - v_2(t-2j\tau)]. \end{cases} \tag{18}$$

However, it is now a system with infinite delays. The convergence conditions of WR in [13, 14] are still not suitable for simulation of transmission lines. This also further illustrates that for this kind of simulation problems it is better to directly use DAEs with delay.

3. WR of DAEs with multiple delays. Let us study the following circuit system of DAEs with multiple constant delays:

$$\begin{cases} C(t)\dfrac{dx(t)}{dt} + G(x(t),t) + DW(t-\tau) = b(t), \\ A(t)x(t) + W(t) + BW(t-\tau) = 0, \\ x(0) = x_0, \quad W(\theta) \equiv \varphi(\theta) \quad (-\tau \le \theta < 0), \quad t \in [0, T_e], \end{cases} \tag{19}$$

where $C(\cdot), A(\cdot)$ are two matrix-valued functions in $\mathbf{R}^{n\times n}$ and $\mathbf{R}^{2m\times n}$; D, B are two constant matrices in $\mathbf{R}^{n\times 2m}$ and $\mathbf{R}^{2m\times 2m}$; $G(\cdot,\cdot)$ is a nonlinear function; and for any t the functions $x(t) \in \mathbf{R}^{n\times 1}$, $W(t-\tau) \in \mathbf{R}^{2m\times 1}$ are to be computed, in which

$$W(t-\tau) = [y_1(t-\tau_1), z_1(t-\tau_1), \ldots, y_m(t-\tau_m), z_m(t-\tau_m)]^t. \tag{20}$$

We also define $\tau' = \min_{1\le i\le m}\{\tau_i\} (> 0)$.

For the above circuit system, $b(\cdot)$ is a known input function, x_0 is an initial value, and $\varphi(\theta)$ is an initial state of the transmission line system such that

$$\varphi(\theta) = [y_1(\theta_1), z_1(\theta_1), \ldots, y_m(\theta_m), z_m(\theta_m)]^t, \tag{21}$$

in which $-\tau_i \le \theta_i < 0$ $(1 \le i \le m)$. We also assume that the initial values x_0, $W_0 (= W(0))$ are consistent; that is, $A(0)x_0 + W_0 + BW(-\tau) = 0$. Further, by invoking the above characteristic of transmission lines, we assume that the form of B in (19) is a block diagonal matrix such that

$$B = \begin{bmatrix} I_d & & 0 \\ & \ddots & \\ 0 & & I_d \end{bmatrix} \in \mathbf{R}^{2m\times 2m}, \tag{22}$$

where $I_d = \left[\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right]$.

In (19), we assume that $C(\cdot)$, $\frac{dC(\cdot)}{dt}$, $A(\cdot)$, and $\frac{\partial G}{\partial x}$ are continuous. Moreover, $C(t)$ for all $t \in [0, T_e]$ are nonsingular and $\frac{\partial G}{\partial x}$ is bounded. In this paper we always assume that (19) has a unique solution for given initial value and state.

Let $F : (\mathbf{R}^n)^2 \times [0, T_e] \mapsto \mathbf{R}^n$ be a splitting function of G which satisfies

$$F(u, u, t) = G(u, t), \quad t \in [0, T_e], \tag{23}$$

where $u \in \mathbf{R}^n$. The WR decoupling of (19) is

$$\begin{cases} C_1(t)\dfrac{dx^{(k)}(t)}{dt} + F(x^{(k)}(t), x^{(k-1)}(t), t) = C_2(t)\dfrac{dx^{(k-1)}(t)}{dt} - DW^{(k-1)}(t-\tau) + b(t), \\ A_1(t)x^{(k)}(t) + W^{(k)}(t) = A_2(t)x^{(k-1)}(t) - BW^{(k-1)}(t-\tau), \\ x^{(k)}(0) = x_0, \quad W^{(k)}(\theta) \equiv \varphi(\theta) \quad (-\tau \le \theta < 0), \quad t \in [0, T_e], \quad k = 1, 2, \ldots, \end{cases} \tag{24}$$

where $C(\cdot) = C_1(\cdot) - C_2(\cdot)$, $A(\cdot) = A_1(\cdot) - A_2(\cdot)$, and $x^{(0)}, W^{(0)}$ are two initial guesses. Similarly, for $i = 1, 2$ we assume that $C_i(\cdot)$, $\frac{dC_i(\cdot)}{dt}$, $A_i(\cdot)$, and $\frac{\partial F}{\partial u_i}$ are continuous, where $\frac{\partial F}{\partial u_i}$ $(i = 1, 2)$ are the partial derivatives of $F(x^{(k)}(\cdot), x^{(k-1)}(\cdot), \cdot)$ with respect to the first two arguments. Moreover, we also assume that $C_1(t)$ for all $t \in [0, T_e]$ are nonsingular and $\frac{\partial F}{\partial u_i}$ $(i = 1, 2)$ are bounded. By the relaxation-based method (24), equation (19) is now decoupled into two independent subsystem ODEs and AEs for any fixed k.

Let the function pair (x, W) be the exact solution of (19). We define $\epsilon^{(l)}(\cdot) = x^{(l)}(\cdot) - x(\cdot)$ and $\delta^{(l)}(\cdot) = W^{(l)}(\cdot) - W(\cdot)$ for an index l such that $\epsilon^{(l)}(0) = 0$ and $\delta^{(l)}(\theta) \equiv 0$, where $-\tau \le \theta < 0$. By (19) and (24), according to the known mean theorem of vector functions we have

$$\begin{cases} C_1(t)\dfrac{d\epsilon^{(k)}(t)}{dt} + \dfrac{\partial F}{\partial u_1}\epsilon^{(k)}(t) + \dfrac{\partial F}{\partial u_2}\epsilon^{(k-1)}(t) = C_2(t)\dfrac{d\epsilon^{(k-1)}(t)}{dt} - D\delta^{(k-1)}(t-\tau), \\ A_1(t)\epsilon^{(k)}(t) + \delta^{(k)}(t) = A_2(t)\epsilon^{(k-1)}(t) - B\delta^{(k-1)}(t-\tau), \\ \epsilon^{(k)}(0) = 0, \quad \delta^{(k)}(\theta) \equiv 0 \quad (-\tau \le \theta < 0), \quad t \in [0, T_e], \quad k = 1, 2, \ldots. \end{cases} \tag{25}$$

We write the differential part of (25) as

$$\begin{cases} \dfrac{d\epsilon^{(k)}(t)}{dt} = -C_1^{-1}(t)\dfrac{\partial F}{\partial u_1}\epsilon^{(k)}(t) + C_1^{-1}(t)C_2(t)\dfrac{d\epsilon^{(k-1)}(t)}{dt} - C_1^{-1}(t)\dfrac{\partial F}{\partial u_2}\epsilon^{(k-1)}(t) \\ \qquad\qquad - C_1^{-1}(t)D\delta^{(k-1)}(t-\tau), \\ \epsilon^{(k)}(0) = 0, \quad t \in [0, T_e], \quad k = 1, 2, \ldots. \end{cases} \tag{26}$$

We now denote $X(\cdot) = -C_1^{-1}(\cdot)\frac{\partial F}{\partial u_1}$ and let the matrix-valued function $\Phi(\cdot)$ satisfy

$$\begin{cases} \dfrac{d\Phi(t)}{dt} = X(t)\Phi(t), \\ \Phi(0) = I, \quad t \in [0, T_e]. \end{cases} \tag{27}$$

Using the fundamental solution matrix $\Phi(\cdot)$ and doing some calculations as in [15],

for $t \in [0, T_e]$ we have

$$\begin{aligned}\epsilon^{(k)}(t) &= C_1^{-1}(t)C_2(t)\epsilon^{(k-1)}(t)\\ &- \Phi(t)\int_0^t \Phi^{-1}(s)\left[C_1^{-1}(s)\frac{\partial F}{\partial u_1}C_1^{-1}(s)C_2(s) + C_1^{-1}(s)\frac{\partial F}{\partial u_2} + \frac{d(C_1^{-1}C_2)(s)}{ds}\right]\epsilon^{(k-1)}(s)ds\\ &- \Phi(t)\int_0^t \Phi^{-1}(s)C_1^{-1}(s)D\delta^{(k-1)}(s-\tau)ds.\end{aligned} \tag{28}$$

For a positive parameter λ, multiplying both sides of (28) by $e^{-\lambda t}$, we have

$$\begin{aligned}e^{-\lambda t}\epsilon^{(k)}(t) &= C_1^{-1}(t)C_2(t)(e^{-\lambda t}\epsilon^{(k-1)}(t))\\ &- e^{-\lambda t}\Phi(t)\int_0^t e^{\lambda s}\Phi^{-1}(s)\left[C_1^{-1}(s)\frac{\partial F}{\partial u_1}C_1^{-1}(s)C_2(s) + C_1^{-1}(s)\frac{\partial F}{\partial u_2} + \frac{d(C_1^{-1}C_2)(s)}{ds}\right]\\ &\qquad \times (e^{-\lambda s}\epsilon^{(k-1)}(s))ds\\ &- e^{-\lambda t}\Phi(t)\int_0^t e^{\lambda s}\Phi^{-1}(s)C_1^{-1}(s)DJ(\tau)(e^{-\lambda(s-\tau)}\delta^{(k-1)}(s-\tau))ds, \quad t \in [0, T_e],\end{aligned} \tag{29}$$

where

$$\begin{aligned}&e^{-\lambda(s-\tau)}\delta^{(k-1)}(s-\tau)\\ = \;& [e^{-\lambda(s-\tau_1)}(y_1^{(k-1)}(s-\tau_1) - y_1(s-\tau_1)), e^{-\lambda(s-\tau_1)}(z_1^{(k-1)}(s-\tau_1) - z_1(s-\tau_1)), \ldots,\\ & e^{-\lambda(s-\tau_m)}(y_m^{(k-1)}(s-\tau_m) - y_m(s-\tau_m)), e^{-\lambda(s-\tau_m)}(z_m^{(k-1)}(s-\tau_m) - z_m(s-\tau_m))]^t\end{aligned}$$

and

$$J(\tau) = \begin{bmatrix} e^{-\lambda\tau_1}I & & 0\\ & \ddots & \\ 0 & & e^{-\lambda\tau_m}I\end{bmatrix} \in \mathbf{R}^{2m\times 2m},$$

in which $I = \left[\begin{smallmatrix}1 & 0\\ 0 & 1\end{smallmatrix}\right]$.

All functions appearing in (29) are bounded due to the stated assumptions. There are two positive constants K_1 and K_2 such that

$$\begin{aligned}\|e^{-\lambda t}\epsilon^{(k)}(t)\| \;\le\; & \|C_1^{-1}(t)C_2(t)\|\|e^{-\lambda t}\epsilon^{(k-1)}(t)\| + e^{-\lambda t}K_1\int_0^t e^{\lambda s}\|e^{-\lambda s}\epsilon^{(k-1)}(s)\|ds\\ & + e^{-\lambda t}K_2\|J(\tau)\|\int_0^t e^{\lambda s}\|e^{-\lambda(s-\tau)}\delta^{(k-1)}(s-\tau)\|ds, \quad t \in [0, T_e],\end{aligned} \tag{30}$$

where the norm is adopted as one of $\|\cdot\|_p$, where $p = 1, 2, \infty$.

We define $\|u\|_t = \sup_{a\le s\le t}\{\|u(s)\|\}$ for a vector or matrix function $u(\cdot)$ on $[a, b]$. The function $\|u\|_t$ is monotonically increasing with respect to t on $[a, b]$. Because $\|J(\tau)\| = e^{-\lambda\tau'}$ and

$$e^{-\lambda t}\int_0^t e^{\lambda s}ds \le \frac{1}{\lambda}, \quad t \in [0, T_e],$$

we can rewrite (30) as

$$\begin{aligned}\|\epsilon^{(k)}\|_t \;&\le\; \|C_1^{-1}C_2\|_t\|\epsilon^{(k-1)}\|_t + \frac{K_1}{\lambda}\|\epsilon^{(k-1)}\|_t + \frac{K_2e^{-\lambda\tau'}}{\lambda}\|\delta^{(k-1)}\|_{t-\tau}\\ &\le\; \left(\|C_1^{-1}C_2\|_t + \frac{K_1}{\lambda}\right)\|\epsilon^{(k-1)}\|_t + \frac{K_2e^{-\lambda\tau'}}{\lambda}\|\delta^{(k-1)}\|_t, \quad t \in [0, T_e].\end{aligned} \tag{31}$$

We now write the algebraic part of (25) for a fixed k as

$$\delta^{(k)}(t) = -A_1(t)\epsilon^{(k)}(t) + A_2(t)\epsilon^{(k-1)}(t) - B\delta^{(k-1)}(t-\tau), \quad t \in [0, T_e]. \tag{32}$$

Using $e^{-\lambda t}$ to multiply its two sides, on $[0, T_e]$ we know that

$$e^{-\lambda t}\delta^{(k)}(t) = -A_1(t)(e^{-\lambda t}\epsilon^{(k)}(t)) + A_2(t)(e^{-\lambda t}\epsilon^{(k-1)}(t)) - e^{-\lambda\tau}B(e^{-\lambda(t-\tau)}\delta^{(k-1)}(t-\tau)), \tag{33}$$

where

$$e^{-\lambda\tau}B = \begin{bmatrix} e^{-\lambda\tau_1}I_d & & 0 \\ & \ddots & \\ 0 & & e^{-\lambda\tau_m}I_d \end{bmatrix} \in \mathbf{R}^{2m\times 2m}.$$

For $t \in [0, T_e]$, it follows that

$$\begin{array}{rcl} \|\delta^{(k)}\|_t & \le & \|A_1\|_t\|\epsilon^{(k)}\|_t + \|A_2\|_t\|\epsilon^{(k-1)}\|_t + \|e^{-\lambda\tau}B\|\|\delta^{(k-1)}\|_{t-\tau} \\ & \le & \|A_1\|_t\|\epsilon^{(k)}\|_t + \|A_2\|_t\|\epsilon^{(k-1)}\|_t + e^{-\lambda\tau'}\|\delta^{(k-1)}\|_t \end{array} \tag{34}$$

due to the fact $\|e^{-\lambda\tau}B\| = e^{-\lambda\tau'}$. Substituting (31) into the above inequality, we get

$$\begin{array}{rcl} \|\delta^{(k)}\|_t & \le & \left[\left(\|C_1^{-1}C_2\|_t + \dfrac{K_1}{\lambda}\right)\|A_1\|_t + \|A_2\|_t\right]\|\epsilon^{(k-1)}\|_t \\ & & + \left(e^{-\lambda\tau'} + \dfrac{K_2e^{-\lambda\tau'}}{\lambda}\|A_1\|_t\right)\|\delta^{(k-1)}\|_t, \quad t \in [0, T_e]. \end{array} \tag{35}$$

By (31) and (35), we have

$$\begin{bmatrix} \|\epsilon^{(k)}\|_{T_e} \\ \|\delta^{(k)}\|_{T_e} \end{bmatrix} \le M(1/\lambda) \begin{bmatrix} \|\epsilon^{(k-1)}\|_{T_e} \\ \|\delta^{(k-1)}\|_{T_e} \end{bmatrix}, \quad k = 1, 2, \ldots, \tag{36}$$

where

$$M(1/\lambda) = \begin{bmatrix} \|C_1^{-1}C_2\|_{T_e} + \frac{K_1}{\lambda} & \frac{K_2e^{-\lambda\tau'}}{\lambda} \\ (\|C_1^{-1}C_2\|_{T_e} + \frac{K_1}{\lambda})\|A_1\|_{T_e} + \|A_2\|_{T_e} & e^{-\lambda\tau'} + \frac{K_2e^{-\lambda\tau'}}{\lambda}\|A_1\|_{T_e} \end{bmatrix}. \tag{37}$$

It is a known conclusion that for any matrix $H(= (h_{ij}))$ its spectral radius $\rho(H)$ is a continuous function of h_{ij} for all i and j. Since the spectral radius of $M(0)$ is $\|C_1^{-1}C_2\|_{T_e}$, the spectral radius of $M(1/\lambda)$ will be less than one for some large λ if the quantity $\|C_1^{-1}C_2\|_{T_e}$ is less than one. Thus, we have proven the following theorem.

THEOREM 3.1. *For the nonlinear circuit system with lossless transmission lines* (19)*, its WR method* (24) *is convergent if*

$$\sup_{0\le t\le T_e} \|C_1^{-1}(t)C_2(t)\| < 1. \tag{38}$$

Let us denote $\alpha = \sup_{0\le t\le T_e} \|C_1^{-1}(t)C_2(t)\|$ and $\beta = \sup_{0\le t\le T_e} \|C_1^{-1}(t)D\|$. We rewrite the WR method (24) as

$$\begin{cases} \dfrac{dx^{(k)}(t)}{dt} = C_1^{-1}(t)C_2(t)\dfrac{dx^{(k-1)}(t)}{dt} - C_1^{-1}(t)F(x^{(k)}(t), x^{(k-1)}(t), t) \\ \qquad\qquad - C_1^{-1}(t)DW^{(k-1)}(t-\tau) + C_1^{-1}(t)b(t), \\ W^{(k)}(t) = -A_1(t)x^{(k)}(t) + A_2(t)x^{(k-1)}(t) - BW^{(k-1)}(t-\tau), \\ x^{(k)}(0) = x_0, \quad W^{(k)}(\theta) \equiv \varphi(\theta) \quad (-\tau \le \theta < 0), \quad t \in [0, T_e], \quad k = 1, 2, \ldots. \end{cases} \tag{39}$$

Now, we briefly define a basic 2×2 matrix as

$$N = \begin{bmatrix} \alpha & \beta \\ 0 & \|B\| \end{bmatrix}. \tag{40}$$

If one tries to use a known convergence result in [8, 12], the condition $\rho(N) < 1$ is necessary. However, under the assumption of Theorem 3.1 in the paper it is impossible because we know

$$\rho(N) = \max\{\alpha, \|B\|\} \tag{41}$$

and $\|B\| = 1$.

To speed up the WR convergence of (24), a windowing technique can be used for a long interval $[0, T_e]$. The decoupled subsystems by WR with windowing are separately solved on windows $[T_i, T_{i+1}]$ with time points T_i $(0 = T_0 < T_1 < \cdots < T_N = T_e)$. The computation of the WR solutions starts at T_0 and goes on from one window to another window until $T_N = T_e$ is reached. Namely,

$$\begin{cases} C_1(t)\dfrac{dx_i^{(k)}(t)}{dt} + F(x_i^{(k)}(t), x_i^{(k-1)}(t), t) = C_2(t)\dfrac{dx_i^{(k-1)}(t)}{dt} - DW_i^{(k-1)}(t-\tau) + b(t), \\ A_1(t)x_i^{(k)}(t) + W_i^{(k)}(t) = A_2(t)x_i^{(k-1)}(t) - BW_i^{(k-1)}(t-\tau), \quad t \in [T_i, T_{i+1}], \\ x_i^{(k)}(T_i) = x_{i-1}^{(k_{i-1})}(T_i), \quad k = 1, 2, \ldots, k_i, \quad i = 0, 1, \ldots, N-1, \end{cases} \tag{42}$$

where $x_{-1}^{(k_{-1})}(0) = x_0$, $W^{(l)}(t-\tau) \equiv \varphi(t-\tau)$ if $t \le \tau$, and the initial guesses $x_i^{(0)}(t) \equiv x_{i-1}^{(k_{i-1})}(T_i)$, $W_i^{(0)}(t-\tau) \equiv W_{i-1}^{(k_{i-1})}(T_i - \tau)$ on $[T_i, T_{i+1}]$ for all i.

4. Numerical experiments. Our numerical experiments are done for three simple circuits with transmission lines.

4.1. Example 1. The circuit is shown in Figure 3. For (12), its WR method is

$$\begin{cases} c_1\dfrac{dv_1^{(k)}(t)}{dt} + \left(\dfrac{1}{R_1} + \dfrac{1}{z_0}\right) v_1^{(k)}(t) = \dfrac{1}{z_0}W_A^{(k-1)}(t-\tau) + \dfrac{E(t)}{R_1}, \\ c_2\dfrac{dv_2^{(k)}(t)}{dt} + \left(\dfrac{1}{R_2} + \dfrac{1}{z_0}\right) v_2^{(k)}(t) = \dfrac{1}{z_0}W_B^{(k-1)}(t-\tau), \\ -2v_2^{(k)}(t) + W_A^{(k)}(t) = -W_B^{(k-1)}(t-\tau), \quad -2v_1^{(k)}(t) + W_B^{(k)}(t) = -W_A^{(k-1)}(t-\tau), \\ [v_1^{(k)}(0), v_2^{(k)}(0)]^t = [v_1(0), v_2(0)]^t, \\ [W_A^{(k)}(\theta), W_B^{(k)}(\theta)]^t \equiv [\varphi_A(\theta), \varphi_B(\theta)]^t \qquad (-\tau \le \theta < 0), \\ t \in [0, T_e], \quad k = 1, 2, \ldots. \end{cases} \tag{43}$$

We assume that the system starts from rest. The parameters are defined as $c_1 = c_2 = 10^{-3}$nF, $R_1 = 50\Omega$, $R_2 = 100\Omega$, $z_0 = 24.5\Omega$, $\tau = 0.244$ns, $T_e = 2.684$ns, and

$$E(t) = \begin{cases} \left(4 + \dfrac{t - 2 \times 10^{-10}}{2 \times 10^{-10}}\right) V, \quad 2 \times 10^{-10} < t \le 4 \times 10^{-10}; \\ 0 \quad \text{otherwise.} \end{cases}$$

The implicit Euler method, where the time-step is 0.0122ns, is taken to compute the decoupled ODEs. We define the iterative error as the sum of the squared differences of successive waveforms taken over all time points. The numerical results are given in Table 1. The far end voltage $v_2(t)$ is shown in Figure 6.

TABLE 1
WR of a linear circuit in Example 1.

Numbers of iterations	Iterative errors
1, 2, 3, 4, 5	$1.3820,\ \ 1.2130,\ \ 5.6123\times10^{-1},\ \ 2.7017\times10^{-1},\ \ 1.2604\times10^{-1}$
6, 7, 8, 9	$6.1703\times10^{-2},\ \ 2.9241\times10^{-2},\ \ 1.4721\times10^{-2},\ \ 6.5511\times10^{-3}$
10, 11	$1.9368\times10^{-3},\ \ 3.4737\times10^{-4}$

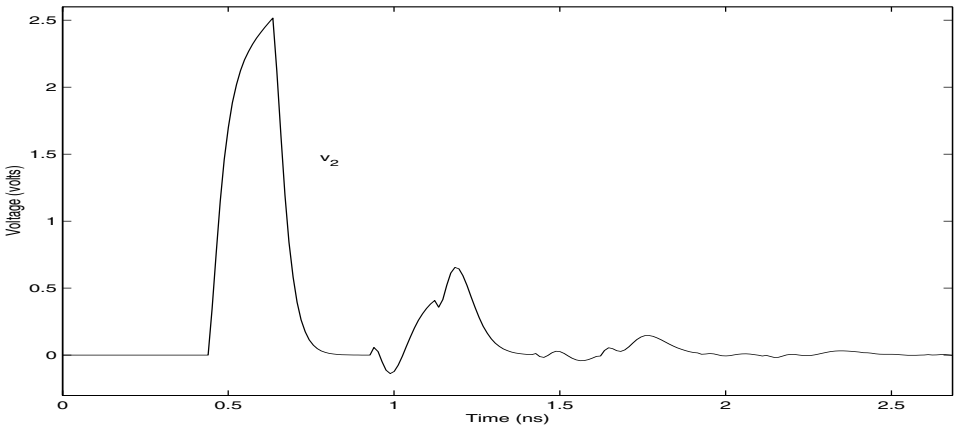

FIG. 6. *Far end voltage of a linear circuit in Example* 1.

4.2. Example 2. The circuit is shown in Figure 5. For (12), its WR method is

$$
\begin{cases}
c_1\dfrac{dv_1^{(k)}(t)}{dt}+\left(\dfrac{1}{R_1}+\dfrac{1}{z_{01}}\right)v_1^{(k)}(t)=\dfrac{1}{z_{01}}W_{A1}^{(k-1)}(t-\tau_1)+\dfrac{E(t)}{R_1},\\
c_2\dfrac{dv_2^{(k)}(t)}{dt}+\left(\dfrac{1}{z_{01}}+\dfrac{1}{z_{02}}+\dfrac{1}{z_{03}}\right)v_2^{(k)}(t)\ =\ \dfrac{1}{z_{01}}W_{B1}^{(k-1)}(t-\tau_1)+\dfrac{1}{z_{02}}W_{A2}^{(k-1)}(t-\tau_2)\\
\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad+\dfrac{1}{z_{03}}W_{A3}^{(k-1)}(t-\tau_3),\\
c_3\dfrac{dv_3^{(k)}(t)}{dt}+\left(\dfrac{1}{R_3}+\dfrac{1}{z_{02}}\right)v_3^{(k)}(t)=\dfrac{1}{z_{02}}W_{B2}^{(k-1)}(t-\tau_2),\\
c_4\dfrac{dv_4^{(k)}(t)}{dt}+\left(\dfrac{1}{R_4}+\dfrac{1}{z_{03}}\right)v_4^{(k)}(t)=\dfrac{1}{z_{03}}W_{B3}^{(k-1)}(t-\tau_3),\\
-2v_2^{(k)}(t)+W_{A1}^{(k)}(t)=-W_{B1}^{(k-1)}(t-\tau_1),\quad -2v_1^{(k)}(t)+W_{B1}^{(k)}(t)=-W_{A1}^{(k-1)}(t-\tau_1),\\
-2v_3^{(k)}(t)+W_{A2}^{(k)}(t)=-W_{B2}^{(k-1)}(t-\tau_2),\quad -2v_2^{(k)}(t)+W_{B2}^{(k)}(t)=-W_{A2}^{(k-1)}(t-\tau_2),\\
-2v_4^{(k)}(t)+W_{A3}^{(k)}(t)=-W_{B3}^{(k-1)}(t-\tau_3),\quad -2v_2^{(k)}(t)+W_{B3}^{(k)}(t)=-W_{A3}^{(k-1)}(t-\tau_3),\\
[v_1^{(k)}(0),v_2^{(k)}(0),v_3^{(k)}(0),v_4^{(k)}(0)]^t=[v_1(0),v_2(0),v_3(0),v_4(0)]^t,\\
[W_{A1}^{(k)}(\theta_1),W_{B1}^{(k)}(\theta_1),\ldots,W_{A3}^{(k)}(\theta_3),W_{B3}^{(k)}(\theta_3)]^t\\
\qquad\equiv[\varphi_{A1}(\theta_1),\varphi_{B1}(\theta_1),\ldots,\varphi_{A3}(\theta_3),\varphi_{B3}(\theta_3)]^t,\\
-\tau_i\le\theta_i\le 0,\quad 1\le i\le 3,\quad t\in[0,T_e],\quad k=1,2,\ldots.
\end{cases}
\tag{44}
$$

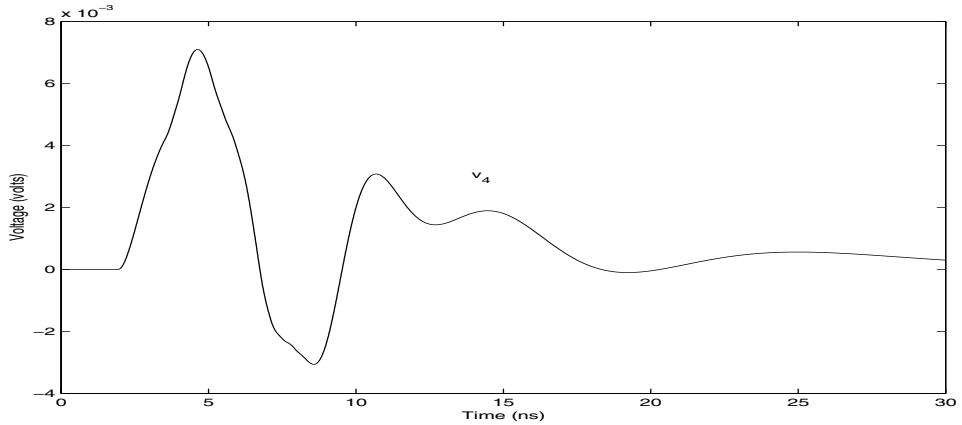

FIG. 7. *Far end voltage of a circuit with multiple transmission lines in Example* 2.

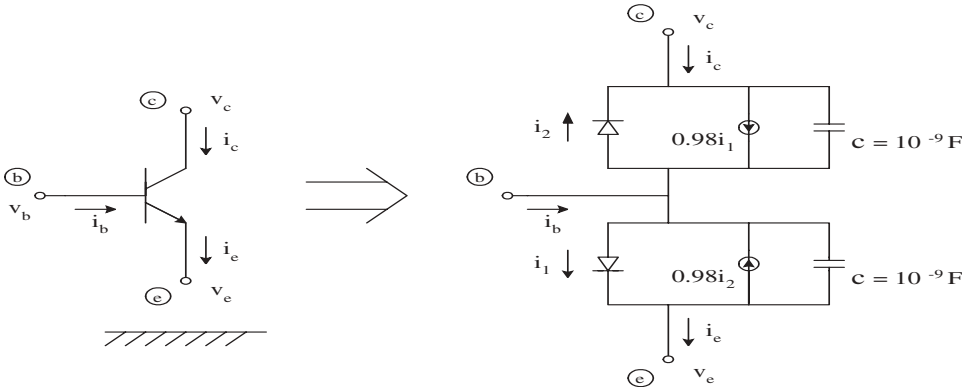

FIG. 8. *A transistor and its circuit.*

We also assume that the system starts from total rest for the example. The parameters are defined as $c_1 = c_4 = 0.1$nF, $c_2 = c_3 = 0.2$nF, $R_1 = 50\Omega$, $R_3 = 50\Omega$, $R_4 = 50\Omega$, $z_{01} = 10\Omega$, $z_{02} = 20\Omega$, $z_{03} = 30\Omega$, $\tau_1 = 1$ns, $\tau_2 = 0.9$ns, $\tau_3 = 0.8$ns, $T_e = 30$ns, and

$$E(t) = \begin{cases} 1\text{V}, & 0.1\text{ns} < t \le 0.2\text{ns}; \\ 0 & \text{otherwise.} \end{cases}$$

We let the time-step be 0.01ns. The far end voltage $v_4(t)$ is shown in Figure 7 after nine waveform iterations.

4.3. Example 3. Now we compute a circuit which includes transistors. The transistor is given in Figure 8. The transistor equations are

$$(45)\quad \begin{cases} i_c = 0.98i_1 - i_2 + c\dfrac{d(v_c - v_b)}{dt}, \\ i_e = -0.98i_2 + i_1 + c\dfrac{d(v_b - v_e)}{dt}, \\ i_b = i_e - i_c, \quad i_1 = 10^{-6}(e^{40(v_b - v_e)} - 1), \quad i_2 = 10^{-6}(e^{40(v_b - v_c)} - 1). \end{cases}$$

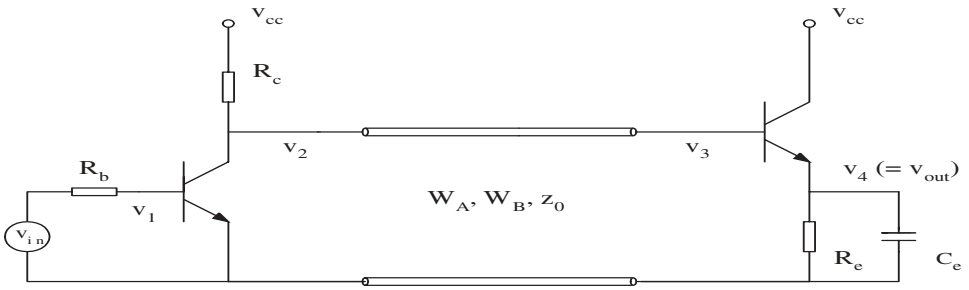

FIG. 9. *A nonlinear circuit with transistors and transmission lines.*

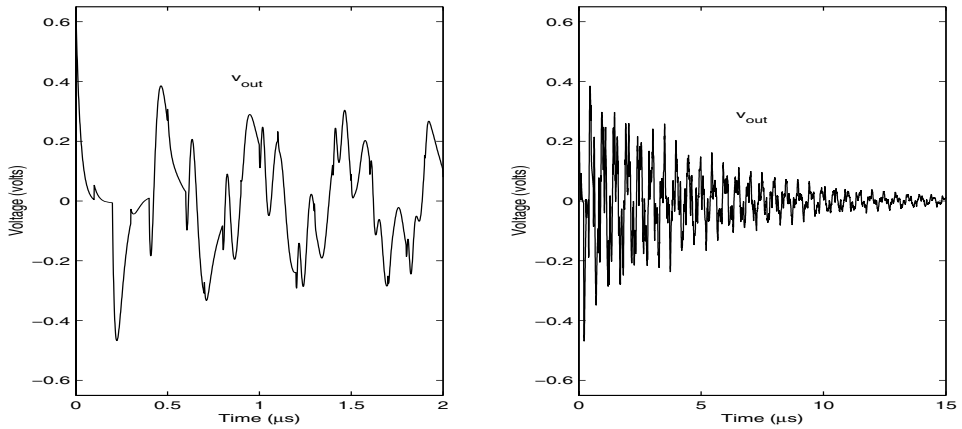

FIG. 10. *Far end voltage of a nonlinear circuit with transistors and transmission lines in Example* 3 *(left: computed result; right: long time behavior).*

The circuit is shown in Figure 9. Its equations are

$$
\begin{cases}
\dfrac{v_{in}-v_1}{R_b} = -0.98\times 10^{-6}(e^{40(v_1-v_2)}-1)+10^{-6}(e^{40v_1}-1) \\
\qquad\qquad +10^{-9}\dfrac{dv_1}{dt}-0.98\times 10^{-6}(e^{40v_1}-1)+10^{-6}(e^{40(v_1-v_2)}-1) \\
\qquad\qquad -10^{-9}\dfrac{d(v_2-v_1)}{dt}, \\
\dfrac{v_{cc}-v_2}{R_c} = \dfrac{v_2-W_A(t-\tau)}{z_0}+0.98\times 10^{-6}(e^{40v_1}-1)-10^{-6}(e^{40(v_1-v_2)}-1) \\
\qquad\qquad +10^{-9}\dfrac{d(v_2-v_1)}{dt}, \\
\dfrac{W_B(t-\tau)-v_3}{z_0}+0.98\times 10^{-6}(e^{40(v_3-v_4)}-1)-10^{-6}(e^{40(v_3-v_{cc})}-1)-10^{-9}\dfrac{dv_3}{dt} \\
\qquad = -0.98\times 10^{-6}(e^{40(v_3-v_{cc})}-1)+10^{-6}(e^{40(v_3-v_4)}-1)+10^{-9}\dfrac{d(v_3-v_4)}{dt}, \\
-0.98\times 10^{-6}(e^{40(v_3-v_{cc})}-1)+10^{-6}(e^{40(v_3-v_4)}-1)+10^{-9}\dfrac{d(v_3-v_4)}{dt} = \dfrac{v_4}{R_e}+c_e\dfrac{dv_4}{dt}, \\
W_A(t)=2v_3(t)-W_B(t-\tau), \quad W_B(t)=2v_2(t)-W_A(t-\tau).
\end{cases}
\tag{46}
$$

The above circuit parameters are set to be $v_{cc} = 5\text{V}$, $R_b = 50\Omega$, $R_c = 1000\Omega$, $R_e = 1000\Omega$, $c_e = 10\text{pF}$, $z_0 = 25\Omega$, $\tau = 0.1\mu\text{s}$, $T_e = 2\mu\text{s}$, $v_1(0) = v_2(0) = v_3(0) = 0.65\text{V}$, $\varphi_A(\theta) \equiv \varphi_B(\theta) \equiv 0$ $(-\tau \le \theta < 0)$, and

$$v_{in}(t) = \begin{cases} 0, & 0.05\mu\text{s} < t \le 0.06\mu\text{s}; \\ 0.8\text{V} & \text{otherwise.} \end{cases}$$

The Gauss–Seidel WR method of (46) is

$$\begin{cases} 2\times 10^{-9}\dfrac{dv_1^{(k)}}{dt} + \dfrac{v_1^{(k)}}{R_b} + 10^{-8}e^{40(v_1^{(k)}-v_2^{(k-1)})} + 10^{-8}e^{40v_1^{(k)}} \\ \qquad = 10^{-9}\dfrac{dv_2^{(k-1)}}{dt} + \dfrac{v_{in}}{R_b} + 2\times 10^{-8}, \\ -10^{-9}\dfrac{dv_1^{(k)}}{dt} + 10^{-9}\dfrac{dv_2^{(k)}}{dt} + \left(\dfrac{1}{R_c} + \dfrac{1}{z_0}\right)v_2^{(k)} + 0.98\times 10^{-6}e^{40v_1^{(k)}} - 10^{-6}e^{40(v_1^{(k)}-v_2^{(k)})} \\ \qquad = \dfrac{W_A^{(k-1)}(t-\tau)}{z_0} + \dfrac{v_{cc}}{R_c} - 2\times 10^{-8}, \\ 2\times 10^{-9}\dfrac{dv_3^{(k)}}{dt} + \dfrac{v_3^{(k)}}{z_0} + 10^{-8}e^{40(v_3^{(k)}-v_{cc})} + 10^{-8}e^{40(v_3^{(k)}-v_4^{(k-1)})} \\ \qquad = 10^{-9}\dfrac{dv_4^{(k-1)}}{dt} + \dfrac{W_B^{(k-1)}(t-\tau)}{z_0} + 2\times 10^{-8}, \\ -10^{-9}\dfrac{dv_3^{(k)}}{dt} + (1+c_e)\times 10^{-9}\dfrac{dv_4^{(k)}}{dt} + \dfrac{v_4^{(k)}}{R_e} - 10^{-6}e^{40(v_3^{(k)}-v_4^{(k)})} + 0.98\times 10^{-6}e^{40(v_3^{(k)}-v_{cc})} \\ \qquad = -2\times 10^{-8}, \\ -2v_3^{(k)}(t) + W_A^{(k)}(t) = -W_B^{(k-1)}(t-\tau), \quad -2v_2^{(k)}(t) + W_B^{(k)}(t) = -W_A^{(k-1)}(t-\tau), \\ [v_1^{(k)}(0), v_2^{(k)}(0), v_3^{(k)}(0), v_4^{(k)}(0)]^t = [v_1(0), v_2(0), v_3(0), v_4(0)]^t, \\ [W_A^{(k)}(\theta), W_B^{(k)}(\theta)]^t \equiv [\varphi_A(\theta), \varphi_B(\theta)]^t, \quad -\tau \le \theta < 0, \quad t \in [0, T_e], \quad k = 1, 2, \ldots. \end{cases} \tag{47}$$

The spectral radius of the Gauss–Seidel splitting on the coefficient matrix of the derivative term in (47) is 0.5. The Gauss–Seidel WR method (47) is convergent by our theorem of the paper. In our computations, we let the time-step be $10^{-3}\mu$s and the number of Newton iterations be 5. After 28 waveform iterations the computed voltage $v_{out}(t)(= v_4(t))$ is shown in Figure 10.

5. Conclusion. We have presented an interesting time-domain approach to solving a circuit with lossless distributed elements. The circuit is described by DAEs with multiple constant delays. The WR process decouples the system into ODEs and AEs. A detailed proof of convergence of the new method is given. This approach directly leads to the solution of the circuit in time-domain, and any of the general-purpose circuit simulators can be used to solve the decoupled subsystems.

A POSTERIORI ERROR ESTIMATES FOR DISCONTINUOUS GALERKIN TIME-STEPPING METHOD FOR OPTIMAL CONTROL PROBLEMS GOVERNED BY PARABOLIC EQUATIONS*

WENBIN LIU†, HEPING MA‡, TAO TANG§, AND NINGNING YAN¶

Abstract. In this paper, we examine the discontinuous Galerkin (DG) finite element approximation to convex distributed optimal control problems governed by linear parabolic equations, where the discontinuous finite element method is used for the time discretization and the conforming finite element method is used for the space discretization. We derive a posteriori error estimates for both the state and the control approximation, assuming only that the underlying mesh in space is nondegenerate. For problems with control constraints of obstacle type, which are the kind most frequently met in applications, further improved error estimates are obtained.

Key words. optimal control, a posteriori error analysis, finite element approximation, discontinuous Galerkin method

1. Introduction.

Optimal control or design is crucial to many engineering applications. Efficient numerical methods are essential to successful applications of optimal control. Nowadays, the finite element method seems to be the most widely used numerical method in computing optimal control problems, and the relevant literature is extensive. Some recent progress in this area has been made in, for example, [40, 41, 43]. Systematic introduction of the finite element method for PDEs and optimal control problems can be found in, for example, [10, 40, 43]. For instance, there have been extensive theoretical studies for finite element approximation of various optimal control problems; see [3, 15, 16, 18, 19], [20, 21, 22, 23, 24, 25, 26], and [37, 39, 44, 45]. For optimal control problems governed by linear elliptic or parabolic state equations, a priori error estimates of finite element approximation were established long ago; see, for example, [15, 18, 26, 37]. Furthermore a priori error estimates have been also established for some important flow control problems; see, e.g., [19, 20]. A priori error estimates have also been obtained for a class of state constrained con-

trol problems in [44], although the state equation is assumed to be linear. In [32], the linear assumption has been removed by reformulating the control problem as an abstract optimization problem in some Banach spaces and then applying nonsmooth analysis. In fact, the state equation there can be a variational inequality.

In this paper, we examine an important class of finite element algorithms for a convex distributed optimal control problem governed by a linear parabolic equation, where the discontinuous polynomial base is used in time discretization and the conforming finite element method is used in space discretization. We present an a posteriori error analysis for this approximation.

Adaptive finite element approximation is among the most important means to boost the accuracy and efficiency of the finite element discretization. It ensures a higher density of nodes in certain areas of the given domain, where the solution is more difficult to approximate using an a posteriori error indicator. The decision about whether further refinement of meshes is necessary is based on the estimate of the discretization error. If further refinement is to be performed, then the error indicator is used as a guide to show how the refinement might be accomplished most efficiently. The literature in this area is huge. Some of the techniques directly relevant to our work can be found in [1, 5, 33, 36, 46]. It is our belief that adaptive finite element enhancement is one of the future directions to pursue in developing sophisticated numerical methods for optimal design problems.

Although adaptive finite element approximation is widely used in numerical simulations, it has not yet been *fully* utilized in optimal design. Initial attempts in this aspect have only been reported recently for some design problems (see, e.g., [2, 4, 38, 42]), and only a posteriori error indicators of a heuristic nature are used in most applications. For instance, in some existing work on adaptive finite element approximation of optimal design, the mesh refinement is guided by a posteriori error estimators based on a posteriori error estimates *solely* from the state equation for a fixed control. Thus error information from the approximation of the control (design) is not utilized. This strategy was found to be inefficient in recent numerical experiments (see [7, 27]). Although these methods may work well in some particular applications, they cannot be applied confidently in general. It is unlikely that the potential power of adaptive finite element approximation has been fully utilized due to the lack of more sophisticated a posteriori error indicators.

It is not straightforward to rigorously derive suitable a posteriori error estimators for general optimal control problems. In particular, it seems difficult to apply gradient recovery techniques since the control is normally not differentiable. Recovering approximation in function values is in general difficult. For a similar reason, it also seems difficult to apply the local solution strategy.

Very recently, some error indicators of residual type were developed in [6, 7, 27, 30, 34, 35, 36]. These error estimators are based on a posteriori estimation of the discretization error for the state *and* the control (design).

When there is no constraint in a control problem, normally the optimality conditions consist of coupled partial differential equations only. Consequently one may be able to write down the dual system of the *whole* optimality conditions, and then to apply the weighted a posteriori error estimation technique to obtain a posteriori estimators for objective functional approximation error of the control problem; see [6, 7]. Such estimators have indeed been derived for some unconstrained elliptic control problems, and have proved quite efficient in the numerical tests carried out in [6].

However, there frequently exist some constraints for the control in applications. In such cases, the optimality conditions often contain a variational inequality and then have some very different properties. For example, the dual system is generally unknown. Thus it does not seem to be always possible to apply the techniques used in [6, 7] to constrained control problems.

In our work, constrained cases are studied via residual estimation using the norms of energy type. A posteriori error estimators are derived for some constrained control problems governed by elliptic and parabolic equations; see [27, 34, 35, 36].

In recent years, the discontinuous Galerkin (DG) discretization has proved useful in computing time-dependent convection and diffusion equations; see [12, 13, 14] for the DG time-stepping method where only time discretization is discontinuous. It will be simply referred as to the DG method in this paper, although we are aware that there exist several DG discretization schemes in the literature. The DG has proved important in diffusion dominated equations, such as the heat equations, which govern our control problems to be examined in this paper. Furthermore the DG method has been found useful in computing optimal control of diffusion dominated systems; see [40]. However, there is a lack of an a posteriori error analysis for the DG approximation of the control systems, which is vital for further studies of mesh adaptivity of the control problems.

The purpose of this work is to extend the approaches in [12, 27, 34, 35, 36] and to derive a posteriori error estimates for the DG finite element approximation of distributed convex optimal problems governed by linear parabolic equations. Deriving such estimates for the DG finite element scheme is much more involved than for the backward-Euler scheme; see [36]. For example, some approaches applied in [12, 13, 14] have to be essentially modified for our purpose. Furthermore, novel approaches are needed to derive the improved estimates for the control with constraints of obstacle type. Optimal control with obstacle constraints is most frequently met in practical control problems. In fact, the majority of the existing research on constrained control concentrates on this type problem; see [28] and [43], for instance.

The plan of the paper is as follows. In section 2 we shall give a brief review of the finite element method and the discontinuous Galerkin discretization, and then construct the approximation schemes for the optimal control problem. In section 3, a posteriori error bounds are derived for the control problem. In section 4, some applications are discussed. In section 5, improved error estimates are derived for the problem with an obstacle constraint.

Let Ω and Ω_U be bounded open sets in $\mathbb{R}^n$ ($n \leq 3$) with Lipschitz boundaries $\partial\Omega$ and $\partial\Omega_U$. In this paper we adopt the standard notation $W^{m,q}(\Omega)$ for Sobolev spaces on Ω with norm $\|\cdot\|_{m,q,\Omega}$ and seminorm $|\cdot|_{m,q,\Omega}$. We denote $W^{m,2}(\Omega)$ by $H^m(\Omega)$ and set $H_0^1(\Omega) \equiv \{v \in H^1(\Omega) : v|_{\partial\Omega} = 0\}$.

We denote by $L^s(0,T;W^{m,q}(\Omega))$ the Banach space of all L^s integrable functions from $(0,T)$ into $W^{m,q}(\Omega)$ with norm $\|v\|_{L^s(0,T;W^{m,q}(\Omega))} = (\int_0^T \|v\|^s_{W^{m,q}(\Omega)} dt)^{\frac{1}{s}}$ for $s \in [1,\infty)$ and the standard modification for $s = \infty$. Similarly, we define the spaces $H^1(0,T;W^{m,q}(\Omega))$ and $C^l(0,T;W^{m,q}(\Omega))$. The details can be found in [29]. In addition c or C denotes a general positive constant independent of h.

2. Approximation scheme of optimal control problems governed by parabolic equations. In this section we study the finite element and the discontinuous Galerkin approximation of distributed convex optimal control problems, where the state is governed by a parabolic equation. In this paper, we shall take the state

space $W = L^2(0,T;Y)$ with $Y = H_0^1(\Omega)$ and the control space $X = L^2(0,T;U)$ with $U = L^2(\Omega_U)$ to fix the idea. Let B be a linear continuous operator from X to $L^2(0,T;Y')$ and K be a closed convex set in X. We are interested in the following optimal control problem:

$$\min_{u\in K}\int_0^T (g(y)+h(u))\,dt$$

subject to

$$\begin{cases} \partial_t y - \operatorname{div}(A\nabla y) = f + Bu, & x\in\Omega, \quad t\in(0,T],\\ y|_{\partial\Omega} = 0, & t\in[0,T],\\ y(x,0) = y_0(x), & x\in\Omega, \end{cases}$$

where $f \in L^2(0,T;Y')$, $y_0 \in H_0^1(\Omega)$, and

$$A(x) = (a_{ij}(x))_{n\times n} \in (C^\infty(\bar\Omega))^{n\times n}$$

such that there is a constant $c > 0$ satisfying

$$(A\xi)\cdot\xi \ge c|\xi|^2 \quad \forall \xi\in\mathbb{R}^n.$$

Let

$$\begin{aligned} a(v,w) &= \int_\Omega (A\nabla v)\cdot\nabla w && \forall v,w\in H^1(\Omega),\\ (f_1,f_2) &= \int_\Omega f_1 f_2 && \forall f_1,f_2\in L^2(\Omega),\\ (v,w)_U &= \int_{\Omega_U} vw && \forall v,w\in L^2(\Omega_U). \end{aligned}$$

It follows from the assumptions on A that there are constants c and $C > 0$ such that

$$a(v,v)\ge c\|v\|_{1,\Omega}^2, \quad |a(v,w)|\le C|v|_{1,\Omega}|w|_{1,\Omega} \quad \forall v,w\in Y.$$

Then a weak formulation of the convex optimal control problem reads as

$$\min_{u\in K}\int_0^T (g(y)+h(u))\,dt, \tag{1}$$

where $y\in W$ is subject to

$$\begin{cases} (\partial_t y, w) + a(y,w) = (f+Bu, w) & \forall w\in Y,\ t\in(0,T],\\ y(0) = y_0. \end{cases}$$

We assume that g is a convex functional which is continuously differentiable on $L^2(\Omega)$, and h is a strictly convex and continuously differentiable function on U. We further assume that $h(u)\to+\infty$ as $\|u\|_U\to\infty$ and that the functional $g(\cdot)$ is bounded below. This setting includes the most widely used quadratic control problem:

$$\min_{u\in K}\left\{\frac{1}{2}\int_0^T (\|y-z_d\|_{L^2(\Omega)}^2 + \|u\|_{L^2(\Omega_U)}^2)dt\right\}\ ,$$

where y, u are defined as above and z_d is a given state. It is well known (see, e.g., [28]) that the control problem (1) has a unique solution (y, u), and that a pair (y, u) is the solution of (1) if and only if there is a costate $p \in W$ such that the triplet (y, p, u) satisfies the following optimality conditions:

$$\text{(2)} \qquad \begin{cases} (\partial_t y, w) + a(y, w) = (f + Bu, w) & \forall w \in Y, \quad y(0) = y_0, \\ -(\partial_t p, q) + a(q, p) = (g'(y), q) & \forall q \in Y, \quad p(T) = 0, \\ \displaystyle\int_0^T (h'(u) + B^* p, v - u)_U \, dt \geq 0 & \forall v \in K, \end{cases}$$

where B^* is the adjoint operator of B.

Let us consider the finite element approximation of the control problem (1). Here we consider only n-simplices Lagrange elements.

Let Ω^h be a polygonal approximation to Ω with boundary $\partial\Omega^h$. Let T^h be a partitioning of Ω^h into disjoint regular n-simplex τ, so that $\bar{\Omega}^h = \cup_{\tau \in T^h} \bar{\tau}$. Each element has at most one face on $\partial\Omega^h$, and joint elements $\bar{\tau}$ and $\bar{\tau}'$ have either only one common vertex or a whole edge or face if τ and $\tau' \in T^h$. We further require that $P_i \in \partial\Omega^h$ implies $P_i \in \partial\Omega$, where $\{P_i\}$ $(i = 1, 2, \ldots, J)$ is the vertex set associated with the triangulation T^h. We assume that Ω is a convex polygon so that $\Omega = \Omega^h$. The convexity assumption is also important to have the H^2 a priori estimate for the dual equations in Lemma 3.4, which is used in deriving our L^2-L^2 and L^∞-L^2 a posteriori error estimates, although it is not needed for L^2-H^1 estimates. Without the convexity assumption, in general the order of our estimates for the state and costate approximation will be lower if $\partial\Omega$ is nonsmooth. We denote by h_τ the maximum diameter of the element τ in T^h.

Associated with T^h is a finite dimensional subspace S^h of $C(\bar{\Omega}^h)$ such that $w|_\tau$ are m-order polynomials $(m \geq 1)$ for all $w \in S^h$ and $\tau \in T^h$. Let $Y^h = S^h \cap H_0^1(\Omega)$, $W^h = L^2(0, T; Y^h)$; it is easy to see that $Y^h \subset Y$, $W^h \subset W$.

Similarly, we do a partitioning of Ω_U and use the following corresponding notations: T_U^h, τ_U, h_{τ_U}, P_i^U $(i = 1, 2, \ldots, J_U)$, and $\Omega_U^h = \Omega_U$.

Associated with T_U^h is another finite dimensional subspace U^h of $L^2(\Omega_U^h)$ such that $v|_{\tau_U}$ are m-order polynomials $(m \geq 0)$ for all $v \in U^h$ and $\tau_U \in T_U^h$. Here there is no requirement for the continuity. Let $X^h = L^2(0, T; U^h)$. It is easy to see that $U^h \subset U$ and $X^h \subset X$.

Let K^h be an approximation of K. Here we assume that $K^h \subset K$ and $K^h \subset X^h$ for ease of exposition. A nonconforming finite element method will be used later for the problem with the constraint of obstacle type. For more general cases, the readers are referred to [35]. Then a possible semidiscrete finite element approximation of (1) is as follows:

$$\text{(3)} \qquad \min_{u_h \in K^h} \int_0^T (g(y_h) + h(u_h)) \, dt$$

with $y_h \in W^h$ subject to

$$\begin{cases} (\partial_t y_h, w) + a(y_h, w) = (f + Bu_h, w) & \forall w \in Y^h, \quad t \in (0, T], \\ y_h(0) = y_0^h, \end{cases}$$

where K^h is a closed convex set in X^h, $y_0^h \in Y^h$ is an approximation of y_0.

It follows that the control problem (3) has a unique solution (y_h, u_h) and that a pair $(y_h, u_h) \in W^h \times K^h$ is the solution of (3) if and only if there is a costate $p_h \in W^h$

such that the triplet $(y_h, p_h, u_h) \in W^h \times W^h \times K^h$ satisfies the following optimality conditions:

$$(4)\quad \begin{cases} (\partial_t y_h, w) + a(y_h, w) = (f + Bu_h, w) & \forall w \in Y^h, \quad y_h(0) = y_0^h, \\ -(\partial_t p_h, q) + a(q, p_h) = (g'(y_h), q) & \forall q \in Y^h, \quad p_h(T) = 0, \\ \displaystyle\int_0^T (h'(u_h) + B^* p_h, v - u_h)_U \, dt \geq 0 & \forall v \in K^h. \end{cases}$$

The optimality conditions in (4) are the semidiscrete approximation to the problem (1). Now, we are going to consider the fully discrete approximation for the above semidiscrete problem by using the DG method.

Let $0 = t_0 < t_1 < \cdots < t_N = T$, $I_k = (t_{k-1}, t_k]$, $\Delta t_k = t_k - t_{k-1}$ $(k = 1, 2, \ldots, N)$. For $k = 1, 2, \ldots, N$, construct the finite element spaces $Y^{h,k} \in H_0^1(\Omega)$ (similar to Y^h) with the mesh $T^{h,k}$, and construct the finite element spaces $U^{h,k} \in L^2(\Omega_U)$ (similar to U^h) with the mesh $T_U^{h,k}$. Let h_{τ^k} $(h_{\tau_U^k})$ denote the maximum diameter of the element τ^k (τ_U^k) in $T^{h,k}$ $(T_U^{h,k})$. To simplify notation, we will regard a discrete quantity Q^k as $Q(t)$ such that $Q(t)|_{I_k} \equiv Q^k$, and we will denote $\tau(t)$, $\tau_U(t)$, $h_\tau(t)$, and $h_{\tau_U}(t)$ by τ, τ_U, h_τ, and h_{τ_U}, respectively. Let

$$\begin{aligned} &W^\delta = \left\{ w \mid w(x,t)|_{\Omega \times I_k} = \sum_{j=0}^{r} t^j \varphi_j(x), \quad \varphi_j \in Y^{h,k} \right\}, \quad r \geq 0, \\ &X^\delta = \{ v \mid v(x,t)|_{\Omega \times I_k} = \psi(x), \quad \psi \in U^{h,k} \}, \qquad K^\delta \subset (X^\delta \cap K), \\ &[w]_k = w_k^+ - w_k^-, \qquad w_k^\pm = \lim_{s \to 0^\pm} w(t_k + s). \end{aligned}$$

The fully discrete approximation scheme is to find $(y_\delta, u_\delta) \in W^\delta \times X^\delta$ such that

$$(5)\qquad \min_{u_\delta \in K^\delta} \int_0^T (g(y_\delta) + h(u_\delta)) \, dt$$

subject to

$$\begin{aligned} \int_0^T ((\partial_t y_\delta, w) + a(y_\delta, w)) \, dt + \sum_{k=1}^{N-1} ([y_\delta]_k, w_k^+) + ((y_\delta)_0^+ - y_0^h, w_0^+) \\ = \int_0^T (f + Bu_\delta, w) \, dt \quad \forall w \in W^\delta, \end{aligned}$$

where $y_0^h \in Y^{h,0}$ is the approximation to y_0. It follows that the control problem (5) has a unique solution (y_δ, u_δ), and that a pair $(y_\delta, u_\delta) \in W^\delta \times X^\delta$ is the solutions of (5) if and only if there is costate $p_\delta \in W^\delta$ such that the triplet $(y_\delta, p_\delta, u_\delta)$ satisfies

the following optimality conditions:

$$
(6)\quad \begin{cases} \displaystyle\int_0^T ((\partial_t y_\delta, w) + a(y_\delta, w))\, dt + \sum_{k=0}^{N-1} ([y_\delta]_k, w_k^+) & \\ \quad = \displaystyle\int_0^T (f + Bu_\delta, w)\, dt & \forall w \in W^\delta, \quad (y_\delta)_0^- = y_0^h, \\ \displaystyle\int_0^T (-(\partial_t p_\delta, q) + a(p_\delta, q))\, dt - \sum_{k=1}^{N} ([p_\delta]_k, q_k^-) & \\ \quad = \displaystyle\int_0^T (g'(y_\delta), q)\, dt & \forall q \in W^\delta, \quad (p_\delta)_N^+ = 0, \\ \displaystyle\int_0^T (h'(u_\delta) + B^* p_\delta, v - u_\delta)_U\, dt \geq 0 & \forall v \in K^\delta. \end{cases}
$$

This is a finite dimensional optimization problem and may be solved by existing mathematical programming methods. The above DG approximation of the control problem has been used in practical problems; see [40].

In order to obtain a numerical solution of acceptable accuracy for the optimal control problem, the finite element meshes have to be refined according to a mesh refinement scheme. Adaptive finite element approximation uses a posteriori error indicator to guide the mesh refinement procedure. In the following section we shall derive some a posteriori error estimates for the DG finite element approximation of the optimal control problem governed by parabolic equations, which can be used as such an error indicator in developing adaptive finite element schemes of the control problem.

3. A posteriori error estimates. In this section we derive a posteriori error estimates for the DG finite element approximation of the convex optimal problem governed by a parabolic equation. In general, analysis of the finite element approximation of a control problem governed by parabolic equations is more involved than is that of a control problem governed by elliptic equations. The main complication is due to the fact that the properties of the time variable and its discretization are quite different from those of the space (elliptic) variables. Thus different techniques are needed to handle the two groups of variables, and their interactions.

We now need more assumptions on B and g in deriving our estimates. We essentially assume that B is bounded from $L^2(0,T;L^2(\Omega_U))$ to $L^2(0,T;L^2(\Omega))$ so that differential operators are excluded. To derive L^∞ estimates, we need a continuity from $L^2(\Omega_U)$ to $L^2(\Omega)$ uniformly with respect to t, while we have embedded U into X. For g we assume that its derivative is Lipschitz continuous. Thus we make the following assumptions:

$$
(7)\qquad |(Bv, w)_X| = |(v, B^* w)| \leq C\|v\|_{0,\Omega_U}\|w\|_{0,\Omega} \qquad \forall\, v \in U, w \in Y,
$$

$$
(8)\qquad |(g'(v) - g'(w), q)| \leq C\|v - w\|_{0,\Omega}\|q\|_{0,\Omega} \qquad \forall\, v, w, q \in Y,
$$

and there is a constant $c > 0$ such that

$$
(9)\qquad (h'(v) - h'(w), v - w) \geq c\|v - w\|^2_{0,\Omega_U} \qquad \forall\, v, w \in U,
$$

$$
(10)\qquad (g'(v) - g'(w), v - w) \geq 0 \qquad \forall\, v, w \in Y,
$$

which are convex conditions on the functionals h and g. These conditions hold for the quadratic control problems where $\Omega = \Omega_U$ and $B = I$.

The following lemma is important in deriving residual type a posteriori error estimates.

LEMMA 3.1. *Let π_h be the average interpolation operator defined in* [21]. *For any $v \in W^{1,q}(\Omega^h)$ and $1 \le q \le \infty$,*

$$\|v - \pi_h v\|_{l,q,\tau} \le C \sum_{\bar{\tau}' \cap \bar{\tau} \neq \emptyset} h_\tau^{m-l} |v|_{m,q,\tau'}, \qquad v \in W^{m,q}(\tau'), \qquad l = 0, 1, \quad l \le m \le 2.$$

REMARK 3.1. *One of the key steps in deriving a posteriori error estimates for the discontinuous Galerkin method is to construct a suitable L^2 stable approximation of the solution of the dual equation. In* [12], *this approximation is defined to be the space-time L^2-projection of the solution. However, for this selection the spatial projection error cannot be bounded locally due to the global nature of the projecting onto continuous piecewise polynomial functions. This leads to the inconvenience restriction in* [12] *on the mesh used in the approximation: the change in the size of the elements in the mesh must be very smooth, which may be unrealistic in an adaptive finite element implementation. We shall define this approximation to be the L^2-projection of the solution of the dual equation in time, but the quasi-interpolant of the solution in space as defined in* [21]. *It follows from Lemma* 3.1 *that this approximation is L^2 stable. Furthermore, optimal approximation results hold on local patches surrounding a particular element. It is then possible to derive a posteriori error estimates assuming only nondegeneracy of the mesh.*

LEMMA 3.2 (see [25]). *For all $v \in W^{1,q}(\Omega)$, $1 \le q \le \infty$,*

$$\|v\|_{0,q,\partial\tau} \le C(h_\tau^{-1/q} \|v\|_{0,q,\tau} + h_\tau^{1-1/q} |v|_{1,q,\tau}). \tag{11}$$

3.1. $L^2(L^2)$ error estimates. First, let us present a lemma which is essential for our a posteriori error estimate analysis. Assuming that one can find an element v in K^δ to approximate the optimal control in an appropriate way, the approximation error in the control is then shown to be represented by an a posteriori error estimator, plus the approximation error in the costate. For constraints of obstacle type, this assumption can be verified for piecewise constant control approximation by taking v to be the integral average of the optimal control; see Examples 3.1 and 3.2.

LEMMA 3.3. *Let (y, p, u) and $(y_\delta, p_\delta, u_\delta)$ be the solutions of* (2) *and* (6). *Assume that* (9), (10), *and* (7) *hold; $K^\delta \subset K$; for all $1 \le k \le N$, $(h'(u_\delta) + B^* p_\delta)|_{\tau_U^k \times I_k} \in H^1(\tau_U^k \times I_k)$; and there is a $v \in K^\delta$ such that*

(12)
$$\begin{aligned} &\left| \int_{I_k} (h'(u_\delta) + B^* p_\delta, v - u)_U \, dt \right| \\ \le\ & C \int_{I_k} \sum_{\tau_U \in T_U^{h,k}} (h_{\tau_U} |h'(u_\delta) + B^* p_\delta|_{1,\tau_U} + \Delta t_k \|\partial_t (h'(u_\delta) + B^* p_\delta)\|_{0,\tau_U}) \|u - u_\delta\|_{0,\tau_U} \, dt. \end{aligned}$$

Then we have

$$\|u - u_\delta\|^2_{L^2(0,T;L^2(\Omega_U))} \le C \left(\eta_1^2 + \|p_\delta - p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))} \right), \tag{13}$$

where

$$\eta_1^2 = \sum_{k=1}^N \sum_{\tau_U \in T_U^{h,k}} \int_{I_k} (h_{\tau_U}^2 |h'(u_\delta) + B^* p_\delta|^2_{1,\tau_U} + \Delta t_k^2 \|\partial_t (h'(u_\delta) + B^* p_\delta)\|^2_{0,\tau_U}) \, dt$$

and $(y^{u_\delta}, p^{u_\delta}) \in W \times W$ *is defined by the following system:*

$$\begin{cases} (\partial_t y^{u_\delta}, w) + a(y^{u_\delta}, w) = (f + Bu_\delta, w) \quad \forall w \in Y, \quad t \in (0,T], \\ y^{u_\delta}(0) = y_0, \end{cases} \tag{14}$$

$$\begin{cases} -(\partial_t p^{u_\delta}, q) + a(q, p^{u_\delta}) = (g'(y^{u_\delta}), q) \quad \forall q \in Y, \quad t \in [0,T), \\ p^{u_\delta}(T) = 0. \end{cases} \tag{15}$$

Proof. It follows from (9), $(2)_3$, and $(6)_3$ that, for any $v \in K^\delta$,

$$\begin{aligned} & c\|u - u_\delta\|^2_{L^2(0,T;L^2(\Omega_U))} \le \int_0^T (h'(u), u - u_\delta)_U \, dt - \int_0^T (h'(u_\delta), u - u_\delta)_U \, dt \\ \le & -\int_0^T (B^*p, u - u_\delta)_U \, dt - \int_0^T (h'(u_\delta), u - u_\delta)_U \, dt + \int_0^T (h'(u_\delta) + B^*p_\delta, v - u_\delta)_U \, dt \\ \le & \int_0^T (h'(u_\delta) + B^*p_\delta, v - u)_U \, dt + \int_0^T (B^*(p_\delta - p^{u_\delta}), u - u_\delta)_U \, dt \\ & + \int_0^T (B^*(p^{u_\delta} - p), u - u_\delta)_U \, dt, \end{aligned} \tag{16}$$

where p^{u_δ} is defined in (15). It is easy to see from (2), (14), and (15) that

$$(\partial_t(y^{u_\delta} - y), w) + a(y^{u_\delta} - y, w) = (B(u_\delta - u), w) \qquad \forall w \in Y, \tag{17}$$

$$-(\partial_t(p^{u_\delta} - p), q) + a(q, p^{u_\delta} - p) = (g'(y^{u_\delta}) - g'(y), q) \quad \forall q \in Y. \tag{18}$$

Taking $w = p^{u_\delta} - p$ in (17) and $q = y^{u_\delta} - y$ in (18) and using $(y^{u_\delta} - y)|_{t=0} = (p^{u_\delta} - p)|_{t=T} = 0$ and (10) lead to

$$\begin{aligned} \int_0^T (B(u_\delta - u), p^{u_\delta} - p) \, dt &= (y^{u_\delta} - y, p^{u_\delta} - p)\Big|_0^T \\ &\quad + \int_0^T (g'(y^{u_\delta}) - g'(y), y^{u_\delta} - y) \, dt \ge 0. \end{aligned} \tag{19}$$

Let v be the function satisfying (12). Then by (12), (7), and (19),

$$c\|u - u_\delta\|^2_{L^2(0,T;L^2(\Omega_U))} \le C\left(\eta_1^2 + \|p_\delta - p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))}\right) + \frac{c}{2}\|u - u_\delta\|^2_{L^2(0,T;L^2(\Omega_U))}, \tag{20}$$

which completes the proof. ∎

The assumption (12) is related to approximation properties of the convex set K. For instance, it always holds for unconstrained control, where $K = U$. For constraints of obstacle type, this assumption can also be verified.

We shall use the following dual equations: For given $f \in L^2(0,T;L^2(\Omega))$,

$$\begin{cases} \partial_t \varphi - \operatorname{div}(A\nabla\varphi) = f, & (x,t) \in \Omega \times (0,T], \\ \varphi|_{\partial\Omega} = 0, \quad t \in [0,T], & \varphi(x,0) = 0, \quad x \in \Omega, \end{cases} \tag{21}$$

and

$$\begin{cases} -\partial_t \psi - \operatorname{div}(A^*\nabla\psi) = f, & (x,t) \in \Omega \times [0,T), \\ \psi|_{\partial\Omega} = 0, \quad t \in [0,T], & \psi(x,T) = 0, \ x \in \Omega. \end{cases} \tag{22}$$

A similar idea is used in [21] for a Lagrange–Galerkin method.

LEMMA 3.4 (see [21]). *Assume that Ω is a convex domain. Let φ and ψ be the solutions of* (21) *and* (22)*, respectively. Then, for $v = \varphi$ or $v = \psi$,*

$$\begin{aligned}
&\|v\|_{L^\infty(0,T;L^2(\Omega))} \le C\|f\|_{L^2(0,T;L^2(\Omega))},\\
&\|\nabla v\|_{L^2(0,T;L^2(\Omega))} \le C\|f\|_{L^2(0,T;L^2(\Omega))},\\
&\|D^2 v\|_{L^2(0,T;L^2(\Omega))} \le C\|f\|_{L^2(0,T;L^2(\Omega))},\\
&\|\partial_t v\|_{L^2(0,T;L^2(\Omega))} \le C\|f\|_{L^2(0,T;L^2(\Omega))},
\end{aligned}$$

where $D^2 v = \max_{1\le i,j\le n} |\partial^2 v/\partial x_i \partial x_j|$.

In the following we deal with the error $\|p_\delta - p^{u_\delta}\|_{L^2(0,T;L^2(\Omega))}$ to derive the final estimates. Let $\partial T^{h,k}$ be the set consisting of all the faces l of any $\tau^k \in T^{h,k}$ such that l is not on $\partial\Omega$. The A-normal derivative jump over the interior face l is defined by

$$[(A\nabla v)\cdot \mathbf{n}]_l = ((A\nabla v)|_{\partial\tau_l^1} - (A\nabla v)|_{\partial\tau_l^2})\cdot \mathbf{n},$$

where $\mathbf{n}$ is the unit outer normal vector of τ_l^1 on $l = \bar\tau_l^1 \cap \bar\tau_l^2$. Let h_l be the maximum diameter of the face l.

LEMMA 3.5. *Let (y,p,u), $(y_\delta, p_\delta, u_\delta)$, and p^{u_δ} be the solutions of* (2), (6), *and* (15)*, respectively. Under the conditions of Lemma* 3.4 *and* (8)*,*

$$\|p_\delta - p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))} \le C \sum_{i=0,2\text{–}7} \eta_i^2,$$

where

$$\begin{aligned}
\eta_0^2 &= \|y_0^h - y_0\|^2_{0,\Omega},\\
\eta_2^2 &= \sum_{k=1}^N \sum_{\tau\in T^{h,k}} \int_{I_k} h_\tau^4 \left\| \partial_t p_\delta + g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta) + \frac{[p_\delta]_k}{\Delta t_k}\right\|^2_{0,\tau} dt,\\
\eta_3^2 &= \sum_{k=1}^N \sum_{\tau\in T^{h,k}} \int_{I_k} \Delta t_k^2 \,\|(\pi_k - I)(g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta))\|^2_{0,\tau}\, dt,\\
\eta_4^2 &= \sum_{k=1}^N \sum_{\tau\in T^{h,k}} \int_{I_k} h_\tau^4 \left\| \partial_t y_\delta - f - Bu_\delta - \operatorname{div}(A\nabla y_\delta) + \frac{[y_\delta]_{k-1}}{\Delta t_k}\right\|^2_{0,\tau} dt,\\
\eta_5^2 &= \sum_{k=1}^N \sum_{\tau\in T^{h,k}} \int_{I_k} \Delta t_k^2 \,\|(\pi_k - I)(f + \operatorname{div}(A\nabla y_\delta))\|^2_{0,\tau}\, dt,\\
\eta_6^2 &= \sum_{k=1}^N \sum_{l\in\partial T^{h,k}} \int_{I_k} h_l^3 (\|[(A\nabla y_\delta)\cdot\mathbf{n}]\|^2_{0,l} + \|[(A^*\nabla p_\delta)\cdot\mathbf{n}]\|^2_{0,l})\, dt,\\
\eta_7^2 &= \sum_{k=1}^N \sum_{\tau\in T^{h,k}} \Delta t_k (\|[y_\delta]_{k-1}\|^2_{0,\Omega} + \|[p_\delta]_k\|^2_{0,\Omega}),
\end{aligned}$$

where $\pi_k : L^2(I_k) \to \mathbb{P}_r(I_k)$ is the L^2-projection operator on the variable t.

Proof. Let φ be the solution of (21) with $f = p_\delta - p^{u_\delta}$ and $\varphi_I \in X^\delta$ be the interpolation of φ such that

$$\varphi_I|_{\Omega\times I_k} = \pi_{h,k}\pi_k\varphi, \qquad k = 1,2,\dots,N, \tag{23}$$

where $\pi_{h,k}$ is defined in Lemma 3.1 corresponding to the partitioning $T^{h,k}$ and $\pi_k : L^2(I_k) \to \mathbb{P}_r(I_k)$ is the L^2-projection operator on the variable t. Then it follows from (21), (15), (6), and Green's formula that

$$\begin{aligned}
&\|p_\delta - p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))} = \int_0^T (p_\delta - p^{u_\delta}, f)\, dt \\
= &\int_0^T (p_\delta - p^{u_\delta}, \partial_t\varphi - \operatorname{div}(A\nabla\varphi))\, dt \\
= &\int_0^T \left(-(\partial_t(p_\delta - p^{u_\delta}), \varphi) + a(\varphi, p_\delta - p^{u_\delta})\right)\, dt - \sum_{k=1}^N ([p_\delta]_k, \varphi_k^-) \\
= &\int_0^T \left(-(\partial_t p_\delta + g'(y^{u_\delta}), \varphi) + a(\varphi, p_\delta) - a(\varphi_I, p_\delta) + (\partial_t p_\delta + g'(y_\delta), \varphi_I)\right)\, dt \\
&+ \sum_{k=1}^N ([p_\delta]_k, (\varphi_I - \varphi)_k^-)\,,
\end{aligned}$$

which leads to

$$\begin{aligned}
&\|p_\delta - p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))} \\
= &\sum_{k=1}^N \int_{I_k} -\left(\partial_t p_\delta + g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta) + \frac{[p_\delta]_k}{\Delta t_k}, \varphi - \varphi_I\right)\, dt \\
&+ \int_0^T (g'(y_\delta) - g'(y^{u_\delta}), \varphi)\, dt + \int_0^T \sum_{l\in\partial T^h} \int_l [(A^*\nabla p_\delta)\cdot\mathbf{n}](\varphi - \varphi_I)\, dt \\
&+ \sum_{k=1}^N \int_{I_k} \left(\frac{[p_\delta]_k}{\Delta t_k}, (\varphi_I)_k^- - \varphi_I + \varphi - \varphi_k^-\right) dt \\
:= &\sum_{i=1}^4 I_i.
\end{aligned} \tag{24}$$

For simplicity, let

$$r_p(x,t)\Big|_{\Omega\times I_k} := \partial_t p_\delta + g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta) + \frac{[p_\delta]_k}{\Delta t_k}.$$

By Lemmas 3.1 and 3.4,

$$\begin{aligned}
&I_1 = \sum_{k=1}^N \int_{I_k} (r_p, (\pi_{h,k} - I)\pi_k\varphi + (\pi_k - I)\varphi)\, dt \\
= &\sum_{k=1}^N \int_{I_k} ((r_p, (\pi_{h,k} - I)\pi_k\varphi) - ((\pi_k - I)(g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta)), (\pi_k - I)\varphi))\, dt \\
\le &C\sum_{k=1}^N \sum_{\tau\in T^{h,k}} \int_{I_k} \left(h_\tau^4 \|r_p\|^2_{0,\tau} + \Delta t_k^2 \|(\pi_k - I)(g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta))\|^2_{0,\tau}\right)\, dt \\
&+ \sigma(\|D^2(\pi_k\varphi)\|^2_{L^2(0,T;L^2(\Omega))} + \|\partial_t\varphi\|^2_{L^2(0,T;L^2(\Omega))}) \\
\le &C(\eta_2^2 + \eta_3^2) + C\sigma\|p^{u_\delta} - p_\delta\|^2_{L^2(0,T;L^2(\Omega))}.
\end{aligned} \tag{25}$$

It is easy to see that from (8) and Lemma 3.4,

$$
\begin{aligned}
I_2 &= \int_0^T (g'(y_\delta) - g'(y^{u_\delta}), \varphi)\, dt \\
&\le C\|y_\delta - y^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))} + \sigma\|p^{u_\delta} - p_\delta\|^2_{L^2(0,T;L^2(\Omega))}.
\end{aligned} \tag{26}
$$

Similarly, by Lemmas 3.1, 3.2, and 3.4,

$$
\begin{aligned}
I_3 &= \int_0^T \sum_{l\in\partial T^h} \int_l [(A^*\nabla p_\delta)\cdot \mathbf{n}](\varphi - \varphi_I)\, dt \\
&= \sum_{k=1}^N \sum_{l\in\partial T^{h,k}} \int_{I_k}\int_l [(A^*\nabla p_\delta)\cdot \mathbf{n}](\varphi - \pi_{h,k}\varphi)\, dt \\
&\le C\sum_{k=1}^N \sum_{l\in\partial T^{h,k}} \int_{I_k} h_l^3 \|[(A^*\nabla p_\delta)\cdot \mathbf{n}]\|^2_{0,l}\, dt + \sigma\|D^2\varphi\|^2_{L^2(0,T;L^2(\Omega))} \\
&\le C\eta_6^2 + C\sigma\|p^{u_\delta} - p_\delta\|^2_{L^2(0,T;L^2(\Omega))}.
\end{aligned} \tag{27}
$$

It follows from Lemma 3.4 and the Schwarz inequality that

$$
\begin{aligned}
I_4 &= \sum_{k=1}^N \int_{I_k} \left(\frac{[p_\delta]_k}{\Delta t_k}, (\varphi_I)_k^- - \varphi_I + \varphi - \varphi_k^- \right) dt \\
&\le \sum_{k=1}^N \Delta t_k \|[p_\delta]_k\|^2_{0,\Omega} + \sigma\left(\|\partial_t\varphi_I\|^2_{L^2(0,T;L^2(\Omega))} + \|\partial_t\varphi\|^2_{L^2(0,T;L^2(\Omega))} \right) \\
&\le C\eta_7^2 + C\sigma\|p^{u_\delta} - p_\delta\|^2_{L^2(0,T;L^2(\Omega))}.
\end{aligned} \tag{28}
$$

Thus, the above estimates give

$$
\|p_\delta - p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))} \le C \sum_{i=2,3,6,7} \eta_i^2 + C\|y_\delta - y^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))}. \tag{29}
$$

Similarly, let ψ be the solution of (22) with $f = y_\delta - y^{u_\delta}$ and $\psi_I \in X^\delta$ be the interpolation of ψ such that

$$
\psi_I|_{\Omega\times I_k} = \pi_{h,k}\pi_k\psi, \qquad k = 1, 2, \ldots, N. \tag{30}
$$

Then, by Lemma 3.4, (14), (6), and Green's formula,

(31)
$$\begin{aligned}
&\|y_\delta - y^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))} = \int_0^T (y_\delta - y^{u_\delta}, f)\,dt = \int_0^T (y_\delta - y^{u_\delta}, -\partial_t\psi - \operatorname{div}(A^*\psi))\,dt\\
=\ & \int_0^T ((\partial_t(y_\delta - y^{u_\delta}),\psi) + a(y_\delta - y^{u_\delta},\psi))\ dt + \sum_{k=1}^{N-1}([y_\delta]_k,\psi_k^+) + ((y_\delta - y^{u_\delta})_0^+,\psi_0^+)\\
=\ & \int_0^T ((\partial_t y_\delta - f - Bu_\delta,\psi) + a(y_\delta,\psi) - a(y_\delta,\psi_I) - (\partial_t y_\delta - f - Bu_\delta,\psi_I))\ dt\\
&+ \sum_{k=0}^{N-1}([y_\delta]_k,(\psi-\psi_I)_k^+) + ((y_\delta - y^{u_\delta})_0^+,\psi_0^+) - ([y_\delta]_0,\psi_0^+)\\
=\ & \sum_{k=1}^{N}\int_{I_k}\left(\partial_t y_\delta - f - Bu_\delta - \operatorname{div}(A\nabla y_\delta) + \frac{[y_\delta]_{k-1}}{\Delta t_k},\psi-\psi_I\right)\ dt\\
&+ \int_0^T \sum_{l\in\partial T^h}\int_l [(A\nabla y_\delta)\cdot\mathbf{n}](\psi-\psi_I)\,dt\\
&+ \sum_{k=1}^{N}\int_{I_k}\left(\frac{[y_\delta]_{k-1}}{\Delta t_k},\psi_{k-1}^+ - \psi + \psi_I - (\psi_I)_{k-1}^+\right)\ dt\\
&+ ((y_\delta)_0^- - (y^{u_\delta})_0^+,\psi_0^+) := \sum_{i=1}^{4} J_i.
\end{aligned}$$

Let

$$r_y(x,t)\Big|_{I_k} := \partial_t y_\delta - f - Bu_\delta - \operatorname{div}(A\nabla y_\delta) + \frac{[y_\delta]_{k-1}}{\Delta t_k}.$$

Then, as in (25), (27), and (28),

(32)
$$\begin{aligned}
J_1 &= \sum_{k=1}^{N}\int_{I_k}(r_y,(\pi_{h,k}-I)\pi_k\psi + (\pi_k - I)\psi)\,dt\\
&= \sum_{k=1}^{N}\int_{I_k}((r_y,(\pi_{h,k}-I)\pi_k\psi) + ((\pi_k - I)(f+\operatorname{div}(A\nabla y_\delta)),(\pi_k-I)\psi))\ dt\\
&\le C\sum_{k=1}^{N}\sum_{\tau\in T^{h,k}}\int_{I_k}\left(h_\tau^4\|r_y\|^2_{0,\tau} + \Delta t_k^2\|(\pi_k - I)(f+\operatorname{div}(A\nabla y_\delta))\|^2_{0,\tau}\right)\ dt\\
&\quad + \sigma(\|D^2(\pi_k\psi)\|^2_{L^2(0,T;L^2(\Omega))} + \|\partial_t\psi\|^2_{L^2(0,T;L^2(\Omega))})\\
&\le C(\eta_4^2+\eta_5^2) + C\sigma\|y^{u_\delta} - y_\delta\|^2_{L^2(0,T;L^2(\Omega))},
\end{aligned}$$

(33)
$$J_2 = \int_0^T \sum_{l\in\partial T^h}\int_l [(A\nabla y_\delta)\cdot\mathbf{n}](\psi-\psi_I)\,dt \le C\eta_6^2 + \sigma\|y^{u_\delta} - y_\delta\|^2_{L^2(0,T;L^2(\Omega))},$$

(34)
$$\begin{aligned}
J_3 &= \sum_{k=1}^{N}\int_{I_k}\left(\frac{[y_\delta]_{k-1}}{\Delta t_k},\psi_{k-1}^+ - \psi + \psi_I - (\psi_I)_{k-1}^+\right)\ dt\\
&\le C\eta_7^2 + \sigma\|y^{u_\delta} - y_\delta\|^2_{L^2(0,T;L^2(\Omega))},
\end{aligned}$$

and

$$J_4 = ((y_\delta)_0^- - (y^{u_\delta})_0^+, \psi_0^+) \le C\eta_0^2 + \sigma \|y^{u_\delta} - y_\delta\|^2_{L^2(0,T;L^2(\Omega))}.$$

Hence

$$\|y_\delta - y^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))} \le C \sum_{i=0,4\text{-}7} \eta_i^2. \tag{35}$$

We complete the proof by combining the estimates (29) and (35). ∎

From Lemmas 3.3 and 3.5, we have the following a posteriori error estimates.

THEOREM 3.1. *Let* (y, p, u) *and* $(y_\delta, p_\delta, u_\delta)$ *be the solutions of* (2) *and* (6). *Assume that the conditions in Lemmas* 3.3–3.5 *are valid; then*

$$\|u - u_\delta\|^2_{L^2(0,T;L^2(\Omega))} + \|y - y_\delta\|^2_{L^2(0,T;L^2(\Omega))} + \|p - p_\delta\|^2_{L^2(0,T;L^2(\Omega))} \le C \sum_{i=0}^{7} \eta_i^2,$$

where η_i *are defined in Lemmas* 3.3 *and* 3.5.

Proof. We obtain from (13), (35), and (29) that

$$\|u - u_\delta\|^2_{L^2(0,T;L^2(\Omega))} + \|y^{u_\delta} - y_\delta\|^2_{L^2(0,T;L^2(\Omega))} + \|p^{u_\delta} - p_\delta\|^2_{L^2(0,T;L^2(\Omega))} \le C \sum_{i=0}^{7} \eta_i^2.$$

Then the desired results follows from the triangle inequality and

$$\|p - p^{u_\delta}\|_{L^2(0,T;L^2(\Omega))} \le C\|y - y^{u_\delta}\|_{L^2(0,T;L^2(\Omega))} \le C\|u - u_\delta\|_{L^2(0,T;L^2(\Omega))}, \tag{36}$$

which can be derived from (17) and (18). ∎

It seems to be difficult to derive any lower error bounds for the control problem. As matter of fact, there seem to be no good lower a posteriori error bounds in the literature even for the full backward-Euler finite element approximation of linear parabolic equations. The main difficulty seems to be that the properties of the time variable and its discretization are quite different from those of the space variables. Novel techniques are yet to be developed to derive lower bounds for such mixed approximations.

REMARK 3.2. *It is clear that the above a posteriori error estimator consists of two parts. The* η_1^2 *part results from the approximation error of the inequality in the optimality condition* (2). *The other (more familiar) part* (η_i^2 $(i = 0, 2, \ldots, 7)$) *is contributed from the approximation error of the state and costate equations and in this sense is more or less standard. Among them,* η_1^2 *mainly indicates the approximation error for the control, and the other part mainly reflects the approximation error for the state and costate.*

The part (η_i^2 $(i = 0, 2, \ldots, 7)$) *can be further divided into two parts: one from the approximation error of the state equation and the other from that of the costate equation. Clearly, a posteriori error estimators obtained solely from the state equation, which only present the part contributed from the state equation, may fail to reflect the main approximation error of the optimal control problem and thus fail to yield efficient mesh refinements.*

The above error estimates are applicable to a wide range of control problems. It may be possible to further improve them in some individual cases, as will be seen in the next section. To this end, it is clear that one needs to derive improved error

estimates for the approximation of the inequality in (2)*, and thus one requires explicit information on the structure of* K*.*

REMARK 3.3. *It is generally difficult to know the exact bounding constant* C *in Theorem* 3.1*, as is true for most a posteriori error estimates of residual type. The constant is contributed from those in the interpolation results (e.g., Lemmas* 3.1–3.2*), the stability results (e.g., Lemmas* 3.3–3.4*), and the Sobolev embedding theorems. For simpler situations, it may be possible to trace down all those constants and to give the bounding constant good upper bounds; see* [9] *for some of the latest advances on this aspect. Generally this is a complex procedure. On the other hand, a posteriori estimators of residual type can be (actually have widely been) used to guide mesh refinements without having exact knowledge on the bounding constants, provided they are not too large. It seems that the magnitude of the bounding constants does not cause any serious problems in guiding mesh refinements for elliptic and parabolic equations, although it does bring up serious concerns in CFD (see* [23]*), since it can indeed be extremely large there.*

In our case, it seems that the bounding constant in Theorems 3.1–3.2 *will have a similar magnitude as those for the standard parabolic equation case, as the only new contribution here is from the constant* C *in Lemma* 3.3*. This constant can be traced down in Examples* 3.1–3.2*, which in turns depends on the bounding constant for the integral averaging interpolator* $\pi^a_{\delta,k}$*. It is known that the bounding constant associated with* $\pi^a_{\delta,k}$ *will not be very large; see* [9] *for the details.*

REMARK 3.4. *It is not straightforward to develop suitable implementation techniques for (x-t) mesh adaptivity of parabolic control problems. To the best of our knowledge, there seems to be no existing work in the literature, even using the same meshes for the state and the control. For instance, it seems impossible to simply extend the mesh adaptivity techniques developed for evolutional equations (e.g., parabolic or Navier–Stokes equations) to the control problem that we have just studied. Although the state equation is evolutional, the* optimal control problem *itself is clearly not. It is impossible to solve the control problem step by step in time, although this is possible for the state equation. This calls for new implementation techniques on mesh adaptivity for the optimal control governed by evolutional state equations. From the above analysis of* η_1^2 *(*η_i^2*), it is also clear that the most suitable implementation, and thus the optimal mesh refinements will greatly depend on what is the most important quantity to be computed in a particular control problem. It also depends on the structure of the meshes used in the computations. Furthermore, as some large discretized optimization problems may need to be repeatedly solved, one may have to use a suitable multigrids method together with mesh adaptivity. Issues like which items in the estimator are more important and how to pick up the constant* C *are also important. It is clear that a systematic study of this is much needed. These issues will be investigated in our future research.*

3.2. $L^\infty(L^2)$ error estimates. In some adaptive schemes, it is more desirable to have $L^\infty(L^2)$ estimates. In this subsection, we give error estimates in $L^\infty(L^2)$-norm. Concretely, we shall use the norm of the following form:

$$\|v\|_{I_k,Q} = \left\{ \frac{1}{\Delta t_k} \int_{I_k} \|v(t)\|^2_{0,Q}\, dt \right\}^{1/2}, \qquad Q = \Omega_U, \tau_U, \Omega, \tau, l.$$

We now need to consider the following dual equations for any $1 \le k \le N-1$:

$$\begin{cases} \partial_t \varphi - \operatorname{div}(A\nabla\varphi) = 0, & (x,t) \in \Omega \times (t_k, T], \\ \varphi|_{\partial\Omega} = 0, \quad t \in [t_k, T], & \varphi(x,t_k) = \varphi_*(x), \quad x \in \Omega, \end{cases} \tag{37}$$

and

$$\begin{cases} -\partial_t \psi - \operatorname{div}(A^*\nabla\psi) = 0, & (x,t) \in \Omega \times [0, t_k), \\ \psi|_{\partial\Omega} = 0, \quad t \in [0, t_k], & \psi(x,t_k) = \psi_*(x), \ x \in \Omega. \end{cases} \tag{38}$$

We have the following stability results [12].

LEMMA 3.6. *Assume that Ω is a convex domain. Let φ and ψ be the solutions of* (37) *and* (38)*, respectively. Then*

$$\begin{aligned} &\|\varphi\|_{L^\infty(t_k,T;L^2(\Omega))} \le C\|\varphi_*\|_{L^2(\Omega)}, \\ &\|\varphi\|_{L^2(t_k,t_k+\varepsilon;L^2(\Omega))} \le C\sqrt{\varepsilon}\|\varphi_*\|_{L^2(\Omega)}, \quad 0 < \varepsilon < T - t_k, \\ &\|\nabla\varphi\|_{L^2(t_k,T;L^2(\Omega))} \le C\|\varphi_*\|_{L^2(\Omega)}, \\ &\|\sqrt{t-t_k}\,|D^2\varphi|\|_{L^2(t_k,T;L^2(\Omega))} \le C\|\varphi_*\|_{L^2(\Omega)}, \\ &\|\sqrt{t-t_k}\,\partial_t\varphi\|_{L^2(t_k,T;L^2(\Omega))} \le C\|\varphi_*\|_{L^2(\Omega)} \end{aligned}$$

and

$$\begin{aligned} &\|\psi\|_{L^\infty(0,t_k;L^2(\Omega))} \le C\|\psi_*\|_{L^2(\Omega)}, \\ &\|\psi\|_{L^2(t_k-\varepsilon,t_k;L^2(\Omega))} \le C\sqrt{\varepsilon}\|\psi_*\|_{L^2(\Omega)}, \quad 0 < \varepsilon < t_k, \\ &\|\nabla\psi\|_{L^2(0,t_k;L^2(\Omega))} \le C\|\psi_*\|_{L^2(\Omega)}, \\ &\|\sqrt{t_k-t}\,|D^2\psi|\|_{L^2(0,t_k;L^2(\Omega))} \le C\|\psi_*\|_{L^2(\Omega)}, \\ &\|\sqrt{t_k-t}\,\partial_t\psi\|_{L^2(0,t_k;L^2(\Omega))} \le C\|\psi_*\|_{L^2(\Omega)}, \end{aligned}$$

where $D^2 v = \max_{1\le i,j\le n} |\partial^2 v/\partial x_i \partial x_j|$.

THEOREM 3.2. *Let (y,p,u) and (y_h,p_h,u_h) be the solutions of* (2) *and* (6)*, respectively. Assume that the conditions in Theorem* 3.1 *and Lemma* 3.6 *are valid; then*

$$\max_{1\le k\le N} \left(\|u-u_h\|^2_{I_k,\Omega_U} + \|y-y_h\|^2_{I_k,\Omega} + \|p-p_h\|^2_{I_k,\Omega}\right) \le C\sum_{i=0}^{8} \mathfrak{N}_i^2,$$

where

$$\begin{aligned} \mathfrak{N}_0^2 &= \|y_0^h - y_0\|^2_{0,\Omega}, \\ \mathfrak{N}_1^2 &= \max_{1\le k\le N} \sum_{\tau_U \in T_U^{h,k}} \left(h^2_{\tau_U}\|\nabla(h'(u_\delta) + B^*p_\delta)\|^2_{I_k,\tau_U} + \Delta t_k^2 \|\partial_t(h'(u_\delta) + B^*p_\delta)\|^2_{I_k,\tau_U}\right), \\ \mathfrak{N}_2^2 &= \max_{1\le k\le N} \sum_{\tau\in T^{h,k}} h_\tau^2(\Delta t_k + L_N h_\tau^2) \left\| \partial_t p_\delta + g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta) + \frac{[p_\delta]_k}{\Delta t_k}\right\|^2_{I_k,\tau}, \\ \mathfrak{N}_3^2 &= \max_{1\le k\le N} \sum_{\tau\in T^{h,k}} \Delta t_k^2 \left\|(\pi_k - I)(g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta))\right\|^2_{I_k,\tau}, \\ \mathfrak{N}_4^2 &= \max_{1\le k\le N} \sum_{l\in\partial T^{h,k}} h_l(\Delta t_k + L_N h_l^2) \left\|[(A^*\nabla p_\delta)\cdot \mathbf{n}]\right\|^2_{I_k,l}, \end{aligned}$$

$$
\begin{aligned}
\mathfrak{N}_5^2 &= \max_{1\le k\le N}\sum_{\tau\in T^{h,k}} h_\tau^2(\Delta t_k + L_N h_\tau^2)\left\|\partial_t y_\delta - f - Bu_\delta - \operatorname{div}(A\nabla y_\delta) + \frac{[y_\delta]_{k-1}}{\Delta t_k}\right\|_{I_k,\tau}^2,\\
\mathfrak{N}_6^2 &= \max_{1\le k\le N}\sum_{\tau\in T^{h,k}} \Delta t_k^2\,\|(\pi_k - I)(f + \operatorname{div}(A\nabla y_\delta))\|_{I_k,\tau}^2,\\
\mathfrak{N}_7^2 &= \max_{1\le k\le N}\sum_{l\in \partial T^{h,k}} h_l(\Delta t_k + L_N h_l^2)\,\|[(A\nabla y_\delta)\cdot \mathbf{n}]\|_{I_k,l}^2,\\
\mathfrak{N}_8^2 &= \max_{1\le k\le N}(\|[y_\delta]_{k-1}\|_{0,\Omega}^2 + \|[p_\delta]_k\|_{0,\Omega}^2),
\end{aligned}
$$

where

$$
L_N = \max\left\{\max_{1\le k\le N-2}\sum_{k'=k+2}^{N}\frac{\Delta t_{k'}}{t_{k'-1}-t_k},\quad \max_{2\le k\le N}\sum_{k'=1}^{k-1}\frac{\Delta t_{k'}}{t_k - t_{k'}}\right\}.
$$

Proof. We first consider $\|u-u_h\|_{L^2(I_k;L^2(\Omega_U))}$. As in (16) and (20), for any $v\in K^\delta$, we have

$$
\begin{aligned}
& c\|u-u_\delta\|_{L^2(I_k;L^2(\Omega_U))}^2 \le \int_{I_k}(h'(u),u-u_\delta)_U\,dt - \int_{I_k}(h'(u_\delta),u-u_\delta)_U\,dt\\
\le\ & \int_{I_k}(h'(u_\delta)+B^*p_\delta, v-u)_U\,dt + \int_{I_k}(B^*(p_\delta-p),u-u_\delta)_U\,dt\\
\le\ & C\int_{I_k}\left(h_{\tau_U}^2|h'(u_\delta)+B^*p_\delta|_{1,\tau_U}^2 + \Delta t_k^2\|\partial_t(h'(u_\delta)+B^*p_\delta)\|_{0,\tau_U}^2\right)dt\\
& + C\left(\|p_\delta - p^{u_\delta}\|_{L^2(I_k;L^2(\Omega))}^2 + \|p^{u_\delta}-p\|_{L^2(I_k;L^2(\Omega))}^2\right) + \frac{c}{2}\|u-u_\delta\|_{L^2(I_k;L^2(\Omega_U))}^2.
\end{aligned}
$$

It is easy to see from (18) and (8) that

$$
\begin{aligned}
\|p^{u_\delta}-p\|_{I_k,\Omega} &\le \|p^{u_\delta}-p\|_{L^\infty(0,T;L^2(\Omega))}^2 \le C\|y^{u_\delta}-y\|_{L^2(0,T;L^2(\Omega))}^2\\
&\le C\|u-u_\delta\|_{L^2(0,T;L^2(\Omega_U))}^2.
\end{aligned}
$$

We thus obtain

$$
\|u-u_\delta\|_{I_k,\Omega_U}^2 \le C\left(\mathfrak{N}_1^2 + \|p_\delta - p^{u_\delta}\|_{I_k,\Omega}^2\right) + C\|u-u_\delta\|_{L^2(0,T;L^2(\Omega_U))}^2. \tag{39}
$$

The last term above has been estimated in Theorem 3.1.

We consider $\|p_\delta - p^{u_\delta}\|_{I_k,\Omega}^2$ for any $1\le k\le N$. Let φ be the solution of the dual problem

$$
\begin{cases}
\partial_t\varphi - \operatorname{div}(A\nabla\varphi) = p_\delta - p^{u_\delta}, & (x,t)\in\Omega\times I_k,\\
\varphi|_{\partial\Omega} = 0,\quad t\in I_k, & \varphi(x,t_{k-1}) = 0,\quad x\in\Omega,
\end{cases}
$$

and let φ_I be defined as in (23). Then, similarly to (24),

$$\begin{aligned}
&\|p_\delta - p^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))} = \int_{I_k} (p_\delta - p^{u_\delta}, \partial_t\varphi - \operatorname{div}(A\nabla\varphi))\,dt\\
=\ & \int_{I_k} (-(\partial_t(p_\delta - p^{u_\delta}),\varphi) + a(\varphi, p_\delta - p^{u_\delta}))\ dt + (p_\delta - p^{u_\delta},\varphi)^-_k\\
=\ & \int_{I_k} (-(\partial_t p_\delta + g'(y^{u_\delta}),\varphi) + a(\varphi,p_\delta) - a(\varphi_I,p_\delta) + (\partial_t p_\delta + g'(y_\delta),\varphi_I))\ dt\\
&+([p_\delta]_k,(\varphi_I)^-_k) + (p_\delta - p^{u_\delta},\varphi)^-_k\\
=\ & \int_{I_k} \left(\partial_t p_\delta + g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta) + \frac{[p_\delta]_k}{\Delta t_k}, \varphi_I - \varphi\right) dt + \int_{I_k} (g'(y_\delta) - g'(y^{u_\delta}),\varphi)\,dt\\
&+\int_{I_k}\sum_{l\in\partial T^h}\int_l [(A^*\nabla p_\delta)\cdot\mathbf{n}](\varphi-\varphi_I)\,dt + \int_{I_k}\left(\frac{[p_\delta]_k}{\Delta t_k}, (\varphi_I)^-_k - \varphi_I + \varphi - \varphi^+_{k-1}\right) dt\\
&+(p_\delta - p^{u_\delta},\varphi)^-_k := \sum_{i=1}^5 \mathcal{I}_i.
\end{aligned}$$

It is easy to see that $\mathcal{I}_i$ ($i = 1$–4) can be estimated in the same way as in (25)–(28) such that

$$\begin{aligned}
(40)\quad \mathcal{I}_1 &\le C\sum_{\tau\in T^h}\int_{I_k}\left(h_\tau^4\|r_p\|^2_{0,\tau} + \Delta t_k^2\|(\pi_k - I)(g'(y_\delta) + \operatorname{div}(A^*\nabla p_\delta))\|^2_{0,\tau}\right) dt\\
&\quad +\sigma\|p_\delta - p^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))},\\
\mathcal{I}_2 &\le C\|y_\delta - y^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))} + \sigma\|p_\delta - p^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))},\\
(41)\quad \mathcal{I}_3 &\le C\sum_{l\in\partial T^h}\int_{I_k} h_l^3\|[(A^*\nabla p_\delta)\cdot\mathbf{n}]\|^2_{0,l}\,dt + \sigma\|p_\delta - p^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))},\\
(42)\quad \mathcal{I}_4 &\le \Delta t_k\|[p_\delta]_k\|^2_{0,\Omega} + \sigma\|p_\delta - p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))}.
\end{aligned}$$

We bound $\mathcal{I}_5$ by

$$(43)\qquad \begin{aligned}
\mathcal{I}_5 &\le \|(p_\delta - p^{u_\delta})^-_k\|_{0,\Omega}\sqrt{\Delta t_k}\,\|\partial_t\varphi\|_{L^2(I_k;L^2(\Omega))}\\
&\le C\Delta t_k\|(p_\delta - p^{u_\delta})^-_k\|^2_{0,\Omega} + \sigma\|p_\delta - p^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))}.
\end{aligned}$$

Thus, the above estimates give

$$(44)\qquad \|p_\delta - p^{u_\delta}\|^2_{I_k,\Omega} \le C\left(\sum_{i=2\text{–}4,8}\mathfrak{N}_i^2 + \|y_\delta - y^{u_\delta}\|^2_{I_k,\Omega} + \|(p_\delta - p^{u_\delta})^-_k\|^2_{0,\Omega}\right).$$

We then consider $\|y_\delta - y^{u_\delta}\|^2_{I_k,\Omega}$. Let ψ be the solution of the dual problem

$$\begin{cases}
-\partial_t\psi - \operatorname{div}(A^*\nabla\psi) = y_\delta - y^{u_\delta}, & (x,t)\in\Omega\times I_k,\\
\psi|_{\partial\Omega} = 0, \quad t\in I_k, & \psi(x,t_k) = 0,\ x\in\Omega,
\end{cases}$$

and let ψ_I be defined as in (30). Then, similarly to (31), for $1 \le k \le N$,

$$\begin{aligned}
&\|y_\delta - y^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))} = \int_{I_k} (y_\delta - y^{u_\delta}, -\partial_t\psi - \operatorname{div}(A^*\psi))\,dt\\
=\ & \int_{I_k} ((\partial_t(y_\delta - y^{u_\delta}),\psi) + a(y_\delta - y^{u_\delta},\psi))\ dt + (y_\delta - y^{u_\delta},\psi)^+_{k-1}\\
=\ & \int_{I_k} ((\partial_t y_\delta - f - Bu_\delta,\psi) + a(y_\delta,\psi) - a(y_\delta,\psi_I) - (\partial_t y_\delta - f - Bu_\delta,\psi_I))\ dt\\
& -([y_\delta]_{k-1},(\psi_I)^+_{k-1}) + (y_\delta - y^{u_\delta},\psi)^+_{k-1}\\
=\ & \int_{I_k} \left(\partial_t y_\delta - f - Bu_\delta - \operatorname{div}(A\nabla y_\delta) + \frac{[y_\delta]_{k-1}}{\Delta t_k}, \psi - \psi_I\right) dt\\
& + \int_{I_k} \sum_{l\in\partial T^h} \int_l [(A\nabla y_\delta)\cdot\mathbf{n}](\psi - \psi_I)\,dt + \int_{I_k} \left(\frac{[y_\delta]_{k-1}}{\Delta t_k}, \psi_k^- - \psi + \psi_I - (\psi_I)^+_{k-1}\right) dt\\
& + (y_\delta - y^{u_\delta},\psi)^+_{k-1} := \sum_{i=1}^4 \mathcal{J}_i,
\end{aligned}$$

where $\mathcal{J}_i$ ($i = 1$–3) can be estimated as in (40)–(43) so that

$$\begin{aligned}
\mathcal{J}_1 \le\ & C\int_{I_k} \left(h_\tau^4\|r_y\|^2_{0,\tau} + \Delta t_k^2\|(\pi_k - I)(f + \operatorname{div}(A\nabla y_\delta))\|^2_{0,\tau}\right) dt\\
& + \sigma\|y_\delta - y^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))},\\
\mathcal{J}_2 \le\ & C\sum_{l\in\partial T^h} \int_{I_k} h_l^3\|[(A\nabla y_\delta)\cdot\mathbf{n}]\|^2_{0,l}\,dt + \sigma\|y_\delta - y^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))},\\
\mathcal{J}_3 \le\ & \Delta t_k\|[y_\delta]_{k-1}\|^2_{0,\Omega} + \sigma\|y_\delta - y^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))},\\
\mathcal{J}_4 \le\ & C\Delta t_k\|(y_\delta - y^{u_\delta})^+_{k-1}\|^2_{0,\Omega} + \sigma\|y_\delta - y^{u_\delta}\|^2_{L^2(I_k;L^2(\Omega))}.
\end{aligned}$$

Therefore,

$$\|y_\delta - y^{u_\delta}\|^2_{I_k,\Omega} \le C\left(\sum_{i=5\text{–}8} \mathfrak{N}_i^2 + \|(y_\delta - y^{u_\delta})^+_{k-1}\|^2_{0,\Omega}\right). \tag{45}$$

We need to further consider $\|(p_\delta - p^{u_\delta})^-_k\|^2_{0,\Omega}$ and $\|(y_\delta - y^{u_\delta})^+_{k-1}\|^2_{0,\Omega}$ ($1 \le k \le N$). We note that $\|(p_\delta - p^{u_\delta})^-_N\|^2 = \|[p_\delta]_N\|^2_{0,\Omega} \le \mathfrak{N}_8^2$. For any $1 \le k \le N-1$, let φ be the solution of (37) with $\varphi_* = (p_\delta - p^{u_\delta})^-_k$ and φ_I be defined as in (23). Then, by (37), (15), and (6),

$$\begin{aligned}
&\|(p_\delta - p^{u_\delta})^-_k\|^2_{0,\Omega} = ((p_\delta - p^{u_\delta})^-_k,\varphi_*) - ((p_\delta - p^{u_\delta})^+_k,\varphi_*) + (p_\delta - p^{u_\delta},\varphi)^+_k\\
=\ & \int_{t_k}^T (-(\partial_t(p_\delta - p^{u_\delta}),\varphi) + a(\varphi, p_\delta - p^{u_\delta}))\ dt - \sum_{k'=k+1}^N ([p_\delta]_{k'},\varphi^-_{k'}) - ([p_\delta]_k,\varphi_*)\\
=\ & \int_{t_k}^T (-(\partial_t p_\delta + g'(y^{u_\delta}),\varphi) + a(\varphi,p_\delta) - a(\varphi_I,p_\delta) + (\partial_t p_\delta + g'(y_\delta),\varphi_I))\ dt\\
& + \sum_{k'=k+1}^N ([p_\delta]_{k'},(\varphi_I - \varphi)^-_{k'}) - ([p_\delta]_k,\varphi_*)
\end{aligned}$$

$$
\begin{aligned}
= & \sum_{k'=k+1}^{N} \int_{I_{k'}} \Big(\partial_t p_\delta + g'(y_\delta) + \operatorname{div}(A^* \nabla p_\delta) + \frac{[p_\delta]_{k'}}{\Delta t_{k'}}, \varphi_I - \varphi \Big) \\
& + \int_{t_k}^{T} (g'(y_\delta) - g'(y^{u_\delta}), \varphi)\, dt \\
& + \int_{t_k}^{T} \sum_{l \in \partial T^h} \int_l [(A^* \nabla p_\delta) \cdot \mathbf{n}](\varphi - \varphi_I)\, dt \\
& + \sum_{k'=k+1}^{N} \int_{I_{k'}} \left(\frac{[p_\delta]_{k'}}{\Delta t_{k'}}, (\varphi_I)_{k'}^- - \varphi_I + \varphi - \varphi_{k'}^- \right) \\
& - ([p_\delta]_k, \varphi_*) := \sum_{i=1}^{5} \mathit{I}_i.
\end{aligned}
$$

We have to treat the cases in which t_k is near T and away from T differently. For simplicity, let $c_k = 1$ for $1 \le k \le N-2$ and $c_{N-1} = 0$. We decompose I_1 as follows:

$$
\begin{aligned}
\mathit{I}_1 &= \left(\sum_{k'=k+1} + c_k \sum_{k'=k+2}^{N} \right) \int_{I_{k'}} ((r_p, (\pi_{h,k} - I)\pi_k \varphi) + ((\pi_k - I) r_p, (\pi_k - I)\varphi))\, dt \\
&:= \mathit{I}_{11} + c_k \mathit{I}_{12}.
\end{aligned}
$$

By Lemmas 3.1 and 3.6, we have

$$
\begin{aligned}
\mathit{I}_{11} &\le C \int_{I_{k+1}} \sum_{\tau \in T^h} h_\tau \|r_p\|_{0,\tau} |\pi_k \varphi|_{1,\tau}\, dt + \int_{I_{k+1}} \|(\pi_k - I) r_p\|_{0,\Omega} \|\varphi\|_{0,\Omega}\, dt \\
&\le C \int_{I_{k+1}} \sum_{\tau \in T^h} h_\tau^2 \|r_p\|_{0,\tau}^2\, dt + \sigma \int_{I_{k+1}} |\varphi|_{1,\Omega}^2\, dt \\
&\quad + C \Delta t_{k+1} \int_{I_{k+1}} \|(\pi_k - I) r_p\|_{0,\Omega}^2\, dt + \sigma \|\varphi\|_{L^\infty(I_{k+1}; L^2(\Omega))}^2 \\
&\le C(\mathfrak{N}_2^2 + \mathfrak{N}_3^2) + C\sigma \|(p_\delta - p^{u_\delta})_k^-\|_{0,\Omega}^2,
\end{aligned} \tag{46}
$$

and

$$
\begin{aligned}
\mathit{I}_{12} &\le C \sum_{k'=k+2}^{N} \left(\int_{I_{k'}} \sum_{\tau \in T^h} h_\tau^2 \|r_p\|_{0,\tau} |\pi_k \varphi|_{2,\tau}\, dt \right. \\
&\qquad \left. + \Delta t_{k'} \|(\pi_k - I) r_p\|_{L^2(I_{k'}; L^2(\Omega))} \|\partial_t \varphi\|_{L^2(I_{k'}; L^2(\Omega))} \right) \\
&\le C \sum_{k'=k+2}^{N} \int_{I_{k'}} (t_{k'-1} - t_k)^{-1} \sum_{\tau \in T^h} h_\tau^4 \|r_p\|_{0,\tau}^2\, dt + \sigma \int_{t_{k+1}}^{T} (t - t_k) \|D^2 \varphi\|_{0,\Omega}^2\, dt \\
&\quad + C \sum_{k'=k+2}^{N} \Delta t_{k'} \|(\pi_k - I) r_p\|_{L^2(I_{k'}; L^2(\Omega))} \frac{1}{\sqrt{t_{k'-1} - t_k}} \|\sqrt{t - t_k} \partial_t \varphi\|_{L^2(I_{k'}; L^2(\Omega))} \\
&\le C L_N \max_{k+2 \le k' \le N} \sum_{\tau \in T^h} \left(h_\tau^4 \|r_p\|_{I_k, \tau}^2 + \Delta t_{k'}^2 \|(\pi_k - I) r_p\|_{I_k, \tau}^2 \right)
\end{aligned} \tag{47}
$$

$$
\begin{aligned}
&+ \sigma \int_{t_{k+1}}^{T} |t - t_k| \left(\|D^2 \varphi\|_{0,\Omega}^2 + \|\partial_t \varphi\|_{0,\Omega}^2 \right) dt \\
&\le C(\mathfrak{N}_2^2 + \mathfrak{N}_3^2) + C\sigma \|(p_\delta - p^{u_\delta})_k^- \|_{0,\Omega}^2.
\end{aligned}
$$

It follows from (8) and Lemma 3.6 that

$$
\mathit{\Pi}_2 \le C\|y_\delta - y^{u_\delta}\|_{L^2(0,T;L^2(\Omega))}^2 + \sigma \|(p_\delta - p^{u_\delta})_k^- \|_{0,\Omega}^2.
$$

By using (11) and Lemma 3.1, we can estimate $\mathit{\Pi}_3$ in the same way as for $\mathit{\Pi}_1$ such that

(48)

$$
\begin{aligned}
\mathit{\Pi}_3 &= \left(\int_{t_k}^{t_{k+1}} + c_k \int_{t_{k+1}}^{T} \right) \sum_{l \in \partial T^h} \int_l [(A^* \nabla p_\delta) \cdot \mathbf{n}](\varphi - \pi_{h,k}\varphi)\, dt \\
&\le C \int_{t_k}^{t_{k+1}} \sum_{l \in \partial T^h} h_l \|[(A^* \nabla p_\delta) \cdot \mathbf{n}]\|_{0,l}^2\, dt + \sigma \int_{t_k}^{t_{k+1}} |\varphi|_{1,\Omega}^2\, dt \\
&\quad + Cc_k \int_{t_{k+1}}^{T} |t - t_k|^{-1} \sum_{l \in \partial T^h} h_l^3 \|[(A^* \nabla p_\delta) \cdot \mathbf{n}]\|_{0,l}^2\, dt + \sigma \int_{t_{k+1}}^{T} |t - t_k| \|D^2 \varphi\|_{0,\Omega}^2\, dt \\
&\le C\mathfrak{N}_4^2 + C\sigma \|(p_\delta - p^{u_\delta})_k^- \|_{0,\Omega}^2.
\end{aligned}
$$

We rewrite $\mathit{\Pi}_4$ as

$$
\mathit{\Pi}_4 = \left(\sum_{k'=k+1} + c_k \sum_{k'=k+2}^{N} \right) \int_{I_{k'}} \left(\frac{[p_\delta]_{k'}}{\Delta t_{k'}}, (\varphi_I)_{k'}^- - \varphi_I + \varphi - \varphi_{k'}^- \right) dt := \mathit{\Pi}_{41} + c_k \mathit{\Pi}_{42}.
$$

We then use Lemma 3.6 again to obtain

(49)

$$
\begin{aligned}
\mathit{\Pi}_{41} &= ([p_\delta]_{k+1}, (\varphi_I - \varphi)_{k+1}^-) + \int_{t_k}^{t_{k+1}} \left(\frac{[p_\delta]_{k+1}}{\Delta t_{k+1}}, \varphi - \pi_{h,k}\varphi \right) dt \\
&\le C\|[p_\delta]_{k+1}\|_{0,\Omega} (\Delta t_{k+1}^{-1/2} \|\varphi\|_{L^2(I_{k+1};L^2(\Omega))} + \|\varphi\|_{L^\infty(I_{k+1};L^2(\Omega))}) \\
&\le C\|[p_\delta]_{k+1}\|_{0,\Omega}^2 + \sigma \|(p^{u_\delta} - p_\delta)_k^- \|_{0,\Omega}^2,
\end{aligned}
$$

(50)

$$
\begin{aligned}
\mathit{\Pi}_{42} &= \sum_{k'=k+2}^{N} \int_{k'} \left(\frac{[p_\delta]_{k'}}{\Delta t_{k'}}, (\varphi_I)_{k'}^- - \varphi_I + \varphi - \varphi_{k'}^- \right) dt \\
&\le C \sum_{k'=k+2}^{N} \|[p_\delta]_{k'}\|_{0,\Omega} \sqrt{\Delta t_{k'}} \|\partial_t \varphi\|_{L^2(I_{k'};L^2(\Omega))} \\
&\le C \sum_{k'=k+2}^{N} \frac{\Delta t_{k'}}{t_{k'-1} - t_k} \|[p_\delta]_{k'}\|_{0,\Omega}^2 + \sigma \|\sqrt{t - t_k}\, \partial_t \varphi\|_{L^2(t_{k+1},T;L^2(\Omega))}^2 \\
&\le CL_N \max_{k+2 \le k' \le N} \|[p_\delta]_{k'}\|_{0,\Omega}^2 + C\sigma \|(p^{u_\delta} - p_\delta)_k^- \|_{0,\Omega}^2,
\end{aligned}
$$

and

$$
\mathit{\Pi}_5 \le C\|[p_\delta]_k\|_{0,\Omega}^2 + \sigma \|(p^{u_\delta} - p_\delta)_k^- \|_{0,\Omega}^2. \tag{51}
$$

We thus have shown that

$$
\|(p^{u_\delta} - p_\delta)_k^- \|_{0,\Omega}^2 \le C \sum_{i=2\text{–}4,8} \mathfrak{N}_i^2 + C\|y_\delta - y^{u_\delta}\|_{L^2(0,T;L^2(\Omega))}^2. \tag{52}
$$

The last term above has been estimated in Theorem 3.1.

It remains to estimate $\|(y_\delta - y^{u_\delta})_k^+\|_{0,\Omega}^2$ $(0 \le k \le N-1)$. Since

$$\|(y_\delta - y^{u_\delta})_0^+\|_{0,\Omega}^2 \le \|[y_\delta]_0\|_{0,\Omega}^2 + \|(y_\delta)_0^- - (y^{u_\delta})_0^+\|_{0,\Omega}^2 \le \mathfrak{N}_8^2 + \mathfrak{N}_0^2,$$

we need only to consider the cases of $1 \le k \le N-1$. Let ψ be the solution of (38) with $\psi_* = (y_\delta - y^{u_\delta})_k^+$ and ψ_I be defined as in (30). Then, by (38) and (14),

$$\begin{aligned}
&\|(y_\delta - y^{u_\delta})_k^+\|_{0,\Omega}^2 = ((y_\delta - y^{u_\delta})_k^+, \psi_*) - (y_\delta - y^{u_\delta}, \psi)_k^- + (y_\delta - y^{u_\delta}, \psi)_k^- \\
= &\int_0^{t_k} ((\partial_t(y_\delta - y^{u_\delta}), \psi) + a(y_\delta - y^{u_\delta}, \psi))\, dt + \sum_{k'=0}^{k-1} ([y_\delta]_{k'}, \psi_{k'}^+) \\
&+ (y_0^h - y_0, \psi_0^+) + ([y_\delta]_k, \psi_*) \\
= &\int_0^{t_k} ((\partial_t y_\delta - f - Bu_\delta, \psi) + a(y_\delta, \psi) - a(y_\delta, \psi_I) - (\partial_t y_\delta - f - Bu_\delta, \psi_I))\, dt \\
&+ \sum_{k'=1}^{k} ([y_\delta]_{k'-1}, (\psi - \psi_I)_{k'-1}^+) + (y_0^h - y_0, \psi_0^+) + ([y_\delta]_k, \psi_*) \\
= &\sum_{k'=1}^{k} \int_{I_{k'}} \left(\partial_t y_\delta - f - Bu_\delta - \operatorname{div}(A\nabla y_\delta + \frac{[y_\delta]_{k'-1}}{\Delta t_{k'}}, \psi - \psi_I\right) \\
&+ \int_0^{t_k} \left(\sum_{l \in \partial T^h} \int_l [(A\nabla y_\delta) \cdot \mathbf{n}](\psi - \psi_I) \right) dt \\
&+ \sum_{k'=1}^{k} \int_{I_{k'}} \left(\frac{[y_\delta]_{k'-1}}{\Delta t_{k'}}, \psi_{k'-1}^+ - \psi + \psi_I - (\psi_I)_{k'-1}^+ \right) \\
&+ (y_0^h - y_0, \psi_0^+) + ([y_\delta]_k, \psi_*) := \sum_{i=1}^{5} \mathcal{J}_i.
\end{aligned}$$

Let $c_1 = 0$ and $c_k = 1$ for $2 \le k \le N-1$. Then, as in (46)–(51),

$$\begin{aligned}
\mathcal{J}_1 &= \left(c_k \sum_{k'=1}^{k-1} + \sum_{k'=k} \right) \int_{I_{k'}} \{(r_y, (\pi_{h,k} - I)\pi_k \psi) + ((\pi_k - I) r_y, (\pi_k - I)\psi)\}\, dt \\
&\le C(\mathfrak{N}_5^2 + \mathfrak{N}_6^2) + \sigma \|(y^{u_\delta} - y_\delta)_k^+\|_{0,\Omega}^2, \\
\mathcal{J}_2 &= \left(c_k \sum_{k'=1}^{k-1} + \sum_{k'=k} \right) \int_{I_{k'}} \sum_{l \in \partial T^h} \int_l [(A\nabla y_\delta) \cdot \mathbf{n}](\psi - \pi_{h,k}\psi)\, dt \\
&\le C\mathfrak{N}_7^2 + \sigma \|(y^{u_\delta} - y_\delta)_k^+\|_{0,\Omega}^2, \\
\mathcal{J}_3 &= \left(c_k \sum_{k'=1}^{k-1} + \sum_{k'=k} \right) \int_{I_{k'}} \left(\frac{[y_\delta]_{k'-1}}{\Delta t_{k'}}, (\psi_I)_{k'}^- - \psi_I + \psi - \psi_{k'}^- \right) dt \\
&\le C\mathfrak{N}_8^2 + \sigma \|(y^{u_\delta} - y_\delta)_k^+\|_{0,\Omega}^2, \\
\mathcal{J}_4 &\le C\|y_0^h - y_0\|_{0,\Omega}^2 + \sigma \|(y^{u_\delta} - y_\delta)_k^+\|_{0,\Omega}^2, \\
\mathcal{J}_5 &\le C\|[y_\delta]_k\|_{0,\Omega}^2 + \sigma \|(y^{u_\delta} - y_\delta)_k^+\|_{0,\Omega}^2.
\end{aligned}$$

Hence

$$\|(y_\delta - y^{u_\delta})_k^+\|_{0,\Omega}^2 \le C \sum_{i=0,5-8} \mathfrak{N}_i^2. \tag{53}$$

We complete the proof by combining the estimates (39), (44), (45), (52), and (53) and the result of Theorem 3.1. ∎

In the rest of the section, we apply the results obtained to some model control problems. We only consider the piecewise constant finite element space for the approximation of the control.

Example 3.1. Consider the case $K = \{v \in X : v \geq \phi_0\}$, where ϕ_0 is a constant. Let $K^\delta = \{v \in X^\delta : v \geq \phi_0\}$. Then it is easy to see that $K^\delta \subset K$. Let v in Lemma 3.3 be such that $v|_{\tau_U^k \times I_k} = \pi^a_{\delta,k} u$, where $\pi^a_{\delta,k} u$ is the integral average of u on $\tau_U^k \times I_k$. Then $v = \pi^a_{\delta,k} u \in K^\delta$, and for $1 \leq k \leq N$,

$$\begin{aligned}
&\left| \int_{I_k} (h'(u_\delta) + B^* p_\delta, v - u)_U \, dt \right| = \left| \int_{I_k} (h'(u_\delta) + B^* p_\delta, \pi^a_{\delta,k} u - u)_U \, dt \right| \\
&= \left| \int_{I_k} ((\pi^a_{\delta,k} - I)(h'(u_\delta) + B^* p_\delta), (\pi^a_{\delta,k} - I)(u - u_\delta))_U \, dt \right| \\
&\leq C \int_{I_k} \sum_{\tau_U \in T_U^{h,k}} (h_{\tau_U} |h'(u_\delta) + B^* p_\delta|_{1,\tau_U} + \Delta t_k \|\partial_t (h'(u_\delta) + B^* p_\delta)\|_{0,\tau_U}) \|u - u_\delta\|_{0,\tau_U} \, dt.
\end{aligned}$$

Hence, the condition (12) in Lemma 3.3 is satisfied. Consequently the estimates obtained in Theorems 3.1–3.2 are applicable.

Example 3.2. Consider the case $K = \{v \in X : \int_{\Omega_U} v \geq 0\}$. Let $K^\delta = \{v \in X^\delta : \int_{\Omega_U} v \geq 0\}$. Then it is easy to see that $K^\delta \subset K$. Let v in Lemma 3.3 be defined as in Example 3.1. Then, the condition (12) in Lemma 3.3 is also satisfied.

4. Improved error estimates for the constraint of obstacle type. It seems to be difficult to further improve the estimates obtained in Theorems 3.1 and 3.2 without having structure information on the constraint set K. In this section, we consider a case where the constraint set is of obstacle type, which is met very frequently in real applications. We are then able to derive improved error estimates for the DG scheme of the finite element approximation to the parabolic optimal control problem (6). As mentioned in section 3, the essential step is to derive improved estimates for the approximation of the inequality in (2), via utilizing the structure information of K. Such improved estimates are found to be useful in computing elliptic control problems; see [27]. We shall only examine piecewise constant or piecewise linear control approximation.

We assume that the constraint on the control is an obstacle such that

$$K = \{v \in X : \ v \geq \phi \ \text{ a.e. in } \Omega_U \times (0, T]\},$$

where $\phi \in X$. We define the coincidence set (contact set) $\Omega_U^-(t)$ and the noncoincidence set (noncontact set) $\Omega_U^+(t)$ as follows:

$$\Omega_U^-(t) := \{x \in \Omega_U : u(x,t) = \phi(x,t)\}, \qquad \Omega_U^+(t) := \{x \in \Omega_U : u(x,t) > \phi(x,t)\}.$$

Let

$$K^\delta = \{v \in X^\delta : \ v \geq \phi^\delta \text{ in } \Omega_U \times (0, T]\}, \tag{54}$$

where $\phi^\delta \in X^\delta$ is an approximation to ϕ satisfying $\phi^\delta \geq \phi$. Hence, we have that $K^\delta \subset K$. In this section, we assume that

$$h(u) = \int_{\Omega_U} j(u),$$

where $j(\cdot)$ is a convex continuously differentiable function on $\mathbb{R}$. Then, it is easy to see that

$$\int_0^T (h'(u), v)_U = \int_0^T (j'(u), v)_U = \int_0^T \int_{\Omega_U} j'(u)v.$$

We shall assume the following uniform convexity condition:

$$(j'(t) - j'(s))(t - s) \geq c(t - s)^2 \quad \forall s, t \in \mathbb{R}.$$

It can be seen that the inequality in (2) is now equivalent to the following:

$$j'(u) + B^*p \geq 0, \quad u \geq \phi, \quad (j'(u) + B^*p)(u - \phi) = 0, \quad \text{a.e. in } \Omega_U \times (0, T]. \tag{55}$$

In order to have the improved a posteriori error estimate, we divide $\Omega_U \times (0, T]$ into the following three subsets:

$$\begin{aligned}
\Omega_\phi &= \{(x, t) \in \Omega_U \times (0, T] : \ (B^*p_\delta)(x, t) \leq -j'(\phi^\delta)\}, \\
\Omega_\phi^0 &= \{(x, t) \in \Omega_U \times (0, T] : \ (B^*p_\delta)(x, t) > -j'(\phi^\delta), \ u_\delta = \phi^\delta\}, \\
\Omega_\phi^+ &= \{(x, t) \in \Omega_U \times (0, T] : \ (B^*p_\delta)(x, t) > -j'(\phi^\delta), \ u_\delta > \phi^\delta\}.
\end{aligned}$$

Then, it is easy to see that the above three subsets do not overlap each other, and

$$\bar{\Omega}_U \times (0, T] = \bar{\Omega}_\phi \cup \bar{\Omega}_\phi^0 \cup \bar{\Omega}_\phi^+.$$

We shall show that $h'(u_\delta) + B^*p_\delta$ can be replaced by $(j'(u_\delta) + B^*p_\delta)|_{\Omega_\phi}$ in the error estimates. Note that $j'(u) + B^*p = 0$ when $u > \phi$. Thus in a sense, the set Ω_ϕ is an approximation of the noncoincidence set $\{(x, t) : x \in \Omega_U^+(t), \ t \in (0, T]\}$.

THEOREM 4.1. *Let (y, p, u) and $(y_\delta, p_\delta, u_\delta)$ be the solutions of (2) and (6), respectively. Assume that all the conditions of Lemma 3.5 hold, and K^δ is defined in (54) with $\phi \in L^2(0, T; L^2(\Omega_U))$. Moreover, assume that $j'(\cdot)$ and $g'(\cdot)$ are locally Lipschitz continuous. Then*

$$\|u_\delta - u\|^2_{L^2(0,T;L^2(\Omega_U))} + \|y_\delta - y\|^2_{L^2(0,T;L^2(\Omega))} + \|p_\delta - p\|^2_{L^2(0,T;L^2(\Omega))} \leq C \sum_{i=0}^{8} \hat{\eta}_i^2,$$

where $\hat{\eta}_i^2 = \eta_i^2$ ($i = 0, 2$–7) are given in Lemma 3.5 and

$$\begin{aligned}
\hat{\eta}_1^2 &= \int_{\Omega_\phi} |j'(u_\delta) + B^*p_\delta|^2, \\
\hat{\eta}_8^2 &= \|\phi - \phi^\delta\|^2_{0,\Omega_\phi^0}.
\end{aligned}$$

Proof. We consider $\|u_\delta - u\|^2_{L^2(0,T;L^2(\Omega_U))}$. From the uniform convexity of j, we

have that

$$
\begin{aligned}
&c\|u-u_\delta\|^2_{L^2(0,T;L^2(\Omega_U))} \le \int_0^T (j'(u)-j'(u_\delta),u-u_\delta)_U\\
&=\int_0^T (j'(u)+B^*p,u-u_\delta)_U+\int_0^T (j'(u_\delta)+B^*p_\delta,u_\delta-u)_U\\
&\quad+\int_0^T (B^*(p_\delta-p^{u_\delta}),u-u_\delta)_U+\int_0^T (B^*(p^{u_\delta}-p),u-u_\delta)_U \qquad (56)\\
&=\int_0^T (j'(u)+B^*p,u-u_\delta)_U+\int_0^T (j'(u_\delta)+B^*p_\delta,u_\delta-u)_U\\
&\quad+\int_0^T (B^*(p_\delta-p^{u_\delta}),u-u_\delta)_U+\int_0^T (y^{u_\delta}-y,y-y^{u_\delta})\\
&\le\int_0^T (j'(u)+B^*p,u-u_\delta)_U+\int_0^T (j'(u_\delta)+B^*p_\delta,u_\delta-u)_U\\
&\quad+\int_0^T (B^*(p_\delta-p^{u_\delta}),u-u_\delta)_U:=\sum_1^3 I_i.
\end{aligned}
$$

We first estimate I_1. Note that

$$
\begin{aligned}
&\int_0^T (j'(u)+B^*p,u-u_\delta)_U \qquad (57)\\
&=\int_{\Omega_\phi\cup\Omega_\phi^+}(j'(u)+B^*p)(u-u_\delta)+\int_{\Omega_\phi^0}(j'(u)+B^*p)(u-\phi^\delta).
\end{aligned}
$$

Let

$$
w=\begin{cases} u_\delta, & (x,t)\in\Omega_\phi\cup\Omega_\phi^+,\\ u, & (x,t)\in\Omega_\phi^0.\end{cases}
$$

Then, $w\in K$, and hence

$$
\int_{\Omega_\phi\cup\Omega_\phi^+}(j'(u)+B^*p)(u-u_\delta)=\int_0^T\int_{\Omega_U}(j'(u)+B^*p)(u-w)\le 0. \qquad (58)
$$

Note that $(j'(u)+B^*p)(u-\phi)=0$. We have that

$$
\begin{aligned}
\int_{\Omega_\phi^0}(j'(u)+B^*p)(u-\phi^\delta)&=\int_{\Omega_\phi^0}(j'(u)+B^*p)((u-\phi)+(\phi-\phi^\delta))\\
&=\int_{\Omega_\phi^0}(j'(u)+B^*p)(\phi-\phi^\delta). \qquad (59)
\end{aligned}
$$

It follows from (57)–(59) that

$$
I_1=\int_0^T (j'(u)+B^*p,u-u_\delta)_U\le\int_{\Omega_\phi^0}(j'(u)+B^*p)(\phi-\phi^\delta). \qquad (60)
$$

Next we estimate I_2. It is clear that

$$\begin{aligned}&\int_0^T (j'(u_\delta)+B^*p_\delta, u_\delta-u)_U\\ &=\int_{\Omega_\phi}(j'(u_\delta)+B^*p_\delta)(u_\delta-u)+\int_{\Omega_\phi^+}(j'(u_\delta)+B^*p_\delta)(u_\delta-u)\\ &\quad+\int_{\Omega_\phi^0}(j'(\phi_h)+B^*p_\delta)(\phi^\delta-u). \qquad (61)\end{aligned}$$

First it is easy to see that

$$\begin{aligned}\int_{\Omega_\phi}(j'(u_\delta)+B^*p_\delta)(u_\delta-u)&\le C\int_{\Omega_\phi}(j'(u_\delta)+B^*p_\delta)^2+C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}\\ &=C\hat\eta_1^2+C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}. \qquad (62)\end{aligned}$$

Second, let $\tau_U\times(t_i,t_{i+1}]$ be such that $u_\delta|_{\tau_U\times(t_i,t_{i+1}]}>\phi^\delta$; it follows from (6) that there exist $\epsilon>0$ and $\psi\in X^\delta$, such that $\psi\ge 0$, $\|\psi\|_{L^\infty(t_i,t_{i+1};L^\infty(\tau_U))}=1$, and

$$\int_{t_i}^{t_{i+1}}\int_{\tau_U}(j'(u_\delta)+B^*p_\delta)(u_\delta-(u_\delta-\epsilon\psi))=\epsilon\int_{t_i}^{t_{i+1}}\int_{\tau_U}(j'(u_\delta)+B^*p_\delta)\psi\le 0.$$

Note that on Ω_ϕ^+, $(j'(u_\delta)+B^*p_\delta)>(j'(\phi^\delta)+B^*p_\delta)>0$. We have that

$$\begin{aligned}&\int_{(\tau_U\times(t_i,t_{i+1}])\cap\Omega_\phi^+}|j'(u_\delta)+B^*p_\delta|\psi=\int_{(\tau_U\times(t_i,t_{i+1}])\cap\Omega_\phi^+}(j'(u_\delta)+B^*p_\delta)\psi\\ &\le-\int_{(\tau_U\times(t_i,t_{i+1}])\cap\Omega_\phi}(j'(u_\delta)+B^*p_\delta)\psi\le\int_{(\tau_U\times(t_i,t_{i+1}])\cap\Omega_\phi}|j'(u_\delta)+B^*p_\delta|.\end{aligned}$$

Let $\hat\tau_{Ut_i}$ be the reference element of $\tau_U\times(t_i,t_{i+1}]$, $\tau^0_{Ut_i}=(\tau_U\times(t_i,t_{i+1}])\cap\Omega_\phi^+$, and $\hat\tau^0_{Ut_i}\subset\hat\tau_{Ut_i}$ be the image of $\tau^0_{Ut_i}$. Let n be the dimension of Ω_U and $k_i=t_{i+1}-t_i$. Note that $j'(\cdot)$ is locally Lipschitz continuous. It follows from the equivalence of the norm in a finite dimensional space that

$$\begin{aligned}&\int_{\tau^0_{Ut_i}}|j'(u_\delta)+B^*p_\delta|^2\le Ch^n_{\tau_U}k_i\int_{\hat\tau^0_{Ut_i}}|j'(u_\delta)+B^*p_\delta|^2\\ &\le Ch^n_{\tau_U}k_i\left(\int_{\hat\tau^0_{Ut_i}}|j'(u_\delta)+B^*p_\delta|\psi\right)^2\le Ch^{-n}_{\tau_U}k_i^{-1}\left(\int_{\tau^0_{Ut_i}}|j'(u_\delta)+B^*p_\delta|\psi\right)^2\\ &\le Ch^{-n}_{\tau_U}k_i^{-1}\left(\int_{\tau_{Ut_i}\cap\Omega_\phi}|j'(u_\delta)+B^*p_\delta|\right)^2\le C\int_{\tau_{Ut_i}\cap\Omega_\phi}|j'(u_\delta)+B^*p_\delta|^2.\end{aligned}$$

Therefore,

$$\begin{aligned}&\int_{\Omega_\phi^+}(j'(u_\delta)+B^*p_\delta)(u_\delta-u)\\ &\le C\int_{\Omega_\phi^+}(j'(u_\delta)+B^*p_\delta)^2+C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}\\ &\le C\int_{\Omega_\phi}(j'(u_\delta)+B^*p_\delta)^2+C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))} \qquad (63)\\ &=C\hat\eta_1^2+C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}.\end{aligned}$$

It follows from the definition of Ω_ϕ^0 that $(j'(\phi^\delta)+B^*p_\delta)>0$ on Ω_ϕ^0. Then we have

$$\begin{aligned}\int_{\Omega_\phi^0}(j'(\phi_h)+B^*p_\delta)(\phi^\delta-u) &= \int_{\Omega_\phi^0}(j'(\phi^\delta)+B^*p_\delta)((\phi^\delta-\phi)+(\phi-u))\\ &\le \int_{\Omega_\phi^0}(j'(u_\delta)+B^*p_\delta)(\phi^\delta-\phi). \end{aligned}\tag{64}$$

Thus it follows from (61)–(64) that

$$\begin{aligned}I_2=\int_0^T(j'(u_\delta)+B^*p_\delta,u_\delta-u)_U &\le C\hat\eta_1^2+\int_{\Omega_\phi^0}(j'(u_\delta)+B^*p_\delta)(\phi^\delta-\phi)\\ &\quad +C\delta\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}.\end{aligned}\tag{65}$$

Then it follows from (60) and (65) that

$$\begin{aligned}&I_1+I_2=\\ &\int_0^T(j'(u)+B^*p,u-u_\delta)_U+\int_0^T(j'(u_\delta)+B^*p_\delta,u_\delta-u)_U\\ &\le C\hat\eta_1^2+\int_{\Omega_\phi^0}(j'(u)+B^*p-j'(u_\delta)-B^*p_\delta)(\phi-\phi^\delta)\\ &\quad +C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}\\ &\le C(\hat\eta_1^2+\|\phi-\phi^\delta\|^2_{0,\Omega_\phi^0})+C\sigma(\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}\\ &\quad +\|j'(u_\delta)-j'(u)\|^2_{L^2(0,T;L^2(\Omega_U))}+\|B^*(p_\delta-p^{u_\delta})\|^2_{L^2(0,T;L^2(\Omega_U))}\\ &\quad +\|B^*(p^{u_\delta}-p)\|^2_{L^2(0,T;L^2(\Omega_U))})\\ &\le C(\hat\eta_1^2+\hat\eta_8^2)+C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}+C\|p_\delta-p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))}.\end{aligned}\tag{66}$$

Here we used the inequalities

$$\|j'(u_\delta)-j'(u)\|^2_{L^2(0,T;L^2(\Omega_U))}\le C\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))},$$

$$\|B^*(p_\delta-p^{u_\delta})\|^2_{L^2(0,T;L^2(\Omega_U))}\le C\|p_\delta-p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega_U))},$$

and

$$\|B^*(p^{u_\delta}-p)\|^2_{L^2(0,T;L^2(\Omega_U))}\le C\|p^{u_\delta}-p\|^2_{L^2(0,T;L^2(\Omega))}\le C\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}.$$

Finally for I_3, it is easy to show that

$$\begin{aligned}I_3&=\int_0^T(B^*(p_\delta-p^{u_\delta}),u-u_\delta)_U\\ &\le C\|B^*(p_\delta-p^{u_\delta})\|^2_{L^2(0,T;L^2(\Omega))}+C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}\\ &\le C\|p_\delta-p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))}+C\sigma\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}.\end{aligned}\tag{67}$$

Thus, we obtain from (56), (66), and (67) that

$$\|u_\delta-u\|^2_{L^2(0,T;L^2(\Omega_U))}\le C(\hat\eta_1+\hat\eta_8+\|p_\delta-p^{u_\delta}\|^2_{L^2(0,T;L^2(\Omega))}).$$

The remainder of the proof is the same as for Lemma 3.5 and Theorem 3.1. ∎

REMARK 4.1. *By the same argument, we can obtain a similar estimate in the* $L^\infty(L^2)$ *norm considered in Theorem* 3.2. *It is worth noting that there may be different approaches to derive sharp a posteriori error bounds for the obstacle constraints. Noticeably, it may be possible to design some penalty schemes to solve the optimality system, and then apply the techniques used in* [8, 17, 22] *to derive sharp bounds.*

REMARK 4.2. *Here the key idea is to remove some inactive data in the coincidence set and to thus obtain sharper error estimates for the approximation of the inequality in* (2). *In fact, as seen in the above proof, only the part where* $j'(u_\delta) + B^* p_\delta \le 0$ *needs to be left in the estimator* $\hat{\eta}_1^2$. *Let us define*

$$\hat{\Omega}_\phi = \{(x,t) \in \Omega_U \times (0,T] : \ (B^* p_\delta)(x,t) \le -j'(u_\delta)\}.$$

In a sense, the set $\hat{\Omega}_\phi$ *is an approximation of the noncoincidence set. It follows that* $(j'(u_\delta) + B^* p_\delta)|_{\hat{\Omega}_\phi} \le 0$, *while* $j'(u) + B^* p \ge 0$. *Thus on* $\hat{\Omega}_\phi$, $j'(u_\delta) + B^* p_\delta$ *truly indicates the error. In fact, we have*

$$\int_{\hat{\Omega}_\phi} |j'(u_\delta) + B^* p_\delta|^2 \le \int_{\hat{\Omega}_\phi} |j'(u_\delta) + B^* p_\delta - (j'(u) + B^* p)|^2$$

$$\le C(\|u - u_\delta\|^2_{L^2(0,T;L^2(\Omega_U))} + \|p - p_\delta\|^2_{L^2(0,T;L^2(\Omega))}).$$

For ease of computation, we have used the set Ω_ϕ, *which is a little larger than* $\hat{\Omega}_\phi$. *However, we still have*

$$\hat{\eta}_1^2 \le C(\|u - u_\delta\|^2_{L^2(0,T;L^2(\Omega_U))} + \|p - p_\delta\|^2_{L^2(0,T;L^2(\Omega))} + \hat{\eta}_8^2).$$

On the coincidence set, $u = \phi$. *Therefore the error should be indicated by* $\hat{\eta}_8$, *and the term* $j'(u_\delta) + B^* p_\delta$ *should not appear there.*

A NEW DISCONTINUOUS FINITE VOLUME METHOD FOR ELLIPTIC PROBLEMS*

XIU YE†

Abstract. We develop and analyze a new discontinuous finite volume method for second order elliptic problems with tensor coefficients. An optimal order error estimate is obtained in a mesh dependent norm. An L^2-error estimate is also obtained.

Key words. finite element methods, discontinuous Galerkin method, finite volume methods, elliptic problems

1. Introduction.

Like the finite element method and the finite difference method, the finite volume method is a discretization technique for solving partial differential equations. The integral formulation of a finite volume scheme for a partial differential equation (PDE) is obtained by integrating the PDE over a control volume, and it represents in general the conservation of a quantity of interest, such as mass, momentum, or energy. Due to this natural association, finite volume methods are widely used in practical problems, such as fluid mechanics computations [18, 19, 20]. Recently, Chou, Kwak, and Vassilevski [10, 12, 13, 11] applied finite volume element methods involving nonconforming trial functions to diffusion, diffusion-reaction, and Stokes problems and obtained optimal order error estimates in a discrete H^1 norm.

Unlike the standard conforming and nonconforming finite element methods, the discontinuous Galerkin method does not require continuity of the approximation functions across the interelement boundary but instead enforces the connection between elements by adding a penalty term. These methods came from the idea of enforcing Dirichlet boundary conditions through penalties (see Lions [17], Aubin [3], Babuska [4], and Nitsche [21]). Because of the use of discontinuous functions, discontinuous Galerkin methods have the advantages of a high order of accuracy, high parallelizability, localizability, and easy handling of complicated geometries. Due to these advantages, the study of discontinuous Galerkin methods has been an active research area since its introduction by Reed and Hill [22]. The discontinuous Galerkin methods have been used to solve hyperbolic and elliptic equations by many researchers. For example, see [5, 6, 7, 8, 9, 14, 15, 16, 23]. Recently, Arnold et al. [2] provided a framework for the analysis of a large class of discontinuous Galerkin methods for second order elliptic problems. Most literature concerning discontinuous Galerkin methods for finite element approximations can be found in the references given in [2].

However, very little has been done using discontinuous functions for the finite volume approximation. In this paper, we developed a new discontinuous finite volume method (DFV) in which discontinuous piecewise polynomials are used for the trial functions. It is natural to assume that the advantages of using discontinuous functions in finite element methods should apply to finite volume methods. The nature of the

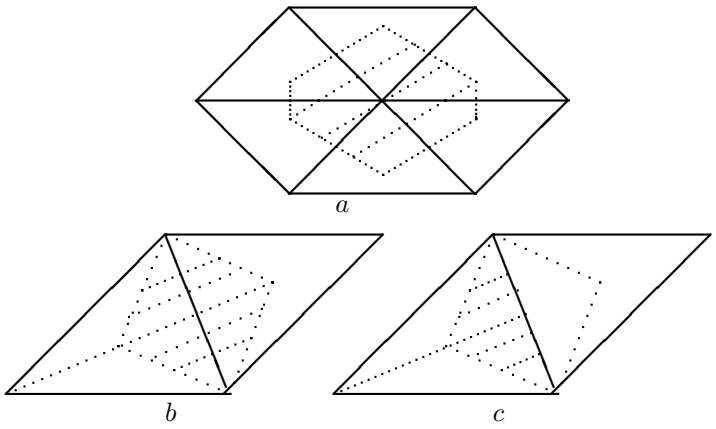

FIG. 1. *Dual partitions.*

discontinuity of the trial function is such that the elements in the corresponding dual partition have the smallest support, as compared with the cases when conforming (classical finite volume methods) and nonconforming elements (more recent finite volume methods [10]) are used for the trial functions. This discontinuous finite volume scheme will be analyzed for the elliptic problems and an optimal order error estimate will be obtained in a discrete H^1 norm. However, our method and analysis can be applied to solve more complex problems, like the Stokes equations, the system of linear elasticity, and plate problems.

In Figure 1, we compare dual partitions associated with conforming elements, nonconforming elements, and our new discontinuous elements. The shaded region in Figure 1(a) represents a typical element in the dual partition when conforming elements are used for trial functions. This region involves six elements in the primary partition. This case is the classical finite volume scheme, where the continuous piecewise linear functions are used for the trial functions. The shaded quadrilateral in Figure 1(b) is an element in the dual partition associated with nonconforming elements [10] which involves two elements of the primary partition. Figure 1(c) shows that the elements of the dual partition associated with our new discontinuous finite volume method have the best local ability when only one element in the primary partition is involved. The localizability of the discontinuous element and its dual partition in our method should provide an advantage for parallel computing.

Since the discontinuous functions are used in the approximation, the number of unknowns is larger. However, the small support of the control volume for this method makes the method more suitable to the domain decomposition such that the information can be updated triangle by triangle in the primary partition.

We consider the model problems

$$-\nabla \cdot B\nabla u = f \quad \text{in } \Omega, \quad u = 0 \quad \text{on } \partial\Omega, \tag{1.1}$$

where Ω is a bounded convex polygon in R^2. $B = (b_{ij})_{2\times 2} \in W^{1,\infty}(\Omega)^4$ is a symmetric matrix value function and satisfies the following condition: there exists a constant $\beta > 0$ such that

$$\beta\xi^T\xi \le \xi^T B\xi \quad \forall \xi \in R^2. \tag{1.2}$$

We will use the standard definitions for the Sobolev spaces $H^s(K)$ and their

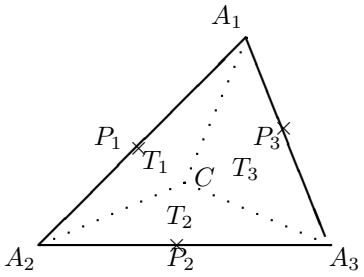

FIG. 2. *A triangular partition and its dual.*

associated inner products $(\cdot,\cdot)_{s,K}$, norms $\|\cdot\|_{s,K}$, and seminorms $|\cdot|_{s,K}$, $s \geq 0$. The space $H^0(K)$ coincides with $L^2(K)$, in which case the norm and inner product are denoted by $\|\cdot\|_K$ and $(\cdot,\cdot)_K$, respectively. If $K = \Omega$, we drop K.

This paper is organized as follows. In section 2, we derive a discontinuous finite volume formulation for the elliptic problems. In section 3, an optimal order error estimate is obtained in a mesh dependent norm and a first order L^2-error estimate is derived.

2. Discontinuous finite volume formulation. The simplicity of the finite volume method is due to its use of piecewise constant functions as test functions. To keep the same dimension for the spaces of the trial functions and test functions, two different triangulations are needed. Let $\mathcal{R}_h$ be a triangulation of Ω with $\text{diam}(K) \leq h,\ K \in \mathcal{R}_h$. Assume that the triangulation $\mathcal{R}_h$ is quasi-uniform. We define the dual partition $\mathcal{T}_h$ of $\mathcal{R}_h$ for the test function space as follows. We divide each $K \in \mathcal{R}_h$ into three triangles by connecting the barycenter and the three corners of the triangle as shown in Figure 2. Let $\mathcal{T}_h$ consist of all these triangles T_j.

We define the finite dimensional space associated with $\mathcal{R}_h$ for the trial functions as

$$V_h = \{v \in L^2(\Omega) :\ v|_K \in P_1(K)\ \ \forall K \in \mathcal{R}_h\} \tag{2.1}$$

and define the finite dimensional space P_h for test functions associated with the dual partition $\mathcal{T}_h$ as

$$P_h = \{q \in L^2(\Omega) :\ q|_T \in P_0(T)\ \ \forall T \in \mathcal{T}_h\},$$

where $P_l(T)$ consists of all the polynomials with degree less than or equal to l defined on T.

Let $V(h) = V_h + H^2(\Omega) \cap H_0^1(\Omega)$. Define a mapping $\gamma :\ V(h) \to P_h$ as

$$\gamma v|_T = \frac{1}{h_e}\int_e v|_T ds, \quad T \in \mathcal{T}_h,$$

as shown in Figure 3. The above idea of connecting the trial function and test function spaces in the Petrov–Galerkin method through an operator was introduced in [10] in the context of elliptic problems.

Multiplying (1.1) by $q \in P_h$, we have

$$-\sum_{T\in\mathcal{T}_h}\int_{\partial T} B\nabla u \cdot \mathbf{n} q ds = (f,\ q), \tag{2.2}$$

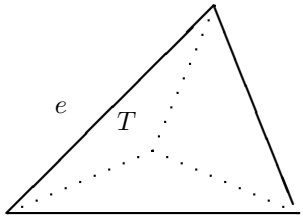

FIG. 3. *Element $T \in \mathcal{T}_h$ and one of its edges e.*

where $\mathbf{n}$ is the unit outward normal vector on ∂T. Let $T_j \in \mathcal{T}_h$ $(j = 1, 2, 3)$ be three triangles in $K \in \mathcal{R}_h$. Then we have

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T} B\nabla u\cdot\mathbf{n}q ds = \sum_{K\in\mathcal{R}_h}\sum_{j=1}^{3}\int_{\partial T_j} B\nabla u\cdot\mathbf{n}q ds \tag{2.3}$$

$$= \sum_{K\in\mathcal{R}_h}\sum_{j=1}^{3}\int_{A_{j+1}CA_j} B\nabla u\cdot\mathbf{n}q ds + \sum_{K\in\mathcal{R}_h}\int_{\partial K} B\nabla u\cdot\mathbf{n}q ds,$$

where $A_4 = A_1$.

Let e be an interior edge shared by two elements K_1 and K_2 in $\mathcal{R}_h$, and let $\mathbf{n}_1$ and $\mathbf{n}_2$ be unit normal vectors on e pointing exterior to K_1 and K_2, respectively. We define the average $\{\cdot\}$ and jump $[\cdot]$ on e for scalar q and vector $\mathbf{w}$, respectively, as (see [2])

$$\{q\} = \frac{1}{2}(q|_{\partial T_1} + q|_{\partial T_2}), \quad [q] = q|_{\partial T_1}\mathbf{n}_1 + q|_{\partial T_2}\mathbf{n}_2,$$

$$\{\mathbf{w}\} = \frac{1}{2}(\mathbf{w}|_{\partial T_1} + \mathbf{w}|_{\partial T_2}), \quad [\mathbf{w}] = \mathbf{w}|_{\partial T_1}\cdot\mathbf{n}_1 + \mathbf{w}|_{\partial T_2}\cdot\mathbf{n}_2.$$

If e is a edge on the boundary of Ω, we define

$$\{q\} = q, \quad [\mathbf{w}] = \mathbf{w}\cdot\mathbf{n}.$$

Let Γ denote the union of the boundaries of the triangle K of $\mathcal{R}_h$ and $\Gamma_0 := \Gamma\backslash\partial\Omega$. A straightforward computation gives

$$\sum_{K\in\mathcal{R}_h}\int_{\partial K} q\mathbf{v}\cdot\mathbf{n} ds = \sum_{e\in\Gamma}\int_e [q]\cdot\{\mathbf{v}\} ds + \sum_{e\in\Gamma_0}\int_e \{q\}[\mathbf{v}] ds. \tag{2.4}$$

Using (2.4) and the fact that $[B\nabla u] = 0$, (2.3) becomes

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T} B\nabla u\cdot\mathbf{n}q ds = \sum_{K\in\mathcal{R}_h}\sum_{j=1}^{3}\int_{A_{j+1}CA_j} B\nabla u\cdot\mathbf{n}q ds + \sum_{e\in\Gamma}\int_e [q]\cdot\{B\nabla u\} ds.$$

Our discontinuous finite volume approximation problem for (1.1) is to find $u_h \in V_h$ such that

$$a(u_h, q) = (f,\ q) \qquad \forall q \in P_h \tag{2.5}$$

with

$$a(v,q) = -\sum_{K\in\mathcal{R}_h}\sum_{j=1}^{3}\int_{A_{j+1}CA_j} B\nabla u\cdot\mathbf{n}q ds - \sum_{e\in\Gamma}\int_e [q]\cdot\{B\nabla v\}ds + \alpha\sum_{e\in\Gamma}[\gamma v]_e\cdot[q]_e,$$

where α is a real number that will be determined later. In the definition of $a(\cdot,\cdot)$, γv and q are piecewise constant functions and so are their jump functions $[\gamma v]_e$ and $[q]_e$. Thus the penalty term in the definition of $a(\cdot,\cdot)$ is the same as the penalty term in many discontinuous Galerkin formulation for the finite element methods [2].

Define the following bilinear form:

$$A(v,\ w) = a(v,\ \gamma w) \quad \forall v, w \in V(h).$$

Then the approximation problem (2.5) becomes the following: find $u_h \in V_h$ such that

$$A(u_h, v) = (f,\ \gamma v) \quad \forall v \in V_h. \tag{2.6}$$

Since $[\gamma u]_e = 0$, it is easy to see that u, the solution of (1.1), satisfies

$$A(u, v) = (f,\ \gamma v) \quad \forall v \in V_h. \tag{2.7}$$

Let

$$A_1(v,w) = -\sum_{K\in\mathcal{R}_h}\sum_{j=1}^{3}\int_{A_{j+1}CA_j} B\nabla u\cdot\mathbf{n}\gamma w ds.$$

Thus

$$A(v,w) = A_1(v,w) - \sum_{e\in\Gamma}\int_e [\gamma w]\cdot\{B\nabla v\}ds + \alpha\sum_{e\in\Gamma}[\gamma v]_e\cdot[\gamma w]_e.$$

Let $\nabla_h v$ be the function whose restriction to each element $K \in \mathcal{R}_h$ is equal to ∇v. Let

$$\bar{B}|_K = \frac{1}{\text{meas}(K)}\int_K B(\mathbf{x})d\mathbf{x} \quad \forall K \in \mathcal{R}_h.$$

We define a norm $|||\cdot|||$ for $V(h)$ as follows:

$$|||v|||^2 = |v|_{1,h}^2 + \sum_e [\gamma v]_e^2, \tag{2.8}$$

where $|v|_{1,h}^2 = \sum_K |v|_{1,K}^2$. It is easy to see that $|||\cdot|||$ defines a norm. (We use C with or without subscripts in this note to denote a generic positive constant, possibly different at different occurrences, that is independent of the mesh size h but may depend on the domain Ω.)

The following trace inequality can be found in [1]. For $w \in H^2(K)$ and for an edge e of K,

$$\|w\|_e^2 \le C(h_e^{-1}|w|_K^2 + h_e|w|_{1,K}^2), \tag{2.9}$$

where C depends only on the minimum angle of K.

LEMMA 2.1. *For any $v, w \in V(h)$, we have*

$$A_1(v,w) = (B\nabla_h v, \nabla_h w) + \sum_K \int_{\partial K} (\gamma w - w) B\nabla v \cdot \mathbf{n} ds + \sum_K (\nabla \cdot B\nabla v, w - \gamma w)_K. \tag{2.10}$$

Furthermore, if $v, w \in V_h$, then

$$A_1(v,w) \geq (B\nabla_h v, \nabla_h w) - C_1 h |\!|\!| v |\!|\!| |\!|\!| w |\!|\!|. \tag{2.11}$$

Proof. Using the divergence theorem on each triangle T_j for $v \in V_h$, we have

$$\begin{aligned}
A_1(v,w) &= -\sum_K \sum_{j=1}^3 \int_{A_{j+1}CA_j} B\nabla v \cdot \mathbf{n} \gamma w ds = -\sum_K \sum_{j=1}^3 \gamma w \int_{A_{j+1}CA_j} B\nabla v \cdot \mathbf{n} ds \\
&= \sum_K \sum_{j=1}^3 \gamma w \int_{A_j A_{j+1}} B\nabla v \cdot \mathbf{n} ds - \sum_K \sum_{T_j} (\nabla \cdot B\nabla v, \gamma w)_{T_j} \\
&= \sum_K \sum_{j=1}^3 \int_{A_j A_{j+1}} (\gamma w - w) B\nabla v \cdot \mathbf{n} ds + \sum_K \int_{\partial K} w B\nabla v \cdot \mathbf{n} ds \\
&- \sum_K \sum_{T_j} (\nabla \cdot B\nabla v, \gamma w)_{T_j} \\
&= \sum_K \int_{\partial K} (\gamma w - w) B\nabla v \cdot \mathbf{n} ds + \sum_K (B\nabla v, \nabla w)_K + \sum_K (\nabla \cdot B\nabla v, w)_K \\
&- \sum_K \sum_{T_j} (\nabla \cdot B\nabla v, \gamma w)_{T_j} \\
&= \sum_K \int_{\partial K} (\gamma w - w) B\nabla v \cdot \mathbf{n} ds + (B\nabla_h v, \nabla_h w) + \sum_K (\nabla \cdot B\nabla v, w - \gamma w)_K.
\end{aligned}$$

If $v, w \in V_h$, the inverse inequality and (2.9) imply

$$\begin{aligned}
&\sum_K \int_{\partial K} (\gamma w - w) B\nabla v \cdot \mathbf{n} ds = \sum_K \int_{\partial K} (\gamma w - w)(B - \bar{B}) \nabla v \cdot \mathbf{n} ds \\
&\leq Ch \|B\|_{1,\infty} \sum_K (h^{-1} \|w - \gamma w\|_K^2 + h |w - \gamma w|_{1,K}^2)^{\frac{1}{2}} \cdot (h^{-1} |v|_{1,K}^2 + h |v|_{2,K}^2)^{\frac{1}{2}} \\
&\leq Ch |\!|\!| v |\!|\!| |\!|\!| w |\!|\!|, \qquad (2.12)
\end{aligned}$$

where $|w - \gamma w|_{1,K}^2 = \sum_{j=1}^3 |w - \gamma w|_{1,T_j}^2$. Let $\nabla(\nabla v) = (\nabla v_{x_1}, \nabla v_{x_2})$, a two by two matrix. Then

$$\sum_K (\nabla \cdot B\nabla v, w - \gamma w)_K = \sum_K (\nabla \cdot B \cdot \nabla v + B : \nabla(\nabla v), w - \gamma w)_K.$$

Since $\nabla(\nabla v) = 0$ for $v \in V_h$,

$$\sum_K (\nabla \cdot B\nabla v, w - \gamma w)_K \leq Ch \|B\|_{1,\infty} |\!|\!| v |\!|\!| |\!|\!| w |\!|\!|. \tag{2.13}$$

Equations (2.12) and (2.13) imply (2.11).

LEMMA 2.2. *There is a constant C independent of h such that for α large enough and h small enough*

$$A(v,v) \geq C|||v|||^2 \qquad \forall v \in V_h. \tag{2.14}$$

Proof. The trace inequality (2.9) and the inverse inequality give that for $v \in V_h$

$$\begin{aligned}
&\sum_e \int_e [\gamma v] \cdot \{B\nabla_h v\} ds \\
&\leq C\|B\|_{1,\infty} \left(\sum_K (|v|_{1,K}^2 + h^2 |v|_{2,K}^2) \right)^{\frac{1}{2}} \left(\sum_e h_e^{-1} \int_e [\gamma v]^2 ds \right)^{\frac{1}{2}} \\
&\leq C|||v||| \left(\sum_e [\gamma v]_e^2 \right)^{\frac{1}{2}}.
\end{aligned}$$

Using the inequality above and Lemma 2.1, we have

$$\begin{aligned}
A(v,v) &\geq (B\nabla_h v, \nabla_h v) + \alpha \sum_e [\gamma v]_e^2 - \sum_e \int_e [\gamma v] \cdot \{B\nabla v\} ds - C_1 h |||v|||^2 \\
&\geq |v|_{1,h}^2 + \alpha \sum_e [\gamma v]_e^2 - C|||v||| \left(\sum_e [\gamma v]_e^2 \right)^{\frac{1}{2}} - C_1 h |||v|||^2 \\
&\geq C|||v|||^2 - C_1 h |||v||| \geq C|||v|||^2.
\end{aligned}$$

The last inequality is obtained by using the generalized arithmetic-geometric mean inequality and choosing α large enough and h small enough .

In the following, we will assume that α is large enough and h small enough so that (2.14) holds.

LEMMA 2.3. *For $v, w \in V(h)$, we have*

$$A(v,w) \leq C \left(|||v||| + \left(\sum_K h^2 |v|_{2,K}^2 \right)^{\frac{1}{2}} \right) |||w|||. \tag{2.15}$$

If $v, w \in V_h$, then

$$A(v,w) \leq C|||v|||||w|||. \tag{2.16}$$

Proof. By Lemma 2.1, the trace inequality (2.9), and the Cauchy–Schwarz inequality, we have

$$\begin{aligned}
|A_1(v,w)| &\leq |(B\nabla_h v, \nabla_h w)| \\
&\quad + \left| \sum_K \int_{\partial K} (w - \gamma w) B\nabla v \cdot \mathbf{n} ds \right| + \left| \sum_K (\nabla \cdot B\nabla v, w - \gamma w)_K \right| \\
&\leq C\|B\|_{1,\infty} (|v|_{1,h}|w|_{1,h} + \sum_K (h^{-1}\|w - \gamma w\|_K^2 + h|w - \gamma w|_{1,K}^2)^{\frac{1}{2}} \cdot (h^{-1}|v|_{1,K}^2 + h|v|_{2,K}^2)^{\frac{1}{2}} \\
&\quad + \sum_K h(|v|_{1,K} + |v|_{2,K})|w|_{1,K}) \\
&\leq C \left(|v|_{1,h}|w|_{1,h} + \left(\sum_K h^2 |v|_{2,K}^2 \right)^{\frac{1}{2}} |w|_{1,h} \right).
\end{aligned}$$

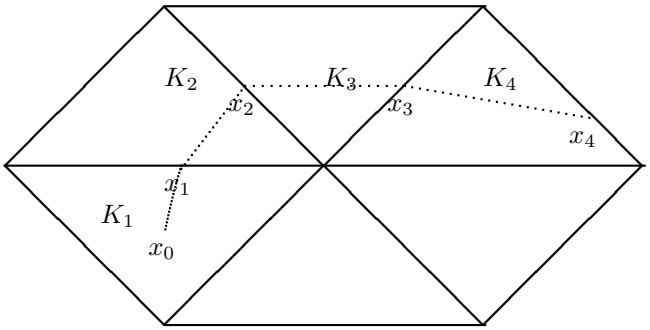

FIG. 4. *A path.*

The definition of $A(v,w)$ and the inequality above imply that

$$\begin{aligned} A(v,w) &\le C(|v|_{1,h}|w|_{1,h} + \left(\sum_K h^2|v|^2_{2,K}\right)^{\frac{1}{2}} |w|_{1,h} \\ &+ \left(\sum_K (|v|^2_{1,K} + h^2|v|^2_{2,K})\right)^{\frac{1}{2}} \left(\sum_e [\gamma w]^2_e\right)^{\frac{1}{2}} \\ &+ \alpha \left(\sum_e [\gamma v]^2_e\right)^{\frac{1}{2}} \left(\sum_e [\gamma w]^2_e)^{\frac{1}{2}}\right) \\ &\le C(|||v||| + \left(\sum_K h^2|v|^2_{2,K})^{\frac{1}{2}}\right) |||w|||. \end{aligned}$$

Equation (2.15) and the inverse inequality imply (2.16).

3. Error estimates. We will derive an optimal order error estimate in the norm $|||\cdot|||$ defined in (2.8) and a first order error estimate in the L^2-norm. We start with the following lemma.

LEMMA 3.1. *There exists a constant C independent of h such that*

$$\|w\| \le C|||w||| \qquad \forall w \in V_h.$$

Proof. The proof is similar to the proof of Lemma 2.1 in [12]. Let $|e|$ denote the length of edge e. Since $[w]$ is continuous on $e_i \in \Gamma$, there exists $\mathbf{x}_i \in e_i$ such that

$$\int_{e_i} [w]ds = [w](\mathbf{x}_i)|e_i|, \tag{3.1}$$

where $[w](\mathbf{x}_i) = w|_{K_1}(\mathbf{x}_i) - w|_{K_2}(\mathbf{x}_i)$ and K_1 and K_2 are the two triangles that share e_i. If e_i is an edge on the boundary, then $\mathbf{x}_i \in e_i$ is a point such that $\int_{e_i} wds = w(\mathbf{x}_i)|e_i|$. For any $\mathbf{x} = \mathbf{x}_0 \in K \in \mathcal{R}_h$, we can find a path from $\mathbf{x}_0$ to $\mathbf{x}_l$, a point on the boundary, by joining a sequence of $\mathbf{x}_i$ as shown in Figure 4, where $\mathbf{x}_i$ $(i = 1, \ldots, l)$ satisfy (3.1). Let C_0 be a constant such that $lh \le C_0$. Let $\{K_i\}_{i=1}^l$ be the sequence of triangles in $\mathcal{R}_h$ containing $\mathbf{x}_i$ $(i = 0, \ldots, l)$ as shown in Figure 4.

Define $w(\mathbf{x}_0^1) = w(\mathbf{x}_0)$, $w(\mathbf{x}_1^2) = w|_{K_1}(\mathbf{x}_1)$, and $w(\mathbf{x}_1^1) = w|_{K_2}(\mathbf{x}_1)$. In general, $w(\mathbf{x}_i^2) = w|_{K_i}(\mathbf{x}_i)$ and $w(\mathbf{x}_i^1) = w|_{K_{i+1}}(\mathbf{x}_i)$. The mean value theorem, the Cauchy–Schwarz inequality, and (3.1) give

$$|w(\mathbf{x})|^2 = |w(\mathbf{x}_0)|^2 = \left| \sum_{i=1}^{l} (w(\mathbf{x}_{i-1}^1) - w(\mathbf{x}_i^2)) + \sum_{i=1}^{l} [w](\mathbf{x}_i) \right|^2 \tag{3.2}$$

$$\leq Cl \left(\sum_{i=1}^{l} (\nabla w(\bar{\mathbf{x}}_i)^2 (\mathbf{x}_{i-1} - \mathbf{x}_i)^2 + \sum_{i=1}^{l} [\gamma w]_{e_i}^2 \right), \tag{3.3}$$

where $\bar{\mathbf{x}}_i \in K_i$ is a point between $\mathbf{x}_{i-1}$ and $\mathbf{x}_i$. As in [12], we have

$$|\nabla w(\bar{\mathbf{x}}_i)|^2 h^2 \leq C |\nabla w|_{K_i}^2. \tag{3.4}$$

Equation (3.4) implies

$$|w(\mathbf{x})|^2 \leq Cl \left(\sum_{i=1}^{l} |\nabla w|_{K_i}^2 + \sum_{i=1}^{l} [\gamma w]_{e_i}^2 \right). \tag{3.5}$$

Integrating (3.5) over K gives

$$\int_K |w(\mathbf{x})|^2 \leq Clh^2 \left(\sum_{i=1}^{l} |\nabla w|_{K_i}^2 + \sum_{i=1}^{l} [\gamma w]_{e_i}^2 \right). \tag{3.6}$$

For each $\mathbf{x} \in \Omega$, choose the path such that, when adding all the $K \in \mathcal{R}_h$, the same K_i appears at most l times. Then using the fact that $lh \leq C_0$, we have

$$\|w\|^2 = \int_\Omega |w(\mathbf{x})|^2 \leq C \left(|w|_{1,h}^2 + \sum_e [\gamma w]_e^2 \right) \leq C |\!|\!| w |\!|\!|^2. \tag{3.7}$$

This completes the proof. □

Let $u_I \in V_h$ be the interpolation of u. It is well known that

$$|u - u_I|_{s,K} \leq Ch^{2-s} |u|_{2,K} \quad \forall K \in \mathcal{R}_h, \ s = 0, 1, \tag{3.8}$$

where C depends only on the angle of K. The Cauchy–Schwarz inequality implies

$$[\gamma v]_e^2 = \left(\frac{1}{h_e} \int_e [v] ds \right)^2 \leq \left(\frac{1}{h_e} \right)^2 \int_e [v]^2 ds \int_e ds$$

$$= \int_e \frac{1}{h_e} [v]^2 ds. \tag{3.9}$$

The definitions of the norm $|\!|\!| \cdot |\!|\!|$, (3.9), (2.9), and (3.8) give

$$|\!|\!| u - u_I |\!|\!|^2 = |u - u_I|_{1,h}^2 + \sum_e [\gamma u - \gamma u_I]_e^2 \tag{3.10}$$

$$\leq C \left(|u - u_I|_{1,h}^2 + \sum_e \int_e h_e^{-1} [u - u_I]^2 ds \right)$$

$$\leq C \left(|u - u_I|_{1,h}^2 + \sum_K h^{-2} \|u - u_I\|_K^2 \right)$$

$$\leq Ch^2 |u|_2^2$$

and

$$\left(\sum_K h^2|u-u_I|_{2,K}^2\right)^{\frac{1}{2}} \le Ch|u|_2. \tag{3.11}$$

THEOREM 3.2. *Let $u_h \in V_h$ and $u \in H^2(\Omega)\cap H_0^1(\Omega)$ be the solutions of* (2.5) *and* (1.1)*, respectively; then there exists a constant C independent of h such that*

$$|||u-u_h||| \le Ch|u|_2 \tag{3.12}$$

and

$$\|u-u_h\| \le Ch|u|_2. \tag{3.13}$$

Proof. Subtracting (2.6) from (2.7) gives

$$A(u-u_h,v)=0 \quad \forall v \in V_h. \tag{3.14}$$

Using (2.14), (3.14), and (2.15), we have

$$\begin{aligned} |||u_h-u_I|||^2 &\le CA(u_h-u_I,u_h-u_I) \\ &= CA(u-u_I,u_h-u_I) \\ &\le C(|||u-u_I||| + \left(\sum_K h^2|u-u_I|_{2,K}^2\right)^{\frac{1}{2}})\,|||u_h-u_I|||. \end{aligned} \tag{3.15}$$

Using (3.15), (3.10), and (3.11), we have

$$|||u_h-u_I||| \le Ch|u|_2. \tag{3.16}$$

The triangle inequality and (3.10) imply (3.12). Using Lemma 3.1 and (3.16), we have

$$\|u_h-u_I\| \le C|||u_h-u_I||| \le Ch|u|_2.$$

Equation (3.8) and the triangle inequality imply (3.13). We have completed the proof. ∎

STEPSIZE RESTRICTIONS FOR THE TOTAL-VARIATION-DIMINISHING PROPERTY IN GENERAL RUNGE–KUTTA METHODS*

L. FERRACINA† AND M. N. SPIJKER†

Abstract. Much attention has been paid in the literature to total-variation-diminishing (TVD) numerical processes in the solution of nonlinear hyperbolic differential equations. For special Runge–Kutta methods, conditions on the stepsize were derived that are sufficient for the TVD property; see, e.g., Shu and Osher [*J. Comput. Phys.*, 77 (1988), pp. 439–471] and Gottlieb and Shu [*Math. Comp.*, 67 (1998), pp. 73–85]. Various basic questions are still open regarding the following issues: 1. the extension of the above conditions to more general Runge–Kutta methods; 2. simple restrictions on the stepsize which are not only sufficient but at the same time necessary for the TVD property; and 3. the determination of optimal Runge–Kutta methods with the TVD property.

In this paper we propose a theory by means of which we are able to clarify the above questions. Moreover, by applying our theory, we settle analogous questions regarding the related strong-stability-preserving (SSP) property (see, e.g., Gottlieb, Shu, and Tadmor [*SIAM Rev.*, 43 (2001), pp. 89–112] and Shu [*Collected Lectures on the Preservation of Stability under Discretization*, D. Estep and S. Tavener, eds., SIAM, Philadelphia, 2002]). Our theory can be viewed as a variant to a theory of Kraaijevanger [*BIT*, 31 (1991), pp. 482–528] on the contractivity of Runge–Kutta methods.

Key words. initial value problem, conservation law, method of lines, Runge–Kutta formula, total-variation-diminishing (TVD), strong-stability-preserving (SSP), monotonicity

DOI. 10.1137/S0036142902415584

1. Introduction.

1.1. The purpose of the paper. In this paper we shall address some natural questions arising in the numerical solution of certain partial differential equations (PDEs). In order to formulate these questions, we consider an initial value problem for a system of ordinary differential equations (ODEs) of the form

$$\frac{d}{dt}U(t) = F(U(t)) \quad (t \geq 0), \quad U(0) = u_0. \tag{1.1}$$

We assume that (1.1) results from an application of the method of lines to a Cauchy problem for a PDE of the form

$$\frac{\partial}{\partial t}u(x,t) + \frac{\partial}{\partial x}f(u(x,t)) = 0 \quad (t \geq 0, \quad -\infty < x < \infty).$$

Here f stands for a given (possibly nonlinear) scalar function, so that the PDE is a simple instance of a conservation law; cf., e.g., Kröner (1997) and LeVeque (2002).

The solution $U(t)$ to (1.1) stands for a (time dependent) vector in $\mathbb{R}^\infty = \{y : y = (\ldots, \eta_{-1}, \eta_0, \eta_1, \ldots)$ with $\eta_j \in \mathbb{R}$ for $j = 0, \pm 1, \pm 2, \ldots\}$. The components $U_j(t)$ of $U(t)$ are to approximate the desired true solution values $u(j\Delta x, t)$ (or cell averages

thereof); here Δx denotes a (positive) mesh-width. Furthermore, F stands for a function from $\mathbb{R}^\infty$ into $\mathbb{R}^\infty$; it depends on the given function f as well as on the process of semidiscretization being used. Finally, $u_0 \in \mathbb{R}^\infty$ depends on the initial data of the original Cauchy problem.

Any Runge–Kutta method, when applied to problem (1.1), yields approximations u_n to $U(n\Delta t)$, where $\Delta t > 0$ denotes the time step and $n = 1, 2, 3, \ldots$. Since $\frac{d}{dt}U(t) = F(U(t))$ stands for a semidiscrete version of a conservation law, it is desirable that the (fully discrete) process be *total-variation-diminishing (TVD)* in the sense that

$$\|u_n\|_{TV} \le \|u_{n-1}\|_{TV}; \tag{1.2}$$

here the function $\|.\|_{TV}$ is defined by

$$\|y\|_{TV} = \sum_{j=-\infty}^{+\infty} |\eta_j - \eta_{j-1}| \quad (\text{for } y \in \mathbb{R}^\infty \text{ with components } \eta_j).$$

For an explanation of the importance of the TVD property, particularly in the numerical solution of nonlinear conservation laws, see, e.g., Harten (1983), Laney (1998), Toro (1999), LeVeque (2002), and Hundsdorfer and Verwer (2003).

By Shu and Osher (1988) (see also, e.g., Gottlieb, Shu, and Tadmor (2001) and Shu (2002)) a simple but very useful approach was described for obtaining (high order) Runge–Kutta methods leading to TVD numerical processes. They considered explicit m-stage Runge–Kutta methods, written in the special form

$$\begin{aligned} y_1 &= u_{n-1}, \\ y_i &= \sum_{j=1}^{i-1} [\lambda_{ij}\, y_j + \Delta t \cdot \mu_{ij} F(y_j)] \quad (2 \le i \le m+1), \\ u_n &= y_{m+1}. \end{aligned} \tag{1.3}$$

Here λ_{ij}, μ_{ij} are real coefficients specifying the Runge–Kutta method, and y_i are intermediate vectors in $\mathbb{R}^\infty$, depending on u_{n-1}, used for computing u_n (for $n = 1, 2, 3, \ldots$). Theorem 1.1 will state one of the conclusions formulated in the three papers just mentioned. It applies to the situation where the semidiscretization of the conservation law has been carried out in such a manner that the forward Euler method, applied to $\frac{d}{dt}U(t) = F(U(t))$, yields a fully discrete process which is TVD, when the stepsize Δt is suitably restricted, i.e.,

$$\|v + \Delta t\, F(v)\|_{TV} \le \|v\|_{TV} \quad (\text{whenever } 0 < \Delta t \le \tau_0 \text{ and } v \in \mathbb{R}^\infty). \tag{1.4}$$

Furthermore, in the theorem it is assumed that

$$\lambda_{i1} + \lambda_{i2} + \cdots + \lambda_{i,i-1} = 1 \quad (2 \le i \le m+1), \tag{1.5a}$$

$$\lambda_{ij} \ge 0, \quad \mu_{ij} \ge 0 \quad (1 \le j < i \le m+1), \tag{1.5b}$$

and the following notation is used:

$$c_{ij} = \lambda_{ij}/\mu_{ij} \ \ (\text{for } \mu_{ij} \ne 0), \quad c_{ij} = \infty \ \ (\text{for } \mu_{ij} = 0), \tag{1.6a}$$

$$c = \min_{i,j} c_{ij}. \tag{1.6b}$$

THEOREM 1.1 (Shu and Osher). *Assume* (1.5)*, and let* c *be defined by* (1.6)*. Suppose* (1.4) *holds, and*

$$0 < \Delta t \le c \cdot \tau_0. \tag{1.7}$$

Then process (1.3) *is TVD; i.e.,* (1.2) *holds whenever* u_n *is computed from* u_{n-1} *according to* (1.3).

It was remarked, notably in Shu and Osher (1988) and Gottlieb, Shu, and Tadmor (2001), that, under the assumptions (1.5), (1.6), the above theorem can be generalized. Let $\mathbb{V}$ be an arbitrary linear subspace of $\mathbb{R}^\infty$ and let $\|.\|$ denote any corresponding seminorm (i.e., $\|u+v\| \le \|u\| + \|v\|$ and $\|\lambda v\| = |\lambda| \cdot \|v\|$ for all $\lambda \in \mathbb{R}$ and $u, v \in \mathbb{V}$). A straightforward generalized version of Theorem 1.1 says that if $F : \mathbb{V} \to \mathbb{V}$ and

$$\|v + \Delta t F(v)\| \le \|v\| \quad (\text{whenever } 0 < \Delta t \le \tau_0 \text{ and } v \in \mathbb{V}), \tag{1.8}$$

then (1.7) still implies that

$$\|u_n\| \le \|u_{n-1}\|, \tag{1.9}$$

when u_n is computed from $u_{n-1} \in \mathbb{V}$ according to (1.3). In the last mentioned paper, time discretization methods for which a positive constant c exists such that (1.7), (1.8) always imply (1.9) were called *strong-stability-preserving (SSP)*. Property (1.9) is important, also with seminorms different from $\|.\|_{TV}$, and also when solving certain differential equations different from conservation laws—see, e.g., Dekker and Verwer (1984), LeVeque (2002), and Hundsdorfer and Verwer (2003).

Clearly, it would be awkward if the factor c, defined in (1.6), would be so small that (1.7) would reduce to a stepsize restriction which is too severe for any practical purposes—in fact, the less restrictions on Δt, the better. One might thus be tempted to take the magnitude of c into account when comparing the effectiveness of different Runge–Kutta processes (1.3), (1.5) to each other. However, it is evident that such a use of c, defined by (1.6), could be quite misleading if, for a given process (1.3), (1.5), the conclusion in Theorem 1.1 would also be valid with some factor c which is (much) larger than the one given by (1.6).

For any given method (1.3) satisfying (1.5), the question thus arises what is the largest factor c, *not necessarily defined via* (1.6), such that the conclusion in Theorem 1.1 is still valid. Moreover, a second question is of whether there exists a positive constant c such that (1.4), (1.7) imply (1.2), also for methods (1.3) satisfying (1.5a) but violating (1.5b). Two analogous questions arise in connection with the generalized version of Theorem 1.1, related to the SSP property, mentioned above.

The purpose of this paper is to propose a general theory which allows us to answer the above questions, as well as related ones.

1.2. Outline of the rest of the paper. In section 2 we present our general theory, just mentioned at the end of section 1.1. Section 2.1 contains notations and definitions which are basic for the rest of our paper. We review here the concept of *monotonicity*, which generalizes the TVD-property (1.2) in the context of arbitrary vector spaces $\mathbb{V}$, with seminorms $\|.\|$, and of general Runge–Kutta schemes (A, b). Furthermore, we introduce the notion of a *stepsize-coefficient* for monotonicity, which formalizes and generalizes the property of the coefficient c as stated in Theorem 1.1. In section 2.2 we recall the concept of irreducibility for general Runge–Kutta schemes (A, b), and we review the crucial quantity $R(A, b)$, introduced by Kraaijevanger (1991). In section 2.3 we present (without proof) our main result, Theorem 2.5. This theorem can be regarded as a variant to a theorem, on contractivity of Runge–Kutta methods, of Kraaijevanger (1991). Theorem 2.5 is relevant to arbitrary irreducible Runge–Kutta schemes (A, b); it tell us that, in the important situations specified by (2.9), (2.10), (2.11), respectively, the largest stepsize-coefficient for monotonicity is equal to $R(A, b)$.

In section 3 we apply Theorem 2.5 to a generalized version of process (1.3). After the introductory section 3.1, we clarify in the sections 3.2 and 3.3, respectively, the questions raised at the end of section 1.1 regarding the TVD and SSP properties of process (1.3). Section 3.4 gives two examples illustrating the superiority of the quantity $R(A, b)$ (to the factor c, given by (1.6)) as a guide to stepsize restrictions for the TVD and SSP properties.

Section 4 is mainly devoted to explicit Runge–Kutta schemes which are optimal, in the sense of their stepsize-coefficients for monotonicity. After the introductory section 4.1, we review, in section 4.2, conclusions of Kraaijevanger (1991) regarding the optimization of $R(A, b)$, in various classes of explicit Runge–Kutta schemes (A, b). Combining these conclusions and our Theorem 2.5, we are able to extend and shed new light on (recent) results in the literature about the optimization of c defined by (1.6). In section 4.3 we describe an algorithm for computing $R(A, b)$, which may be useful in determining further optimal Runge–Kutta methods. Section 4.4 contains a brief discussion of a few important related issues.

In order to look at our main result in the right theoretical perspective, we give in the final section, section 5, not only the formal proof of Theorem 2.5, but we present a short account of related material from Kraaijevanger (1991) as well. In section 5.1 we review Kraaijevanger's theorem mentioned above, and we compare it with our Theorem 2.5. In section 5.2 we give the proof of our main result.

We have framed our paper purposefully in the way just described: the reader who is primarily interested in our Theorem 2.5 and its applications (rather than in the underlying theory) will not be hampered by unnecessary digressions when reading sections 2, 3, and 4.

2. A general theory for monotonic Runge–Kutta processes.

2.1. Stepsize-coefficients for monotonicity in a general context. We want to study properties like (1.2) and (1.9) in a general setting. For that reason, we assume that $\mathbb{V}$ is an arbitrary real vector space, and that $F(v)$ is a given function, defined for all $v \in \mathbb{V}$, with values in $\mathbb{V}$. We consider a formal generalization of (1.1),

$$\frac{d}{dt}U(t) = F(U(t)) \quad (t \geq 0), \quad U(0) = u_0, \tag{2.1}$$

where u_0 and $U(t)$ stand for vectors in $\mathbb{V}$.

The general Runge–Kutta method with m stages, (formally) applied to the abstract problem (2.1), provides us with vectors $u_1, u_2, u_3, \ldots$ in $\mathbb{V}$ (see, e.g., Dekker and Verwer (1984), Butcher (1987), and Hairer and Wanner (1996)). Here u_n is related to u_{n-1} by the formula

$$u_n = u_{n-1} + \Delta t \sum_{j=1}^{m} b_j F(y_j), \tag{2.2a}$$

where the vectors y_j in $\mathbb{V}$ satisfy

$$y_i = u_{n-1} + \Delta t \sum_{j=1}^{m} a_{ij} F(y_j) \quad (1 \leq i \leq m). \tag{2.2b}$$

In these formulas, $\Delta t > 0$ denotes the stepsize and b_j, a_{ij} are real parameters, specifying the Runge–Kutta method. We always assume that $b_1 + b_2 + \cdots + b_m = 1$. If

$a_{ij} = 0$ (for $j \geq i$), the Runge–Kutta method is called *explicit*. Defining the $m \times m$ matrix A by $A = (a_{ij})$ and the column vector $b \in \mathbb{R}^m$ by $b = (b_1, b_2, b_3, \ldots, b_m)^T$, we can identify the Runge–Kutta method with the *coefficient scheme* (A, b).

Let $\|.\|$ denote an arbitrary seminorm on $\mathbb{V}$ (i.e., $\|u+v\| \leq \|u\| + \|v\|$ and $\|\lambda v\| = |\lambda| \cdot \|v\|$ for all real λ and $u, v \in \mathbb{V}$). The following inequality generalizes (1.2) and (1.9):

$$\|u_n\| \leq \|u_{n-1}\|. \tag{2.3}$$

We shall say that the Runge–Kutta method is *monotonic* (for the stepsize Δt, function F, and seminorm $\|.\|$) if (2.3) holds whenever the vectors u_{n-1} and u_n in $\mathbb{V}$ are related to each other as in (2.2). Our use of the term "monotonic" is nicely in agreement with earlier use of this term, e.g., by Burrage and Butcher (1980), Dekker and Verwer (1984, p. 263), Spijker (1986), Butcher (1987, p. 392), and Hundsdorfer, Ruuth, and Spiteri (2003). Property (2.3) is related to what sometimes is called *practical stability* or *strong stability*; see, e.g., Morton (1980) and Gottlieb, Shu, and Tadmor (2001).

In order to study stepsize restrictions for monotonicity, we start from a given stepsize $\tau_0 \in (0, \infty)$. We shall deal with the situation where F is a function from $\mathbb{V}$ into $\mathbb{V}$, satisfying

$$\|v + \tau_0 F(v)\| \leq \|v\| \quad (\text{for all } v \in \mathbb{V}). \tag{2.4}$$

The last inequality implies, for $0 < \Delta t \leq \tau_0$, that $\|v + \Delta t F(v)\| = \|(1 - \Delta t/\tau_0)v + (\Delta t/\tau_0)(v + \tau_0 F(v))\| \leq \|v\|$. Consequently, (2.4) is equivalent to the following generalized version of (1.4) and (1.8):

$$\|v + \Delta t F(v)\| \leq \|v\| \quad (\text{whenever } 0 < \Delta t \leq \tau_0 \text{ and } v \in \mathbb{V}).$$

Let a Runge–Kutta method (A, b) be given. We shall study monotonicity of the method under arbitrary stepsize restrictions of the form

$$0 < \Delta t \leq c \cdot \tau_0. \tag{2.5}$$

Definition 2.1 (stepsize-coefficient for monotonicity). *A value $c \in (0, \infty]$ is called a stepsize-coefficient for monotonicity (with respect to $\mathbb{V}$ and $\|.\|$) if the Runge–Kutta method is monotonic, as in* (2.3)*, whenever F is a function from $\mathbb{V}$ to $\mathbb{V}$ satisfying* (2.4)*, and Δt is a (finite) stepsize satisfying* (2.5)*.*

It is easily verified that this definition is independent of the above value τ_0: if c is a stepsize-coefficient for monotonicity, with respect to $\mathbb{V}$ and $\|.\|$, using one particular value $\tau_0 > 0$, then c will have the same property when using any other value, say $\tau_0' > 0$.

The concept of a stepsize-coefficient as introduced in the above definition, corresponds to what is sometimes called a *CFL coefficient* in the context of discretizations for hyperbolic problems; see, e.g., Gottlieb and Shu (1998) and Shu (2002).

In subsection 2.3 we shall give maximal stepsize-coefficients for monotonicity with respect to various spaces $\mathbb{V}$ and seminorms $\|.\|$.

2.2. Irreducible Runge–Kutta schemes and the quantity $R(A, b)$. In this subsection we give some definitions which will be needed when we formulate our results, in subsection 2.3, about maximal stepsize-coefficients c. We start with the fundamental concepts of reducibility and irreducibility.

DEFINITION 2.2 (reducibility and irreducibility). *An m-stage Runge–Kutta scheme (A, b) is called reducible if (at least) one of the following two statements* (i), (ii) *is true; it is called irreducible if neither* (i) *nor* (ii) *is true.*

(i) *There exist nonempty, disjoint index sets M, N with $M \cup N = \{1, 2, \ldots, m\}$ such that $b_j = 0$ (for $j \in N$) and $a_{ij} = 0$ (for $i \in M$, $j \in N$);*

(ii) *there exist nonempty, pairwise disjoint index sets $M_1, M_2, \ldots, M_r$, with $1 \leq r < m$ and $M_1 \cup M_2 \cup \cdots \cup M_r = \{1, 2, \ldots, m\}$, such that $\sum_{k \in M_q} a_{ik} = \sum_{k \in M_q} a_{jk}$ whenever $1 \leq p \leq r$, $1 \leq q \leq r$, and $i, j \in M_p$.*

In case the above statement (i) is true, the vectors y_j in (2.2) with $j \in N$ have no influence on u_n, and the Runge–Kutta method is equivalent to a method with less than m stages. Also in case of (ii), the Runge–Kutta method essentially reduces to a method with less then m stages; see, e.g., Dekker and Verwer (1984) or Hairer and Wanner (1996). Clearly, for all practical purposes, it is enough to consider only Runge–Kutta schemes which are irreducible.

Next, we turn to a very useful characteristic quantity for Runge–Kutta schemes introduced by Kraaijevanger (1991). Following this author, we shall denote his quantity by $R(A, b)$, and in defining it, we shall use, for real ξ, the notations

$$A(\xi) = A(I - \xi A)^{-1}, \qquad b(\xi) = (I - \xi A)^{-T} b,$$
$$e(\xi) = (I - \xi A)^{-1} e, \qquad \varphi(\xi) = 1 + \xi b^T (I - \xi A)^{-1} e.$$

Here $^{-T}$ stands for transposition after inversion, I denotes the identity matrix of order m, and e stands for the column vector in $\mathbb{R}^m$, all of whose components are equal to 1. We shall focus on values $\xi \leq 0$ for which

$$I - \xi A \text{ is invertible}, \quad A(\xi) \geq 0, \quad b(\xi) \geq 0, \quad e(\xi) \geq 0, \quad \text{and} \quad \varphi(\xi) \geq 0. \tag{2.6}$$

The first inequality in (2.6) should be interpreted entrywise, the second and the third ones componentwise. Similarly, all inequalities for matrices and vectors occurring below are to be interpreted entrywise and componentwise, respectively.

DEFINITION 2.3 (the quantity $R(A, b)$). *Let (A, b) be a given coefficient scheme. In case $A \geq 0$ and $b \geq 0$, we define*

$$R(A, b) = \sup\{r : \ r \geq 0 \ \text{ and } (2.6) \text{ holds for all } \xi \text{ with } -r \leq \xi \leq 0\}.$$

In case (at least) one of the inequalities $A \geq 0$, $b \geq 0$ is violated, we define $R(A, b) = 0$.

Definition 2.3 suggests that it may be difficult to determine $R(A, b)$ for given coefficient schemes (A, b). However, in section 4 we shall see that (for explicit Runge–Kutta methods) *a simple algorithm exists for computing $R(A, b)$*. Moreover, Kraaijevanger (1991, p. 497) gave the following simple criterion (2.7) for determining whether $R(A, b) = 0$ or $R(A, b) > 0$. For any given $k \times l$ matrix $B = (b_{ij})$, we define the corresponding $k \times l$ *incidence matrix* by

$$\mathrm{Inc}(B) = (c_{ij}), \quad \text{with } c_{ij} = 1 \text{ (if } b_{ij} \neq 0) \text{ and } c_{ij} = 0 \text{ (if } b_{ij} = 0).$$

THEOREM 2.4 (about positivity of $R(A, b)$). *Let (A, b) be a given irreducible coefficient scheme. Then $R(A, b) > 0$ if and only if*

$$A \geq 0, \quad b > 0, \quad \textit{and} \quad \mathrm{Inc}(A^2) \leq \mathrm{Inc}(A). \tag{2.7}$$

Proof. For ξ sufficiently close to zero, the matrix $I - \xi A$ is invertible and $e(\xi) \geq 0$, $\varphi(\xi) \geq 0$. Therefore, it is sufficient to analyze the inequalities $A(\xi) \geq 0$ and $b(\xi) \geq 0$. With no loss of generality, we assume $A \geq 0$, $b \geq 0$.

For ξ close to zero, we have

$$A(\xi) = (A + \xi A^2)\sum_{k=0}^{\infty}(\xi A)^{2k} \quad \text{and} \quad b(\xi)^T = (b^T + \xi b^T A)\sum_{k=0}^{\infty}(\xi A)^{2k}.$$

From these two expressions, one easily sees that there exists a positive r, with

$$A(\xi) \geq 0 \quad \text{and} \quad b(\xi)^T \geq 0 \quad (\text{for } -r \leq \xi \leq 0)$$

if and only if $\text{Inc}(A^2) \leq \text{Inc}(A)$ and $\text{Inc}(b^T A) \leq \text{Inc}(b^T)$. Since statement (i) in Definition 2.2 is *not* true, we conclude that the last inequality is equivalent to $b > 0$. □

We note that, in Kraaijevanger (1991), one can find various other interesting properties related to $R(A, b)$, among them characterizations different from Definition 2.3.

2.3. Formulation of our main theorem. In this subsection we shall determine maximal stepsize-coefficients (Definition 2.1) with respect to general spaces $\mathbb{V}$ and seminorms $\|.\|$. Moreover, we shall pay special attention to the particular (semi)norms

$$\|y\|_\infty = \sup_{-\infty<j<\infty} |\eta_j|, \quad \|y\|_1 = \sum_{-\infty}^{\infty} |\eta_j|, \quad \|y\|_{TV} = \sum_{-\infty}^{\infty} |\eta_j - \eta_{j-1}|$$

for $y = (\ldots, \eta_{-1}, \eta_0, \eta_1, \ldots) \in \mathbb{R}^\infty$. Furthermore, for integers $s \geq 1$ and vectors $y \in \mathbb{R}^s$ with components η_j $(1 \leq j \leq s)$, we shall focus on the (semi)norms

$$\|y\|_\infty = \max_{1\leq j\leq s} |\eta_j|, \quad \|y\|_1 = \sum_{j=1}^{s} |\eta_j|, \quad \|y\|_{TV} = \sum_{j=2}^{s} |\eta_j - \eta_{j-1}|$$

(where $\sum_{j=2}^{s} |\eta_j - \eta_{j-1}| = 0$ for $s = 1$). In our Theorem 2.5, the following inequality will play a prominent part:

$$c \leq R(A, b). \tag{2.8}$$

Here is our main theorem, about stepsize-coefficients of irreducible Runge–Kutta schemes (Definitions 2.1 and 2.2).

THEOREM 2.5 (relating monotonicity to $R(A, b)$). *Consider an arbitrary irreducible Runge–Kutta scheme (A, b). Let c be a given value with $0 < c \leq \infty$. Choose one of the three (semi)norms $\|.\|_\infty$, $\|.\|_1$, or $\|.\|_{TV}$, and denote it by $|\!|.|\!|$. Then each of the following three statements is equivalent to* (2.8).

(2.9) *c is a stepsize-coefficient for monotonicity, with respect to all vector spaces $\mathbb{V}$ and seminorms $\|.\|$ on $\mathbb{V}$;*

(2.10) *c is a stepsize-coefficient for monotonicity, with respect to the special space $\mathbb{V} = \{y : \ y \in \mathbb{R}^\infty \text{ and } |\!|y|\!| < \infty\}$ and seminorm $\|.\| = |\!|.|\!|$;*

(2.11) *c is a stepsize-coefficient for monotonicity, with respect to the finite dimensional space $\mathbb{V} = \mathbb{R}^s$ and seminorm $\|.\| = |\!|.|\!|$ for $s = 1, 2, 3, \ldots$.*

Clearly, (2.9) is a priori a stronger statement than (2.10) or (2.11). Accordingly, the essence of Theorem 2.5 is that the (algebraic) property (2.8) implies the (strong) statement (2.9), whereas already either of the (weaker) statements (2.10) or (2.11) implies (2.8).

The above theorem highlights the importance of Kraaijevanger's quantity $R(A, b)$. Theorem 2.5 shows that, with respect to each of the three situations specified in (2.9), (2.10), and (2.11), *the maximal stepsize-coefficient for monotonicity is equal to* $R(A, b)$.

The above theorem will be compared with a theorem on nonlinear contractivity of Kraaijevanger (1991) in section 5.1, and it will be proved in section 5.2.

3. The application of our main theorem to the questions raised in subsection 1.1.

3.1. The equivalence of (a generalized version of) process (1.3) to method (2.2). In section 3 we study time stepping processes producing numerical approximations $u_n \in \mathbb{R}^\infty$ to $U(n\Delta t)$ (for $n \geq 1$), where $U(t) \in \mathbb{R}^\infty$ satisfies (1.1). We focus on processes of the form

$$y_1 = u_{n-1}, \tag{3.1a}$$

$$y_i = \sum_{j=1}^{m} [\lambda_{ij} y_j + \Delta t \cdot \mu_{ij} F(y_j)] \quad (2 \leq i \leq m), \tag{3.1b}$$

$$u_n = \sum_{j=1}^{m} [\lambda_{m+1,j} y_j + \Delta t \cdot \mu_{m+1,j} F(y_j)]. \tag{3.1c}$$

Here λ_{ij}, μ_{ij} are arbitrary real coefficients with

$$\lambda_{i1} + \lambda_{i2} + \cdots + \lambda_{im} = 1 \quad (2 \leq i \leq m+1). \tag{3.2a}$$

Clearly, if $\lambda_{ij} = \mu_{ij} = 0$ (for $j \geq i$), the above process reduces to algorithm (1.3). Moreover, process (3.1) is sufficiently general to also cover other algorithms, such as the one in Gottlieb, Shu, and Tadmor (2001, p. 109), which was considered recently for solving (1.1).

In order to relate (3.1) to a Runge–Kutta method in the standard form (2.2), we define $\lambda_{ij} = \mu_{ij} = 0$ (for $i = 1$ and $1 \leq j \leq m$), and we introduce the $(m+1) \times m$ matrices $L = (\lambda_{ij})$, $M = (\mu_{ij})$. The $m \times m$ submatrices composed of the first m rows of L and M, respectively, will be denoted by L_0 and M_0. Furthermore, the last rows of L and M—that is, $(\lambda_{m+1,1}, \ldots, \lambda_{m+1,m})$ and $(\mu_{m+1,1}, \ldots, \mu_{m+1,m})$, respectively—will be denoted by L_1 and M_1, so that

$$L = \begin{pmatrix} L_0 \\ L_1 \end{pmatrix} \quad \text{and} \quad M = \begin{pmatrix} M_0 \\ M_1 \end{pmatrix}. \tag{3.2b}$$

We assume that

$$\text{the } m \times m \text{ matrix } I - L_0 \text{ is invertible.} \tag{3.2c}$$

We shall now show that the relations (3.1) imply (2.2), with matrix $A = (a_{ij})$ and column vector $b = (b_i)$ specified by

$$A = (I - L_0)^{-1} M_0 \quad \text{and} \quad b^T = M_1 + L_1 A. \tag{3.3}$$

We denote the entries of the matrix $(I - L_0)^{-1}$ by γ_{ij}, and note that the relations (3.1a), (3.1b) can be rewritten as

$$\sum_{k=1}^{m} (\delta_{jk} - \lambda_{jk}) y_k = \delta_{j,1} u_{n-1} + \sum_{k=1}^{m} \mu_{jk} F_k \quad (\text{for } 1 \leq j \leq m), \tag{3.4}$$

where δ_{jk} is the Kronecker index and $F_k = \Delta t \cdot F(y_k)$. Multiplying (3.4) by γ_{ij} and summing over $j = 1, 2, \ldots, m$, we obtain, for $1 \le i \le m$, the equality $y_i = (\sum_{j=1}^{m} \gamma_{ij}\delta_{j,1})u_{n-1} + \sum_{k=1}^{m}(\sum_{j=1}^{m} \gamma_{ij}\mu_{jk})F_k$. In view of (3.2a), the first sum in the right-hand member of the last equality is equal to 1; hence (2.2b) holds with $(a_{ij}) = (I - L_0)^{-1}M_0$. Furthermore, in view of (3.1c), we easily arrive at (2.2a) with $(b_1, b_2, \ldots, b_m) = M_1 + L_1 A$.

Similarly to the above, the relations (2.2), (3.3) can be proved to imply (3.1), so that the following conclusion is valid.

LEMMA 3.1. *Let λ_{ij} and μ_{ij} be given coefficients satisfying* (3.2a), (3.2b), (3.2c). *Define the Runge–Kutta scheme (A, b) by* (3.3). *Then the relations* (3.1) *are equivalent to* (2.2).

In the following subsections, we shall use this lemma for relating the monotonicity properties of process (3.1) to those of the corresponding Runge–Kutta scheme (A, b) given by (3.3).

3.2. The total-variation-diminishing property of process (3.1). Our following Theorem 3.2 gives a stepsize restriction guaranteeing the TVD-property for the general process (3.1). Since (3.1) is more general than process (1.3), our theorem is highly relevant to (1.3). In the theorem, we shall use the notation

$$\mathbb{R}^{\infty}_{TV} = \{y : \ y \in \mathbb{R}^{\infty} \text{ with } \|y\|_{TV} < \infty\},$$

where $\|.\|_{TV}$ has the same meaning as in subsection 1.1. We shall deal with functions F from $\mathbb{R}^{\infty}_{TV}$ into $\mathbb{R}^{\infty}_{TV}$, satisfying

$$\|v + \tau_0 F(v)\|_{TV} \le \|v\|_{TV} \quad (\text{whenever } v \in \mathbb{R}^{\infty}_{TV}), \tag{3.5}$$

and with stepsize restrictions of the form

$$0 < \Delta t \le R(A, b) \cdot \tau_0 \tag{3.6}$$

(see Definition 2.3).

THEOREM 3.2 (optimal stepsize restriction for the TVD-property in process (3.1)). *Let λ_{ij} and μ_{ij} be given coefficients satisfying* (3.2a), (3.2b), (3.2c). *Define the matrix A and the vector b by* (3.3), *and suppose that the coefficient scheme (A, b) is irreducible (Definition* 2.2). *Let F be a function from $\mathbb{R}^{\infty}_{TV}$ into $\mathbb{R}^{\infty}_{TV}$ satisfying* (3.5), *and let Δt be a (finite) stepsize satisfying* (3.6).

Then, process (3.1) *is TVD; i.e., the inequality* (1.2) *holds whenever $u_{n-1}, u_n \in \mathbb{R}^{\infty}_{TV}$ are related to each other as in* (3.1).

Proof. We apply Lemma 3.1, and consider the Runge–Kutta scheme (A, b) specified by the lemma. Next, we apply Theorem 2.5: choosing $c = R(A, b)$, we have (2.8) so that (2.10) must be fulfilled with $|\!|.|\!| = \|.\|_{TV}$. An application of Definition 2.1 completes the proof of the theorem. □

Remark 3.3. The above theorem has a *wider scope than Theorem* 1.1. The class of numerical methods (3.1) satisfying (3.2a), (3.2b), (3.2c) encompasses all processes (1.3) satisfying (1.5a), as well as other (implicit) procedures. Specifically, unlike Theorem 1.1, the above Theorem 3.2 is relevant to processes (1.3) satisfying (1.5a) but violating (1.5b)—see Example 3.7 in subsection 3.4 for an illustration.

Remark 3.4. The above theorem, when applied to any process (1.3) satisfying (1.5a), (1.5b), gives a *stronger conclusion than Theorem* 1.1. By Theorem 2.5, property (2.10) with $|\!|.|\!| = \|.\|_{TV}$ implies inequality (2.8). Therefore the coefficient c, given by Theorem 1.1, satisfies $c \le R(A, b)$; this means that the stepsize restriction (3.6) of

Theorem 3.2 is, in general, less severe than the restriction (1.7) of Theorem 1.1—see Example 3.8 in subsection 3.4 for an illustration.

Remark 3.5. Theorem 3.2 gives a stepsize restriction which is *optimal* in that the conclusion of the theorem would no longer be valid if the factor $R(A,b)$ in (3.6) would be replaced by any factor $c > R(A,b)$. This follows again from Theorem 2.5.

3.3. The strong-stability-preserving property of process (3.1). Let $\mathbb{V}$ be an arbitrary linear subspace of $\mathbb{R}^\infty$, and let $\|.\|$ denote any seminorm on $\mathbb{V}$. For functions $F : \mathbb{V} \longrightarrow \mathbb{V}$ satisfying

$$\|v + \tau_0 F(v)\| \leq \|v\| \quad (\text{whenever } v \in \mathbb{V}), \tag{3.7}$$

we shall consider process (3.1) under a stepsize restriction of the form

$$0 < \Delta t \leq c \cdot \tau_0. \tag{3.8}$$

Following the terminology of Gottlieb, Shu, and Tadmor (2001), already reviewed in subsection 1.1, we shall say that process (3.1) is *strong-stability-preserving* (SSP) if a positive constant c exists (only depending on λ_{ij} and μ_{ij}) such that (1.9) holds whenever (3.1), (3.7), (3.8) are fulfilled.

THEOREM 3.6 (criterion for the SSP property of process (3.1)). *Let λ_{ij} and μ_{ij} be given coefficients satisfying* (3.2a), (3.2b), (3.2c). *Define the matrix A and vector b by* (3.3), *and suppose that the coefficient scheme (A,b) is irreducible (Definition* 2.2). *Then process* (3.1) *is SSP if and only if* (2.7) *holds.*

Proof. By Lemma 3.1 and Theorem 2.5, process (3.1) is SSP if and only if $R(A,b) > 0$. According to Theorem 2.4, the last inequality is equivalent to (2.7). ∎

It is clear that the above Theorem 3.6, similarly as Theorem 3.2, is highly relevant to all numerical processes (1.3) satisfying (1.5a); see Examples 3.7 and 3.8 below for illustrations.

3.4. Illustrations to Theorems 3.2 and 3.6. We give two examples illustrating Theorems 3.2 and 3.6.

Example 3.7. Consider process (1.3), with $m = 3$ and coefficients λ_{ij}, μ_{ij} given by the relations

$$\begin{pmatrix} \lambda_{21} & & \\ \lambda_{31} & \lambda_{32} & \\ \lambda_{41} & \lambda_{42} & \lambda_{43} \end{pmatrix} = \begin{pmatrix} 1 & & \\ \frac{1}{4} & \frac{3}{4} & \\ 1 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} \mu_{21} & & \\ \mu_{31} & \mu_{32} & \\ \mu_{41} & \mu_{42} & \mu_{43} \end{pmatrix} = \begin{pmatrix} 1 & & \\ -\frac{1}{2} & \frac{1}{4} & \\ \frac{1}{6} & \frac{1}{6} & \frac{2}{3} \end{pmatrix}.$$

Since $\mu_{31} < 0$, condition (1.5b) is violated; therefore Theorem 1.1 does not apply.

For the corresponding matrix $A = (a_{ij})$ and vector $b = (b_i)$ (see (3.3)), we have $a_{ij} = 0$ $(j \geq i)$, $a_{21} = 1$, $a_{31} = a_{32} = 1/4$ and $b_1 = b_2 = 1/6$, $b_3 = 2/3$, respectively. It is very easy to see that (2.7) holds; by virtue of Theorem 3.6, the numerical process is thus SSP. Moreover, according to Kraaijevanger (1991, Theorem 9.4), for this process we have $R(A,b) = 1$. By Theorem 3.2 we conclude that the process is TVD, under the assumption (3.5) if $0 < \Delta t \leq \tau_0$. We note that essentially the same numerical process was presented earlier by Shu and Osher (1988); we shall come back to it in section 4.2 (Remark 4.4; $m = p = 3$).

Example 3.8. Consider process (1.3), with $m = 2$ and

$$\begin{pmatrix} \lambda_{21} & \\ \lambda_{31} & \lambda_{32} \end{pmatrix} = \begin{pmatrix} 1 & \\ 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} \mu_{21} & \\ \mu_{31} & \mu_{32} \end{pmatrix} = \begin{pmatrix} 1/2 & \\ 1/2 & 1/2 \end{pmatrix}.$$

The conditions (1.5a), (1.5b) are neatly fulfilled, but the coefficient c, defined by (1.6), is equal to 0.

For the corresponding Runge–Kutta scheme (A, b), defined by (3.3), we have $a_{ij} = 0$ $(j \geq i)$, $a_{21} = 1/2$ and $b_1 = b_2 = 1/2$. Clearly, (2.7) is fulfilled, guaranteeing the SSP property (see Theorem 3.6). Moreover, according to Kraaijevanger (1991, Theorem 9.2), we have $R(A, b) = 2$. Therefore, by Theorem 3.2, the numerical process is TVD, under assumption (3.5), if $0 < \Delta t \leq 2 \cdot \tau_0$. We note that the same method was presented by Spiteri and Ruuth (2002); we shall come back to it in section 4.2 (Remark 4.4; $m = 2$, $p = 1$).

4. Optimal Runge–Kutta methods.

4.1. Preliminaries. For integer values $m \geq 1$ and $p \geq 1$, we shall denote by $E_{m,p}$ the class of all explicit m-stage Runge–Kutta methods (A, b) with (classical) order of accuracy at least p. Considerable attention has been paid, in the literature, to identifying methods of class $E_{m,p}$ of the special form (1.3), (1.5) which are optimal in the sense of the coefficient c given by (1.6); see notably Shu and Osher (1988), Gottlieb and Shu (1998), Ruuth and Spiteri (2002), Shu (2002), and Spiteri and Ruuth (2002). Independently of this work, Kraaijevanger (1991) dealt with the optimization, in the full class $E_{m,p}$, of his quantity $R(A, b)$. Our theory (section 2) can be used to relate his conclusions to the work just mentioned about optimization of c defined in (1.6).

In section 4.2 we shall briefly review some of Kraaijevanger's conclusions so as to arrive at extensions and completions of the material, referred to above, on optimality in the sense of c (1.6). Furthermore, we shall consider scaled stepsize-coefficients which reflect the efficiency of the methods better than the unscaled coefficients; in Table 4.1 we shall display optimal scaled stepsize-coefficients. Next, in section 4.3, we shall focus on an algorithm for computing $R(A, b)$; the authors feel that it can be useful in (future) calculations for determining, numerically, optimal Runge–Kutta methods. Finally, in section 4.4 we touch upon a few important related issues.

4.2. Optimal methods in the class $E_{m,p}$. We start with the following fundamental lemma, which gives a simple upper bound for $R(A, b)$ in the class $E_{m,p}$.

LEMMA 4.1 (Kraaijevanger (1991, p. 517)). *Let $1 \leq p \leq m$, and consider an arbitrary Runge–Kutta method (A, b) of class $E_{m,p}$. Then $R(A, b) \leq m - p + 1$.*

Remark 4.2. Ruuth and Spiteri (2002, Theorem 3.1) showed that, for Runge–Kutta methods in class $E_{m,p}$ of the special form (1.3), (1.5), the coefficient c defined by (1.6) satisfies $c \leq m-p+1$. Clearly, a combination of the above lemma and our theory (section 2) yields an extension and improvement over the last bound on c: for *any* Runge–Kutta method of class $E_{m,p}$, *any* stepsize-coefficient for monotonicity, say c', and *any* of the situations covered by (2.9), (2.10), or (2.11), we have $c' \leq m - p + 1$.

The following theorem specifies methods (A, b) for which the upper bound $R(A, b) \leq m - p + 1$ of Lemma 4.1 becomes an equality.

THEOREM 4.3 (Kraaijevanger (1991, pp. 518–520)).

(a) *Let $p = 1 \leq m$. Then there is a unique method (A, b) of class $E_{m,p}$ with $R(A, b) = m$; it is given by $a_{ij} = 1/m$ $(1 \leq j < i \leq m)$ and $b_i = 1/m$ $(1 \leq i \leq m)$.*

(b) *Let $p = 2 \leq m$. Then there is a unique method (A, b) of class $E_{m,p}$ with $R(A, b) = m - 1$; it is given by $a_{ij} = 1/(m - 1)$ $(1 \leq j < i \leq m)$ and $b_i = 1/m$ $(1 \leq i \leq m)$.*

(c) *Let $p = 3$, $m = 3$. Then there is a unique method (A, b) of class $E_{m,p}$ with $R(A, b) = 1$; it is given by $a_{21} = 1$, $a_{31} = a_{32} = 1/4$, $b_1 = b_2 = 1/6$, and $b_3 = 2/3$.*

(d) *Let $p = 3$, $m = 4$. Then there is a unique method (A, b) of class $E_{m,p}$ with $R(A, b) = 2$; it is given by $a_{21} = a_{31} = a_{32} = b_4 = 1/2$ and $a_{4,i} = b_i = 1/6$ $(1 \le i \le 3)$.*

Remark 4.4. Essentially the same methods as specified in the above theorem, for $m = p = 2$ and $m = p = 3$, were already found by Shu and Osher (1988) in a search for methods in $E_{m,p}$, of the special type (1.3), (1.5), with maximal c (defined in (1.6)); Gottlieb and Shu (1998) proved optimality for these two methods with respect to c, (1.6). In an analogous search, Spiteri and Ruuth (2002) arrived at all other methods specified by the theorem, and proved optimality in the sense of c, (1.6). Similarly as in Remark 4.2, our theory (section 2) can be used here to conclude that all methods given in Theorem 4.3 are optimal (with respect to their stepsize-coefficients for monotonicity) in a *stronger sense*, and over a *larger class* of Runge–Kutta methods, than can be concluded from the three papers just mentioned.

Kraaijevanger (1991) did not specify analytically any methods (A, b) in $E_{m,p}$ with maximal $R(A, b)$, for pairs p, m different from those in Theorem 4.3. However, he arrived at interesting (negative) conclusions: if method (A, b) is of class $E_{m,p}$ and $p = 3$, $m \ge 5$, then $R(A, b) < m-p+1$; and if (A, b) belongs to $E_{m,p}$ with $p = m = 4$ or $p \ge 5$, then $R(A, b) = 0$. Moreover, by combining Kraaijevanger (1986, Theorem 5.1), Spijker (1983), and our Theorem 2.5, one can conclude that $R(A, b) < m - p + 1$ also for all (A, b) in $E_{m,p}$ with $p = 4$, $m \ge 6$. A combination of these conclusions and our theory (section 2) amounts to a far-reaching extension of related results obtained in Ruuth and Spiteri (2002).

Kraaijevanger (1991, pp. 522–523) constructed numerically an explicit 5-stage method (A, b) of order 4, with $R(A, b) \approx 1.508$. It is interesting to note that the same method was found by Spiteri and Ruuth (2002) in a numerical search within the class of methods (1.3) satisfying (1.5). By a similar search, the last authors also found a 5-stage method of order 3 with $c \approx 2.651$ (given by (1.6)). In view of Kraaijevanger (1986, Theorem 5.3), Spijker (1983), and our Theorem 2.5, we can conclude that this method has a value $R(A, b) \approx 2.651$, and is optimal in a *stronger sense* and over a *larger class* of methods than follows from Spiteri and Ruuth (2002).

Clearly, when comparing two explicit Runge–Kutta methods to each other, one cannot simply say that the one with the largest value $R(A, b)$ is the most efficient one. However, assuming that the stepsize Δt, used for solving (1.1) over some interval $[0, T]$, is governed by monotonicity (TVD) demands, it seems reasonable to use the quantity $m \cdot T/R(A, b)$ as a measure of the amount of computational labor of a Runge–Kutta method (A, b) with m stages—cf. Jeltsch and Nevanlinna (1981), Kraaijevanger (1986), and Spiteri and Ruuth (2002) for related considerations. In line with the terminology in the first two of these papers, we shall refer to the ratio $R(A, b)/m$ as a *scaled stepsize-coefficient*. The above mentioned measure, for the amount of computational labor, is inversely proportional to $R(A, b)/m$, so the scaled stepsize-coefficient is a more realistic guide than $R(A, b)$ for comparing the efficiency of different methods to each other.

In Table 4.1 we display scaled stepsize-coefficients of Runge–Kutta methods (A, b), which were reviewed above and are optimal in $E_{m,p}$ with respect to $R(A, b)$.

From the table, one may conclude that, for given p, it is advantageous to use optimal methods with relatively large m. Clearly, this conclusion is (only) justifiable under the above assumption about Δt being determined by monotonicity demands. For related numerical experiments, see, e.g., Gottlieb and Shu (1998) and Spiteri and Ruuth (2002).

TABLE 4.1
Scaled stepsize-coefficients $R(A,b)/m$ for optimal Runge–Kutta methods in $E_{m,p}$.

	$m=1$	$m=2$	$m=3$	$m=4$	$m=5$
$p=1$	1	1	1	1	1
$p=2$		0.500	0.667	0.750	0.800
$p=3$			0.333	0.500	0.530
$p=4$					0.302

4.3. An algorithm for computing $R(A,b)$, for methods of class $E_{m,p}$. Below we will describe a simple algorithm for computing $R(A,b)$ whenever (A,b) is an irreducible Runge–Kutta scheme of class $E_{m,p}$. The following lemma plays a fundamental role in the algorithm.

LEMMA 4.5 (Kraaijevanger (1991, pp. 497–498)). *Let (A,b) be an irreducible coefficient scheme and r a positive real number. Then $R(A,b) \geq r$ if and only if $A \geq 0$ and the conditions* (2.6) *are fulfilled at $\xi = -r$.*

It was noted by Kraaijevanger (1991) that the above lemma simplifies calculating $R(A,b)$ if $A \geq 0$: for checking the conditions (2.6) on the whole of an interval $[-r,0]$, it is sufficient to consider only the left endpoint $\xi = -r$.

Let Test1 and Test2(x) be boolean functions defined by

$$\mathsf{Test1} = \begin{cases} \mathsf{true} & \text{if (2.7) holds,} \\ \mathsf{false} & \text{otherwise;} \end{cases} \qquad \mathsf{Test2(x)} = \begin{cases} \mathsf{true} & \text{if (2.6) holds at } \xi = \mathsf{x}, \\ \mathsf{false} & \text{otherwise.} \end{cases}$$

From Lemma 4.1 we know that if (A,b) is a coefficient scheme of class $E_{m,p}$, then $R(A,b) \leq m - p + 1$. In view of the last inequality, Theorem 2.4, and Lemma 4.5, we can calculate $R(A,b)$ with the wanted precision Tol, by using the above boolean functions as well as two pointers LeftExtr and RightExtr. The following algorithm finds $R(A,b)$ with error $\leq$ Tol.

```
x=0
if Test1
   LeftExtr=-(m-p+1),   RightExtr=0,   x=LeftExtr
   while (RightExtr-LeftExtr ≥ 2·Tol)
      if Test2(x)
         RightExtr=x,   x=(LeftExtr+RightExtr)/2
      else
         LeftExt=x,   x=(LeftExtr+RightExtr)/2
      end
   end
end
R(A,b)=−x.
```

4.4. Final remarks. For completeness, we note that Gottlieb and Shu (1998), Shu (2002), and Spiteri and Ruuth (2002) gave useful results regarding the optimization of c, (1.6), over classes of low-storage schemes of the (special) form (1.3), (1.5). Furthermore, Kennedy, Carpenter, and Lewis (2000) obtained interesting related results regarding the optimization of $R(A,b)$ over general classes of low-storage schemes (A,b). Clearly, our theory (section 2) is fit to put also this work in a wider perspective.

Above, in section 4, we dealt exclusively with explicit Runge–Kutta schemes. However, in Kraaijevanger (1991) also (a few) results were obtained, regarding the size of $R(A,b)$, relevant to implicit schemes—see below. A combination of these results

with our Theorem 2.5 immediately leads to interesting conclusions about stepsize-coefficients for monotonicity.

For arbitrary (possibly implicit) schemes (A, b) of order p, the following general results were obtained in Kraaijevanger (1991, pp. 514, 516): if $p \geq 2$, then $R(A, b) < \infty$; and if $p \geq 7$, then $R(A, b) = 0$. Moreover (on p. 516 of that article), a notable implicit method (A, b) was given, with a value $R(A, b)$ exceeding the upper bound of Lemma 4.1: the method with $m = 2$, $a_{1,1} = a_{1,2} = 0$, $a_{2,1} = a_{2,2} = 3/8$, $b_1 = 1/3$, $b_2 = 2/3$ is of order $p = 2$ and has a value $R(A, b) = 8/3$. The last value is considerably larger than the optimal value $m - p + 1 = 1$, which can be achieved in $E_{2,2}$ (cf. section 4.2); but this advantage should of course be balanced against the additional amount of work per step due to the implicitness of the method.

We think that it would be very useful to perform a systematic search for implicit methods which are optimal, for given m and p, in the sense of $R(A, b)$. Because such a search is beyond the scope of our present work, we do not go further into this matter here.

Finally, we note that our algorithm in section 4.3 can easily be adapted so as to compute $R(A, b)$ also for methods (A, b), of order at least 2, which are implicit: we still base the algorithm on Lemma 4.5, and (instead of using Lemma 4.1) we start with $\mathsf{LeftExtr} = \xi$, where ξ is a negative value at which (2.6) is violated; in view of the bound $R(A, b) < \infty$, such a ξ can be found, e.g., by a simple doubling process.

5. Kraaijevanger's theory and our proof of Theorem 2.5.

5.1. A theorem of Kraaijevanger on contractivity. Kraaijevanger (1991) presented an interesting theory, relevant to method (2.2) in the situation where F is a function from $\mathbb{R}^s$ into $\mathbb{R}^s$, and $\|.\|$ is a norm on $\mathbb{R}^s$. The focus in his paper is on numerical processes which, for given F, $\|.\|$, and Δt, are *contractive* in the sense that

$$\|\tilde{u}_n - u_n\| \leq \|\tilde{u}_{n-1} - u_{n-1}\| \tag{5.1}$$

whenever both the vectors u_{n-1}, u_n and the vectors $\tilde{u}_{n-1}, \tilde{u}_n$ are related to each other as in (2.2). Kraaijevanger studied property (5.1) for functions F satisfying

$$\|F(\tilde{v}) - F(v) + \rho(\tilde{v} - v)\| \leq \rho\|\tilde{v} - v\| \quad (\text{for all } v, \tilde{v} \in \mathbb{R}^s). \tag{5.2}$$

Here ρ is a positive constant; in the literature on numerical ODEs one often refers to (5.2) as a *circle condition* (with radius ρ) on the function F—cf. Kraaijevanger (1991).

In order to be able to reformulate one of Kraaijevanger's main results in such a way that it can easily be compared to our Theorem 2.5, we consider stepsize-restrictions of the form

$$0 < \Delta t \leq c/\rho. \tag{5.3}$$

Furthermore, adapting our Definition 2.1 to the situation at hand, we arrive at the following definition.

DEFINITION 5.1 (stepsize-coefficient for contractivity). *A value $c \in (0, \infty]$ is a stepsize-coefficient for contractivity (with respect to $\mathbb{R}^s$ and $\|.\|$) if the Runge–Kutta method is contractive, as in* (5.1)*, whenever $F : \mathbb{R}^s \to \mathbb{R}^s$ satisfies* (5.2) *and Δt is a (finite) stepsize satisfying* (5.3).

The subsequent theorem is an easy consequence of Kraaijevanger (1991, Theorem 5.4); it relates stepsize-coefficients for contractivity to the inequality

$$c \leq R(A, b). \tag{5.4}$$

THEOREM 5.2 (relating contractivity to $R(A,b)$). *Consider an arbitrary irreducible Runge–Kutta scheme (A,b). Let c be a given value with $0 < c \leq \infty$. Then both of the following statements are equivalent to* (5.4)*:*

(5.5) *c is a stepsize-coefficient for contractivity, with respect to $\mathbb{R}^s$ and $\|.\|$ for each $s \geq 1$ and each norm $\|.\|$ on $\mathbb{R}^s$;*

(5.6) *c is a stepsize-coefficient for contractivity, with respect to $\mathbb{R}^s$ and the special norm $\|.\|_\infty$ for each $s \geq 1$.*

Since condition (5.2) is equivalent to requiring that the forward Euler method with stepsize $\tau_0 = 1/\rho$ is contractive, there is a close resemblance between (5.2) and (2.4) (with $\mathbb{V} = \mathbb{R}^s$). Accordingly, one might think that (part of) our Theorem 2.5 is a simple consequence of Theorem 5.2. However, the following three remarks indicate that the relation between the two theorems is far from being that simple.

Remark 5.3. Let c be as in statement (2.11), with seminorm $\|.\| = \|.\|_1$ or $\|.\| = \|.\|_{TV}$. Theorem 2.5 claims that this coefficient c must satisfy $c \leq R(A,b)$. This claim cannot be expected to follow from the above Theorem 5.2; at best, it might follow from a version of that theorem in which the norm $\|.\|_\infty$ (in (5.6)) would simply be replaced by $\|.\|_1$ or $\|.\|_{TV}$. However, it is not known whether such a version is actually valid—Kraaijevanger's proof, underlying Theorem 5.2 as formulated above, makes an essential use of a specific (geometric) property of the norm $\|.\|_\infty$ which is *not* valid for $\|.\|_1$ or $\|.\|_{TV}$; cf. Kraaijevanger (1991, p. 505) and Schönbeck (1967, Theorem 2.4) for more details.

Remark 5.4. Let c be as in (2.11), with $\|.\| = \|.\|_\infty$. Even in this more convenient situation, it is not evident how the inequality $c \leq R(A,b)$, claimed by Theorem 2.5, could follow from Theorem 5.2. The fact is that (2.11) (with $\|.\| = \|.\|_\infty$) does not imply (5.6), because, in general, monotonicity does *not* imply contractivity.

Remark 5.5. Suppose $c \leq R(A,b)$. Then Theorem 2.5 claims that (2.9) is valid so that c would certainly be a stepsize-coefficient for monotonicity, with respect to $\mathbb{R}^s$ and any norm on $\mathbb{R}^s$. Even this last property of c does not follow from a simple application of Theorem 5.2, because it is no obvious consequence of (5.5)—note that (2.4) (with $\mathbb{V} = \mathbb{R}^s$) does *not* imply (5.2) (with $\rho = 1/\tau_0$).

The above three remarks make clear that our Theorem 2.5 can be viewed as a variant of Theorem 5.2 covering essentially new situations.

5.2. The proof of Theorem 2.5.

5.2.1. Preliminaries. Throughout this section 5.2 we assume, unless specified otherwise, that (A,b), c, and $|\!|.|\!|$ are as explained at the beginning of Theorem 2.5. With no loss of generality, we assume that c is finite. Below we shall prove the theorem by showing that the following five implications are valid: (2.8) $\Longrightarrow$ (2.9), (2.9) $\Longrightarrow$ (2.10), (2.10) $\Longrightarrow$ (2.11), [(2.11) with $|\!|.|\!| = \|.\|_{TV}$] $\Longrightarrow$ [(2.11) with $|\!|.|\!| = \|.\|_1$], and finally [(2.11) with $|\!|.|\!| = \|.\|_1$ or $\|.\|_\infty$] $\Longrightarrow$ (2.8).

The first implication will be proved in section 5.2.2, using arguments which are analogous to arguments for proving that (5.4) implies (5.5) (see Kraaijevanger (1991, pp. 502–504)).

The second implication is trivial, whereas the third and fourth implication will be proved in section 5.2.3. The proofs, in this section, are *not* related to arguments used in Kraaijevanger (1991), but are based on Lemma 5.6. This lemma gives a general framework in which the property of c being a stepsize-coefficient for monotonicity

can be carried over from a space $\mathbb{Y}$ with seminorm $\|.\|_{\mathbb{Y}}$ to another space $\mathbb{X}$ with seminorm $\|.\|_{\mathbb{X}}$.

The proof of the fifth implication will be given in section 5.2.4.

In that section we shall first deal with a linear variant of process (2.2). Lemma 5.7 tells us that a monotonicity property of that variant implies (2.8); the lemma is relevant to the norms $\|.\|_p$, with $p = 1$ and $p = \infty$. This lemma, with value $p = \infty$, was used implicitly by Kraaijevanger (1991, pp. 507–508) in a proof related to the implication (5.6) $\Longrightarrow$ (5.4) (cf. Theorem 5.2).

Next, we shall give Lemma 5.8, which states that property (2.11), with $|\!|.|\!| = \|.\|_p$ and $p = 1$ or $p = \infty$, implies the monotonicity property of the linear variant considered in Lemma 5.7. A combination of Lemmas 5.7 and 5.8 proves the fifth implication. Our proof of Lemma 5.8 has no relation to arguments in Kraaijevanger (1991); it makes use, among other things, of arguments employed earlier in Spijker (1986).

For completeness we mention that no counterpart of Lemma 5.8 is known to the authors which is relevant to contractivity with respect to $\mathbb{R}^s$ and $\|.\|_1$—cf. Remark 5.3 and Kraaijevanger (1991, p. 505).

5.2.2. Statement (2.8) $\Longrightarrow$ statement (2.9). We start this subsection by introducing some notation relevant to the vector space $\mathbb{V}$. For any vectors $v_1, v_2, \ldots, v_m$ in $\mathbb{V}$, we shall denote the vector in $\mathbb{V}^m$ with components v_j by

$$v = [v_j] = \begin{pmatrix} v_1 \\ \vdots \\ v_m \end{pmatrix} \in \mathbb{V}^m.$$

Furthermore, for any (real) $l \times m$ matrix $B = (b_{ij})$, we define a corresponding linear operator $B_{\mathbb{V}}$, from $\mathbb{V}^m$ to $\mathbb{V}^l$, by $B_{\mathbb{V}}(v) = w$, for $v = [v_j] \in \mathbb{V}^m$, where $w = [w_i] \in \mathbb{V}^l$ with $w_i = \sum_{j=1}^m b_{ij} v_j$ $(1 \le i \le l)$. Clearly, if B and C are $l \times m$ matrices and D is an $m \times k$ matrix, then $(B + C)_{\mathbb{V}} = B_{\mathbb{V}} + C_{\mathbb{V}}$, $(\lambda B)_{\mathbb{V}} = \lambda \cdot B_{\mathbb{V}}$, and $(BD)_{\mathbb{V}} = B_{\mathbb{V}} \cdot D_{\mathbb{V}}$. Here, the addition and multiplications occurring in the last three left-hand members stand for the usual algebraic operations for matrices, whereas the addition and multiplications in the right-hand members apply to linear operators. The last three equalities will underlie part of our subsequent calculations.

Assume (2.8), and let F be a function from $\mathbb{V}$ to $\mathbb{V}$ satisfying (2.4). We have to prove that c is a stepsize-coefficient for monotonicity; i.e., $0 < \Delta t \le c \cdot \tau_0$ implies $\|u_n\| \le \|u_{n-1}\|$ whenever u_n and u_{n-1} are related to each other by (2.2).

Assuming (2.2), with $0 < \Delta t \le c \cdot \tau_0$, we obtain

$$u_n = u_{n-1} + \sum_{j=1}^m b_j w_j, \tag{5.7a}$$

$$y_i = u_{n-1} + \sum_{j=1}^m a_{ij} w_j \quad (1 \le i \le m), \tag{5.7b}$$

where $w_j = \Delta t F(y_j)$. Putting $\gamma = \Delta t/\tau_0$, we have $\|w_i + c y_i\| = \gamma \|(c/\gamma) y_i + \tau_0 F(y_i)\| \le \gamma\{(c/\gamma - 1)\|y\| + \|y_i + \tau_0 F(y_i)\|\}$. Therefore, in view of (2.4),

$$\|w_i + c y_i\| \le c \|y_i\|. \tag{5.8}$$

Defining $y = [y_i] \in \mathbb{V}^m$, $w = [w_i] \in \mathbb{V}^m$, and $e = (1, \ldots, 1)^T \in \mathbb{R}^m$, we can rewrite (5.7) as

$$u_n = u_{n-1} + \mathbf{b}^T w, \tag{5.9a}$$

$$y = \mathbf{e}u_{n-1} + \mathbf{A}w, \tag{5.9b}$$

where $\mathbf{b}^T = (b^T)_{\mathbb{V}}$, $\mathbf{e} = (e)_{\mathbb{V}}$, and $\mathbf{A} = A_{\mathbb{V}}$. Denoting the identity in $\mathbb{V}^m$ by $\mathbf{I}$, we see from (5.9b) that $(\mathbf{I} + c\mathbf{A})y = \mathbf{e}u_{n-1} + \mathbf{A}w + c\mathbf{A}y = \mathbf{e}u_{n-1} + \mathbf{A}(w + cy)$. From Lemma 4.5, we conclude that (2.6) holds with $\xi = -c$ and that $A \geq 0$. Therefore, $\mathbf{I} + c\mathbf{A}$ is invertible and

$$y = (\mathbf{I} + c\mathbf{A})^{-1}\mathbf{e}u_{n-1} + \mathbf{A}(\mathbf{I} + c\mathbf{A})^{-1}(w + cy). \tag{5.10}$$

Since $(I + cA)^{-1}e = e(-c) \geq 0$ and $A(I + cA)^{-1} = A(-c) \geq 0$ we arrive at the inequality $[\|y_i\|] \leq \|u_{n-1}\|(I + cA)^{-1}e + A(I + cA)^{-1}[\|w_i + cy_i\|]$. In view of (5.8), there follows $[\|y_i\|] \leq \|u_{n-1}\|(I + cA)^{-1}e + cA(I + cA)^{-1}[\|y_i\|]$, which is the same as $(I + cA)^{-1}[\|y_i\|] \leq \|u_{n-1}\|(I + cA)^{-1}e$. Multiplying the last inequality by the matrix $I + cA \geq 0$, we can conclude that

$$\|y_i\| \leq \|u_{n-1}\| \quad (1 \leq i \leq m). \tag{5.11}$$

Using (5.9a), (5.10), we obtain

$$\begin{aligned} u_n &= u_{n-1} + \mathbf{b}^T w = u_{n-1} - c\mathbf{b}^T y + \mathbf{b}^T(w + cy) \\ &= u_{n-1} - c\mathbf{b}^T\{(\mathbf{I} + c\mathbf{A})^{-1}\mathbf{e}u_{n-1} + \mathbf{A}(\mathbf{I} + c\mathbf{A})^{-1}(w + cy)\} + \mathbf{b}^T(w + cy) \\ &= \{1 - cb^T(I + cA)^{-1}e\}u_{n-1} + \mathbf{b}^T(\mathbf{I} + c\mathbf{A})^{-1}(w + cy). \end{aligned}$$

Since $\varphi(-c) \geq 0$, $b(-c) \geq 0$, and (5.8), (5.11) are valid, we see from the last expression for u_n that

$$\begin{aligned} \|u_n\| &\leq \{1 - cb^T(I + cA)^{-1}e\}\|u_{n-1}\| + b^T(I + cA)^{-1}[\|w_i + cy_i\|] \\ &\leq \{1 - cb^T(I + cA)^{-1}e\}\|u_{n-1}\| + (cb^T(I + cA)^{-1}e)\|u_{n-1}\| = \|u_{n-1}\|. \end{aligned}$$

This completes the proof of (2.9).

5.2.3. Statement (2.10) $\Longrightarrow$ statement(2.11); and statement (2.11) with $|.| = \|.\|_{TV} \Longrightarrow$ statement (2.11) with $|.| = \|.\|_1$. We start this subsection by giving Lemma 5.6. The lemma deals with a general situation where

(5.12a) $\mathbb{X}$ and $\mathbb{Y}$ are vector spaces, with seminorms $\|.\|_{\mathbb{X}}$ and $\|.\|_{\mathbb{Y}}$, respectively,

(5.12b) $S : \mathbb{X} \to \mathbb{Y}$ is a linear operator,

(5.12c) $Sx = 0$ only for $x = 0$, and

(5.12d) $\|x\|_{\mathbb{X}} = \|Sx\|_{\mathbb{Y}}$ (for all $x \in \mathbb{X}$).

LEMMA 5.6. *Assume* (5.12) *and let c be a stepsize-coefficient for monotonicity, with respect to $\mathbb{Y}$ and $\|.\|_{\mathbb{Y}}$. Then c is also a stepsize-coefficient for monotonicity, with respect to $\mathbb{X}$ and $\|.\|_{\mathbb{X}}$.*

Proof. Let Δt be a stepsize with $0 < \Delta t \leq c \cdot \tau_0$, and let $F : \mathbb{X} \to \mathbb{X}$ with

$$\|x + \tau_0 F(x)\|_{\mathbb{X}} \leq \|x\|_{\mathbb{X}} \quad (\text{on } \mathbb{X}). \tag{5.13a}$$

Suppose the relations (2.2) are fulfilled. We have to prove that

$$\|u_n\|_{\mathbb{X}} \leq \|u_{n-1}\|_{\mathbb{X}}. \tag{5.13b}$$

We define the subspace $\mathbb{Y}_0 = \{y : \ y = Sx \text{ for some } x \in \mathbb{X}\}$ and we introduce a linear transformation T, from $\mathbb{Y}_0$ onto $\mathbb{X}$, by $Ty = x$ (for $y = Sx \in \mathbb{Y}_0$).

In view of (2.2), the vector $v_n = Su_n$ is generated from $v_{n-1} = Su_{n-1}$ by applying the Runge–Kutta method to the function $G_0 : \mathbb{Y}_0 \to \mathbb{Y}_0$, defined by $G_0(y) = SFT(y)$ (for $y \in \mathbb{Y}_0$). Using (5.12d) and (5.13a), one easily sees that $\|y + \tau_0 G_0(y)\|_{\mathbb{Y}} \le \|y\|_{\mathbb{Y}}$ (for all $y \in \mathbb{Y}_0$).

We define $G : \mathbb{Y} \to \mathbb{Y}$ by $G(y) = G_0(y)$ (for $y \in \mathbb{Y}_0$) and $G(y) = 0$ (for $y \in \mathbb{Y} \setminus \mathbb{Y}_0$). Clearly $\|y + \tau_0 G(y)\|_{\mathbb{Y}} \le \|y\|_{\mathbb{Y}}$ (for all $y \in \mathbb{Y}$). Moreover, the vector v_n can be viewed as being generated from v_{n-1} by applying the Runge–Kutta method, with stepsize Δt, to the function G. Consequently, $\|v_n\|_{\mathbb{Y}} \le \|v_{n-1}\|_{\mathbb{Y}}$. Combining this inequality and (5.12d), we arrive at (5.13b). □

Now assume (2.10). We shall prove (2.11) by applying Lemma 5.6.

We define $\mathbb{X} = \mathbb{R}^s$, $\mathbb{Y} = \{y : \ y \in \mathbb{R}^\infty$, and $\left|y\right| < \infty\}$, and $\|x\|_{\mathbb{X}} = \left|x\right|$, $\|y\|_{\mathbb{Y}} = \left|y\right|$ (for $x \in \mathbb{X}$ and $y \in \mathbb{Y}$, respectively). Furthermore, we introduce the operator S by

$$Sx = \begin{cases} (\dots, 0, 0, x_1, x_2, .., x_s, 0, 0 \dots) & \text{if } \ \left|.\right| = \|.\|_\infty \text{ or } \|.\|_1, \\ (\dots, x_1, x_1, x_1, x_2, \dots, x_s, x_s, x_s \dots) & \text{if } \ \left|.\right| = \|.\|_{TV} \end{cases}$$

for $x = (x_1, x_2, \dots, x_s) \in \mathbb{X}$.

With these definitions, the conditions (5.12) are fulfilled. In view of (2.10), we can apply Lemma 5.6 so as to conclude that (2.11) holds.

Finally assume (2.11) with $\left|.\right| = \|.\|_{TV}$. Let $s \ge 1$ and $\mathbb{X} = \mathbb{R}^s$, $\|x\|_{\mathbb{X}} = \|x\|_1$ (for $x \in \mathbb{X}$). We want to prove that c is a stepsize-coefficient for monotonicity with respect to $\mathbb{X}$ and $\|.\|_{\mathbb{X}}$.

In order to be able to apply Lemma 5.6 to the situation at hand, we define $\mathbb{Y} = \mathbb{R}^{s+1}$, $\|y\|_{\mathbb{Y}} = \|y\|_{TV}$ (for $y \in \mathbb{Y}$). Furthermore, for $x = (x_1, x_2, \dots, x_s) \in \mathbb{X}$ we define $Sx = (y_1, \dots, y_{s+1})$ with $y_1 = 0$ and $y_i = x_1 + x_2 + \cdots + x_{i-1}$ (for $2 \le i \le s+1$).

One easily sees that, with the above definitions, all assumptions of Lemma 5.6 are fulfilled. Hence, c has the required property.

5.2.4. (2.11) with $\left|.\right| = \|.\|_1$ or $\|.\|_\infty \implies$ (2.8). Throughout this subsection we shall use, for $p = 1, \infty$ and $s \times s$ matrices G, the notation $\|G\|_p = \max \|Gv\|_p / \|v\|_p$, where the maximum is over all nonzero vectors v in $\mathbb{R}^s$. Furthermore, we shall denote the $s \times s$ identity matrix by I.

Let $G_1, G_2, \dots, G_m$ be given $s \times s$ matrices. We consider a linear variant of (2.2) (with $n = 1$, $u_0 \in \mathbb{V} = \mathbb{R}^s$) in which all vectors $F(y_j)$ are replaced by $G_j\, y_j$. Furthermore, we consider the following linear variant of condition (2.4): $\|I + \tau_0 G_i\|_p \le 1$ $(1 \le i \le m)$.

Choose $\Delta t = c\,\tau_0$ and write $Z_i = \Delta t G_i$. Then the above linear variants of (2.2) and (2.4), respectively, can be written in the form

$$u_1 = u_0 + \sum_{j=1}^{m} b_j Z_j y_j, \tag{5.14a}$$

$$y_i = u_0 + \sum_{j=1}^{m} a_{ij} Z_j y_j \quad (1 \le i \le m), \tag{5.14b}$$

and

$$\|cI + Z_i\|_p \le c \quad (1 \le i \le m). \tag{5.15}$$

In the following we shall focus on ordered m-tuples $\mathbf{Z} = (Z_1, Z_2, \ldots, Z_m)$, where the Z_i are $s \times s$ matrices, such that (5.15) holds and the system of equations (5.14b) has a unique solution $y_1, y_2, \ldots, y_m$. The set consisting of all of these $\mathbf{Z}$ will be denoted by $\mathscr{D}_p(c, s)$.

For any $\mathbf{Z}$ in $\mathscr{D}_p(c, s)$, the vector u_1 in (5.14) depends uniquely and linearly on u_0; we denote the $s \times s$ matrix transforming u_0 into u_1 by $\mathbf{K}(\mathbf{Z})$. We thus have

$$u_1 = \mathbf{K}(\mathbf{Z})u_0 \text{ whenever } \mathbf{Z} \in \mathscr{D}_p(c, s) \text{ and } u_0, u_1 \in \mathbb{R}^s \text{ satisfy (5.14).} \tag{5.16}$$

The inequality

$$\|\mathbf{K}(\mathbf{Z})\|_p \leq 1 \text{ (for all } \mathbf{Z} \in \mathscr{D}_p(c, s) \text{ and } s \geq 1) \tag{5.17}$$

amounts to a monotonicity condition on process (5.14). It will be related to (2.8) and to (2.11) in Lemmas 5.7 and 5.8, respectively.

LEMMA 5.7. *Consider an arbitrary irreducible Runge–Kutta scheme* (A, b)*, and let* $p = 1$ *or* $p = \infty$*. Let* $0 < c < \infty$*, and assume condition* (5.17) *is fulfilled. Then* c *satisfies* (2.8).

Proof. In Kraaijevanger (1991) this lemma was proved (implicitly) for $p = \infty$. The proof in that paper is long and technical but is presented in a very clear way. Therefore, we do not repeat it here but note that the actual proof (given on pp. 507–508 of the paper) consists in a combination of conclusions regarding absolute monotonicity (on pp. 485–496) with Lemma 5.10 (on p. 505). The conclusions stated on pp. 485–496 are independent of the norm in $\mathbb{R}^s$, whereas Lemma 5.10 is tuned to the special norm $\|.\|_\infty$. It is not difficult to adapt the proof of the last mentioned lemma to the norm $\|.\|_1$ so as to conclude that Lemma 5.10 is verbatim valid for $\|.\|_1$ as well. As a result, the arguments in Kraaijevanger (1991, pp. 507–508) prove our Lemma 5.7 also for $p = 1$. □

A combination of the following lemma and Lemma 5.7 immediately leads to the desired implication ((2.11) with $|\!|.|\!| = \|.\|_1$ or $\|.\|_\infty \Longrightarrow$ (2.8)).

LEMMA 5.8. *Consider an arbitrary irreducible Runge–Kutta schema* (A, b)*, and let* $p = 1$ *or* $p = \infty$*. Let* $0 < c < \infty$*, and assume* (2.11) *with* $|\!|.|\!| = \|.\|_p$*. Then condition* (5.17) *is fulfilled.*

Proof. The proof will be given in three steps.

Step 1. Let

$$s \geq 1,\ u_0 \in \mathbb{R}^s,\ \mathbf{Z} = (Z_1, \ldots, Z_m) \in \mathscr{D}_p(c, s), \tag{5.18}$$

and assume that the corresponding vectors y_i, defined by (5.14b), satisfy

$$y_i \neq y_j \quad (\text{for } i \neq j). \tag{5.19}$$

We shall prove that

$$\|\mathbf{K}(\mathbf{Z})u_0\|_p \leq \|u_0\|_p. \tag{5.20}$$

Choose any $\tau_0 > 0$, and define $F : \mathbb{R}^s \to \mathbb{R}^s$ by $F(v) = (c\tau_0)^{-1} Z_i y_i$ (for $v = y_i$) and $F(v) = 0$ (for all other $v \in \mathbb{R}^s$). In view of (5.15), the function F satisfies (2.4) with $\mathbb{V} = \mathbb{R}^s$, $\|.\| = \|.\|_p$. Furthermore, we see from (5.14), (5.16) that the vector $\mathbf{K}(\mathbf{Z})u_0$ is generated from u_0 by applying the Runge–Kutta method with stepsize $\Delta t = c\tau_0$ to the function F. By virtue of (2.11) (with $|\!|.|\!| = \|.\|_p$), we conclude that (5.20) holds.

Step 2. Due to the restriction (5.19) in Step 1, the proof of (5.17) is not yet complete. Below, in Step 3, we shall get rid of this restriction by using (real) values γ_i, η_i (for $1 \le i \le m$) with the following properties:

$$0 < \gamma_i < c \quad (1 \le i \le m); \tag{5.21a}$$

$$\text{the } m \times m \text{ matrix } I + A \cdot \mathrm{diag}(\gamma_i) \text{ is invertible;} \tag{5.21b}$$

$$\eta_i = 1 - \sum_{j=1}^{m} a_{ij}\gamma_j\eta_j \quad (1 \le i \le m); \tag{5.21c}$$

$$\eta_i \ne \eta_j \quad (\text{whenever } i \ne j). \tag{5.21d}$$

In this (second) step we shall prove the existence of γ_i, η_i satisfying (5.21).

Since (A, b) is irreducible, statement (ii) (of Definition 2.2) is not true. It follows that the polynomials $p_i(t) = \sum_{j=1}^{m} a_{ij}t^j$ are different from each other. Therefore, there is a positive t_0 with $p_i(t_0) \ne p_j(t_0)$ (for all $i \ne j$). Writing $t_i = (t_0)^i$, we thus have

$$\sum_{k=1}^{m} a_{ik}t_k \ne \sum_{k=1}^{m} a_{jk}t_k \quad (\text{whenever } i \ne j).$$

Let $\gamma_i = \lambda t_i$, with $\lambda > 0$. We choose λ sufficiently small to guarantee (5.21a) and (5.21b). The corresponding values $\eta_i = \eta_i(\lambda)$, solving (5.21c), satisfy

$$\eta_i(\lambda) = 1 - \lambda \sum_{k=1}^{m} a_{ik}t_k + O(\lambda^2) \quad (\text{for } \lambda \downarrow 0).$$

Choosing λ sufficiently small, we conclude that γ_i, η_i exist satisfying (5.21).

Step 3. Assume (5.18). We shall prove (5.20).

Let y_i satisfy (5.14b), and choose any γ_i, η_i as in (5.21). We choose $\varepsilon > 0$ and define

$$u_0^* = \begin{pmatrix} u_0 \\ \varepsilon \end{pmatrix}, \qquad Z_i^* = \begin{pmatrix} Z_i & 0 \\ 0 & -\gamma_i \end{pmatrix}, \qquad y_i^* = \begin{pmatrix} y_i \\ \varepsilon\eta_i \end{pmatrix}.$$

Since $\mathbf{Z} \in \mathscr{D}_p(c, s)$ and (5.21a), (5.21b) hold, the m-tuple $\mathbf{Z}^* = (Z_1^*, Z_2^*, \ldots, Z_m^*)$ belongs to $\mathscr{D}_p(c, s+1)$. Furthermore, $y_i^* = u_0^* + \sum_{j=1}^{m} a_{ij}Z_j^*y_j^*$ $(1 \le i \le m)$ and $y_i^* \ne y_j^*$ (for $i \ne j$). Consequently, the conclusion of the above Step 1 can be applied (to $u_0^* \in \mathbb{R}^{s+1}$ and $\mathbf{Z}^* \in \mathscr{D}_p(c, s+1)$) so as to obtain $\|\mathbf{K}(\mathbf{Z}^*)u_0^*\|_p \le \|u_0^*\|_p$.

Since $\|\mathbf{K}(\mathbf{Z})u_0\|_p \le \|\mathbf{K}(\mathbf{Z}^*)u_0^*\|_p$ and $\|u_0^*\|_p \le \|u_0\|_p + \varepsilon$, we arrive at (5.20) by letting $\varepsilon \to 0$. □

Acknowledgments. The authors are most thankful to Dr. W. H. Hundsdorfer for useful discussions and information regarding the topic of this paper. Moreover, they are indebted to three anonymous referees for constructive criticism regarding an earlier version of the paper.

CONVERGENCE OF BINOMIAL TREE METHODS FOR EUROPEAN/AMERICAN PATH-DEPENDENT OPTIONS*

LISHANG JIANG† AND MIN DAI‡

Abstract. The binomial tree method, first proposed by Cox, Ross, and Rubinstein [*Journal of Financial Economics,* 7 (1979), pp. 229–263], is one of the most popular approaches to pricing options. By introducing an additional path-dependent variable, such methods can be readily extended to the valuation of path-dependent options. In this paper, using numerical analysis and the notion of viscosity solutions, we present a unifying theoretical framework to show the uniform convergence of binomial tree methods for European/American path-dependent options, including arithmetic average options, geometric average options, and lookback options.

Key words. binomial tree method, European/American path-dependent options, convergence

DOI. 10.1137/S0036142902414220

1. Introduction.

Path-dependent options are options whose payoffs depend on historical values of the underlying asset over a given time period as well as its current price. Well-known examples are Asian arithmetic/geometric average options, lookback options, etc. The binomial tree method (BTM), first proposed by Cox, Ross, and Rubinstein [6], has become one of the most popular approaches to pricing vanilla options due to its simplicity and flexibility. By introducing an additional path-dependent variable at each node, BTM can be readily extended to the valuation of path-dependent options.

Many authors have shown that the prices of European vanilla options computed from BTM converge to their corresponding continuous-time model values (see [12] and references therein). Amin and Khanna [1] and Jiang and Dai [14] produce the convergence proofs for American vanilla options by using the probabilistic approach and the partial differential equation (PDE) approach, respectively. In this paper, using the PDE approach, a unifying framework is given to show uniform convergence of BTMs for both European and American path-dependent options, including Asian arithmetic/geometric average options and lookback options. The basic idea stems from the result of Barles and Souganidis [4], which essentially says that any stable, monotone, and consistent numerical scheme converges, provided that one has a strong comparison principle in the sense of viscosity solution for the limiting equation. For Asian options and lookback options, the BTMs are clearly monotone and the needed strong comparison principles can be deduced from Crandall, Ishii, and Lions [8] and Barles, Daher, and Romano [2]. Hence, in addition to showing consistency, the key point of the proof is to prove stability, namely, to obtain uniform estimates of bounds of the approximate solutions sequences computed by BTMs. We arrive at this by two steps: first, it is shown that values of lookback options (computed

from BTMs) are the most expensive among those path-dependent options; second, by constructing a suitable auxiliary function, we give a uniform estimate of bounds for the price functions of lookback options. On the basis of the estimates, we then make use of the notion of viscosity solutions and numerical analysis to prove the uniform convergence.

Throughout this paper we only consider continuously monitored path-dependent options. Actually, all results can be generalized to the case of discrete monitoring because the key proof of boundedness follows from the fact that all prices of the options with discrete monitoring are not greater than that of the corresponding continuously monitored lookback option.

The outline for this paper is as follows. In the next section we recall algorithms of BTMs for arithmetic average, geometric average, and lookback options, respectively. Section 3 is devoted to the consistency of BTMs and PDEs in each case. In section 4 we establish the relationship of BTMs and finite difference methods. In sections 5 and 6 we compare prices of the above three path-dependent options and present bounds of solutions of BTMs. We prove the convergence of BTMs in section 7.

2. Algorithms. As is common in the risk neutral world, the underlying asset price S is assumed to follow the lognormal diffusion process

$$dS = rSdt + \sigma SdW, \tag{2.1}$$

where dW is a Wiener process and r and σ represent the interest rate and volatility, respectively. Consider a path-dependent option with the lifetime $[0, T]$ and the payoff

$$\Lambda(S, A) = \begin{cases} (S - A)^+ \text{ for floating strike call,} \\ (A - S)^+ \text{ for floating strike put,} \\ (A - X)^+ \text{ for fixed strike call,} \\ (X - A)^+ \text{ for fixed strike put,} \end{cases}$$

where A is the path-dependent variable and X is the strike price.

If N is the number of discrete time points, we have time points $t_n = n\Delta t$, $n = 0, 1, \ldots, N$, with $\Delta t = T/N$. Let $V^n(S, A)$ be the option price at time t_n with underlying asset value S and path-dependent variable A. Here we might as well assume

$$A = \begin{cases} \frac{1}{n}\Sigma_{i=1}^{n} S_{t_i} \text{ for arithmetic average,} \\ (\Pi_{i=1}^{n} S_{t_i})^{1/n} \text{ for geometric average,} \\ \max_{0\le i\le n} S_{t_i} \text{ for floating (fixed) strike lookback put (call) and } S \le A, \\ \min_{0\le i\le n} S_{t_i} \text{ for floating (fixed) strike lookback call (put) and } S \ge A. \end{cases} \tag{2.2}$$

S_{t_i} stands for the underlying asset value of such path at time t_i, $i = 0, 1, \ldots, n$ (note $S_{t_n} = S$). It is assumed that S will either jump up to Su with probability p or down to Sd with probability $1 - p$ at time t_{n+1}. Consequently, A will become either A^u or A^d, where

$$A^u = \begin{cases} \frac{nA+Su}{n+1} \text{ for arithmetic average,} \\ (A^n Su)^{1/(n+1)} \text{ for geometric average,} \\ \max(A, Su) \text{ for floating (fixed) strike lookback put (call) and } S \le A, \\ A \text{ for floating (fixed) strike lookback call (put) and } S \ge A \end{cases} \tag{2.3}$$

and

$$A^d = \begin{cases} \frac{nA+Sd}{n+1} \text{ for arithmetic average,} \\ (A^n Sd)^{1/(n+1)} \text{ for geometric average,} \\ A \text{ for floating (fixed) strike lookback put (call) and } S \le A, \\ \min(A, Sd) \text{ for floating (fixed) strike lookback call (put) and } S \ge A. \end{cases}$$

(2.4)

By no-arbitrage argument, one has for European path-dependent options

$$V^n(S,A) = e^{-r\Delta t}[pV^{n+1}(Su, A^u) + (1-p)V^{n+1}(Sd, A^d)], \tag{2.5}$$

where $p = \frac{e^{r\Delta t}-d}{u-d}$. Setting $ud = 1$ and combining with stochastic differential equation (2.1), we get

$$u = e^{\sigma\sqrt{\Delta t}},\ d = e^{-\sigma\sqrt{\Delta t}}$$

and thus

$$p = \frac{e^{r\Delta t} - e^{\sigma\sqrt{\Delta t}}}{e^{\sigma\sqrt{\Delta t}} - e^{-\sigma\sqrt{\Delta t}}}.$$

At expiration time $T = N\Delta t$, we have

$$V^N(S,A) = \Lambda(S,A). \tag{2.6}$$

Using the backward induction (2.5)–(2.6), option prices can be calculated. This is the so-called binomial tree model.

For American path-dependent options, (2.5) is replaced by

$$V^n(S,A) = \max\{e^{-r\Delta t}[pV^{n+1}(Su, A^u) + (1-p)V^{n+1}(Sd, A^d)], \Lambda(S,A)\}. \tag{2.7}$$

3. Consistency. For the continuous model, the path-dependent variable is given as follows:

$$A_t = \begin{cases} \frac{1}{t}\int_0^t S(\tau)d\tau \text{ for arithmetic average,} \\ \exp(\frac{1}{t}\int_0^t \ln S(\tau)d\tau) \text{ for geometric average,} \\ \max_{0\le\tau\le t} S(\tau) \text{ for floating (fixed) strike lookback put (call),} \\ \min_{0\le\tau\le t} S(\tau) \text{ for floating (fixed) strike lookback call (put).} \end{cases}$$

Let $V(S,A,t)$ be the path-dependent option value. Note that S, A, and t are mutually independent from the view point of PDEs. The pricing model of European path-dependent options is (see Kwok [16] or Wilmott, Dewynne, and Howison [17])

$$\frac{\partial V}{\partial t} + \mathcal{L}V = 0, \qquad t \in (0,T),\ (S,A) \in \mathcal{D}, \tag{3.1}$$

with the final value condition

$$V(S,A,T) = \Lambda(S,A), \tag{3.2}$$

where

$$\mathcal{L}V = \begin{cases} \frac{1}{t}(S-A)\frac{\partial V}{\partial A} + \frac{1}{2}\sigma^2 S^2 \frac{\partial^2 V}{\partial S^2} + rS\frac{\partial V}{\partial S} - rV \text{ for arithmetic average,} \\ \frac{A}{t}(\ln S - \ln A)\frac{\partial V}{\partial A} + \frac{1}{2}\sigma^2 S^2 \frac{\partial^2 V}{\partial S^2} + rS\frac{\partial V}{\partial S} - rV \text{ for geometric average,} \\ \frac{1}{2}\sigma^2 S^2 \frac{\partial^2 V}{\partial S^2} + rS\frac{\partial V}{\partial S} - rV \text{ for lookback} \end{cases}$$

and

$$\mathcal{D} = \begin{cases} (0,\infty)\times(0,\infty) \text{ for arithmetic or geometric average,} \\ \{(S,A): 0<S<A<\infty\} \text{ for floating (fixed) strike lookback put (call),} \\ \{(S,A): 0<A<S<\infty\} \text{ for floating (fixed) strike lookback call (put).} \end{cases}$$

In addition, for lookback options, one has an additional boundary condition

$$\frac{\partial V}{\partial A}(S,S,t) = 0. \tag{3.3}$$

REMARK 1. *Note that $\mathcal{L}V$ is not well defined at $t = 0$ for Asian options. To remove the singularity, we can take the transformation*

$$I = \begin{cases} tA \text{ for arithmetic average,} \\ t\ln A \text{ for geometric average} \end{cases} \tag{3.4}$$

to get

$$\mathcal{L}V = \begin{cases} S\frac{\partial V}{\partial I} + \frac{1}{2}\sigma^2 S^2 \frac{\partial^2 V}{\partial S^2} + rS\frac{\partial V}{\partial S} - rV \text{ for arithmetic average,} \\ \ln S\frac{\partial V}{\partial I} + \frac{1}{2}\sigma^2 S^2 \frac{\partial^2 V}{\partial S^2} + rS\frac{\partial V}{\partial S} - rV \text{ for geometric average,} \end{cases} \tag{3.5}$$

where $I \in (0,\infty)$ for the arithmetic average and $I \in (-\infty,\infty)$ for the geometric average.

REMARK 2. *One does not need to give boundary conditions at $S = 0$ that reduce to $x = -\infty$ by the transformation $x = \ln S$. Similarly, noting* (3.5) *and the directions of the characteristic lines, we do not impose boundary conditions at $A = 0$ (i.e., $I = 0$ or $-\infty$) for Asian options. We always assume that option values do not grow too fast at $S = \infty$ and $A = \infty$.*

For American options, (3.1) is replaced by a variational inequality

$$\min\left\{-\frac{\partial V}{\partial t} - \mathcal{L}V, V - \Lambda\right\} = 0, \qquad t \in (0,T),\ (S,A) \in \mathcal{D}. \tag{3.6}$$

with the final condition (3.2) (and boundary condition (3.3) for lookback options).

REMARK 3. *For American Asian options, even if the transformation* (3.4) *is employed, one cannot remove the singularity of* (3.6) *at $t = 0$ because $\Lambda = (S-A)^+ = (S - \frac{I}{t})^+$ (floating strike call, for example) is, as of yet, not well defined at $t = 0$. The financial background gives $S = A$ (i.e. $I = 0$) at $t = 0$. However, S and A are mutually independent variables in* (3.6) *and the behavior of the solution at the point $(S,S,0)$ remains to be studied further. Throughout this paper we always confine ourselves to the interval $(0,T]$ instead of $[0,T]$, except for special claim options.*

In what follows, we will show the consistency of binomial tree methods and PDEs.

THEOREM 3.1. *The binomial tree methods* (2.5) *(resp.,* (2.7)*) are consistent with the corresponding PDE* (3.1) *(resp.,* (3.6)*).*

Proof. We only take the European type arithmetic average option as an example since it is similar for other cases. We need to show that for sufficiently smooth function $\phi(S,A,t)$ and $(S_0,A_0,t_0) \in \mathcal{D}\times(0,T)$,

$$\lim_{\substack{\Delta t\to 0 \\ (S,A,t)\to(S_0,A_0,t_0)}} \frac{1}{\Delta t}(\phi - F_{\Delta t}\phi)(S,A,t) = -\frac{\partial V}{\partial t} - \mathcal{L}V\Big|_{(S_0,A_0,t_0)},$$

where

$$F_{\Delta t}\phi(S,A,t) = e^{-r\Delta t}[p\phi(Su, A^u, t) + (1-p)\phi(Sd, A^d, t)], \tag{3.7}$$

$$A^u = \frac{(t-\Delta t)A + Su\Delta t}{t} \text{ and } A^d = \frac{(t-\Delta t)A + Sd\Delta t}{t}.$$

By Taylor expansions and the identities

$$e^{-r\Delta t}[p(u-1) + (1-p)(d-1)] = r\Delta t + O(\Delta t^2),$$
$$e^{-r\Delta t}[p(u-1)^2 + (1-p)(d-1)^2] = \sigma^2\Delta t + O\left(\Delta t^2\right),$$
$$e^{-r\Delta t}[p(u-1)^3 + (1-p)(d-1)^3] = O\left(\Delta t^2\right),$$

(3.7) reduces to

$$\begin{aligned}
&(\phi - F_{\Delta t}\phi)(S,A,t)\\
&= -\left[\frac{\partial\phi}{\partial t}(S,A,t) + rS\frac{\partial\phi}{\partial S}(S,A,t) + \frac{1}{2}\sigma^2S^2\frac{\partial^2\phi}{\partial S^2}(S,A,t) - r\phi(S,A,t)\right]\Delta t\\
&\quad -e^{-r\Delta t}[p(A^u - A) + (1-p)(A^d - A)]\frac{\partial\phi}{\partial A}(S,A,t)\\
&\quad -e^{-r\Delta t}[p(u-1)(A^u - A) + (1-p)(d-1)(A^d - A)]S\frac{\partial^2\phi}{\partial S\partial A}(S,A,t)\\
&\quad +O(\Delta t^2) + O((A^u - A)\Delta t) + O((A^d - A)\Delta t) + O((A^u - A)^2) + O((A^d - A)^2).
\end{aligned} \tag{3.8}$$

Noting that $A^u - A = \frac{Su-A}{t}\Delta t$ and $A^d - A = \frac{Sd-A}{t}\Delta t$, we have

$$e^{-r\Delta t}[p(A^u - A) + (1-p)(A^d - A)] = \frac{S-A}{t}\Delta t + O(\Delta t^2),$$
$$e^{-r\Delta t}[\,p(u-1)(A^u - A) + (1-p)(d-1)(A^d - A)] = O(\Delta t^2).$$

Then we get

$$\begin{aligned}
\frac{1}{\Delta t}(\phi - F_{\Delta t}\phi)(S,A,t) = &-\left.\frac{\partial\phi}{\partial t} - \frac{1}{t}(S-A)\frac{\partial\phi}{\partial A} - \frac{1}{2}\sigma^2S^2\frac{\partial^2\phi}{\partial S^2} - rS\frac{\partial\phi}{\partial S} + r\phi\right|_{(S,A,t)}\\
&+ O(\Delta t).
\end{aligned} \tag{3.9}$$

The proof is complete.

REMARK 4. *For lookback options, the consistency of BTMs and the boundary condition* (3.3) *in the sense of the viscosity solution will be shown implicitly in the convergence proof of section* 7.

4. Relationship between BTM and finite difference method. It has been pointed out by many authors that, for vanilla options, the BTM is equivalent to certain explicit difference schemes. In this section we establish the relationship between BTMs and finite difference methods for path-dependent options.

To illustrate the basic idea, we confine ourselves to European arithmetic average options. The governing equation is

$$\frac{\partial V}{\partial t} + \frac{1}{t}(S-A)\frac{\partial V}{\partial A} + \frac{1}{2}\sigma^2S^2\frac{\partial^2 V}{\partial S^2} + rS\frac{\partial V}{\partial S} - rV = 0.$$

Consider the characteristic line of $\frac{\partial V}{\partial t} + \frac{1}{t}(S-A)\frac{\partial V}{\partial A} = 0$ in $[t_n, t_{n+1}]$

$$\begin{cases} \frac{dt}{1} = \frac{dA}{\frac{1}{t}(S-A)}, & t_n \le t \le t_{n+1}, \\ A(t_n) = A_n, \end{cases}$$

whose solution is

$$A(t) = S - \frac{t_n}{t}(S - A_n).$$

The governing equation is thereby rewritten as

$$\frac{dV}{dt}\left(S, S - \frac{t_n}{t}(S-A_n), t\right) + \left(\frac{\sigma^2}{2}S^2\frac{\partial^2 V}{\partial S^2} + rS\frac{\partial V}{\partial S} - rV\right)\Big|_{A=S+\frac{t_n}{t}(S-A_n)} = 0, \quad t_n \le t \le t_{n+1}.$$

By adding the following three small terms to the above equation at $(S, S + \frac{t_n}{t}(S - A_n), t)$,

$$\frac{\sigma^2}{2}\left[\frac{t-t_n}{t}S\right]^2\frac{\partial^2 V}{\partial A^2} + \sigma^2 S\frac{t-t_n}{t}S\frac{\partial^2 V}{\partial A \partial S} + \left(r - \frac{\sigma^2}{2}\right)S\frac{t-t_n}{t}\frac{\partial V}{\partial A} \quad (t_n \le t \le t_{n+1}),$$

we have

$$\begin{aligned} &\frac{d}{dt}V\left(S, S - \frac{t_n}{t}(S-A_n), t\right) + \frac{\sigma^2}{2}S\frac{d}{dS}\left(S\frac{d}{dS}V\left(S, S - \frac{t_n}{t}(S-A_n), t\right)\right) \\ &+ \left(r - \frac{\sigma^2}{2}\right)S\frac{d}{dS}V\left(S, S - \frac{t_n}{t}(S-A_n), t\right) - rV\left(S, S - \frac{t_n}{t}(S-A_n), t\right) = 0, \\ &\qquad t_n \le t \le t_{n+1}. \end{aligned} \tag{4.1}$$

Noting that $\frac{d}{dS}$ is a total differential operator, (4.1) can be regarded as a Black–Scholes equation in $[t_n, t_{n+1}]$. By taking the explicit difference scheme for (4.1), we can get

$$V(S, A_n, t_n) = \frac{1}{1 + r\Delta t}[aV(Su, A_n^u, t_{n+1}) + (1-a)V(Sd, A_n^d, t_{n+1})],$$

where

$$a = \frac{1}{2} + \frac{\sqrt{\Delta t}}{2\sigma}\left(r - \frac{\sigma^2}{2}\right).$$

Since $e^{r\Delta t} = 1 + r\Delta t + O(\Delta t^2)$ and

$$p = a + O(\Delta t^{3/2}),$$

we conclude that by neglecting a high order of Δt, BTM is equivalent to the above explicit difference scheme with method of characteristic line.

REMARK 5. *For geometric average options and lookback options, we have similar results.*

5. Comparison of path-dependent options prices. In this section we will compare prices of arithmetic average options, geometric average options, and lookback options computed from the binomial tree approximation (2.6)–(2.7). To illustrate this method, we will consider the American floating strike put option and the fixed strike call option.

For Δt given and $0 \le n \le N = T/\Delta t$, we can compute $V^n(S, A)$ for all $(S, A) \in D$ by (2.6)–(2.7). In the following, $V^n(S, A)$ is regarded as a function defined by (2.6)–(2.7) in $\mathcal{D}$. In addition, we always suppose

$$0 < p < 1, \tag{5.1}$$

which is a fact for sufficiently small Δt. Under the assumption (5.1), BTMs are monotone schemes.

LEMMA 5.1. *Let $V^n(S, A)$ be the function defined by (2.6)–(2.7) in $\mathcal{D}$ for the American floating strike put option (or fixed strike call option) with payoff $(A - S)^+$ (or $(A - X)^+$). If $A_1 \le A_2$, then*

$$V^n(S, A_1) \le V^n(S, A_2)$$

for all $0 \le n \le N$.

Proof. The proof is obvious.

LEMMA 5.2. *Let $V_G^n(S, A)$, $V_A^n(S, A)$, and $V_L^n(S, A)$ be the functions defined by (2.6)–(2.7) in $\mathcal{D}$ for American floating strike geometric average, arithmetic average, and lookback put options (or corresponding fixed strike call options) with payoffs $(A - S)^+$ (or $(A - X)^+$).*

(1) *For all $0 \le n \le N$, we have*

$$V_G^n(S, A) \le V_A^n(S, A) \le V_L^n(S, \max(S, A)). \tag{5.2}$$

(2) *Let A_g, A_a, and A_l be values of the path-dependent variable for an identical path. Then for all $0 \le n \le N$*

$$V_G^n(S, A_g) \le V_A^n(S, A_a) \le V_L^n(S, \max(S, A_l)). \tag{5.3}$$

Proof. We take floating strike put options for example.

(1) Suppose (5.2) is true for $n + 1$:

$$\begin{aligned} V_A^n(S, A) &= \max\{e^{-r\Delta t}[pV_A^{n+1}(Su, A_A^u) + (1 - p)V_A^{n+1}(Sd, A_A^d)], (A - S)^+\} \\ &\ge \max\{e^{-r\Delta t}[pV_G^{n+1}(Su, A_A^u) + (1 - p)V_G^{n+1}(Sd, A_A^d)], (A - S)^+\}. \end{aligned}$$

Here

$$A_A^u = \frac{nA + Su}{n + 1} \ge (A^n Su)^{1/(n+1)} = A_G^u,$$

and similarly

$$A_A^d \ge A_G^d;$$

it follows from Lemma 5.1 that

$$\begin{aligned} V_A^n(S, A) &\ge \max\{e^{-r\Delta t}[pV_G^{n+1}(Su, A_G^u) + (1 - p)V_G^{n+1}(Sd, A_G^d)], (A - S)^+\} \\ &= V_G^{n+1}(S, A), \end{aligned}$$

which is the desired result. Combining with Lemma 5.1 and noticing that $V_L^n(S,A)$ is defined for $S \le A$, the right inequality follows similarly.

(2) For an identical path, by the definition (2.2), one has

$$A_g \le A_a \le A_l,$$

which yields (5.3) due to (5.2) and Lemma 5.1.

REMARK 6. *Lemmas* 5.1 and 5.2 *remain valid for European path-dependent options. Similar results also hold for floating strike call and fixed strike put options.*

6. Boundedness. In this section we will present bounds of solutions of BTMs, which is crucial in the proof of convergence.

LEMMA 6.1. *Let $V^n(S,A)$ be the function defined by* (2.6)–(2.7) *in $\mathcal{D}$ for an American fixed strike put option with payoff $(X-A)^+$. Then*

$$V^n(S,A) \le X$$

for all $0 \le n \le N$.

Proof. By induction, the result is obvious.

LEMMA 6.2. *Let $V^n(S,A)$ be the function defined by* (2.6)–(2.7) *in $\mathcal{D}$ for an American floating strike call option with payoff $(S-A)^+$. Then*

$$V^n(S,A) \le S$$

for all $0 \le n \le N$.

Proof. Let $V^n(S,A) = S\overline{V}^n(S,A)$ for all $0 \le n \le N$. It suffices to show that for all $0 \le n \le N$

$$\overline{V}^n(S,A) \le 1. \tag{6.1}$$

Clearly for $n < N$,

$$\overline{V}^n(S,A) = \max\left\{e^{-r\Delta t}[pu\overline{V}^{n+1}(Su,A^u) + (1-p)d\overline{V}^{n+1}(Sd,A^d)], \left(1-\frac{A}{S}\right)^+\right\}.$$

Since $\overline{V}^N(S,A) = (1-\frac{A}{S})^+ \le 1$, one might as well assume that (6.1) holds for $n+1$ and hence

$$\begin{aligned}\overline{V}^n(S,A) &\le \max\left\{e^{-r\Delta t}[pu+(1-p)d], \left(1-\frac{A}{S}\right)^+\right\}\\ &= \max\left\{1, \left(1-\frac{A}{S}\right)^+\right\} \le 1,\end{aligned}$$

which arrives at the conclusion.

LEMMA 6.3. *Let $V_L^n(S,A)$ be the function defined by* (2.6)–(2.7) *in $\mathcal{D}$ for an American floating strike lookback put option (or fixed strike call option) with payoff $(A-S)^+$ (or $(A-X)^+$). Let $\alpha > 0$ and $W^n(S,A)$ be the solution to the following problem:*

$$\begin{cases} W^n(S,A) \\ \quad = \max\{e^{-r\Delta t}[pW^{n+1}(Su,\max(Su,A)) + (1-p)W^{n+1}(Sd,A)], e^{\alpha(N-n)\Delta t}A\}, & S \le A,\\ W^N(S,A) = A. \end{cases} \tag{6.2}$$

Then for all $0 \le n \le N$ *and* $S \le A$

$$V_L^n(S,A) \le W^n(S,A). \tag{6.3}$$

Proof. We take floating strike put options for example. Since $W^N(S,A) = A \ge V_L^N(S,A)$, we may suppose (6.3) holds for $n+1$. Because $\alpha > 0$,

$$\begin{aligned} W^n(S,A) &= \max\{e^{-r\Delta t}[pW^{n+1}(Su,\max(Su,A)) + (1-p)W^{n+1}(Sd,A)], e^{\alpha(N-n)\Delta t}A\} \\ &\ge \max\{e^{-r\Delta t}[pV_L^{n+1}(Su,\max(Su,A)) + (1-p)V_L^{n+1}(Sd,A)], (A-S)^+\} \\ &= V_L^{n+1}(S,A). \end{aligned}$$

The proof is complete.

7. Convergence. In this section, we will employ the notion of viscosity solutions to show the convergence of binomial tree method. Let us first recall the notion of viscosity solutions. For convenience, we use the following notations:

$$H(V,S,A,t) = \begin{cases} -\frac{\partial V}{\partial t} - \mathcal{L}V \text{ for European options,} \\ \min\{-\frac{\partial V}{\partial t} - \mathcal{L}V, V - \Lambda\} \text{ for American options,} \end{cases}$$

$$B(V,S,A,t) = \begin{cases} -\frac{\partial V}{\partial A} \text{ for floating (fixed) strike lookback put (call),} \\ \frac{\partial V}{\partial A} \text{ for floating (fixed) strike lookback call (put),} \end{cases} \tag{7.1}$$

and

$$\overline{\mathcal{D}} = \mathcal{D} \cup \partial\mathcal{D},\ \partial\mathcal{D} = \begin{cases} \emptyset \text{ for Asian options,} \\ \{(S,A) : 0 < S = A < \infty\} \text{ for lookback options.} \end{cases}$$

REMARK 7. *In* (7.1)*, the sign before* $\frac{\partial V}{\partial A}$ *is determined by the outward unit normal to* $\partial\mathcal{D} \times (0,T)$ *(see* [8]*).*

DEFINITION 7.1. *A function* $V \in USC(\overline{\mathcal{D}} \times (0,T])$ *(resp.,* $LSC(\overline{\mathcal{D}} \times (0,T])$*) is a viscosity subsolution (resp., supersolution) of the problem* (3.6)*,* (3.2) *(and* (3.3) *for lookback options) if* $V(S,A,T) \le \Lambda(x)$ *(resp.,* $V(S,A,T) \ge \Lambda(x)$*), and whenever* $\phi \in C^{2,1}(\overline{\mathcal{D}} \times (0,T))$*,* $V - \phi$ *attains its local maximum (resp., local minimum) at* $(S_0,A_0,t_0) \in \overline{\mathcal{D}} \times (0,T)$ *and* $(V-\phi)(S_0,A_0,t_0) = 0$*, we have*

$$H(\phi,S_0,A_0,t_0) \le 0 \text{ for } (S_0,A_0,t_0) \in \mathcal{D} \times (0,T)$$

(resp.,

$$H(\phi,S_0,A_0,t_0) \ge 0 \text{ for } (S_0,A_0,t_0) \in \mathcal{D} \times (0,T)),$$

and (only for lookback option)

$$\min\{H(\phi,S_0,A_0,t_0), B(\phi,S_0,A_0,t_0)\} \le 0 \text{ for } (S_0,A_0,t_0) \in \partial\mathcal{D} \times (0,T)$$

(resp.,

$$\max\{H(\phi,S_0,A_0,t_0), B(\phi,S_0,A_0,t_0)\} \ge 0 \text{ for } (S_0,A_0,t_0) \in \partial\mathcal{D} \times (0,T)).$$

We call $V \in C(\overline{\mathcal{D}} \times (0,T])$ *a viscosity solution of* (3.6)*,* (3.2) *(and* (3.3) *for lookback options) if it is both a viscosity subsolution and a supersolution.*

The convergence proof needs the strong comparison principle that holds for Asian options (see Remark 1 and [8], [9], and [11] and references therein). For lookback options where the oblique derivative boundary condition is involved, Barles, Daher, and Romano have shown that the strong comparison principle still remains valid (see [2] and [3]). Then we get the following.

LEMMA 7.2. *The strong comparison principle holds for problem* (3.6), (3.2) *(and* (3.3) *for lookback options); namely, if u and v are the viscosity subsolution and supersolution of the problem, respectively, then $u \le v$.*

Let $V^n(S,A)$ be the function defined by (2.6)–(2.7) in $\mathcal{D}$ for American path-dependent option. We now define the extension function $V_{\Delta t}(S,A,t)$ as follows: for $t \in [n\Delta t, (n+1)\Delta t]$, $n = 0, 1, \ldots, N-1$,

$$V_{\Delta t}(S,A,t) = \frac{(n+1)\Delta t - t}{\Delta t} V^n(S,A) + \frac{t - n\Delta t}{\Delta t} V^{n+1}(S,A).$$

THEOREM 7.3. *Suppose that $V(S,A,t)$ is the viscosity solution to the problem* (3.6), (3.2) *(and* (3.3) *for lookback options). Then, as $\Delta t \to 0$, we have $V_{\Delta t}(S,A,t)$ converges uniformly to $V(S,A,t)$ in any bounded closed subdomain of $\mathcal{D} \times (0,T)$.*

In order to prove this theorem, we have to show $V^*(S,A,t)$ and $V_*(S,A,t)$ are well defined at first, where

$$V^*(S,A,t) = \limsup_{\Delta t \to 0, (x,y,z) \to (S,A,t)} V_{\Delta t}(x,y,z),$$
$$V_*(S,A,t) = \liminf_{\Delta t \to 0, (x,y,z) \to (S,A,t)} V_{\Delta t}(x,y,z).$$

In fact, due to Lemmas 6.1 and 6.2, it is true for fixed strike put options and floating strike call options. As for fixed strike call options and floating strike put options, by Lemma 6.3, it suffices to show the following.

LEMMA 7.4. *Let $W^n(S,A)$ be the solution to* (6.2) *with $\alpha > 0$. Then we have*

$$W^n(S,A) \le e^{\alpha T} \left(\max\left(A, \left(\frac{\lambda_-(\lambda_+ - 1)}{\lambda_+(\lambda_- - 1)} \right)^{1/(\lambda_- - \lambda_+)} S \right) + 1 \right) \tag{7.2}$$

for sufficiently small Δt, where

$$\lambda_\pm = \frac{r}{\sigma^2} + \frac{1}{2} \pm \sqrt{\left(\frac{r}{\sigma^2} + \frac{1}{2} \right)^2 + \frac{2\alpha}{\sigma^2}}. \tag{7.3}$$

REMARK 8. *In Lemma* 7.4, *$\alpha > 0$ guarantees* $(\frac{\lambda_-(\lambda_+ - 1)}{\lambda_+(\lambda_- - 1)})^{1/(\lambda_- - \lambda_+)} < \infty$.

Before proving Lemma 7.4 we inquire into some properties of the solution to the problem (6.2). By transformations

$$x = \ln \frac{A}{S} \text{ and } \overline{W}^n(x) = e^{-\alpha(N-n)\Delta t} \frac{W^n(S,A)}{S}, \tag{7.4}$$

the numerical scheme (6.2) is reduced to

$$\begin{cases} \overline{W}^n(x) = \max\{e^{-(r+\alpha)\Delta t}[p u\overline{W}^{n+1}((x - \sigma\sqrt{\Delta t})^+) + (1-p) d\overline{W}^{n+1}(x + \sigma\sqrt{\Delta t})], e^x\}, \\ \qquad x \ge 0, \\ \overline{W}^N(x) = e^x. \end{cases} \tag{7.5}$$

LEMMA 7.5. *Let* $\overline{W}^n(x)$ *be the solution to* (7.5). *Then we have*
(a) $\overline{W}^{n+1}(x) \le \overline{W}^n(x)$,
(b) $\overline{W}^n(x_1) \le \overline{W}^n(x_2)$ *if* $x_1 \le x_2$,
(c) *for each* $n \le N$,

$$\overline{W}^n(x) = e^x \text{ if } x \ge (N-n)\sigma\sqrt{\Delta t}. \tag{7.6}$$

Proof. (a) and (b) are obvious. In order to prove (c), we use induction. Suppose (7.6) holds for $n = k+1$, namely $\overline{W}^{k+1}(x) = e^x$ for $x \ge (N-k-1)\sigma\sqrt{\Delta t}$. If $x \ge (N-k)\sigma\sqrt{\Delta t}$, then

$$\begin{aligned}\overline{W}^k(x) &= \max\{e^{-(r+\alpha)\Delta t}[pu\overline{W}^{k+1}((x-\sigma\sqrt{\Delta t})^+) + (1-p)d\overline{W}^{k+1}(x+\sigma\sqrt{\Delta t})], e^x\}\\ &= \max\{e^{-(r+\alpha)\Delta t}[pue^{x-\sigma\sqrt{\Delta t}} + (1-p)de^{x+\sigma\sqrt{\Delta t}}], e^x\}\\ &= \max\{e^{-(r+\alpha)\Delta t}e^x, e^x\} = e^x,\end{aligned}$$

which is the desired result.

To simplify notation, (7.5) will also be written as

$$\overline{W}^n(x) = F(\Delta t)\overline{W}^{n+1}(x). \tag{7.7}$$

LEMMA 7.6. *For* Δt *given, there exists unique element* $\overline{W}_{\Delta t}(x)$ *satisfying* $\overline{W}_{\Delta t}(x) - e^x \in L^\infty(R^+)$ *such that*

$$\overline{W}_{\Delta t}(x) = F(\Delta t)\overline{W}_{\Delta t}(x). \tag{7.8}$$

In addition, $\overline{W}_{\Delta t}(x)$ *is a monotone function of* x *and*

$$\overline{W}^n(x) \le \overline{W}_{\Delta t}(x). \tag{7.9}$$

Proof. Let $\widetilde{W}^n(x) = \overline{W}^n(x) - e^x$. Then $\widetilde{W}^n(x)$ satisfies

$$\widetilde{W}^n(x) = F(\Delta t)(\widetilde{W}^{n+1}(x) + e^x) - e^x \widehat{=} G(\Delta t)\widetilde{W}^{n+1}(x).$$

By (7.6), $\widetilde{W}^n(x) \in L^\infty(R^+)$. Hence $G(\Delta t)$ can be regarded as a mapping from $L^\infty(R^+)$ to $L^\infty(R^+)$. Next we will show $G(\Delta t)$ is a contraction mapping. Let $U(x)$, $V(x) \in L^\infty(R^+)$. Then

$$\begin{aligned}&\|G(\Delta t)U(x) - G(\Delta t)V(x)\|_\infty\\ &= \|F(\Delta t)(U(x)+e^x) - F(\Delta t)(V(x)+e^x)\|_\infty\\ &\le e^{-(r+\alpha)\Delta t}[pu + (1-p)d]\,\|U(x) - V(x)\|_\infty\\ &= e^{-\alpha\Delta t}\,\|U(x) - V(x)\|_\infty.\end{aligned}$$

Therefore, there exists a unique element $\widetilde{W}_{\Delta t}(x) \in L^\infty(R^+)$ such that $\widetilde{W}_{\Delta t}(x) = G(\Delta t)\widetilde{W}_{\Delta t}(x)$. Owing to Lemma 7.5, $\widetilde{W}_{\Delta t}(x)$ is a monotone function of x and

$$\widetilde{W}^n(x) \le \widetilde{W}_{\Delta t}(x).$$

This completes the proof by denoting $\overline{W}_{\Delta t}(x) = \widetilde{W}_{\Delta t}(x) + e^x$.

Proof of Lemma 7.4. The idea of the proof stems from Dai [10]. Let $\Delta x = \sigma\sqrt{\Delta t}$, $x_j = j\Delta x$, and $u^j = e^{x_j}$, $j = 0, 1, \ldots$. It is not hard to see that $\overline{W}_{\Delta t}(x_j)$ satisfies

$$\begin{cases} \overline{W}_{\Delta t}(x_j) = \max\{e^{-(r+\alpha)\Delta t}[pu\overline{W}_{\Delta t}(x_{j-1}) + (1-p)d\overline{W}_{\Delta t}(x_{j+1})], u^j\}, \ j \geq 1, \\ \overline{W}_{\Delta t}(x_0) = e^{-(r+\alpha)\Delta t}[pu\overline{W}_{\Delta t}(x_0) + (1-p)d\overline{W}_{\Delta t}(x_1)], \end{cases}$$

which is equivalent to a free boundary problem of a difference equation as follows:

$$\overline{W}_{\Delta t}(x_j) = e^{-(r+\alpha)\Delta t}[pu\overline{W}_{\Delta t}(x_{j-1}) + (1-p)d\overline{W}_{\Delta t}(x_{j+1})] \text{ for } 1 \leq j < j_\infty,$$

$$\overline{W}_{\Delta t}(x_0) = e^{-(r+\alpha)\Delta t}[pu\overline{W}_{\Delta t}(x_0) + (1-p)d\overline{W}_{\Delta t}(x_1)], \tag{7.10}$$

$$\overline{W}_{\Delta t}(x_{j_\infty}) = u^{j_\infty}, \qquad \overline{W}_{\Delta t}(x_{j_\infty+1}) = u^{j_\infty+1}. \tag{7.11}$$

Here j_∞ is the point of free boundary to be determined. We claim

$$\overline{W}_{\Delta t}(x_j) = C_1\xi_1^j + C_2\xi_2^j \text{ for } 0 \leq j \leq j_\infty + 1, \tag{7.12}$$

where ξ_1, ξ_2 are two real roots of the equation $\xi = e^{-(r+\alpha)\Delta t}(pu + (1-p)d\xi^2)$, namely,

$$\xi_{1,2} = \frac{e^{(r+\alpha)\Delta t} \pm \sqrt{e^{2(r+\alpha)\Delta t} - 4p(1-p)}}{2(1-p)d}. \tag{7.13}$$

To determine constants C_1, C_2, and j_∞, we make use of boundary condition (7.10) and free boundary condition (7.11); we have

$$\frac{C_1}{C_2} = \frac{(e^{(r+\alpha)\Delta t} - pu) - (1-p)d\xi_2}{(1-p)d\xi_1 - (e^{(r+\alpha)\Delta t} - pu)}, \tag{7.14}$$

$$\overline{W}_{\Delta t}(x_{j_\infty}) = C_1\xi_1^{j_\infty} + C_2\xi_2^{j_\infty} = u^{j_\infty}, \tag{7.15}$$

$$\overline{W}_{\Delta t}(x_{j_\infty+1}) = C_1\xi_1^{j_\infty+1} + C_2\xi_2^{j_\infty+1} = u^{j_\infty+1}. \tag{7.16}$$

By solving (7.14)–(7.16), we get

$$C_1 = \frac{\xi_2 u^{j_\infty} - u^{j_\infty+1}}{\xi_1^{j_\infty}(\xi_2 - \xi_1)}, \qquad C_2 = \frac{\xi_1 u^{j_\infty} - u^{j_\infty+1}}{\xi_2^{j_\infty}(\xi_1 - \xi_2)}, \tag{7.17}$$

and

$$j_\infty = \frac{1}{\ln\xi_2 - \ln\xi_1} \ln\left(-\frac{(e^{(r+\alpha)\Delta t} - pu) - (1-p)d\xi_2}{(1-p)d\xi_1 - (e^{(r+\alpha)\Delta t} - pu)} \frac{\xi_1 - u}{\xi_2 - u}\right) \tag{7.18}$$

Noticing that $\overline{W}_{\Delta t}(x)$ is monotone with respect to x and combining with (7.12), we have

$$\overline{W}_{\Delta t}(x) \leq \max(e^{x+\Delta x}, e^{j_\infty \Delta x}).$$

By symbol operation, one gets

$$\lim_{\Delta t \to 0} j_\infty \Delta x = \frac{1}{\lambda_- - \lambda_+} \ln\frac{\lambda_-(\lambda_+ - 1)}{\lambda_+(\lambda_- - 1)} < \infty,$$

where $\lambda_\pm$ are given by (7.3). Then for sufficiently small Δt,

$$\overline{W}_{\Delta t}(x) \leq \max\left(e^x, \left(\frac{\lambda_-(\lambda_+ - 1)}{\lambda_+(\lambda_- - 1)}\right)^{1/(\lambda_- - \lambda_+)}\right) + 1.$$

Together with (7.4) and (7.9), this implies (7.2), which completes the proof of Lemma 7.4.

We now prove Theorem 7.3. The idea is based on [4] and [14].

Proof of Theorem 7.3. Since V^* and V_* are well defined, it is obvious that $V^* \in USC$ and $V_* \in LSC$, and $V_*(S,A,t) \le V^*(S,A,t)$. If we show that V^* and V_* are the viscosity subsolution and supersolution of (3.6), respectively, then in terms of the comparison principle (Lemma 7.2), we deduce $V^*(S,A,t) \le V_*(S,A,t)$ and thus $V^*(S,A,t) = V_*(S,A,t) = V(S,A,t)$, which is the desired conclusion.

We need only to show that V^* is a subsolution of (3.6), (3.2) (and (3.3) for lookback options). It can be shown that $V^*(S,A,T) \le \Lambda(S,A)$ (see [11]). Suppose that for $\phi \in C^{2,1}(\mathcal{D} \times (0,T])$, $V^* - \phi$ attains a local maximum at $(S_0,A_0,t_0) \in \mathcal{D} \times (0,T)$ and $(V^* - \phi)(S_0,A_0,t_0) = 0$. We might as well assume that (S_0,A_0,t_0) is a strict local maximum on $B_r = \{t_0 \le t \le t_0 + r, |S - S_0| \le r, |A - A_0| \le r\}$, $r > 0$. By the definition of V^*, there exists a sequence $u_{\Delta t_k}(S_k,A_k,t_k)$ such that $\Delta t_k \to 0$, $(S_k,A_k,t_k) \to (S_0,A_0,t_0)$, $V_{\Delta t_k}(S_k,A_k,t_k) \to V^*(S_0,A_0,t_0)$ when $k \to \infty$. Assuming that $(\widehat{S}_k,\widehat{A}_k,\widehat{t}_k)$ is a global maximum point of $V_{\Delta t_k} - \phi$ on B_r, we can deduce that there is a subsequence $V_{\Delta t_{k_i}}(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i})$ such that

$$\begin{aligned} &\Delta t_{k_i} \to 0,\ (\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) \to (S_0,A_0,t_0), \\ &(V_{\Delta t_{k_i}} - \phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) \to (V^* - \phi)(S_0,A_0,t_0) \\ &\qquad\qquad\qquad\qquad\qquad\qquad \text{as } k_i \to \infty. \end{aligned} \tag{7.19}$$

Indeed, suppose $(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) \to (\widehat{S},\widehat{A},\widehat{t})$; then

$$\begin{aligned} (V^* - \phi)(S_0,A_0,t_0) &= \lim_{k_i \to \infty} (V_{\Delta t_{k_i}} - \phi)(S_{k_i},A_{k_i},t_{k_i}) \\ &\le \lim_{k_i \to \infty} (V_{\Delta t_{k_i}} - \phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) \le (V^* - \phi)(\widehat{S},\widehat{A},\widehat{t}), \end{aligned}$$

which forces $(\widehat{S},\widehat{A},\widehat{t}) = (S_0,A_0,t_0)$ since (S_0,A_0,t_0) is a local strict maximum point of $V^* - \phi$. Therefore

$$(V_{\Delta t_{k_i}} - \phi)(\cdot,\cdot,\widehat{t}_{k_i} + \Delta t_{k_i}) \le (V_{\Delta t_{k_i}} - \phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) \ \ in\ B_r;$$

that is,

$$V_{\Delta t_{k_i}}(\cdot,\cdot,\widehat{t}_{k_i} + \Delta t_{k_i}) \le \phi(\cdot,\cdot,\widehat{t}_{k_i} + \Delta t_{k_i}) + (V_{\Delta t_{k_i}} - \phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) \quad \text{in } B_r.$$

Then

$$\begin{aligned} &V_{\Delta t_{k_i}}(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) \\ &= \max\{F_{\Delta t_{k_i}} V_{\Delta t_{k_i}}(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}), \Lambda(\widehat{S}_{k_i},\widehat{A}_{k_i})\} \\ &\le \max\{F_{\Delta t_{k_i}} \phi(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) + e^{-r\Delta t_{k_i}}(V_{\Delta t_{k_i}} - \phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}), \Lambda(\widehat{S}_{k_i},\widehat{A}_{k_i})\}, \end{aligned}$$

namely,

$$\begin{aligned} \min\{&(\phi - F_{\Delta t_{k_i}}\phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) + (1 - e^{-r\Delta t_{k_i}})(V_{\Delta t_{k_i}} - \phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}), \\ &V(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) - \Lambda(\widehat{S}_{k_i},\widehat{A}_{k_i})\} \le 0. \end{aligned} \tag{7.20}$$

Here the operator $F_{\Delta t_{k_i}}$ is given by (3.7). Dividing the first argument in the min by

$\Delta t e^{-r\Delta t_{k_i}}$, letting $k_i \to \infty$, and noticing that

$$\frac{1-e^{-r\Delta t_{k_i}}}{\Delta t e^{-r\Delta t_{k_i}}}(V_{\Delta t_{k_i}}-\phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) \to (V^*-\phi)(S_0,A_0,t_0)=0, \tag{7.21}$$

we get by consistency and (7.19) that

$$\min\left\{-\frac{\partial\phi}{\partial t}-\mathcal{L}\phi, V^*-\Lambda\right\}_{(S_0,A_0,t_0)} \le 0,$$

which yields the desired result because of $V^*(S_0,A_0,t_0)=\phi(S_0,A_0,t_0)$.

For lookback options (fixed strike call, for example), if $(S_0,A_0,t_0)\in\partial\mathcal{D}\times(0,T)$ and (7.19) holds, we might as well assume either $(\widehat{S}_{k_i},\widehat{A}_{k_i})\in\mathcal{D}$ for all k_i or $(\widehat{S}_{k_i},\widehat{A}_{k_i})\in\partial\mathcal{D}$ for all k_i. If it is the former, we can use the same argument as before to get $\min\{-\frac{\partial\phi}{\partial t}-\mathcal{L}\phi,\phi-\Lambda\}_{(S_0,A_0,t_0)}\le 0$. If $(\widehat{S}_{k_i},\widehat{A}_{k_i})\in\partial\mathcal{D}$, i.e., $\widehat{S}_{k_i}=\widehat{A}_{k_i}$, then

$$\widehat{A}^u_{k_i}=\widehat{S}_{k_i}u \text{ and } \widehat{A}^d_{k_i}=\widehat{S}_{k_i} \tag{7.22}$$

Using (7.22) and (3.8), we get

$$\begin{aligned}(\phi-F_{\Delta t_{k_i}}\phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}) &= \left(-\frac{\partial\phi}{\partial t}-\mathcal{L}\phi\right)\Delta t_{k_i}-\frac{\sigma\widehat{S}_{k_i}}{2}\frac{\partial\phi}{\partial A}\Delta t_{k_i}^{1/2}+O(\Delta t_{k_i}^2)\\ &= -\frac{\sigma\widehat{S}_{k_i}}{2}\frac{\partial\phi}{\partial A}\Delta t_{k_i}^{1/2}+O(\Delta t_{k_i}).\end{aligned}$$

Combining with (7.20), which can also be similarly obtained in this case, we deduce

$$\min\left\{-\frac{\sigma\widehat{S}_{k_i}}{2}\frac{\partial\phi}{\partial A}\Delta t_{k_i}^{1/2}+O(\Delta t_{k_i})+(1-e^{-r\Delta t_{k_i}})(V_{\Delta t_{k_i}}-\phi)(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i}),\right.$$
$$\left. V(\widehat{S}_{k_i},\widehat{A}_{k_i},\widehat{t}_{k_i})-\Lambda(\widehat{S}_{k_i},\widehat{A}_{k_i})\right\}\le 0.$$

Dividing the first argument in the min by $\frac{\sigma\widehat{S}_{k_i}}{2}\Delta t^{1/2}e^{-r\Delta t_{k_i}}$, letting $k_i\to\infty$, and noticing (7.21), we then get by (7.19)

$$\min\left\{-\frac{\partial\phi}{\partial A},\phi-\Lambda\right\}_{(S_0,A_0,t_0)}\le 0.$$

Hence, in either case, we have

$$\min\left\{\min\left\{-\frac{\partial\phi}{\partial t}-\mathcal{L}\phi,\phi-\Lambda\right\},-\frac{\partial\phi}{\partial A}\right\}_{(S_0,A_0,t_0)}\le 0.$$

The proof is complete.

Theorem 7.3 indicates that BTMs for American path-dependent options are locally uniformly convergent. It is clear that V^* and V_* are well defined for European path-dependent options because the prices of European options computing by BTMs are always less than those of the corresponding American options. Similar arguments

also give the convergence of BTMs for European path-dependent options. As a result, we assert the following.

THEOREM 7.7. *Binomial tree methods for European/American path-dependent options are uniformly convergent in any bounded closed domain of* $\mathcal{D} \times (0, T)$.

REMARK 9. *Clearly the convergence proof of BTMs remains valid at* $t = 0$ *for lookback options. By virtue of Remark* 1*, the convergence result at* $t = 0$ *for European Asian options is not too difficult an extension. However, for American Asian options, the convergence at* $t = 0$ *is currently not available because we cannot prove the strong comparison principle in* $\mathcal{D} \times [0, T)$ *(see also Remark* 3*).*

Due to Lemma 5.2 and Theorems 7.3 and 7.7, we have the following.

COROLLARY 7.8. *Let* $V_G(S, A, t)$*,* $V_A(S, A, t)$*, and* $V_L(S, A, t)$ *be the solutions of the continuous models for floating strike geometric average, arithmetic average, and lookback put options (or corresponding fixed strike call options); then we have*

$$V_G(S, A, t) \le V_A(S, A, t) \le V_L(S, \max(S, A), t).$$

We conclude the paper with the following remark.

REMARK 10. *It is well known that the BTM is not feasible for pricing arithmetic average options because the number of possible arithmetic average values increases exponentially with the number of timesteps. Barraquand and Pudet* [5] *and Hull and White* [13] *present modified BTMs that restrict the possible average values to a set of predetermined values. Our technique can also be applied to prove the convergence of their methods. We refer interested readers to* [15] *for details.*

CONVERGENCE OF PETVIASHVILI'S ITERATION METHOD FOR NUMERICAL APPROXIMATION OF STATIONARY SOLUTIONS OF NONLINEAR WAVE EQUATIONS*

DMITRY E. PELINOVSKY† AND YURY A. STEPANYANTS‡

In memory of Vladimir I. Petviashvili (1936–1993)*, who made an outstanding contribution to the theory of nonlinear waves.*

Abstract. We analyze a heuristic numerical method suggested by V.I. Petviashvili in 1976 for approximation of stationary solutions of nonlinear wave equations. The method is used to construct numerically the solitary wave solutions, such as solitons, lumps, and vortices, in a space of one and higher dimensions. Assuming that the stationary solution exists, we find conditions when the iteration method converges to the stationary solution and when the rate of convergence is the fastest. The theory is illustrated with examples of physical interest such as generalized Korteweg–de Vries, Benjamin–Ono, Zakharov–Kuznetsov, Kadomtsev–Petviashvili, and Klein–Gordon equations.

Key words. nonlinear evolution equations, solitary waves, numerical approximations, iteration methods, convergence and stability, linearized operators

1. Introduction.

Nonlinear waves and vortices are often described by partial differential equations, whose solutions cannot be found analytically even in a space of one dimension. Numerical computations are used to approximate various solutions, including stationary solutions. An effective numerical method for computing solitary wave solutions in a space of two dimensions was proposed by V. I. Petviashvili in the context of the Kadomtsev–Petviashvili equation with positive dispersion (KPI equation) [P76]. The numerical method was shown to converge to a stationary solution, but no analysis or proof was given. One year later, the very same solution was found analytically [MZ77], referred to as the two-dimensional soliton or lump. After the pioneering work [P76], Petviashili's numerical method was applied to numerous nonlinear problems in modern mathematical physics [PP92].

In this paper, we prove the convergence theorem for Petviashvili's numerical method in a context of a nonlinear scalar wave equation with power nonlinearity. We assume that the stationary solution exists in a suitable function space, when the method is well defined. The method clearly diverges in the cases when no stationary solution exists in such spaces. We derive conditions on parameters of the numerical method and on the spectrum of a linearized operator associated with the stationary solution, when the method converges to the stationary solution.

We start with a nonlinear scalar wave equation with power nonlinearity in one dimension:

$$u_t - (\mathcal{L}u)_x + pu^{p-1}u_x = 0, \tag{1.1}$$

where $u : \mathbb{R} \times \mathbb{R}_+ \mapsto \mathbb{R}$, $p > 1$, and $\mathcal{L}$ is a linear self-adjoint nonnegative pseudodiffer-

‡Environment at ANSTO, PMB 1, Menai, NSW, 2234, Australia (ysx@ansto.gov.au).

ential operator in x with constant coefficients, such that

$$\langle u, \mathcal{L}u\rangle = \langle \mathcal{L}u, u\rangle \geq 0, \qquad \langle f, g\rangle = \int_{-\infty}^{\infty} \bar{f}(x)g(x)\,dx. \tag{1.2}$$

Stationary solutions of (1.1) are of the form $u(x,t) = \Phi(x - ct)$, where c is an eigenvalue and $\Phi(x)$ is a bound state of the boundary-value problem on $x \in \mathbb{R}$,

$$c\Phi + \mathcal{L}\Phi = \Phi^p, \tag{1.3}$$

such that $\lim_{|x|\to\infty} \Phi(x) = 0$. The paramater c, which is typically continuous, has a physical meaning of a speed of the stationary wave. The bound state $\Phi(x)$ belongs to the function space $X(\mathbb{R})$, defined in Assumption 1.1.

We employ the Fourier transform,

$$u(x) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \hat{u}(k)e^{ikx}dk, \quad \hat{u}(k) = \int_{-\infty}^{\infty} u(x)e^{-ikx}\,dx \tag{1.4}$$

and rewrite the boundary–value problem (1.3) in the form

$$[c + v(k)]\,\hat{\Phi}(k) = \widehat{\Phi^p}(k), \tag{1.5}$$

where $v(k)$ is the range of $\mathcal{L}$ in the Fourier space. If $\mathcal{L}$ is a nonnegative pseudodifferential operator of order m, the function $v(k)$ is an mth order polynomial of $|k|$, such that $v(k) \geq 0$. The function $v(k)$ has meaning of phase velocity of linear waves (infinitesimal perturbations) of the scalar wave equation (1.1). Resonance between nonlinear bound states and linear waves is excluded if $c + v(k) \neq 0$ for any $k \in \mathbb{R}$. For the nonnegative operator $\mathcal{L}$ with $v(k) \geq 0$, the resonance is excluded for $c > 0$.

Assumption 1.1. Let m be the order of a linear pseudodifferential operator $\mathcal{L}$, $p > 1$, $v(k) \geq 0$, and $c > 0$. There exists a real analytical solution of the boundary-value problem (1.5) in the function space

$$X = L^2(\mathbb{R}) \cap L^{p+1}(\mathbb{R}) \cap H^{m/2}(\mathbb{R}). \tag{1.6}$$

A naive iterative algorithm for numerical approximation of $\hat{\Phi}(k)$ in the problem (1.5) can be proposed in the form

$$\widehat{u}_{n+1}(k) = \frac{\widehat{u_n^p}(k)}{c + v(k)}, \tag{1.7}$$

where $\widehat{u}_n(k)$ is the Fourier transform of $u_n(x)$ and $u_n(x)$ is the nth iteration of the numerical solution. However, this algorithm usually diverges, even if a fixed point $\hat{\Phi}(k)$ exists in the nonlinear problem (1.5). A modified iterative procedure is proposed by introducing the stabilizing factor M_n [P76],

$$\widehat{u}_{n+1}(k) = M_n^{\gamma}\frac{\widehat{u_n^p}(k)}{c + v(k)}, \tag{1.8}$$

where the stabilizing factor M_n is computed as

$$M_n = M_n[\widehat{u}_n] = \frac{\int_{-\infty}^{\infty} [c + v(k)]\,[\widehat{u}_n(k)]^2\,dk}{\int_{-\infty}^{\infty} \widehat{u}_n(k)\widehat{u_n^p}(k)\,dk}, \tag{1.9}$$

and γ is a free parameter, which must be chosen for convergence of the sequence $\{u_n(x)\}_{n=0}^{\infty}$. The fixed points of the iterative map (1.8)–(1.9) are the same as the bound states $\hat{\Phi}(k)$ of the nonlinear boundary-value problem (1.5).

LEMMA 1.2. *A set of fixed points of the iteration map* (1.8)–(1.9) *coincides with a set of bound states* $\hat{\Phi}(k)$ *of the boundary-value problem* (1.5)*, provided that* $\gamma \neq 1+2n$, $n \in \mathbb{Z}$.

Proof. If $\widehat{u}_n(k) = \hat{\Phi}(k)$ is a solution of the boundary-value problem (1.5), then $M_n = 1$ from (1.9) and $\widehat{u}_{n+1}(k) = \hat{\Phi}(k)$ from (1.8). Therefore, the solution $\hat{\Phi}(k)$ is a fixed point of the iteration map (1.8)–(1.9). In the other direction, let $\widehat{u}_*(k)$ be a fixed point of the iteration map (1.8)–(1.9). Multiplying (1.8) by $[c+v(k)]\widehat{u}_*(k)$ and integrating over k, we find $M_* = M_*^{\gamma}$. When $\gamma \neq 1+2n$, $n \in \mathbb{Z}$, there exist only two solutions: $M_* = 0$ or $M_* = 1$. Since $c + v(k) > 0$ for any $k \in \mathbb{R}$, the former solution is equivalent to a trivial zero fixed point: $\widehat{u}_*(k) = 0$. The fixed point of (1.8) with $M_* = 1$ satisfies the boundary-value problem (1.5), such that $\widehat{u}_*(k) = \hat{\Phi}(k)$. □

When $\gamma = 0$, the iterative method (1.8) is the same as in (1.7) and it diverges in most cases as was mentioned above. Nevertheless, a nonempty range for γ can be found empirically, when the method converges to the bound state $\Phi(x)$, starting with $u_0 \in X(\mathbb{R})$ such that $u_n \in X(\mathbb{R})$, $\lim_{n\to\infty} u_n(x) = \Phi(x)$, and $\lim_{n\to\infty} M_n = 1$. For $p = 2$ (quadratic nonlinearity), Petviashvili has found empirically that the iteration method (1.8)–(1.9) converges for $1 < \gamma < 3$, with the fastest rate of convergence at $\gamma = 2$ [PP92]. He also noticed that the fastest rate of convergence occurs when the degree of the uniformity of the right-hand side of (1.8) is zero with respect to $\widehat{u}_n(k)$. The convergence results do not depend on the actual dependence $v(k)$, provided that $c + v(k) > 0$ [PP92].

In this paper, we prove that the iteration method (1.8)–(1.9) converges for $1 < \gamma < (p+1)/(p-1)$ under some additional assumptions on the spectrum of a linearized operator associated with the bound state $\Phi(x)$. The fastest rate of convergence occurs for $\gamma = \gamma_* = p/(p-1)$.

From a practical point, the iteration procedure can be stopped when $|M_n - 1| \leq \varepsilon$ for any given small $\varepsilon > 0$. Therefore, parameter ε defines the distance between $u_n(x)$ and $\Phi(x)$ that measures the numerical error in the sense of the integrals in (1.9). Two additional sources of numerical errors come from the use of spectral methods, such as (i) the truncation of the integration domain $k \in \mathbb{R}$ by a finite interval $k \in [-K, K]$ and (ii) the discretization of the integrals at a finite number of grid points.

The paper is organized as follows. Section 2 describes properties of the linearized operator associated with the scalar wave equation (1.1) and also formulates the main convergence theorem. Section 3 presents the proof of the convergence theorem. Convergence of the special sequences, which are self-similar to the bound states, is considered in section 4. Examples of the iteration method (1.8)–(1.9) in one and two dimensions are studied in sections 5 and 6.

2. Spectral properties of the linearized operator. Here we study properties of the linearized operator associated with the nonlinear wave equation (1.1) at $u = \Phi(x - ct)$,

$$\mathcal{H} = c + \mathcal{L} - p\Phi^{p-1}(x), \tag{2.1}$$

such that $\mathcal{H} : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ and $\langle f, \mathcal{H}g\rangle = \langle \mathcal{H}f, g\rangle$. Since the operator $\mathcal{H}$ is self-adjoint in $L^2(\mathbb{R})$, its spectrum is real, eigenvalues of the discrete spectrum have equal geometric and algebraic multiplicities, and the spectral decomposition of $L^2(\mathbb{R})$ is orthogonal.

The continuous spectrum of $\mathcal{H}$ is positive and bounded away from zero under Assumption 1.1. The null-space of $\mathcal{H}$ is not empty and includes at least one eigenfunction: $\mathcal{H}\Phi'(x) = 0$, since the nonlinear equation (1.1) has the translation symmetry: $u(x,t) \to u(x-x_0,t)$. The negative spectrum of $\mathcal{H}$ is not empty, since $\mathcal{H}\Phi(x) = (1-p)\Phi^p(x)$ and

$$\begin{aligned}\langle \mathcal{H}\Phi, \Phi\rangle = -(p-1)\langle \Phi^p, \Phi\rangle &= -\frac{(p-1)}{2\pi}\int_{-\infty}^{\infty} \widehat{\Phi}(k)\widehat{\Phi^p}(k)dk \\ &= -\frac{(p-1)}{2\pi}\int_{-\infty}^{\infty} [c+v(k)]\left[\hat{\Phi}(k)\right]^2 dk \ < 0. \end{aligned} \tag{2.2}$$

The analysis does not depend on the number and type of positive eigenvalues of $\mathcal{H}$. We summarize the main properties of the spectrum of $\mathcal{H}$ in the following assumption.

Assumption 2.1. The spectrum of $\mathcal{H}$ in $L^2(\mathbb{R})$ consists of eigenvalues μ of the discrete spectrum for $\mu < c$ and the continuous spectrum for $\mu \geq c$. The null-space of $\mathcal{H}$ is one dimensional with the eigenfunction $\Phi'(x)$. The negative space of $\mathcal{H}$ has dimension $n(\mathcal{H}) \geq 1$.

Two linear eigenvalue problems are associated with the linearized operator $\mathcal{H}$ on $x \in \mathbb{R}$:

$$\text{Problem I:} \qquad \partial_x \mathcal{H} U = \lambda U \tag{2.3}$$

and

$$\text{Problem II:} \qquad \mathcal{H} U = \lambda(c + \mathcal{L})U. \tag{2.4}$$

Problem I occurs in the linearization of the nonlinear wave equation (1.1) with a small perturbation to the bound state: $u = \Phi(x-ct) + U(x-ct)e^{\lambda t}$. The nonzero spectrum of $\partial_x \mathcal{H}$ is defined in the constrained function space $X_c(\mathbb{R})$,

$$X_c = \{U \in L^2(\mathbb{R}) : \ \langle \Phi, U\rangle = 0\}, \tag{2.5}$$

since $\lambda\langle \Phi, U\rangle = \langle \Phi, \partial_x \mathcal{H} U\rangle = -\langle \mathcal{H}\Phi', U\rangle = 0$. The spectrum of $\partial_x \mathcal{H}$ in $X_c(\mathbb{R})$ gives stability or instability of the bound state $\Phi(x)$ in the time evolution of the nonlinear wave equation (1.1). If there exists $\lambda \in \mathbb{C}$ such that $\mathrm{Re}(\lambda) > 0$, the bound state is spectrally unstable and the perturbations grow exponentially in time. If the spectrum is located at the axis $\mathrm{Re}(\lambda) = 0$, the bound state is weakly spectrally stable and the perturbation may grow at most as powers of time. The spectral stability-instability theorem for the scalar wave equation (1.1) can be formulated as follows.

THEOREM 2.2 ([BSS87, PW92]). *. Let $P_s(c) = \langle \Phi, \Phi\rangle$ be a C^1 function of c for $c > 0$ and Assumptions* 1.1 *and* 2.1 *be satisfied. The bound state $\Phi(x)$ is weakly spectrally stable with respect to the time evolution problem* (2.3) *if $n(\mathcal{H}) = 1$ and $P_s'(c) > 0$. The bound state $\Phi(x)$ is spectrally unstable if $n(\mathcal{H}) = 1$ and $P_s'(c) < 0$. The negative space of the operator $\mathcal{H}$ in the constrained function space $X_c(\mathbb{R})$ has the dimension $n(\mathcal{H}) - 1$ if $P_s'(c) > 0$ and the dimension $n(\mathcal{H})$ if $P_s'(c) < 0$.*

Spectral stability of the bound state $\Phi(x)$ occurs if the negative space of $\mathcal{H}$ is empty in the constrained function space $X_c(\mathbb{R})$ and the spectral instability occurs if the negative space of $\mathcal{H}$ is one dimensional in $X_c(\mathbb{R})$. On the contrary, the convergence of the iteration method (1.8)–(1.9) does not depend on spectral stability or instability of bound states. Convergence of the iteration method is related to the spectrum of Problem II, which occurs in the linearization of the iteration method (1.8)–(1.9); see (3.5) below.

We consider the spectrum of the operator $(c+\mathcal{L})^{-1}\mathcal{H}$ in a different constrained space $X_p(\mathbb{R})$,

$$X_p = \{U \in L^2(\mathbb{R}): \ \langle \Phi^p, U\rangle = 0\}. \tag{2.6}$$

The spectrum of $(c+\mathcal{L})^{-1}\mathcal{H}$ diagonalizes simultaneously two linear operators: $\mathcal{H}$ and $(c+\mathcal{L})$. Since $(c+\mathcal{L})$ is positive, all eigenvalues λ are real and the algebraic multiplicity of eigenvalues equals to their geometric multiplicity. Therefore, the spectral decomposition of $L^2(\mathbb{R})$ is orthogonal with respect to the positive weighted inner product $\langle U, (c+\mathcal{L})U\rangle$. In particular, due to the constraint (2.6), the eigenfunction $U(x)$ is orthogonal with respect to $(c+\mathcal{L})$ to $\Phi(x)$, which is the eigenfunction of Problem II for $\lambda = 1-p < 0$.

Before formulating our main result (Theorem 2.8), we study the spectrum of $(c+\mathcal{L})^{-1}\mathcal{H}$ in $X_p(\mathbb{R})$ under Assumption 2.1. Our analysis appears similar to the Birman–Schwinger principle for Schrödinger operators in quantum mechanics [BS87].

LEMMA 2.3. *The negative space of $\mathcal{H}$ in $X_p(\mathbb{R})$ has the dimension $n(\mathcal{H})-1$.*

Proof. The number of eigenvalues of $\mathcal{H}$ in the constrained function space $X_p(\mathbb{R})$ can be found from the constrained eigenvalue problem

$$\mathcal{H}\psi = \mu\psi - \nu\Phi^p(x), \tag{2.7}$$

where (μ,ψ) is the eigenvalue-eigenfunction pair of $\mathcal{H}$ in $X_p(\mathbb{R})$ and ν is the Lagrange multiplier defined from the constraint $\langle \Phi^p, \psi\rangle = 0$. The operator $\mathcal{H}-\mu$ is invertible for any μ not in the spectrum of $\mathcal{H}$, where the spectral decomposition for $\psi(x)$ takes the form

$$\psi(x) = \nu\left[\sum_{\mu_k<0}\frac{\langle u_k,\Phi^p\rangle}{\mu-\mu_k}u_k(x) + \sum_{\mu_k>0}\frac{\langle u_k,\Phi^p\rangle}{\mu-\mu_k}u_k(x)\right]. \tag{2.8}$$

Here (μ_k,u_k) is the eigenvalue-eigenfunction pair of $\mathcal{H}$ in $L^2(\mathbb{R})$ and the formal sum $\sum_{\mu_k>0}$ includes also the integral over the positive continuous spectrum of $\mathcal{H}$. The set of eigenfunctions $\{u_k(x)\}_k$ is assumed to be orthogonal and normalized. The set of eigenvalues μ of $\mathcal{H}$ in $X_p(\mathbb{R})$ consists of two subsets. The first subset is given by eigenvalues μ_k, whose eigenfunctions $u_k(x)$ belong to $X_p(\mathbb{R})$. The other subset is defined by zeros of the function

$$F(\mu) = \frac{1}{\nu}\langle\Phi^p,\psi\rangle = \sum_{\mu_k<0}\frac{|\langle\Phi^p,u_k\rangle|^2}{\mu-\mu_k} + \sum_{\mu_k>0}\frac{|\langle\Phi^p,u_k\rangle|^2}{\mu-\mu_k}. \tag{2.9}$$

We study zeros of $F(\mu)$ by direct application of the theory of constrained variational problems [P04]. The function $F(\mu)$ is monotonically decreasing for $\mu\le 0$ and $\mu\neq\mu_k$. Assume for simplicity that $\mu=\mu_k$ is a single eigenvalue. The function $F(\mu)$ has a jump from negative infinity at $\mu=\mu_k-0$ to positive infinity at $\mu=\mu_k+0$, if the eigenfunction $u_k(x)$ at $\mu=\mu_k$ does not belong to constrained function space $X_p(\mathbb{R})$. Otherwise, i.e., if $u_k(x)$ lies in $X_p(\mathbb{R})$, the function $F(\mu)$ is continuous at $\mu=\mu_k$. The function $F(\mu)$ approaches -0 in the limit $\mu\to-\infty$ and it approaches a positive value in the limit $\mu\to 0$,

$$F(0) = -\langle\Phi^p,\mathcal{H}^{-1}\Phi^p\rangle = \frac{1}{p-1}\langle\Phi^p,\Phi\rangle > 0, \tag{2.10}$$

where we have used the Parseval identity (2.2). The number of negative eigenvalues μ of operator $\mathcal{H}$ in $X_p(\mathbb{R})$ equals the number of zeros of the function $F(\mu)$ for $\mu<0$ and

the number of eigenfunctions $u_k(x)$ of operator $\mathcal{H}$ that belongs to the space $X_p(\mathbb{R})$ for $\mu_k < 0$. By continuity of the decreasing function $F(\mu)$ between $\mu \in [\mu_k, \mu_{k+1}]$ and by counting the jump discontinuity of $F(\mu)$ at $\mu = \mu_k$ [P04], we conclude that the number of negative eigenvalues μ of $\mathcal{H}$ in $X_p(\mathbb{R})$ equals $n(\mathcal{H}) - 1$. □

LEMMA 2.4. *The spectrum of* $(c+\mathcal{L})^{-1}\mathcal{H}$ *in* $X_p(\mathbb{R})$ *has* $n(\mathcal{H})-1$ *negative eigenvalues* λ.

Proof. By Sylvester's inertial theorem [M88, P04], the dimension of the negative space of the quadratic form $\langle U, \mathcal{H}U\rangle$ is invariant in any orthogonal basis of $X_p(\mathbb{R})$ that diagonalizes $\langle U, \mathcal{H}U\rangle$ with respect to a positive weighted inner product. One orthogonal basis for $X_p(\mathbb{R})$ is given by the eigenfunctions $\psi(x)$ of the constrained problem (2.7). The other orthogonal basis with respect to $(c + \mathcal{L})$ is defined by the eigenvalue problem (2.4). By invariance of the negative index of $\mathcal{H}$ in $X_p(\mathbb{R})$, we have $n(\mathcal{H}) - 1$ negative eigenvalues λ in Problem II. □

LEMMA 2.5. *The positive spectrum of* $(c+\mathcal{L})^{-1}\mathcal{H}$ *in* $X_p(\mathbb{R})$ *consists of infinitely many discrete eigenvalues* λ *in the interval* $0 < \lambda < 1$, *accumulating to* $\lambda \to 1^-$. *If* $\Phi^{p-1}(x) \geq 0$ *for* $x \in \mathbb{R}$, *no eigenvalues* λ *exists for* $\lambda > 1$. *If there exists* $x_0 \in \mathbb{R}$ *such that* $\Phi^{p-1}(x_0) < 0$, *the spectrum of* $(c+\mathcal{L})^{-1}\mathcal{H}$ *also includes infinitely many discrete eigenvalues in the interval* $1 < \lambda \leq \lambda_{\max}$, *accumulating to* $\lambda \to 1^+$, *where*

$$\lambda_{\max} < 1 + \frac{p}{c}\left|\min_{x\in\mathbb{R}} \Phi^{p-1}(x)\right| < \infty. \tag{2.11}$$

Proof. Positive eigenvalues λ can be estimated from (2.4) rewritten in the form

$$(c+\mathcal{L})U - \frac{p}{1-\lambda}\Phi^{p-1}(x)U = 0. \tag{2.12}$$

Since $(c + \mathcal{L})$ is positive, no continuous spectrum of the problem (2.12) exists. It was proved in [CM99] for a similar spectral problem that the spectrum of the problem (2.12) is discrete since $\mathrm{tr}M^2 < \infty$, where $M = (c+\mathcal{L})^{-1/2}\Phi^{p-1}(c+\mathcal{L})^{-1/2}$ is a bounded operator. Since the spectrum of $\Phi^{p-1}(x)$ is infinite-dimensional, the spectrum of the bounded operator M cannot be a finite rank [C01]. The potential term in (2.12) becomes singular in the limit $\lambda \to 1$ and therefore the point $\lambda = 1$ is an accumulation point of the discrete eigenvalues. If $\Phi^{p-1}(x) \geq 0$ for any $x \in \mathbb{R}$, the positive part of M and the spectrum of the problem (2.12) in the interval $0 < \lambda < 1$ are infinite-dimensional, with eigenvalues accumulating to $\lambda \to 1^-$. In this case, no eigenvalues exist for $\lambda > 1$, since

$$\lambda = 1 - p\frac{\langle U, \Phi^{p-1}U\rangle}{\langle U, (c+\mathcal{L})U\rangle} < 1. \tag{2.13}$$

If $\Phi^{p-1}(x)$ changes sign on $x \in \mathbb{R}$, the negative part of M and the spectrum of the problem (2.12) for $\lambda > 1$ are infinite-dimensional, with eigenvalues accumulating to $\lambda \to 1^+$ [C01]. Since $\langle U, \mathcal{L}U\rangle \geq 0$ and

$$\langle U, \Phi^{p-1}U\rangle > -\left(\min_{x\in\mathbb{R}} |\Phi^{p-1}(x)|\right)\ \langle U, U\rangle,$$

the largest positive eigenvalue $\lambda = \lambda_{\max}$ is bounded from above by (2.11). The spectrum of $(c + \mathcal{L})^{-1}\mathcal{H}$ is shown schematically on Figure 1. □

COROLLARY 2.6. *The spectrum of* $(c+\mathcal{L})^{-1}\mathcal{H}$ *is located below* $\lambda < 1$ *if and only if* p *is odd or the bound state of the nonlinear problem* (1.3) *is nonnegative,* $\Phi(x) \geq 0$ *on* $x \in \mathbb{R}$.

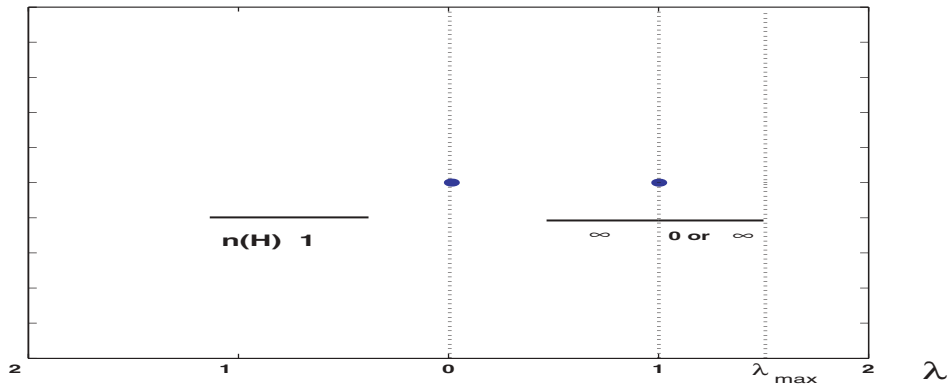

FIG. 1. *Schematical representation of the spectrum of the operator* $(c+\mathcal{L})^{-1}\mathcal{H}$.

Assumption 2.7. Either $\Phi^{p-1}(x) \geq 0$ on $x \in \mathbb{R}$ or $\lambda_{\max} < 2$.

Our main theorem prescribes convergence or divergence of the iteration method (1.8)–(1.9).

THEOREM 2.8. *Let* $\hat{\Phi}(k)$ *be a solution of the boundary-value problem* (1.5) *and Assumptions* 1.1 *and* 2.1 *be satisfied. The iteration method* (1.8)–(1.9) *converges to* $\hat{\Phi}(k)$ *in a small open neighborhood of* $\hat{\Phi}(k)$ *if* (i) $1 < \gamma < (p+1)/(p-1)$, (ii) $n(\mathcal{H}) = 1$, *and* (iii) *Assumption* 2.7 *is met. The fastest rate of convergence occurs for* $\gamma = \gamma_* \equiv p/(p-1)$. *If any of the three conditions are not met, the iteration method* (1.8)–(1.9) *diverges from* $\hat{\Phi}(k)$.

3. Contraction of the iterative method near the fixed point. Our proof of Theorem 2.8 is based on the spectral analysis of the iteration operator (1.8)–(1.9), linearized at $\hat{\Phi}(k)$, and on the application of the contraction mapping principle for nonlinear operators [HP80].

PROPOSITION 3.1. *The iteration operator* (1.8)–(1.9), *linearized at* $\hat{\Phi}(k)$, *has a spectral radius smaller than one if and only if* (i) $1 < \gamma < (p+1)/(p-1)$, (ii) $n(\mathcal{H}) = 1$, *and* (iii) *Assumption* 2.7 *is met.*

Proof. Consider $\widehat{w}_0(k) = \widehat{u}_0(k) - \hat{\Phi}(k)$ be a small perturbation to $\hat{\Phi}(k)$, such that $\langle \Phi', w_0 \rangle = 0$. The sequence $\widehat{w}_n(k) = \widehat{u}_n(k) - \hat{\Phi}(k)$ is generated by the iteration operator (1.8), linearized at $\hat{\Phi}(k)$,

$$\widehat{w}_{n+1}(k) = \gamma m_n \hat{\Phi}(k) + p \frac{\widehat{\Phi^{p-1}} * \widehat{w}_n(k)}{c + v(k)}, \tag{3.1}$$

where $*$ is the convolution operator and $m_n = M_n - 1$. The correction m_n is generated by the stabilizing factor (1.9), linearized at $\hat{\Phi}(k)$,

$$m_n = (1-p) \frac{\int_{-\infty}^{\infty} \widehat{\Phi^p}(k) \widehat{w}_n(k)\, dk}{\int_{-\infty}^{\infty} \widehat{\Phi^p}(k) \hat{\Phi}(k)\, dk}. \tag{3.2}$$

The correction term $w_n(x)$ can be decomposed explicitly as

$$w_n = a_n \Phi(x) + q_n(x), \qquad q_n \in X_p(\mathbb{R}), \tag{3.3}$$

where $X_p(\mathbb{R})$ is defined by (2.6). It follows from (3.1) and (3.2) that $m_n = (1-p)a_n$ and m_n solves the linear map

$$m_{n+1} = [p - \gamma(p-1)]\, m_n. \tag{3.4}$$

On the other hand, the correction term $q_n(x)$ solves the homogeneous part of the problem (3.1), which is equivalently rewritten on $x \in \mathbb{R}$ as

$$q_{n+1}(x) = q_n(x) - (c + \mathcal{L})^{-1}\mathcal{H}q_n(x). \tag{3.5}$$

If $1 < \gamma < (p+1)/(p-1)$, then $\lim_{n\to\infty} m_n = 0$, such that $\lim_{n\to\infty} M_n = 1$ for the stabilizing factor $M_n = 1 + m_n$. Therefore, the first term in the decomposition (3.3) vanishes as $n \to \infty$. The second term $q_n(x)$ may, however, remain finite or even grow with the number of iterations. We derive the conditions when $q_n(x)$ converges to zero as $n \to \infty$.

If $w_0(x)$ is orthogonal to Φ', then $\langle \Phi', q_0 \rangle = 0$. It follows from (3.5) that $\langle \Phi', q_n \rangle = 0$, $\forall n$. We apply, therefore, the spectral decomposition of $X_p(\mathbb{R})$, described in Lemmas 2.4 and 2.5. The sequence $\{q_n(x)\}_{n=0}^{\infty}$ is decomposed through eigenfunctions $U_k(x)$ of the operator $(c + \mathcal{L})^{-1}\mathcal{H}$ as follows:

$$q_n(x) = \sum_{k=1}^{n(\mathcal{H})-1} \alpha_k^{(n)} U_k(x) + \sum_{0<\lambda_k<1} \beta_k^{(n)} U_k(x) + \sum_{1<\lambda_k\le\lambda_{\max}} \gamma_k^{(n)} U_k(x), \tag{3.6}$$

where the first sum represents the finite-dimensional negative space of $X_p(\mathbb{R})$, the second sum represents the infinite-dimensional positive space of $X_p(\mathbb{R})$ for $0 < \lambda < 1$, and the third sum represents the infinite-dimensional positive space of $X_p(\mathbb{R})$ for $1 < \lambda \le \lambda_{\max}$, if the latter exists. The linear maps for coefficients of expansions are

$$\alpha_k^{(n+1)} = (1 + |\lambda_k|)\alpha_k^{(n)}, \quad \lambda_k < 0, \tag{3.7}$$

$$\beta_k^{(n+1)} = (1 - \lambda_k)\beta_k^{(n)}, \quad 0 < \lambda_k < 1, \tag{3.8}$$

and

$$\gamma_k^{(n+1)} = (1 - \lambda_k)\gamma_k^{(n)}, \quad 1 < \lambda_k \le \lambda_{\max}. \tag{3.9}$$

Iterations for coefficients $\alpha_k^{(n)}$ diverge for any $\lambda_k < 0$. Iterations for coefficients $\beta_k^{(n)}$ converges for any $0 < \lambda_k < 1$. Iterations for coefficients $\gamma_k^{(n)}$ diverge for any $\lambda_k \ge 2$ and converge for $1 < \lambda_k < 2$. In the limit $n \to \infty$, the correction $q_n(x)$ uniformly converges to zero if the negative space of $X_p(\mathbb{R})$ is empty, i.e., $n(\mathcal{H}) = 1$, and the positive space of $X_p(\mathbb{R})$ is empty for $\lambda_k \ge 2$. The latter condition is satisfied under Assumption 2.7, i.e., when either the third sum in (3.6) is absent (p is odd or $\Phi(x) \ge 0$ on $x \in \mathbb{R}$) or $\lambda_{\max} < 2$. We note that $\lambda_{\max}$ is bounded from above by (2.11). □

Remark 3.2. In the proof of Proposition 3.1, we have assumed that $\langle \Phi', w_0 \rangle = 0$. If $w_0(x)$ does not satisfy the constraint, iterations of the linearized operator (3.1)–(3.2) converge to the eigenfunction $\Phi'(x)$ of the kernel of $\mathcal{H}$, which simply translates the bound state $\Phi(x)$ in x.

When the kernel of $\mathcal{H}$ has dimension greater than one, the corresponding eigenfunctions translate the bound state $\Phi(x)$ to some other solutions, which typically implies bifurcations of the bound states. It is expected that the iteration method (1.8)–(1.9) selects only one branch of solutions beyond the bifurcation, i.e., the other branches of solutions have the negative index $n(\mathcal{H}) > 1$. We eliminate the bifurcation cases by Assumption 2.1, which ensures that the kernel of $\mathcal{H}$ is one dimensional.

Remark 3.3. The rate of convergence of the stabilizing factor $M_n = 1 + m_n$ becomes superlinear if $\gamma = \gamma_* = p/(p-1)$, see (3.4). However, the corrections $q_n(x)$

still converge with the linear rate at $\gamma = \gamma_*$; see (3.5). Thus, the fastest but linear rate of convergence occurs at $\gamma = \gamma_*$. This conclusion confirms the Petviashvili's conjecture on the fastest rate of convergence [PP92].

PROPOSITION 3.4. *The iteration operator* (1.8)–(1.9)*, linearized at the sequence* $\{\hat{\phi}_n(k)\}_{n=0}^{\infty}$*, is continuous in a small open neighborhood of* $\hat{\Phi}(k)$*.*

Proof. Consider a difference $\delta\hat{u}_n(k) = \hat{u}_n(k) - \hat{\phi}_n(k)$ between any two sequences $\{\hat{u}_n(k)\}_{n=0}^{\infty}$ and $\{\hat{\phi}_n(k)\}_{n=0}^{\infty}$ generated by the iteration operator (1.8)–(1.9). The sequence $\delta\hat{u}_n(k)$ is defined by the iteration operator (1.8), linearized at $\hat{\phi}_n(k)$,

$$\delta\hat{u}_{n+1}(k) = \gamma\frac{\delta M_n}{M_n}\hat{\phi}_{n+1}(k) + pM_n^{\gamma}\frac{\widehat{\phi_n^{p-1}} * \delta\hat{u}_n(k)}{c + v(k)}, \tag{3.10}$$

where $M_n = M_n[\hat{\phi}_n]$ and $\delta M_n = M_n[\hat{\phi}_n + \delta\hat{u}_n] - M_n[\hat{\phi}_n]$. The correction δM_n is generated by the stabilizing factor (1.9), linearized at $\hat{\phi}_n(k)$,

$$\delta M_n = \frac{2\int_{-\infty}^{\infty}[c + v(k)]\,\hat{\phi}_n(k)\delta\hat{u}_n(k)\,dk - (1+p)M_n\int_{-\infty}^{\infty}\widehat{\phi_n^p}(k)\delta\hat{u}_n(k)\,dk}{\int_{-\infty}^{\infty}\widehat{\phi_n^p}(k)\hat{\phi}_n(k)\,dk}. \tag{3.11}$$

The linearized iteration operator (3.10)–(3.11) is continuous with respect to $\phi_n \in X(\mathbb{R})$, where $X(\mathbb{R})$ is defined by (1.6). □

Proof of Theorem 2.8. The iteration method (1.8)–(1.9) represents a nonlinear operator $\hat{u}_{n+1} = \mathcal{A}(\hat{u}_n)$ in function space $X(\mathbb{R})$. The operator $\mathcal{A}(\hat{u}_n)$ has a continuous Frechet derivative $\mathcal{A}'(\hat{u}_n)$ in small open neighborhood of $\hat{\Phi}$ in $X(\mathbb{R})$. Under the three conditions of Proposition 3.1, the spectral radius of $\mathcal{A}'(\hat{\Phi})$ is smaller than one, i.e., $||\mathcal{A}'(\hat{\Phi})|| < 1$. By continuity of the Frechet derivative, for any ϵ with $0 < \epsilon < 1 - ||\mathcal{A}'(\hat{\Phi})||$, there is a small open ball $S(\hat{\Phi}, \delta) \in X(\mathbb{R})$ centered at $\hat{\Phi}(k)$ with the radius $\delta = \delta(\epsilon)$, such that

$$q = \sup_{\hat{u}_n \in S(\hat{\Phi},\delta)} ||\mathcal{A}'(\hat{u}_n)|| < 1. \tag{3.12}$$

It follows from [HP80, Lemma 4.4.7] that

$$||\mathcal{A}(\hat{f}) - \mathcal{A}(\hat{g})|| \leq q||\hat{f} - \hat{g}|| \tag{3.13}$$

for any $\hat{f}, \hat{g} \in S(\hat{\Phi}, \delta)$. Then, the contraction mapping theorem [HP80, Theorem 4.3.4] applies and the nonlinear operator $\mathcal{A}(\hat{u}_n)$ has a unique asymptotically stable fixed point for $\hat{u}_n \in S(\hat{\Phi}, \delta)$. Moreover, the asymptotic rate of convergence is determined by the Frechet derivative at $\hat{\Phi}$ as follows:

$$||\hat{u}_n - \hat{\Phi}|| \leq \left(||\mathcal{A}'(\hat{\Phi})|| + \epsilon\right)^n ||\hat{u}_0 - \hat{\Phi}||. \tag{3.14}$$

See [HP80, Lemma 4.4.8] for further details. □

4. Convergence of self-similar sequences. Here we derive conditions for convergence of a special sequence $\{x_n\hat{\Phi}(k)\}_{n=0}^{\infty}$, which is self-similar to $\hat{\Phi}(k)$ module to amplitude scaling. We also consider convergence of a general sequence in the small open neighborhood of $\{x_n\hat{\Phi}(k)\}_{n=0}^{\infty}$.

PROPOSITION 4.1. *Let* $\hat{\Phi}(k)$ *be a solution of the boundary-value problem* (1.5) *and Assumption* 1.1 *be satisfied. There exists a sequence* $\{x_n\hat{\Phi}(k)\}_{n=0}^{\infty}$ *in the iteration map* (1.8)–(1.9)*, which converges to* $\hat{\Phi}(k)$ *for any* $x_0 > 0$ *if* $1 < \gamma < (p+1)/(p-1)$*.*

Proof. Define $\hat{u}_0(k) = x_0\hat{\Phi}(k)$ for any $x_0 > 0$. Then, it follows from (1.5), (1.8), and (1.9) that $\hat{u}_n(k) = x_n\hat{\Phi}(k)$ for any $n \geq 0$, where x_n is defined by the power iteration map

$$x_{n+1} = M_n^\gamma x_n^p = x_n^{p-\gamma(p-1)}, \tag{4.1}$$

where $M_n = x_n^{1-p}$. The iteration map converges for $1 < \gamma < (p+1)/(p-1)$ with the limit $\lim_{n\to\infty} x_n = 1$. As a result, $\lim_{n\to\infty} \hat{u}_n(k) = \hat{\Phi}(k)$. ∎

Remark 4.2. The rate of convergence of the power iteration map (4.1) is linear for $\gamma \neq \gamma_*$, where $\gamma_* = p/(p-1)$. When $\gamma = \gamma_*$, the convergence occurs in a single iteration: $\hat{u}_1(k) = \hat{\Phi}(k)$ for any $x_0 > 0$. The starting value $\hat{u}_0(k)$ is self-similar to the bound state $\hat{\Phi}(k)$ module to amplitude scaling. The special sequence $\{\hat{u}_n(k)\}_{n=0}^\infty$ exists in the iteration map (1.8)–(1.9) due to the power nonlinearity. The special sequence does not exist for general nonlinear functions.

PROPOSITION 4.3. *Let $\hat{\Phi}(k)$ be a solution of the boundary-value problem* (1.5) *and Assumptions* 1.1 *and* 2.1 *be satisfied. Let $\{x_n\hat{\Phi}(k)\}_{n=0}^\infty$ be a self-similar sequence, where x_n is generated by the power iteration map* (4.1) *with any $x_0 > 0$. The iteration operator* (1.8)–(1.9)*, linearized at $\{x_n\hat{\Phi}(k)\}_{n=0}^\infty$, has a spectral radius smaller than one if and only if* (i) $1 < \gamma < (p+1)/(p-1)$, (ii) $n(\mathcal{H}) = 1$, *and* (iii) *Assumption* 2.7 *is met.*

Proof. We use the linear map (3.10)–(3.11) with $\hat{\phi}_n(k) = x_n\hat{\Phi}(k)$, where x_n solves the power iteration map (4.1). As a result, we find that $M_n = x_n^{1-p}$. The linear map (3.10)–(3.11) is then equivalent to the linear map (3.1)–(3.2) with the relations

$$\hat{w}_n(k) = \frac{\delta\hat{u}_n(k)}{x_n}, \quad m_n = \frac{\delta M_n}{x_n^p}.$$

Thus, Proposition 4.3 is equivalent to Proposition 3.1. ∎

5. Examples in one dimension. Here we discuss two examples of the scalar wave equation (1.1), where the iteration method (1.8)–(1.9) can be used for finding stationary solutions such as solitary waves.

Example 5.1 (generalized Korteweg–de Vries (KdV) equations). A family of generalized KdV equations is defined for $\mathcal{L} = -\partial_x^2$, such that $v(k) = k^2 \geq 0$ and $m = 2$. The bound state solutions of the boundary-value problem (1.3) exist for $p > 1$ in the analytical form (see, e.g., [PW92])

$$\Phi(x) = \left[\sqrt{\frac{(p+1)c}{2}}\,\operatorname{sech}\left(\frac{p-1}{2}\sqrt{c}x\right)\right]^{\frac{2}{p-1}}. \tag{5.1}$$

It follows from (5.1) that the bound state $\Phi(x)$ decays exponentially as

$$\lim_{|x|\to\infty} \Phi(x)e^{\sqrt{c}|x|} = a_\infty, \quad a_\infty = [2(p+1)c]^{\frac{1}{p-1}}. \tag{5.2}$$

The function $\Phi(x)$ belongs to $X(\mathbb{R})$ of Assumption 1.1. Since $\Phi(x) \geq 0$ on $x \in \mathbb{R}$, it also satisfies Assumption 2.7. The linearized operator $\mathcal{H}$ becomes a Schrödinger operator with a solvable potential,

$$\mathcal{H} = c - \partial_x^2 - \frac{p(p+1)c}{2}\operatorname{sech}^2\left(\frac{p-1}{2}\sqrt{c}x\right). \tag{5.3}$$

The Schrödinger operator (5.3) satisfies Assumption 2.1. Since $\mathcal{H}\Phi'(x) = 0$ and $\Phi(x)$ has no nodes on $x \in \mathbb{R}$, the Sturm oscillation theorem predicts only one negative eigenvalue of $\mathcal{H}$, i.e., $n(\mathcal{H}) = 1$. As a result, Theorem 2.8 applies and the iteration method (1.8)–(1.9) converges to the bound state $\hat{\Phi}(k)$ in the generalized KdV equation for any value of $p > 1$ if $1 < \gamma < (p+1)/(p-1)$.

Remark 5.2. In accordance with Theorem 2.2, the bound state $\Phi(x)$ is weakly spectrally stable with respect to the time evolution problem for $p < 5$ and spectrally unstable for $p \geq 5$ (see also [BSS87, PW92]). On the other hand, the iteration method (1.8)–(1.9) converges for any $p > 1$, irrelevantly to the stability of bound states in the time evolution problem. For instance, the interval of convergence with $p = 5$ is $1 < \gamma < 3/2$ and the interval shrinks to zero when $p \to \infty$.

Example 5.3 (generalized Benjamin–Ono (BO) equations). A family of generalized BO equations is defined for $\mathcal{L} = -\partial_x H$, where $H(u)$ is the Hilbert transform of $u(x)$,

$$H(u) = \frac{1}{\pi} \wp \int_{-\infty}^{\infty} \frac{u(z)dz}{z - x}, \tag{5.4}$$

and the symbol $\wp$ denotes the principal value of the integral. In this case, $v(k) = |k| \geq 0$ and $m = 1$. The bound state solutions of the nonlinear problem (1.3) are unknown in the analytical form except for the case $p = 2$, when

$$\Phi(x) = \frac{2c}{1 + c^2 x^2}. \tag{5.5}$$

Using the asymptotic representation for $\Phi(x) \in L^1(\mathbb{R})$,

$$H(\Phi) = -\frac{1}{\pi x} \int_{-\infty}^{\infty} \Phi(z)dz + \mathrm{O}\left(\frac{1}{x^2}\right),$$

and the balance of inverse powers of x in the problem (1.3), we derive the algebraic decay of $\Phi(x)$ at infinity,

$$\lim_{|x| \to \infty} x^2 \, \Phi(x) = a_{-2}, \quad a_{-2} = \frac{1}{\pi c} \int_{-\infty}^{\infty} \Phi(x)dx. \tag{5.6}$$

The function $\Phi(x)$ has sufficient decay at infinity to belong to $X(\mathbb{R})$ of Assumption 1.1, if it exists for $p > 1$. Since $\Phi(x) \geq 0$ on $x \in \mathbb{R}$ as follows from our numerical approximations (see Figure 2), Assumption 2.7 is satisfied. The linearized operator $\mathcal{H}$ becomes a nonlocal operator,

$$\mathcal{H} = c - \partial_x H - p\Phi^{p-1}(x). \tag{5.7}$$

It was proved in [CK80] for $p = 2$ that the nonlocal linearized operator (5.7) satisfies Assumption 2.1 and has only one negative eigenvalue, i.e., $n(\mathcal{H}) = 1$. As a result, Theorem 2.8 states that the iteration method (1.8)–(1.9) converges to the bound state $\hat{\Phi}(k)$ for the case $p = 2$ if $1 < \gamma < 3$.

We have computed the bound states $\Phi(x)$ for $p = 2, 3, 4, 5$ from the iteration method (1.8)–(1.9) starting with the Gaussian approximation $u_0(x) = \exp(-x^2)$ for $c = 1$ (see also [AS87]). The numerical approximations are plotted on Figure 2, where dots for $p = 2$ show the exact values from (5.5). Figure 3 shows convergence of the stabilizing factor M_n in the iteration method (1.8)–(1.9) with $p = 2$, for three

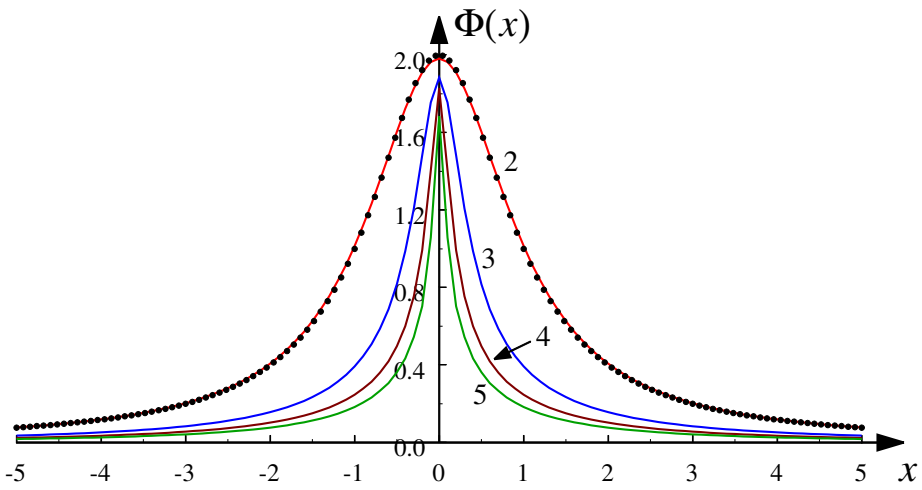

FIG. 2. *Numerical approximations of the bound states* $\Phi(x)$ *of the generalized BO equation for* $p = 2, 3, 4, 5$. *Dots on curve* 2 *show exact values from the analytical solution* (5.5).

different values of γ: $\gamma = 2$ (dots), when the rate of convergence is the fastest; $\gamma = 1.1$ (triangles), near the left boundary of the convergence interval; and $\gamma = 2.9$ (crosses), near the right boundary of the convergence interval. We conclude that the iteration method (1.8)–(1.9) converges to the bound state of the generalized BO equation for $p = 2, 3, 4, 5$ if $1 < \gamma < (p + 1)/(p - 1)$. Moreover, numerical computations show convergence of the method to a positive-definite bound state $\Phi(x)$ for any $p > 1$, including noninteger values of p.

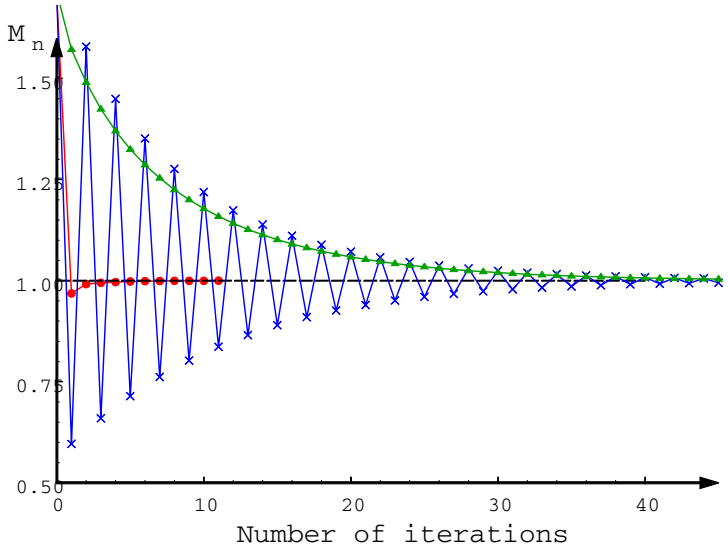

FIG. 3. *Stabilizing factor* M_n *versus* n *for the iteration method* (1.8)–(1.9) *with* $p = 2$ *for* $\gamma = 2$ *(dots),* $\gamma = 1.1$ *(triangles), and* $\gamma = 2.9$ *(crosses).*

Remark 5.4. The bound state $\Phi(x)$ is spectrally stable with respect to the time evolution problem for $p = 2$ and spectrally unstable for $p \geq 3$ [BSS87, CK80]. Under assumption that $n(\mathcal{H}) = 1$ and $\Phi(x) \geq 0$ on $x \in \mathbb{R}$ for any $p > 1$, the iteration method (1.8)–(1.9) converges to the bound state for any $p > 1$, irrelevantly to the stability of bound states in the time evolution problem. Therefore, the method becomes useful for numerical approximations of the bound states in the generalized BO equation, when exact analytical expressions are not available. In fact, the iteration method (1.8)–(1.9) was successfully used for numerical approximations of soliton solutions in the generalized BO and KdV equations in [AS87]. Another numerical method is developed with the help of Newton iteration algorithms but the Newton iterations have convergence problems as pointed out in [BK03]. We notice that Petviashvili's iteration method (1.8)–(1.9) is not sensitive to the choice of a starting function, which is its great advantage compared to the Newton's iteration method.

6. Examples in two dimensions. We finish the article with generalizations of the iteration method (1.8)–(1.9) for the scalar wave equation in space of two dimensions,

$$u_t - (\mathcal{L}u)_x + pu^{p-1}u_x = 0, \tag{6.1}$$

where $u : \mathbb{R}^2 \times \mathbb{R}_+ \mapsto \mathbb{R}$, $p > 1$, and $\mathcal{L}$ is a linear self-adjoint nonnegative pseudo-differential operator in x and y with constant coefficients. If the Fourier transform (1.4) is replaced by the double Fourier transform in $L^2(\mathbb{R}^2)$, the iteration method (1.8)–(1.9) can be applied to the scalar wave equation (6.1) in two dimensions. The only modification is required for Assumption 2.1, since the kernel of $\mathcal{H} = c + \mathcal{L} - p\Phi^{p-1}(x, y)$ has at least two eigenfunctions $\partial_x\Phi(x, y)$ and $\partial_y\Phi(x, y)$.

Assumption 6.1. The spectrum of $\mathcal{H}$ in $L^2(\mathbb{R}^2)$ consists of eigenvalues μ of the discrete spectrum for $\mu < c$ and the continuous spectrum for $\mu \geq c$. The null-space of $\mathcal{H}$ is two dimensional with the eigenfunctions $\partial_x\Phi(x, y)$ and $\partial_y\Phi(x, y)$. The negative space of $\mathcal{H}$ has dimension $n(\mathcal{H}) \geq 1$.

With this modification, we formulate the results of sections 2 and 3 as the following theorem.

THEOREM 6.2. *Let $\hat{\Phi}(k)$ be a solution of the boundary-value problem* (1.5) *and Assumptions* 1.1 *and* 6.1 *be satisfied. The iteration method* (1.8)–(1.9) *converges to $\hat{\Phi}(k)$ in a small open neighborhood of $\hat{\Phi}(k)$ if* (i) $1 < \gamma < (p+1)/(p-1)$, (ii) $n(\mathcal{H}) = 1$, *and* (iii) *Assumption* 2.7 *is met. The fastest rate of convergence occurs for $\gamma = \gamma_* \equiv p/(p-1)$. If any of the three conditions are not met, the iteration method* (1.8)–(1.9) *diverges from $\hat{\Phi}(k)$.*

Here we discuss three examples of the scalar wave equation (6.1) in two dimensions, where the iteration method (1.8)–(1.9) can be used for finding stationary solutions such as solitary waves.

Example 6.3 (generalized Zakharov–Kuznetsov (ZK) equations). The generalized KdV equations of Example 5.1 are extended to the two-dimensional ZK equations, when $\mathcal{L}$ is an isotropic operator,

$$\mathcal{L} = -(\partial_x^2 + \partial_y^2), \tag{6.2}$$

such that $v(k) = k_x^2 + k_y^2 \geq 0$. The bound state $u = \Phi(x - ct, y)$ satisfies the nonlinear problem

$$c\Phi - \Delta\Phi = \Phi^p. \tag{6.3}$$

Existence and uniqueness of positive solutions of the nonlinear elliptic problem (6.3) was proved for any $p > 1$ [GNN81, K89] such that $\Phi(x, y) = \Phi(r)$ is radially symmetric, where $r = \sqrt{x^2 + y^2}$, and satisfies the limiting decay

$$\lim_{r\to\infty} e^{\sqrt{c}r} r^{1/2} \Phi(r) = a_\infty > 0. \tag{6.4}$$

The positive solutions $\Phi(r)$ satisfy Assumptions 1.1 and 2.7. The linearized operator $\mathcal{H}$ becomes the Schrödinger operator with the radially symmetric potential

$$\mathcal{H} = c - \partial_x^2 - \partial_y^2 + p\Phi^{p-1}(r). \tag{6.5}$$

Assumption 6.1 is satisfied for the Schrödinger operator (6.5) and the negative index of $\mathcal{H}$ for the positive ground state $\Phi(r)$ is one, i.e., $n(\mathcal{H}) = 1$ [S9, p. 63]. Therefore, iterations of the numerical method (1.8)–(1.9) converge for $1 < \gamma < (p + 1)/(p - 1)$, according to Theorem 6.2 for any $p > 1$. This result justifies the use of the iteration method (1.8)–(1.9) for numerical approximation of bound states of the generalized ZK equations.

Example 6.4 (generalized Kadomtsev–Petviashvili (KP) equations). The generalized KdV equations of Example 5.1 are extended to the two-dimensional KP equations, when $\mathcal{L}$ is an anisotropic operator,

$$\mathcal{L} = -\partial_x^2 + \partial_x^{-2}\partial_y^2, \tag{6.6}$$

such that $v(k) = k_x^2 + k_x^{-2}k_y^2 \geq 0$. The linear operator $\mathcal{L}$ in (6.6) corresponds to the KPI equation with two-dimensional solitons, called lumps. The nonlocal ∂_x^{-1} operator is well posed subject to the constraint on $u(x, y, t)$

$$\int_{-\infty}^{\infty} u(x, y, t)\, dx = 0. \tag{6.7}$$

The bound state $u = \Phi(x - ct, y)$ satisfies the nonlinear problem

$$c\Phi - \Phi_{xx} + \partial_x^{-2}\Phi_{yy} = \Phi^p. \tag{6.8}$$

The exact analytical solution for $\Phi(x, y)$ exists for $p = 2$ [MZ77],

$$\Phi(x, y) = 12c\frac{3 + c^2y^2 - cx^2}{(3 + c^2y^2 + cx^2)^2}. \tag{6.9}$$

The bound state $\Phi(x, y)$ is sign-indefinite due to the constraint (6.7). Existence of sign-indefinite bound states in the nonlinear problem (6.8) was proved for $p = 3, 4$ by using constrained minimization [BS97]. It was also shown that the solution exists only for $p < 5$ and $p = p_1/p_2$, where p_1 is any even integer and p_2 is any odd integer [LW97]. Bound states $\Phi(x, y)$ satisfy Assumption 1.1.

It can be shown with the Riemann–Hilbert inverse scattering method [PS00] that the spectrum of $\mathcal{H}$ for $p = 2$ satisfies Assumption 6.1 with $n(\mathcal{H}) = 1$. Since the bound states $\Phi(x, y)$ are nonpositive, they satisfy Assumption 2.7 only if $\lambda_{\max} < 2$. It follows from (6.9) for $p = 2$ that

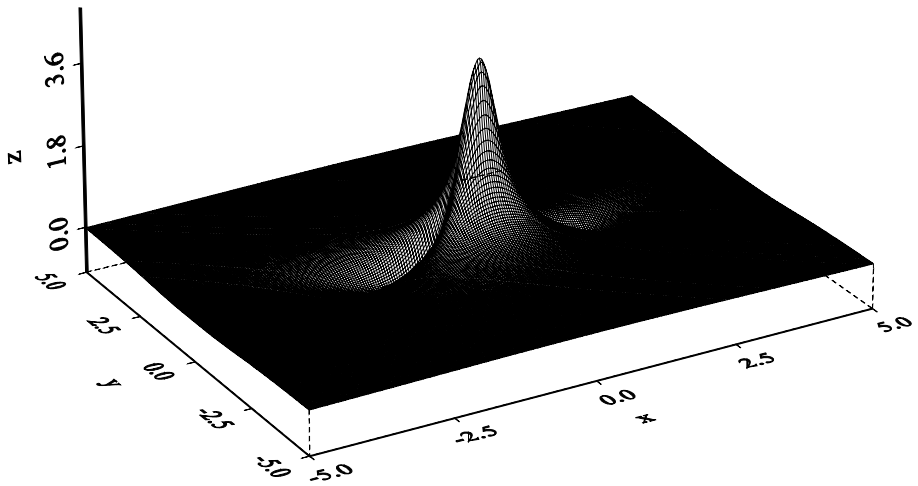

FIG. 4. *A numerical approximation of the bound state $\Phi(x,y)$ of the generalized KPI equation with $p=3$.*

$$\min_{(x,y)\in\mathbb{R}^2} \Phi(x,y) = \Phi\left(\pm\frac{3}{\sqrt{c}},0\right) = -\frac{c}{2}.$$

Therefore, the upper bound (2.11) applies with $\lambda_{\max} < 1+1 = 2$, i.e., Assumption 2.7 is also satisfied. Theorem 6.2 states that the iteration method (1.8)–(1.9) converges to $\Phi(x,y)$ for $p=2$ if $1<\gamma<3$. This analysis justifies the use of the numerical iteration method (1.8)–(1.9), proposed originally by Petviashvili [P76].

We have computed the bound states $\Phi(x,y)$ for $p=2,3,4$ from the iteration method (1.8)–(1.9) starting with the lump solution (6.9) with $c=1$. The constraint (6.7) is built into the algorithm as zero Fourier mode with $k_x=0$. The final solution $\Phi(x,y)$ is shown on Figure 4 for $p=3$ (see also [AS87]). Cross-sections $\Phi(x,0)$ and $\Phi(0,y)$ are shown on Figure 5(a,b) for $p=2,3,4$, where dots for $p=2$ show exact values from (6.9). Figure 6 shows convergence of the stabilizing factor M_n in the iteration method (1.8)–(1.9) with the fastest rate $\gamma=p/(p-1)$ for $p=2,3,4$. We conclude that the iteration method (1.8)–(1.9) converges to the bound state of the generalized KP equation for $p=2,3,4$ if $1<\gamma<(p+1)/(p-1)$.

Remark 6.5. Nonpositive bound states of the generalized KP equations may consist of several individual lumps. Multilump solutions of the KPI equation with $p=2$ were discovered both numerically [AS85] and analytically [PS93]. However, a discrepancy occurs between the numerical and analytical solutions for a double-lump; the analytical solution is unique for the double-lump [PS93], while the numerical solution represents a continuous family with a free parameter of the distance between the two lumps [AS85]. This discrepancy is likely to be explained by low accuracy of the numerical procedure in [AS85], i.e., low resolution of the numerical mesh and small grid size. Since the negative index of $\mathcal{H}$ for multilump solutions typically exceeds one, the iteration method (1.8)–(1.9) must diverge in the neighborhood of multilump solutions, according to Theorem 6.2. Numerical approximations obtained in [AS85] are likely supported by the truncation of the domain on $\mathbb{R}^2$ and the discretization

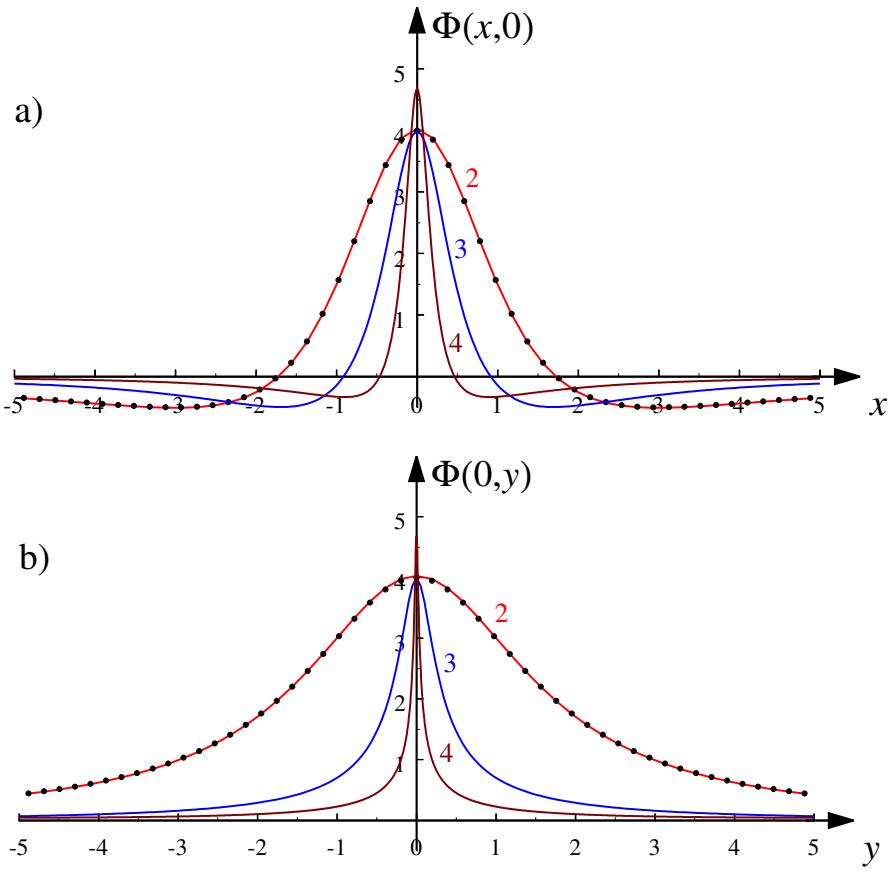

FIG. 5. *Cross sections* $\Phi(x,0)$ *and* $\Phi(0,y)$ *of numerical approximations of the bound states* $\Phi(x,y)$ *of the generalized KPI equation with* $p = 2,3,4$. *Dots on curves* 2 *show exact values from the analytical solution* (6.9).

of the numerical grid (x,y). This example shows a danger of the direct use of the iteration method (1.8)–(1.9) without analysis of the three conditions of convergence in Theorems 2.8 and 6.2.

Example 6.6 (generalized Klein–Gordon (KG) equations). Our last example shows that the iteration method (1.8)–(1.9) can be used for other nonlinear problems, such as the generalized KG equation,

$$u_{tt} - c_0^2(u_{xx} + u_{yy}) + u = u^p. \tag{6.10}$$

Travelling wave solutions of (6.10) are of the form $u(x,y,t) = \Phi(x - ct, y)$, where $\Phi(x,y)$ satisfies the boundary–value problem

$$\Phi - (c_0^2 - c^2)\Phi_{xx} - c_0^2\Phi_{yy} = \Phi^p. \tag{6.11}$$

If $|c| < c_0$, the boundary–value problem (6.11) can be reduced to the form (6.3) of Example 6.3 with a simple rescaling of variables x and y.

Γ-CONVERGENCE OF DISCRETE FUNCTIONALS WITH NONCONVEX PERTURBATION FOR IMAGE CLASSIFICATION*

GILLES AUBERT†, LAURE BLANC-FÉRAUD‡, AND RICCARDO MARCH§

Abstract. The purpose of this paper is to show the theoretical soundness of a variational method proposed in image processing for supervised classification. Based on works developed for phase transitions in fluid mechanics, the classification is obtained by minimizing a sequence of functionals. The method provides an image composed of homogeneous regions with regular boundaries, a region being defined as a set of pixels belonging to the same class. In this paper, we show the Γ-convergence of the sequence of functionals which differ from the ones proposed in fluid mechanics in the sense that the perturbation term is not quadratic but has a finite asymptote at infinity, corresponding to an edge-preserving regularization term in image processing.

Key words. Γ-convergence, finite elements, image processing, phase transitions

1. Introduction.

Image classification consists of assigning a label to each site of an image to produce a partition of the image into homogeneous labelled areas. The classification problem concerns many applications as, for instance, land use management in remote sensing.

Based on results conducted in the Van der Waals–Cahn–Hilliard theory framework for phase transitions in fluid mechanics [2, 4, 13, 18, 20], we have recently proposed a sequence of functionals for image classification [19]. The soundness of such a method relies upon Γ-convergence theory. The purpose of this paper is to prove the Γ-convergence of the sequence of functionals we use, which differs from the one used in fluid mechanics in the sense that the perturbation term is not quadratic, but it is an edge-preserving regularization term as defined in image processing.

Let Ω be an open bounded subset of $\mathbf{R}^2$, $I : \Omega \to \mathbf{R}$ the observed data to classify, $I \in L^\infty(\Omega)$. A class is characterized by parameters of the spatial distribution of intensity, i.e., the mean and standard deviation for Gaussian hypothesis. This work takes place in the general framework of supervised classification, which means that the number n of classes and the parameters of the Gaussian distribution of the classes (a_i, σ_i) are known a priori. These values either are given by an expert or are precomputed by using a fuzzy C means algorithm with an entropy term (see [16], for instance). Knowing (a_i, σ_i), $i = 1, \ldots, n$, the question is now to find a partition of Ω based on the observed image, where a component is the set of pixels in class i. We also add a regularity constraint on the partition. In order to assign a class i to each

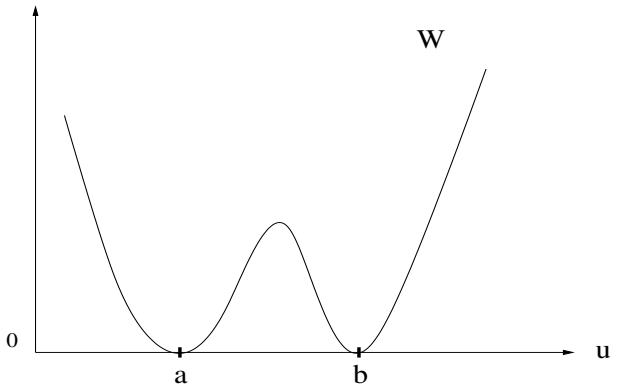

FIG. 1.1. *Example of double-well potential W, in the case of two classes with $a_1 = a, a_2 = b$.*

pixel x, we have proposed in [19] the sequence of functionals

$$F_\varepsilon(u) = \underbrace{\int_\Omega |u(x) - I(x)|^2 \, dx}_{\text{data term}} + \varepsilon \underbrace{\int_\Omega \varphi(|\nabla u(x)|) dx}_{\text{restoration term}} + \frac{1}{\varepsilon} \underbrace{\int_\Omega W(u(x)) dx}_{\text{classification}}, \tag{1.1}$$

and the associated problem consists of finding u_0 such that

$$u_0 = \lim_{\varepsilon \to 0^+} \Big[\arg\min_u F_\varepsilon(u) \Big]. \tag{1.2}$$

Let us first consider the functional with a fixed ε. The first two terms of (1.1) are standard for noisy image restoration by nonquadratic regularization [10, 3]. Function φ is a smoothing function that will be defined later.

The third term of (1.1) is a level constraint such that $W : \mathbf{R} \to \mathbf{R}^+$ attracts the values of $u(x)$ towards the mean a_i of class i, taking into account the standard deviation σ_i. W has n minima at a_i such that $W(a_i) = 0 \; \forall \; i = 1, \ldots, n$. W is quadratic around each minimum (from the Gaussian distribution hypothesis), i.e., around the a_i, $W(t) = (\frac{t - a_i}{\sigma_i})^2$, and is piecewise parabolic between the wells (see Figure 1.1).

Considering a sequence of energies F_ε when $\varepsilon \to 0$ is inspired from works conducted in the Van der Waals–Cahn–Hilliard theory framework for phase transitions in fluid mechanics [2, 4, 13, 18, 20] using Γ-convergence.

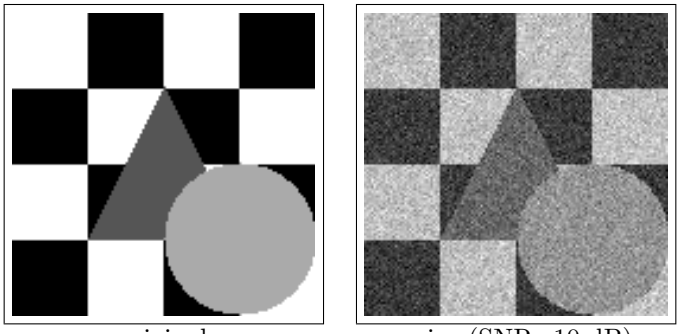
We recall the definition and some properties of Γ-convergence (see [12]). Let X be a metric space, and let $f_\varepsilon : X \to [0, +\infty]$ be a family of functions indexed by $\varepsilon > 0$. We say that f_ε Γ-converge as $\varepsilon \to 0^+$ to $f : X \to [0, +\infty]$ if the two conditions

$$\forall x_\varepsilon \to x, \quad \liminf_{\varepsilon \to 0^+} f_\varepsilon(x_\varepsilon) \geq f(x) \tag{1.3}$$

and

$$\exists x_\varepsilon \to x, \quad \limsup_{\varepsilon \to 0^+} f_\varepsilon(x_\varepsilon) \leq f(x) \tag{1.4}$$

are fulfilled for every $x \in X$. The Γ-limit, if it exists, is unique and lower semicontinuous. The Γ-convergence is stable under continuou perturbations, that is, $(f_\varepsilon + v)$



original noisy (SNR=10 dB)

FIG. 1.2. *Synthetic "check" image.*

Γ-converge to $(f+v)$ if f_ε Γ-converge to f and v is continuous. The most important property of Γ-convergence is the following: if $\{x_\varepsilon\}_\varepsilon$ is asymptotically minimizing, i.e.,

$$\lim_{\varepsilon \to 0^+} \left(f_\varepsilon(x_\varepsilon) - \inf_X f_\varepsilon \right) = 0, \tag{1.5}$$

and if $\{x_{\varepsilon_h}\}_h$ converge to x for some sequence $\varepsilon_h \to 0$, then x minimizes f.

The minimization problem (1.2) relies upon Γ-convergence arguments. If $\varphi(t) = t^2$, then it can be shown from [4] that the sequence of functionals (1.1) Γ-converges to

$$F_0(u) = \begin{cases} \displaystyle\sum_{i=1}^{n} \int_{A_i} |a_i - I|^2 dx \quad + \displaystyle\sum_{i,l=1}^{n} |\kappa_{i,l}| \mathcal{H}^1(\partial^* A_i \cap \partial^* A_l \cap \Omega) \\ \qquad\qquad\qquad\qquad \text{if } u \in BV(\Omega; \{a_1, \ldots, a_n\}), \\ +\infty \qquad\qquad\qquad\qquad \text{elsewhere in} L^2(\Omega), \end{cases} \tag{1.6}$$

where $BV(\Omega)$ is the space of functions of bounded variation [1], $\mathcal{H}^1$ is the one-dimensional Hausdorff measure, and $\partial^* A_i$ is the essential boundary of the subset A_i. For $u \in BV(\Omega; \{a_1, \ldots, a_n\})$, $A_i = \{x \in \Omega : u(x) = a_i\}$ for any $i = 1, \ldots, n$. Then the sets $A_1, \ldots, A_n$ define a partition of Ω into sets with finite perimeter. This partition is the classification result. The weight $\kappa_{i,l}$ is defined by

$$\kappa_{i,l} = \int_{a_i}^{a_l} \sqrt{W(t)} dt. \tag{1.7}$$

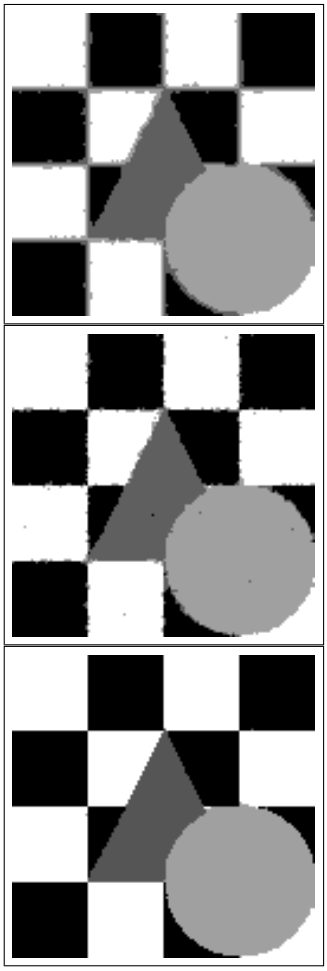
From Γ-convergence and compactness results, we know that the sequence of minimizers u_ε of $F_\varepsilon(u)$ converges (up to a subsequence) to a minimizer of F_0. So u_0 defines a partition of Ω according to the predefined classes, with minimal interfaces with respect to the weighted length (1.6), (1.7).

From the numerical point of view, when ε decreases, the functional turns from a restoration process (the third term in (1.1) is negligible) into a classification process.

We do not use the quadratic function for φ but an edge-preserving regularizing function $\varphi(t) = \frac{t^2}{1+\mu t^2}$ because, numerically, it gives better results by preserving high gradients which represent edges [10]. This is illustrated on a synthetic image of size 128×128 pixels ("check" image), containing four classes.

The white Gaussian noise introduced is such that the signal-to-noise ratio (SNR) given by $SNR = 10 \log_{10} \frac{nonnoisy\ signal\ variance}{noise\ variance}$ is 10 dB. Figure 1.2 presents the

synthetic image (nonnoisy and noisy). From the noisy one, we compute the classification as in (1.2) for different φ-functions (see [19] for the detailed algorithm). The results are presented in Figure 1.3. For a Tikhonov regularization ($\varphi(t) = t^2$), edges are oversmoothed. With a convex φ, there are still many misclassified pixels on the boundaries. Best results are provided with the use of the nonconvex function $\varphi(t) = \frac{t^2}{1+\mu t^2}$, with $\mu > 0$.



$\varphi(t) = t^2$: convex (Tikhonov)

$\varphi(t) = \log(\cosh(t))$: convex (Green)

$\varphi(t) = \frac{t^2}{1+\mu t^2}$: nonconvex (Geman & McClure)

FIG. 1.3. *Classification of "check" image with different functions φ. Nonconvex functions provide better results than convex functions which lead to oversmooth results: we get damaged edges.*

Before stating the result shown in this paper, we observe that the family of functionals F_ε in (1.1) does not Γ-converge to the limit F_0 given in (1.6) if $\varphi(t) = \frac{t^2}{1+\mu t^2}$ as it does when $\varphi(t) = t^2$.

Let, for instance, $n = 2$ and $u_0 \in BV(\Omega; \{a_1, a_2\})$ with $a_1 < a_2$. Let A_ε be the tubular neighborhood of S_{u_0}, the set of jumps of u_0, defined by $A_\varepsilon = \{x \in \Omega : \operatorname{dist}(x, S_{u_0}) < \lambda_\varepsilon\}$, with $\lambda_\varepsilon > 0$. Then let $u_\varepsilon \in W^{1,2}(\Omega)$ be a function which makes a sharp transition between the values a_1 and a_2 in the set A_ε and takes the values a_1 and a_2 outside of A_ε.

If we neglect the term $\int_\Omega |u_\varepsilon(x) - I(x)|^2 \, dx$, since it is a continuous perturbation,

it is easy to check that the remaining part of the energy, denoted by $E_\varepsilon(u_\varepsilon)$, is bounded by const. $|A_\varepsilon|/\varepsilon$, where $|\cdot|$ denotes the Lebesgue measure. As λ_ε can be chosen in such a way that $|A_\varepsilon| \to 0$ as fast as we want with ε, then $E_\varepsilon(u_\varepsilon)$ converges to 0 as $\varepsilon \to 0$. So u_ε is a counterexample to the lower inequality of the Γ-convergence. This example shows that too-sharp transitions make the proof of the Γ-convergence fail. In order to obtain the Γ-convergence with the nonconvex function φ, we have to consider the subspace of $W^{1,2}(\Omega)$ of finite elements and to use a method introduced by Chambolle and Dal Maso in [9]. The meshsize of the discretization will limit the sharpness of the transitions.

The paper is organized as follows. In section 2 we define the sequence of functionals and we state the Γ-convergence result. The proof of Γ-convergence is given in sections 3 and 4. Section 5 is devoted to the compactness of the minimizers for the sequence of functionals. In section 6 we show that the evaluation of the discrete functionals via the vertex quadrature rule does not affect the Γ-convergence and compactness results.

2. Mathematical preliminaries and statement of the result. In the following, $|A|$ denotes the two-dimensional Lebesgue measure of a set $A \subset \mathbf{R}^2$, and $\mathcal{H}^1(\partial A)$ denotes the one-dimensional Hausdorff measure of ∂A.

Let $\Omega \subset \mathbf{R}^2$ be a bounded open set. We will use standard notation for the Lebesgue and Sobolev spaces $L^p(\Omega)$ and $W^{1,p}(\Omega)$. We say that $u \in L^1(\Omega)$ is a function of bounded variation in Ω, and we write $u \in BV(\Omega)$, if the distributional derivative Du of u is a vector-valued Radon measure with finite total variation in Ω. We denote by $|Du|$ the total variation of Du and by ∇u the density of the absolutely continuous part of Du with respect to the Lebesgue measure. It can be proved [1] that ∇u coincides almost everywhere with the approximate differential of u. We denote by $u^-(x)$, $u^+(x)$ the approximate lower and upper limit of u at the point x, and we denote by S_u the discontinuity set of u in an approximate sense, defined as

$$S_u = \{x \in \Omega : u^-(x) < u^+(x)\}.$$

We say that a Borel set $A \subset \mathbf{R}^2$ is a set with finite perimeter in Ω if $\chi_A \in BV(\Omega)$, where χ_A denotes the characteristic function of A. We denote by $\partial^* A$ the essential boundary of A, i.e., the set of points where A does not have density 0 or 1. The perimeter of A in Ω is then given by $|D\chi_A|(\Omega) = \mathcal{H}^1(\partial^* A \cap \Omega)$.

In the following, $\Omega \subset \mathbf{R}^2$ will denote an open polygonal domain. Let θ_0 be an angle such that $0 < \theta_0 \leq \pi/3$, and let $\nu(h)$ be a function such that $\nu(h) \geq h$ for any $h > 0$ and $\nu(h) = O(h)$ as $h \to 0^+$. Let us denote by $\{\mathbf{T}_h\}_h$ a family of triangulations of Ω made of triangles whose edges, for any $h > 0$, have length between h and $\nu(h)$, and whose angles are all greater than or equal to θ_0.

We denote by $V_h(\Omega) \subset W^{1,2}(\Omega) \cap C^0(\overline{\Omega})$ the linear finite element space

$$V_h(\Omega) = \{u : \Omega \to \mathbf{R} \ : \ u \text{ continuous}, u|_T \in P_1(T) \ \forall T \in \mathbf{T}_h\},$$

where T denotes a triangle of $\mathbf{T}_h$, $u|_T$ denotes the restriction of u to T, and $P_1(T)$ denotes the space of polynomials of degree 1 on T. We denote by $\pi_h : C^0(\overline{\Omega}) \to V_h(\Omega)$ the Lagrange interpolation operator.

Let $\{a_1, \ldots, a_n\} \subset \mathbf{R}$ with $a_1 < a_2 < \cdots < a_n$. Let $W : \mathbf{R} \to \mathbf{R}$ be a function with the following properties:

(i) W is $\mathcal{C}^1(\mathbf{R})$ with Lipschitz continuous derivative;

(ii) W is $\mathcal{C}^2$ in a neighborhood of a_i for any $i \in \{1, \ldots, n\}$;

(iii) $W(t) > 0$ for any $t \notin \{a_1, \dots, a_n\}$ and

$$W(a_i) = 0, \quad W'(a_i) = 0, \quad W''(a_i) > 0 \qquad \forall i \in \{1, \dots, n\}; \tag{2.1}$$

(iv) $W(t)$ is monotone increasing for $t \geq a_n$, and monotone decreasing for $t \leq a_1$. For any $i, l \in \{1, \dots, n\}$ we set

$$\kappa_{i,l} = \int_{a_i}^{a_l} \sqrt{W(t)}dt.$$

For any $I \in L^\infty(\Omega)$ such that $\|I\|_{L^\infty(\Omega)} \leq K < +\infty$, we set

$$+\infty > M > \max\{|a_1|, |a_n|, K\}. \tag{2.2}$$

For any $h > 0$ and any $\varepsilon > 0$ we define the functional $E_{\varepsilon,h} : L^2(\Omega) \to [0, +\infty]$ by

$$E_{\varepsilon,h}(u) = \begin{cases} \varepsilon \displaystyle\int_\Omega \frac{|\nabla u|^2}{1 + \mu_{\varepsilon,h}|\nabla u|^2} dx + \frac{1}{\varepsilon} \int_\Omega W(u)dx & \text{if } u \in \mathcal{D}(E_{\varepsilon,h}), \\ +\infty & \text{elsewhere in } L^2(\Omega), \end{cases}$$

where $\mu_{\varepsilon,h} > 0$ and $\mathcal{D}(E_{\varepsilon,h}) = \{u \in V_h(\Omega) : \|u\|_{L^\infty(\Omega)} \leq M\}$.

We say that n Borel sets $A_1, \dots, A_n$ define a partition of Ω if

$$A_i \cap A_l = \emptyset \quad \forall i, l \in \{1, \dots, n\},\ i \neq l, \qquad |\Omega \setminus \cup_{i=1}^n A_i| = 0.$$

Let $u \in BV(\Omega; \{a_1, \dots, a_n\})$ and let $A_i = \{x \in \Omega : u(x) = a_i\}$ for any $i = 1, \dots, n$. Then the sets $A_1, \dots, A_n$ define a partition of Ω into sets with finite perimeter.

Then we define the functional $E_0 : L^2(\Omega) \to [0, +\infty]$ by

$$E_0(u) = \begin{cases} 2 \displaystyle\sum_{\substack{i,l=1 \\ i<l}}^n \kappa_{i,l} \mathcal{H}^1(\partial^* A_i \cap \partial^* A_l \cap \Omega) & \text{if } u \in BV(\Omega; \{a_1, \dots, a_n\}), \\ +\infty & \text{elsewhere in } L^2(\Omega). \end{cases}$$

Finally we state the main result of the paper. We define

$$F_{\varepsilon,h}(u) = \int_\Omega (u - I)^2 dx + E_{\varepsilon,h}(u),$$

and we will prove the following theorems.

THEOREM 2.1. *Assume that $h = o(\varepsilon|\log\varepsilon|^{-1})$ and that $\mu_{\varepsilon,h} = o(\varepsilon h)$. Then the family $\{F_{\varepsilon,h}\}_\varepsilon$ Γ-converges to the functional*

$$\int_\Omega (u - I)^2 dx + E_0(u)$$

in the $L^2(\Omega)$-topology as $\varepsilon \to 0^+$.

Since the term $\int_\Omega (u - I)^2 dx$ is a continuous perturbation with respect to the strong-$L^2(\Omega)$ topology, in order to prove the theorem it will be enough to prove that the family of functionals $\{E_{\varepsilon,h}\}_\varepsilon$ Γ-converges to the functional E_0.

THEOREM 2.2. *Assume that $h = o(\varepsilon|\log\varepsilon|^{-1})$ and that $\mu_{\varepsilon,h} = o(\varepsilon h)$. Then any family $\{u_{\varepsilon,h}\}_\varepsilon$ of absolute minimizers of $F_{\varepsilon,h}$ is relatively compact in $L^2(\Omega)$, and each of its limit points minimizes the functional*

$$\int_\Omega (u - I)^2 dx + E_0(u).$$

3. Lower inequality. In this section we investigate the Γ-convergence lower inequality (1.3) with $f_\varepsilon = E_{\varepsilon,h}$ and $f = E_0$.

THEOREM 3.1. *Let $\mu_{\varepsilon,h} = o(\varepsilon h)$ and $h = h(\varepsilon)$ with $\lim_{\varepsilon\to 0^+} h(\varepsilon) = 0$. Then, for every function $u_0 \in L^2(\Omega)$ and for every sequence $\{u_{\varepsilon,h}\}_\varepsilon \subset L^2(\Omega)$ converging to u_0 in $L^2(\Omega)$ as $\varepsilon \to 0^+$, we have*

$$\liminf_{\varepsilon\to 0^+} E_{\varepsilon,h}(u_{\varepsilon,h}) \geq E_0(u_0).$$

We need the following lemma.

LEMMA 3.2. *Assume that $\mu_{\varepsilon,h} = o(\varepsilon h)$. Then, for every $\varepsilon > 0$ and for every $u \in V_h(\Omega)$ $(0 < h < 1)$, there exists $v \in BV(\Omega)$ such that*

$$E_{\varepsilon,h}(u) \geq (1-\delta_h)\varepsilon \int_\Omega |\nabla v|^2 dx + \frac{1}{\varepsilon}\int_\Omega W(v)dx + 2\kappa_{1,n}\mathcal{H}^1(S_v), \tag{3.1}$$

$$\frac{h}{c}E_{\varepsilon,h}(u) \geq |\{x \in \Omega : v(x) \neq u(x)\}|, \tag{3.2}$$

where $v(x) = a_1$ for any $x \in \Omega$ such that $v(x) \neq u(x)$, $\{\delta_h\}_h$ is a sequence of positive numbers converging to zero, and c is a constant independent of h.

The proof of the lemma is essentially the same of Proposition 3.3 in [9], with some slight modifications which can be found in the appendix.

Proof of Theorem 3.1. Up to the extraction of a subsequence, we may assume that $\{u_{\varepsilon,h}\}_\varepsilon \subset \mathcal{D}(E_{\varepsilon,h})$, and

$$+\infty > \liminf_{\varepsilon\to 0^+} E_{\varepsilon,h}(u_{\varepsilon,h}) = \lim_{\varepsilon\to 0^+} E_{\varepsilon,h}(u_{\varepsilon,h}); \tag{3.3}$$

otherwise the result is trivial. To simplify the notation we set $u_\varepsilon = u_{\varepsilon,h(\varepsilon)}$ and we assume that u_ε converges a.e. to u_0 as $\varepsilon \to 0^+$.

Using (3.3) and Fatou's lemma, we deduce that $\int_\Omega W(u_0)dx = 0$; thus $W(u_0(x)) = 0$ a.e. in Ω. Then, using (2.1), there exists a partition $\{A_i\}_{i=1,\dots,n}$ of Ω into measurable subsets such that $u_0(x) = \sum_{i=1}^n a_i \chi_{A_i}(x)$.

For any $\varepsilon > 0$, Lemma 3.2 provides a function $v_\varepsilon \in BV(\Omega)$ which satisfies (3.1) and (3.2). Since $\|v_\varepsilon\|_{L^\infty(\Omega)} \leq M$, we have $|v_\varepsilon - u_0| \leq 2M$ a.e. in Ω. Then, using (3.2) and (3.3), we have $|\{v_\varepsilon \neq u_\varepsilon\}| \to 0$ as $\varepsilon \to 0^+$, from which we deduce that v_ε converges to u_0 in $L^2(\Omega)$ as $\varepsilon \to 0^+$.

Let $\widehat{v}_\varepsilon$, with $a_1 \leq \widehat{v}_\varepsilon \leq a_n$, denote the truncated function

$$\widehat{v}_\varepsilon = \max\{a_1, \min\{v_\varepsilon, a_n\}\}.$$

We have that $\widehat{v}_\varepsilon$ converges to u_0 in $L^2(\Omega)$ as $\varepsilon \to 0^+$. Now we define the two functions

$$g(y) = \int_{a_1}^y \sqrt{W(t)}dt \tag{3.4}$$

and $\psi_\varepsilon(x) = g(\widehat{v}_\varepsilon(x))$. Since g is Lipschitz continuous, we have $\psi_\varepsilon \to g(u_0)$ in $L^2(\Omega)$ and

$$g(u_0(x)) = \kappa_{1,l} \quad \text{if } u_0(x) = a_l \quad \forall l \in \{1,\dots,n\}. \tag{3.5}$$

For any ε we have $\psi_\varepsilon \in BV(\Omega)$, $S_{\psi_\varepsilon} \subseteq S_{v_\varepsilon} = S_{v_\varepsilon}$, and the approximate differential is given by

$$\nabla\psi_\varepsilon(x) = \sqrt{W(\widehat{v}_\varepsilon(x))}\nabla\widehat{v}_\varepsilon(x).$$

The following estimate then holds for the total variation:

$$|D\psi_\varepsilon|(\Omega) = \int_\Omega |\nabla\psi_\varepsilon|dx + \int_{S_{\psi_\varepsilon}} |\psi_\varepsilon^+ - \psi_\varepsilon^-|d\mathcal{H}^1 \le \int_\Omega |\nabla\psi_\varepsilon|dx + \kappa_{1,n}\mathcal{H}^1(S_{v_\varepsilon}).$$

Using (3.1) and the above estimate we have

$$\begin{aligned} E_{\varepsilon,h}(u_\varepsilon) &\ge (1-\delta_h)\varepsilon\int_\Omega |\nabla v_\varepsilon|^2dx + \frac{1}{\varepsilon}\int_\Omega W(v_\varepsilon)dx + 2\kappa_{1,n}\mathcal{H}^1(S_{v_\varepsilon}) \\ &\ge (1-\delta_h)\varepsilon\int_\Omega |\nabla\widehat{v}_\varepsilon|^2dx + \frac{1}{\varepsilon}\int_\Omega W(\widehat{v}_\varepsilon)dx + 2\kappa_{1,n}\mathcal{H}^1(S_{v_\varepsilon}) \\ &\ge 2(1-\delta_h)^{1/2}\int_\Omega \sqrt{W(\widehat{v}_\varepsilon)}|\nabla\widehat{v}_\varepsilon|dx + 2\kappa_{1,n}\mathcal{H}^1(S_{v_\varepsilon}) \\ &\ge 2(1-\delta_h)^{1/2}|D\psi_\varepsilon|(\Omega), \end{aligned} \tag{3.6}$$

from which, using (3.3) and the compactness theorem in BV [14], it follows that $g(u_0) \in BV(\Omega)$. Then the sets A_i have finite perimeter, so that $u_0 \in BV(\Omega;\{a_1,\dots,a_n\})$ and $E_0(u_0) < +\infty$.

Using (3.6) and the lower semicontinuity of the total variation, we find

$$\liminf_{\varepsilon\to 0^+} E_{\varepsilon,h}(u_\varepsilon) \ge 2\lim_{\varepsilon\to 0^+}(1-\delta_h)^{1/2}\liminf_{\varepsilon\to 0^+}|D\psi_\varepsilon|(\Omega) \ge 2|Dg(u_0)|(\Omega).$$

Then, using (3.5), we have

$$|Dg(u_0)|(\Omega) = \int_{S_{g(u_0)}} |g(u_0)^+ - g(u_0)^-|d\mathcal{H}^1 = \sum_{\substack{i,l=1\\ i<l}}^n \kappa_{i,l}\mathcal{H}^1(\partial^*A_i\cap\partial^*A_l\cap\Omega), \tag{3.7}$$

which concludes the proof. □

4. Upper inequality. In this section we investigate the Γ-convergence upper inequality (1.4) with $f_\varepsilon = E_{\varepsilon,h}$ and $f = E_0$.

THEOREM 4.1. *Assume that $h = o(\varepsilon|\log\varepsilon|^{-1})$. Then, for every function $u_0 \in L^2(\Omega)$ there exists a sequence $\{u_{\varepsilon,h}\}_\varepsilon \subset L^2(\Omega)$ converging to u_0 in $L^2(\Omega)$ as $\varepsilon \to 0^+$ such that*

$$\limsup_{\varepsilon\to 0^+} E_{\varepsilon,h}(u_{\varepsilon,h}) \le E_0(u_0).$$

First we need the following lemma.

LEMMA 4.2. *For any $i,l \in \{1,\dots,n\}$ with $i < l$, there exists a sequence of functions $\{\gamma_\varepsilon^{(i,l)}\}_\varepsilon \subset \mathcal{C}^1(\mathbf{R})$ with the following properties:*

(i) *$\gamma_\varepsilon^{(i,l)}(t) = a_l$ for $t \ge \rho_\varepsilon$, $\gamma_\varepsilon^{(i,l)}(t) = a_i$ for $t \le -\rho_\varepsilon$, with $\rho_\varepsilon > 0$ independent of the pair (i,l) and $\rho_\varepsilon = O(\varepsilon|\log\varepsilon|)$;*

(ii)

$$\|d\gamma_\varepsilon^{(i,l)}/dt\|_{L^\infty(-\rho_\varepsilon,\rho_\varepsilon)} = O\left(\frac{1}{\varepsilon}\right), \qquad \|d^2\gamma_\varepsilon^{(i,l)}/dt^2\|_{L^\infty(-\rho_\varepsilon,\rho_\varepsilon)} = O\left(\frac{1}{\varepsilon^2}\right);$$

(iii)

$$\lim_{\varepsilon\to 0^+}\int_{-\infty}^{+\infty}\left[\varepsilon\left(\frac{d\gamma_\varepsilon^{(i,l)}}{dt}\right)^2+\frac{1}{\varepsilon}W(\gamma_\varepsilon^{(i,l)})\right]dt=2\kappa_{i,l}.$$

In the proof of this lemma a standard construction of Γ-convergence theory, used for a double-well potential (see, for instance, [20]), is extended to the case when the potential W has multiple wells on the real axis. The resulting construction of the functions $\gamma_\varepsilon^{(i,l)}$ is sketched in the appendix.

In order to prove Theorem 4.1 we need the following density result.

LEMMA 4.3. *Let $u_0\in BV(\Omega;\{a_1,\dots,a_n\})$; then there exists a sequence $\{u_\varepsilon\}_\varepsilon\subset BV(\Omega;\{a_1,\dots,a_n\})$ such that*

(i) *the set $A_i^\varepsilon=\{x\in\Omega : u_\varepsilon(x)=a_i\}$ is polygonal and $\mathcal{H}^1(\partial A_i^\varepsilon\cap\partial\Omega)=0$ for any $i=1,\dots n$ and for any $\varepsilon>0$;*

(ii) *$u_\varepsilon\to u_0$ in $L^2(\Omega)$ as $\varepsilon\to 0^+$;*

(iii)

$$\lim_{\varepsilon\to 0^+}E_0(u_\varepsilon)=E_0(u_0).$$

Proof. This approximation lemma is due to Baldo [4, Lemma 3.1]. Parts (i) and (ii) are stated exactly as above in Baldo [4]. Part (iii) needs some developments. We first set out Baldo's result and then we explain how we can use it in our context.

Let W be given as in (2.1) and let us define on $\mathbf{R}$ the metric

$$d(\xi_1,\xi_2)=\inf\left\{\int_0^1\sqrt{W(\gamma(t))}|\gamma'(t)|dt\quad;\quad\gamma(0)=\xi_1,\,\gamma(1)=\xi_2,\,\gamma\in\mathcal{C}^1\left([0,1];\mathbf{R}\right)\right\}.$$

Then let us set $g_i(\xi)=d(a_i,\xi)$, and let us define the Borel measures

$$\mu_i(B)=\int_B|Dg_i(u_0)|,\qquad\mu_i^\varepsilon(B)=\int_B|Dg_i(u_\varepsilon)|,$$

where B is a Borel set. In [4], Baldo proved the following result:

$$\lim_{\varepsilon\to 0^+}\left(\bigvee_{i=1}^n\mu_i^\varepsilon\right)(\Omega)=\left(\bigvee_{i=1}^n\mu_i\right)(\Omega)=\frac{1}{2}\sum_{i,j=1}^n d(a_i,a_j)\mathcal{H}^1(\partial^*A_i\cap\partial^*A_j\cap\Omega),\tag{4.1}$$

where the symbol $\bigvee$ denotes the supremum of a family of measures. In what follows we show that (4.1) is nothing else than part (iii) of Lemma 4.3.

First, one can prove that for any $i,j=1,\dots,n$, $i<j$, we have

$$d(a_i,a_j)=\kappa_{i,j}=\int_{a_i}^{a_j}\sqrt{W(y)}dy.$$

Hence, if $\{\mu_\alpha\}_{\alpha\in A}$ is a family of regular positive Borel measures, the supremum of $\{\mu_\alpha\}_{\alpha\in A}$ is defined as follows: let E be any subset of Ω; then

$$\left(\bigvee_{\alpha\in A}\mu_\alpha\right)(E)=\sup\left\{\sum_{\alpha\in A'}\mu_\alpha(E_\alpha);\ E_\alpha\text{ disjoint open sets in }\Omega, E=\bigcup_{\alpha\in A'}E_\alpha\right\},$$

where A' is any finite or countable subfamily of A. For any open subset $\Omega' \subset \Omega$ we have

$$\left(\bigvee_{i=1}^{n} \mu_i^\varepsilon\right)(\Omega') = \sup\left\{\sum_i \mu_i^\varepsilon(\Omega_i);\ \Omega_i \text{ open disjoint},\ \Omega' = \bigcup \Omega_i\right\}.$$

But with the same computations used in (3.7) we get

$$\begin{aligned}\sum_i \mu_i^\varepsilon(\Omega_i) &= \sum_i \sum_{j<k} \kappa_{jk}\mathcal{H}^1(\partial A_k^\varepsilon \cap \partial A_j^\varepsilon \cap \Omega_i) = \sum_{j<k} \kappa_{jk} \sum_i \mathcal{H}^1(\partial A_k^\varepsilon \cap \partial A_j^\varepsilon \cap \Omega_i)\\ &\le \sum_{j<k} \kappa_{jk}\mathcal{H}^1(\partial A_k^\varepsilon \cap \partial A_j^\varepsilon \cap \Omega').\end{aligned}$$

Since the sets A_i^ε are polygonal, there exists a partition of Ω' into open subsets Ω_i such that $\mathcal{H}^1(\partial A_k^\varepsilon \cap \partial A_j^\varepsilon \cap \partial\Omega_i) = 0$ for any $i, j, k \in \{1, \dots, n\}$, so that the above inequality becomes an equality. Thus for all $\Omega' \subset \Omega$ and for any $\varepsilon > 0$, we obtain

$$\left(\bigvee_{i=1}^{n} \mu_i^\varepsilon\right)(\Omega') = \sum_{j<k} \kappa_{jk}\mathcal{H}^1(\partial A_k^\varepsilon \cap \partial A_j^\varepsilon \cap \Omega');$$

i.e., the supremum with respect to i "disappears." In particular for $\Omega' = \Omega$ Baldo's result (4.1) reads as

$$\lim_{\varepsilon\to 0^+} \sum_{j<k} \kappa_{jk}\mathcal{H}^1(\partial A_k^\varepsilon \cap \partial A_j^\varepsilon) = \sum_{j<k} \kappa_{jk}\mathcal{H}^1(\partial^* A_k \cap \partial^* A_j \cap \Omega),$$

which exactly means that

$$\lim_{\varepsilon\to 0^+} E_0(u_\varepsilon) = E_0(u_0),$$

i.e., part (iii) of Lemma 4.3. □

We can now prove the upper inequality.

Proof of Theorem 4.1. In the following we use a method developed by Bellettini, Paolini, and Verdi in [6]. Since most of the estimates we need can be proved in the same way as in [6, proof of Theorem 2.1], we will omit the details.

We assume $u_0 \in BV(\Omega; \{a_1, \dots, a_n\})$; otherwise the inequality is trivial. Using Lemma 4.3 and a diagonal argument, we can suppose that the set $A_i = \{x \in \Omega : u_0(x) = a_i\}$ is a polygonal domain with $\mathcal{H}^1(\partial A_i \cap \partial\Omega) = 0$ for any $i = 1, \dots, n$. We have

$$S_{u_0} = \bigcup_{\substack{i,l=1\\ i<l}}^{n} (\partial A_i \cap \partial A_l \cap \Omega).$$

We denote by $\mathcal{P}_i$ the set of the vertices of the polygon A_i, and we set $\mathcal{P} = \cup_{i=1}^n \mathcal{P}_i$; hence $\mathcal{P}$ is a finite set of points. We denote by ω the minimum angle between the edges of S_{u_0}.

Following [6], we introduce the following notations. We set

$$\begin{aligned}(S_{u_0})_{\rho_\varepsilon} &= \{x \in \Omega : \operatorname{dist}(x, S_{u_0}) \le \rho_\varepsilon\};\\ \Pi_{S_{u_0}}(x) &= \{y \in S_{u_0} : |y - x| = \operatorname{dist}(x, S_{u_0})\};\\ Q_\varepsilon &= \left\{x \in (S_{u_0})_{\rho_\varepsilon} : \operatorname{dist}(\Pi_{S_{u_0}}(x), \mathcal{P}) \le \cot\left(\frac{\omega}{2}\right)\rho_\varepsilon\right\};\\ Q_{\varepsilon,h} &= \bigcup\{T \in \mathbf{T}_h : T \cap Q_\varepsilon \ne \emptyset\}.\end{aligned}$$

We denote by $\mathcal{M}$ the set of all the pairs of integers (i,l) such that $i,l \in \{1,\dots,n\}$, $i<l$, and $\mathcal{H}^1(\partial A_i \cap \partial A_l) > 0$. Then for any $(i,l) \in \mathcal{M}$ we set

$$d_{i,l}(x) = \begin{cases} \operatorname{dist}(x, \partial A_i \cap \partial A_l) & \text{if } x \in A_l, \\ -\operatorname{dist}(x, \partial A_i \cap \partial A_l) & \text{if } x \in A_i; \end{cases}$$
$$L_\varepsilon^{(i,l)} = \{x \in \Omega : |d_{i,l}(x)| \le \rho_\varepsilon\};$$
$$L_{\varepsilon,h}^{(i,l)} = \bigcup \{T \in \mathbf{T}_h : T \cap L_\varepsilon^{(i,l)} \neq \emptyset\}.$$

Using the above definitions, we have for any $(i,l) \in \mathcal{M}$

$$|Q_\varepsilon| = O\left(\varepsilon^2 |\log \varepsilon|^2\right), \qquad |L_\varepsilon^{(i,l)}| = O\left(\varepsilon |\log \varepsilon|\right). \tag{4.2}$$

Then we define the following function u_ε on $\Omega \setminus Q_\varepsilon$:

$$u_\varepsilon(x) = \begin{cases} u_0(x) & \text{if } x \in \Omega \setminus (S_{u_0})_{\rho_\varepsilon}, \\ \gamma_\varepsilon^{(i,l)}(d_{i,l}(x)) & \text{if } x \in L_\varepsilon^{(i,l)} \setminus Q_\varepsilon \quad \forall\ (i,l) \in \mathcal{M}. \end{cases} \tag{4.3}$$

Using the properties (i) and (ii) of Lemma 4.2, we have that u_ε is Lipschitz continuous in $\Omega \setminus Q_\varepsilon$ with $\operatorname{Lip}(u_\varepsilon) = O(\varepsilon^{-1})$. Then u_ε can be extended [6] on the whole Ω as a Lipschitz continuous function with $\operatorname{Lip}(u_\varepsilon) = O(\varepsilon^{-1})$. Moreover, we have $u_\varepsilon \to u_0$ in $L^2(\Omega)$ as $\varepsilon \to 0^+$.

Now we define $u_{\varepsilon,h} = \pi_h(u_\varepsilon)$. Using (2.2), we have $u_{\varepsilon,h} \in \mathcal{D}(E_{\varepsilon,h})$ for any ε small enough. Then, using the properties of the Lagrange interpolation operator [11] and the condition $h = o(\varepsilon |\log \varepsilon|^{-1})$, we have $u_{\varepsilon,h} \to u_0$ in $L^2(\Omega)$ (see [6, proof of Theorem 2.1]). Now we observe that

$$\begin{aligned} E_{\varepsilon,h}(u_{\varepsilon,h}) &= \varepsilon \int_\Omega \frac{|\nabla u_{\varepsilon,h}|^2}{1+\mu_{\varepsilon,h}|\nabla u_{\varepsilon,h}|^2} dx + \frac{1}{\varepsilon}\int_\Omega W(u_{\varepsilon,h}) dx \\ &\le \varepsilon \int_\Omega |\nabla u_{\varepsilon,h}|^2 dx + \frac{1}{\varepsilon}\int_\Omega W(u_{\varepsilon,h}) dx, \end{aligned}$$

and, following the method of [6], we split the functional on the right-hand side as follows:

$$\begin{aligned} E_{\varepsilon,h}(u_{\varepsilon,h}) \le{}& \varepsilon \int_\Omega |\nabla u_\varepsilon|^2 dx + \frac{1}{\varepsilon}\int_\Omega W(u_\varepsilon) dx + \varepsilon \int_\Omega \left(|\nabla u_{\varepsilon,h}|^2 - |\nabla u_\varepsilon|^2\right) dx \\ &+ \frac{1}{\varepsilon}\int_\Omega \left(W(u_{\varepsilon,h}) - W(u_\varepsilon)\right) dx = I_{\varepsilon,h} + II_{\varepsilon,h} + III_{\varepsilon,h}. \end{aligned}$$

First we prove that $\limsup_{\varepsilon \to 0^+} I_{\varepsilon,h} \le E_0(u_0)$. Using (4.3), we have that the contribution of the integrals on the set $\Omega \setminus (S_{u_0})_{\rho_\varepsilon}$ is zero. Moreover, since $\operatorname{Lip}(u_\varepsilon) = O(\varepsilon^{-1})$, using (4.2), we have

$$\varepsilon \int_{Q_\varepsilon} |\nabla u_\varepsilon|^2 dx + \frac{1}{\varepsilon}\int_{Q_\varepsilon} W(u_\varepsilon) dx = O\left(\varepsilon |\log \varepsilon|^2\right). \tag{4.4}$$

For any $(i,l) \in \mathcal{M}$ we set

$$J_\varepsilon^{(i,l)} = \varepsilon \int_{L_\varepsilon^{(i,l)} \setminus Q_\varepsilon} |\nabla u_\varepsilon|^2 dx + \frac{1}{\varepsilon}\int_{L_\varepsilon^{(i,l)} \setminus Q_\varepsilon} W(u_\varepsilon) dx.$$

A standard computation in Γ-convergence theory [6, 17, 20] yields

$$\limsup_{\varepsilon\to 0^+} J_\varepsilon^{(i,l)} \le \mathcal{H}^1(\partial A_i \cap \partial A_l \cap \Omega) \lim_{\varepsilon\to 0^+} \int_{-\infty}^{+\infty} \left[\varepsilon \left(\frac{d\gamma_\varepsilon^{(i,l)}}{dt} \right)^2 + \frac{1}{\varepsilon} W(\gamma_\varepsilon^{(i,l)}) \right] dt,$$

from which, using (4.4) and the property (iii) of Lemma 4.2, we obtain

$$\limsup_{\varepsilon\to 0^+} I_{\varepsilon,h} = \limsup_{\varepsilon\to 0^+} \sum_{(i,l)\in\mathcal{M}} J_\varepsilon^{(i,l)} \le 2 \sum_{\substack{i,l=1 \\ i<l}}^{n} \kappa_{i,l} \mathcal{H}^1(\partial A_i \cap \partial A_l \cap \Omega) = E_0(u_0).$$

Now we prove that the terms $II_{\varepsilon,h}$ and $III_{\varepsilon,h}$ vanish as $\varepsilon \to 0^+$. In [6, proof of Theorem 2.1], the following estimate has been proved:

$$II_{\varepsilon,h} \le \frac{C_1}{\varepsilon} |Q_{\varepsilon,h}| + C_2 h \sum_{(i,l)\in\mathcal{M}} |L_{\varepsilon,h}^{(i,l)} \setminus Q_{\varepsilon,h}| \, \|\nabla^2 u_\varepsilon\|_{L^\infty(L_\varepsilon^{(i,l)} \setminus Q_\varepsilon)} . \tag{4.5}$$

Since $d_{i,l}$ is a distance function from polygonal boundaries, we have $\nabla^2 d_{i,l} = 0$ on $L_\varepsilon^{(i,l)} \setminus Q_\varepsilon$, so that, using (4.3) and the property (ii) of Lemma 4.2, it follows

$$\|\nabla^2 u_\varepsilon\|_{L^\infty(L_\varepsilon^{(i,l)} \setminus Q_\varepsilon)} \le \|d^2 \gamma_\varepsilon^{(i,l)}/dt^2\|_{L^\infty(-\rho_\varepsilon,\rho_\varepsilon)} = O\left(\frac{1}{\varepsilon^2}\right).$$

Then, using (4.2), (4.5), and the condition $h = o(\varepsilon|\log\varepsilon|^{-1})$, we obtain that the term $II_{\varepsilon,h}$ vanishes.

Using again the results obtained in the proof of Theorem 2.1 of [6], the following estimate holds:

$$III_{\varepsilon,h} \le C \frac{h}{\varepsilon} \|\nabla u_\varepsilon\|_{L^\infty(\Omega)} \sum_{(i,l)\in\mathcal{M}} |L_{\varepsilon,h}^{(i,l)}|. \tag{4.6}$$

Since $\|\nabla u_\varepsilon\|_{L^\infty(\Omega)} = O(1/\varepsilon)$, using (4.2), (4.6), and the condition $h = o(\varepsilon|\log\varepsilon|^{-1})$, we obtain that also the term $III_{\varepsilon,h}$ vanishes, concluding the proof. □

Theorem 2.1 then follows from Theorem 3.1, Theorem 4.1, and the fact that the term $\int_\Omega |u(x) - I(x)|^2 \, dx$ is a continuous perturbation.

5. Convergence of minimizers. In this section we prove Theorem 2.2 stated in section 2.

Proof of Theorem 2.2. The existence of a minimizer u_ε of $F_{\varepsilon,h(\varepsilon)}$ is obtained easily since in fact we search for a minimizer in a compact subset of the space V_h which is of finite dimension. Moreover, there exists a constant $C > 0$ such that

$$F_{\varepsilon,h(\varepsilon)}(u_\varepsilon) \le C. \tag{5.1}$$

For any $\varepsilon > 0$, Lemma 3.2 provides a function $v_\varepsilon \in BV(\Omega)$ which satisfies (3.1) and (3.2). Let $\psi_\varepsilon(x) = g(v_\varepsilon(x))$, where g is the function defined by (3.4). We have $\psi_\varepsilon \in BV(\Omega)$ and $S_{\psi_\varepsilon} \subseteq S_{v_\varepsilon}$.

Set $c_M = \int_{-M}^{M} \sqrt{W(t)} dt$. Since $\|v_\varepsilon\|_{L^\infty(\Omega)} \le M$, the following estimates hold for any $\varepsilon > 0$:

$$\|\psi_\varepsilon\|_{L^\infty(\Omega)} < c_M, \qquad |D\psi_\varepsilon|(\Omega) \le \int_\Omega |\nabla\psi_\varepsilon| dx + c_M \mathcal{H}^1(S_{v_\varepsilon}). \tag{5.2}$$

Arguing as in the proof of Theorem 3.1, see (3.6), and using (5.1) and (3.1), we find

$$\begin{aligned} C \geq E_{\varepsilon,h}(u_\varepsilon) &\geq (1-\delta_h)\varepsilon \int_\Omega |\nabla v_\varepsilon|^2 dx + \frac{1}{\varepsilon}\int_\Omega W(v_\varepsilon)dx + 2\kappa_{1,n}\mathcal{H}^1(S_{v_\varepsilon}) \\ &\geq 2(1-\delta_h)^{1/2}\left[\int_\Omega |\nabla \psi_\varepsilon| dx + \kappa_{1,n}\mathcal{H}^1(S_{v_\varepsilon})\right] \\ &\geq 2\frac{\kappa_{1,n}}{c_M}(1-\delta_h)^{1/2}\left[\int_\Omega |\nabla \psi_\varepsilon| dx + c_M\mathcal{H}^1(S_{v_\varepsilon})\right], \end{aligned}$$

where we have used $c_M \geq \kappa_{1,n}$; see (2.2). Using (5.2), it follows that ψ_ε is uniformly bounded in $BV(\Omega)$ with respect to ε, for ε small enough. Then, using the compactness theorem in BV [14], there exists a subsequence $\{\psi_{\varepsilon_j}\}_j$ converging in $L^2(\Omega)$ to a function ψ_0.

Set $u_0 = g^{-1}(\psi_0)$. Since the function g is monotone increasing, using the properties of the potential W, it follows that the inverse function g^{-1} is bounded and uniformly continuous on compact subsets of $\mathbf{R}$. Then

$$v_{\varepsilon_j} = g^{-1} \circ \psi_{\varepsilon_j} \to u_0 \quad \text{in } L^2(\Omega) \text{ as } \varepsilon_j \to 0^+;$$

see also [18, proof of Proposition 3]. Reasoning as in the proof of Theorem 3.1 and using Lemma 3.2, we find that $u_{\varepsilon_j} \to u_0$ in $L^2(\Omega)$ as $\varepsilon_j \to 0^+$.

Hence, the statement of Theorem 2.2 follows from Theorem 2.1 and the property (1.5) of Γ-convergence. □

The condition $h = o(\varepsilon|\log\varepsilon|^{-1})$ deserves a discussion about the numerical implementation of the Γ-convergent approximation. According to such a condition in practical computations, h should be much smaller than ε, so that a very fine mesh has to be used. Nevertheless, this criterion is required only close to the discontinuity curves, so that fine meshing is necessary only across the boundaries of the classification.

For small ε, a minimizer u_ε of $F_{\varepsilon,h(\varepsilon)}$ is essentially constant, with values a_i in large regions corresponding to the sets A_i, whereas it exhibits sharp transitions in narrow strips across the jump set S_{u_0}. Hence an accurate reconstruction of the boundaries can be achieved by resorting to adaptive mesh generation, i.e., refining the mesh locally within the strips surrounding the transitions of the function u_ε. Such an approach has been numerically implemented for functionals with convex perturbation in [7]. In the application to image processing, the input image I has to be opportunely regularized (see next section), the parameter ε should be set equal to the width of the pixel, and the mesh locally refined at the subpixel level by taking $h \ll \varepsilon$. A different approach based on adaptive mesh optimization can be found in [8] for the numerical approximation of the Mumford–Shah functional.

The problem of numerical implementation that arises in the Γ-convergent approximation is related to a crucial problem of image processing: the computation of the length of curves in digitized images. This problem has been addressed in [15], where it has been shown that the computations must become nonlocal as the digitization gets finer and finer. The mesh refined across the discontinuity curves yields asymptotically a nonlocal computation in order to recover the length of such curves in the continuum limit.

6. Numerical integration. In this section we show that the numerical approximation of the lower order terms in the energy via the vertex quadrature rule does not change the results previously obtained (see [5, 6]). More precisely, for any $\varepsilon > 0$

let $I_\varepsilon \in \mathcal{C}_0^\infty(\Omega)$ approximate the function $I \in L^\infty(\Omega)$ so that [5] $I_\varepsilon \to I$ in $L^2(\Omega)$, $\|I_\varepsilon\|_{L^\infty(\Omega)} \le \|I\|_{L^\infty(\Omega)}$, and $\|\nabla I_\varepsilon\|_{L^\infty(\Omega)} \le C/\varepsilon$.

For any $h > 0$ and any $\varepsilon > 0$ we define the functional $\widehat{E}_{\varepsilon,h}$ by

$$\widehat{E}_{\varepsilon,h}(u) = \varepsilon \int_\Omega \frac{|\nabla u|^2}{1 + \mu_{\varepsilon,h}|\nabla u|^2} dx + \frac{1}{\varepsilon} \int_\Omega \pi_h(W(u)) dx$$

and the functional $\widehat{F}_{\varepsilon,h} : L^2(\Omega) \to [0, +\infty]$ by

$$\widehat{F}_{\varepsilon,h}(u) = \begin{cases} \widehat{E}_{\varepsilon,h}(u) + \displaystyle\int_\Omega \pi_h((u - I_\varepsilon)^2) dx & \text{if } u \in \mathcal{D}(\widehat{F}_{\varepsilon,h}), \\ \\ +\infty & \text{elsewhere in } L^2(\Omega), \end{cases}$$

where $\mathcal{D}(\widehat{F}_{\varepsilon,h}) = \{u \in V_h(\Omega) : \|u\|_{L^\infty(\Omega)} \le M\}$. The integrals in $\widehat{F}_{\varepsilon,h}$ can be evaluated via the vertex quadrature rule, which is exact for piecewise linear functions.

Let $u \in V_h(\Omega)$ and let $\mathcal{N}_h$ denote the set of all nodes of the triangulation $\mathbf{T}_h$. Define the function $\tilde{u} \in V_h(\Omega)$ in the following way: for any $q \in \mathcal{N}_h$ set $\tilde{u}(q) = u(q)$ if $|u(q)| \le M$, $\tilde{u}(q) = M$ if $u(q) > M$, and $\tilde{u}(q) = -M$ if $u(q) < -M$. Since the function $\varphi(t) = \frac{t^2}{1+\mu t^2}$ is monotone increasing for $t \ge 0$, by using the property (iv) of the potential W, we have

$$\widehat{E}_{\varepsilon,h}(\tilde{u}) + \int_\Omega \pi_h((\tilde{u} - I_\varepsilon)^2) dx \le \widehat{E}_{\varepsilon,h}(u) + \int_\Omega \pi_h((u - I_\varepsilon)^2) dx.$$

It follows that any absolute minimizer $u_{\varepsilon,h}$ of the above energy belongs to the domain $\mathcal{D}(\widehat{F}_{\varepsilon,h})$.

We prove the following proposition.

PROPOSITION 6.1. *Assume that $h = o(\varepsilon|\log\varepsilon|^{-1})$ and that $\mu_{\varepsilon,h} = o(\varepsilon h)$. Then the family $\{\widehat{F}_{\varepsilon,h}\}_\varepsilon$ Γ-converges to the functional*

$$F_0(u) = \int_\Omega (u - I)^2 dx + E_0(u)$$

in the $L^2(\Omega)$-topology as $\varepsilon \to 0^+$.

Moreover, any family $\{u_{\varepsilon,h}\}_\varepsilon$ of absolute minimizers of $\widehat{F}_{\varepsilon,h}$ is relatively compact in $L^2(\Omega)$, and each of its limit points minimizes F_0.

The proof of the proposition, which is based on Lemma 3.2 and on the estimates obtained in [5, 6], is given in the appendix.

For instance, let be $\Omega = [0,1]^2$, and let $\mathbf{T}_h$ consist of a uniform mesh of triangles formed by dividing Ω into uniform squares of size $h \times h$ and dividing each square into two triangles by cutting along the (1,–1) direction. The resulting discrete scheme is then equivalent to the finite difference method used in [19] for the classification of real images.

Appendix. First we prove Lemma 3.2. Since the proof is essentially the same as that of Proposition 3.3 in [9], we omit the details and underline the slight modifications which are useful in proving Theorem 3.1.

Proof of Lemma 3.2. For any $\delta_h \in (0,1)$ we have

$$\frac{t^2}{1 + \mu_{\varepsilon,h} t^2} \ge \min\left\{(1 - \delta_h)t^2, \frac{\delta_h}{\mu_{\varepsilon,h}}\right\} \qquad \forall t \ge 0. \tag{A.1}$$

Let ∇u_T denote the constant value of the gradient of u on each triangle $T \in \mathbf{T}_h$, and let $\mathbf{T}_h^1 = \{T \in \mathbf{T}_h : (1-\delta_h)|\nabla u_T|^2 > \frac{\delta_h}{\mu_{\varepsilon,h}}\}$. We define the function v in the following way:

$$v(x) = \begin{cases} a_1 & \text{on every } T \in \mathbf{T}_h^1, \\ u(x) & \text{on every } T \in \mathbf{T}_h \setminus \mathbf{T}_h^1. \end{cases}$$

Clearly we have $v \in BV(\Omega)$. Using inequality (A.1), the definition of v, and the same method of proof of Proposition 3.3 of [9], we find

$$E_{\varepsilon,h}(u) \geq (1-\delta_h)\varepsilon \int_\Omega |\nabla v|^2 dx + \frac{1}{\varepsilon}\int_\Omega W(v)dx + \frac{\delta_h \varepsilon}{\mu_{\varepsilon,h}} \sum_{T \in \mathbf{T}_h^1} |T|. \tag{A.2}$$

By the assumptions on the triangulation, the following inequality has been proved in [9]:

$$\sum_{T \in \mathbf{T}_h^1} |T| \geq \frac{1}{6} \cdot h \sin\theta_0 \cdot \mathcal{H}^1(S_v). \tag{A.3}$$

We now set

$$\delta_h = c\frac{\mu_{\varepsilon,h}}{\varepsilon h}, \qquad c = \frac{12\kappa_{1,n}}{\sin\theta_0}.$$

The estimate (3.1) then follows by using (A.2) and (A.3). The inequality (A.2) implies

$$E_{\varepsilon,h}(u) \geq \frac{c}{h} \sum_{T \in \mathbf{T}_h^1} |T|,$$

from which the estimate (3.2) follows. □

Now we prove Lemma 4.2. The extension of the standard construction method for a double-well potential [20] to the case of the potential W does not create particular difficulties, because the wells lie on the real axis. Hence we give the main steps of the construction omitting the details.

Proof of Lemma 4.2. Fix $m \in \{i, \dots, l-1\}$ and consider the solution $\eta^{(m,m+1)}$ of the ordinary differential equation:

$$\frac{d\eta^{(m,m+1)}}{dt} = \sqrt{W(\eta^{(m,m+1)})}, \qquad \eta^{(m,m+1)}(0) = \frac{1}{2}(a_m + a_{m+1}). \tag{A.4}$$

Using the properties of the function W and arguing as in section 1-B of [20], the solution can be defined on all of $\mathbf{R}$, and it is a monotone increasing function such that $a_m < \eta^{(m,m+1)}(t) < a_{m+1}$ for any t, and having the following asymptotic behavior:

$$\lim_{t \to +\infty} \frac{a_{m+1} - \eta^{(m,m+1)}(t)}{\exp(-\sqrt{\alpha_{m+1}}t)} = B_{m,m+1}, \qquad \lim_{t \to -\infty} \frac{\eta^{(m,m+1)}(t) - a_m}{\exp(\sqrt{\alpha_m}t)} = C_{m,m+1}, \tag{A.5}$$

where $2\alpha_m = W''(a_m)$, $2\alpha_{m+1} = W''(a_{m+1})$, and $B_{m,m+1}$, $C_{m,m+1}$ are positive constants. Now we set $t_{m,\varepsilon} = \varepsilon|\log\varepsilon|/\sqrt{\alpha_m}$ and we define $\eta_\varepsilon^{(m,m+1)} : \mathbf{R} \to \mathbf{R}$ in the

following way:

$$\eta_\varepsilon^{(m,m+1)}(t) = \begin{cases} \eta^{(m,m+1)}\left(\dfrac{t}{\varepsilon}\right) & \text{if } -t_{m,\varepsilon} \le t \le t_{m+1,\varepsilon}, \\ q_{m,\varepsilon}(t) & \text{if } -2t_{m,\varepsilon} \le t \le -t_{m,\varepsilon}, \\ a_m & \text{if } t \le -2t_{m,\varepsilon}, \\ p_{m+1,\varepsilon}(t) & \text{if } t_{m+1,\varepsilon} \le t \le 2t_{m+1,\varepsilon}, \\ a_{m+1} & \text{if} t \ge 2t_{m+1,\varepsilon}, \end{cases}$$

where $q_{m,\varepsilon}$, $p_{m+1,\varepsilon}$ are cubic polynomials chosen in such a way that $\eta_\varepsilon^{(m,m+1)} \in \mathcal{C}^1(\mathbf{R})$ for any $\varepsilon > 0$. One can verify that

$$\|d\eta_\varepsilon^{(m,m+1)}/dt\|_{L^\infty(-2t_{m,\varepsilon},2t_{m+1,\varepsilon})} = O\left(\frac{1}{\varepsilon}\right), \tag{A.6}$$

$$\|d^2\eta_\varepsilon^{(m,m+1)}/dt^2\|_{L^\infty(-2t_{m,\varepsilon},2t_{m+1,\varepsilon})} = O\left(\frac{1}{\varepsilon^2}\right). \tag{A.7}$$

Now we set

$$I_\varepsilon^{(m,m+1)} = \int_{-\infty}^{+\infty} \left[\varepsilon\left(\frac{d\eta_\varepsilon^{(m,m+1)}}{dt}\right)^2 + \frac{1}{\varepsilon}W(\eta_\varepsilon^{(m,m+1)})\right] dt.$$

By using (A.4) and (A.5), a standard computation of Γ-convergence applied to phase transition problems [20] yields

$$\lim_{\varepsilon\to 0^+} I_\varepsilon^{(m,m+1)} = 2\kappa_{m,m+1}. \tag{A.8}$$

The function $\gamma_\varepsilon^{(i,l)} : \mathbf{R} \to \mathbf{R}$ is then constructed by means of translations of the functions $\eta_\varepsilon^{(m,m+1)}$ in such a way that the smooth transitions between the values a_m, a_{m+1} do not overlap. We set

$$\rho_\varepsilon = \varepsilon|\log\varepsilon| \sum_{m=1}^{n-1} \left(\frac{1}{\sqrt{\alpha_m}} + \frac{1}{\sqrt{\alpha_{m+1}}}\right),$$

and we define a partition of the interval $[-\rho_\varepsilon, \rho_\varepsilon]$ into closed subintervals with disjoint interiors:

$$[-\rho_\varepsilon, \rho_\varepsilon] = \bigcup_{m=i}^{l-1} [\xi_{m,\varepsilon}, \xi_{m+1,\varepsilon}], \quad \xi_{m+1,\varepsilon} - \xi_{m,\varepsilon} = 2(t_{m,\varepsilon} + t_{m+1,\varepsilon}) \quad \text{for} i \le m < l-1,$$

with $\xi_{i,\varepsilon} = -\rho_\varepsilon$ and $\xi_{l,\varepsilon} = \rho_\varepsilon$. In each subinterval $[\xi_{m,\varepsilon}, \xi_{m+1,\varepsilon}]$ we set $\gamma_\varepsilon^{(i,l)}$ equal to $\eta_\varepsilon^{(m,m+1)}$ translated in such a way that $\gamma_\varepsilon^{(i,l)}(\xi_{m,\varepsilon}) = a_m$ and $\gamma_\varepsilon^{(i,l)}(\xi_{m+1,\varepsilon}) = a_{m+1}$. It is easy to check that such a function $\gamma_\varepsilon^{(i,l)}$ satisfies the property (i) of the statement of the lemma. The property (ii) then follows from (A.6) and (A.7).

By the construction of $\gamma_\varepsilon^{(i,l)}$, using (A.8), we obtain

$$\begin{aligned} \lim_{\varepsilon\to 0^+} \int_{-\infty}^{+\infty} \left[\varepsilon\left(\frac{d\gamma_\varepsilon^{(i,l)}}{dt}\right)^2 + \frac{1}{\varepsilon}W(\gamma_\varepsilon^{(i,l)})\right] dt &= \lim_{\varepsilon\to 0^+} \sum_{m=i}^{l-1} I_\varepsilon^{(m,m+1)} \\ &= \sum_{m=i}^{l-1} \lim_{\varepsilon\to 0^+} I_\varepsilon^{(m,m+1)} = \sum_{m=i}^{l-1} 2\kappa_{m,m+1} = 2\kappa_{i,l}, \end{aligned}$$

and we have proved the property (iii). ∎

Proof of Proposition 6.1. We prove first the lower inequality: for every function $u_0 \in L^2(\Omega)$ and for every sequence $\{u_{\varepsilon,h}\}_\varepsilon \subset L^2(\Omega)$ converging to u_0 in $L^2(\Omega)$ we have

$$\liminf_{\varepsilon\to 0^+} \widehat{F}_{\varepsilon,h}(u_{\varepsilon,h}) \geq \int_\Omega (u_0 - I)^2 dx + E_0(u_0). \tag{A.9}$$

We can suppose, possibly extracting a subsequence, that $\{u_{\varepsilon,h}\}_\varepsilon \subset \mathcal{D}(\widehat{F}_{\varepsilon,h})$ and $\liminf_{\varepsilon\to 0^+} \widehat{F}_{\varepsilon,h}(u_{\varepsilon,h}) = \lim_{\varepsilon\to 0^+} \widehat{F}_{\varepsilon,h}(u_{\varepsilon,h}) = L < +\infty$; otherwise (A.9) is obvious. Following the method of [5, 6], we split $\widehat{F}_{\varepsilon,h}(u_{\varepsilon,h})$ as follows:

$$\begin{aligned}\widehat{F}_{\varepsilon,h}(u_{\varepsilon,h}) &= F_{\varepsilon,h}(u_{\varepsilon,h}) + \frac{1}{\varepsilon}\int_\Omega [\pi_h(W(u_{\varepsilon,h})) - W(u_{\varepsilon,h})]dx \\ &\quad + \int_\Omega [\pi_h((u_{\varepsilon,h} - I_\varepsilon)^2) - (u_{\varepsilon,h} - I)^2]dx = F_{\varepsilon,h}(u_{\varepsilon,h}) + I_{\varepsilon,h} + II_{\varepsilon,h}.\end{aligned} \tag{A.10}$$

In view of Theorem 2.1, in order to show (A.9) it will be enough to prove that $\lim_{\varepsilon\to 0^+} I_{\varepsilon,h} = \lim_{\varepsilon\to 0^+} II_{\varepsilon,h} = 0$. Arguing as in the proof of (A.2), we have for a fixed $\delta \in (0,1)$ and ε small enough

$$L + 1 \geq (1-\delta)\varepsilon \int_{\mathcal{A}_{\varepsilon,h}} |\nabla u_{\varepsilon,h}|^2 dx + \frac{\delta\varepsilon}{\mu_{\varepsilon,h}} |\Omega \setminus \mathcal{A}_{\varepsilon,h}|, \tag{A.11}$$

where $\mathcal{A}_{\varepsilon,h} = \bigcup_{T\in\mathbf{T}_h\setminus\mathbf{T}_h^1} T$. Using the estimates obtained in the proof of Theorem 2.1 of [6] and the properties of the potential W, we have

$$|I_{\varepsilon,h}| \leq C_1 \mathrm{Lip}(W')\frac{h^2}{\varepsilon}\int_{\mathcal{A}_{\varepsilon,h}} |\nabla u_{\varepsilon,h}|^2 dx + \frac{C_2}{\varepsilon}|\Omega \setminus \mathcal{A}_{\varepsilon,h}|. \tag{A.12}$$

Hence, using (A.11), (A.12), and the conditions $h = o(\varepsilon|\log\varepsilon|^{-1})$ and $\mu_{\varepsilon,h} = o(\varepsilon h)$, we find that the term $I_{\varepsilon,h}$ vanishes. Analogously we have

$$|II_{\varepsilon,h}| \leq \int_{\mathcal{A}_{\varepsilon,h}} |\pi_h((u_{\varepsilon,h} - I_\varepsilon)^2) - (u_{\varepsilon,h} - I)^2| dx + C_2|\Omega \setminus \mathcal{A}_{\varepsilon,h}|. \tag{A.13}$$

Arguing as in the proof of Theorem 4.1 of [5], it follows that the first term in the right-hand side of (A.13) converges to zero. Hence, using (A.11), we find that also the term $II_{\varepsilon,h}$ vanishes. This concludes the proof of (A.9).

We now prove the upper inequality. Let $u_0 \in BV(\Omega;\{a_1,\dots,a_n\})$, and let $\{u_{\varepsilon,h}\}_\varepsilon$ be the sequence converging to u_0 constructed in the proof of Theorem 4.1 and such that $\limsup_{\varepsilon\to 0^+} E_{\varepsilon,h}(u_{\varepsilon,h}) \leq E_0(u_0)$. The proof of Theorem 4.1 shows that the following estimate holds:

$$\int_\Omega |\nabla u_{\varepsilon,h}|^2 dx \leq \frac{C}{\varepsilon}. \tag{A.14}$$

Let us split $\widehat{F}_{\varepsilon,h}(u_{\varepsilon,h})$ as in (A.10). Then the results obtained in the proof of the lower inequality and the estimate (A.14) guarantee that the terms $I_{\varepsilon,h}$ and $II_{\varepsilon,h}$ again vanish as $\varepsilon \to 0^+$. Hence

$$\limsup_{\varepsilon\to 0^+} \widehat{F}_{\varepsilon,h}(u_{\varepsilon,h}) = \limsup_{\varepsilon\to 0^+} F_{\varepsilon,h}(u_{\varepsilon,h}) \leq \int_\Omega (u_0 - I)^2 dx + E_0(u_0),$$

which yields the upper inequality and concludes the proof of Γ-convergence.

Finally, the convergence of the minimizers follows by splitting again the functional $\widehat{F}_{\varepsilon,h}(u_{\varepsilon,h})$ as in (A.10) and arguing as in the proof of Theorem 2.2. □

POINTWISE ERROR ESTIMATES OF DISCONTINUOUS GALERKIN METHODS WITH PENALTY FOR SECOND-ORDER ELLIPTIC PROBLEMS*

ZHANGXIN CHEN† AND HONGSEN CHEN‡

Abstract. In this paper discontinuous Galerkin methods with penalty for solving second-order elliptic problems are considered. Error estimates are studied for these methods. In particular, optimal localized pointwise error estimates are established on quasi-uniform grids in R^N $(N \geq 2)$.

Key words. discontinuous Galerkin method, pointwise error estimate, elliptic problem

DOI. 10.1137/S0036142903421527

1. Introduction.

Considerable attention has been recently paid to the development and analysis of discontinuous Galerkin (DG) methods for second-order elliptic problems. The DG methods with penalty are nowadays widely used in many problems and applications [11]. In a DG method the approximation space typically consists of discontinuous piecewise polynomials, with boundary conditions and continuity on interelement boundaries weakly imposed through a bilinear form. For second-order elliptic problems these methods trace back originally to the work of Nitsche [15], which was further developed and analyzed by Douglas and Dupont [12], Baker [4], Wheeler [23], and Arnold [2]. More recent developments of the DG methods for elliptic problems can be found in Oden, Babuška, and Baumann [16], Brezzi et al. [5], Castillo et al. [6], Rivière, Wheeler, and Girault [18], Chen and Chen [7], and Chen, Chen, and Li [8] (also see Cockburn, Karniadakis, and Shu [11]). We refer to Chen [9] and Arnold et al. [3] for a review on the relationships and properties of different DG methods. Optimal error estimates for the DG methods with penalty have been obtained in [2, 18] in energy and L^2 norms.

The aim of this paper is to derive localized pointwise error estimates for the DG methods. The results in this paper represent an improvement and extension to those obtained by Kanschat and Rannacher [14]. Our analysis is based on the technique developed by Schatz [19, 20] for the standard continuous finite element methods for second-order elliptic problems. Therefore, the new pointwise error estimates obtained in this paper indicate a more localized dependence of the error on the derivatives of the true solution. We will give a more detailed description on our results and on the difference between our results and those of [14]. The error estimate of optimal order for the DG methods with penalty takes the form

$$\|u - u_h\|_{L^2(\Omega)} + h|||u - u_h|||_{H_h^1(\Omega)} \leq Ch^{1+r}\|u\|_{H^{1+r}(\Omega)},$$

where u and u_h are the true and approximate solutions, respectively; r is the order of polynomials used in the finite element space; and $|||\cdot|||_{H_h^1(\Omega)}$ is a special energy

norm involving measures on the jumps of discontinuous functions on the boundaries of interelements. In [14] the local pointwise error estimate was obtained:

$$|(u-u_h)(z)| \le Ch^2 \ln h^{-1} \|D^2 u\|_{L^\infty(B_a)} + Ch^2 \|D^2 u\|_{L^2(\Omega)}, \tag{1.1}$$

where B_a is a ball centered at $z \in \Omega$ and with a fixed radius $a = \mathcal{O}(1)$. Estimate (1.1) was proved for the model Laplacian equation in a two-dimensional domain and for the space of (discontinuous) piecewise linear functions. The proof of (1.1) in [14] relies on the technique of the discrete Green's function developed by Frehse and Rannacher [13] and Rannacher and Scott [17]. In this paper we derive pointwise error estimates for general second-order elliptic problems defined in a domain of R^N and for general finite element spaces. Moreover, our analysis is based on the technique developed by Schatz [19, 20] and Schatz and Wahlbin [21] for the standard conforming (continuous) finite element methods. Therefore, more localized and sharper results are obtained in this paper. In fact, the new pointwise error estimates obtained in this paper, which are for the symmetric DG method, are the following:

$$\begin{aligned} &|(u-u_h)(z)| \le Ch^{1+r} \left(\ln h^{-1}\right)^{\bar{s}} \|u\|_{W^{1+r,\infty}(\Omega),z,s}, \quad 0 \le s \le r-1, \\ &|\nabla(u-u_h)(z)| \le Ch^{r} \left(\ln h^{-1}\right)^{\bar{\bar{s}}} \|u\|_{W^{1+r,\infty}(\Omega),z,s}, \quad 0 \le s \le r, \end{aligned} \tag{1.2}$$

where $\bar{s} = 0$ if $0 \le s < r-1$ and $\bar{s} = 1$ if $s = r-1$; $\bar{\bar{s}} = 0$ if $0 \le s < r$ and $\bar{\bar{s}} = 1$ if $s = r$. The norm $\|\cdot\|_{W^{1+r,\infty}(\Omega),z,s}$ is a weighted Sobolev norm with the weight function $\sigma_{z,h}^s = (h/(|z-x|+h))^s$. The gradient operator in (1.2) is understood elementwise. According to the estimates in (1.2), the higher order of the finite element approximation, the more localized dependence of the errors on the true solution. As special consequences of (1.2), we have

$$\begin{aligned} &\|u-u_h\|_{L^\infty(\Omega)} \le Ch^{1+r} \left(\ln h^{-1}\right)^{\bar{r}} \|u\|_{W^{1+r,\infty}(\Omega)}, \\ &\|\nabla(u-u_h)\|_{L^\infty(\Omega)} \le Ch^{r} \|u\|_{W^{1+r,\infty}(\Omega)}, \end{aligned}$$

where $\bar{r} = 0$ if $r > 1$ and $\bar{r} = 1$ if $r = 1$. The pointwise error estimates obtained in this paper will be bounded by global estimates. Local bounds will be studied in a forthcoming paper.

2. Preliminaries. We consider the following homogeneous Dirichlet boundary value problem:

$$\begin{aligned} \mathcal{L}u \equiv -\sum_{i,j=1}^{N} \frac{\partial}{\partial x_j}\left(a_{ij}(x)\frac{\partial u}{\partial x_i}\right) + \sum_{i=1}^{N} b_i(x)\frac{\partial u}{\partial x_i} + c(x)u = f(x) \quad &\text{in } \Omega, \\ u = 0 \quad &\text{on } \partial\Omega, \end{aligned} \tag{2.1}$$

where $\Omega \subset R^N$ $(N \ge 2)$ is a bounded domain with smooth boundary $\partial\Omega$ and f is a given function. For the sake of simplicity, we assume that the coefficients a_{ij}, b_i, and c are in $C^\infty(\Omega)$ and the operator $\mathcal{L}$ is uniformly elliptic in the sense that there exists a constant $C_L > 0$ such that

$$C_L \sum_{i=1}^{N} \zeta_i^2 \le \sum_{i,j=1}^{N} a_{ij}(x)\zeta_i\zeta_j \qquad \forall\ \zeta \in R^N \ \text{ and } \ x \in \Omega. \tag{2.2}$$

We will use the standard notation for the Sobolev spaces and their norms. For any open subset $D \subset \Omega$, nonnegative integer ℓ, and real number $1 \le p \le \infty$, denote the Sobolev spaces by $W^{\ell,p}(D) = \{v :\ \|v\|_{W^{\ell,p}(D)} < \infty\}$, with

$$\|v\|^p_{W^{\ell,p}(D)} = \sum_{i=0}^{\ell} |v|^p_{W^{i,p}(D)},\ |v|^p_{W^{i,p}(D)} = \sum_{|\alpha|=i} \int_D \left| \frac{\partial^\alpha v(x)}{\partial x^\alpha} \right|^p \, dx.$$

(When $p = \infty$, a standard modification applies to these norms [1].) Let $W_0^{\ell,p}(D)$ be the completion of $C_0^\infty(D)$ according to the norm $\|\cdot\|_{W^{\ell,p}(D)}$, where $C_0^\infty(D)$ represents the space of functions with continuous derivatives of arbitrary order and compact support in D. We also adopt the usual notation for the Hilbert H^ℓ and L^p spaces:

$$H^\ell(D) = W^{\ell,2}(D), \quad H_0^\ell(D) = W_0^{\ell,2}(D), \quad L^p(D) = W^{0,p}(D).$$

Denote by $(\cdot,\cdot)$ the inner product in $L^2(\Omega)$: $(u,v) = \int_\Omega u(x)v(x)\,dx$. For $\ell \geq 0$, the negative norm $\|\cdot\|_{H^{-\ell}(D)}$ is defined as follows:

$$\|v\|_{H^{-\ell}(D)} = \sup_{\varphi \in C_0^\infty(D),\ \|\varphi\|_{H^\ell(D)}=1} (v,\varphi).$$

To introduce the DG methods, let $\mathcal{J}_h$ denote a partition of the domain Ω into a finite number N_h of open subdomains K_j, $j = 1, 2, \ldots, N_h$, such that

$$\bar{\Omega} = \bigcup_{K_j \in \mathcal{J}_h} \bar{K}_j \quad \text{and} \quad K_i \cap K_j = \emptyset \quad \text{if } i \neq j.$$

We assume that the partition $\mathcal{J}_h$ is shape-regular. To be more precise, let $B_\theta(z)$ denote the ball centered at $z \in R^N$ and with radius θ. We set

$$h_K = \operatorname{diam}(K), \quad \theta_K = \max\{\theta :\ B_\theta(z) \subset K, z \in K\}, \quad h = \max_{K \in \mathcal{J}_h} h_K.$$

There are constants $C_1 > 0$ and $C_2 > 0$ independent of h and $K \in \mathcal{J}_h$ such that

$$h_K/\theta_K \leq C_1, \quad h \leq C_2 h_K, \qquad \forall\ K \in \mathcal{J}_h.$$

Note that the mesh $\mathcal{J}_h$ is not required to be conforming; i.e., a vertex of an element may lie on the boundary of another element and there may be hanging nodes.

Furthermore, let Γ_h denote the set of $(N-1)$-dimensional open subsets e_j, $j = 1, 2, \ldots, N_h^e$, such that

$$\bigcup_{j=1}^{N_h} \partial K_j = \bigcup_{j=1}^{N_h^e} \bar{e}_j \quad \text{and} \quad e_i \cap e_j = \emptyset \quad \text{if} \quad i \neq j,$$

and let

$$\Gamma_h^0 = \{e \in \Gamma_h :\ e \cap \partial\Omega = \emptyset\}.$$

We assume that for each $e \in \Gamma_h^0$, $e \subset \partial K \cap \partial K'$ for some K, $K' \in \mathcal{J}_h$. For each $e \in \Gamma_h$, we define $h_e = (h_K + h_{K'})/2$ if $e \subset \partial K \cap \partial K'$ and $h_e = h_K$ if $e \in \partial K \cap \partial\Omega$, and for $K \in \mathcal{J}_h$, let $n_K \in R^N$ denote the unit outward normal vector to ∂K.

Define the discontinuous Sobolev space

$$W_h^{\ell,p}(D) = \{v :\ v \in W^{\ell,p}(K \cap D) \ \text{ for each } K \in \mathcal{J}_h \ \text{ and } \ \|v\|_{W_h^{\ell,p}(D)} < \infty\},$$

equipped with the norm

$$\|v\|^p_{W_h^{\ell,p}(D)} = \sum_{i=0}^{\ell} |v|^p_{W_h^{i,p}(D)},\ |v|^p_{W_h^{i,p}(D)} = \sum_{K\in\mathcal{J}_h} |v|^p_{W^{i,p}(K\cap D)}.$$

When $p = 2$, we set $H_h^\ell(D) = W_h^{\ell,2}(D)$.

For any $v \in H_h^\ell(\Omega)$ $(\ell > 1/2)$, we define its average and jump on an intersection of any two elements as follows: For any $e \in \Gamma_h$, we define

$$\{\!\{v\}\!\}|_e = \begin{cases} \dfrac{1}{2}(v|_K + v|_{K'}) & \text{if } e \in \Gamma_h^0 \text{ and } e \subset \partial K \cap \partial K', \\ v|_K & \text{if } e \in \Gamma_h\backslash\Gamma_h^0 \text{ and } e \in \partial K, \end{cases}$$

$$[\![v]\!]|_e = \begin{cases} v|_K\, n_K + v|_{K'}\, n_{K'} & \text{if } e \in \Gamma_h^0 \text{ and } e \subset \partial K \cap \partial K', \\ v|_K\, n_K & \text{if } e \in \Gamma_h\backslash\Gamma_h^0 \text{ and } e \in \partial K. \end{cases}$$

It is clear that $[\![v]\!] \in R^N$ is a vector with components $[\![v]\!]_i = v|_K\, n_{K,i} + v|_{K'}\, n_{K',i}$ if $e \subset \partial K \cap \partial K'$ and $[\![v]\!]_i = v|_K\, n_{K,i}$ if $e \in \partial K \cap (\Gamma_h\backslash\Gamma_h^0)$ for $1 \le i \le N$.

Multiplying (2.1) by $v \in H_h^2(\Omega)$, integrating over $K \in \mathcal{J}_h$, using the continuity of u and its fluxes across each $e \in \Gamma_h^0$, and adding on all $K \in \mathcal{J}_h$, it follows that

$$a(u, v) - b(u, v) = (f, v), \tag{2.3}$$

where

$$a(u,v) = \sum_{K\in\mathcal{J}_h} \int_K \left(\sum_{i,j=1}^N a_{ij}(x) \frac{\partial u}{\partial x_i} \frac{\partial v}{\partial x_j} + \sum_{i=1}^N b_i \frac{\partial u}{\partial x_i} v + cuv \right) dx,$$

$$b(u,v) = \sum_{e\in\Gamma_h} \int_e \sum_{i,j=1}^N \left\{\!\!\left\{ a_{ij} \frac{\partial u}{\partial x_i} \right\}\!\!\right\} [\![v]\!]_j \, ds.$$

Here and throughout this paper, a differential operator is defined elementwise when it is not valid globally. To enforce stability of the DG methods, a term $b(v, u)$ involving continuity of the true solution at interelement interfaces and a penalty term $\lambda(u, v)$ are added to the left-hand side of (2.3) to obtain the bilinear form $A(\cdot, \cdot)$:

$$A(u, v) = a(u, v) - b(u, v) - \tau b(v, u) + \lambda(u, v), \tag{2.4}$$

where $\tau = 1$ or -1 and

$$\lambda(u, v) = \sum_{e\in\Gamma_h} \frac{\lambda_e}{h_e} \int_e [\![u]\!][\![v]\!] \, ds. \tag{2.5}$$

Here, for each $e \in \Gamma_h$, λ_e is a real number satisfying

$$C_\lambda \le \lambda_e < \infty \qquad \forall\ e \in \mathcal{J}_h. \tag{2.6}$$

The constant C_λ in (2.6) will be determined later and should be large enough to enforce the stability of the DG methods.

Let $S^h \subset W_h^{2,\infty}(\Omega)$ be a finite dimensional subspace. For simplicity, we assume that S^h consists of piecewise polynomials of degree $r \geq 1$:

$$S^h = \{v \in L^\infty(\Omega) : \ v|_K \in \mathcal{S}(K), \ K \in \mathcal{J}_h\},$$

where $\mathcal{P}_r(K) \subset \mathcal{S}(K) \subset \mathcal{P}_{r_1}(K)$ for some integers $1 \leq r \leq r_1$ and $\mathcal{P}_r(K)$ denotes the set on K of all polynomials of degree less than or equal to r. We define the finite element approximation $u_h \in S^h$ of $u \in H_0^1(\Omega)$ to be the solution of

$$A(u_h, v) = (f, v) \qquad \forall \ v \in S^h. \tag{2.7}$$

Noting that the bilinear form $A(\cdot, \cdot)$ is *consistent* with (2.1) in the sense that

$$A(u, v) = (f, v) \qquad \forall \ v \in H_h^2(\Omega), \tag{2.8}$$

we have the following error equation:

$$A(u - u_h, v) = 0 \qquad \forall \ v \in S^h. \tag{2.9}$$

The cases $\tau = 1$ and $\tau = -1$ correspond to the symmetric and nonsymmetric interior penalty DG methods, respectively.

For any $D \subset \Omega$, we will need a special norm $|||\cdot|||_{W_h^{1,p}(D)}$ defined by

$$\begin{aligned} |||v|||_{W_h^{1,p}(D)} = \|v\|_{W_h^{1,p}(D)} &+ \left(\sum_{e \in \Gamma_h} h_e^{1-p} \int_{e \cap D} |[\![v]\!]|^p \ ds \right)^{1/p} \\ &+ \left(\sum_{e \in \Gamma_h} h_e \int_{e \cap D} \sum_{i=1}^N \left| \left\{\!\!\left\{ \frac{\partial v}{\partial x_i} \right\}\!\!\right\} \right|^p \ ds \right)^{1/p}, \end{aligned} \tag{2.10}$$

where $1 \leq p < \infty$. For $p = \infty$, we have the modification

$$\begin{aligned} |||v|||_{W_h^{1,\infty}(D)} = \|v\|_{W_h^{1,\infty}(D)} &+ \max_{e \in \Gamma_h} h_e^{-1} \|[\![v]\!]\|_{L^\infty(e \cap D)} \\ &+ \max_{e \in \Gamma_h} \|\{\!\{\nabla v\}\!\}\|_{L^\infty(e \cap D)}. \end{aligned} \tag{2.11}$$

When $p = 2$, we use $|||v|||_{H_h^1(D)} = |||v|||_{W_h^{1,2}(D)}$. We also need a weighted analogue of $|||\cdot|||_{W_h^{1,p}(D)}$. To this end, following Schatz [19] we introduce the weight function

$$\sigma_{z,h}^s(x) = \left(\frac{h}{|x - z| + h} \right)^s. \tag{2.12}$$

Clearly, $\sigma_{z,h}^s(x) = \mathcal{O}(1)$ if $s > 0$ and $|x - z| = \mathcal{O}(h)$, and $\sigma_{z,h}^s(x) = \mathcal{O}(h^s)$ if $|x - z| = \mathcal{O}(1)$. For $1 \leq p < \infty$ and fixed z, we define the following weighted norm:

$$\begin{aligned} |||v|||_{W_h^{1,p}(D),z,s}^p = \|v\|_{W_h^{1,p}(D),z,s}^p &+ \sum_{e \in \Gamma_h} h_e^{1-p} \int_{e \cap D} |\sigma_{z,h}^s [\![v]\!]|^p \ ds \\ &+ \sum_{e \in \Gamma_h} h_e \int_{e \cap D} \sum_{i=1}^N \left| \sigma_{z,h}^s \left\{\!\!\left\{ \frac{\partial v}{\partial x_i} \right\}\!\!\right\} \right|^p \ ds, \end{aligned} \tag{2.13}$$

where $\|v\|_{W_h^{1,p}(D),z,s}^p = \|\sigma_{z,h}^s v\|_{L^p(D)}^p + \|\sigma_{z,h}^s \nabla v\|_{L^p(D)}^p$. For $p = \infty$, a modification similar to (2.11) can be made.

Next, we will collect some well-known results about approximation properties, inverse properties, and superapproximation properties. For the proof of Propositions 2.1 and 2.2 below, refer to [10]. The proof of Proposition 2.4 can be found in Schatz and Wahlbin [21]. Below we assume that $\kappa > 0$ is a fixed constant.

PROPOSITION 2.1. *Let $1 \le p \le \infty$ and $0 \le i \le 1 \le j \le 1 + r$.*

(i) *If $v \in W^{j,p}(K)$, then there exists a $\chi \in S^h$ such that for any $K \in \mathcal{J}_h$,*

$$\|v - \chi\|_{W^{i,p}(K)} \le Ch^{j-i}\|v\|_{W^{j,p}(K)},$$

where the constant C is independent of v, h, and K.

(ii) *If $D_1 \subset D_2$ satisfies $dist(D_1, \partial D_2 \backslash \partial\Omega) \ge \kappa h$ and $v \in W_h^{j,p}(D_2)$, then there exists a $\chi \in S^h(D_2)$ such that*

$$\|v - \chi\|_{W_h^{i,p}(D_1)} \le Ch^{j-i}\|v\|_{W_h^{j,p}(D_2)},$$

where the constant C is independent of v, h, D_1, and D_2.

PROPOSITION 2.2. *Let $1 \le q \le p \le \infty$ and $0 \le i \le j \le 1 + r$.*

(i) *If $v \in S^h$, then*

$$\|v\|_{W^{i,p}(K)} \le Ch^{i-j+N(1/q-1/p)}\|v\|_{W^{j,q}(K)}, \quad K \in \mathcal{J}_h,$$

where the constant C is independent of v, h, and K.

(ii) *If $D_1 \subset D_2$ with $dist(D_1, \partial D_2 \backslash \partial\Omega) \ge \kappa h$ and $v \in S^h(D_2)$, then*

$$\|v\|_{W_h^{i,p}(D_1)} \le Ch^{i-j+N(1/q-1/p)}\|v\|_{W_h^{j,q}(D_2)}$$

and

$$|||v|||_{H_h^1(D_1)} \le Ch^{-1}\|v\|_{L^2(D_2)},$$

where the constant C is independent of v, h, D_1, and D_2.

A superapproximation property in $|||\cdot|||_{H_h^1}$ is needed in the proof of interior error estimates. To state it, we need additional notation. For any subsets $D_1 \subset \Omega$ and $D_2 \subset \Omega$, by $D_1 \Subset D_2$ we mean $D_1 \subset D_2$ and $\mathrm{dist}(D_1, \partial D_2 \backslash \partial\Omega) > 0$. Moreover, for any $D \subset \Omega$, $C_<^\infty(D)$ denotes the subspace of $C^\infty(D)$ defined by

$$C_<^\infty(D) = \{v \in C^\infty(D) : \ \mathrm{supp}(v) \Subset D\}.$$

PROPOSITION 2.3. *Let $D_0 \subset D_1 \subset D_2 \subset \Omega$, with the conditions $dist(D_0, \partial D_1 \backslash \partial\Omega) \ge \kappa h$, $dist(D_1, \partial D_2 \backslash \partial\Omega) \ge \kappa h$, and $\omega \in C_<^\infty(D_1)$. Then, for any $v \in S^h(D_2)$ there exists a $\chi \in S^h(D_2)$ such that* $\mathrm{supp}(\chi) \Subset D_2$ *and*

$$|||\omega v - \chi|||_{H_h^1(D_2)} \le Ch|||v|||_{H_h^1(D_2)}.$$

Proof. It suffices to show this property on each element $K \in \mathcal{J}_h$:

$$|||\omega v - \chi|||_{H^1(K)} \le Ch|||v|||_{H^1(\hat{K})},$$

which is apparently true (see Ciarlet [10] and Schatz and Wahlbin [21]). Here $\hat{K}$ denotes the union of elements whose boundary intersects with ∂K. ∎

The last proposition is about a scaling property. This property is used to obtain an explicit dependence on the distance between two subdomains in the local error estimates, which is crucial for the proof of pointwise error estimates.

PROPOSITION 2.4. *Let $x_0 \in \bar{\Omega}$ and $d \ge kh$. The linear transformation $y = (x - x_0)/d$ maps the set $B_d(x_0) = \{x \in \Omega : \ |x - x_0| < d\}$ into a new set $\hat{B}_1(x_0)$ and the space $S^h(B_d(x_0))$ into a new space $\hat{S}^{h/d}(\hat{B}_1(x_0))$. Moreover, $\hat{S}^{h/d}(\hat{B}_1(x_0))$ satisfies Propositions* 2.1–2.3 *with h replaced by h/d. The constants occurring in these propositions remain unchanged, in particular independent of d.*

3. Stability and boundedness. In this section we discuss the stability and boundedness of $A(\cdot,\cdot)$. By *stability* we mean the coercivity of $A(\cdot,\cdot)$ in $H_h^1(\Omega)$ (see (3.5) in Lemma 3.2). This coercivity is essential to guarantee existence and uniqueness of the finite element solution u_h of (2.7). The boundedness of $A(\cdot,\cdot)$ in $|||\cdot|||_{W_h^{1,p}(\Omega)}$ is proved in Lemma 3.3. These results will be used in the proofs in the fourth and fifth sections. It is well known that for any $v \in H_0^1(\Omega)$, $\|v\|_{L^2(\Omega)} \le C\|\nabla v\|_{L^2(\Omega)}$. The result in the next lemma is a discontinuous version of this inequality.

LEMMA 3.1. *There is a constant $C > 0$ such that for any $v \in S^h$ we have*

$$\|v\|_{L^2(\Omega)}^2 \le C \sum_{e\in\Gamma_h} h_e^{-1} \int_e |[\![v]\!]|^2 \, ds + C|v|_{H_h^1(\Omega)}^2. \tag{3.1}$$

Proof. For any $K \in \mathcal{J}_h$ and $x \in K$, choose

$$\{K_1, K_2, \ldots, K_{i_K}\} \subset \mathcal{J}_h \quad \text{and} \quad \{e_1, e_2, \ldots, e_{i_K}\} \subset \Gamma_h$$

such that $K_1 = K$, $i_k \le Ch^{-1}$, $e_i \subset \partial K_i \cap \partial K_{i+1}$ for $1 \le i \le i_K - 1$, and $e_{i_K} \subset \partial K_{i_K} \cap \partial\Omega$. Then, for any $s \in e_1$ and $y \in K_2$,

$$v(x) = (v|_{K_1}(s) - v|_{K_2}(s)) + (v(x) - v|_{K_1}(s)) + (v|_{K_2}(s) - v(y)) + v(y),$$

which implies

$$\begin{aligned} |v(x)| &\le |[\![v]\!](s)| + Ch\|\nabla v\|_{L^\infty(K_1\cup K_2)} + |v(y)| \\ &\le |[\![v]\!](s)| + Ch^{1-N/2}\|\nabla v\|_{L^2(K_1\cup K_2)} + |v(y)|. \end{aligned} \tag{3.2}$$

Integrating on e_1 with respect to s, it follows from (3.2) that

$$\begin{aligned} |v(x)| &\le Ch^{1-N} \int_{e_1} |[\![v]\!]| \, ds + Ch^{1-N/2}\|\nabla v\|_{L^2(K_1\cup K_2)} + |v(y)| \\ &\le Ch^{(1-N)/2} \left(\int_{e_1} |[\![v]\!]|^2 \, ds \right)^{1/2} + Ch^{1-N/2}\|\nabla v\|_{L^2(K_1\cup K_2)} + |v(y)|. \end{aligned}$$

Reasoning in the same way, we have for each $1 \le i \le i_K - 1$, $x \in K_i$, and $y \in K_{i+1}$,

$$|v(x)| \le Ch^{(1-N)/2} \left(\int_{e_i} |[\![v]\!]|^2 \, ds \right)^{1/2} + Ch^{1-N/2}\|\nabla v\|_{L^2(K_i\cup K_{i+1})} + |v(y)|.$$

Using the fact that $[\![v]\!] = v$ on $e_{i_K} \subset \partial\Omega$, for any $y \in K_{i+1}$ we have

$$|v(y)| \le Ch^{(1-N)/2} \left(\int_{e_{i_K}} |[\![v]\!]|^2 \, ds \right)^{1/2} + Ch^{1-N/2}\|\nabla v\|_{L^2(K_{i_K})}.$$

Thus we conclude that for $x \in K$,

$$|v(x)| \le Ch^{1-N/2} \sum_{i=1}^{i_K} \left(h_e^{-1} \int_{e_i} |[\![v]\!]|^2 \, ds \right)^{1/2} + Ch^{1-N/2} \sum_{i=1}^{i_K} \|\nabla v\|_{L^2(K_i)},$$

which further yields

$$|v(x)|^2 \le Ch^{1-N} \sum_{i=1}^{i_K} h_e^{-1} \int_{e_i} |[\![v]\!]|^2 \, ds + Ch^{1-N} \sum_{i=1}^{i_K} \|\nabla v\|_{L^2(K_i)}^2. \tag{3.3}$$

Integrating (3.3) on K with respect to x, we obtain

$$\|v\|^2_{L^2(K)} \le Ch \sum_{i=1}^{i_K} h_e^{-1} \int_{e_i} |[\![v]\!]|^2 \, ds + Ch \sum_{i=1}^{i_K} \|\nabla v\|^2_{L^2(K_i)}. \tag{3.4}$$

Taking summation over $K \in \mathcal{J}_h$ in (3.4) and noting that the integrals on the right-hand side of (3.4) may repeat at most Ch^{-1} times, the result (3.1) follows. ∎

LEMMA 3.2. *For sufficiently large constants C_L and C_λ defined in* (2.2) *and* (2.6)*, there is a constant $C > 0$ such that*

$$C|||v|||^2_{H_h^1(\Omega)} \le A(v,v) \qquad \forall\ v \in S^h. \tag{3.5}$$

Proof. For any $v \in S^h$, by the definition of the bilinear form $A(\cdot,\cdot)$, we have

$$\begin{aligned} A(v,v) &= a(v,v) - (\tau+1)b(v,v) + \lambda(v,v) \\ &\ge C_L |v|^2_{H_h^1(\Omega)} + C_\lambda \sum_{e \in \mathcal{J}_h} h_e^{-1} \int_e |[\![v]\!]|^2 \, ds \\ &\quad + \int_\Omega \sum_{i=1}^N b_i \frac{\partial v}{\partial x_i} v \, dx - (\tau+1) b(v,v). \end{aligned} \tag{3.6}$$

In virtue of (3.1) and Hölder's inequality, we see that

$$\int_\Omega \sum_{i=1}^N b_i \frac{\partial v}{\partial x_i} v \, dx \le C|v|_{H_h^1(\Omega)} \|v\|_{L^2(\Omega)} \le C|v|^2_{H_h^1(\Omega)} + C \sum_{e \in \Gamma_h} h_e^{-1} \int_e |[\![v]\!]|^2 \, ds. \tag{3.7}$$

By the definition of $b(\cdot,\cdot)$, we have

$$b(v,v) \le C \sum_{e \in \Gamma_h} h_e \int_e \sum_{i=1}^N \left| \left\{ \frac{\partial v}{\partial x_i} \right\} \right|^2 \, ds + C \sum_{e \in \Gamma_h} h_e^{-1} \int_e |[\![v]\!]|^2 \, ds. \tag{3.8}$$

We recall the trace inequality

$$\int_e \sum_{i=1}^N \left| \left\{ \frac{\partial v}{\partial x_i} \right\} \right|^2 \, ds \le C h_e^{-1} |v|^2_{H^1(K)} + C h_e |v|^2_{H^2(K)}, \tag{3.9}$$

where $K \in \mathcal{J}_h$ and $e \subset \partial K$. Inserting (3.9) into (3.8) and using an inverse inequality, we have

$$b(v,v) \le C|v|^2_{H_h^1(\Omega)} + C \sum_{e \in \Gamma_h} h_e^{-1} \int_e |[\![v]\!]|^2 \, ds. \tag{3.10}$$

Applying (3.7) and (3.10) in (3.6) and choosing C_L and C_λ sufficiently large, we obtain

$$A(v,v) \ge C \left(|v|^2_{H_h^1(\Omega)} + \sum_{e \in \Gamma_h} h_e^{-1} \int_e |[\![v]\!]|^2 \, ds \right). \tag{3.11}$$

Using the trace inequality (3.9), an inverse inequality, and (3.1), we can easily see that

$$|||v|||^2_{H_h^1(\Omega)} \le C \left(|v|^2_{H_h^1(\Omega)} + \sum_{e \in \Gamma_h} h_e^{-1} \int_e |[\![v]\!]|^2 \, ds \right),$$

which, along with (3.11), shows the desired result (3.5). ∎

From now on, we assume that the constants C_L and C_λ are sufficiently large so that inequality (3.5) of Lemma 3.2 holds. Using the result in Lemma 3.2, we obtain the unique solvability of problem (2.7). To obtain error estimates, we further need the following boundedness of the bilinear form $A(\cdot,\cdot)$:

LEMMA 3.3. *For $1 \le p \le \infty$, there is a constant $C > 0$ such that for any $v \in W_h^{2,p}(\Omega)$ and $w \in W_h^{2,p'}(\Omega)$, it holds that*

$$A(v,w) \le C|||v|||_{W_h^{1,p}(\Omega)}|||w|||_{W_h^{1,p'}(\Omega)}, \tag{3.12}$$

where p' is the conjugate of p, i.e., $1/p + 1/p' = 1$.

Proof. From the definition (2.4) of $A(\cdot,\cdot)$, we see that it suffices to bound each of $a(v,w)$, $b(v,w)$, $b(w,v)$, and $\lambda(v,w)$ by the right-hand side of (3.12). In fact, by Hölder's inequality, we have

$$a(v,w) \le C\|v\|_{W_h^{1,p}(\Omega)}\|w\|_{W_h^{1,p'}(\Omega)},$$

$$b(v,w) \le C\left(\sum_{e\in\Gamma_h} h_e \int_e \sum_{i=1}^N \left|\left\{\left\{\frac{\partial v}{\partial x_i}\right\}\right\}\right|^p \, ds\right)^{1/p} \left(\sum_{e\in\Gamma_h} h_e^{1-p'} \int_e |[\![w]\!]|^{p'} \, ds\right)^{1/p'},$$

$$b(w,v) \le C\left(\sum_{e\in\Gamma_h} h_e^{1-p} \int_e |[\![v]\!]|^{p} \, ds\right)^{1/p} \left(\sum_{e\in\Gamma_h} h_e \int_e \sum_{i=1}^N \left|\left\{\left\{\frac{\partial w}{\partial x_i}\right\}\right\}\right|^{p'} \, ds\right)^{1/p'},$$

$$\lambda(v,w) \le C\left(\sum_{e\in\Gamma_h} h_e^{1-p} \int_e |[\![v]\!]|^{p} \, ds\right)^{1/p} \left(\sum_{e\in\Gamma_h} h_e^{1-p'} \int_e |[\![w]\!]|^{p'} \, ds\right)^{1/p'}.$$

Substituting the above four inequalities into (2.4) and recalling the definition of the norm (2.10) completes the proof of this lemma. ∎

LEMMA 3.4. *Suppose that $u \in H_0^1(\Omega)$ and $u_h \in S^h$ satisfy (2.9). Then*

$$|||u - u_h|||_{H_h^1(\Omega)} \le C \inf_{\chi\in S^h} |||u - \chi|||_{H_h^1(\Omega)}. \tag{3.13}$$

Proof. Inequality (3.13) follows immediately from the error equation (2.9), the stability estimate (3.5), the boundedness result (3.12), and Hölder's inequality. ∎

4. Interior error estimates. To prepare for the proof of pointwise error estimates, we show local error estimates in the energy and L^2 norms for the error of the finite element approximation and local a priori estimates for the solution of the elliptic problem (2.1). The result in Lemma 4.1 indicates that the local error of the finite element solution measured in the H_h^1 norm is bounded by the local approximation property of the finite element space in this norm plus the error measured in the weaker L^2 norm.

LEMMA 4.1. *Let $\Omega_0 \subset \Omega_1 \subset \Omega$ with $d = dist(\Omega_0, \partial\Omega_1\backslash\partial\Omega) \ge 4\kappa h$. If $u \in H_0^1(\Omega)$ and $u_h \in S^h$ satisfy (2.9), then*

$$|||u - u_h|||_{H_h^1(\Omega_0)} \le C \inf_{\chi\in S^h(\Omega_1)} |||u - \chi|||_{H_h^1(\Omega_1)} + C\|u - u_h\|_{L^2(\Omega_1)}, \tag{4.1}$$

where the constant $C > 0$ depends on d but is independent of h and u.

Proof. Let $\Omega_0 \subset \Omega_2 \subset \Omega_3 \subset \Omega_4 \subset \Omega_1$ satisfy

$$\operatorname{dist}(\Omega_0, \partial\Omega_2 \backslash \partial\Omega) = \operatorname{dist}(\Omega_2, \partial\Omega_3 \backslash \partial\Omega) = \operatorname{dist}(\Omega_3, \partial\Omega_4 \backslash \partial\Omega) = \operatorname{dist}(\Omega_4, \partial\Omega_1 \backslash \partial\Omega) = d/4.$$

Also, let $\omega \in C_0^\infty(\Omega_2)$ satisfy $\omega \equiv 1$ on Ω_0. Then, by Proposition 2.3, we choose $\eta \in S^h(\Omega_3)$ such that $\operatorname{supp}(\eta) \not\subset \Omega_3$ and

$$|||\omega(\chi - u_h) - \eta|||_{H_h^1(\Omega_3)} \le Ch|||\chi - u_h|||_{H_h^1(\Omega_3)}. \tag{4.2}$$

Using the triangle inequality, (3.5), and (4.2), we have

$$\begin{aligned} |||\chi - u_h|||_{H_h^1(\Omega_0)} &\le |||\omega(\chi - u_h)|||_{H_h^1(\Omega)} \\ &\le |||\eta|||_{H_h^1(\Omega)} + |||\omega(\chi - u_h) - \eta|||_{H_h^1(\Omega_3)} \\ &\le C\left(\sqrt{A(\eta,\eta)} + h|||\chi - u_h|||_{H_h^1(\Omega_2)}\right). \end{aligned} \tag{4.3}$$

With some straightforward manipulations, we have the identity

$$\begin{aligned} A(\eta,\eta) = {} & A(\omega(\chi - u_h), \omega(\chi - u_h)) + A(\eta - \omega(\chi - u_h), \eta - \omega(\chi - u_h)) \\ & + A(\omega(\chi - u_h), \eta - \omega(\chi - u_h)) + A(\eta - \omega(\chi - u_h), \omega(\chi - u_h)). \end{aligned} \tag{4.4}$$

From (3.12), (4.2), and (4.4), it follows that

$$\begin{aligned} A(\eta,\eta) \le {} & A(\omega(\chi - u_h), \omega(\chi - u_h)) + Ch^2|||\chi - u_h|||^2_{H_h^1(\Omega_3)} \\ & + \varepsilon|||\omega(\chi - u_h)|||^2_{H_h^1(\Omega)}, \end{aligned} \tag{4.5}$$

where $\varepsilon > 0$ is an arbitrary but fixed real number, which will be determined later in this proof. We will now estimate the first term on the right-hand side of (4.5). Some simple calculations lead to the following equation:

$$\begin{aligned} A(\omega(\chi - u_h), \omega(\chi - u_h)) = {} & A(\chi - u_h, \omega^2(\chi - u_h)) + I_\omega(\chi - u_h) \\ & - (\tau + 1) \sum_{e \in \Gamma_h} \int_e \sum_{i,j=1}^N a_{ij} \frac{\partial \omega}{\partial x_i} \{\!\{\chi - u_h\}\!\} [\![\omega(\chi - u_h)]\!]_j \, ds, \end{aligned} \tag{4.6}$$

where

$$\begin{aligned} I_\omega(v) = {} & \int_\Omega \sum_{i,j=1}^N a_{ij} \left(v \frac{\partial \omega}{\partial x_i} \frac{\partial(\omega v)}{\partial x_j} - v \frac{\partial \omega}{\partial x_j} \frac{\partial(\omega v)}{\partial x_i} + v^2 \frac{\partial \omega}{\partial x_i} \frac{\partial \omega}{\partial x_j} \right) dx \\ & + \int_\Omega \omega v^2 \sum_{i=1}^N b_i \frac{\partial \omega}{\partial x_i} \, dx. \end{aligned} \tag{4.7}$$

By (4.7) and Hölder's inequality, $I_\omega(\chi - u_h)$ can be estimated as follows:

$$I_\omega(\chi - u_h) \le C\|\chi - u_h\|^2_{L^2(\Omega_2)} + \varepsilon\|\omega(\chi - u_h)\|^2_{H_h^1(\Omega)}. \tag{4.8}$$

To estimate the first term in the right-hand side of (4.6), we use the superapproximation property in Proposition 2.3 and choose a function $\eta_1 \in S^h(\Omega_3)$ such that $\operatorname{supp}(\eta_1) \not\subset \Omega_3$ and

$$|||\omega^2(\chi - u_h) - \eta_1|||_{H_h^1(\Omega_3)} \le Ch|||\chi - u_h|||_{H_h^1(\Omega_3)}. \tag{4.9}$$

Then, from (2.9), inequality (3.12), and estimate (4.9), it follows that

$$
\begin{aligned}
(4.10)\qquad & A(\chi-u_h,\omega^2(\chi-u_h))\\
&= A(\chi-u,\omega^2(\chi-u_h))+A(u-u_h,\omega^2(\chi-u_h)-\eta_1)\\
&\le C|||u-\chi|||_{H_h^1(\Omega_2)}|||\omega(\chi-u_h)|||_{H_h^1(\Omega)}\\
&\quad +Ch|||u-u_h|||_{H_h^1(\Omega_3)}|||\chi-u_h|||_{H_h^1(\Omega_3)}\\
&\le C|||u-\chi|||^2_{H_h^1(\Omega_3)}+\varepsilon|||\omega(\chi-u_h)|||^2_{H_h^1(\Omega)}+Ch|||\chi-u_h|||^2_{H_h^1(\Omega_3)}.
\end{aligned}
$$

For the last term in the right-hand side of (4.6), applying Hölder's inequality, a trace theorem, and an inverse inequality, we have

$$
\begin{aligned}
(4.11)\qquad & \sum_{e\in\Gamma_h}\int_e\sum_{i,j=1}^N a_{ij}\frac{\partial\omega}{\partial x_i}\{\chi-u_h\}[\![\omega(\chi-u_h)]\!]_j\,ds\\
&\le C\left(\sum_{e\in\Gamma_h}h_e^{-1}\int_e|[\![\omega(\chi-u_h)]\!]|^2\,ds\right)^{1/2}\left(\sum_{e\in\Gamma_h}h_e\int_e|\{\chi-u_h\}|^2\,ds\right)^{1/2}\\
&\le \varepsilon|||\omega(\chi-u_h)|||^2_{H_h^1(\Omega)}+C\|\chi-u_h\|^2_{L^2(\Omega_3)}.
\end{aligned}
$$

Now, using estimates (4.3), (4.5), (4.6), (4.8), (4.10), and (4.11), we obtain

$$
\begin{aligned}
(4.12)\qquad |||\omega(\chi-u_h)|||^2_{H_h^1(\Omega)} &\le C\varepsilon|||\omega(\chi-u_h)|||^2_{H_h^1(\Omega)}+Ch|||\chi-u_h|||^2_{H_h^1(\Omega_3)}\\
&\quad +C|||u-\chi|||^2_{H_h^1(\Omega_3)}+C\|u-u_h\|^2_{L^2(\Omega_3)}.
\end{aligned}
$$

Next, choosing ε sufficiently small so that the term $\varepsilon|||\omega(\chi-u_h)|||^2_{H_h^1(\Omega)}$ can be kicked back to the left-hand side of (4.12) and then using (4.3), we get

$$
\begin{aligned}
(4.13)\qquad & |||\chi-u_h|||^2_{H_h^1(\Omega_0)}\\
&\le C\left(h|||\chi-u_h|||^2_{H_h^1(\Omega_3)}+|||u-\chi|||^2_{H_h^1(\Omega_3)}+\|u-u_h\|^2_{L^2(\Omega_3)}\right).
\end{aligned}
$$

Using (4.13) with Ω_0 replaced by Ω_3, we also have

$$
\begin{aligned}
(4.14)\qquad & |||\chi-u_h|||^2_{H_h^1(\Omega_3)}\\
&\le C\left(h|||\chi-u_h|||^2_{H_h^1(\Omega_4)}+|||u-\chi|||^2_{H_h^1(\Omega_4)}+\|u-u_h\|^2_{L^2(\Omega_4)}\right).
\end{aligned}
$$

Inserting (4.14) into (4.13) and applying an inverse inequality, we obtain

$$
\begin{aligned}
(4.15)\qquad & |||\chi-u_h|||^2_{H_h^1(\Omega_0)}\\
&\le C\left(h^2|||\chi-u_h|||^2_{H_h^1(\Omega_4)}+|||u-\chi|||^2_{H_h^1(\Omega_4)}+\|u-u_h\|^2_{L^2(\Omega_4)}\right)\\
&\le C|||u-\chi|||^2_{H_h^1(\Omega_1)}+C\|u-u_h\|^2_{L^2(\Omega_1)}.
\end{aligned}
$$

Estimate (4.15) and the triangle inequality imply (4.1). □

An explicit dependence of the bound in (4.1) on the distance d between Ω_0 and Ω_1 can be determined through Proposition 2.4 and a scaling argument.

LEMMA 4.2. *Let $\Omega_0\subset\Omega_1\subset\Omega$ with $d=dist(\Omega_0,\partial\Omega_1\backslash\partial\Omega)\ge\kappa h$. If $u\in H_0^1(\Omega)$ and $u_h\in S^h$ satisfy* (2.9)*, then*

$$
(4.16)\qquad |||u-u_h|||_{H_h^1(\Omega_0)}\le Ch^r\|u\|_{H^{1+r}(\Omega_1)}+Cd^{-1}\|u-u_h\|_{L^2(\Omega_1)}.
$$

Proof. Without loss of generality, we assume that Ω is the unit ball in R^N. It suffices to show (4.16) with Ω_0 and Ω_1 being the spheres of radii $d/2$ and d, respectively, with centers at x_0. Assume that $x_0 = 0$ and x denotes the variable on Ω. Let $\tilde{x} = x/d$ be the new variable on the transferred regions $\tilde{\Omega}_0$ and $\tilde{\Omega}_1$. Then $\operatorname{dist}(\tilde{\Omega}_0, \partial\tilde{\Omega}_1) = 1/2$. Set $\tilde{u}(\tilde{x}) = u(\tilde{x}d)$ and $\tilde{u}_h = u_h(\tilde{x}d)$. Then we see that

$$\tilde{A}(\tilde{u} - \tilde{u}_h, \tilde{\chi}) = 0 \qquad \forall\ \tilde{\chi} \in \tilde{S}^h,$$

where $\tilde{S}^h$ is the transferred space of S^h,

$$\tilde{A}(\tilde{v}, \tilde{w}) = \tilde{a}(\tilde{v}, \tilde{w}) - \tilde{b}(\tilde{v}, \tilde{w}) - \tau\tilde{b}(\tilde{w}, \tilde{v}) + \tilde{\lambda}(\tilde{v}, \tilde{w}),$$

and

$$\tilde{a}(\tilde{v}, \tilde{w}) = \sum_{\tilde{K} \in \tilde{\mathcal{J}}_h} \int_{\tilde{K}} \left(\sum_{i,j=1}^{N} \tilde{a}_{ij}(\tilde{x}) \frac{\partial \tilde{v}}{\partial \tilde{x}_i} \frac{\partial \tilde{w}}{\partial \tilde{x}_j} + d \sum_{i}^{N} \tilde{b}(\tilde{x}) \frac{\partial \tilde{v}}{\partial \tilde{x}_i} \tilde{w} + d^2 \tilde{c}(\tilde{x}) \tilde{v}\tilde{w} \right) d\tilde{x},$$

$$\tilde{b}(\tilde{v}, \tilde{w}) = \sum_{\tilde{e} \in \tilde{\Gamma}_h} \int_{\tilde{e}} \sum_{i,j=1}^{N} \left\{ \tilde{a}_{ij} \frac{\partial \tilde{v}}{\partial \tilde{x}_i} \right\} [\![\tilde{w}]\!]_j \, d\tilde{s},$$

$$\tilde{\lambda}(\tilde{v}, \tilde{w}) = \sum_{\tilde{e} \in \tilde{\Gamma}_h} \frac{\lambda_e}{h_e/d} \int_{\tilde{e}} [\![\tilde{v}]\!] [\![\tilde{w}]\!] \, d\tilde{s}.$$

Since the coefficients $\tilde{a}_{ij}$ in the bilinear form $\tilde{A}(\cdot, \cdot)$ satisfy inequality (2.2) with the same constant C_L, and the upper bounds of the derivatives of the transferred coefficients in this form are reduced compared to those of the original coefficients in $A(\cdot, \cdot)$, using Proposition 2.4 and estimate (4.1) for the error $\tilde{u} - \tilde{u}_h$ we deduce that

$$|||\tilde{u} - \tilde{u}_h|||_{H_h^1(\tilde{\Omega}_0)} \le C \inf_{\tilde{\chi} \in \tilde{S}^h} |||\tilde{u} - \tilde{\chi}|||_{H_h^1(\tilde{\Omega}_1)} + C\|\tilde{u} - \tilde{u}_h\|_{L^2(\tilde{\Omega}_1)}. \tag{4.17}$$

Using (4.17) and the approximation properties in space $\tilde{S}^h$, we see that

$$\begin{aligned} |||\tilde{u} - \tilde{u}_h|||_{H_h^1(\tilde{\Omega}_0)} &\le C(h/d)^r |\tilde{u}|_{H^{1+r}(\tilde{\Omega}_1)} + C\|\tilde{u} - \tilde{u}_h\|_{L^2(\tilde{\Omega}_1)} \\ &\le Ch^r d^{1-N/2} |u|_{H^{1+r}(\Omega_1)} + Cd^{-N/2} \|u - u_h\|_{L^2(\Omega_1)}. \end{aligned} \tag{4.18}$$

From (4.18) and the inequality

$$|||u - u_h|||_{H_h^1(\Omega_0)} \le Cd^{N/2-1} |||\tilde{u} - \tilde{u}_h|||_{H_h^1(\tilde{\Omega}_0)},$$

we obtain the desired result (4.16). ∎

Without loss of generality we assume *in the rest of the paper* that $\operatorname{diam}(\Omega) \le 1$ and define

$$d_j = 2^{-j} \quad \text{for} \quad j = 0, 1, 2, \ldots,$$

and for any fixed $x \in \bar{\Omega}$, set

$$\begin{aligned} \Omega_j &= \{x \in \Omega :\ d_{j+1} < |x - z| < d_j\}, \\ \Omega_j^{(1)} &= \{x \in \Omega :\ d_{j+2} < |x - z| < d_{j-1}\}, \\ \Omega_j^{(2)} &= \{x \in \Omega :\ d_{j+3} < |x - z| < d_{j-2}\}. \end{aligned} \tag{4.19}$$

LEMMA 4.3. *For $\rho \in L^\infty(\Omega)$, let $g \in H_0^1(\Omega)$ be the solution of*

$$\mathcal{L}g = \rho \quad \text{in } \Omega$$

and $g_h \in S^h$ be the finite element approximation of g:

$$A(g - g_h, v) = 0 \qquad \forall\ v \in S^h.$$

If ρ has compact support in $B_{Mh}(z)$ for some $M > 1$ and $\|\rho\|_{L^2(B_{Mh}(z))} \le Ch^{-N/2}$,

$$|||g - g_h|||_{H_h^1(\Omega_j)} \le Ch^r d_j^{1-r-N/2} + d_j^{-1}\|g - g_h\|_{L^2(\Omega_j^{(1)})}. \tag{4.20}$$

Proof. Using (4.16), we have

$$|||g - g_h|||_{H_h^1(\Omega_j)} \le Ch^r \|g\|_{H^{1+r}(\Omega_j^{(1)})} + d_j^{-1}\|g - g_h\|_{L^2(\Omega_j^{(1)})}. \tag{4.21}$$

For any $x \in \Omega_j^{(1)}$, let G_x be Green's function for problem (2.1) with singularity at x. Then we have (see Solonnikov [22])

$$g(x) = \int_\Omega G_x(y)\rho(y)\ dy \tag{4.22}$$

and

$$\left|\frac{\partial^{\alpha+\beta} G_x(y)}{\partial x^\alpha \partial y^\beta}\right| \le C|x - y|^{2-N-|\alpha|-|\beta|} \quad \text{for } |\alpha| + |\beta| > 0. \tag{4.23}$$

Differentiating (4.22) with respect to x, for $x \in \Omega_j^{(1)}$ and $|\alpha| \le 1 + r$ we have

$$\begin{aligned}\left|\frac{\partial^\alpha g(x)}{\partial x^\alpha}\right| &= \left|\int_\Omega \frac{\partial^\alpha G_x(y)}{\partial x^\alpha}\rho(y)\ dy\right| \\ &\le C\int_{B_{Mh}(z)} |x - y|^{2-N-|\alpha|}\,|\rho(y)|\ dy \\ &\le Cd_j^{1-N-r}h^{N/2}\|\rho\|_{L^2(B_{Mh}(z))} \le Cd_j^{1-N-r}.\end{aligned} \tag{4.24}$$

Integrating (4.24) over $\Omega_j^{(1)}$ gives

$$\|g\|_{H^{1+r}(\Omega_j^{(1)})} \le Cd_j^{1-N/2-r}.$$

Substituting this into (4.21) implies the desired result (4.20). ∎

LEMMA 4.4. *For $\varphi \in C_0^\infty(B_{Mh}(z))$ satisfying $\|\varphi\|_{H^1(B_{Mh}(z))} = 1$, let $g \in H_0^1(\Omega)$ be the solution of*

$$\mathcal{L}g = -h^{-N/2-1}\frac{\partial \varphi}{\partial x_i} \quad \text{in } \Omega$$

and $g_h \in S^h$ be the finite element approximation of g:

$$A(g - g_h, v) = 0 \qquad \forall\ v \in S^h.$$

Then it holds that

$$|||g-g_h|||_{H_h^1(\Omega_j)} \le Ch^r d_j^{-r-N/2} + d_j^{-1}\|g-g_h\|_{L^2(\Omega_j^{(1)})}. \tag{4.25}$$

Proof. The proof is the same as that of Lemma 4.3. The only difference is that instead of (4.22), for $x \in \Omega_j$ and $|\alpha| = 1+r$ we have

$$\begin{aligned}\left|\frac{\partial^\alpha g(x)}{\partial x^\alpha}\right| &= h^{-N/2-1}\left|\int_\Omega \frac{\partial^\alpha G_x(y)}{\partial x^\alpha}\frac{\partial\varphi(y)}{\partial y_i}\,dy\right| \\ &= h^{-N/2-1}\left|\int_{B_{Mh}(z)} \frac{\partial}{\partial y_i}\frac{\partial^\alpha G_x(y)}{\partial x^\alpha}\varphi(y)\,dy\right| \\ &\le Cd_j^{-N-r}h^{-1}\|\varphi\|_{L^2(B_{Mh}(z))}.\end{aligned} \tag{4.26}$$

Using the fact that $\varphi \in C_0^\infty(B_{Mh}(z))$, we have

$$\|\varphi\|_{L^2(B_{Mh}(z))} \le Ch\|\nabla\varphi\|_{L^2(B_{Mh}(z))} \le Ch.$$

Inserting this into (4.26) and integrating over Ω_j, we conclude that

$$\|g\|_{H^{1+r}(\Omega_j)} \le Cd_j^{-N/2-r}, \tag{4.27}$$

which completes the proof. ∎

LEMMA 4.5. *For $\varphi \in C_0^\infty(\Omega_j^{(1)})$ satisfying $\|\varphi\|_{L^2(\Omega)} = 1$, let $\Phi \in H_0^1(\Omega)$ be the solution of $\mathcal{L}\Phi = \varphi$ in Ω. Then it holds that*

$$\|\Phi\|_{W^{1+r,\infty}(\Omega\setminus\Omega_j^{(2)})} \le Cd_j^{1-r-N/2}. \tag{4.28}$$

Proof. Estimate (4.28) follows immediately from differentiating the representation

$$\Phi(x) = \int_{\Omega)} G_x(y)\varphi(y)\,dy$$

and using inequality (4.23). ∎

5. Pointwise error estimates. In this section we prove our main results: the optimal localized pointwise error estimates. These results are stated in Theorems 5.1 and 5.3. We concentrate on the case $\tau = 1$, i.e., the symmetric interior penalty DG method. The technique used here (see (5.5) and (5.6) below) cannot be easily extended to the nonsymmetric case. Pointwise error estimates for this case will be investigated in the future.

THEOREM 5.1. *Let $u \in W_0^{1,\infty}(\Omega)$ and $u_h \in S^h$ satisfy (2.9) and $0 \le s \le r-1$. Then there is a constant $C > 0$ such that for any $z \in \bar\Omega$,*

$$|(u-u_h)(z)| \le Ch\left(\ln h^{-1}\right)^{\bar s}\inf_{\chi\in S^h}|||u-\chi|||_{W_h^{1,\infty}(\Omega),z,s}, \tag{5.1}$$

where $\bar s = 0$ if $0 \le s < r-1$ and $\bar s = 1$ if $s = r-1$.

Proof. Let $K_z \in \mathcal{J}_h$ be such that $z \in \bar K_z$. By choosing appropriately a $\psi \in S^h$ according to Proposition 2.1, the triangle inequality and Proposition 2.2 yield

$$\begin{aligned}|(u-u_h)(z)| &\le |(u-\psi)(z)| + Ch^{-N/2}\|\psi-u_h\|_{L^2(K_z)} \\ &\le C\|u-\psi\|_{L^\infty(K_z)} + Ch^{-N/2}\|u-u_h\|_{L^2(K_z)} \\ &\le Ch\|u\|_{W_h^{1,\infty}(\Omega),z,s} + Ch^{-N/2}\|u-u_h\|_{L^2(K_z)}.\end{aligned} \tag{5.2}$$

Obviously, (5.2) holds also for u replaced by $u-\chi$ for any $\chi \in S^h$. Therefore, noting that $u-\chi-(u-\chi)_h = u-u_h$, (5.2) implies

$$|(u-u_h)(z)| \le Ch\|u-\chi\|_{W_h^{1,\infty}(\Omega),z,s} + Ch^{-N/2}\|u-u_h\|_{L^2(K)}. \tag{5.3}$$

Define

$$\rho(x) = h^{-N/2}(u-u_h)(x)/\|u-u_h\|_{L^2(K_z)} \tag{5.4}$$

and let $g_z \in H_0^1(\Omega)$ be the solution of

$$\mathcal{L}^* g_z = \rho, \tag{5.5}$$

where $\mathcal{L}^*$ is the adjoint operator of $\mathcal{L}$. Furthermore, let $g_{z,h}$ be the finite element approximation of g_z satisfying

$$A(v, g_z - g_{z,h}) = 0 \qquad \forall\ v \in S^h. \tag{5.6}$$

Then, from (2.9), (3.12), and (5.6), for any $\chi \in S^h$ it follows that

$$\begin{aligned} h^{-N/2}\|u-u_h\|_{L^2(K_z)} &= (\rho, u-u_h) = A(u-\chi, g_z - g_{z,h}) \\ &\le C|||u-\chi|||_{W_h^{1,\infty}(\Omega),z,s}|||g_z - g_{z,h}|||_{W_h^{1,1}(\Omega),z,-s}, \end{aligned} \tag{5.7}$$

which, along with (5.8) in Lemma 5.2 below, deduces the desired result (5.1). ∎

LEMMA 5.2. *Let $g_z \in H_0^1(\Omega)$ and $g_{z,h} \in S^h$ satisfy* (5.5) *and* (5.6). *Then it holds that for $0 \le s \le r-1$,*

$$|||g_z - g_{z,h}|||_{W_h^{1,1}(\Omega),z,-s} \le Ch\left(\ln h^{-1}\right)^{\bar{s}}, \tag{5.8}$$

where $\bar{s}=0$ if $0 \le s < r-1$ and $\bar{s}=1$ if $s = r-1$.

Proof. Let $M > 1$ be a real number to be determined later and J be an integer such that $Mh = 2^{-J}$. Then $J \le C\ln(1/h)$. For notational convenience, set $E = g_z - g_{z,h}$. In view of $\Omega = B_{Mh}(z) \cup (\cup_{j=0}^J \Omega_j)$, it follows that

$$|||E|||_{W_h^{1,1}(\Omega),z,-s} \le |||E|||_{W_h^{1,1}(B_{Mh}(z)),z,-s} + \sum_{j=0}^{J} |||E|||_{W_h^{1,1}(\Omega_j),z,-s}. \tag{5.9}$$

Recall the definition of $|||E|||_{W_h^{1,1}(\Omega_j),z,-s}$:

$$\begin{aligned} |||E|||_{W_h^{1,1}(\Omega_j),z,-s} &= \|E\|_{W_h^{1,1}(\Omega_j),z,-s} + \sum_{e\in\Gamma_h}\int_{e\cap\Omega_j} |\sigma_{z,h}^s [\![E]\!]|\ ds \\ &\quad + \sum_{e\in\Gamma_h} h_e \int_{e\cap\Omega_j} \sum_{i=1}^{N} \left|\sigma_{z,h}^s \left\{\!\!\left\{\frac{\partial E}{\partial x_i}\right\}\!\!\right\}\right|\ ds. \end{aligned} \tag{5.10}$$

We will handle each of the three terms on the right-hand side of (5.10) separately. By Hölder's inequality, we see that

$$\|E\|_{W_h^{1,1}(\Omega_j),z,-s} \le C d_j^{N/2+s} h^{-s} \|E\|_{H_h^1(\Omega_j)}, \tag{5.11}$$

$$\sum_{e\in\Gamma_h}\int_{e\cap\Omega_j}|\sigma_{z,h}^s[\![E]\!]|\,ds \le d_j^s h^{(N-1)/2-s}\sum_{e\in\Gamma_h}\left(\int_{e\cap\Omega_j}|[\![E]\!]|^2\,ds\right)^{1/2} \le Cd_j^{N/2+s}h^{-s}\left(\sum_{e\in\Gamma_h}h_e^{-1}\int_{e\cap\Omega_j}|[\![E]\!]|^2\,ds\right)^{1/2}, \tag{5.12}$$

$$\sum_{e\in\Gamma_h}h_e\int_{e\cap\Omega_j}\sum_{i=1}^N\sigma_{z,h}^s\left|\left\{\!\!\left\{\frac{\partial E}{\partial x_i}\right\}\!\!\right\}\right|\,ds \le Cd_j^{N/2+s}h^{-s}\left(\sum_{e\in\Gamma_h}h_e\int_{e\cap\Omega_j}\sum_{i=1}^N\left|\left\{\!\!\left\{\frac{\partial E}{\partial x_i}\right\}\!\!\right\}\right|^2\,ds\right)^{1/2}. \tag{5.13}$$

Inserting (5.11)–(5.13) into (5.10) gives

$$|||E|||_{W_h^{1,1}(\Omega_j),z,-s} \le Cd_j^{N/2+s}h^{-s}|||E|||_{H_h^1(\Omega_j)}. \tag{5.14}$$

Similar to (5.14) (with Ω_j replaced by $B_{Mh}(z)$), it can easily be seen that

$$|||E|||_{W_h^{1,1}(B_{Mh}(z)),z,-s} \le CM^{N/2+s}h^{N/2}|||E|||_{H_h^1(B_{Mh}(z))}. \tag{5.15}$$

Using Lemma 3.4, the approximation properties in Proposition 2.1, and an elliptic regularity on g_z, we have

$$|||E|||_{H_h^1(B_{Mh}(z))} \le Ch\|g_z\|_{H^2(\Omega)} \le Ch\|\rho\|_{L^2(K_z)} \le Ch^{1-N/2},$$

which, along with (5.15), yields

$$|||E|||_{W_h^{1,1}(B_{Mh}(z)),z,-s} \le CM^{N/2+s}h. \tag{5.16}$$

Inserting (5.14) and (5.16) into (5.9), we have

$$|||E|||_{W_h^{1,1}(\Omega),z,-s} \le CM^{N/2+s}h + CL, \tag{5.17}$$

where

$$L = \sum_{j=0}^J d_j^{N/2+s}h^{-s}|||E|||_{H_h^1(\Omega_j)}.$$

To estimate L, we use (4.20) to obtain

$$L \le C\sum_{j=0}^J h^{r-s}d_j^{1+s-r} + C\sum_{j=0}^J d_j^{s+N/2-1}h^{-s}\|E\|_{L^2(\Omega_j^{(1)})} = Ch\Theta(r-1-s) + \sum_{j=0}^J d_j^{s+N/2-1}h^{-s}\|E\|_{L^2(\Omega_j^{(1)})}, \tag{5.18}$$

where $\Theta(\gamma)$ is the following function:

$$\Theta(\gamma) = \sum_{j=0}^J (h/d_j)^\gamma.$$

We note that since $d_j = 2^{-j}$ and $J \le C \ln 1/h$, it holds that

$$\Theta(\gamma) = \sum_{j=0}^{J} \left(\frac{h}{d_j}\right)^{\gamma} \le C \begin{cases} \ln h^{-1} & \text{if } \gamma = 0, \\ \dfrac{1}{M^{\gamma}(1-2^{-\gamma})} & \text{if } \gamma > 0. \end{cases} \tag{5.19}$$

To estimate L, we now estimate $\|E\|_{L^2(\Omega_j^{(1)})}$ for each $0 \le j \le J$. By duality, we have

$$\|E\|_{L^2(\Omega_j^{(1)})} = \sup_{\varphi \in C_0^{\infty}(\Omega_j^{(1)}),\ \|\varphi\|_{L^2(\Omega)}=1} (E, \varphi). \tag{5.20}$$

For each $\varphi \in C_0^{\infty}(\Omega_j^{(1)})$, let $\Phi \in H_0^1(\Omega)$ be the solution of $\mathcal{L}\Phi = \varphi$. Then

$$(E, \varphi) = A(\Phi, E) = A(\Phi - \eta, E) = I_1 + I_2, \tag{5.21}$$

where

$$I_1 = A_{\Omega \setminus \Omega_j^{(2)}}(\Phi - \eta, E), \quad I_2 = A_{\Omega_j^{(2)}}(\Phi - \eta, E).$$

We will now estimate I_1 and I_2 separately. For I_1, by inequality (3.12), the approximation properties in Proposition 2.1, and (4.28) in Lemma 4.5, we see that

$$\begin{aligned} I_1 &\le C|||\Phi - \eta|||_{W_h^{1,\infty}(\Omega \setminus \Omega_j^{(2)})} |||E|||_{W_h^{1,1}(\Omega \setminus \Omega_j^{(2)})} \\ &\le Ch^r \|\Phi\|_{W^{1+r,\infty}(\Omega \setminus \Omega_j^{(2)})} |||E|||_{W_h^{1,1}(\Omega \setminus \Omega_j^{(2)})} \le Ch^r d_j^{1-r-N/2} |||E|||_{W_h^{1,1}(\Omega)}. \end{aligned} \tag{5.22}$$

For I_2, from (3.12) and Proposition 2.1, we have

$$\begin{aligned} I_2 &\le C|||\Phi - \eta|||_{H_h^1(\Omega_j^{(2)})} |||E|||_{H_h^1(\Omega_j^{(2)})} \le Ch\|\Phi\|_{H^2(\Omega)} |||E|||_{H_h^1(\Omega_j^{(2)})} \\ &\le Ch|||E|||_{H_h^1(\Omega_j^{(2)})}. \end{aligned} \tag{5.23}$$

Using (5.20)–(5.23), we obtain

$$\|E\|_{L^2(\Omega_j^{(1)})} \le Ch^r d_j^{1-r-N/2} |||E|||_{W_h^{1,1}(\Omega)} + Ch|||E|||_{H_h^1(\Omega_j^{(2)})}, \tag{5.24}$$

which leads to

$$\begin{aligned} &\sum_{j=0}^{J} d_j^{s+N/2-1} h^{-s} \|E\|_{L^2(\Omega_j^{(1)})} \\ &\quad \le C \sum_{j=0}^{J} (h/d_j)^{r-s} |||E|||_{W_h^{1,1}(\Omega)} + C \sum_{j=0}^{J} d_j^{s+N/2-1} h^{1-s} |||E|||_{H_h^1(\Omega_j^{(2)})} \\ &\quad \le C\Theta(r-s) |||E|||_{W_h^{1,1}(\Omega)} + CM^{N/2+s} h + CL/M. \end{aligned}$$

Hence, according to inequality (5.18) and choosing M sufficiently large, we have

$$L \le CM^{N/2+s} h + Ch\Theta(r-1-s) + C\Theta(r-s) |||E|||_{W_h^{1,1}(\Omega)}. \tag{5.25}$$

Substituting this into (5.17), we get

$$|||E|||_{W_h^{1,1}(\Omega),z,-s} \le CM^{N/2+s} h + Ch\Theta(r-1-s) + C\Theta(r-s) |||E|||_{W_h^{1,1}(\Omega)}. \tag{5.26}$$

The particular case where $s = 0$ in inequality (5.26) implies

$$|||E|||_{W_h^{1,1}(\Omega)} \le CM^{N/2}h + Ch\Theta(r-1) + C\Theta(r)|||E|||_{W_h^{1,1}(\Omega)}. \tag{5.27}$$

By choosing M large enough such that $C\Theta(r) < 1/2$, it follows from (5.27) that

$$|||E|||_{W_h^{1,1}(\Omega)} \le CM^{N/2}h + Ch\Theta(r-1) \le Ch\Theta(r-1). \tag{5.28}$$

Inserting (5.28) into (5.26), we obtain

$$\begin{aligned} |||E|||_{W_h^{1,1}(\Omega),z,-s} &\le CM^{N/2+s}h + Ch\Theta(r-1-s) + Ch\Theta(r-1)\Theta(r-s) \\ &\le Ch\left(\ln 1/h\right)^{\bar{\bar{s}}}, \end{aligned}$$

which proves the desired result (5.8). ∎

THEOREM 5.3. *Let $u \in W_0^{1,\infty}(\Omega)$ and $u_h \in S^h$ satisfy (2.9) and $0 \le s \le r$. Then there is a constant $C > 0$ such that for any $z \in \bar{\Omega}$,*

$$|\nabla(u-u_h)(z)| \le C\left(\ln h^{-1}\right)^{\bar{\bar{s}}} \inf_{\chi\in S^h} |||u-\chi|||_{W_h^{1,\infty}(\Omega),z,s}, \tag{5.29}$$

where $\bar{\bar{s}} = 0$ if $0 \le s < r$ and $\bar{\bar{s}} = 1$ if $s = r$.

Proof. For any $x \in \bar{\Omega}$, let $z \in K_z$ for some $K_z \in \mathcal{J}_h$. Following a similar procedure as in the derivation of (5.2), we have

$$\begin{aligned} \left|\frac{\partial}{\partial x_i}(u-u_h)(z)\right| \le{}& \left\|\frac{\partial}{\partial x_i}(u-\chi)\right\|_{L^\infty(K_z)} \\ &+ Ch^{-N/2-1}\left\|\frac{\partial}{\partial x_i}(u-u_h)\right\|_{H^{-1}(K_z)}, \end{aligned} \tag{5.30}$$

where $\chi \in S^h$ is any function. Using integration by parts, it follows that

$$\begin{aligned} &h^{-N/2-1}\left\|\frac{\partial}{\partial x_i}(u-u_h)\right\|_{H^{-1}(K_z)} \\ &\quad= \sup_{\varphi\in C_0^\infty(K_z),\ \|\varphi\|_{H^1(K_z)}=1} \left(h^{-N/2-1}\frac{\partial}{\partial x_i}(u-u_h), \varphi\right) \\ &\quad= \sup_{\varphi\in C_0^\infty(K_z),\ \|\varphi\|_{H^1(K_z)}=1} \left(u-u_h, -h^{-N/2-1}\frac{\partial\varphi}{\partial x_i}\right). \end{aligned} \tag{5.31}$$

For any $\varphi \in C_0^\infty(K_z)$ satisfying $\|\varphi\|_{H^1(K_z)} = 1$, let $\hat{g}_z \in H_0^1(\Omega)$ be the solution of

$$\mathcal{L}^*\hat{g}_z = -h^{-N/2-1}\frac{\partial\varphi}{\partial x_i}. \tag{5.32}$$

Then, in view of (2.9) and (5.32), we have

$$\left(u-u_h, -h^{-N/2-1}\frac{\partial\varphi}{\partial x_i}\right) = A(u-u_h, \hat{g}_z) = A(u-\chi, \hat{g}_z - \hat{g}_{z,h}), \tag{5.33}$$

where $\hat{g}_{z,h} \in S^h$ is the finite element solution of $\hat{g}_z$

$$A(\chi, \hat{g}_z - \hat{g}_{z,h}) = 0 \qquad \forall\ \chi \in S^h. \tag{5.34}$$

Using (5.33), inequality (3.12), and the result in Lemma 5.4, we have

$$\begin{aligned}(5.35)\qquad &\left(u-u_h,-h^{-N/2-1}\frac{\partial\varphi}{\partial x_i}\right)\\ &\le C|||u-\chi|||_{W_h^{1,\infty}(\Omega),z,s}|||\hat{g}_z-\hat{g}_{z,h}|||_{W_h^{1,1}(\Omega),z,s}\\ &\le C\left(\ln h^{-1}\right)^{\bar{\bar{s}}}|||u-\chi|||_{W_h^{1,\infty}(\Omega),z,s}.\end{aligned}$$

From (5.30), (5.31), (5.35), and (5.36), the desired estimate (5.29) follows. ∎

LEMMA 5.4. *Let $\hat{g}_z\in H_0^1(\Omega)$ and $\hat{g}_{z,h}\in S^h$ satisfy* (5.32) *and* (5.34). *Then, for $0\le s\le r$ it holds that*

$$(5.36)\qquad |||\hat{g}_z-\hat{g}_{z,h}|||_{W_h^{1,1}(\Omega),z-s}\le C\left(\ln h^{-1}\right)^{\bar{\bar{s}}},$$

where $\bar{\bar{s}}=0$ if $0\le s<r$ and $\bar{\bar{s}}=1$ if $s=r$.

Proof. Let $M>1$ and J be as before. Again, for notational convenience, set $\hat{E}=\hat{g}_z-\hat{g}_{z,h}$. Similar to (5.17), we have

$$(5.37)\qquad |||\hat{E}|||_{W_h^{1,1}(\Omega),z,-s}\le CM^{N/2+s}+C\hat{L},$$

where

$$\hat{L}=\sum_{j=0}^{J}d_j^{N/2+s}h^{-s}|||\hat{E}|||_{H_h^1(\Omega_j)}.$$

Using (4.16), we obtain

$$(5.38)\qquad \hat{L}\le C\Theta(r-s)+C\sum_{j=0}^{J}d_j^{s+N/2-1}h^{-s}\|\hat{E}\|_{L^2(\Omega_j^{(1)})}.$$

The norm $\|\hat{E}\|_{L^2(\Omega_j^{(1)})}$ can be estimated in the same way as for $\|E\|_{L^2(\Omega_j^{(1)})}$ in (5.24). Thus we have

$$(5.39)\qquad \|\hat{E}\|_{L^2(\Omega_j^{(1)})}\le Ch^r d_j^{1-r-N/2}|||\hat{E}|||_{W_h^{1,1}(\Omega)}+Ch|||\hat{E}|||_{H_h^1(\Omega_j^{(2)})},$$

which implies

$$\begin{aligned}&\sum_{j=0}^{J}d_j^{s+N/2-1}h^{-s}\|\hat{E}\|_{L^2(\Omega_j^{(1)})}\\ &\quad\le C\sum_{j=0}^{J}(h/d_j)^{r-s}\,|||\hat{E}|||_{W_h^{1,1}(\Omega)}+C\sum_{j=0}^{J}d_j^{s+N/2-1}h^{1-s}|||\hat{E}|||_{H_h^1(\Omega_j^{(2)})}\\ &\quad\le C\Theta(r-s)|||\hat{E}|||_{W_h^{1,1}(\Omega)}+CM^{N/2+s}+CL/M.\end{aligned}$$

Hence, using the definition of $\hat{L}$ and choosing M sufficiently large, we see that

$$\hat{L}\le CM^{N/2+s}+C\Theta(r-s)+C\Theta(r-s)|||\hat{E}|||_{W_h^{1,1}(\Omega)}.$$

Substituting this into (5.37), we get

$$(5.40)\qquad |||\hat{E}|||_{W_h^{1,1}(\Omega),z,-s}\le CM^{N/2+s}+C\Theta(r-s)+C\Theta(r-s)|||\hat{E}|||_{W_h^{1,1}(\Omega)}.$$

Inequality (5.40) with $s = 0$ implies

$$|||\hat{E}|||_{W_h^{1,1}(\Omega)} \le CM^{N/2} + C\Theta(r) + C\Theta(r)|||E|||_{W_h^{1,1}(\Omega)}. \tag{5.41}$$

By choosing M large enough such that $C\Theta(r) < 1/2$, it follows from (5.41) that

$$|||\hat{E}|||_{W_h^{1,1}(\Omega)} \le CM^{N/2} + C\Theta(r) \le C. \tag{5.42}$$

Inserting (5.42) into (5.40), we obtain

$$|||\hat{E}|||_{W_h^{1,1}(\Omega),z,-s} \le CM^{N/2+s} + C\Theta(r-s) + C\Theta(r-s) \le C\left(\ln 1/h\right))^{\bar{\bar{s}}},$$

which proves the desired result (5.36). ∎

Using the results in Theorems 5.1 and 5.3, we have the following corollaries.

COROLLARY 5.5. *Let $u \in W_0^{1,\infty}(\Omega) \cap W^{1+r}(\Omega)$, $u_h \in S^h$ satisfy* (2.9)*, and $0 \le s \le r$. Then there is a constant $C > 0$ such that for any $z \in \bar{\Omega}$,*

$$|(u - u_h)(z)| \le Ch^{1+r}\left(\ln h^{-1}\right)^{\bar{s}} \|u\|_{W^{1+r,\infty}(\Omega),z,s}, \tag{5.43}$$

where $\bar{s}$ is the same as in Theorem 5.1.

Proof. Estimate (5.43) follows immediately from (5.1) and the property

$$\inf_{\chi \in S^h} |||u - \chi|||_{W_h^{1+r,\infty}(\Omega),z,s} \le Ch^r \|u\|_{W^{1+r,\infty}(\Omega),z,s}, \tag{5.44}$$

which can be easily obtained from Proposition 2.1. ∎

COROLLARY 5.6. *Let $u \in W_0^{1,\infty}(\Omega) \cap W^{1+r,\infty}(\Omega)$, $u_h \in S^h$ satisfy* (2.9)*, and $0 \le s \le r$. Then there is a constant $C > 0$ such that for any $z \in \bar{\Omega}$,*

$$|\nabla(u - u_h)(z)| \le Ch^r\left(\ln h^{-1}\right)^{\bar{\bar{s}}} \|u\|_{W^{1+r,\infty}(\Omega),z,s}, \tag{5.45}$$

where $\bar{\bar{s}}$ is the same is in Theorem 5.3.

Proof. Estimate (5.45) follows immediately from (5.29) and (5.44). ∎

STABILITY AND CONVERGENCE OF COLLOCATION SCHEMES FOR RETARDED POTENTIAL INTEGRAL EQUATIONS*

PENNY J. DAVIES† AND DUGALD B. DUNCAN‡

Abstract. Time domain boundary integral formulations of transient scattering problems involve retarded potential integral equations. Solving such equations numerically is both complicated and computationally intensive, and numerical methods often prove to be unstable. Collocation schemes are easier to implement than full finite element formulations, but little appears to be known about their stability and convergence. Here we derive and analyze some new stable collocation schemes for the single layer equation for transient acoustic scattering, and use (spatial) Fourier and (temporal) Laplace transform techniques to demonstrate that such stable schemes are second order convergent.

Key words. convergence, stability, retarded potential, boundary integral

1. Introduction.

The scalar integral equation for $u(\boldsymbol{x},t)$ on $\Gamma\times(0,T)$

$$\int_\Gamma \frac{u(\boldsymbol{x}',t-|\boldsymbol{x}'-\boldsymbol{x}|)}{|\boldsymbol{x}'-\boldsymbol{x}|}\,d\boldsymbol{x}' = a(\boldsymbol{x},t) \tag{1.1}$$

is the single layer potential equation for transient acoustic scattering from the two-dimensional surface $\Gamma\subset\mathbb{R}^3$ [27, sect. 2.3]. Here a is given on $\Gamma\times(0,T)$ for fixed $T>0$, and u and a satisfy the causality condition

$$u\equiv 0,\quad a\equiv 0 \quad \text{for all } t\le 0. \tag{1.2}$$

Once the potential u has been calculated on Γ, the scattered field can be computed anywhere in $\mathbb{R}^3$. The time argument of the integrand in (1.1) is delayed or retarded, and such equations are commonly called retarded potential integral equations (RPIEs). They also arise in boundary integral formulations of electromagnetic scattering problems [2, 21, 28, 29, 30, 31].

Existence, uniqueness, and well-posedness results for (1.1) are given in [3, 19, 20, 27]. A similar argument to that used by Lubich [27, sect. 2.3] in the case that Γ is a smooth, closed surface (based on results of Bamberger and Ha-Duong [3, Prop. 3]) can be used to deduce the following result from [19] when Γ is a flat plate. We use the notation

$$H^m_*(0,T) = \big\{ f\,\big|_{(0,T)} : f\in H^m(\mathbb{R}) \text{ with } f\equiv 0 \text{ on } (-\infty,0)\big\},$$

(this space is called H^m_0 in [27, Chap. 2]), where $H^m(\mathbb{R})$ denotes the usual Sobolev space of order m [1, Chap. 6].

PROPOSITION 1.1 (Ha-Duong [19, Thm. 3], Lubich [27, sect. 2.3]). *For temporally smooth data $a(\cdot,t)\in H^{1/2}(\Gamma)$ which vanish near $t=0$, the RPIE* (1.1) *has*

a unique smooth solution $u(\cdot,\, t) \in H^{-1/2}(\Gamma)$. *Moreover there exists a constant* C *depending only on* T *and* Γ *such that*

$$\|u\|_{H_*^m\left(0,T;H^{-1/2}(\Gamma)\right)} \leq C\, \|a\|_{H_*^{m+1}\left(0,T;H^{1/2}(\Gamma)\right)} \quad (m \in \mathbb{R})\,.$$

The spaces $H_*^m\,(0,T;X)$ and their norms are as defined by Lions and Magenes [25, Chaps. 1.1, 4.2]; namely

$$\|f\|^2_{H_*^m(0,T;X)} = \sum_{k=0}^{m} \|f^{(k)}\|^2_{L^2(0,T;X)}, \tag{1.3}$$

where $f^{(k)} = \partial^k f/\partial t^k$ and

$$\|f\|_{L^2(0,T;X)} = \left(\int_0^T \|f\|_X^2\, dt\right)^{1/2}.$$

Various numerical methods for computing u have been reported in the literature. Bamberger and Ha-Duong [3] describe a variational method for the problem when Γ is closed and smooth, one that is based on the coercivity of a bilinear form corresponding to a full Galerkin approximation in time and space. This approach has been extended to deal with the case when Γ is a flat surface by Ha-Duong [19], who also gives a comprehensive survey of the numerical analysis of such schemes in [20]. However, the variational method is complicated (and costly) to implement since it involves calculating five-dimensional integrals over $\Gamma\times\Gamma\times(0,T)$, and collocation schemes are frequently used for RPIEs in electromagnetic scattering problems [28, 29, 31]. In both approaches it takes $O(N_T\, N_S^2)$ flops to compute the solution up to time $T = N_T\,\Delta t$, where N_S is the number of spatial degrees of freedom used in the approximation, so RPIE algorithms are highly computationally intensive. Recently Michielssen and co-workers [15, 16, 26] have introduced "fast methods" for time-dependent boundary integral equations (BIEs) such as (1.1) that reduce the operation count to $O(N_T\, N_S^{3/2}\, \log N_S)$ (for a two-level scheme), or $O(N_T\, N_S\, \log^2 N_S)$ (multilevel). Although complicated to implement, these make the BIE approach for time-dependent scattering problems viable compared to methods based on solving PDEs in three-dimensional space.

The usefulness of collocation methods is often limited by the fact that they tend to exhibit numerical instabilities (see, e.g., [22, sect. 5]). Fourier analysis [6, 7, 10] indicates that the most likely cause of instability is the inaccurate approximation of (1.1). Here we present two new *stable* collocation methods for the problem (1.1)–(1.2). Our other main result is a proof that these schemes converge. The proof relies on the spatial Fourier transform of (1.1) being a convolution equation in time, and we use the Laplace and Z transform techniques of Lubich [27] to bound the Fourier transform of the approximation error. We then use classical estimates derived by Bramble and Hilbert [4] and Thomée [33] to bound the discrete norm of the error as the mesh-size tends to zero. We believe that this is the first convergence proof for an actual collocation RPIE scheme.

2. Preliminaries. We now describe the notation and some basic results used in the manuscript. The stability and convergence analysis in sections 4–5 is for the scalar RPIE (1.1) posed on an infinite flat surface, i.e., for

$$\int_{\mathbb{R}^2} \frac{u(\boldsymbol{x}',\, t-|\boldsymbol{x}'-\boldsymbol{x}|)}{|\boldsymbol{x}'-\boldsymbol{x}|}\, d\boldsymbol{x}' = a(\boldsymbol{x},t) \quad \text{on } \mathbb{R}^2\times(0,T)\,, \tag{2.1}$$

where u and a satisfy (1.2).

The singularity in the integrand can be removed by the polar coordinate transformation $\boldsymbol{x}' = \boldsymbol{x} + R\,\boldsymbol{e}_\theta$, where $\boldsymbol{e}_\theta = (\cos\theta,\, \sin\theta)$ (see also [5, 9]). When $\Gamma = \mathbb{R}^2$ causality (1.2) results in the RPIE

$$\int_0^t \int_0^{2\pi} u(\boldsymbol{x} + R\,\boldsymbol{e}_\theta,\, t-R)\; d\theta\; dR = a(\boldsymbol{x}, t). \tag{2.2}$$

If Γ is finite, then the integral is over the appropriate region of (R, θ)-space (which depends on $\boldsymbol{x}$).

2.1. Continuous and discrete spatial Fourier transforms. The continuous Fourier transform (CFT) of a function $g \in L^2(\mathbb{R}^2)$ is $\widehat{g} \in L^2(\mathbb{R}^2)$ defined by

$$\widehat{g}(\boldsymbol{\omega}) \equiv \int_{\mathbb{R}^2} g(\boldsymbol{x})\, e^{-i\boldsymbol{x}\cdot\boldsymbol{\omega}}\, d\boldsymbol{x},$$

and the inverse transform is

$$g(\boldsymbol{x}) = \frac{1}{4\pi^2} \int_{\mathbb{R}^2} \widehat{g}(\boldsymbol{\omega})\, e^{i\boldsymbol{x}\cdot\boldsymbol{\omega}}\, d\boldsymbol{\omega}.$$

Note that this definition of the CFT is that used by Bramble and Hilbert [4] and differs from that of [1] by a factor of 2π. The CFT can be used to define the norm in $H^r(\mathbb{R}^2)$ when $r \geq 0$:

$$\|g\|_r = \|(1+\omega)^r\, \widehat{g}\|_{\mathcal{F}} \equiv \frac{1}{2\pi} \left(\int_{\mathbb{R}^2} |(1+\omega)^r\, \widehat{g}(\boldsymbol{\omega})|^2\; d\boldsymbol{\omega} \right)^{1/2}, \tag{2.3}$$

where $\omega = |\boldsymbol{\omega}|$ (see [27, sect. 2.1]). When $r = 0$ this is the Parseval–Plancherel identity. The discrete Fourier transform (DFT) of a function g evaluated at the nodes of a uniform $h \times h$ space mesh in $\mathbb{R}^2$ is denoted by $\tilde{g}$ and defined by

$$\tilde{g}(\boldsymbol{\omega}) = h^2 \sum_{j,k=-\infty}^{\infty} g(\boldsymbol{x}_{j,k}) e^{-i\boldsymbol{\omega}\cdot\boldsymbol{x}_{j,k}} \tag{2.4}$$

for $\boldsymbol{\omega} \in S_h = \{(\omega_1, \omega_2) : |\omega_1|, |\omega_2| \leq \pi/h\}$, where $(j,k) \in \mathbb{Z}^2$ and $\boldsymbol{x}_{j,k} = (jh, kh)$. The function $\tilde{g}$ is $2\pi/h$ periodic in each component of $\boldsymbol{\omega}$. The DFT is defined for $g \in H^r(\mathbb{R}^2)$ with $r > 1$ [4, sect. 4] and satisfies the discrete analogue of Parseval's identity:

$$\|\tilde{g}\|_{\mathcal{F}_h} = \|g\|_h, \tag{2.5}$$

where

$$\|\tilde{g}\|_{\mathcal{F}_h} = \left(\frac{1}{4\pi^2} \int_{S_h} |\tilde{g}(\boldsymbol{\omega})|^2\, d\boldsymbol{\omega} \right)^{1/2}$$

is the discrete Fourier norm and

$$\|g\|_h = \left(h^2 \sum_{j,k} |g(\boldsymbol{x}_{j,k})|^2 \right)^{1/2}$$

is the discrete L^2 norm.

The following results due to Bramble and Hilbert [4] link the discrete and continuous Fourier transforms of a function.

PROPOSITION 2.1 (see [4, Theorem 5]). *Let $g \in H^r(\mathbb{R}^2)$ for $r > 1$. Then there exists a constant C independent of h and g such that*

$$\|\tilde{g} - \widehat{g}\|_{\mathcal{F}_h} \leq Ch^r \|g\|_r. \tag{2.6}$$

PROPOSITION 2.2 (Poisson sum formula [4, Theorem 6]). *Let $g \in H^r(\mathbb{R}^2)$ for $r > 1$. Then*

$$\tilde{g}(\boldsymbol{\omega}) = \sum_{j,k} \widehat{g}(\boldsymbol{\omega} + 2\pi(j,k)/h) \quad a.e. \tag{2.7}$$

2.2. Laplace and *Z* transforms in time. The Laplace transform of the causal function $f(t)$ (i.e., $f(t) \equiv 0$, $t < 0$) is

$$\bar{f}(s) = \int_0^\infty f(t) e^{-st}\, dt,$$

where $s = \sigma + i\eta$ with $\sigma > 0$ and $\eta \in \mathbb{R}$. Throughout the paper σ is always assumed to be the **same** fixed positive constant. The Parseval Laplace identity is

$$\|e^{-\sigma t} f(t)\|_{L^2(\mathbb{R}^+)} = \frac{1}{\sqrt{2\pi}} \left(\int_{-\infty}^{\infty} |\bar{f}(\sigma + i\eta)|^2\, d\eta \right)^{1/2}. \tag{2.8}$$

This is equivalent to the one-dimensional version of (2.3) applied to the causal function $e^{-\sigma t} f(t)$ with $r = 0$. It follows that if $f \in H^m_*(\mathbb{R}^+)$, then

$$C \int_{-\infty}^{\infty} (1+|s|)^{2m} |\bar{f}|^2\, d\eta \leq 2\pi \sum_{k=0}^{m} \left\| \frac{\partial^k}{\partial t^k} \left(e^{-\sigma t} f(t) \right) \right\|^2_{L^2(\mathbb{R}^+)} \leq \int_{-\infty}^{\infty} (1+|s|)^{2m} |\bar{f}|^2\, d\eta, \tag{2.9}$$

where the constant C depends only on σ and m.

The Z transform is the discrete version of the Laplace transform defined by

$$Zf(s) = \sum_{n=0}^{\infty} f(n\Delta t) e^{-sn\Delta t}, \tag{2.10}$$

where again $s = \sigma + i\eta$, but now $\eta \in [-\pi/\Delta t, \pi/\Delta t]$. The inversion formula is

$$f(n\Delta t) = \frac{\Delta t}{2\pi i} \int_{-\pi/\Delta t}^{\pi/\Delta t} e^{n\Delta t(\sigma + i\eta)} Zf(\sigma + i\eta)\, d\eta \tag{2.11}$$

for $n \in \mathbb{N}$. The Z and Laplace transforms are related by the Poisson sum formula

$$\Delta t\, Zf(s) = \sum_{k=-\infty}^{\infty} \bar{f}\left(s + i\, \frac{2\pi k}{\Delta t} \right), \tag{2.12}$$

a one-dimensional version of (2.7), valid for $e^{-\sigma t} f(t) \in H^r(\mathbb{R}^+)$ with $r > 1/2$.

2.3. Fourier transformed RPIE. We suppose that $a(\cdot,t)$, $u(\cdot,t) \in L^2(\mathbb{R}^2)$ for $t \in (0,T)$ and take the CFT of the RPIE (2.2). This gives the first kind convolution Volterra integral equation

$$2\pi \int_0^t \widehat{u}(\boldsymbol{\omega}, t-R)\, J_0(\omega R)\, dR = \widehat{a}(\boldsymbol{\omega}, t) \quad \text{for } \boldsymbol{\omega} \in \mathbb{R}^2,\ t \in (0,T), \tag{2.13}$$

where J_0 is the first kind Bessel function of order zero. We use the identity [18, sect. 8.41]

$$J_0(z) = \frac{1}{2\pi} \int_0^{2\pi} e^{iz\sin\theta}\, d\theta \tag{2.14}$$

to obtain the integral equation.

The results of [27, sect. 2.1] apply to give the following result for the infinite flat surface, analogous to Proposition 1.1 for the finite surface.

LEMMA 2.3. *Suppose that* $a \in H_*^{m+1}\left(0,T; H^{r+1}(\mathbb{R}^2)\right)$ *for integer* $m \geq 0$ *and* $r \in [0,\infty)$. *Then the solution* $u(\boldsymbol{x},t)$ *defined by* (2.17) *satisfies* $u \in H_*^m\left(0,T; H^r(\mathbb{R}^2)\right)$.

Proof. We essentially use the operator version of [27, Lemma 2.1] to obtain this result. We first extend the range of definition of a in time from $(0,T)$ to $(0,\infty)$ so that

$$\|a\|_{H_*^{m+1}(\mathbb{R}^+; H^{r+1}(\mathbb{R}^2))} \leq C \|a\|_{H_*^{m+1}(0,T; H^{r+1}(\mathbb{R}^2))} \tag{2.15}$$

(see, e.g., [1, Thm. 6.3.5]). Then extending the definition of the convolution (2.13) to $\mathbb{R}^+$ and taking the Laplace transform in time gives

$$\frac{2\pi}{\sqrt{\omega^2+s^2}}\, \bar{\widehat{u}}(\boldsymbol{\omega}, s) = \bar{\widehat{a}}(\boldsymbol{\omega}, s), \tag{2.16}$$

where the overbar denotes Laplace transform in t, and s is the Laplace transform parameter. Hence

$$\bar{\widehat{u}}(\boldsymbol{\omega}, s) = \frac{\sqrt{\omega^2+s^2}}{2\pi}\, \bar{\widehat{a}}(\boldsymbol{\omega}, s) \tag{2.17}$$

and so

$$|\bar{\widehat{u}}(\boldsymbol{\omega}, s)|^2 \leq \frac{\omega^2+|s|^2}{4\pi^2}\, |\bar{\widehat{a}}(\boldsymbol{\omega}, s)|^2 \leq \frac{(1+\omega)^2(1+|s|)^2}{4\pi^2}\, |\bar{\widehat{a}}(\boldsymbol{\omega}, s)|^2. \tag{2.18}$$

It follows from definition (1.3) that

$$\|u\|^2_{H_*^m(0,T;H^r(\mathbb{R}^2))} \leq e^{2\sigma T} \sum_{k=0}^m \int_0^\infty e^{-2\sigma t} \|u^{(k)}(\cdot,t)\|^2_{H^r(\mathbb{R}^2)}\, dt \equiv I_1.$$

The characterization (2.3) of $H^r(\mathbb{R}^2)$ in terms of Fourier transforms gives

$$I_1 = \frac{e^{2\sigma T}}{4\pi^2} \sum_{k=0}^m \int_0^\infty \int_{\mathbb{R}^2} e^{-2\sigma t} (1+\omega)^{2r} |\widehat{u}^{(k)}(\boldsymbol{\omega}, t)|^2\, d\boldsymbol{\omega}\, dt$$

and reversing the order of integration and using the Laplace Parseval equality (2.8) result in

$$I_1 = \frac{e^{2\sigma T}}{8\pi^3} \sum_{k=0}^m \int_{\mathbb{R}^2} \int_{\mathbb{R}} (1+\omega)^{2r} |s|^{2k} |\bar{\widehat{u}}(\boldsymbol{\omega}, s)|^2\, d\eta\, d\boldsymbol{\omega}.$$

Now using the inequality (2.18) and reversing the steps above we get

$$I_1 \le \frac{e^{2\sigma T}}{8\pi^5} \sum_{k=0}^{m+1} \int_{\mathbb{R}^2} \int_{\mathbb{R}} (1+\omega)^{2r+2} |s|^{2k} |\bar{\widehat{a}}(\boldsymbol{\omega}, s)|^2 \, d\eta \, d\boldsymbol{\omega}$$
$$= \frac{e^{2\sigma T}}{\pi^2} \sum_{k=0}^{m+1} \int_0^\infty e^{-2\sigma t} \|a^{(k)}(\cdot, t)\|^2_{H^{r+1}(\mathbb{R}^2)} \, dt \le \frac{e^{2\sigma T}}{\pi^2} \|a\|^2_{H^{m+1}_*(\mathbb{R}^+; H^{r+1}(\mathbb{R}^2))}.$$

Finally we use the extension result (2.15) to get

$$\|u\|_{H^m_*(0,T;H^r(\mathbb{R}^2))} \le \sqrt{I_1} \le C \, \|a\|_{H^{m+1}_*(0,T;H^{r+1}(\mathbb{R}^2))},$$

where C depends only on m, r, σ, and T, and the result follows. ∎

We also require the following pointwise bound on $\widehat{u}$.

LEMMA 2.4. *Under the conditions of the previous lemma, there exists a constant C such that*

$$|\widehat{u}(\boldsymbol{\omega}, t)| \le \frac{e^{\sigma T}}{\sqrt{2\pi}} \|e^{-\sigma t} \widehat{u}(\boldsymbol{\omega}, \cdot)\|_{H^1(\mathbb{R}^+)} \le C \, (1+\omega) \, \|\widehat{a}(\boldsymbol{\omega}, \cdot)\|_{H^2(\mathbb{R}^+)}$$

for $t \in (0, T)$.

Proof. The first inequality follows from the standard result

$$|f(t)| \le \frac{1}{\sqrt{2\pi}} \|f\|_{H^1(\mathbb{R}^+)} \tag{2.19}$$

[1, Ex. 6.4.5] applied with $f(t) = e^{-\sigma t} \widehat{u}(\boldsymbol{\omega}, t)$. Multiplying (2.18) by $(1+|s|)^2$, where $s = \sigma + i\eta$, and using the norm equivalence (2.9), gives

$$\|e^{-\sigma t} \widehat{u}(\boldsymbol{\omega}, t)\|_{H^1(\mathbb{R}^+)} \le C_1 \, (1+\omega) \|e^{-\sigma t} \widehat{a}(\boldsymbol{\omega}, t)\|_{H^2(\mathbb{R}^+)} \le C_2 \, (1+\omega) \|\widehat{a}(\boldsymbol{\omega}, \cdot)\|_{H^2(\mathbb{R}^+)}$$

for constants C_1 and C_2, which results in the second inequality. ∎

3. Algorithms. Because we are primarily interested in the analysis of RPIE algorithms here, we concentrate on the case $\Gamma = \mathbb{R}^2$. The restriction to finite Γ should be obvious. The RPIE (2.1) is approximated on a square space grid of side h and uniformly spaced time levels $t^n = n\Delta t$ for $n \in \mathbb{Z}^+$ in terms of piecewise constant or linear space and time basis functions, i.e., the approximate solution is expanded as

$$u(\boldsymbol{x}, t) \approx U(\boldsymbol{x}, t) = \sum_{m \ge 1} \sum_{j,k} U^m_{j,k} \, \phi^{[\alpha]}_j(x) \, \phi^{[\alpha]}_k(y) \, \psi^{[\beta]}_m(t)$$

for $\boldsymbol{x} = (x, y) \in \mathbb{R}^2$, where $\alpha, \beta \in \{0, 1\}$ indicate the orders of the space and time basis functions respectively. The spatial basis functions are defined by

$$\phi^{[\alpha]}_j(x) = \phi^{[\alpha]}(x/h - j),$$

where

$$\phi^{[0]}(z) = \begin{cases} 1 & \text{if } |z| < 1/2, \\ 0 & \text{otherwise} \end{cases} \quad \text{and} \quad \phi^{[1]}(z) = \begin{cases} 1 - |z| & \text{if } |z| < 1, \\ 0 & \text{otherwise} \end{cases}$$

are the standard constant "pulse" and linear "hat" basis functions. The basis functions in time are

$$\psi^{[0]}_m(t) = \phi^{[0]}(t/\Delta t - m + 1/2) \quad \text{and} \quad \psi^{[1]}_m(t) = \phi^{[1]}(t/\Delta t - m).$$

When the temporal basis functions are piecewise linear (resp., constant) the approximate solution $U(\boldsymbol{x},t)$ is evaluated at time $t=t^n$ (resp., $t=t^{n-1/2}$), where n is an integer. Hence the coefficients $U^n_{j,k}$ correspond to the approximate solution at time $t=(n-(1-\beta)/2)\Delta t$ and

$$U(\boldsymbol{x},t^{n-(1-\beta)/2})=\sum_{j,k}U^n_{j,k}\,\phi^{[\alpha]}_j(x)\,\phi^{[\alpha]}_k(y)\,.$$

Note that the approximate solution automatically satisfies the causality condition $U(x,t)=0$ for $t\le 0$.

We shall consider the four schemes denoted by SαTβ, for $\alpha,\,\beta\in\{0,1\}$ to indicate the degree of the basis functions in space ("S") and time ("T"). They are obtained by substituting U for u in the RPIE (2.1), evaluating (collocating) at each space mesh node $\boldsymbol{x}=\boldsymbol{x}_{p,q}$ and time level $t=t^n$, and carrying out all the required integrations *exactly*. This can be written as

$$a(\boldsymbol{x}_{p,q},t^n)=\int_{\mathbb{R}^2}\frac{U(\boldsymbol{x}'+\boldsymbol{x}_{p,q},t^n-|\boldsymbol{x}'|)}{|\boldsymbol{x}'|}\,d\boldsymbol{x}'=\sum_{m=0}^{n-1}\sum_{j,k}C^m_{j,k}\,U^{n-m}_{p+j,q+k},\tag{3.1}$$

where the coefficients

$$C^m_{j,k}=\int_{\mathbb{R}^2}\frac{\phi^{[\alpha]}_j(x')\,\phi^{[\alpha]}_k(y')\,\psi^{[\beta]}_m(|\boldsymbol{x}'|)}{|\boldsymbol{x}'|}\,d\boldsymbol{x}'\tag{3.2}$$

are evaluated exactly. Because of the finite support of the spatial and temporal basis functions, $C^m_{j,k}$ is zero unless $\big||\boldsymbol{x}_{j,k}|-t^{m-(1-\beta)/2}\big|\le(1+\beta)\Delta t/2+(1+\alpha)h/\sqrt{2}$. Also, it follows from the definition of the basis functions that

$$C^m_{j,k}=C^m_{k,j}=C^m_{-j,k}=C^m_{j,-k}.$$

The approximation scheme can hence be written as

$$\sum_{m=0}^{n-1}\mathbb{Q}^m U^{n-m}_{p,q}=a(\boldsymbol{x}_{p,q},t^n),\tag{3.3}$$

where $\mathbb{Q}^m=\sum_{j,k}C^m_{j,k}\,S^j_x\,S^k_y$ for $m\ge 0$ are discrete operators written in terms of unit shift operators S_x and S_y defined by $S^j_x\,U_{p,q}=U_{p+j,q}$, $S^k_y\,U_{p,q}=U_{p,q+k}$.

The sum can be rearranged to give

$$\mathbb{Q}^0U^n_{p,q}=a(\boldsymbol{x}_{p,q},t^n)-\sum_{m=1}^{n-1}\mathbb{Q}^{n-m}U^m_{p,q}\qquad\text{for } n\ge 1$$

and solved at successive time-levels, provided the difference operator $\mathbb{Q}^0$ is invertible. We examine this and other aspects of these schemes in the next section.

4. Stability. We use Fourier methods developed in [6, 7, 10] to analyze the stability of each of the schemes of the previous section. The analysis is for the RPIE (2.1) on an infinite uniform space mesh with uniform time steps, and is analogous to a von Neumann stability analysis for a PDE approximation. Results for the more general RPIE (1.1) approximated on nonuniform grids cannot be obtained this way. However it is clear that infinite mesh stability is necessary for a scheme to be stable in more general circumstances as the mesh is refined [6, sect. 4].

4.1. DFT of the schemes. Using definition (2.4), the DFT of the difference equation (3.3) over the space mesh node points is

$$\sum_{m=0}^{n-1} q_m(\boldsymbol{\omega})\, \tilde{U}^{n-m}(\boldsymbol{\omega}) = \tilde{a}(\boldsymbol{\omega}, t^n) \tag{4.1}$$

for all $\boldsymbol{\omega} \in S_h$ and $n \geq 1$, where the functions $q_m(\boldsymbol{\omega})$ are the discrete transforms of the difference operators $\mathbb{Q}^m$ and are given by

$$q_m(\boldsymbol{\omega}) = \sum_{j,k} C^m_{j,k}\, e^{ih(j\omega_1 + k\omega_2)} \quad \text{for } m \geq 0, \tag{4.2}$$

where the $C^m_{j,k}$ are defined in (3.2). If $q_0(\boldsymbol{\omega}) \neq 0$ then the solution of the scalar convolution sum equation (4.1) is

$$\tilde{U}^n(\boldsymbol{\omega}) = \frac{1}{q_0(\boldsymbol{\omega})} \sum_{m=1}^{n} p_m(\boldsymbol{\omega})\, \tilde{a}(\boldsymbol{\omega}, t^{n-m+1}), \tag{4.3}$$

where the coefficients p_n are defined recursively for all $\boldsymbol{\omega} \in S_h$ by

$$p_1(\boldsymbol{\omega}) = 1\ , \quad p_n(\boldsymbol{\omega}) = \frac{-1}{q_0(\boldsymbol{\omega})} \sum_{m=1}^{n-1} q_m(\boldsymbol{\omega})\, p_{n-m}(\boldsymbol{\omega}) \quad \text{for } n \geq 2. \tag{4.4}$$

The assumption that $q_0(\boldsymbol{\omega}) \neq 0$ for all $\boldsymbol{\omega} \in S_h$ is equivalent to the invertibility of the difference operator $\mathbb{Q}^0$ [8, 14]. The following two lemmas provide more information about q_0 and the other q_m.

LEMMA 4.1. *The coefficients q_m for scheme $S\alpha T\beta$ defined in* (4.2) *satisfy*

$$q_m(\boldsymbol{\omega}) = 2\pi \sum_{j,k} \Phi^{[\alpha]}(h\omega_1 + 2\pi j)\, \Phi^{[\alpha]}(h\omega_2 + 2\pi k)\, I^m_{j,k}(\boldsymbol{\omega}), \tag{4.5}$$

where

$$\Phi^{[0]}(z) = 2\sin(z/2)/z\ , \quad \Phi^{[1]}(z) = 2(1-\cos z)/z^2 \tag{4.6}$$

are the Fourier transforms of the basis functions $\phi^{[\alpha]}(x)$ defined in section 3 *and*

$$I^m_{j,k}(\boldsymbol{\omega}) = \int_0^\infty \psi^{[\beta]}_{m^*}(R)\, J_0\left(R\,|\boldsymbol{\omega} + 2\pi(j,k)/h|\right)\, dR \quad \textit{for } m \geq 0, \tag{4.7}$$

where $m^* = m + 1 - \beta$.

Proof. Recall the labelling of the schemes used in section 3: $\alpha, \beta \in \{0, 1\}$ indicate the order of the space and time basis functions respectively. We first substitute the approximate solution U for u in the left-hand side of the RPIE (2.2) at time $t = t^n$ and use this to define

$$A(\boldsymbol{x}, t^n) = \sum_{m=0}^{n-1} \sum_{j,k} U^{n-m}_{j,k} \int_0^\infty \psi^{[\beta]}_{m^*}(R) \int_0^{2\pi} \phi^{[\alpha]}_j(x + R\cos\theta)\, \phi^{[\alpha]}_k(y + R\sin\theta)\, d\theta\, dR.$$

Note that it follows from the numerical scheme (3.1) that $A(\boldsymbol{x}_{p,q}, t^n) = a(\boldsymbol{x}_{p,q}, t^n)$ on the grid, resulting in

$$\tilde{A} = \tilde{a}. \tag{4.8}$$

Taking the CFT of A with respect to $\boldsymbol{x}$ gives

$$\sum_{m=0}^{n-1}\sum_{j,k} U_{j,k}^{n-m}\int_0^\infty \psi_{m^*}^{[\beta]}(R)\int_0^{2\pi}\Phi^{[\alpha]}(h\omega_1)\,\Phi^{[\alpha]}(h\omega_2)\,e^{i\boldsymbol{\omega}\cdot(h(j,k)+R\boldsymbol{e}_\theta)}\,d\theta\,dR = \widehat{A}(\boldsymbol{\omega},t^n),$$

which can be rearranged as

$$2\pi\sum_{m=0}^{n-1}\tilde{U}^{n-m}(\boldsymbol{\omega})\Phi^{[\alpha]}(h\omega_1)\,\Phi^{[\alpha]}(h\omega_2)\int_0^\infty \psi_{m^*}^{[\beta]}(R)J_0(\omega R)dR = \widehat{A}(\boldsymbol{\omega},t^n)$$

using the definition (2.4) and the Bessel function identity (2.14). Finally we apply the Poisson sum formula (2.7) to both sides of this equation and use (4.8) and the periodicity of the DFT $\tilde{U}^m(\boldsymbol{\omega}+2\pi(j,k)/h)=\tilde{U}^m(\boldsymbol{\omega})$ to obtain

$$2\pi\sum_{j,k}\sum_{m=0}^{n-1}\tilde{U}^{n-m}(\boldsymbol{\omega})\Phi^{[\alpha]}(h\omega_1+2\pi j)\,\Phi^{[\alpha]}(h\omega_2+2\pi k)I_{j,k}^m(\boldsymbol{\omega}) = \tilde{a}(\boldsymbol{\omega},t^n).$$

The result follows by comparing this with (4.1). ∎

LEMMA 4.2. *The coefficient $q_0(\boldsymbol{\omega})\ge C\Delta t$ for all $\boldsymbol{\omega}\in S_h$ where $C>0$ depends only on the mesh ratio $\Delta t/h$ (which is a fixed number in the scheme).*

Proof. We first show that each term in the summation (4.5) for q_0 is nonnegative for each of the four schemes under consideration. Clearly $\Phi^{[\alpha]}(h\omega_1+2\pi j)\ge 0$ for all $j\in\mathbb{Z}$, $\boldsymbol{\omega}\in S_h$ by definition (4.6). Also, (4.7) with $m=0$ can be written as $I_{j,k}^0=\omega_{j,k}^{-1}F^{[\beta]}(\Delta t\omega_{j,k})$, where $\omega_{j,k}=|\boldsymbol{\omega}+2\pi(j,k)/h|$,

$$F^{[0]}(t)=\int_0^t J_0(s)\,ds \quad\text{and}\quad F^{[1]}(t)=\int_0^t(1-s/t)J_0(s)ds=\int_0^t s^{-1}J_1(s)\,ds.$$

It follows from results in [32, sect. 5] that $F^{[\beta]}(t)>0$ for $\beta\in\{0,1\}$ and all $t>0$, and hence each term in the summation (4.5) for q_0 is nonnegative.

Pulling out the term with $j=k=0$ and using the definition (4.6) then gives

$$q_0(\boldsymbol{\omega})\ge 2\pi\Phi^{[\alpha]}(h\omega_1)\,\Phi^{[\alpha]}(h\omega_2)\,I_{0,0}^0(\boldsymbol{\omega})\ge 2\pi(2/\pi)^{2(\alpha+1)}\,I_{0,0}^0(\boldsymbol{\omega})$$

for $\boldsymbol{\omega}\in S_h$, $\beta\in\{0,1\}$ where $I_{0,0}^0(\boldsymbol{\omega})=\omega^{-1}F^{[\beta]}(\omega\Delta t)$. The turning points of the functions $F^{[\beta]}$ occur at the zeros $z_{\beta,l}$ of the Bessel function J_β, and following [32, sect. 5], it can be shown that $F^{[\beta]}(t)\ge F^{[\beta]}(z_{\beta,2})$ for all $t\ge z_{\beta,1}$. After a little manipulation we have $I_{0,0}^0(\boldsymbol{\omega})\ge \Delta t F^{[\beta]}(z_{\beta,2})/\max(z_{\beta,1},\sqrt{2}\,\pi\,\Delta t/h)$ where $\Delta t\omega\le\sqrt{2}\,\pi\,\Delta t/h$ for all $\boldsymbol{\omega}\in S_h$. ∎

4.2. Stability results. To define stability we follow [6] and investigate the growth of perturbations in the solution of the homogeneous problem for which $a\equiv 0$. Because of linearity, it is enough to consider the propagation of nonzero initial data $U^1\ne 0$. The homogeneous stability problem is thus (3.3) with $a\equiv 0$ and U^1 a given, nonzero mesh function, i.e.,

$$\mathbb{Q}^0U_{p,q}^n = -\sum_{m=1}^{n-1}\mathbb{Q}^mU_{p,q}^{n-m} \tag{4.9}$$

for $n\ge 2$ with $U_{p,q}^1\not\equiv 0$.

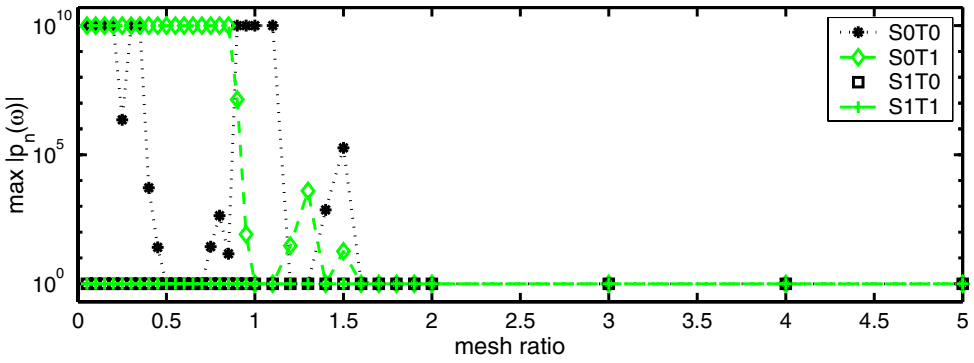

FIG. 4.1. *Stability plot for each of the four schemes* $S\alpha T\beta$. *The graph shows* $\min(\max_{n,j,k}\{|p_n(\boldsymbol{\omega}_{j,k})|\},\ 1e10)$ *plotted against the mesh ratio* $\rho = \Delta t/h$, *where the maximum is taken over timesteps* $n \le \min(1000, 1000/\rho)$ *and frequencies* $\boldsymbol{\omega}_{j,k} = 0.1\,\pi\,(j,k)/h$ *for* $0 \le j,\ k \le 10$.

DEFINITION 4.3. *The numerical scheme* (4.9) *is said to be stable on* $(0,T)$ *if there exists a constant* C *independent of* n *and* h *such that*

$$\|U^n\|_h \le C\,\|U^1\|_h$$

whenever $t^n < T$, *for all functions* U^1 *for which* $\|U^1\|_h < \infty$.

It is straightforward to show that stability corresponds to the existence of a constant C such that $|p_n(\boldsymbol{\omega})| \le C$ for all n and all $\boldsymbol{\omega} \in S_h$ (details are given in [6]). Unfortunately there appears to be no obvious way to check this condition by analysis, and we resort to testing it numerically for many individual frequencies $\boldsymbol{\omega} \in S_h$ to determine the stability of the four schemes. Results are shown in Figure 4.1 and indicate that the two schemes based on piecewise constant spatial basis functions (S0T0 and S0T1) are unstable for many values of mesh ratio, whereas the two schemes based on piecewise linear spatial basis functions (S1T0 and S1T1) appear stable over the range of mesh ratios tested. Stability over a wide range of mesh ratios is very important, since practical calculations over general surfaces may involve space mesh elements of vastly different sizes. Hence we do not consider schemes S0T0 and S0T1 further here.

It is shown in [11] that removing the singularity in the RPIE integrals (1.1) by using local polar coordinates (see also [5, 9]) can also lead to stable collocation schemes. The polar approximation based on the trapezoidal rule in R and arbitrarily accurate integration in θ for which the temporal and spatial basis functions are piecewise linear also appears stable over all values of mesh ratio considered [11]. The disadvantage of this scheme is that the transformed region of integration has a complicated shape that depends on $\boldsymbol{x}$ when Γ is finite and so the scheme is not straightforward to implement in practice. We note also that the collocation RPIE scheme due to Rynne and Smith [31] (which uses piecewise constant basis functions in space, piecewise linears in time, and the midpoint quadrature rule to evaluate the coefficients $C^m_{j,k}$) can be made stable at any value of mesh ratio by averaging in time [7, 10, 31] (which filters out high frequency instabilities). However, this is not entirely satisfactory because, for example, electromagnetic scattering problems involve more complicated RPIEs and hence are harder to stabilize [8]. We believe that a minimum requirement for a scalar RPIE scheme to be generally useful is that it should be stable over a wide range of mesh ratio when applied on an infinite flat plate without recourse to any filtering.

4.3. Further properties of the Fourier transformed schemes. This subsection lays the groundwork for the convergence analysis of S1T0 and S1T1, which appear stable for a wide range of mesh ratio values. We make precise the relationship between the stability coefficients q_m for the schemes and appropriate quadrature approximations of the Fourier transformed RPIE (2.13). The connection between q_m for piecewise linear in time RPIE schemes (like S1T1) and the trapezoidal rule approximation of (2.13) was first described in [10]. The q_m for the piecewise constant in time scheme S1T0 are similarly connected to the midpoint rule approximation of (2.13).

Letting $\widehat{u}_{\Delta t}^{m+1/2}(\boldsymbol{\omega})$ denote the approximation of $\widehat{u}(\boldsymbol{\omega}, t^{m+1/2})$ obtained by using the composite midpoint rule for (2.13) with spacing Δt, we have

$$2\pi\Delta t \sum_{m=0}^{n-1} J_0(\omega t^{n-m-1/2})\, \widehat{u}_{\Delta t}^{m+1/2}(\boldsymbol{\omega}) = \widehat{a}(\boldsymbol{\omega}, t^n).$$

Comparing this with the DFT equation (4.1) and matching the q_m and Bessel function terms gives $q_m(\boldsymbol{\omega}) \sim 2\pi\Delta t J_0(\omega t^{m+1/2})$ for $m \geq 0$. Similarly, comparing the coefficients for S1T1 with the trapezoidal rule approximation of (2.13) gives $q_0(\boldsymbol{\omega}) \sim \pi\Delta t J_0(0)$ and $q_m(\boldsymbol{\omega}) \sim 2\pi\Delta t J_0(\omega t^m)$ for $m \geq 1$ [10]. To see just how close this match is we define $\alpha_m(\boldsymbol{\omega})$ for each scheme by

$$\alpha_0(\boldsymbol{\omega}) \equiv J_0(\omega\, t^{(1-\beta)/2})/(\beta+1) - q_0(\boldsymbol{\omega})/(2\pi\Delta t), \tag{4.10a}$$

$$\alpha_m(\boldsymbol{\omega}) \equiv J_0(\omega\, t^{m+(1-\beta)/2}) - q_m(\boldsymbol{\omega})/(2\pi\Delta t) \quad \text{for } m \geq 1, \tag{4.10b}$$

where we recall that $\beta = 0$ for S1T0 and $\beta = 1$ for S1T1. The following result states the small $h\omega$ behavior of the α_m.

LEMMA 4.4. *There exists a constant C independent of h, $\boldsymbol{\omega}$, and m such that the coefficients α_m for S1T0 and S1T1 satisfy*

$$|\alpha_m(\boldsymbol{\omega})| \leq C(h\omega)^2 \tag{4.11}$$

for all $m \geq 0$ and $\boldsymbol{\omega} \in S_h$.

Proof. We prove the result for scheme S1T0 and note that the details for S1T1 are similar. Substituting the q_m equation (4.5) for S1T0 into the definition (4.10) of α_m gives

$$\begin{aligned}\alpha_m(\boldsymbol{\omega}) &= J_0(\omega\, t^{m+1/2}) - \frac{1}{\Delta t}\sum_{j,k} \Phi^{[1]}(h\omega_1 + 2\pi j)\, \Phi^{[1]}(h\omega_2 + 2\pi k)\, I_{j,k}^m(\boldsymbol{\omega}) \\ &= (T_1 - T_2 - T_3 - T_4)/\Delta t,\end{aligned}$$

where, using the definition (4.6) of $\Phi^{[1]}$,

$$\begin{aligned}T_1 &= (1 - \Phi^{[1]}(h\omega_1)\, \Phi^{[1]}(h\omega_2))\, I_{0,0}^m(\boldsymbol{\omega}) + 2\Delta t J_0(t^{m+1/2}\omega) - I_{0,0}^m(\boldsymbol{\omega}), \\ T_2 &= 2\, \Phi^{[1]}(h\omega_1)\, (1 - \cos(h\omega_2)) \sum_{k\neq 0} \frac{I_{0,k}^m(\boldsymbol{\omega})}{(h\omega_2 + 2\pi k)^2}, \\ T_3 &= 2\, \Phi^{[1]}(h\omega_2)\, (1 - \cos(h\omega_1)) \sum_{j\neq 0} \frac{I_{j,0}^m(\boldsymbol{\omega})}{(h\omega_1 + 2\pi j)^2}, \quad \text{and} \\ T_4 &= 4\, (1 - \cos(h\omega_1))\, (1 - \cos(h\omega_2)) \sum_{j,k\neq 0} \frac{I_{j,k}^m(\boldsymbol{\omega})}{(h\omega_1 + 2\pi j)^2 (h\omega_2 + 2\pi k)^2}.\end{aligned}$$

Since $|\psi_m^{[0]}(z)| \leq 1$ and $|J_0(z)| \leq 1$ for all $z \in \mathbb{R}$ it follows from definition (4.7) that $|I_{j,k}^m(\boldsymbol{\omega})| \leq \Delta t$ for all $(j,k) \in \mathbb{Z}^2$ and $m \geq 0$. It then follows from the inequalities $|1 - \cos z| \leq z^2/2$ and $|\Phi^{[1]}(z)| \leq 1$, and the boundedness of the sum $\sum_{k \neq 0} k^{-2}$ that $|T_2|$, $|T_3| \leq C\, h^2\omega^2\Delta t$ and $|T_4| \leq C\,(h\omega_1)^2(h\omega_2)^2\Delta t$, and hence is also bounded by $C\, h^2\omega^2\Delta t$ for $\boldsymbol{\omega} \in S_h$.

Using standard results for the midpoint quadrature rule [12] gives

$$I_{0,0}^m(\boldsymbol{\omega}) = \Delta t J_0(t^{m+1/2}\omega) + \omega^2\Delta t^3 J_0''(\omega R_m)/24$$

for some $R_m \in (t^m, t^{m+1})$, and hence

$$\left| I_{0,0}^m(\boldsymbol{\omega}) - \Delta t J_0(t^{m+1/2}\omega) \right| \leq C\Delta t (h\omega)^2$$

since $|J_0''(z)|$ is bounded for all $z \in \mathbb{R}$. It thus follows from the triangle inequality and the additional bound $|1 - \Phi^{[1]}(z)| \leq z^2/12$ that $|T_1| \leq C\, h^2\omega^2\Delta t$. ∎

This result means that the scaled coefficients $q_m(\boldsymbol{\omega})$ (which are DFTs of the difference operators $\mathbb{Q}^m$) are second order accurate approximations of the Bessel functions in the Fourier transformed RPIE (2.13). We use this to establish convergence of the schemes S1T0 and S1T1 in the next section.

The midpoint and trapezoidal quadrature rules are both known to give stable schemes for Volterra equations like (2.13), although the leading error term for the trapezoidal rule solution is oscillatory [17, 23, 24]. It is also known [17, 24] that all higher order Newton–Cotes quadrature rules give rise to unstable approximations of (2.13). Hence one would need to be careful in constructing approximations of (2.1) that use temporal basis functions of higher degree, in case they give rise to the same instabilities.

5. Convergence. In this section we demonstrate that the schemes S1T0 and S1T1 for the infinite flat plate problem (2.1) are convergent for values of the mesh ratio $\Delta t/h$ at which they are stable. We work with spatially Fourier transformed quantities and also use Laplace and Z transforms in time to obtain the results. The proof relies on the Fourier transformed RPIE (2.13) being a convolution equation in time and we use techniques due originally to Lubich [27] to obtain bounds for the Fourier transform of the approximation error. We then use arguments similar to those used to prove convergence of approximation schemes for a linear PDE by Thomée [33] (similar techniques are used for hyperbolic equations in [13]). This type of convergence analysis relies crucially on estimates given by Bramble and Hilbert [4] and Thomée [33]. The analysis of schemes for retarded potential integrals is much more complicated than those for PDEs, and much of this section is devoted to formulating the problem in such a way so as to use these estimates.

Throughout this section, C will denote a generic constant that can depend upon the mesh ratio, σ, T, and the norm exponents m and r but is independent of u, a, and h.

5.1. Hypotheses and definitions. We make the following assumptions on the problem and numerical solution.

HYPOTHESES. *Suppose that*

(H1) *the incident field* $a \in H_*^{5+\beta}(0,T;H^{6+\beta}(\mathbb{R}^2))$*;*

(H2) *numerical scheme S1Tβ for* (2.1) *is stable at the mesh ratio* $\rho = \Delta t/h \in (0,\infty)$*, and the mesh ratio remains fixed as* Δt *and* h *go to zero.*

As in section 3, the approximate solution corresponding to S1Tβ for $\beta \in \{0,1\}$ is denoted by $U(\boldsymbol{x},t)$. We explicitly need to make assumption (H2) because stability for these schemes has only been verified numerically and not proved rigorously. Note that it follows from (H1) and Lemma 2.3 that $u \in H_*^{4+\beta}(0,T;H^{5+\beta}(\mathbb{R}^2))$.

We now define convergence for an RPIE scheme, and in the subsequent lemma we show what quantities need to be bounded in order to prove that the schemes converge.

DEFINITION 5.1. *A scheme for the RPIE* (2.1) *is convergent on* $(0,T)$ *if the difference between the exact and approximate solutions* $\|u(\cdot,t)-U(\cdot,t)\|_h \to 0$ *as* $h \to 0$ *whenever* $t < T$.

LEMMA 5.2. *For RPIE* (2.1) *with* $a(\boldsymbol{x},t)$ *satisfying* (H1), *schemes S1T*β *for* $\beta \in \{0,1\}$ *satisfy*

$$\|u(\cdot,t^{n*})-U(\cdot,t^{n*})\|_h \le Ch^r \|a\|_{H_*^2(0,T;H^{r+2}(\mathbb{R}^2))} + \|\varepsilon_n\|_{\mathcal{F}_h}$$

for $1 < r \le 4+\beta$, *where* $t^{n*} = t^{n-(1-\beta)/2}$ *and* ε_n *satisfies the convolution equation*

$$\sum_{m=1}^{n} q_{n-m}(\boldsymbol{\omega})\, \varepsilon_m(\boldsymbol{\omega}) = \mathcal{E}_n(\boldsymbol{\omega}) \tag{5.1}$$

with

$$\mathcal{E}_n(\boldsymbol{\omega}) = 2\pi \int_0^{t^n} J_0(\omega(t^n - R))\, \widehat{u}(\boldsymbol{\omega},R)\, dR - \sum_{m=1}^{n} q_{n-m}(\boldsymbol{\omega})\, \widehat{u}(\boldsymbol{\omega}, t^{m-(1-\beta)/2}) \tag{5.2}$$

and the q_m *given by* (4.5). *Hence they are convergent if* $\|\varepsilon_n\|_{\mathcal{F}_h} \to 0$ *as* $h \to 0$.

Proof. It follows from the discrete Parseval identity (2.5) and the triangle inequality that

$$\|u(\cdot,t^{n*})-U(\cdot,t^{n*})\|_h \le \|\tilde{u}(\cdot,t^{n*})-\widehat{u}(\cdot,t^{n*})\|_{\mathcal{F}_h} + \|\tilde{U}^n - \widehat{u}(\cdot,t^{n*})\|_{\mathcal{F}_h}.$$

The first term on the right-hand side above can be bounded using Proposition 2.1. When $r > 1$ this gives

$$\begin{aligned} \|\widehat{u}(\cdot,t)-\tilde{u}(\cdot,t)\|_{\mathcal{F}_h} &\le Ch^r \|u(\cdot,t)\|_{H^r(\mathbb{R}^2)} \\ &\le Ch^r \|u\|_{H_*^1(0,T;H^r(\mathbb{R}^2))} \\ &\le Ch^r \|a\|_{H_*^2(0,T;H^{r+1}(\mathbb{R}^2))} \end{aligned} \tag{5.3}$$

from Lemma 2.3.

We now examine the second term. Comparing the Fourier transformed RPIE (2.13) at $t = t^n$ with the DFT of the numerical scheme (4.1) gives

$$\sum_{m=1}^{n} q_{n-m}(\boldsymbol{\omega})\, (\tilde{U}^m(\boldsymbol{\omega}) - \widehat{u}(\boldsymbol{\omega},t^{m*})) = \tilde{a}^n(\boldsymbol{\omega}) - \widehat{a}^n(\boldsymbol{\omega}) + \mathcal{E}_n(\boldsymbol{\omega}).$$

Setting

$$\beta_m(\boldsymbol{\omega}) = \tilde{U}^m(\boldsymbol{\omega}) - \widehat{u}(\boldsymbol{\omega},t^{m*}) - \varepsilon_m(\boldsymbol{\omega}),$$

it follows from the definition (5.1) of ε_m that

$$\sum_{m=1}^{n} q_{n-m}(\boldsymbol{\omega})\, \beta_m(\boldsymbol{\omega}) = \tilde{a}^n(\boldsymbol{\omega}) - \widehat{a}^n(\boldsymbol{\omega}). \tag{5.4}$$

The triangle inequality gives

$$\|\tilde{U}^n - \widehat{u}(\cdot, t^{n*})\|_{\mathcal{F}_h} \le \|\varepsilon_n\|_{\mathcal{F}_h} + \|\beta_n\|_{\mathcal{F}_h}$$

and so it remains only to show that $\|\beta_n\|_{\mathcal{F}_h} \to 0$ as $h \to 0$.

Inverting the convolution sum (5.4) using the formula (4.3) gives

$$\beta_n = q_0^{-1} \sum_{m=1}^{n} p_{n+1-m} \left(\tilde{a}^m - \widehat{a}^m\right),$$

where the p_m are defined by (4.4). The scheme is stable by hypothesis (H2), which means that the p_n are bounded, and hence it follows from the triangle inequality and the lower bound on q_0 given in Lemma 4.2 that

$$\|\beta_n\|_{\mathcal{F}_h} \le C\, h^{-1} \sum_{m=1}^{n} \|\tilde{a}^m - \widehat{a}^m\|_{\mathcal{F}_h}$$

for some constant C. Hypothesis (H1) and Proposition 2.1 together give

$$\|\tilde{a}(\cdot,t) - \widehat{a}(\cdot,t)\|_{\mathcal{F}_h} \le C\, h^{r+2}\, \|a(\cdot,t)\|_{H^{r+2}(\mathbb{R}^2)} \le C\, h^{r+2}\, \|a\|_{H^1_*(0,T;H^{r+2}(\mathbb{R}^2))}$$

when $t < T$, for any $r > -1$. Thus

$$\|\beta_n\|_{\mathcal{F}_h} \le C\, h^{-1} \sum_{m=1}^{n} \|\tilde{a}^m - \widehat{a}^m\|_{\mathcal{F}_h} \le C\, h^{r}\, \|a\|_{H^1_*(0,T;H^{r+2}(\mathbb{R}^2))}$$

since $n \le T/(\rho h)$ (where ρ is the mesh ratio). Combining this with inequality (5.3) completes the proof. ∎

The rest of this section is devoted to deriving two different bounds on ε_n; the first bound is valid for all $\boldsymbol{\omega}$ in S_h and the second when $h\omega$ is small. These bounds are then combined to show that $\|\varepsilon_n\|_{\mathcal{F}_h} = O(h^2)$ as $h \to 0$, and hence that we can use the previous lemma with $r = 2$ to prove second order convergence for the schemes S1Tβ.

5.2. Bound on $\boldsymbol{\varepsilon_n}$ for all $\boldsymbol{\omega \in S_h}$. Here we combine a bound on the size of the error term $\mathcal{E}_n(\boldsymbol{\omega})$ defined in (5.2) with the stability hypothesis (H2) in order to bound ε_n.

LEMMA 5.3. *Under hypotheses* (H1) *and* (H2), *there exists* ζ *with* $(1+\omega)^2\zeta(\omega) \in L^2(\mathbb{R}^2)$ *such that*

$$|\varepsilon_n(\boldsymbol{\omega})| \le \zeta(\boldsymbol{\omega}) \quad \textit{when } t^n < T. \tag{5.5}$$

Proof. Using (4.10) to replace the q_m terms in (5.2) gives

$$\frac{\mathcal{E}_n}{2\pi} = \int_0^{t^n} J_0(\omega(t^n - R))\, \widehat{u}(\boldsymbol{\omega}, R)\, dR - \Delta t \sum_{m=1}^{n} \left[J_0(\omega t^{n-m*}) - \alpha_{n-m}(\boldsymbol{\omega})\right] \widehat{u}(\boldsymbol{\omega}, t^{m*}).$$

This is the error in the midpoint (resp., trapezoidal) rule approximation of the integral when $\beta = 0$ (resp., 1), with additional terms involving the α's. It follows from standard results for these quadrature rules that if $t^n < T$ then

$$\left|\frac{\mathcal{E}_n}{2\pi}\right| \le Ch^2 \left|\frac{\partial^2}{\partial R^2} J_0(\omega(t^n - R))\, \widehat{u}(\boldsymbol{\omega}, R)\right|_{R=\mu} + \Delta t \sum_{m=1}^{n} |\alpha_{n-m}(\boldsymbol{\omega})\, \widehat{u}(\boldsymbol{\omega}, {}^{m*})|$$

for some $\mu \in (0, t^n)$. Hence, using the bound (4.11) on the size of the $|\alpha_m|$, and the fact that $J_0(z)$, $J_0'(z)$, and $J_0''(z)$ are all bounded it follows that

$$|\mathcal{E}_n| \le Ch^2(\omega^2|\widehat{u}(\boldsymbol{\omega},\mu)| + \omega|\widehat{u}^{(1)}(\boldsymbol{\omega},\mu)| + |\widehat{u}^{(2)}(\boldsymbol{\omega},\mu)|)$$

and the pointwise bound from Lemma 2.4 then gives

$$|\mathcal{E}_n| \le Ch^2(1+\omega)^3\|\widehat{a}(\boldsymbol{\omega},\cdot)\|_{H^4(0,T)}. \tag{5.6}$$

Now inverting the convolution sum (5.1) and using an identical argument to Lemma 5.2, we get

$$|\varepsilon_n| \le C\,h^{-1}\sum_{m=1}^{n}|\mathcal{E}_m| \le C\,(1+\omega)^3\|\widehat{a}(\boldsymbol{\omega},\cdot)\|_{H^4(0,T)} \equiv \zeta(\boldsymbol{\omega})$$

for $t_n \le T$. Hypothesis (H1) guarantees that $(1+\omega)^2\zeta(\boldsymbol{\omega}) \in L^2(\mathbb{R}^2)$ as required. ∎

5.3. Bound on $\boldsymbol{\varepsilon_n}$ for small $\boldsymbol{h\omega}$. This is the most technical part of the convergence proof. We need to get an $O(h^2)$ bound on $\|\varepsilon_n\|$ when $h\omega$ is sufficiently small. Taking the Z transform (2.10) of the convolution sum (5.1) gives

$$Zq(\boldsymbol{\omega},s)\,Z\varepsilon(\boldsymbol{\omega},s) = Z\mathcal{E}(\boldsymbol{\omega},s)$$

and hence

$$|Z\varepsilon(\boldsymbol{\omega},s)| = |Zq(\boldsymbol{\omega},s)|^{-1}|Z\mathcal{E}(\boldsymbol{\omega},s)|$$

(for $Zq \ne 0$) where $s = \sigma + i\eta$ and $\eta \in [-\pi/\Delta t, \pi/\Delta t]$. Ideally, we would obtain upper bounds on $1/|Zq|$ and $|Z\mathcal{E}|$, use them to bound $|Z\varepsilon|$, and use the inverse Z transform to bound $|\varepsilon_n|$. Unfortunately this is not straightforward, but we can make progress by a less direct route. We first use (4.10) and Lemma 4.4 to obtain the following information on the Z transform of the q_m.

LEMMA 5.4. *We can write $q_m = q_m^a + q_m^b$ for all $0 \le m\Delta t \le T$, where*

$$|q_m^b| \le C\Delta t(h\omega)^2$$

and the sequence q_m^a is defined through its Z transform

$$Zq^a(\boldsymbol{\omega},s) = 2\pi\begin{cases} e^{s\Delta t/2}\left(\dfrac{1}{\sqrt{s^2+\omega^2}} - \dfrac{1}{s} + \dfrac{\Delta t}{e^{s\Delta t/2}-e^{-s\Delta t/2}}\right), & \beta = 0, \\ \dfrac{1}{\sqrt{s^2+\omega^2}} - \dfrac{1}{s} + \dfrac{\Delta t}{2}\left(\dfrac{e^{s\Delta t}+1}{e^{s\Delta t}-1}\right), & \beta = 1. \end{cases}$$

Proof. The two cases are very similar so we just consider $\beta = 0$. From Lemma 4.4 we have $q_m = 2\pi\Delta t J_0(\omega t^{m+1/2}) - 2\pi\Delta t\alpha_m$ with $|\alpha_m| \le C(h\omega)^2$. We write the Bessel function term as $J_0(\omega t) = f(t) + 1$, where $f(t) \equiv J_0(\omega t) - 1$ and take its Z transform to get

$$\sum_{m=0}^{\infty} J_0(\omega t^{m+1/2})\,e^{-sm\Delta t} = \sum_{m=0}^{\infty} f(t^{m+1/2})\,e^{-sm\Delta t} + \frac{1}{1-e^{-s\Delta t}}\,. \tag{5.7}$$

(The reason for working with f rather than directly with $J_0(\omega t)$ is that $f(0) = 0$.) Splitting the sum $\sum_{m=0}^{\infty} f_{m/2}\, e^{-sm\Delta t/2}$ into odd and even terms and rearranging give

$$\sum_{m=0}^{\infty} f(\omega t^{m+1/2})\, e^{-sm\Delta t} = e^{s\Delta t/2} \left(\sum_{m=0}^{\infty} f(\omega t^{m/2})\, e^{-sm\Delta t/2} - \sum_{m=0}^{\infty} f(\omega t^{m})\, e^{-sm\Delta t} \right).$$

The Laplace Poisson sum formula (2.12) with spacing Δt is

$$\Delta t \sum_{m=0}^{\infty} f(\omega t^m) e^{-sm\Delta t} = \frac{1}{\sqrt{s^2+\omega^2}} - \frac{1}{s} + \sum_{l\neq 0} \theta_l(s,\omega,\Delta t),$$

where

$$\theta_l(s,\omega,\Delta t) = \frac{1}{\sqrt{s_l^2+\omega^2}} - \frac{1}{s_l} \quad \text{for} \quad s_l = s + i\,\frac{2\pi l}{\Delta t}.$$

Substituting this and the similar Poisson sum formula with spacing $\Delta t/2$ into the above identity for f gives

$$\Delta t \sum_{m=0}^{\infty} f(\omega t^{m+1/2})\, e^{-sm\Delta t} = e^{s\Delta t/2} \left(\frac{1}{\sqrt{s^2+\omega^2}} - \frac{1}{s} + \Theta \right),$$

where

$$\Theta = \sum_{l\neq 0} \{2\theta_l(s,\omega,\Delta t/2) - \theta_l(s,\omega,\Delta t)\}.$$

It then follows from (5.7) that

$$2\pi\Delta t \sum_{m=0}^{\infty} J_0(\omega t^{m+1/2}) e^{-sm\Delta t} = Zq^a(\boldsymbol{\omega}, s) + Z\kappa, \tag{5.8}$$

where $\{\kappa_m\}$ is the inverse Z transform of $2\pi e^{s\Delta t/2}\Theta$.

It can be shown that if $hw < 1/(\rho\sqrt{2})$ and h is sufficiently small, then $|\Theta| \leq C\Delta t\,(h\omega)^2$. Hence it follows from the inverse transform formula (2.11) that

$$|\kappa_n| \leq \Delta t\, e^{\sigma(n+1/2)\Delta t} \int_{-\pi/\Delta t}^{\pi/\Delta t} |\Theta| d\eta \leq C e^{T\sigma} \Delta t (h\omega)^2$$

for $n\Delta t \leq T$. The result then follows upon comparing (5.8) with (4.10) and using the bound on $|\alpha_m|$ given in Lemma 4.4. ∎

We next obtain upper bounds on $1/|Zq^a|$.

LEMMA 5.5. *If $\omega\Delta t \leq \pi/\sqrt{2}$ and Δt is small enough, then the Z transforms defined in the previous lemma satisfy*

$$\frac{1}{|Zq^a|} \leq \begin{cases} \frac{2}{\pi}\,|\sqrt{s^2+\omega^2}|\,, & \beta = 0, \\ (2\pi\sigma)^{-1}|s^2+\omega^2|\,, & \beta = 1, \end{cases}$$

where $s = \sigma + i\eta$ and $\eta \in [-\pi/\Delta t, \pi/\Delta t]$.

Proof. The two cases work quite differently, and a great deal of algebraic manipulation (the details are omitted) is required to obtain the results.

Case $\boldsymbol{\beta = 0}$. Set

$$P = \frac{1}{\sqrt{s^2+\omega^2}} \quad \text{and} \quad Q = \frac{\Delta t}{(e^{s\Delta t/2} - e^{-s\Delta t/2})} - \frac{1}{s}\,.$$

Then

$$|Zq^a| = 2\pi\, e^{\sigma\Delta t/2}\ \{|P+Q|\} \geq 2\pi\, e^{\sigma\Delta t/2}\ \{|P| - |Q|\}.$$

It can be shown that $|Q|$ is monotonic increasing in $\eta\Delta t$ for $\eta\Delta t \in [0,\pi]$, and hence

$$|Q| \leq |Q|_{\eta\Delta t=\pi} = \frac{\Delta t}{\pi}\sqrt{1-\pi+\pi^2/4} + O(\Delta t^2).$$

So if Δt is sufficiently small, then $|Q| \leq 3\Delta t/(5\pi)$. It can also be shown that $|P| \geq 4\Delta t/(5\pi)$ if Δt is sufficiently small and $\omega\Delta t \leq \pi/\sqrt{2}$. Hence under these conditions we have $|Q| \leq 3|P|/4$ and so

$$|Zq^a| \geq \pi\, e^{\sigma\Delta t/2}\, |P|/2 \geq \pi|P|/2,$$

and the result follows from the definition of P.

Case $\boldsymbol{\beta = 1}$. We use P as above and define

$$R = \frac{\Delta t}{2}\frac{(e^{s\Delta t}+1)}{(e^{s\Delta t}-1)} - \frac{1}{s}\,.$$

Then

$$|Zq^a| = 2\pi\,|P+R| \geq 2\pi\,\Re(P+R) = 2\pi\ \{\Re(P) + \Re(R)\}.$$

It can be shown that

$$\Re(P) \geq \frac{\sigma}{|s^2+\omega^2|} > 0 \quad \text{and} \quad \Re(R) \geq 0,$$

from which the result follows immediately. ∎

We split the error from (5.1) into two parts, $\varepsilon_n = \varepsilon_n^a + \varepsilon_n^b$, satisfying

$$\sum_{m=0}^{n} q^a_{n-m}(\boldsymbol{\omega})\varepsilon^a_m(\boldsymbol{\omega}) = \mathcal{E}_n(\boldsymbol{\omega}) \quad \text{and} \quad \sum_{m=0}^{n} q_{n-m}(\boldsymbol{\omega})\varepsilon^b_m(\boldsymbol{\omega}) = -\sum_{m=0}^{n} q^b_{n-m}(\boldsymbol{\omega})\varepsilon^a_m(\boldsymbol{\omega}),$$

where $q_m = q^a_m + q^b_m$ as defined in Lemma 5.4, and we have taken all sums to start from $m=0$ rather than $m=1$ for ease of manipulation (the $m=0$ terms are zero by causality). We first bound $|\varepsilon^b_m|$ in terms of $|\varepsilon^a_m|$, so that the problem reduces to finding a bound on $|\varepsilon^a_m|$. Inverting the second convolution sum gives

$$\varepsilon^b_n = \frac{-1}{q_0}\sum_{m=0}^{n} p_{n-m}\sum_{k=0}^{m} q^b_{m-k}\varepsilon^a_m,$$

where $|p_m| \leq C$ by the stability hypothesis (H2), and $q_0 \geq C\Delta t$ from Lemma 4.2. If $n\Delta t \leq T$, then it follows from Lemma 5.4 that

$$|\varepsilon^b_n| \leq \frac{C}{\Delta t}\sum_{m=0}^{n}\sum_{k=0}^{m}|q^b_{m-k}|\,|\varepsilon^a_m| \leq \frac{CT^2h^2\omega^2}{\Delta t^2}\max_{m\leq n}|\varepsilon^a_m| \leq C\omega^2\max_{m\leq n}|\varepsilon^a_m|\,. \tag{5.9}$$

It remains to bound $|\varepsilon_n^a(\boldsymbol{\omega})|$. To do this we embed the time-discrete convolution $\sum_{m=0}^n q_m^a \varepsilon_{n-m}^a = \mathcal{E}_n$ into a time-continuous problem

$$\sum_{m=0}^{\infty} q_m^a(\boldsymbol{\omega})\varepsilon^a(\boldsymbol{\omega}, t-t_m) = \mathcal{E}(\boldsymbol{\omega}, t), \tag{5.10}$$

where $\mathcal{E}(\boldsymbol{\omega}, t)$ and $\varepsilon^a(\boldsymbol{\omega}, t)$ interpolate $\mathcal{E}_n$ and ε_n^a at time levels $t = t_n$. The aim is to obtain a bound on $\|\varepsilon^a(\boldsymbol{\omega}, \cdot)\|_{H^1(\mathbb{R}^+)}$ and hence on the point values $|\varepsilon_n^a(\boldsymbol{\omega})| = |\varepsilon^a(\boldsymbol{\omega}, t_n)|$ via (2.19). We generalize the formula (5.2) for $\mathcal{E}_n$ to obtain the interpolant

$$\mathcal{E}(\boldsymbol{\omega}, t) = 2\pi\int_0^{\infty} J_0(\omega R)\, \widehat{u}(\boldsymbol{\omega}, t-R)dR - \sum_{m=0}^{\infty} q_m(\boldsymbol{\omega})\, \widehat{u}(\boldsymbol{\omega}, t - t^{m+(1-\beta)/2}), \tag{5.11}$$

and note that it follows from causality of u that $\mathcal{E}(\boldsymbol{\omega}, t_n) = \mathcal{E}_n(\boldsymbol{\omega})$.

We bound $\|\varepsilon^a(\boldsymbol{\omega}, \cdot)\|_{H^1(\mathbb{R}^+)}$ via the Laplace transform of the time-continuous problem (5.10):

$$\bar{\varepsilon^a}(\boldsymbol{\omega}, s)\, Zq^a(\boldsymbol{\omega}, s) = \bar{\mathcal{E}}(\boldsymbol{\omega}, s).$$

This implies

$$|\bar{\varepsilon^a}(\boldsymbol{\omega}, s)| \le |Zq^a(\boldsymbol{\omega}, s)|^{-1}\, |\bar{\mathcal{E}}(\boldsymbol{\omega}, s)|,$$

with the upper bound on $|Zq^a|^{-1}$ given in Lemma 5.5. Using this bound, multiplying by $1 + |s|$ and applying the equivalence inequality (2.9), then gives

$$\|e^{-\sigma t}\varepsilon^a(\boldsymbol{\omega}, t)\|_{H^1(\mathbb{R}^+)} \le \begin{cases} C(1+\omega)\|e^{-\sigma t}\mathcal{E}(\boldsymbol{\omega}, t)\|_{H^2(\mathbb{R}^+)}, & \beta = 0 \\ C(1+\omega)^2\|e^{-\sigma t}\mathcal{E}(\boldsymbol{\omega}, t)\|_{H^3(\mathbb{R}^+)}, & \beta = 1. \end{cases} \tag{5.12}$$

The pointwise result

$$|\varepsilon^a(\boldsymbol{\omega}, t)| \le \frac{e^{\sigma T}}{\sqrt{2\pi}}\, \|e^{-\sigma t}\varepsilon^a(\boldsymbol{\omega}, t)\|_{H^1(\mathbb{R}^+)} \tag{5.13}$$

for $t \in (0, T)$, then follows from (2.19), and the next lemma provides the crucial $O(h^2)$ term that leads to the second order convergence result.

LEMMA 5.6. *The error term $\mathcal{E}(\boldsymbol{\omega}, t)$ defined by* (5.11) *satisfies*

$$\|e^{-\sigma t}\mathcal{E}(\boldsymbol{\omega}, t)\|_{H^m(0,T)} \le Ch^2(1+\omega)^3\|\widehat{a}(\boldsymbol{\omega}, \cdot)\|_{H^{m+3}(0,T)}$$

for $1 \le m \le 2 + \beta$.

Proof. The Laplace transform of (5.11) is

$$\bar{\mathcal{E}}(\boldsymbol{\omega}, s) = E(\boldsymbol{\omega}, s)\, \bar{\widehat{u}}(\boldsymbol{\omega}, s), \tag{5.14}$$

where

$$E(\boldsymbol{\omega}, s) \stackrel{\text{def}}{=} \left(\frac{2\pi}{\sqrt{\omega^2 + s^2}} - Zq(\boldsymbol{\omega}, s)e^{s\Delta t(\beta-1)/2}\right).$$

Multiplying by $(1 + |s|)^m$, square integrating over $\mathbb{R}$, and using (2.9) give

$$\|e^{-\sigma t}\, \mathcal{E}(\boldsymbol{\omega}, t)\|^2_{H^m(\mathbb{R}^+)} \le C\int_{-\infty}^{\infty} (1+|s|)^{2m}|E(\boldsymbol{\omega}, s)|^2|\bar{\widehat{u}}(\boldsymbol{\omega}, s)|^2 d\eta,$$

where $s = \sigma + i\eta$. We obtain two different bounds for $|E(\boldsymbol{\omega}, s)|$, valid for "high" and "low" values of $|\eta|$.

When $|\eta\Delta t| > \pi$, the triangle inequality implies that

$$|E(\boldsymbol{\omega}, s)| \leq \frac{2\pi}{|\sqrt{\omega^2 + s^2}|} + e^{(\beta-1)\sigma\Delta t/2}\,|Zq(\boldsymbol{\omega}, s)|$$

and we consider each term separately. If $|\eta\Delta t| > \pi$, then

$$\frac{1}{|\omega^2 + s^2|^2} \leq \frac{\Delta t^2}{2\sigma^2\pi^2} \leq C$$

when Δt is small. The second term can also be bounded by a constant: by definition

$$|Zq(\boldsymbol{\omega}, s)| \leq \sum_{n=0}^{\infty} |q_n\, e^{-sn\Delta t}| \leq C\Delta t \sum_{n=0}^{\infty} e^{-\sigma n\Delta t}$$

since (4.10) and (4.11) imply that each $|q_n| < C\Delta t$. Hence

$$|Zq(\boldsymbol{\omega}, s)| \leq \frac{C\Delta t}{1 - e^{-\sigma\Delta t}} \leq C$$

if Δt is sufficiently small.

Thus we have shown that if $|\eta\Delta t| > \pi$ then $|E(\boldsymbol{\omega}, s)| \leq C$. In this region $|s| > |\eta| > \pi/\Delta t$, and so $|s|\Delta t/\pi > 1$, which means that

$$|E(\boldsymbol{\omega}, s)| \leq C < C\,(|s|\Delta t/\pi)^2 = C\,|s|^2\,h^2$$

since $\Delta t/h$ is fixed.

When $|\eta\Delta t| \leq \pi$ we use Lemma 5.4 and consider the cases $\beta = 0$ and $\beta = 1$ separately. Define

$$E_0 = \frac{1}{s} - \frac{\Delta t}{e^{s\Delta t/2} - e^{-s\Delta t/2}}\,, \quad E_1 = \frac{1}{s} - \frac{\Delta t}{2}\left(\frac{e^{s\Delta t} + 1}{e^{s\Delta t} - 1}\right)$$

so that $E = E_\beta - Zq^b\, e^{(\beta-1)s\Delta t/2}$. Lemma 5.4 implies that $|q_n^b| \leq C\Delta t(h\omega)^2$ in either case, and so it follows from an identical argument to that used above to bound $|Zq|$ that $|Zq^b\, e^{(\beta-1)s\Delta t/2}| \leq e^{(\beta-1)\sigma\Delta t/2}\, C\,(h\omega)^2 \leq C\,(h\omega)^2$ if Δt is sufficiently small. It can be shown (again by considerable algebraic manipulation) that $|E_\beta| \leq \Delta t^2\,|s|$ for $\beta = 0,\ 1$ when $|\eta\Delta t| \leq \pi$. Hence if $|\eta\Delta t| \leq \pi$ and Δt is sufficiently small, we get $|E| \leq C\,\left(\Delta t^2\,|s| + h^2\omega^2\right)$.

We thus have the bound

$$|E(\boldsymbol{\omega}, s)| \leq Ch^2(1+\omega)^2(1+|s|)^2 \quad \forall \eta \in \mathbb{R}\,.$$

Inserting this into the integral in (5.14) gives

$$\|e^{-\sigma t}\mathcal{E}(\boldsymbol{\omega}, t)\|_{H^m(\mathbb{R}^+)} \leq Ch^2(1+\omega)^2\|e^{-\sigma t}\widehat{u}(\boldsymbol{\omega}, t)\|_{H^{m+2}(\mathbb{R}^+)}$$

and the result follows from Lemma 2.4. ∎

We now use this result to bound $|\varepsilon_n|$: (5.9) implies that

$$|\varepsilon_n(\boldsymbol{\omega})| \leq C(1+\omega)^2 \max_{n \leq T/\Delta t} |\varepsilon_n^a(\boldsymbol{\omega})|$$

for $n\Delta t \leq T$, and using bounds (5.12) and (5.13) gives

$$|\varepsilon_n(\boldsymbol{\omega})| \leq Ch^2(1+\omega)^{6+\beta}\|\widehat{a}(\boldsymbol{\omega}, \cdot)\|_{H^{5+\beta}(0,T)} \equiv h^2\zeta_\beta(\boldsymbol{\omega}) \tag{5.15}$$

for $\beta = 0, 1$. Hypothesis (H1) guarantees that $\zeta_\beta(\boldsymbol{\omega}) \in L_2(\mathbb{R}^2)$, which completes the small $h\omega$ bound calculation.

5.4. A bound for $\|\varepsilon_n\|_{\mathcal{F}_h}$. We split the range of integration of the Fourier norm $\|\varepsilon_n\|_{\mathcal{F}_h}$ into a "low" frequency section $\boldsymbol{\omega} \in L_h \equiv \{\boldsymbol{\omega} : h\omega < \gamma\}$, where inequality (5.15) is used (where the constant γ is chosen to be less than $1/(\rho\sqrt{2})$ so that all the small $h\omega$ bounds hold), and a "high" frequency section $\boldsymbol{\omega} \in S_h \backslash L_h$, where inequality (5.5) is used. The result is

$$\|\varepsilon_n\|_{\mathcal{F}_h} \le Ch^2 \left(\int_{L_h} |\zeta_\beta(\boldsymbol{\omega})|^2 \, d\boldsymbol{\omega} \right)^{1/2} + C \left(\int_{S_h \backslash L_h} |\zeta(\boldsymbol{\omega})|^2 \, d\boldsymbol{\omega} \right)^{1/2},$$

where ζ was introduced in section 5.2. The integral over low frequencies satisfies

$$\int_{L_h} |\zeta_\beta(\boldsymbol{\omega})|^2 \, d\boldsymbol{\omega} \le \int_{\mathbb{R}^2} |\zeta_\beta(\boldsymbol{\omega})|^2 \, d\boldsymbol{\omega} \le \|a\|^2_{H_*^{5+\beta}(0,T;H^{6+\beta}(\mathbb{R}^2))}.$$

Following the arguments used by Thomeé [33], the high frequency integral satisfies

$$\int_{S_h \backslash L_h} |\zeta(\boldsymbol{\omega})|^2 \, d\boldsymbol{\omega} \le \int_{S_h \backslash L_h} \left| \left(\frac{\omega h}{\gamma} \right)^2 \zeta(\boldsymbol{\omega}) \right|^2 d\boldsymbol{\omega} \le Ch^4,$$

since $\omega^2 \zeta(\boldsymbol{\omega}) \in L^2(\mathbb{R}^2)$ by Lemma 5.3.

Combining the low and high frequency bounds above and using Lemma 5.2 with $r = 2$ yield the final result.

THEOREM 5.7. *Under hypotheses* (H1) *and* (H2) *for* $\beta = 0, 1$, *the global error for schemes* $S1T\beta$ *satisfies the bound*

$$\|u(\cdot, t^{n-(1-\beta)/2}) - U(\cdot, t^{n-(1-\beta)/2})\|_h \le Ch^2$$

as $h \to 0$ *whenever* $t^n \le T$, *where* C *is a constant.*

6. Conclusions. We have presented two new schemes for the RPIE (2.1) that appear stable over a wide range of mesh ratio values, and are hence likely to be useful and reliable in practice. We have also given what we believe is the first rigorous convergence proof with reasonable, checkable hypotheses that RPIE collocation schemes converge at the optimal $O(h^2)$ rate one would expect from the underlying approximation methods. This is a great improvement on our earlier work [11], where we obtained proof of covergence at the rate $O(1/|\ln h|)$ for all but extremely smooth incident fields, whose spatial Fourier transforms decay faster than $e^{-\gamma_0 \omega}$ for a constant γ_0.

This improved result is mostly due to a change in approach to the error analysis for low spatial frequencies (section 5.3) from a Volterra integral equation analysis in the style of [17, 23, 24], to an approach using Z and Laplace transforms in the style of Lubich [27]. We believe that our new smoothness requirements may be relaxed further by more refined or alternative methods of proof, and we conjecture that this convergence rate will be achieved for a wider class of excitations.

Acknowledgments. We are indebted to the anonymous referee of the first version of this manuscript who very kindly pointed out how we could use Z transforms to improve our convergence rate from $O(1/|\ln h|)$ to $O(h^2)$. We are also grateful to B. P. Rynne for many helpful discussions.

This work was completed when we visited the Isaac Newton Institute for Mathematical Sciences in Cambridge, UK, as participants of the Computational Challenges in PDEs programme.

AN ABSOLUTELY STABLE PRESSURE-POISSON STABILIZED FINITE ELEMENT METHOD FOR THE STOKES EQUATIONS*

PAVEL BOCHEV† AND MAX GUNZBURGER‡

Abstract. The pressure-Poisson stabilized Galerkin method for the Stokes equation requires the choice of a positive parameter. Existing theoretical predictions for the range of parameter values that yield stable discretizations seem to be very pessimistic when compared to the computational evidence. Motivated by this wide gap, we first examine a continuous prototype for this class of schemes. We show that the prototype is absolutely stable; i.e., it is stable for all parameter values, and is optimally accurate. We then define a new, practical variant of the well-known pressure-Poisson stabilized scheme. We prove that the new method is absolutely stable just like its continuous prototype and that it achieves optimal convergence rates with respect to the same mesh-independent norms. The new method differs from the standard pressure-Poisson stabilized method in several important aspects. First, its definition does not degrade to a penalty formulation for the lowest order nodal spaces. Second, the method is absolutely stable with respect to the natural norm for the problem, while the standard pressure-Poisson stabilized method is stable with respect to a mesh-dependent norm.

Key words. stabilized finite element methods, mixed methods, Stokes problem

1. Introduction.

The stable and accurate finite element solution of the Stokes problem requires pairs of velocity and pressure spaces that satisfy the inf-sup (or LBB) compatibility condition; see, e.g., [7, 15, 16]. In the past two decades, the formulation of finite element methods that either circumvent or ameliorate this restrictive condition has attracted significant attention. Examples include augmented Lagrangian methods [12], least-squares finite element methods [4], and a group of methods collectively known as *consistently stabilized* Galerkin methods; see [1, 3, 8, 11, 13, 14, 17, 18, 19]. In what follows, we will refer to the members of the latter group as the *standard stabilized methods*.

In this paper, we develop and analyze a new stabilized formulation that can be related to one of the standard methods originally proposed in [18] and widely known as the *pressure-Poisson stabilized Galerkin method*. To demonstrate the connection between the new and the standard methods, we introduce the notion of continuous stabilized prototypes. Continuous prototypes are idealized finite element methods that are not necessarily practical. Their role is to provide a template that reveals the proper functional settings and guides the development of practical schemes. In

addition, prototypes serve as a gauge to measure the deviation of practical methods from the idealized mathematical setting. All practical methods associated with a particular prototype form a class of methods. Here, we will derive the prototypes that engender the three most commonly used stabilized methods for the Stokes problem. For reasons that will be explained later, we call the three classes the GLS, SGLS, and RGLS method classes.

Consistently stabilized methods contain a positive parameter that must be set to define the method. It is well known that standard stabilized methods can be divided into those that are conditionally stable and those that are absolutely stable, i.e., those that are stable only for a set of restricted values of the parameter and those that are stable for all values of the parameter, respectively. According to previous theoretical analyses, the standard Galerkin least-squares [17] and pressure-Poisson [18] methods fall into the first category while the method of [11] is an example of an absolutely stable method. Stability classifications of stabilized methods are based on sufficient (weak or strong) coercivity conditions for the corresponding forms. Thus, in principle, they represent the worst case scenario and, in practice, there may be a gap between the theoretically predicted stability range of a method and the stability range observed in computational implementations. For the GLS method this gap is very narrow if it exists at all; see [13] or [2]. In other words, for this method, the stability range predicted by existing theory agrees with great accuracy with its practical stability range.

The main focus of this paper will be on the SGLS class which contains the standard pressure-Poisson stabilized method. Our interest in this class is not incidental. In [2], we reported an unusually large discrepancy between the well-known theoretical stability analysis of [8] and the actual, computationally observed stability range of the standard pressure-Poisson Galerkin method. In fact, what was observed computationally indicates that this method is actually absolutely stable. In this paper, we show that there are indeed grounds for such a stability pattern. Most notably, we prove that the continuous SGLS prototype is absolutely stable. Then we define a new discrete member of this class which also turns out to be absolutely stable.

Our new method differs from the standard pressure-Poisson Galerkin formulation in several important aspects. First, its definition does not degrade to a penalty formulation for the lowest-order nodal spaces. Second, we show that our method is absolutely stable with respect to the natural norm on $\mathbf{H}^1(\Omega) \times L_0^2(\Omega)$, while stability of the standard method is with respect to a mesh-dependent norm. Last, while the new method is not fully consistent, it is weakly inconsistent in the sense that finite element approximations converge to all smooth solutions at the best possible rate.

Our analysis suggests that the new, implementable SGLS method is a potentially strong contender in the field of stabilized formulations for the Stokes problem. The absolute stability makes it an attractive alternative to GLS methods that, both theoretically and practically, are known to be only conditionally stable. Compared with the absolutely stable RGLS methods, the new formulation avoids the appearance of local biharmonic terms that in principle should lead to better conditioned matrices. This conjecture is supported by our studies in [2] which suggest that Krylov subspace solvers generally tend to perform better for members of the SGLS family of stabilized methods. Nevertheless, further numerical studies will be needed to reach a definitive conclusion about the practical performance of our new method. These will be reported in a forthcoming paper.

We have organized the paper as follows. In section 2, we summarize notations

and quote technical results that are used throughout the paper. Section 3 develops the notion of continuous stabilized prototypes starting from a penalized Lagrangian formulation of the Stokes problem. Sections 4 and 5 are the core of this paper. Their focus is on the SGLS class of stabilized methods. In section 4, we consider the continuous prototype of this class and show that it is absolutely stable. Then, in section 5, we proceed to define a new discrete member of the SGLS class and establish its absolute stability and optimal convergence. In section 6, we conclude the paper with several remarks concerning implementation of the new method.

2. Quotation of results. Let Ω denote a bounded region in $\mathbb{R}^n$, $n = 2, 3$, with a Lipschitz continuous boundary $\Gamma = \partial\Omega$. For $p > 0$, $H^p(\Omega)$ denotes a Sobolev space of order p with norm and inner product denoted by $\|\cdot\|_p$ and $(\cdot,\cdot)_p$, respectively. When $p = 0$ we use the standard notation $L^2(\Omega)$. The symbol $|\cdot|_k$, $0 \le k \le p$, denotes the kth seminorm on $H^p(\Omega)$. We recall the subspace $L^2_0(\Omega)$ of all square integrable functions with vanishing mean and the subspace $H^1_0(\Omega)$ of all $H^1(\Omega)$ functions with vanishing trace. The Poincaré's inequality

$$C_P\|\phi\|_0 \le \|\nabla\phi\|_0 \quad \forall\, \phi \in H^p(\Omega) \cap H^1_0(\Omega) \tag{2.1}$$

implies that the seminorm $|\phi|_1 = \|\nabla\phi\|_0$ is an equivalent norm on $H^1_0(\Omega)$. Vector analogues of the Sobolev spaces along with vector-valued functions are denoted by upper and lower case bold face font, respectively, e.g., $\mathbf{H}^1(\Omega)$, $\mathbf{L}^2(\Omega)$, and $\mathbf{u}$. For vectors in Euclidean spaces, we use vector notation, e.g., $\vec{\mathbf{x}}$ and $\vec{\mathbf{y}}$. Matrices are denoted by block letters, e.g., $\mathbb{A}$ and $\mathbb{B}$.

$\mathbf{V}^h$ and S^h will denote a pair of finite element subspaces of $\mathbf{H}^1_0(\Omega)$ and $L^2_0(\Omega)$, respectively. We assume that these spaces are defined with respect to the *same* regular triangulation $\mathcal{T}_h$ of the domain Ω into finite elements $\mathcal{K}$, where h denotes some measure of the grid size. For example, $\mathcal{K}$ can be hexahedrons or tetrahedrons in three dimensions or triangles or quadrilaterals in two dimensions. We will use C to denote a generic constant that is independent of h but whose value may change from place to place. Let $r > 0$ and $s > 0$ be two integers. It is further assumed that for every $\mathbf{u} \in \mathbf{H}^{r+1}(\Omega)$ and $p \in H^{s+1}(\Omega)$, there exist functions $\mathbf{u}^h_I \in \mathbf{V}^h$ and $p^h_I \in S^h$ such that

$$\|\mathbf{u} - \mathbf{u}^h_I\|_0 + h\|\mathbf{u} - \mathbf{u}^h_I\|_1 \le Ch^{r+1}\|\mathbf{u}\|_{r+1} \tag{2.2}$$

and

$$\|p - p^h_I\|_0 + h\|p - p^h_I\|_1 \le Ch^{s+1}\|p\|_{s+1}, \tag{2.3}$$

respectively. We recall the inverse inequalities

$$\|\mathbf{u}^h\|_1 \le C_I h^{-1}\|\mathbf{u}^h\|_0 \qquad \text{and} \qquad \|p^h\|_1 \le C_I h^{-1}\|p^h\|_0 \tag{2.4}$$

that hold for finite element spaces on regular triangulations; see [10] or [15].

2.1. Negative norm and inner product. Let $\mathbf{H}^{-1}(\Omega)$ denote the dual of $\mathbf{H}^1_0(\Omega)$. Using the equivalence of $|\cdot|_1$ and $\|\cdot\|_1$ on $\mathbf{H}^1_0(\Omega)$, we equip $\mathbf{H}^{-1}(\Omega)$ with the norm

$$\|\mathbf{f}\|_{-1} = \sup_{\boldsymbol{\phi}\in\mathbf{H}^1_0(\Omega)} \frac{(\mathbf{f}, \boldsymbol{\phi})_0}{|\boldsymbol{\phi}|_1} \quad \forall\, \mathbf{f} \in \mathbf{H}^{-1}(\Omega). \tag{2.5}$$

The following representation results hold (cf. [5, 6]).

LEMMA 2.1. *For all* $\mathbf{f} \in \mathbf{H}^{-1}(\Omega)$*, we have*

$$\|\mathbf{f}\|_{-1}^2 = (\mathbf{S}\mathbf{f}, \mathbf{f})_0,$$

where $\mathbf{S} : \mathbf{H}^{-1}(\Omega) \mapsto \mathbf{H}_0^1(\Omega)$ *is the solution operator for the vector Poisson equation*

$$-\triangle \mathbf{u} = \mathbf{f} \quad \textit{in } \Omega \qquad \textit{and} \qquad \mathbf{u} = 0 \quad \textit{on } \Gamma,$$

i.e., $\mathbf{u} = \mathbf{S}\mathbf{f}$ *if and only if*

$$(\nabla \mathbf{u}, \nabla \mathbf{v})_0 = (\mathbf{f}, \mathbf{v})_0 \quad \forall\, \mathbf{v} \in \mathbf{H}_0^1(\Omega).$$

If $(\cdot,\cdot)_{-1}$ *is the inner product associated with* $\|\cdot\|_{-1}$*, then*

$$(\mathbf{f}, \mathbf{g})_{-1} = (\mathbf{S}\mathbf{f}, \mathbf{g})_0 = (\mathbf{f}, \mathbf{S}\mathbf{g})_0 \quad \forall\, \mathbf{f}, \mathbf{g} \in \mathbf{H}^{-1}(\Omega). \tag{2.6}$$

Using (2.6), it is not difficult to show that

$$(-\triangle \mathbf{u}, \mathbf{v})_{-1} = (\mathbf{u}, \mathbf{v})_0 \quad \forall\, \mathbf{u} \in \mathbf{H}_0^1(\Omega),\ \mathbf{v} \in \mathbf{H}^{-1}(\Omega). \tag{2.7}$$

We also recall the well-known result (cf. [15, p. 20]) that for any connected Ω there exists a $C_N > 0$ such that

$$C_N \|p\|_0 \le \|\nabla p\|_{-1} \quad \forall\, p \in L_0^2(\Omega). \tag{2.8}$$

3. Stabilization of mixed methods for the Stokes problem. We consider the Stokes equations

$$\begin{aligned} -\triangle \mathbf{u} + \nabla p &= \mathbf{f} \quad \text{in } \Omega, \\ \nabla \cdot \mathbf{u} &= 0 \quad \text{in } \Omega, \\ \mathbf{u} &= \mathbf{0} \quad \text{on } \Gamma. \end{aligned} \tag{3.1}$$

A weak formulation of the Stokes problem is to seek $(\mathbf{u}, p) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ such that

$$A(\mathbf{u}, \mathbf{v}) + B(\mathbf{v}, p) = F(\mathbf{v}) \quad \forall\, \mathbf{v} \in \mathbf{H}_0^1(\Omega), \tag{3.2}$$

$$B(\mathbf{u}, q) = 0 \quad \forall\, q \in L_0^2(\Omega), \tag{3.3}$$

where $A(\cdot,\cdot)$, $B(\cdot,\cdot)$, and $F(\cdot)$ are defined by

$$A(\mathbf{u}, \mathbf{v}) = \int_\Omega \nabla \mathbf{u} : \nabla \mathbf{v}\, d\Omega, \quad B(\mathbf{v}, p) = -\int_\Omega p \nabla \cdot \mathbf{v}\, d\Omega, \quad \text{and} \quad F(\mathbf{v}) = \int_\Omega \mathbf{f} \cdot \mathbf{v}\, d\Omega,$$

respectively. We recall that (3.2)–(3.3) is the optimality system for the saddle-point $(\mathbf{u}, p)$ of the Lagrangian functional

$$L(\mathbf{v}, q) = \frac{1}{2} A(\mathbf{v}, \mathbf{v}) - F(\mathbf{v}) + B(\mathbf{v}, q). \tag{3.4}$$

Therefore, the pressure p is the Lagrange multiplier that is introduced into (3.4) to enforce the (weak) incompressibility constraint (3.3). The restriction of (3.2)–(3.3) to a pair of finite element subspaces $\mathbf{V}^h \subset \mathbf{H}_0^1(\Omega)$ and $S^h \subset L_0^2(\Omega)$ yields the *Galerkin mixed method*: seek $(\mathbf{u}^h, p^h) \in \mathbf{V}^h \times S^h$ such that

$$A(\mathbf{u}^h, \mathbf{v}^h) + B(\mathbf{v}^h, p^h) = F(\mathbf{v}^h) \quad \forall\, \mathbf{v}^h \in \mathbf{V}^h, \tag{3.5}$$

$$B(\mathbf{u}^h, q^h) = 0 \quad \forall\, q^h \in S^h. \tag{3.6}$$

For continuous pressure approximations and for velocity fields that vanish on the boundary, $B(\cdot,\cdot)$ can be replaced by the equivalent bilinear form

$$B^*(\mathbf{v}, p) = \int_\Omega \mathbf{v} \cdot \nabla p \, d\Omega.$$

It is easy to see that (3.5)–(3.6) is equivalent to the symmetric, indefinite linear algebraic system

$$\begin{pmatrix} \mathbb{A} & \mathbb{B}^T \\ \mathbb{B} & 0 \end{pmatrix} \begin{pmatrix} \vec{\mathbf{u}} \\ \vec{\mathbf{p}} \end{pmatrix} = \begin{pmatrix} \vec{\mathbf{f}} \\ \vec{\mathbf{0}} \end{pmatrix}, \tag{3.7}$$

where the elements of $\vec{\mathbf{u}}$ and $\vec{\mathbf{p}}$ are the coefficients in the representation in terms of bases of the finite element pair $(\mathbf{u}^h, p^h)$; the matrices $\mathbb{A}$ and $\mathbb{B}$ are deduced in the usual manner, using the bases for $\mathbf{V}^h$ and S^h, from the bilinear forms $A(\cdot,\cdot)$ and $B(\cdot,\cdot)$ (or $B^*(\cdot,\cdot)$), respectively.

The problems (3.5)–(3.6) and (3.7) are equivalent representations of the optimality system for the saddle-point $(\mathbf{u}^h, p^h)$ of (3.4) out of $\mathbf{V}^h \times S^h$; i.e., they represent a discrete saddle-point problem. As a result, they lead to stable and accurate approximations of $(\mathbf{u}, p)$ if and only if the pair $(\mathbf{V}^h, S^h)$ satisfies the following conditions: first, the inf-sup condition (see [7, 15, 16]) *there exists $C > 0$, independent of h, such that*

$$\sup_{\mathbf{v}^h \in \mathbf{V}^h} \frac{B(\mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_1} \geq C \|q^h\|_0 \quad \forall\, q^h \in S^h,$$

and second, $A(\cdot,\cdot)$ is coercive on $\mathbf{Z}^h \times \mathbf{Z}^h$, where $\mathbf{Z}^h = \{\mathbf{v}^h \in \mathbf{V}^h \mid B(q^h, \mathbf{v}^h) = 0 \; \forall\, q \in S^h\}$ is the subspace of discretely solenoidal functions belonging to $\mathbf{V}^h$. Examples of unstable pairs include all equal order interpolation spaces defined with respect to the same triangulation of Ω into finite elements, as well as such combinations as the bilinear-constant pair; see [15, 16].

3.1. Continuous stabilized prototypes. In the literature, the term *finite element stabilization* is commonly applied to describe the application of various regularization techniques either to (3.4) or directly to (3.5)–(3.6) in order to circumvent the inf-sup condition. Stabilization leads to finite element methods that allow for an unrestricted choice of velocity and pressure spaces, including the choice of equal order interpolation. *Consistent stabilization* is one of the most popular types of regularization because it avoids penalty errors and can, in principle, be extended to achieve an arbitrarily high order of accuracy. Typically, consistently stabilized methods are defined at the discrete level and employ mesh-dependent norms and inner products. In this section, we formulate continuous prototypes for these methods. The prototypes represent idealized variational problems that can be used to derive practical finite element schemes. The origin of the continuous prototypes can be best understood by considering first the regularization of (3.4) by penalty. The relevant penalized Lagrangian functional is

$$L(\mathbf{v}, q) = \frac{1}{2} A(\mathbf{v}, \mathbf{v}) - F(\mathbf{v}) + B(\mathbf{v}, q) - \delta \|q\|_0^2. \tag{3.8}$$

The optimality system for (3.8) is to seek $(\mathbf{u}, p) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ such that

$$A(\mathbf{u}, \mathbf{v}) + B(\mathbf{v}, p) = F(\mathbf{v}) \quad \forall\, \mathbf{v} \in \mathbf{H}_0^1(\Omega), \tag{3.9}$$

$$B(\mathbf{u}, q) - \delta M(p, q) = 0 \quad \forall\, q \in L_0^2(\Omega), \tag{3.10}$$

where $M(p, q) = (p, q)_0$. Thus, the effect emanating from the penalty term in (3.8) is to relax the constraint in (3.3). In terms of algebraic problems, this means that instead of the indefinite problem (3.7), now finite element discretization yields a linear system of the form

$$\begin{pmatrix} \mathbb{A} & \mathbb{B} \\ \mathbb{B}^T & -\delta\mathbb{M} \end{pmatrix} \begin{pmatrix} \vec{\mathbf{u}} \\ \vec{\mathbf{p}} \end{pmatrix} = \begin{pmatrix} \vec{\mathbf{f}} \\ \vec{\mathbf{0}} \end{pmatrix}, \tag{3.11}$$

having a "definite" coefficient matrix.[1] As a result, one can show that a finite element method based on (3.8) is stable for any conforming choice of $\mathbf{V}^h$ and S^h. The trouble with (3.8) is the penalty error that limits the order of approximation to $O(\sqrt{\delta})$, regardless of the interpolation order of the pair $(\mathbf{V}^h, S^h)$.

The idea of consistent stabilization is to modify (3.2) and (3.3) to a problem like (3.9) and (3.10) but without incurring a penalty error. This requires a term that will generate the desired stabilizing contribution but will vanish on all sufficiently smooth exact solutions. To construct such a term, note that thanks to (2.8)

$$C_P \|p\|_0 \le \|\nabla p\|_{-1} \le C \|p\|_0,$$

i.e., $\|\nabla p\|_{-1}$ is an equivalent norm on $L_0^2(\Omega)$. As a result, $\|\nabla p\|_{-1}^2$ will have the same stabilization effect as $\|p\|_0^2$. However, unlike the latter, $\|\nabla p\|_{-1}^2$ can be included via the residual of (3.1) and so, when added to (3.2)–(3.3), the term

$$\delta(-\triangle \mathbf{u} + \nabla p - \mathbf{f}, -\alpha \triangle \mathbf{v} + \nabla q)_{-1}$$

will generate the appropriate stabilizing contribution but without the penalty error. This leads to a family of *continuous stabilized prototypes*: seek $(\mathbf{u}^h, p^h) \in \mathbf{V}^h \times S^h$ such that

$$Q_\alpha^\beta(\mathbf{u}^h, p^h; \mathbf{v}^h, q^h) = F_\alpha^\beta(\mathbf{v}^h, q^h) \tag{3.12}$$

for all $(\mathbf{v}^h, q^h) \in \mathbf{V}^h \times S^h$, where

$$\begin{aligned} Q_\alpha^\beta(\mathbf{u}, p; \mathbf{v}, q) = {} & A(\mathbf{u}, \mathbf{v}) + B(\mathbf{v}, p) + \beta B(\mathbf{u}, q) \\ & -\delta(-\triangle \mathbf{u} + \nabla p, -\alpha \triangle \mathbf{v} + \beta \nabla q)_{-1} \end{aligned} \tag{3.13}$$

and

$$F_\alpha^\beta(\mathbf{v}, q) = F(\mathbf{v}) - \delta(\mathbf{f}, -\alpha \triangle \mathbf{v} + \beta \nabla q)_{-1} \tag{3.14}$$

[1] The matrix in (3.11) is definite in the sense that

$$\begin{pmatrix} \mathbb{A} & \mathbb{B} \\ -\mathbb{B}^T & +\delta\mathbb{M} \end{pmatrix},$$

which is obtained from the coefficient matrix in (3.11) by multiplying the lower block of equations by -1, is real, positive definite.

are a bilinear form $[\mathbf{H}_0^1(\Omega)\times L^2(\Omega)]^2 \mapsto \mathbb{R}$ and a linear functional $\mathbf{H}_0^1(\Omega)\times L^2(\Omega)\mapsto\mathbb{R}$ parametrized by α, β, and δ. In (3.13) and (3.14), α and β take on the values $\{-1,0,1\}$ and $\{-1,1\}$, respectively, and δ is a positive, real valued parameter. A method is called *absolutely stable* if the form Q_β^α is weakly or strongly coercive for all values of δ. If this is true only for selected values of δ, the method is called *conditionally stable*. In what follows, we will work exclusively with continuous pressure approximations, in which case we can write

$$\begin{aligned} Q_\alpha^\beta(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h) \equiv{}& A(\mathbf{u}^h,\mathbf{v}^h)+B^*(\mathbf{v}^h,p^h)+\beta B^*(\mathbf{u}^h,q^h)\\ &-\delta(-\triangle\mathbf{u}^h+\nabla p^h,-\alpha\triangle\mathbf{v}^h+\beta\nabla q^h)_{-1}. \end{aligned} \tag{3.15}$$

We call (3.12) *prototypes* because the $\mathbf{H}^{-1}(\Omega)$ inner product is not computable so that (3.13) or (3.15) and (3.14) cannot be used directly in a finite element method. However, if the $\mathbf{H}^{-1}(\Omega)$ inner product appearing in (3.13) or (3.15) and (3.14) is replaced by a discrete approximation, each prototype will give rise to a practical method. All methods that can be associated with a particular prototype by virtue of such a substitution form the stabilized class generated by this prototype.

Remark 3.1. While the stabilized problem (3.12) is a modification of an equation that represents an optimality system, it is not necessarily itself an optimality system of some modified Lagrangian. Many of the methods defined by (3.12) can only be derived as modifications of (3.5) and (3.6); i.e., they cannot be formulated starting from a modification of (3.4) and then deriving the associated optimality system.

Remark 3.2. If $\mathbf{u}$ is approximated by piecewise linear or bilinear finite element functions, the second order derivative terms in (3.13) vanish and the prototypes (3.12) reduce to a penalized formulation in which the Lagrangian functional (3.4) is penalized by $-\delta\|\nabla q\|_{-1}^2$.

Introducing the bilinear forms

$$D(\mathbf{u},\mathbf{v})=\delta(-\triangle\mathbf{u},-\triangle\mathbf{v})_{-1},\qquad C(\mathbf{v},q)=\delta(\triangle\mathbf{v},\nabla q)_{-1},$$

and

$$K(p,q)=\delta(\nabla p,\nabla q)_{-1}$$

defined on $\mathbf{H}_0^1(\Omega)\times\mathbf{H}_0^1(\Omega)$, $\mathbf{H}_0^1(\Omega)\times L^2(\Omega)$, and $L^2(\Omega)\times L^2(\Omega)$, respectively, we can write (3.15) in the form

$$\begin{aligned} Q_\alpha^\beta(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h) = {}& A(\mathbf{u}^h,\mathbf{v}^h)+B^*(\mathbf{v}^h,p^h)+\beta B^*(\mathbf{u}^h,q^h)\\ &-\alpha D(\mathbf{u}^h,\mathbf{v}^h)+\alpha C(\mathbf{v}^h,p^h)+\beta C(\mathbf{u}^h,q^h)-\beta K(p^h,q^h). \end{aligned}$$

It is then easy to see that the discrete system (3.12) is equivalent to a family of linear algebraic systems of the form

$$\begin{pmatrix} \mathbb{A}-\alpha\mathbb{D} & \mathbb{B}+\alpha\mathbb{C}\\ \beta(\mathbb{B}+\mathbb{C})^T & -\beta\mathbb{K}\end{pmatrix}\begin{pmatrix}\vec{\mathbf{u}}\\ \vec{\mathbf{p}}\end{pmatrix}=\begin{pmatrix}\vec{\mathbf{f}}_1\\ \vec{\mathbf{f}}_2\end{pmatrix}, \tag{3.16}$$

where the matrices $\mathbb{C}$, $\mathbb{D}$, and $\mathbb{K}$ are respectively deduced in the usual manner from the bilinear forms $C(\cdot,\cdot)$, $D(\cdot,\cdot)$, and $K(\cdot,\cdot)$.

Choosing different α and β gives rise to different bilinear forms in (3.13) and to different matrices in (3.16). It is easy to see that the choices $\{\alpha,\beta\}$ and $\{\alpha,-\beta\}$ define variational problems that can be derived from one another by simply changing

the pressure test function in (3.12) from q^h to $-q^h$. Likewise, the linear system (3.16) generated by the choice $\{\alpha, -\beta\}$ can be derived from that for the choice $\{\alpha, \beta\}$ by simply scaling the second row of blocks by -1. Therefore, the linear systems produced by the two choices $\{\alpha, \beta\}$ and $\{\alpha, -\beta\}$ are equivalent in the sense that they have exactly the same solution. [2] We will call these variational problems, along with their associated bilinear forms and linear algebraic systems, *complementary*. The choice of α determines the class of complementary forms while the two forms within each class are generated by selecting β equal to either 1 or -1.

For consistency with the established terminology, we call the prototype corresponding to $\alpha = 1$ *Galerkin least-squares*, or GLS. Since taking $\alpha = 0$ "simplifies" the weighting function, we call this class of methods *simplified Galerkin least-squares*, or SGLS. Finally, choosing $\alpha = -1$ "reflects" the sign of the second order term and so we refer to this prototype as *reflected Galerkin least-squares*, or RGLS.

The *standard members of the GLS, SGLS, and RGLS classes of methods* are obtained when the $\mathbf{H}^{-1}(\Omega)$ inner product appearing in (3.15) and (3.14) is approximated by a weighted $\mathbf{L}^2$ inner product in the following manner:

$$
\begin{aligned}
Q^{\beta}_{\alpha,h}(\mathbf{u}^h, p^h; \mathbf{v}^h, q^h) &= A(\mathbf{u}^h, \mathbf{v}^h) + B^*(\mathbf{v}^h, p^h) + \beta B^*(\mathbf{u}^h, q^h) \\
&\quad - \sum_{\mathcal{K}\in\mathcal{T}_h} \delta h^2_{\mathcal{K}} (-\triangle \mathbf{u}^h + \nabla p^h, -\alpha \triangle \mathbf{v}^h + \beta \nabla q^h)_{0,\mathcal{K}}
\end{aligned} \tag{3.17}
$$

and

$$
F^{\beta}_{\alpha,h}(\mathbf{v}^h, q^h) = F(\mathbf{v}^h) - \sum_{\mathcal{K}\in\mathcal{T}_h} \delta h^2_{\mathcal{K}} (\mathbf{f}, -\alpha \triangle \mathbf{v}^h + \beta \nabla q^h)_{0,\mathcal{K}}, \tag{3.18}
$$

respectively. When $\alpha = 1$ and $\beta = 1$, we recover from (3.17) and (3.18) the original GLS method of [17]. For $\alpha = 0$ and $\beta = -1$, they give the original pressure-Poisson stabilized mixed method of [18]. The case $\alpha = -1$ and $\beta = 1$ gives the method of [11].

The weighted L^2 norm is not a particularly accurate approximation of the negative norm. Its main defect is that

$$
C_1(h\|\mathbf{u}^h\|_0) \le \|\mathbf{u}^h\|_{-1} \le C_2 h^{-1}(h\|\mathbf{u}^h\|_0).
$$

This equivalence relation, including the factor h^{-1} in the upper bound, is sharp, and means that (3.17) is stable with respect to a mesh-dependent norm that is not uniformly (in h) equivalent to the norm on $\mathbf{H}^1(\Omega) \times L^2(\Omega)$. A more sophisticated but also more complicated approximation is to use a discrete equivalent proposed in [6] in the context of least-squares finite element methods. For stabilized methods based on this norm, we refer to [9].

Analyses of the standard GLS and RGLS methods in [17] and [11], respectively, classify the first one as a conditionally stable scheme and the second one as an absolutely stable scheme. This means that for $\alpha = 1$, the choice of δ in (3.17) and (3.18) is restricted to some finite interval $0 < \delta_0 \le \delta \le \delta_{\max}$, while for $\alpha = -1$, the form in (3.17) is stable for any positive δ. In both cases, theoretical classifications agree well with the practical stability of the respective finite element methods; see [13] and

[2] Although the choices $\{\alpha, \beta\}$ and $\{\alpha, -\beta\}$ yield the same solution, the algebraic properties of the corresponding coefficient matrices can be vastly different. As a result, the performance of iterative solution techniques can also be vastly different; cf. [2].

[2]. However, this is not so for the standard SGLS method. The formal analysis of [8] classified this method as conditionally stable, with a stability range estimate very close to that of the standard GLS method. In practice, after extensive numerical experiments, we found that the standard SGLS behaves much more like the absolutely stabilized RGLS method; see [2]. This unexpected practical stability prompted us to reexamine the SGLS class starting from its continuous prototype. Thus, for the remainder of this paper, our focus will be on SGLS methods.

4. Continuous SGLS. In this section, we show that the continuous SGLS prototype

$$Q_0^{\pm}(\mathbf{u},p;\mathbf{v},q) = A(\mathbf{u},\mathbf{v}) + B^*(\mathbf{v},p) \pm B^*(\mathbf{u},q) - \delta(-\triangle\mathbf{u} + \nabla p, \pm\nabla q)_{-1}$$

is absolutely stable.

THEOREM 4.1. *Let $\mathbf{V}^h \subset \mathbf{H}_0^1(\Omega)$ and $S^h \subset L_0^2(\Omega) \cap H^1(\Omega)$. Then $Q_0^-(\cdot;\cdot)$ is coercive for $0 < \delta < 4$ and $Q_0^{\pm}(\cdot;\cdot)$ are weakly coercive for any $\delta \geq 4$; i.e., there exists $C > 0$, independent of h, such that*

$$Q_0^-(\mathbf{u}^h,p^h;\mathbf{u}^h,p^h) \geq C\left(\|\mathbf{u}^h\|_1^2 + \|p^h\|_0^2\right) \quad \forall\, 0 < \delta < 4$$

and

$$\left.\begin{aligned} \sup_{(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h} \frac{Q_0^{\pm}(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h)}{\|\mathbf{u}^h\|_1 + \|p^h\|_0} &\geq C(\|\mathbf{u}^h\|_1 + \|p^h\|_0) \\ \sup_{(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h} \frac{Q_0^{\pm}(\mathbf{v}^h,q^h;\mathbf{u}^h,p^h)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0} &> 0 \end{aligned}\right\} \quad \forall \delta \geq 4$$

for any $(\mathbf{u}^h,p^h) \in \mathbf{V}^h \times S^h$.

Proof. Since complementary forms can be obtained from one another by changing the sign of the pressure test functions, it suffices to carry out the proofs for only one of the forms. Here, we choose to work with the minus form Q_0^-. Using (2.7), the stabilizing term in Q_0^- simplifies to

$$\delta(-\triangle\mathbf{u}^h + \nabla p^h, \nabla q^h)_{-1} = \delta((\mathbf{u}^h, \nabla q^h)_0 + (\nabla p^h, \nabla q^h)_{-1}).$$

As a result,

$$Q_0^-(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h) = A(\mathbf{u}^h,\mathbf{v}^h) + (\nabla p^h,\mathbf{v}^h)_0 + (\delta-1)(\nabla q^h,\mathbf{u}^h)_0 + \delta(\nabla p^h,\nabla q^h)_{-1}.$$

To prove strong the coercivity result, let δ be a number between 0 and 4 and consider $Q_0^-(\mathbf{u}^h,p^h;\mathbf{u}^h,p^h)$. Using Cauchy's inequality and the ϵ inequality,

$$\begin{aligned} Q_0^-(\mathbf{u}^h,p^h;\mathbf{u}^h,p^h) &= A(\mathbf{u}^h,\mathbf{u}^h) + \delta(\nabla p^h,\mathbf{u}^h)_0 + \delta(\nabla p^h,\nabla p^h)_{-1} \\ &\geq |\mathbf{u}^h|_1^2 + \delta\|\nabla p^h\|_{-1}^2 - \delta\|\nabla p^h\|_{-1}|\mathbf{u}^h|_1 \\ &\geq \left(1 - \frac{\delta}{2\epsilon}\right)|\mathbf{u}^h|_1^2 + \delta\left(1 - \frac{\epsilon}{2}\right)\|\nabla p^h\|_{-1}^2. \end{aligned}$$

To ensure coercivity, both coefficients above must be positive. Therefore, δ and ϵ must satisfy the inequalities

$$0 < \delta < 2\epsilon \quad \text{and} \quad \epsilon < 2.$$

This is always possible when $0 < \delta < 4$. Since $p^h \in L_0^2(\Omega)$ and $\mathbf{u}^h \in \mathbf{H}_0^1(\Omega)$, the final bound

$$Q_0^-(\mathbf{u}^h, p^h; \mathbf{u}^h, p^h) \geq C(\delta, C_P, C_N)\left(\|\mathbf{u}^h\|_1^2 + \|p\|_0^2\right)$$

follows from (2.8) and (2.1).

To show that Q_0^- is weakly coercive for $\delta \geq 4$, let $(\widetilde{\mathbf{v}}^h, \widetilde{q}^h) = (\mathbf{u}^h, \gamma p^h)$ for some positive γ. Then

$$Q_0^-(\mathbf{u}^h, p^h; \widetilde{\mathbf{v}}^h, \widetilde{q}^h) = |\mathbf{u}^h|_1^2 + \gamma\delta\|\nabla p^h\|_{-1}^2 + (1 + \gamma(\delta - 1))(\nabla p^h, \mathbf{u}^h)_0.$$

Letting $\gamma = 1/(\delta - 1)$, the Cauchy and ϵ inequalities further give

$$\begin{aligned} Q_0^-(\mathbf{u}^h, p^h; \widetilde{\mathbf{v}}^h, \widetilde{q}^h) &\geq |\mathbf{u}^h|_1^2 + \frac{\delta}{\delta - 1}\|\nabla p^h\|_{-1}^2 - 2\|\nabla p^h\|_{-1}|\mathbf{u}^h|_1 \\ &\geq (1 - \epsilon)|\mathbf{u}^h|_1^2 + \left(\frac{\delta}{\delta - 1} - \frac{1}{\epsilon}\right)\|\nabla p^h\|_{-1}^2. \end{aligned}$$

Since $\delta \geq 4$, we can always choose a positive ϵ such that

$$\frac{\delta - 1}{\delta} < \epsilon < 1.$$

This makes both coefficients in the lower bound positive and we can conclude that there exists $C(\delta, C_P, C_N)$, independent of h, such that

$$Q_0^-(\mathbf{u}^h, p^h; \widetilde{\mathbf{v}}^h, \widetilde{q}^h) \geq C(\delta, C_P, C_N)\left(\|\mathbf{u}^h\|_1^2 + \|p^h\|_0^2\right).$$

To complete the proof of the first weak coercivity condition, we note that $\|\widetilde{\mathbf{v}}^h\|_1 + \|\widetilde{q}^h\|_0 = \|\mathbf{u}^h\|_1 + \frac{1}{\delta - 1}\|p^h\|_0$ so that the last inequality can be recast into

$$Q_0^-(\mathbf{u}^h, p^h; \widetilde{\mathbf{v}}^h, \widetilde{q}^h) \geq C(\delta, C_P, C_N)\left(\|\mathbf{u}^h\|_1 + \|p^h\|_0\right)\left(\|\widetilde{\mathbf{v}}^h\|_1 + \|\widetilde{q}^h\|_0\right).$$

To prove the second weak coercivity condition, we choose $\mathbf{v}^h = -\mathbf{S}(\nabla p^h)$ and $q^h \equiv p^h$. Using Lemma 2.1

$$A(-\mathbf{S}(\nabla p^h), \mathbf{u}^h) = -(\nabla p^h, \mathbf{u}^h) \qquad \text{and} \qquad -\triangle(-\mathbf{S}(\nabla p^h)) = -\nabla p^h.$$

It is now easy to see that

$$Q_0^-(-\mathbf{S}(\nabla p^h), p^h; \mathbf{u}^h, p^h) = (\mathbf{S}(\nabla p^h), \nabla p^h)_0 = \|\nabla p^h\|_{-1}^2 > 0,$$

where the last identity follows again from Lemma 2.1. ∎

It is a straightforward matter to demonstrate that $Q_0^{\pm}$ is continuous. Then standard finite element arguments can be used to show that the method is optimally accurate.

THEOREM 4.2. *Let* $(\mathbf{u}, p) \in \mathbf{H}_0^1(\Omega) \cap \mathbf{H}^{r+1}(\Omega) \times L_0^2(\Omega) \cap H^{s+1}(\Omega)$ *denote a solution of the Stokes problem and let* $(\mathbf{u}^h, p^h)$ *solve* (3.12) *for* $\alpha = 0$. *Then there exists a constant* $C > 0$ *independent of* h *such that*

$$\|\mathbf{u} - \mathbf{u}^h\|_1 + \|p - p^h\|_0 \leq C(h^r\|\mathbf{u}\|_{r+1} + h^{s+1}\|p\|_{s+1}).$$

We note for future reference that the stability and error estimates of the SGLS prototype are given in terms of the natural mesh-independent norm of $\mathbf{H}^1(\Omega) \times L^2(\Omega)$.

5. Discrete SGLS. While the continuous SGLS prototype is not a practical method, its analysis hints at a possibility that members of the SGLS family of methods may have far better stability properties than previously thought. In this section we will define a new member of this family that not only is practical but also inherits the absolute stability of its continuous prototype in terms of the same mesh-independent norms. In addition, the new method is also optimally accurate and converges at the same rate as the continuous prototype. To formulate and analyze the new method, we will make use of several discrete operators along with their relevant properties. These are reviewed next.

5.1. Discrete operators. Given a finite element subspace $\mathbf{V}^h \subset \mathbf{H}_0^1(\Omega)$, we define the *discrete Laplace operator* $-\triangle^h$ as the mapping $-\triangle^h : \mathbf{H}_0^1(\Omega) \mapsto \mathbf{V}^h$ such that $-\triangle^h \mathbf{u} = \mathbf{z}^h$ if and only if

$$(\mathbf{z}^h, \mathbf{v}^h)_0 = (\nabla \mathbf{u}, \nabla \mathbf{v}^h)_0 \quad \forall\, \mathbf{v}^h \in \mathbf{V}^h. \tag{5.1}$$

The *discrete inverse Laplace operator* $\mathbf{S}^h$ is the mapping $\mathbf{S}^h : \mathbf{H}^{-1}(\Omega) \mapsto \mathbf{V}^h$ such that $\mathbf{S}^h \mathbf{u} = \mathbf{z}^h$ if and only if

$$(\nabla \mathbf{z}^h, \nabla \mathbf{v}^h)_0 = (\mathbf{u}, \mathbf{v}^h)_0 \quad \forall\, \mathbf{v}^h \in \mathbf{V}^h. \tag{5.2}$$

The last operator that we will need is the L^2 *projection operator onto* $\mathbf{V}^h$. This operator is the mapping $\mathbf{Q}^h : \mathbf{L}^2(\Omega) \mapsto \mathbf{V}^h$ such that $\mathbf{Q}^h \mathbf{u} = \mathbf{z}^h$ if and only if

$$(\mathbf{z}^h, \mathbf{v}^h)_0 = (\mathbf{u}, \mathbf{v}^h)_0 \quad \forall\, \mathbf{v}^h \in \mathbf{V}^h. \tag{5.3}$$

If the supremum in (2.5) is restricted to the subspace $\mathbf{V}^h \subset \mathbf{H}_0^1(\Omega)$, we obtain the *discrete negative seminorm*

$$\|\mathbf{f}\|_{-h} = \sup_{\boldsymbol{\phi}^h \in \mathbf{V}^h} \frac{(\mathbf{f}, \boldsymbol{\phi}^h)_0}{|\boldsymbol{\phi}^h|_1} \quad \forall\, \mathbf{f} \in \mathbf{H}^{-1}(\Omega). \tag{5.4}$$

The next theorem summarizes the properties of the discrete operators and norms that are relevant to our analysis; for part 3, note that

$$\|(\mathbf{I} - \mathbf{Q}^h)\mathbf{u}\|_{-k} = \sup_{\boldsymbol{\phi} \in \mathbf{H}_0^k(\Omega)} \frac{((\mathbf{I} - \mathbf{Q}^h)\mathbf{u}, \boldsymbol{\phi})_0}{\|\boldsymbol{\phi}\|_k},$$

where $\mathbf{H}_0^k(\Omega) \equiv \mathbf{H}^k(\Omega) \cap \mathbf{H}_0^1(\Omega)$.

THEOREM 5.1. 1. *For any* $\mathbf{f}, \mathbf{g} \in \mathbf{H}^{-1}(\Omega)$, *define* $(\mathbf{f}, \mathbf{g})_{-h} = (\mathbf{S}^h \mathbf{f}, \mathbf{g})_0 = (\mathbf{f}, \mathbf{S}^h \mathbf{g})_0$. *Then*

$$\|\mathbf{f}\|_{-h}^2 = (\mathbf{f}, \mathbf{f})_{-h}. \tag{5.5}$$

2. *For any* $\mathbf{u} \in \mathbf{L}^2(\Omega)$

$$\|\mathbf{Q}^h \mathbf{u}\|_0 \le C_I h^{-1} \|\mathbf{u}\|_{-h}, \tag{5.6}$$

$$\|\mathbf{u}\|_{-1}^2 \le C \left(h^2 \|\mathbf{u}\|_0^2 + \|\mathbf{u}\|_{-h}^2 \right), \tag{5.7}$$

$$-\triangle^h \cdot \mathbf{S}^h \mathbf{u} = \mathbf{Q}^h \mathbf{u}. \tag{5.8}$$

3. *For any* $\mathbf{u} \in \mathbf{L}^2(\Omega)$ *and* $0 < k \leq r+1$

$$\|(\mathbf{I}-\mathbf{Q}^h)\mathbf{u}\|_{-k} \leq Ch^k\|\mathbf{u}\|_0. \tag{5.9}$$

Proof. For the proof of the characterization (5.5) and the lower equivalence bound (5.7), we refer to [5] or [6]. Here, we will only demonstrate the proofs for the inverse inequality (5.6), the identity (5.8), and the duality estimate (5.9).

Let $\mathbf{u} \in \mathbf{L}^2(\Omega)$. Using the definition (5.3) of $\mathbf{Q}^h$ in (5.4),

$$\|\mathbf{u}\|_{-h} = \sup_{\boldsymbol{\phi}^h \in \mathbf{V}^h} \frac{(\mathbf{u},\boldsymbol{\phi}^h)_0}{|\boldsymbol{\phi}^h|_1} = \sup_{\boldsymbol{\phi}^h \in \mathbf{V}^h} \frac{(\mathbf{Q}^h\mathbf{u},\boldsymbol{\phi}^h)_0}{|\boldsymbol{\phi}^h|_1} \geq \frac{(\mathbf{Q}^h\mathbf{u},\mathbf{Q}^h\mathbf{u})_0}{|\mathbf{Q}^h\mathbf{u}|_1}.$$

Using the first inequality in (2.4) for $\mathbf{Q}^h\mathbf{u}$ gives that

$$|\mathbf{Q}^h\mathbf{u}|_1 \leq C_I h^{-1}\|\mathbf{Q}^h\mathbf{u}\|_0.$$

As a result,

$$\|\mathbf{u}\|_{-h} \geq \frac{\|\mathbf{Q}^h\mathbf{u}\|_0^2}{|\mathbf{Q}^h\mathbf{u}|_1} \geq \frac{h\|\mathbf{Q}^h\mathbf{u}\|_0^2}{C_I\|\mathbf{Q}^h\mathbf{u}\|_0} = hC_I^{-1}\|\mathbf{Q}^h\mathbf{u}\|_0,$$

which proves (5.6). A straightforward application of (5.1)–(5.3) shows that

$$(-\triangle^h \mathbf{S}^h\mathbf{u},\mathbf{v}^h) = (\nabla(\mathbf{S}^h\mathbf{u}),\nabla\mathbf{v}^h) = (\mathbf{u},\mathbf{v}^h),$$

which proves (5.8). To prove (5.9), we use the definition (5.3) of $\mathbf{Q}^h$ and Cauchy's inequality to show that

$$((\mathbf{I}-\mathbf{Q}^h)\mathbf{u},\boldsymbol{\phi})_0 = (\mathbf{u},(\mathbf{I}-\mathbf{Q}^h)\boldsymbol{\phi})_0 \leq \|\mathbf{u}\|_0\|(\mathbf{I}-\mathbf{Q}^h)\boldsymbol{\phi}\|_0$$

and then use (2.2) to obtain

$$\|(\mathbf{I}-\mathbf{Q}^h)\boldsymbol{\phi}\|_0 \leq Ch^k\|\boldsymbol{\phi}\|_k.$$

Combining these bounds shows that

$$\|(\mathbf{I}-\mathbf{Q}^h)\mathbf{u}\|_{-k} \leq \sup_{\boldsymbol{\phi}\in\mathbf{H}_0^k(\Omega)} \frac{h^k C\|\mathbf{u}\|_0\|\boldsymbol{\phi}\|_k}{\|\boldsymbol{\phi}\|_k} = Ch^k\|\mathbf{u}\|_0. \qquad \square$$

5.2. An absolutely stable discrete SGLS method. We introduce the bilinear form

$$\begin{aligned} Q_{0,h}^{\pm}(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h) = {} & A(\mathbf{u}^h,\mathbf{v}^h) + B^*(\mathbf{v}^h,p^h) \pm B^*(\mathbf{u}^h,q^h) \\ & -\delta h^2(-\triangle^h\mathbf{u}^h + \nabla p^h, \pm\nabla q^h)_0 \end{aligned} \tag{5.10}$$

and the linear functional

$$F_{0,h}^{\pm}(\mathbf{v}^h,q^h) = F(\mathbf{v}^h) - \delta h^2(\mathbf{f},\pm\nabla q^h)_0.$$

The new member of the SGLS family of methods is to seek $(\mathbf{u}^h,p^h) \in \mathbf{V}^h \times S^h$ such that

$$Q_{0,h}^{\pm}(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h) = F_{0,h}^{\pm}(\mathbf{v}^h,q^h) \quad \forall\,(\mathbf{v}^h,q^h) \in \mathbf{V}^h \times S^h. \tag{5.11}$$

Before we continue with the stability and error analysis of the new method, let us point out that thanks to definition (5.1)

$$A(\mathbf{u}^h, \mathbf{v}^h) \equiv (\nabla \mathbf{u}^h, \nabla \mathbf{v}^h)_0 = (-\triangle^h \mathbf{u}^h, \mathbf{v}^h)_0.$$

As a result,

$$\begin{aligned} Q^{\pm}_{0,h}(\mathbf{u}^h, p^h; \mathbf{v}^h, q^h) &= (-\triangle^h \mathbf{u}^h + \nabla p^h, \mathbf{v}^h)_0 \pm B^*(\mathbf{u}^h, q^h) \\ &\quad -\delta h^2 \left(-\triangle^h \mathbf{u}^h + \nabla p^h, \pm \nabla q^h\right)_0 \\ &= \left(-\triangle^h \mathbf{u}^h + \nabla p^h, \mathbf{v}^h \mp \delta h^2 \nabla q^h\right)_0 \pm B^*(\mathbf{u}^h, q^h) \end{aligned} \tag{5.12}$$

is an equivalent representation of (5.10) and

$$(-\triangle^h \mathbf{u}^h + \nabla p^h, \mathbf{v}^h \mp \delta h^2 \nabla q^h)_0 \pm B^*(\mathbf{u}^h, q^h) = (\mathbf{f}, \mathbf{v}^h \mp \delta h^2 \nabla q^h)_0 \tag{5.13}$$

is an equivalent form of (5.11). Problem (5.13) leads to an interesting interpretation for the new method: it can be viewed as a Petrov–Galerkin-like scheme obtained by modification of the velocity weight function to $\mathbf{v}^h \mp \delta h^2 \nabla q^h$.

Because we have replaced $-\triangle \mathbf{u}^h$ with $-\triangle^h \mathbf{u}^h$ in the definition of the method, the term

$$(-\triangle^h \mathbf{u} + \nabla p - \mathbf{f}, \mp \delta h^2 \nabla q^h)_0 \neq 0;$$

i.e., the new method, is not, strictly speaking, a consistent formulation. However, as we will see in the next lemma, the inconsistency is very weak. In particular, we will prove that it does not degrade the optimal convergence rate of the method.

LEMMA 5.2. *Let* $(\mathbf{u}, p) \in \mathbf{H}^1_0(\Omega) \cap \mathbf{H}^{r+1}(\Omega) \times L^2_0(\Omega) \cap H^{s+1}(\Omega)$ *denote a solution of the Stokes problem and let* $(\mathbf{u}^h, p^h)$ *be a solution of* (5.11). *Then*

$$\begin{aligned} Q^{\pm}_{0,h}(\mathbf{u} - \mathbf{u}^h, p - p^h; \mathbf{v}^h, q^h) &= \delta h^2 (-\triangle \mathbf{u}, (\mathbf{Q}^h - \mathbf{I}) \nabla q^h)_0 \\ &\leq \delta C h^r \|\mathbf{u}\|_{r+1} \|q^h\|_0 \end{aligned} \tag{5.14}$$

for all $(\mathbf{v}^h, q^h) \in \mathbf{V}^h \times S^h$.

Proof. Consider the minus form. It is easy to see that

$$\begin{aligned} Q^{-}_{0,h}(\mathbf{u} - \mathbf{u}^h, p - p^h; \mathbf{v}^h, q^h) &= \delta h^2 (-\triangle^h \mathbf{u} + \nabla p - \mathbf{f}, \nabla q^h)_0 \\ &= \delta h^2 (-(\triangle^h - \triangle) \mathbf{u}, \nabla q^h)_0. \end{aligned}$$

From the fact that $-\triangle^h \mathbf{u} \in \mathbf{V}^h$, the definition (5.3) of the L^2 projection, and the definition (5.1) of $-\triangle^h$, it follows that

$$(-\triangle^h \mathbf{u}, \nabla q^h)_0 = (-\triangle^h \mathbf{u}, \mathbf{Q}^h \nabla q^h)_0 = (\nabla \mathbf{u}, \nabla \mathbf{Q}^h \nabla q^h)_0 = (-\triangle \mathbf{u}, \mathbf{Q}^h \nabla q^h)_0$$

and so

$$(-(\triangle^h - \triangle) \mathbf{u}, \nabla q^h)_0 = (-\triangle \mathbf{u}, (\mathbf{Q}^h - \mathbf{I}) \nabla q^h)_0$$

so that the equality in (5.14) is proved. Next, with the help of (5.9) and the inverse inequality (2.4), we have

$$\begin{aligned} (-\triangle \mathbf{u}, (\mathbf{Q}^h - \mathbf{I}) \nabla q^h)_0 &\leq \|\triangle \mathbf{u}\|_{r-1} \, \|(\mathbf{Q}^h - \mathbf{I}) \nabla q^h\|_{1-r} \\ &\leq C h^{r-1} \|\mathbf{u}\|_{r+1} \|\nabla q^h\|_0 \\ &\leq C h^{r-2} \|\mathbf{u}\|_{r+1} \|q^h\|_0, \end{aligned}$$

from which the inequality in (5.14) follows. ∎

5.3. Stability and convergence. The main results of this section are to show that the method (5.11) is absolutely stable and that finite element solutions of (5.11) converge at optimal rates. We begin by establishing the absolute stability of the method, i.e., that the bilinear form (5.10) is weakly coercive for all values of the parameter δ. The proof relies upon a technical result presented in the next lemma.

LEMMA 5.3. *For any* $q^h \in S^h$

$$\|\nabla q^h\|_{-1}^2 \le C\left(h^2\|(\mathbf{I}-\mathbf{Q}^h)\nabla q^h\|_0^2 + \|\nabla q^h\|_{-h}^2\right). \tag{5.15}$$

Proof. Since we restrict attention to continuous pressure approximations, $\nabla q^h \in L^2(\Omega)$. Therefore, (5.7) from Theorem 5.1 implies that

$$\|\nabla q^h\|_{-1}^2 \le C\left(h^2\|\nabla q^h\|_0^2 + \|\nabla q^h\|_{-h}^2\right).$$

Adding and subtracting $\mathbf{Q}^h\nabla q^h$ to the first term and using the triangle inequality give the upper bound

$$\|\nabla q^h\|_{-1}^2 \le C\left(h^2\|(\mathbf{I}-\mathbf{Q}^h)\nabla q^h\|_0^2 + h^2\|\mathbf{Q}^h\nabla q^h\|_0^2 + \|\nabla q^h\|_{-h}^2\right).$$

The lemma follows by using the inverse inequality (5.6) to bound $h^2\|\mathbf{Q}^h\nabla q^h\|_0^2$ by $C_I\|\nabla q^h\|_{-h}^2$. ∎

THEOREM 5.4. *Assume that* $\mathbf{V}^h \subset \mathbf{H}_0^1(\Omega)$ *and* $S^h \subset L_0^2(\Omega)\cap H^1(\Omega)$. *Then, for any* $\delta > 0$, *there exists a positive constant* $C(\delta)$, *independent of* h, *such that*

$$\begin{aligned}
&\sup_{(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h} \frac{Q_{0,h}^{\pm}(\mathbf{u}^h,p^h;\mathbf{v}^h,q^h)}{\|\mathbf{v}^h\|_1+\|q^h\|_0} \ge C(\delta)(\|\mathbf{u}^h\|_1+\|p^h\|_0),\\
&\sup_{(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h} \frac{Q_{0,h}^{\pm}(\mathbf{v}^h,q^h;\mathbf{u}^h,p^h)}{\|\mathbf{v}^h\|_1+\|q^h\|_0} > 0
\end{aligned} \tag{5.16}$$

for all $(\mathbf{u}^h,p^h)\in\mathbf{V}^h\times S^h$.

Proof. We recall that the complementary plus and minus forms define equivalent problems, and so it suffices to carry the proof for just one of the forms. Here, we choose again to work with the minus form. Given a positive δ, we will construct a test function $(\widetilde{\mathbf{v}}^h,\widetilde{q}^h)$ such that

$$Q_{0,h}^{-}(\mathbf{u}^h,p^h;\widetilde{\mathbf{v}}^h,\widetilde{q}^h) \ge C(\|\mathbf{u}^h\|_1+\|p^h\|_0)\left(\|\widetilde{\mathbf{v}}^h\|_1+\|\widetilde{q}^h\|_0\right).$$

To find such a function, note that definition (5.2) implies the identity

$$(\nabla\mathbf{u}^h,\nabla\mathbf{S}^h(\nabla q^h))_0 = (\mathbf{u}^h,\nabla q^h)_0.$$

Thus, if $q^h\in S^h$ is arbitrary and $\mathbf{v}_1^h = \mathbf{S}^h(\nabla q^h)$,

$$Q_{0,h}^{-}(\mathbf{u}^h,p^h;\mathbf{v}_1^h,q^h) = (\nabla p^h,\mathbf{S}^h\nabla q^h)_0 + \delta h^2(-\triangle^h\mathbf{u}^h+\nabla p^h,\nabla q^h)_0.$$

Adding and subtracting $\mathbf{Q}^h\nabla p^h$ from the last term give

$$\begin{aligned}
Q_{0,h}^{-}(\mathbf{u}^h,p^h;\mathbf{v}_1^h,q^h) = (\nabla p^h,\mathbf{S}^h\nabla q^h)_0 &+ \delta h^2((\mathbf{I}-\mathbf{Q}^h)\nabla p^h,\nabla q^h)_0\\
&+\delta h^2(-\triangle^h\mathbf{u}^h+\mathbf{Q}^h\nabla p^h,\nabla q^h)_0
\end{aligned}$$

while the orthogonality

$$((\mathbf{I}-\mathbf{Q}^h)\nabla p^h,\mathbf{Q}^h\nabla q^h) = 0$$

and the fact that $-\triangle^h \mathbf{u}^h + \mathbf{Q}^h \nabla p^h \in \mathbf{V}^h$ allow us to rewrite the last identity as

$$\begin{aligned} Q^-_{0,h}(\mathbf{u}^h, p^h; \mathbf{v}_1^h, q^h) &= (\nabla p^h, \mathbf{S}^h \nabla q^h)_0 + \delta h^2((\mathbf{I}-\mathbf{Q}^h)\nabla p^h, (\mathbf{I}-\mathbf{Q}^h)\nabla q^h)_0 \\ &\quad + \delta h^2 \left(-\triangle^h \mathbf{u}^h + \mathbf{Q}^h \nabla p^h, \mathbf{Q}^h \nabla q^h\right)_0. \end{aligned} \tag{5.17}$$

Next, (5.12) implies that

$$Q^-_{0,h}(\mathbf{u}^h, p^h; \mathbf{v}^h, 0) = (-\triangle^h \mathbf{u}^h + \mathbf{Q}^h \nabla p^h, \mathbf{v}^h)_0.$$

Choosing $\mathbf{v}_2^h = -\delta h^2 \mathbf{Q}^h \nabla q^h$ then gives the identity

$$Q^-_{0,h}(\mathbf{u}^h, p^h; \mathbf{v}_2^h, 0) = -\delta h^2 (-\triangle^h \mathbf{u}^h + \mathbf{Q}^h \nabla p^h, \mathbf{Q}^h \nabla q^h)_0. \tag{5.18}$$

Therefore, if $q^h = p^h$, (5.17), (5.18), and (5.15) together with the discrete negative norm characterization in (5.5) imply that

$$\begin{aligned} Q^-_{0,h}(\mathbf{u}^h, p^h; \mathbf{v}_1^h + \mathbf{v}_2^h, p^h) &= (\nabla p^h, \mathbf{S}^h \nabla p^h)_0 + \delta h^2((\mathbf{I}-\mathbf{Q}^h)\nabla p^h, (\mathbf{I}-\mathbf{Q}^h)\nabla p^h)_0 \\ &= \|\nabla p^h\|^2_{-h} + \delta h^2 \|(\mathbf{I}-\mathbf{Q}^h)\nabla p^h\|_0^2 \geq C(\delta)\|\nabla p^h\|^2_{-1}. \end{aligned}$$

Since $p^h \in L^2_0(\Omega)$, the last inequality in combination with (2.8) gives a bound in terms of L^2 pressure norm:

$$Q^-_{0,h}(\mathbf{u}^h, p^h; \mathbf{v}_1^h + \mathbf{v}_2^h, p^h) \geq C_1(\delta)\|p^h\|_0^2. \tag{5.19}$$

To complete the proof of the first weak coercivity condition, note that

$$\begin{aligned} Q^-_{0,h}(\mathbf{u}^h, p^h; \mathbf{u}^h, 0) &= |\mathbf{u}^h|_1^2 + (\nabla p^h, \mathbf{u}^h)_0 = |\mathbf{u}^h|_1^2 - (p^h, \nabla \cdot \mathbf{u}^h)_0 \\ &\geq C_P^2 \|\mathbf{u}^h\|_1^2 - \sqrt{n}\|p^h\|_0 \|\mathbf{u}^h\|_1 \geq \frac{C_P^2}{2}\|\mathbf{u}^h\|_1^2 - \frac{n}{2C_P^2}\|p^h\|_0^2. \end{aligned}$$

Therefore, letting $\mathbf{v}_3^h = n^{-1} C_1(\delta) C_P^2 \mathbf{u}^h$ gives

$$Q^-_{0,h}(\mathbf{u}^h, p^h; \mathbf{v}_3^h, 0) \geq \frac{C_1(\delta) C_P^4}{2n}\|\mathbf{u}^h\|_1^2 - \frac{C_1(\delta)}{2}\|p^h\|_0^2,$$

where $C_1(\delta)$ is the constant from (5.19). As a result,

$$Q^-_{0,h}(\mathbf{u}^h, p^h; \mathbf{v}_1^h + \mathbf{v}_2^h + \mathbf{v}_3^h, p^h) \geq \frac{C_1(\delta) C_P^4}{2n}\|\mathbf{u}^h\|_1^2 + \frac{C_1(\delta)}{2}\|p^h\|_0^2 \tag{5.20}$$

and the association

$$(\widetilde{\mathbf{v}}^h, \widetilde{q}^h) = (\mathbf{v}_1^h + \mathbf{v}_2^h + \mathbf{v}_3^h, p^h)$$

will fit our purpose if we can show that $\|\widetilde{\mathbf{v}}^h\|_1 + \|\widetilde{q}^h\|_0$ is bounded by $\|\mathbf{u}^h\|_1 + \|p^h\|_0$. Using Poincaré's inequality (2.1), we have

$$\begin{aligned} \|\widetilde{\mathbf{v}}^h\|_1 &\leq C\|\nabla \widetilde{\mathbf{v}}^h\|_0 \\ &\leq C(\|\nabla \mathbf{v}_1^h\|_0 + \|\nabla \mathbf{v}_2^h\|_0 + \|\nabla \mathbf{v}_3^h\|_0) \\ &\leq C(\|\nabla(\mathbf{S}^h \nabla p^h)\|_0 + \delta h^2 \|\nabla(\mathbf{Q}^h \nabla p^h)\|_0 + \|\nabla \mathbf{u}^h\|_0). \end{aligned}$$

To estimate the first term, we use the definition of $\mathbf{S}^h$ and Poincaré's inequality to find that

$$\begin{aligned}\|\nabla(\mathbf{S}^h\nabla p^h)\|_0^2 &= (\nabla\mathbf{S}^h\nabla p^h, \nabla\mathbf{S}^h\nabla p^h)_0\\ &= (\nabla p^h, \mathbf{S}^h\nabla p^h)_0 = -(p^h, \nabla\cdot\mathbf{S}^h\nabla p^h)_0\\ &\le \sqrt{n}\|p^h\|_0\|\mathbf{S}^h\nabla p^h\|_1 \le C\|p^h\|_0\|\nabla\mathbf{S}^h\nabla p^h\|_0\end{aligned}$$

and, as a result,

$$\|\nabla(\mathbf{S}^h\nabla p^h)\|_0 \le C\|p^h\|_0.$$

For the second term, application of the inverse inequality (2.4) twice and the fact that $\mathbf{Q}^h$ is bounded gives

$$\delta h^2\|\nabla(\mathbf{Q}^h\nabla p^h)\|_0 \le \delta h C_I\|\mathbf{Q}^h\nabla p^h\|_0 \le \delta h C_I\|\nabla p^h\|_0 \le \delta C_I^2\|p^h\|_0.$$

Combining all bounds shows that

$$\|\widetilde{\mathbf{v}}^h\|_1 \le C(\|p^h\|_0 + \|\mathbf{u}^h\|_1)$$

and so we can rewrite (5.20) as

$$Q_{0,h}^-(\mathbf{u}^h, p^h; \widetilde{\mathbf{v}}^h, \widetilde{q}^h) \ge C(\|\mathbf{u}^h\|_1 + \|p^h\|_0)(\|\widetilde{\mathbf{v}}^h\|_1 + \|\widetilde{q}^h\|_0),$$

which proves the first part of (5.16). To prove the second weak coercivity condition we proceed as in the proof of Theorem 4.1 and set $\mathbf{v}^h = -\mathbf{S}^h\nabla p^h$ and $q^h \equiv p^h$. Using definitions (5.1)–(5.3) and Lemma 5.3, we find that

$$\begin{aligned}Q_{0,h}^-(-\mathbf{S}^h\nabla p^h, p^h; \mathbf{u}^h, p^h) &= (\mathbf{S}^h\nabla p^h, \nabla p^h) + \delta h^2((\mathbf{I}-\mathbf{Q}^h)\nabla p^h, \nabla p^h)\\ &= \|\nabla p^h\|_{-h}^2 + \delta h^2\|(\mathbf{I}-\mathbf{Q}^h)\nabla p^h\|_0^2 \ge C(\delta)\|\nabla p^h\|_0^2 > 0. \qquad \square\end{aligned}$$

This theorem shows that the new discrete method is stable with respect to the same norms as its continuous prototype, i.e., the natural norm on $\mathbf{H}^1(\Omega)\times L^2(\Omega)$. This valuable feature of the new method distinguishes it from the standard discrete SGLS of [18], which is stable with respect to a mesh-dependent norm.

Let us now consider the convergence of finite element solutions. The next theorem shows that the new method yields the same convergence rates as its continuous prototype with respect to the same mesh-independent norms.

THEOREM 5.5. *Let* $(\mathbf{u}, p) \in \mathbf{H}_0^1(\Omega)\cap\mathbf{H}^{r+1}(\Omega)\times L_0^2(\Omega)\cap H^{s+1}(\Omega)$ *denote a solution of the Stokes problem and let* $(\mathbf{u}^h, p^h)$ *solve* (5.11). *Then*

$$\|\mathbf{u}-\mathbf{u}^h\|_1 + \|p-p^h\|_0 \le C(h^r\|\mathbf{u}\|_{r+1} + h^{s+1}\|p\|_{s+1}). \tag{5.21}$$

Proof. We begin by splitting the error into discrete and approximation theoretic parts:

$$\|\mathbf{u}-\mathbf{u}^h\|_1 + \|p-p^h\|_0 \le (\|\mathbf{u}_I^h-\mathbf{u}^h\|_1 + \|p_I^h-p^h\|_0) + (\|\mathbf{u}-\mathbf{u}_I^h\|_1 + \|p-p_I^h\|_0).$$

Since the interpolation error is of optimal order, to prove the theorem it suffices to

estimate the discrete error. Using (5.16),

$$C(\delta)(\|\mathbf{u}_I^h - \mathbf{u}^h\|_1 + \|p_I^h - p^h\|_0) \le \sup_{(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h} \frac{Q_{0,h}^{\pm}(\mathbf{u}_I^h - \mathbf{u}^h, p_I^h - p^h; \mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0}$$

$$\le \sup_{(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h} \frac{Q_{0,h}^{\pm}(\mathbf{u} - \mathbf{u}^h, p - p^h; \mathbf{v}^h, q^h) + Q_{0,h}^{\pm}(\mathbf{u}_I^h - \mathbf{u}, p_I^h - p; \mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0}$$

$$\le \sup_{(\mathbf{v}^h,q^h)\in\mathbf{V}^h\times S^h} \frac{Q_{0,h}^{\pm}(\mathbf{u} - \mathbf{u}^h, p - p^h; \mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_1 + \|q^h\|_0} + C(\|\mathbf{u} - \mathbf{u}_I^h\|_1 + \|p - p_I^h\|_0)$$

$$\le \sup_{q^h\in S^h} \frac{\delta h^2(-\triangle\mathbf{u}, (\mathbf{Q}^h - \mathbf{I})\nabla q^h)_0}{\|q^h\|_0} + C(h^r\|\mathbf{u}\|_{r+1} + h^{s+1}\|p\|_{s+1}),$$

where to obtain the last bound we have used (5.14) in Lemma 5.2 and (2.2) and (2.3). From (5.14), it easily follows that

$$\sup_{q^h\in S^h} \frac{\delta h^2(-\triangle\mathbf{u}, (\mathbf{Q}^h - \mathbf{I})\nabla q^h)_0}{\|q^h\|_0} \le Ch^r\|\mathbf{u}\|_{r+1}.$$

This means that the discrete error is of optimal order, i.e.,

$$\|\mathbf{u}_I^h - \mathbf{u}^h\|_1 + \|p_I^h - p^h\|_0 \le C(h^r\|\mathbf{u}\|_{r+1} + h^{s+1}\|p\|_{s+1})$$

and since the interpolation error is of the same order, (5.21) immediately follows. ∎

6. Concluding remarks. Using the notion of continuous prototypes, we formulated a new absolutely stable method for the Stokes problem. The new method is a close relative of the standard pressure-Poisson stabilized method of [18] in the sense that they share the same continuous prototype.

However, the two methods differ in several important aspects. The new formulation is weakly inconsistent in the sense that, although being strictly speaking not consistent, it still leads to optimal error estimates for all C^0 finite element subspaces, including the lowest order piecewise linear case. In contrast, the standard method not only is not consistent for piecewise linear approximations (because the Laplace operator annihilates the linear velocity field in (3.17) and (3.18)) but also results in errors that do not vanish with vanishing grid sizes; i.e., there remains an error proportional to the parameter δ. Furthermore, the new method is stable with respect to the norm on $\mathbf{H}^1(\Omega) \times L^2(\Omega)$, while the standard method is stable with respect to a mesh-dependent norm that is not *equivalent* to the norm on $\mathbf{H}^1(\Omega) \times L^2(\Omega)$.

Implementation of the new method requires evaluation of the discrete operator $-\triangle^h$. Given a finite element function $\mathbf{u}^h \in \mathbf{V}^h$, the coefficients $\vec{\mathbf{z}}$ of $\mathbf{z}^h = -\triangle^h\mathbf{u}^h$ can be determined from definition (5.1) by solving the linear system

$$\mathbb{M}\,\vec{\mathbf{z}} = \vec{\mathbf{r}}.$$

$\mathbb{M}$ is a mass matrix that can be assembled in the usual manner and $\vec{\mathbf{r}}$ is a vector with components

$$\vec{\mathbf{r}}_i = (\nabla\mathbf{u}^h, \nabla\boldsymbol{\phi}_i^h)_0,$$

where $\{\boldsymbol{\phi}_k^h\}_{k=1}^N$ is a nodal basis for $\mathbf{V}^h$. In practical computations, $\mathbb{M}$ can be replaced by a lumped mass matrix or local projection.

While computation of $-\triangle^h$ may seem as an additional overhead compared to the implementation of the standard method, it is well worth the effort thanks to the improved accuracy, especially when *piecewise linear* finite elements are used, and the guaranteed absolute, mesh-independent stability of the new method. It should be mentioned that essentially the same auxiliary problem, involving the inversion of a mass matrix, arises in standard stabilized methods with improved consistency; see [19]. These methods aim to restore the loss of consistency caused by the annihilation of all second order derivatives in the element residual when piecewise linear elements are used. The idea of [19] is to apply an L^2 projection to the first derivative of the finite element solution *before* the application of the second derivative so as to avoid its annihilation. Specialized to our context, this method can be viewed as providing an alternative definition for the discrete Laplace operator. Instead of the operator $-\triangle^h : \mathbf{H}_0^1(\Omega) \mapsto \mathbf{V}^h$ used in our method, they use the operator $-\triangle_A^h : \mathbf{V}^h \mapsto \mathbf{L}^2(\Omega)$ defined by

$$-\triangle_A^h = -\nabla \cdot (\mathbf{Q}^h \nabla \mathbf{u}^h). \tag{6.1}$$

Let us conclude by noting that an important open question that remains to be answered is whether or not the absolute stability of the continuous SGLS prototype is inherited by other members of this class. It seems particularly worthwhile to exploit extensions of our analysis to an SGLS method defined using the alternative discrete operator (6.1) and to the original pressure-Poisson method of [18] which, as we recall, behaves numerically just like an absolutely stable formulation. Extending our results to discontinuous pressure spaces would also be valuable.

ANALYSIS OF THE BREZZI–PITKÄRANTA STABILIZED GALERKIN SCHEME FOR CREEPING FLOWS OF BINGHAM FLUIDS*

J.-C. LATCHÉ† AND D. VOLA†

Abstract. In this paper we propose and analyze a finite element scheme for a class of variational nonlinear and nondifferentiable mixed inequalities including balance equations governing incompressible creeping flows of Bingham fluids. For numerical efficiency reasons, equal-order piecewise linear approximations are used for both velocity and pressure, and the numerical scheme is stabilized by a Brezzi–Pitkäranta perturbation term. We obtain error estimates of the same order as for stable discretizations, namely $h^{1/2}$ for velocity and pressure solutions in $\left[\mathbf{H}^2(\Omega)\right]^d$ and $\mathbf{H}^1(\Omega)$, respectively. A decomposition-coordination algorithm to solve the discrete nonlinear algebraic system is presented, together with its convergence properties. Finally, numerical tests are performed. The solution of the problem under consideration presents particular regularity properties that are shown to permit convergence order improvement to $h|\log(h)|^{1/2}$. This estimate is confirmed by numerical results.

Key words. variational inequality, finite element method, Brezzi–Pitkäranta stabilization, error bound, Bingham fluid, creeping flow, decomposition- coordination method, augmented Lagrangian, algorithm convergence

1. Introduction.

Balance equations governing Bingham fluid flows take the form of nonlinear and nondifferentiable variational inequality problems, and their numerical solution is still a challenging task.

Steady one-directional flow in a pipe was the first of this type of flows to be the subject of an in-depth study. In the early 1980s, Fortin and Glowinski developed the so-called decomposition-coordination method for this particular situation; see [8], [10] and references therein. The principle of this numerical method is to isolate the nonlinear and nondifferentiable terms in the variational problem by introducing an auxiliary variable, the strain rate tensor, to enforce the consistency of this new variable and the velocity field by a duality method, and to solve the mixed problem by Uzawa algorithm variants. If the approximation space for the strain rate tensor is chosen so that no interelement continuity is required, it appears that the global nonlinear minimization problem degenerates in the Uzawa algorithm into a family of element-related subproblems which then can be solved efficiently, and even explicitly for a piecewise constant approximation. This aspect represents the main interest of the decomposition-coordination technique. In addition, the use of the constitutive relation is localized to the subproblems, which allows effortless changes. This numerical method was first used by Begis [10, Chapter VI] in the stream-function-vorticity formulation framework and then applied by several authors to pipe flows; see [13], [17].

The extension of this method to multidimensional incompressible flows was tested by Fortin, Côté, and Tanguy [7] and Roquet and Saramito [16]. To our knowledge,

the first analysis of this scheme is due to Han and Reddy [11], who dealt with the same mathematical problem for elastoplasticity applications (see [3] for a formulation for Bingham fluid flows and in the frame of the decomposition-coordination method). Convergence is proven and the error is found to be bounded by the square root of the so-called interpolation error, the latter depending on the discretization spaces and solution regularity. This analysis is based on the usual discrete Babuska–Brezzi stability condition for velocity/pressure approximation. Unfortunately, in our applications to Bingham fluid flows this limitation appeared to be somewhat restrictive, because it leads us to employ high degree approximations for the velocity that are not well suited to the poor regularity which can be expected from the solution. Moreover, the construction of strain rate approximation spaces which preserve the scheme accuracy and efficiency for high degree velocity approximations did not appear straightforward.

This explains the attractiveness of using piecewise linear equal-order approximation for the velocity and the pressure. This finite element is known to be cost-effective, and the discretization of the strain rate by piecewise constants would allow us to match the coherence constraint between velocity and strain rate perfectly. Of course, a stabilizing procedure must be applied with this approximation. The usual derivation of consistently stabilized schemes (e.g., [12], [9]) requires making the numerical residuals explicit which, in turn, needs a "strong differential formulation" of the problem. The latter can be obtained by regularizing the constitutive law. A numerical method built following these lines is presented in [14]. Conversely, if one chooses to deal with the problem without regularization, the natural choice then seems to be to implement a Brezzi–Pitkäranta stabilization [4]. The main purpose of this paper is to analyze such a scheme, combining ideas from [11] and from the analysis of stabilized schemes for Newtonian flows [9].

In section 2, we present the error analysis of a stabilized approximation of an abstract mixed nonlinear variational inequality. The application of this result to Bingham creeping flows problems is performed in section 3. Section 4 is devoted to the extension of the decomposition-coordination method to the stabilized scheme and the presentation of the solution algorithm and of its convergence properties. In section 5, we present numerical tests. As the solution of the considered problem presents extra regularity properties, the analysis of sections 2 and 3 yields an improved error bound, which is established.

Throughout this paper, Ω stands for an open and bounded subset of $\mathbb{R}^d$, $d \leq 3$, with Lipschitz domain boundary $\partial\Omega$, and we use standard notation for Sobolev spaces $\mathbf{L}^2(\Omega)$, $\mathbf{H}^1(\Omega)$, $\mathbf{H}_0^1(\Omega)$, $\mathbf{H}^2(\Omega)$, (see [1]). $\|.\|_0$ and $\|.\|_1$ stand for the norms of $\mathbf{L}^2(\Omega)$ and $\mathbf{H}^1(\Omega)$, and $|.|_1$ and $|.|_2$ are the usual seminorms of $\mathbf{H}^1(\Omega)$ and $\mathbf{H}^2(\Omega)$, respectively.

2. An abstract convergence result. The aim of this section is to analyze a numerical scheme to solve the following abstract variational inequality:

(2.1)

Find u and p in $\left[\mathbf{H}_0^1(\Omega)\right]^d$ and $\mathbf{L}^2(\Omega)$, respectively, such that

$$\left|\begin{array}{ll} a(u, v-u) + j(v) - j(u) + b(v-u, p) \geq \langle f, v-u\rangle & \forall v \in \left[\mathbf{H}_0^1(\Omega)\right]^d, \\ b(u, q) = \langle g, q\rangle & \forall q \in \mathbf{L}^2(\Omega), \end{array}\right.$$

where $a(.,.)$ and $b(.,.)$ are two continuous bilinear forms defined on $\left[\mathbf{H}_0^1(\Omega)\right]^d \times \left[\mathbf{H}_0^1(\Omega)\right]^d$ and $\left[\mathbf{H}_0^1(\Omega)\right]^d \times \mathbf{L}^2(\Omega)$, respectively, and $j(.)$ is a real convex Lipschitz-continuous function defined on $\left[\mathbf{H}_0^1(\Omega)\right]^d$. f and g belong to the dual space of

$\left[\mathbf{H}_0^1(\Omega)\right]^d$ and $\mathbf{L}^2(\Omega)$, respectively, and $\langle .,. \rangle$ stands for the duality product. Finally, we suppose that the bilinear form $a(.,.)$ is coercive over $\left[\mathbf{H}_0^1(\Omega)\right]^d$, and we note $|a|$, δ, $|b|$, and, β four positive real usual constants such that

$$\begin{aligned}
&a(u,v) \le |a|\ \|u\|_1\ \|v\|_1 && \forall\ u,v \in \left[\mathbf{H}_0^1(\Omega)\right]^d,\\
&a(u,u) \ge \delta\ \|u\|_1^2 && \forall\ u \in \left[\mathbf{H}_0^1(\Omega)\right]^d,\\
&b(v,q) \le |b|\ \|v\|_1\ \|q\|_0 && \forall\ v \in \left[\mathbf{H}_0^1(\Omega)\right]^d,\ \forall q \in \mathbf{L}^2(\Omega),\\
&j(u) - j(v) \le \beta\ \|u-v\|_1 && \forall\ u,v \in \left[\mathbf{H}_0^1(\Omega)\right]^d.
\end{aligned}$$

We suppose, in addition, that the Babuska–Brezzi condition is satisfied:

$$\exists c > 0 \text{ such that } \quad \forall q \in \mathbf{L}^2(\Omega), \quad \sup_{v \in \left[\mathbf{H}_0^1(\Omega)\right]^d} \frac{b(v,q)}{\|v\|_1} \ge c\|q\|_0.$$

Under the preceding assumptions, the existence of solutions and the uniqueness of u are proven in [11].

Let $\mathbf{U}_h$ and $\mathbf{Q}_h$ be two finite element spaces such that $\mathbf{U}_h \subset \left[\mathbf{H}_0^1(\Omega)\right]^d$, $\mathbf{Q}_h \subset \mathbf{H}^1(\Omega)$, and the following interpolation results are satisfied:

$$\exists c \text{ independent of the discretization step, } h, \text{ such that } \forall\ u \in \left[\mathbf{H}^2(\Omega)\right]^d,$$
$$\exists\ r_h u \in \mathbf{U}_h \text{ satisfying } \quad \left| \begin{array}{l} \|u - r_h u\|_1 \le ch\ |u|_2, \\ \|u - r_h u\|_0 \le ch^2\ |u|_2, \end{array} \right.$$

$$\exists c \text{ independent of } h \text{ such that } \forall p \in \mathbf{H}^1(\Omega),$$
$$\exists\ r_h p \in \mathbf{Q}_h \text{ satisfying } \left| \begin{array}{l} \|p - r_h p\|_0 \le ch\ |p|_1, \\ \|p - r_h p\|_1 \le c\ |p|_1, \end{array} \right.$$

where h stands for the discretization step, with the standard definition.

The numerical scheme considered here reads as follows:

(2.2)
Find $u_h \in \mathbf{U}_h$ and $p_h \in \mathbf{Q}_h$ such that

$$\left| \begin{array}{ll} a(u_h, v_h - u_h) + j(v_h) - j(u_h) + b(v_h - u_h, p_h) \ge \langle f, v_h - u_h \rangle & \forall v_h \in \mathbf{V}_h, \\ -b(u_h, q_h) + \alpha\ c_h(p_h, q_h) = -\langle g, q_h \rangle & \forall q_h \in \mathbf{Q}_h, \end{array} \right.$$

where α is a positive parameter and $c_h(.,.)$ is a mesh-dependent bilinear form such that the following assumptions hold:

(H1) $c_h(p,q)$ is defined for any couple of functions $p,\ q \in \mathbf{H}^1(\Omega)$.

(H2) $[.]_h$ defined by $[q_h]_h^2 = c_h(q_h, q_h)$ is a mesh-dependent norm.

(H3) $\forall p_h,\ q_h \in \mathbf{Q}_h, \quad c_h(p_h, q_h) \le [p_h]_h\ [q_h]_h$.

(H4) $\exists \gamma$, a positive constant independent of h, and $k > 0$ such that
$$\forall v_h \in \mathbf{U}_h, \forall q_h \in \mathbf{Q}_h, \quad b(v_h, q_h) \le \gamma\ \frac{1}{h^k}\ \|v_h\|_0\ [q_h]_h$$
(in further practical applications, $k = \frac{1}{2}$ or 1).

(H5) $\exists c$, a positive constant independent of h, such that
$$\forall q \in \mathbf{H}^1(\Omega), \quad [q]_h \le ch^k\ \|q\|_1.$$

We define as $B(.,.)$ and $B_h(.,.)$, the bilinear forms defined on $(\mathbf{V}_h \times \mathbf{Q}_h) \times (\mathbf{V}_h \times \mathbf{Q}_h)$, by

$$B(u_h, p_h; v_h, q_h) = a(u_h, v_h) + b(v_h, p_h) - b(u_h, q_h),$$
$$B_h(u_h, p_h; v_h, q_h) = B(u_h, p_h; v_h, q_h) + \alpha\ c_h(p_h, q_h).$$

The following stability lemma holds.

LEMMA 2.1. *For any $v_h \in \mathbf{U}_h$ and $q_h \in \mathbf{Q}_h$, we have*

$$B_h(u_h, p_h; u_h, p_h) \geq \delta \|u_h\|_1^2 + \alpha [p_h]_h^2.$$

Proof. This result is a straightforward consequence of the coercivity of the bilinear form $a(.,.)$ in $\left[\mathbf{H}_0^1(\Omega)\right]^d$, combined with the fact that we use a conforming discretization ($\mathbf{U}_h \subset \left[\mathbf{H}_0^1(\Omega)\right]^d$). ∎

COROLLARY 2.2. *There exists a unique solution to problem* (2.2).

Proof. Let $\mathbf{X}_h$ be the product space $\mathbf{V}_h \times \mathbf{Q}_h$, provided with the norms inherited from $\left[\mathbf{H}_0^1(\Omega)\right]^d$ and $\mathbf{L}^2(\Omega)$, respectively. Let $J(.)$ be the convex Lipschitz-continuous functional defined from $\mathbf{X}_h$ to $\mathbb{R}$ by

$$J(v_h, q_h) = j(v_h)$$

and F be the element of the dual of $\mathbf{X}_h$ such that

$$\langle F; (v_h, q_h)\rangle = \langle f, v_h\rangle - \langle g, q_h\rangle.$$

With these notations, problem (2.2) reads as follows.

Find $(u_h, p_h) \in \mathbf{X}_h$such that,$\forall (v_h, q_h) \in \mathbf{X}_h$,

$$B_h(u_h, p_h; (v_h, q_h) - (u_h, p_h)) + J(v_h, q_h) - J(u_h, p_h) \geq \langle F; (v_h, q_h) - (u_h, p_h)\rangle.$$

As on finite dimensional spaces all norms are equivalent, the preceding lemma shows the coercivity of the bilinear form $B_h(.,.)$, and the existence and uniqueness of the solution follow by standard optimization results [8]. ∎

We are now in position to prove the following convergence result.

THEOREM 2.3. *Let u and p be a solution of problem* (2.1) *and u_h and p_h be the solution of* (2.2). *We suppose, in addition, that $u \in \left[\mathbf{H}^2(\Omega)\right]^d$ and $p \in \mathbf{H}^1(\Omega)$. Then the following error bound holds:*

$$\|u - u_h\|_1 \leq c\ h^{\frac{1}{2}}\ (|u|_2 + |p|_1).$$

Proof. Let v_h and q_h be generic elements of $\mathbf{V}_h$ and $\mathbf{Q}_h$, respectively. We suppose that $p \in \mathbf{H}^1(\Omega)$, and consequently, $[p]_h$ is well defined. By the triangular inequality,

$$\begin{aligned} &\delta\ \|u - u_h\|_1^2 + \alpha\ [p - p_h]_h^2 \\ &\qquad \leq \delta\ (\|u - v_h\|_1 + \|u_h - v_h\|_1)^2 + \alpha\ ([p - q_h]_h + [p_h - q_h]_h)^2 \\ &\qquad \leq 2\ [\ \delta \|u - v_h\|_1^2 + \alpha [p - q_h]_h^2 + \underbrace{\delta \|u_h - v_h\|_1^2 + \alpha [p_h - q_h]_h^2}_{\text{(i)}}\ ]. \end{aligned} \tag{2.3}$$

By the stability Lemma 2.1, we obtain the following bound of the last term of this relation:

$$\begin{aligned} \text{(i)} \quad &\leq B_h(u_h - v_h, p_h - q_h; u_h - v_h, p_h - q_h) \\ &= \underbrace{B_h(u_h, p_h; u_h - v_h, p_h - q_h)}_{\text{(ii)}} - B_h(v_h, q_h; u_h - v_h, p_h - q_h). \end{aligned} \tag{2.4}$$

Developing term (ii) of this inequality yields

$$\text{(ii)} = \underbrace{a(u_h, u_h - v_h) + b(u_h - v_h, p_h)}_{\text{(iii)}} - \underbrace{b(u_h, p_h - q_h) + \alpha\ c_h(p_h, p_h - q_h)}_{\text{(iv)}}. \tag{2.5}$$

By the second relation of (2.2) then the second one of (2.1), we get for (iv) the following expression:

$$\text{(iv)} = -\langle \mathrm{g}, \mathrm{p_h} - \mathrm{q_h} \rangle = -\mathrm{b}(\mathrm{u}, \mathrm{p_h} - \mathrm{q_h}). \tag{2.6}$$

Taking $v = u_h$ and then $v = 2u - v_h$ as test functions in the first relation of (2.1) yields

$$\begin{aligned} a(u, u_h - u) + j(u_h) - j(u) + b(u_h - u, p) &\geq \langle f, u_h - u \rangle, \\ a(u, u - v_h) + j(2u - v_h) - j(u) + b(u - v_h, p) &\geq \langle f, u - v_h \rangle. \end{aligned}$$

Summing up these inequalities, we obtain

$$\langle f, u_h - v_h \rangle \leq a(u, u_h - v_h) + j(u_h) - j(u) + j(2u - v_h) - j(u) + b(u_h - v_h, p)$$

and, by the first relation of (2.2),

$$\begin{aligned} \text{(iii)} \quad &\leq \langle f, u_h - v_h \rangle - j(u_h) + j(v_h) \\ &\leq a(u, u_h - v_h) + j(v_h) + j(2u - v_h) - 2j(u) + b(u_h - v_h, p). \end{aligned} \tag{2.7}$$

Using (2.6) and (2.7) in (2.5), we get

$$\text{(ii)} \leq a(u, u_h - v_h) + b(u_h - v_h, p) - b(u, p_h - q_h) + j(v_h) + j(2u - v_h) - 2j(u).$$

And, finally, using this estimate for (ii) in (2.4) and developing the term $B_h(v_h, q_h; u_h - v_h, p_h - q_h)$, we obtain

(2.8)

$$\begin{aligned} \text{(i)} \quad &\leq \quad a(u, u_h - v_h) + b(u_h - v_h, p) - b(u, p_h - q_h) + j(v_h) + j(2u - v_h) - 2j(u) \\ &\quad - [a(v_h, u_h - v_h) + b(u_h - v_h, q_h) - b(v_h, p_h - q_h) + \alpha\ c_h(q_h, p_h - q_h)] \\ &= \quad \underbrace{a(u - v_h, u_h - v_h)}_{\text{(v)}} + \underbrace{b(u_h - v_h, p - q_h)}_{\text{(vi)}} - \underbrace{b(u - v_h, p_h - q_h)}_{\text{(vii)}} \\ &\quad + \underbrace{j(v_h) + j(2u - v_h) - 2j(u)}_{\text{(viii)}} + \underbrace{\alpha\ c_h(p - q_h, p_h - q_h)}_{\text{(ix)}} - \underbrace{\alpha\ c_h(p, p_h - q_h)}_{\text{(x)}}. \end{aligned}$$

Tracing back the origin of the last term (x) of the preceding relation, it may be checked that it appears because $B_h(u_h, p_h; u_h - v_h, p_h - q_h)$ is used as a discrete counterpart of $B(u, p; u_h - v_h, p_h - q_h)$, which cannot be identified, under regularity assumptions on u and p, to $B_h(u, p; u_h - v_h, p_h - q_h)$, as would be the case for a consistently stabilized scheme. It thus can be viewed as the consistency error of the scheme.

The next step consists of bounding each of the terms of the relation (2.8):

$$
\begin{aligned}
\text{(v)} \quad &\leq |a|\ \|u-v_h\|_1\ \|u_h-v_h\|_1 \leq \frac{|a|^2}{2\delta c_1}\ \|u-v_h\|_1^2 + \frac{c_1\delta}{2}\ \|u_h-v_h\|_1^2,\\
\text{(vi)} \quad &\leq |b|\ \|u_h-v_h\|_1\ \|p-q_h\|_0 \leq \frac{|b|^2}{2\delta c_2}\ \|p-q_h\|_0^2 + \frac{c_2\delta}{2}\ \|u_h-v_h\|_1^2,\\
\text{(vii)} \quad &\leq \frac{\gamma}{h^k}\ \|u-v_h\|_0\ [p_h-q_h]_h \qquad \text{(by assumption (H4))}\\
&\leq \frac{\gamma^2}{2\alpha c_3 h^{2k}}\ \|u-v_h\|_0^2 + \frac{c_3\alpha}{2}\ [p_h-q_h]_h^2,\\
\text{(viii)} \quad &= (j(2u-v_h)-j(u))-(j(u)-j(v_h))\\
&\leq 2\beta\|u-v_h\|_1 \qquad \text{(by the Lipschitz continuity of } j(.)),\\
\text{(ix)} \quad &\leq \alpha\ [q_h-p]_h\ [p_h-q_h]_h \qquad \text{(by assumption (H3))}\\
&\leq \frac{\alpha}{2c_4}\ [q_h-p]_h^2 + \frac{\alpha c_4}{2}\ [p_h-q_h]_h^2,\\
\text{(x)} \quad &\leq \frac{\alpha}{2c_5}\ [p]_h^2 + \frac{\alpha c_5}{2}\ [p_h-q_h]_h^2 \qquad \text{(idem).}
\end{aligned}
$$

Choosing $c_1 = c_2 = 1/2$, $c_3 = c_4 = c_5 = 1/3$, substituting these expressions for (v)–(x) in 2.8, and combining terms on the left-hand side, we get

$$
\begin{aligned}
&\frac{1}{2}\ \left[\delta\ \|u_h-v_h\|_1^2 + \alpha[p_h-q_h]_h^2\right]\\
&\quad\leq \frac{|a|^2}{\delta}\ \|u-v_h\|_1^2 + \frac{3\gamma^2}{2\alpha h^{2k}}\ \|u-v_h\|_0^2 + 2\beta\ \|u-v_h\|_1 + \frac{|b|^2}{\delta}\ \|p-q_h\|_0^2\\
&\qquad + \frac{3\alpha}{2}\ [p-q_h]_h^2 + \frac{3\alpha}{2}\ [p]_h^2.
\end{aligned}
$$

Combined with the initial triangular inequality (2.3), this last relation yields

$$
\begin{aligned}
&\delta\ \|u-u_h\|_1^2 + \alpha[p-p_h]_h^2\\
&\leq \inf_{v_h\in\mathbf{V}_h}\left[\left(\frac{4|a|^2}{\delta}+2\delta\right)\ \|u-v_h\|_1^2 + \frac{6\gamma^2}{\alpha h^{2k}}\ \|u-v_h\|_0^2 + 8\beta\ \|u-v_h\|_1\right]\\
&+ \inf_{q_h\in\mathbf{Q}_h}\left[\frac{4|b|^2}{\delta}\ \|p-q_h\|_0^2 + 7\alpha\ [p-q_h]_h^2\right] + 6\alpha\ [p]_h^2.
\end{aligned}
\tag{2.9}
$$

Associated with the assumed approximation properties of the spaces $\mathbf{V}_h$ and $\mathbf{Q}_h$ and hypothesis (H5), this last inequality completes the proof. □

Remark. Due to the fact that the seminorm $[.]_h$ behaves like $h^k\ \|.\|_1$, the presence of the term $[p-q_h]_h$ on the left-hand side of inequality (2.9) does not provide any convergence result for the approximation of p. This was expected: p is not even guaranteed to be unique. However, we obtain the following weaker result: as soon as $k \leq \frac{1}{2}$, the solution of the numerical scheme p_h remains bounded independently of the discretization step.

The sharpest result for the convergence of u_h toward the solution u is obtained with $k \geq 1$. In this case, the leading-order term on the right-hand side of inequality 2.9 is $\beta\ \|u-v_h\|_1$ and stems from the nonlinearity of the problem.

3. A numerical scheme for Bingham fluid creeping flows. The so-called Bingham fluids belong to the category of fluids exhibiting a yield stress, i.e., which behave as a solid in regions of the flow where the shear stress magnitude falls under a threshold value. Their constitutive law reads as

$$\begin{cases} \text{if } \|\tau\| \leq \tau_{\text{YS}}, \quad \dot{\varepsilon}(v) = 0, \\ \text{if } \|\tau\| \geq \tau_{\text{YS}}, \quad \tau = \left(\dfrac{\tau_{\text{YS}}}{\|\dot{\varepsilon}\|} + 2\mu \right) \dot{\varepsilon}(v), \end{cases}$$

where v stands for the fluid velocity, $\dot{\varepsilon}(.)$ for the usual strain rate tensor, τ for the shear stress tensor, μ for the dynamic viscosity, τ_{YS} for the fluid yield stress, and $\|.\|$ is the Euclidean norm in $\mathbb{R}^{d\times d}$.

The creeping flow of a Bingham fluid in a domain Ω of $\mathbb{R}^d$ with adherence conditions at the boundaries is governed by a set of balance equations that admit a variational formulation of general form (2.1) [6, Chapter 6], with the following specific expressions for each bilinear and linear form of the problem,

$$a(u,v) = \int_\Omega 2\mu \ \dot{\varepsilon}(u) : \dot{\varepsilon}(v), \qquad b(v,p) = -\int_\Omega p \ \nabla \cdot u, \qquad \langle f, v\rangle = \int_\Omega f.v,$$

and for the Lipschitz-continuous functional,

$$j(v) = \int_\Omega \tau_{\text{YS}} \ \|\dot{\varepsilon}(v)\|,$$

where f stands for the volume forces. The assumptions of continuity and coercivity of $a(.,.)$, continuity of $b(.,.)$, and the Babuska–Brezzi condition are standard results of theoretical computational fluid dynamics. The Lipschitz–continuity of $j(.)$ is a consequence of the Lipschitz–continuity of the Euclidean norm.

We suppose a given family of triangulations of the domain, and we choose as approximation space the standard Lagrange linear continuous finite element space for both the velocity and the pressure. For a particular triangulation T_h of n d-simplexes $(K_i)_{i\leq n}$, the finite element subspaces are given by

$$\mathbf{U}_h = \{v_h \in [C^1(\bar{\Omega})]^d, \quad v_h|_{K_i} \in [\mathbb{P}_1(K_i)]^d, \quad 1 \leq i \leq n, \quad \text{and } v_h = 0 \text{ on } \partial\Omega\},$$
$$\mathbf{Q}_h = \{q_h \in C^1(\bar{\Omega}), \quad q_h|_{K_i} \in \mathbb{P}_1(K_i), \quad 1 \leq i \leq n\},$$

where $\mathbb{P}_1(K_i)$ stands for the space of degree ≤ 1 polynomials over the polyhedron K_i.

These finite element spaces verify the regularity and approximation properties used in the preceding section, provided that the meshing is regular (i.e., the ratio between the diameter of the largest inscribed ball and the mesh diameter is bounded away from zero for each element of the family of triangulations [5]).

The numerical scheme considered here uses the following stabilization bilinear form:

$$c_h(p_h, q_h) = c_{\text{b}} \sum_{i=1}^{n} h_{K_i}^2 \int_{K_i} \nabla p_h . \nabla q_h.$$

With this definition, the assumptions (H1), (H2), (H3), and (H5) are easily checked (with the usual restriction to zero mean value functions for the pressure space). The following lemma means that the hypothesis (H4) stands, under an additional constraint for the family of triangulations.

LEMMA 3.1. *We assume that the family of triangulations is quasi-uniform, i.e., that the ratio of the smallest element diameter to the largest one is bounded away from zero. Then there exists a positive constant c independent of h such that, for any* $v_h \in \mathbf{U}_h$ *and* $q_h \in \mathbf{Q}_h$*, we have*

$$|b(v_h, q_h)| \leq c\ \frac{1}{h}\ \|v_h\|_0\ [q_h]_h.$$

Proof. From one part, we have

$$[q_h]_h^2 = c_{\mathrm{b}}\ \sum_{i=1}^{n}\ h_{K_i}^2\ \int_{K_i} \nabla\, q_h.\nabla\, q_h \quad \geq c_{\mathrm{b}}\ \left(\min_{0\leq i\leq n} h_{K_i}\right)^2\ \sum_{i=1}^{n}\ \int_{K_i} \nabla\, q_h.\nabla\, q_h$$
$$\geq c_{\mathrm{b}}\ \left(\frac{\min_{0\leq i\leq n} h_{K_i}}{h}\right)^2\ h^2\ |q_h|_1^2.$$

The first factor of this last expression is bounded away from zero if the family of triangulations is quasi-uniform.

On the other hand, as $\mathbf{Q}_h \subset \mathbf{H}^1(\Omega)$ and $\mathbf{V}_h \subset \left[\mathbf{H}_0^1(\Omega)\right]^d$, the following integration by parts is valid:

$$b(v_h, q_h) = -\int_\Omega q_h \nabla \cdot v_h = \int_\Omega \nabla\, q_h.v_h$$

and, by the Cauchy–Schwarz inequality,

$$b(v_h, q_h) \leq \|v_h\|_0 |q_h|_1.$$

The result is obtained by combining both inequalities. ∎

As a consequence, we obtain the following error estimate for the numerical scheme under consideration.

THEOREM 3.2. *Let u be the solution of the problem. Let* u_h *be the generic element of a family of approximate solutions obtained with the present scheme using a family of regular and quasi-uniform triangulations. If we assume that* $u \in \left[\mathbf{H}^2(\Omega)\right]^d$*, the following error bound holds:*

$$\|u - u_h\|_1 \leq c\ h^{1/2}\ |u|_2,$$

where the positive constant c is independent of h.

Remark. The extension of this analysis to problems with nonhomogeneous Dirichlet boundary conditions can be performed as for the Newtonian Stokes problem, without any additional difficulty (e.g., [15]).

4. Practical implementation: The decomposition-coordination method. The object of this section is first to adapt the decomposition-coordination method of Fortin and Glowinski [8] to the numerical scheme under consideration, then to describe an algorithm for solving the discrete problem and to analyze its convergence. The difficulty of the first task lies in the fact that, due to the presence of the stabilization term, the standard theory does not apply to the problem under consideration, and the equivalence (in a sense to be defined) between the final discrete system and the initial one has to be proven.

Our starting point is the approximate problem:

Find $u_h \in \mathbf{U}_h$ and $p_h \in \mathbf{Q}_h$ such that

$$
\left|
\begin{aligned}
&\int_\Omega 2\mu\ \dot{\varepsilon}(u_h) : \dot{\varepsilon}(v_h - u_h) - \int_\Omega p_h\ \nabla \cdot (v_h - u_h) \\
&\qquad + \int_\Omega \tau_{\text{YS}}\ \|\dot{\varepsilon}(v_h)\| - \int_\Omega \tau_{\text{YS}}\ \|\dot{\varepsilon}(u_h)\| \geq \int_\Omega f.(v_h - u_h) \qquad \forall v_h \in \mathbf{U}_h, \\
&\int_\Omega p_h\ \nabla \cdot u_h + c_{\text{b}} \sum_{i=1}^{n} h_{K_i}^2 \int_{K_i} \nabla p_h . \nabla q_h = 0 \qquad \forall q_h \in \mathbf{Q}_h.
\end{aligned}
\right. \tag{4.1}
$$

Let $\mathbf{W}_h$ be the following finite element space:

$$\mathbf{W}_h = \{z_h \in [\mathbf{L}^2(\Omega)]^{d\times d}, \quad z_h|_{K_i} \in [\mathbb{P}_0(K_i)]^{d\times d}, \quad 1 \leq i \leq n\},$$

where $\mathbb{P}_0(K_i)$ stands for the space of constant functions over polyhedron K_i.

We introduce the following discrete variational problem:

Find $u_h \in \mathbf{U}_h,\ p_h \in \mathbf{Q}_h,\ w_h \in \mathbf{W}_h,$ and $s_h \in \mathbf{W}_h$ such that

$$
\left|
\begin{aligned}
&\int_\Omega 2\mu\ w_h : (z_h - w_h) - \int_\Omega (z_h - w_h) : s_h \\
&\qquad + \int_\Omega \tau_{\text{YS}}\ \|z_h\| - \int_\Omega \tau_{\text{YS}}\ \|w_h\| \\
&\qquad + \sum_{i=1}^{n} r_i \int_{K_i} [w_h - \dot{\varepsilon}(u_h)] : [z_h - w_h] \geq 0 \qquad \forall z_h \in \mathbf{W}_h, \\
&\sum_{i=1}^{n} r_i \int_{K_i} [\dot{\varepsilon}(u_h) - w_h] : \dot{\varepsilon}(v_h) - \int_\Omega p_h\ \nabla \cdot v_h \\
&\qquad + \int_\Omega \dot{\varepsilon}(v_h) : s_h = \int_\Omega f.v_h \qquad \forall v_h \in \mathbf{U}_h, \\
&\int_\Omega q_h\ \nabla \cdot u_h + c_{\text{b}} \sum_{i=1}^{n} h_{K_i}^2 \int_{K_i} \nabla p_h . \nabla q_h = 0 \qquad \forall q_h \in \mathbf{Q}_h, \\
&\int_\Omega (\dot{\varepsilon}(u_h) - w_h) : t_h = 0 \qquad \forall t_h \in \mathbf{W}_h.
\end{aligned}
\right. \tag{4.2}
$$

The family of parameters r_i is chosen such that $0 < r_i$ for each $1 \geq i \geq n$.

We then have the following result.

PROPOSITION 4.1. *Problem* (4.2) *has at least one solution; in addition, the first three components u_h, w_h, p_h are the same for any solution of the problem.*

Moreover, if u_h and p_h are (part of) one solution of (4.2)*, u_h and p_h are solutions of* (4.1).

Proof. Let $A(.,.)$ be the bilinear form defined over $(\mathbf{U}_h \times \mathbf{W}_h \times \mathbf{Q}_h) \times (\mathbf{U}_h \times \mathbf{W}_h \times \mathbf{Q}_h)$, $B(.,.)$ be the bilinear form defined over $(\mathbf{U}_h \times \mathbf{W}_h \times \mathbf{Q}_h) \times \mathbf{W}_h$, and $J(.)$ and $F(.)$ be, respectively, the form and the nonlinear convex functional defined over

$\mathbf{U}_h \times \mathbf{W}_h \times \mathbf{Q}_h$ as follows:

$$\begin{aligned} A((u_h,w_h,p_h);(v_h,z_h,q_h)) &= \int_\Omega 2\mu\ w_h : z_h + \sum_{i=1}^{n} r_i \int_{K_i} [w_h - \dot{\varepsilon}(u_h)] : z_h \\ &+ \sum_{i=1}^{n} r_i \int_{K_i} [\dot{\varepsilon}(u_h) - w_h] : \dot{\varepsilon}(v_h) - \int_\Omega p_h\ \nabla\cdot v_h + \int_\Omega q_h\ \nabla\cdot u_h \\ &+ c_{\mathrm{b}} \sum_{i=1}^{n} h_{K_i}^2 \int_{K_i} \nabla p_h . \nabla q_h, \end{aligned}$$

$$B((v_h,z_h,q_h);t_h) = \int_\Omega (\dot{\varepsilon}(u_h) - w_h) : t_h,$$

$$J(v_h,z_h,q_h) = j(z_h),$$

$$F(v_h,z_h,q_h) = \int_\Omega f.v_h.$$

With these notations, problem (4.2) can be recast under the form of the following nonlinear mixed variational inequality:

Find $(u_h,w_h,p_h) \in (\mathbf{U}_h \times \mathbf{W}_h \times \mathbf{Q}_h)$ and $s_h \in \mathbf{W}_h$ such that

$$\left|\begin{array}{ll} A((u_h,w_h,p_h);(v_h,z_h,q_h)-(u_h,w_h,p_h)) + J(v_h,z_h,q_h) - J(u_h,w_h,p_h) & \\ \qquad + B((v_h,z_h,q_h);s_h) \geq F((v_h,z_h,q_h)-(u_h,w_h,p_h)) & \\ \qquad \forall (v_h,z_h,q_h) \in (\mathbf{U}_h \times \mathbf{W}_h \times \mathbf{Q}_h), & \\ B((u_h,w_h,p_h);t_h) = 0 & \forall t_h \in \mathbf{W}_h. \end{array}\right.$$

We find the following result in [11]: assuming that $A(.,.)$ is coercive, the LBB condition holds for $B(.,.)$, and $J(.)$ is Lipschitz-continuous and convex, this variational problem has solutions; moreover, the primal component of the solution (u_h,w_h,p_h) is unique.

Checking the LBB condition is straightforward here. We are going to prove the coercivity of the bilinear form $A(.,.)$:

$$\begin{aligned} A((u_h,w_h,p_h);(u_h,w_h,p_h)) &= \int_\Omega 2\mu\ w_h : w_h + c_{\mathrm{b}} \sum_{i=1}^{n} h_{K_i}^2 \int_{K_i} \nabla p_h . \nabla p_h \\ &+ \sum_{i=1}^{n} r_i \int_{K_i} [w_h - \dot{\varepsilon}(u_h)] : [w_h - \dot{\varepsilon}(u_h)]. \end{aligned}$$

Developing and using the Cauchy–Schwarz inequality yields, for any strictly positive constant α,

$$\begin{aligned} &A((u_h,w_h,p_h);(u_h,w_h,p_h)) \\ &\quad = 2\mu\|w_h\|_0^2 + c_{\mathrm{b}}[p_h]_h^2 + \sum_{i=1}^{n} r_i \left[\|w_h\|_{0,\mathrm{K}}^2 + \|\dot{\varepsilon}(u_h)\|_{0,\mathrm{K}}^2 + \int_{K_i} w_h : \dot{\varepsilon}(u_h) \right] \\ &\quad \geq 2\mu\|w_h\|_0^2 + c_{\mathrm{b}}[p_h]_h^2 + \sum_{i=1}^{n} r_i \left[(1-\alpha)\ \|w_h\|_{0,\mathrm{K}}^2 + \left(1 - \frac{1}{\alpha}\right)\ \|\dot{\varepsilon}(u_h)\|_{0,\mathrm{K}}^2 \right]. \end{aligned}$$

In finite dimensional spaces, all norms are equivalent; the coercivity of $A(.,.)$ then follows by choosing $\alpha > 1$ such that $(\alpha - 1)r_i \leq \mu$ for all $1 \leq i \leq n$.

Due to the choice of the discrete spaces, the constraint $\dot{\varepsilon}(u_h) = w_h$ holds exactly. As a consequence, the first equation of (4.1) is recovered by summing up the first two equations of (4.2) and choosing $z_h = \dot{\varepsilon}(v_h)$ as a test function. As the second equation of (4.1) remains valid, the solution of (4.1) and the first and third components of the solution of (4.2) are the same. ∎

Replacing the last third relations with their algebraic counterpart, problem (4.2) reads as follows:

(i) Find $w_h \in \mathbf{W}_h$ such that

$$\int_\Omega 2\mu\ w_h : (z_h - w_h) - \int_\Omega (z_h - w_h) : s_h + \int_\Omega \tau_{\text{YS}}\ \|z_h\| - \int_\Omega \tau_{\text{YS}}\ \|w_h\| + \sum_{i=1}^{n} r_i \int_{K_i} [w_h - \dot{\varepsilon}(u_h)] : [z_h - w_h] \geq 0 \qquad \forall z_h \in \mathbf{W}_h,$$

(ii) $\mathrm{A}\,\mathbf{u}_h - \mathrm{D}\,\mathbf{w}_h - \mathrm{B}^{\,t}\mathbf{p}_h + \mathrm{D}\,\mathbf{s}_h = \mathbf{f}$,

(iii) $\mathrm{B}\,\mathbf{u}_h + \mathrm{C}\,\mathbf{p}_h = 0$,

(iv) $\mathrm{D}\,\mathbf{u}_h - \mathrm{E}_w\mathbf{w}_h = 0$,

where, in the last three relations, the expressions typed in boldface stand for usual finite element vectors of degrees of freedom and the discrete operators are obtained by using the standard finite element process. With the particular discrete spaces used here, a suitable choice of the parameters r_i leads to $\mathrm{A} = r_1 \mathrm{D}\,\mathrm{E}_w^{-1}\mathrm{D}$, where r_1 is a positive augmentation parameter and E_w is the strain rates mass matrix.

Finally, we simulate an augmentation relative to the divergence constraint by premultiplying the equation (iii) by $r_2 \mathrm{B}^{\,t}\mathrm{E}_p^{-1}$, with E_p the lumped pressure mass matrix, and adding the obtained relation to equation (ii). The final system reads as follows:

(4.3)

(i) Find $w_h \in \mathbf{W}_h$ such that

$$\int_\Omega 2\mu\ w_h : (z_h - w_h) - \int_\Omega (z_h - w_h) : s_h + \int_\Omega \tau_{\text{YS}}\ \|z_h\| - \int_\Omega \tau_{\text{YS}}\ \|w_h\| + \sum_{i=1}^{n} r_i \int_{K_i} [w_h - \dot{\varepsilon}(u_h)] : [z_h - w_h] \geq 0 \qquad \forall z_h \in \mathbf{W}_h,$$

(ii) $(r_1 \mathrm{D}\,\mathrm{E}_w^{-1}\mathrm{D} + r_2 \mathrm{B}^{\,t}\mathrm{E}_p^{-1}\mathrm{B})\mathbf{u}_h - \mathrm{C}\,\mathbf{w}_h + (r_2 \mathrm{B}^{\,t}\mathrm{E}_p^{-1}\mathrm{C} - \mathrm{B}^{\,t})\mathbf{p}_h + \mathrm{D}\,\mathbf{s}_h = \mathbf{f}$,

(iii) $\mathrm{B}\,\mathbf{u}_h + \mathrm{C}\,\mathbf{p}_h = 0$,

(iv) $\mathrm{D}\,\mathbf{u}_h - \mathrm{E}_w\mathbf{w}_h = 0$.

This last algebraic manipulation does not change the properties of the system.

Thanks to the particular structure of the approximation space $\mathbf{W}_h$, the variational inequality (i) of (4.3) degenerates to a family of scalar minimization problems that

admit an explicit solution for $\mathbf{w}_h$ as a function of the other unknowns $\mathbf{u}_h$ and $\mathbf{s}_h$:

$$\text{For } 1 \le i \le n$$

$$\left| \begin{array}{ll} \text{if } \|\sigma_i\| < \tau_{\text{YS}}, & \mathbf{w}_{hi} = 0, \\ \text{if } \|\sigma_i\| < \tau_{\text{YS}}, & \mathbf{w}_{hi} = \dfrac{1 - \tau_{\text{YS}}/\|\sigma_i\|}{2(\mu + r_1/2)}\ \sigma_i, \end{array} \right. \tag{4.4}$$

$$\text{where } \sigma_i = \mathbf{s}_{hi} + \frac{r_1}{meas(K_i)} \int_{K_i} \dot{\varepsilon}(\mathbf{u}_h).$$

The nonlinear system is solved by an Uzawa-like algorithm that reads as follows:

$\mathbf{u}_h^{n-1}, \mathbf{w}_h^{n-1}, \mathbf{p}_h^{n-1}, \mathbf{s}_h^{n-1}$ being known,

(1) compute $\mathbf{u}_h^n$ as a function of $\mathbf{w}_h^{n-1}, \mathbf{p}_h^{n-1}, \mathbf{s}_h^{n-1}$ by (ii),

(2) compute $\mathbf{w}_h^n$ as a function of $\mathbf{u}_h^n, \mathbf{s}_h^{n-1}$ by (4.4),

(3) compute $\mathbf{p}_h^n$ and $\mathbf{s}_h^n$ by

$$\left| \begin{array}{l} \left(\dfrac{1}{\rho_2}\mathrm{E}_p + \mathrm{C}\right)\ \mathbf{p}_h^n = \dfrac{1}{\rho_2}\mathrm{E}_p\ \mathbf{p}_h^{n-1} - \mathrm{B}\,\mathbf{u}_h^n, \\ \dfrac{1}{\rho_1}\mathrm{E}_w\ \mathbf{s}_h^n = \dfrac{1}{\rho_1}\mathrm{E}_w\ \mathbf{s}_h^{n-1} - (\mathrm{D}\,\mathbf{u}_h^n - \mathrm{E}_w \mathbf{w}_h^n). \end{array} \right. \tag{4.5}$$

We have the following convergence results.

THEOREM 4.2. *Algorithm* (4.5) *converges to a solution of the system* (4.3)*, provided the following condition holds:*

$$\rho_1 < \frac{1+\sqrt{5}}{2}\ r_1 \qquad \textit{and} \qquad \rho_2 < 2r_2.$$

Proof. The proof of this theorem is obtained by minor modifications of the convergence study of the standard algorithm (i.e., without regularization term) that can be found in [3]. This development closely follows the seminal work of Fortin and Glowinski [8], [10]. □

5. Numerical experiment. In this section we are interested in the numerical validation of the proven error estimates against a particular problem that admits an explicit solution. We will see that, under particular regularity assumptions verified by the problem being considered, the convergence proof of section 2 can yield an improvement of the convergence rate to $h|\log(h)|^{1/2}$; this error bound is then confirmed by numerical experiments.

5.1. Position of the test problem. To our knowledge, no problem admitting an analytic solution and set on a general multidimensional polygonal domain is found in the literature. As an alternative, we consider an axisymmetrical problem, treated in the following as a fully bidimensional one: the tangential flow of a Bingham fluid in a viscosimeter made of two coaxial cylinders. The inner cylinder of radius $r_{inn} = 0.5$ is kept fixed, whereas a constant angular velocity $W = 1$ is imposed on the outer cylinder (radius $r_{out} = 1$). Finally, the fluid is assumed to stick to the apparatus boundaries, and we recall here the problem solution [2, section 4.5]. As the plasticity

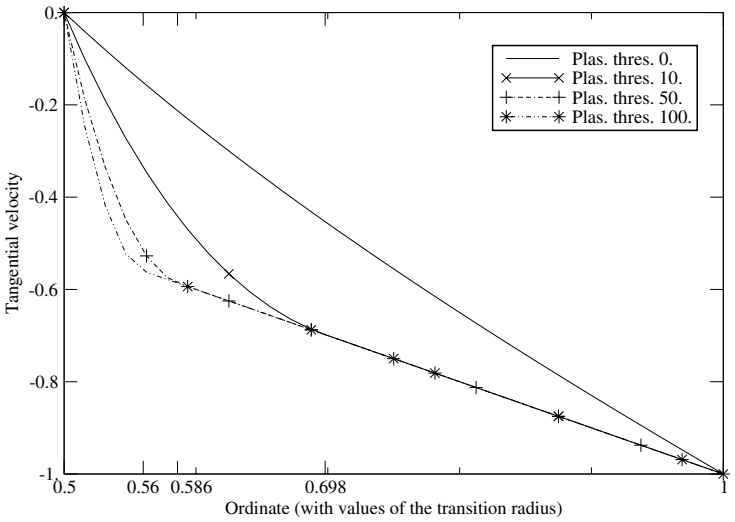

FIG. 5.1. *Tangential velocity at* $(x = 0, y \in [0.5; 1])$*, analytical solution.*

threshold increases, a rigid zone appears near the outer cylinder. The transition radius r_{tra} between the "flow" region and the "rigid" zone obeys the nonlinear equation

$$(2r_{tra})^2 - 2\ln(2r_{tra}) - 2\sqrt{2}\frac{\mu}{\tau_{\text{YS}}} = 1, \tag{5.1}$$

and the following tangential velocity and pressure are solution to the problem:

$$\begin{aligned}
&\text{if } r \geq r_{tra}, && v_\theta(r) = r;\\
&\text{if } r < r_{tra}, && v_\theta(r) = r\left[1 + \frac{\sqrt{2}\tau}{2\mu}\left(\frac{1}{2} - \frac{1}{2}\left(\frac{r_{tra}}{r}\right)^2 + ln\left(\frac{r_{tra}}{r}\right)\right)\right];\\
&r_{inn} \leq r \leq r_{out}, && p = 0.
\end{aligned}$$

This analytical solution has been plotted for various plasticity threshold values in Figure 5.1.

5.2. An improved error estimate for the particular problem at hand. We begin with a technical lemma.

LEMMA 5.1. *Let* u *and* v *be two nonzero vectors of* $\mathbb{R}^d$*. The following relation holds:*

$$\|v\| - \|u\| = \frac{u}{\|u\|}.(v-u) + \frac{\|v-u\|^2 - \left[\frac{u}{\|u\|}.(v-u)\right]^2}{\|v\| + \frac{u}{\|u\|}.v}.$$

The solution u of the problem under consideration is continuous and belongs to the Sobolev space $[\mathbf{W}^{2,\infty}(\Omega)]^d$ of fields whose components' first and second derivatives are essentially bounded. As a consequence, the Lagrangian interpolate of u, $r_h u$ is well defined and the following estimates hold:

$$\|u - r_h u\|_{1,\infty} \leq c\ h\ |u|_{2,\infty}, \tag{5.2}$$

where $c_{\rm a}$ is a positive constant independent of the discretization step h.

For the particular problem at hand, we will prove the following improved error estimate.

PROPOSITION 5.2. *For a sufficiently small discretization step h, the numerical solution of the problem is such that*

$$\|u - u_h\|_1 \leq c\ \tau_{\rm YS}^{1/2}\ h\ |\log(h)|^{1/2},$$

where c is a positive constant dependent on the solution u but independent of h.

Proof. To obtain the preceding estimate, it is sufficient to prove that, for h small enough, the following relation holds:

$$j(2u - r_h u) + j(r_h u) - 2j(u) \leq c\ \tau_{\rm YS}\ h^2\ |\log(h)|.$$

By definition, the left-hand member of this inequality reads as

$$(j(2u - r_h u) - j(u)) - (j(u) - j(r_h u)) = \tau_{\rm YS} \int_\Omega \|\dot\varepsilon(2u - r_h u)\| + \|\dot\varepsilon(r_h u)\| - 2\ \|\dot\varepsilon(u)\|.$$

We split this integral into three parts:

$$\begin{aligned} & 2\pi \underbrace{\int_{r_{inn}}^{r_{tra}-\gamma h} [\ \|\dot\varepsilon(2u - r_h u)\| + \|\dot\varepsilon(r_h u)\| - 2\ \|\dot\varepsilon(u)\|\ ]\ r\ dr}_{\rm (i)} \\ + \quad & 2\pi \underbrace{\int_{r_{tra}-\gamma h}^{r_{tra}+h} [\ \|\dot\varepsilon(2u - r_h u)\| + \|\dot\varepsilon(r_h u)\| - 2\ \|\dot\varepsilon(u)\|\ ]\ r\ dr}_{\rm (ii)} \\ + \quad & 2\pi \underbrace{\int_{r_{tra}+h}^{r_{out}} [\ \|\dot\varepsilon(2u - r_h u)\| + \|\dot\varepsilon(r_h u)\| - 2\ \|\dot\varepsilon(u)\|\ ]\ r\ dr}_{\rm (iii)}, \end{aligned}$$

where γ is a positive parameter independent of h to be chosen later.

The three vertices of each element that intersects the integration domain of (iii) lie in the rigid zone. As the solution in this zone is linear, u and $r_h u$ are equal and $\dot\varepsilon(r_h u)$ also vanishes with $\dot\varepsilon(u)$. As a consequence, (iii) $= 0$.

By the triangular inequality for the norm in $\mathbb{R}^{d\times d}$,

$$\begin{aligned} & \|\dot\varepsilon(2u - r_h u)\| + \|\dot\varepsilon(r_h u)\| - 2\ \|\dot\varepsilon(u)\| \\ & \qquad = (\|\dot\varepsilon(2u - r_h u)\| - \|\dot\varepsilon(u)\|) - (\|\dot\varepsilon(u)\| - \|\dot\varepsilon(r_h u)\|) \\ & \qquad \leq \|\dot\varepsilon(2u - r_h u) - \dot\varepsilon(u)\| + \|\dot\varepsilon(u) - \dot\varepsilon(r_h u)\| \\ & \qquad = 2\ \|\dot\varepsilon(u) - \dot\varepsilon(r_h u)\|. \end{aligned}$$

As a consequence of the approximation inequality (5.2), the following pointwise estimate holds:

$$\|\dot\varepsilon(u) - \dot\varepsilon(r_h u)\|_{0,\infty} \leq c_{\rm a}\ h\ |u|_{2,\infty}$$

and

$$\text{(ii)} \leq c\ h|u|_{2,\infty} \int_{r_{tra}-\gamma h}^{r_{tra}+h} r dr \leq c\ |u|_{2,\infty}\ (r_{tra} + h)\ (\gamma + 1)\ h^2.$$

For $r \leq r_{tra}$, the solution u is such that

$$\|\dot{\varepsilon}(u)\| \geq c_{\mathrm{e}}\ (r_{tra} - r) \qquad \text{with} \quad c_{\mathrm{e}} = \max\left(1, \frac{\sqrt{2}\ \tau_{\mathrm{YS}}}{\mu}\right)\ \frac{r_{tra} + r_{inn}}{r_{tra}^2}. \tag{5.3}$$

As a consequence of the approximation inequality (5.2) and the triangular inequality for the Euclidean norm of $\mathbb{R}^{d\times d}$, for a value of the parameter γ such that $c_{\mathrm{e}}\gamma > c_{\mathrm{a}}\ |u|_{2,\infty}$,

$$\left.\begin{array}{l} \|\dot{\varepsilon}(r_h u)\| > 0 \\ \|\dot{\varepsilon}(2u - r_h u)\| > 0 \end{array}\right| \quad \forall r \in [r_{inn}, r_{tra}].$$

We choose the following value for γ:

$$\gamma = 2\ \frac{c_{\mathrm{a}}\ |u|_{2,\infty}}{c_{\mathrm{e}}}. \tag{5.4}$$

This choice is possible for a value of h such that $\gamma h < r_{tra} - r_{inn}$. Lemma 5.1 then applies, and

$$\begin{aligned} \text{(i)} \quad &= \int_{r_{inn}}^{r_{tra}-\gamma h} [(\|\dot{\varepsilon}(2u - r_h u)\| - \|\dot{\varepsilon}(u)\|) - (\|\dot{\varepsilon}(u)\| - \|\dot{\varepsilon}(r_h u)\|)]\ r\ dr \\ &= \int_{r_{inn}}^{r_{tra}-\gamma h} \left[\left(\frac{\dot{\varepsilon}(u)}{\|\dot{\varepsilon}(u)\|} : \dot{\varepsilon}(u - r_h u) + \frac{N(u, r_h u)}{D_1(u, r_h u)}\right)\right. \\ &\qquad \left. - \left(\frac{\dot{\varepsilon}(u)}{\|\dot{\varepsilon}(u)\|} : \dot{\varepsilon}(u - r_h u) + \frac{N(u, r_h u)}{D_2(u, r_h u)}\right)\right]\ r\ dr, \end{aligned}$$

where

$$N(u, r_h u) = \|\dot{\varepsilon}(u) - \dot{\varepsilon}(r_h u)\|^2 + \left[\frac{\dot{\varepsilon}(u)}{\|\dot{\varepsilon}(u)\|} : (\dot{\varepsilon}(u) - \dot{\varepsilon}(r_h u))\right]^2,$$

$$D_1(u, r_h u) = \|\dot{\varepsilon}(2u) - \dot{\varepsilon}(r_h u)\| + \left[\frac{\dot{\varepsilon}(u)}{\|\dot{\varepsilon}(u)\|} : [\dot{\varepsilon}(2u) - \dot{\varepsilon}(r_h u)\right],$$

$$D_2(u, r_h u) = \|\dot{\varepsilon}(r_h u)\| + \frac{\dot{\varepsilon}(u)}{\|\dot{\varepsilon}(u)\|} : \dot{\varepsilon}(r_h u).$$

By the approximation inequality (5.2), we then get

$$|N(u, r_h u)| \leq c\ h^2\ |u|_{2,\infty} \qquad \forall r \in [r_{inn}, r_{tra} - \gamma h]$$

and, by the triangular inequality for the Euclidean norm of $\mathbb{R}^{d\times d}$,

$$|D_1(u, r_h u) - 2\ \|\dot{\varepsilon}(u)\|| \leq 2\ \|\dot{\varepsilon}(u) - \dot{\varepsilon}(r_h u)\|.$$

Inequality (5.3) then implies, with the particular choice for γ given by (5.4),

$$|D_1(u, r_h u)| < 2c_{\mathrm{e}}\ \left(\left(r_{tra} - \frac{\gamma}{2}\ h\right) - r\right) \qquad \forall r \in [r_{inn}, r_{tra} - \gamma h].$$

Consequently,

$$\begin{aligned} \int_{r_{inn}}^{r_{tra}-\gamma h} \frac{N(u, r_h u)}{D_1(u, r_h u)}\ r\ dr &\leq c\ h^2\ |u|_{2,\infty} \int_{r_{inn}}^{r_{tra}-\gamma h} \frac{1}{(r_{tra} - \frac{\gamma}{2}\ h) - r}\ r\ dr \\ &\leq c\ h^2\ \log\left(\frac{\gamma}{2}\ h\right). \end{aligned}$$

A similar estimate of the second part of (i) follows, applying the same arguments. □

Remark. The regularity of the solution of the problem under consideration is far beyond what can be expected in the general case. However, arguments similar to those employed in the preceding proof may extend to a wide range of practical situations, where, in particular, regularity of the rigid zones boundaries, often suggested a posteriori by numerical results, can be conjectured.

5.3. Numerical tests. The whole domain has been meshed with triangles; see, for example, a coarse mesh in Figure 5.2. Each mesh is used to build a finer one by cutting each of its right triangles into four right triangles of equal size. In Figure 5.3, we present the velocity cuts for various values of the meshing parameter. h_0 corresponds to a coarser mesh than the mesh presented in Figure 5.2, as it has only two layers of triangles in the radial direction.

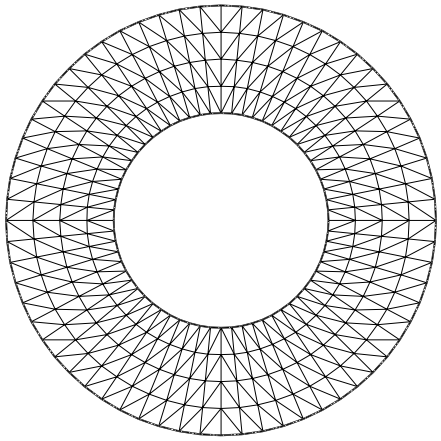

FIG. 5.2. *Coarse mesh.*

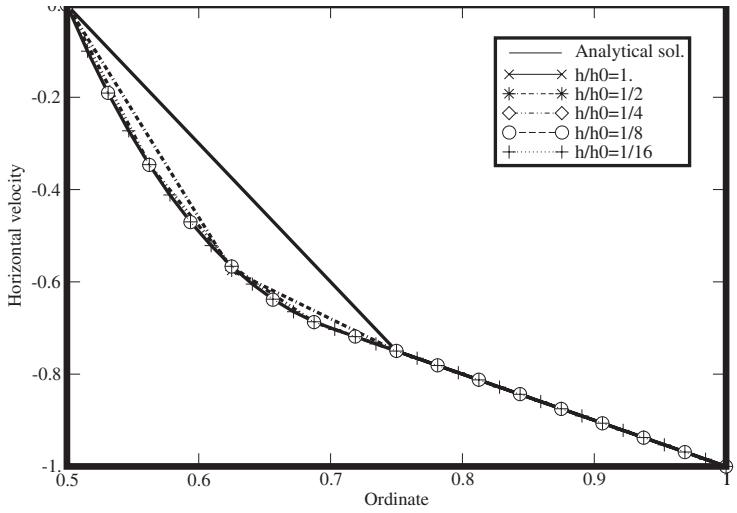

FIG. 5.3. *Velocity cuts for various meshing parameters,* $\tau_{YS} = 10Mpa$.

The $\mathcal{H}_1$ estimates for the velocity are drawn on Figure 5.4 as a function of the meshing parameter for various values of the plasticity threshold. One can observe that in this specific case the estimate is of order $O(h)$, thus confirming the preceding analysis.

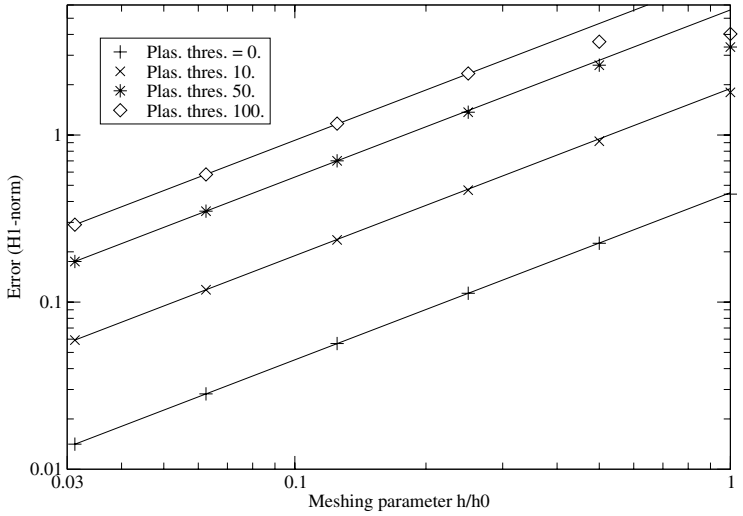

FIG. 5.4. *Error bound versus meshing parameter for various plasticity thresholds,* H1-norm.

6. Conclusion. We have proposed and analyzed in this paper a stabilized finite element scheme for the computation of incompressible creeping flows of Bingham fluids, using equal-order piecewise linear approximations for both velocity and pressure. This numerical scheme has shown several advantages due to the low degree of the velocity approximation: its convergence rate is the same as equivalent stable schemes, with an improved efficiency; in addition, the decomposition-coordination method can be used with a perfect matching of the consistency constraint between the auxiliary variable, namely the strain rate tensor, and the velocity field.

This numerical method can be extended straightforwardly to noncreeping Bingham flows using a characteristic-Galerkin strategy. Some results obtained in this way have been published in [18].

Acknowledgments. This work was performed at the French Institut de Radioprotection et Sûreté Nucléaire (IRSN), in the framework of reactor safety modeling activities. Developments were implemented in C++ as an application of PELICANS, an object-oriented platform developed by our team to provide general frameworks and software components for the implementation of PDE solvers.

ON THE CONSTRUCTION AND ANALYSIS OF HIGH ORDER LOCALLY CONSERVATIVE FINITE VOLUME-TYPE METHODS FOR ONE-DIMENSIONAL ELLIPTIC PROBLEMS*

MICHAEL PLEXOUSAKIS† AND GEORGIOS E. ZOURARIS‡

Abstract. Locally conservative, finite volume-type methods based on continuous piecewise polynomial functions of degree $r \geq 2$ are introduced and analyzed in the context of indefinite elliptic problems in one space dimension. The new methods extend and generalize the classical finite volume method based on piecewise linear functions. We derive a priori error estimates in the L^2, H^1, and L^∞ norm and discuss superconvergence effects for the error and its derivative. Explicit, residual-based a posteriori error bounds in the L^2 and energy norm are also derived. We compute the experimental order of convergence and show the results of an adaptive algorithm based on the a posteriori error estimates.

Key words. elliptic problems, finite volume methods, locally conservative methods, a priori error estimates, superconvergence, a posteriori error estimates, adaptive computations

1. Introduction.

1.1. Locally conservative and finite volume methods. Let $\Omega = (x_L, x_R)$ be a bounded interval and consider the following two-point boundary value problem: seek $u : \overline{\Omega} \to \mathbb{R}$ satisfying

$$Lu \equiv -(a(x)u')' + \beta(x)u' + \gamma(x)u = f(x) \quad \forall\, x \in \Omega, \tag{1.1a}$$

$$u(x_L) = u'(x_R) = 0, \tag{1.1b}$$

where a, β, γ, f are smooth, real-valued functions defined on $\overline{\Omega}$, and

$$0 < a_* \leq a(x) \quad \forall\, x \in \overline{\Omega}. \tag{1.1c}$$

We assume that (1.1) has a unique solution which is sufficiently smooth. In what follows, we shall operate under the assumptions that $f \in H^m(\Omega)$, $a \in C^{m+1}(\overline{\Omega})$, and $\beta, \gamma \in C^m(\overline{\Omega})$ for some $m \in \mathbb{N}$, which ensure that $u \in H^{m+2}(\Omega)$ (see, e.g., [1], [22]). The assumption (1.1c) ensures the strict ellipticity of L in the sense of [1] or [22].

Integrating (1.1a) over a subinterval $\omega = (\omega_L, \omega_R)$ of Ω we obtain

$$\mathcal{F}(u, \omega) \equiv -\big[(au')(\omega_R^-) - (au')(\omega_L^+)\big] + \int_\omega (\beta u' + \gamma u)\, dx - \int_\omega f\, dx = 0, \tag{1.2a}$$

which, when $\omega_R = x_R$, is written as

$$\mathcal{G}(u, \omega) \equiv (au')(\omega_L^+) + \int_\omega (\beta u' + \gamma u)\, dx - \int_\omega f\, dx = 0, \tag{1.2b}$$

due to the Neumann boundary condition (1.1b). When $\beta = \gamma = 0$ the relations (1.2a)–(1.2b) express a local *conservation* property for the solution of (1.1a)–(1.1b). The physical interpretation of this property depends on the situation where the equation is used as a model. For example, considering (1.1) as the steady state of a heat flow problem in a rod Ω, the property (1.2a) expresses the conservation of the thermal energy in a part ω of the rod.

A *locally conservative finite volume-type method* (or simply, *locally conservative method*) approximates the solution u of (1.1a)–(1.1b) by a function u_h, in a given finite element space X_h, that satisfies (1.2a) or (1.2b) on the subintervals of a covering $\{\Omega_j\}_{j=1}^{M_h}$ of Ω, where M_h depends on the dimension of X_h. We shall say that a locally conservative method for (1.1) is a *finite volume method* if the approximation $u_h \in X_h$ is entirely determined by the fulfillment of (1.2a) and/or (1.2b) on the subintervals $\{\Omega_j\}_{j=1}^{M_h}$. In the context of finite volume methods, the subintervals $\{\Omega_j\}_{j=1}^{M_h}$ are known as *control volumes* and we shall use the same terminology even in the case of locally conservative methods. If u_h satisfies (1.2a) (resp., (1.2b)) on a boundary subinterval $\omega = (\omega_L, x_R)$, then we shall say that ω is a boundary control volume of type I (resp., type II). A consequence of the above definition is that a locally conservative method requires less computational effort to assemble the matrix of the resulting linear system and the right-hand side, compared to the standard finite element method. In particular, the stiffness matrix (i.e., the part of the system matrix related to a) in the finite volume method does not require numerical quadrature.

The finite volume method has wide applicability in the approximation of solutions of hyperbolic equations of conservation laws (see, e.g., [30], [23], [26] and the references therein). These equations contain a term in space-divergence form and therefore a local conservation property, analogous to (1.2a), holds. The interest in extending the finite volume method to elliptic problems arises from the need to treat a second-order, regularizing viscosity term (e.g., a Laplacian), which is also written in space-divergence form. However, the finite volume method has also had early applications in the approximation of solutions of elliptic equations (see, e.g., [32]). In the bibliography, the proposed locally conservative methods for the approximation of solutions of elliptic problems are, mainly, of the finite volume type, and X_h consists of either piecewise constant functions (see, e.g., [21]), piecewise linear functions (see, e.g., [5], [24], [11], [10]), or piecewise quadratic functions [31]. The piecewise constant finite volume approach has a well developed theoretical background and wide applicability, and for some applications (e.g., digital image processing) is probably the most natural (see, e.g., [21], [34]). Variants of the finite volume method on piecewise linear functions, where (1.2a) is not satisfied, have also been proposed (see, e.g., [8], [24], [14]). Similar in spirit are the generalized finite difference schemes analyzed in, e.g., [29] or [39], which are based on Steklov averaging operators. Recently, the locally discontinuous Galerkin method (LDG) has been introduced (see, e.g., [12], [4]) with the aim of constructing approximations of solutions of elliptic problems in one or two space dimensions that have local conservation properties. The main idea in these methods is to rewrite the elliptic problem as a first-order system for the unknowns u and u' (or ∇u). Then the method constructs approximations $u_h \in X_h$ and $q_h \in X_h$ (or $q_h \in (X_h)^2$) of u and u' (or ∇u) in a finite element space X_h consisting of discontinuous functions. From the corresponding variational formulation follows that q_h has a local conservation property resembling (1.2a). In contrast, in the locally conservative methods investigated in this paper, the finite element space X_h consists of continuous functions and an approximation $u_h \in X_h$ is sought which, along with its derivative, satisfies the balance equation (1.2a).

As the references cited above indicate, a great deal of attention has been given to the construction and analysis of finite volume methods for elliptic problems in two space dimensions. The main tool in that analysis is the early idea (cf. [33]) to connect (1.2a) with a variational formulation similar to that of the finite element method (cf., e.g., [5], [24], [15], [14], [20]). In the piecewise linear case, and for self-adjoint or non-self-adjoint elliptic operators in two space dimensions, optimal first-order H^1 error estimates have been obtained by several authors under the regularity assumption $u \in H^2$ (cf., e.g., [5], [24], [25], [13], [35], [20]). Also, the authors of [9], [10], and [11] prove some second-order error estimates in a discrete H^1 norm. An optimal L^2 second-order error estimate for the Poisson equation is obtained by Hackbusch in [24] by assuming $u \in H^2$ and $f \in H^1$. Later, Jianguo and Shitong in [25], and Ewing, T. Lin, and Y. Lin in [20], show by examples in one and two dimensions that, in general, it is not possible to obtain optimal second-order L^2 convergence by assuming $u \in H^2$ and $f \in L^2$. Optimal order L^2 error estimates for general self-adjoint elliptic problems have been obtained by Chatzipantelidis in [13], for a nonconforming finite volume method, and by Chou and Li in [15] for a conforming one. The result in [13] relies on the assumption $u \in H^2$ and $f \in H^1$, while in [15] it is assumed that $u \in H^3$; here the second assumption is stronger because, in general, the regularity of the solution of an elliptic problem in the two-dimensional case also depends on the regularity of the boundary of the domain and not only on the regularity of the data. Analogous results are obtained in [27] for the Stokes problem and in [18], [19] for one-dimensional integro-differential equations. Recently in [20], Ewing, T. Lin, and Y. Lin show that if $f \in H^\alpha$ and $u \in H^{1+\alpha}$ for $\alpha \in (0, 1]$, then the order of the L^2 convergence of the finite volume method considered in [15] is equal to 2α. For the piecewise quadratic case, a finite volume method proposed by Liebau in [31] attains optimal, second-order convergence in the H^1 norm assuming $u \in H^3$. To the best of our knowledge, this is the only finite volume method based on piecewise polynomial functions of degree greater than one. The absence of a general theory for finite volume methods based on piecewise polynomial approximation spaces, analogous to that of the finite element method (cf., e.g., [7], [16]), is apparent.

An interesting step forward could be to find a systematic way of deriving finite volume methods for elliptic problems, based on finite element spaces X_h consisting of functions which are piecewise polynomials of degree greater than one. The main difficulty in achieving this goal arises from the fact that the definition of a finite volume method requires (except from the finite element space X_h) a set of control volumes with cardinal number proportional to the dimension of X_h. Hence, the control volume quest seems to be a very complicated procedure when the degree of the piecewise polynomial functions of X_h increases. It is worthwhile to notice that the choice of the control volumes may influence, apart from the well-posedness, the order of convergence of the obtained finite volume method. This phenomenon has been observed in the piecewise linear case where only special families of control volumes lead to a finite volume method which has the same order of convergence with that of the corresponding finite element method (cf. [24], [13], [15]). In the recent work of Liebau [31] the finite volume method has been extended on quadratics over a triangular mesh, but still we do not know if a finite volume method based on quadratics can attain optimal order of convergence in the L^2 norm.

1.2. Description of the results of the paper. In this paper we derive general classes of *new* optimal order, locally conservative, finite volume-type methods for the problem (1.1a)–(1.1b), based on continuous piecewise polynomial spaces of degree

$r \geq 2$. For these methods, we provide a general error estimation theory in the H^1, L^2, and L^∞ norms, analogous to that of the finite element method. Also, we discuss some pointwise error estimates for $r \geq 2$ and some a posteriori error estimates for $r = 2$.

Even though the "battlefield" of the current research in the area of the finite volume methods is the two-dimensional case, we restrict ourselves to the one-dimensional case so as to fix the ideas and gain insight into the structure of such methods. This choice came after preliminary work on the two-dimensional case. In particular, we arrived at the conclusion that, using integration rules, we may construct finite volume methods based on quadratic finite elements over a triangular mesh which are different from that of [31] and have optimal order of convergence in the H^1 norm. However, the existence of such a finite volume method with optimal order of convergence in the L^2 norm seems to be unsure. Then, we thought that we might find an answer to this question if we knew how to construct systematically finite volume methods, based on high order finite element spaces, in the one-dimensional case where the finite element geometry is simpler. The extension of the work at hand to the two-dimensional case, which is the our next step, is not straightforward because of the greater variety of the geometry of the relevant finite element spaces. However, the ideas and methods developed here may be used in two-dimensional problems when the discretization of the computational domain is achieved by rectangular elements (cf. Remark 2.2).

Before presenting a summary of the present paper, we list the basic results of our work:

- For every $r \geq 2$, we construct *locally conservative* methods for (1.1a)–(1.1b) where part of the degrees of freedoms are determined by finite element equations and the rest by equations concerning local conservativity in the mean of (1.2) (cf. Propositions 3.1–3.2). The interesting fact is that these methods have optimal order of convergence in the H^1, L^2, and L^∞ norm assuming the same regularity as in the finite element method.
- If $r = 2, 4$, or 6, we construct *finite volume* methods for (1.1a)–(1.1b) which have optimal order of convergence in the H^1, L^2, and L^∞ norm (cf. Proposition 3.7). Their control volumes are related to a dual mesh based on the roots of the well-known Legendre polynomial with degree r. Our opinion is that the technique used in deriving these finite volume methods works only for all *even* r but we are not able to provide a general proof for this fact.
- For every $r \geq 3$ we construct a general family of *finite volume* methods for (1.1a)–(1.1b) which have optimal order of convergence in the H^1 norm (cf. Proposition 3.6). Their control volumes are related to a dual mesh based on $r - 2$ arbitrary internal nodes of $[0, 1]$.

Let us present briefly the contents of the work at hand. Here, we extend and modify the framework proposed in [14] for the analysis of finite volume methods for elliptic problems in two space dimensions based on piecewise linear finite element spaces, in order to construct locally conservative methods for problem (1.1a)–(1.1b). Hence, we consider a general class of numerical methods based on continuous piecewise polynomial spaces which have a common variational formulation of the form

$$B_h(u_h, \chi) = (f, \Lambda_h \chi) \quad \text{for } \chi \in X_h, \tag{1.3}$$

where Λ_h is a linear operator defined on piecewise $\mathbb{P}^r$ functions into a finite-dimensional space consisting of piecewise polynomial functions, and B_h is a bilinear form that depends on Λ_h. The exact description of B_h is given in (2.9). We assume throughout

that the operator Λ_h satisfies (2.7), a *local* L^2 approximation property of order $\alpha \geq 1$, i.e.,

$$\| \Lambda_h v - v \|_{L^2(x_1,x_2)} \leq C\,(x_2 - x_1)^s \, \|v\|_{H^s(x_1,x_2)}, \quad s = 1, \ldots, \alpha, \tag{1.4}$$

and (2.8), a *local* error orthogonality property on $\mathbb{P}^{r-2+\sigma}$ with $\sigma = 0$ or 1, i.e.,

$$(\Lambda_h v - v, q)_{L^2(x_1,x_2)} = 0 \quad \forall q \in \mathbb{P}^{r-2+\sigma}(x_1, x_2), \tag{1.5}$$

where x_1, x_2 are consecutive nodes of a partition of Ω.

In section 3, we construct two large families of methods based on specific operators Λ_h satisfying(1.4)–(1.5), and yielding conservative equations of the form (1.2a), i.e., producing locally conservative methods. For the first family of the methods (see section 3.1) the operator Λ_h is defined as a local L^2-projection from $\mathbb{P}^r$ to $\mathbb{P}^{r-1}$ or $\mathbb{P}^{r-2}$, while for the second family of methods (see section 3.2) the operator Λ_h is defined via a special projection (see Proposition 3.5) from $\mathbb{P}^r$ to a space of piecewise constant functions. Both families of methods are infinite, with respect to the degree r of the underlying polynomial space. The methods of section 3.1 are *locally conservative* with $\alpha \geq 2$ and $\sigma = 0$ (see Proposition 3.1) or $\sigma = 1$ (see Proposition 3.2), while those of section 3.2 are of the *finite volume* type or *locally conservative* with $\alpha = 1$ and $\sigma = 0$ (see Proposition 3.6) or $\sigma = 1$ (see Proposition 3.7, Remark 3.5). In particular, for the methods of Proposition 3.1 and Proposition 3.6 we show that the discrete approximation u_h belongs to $C^1(\overline{\Omega})$ and satisfies the Neumann boundary condition at x_R. We note that the generality of the variational formulation (1.3) allows us to include as particular members, finite volume methods based on piecewise quadratic functions, where $\alpha = 1$, σ takes only the value 0, and the control volumes are related to the nodes of a quadrature rule (e.g., Simpson, Radau). The latter methods were introduced in [36] but cannot be generalized to $r \geq 3$ so that (2.8) is satisfied, and this is the reason we keep them out of our presentation. Hence, the connection of a finite volume method to a quadrature rule has a limited usefulness when $r \geq 2$.

The main result of the a priori error analysis in the L^2 and H^1 norms, for the general methods (1.3) introduced in section 2, is contained in Theorem 4.6 of section 4. There it is shown that convergence in the H^1 norm is always of optimal order r, while the optimal rate of convergence $r + 1$ in the L^2 norm is attained when $\alpha \geq 2$ or $\sigma = 1$. The latter result holds for the methods of Proposition 3.1 with $r \geq 3$, where $\alpha = r - 1$, the methods of Proposition 3.2 where $\alpha = r = 2m$, the methods of Remark 3.5 where $\alpha = 1$ and $\sigma = 1$, and finally for the *new* finite volume methods derived in Proposition 3.7 where also $\alpha = 1$ and $\sigma = 1$. The exact solution u is assumed to be in $H^{s_0}(\Omega)$, where for the H^1 estimate $s_0 = r + 1$ and for the L^2 estimate $s_0 = r + 1$ if $\alpha \geq 2$ and $s_0 = r + 1 + \sigma$ if $\alpha = 1$.

The a priori error analysis in L^∞ is carried out in section 5. We show that the methods with optimal order of L^2 convergence also attain optimal order of convergence in the L^∞ norm. Theorem 5.5 covers the case $\alpha \geq 2$ under the additional condition that Λ_h preserves piecewise linear functions which holds for the optimal order methods of section 3.1 (cf. Proposition 3.1, Proposition 3.2), while Theorem 5.7 covers the case $\alpha = 1$ and $\sigma = 1$ (cf. Proposition 3.7, Remark 3.5).

In section 6 we prove a pointwise error estimate of order $r+\alpha+\sigma-1$ at the nodes of the finite element partition (cf. Proposition 6.1). This is a superconvergence result when $\alpha \geq 3$ and $\sigma = 0$, or $\alpha \geq 2$ and $\sigma = 1$, which is the case of the locally conservative methods in Proposition 3.1 for $r \geq 4$ ($\sigma = 0$, $\alpha = r - 1$) and in Proposition 3.2 ($\sigma = 1$, $\alpha = r = 2m$). In addition, if a locally conservative approximation is C^1 at

the boundary points of a set of nonoverlapping control volumes and the boundary control volume is of type II, then we prove a general error estimate for the derivative of the error at these points (cf. Proposition 6.2, Remark 6.4). This result holds for the methods of Propositions 3.1, 3.6, and 3.7 and Remark 3.5.

The a posteriori error analysis for the case of quadratic finite element spaces is elaborated in section 7. We develop a residual-based a posteriori error analysis by extending the corresponding framework of the finite element method. In section 8 we verify numerically the convergence rates of some of the methods of section 3 and compare with the finite element method. In addition, we use the a posteriori error bounds of section 7 to construct an adaptive algorithm and test its performance by applying it to an appropriate test-problem.

2. Preliminaries and the formulation of the numerical method.

2.1. Notation and preliminaries. For $I \subset \mathbb{R}$ an open and bounded interval, $s \in \mathbb{N}_0$ and $1 \le p \le \infty$, we let $W^{s,p}(I)$ denote the Sobolev space of functions having generalized derivatives up to order s in the space $L^p(I)$. The norm of $v \in W^{s,p}(I)$ will be denoted by $\|v\|_{s,p,I} = (\sum_{j=0}^{s} \int_I |D^j v|^p \, dx)^{\frac{1}{p}}$ for $1 \le p < \infty$ and $\|v\|_{s,\infty,I} = \max_{0\le j\le s} (\operatorname{ess\,sup}_I |D^j v|)$ for $p = \infty$. We shall write $H^s(I) = W^{s,2}(I)$ and omit the index 2 from the symbol of its norm, i.e., $\|\cdot\|_{s,I} = \|\cdot\|_{s,2,I}$. $H_0^1(I)$ will denote the subspace of $H^1(I)$ consisting of functions which vanish at the endpoints of I in the sense of trace. The inner product and norm of $L^2(I)$ will be denoted by $(\cdot,\cdot)_I$ and $\|\cdot\|_{0,I}$, respectively, and the norm of $L^\infty(I)$ by $|\cdot|_{\infty,I}$. We shall also omit the index I from the norm and inner product symbols when $I = \Omega$. $C_B^s(I)$ will denote the space of $C^s(I)$-functions which, along with their classical derivatives up to order s, are continuously extensible to $\overline{I}$. Finally, we denote the restriction of L on $H^2(I)$ by L_I, so that $L \equiv L_\Omega$, and the characteristic function of I by $\mathcal{X}_I$.

The length of the interval I will be denoted by h_I. Further, if $I = (y_L, y_R)$ and $v \in L^2(I)$ is such that there exists $\delta > 0$ for which $v|_{(y_L, y_L+\delta)} \in C_B^0(y_L, y_L + \delta)$ and $v|_{(y_R-\delta, y_R)} \in C_B^0(y_R - \delta, y_R)$, we shall write $[\![v]\!]_{\partial I} = v(y_R - 0) - v(y_L + 0)$. Here, and in what follows, $v(x \pm 0) = \lim_{\varepsilon\to 0^+} v(x \pm \varepsilon)$. We also let $\mathcal{H}(I) = \{v \in H^1(I) : v(y_L) = 0\}$.

For $h \in (0,1)$, let $\mathcal{P}_h$ denote a (nonuniform) partition of Ω with J_h+1 nodes, $x_L = x_0^h < x_1^h < \cdots < x_{J_h}^h = x_R$, such that $\max_{1\le j\le J_h}(x_j^h - x_{j-1}^h) \le C\,h$ for some positive constant C independent of h. We stress that this weak mesh assumption is sufficient for the error estimates of sections 4–7, and thus, a stronger mesh assumption such as quasi uniformity is not required. We shall write $I_j^h = (x_{j-1}^h, x_j^h)$ for $j = 1, \ldots, J_h$ and $x_{j+z}^h = x_j^h + z h_{I_{j+1}^h}$ for $j = 0, \ldots, J_h - 1$ and $z \in [0,1]$; furthermore, we let $x_{j-z}^h = x_{j-1+(1-z)}^h$ for $j = 1, \ldots, J_h$ and $z \in [0,1]$. Also, for $j = 1, \ldots, J_h$, we define $\xi_j^h : I_j^h \to [0,1]$ by $\xi_j^h(x) := (x - x_{j-1}^h)/h_{I_j^h}$ for $x \in I_j^h$.

For $m \in \mathbb{N}_0$, we denote by $\mathbb{P}^m(I)$ the space of polynomials of degree less than or equal to m, restricted on I, and let $\mathbb{P}_h^m = \{v \in L^2(\Omega) : v|_I \in \mathbb{P}^m(I)\ \forall\, I \in \mathcal{P}_h\}$. Letting $\mathcal{L}_m \in \mathbb{P}^m(-1,1)$ be the well-known Legendre polynomial of degree m corresponding to the weight function $w \equiv 1$ (cf., e.g., [38]), we denote by W_m its shift to $(0,1)$, i.e., $W_m \in \mathbb{P}^m(0,1)$ and $W_m(x) = \mathcal{L}_m(2x-1)$ for $x \in (0,1)$. Then W_m has m discrete roots in $(0,1)$ and satisfies $W_m(0) = (-1)^m$ and $W_m(1) = 1$. We shall also make use of the space $\mathcal{C}_h^m = \{v \in L^2(\Omega) : v|_I \in C_B^m(I)\ \ \forall\, I \in \mathcal{P}_h\}$. In addition, we introduce the space $H_h^m = \{v \in L^2(\Omega) : v|_I \in H^m(I)\ \ \forall\, I \in \mathcal{P}_h\}$ and equip it with the mesh-dependent norm $\|v\|_{m,h} = \{\sum_{I\in\mathcal{P}_h} \|v\|_{m,I}^2\}^{\frac{1}{2}}$ for $v \in H_h^m$.

We shall seek approximations of the solution u of (1.1a)–(1.1b) in the space S_h^r, $r \geq 2$, of continuous functions which vanish at $x_{_L}$ and reduce to polynomials of degree less than or equal to r on each $I \in \mathcal{P}_h$, i.e., $S_h^r = \mathbb{P}_h^r \cap \mathcal{H}(\Omega)$. Since the polynomial spaces, restricted to I, have finite dimension, all the norms are equivalent but the constants depend on h_I. In particular, the following *local inverse property* holds (see, e.g., [7, section 4.5]): there exists a constant $C = C(r)$, independent of h, such that for $0 \leq m \leq \ell \leq r$

$$\|\chi\|_{\ell,I} \leq C\, h_I^{m-\ell} \|\chi\|_{m,I} \quad \forall\, I \in \mathcal{P}_h, \quad \forall\, \chi \in \mathbb{P}_h^r. \tag{2.1}$$

For $v \in \mathcal{C}_h^0$ and $m \in \mathbb{N}$, we denote by $\mathcal{I}_h^m v$ the Lagrange interpolant of v, i.e., the unique function of $\mathbb{P}_h^m$ which, for $j = 0, \ldots, J_h - 1$, satisfies $(\mathcal{I}_h^m v - v)(x^h_{j+\frac{k}{m}}) = 0$, $k = 1, \ldots, m-1$, $(\mathcal{I}_h^m v - v)(x_j^h + 0) = 0$, and $(\mathcal{I}_h^m v - v)(x_{j+1}^h - 0) = 0$. It is well known (cf., e.g., [7, section 4.4]) that $\mathcal{I}_h^m$ possesses the following approximation properties:

$$\sum_{s=0}^{m} h_I^s \, \|\mathcal{I}_h^m v - v\|_{s,I} \leq \widetilde{C}_m \, h_I^{m+1} \, \|v\|_{m+1,I} \quad \forall\, v \in H^{m+1}(I), \quad \forall\, I \in \mathcal{P}_h, \tag{2.2}$$

$$|\mathcal{I}_h^m v - v|_{\infty,I} \leq \widetilde{C}_{\infty,m} \, h_I^{m+1} \, \|v\|_{m+1,\infty,I} \quad \forall\, v \in W^{m+1,\infty}(I), \quad \forall\, I \in \mathcal{P}_h, \tag{2.3}$$

$$\|\mathcal{I}_h^1 v - v\|_{0,I} \leq h_I \, \|v\|_{1,I} \quad \forall\, v \in H^1(I), \quad \forall\, I \in \mathcal{P}_h. \tag{2.4}$$

We shall also make use of the L^2-projection operator Π_h on $\mathbb{P}_h^0$, defined by

$$(\Pi_h v, q) = (v, q) \quad \forall\, q \in \mathbb{P}_h^0, \quad \forall\, v \in L^2(\Omega).$$

It is easy to show that $\Pi_h v|_I = \frac{1}{h_I} \int_I v \, dx \;\forall\, I \in \mathcal{P}_h$, $\forall\, v \in L^2(\Omega)$, and

$$\|v - \Pi_h v\|_{0,I} \leq h_I \, \|v'\|_{0,I} \quad \forall\, I \in \mathcal{P}_h, \quad \forall\, v \in H_h^1, \tag{2.5}$$

$$|v - \Pi_h v|_{\infty,I} \leq h_I \, |v'|_{\infty,I} \quad \forall\, I \in \mathcal{P}_h, \quad \forall\, v \in \mathcal{C}_h^1. \tag{2.6}$$

2.2. A variational formulation of the method: The parameters $\boldsymbol{\alpha}$ and $\boldsymbol{\sigma}$. In this section we formulate a family of numerical methods for the approximation of the solution of (1.1a)–(1.1b) from the finite element space S_h^r, $r \geq 2$, which are generalizations of the standard Galerkin method. As we shall see later in section 3, we can define *finite volume* and general *locally conservative* methods as particular members of this family. A similar approach has been introduced in [14] for the analysis of finite volume element methods based on piecewise linear functions and applied to two-dimensional linear elliptic problems.

The basic ingredient in the definition of our numerical methods is a linear operator $\Lambda_h \colon \mathbb{P}_h^r \to L^2(\Omega)$, satisfying the following stability- and consistency-like assumptions:

$$\exists\, \alpha \in \mathbb{N} : \; \|\Lambda_h v - v\|_{0,I} \leq \widehat{C}_{r,s} \, h_I^s \, \|v\|_{s,I} \quad \forall\, I \in \mathcal{P}_h, \quad s = 1, \ldots, \alpha, \; \forall\, v \in \mathbb{P}_h^r, \tag{2.7}$$

$$\exists\, \sigma \in \{0, 1\} : \; (\Lambda_h v - v, q)_I = 0 \quad \forall\, q \in \mathbb{P}^{r-2+\sigma}(I), \quad \forall\, I \in \mathcal{P}_h, \; \forall\, v \in \mathbb{P}_h^r. \tag{2.8}$$

A discrete variational formulation of (1.1a)–(1.1b) is then defined as follows: for $h \in (0, 1)$ we seek $u_h \in S_h^r$ such that

$$B_h(u_h, \chi) = (f, \Lambda_h \chi) \quad \forall\, \chi \in S_h^r, \tag{2.9}$$

where the bilinear form $B_h : H_h^2 \times \mathbb{P}_h^r \to \mathbb{R}$ is defined as

$$B_h(v, \chi) = \sum_{I \in \mathcal{P}_h} \left\{ [\![a v' \chi]\!]_{\partial I} + (L_I v, \Lambda_h \chi)_I \right\} \quad \forall\, v \in H_h^2, \quad \forall\, \chi \in \mathbb{P}_h^r.$$

That the method (2.9) is well defined is discussed later, in Proposition 4.4. However, the consistency of the method (2.9) is straightforward. Indeed, the solution $u \in H^2(\Omega)$ of (1.1) satisfies $B_h(u,\chi) = (f, \Lambda_h\chi)$ for $\chi \in S_h^r$, since $u', \chi \in H^1(\Omega) \subset C(\overline{\Omega})$. Thus we arrive at

$$B_h(u - u_h, \chi) = 0 \quad \forall\, \chi \in S_h^r, \tag{2.10}$$

which is analogous to the orthogonality property of the finite element method. Note also that in the standard Galerkin finite element method we seek $\widetilde{u}_h \in S_h^r$ such that $B(\widetilde{u}_h, \chi) = (f, \chi)\ \forall\, \chi \in S_h^r$, where

$$B(v,\chi) = \sum_{I \in \mathcal{P}_h} \left\{ (av', \chi')_I + (\beta v', \chi)_I + (\gamma v, \chi)_I \right\} \quad \forall\, v, \chi \in H_h^1.$$

Using integration by parts we obtain the fundamental, for the error estimation, identity

$$B_h(v,\chi) = B(v,\chi) + \sum_{I \in \mathcal{P}_h} (L_I v, \Lambda_h\chi - \chi)_I \quad \forall\, v \in H_h^2, \quad \forall\, \chi \in \mathbb{P}_h^r, \tag{2.11}$$

relating the bilinear forms of the finite element and the locally conservative methods. Thus, the standard Galerkin finite element method and (2.9) coincide when we choose $\Lambda_h\chi = \chi$, for $\chi \in \mathbb{P}_h^r$.

REMARK 2.1. *Let us consider the two-point boundary value problem*

$$-(\widehat{a}(x)\,\widehat{u}' - \widehat{\beta}(x)\,\widehat{u})' + \widehat{\gamma}(x)\,\widehat{u} = \widehat{f}(x)\ \forall\, x \in \Omega, \quad \widehat{u}(x_L) = \widehat{u}'(x_R) = 0, \tag{2.12}$$

where $\inf_\Omega \widehat{a} > 0$, $\widehat{a}, \widehat{\beta} \in C^1(\overline{\Omega})$, $\widehat{\gamma} \in C^0(\overline{\Omega})$, *and* $\widehat{f} \in L^2(\Omega)$. *We can construct an approximation* $\widehat{u}_h \in S_h^r$ *of the solution* $\widehat{u}$ *by writing* (2.12) *in the equivalent form* (1.1a) *with* $a = \widehat{a}$, $\beta = \widehat{\beta}$, $\gamma = \widehat{\gamma} + \widehat{\beta}'$ *and applying method* (2.9). *Next, let us also assume that* (2.9) *is locally conservative with control volumes* $\omega \in \mathcal{V}$. *Then* $-[\![\widehat{a}\,\widehat{u}_h']\!]_{\partial\omega} + \int_\omega (\widehat{\beta}\,\widehat{u}_h' + \gamma\,\widehat{u}_h)\,dx = \int_\omega \widehat{f}\,dx$ *for* $\omega \in \mathcal{V}$. *Since* $\widehat{\beta}\,\widehat{u}_h \in H^1(\Omega)$ *we obtain* $-[\![\widehat{a}\,\widehat{u}_h' - \widehat{\beta}\,\widehat{u}_h]\!]_{\partial\omega} + \int_\omega \widehat{\gamma}\,\widehat{u}_h\,dx = \int_\omega \widehat{f}\,dx$ *for* $\omega \in \mathcal{V}$. *If* ω *is a boundary control volume of type* II *we have* $(\widehat{a}\,\widehat{u}_h')(\omega_L^+) + [\![\widehat{\beta}\,\widehat{u}_h]\!]_{\partial\omega} + \int_\omega \widehat{\gamma}\,\widehat{u}_h\,dx = \int_\omega \widehat{f}\,dx$, *where* ω_L *is the left endpoint of* ω. *Hence, if the method* (2.9) *is locally conservative for the problem* (1.1a)–(1.1b), *then we can use it to derive locally conservative approximations of problem* (2.12), *which is the conservative form of* (1.1a)–(1.1b).

REMARK 2.2. *In a two-dimensional setting, the derivation of a high order, locally conservative method requires that the term* $[\![av'\chi]\!]_{\partial I}$ *in the definition of* $B_h(v,\chi)$ *be replaced by* $\int_\tau A\nabla v \cdot n\, Q_h\chi\,dS$, *where* A *is the diffusion matrix of the elliptic problem,* τ *is an element of a partition of the domain* Ω, *and* Q_h *is some appropriate operator with properties analogous to those of* Λ_h (*cf.* [14] *for finite volume methods based on piecewise linear functions*). *In the case of triangular elements it is not obvious how to construct an operator* Q_h *yielding locally conservative methods with optimal order convergence properties. In the case where the discretization of the computational domain is achieved by rectangular elements, it seems possible to construct such an operator* Q_h *using the techniques of the present work.*

3. Examples of locally conservative methods. In this section, for $r \geq 2$, we provide examples of operators $\Lambda_h : \mathbb{P}_h^r \to L^2(\Omega)$ satisfying the assumptions (2.7)–(2.8) and yielding locally conservative methods based on S_h^r. We note that for $r = 2$ we can construct locally conservative and finite volume methods using *quadrature rules* exact for polynomials of degree at least two (cf. [36] for details). These methods, however, cannot be generalized to $r \geq 3$ so that (2.8) is satisfied.

3.1. Methods based on local L^2 projections. We present here some locally conservative methods on S_h^r based on a local L^2 projection of $\mathbb{P}^r$ onto $\mathbb{P}^{r-2}$ for $r \geq 2$ (cf. Proposition 3.1), or a local L^2 projection of $\mathbb{P}^r$ onto $\mathbb{P}^{r-1}$ for even $r \geq 2$ (cf. Proposition 3.2). The basic characteristic of these methods is that (2.7) holds with $\alpha \geq 2$, and thus, as we shall show later in sections 4 and 5, we may obtain optimal order of convergence in the H^1, L^2, and L^∞ norm, assuming for u the same regularity as in the standard finite element method. These methods can be considered as a bridge between the finite element and the finite volume method.

PROPOSITION 3.1. *Let $r \geq 2$ and $\Lambda_h : \mathbb{P}_h^r \to \mathbb{P}_h^{r-2}$ be defined by*

$$(\Lambda_h p - p, q) = 0 \quad \forall\, q \in \mathbb{P}_h^{r-2}, \quad \forall\, p \in \mathbb{P}_h^r.$$

Then (2.7) holds with $\alpha = r-1$ and (2.8) is satisfied with $\sigma = 0$. Also, the method (2.9) is a locally conservative method on S_h^r with overlapping control volumes $\{I_j^h\}_{j=1}^{J_h}$ and $\{(x_{j-1}^h, x_{j+1}^h)\}_{j=1}^{J_h-1}$, where the interval $I_{J_h}^h$ is a boundary control volume of both types I *and* II. *Moreover, the corresponding approximation u_h belongs to $S_h^r \cap C^1(\overline{\Omega})$ and satisfies a homogeneous Neumann boundary condition at x_R.*

Proof. The definition of Λ_h immediately implies (2.8) for $\sigma = 0$. Let $I \in \mathcal{P}_h$ and $v \in \mathbb{P}^r(I)$. Since $\|\Lambda_h v - v\|_{0,I} = \inf_{\chi \in \mathbb{P}^{r-2}(I)} \|\chi - v\|_{0,I}$, using (2.2), (2.5), and (2.4) we conclude that (2.7) holds with $\alpha = r-1$.

Let θ_1, $\theta_2 \in \{0,1\}$ and $\theta = (\theta_1, \theta_2)$. We can find a polynomial $p_\theta \in \mathbb{P}^r(0,1)$ such that $p_\theta(0) = \theta_1$, $p(1) = \theta_2$ and whose L^2-projection on $\mathbb{P}^{r-2}(0,1)$ is the constant 1. Indeed, if p_θ is such a polynomial, then $p_\theta(x) = w_\theta(x)\left(\sum_{j=1}^{r-1} a_j^\theta\, x^{j-1}\right)$, where $w_\theta(x) = |x-\theta_1|\,|x-\theta_2|$. Requiring $\int_0^1 x^{\ell-1}\, p_\theta(x)\, dx = \frac{1}{\ell}$, $\ell = 1, \ldots, r-1$, we get $\sum_{j=1}^{r-1} a_j^\theta\, A_{\ell j}^\theta = \frac{1}{\ell}$ for $\ell = 1, \ldots, r-1$, where $A_{\ell j}^\theta = \int_0^1 w_\theta(x)\, x^{\ell-1} x^{j-1}\, dx$. A^θ is invertible being the Gram matrix of the linearly independent vectors $\{\sqrt{w_\theta(x)}\, x^{k-1}\}_{k=1}^{r-1}$ of $L^2(0,1)$. Thus, p_θ is fully determined.

Set now $\overline{p} = p_{(0,0)}$ and $\widetilde{p} = p_{(0,1)}$, and consider the linearly independent functions $\{\overline{\phi}_j, \widetilde{\phi}_j\}_{j=1}^{J_h}$ of S_h^r defined by $\overline{\phi}_j = (\overline{p} \circ \xi_j^h)\, \mathcal{X}_{I_j^h}$ for $j = 1, \ldots, J_h$, $\widetilde{\phi}_j = (\widetilde{p} \circ \xi_j^h)\, \mathcal{X}_{I_j^h} + (\widetilde{p} \circ (1 - \xi_{j+1}^h))\, \mathcal{X}_{I_{j+1}^h}$ for $j = 1, \ldots, J_h - 1$, and $\widetilde{\phi}_{J_h} = (\widetilde{p} \circ \xi_{J_h}^h)\, \mathcal{X}_{I_{J_h}^h}$. Then we have $\Lambda_h \overline{\phi}_j = \mathcal{X}_{I_j^h}$ for $j = 1, \ldots, J_h$, $\Lambda_h \widetilde{\phi}_j = \mathcal{X}_{I_j^h \cup I_{j+1}^h}$ for $j = 1, \ldots, J_h - 1$, and $\Lambda_h \widetilde{\phi}_{J_h} = \mathcal{X}_{I_{J_h}^h}$. Setting $\chi = \overline{\phi}_j$ in (2.9) we obtain

$$\int_{I_j^h} L_{I_j^h} u_h\, dx = \int_{I_j^h} f\, dx, \quad j = 1, \ldots, J_h. \tag{3.1}$$

With $\chi = \widetilde{\phi}_j$ in (2.9) we get

$$(au_h')(x_j^h - 0) - (au_h')(x_j^h + 0) + \sum_{\ell \in \{j, j+1\}} \int_{I_\ell^h} \left(L_{I_\ell^h} u_h - f\right) dx = 0 \tag{3.2}$$

for $j = 1, \ldots, J_h - 1$ and

$$(au_h')(x_{J_h}^h - 0) + \int_{I_{J_h}^h} \left(L_{I_{J_h}^h}\, u_h - f\right) dx = 0. \tag{3.3}$$

Using integration by parts, we arrive at

$$\mathcal{F}(u_h, (x_{j-1}^h, x_{j+1}^h)) = 0, \quad j = 1, \ldots, J_h - 1, \quad \mathcal{G}(u_h, I_{J_h}^h) = 0, \tag{3.4}$$

$$\mathcal{F}(u_h, I_j^h) = 0, \quad j = 1, \ldots, J_h. \tag{3.5}$$

The relations in (3.4) and (3.5) show that the method (2.9) is a locally conservative method with control volumes $\{I_j^h\}_{j=1}^{J_h}$ and $\{(x_{j-1}^h, x_{j+1}^h)\}_{j=1}^{J_h-1}$. The interval $I_{J_h}^h$ is a boundary control volume of type I due to (3.5) and of type II due to the second equation in (3.4). Also, (3.2), (3.3), and (3.1) imply $u_h'(x_R - 0) = 0$ and $u_h'(x_j^h - 0) = u_h'(x_j^h + 0)$ for $j = 1, \ldots, J_h - 1$, which completes the proof. ∎

REMARK 3.1. *We note that the method of Proposition* 3.1 *with* $r = 2$ *is a finite volume method.*

PROPOSITION 3.2. *Let* $m \in \mathbb{N}$, $r = 2m$, *and* $\Lambda_h : \mathbb{P}_h^r \to \mathbb{P}_h^{r-1}$ *be defined by*

$$(\Lambda_h p - p, q) = 0 \quad \forall\, q \in \mathbb{P}_h^{r-1}, \quad \forall\, p \in \mathbb{P}_h^r. \tag{3.6}$$

Then (2.7) *holds with* $\alpha = r$ *and* (2.8) *is satisfied with* $\sigma = 1$. *Also, the method* (2.9) *is a locally conservative method on* S_h^r *with control volumes* $\{I_j^h\}_{j=1}^{J_h}$, *where the interval* $I_{J_h}^h$ *is a boundary control volume of type* I.

Proof. The definition of Λ_h immediately yields that (2.8) holds for $\sigma = 1$. Let $I \in \mathcal{P}_h$ and $v \in \mathbb{P}^r(I)$. Since $\|\Lambda_h v - v\|_{0,I} \le \|\mathcal{I}_h^{r-1} v - v\|_{0,I}$, the use of (2.2) and (2.4), implies that (2.7) holds with $\alpha = r$.

We define $\widehat{p} \in \mathbb{P}^r(0,1)$ by $\widehat{p}(x) = 1 - W_r(x)$ for $x \in (0,1)$ (cf. section 2.1). Then we have $\widehat{p}(0) = 0$, $\widehat{p}(1) = 0$ and $\int_0^1 (\widehat{p}(x) - 1)\, \widehat{q}(x) dx = 0$ $\forall \widehat{q} \in \mathbb{P}^{r-1}(0,1)$, because of the orthogonality property of the Legendre polynomials, i.e., $\int_{-1}^1 \mathcal{L}_r(x)\, q(x) dx = 0$ $\forall q \in \mathbb{P}^{r-1}(-1,1)$. Consider the linearly independent functions $\{\widehat{\phi}_j\}_{j=1}^{J_h} \subset S_h^r$ defined by $\widehat{\phi}_j = (\widehat{p} \circ \xi_j^h) \mathcal{X}_{I_j^h}$, $j = 1, \ldots, J_h$. By construction we have that $\Lambda_h \widehat{\phi}_j = \mathcal{X}_{I_j^h}$, $j = 1, \ldots, J_h$. Setting $\chi = \widehat{\phi}_j$ in (2.9) we arrive at $\mathcal{F}(u_h, I_j^h) = 0$, $j = 1, \ldots, J_h$, which completes the proof of the proposition. ∎

REMARK 3.2. *Let* $m \in \mathbb{N}$, $r = 2m$, Λ_h *be defined by* (3.6) *and* $\widehat{B} = \{\widehat{\phi}_j\}_{j=1}^{J_h}$ *be the set of linearly independent functions of* S_h^r *defined in the proof of Proposition* 3.2. *If* $\widetilde{B}$ *is a basis of* S_h^{r-1}, *then the set* $\widetilde{B} \cup \widehat{B}$ *is a basis of* S_h^r *because* $\mathrm{card}(\widetilde{B}) = (r-1)J_h$ *and* $\widehat{\phi}_j|_{I_j^h} \in \mathbb{P}^r(I_j^h) \backslash \mathbb{P}^{r-1}(I_j^h)$ *for* $j = 1, \ldots, J_h$. *Since* $\Lambda_h \widetilde{\phi} = \widetilde{\phi}$, *for* $\widetilde{\phi} \in \widetilde{B}$, *the rest degrees of freedom of the approximation* u_h *are specified by the finite element-type equations*: $B(u_h, \widetilde{\phi}) = (f, \widetilde{\phi})$ *for* $\widetilde{\phi} \in \widetilde{B}$.

REMARK 3.3. *Let* $m \in \mathbb{N}$, $r = 2m + 1$ *and* Λ_h *be defined by* (3.6). *Proceeding as in the proof of Proposition* 3.1, *we conclude that there is a unique polynomial* $p_* \in \mathbb{P}^r(0,1)$ *such that* $p_*(0) = 0$ *and whose* L^2 *projection on* $\mathbb{P}^{r-1}(0,1)$ *is equal to* 1, *i.e.,* $\int_0^1 (p_*(x) - 1)\, q(x) dx = 0$ $\forall q \in \mathbb{P}^{r-1}(0,1)$. *Setting* $q = p_*' \in \mathbb{P}^{r-1}(0,1)$ *we obtain* $p_*(1)(p_*(1) - 2) = 0$, *so that either* $p_*(1) = 0$ *or* $p_*(1) = 2$. *Since* r *is odd, it is easily seen that* $p_* = W_r + 1$, *which yields* $p_*(1) = 2$. *This means that it is not possible to have* $p_*(1) = 0$ *or* $p_*(1) = 1$, *and hence we cannot employ the technique used in Propositions* 3.1 *and* 3.2 *to show that the method is locally conservative.*

3.2. Methods based on a special projection of $\mathcal{C}_h^0$ onto piecewise constants. In this subsection we define a special projection of the piecewise continuous functions of $\mathcal{C}_h^0$ onto a space consisting of piecewise constant functions and use it to derive finite volume methods on S_h^r, for $r \ge 2$. For these finite volume methods, (2.7) holds with $\alpha = 1$ and (2.8) is satisfied with $\sigma = 0$ or 1. The convergence analysis of sections 4 and 5 shows that the order of convergence is optimal in the H^1 norm when $\sigma = 0$ and in the H^1, L^2, and L^∞ norm when $\sigma = 1$.

Let $s \ge 2$ and $\varrho = \{\varrho_j\}_{j=0}^s \subset \mathbb{R}$ be the nodes of a partition of $[0,1]$, i.e., $\varrho_0 = 0$, $\varrho_s = 1$, and $\varrho_{j-1} < \varrho_j$ for $j = 1, \ldots, s$. The next lemma shows that there is a unique

polynomial of degree less than or equal to $s-1$ with prescribed integral over each subinterval of the partition.

LEMMA 3.3. *Let $s \geq 2$ and $\varrho = \{\varrho_j\}_{j=0}^s$ be the nodes of a partition of $[0,1]$. Then, for given $E = \{\varepsilon_j\}_{j=1}^s \subset \mathbb{R}$ there exists a unique $p_E \in \mathbb{P}^{s-1}[0,1]$ such that*

$$\int_{\varrho_{j-1}}^{\varrho_j} p_E(x)\, dx = \varepsilon_j, \quad j = 1, \ldots, s. \tag{3.7}$$

Proof. Observing that every $p \in \mathbb{P}^{s-1}[0,1]$ has a unique representation as $p(x) = \sum_{i=1}^s i\, a_i\, x^{i-1}$, it is easily seen that (3.7) is equivalent to $\sum_{i=1}^s a_i\, (\varrho_j^i - \varrho_{j-1}^i) = \varepsilon_j$, $j = 1, \ldots, s$. Since $\varrho_0 = 0$, the last relation and a simple induction argument yields that (3.7) is, finally, equivalent to $\sum_{i=1}^s a_i\, \hat{A}_{ji} = \frac{\varepsilon_j + \varepsilon_{j-1}}{\varrho_j}$ $j = 1, \ldots, s$, where $\hat{A}_{ji} = (\varrho_j)^{i-1}$ and $\varepsilon_0 = 0$. Since $\hat{A} \in \mathbb{R}^{s\times s}$ is a Vandermonde matrix, the coefficients $\{a_i\}_{i=1}^s$ are uniquely determined and this proves the assertion of the lemma. ∎

The result of Lemma 3.3 allows us to construct a basis of $\mathbb{P}^{s-1}$ for $s \geq 2$ that is useful for our purposes.

LEMMA 3.4. *Let $s \geq 2$ and $\varrho = \{\varrho_j\}_{j=0}^s$ be the nodes of a partition of $[0,1]$. The polynomials $\{z_\ell^{\varrho,s-1}\}_{\ell=1}^s \subset \mathbb{P}^{s-1}[0,1]$ satisfying*

$$\int_{\varrho_{j-1}}^{\varrho_j} z_\ell^{\varrho,s-1}(x)\, dx = \delta_{\ell j}, \quad j, \ell = 1, \ldots, s, \tag{3.8}$$

form a basis of $\mathbb{P}^{s-1}[0,1]$.

Proof. Lemma 3.3 ensures that $\{z_\ell^{\varrho,s-1}\}_{\ell=1}^s$ are well-defined elements of $\mathbb{P}^{s-1}[0,1]$. To show that they are linearly independent, we assume that there exist real numbers $\{\lambda_j\}_{j=1}^s$ such that $\sum_{j=1}^s \lambda_j\, z_j^{\varrho,s-1} = 0$. Then, for $j_0 = 1, \ldots, s$, integrate the last relation over $[\varrho_{j_0-1}, \varrho_{j_0}]$ and use (3.8) to obtain $\sum_{j=1}^s \lambda_j\, \delta_{jj_0} = 0$, or $\lambda_{j_0} = 0$. ∎

REMARK 3.4. *Let $\{w_\ell^{\varrho,s}\}_{\ell=1}^s \subset \mathbb{P}^s(0,1)$ be such that $w_\ell^{\varrho,s}(\varrho_j) = 0$ for $j = 0, \ldots, \ell-1$ and $w_\ell^{\varrho,s}(\varrho_j) = 1$ for $j = \ell, \ldots, s$. Then we have $z_\ell^{\varrho,s-1} = (w_\ell^{\varrho,s})'$ for $\ell = 1, \ldots, s$.*

We define now a linear operator that maps the piecewise continuous functions $\mathcal{C}_h^0$ onto piecewise constant functions and has properties analogous to (2.7) and (2.8).

PROPOSITION 3.5. *Let $s \geq 2$, $\varrho = \{\varrho_j\}_{j=0}^s$ be the nodes of a partition of $[0,1]$, $\{z_\ell^{\varrho,s-1}\}_{\ell=1}^s$ be the basis of $\mathbb{P}^{s-1}[0,1]$ described in Lemma 3.4 and $\widetilde{\Lambda}_h^{\varrho,s} : \mathcal{C}_h^0 \to L^2(\Omega)$ be a linear operator defined by*

$$\widetilde{\Lambda}_h^{\varrho,s} v|_{I_j^h} = \frac{1}{h_{I_j^h}} \sum_{\ell=1}^s \big(v, (z_\ell^{\varrho,s-1} \circ \xi_j^h)\big)_{I_j^h}\, \mathcal{X}_{I_{j,\ell}^{\varrho,h}}, \quad j = 1, \ldots, J_h, \tag{3.9}$$

where $I_{j,\ell}^{\varrho,h} = (x_{j-1+\varrho_{\ell-1}}^h, x_{j-1+\varrho_\ell}^h)$. Then, it holds that

$$\big(\widetilde{\Lambda}_h^{\varrho,s} v - v, q\big)_I = 0 \quad \forall\, q \in \mathbb{P}^{s-1}(I), \quad \forall\, I \in \mathcal{P}_h, \quad \forall\, v \in \mathcal{C}_h^0, \tag{3.10}$$

$$\big\|\widetilde{\Lambda}_h^{\varrho,s} \tilde{v} - \tilde{v}\big\|_{0,I} \leq\ C\, h_I\, \|\tilde{v}\|_{1,I} \quad \forall\, I \in \mathcal{P}_h, \quad \forall\, \tilde{v} \in H_h^1. \tag{3.11}$$

Proof. Let $v \in \mathcal{C}_h^0$, $\tilde{v} \in H_h^1$, and $j \in \{1, \ldots, J_h\}$. Using (3.8) and (3.9), we obtain

$$\begin{aligned}\big(\widetilde{\Lambda}_h^{\varrho,s} v, (z_i^{\varrho,s-1} \circ \xi_j^h)\big)_{I_j^h} &= \sum_{\ell=1}^s \big(v, (z_\ell^{\varrho,s-1} \circ \xi_j^h)\big)_{I_j^h} \int_{\varrho_{\ell-1}}^{\varrho_\ell} z_i^{\varrho,s-1}(x)\, dx \\ &= \big(v, (z_i^{\varrho,s-1} \circ \xi_j^h)\big)_{I_j^h}, \quad i = 1, \ldots, s,\end{aligned}$$

which proves (3.10) since $\{z_i^{\varrho,s-1} \circ \xi_j^h\}_{i=1}^s$ is a basis of $\mathbb{P}^{s-1}(I_j^h)$. By (3.8) and (3.9) we have

$$\int_{I_j^h} |\widetilde{\Lambda}_h^{\varrho,s}\tilde{v} - \tilde{v}|^2\, dx = \sum_{\ell=1}^{s} \int_{I_{j,\ell}^{\varrho,h}} \left| \int_0^1 \left(\tilde{v}(x_{j-1}^h + z h_{I_j^h}) - \tilde{v}(x)\right) z_\ell^{\varrho,s-1}(z)\, dz \right|^2 dx$$
$$\leq \sum_{\ell=1}^{s} |I_{j,\ell}^{\varrho,h}| \left(\int_{I_j^h} |\widetilde{v}'|\, dx \right)^2 \left(\int_0^1 |z_\ell^{\varrho,s-1}|\, dz \right)^2.$$

Using Cauchy–Schwarz's inequality and the equality $|I_{j,\ell}^{\varrho,h}| = (\varrho_\ell - \varrho_{\ell-1}) h_{I_j^h}$ we obtain

$$\int_{I_j^h} |\widetilde{\Lambda}_h^{\varrho,s}\tilde{v} - \tilde{v}|^2\, dx \leq\ h_{I_j^h}^2\ \|\tilde{v}\|_{1,I_j^h}^2\ \left\{ \sum_{\ell=1}^{s} (\varrho_\ell - \varrho_{\ell-1})\ \left(\int_0^1 |z_\ell^{\varrho,s-1}|\, dz \right)^2 \right\},$$

which yields (3.11). ∎

Next, we show that it is possible to construct arbitrarily high order finite volume methods based on the projection on piecewise constants introduced in Proposition 3.5.

PROPOSITION 3.6. *Let $r \geq 3$, $\varrho = \{\varrho_i\}_{i=0}^{r-1}$ be the nodes of a partition of $[0,1]$, and*

$$\Lambda_h = \widetilde{\Lambda}_h^{\varrho,r-1}|_{\mathbb{P}_h^r}. \tag{3.12}$$

Then Λ_h satisfies (2.7) with $\alpha = 1$ and (2.8) with $\sigma = 0$. Also, the method (2.9) is a finite volume method with control volumes $\left\{\{(x_{j-1+\varrho_{i-1}}^h, x_{j-1+\varrho_i}^h)\}_{i=1}^{r-1}\right\}_{j=1}^{J_h}$ and $\{(x_{j-1+\varrho_{r-2}}^h, x_{j+\varrho_1}^h)\}_{j=1}^{J_h-1}$, where the interval $(x_{J_h-1+\varrho_{r-2}}^h, x_{J_h}^h)$ is a boundary control volume of both types I *and* II. *Moreover, the corresponding approximation u_h belongs to $S_h^r \cap C^1(\overline{\Omega})$ and satisfies a homogeneous Neumann boundary condition at x_R.*

Proof. Proposition 3.5, for $s = r-1$, yields that (2.7) holds with $\alpha = 1$ and (2.8) is satisfied with $\sigma = 0$. We shall show that the method (2.9) (under the choice (3.12) for Λ_h) is a finite volume method by constructing an appropriate basis of S_h^r.

Let $\theta_1,\ \theta_2 \in \{0,1\}$, and $\theta = (\theta_1, \theta_2)$. We consider the problem of finding a polynomial $p_\theta \in \mathbb{P}^r[0,1]$ such that $p_\theta(0) = \theta_1$, $p_\theta(1) = \theta_2$ and $\int_0^1 p_\theta(x)\ z_\ell^{\varrho,r-2}(x)\, dx = \varepsilon_\ell^\theta$ for $\ell = 1, \ldots, r-1$, where $\{\varepsilon_\ell^\theta\}_{\ell=1}^{r-1}$ are given real numbers. Using Lemma 3.4, the first two conditions for p_θ are equivalent to $p_\theta = w_\theta\, (\sum_{i=1}^{r-1} a_i^\theta\ z_i^{\varrho,r-2})$, where $w_\theta(x) = |x-\theta_1|\, |x-\theta_2|$. Hence, the conditions for p_θ are equivalent to $\sum_{i=1}^{r-1} a_i^\theta\ A_{\ell i}^\theta = \varepsilon_\ell^\theta$ for $\ell = 1, \ldots, r-1$, where $A_{\ell i}^\theta = \int_0^1 w_\theta(x)\, z_\ell^{\varrho,r-2}(x)\, z_i^{\varrho,r-2}(x)\, dx$. Since A^θ is invertible being the Gram matrix corresponding to the linearly independent vectors $\left\{\sqrt{w^\theta}\ z_k^{\varrho,r-2}\right\}_{k=1}^{r-1}$ of $L^2(0,1)$, there exists a unique $p_\theta \in \mathbb{P}^r[0,1]$ with the aforementioned properties.

For $i = 1, \ldots, r-1$, we denote by $\widetilde{p}_i$ the polynomial $p_{(0,0)}$ when $\varepsilon_\ell^{(0,0)} = \delta_{i\ell}$ for $\ell = 1, \ldots, r-1$. By $\overline{p}_*$ we denote the polynomial $p_{(1,0)}$, when $\varepsilon_1^{(1,0)} = 1$ and $\varepsilon_\ell^{(1,0)} = 0$ for $\ell = 2, \ldots, r-1$. In addition, we shall denote by $\widehat{p}_*$ the polynomial $p_{(0,1)}$, when $\varepsilon_\ell^{(0,1)} = 0$ for $\ell = 1, \ldots, r-2$, and $\varepsilon_{r-1}^{(0,1)} = 1$.

Now, we define $\Psi = \left\{\{\psi_{i,j}\}_{j=1}^{J_h}\right\}_{i=1}^{r} \subset S_h^r$ by $\psi_{i,j} = (\widetilde{p}_i \circ \xi_j^h)\ \mathcal{X}_{I_j^h}$ for $i = 1, \ldots, r-1$ and $j = 1, \ldots, J_h$, $\psi_{r,j} = (\widehat{p}_* \circ \xi_j^h)\ \mathcal{X}_{I_j^h} + (\overline{p}_* \circ \xi_{j+1}^h)\ \mathcal{X}_{I_{j+1}^h}$ for $j = 1, \ldots, J_h - 1$, and $\psi_{r,J_h} = (\widehat{p}_* \circ \xi_{J_h}^h)\ \mathcal{X}_{I_{J_h}^h}$. The definition of Λ_h, $\widehat{p}_*$, $\overline{p}_*$, and $\{\widetilde{p}_i\}_{i=1}^{r-1}$ yields $\Lambda_h \psi_{i,j} = \mathcal{X}_{I_{j,i}^{\varrho,h}}$ for $i = 1, \ldots, r-1$ and $j = 1, \ldots, J_h$, $\Lambda_h \psi_{r,j} = \mathcal{X}_{I_{j,r-1}^{\varrho,h} \cup I_{j+1,1}^{\varrho,h}}$ for $j = 1, \ldots, J_h - 1$, and $\Lambda_h \psi_{r,J_h} = \mathcal{X}_{I_{J_h,r-1}^{\varrho,h}}$. To prove that the elements of Ψ are linearly independent we

assume that there exist $\big\{\{\lambda_{i,j}\}_{j=1}^{J_h}\big\}_{i=1}^{r} \subset \mathbb{R}$ such that $\psi \equiv \sum_{i=1}^{r}\sum_{j=1}^{J_h} \lambda_{i,j}\,\psi_{i,j} = 0$. Evaluating ψ at $\{x_j^h\}_{j=1}^{J_h}$, we obtain $\lambda_{r,j} = 0$ for $j = 1,\dots,J_h$. Since $\Lambda_h\psi = 0$, we conclude that $\sum_{i=1}^{r-1}\sum_{j=1}^{J_h} \lambda_{i,j}\mathcal{X}_{I_{j,i}^{\varrho,h}} = 0$, which obviously yields $\lambda_{i,j} = 0$ for $i = 1,\dots,r-1$ and $j = 1,\dots,J_h$. Since $\dim(S_h^r) = rJ_h$, Ψ is a basis of S_h^r.

Setting $\chi = \psi_{i,j}$ in (2.9), we obtain

$$\int_{I_{j,i}^{\varrho,h}} L_{I_j^h} u_h \, dx = \int_{I_{j,i}^{\varrho,h}} f \, dx, \quad i = 1,\dots,r-1, \quad j = 1,\dots,J_h, \tag{3.13}$$

$$\begin{aligned}(au_h')(x_j^h - 0) - (au_h')(x_j^h + 0) + \int_{I_{j,r-1}^{\varrho,h}} (L_{I_j^h} u_h - f)\, dx \\ + \int_{I_{j+1,1}^{\varrho,h}} (L_{I_{j+1}^h} u_h - f)\, dx = 0, \quad j = 1,\dots,J_h - 1,\end{aligned} \tag{3.14}$$

$$(au_h')(x_{J_h}^h - 0) + \int_{I_{J_h,r-1}^{\varrho,h}} (L_{I_{J_h}^h} u_h - f)\, dx = 0. \tag{3.15}$$

Integration by parts, (3.14), and (3.15) yield

$$\mathcal{F}\big(u_h, (x_{j-1+\varrho_{r-2}}^h, x_{j+\varrho_1}^h)\big) = 0,\ j = 1,\dots,J_h - 1, \quad \mathcal{G}\big(u_h, I_{J_h,r-1}^{\varrho,h}\big) = 0. \tag{3.16}$$

The relations (3.13) and (3.16) show that the method (2.9) with Λ_h given by (3.12) is a finite volume method, the control volumes of which are $\{(x_{j-1+\varrho_{r-2}}^h, x_{j+\varrho_1}^h)\}_{j=1}^{J_h-1}$ and $\big\{\{I_{j,i}^{\varrho,h}\}_{j=1}^{J_h}\big\}_{i=1}^{r-1}$. We note that the interval $I_{J_h,r-1}^{\varrho,h}$ is a boundary control volume both of types I and II. Also, we combine (3.13), (3.14), and (3.15) to get $u_h'(x_R - 0) = 0$ and $u_h'(x_j^h - 0) = u_h'(x_j^h + 0)$ for $j = 1,\dots,J_h - 1$, which completes the proof. ∎

We close this subsection by discussing the possibility of constructing finite volume methods of the form (2.9) with $\alpha = 1$, $\sigma = 1$.

PROPOSITION 3.7. *Let $m \in \mathbb{N}$, $r = 2m$, $\varrho = \{\varrho_i\}_{i=0}^{r}$ be the nodes of a partition of $[0,1]$, and*

$$\Lambda_h = \widetilde{\Lambda}_h^{\varrho,r}|_{\mathbb{P}_h^r}. \tag{3.17}$$

Then Λ_h satisfies (2.7) *with $\alpha = 1$ and* (2.8) *with $\sigma = 1$. Also, the method* (2.9) *is a locally conservative method with control volumes $\{I_j^h\}_{j=1}^{J_h}$, where $I_{J_h}^h$ is a boundary control volume of type* I. *Moreover, if $r \in \{2,4,6\}$ and*

$$\{\varrho_j\}_{j=1}^{r-1} \subset \{z \in (0,1) : W_r(z) = 0\}, \tag{3.18}$$

then the method (2.9) *is a finite volume method with rJ_h overlapping control volumes:*

$$\{I_j^h\}_{j=1}^{J_h}, \quad \big\{\{(x_{j-1+\varrho_{r-i}}^h,\ x_{j+\varrho_i}^h)\}_{i=1}^{r-1}\big\}_{j=1}^{J_h-1}, \quad \{(x_{J_h-1+\varrho_{r-i}}^h,\ x_{J_h}^h)\}_{i=1}^{r-1}, \tag{3.19}$$

where the latter intervals are boundary control volumes of type II *and $I_{J_h}^h$ is a boundary control volume of type* I.

Proof. Proposition 3.5, for $s = r$, yields (2.7) with $\alpha = 1$ and (2.8) is satisfied with $\sigma = 1$. Proceeding as in the proof of Proposition 3.6, we conclude that for $\theta_0 \in \{0,1\}$ there is only one polynomial $\overline{p}_{\theta_0} \in \mathbb{P}^r(0,1)$ such that $\overline{p}_{\theta_0}(\theta_0) = 0$ and

$\int_0^1 \overline{p}_{\theta_0}(x)\ z_\ell^{\varrho,r-1}(x)\ dx = \overline{\varepsilon}_\ell$, $\ell = 1,\dots,r$, where $\{\overline{\varepsilon}_\ell\}_{\ell=1}^r$ are given real numbers. For $i = 1,\dots,r-1$, we set $\widetilde{p}_i = \overline{p}_0$ when $\overline{\varepsilon}_\ell = 0$ for $\ell = 1,\dots,r-i$ and $\overline{\varepsilon}_\ell = 1$ for $\ell = r-i+1,\dots,r$, and $\widetilde{q}_i = \overline{p}_1$ when $\overline{\varepsilon}_\ell = 1$ for $\ell = 1,\dots,i$ and $\overline{\varepsilon}_\ell = 0$ for $\ell = i+1,\dots,r$. We also set $\widetilde{p}_r = \overline{p}_0$ when $\overline{\varepsilon}_\ell = 1$ for $\ell = 1,\dots,r$.

Since r is even, using the orthogonality property of the Legendre polynomials and (3.8) we conclude that $\widetilde{p}_r = 1 - W_r$, so we have, in addition, that $\widetilde{p}_r(1) = 0$. Now we consider the linearly independent functions $\{\psi_j^r\}_{j=1}^{J_h} \subset S_h^r$ defined by $\psi_j^r = (\widetilde{p}_r \circ \xi_j^h)\ \mathcal{X}_{I_j^h}$ for $j = 1,\dots,J_h$. By construction we get $\Lambda_h\psi_j^r = \mathcal{X}_{I_j^h}$ for $j = 1,\dots,J_h$. For $\chi = \psi_j^r$, (2.9) yields (3.5), so the method is locally conservative with control volumes $\{I_j^h\}_{j=1}^{J_h}$, and the interval $I_{J_h}^h$ is a boundary control volume of type I.

Let $r \in \{2,4,6\}$ and $i \in \{1,\dots,r-1\}$. A long but straightforward calculation reveals that

$$\widetilde{p}_i(1) = 1 - W_r(\varrho_{r-i}) \quad \text{and} \quad \widetilde{q}_i(0) = 1 - W_r(\varrho_i). \tag{3.20}$$

Since (3.18) holds we finally obtain that $\widetilde{p}_i(1) = \widetilde{q}_i(0) = 1$. Now, we define $\{\psi_j^i\}_{j=1}^{J_h} \subset S_h^r$ by $\psi_j^i = (\widetilde{p}_i \circ \xi_j^h)\ \mathcal{X}_{I_j^h} + (\widetilde{q}_i \circ \xi_{j+1}^h)\ \mathcal{X}_{I_{j+1}^h}$ for $j = 1,\dots,J_h-1$ and $\psi_{J_h}^i = (\widetilde{p}_i \circ \xi_{J_h}^h)\ \mathcal{X}_{I_{J_h}^h}$. Then, we have $\Lambda_h\psi_j^i = \mathcal{X}_{(x^h_{j-1+\varrho_{r-i}},\, x^h_{j+\varrho_i})}$ for $j = 1,\dots,J_h-1$, and $\Lambda_h\psi_{J_h}^i = \mathcal{X}_{(x^h_{J_h-1+\varrho_{r-i}},\, x^h_{J_h})}$. Setting $\chi = \psi_j^i$ in (2.9) we get

$$\begin{gathered}\mathcal{F}\big(u_h,(x^h_{j-1+\varrho_{r-i}},x^h_{j+\varrho_i})\big) = 0, \quad j = 1,\dots,J_h-1,\\ \mathcal{G}\big(u_h,(x^h_{J_h-1+\varrho_{r-i}},x^h_{J_h})\big) = 0.\end{gathered} \tag{3.21}$$

The last step in our proof is to show that the set $\Psi = \big\{\{\psi_j^i\}_{i=1}^r\big\}_{j=1}^{J_h} \subset S_h^r$ consists of linearly independent functions. Let $\big\{\{\lambda_j^i\}_{i=1}^r\big\}_{j=1}^{J_h} \subset \mathbb{R}$ such that $\psi \equiv \sum_{i=1}^r \sum_{j=1}^{J_h} \lambda_j^i\ \psi_j^i = 0$. Evaluating ψ at $\{x_j^h\}_{j=1}^{J_h}$ we get

$$\sum_{i=1}^{r-1} \lambda_j^i = 0, \quad j = 1,\dots,J_h. \tag{3.22}$$

Since $\Lambda_h\psi\big|_{I_{1,1}^{\varrho,h}} = \lambda_1^r$ and $\Lambda_h\psi\big|_{I_{j,1}^{\varrho,h}} = \lambda_j^r + \sum_{i=1}^{r-1}\lambda_{j-1}^i$ for $j = 2,\dots,J_h$, using that $\Lambda_h\psi = 0$ and the result (3.22), we obtain

$$\lambda_j^r = 0, \quad j = 1,\dots,J_h. \tag{3.23}$$

Using (3.23), we have

$$\Lambda_h\psi\big|_{I_{1,i+1}^{\varrho,h}} = \sum_{m=r-i}^{r-1} \lambda_1^m \quad \text{and} \quad \Lambda_h\psi\big|_{I_{j,i+1}^{\varrho,h}} = \sum_{m=r-i}^{r-1} \lambda_j^m + \sum_{m'=i+1}^{r-1} \lambda_{j-1}^{m'} \tag{3.24}$$

for $i = 1,\dots,r-1$ and $j = 2,\dots,J_h$. Since $\Lambda_h\psi = 0$, applying an induction argument on (3.24) we conclude that

$$\lambda_j^i = 0, \quad i = 1,\dots,r-1, \quad j = 1,\dots,J_h. \tag{3.25}$$

The relations (3.25) and (3.23) complete the independence proof. Hence, Ψ is a basis of S_h^r. Finally, (3.5) and (3.21) yield that (2.9) (under the choice (3.17) for Λ_h) is a finite volume method with the control volumes defined in (3.19). ∎

REMARK 3.5. *Let $r \in \{3,5\}$ and Λ_h be defined by* (3.17)*. Then, by Proposition* 3.5*, we have $\alpha = 1$ and $\sigma = 1$. Since r is odd, we have $\widetilde{p}_r = 1 + W_r$ and hence $\widetilde{p}_r(1) = 2 \notin \{0,1\}$. Moreover, we get*

$$\widetilde{p}_i(1) = 1 - W_r(\varrho_{r-i}) \quad \text{and} \quad \widetilde{q}_i(0) = 1 + W_r(\varrho_i), \quad i = 1, \dots, r-1. \tag{3.26}$$

Assuming that (3.18) *holds,* (3.26) *yields $\widetilde{p}_i(1) = \widetilde{q}_i(0) = 1$ for $i = 1, \dots, r-1$. Therefore, proceeding as in the proof of Proposition* 3.7 *we conclude that in the case above the method* (2.9) *is a locally conservative method with control volumes $\big\{\{(x^h_{j-1+\varrho_{r-i}},\, x^h_{j+\varrho_i})\}_{i=1}^{r-1}\big\}_{j=1}^{J_h-1}$ and $\{(x^h_{J_h-1+\varrho_{r-i}},\, x^h_{J_h})\}_{i=1}^{r-1}$, which are boundary control volumes of type* II*.*

REMARK 3.6. *It is our opinion that* (3.20) *is true for all even r and that* (3.26) *is true for all odd r, but we are not able to provide a general proof of this fact.*

4. A priori estimates in the L^2 and H^1 norm. Our aim in this section is to derive a priori error estimates, in the usual Sobolev norms, for the method (2.9) under the assumptions (2.7) and (2.8). In particular, in Theorem 4.6 we shall show that (i) in the H^1 norm the order of convergence is always optimal and (ii) in the L^2 norm the order of convergence is optimal when $\alpha \geq 2$, or $\alpha = 1$ and $\sigma = 1$.

The following lemmata will be used throughout the remainder of this paper.

LEMMA 4.1. *Let $r \geq 2$, $j \in \{0, \sigma\}$, and assume that Λ_h satisfies* (2.7) *and* (2.8)*. Then $\forall\, h \in (0,1)$, $v \in H_h^{r+1+j}$ and $p \in \mathbb{P}_h^r$, we have*

$$\big|B_h(v - \mathcal{I}_h^\ell v, p) - B(v - \mathcal{I}_h^\ell v, p)\big| \leq C\, h^{s+\ell-1+j}\, \|v\|_{\ell+1+j,h}\, \|p\|_{s,h}$$

for $s = 1, \dots, \alpha$ and $\ell = 1, \dots, r$.

Proof. Let $h \in (0,1)$, $v \in H_h^{r+1+j}$, $p \in \mathbb{P}_h^r$, $s \in \{1, \dots, \alpha\}$ and $\ell \in \{1, \dots, r\}$. Also, for simplicity we set $g = v - \mathcal{I}_h^\ell v$. From (2.11) we have

$$B_h(g,p) - B(g,p) = G_{_A} + G_{_B}, \tag{4.1}$$

where $G_{_A} = -\sum_{I \in \mathcal{P}_h} (ag'', \Lambda_h p - p)_I$ and $G_{_B} = \sum_{I \in \mathcal{P}_h} \big((\beta - a')g' + \gamma g, \Lambda_h p - p\big)_I$. Using (2.8), (2.6), (2.2), and (2.7) it follows that

$$\begin{aligned}
|G_{_A}| &= \Bigg| \sum_{I \in \mathcal{P}_h} \int_I g''\, (a - \Pi_h a)\, (\Lambda_h p - p)\, dx \\
&\qquad - \sum_{I \in \mathcal{P}_h} \int_I \Pi_h a\, (v'' - \mathcal{I}_h^{\ell-2+j} v'')\, (\Lambda_h p - p)\, dx \Bigg| \\
&\leq C \sum_{I \in \mathcal{P}_h} h_I^s \left(h_I\, \|g''\|_{0,I} + h_I^{\ell-1+j}\, \|v''\|_{\ell-1+j,I}\right) \|p\|_{s,I} \\
&\leq C \sum_{I \in \mathcal{P}_h} h_I^s \left(h_I^\ell\, \|v\|_{\ell+1,I} + h_I^{\ell-1+j}\, \|v\|_{\ell+1+j,I}\right) \|p\|_{s,I} \\
&\leq C \sum_{I \in \mathcal{P}_h} h_I^{s+\ell-1+j}\, \|v\|_{\ell+1+j,I}\, \|p\|_{s,I} \\
&\leq C\, h^{s+\ell-1+j}\, \|v\|_{\ell+1+j,h}\, \|p\|_{s,h}.
\end{aligned}$$

To estimate G_B we use (2.7) and (2.2) to obtain

$$\begin{aligned}|G_B| &\le C \sum_{I\in\mathcal{P}_h} h_I^s \, \|g\|_{1,I} \, \|p\|_{s,I} \\ &\le C \sum_{I\in\mathcal{P}_h} h_I^{\ell+s} \, \|v\|_{\ell+1,I} \, \|p\|_{s,I} \\ &\le C \, h^{\ell+s} \, \|v\|_{\ell+1,h} \, \|p\|_{s,h}.\end{aligned}$$

The lemma now follows from (4.1) and the estimates for G_A and G_B above. ∎

LEMMA 4.2. *Let $r \ge 2$ and assume that Λ_h satisfies* (2.7) *and* (2.8). *Then $\forall\, h \in (0,1)$ we have*

$$\big|B_h(\phi,p) - B(\phi,p)\big| \le C \, h^{s+\sigma} \, \|\phi\|_{1,h} \, \|p\|_{s,h}, \quad s = 1,\dots,\alpha, \quad \forall\, \phi, p \in \mathbb{P}_h^r.$$

Proof. Let $h \in (0,1)$, $s \in \{1,\dots,\alpha\}$ and $\phi, p \in \mathbb{P}_h^r$. From (2.11) we have

$$B_h(\phi,p) - B(\phi,p) = E_A + E_B + E_C, \tag{4.2}$$

where $E_A = \sum_{I\in\mathcal{P}_h} \big((\beta - a')\phi', \Lambda_h p - p\big)_I$, $E_B = \sum_{I\in\mathcal{P}_h} \big(\gamma\phi, \Lambda_h p - p\big)_I$ and $E_C = -\sum_{I\in\mathcal{P}_h} (a\phi'', \Lambda_h p - p)_I$. If $\sigma = 0$ in (2.8), then using (2.7) it follows that

$$\begin{aligned}|E_A| + |E_B| &\le C \sum_{I\in\mathcal{P}_h} h_I^s \, \|\phi\|_{1,I} \, \|p\|_{s,I} \\ &\le C \, h^s \, \|\phi\|_{1,h} \, \|p\|_{s,h}.\end{aligned}$$

If $\sigma = 1$ in (2.8), then using (2.8), (2.6), (2.5), and (2.7), it follows that

$$\begin{aligned}|E_A| &= \left| \sum_{I\in\mathcal{P}_h} \int_I \phi' \, \big((\beta - a') - \Pi_h(\beta - a')\big) \, (\Lambda_h p - p) \, dx \right| \\ &\le C \sum_{I\in\mathcal{P}_h} h_I^{s+1} \, \|\phi\|_{1,I} \, \|p\|_{s,I} \\ &\le C \, h^{s+1} \, \|\phi\|_{1,h} \, \|p\|_{s,h}\end{aligned}$$

and

$$\begin{aligned}|E_B| &= \left| \sum_{I\in\mathcal{P}_h} \int_I \phi \, \big(\gamma - \Pi_h\gamma\big) \, (\Lambda_h p - p) \, dx + \sum_{I\in\mathcal{P}_h} \int_I \Pi_h\gamma \, (\phi - \Pi_h\phi) \, (\Lambda_h p - p) \, dx \right| \\ &\le C \sum_{I\in\mathcal{P}_h} h_I^{s+1} \, \|\phi\|_{1,I} \, \|p\|_{s,I} \\ &\le C \, h^{s+1} \, \|\phi\|_{1,h} \, \|p\|_{s,h}.\end{aligned}$$

To estimate E_C we use (2.8), (2.2) or (2.3), (2.1), and (2.7) to obtain

$$\begin{aligned}|E_C| &= \left| \sum_{I\in\mathcal{P}_h} \int_I \phi''(a - \mathcal{I}_h^* a)(\Lambda_h p - p) \, dx \right| \\ &\le C \sum_{I\in\mathcal{P}_h} h_I^{\sigma+1} \, \|\phi''\|_{0,I} \, \|\Lambda_h p - p\|_{0,I} \\ &\le C \sum_{I\in\mathcal{P}_h} h_I^{\sigma} \, \|\phi\|_{1,I} \, \|\Lambda_h p - p\|_{0,I} \\ &\le C \, h^{s+\sigma} \, \|\phi\|_{1,h} \, \|p\|_{s,h},\end{aligned}$$

where $\mathcal{I}_h^* = \Pi_h$ when $\sigma = 0$, and $\mathcal{I}_h^* = \mathcal{I}_h^1$ when $\sigma = 1$. The lemma now follows from (4.2) and the estimates for E_A, E_B, and E_C above. ∎

Next we show that B_h, like B, satisfies a Gårding-type inequality.

LEMMA 4.3. *Let $r \geq 2$ and assume that Λ_h satisfies (2.7) and (2.8). Then, there exists $\widetilde{h}_0 \in (0,1)$ and constants $C_G \geq 0$, $C_E > 0$, such that*

$$B_h(\phi,\phi) + C_G \|\phi\|_0^2 \geq C_E \|\phi\|_1^2 \quad \forall\, \phi \in S_h^r, \quad \forall\, h \in (0, \widetilde{h}_0). \tag{4.3}$$

In particular, if $\beta = \gamma = 0$, then $C_G = 0$.

Proof. Let $h \in (0,1)$ and $\phi \in S_h^r$. It is well known that there exist constants $C_\Gamma \geq 0$ and $C_\Delta > 0$, independent of ϕ, such that

$$B(\phi,\phi) + C_\Gamma \|\phi\|_0^2 \geq C_\Delta \|\phi\|_1^2. \tag{4.4}$$

Lemma 4.2 now gives $\big|B_h(\phi,\phi) - B(\phi,\phi)\big| \leq C_Z\, h^{\sigma+1} \|\phi\|_1^2$, which along with (4.4) yields

$$B_h(\phi,\phi) + C_\Gamma \|\phi\|_0^2 \geq (C_\Delta - h^{\sigma+1}\, C_Z)\, \|\phi\|_1^2.$$

If $C_Z = 0$, then (4.3) holds with $\widetilde{h}_0 = 1$, $C_G = C_\Gamma$ $C_E = C_\Delta$. If $C_Z > 0$, then (4.3) holds, for example, with $\widetilde{h}_0 = \min\{1, (\frac{C_\Delta}{2C_Z})^{\frac{1}{\sigma+1}}\}$, $C_G = C_\Gamma$, $C_E = \frac{C_\Delta}{2}$. If $\beta = \gamma = 0$, then $C_\Gamma = 0$ from the Poincaré–Friedrichs inequality. Consequently, $C_G = 0$. ∎

REMARK 4.1. *For later use we note that if $\beta = \gamma = 0$, then*

$$B_h(\phi,\phi) + C_Z\, h^{\sigma+1}\, \|\phi\|_1^2 \geq a_*\, \|\phi'\|_0^2 \quad \forall\, \phi \in \mathbb{P}_h^r, \quad \forall\, h \in (0,1).$$

As in the finite element analysis (cf. [40]), we relate the approximation error in the L^2 norm to that in the H^1 norm.

PROPOSITION 4.4. *Let $r \geq 2$, $m \in \{0, \sigma\}$, and assume that Λ_h satisfies (2.7) and (2.8). If $u \in H^{r+1+m}(\Omega) \cap \mathcal{H}(\Omega)$, then there exists $\widehat{h}_0 \in (0, \widetilde{h}_0)$ such that for $h \in (0, \widehat{h}_0)$ the method (2.9) is well defined and*

$$\|u - u_h\|_0 \leq C\, h\, \|u - u_h\|_1 + C\, h^{r+m+\alpha^*-1}\, \|u\|_{r+1+m}, \tag{4.5}$$

where $\alpha^* = \min\{\alpha, 2\}$ and $\widetilde{h}_0$ is the constant specified in Lemma 4.3.

Proof. Let $h \in (0, \widetilde{h}_0)$ and $w \in H^2(\Omega)$ be the solution of the dual problem

$$L^* w \equiv -(a(x)w')' - \beta(x)w' + (\gamma(x) - \beta'(x))w = \psi(x) \quad \forall\, x \in \Omega, \tag{4.6a}$$

$$w(x_L) = 0, \quad a(x_R)w'(x_R) + \beta(x_R)w(x_R) = 0, \tag{4.6b}$$

with $\psi \in L^2(\Omega)$, [28]. We let T^* denote the solution operator of (4.6), so that $w = T^*\psi$. Under the assumptions on the data of (1.1) stated in section 1.1, $w \in H^2(\Omega)$ and elliptic regularity yields

$$\|w\|_2 \leq C_R\, \|\psi\|_0 \tag{4.7}$$

for some constant C_R which depends only on the domain Ω and the coefficients of L^*. Taking the $L^2(\Omega)$-inner product of (4.6a) with $\psi \in \mathcal{H}(\Omega)$ and using (2.2) we have

$$\begin{aligned} \|\psi\|_0^2 &= B(\psi, w - \mathcal{I}_h^1 w) + B(\psi, \mathcal{I}_h^1 w) \\ &\leq C\, h\, \|\psi\|_1 \|w\|_2 + B(\psi, \mathcal{I}_h^1 w), \end{aligned}$$

which, along with (4.7), yields

$$\|\psi\|_0^2 \leq C\, h\, \|\psi\|_1 \|\psi\|_0 + B(\psi, \mathcal{I}_h^1 w). \tag{4.8}$$

We shall first show that the method (2.9) is well defined. Obviously, (2.9) is equivalent to a linear system of algebraic equations with matrix M with $M_{ij} = B_h(\phi_j, \phi_i)$, $i, j = 1, \ldots, N_h$, where $N_h = \dim(S_h^r)$ and $\{\phi_j\}_{j=1}^{N_h}$ is a basis of S_h^r. If M were not invertible there would exist a nonzero $\phi_* \in S_h^r$ such that

$$B_h(\phi_*, \chi) = 0 \quad \forall\, \chi \in S_h^r. \tag{4.9}$$

Then, from (4.3) we have

$$\|\phi_*\|_1 \le C\, \|\phi_*\|_0. \tag{4.10}$$

Choosing $\psi = \phi_*$ in (4.6) and using (4.8) and (4.10) it follows that

$$(1 - Ch)\|\phi_*\|_0^2 \le B(\phi_*, \mathcal{I}_h^1 w), \tag{4.11}$$

where $w = T^*\phi_*$. Also, (4.9) yields $B(\phi_*, \mathcal{I}_h^1 w) = B(\phi_*, \mathcal{I}_h^1 w) - B_h(\phi_*, \mathcal{I}_h^1 w)$. Thus, from Lemma 4.2 with $s = 1$, (2.2), and (4.7) we have

$$\begin{aligned} B(\phi_*, \mathcal{I}_h^1 w) &\le C\, h^{1+\sigma}\, \|\phi_*\|_1\, \|\mathcal{I}_h^1 w\|_1 \\ &\le C\, h^{1+\sigma}\, \|\phi_*\|_1\, \|w\|_2 \\ &\le C\, h^{1+\sigma}\, \|\phi_*\|_1\, \|\phi_*\|_0, \end{aligned}$$

which along with (4.10) yields

$$B(\phi_*, \mathcal{I}_h^1 w) \le C\, h^{1+\sigma}\, \|\phi_*\|_0^2. \tag{4.12}$$

From (4.11) and (4.12) we now have $(1 - C_* h)\|\phi_*\|_0^2 \le 0$. We set $\widehat{h}_0 = \widetilde{h}_0$ when $C_* = 0$ and $\widehat{h}_0 = \min\{\widetilde{h}_0, \frac{1}{2C_*}\}$ otherwise. If $h \in (0, \widehat{h}_0)$, then $\phi_* = 0$, which is a contradiction; consequently, M is invertible and (2.9) is well defined.

To prove (4.5), let $h \in (0, \widehat{h}_0)$ and write $e = u_h - u = (u_h - \mathcal{I}_h^r u) + (\mathcal{I}_h^r u - u) = \theta_h + \eta$. From (2.10) and (4.6a) with $\psi = e$, so that $w = T^* e$, we have

$$\begin{aligned} B(e, \mathcal{I}_h^1 w) &= B(e, \mathcal{I}_h^1 w) - B_h(e, \mathcal{I}_h^1 w) \\ &= D_A + D_B, \end{aligned} \tag{4.13}$$

where $D_A = B(\eta, \mathcal{I}_h^1 w) - B_h(\eta, \mathcal{I}_h^1 w)$ and $D_B = B(\theta_h, \mathcal{I}_h^1 w) - B_h(\theta_h, \mathcal{I}_h^1 w)$. Using Lemma 4.1 (with $s = \alpha^*$, $\ell = r$, and $j = m$), (2.2), and (4.7) it follows that

$$\begin{aligned} |D_A| &\le C\, h^{r+m+\alpha^*-1}\, \|u\|_{r+1+m}\, \|\mathcal{I}_h^1 w\|_1 \\ &\le C\, h^{r+m+\alpha^*-1}\, \|u\|_{r+1+m}\, \|w\|_2 \\ &\le C\, h^{r+m+\alpha^*-1}\, \|u\|_{r+1+m}\, \|e\|_0. \end{aligned} \tag{4.14}$$

To estimate D_B we note that Lemma 4.2 with $s = \alpha^*$ yields

$$|D_B| \le C\, h^{\alpha^*+\sigma}\, \|\theta_h\|_1\, \|\mathcal{I}_h^1 w\|_1,$$

so again using (2.2) and (4.7) we obtain

$$|D_B| \le C\, h^{\alpha^*+\sigma}\, (h^r \|u\|_{r+1} + \|e\|_1)\, \|e\|_0. \tag{4.15}$$

The estimate (4.5) follows by combining (4.8) with $\psi = e$, (4.13), (4.14), and (4.15). ∎

PROPOSITION 4.5. *Let $r \geq 2$, $\widehat{h}_0$ be the constant specified in* Proposition 4.4*, and assume that Λ_h satisfies* (2.7) *and* (2.8)*. If $u \in H^{r+1}(\Omega) \cap \mathcal{H}(\Omega)$, then*

$$\|u_h - \mathcal{I}_h^r u\|_1^2 \leq C\, h^r\, \|u\|_{r+1}\, \|u_h - \mathcal{I}_h^r u\|_1 + \tfrac{C_G}{C_E}\, \|u_h - \mathcal{I}_h^r u\|_0^2 \quad \forall\, h \in (0, \widehat{h}_0). \tag{4.16}$$

Proof. Let $h \in (0, \widehat{h}_0)$ and, as before, $\theta_h = u_h - \mathcal{I}_h^r u$, $\eta = \mathcal{I}_h^r u - u$. Using (2.10) and Lemma 4.1 with $\ell = r$, $s = 1$, and $j = 0$, we obtain

$$\begin{aligned} B_h(\theta_h, \theta_h) &= -B_h(\eta, \theta_h) \\ &= \big[B(\eta, \theta_h) - B_h(\eta, \theta_h)\big] - B(\eta, \theta_h) \\ &\leq C\, \left(h^r\, \|u\|_{r+1} + \|\eta\|_1\right)\, \|\theta_h\|_1. \end{aligned}$$

The interpolation estimate (2.2) and the above relation imply

$$B_h(\theta_h, \theta_h) \leq C\, h^r\, \|u\|_{r+1}\, \|\theta_h\|_1. \tag{4.17}$$

The proposition now follows by combining (4.3) and (4.17). ∎

We are now ready to prove the main error estimate of this section.

THEOREM 4.6. *Let $r \geq 2$, $\widehat{h}_0$ be the constant specified in Proposition* 4.4*, and assume that Λ_h satisfies* (2.7) *and* (2.8)*. Also, let $\overline{m}_\alpha = 0$ when $\alpha \geq 2$, and $\overline{m}_\alpha = \sigma$ when $\alpha = 1$. If $u \in H^{r+1+\overline{m}_\alpha}(\Omega) \cap \mathcal{H}(\Omega)$, then there exists $h_0 \in (0, \widehat{h}_0)$ such that $\forall\, h \in (0, h_0)$,*

$$\|u - u_h\|_1 \leq C\, h^r \|u\|_{r+1}, \tag{4.18}$$

$$\|u - u_h\|_0 \leq C\, h^{r+\min\{\overline{m}_\alpha + \alpha - 1, 1\}}\, \|u\|_{r+1+\overline{m}_\alpha}. \tag{4.19}$$

Proof. Let $h \in (0, \widehat{h}_0)$ and $e = u - u_h$. Combining (4.16), (4.5), and (2.2) we obtain $\|e\|_1^2 \leq C_1\, h^{2r}\, \|u\|_{r+1}^2 + C_2\, h^2\, \|e\|_1^2 + \frac{1}{2}\|e\|_1^2$, or equivalently

$$\left(\frac{1}{2} - C_2\, h^2\right)\, \|e\|_1^2 \leq C_1\, h^{2r}\, \|u\|_{r+1}^2.$$

The estimate (4.18) follows from the above relation for h sufficiently small. The estimate (4.19) follows from (4.18) and (4.5). ∎

5. A priori estimates in the L^∞ norm. This section is devoted to the derivation of a priori error estimates in the L^∞ norm for the method (2.9), under the assumptions (2.7) and (2.8). Since we work in one space dimension, the L^∞ norm is dominated by the H^1 norm. Hence, when $\alpha = 1$ and $\sigma = 0$, using Theorem 4.6 we obtain the error estimate $|u - u_h|_\infty \leq C\, h^r\, \|u\|_{r+1}$, the suboptimal order of which has been observed numerically for the method of Proposition 3.1 with $r = 2$ (see Table 8.4 in section 8). For this reason, in the rest of this section we shall examine the following two cases: (i) $\alpha \geq 2$ and Λ_h is identity on $\mathbb{P}_h^1$, and (ii) $\alpha = 1$ and $\sigma = 1$, where, according to Theorem 4.6, the order of convergence in the L^2 norm is optimal.

5.1. Maximum norm estimates when $\alpha \geq 2$. In this subsection we shall assume that (2.7) holds with $\alpha \geq 2$. Moreover, we shall make the hypothesis that the operator $\Lambda_h : \mathbb{P}_h^r \to L^2(\Omega)$ has the property

$$\Lambda_h p = p \quad \forall\, p \in \mathbb{P}_h^1, \tag{5.1}$$

which is obviously satisfied for the methods of Proposition 3.1 for $r \geq 3$, and the methods of Proposition 3.2. In the analysis below, we follow the steps of the L^∞ estimate of [44] for the standard Galerkin finite element method.

For an open interval $I \subset \Omega$ and $v \in H^2(I)$ we let $\mathcal{L}_I v = -(av')'$, where a is the diffusion coefficient of the problem (1.1). For $h \in (0,1)$ and $r \geq 2$, we define the bilinear form $\widetilde{B}_h : H_h^2 \times \mathbb{P}_h^r \to \mathbb{R}$ by

$$\widetilde{B}_h(v,\chi) = \sum_{I \in \mathcal{P}_h} \left\{ [\![a v' \chi]\!]_{\partial I} + (\mathcal{L}_I v, \Lambda_h \chi)_I \right\} \quad \forall\, v \in H_h^2, \quad \forall\, \chi \in \mathbb{P}_h^r. \tag{5.2}$$

From Lemma 4.3 there exists $\overline{h}_0 \in (0,1)$ such that

$$\widetilde{B}_h(\phi,\phi) \geq C_E^* \, \|\phi\|_1^2 \quad \forall\, \phi \in S_h^r, \quad \forall\, h \in (0, \overline{h}_0). \tag{5.3}$$

For $h \in (0,\overline{h}_0)$, we introduce a Ritz projection operator $R_h^r : H_h^2 \to S_h^r$ by

$$\widetilde{B}_h(R_h^r v - v, \chi) = 0 \quad \forall\, \chi \in S_h^r, \quad \forall\, v \in H_h^2, \tag{5.4}$$

which in view of (5.3) is well defined. Moreover, when Λ_h satisfies (2.8) and (2.7) with $\alpha \geq 2$, the orthogonality property (5.4) and the analysis of section 4 yield

$$\|R_h^r v - v\|_0 + h \, \|R_h^r v - v\|_1 \leq C \, h^{r+1} \, \|v\|_{r+1} \tag{5.5}$$

$\forall\, h \in (0,\overline{h}_0)$ and $v \in H^{r+1}(\Omega) \cap \mathcal{H}(\Omega)$.

The first step towards obtaining a maximum norm error estimate is the estimation of the difference $R_h^r u - u$ at the nodes of the partition $\mathcal{P}_h$.

LEMMA 5.1. *Let $r \geq 2$ and assume that Λ_h satisfies* (2.8), (5.1), *and* (2.7) *with $\alpha \geq 2$. If $u \in H^{r+1}(\Omega) \cap \mathcal{H}(\Omega)$, then we have*

$$\max_{1 \leq j \leq J_h} \left| (R_h^r u - u)(x_j^h) \right| \leq C \, h^{r+1} \, \|u\|_{r+1} \quad \forall\, h \in (0,\overline{h}_0). \tag{5.6}$$

Proof. Let $h \in (0,\overline{h}_0)$. For $j \in \{1,\ldots,J_h\}$, we define the function

$$g_{x_j^h}(z) = \begin{cases} z - x_{\scriptscriptstyle L}, & z \leq x_j^h, \\ x_j^h - x_{\scriptscriptstyle L}, & z \geq x_j^h, \end{cases} \quad \forall\, z \in \overline{\Omega}, \tag{5.7}$$

which clearly belongs to $S_h^r \cap \mathbb{P}_h^1$. So with $\zeta = R_h^r u - u$, using the definition of R_h^r and (5.1), we obtain

$$\begin{aligned} 0 = \widetilde{B}_h(\zeta, g_{x_j^h}) &= \sum_{I \in \mathcal{P}_h} \left\{ [\![a \zeta' g_{x_j^h}]\!]_{\partial I} + (\mathcal{L}_I \zeta, g_{x_j^h})_I \right\} \\ &= (a\zeta', g'_{x_j^h}) \\ &= (a\zeta)(x_j^h) - \int_{x_{\scriptscriptstyle L}}^{x_j^h} a' \, \zeta \, dx, \quad j = 1,\ldots,J_h, \end{aligned}$$

and consequently, $\max_{1 \leq j \leq J_h} \left| \zeta(x_j^h) \right| \leq \frac{\|a'\|_0}{a_*} \, \|\zeta\|_0$. The proof of the lemma now follows from the latter relation and (5.5). ∎

Our next step is the estimation of the error $u_h - u$ at the right endpoint $x_{\scriptscriptstyle R}$ of Ω.

LEMMA 5.2. *Let $r \geq 2$, h_0 be the constant specified in* Theorem 4.6, *and assume that Λ_h satisfies* (2.8) *and* (2.7) *with $\alpha \geq 2$. If $u \in H^{r+1}(\Omega) \cap \mathcal{H}(\Omega)$, then*

$$\left| (u - u_h)(x_{\scriptscriptstyle R}) \right| \leq C \, h^{r+1} \, \|u\|_{r+1} \quad \forall\, h \in (0, h_0).$$

Proof. Consider the dual elliptic problem

$$-(a\ w')' - \beta\ w' + (\gamma_0 + \gamma - \beta')\ w = 0 \quad \text{on}\,\Omega, \tag{5.8a}$$

$$w(x_{_L}) = 0, \quad a(x_{_R})\ w'(x_{_R}) + \beta(x_{_R})\ w(x_{_R}) = 1, \tag{5.8b}$$

where γ_0 is a positive real number, sufficiently large to ensure the existence of an $H^2(\Omega)$-solution of the problem (cf. [1]). Note that this problem, in contrast with the dual problem (4.6) when $\psi = u_h - u$, is independent of h. Now taking the inner product of (5.8a) with the error, $e = u_h - u$, and using integration by parts we obtain

$$\begin{aligned} e(x_{_R}) &= B(e, w) + \gamma_0\ (e, w) \\ &= B(e, w - \mathcal{I}_h^1 w) + B(e, \mathcal{I}_h^1 w) + \gamma_0\ (e, w). \end{aligned} \tag{5.9}$$

First, using Theorem 4.6 and (2.2) we have

$$\big|B(e, w - \mathcal{I}_h^1 w)\big| \le\ C\ h^{r+1}\ \|u\|_{r+1}\ \|w\|_2, \tag{5.10}$$

$$\big|\gamma_0\ (e, w)\big| \le\ C\ h^{r+1}\ \|u\|_{r+1}\ \|w\|_0. \tag{5.11}$$

The term $B(e, \mathcal{I}_h^1 w)$ may be estimated as the corresponding term in (4.13) using (2.10) and Lemmas 4.1 and 4.2, so that

$$\big|B(e, \mathcal{I}_h^1 w)\big| \le\ C\ \big(h^{r+1}\ \|u\|_{r+1} + h\ \|u_h - \mathcal{I}_h^r u\|_1\big)\ \|\mathcal{I}_h^1 w\|_1.$$

Using again Theorem 4.6 and (2.2) in the relation above we obtain

$$\big|B(e, \mathcal{I}_h^1 w)\big| \le C\ h^{r+1}\ \|u\|_{r+1}\ \|w\|_2. \tag{5.12}$$

The lemma now follows by combining (5.10), (5.11), and (5.12) with (5.9). ∎

Next we present an H^1-superconvergent estimate for the difference $R_h^r u - u_h$.

PROPOSITION 5.3. *Let $r \ge 2$. Assume that Λ_h satisfies* (2.8) *and* (2.7) *with $\alpha \ge 2$. If u belongs to $H^{r+1}(\Omega) \cap \mathcal{H}(\Omega)$, then, for h sufficiently small, we have*

$$\|R_h^r u - u_h\|_1 \le\ C\ h^{r+1}\ \|u\|_{r+1}. \tag{5.13}$$

Proof. Let $e = u_h - u$ and $\nu_h = R_h^r u - u_h$. From (5.4) and (2.10) it follows that

$$\widetilde{B}_h(\nu_h, \nu_h) = D_1 + D_2, \tag{5.14}$$

where $D_1 = -(\beta e' + \gamma e, \Lambda_h \nu_h - \nu_h)$ and $D_2 = -(\beta e' + \gamma e, \nu_h)$. From (2.7) and Theorem 4.6 we have

$$\begin{aligned} \big|D_1\big| &\le\ C\ \sum_{I \in \mathcal{P}_h} h_I\ \|e\|_{1,I}\ \|\nu_h\|_{1,I} \\ &\le\ C\ h^{r+1}\ \|u\|_{r+1}\ \|\nu_h\|_1. \end{aligned} \tag{5.15}$$

Using integration by parts, Lemma 5.2, and the Sobolev inequality, we obtain

$$\begin{aligned} \big|D_2\big| &\le\ C\ \|e\|_0\ \|\nu_h\|_0 + \big|(\beta\ e\ \nu_h)(x_{_R}) - (e, \beta'\ \nu_h + \beta\ \nu_h')\big| \\ &\le\ C\big(\ \|e\|_0\ \|\nu_h\|_1 + |e(x_{_R})|\ |\nu_h(x_{_R})|\ \big) \\ &\le\ C\ h^{r+1}\ \|u\|_{r+1}\ \|\nu_h\|_1. \end{aligned} \tag{5.16}$$

The claim of the proposition now follows by (5.14), (5.15), (5.16), and (5.3). ∎

For $h \in (0,1)$ and $I \in \mathcal{P}_h$, we define the local bilinear forms $\widetilde{B}_I : H^2(I) \times \mathbb{P}^r(I) \to \mathbb{R}$ and $B_I : H^1(I) \times H^1(I) \to \mathbb{R}$ by

$$\widetilde{B}_I(v,p) = [\![av'p]\!]_{\partial I} + (\mathcal{L}_I v, \Lambda_h p)_I \quad \forall\, v \in H^2(I), \quad \forall\, p \in \mathbb{P}^r(I),$$
$$B_I(v,p) = (av', p')_I \quad \forall\, v, p \in H^1(I).$$

Following the proof of Lemma 4.2 we have

$$\left|\widetilde{B}_I(\phi,p) - B_I(\phi,p)\right| \le C\ h_I\ \|\phi\|_{1,I}\ \|p\|_{1,I} \quad \forall\, \phi, p \in \mathbb{P}^r(I).$$

Moreover, proceeding as in the proof of Lemma 4.3 we conclude that there exists $h_\infty \in (0,1)$ such that

$$\widetilde{B}_I(\phi,\phi) \ge C\ \|\phi\|^2_{1,I} \quad \forall\, \phi \in \mathbb{P}^r_0(I), \quad \forall\, h \in (0, h_\infty), \tag{5.17}$$

where $\mathbb{P}^r_0(I)$ is the subset of $\mathbb{P}^r(I)$ consisting of functions which vanish at the endpoints of I. Next, for $h \in (0, h_\infty)$ we define the operator $Y_I : H^1_0(I) \to \mathbb{P}^r_0(I)$ by

$$\widetilde{B}_I(Y_I v, p) = \widetilde{B}_I(v,p) \quad \forall\, p \in \mathbb{P}^r_0(I), \quad \forall\, v \in H^1_0(I).$$

In view of (5.17), the operator Y_I is well defined. We shall also make use of the operator $\mu_I : H^1(I) \to \mathbb{P}^r(I)$, defined by $\mu_I v := Y_I(v - \mathcal{I}^1_h v) + \mathcal{I}^1_h v \ \ \forall\, v \in H^1(I)$. The next proposition establishes an approximation property of μ_I in the L^∞ norm.

PROPOSITION 5.4. *Let $r \ge 2$ and assume that Λ_h satisfies* (2.7) *and* (2.8). *If $v \in W^{r+1,\infty}(\Omega)$, then we have*

$$|\mu_I v - v|_{\infty,I} \le\ C\ h_I^{r+1}\ \|v\|_{r+1,\infty} \quad \forall\, I \in \mathcal{P}_h, \quad \forall\, h \in (0, h_\infty). \tag{5.18}$$

Proof. Let $h \in (0, h_\infty)$. It is enough to prove (5.18) for $v \in C^{r+1}(\overline{\Omega})$. Indeed, if $I = (x_A, x_B) \in \mathcal{P}_h$, Taylor's theorem implies that

$$v(x) = \sum_{\ell=0}^{r} \frac{(x - x_A)^\ell}{\ell!}\ v^{(\ell)}(x_A) + \Phi(x) \quad \forall\, x \in I,$$

where $\Phi(x) = \frac{1}{r!} \int_{x_A}^x (x-z)^r\ v^{(r+1)}(z)\ dz \ \ \forall\, x \in I$. From the fact that $\mu_I p = p$, for $p \in \mathbb{P}^r(I)$, it follows that

$$\begin{aligned} |\mu_I v - v|_{\infty,I} &= |\mu_I \Phi - \Phi|_{\infty,I} \\ &\le |\mu_I \Phi - \mathcal{I}^1_h \Phi|_{\infty,I} + |\mathcal{I}^1_h \Phi - \Phi|_{\infty,I}. \end{aligned} \tag{5.19}$$

Since $E := \mu_I \Phi - \mathcal{I}^1_h \Phi \in \mathbb{P}^r_0(I)$, the definition of μ_I implies that

$$\begin{aligned} \widetilde{B}_I(E,E) &= \widetilde{B}_I(Y_I(\Phi - \mathcal{I}^1_h \Phi), E) \\ &= \widetilde{B}_I(\Phi - \mathcal{I}^1_h \Phi, E) \\ &= D_1 + D_2 + D_3, \end{aligned} \tag{5.20}$$

where $D_1 = \big(a(\Phi - \mathcal{I}^1_h\Phi)'', \Lambda_h E - E\big)_I$, $D_2 = \big(a'(\Phi - \mathcal{I}^1_h\Phi)', \Lambda_h E - E\big)_I$, $D_3 = \big(a(\Phi - \mathcal{I}^1_h\Phi)', E'\big)_I$. Using (2.7) and the fact that $\|\Phi''\|_{0,I} \le \frac{1}{(r-2)!}\ h_I^{r-\frac{1}{2}}\ \|v\|_{r+1,\infty}$, we obtain

$$|D_1| \le C\ h_I^{r+\frac{1}{2}}\ \|v\|_{r+1,\infty}\ \|E\|_{1,I}.$$

The identity $(\mathcal{I}_h^1\Phi)' = \Pi_h\Phi'$, the estimate for $\|\Phi''\|_{0,I}$ above, and (2.7), (2.5) yield

$$\begin{aligned}|D_2| &\le C\ h_I\ \|\Phi' - \Pi_h\Phi'\|_{0,I}\ \|E\|_{1,I}\\ &\le C\ h_I^2\ \|\Phi''\|_{0,I}\ \|E\|_{1,I}\\ &\le C\ h_I^{r+\frac{3}{2}}\ \|v\|_{r+1,\infty}\ \|E\|_{1,I},\end{aligned}$$

and similarly,

$$|D_3| \le C\ h_I^{r+\frac{1}{2}}\ \|v\|_{r+1,\infty}\ \|E\|_{1,I}.$$

Using (5.17) in (5.20) and the estimates for D_1, D_2, D_3 above we conclude that

$$\begin{aligned}|E|_{\infty,I} &\le C\ \sqrt{h_I}\ \|E\|_{1,I}\\ &\le C\ h^{r+1}\ \|v\|_{r+1,\infty}.\end{aligned} \tag{5.21}$$

Finally, (5.19), (5.21), and the estimate

$$\begin{aligned}|\mathcal{I}_h^1\Phi - \Phi|_{\infty,I} &\le |\Phi|_{\infty,I}\\ &\le C\ h_I^{r+1}\ \|v\|_{r+1,\infty},\end{aligned}$$

complete the proof of the proposition. ∎

We are now ready to prove the main result of this section.

THEOREM 5.5. *Let $r \ge 2$ and assume that Λ_h satisfies* (5.1), (2.8), *and* (2.7) *with $\alpha \ge 2$. If $u \in W^{r+1,\infty}(\Omega) \cap \mathcal{H}(\Omega)$, then, for h sufficiently small, we have*

$$|u - u_h|_\infty \le\ C\ h^{r+1}\ \|u\|_{r+1,\infty}. \tag{5.22}$$

Proof. Let $I \in \mathcal{P}_h$. Since $\alpha \ge 2$, in view of Propositions 5.3 and 5.4, we have

$$\begin{aligned}|e|_{\infty,I} &\le |u_h - R_h^r u|_{\infty,I} + |R_h^r u - \mu_I u|_{\infty,I} + |\mu_I u - u|_{\infty,I}\\ &\le C\ h^{r+1}\ \|u\|_{r+1,\infty} + |R_h^r u - \mu_I u|_{\infty,I}.\end{aligned} \tag{5.23}$$

Hence, it remains for us to estimate $\xi_I := R_h^r u|_I - \mu_I u \in \mathbb{P}^r(I)$. From the definitions of the operators R_h^r and μ_I we obtain $\widetilde{B}_I(\xi_I, p) = 0 \quad \forall\ p \in \mathbb{P}_0^r(I)$. Setting $p = \xi_I - \mathcal{I}_h^1\xi_I$ in the latter relation and using Remark 4.1 and (5.1), we obtain

$$\begin{aligned}a_*\ \|\xi_I'\|_{0,I}^2 &\le \widetilde{B}_I(\xi_I, \xi_I) + C\ h\ \|\xi_I\|_{1,I}^2\\ &= B_I(\xi_I, \mathcal{I}_h^1\xi_I) + C\ h\ \|\xi_I\|_{1,I}^2\\ &\le C\ h_I^{-\frac{1}{2}} \max_{1\le j\le J_h} \left|(R_h^r u - u)(x_j^h)\right|\ \|\xi_I'\|_{0,I} + C\ h\ (\|\xi_I\|_{0,I}^2 + \|\xi_I'\|_{0,I}^2),\end{aligned} \tag{5.24}$$

where we have used the fact that ξ_I and $R_h^r u - u$ coincide at the nodes of the partition. Also, using (5.5) and (5.18) we have

$$\|\xi_I\|_{0,I} \le C\ h^{r+1}\|u\|_{r+1,\infty}. \tag{5.25}$$

Combining (5.24), (5.25), and Lemma 5.1 we conclude that

$$\|\xi_I'\|_{0,I} \le C\ h^{r+\frac{1}{2}}\ \|u\|_{r+1,\infty} \tag{5.26}$$

for h sufficiently small. Since $|\xi_I|_{\infty,I} \le \max_{1\le j\le J_h} |\xi_I(x_j^h)| + \sqrt{h_I}\ \|\xi_I'\|_{0,I}$, from (5.26) and Lemma 5.1 we obtain

$$|\xi_I|_{\infty,I} \le C\ h^{r+1}\ \|u\|_{r+1,\infty}. \tag{5.27}$$

The theorem now follows by combining (5.27) and (5.23). ∎

5.2. Maximum norm estimates when $\alpha = 1$ and $\sigma = 1$. Here, we shall assume that $\alpha = 1$ and $\sigma = 1$, which covers the methods in Proposition 3.7 and Remark 3.5. Also, the assumption (5.1) for Λ_h, which was fundamental in the analysis of the previous subsection, is not needed now.

For $r \geq 2$ and $h \in (0,1)$, we define the bilinear form $\overline{B} : H_h^1 \times H_h^1 \to \mathbb{R}$ by $\overline{B}(v,\chi) = (a\, v', \chi')$ for $v, \chi \in H_h^1$ and introduce the standard elliptic projection operator $\overline{R}_h^r : H^1(\Omega) \to S_h^r$ by

$$\overline{B}(\overline{R}_h^r v - v, \chi) = 0 \quad \forall\, \chi \in S_h^r, \quad \forall\, v \in H^1(\Omega). \tag{5.28}$$

Using (1.1c) and the Poincaré–Friedrichs inequality we obtain $\overline{B}(\tilde{v},\tilde{v}) \geq C_{E,*}\, \|\tilde{v}\|_1^2$ for $\tilde{v} \in \mathcal{H}(\Omega)$, where $C_{E,*}$ is a positive constant. Thus, the projection $\overline{R}_h^r$ is well defined. Also, it is well known (cf. [41]) that $\overline{R}_h^r$ has the following approximation property:

$$\|\overline{R}_h^r v - v\|_0 + h\, \|\overline{R}_h^r v - v\|_1 \leq\ C\, h^{r+1}\, \|v\|_{r+1} \tag{5.29}$$

$\forall\, h \in (0,1)$ and $v \in H^{r+1}(\Omega) \cap \mathcal{H}(\Omega)$.

We start by estimating the difference $\overline{R}_h^r u - u$ at the nodes of the partition $\mathcal{P}_h$.

LEMMA 5.6. *Let $r \geq 2$. If $u \in H^{r+1}(\Omega) \cap \mathcal{H}(\Omega)$, then we have*

$$\max_{1 \leq j \leq J_h} \left|(\overline{R}_h^r u - u)(x_j^h)\right| \leq\ C\, h^{r+1}\, \|u\|_{r+1} \quad \forall\, h \in (0,1). \tag{5.30}$$

Proof. Let $h \in (0,1)$ and $\overline{\zeta} = \overline{R}_h^r u - u$. Also, we consider the functions $\{g_{x_j^h}\}_{j=1}^{J_h} \subset S_h^r$ defined in (5.7). Using (5.28) we obtain $(a\, \overline{\zeta}', g'_{x_j^h}) = 0$ for $j = 1, \ldots, J_h$. Proceeding now as in the proof of Lemma 5.1, we get $\max_{1 \leq j \leq J_h} |\overline{\zeta}(x_j^h)| \leq \frac{\|a'\|_0}{a_*}\, \|\overline{\zeta}\|_0$. The estimate (5.30) follows by combining the last estimate and (5.29). ∎

The next theorem is the maximum norm error estimate when $\alpha = 1$ and $\sigma = 1$.

THEOREM 5.7. *Let $r \geq 2$ and assume that Λ_h satisfies (2.7) with $\alpha = 1$ and (2.8) with $\sigma = 1$. If $u \in H^{r+2}(\Omega) \cap \mathcal{H}(\Omega)$, then, for h sufficiently small, we have*

$$|u - u_h|_\infty \leq\ C\, h^{r+1}\, \|u\|_{r+2}. \tag{5.31}$$

Proof. Let $h \in (0, h_0)$, $\overline{\nu}_h = \overline{R}_h^r u - u_h \in S_h^r$, $\overline{\zeta} = \overline{R}_h^r u - u$, and $\overline{e} = u - u_h$, where h_0 is the constant specified in Theorem 4.6. Thus, we have $\overline{\nu}_h = \overline{\zeta} + \overline{e}$. Now using (2.10) and (5.28), we obtain

$$B_h(\overline{\nu}_h, \overline{\nu}_h) = D_A + D_B + D_C, \tag{5.32}$$

where $D_A = B_h(\overline{R}_h^r u - \mathcal{I}_h^r u, \overline{\nu}_h) - B(\overline{R}_h^r u - \mathcal{I}_h^r u, \overline{\nu}_h)$, $D_B = B_h(\mathcal{I}_h^r u - u, \overline{\nu}_h) - B(\mathcal{I}_h^r u - u, \overline{\nu}_h)$, and $D_C = (\beta\, \overline{\zeta}' + \gamma\, \overline{\zeta}, \overline{\nu}_h)$. Using Lemma 4.2, (5.29), and (2.2), we have

$$\begin{aligned} \left|D_A\right| &\leq C\, h^2\, \|\overline{R}_h^r u - \mathcal{I}_h^r u\|_1\, \|\overline{\nu}_h\|_1 \\ &\leq C\, h^{r+2}\, \|u\|_{r+1}\, \|\overline{\nu}_h\|_1. \end{aligned} \tag{5.33}$$

Lemma 4.1 directly yields

$$\left|D_B\right| \leq\ C\, h^{r+1}\, \|u\|_{r+2}\, \|\overline{\nu}_h\|_1. \tag{5.34}$$

Using integration by parts, the Sobolev inequality, (5.29), and Lemma 5.6, we get

$$\begin{aligned} \left|D_C\right| &\le C\,\|\overline{\zeta}\|_0\,\|\overline{\nu}_h\|_0 + \left|(\beta\,\overline{\zeta}\,\overline{\nu}_h)(x_R) - (\overline{\zeta},\beta'\,\overline{\nu}_h + \beta\,\overline{\nu}_h')\right| \\ &\le C\,\left(\,\|\overline{\zeta}\|_0 + |\overline{\zeta}(x_R)|\,\right)\,\|\overline{\nu}_h\|_1 \\ &\le C\,h^{r+1}\,\|u\|_{r+1}\,\|\overline{\nu}_h\|_1. \end{aligned} \tag{5.35}$$

Combining (5.32), (5.33), (5.34), (5.35), and Lemma 4.3, we have

$$\|\overline{\nu}_h\|_1^2 \le\ C\,h^{r+1}\,\|u\|_{r+2}\,\|\overline{\nu}_h\|_1 + C\,\|\overline{\nu}_h\|_0^2.$$

The inequality above, along with (5.29) and Theorem 4.6, yields

$$\|\overline{\nu}_h\|_1 \le\ C\,h^{r+1}\,\|u\|_{r+2}, \tag{5.36}$$

which is an H^1-superconvergent estimate analogous to that of Proposition 5.3.

When $\Lambda_h p = p$ for $p \in \mathbb{P}_h^r$ in (5.2), then from (5.4) and (5.28) we have $R_h^r u = \overline{R}_h^r u$. Thus the analysis of the previous subsection (cf. Theorem 5.5) yields

$$|\overline{\zeta}|_\infty \le\ C\,h^{r+1}\,\|u\|_{r+1,\infty}. \tag{5.37}$$

The estimate (5.31) follows, combining (5.36) and (5.37). ∎

6. Some pointwise estimates. In the first proposition of this section we present a pointwise estimate for the error $u_h - u$ at the nodes of the partition, generalizing the well-known superconvergence results from the finite element case (see, e.g., [43] and the references therein).

PROPOSITION 6.1. *Let $r \ge 2$, h_0 be the constant defined in* Theorem 4.6*, and assume that Λ_h satisfies* (2.7) *and* (2.8)*. If $u \in H^{r+1+\sigma}(\Omega) \cap \mathcal{H}(\Omega)$, then we have*

$$\max_{1\le j\le J_h} \left|(u-u_h)(x_j^h)\right| \le C\,h^{r+\alpha+\sigma-1}\,\|u\|_{r+1+\sigma} \quad \forall\, h \in (0,h_0). \tag{6.1}$$

Proof. Let $h \in (0,h_0)$. For ξ a node of the partition $\mathcal{P}_h$, denote by $G_\xi \in H^1(\Omega)$ the Green's function of problem (1.1a)–(1.1b) (cf., e.g., [37]), which satisfies

$$B(v,G_\xi) = v(\xi) \quad \forall\, v \in H^1(\Omega). \tag{6.2}$$

In addition, we have $G_\xi \in H^{r+1}(x_L,\xi) \cap H^{r+1}(\xi,x_R)$ and

$$\|G_\xi\|_{r+1,(x_L,\xi)} + \|G_\xi\|_{r+1,(\xi,x_R)} \le \overline{C} \tag{6.3}$$

for some constant $\overline{C}$ depending only on Ω and the coefficients of L. Hence, from (2.2) we obtain

$$\|G_\xi - \mathcal{I}_h^r G_\xi\|_1 \le C\,h^r. \tag{6.4}$$

With $v = e = u_h - u$, (6.2) yields the error representation

$$e(\xi) = B(e, G_\xi - \mathcal{I}_h^r G_\xi) + B(e, \mathcal{I}_h^r G_\xi). \tag{6.5}$$

Using Theorem 4.6 and (6.4) we conclude that

$$\left|B(e, G_\xi - \mathcal{I}_h^r G_\xi)\right| \le C\,h^{2r}\,\|u\|_{r+1}. \tag{6.6}$$

To estimate $B(e,\mathcal{I}_h^r G_\xi)$ we use the orthogonality property (2.10) to write it as

$$\begin{aligned} B(e,\mathcal{I}_h^r G_\xi) &= B(e,\mathcal{I}_h^r G_\xi) - B_h(e,\mathcal{I}_h^r G_\xi) \\ &= E_A + E_B, \end{aligned} \tag{6.7}$$

where $E_A = B(\eta,\mathcal{I}_h^r G_\xi) - B_h(\eta,\mathcal{I}_h^r G_\xi)$, $E_B = B(\theta_h,\mathcal{I}_h^r G_\xi) - B_h(\theta_h,\mathcal{I}_h^r G_\xi)$, and $\theta_h = u_h - \mathcal{I}_h^r u$, $\eta = \mathcal{I}_h^r u - u$. First, from Lemma 4.1 (with $\ell = r$, $s = \alpha$, and $j = \sigma$), (2.2), and the bound (6.3), we have

$$\begin{aligned} \big|E_A\big| &\le C\, h^{\alpha+r-1+\sigma}\, \|u\|_{r+1+\sigma}\, \|\mathcal{I}_h^r G_\xi\|_{\alpha,I} \\ &\le C\, h^{\alpha+r-1+\sigma}\, \|u\|_{r+1+\sigma}. \end{aligned} \tag{6.8}$$

To estimate E_B we note that from Lemma 4.2 (with $s = \alpha$), Theorem 4.6, (2.2), and (6.3), we have

$$\begin{aligned} \big|E_B\big| &\le C\, h^{\alpha+\sigma}\, \|\theta_h\|_1\, \|\mathcal{I}_h^r G_\xi\|_{\alpha,h} \\ &\le C\, h^{\alpha+r+\sigma}\, \|u\|_{r+1}. \end{aligned} \tag{6.9}$$

The estimate (6.1) now follows by combining (6.5)–(6.9). ∎

REMARK 6.1. *The result of* Proposition 6.1 *is a superconvergence estimate for the error e, when the order of convergence $r+\alpha+\sigma-1$ is greater than the order of convergence in the L^∞ norm. This happens when $\alpha+\sigma-1 \ge 2$, which means $\alpha \ge 3$ when $\sigma = 0$ and $\alpha \ge 2$ when $\sigma = 1$. For $r \ge 4$ and for the locally conservative methods of Proposition* 3.1*, the order of convergence in* (6.1) *is equal to $2(r-1)$, since $\sigma = 0$ and $\alpha = r-1$. For $r = 2m$ and for the methods of Proposition* 3.2*, the order of convergence in* (6.1) *is equal to $2r$ since $\alpha = r$ and $\sigma = 1$ (cf. Table* 8.5 *in section* 8 *for $r = 2$), which is the same as that of the finite element method. For $r \in \{2,4,6\}$ and for the finite volume methods in Proposition* 3.7 *we do not have a superconvergence result. Indeed the order of convergence in* (6.1) *is equal to $r+1$ (since $\alpha = 1$ and $\sigma = 1$) and has been observed numerically (cf. Table* 8.6 *in section* 8 *for $r = 2$).*

The next proposition presents a pointwise bound for the derivative of the error $u_h - u$. This is interesting because it is related to the characteristic property (1.2a) of the locally conservative methods and the Neumann boundary condition in (1.1b).

PROPOSITION 6.2. *Let $r \ge 2$. Assume that $u_h \in S_h^r$ satisfies*

$$\mathcal{F}\big(u_h,(\omega_{j-1}^h,\omega_j^h)\big) = 0, \quad j = 1,\dots,M_h-1, \tag{6.10a}$$

$$\mathcal{G}\big(u_h,(\omega_{M_h-1}^h,\omega_{M_h}^h)\big) = 0, \quad u_h'(\omega_j^h-0) = u_h'(\omega_j^h+0), \quad j = 1,\dots,M_h-1, \tag{6.10b}$$

where $\{(\omega_{j-1}^h,\omega_j^h)\}_{j=1}^{M_h} \subset \Omega$ are open intervals with $x_L \le \omega_0^h$, $\omega_{M_h}^h = x_R$ and $\omega_{j-1}^h < \omega_j^h$, $j = 1,\dots,M_h$, i.e., $(\omega_{M_h-1}^h,\omega_{M_h}^h)$ is a boundary control volume of type II. *Then we have*

$$\max_{0\le m\le M_h-1} \big|(u-u_h)'(\omega_m^h)\big| \le C\, \left\{ \max_{0\le m\le M_h} \big|(u-u_h)(\omega_m^h)\big| + \|u-u_h\|_0 \right\}. \tag{6.11}$$

Proof. Let $e = u_h - u$. From (6.10) and (1.2) we obtain

$$a(\omega_j^h)e'(\omega_j^h) - a(\omega_{j-1}^h)e'(\omega_{j-1}^h) = \int_{\omega_{j-1}^h}^{\omega_j^h} (\beta e' + \gamma e)\, dx, \quad j = 1,\dots,M_h-1,$$

$$-a(\omega_{M_h-1}^h)\, e'(\omega_{M_h-1}^h) = \int_{\omega_{M_h-1}^h}^{x_R} (\beta e' + \gamma e)\, dx.$$

Adding the above equalities with respect to j we arrive at

$$a(\omega_m^h)\, e'(\omega_m^h) = -\int_{\omega_m^h}^{x_R} (\beta\, e' + \gamma\, e)\, dx, \quad m = 0, \ldots, M_h - 1.$$

Using integration by parts we obtain

$$a(\omega_m^h) e'(\omega_m^h) = \beta(\omega_m^h)\, e(\omega_m^h) - \beta(x_R)\, e(x_R) + \int_{\omega_m^h}^{x_R} (\beta' - \gamma)\, e\, dx \tag{6.12}$$

for $m = 0, \ldots, M_h - 1$, which yields (6.11). ∎

REMARK 6.2. *A final error estimate follows by combining* (6.11) *with the estimates in Theorems* 4.6, 5.5, *and* 5.7. *We also note that when* $\beta = \gamma = 0$ *then* $u_h'(\omega_j^h) = u'(\omega_j^h)$, *for* $j = 0, \ldots, M_h - 1$, *which is not the case for the finite element method.*

REMARK 6.3. *The methods in Proposition* 3.2 *satisfy the assumptions* (6.10a) *with* $M_h = J_h$ *and* $\omega_j^h = x_j^h$, $j = 0, \ldots, J_h$, *but not* (6.10b). *The result* (6.11) *also applies to the methods of Propositions* 3.6–3.7 *and Remark* 3.5.

REMARK 6.4. *For the locally conservative methods of Proposition* 3.1 *with* $r \geq 4$ *we have* $M_h = J_h$ *and* $\omega_j^h = x_j^h$ *for* $j = 0, \ldots, J_h$. *From* (6.12) *and Remark* 6.1 *we obtain*

$$\max_{0 \leq m \leq J_h - 1} |e'(x_m^h)| \leq\ C\ \left\{ h^{2(r-1)}\ \|u\|_{r+1} + \max_{0 \leq m \leq J_h - 1} \left| \int_{x_m^h}^{x_R} (\beta' - \gamma) e\, dx \right| \right\}. \tag{6.13}$$

Let $\xi \in [x_L, x_R)$ *and* $g = \mathcal{X}_{(\xi, x_R)}$. *For* $\delta \in (0,1)$ *there exists* $g_\delta \in C^{r-3}(\Omega)$ *such that*

$$\int_\Omega |g_\delta - g|\, dx \leq C\, \delta \qquad \text{and} \qquad \|g_\delta\|_{r-3} \leq C\, \delta^{-(r-3)+\frac{1}{2}}, \tag{6.14}$$

where the constant C *is independent of* ξ *and* δ. *Using* g *and* g_δ, *we introduce the following splitting:*

$$\int_\xi^{x_R} (\beta' - \gamma)\, e\, dx = \int_{x_L}^{x_R} (\beta' - \gamma)\, e\, (g - g_\delta)\, dx + \int_{x_L}^{x_R} (\beta' - \gamma)\, e\, g_\delta\, dx.$$

From Theorem 5.5 *and* (6.14), *we have*

$$\left| \int_{x_L}^{x_R} (\beta' - \gamma)\, e\, (g - g_\delta)\, dx \right| \leq C\, \delta\, h^{r+1}\, \|u\|_{r+1,\infty}. \tag{6.15}$$

For $w_\delta = T^*\big((\beta' - \gamma) g_\delta\big)$, *where* T^* *is the solution operator of* (4.6), *we obtain the identity*

$$\int_{x_L}^{x_R} e\, (\beta' - \gamma)\, g_\delta\, dx = B(e, w_\delta - \mathcal{I}_h^{r-2} w_\delta) + B(e, \mathcal{I}_h^{r-2} w_\delta).$$

From the definition of Λ_h *in Proposition* 3.1, (2.10), *and* (2.11), *we conclude that* $B(e, \mathcal{I}_h^{r-2} w_\delta) = 0$. *Hence, using* (2.2), (4.18), *the fact that* $\|w_\delta\|_{r-1} \leq C\, \|g_\delta\|_{r-3}$, *and* (6.14), *it follows that*

$$\begin{aligned} \left| \int_{x_L}^{x_R} e\, (\beta' - \gamma)\, g_\delta\, dx \right| &\leq C\, h^{2(r-1)}\, \|g_\delta\|_{r-3}\, \|u\|_{r+1} \\ &\leq C\, h^{2(r-1)}\, \delta^{-(r-3)+\frac{1}{2}}\, \|u\|_{r+1}. \end{aligned} \tag{6.16}$$

With $\delta = h^\nu$, *where* $\nu = \frac{2(r-3)}{2(r-3)+1}$, *the estimates* (6.13), (6.15), *and* (6.16) *yield* $\max_{0 \leq m \leq J_h - 1} \big|e'(x_m^h)\big| \leq\ C\, h^{r+1+\nu}\, \|u\|_{r+1,\infty}$.

7. A posteriori estimates. In this section we derive explicit residual-based a posteriori error estimates in the energy and L^2 norm for the methods of section 2 with $r = 2$, following the approach of [17] for the standard Galerkin finite element method. Our estimates are based on the general formulation (2.9) and make use of the orthogonality properties (2.8) and (2.10). We refer to [2] and [6] for a posteriori error estimates in the L^2 norm for finite volume methods based on piecewise linear polynomial spaces and applied to linear and nonlinear elliptic problems in two space dimensions.

PROPOSITION 7.1. *Let $r = 2$ and assume that Λ_h satisfies* (2.7) *and* (2.8). *For $h \in (0, \widehat{h}_0)$, we define the residual $R_E^h \in L^2(\Omega)$ of* (2.9) *by $R_E^h|_I = f - L_I u_h$ for $I \in \mathcal{P}_h$, where $\widehat{h}_0$ is the constant specified in Proposition* 4.4. *If $\sigma = 0$ in* (2.8), *then there exists a constant $C^P_{\alpha^*,0}$, independent of the solution u and the right-hand side function f, such that*

$$\|u - u_h\|_0 \le C^P_{\alpha^*,0} \left\{ \sum_{I\in\mathcal{P}_h} h_I^{2\alpha^*} \lambda^2_{\alpha^*}(h_I) \|R_E^h\|^2_{0,I} \right\}^{\frac{1}{2}} \quad \forall\, h \in (0, \widehat{h}_0), \tag{7.1}$$

where $\alpha^* = \min\{2, \alpha\}$, $\lambda_{\alpha^*}(h_I) = 1 + \widehat{C}_{2,1}(1 + h_I)$ when $\alpha^* = 1$, and $\lambda_{\alpha^*}(h_I) = \widetilde{C}_1 + \widehat{C}_{2,2}(1 + h_I)$ when $\alpha^* = 2$. If $\alpha = 1$ in (2.7) *and $\sigma = 1$ in* (2.8), *then there exists a constant $C^P_{1,1}$, independent of the solution u and the right-hand side function f, such that*

$$\|u - u_h\|_0 \le C^P_{1,1} \left\{ \sum_{I\in\mathcal{P}_h} h_I^2 \left(\widetilde{C}_1\, h_I \|R_E^h\|_{0,I} + \widehat{C}_{2,1}\,(1 + h_I) \|R_E^h - \mathcal{I}_h^1 R_E^h\|_{0,I} \right)^2 \right\}^{\frac{1}{2}} \tag{7.2}$$

$\forall\, h \in (0, \widehat{h}_0)$. *In the estimates above, $\widehat{C}_{2,1}$ and $\widehat{C}_{2,2}$ are the constants in* (2.7), *and $\widetilde{C}_1$ is the constant in* (2.2).

Proof. Let $h \in (0, \widehat{h}_0)$, $e = u - u_h$, and $w = T^* e \in H^2(\Omega) \cap \mathcal{H}(\Omega)$. Using integration by parts and (2.9) we have

$$\begin{aligned}
\|e\|_0^2 &= B(e, w) \\
&= (f, w) - B(u_h, w) \\
&= \sum_{I\in\mathcal{P}_h} (R_E^h, w - \Lambda_h \mathcal{I}_h^1 w)_I \\
&= \sum_{I\in\mathcal{P}_h} \left[(R_E^h, w - \mathcal{I}_h^1 w)_I + (R_E^h, \mathcal{I}_h^1 w - \Lambda_h \mathcal{I}_h^1 w)_I \right].
\end{aligned}$$

When $\alpha = 1$ and $\sigma = 0$, using the identity $(\mathcal{I}_h^1 w)' = \Pi_h w'$, (2.4), and (2.7), we have

$$\begin{aligned}
\|e\|_0^2 &\le \sum_{I\in\mathcal{P}_h} h_I \|R_E^h\|_{0,I} \left(\|w\|_{1,I} + \widehat{C}_{2,1} \|\mathcal{I}_h^1 w\|_{1,I} \right) \\
&\le \sum_{I\in\mathcal{P}_h} h_I \lambda_1(h_I) \|R_E^h\|_{0,I} \|w\|_{1,I} \\
&\le C_Q \left\{ \sum_{I\in\mathcal{P}_h} h_I^2 \lambda_1^2(h_I) \|R_E^h\|^2_{0,I} \right\}^{\frac{1}{2}} \|e\|_0,
\end{aligned}$$

where $C_{_Q} = \sup\big\{\|T^*g\|_1 : \ g \in L^2(\Omega) \ \text{ with } \ \|g\|_0 = 1\big\}$. When $\alpha \geq 2$ and $\sigma = 0$, using (2.2), (2.4), and (2.7), we have

$$\begin{aligned}\|e\|_0^2 &\leq \sum_{I\in\mathcal{P}_h} h_I^2 \, \|R_{_E}^h\|_{0,I} \, (\widetilde{C}_1 \, \|w\|_{2,I} + \widehat{C}_{2,2} \, \|\mathcal{I}_h^1 w\|_{2,I}) \\ &\leq \sum_{I\in\mathcal{P}_h} h_I^2 \, \lambda_2(h_I) \, \|R_{_E}^h\|_{0,I} \, \|w\|_{2,I} \\ &\leq C_{_R} \, \left\{ \sum_{I\in\mathcal{P}_h} h_I^4 \, \lambda_2^2(h_I) \, \|R_{_E}^h\|_{0,I}^2 \right\}^{\frac{1}{2}} \, \|e\|_0,\end{aligned}$$

where $C_{_R}$ is the constant of the elliptic regularity estimate (4.7). The estimates above yield (7.1) with $C_{1,0}^{_P} = C_{_Q}$ and $C_{2,0}^{_P} = C_{_R}$. When $\alpha = 1$ and $\sigma = 1$, we use the orthogonality property (2.8) and the estimates (2.2), (2.7), (2.4) to get

$$\|e\|_0^2 \leq \sum_{I\in\mathcal{P}_h} h_I \, \big(\widetilde{C}_1 \, h_I \, \|R_{_E}^h\|_{0,I} + \widehat{C}_{2,1} \, (1+h_I) \, \|R_{_E}^h - \mathcal{I}_h^1 R_{_E}^h\|_{0,I}\big) \, \|w\|_{2,I}$$

which along with (4.7) yields (7.2) with $C_{1,1}^{_P} = C_{_R}$. □

Remark 7.1. *When* (5.1) *holds, we have* $\Lambda_h \mathcal{I}_h^1 w = \mathcal{I}_h^1 w$, *so, instead of* (7.1) *we obtain* $\|u - u_h\|_0 \leq \widetilde{C}_1 \, C_{_R} \, \{\sum_{I\in\mathcal{P}_h} h_I^2 \, \|R_{_E}^h\|_{0,I}^2\}^{1/2}$ *for* $h \in (0, \widehat{h}_0)$, *which has the form of a finite element a posteriori error estimator.*

Remark 7.2. *If we assume that* $C_{_\Gamma} = 0$ *in* (4.4), *then we also have* $C_{_G} = 0$ *in* (4.3). *Proceeding as in Proposition* 7.1, *we conclude that*

$$B(e,e) = \sum_{I\in\mathcal{P}_h} (R_{_E}^h, e - \Lambda_h \mathcal{I}_h^1 e)_I \leq \ \Big\{ \sum_{I\in\mathcal{P}_h} h_I^2 \, \lambda_1^2(h_I) \, \|R_{_E}^h\|_{0,I}^2 \Big\}^{\frac{1}{2}} \, \|e\|_1.$$

Using (4.4) *we obtain* $\big[B(e,e)\big]^{1/2} \leq (C_{_\Delta})^{-1/2} \, \big\{\sum_{I\in\mathcal{P}_h} h_I^2 \, \lambda_1^2(h_I) \, \|R_{_E}^h\|_{0,I}^2\big\}^{\frac{1}{2}}$, *which is an a posteriori error bound in the energy norm.*

Remark 7.3. *We note that in the a posteriori error bounds of Proposition* 7.1 *and Remarks* 7.1 *and* 7.2 *the jump of the derivative at the interval boundaries is absent. This is due to the use of the interpolation operator* $\mathcal{I}_h^1$ *and this also applies in the finite element case in one space dimension* (*see, e.g.,* [17]).

Remark 7.4. *Assume that* $f \in H^1(\Omega)$ *or* $f \in H^2(\Omega)$. *Observing that*

$$B(u - u_h, v) = \sum_{I\in\mathcal{P}_h} \big\{(R_{_E}^h, v)_I - [\![a u_h' v]\!]_{\partial I}\big\} \quad \forall \, v \in H^1(\Omega),$$

and moving along the lines of [42] *or section* 3.4 *in* [3], *we can show that*

$$\|R_{_E}^h\|_{0,I} \leq C \, \big\{\|R_{_E}^h - \mathcal{I}_h^1 R_{_E}^h\|_{0,I} + \tfrac{1}{h_I} \, \|e\|_{1,I}\big\} \quad \forall \, I \in \mathcal{P}_h.$$

Since $L_I u_h \in C_{_B}^2(I)$, *using* (2.4), (2.2), *and* (2.1), *we obtain*

$$\begin{aligned}\|R_{_E}^h - \mathcal{I}_h^1 R_{_E}^h\|_{0,I} &\leq C \, \big(\|f - \mathcal{I}_h^1 f\|_{0,I} + h_I^2 \, \|L_I u_h\|_{2,I}\big) \\ &\leq C \, \big(h_I^s \, \|f\|_{s,I} + h_I^2 \, \|u_h\|_{2,I}\big) \\ &\leq C \, h_I^s \, \big(\|f\|_{s,I} + \|u_h\|_{1,I}\big), \quad s = 1, 2, \quad \forall \, I \in \mathcal{P}_h.\end{aligned}$$

We conclude from the two relations above that

$$\|R_E^h\|_{0,I} \le C\left\{h_I^s\,(\|f\|_{1,I}+\|u_h\|_{1,I})+\tfrac{1}{h_I}\,\|e\|_{1,I}\right\}\quad\forall\, I\in\mathcal{P}_h,\quad s=1,2. \tag{7.3}$$

The estimates above yield

$$\left\{\sum_{I\in\mathcal{P}_h} h_I^{2\overline{\alpha}}\,\|R_E^h\|_{0,I}^2\right\}^{\frac12} \le C\,\{h^{\overline{\alpha}+1}\,(\|f\|_1+\|u_h\|_1)+h^{\overline{\alpha}-1}\,\|e\|_1\}\quad\forall\,\overline{\alpha}\in\mathbb{N},$$

$$\left\{\sum_{I\in\mathcal{P}_h} h_I^2\,\|R_E^h-\mathcal{I}_h^1 R_E^h\|_{0,I}^2\right\}^{\frac12} \le C\,h^3\,(\|f\|_2+\|u_h\|_1).$$

Hence, the a posteriori error estimators of Proposition 7.1 *and Remarks* 7.1 *and* 7.2 *and the corresponding approximation errors are of the same order, and we expect them to be useful in the construction of an adaptive algorithm. In addition, using* (7.3) *we obtain the following lower bound of the* H^1 *error (cf. Theorem* 3.7 *in* [3]*):*

$$\sum_{I\in\mathcal{P}_h} h_I^2\|R_E^h\|_{0,I}^2 \le C\,\left\{\sum_{I\in\mathcal{P}_h} h_I^{2s+2}\,(\|f\|_{s,I}+\|u_h\|_{1,I})^2+\|e\|_1^2\right\},\quad s=1,2.$$

For the purpose of describing later in section 8 an algorithm for the control of the L^2 approximation error, we shall write our error estimators in the form

$$\mathcal{E}_h = C_{_M}\,\left\{\sum_{I\in\mathcal{P}_h}\eta_I^2\right\}^{\frac12}, \tag{7.4}$$

where η_I is a nonnegative, computable error indicator for the interval $I\in\mathcal{P}_h$. Indeed, for the error estimator (7.1) of Proposition 7.1 we have

$$C_{_M}=C^{P}_{\alpha^*,0},\quad \eta_I = h_I^{\alpha^*}\lambda_{\alpha^*}(h_I)\,\|R_E^h\|_{0,I}, \tag{7.5}$$

while for the error estimator (7.2)

$$C_{_M}=C^{P}_{1,1},\quad \eta_I = h_I\,\big(\widetilde{C}_1\,h_I\,\|R_E^h\|_{0,I}+\widehat{C}_{2,1}\,(1+h_I)\,\|R_E^h-\mathcal{I}_h^1R_E^h\|_{0,I}\big). \tag{7.6}$$

8. Numerical experiments. In this section we present the results of numerical experiments performed with some of the methods of section 3, based on piecewise quadratic functions. We shall refer to the method of Proposition 3.2 with $r=2$ as Method 3.1 and to the method of Proposition 3.6 with $r=2$ and $\varrho_1=\frac12-\frac{\sqrt3}{6}$ as Method 3.2. All numerical schemes were implemented in a `FORTRAN` program using double precision arithmetic. The resulting linear systems were solved using the `LINPACK` subroutines `DGBFA` and `DGBSL`. All runs were performed on a Sun UltraSparc 5 running SunOS 5.6, using the native version of the `FORTRAN` compiler.

8.1. Experimental order of convergence. Our first task is to verify numerically the convergence rate of Methods 3.1 and 3.2 and compare them with the standard Galerkin finite element method based on S_h^2. To do this we consider the problem

$$-\big((2+\cos(\tfrac{\pi}{2}x))\,u'\big)'+u'+u=f(x)\quad\forall\,x\in(0,1),\quad u(0)=u'(1)=0, \tag{8.1}$$

TABLE 8.1

where f is chosen so that the problem admits the C^∞–solution $u(x) = \sin(\frac{\pi}{2}x)$. This problem was solved numerically on a uniform grid consisting of $J_h = 20$, 40, 80, or 160 intervals. The L^2 and H^1 norms of the error $e = u - u_h$ were computed using an eight-point Gauss quadrature rule, and the L^∞ norm of the error was estimated by a finite sampling at the abscissae of the aforementioned quadrature rule. The results of these computations are summarized in Tables 8.1–8.2 and clearly confirm the convergence estimates of sections 4 and 5. The experimental rate of convergence and the discretization error for the standard Galerkin finite element method based on S_h^2 are shown in Table 8.3. The close agreement between the discretization errors of Method 3.1 and the finite element method is easily explained by the fact that u_h satisfies the finite element equations in addition to the finite volume equations (cf. Remark 3.2). Moreover, it is worth noting that the H^1 norm of the discretization error is approximately the same for all three methods.

For the sake of completeness we performed similar experiments with the first member of the infinite family of the methods constructed in Proposition 3.1 (cf. Remark 3.1) and listed the results in Table 8.4. Recall that for this method (referred to in Table 8.4 as the "Π_h-method") we have $\Lambda_h = \Pi_h$ and $\alpha = 1$, $\sigma = 0$. The experimental rates of convergence clearly agree with the rates predicted in Theorem 4.6.

To confirm the results of Proposition 6.1 (see also Remark 6.1) we determined the rate of convergence of the quantities $|e(1/4)|$, $|e(4/5)|$, and $|e(1)|$ for Methods 3.1–3.2, applied to the test problem (8.1). The results are shown in Tables 8.5–8.6.

8.2. Adaptive computations. As our next task we undertake the development and testing of an adaptive algorithm based on Methods 3.1 and 3.2, which uses the

a posteriori error bounds derived in section 7 to control the L^2 norm of the error. The goal is to compute an approximation u_h of the exact solution u of (1.1a)–(1.1b) such that $\|u-u_h\|_0 \le \text{TOL}$, for a given tolerance $\text{TOL} > 0$. In what follows, for $m \in \mathbb{N}_0$, we shall denote by $\mathcal{P}^{(m)}$ a partition of Ω with $J^{(m)}$ intervals and by $S^{(m)} \subset \mathcal{H}(\Omega)$ the finite element space consisting of functions which vanish at x_L and reduce to polynomials of degree less than or equal to two on each interval I of the partition $\mathcal{P}^{(m)}$. The adaptive algorithm starts with an initial partition $\mathcal{P}^{(0)}$ and an initial approximation $u^{(0)} \in S^{(0)}$ of u. Then it computes successive approximations $u^{(k)} \in S^{(k)}$, $k \ge 1$, where $S^{(k-1)} \subset S^{(k)}$, by means of the following iterative procedure.

Step 1. Given an approximate solution $u^{(k-1)} \in S^{(k-1)}$, compute the error indicators $\eta_I^{(k-1)}$ for $I \in \mathcal{P}^{(k-1)}$ and the corresponding error estimator $\mathcal{E}_h^{(k-1)}$ from (7.4).

Step 2. If $\mathcal{E}_h^{(k-1)} \le \text{TOL}$ stop. Otherwise, construct a new partition $\mathcal{P}^{(k)}$ of Ω by bisecting the intervals I of $\mathcal{P}^{(k-1)}$ for which $\eta_I^{(k-1)} > \frac{\text{TOL}}{C_M\sqrt{J^{(k-1)}}}$.

Step 3. Compute a new approximate solution $u^{(k)} \in S^{(k)}$, increment k, and go to Step 1.

We shall apply this adaptive algorithm on the test problem

$$-((x+\epsilon)\,u')' = 1 \quad \forall\, x \in (0,1), \quad u(0) = u'(1) = 0, \tag{8.2}$$

where $\epsilon > 0$ is a parameter. The exact solution of (8.2) is $u(x) = (1+\epsilon)\,\ln\big(1+\frac{x}{\epsilon}\big) - x$. We note that, for small ϵ, u and u' change rapidly near $x = 0$ and thus a locally fine grid is required to approximate u accurately. The constant C_M needed in the adaptive algorithm depends on the constants C_R, $\widetilde{C}_1$, and $C_{1,1}^P$ of the a posteriori

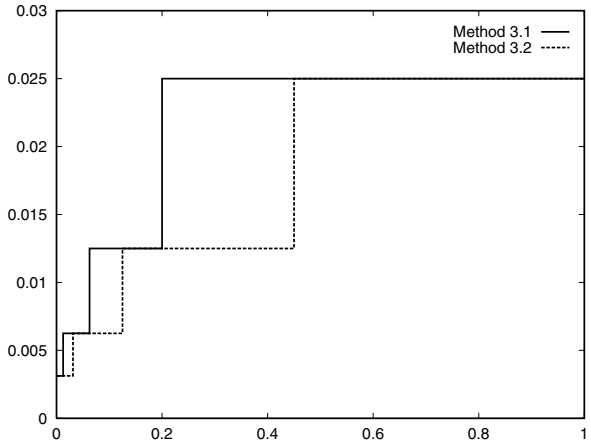

FIG. 8.1. *The mesh-size function for problem* (8.2) *with* $\epsilon = 0.01$ *and* TOL $= 0.0001$.

error estimates; cf. (7.4), (7.5), (7.6), and Remark 7.1. For Method 3.1 we have $C_M = \widetilde{C}_1\, C_R = \frac{1}{8}\, C_R$ (cf. [17]), while for Method 3.2 we have $C_M = C_R$. The constant $\widehat{C}_{2,1}$, needed in the computation of the error indicators for Method 3.2, may be estimated as in the proof of Proposition 3.5, and we have $\widehat{C}_{2,1} = \frac{17}{8} - \varrho_1$. To find upper bounds for the constants C_Q and C_R we observe that if $g \in L^2(\Omega)$ and $w = T^* g$, then for (8.2) we have $w'(x) = \frac{1}{x+\epsilon} \int_x^1 g(s)\, ds$ for $x \in [0,1]$. It follows that $C_Q \le \widetilde{C}_Q = \sqrt{A}$ and $C_R \le \widetilde{C}_R = \{(\frac{1}{\epsilon} + B)^2 + \frac{3}{2}\widetilde{C}_Q\}^{\frac{1}{2}}$, where $A = \int_0^1 \frac{1-x}{(x+\epsilon)^2}\, dx$ and $B = \int_0^1 \frac{1-x}{(x+\epsilon)^4}\, dx$. In the numerical experiments we used the upper bounds $\widetilde{C}_Q$ and $\widetilde{C}_R$ instead of C_Q and C_R, respectively. Figure 8.1 shows the local mesh-size function (i.e., the piecewise constant function whose restriction on each interval of the partition equals the length of the interval) after our adaptive algorithm terminated. We used $\epsilon = 0.01$, TOL $= 0.0001$, and an initial uniform partition of $[0,1]$ with 20 intervals. The final number of subintervals and the L^2 norm of the exact error for Method 3.1 were 47 and 2.33017(-5), respectively, and for Method 3.2 they were 55 and 3.19060(-5), respectively. The corresponding errors on uniform grids with the same number of intervals, 0.78595(-3) and 0.634621(-3), are both greater than TOL. We also note that for both methods the length of the smallest interval is the same, but for Method 3.2 the size of the finest grid region is approximately twice as large as that of Method 3.1. This is in good agreement with the discretization errors of Tables 8.1–8.2.

CONVERGENCE ANALYSIS OF A MULTIGRID METHOD FOR A CONVECTION-DOMINATED MODEL PROBLEM*

MAXIM A. OLSHANSKII† AND ARNOLD REUSKEN‡

Abstract. The paper presents a convergence analysis of a multigrid solver for a system of linear algebraic equations resulting from the discretization of a convection-diffusion problem using a finite element method. We consider piecewise linear finite elements in combination with a streamline diffusion stabilization. We analyze a multigrid method that is based on canonical intergrid transfer operators, a "direct discretization" approach for the coarse-grid operators and a smoother of line-Jacobi type. A robust (diffusion and h-independent) bound for the contraction number of the two-grid method and the multigrid W-cycle are proved for a special class of convection-diffusion problems, namely with Neumann conditions on the outflow boundary, Dirichlet conditions on the rest of the boundary, and a flow direction that is constant and aligned with gridlines. Our convergence analysis is based on modified smoothing and approximation properties. The arithmetic complexity of one multigrid iteration is optimal up to a logarithmic term.

1. Introduction.

Concerning the theoretical analysis of multigrid methods, different fields of application have to be distinguished. For linear self-adjoint elliptic boundary value problems the convergence theory is well developed (cf. [5, 9, 35, 36]). In other areas the state of the art is (far) less advanced. For example, for convection-diffusion problems the development of a multigrid convergence analysis is still in its infancy. In this paper we present a convergence analysis of a multilevel method for a special class of two-dimensional convection-diffusion problems.

An interesting class of problems for the analysis of multigrid convergence is given by

$$\begin{cases} -\varepsilon\Delta u + b\cdot\nabla u = f & \text{in } \Omega = (0,1)^2, \\ u = g & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

with $\varepsilon > 0$ and $b = (\cos\phi, \sin\phi)$, $\phi \in [0, 2\pi)$. The application of a discretization method results in a large sparse linear system which depends on a mesh size parameter h_k. For a discussion of discretization methods for this problem we refer to [28, 1, 2] and the references therein. Note that in the discrete problem we have three interesting parameters: h_k (mesh size), ε (convection-diffusion ratio), and ϕ (flow direction). For the approximate solution of this type of problems *robust* multigrid methods have been developed which are efficient solvers for a large range of relevant values for the parameters h_k, ε, ϕ. To obtain good robustness properties the components in the multigrid method have to be chosen in a special way because, in general, the

"standard" multigrid approach used for a diffusion problem does not yield satisfactory results when applied to a convection-dominated problem. To improve robustness several modifications have been proposed in the literature, such as "robust" smoothers, matrix-dependent prolongations, and restrictions and semicoarsening techniques. For an explanation of these methods we refer to [9, 33, 4, 13, 14, 18, 19, 37]. These modifications are based on heuristic arguments and empirical studies and rigorous convergence analysis proving robustness is still missing for most of these modifications.

Related to the theoretical analysis of multigrid applied to convection-diffusion problems we note the following. In the literature one finds convergence analyses of multigrid methods for nonsymmetric elliptic boundary value problems which are based on perturbation arguments [6, 9, 17, 32]. If these analyses are applied to the problem in (1.1) the constants in the estimates depend on ε and the results are not satisfactory for the case $\varepsilon \ll 1$. In [11, 25] multigrid convergence for a one-dimensional convection-diffusion problem is analyzed. These analyses, however, are restricted to the one-dimensional case. In [23, 26] convection-diffusion equations as in (1.1) with *periodic* boundary conditions are considered. A Fourier analysis is applied to analyze the convergence of two- or multigrid methods. In [23] the problem (1.1) with periodic boundary conditions and $\phi = 0$ is studied. For the discretization the streamline diffusion finite element method on a uniform grid is used. A bound for the contraction number of a multigrid V-cycle with point Jacobi smoother is proved which is uniform in ε and h_k provided $\varepsilon \sim h_k$ is satisfied. Note that due to the fact that a point Jacobi smoother is used one can not expect robustness of this method for $h_k \gg \varepsilon \downarrow 0$. In [26] a two-grid method for solving a first order upwinding finite difference discretization of the problem (1.1) with periodic boundary conditions is analyzed, and it is proved that the two-grid contraction number is bounded by a constant smaller than one which does not depend on any of the parameters ε, h_k, ϕ. In [3] the application of the hierarchical basis multigrid method to a finite element discretization of problems as in (1.1) is studied. The analysis there shows how the convergence rate depends on ε and on the flow direction, but the estimates are not uniform with respect to the mesh size parameter h_k. In [27] the convergence of a multigrid method applied to a standard finite difference discretization of the problem (1.1) with $\phi = 0$ is analyzed. This method is based on *semicoarsening* and a matrix-dependent prolongation and restriction. It is proved that the multigrid W-cycle has a contraction number smaller than one independent of h_k and ε. The analysis in [27] is based on linear algebra arguments only and is not applicable in a finite element setting. Moreover, the case with *standard coarsening*, which will be treated in the present paper, is not covered by the analysis in [27].

In the present paper we consider the convection-diffusion problem

$$\begin{aligned} -\varepsilon \Delta u + u_x &= f \quad \text{in} \quad \Omega := (0,1)^2, \\ \frac{\partial u}{\partial x} &= 0 \quad \text{on} \quad \Gamma_E := \{\, (x,y) \in \overline{\Omega} \mid x = 1 \,\}, \\ u &= 0 \quad \text{on} \quad \partial\Omega \setminus \Gamma_E. \end{aligned} \tag{1.2}$$

In this problem we have Neumann boundary conditions on the outflow boundary and Dirichlet boundary conditions on the remaining part of the boundary. Hence, the solution may have parabolic layers but exponential boundary layers at the outflow boundary do not occur. For this case an a priori regularity estimate of the form $\|u\|_{H^2} \leq c\,\varepsilon^{-1}\|f\|_{L^2}$ holds, whereas for the case with an exponential boundary layer one only has $\|u\|_{H^2} \leq c\,\varepsilon^{-\frac{3}{2}}\|f\|_{L^2}$. Due to the Dirichlet boundary conditions a Fourier analysis is not applicable.

For the discretization we use conforming linear finite elements. As far as we know there is no multigrid convergence analysis for convection-dominated problems known in the literature that can be applied in a finite element setting with nonperiodic boundary conditions and yields robustness for the parameter range $0 \leq \varepsilon \leq h_k \leq 1$. In this paper we present an analysis which partly fills this gap. We use the streamline diffusion finite element method (SDFEM). The SDFEM ensures a higher order of accuracy than a first order upwind finite difference method (cf. [28, 38]). In SDFEM a mesh-dependent anisotropic diffusion, which acts only in the streamline direction, is added to the discrete problem. Such anisotropy is important for the high order of convergence of this method and also plays a crucial role in our convergence analysis of the multigrid method. In this paper we only treat the case of a uniform triangulation which is taken such that the streamlines are aligned with gridlines. Whether our analysis can be generalized to the situation of an unstructured triangulation is an open question.

We briefly discuss the different components of the multigrid solver.

- For the *prolongation and restriction* we use the canonical intergrid transfer operators that are induced by the nesting of the finite element spaces.
- The hierarchy of *coarse grid discretization operators* is constructed by applying the SDFEM on each grid level. Note that due to the level-dependent stabilization term we have level-dependent bilinear forms and the Galerkin property $A_{k-1} = r_k A_k p_k$ does not hold.
- Related to the *smoother* we note the following. First we emphasize that due to a certain crosswind smearing effect in the finite element discretization the x-line Jacobi or Gauss–Seidel methods do *not* yield robust smoothers (i.e., they do not result in a direct solver in the limit case $\varepsilon = 0$; cf. [9]). This is explained in more detail in Remark 6.1 in section 6. In the present paper we use a smoother of x-line-Jacobi type.

These components are combined in a standard W-cycle algorithm.

The convergence analysis of the multigrid method is based on the framework of the smoothing- and approximation property as introduced by Hackbusch [9, 10]. However, the splitting of the two-grid iteration matrix that we use in our analysis is not the standard one. This splitting is given in (6.8). It turns out to be essential to keep the preconditioner corresponding to the smoother (W_k in (6.8)) as part of the approximation property. Moreover, in the analysis we have to distinguish between residuals which after presmoothing are zero close to the inflow boundary and those that are nonzero. This is done by using a cut-off operator (Φ_k in (6.8)). The main reason for this distinction is the following. As is usually done in the analysis of the approximation property we use finite element error bounds combined with regularity results. In the derivation of a L^2 bound for the finite element discretization error we use a duality argument. However, the formal dual problem has poor regularity properties, since the inflow boundary of the original problem is the outflow boundary of the dual problem. Thus Dirichlet outflow boundary conditions would appear and we obtain poor estimates due to the poor regularity. To avoid this, we consider a dual problem with Neumann outflow and Dirichlet inflow conditions. To be able to deal with the inconsistency caused by these "wrong" boundary conditions we assume the input residuals for the coarse grid correction to be zero near the inflow boundary. Numerical experiments from section 11 related to the approximation property show that such analysis is sharp.

In our estimates there are terms that grow logarithmically if the mesh size parameter h_k tends to zero. To compensate this the number of presmoothings has to

be taken level dependent. This then results in a two-grid method with a contraction number $\|T_k\|_{A^TA} \leq c < 1$ and a complexity $\mathcal{O}(N_k(\ln N_k)^4)$, with $N_k = h_k^{-2}$. Using standard arguments we obtain a similar convergence result for the multigrid W-cycle.

The remainder of this paper is organized as follows. In section 2 we give the weak formulation of the problem (1.2) and describe the SDFEM. In section 3 some useful properties of the stiffness matrix are derived. In section 4 we prove some a priori estimates for the continuous and the discrete solution. In section 5 we derive quantitative results concerning the upstream influence of a right-hand side on the solution. These results are needed in the proof of the modified approximation property. *Section 6 contains the main results of this paper*. In this section we describe the multigrid algorithm and present the convergence analysis. In sections 7–10 we give proofs of some important results that are used in the analysis in section 6. In section 11 we present results of a few numerical experiments.

2. The continuous problem and its discretization. For the weak formulation of the problem (1.2) we use the $L^2(\Omega)$ scalar product which is denoted by $(\cdot,\cdot)$. For the corresponding norm we use the notation $\|\cdot\|$. With the Sobolev space $\mathbf{V} := \{\, v \in H^1(\Omega) \mid v = 0 \ \text{ on } \ \partial\Omega \setminus \Gamma_E \,\}$ the weak formulation is as follows: find $u \in \mathbf{V}$ such that

$$a(u,v) := \varepsilon(u_x, v_x) + \varepsilon(u_y, v_y) + (u_x, v) = (f, v) \ \text{ for all } \ v \in \mathbf{V}. \tag{2.1}$$

From the Lax–Milgram lemma it follows that a unique solution of this problem exists. For the discretization we use linear finite elements on a uniform triangulation. For this we use a mesh size $h_k := 2^{-k}$ and grid points $x_{i,j} = (ih_k, jh_k)$, $0 \leq i,j \leq h_k^{-1}$. A uniform triangulation is obtained by inserting diagonals that are oriented from southwest to northeast. Let $\mathbb{V}_k \subset \mathbf{V}$ be the space of continuous functions that are piecewise linear on this triangulation and have zero values on $\partial\Omega \setminus \Gamma_E$. For the discretization of (2.1) we consider the SDFEM: find $u_k \in \mathbb{V}_k$ satisfying

$$(\varepsilon + \delta_k h_k)((u_k)_x, v_x) + \varepsilon((u_k)_y, v_y) + ((u_k)_x, v) = (f, v + \delta_k h_k v_x) \ \text{ for all } \ v \in \mathbb{V}_k \tag{2.2}$$

with

$$\delta_k = \begin{cases} \bar{\delta} & \text{if } \ \frac{h_k}{2\varepsilon} \geq 1, \\ 0 & \text{otherwise.} \end{cases} \tag{2.3}$$

The stabilization parameter $\bar{\delta}$ is a given constant of order 1. For an analysis of the SDFEM we refer to [28, 15]. In this paper we assume

$$\bar{\delta} \in \left[\frac{1}{3}, 1\right]. \tag{2.4}$$

The value $\frac{1}{3}$ for the lower bound is important for our analysis. The choice of 1 for the upper bound is made for technical reasons and this value is rather arbitrary. The finite element formulation (2.2) gives rise to the (stabilized) bilinear form

$$a_k(u,v) := (\varepsilon + \delta_k h_k)(u_x, v_x) + \varepsilon(u_y, v_y) + (u_x, v), \quad u, v \in \mathbf{V}. \tag{2.5}$$

Note the following relation for the bilinear form $a_k(\cdot,\cdot)$:

$$a_k(v,v) = \varepsilon\|v_y\|^2 + (\varepsilon + \delta_k h_k)\|v_x\|^2 + \frac{1}{2}\int_{\Gamma_E} v^2\, dy \quad \text{for } \ v \in \mathbf{V}. \tag{2.6}$$

The main topic of this paper is a convergence analysis of a multigrid solver for the algebraic system of equations that corresponds to (2.2). In this convergence analysis the particular form of the right-hand side in (2.2), which is essential for consistency in the SDFEM, does not play a role. Therefore for an arbitrary $f \in \mathrm{L}^2(\Omega)$ we will consider the problems

$$u \in \mathbf{V} \quad \text{such that} \quad a_k(u,v) = (f,v) \quad \text{for all} \quad v \in \mathbf{V}, \tag{2.7}$$

$$u_k \in \mathbb{V}_k \quad \text{such that} \quad a_k(u_k,v_k) = (f,v_k) \quad \text{for all} \quad v_k \in \mathbb{V}_k. \tag{2.8}$$

Note that u and u_k depend on the stabilization term in the bilinear form and that these solutions differ from those in (2.1) and (2.2).

3. Representation of the stiffness matrix. We now derive a representation of the stiffness matrix corresponding to the bilinear form $a_k(\cdot,\cdot)$ that will be used in the analysis below. The standard nodal basis in $\mathbb{V}_k$ is denoted by $\{\phi_\ell\}_{1\le\ell\le N_k}$ with N_k the dimension of the finite element space, $N_k := h_k^{-1}(h_k^{-1}-1)$. Define the isomorphism:

$$P_k : X_k := \mathbb{R}^{N_k} \to \mathbb{V}_k, \quad P_k x = \sum_{i=1}^{N_k} x_i \phi_i.$$

On X_k we use a scaled Euclidean scalar product $\langle x,y\rangle_k = h_k^2 \sum_{i=1}^{N_k} x_i y_i$ and corresponding norm denoted by $\|\cdot\|$ (note that this notation is also used to denote the $\mathrm{L}^2(\Omega)$ norm). The adjoint $P_k^* : \mathbb{V}_k \to X_k$ satisfies $(P_k x, v) = \langle x, P_k^* v\rangle_k$ for all $x \in X_k,\ v \in \mathbb{V}_k$. The following norm equivalence holds:

$$C^{-1}\|x\| \le \|P_k x\| \le C\|x\| \quad \text{for all} \quad x \in \mathrm{X}_k, \tag{3.1}$$

with a constant C independent of k. The stiffness matrix A_k on level k is defined by

$$\langle A_k x, y\rangle_k = a_k(P_k x, P_k y) \quad \text{for all} \quad x,y \in \mathrm{X}_k. \tag{3.2}$$

In an interior grid point the discrete problem has the stencil

$$\frac{1}{h_k^2}\begin{bmatrix} 0 & -\varepsilon & 0 \\ -\varepsilon_k & 2(\varepsilon_k+\varepsilon) & -\varepsilon_k \\ 0 & -\varepsilon & 0 \end{bmatrix} + \frac{1}{h_k}\begin{bmatrix} 0 & -\frac{1}{6} & \frac{1}{6} \\ -\frac{1}{3} & 0 & \frac{1}{3} \\ -\frac{1}{6} & \frac{1}{6} & 0 \end{bmatrix}, \qquad \varepsilon_k := \varepsilon + \delta_k h_k\ . \tag{3.3}$$

For a matrix representation of the discrete operator we first introduce some notation and auxiliary matrices. Let $n_k := h_k^{-1}$ and

$$\hat{D}_x := \frac{1}{h_k}\mathrm{tridiag}(-1,1,0) \in \mathbb{R}^{n_k\times n_k}\ ,$$

$$\hat{A}_x := \hat{D}_x^T\hat{D}_x = \frac{1}{h_k^2}\begin{pmatrix} 2 & -1 & & & \\ -1 & 2 & -1 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 2 & -1 \\ & & & -1 & 1 \end{pmatrix} \in \mathbb{R}^{n_k\times n_k}\ ,$$

$$\hat{A}_y := \frac{1}{h_k^2}\mathrm{tridiag}(-1,2,-1) \in \mathbb{R}^{(n_k-1)\times(n_k-1)}\ ,$$

$$\hat{J} := \begin{pmatrix} 1 & & & \\ & \ddots & & \\ & & 1 & \\ & & & \frac{1}{2} \end{pmatrix} \in \mathbb{R}^{n_k\times n_k}, \quad \hat{T} := \mathrm{tridiag}(0,0,1) \in \mathbb{R}^{n_k\times n_k}\ .$$

Furthermore, let I_m be the $m \times m$ identity matrix. We finally introduce the following $N_k \times N_k$ matrices

$$D_x := I_{n_k-1} \otimes \hat{D}_x \ , \quad A_x := I_{n_k-1} \otimes \hat{A}_x = D_x^T D_x \ , \quad A_y := \hat{A}_y \otimes \hat{J}$$

and the $N_k \times N_k$ blocktridiagonal matrix

$$B := \text{blocktridiag}(I_{n_k}, 4I_{n_k}, \hat{T}) \ .$$

Using all this notation we consider the following representation for the stiffness matrix A_k in (3.2):

$$A_k = \left(\varepsilon + \left(\delta_k - \frac{1}{3}\right) h_k\right) A_x + \varepsilon A_y + \frac{1}{6} B D_x. \tag{3.4}$$

The latter decomposition can be written in stencil notation as

$$\frac{\bar{\varepsilon}_k}{h_k^2} \begin{bmatrix} 0 & 0 & 0 \\ -1 & 2 & -1 \\ 0 & 0 & 0 \end{bmatrix} + \frac{\varepsilon}{h_k^2} \begin{bmatrix} 0 & -1 & 0 \\ 0 & 2 & 0 \\ 0 & -1 & 0 \end{bmatrix} + \frac{1}{6h_k} \begin{bmatrix} 0 & -1 & 1 \\ -4 & 4 & 0 \\ -1 & 1 & 0 \end{bmatrix} \tag{3.5}$$

with $\bar{\varepsilon}_k = \varepsilon + (\delta_k - \frac{1}{3})h_k > 0$.

Some properties of the matrices used in the decomposition (3.4) are collected in the following lemma.

For $B, C \in \mathbb{R}^{n \times n}$ we write $B \geq C$ iff $x^T B x \geq x^T C x$ for all $x \in \mathbb{R}^n$.

LEMMA 3.1. *The following inequalities hold:*

$$A_x D_x^{-1} \geq 0, \tag{3.6}$$

$$A_y D_x^{-1} \geq 0, \tag{3.7}$$

$$B \geq 2I, \tag{3.8}$$

$$A_k D_x^{-1} \geq \frac{1}{3} I, \tag{3.9}$$

$$\|D_x A_k^{-1}\| \leq 3. \tag{3.10}$$

Proof. To check (3.6) observe $A_x D_x^{-1} = D_x^T D_x D_x^{-1} = D_x^T$. Now note that $D_x^T + D_x$ is symmetric positive definite.

To prove (3.7) it suffices to show that $D_x^T A_y \geq 0$ holds. We have

$$K := D_x^T A_y = (I_{n_k-1} \otimes \hat{D}_x^T)(\hat{A}_y \otimes \hat{J}) = \hat{A}_y \otimes \tilde{D}_x^T \ ,$$

with the matrix

$$\tilde{D}_x^T = \frac{1}{h_k} \begin{pmatrix} 1 & -1 & & \\ & \ddots & \ddots & \\ & & 1 & -\frac{1}{2} \\ & & & \frac{1}{2} \end{pmatrix}.$$

Hence in the matrix $K + K^T = \hat{A}_y \otimes (\tilde{D}_x^T + \tilde{D}_x)$ both factors $\hat{A}_y$ and $\tilde{D}_x^T + \tilde{D}_x$ are symmetric positive definite. From this the result follows.

To prove (3.8) we define $R := B - 4I$ and note that $\|R\|^2 \leq \|R\|_\infty \|R\|_1 \leq 4$. Using this we get

$$\langle Bx, x\rangle_k = 4\|x\|^2 + \langle Rx, x\rangle_k \geq 4\|x\|^2 - \|R\|\|x\|^2 \geq 2\|x\|^2$$

which proves the desired result. Inequality (3.9) follows immediately from the representation of A_k in (3.4) and inequalities (3.6)–(3.8). From the result in (3.9) it follows that $D_x^T A_k \geq \frac{1}{3} D_x^T D_x$. This implies $\|D_x x\|^2 \leq 3\langle A_k x, D_x x\rangle_k \leq 3\|A_k x\|\|D_x x\|$ for all $x \in \mathrm{X}_k$ and thus estimate (3.10) is also proved. ∎

4. A priori estimates. In this paper we study the convergence of a multigrid method for solving the system of equations

$$A_k x_k = b, \tag{4.1}$$

with A_k the stiffness matrix from the previous section. As already noted in the introduction, our analysis relies on smoothing and approximation properties. For establishing a suitable approximation property we will use regularity results and a priori estimates for solutions of the continuous and the discrete problems. Such results are collected in this section. In the remainder of the paper we restrict ourselves to the convection-dominated case.

Assumption 4.1. We consider only values of k and ε such that $\varepsilon \leq \frac{1}{2} h_k$.

If instead of the factor $\frac{1}{2}$ in this assumption we take another constant C, our analysis can still be applied but some technical modifications are needed (to distinguish between $\delta_k = \bar{\delta}$ and $\delta_k = 0$) which make the presentation less transparent.

We consider this convection-dominated case to be the most interesting one. Many results that will be presented also hold for the case of an arbitrary positive ε but the proofs for the diffusion-dominated case often differ from those for the convection-dominated case. In view of the presentation we decided to treat only the convection-dominated case. Note that then

$$\delta_k = \bar{\delta} \in \left[\frac{1}{3}, 1\right] \quad \text{and} \quad \frac{1}{3} h_k \leq \varepsilon_k = \varepsilon + \bar{\delta} h_k \leq \frac{3}{2} h_k. \tag{4.2}$$

For the inflow boundary we use the notation $\Gamma_W := \{(x, y) \in \overline{\Omega} \mid x = 0\}$. For the continuous solution u the following a priori estimates hold.

THEOREM 4.1. *For $f \in L_2(\Omega)$ let u be the solution of* (2.7). *There is a constant c independent of k and ε such that*

$$\|u\| + \|u_x\| \leq c\|f\|, \tag{4.3}$$

$$\sqrt{\varepsilon}\|u_y\| \leq c\|f\|, \tag{4.4}$$

$$h_k\|u_{xx}\| + \sqrt{\varepsilon h_k}\|u_{xy}\| + \varepsilon\|u_{yy}\| \leq c\|f\|, \tag{4.5}$$

$$\int_{\Gamma_E} u^2\, dy + h_k \int_{\Gamma_W} u_x^2\, dy + \varepsilon \int_{\Gamma_E} u_y^2\, dy \leq c\|f\|^2. \tag{4.6}$$

Proof. Since $f \in L_2(\Omega)$, the regularity theory from [8] ensures that the solution u of (2.7) belongs to $\mathrm{H}^2(\Omega)$. Hence we can consider the strong formulation of (2.7),

$$-\varepsilon u_{yy} - \varepsilon_k u_{xx} + u_x = f, \tag{4.7}$$

with boundary conditions as in (1.2). Now we multiply (4.7) with u_x and integrate by parts. Taking boundary conditions into account, we get the following terms:

$$\begin{aligned}
-\varepsilon(u_{yy},u_x) &= \frac{\varepsilon}{2}((u_y^2)_x,1) = \frac{\varepsilon}{2}\int_{\Gamma_E} u_y^2\,dy,\\
-\varepsilon_k(u_{xx},u_x) &= -\frac{\varepsilon_k}{2}((u_x^2)_x,1) = \frac{\varepsilon_k}{2}\int_{\Gamma_W} u_x^2\,dy \geq c\,h_k\int_{\Gamma_W} u_x^2\,dy \quad \text{(we use (4.2))},\\
(u_x,u_x) &= \|u_x\|^2 \geq \|u\|^2,\\
(f,u_x) &\leq \frac{1}{2}\|f\|^2 + \frac{1}{2}\|u_x\|^2.
\end{aligned}$$

From these relations the results (4.3) and (4.6), except the bound for $\int_{\Gamma_E} u^2\,dy$, easily follow. Next we multiply (4.7) with u and integrate by parts to obtain

$$\varepsilon\|u_y\|^2 + \varepsilon_k\|u_x\|^2 + \frac{1}{2}\int_{\Gamma_E} u^2\,dy = (f,u) \leq \|f\|\|u\| \leq c\,\|f\|^2 \quad \text{(we use (4.3))}.$$

Estimate (4.4) and the remainder of (4.6) now follow. To prove (4.5) we introduce $F = f - u_x$. Due to (4.3) we have $\|F\| \leq c\,\|f\|$. Moreover $-\varepsilon u_{yy} - \varepsilon_k u_{xx} = F$ holds. If we square both sides of this equality and integrate over Ω we obtain

$$\varepsilon^2\|u_{yy}\|^2 + 2\varepsilon\varepsilon_k(u_{yy},u_{xx}) + \varepsilon_k^2\|u_{xx}\|^2 = \|F\|^2 \leq c\,\|f\|^2. \tag{4.8}$$

Further note that for any sufficiently smooth function v, satisfying the boundary conditions in (1.2), the relations

$$v_{xx}(x,0) = v_{xx}(x,1) = 0,\ x \in (0,1), \quad v_y(0,y) = v_{xy}(1,y) = 0,\ y \in (0,1),$$

hold, and thus

$$(v_{yy},v_{xx}) = -(v_y,v_{xxy}) = (v_{xy},v_{xy}).$$

Using a standard density argument we conclude that for the solution $u \in \mathrm{H}^2(\Omega)$ of (2.7) the relation $(u_{yy},u_{xx}) = (u_{xy},u_{xy})$ holds. Now (4.8) gives

$$\varepsilon^2\|u_{yy}\|^2 + 2\varepsilon\varepsilon_k\|u_{xy}\|^2 + \varepsilon_k^2\|u_{xx}\|^2 \leq c\,\|f\|^2.$$

In combination with (4.2) this yields (4.5). ∎

The next lemma states that the x-derivative of the *discrete* solution is also uniformly bounded if the right-hand side is from $\mathbb{V}_k$.

LEMMA 4.2. *For $f_k \in \mathbb{V}_k$ let $u_k \in \mathbb{V}_k$ be a solution to* (2.8)*; then*

$$\|(u_k)_x\| \leq c\,\|f_k\|. \tag{4.9}$$

Proof. The result in (4.9) follows from the estimate (3.10) in Lemma 3.1. To show this we need some technical considerations.

First we show how the size of the x-derivative of a finite element function $v \in \mathbb{V}_k$ can be determined from its corresponding coefficient vector $P_k^{-1}v \in X_k$. Let $\mathcal{I}$ be the index set $\{(i,j) \mid 0 \leq i \leq n_k - 1,\ \ 1 \leq j \leq n_k - 1\}$. For $(i,j) \in \mathcal{I}$ let $T^l_{(i,j)}$ and $T^u_{(i,j)}$ be the two triangles in the triangulation which have the line between the grid

points $x_{i,j}$ and $x_{i+1,j}$ as a common edge. Let $v \in \mathbb{V}_k$ be given. For $1 \le j \le n_k - 1$ we introduce the vector $\mathbf{v}_j = (v(x_{1,j}), \dots, v(x_{n_k,j}))^T$. We then obtain

$$\begin{aligned}\|v_x\|^2 &= \sum_{(i,j)\in\mathcal{I}} \left(\int_{T^l_{(i,j)}} v_x^2 \, dxdy + \int_{T^u_{(i,j)}} v_x^2 \, dxdy \right) \\ &= \sum_{(i,j)\in\mathcal{I}} \left(\frac{v(x_{i+1,j}) - v(x_{i,j})}{h_k} \right)^2 h_k^2 = h_k^2 \sum_{1\le j\le n_k-1} \big(D_x\mathbf{v}_j\big)^T (D_x\mathbf{v}_j) \\ &= h_k^2 \big(D_x P_k^{-1} v\big)^T \big(D_x P_k^{-1} v\big) = \|D_x P_k^{-1} v\|^2.\end{aligned}$$

Therefore

$$\|v_x\| = \|D_x P_k^{-1} v\| \quad \text{for any} \quad v \in \mathbb{V}_k. \tag{4.10}$$

For the discrete solution of (2.8) with $f = f_k$ we have the representation $u_k = P_k A_k^{-1} P_k^* f_k$. Now from (3.10) and (4.10) it follows that

$$\|(u_k)_x\| = \|D_x A_k^{-1} P_k^* f_k\| \le 3 \, \|P_k^* f_k\| \le c \, \|f_k\|$$

with a constant c independent of k and ε. ∎

The next lemma gives some bounds on the difference between discrete and continuous solutions

LEMMA 4.3. *Define the error $e_k = u - u_k$, where u and u_k are solutions of the problems* (2.7) *and* (2.8) *with right-hand side $f = f_k \in \mathbb{V}_k$. Then the following estimates hold:*

$$\|(e_k)_x\| \le c\|f_k\| \tag{4.11}$$

$$\varepsilon\|(e_k)_y\|^2 + \frac{1}{2}\int_{\Gamma_E} e_k^2 \, dy \le \, c\frac{h_k^2}{\varepsilon}\|f_k\|^2. \tag{4.12}$$

Proof. Estimate (4.11) directly follows from (4.3) and (4.9) by a triangle inequality. The proof of (4.12) is based on standard arguments: the Galerkin orthogonality, approximation properties of $\mathbb{V}_k$, and a priori estimates from (4.5). Indeed

$$\begin{aligned}&\varepsilon\|(e_k)_y\|^2 + (\varepsilon + \bar\delta h_k)\|(e_k)_x\|^2 + \frac{1}{2}\int_{\Gamma_E} e_k^2 \, dy = a_k(e_k, e_k) = \inf_{v_k\in\mathbb{V}_k} a_k(e_k, u - v_k) \\ &\quad\le \inf_{v_k\in\mathbb{V}_k} \big(\varepsilon\|(e_k)_y\|\|(u-v_k)_y\| + (\varepsilon + \bar\delta h_k)\|(e_k)_x\|\|(u-v_k)_x\| + \|(e_k)_x\|\|u - v_k\|\big) \\ &\quad\le c\,(\varepsilon\, h_k\|(e_k)_y\|\|u\|_{H^2} + h_k^2\|(e_k)_x\|\|u\|_{H^2}) \\ &\quad\le c\left(h_k\|(e_k)_y\|\|f_k\| + \frac{h_k^2}{\varepsilon}\|f_k\|^2\right) \le \frac{\varepsilon}{2}\|(e_k)_y\|^2 + c\frac{h_k^2}{\varepsilon}\|f_k\|^2.\end{aligned}$$

The estimate (4.12) follows. ∎

5. Upstream influence of the streamline diffusion method. Consider the continuous problem (2.7). The goal of this section is to estimate the upstream influence of the right-hand side function f on the solution u. The same will be done for the corresponding discrete problem. In the literature, results of such type are known for the problem with Dirichlet boundary conditions and typically formulated

in the form of estimates on the (discrete) Greens function (see, e.g., [31, 20, 16]). A typical result is that the value of the solution at a point x is essentially determined by the values of the right-hand side in a "small" strip that contains x. This strip has a crosswind width of size $O(\varepsilon^*|\ln h|)$, where $\varepsilon^* = \max\{\varepsilon, h^{\frac{3}{2}}\}$, and in the streamline direction it ranges from the inflow boundary to a $\mathcal{O}(h|\ln h|)$ upstream distance from x. In our analysis we need precise quantitative results for the case with Neumann outflow boundary conditions. In the literature we did not find such results. Hence we present proofs of the results that are needed for the multigrid convergence analysis further on. Our analysis uses the known technique of cut-off functions (e.g., [7, 16]), it avoids the use of an adjoint problem and is based on the following lemma.

LEMMA 5.1. *For $\varepsilon_k = \varepsilon + \bar{\delta} h_k$ assume a function $\phi \in H^1_\infty(0,1)$, such that $0 \le -\varepsilon_k \phi_x \le \phi$. Denote by $\|\cdot\|_\phi$ a semi-norm induced by the scalar product $(\phi\cdot,\cdot)$. Then the solution u of (2.7) satisfies*

$$\|u_x\|_\phi \le 2\|f\|_\phi, \tag{5.1}$$

$$\varepsilon_k \ \phi(0) \int_{\Gamma_W} u_x^2 \, dy \le \|f\|_\phi^2, \tag{5.2}$$

$$\frac{1}{4}\|u\|^2_{-\phi_x} + \varepsilon \|u_y\|_\phi^2 \le (\phi\, f, u). \tag{5.3}$$

Proof. We consider the strong formulation (4.7) and multiply it with ϕu_x and integrate by parts. We then get the following terms:

$$\begin{aligned}
-\varepsilon(u_{yy}, \phi u_x) &= \frac{\varepsilon}{2}\|u_y\|^2_{-\phi_x} + \frac{\varepsilon}{2}\phi(1)\int_{\Gamma_E} u_y^2 \, dy \ge 0,\\
-\varepsilon_k(u_{xx}, \phi u_x) &= -\frac{\varepsilon_k}{2}\|u_x\|^2_{-\phi_x} + \frac{\varepsilon_k}{2}\phi(0)\int_{\Gamma_W} u_x^2 \, dy \ge -\frac{1}{2}\|u_x\|_\phi^2 + \frac{\varepsilon_k}{2}\phi(0)\int_{\Gamma_W} u_x^2 \, dy,\\
(u_x, \phi u_x) &= \|u_x\|_\phi^2,\\
(f, \phi u_x) &\le \|f\|_\phi \|u_x\|_\phi \le \|f\|_\phi^2 + \frac{1}{4}\|u_x\|_\phi^2.
\end{aligned}$$

Now (5.1) and (5.2) immediately follow. To obtain the estimate (5.3) we multiply (4.7) with $\phi\, u$ and integrate by parts. We get the following terms:

$$\begin{aligned}
-\varepsilon(u_{yy}, \phi\, u) &= \varepsilon\|u_y\|_\phi^2,\\
-\varepsilon_k(u_{xx}, \phi\, u) &= \varepsilon_k\|u_x\|_\phi^2 + \varepsilon_k(u_x, \phi_x\, u)\\
&\ge \varepsilon_k\|u_x\|_\phi^2 - \varepsilon_k^2\|u_x\|^2_{-\phi_x} - \frac{1}{4}\|u\|^2_{-\phi_x} \ge -\frac{1}{4}\|u\|^2_{-\phi_x},\\
(u_x, \phi\, u) &= \frac{1}{2}\|u\|^2_{-\phi_x} + \frac{\phi(1)}{2}\int_{\Gamma_E} u^2 \, dy.
\end{aligned}$$

Thus (5.3) follows. ∎

For arbitrary $\xi \in [0,1]$ consider the function

$$\phi_\xi(x) = \begin{cases} 1 & \text{for } x \in [0,\xi],\\ \exp\left(-\frac{x-\xi}{\varepsilon_k}\right) & \text{for } x \in (\xi, 1]. \end{cases}$$

For any ξ the function $\phi_\xi(x)$ satisfies the assumptions of Lemma 5.1. For $0 < \xi < \eta < 1$ we define the domains

$$\Omega_\xi = \{(x,y) \in \Omega : x < \xi\}, \quad \Omega_\eta = \{(x,y) \in \Omega : x > \eta\}.$$

Direct application of Lemma 5.1 with $\phi = \phi_\xi$ gives the following corollary.

COROLLARY 5.2. *Consider $f \in L_2(\Omega)$ such that* $\mathrm{supp}(f) \in \Omega_\eta$ *and let u be the corresponding solution of problem* (2.7). *Assume $\eta - \xi \geq 2\,\varepsilon_k\, p\,|\ln h_k|,\ p > 0$. Then we have*

$$\|u_x\|_{L_2(\Omega_\xi)} \leq h_k^p \|f\|, \tag{5.4}$$

$$\varepsilon_k \int_{\Gamma_W} u_x^2\, dy \leq h_k^{2p} \|f\|^2, \tag{5.5}$$

$$\sqrt{\varepsilon}\|u_y\|_{L_2(\Omega_\xi)} \leq \sqrt{\varepsilon_k}\, h_k^p \|f\|. \tag{5.6}$$

Proof. The estimate $\|f\|_\phi^2 = (\phi f, f)_{\Omega_\eta} \leq \phi(\eta)\|f\|_{\Omega_\eta}^2 = h_k^{2p}\|f\|^2$ and (5.1), (5.2) imply the results (5.4) and (5.5). We also have

$$\begin{aligned}(\phi f, u) = (\phi f, u)_{\Omega_\eta} &\leq \varepsilon_k \|f\|_\phi^2 + \frac{1}{4\varepsilon_k}(\phi u, u)_{\Omega_\eta} = \varepsilon_k \|f\|_\phi^2 + \frac{1}{4}(-\phi_x u, u)_{\Omega_\eta} \\ &\leq \varepsilon_k \|f\|_\phi^2 + \frac{1}{4}\|u\|_{-\phi_x}^2.\end{aligned}$$

Together with (5.3) this yields (5.6). ∎

We need an analogue of estimate (5.1) for the finite element solution u_k of (2.8). To this end consider a vector $\phi = (\phi_0, \ldots, \phi_{n_k})$, such that $\phi_i > 0$ for all i and

$$0 \leq -\varepsilon_k \frac{\phi_i - \phi_{i-1}}{h_k} \leq c_0 \phi_i, \quad i = 1, \ldots, n_k, \tag{5.7}$$

with a constant $c_0 \in (0, \frac{4}{9})$ and $\varepsilon_k = \varepsilon + \bar{\delta} h_k$.

Define $\hat{\Phi}_k := \mathrm{diag}(\phi_i)_{1 \leq i \leq n_k}$, $\Phi_k := I_{n_k - 1} \otimes \hat{\Phi}_k$ with ϕ_i satisfying (5.7). Let $\langle \cdot, \cdot \rangle_\Phi = \langle \Phi_k \cdot, \cdot \rangle_k$.

LEMMA 5.3. *There exists a constant $c > 0$ independent of k and ε such that*

$$\langle A_k x, D_x x \rangle_\Phi \geq c\, \|D_x x\|_\Phi^2 \quad \textit{for all} \ \ x \in X_k.$$

Proof. We use similar arguments as in the proof of (3.10). We use the representation (3.4) of the stiffness matrix: $A_k = \bar{\varepsilon}_k A_x + \varepsilon A_y + \frac{1}{6} B D_x$. Note that

$$D_x^T \Phi_k A_y = (I_{n_k - 1} \otimes \hat{D}_x^T)(I_{n_k - 1} \otimes \hat{\Phi}_k)(\hat{A}_y \otimes \hat{J}) = \hat{A}_y \otimes \hat{D}_x^T \hat{\Phi}_k \hat{J}.$$

The matrix $\hat{A}_y$ is symmetric positive definite. Using $\phi_i \leq \phi_{i-1}$ and a Gershgorin theorem it follows that $\hat{D}_x^T \hat{\Phi}_k \hat{J} + \hat{J} \hat{\Phi}_k \hat{D}_x$ is symmetric positive definite, too. Hence, $D_x^T \Phi_k A_y \geq 0$ holds, i.e.,

$$\langle A_y x, D_x x \rangle_\Phi \geq 0 \quad \text{for all} \ \ x \in X_k. \tag{5.8}$$

From the assumption on ϕ it follows that $\phi_{i-1} \leq (1 + \frac{c_0 h_k}{\varepsilon_k})\phi_i$ for all i. Using this and the relation

$$\frac{1}{2}(\hat{\Phi}_k^{\frac{1}{2}} \hat{D}_x^T \hat{\Phi}_k^{-\frac{1}{2}} + \hat{\Phi}_k^{-\frac{1}{2}} \hat{D}_x \hat{\Phi}_k^{\frac{1}{2}}) = \frac{1}{2h_k} \mathrm{tridiag}\left(\sqrt{\frac{\phi_{i-1}}{\phi_i}}\,,\, 2\,,\, \sqrt{\frac{\phi_i}{\phi_{i+1}}} \right)$$

it follows that

$$\Phi_k^{\frac{1}{2}} D_x^T \Phi_k^{-\frac{1}{2}} \geq \frac{1}{2h_k}\left(2 - 2\sqrt{1+\frac{c_0 h_k}{\varepsilon_k}}\right) I \geq -\frac{c_0}{2\varepsilon_k} I \geq -\frac{c_0}{2\bar{\varepsilon}_k} I$$

holds. And thus

$$\bar{\varepsilon}_k \langle A_x x, D_x x\rangle_\Phi = \bar{\varepsilon}_k \langle \Phi_k D_x^T D_x x, D_x x\rangle \geq -\frac{1}{2} c_0 \langle D_x x, D_x x\rangle_\Phi \quad \text{for all } \ x \in X_k. \tag{5.9}$$

We decompose B as $B = 4I - R$. A simple computation yields

$$\|\Phi_k^{\frac{1}{2}} R \Phi_k^{-\frac{1}{2}}\|_1 \leq 1 + \sqrt{1+\frac{c_0 h_k}{\varepsilon_k}} \leq 1 + \sqrt{1+3c_0} \leq 2 + \frac{3}{2} c_0.$$

Similarly we get $\|\Phi_k^{\frac{1}{2}} R \Phi_k^{-\frac{1}{2}}\|_\infty \leq 2 + \frac{3}{2} c_0$ and thus $\|\Phi_k^{\frac{1}{2}} R \Phi_k^{-\frac{1}{2}}\| \leq 2 + \frac{3}{2} c_0$. Hence

$$\Phi_k^{\frac{1}{2}} B \Phi_k^{-\frac{1}{2}} \geq \left(4 - \left(2 + \frac{3}{2} c_0\right)\right) I = \left(2 - \frac{3}{2} c_0\right) I$$

and thus

$$\frac{1}{6}\langle B D_x x, D_x x\rangle_\Phi \geq \left(\frac{1}{3} - \frac{1}{4} c_0\right) \langle D_x x, D_x x\rangle_\Phi \quad \text{for all } \ x \in X_k. \tag{5.10}$$

Combination of the results in (5.8), (5.9), and (5.10) yields

$$\langle A_k x, D_x x\rangle_\Phi \geq \left(\frac{1}{3} - \frac{3}{4} c_0\right) \langle D_x x, D_x x\rangle_\Phi \geq c \langle D_x x, D_x x\rangle_\Phi \quad \text{for all } \ x \in X_k$$

with a constant $c > 0$ (use that $c_0 \in (0, \frac{4}{9})$). ∎

LEMMA 5.4. *For $f = f_k \in \mathbb{V}_k$ let u_k be the solution of the problem* (2.8)*. Then*

$$\sum_{i=1}^{n_k} \sum_{j=1}^{n_k - 1} h_k^2 \phi_i \left(\frac{u_{i,j} - u_{i-1,j}}{h_k}\right)^2 \leq C \sum_{i=1}^{n_k} \sum_{j=1}^{n_k - 1} h_k^2 \phi_i (M_k \hat{f})_{i,j}^2 \tag{5.11}$$

holds. Here u_{ij} is the nodal value of u_k at the grid point $x_{i,j}$, $\hat{f}$ is the vector of nodal values of f_k, M_k is the mass matrix, and ϕ_i satisfies (5.7)*.*

Proof. Let $\hat{u}_k = P_k^{-1} u_k \in X_k$ be the vector of nodal values of u_k; then

$$A_k \hat{u}_k = M_k \hat{f} =: \hat{b}_k. \tag{5.12}$$

The diagonal matrices Φ_k and $\hat{\Phi}_k$ are as in Lemma 5.3. The statement of the lemma is equivalent to $\langle \Phi_k D_x \hat{u}_k, D_x \hat{u}_k\rangle_k \leq c \langle \Phi_k \hat{b}_k, \hat{b}_k\rangle_k$, with a constant c that is independent of $\hat{b}_k$. This is the same as

$$\|D_x A_k^{-1}\|_\Phi \leq c. \tag{5.13}$$

Note that (5.13) is a generalization of the result in (3.10). From Lemma 5.3 we obtain

$$\|D_x x\|_{\hat{\Phi}}^2 < \frac{1}{c}\langle A_k x, D_x x\rangle_{\hat{\Phi}} \leq \frac{1}{c}\|A_k x\|_\Phi \|D_x x\|_\Phi \quad \text{for all } \ x \in X_k;$$

thus $\|D_x x\|_\Phi \leq \tilde{c}\|A_k x\|_\Phi$ for all x. Hence we have proved the result in (5.13). ∎

For the discrete case we consider

$$\phi_i^\xi = \begin{cases} 1 & \text{for } ih_k \in [0,\xi], \\ \exp\left(-\frac{ih_k-\xi}{4h_k}\right) & \text{for } ih_k > \xi. \end{cases} \tag{5.14}$$

It is straightforward to check that $-(\phi_i^\xi - \phi_{i-1}^\xi) = (\exp(\frac{1}{4}) - 1)\,\phi_i^\xi$ if $ih_k > \xi$. Therefore, using $\varepsilon_k \le \frac{3}{2}h_k$,

$$0 \le -\varepsilon_k \frac{\phi_i^\xi - \phi_{i-1}^\xi}{h_k} \le \frac{3}{2}\left(\exp\left(\frac{1}{4}\right) - 1\right)\phi_i^\xi, \quad i = 1, 2, \ldots . \tag{5.15}$$

For any ξ the vector ϕ_i^ξ, $1 \le i \le n_k$, satisfies the condition (5.7) with $c_0 = \frac{3}{2}(\exp(\frac{1}{4}) - 1)$. This constant is less than $\frac{4}{9}$. As a consequence of Lemma 5.4 we obtain discrete versions of the results in Corollary 5.2.

COROLLARY 5.5. *Consider $f_k \in \mathbb{V}_k$ such that $\operatorname{supp}(f_k) \in \Omega_\eta$ and let u_k be a the corresponding solution of problem* (2.8). *Assume $\eta - \xi \ge 8\,h_k\,p\,|\ln h_k|$, $p > 0$; then*

$$\|(u_k)_x\|_{L_2(\Omega_\xi)} \le c\,h_k^p \|f_k\|, \tag{5.16}$$

$$\|(u_k)_y\|_{L_2(\Omega_\xi)} \le c\,\xi\,h_k^{p-1} \|f_k\|. \tag{5.17}$$

Proof. Estimate (5.16) is a consequence of (5.11). Indeed, observe the following inequalities:

$$\begin{aligned} \|(u_k)_x\|_{L_2(\Omega_\xi)} &\le c \sum_{i:\, ih \le \xi} \sum_{j=1}^{n_k-1} h_k^2 \left(\frac{u_{i,j} - u_{i-1,j}}{h_k}\right)^2 \\ &= c \sum_{i:\, ih \le \xi} \sum_{j=1}^{n_k-1} h_k^2 \phi_i \left(\frac{u_{i,j} - u_{i-1,j}}{h_k}\right)^2 \le c \sum_{i=1}^{n_k} \sum_{j=1}^{n_k-1} h_k^2 \phi_i (M_k \hat{f})_{i,j}^2 \\ &\le c \left(\max_{ih \ge \eta} \phi_i\right) \sum_{i=1}^{n_k} \sum_{j=1}^{n_k-1} h_k^2 (M_h \hat{f})_{i,j}^2 \le c \left(\max_{ih \ge \eta} \phi_i\right) \|f_k\|^2 \le c\,h_k^{2p} \|f_k\|^2. \end{aligned}$$

Estimate (5.17) follows from an inverse inequality, the Friedrichs inequality, and (5.16):

$$\|(u_k)_y\|_{L_2(\Omega_\xi)} \le c\,h_k^{-1} \|u_k\|_{L_2(\Omega_\xi)} \le c\,\xi\,h_k^{-1} \|(u_k)_x\|_{L_2(\Omega_\xi)} \le c\,\xi h_k^{p-1} \|f\|. \qquad \square$$

COROLLARY 5.6. *Consider $f_k \in \mathbb{V}_k$ such that $\operatorname{supp}(f_k) \in \Omega_\eta$. Let u and u_k be the solutions* (2.7) *and* (2.8), *respectively. Assume $\eta - \xi \ge 8\,h_k\,p\,|\ln h_k|$, $p > 0$. Then for $e_k = u - u_k$ we have*

$$\begin{aligned} &\|(e_k)_x\|_{L_2(\Omega_\xi)} \le c\,h_k^p \|f_k\|, \\ &\|(e_k)_y\|_{L_2(\Omega_\xi)} \le c \max\left\{\sqrt{\frac{\varepsilon_k}{\varepsilon}};\ \frac{\xi}{h_k}\right\} h_k^p \|f_k\|. \end{aligned}$$

Proof. The proof is made by direct superposition of estimates in Corollaries 5.2 and 5.5. $\square$
