SEMIDISCRETE FINITE ELEMENT APPROXIMATIONS OF A LINEAR FLUID-STRUCTURE INTERACTION PROBLEM*

Q. DU†, M. D. GUNZBURGER‡, L. S. HOU§, AND J. LEE¶

Abstract. Semidiscrete finite element approximations of a linear fluid-structure interaction problem are studied. First, results concerning a divergence-free weak formulation of the interaction problem are reviewed. Next, semidiscrete finite element approximations are defined, and the existence of finite element solutions is proved with the help of an auxiliary, discretely divergence-free formulation. A discrete inf-sup condition is verified, and the existence of a finite element pressure is established. Strong a priori estimates for the finite element solutions are also derived. Then, by passing to the limit in the finite element approximations, the existence of a strong solution is demonstrated and semidiscrete error estimates are obtained.

Key words. fluid-structure interactions, finite element methods, error estimates

1. Introduction.

Fluid-structure interaction problems have been extensively studied in recent years both analytically and computationally. The book [28] and the special issue [30] give accounts of the state of the art from the engineering points of view. In addition, a short discussion of the literature can be found in [10]. The references in [10] include [4, 18, 29] for fluid-structure interactions involving elementary fluids, [2, 3, 32] for fluid-structure interactions involving inviscid fluids, and [6, 7, 8, 9, 11, 13, 14, 15, 16, 17, 20, 21, 22, 26, 27, 33, 34] for interactions between viscous, incompressible fluids and elastic solids.

In [10], we analyzed a model for the interactions between Stokesian fluids and linear elastic solids. This paper is devoted to the finite element analysis of that model. As in [10], we assume that the fluid and solid occupy two adjacent open Lipschitz domains, $\Omega_1 \subset \mathbb{R}^d$ and $\Omega_2 \subset \mathbb{R}^d$, respectively, where $d = 2$ or 3 is the space dimension. We denote by Ω the entire fluid-solid region under consideration; i.e., Ω is the interior of $\overline{\Omega}_1 \cup \overline{\Omega}_2$. Let $\Gamma_0 = \partial\Omega_1 \cap \partial\Omega_2$ denote the interface between the fluid and solid, and let $\Gamma_1 = \partial\Omega_1 \setminus \Gamma_0$ and $\Gamma_2 = \partial\Omega_2 \setminus \Gamma_0$ denote the parts of the fluid and solid boundaries, respectively, excluding the interface Γ_0. For obvious reasons we assume that $\text{meas}(\Gamma_1 \cup \Gamma_2) \neq 0$.

In the fluid region Ω_1, we apply the Stokes system

$$\begin{cases} \rho_1 \mathbf{v}_t + \nabla p - \mu_1 \nabla \cdot (\nabla \mathbf{v} + \nabla \mathbf{v}^T) = \rho_1 \mathbf{f}_1 & \text{in } \Omega_1, \\ \nabla \cdot \mathbf{v} = 0 & \text{in } \Omega_1, \\ \mathbf{v} = 0 & \text{on } \Gamma_1, \\ \mathbf{v}|_{t=0} = \mathbf{v}_0 & \text{in } \Omega_1, \end{cases} \tag{1.1}$$

where $\mathbf{v}$ denotes the fluid velocity, p the fluid pressure, $\mathbf{f}_1$ the given body force per unit mass, ρ_1 and μ_1 the constant fluid density and viscosity, and $\mathbf{v}_0$ the given initial velocity.

In the solid region, we apply the equations of linear elasticity

$$\begin{cases} \rho_2 \mathbf{u}_{tt} - \mu_2 \nabla \cdot (\nabla \mathbf{u} + \nabla \mathbf{u}^T) - \lambda_2 \nabla (\nabla \cdot \mathbf{u}) = \rho_2 \mathbf{f}_2 & \text{in } \Omega_2, \\ \mathbf{u} = 0 & \text{on } \Gamma_2, \\ \mathbf{u}|_{t=0} = \mathbf{u}_0 \quad \text{and} \quad \mathbf{u}_t|_{t=0} = \mathbf{u}_1 & \text{in } \Omega_2, \end{cases} \tag{1.2}$$

where $\mathbf{u}$ denotes the displacement of the solid, $\mathbf{f}_2$ the given loading force per unit mass, μ_2 and λ_2 the Lamé constants, ρ_2 the constant solid density, and $\mathbf{u}_0$ and $\mathbf{u}_1$ the given initial data.

Across the *fixed* interface Γ_0 between the fluid and solid, the velocity and stress vector are continuous. Thus, we have

$$\mathbf{u}_t = \mathbf{v} \qquad \text{on } \Gamma_0 \tag{1.3}$$

and

$$\mu_2 (\nabla \mathbf{u} + \nabla \mathbf{u}^T) \cdot \mathbf{n}_2 + \lambda_2 (\nabla \cdot \mathbf{u}) \mathbf{n}_2 = p \mathbf{n}_1 - \mu_1 (\nabla \mathbf{v} + \nabla \mathbf{v}^T) \cdot \mathbf{n}_1 \qquad \text{on } \Gamma_0, \tag{1.4}$$

where $\mathbf{n}_i$ is the outward-pointing unit normal vector along $\partial\Omega_i$, $i = 1, 2$.

The physical validity of the model (1.1)–(1.4) was explained in [10]. Previous work concerning this model include, as cited in [10], eigenmode analysis [34], homogenization [8], the one-dimensional case [11], and a numerical algorithm [13]. In [10], weak formulations for (1.1)–(1.4) were defined, and the existence of weak solutions was established. The proof for the existence result was based on Galerkin approximations using divergence-free basis functions, and the pressure term was absent in the Galerkin approximations.

The objective of this paper is to define semidiscrete finite element approximations, prove the convergence of finite element solutions, and derive error estimates for the finite element approximations. We point out that finite element basis functions in general are not divergence-free, and finite element formulations must be studied with the pressure term. The proof for the convergence of finite element solutions provides an alternative proof to that found in [10] for the existence of a weak solution; the results of this paper do not rely on those of [10] concerning the existence of a divergence-free weak solution. Moreover, the regularity and compatibility assumptions made on the data in this paper lead to a stronger solution. The details for the divergence-free Galerkin approximations of [10] and the discretely divergence-free finite element approximations are sufficiently different so that separate treatments are warranted.

A few technical aspects contained in this paper are particularly noteworthy: the finite element initial conditions are defined asymmetrically about the two subdomains Ω_1 and Ω_2; two inf-sup conditions are verified that facilitate the analysis of certain steady-state saddle point problems (these inf-sup conditions are also useful in dealing with approximations of mixed boundary value problems for the Stokes equations); and error estimates for a weighted L^2 projection onto discretely divergence-free spaces are derived.

The plan of the paper is as follows. In section 2, we recall relevant results of [10], in particular the weak formulations and the existence theorems. In section 3, we define semidiscrete finite element approximations and establish the existence of and a priori estimates for the finite element solutions. In section 4, we show the convergence of finite element solutions and derive error estimates.

2. Notations and results concerning divergence-free weak formulations. In this section we will recall the notation, weak formulations, and existence results of [10].

Throughout this paper, C denotes a positive constant, depending on the domains Ω, Ω_1, and Ω_2, whose meaning and value changes with context. $H^s(\mathcal{D})$, $s \in \mathbb{R}$, denotes the standard Sobolev space of order s with respect to the set $\mathcal{D}$ equipped with the standard norm $\|\cdot\|_{s,\mathcal{D}}$. Vector-valued Sobolev spaces are denoted by $\mathbf{H}^s(\mathcal{D})$, with norms still denoted by $\|\cdot\|_{s,\mathcal{D}}$. $H_0^1(\mathcal{D})$ denotes the space of functions belonging to $H^1(\mathcal{D})$ that vanish on the boundary $\partial\mathcal{D}$ of $\mathcal{D}$; $\mathbf{H}_0^1(\mathcal{D})$ denotes the vector-valued counterpart.

We will use the following L^2 inner product notations on scalar and vector-valued L^2 spaces:

$$[p,q]_{\mathcal{D}} = \int_{\mathcal{D}} pq\, d\mathcal{D} \quad \forall\, p,q \in L^2(\mathcal{D}), \qquad [\mathbf{u},\mathbf{v}]_{\mathcal{D}} = \int_{\mathcal{D}} \mathbf{u}\cdot\mathbf{v}\, d\mathcal{D} \quad \forall\, \mathbf{u},\mathbf{v} \in \mathbf{L}^2(\mathcal{D}),$$

where the spatial set $\mathcal{D}$ is Ω or Γ_0 or Ω_i, for $i = 1, 2$.

We introduce the function spaces

$$X_i = [\mathbf{H}_0^1(\Omega)]|_{\Omega_i} \quad \text{with the norm } \|\cdot\|_{X_i} = \|\cdot\|_{1,\Omega_i}, \quad i = 1,2,$$

and

$$\boldsymbol{\Psi} = \{\boldsymbol{\eta} \in \mathbf{H}_0^1(\Omega) : \operatorname{div}\boldsymbol{\eta} = 0 \text{ in } \Omega_1\} \quad \text{with the norm } \|\cdot\|_{1,\Omega}.$$

We define the weighted $\mathbf{L}^2(\Omega)$ inner product $[[\cdot,\cdot]]$ by

$$[[\boldsymbol{\xi},\boldsymbol{\eta}]] = [\rho_1\boldsymbol{\xi},\boldsymbol{\eta}]_{\Omega_1} + [\rho_2\boldsymbol{\xi},\boldsymbol{\eta}]_{\Omega_2} \qquad \forall\, \boldsymbol{\xi},\boldsymbol{\eta} \in \mathbf{L}^2(\Omega). \tag{2.1}$$

We denote by $\langle\langle\cdot,\cdot\rangle\rangle$ the duality pairing between $\boldsymbol{\Psi}^*$ and $\boldsymbol{\Psi}$ that is generated from the weighted $\mathbf{L}^2(\Omega)$ inner product $[[\cdot,\cdot]]$. The norm on the dual space $\boldsymbol{\Psi}^*$ is defined in the conventional manner:

$$\|\mathbf{g}\|_{\boldsymbol{\Psi}^*} = \sup_{\boldsymbol{\eta}\in\boldsymbol{\Psi},\, \|\boldsymbol{\eta}\|_{1,\Omega}\le 1} |\langle\langle \mathbf{g},\boldsymbol{\eta}\rangle\rangle| \qquad \forall\, \mathbf{g} \in \boldsymbol{\Psi}^*.$$

We define the bilinear forms

$$a_1[\mathbf{u},\mathbf{v}] = 2\int_{\Omega_1} \mu_1(\nabla\mathbf{u}+\nabla\mathbf{u}^T) : (\nabla\mathbf{v}+\nabla\mathbf{v}^T)\, d\Omega \qquad \forall\, \mathbf{u},\mathbf{v}\in X_1,$$

$$a_2[\mathbf{u},\mathbf{v}] = \int_{\Omega_2} \Big\{2\mu_2(\nabla\mathbf{u}+\nabla\mathbf{u}^T) : (\nabla\mathbf{v}+\nabla\mathbf{v}^T) + \lambda_2(\nabla\cdot\mathbf{u})(\nabla\cdot\mathbf{v})\Big\}\, d\Omega \ \ \forall \mathbf{u},\mathbf{v}\in X_2,$$

$$b[\mathbf{v},q] = -\int_{\Omega_1} q\nabla\cdot\mathbf{v}\, d\Omega \qquad \forall\, \mathbf{v}\in X_1,\ \forall\, q\in L^2(\Omega_1).$$

It can be verified with the help of Korn's inequalities [31, pp. 31, 120] that for $i = 1, 2$,

$$a_i[\boldsymbol{\eta},\boldsymbol{\eta}] \geq k_i\|\boldsymbol{\eta}\|^2_{1,\Omega_i} \quad \forall\, \boldsymbol{\eta}\in X_i \qquad \text{if meas } (\Gamma_i)\neq 0 \tag{2.2}$$

and

$$[\boldsymbol{\eta},\boldsymbol{\eta}]_{\Omega_i} + a_i[\boldsymbol{\eta},\boldsymbol{\eta}] \geq k_i\|\boldsymbol{\eta}\|^2_{1,\Omega_i} \quad \forall\, \boldsymbol{\eta}\in X_i \qquad \text{if meas } (\Gamma_i) = 0. \tag{2.3}$$

The bounded bilinear form $b[\cdot,\cdot]$ was shown in [10] to satisfy the inf-sup conditions

$$\inf_{q\in L^2(\Omega_1)} \sup_{\boldsymbol{\eta}\in\mathbf{H}^1_0(\Omega)} \frac{b[\boldsymbol{\eta},q]}{\|\boldsymbol{\eta}\|_{1,\Omega}\|q\|_{0,\Omega_1}} \geq k_b \tag{2.4}$$

and

$$\inf_{q\in L^2(\Omega_1)} \sup_{\mathbf{v}\in X_1} \frac{b[\mathbf{v},q]}{\|\mathbf{v}\|_{1,\Omega_1}\|q\|_{0,\Omega_1}} \geq k_b, \tag{2.5}$$

where $k_b > 0$ is a constant.

For functions that also depend on time, we introduce the space $L^2(0,T;X)$ that consists of L^2-integrable functions from $[0,T]$ into the space X and which is equipped with the norm

$$\left(\int_0^t \|f\|^2_X\, dt\right)^{1/2}.$$

Similarly, we introduce the space $C(0,T;X)$ that consists of continuous functions from $[0,T]$ into the space X and which is equipped with the norm

$$\sup_{t\in[0,T]} \|f\|_X.$$

The divergence-free weak formulation for (1.1)–(1.4) was defined in [10] as follows. Given

$$\begin{cases} \mathbf{f}_1\in C([0,T];\mathbf{L}^2(\Omega_1)), \quad \mathbf{f}_2\in C([0,T];\mathbf{L}^2(\Omega_2)), \quad \mathbf{u}_0\in X_2, \\ \mathbf{v}_0\in X_1, \quad \operatorname{div}\mathbf{v}_0 = 0 \text{ in } \Omega_1, \quad \mathbf{u}_1\in X_2, \quad \mathbf{v}_0|_{\Gamma_0} = \mathbf{u}_1|_{\Gamma_0}, \end{cases} \tag{2.6}$$

seek a pair $(\mathbf{v},\mathbf{u})$ such that

$$(\mathbf{v},\mathbf{u})\in L^2(0,T;X_1)\times L^2(0,T;X_2), \qquad \operatorname{div}\mathbf{v} = 0, \tag{2.7}$$

$$\begin{aligned} &\frac{d}{dt}\Big(\rho_1[\mathbf{v},\boldsymbol{\eta}]_{\Omega_1} + \rho_2[\partial_t\mathbf{u},\boldsymbol{\eta}]_{\Omega_2}\Big) + a_1[\mathbf{v},\boldsymbol{\eta}] + a_2[\mathbf{u},\boldsymbol{\eta}] \\ &\qquad = \rho_1[\mathbf{f}_1,\boldsymbol{\eta}]_{\Omega_1} + \rho_2[\mathbf{f}_2,\boldsymbol{\eta}]_{\Omega_2} \qquad \forall\, \boldsymbol{\eta}\in\boldsymbol{\Psi}, \end{aligned} \tag{2.8}$$

$$\mathbf{v}|_{t=0} = \mathbf{v}_0, \qquad \mathbf{u}|_{t=0} = \mathbf{u}_0, \qquad \mathbf{u}_t|_{t=0} = \mathbf{u}_1, \tag{2.9}$$

and

$$\int_0^t \mathbf{v}(s)|_{\Gamma_0}\, ds = \mathbf{u}(t)|_{\Gamma_0} - \mathbf{u}_0|_{\Gamma_0} \quad \text{a.e. } t. \tag{2.10}$$

The "natural" interface condition (1.4) is built into (2.8), and the "essential" interface condition (1.3) is enforced weakly in the sense of (2.10).

By defining

$$\boldsymbol{\xi} = \begin{cases} \mathbf{v} & \text{in } \Omega_1, \\ \mathbf{u}_t & \text{in } \Omega_2, \end{cases} \qquad \boldsymbol{\xi}_0 = \begin{cases} \mathbf{v}_0 & \text{in } \Omega_1, \\ \mathbf{u}_1 & \text{in } \Omega_2, \end{cases} \quad \text{and} \quad \mathbf{f} = \begin{cases} \mathbf{f}_1 & \text{in } \Omega_1, \\ \mathbf{f}_2 & \text{in } \Omega_2, \end{cases} \tag{2.11}$$

(2.7)–(2.10) was conveniently recast in [10] into the following equivalent, auxiliary divergence-free weak formulation: seek a $\boldsymbol{\xi}$ such that

$$\begin{aligned} &\boldsymbol{\xi} \in L^2(0,T;\mathbf{L}^2(\Omega)), \qquad \partial_t \boldsymbol{\xi} \in L^2(0,T;\boldsymbol{\Psi}^*), \\ &\boldsymbol{\xi}|_{\Omega_1} \in L^2(0,T;X_1), \qquad \operatorname{div} \boldsymbol{\xi}|_{\Omega_1} = 0, \qquad \textstyle\int_0^t \boldsymbol{\xi}(s)|_{\Omega_2}\, ds \in L^2(0,T;X_2), \end{aligned} \tag{2.12}$$

$$\langle\langle \boldsymbol{\xi}_t, \boldsymbol{\eta} \rangle\rangle + a_1[\boldsymbol{\xi}, \boldsymbol{\eta}] + a_2\left[\int_0^t \boldsymbol{\xi}(s)\, ds, \boldsymbol{\eta}\right] = [[\mathbf{f}, \boldsymbol{\eta}]] - a_2[\mathbf{u}_0, \boldsymbol{\eta}] \quad \forall\, \boldsymbol{\eta} \in \boldsymbol{\Psi}, \text{ a.e. } t, \tag{2.13}$$

$$\boldsymbol{\xi}(0) = \boldsymbol{\xi}_0, \tag{2.14}$$

and

$$\int_0^t (\boldsymbol{\xi}(s)|_{\Omega_1})\Big|_{\Gamma_0}\, ds = \int_0^t (\boldsymbol{\xi}(s)|_{\Omega_2})\Big|_{\Gamma_0}\, ds \qquad \text{a.e. } t. \tag{2.15}$$

The existence and uniqueness of a solution for the auxiliary problem (2.12)–(2.15) was proved in [10].

THEOREM 2.1. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2$, *and* $\mathbf{u}_0$ *satisfy* (2.6). *Then, there exists a unique solution* $\boldsymbol{\xi}$ *for* (2.12)–(2.15). *Moreover,* $\boldsymbol{\xi}$ *satisfies the estimates*

$$\begin{aligned} &\|\boldsymbol{\xi}(t)\|_{0,\Omega}^2 + \|\boldsymbol{\xi}\|_{L^2(0,T;\mathbf{H}^1(\Omega_1))}^2 + \left\|\int_0^t \boldsymbol{\xi}(s)\, ds\right\|_{\mathbf{H}^1(\Omega_2)}^2 \\ &\quad \le Ce^{CT}(\|\mathbf{f}\|_{L^2(0,T;\mathbf{L}^2(\Omega))}^2 + \|\mathbf{u}_0\|_{1,\Omega_2}^2 + \|\mathbf{v}_0\|_{1,\Omega_1}^2 + \|\mathbf{u}_1\|_{1,\Omega_2}^2) \quad \forall\, t \in [0,T] \end{aligned} \tag{2.16}$$

and

$$\begin{aligned} &\|\partial_t \boldsymbol{\xi}\|_{L^2(0,T;\boldsymbol{\Psi}^*)}^2 \\ &\quad \le Ce^{CT}(\|\mathbf{f}\|_{L^2(0,T;\mathbf{L}^2(\Omega))}^2 + \|\mathbf{u}_0\|_{1,\Omega_2}^2 + \|\mathbf{v}_0\|_{1,\Omega_1}^2 + \|\mathbf{u}_1\|_{1,\Omega_2}^2). \end{aligned} \tag{2.17}$$

Using relation (2.11) reversely, i.e., setting $\mathbf{v} = \boldsymbol{\xi}|_{\Omega_1}$ and $\mathbf{u} = \mathbf{u}_0 + \int_0^t \boldsymbol{\xi}(s)|_{\Omega_2}\, ds$, Theorem 2.1 immediately yields the following existence result for (2.7)–(2.10).

THEOREM 2.2. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6). *Then, there exists a unique solution* $(\mathbf{v}, \mathbf{u}) \in L^2(0,T;X_1) \times L^2(0,T;X_2)$ *for* (2.7)–(2.10), *where* (2.8) *holds in the sense of distributions on* $(0,T)$. *Moreover,*

(2.18)
$$\|\mathbf{v}(t)\|^2_{0,\Omega_1} + \|\mathbf{u}_t(t)\|^2_{0,\Omega_2} + \|\mathbf{v}\|^2_{L^2(0,T;\mathbf{H}^1(\Omega_1))} + \|\mathbf{u}(t)\|^2_{\mathbf{H}^1(\Omega_2)}$$
$$\leq Ce^{CT}(\|\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{1,\Omega_2} + \|\mathbf{v}_0\|^2_{0,\Omega_1} + \|\mathbf{u}_1\|^2_{0,\Omega_2}) \quad \forall\, t \in [0,T].$$

The existence of a stronger solution and an L^2-integrable pressure was also established in [10].

THEOREM 2.3. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6) *and*

$$\partial_t \mathbf{f}_i \in L^2(0,T;\mathbf{L}^2(\Omega_i)),\ i = 1,2, \quad \mathbf{v}_0 \in \mathbf{H}^2(\Omega_1), \quad \mathbf{u}_1 \in \mathbf{H}^1(\Omega_2), \quad \mathbf{u}_0 \in \mathbf{H}^2(\Omega_2).$$

Assume further that there exists a $p_0 \in H^1(\Omega_1)$ *such that*

$$(p_0\mathbf{n}_1 - \mu_1(\nabla \mathbf{v}_0 + \nabla \mathbf{v}_0^T)\cdot \mathbf{n}_1)|_{\Gamma_0} = (\mu_2(\nabla \mathbf{u}_0 + \nabla \mathbf{u}_0^T)\cdot \mathbf{n}_2 + (\lambda_2+\mu_2)(\operatorname{div} \mathbf{u}_0)\mathbf{n}_2)|_{\Gamma_0},$$

where $\mathbf{n}_i$ *denotes the outward-pointing normal along* $\partial\Omega_i$. *Then, the solution* $(\mathbf{v}, \mathbf{u})$ *to* (2.7)–(2.10) *satisfies*

$$\mathbf{v} \in L^\infty(0,T;\mathbf{L}^2(\Omega_1)) \cap L^2(0,T;X_1), \quad \mathbf{u} \in L^\infty(0,T;X_2),$$

$$\mathbf{v}_t \in L^\infty(0,T;\mathbf{L}^2(\Omega_1)) \cap L^2(0,T;X_1), \quad \mathbf{u}_t \in L^\infty(0,T;X_2), \quad \mathbf{u}_{tt} \in L^\infty(0,T;\mathbf{L}^2(\Omega_2)),$$

and

$$\|\partial_t \mathbf{v}(t)\|^2_{0,\Omega_1} + \|\partial_{tt}\mathbf{u}(t)\|^2_{0,\Omega_2} + \|\partial_t \mathbf{v}\|^2_{L^2(0,T;X_1)} + \|\partial_t \mathbf{u}(t)\|^2_{1,\Omega_2)}$$
$$\leq Ce^{CT}(\|\mathbf{f}\|^2_{H^1(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{2,\Omega_2} + \|\mathbf{v}_0\|^2_{2,\Omega_1} + \|p_0\|^2_{1,\Omega_1} + \|\mathbf{u}_1\|^2_{1,\Omega_2})\ \forall t \in [0,T].$$

Furthermore, there exists a unique $p \in L^2(0,T;L^2(\Omega_1))$ *such that*

(2.19)
$$\rho_1[\mathbf{v}_t, \boldsymbol{\eta}]_{\Omega_1} + b[\boldsymbol{\eta}, p] + a_1[\mathbf{v}, \boldsymbol{\eta}] + \rho_2[\mathbf{u}_{tt}, \boldsymbol{\eta}]_{\Omega_2} + a_2[\mathbf{u}, \boldsymbol{\eta}]$$
$$= \rho_1[\mathbf{f}_1, \boldsymbol{\eta}]_{\Omega_1} + \rho_2[\mathbf{f}_2, \boldsymbol{\eta}]_{\Omega_2} \qquad \forall\, \boldsymbol{\eta} \in \mathbf{H}^1_0(\Omega),\ a.e.\ t$$

and

$$\|p\|_{L^2(0,T;L^2(\Omega_1))} \leq Ce^{CT}(\|\mathbf{f}\|^2_{H^1(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{2,\Omega_2} + \|\mathbf{v}_0\|^2_{2,\Omega_1} + \|p_0\|^2_{1,\Omega_1} + \|\mathbf{u}_1\|^2_{1,\Omega_2}).$$

3. Semidiscrete finite element approximations. In this section we will define semidiscrete finite element approximations, prove the existence of finite element solutions on discretely divergence-free spaces and derive energy estimates, and establish the existence of a discrete pressure by verifying inf-sup conditions for finite element space pairs.

As alluded to previously, finite element solutions in general are not divergence-free, and finite element formulations should include the pressure term. Of course, the corresponding continuous weak formulation should also contain the pressure term. Such a weak formulation requires additional regularity on $\mathbf{v}_t$ and $\mathbf{u}_{tt}$. The continuous weak formulation we consider is as follows: given $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2$, and $\mathbf{u}_0$ satisfying (2.6), seek a triplet $(\mathbf{v}, p, \mathbf{u})$ such that

(3.1)
$$(\mathbf{v}, p, \mathbf{u}) \in L^2(0,T;X_1) \times L^2(0,T;L^2(\Omega_1)) \times L^2(0,T;X_2),$$

$$\mathbf{v}_t \in L^2(0,T;\mathbf{L}^2(\Omega_1)), \qquad \mathbf{u}_t \in L^2(0,T;X_2), \qquad \mathbf{u}_{tt} \in L^2(0,T;\mathbf{L}^2(\Omega_2)), \tag{3.2}$$

$$\begin{aligned} &\rho_1[\mathbf{v}_t,\boldsymbol{\eta}]_{\Omega_1} + b[\boldsymbol{\eta},p] + a_1[\mathbf{v},\boldsymbol{\eta}] + \rho_2[\mathbf{u}_{tt},\boldsymbol{\eta}]_{\Omega_2} + a_2[\mathbf{u},\boldsymbol{\eta}] \\ &\quad = \rho_1[\mathbf{f}_1,\boldsymbol{\eta}]_{\Omega_1} + \rho_2[\mathbf{f}_2,\boldsymbol{\eta}]_{\Omega_2} \qquad \forall\, \boldsymbol{\eta} \in \mathbf{H}_0^1(\Omega),\ \text{a.e. } t \in [0,T], \end{aligned} \tag{3.3}$$

$$b[\mathbf{v},q] = 0 \qquad \forall\, q \in L^2(\Omega_1),\ \text{a.e. } t \in [0,T], \tag{3.4}$$

$$\mathbf{v}|_{t=0} = \mathbf{v}_0, \qquad \mathbf{u}|_{t=0} = \mathbf{u}_0, \qquad \mathbf{u}_t|_{t=0} = \mathbf{u}_1, \tag{3.5}$$

$$\mathbf{v}|_{\Gamma_0} = \mathbf{u}_t|_{\Gamma_0} \quad \text{a.e. } t. \tag{3.6}$$

We will define finite element approximations to (3.3)–(3.6). By showing the convergence of finite element solutions, we establish the existence of a solution for (3.1)–(3.6). For reasons connected with the derivation of the regularity results (3.2), we will define finite element initial conditions in a nonstandard manner.

3.1. Finite element discretization. In what follows we assume that Ω_1 and Ω_2 are two-dimensional polygons or three-dimensional polyhedra. Let h denote a discretization parameter associated with the triangulation $\mathcal{T}^h(\Omega)$ of Ω. We assume that elements of $\mathcal{T}^h$ do not cross the interface Γ_0. We assume that the triangulation $\mathcal{T}^h$ consists of triangular elements in two dimensions or tetrahedral elements in three dimensions, though our results can be extended to other types of triangulations. Furthermore, we assume that there exists a triangulation $\mathcal{T}^{h_0}(\Omega)$ such that, for each $h < h_0$, $\mathcal{T}^h(\Omega)$ is a refinement of $\mathcal{T}^{h_0}(\Omega)$.

For each h, we choose $X^h \subset \mathbf{C}(\overline{\Omega}) \cap \mathbf{H}_0^1(\Omega)$ and $Q_1^h \subset L^2(\Omega_1)$ as finite element subspaces over the triangulation $\mathcal{T}^h(\Omega)$. We assume that X^h contains piecewise linear functions. We set

$$X_i^h = X^h|_{\Omega_i}, \quad i = 1,2,$$

and

$$\boldsymbol{\Psi}^h = \{\boldsymbol{\eta}_h \in X^h : b[\boldsymbol{\eta}_h, q_h] = 0\ \forall\, q_h \in Q_1^h\}.$$

We assume that the finite element spaces X_1^h, X_2^h, and Q_1^h satisfy the standard approximation properties [5]; i.e., there exist an integer $k > 0$ and constant $C > 0$ such that

$$\inf_{\mathbf{v}^h \in X_i^h} \|\mathbf{v} - \mathbf{v}^h\|_{0,\Omega_i} \le Ch^{r+1}\|\mathbf{v}\|_{r+1,\Omega_i} \qquad \forall\, \mathbf{v} \in \mathbf{H}^{r+1}(\Omega_i) \cap X_i,\ r \in [0,k], \tag{3.7}$$

$$\inf_{\mathbf{v}^h \in X_i^h} \|\mathbf{v} - \mathbf{v}^h\|_{1,\Omega_i} \le Ch^{r}\|\mathbf{v}\|_{r+1,\Omega_i} \qquad \forall\, \mathbf{v} \in \mathbf{H}^{r+1}(\Omega_i) \cap X_i,\ r \in [0,k], \tag{3.8}$$

and

$$\inf_{q^h \in Q_1^h} \|q - q^h\|_{0,\Omega_1} \le Ch^{r}\|p\|_{r,\Omega_1} \qquad \forall\, q \in H^r(\Omega_1),\ r \in [0,k]. \tag{3.9}$$

Also, X^h satisfies the approximation properties

$$\inf_{\boldsymbol{\eta}^h \in X^h} \|\boldsymbol{\eta} - \boldsymbol{\eta}^h\|_{0,\Omega} \le Ch^{r+1}\|\boldsymbol{\eta}\|_{r+1,\Omega} \qquad \forall\, \boldsymbol{\eta} \in \mathbf{H}^{r+1}(\Omega) \cap \mathbf{L}^2(\Omega),\ r \in [0,k], \tag{3.10}$$

and

$$\inf_{\boldsymbol{\eta}^h \in X^h} \|\boldsymbol{\eta} - \boldsymbol{\eta}^h\|_{1,\Omega_i} \le Ch^{r}\|\boldsymbol{\eta}\|_{r+1,\Omega} \qquad \forall\, \boldsymbol{\eta} \in \mathbf{H}^{r+1}(\Omega) \cap \mathbf{H}_0^1(\Omega),\ r \in [0,k]. \tag{3.11}$$

We assume that the finite element pair $\{\widetilde{X}_1^h, M^h\} \equiv \{X_1^h \cap \mathbf{H}_0^1(\Omega_1), Q_1^h \cap L_0^2(\Omega_1)\}$ satisfies the discrete inf-sup condition

$$\inf_{q^h \in M^h(\Omega_1)} \sup_{\mathbf{v}^h \in \widetilde{X}^h(\Omega_1)} \frac{b[\mathbf{v}^h, q^h]}{\|\mathbf{v}^h\|_{1,\Omega_1}\|q^h\|_{0,\Omega_1}} \ge C. \tag{3.12}$$

Choices of finite element spaces satisfying (3.12) are well known [19]. Note that functions in $\widetilde{X}_1^h$ vanish on Γ_0.

We also assume that triangulations are uniformly regular so that the following inverse inequalities hold:

$$\begin{aligned} &\|\mathbf{v}^h\|_{1,\Omega} \le Ch^{-1}\|\mathbf{v}^h\|_{0,\Omega} \quad \forall\, \mathbf{v}^h \in X^h; \\ &\|\mathbf{v}^h\|_{1,\Omega_i} \le Ch^{-1}\|\mathbf{v}^h\|_{0,\Omega_i} \quad \forall\, \mathbf{v}^h \in X_i^h,\ i = 1,2. \end{aligned} \tag{3.13}$$

Semidiscrete finite element approximations of the weak form (3.3)–(3.6) are defined as follows: seek $(\mathbf{v}^h, p^h, \mathbf{u}^h) \in C^1([0,T]; X_1^h) \times C([0,T]; Q_1^h) \times C^1([0,T]; X_2^h)$ such that

$$\begin{aligned} &\rho_1[\partial_t \mathbf{v}_h, \boldsymbol{\eta}_h]_{\Omega_1} + b[\boldsymbol{\eta}_h, p_h] + a_1[\mathbf{v}_h, \boldsymbol{\eta}_h] + \rho_2[\partial_{tt}\mathbf{u}_h, \boldsymbol{\eta}_h]_{\Omega_2} + a_2[\mathbf{u}_h, \boldsymbol{\eta}_h] \\ &\quad = \rho_1[\mathbf{f}_1, \boldsymbol{\eta}_h]_{\Omega_1} + \rho_2[\mathbf{f}_2, \boldsymbol{\eta}_h]_{\Omega_2} \qquad \forall\, \boldsymbol{\eta}_h \in X^h,\ \text{a.e. } t, \end{aligned} \tag{3.14}$$

$$b[\mathbf{v}_h, q_h] = 0 \qquad \forall\, q_h \in Q_1^h,\ \text{a.e. } t, \tag{3.15}$$

$$\mathbf{v}_h|_{\Gamma_0} = \partial_t \mathbf{u}_h|_{\Gamma_0} \qquad \text{a.e. } t \in [0,T], \tag{3.16}$$

$$\mathbf{v}_h|_{t=0} = \mathbf{v}_{0,h}, \qquad \mathbf{u}_h|_{t=0} = \mathbf{u}_{0,h}, \qquad \partial_t \mathbf{u}_h|_{t=0} = \mathbf{u}_{1,h}, \tag{3.17}$$

where $\mathbf{v}_{0,h} \in \boldsymbol{\Psi}^h|_{\Omega_1}$, $\mathbf{u}_{0,h} \in X_2^h$, and $\mathbf{u}_{1,h} \in X_2^h$ are finite element approximations of $\mathbf{v}_0$, $\mathbf{u}_0$, and $\mathbf{u}_1$, respectively. We assume that $(\mathbf{v}_{0,h}, \mathbf{u}_{1,h})$ satisfies

$$b[\mathbf{v}_{0,h}, q_h] = 0 \quad \forall\, q_h \in Q_1^h, \qquad \mathbf{v}_{0,h}|_{\Gamma_0} = \mathbf{u}_{1,h}|_{\Gamma_0} \tag{3.18}$$

and that $\mathbf{u}_{0,h}$ is defined by

$$a_2[\mathbf{u}_{0,h}, \mathbf{w}_h] = a_2[\mathbf{u}_0, \mathbf{w}_h] \qquad \forall\, \mathbf{w}_h \in X_2^h. \tag{3.19}$$

3.2. The existence of discretely divergence-free finite element solutions. The existence of finite element solutions $\{(\mathbf{v}^h, \mathbf{u}^h)\}$ can be established in a manner analogous to the analysis of the Galerkin approximations $\{(\mathbf{v}_m, \mathbf{u}_m)\}$ in [10]. However, it should be noted that finite element approximations are not special cases of the Galerkin approximations due to the fact that the basis functions used in the Galerkin approximations are divergence-free in Ω_1, whereas the finite element solutions are only discretely divergence-free in Ω_1 in the sense of (3.15), i.e., they belong to the space of discretely divergence-free functions $\boldsymbol{\Psi}^h$.

We first formulate auxiliary semidiscrete finite element approximations on the discretely divergence-free space $\boldsymbol{\Psi}^h$. Through the relation

$$\boldsymbol{\xi}_h = \begin{cases} \mathbf{v}_h & \text{in } \Omega_1, \\ \partial_t \mathbf{u}_h & \text{in } \Omega_2, \end{cases} \tag{3.20}$$

we see that (3.14)–(3.19) can be recast into the system

$$\begin{aligned} &\rho_1[\partial_t \boldsymbol{\xi}_h, \boldsymbol{\eta}_h]_{\Omega_1} + \rho_2[\partial_t \boldsymbol{\xi}_h, \boldsymbol{\eta}_h]_{\Omega_2} + a_1[\boldsymbol{\xi}_h, \boldsymbol{\eta}_h] + a_2\left[\int_0^t \boldsymbol{\xi}_h(s)\, ds, \boldsymbol{\eta}_h\right] \\ &\quad = \rho_1[\mathbf{f}_1, \boldsymbol{\eta}_h]_{\Omega_1} + \rho_2[\mathbf{f}_2, \boldsymbol{\eta}_h]_{\Omega_2} - a_2[\mathbf{u}_0, \boldsymbol{\eta}_h] \qquad \forall\, \boldsymbol{\eta}_h \in \boldsymbol{\Psi}^h,\ t \in [0, T] \end{aligned} \tag{3.21}$$

and

$$\boldsymbol{\xi}_h(0) = \boldsymbol{\xi}_{0,h} \equiv \begin{cases} \mathbf{v}_{0,h} & \text{in } \Omega_1, \\ \mathbf{u}_{1,h} & \text{in } \Omega_2. \end{cases} \tag{3.22}$$

Let $\{\boldsymbol{\psi}_j^h\}_{j=1}^{J_h}$ be a finite element basis for $\boldsymbol{\Psi}^h$. Assumption (3.18) implies that $\boldsymbol{\xi}_{0,h} \in \boldsymbol{\Psi}^h$, so that we can write

$$\boldsymbol{\xi}_{0,h} = \sum_{j=1}^{J_h} d_j \boldsymbol{\psi}_j^h.$$

The solution $\boldsymbol{\xi}^h \in C([0, T]; \boldsymbol{\Psi}^h)$ for (3.21)–(3.22) can be expressed in the form

$$\boldsymbol{\xi}_h = \sum_{j=1}^{J_h} g_j^h(t) \boldsymbol{\psi}_j^h(\mathbf{x}) \tag{3.23}$$

so that system (3.21)–(3.22) is equivalent to the following linear system of ordinary differential equations for $\{g_j^h\}_{j=1}^{J_h}$:

$$\begin{cases} \displaystyle\sum_{j=1}^{J_h} [[\boldsymbol{\psi}_j^h, \boldsymbol{\psi}_i^h]] \frac{d}{dt} g_j^h(t) + \sum_{j=1}^{J_h} a_1[\boldsymbol{\psi}_j^h, \boldsymbol{\psi}_i^h]\, g_j^h(t) + \sum_{j=1}^{J_h} a_2[\boldsymbol{\psi}_j^h, \boldsymbol{\psi}_i^h] \int_0^t g_j^h(s)\, ds \\ \qquad = [\rho_1 \mathbf{f}_1(t), \boldsymbol{\psi}_i^h]_{\Omega_1} + [\rho_2 \mathbf{f}_2(t), \boldsymbol{\psi}_i^h]_{\Omega_2} - a_2[\mathbf{u}_0, \boldsymbol{\psi}_i^h], \qquad i = 1, \ldots, J_h,\ t \in [0, T], \\ g_i^h(0) = d_i, \qquad i = 1, \ldots, J_h. \end{cases}$$

We have the following results concerning the existence of and a priori estimates for a finite element solution $\boldsymbol{\xi}_h$ of (3.21)–(3.22). The proof is the same as that in [10] for the Galerkin approximations and thus is omitted.

THEOREM 3.1. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6). *Then, there exists a unique function* $\boldsymbol{\xi}_h \in C^1([0,T];\boldsymbol{\Psi}^h)$ *which satisfies* (3.21)–(3.22) *and the estimate*

$$\begin{aligned}(3.24)\quad &\|\boldsymbol{\xi}_h(t)\|^2_{0,\Omega} + \|\boldsymbol{\xi}_h\|^2_{L^2(0,T;\mathbf{H}^1(\Omega_1))} + \left\|\int_0^t \boldsymbol{\xi}_h(s)\,ds\right\|^2_{\mathbf{H}^1(\Omega_2)} \\ &\le Ce^{CT}(\|\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{1,\Omega_2} + \|\mathbf{v}_{0,h}\|^2_{0,\Omega_1} + \|\mathbf{u}_{1,h}\|^2_{0,\Omega_2})\,\forall t \in [0,T].\end{aligned}$$

Setting $\mathbf{v}_h = \boldsymbol{\xi}_h|_{\Omega_1}$, $\mathbf{u}_h = \mathbf{u}_{0,h} + \int_0^t \boldsymbol{\xi}_h(s)|_{\Omega_2}\,ds$ and using (3.19), we immediately obtain the existence of a $(\mathbf{v}_h, \mathbf{u}_h)$ satisfying the discretely divergence-free version of (3.14)–(3.19), as follows.

THEOREM 3.2. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6). *Then, there exists a unique* $(\mathbf{v}_h, \mathbf{u}_h) \in C^1([0,T];\boldsymbol{\Psi}^h|_{\Omega_1}) \times C^2([0,T];X_2)$ *satisfying*

$$\begin{aligned}(3.25)\quad &\rho_1[\partial_t \mathbf{v}_h, \boldsymbol{\eta}_h]_{\Omega_1} + a_1[\mathbf{v}, \boldsymbol{\eta}_h] + \rho_2[\partial_{tt}\mathbf{u}_h, \boldsymbol{\eta}_h]_{\Omega_2} + a_2[\mathbf{u}_h, \boldsymbol{\eta}_h] \\ &\qquad = \rho_1[\mathbf{f}_1, \boldsymbol{\eta}_h]_{\Omega_1} + \rho_2[\mathbf{f}_2, \boldsymbol{\eta}_h]_{\Omega_2} \qquad \forall\, \boldsymbol{\eta}_h \in \boldsymbol{\Psi}^h,\ t \in [0,T]\end{aligned}$$

and (3.15)–(3.19). *Moreover, the following estimate holds:*

$$\begin{aligned}(3.26)\quad &\|\mathbf{v}_h(t)\|^2_{0,\Omega_1} + \|\partial_t \mathbf{u}_h(t)\|^2_{0,\Omega_2} + \|\mathbf{v}_h\|^2_{L^2(0,T;\mathbf{H}^1(\Omega_1))} + \|\mathbf{u}_h\|^2_{\mathbf{H}^1(\Omega_2)} \\ &\le Ce^{CT}(\|\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{1,\Omega_2} + \|\mathbf{v}_{0,h}\|^2_{0,\Omega_1} + \|\mathbf{u}_{1,h}\|^2_{0,\Omega_2})\ \forall t \in [0,T].\end{aligned}$$

3.3. The discrete inf-sup conditions and discrete pressure fields. We have proved the existence of a finite element solution in the discretely divergence-free formulation consisting of (3.25) and (3.15)–(3.19). We will show the existence of a discrete pressure p_h such that (3.14) holds. A crucial step towards this goal is the verification of discrete inf-sup conditions. The discrete inf-sup conditions will also play a role in deriving strong energy estimates in a subsequent section.

We rewrite (3.14) as

$$\begin{aligned}(3.27)\quad b[\boldsymbol{\eta}_h, p_h] &= -\rho_1[\partial_t \mathbf{v}_h, \boldsymbol{\eta}_h]_{\Omega_1} - a_1[\mathbf{v}, \boldsymbol{\eta}_h] - \rho_2[\partial_{tt}\mathbf{u}_h, \boldsymbol{\eta}_h]_{\Omega_2} - a_2[\mathbf{u}_h, \boldsymbol{\eta}_h] \\ &\quad + \rho_1[\mathbf{f}_1, \boldsymbol{\eta}_h]_{\Omega_1} + \rho_2[\mathbf{f}_2, \boldsymbol{\eta}_h]_{\Omega_2} \qquad \forall\, \boldsymbol{\eta}_h \in X^h,\ t \in [0,T].\end{aligned}$$

In terms of the auxiliary variable $\boldsymbol{\xi}_h$, (3.27) is equivalent to

$$\begin{aligned}(3.28)\quad b[\boldsymbol{\eta}_h, p_h] &= -[[\partial_t \boldsymbol{\xi}_h, \boldsymbol{\eta}_h]] - a_1[\mathbf{v}_h, \boldsymbol{\eta}_h] \\ &\quad - a_2[\mathbf{u}_h, \boldsymbol{\eta}_h] + [[\mathbf{f}, \boldsymbol{\eta}_h]] \qquad \forall\, \boldsymbol{\eta}_h \in X^h,\ \forall\, t \in [0,T].\end{aligned}$$

To show the existence of a $p_h \in C([0,T];Q_1^h)$ satisfying (3.27) or (3.28), we need to verify a discrete inf-sup condition for $b[\cdot,\cdot]$, which will be presented below; this will be the task of this subsection. To derive an estimate for p_h, we need an estimate for $\|\partial_t \boldsymbol{\xi}_h\|_{0,\Omega}$, or $\|\partial_t \mathbf{v}_h\|_{0,\Omega_1}$ and $\|\partial_{tt}\mathbf{u}_h\|_{0,\Omega_2}$; these will be derived in section 3.4.

The inf-sup condition we will verify is

$$(3.29)\qquad \inf_{q_h \in Q_1^h} \sup_{\boldsymbol{\eta}_h \in X^h} \frac{b[\boldsymbol{\eta}_h, q_h]}{\|\boldsymbol{\eta}_h\|_{1,\Omega}\|q_h\|_{0,\Omega_1}} \ge C.$$

This inf-sup condition was proved in [2] for a special choice of X_h and Q_1^h. We will establish (3.29) for the general case under assumption (3.12). To this end, we will

first need the following lemma, and we will need to prove the inf-sup condition

$$\inf_{q_h\in Q_1^h}\sup_{\mathbf{v}_h\in X_1^h}\frac{b[\mathbf{v}_h,q_h]}{\|\mathbf{v}_h\|_{1,\Omega_1}\|q_h\|_{0,\Omega_1}}\geq C. \tag{3.30}$$

LEMMA 3.3. *For each constant d, there exists a piecewise linear function $\mathbf{v}\in X_1^{h_0}$ such that*

$$\int_{\Gamma_0}\mathbf{v}\cdot\mathbf{n}\,d\Gamma=-d,\qquad b[\mathbf{v},d]=|d|^2,\qquad \textit{and}\qquad \|\mathbf{v}\|_{1,\Omega_1}\leq C|d|,$$

where $\mathbf{n}$ denotes the unit outward-pointing normal along $\partial\Omega_1$, and the constant C depends only on the coarse triangulation $\mathcal{T}^{h_0}(\Omega_1)$.

Proof. We give the complete proof for the two-dimensional case and discuss the ideas for the three-dimensional case in an ensuing remark.

We choose from $\mathcal{T}^{h_0}(\Omega)$ a layer of triangles $K\equiv\cup_{j=1}^{J_0}K_j\subset\overline{\Omega}_1$ adjacent to Γ_0, i.e., each K_j has either a side or a vertex on Γ_0. We denote the vertices on $\Gamma_0\cap\partial K$ by $A_j, j=0,1,\ldots,J_0$. We define the C^0, piecewise linear vector function $\mathbf{v}=(v_1,v_2)$ on K as follows:

$$\begin{cases}\mathbf{v}=\mathbf{0}\text{ at points }A_0\text{ and }A_{J_0},\\ \mathbf{v}=\mathbf{0}\text{ at all vertices of }K\text{ belonging to the interior of }\Omega_1,\\ \mathbf{v}\cdot\mathbf{n}_{j-1}=-\overline{d}\text{ and }\mathbf{v}\cdot\mathbf{n}_j=-\overline{d}\text{ at }A_j,\quad j=1,\ldots,J_0-1,\ \mathbf{n}_{j-1}\neq\mathbf{n}_j,\\ \mathbf{v}\cdot\mathbf{n}_{j-1}=-\overline{d}\text{ and }\mathbf{v}\cdot\boldsymbol{\tau}_j=0\text{ at }A_j,\quad j=1,\ldots,J_0-1,\ \mathbf{n}_{j-1}=\mathbf{n}_j,\end{cases}$$

where

$$\overline{d}=d\Bigg/\left(|\overline{A_0A_1}|/2+\sum_{j=2}^{J_0-1}|\overline{A_{j-1}A_j}|+|\overline{A_{J_0-1}A_{J_0}}|/2\right)$$

and $\mathbf{n}_j$ and $\boldsymbol{\tau}_j$ denote the unit, outward-pointing normal and unit tangent vectors, respectively, on $\partial\Omega_1\cap\overline{A_{j-1}A_j}$. Note that $\mathbf{n}_j$ and $\boldsymbol{\tau}_j$ are defined with respect to the *segment* $\overline{A_{j-1}A_j}$ so that they are well defined. Clearly, the values of $v_1(A_j)$ and $v_2(A_j)$ are proportional to $\overline{d}$. We can write

$$v_i(\mathbf{x})=\sum_{j=1}^{J_0-1}v_i(A_j)L_j^{h_0}(\mathbf{x}),\qquad i=1,2,$$

where for each j, $L_j^{h_0}(\mathbf{x})$ is the continuous piecewise linear basis function (the shape function) associated with the vertex A_j. Then,

$$\|v_i\|_{1,K}^2\leq C\sum_{j=1}^{J_0-1}|v_i(A_j)|^2\|L_j^{h_0}\|_{1,K}^2\leq C|\overline{d}|^2\sum_{j=1}^{J_0-1}\|L_j^{h_0}\|_{1,K}^2$$

so that

$$\|\mathbf{v}\|_{1,K}\leq C|\overline{d}|.$$

We extend $\mathbf{v}$ to Ω_1 by zero outside K and denote the extended function still by $\mathbf{v}$. Then we readily have $\mathbf{v} \in X_1^{h_0}$,

$$\|\mathbf{v}\|_{1,\Omega_1} = \|\mathbf{v}\|_{1,K} \le C|\overline{d}| \le C|d|,$$

and

$$\int_{\Gamma_0} \mathbf{v}\cdot\mathbf{n}\, d\Gamma = \sum_{j=1}^{J_0} \int_{\overline{A_{j-1}A_j}} \mathbf{v}\cdot\mathbf{n}\, d\Gamma$$
$$= -\overline{d}\left(|\overline{A_0A_1}|/2 + \sum_{j=2}^{J_0-1} |\overline{A_{j-1}A_j}| + |\overline{A_{J_0-1}A_{J_0}}|/2 \right) = -d.$$

Using Green's theorem and the last equality, we have

$$b[\mathbf{v}, d] = -d\int_{\Omega_1} \nabla\cdot\mathbf{v}\, d\Omega = -d\int_{\Gamma_0} \mathbf{v}\cdot\mathbf{n}\, d\Gamma = d^2. \qquad \square$$

Remark 1. In the three-dimensional case we merely need assume that $[\mathcal{T}^{h_0}(\Omega)]|_{\Gamma_0}$ contains a vertex P_0 shared by exactly three triangles. Indeed, in forming the coarse triangulation $\mathcal{T}^{h_0}(\Omega)$, we may simply choose a partition on a flat piece of Γ_0 to meet this requirement. Then, we define a $\mathbf{v}$ to satisfy $\mathbf{v}\cdot\mathbf{n} = \overline{d}$ and $\mathbf{v}\times\mathbf{n} = \mathbf{0}$ at P_0, and $\mathbf{v} = \mathbf{0}$ at all other vertices, where $\overline{d}$ is a suitable scaling of d.

Next we prove inf-sup condition (3.30) based on the inf-sup assumption (3.12) for the pair $\{\widetilde{X}_1^h, M_1^h\} \equiv \{X_1^h \cap \mathbf{H}_0^1(\Omega_1), Q_1^h \cap L_0^2(\Omega_1)\}$.

THEOREM 3.4. *The pair* $\{X_1^h, Q_1^h\}$ *satisfies inf-sup condition* (3.30).

Proof. Owing to [19, Remark 1.4, p. 118], the inf-sup condition (3.30) is equivalent to

$$\begin{aligned} &\forall\, q_h \in Q_1^h, \quad \text{there exists} \quad \mathbf{v}_h \in X_1^h \quad \text{such that} \\ &\quad b[\mathbf{v}_h, q_h] \ge C\|q_h\|_{0,\Omega_1}^2 \quad \text{and} \quad \|\mathbf{v}_h\|_{1,\Omega_1} \le C\|q_h\|_{0,\Omega_1}. \end{aligned} \tag{3.31}$$

Let $q_h \in Q_1^h$ be given. Set

$$\overline{q}_h = \frac{1}{|\Omega_1|}\int_{\Omega_1} q_h\, d\Omega \qquad \text{and} \qquad \widetilde{q}_h = q_h - \overline{q}_h.$$

Then $q_h = \widetilde{q}_h + \overline{q}_h$ in Ω_1 and $\|q_h\|_{0,\Omega_1}^2 = \|\widetilde{q}_h\|_{0,\Omega_1}^2 + \|\overline{q}_h\|_{0,\Omega_1}^2$. Obviously, $\widetilde{q}_h \in M_1^h \equiv Q_1^h \cap L_0^2(\Omega_1)$ so that, by inf-sup condition (3.12) for the pair $\{\widetilde{X}_1^h, M_1^h\}$, we may choose a $\widetilde{\mathbf{v}}_h \in \widetilde{X}_1^h$ such that

$$b[\widetilde{\mathbf{v}}_h, \widetilde{q}_h] = \|\widetilde{q}_h\|_{0,\Omega_1}^2 \qquad \text{and} \qquad \|\widetilde{\mathbf{v}}_h\|_{1,\Omega_1} \le C\|\widetilde{q}_h\|_{0,\Omega_1}.$$

By Lemma 3.3 with $d = \|\overline{q}_h\|_{0,\Omega_1}$, we may choose a $\overline{\mathbf{v}}_h \in X_1^h$ such that

$$b[\overline{\mathbf{v}}_h, \overline{q}_h] = \|\overline{q}_h\|_{0,\Omega_1}^2 \qquad \text{and} \qquad \|\overline{\mathbf{v}}_h\|_{1,\Omega_1} \le C\|\overline{q}_h\|_{0,\Omega_1}.$$

(We recall that we assumed that $\mathcal{T}^h(\Omega_1)$ is a refinement of a coarse triangulation $\mathcal{T}^{h_0}(\Omega_1)$ so that a piecewise linear function on $\mathcal{T}^{h_0}(\Omega_1)$ belongs to X_1^h.) Setting

$\mathbf{v}_h = \widetilde{\mathbf{v}}_h + \alpha\overline{\mathbf{v}}_h$ for some $\alpha > 0$ (to be determined), we have

$$\begin{aligned} b[\mathbf{v}_h, q_h] &= b[\widetilde{\mathbf{v}}_h, \widetilde{q}_h] + b[\widetilde{\mathbf{v}}_h, \overline{q}_h] + \alpha b[\overline{\mathbf{v}}_h, \widetilde{q}_h] + \alpha b[\overline{\mathbf{v}}_h, \overline{q}_h] \\ &\geq \|\widetilde{q}_h\|^2_{0,\Omega_1} + 0 - C\alpha\|\widetilde{q}_h\|_{0,\Omega_1}\|\overline{\mathbf{v}}_h\|_{1,\Omega_1} + \alpha\|\overline{q}_h\|^2_{0,\Omega_1} \\ &\geq \|\widetilde{q}_h\|^2_{0,\Omega_1} - C\alpha\|\widetilde{q}_h\|_{0,\Omega_1}\|\overline{q}_h\|_{0,\Omega_1} + \alpha\|\overline{q}_h\|^2_{0,\Omega_1} \\ &\geq \|\widetilde{q}_h\|^2_{0,\Omega_1} - [C\alpha\|\widetilde{q}_h\|^2_{0,\Omega_1} + \frac{\alpha}{2}\|\overline{q}_h\|^2_{0,\Omega_1}] + \alpha\|\overline{q}_h\|^2_{0,\Omega_1} \\ &= (1 - C\alpha)\|\widetilde{q}_h\|^2_{0,\Omega_1} + \frac{\alpha}{2}\|\overline{q}_h\|^2_{0,\Omega_1} \end{aligned}$$

so that by choosing a sufficiently small $\alpha > 0$ we obtain

$$b[\mathbf{v}_h, q_h] \geq \min\{1 - C\alpha, \alpha/2\}\left(\|\widetilde{q}_h\|^2_{0,\Omega_1} + \frac{1}{2}\|\overline{q}_h\|^2_{0,\Omega_1}\right) \geq C\|q_h\|^2_{0,\Omega_1}.$$

Also,

$$\|\mathbf{v}_h\|_{1,\Omega_1} \leq \|\widetilde{\mathbf{v}}_h\|_{1,\Omega_1} + \|\overline{\mathbf{v}}_h\|_{1,\Omega_1} \leq C\|\widetilde{q}_h\|_{0,\Omega_1} + C\|\overline{q}_h\|_{0,\Omega_1} \leq C\|q_h\|_{0,\Omega_1}.$$

Hence, we have proved (3.31) which is equivalent to (3.30). ∎

We now prove inf-sup condition (3.29) for $\{X^h, Q_1^h\}$.

THEOREM 3.5. *$\{X^h, Q_1^h\}$ satisfies the inf-sup condition* (3.29).

Proof. Let the discrete extension operator $E^h : X_1^h \to X^h$ be defined as follows: for any $\mathbf{v}_h \in X_1^h$, $(E^h\mathbf{v}_h)|_{\overline{\Omega}_1} = \mathbf{v}_h$ and $(E^h\mathbf{v}_h)|_{\Omega_2} \in X_2^h$ is the solution of

$$[\nabla(E^h\mathbf{v}_h), \nabla\mathbf{z}_h]_{\Omega_2} = 0 \quad \forall\, \mathbf{z}_h \in X_2^h \cap \mathbf{H}_0^1(\Omega_2), \quad (E^h\mathbf{v}_h)|_{\Gamma_2} = \mathbf{0}, \quad (E^h\mathbf{v}_h)|_{\Gamma_0} = \mathbf{v}_h|_{\Gamma_0}.$$

It is well known (see, e.g., [23] and [1]) that $\|E^h\mathbf{v}_h\|_{1,\Omega_2} \leq C\|\mathbf{v}_h\|_{1/2,\Gamma_0}$ so that

$$\begin{aligned} \|E^h\mathbf{v}_h\|_{1,\Omega} &\leq C\|(E^h\mathbf{v}_h)|_{\Omega_1}\|_{1,\Omega_1} + \|(E^h\mathbf{v}_h)|_{\Omega_2}\|_{1,\Omega_2} \\ &\leq C(\|\mathbf{v}_h\|_{1,\Omega_1} + \|\mathbf{v}_h\|_{1/2,\Gamma_0}) \leq C\|\mathbf{v}_h\|_{1,\Omega_1} \qquad \forall\, \mathbf{v}_h \in X_1^h. \end{aligned}$$

Then, for every $q_h \in Q_1^h$ we have

$$\begin{aligned} \sup_{\boldsymbol{\eta}_h \in X^h} \frac{b[\boldsymbol{\eta}_h, q_h]}{\|q_h\|_{0,\Omega_1}\,\|\boldsymbol{\eta}_h\|_{1,\Omega}} &\geq \sup_{\mathbf{v}_h \in X_1^h} \frac{b[E^h\mathbf{v}_h, q_h]}{\|q_h\|_{0,\Omega_1}\,\|E^h\mathbf{v}_h\|_{1,\Omega}} \\ &\geq C \sup_{\mathbf{v}_h \in X_1^h} \frac{b[E^h\mathbf{v}_h, q_h]}{\|q_h\|_{0,\Omega_1}\,\|\mathbf{v}_h\|_{1,\Omega_1}} = C \sup_{\mathbf{v}_h \in X_1^h} \frac{b[\mathbf{v}_h, q_h]}{\|q_h\|_{0,\Omega_1}\,\|\mathbf{v}_h\|_{1,\Omega_1}} \geq C, \end{aligned}$$

where the last step is valid because of (3.30). ∎

As a direct consequence of [19, Lemma 4.1, p. 58], Theorem 3.8, and the inf-sup condition (3.29), we obtain the following theorem concerning the existence of a discrete pressure. Note that an estimate for p_h will be established in section 3.4 only after we have derived strong energy estimates, particularly the estimate for $\|\partial_t\boldsymbol{\xi}_h\|_{L^2(0,T;\mathbf{L}^2(\Omega))}$.

THEOREM 3.6. *Assume that $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, and $\mathbf{u}_1$ satisfy* (2.6)*, and let $\boldsymbol{\xi}_h \in C^1([0,T]; \boldsymbol{\Psi}^h)$ be the solution of* (3.21)–(3.22)*. Let $(\mathbf{v}_h, \mathbf{u}_h) \in C^1([0,T]; X^h|_{\Omega_1}) \times C^1([0,T]; X_2^h)$ be the solution of* (3.25) *and* (3.15)–(3.19)*. Then there exists a unique $p_h \in C([0,T]; Q_1^h)$ satisfying* (3.28) *and* (3.15)*.*

Proof. The existence and uniqueness of a $p_h \in C([0,T]; Q_1^h)$ satisfying (3.28) follow directly from [19, Lemma 4.1, p. 58], Theorem 3.8, and the inf-sup condition (3.29). Since (3.28) is equivalent to (3.27), we also conclude that p_h satisfies (3.27) and is the unique such solution. ∎

3.4. Strong a priori energy estimates for the finite element solutions. In the finite element system (3.25) and (3.15)–(3.19) the discrete initial conditions are arbitrary approximations of the corresponding continuous initial data. We now make a particular choice of discrete initial data that will allow us to derive an estimate for $\|\partial_t \boldsymbol{\xi}_h\|_{0,\Omega}$ under additional assumptions on the data. Such an estimate can then be used to derive an estimate for $\|p_h\|_{L^2(0,T;L^2(\Omega_1))}$. (The existence of a discrete pressure p_h satisfying (3.14) was shown in section 3.3.) The estimates on p_h and $\partial_t \boldsymbol{\xi}_h$ will be needed in order to prove the convergence of finite element solutions, since finite element formulations involve the term $b[\boldsymbol{\eta}_h, p_h]$, which, in general, does not vanish for $\boldsymbol{\eta}_h \in X^h$.

We first study the approximation of the initial condition. We choose $(\mathbf{v}_{0,h}, \mathbf{u}_{1,h}) \in \boldsymbol{\Psi}^h$ and $p_{0,h} \in Q_1^h$ to be the solution of

$$\begin{aligned} &a_1[\mathbf{v}_{0,h}, \boldsymbol{\eta}_h] + [\mathbf{u}_{1,h}, \boldsymbol{\eta}_h]_{\Omega_2} + b[\boldsymbol{\eta}_h, p_{0,h}] \\ &\qquad = a_1[\mathbf{v}_0, \boldsymbol{\eta}_h] + [\mathbf{u}_1, \boldsymbol{\eta}_h]_{\Omega_2} + b[\boldsymbol{\eta}_h, p_0] \qquad \forall\, \boldsymbol{\eta}_h \in X^h, \end{aligned} \tag{3.32}$$

$$b[\mathbf{v}_{0,h}, q_h] = 0 \quad \forall\, q_h \in Q_1^h \qquad \text{and} \qquad \mathbf{v}_{0,h}|_{\Gamma_0} = \mathbf{u}_{1,h}|_{\Gamma_0}, \tag{3.33}$$

where p_0 is the initial pressure field associated with the initial velocity field $\mathbf{v}_0$.

LEMMA 3.7. *Assume that* $\mathbf{v}_0 \in X_1$, $p_0 \in L^2(\Omega_1)$, $\mathbf{u}_1 \in X_2$, *and* $\mathbf{v}_0|_{\Gamma_0} = \mathbf{u}_1|_{\Gamma_0}$. *Then there exists a unique triplet* $(\mathbf{v}_{0,h}, p_{0,h}, \mathbf{u}_{1,h}) \in X_1^h \times Q_1^h \times X_2^h$ *which satisfies* (3.32)–(3.33) *and*

$$\begin{aligned} &\|\mathbf{v}_{0,h} - \mathbf{v}_0\|_{1,\Omega_1} + \|\mathbf{u}_{1,h} - \mathbf{u}_1\|_{0,\Omega_2} + \|p_{0,h} - p_0\|_{0,\Omega_1} \\ &\quad \le C(\|\boldsymbol{\eta}_h - \mathbf{v}_0\|_{1,\Omega_1} + \|\boldsymbol{\eta}_h - \mathbf{u}_1\|_{0,\Omega_2} + \|q_h - p_0\|_{0,\Omega_1}) \qquad \forall\, (\boldsymbol{\eta}_h, q_h) \in X^h \times Q_1^h. \end{aligned} \tag{3.34}$$

If, in addition, $\mathbf{v}_0 \in \mathbf{H}^{r+1}(\Omega_1)$, $p_0 \in H^r(\Omega_1)$, *and* $\mathbf{u}_1 \in \mathbf{H}^{r+1}(\Omega_2)$ *for some* $r \in [0, k]$ (k *being the integer appearing in the approximation properties*), *then*

$$\begin{aligned} &\|\mathbf{v}_{0,h} - \mathbf{v}_0\|_{1,\Omega_1} + \|\mathbf{u}_{1,h} - \mathbf{u}_1\|_{0,\Omega_2} + \|p_{0,h} - p_0\|_{0,\Omega_1} \\ &\qquad \le C h^r (\|\mathbf{v}_0\|_{r+1,\Omega_1} + \|\mathbf{u}_1\|_{r+1,\Omega_2} + \|p_0\|_{r,\Omega_1}). \end{aligned} \tag{3.35}$$

Proof. We set $\widetilde{X} = \{\boldsymbol{\eta} \in \mathbf{L}^2(\Omega) : \boldsymbol{\eta}|_{\Omega_1} \in X_1, \operatorname{div} \boldsymbol{\eta}|_{\Omega_1} = 0\}$ and equip $\widetilde{X}$ with the inner product

$$[\boldsymbol{\xi}, \boldsymbol{\eta}]_{\widetilde{X}} = a_1[\boldsymbol{\xi}, \boldsymbol{\eta}] + [\boldsymbol{\xi}, \boldsymbol{\eta}]_{\Omega_2} \qquad \forall\, \boldsymbol{\xi}, \boldsymbol{\eta} \in \widetilde{X}.$$

It is easy to check that $\widetilde{X}$ is a Hilbert space. The continuous inf-sup condition (2.4) implies

$$\begin{aligned} \inf_{q \in L^2(\Omega_1)} \sup_{\boldsymbol{\eta} \in \widetilde{X}} \frac{b[\boldsymbol{\eta}, q]}{\|\boldsymbol{\eta}\|_{\widetilde{X}} \|q\|_{0,\Omega_1}} &\ge \inf_{q \in L^2(\Omega_1)} \sup_{\boldsymbol{\eta} \in \mathbf{H}_0^1(\Omega)} \frac{b[\boldsymbol{\eta}, q]}{\|\boldsymbol{\eta}\|_{\widetilde{X}} \|q\|_{0,\Omega_1}} \\ &\ge \inf_{q \in L^2(\Omega_1)} \sup_{\boldsymbol{\eta} \in \mathbf{H}_0^1(\Omega)} \frac{b[\boldsymbol{\eta}, q]}{\|\boldsymbol{\eta}\|_{1,\Omega} \|q\|_{0,\Omega_1}} \ge C. \end{aligned}$$

Thus, by [19, Theorem 1.1, p. 114], there exists a unique $(\widetilde{\boldsymbol{\xi}}_0, \widetilde{p}_0) \in \widetilde{X} \times L^2(\Omega_1)$ satisfying

$$[\widetilde{\boldsymbol{\xi}}_0, \boldsymbol{\eta}]_{\widetilde{X}} + b[\boldsymbol{\eta}, \widetilde{p}_0] = a_1[\mathbf{v}_0, \boldsymbol{\eta}] + [\mathbf{u}_1, \boldsymbol{\eta}]_{\Omega_2} + b[\boldsymbol{\eta}, p_0] \qquad \forall\, \boldsymbol{\eta} \in \widetilde{X}, \tag{3.36}$$

$$b[\widetilde{\boldsymbol{\xi}}_0, q] = 0 \qquad \forall\, q \in L^2(\Omega_1). \tag{3.37}$$

As $\boldsymbol{\xi}_0$ defined by (2.11) and p_0 constitute an obvious solution to (3.36)–(3.37), we have

$$\widetilde{\boldsymbol{\xi}}_0 = \boldsymbol{\xi}_0 = \left\{ \begin{array}{l} \boldsymbol{\xi}|_{\Omega_1} = \mathbf{v}_0, \\ \boldsymbol{\xi}|_{\Omega_2} = \mathbf{u}_1, \end{array} \right. \qquad \text{and} \qquad \widetilde{p}_0 = p_0. \tag{3.38}$$

Similarly, the discrete inf-sup condition (3.29) implies

$$\inf_{q_h \in Q_1^h} \sup_{\boldsymbol{\eta}_h \in X^h} \frac{b[\boldsymbol{\eta}_h, q_h]}{\|\boldsymbol{\eta}_h\|_{\widetilde{X}} \|q_h\|_{0,\Omega_1}} \geq \inf_{q_h \in Q_1^h} \sup_{\boldsymbol{\eta}_h \in X^h} \frac{b[\boldsymbol{\eta}_h, q_h]}{\|\boldsymbol{\eta}_h\|_{1,\Omega} \|q_h\|_{0,\Omega_1}} \geq C,$$

so that by [19, Theorem 1.1, p. 114] there exists a unique $(\boldsymbol{\xi}_{0,h}, p_{0,h}) \in X^h \times Q_1^h$ satisfying

$$[\boldsymbol{\xi}_{0,h}, \boldsymbol{\eta}_h]_{\widetilde{X}} + b[\boldsymbol{\eta}_h, p_{0,h}] = a_1[\mathbf{v}_0, \boldsymbol{\eta}_h] + [\mathbf{u}_1, \boldsymbol{\eta}_h]_{\Omega_2} + b[\boldsymbol{\eta}_h, p_0] \qquad \forall\, \boldsymbol{\eta}_h \in X^h, \tag{3.39}$$

$$b[\boldsymbol{\xi}_{0,h}, q_h] = 0 \qquad \forall\, q \in Q_1^h; \tag{3.40}$$

moreover, the following error estimate holds:

$$\begin{aligned} &\|\boldsymbol{\xi}_{0,h} - \boldsymbol{\xi}_0\|_{\widetilde{X}} + \|p_{0,h} - p_0\|_{0,\Omega_1} \\ &\qquad \leq C(\|\boldsymbol{\eta}_h - \boldsymbol{\xi}_0\|_{\widetilde{X}} + \|q_h - p_0\|_{0,\Omega_1}) \qquad \forall\, (\boldsymbol{\eta}_h, q_h) \in X^h \times Q_1^h. \end{aligned} \tag{3.41}$$

By setting

$$\mathbf{v}_{0,h} = \boldsymbol{\xi}_{0,h}|_{\Omega_1} \quad \text{and} \quad \mathbf{u}_{1,h} = \boldsymbol{\xi}_{0,h}|_{\Omega_2}, \tag{3.42}$$

we see that (3.41) is equivalent to (3.34) and that (3.32)–(3.33) are satisfied. The uniqueness of the solution $(\mathbf{v}_{0,h}, p_{0,h}, \mathbf{u}_{1,h})$ for (3.32)–(3.33) follows from the uniqueness of the solution $(\boldsymbol{\xi}_{0,h}, p_{0,h})$ for (3.39)–(3.40).

Next, assuming that $\mathbf{v}_0 \in \mathbf{H}^{r+1}(\Omega_1)$, $p_0 \in H^r(\Omega_1)$, and $\mathbf{u}_1 \in \mathbf{H}^{r+1}(\Omega_2)$ for some $r \in [1, k]$, we proceed to prove (3.35) by making a particular choice of $\boldsymbol{\eta}_h$ in (3.34). Let $(\overline{\mathbf{v}}_{0,h}, \overline{p}_{0,h}) \in X_1^h \times Q_1^h$ be the unique finite element solution of the following Stokes system on Ω_1:

$$a_1[\overline{\mathbf{v}}_{0,h}, \mathbf{z}_h] + b[\mathbf{z}_h, \overline{p}_{0,h}] = a_1[\mathbf{v}_0, \mathbf{z}_h] + b[\mathbf{z}_h, \overline{p_0}] \qquad \forall\, \mathbf{z}_h \in X_1^h \cap \mathbf{H}_0^1(\Omega_1),$$

$$b[\overline{\mathbf{v}}_{0,h}, q_h] = 0 \qquad \forall\, q_h \in Q_1^h \cap L_0^2(\Omega_1),$$

$$\overline{\mathbf{v}}_{0,h}|_{\Gamma_1} = \mathbf{0} \qquad \text{and} \qquad [\overline{\mathbf{v}}_{0,h}, \mathbf{s}_h]_{0,\Gamma_0} = [\mathbf{v}_0, \mathbf{s}_h]_{0,\Gamma_0} \quad \forall\, \mathbf{s}_h \in X_1^h|_{\Gamma_0},$$

where $\overline{p_0} = p_0 - (1/|\Omega_1|) \int_{\Omega_1} p_0 \, d\mathbf{x}$. Using the results of [23] concerning error estimates for the finite element approximations of the Stokes equations with inhomogeneous boundary conditions, we obtain

$$\begin{aligned} &\|\overline{\mathbf{v}}_{0,h} - \mathbf{v}_0\|_{1,\Omega_1} + \|\overline{p}_{0,h} - \overline{p_0}\|_{0,\Omega_1} \\ &\qquad \leq Ch^r(\|\mathbf{v}_0\|_{r+1,\Omega_1} + \|\overline{p_0}\|_{r,\Omega_1}) \leq Ch^r(\|\mathbf{v}_0\|_{r+1,\Omega_1} + \|p_0\|_{r,\Omega_1}). \end{aligned} \tag{3.43}$$

Analogously, let $\overline{\mathbf{u}}_{1,h} \in X_2^h$ be the unique finite element solution of the following elliptic system on Ω_2 with an inhomogeneous boundary condition:

$$
\begin{aligned}
&[\nabla\overline{\mathbf{u}}_{1,h}, \nabla\mathbf{w}_h]_{\Omega_2} = [\nabla\mathbf{u}_1, \nabla\mathbf{w}_h]_{\Omega_2} \qquad \forall\, \mathbf{w}_h \in X_2^h \cap \mathbf{H}_0^1(\Omega_2),\\
&\overline{\mathbf{u}}_{1,h}|_{\Gamma_2} = \mathbf{0} \qquad \text{and} \qquad [\overline{\mathbf{u}}_{1,h}, \mathbf{s}_h]_{0,\Gamma_0} = [\mathbf{u}_1, \mathbf{s}_h]_{0,\Gamma_0} \quad \forall\, \mathbf{s}_h \in X_2^h|_{\Gamma_0}.
\end{aligned} \tag{3.44}
$$

Then we have

$$
\|\overline{\mathbf{u}}_{1,h} - \mathbf{u}_1\|_{0,\Omega_2} \le \|\overline{\mathbf{u}}_{1,h} - \mathbf{u}_1\|_{1,\Omega_2} \le Ch^r \|\mathbf{u}_1\|_{r+1,\Omega_2}. \tag{3.45}
$$

The assumption $\mathbf{v}_0|_{\Gamma_0} = \mathbf{u}_1|_{\Gamma_0}$ implies $\overline{\mathbf{v}}_{0,h}|_{\Gamma_0} = \overline{\mathbf{u}}_{1,h}|_{\Gamma_0}$, so that the element $\overline{\boldsymbol{\eta}}_h$ defined by

$$
\overline{\boldsymbol{\eta}}_h|_{\Omega_1} = \begin{cases} \overline{\mathbf{v}}_{0,h} & \text{in } \Omega_1, \\ \overline{\mathbf{u}}_{1,h} & \text{in } \Omega_2 \end{cases}
$$

satisfies $\overline{\boldsymbol{\eta}}_h \in X^h$. By choosing $\boldsymbol{\eta}_h = \overline{\boldsymbol{\eta}}_h$ and $q_h = \overline{p}_{0,h} + (1/|\Omega_1|)\int_{\Omega_1} p_0\, d\mathbf{x}$ in (3.34) and using (3.43)–(3.45), we arrive at (3.35). ∎

We now derive a strong a priori energy estimate for the auxiliary finite element solution $\boldsymbol{\xi}_h$.

THEOREM 3.8. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6) *and*

$$
\partial_t \mathbf{f}_i \in L^2(0,T;\mathbf{L}^2(\Omega_i)),\ i = 1,2, \quad \mathbf{v}_0 \in \mathbf{H}^2(\Omega_1),\ \mathbf{u}_1 \in \mathbf{H}^2(\Omega_1),\ \mathbf{u}_0 \in \mathbf{H}^2(\Omega_2). \tag{3.46}
$$

Assume further that there exists a $p_0 \in H^1(\Omega_1)$ *such that*

$$
(p_0\mathbf{n}_1 - \mu_1 \nabla\mathbf{v}_0 \cdot \mathbf{n}_1)|_{\Gamma_0} = (\mu_2 \nabla\mathbf{u}_0 \cdot \mathbf{n}_2 + (\lambda_2 + \mu_2)(\operatorname{div}\mathbf{u}_0)\mathbf{n}_2)|_{\Gamma_0}, \tag{3.47}
$$

where $\mathbf{n}_i$ *denotes the outward-pointing normal along* $\partial\Omega_i$, $i = 1, 2$. *Then there exists a unique solution* $\boldsymbol{\xi}_h \in C^1([0,T];\boldsymbol{\Psi}^h)$ *for* (3.21)–(3.22) *with the initial condition* $\boldsymbol{\xi}_{0,h}$ *defined by*

$$
\boldsymbol{\xi}_{0,h}|_{\Omega_1} = \mathbf{v}_{0,h} \quad \textit{and} \quad \boldsymbol{\xi}_{0,h}|_{\Omega_2} = \mathbf{u}_{1,h}, \tag{3.48}
$$

where $\mathbf{v}_{0,h}$ *and* $\mathbf{u}_{1,h}$ *are determined by* (3.32)–(3.33). *Moreover,* $\boldsymbol{\xi}_h$ *satisfies the estimates*

$$
\begin{aligned}
&\|\boldsymbol{\xi}_h\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\boldsymbol{\xi}_h\|^2_{L^2(0,T;\mathbf{H}^1(\Omega_1))} + \left\| \int_0^t \boldsymbol{\xi}_h(s)\, ds \right\|^2_{L^\infty(0,T;\mathbf{H}^1(\Omega_2))} \\
&\quad \le Ce^{CT}(\|\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{1,\Omega_2} + \|\mathbf{v}_0\|^2_{1,\Omega_1} + \|\mathbf{u}_1\|^2_{0,\Omega_2} + \|p_0\|^2_{0,\Omega_1})
\end{aligned} \tag{3.49}
$$

and

$$
\begin{aligned}
&\|\partial_t\boldsymbol{\xi}_h\|^2_{L^\infty(0,T;\mathbf{L}^2(\Omega))} + \|\partial_t\boldsymbol{\xi}_h\|^2_{L^2(0,T;\mathbf{H}^1(\Omega_1))} + \left\| \int_0^t \partial_t\boldsymbol{\xi}_h(s)\, ds \right\|^2_{L^\infty(0,T;\mathbf{H}^1(\Omega_2))} \\
&\quad \le Ce^{CT}(\|\mathbf{f}\|^2_{H^1(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{2,\Omega_2} + \|\mathbf{v}_0\|^2_{2,\Omega_1} + \|p_0\|^2_{1,\Omega_1} + \|\mathbf{u}_1\|^2_{2,\Omega_2}).
\end{aligned} \tag{3.50}
$$

Proof. By Theorem 3.1, there exists a unique solution $\boldsymbol{\xi}_h \in C^1([0,T];\boldsymbol{\Psi}^h)$ for (3.21)–(3.22) and (3.24). We note that, by virtue of Lemma 3.7, the initial condition $\boldsymbol{\xi}_{0,h} \in \boldsymbol{\Psi}^h$ satisfies the estimate

$$
\|\boldsymbol{\xi}_{0,h}\|_{1,\Omega_1} + \|\boldsymbol{\xi}_{0,h}\|_{0,\Omega_2} \le C(\|\mathbf{v}_0\|_{1,\Omega_1} + \|p_0\|_{0,\Omega_1} + \|\mathbf{u}_1\|_{0,\Omega_2}).
$$

Thus (3.49) follows from the last estimate and (3.24).

Defining $\boldsymbol{\zeta}_h = \partial_t \boldsymbol{\xi}_h$ and differentiating (3.21), we obtain that for each $t \in [0,T]$

$$\begin{aligned}(3.51)\qquad &\rho_1[\partial_t\boldsymbol{\zeta}_h,\boldsymbol{\eta}_h]_{\Omega_1} + \rho_2[\partial_t\boldsymbol{\zeta}_h,\boldsymbol{\eta}_h]_{\Omega_2} + a_1[\boldsymbol{\zeta}_h,\boldsymbol{\eta}_h] + a_2\left[\int_0^t \boldsymbol{\zeta}_h(s)\,ds,\boldsymbol{\eta}_h\right]\\ &\quad = \rho_1[\partial_t\mathbf{f}_1,\boldsymbol{\eta}_h]_{\Omega_1} + \rho_2[\partial_t\mathbf{f}_2,\boldsymbol{\eta}_h]_{\Omega_2} - a_2[\boldsymbol{\xi}_h(0),\boldsymbol{\eta}_h] \qquad \forall\,\boldsymbol{\eta}_h \in \boldsymbol{\Psi}^h.\end{aligned}$$

Setting $\boldsymbol{\eta}_h = \boldsymbol{\zeta}_h(t)$ in (3.51) and integrating in t, we obtain

$$\begin{aligned}&[[\boldsymbol{\zeta}_h(t),\boldsymbol{\zeta}_h(t)]] + \int_0^t a_1[\boldsymbol{\zeta}_h(s),\boldsymbol{\zeta}_h(s)]\,ds + a_2\left[\int_0^t \boldsymbol{\zeta}_h(s)\,ds,\int_0^t \boldsymbol{\zeta}_h(s)\,ds\right]\\ &\quad\le C(\|\boldsymbol{\zeta}_h(0)\|_{0,\Omega}^2 + \|\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))}) + a_2\left[\mathbf{u}_0,\int_0^t \boldsymbol{\zeta}_h(s)\,ds\right] + \int_0^t \|\boldsymbol{\zeta}_h(s)\|_{0,\Omega}^2\,ds\\ &\quad\le C(\|\boldsymbol{\zeta}_h(0)\|_{0,\Omega}^2 + \|\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{1,\Omega_2})\\ &\qquad + \frac{1}{2}a_2\left[\int_0^t \boldsymbol{\zeta}_h(s)\,ds,\textstyle\int_0^t \boldsymbol{\zeta}_h(s)\,ds\right] + \int_0^t \|\boldsymbol{\zeta}_h(s)\|_{0,\Omega}^2\,ds,\end{aligned}$$

so that

$$\begin{aligned}(3.52)\qquad &\|\boldsymbol{\zeta}_h(t)\|_{0,\Omega}^2 + \int_0^t a_1[\boldsymbol{\zeta}_h(t),\boldsymbol{\zeta}_h(t)]\,dt + a_2\left[\int_0^t \boldsymbol{\zeta}_h(s)\,ds,\int_0^t \boldsymbol{\zeta}_h(s)\,ds\right]\\ &\quad\le C(\|\boldsymbol{\zeta}_h(0)\|_{0,\Omega}^2 + \|\partial_t\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\boldsymbol{\xi}_h(0)\|^2_{1,\Omega_2}) + \int_0^t \|\boldsymbol{\zeta}_h(s)\|_{0,\Omega}^2\,ds.\end{aligned}$$

Dropping the second and third terms on the left-hand side of (3.52) and then applying the following version of Gronwall's inequality [12, p. 625],

$$(3.53)\qquad \text{if}\ \ r(t) \le C_1 + C_2\int_0^t r(s)\,ds,\ \ \text{then}\ \ r(t) \le C_1(1+C_2t)e^{C_2t},$$

we deduce

$$\|\boldsymbol{\zeta}_h(t)\|_{0,\Omega}^2 \le Ce^{CT}(\|\boldsymbol{\zeta}_h(0)\|_{0,\Omega}^2 + \|\boldsymbol{\xi}_h(0)\|^2_{1,\Omega_2} + \|\partial_t\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))}).$$

The last estimate and (3.52) yield

$$\begin{aligned}(3.54)\qquad &\|\boldsymbol{\zeta}_h(t)\|_{0,\Omega}^2 + \int_0^t a_1[\boldsymbol{\zeta}_h(t),\boldsymbol{\zeta}_h(t)]\,dt + a_2\left[\int_0^t \boldsymbol{\zeta}_h(s)\,ds,\int_0^t \boldsymbol{\zeta}_h(s)\,ds\right]\\ &\quad\le Ce^{CT}(\|\boldsymbol{\zeta}_h(0)\|_{0,\Omega}^2 + \|\partial_t\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\boldsymbol{\xi}_h(0)\|^2_{1,\Omega_2}).\end{aligned}$$

The term $\|\boldsymbol{\xi}_h(0)\|^2_{1,\Omega_2}$ on the right-hand side of (3.54) can be estimated with the help of inverse inequalities (3.13), (3.45), and (3.35) with $r = 1$:

$$\begin{aligned}\|\boldsymbol{\xi}_h(0)\|_{1,\Omega_2} &\le \|\boldsymbol{\xi}_{0,h} - \overline{\mathbf{u}}_{1,h}\|_{1,\Omega_2} + \|\overline{\mathbf{u}}_{1,h} - \mathbf{u}_1\|_{1,\Omega_2} + \|\mathbf{u}_1\|_{1,\Omega_2}\\ &\le \frac{C}{h}\|\boldsymbol{\xi}_{0,h} - \overline{\mathbf{u}}_{1,h}\|_{0,\Omega_2} + Ch\|\mathbf{u}_1\|_{2,\Omega_2} + \|\mathbf{u}_1\|_{1,\Omega_2}\\ &\le \frac{C}{h}\|\boldsymbol{\xi}_{0,h} - \mathbf{u}_1\|_{0,\Omega_2} + \frac{C}{h}\|\mathbf{u}_1 - \overline{\mathbf{u}}_{1,h}\|_{0,\Omega_2} + Ch\|\mathbf{u}_1\|_{2,\Omega_2} + \|\mathbf{u}_1\|_{1,\Omega_2}\\ &\le C(\|\mathbf{v}_0\|_{2,\Omega_1} + \|\mathbf{u}_1\|_{2,\Omega_2} + \|p_0\|_{0,\Omega_1}),\end{aligned}\qquad (3.55)$$

where $\overline{\mathbf{u}}_{1,h}$ is defined by (3.44). The term $\|\boldsymbol{\zeta}_h(0)\|_{0,\Omega}^2$ can be estimated as follows. Evaluating (3.21) at $t = 0$, then setting $\boldsymbol{\eta}_h = \partial_t \boldsymbol{\xi}_h(0)$ and using (3.52), we have

$$\begin{aligned}
&[[\partial_t \boldsymbol{\xi}_h(0), \partial_t \boldsymbol{\xi}_h(0)]] = [[\mathbf{f}(0), \partial_t \boldsymbol{\xi}_h(0)]] - a_2[\mathbf{u}_0, \partial_t \boldsymbol{\xi}_h(0)] - a_1[\boldsymbol{\xi}_h(0), \partial_t \boldsymbol{\xi}_h(0)] \\
&= [[\mathbf{f}(0), \partial_t \boldsymbol{\xi}_h(0)]] - a_2[\mathbf{u}_0, \partial_t \boldsymbol{\xi}_h(0)] - b[\partial_t \boldsymbol{\xi}_h(0), p_0] - a_1[\mathbf{v}_0, \partial_t \boldsymbol{\xi}_h(0)] \\
&\quad - [\mathbf{u}_1, \partial_t \boldsymbol{\xi}_h(0)]_{\Omega_2} + [\boldsymbol{\xi}_h(0), \partial_t \boldsymbol{\xi}_h(0)]_{\Omega_2} \\
&= [[\mathbf{f}(0), \partial_t \boldsymbol{\xi}_h(0)]] + [\Delta \mathbf{u}_0 + \nabla(\operatorname{div} \mathbf{u}_0), \partial_t \boldsymbol{\xi}_h(0)]_{\Omega_2} + [\Delta \mathbf{v}_0 - \nabla p_0, \partial_t \boldsymbol{\xi}_h(0)] \\
&\quad + \int_{\Gamma_0} (-\mu_2 \nabla \mathbf{u}_0 \cdot \mathbf{n}_2 - (\lambda_2 + \mu_2)(\operatorname{div} \mathbf{u}_0)\mathbf{n}_2 + p_0 \mathbf{n}_1 - \nabla \mathbf{v}_0 \cdot \mathbf{n}_1) \cdot \partial_t \boldsymbol{\xi}_h(0)\, d\Gamma \\
&\quad - [\mathbf{u}_1, \partial_t \boldsymbol{\xi}_h(0)]_{\Omega_2} + [\boldsymbol{\xi}_h(0), \partial_t \boldsymbol{\xi}_h(0)]_{\Omega_2}.
\end{aligned}$$

Applying assumption (3.47) and initial condition (3.32)–(3.33) to the last relation, we are led to

$$\begin{aligned}
[[\partial_t \boldsymbol{\xi}_h(0), \partial_t \boldsymbol{\xi}_h(0)]] &= [[\mathbf{f}(0), \partial_t \boldsymbol{\xi}_h(0)]] + [\Delta \mathbf{u}_0 + \nabla(\operatorname{div} \mathbf{u}_0), \partial_t \boldsymbol{\xi}_h(0)]_{\Omega_2} \\
&\quad + [\Delta \mathbf{v}_0 - \nabla p_0, \partial_t \boldsymbol{\xi}_h(0)] - [\mathbf{u}_1, \partial_t \boldsymbol{\xi}_h(0)]_{\Omega_2} + [\boldsymbol{\xi}_h(0), \partial_t \boldsymbol{\xi}_h(0)]_{\Omega_2} \\
&\le C(\|\mathbf{f}(0)\|_{\mathbf{L}^2(\Omega)}^2 + \|\mathbf{u}_0\|_{2,\Omega_2}^2 + \|\mathbf{v}_0\|_2^2 + \|\mathbf{u}_1\|_{2,\Omega_2}^2 + \|p_0\|_{1,\Omega_1}^2) \\
&\quad + C\|\boldsymbol{\xi}_{0,h}\|_{0,\Omega}^2 + \frac{1}{2}[[\partial_t \boldsymbol{\xi}_h(0), \partial_t \boldsymbol{\xi}_h(0)]],
\end{aligned}$$

so that, using (3.55), the last relation simplifies to

$$\|\partial_t \boldsymbol{\xi}_h(0)\|_{0,\Omega}^2 \le C(\|\mathbf{f}\|_{H^1(0,T;\mathbf{L}^2(\Omega))}^2 + \|\mathbf{u}_0\|_{2,\Omega_2}^2 + \|\mathbf{v}_0\|_{2,\Omega_1}^2 + \|p_0\|_{1,\Omega_1}^2 + \|\mathbf{u}_1\|_{2,\Omega_2}^2).$$

Combining (3.54), (3.55), and the last relation, we obtain (3.50). ∎

Remark 2. The particular choice of the initial condition (3.32)–(3.33) played a key role in the estimation of $[[\partial_t \boldsymbol{\xi}_h(0), \partial_t \boldsymbol{\xi}_h(0)]]$.

Using relation (3.20) in reverse, i.e., setting $\mathbf{u}_h = \mathbf{u}_{0,h} + \int_0^t \boldsymbol{\xi}_h(s)|_{\Omega_2}\, ds$ and $\mathbf{v}_h = \boldsymbol{\xi}_h|_{\Omega_1}$, we arrive at the following theorem.

THEOREM 3.9. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6) *and* (3.46). *Assume further that there exists a* $p_0 \in H^1(\Omega_1)$ *such that* (3.47) *holds. Then there exists a unique solution* $(\mathbf{v}_h, p_h, \mathbf{u}_h) \in C^1([0,T]; X_1^h) \times C([0,T]; Q_1^h) \times C^1([0,T]; X_2^h)$ *for* (3.14)–(3.19) *with the initial conditions* $(\mathbf{v}_{0,h}, \mathbf{u}_{1,h})$ *defined by* (3.32)–(3.33). *Moreover,* $(\mathbf{v}_h, p_h, \mathbf{u}_h)$ *satisfies the estimates*

$$\begin{aligned}
&\|\mathbf{v}_h\|_{L^\infty(0,T;\mathbf{L}^2(\Omega_1))}^2 + \|\partial_t \mathbf{u}_h\|_{L^\infty(0,T;\mathbf{L}^2(\Omega_2))}^2 \\
&\qquad + \|\mathbf{v}_h\|_{L^2(0,T;\mathbf{H}^1(\Omega_1))}^2 + \|\mathbf{u}_h\|_{L^\infty(0,T;\mathbf{H}^1(\Omega_2))}^2 \\
&\le Ce^{CT}(\|\mathbf{f}\|_{L^2(0,T;\mathbf{L}^2(\Omega))}^2 + \|\mathbf{u}_0\|_{1,\Omega_2}^2 + \|\mathbf{v}_0\|_{1,\Omega_1}^2 + \|p_0\|_{0,\Omega_1}^2 + \|\mathbf{u}_1\|_{0,\Omega_2}^2)
\end{aligned} \tag{3.56}$$

and

$$\begin{aligned}
&\|\partial_t \mathbf{v}_h\|_{L^\infty(0,T;L^2(\Omega_1))}^2 + \|\partial_{tt} \mathbf{u}_h\|_{L^\infty(0,T;L^2(\Omega_2))}^2 \\
&\qquad + \|\partial_t \mathbf{v}_h\|_{L^2(0,T;\mathbf{H}^1(\Omega_1))}^2 + \|\partial_t \mathbf{u}_h\|_{L^\infty(0,T;\mathbf{H}^1(\Omega_2))}^2 \\
&\le Ce^{CT}(\|\mathbf{f}\|_{H^1(0,T;\mathbf{L}^2(\Omega))}^2 + \|\mathbf{u}_0\|_{2,\Omega_2}^2 + \|\mathbf{v}_0\|_{2,\Omega_1}^2 + \|p_0\|_{1,\Omega_1}^2 + \|\mathbf{u}_1\|_{2,\Omega_2}^2).
\end{aligned} \tag{3.57}$$

Recall that Theorem 3.6 stated only the existence and uniqueness of a discrete pressure p_h satisfying (3.28), (3.27) and (3.14). By virtue of the strong energy estimates (3.57) and the discrete inf-sup conditions, we now can establish an estimate for p_h.

THEOREM 3.10. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6) *and* (3.46). *Assume further that there exists a* $p_0 \in H^1(\Omega_1)$ *such that* (3.47) *holds. Let* $(\mathbf{v}_h, p_h, \mathbf{u}_h) \in C^1([0,T]; X_1^h) \times C([0,T]; Q_1^h) \times C^1([0,T]; X_2^h)$ *be the solution for* (3.14)–(3.19) *with the initial conditions* $(\mathbf{v}_{0,h}, \mathbf{u}_{1,h})$ *defined by* (3.32)–(3.33). *Then* p_h *satisfies the estimate*

(3.58)
$$\|p_h\|^2_{L^2(0,T;L^2(\Omega_1))} \le Ce^{CT}\Big(\|\mathbf{f}\|^2_{H^1(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{2,\Omega_2} + \|\mathbf{v}_0\|^2_{2,\Omega_1} + \|p_0\|^2_{1,\Omega_1} + \|\mathbf{u}_1\|^2_{2,\Omega_2}\Big).$$

Proof. We observe that from (3.28) we have

$$\|p_h\|_{L^2(0,T;L^2(\Omega_1))} \le C\Big(\|\partial_t \boldsymbol{\xi}_h\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\boldsymbol{\xi}_h\|_{L^2(0,T;X_1)} + \|\textstyle\int_0^t \boldsymbol{\xi}_h(s)\,ds\|_{L^2(0,T;X_1)}\Big).$$

Thus, (3.58) follows from the last relation and energy estimate (3.50) for $\boldsymbol{\xi}_h$. ∎

Remark 3. Note that Theorems 3.8, 3.9, and 3.10 require the specification of an initial pressure p_0 and the initial interface stress condition (3.47). From a physical point of view, these requirements are entirely reasonable.

4. The convergence of finite element solutions and error estimates. Having proved the existence of finite element solutions $(\mathbf{v}_h, p_h, \mathbf{u}_h)$ for problem (3.14)–(3.19) and (3.32)–(3.33), we now prove the convergence of the finite element solutions and derive error estimates.

4.1. The convergence of finite element solutions. We first consider the convergence of the finite element approximations.

THEOREM 4.1. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6) *and* (3.46) *and that there exists a* $p_0 \in H^1(\Omega_1)$ *such that* (3.47) *holds. Let* $(\mathbf{v}_h, p_h, \mathbf{u}_h) \in C^1([0,T]; X_1^h) \times C([0,T]; Q_1^h) \times C^1([0,T]; X_2^h)$ *be the unique solution of* (3.14)–(3.19) *with the initial conditions* $(\mathbf{v}_{0,h}, \mathbf{u}_{1,h})$ *defined by* (3.32)–(3.33). *Assume further that the finite element meshes are nested, i.e., that the triangulation* $\mathcal{T}^{h_2}(\Omega)$ *is a refinement of the triangulation* $\mathcal{T}^{h_1}(\Omega)$ *whenever* $h_2 < h_1$. *Then, there exists a unique* $(\mathbf{v}, p, \mathbf{u})$ *such that*

$$\begin{cases} \mathbf{v} \in L^\infty(0,T;\mathbf{L}^2(\Omega_1)) \cap L^2(0,T;X_1), \\ \partial_t \mathbf{v} \in L^\infty(0,T;\mathbf{L}^2(\Omega_1)) \cap L^2(0,T;X_1), \quad p \in L^2(0,T;L^2(\Omega_1)), \\ \mathbf{u} \in L^\infty(0,T;X_2), \quad \partial_t \mathbf{u} \in L^\infty(0,T;X_2), \quad \partial_{tt}\mathbf{u} \in L^\infty(0,T;\mathbf{L}^2(\Omega_2)), \end{cases} \tag{4.1}$$

$$\mathbf{v}_h \rightharpoonup \mathbf{v} \quad \text{in } L^2(0,T;X_1), \qquad \mathbf{v}_h \overset{*}{\rightharpoonup} \mathbf{v} \quad \text{in } L^\infty(0,T;\mathbf{L}^2(\Omega_1)), \tag{4.2}$$

$$\partial_t \mathbf{v}_h \overset{*}{\rightharpoonup} \partial_t \mathbf{v} \quad \text{in } L^\infty(0,T;\mathbf{L}^2(\Omega_1)), \qquad \partial_t \mathbf{v}_h \rightharpoonup \partial_t \mathbf{v} \quad \text{in } L^2(0,T;X_1), \tag{4.3}$$

$$\mathbf{u}_h \overset{*}{\rightharpoonup} \mathbf{u} \quad \text{in } L^\infty(0,T;X_2), \tag{4.4}$$

$$\partial_t \mathbf{u}_h \overset{*}{\rightharpoonup} \partial_t \mathbf{u} \quad \text{in } L^\infty(0,T;\mathbf{L}^2(\Omega_1)), \qquad \partial_t \mathbf{u}_h \overset{*}{\rightharpoonup} \partial_t \mathbf{u} \quad \text{in } L^\infty(0,T;X_2), \tag{4.5}$$

$$\partial_{tt} \mathbf{u}_h \overset{*}{\rightharpoonup} \partial_{tt} \mathbf{u} \quad \text{in } L^\infty(0,T;\mathbf{L}^2(\Omega_2)), \tag{4.6}$$

and

$$p^h \rightharpoonup p \quad \text{weakly in } L^2(0,T;L^2(\Omega_1)). \tag{4.7}$$

Furthermore, $(\mathbf{v}, p, \mathbf{u})$ *satisfies* (3.3)–(3.6) *and the estimates*

$$\begin{aligned} &\|\mathbf{v}\|^2_{L^\infty(0,T;\mathbf{L}^2(\Omega_1))} + \|\partial_t \mathbf{u}\|^2_{L^\infty(0,T;\mathbf{L}^2(\Omega_2))} \\ &\qquad + \|\mathbf{v}\|^2_{L^2(0,T;\mathbf{H}^1(\Omega_1))} + \|\mathbf{u}\|^2_{L^\infty(0,T;\mathbf{H}^1(\Omega_2))} \\ &\quad \le Ce^{CT}(\|\mathbf{f}\|^2_{L^2(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{2,\Omega_2} + \|\mathbf{v}_0\|^2_{2,\Omega_1} + \|p_0\|^2_{1,\Omega_1} + \|\mathbf{u}_1\|^2_{2,\Omega_2}) \end{aligned} \tag{4.8}$$

and

$$\begin{aligned} &\|\partial_t \mathbf{v}\|^2_{L^\infty(0,T;\mathbf{L}^2(\Omega_1))} + \|\partial_t \mathbf{v}\|^2_{L^2(0,T;\mathbf{H}^1(\Omega_1))} + \|p\|^2_{L^2(0,T;L^2(\Omega_1))} \\ &\qquad + \|\partial_{tt} \mathbf{u}(t)\|^2_{L^\infty(0,T;\mathbf{L}^2(\Omega_2))} + \|\partial_t \mathbf{u}\|^2_{L^\infty(0,T;\mathbf{H}^1(\Omega_2))} \\ &\quad \le Ce^{CT}(\|\mathbf{f}\|^2_{H^1(0,T;\mathbf{L}^2(\Omega))} + \|\mathbf{u}_0\|^2_{2,\Omega_2} + \|\mathbf{v}_0\|^2_{2,\Omega_1} + \|p_0\|^2_{1,\Omega_1} + \|\mathbf{u}_1\|^2_{2,\Omega_2}). \end{aligned} \tag{4.9}$$

Proof. We have that $\{(\mathbf{v}_h, p_h, \mathbf{u}_h)\}$ satisfies the estimates (3.56)–(3.57) and (3.58). Using these estimates, we may extract a subsequence $\{(\mathbf{v}_{h_n}, p_{h_n}, \mathbf{u}_{h_n})\}$ of $\{(\mathbf{v}_h, p_h, \mathbf{u}_h)\}$, with $\{h_n\}$ decreasing to 0 as $n \to \infty$, such that (4.2)–(4.7) hold for the subsequence $\{(\mathbf{v}_{h_n}, p_{h_n}, \mathbf{u}_{h_n})\}$ for a $(\mathbf{v}, p, \mathbf{u})$ satisfying (4.1).

Equation (3.17) holds for $h = h_n$, and thus, by passing to the limit as $n \to \infty$ in that equation, we obtain (3.6). Also, $\mathbf{u}(0) = \mathbf{u}_0$ trivially holds.

To prove that $(\mathbf{v}, p, \mathbf{u})$ satisfies (3.3) we begin from (3.14) with $h = h_n$. We arbitrarily fix an integer N and a function $\boldsymbol{\eta} \in C^1([0,T]; X^{h_N})$. For each $n > N$ we obtain from (3.14) and the nesting assumption on the triangulation family $\mathcal{T}^h(\Omega)$ that

$$\begin{aligned} &\int_0^T \Big(\rho_1[\partial_t \mathbf{v}_{h_n}, \boldsymbol{\eta}]_{\Omega_1} + a_1[\mathbf{v}_{h_n}, \boldsymbol{\eta}] + b[\boldsymbol{\eta}, p_{h_n}] + \rho_2[\partial_{tt} \mathbf{u}_{h_n}, \boldsymbol{\eta}]_{\Omega_2} + a_2[\mathbf{u}_{h_n}, \boldsymbol{\eta}]\Big)\, dt \\ &\qquad = \int_0^T \Big(\rho_1[\mathbf{f}_1, \boldsymbol{\eta}]_{\Omega_1} + \rho_2[\mathbf{f}_2, \boldsymbol{\eta}]_{\Omega_2}\Big)\, dt. \end{aligned} \tag{4.10}$$

Passing to the limit as $n \to \infty$, we find

$$\begin{aligned} &\int_0^T \Big(\rho_1[\partial_t \mathbf{v}, \boldsymbol{\eta}]_{\Omega_1} + a_1[\mathbf{v}, \boldsymbol{\eta}] + b[\boldsymbol{\eta}, p] + \rho_2[\partial_{tt} \mathbf{u}, \boldsymbol{\eta}]_{\Omega_2} + a_2[\mathbf{u}, \boldsymbol{\eta}]\Big)\, dt \\ &\qquad = \int_0^T \Big(\rho_1[\mathbf{f}_1, \boldsymbol{\eta}]_{\Omega_1} + \rho_2[\mathbf{f}_2, \boldsymbol{\eta}]_{\Omega_2}\Big)\, dt. \end{aligned} \tag{4.11}$$

Equality (4.11) then holds for all $\boldsymbol{\eta} \in L^2(0,T;\mathbf{H}^1_0(\Omega))$, as $\bigcup_{n=N}^{\infty} C([0,T];X^{h_n})$ is dense in $L^2(0,T;\mathbf{H}^1_0(\Omega))$ for the $L^2(0,T;\mathbf{H}^1_0(\Omega))$ norm. Hence,

$$\begin{aligned}\rho_1[\partial_t \mathbf{v},\boldsymbol{\eta}]_{\Omega_1} + a_1[\mathbf{v},\boldsymbol{\eta}] + b[\boldsymbol{\eta},p] + \rho_2[\partial_{tt}\mathbf{u},\boldsymbol{\eta}]_{\Omega_2} + a_2[\mathbf{u},\boldsymbol{\eta}]\\ = \rho_1[\mathbf{f}_1,\boldsymbol{\eta}]_{\Omega_1} + \rho_2[\mathbf{f}_2,\boldsymbol{\eta}]_{\Omega_2} \qquad \forall\, \boldsymbol{\eta} \in \mathbf{H}^1_0(\Omega),\ \text{a.e. } t,\end{aligned}$$

which is precisely (3.3).

From (3.15) we obtain

$$\int_0^T b[\mathbf{v}_{h_n}, q]\, ds = 0$$

for all $q \in L^2(0,T;Q_1^{h_N})$ and all $n \geq N$. Passing to the limit as $n \to \infty$ leads us to

$$\int_0^T b[\mathbf{v}, q]\, ds = 0 \tag{4.12}$$

for all $q \in L^2(0,T;Q_1^{h_N})$. Using the denseness (with respect to the $L^2(0,T;L^2(\Omega_1))$ norm) of $\bigcup_{n=N}^{\infty} L^2(0,T;Q_1^{h_n})$ in $L^2(0,T;L^2(\Omega_1))$, we see that (4.12) holds for all $q \in L^2(0,T;L^2(\Omega_1))$. In particular, this implies (3.4).

To verify the initial condition (3.5) we first note that the regularity results (4.1) imply that $\mathbf{v} \in C([0,T];\mathbf{L}^2(\Omega_1)) \cap C([0,T;X_1)$, $\mathbf{u} \in C([0,T];\mathbf{L}^2(\Omega_2)) \cap C([0,T;X_2)$, and $\partial_t \mathbf{u} \in C([0,T];\mathbf{L}^2(\Omega_2))$. For each $\boldsymbol{\eta} \in C^1([0,T];\mathbf{H}^1_0(\Omega))$ with $\boldsymbol{\eta}(T) = \mathbf{0}$ we obtain, from (4.11), by integration by parts that

$$\begin{aligned}\int_0^T \Big(-\rho_1[\mathbf{v},\partial_t\boldsymbol{\eta}]_{\Omega_1} - \rho_2[\partial_t\mathbf{u},\partial_t\boldsymbol{\eta}]_{\Omega_2} + a_1[\mathbf{v},\boldsymbol{\eta}] + b[\boldsymbol{\eta},\widehat{p}] + a_2[\mathbf{u},\boldsymbol{\eta}]\Big)\, dt\\ = \int_0^T [[\mathbf{f},\boldsymbol{\eta}]]\, dt + \rho_1[\mathbf{v}(0),\boldsymbol{\eta}(0)]_{\Omega_1} + \rho_2[\partial_t\mathbf{u}(0),\boldsymbol{\eta}(0)]_{\Omega_2}.\end{aligned} \tag{4.13}$$

On the other hand, from (4.10), we deduce that for all $\boldsymbol{\eta} \in C^1([0,T];X^{h_N})$ and all $n > N$,

$$\begin{aligned}\int_0^T \Big(-\rho_1[\mathbf{v}_{h_n},\partial_t\boldsymbol{\eta}]_{\Omega_1} - \rho_2[\partial_t\mathbf{u}_{h_n},\partial_t\boldsymbol{\eta}]_{\Omega_2}\\ + a_1[\mathbf{v}_{h_n},\boldsymbol{\eta}] + b[\boldsymbol{\eta},p_{h_n}] + a_2[\mathbf{u}_{h_n},\boldsymbol{\eta}]\Big)\, dt\\ = \int_0^T [[\mathbf{f},\boldsymbol{\eta}]]\, dt + \rho_1[\mathbf{v}_{h_n}(0),\boldsymbol{\eta}(0)]_{\Omega_1} + \rho_2[\partial_t\mathbf{u}_{h_n}(0),\boldsymbol{\eta}(0)]_{\Omega_2}.\end{aligned} \tag{4.14}$$

Holding N fixed and passing to the limit as $n \to \infty$ in (4.14) and utilizing (3.35), we arrive at

$$\begin{aligned}\int_0^T \Big(-\rho_1[\mathbf{v},\partial_t\boldsymbol{\eta}]_{\Omega_1} - \rho_2[\partial_t\mathbf{u},\partial_t\boldsymbol{\eta}]_{\Omega_2} + a_1[\mathbf{v},\boldsymbol{\eta}] + b[\boldsymbol{\eta},\widehat{p}] + a_2[\mathbf{u},\boldsymbol{\eta}]\Big)\, dt\\ = \int_0^T [[\mathbf{f},\boldsymbol{\eta}]]\, dt + \rho_1[\mathbf{v}_0,\boldsymbol{\eta}(0)]_{\Omega_1} + \rho_2[\mathbf{u}_1,\boldsymbol{\eta}(0)]_{\Omega_2}\end{aligned} \tag{4.15}$$

for all $\boldsymbol{\eta} \in C^1([0,T];X^{h_N})$. Comparing (4.13) and (4.15), we obtain

$$\rho_1[\mathbf{v}(0)-\mathbf{v}_0,\boldsymbol{\eta}(0)]_{\Omega_1} + \rho_2[\partial_t\mathbf{u}(0)-\mathbf{u}_1,\boldsymbol{\eta}(0)]_{\Omega_2} = 0 \tag{4.16}$$

for all $\boldsymbol{\eta}(0) \in X^{h_N}$. Since $\bigcup_{n=N}^{\infty} X^{h_n}$ is dense in $\mathbf{L}^2(\Omega)$ for the $\mathbf{L}^2(\Omega)$ norm, we derive

$$\mathbf{v}(0) = \mathbf{v}_0 \quad \text{in } \mathbf{L}^2(\Omega_1) \qquad \text{and} \qquad \partial_t \mathbf{u}(0) = \mathbf{u}_1 \quad \text{in } \mathbf{L}^2(\Omega_2).$$

To check $\mathbf{u}(0) = \mathbf{u}_0$ we first note that with regularity (4.1) we are justified to write

$$\mathbf{u} = \mathbf{u}(0) + \int_0^t \partial_t \mathbf{u}(s)\, ds. \tag{4.17}$$

From the compact embedding $H^1(0,T;B) \hookrightarrow\hookrightarrow L^2(0,T;B)$ for any Banach space B and the weak convergence (4.2)–(4.5) we deduce that for a further subsequence h_{n_j} we have

$$\partial_t \mathbf{u}_{h_{n_j}} \to \partial_t \mathbf{u} \quad \text{in } L^2(0,T;\mathbf{L}^2(\Omega_2)) \qquad \text{and} \qquad \mathbf{u}_{h_{n_j}} \to \mathbf{u} \quad \text{in } L^2(0,T;\mathbf{L}^2(\Omega_2)),$$

so that, passing to the limit in the relation

$$\mathbf{u}_{h_n} = \mathbf{u}_{0,h_n} + \int_0^t \partial_t \mathbf{u}_{h_n}(s)\, ds$$

and noting that $\|\mathbf{u}_{0,h} - \mathbf{u}_0\|_{0,\Omega_2} \to 0$ as $h \to 0$, we obtain

$$\mathbf{u} = \mathbf{u}_0 + \int_0^t \partial_t \mathbf{u}(s)\, ds. \tag{4.18}$$

A comparison of (4.17) and (4.18) yields $\mathbf{u}(0) = \mathbf{u}_0$.

Hence we have verified that $(\mathbf{v}, p, \mathbf{u})$ satisfies (3.1)–(3.6). Of course, $(\mathbf{v}, \mathbf{u})$ is also a solution for (2.7)–(2.10), so that, by Theorem 2.2, $(\mathbf{v}, \mathbf{u})$ is the unique solution of (2.7)–(2.10) and estimate (4.8) holds. Then, by Theorem 2.3, we obtain the uniqueness of p. Estimate (4.9) follows from (3.57) and (3.58).

Finally, it follows from the uniqueness of the limit $(\mathbf{v}, p, \mathbf{u})$ that the entire family of finite element solutions $(\mathbf{v}_h, p_h, \mathbf{u}_h)$ satisfies (4.2)–(4.7) as $h \to 0$. □

We also have the following strong convergence, the proof of which is contained in that of Theorem 4.1.

COROLLARY 4.2. *Assume that all hypotheses of Theorem* 4.1 *hold. Then*

$$\mathbf{v}_h \to \mathbf{v} \quad \textit{in } L^2(0,T;\mathbf{L}^2(\Omega_1)), \qquad \mathbf{u}_h \to \mathbf{u} \quad \textit{in } L^2(0,T;X_2)$$

and

$$\partial_t \mathbf{u}_h \to \partial_t \mathbf{u} \quad \textit{in } L^2(0,T;\mathbf{L}^2(\Omega_2)).$$

4.2. Error estimates for finite element approximations. We will estimate the error between the continuous solution defined by (3.3)–(3.6) and the finite element solution defined by (3.14)–(3.19) and (3.32)–(3.33). To this end we introduce the weighted $\mathbf{L}^2(\Omega)$ projection operator onto the discretely divergence-free space $\boldsymbol{\Psi}^h$. ($\boldsymbol{\Psi}^h$ is discretely divergence-free in Ω_1.)

The projection operator $\mathcal{P}^h : \mathbf{L}^2(\Omega) \to \boldsymbol{\Psi}^h$ with respect to the weighted $\mathbf{L}^2(\Omega)$ inner product is defined as follows: for every $\boldsymbol{\eta} \in \mathbf{L}^2(\Omega)$, $\mathcal{P}^h\boldsymbol{\eta} \in \boldsymbol{\Psi}^h$ is the solution of

$$[[\mathcal{P}^h\boldsymbol{\eta}, \mathbf{z}^h]] = [[\boldsymbol{\eta}, \mathbf{z}^h]] \qquad \forall\, \mathbf{z}^h \in \boldsymbol{\Psi}^h. \tag{4.19}$$

Note that the definition of $\mathbf{\Psi}^h$ implies

$$b[\mathcal{P}^h\boldsymbol{\eta}, q^h] = 0 \qquad \forall\, q^h \in Q_1^h. \tag{4.20}$$

We assume that the domains Ω_1 and Ω_2 satisfy the following regularity assumptions.

Hypothesis (H1). The problem

$$\begin{cases} (\bar{\mathbf{v}}, \bar{p}) \in \mathbf{H}_0^1(\Omega_1) \times L_0^2(\Omega_1), \\ [\nabla\bar{\mathbf{v}}, \nabla\mathbf{z}]_{\Omega_1} + b[\mathbf{z}, \bar{p}] = [\bar{\mathbf{f}}_1, \mathbf{z}]_{\Omega_1} \qquad \forall\, \mathbf{z} \in \mathbf{H}_0^1(\Omega_1), \\ b[\mathbf{v}, q] = 0 \qquad \forall\, q \in L^2(\Omega_1) \end{cases} \tag{4.21}$$

is $\mathbf{H}^{2-\epsilon_1}$ regular for an $\epsilon_1 \in (0,1)$; i.e., for every $\bar{\mathbf{f}}_1 \in \mathbf{L}^2(\Omega_1)$, the solution $(\bar{\mathbf{v}}, \bar{p})$ to problem (4.21) belongs to $\mathbf{H}^{2-\epsilon_1}(\Omega_1) \times H^{1-\epsilon_1}(\Omega_1)$, $-\bar{p}\mathbf{n}_1 + (\nabla\bar{\mathbf{v}} + \nabla\bar{\mathbf{v}}^T)\mathbf{n}_1 \in \mathbf{H}^{1/2-\epsilon_1}(\Gamma_0)$, and

$$\|\bar{\mathbf{v}}\|_{\mathbf{H}^{2-\epsilon_1}(\Omega_1)} + \|\bar{p}\|_{H^{1-\epsilon_1}(\Omega_1)}\| - \bar{p}\mathbf{n}_1 + (\nabla\bar{\mathbf{v}} + \nabla\bar{\mathbf{v}}^T)\mathbf{n}_1\|_{1/2-\epsilon_1,\Gamma_0} \le C\|\bar{\mathbf{f}}_1\|_{0,\Omega_1}.$$

Hypothesis (H2). The problem

$$\begin{cases} \bar{\mathbf{u}} \in \mathbf{H}_0^1(\Omega_1), \\ [\nabla\bar{\mathbf{u}}, \nabla\mathbf{w}]_{\Omega_1} = [\bar{\mathbf{f}}_2, \mathbf{w}]_{\Omega_1} \qquad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega_2) \end{cases} \tag{4.22}$$

is $\mathbf{H}^{2-\epsilon_2}$ regular for an $\epsilon_2 \in (0,1)$; i.e., for every $\bar{\mathbf{f}}_2 \in \mathbf{L}^2(\Omega_2)$, the solution $\bar{\mathbf{u}}$ to problem (4.22) belongs to $\mathbf{H}^{2-\epsilon_2}(\Omega_2)$, $\nabla\bar{\mathbf{u}} \cdot \mathbf{n}_2 \in \mathbf{H}^{1/2-\epsilon_2}(\Gamma_0)$, and

$$\|\bar{\mathbf{u}}\|_{\mathbf{H}^{2-\epsilon_2}(\Omega_2)}\|\nabla\bar{\mathbf{u}} \cdot \mathbf{n}_2\|_{1/2-\epsilon_2,\Gamma_0} \le C\|\bar{\mathbf{f}}_2\|_{0,\Omega_2}.$$

Remark 4. Hypotheses (H1)–(H2) are simply equivalent to angle conditions on Ω_1 and Ω_2 owing to the well-known regularity results on polygonal domains for boundary value problems (4.21) and (4.22); see [24] and [19]. In particular, if both Ω_1 and Ω_2 are convex (in which case Γ_0 is necessarily a straight line), then ϵ_1 and ϵ_2 can be chosen arbitrarily small.

Under Hypotheses (H1)–(H2), we may prove the following error estimates for the projection operator $\mathcal{P}^h$:

$$\begin{aligned} &\|\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}\|_{1,\Omega} \le Ch^{r-\epsilon}(\|\boldsymbol{\zeta}\|_{r+1,\Omega_1} + \|\boldsymbol{\zeta}\|_{r+1,\Omega_2}) \\ &\qquad \forall\, \boldsymbol{\zeta} \in \mathbf{\Psi} \quad \text{ with } \boldsymbol{\zeta}|_{\Omega_i} \in \mathbf{H}^{r+1}(\Omega_i), \quad i = 1, 2, r \in [0, k], \end{aligned} \tag{4.23}$$

and

$$\begin{aligned} &\|\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}\|_{0,\Omega} \le Ch^{r+1-\epsilon}(\|\boldsymbol{\zeta}\|_{r+1,\Omega_1} + \|\boldsymbol{\zeta}\|_{r+1,\Omega_2}) \\ &\qquad \forall\, \boldsymbol{\zeta} \in \mathbf{\Psi} \quad \text{ with } \boldsymbol{\zeta}|_{\Omega_i} \in \mathbf{H}^{r+1}(\Omega_i), \quad i = 1, 2, r \in [0, k]. \end{aligned} \tag{4.24}$$

The proof of (4.23)–(4.24) will be given in the appendix, Theorem A.3.

Now we prove the following error estimates for the semidiscrete finite element approximations of the fluid-solid interaction problem.

THEOREM 4.3. *Assume that* $\mathbf{f}_1, \mathbf{v}_0, \mathbf{f}_2, \mathbf{u}_0$, *and* $\mathbf{u}_1$ *satisfy* (2.6) *and* (3.46) *and that there exists a* $p_0 \in H^1(\Omega_1)$ *such that* (3.47) *holds. Assume also that* (H1)–(H2) *hold.*

Let $(\mathbf{v}, p, \mathbf{u})$ *be the solution of* (3.1)–(3.6)*, and* $(\mathbf{v}_h, p_h, \mathbf{u}_h)$ *be the solution of* (3.14)–(3.19) *and* (3.32)–(3.33)*. Assume that for some* $r \in [1, k]$*,* $\mathbf{v} \in L^2(0,T;\mathbf{H}^{r+1}(\Omega_1))$*,* $\partial_t \mathbf{v} \in L^2(0,T;\mathbf{H}^{r-1}(\Omega_1))$*,* $p \in L^2(0,T;H^r(\Omega_1))$*,* $\partial_t \mathbf{u} \in L^2(0,T;\mathbf{H}^{r+1}(\Omega_2))$*,* $\partial_{tt}\mathbf{u} \in L^2(0,T;\mathbf{H}^{r-1}(\Omega_2))$*,* $\mathbf{v}_0 \in \mathbf{H}^{r+1}(\Omega_1)$*,* $\mathbf{u}_1 \in \mathbf{H}^{r+1}(\Omega_2)$*,* $\mathbf{u}_0 \in \mathbf{H}^{r+1}(\Omega_2)$*, and* $p_0 \in H^r(\Omega_1)$*. Then,*

$$
\begin{aligned}
&\|\mathbf{v}(t) - \mathbf{v}_h(t)\|_{0,\Omega_1}^2 + \|\mathbf{v} - \mathbf{v}_h\|_{L^2(0,T;X_1)}^2 \\
&\quad + \|\partial_t \mathbf{u}(t) - \partial_t \mathbf{u}_h(t)\|_{0,\Omega_2}^2 + \|\mathbf{u}(t) - \mathbf{u}_h(t)\|_{1,\Omega_2}^2 \\
&\le Ce^{CT} h^{2r} \big(\|\mathbf{v}_0\|_{r+1,\Omega_1}^2 + \|\mathbf{u}_1\|_{r+1,\Omega_2}^2 + \|\mathbf{u}_0\|_{r+1,\Omega_2}^2 + \|p_0\|_{r,\Omega_1}^2 \\
&\quad + \|p\|_{L^2(0,T;H^r(\Omega_1))}^2 \big) + Ce^{CT} h^{2(r-\epsilon)} (\|\mathbf{v}\|_{L^2(0,T;\mathbf{H}^{r+1}(\Omega_1))}^2 \\
&\quad + \|\mathbf{u}_t\|_{L^2(0,T;\mathbf{H}^{r+1}(\Omega_2))}^2 + \|\partial_t \mathbf{v}\|_{L^2(0,T;\mathbf{H}^{r-1}(\Omega_1))}^2 + \|\partial_{tt}\mathbf{u}\|_{L^2(0,T;\mathbf{H}^{r-1}(\Omega_2))}^2)
\end{aligned} \tag{4.25}
$$

for all $t \in [0,T]$*.*

Proof. Let $\boldsymbol{\xi}$ and $\boldsymbol{\xi}_h$ be defined by (2.11) and (3.20), respectively. We set $\widetilde{\mathbf{v}}_h(t) = [\mathcal{P}^h \boldsymbol{\xi}(t)]|_{\Omega_1}$ and $\widetilde{\mathbf{w}}_h(t) = [\mathcal{P}^h \boldsymbol{\xi}(t)]|_{\Omega_2}$.

By subtracting (3.14)–(3.15) from the corresponding equations of (3.3)–(3.4), we obtain the following "orthogonality conditions":

$$
\begin{aligned}
&\rho_1[\partial_t \mathbf{v} - \partial_t \mathbf{v}_h, \boldsymbol{\eta}_h]_{\Omega_1} + b[\boldsymbol{\eta}_h, p - p_h] + a_1[\mathbf{v} - \mathbf{v}_h, \boldsymbol{\eta}_h] \\
&\qquad + \rho_2[\mathbf{u}_{tt} - \partial_{tt}\mathbf{u}_h, \boldsymbol{\eta}_h]_{\Omega_2} + a_2[\mathbf{u} - \mathbf{u}_h, \boldsymbol{\eta}_h] = 0 \qquad \forall\, \boldsymbol{\eta}_h \in X^h, \text{ a.e. } t,
\end{aligned} \tag{4.26}
$$

$$
b[\mathbf{v} - \mathbf{v}_h, q_h] = 0 \qquad \forall\, q_h \in Q_1^h, \text{ a.e. } t. \tag{4.27}
$$

By adding/subtracting terms and using (4.26)–(4.27), we deduce that

$$
\begin{aligned}
&\rho_1[\partial_t \mathbf{v}_h - \partial_t \mathbf{v}_h, \mathbf{v} - \mathbf{v}_h]_{\Omega_1} + a_1[\mathbf{v} - \mathbf{v}_h, \mathbf{v} - \mathbf{v}_h] \\
&\qquad + \rho_2[\partial_{tt}\mathbf{u} - \partial_{tt}\mathbf{u}_h, \partial_t \mathbf{u} - \partial_t \mathbf{u}_h]_{\Omega_2} + a_2[\mathbf{u} - \mathbf{u}_h, \partial_t \mathbf{u} - \mathbf{u}_h] \\
&= \rho_1[\partial_t \mathbf{v} - \partial_t \mathbf{v}_h, \mathbf{v} - \widetilde{\mathbf{v}}_h]_{\Omega_1} + a_1[\mathbf{v} - \mathbf{v}_h, \mathbf{v} - \widetilde{\mathbf{v}}_h] \\
&\qquad + \rho_2[\partial_{tt}\mathbf{u} - \partial_{tt}\mathbf{u}_h, \partial_t \mathbf{u} - \widetilde{\mathbf{w}}_h]_{\Omega_2} + a_2[\mathbf{u} - \mathbf{u}_h, \partial_t \mathbf{u} - \widetilde{\mathbf{w}}_h] \\
&\qquad - b[\widetilde{\mathbf{v}}_h - \mathbf{v}_h, p - p_h] + \rho_1[\partial_t \mathbf{v} - \partial_t \mathbf{v}_h, \widetilde{\mathbf{v}}_h - \mathbf{v}_h]_{\Omega_1} \\
&\qquad + a_1[\mathbf{v} - \mathbf{v}_h, \widetilde{\mathbf{v}} - \mathbf{v}_h] + \rho_2[\partial_{tt}\mathbf{u} - \partial_{tt}\mathbf{u}_h, \widetilde{\mathbf{w}}_h - \partial_t \mathbf{u}_h]_{\Omega_2} \\
&\qquad + a_2[\mathbf{u} - \mathbf{u}_h, \widetilde{\mathbf{w}}_h - \partial_t \mathbf{u}_h] + b[\widetilde{\mathbf{v}}_h - \mathbf{v}_h, p - p_h] \\
&= \rho_1[\partial_t \mathbf{v} - \partial_t \mathbf{v}_h, \mathbf{v} - \widetilde{\mathbf{v}}_h]_{\Omega_1} + a_1[\mathbf{v} - \mathbf{v}_h, \mathbf{v} - \widetilde{\mathbf{v}}_h] \\
&\qquad + \rho_2[\partial_{tt}\mathbf{u} - \partial_{tt}\mathbf{u}_h, \partial_t \mathbf{u} - \widetilde{\mathbf{w}}_h]_{\Omega_2} + a_2[\mathbf{u} - \mathbf{u}_h, \partial_t \mathbf{u} - \widetilde{\mathbf{w}}_h] \\
&\qquad + b[\mathbf{v}_h - \widetilde{\mathbf{v}}_h, p - p_h].
\end{aligned} \tag{4.28}
$$

By the definition of $\widetilde{\mathbf{v}}_h$ and (4.20), we obtain

$$
b[\widetilde{\mathbf{v}}_h(t), p_h] = b[\mathcal{P}^h \boldsymbol{\xi}(t), p_h] = 0 = b[\mathcal{P}^h \boldsymbol{\xi}(t), q_h] = b[\widetilde{\mathbf{v}}_h(t), q_h] \qquad \forall\, q_h \in Q_1^h\,. \tag{4.29}
$$

Utilizing (3.15), we have

$$b[\mathbf{v}_h(t), p_h] = 0 = b[\mathbf{v}_h(t), q_h] \qquad \forall\, q_h \in Q_1^h. \tag{4.30}$$

Additionally,

$$\begin{aligned}
&\rho_1[\partial_t \mathbf{v} - \partial_t \mathbf{v}_h, \mathbf{v} - \widetilde{\mathbf{v}}_h]_{\Omega_1} + \rho_2[\partial_{tt}\mathbf{u} - \partial_{tt}\mathbf{u}_h, \partial_t \mathbf{u} - \widetilde{\mathbf{w}}]_{\Omega_2} \\
&\quad = [[\partial_t \boldsymbol{\xi}(t) - \partial_t \boldsymbol{\xi}_h(t), \boldsymbol{\xi}(t) - \mathcal{P}^h \boldsymbol{\xi}(t)]] = [[\partial_t \boldsymbol{\xi}(t), \boldsymbol{\xi}(t) - \mathcal{P}^h \boldsymbol{\xi}(t)]] \\
&\quad = [[\partial_t \boldsymbol{\xi}(t) - \partial_t \mathcal{P}^h \boldsymbol{\xi}(t), \boldsymbol{\xi}(t) - \mathcal{P}^h \boldsymbol{\xi}(t)]] \\
&\quad = \frac{1}{2}\frac{d}{dt}[[\boldsymbol{\xi}(t) - \mathcal{P}^h \boldsymbol{\xi}(t), \boldsymbol{\xi}(t) - \mathcal{P}^h \boldsymbol{\xi}(t)]] \\
&\quad = \frac{\rho_1}{2}\frac{d}{dt}\|\mathbf{v} - \widetilde{\mathbf{v}}_h\|^2_{0,\Omega_1} + \frac{\rho_2}{2}\frac{d}{dt}\|\partial_t \mathbf{u} - \widetilde{\mathbf{w}}_h\|^2_{0,\Omega_2}.
\end{aligned} \tag{4.31}$$

Combining (4.28)–(4.31), we deduce that for all $q_h \in L^2(0,T;Q_1^h)$

$$\begin{aligned}
&\frac{\rho_1}{2}\frac{d}{dt}\|\mathbf{v} - \mathbf{v}_h\|^2_{0,\Omega_1} + a_1[\mathbf{v} - \mathbf{v}_h, \mathbf{v} - \mathbf{v}_h] + \frac{\rho_2}{2}\frac{d}{dt}\|\partial_t \mathbf{u} - \partial_t \mathbf{u}_h\|^2_{0,\Omega_2} \\
&\qquad + \frac{1}{2}\frac{d}{dt}a_2[\mathbf{u} - \mathbf{u}_h, \mathbf{u} - \mathbf{u}_h] \\
&= \frac{\rho_1}{2}\frac{d}{dt}\|\mathbf{v} - \widetilde{\mathbf{v}}_h\|^2_{0,\Omega_1} + a_1[\mathbf{v} - \mathbf{v}_h, \mathbf{v} - \widetilde{\mathbf{v}}_h] + \frac{\rho_2}{2}\frac{d}{dt}\|\partial_t \mathbf{u} - \widetilde{\mathbf{w}}_h\|^2_{0,\Omega_2} \\
&\qquad + a_2[\mathbf{u} - \mathbf{u}_h, \partial_t \mathbf{u} - \widetilde{\mathbf{w}}^h] + b[\mathbf{v}_h - \widetilde{\mathbf{v}}_h, p - q_h] \\
&\le \frac{\rho_1}{2}\frac{d}{dt}\|\mathbf{v} - \widetilde{\mathbf{v}}_h\|^2_{0,\Omega_1} + \frac{k_1}{4}\|\mathbf{v}(t) - \mathbf{v}_h(t)\|^2_{1,\Omega_1} + C\|\mathbf{v}(t) - \widetilde{\mathbf{v}}_h(t)\|^2_{1,\Omega_1} \\
&\qquad + \frac{\rho_2}{2}\frac{d}{dt}\|\partial_t \mathbf{u} - \widetilde{\mathbf{w}}_h\|^2_{0,\Omega_2} + \|\mathbf{u}(t) - \mathbf{u}_h(t)\|^2_{0,\Omega_2} + C\|\partial_t \mathbf{u}(t) - \widetilde{\mathbf{w}}_h(t)\|^2_{1,\Omega_2} \\
&\qquad + C\|\mathbf{v}(t) - \widetilde{\mathbf{v}}_h(t)\|^2_{1,\Omega_2} + \frac{k_1}{4}\|\mathbf{v}(t) - \mathbf{v}_h(t)\|^2_{1,\Omega_2} + C\|p(t) - q_h\|^2_{0,\Omega_1}.
\end{aligned}$$

Applying (2.2)–(2.3) to the last relation and integrating in t, we obtain

$$\begin{aligned}
&\rho_1\|\mathbf{v}(t) - \mathbf{v}_h(t)\|^2_{0,\Omega_1} + k_1\|\mathbf{v} - \mathbf{v}_h\|^2_{L^2(0,T;\mathbf{H}^1(\Omega_1))} \\
&\qquad + \rho_2\|\partial_t \mathbf{u}(t) - \partial_t \mathbf{u}_h(t)\|^2_{0,\Omega_2} + \|\mathbf{u}(t) - \mathbf{u}_h(t)\|^2_{1,\Omega_2} \\
&\le C\Big(\|\mathbf{v}(0) - \mathbf{v}_{0,h}\|^2_{0,\Omega_1} + \|\partial_t \mathbf{u}(0) - \mathbf{u}_{1,h}\|^2_{0,\Omega_2} + \|\mathbf{u}_0 - \mathbf{u}_{0,h}\|^2_{1,\Omega_2} \\
&\qquad + \|\boldsymbol{\xi}_0 - \mathcal{P}^h \boldsymbol{\xi}_0\|^2_{0,\Omega} + \|\boldsymbol{\xi}(t_0) - \mathcal{P}^h \boldsymbol{\xi}(t_0)\|^2_{0,\Omega_1} + \|\boldsymbol{\xi} - \mathcal{P}^h \boldsymbol{\xi}\|^2_{L^2(0,T;\mathbf{H}^1(\Omega))} \\
&\qquad + \|p - q_h\|^2_{L^2(0,T;L^2(\Omega_1))}\Big) + \int_0^t \|\mathbf{u}(s) - \mathbf{u}_h(s)\|^2_{1,\Omega_2} ds
\end{aligned} \tag{4.32}$$

for all $q_h \in L^2(0,T;Q_1^h)$, where $t_0 \in [0,T]$ is such that

$$\|\boldsymbol{\xi}(t_0) - \mathcal{P}^h \boldsymbol{\xi}(t_0)\|^2_{0,\Omega} = \max_{t\in[0,T]} \|\boldsymbol{\xi}(t) - \mathcal{P}^h \boldsymbol{\xi}(t)\|^2_{0,\Omega}\,.$$

The error estimate (3.34) yields

$$\begin{aligned}\|\mathbf{v}_0-\mathbf{v}_{0,h}\|_{0,\Omega_1}^2+\|\mathbf{u}_1-\mathbf{u}_{1,h}\|_{0,\Omega_2}^2\\ =Ch^{2r}(\|\mathbf{v}_0\|_{r+1,\Omega_1}^2+\|\mathbf{u}_1\|_{r+1,\Omega_2}^2+\|p_0\|_{r,\Omega_1}^2).\end{aligned}\tag{4.33}$$

Equation (3.19) and the approximation properties imply

$$\|\mathbf{u}_0-\mathbf{u}_{0,h}\|_{1,\Omega_2}^2\le Ch^{2r}\|\mathbf{u}_0\|_{r+1,\Omega_1}^2.\tag{4.34}$$

Also, by virtue of (4.24), we have

$$\begin{aligned}\|\boldsymbol{\xi}(t_0)-\mathcal{P}^h\boldsymbol{\xi}(t_0)\|_{0,\Omega}^2&\le Ch^{2r-2\epsilon}\Big(\|\mathbf{v}(t_0)\|_{r,\Omega_1}^2+\|\partial_t\mathbf{u}(t_0)\|_{r,\Omega_2}^2\Big)\\ &\le Ch^{2r-2\epsilon}\Big(\|\mathbf{v}\|_{L^2(0,T;\mathbf{H}^{r+1}(\Omega_1))}^2+\|\partial_t\mathbf{v}\|_{L^2(0,T;\mathbf{H}^{r-1}(\Omega_1))}^2\\ &\qquad+\|\mathbf{u}\|_{L^2(0,T;\mathbf{H}^{r+1}(\Omega_2))}^2+\|\partial_t\mathbf{u}\|_{L^2(0,T;\mathbf{H}^{r-1}(\Omega_2))}^2\Big).\end{aligned}\tag{4.35}$$

Thus, utilizing (4.33)–(4.35), (4.23), and (3.9), we may simplify (4.32) to

$$\begin{aligned}&\rho_1\|\mathbf{v}(t)-\mathbf{v}_h(t)\|_{0,\Omega_1}^2+k_1\|\mathbf{v}-\mathbf{v}_h\|_{L^2(0,T;\mathbf{H}^1(\Omega_1))}^2\\ &\qquad+\rho_2\|\partial_t\mathbf{u}(t)-\partial_t\mathbf{u}_h(t)\|_{0,\Omega_2}^2+\|\mathbf{u}(t)-\mathbf{u}_h(t)\|_{1,\Omega_2}^2\\ &\le Ch^{2r}\Big(\|\mathbf{v}_0\|_{r+1,\Omega_1}^2+\|\mathbf{u}_1\|_{r+1,\Omega_2}^2+\|p_0\|_{r,\Omega_1}^2+\|\mathbf{u}_0\|_{r+1,\Omega_1}^2\\ &\qquad+\|p\|_{L^2(0,T;H^r(\Omega_1))}^2\Big)+Ch^{2r-2\epsilon}\Big(\|\mathbf{v}\|_{L^2(0,T;\mathbf{H}^{r+1}(\Omega_1))}^2\\ &\qquad+\|\partial_t\mathbf{v}\|_{L^2(0,T;\mathbf{H}^{r-1}(\Omega_1))}^2+\|\mathbf{u}\|_{L^2(0,T;\mathbf{H}^{r+1}(\Omega_2))}^2\\ &\qquad+\|\partial_t\mathbf{u}\|_{L^2(0,T;\mathbf{H}^{r-1}(\Omega_2))}^2\Big)+\int_0^t\|\mathbf{u}(s)-\mathbf{u}_h(s)\|_{1,\Omega_2}^2ds.\end{aligned}\tag{4.36}$$

By dropping the first three terms on the left-hand side of (4.36) and applying the Gronwall's inequality (3.53), we obtain

$$\begin{aligned}\|\mathbf{u}(t)-\mathbf{u}_h(t)\|_{1,\Omega_2}^2&\le Ce^{CT}h^{2r}\Big[\|\mathbf{v}_0\|_{r+1,\Omega_1}^2+\|\mathbf{u}_1\|_{r+1,\Omega_2}^2\\ &\qquad+\|p_0\|_{r,\Omega_1}^2+\|\mathbf{u}_0\|_{r+1,\Omega_1}^2+\|p\|_{L^2(0,T;H^r(\Omega_1))}^2\Big]\\ &\qquad+Ce^{CT}h^{2r-2\epsilon}\Big(\|\mathbf{v}\|_{L^2(0,T;\mathbf{H}^{r+1}(\Omega_1))}^2+\|\partial_t\mathbf{v}\|_{L^2(0,T;\mathbf{H}^{r-1}(\Omega_1))}^2\\ &\qquad+\|\mathbf{u}\|_{L^2(0,T;\mathbf{H}^{r+1}(\Omega_2))}^2+\|\partial_t\mathbf{u}\|_{L^2(0,T;\mathbf{H}^{r-1}(\Omega_2))}^2\Big).\end{aligned}\tag{4.37}$$

Hence, (4.25) follows from (4.36)–(4.37). ∎

Appendix. Error estimates for the weighted L^2 projection onto $\boldsymbol{\Psi}^h$. The objective of this subsection is to prove error estimates (4.23)–(4.24) for the weighted L^2 projection operator $\mathcal{P}^h$ defined by (4.19).

We introduce an operator $\mathcal{S}^h:\boldsymbol{\Psi}\to\boldsymbol{\Psi}^h$ as follows. For each $\boldsymbol{\zeta}\in\boldsymbol{\Psi}\subset\mathbf{H}_0^1(\Omega)$,

$$\mathcal{S}^h\boldsymbol{\zeta}=\begin{cases}\boldsymbol{\zeta}_{1,h} & \text{in } \Omega_1,\\ \boldsymbol{\zeta}_{2,h} & \text{in } \Omega_2,\end{cases}\tag{A.1}$$

where $\boldsymbol{\zeta}_{1,h} \in X_1^h$ together with some $\sigma_h \in Q_1^h$ is the finite element solution of

$$\begin{cases} a_1[\boldsymbol{\zeta}_{1,h}, \mathbf{z}_h] + b[\mathbf{z}_h, \overline{\sigma}_h] = [\boldsymbol{\zeta}, \mathbf{z}_h] \qquad \forall\, \mathbf{z}_h \in X_1^h \cap \mathbf{H}_0^1(\Omega_1), \\ b[\boldsymbol{\zeta}_{1,h}, q_h] = 0 \qquad \forall\, q_h \in Q_1^h \cap L_0^2(\Omega_1), \\ \boldsymbol{\zeta}_{1,h}|_{\Gamma_1} = \mathbf{0} \qquad \text{and} \qquad [\boldsymbol{\zeta}_{1,h}, \mathbf{s}_h]_{0,\Gamma_0} = [\boldsymbol{\zeta}, \mathbf{s}_h]_{0,\Gamma_0} \quad \forall\, \mathbf{s}_h \in X_1^h|_{\Gamma_0}, \end{cases}$$

and $\boldsymbol{\zeta}_{2,h} \in X_2^h$ is the finite element solution of

$$\begin{cases} [\nabla \boldsymbol{\zeta}_{2,h}, \nabla \mathbf{w}_h]_{\Omega_2} = [\nabla \boldsymbol{\zeta}, \nabla \mathbf{w}_h]_{\Omega_2} \qquad \forall\, \mathbf{w}_h \in X_2^h \cap \mathbf{H}_0^1(\Omega_2), \\ \boldsymbol{\zeta}_{2,h}|_{\Gamma_2} = \mathbf{0} \qquad \text{and} \qquad [\boldsymbol{\zeta}_{2,h}, \mathbf{s}_h]_{0,\Gamma_0} = [\boldsymbol{\zeta}, \mathbf{s}_h]_{0,\Gamma_0} \quad \forall\, \mathbf{s}_h \in X_2^h|_{\Gamma_0}. \end{cases}$$

Evidently, $\boldsymbol{\zeta}_{1,h}|_{\Gamma_0} = \boldsymbol{\zeta}_{2,h}|_{\Gamma_0}$, so that $\mathcal{S}^h\boldsymbol{\zeta}$ defined by (A.1) indeed satisfies $\mathcal{S}^h\boldsymbol{\zeta} \in \boldsymbol{\Psi}^h$.

Using the results of [23, 25] concerning error estimates for the finite element approximations of the Stokes equations (noting that $\operatorname{div} \boldsymbol{\zeta}|_{\Omega_1} = 0$) with inhomogeneous boundary conditions, we obtain

$$\|\boldsymbol{\zeta}_{1,h} - \boldsymbol{\zeta}\|_{1,\Omega_1} \le Ch^r \|\boldsymbol{\zeta}\|_{r+1,\Omega_1} \quad \text{if } \boldsymbol{\zeta}|_{\Omega_1} \in \mathbf{H}^{r+1}(\Omega_1). \tag{A.2}$$

Furthermore, under assumption (H1), we may adapt straightforwardly the proof in [23] for an Aubin–Nitsche-type result to obtain

$$\|\boldsymbol{\zeta}_{1,h} - \boldsymbol{\zeta}\|_{0,\Omega_1} \le Ch^{1-\epsilon_1} \|\boldsymbol{\zeta}_{1,h} - \boldsymbol{\zeta}\|_{1,\Omega_1}. \tag{A.3}$$

Likewise,

$$\|\boldsymbol{\zeta}_{2,h} - \boldsymbol{\zeta}\|_{1,\Omega_2} \le Ch^r \|\boldsymbol{\zeta}\|_{r+1,\Omega_2} \quad \text{if } \boldsymbol{\zeta}|_{\Omega_2} \in \mathbf{H}^{r+1}(\Omega_2), \tag{A.4}$$

and, under assumption (H2),

$$\|\boldsymbol{\zeta}_{2,h} - \boldsymbol{\zeta}\|_{0,\Omega_2} \le Ch^{1-\epsilon_2} \|\boldsymbol{\zeta}_{2,h} - \boldsymbol{\zeta}\|_{1,\Omega_2}. \tag{A.5}$$

To summarize, we have the following results.

PROPOSITION A.1. *If $\boldsymbol{\zeta} \in \boldsymbol{\Psi}$ and $\boldsymbol{\zeta}|_{\Omega_i} \in \mathbf{H}^{r+1}(\Omega_i)$ $(i = 1, 2)$ for some $r \in [0, k]$, then*

$$\|\mathcal{S}^h\boldsymbol{\zeta} - \boldsymbol{\zeta}\|_{1,\Omega} \le Ch^r (\|\boldsymbol{\zeta}\|_{r+1,\Omega_1} + \|\boldsymbol{\zeta}\|_{r+1,\Omega_2}). \tag{A.6}$$

If, in addition, assumptions (H1)–(H2) *hold, then*

$$\|\mathcal{S}^h\boldsymbol{\zeta} - \boldsymbol{\zeta}\|_{0,\Omega} \le Ch^{1-\epsilon} \|\mathcal{S}^h\boldsymbol{\zeta} - \boldsymbol{\zeta}\|_{1,\Omega}, \tag{A.7}$$

where $\epsilon = \max\{\epsilon_1, \epsilon_2\}$

The following proposition establishes relationships between approximation properties for the operator $\mathcal{P}^h$ and those for the operator $\mathcal{S}^h$.

PROPOSITION A.2. *Assume that* (H1)–(H2) *hold. Then,*

$$\|\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}\|_{1,\Omega} \le Ch^{-\epsilon} \|\boldsymbol{\zeta} - \mathcal{S}^h\boldsymbol{\zeta}\|_{1,\Omega} \qquad \forall\, \boldsymbol{\zeta} \in \boldsymbol{\Psi}. \tag{A.8}$$

Proof. Let $\boldsymbol{\zeta} \in \boldsymbol{\Psi}$ be given. The best approximation property of a projection operator implies that

$$\|\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}\|_{0,\Omega} \le \|\mathcal{S}^h\boldsymbol{\zeta} - \boldsymbol{\zeta}\|_{0,\Omega}. \tag{A.9}$$

Using the triangle inequality, the inverse inequality (3.13), and inequality (A.9), we deduce that

$$\begin{aligned}\|\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}\|_{1,\Omega} &\le \|\boldsymbol{\zeta} - \mathcal{S}^h\boldsymbol{\zeta}\|_{1,\Omega} + \|\mathcal{S}^h\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}\|_{1,\Omega} \\ &\le \|\boldsymbol{\zeta} - \mathcal{S}^h\boldsymbol{\zeta}\|_{1,\Omega} + \frac{C}{h}\|\mathcal{S}^h\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}\|_{0,\Omega} \\ &\le \|\boldsymbol{\zeta} - \mathcal{S}^h\boldsymbol{\zeta}\|_{1,\Omega} + \frac{C}{h}\|\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}\|_{0,\Omega} + \frac{C}{h}\|\mathcal{S}^h\boldsymbol{\zeta} - \boldsymbol{\zeta}\|_{0,\Omega} \\ &\le \|\boldsymbol{\zeta} - \mathcal{S}^h\boldsymbol{\zeta}\|_{1,\Omega} + \frac{C}{h}\|\mathcal{S}^h\boldsymbol{\zeta} - \boldsymbol{\zeta}\|_{0,\Omega}.\end{aligned}$$

Thus, (A.8) follows from the last inequality and (A.7). □

Finally, as obvious consequences of (A.8) and (A.6)–(A.7), we obtain the following error estimates for $\boldsymbol{\zeta} - \mathcal{P}^h\boldsymbol{\zeta}$:

THEOREM A.3. *Assume that* (H1)–(H2) *hold. Then the operator* $\mathcal{P}^h$ *satisfies the error estimates* (4.23) *and* (4.24).

ON THE NORMS OF INVERSES OF PSEUDOSPECTRAL DIFFERENTIATION MATRICES*

DAVID M. SLOAN†

Abstract. In this paper we give integral expressions for the elements of the inverses of second-order pseudospectral differentiation matrices. Simple upper bounds are given for the maximum norms of these inverse matrices when Chebyshev collocation points are used. Comment is made on the failure to obtain upper bounds that are uniform in the number of collocation points when the points are evenly spaced. We also give integral expressions for inverses of first-order Chebyshev pseudospectral differentiation matrices.

Key words. pseudospectral, differentiation matrices, Chebyshev

1. Introduction. Spectral collocation provides powerful methods—known as pseudospectral methods—for computing approximate solutions of ordinary and partial differential equations. Over the last two decades, pseudospectral methods have emerged as viable alternatives in many situations to finite difference and finite element methods. In the pseudospectral approach, the unknown solution of the differential equation is approximated by a global interpolant, such as an algebraic or trigonometric polynomial of high degree. The derivatives appearing in the differential equation are approximated by exact differentiation of the interpolant, and the unknown coefficients in the interpolant are then obtained by setting the residual to zero at an appropriate number of collocation points in the domain of the problem. Since interpolation and differentiation are linear operations, the process of obtaining approximations to the values of the derivative of a function at the set of collocation points can be expressed as a matrix-vector multiplication: the matrices involved are called *pseudospectral differentiation matrices*. A Chebyshev pseudospectral differentiation matrix is one for which the domain in the direction of differentiation is the finite interval $[-1, 1]$, the interpolant is an algebraic polynomial, and the collocation points are chosen to be the extrema or zeros of a Chebyshev polynomial.

The aim of this paper is to give integral expressions for the elements of the inverses of second-order pseudospectral differentiation matrices, and to show that these inverse matrices have simple upper bounds in the maximum norm if the collocation points are Chebyshev extrema or zeros. Integral expressions are also given for the elements of the inverses of first-order pseudospectral differentiation matrices. Comments are made on the failure to obtain upper bounds for the inverse matrices when the collocation points are evenly spaced and the interpolant is an algebraic polynomial.

The main advantage of pseudospectral methods for approximate solution of differential equations is their high accuracy for problems whose solutions are sufficiently smooth. Such methods converge exponentially fast [3, 11, 14], whereas finite differences and finite elements have algebraic rates of convergence. In practical computations this means that high accuracy can be achieved with relatively coarse

discretizations. Disadvantages include the occurrence of full rather than sparse differentiation matrices, and less flexibility when dealing with irregular domains. For a full treatment of numerical solution of differential equations by pseudospectral methods, the reader is referred to [2, 3, 7, 8, 9].

The computation of pseudospectral differentiation matrices for derivatives of arbitrary order has been considered by Huang and Sloan [12] and by Welfert [16]. A MATLAB package by Weideman and Reddy [15] may be used to generate pseudospectral differentiation matrices and to solve differential equations by the pseudospectral method. FORTRAN packages for pseudospectral computations have been produced by Funaro [10] and by Don and Solomonoff [6].

The outline of this paper is as follows. Section 2 presents integral expressions for the elements of second-order pseudospectral differentiation matrices for algebraic polynomial interpolants and arbitrary distributions of collocation points. Upper bounds on the inverse matrices are given in the maximum norm when the collocation points are extrema or zeros of Chebyshev polynomials. It is also shown that the elements become unbounded as the number of collocation points tends to infinity when the points are evenly spaced. Section 3 presents integral expressions for the elements of first-order pseudospectral differentiation matrices, and conclusions and comments are given in section 4. The analysis leading to the upper bound on the inverses of second-order matrices depends on a negativity property of the elements, and this property is examined in the appendix.

2. Second-order differentiation matrices.

2.1. Background. We consider pseudospectral differentiation of nonperiodic functions on the domain $[-1, 1]$. Let $\{x_j\}_{j=0}^N$ be a set of $N+1$ distinct collocation points, or nodes, satisfying

$$-1 = x_0 < x_1 < \cdots < x_{N-1} < x_N = 1 \tag{2.1}$$

but otherwise arbitrary. If u is a real function defined on this set of nodes, the approximating polynomial interpolant $p_N \in P_N$ is defined by

$$p_N(x) = \sum_{j=0}^{N} u(x_j)\, L_j^{(N)}(x), \tag{2.2}$$

where P_N is the set of real polynomials of degree at most N and $L_j^{(N)}(x)$ is the Lagrange interpolation polynomial

$$L_j^{(N)}(x) = \prod_{\substack{i=0 \\ i\neq j}}^{N} \left(\frac{x - x_i}{x_j - x_i} \right). \tag{2.3}$$

$L_j^{(N)}$ is determined by the conditions

$$L_j^{(N)}(x_i) = \begin{cases} 0 & \text{if} \quad j \neq i, \\ 1 & \text{if} \quad j = i, \end{cases} \quad \text{for } 0 \leq i, j \leq N. \tag{2.4}$$

For $0 \leq i \leq N$, the second-order derivative of u at $x = x_i$ is approximated by $p_N''(x_i)$. Now set

$$\mathbf{u} := [u(x_0), u(x_1), \ldots, u(x_N)]^T \quad \text{and} \quad \mathbf{w} := [p_N''(x_0), p_N''(x_1), \ldots, p_N''(x_N)]^T,$$

and it follows from (2.2) that

$$\mathbf{w} = D_N^{(2)}\,\mathbf{u}, \tag{2.5}$$

where $D_N^{(2)} \in \mathbb{R}^{(N+1)\times(N+1)}$, with the element of row index i and column index j given by

$$D_N^{(2)}(i,j) = \left(\frac{d^2\,L_j^{(N)}}{dx^2}\right)(x_i) \quad \text{for } 0 \le i,j \le N. \tag{2.6}$$

The vector $\mathbf{w}$ is the discrete second derivative vector, and $D_N^{(2)}$ is the second-order pseudospectral differentiation matrix based on the nodes (2.1).

It is readily shown using (2.2) and (2.3) that $D_N^{(2)}\,\mathbf{v}_0 = D_N^{(2)}\,\mathbf{v}_1 = \mathbf{0}$, where $\mathbf{v}_0$ and $\mathbf{v}_1$ are vectors in $\mathbb{R}^{(N+1)}$ defined by $\mathbf{v}_0 = [1,1,\ldots,1]^T$ and $\mathbf{v}_1 = [x_0,x_1,\ldots,x_N]^T$, and it follows that $D_N^{(2)}$ is singular. To obtain the nonsingular differentiation matrix that arises in pseudospectral solution of differential equations, consider the simple one-dimensional Poisson equation

$$\frac{d^2u}{dx^2} = f(x), \quad -1 < x < 1, \quad u(\pm 1) = 0,$$

where $f \in C[-1,1]$. If u_j denotes the pseudospectral approximation to u at $x = x_j$ $(j = 0,1,\ldots,N)$, then $u_0 := 0$, $u_N := 0$, and the approximation to u'' at $x = x_i$ is given by (2.2) as $p_N''(x_i)$, where $p_N(x) = \sum_{j=1}^{N-1} u_j\,L_j^{(N)}(x)$. The unknown coefficients $\{u_j\}_{j=1}^{N-1}$ are obtained from the conditions

$$p_N''(x_i) = f(x_i), \quad 1 \le i \le N-1.$$

This system may be written as

$$\tilde{D}_N^{(2)}\,\mathbf{v} = \mathbf{f}, \tag{2.7}$$

where $\mathbf{f} = [f(x_1), f(x_2), \ldots, f(x_{N-1})]^T$, $\mathbf{v} = [u_1, u_2, \ldots, u_{N-1}]^T$, and $\tilde{D}_N^{(2)} \in \mathbb{R}^{(N-1)\times(N-1)}$ is obtained by deleting the first and last rows and columns from $D_N^{(2)}$. Henceforth we shall refer to $\tilde{D}_N^{(2)}$ as the second-order pseudospectral differentiation matrix based on the nodes (2.1). The matrix $\tilde{D}_N^{(2)}$ is nonsingular: the objective now is to give expressions for the elements of its inverse and to obtain an upper bound for the inverse when the nodes (2.1) are suitably chosen.

2.2. Formation of $(\tilde{D}_N^{(2)})^{-1}$. Let $\psi_j^{(N-2)} \in P_{N-2}$ be the Lagrange polynomial satisfying

$$\psi_j^{(N-2)}(x_i) = \begin{cases} 0 & \text{if} \quad j \ne i, \\ 1 & \text{if} \quad j = i, \end{cases} \quad \text{for} \;\; 1 \le i,\, j \le N-1. \tag{2.8}$$

Now define $\phi_j^{(N)} \in P_N$ by

$$\left.\begin{aligned} &\frac{d^2\phi_j^{(N)}}{dx^2}(x) = \psi_j^{(N-2)}(x), \quad j = 1,2,\ldots,N-1, \\ &\text{subject to} \;\; \phi_j^{(N)}(\pm 1) = 0. \end{aligned}\right\} \tag{2.9}$$

It is clear from the construction of $D_N^{(2)}$ that if $\phi_j \in P_N$ and $\boldsymbol{\phi}_j = [\phi_j(x_0), \phi_j(x_1), \ldots, \phi_j(x_N)]^T$, then $D_N^{(2)}\,\boldsymbol{\phi}_j = \boldsymbol{\psi}_j$, where $\boldsymbol{\psi}_j = [\phi_j''(x_0), \phi_j''(x_1), \ldots, \phi_j''(x_N)]^T$. In other words, pseudospectral differentiation of order 2 is exact for functions in P_N. (This is true for fixed N and differentiation of any order.)

Equation (2.5), with $\mathbf{w} := \boldsymbol{\psi}_j^{(N-2)} = [\psi_j^{(N-2)}(x_0),\ \psi_j^{(N-2)}(x_1), \ldots, \psi_j^{(N-2)}(x_N)]^T$ and $\mathbf{u} := \boldsymbol{\phi}_j^{(N)} = [\phi_j^{(N)}(x_0),\ \phi_j^{(N)}(x_1), \ldots, \phi_j^{(N)}(x_N)]^T$ becomes the identity

$$D_N^{(2)}\,\boldsymbol{\phi}_j^{(N)} = \boldsymbol{\psi}_j^{(N-2)}.$$

If $\Phi = [\boldsymbol{\phi}_1^{(N)}, \boldsymbol{\phi}_2^{(N)}, \ldots, \boldsymbol{\phi}_{N-1}^{(N)}]$ and $\Psi = [\boldsymbol{\psi}_1^{(N-2)}, \boldsymbol{\psi}_2^{(N-2)}, \ldots, \boldsymbol{\psi}_{N-1}^{(N-2)}]$, we may utilize conditions (2.8) in

$$D_N^{(2)}\,\Phi = \Psi$$

to obtain

$$D_N^{(2)}\,\Phi = \begin{bmatrix} \psi_1^{(N-2)}(x_0) & \psi_2^{(N-2)}(x_0) & \cdots & \psi_{N-1}^{(N-2)}(x_0) \\ 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ \psi_1^{(N-2)}(x_N) & \psi_2^{(N-2)}(x_N) & \cdots & \psi_{N-1}^{(N-2)}(x_N) \end{bmatrix}.$$

If we identify elements from rows 2 to N in the above equation, we obtain

$$\tilde{D}_N^{(2)}(\tilde{D}_N^{(2)})^{-1} = I,$$

where

$$(\tilde{D}_N^{(2)})^{-1}(i,j) = \phi_j^{(N)}(x_i), \quad 1 \le i,\, j \le N-1. \tag{2.10}$$

The elements of the inverse of the matrix $\tilde{D}_N^{(2)}$ are thus given by solutions of the differential equations (2.9).

The solution of (2.9) may be written as

$$\phi_j^{(N)}(x) = \int_{-1}^{1} G(z;x)\psi_j^{(N-2)}(z)dz, \quad 1 \le j \le N-1, \tag{2.11}$$

where $G(z;x)$ is the Green's function defined by

$$G(z;x) = \begin{cases} \dfrac{(z+1)(x-1)}{2}, & -1 \le z \le x, \\ \dfrac{(z-1)(x+1)}{2}, & x < z \le 1. \end{cases} \tag{2.12}$$

Note that $-\frac{1}{2} \le G(z;x) < 0$ for $z, x \in (-1,1)$.

An equivalent representation is

$$\phi_j^{(N)}(x) = \int_{-1}^{x} (x-z)\psi_j^{(N-2)}(z)dz + \frac{(x+1)}{2}\int_{-1}^{1} (z-1)\psi_j^{(N-2)}(z)dz. \tag{2.13}$$

The elements $(\tilde{D}_N^{(2)})^{-1}(i,j),\ 1 \le i,j \le N-1$, are now obtained by evaluating $\phi_j^{(N)}(x)$ at $x = x_i$.

2.3. Symmetry properties of $(\tilde{D}_N^{(2)})^{-1}$. Henceforth we shall assume that the nodes (2.1) are symmetrically located around $x = 0$. Thus $x_j = -x_{N-j}$ for $1 \le j \le N/2$, and there is a node at $x = 0$ if and only if N is even. With a nodal distribution of this type it is readily seen that $L_j^{(N)}(x) = L_{N-j}^{(N)}(-x)$. Hence

$$\begin{aligned}\tilde{D}_N^{(2)}(i,j) &= \frac{d^2 L_j^{(N)}}{dx^2}(x_i) = \frac{d^2 L_{N-j}^{(N)}}{dx^2}(-x_i) = \frac{d^2 L_{N-j}^{(N)}}{dx^2}(x_{N-i}) \\ &= \tilde{D}_N^{(2)}(N-i, N-j),\end{aligned} \tag{2.14}$$

which shows that $\tilde{D}_N^{(2)}$ is a *centrosymmetric matrix* [1]. The centrosymmetric property may be written as $\tilde{D}_N^{(2)} = P\tilde{D}_N^{(2)}P$, with

$$P = P^T = P^{-1} = \begin{bmatrix} & & & & 1 \\ & & & \cdot & \\ & & \cdot & & \\ & \cdot & & & \\ 1 & & & & \end{bmatrix}.$$

Clearly

$$(\tilde{D}_N^{(2)})^{-1} = P^{-1}(\tilde{D}_N^{(2)})^{-1}P^{-1} = P(\tilde{D}_N^{(2)})^{-1}P,$$

and it follows that $(\tilde{D}_N^{(2)})^{-1}$ is also centrosymmetric.

2.4. Upper bounds on $(\tilde{D}_N^{(2)})^{-1}$. We now consider three specific distributions of the collocation points (2.1):

$$\begin{aligned}&\text{(a)}\quad \textit{Chebyshev extrema} \quad : \quad x_j := t_j = -\cos\left(\frac{\pi j}{N}\right), \quad j = 0, 1, \ldots, N; \\ &\text{(b)}\quad \textit{Chebyshev zeros} \quad : \quad x_0 := s_0 = -1,\ x_N := s_N = +1, \quad \text{and} \\ &\qquad\qquad\qquad\qquad\quad x_j := s_j = -\cos\left(\frac{\pi(2j-1)}{2(N-1)}\right), \quad j = 1, 2, \ldots, N-1; \\ &\text{(c)}\quad \textit{Evenly spaced} \quad : \quad x_j := \rho_j = -1 + 2 \times \frac{j}{N}, \quad j = 0, 1, \ldots, N.\end{aligned} \tag{2.15}$$

The points $\{t_j\}_{j=0}^N$ are the extrema of the Chebyshev polynomial T_N in $[-1, 1]$, and $\{s_j\}_{j=1}^{N-1}$ are the zeros of T_{N-1} (see [13]). The distributions (a) and (b) are popular choices for pseudospectral solution of differential equations [2, 3, 7, 8].

In the case of nodes based on Chebyshev extrema, it is readily shown that (see [4, 13])

$$\psi_j^{(N-2)}(x) = \frac{T_N'(x)}{(x - t_j)\, T_N''(t_j)}, \quad j = 1, 2, \ldots, N-1,$$

and if this is substituted into (2.11), we obtain

$$\phi_j^{(N)}(x) = \frac{1}{T_N''(t_j)} \int_{-1}^{1} \frac{G(z;x) T_N'(z)}{(z - t_j)}\, dz, \quad j = 1, 2, \ldots, N-1. \tag{2.16}$$

With nodes based on Chebyshev zeros, we find

$$\psi_j^{(N-2)}(x) = \frac{T_{N-1}(x)}{(x - s_j) T_{N-1}'(s_j)}, \quad j = 1, 2, \ldots, N-1,$$

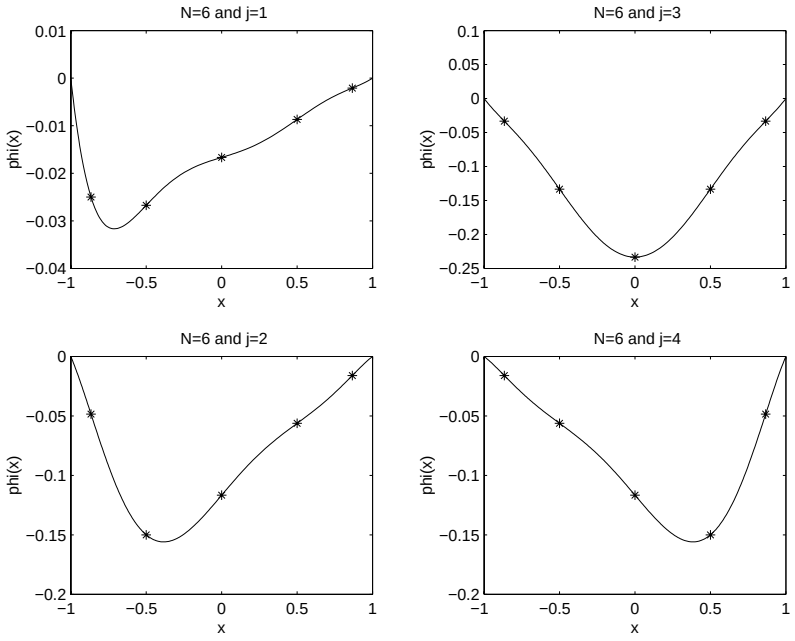

FIG. 1. $\phi_j^{(N)}(x)$ *corresponding to Chebyshev extrema nodes.* $N = 6$ *throughout, and* $j = 1, 3, 2,$ *and* 4 *as indicated above each panel.*

which yields

$$\phi_j^{(N)}(x) = \frac{1}{T'_{N-1}(s_j)} \int_{-1}^{1} \frac{G(z;x)T_{N-1}(z)}{(z - s_j)}\, dz, \quad j = 1, 2, \ldots, N-1. \tag{2.17}$$

The functions $\phi_j^{(N)}(x)$ were determined for a range of values of N and j, using the three nodal distributions given in (2.15). Evaluations are readily effected using the representation (2.13), with the MATLAB routines ode45 and quadl employed to compute the first and second integrals, respectively, in (2.13). Numerical experiments suggest that for both Chebyshev distributions of nodes, $\phi_j^{(N)}(x) < 0$ on $(-1, 1)$ for any positive integer N and for all $j = 1, 2, \ldots, N-1$. For evenly spaced nodes, this negativity result does not hold. To illustrate this observation, Figure 1 shows $\phi_j^{(N)}(x)$ corresponding to the Chebyshev extrema nodes (2.15(a)), with $N = 6$ and $j = 1, 2, 3,$ and 4. The profiles corresponding to the Chebyshev zero nodes have similar qualitative features. The centrosymmetry property of $(\tilde{D}_N^{(2)})^{-1}$ implies that $\phi_j^{(N)}(x) = \phi_{N-j}^{(N)}(-x)$ for $1 \le j \le N-1$, and this symmetry is seen in the plots corresponding to $N = 6$, $j = 2$ and $N = 6$, $j = 4$. In Figure 2, $\phi_j^{(N)}(x)$ is shown for the same values of N and j on evenly spaced nodes. Here again, the property $\phi_j^{(N)}(x) = \phi_{N-j}^{(N)}(-x)$ is illustrated by the plots $N = 6$, $j = 2$ and $N = 6$, $j = 4$. In the case of evenly spaced nodes, $\phi_j^{(N)}(x)$ can take positive values; in particular, elements of the inverse differentiation matrix are given by the values of $\phi_j^{(N)}(x)$ at the asterisks, and some of these values are positive. Thus, the computational results show that $(\tilde{D}_N^{(2)})^{-1}$ is a negative matrix for Chebyshev nodes, but not necessarily for evenly spaced nodes.

$$-10^{-1} \times \begin{bmatrix} 1.223 & -0.062 & 1.412 & -0.123 & 0.328 \\ 1.062 & 0.691 & 1.926 & 0.198 & 0.568 \\ 0.812 & 0.500 & 2.375 & 0.500 & 0.812 \\ 0.568 & 0.198 & 1.926 & 0.691 & 1.062 \\ 0.328 & -0.123 & 1.412 & -0.062 & 1.223 \end{bmatrix}$$

The inverse matrices $(\tilde{D}_N^{(2)})^{-1}$ corresponding to $N = 6$ are given in Tables 1 and 2 for Chebyshev extrema nodes and evenly spaced nodes, respectively. The matrices displayed in Tables 1 and 2 were obtained by inverting the appropriate pseudospectral differentiation matrices computed using the MATLAB codes of Weideman and Reddy [15].

Note that $(\tilde{D}_6^{(2)})^{-1}$ is negative in Table 1, but there are positive elements in Table 2. The matrices are centrosymmetric for both sets of nodes.

To obtain upper bounds for $(\tilde{D}_N^{(2)})^{-1}$ we first consider the row sums of the inverse matrix. The sum of the elements in row i $(i = 1, 2, \ldots, N-1)$ of $(\tilde{D}_N^{(2)})^{-1}$, for any distribution of nodes (2.1), is given by

$$S_i^{(N)} = \sum_{j=1}^{N-1} \phi_j^{(N)}(x_i). \tag{2.18}$$

Now define $\phi^{(N)}(x) = \sum_{j=1}^{N-1} \phi_j^{(N)}(x)$ and $\psi^{(N-2)}(x) = \sum_{j=1}^{N-1} \psi_j^{(N-2)}(x)$. From (2.9) we see that $\phi^{(N)}$ is defined by

$$\left.\begin{array}{l} \dfrac{d^2\phi^{(N)}}{dx^2}(x) = \psi^{(N-2)}(x), \\ \text{with} \quad \phi^{(N)}(\pm 1) = 0. \end{array}\right\} \tag{2.19}$$

Clearly, $\psi^{(N-2)} \in P_{N-2}$ and $\psi^{(N-2)}(x_i) = 1$ for $i = 1, 2, \ldots, N-1$. The unique polynomial in P_{N-2} satisfying these conditions is $\psi^{(N-2)}(x) \equiv 1$, and it follows from (2.19) that

$$\phi^{(N)}(x) = \frac{1}{2}(x^2 - 1). \tag{2.20}$$

It follows from (2.18) and (2.20) that the row sum is given by

$$S_i^{(N)} = \frac{1}{2}(x_i^2 - 1) \quad \text{for} \quad i = 1, 2, \ldots, N-1. \tag{2.21}$$

To obtain upper bounds for the maximum norms of $(\tilde{D}_N^{(2)})^{-1}$ when the nodes are Chebyshev extrema or Chebyshev zeros, we note that $(\tilde{D}_N^{(2)})^{-1}(i,j) < 0$ for $1 \le i, j \le N-1$. This negativity property, which is established in the appendix, is equivalent to the conditions $\phi_j^{(N)}(t_i) < 0$ and $\phi_j^{(N)}(s_i) < 0$ for $1 \le i, j \le N-1$. The numerical experiments described above and the analysis in the appendix show that $\phi_j^{(N)}(x) < 0$ for $1 \le j \le N-1$ and $x \in (-1, 1)$, with each of the Chebyshev nodal distributions. Under this negativity assumption, it follows from (2.21) that

$$\sum_{j=1}^{N-1} \left| (\tilde{D}_N^{(2)})^{-1}(i,j) \right| = \frac{1}{2}(1 - x_i^2), \quad 1 \le i \le N-1.$$

The maximum value of this quantity occurs at $i = N/2$ if N is even and at $i = (N \pm 1)/2$ if N is odd. The key results are contained in the following theorem.

THEOREM 2.1. *For either of the two Chebyshev nodal distributions in* (2.15),

$$\|(\tilde{D}_N^{(2)})^{-1}\|_\infty = \frac{1}{2} \quad \textit{if} \quad N \quad \textit{is even.} \tag{2.22}$$

If N is odd, then

$$\|(\tilde{D}_N^{(2)})^{-1}\|_\infty = \frac{1}{2}(1 - t_{(N-1)/2}^2) = \frac{1}{2}\cos^2\left(\frac{\pi}{2N}\right) \tag{2.23}$$

for the Chebyshev extrema distribution, and

$$\|(\tilde{D}_N^{(2)})^{-1}\|_\infty = \frac{1}{2}(1 - s_{(N-1)/2}^2) = \frac{1}{2}\cos^2\left(\frac{\pi}{2(N-1)}\right) \tag{2.24}$$

TABLE 3
$\|(\tilde{D}_N^{(2)})^{-1}\|_\infty$ *for evenly spaced nodes.*

for the Chebyshev zeros distribution. For distributions (2.15(a)) *or* (2.15(b)),

$$\|(\tilde{D}_N^{(2)})^{-1}\|_\infty \le \frac{1}{2}, \quad \textit{with equality if } N \textit{ is even.} \tag{2.25}$$

The values of the norms given in (2.22)–(2.24) are readily verified numerically.

If the nodes are evenly spaced, the inverse matrix does not satisfy the negativity property (unless $N \le 5$), and the bound given in (2.25) does not apply if $N \ge 8$. Table 3 gives $\|(\tilde{D}_N^{(2)})^{-1}\|_\infty$ for evenly spaced nodes at several values of N.

The results show that the norm increases rapidly with N. One expects that nodal distributions with clustering at the ends [8] will be a prerequisite for the existence of bounds on the inverse differentiation matrix. Numerical results show, for example, that if the collocation points $\{s_j\}_{j=1}^{N-1}$ in (2.15) denote the zeros of the Legendre polynomial of degree $N-1$, then $(\tilde{D}_N^{(2)})^{-1})$ is negative. Furthermore, $\|(\tilde{D}_N^{(2)})^{-1}\|_\infty$ takes values $\frac{1}{2}$ or $\frac{1}{2}(1 - s^2_{(N-1)/2})$ for N even or odd.

3. First-order differentiation matrices.

3.1. Background. Here we follow the method adopted in the preceding section to give a brief presentation of expressions for the elements of the inverses of first-order pseudospectral differentiation matrices. The element of row index i and column index j of the first-order pseudospectral differentiation matrix $D_N^{(1)} \in \mathbb{R}^{(N+1)\times(N+1)}$ associated with nodes (2.1) is given by

$$D_N^{(1)}(i,j) = \left(\frac{dL_j^{(N)}}{dx}\right)(x_i) \quad \text{for} \quad 0 \le i,j \le N.$$

In the notation of subsection 2.1, $D_N^{(1)}\mathbf{v}_0 = \mathbf{0}$, and $D_N^{(1)}$ is therefore singular. To obtain a nonsingular differentiation matrix that arises in pseudospectral solution of differential equations, we consider the simple differential problem

$$\frac{du}{dx} = f(x), \quad -1 < x \le 1, \quad u(-1) = 0,$$

where $f \in C[-1,1]$. The pseudospectral solution is obtained from

$$\tilde{D}_N^{(1)}\,\mathbf{v} = \mathbf{f}, \tag{3.1}$$

where $\mathbf{f} = [f(x_1), f(x_2), \ldots, f(x_N)]^T$, $\mathbf{v} = [u_1, u_2, \ldots, u_N]^T$, and $\tilde{D}_N^{(1)} \in \mathbb{R}^{N\times N}$ is obtained by deleting the first row and column from $D_N^{(1)}$. (If the boundary condition of the first-order differential problem is imposed at $x = +1$, then the last row and column of $D_N^{(1)}$ are deleted.)

3.2. Formation of $(\tilde{\boldsymbol{D}}_{\boldsymbol{N}}^{(\mathbf{1})})^{-\mathbf{1}}$. Let $\psi_j^{(N-1)} \in P_{N-1}$ be the Lagrange polynomial satisfying

$$\psi_j^{(N-1)}(x_i) = \begin{cases} 0 & \text{if} \quad j \neq i, \\ 1 & \text{if} \quad j = i, \end{cases} \quad \text{for} \;\; 1 \leq i, j \leq N. \tag{3.2}$$

Now define $\phi_j^{(N)} \in P_N$ by

$$\left.\begin{aligned} &\frac{d\phi_j^{(N)}}{dx}(x) = \psi_j^{(N-1)}(x), \quad j = 1, 2, \ldots, N, \\ &\text{subject to} \;\; \phi_j^{(N)}(-1) = 0. \end{aligned}\right\} \tag{3.3}$$

The notation here is inconsistent with that adopted in section 2; however, the aim in this choice of notation is to simplify the presentation.

Following the steps taken in subsection 2.1, we find that

$$(\tilde{D}_N^{(1)})^{-1}(i, j) = \phi_j^{(N)}(x_i), \quad 1 \leq i, j \leq N. \tag{3.4}$$

The matrix elements are given by the solution of (3.3), which is

$$\phi_j^{(N)}(x) = \int_{-1}^{x} \psi_j^{(N-1)}(z)dz, \quad 1 \leq j \leq N. \tag{3.5}$$

In the case of the Chebyshev extrema nodes (see [13]),

$$\psi_j^{(N-1)}(x) = \frac{(x-1)T_N'(x)}{(t_j-1)(x-t_j)T_N''(t_j)}, \quad 1 \leq j \leq N-1,$$

and

$$\psi_N^{(N-1)}(x) = \frac{T_N'(x)}{T_N'(t_N)}.$$

Hence

$$\phi_j^{(N)}(x) = \frac{1}{(t_j-1)T_N''(t_j)} \int_{-1}^{x} \frac{(z-1)T_N'(z)}{(z-t_j)}\, dz, \quad 1 \leq j \leq N-1, \tag{3.6}$$

and

$$\phi_N^{(N)}(x) = \frac{1}{T_N'(t_N)} \int_{-1}^{x} T_N'(z)dz = \frac{T_N(x) - T_N(t_0)}{T_N'(t_N)}. \tag{3.7}$$

With the Chebyshev zeros nodal distribution,

$$\psi_j^{(N-1)}(x) = \frac{(x-1)T_{N-1}(x)}{(s_j-1)(x-s_j)T_{N-1}'(s_j)}, \quad 1 \leq j \leq N-1,$$

and

$$\psi_N^{(N-1)}(x) = \frac{T_{N-1}(x)}{T_{N-1}(s_N)}\,.$$

Hence

$$\phi_j^{(N)}(x) = \frac{1}{(s_j-1)T'_{N-1}(s_j)} \int_{-1}^{x} \frac{(z-1)T_{N-1}(z)}{(z-s_j)}\,dz, \quad 1 \le j \le N-1, \tag{3.8}$$

and

$$\begin{aligned}\phi_N^{(N)}(x) &= \frac{1}{T_{N-1}(s_N)} \int_{-1}^{x} T_{N-1}(z)dz \\ &= \int_{-1}^{x} T_{N-1}(z)dz \\ &= \frac{1}{2}\left[\frac{T_N(x)}{N} - \frac{T_{N-2}(x)}{N-2}\right] + \frac{(-1)^N}{N(N-2)}\,. \end{aligned} \tag{3.9}$$

The first-order inverse matrices $(\tilde{D}_N^{(1)})^{-1}$ have a row sum property which is the analogue of the condition (2.21) that applies to $(\tilde{D}_N^{(2)})^{-1}$. If $\phi^{(N)}(x) = \sum_{j=1}^N \phi_j^{(N)}(x)$ and $\psi^{(N-1)}(x) = \sum_{j=1}^N \psi_j^{(N-1)}(x)$, then

$$\left.\begin{aligned} &\frac{d\phi^{(N)}}{dx}\,(x) = \psi^{(N-1)}(x), \\ &\text{with} \quad \phi^{(N)}(-1) = 0. \end{aligned}\right\} \tag{3.10}$$

Here $\phi^{(N)} \in P_N, \psi^{(N-1)} \in P_{N-1}$, and $\psi^{(N-1)}(x_i) = 1$ for $i = 1, 2, \ldots, N$. Clearly $\psi^{(N-1)}(x) \equiv 1$ and

$$\phi^{(N)}(x) = x + 1. \tag{3.11}$$

It follows that

$$\phi^{(N)}(x_i) = \sum_{j=1}^{N} (\tilde{D}_N^{(1)})^{-1}(i,j) = x_i + 1, \quad 1 \le i \le N,$$

and

$$\max_{1 \le i \le N} \phi^{(N)}(x_i) = \phi^N(x_N) = 2.$$

It may be shown (see the appendix) that, for each of the Chebyshev nodal distributions, the elements $\phi_j^{(N)}(x_N)$ have a constant sign for $1 \le j \le N$, from which it follows that $\sum_{j=1}^N |(\tilde{D}_N^{(1)})^{-1}(N,j)| = 2$. However, numerical experiments indicate that elements in $(\tilde{D}_N^{(1)})^{-1}$ do not have a uniform sign, and, as a result of cancellation, it may not be the case that

$$\|(\tilde{D}_N^{(1)})^{-1}\|_\infty \le 2. \tag{3.12}$$

TABLE 4
$\|(\tilde{D}_N^{(1)})^{-1}\|_\infty$ *for Chebyshev zeros nodes.*

N	$\|(\tilde{D}_N^{(1)})^{-1}\|_\infty$
4	2.3769
8	2.0924
16	2.0211
32	2.0050
64	2.0012
128	2.0003
256	2.0001
257	2.0001

$\|(\tilde{D}_N^{(1)})^{-1}\|_\infty$ was computed for each of the two Chebyshev nodal distributions over a range of values of N. In the case of Chebyshev extrema nodes, the norm was found to have the value 2 for a selection of values of N between 4 and 257. In the case of Chebyshev zeros nodes, the computed values of $\|(\tilde{D}_N^{(1)})^{-1}\|_\infty$ for several values of N are given in Table 4. The computed results suggest that (3.12) holds for nodal distribution (2.15(a)), and that $\|(\tilde{D}_N^{(1)})^{-1}\|_\infty$ tends to 2 from above as N increases for distribution (2.15(b)). Further comments on the structure of $\|(\tilde{D}_N^{(1)})^{-1}\|_\infty$ are given in the appendix.

4. Comments. Expressions have been given for the elements of the inverses of first- and second-order pseudospectral differentiation matrices. Simple upper bounds have been presented for the maximum norms of the second-order differentiation matrices when Chebyshev collocation points are used. The analytic expressions for the matrix elements may be useful in studying properties of the inverse matrices, and the bounds can be utilized in obtaining error bounds for the computed solutions of differential equations by the Chebyshev pseudospectral method. The bounds on $\|(\tilde{D}_N^{(2)})^{-1}\|_\infty$ for the Chebyshev distributions of nodes indicate that, in the maximum norm, the growth rate of the condition number of $\tilde{D}_N^{(2)}$ with N is similar to the growth of $\|D_N^{(2)}\|_\infty$: it is readily shown numerically that this is $O(N^4)$ as N increases. It would be of interest to investigate analogous properties of differentiation matrices associated with other sets of nodal distributions that have quadratic clustering—minimum node spacing decreasing like $O(1/N^2)$.

It may also be of interest to note that, for both Chebyshev distributions, $\|(\tilde{D}_N^{(2)})^{-1}\|_1$ and $\|(\tilde{D}_N^{(2)})^{-1}\|_2$ tend to 0.5708 and 0.4076, respectively, as N increases. In the case of the first-order differentiation matrix, $\|(\tilde{D}_N^{(1)})^{-1}\|_1$ and $\|(\tilde{D}_N^{(1)})^{-1}\|_2$ tend to 1.8 and 1.4, respectively, as N increases: the convergence rate is slower for the inverses of the first-order matrices. With evenly spaced nodes, the 1-norm and the 2-norm increase rapidly with N. These results are obtained by direct computation.

5. Appendix.

5.1. Negativity property of $(\tilde{D}_N^{(2)})^{-1}$.

Signs of $\frac{d\phi_j^{(N)}}{dx}$ at $x = \pm 1$. In the appendix we confine our analysis to the Chebyshev extrema distribution of nodes. Results may be obtained for the Chebyshev zeros case using an analogous approach.

LEMMA 5.1. $I_j^{(N)} := \int_{-1}^{1} \psi_j^{(N-2)}(x)dx > 0$ *for* $j = 1, 2, \ldots, N-1$, *with*

$$\psi_j^{(N-2)}(x) = \frac{T_N'(x)}{(x - t_j)T_N''(t_j)}$$

and $t_j = -\cos(\frac{\pi j}{N})$.

Note that $\{t_j\}_{j=1}^{N-1}$ are the zeros of $U_{N-1}(x)$, the Chebyshev polynomial of the second kind of degree $(N-1)$ [13]. Using the orthogonality properties of $\{U_k\}_{k=0}^{N-2}$, we may write

$$\psi_j^{(N-2)}(x) = \sum_{k=0}^{N-2} c_{j,k}\, U_k(x), \tag{5.1}$$

where $c_{j,k} = \frac{2}{\pi} \int_{-1}^{1} (1-x^2)^{\frac{1}{2}} \psi_j^{(N-2)}(x) U_k(x)dx$. For $0 \le k \le N-2$, $\psi_j^{(N-2)}\, U_k \in P_{2N-4}$, and we may therefore use the Gaussian quadrature rule (see [5])

(5.2)

$$\int_{-1}^{1} (1-x^2)^{\frac{1}{2}} f(x)dx = \sum_{i=1}^{N-1} w_i\, f(t_i) + \frac{\pi}{2^{2N-1}(2N-2)!}\, f^{(2N-2)}(\xi), \quad -1 < \xi < 1,$$

with zero error term ($f \equiv \psi_j^{(N-2)}\, U_k$), where $w_i = \frac{\pi}{N} \sin^2(\frac{\pi i}{N})$. This enables us to write

$$\begin{aligned} c_{j,k} &= \frac{2}{\pi} \sum_{l=1}^{N-1} w_l\, \psi_j^{(N-2)}(t_l) U_k(t_l) \\ &= \frac{2}{\pi}\, w_j\, U_k(t_j) \\ &= \frac{2}{N}\, (-1)^k \sin(\eta_j^{(N)}) \sin[(k+1)\eta_j^{(N)}], \end{aligned}$$

where $\eta_j^{(N)} = \frac{\pi j}{N}$. Hence

$$\begin{aligned} I_j^{(N)} &= \sum_{k=0}^{N-2} c_{j,k} \int_{-1}^{1} U_k(x)dx \\ &= \sum_{k=0}^{N-2} c_{j,k}\, \nu_k, \quad \text{where } \nu_k = \begin{cases} 0, & k \text{ odd}, \\ \frac{2}{k+1}, & k \text{ even}, \end{cases} \\ &= \sum_{m=0}^{q} c_{j,2m}\, \nu_{2m}, \quad \text{where } 2q = \begin{cases} N-2, & N \text{ even}, \\ N-3, & N \text{ odd}, \end{cases} \\ &= \frac{4}{N} \sin(\eta_j^{(N)}) \sum_{m=0}^{q} \frac{1}{(2m+1)} \sin[(2m+1)\eta_j^{(N)}]. \end{aligned}$$

This may be written as

$$I_j^{(N)} = \frac{2}{N} \left\{ 1 - \sum_{m=1}^{q} b_m \cos(2m\eta_j^{(N)}) - \frac{1}{2q+1} \cos[2(q+1)\eta_j^{(N)}] \right\},$$

where $b_m = \frac{2}{(2m-1)(2m+1)}$. Clearly,

$$I_j^{(N)} > \frac{2}{N}\left\{1 - \left(1 - \frac{1}{3}\right) - \left(\frac{1}{3} - \frac{1}{5}\right) - \cdots - \left(\frac{1}{2q-1} - \frac{1}{2q+1}\right) - \frac{1}{2q+1}\right\}$$
$$> 0.$$

This establishes the inequality given as Lemma 5.1.

The inequality in Lemma 5.1 may be strengthened to $I_j^{(N)} > 4/N^2$, and this stronger result is required later. It is clear that $I_j^{(N)} = I_{N-j}^{(N)}$ for $j = 1, 2, \ldots, N-1$, so we need only consider $j = 1, 2, \ldots, jmax$, where $jmax = N/2$ or $jmax = (N-1)/2$, depending on whether N is even or odd. Numerical experiments indicate that the quantity

$$F_j^{(N)} = \frac{N}{4}(I_j^{(N)} - I_1^{(N)}) > 0$$

for $j = 2, 3, \ldots, jmax$: the minimum value of $I_j^{(N)}$ occurs at $j = 1$, and it is therefore sufficient to show that $I_1^{(N)} > 4/N^2$.

The positivity of $F_j^{(N)}$ is more readily appreciated if we write $F_j^{(N)}$ in the form

$$F_j^{(N)} = \sum_{m=1}^{q} b_m \sin(m\eta_{j+1}^{(N)}) \sin(m\eta_{j-1}^{(N)}) + \frac{1}{2q+1} \sin[(q+1)\eta_{j+1}^{(N)}] \sin[(q+1)\eta_{j-1}^{(N)}].$$

For $j = 2, 3, \ldots, jmax$, the initial terms in this summation are positive, and the sum of the initial set of positive terms exceeds the sum of the moduli of the remaining terms.

LEMMA 5.2.

$$I_j^{(N)} > 4/N^2 \quad \textit{for} \quad j = 1, 2, \ldots, jmax.$$

Given that $I_j^{(N)} \geq I_1^{(N)}$ for $j = 1, 2, \ldots, jmax$, it is sufficient to establish the inequality for $j = 1$.

If N is even ($2q = N - 2$),

$$\frac{N}{2} I_1^{(N)} = 1 + \frac{1}{N-1} - \sum_{m=1}^{q} b_m \cos(2m\eta_1^{(N)})$$
$$> \frac{N}{N-1} - \left\{\left(1 - \frac{1}{3}\right) + \left(\frac{1}{3} - \frac{1}{5}\right) + \cdots + \left(\frac{1}{2q-1} - \frac{1}{2q+1}\right)\right\}$$
$$= \frac{N}{N-1} - \left(1 - \frac{1}{N-1}\right) = \frac{2}{N-1}$$
$$> \frac{2}{N}.$$

Hence $I_1^{(N)} > 4/N^2$ if N is even.

If N is odd ($2q = N-3$),

$$\begin{aligned}\frac{N}{2}\, I_1^{(N)} &= 1 + \frac{1}{N-2}\,\cos\left(\frac{\pi}{N}\right) - \sum_{m=1}^{q} b_m\,\cos(2m\eta_1^{(N)}) \\ &> 1 + \frac{1}{N-2}\,\cos\left(\frac{\pi}{N}\right) - \left(1 - \frac{1}{N-2}\right) \\ &= \frac{1}{N-2}\,\left(1 + \cos\left(\frac{\pi}{N}\right)\right) \\ &> \frac{1}{N-2}\,\left(2 - \frac{\pi^2}{2N^2}\right) \quad \text{if} \quad N \geq 3, \\ &> \frac{1}{N-2}\,\left(2 - \frac{4}{N}\right) \\ &= \frac{2}{N}.\end{aligned}$$

Hence $I_1^{(N)} > 4/N^2$ if N is odd. This establishes the inequality given as Lemma 5.2.

LEMMA 5.3.

$$J_j^{(N)} := \int_{-1}^{1} (x-1)\psi_j^{(N-2)}(x)dx < 0 \quad \textit{for} \quad j = 1, 2, \ldots, N-1,$$

where $\psi_j^{(N-2)}$ *is as defined in Lemma* 5.1.

In this case we write

$$(x-1)\psi_j^{(N-2)}(x) = \sum_{k=0}^{N-1} d_{j,k}\, U_k(x), \tag{5.3}$$

where $d_{j,k} = \frac{2}{\pi}\int_{-1}^{1}(1-x^2)^{\frac{1}{2}}(x-1)\psi_j^{(N-2)}(x)\, U_k(x)dx$. For $k = 0, 1, \ldots, N-2$ we evaluate this integral as in Lemma 5.1 above, since $(x-1)\psi_j^{(N-2)}(x)U_k(x)$ is a polynomial of degree at most $(2N-3)$. It is readily shown that

$$d_{j,k} = (t_j - 1)c_{j,k} \quad \text{for} \quad k = 0, 1, \ldots, N-2.$$

The coefficient $d_{j,N-1}$ may be obtained by equating coefficients of x^{N-1} in (5.2). This identification gives $d_{j,N-1} = N/T_N''(t_j)$. From (5.1) and (5.2) we now obtain

$$\begin{aligned}J_j^{(N)} &= (t_j - 1)I_j^{(N)} + d_{j,N-1}\int_{-1}^{1} U_{N-1}(x)dx \\ &= (t_j - 1)I_j^{(N)} + \frac{1}{N}\, d_{j,N-1}(1 - (-1)^N) \\ &= (t_j - 1)I_j^{(N)} + \frac{(-1)^j}{N^2}\,\sin^2(\eta_j^{(N)})(1 - (-1)^N).\end{aligned}$$

It follows that

$$J_j^{(N)} = \begin{cases} (t_j - 1)I_j^{(N)}, & N \text{ even}, \\ (t_j - 1)\left[I_j^{(N)} - \dfrac{2(-1)^j}{N^2}\,(t_j + 1)\right], & N \text{ odd}. \end{cases} \tag{5.4}$$

Since $(t_j - 1) < 0$ and $I_j^{(N)} > 0$, then $J_j^{(N)} < 0$ if N is even. Furthermore, since $I_j^{(N)} > 4/N^2$, then $J_j^{(N)} < 0$ if N is odd. Lemma 5.3 is now established for any positive integer N and $j = 1, 2, \ldots, N-1$.

LEMMA 5.4.

$$K_j^{(N)} := \int_{-1}^{1} (x+1)\psi_j^{(N-2)}(x)dx > 0 \quad \textit{for} \quad j = 1, 2, \ldots, N-1,$$

where $\psi_j^{(N-2)}$ *is as defined in Lemma* 5.1.

Note that

$$K_j^{(N)} = J_j^{(N)} + 2I_j^{(N)} = \begin{cases} (t_j+1)I_j^{(N)}, & N \text{ even}, \\ (t_j+1)\left[I_j^{N)} - \dfrac{2(-1)^j}{N^2}(t_j - 1)\right], & N \text{ odd}. \end{cases} \tag{5.5}$$

Since $(t_j+1) > 0$ and $I_j^{(N)} > 4/N^2$, the proof of Lemma 5.4 follows immediately from (5.4).

From equation (2.13), we see that $\frac{d\phi_j^{(N)}}{dx}(-1) = \frac{1}{2} J_j^{(N)}$ and $\frac{d\phi_j^{(N)}}{dx}(+1) = \frac{1}{2} K_j^{(N)}$. Lemmas 5.3 and 5.4 show that for the Chebyshev extrema distribution of nodes, the gradients of $\phi_j^{(N)}$ at the boundaries satisfy $\frac{d\phi_j^{(N)}}{dx}(-1) < 0$ and $\frac{d\phi_j^{(N)}}{dx}(+1) > 0$. Similar results can be derived for the Chebyshev zeros distribution of nodes: in this latter case, the expansions (5.1) and (5.2) are effected in terms of Chebyshev polynomials of the first kind.

Sign of $\boldsymbol{\phi_j^{(N)}(x)}$ in $\boldsymbol{(-1, 1)}$. For the Chebyshev extrema distribution of nodes, (2.9) in $\phi_j^{(N)}$ takes the form

$$T_N''(t_j)(x - t_j)\frac{d^2\phi_j^{(N)}}{dx^2}(x) = T_N'(x). \tag{5.6}$$

A first integration of (5.5), making use of boundary conditions at $x = -1$, is

$$T_N''(t_j)\left[(x - t_j)\frac{d\phi_j^{(N)}}{dx}(x) - \phi_j^{(N)}(x)\right] = T_N(x) + A,$$

where $A = -T_N''(t_j)(1 + t_j)\frac{d\phi_j^{(N)}}{dx}(-1) - T_N(-1)$. The solution may now be written as

$$\phi_j^{(N)}(x) = -(x - t_j)\int_x^1 \frac{f(z)}{(z - t_j)^2}\, dz, \tag{5.7}$$

where $f(x) = (T_N(x) + A)/T_N''(t_j)$. Alternatively, if the first integral incorporates the boundary conditions at $x = +1$, the solution is written as

$$\phi_j^{(N)}(x) = (x - t_j)\int_{-1}^x \frac{g(z)}{(z - t_j)^2}\, dz, \tag{5.8}$$

where $g(x) = (T_N(x) + B)/T_N''(t_j)$ and $B = T_N''(t_j)(1 - t_j)\frac{d\phi^{(N)}}{dx}(+1) - T_N(+1)$. To obtain approximations to $\phi_j^{(N)}(x)$ by means of (5.6) and (5.7) we first show that

the dominant terms in $f(x)$ and $g(x)$ are, respectively, $-(1+t_j)\,\frac{d\phi_j^{(N)}}{dx}\,(-1)$ and $(1-t_j)\,\frac{d\phi_j^{(N)}}{dx}\,(+1)$. To establish this, note that

$$\begin{aligned}\left|\frac{T_N(x)-T_N(\pm1)}{T_N''(t_j)}\right| &\le \frac{2}{|T_N''(t_j)|}\\ &= \frac{2}{N^2}\,(1-t_j^2)\\ &< (1-t_j^2)\,\frac{I_j^{(N)}}{2}\\ &\le \frac{1}{2}\max\left(-(1+t_j)J_j^{(N)},(1-t_j)K_j^{(N)}\right)\\ &= \max\left(-(1+t_j)\frac{d\phi_j^{(N)}}{dx}\,(-1),(1-t_j)\frac{d\phi_j^{(N)}}{dx}\,(+1)\right).\end{aligned}$$

If $f(x)$ and $g(x)$ are replaced by their respective dominant terms, then approximations to $\phi_j^{(N)}(x)$ may now be obtained from (5.6) and (5.7) as

$$\phi_j^{(N)}(x) \sim (1+t_j)\,\frac{d\phi_j^{(N)}}{dx}\,(-1)\frac{(1-x)}{(1-t_j)} \tag{5.9}$$

and

$$\phi_j^{(N)}(x) \sim -(1-t_j)\,\frac{d\phi_j^{(N)}}{dx}\,(+1)\frac{(x+1)}{(1+t_j)}. \tag{5.10}$$

If N is even, then

$$-(1+t_j)\frac{d\phi_j^{(N)}}{dx}\,(-1) = (1-t_j)\frac{d\phi_j^{(N)}}{dx}\,(+1) = \frac{1}{2}\,(1-t_j^2)I_j^{(N)},$$

and $\phi_j^{(N)}(x)$ may be represented by either (5.8) or (5.9). If N is odd, then

$$(1-t_j)\frac{d\phi_j^{(N)}}{dx}\,(+1) + (1+t_j)\frac{d\phi_j^{(N)}}{dx}\,(-1) = \frac{2(-1)^j}{N^2}\,(1-t_j^2),$$

and $\phi_j^{(N)}(x)$ may be approximated by (5.9) and (5.10), depending on whether j is odd or even. In either case, the dominant terms in the solution indicate that $\phi_j^{(N)}(x) < 0$ in $(-1,1)$.

5.2. Comments on the structure of $(\tilde{D}_N^{(1)})^{-1}$. The Nth row of $(\tilde{D}_N^{(1)})^{-1}$ is $[\phi_1^{(N)}(t_N),\phi_2^{(N)}(t_N),\ldots,\phi_N^{(N)}(t_N)]$. For the Chebyshev extrema distribution of nodes, we see from (3.7) that $\phi_N^{(N)}(t_N)$ takes values 0 or $2/N^2$ for N even or odd. For $j=1,2,\ldots,N-1$, we see from (3.6) that

$$\begin{aligned}\phi_j^{(N)}(t_N) &= \frac{1}{(t_j-1)T_N''(t_j)}\int_{-1}^{1}\frac{(z-1)T_N'(z)}{(z-t_j)}\,dz\\ &= \frac{1}{(t_j-1)}\int_{-1}^{1}(z-1)\psi_j^{(N-2)}(z)dz,\end{aligned}$$

where $\psi_j^{(N-2)}$ is the interpolation polynomial for extrema nodes used in section 5.1. It follows that $\phi_j^{(N)}(t_N) = J_j^{(N)}/(t_j - 1)$, which is strictly positive since $J_j^{(N)} < 0$ and $(t_j - 1) < 0$. Thus $\phi_j^{(N)}(t_N) \geq 0$ for any positive integer N and $j = 1, 2, \ldots, N$. It has been shown in section 3.2 that the sum of these nonnegative elements in the Nth row of $(\tilde{D}_N^{(1)})^{-1}$ is 2. Direct computation shows that

$$\sum_{j=1}^{N} \left| (\tilde{D}_N^{(1)})^{-1}(i,j) \right| < 2 \quad \text{for} \quad i = 1, 2, \ldots, N-1.$$

The maximum row sum is

$$\sum_{j=1}^{N} \left| (\tilde{D}_N^{(1)})^{-1}(N,j) \right| = \sum_{j=1}^{N} (\tilde{D}_N^{(1)})^{-1}(N,j) = 2.$$

For the Chebyshev zeros distribution of nodes, an argument similar to that used above (assuming that the appropriate $J_j^{(N)}$ is negative) shows that $\phi_j^{(N)}(s_N) \geq 0$ for any positive integer N and $j = 1, 2, \ldots, N$. The sum of these nonnegative elements in the Nth row of $(\tilde{D}_N^{(1)})^{-1}$ is 2, as shown in section 3.2. In this case, direct computation shows that the maximum value of $\sum_{j=1}^{N} |(\tilde{D}_N^{(1)})^{-1}(i,j)|$ occurs at $i = N-2$, and it is this value that gives rise to the entries in Table 4. The value of $\sum_{j=1}^{N} |(\tilde{D}_N^{(1)})^{-1}(i,j)|$ is strictly less than 2 if i differs from $N-2$ or N. Furthermore, $\sum_{j=1}^{N} |(\tilde{D}_N^{(1)})^{-1}(i,j)|$ is strictly monotonic increasing with i for $i = 1, 2, \ldots, N-2$.

The structure of the inverses of the first-order Chebyshev pseudospectral differentiation matrices is worthy of further investigation.

Acknowledgments. I wish to thank Andre Weideman for suggesting this problem. The work was initiated while I was visiting the University of Stellenbosch, South Africa, in November and December, 2001. I am also grateful to a reviewer for valuable comments that led to some improvements in the presentation of this work.

FINITE ELEMENT APPROXIMATIONS TO THE DISCRETE SPECTRUM OF THE SCHRÖDINGER OPERATOR WITH THE COULOMB POTENTIAL*

WEIYING ZHENG† AND LUNG-AN YING†

Abstract. In the present paper, the authors consider the Schrödinger operator H with the Coulomb potential defined in R^{3m}, where m is a positive integer. Both bounded domain approximations to multielectron systems and finite element approximations to the helium system are analyzed. The spectrum of H becomes completely discrete when confined to bounded domains. The error estimate of the bounded domain approximation to the discrete spectrum of H is obtained. Since numerical solution is difficult for a higher-dimensional problem of dimension more than three, the finite element analyses in this paper are restricted to the S-state of the helium atom. The authors transform the six-dimensional Schrödinger equation of the helium S-state into a three-dimensional form. Optimal error estimates for the finite element approximation to the three-dimensional equation, for all eigenvalues and eigenfunctions of the three-dimensional equation, are obtained by means of local regularization. Numerical results are shown in the last section.

Key words. spectrum approximation, Schrödinger equation, weighted norm, local regularization, finite element method

1. Introduction.

The multielectron Coulomb problem in quantum mechanics cannot be solved in a finite form. Nevertheless it challenges and stimulates many mathematicians and physicists to devote themselves to developing efficient methods for solving the system.

Several successful approximation techniques in quantum physics/chemistry have been developed for this problem. They include the Hartree–Fock method [15], the finite difference method [19], [35], the correlation-function hyperspherical-harmonic method [18], [24], and various variational approximations. For the Hartree–Fock method, every electron is considered independently to be in a central electric field formed by the nucleus and other electrons. The finite difference method needs a rectangular domain in R^N and uniform grids. The double and triple basis set methods (which are variational methods indeed) are very powerful for the eigenvalue problem of the helium atom. Kono and Hattori (see [21], [22]) used two sets of basis functions $r_1^i r_2^j r_{12}^k e^{-\xi r_1 - \eta r_2} A$ ("ξ terms") and $r_1^i r_2^j r_{12}^k e^{-\zeta(r_1+r_2)} A$ ("ζ terms") to calculate the energy levels for the S, P, and D states of the helium atom. (A is an appropriate angular factor.) The former set of functions is expected to describe the whole wave function roughly, while the latter is expected to describe the short- and middle-range correlation effects. Their calculations yield 9–10 significant digits for S states. Kleindienst, Lüchow, and Merckens [20] and Drake and Yan [12] applied the double basis set method to S-states of helium. Their basis functions are $r_1^i r_2^j r_{12}^k e^{-\xi_1 r_1 - \eta_1 r_2}$ and $r_1^i r_2^j r_{12}^k e^{-\xi_2 r_1 - \eta_2 r_2}$. Drake and Yan employed truncations to ensure numerical stability and convergence. By complete optimization of the exponential scale factors ξ_1,

η_1, ξ_2, and η_2, they achieved more than 15 significant digits. Recently, Drake, Cassar, and Nistor [13] obtained 21 significant digits for the ground state of helium by the triple basis set method. Korobov [23] even obtained 25 significant digits for the ground state of helium. That work can be used as a benchmark for other approaches for three-body systems. All three of these excellent works in variational methods promote the development of few-body problems in quantum mechanics.

The finite element method (FEM) is used initially in elastic mechanics and fluid mechanics. It uses local interpolation functions to approximate the unknown function (see [8] and [36]), and thus can describe the local properties of wave functions. Therefore, we can expect to obtain good approximations to the energy. Important works on FEM applied to atomic and molecular problems first appeared in 1975 (see [3]). They were devoted to one- or two-dimensional problems [3], [4], [14], [16], [30]. In 1985, Levin and Schertzer [25] published the first work applying FEM to three-dimensional problems. They calculated the ground state of the helium atom. Most of the works applying FEM to three-body problems have appeared since 1990 (i.e., [1], [6], [31], [37]). All of the cited works obtained very good results.

To apply FEM to quantum mechanics, we should consider three aspects of the problem. The first is the spectrum approximation of the whole space Schrödinger operator by the operator defined on some bounded domain. The second is the error estimate for FEM approximation. The third is the real computation of approximate solutions. To the best of our knowledge, we have not found any work analyzing the first two aspects.

In this paper, we consider the first aspect for the system of an arbitrary atom. But as for the finite element aspect, since any problem of dimension more than three is a great challenge for both modern numerical methods and computers, we restrict the finite element analysis and computation to the S-state of the helium atom. In fact, we can transform the $3m$-dimensional Schrödinger equation (see [38] for $m = 2, 3$) into a $3(m-1)$-dimensional form rigorously, and theoretical analysis of the FEM applied to the simplified equation can be obtained similarly, in view of the argument of sections 3, 4, and 5 in the present paper. However, real computations are very difficult to carry out because of numerous degrees of freedom. Our numerical results on the lithium atom (the Schrödinger equation is nine-dimensional) will appear in another paper [39].

The present paper consists of three parts. First, we consider the bounded domain approximation of the $3m$-dimensional Schrödinger equation (m is the number of electrons in an ion). The spectrum of the Schrödinger operator H consists of the discrete spectrum included in $(-a, 0)$(for some $a > 0$) and the continuous spectrum $[0, +\infty)$. We show that the spectrum of H becomes completely discrete if it is restricted to bounded domains. In section 2, we show that for any eigenvalue of the whole space problem and for any $\epsilon > 0$, assuming the bounded domain large enough, there is an eigenpair of the bounded domain problem such that the errors of both the eigenvalue and the eigenfunction are smaller than ϵ. Secondly, we analyze the finite element approximation of the S-state of the helium atom. In section 3, the six-dimensional Schrödinger equation is transformed into a three-dimensional form, and some Hilbert spaces with weighted inner products and norms are defined. Because we cannot say that the solutions of both the three-dimensional equation and the six-dimensional one are continuous, the technique of local regularization [25] is used to prove the convergency of the finite element scheme. In section 4, we describe the three-dimensional local regularization operator in detail. In section 5, an equivalent variational equation of the three-dimensional equation and its FEM approximation are given for the

helium atom of the S-state. The optimal order error estimate of the finite element scheme is obtained. Thirdly, we have calculated approximate solutions by the finite element scheme. In section 6, we give the numerical results from two kinds of FEM approximations to the three-dimensional energy equation. The results are better than existing finite element results. Furthermore, from the figures we can see that our approximate wave functions coincide very well with many physical properties well known to physicists, and with many essential physical assumptions in quantum mechanics which are not added into our computations a priori.

The difficulties appear in three aspects: 1. the proof of the continuity and coercivity of the bilinear forms in the variational equations with the presence of the singularities in the Coulomb potential, 2. the proof of the convergency of the finite element scheme while the variational spaces are not standard Sobolev spaces, and 3. obtaining precise results in presence of numerous unknowns and singular integrals.

Through the paper, C represents the generic constant independent of minded parameters; the symbol "$\Longleftrightarrow$" means "be equivalent to." We use atomic units except where explicitly explained, i.e., Bohr radius a_0 for length, Rydberg (Hartree only in section 6) for energy. We consider the nonrelativistic and spin-independent case.

2. Discrete spectrum approximations of the Schrödinger operator in bounded domains. Let $m > 0$ be an integer, $N = 3m$. The Schrödinger equation of an m-electron ion is

$$H\psi = E\psi \quad \text{in } R^N, \tag{2.1}$$

where

$$\begin{aligned} H\psi &= -\Delta\psi + V\psi, \\ \Delta\psi &= \sum_{i=1}^{m} \left(\frac{\partial^2}{\partial x_i^2} + \frac{\partial^2}{\partial y_i^2} + \frac{\partial^2}{\partial z_i^2} \right), \\ V &= -\sum_{i=1}^{m} \frac{2Z}{r_i} + \sum_{1 \le i < j \le m} \frac{2}{r_{ij}}; \end{aligned}$$

(x_i, y_i, z_i) are the coordinates of the ith electron, $r_i = \sqrt{x_i^2 + y_i^2 + z_i^2}$ is the distance between the ith electron and the nucleus, $1 \le i \le m$; and $r_{ij} = [(x_i - x_j)^2 + (y_i - y_j)^2 + (z_i - z_j)^2]^{1/2}$ is the distance between the ith electron and the jth electron, $1 \le i < j \le m$. Z is the charge number of the nucleus.

It is well known that H is self-adjoint and bounded below (Theorem 10.33 and the analysis on p. 323 of [34]). Its spectrum $\sigma(H)$ is included in R^1. Furthermore, the continuous spectrum of H is $[0, +\infty)$, and $\forall s \in \sigma(H) \bigcap (-\infty, 0)$, s is an eigenvalue of H (see Theorems 10.30 and 10.31 in [34]).

LEMMA 2.1. *Let $1 \le p < 2$, $3/2 < q < 2$, $1 \le q_1 < \min(3, \frac{Nq}{N-2q})$. Then there exists a constant C such that $\forall v \in H^1(R^N)$, $u \in W^{2,q}(R^N)$,*

$$\frac{u}{r_i}, \quad \frac{u}{r_{ij}} \in L^{q_1}(R^N), \tag{2.2}$$

and

$$\begin{cases} \displaystyle\int_{R^N} \frac{v^2}{r_i^p} dx, \quad \int_{R^N} \frac{v^2}{r_{ij}^p} dx \le C \|v\|_{1,R^N}^2, \\ \displaystyle\left\| \frac{u}{r_i} \right\|_{0,q_1,R^N}, \quad \left\| \frac{u}{r_{ij}} \right\|_{0,q_1,R^N} \le C \|u\|_{2,q,R^N}; \end{cases} \tag{2.3}$$

moreover, if v is compactly supported in R^N, then

$$\frac{v}{r_i}, \quad \frac{v}{r_{ij}} \in L^p(R^N), \tag{2.4}$$

and

$$\left\| \frac{v}{r_i} \right\|_{0,p,R^N}, \ \left\| \frac{v}{r_{ij}} \right\|_{0,p,R^N} \le C\|v\|_{1,R^N}, \tag{2.5}$$

where $1 \le i, j \le m$ and $i < j$.

Proof. (1) $\forall x \in R^N$, set $x = (x^{(1)}, \dots, x^{(m)})$, $x^{(i)} = (x_i, y_i, z_i)$, $\tilde{x}^{(i)} = (x^{(1)}, \dots, x^{(i-1)}, x^{(i+1)}, \dots, x^{(m)})$. Define $B_i = \{(x_i, y_i, z_i) \mid x_i^2 + y_i^2 + z_i^2 \le 1\}$, $i = 1, \dots, m$. Since $H^1(B_i) \hookrightarrow L^6(B_i)$, $W^{2,q}(B_i) \hookrightarrow C(B_i)$, $W^{2,q}(R^3) \hookrightarrow W^{1,q}(R^3) \hookrightarrow L^2(R^3)$, let $0 \le t < 2, 0 \le s < 3$; then $\forall v \in H^1(R^N)$, $u \in W^{2,q}(R^N)$,

$$\int_{R^3 \setminus B_i} \frac{v^2}{r_i^t} dx^{(i)} \le \|v\|_{0,R^3}^2 \le \|v\|_{1,R^3}^2, \quad \int_{R^3 \setminus B_i} \frac{u^2}{r_i^s} dx^{(i)} \le \|u\|_{0,R^3}^2 \le C\|u\|_{2,q,R^3}^2,$$

$$\int_{B_i} \frac{v^2}{r_i^t} dx^{(i)} \le \left(\int_{B_i} v^6 dx^{(i)} \right)^{\frac{1}{3}} \left(\int_{B_i} r_i^{-\frac{3t}{2}} dx^{(i)} \right)^{\frac{2}{3}} \le C\|v\|_{0,6,B_i}^2 \le C\|v\|_{1,B_i}^2,$$

$$\int_{B_i} \frac{u^2}{r_i^s} dx^{(i)} \le \|u\|_{0,\infty,B_i}^2 \int_{B_i} r_i^{-s} dx^{(i)} \le C\|u\|_{2,q,B_i}^2 \quad \text{for almost every } \tilde{x}^{(i)} \in R^{N-3}.$$

Hence

$$\int_{R^3} \frac{v^2}{r_i^t} dx^{(i)} \le C\|v\|_{1,R^3}^2, \quad \int_{R^3} \frac{u^2}{r_i^s} dx^{(i)} \le C\|u\|_{2,q,R^3}^2. \tag{2.6}$$

By Tonelli's theorem [34], integrating (2.6) with respect to the rest variables gives

$$\int_{R^N} \frac{v^2}{r_i^t} dx \le C\|v\|_{1,R^N}^2, \quad \int_{R^N} \frac{u^2}{r_i^s} dx \le C\|u\|_{2,q,R^N}^2. \tag{2.7}$$

Setting $s = \frac{N(q-2)+4q}{N(q-q_1)+2qq_1} q_1$, by (2.7) we have

$$\int_{R^N} \left(\frac{u}{r_i} \right)^{q_1} dx \le \left(\int_{R^N} \frac{u^2}{r_i^s} dx \right)^{\frac{q_1}{s}} \left(\int_{R^N} u^{\frac{q_1(s-2)}{s-q_1}} dx \right)^{\frac{s-q_1}{s}} \le C\|u\|_{2,q,R^N}^{q_1}.$$

If the support of $v \in H^1(R^N)$ is compact, set $R > 0$ large enough and define

$$B_i(0,R) = \left\{ (x_i, y_i, z_i) \in R^3 \ \middle| \ \sqrt{x_i^2 + y_i^2 + z_i^2} \le R \right\},$$

$$\Omega_R = \left\{ (x^{(1)}, \dots, x^{(m)}) \in R^N \ \middle| \ \sqrt{x_i^2 + y_i^2 + z_i^2} \le R, \quad i = 1, 2, \dots, m \right\}.$$

Assuming $\operatorname{supp} v \subset \Omega_R$, by Hölder's inequality there exists a positive constant C, depending on R and p, such that

$$\int_{R^3} \left(\frac{v}{r_i} \right)^p dx^{(i)} = \int_{B_i(0,R)} \left(\frac{v}{r_i} \right)^p dx^{(i)} \le C\|v\|_{0,6,B_i(0,R)}^p \le C\|v\|_{1,B_i(0,R)}^p. \tag{2.8}$$

Integrating (2.8) with respect to the rest of the variables produces the following:

$$\int_{R^N}\left(\frac{v}{r_i}\right)^p d\tilde{x}^{(i)} \le C\int_{R^{N-3}} \|v\|^p_{1,B_i(0,R)} d\tilde{x}^{(i)} \le C\|v\|^p_{1,R^N}.$$

(2) For any $1 \le i < j \le m$, let $\xi^{(i)} = x^{(i)} - x^{(j)}$, $\xi^{(i)} = (\xi_i, \eta_i, \zeta_i)$, $x^{(i)} = (x_i, y_i, z_i)$. For any $v = v(x^{(1)}, \dots, x^{(m)}) \in H^1(R^N)$, define

$$v_{ij}(x^{(1)}, \dots, \xi^{(i)}, \dots, x^{(m)}) = v(x^{(1)}, \dots, \xi^{(i)} + x^{(j)} \dots, x^{(m)}),$$

By Tonelli's theorem [34], we have

$$\begin{aligned}\int_{R^{N-3}}\int_{R^3} & v^2(x^{(1)}, \dots, x^{(i)}, \dots, x^{(m)}) dx^{(i)} d\tilde{x}^{(i)} \\ &= \int_{R^{N-3}}\int_{R^3} v_{ij}^2(x^{(1)}, \dots, \xi^{(i)}, \dots, x^{(m)}) d\xi^{(i)} d\tilde{x}^{(i)} \\ &= \int_{R^N} v_{ij}^2 dx \qquad \forall v \in H^1(R^N).\end{aligned}$$

Thus $v_{ij} \in L^2(R^N)$. In the same way, we have

$$\frac{\partial v_{ij}}{\partial x_k}, \quad \frac{\partial v_{ij}}{\partial y_k}, \quad \frac{\partial v_{ij}}{\partial z_k} \in L^2(R^N), \quad 1 \le k \le N, \quad k \ne i, j.$$

Since $\frac{\partial v_{ij}}{\partial \xi_i} = \frac{\partial v}{\partial x_i}$, $\frac{\partial v_{ij}}{\partial x_j} = \frac{\partial v}{\partial x_i} + \frac{\partial v}{\partial x_j}$, we have

$$\int_{R^{N-3}}\int_{R^3}\left|\frac{\partial v}{\partial \xi_i}\right|^2 d\xi^{(i)} d\tilde{x}^{(i)} = \int_{R^{N-3}}\int_{R^3}\left|\frac{\partial v}{\partial x_i}\right|^2 d\xi^{(i)} d\tilde{x}^{(i)} = \int_{R^{N-3}}\int_{R^3}\left|\frac{\partial v}{\partial x_i}\right|^2 dx^{(i)} d\tilde{x}^{(i)},$$

i.e., $\frac{\partial v_{ij}}{\partial \xi_i} \in L^2(R^N)$. Similarly, we have

$$\frac{\partial v_{ij}}{\partial \eta_i}, \quad \frac{\partial v_{ij}}{\partial \zeta_i}, \quad \frac{\partial v_{ij}}{\partial x_j}, \quad \frac{\partial v_{ij}}{\partial y_j}, \quad \frac{\partial v_{ij}}{\partial z_j} \in L^2(R^N).$$

Therefore $v_{ij} \in H^1(R^N)$. In the same way, if $u \in W^{2,q}(R^N)$, we have $u_{ij} \in W^{2,q}(R^N)$, $1 \le i, j, \le m$. By (1), $v/r_{ij} = v_{ij}/|\xi_{(i)}|$, $u/r_{ij} = u_{ij}/|\xi_{(i)}|$ satisfy (2.3)–(2.5). ∎

Let $\sigma > 0$ be a constant, $\hat{x} = (\hat{x}^{(1)}, \dots, \hat{x}^{(m)}) = \sigma x$, $\hat{x}^{(i)} = (\hat{x}_i, \hat{y}_i, \hat{z}_i)$, $\hat{\psi}(\hat{x}) = \psi(\sigma x)$ for any $x \in R^N$. Then (2.1) becomes

$$-\sigma^2\hat{\Delta}\hat{\psi} - \sigma\sum_{i=1}^m \frac{2Z\hat{\psi}}{\hat{r}_i} + \sigma\sum_{1\le i<j\le m}\frac{2\hat{\psi}}{\hat{r}_{ij}} = E\hat{\psi} \qquad \text{in } R^N, \tag{2.9}$$

where $\hat{\Delta}$ concerns the derivatives with respect to $\hat{x}$. Obviously, $\psi \in H^1(R^N) \Longleftrightarrow \hat{\psi} \in H^1(R^N)$. By Lemma 2.1, we can choose σ, K large enough such that

$$2\sigma\sum_{i=1}^m \int_{R^N}\frac{2Z\hat{\varphi}^2}{\hat{r}_i} d\hat{x} \le \sigma^2|\hat{\varphi}|^2_{1,R^N} + K\|\hat{\varphi}\|^2 \quad \forall \hat{\varphi} \in H^1(R^N). \tag{2.10}$$

Let $\lambda = E + K$; then the variational form of (2.9) is the following: Find $(\lambda, \hat{\psi}) \in R^1 \times H^1(R^N)$ and $\hat{\psi} \ne 0$ such that

$$\hat{a}(\hat{\psi}, \hat{\varphi}) = \lambda\int_{R^N}\hat{\psi}\hat{\varphi} d\hat{x} \quad \forall \hat{\varphi} \in H^1(R^N), \tag{2.11}$$

where

$$\hat{a}(\hat{\psi},\hat{\varphi}) = \sigma^2 \int_{R^N} \hat{\nabla}\hat{\psi}\cdot\hat{\nabla}\hat{\varphi}d\hat{x} + \int_{R^N}\left(-\sum_{i=1}^{m}\frac{2Z\sigma}{\hat{r}_i} + \sum_{1\le i<j\le m}\frac{2\sigma}{\hat{r}_{ij}} + K\right)\hat{\psi}\hat{\varphi}d\hat{x}.$$

It is easy to see that $\hat{a}(\cdot,\cdot)$ is continuous and coercive on $H^1(R^N)$ by Lemma 2.1 and (2.10).

The weak form of (2.1) is the following: Find $(\lambda,\psi)\in R^1\times H^1(R^N)$ and $\psi\neq 0$ such that

$$a(\psi,\varphi) = \lambda\int_{R^N}\psi\varphi dx \qquad \forall\varphi\in H^1(R^N), \tag{2.12}$$

where

$$a(\psi,\varphi) = \int_{R^N}\nabla\psi\cdot\nabla\varphi dx + \int_{R^N}\left(-\sum_{i=1}^{m}\frac{2Z}{r_i} + \sum_{1\le i<j\le m}\frac{2}{r_{ij}} + K\right)\psi\varphi dx.$$

By the transform $a(\psi,\varphi)=\sigma^{-N}\hat{a}(\hat{\psi},\hat{\varphi})$ and

$$\min\{\sigma^N,\sigma^{N-2}\}\|\psi\|^2_{1,R^N}\le\|\hat{\psi}\|^2_{1,R^N}\le\max\{\sigma^N,\sigma^{N-2}\}\|\psi\|^2_{1,R^N},$$

we know that $a(\cdot,\cdot)$ is continuous and coercive on $H^1(R^N)$. For the sake of simplicity in notation, we drop the continuity and coercivity constants and write $\|\cdot\|_{1,R^N}=\sqrt{a(\cdot,\cdot)}$ throughout this paper.

We consider the approximation of (2.12) in a bounded domain. Let $R>0$ be large enough and $B=B(0,R)\subset R^N$ be the ball with radius R and center at the origin. The approximation of (2.12) is defined as follows: Find $(\lambda_B,\psi_B)\in R^1\times H_0^1(B)$ and $\psi_B\neq 0$ such that

$$a(\psi_B,\phi_B) = \lambda\int_{R^N}\psi_B\phi_B dx \quad \forall\phi_B\in H_0^1(B). \tag{2.13}$$

For all $\phi_B\in H_0^1(B)$, we extend ϕ_B by zero to the exterior of B and still denote the extension as $\phi_B\in H^1(R^N)$. Thus (2.13) is the Galerkin approximation of (2.12). $a(\cdot,\cdot)$ is continuous and coercive on $H_0^1(B)$, and the continuity and coercivity constants are independent of the radius R.

THEOREM 2.2. *If the Schrödinger operator H is restricted to the bounded domain B, then its spectrum is discrete. It has the form*

$$0<\lambda_{B1}\le\lambda_{B2}\le\cdots\to+\infty, \tag{2.14}$$

where $\lambda_{Bi}=\lambda_{B,i+1}$ means that λ_{Bi} is multiple. If ψ_B is the eigenfunction in (2.13) *associated with λ_B, then $\psi_B\in H^2(B)\bigcap H_0^1(B)$.*

Proof. Since $H_0^1(B)\hookrightarrow\hookrightarrow L^2(B)$, by the Lax–Milgram theorem [9], we know that (2.13) has eigenvalues and eigenfunctions. Its spectrum is discrete and has the form of (2.14).

Let (λ_B,ψ_B) be an eigenpair of (2.13), i.e.,

$$\begin{cases} -\Delta\psi_B - \displaystyle\sum_{i=1}^{m}\frac{2Z\psi_B}{r_i} + \sum_{1\le i<j\le m}\frac{2\psi_B}{r_{ij}} = E\psi_B & \text{in } B,\\ \psi = 0 \quad \text{on } \partial B. \end{cases} \tag{2.15}$$

By Lemma 2.1, we have

$$\frac{\psi_B}{r_i}, \quad \frac{\psi_B}{r_{ij}} \in L^p(B), \quad 1 \le i < j \le m, \quad \forall\, 1 < p < 2.$$

By the L^p theory of elliptic equations [17], $\psi_B \in W^{2,p}(B)$ for any $1 < p < 2$. Then by Lemma 2.1,

$$\frac{\psi_B}{r_i}, \quad \frac{\psi_B}{r_{ij}} \in L^2(B), \quad 1 \le i < j \le m.$$

Thus $\psi_B \in H^2(B)$. □

THEOREM 2.3. *If (λ, ψ) is an eigenpair of (2.12) with $\|\psi\|_{1,R^N} = 1$, then for any $\epsilon > 0$ there exist $R > 0$ and an eigenpair (λ_B, ψ_B) of (2.13) such that*

$$|\lambda - \lambda_B| < C\epsilon^2, \tag{2.16}$$

$$\|\psi - \psi_B\|_{1,R^N} < C\epsilon, \tag{2.17}$$

where ψ_B is extended by zero to the exterior of B and C is a positive constant independent of R and ϵ.

Proof. By Theorem 10.33 in [34] and the coercivity of $a(\cdot,\cdot)$, we know that the discrete spectrum of (2.12) is

$$0 < \lambda_1 \le \lambda_2 \le \cdots < K,$$

where $\lambda_i = \lambda_{i+1}$ means that λ_i is multiple, and K is the unique accumulation. By the minmax theorem [10],

$$\lambda_i \le \lambda_{Bi}, \quad i = 1, 2, \ldots .$$

Define V_i, V_{Bi} as the eigenspaces associated with λ_i and λ_{Bi}, respectively. We assume $\psi \in V_i$. By the theory of abstract spectrum approximation (p. 699 of [10]), there exists $\psi_{Bi} \in V_{Bi}$ such that

$$|\lambda_i - \lambda_{Bi}| \le C(\varepsilon_B(\lambda_i))^2, \tag{2.18}$$

$$\|\psi - \psi_{Bi}\|_{1,R^N} \le C\varepsilon_B(\lambda_i), \tag{2.19}$$

where

$$\varepsilon_B(\lambda_i) = \sup_{\substack{u \in V_i, \\ \|u\|_{1,R^N}=1}} \inf_{v \in H_0^1(B)} \|u - v\|_{1,R^N}. \tag{2.20}$$

C is a constant depending on the continuity and coercivity constants of the bilinear form $a(\cdot,\cdot)$ and λ_i, but is independent of R.

Let $\{\psi_1, \ldots, \psi_l\}$ be an orthonormal basis of V_i with respect to the norm of $H^1(R^N)$, and let l be the multiplicity of λ_i. For any $\epsilon > 0$, since $\psi_k \in H^1(R^N)$, there exists a $\phi_k \in C_0^\infty(R^N)$ such that $\|\psi_k - \phi_k\|_{1,R^N} < \epsilon/l$. Set R large enough such that $\cup_{k=1}^l \operatorname{supp}\phi_k \subset B = B(0,R)$; then

$$\varepsilon_B(\lambda_i) \le \sum_{k=1}^{l} \|\psi_k - \phi_k\|_{1,R^N} < \epsilon. \tag{2.21}$$

In view of (2.18)–(2.21), we have (2.16) and (2.17). □

3. Weighted norms and Hilbert spaces. We consider the eigenvalue problem of the S-state of the helium atom, i.e., $Z = m = 2$. The eigenvalue equations of the Hamiltonian and the square of the angular momentum are

$$-\Delta_1\psi - \Delta_2\psi + \left(\frac{2}{r_{12}} - \frac{4}{r_1} - \frac{4}{r_2}\right)\psi = E\psi, \tag{3.1}$$

$$\begin{aligned}\Bigg\{&\left[\sum_{i=1}^{2}\left(y_i\frac{\partial}{\partial z_i} - z_i\frac{\partial}{\partial y_i}\right)\right]^2 + \left[\sum_{i=1}^{2}\left(z_i\frac{\partial}{\partial x_i} - x_i\frac{\partial}{\partial z_i}\right)\right]^2\\ &+ \left[\sum_{i=1}^{2}\left(x_i\frac{\partial}{\partial y_i} - y_i\frac{\partial}{\partial x_i}\right)\right]^2 + l(l+1)\Bigg\}\psi = 0,\end{aligned} \tag{3.2}$$

where $l = 0, 1, \ldots$. Let θ', ϕ, ϕ' be three Euler angles such that (r_1, θ', ϕ') are the spherical coordinates of the first electron in the fixed system $o - xyz$, ϕ is the interfractial angle between the $r_1 - z$ plane and the $r_1 - r_2$ plane, and θ is the interelectronic angle. We introduce the Hylleraas–Breit transform [7]:

$$\begin{cases} x_1 = r_1\sin\theta'\cos\phi', \\ y_1 = r_1\sin\theta'\sin\phi', \\ z_1 = r_1\cos\theta', \\ x_2 = r_2(\sin\theta\cos\theta'\cos\phi\cos\phi' - \sin\theta\sin\phi\sin\phi' + \cos\theta\sin\theta'\cos\phi'), \\ y_2 = r_2(\sin\theta\cos\phi\cos\theta'\sin\phi' + \sin\theta\sin\phi\cos\phi' + \cos\theta\sin\theta'\sin\phi'), \\ z_2 = r_2(\cos\theta\cos\theta' - \sin\theta\sin\theta'\cos\phi). \end{cases} \tag{3.3}$$

We can transform (3.1) and (3.2) into the following forms by (3.3):

$$L(\psi) - \frac{A_1(\psi)}{r_1^2} - \frac{A_2(\psi)}{r_2^2} = E\psi, \tag{3.4}$$

$$\left[\frac{\partial^2}{\partial\theta'^2} + \mathrm{ctg}\theta'\frac{\partial}{\partial\theta'} + \frac{1}{\sin^2\theta'}\left(\frac{\partial^2}{\partial\phi^2} + \frac{\partial^2}{\partial\phi'^2}\right) - \frac{2\cos\theta'}{\sin^2\theta'}\frac{\partial^2}{\partial\phi\partial\phi'} + l(l+1)\right]\psi = 0, \tag{3.5}$$

where

$$\begin{aligned} L(\psi) = &-\frac{1}{r_1^2}\frac{\partial}{\partial r_1}\left(r_1^2\frac{\partial\psi}{\partial r_1}\right) - \frac{1}{r_2^2}\frac{\partial}{\partial r_2}\left(r_2^2\frac{\partial\psi}{\partial r_2}\right)\\ &- \left(\frac{1}{r_1^2} + \frac{1}{r_2^2}\right)\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\psi}{\partial\theta}\right) + \left(\frac{2}{r_{12}} - \frac{4}{r_1} - \frac{4}{r_2}\right)\psi,\\ A_1(\psi) = &\frac{1}{\sin\theta'}\frac{\partial}{\partial\theta'}\left(\sin\theta'\frac{\partial\psi}{\partial\theta'}\right) + (\mathrm{ctg}^2\theta + \mathrm{ctg}^2\theta' + 2\mathrm{ctg}\theta\mathrm{ctg}\theta'\cos\phi)\frac{\partial^2\psi}{\partial\phi^2}\\ &+ \frac{1}{\sin\theta'}\frac{\partial^2\psi}{\partial\phi'^2} - 2\cos\phi\frac{\partial^2\psi}{\partial\theta\partial\theta'} - 2\frac{\sin\phi}{\sin\theta'}\frac{\partial^2\psi}{\partial\theta\partial\phi'} + 2\sin\phi\mathrm{ctg}\theta\frac{\partial^2\psi}{\partial\phi\partial\theta'}\\ &+ 2\mathrm{ctg}\theta'\sin\phi\frac{\partial^2\psi}{\partial\theta\partial\phi} - \frac{2}{\sin\theta'}(\mathrm{ctg}\theta' + \mathrm{ctg}\theta\cos\phi)\frac{\partial^2\psi}{\partial\phi\partial\phi'},\\ A_2(\psi) = &\frac{1}{\sin^2\theta}\frac{\partial^2\psi}{\partial\phi^2}. \end{aligned}$$

For the S-state of the helium atom, $l = 0$; then (3.5) has only constant solutions. Thus any wave function u of the S-state depends on only three variables r_1, r_2, and θ. Therefore, we can transform (3.4) of the S-state into a three-dimensional form

$$L(u) = Eu. \tag{3.6}$$

Assume that $\Omega \subset X = [0, +\infty) \times [0, +\infty) \times [0, \pi]$ is a bounded domain. $u = u(r_1, r_2, \theta)$, $v = v(r_1, r_2, \theta)$. We define inner products, norms, and Hilbert spaces as follows:

$$(u, v)_0 = \int_\Omega uvr_1^2 r_2^2 \sin\theta dr_1 dr_2 d\theta, \quad \|u\|_{0,r,\Omega}^2 = \int_\Omega u^2 r_1^2 r_2^2 \sin\theta dr_1 dr_2 d\theta,$$

$$(u, v)_1 = (u, v)_0 + \int_\Omega \left[r_1^2 r_2^2 \frac{\partial u}{\partial r_1}\frac{\partial v}{\partial r_1} + r_1^2 r_2^2 \frac{\partial u}{\partial r_2}\frac{\partial v}{\partial r_2} + (r_1^2 + r_2^2)\frac{\partial u}{\partial \theta}\frac{\partial v}{\partial \theta}\right] \sin\theta dr_1 dr_2 d\theta,$$

$$|u|_{1,r,\Omega}^2 = \int_\Omega \left[r_1^2 r_2^2 \left(\frac{\partial u}{\partial r_1}\right)^2 + r_1^2 r_2^2 \left(\frac{\partial u}{\partial r_2}\right)^2 + (r_1^2 + r_2^2)\left(\frac{\partial u}{\partial \theta}\right)^2\right] \sin\theta dr_1 dr_2 d\theta,$$

$$|u|_{2,r,\Omega}^2 = \left|\frac{\partial u}{\partial r_1}\right|_{1,r,\Omega}^2 + \left|\frac{\partial u}{\partial r_2}\right|_{1,r,\Omega}^2 + \left|\frac{\partial u}{\partial \theta}\right|_{1,r,\Omega}^2,$$

$$\|u\|_{i+1,r,\Omega}^2 = \|u\|_{i,r,\Omega}^2 + |u|_{i+1,r,\Omega}^2, \quad i = 0, 1,$$

$$H_r^i(\Omega) = \left\{ v \mid \ \|v\|_{i,r,\Omega}^2 < +\infty \right\}, \quad i = 0, 1,$$

$$H_r^2(\Omega) = \left\{ v \| v\|_{2,r,\Omega}^2 < +\infty, \ \int_\Omega u^2 (r_1^2 + r_2^2) \sin\theta dr_1 dr_2 d\theta < \infty \right\}.$$

LEMMA 3.1. *Assume that $\Omega \subset X$ is a bounded domain; then*

$$H_r^1(\Omega) \hookrightarrow\hookrightarrow H_r^0(\Omega). \tag{3.7}$$

Furthermore, if there exists a constant $d_\Omega > 0$, such that for any $(r_1, r_2, \theta) \in \Omega$, $r_1, r_2 \geq d_\Omega$, then

$$H_r^2(\Omega) \hookrightarrow\hookrightarrow H_r^1(\Omega). \tag{3.8}$$

Proof. (1): Proof of (3.7). Let $x = (x_1, y_1, z_1, x_2, y_2, z_2) = \mathsf{H}(r_1, r_2, \theta, \theta', \phi, \phi')$ be the Hylleraas–Breit transform defined by (3.3), and let $\hat{\Omega} \subset R^6$ be a bounded domain defined by

$$\hat{\Omega} = \{x \mid x = \mathsf{H}(r_1, r_2, \theta, \theta', \phi, \phi'), \ (r_1, r_2, \theta) \in \Omega, \ 0 \leq \theta' \leq \pi, \ 0 \leq \phi, \phi' \leq 2\pi\}. \tag{3.9}$$

The Jacobian determinant of (3.3) is

$$\det\left(\frac{\partial(x_1, y_1, z_1, x_2, y_2, z_2)}{\partial(r_1, r_2, \theta, \theta', \phi, \phi')}\right) = r_1^2 r_2^2 \sin\theta \sin\theta'. \tag{3.10}$$

By direct calculation, we have $\|u\|_{i,r,\Omega}^2 = \frac{1}{8\pi^2}\|u\|_{i,\hat{\Omega}}^2$, where $\|\cdot\|_{i,\hat{\Omega}}$ is the norm of the standard Sobolev space $H^i(\hat{\Omega})$, $i = 0, 1$. It is easy to show that $H_r^0(\Omega)$ and $H_r^1(\Omega)$ are Hilbert spaces, and $H_r^1(\Omega) \hookrightarrow\hookrightarrow H_r^0(\Omega)$.

(2): Proof of (3.8). Let $\{v_n\}$ be a bounded sequence in $H_r^2(\Omega)$; then $\{v_n\}, \{\frac{\partial v_n}{\partial r_1}\}$, $\{\frac{\partial v_n}{\partial r_2}\}, \{\frac{\partial v_n}{\partial \theta}\}$ are bounded uniformly in $H_r^1(\Omega)$. By (1), we can choose (successively) a subsequence denoted as $\{v_n\}$ too, such that $\{v_n\}, \{\frac{\partial v_n}{\partial r_1}\}, \{\frac{\partial v_n}{\partial r_2}\}, \{\frac{\partial v_n}{\partial \theta}\}$ are Cauchy sequences in $H_r^0(\Omega)$. Thus $\{v_n\}$ is a Cauchy sequence in the measure

$$\left\{ \|v_n\|_{0,r,\Omega}^2 + \int_\Omega \left(\left| \frac{\partial v_n}{\partial r_1} \right|^2 + \left| \frac{\partial v_n}{\partial r_2} \right|^2 + \left| \frac{\partial v_n}{\partial \theta} \right|^2 \right) r_1^2 r_2^2 \sin\theta dr_1 dr_2 d\theta \right\}^{1/2}.$$

It is clear that

$$\int_\Omega \left| \frac{\partial v_n}{\partial \theta} \right|^2 (r_1^2 + r_2^2) \sin\theta dr_1 dr_2 d\theta \le \frac{2}{d_\Omega^2} \int_\Omega \left| \frac{\partial v_n}{\partial \theta} \right|^2 r_1^2 r_2^2 \sin\theta dr_1 dr_2 d\theta,$$

and so we have

$$\|v_n\|_{1,r,\Omega}^2 \le \max\left\{1, 2/d_\Omega^2\right\} \left(\|v_n\|_{0,r,\Omega}^2 + \left\| \frac{\partial v_n}{\partial r_1} \right\|_{0,r,\Omega}^2 + \left\| \frac{\partial v_n}{\partial r_2} \right\|_{0,r,\Omega}^2 + \left\| \frac{\partial v_n}{\partial \theta} \right\|_{0,r,\Omega}^2 \right).$$

Therefore $\{v_n\}$ is a Cauchy sequence in $H_r^1(\Omega)$ and converges. □

Remark 3.2. Suppose that Ω is bounded. For any integer $k > 0$, define

$$P_k(\Omega) = \left\{ p = \sum_{0 \le l+m+n \le k} \alpha_{lmn} r_1^l r_2^m \theta^n \;\middle|\; \alpha_{lmn} \in R^1,\ (r_1, r_2, \theta) \in \Omega \right\};$$

then $P_k(\Omega) \subset H^2(\Omega) \subset H_r^2(\Omega)$.

LEMMA 3.3. *Supposing $R > 0$ is a constant, there exists a constant C independent of R such that, for any $f \in H^1([0, R])$,*

$$\int_0^R f^2 dx \le C \max\{R^2, R^{-2}\} \left(\int_0^R x^2 f^2 dx + \int_0^R f'^2 dx \right). \tag{3.11}$$

Proof. For any $f \in C^1([R/2, R])$ there exists $\xi \in [R/2, R]$ such that

$$f(\xi) = \frac{2}{R} \int_{R/2}^R f(x) dx.$$

Then for any $x \in [R/2, R]$, by Hölder's inequality we have

$$\begin{aligned} |f(x)| &= \left| f(\xi) + \int_\xi^x f'(t) dt \right| \le \frac{2}{R} \int_{R/2}^R |f(t)| dt + \int_{R/2}^R |f'(t)| dt \\ &\le \left(\frac{2}{R} \int_{R/2}^R |f(t)|^2 dt \right)^{1/2} + \left(\frac{R}{2} \int_{R/2}^R |f'(t)|^2 dt \right)^{1/2}. \end{aligned}$$

Thus there exists a positive constant C independent of R such that

$$|f|_{0,\infty,[R/2,R]} \le C \max\{\sqrt{R}, 1/\sqrt{R}\} \|f\|_{1,[R/2,R]}. \tag{3.12}$$

Set $x_0 \in [R/2, R]$. By (3.12), we have, for any $x \in [0, R]$ and $f \in C^\infty([0, R])$,

$$f^2(x) \le 2\left\{f^2(x_0) + \left[\int_{x_0}^{x} f'(x)dx\right]^2\right\} \le C\left\{f^2(x_0) + R\int_0^R f'^2(x)dx\right\} \tag{3.13}$$
$$\le C\max\{R, R^{-3}\}\left(\int_{R/2}^R x^2 f^2(x)dx + \int_0^R f'^2(x)dx\right) \quad \forall x \in [0, R],$$

where C is a constant independent of R. We obtain (3.11) for all functions in $C^\infty([0, R])$ by integrating both sides of (3.13) over $[0, R]$. Therefore (3.11) is true for all functions in $H^1([0, R])$ by the density of $C^\infty([0, R])$ in $H^1([0, R])$. □

Now, we expand each function $u(r_1, r_2, \theta)$ in some Banach space defined on Ω to $R^3 \setminus \Omega$. Thus r_1, r_2, θ are not the distances and the interelectronic angle in the previous sense. For any $u = u(r_1, r_2, \theta)$, define

$$|||u|||^2_{0,\Omega} = \int_\Omega u^2 r_1^2 r_2^2 |\sin\theta| dr_1 dr_2 d\theta, \tag{3.14}$$

$$|||u|||^2_{1,\Omega} = \int_\Omega \left[\left(\frac{\partial u}{\partial r_1}\right)^2 + \left(\frac{\partial u}{\partial r_2}\right)^2 + \left(\frac{\partial u}{\partial \theta}\right)^2\right](r_1^2 + r_2^2)|\sin\theta| dr_1 dr_2 d\theta, \tag{3.15}$$

$$H(\Omega) = \{u \mid |||u|||^2_{0,\Omega} + |||u|||^2_{1,\Omega} < \infty\}.$$

THEOREM 3.4. *Suppose that $\Omega \subset X$ is a bounded open domain satisfying C^1-regularity* [2]. *There exists a linear operator*

$$\mathsf{E}: \quad H(\Omega) \to H(R^3)$$

such that, for any $u \in H(\Omega)$,

$$\mathsf{E}u(r_1, r_2, \theta) = u(r_1, r_2, \theta), \quad \textit{almost everywhere in } (r_1, r_2, \theta) \in \Omega, \tag{3.16}$$

$$|||\mathsf{E}u|||_{i,R^3} \le C|||u|||_{i,\Omega}, \quad i = 0, 1, \tag{3.17}$$

where C is a constant depending on Ω.

Proof. Let $B(0, 1)$ be the open unit ball in R^3. Since Ω is bounded and C^1-regular, there exist a finite number of bounded open sets $O_0, \ldots, O_M$ such that $O_0 \subset\subset \Omega$, $\partial\Omega \subset \cup_{i=1}^M O_i$, and $\Omega \subset \cup_{i=0}^M O_i$, and there exist $m + 1$ transforms $(\xi, \eta, \zeta) = \varphi_i(r_1, r_2, \theta)$ such that

$$\varphi_i(O_i) = B(0, 1), \quad \varphi_i(O_i \cap \partial\Omega) = \Sigma = B(0, 1) \cap \{\zeta = 0\},$$
$$\varphi_i(O_i \cap \Omega) = B^+(0, 1) = \{(\xi, \eta, \zeta) \in B(0, 1) \mid \zeta > 0\},$$
$$\varphi_i \in C^1(\overline{O_i \cap \partial\Omega}), \quad \varphi_i^{-1} \in C^1(\bar{\Sigma}).$$

For the convenience of notation, define $\mathbf{x} = (r_1, r_2, \theta)$ and $\hat{\mathbf{x}} = (\xi, \eta, \zeta)$. We choose a partition of unity $\{\alpha_i\}$ associated with $\{O_i\}$ satisfying

$$\alpha_i \in C_0^\infty(O_i),\ 0 \le \alpha_i \le 1,\ 0 \le i \le M, \qquad \sum_{i=0}^M \alpha_i(\mathbf{x}) = 1 \quad \forall \mathbf{x} \in \Omega.$$

(1): Proof for functions $u \in C^1(\bar{\Omega})$. Set $u_i = u\alpha_i$; then $u = \sum_{i=0}^M u_i$. Let

$$\begin{aligned} &\varrho(\mathbf{x}) = r_1^2 r_2^2 |\sin\theta|, && \varrho_i(\hat{\mathbf{x}}) = \varrho(\varphi_i^{-1}(\hat{\mathbf{x}})), \\ &\omega(\mathbf{x}) = (r_1^2 + r_2^2)|\sin\theta|, && \omega_i(\hat{\mathbf{x}}) = \omega(\varphi_i^{-1}(\hat{\mathbf{x}})), \\ &v_i(\hat{\mathbf{x}}) = u_i(\varphi_i^{-1}(\hat{\mathbf{x}})) = u_i(\mathbf{x}). \end{aligned} \tag{3.18}$$

For any $0 \le i \le M$, since $\frac{\partial v_i}{\partial \hat{\mathbf{x}}_k} = \sum_{l=1}^{3} \frac{\partial u_i}{\partial \mathbf{x}_l} \frac{\partial \mathbf{x}_l}{\partial \hat{\mathbf{x}}_k}$, $\frac{\partial u_i}{\partial \mathbf{x}_l} = \sum_{k=1}^{3} \frac{\partial v_i}{\partial \hat{\mathbf{x}}_k} \frac{\partial \hat{\mathbf{x}}_k}{\partial \mathbf{x}_l}$, there exists a constant C depending only on φ_i and φ_i^{-1} such that

$$\int_{B^+(0,1)} |v_i|^2 \varrho_i d\hat{\mathbf{x}} = \int_{\Omega \bigcap O_i} |u_i|^2 \varrho J_i d\mathbf{x} \le C \, |||u_i|||^2_{0,\Omega \bigcap O_i} , \tag{3.19}$$

$$\begin{aligned} \int_{B^+(0,1)} \left| \frac{\partial v_i}{\partial \hat{\mathbf{x}}_k} \right|^2 \omega_i d\hat{\mathbf{x}} &\le C \sum_{l=1}^{3} \int_{B^+(0,1)} \left| \frac{\partial u_i}{\partial \mathbf{x}_l} \right|^2 \left| \frac{\partial \mathbf{x}_l}{\partial \hat{\mathbf{x}}_k} \right|^2 \omega_i d\hat{\mathbf{x}} \\ &\le C \sum_{l=1}^{3} \left| \left| \left| \frac{\partial u_i}{\partial \mathbf{x}_l} \right| \right| \right|^2_{0,\Omega \bigcap O_i} , \end{aligned} \tag{3.20}$$

where $J_i = \det(\frac{\partial \varphi_i}{\partial \mathbf{x}})$ is the Jacobian determinant. Similarly, we have

$$|||u_i|||^2_{0,\Omega \bigcap O_i} \le C \int_{B^+(0,1)} |v_i|^2 \varrho_i d\hat{\mathbf{x}}, \tag{3.21}$$

$$\left| \left| \left| \frac{\partial u_i}{\partial \mathbf{x}_l} \right| \right| \right|^2_{0,\Omega \bigcap O_i} \le C \sum_{k=1}^{3} \int_{B^+(0,1)} \left| \frac{\partial v_i}{\partial \hat{\mathbf{x}}_k} \right|^2 \omega_i d\hat{\mathbf{x}}. \tag{3.22}$$

We expand u_0 by zero to the exterior of O_0 and denote the extension as $\tilde{u}_0$; then $\tilde{u}_0 \in C_0^1(R^3)$. We expand $v_i(\hat{\mathbf{x}})$ as follows:

$$\tilde{v}_i(\hat{\mathbf{x}}) = \begin{cases} v_i(\hat{\mathbf{x}}), & \hat{\mathbf{x}} \in B^+(0,1) \cup \Sigma, \\ 4v_i(\xi, \eta, -\frac{1}{2}\zeta) - 3v_i(\xi, \eta, -\zeta), & \hat{\mathbf{x}} \in B^-(0,1), \end{cases} \tag{3.23}$$

where $B^-(0,1) = \{\hat{\mathbf{x}} \in B(0,1) \,|\, \zeta < 0\}$. Obviously, $\tilde{v}_i \in C^1(B^+(0,1) \cup B^-(0,1))$. For any multiple index $\alpha \in \{(0,0,0), (1,0,0), (0,1,0), (0,0,1)\}$ and $\hat{\mathbf{x}}^0 \in \Sigma$, we have

$$\lim_{\substack{\hat{\mathbf{x}} \in B^+(0,1) \\ \hat{\mathbf{x}} \to \hat{\mathbf{x}}^0}} D^\alpha \tilde{v}_i(\hat{\mathbf{x}}) = D^\alpha v_i(\hat{\mathbf{x}}^0),$$

$$\begin{aligned} \lim_{\substack{\hat{\mathbf{x}} \in B^-(0,1) \\ \hat{\mathbf{x}} \to \hat{\mathbf{x}}^0}} D^\alpha \tilde{v}_i(\hat{\mathbf{x}}) &= \lim_{\substack{\hat{\mathbf{x}} \in B^-(0,1) \\ \hat{\mathbf{x}} \to \hat{\mathbf{x}}^0}} \left[4\left(-\frac{1}{2}\right)^{\alpha_3} D^\alpha v_i\left(\xi, \eta, -\frac{1}{2}\zeta\right) + 3(-1)^{\alpha_3+1} D^\alpha v_i(\xi, \eta, -\zeta) \right] \\ &= D^\alpha v_i(\hat{\mathbf{x}}^0). \end{aligned}$$

Thus $\tilde{u}_i(\mathbf{x}) = \tilde{v}_i(\varphi_i(\mathbf{x})) \in C_0^1(O_i)$. Expand $\tilde{u}_i$ by zero to the exterior of O_i and denote the extension by $\tilde{u}_i$ too; then $\tilde{u}_i \in C_0^1(R^3)$. Define $\mathsf{E}u = \sum_{i=0}^{M} \tilde{u}_i$; then $(\mathsf{E}u)(\mathbf{x}) = \sum_{i=0}^{M} u_i(\mathbf{x}) = u(\mathbf{x})$ $\forall \mathbf{x} \in \Omega$. Combing (3.19)–(3.23) yields (3.16) and (3.17).

(2): Proof for functions $u \in H(\Omega)$. Let $\hat{\Omega}$ be defined as in (3.9). In view of

$$\|u\|^2_{i,r,\Omega} = \frac{1}{8\pi^2} \|u\|^2_{i,\hat{\Omega}},$$

we have $H_r^i(\Omega) \hookrightarrow H^i(\hat{\Omega})$, $i = 0, 1$, in the sense of isomorphism. Since $C^1(\overline{\hat{\Omega}})$ is dense in $H^i(\hat{\Omega})$, for any $v(r_1, r_2, \theta) \in H_r^i(\Omega) \hookrightarrow H^i(\hat{\Omega})$ there exists $\{v_n(r_1, r_2, \theta)\} \subset C^1(\overline{\hat{\Omega}})$ such that $v_n(r_1, r_2, \theta)$ converge to $v(r_1, r_2, \theta)$ in $H^i(\hat{\Omega})$, and hence in $H_r^i(\Omega)$, $i = 0, 1$. Since $\frac{\partial v_n}{\partial \xi} = \sum_{i=1}^{6} \frac{\partial v_n}{\partial x_i} \frac{\partial x_i}{\partial \xi}$, $\frac{\partial v_n}{\partial x_i}$, and $\frac{\partial x_i}{\partial \xi}$ are continuous and bounded, we

have $v_n(r_1, r_2, \theta) \in C^1(\bar{\Omega})$, where $\xi = r_1, r_2, \theta, \theta', \phi, \phi'$. Thus $C^1(\bar{\Omega})$ is dense in $H_r^i(\Omega)$, $i = 0, 1$.

Since $\Omega \subset X$, $C^1(\bar{\Omega})$ is dense in $H(\Omega)$ in view of $H(\Omega) \hookrightarrow H_r^1(\Omega)$. There exists a sequence $\{u_n\} \subset C^1(\bar{\Omega})$ converging to u in $H(\Omega)$. By (3.18), $\{\mathsf{E}u_n\}$ is a Cauchy sequence in $H(R^3)$ and hence converges to some $w \in H(R^3)$. Set $\mathsf{E}u = w$. Since $|||u_n - \mathsf{E}u|||_{i,\Omega} = |||\mathsf{E}u_n - \mathsf{E}u|||_{i,\Omega} \to 0$, we have $\mathsf{E}u = u$, a.e. in Ω. Furthermore,

$$|||\mathsf{E}u|||_{i,R^3} = \lim_{n\to\infty} |||\mathsf{E}u_n|||_{i,R^3} \le C \lim_{n\to\infty} |||u_n|||_{i,\Omega} = C|||u|||_{i,\Omega}, \quad i = 0, 1.$$

The proof is complete. □

We define $\Omega_{r_1,\theta}$ as the projection of Ω onto the $r_1-\theta$ plane. For any $(r_1, \theta) \in \Omega_{r_1,\theta}$, define

$$\Omega_{r_2}(r_1, \theta) = \{r_2 \mid (r_1, r_2, \theta) \in \Omega\}.$$

$\Omega_{r_2,\theta}$ and $\Omega_{r_1}(r_2, \theta)$ are defined in the same way.

THEOREM 3.5. *Let $\Omega \subset X$ be a bounded domain satisfying one of the following two conditions:*

(a) *Ω is C^1-regular;*

(b) *The boundary $\partial\Omega$ is Lipschitz continuous, and there exists a constant $d > 0$ such that, for almost every $(r_2, \theta) \in \Omega_{r_2,\theta}$ (respectively, $(r_1, \theta) \in \Omega_{r_1,\theta}$), if $\Omega_r \subset \Omega_{r_1}(r_2, \theta)$ (respectively, $\Omega_{r_2}(r_1, \theta)$) is a maximal simply connected set, then meas$(\Omega_r) \ge d$.*

Furthermore, we assume that there are $f_1, f_2, \ldots, f_M \in (H_r^m(\Omega))'$ satisfying

$$\forall p \in P_{m-1}(\Omega), \quad \sum_{i=1}^{M} f_i(p) = 0 \Longleftrightarrow p = 0. \tag{3.24}$$

Then there exists a constant $C(\Omega)$ such that

$$\|v\|_{m,r,\Omega} \le C(\Omega) \left\{ |v|_{m,r,\Omega} + \left| \sum_{i=1}^{M} f_i(v) \right| \right\} \quad \forall v \in H_r^m(\Omega),\ m = 1, 2. \tag{3.25}$$

Proof. (1) In view of (3.7), we can prove (3.25) in the case of $m = 1$ by the argument of Theorem 3.1.1 in [9, p. 115].

(2) Proof of (3.25) in the case of $m = 2$. If (3.25) were false, then for any integer $n > 0$ there should exist $v_n \in H_r^2(\Omega)$ such that $\|v_n\|_{2,r,\Omega} = 1$ and

$$|v_n|_{2,r,\Omega} + \left| \sum_{i=1}^{M} f_i(v_n) \right| < \frac{1}{n}. \tag{3.26}$$

In view of Theorem 3.4, the definition of $\|\cdot\|_{2,r,\Omega}$, and (3.25) for $m = 1$, there exists a subsequence of $\{v_n\}$ (also denoted as $\{v_n\}$), which is a Cauchy sequence under the following measures:

$$\begin{cases} \|\cdot\|_{0,r,\Omega}, \quad \left\| \dfrac{\partial \cdot}{\partial\theta} \right\|_{0,r,\Omega}, \quad \left\| \dfrac{\partial \cdot}{\partial r_i} \right\|_{0,r,\Omega}, \quad i = 1, 2, \\ \left\{ \displaystyle\int_\Omega \left[\left(\frac{\partial^2 \cdot}{\partial r_1 \partial\theta} \right)^2 + \left(\frac{\partial^2 \cdot}{\partial r_2 \partial\theta} \right)^2 + \left(\frac{\partial^2 \cdot}{\partial\theta^2} \right)^2 \right] (r_1^2 + r_2^2) \sin\theta dr_1 dr_2 d\theta \right\}^{1/2}. \end{cases} \tag{3.27}$$

(i) Suppose that Ω satisfies the condition (a). We set $u_n = \frac{\partial v_n}{\partial \theta}$; then $u_n \in H(\Omega)$. Choose $R > 0$ to be sufficiently large such that $\Omega \subset [0, R] \times [0, R] \times [0, \pi]$. By Lemma 3.3 and Theorem 3.4, we have

$$\int_{\Omega_{r_2}(r_1,\theta)} \left(\frac{\partial v_n}{\partial \theta}\right)^2 r_1^2 \sin\theta dr_2 \le \int_0^R (\mathsf{E}u_n)^2 r_1^2 \sin\theta dr_2$$
$$\le C\left\{\int_0^R (\mathsf{E}u_n)^2 r_1^2 r_2^2 \sin\theta dr_2 + \int_0^R \left(\frac{\partial \mathsf{E}u_n}{\partial r_2}\right)^2 r_1^2 \sin\theta dr_2\right\} \quad \forall (r_1, \theta) \in \Omega_{r_1,\theta},$$

where C depends on R. By Lemma 3.3, integrating both sides of the above inequality over $\Omega_{r_1,\theta}$ produces

$$\int_\Omega \left(\frac{\partial v_n}{\partial \theta}\right)^2 r_1^2 \sin\theta dr_1 dr_2 d\theta \le C \sum_{i=0}^{1} |||\mathsf{E}u_n|||^2_{i,[0,R]\times[0,R]\times[0,\pi]} \le C \sum_{i=0}^{1} |||u_n|||^2_{i,\Omega}. \tag{3.28}$$

Thus $\{v_n\}$ is a Cauchy sequence under $[\int_\Omega (\frac{\partial \cdot}{\partial \theta})^2 r_1^2 \sin\theta dr_1 dr_2 d\theta]^{1/2}$. Similarly, $\{v_n\}$ is a Cauchy sequence under $[\int_\Omega (\frac{\partial \cdot}{\partial \theta})^2 r_2^2 \sin\theta dr_1 dr_2 d\theta]^{1/2}$. Consequently, $\{v_n\}$ is a Cauchy sequence in $H_r^1(\Omega)$ by (3.27), and so in $H_r^2(\Omega)$ by (3.26). Suppose $v_n \to v \in H_r^2(\Omega)$; then $|v|_{2,r,\Omega} = 0$ and $\sum_{i=1}^M f_i(v) = 0$ by (3.26). Thus $v \in P_1(\Omega)$, and $v = 0$ by (3.24). Therefore, $v = 0$ contradicts the following identities: $\|v\|_{2,r,\Omega} = \lim_{n\to\infty} \|v_n\|_{2,r,\Omega} = 1$. Thus (3.25) is true for $m = 2$.

(ii) Suppose that Ω satisfies the condition (b). Without loss of generality, we may suppose that $\Omega_{r_2}(r_1, \theta)$ is simply connected for any $(r_1, \theta) \in \Omega_{r_1,\theta}$. By Lemma 3.3, we have

$$\int_{\Omega_{r_2}(r_1,\theta)} \left(\frac{\partial v_n}{\partial \theta}\right)^2 r_1^2 \sin\theta dr_2 \le C \int_{\Omega_{r_2}(r_1,\theta)} \left[\left(\frac{\partial v_n}{\partial \theta}\right)^2 r_2^2 + \left(\frac{\partial^2 v_n}{\partial r_2 \partial \theta}\right)^2\right] r_1^2 \sin\theta dr_2$$

$\forall (r_1, \theta) \in \Omega_{r_1,\theta}$, where C depends on d but is independent of (r_1, θ). Thus we can get (3.25) by the argument of (i). □

Remark 3.6. Assume that Ω satisfies the conditions in Theorem 3.5. Define

$$|\Omega| = \int_\Omega r_1^2 r_2^2 \sin\theta dr_1 dr_2 d\theta, \quad f(v) = \frac{1}{|\Omega|} \int_\Omega v r_1^2 r_2^2 \sin\theta dr_1 dr_2 d\theta.$$

By Hölder's inequality, we have $|f(v)| \le |\Omega|^{-2} \|v\|_{0,r,\Omega}$. Thus $f \in (H_r^1(\Omega))'$. Now (3.26) implies

$$\|v - f(v)\|_{1,r,\Omega} \le |v|_{1,r,\Omega} \quad \forall v \in H_r^1(\Omega). \tag{3.29}$$

Remark 3.7. Assume $R > 0$ and $\Omega = [0, R] \times [0, R] \times [0, \pi]$. Define

$$H_{0r}^1(\Omega) = \{v \in H_r^1(\Omega) |\ v|_{r_1=R} = v|_{r_2=R} = 0\}.$$

Then we have $H_{0r}^1(\Omega) \hookrightarrow H_0^1(\hat{\Omega})$ in the sense of isomorphism, and, by Poincáre's inequality,

$$\|v\|_{1,r,\Omega} = \frac{\sqrt{2}}{4\pi} \|v\|_{1,\hat{\Omega}} \le C(\Omega)|v|_{1,\hat{\Omega}} = \sqrt{8}\pi C(\Omega)|v|_{1,r,\Omega}. \tag{3.30}$$

Equations (3.29) and (3.30) are the so-called Friedrichs-type inequality and Poincáre-type inequality, respectively.

THEOREM 3.8. *Let $\Omega \subset X$ be the domain in Theorem 3.5 and $T: H_r^k(\Omega) \to H_r^m(\Omega)$ be a linear and continuous mapping satisfying*

$$Tp = p \quad \forall p \in P_{k-1}(\Omega). \tag{3.31}$$

Then there exists a constant $C(\Omega)$ such that

$$\|u - Tu\|_{m,r,\Omega} \le C(\Omega)|u|_{k,r,\Omega} \quad \forall u \in H_r^k(\Omega), \tag{3.32}$$

where $0 \le m \le 2$, $1 \le k \le 2$, $m \le k$.

Proof. (3.32) can be proved by virtue of Theorem 3.5 and the argument of Theorem 3.1.4 in [9, p. 121]. □

4. Local regularization operator. Because we cannot say that the solutions of (2.13) and (5.1) are continuous, difficulties appear in proving the convergency of the finite element scheme. The technique of local regularization (Clément's interpolation [11]) will be used. Thus we are in the position of describing the construction of the three-dimensional local regularization operator.

Set $R > 0$ be large enough, and define

$$\begin{aligned}
&\Omega = [0,R] \times [0,R] \times [0,\pi], && \partial\Omega = \{(r_1,r_2,\theta) \in \Omega |\ r_1 = R \text{ or } r_2 = R\},\\
&\Gamma_1 = \{(r_1,r_2,\theta) \in \partial\Omega \,|\, r_1 = 0\}, && \Gamma_2 = \{(r_1,r_2,\theta) \in \partial\Omega \,|\, r_2 = 0\},\\
&\Gamma_3 = \{(r_1,r_2,\theta) \in \partial\Omega \,|\, \theta = 0\}, && \Gamma_4 = \{(r_1,r_2,\theta) \in \partial\Omega \,|\, \theta = \pi\}.
\end{aligned}$$

Suppose that $\mathcal{T}_h$ is a regular subdivision of Ω. Each element in $\mathcal{T}_h$ is a cuboid. (We can also obtain similar results for regular hexahedrons, but the analysis is very tedious.) h is the maximal diameter of all elements. The regularity of K means that there exists a constant σ independent of K such that $\forall K \in \mathcal{T}_h$, $h_K \le \sigma|e|$; here h_K is the diameter of K, e is any edge of K. Denote all nodes of $\bar{\Omega}$ by $A_1, A_2, \ldots, A_I$, and define $\triangle_i = \cup_{K \in \mathcal{T}_h, A_i \in K} K$ as the macro element associated with the node A_i.

$$Q_k(K) = \left\{ p \,|\, p = \sum_{l,m,n=0}^{k} \alpha_{lmn} r_1^l r_2^m \theta^n,\ (r_1,r_2,\theta) \in K \right\}.$$

Since the behaviors of the weights (see (3.18)) on an inner element differ from those on a boundary element, different kinds of elements or macro elements must be affine equivalent to different reference elements or macro elements, respectively. Each macro element must be one of the following four cases:

1. An element in $\mathcal{T}_h$. Let $l_{10} = [0,1]$, $l_{11} = [1,2]$; its affine equivalent reference macro element must be one of $l_{1i} \times l_{1j} \times l_{1k}$, $0 \le i,j,k \le 1$.
2. The combination of two elements with a common face. Let $l_{20} = [0,2]$, $l_{21} = [1,3]$; its affine equivalent reference macro element must be one of $l_{2i} \times l_{1j} \times l_{1k}$, $l_{1i} \times l_{2j} \times l_{1k}$, or $l_{1i} \times l_{1j} \times l_{2k}$, $0 \le i,j,k \le 1$.
3. The combination of four elements with a common edge. Its affine equivalent reference macro element must be one of $l_{1i} \times l_{2j} \times l_{2k}$, $l_{2i} \times l_{1j} \times l_{2k}$, or $l_{2i} \times l_{2j} \times l_{1k}$, $0 \le i,j,k \le 1$.
4. The combination of eight elements with a common vertex. Its affine equivalent reference macro element must be one of $l_{2i} \times l_{2j} \times l_{2k}$, $0 \le i,j,k \le 1$.

Each reference element is a cube with unit volume and is included in some reference macro element. Clearly, the total number of reference elements and reference macro elements is finite.

Suppose $h_\Delta < \sigma h_K$, for any $K \subset \Delta$, where h_Δ is the diameter of Δ. For any $K \in \mathcal{T}_h$, $F_K : \hat{K} \to K$ is the affine transform from some reference element $\hat{K}$ to K. For any macro element Δ, assume that $\hat{\Delta} = \cup_{K\subset\Delta} F_K^{-1}(K)$ is a macro reference element defined in cases $1, 2, 3$, or 4. Define F_Δ: $F_\Delta|_K = F_K$ and F_Δ^{-1}: $F_\Delta^{-1}|_{\hat{K}} = F_K^{-1}$, with $F_K(\hat{K}) = K$.

If v is a function defined on Δ and $\hat{u}$ is defined on $\hat{\Delta}$, denote $\hat{v} := v \circ F_\Delta$ and $u := \hat{u} \circ F_\Delta^{-1}$, respectively. Without ambiguity, we also use piecewise-defined norms on macro elements:

$$|\hat{v}|^2_{m,r,\hat{\Delta}} = \sum_{\hat{K}\subset\hat{\Delta}} |v \circ F_\Delta|^2_{m,r,\hat{K}}, \qquad |u|^2_{m,r,\Delta} = \sum_{K\subset\Delta} |\hat{u} \circ F_\Delta^{-1}|^2_{m,r,K}. \tag{4.1}$$

In view of (4.1), it is easy to prove $v \in H_r^m(\Delta) \Longleftrightarrow \hat{v} \in H_r^m(\hat{\Delta})$, $m = 0, 1, 2$.

We define the H_r^0-projection $\mathcal{P}_{\hat{\Delta}} : H_r^0(\hat{\Delta}) \to P_k(\hat{\Delta})$ as follows: $\forall v \in H_r^0(\hat{\Delta})$,

$$(\mathcal{P}_{\hat{\Delta}} v, p)_0 = (v, p)_0 \quad \forall p \in P_k(\hat{\Delta}). \tag{4.2}$$

Since the weights vanish on some boundary elements $K \cap (\cup_{i=1}^4 \Gamma_i) \neq \emptyset$, we need to deal with their transformations under the affine transforms by detailed analysis. To do so, we first need the following estimate for the transformation of $\sin\theta$. Define

$$\Lambda(\theta, h) = \begin{cases} 1, & \pi/2 - h \le \theta \le \pi/2, \\ \sin\theta, & \theta \ge \pi/2, \\ \sin(\theta + h), & \theta \le \pi/2 - h. \end{cases} \tag{4.3}$$

LEMMA 4.1. *Let $\sigma > 0$ be a constant, $h_1, h_2 \le h \le \sigma \min\{h_1, h_2\}$, $\theta \ge h_1$, and $\theta + h_1 + h_2 + h/\sigma \le \pi$. When h is sufficiently small, there exists a constant C independent of h and θ such that*

$$\Lambda(\theta, h_1) \cdot \max\left\{\frac{1}{\sin\theta}, \frac{1}{\sin(\theta + h_1)}, \frac{1}{\sin(\theta + h_1 + h_2)}\right\} \le C. \tag{4.4}$$

Proof. Let $M = \max\{1/\sin\theta, 1/\sin(\theta + h_1), 1/\sin(\theta + h_1 + h_2)\}$. We consider (4.4) in three cases:

1. When $\pi/2 - h_1 - h_2 \le \theta \le \pi/2$, $\Lambda \cdot M \le M$, since h is small enough, (4.4) is true obviously.
2. When $\theta \ge \pi/2$, it is clear that

$$\Lambda M \le \frac{\sin\theta}{\sin(\theta + h_1 + h_2)} = \frac{\sin(\pi - \theta)}{\sin(\pi - \theta - h_1 - h_2)}.$$

   If $\theta \le \pi - 2(h_1 + h_2)$, then

$$\Lambda M \le \frac{\sin(\pi - \theta)}{\sin((\pi - \theta)/2)} \le 2.$$

   If $\theta \ge \pi - 2(h_1 + h_2)$, we need only to choose h such that $2\sin(h/\sigma) \ge h/\sigma$; then

$$\Lambda M \le \frac{\sin 2(h_1 + h_2)}{\sin(h/\sigma)} \le \frac{4h}{h/(2\sigma)} \le \frac{8}{\sigma}.$$

3. When $\theta \le \pi/2 - h_1 - h_2$, $\Lambda M \le \frac{\sin(\theta + h_1)}{\sin\theta} \le \frac{\sin 2\theta}{\sin\theta} \le 2$.

The proof is complete. ∎

THEOREM 4.2. *Suppose that $\Delta = F_\Delta(\hat{\Delta})$ is a macro element associated with some node of $\mathcal{T}_h$, $u \in H_r^m(\Delta)$. Define $\mathcal{P}_\Delta u = (\mathcal{P}_{\hat{\Delta}}\hat{u}) \circ F_\Delta^{-1}$. Then*

$$|u - \mathcal{P}_\Delta u|_{l,r,\Delta} \le C h_\Delta^{m-l} |u|_{m,r,\Delta}, \quad 0 \le l \le m \le 2, \tag{4.5}$$

where C is a constant independent of h.

Proof. For the sake of simplicity, without loss of generality, we may suppose $\Delta = \cup_{i=1}^4 K_i$ and analyze K_i in two representative cases.

(1) $K_1, \dots, K_4$ are boundary elements where the weights degenerate. Suppose h_Δ is small enough and

$$\begin{aligned} K_1 &= [0,h_1]\times[0,h_2]\times[0,h_3], & K_2 &= [0,h_1]\times[0,h_2]\times[h_3,h_3+h_3^{K_2}],\\ K_3 &= [0,h_1]\times[h_2,h_2+h_2^{K_3}]\times[0,h_3], & K_4 &= [0,h_1]\times[h_2,h_2+h_2^{K_3}]\times[h_3,h_3+h_3^{K_2}]. \end{aligned}$$

The reference macro element and reference elements are defined as

$$\hat{\Delta} = [0,1]\times[0,2]\times[0,2], \quad \hat{K}_1 = [0,1]\times[0,1]\times[0,1],$$
$$\hat{K}_2 = [0,1]\times[0,1]\times[1,2], \quad \hat{K}_3 = [0,1]\times[1,2]\times[0,1], \quad \hat{K}_4 = [0,1]\times[1,2]\times[1,2].$$

On any finite-dimensional space, all norms are equivalent, and so we have

$$\|\mathcal{P}_{\hat{\Delta}}\hat{u}\|_{i,r,\hat{\Delta}}^2 \le C\|\mathcal{P}_{\hat{\Delta}}\hat{u}\|_{0,r,\hat{\Delta}}^2 \le C\|\hat{u}\|_{0,r,\hat{\Delta}}^2. \tag{4.6}$$

Hence the projection $\mathcal{P}_{\hat{\Delta}}$ is stable on $\|\cdot\|_{i,r,\hat{\Delta}}$, $i = 1, 2$. By (4.2) and Theorem 3.8, we have

$$\begin{aligned} \|u - \mathcal{P}_\Delta u\|_{0,r,K_1}^2 &\le h_1^3 h_2^3 h_3 \int_{\hat{K}_1} |\hat{u} - \mathcal{P}_{\hat{\Delta}}\hat{u}|^2 \xi^2 \eta^2 \sin(h_3\zeta) d\xi d\eta d\zeta \\ &\le \max\{2, 1/\sin\zeta_0\} h_1^3 h_2^3 h_3^2 \|\hat{u} - \mathcal{P}_{\hat{\Delta}}\hat{u}\|_{0,r,\hat{K}_1}^2 \\ &\le C h_\Delta^8 |\hat{u}|_{m,r,\hat{\Delta}}^2, \qquad m = 1, 2, \end{aligned} \tag{4.7}$$

where $\zeta_0 \in (0,1)$ satisfies $\zeta_0 \le 2\sin\zeta_0$. Similarly, we have

$$\begin{aligned} \|u - \mathcal{P}_\Delta u\|_{0,r,K_4}^2 &\le h_1^3 h_2^{K_3} h_3^{K_2} (h_2 + h_2^{K_3})^2 \Lambda(h_3, h_3^{K_2}) \int_{\hat{K}_4} |\hat{u} - \mathcal{P}_{\hat{\Delta}}\hat{u}|^2 \xi^2 d\xi d\eta d\zeta \\ &\le C h_1^3 h_2^{K_3} h_3^{K_2} (h_2 + h_2^{K_3})^2 \Lambda(h_3, h_3^{K_2}) \|\hat{u} - \mathcal{P}_{\hat{\Delta}}\hat{u}\|_{0,r,\hat{K}_1}^2 \\ &\le C h_\Delta^8 |\hat{u}|_{m,r,\hat{\Delta}}^2, \quad m = 1, 2; \end{aligned} \tag{4.8}$$

$$\|u - \mathcal{P}_\Delta u\|_{0,r,K_2\cup K_3}^2 \le C h_\Delta^8 |\hat{u}|_{m,r,\hat{\Delta}}^2, \quad m = 1, 2, \tag{4.9}$$

$$|u - \mathcal{P}_\Delta u|_{1,r,\Delta}^2 \le C h_\Delta^6 |\hat{u}|_{m,r,\hat{\Delta}}^2, \quad m = 1, 2. \tag{4.10}$$

Set h_Δ small enough such that $h_\Delta < \sin(2h_\Delta)$; by detailed analysis similar to (4.7) and (4.8), we have

$$|\hat{u}|_{m,r,\hat{\Delta}}^2 \le C h_\Delta^{2m-8} |u|_{m,r,\Delta}^2, \quad m = 1, 2, \tag{4.11}$$

where C depends only on R and σ. Combining (4.7)–(4.11) yields (4.5).

(2) $K_1, \ldots, K_4$ are inner elements where the weights are strictly positive:

$$
\begin{aligned}
K_1 &= [r_{10}, r_{10}+h_1] \times [r_{20}, r_{20}+h_2] \times [\theta_0, \theta_0+h_3],\\
K_2 &= [r_{10}, r_{10}+h_1] \times [r_{20}+h_2, r_{20}+h_2+h_2^{K_2}] \times [\theta_0, \theta_0+h_3],\\
K_3 &= [r_{10}, r_{10}+h_1] \times [r_{20}, r_{20}+h_2] \times [\theta_0+h_3, \theta_0+h_3+h_3^{K_3}],\\
K_4 &= [r_{10}, r_{10}+h_1] \times [r_{20}+h_2, r_{20}+h_2+h_2^{K_2}] \times [\theta_0+h_3, \theta_0+h_3+h_3^{K_3}],
\end{aligned}
$$

where $r_{10}, r_{20}, \theta_0 \geq \sigma h_\Delta$. The reference macro element and reference elements are defined as

$$
\hat{\Delta} = [1,2] \times [1,3] \times [1,3], \quad \hat{K}_1 = [1,2] \times [1,2] \times [1,2],
$$
$$
\hat{K}_2 = [1,2] \times [2,3] \times [1,2], \quad \hat{K}_3 = [1,2] \times [1,2] \times [2,3], \quad \hat{K}_4 = [1,2] \times [2,3] \times [2,3].
$$

Then for $m = 1, 2$, by affine transforms, there exists a generic constant C independent of h, such that

$$
\begin{aligned}
\|u - \mathcal{P}_\Delta u\|^2_{0,r,K_1} &\leq C h_1 h_2 h_3 \Lambda(\theta_0, h_3)(r_{10}+h_1)^2 (r_{20}+h_2)^2 \|\hat{u} - \mathcal{P}_{\hat{\Delta}} \hat{u}\|^2_{0,\hat{K}_1}\\
&\leq C h_1 h_2 h_3 \Lambda(\theta_0, h_3)(r_{10}+h_1)^2 (r_{20}+h_2)^2 \|\hat{u} - \mathcal{P}_{\hat{\Delta}} \hat{u}\|^2_{0,r,\hat{K}_1}\\
&\leq C h_\Delta^3 (r_{10}+h_\Delta)^2 (r_{20}+h_\Delta)^2 \Lambda(\theta_0, h_3) |\hat{u}|^2_{m,r,\hat{\Delta}}.
\end{aligned} \tag{4.12}
$$

Similarly, for $i = 2, 3, 4$ we have

$$
\begin{aligned}
\|u - \mathcal{P}_\Delta u\|^2_{0,r,K_i} &\leq C h_\Delta^3 (r_{10}+h_\Delta)^2 (r_{20}+h_\Delta)^2\\
&\quad \times [\Lambda(\theta_0, h_3) + \Lambda(\theta_0+h_3, h_3+h_3^{K_3})] |\hat{u}|^2_{m,r,\hat{\Delta}},
\end{aligned} \tag{4.13}
$$

$$
\begin{aligned}
|u - \mathcal{P}_\Delta u|^2_{1,r,\Delta} &\leq C h_\Delta (r_{10}+h_\Delta)^2 (r_{20}+h_\Delta)^2\\
&\quad \times [\Lambda(\theta_0, h_3) + \Lambda(\theta_0+h_3, h_3+h_3^{K_3})] |\hat{u}|^2_{m,r,\hat{\Delta}}.
\end{aligned} \tag{4.14}
$$

Set h_Δ small enough such that $h_\Delta < \sin(2h_\Delta)$; by affine transforms and detailed analysis similar to (4.13), we have

$$
\begin{aligned}
|\hat{u}|^2_{m,r,\hat{\Delta}} &\leq C \max\left\{1/\sin\theta_0, 1/\sin(\theta_0+h_3), 1/\sin(\theta_0+h_3+h_3^{K_3})\right\}\\
&\quad \times r_{10}^{-2} (r_{20}+h_2)^{-2} h_\Delta^{2m-3} |u|^2_{m,r,\Delta}.
\end{aligned} \tag{4.15}
$$

Combining (4.12)–(4.15), we obtain (4.5) by Lemma 4.1.

We can prove (4.5) for other macro elements similarly. □

5. Finite element approximations. The equivalent weak form of (3.6) is the following: Find $(\lambda, u) \in R^1 \times H^1_{0r}(\Omega)$ and $u \neq 0$ such that

$$
a_r(u, v) = \lambda\,(u, v)_0 \quad \forall v \in H^1_{0r}(\Omega), \tag{5.1}
$$

where $\lambda = K + E$, K is the constant in (2.10), and

$$
\begin{aligned}
a_r(u, v) = \int_\Omega \Bigg[& r_1^2 r_2^2 \left(\frac{\partial u}{\partial r_1}\frac{\partial v}{\partial r_1} + \frac{\partial u}{\partial r_2}\frac{\partial v}{\partial r_2} \right) + (r_1^2 + r_2^2) \frac{\partial u}{\partial \theta}\frac{\partial v}{\partial \theta}\\
& + \left(\frac{2 r_1^2 r_2^2}{\sqrt{r_1^2 + r_2^2 - 2 r_1 r_2 \cos\theta}} - 4 r_1^2 r_2 - 4 r_1 r_2^2 \right) uv \Bigg] \sin\theta\, dr_1 dr_2 d\theta.
\end{aligned}
$$

Since $a(\cdot,\cdot)$ is continuous and coercive on $H_0^1(\hat{\Omega})$, where $\hat{\Omega}$ is defined as that in (3.9), we know that $a_r(\cdot,\cdot)$ is continuous and coercive on $H_{0r}^1(\Omega)$ by the proof of Lemma 3.1. We define $\|\cdot\|_{1,r,\Omega} = \sqrt{a_r(\cdot,\cdot)}$ for the sake of simplicity in notation.

We consider the Lagrangian finite element approximation to (5.1). For any $K \in \mathcal{T}_h$, denote the set of nodes in K as

$$\mathcal{V}(K) = \{8 \text{ vertices and } (k+1)^3 - 8 \ k\text{-section points of } K\}.$$

$\cup_{K\in\mathcal{T}_h}\mathcal{V}(K)$ is the set of nodes of $\mathcal{T}_h$. Define the finite element space as

$$V_h = \{v(r_1, r_2, \theta) \in C^0(\Omega) \mid v|_{\partial\Omega} = 0,\ v|_K \in Q_k(K)\ \forall K \in \Im_h\}.$$

The discrete approximation of (5.1) is the following: Find $(\lambda_h, u_h) \in R^1 \times V_h$ and $u_h \neq 0$ such that

$$a_r(u_h, v_h) = \lambda_h\,(u_h, v_h)_0 \quad \forall v_h \in V_h. \tag{5.2}$$

Obviously, $V_h \subset C^0(\Omega) \cap H_{0r}^1(\Omega)$, and so (5.2) is the Galerkin approximation of (5.1). We drop the subscript "B" in (2.13) (or (5.1)) and suppose that $0 < \lambda_1 \leq \lambda_2 \leq \cdots$ are the eigenvalues of (5.1), $0 < \lambda_{h1} \leq \lambda_{h2} \leq \cdots < \lambda_{N_h}$ are the eigenvalues of (5.2), $N_h = \dim(V_h)$. Denote the eigenspaces associated with λ_i and λ_{hj} as V_i and V_{hj}, respectively, $1 \leq i \leq \cdots$, $1 \leq j \leq N_h$. By the minmax theorem [10], $\lambda_i \leq \lambda_{hi}$, $1 \leq i \leq N_h$.

Let $\hat{\Delta}$ be a reference macro element and $\hat{K} \subset \hat{\Delta}$ be a reference element. Define

$$\mathcal{V}(\hat{K}) = \{a_i^{\hat{K}} \mid 1 \leq i \leq (k+1)^3\}$$

associated with a basis $\{\hat{\varphi}_i^{\hat{K}} \mid 1 \leq i \leq (k+1)^3\}$ of $Q_k(\hat{K})$. Assume

$$\hat{\varphi}_i^{\hat{K}}(a_j^{\hat{K}}) = \delta_{ij}, \quad 1 \leq i, j \leq (k+1)^3,$$

where $\delta_{ij} = 1$ if $i = j$, $\delta_{ij} = 0$ if $i \neq j$. For any $\hat{v} \in H_r^0(\hat{K})$, we define the finite element interpolation operator by means of the local regularization as follows:

$$\pi_{\hat{K}}\hat{v} = \sum_{i=1}^{(k+1)^3} (\mathcal{P}_{\hat{\Delta}}\hat{v})(a_i^{\hat{K}})\hat{\varphi}_i^{\hat{K}}. \tag{5.3}$$

Suppose $v \in H_r^0(\Omega)$. For any $K = F_K(\hat{K}) \in \mathcal{T}_h$, define the finite element interpolation operator on $\hat{\Delta}$, K, and Ω as follows: $\pi_{\hat{\Delta}}\hat{v}|_{\hat{K}} = \pi_{\hat{K}}\hat{v}$, $\pi_K v = (\pi_{\hat{K}}\hat{v}) \circ F_K^{-1}$, $\pi v|_K = \pi_K v$, where $\hat{K} \subset \hat{\Delta}$ is some reference element. On any space of finite dimension, all norms are equivalent. There exists a constant C such that

$$\|\pi_{\hat{K}}\hat{v}\|_{m,r,\hat{K}} \leq C\|\mathcal{P}_{\hat{\Delta}}\hat{v}\|_{0,\infty,\hat{K}} \leq C\|\mathcal{P}_{\hat{\Delta}}\hat{v}\|_{0,r,\hat{K}} \leq \|\hat{u}\|_{0,r,\hat{\Delta}}. \tag{5.4}$$

Thus the operator $\pi_{\hat{K}} : H_r^0(\hat{\Delta}) \to H_r^m(\hat{K})$ is linear and continuous, $m = 0, 1$.

THEOREM 5.1. *There exists a constant C independent of h such that for any $v \in H_r^2(\Omega)$,*

$$\|v - \pi v\|_{m,r,\Omega} \leq Ch^{2-m}|v|_{2,r,\Omega}, \quad m = 0, 1. \tag{5.5}$$

Proof. Suppose that $\hat{\Delta}$ is a reference macro element and $\hat{K} \subset \hat{\Delta}$ is a reference element. By the definition of the operators $\pi_{\hat{K}}$, $\pi_{\hat{\Delta}}$, and $\mathcal{P}_{\hat{\Delta}}$, we have

$$\pi_{\hat{\Delta}} p = p \quad \forall p \in P_k(\hat{\Delta}). \tag{5.6}$$

By (5.4), (5.6), and Theorem 3.8, for any $\hat{v} \in H_r^2(\hat{\Delta})$ we have

$$\|\hat{v} - \pi_{\hat{\Delta}} \hat{v}\|_{m,r,\hat{\Delta}} \leq C|\hat{v}|_{2,r,\hat{\Delta}}, \quad m = 0, 1. \tag{5.7}$$

For any macro element Δ, by affine transforms, (5.7), and the argument in the proof of Theorem 4.2, we know that there exists a constant C independent of h such that

$$\|v - \pi v\|_{m,r,\Delta} \leq C h_{\Delta}^{2-m} |v|_{2,r,\Delta}, \quad m = 0, 1. \tag{5.8}$$

Summing up each side of (5.8) over all macro elements, we get (5.5). □

THEOREM 5.2. *For any $1 \leq i \leq N_h$, suppose (λ_i, u_i) is an eigenpair of* (5.1) *with $\|u_i\|_{0,r,\Omega} = 1$. There exist a constant C independent of h and an eigenfunction $u_{hi} \in V_{hi}$ with $\|u_{hi}\|_{0,r,\Omega} = 1$ such that*

$$|\lambda_i - \lambda_{hi}| < Ch^2, \tag{5.9}$$

$$\|u_i - u_{hi}\|_{m,r,\Omega} < Ch^{2-m}, \quad m = 0, 1. \tag{5.10}$$

Proof. By the theory of abstract spectrum approximation (p. 699 of [10]), we know that, for any $1 \leq i \leq N_h$, there exists a constant C independent of h such that

$$|\lambda_i - \lambda_{hi}| < C\varepsilon(\lambda_i)^2, \tag{5.11}$$

where

$$\varepsilon(\lambda_i) = \sup_{v \in V_i, \|v\|_{1,r,\Omega}=1} \inf_{v_h \in V_h} \|v - v_h\|_{1,r,\Omega}. \tag{5.12}$$

Let $\{u_{ij},\ 1 \leq j \leq N_i\}$ be a basis of V_i, $\|u_{ij}\|_{1,r,\Omega} = 1$, $N_i = \dim V_i$. By Theorem 5.1, we have

$$\varepsilon(\lambda_i) \leq \sum_{j=1}^{N_i} \|u_{ij} - \pi u_{ij}\|_{1,r,\Omega} \leq Ch \sum_{j=1}^{N_i} |u_{ij}|_{2,r,\Omega} \leq Ch. \tag{5.13}$$

Thus (5.9) is true.

We can prove (5.10) by Theorem 5.2 and the argument of Theorem 6.2 in [32, p. 235], but we do not give the tedious description here. □

Remark 5.3. In real computation, we have introduced a variational equation equivalent to (5.1). Define $\mu = \cos\theta$; then $\Omega = [0, R] \times [0, R] \times [-1, 1]$, and the

corresponding bilinear form, inner products, and norms are

$$(u,v)_0 = \int_\Omega uvr_1^2r_2^2dr_1dr_2d\mu, \qquad \|u\|_{0,r,\Omega}^2 = \int_\Omega u^2r_1^2r_2^2dr_1dr_2d\mu,$$

$$(u,v)_1 = (u,v)_0 + \int_\Omega \left[r_1^2r_2^2\frac{\partial u}{\partial r_1}\frac{\partial v}{\partial r_1} + r_1^2r_2^2\frac{\partial u}{\partial r_2}\frac{\partial v}{\partial r_2} + (r_1^2+r_2^2)(1-\mu^2)\frac{\partial u}{\partial \mu}\frac{\partial v}{\partial \mu}\right] dr_1dr_2d\mu,$$

$$|u|_{1,r,\Omega}^2 = \int_\Omega \left[r_1^2r_2^2\left(\frac{\partial u}{\partial r_1}\right)^2 + r_1^2r_2^2\left(\frac{\partial u}{\partial r_2}\right)^2 + (r_1^2+r_2^2)(1-\mu^2)\left(\frac{\partial u}{\partial \mu}\right)^2\right] dr_1dr_2d\mu,$$

$$\|u\|_{1,r,\Omega}^2 = \|u\|_{0,r,\Omega}^2 + |u|_{1,r,\Omega}^2, \qquad H_r^i(\Omega) = \{v|\ \ \|v\|_{i,r,\Omega}^2 < +\infty\}, \quad i = 0,1,$$

$$a_r(u,v) = \int_\Omega \left[r_1^2r_2^2\left(\frac{\partial u}{\partial r_1}\frac{\partial v}{\partial r_1} + \frac{\partial u}{\partial r_2}\frac{\partial v}{\partial r_2}\right) + (r_1^2+r_2^2)(1-\mu^2)\frac{\partial u}{\partial \mu}\frac{\partial v}{\partial \mu} + \left(\frac{2r_1^2r_2^2}{\sqrt{r_1^2+r_2^2-2r_1r_2\mu}} - 4r_1^2r_2 - 4r_1r_2^2\right)uv\right] dr_1dr_2d\mu.$$

We define $H_{0r}^1(\Omega)$ as in Remark 3.7. A variational equation equivalent to (5.1) is the following: Find $(\lambda, u) \in R^1 \times H_{0r}^1(\Omega)$ and $u \neq 0$ such that

$$a_r(u,v) = \lambda\,(u,v)_0 \qquad \forall v \in H_{0r}^1(\Omega). \tag{5.14}$$

The partitions $\mathcal{T}_h$ for $\Omega = [0,R] \times [0,R] \times [-1,1]$ are similar to those in section 4. $\forall K \in \mathcal{T}_h$ define

$$Q_k(K) = \left\{ p \,\middle|\ p = \sum_{l,m,n=0}^{k} \alpha_{lmn} r_1^l r_2^m \mu^n,\ (r_1,r_2,\mu) \in K \right\}.$$

The finite element approximation to (5.14) is: Find $(\lambda_h, u_h) \in R^1 \times V_h$ and $u_h \neq 0$ such that

$$a_r(u_h,v_h) = \lambda_h\,(u_h,v_h)_0 \qquad \forall v \in V_h, \tag{5.15}$$

where

$$V_h = \{v(r_1,r_2,\mu) \in C(\Omega)|\ v|_K \in Q_k(K)\ \forall K \in \mathcal{T}_h;\ v|_{\partial\Omega} = 0\}$$

is the finite element space.

Comparing (5.15) with (5.2) in real computation, we have found that (5.15) gives more precise results with the same number of unknowns. The analysis for (5.15) will be the subject of our future research.

6. Numerical results. Since V_h is a finite-dimensional space, define $N = \dim(V_h)$. We can choose a basis $\{\Phi_1, \ldots, \Phi_N\}$ of V_h such that

$$\text{supp}\Phi_i = \cup_{K \in \Im_h, a_i \in \Sigma_K} K,$$

where a_i is a node of $\mathcal{T}_h$. Let $u_h = \sum_{i=1}^N \alpha_i\Phi_i$ and $v_h = \Phi_i$, $1 \le i \le N$, in (5.2) and (5.15). Then we obtain an equivalent generalized eigenvalue problem:

$$A\,X = \lambda_h\,M\,X, \tag{6.1}$$

where $X = (\alpha_1, \ldots, \alpha_N)^T$, $A = (a(\Phi_i, \Phi_j))_{N\times N}$, $M = ((\Phi_i, \Phi_j))_{N\times N}$.

We use the inverse iteration method [5] to solve the generalized eigenvalue problem (6.1). This method is convenient for computing the smallest (real) eigenvalue of an (unsymmetric) generalized eigenvalue problem with large and sparse matrices. In each step of iteration, the main computational cost is the solution of the following system of equations for Y:

$$AY = F. \tag{6.2}$$

However, in fact we need only solve (6.2) in the first step if using LU-factorization of A, since we can store the inverse matrix of A for all following steps.

The computational cost of (6.2) is of order $O(N^3)$ for a dense matrix. Since the finite element matrices are banded, and their band widths are bounded by some positive integer $M \ll N$, the cost of (6.2) is not more than $2MN^2$. Thus the first iteration of our eigenvalue solver needs $O(N^2)$ floating point operations, but each of the following iterations needs only $O(N)$ floating point operations. For the solution of large sparse generalized eigenvalue problems, improvements of this method have been developed rapidly. They devote themselves to reducing the cost of the first iteration; i.e., they solve (6.2) by efficient iterative methods instead of LU-factorization. Each iterative step of their eigenvalue solvers (such as *preconditioned inverse iteration* [26]) needs only $O(N)$ operations. For more detailed analyses, we refer to Neymeyr's excellent work [26], or to the journal articles [27], [28], [29] and references therein. We consider the improvement of our eigenvalue solver as future work.

We carried out our computation on a personal computer: Intel PIII750 with 1G SDRAM. The experiment shows that 1. the energy errors decrease with R or the number of nodes increasing; 2. with the considered state becoming more highly exited, R should be larger, and more nodes far from the nucleus are needed; 3. very large R makes no remarkable improvement in the precision.

The main error concerns the potential $V = -\frac{2}{r_1} - \frac{2}{r_2} + \frac{1}{r_{12}}$. For the triplet, the wave function is antisymmetric with respect to the two electrons, so they cannot be very close to each other. That is to say, when r_{12} is very small, the wave function u tends to zero. When we calculate $\int_\Omega \frac{u^2}{r_{12}} dr_1 dr_2 d\mu$ with a Gaussian integration formula [33], the error for the triplet is much smaller than that for the singlet with the same number of Gaussian points. Furthermore, from the figures below, we can see that the wave function $|u|$ of the ground state is much larger than that of excited states in the domain where r_{12} is small and in the neighborhood of the nucleus containing the singularities. Thus we have used more and more Gaussian points and grid points along the μ-direction, when the state varies from the triplet, the singlet to the ground state.

All matrix elements are computed by the standard Gaussian integration formula. With the number of Gaussian points increasing, the computing time becomes longer. Let N_e be the number of elements associated with some partition of Ω, N_g be the number of Gaussian points along one direction, and T_e be the CPU time to compute a pair of element matrices by the one-point Gaussian formula. The CPU time to obtain the global stiffness matrix and mass matrix is

$$T \approx N_e \times T_e \times N_g^3. \tag{6.3}$$

The number of degrees of freedom (DOF), number of Gaussian points (GPs), and the computational time T are listed in Table 6.1.

We place grid points symmetrically along r_1 and r_2 for all states. The grid points are (for r_1, r_2, μ)

1. $1s1s\ ^1S$:
   - 0.0, 0.05, 0.1, 0.15, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 1.0, 1.2, 1.6, 2.0, 2.6, 3.2, 4.2, 6.0, 9.0, 15.0;
   - -1.0, -0.6, -0.2, 0.2, 0.6, 1.0;
2. $1s2s\ ^1S$:
   - 0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 1.0, 1.2, 1.4, 1.6, 1.8, 2.0, 2.2, 2.4, 2.6, 3.0, 3.4, 3.8, 4.2, 4.8, 5.6, 8.0, 11.5, 15.0, 20.0;
   - -1.0, -0.5, 0.5, 1.0;
3. $1s2s\ ^3S$:
   - 0.0, 0.05, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0, 1.2, 1.4, 1.6, 1.8, 2.0, 2.2, 2.4, 2.6, 2.8, 3.0, 3.2, 3.4, 3.6, 4.0, 4.5, 5.5, 7.0, 10.0, 13.0, 16.0, 20.0, 25.0;
   - -1.0, 0.0, 1.0.

The relative error of our approximate eigenvalue for the ground ($1s1s$-) state is 10^{-7}a.u., and those for the $1s2s$-states are 10^{-8}a.u. by (5.15). The precisions of existing finite element eigenvalues are generally $10^{-4} - 10^{-6}$a.u. (see Table 6.2).

From the graphs of approximate wave functions (see Figures 6.1–6.2), we can get the following properties. 1. Although we add no physical assumptions to our computations a priori, such as the symmetry (for the singlets) and the antisymmetry (for the triplet), our approximate wave functions coincide with these properties very well. 2. Wave functions oscillate heavily in the neighborhood of the nucleus where the singularity of the Coulomb potential is very strange. This is well known by physicists and chemists. 3. In a sufficiently small neighborhood of the nucleus, absolute values $|u_h|$ of wave functions are very small. This implies that electrons seldom visit there. 4. With the distance between each electron and the nucleus increasing, wave functions decrease quickly. Thus it is reasonable to solve the Schrödinger equation in bounded domains.

TIME-SPACE DISCRETIZATION OF THE NONLINEAR HYPERBOLIC SYSTEM $u_{tt} = \operatorname{div}(\sigma(Du) + Du_t)$*

CARSTEN CARSTENSEN† AND GEORG DOLZMANN‡

Abstract. The numerical treatment of the hyperbolic system of nonlinear wave equations with linear viscosity, $u_{tt} = \operatorname{div}(\sigma(Du) + Du_t)$, is studied for a large class of globally Lipschitz continuous functions σ, including nonmonotone stress-strain relations. The analyzed method combines an implicit Euler scheme in time with Courant (continuous and piecewise affine) finite elements in space for a class of varying time steps with varying meshes. Explicit a priori error bounds in $L^\infty(L^2)$, $L^2(W^{1,2})$, and $W^{1,2}(L^2)$ are established for the solutions of the fully discrete scheme.

Key words. finite elements, a priori error estimates, nonlinear wave equations

1. Introduction.

In this paper we study the numerical treatment of the nonlinear hyperbolic system

$$u_{tt} = \operatorname{div}(\sigma(Du) + Du_t) \text{ in } \Omega \times (0,T) \tag{1.1}$$

subject to the boundary and initial conditions

$$\begin{aligned} u &= 0 \quad \text{on } \partial\Omega\times(0,T),\\ u &= u_0 \text{ in } \quad \Omega\times\{0\},\\ u_t &= v_0 \text{ in } \quad \Omega\times\{0\}. \end{aligned}$$

Here, u is a vector-valued mapping from $\Omega \subset \mathbb{R}^n$ into $\mathbb{R}^m$, and the initial data satisfy $u_0 \in W_0^{1,2}(\Omega;\mathbb{R}^m)$ and $v_0 \in L^2(\Omega;\mathbb{R}^m)$.

The physical interest in this equation lies in the fact that it describes for $m = n$ the evolution of a viscoelastic body with reference configuration Ω. Nonmonotone stress-strain relations, modeled by $\sigma = D\Phi$ for nonconvex energy density functions Φ, are of main interest in simulations of solid-solid phase transitions; see, e.g., [1, 9, 10, 4, 5]. This equation arises also in the two-dimensional scalar case ($n = 2$ and $m = 1$) for the out-of-plane displacement field of an antiplane shear deformation [11]. Numerical experiments in [7] employed a discontinuous stabilized approximation because of difficulties with Q_1 finite elements. Our analysis shows that a P_1 finite element discretization leads to a convergent scheme provided that the solution is sufficiently regular.

Inspired by the uniqueness proof for Lipschitz continuous stresses σ in [10, 6], we present in this paper the a priori error analysis for an approximating scheme for the

system (1.1) that combines continuous finite elements in spaces with a discontinuous Galerkin approximation in time. We obtain estimates for the approximation error of the deformation u, the deformation gradient Du, and the velocity field $v = u_t$ under very general assumptions. In particular, the time step size k_j has only to satisfy the condition $k_j \le Qk_{j+1}$ for a global constant $Q > 0$, and the spatial triangulations are only assumed to be quasiuniform at each time step with a typical diameter h_j of the elements. The spatial L^2-approximation error is balanced with the time step error through an interesting coupling of k_j and h_j. The quotient h_j^2/k_j should not become too large; i.e., the time steps should not be too small compared to the square of the spatial discretization parameter h_j. Our general result, Theorem 4.1, immediately implies the following convergence estimates (see section 2 for the precise definitions).

THEOREM 1.1. *Let Ω be a bounded polygonal domain in $\mathbb{R}^n$. Fix $T > 0$ and define discrete times $0 = t_0 < t_1 < \cdots < t_N = T$. Suppose that $\mathcal{T}_j$ is a regular triangulation of Ω for $j = 0, \dots, N$ such that $\mathcal{T}_j$ is a refinement of $\mathcal{T}_{j-1}$. Assume that $\mathcal{S}_{0,j}(\mathcal{T}_j)$ is the space of all continuous functions that vanish on $\partial\Omega$ and are affine on the elements in $\mathcal{T}_j$. Let $U_j \in \mathcal{S}_{0,j}$ be the solution of the implicit Euler scheme defined in section 2.3 and let*

$$k_j = t_j - t_{j-1}, \quad k = \max_{j=1,\dots,N} k_j, \quad Q = \max_{j=2,\dots,N} \frac{k_j}{k_{j-1}}, \quad h = \max_{j=0,\dots,N} h_j.$$

Assume, furthermore, that σ is globally Lipschitz continuous and that the solution u of the system (1.1) belongs to $W^{1,\infty}(W^{2,2}) \cap W^{2,2}(W^{1,2})$. Finally, define the discretization errors e_j and δ_j at the time step t_j by

$$e_j = u(t_j) - U_j, \quad \delta_j = v(t_j) - \frac{1}{k_j}\big(U_j - U_{j-1}\big).$$

Then there exist constants c_1 and c_2 such that the following holds: If $c_1 k < 1$, then

$$\max_{\nu=1,\dots,N} \|e_\nu\|^2 + \sum_{\nu=1}^{N} k_\nu \big(\|\delta_\nu\|^2 + \|De_\nu\|^2\big) \le c_2(T + T^2 + h^4 + h^8) \exp\big(c_1 T\big) \|u\|_{h,k}^2,$$

where

$$\|u\|_{h,k}^2 = k^2 \| \, |u_{tt}| + |Du_{tt}| + |Du_t| \, \|_{L^2(L^2)}^2 + h^2 \left(1 + \max_{j=1,\dots,N} \frac{h_j^2}{k_j}\right) \|u\|_{W^{1,\infty}(W^{2,2})}^2.$$

The constants c_1 and c_2 depend only on the Lipschitz constant of σ, on the shape of the triangles in the triangulations $\mathcal{T}_j$, and on k_j via Q, but neither on h_j nor on u.

Remarks. (1) The statement of the theorem assumes tacitly that the initial data can be approximated sufficiently well; see estimate (2.7) below.

(2) The assumption $c_1 k \le 1$ implies that $2k_j \operatorname{Lip}(\sigma) < 1$ for $j = 1, \dots, N$. This condition ensures that the discrete scheme has a unique solution; see Theorem 2.2.

(3) The constants c_1 and c_2 depend on $\operatorname{Lip}(\sigma)$. The geometry of the mesh enters via the quotient of the diameters of the largest ball contained in an element and the smallest ball that contains the element. The definition of Q shows that the constants do not depend on k_j if the time steps are fixed or decreasing in j. The condition that time step k_{j+1} should not be much bigger than the previous time step k_j is related to a discrete integration by parts formula in Proposition 3.5.

(4) The regularity assumptions in Theorem 4.1 (and thus in Theorem 1.1) are stronger than the regularity properties guaranteed by the known existence results in

Theorem 2.1. However, the class of equations covered by our general convergence analysis includes, for example, the (smooth) solutions of the system

$$u_{tt} = \Delta u + \Delta u_t \tag{1.2}$$

with smooth and consistent initial values. The regularity of solutions of (1.2) is intermediate between that of the heat equation and the wave equation. This can be seen by using the transformation $v(t) = \exp(t)u(t)$ in (1.2), which, after integration in time, leads to the equation

$$v_t = \Delta v + F(v) \tag{1.3}$$

for v and $F(v)(t) = f + 2v(t) - \int_0^t v(\tau)\mathrm{d}\tau$. The regularity of solutions to the perturbed heat equation (1.3) follows from a successive application of the regularity theory for the heat equation.

(5) The existence result in Theorem 2.1 is obtained by analyzing a time-discrete problem and the convergence of its solutions. A second natural technique is the Galerkin method based on a spatial discretization and the solution of a family of ordinary differential equations in time. It is an open question whether the Galerkin method converges of not. This suggests that a (mild) constraint on the discretization parameters in space and time might be necessary to guarantee convergence.

(6) In general, solutions of (1.1) may fail to be smooth, and hence it remains an open problem whether or not the proposed numerical scheme converges under the regularity of the solutions guaranteed by Theorem 2.1. The coupling of the discretization parameters discussed in remark (5) is one key point which requires higher regularity.

The paper is organized as follows. We define the discrete scheme in section 2 and prove existence and uniqueness of the discrete solution. Section 3 contains a series of estimates for the solutions of the approximating scheme which are used in section 4 to prove the general convergence result in Theorem 4.1 which contains Theorem 1.1 as a special case.

2. The discrete scheme. In this section, we introduce the relevant notation and define the discrete scheme. Then we prove existence and uniqueness of the discrete solutions and derive an identity in the spirit of Galerkin orthogonality. This relation replaces in our convergence analysis the identity

$$(u - \overline{u})_{tt} = \operatorname{div}\big(\sigma(Du) - \sigma(D\overline{u}) + D(u - \overline{u})_t\big)$$

for the difference of two solutions u and $\overline{u}$ of the system (1.1) and from which one easily deduces uniqueness of solutions for Lipschitz continuous σ; see section 2.2.

2.1. Notation. We assume that $\Omega \subset \mathbb{R}^n$ is a polygonal domain with boundary $\Gamma = \partial\Omega$ and exterior normal ν to Γ. We use the standard notation for the Lebesgue spaces $L^p(\Omega;\mathbb{R}^m)$ with norm $\|\cdot\|_p$, and we write $(\cdot,\cdot)$ for the inner product in L^2. The Sobolev spaces $W^{k,p}(\Omega;\mathbb{R}^m)$ are equipped with the standard norm $\|\cdot\|_{k,p}$ and the seminorm $|\cdot|_{k,p}$, respectively. We frequently abbreviate $X(0,T;Y(\Omega))$ by $X(Y)$ if the corresponding domain Ω, the time interval $(0,T)$, and the range of the functions is clear from the context. Thus $L^2(L^2)$ denotes, for example, both $L^2(0,T;L^2(\Omega))$ and $L^2(0,T;L^2(\Omega;\mathbb{R}^m))$. The space of all real $m \times n$ matrices $\mathbb{M}^{m\times n}$ is equipped with the Frobenius norm, $|A|^2 = \operatorname{tr}(A^T A)$, where A^T denotes the transpose of the matrix A, and with the inner product $F : G$ that is induced by the scalar product in $\mathbb{R}^{mn}$.

Let $0 = t_0 < t_1 < \cdots < t_N = T$ be a partition of the time interval $[\,0,T\,]$ into N subintervals $I_j = (t_{j-1}, t_j)$ of length $k_j = t_j - t_{j-1}$, $j = 1, \ldots, N$. Suppose that $(\mathcal{T}_j)_{j=0,\ldots,N}$ is a family of regular triangulations in the sense of [2] with maximal mesh-size h_j and that the union of all elements in $\mathcal{T}_j$ is equal to $\overline{\Omega}$. We denote by $\mathcal{S}_{0,j} = \mathcal{S}_{0,j}(\mathcal{T}_j)$ the finite element space of continuous functions $u_h : \Omega \to \mathbb{R}^m$ that have zero boundary values on Γ and are affine on the elements in $\mathcal{T}_j$. We use the interpolation operator Π_j onto $\mathcal{S}_{0,j}$, due to Scott and Zhang [13], which satisfies the projection property

$$\Pi_j v = v \quad \text{for all } v \in \mathcal{S}_{0,j}, \tag{2.1}$$

the stability estimate

$$\|D\Pi_j u\| \le c_S \|Du\| \quad \text{for all } u \in W_0^{1,2}(\Omega), \tag{2.2}$$

and the approximation estimate

$$\|u - \Pi_j u\| + h_j \|Du - D\Pi_j u\| \le c_A h_j^2 \|D^2 u\| \quad \text{for all } u \in W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega). \tag{2.3}$$

Throughout the paper, u denotes the unique solution of the system (1.1) guaranteed by Theorem 2.1 below. We define the discrete solution $U_j \in \mathcal{S}_{0,j}$ at the time step t_j in section 2.3, and we use $V_j = (U_j - U_{j-1})/k_j$ for $j = 1, \ldots, N$ as an approximation for the discrete velocities.

The goal of our analysis is to estimate the errors in u and in u_t. To simplify the notation, we set $v = u_t$, $u_j = u(t_j)$, $v_j = v(t_j)$, and

$$e_j = u_j - U_j = u(t_j) - U_j, \quad \delta_j = v_j - V_j = v(t_j) - V_j \quad \text{for } j = 1, \ldots, N.$$

2.2. Existence and uniqueness for Lipschitz continuous stress functions. Our analysis relies on the existence result [6] for the system (1.1) which requires that $\sigma(F) = \partial\Phi(F)/\partial F$, where the stored energy function Φ has the following three properties (H1), (H2), and (H3).

(H1) $\Phi \in C^2(\mathbb{M}^{m\times n})$.

(H2) There exist constants $\overline{c}$, $\overline{C} > 0$, and $p \ge 2$ such that

$$\overline{c}|F|^p - \overline{C} \le \Phi(F) \le \overline{C}\big(|F|^p + 1\big), \quad |\sigma(F)| \le \overline{C}(|F|^{p-1} + 1)$$

for all $F \in \mathbb{M}^{m\times n}$.

(H3) There exists a constant $K > 0$ such that

$$-K|F - G|^2 \le \big(\sigma(F) - \sigma(G)\big) : (F - G) \quad \text{for all } F, G \in \mathbb{M}^{m\times n}.$$

Hypothesis (H3) follows, for example, from monotonicity or global Lipschitz continuity of σ. In the latter case one can choose $K = \mathrm{Lip}(\sigma)$. In this situation, the following existence result holds (see [4, 5] for related results).

THEOREM 2.1 (see [6, Theorem 4.1]). *Under the foregoing assumptions, the system* (1.1) *has a weak solution*

$$\begin{aligned} u \in\ & L^\infty(0,\infty; W_0^{1,2}(\Omega;\mathbb{R}^m)) \cap W^{1,\infty}(0,\infty; L^2(\Omega;\mathbb{R}^m)) \\ & \cap W^{1,2}_{loc}([0,\infty); W^{1,2}(\Omega;\mathbb{R}^m)) \cap W^{2,2}_{loc}([0,\infty); W^{-1,2}(\Omega;\mathbb{R}^m)); \end{aligned}$$

i.e., $u(\cdot,0)=u_0$, $u_t(\cdot,0)=v_0$, *and, for all* $\zeta\in C_0^\infty(\Omega\times(0,\infty);\mathbb{R}^m)$,

$$\int_0^\infty\int_\Omega \big((\sigma(Du)+Du_t):D\zeta-u_t\cdot\zeta_t\big)\mathrm{d}x\,\mathrm{d}t=0. \tag{2.4}$$

Moreover, u *satisfies the dissipation inequality*

$$E[u(t),u_t(t)]-E[u_0,v_0]\le-\int_0^t\int_\Omega|Du_t|^2\mathrm{d}x\,\mathrm{d}s$$

for almost every $t>0$, *where the total energy is given by*

$$E[u,v]=\int_\Omega\left(\Phi(Du)+\frac{1}{2}|v|^2\right)\mathrm{d}x\,.$$

If σ is globally Lipschitz continuous, then the following inequalities imply uniqueness of the weak solution u (see [6, 10]). Suppose that u and $\overline{u}$ are solutions with the same initial and boundary conditions. If we test the difference of the two equations

$$u_{tt}=\operatorname{div}\big(\sigma(Du)+Du_t\big),\quad \overline{u}_{tt}=\operatorname{div}\big(\sigma(D\overline{u})+D\overline{u}_t\big)$$

by $u-\overline{u}$ and integrate in space and time, then we obtain

$$\begin{aligned}\partial_T\frac{1}{2}\left(\int_0^T\int_\Omega|Du-D\overline{u}|^2\mathrm{d}x\,\mathrm{d}t+\int_\Omega|u(T)-\overline{u}(T)|^2\mathrm{d}x\right)\\ \le\operatorname{Lip}(\sigma)\int_0^T\int_\Omega\big(|Du-D\overline{u}|^2+|u_t-\overline{u}_t|^2\big)\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{2.5}$$

Similarly, if we use $u_t-\overline{u}_t$ as a test function, we get

$$\partial_T\frac{1}{2}\int_0^T\int_\Omega|u_t-\overline{u}_t|^2\mathrm{d}x\,\mathrm{d}t\le\frac{1}{4}\operatorname{Lip}^2(\sigma)\int_0^T\int_\Omega|Du-D\overline{u}|^2\mathrm{d}x\,\mathrm{d}t. \tag{2.6}$$

The asserted uniqueness follows by applying Gronwall's inequality (see, e.g., [12]) to the sum of the two inequalities. A discrete version of this Gronwall argument is used in section 3 as the key ingredient in Theorem 4.1.

2.3. Definition of the implicit scheme. In order to define the discrete scheme, let U_0, $V_0\in\mathcal{S}_0$ denote given approximations to u_0 and v_0. We assume that

$$\|e_0\|=\|u_0-U_0\|\le c_Ah_0\|Du_0\|,$$

and additionally for $u_0\in W^{2,2}(\Omega;\mathbb{R}^m)$ and $v_0\in W^{1,2}(\Omega;\mathbb{R}^m)$, that

$$\|e_0\|+h_0\|De_0\|\le c_Ah_0^2\|D^2u_0\|,\quad \|\delta_0\|=\|v_0-V_0\|\le c_Ah_0\|Dv_0\|. \tag{2.7}$$

We then define successively the discrete solution U_j at time t_j by minimizing the variational integral (2.8) below. Since we allow a variable step-size in the time discretization, we cannot discretize the second derivatives with a second difference quotient, and we use a backward difference quotient for the discrete velocities instead.

THEOREM 2.2. *Suppose that* $\sigma=D\Phi$ *is Lipschitz continuous with Lipschitz constant* $\operatorname{Lip}(\sigma)$ *and that* k *is small enough such that* $2k\operatorname{Lip}(\sigma)\le1$. *Then there exists for* $j=1,\dots,N$ *a unique solution* U_j *of the variational problem: Minimize*

$$\int_\Omega\left(\Phi(DU)+\frac{1}{2k_j}|DU-DU_{j-1}|^2+\frac{1}{2}\left|\frac{1}{k_j}(U-U_{j-1})-V_{j-1}\right|^2\right)\mathrm{d}x \tag{2.8}$$

among all functions $U \in \mathcal{S}_{0,j}$. The minimizer U_j is a solution of the corresponding Euler–Lagrange system in weak form, i.e., a solution of

$$\int_\Omega \big(\big(k_j\sigma(DU_j) + D(U_j - U_{j-1})\big) : DW_j + (V_j - V_{j-1})\cdot W_j\big)\mathrm{d}x = 0 \tag{2.9}$$

for all $W_j \in \mathcal{S}_{0,j}$.

Proof. We need only to show that the variational integral has a convex integrand. Existence and uniqueness of solutions follow then from the direct method in the calculus of variations (see, e.g., [3]). By assumption,

$$0 \le \frac{1}{k_j}|A-B|^2 - \mathrm{Lip}(\sigma)|A-B|^2 \le \left(\sigma(A) + \frac{1}{k_j}A - \left(\sigma(B) + \frac{1}{k_j}B\right)\right) : (A-B);$$

that is, $\sigma(F) + k_j^{-1}F$ is monotone, and hence $\Phi(F) + |F|^2/(2k_j)$ is convex. ∎

Remark. The structural assumption $\sigma = D\Phi$ guarantees the existence of the solution u and U_j of the continuous and the discretized system. The error analysis below is entirely based on the Galerkin orthogonality (2.8) and does not rely on this assumption.

2.4. Discrete orthogonality. The following version of the Galerkin orthogonality is an important ingredient in the proof of Theorem 4.1.

PROPOSITION 2.3. *Suppose that u is the unique solution of the system* (1.1) *and that $\{U_j\}$ is the unique approximation constructed in* (2.8). *Then*

$$(\delta_j - \delta_{j-1}, W_j) + \int_{I_j} \big(\sigma(Du) - \sigma(DU_j), DW_j\big)\mathrm{d}t + (De_j - De_{j-1}, DW_j) = 0 \tag{2.10}$$

for $j = 1, \dots, N$ and for all $W_j \in \mathcal{S}_{0,j}$.

Proof. The idea is to test the weak formulation (2.4) by $\chi_j W_j$ in order to get an analogue of (2.9); χ_j denotes the characteristic function of the time interval I_j. Let $W_j^\ell \in C_0^\infty(\Omega;\mathbb{R}^m)$ be a sequence of smooth functions with $\|W_j - W_j^\ell\|_{W^{1,2}(\Omega)} \to 0$ as $\ell \to \infty$, and choose $\psi_\mu \in C_0^\infty(I_j)$ with $\psi_\mu \equiv 1$ on $(t_{j-1}+\mu, t_j - \mu)$. Then

$$\int_0^\infty \int_\Omega \left((\sigma(Du) + Du_t) : DW_j^\ell(x)\psi_\mu(t) - u_t \cdot W_j^\ell(x)\frac{\partial}{\partial t}\psi_\mu(t)\right)\mathrm{d}x\,\mathrm{d}t = 0$$

for $\mu \in (0, k_j/4)$ and $\ell \in \mathbb{N}$. This expression converges for $\ell \to \infty$ and $\mu \to 0$ to

$$\int_{I_j} \big(\sigma(Du(t,x)) + Du_t(t,x), DW_j\big)\,\mathrm{d}t + (v_j - v_{j-1}, W_j) = 0.$$

The assertion of the proposition follows by subtracting this equation from the Euler–Lagrange equation (2.9). ∎

2.5. A discrete Gronwall inequality. Our convergence result is based on the following discrete Gronwall inequality.

LEMMA 2.4 (see [8, Lemma 1.4.2]). *Suppose that $a > 0$ and that $\{b_\nu\}$, $\{\tau_\nu\}$ are sequences of nonnegative real numbers. Assume that the sequence $\{\varphi_\nu\}$ satisfies*

$$\varphi_0 \le a \quad \text{and} \quad \varphi_\nu \le a + \sum_{j=1}^{\nu} b_j + \sum_{j=0}^{\nu-1} \tau_j\varphi_j$$

for $n \geq 1$. Then

$$\varphi_\nu \leq \left(a + \sum_{j=1}^{\nu} b_j\right) \exp\left(\sum_{k=0}^{\nu-1} \tau_k\right).$$

3. Estimates for the solution of the discrete system. In our estimates, we will frequently express a difference $(e_j - e_{j-1})/k_j$ of spatial errors as an error in velocities, δ_j. The resulting correction term K_j is characterized in the following lemma.

LEMMA 3.1. *Let K_j, $j = 1, \ldots, N$, be given by*

$$K_j = \frac{1}{k_j} \int_{t_{j-1}}^{t_j} (s - t_{j-1}) u_{tt}(s) \mathrm{d}s.$$

Then, for $j = 1, \ldots, N$,

$$\frac{1}{k_j}(e_j - e_{j-1}) = \delta_j + K_j \tag{3.1}$$

and

$$\|K_j\|^2 \leq \frac{k_j}{3} \int_{t_{j-1}}^{t_j} \int_\Omega u_{tt}^2 \mathrm{d}x\, \mathrm{d}t, \quad \|DK_j\|^2 \leq \frac{k_j}{3} \int_{t_{j-1}}^{t_j} \int_\Omega |Du_{tt}|^2 \mathrm{d}x\, \mathrm{d}t. \tag{3.2}$$

Proof. It follows from Taylor's formula that

$$u(t_j, x) = u(t_{j-1}, x) + k_j u_t(t_j, x) - \int_{t_{j-1}}^{t_j} (s - t_{j-1}) u_{tt}(s, x) \mathrm{d}s.$$

This allows us to estimate

$$\begin{aligned} \frac{1}{k_j}(e_j - e_{j-1}) &= \frac{U_j - U_{j-1}}{k_j} - \frac{u(t_j) - u(t_{j-1})}{k_j} \\ &= V_j - v(t_j) + K_j = \delta_j + K_j. \end{aligned}$$

Finally, by Hölder's inequality,

$$\begin{aligned} \|K_j\|^2 &= \int_\Omega \left(\frac{1}{k_j} \int_{t_{j-1}}^{t_j} (s - t_j) u_{tt}(s) \mathrm{d}s \right)^2 \mathrm{d}x \\ &\leq \frac{1}{k_j^2} \left(\int_{t_{j-1}}^{t_j} (s - t_{j-1})^2 \mathrm{d}s \right) \left(\int_{t_{j-1}}^{t_j} \int_\Omega u_{tt}^2 \mathrm{d}x\, \mathrm{d}t \right) \\ &= \frac{k_j}{3} \int_{t_{j-1}}^{t_j} \int_\Omega u_{tt}^2 \mathrm{d}x\, \mathrm{d}t. \end{aligned}$$

This concludes the proof of the lemma. ∎

The next proposition is a discrete analogue of (2.6). The idea is to use the orthogonality (2.10) with $\Pi_j \delta_j = \delta_j + (\Pi_j \delta_j - \delta_j)$ and to recover the structure of (2.6) plus approximation errors.

PROPOSITION 3.2. *The following estimate holds for $j = 1, \dots, N$:*

$$\begin{aligned}
&\frac{1}{2}\|\delta_j\|^2 - \frac{1}{2}\|\delta_{j-1}\|^2 + \frac{1}{4}\|\delta_j - \delta_{j-1}\|^2 \\
&\quad \le 2c_S^2 \operatorname{Lip}^2(\sigma) k_j \|De_j\|^2 - \frac{k_j}{2}\|D\delta_j\|^2 + \|\delta_j - \Pi_j\delta_j\|^2 \\
&\qquad + \frac{5k_j}{2}\|D\delta_j - D\Pi_j\delta_j\|^2 + \frac{5k_j}{2}\|DK_j\|^2 + c_S^2 \operatorname{Lip}^2(\sigma)\, k_j^2 \|Du_t\|^2_{L^2(I_j;L^2)}.
\end{aligned}$$

Proof. It follows from (2.10) with $W_j = \Pi_j\delta_j$ that

$$\begin{aligned}
\frac{1}{2}\|\delta_j\|^2 - \frac{1}{2}\|\delta_{j-1}\|^2 + \frac{1}{2}\|\delta_j - \delta_{j-1}\|^2 &= (\delta_j, \delta_j - \delta_{j-1}) \\
&= (\delta_j - \delta_{j-1}, \delta_j - \Pi_j\delta_j) - (De_j - De_{j-1}, D\Pi_j\delta_j) \\
&\quad - \int_{I_j} \big(\sigma(Du) - \sigma(DU_j), D\Pi_j\delta_j\big)\mathrm{d}t.
\end{aligned}$$

We denote the three terms on the right-hand side by T_1, T_2, and T_3. Then

$$T_1 \le \frac{1}{4}\|\delta_j - \delta_{j-1}\|^2 + \|\delta_j - \Pi_j\delta_j\|^2,$$

and by (3.1)

$$\begin{aligned}
T_2 &= -k_j\big(D\delta_j + DK_j, D\delta_j - D\delta_j + D\Pi_j\delta_j\big) \\
&\le k_j\bigg(-\frac{3}{4}\|D\delta_j\|^2 + \frac{5}{2}\|DK_j\|^2 + \frac{5}{2}\|D\delta_j - D\Pi_j\delta_j\|^2\bigg).
\end{aligned}$$

We have by Hölder's inequality, Young's inequality, and the stability estimate (2.2) that

$$\begin{aligned}
|T_3| &\le \int_{I_j} \|\sigma(Du) - \sigma(DU_j)\|\, \|D\Pi_j\delta_j\|\mathrm{d}t \\
&\le \sqrt{k_j}\|\sigma(Du) - \sigma(DU_j)\|_{L^2(I_j;L^2)}\, \|D\Pi_j\delta_j\| \\
&\le c_S^2 \operatorname{Lip}^2(\sigma) \int_{I_j}\int_\Omega |Du - DU_j|^2 \mathrm{d}x\,\mathrm{d}t + \frac{k_j}{4c_S^2}\|D\Pi_j\delta_j\|^2 \\
&\le 2c_S^2 \operatorname{Lip}^2(\sigma) \int_{I_j}\int_\Omega \big(|Du - Du_j|^2 + |Du_j - DU_j|^2\big)\mathrm{d}x\,\mathrm{d}t + \frac{k_j}{4}\|D\delta_j\|^2.
\end{aligned}$$

Since

$$|Du - Du_j|^2 = \bigg|\int_t^{t_j} Du_t(s)\mathrm{d}s\bigg|^2 \le (t_j - t)\int_t^{t_j} |Du_t(s)|^2\mathrm{d}s$$

and

$$\int_{t_{j-1}}^{t_j} (t_j - t)\int_t^{t_j} |Du_t|^2\mathrm{d}s\,\mathrm{d}t \le \int_{t_{j-1}}^{t_j} (t_j - t)\mathrm{d}t \int_{t_{j-1}}^{t_j} |Du_t|^2\mathrm{d}s = \frac{k_j^2}{2}\int_{t_{j-1}}^{t_j} |Du_t|^2\mathrm{d}t,$$

we obtain

$$\int_{I_j}\int_\Omega |Du - Du_j|^2\mathrm{d}x\,\mathrm{d}t \le \frac{k_j^2}{2}\int_{I_j}\int_\Omega |Du_t|^2\mathrm{d}x\,\mathrm{d}t.$$

The assertion of the proposition follows easily from the foregoing estimates. ∎

In the next proposition we derive the analogue of the estimate (2.5) for the discrete scheme.

PROPOSITION 3.3. *The following estimate holds for $j = 1, \dots, N$:*

$$\begin{aligned}
&\frac{1}{2}\|De_j\|^2 - \frac{1}{2}\|De_{j-1}\|^2 + \frac{1}{4}\|De_j - De_{j-1}\|^2 \\
&\quad \le \left(c_S^2 \operatorname{Lip}^2(\sigma) + \frac{1}{2}\right) k_j \|De_j\|^2 - (\delta_j - \delta_{j-1}, e_j) + \frac{k_j}{2}\|D\delta_j\|^2 \\
&\qquad + \frac{1}{4}\|\delta_j - \delta_{j-1}\|^2 + \|e_j - \Pi_j e_j\|^2 + k_j \|De_j - D\Pi_j e_j\|^2 \\
&\qquad + \frac{k_j}{2}\|DK_j\|^2 + \frac{1}{2}\, c_S^2 \operatorname{Lip}^2(\sigma) k_j^2 \, \|Du_t\|^2_{L^2(I_j;L^2)}.
\end{aligned}$$

Proof. We obtain from (2.10) with $W_j = \Pi_j e_j$ that

$$\begin{aligned}
\frac{1}{2}\|De_j\|^2 - \frac{1}{2}\|De_{j-1}\|^2 + \frac{1}{2}\|De_j - De_{j-1}\|^2 &= \big(De_j - De_{j-1}, De_j - D\Pi_j e_j\big) \\
- (\delta_j - \delta_{j-1}, \Pi_j e_j) - \int_{I_j} \big(\sigma(Du) - \sigma(DU_j), D\Pi_j e_j\big) \mathrm{d}t.&
\end{aligned}$$

We denote the three terms on the right-hand side by T_1, T_2, and T_3. By Lemma 3.1,

$$\begin{aligned}
T_1 &= k_j \big(D\delta_j + DK_j, De_j - D\Pi_j e_j\big) \\
&\le k_j \left(\frac{1}{2}\|D\delta_j\|^2 + \frac{1}{2}\|DK_j\|^2 + \|De_j - D\Pi_j e_j\|^2\right),
\end{aligned}$$

and by Young's inequality

$$\begin{aligned}
T_2 &= (\delta_j - \delta_{j-1}, e_j - \Pi_j e_j) - (\delta_j - \delta_{j-1}, e_j) \\
&\le -(\delta_j - \delta_{j-1}, e_j) + \frac{1}{4}\|\delta_j - \delta_{j-1}\|^2 + \|e_j - \Pi_j e_j\|^2.
\end{aligned}$$

Finally, T_3 can be estimates as in the proof of Proposition 3.2 by

$$\begin{aligned}
T_3 &\le \sqrt{k_j} \operatorname{Lip}(\sigma) \|Du - DU_j\|_{L^2(I_j;L^2)} \|D\Pi_j e_j\| \\
&\le \frac{1}{2}\, c_S^2 \operatorname{Lip}^2(\sigma) \, \|Du - DU_j\|^2_{L^2(I_j;L^2)} + \frac{k_j}{2c_S^2}\|D\Pi_j e_j\|^2 \\
&\le \frac{1}{2}\, c_S^2 \operatorname{Lip}^2(\sigma) k_j^2 \, \|Du_t\|^2_{L^2(I_j;L^2)} + \left(c_S^2 \operatorname{Lip}^2(\sigma) + \frac{1}{2}\right) k_j \|De_j\|^2.
\end{aligned}$$

The assertion of the proposition follows from the foregoing inequalities. ∎

We now combine the estimates in Propositions 3.2 and 3.3 to obtain an estimate on the time interval I_j.

COROLLARY 3.4. *Let $\mathcal{A}_j$ denote the approximation errors,*

$$\mathcal{A}_j = \|\delta_j - \Pi_j \delta_j\|^2 + \frac{5}{2}\, k_j \|D\delta_j - D\Pi_j \delta_j\|^2 + \|e_j - \Pi_j e_j\|^2 + k_j \|De_j - D\Pi_j e_j\|^2,$$

and $\mathcal{R}_j$ the terms depending on the regularity of u,

$$\mathcal{R}_j = \frac{k_j}{2}\, \|K_j\|^2 + 3k_j \|DK_j\|^2 + \frac{3}{2}\, c_S^2 \operatorname{Lip}^2(\sigma) k_j^2 \|Du_t\|^2_{L^2(I_j;L^2)}.$$

Then the following estimate holds for $j = 1, \dots, N$:

$$\begin{aligned}(3.3)\qquad &\frac{1}{2}\|\delta_j\|^2 - \frac{1}{2}\|\delta_{j-1}\|^2 + \frac{1}{2}\|De_j\|^2 - \frac{1}{2}\|De_{j-1}\|^2 + \frac{1}{4}\|De_j - De_{j-1}\|^2 \\ &\le \left(3c_S^2 \operatorname{Lip}^2(\sigma) + \frac{1}{2}\right) k_j \|De_j\|^2 - (\delta_j - \delta_{j-1}, e_j) + \mathcal{A}_j + \mathcal{R}_j - \frac{k_j}{2}\|K_j\|^2.\end{aligned}$$

Remark. The discrete Gronwall inequality will be applied to the sum of (3.3) in j. The sum of the terms $-(\delta_j - \delta_{j-1}, e_j)$ on the right-hand side is estimated by a discrete summation by parts which leads to the (discrete) time integral of $\|\delta_j\|^2$.

PROPOSITION 3.5. *Let*

$$(3.4)\qquad q_j = \frac{k_j}{k_{j-1}}, \quad Q_\nu = \max_{j=2,\dots,\nu} q_j, \quad c_3 = \max\left\{3c_S^2 \operatorname{Lip}^2(\sigma) + \frac{1}{2}, Q_N + \frac{1}{2}\right\}.$$

Then the following estimate holds for $\nu = 1, \dots, N$:

$$\begin{aligned}\frac{1}{2}\|\delta_\nu\|^2 + \frac{1}{2}\|De_\nu\|^2 \le c_3 \sum_{j=1}^{\nu} k_j\big(\|\delta_j\|^2 + \|De_j\|^2\big) - (\delta_\nu, e_\nu) + (\delta_0, e_1) \\ + \sum_{j=1}^{\nu}(\mathcal{A}_j + \mathcal{R}_j) + \frac{1}{2}\|\delta_0\|^2 + \frac{1}{2}\|De_0\|^2.\end{aligned}$$

Proof. We take the sum of the inequality (3.3) for $j = 1, \dots, \nu$ and obtain

$$\begin{aligned}\frac{1}{2}\|\delta_\nu\|^2 + \frac{1}{2}\|De_\nu\|^2 \le \left(3c_S^2 \operatorname{Lip}^2(\sigma) + \frac{1}{2}\right) \sum_{j=1}^{\nu} k_j \|De_j\|^2 - \sum_{j=1}^{\nu} \big(\delta_j - \delta_{j-1}, e_j\big) \\ + \sum_{j=1}^{\nu} \left(\mathcal{A}_j + \mathcal{R}_j - \frac{k_j}{2}\|K_j\|^2\right) + \frac{1}{2}\|\delta_0\|^2 + \frac{1}{2}\|De_0\|^2.\end{aligned}$$

With a discrete summation by parts in the second term on the right-hand side, we deduce that

$$\begin{aligned}-\sum_{j=1}^{\nu} \big(\delta_j - \delta_{j-1}, e_j\big) &= -(\delta_\nu, e_\nu) + (\delta_0, e_1) + \sum_{j=1}^{\nu-1} \big(\delta_j, e_{j+1} - e_j\big) \\ &= -(\delta_\nu, e_\nu) + (\delta_0, e_1) + \sum_{j=1}^{\nu-1} k_{j+1}\big(\delta_j, \delta_{j+1} + K_{j+1}\big) \\ &\le -(\delta_\nu, e_\nu) + (\delta_0, e_1) + \sum_{j=1}^{\nu-1} k_{j+1}\left(\|\delta_j\|^2 + \frac{1}{2}\|\delta_{j+1}\|^2 + \frac{1}{2}\|K_{j+1}\|^2\right).\end{aligned}$$

The assertion follows from this inequality since $k_{j+1}\|\delta_j\|^2 = q_{j+1}k_j\|\delta_j\|^2$. ∎

In order to apply Gronwall's inequality, we need a further summation of the inequality in Proposition 3.5. The term $-(\delta_\nu, e_\nu)$ corresponds to the spatial integral of $u_t u = \partial_t |u|^2/2$ which fits naturally in the formulation of Gronwall's inequality in section 2.2. This is not the case in the implicit time discretization used here.

PROPOSITION 3.6. *Let*

$$(3.5)\qquad \varphi_\nu = \|e_\nu\|^2 + \sum_{j=1}^{\nu} k_j\big(\|\delta_j\|^2 + \|De_j\|^2\big).$$

Then

$$\frac{1}{2}\varphi_N \le \left(c_3+\frac{1}{2}\right)\sum_{\nu=1}^{N} k_\nu\varphi_\nu + T(\delta_0,e_1) + \frac{1}{2}\|e_0\|^2 + \frac{T}{2}\big(\|\delta_0\|^2+\|De_0\|^2\big) + 2\sum_{\nu=1}^{N} k_\nu \sum_{j=1}^{\nu}\big(\mathcal{A}_j+\mathcal{R}_j\big),$$

and

$$\big|T(\delta_0,e_1)\big| \le k_1\sum_{\nu=1}^{N} k_\nu\varphi_\nu + 2k_1T\mathcal{R}_1 + \frac{3T}{4}\,\|\delta_0\|^2 + T\|e_0\|^2. \tag{3.6}$$

Proof. We multiply the inequality in the assertion of Proposition 3.5 by k_ν and take the sum of the resulting inequalities from $\nu=1$ to N. This leads to

$$\frac{1}{2}\sum_{\nu=1}^{N} k_\nu\big(\|\delta_\nu\|^2+\|De_\nu\|^2\big) \le c_3\sum_{\nu=1}^{N} k_\nu\sum_{j=1}^{\nu} k_j\big(\|\delta_j\|^2+\|De_j\|^2\big)$$
$$-\sum_{\nu=1}^{N} k_\nu(\delta_\nu,e_\nu) + T(\delta_0,e_1) + \sum_{\nu=1}^{N} k_\nu\sum_{j=1}^{\nu}\big(\mathcal{A}_j+\mathcal{R}_j\big) + \frac{T}{2}\big(\|\delta_0\|^2+\|De_0\|^2\big).$$

In view of Lemma 3.1,

$$\begin{aligned}-\sum_{\nu=1}^{N} k_\nu(\delta_\nu,e_\nu) &= -\sum_{\nu=1}^{N}(e_\nu-e_{\nu-1}-k_\nu K_\nu,e_\nu)\\ &= -\frac{1}{2}\sum_{\nu=1}^{N}\big(\|e_\nu\|^2-\|e_{\nu-1}\|^2+\|e_\nu-e_{\nu-1}\|^2\big)+\sum_{\nu=1}^{N} k_\nu(K_\nu,e_\nu)\\ &\le -\frac{1}{2}\,\|e_N\|^2+\frac{1}{2}\,\|e_0\|^2+\frac{1}{2}\sum_{\nu=1}^{N} k_\nu\big(\|e_\nu\|^2+\|K_\nu\|^2\big).\end{aligned}$$

This implies

$$\begin{aligned}&\frac{1}{2}\left\{\|e_N\|^2+\sum_{\nu=1}^{N} k_\nu\big(\|\delta_\nu\|^2+\|De_\nu\|^2\big)\right\}\\ &\le \left(c_3+\frac{1}{2}\right)\sum_{\nu=1}^{N} k_\nu\left\{\|e_\nu\|^2+\sum_{j=1}^{\nu} k_j\big(\|\delta_j\|^2+\|De_j\|^2\big)\right\}\\ &\quad + T(\delta_0,e_1)+\frac{1}{2}\|e_0\|^2+\frac{T}{2}\big(\|\delta_0\|^2+\|De_0\|^2\big)+2\sum_{\nu=1}^{N} k_\nu\sum_{j=1}^{\nu}\big(\mathcal{A}_j+\mathcal{R}_j\big).\end{aligned}$$

It remains only to estimate the term $T(\delta_0,e_1)$ on the right-hand side. This is accomplished by showing that

$$\big|T(\delta_0,e_1)\big| \le k_1\sum_{\nu=1}^{N} k_\nu\varphi_\nu + 2k_1T\mathcal{R}_1 + \frac{3T}{4}\,\|\delta_0\|^2 + T\|e_0\|^2.$$

Indeed, it follows from (3.1) that

$$\begin{aligned}\big|(\delta_0,e_1)\big| &\le \big|(\delta_0,e_1-e_0)\big| + \big|(\delta_0,e_0)\big| \le \big|k_1(\delta_0,\delta_1+K_1)\big| + \big|(\delta_0,e_0)\big| \\ &\le \frac{1}{4}\|\delta_0\|^2 + k_1^2\|\delta_1\|^2 + \frac{1}{4}\|\delta_0\|^2 + k_1^2\|K_1\|^2 + \frac{1}{4}\|\delta_0\|^2 + \|e_0\|^2.\end{aligned}$$

By definition, $k_1\|K_1\|^2 \le 2\mathcal{R}_1$ and $k_1\|\delta_1\|^2 \le \varphi_\nu$ for $\nu = 1,\dots,N$. Thus

$$T\big|(\delta_0,e_1)\big| \le \frac{3T}{4}\,\|\delta_0\|^2 + T\|e_0\|^2 + k_1\sum_{\nu=1}^{N} k_\nu\varphi_\nu + 2k_1\sum_{\nu=1}^{N} k_\nu\mathcal{R}_1.$$

This implies the assertion of the proposition. □

4. General convergence result. We are now in a position to state and prove the convergence result for the approximation of solutions of the system (1.1) by the implicit Euler scheme defined in section 2.3. Recall that $\mathcal{A}_j$, $\mathcal{R}_j$, and φ_ν have been defined in Proposition 3.4 and Corollary 3.6, respectively. Moreover, we set

$$\mathcal{A}(T) = 8\big(1+k_1\big)\sum_{\nu=1}^{N} k_\nu \sum_{j=1}^{\nu}\mathcal{A}_j, \quad \mathcal{R}(T) = 8\big(1+k_1\big)\sum_{\nu=1}^{N} k_\nu \sum_{j=1}^{\nu}\mathcal{R}_j,$$

and

$$a = 2(2T+1)\|e_0\|^2 + 2T\|De_0\|^2 + 5T\|\delta_0\|^2. \tag{4.1}$$

Finally, we define $c_4 = c_4(\mathrm{Lip}(\sigma), Q_N)$ and $c_5 = c_5(\mathrm{Lip}(\sigma), Q_N)$ by

$$c_4 = 4\bigg(c_3 + \frac{1}{2} + k_1\bigg), \quad c_5 = \max\bigg\{\frac{3}{2}\,c_S^2\,\mathrm{Lip}^2(\sigma), 1\bigg\}, \tag{4.2}$$

respectively.

THEOREM 4.1. *Suppose that Ω, $\mathcal{T}_j$, and $\mathcal{S}_{0,j}$ satisfy the assumptions in section* 2.1 *and that there exists a $Q_N > 0$ such that $k_{j-1} \le Q_N k_j$ for $j = 2,\dots,N$. Assume, furthermore, that σ is globally Lipschitz continuous and that the unique solution of the system* (1.1) *belongs to $W^{1,2}(W^{1,2})$. Suppose that $k < 1/c_4$. Then*

$$\max_{\nu=1,\dots,N}\|e_\nu\|^2 + \sum_{\nu=1}^{N} k_\nu\big(\|\delta_\nu\|^2 + \|De_\nu\|^2\big) \le \big(a + \mathcal{A}(T) + \mathcal{R}(T)\big)\exp\big(c_4T\big).$$

Moreover, if $u \in W^{1,\infty}(W^{2,2}) \cap W^{2,2}(W^{1,2})$, then

$$\mathcal{R}(T) \le 12c_5T\,k^2\,\Big(\|u_{tt}\|^2_{L^2(L^2)} + \|Du_{tt}\|^2_{L^2(L^2)} + \|Du_t\|^2_{L^2(L^2)}\Big),$$

and

$$\mathcal{A}(T) \le 60c_A^2T^2h^2\max_{j=1,\dots,N}\bigg(\frac{h_j^2}{k_j}+1\bigg)\|u\|^2_{W^{1,\infty}(W^{2,2})} + \mathcal{C}(T),$$

where $\mathcal{C}(T)$ is the coarsening error,

$$\mathcal{C}(T) = 12T\sum_{j=1}^{N}\bigg\{\frac{2}{k_j^2}\big\|U_{j-1} - \Pi_jU_{j-1}\big\| + \frac{5}{k_j}\big|U_{j-1} - \Pi_jU_{j-1}\big|^2_{1,2}\bigg\},$$

which vanishes if $\mathcal{T}_j$ is a refinement of $\mathcal{T}_{j-1}$. Finally, if the approximation estimate (2.7) *holds, then*

$$a \le c_A^2 h_0^2\big((4T+2)h_0^2 + 4T\big)\,\big(\|D^2 u_0\|^2 + \|Dv_0\|^2\big).$$

Remark. Theorem 4.1 constitutes the best a priori estimates known for the system (1.1) provided that the solution is sufficiently regular. Under the assumption that the triangulation is only refined in time but not coarsened (i.e., that $\mathcal{C}(T) = 0$), we obtain an estimate of order $\exp(T)(h^2 + k^2)$; cf. Theorem 1.1.

Proof of Theorem 4.1. Based on the estimates of section 3, we first show that φ_ν satisfies the assumptions in the discrete Gronwall inequality of Lemma 2.4. It follows from Proposition 3.6 and (3.6) that

$$\begin{aligned}\frac{1}{2}\varphi_N \le \left(c_3 + \frac{1}{2} + k_1\right)\sum_{\nu=1}^{N} k_\nu \varphi_\nu + 2\big(1+k_1\big)\sum_{\nu=1}^{N} k_\nu \sum_{j=1}^{\nu}\big(\mathcal{A}_j + \mathcal{R}_j\big)\\ + \left(T + \frac{1}{2}\right)\|e_0\|^2 + \frac{T}{2}\,\|De_0\|^2 + \frac{5T}{4}\|\delta_0\|^2.\end{aligned}$$

By assumption, $k_N \le k$ and thus $c_4 k_N = 4\big(c_3 + 1/2 + k_1\big)k_N \le 1$. This allows us to absorb the term $\big(c_3 + \frac{1}{2} + k_1\big)k_N\varphi_N \le \varphi_N/4$ on the left-hand side. We obtain

$$\begin{aligned}\varphi_N \le c_4 \sum_{\nu=1}^{N-1} k_\nu \varphi_\nu + 8(1+k_1)\sum_{\nu=1}^{N} k_\nu \sum_{j=1}^{\nu}\big(\mathcal{A}_j + \mathcal{R}_j\big)\\ + 2(2T+1)\|e_0\|^2 + 2T\|De_0\|^2 + 5T\|\delta_0\|^2.\end{aligned}$$

It follows that the assumptions in the discrete Gronwall inequality in Lemma 2.4 are satisfied with a as defined in (4.1) and

$$b_\nu = 8(1+k_1)k_\nu \sum_{j=1}^{\nu}\big(\mathcal{A}_j + \mathcal{R}_j\big), \quad \tau_\nu = c_4 k_\nu, \quad \nu = 1, \dots, N.$$

Thus

$$\varphi_N \le \left(a + \sum_{\nu=1}^{N} b_\nu\right)\exp(c_4 T) = \big(a + \mathcal{A}(T) + \mathcal{R}(T)\big)\,\exp(c_4 T).$$

We now estimate $\mathcal{A}(T)$ and $\mathcal{R}(T)$. By definition of $\mathcal{R}_j$ in Corollary 3.4 and by (3.2) we infer

$$\mathcal{R}_j \le c_5 k_j^2\,(\|u_{tt}\|^2_{L^2(I_j;L^2)} + \|Du_{tt}\|^2_{L^2(I_j;L^2)} + \|Du_t\|^2_{L^2(I_j;L^2)}).$$

This implies

$$\sum_{\nu=1}^{N} k_\nu \sum_{j=1}^{\nu}\mathcal{R}_j \le c_5 T\,k^2\,\big(\|u_{tt}\|^2_{L^2(L^2)} + \|Du_{tt}\|^2_{L^2(L^2)} + \|Du_t\|^2_{L^2(L^2)}\big).$$

Since $kc_4 \le 1$ implies $k_1 \le 1/2$, we obtain

$$\mathcal{R}(T) \le 12 c_5 T\,k^2\,(\|u_{tt}\|^2_{L^2(L^2)} + \|Du_t\|^2_{L^2(L^2)} + \|Du_t\|^2_{L^2(L^2)}).$$

It remains to estimate the approximation error. By definition of e_j and (2.1),

$$e_j - \Pi_j e_j = u(t_j) - U_j - \Pi_j\big(u(t_j) - U_j\big) = u(t_j) - \Pi_j u(t_j).$$

The approximation estimate (2.3) implies

$$\|e_j - \Pi_j e_j\|^2 + k_j\|De_j - D\Pi_j e_j\|^2 \le c_A^2 h_j^2\big(h_j^2 + k_j\big)\|D^2 u(t_j)\|^2.$$

Similarly,

$$\delta_j - \Pi_j\delta_j = v(t_j) - \Pi_j v(t_j) + \frac{1}{k_j}\big(U_{j-1} - \Pi_j U_{j-1}\big).$$

This estimate and (2.2)–(2.3) yield

$$\begin{aligned}\|\delta_j - \Pi_j\delta_j\|^2 + \frac{5}{2}k_j\|D\delta_j - D\Pi_j\delta_j\|^2 &\le 2c_A^2 h_j^2\left(h_j^2 + \frac{5}{2}k_j\right)\|D^2 u_t(t_j)\|^2\\ &\quad + \frac{2}{k_j^2}\|U_{j-1} - \Pi_j U_{j-1}\|^2 + \frac{5}{k_j}|U_{j-1} - \Pi_j U_{j-1}|_{1,2}^2.\end{aligned}$$

We conclude from the foregoing estimates that

$$\begin{aligned}\sum_{j=1}^N \mathcal{A}_j &\le 5\sum_{j=1}^N h_j^2 c_A^2\big(h_j^2 + k_j\big)\big(\|D^2 u(t_j)\|^2 + \|D^2 u_t(t_j)\|^2\big) + \frac{1}{12T}\,\mathcal{C}(T)\\ &\le 5c_A^2 T h^2 \max_{j=1,\dots,N}\left(\frac{h_j^2}{k_j} + 1\right)\|u\|_{W^{1,\infty}(W^{2,2})}^2 + \frac{1}{12T}\,\mathcal{C}(T).\end{aligned}$$

Hence

$$\mathcal{A}(T) \le 12\,T\sum_{j=1}^N \mathcal{A}_j \le 60c_A^2 T^2 h^2 \max_{j=1,\dots,N}\left(1 + \frac{h_j^2}{k_j}\right)\|u\|_{W^{1,\infty}(W^{2,2})}^2 + \mathcal{C}(T).$$

Clearly, if $\mathcal{T}_j$ is a refinement of $\mathcal{T}_{j-1}$, then, by (2.1), $\mathcal{C}(T) = 0$. Finally, if (2.7) holds, then

$$a \le c_A^2\big(2(2T+1)h_0^4 + 2Th_0^2\big)\|D^2 u_0\|^2 + 4Th_0^2\|Dv_0\|^2.$$

This proves the assertion of the theorem. □

Proof of Theorem 1.1. This is a special case of Theorem 4.1. □

Acknowledgment. It is our pleasure to thank Constantine Dafermos for discussions on the regularity of hyperbolic equations and remarks (4) and (5) in the introduction.

ANALYSIS OF A MULTIGRID ALGORITHM FOR TIME HARMONIC MAXWELL EQUATIONS*

JAYADEEP GOPALAKRISHNAN†, JOSEPH E. PASCIAK‡, AND LESZEK F. DEMKOWICZ§

Abstract. This paper considers a multigrid algorithm suitable for efficient solution of indefinite linear systems arising from finite element discretization of time harmonic Maxwell equations. In particular, a "backslash" multigrid cycle is proven to converge at rates independent of refinement level if certain indefinite block smoothers are used. The method of analysis involves comparing the multigrid error reduction operator with that of a related positive definite multigrid operator. This idea has previously been used in multigrid analysis of indefinite second order elliptic problems. However, the Maxwell application involves a nonelliptic indefinite operator. With the help of a few new estimates, the earlier ideas can still be applied. Some numerical experiments with lowest order Nedelec elements are also reported.

Key words. multigrid, indefinite, Maxwell equations, preconditioner, Nedelec space, Jacobi, Gauss–Seidel, Poincaré inequality, finite element

1. Introduction.

The purpose of this paper is to study certain multigrid methods for the solution of the discrete equations which result from time harmonic Maxwell equations. Since the introduction of Nedelec elements [22], finite element methods using these **curl**-conforming elements have become a popular choice for discretization of Maxwell equations. An analysis of the finite element method in the time harmonic case and lossless media was provided in [20]. However, the efficient solution of the resulting linear systems has remained a challenge, mainly for two reasons: the linear systems are indefinite, and the differential operator **curl** has a large null space.

For the time harmonic problem, although a multigrid analysis has been lacking, numerical experiments indicating the suitability of certain two-level and multilevel algorithms can be found in literature [3, 4, 23]. Numerical results for parallel preconditioners based on Schwarz overlapping techniques were reported in [23]. Computational experiments with a multigrid V-cycle have been reported [3, 4]. More recently, an analysis for an additive overlapping preconditioner and a two-level multiplicative variant were given in [16].

Two works that made recent advances related to the development of preconditioners for Maxwell equations, [1] and [17], deserve special mention. Both provided smoothers for use in a multigrid V-cycle for the positive definite bilinear form $\mathbf{\Lambda}(\cdot,\cdot)$ defined later in (2.1). These smoothers are based on two different subspace decompositions of the Nedelec space. Our smoothers for the indefinite problem are constructed

based on the same decompositions, and our analysis makes use of the results in [1] and [17].

The current paper provides an analysis for a multilevel algorithm. Specifically, we prove that the so-called *backslash cycle* gives a convergent linear iterative method with a convergence rate independent of mesh size, provided the coarse grid is sufficiently fine. The latter restriction stems from the indefiniteness and seems unavoidable both in theory and practice. Fundamentally different solution methods may be needed to overcome this. Nonetheless, in spite of this restriction there are many practical applications (of moderate frequencies) where a multigrid iteration using a relatively fine coarse grid can reduce computational effort significantly.

The analysis we will provide is based on [16] and an earlier paper on multigrid applied to elliptic nonsymmetric and indefinite problems [6] (see also [8]). In [6], a perturbation technique to analyze a multigrid algorithm for indefinite or nonsymmetric operators was developed. This involves comparing the error propagation operator of the multigrid algorithm with that of a multigrid algorithm for a corresponding positive definite operator. The difference between these operators was then proved small for elliptic problems that may be nonsymmetric or indefinite. However, our application involves a nonelliptic operator. We will show that techniques in [6] can still be applied. In [16], some fundamental estimates were developed concerning the approximation properties of the discrete solution operator corresponding to the time harmonic Maxwell approximation. These estimates will play an important role in the analysis given here.

The outline of the remainder of the paper is as follows. In section 2, we define the problem and give the multigrid algorithm. Smoothers are defined and analyzed in section 3. Convergence estimates for the multigrid algorithm are given in section 4. Finally, the results of numerical experiments are given in section 5.

2. The problem and multigrid algorithm. We set up a model problem arising from time harmonic Maxwell equations and a simple multigrid algorithm in this section. First we establish notation for some spaces and their norms. Let Ω be an open bounded connected polyhedral domain in $\mathbb{R}^3$, and let $L^2(\Omega)$ denote the space of square integrable functions on Ω. We will use $(\cdot,\cdot)_\Omega$ and $\|\cdot\|_{0,\Omega}$ to denote the innerproduct and norm, respectively, in $L^2(\Omega)$ or $L^2(\Omega)^3$. The latter will often be abbreviated to $\|\cdot\|$. In the space of vector functions in $L^2(\Omega)^3$ with square integrable $\mathbf{curl}$, tangential traces $\boldsymbol{n}\times\boldsymbol{u}$ on the boundary $\partial\Omega$ are well defined [15], and we define

$$H_0(\mathbf{curl}\,;\Omega) = \{\boldsymbol{u}\in (L^2(\Omega))^3 : \mathbf{curl}\,\boldsymbol{u}\in (L^2(\Omega))^3,\ \boldsymbol{n}\times\boldsymbol{u}=0 \text{ on } \partial\Omega\}.$$

Here $\boldsymbol{n}$ is the unit outward normal on the boundary $\partial\Omega$. This space is normed with $\|\cdot\|_{\boldsymbol{\Lambda},\Omega} = \boldsymbol{\Lambda}(\cdot,\cdot)^{1/2}$, where

$$\boldsymbol{\Lambda}(\boldsymbol{u},\boldsymbol{v}) = (\boldsymbol{u},\boldsymbol{v})_\Omega + (\mathbf{curl}\,\boldsymbol{u},\mathbf{curl}\,\boldsymbol{v})_\Omega. \tag{2.1}$$

Analogous definitions hold for $\|\cdot\|_{0,D}$, $(\cdot,\cdot)_D$, and $\|\cdot\|_{\boldsymbol{\Lambda},D}$ in domains D different from Ω. In the notation for function spaces and their norms, when the domain is absent, it is to be taken as Ω; for example, $H_0(\mathbf{curl}) \equiv H_0(\mathbf{curl}\,;\Omega)$.

We restrict our attention to the time harmonic Maxwell equations in a homogeneous lossless media occupying Ω and also assume that the boundary of Ω is adjacent to a perfect conductor. The following equation is a variational system for the electric field $\boldsymbol{U}\in H_0(\mathbf{curl}\,;\Omega)$ given by Maxwell equations [11, 20] in the simple case of unit

material properties:

$$\boldsymbol{A}(\boldsymbol{U},\boldsymbol{v}) = (\boldsymbol{F},\boldsymbol{v}) \quad \text{for all } \boldsymbol{v} \in H_0(\mathbf{curl}\,;\Omega), \tag{2.2}$$

where

$$\boldsymbol{A}(\boldsymbol{U},\boldsymbol{v}) = (\mathbf{curl}\,\boldsymbol{U},\mathbf{curl}\,\boldsymbol{v}) - \omega^2(\boldsymbol{U},\boldsymbol{v}).$$

The vector $\boldsymbol{F}$, being a constant multiple of electric current, has zero divergence, and consequently $\operatorname{div}\boldsymbol{U} = 0$. In (2.2), ω is a real number denoting frequency of propagation. Note that there is a countable set of real values for ω for which (2.2) does not have a unique solution [19]. Throughout this paper we assume that ω is not one of these values and so (2.2) is uniquely solvable.

In our arguments later, we will need the solutions to (2.2) to be regular, and hence we assume that Ω is convex. It is well known [14, 20] that $\boldsymbol{U}, \mathbf{curl}\,\boldsymbol{U} \in (H^1(\Omega))^3$ and there is a constant C_Ω depending only on Ω such that

$$\|\boldsymbol{U}\|_{H^1} + \|\mathbf{curl}\,\boldsymbol{U}\|_{H^1} \le C_\Omega \|\boldsymbol{F}\|. \tag{2.3}$$

In (2.3), $\|\cdot\|_{H^1}$ denotes the norm in $(H^1(\Omega))^3$ and $H^1(\Omega) = \{u \in L^2(\Omega) : \mathbf{grad}\ u \in (L^2(\Omega))^3\}$. For later use, let us also denote $H^1_0(\Omega)$ to be the set of functions in $H^1(\Omega)$ which vanish on $\partial\Omega$.

The preconditioner which we shall consider is developed in terms of multilevel approximation subspaces of $H_0(\mathbf{curl})$. We start with a coarse partitioning of Ω into (nonoverlapping) tetrahedra $\mathcal{T}_1 = \{\tau_1^i : \ i = 1, \dots, N_0\}$. This forms a quasi-uniform mesh of mesh size d_1. A nested sequence of shape regular meshes $\mathcal{T}_k$, $k = 2, 3, \dots$, can be obtained by successively refining $\mathcal{T}_1$, using, e.g., techniques given in [2]. For a given tetrahedron τ, let h_τ denote the radius of the largest ball contained in τ, and let H_τ denote the diameter of τ. By uniformity, we assume that there is a constant ζ not depending on $\mathcal{T}_i$ satisfying

$$\zeta h_\tau \ge H_\tau \quad \text{for all } \tau \in \mathcal{T}_i, \quad i = 1, \dots, j. \tag{2.4}$$

Our goal is to solve the problem associated with the finest mesh $\mathcal{T}_j$ for some integer $j > 1$. The mesh size of $\mathcal{T}_1$ will be denoted by d_1 and can be taken to be the diameter of the largest tetrahedron. The mesh size of $\mathcal{T}_k$ is essentially $2^{1-k}d_1$.

For theoretical and practical purposes, the coarsest grid in the multilevel algorithm must be sufficiently fine. For $k = 1, \dots, J$, let M_k denote the lowest order Nedelec finite element subspaces [22] of $H_0(\mathbf{curl})$ (of the first kind) based on $\mathcal{T}_{k+L}$ for some $L \ge 0$. The coarsest approximation subspace M_1 can be made sufficiently accurate by increasing L. Since the meshes are nested, it follows that

$$M_1 \subset M_2 \subset \cdots \subset M_J.$$

The space M_k has a mesh size of $h_k = 2^{1-L-k}d_1 = 2^{1-k}h_1$. Also let W_k be the subspace of continuous scalar functions which are linear in every element of $\mathcal{T}_{k+L}$. In the appendix, we show how our results can be generalized to higher order Nedelec elements.

It was shown in [20] (see also [21]) that the discrete problem of finding $\boldsymbol{U}_k \in M_k$ satisfying

$$\boldsymbol{A}(\boldsymbol{U}_k,\boldsymbol{v}) = (\boldsymbol{F},\boldsymbol{v}) \quad \text{for all } \boldsymbol{v} \in M_k \tag{2.5}$$

has a unique solution provided h_k is small enough. We will assume that h_1 is small enough (or, equivalently, L is large enough) so that (2.5) is uniquely solvable for $k = 1, 2, \ldots, J$.

In our analysis, we shall use the projector $\boldsymbol{P}_k : H_0(\mathbf{curl}) \mapsto M_k$ defined by

$$\boldsymbol{A}(\boldsymbol{P}_k\boldsymbol{u}, \boldsymbol{v}) = \boldsymbol{A}(\boldsymbol{u}, \boldsymbol{v}) \quad \text{for all } \boldsymbol{v} \in M_k$$

and the orthogonal L^2-projector $\boldsymbol{Q}_k : (L^2(\Omega))^3 \mapsto M_k$ defined by

$$(\boldsymbol{Q}_k\boldsymbol{u}, \boldsymbol{v}) = (\boldsymbol{u}, \boldsymbol{v}) \quad \text{for all } \boldsymbol{v} \in M_k.$$

That $\boldsymbol{P}_k$ is well defined (for $k = 1, 2, \ldots, J$) follows from the unique solvability of (2.5). Let us also introduce, for each k, an operator $\boldsymbol{A}_k : M_k \to M_k$ defined by

$$(\boldsymbol{A}_k\boldsymbol{u}, \boldsymbol{v}) = \boldsymbol{A}(\boldsymbol{u}, \boldsymbol{v}) \quad \text{for all } \boldsymbol{v} \in M_k.$$

Problem (2.5), on level J, can be rewritten in the above notation as

$$\boldsymbol{A}_J\boldsymbol{U}_J = \boldsymbol{Q}_J\boldsymbol{F}. \tag{2.6}$$

We describe a simple multigrid algorithm for iteratively computing the solution $\boldsymbol{U}_J$ of (2.6). Given an initial iterate $\boldsymbol{u}_0 \in M_J$, we define a sequence approximating $\boldsymbol{U}_J$ by

$$\boldsymbol{u}_{i+1} = \boldsymbol{Mg}_J(\boldsymbol{u}_i, \boldsymbol{Q}_J\boldsymbol{F}). \tag{2.7}$$

Here $\boldsymbol{Mg}_J(\cdot, \cdot)$ is the map of $M_J \times M_J$ into M_J defined by the following algorithm.

ALGORITHM 2.1. *Set* $\boldsymbol{Mg}_1(\boldsymbol{v}, \boldsymbol{w}) = \boldsymbol{A}_1^{-1}\boldsymbol{w}$. *Let* $k > 1$ *and* $\boldsymbol{v}, \boldsymbol{w} \in M_k$. *Assuming that* $\boldsymbol{Mg}_{k-1}(\cdot, \cdot)$ *has been defined, we define* $\boldsymbol{Mg}_k(\boldsymbol{v}, \boldsymbol{w})$ *as follows:*

(1) *Set* $\boldsymbol{x} = \boldsymbol{v} + \boldsymbol{R}_k(\boldsymbol{w} - \boldsymbol{A}_k\boldsymbol{v})$.

(2) $\boldsymbol{Mg}_k(\boldsymbol{v}, \boldsymbol{w}) = \boldsymbol{x} + \boldsymbol{Mg}_{k-1}(\boldsymbol{0}, \boldsymbol{Q}_{k-1}(\boldsymbol{w} - \boldsymbol{A}_k\boldsymbol{x}))$.

Here $\boldsymbol{R}_k : M_k \mapsto M_k$ is a linear smoothing operator. Note that in this multigrid algorithm (often called a "backslash cycle") we smooth only as we proceed to coarser grids. Our smoothing operators will always be based on a generalized block Jacobi or block Gauss–Seidel iteration. In this case, the Gramm matrix inversions associated with $\boldsymbol{Q}_k$, $k = 2, \ldots, J$, are avoided (see [5] or [24]). The smoother $\boldsymbol{R}_k$ will be defined in section 3.

$\boldsymbol{Mg}_J(\cdot, \cdot)$ is a linear map from $M_J \times M_J$ into M_J. Moreover, the scheme is consistent in the sense that $\boldsymbol{v} = \boldsymbol{Mg}_J(\boldsymbol{v}, \boldsymbol{A}_J\boldsymbol{v})$ for all $\boldsymbol{v} \in M_J$. It easily follows that the linear operator $\boldsymbol{E} = \boldsymbol{Mg}_J(\cdot, 0)$ is the error reduction operator for (2.7), that is,

$$\boldsymbol{u} - \boldsymbol{u}_{i+1} = \boldsymbol{E}(\boldsymbol{u} - \boldsymbol{u}_i).$$

Error reduction operators for variational multigrid algorithms generally have a product representation (see, e.g., [7]). Let $\boldsymbol{T}_k = \boldsymbol{R}_k\boldsymbol{A}_k\boldsymbol{P}_k$ for $k > 1$ and set $\boldsymbol{T}_1 = \boldsymbol{P}_1$. Let $\boldsymbol{E}_k\boldsymbol{u} = \boldsymbol{u} - \boldsymbol{Mg}_k(\boldsymbol{0}, \boldsymbol{A}_k\boldsymbol{P}_k\boldsymbol{u})$ and $\boldsymbol{E}_0 \equiv \boldsymbol{I}$, the identity operator. Then

$$\boldsymbol{E}_k = \boldsymbol{E}_{k-1}(\boldsymbol{I} - \boldsymbol{T}_k)$$

and

$$\boldsymbol{E} = (\boldsymbol{I} - \boldsymbol{T}_1)(\boldsymbol{I} - \boldsymbol{T}_2)\cdots(\boldsymbol{I} - \boldsymbol{T}_J). \tag{2.8}$$

The product representation of the error operator given above will be a fundamental ingredient in the convergence analysis presented in section 4.

The above algorithm is a special case of more general multigrid algorithms in that we use only presmoothing. Alternatively, we could define an algorithm with just postsmoothing or both pre- and postsmoothing. The analysis of these algorithms is similar to that above and will not be presented. Algorithms with more than one smoothing are not generally advised since the smoothing iteration may be unstable.

Our multigrid analysis is based on perturbation and the estimates for the positive definite case. We define $\widetilde{\boldsymbol{P}}_k$, $\boldsymbol{\Lambda}_k$, and $\widetilde{\boldsymbol{T}}_k$ analogously to $\boldsymbol{P}_k$, $\boldsymbol{A}_k$, and $\boldsymbol{T}_k$ using the form $\boldsymbol{\Lambda}$ instead of $\boldsymbol{A}$.

3. Smoothers. In this section, we consider some smoothers appropriate for the multigrid algorithm (Algorithm 2.1). These smoothers are generalized Jacobi or Gauss–Seidel iterations, based on subspace decompositions of [1] and [17].

First, let us review the decomposition of [1]. For any $k \in \{2, 3, \dots, J\}$, let $x_{k,i}$, $i = 1, \dots, N_k^{\mathrm{I}}$, denote the interior vertices of the mesh $\mathcal{T}_{k+L}$. Let $\Omega_{k,i}^{\mathrm{I}}$ denote the interior of the union of the closures of the elements of $\mathcal{T}_{k+L}$ whose boundary contains $x_{k,i}$. Let $M_{k,i}^{\mathrm{I}}$ (resp., $W_{k,i}^{\mathrm{I}}$) denote the functions in M_k (resp., W_k) whose support is contained in $\overline{\Omega}_{k,i}^{\mathrm{I}}$. Then M_k admits the decomposition

$$M_k = \sum_{i=0}^{N_k^{\mathrm{I}}} M_{k,i}^{\mathrm{I}}.$$

Next, consider the decomposition of [17]. Let $\{\boldsymbol{\phi}_{k,i} : i = 1, \dots, n_k^M\}$ and $\{\psi_{k,i} : i = 1, \dots, n_k^W\}$ denote the usual nodal bases of M_k and W_k, respectively. Then this decomposition is given by

$$M_k = \sum_{i=0}^{N_k^{\mathrm{II}}} M_{k,i}^{\mathrm{II}},$$

where $M_{k,i}^{\mathrm{II}}$ equals the span of $\boldsymbol{\phi}_{k,i}$ for $i = 1, \dots, n_k^M$, while for $i = n_k^M + j$, $j = 1, \dots, n_k^W$, it equals the span of $\mathbf{grad}\ \psi_{k,j}$, and $N_k^{\mathrm{II}} = n_k^M + n_k^W$. Also let $\Omega_{k,i}^{\mathrm{II}}$ be such that $\overline{\Omega}_{k,i}^{\mathrm{II}}$ equals the support of nonzero functions in $M_{k,i}^{\mathrm{II}}$,

$$\mathring{M}_{k,i}^{\mathrm{I}} = \{\boldsymbol{u} \in M_{k,i}^{\mathrm{I}} \ :\ (\boldsymbol{u}, \mathbf{grad}\ \theta)_{\Omega_{k,i}^{\mathrm{I}}} = 0 \text{ for all } \theta \in W_{k,i}^{\mathrm{I}}\} \quad \text{for } i = 1, \dots, N_k^{\mathrm{I}},$$
$$\mathring{M}_{k,i}^{\mathrm{II}} = M_{k,i}^{\mathrm{II}} \quad \text{for } i = 1, \dots, n_k^M,$$

and let $\mathring{M}_{k,i}^{\mathrm{II}}$ for $i = n_k^M + 1, \dots, N_k^{\mathrm{II}}$ be empty.

Our smoothers for the indefinite form are based on the above decompositions. Let $d \in \{\mathrm{I}, \mathrm{II}\}$. Operators $\boldsymbol{Q}_{k,i}^d$, $\boldsymbol{\Lambda}_{k,i}^d$, and $\boldsymbol{A}_{k,i}^d$ are defined analogously to $\boldsymbol{Q}_k$, $\boldsymbol{\Lambda}_k$, and $\boldsymbol{A}_k$ by replacing M_k with $M_{k,i}^d$. The smoothing operators involve local solves on $M_{k,i}^d$, so before we define them we must ensure that the operators $\{\boldsymbol{A}_{k,i}^d\}$ are invertible. That this is the case if h_1 is taken sufficiently small is a consequence of the Poincaré–Friedrichs-type inequality of the next lemma. This inequality will also be important for a subsequent perturbation analysis.

In the remainder of the paper, we adopt the convention of denoting by C or c a generic constant independent of all mesh sizes $\{h_k\}$ and the number of levels J. It

will be explicitly stated when such an independence holds only in a range $0 < h_k < H$ for some H (i.e., only for small enough mesh sizes).

LEMMA 3.1. *For any* $\boldsymbol{q} \in \mathring{M}^d_{k,i}$, $d \in \{\mathrm{I}, \mathrm{II}\}$, $k = 2, \ldots, J$,

$$\|\boldsymbol{q}\| \le C h_k \|\mathbf{curl}\, \boldsymbol{q}\|. \tag{3.1}$$

Remark 3.1. Note that for discretely divergence free functions on a convex domain, such an inequality is proved in [15]. However, $\Omega^d_{k,i}$ may be nonconvex and we need the constant in the inequality to be independent of the shape of the mesh patches. The proof does not follow from a simple scaling argument as the discrete divergence free condition does not carry over under linear mapping unless the transformation is unitary.

Remark 3.2. In the case $d = \mathrm{II}$ and lowest order elements, this inequality is well known [17] and a simple proof can be given by a scaling argument.

Proof. Consider first a tetrahedron τ with a face f contained in the x–y plane with the origin at the barycenter of the face. A function $\boldsymbol{\phi}$ in the lowest order Nedelec edge space on τ with vanishing tangential components on f has the form

$$\boldsymbol{\phi} = (0, 0, \eta) + (\alpha_1, \alpha_2, 0) \times (x, y, z). \tag{3.2}$$

Here η, α_1, and α_2 are constants. Moreover, $\mathbf{curl}\, \boldsymbol{\phi} = 2\boldsymbol{\alpha}$, where $\boldsymbol{\alpha} = (\alpha_1, \alpha_2, 0)$. Also note that if $\boldsymbol{a}$ is the vertex of τ not in f and $\boldsymbol{c}$ is any vertex of f, then the tangential component of $\boldsymbol{\phi}$ along the edge connecting $\boldsymbol{a}$ to $\boldsymbol{c}$ is given by

$$(\eta\, a_3 + (\boldsymbol{\alpha} \times \boldsymbol{c}) \cdot \boldsymbol{a})/|\boldsymbol{a} - \boldsymbol{c}|, \tag{3.3}$$

where a_3 is the z-component of $\boldsymbol{a}$. We will now prove the lemma for decompositions I and II separately.

Case $d = \mathrm{I}$. Let D be the domain formed by a collection of unit sized tetrahedra τ_j, $j = 0, 1, \ldots, N$, meeting at vertex $\boldsymbol{a}$, and let the corresponding approximation spaces (of $H_0(\mathbf{curl}\,; D)$ and $H^1_0(D)$, resp.) be denoted by M'_D and W'_D. Furthermore, let $\mathring{M}'_D = \{\boldsymbol{v} \in M'_D : (\boldsymbol{v}, \mathbf{grad}\, \theta)_D = 0 \text{ for all } \theta \in W'_D\}$. If we show that

$$\|\boldsymbol{v}\| \le C \|\mathbf{curl}\, \boldsymbol{v}\| \quad \text{for all } \boldsymbol{v} \in \mathring{M}'_D, \tag{3.4}$$

the required result follows easily by dilation.

Let $\boldsymbol{\phi} \in M'_D$, let f_j denote the face of τ_j not containing $\boldsymbol{a}$, and let $\boldsymbol{c}$ be a vertex of f_j. Let $\boldsymbol{a}$ and $\boldsymbol{c}$ have local coordinate triples $\boldsymbol{a}_j \equiv (a_{j,1}, a_{j,2}, a_{j,3})$ and $\boldsymbol{c}_j$, respectively, in the coordinate system on each tetrahedron which has f_j in the x–y plane, and the origin at its barycenter. Then, by (3.2), $\boldsymbol{\phi}$ has the form $\boldsymbol{\phi} = (0, 0, \eta_j) + \boldsymbol{\alpha}_j \times (x, y, z)$. By (3.3), the tangential component of $\boldsymbol{\phi}$ along the edge connecting $\boldsymbol{a}$ to $\boldsymbol{c}$ is given by $(\eta_j\, a_{j,3} + (\boldsymbol{\alpha}_j \times \boldsymbol{c}_j) \cdot \boldsymbol{a}_j)/|\boldsymbol{a}_j - \boldsymbol{c}_j|$. If τ_l is another tetrahedron in D sharing the vertex $\boldsymbol{c}$, then the same quantity is also given by $(\eta_l\, a_{l,3} + (\boldsymbol{\alpha}_l \times \boldsymbol{c}_l) \cdot \boldsymbol{a}_l)/|\boldsymbol{a}_l - \boldsymbol{c}_l|$. Here subscripts l indicate coordinates in the τ_l system. Thus

$$\eta_l = \frac{\eta_j\, a_{j,3} + (\boldsymbol{\alpha}_j \times \boldsymbol{c}_j) \cdot \boldsymbol{a}_j - (\boldsymbol{\alpha}_l \times \boldsymbol{c}_l) \cdot \boldsymbol{a}_l}{a_{l,3}}. \tag{3.5}$$

Let $\boldsymbol{v} \in \mathring{M}'_D$. We will construct a function $\boldsymbol{\phi}$ in M'_D which satisfies

$$\mathbf{curl}\, \boldsymbol{\phi} = \mathbf{curl}\, \boldsymbol{v} \quad \text{and} \quad \|\boldsymbol{\phi}\| \le C \|\mathbf{curl}\, \boldsymbol{v}\|, \tag{3.6}$$

with C depending only on the quasi uniformity condition. Note that $\boldsymbol{v} - \boldsymbol{\phi}$ is a gradient of a function in W_D', so

$$\|\boldsymbol{v}\| \le \|\boldsymbol{\phi}\| \le C\|\mathbf{curl}\,\boldsymbol{v}\|;$$

i.e., (3.4) follows if we construct $\boldsymbol{\phi}$ satisfying (3.6).

We define $\boldsymbol{\phi} = \boldsymbol{v} - \mu\mathbf{grad}\,\psi_{\boldsymbol{a}}$, where $\psi_{\boldsymbol{a}}$ is the nodal function in W_D' which is one on $\boldsymbol{a}$ and μ is to be determined. Clearly, $\mathbf{grad}\,\psi_{\boldsymbol{a}}$ has a local representation of the form

$$\mathbf{grad}\,\psi_{\boldsymbol{a}} = (0, 0, \zeta_j)$$

on τ_j with $\zeta_j \neq 0$. We choose μ so that $\eta_0 = 0$ in the above representation of $\boldsymbol{\phi}$. All of the remaining η_j's in the representation of $\boldsymbol{\phi}$ can be determined from the $\boldsymbol{\alpha}_j$'s by (3.5). By quasi uniformity, $\{a_{l,3}\}$ are uniformly bounded away from zero, so magnitudes of the η_l's can be bounded in terms of the $\boldsymbol{\alpha}$'s. Now (3.6) follows by quasi uniformity and the fact that the $\boldsymbol{\alpha}$'s can be bounded in terms of $\|\mathbf{curl}\,\boldsymbol{v}\|$.

Case $d = \mathrm{II}$. Let τ, f, $\boldsymbol{a}$, and $\boldsymbol{c}$ be as in the beginning of this proof. Then, in the coordinate system there, the nodal basis function $\boldsymbol{\phi}$ of the edge connecting $\boldsymbol{a}$ to $\boldsymbol{c}$ has the representation (3.2). Moreover, if $\boldsymbol{b}$ is an alternate vertex of f, then $\eta = -(\boldsymbol{\alpha} \times \boldsymbol{b}) \cdot \boldsymbol{a}/a_3$. Since η can be bounded by $\boldsymbol{\alpha} = \mathbf{curl}\,\boldsymbol{\phi}/2$, the proof can be finished in the same way as before. ∎

PROPOSITION 3.1. *There exists an* $H > 0$ *such that whenever* $h_1 \le H$, *any solution* $\boldsymbol{p}^d_{k,i} \in M^d_{k,i}$ *of the square system*

$$\boldsymbol{A}(\boldsymbol{p}^d_{k,i}, \boldsymbol{v}_{k,i}) = \boldsymbol{A}(\boldsymbol{u}, \boldsymbol{v}_{k,i}) \quad \textit{for all } \boldsymbol{v}_{k,i} \in M^d_{k,i}$$

satisfies

$$\left\|\boldsymbol{p}^d_{k,i}\right\|_{\boldsymbol{\Lambda},\Omega^d_{k,i}} \le C\,\|\boldsymbol{u}\|_{\boldsymbol{\Lambda},\Omega^d_{k,i}} \tag{3.7}$$

for $\boldsymbol{u} \in M_k$ *and for all* $i = 1, \ldots, N_k$ *and* $d \in \{\mathrm{I}, \mathrm{II}\}$. *It follows that* $\boldsymbol{A}^d_{k,i}$ *is nonsingular.*

Proof. In the case of decomposition I, the proof proceeds exactly as an analogous result in [16, Lemma 4.2], and we omit it.

In the case $d = \mathrm{II}$, for $i = 1, \ldots, n^M_k$, (3.7) follows for sufficiently small h_k from

$$\|\mathbf{curl}\,\boldsymbol{p}^d_{k,i}\|^2 - \omega^2\|\boldsymbol{p}^d_{k,i}\|^2 = (\mathbf{curl}\,\boldsymbol{u}, \mathbf{curl}\,\boldsymbol{p}^d_{k,i}) - \omega^2(\boldsymbol{u}, \boldsymbol{p}^d_{k,i})$$

by applying the Cauchy–Schwarz inequality on the right-hand side and Lemma 3.1 on the left-hand side. For the remaining i, since $\omega > 0$,

$$\|\boldsymbol{p}^d_{k,i}\|^2 = (\boldsymbol{u}, \boldsymbol{p}^d_{k,i}),$$

so (3.7) follows. ∎

Not only does Proposition 3.1 yield the invertibility of $\boldsymbol{A}^d_{k,i}$, but it also implies that the projection operator, $\boldsymbol{P}^d_{k,i} : M_k \mapsto M_{k,i}$, given by

$$\boldsymbol{A}(\boldsymbol{P}^d_{k,i}\boldsymbol{u}, \boldsymbol{v}_{k,i}) = \boldsymbol{A}(\boldsymbol{u}, \boldsymbol{v}_{k,i}) \quad \text{for all } \boldsymbol{u} \in M_k, \boldsymbol{v}_{k,i} \in M^d_{k,i}, \quad d \in \{\mathrm{I}, \mathrm{II}\}, \tag{3.8}$$

is well defined. Moreover, (3.7) implies

$$\left\|\boldsymbol{P}^d_{k,i}\boldsymbol{u}\right\|_{\boldsymbol{\Lambda},\Omega^d_{k,i}} \le C\,\|\boldsymbol{u}\|_{\boldsymbol{\Lambda},\Omega^d_{k,i}} \tag{3.9}$$

for all $\boldsymbol{u} \in M_k$. Also define $\widetilde{\boldsymbol{P}}_{k,i}^d$ analogously to $\boldsymbol{P}_{k,i}^d$ by replacing $\boldsymbol{A}$ with $\boldsymbol{\Lambda}$ in (3.8).

Now that we have proven the invertibility of $\boldsymbol{A}_{k,i}^d$, we can define the smoothers for the indefinite problem. Jacobi-type smoothers $\boldsymbol{J}_k^{\mathrm{I}}$ and $\boldsymbol{J}_k^{\mathrm{II}}$ are given by

$$\boldsymbol{J}_k^d = \gamma \sum_{i=0}^{N_k^d} (\boldsymbol{A}_{k,i}^d)^{-1} \boldsymbol{Q}_{k,i}, \qquad d \in \{\mathrm{I}, \mathrm{II}\}, \tag{3.10}$$

where γ is a scaling factor. Gauss–Seidel-type smoothers $\boldsymbol{G}_k^d$ for $d \in \{\mathrm{I}, \mathrm{II}\}$ are defined by the following algorithm.

ALGORITHM 3.1 (indefinite Gauss–Seidel). *Let $\boldsymbol{f}$ be in M_k. We define $\boldsymbol{G}_k^d$ by the following:*

(1) *Set $\boldsymbol{v}_0 = 0 \in M_k$.*

(2) *Define $\boldsymbol{v}_i$, for $i = 1, \ldots, N_k^d$, by*

$$\boldsymbol{v}_i = \boldsymbol{v}_{i-1} + (\boldsymbol{A}_{k,i}^d)^{-1} \boldsymbol{Q}_{k,i}^d (\boldsymbol{f} - \boldsymbol{A}_k \boldsymbol{v}_{i-1}).$$

(3) *Set $\boldsymbol{G}_k^d \boldsymbol{f} = \boldsymbol{v}_{N_k^d}$.*

The analogous Jacobi and Gauss–Seidel smoothers were given in [1] and [17] for the positive definite operators $\boldsymbol{\Lambda}_k$. These are denoted here by $\widetilde{\boldsymbol{J}}_k^d$ and $\widetilde{\boldsymbol{G}}_k^d$ and are again defined by (3.10) and Algorithm 3.1, respectively, but with $\boldsymbol{\Lambda}$ in place of $\boldsymbol{A}$. The scaling factor γ in (3.10) is chosen such that the $\boldsymbol{\Lambda}$-norm of $\boldsymbol{I} - \widetilde{\boldsymbol{J}}_k^d \boldsymbol{\Lambda}_k$ is less than or equal to one for $k = 2, \ldots, J$. Such a γ can be chosen independent of J by the limited overlap property of the subspaces.

Remark 3.3. In implementation, the application of the operator $(\boldsymbol{A}_{k,i}^d)^{-1} \boldsymbol{Q}_{k,i}^d$ reduces to solving a linear system involving the stiffness matrix associated with the indefinite form $\boldsymbol{A}(\cdot, \cdot)$, and the Gramm matrix inversion corresponding to $\boldsymbol{Q}_{k,i}^d$ is avoided.

4. Analysis of the multigrid iteration. In this section we provide an analysis of the multigrid iteration of section 2. This analysis is based on the product representation of the error operator (2.8). As done in [6] for second order elliptic problems, our analysis is based on perturbation from the uniform multigrid convergence estimates for a related symmetric positive definite problem.

We start with the estimate for the positive definite problem. For operators on M_k, $k = 1, \ldots, J$, we will use $\|\cdot\|_{\boldsymbol{\Lambda}}$ to denote the operator norm induced by the vector norm $\boldsymbol{\Lambda}(\cdot, \cdot)^{1/2}$. Set $\widetilde{\boldsymbol{R}}_k$ to be any one of $\widetilde{\boldsymbol{J}}_k^{\mathrm{I}}, \widetilde{\boldsymbol{J}}_k^{\mathrm{II}}, \widetilde{\boldsymbol{G}}_k^{\mathrm{I}}$, and $\widetilde{\boldsymbol{G}}_k^{\mathrm{II}}$. Let $\widetilde{\boldsymbol{T}}_k = \widetilde{\boldsymbol{R}}_k \boldsymbol{\Lambda}_k \widetilde{\boldsymbol{P}}_k$ for $k > 1$ and $\widetilde{\boldsymbol{T}}_1 = \widetilde{\boldsymbol{P}}_1$. Consider Algorithm 2.1 with $\boldsymbol{\Lambda}_k$ in place of $\boldsymbol{A}_k$ and $\widetilde{\boldsymbol{R}}_k$ in place of $\boldsymbol{R}_k$. Its error reduction operator is

$$\widetilde{\boldsymbol{E}} = (\boldsymbol{I} - \widetilde{\boldsymbol{T}}_1)(\boldsymbol{I} - \widetilde{\boldsymbol{T}}_2) \cdots (\boldsymbol{I} - \widetilde{\boldsymbol{T}}_J). \tag{4.1}$$

The following result is contained in [1, Theorems 3.1 and 4.2], [17, Theorem 3.1], and [18, Theorem 5.4].

THEOREM 4.1. *The multigrid error reduction operator in the case of the positive definite problem satisfies*

$$\boldsymbol{\Lambda}(\widetilde{\boldsymbol{E}}\boldsymbol{u}, \widetilde{\boldsymbol{E}}\boldsymbol{u}) \leq \hat{\delta}^2 \boldsymbol{\Lambda}(\boldsymbol{u}, \boldsymbol{u}) \quad \text{for all } \boldsymbol{u} \in M_J, \tag{4.2}$$

with $0 < \hat{\delta} < 1$ independent of J.

Remark 4.1. Although the results in [1] are formulated only for symmetric smoothers, let us verify that (4.2) holds for the nonsymmetric Gauss–Seidel smoother

$\widetilde{\boldsymbol{G}}_k^{\mathrm{I}}$ as well, as stated in Theorem 4.1. Indeed, we can be more general and consider instead the smoothing operator $\widetilde{\boldsymbol{R}}_k$ of a block successive overrelaxation iteration (SOR(α)) with a relaxation parameter $0 < \alpha < 2$ (with the blocks based on $\{M_{k,i}^d\}$, $d \in \{\mathrm{I}, \mathrm{II}\}$). We appeal to [9, Lemma 2.2], which shows that (4.2) holds for the $\widetilde{\boldsymbol{E}}$ obtained by any $\widetilde{\boldsymbol{R}}_k$, provided

$$\|\boldsymbol{I} - \widetilde{\boldsymbol{R}}_k \boldsymbol{\Lambda}_k\|_{\boldsymbol{\Lambda}} \le 1 \quad \text{and} \tag{4.3}$$

$$(\underline{\widetilde{\boldsymbol{R}}}_k^{-1} \boldsymbol{u}, \boldsymbol{u}) \le C\boldsymbol{\Lambda}(\boldsymbol{u}, \boldsymbol{u}) \quad \text{for all } \boldsymbol{u} \in (\boldsymbol{I} - \widetilde{\boldsymbol{P}}_{k-1}) M_k, \tag{4.4}$$

where $\underline{\widetilde{\boldsymbol{R}}}_k = \widetilde{\boldsymbol{R}}_k + \widetilde{\boldsymbol{R}}_k^t - \widetilde{\boldsymbol{R}}_k^t \boldsymbol{\Lambda}_k \widetilde{\boldsymbol{R}}_k$. Here $\widetilde{\boldsymbol{R}}_k^t$ is the L^2-adjoint of $\widetilde{\boldsymbol{R}}_k$. That inequality (4.3) holds for the $\widetilde{\boldsymbol{R}}_k$ of SOR(α) follows immediately from the product representation,

$$\boldsymbol{I} - \widetilde{\boldsymbol{R}}_k \boldsymbol{\Lambda}_k = (\boldsymbol{I} - \alpha \widetilde{\boldsymbol{P}}_{k,N_k}^{\mathrm{I}}) \cdots (\boldsymbol{I} - \alpha \widetilde{\boldsymbol{P}}_{k,1}^{\mathrm{I}}).$$

It remains to see that (4.4) holds for this smoother. Techniques in [1] can be used to prove

$$\inf_{\{\boldsymbol{u}_i\}} \sum_{i=1}^{N_k^d} \boldsymbol{\Lambda}(\boldsymbol{u}_i, \boldsymbol{u}_i) \le C\boldsymbol{\Lambda}(\boldsymbol{u}, \boldsymbol{u}) \quad \text{for all } \boldsymbol{u} \in (\boldsymbol{I} - \widetilde{\boldsymbol{P}}_{k-1}) M_k,$$

where the infimum is taken over all decompositions $\boldsymbol{u} = \sum_{i=1}^{N_k^d} \boldsymbol{u}_i$ such that $\boldsymbol{u}_i \in M_{k,i}^d$. It can be shown as in [7, Theorem 2.2] that for the $\widetilde{\boldsymbol{R}}_k$ of SOR(α),

$$(\underline{\widetilde{\boldsymbol{R}}}_k^{-1} \boldsymbol{u}, \boldsymbol{u}) \le \frac{(1 + c\alpha)^2}{2 - \alpha} \inf_{\{\boldsymbol{u}_i\}} \sum_{i=1}^{N_k^d} \boldsymbol{\Lambda}(\boldsymbol{u}_i, \boldsymbol{u}_i) \quad \text{for all } \boldsymbol{u} \in M_k.$$

Thus, Theorem 4.1 holds for the SOR(α) smoother.

We will analyze the multigrid algorithm by examining the difference between $\boldsymbol{E}$ and $\widetilde{\boldsymbol{E}}$. Let $\boldsymbol{Z}_k = \boldsymbol{T}_k - \widetilde{\boldsymbol{T}}_k$, and suppose we have

$$\|\boldsymbol{Z}_1\|_{\boldsymbol{\Lambda}} \le \epsilon \qquad \text{and} \tag{4.5}$$

$$\|\boldsymbol{Z}_k\|_{\boldsymbol{\Lambda}} \le C_1 h_k \quad \text{for } k = 2, \ldots, J. \tag{4.6}$$

Then, it can be shown that the difference $\boldsymbol{E}_k - \widetilde{\boldsymbol{E}}_k$ is small by an argument of [6] (see also [8, Lemma 11.1]). We include the argument here for the sake of completeness: First, note that by the triangle inequality, the $\boldsymbol{\Lambda}$-norm of $(\boldsymbol{I} - \boldsymbol{T}_k) = (\boldsymbol{I} - \widetilde{\boldsymbol{T}}_k - \boldsymbol{Z}_k)$ is less than or equal to $1 + ch_k$. Therefore,

$$\|\boldsymbol{E}_k\|_{\boldsymbol{\Lambda},\Omega} \le (1 + c\epsilon) \prod_{i=2}^{k} (1 + ch_i),$$

which can be bounded by a convergent infinite product. Thus $\|\boldsymbol{E}_k\|_{\boldsymbol{\Lambda},\Omega} \le C$.

To continue, we observe the following recursion:

$$\boldsymbol{E}_k - \widetilde{\boldsymbol{E}}_k = (\boldsymbol{E}_{k-1} - \widetilde{\boldsymbol{E}}_{k-1})(\boldsymbol{I} - \widetilde{\boldsymbol{T}}_k) - \boldsymbol{E}_{k-1} \boldsymbol{Z}_k, \tag{4.7}$$

which implies that for $k > 1$,

$$\begin{aligned} \|\boldsymbol{E}_k - \widetilde{\boldsymbol{E}}_k\|_{\boldsymbol{\Lambda},\Omega} &\le \|\boldsymbol{E}_{k-1} - \widetilde{\boldsymbol{E}}_{k-1}\|_{\boldsymbol{\Lambda},\Omega} \|\boldsymbol{I} - \widetilde{\boldsymbol{T}}_k\|_{\boldsymbol{\Lambda},\Omega} + \|\boldsymbol{E}_{k-1}\|_{\boldsymbol{\Lambda},\Omega} \|\boldsymbol{Z}_k\|_{\boldsymbol{\Lambda},\Omega} \\ &\le \|\boldsymbol{E}_{k-1} - \widetilde{\boldsymbol{E}}_{k-1}\|_{\boldsymbol{\Lambda},\Omega} + Ch_k. \end{aligned}$$

Repeated application of this inequality shows that the difference $\boldsymbol{E}_k - \widetilde{\boldsymbol{E}}_k$ is small:

$$\|\boldsymbol{E}_J - \widetilde{\boldsymbol{E}}_J\|_{\boldsymbol{\Lambda},\Omega} \le c(h_1 + \epsilon).$$

Thus, we have proven the following theorem.

THEOREM 4.2. *Let* $\boldsymbol{E}$ *satisfy* (2.8) *and* $\widetilde{\boldsymbol{E}}$ *satisfy* (4.1). *Assume that* (4.5) *and* (4.6) *hold. Then there are positive constants* C, $\hat{h}_1$, *and* $\hat{\epsilon}$ *depending only on* C_1 *above such that if* $h_1 \le \hat{h}_1$ *and* $\epsilon \le \hat{\epsilon}$,

$$\|\boldsymbol{E}\|_{\boldsymbol{\Lambda}} \le \|\widetilde{\boldsymbol{E}}\|_{\boldsymbol{\Lambda}} + C(h_1 + \epsilon).$$

In (4.5) and (4.6), the operator norm of $\boldsymbol{Z}_k$ can be taken to be that of $\boldsymbol{Z}_k : M_J \mapsto M_k$ or $\boldsymbol{Z}_k : M_k \mapsto M_k$, as both norms are equal. The proofs of our main results proceed by verifying (4.5) and (4.6). In the verification of (4.5), the nature of the subspace decompositions is immaterial, and a coarse grid estimate of [16] is critical, as seen in the following lemma.

LEMMA 4.3. *There exists* $H > 0$ *such that if* $h_1 \le H$, *then* (4.5) *holds with* $\epsilon = ch_1$.

Proof. For $\boldsymbol{u}, \boldsymbol{v} \in M_J$, the following identity holds:

$$\begin{aligned} \boldsymbol{\Lambda}(\boldsymbol{Z}_1\boldsymbol{u}, \boldsymbol{v}) &= \boldsymbol{\Lambda}(\boldsymbol{P}_1\boldsymbol{u} - \boldsymbol{u}, \widetilde{\boldsymbol{P}}_1\boldsymbol{v}) \\ &= \boldsymbol{A}(\boldsymbol{P}_1\boldsymbol{u} - \boldsymbol{u}, \widetilde{\boldsymbol{P}}_1\boldsymbol{v}) + (\omega^2 + 1)(\boldsymbol{P}_1\boldsymbol{u} - \boldsymbol{u}, \widetilde{\boldsymbol{P}}_1\boldsymbol{v}) \\ &= (\omega^2 + 1)(\boldsymbol{P}_1\boldsymbol{u} - \boldsymbol{u}, \widetilde{\boldsymbol{P}}_1\boldsymbol{v}). \end{aligned} \tag{4.8}$$

It is shown in [16], using a duality argument utilizing the regularity assumption, that there exists $H > 0$ such that if $h_1 \le H$, then

$$(\boldsymbol{u} - \boldsymbol{P}_1\boldsymbol{u}, \boldsymbol{w}) \le Ch_1 \|\boldsymbol{u} - \boldsymbol{P}_1\boldsymbol{u}\|_{\boldsymbol{\Lambda}} \|\boldsymbol{w}\|_{\boldsymbol{\Lambda}}$$

for all $\boldsymbol{u} \in M_J$ and $\boldsymbol{w} \in M_1$. Thus, the lemma follows. ∎

While verifying (4.6) for specific smoothers, it will be useful to have bounds for the perturbation operators $\boldsymbol{Z}^d_{k,i} : M_J \mapsto M^d_{k,i}$, $d \in \{\mathrm{I}, \mathrm{II}\}$, defined by

$$\boldsymbol{Z}^d_{k,i} = \boldsymbol{P}^d_{k,i} - \widetilde{\boldsymbol{P}}^d_{k,i}.$$

Note that in the case of subspaces of gradients of decomposition II,

$$\boldsymbol{Z}^{\mathrm{II}}_{k,i} = 0 \quad \text{for } i = n^M_k + 1, \ldots, N^{\mathrm{II}}_k.$$

An identity similar to (4.8) can be obtained for $\boldsymbol{Z}^d_{k,i}$:

$$\boldsymbol{\Lambda}(\boldsymbol{Z}^d_{k,i}\boldsymbol{u}, \boldsymbol{v}) = -(\omega^2 + 1)(\boldsymbol{u} - \boldsymbol{P}^d_{k,i}\boldsymbol{u}, \widetilde{\boldsymbol{P}}^d_{k,i}\boldsymbol{v}). \tag{4.9}$$

LEMMA 4.4. *There exists* $H > 0$ *such that if* $h_1 \le H$,

$$(\boldsymbol{u} - \boldsymbol{P}^d_{k,i}\boldsymbol{u}, \boldsymbol{v}_{k,i}) \le Ch_k \|\boldsymbol{u} - \boldsymbol{P}^d_{k,i}\boldsymbol{u}\|_{0,\Omega^d_{k,i}} \|\mathbf{curl}\, \boldsymbol{v}_{k,i}\|_{0,\Omega^d_{k,i}}$$

for all $\boldsymbol{u} \in M_J$ *and* $\boldsymbol{v}_{k,i} \in M^d_{k,i}$, $d \in \{\mathrm{I}, \mathrm{II}\}$, $k = 2, \ldots, J$.

Proof. In the case $d = \mathrm{I}$, observe that for any $\boldsymbol{u} \in M_J$, $\boldsymbol{u} - \boldsymbol{P}^{\mathrm{I}}_{k,i}\boldsymbol{u}$ is L^2-orthogonal to functions of the form $\mathbf{grad}\, w$ for any $w \in W^{\mathrm{I}}_{k,i}$. Decomposing $\boldsymbol{v}_{k,i} = \mathbf{grad}\, w + \boldsymbol{x}$, where $w \in W^{\mathrm{I}}_{k,i}$ and $\boldsymbol{x} \in \mathring{M}^{\mathrm{I}}_{k,i}$, and applying Lemma 3.1 give

$$\begin{aligned} (\boldsymbol{u} - \boldsymbol{P}_{k,i}\boldsymbol{u}, \boldsymbol{v}_{k,i}) = (\boldsymbol{u} - \boldsymbol{P}_{k,i}\boldsymbol{u}, \boldsymbol{x}) &\le Ch_k \|\boldsymbol{u} - \boldsymbol{P}_{k,i}\boldsymbol{u}\|_{0,\Omega_{k,i}} \|\mathbf{curl}\, \boldsymbol{x}\|_{0,\Omega_{k,i}} \\ &= Ch_k \|\boldsymbol{u} - \boldsymbol{P}_{k,i}\boldsymbol{u}\|_{0,\Omega_{k,i}} \|\mathbf{curl}\, \boldsymbol{v}_{k,i}\|_{0,\Omega_{k,i}}. \end{aligned}$$

In the case $d = \mathrm{II}$, the result immediately follows from Cauchy–Schwarz inequality and Lemma 3.1 for $\boldsymbol{v}_{k,i} \in \mathring{M}^{\mathrm{II}}_{k,i}$. For the remaining $\boldsymbol{v}_{k,i} \in M^{\mathrm{II}}_{k,i}$, both sides of the inequality of the lemma are zero. ∎

The following theorem is our main result.

THEOREM 4.5. *In Algorithm* 2.1*, set* $\boldsymbol{R}_k$ *to any of the smoothers* $\boldsymbol{J}^{\mathrm{I}}_k, \boldsymbol{G}^{\mathrm{I}}_k, \boldsymbol{J}^{\mathrm{II}}_k$*, and* $\boldsymbol{G}^{\mathrm{II}}_k$ *defined earlier. Then there exists an* $H > 0$ *such that whenever* $h_1 \le H$*,*

$$\boldsymbol{\Lambda}(\boldsymbol{E}\boldsymbol{u}, \boldsymbol{E}\boldsymbol{u}) \le \delta^2 \boldsymbol{\Lambda}(\boldsymbol{u}, \boldsymbol{u}) \quad \text{for all } \boldsymbol{u} \in M_J,$$

for $\delta = \hat{\delta} + ch_1$*. Here* $\hat{\delta}$ *is less than one (and independent of* J*) and is given by Theorem* 4.1 *applied to the corresponding smoother* $\widetilde{\boldsymbol{R}}_k$*. In addition,* c *is independent of* h_1*.*

Proof. We apply Theorem 4.2. By Lemma 4.3, we need only verify (4.6) for each of the smoothers $\boldsymbol{J}^{\mathrm{I}}_k, \boldsymbol{G}^{\mathrm{I}}_k, \boldsymbol{J}^{\mathrm{II}}_k$, and $\boldsymbol{G}^{\mathrm{II}}_k$. Since the proof for the case of the latter two smoothers is completely analogous to that for the case of the smoothers based on decomposition I, we give only the proof for $\boldsymbol{J}^{\mathrm{I}}_k$ and $\boldsymbol{G}^{\mathrm{I}}_k$.

In the case of $\boldsymbol{R}_k = \boldsymbol{J}^{\mathrm{I}}_k$, the perturbation operator $\boldsymbol{Z}_k$, $k > 1$, satisfies

$$\boldsymbol{Z}_k \boldsymbol{u} = \gamma \sum_{i=1}^{N_k} (\boldsymbol{P}^{\mathrm{I}}_{k,i} - \widetilde{\boldsymbol{P}}^{\mathrm{I}}_{k,i})\boldsymbol{u} = \gamma \sum_{i=1}^{N_k} \boldsymbol{Z}^{\mathrm{I}}_{k,i} \boldsymbol{u}$$

for any $\boldsymbol{u} \in M_k$. By (4.9), Lemma 4.4, and (3.9),

$$\boldsymbol{\Lambda}(\boldsymbol{Z}^{\mathrm{I}}_{k,i}\boldsymbol{u}, \boldsymbol{v}) = (\omega^2 + 1)(\boldsymbol{P}^{\mathrm{I}}_{k,i}\boldsymbol{u} - \boldsymbol{u}, \widetilde{\boldsymbol{P}}^{\mathrm{I}}_{k,i}\boldsymbol{v}) \le ch_k \, \|\boldsymbol{u}\|_{\boldsymbol{\Lambda}, \Omega^{\mathrm{I}}_{k,i}} \, \|\boldsymbol{v}\|_{\boldsymbol{\Lambda}, \Omega^{\mathrm{I}}_{k,i}} \tag{4.10}$$

for any $\boldsymbol{u}, \boldsymbol{v} \in M_k$. Hence,

$$\boldsymbol{\Lambda}(\boldsymbol{Z}_k \boldsymbol{u}, \boldsymbol{v}) \le ch_k \sum_{i=1}^{N_k} \|\boldsymbol{u}\|_{\boldsymbol{\Lambda}, \Omega^{\mathrm{I}}_{k,i}} \, \|\boldsymbol{v}\|_{\boldsymbol{\Lambda}, \Omega^{\mathrm{I}}_{k,i}}.$$

The inequality (4.6) now easily follows using the limited overlap properties of the domains $\Omega^{\mathrm{I}}_{k,i}$. This completes the proof of the theorem when $\boldsymbol{R}_k = \boldsymbol{J}^{\mathrm{I}}_k$.

Now consider the case $\boldsymbol{R}_k = \boldsymbol{G}^{\mathrm{I}}_k$. As before, it suffices to verify (4.6). Define $\widetilde{\boldsymbol{\mathcal{E}}}_i$ and $\boldsymbol{\mathcal{E}}_i$ by

$$\begin{aligned} \widetilde{\boldsymbol{\mathcal{E}}}_i &= (\boldsymbol{I} - \widetilde{\boldsymbol{P}}^{\mathrm{I}}_{k,i})(\boldsymbol{I} - \widetilde{\boldsymbol{P}}^{\mathrm{I}}_{k,i-1}) \cdots (\boldsymbol{I} - \widetilde{\boldsymbol{P}}^{\mathrm{I}}_{k,1}) \text{ and} \\ \boldsymbol{\mathcal{E}}_i &= (\boldsymbol{I} - \boldsymbol{P}^{\mathrm{I}}_{k,i})(\boldsymbol{I} - \boldsymbol{P}^{\mathrm{I}}_{k,i-1}) \cdots (\boldsymbol{I} - \boldsymbol{P}^{\mathrm{I}}_{k,1}), \end{aligned}$$

and let $\widetilde{\boldsymbol{\mathcal{E}}}_0 = \boldsymbol{\mathcal{E}}_0 = \boldsymbol{I}$. Then the perturbation operator $\boldsymbol{Z}_k : M_k \mapsto M_k$ for this example is

$$\boldsymbol{Z}_k = \boldsymbol{T}_k - \widetilde{\boldsymbol{T}}_k = \widetilde{\boldsymbol{\mathcal{E}}}_{N_k} - \boldsymbol{\mathcal{E}}_{N_k}.$$

We clearly have that

$$\widetilde{\boldsymbol{\mathcal{E}}}_i - \boldsymbol{\mathcal{E}}_i = (\boldsymbol{I} - \widetilde{\boldsymbol{P}}^{\mathrm{I}}_{k,i})(\widetilde{\boldsymbol{\mathcal{E}}}_{i-1} - \boldsymbol{\mathcal{E}}_{i-1}) - \boldsymbol{Z}^{\mathrm{I}}_{k,i} \boldsymbol{\mathcal{E}}_{i-1}.$$

Since the terms on the right are orthogonal with respect to $\boldsymbol{\Lambda}(\cdot, \cdot)$,

$$\|(\widetilde{\boldsymbol{\mathcal{E}}}_i - \boldsymbol{\mathcal{E}}_i)\boldsymbol{u}\|^2_{\boldsymbol{\Lambda}, \Omega} = \|(\boldsymbol{I} - \widetilde{\boldsymbol{P}}^{\mathrm{I}}_{k,i})(\widetilde{\boldsymbol{\mathcal{E}}}_{i-1} - \boldsymbol{\mathcal{E}}_{i-1})\boldsymbol{u}\|^2_{\boldsymbol{\Lambda}, \Omega} + \|\boldsymbol{Z}^{\mathrm{I}}_{k,i} \boldsymbol{\mathcal{E}}_{i-1} \boldsymbol{u}\|^2_{\boldsymbol{\Lambda}, \Omega}.$$

It follows from (4.10) that $\|\boldsymbol{Z}^{\mathrm{I}}_{k,i}\boldsymbol{v}\|_{\boldsymbol{\Lambda},\Omega} \le Ch_k\|\boldsymbol{v}\|_{\boldsymbol{\Lambda},\Omega^{\mathrm{I}}_{k,i}}$. This and the fact that the $\boldsymbol{\Lambda}$-operator norm of $(\boldsymbol{I}-\widetilde{\boldsymbol{P}}^{\mathrm{I}}_{k,i})$ is bounded by one imply that

$$\|(\widetilde{\boldsymbol{\mathcal{E}}}_i-\boldsymbol{\mathcal{E}}_i)\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} \le \|(\widetilde{\boldsymbol{\mathcal{E}}}_{i-1}-\boldsymbol{\mathcal{E}}_{i-1})\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} + Ch_k^2\|\boldsymbol{\mathcal{E}}_{i-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega_{k,i}}.$$

Summing over i and obvious manipulations give

$$\|(\widetilde{\boldsymbol{\mathcal{E}}}_{N_k}-\boldsymbol{\mathcal{E}}_{N_k})\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} \le Ch_k^2\sum_{i=1}^{N_k}\|\boldsymbol{\mathcal{E}}_{i-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega_{k,i}}. \tag{4.11}$$

We shall now show that for sufficiently small h_1,

$$\sum_{i=1}^{N_k}\|\boldsymbol{\mathcal{E}}_{i-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega_{k,i}} \le C\|\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega}. \tag{4.12}$$

We first note the identity

$$\boldsymbol{I}-\boldsymbol{\mathcal{E}}_i = \sum_{m=1}^{i}\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}.$$

Thus, by the arithmetic-geometric mean inequality, the definition of $\boldsymbol{\mathcal{E}}_i$, and the limited interaction property, it follows that

$$\begin{aligned}
\sum_{i=1}^{N_k}\|\boldsymbol{\mathcal{E}}_{i-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega^{\mathrm{I}}_{k,i}} &\le 2\sum_{i=1}^{N_k}\|\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega^{\mathrm{I}}_{k,i}} + 2\sum_{i=1}^{N_k}\|\boldsymbol{u}-\boldsymbol{\mathcal{E}}_{i-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega^{\mathrm{I}}_{k,i}}\\
&\le C\|\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} + 2\sum_{i=1}^{N_k}\left\|\sum_{m=1}^{i-1}\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\right\|^2_{\boldsymbol{\Lambda},\Omega^{\mathrm{I}}_{k,i}}\\
&\le C\left(\|\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} + \sum_{m=1}^{N_k}\sum_{i=1}^{N_k}\|\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega^{\mathrm{I}}_{k,i}}\right)\\
&\le C\left(\|\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} + \sum_{m=1}^{N_k}\|\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega}\right).
\end{aligned} \tag{4.13}$$

In order to estimate the last term on the right of (4.13), we write

$$\begin{aligned}
\|\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} &= \|\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} - \|\boldsymbol{\mathcal{E}}_m\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega}\\
&\quad - 2\boldsymbol{\Lambda}(\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u},(\boldsymbol{I}-\boldsymbol{P}^{\mathrm{I}}_{k,m})\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}).
\end{aligned} \tag{4.14}$$

Now by (4.9),

$$\boldsymbol{\Lambda}(\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u},(\boldsymbol{I}-\boldsymbol{P}^{\mathrm{I}}_{k,m})\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}) = (1+\omega^2)(\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u},(\boldsymbol{I}-\boldsymbol{P}^{\mathrm{I}}_{k,m})\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}),$$

so by Lemma 4.4 we have

$$\|\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} \le C(\|\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} - \|\boldsymbol{\mathcal{E}}_m\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega}) + Ch_k^2\|\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega^{\mathrm{I}}_{k,m}}.$$

Summing over m, we conclude that

$$\sum_{m=1}^{N_k} \|\boldsymbol{P}^{\mathrm{I}}_{k,m}\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} \le C\left(\|\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega} + h_k^2 \sum_{m=1}^{N_k} \|\boldsymbol{\mathcal{E}}_{m-1}\boldsymbol{u}\|^2_{\boldsymbol{\Lambda},\Omega^{\mathrm{I}}_{k,m}}\right). \tag{4.15}$$

Clearly (4.15) and (4.13) yield (4.12) for small enough h_1.

Finally, we obtain from (4.12) and (4.11) that for $k > 1$,

$$\|\boldsymbol{Z}_k\|_{\boldsymbol{\Lambda},\Omega} \le Ch_k.$$

The theorem follows from Lemma 4.3 and Theorem 4.2. ∎

Remark 4.2. The same analysis could be used for the SOR(α) iteration considered in Remark 4.1. In that case,

$$\boldsymbol{\mathcal{E}}_l = (\boldsymbol{I} - \alpha\boldsymbol{P}^d_{k,l})(\boldsymbol{I} - \alpha\boldsymbol{P}^d_{k,l-1})\cdots(\boldsymbol{I} - \alpha\boldsymbol{P}^d_{k,1}).$$

Also, by Remark 4.1, Theorem 4.1 holds with the SOR(α) smoother.

5. Numerical results. Numerical experiments were conducted using lowest order Nedelec elements on cubes. We report results of some of these experiments in this section. First, let us note that not only can Algorithm 2.1 be used as a linear solver for (2.6), but it can also be used to develop a preconditioner. Specifically, the operator $\boldsymbol{B}_J : M_J \mapsto M_J$ defined by $\boldsymbol{B}_J\boldsymbol{g} = \boldsymbol{Mg}_J(\boldsymbol{0}, \boldsymbol{g})$ is a preconditioner for $\boldsymbol{A}_J$ in the sense that the inequalities

$$\begin{aligned} &(1-\delta)\,\boldsymbol{\Lambda}(\boldsymbol{u},\boldsymbol{u}) \le \boldsymbol{\Lambda}(\boldsymbol{B}_J\boldsymbol{A}_J\boldsymbol{u},\boldsymbol{u}) \quad \text{and} \\ &\boldsymbol{\Lambda}(\boldsymbol{B}_J\boldsymbol{A}_J\boldsymbol{u},\boldsymbol{v}) \le (1+\delta)\boldsymbol{\Lambda}(\boldsymbol{u},\boldsymbol{u})^{1/2}\boldsymbol{\Lambda}(\boldsymbol{v},\boldsymbol{v})^{1/2} \end{aligned} \tag{5.1}$$

hold for all $\boldsymbol{u}, \boldsymbol{v} \in M_J$, for sufficiently small coarse mesh sizes. These bounds easily follow from Theorem 4.5, and δ is as in the theorem. They imply that when GMRES in the $\boldsymbol{\Lambda}(\cdot,\cdot)$ innerproduct is used to solve (2.6) with $\boldsymbol{B}_J$ as preconditioner, the number of iterations remains bounded independently of refinement level [12, 16]. In this section we will investigate the performance of $\boldsymbol{B}_J$ as a preconditioner for use in GMRES as well as that of the linear solver $\boldsymbol{Mg}_J(\cdot,\cdot)$ given by Algorithm 2.1.

In all experiments, our computational domain was $\Omega = (0,1)^3$. We investigate only the multigrid algorithm with the smoother $\boldsymbol{G}^{\mathrm{I}}_k$ based on decomposition I. The domain $(0,1)^3$ was meshed by a hierarchy of multilevel uniform cubic meshes. Each mesh is obtained by breaking up every cubic element of a coarser mesh into eight congruent cubes, the coarsest mesh being just $\{\Omega\}$. Clearly, our analysis holds in this situation. (In particular, a Poincaré–Friedrichs inequality like that of Lemma 3.1 is obvious for uniform cubic meshes.)

The linear system (2.6) is solved on a fine ($k = J$) mesh of mesh size h using one of the two above-mentioned iterative methods. The coarse solves of the multigrid algorithm are done on a coarse ($k = 1$) mesh of mesh size H. All coarse solves were done by direct methods of UMFPACK2.2 [10]. The right-hand side of (2.6) was chosen so that the true solution equals the interpolant of $\boldsymbol{U}(x,y,z) = [y(1-y)z(1-z), yx(1-x)z(1-z), x(1-x)y(1-y)]$. We report iteration counts for a set of combinations of h and H. The starting iterate was always zero. When the linear multigrid solver was used, the stopping criterion was that the $\boldsymbol{\Lambda}$-norm of error be reduced by a factor of 10^{-6}. The stopping criterion for GMRES was that the $\boldsymbol{\Lambda}$-norm of the residual (premultiplied by $\boldsymbol{B}_J$) was reduced by a factor of 10^{-6}. GMRES was set to restart after 50 iterations.

TABLE 5.1
Preconditioned GMRES iteration counts for the $\omega = 1$ case. Degrees of freedom at each refinement level are also shown in the last column.

	1/64	$\star$	266	62	15	8
	1/128	$\star$	285	67	16	10

We start with the case $\omega = 1$. GMRES iteration counts are reported in Table 5.1. The preconditioner appears to be uniform, as iteration counts never exceeded 11 for all combinations of h and H we considered. For comparison, the case $h = 1/128$ without preconditioner did not converge even after 5000 iterations.

Iteration counts obtained using the linear multigrid solver are reported in Table 5.2, and these are in accordance with Theorem 4.5. Although, in the case $\omega = 1$, the algorithm gives uniform iteration counts for all choices of H considered, this is no longer the case for a higher wave number, as seen in Table 5.3. This is again in accordance with Theorem 4.5, as its conclusion holds only whenever the coarse mesh is sufficiently fine.

We have also considered the performance of $\boldsymbol{B}_J$ as a preconditioner in GMRES for the case of a higher wave number $\omega = 10$. It is a good preconditioner only for smaller coarse mesh sizes, as Table 5.4 shows. In other (unreported) experiments, the linear multigrid algorithm for this wave number converged only for one of the combinations of h and H considered. Theoretically, (5.1) guarantees that $\boldsymbol{B}_J$ is a good preconditioner only when $\boldsymbol{Mg}_J(\cdot,\cdot)$ is a good contraction. Nonetheless, our experiments indicate that the coarse mesh size at which $\boldsymbol{B}_J$ becomes a good preconditioner is larger than that required for $\boldsymbol{Mg}_J(\cdot,\cdot)$ to be a good contraction. Similar observations have been

TABLE 5.4

Preconditioned GMRES iteration counts for $\omega = 10$ case. An entry of the form $n^{\times}$ indicates that although the residual of the nth GMRES iterate met the stopping criterion, the iterate differed from the true solution by more than 10^{-3} in the $\mathbf{\Lambda}$-norm.

$\omega = 5$

made in studies of multigrid algorithms for the Helmholtz equation [13]. This may be an argument in favor of using GMRES preconditioned with multigrid as a solution strategy, rather than the linear multigrid solver. However, we must also keep in mind that if too large a mesh size is used, GMRES may find the residual too small and stop, even though the iterate is far from the true solution (see entries $n^{\times}$).

We conclude by providing numerical convergence rates for the linear multigrid iteration which also confirm our theoretical results. Entries of Table 5.5 provide estimates for $\|\boldsymbol{I} - \boldsymbol{B}_J \boldsymbol{A}_J\|_{\mathbf{\Lambda}}$ obtained by means of the power method in the cases $\omega = 1$ and $\omega = 5$ for a few combinations of h and H. We see that the only difference between the two cases is that larger ω requires a smaller coarse grid size. Note, though, that once the coarse grid is small enough, both cases give rise to approximately the same reduction rates.

Appendix. Here we will indicate how the main result of this paper can be generalized to higher order Nedelec spaces (of the first kind). Let M_k be defined with rth order Nedelec spaces on each tetrahedron, and let W_k be the corresponding conforming approximation space with polynomials of degree at most $r + 1$. The algorithms and definitions of subspace decompositions and smoothers generalize in an obvious way for the case of decomposition I. As we shall see, Case II can also be generalized provided a suitable choice of nodal basis is made.

Case I. First, note that Theorem 4.1 holds with the higher order spaces, as shown in [1]. The only proof in the previous sections that depended on the order of the spaces is that of Lemma 3.1. We will now prove that the inequality of the lemma holds for higher order spaces as well.

We start by considering the set S of all possible quasi-uniform tetrahedral meshes contained in the unit ball with at least one vertex on the unit sphere, every element having the origin as a vertex and the origin being an interior point of the mesh. Note that this implies that the resulting mesh domains are simply connected with only one

connected boundary component.

Each element in S is represented by a list of vertices and a list of tetrahedra (a tetrahedron number to vertex number list). We can assign labels to the members of S so that two members have the same label if and only if they have the same tetrahedron to vertex list. Quasi uniformity implies that the number of labels can be bounded in terms of ζ appearing in (2.4). Let R_l be the subset of elements of S with the lth label.

Any subdomain $\Omega^{\mathrm{I}}_{k,i}$ can be dilated and translated to an element of S. Thus, it suffices to prove that (3.4) holds for each D in R_l with constant independent of D. The general result holds, taking the minimum of these constants over $\{R_l\}$.

Clearly, each domain $D \in R_l$ has the same number of vertices, say, m. We can define a distance on R_l by using any norm on the vertex set, e.g., the Euclidean norm on $\mathbb{R}^{3m}$. It follows from quasi uniformity that R_l is a closed and bounded set in this norm and hence compact.

Let D be in R_l. Denote the corresponding approximation spaces (of $H_0(\mathbf{curl}\,; D)$ and $H^1_0(D)$, resp.) by M'_D and W'_D, and set $\mathring{M}'_D = \{\boldsymbol{q} \in M'_D : (\boldsymbol{q}, \mathbf{grad}\ \theta)_D = 0, \text{ for all } \theta \in W'_D\}$. Let

$$\mathcal{I}(D) = \inf_{\boldsymbol{q} \in \mathring{M}'_D} \frac{\|\mathbf{curl}\,\boldsymbol{q}\|_{0,D}}{\|\boldsymbol{q}\|_{0,D}}. \tag{A.1}$$

Note that since D is simply connected with a connected boundary, if $\mathbf{curl}\,\boldsymbol{q} = 0$ and $\boldsymbol{q} \in M'_D$, then $\boldsymbol{q}$ is a gradient of a function in W'_D. It follows that $\mathcal{I}(D) > 0$ for any $D \in R_l$. Thus, to prove that (3.4) holds uniformly for $D \in R_l$, it suffices to show that $\mathcal{I}(D)$ is continuous.

Suppose p and q are vertex sets of two meshes in R_l, with corresponding domains D_p and D_q, respectively. Let $\epsilon > 0$ be given. For $s \in \{p, q\}$, let $\{\boldsymbol{e}^s_i\}_{i=1}^{n_l}$ denote a nodal basis for M'_{D_s}. We identify functions in the above spaces with their extension by zero to the unit ball B. Let $\boldsymbol{z} \in \mathring{M}'_{D_p}$ be a function with $\|\boldsymbol{z}\|_{0,B} = 1$ for which the infimum in (A.1) is attained, and let

$$\boldsymbol{z} = \sum_{i=1}^{n_l} c_i \boldsymbol{e}^p_i \quad \text{and} \quad \boldsymbol{z}' = \sum_{i=1}^{n_l} c_i \boldsymbol{e}^q_i.$$

By quasi uniformity, it is easy to see that if $|p - q|$ is small enough (depending on ϵ), $\|\boldsymbol{z} - \boldsymbol{z}'\|_{\boldsymbol{\Lambda},B} \le \epsilon$. Note that $\boldsymbol{z}'$ is, in general, not in $\mathring{M}'_{D_q}$. Define $\psi' \in W'_{D_q}$ by

$$(\mathbf{grad}\ \psi', \mathbf{grad}\ \phi)_B = (\boldsymbol{z}', \mathbf{grad}\ \phi)_B \quad \text{for all } \phi \in W'_{D_q}.$$

Then $\boldsymbol{z}'' = \boldsymbol{z}' - \mathbf{grad}\ \psi'$ is in $\mathring{M}'_{D_q}$. Moreover, if $|p - q|$ is small enough, it can easily be shown that $\|\boldsymbol{z}'' - \boldsymbol{z}'\|_{\boldsymbol{\Lambda},B} \le \epsilon$, so

$$\|\boldsymbol{z} - \boldsymbol{z}''\|_{\boldsymbol{\Lambda},B} \le 2\epsilon.$$

Consequently,

$$\mathcal{I}(q) - \mathcal{I}(p) \le \frac{\|\mathbf{curl}\,\boldsymbol{z}''\|_{0,D_q}}{\|\boldsymbol{z}''\|_{0,D_q}} - \mathcal{I}(p) \le C\epsilon.$$

Interchanging the roles of p and q in the above argument, we also get that $\mathcal{I}(p) - \mathcal{I}(q) \le C\epsilon$. Thus, $\mathcal{I}(p)$ is continuous on R_l. This finishes the proof of Lemma 3.1 when $d = \mathrm{I}$.

Case II. Smoothing algorithms of this type can be generalized to higher order spaces provided a suitable choice of nodal basis is made. Note that there are choices of nodal basis for which Lemma 3.1 does not hold. We will provide one example of a nodal basis for which our analysis generalizes.

Once a set of degrees of freedom for M_k is defined, a corresponding nodal basis immediately follows. The particular choice of the degrees of freedom we have in mind consists of edge, face, and tetrahedral moments. For any domain D, let $P_l(D)$ denote the set of polynomials of degree at most l, and let $\mathcal{P}_l(D)$ denote any basis for $P_l(D)$. For every interior edge e and interior face f of the kth level mesh, define the edge and face moments

$$\alpha_e^p(\boldsymbol{u}) = \int_e p(\boldsymbol{u}\cdot\boldsymbol{t})\,dt, \quad \alpha_f^{\boldsymbol{q}}(\boldsymbol{u}) = \int_f \boldsymbol{q}\cdot(\boldsymbol{u}\times\boldsymbol{n})\,ds$$

for $p \in \mathcal{P}_{r-1}(e)$ and $\boldsymbol{q} \in (\mathcal{P}_{r-2}(f))^2$. The tetrahedral moments are defined by mapping to the reference tetrahedron $\hat{\tau}$ bounded by the planes $x = 0$, $y = 0$, $z = 0$, and $x + y + z = 1$. Let $\mathcal{R}_{r-3}$ be the set of all vector polynomials that are monomials of degree at most $r-3$ in one coordinate direction and zero in others; e.g., $\boldsymbol{r} = (x^i y^j z^k, 0, 0)$ is in $\mathcal{R}_{r-3}$. For every tetrahedron τ in the kth level mesh, define the tetrahedral moments

$$\alpha_\tau^{\boldsymbol{r}}(\boldsymbol{u}) = \int_{\hat{\tau}} \boldsymbol{r}\cdot\widehat{\boldsymbol{u}}\,dx,$$

where $\boldsymbol{r} \in \mathcal{R}_{r-3}$, $\widehat{\boldsymbol{u}}(\widehat{\boldsymbol{x}}) = B^t\boldsymbol{u}(\boldsymbol{x})$, and B is the matrix in the affine correspondence $\widehat{\tau} \overset{B\widehat{\boldsymbol{x}}+b}{\mapsto} \tau$. The edge, face, and tetrahedral moments defined above form a set of degrees of freedom for M_k and define a corresponding nodal basis $\mathcal{B}$ for M_k.

The basis $\mathcal{B}$ is divided into edge basis functions, face basis functions, and interior basis functions. An edge basis function $\boldsymbol{\phi}_e^p$ corresponding to an interior edge e has all of the above-defined degrees of freedom equal to zero except $\alpha_e^p(\boldsymbol{\phi}_e^p) = 1$ for some polynomial $p \in \mathcal{P}_{r-1}(e)$. Similarly, a face basis function $\boldsymbol{\phi}_f^{\boldsymbol{q}}$ has all its moments zero except $\alpha_f^{\boldsymbol{q}}(\boldsymbol{\phi}_f^{\boldsymbol{q}}) = 1$ for some interior face f and some $\boldsymbol{q} \in \mathcal{P}_{r-2}(f)^2$. Finally, we have interior basis functions $\boldsymbol{\phi}_\tau^{\boldsymbol{r}}$ supported on τ such that all its moments are zero except $\alpha_\tau^{\boldsymbol{r}}(\boldsymbol{\phi}_\tau^{\boldsymbol{r}}) = 1$ for some $\boldsymbol{r} \in \mathcal{R}_{r-3}$. Thus,

$$\begin{aligned}\mathcal{B} =& \{\boldsymbol{\phi}_e^p : \text{ for all interior mesh edges } e \text{ and } p \in \mathcal{P}_{r-1}(e)\}\\ &\cup\{\boldsymbol{\phi}_f^{\boldsymbol{q}} : \text{ for all interior mesh faces } f \text{ and } \boldsymbol{q} \in (\mathcal{P}_{r-2}(f))^2\}\\ &\cup\{\boldsymbol{\phi}_\tau^{\boldsymbol{r}} : \text{ for all } \boldsymbol{r} \in \mathcal{R}_{r-3} \text{ and all mesh tetrahedra } \tau\}.\end{aligned}$$

Our analysis generalizes to the case when M_k is decomposed as

$$M_k \;=\; \sum_{\boldsymbol{\phi}\in\mathcal{B}} \operatorname{span}(\boldsymbol{\phi}) \;\oplus\; \sum_i \operatorname{span}(\mathbf{grad}\ \psi_{k,i}),$$

where $\{\psi_{k,i}\}$ is a local nodal basis for W_k. To show this, we first note that Theorem 4.1 holds for this decomposition, as can be seen by following the arguments of [1]. The only other ingredient in our analysis that requires generalization is Lemma 3.1. We now show that $\|\boldsymbol{\phi}\|_{0,\Omega} \le Ch_k\|\mathbf{curl}\,\boldsymbol{\phi}\|_{0,\Omega}$ for all $\boldsymbol{\phi} \in \mathcal{B}$.

It suffices to prove that there is a $\hat{C} > 0$ such that

$$\|\widehat{\boldsymbol{\phi}}\|_{0,\hat{\tau}} \le \hat{C}\|\mathbf{curl}\,\widehat{\boldsymbol{\phi}}\|_{0,\hat{\tau}} \tag{A.2}$$

for all $\boldsymbol{\phi} \in \mathcal{B}$ with $\hat{C}$ independent of τ. Here, as before, $\widehat{\boldsymbol{\phi}}(\widehat{\boldsymbol{x}}) = B^t\,\boldsymbol{\phi}(\boldsymbol{x})$ for $\boldsymbol{x} \in \tau$ for some τ on which $\boldsymbol{\phi}$ is nonzero. Clearly, (3.1) follows from (A.2) by quasi uniformity and standard affine equivalence arguments since $\|\boldsymbol{\phi}\|_{0,\tau} \le Ch_k^{1/2}\|\widehat{\boldsymbol{\phi}}\|_{0,\hat{\tau}}$ and $\|\mathbf{curl}\,\widehat{\boldsymbol{\phi}}\|_{0,\hat{\tau}} \le Ch_k^{1/2}\|\mathbf{curl}\,\boldsymbol{\phi}\|_{0,\tau}$.

We prove (A.2) for each type of basis function. First, we consider $\widehat{\boldsymbol{\phi}}_{\widehat{e}}^{\,p}$. Let $L_{\widehat{e}}$ denote the space of functions $\boldsymbol{v}$ in the rth order Nedelec space on $\widehat{\tau}$ for which all edge, face, and tetrahedral moments are zero except those associated to the edge $\widehat{e}$, which is the image of e. Clearly, $\widehat{\boldsymbol{\phi}}_{\widehat{e}}^{\,p}$ is in $L_{\widehat{e}}$. For any nonzero function $\widehat{\boldsymbol{\phi}} \in L_{\widehat{e}}$, there exists a $p \in P_{r-1}(\widehat{f})$ on a face $\widehat{f}$ adjacent to $\widehat{e}$, such that

$$0 \neq (\widehat{\boldsymbol{\phi}} \cdot \boldsymbol{t}, p)_{\partial\widehat{f}} = (p, \mathbf{curl}\,\widehat{\boldsymbol{\phi}} \cdot \boldsymbol{n})_{\widehat{f}} - (\mathbf{grad}\; p \times \boldsymbol{n}, \widehat{\boldsymbol{\phi}})_{\widehat{f}} = (p, \mathbf{curl}\,\widehat{\boldsymbol{\phi}} \cdot \boldsymbol{n})_{\widehat{f}},$$

where $\boldsymbol{n}$ is the outward unit normal on $\widehat{f}$ and $\boldsymbol{t}$ is a unit tangent vector on $\partial\widehat{f}$ (appropriately oriented). Since the left-hand side is nonzero, $\mathbf{curl}\,\widehat{\boldsymbol{\phi}} \neq 0$. Thus by the finite dimensionality of $L_{\widehat{e}}$, (A.2) holds for all $\widehat{\boldsymbol{\phi}} \in L_{\widehat{e}}$ and hence holds for $\widehat{\boldsymbol{\phi}}_{\widehat{e}}^{\,p}$.

Next, let us show (A.2) for a mapped face basis function $\widehat{\boldsymbol{\phi}}_{\widehat{f}}^{\,\boldsymbol{q}}$. Let $L_{\widehat{f}}$ denote the subspace of the rth order Nedelec space on $\widehat{\tau}$ for which all edge, face, and tetrahedral moments are zero, except for moments on face $\widehat{f}$. Clearly, $\widehat{\boldsymbol{\phi}}_{\widehat{f}}^{\,\boldsymbol{q}}$ is in $L_{\widehat{f}}$. For any nonzero $\widehat{\boldsymbol{\phi}} \in L_{\widehat{f}}$, there is a $\boldsymbol{q} \in P_{r-2}(\widehat{\tau})^3$ such that

$$0 \neq (\widehat{\boldsymbol{\phi}} \times \boldsymbol{n}, \boldsymbol{q})_{\partial\widehat{\tau}} = (\mathbf{curl}\,\widehat{\boldsymbol{\phi}}, \boldsymbol{q})_{\widehat{\tau}} - (\widehat{\boldsymbol{\phi}}, \mathbf{curl}\,\boldsymbol{q})_{\widehat{\tau}} = (\mathbf{curl}\,\widehat{\boldsymbol{\phi}}, \boldsymbol{q})_{\widehat{\tau}}.$$

Thus, $\mathbf{curl}\,\widehat{\boldsymbol{\phi}} \neq 0$ for all $\widehat{\boldsymbol{\phi}} \in L_{\widehat{f}}$ and (A.2) follows for $\widehat{\boldsymbol{\phi}}_{\widehat{f}}^{\,\boldsymbol{q}}$.

Finally, consider an interior basis function $\boldsymbol{\phi}_{\tau}^{\boldsymbol{r}}$. Obviously, all face and edge moments of $\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}}$ are zero. We will now show only that for $\boldsymbol{r} = (x^i y^j z^k, 0, 0)$, $\mathbf{curl}\,\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}} \neq 0$, as the argument is similar for other $\boldsymbol{r} \in \mathcal{R}_{r-3}$. We argue by contradiction. If $\mathbf{curl}\,\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}} = 0$, then $\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}} = \mathbf{grad}\;\psi$ for some $\psi \in P_r(\widehat{\tau})$. Moreover, since face and edge moments of $\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}}$ are zero, ψ can be chosen such that $\psi|_{\partial\widehat{\tau}} = 0$. Therefore,

$$1 = (\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}}, \boldsymbol{r})_{\widehat{\tau}} = -(\psi, \operatorname{div}\boldsymbol{r})_{\widehat{\tau}}.$$

If $i = 0$, i.e., $\boldsymbol{r} = (y^j z^k, 0, 0)$, then $\operatorname{div}\boldsymbol{r} = 0$, which is a contradiction. If $i \ge 1$, then by the definition of $\boldsymbol{\phi}_{\tau}^{\boldsymbol{r}}$, $(\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}}, \widetilde{\boldsymbol{r}}) = 0$ for $\widetilde{\boldsymbol{r}} = (0, ix^{i-1}y^{j+1}z^k/(j+1), 0)$. However, $(\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}}, \widetilde{\boldsymbol{r}})_{\widehat{\tau}} = (\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}}, \boldsymbol{r})_{\widehat{\tau}}$, which is a contradiction. Therefore, $\mathbf{curl}\,\widehat{\boldsymbol{\phi}}_{\tau}^{\boldsymbol{r}} \neq 0$, and (A.2) follows for the interior basis functions as well. Thus, we have shown that Lemma 3.1 holds for the nodal basis functions of $\mathcal{B}$.

It is easy to see that there are various other choices of nodal bases for which the lemma does not hold. For instance, in the case $r \ge 4$ the function $\mathbf{grad}\;(\lambda_1\lambda_2\lambda_3\lambda_4)$ (where λ_i are the barycentric coordinates of a tetrahedron τ) is an example of an interior basis function for which Lemma 3.1 does not hold. Another example is the function $\lambda_i\mathbf{grad}\;\lambda_j + \lambda_j\mathbf{grad}\;\lambda_i$ in the case $r = 2$. This function has only one nonzero edge moment so may be a candidate for an edge basis function. However, it has nonzero face moments. Our analysis does not hold for decompositions based on such basis functions, and it is not clear if the associated indefinite multigrid method is convergent.

A MULTIGRID METHOD FOR VISCOELASTIC FLUID FLOW*

HYESUK LEE†

Abstract. We study a multigrid finite element method for a viscoelastic fluid flow obeying an Oldroyd-B–type constitutive law. The multigrid method is a time-saving method in which the full nonlinear system is solved on a coarse grid, and subsequent approximations are generated on a succession of refined grids by solving a linearized problem. We show that the linearized problem has an approximate solution and present an error bound for a two-grid method. We also numerically demonstrate that the multigrid method is significantly more efficient than the standard one-grid finite element method.

Key words. multigrid method, viscoelastic fluid, finite elements

1. Introduction.

In this paper we consider a multigrid method for a viscoelastic fluid flow obeying an Oldroyd-B–type constitutive law. Over the last decades, significant progress has been made in developing finite element algorithms for viscoelastic fluids, resulting in commercial software packages available today. The difficulty in approximating a solution to the viscoelastic flow model arises from the hyperbolic nature of the constitutive equation, which requires stabilization in computation. Streamline upwinding was first considered in [9] for viscoelastic flow, and in [4] the discontinuous Galerkin method was implemented. In [1], a preconditioner for the GMRES iterative solver was specifically tailored to the characteristics of the discrete elastic-viscous split-stress method (DEVSS) algorithm. More mathematical studies on finite element methods for the solution of viscoelastic fluid flow are found in [2] and [12]. In [2] a discontinuous Galerkin method was studied for approximating the stress, and in [12] the streamline upwinding Petrov–Galerkin (SUPG) method for continuous approximation of the stress was analyzed.

When a discontinuous Galerkin method is used for stabilizing the approximation, the generated linear system is considerably larger than that resulting from a standard Galerkin method. In this sense, a multigrid method can give more savings in computing time when used together with the discontinuous finite element method. In [8] we studied a multigrid method derived from the decoupled algorithm presented in [10]. The advantage of that method is in the decoupling of a momentum equation from a constitutive equation on a finer mesh. After solving a full nonlinear equation on a coarse grid using an appropriate iteration method, one needs to solve two smaller linear systems on a fine grid instead of one large system. However, convergence of the decoupled algorithm is slow and mesh-dependent, so it is necessary to use several iterations on a finer grid.

The multilevel method considered in this paper is based on Newton linearization. A similar multigrid method for the Navier–Stokes equation was studied in [6] and [7].

For the viscoelastic flow problem, we solve a full nonlinear system on a coarse grid and one linear system on a fine grid with appropriately chosen coarse and fine grids.

An outline of this paper is as follows. In the remainder of this section, we introduce the model equation, some notation that will be used throughout the paper, and a weak formulation of the model equation. In section 2, a finite element approximation for a standard one-grid method is described and the error estimate proved in [2] is presented. In section 3, we present a multigrid algorithm and prove the existence of a solution to the discrete linearized problem. An error bound of the multigrid method is proved in section 4. Then, in the last section we present some numerical results demonstrating efficiency of the method.

Let Ω be a bounded domain in $\mathbb{R}^2$ with the Lipschitz continuous boundary Γ, and let $\mathbf{n}$ be the unit outward normal to the boundary Γ. Consider the model problem

$$\boldsymbol{\sigma} + \lambda(\mathbf{u}\cdot\nabla)\boldsymbol{\sigma} + \lambda g_a(\boldsymbol{\sigma},\nabla\mathbf{u}) - 2\,\alpha\, d(\mathbf{u}) = \mathbf{h} \quad \text{in } \Omega\,, \tag{1.1}$$

$$-\nabla\cdot\boldsymbol{\sigma} - 2(1-\alpha)\,\nabla\cdot d(\mathbf{u}) + \nabla p = \mathbf{f} \quad \text{in } \Omega\,, \tag{1.2}$$

$$\operatorname{div}\mathbf{u} = g \quad \text{in } \Omega\,, \tag{1.3}$$

$$\mathbf{u} = \mathbf{u}_\Gamma \quad \text{on } \Gamma\,, \tag{1.4}$$

$$\boldsymbol{\sigma} = \boldsymbol{\sigma}_{\Gamma_-} \quad \text{on } \Gamma_-\,, \tag{1.5}$$

where $\boldsymbol{\sigma}$ denotes the stress tensor, $\mathbf{u}$ the velocity vector, p the pressure of fluid, and λ the Weissenberg number. Assume that p has zero mean value over Ω. In (1.1) and (1.2), $d(\mathbf{u}) := (\nabla\mathbf{u} + \nabla\mathbf{u}^T)/2$ is the rate of the strain tensor, and α is a number such that $0 < \alpha < 1$, which may be considered as the fraction of viscoelastic viscosity. In (1.1), $g_a(\boldsymbol{\sigma},\nabla\mathbf{u})$ is defined by

$$g_a(\boldsymbol{\sigma},\nabla\mathbf{u}) := \frac{1-a}{2}(\boldsymbol{\sigma}\nabla\mathbf{u} + \nabla\mathbf{u}^T\boldsymbol{\sigma}) - \frac{1+a}{2}(\nabla\mathbf{u}\,\boldsymbol{\sigma} + \boldsymbol{\sigma}\nabla\mathbf{u}^T) \tag{1.6}$$

for $a \in [-1,1]$. In (1.5), Γ_- denotes the inflow boundary, where $\Gamma_- = \{\mathbf{x}\in\Gamma | \mathbf{u}\cdot\mathbf{n} < 0\}$. Note that if $\mathbf{u}_\Gamma = \mathbf{0}$, then there is no inflow boundary, so the boundary condition for the stress (1.5) is not necessary. The right-hand-side functions $\mathbf{h}$ and g are usually set to be zero in viscoelastic model equations by a constitutive law and the incompressibility condition.

We use the Sobolev spaces $W^{m,p}(D)$ with norms $\|\cdot\|_{m,p,D}$ if $p < \infty$ and $\|\cdot\|_{m,\infty,D}$ if $p = \infty$. We denote the Sobolev space $W^{m,2}$ by H^m, with the norm $\|\cdot\|_m$. Let $\mathbf{H}^m$ denote the corresponding spaces of vector-valued and tensor-valued functions. We will denote H^0 by L^2 and the standard L^2 inner product by $(\cdot,\cdot)_D$. If $D = \Omega$, D is omitted; i.e., $(\cdot,\cdot) = (\cdot,\cdot)_\Omega$ and $\|\cdot\| = \|\cdot\|_\Omega$.

An existence result for the problem (1.1)–(1.5) has been documented by Renardy [11] for the case that $\mathbf{h} = \mathbf{0}$, $g = 0$, and $\mathbf{u}_\Gamma = \mathbf{0}$, with the small data condition. He showed that if $\mathbf{f}\in\mathbf{H}^2(\Omega)$ and $\|\mathbf{f}\|_2$ is sufficiently small, the problem (1.1)–(1.5) admits a unique bounded solution $(\mathbf{u},\boldsymbol{\sigma},p)\in\mathbf{H}^3(\Omega)\times\mathbf{H}^2(\Omega)\times H^2(\Omega)$. In order to simplify our analysis, we make the assumption that $\mathbf{h} = \mathbf{0}$, $g = 0$, and $\mathbf{u}_\Gamma = \mathbf{0}$. However, it will be shown in section 5 that these conditions are not necessary for computations by our multigrid method.

Next, we define the function spaces for the velocity $\mathbf{u}$, the pressure p, and the

stress $\boldsymbol{\sigma}$, respectively:

$$\mathbf{H}_0^1(\Omega) := \{\mathbf{v} \in \mathbf{H}^1(\Omega) : \ \mathbf{v} = \mathbf{0} \quad \text{on } \Gamma\},$$
$$L_0^2(\Omega) := \{q \in L^2(\Omega) : \ \textstyle\int_\Omega q \, d\Omega = 0\},$$
$$\boldsymbol{\Sigma} := (L^2(\Omega))^{2\times 2} \cap \{\boldsymbol{\tau} = (\tau_{ij}) : \tau_{ij} = \tau_{ji}, \ \mathbf{u} \cdot \nabla \boldsymbol{\tau} \in (L^2(\Omega))^{2\times 2} \quad \forall \mathbf{u} \in \mathbf{H}_0^1(\Omega)\}.$$

Under the assumption that $\mathbf{h} = \mathbf{0}$, $g = 0$, and $\mathbf{u}_\Gamma = \mathbf{0}$, the corresponding variational form of (1.1)–(1.5) is obtained in the standard manner. Taking the inner product of (1.1)–(1.3) with stress, velocity, and pressure test functions, respectively, we obtain

$$(\boldsymbol{\sigma}, \boldsymbol{\tau}) + \lambda\left((\mathbf{u} \cdot \nabla)\boldsymbol{\sigma}, \boldsymbol{\tau}\right) + (g_a(\boldsymbol{\sigma}, \nabla \mathbf{u}), \boldsymbol{\tau}) - 2\alpha(d(\mathbf{u}), \boldsymbol{\tau}) = 0 \quad \forall \boldsymbol{\tau} \in \boldsymbol{\Sigma}, \tag{1.7}$$

$$(\boldsymbol{\sigma}, d(\mathbf{v})) + 2(1-\alpha)(d(\mathbf{u}), d(\mathbf{v})) + (p, \nabla \cdot \mathbf{v}) = (\mathbf{f}, \mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{H}_0^1(\Omega), \tag{1.8}$$

$$(q, \nabla \cdot \mathbf{u}) = 0 \quad \forall q \in L_0^2(\Omega). \tag{1.9}$$

We define the weak divergence free space

$$\mathbf{V} := \{\mathbf{v} \in \mathbf{H}_0^1(\Omega) : (q, \nabla \cdot \mathbf{v}) = 0 \quad \forall q \in L_0^2(\Omega)\} \tag{1.10}$$

to be used for the analysis. Note that, using (1.10), the weak formulation (1.7)–(1.9) is equivalent to:

$$(\boldsymbol{\sigma}, \boldsymbol{\tau}) + \lambda\left((\mathbf{u} \cdot \nabla)\boldsymbol{\sigma}, \boldsymbol{\tau}\right) + (g_a(\boldsymbol{\sigma}, \nabla \mathbf{u}), \boldsymbol{\tau}) - 2\alpha(d(\mathbf{u}), \boldsymbol{\tau}) = \mathbf{0} \quad \forall \boldsymbol{\tau} \in \boldsymbol{\Sigma}, \tag{1.11}$$

$$(\boldsymbol{\sigma}, d(\mathbf{v})) + 2(1-\alpha)(d(\mathbf{u}), d(\mathbf{v})) = (\mathbf{f}, \mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{V}. \tag{1.12}$$

In the following finite element analysis we will use the bilinear form A defined on $\boldsymbol{\Sigma} \times \mathbf{V}$ by

$$\begin{aligned} &A((\boldsymbol{\sigma}, \mathbf{u}), (\boldsymbol{\tau}, \mathbf{v})) \\ &\quad := (\boldsymbol{\sigma}, \boldsymbol{\tau}) - 2\alpha(d(\mathbf{u}), \boldsymbol{\tau}) + 2\alpha(\boldsymbol{\sigma}, d(\mathbf{v})) + 4\alpha(1-\alpha)\,(d(\mathbf{u}), d(\mathbf{v})). \end{aligned} \tag{1.13}$$

It is easily shown that A is continuous and coercive on $\boldsymbol{\Sigma} \times \mathbf{V}$, i.e.,

$$\begin{aligned} A((\boldsymbol{\sigma}, \mathbf{u}), (\boldsymbol{\tau}, \mathbf{v})) &\le \|\boldsymbol{\sigma}\|_0 \|\boldsymbol{\tau}\|_0 + 2\alpha \|\nabla \mathbf{u}\|_0 \|\boldsymbol{\tau}\|_0 + 2\alpha \|\boldsymbol{\sigma}\|_0 \|\nabla \mathbf{v}\|_0 \\ &\quad + \ 4\alpha(1-\alpha)\|\nabla \mathbf{u}\|_0 \|\nabla \mathbf{v}\|_0 \\ &\le C(\|\boldsymbol{\sigma}\|_0 + \|\nabla \mathbf{u}\|_0)(\|\boldsymbol{\tau}\|_0 + \|\nabla \mathbf{v}\|_0) \\ &\le C\sqrt{\|\boldsymbol{\sigma}\|_0^2 + \|\nabla \mathbf{u}\|_0^2}\sqrt{\|\boldsymbol{\tau}\|_0^2 + \|\nabla \mathbf{v}\|_0^2} \\ &\le C\|(\boldsymbol{\sigma}, \mathbf{u})\|_{(L^2(\Omega))^{2\times 2} \times \mathbf{H}_0^1(\Omega)} \|(\boldsymbol{\tau}, \mathbf{v})\|_{(L^2(\Omega))^{2\times 2} \times \mathbf{H}_0^1(\Omega)}, \end{aligned} \tag{1.14}$$

and

$$\begin{aligned} A((\boldsymbol{\sigma}, \mathbf{u}), (\boldsymbol{\sigma}, \mathbf{u})) &= \|\boldsymbol{\sigma}\|_0^2 + 4\alpha(1-\alpha)\|d(\mathbf{u})\|_0^2 \\ &\ge C\|(\boldsymbol{\sigma}, \mathbf{u})\|^2_{(L^2(\Omega))^{2\times 2} \times \mathbf{H}_0^1(\Omega)} \end{aligned} \tag{1.15}$$

by the second Korn inequality. These properties of A will be used to show the existence of the solution of a linear fine-grid problem and to obtain an error estimation.

2. Finite element approximation. Suppose Ω is a polygonal domain and T_h is a triangulation of Ω such that $\overline{\Omega} = \{\cup K : K \in T_h\}$. Assume that there exist positive constants c_1, c_2 such that

$$c_1 h \le h_K \le c_2 \rho_K,$$

where h_K is the diameter of K, ρ_K is the diameter of the greatest ball included in K, and $h = \max_{K\in T_h} h_K$.

Let $P_k(K)$ denote the space of polynomials of degree less than or equal to k on $K \in T_h$. Then we define finite element spaces for the approximate of $(\mathbf{u}, p)$:

$$\begin{aligned}
\mathbf{X}^h &:= \{\mathbf{v} \in \mathbf{H}_0^1(\Omega) \cap (C^0(\overline{\Omega}))^2 : \mathbf{v}|_K \in P_2(K)^2 \ \forall K \in T_h\}, \\
S^h &:= \{q \in L_0^2(\Omega) \cap C^0(\overline{\Omega}) : q|_K \in P_1(K) \ \forall K \in T_h\}, \\
\mathbf{V}^h &:= \{\mathbf{v} \in \mathbf{X}^h : (q, \nabla \cdot \mathbf{v}) = 0 \ \forall q \in S^h\}.
\end{aligned}$$

The stress $\boldsymbol{\sigma}$ is approximated in the discontinuous finite element space of piecewise linears:

$$\boldsymbol{\Sigma}^h := \{\boldsymbol{\tau} \in \boldsymbol{\Sigma} : \boldsymbol{\tau}|_K \in P_1(K)^{2\times 2} \ \forall K \in T_h\}.$$

The finite element spaces defined above satisfy the standard approximation properties (see [3] or [5]), i.e., there exist an integer k and a constant C such that

$$\inf_{\mathbf{v}^h \in \mathbf{X}^h} \|\mathbf{v} - \mathbf{v}^h\|_1 \le C h^2 \|\mathbf{v}\|_3 \quad \forall\, \mathbf{v} \in \mathbf{H}^3(\Omega), \tag{2.1}$$

$$\inf_{q^h \in S^h} \|q - q^h\|_0 \le C h^2 \|q\|_2 \quad \forall\, q \in H^2(\Omega), \tag{2.2}$$

and

$$\inf_{\boldsymbol{\tau}^h \in \Sigma^h} \|\boldsymbol{\tau} - \boldsymbol{\tau}^h\|_0 \le C h^2 \|\boldsymbol{\tau}\|_2 \quad \forall\, \boldsymbol{\tau} \in \mathbf{H}^2(\Omega). \tag{2.3}$$

It is also well known that the Taylor–Hood pair $(\mathbf{X}^h, S^h)$ satisfies the inf-sup (or LBB) condition,

$$\inf_{0\neq q^h \in S^h} \sup_{0\neq \mathbf{v}^h \in \mathbf{X}^h} \frac{(q^h, \nabla \cdot \mathbf{v}^h)}{\|\mathbf{v}^h\|_1 \|q^h\|_0} \ge C, \tag{2.4}$$

where C is a positive constant independent of h.

Below we introduce some notation used in [2] in order to analyze an approximate solution by the discontinuous Galerkin method. We define

$$\partial K^-(\mathbf{u}) := \{\mathbf{x} \in \partial K, \ \mathbf{u} \cdot \mathbf{n} < 0\},$$

where ∂K is the boundary of K and $\mathbf{n}$ is the outward unit normal to ∂K,

$$\Gamma^h = \{\cup \partial K, K \in T_h\} \setminus \Gamma,$$

and

$$\boldsymbol{\tau}^{\pm}(\mathbf{u}) := \lim_{\epsilon \to 0^{\pm}} \boldsymbol{\tau}(\mathbf{x} + \epsilon \mathbf{u}(\mathbf{x})).$$

We also define

$$(\boldsymbol{\sigma},\boldsymbol{\tau})_h := \sum_{K\in T_h} (\boldsymbol{\sigma},\boldsymbol{\tau})_K,$$

$$\langle \boldsymbol{\sigma}^{\pm},\boldsymbol{\tau}^{\pm}\rangle_{h,\mathbf{u}} := \sum_{K\in T_h} \int_{\partial K^-(\mathbf{u})} (\boldsymbol{\sigma}^{\pm}(\mathbf{u}) : \boldsymbol{\tau}^{\pm}(\mathbf{u}))|\mathbf{n}\cdot\mathbf{u}|\, ds,$$

$$\|\boldsymbol{\tau}\|_{0,\Gamma^h} := \left(\sum_{K\in T_h} |\boldsymbol{\tau}|^2_{0,\partial K}\right)^{1/2}$$

for $\boldsymbol{\sigma},\boldsymbol{\tau} \in \prod_{K\in T_h}(L^2(K))^{2\times 2}$ and

$$\|\boldsymbol{\xi}\|_{m,p,h} := \left(\sum_{K\in T_h} |\boldsymbol{\xi}|^p_{m,p,K}\right)^{1/p}$$

for $\boldsymbol{\xi} \in \prod_{K\in T_h}(W^{m,p}(K))^{2\times 2}$ if $p<\infty$.

We introduce the operator B^h on $\mathbf{X}^h \times \boldsymbol{\Sigma}^h \times \boldsymbol{\Sigma}^h$ defined by

$$B^h(\mathbf{u},\boldsymbol{\sigma},\boldsymbol{\tau}) := ((\mathbf{u}\cdot\nabla)\boldsymbol{\sigma},\boldsymbol{\tau})_h + \frac{1}{2}(\nabla\cdot\mathbf{u}\,\boldsymbol{\sigma},\boldsymbol{\tau}) + \langle \boldsymbol{\sigma}^+ - \boldsymbol{\sigma}^-, \boldsymbol{\tau}^+\rangle_{h,\mathbf{u}}. \tag{2.5}$$

Note that the second term vanishes when $\nabla\cdot\mathbf{u}^h = 0$. This extra term is used to obtain coercivity of B^h. Using integration by parts, B^h may be written as

$$B^h(\mathbf{u},\boldsymbol{\sigma},\boldsymbol{\tau}) = -((\mathbf{u}\cdot\nabla)\boldsymbol{\tau},\boldsymbol{\sigma})_h - \frac{1}{2}(\nabla\cdot\mathbf{u}\,\boldsymbol{\tau},\boldsymbol{\sigma}) + \langle \boldsymbol{\sigma}^-, \boldsymbol{\tau}^- - \boldsymbol{\tau}^+\rangle_{h,\mathbf{u}}. \tag{2.6}$$

Hence, combining (2.5) and (2.6), we obtain

$$B^h(\mathbf{u}^h,\boldsymbol{\sigma}^h,\boldsymbol{\sigma}^h) = \frac{1}{2}\langle \boldsymbol{\sigma}^{h+} - \boldsymbol{\sigma}^{h-}, \boldsymbol{\sigma}^{h+} - \boldsymbol{\sigma}^{h-}\rangle_{h,\mathbf{u}^h} \geq 0. \tag{2.7}$$

The discontinuous Galerkin finite element approximation of (1.7)–(1.9) is then as follows: *find* $\mathbf{u}^h \in \mathbf{X}^h$, $p^h \in S^h$, $\boldsymbol{\sigma}^h \in \boldsymbol{\Sigma}^h$ *such that*

$$\begin{aligned}(\boldsymbol{\sigma}^h,\boldsymbol{\tau}^h) + \lambda B^h(\mathbf{u}^h,\boldsymbol{\sigma}^h,\boldsymbol{\tau}^h) + \lambda(g_a(\boldsymbol{\sigma}^h,\nabla\mathbf{u}^h),\boldsymbol{\tau}^h)& \\ - 2\alpha(d(\mathbf{u}^h),\boldsymbol{\tau}^h) = 0 \quad \forall \boldsymbol{\tau}^h \in \boldsymbol{\Sigma}^h,&\end{aligned} \tag{2.8}$$

$$(\boldsymbol{\sigma}^h, d(\mathbf{v}^h)) + 2(1-\alpha)\,(d(\mathbf{u}^h), d(\mathbf{v}^h)) - (p^h, \nabla\cdot\mathbf{v}^h) = (\mathbf{f},\mathbf{v}^h) \quad \forall \mathbf{v}^h \in \mathbf{X}^h, \tag{2.9}$$

$$(q^h, \nabla\cdot\mathbf{u}^h) = 0 \quad \forall q^h \in S^h. \tag{2.10}$$

Existence of a solution to the discrete problem (2.8)–(2.10) is proved in [2], under the assumption that there exists a bounded exact solution $(\mathbf{u},\boldsymbol{\sigma},p) \in \mathbf{H}^3(\Omega)\times\mathbf{H}^2(\Omega)\times H^2(\Omega)$. The following error estimations are also derived there:

$$\|\boldsymbol{\sigma} - \boldsymbol{\sigma}^h\|_0 + \|\nabla(\mathbf{u}-\mathbf{u}^h)\|_0 \leq N\, h^{3/2}\,, \tag{2.11}$$

$$\|p - p^h\|_0 \leq N\, h^{3/2} \tag{2.12}$$

for some $N > 0$. It is then clear that

$$\|\boldsymbol{\sigma}^h\|_0 \le M + N\,h^{3/2}\,, \tag{2.13}$$

$$\|\nabla \mathbf{u}^h\|_0 \le M + N\,h^{3/2}\,, \tag{2.14}$$

where $M = \max\{\|\mathbf{u}\|_3, \|\boldsymbol{\sigma}\|_2\}$. Note that, in view of (2.4), (2.8)–(2.10) are equivalent to the following: *find* $\mathbf{u}^h \in \mathbf{V}^h$ *and* $\boldsymbol{\sigma} \in \boldsymbol{\Sigma}^h$ *such that*

$$\begin{aligned}(\boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) + \lambda B^h(\mathbf{u}^h, \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) + \lambda(g_a(\boldsymbol{\sigma}^h, \nabla \mathbf{u}^h), \boldsymbol{\tau}^h) \\ - 2\alpha(d(\mathbf{u}^h), \boldsymbol{\tau}^h) = 0 \quad \forall \boldsymbol{\tau}^h \in \boldsymbol{\Sigma}^h,\end{aligned} \tag{2.15}$$

$$(\boldsymbol{\sigma}^h, d(\mathbf{v}^h)) + 2(1-\alpha)\,(d(\mathbf{u}^h), d(\mathbf{v}^h)) = (\mathbf{f}, \mathbf{v}^h) \quad \forall \mathbf{v}^h \in \mathbf{V}^h. \tag{2.16}$$

Using the bilinear form A defined by (1.13), (2.15)–(2.16) can equivalently be written as

$$\begin{aligned}A((\boldsymbol{\sigma}^h, \mathbf{u}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h)) + \lambda B^h(\mathbf{u}^h, \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) \\ + \lambda(g_a(\boldsymbol{\sigma}^h, \nabla \mathbf{u}^h), \boldsymbol{\tau}^h) = 2\alpha(\mathbf{f}, \mathbf{v}^h) \quad \forall (\boldsymbol{\tau}^h, \mathbf{v}^h) \in \boldsymbol{\Sigma}^h \times \mathbf{V}^h.\end{aligned} \tag{2.17}$$

3. Two-grid problem. We consider two finite element meshes with $H > h$ and finite element spaces (X^H, S^H, Σ^H), (X^h, S^h, Σ^h). The two-grid method for approximating the solution of (1.7)–(1.9) is as follows.

ALGORITHM 3.1 (two-grid method).

Step 1. *Solve the nonlinear problem on the coarse mesh* H: *find* $\mathbf{u}^H \in \mathbf{X}^H$, $p^H \in S^H$, $\boldsymbol{\sigma}^H \in \boldsymbol{\Sigma}^H$ *such that*

$$\begin{aligned}&(\boldsymbol{\sigma}^H, \boldsymbol{\tau}^H) + \lambda B^H(\mathbf{u}^H, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^H) + \lambda(g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^H), \boldsymbol{\tau}^H) \\ &\qquad - 2\alpha(d(\mathbf{u}^H), \boldsymbol{\tau}^H) = 0 \quad \forall \boldsymbol{\tau}^H \in \boldsymbol{\Sigma}^H, \\ &(\boldsymbol{\sigma}^H, d(\mathbf{v}^H)) + 2(1-\alpha)\,(d(\mathbf{u}^H), d(\mathbf{v}^H)) - (p^H, \nabla \cdot \mathbf{v}^H) \\ &\qquad = (\mathbf{f}, \mathbf{v}^H) \quad \forall \mathbf{v}^H \in \mathbf{X}^H, \\ &(q^H, \nabla \cdot \mathbf{u}^H) = 0 \quad \forall q^H \in S^H.\end{aligned}$$

Step 2. *Solve the linearized problem on the fine mesh* h: *find* $\mathbf{u}^h \in \mathbf{X}^h$, $p^h \in S^h$, $\boldsymbol{\sigma}^h \in \boldsymbol{\Sigma}^h$ *such that*

$$\begin{aligned}&(\boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) + \lambda\left[B^h(\mathbf{u}^H, \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) + B^h(\mathbf{u}^h, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + \ (g_a(\boldsymbol{\sigma}^h, \nabla \mathbf{u}^H), \boldsymbol{\tau}^h)\right. \\ &\qquad \left. + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^h), \boldsymbol{\tau}^h)\right] - 2\alpha(d(\mathbf{u}^h), \boldsymbol{\tau}^h) \\ &\qquad\quad = \lambda\left[B^h(\mathbf{u}^H, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^H), \boldsymbol{\tau}^h)\right] \quad \forall \boldsymbol{\tau}^h \in \boldsymbol{\Sigma}^h, \\ &(\boldsymbol{\sigma}^h, d(\mathbf{v}^h)) + 2(1-\alpha)(d(\mathbf{u}^h), d(\mathbf{v}^h)) - (p^h, \nabla \cdot \mathbf{v}^h) = (\mathbf{f}, \mathbf{v}^h) \quad \forall \mathbf{v}^h \in \mathbf{X}^h, \\ &(q^h, \nabla \cdot \mathbf{u}^h) = 0 \quad \forall q^h \in S^h.\end{aligned}$$

In the second step of the above algorithm $\mathbf{u}^H$, $\boldsymbol{\sigma}^H$ are interpolates of $\mathbf{u}^H$, $\boldsymbol{\sigma}^H$ in $\mathbf{V}^h$ and $\boldsymbol{\Sigma}^h$, respectively. In the remainder of this section, we prove existence of a solution to the linear problem in Step 2 under the assumption that λ is sufficiently small.

Using the discrete divfree space $\mathbf{V}^h$, the linear problem in Step 2 may be written in an equivalent form: *find* $\mathbf{u}^h \in \mathbf{V}^h$, $\boldsymbol{\sigma} \in \boldsymbol{\Sigma}^h$ *such that*

$$\begin{aligned}(\boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) + \lambda \big[B^h(\mathbf{u}^h, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + B^h(\mathbf{u}^H, \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^h, \nabla \mathbf{u}^H), \boldsymbol{\tau}^h) \\ + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^h), \boldsymbol{\tau}^h)\big] - 2\alpha(d(\mathbf{u}^h), \boldsymbol{\tau}^h) \\ = \lambda \big(B^h(\mathbf{u}^H, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^H), \boldsymbol{\tau}^h)\big) \quad \forall \boldsymbol{\tau}^h \in \boldsymbol{\Sigma}^h, \end{aligned} \tag{3.1}$$

$$(\boldsymbol{\sigma}^h, d(\mathbf{v}^h)) + 2(1-\alpha)(d(\mathbf{u}^h), d(\mathbf{v}^h)) = (\mathbf{f}, \mathbf{v}^h) \quad \forall \mathbf{v}^h \in \mathbf{V}^h. \tag{3.2}$$

Using the bilinear form defined by (1.13), (3.1)–(3.2) may be written as

$$\begin{aligned} A\big((\boldsymbol{\sigma}^h, \mathbf{u}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h)\big) + \lambda \big[B^h(\mathbf{u}^h, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + B^h(\mathbf{u}^H, \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) \\ + (g_a(\boldsymbol{\sigma}^h, \nabla \mathbf{u}^H), \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^h), \boldsymbol{\tau}^h)\big] \\ = \lambda \big[B^h(\mathbf{u}^H, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^H), \boldsymbol{\tau}^h)\big] \\ + 2\alpha(\mathbf{f}, \mathbf{v}^h) \quad \forall (\boldsymbol{\tau}^h, \mathbf{v}^h) \in \boldsymbol{\Sigma}^h \times \mathbf{V}^h. \end{aligned} \tag{3.3}$$

In order to simplify our notation, we introduce the bilinear operator Φ defined on $\boldsymbol{\Sigma}^h \times \mathbf{V}^h \times \boldsymbol{\Sigma}^h \times \mathbf{V}^h$ by

$$\begin{aligned}\Phi((\boldsymbol{\sigma}^h, \mathbf{u}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h)) := A\big((\boldsymbol{\sigma}^h, \mathbf{u}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h)\big) + \lambda \big[B^h(\mathbf{u}^h, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) \\ + B^h(\mathbf{u}^H, \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^h, \nabla \mathbf{u}^H), \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^h), \boldsymbol{\tau}^h)\big]. \end{aligned} \tag{3.4}$$

Note that

$$\begin{aligned}\Phi((\boldsymbol{\sigma}^h, \mathbf{u}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h)) \\ = \lambda \big[B^h(\mathbf{u}^H, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^H), \boldsymbol{\tau}^h)\big] + 2\alpha(\mathbf{f}, \mathbf{v}^h) \end{aligned} \tag{3.5}$$

if $(\boldsymbol{\sigma}^h, \mathbf{u}^h)$ satisfies (3.3).

Next, we present some inverse estimates (see [3] or [5]), which will be used to prove theorems in this paper: for $\mathbf{u}^h \in \mathbf{V}^h$ and $\boldsymbol{\sigma}^h \in \boldsymbol{\Sigma}^h$

$$\|\mathbf{u}^h\|_\infty \le Ch^{-1/2}\|\mathbf{u}^h\|_{0,4}\,, \tag{3.6}$$

$$\|\mathbf{u}^h\|_\infty \le Ch^{-1/2}\|\nabla \mathbf{u}^h\|_0\,, \tag{3.7}$$

$$\|\boldsymbol{\sigma}^h\|_\infty \le Ch^{-1}\|\boldsymbol{\sigma}^h\|_0\,, \tag{3.8}$$

$$\|\nabla \boldsymbol{\sigma}^h\|_{0,4,h} \le Ch^{-3/2}\|\boldsymbol{\sigma}^h\|_0\,. \tag{3.9}$$

The local inverse inequality [13, sec. 4.6.1]

$$\|\boldsymbol{\sigma}\|^2_{0,\partial K} \;\le\; C\frac{1}{h_K}\|\boldsymbol{\sigma}\|^2_{0,K} \tag{3.10}$$

will be also used to bound the jump term of B^h, where h_K denotes the local mesh parameter. The local inverse inequality then implies that

$$\begin{aligned}\langle \boldsymbol{\sigma}^{h^+} - \boldsymbol{\sigma}^{h^-}, \boldsymbol{\tau}^{h^+}\rangle_{h,\mathbf{u}} &\le \|\mathbf{u}\|_\infty \|\boldsymbol{\sigma}^h\|_{0,\Gamma^h}\|\boldsymbol{\tau}^h\|_{0,\Gamma^h} \\ &\le C\|\mathbf{u}\|_\infty (h^{-1/2}\|\boldsymbol{\sigma}^h\|_{0,\Omega})(h^{-1/2}\|\boldsymbol{\tau}^h\|_{0,\Omega}) \end{aligned} \tag{3.11}$$

for $\boldsymbol{\sigma}^h, \boldsymbol{\tau}^h \in \boldsymbol{\Sigma}^h$.

THEOREM 3.2. *The linear problem in Step* 2 *of the algorithm admits a unique solution* $(\mathbf{u}^h, \boldsymbol{\sigma}^h, p^h)$ *if* λ *is sufficiently small.*

Proof. We will use the Lax–Milgram theorem to prove that (3.4) has a unique solution. In the proof we use C^h to denote a constant depending on h.

(i) *If* λ *is sufficiently small, then* Φ *is coercive and* $\|(\boldsymbol{\sigma}^h, \mathbf{u}^h)\|_{(L^2(\Omega))^{2\times 2}\times \mathbf{H}^1_0(\Omega)}$ *is bounded.* Using the imbedding of H^1 in L^4, (2.13), (3.7)–(3.9), (3.11), the Poincaré–Friedrichs inequality, and Young's inequality with $\epsilon_1 > 0$, we have

$$
\begin{aligned}
&B^h(\mathbf{u}^h, \boldsymbol{\sigma}^H, \boldsymbol{\sigma}^h)\\
&\quad = ((\mathbf{u}^h \cdot \nabla)\boldsymbol{\sigma}^H, \boldsymbol{\sigma}^h)_h + \frac{1}{2}(\nabla \cdot \mathbf{u}^h\, \boldsymbol{\sigma}^H, \boldsymbol{\sigma}^h) + \langle \boldsymbol{\sigma}^{H^+} - \boldsymbol{\sigma}^{H^-}, \boldsymbol{\sigma}^{h^-}\rangle_{h,\mathbf{u}^h}\\
&\quad \le C_1 \left[\|\mathbf{u}^h\|_{0,4}\, \|\nabla \boldsymbol{\sigma}^H\|_{0,4,h}\, \|\boldsymbol{\sigma}^h\|_0 + \|\nabla \mathbf{u}^h\|_0\, \|\boldsymbol{\sigma}^H\|_\infty\, \|\boldsymbol{\sigma}^h\|_0\right]\\
&\qquad\qquad + C_1^h\, \|\boldsymbol{\sigma}^H\|_0\, \|\boldsymbol{\sigma}^h\|_0\, \|\mathbf{u}^h\|_\infty\\
&\quad \le C_2 \left[\|\nabla \mathbf{u}^h\|_0\, (h^{-3/2}\, \|\boldsymbol{\sigma}^H\|_0)\, \|\boldsymbol{\sigma}^h\|_0 + \|\nabla \mathbf{u}^h\|_0\, (h^{-1}\, \|\boldsymbol{\sigma}^H\|_0)\, \|\boldsymbol{\sigma}^h\|_0\right]\\
&\qquad\qquad + C_2^h\, \|\boldsymbol{\sigma}^H\|_0\, \|\boldsymbol{\sigma}^h\|_0\, (h^{-1/2}\|\nabla \mathbf{u}^h\|_0)\\
&\quad = \|\boldsymbol{\sigma}^H\|_0 \left[C_2 h^{-3/2} + C_2 h^{-1} + C_2^h h^{-1/2}\right]\, \|\boldsymbol{\sigma}^h\|_0\, \|\nabla \mathbf{u}^h\|_0\\
&\quad \le (M + NH^{3/2}) \left[\frac{1}{4\epsilon_1}\|\boldsymbol{\sigma}^h\|_0^2 + \epsilon_1\, (C_2 h^{-3/2} + C_2 h^{-1} + C_2^h h^{-1/2})^2\, \|\nabla \mathbf{u}^h\|_0^2\right]. \qquad (3.12)
\end{aligned}
$$

Also, by (2.13)–(2.14) and (3.8),

$$
\begin{aligned}
&(g_a(\boldsymbol{\sigma}^h, \nabla \mathbf{u}^H), \boldsymbol{\sigma}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^h), \boldsymbol{\sigma}^h)\\
&\qquad \le C_3 \left[\|\boldsymbol{\sigma}^h\|_0\, \|\nabla \mathbf{u}^H\|_\infty\, \|\boldsymbol{\sigma}^h\|_0 + \|\boldsymbol{\sigma}^H\|_\infty\, \|\nabla \mathbf{u}^h\|_0\, \|\boldsymbol{\sigma}^h\|_0\right]\\
&\qquad \le C_4 \left[h^{-1}\, \|\nabla \mathbf{u}^H\|_0\, \|\boldsymbol{\sigma}^h\|_0^2 + h^{-1}\, \|\boldsymbol{\sigma}^H\|_0\, \|\nabla \mathbf{u}^h\|_0\, \|\boldsymbol{\sigma}^h\|_0\right]\\
&\qquad \le C_4\, h^{-1}\, (M + NH^{3/2}) \left[\left(1 + \frac{1}{4\epsilon_2}\right)\, \|\boldsymbol{\sigma}^h\|_0^2 + \epsilon_2\, \|\nabla \mathbf{u}^h\|_0^2\right], \qquad (3.13)
\end{aligned}
$$

where $\epsilon_2 > 0$. Therefore, (1.15), (2.7), (3.12), and (3.13) imply that

$$
\begin{aligned}
&\Phi((\boldsymbol{\sigma}^h, \mathbf{u}^h), (\boldsymbol{\sigma}^h, \mathbf{u}^h))\\
&\quad \ge A((\boldsymbol{\sigma}^h, \mathbf{u}^h), (\boldsymbol{\sigma}^h, \mathbf{u}^h)) + \lambda B^h(\mathbf{u}^H, \boldsymbol{\sigma}^h, \boldsymbol{\sigma}^h) - \lambda \mid B^h(\mathbf{u}^h, \boldsymbol{\sigma}^H, \boldsymbol{\sigma}^h)\\
&\qquad\qquad + (g_a(\boldsymbol{\sigma}^h, \nabla \mathbf{u}^H), \boldsymbol{\sigma}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla \mathbf{u}^h), \boldsymbol{\sigma}^h) \mid\\
&\quad \ge \left[1 - \lambda(M + NH^{3/2}) \left(\frac{1}{4\epsilon_1} + C_4 h^{-1} \left(1 + \frac{1}{4\epsilon_2}\right)\right)\right] \|\boldsymbol{\sigma}^h\|_0^2\\
&\qquad\qquad + \Big[C_5 \alpha(1-\alpha) - \lambda(M + NH^{3/2})\\
&\qquad\qquad \cdot \Big(\epsilon_1 (C_2 h^{-3/2} + C_2 h^{-1} + C_2^h h^{-1/2})^2 + \epsilon_2 C_4 h^{-1}\Big)\Big]\, \|\nabla \mathbf{u}^h\|_0^2.
\end{aligned}
$$

Choosing ϵ_1, ϵ_2 appropriately and using the Poincaré–Friedrichs inequality, we have

$$
\Phi((\boldsymbol{\sigma}^h, \mathbf{u}^h), (\boldsymbol{\sigma}^h, \mathbf{u}^h)) \ge C^h(\|\boldsymbol{\sigma}^h\|_0^2 + \|\nabla \mathbf{u}^h\|_0^2) \ge C^h(\|\boldsymbol{\sigma}^h\|_0^2 + \|\mathbf{u}^h\|_1^2) \qquad (3.14)
$$

if λ is sufficiently small.

On the other hand, using (3.11), the inverse estimates, and the imbedding of H^1 in L^4,

$$
\begin{aligned}
&B^h(\mathbf{u}^H,\boldsymbol{\sigma}^H,\boldsymbol{\tau}^h)+(g_a(\boldsymbol{\sigma}^H,\nabla\mathbf{u}^H),\boldsymbol{\tau}^h)\\
&\quad=((\mathbf{u}^H\cdot\nabla)\boldsymbol{\sigma}^H,\boldsymbol{\tau}^h)_h+\frac{1}{2}(\nabla\cdot\mathbf{u}^H\,\boldsymbol{\sigma}^H,\boldsymbol{\tau}^h)\ +\langle\boldsymbol{\sigma}^{H^+}-\boldsymbol{\sigma}^{H^-},\boldsymbol{\tau}^{h^-}\rangle_{h,\mathbf{u}^H}\\
&\qquad\qquad+(g_a(\boldsymbol{\sigma}^H,\nabla\mathbf{u}^H),\boldsymbol{\tau}^h)\\
&\quad\le C_6\left[\|\mathbf{u}^H\|_{0,4}\,\|\nabla\boldsymbol{\sigma}^H\|_{0,4,h}\|\boldsymbol{\tau}^h\|_0+\|\nabla\mathbf{u}^H\|_0\,\|\boldsymbol{\sigma}^H\|_\infty\|\boldsymbol{\tau}^h\|_0\right]\\
&\qquad\qquad+C_3^h\,\|\boldsymbol{\sigma}^H\|_0\,\|\mathbf{u}^H\|_\infty\,\|\boldsymbol{\tau}^h\|_0+C_7\|\boldsymbol{\sigma}^H\|_0\,\|\nabla\mathbf{u}^H\|_\infty\,\|\boldsymbol{\tau}^h\|_0\\
&\quad\le\Big[C_8\left(\|\nabla\mathbf{u}^H\|_0\,(h^{-3/2}\|\boldsymbol{\sigma}^H\|_0)+\|\nabla\mathbf{u}^H\|_0\,(h^{-1}\|\boldsymbol{\sigma}^H\|_0)\right.\\
&\qquad\qquad\left.+\,\|\boldsymbol{\sigma}^H\|_0(h^{-1}\,\|\nabla\mathbf{u}^H\|_0)\right)+C_4^h\,\|\boldsymbol{\sigma}^H\|_0\,(h^{-1/2}\|\nabla\mathbf{u}^H\|_0)\Big]\,\|\boldsymbol{\tau}^h\|_0\\
&\quad=\left[C_8h^{-3/2}+2C_8h^{-1}+C_4^hh^{-1/2}\right]\,\|\nabla\mathbf{u}^H\|_0\,\|\boldsymbol{\sigma}^H\|_0\,\|\boldsymbol{\tau}^h\|_0\,. \qquad (3.15)
\end{aligned}
$$

Hence, using (3.5), (3.14), and (3.15), we have

$$
\|(\boldsymbol{\sigma}^h,\mathbf{u}^h)\|_{(L^2(\Omega))^{2\times2}\times\mathbf{H}_0^1(\Omega)}\le C^h(\|\nabla\mathbf{u}^H\|_0\|\boldsymbol{\sigma}^H\|_0+\|\mathbf{f}\|_{-1})\,.
$$

(ii) Φ *is continuous.* Using the imbedding of H^1 in L^4, (2.13)–(2.14), (3.7)–(3.9), (3.11), and the Poincaré–Friedrichs inequality, we have

$$
\begin{aligned}
&B^h(\mathbf{u}^H,\boldsymbol{\sigma}^h,\boldsymbol{\tau}^h)+B^h(\mathbf{u}^h,\boldsymbol{\sigma}^H,\boldsymbol{\tau}^h)\\
&\quad=((\mathbf{u}^H\cdot\nabla)\boldsymbol{\sigma}^h,\boldsymbol{\tau}^h)_h+\frac{1}{2}(\nabla\cdot\mathbf{u}^H\,\boldsymbol{\sigma}^h,\boldsymbol{\tau}^h)+\langle\boldsymbol{\sigma}^{h^+}-\boldsymbol{\sigma}^{h^-},\boldsymbol{\tau}^{h^-}\rangle_{h,\mathbf{u}^H}\\
&\qquad+((\mathbf{u}^h\cdot\nabla)\boldsymbol{\sigma}^H,\boldsymbol{\tau}^h)_h+\frac{1}{2}(\nabla\cdot\mathbf{u}^h\,\boldsymbol{\sigma}^H,\boldsymbol{\tau}^h)+\langle\boldsymbol{\sigma}^{H^+}-\boldsymbol{\sigma}^{H^-},\boldsymbol{\tau}^{h^-}\rangle_{h,\mathbf{u}^h}\\
&\quad\le\big[C_9\left(\,\|\mathbf{u}^H\|_{0,4}\,\|\nabla\boldsymbol{\sigma}^h\|_{0,4,h}+\|\nabla\mathbf{u}^H\|_0\,\|\boldsymbol{\sigma}^h\|_\infty\right)+C_5^h\,\|\boldsymbol{\sigma}^h\|_0\,\|\mathbf{u}^H\|_\infty\\
&\qquad+C_{10}\,\left(\|\mathbf{u}^h\|_{0,4}\,\|\nabla\boldsymbol{\sigma}^H\|_{0,4,h}+\|\nabla\mathbf{u}^h\|_0\,\|\boldsymbol{\sigma}^H\|_\infty\right)\\
&\qquad+C_6^h\,\|\boldsymbol{\sigma}^H\|_0\,\|\mathbf{u}^h\|_\infty\big]\,\|\boldsymbol{\tau}^h\|_0\\
&\quad\le\Big[C_{11}\,\Big(\|\nabla\mathbf{u}^H\|_0\,(h^{-3/2}\|\boldsymbol{\sigma}^h\|_0)+\|\nabla\mathbf{u}^H\|_0\,(h^{-1}\|\boldsymbol{\sigma}^h\|_0)\\
&\qquad+\|\nabla\mathbf{u}^h\|_0\,(h^{-3/2}\|\boldsymbol{\sigma}^H\|_0)+\|\nabla\mathbf{u}^h\|_0\,(h^{-1}\|\boldsymbol{\sigma}^H\|_0)\Big)\\
&\qquad+C_7^h\,\Big(\|\boldsymbol{\sigma}^h\|_0\,(h^{-1/2}\|\nabla\mathbf{u}^H\|_0)+\|\boldsymbol{\sigma}^H\|_0\,(h^{-1/2}\|\nabla\mathbf{u}^h\|_0)\Big)\Big]\,\|\boldsymbol{\tau}^h\|_0\\
&\quad\le(M+NH^{3/2})(C_{11}h^{-3/2}+C_{11}h^{-1}+C_7^hh^{-1/2})\,\left[\|\boldsymbol{\sigma}^h\|_0+\|\nabla\mathbf{u}^h\|_0\right]\,\|\boldsymbol{\tau}^h\|_0\\
&\quad\le C_8^h\,(\|\boldsymbol{\sigma}^h\|_0+\|\nabla\mathbf{u}^h\|_0)\,\|\boldsymbol{\tau}^h\|_0\\
&\quad\le C_9^h\,\sqrt{\|\boldsymbol{\sigma}^h\|_0^2+\|\nabla\mathbf{u}^h\|_0^2}\,\sqrt{\|\boldsymbol{\tau}^h\|_0^2+\|\nabla\mathbf{v}^h\|_0^2}\,. \qquad (3.16)
\end{aligned}
$$

By (2.13)–(2.14) and (3.8),

$$
\begin{aligned}
&(g_a(\boldsymbol{\sigma}^h,\nabla\mathbf{u}^H),\boldsymbol{\tau}^h)+(g_a(\boldsymbol{\sigma}^H,\nabla\mathbf{u}^h),\boldsymbol{\tau}^h)\\
&\qquad\le C_{12}\left[\,\|\boldsymbol{\sigma}^h\|_0\,\|\nabla\mathbf{u}^H\|_\infty+\|\boldsymbol{\sigma}^H\|_\infty\,\|\nabla\mathbf{u}^h\|_0\,\right]\,\|\boldsymbol{\tau}^h\|_0\\
&\qquad\le C_{13}\left[\|\boldsymbol{\sigma}^h\|_0\,(h^{-1}\,\|\nabla\mathbf{u}^H\|_0)+h^{-1}\,\|\boldsymbol{\sigma}^H\|_0\,\|\nabla\mathbf{u}^h\|_0\,\right]\,\|\boldsymbol{\tau}^h\|_0\\
&\qquad\le C_{13}\,(M+NH^{3/2})\,h^{-1}\left[\,\|\boldsymbol{\sigma}^h\|_0+\|\nabla\mathbf{u}^h\|_0\,\right]\,\|\boldsymbol{\tau}^h\|_0\\
&\qquad\le C_{10}^h\sqrt{\|\boldsymbol{\sigma}^h\|_0^2+\|\nabla\mathbf{u}^h\|_0^2}\,\sqrt{\|\boldsymbol{\tau}^h\|_0^2+\|\nabla\mathbf{v}^h\|_0^2}\,. \qquad (3.17)
\end{aligned}
$$

Therefore, using (1.14) and (3.16)–(3.17), we obtain

$$
\Phi((\boldsymbol{\sigma}^h,\mathbf{u}^h),(\boldsymbol{\tau}^h,\mathbf{v}^h))\le C^h\sqrt{\|\boldsymbol{\sigma}^h\|_0^2+\|\nabla\mathbf{u}^h\|_0^2}\,\sqrt{\|\boldsymbol{\tau}^h\|_0^2+\|\nabla\mathbf{v}^h\|_0^2}\,. \qquad (3.18)
$$

(iii) By the Lax–Milgram theorem, (3.4) has a unique solution $(\boldsymbol{\sigma}^h, \mathbf{u}^h) \in \boldsymbol{\Sigma}^h \times \mathbf{V}^h$. Since $(\mathbf{X}^h, S^h)$ satisfies the LBB condition (2.4), there exists $p^h \in S^h$ such that

$$(\boldsymbol{\sigma}^h, d(\mathbf{v}^h)) + 2(1-\alpha)\,(d(\mathbf{u}^h), d(\mathbf{v}^h)) - (p^h, \nabla\cdot\mathbf{v}^h) = (\mathbf{f}, \mathbf{v}^h) \quad \forall \mathbf{v}^h \in \mathbf{X}^h\,. \qquad \square$$

REMARK 3.3. *The above theorem establishes existence and uniqueness of the solution $(\mathbf{u}^h, \boldsymbol{\sigma}^h, p^h)$ in the fixed finite element space (X^h, S^h, Σ^h). (Note the dependence of the continuity and coercivity constants on h.) In the error estimates below, more involved analysis is used to establish bounds in which the constants are independent of h.*

REMARK 3.4. *The two-grid method is easily extended to a multigrid method as follows. Consider a sequence of mesh spacings, h_i, $i = 1, 2, \ldots, K$, such that $H > h_1 > h_2 > \cdots > h_K$, and let $(\mathbf{X}^{h_i}, S^{h_i}, \boldsymbol{\Sigma}^{h_i})$ be the finite element space corresponding to each mesh size h_i. Then in Step 2, we solve the linear problems.*

- *Set $(\boldsymbol{\sigma}^{h_0}, \mathbf{u}^{h_0}) = (\boldsymbol{\sigma}^H, \mathbf{u}^H)$.*
- *For $i = 1, 2, \ldots, K$, find $\mathbf{u}^{h_i} \in \mathbf{X}^{h_i}$, $p^{h_i} \in S^{h_i}$, $\boldsymbol{\sigma}^{h_i} \in \boldsymbol{\Sigma}^{h_i}$ such that*

$$\begin{aligned}
&(\boldsymbol{\sigma}^{h_i}, \boldsymbol{\tau}^{h_i}) + \lambda\left[B^h(\mathbf{u}^{h_{i-1}}, \boldsymbol{\sigma}^{h_i}, \boldsymbol{\tau}^{h_i}) + B^h(\mathbf{u}^{h_i}, \boldsymbol{\sigma}^{h_{i-1}}, \boldsymbol{\tau}^{h_i})\right.\\
&\quad \left.+(g_a(\boldsymbol{\sigma}^{h_i}, \nabla\mathbf{u}^{h_{i-1}}), \boldsymbol{\tau}^{h_i}) + (g_a(\boldsymbol{\sigma}^{h_{i-1}}, \nabla\mathbf{u}^{h_i}), \boldsymbol{\tau}^{h_i})\right] - 2\alpha(d(\mathbf{u}^{h_i}), \boldsymbol{\tau}^{h_i})\\
&\quad = \lambda\left[B^h(\mathbf{u}^{h_{i-1}}, \boldsymbol{\sigma}^{h_{i-1}}, \boldsymbol{\tau}^{h_i}) + (g_a(\boldsymbol{\sigma}^{h_{i-1}}, \nabla\mathbf{u}^{h_{i-1}}), \boldsymbol{\tau}^{h_i})\right] \quad \forall \boldsymbol{\tau}^{h_i} \in \boldsymbol{\Sigma}^{h_i}\,,\\
&(\boldsymbol{\sigma}^{h_i}, d(\mathbf{v}^{h_i})) + 2(1-\alpha)(d(\mathbf{u}^{h_i}), d(\mathbf{v}^{h_i})) - (p^{h_i}, \nabla\cdot\mathbf{v}^{h_i})\\
&\qquad\qquad = (\mathbf{f}, \mathbf{v}^{h_i}) \quad \forall \mathbf{v}^{h_i} \in \mathbf{X}^{h_i}\,,\\
&(q^{h_i}, \nabla\cdot\mathbf{u}^{h_i}) = 0 \quad \forall q^{h_i} \in S^{h_i}\,.
\end{aligned}$$

Extending the analysis in the proof of Theorem 3.2 to the multigrid method is straightforward. Numerical tests by the multigrid method will be discussed in section 5.

4. Error estimate. In this section we derive an error estimation for the two-grid method.

THEOREM 4.1. *The unique solution $(\mathbf{u}^h, \boldsymbol{\sigma}^h, p^h)$ to the linear problem in Step 2 satisfies*

$$\begin{aligned}
&\|\boldsymbol{\sigma} - \boldsymbol{\sigma}^h\|_0 + \|\nabla(\mathbf{u} - \mathbf{u}^h)\|_0\\
&\qquad \le\ \overline{C}\,h^2 + C\,\lambda^{1/2}\,\Big[M^2\,h + Mh^{1/2}(\,\|\nabla(\mathbf{u} - \mathbf{u}^H)\|_0 + \|\boldsymbol{\sigma} - \boldsymbol{\sigma}^H\|_0\,)\\
&\qquad\quad +h^{-3/2}\,\|\boldsymbol{\sigma} - \boldsymbol{\sigma}^H\|_0\,\|\nabla(\mathbf{u} - \mathbf{u}^H)\|_0\Big]
\end{aligned}$$

if λ is sufficiently small, where $\overline{C}$, C are constants independent of H and h.

Proof. If $(\mathbf{u}, \boldsymbol{\sigma})$ is an exact solution of the problem (1.1)–(1.4) with $\mathbf{h} = \mathbf{0}$, $g = 0$, and $\mathbf{u}_\Gamma = \mathbf{0}$, it also satisfies (1.11)–(1.12). Subtracting (3.1) and (3.2) from (1.11) and (1.12), respectively, we have

$$\begin{aligned}
&(\boldsymbol{\sigma} - \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) - 2\alpha(d(\mathbf{u} - \mathbf{u}^h), \boldsymbol{\tau}^h)\\
&\quad +\lambda\left[((\mathbf{u}, \nabla)\boldsymbol{\sigma}, \boldsymbol{\tau}^h) - B^h(\mathbf{u}^H, \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) - B^h(\mathbf{u}^h, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h)\right.\\
&\quad \left.+(g_a(\boldsymbol{\sigma}, \nabla\mathbf{u}), \boldsymbol{\tau}^h) - (g_a(\boldsymbol{\sigma}^h, \nabla\mathbf{u}^H), \boldsymbol{\tau}^h) - (g_a(\boldsymbol{\sigma}^H, \nabla\mathbf{u}^h), \boldsymbol{\tau}^h)\right]\\
&\qquad = -\lambda\left[B^h(\mathbf{u}^H, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla\mathbf{u}^H), \boldsymbol{\tau}^h)\right] \quad \forall \boldsymbol{\tau}^h \in \Sigma^h, \qquad (4.1)
\end{aligned}$$

$$(\boldsymbol{\sigma} - \boldsymbol{\sigma}^h, d(\mathbf{v}^h)) + 2(1-\alpha)(d(\mathbf{u} - \mathbf{u}^h), d(\mathbf{v}^h)) = 0 \quad \forall \mathbf{v}^h \in \mathbf{V}^h. \qquad (4.2)$$

Note that the exact solution $(\boldsymbol{\sigma}, \mathbf{u})$ satisfies the relation

$$((\mathbf{u}\cdot\nabla)\boldsymbol{\sigma}, \boldsymbol{\tau}^h) = B^h(\mathbf{u}, \boldsymbol{\sigma}, \boldsymbol{\tau}^h)$$

since $\boldsymbol{\sigma}$ is continuous and $\nabla\cdot\mathbf{u} = 0$. Multiplying (4.2) by 2α and adding to (4.1), we get

$$\begin{aligned} &A((\boldsymbol{\sigma}-\boldsymbol{\sigma}^h, \mathbf{u}-\mathbf{u}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h)) \\ &\quad +\lambda\left[B^h(\mathbf{u}, \boldsymbol{\sigma}, \boldsymbol{\tau}^h) - B^h(\mathbf{u}^H, \boldsymbol{\sigma}^h, \boldsymbol{\tau}^h) - B^h(\mathbf{u}^h, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h)\right. \\ &\quad \left.+(g_a(\boldsymbol{\sigma}, \nabla\mathbf{u}), \boldsymbol{\tau}^h) - (g_a(\boldsymbol{\sigma}^h, \nabla\mathbf{u}^H), \boldsymbol{\tau}^h) - (g_a(\boldsymbol{\sigma}^H, \nabla\mathbf{u}^h), \boldsymbol{\tau}^h)\right] \\ &\qquad\qquad = -\lambda\left[B^h(\mathbf{u}^H, \boldsymbol{\sigma}^H, \boldsymbol{\tau}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla\mathbf{u}^H), \boldsymbol{\tau}^h)\right]. \end{aligned} \tag{4.3}$$

Let $\tilde{\boldsymbol{\sigma}}^h$ be the L^2 projection of $\boldsymbol{\sigma}$ in $\boldsymbol{\Sigma}^h$, and let $\tilde{\mathbf{u}}^h \in \mathbf{V}^h$ be defined by

$$(\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h), \nabla\mathbf{v}^h) = 0 \qquad \forall \mathbf{v}^h \in \mathbf{V}^h.$$

We have then the following standard results from [10]: for $\mathbf{u} \in (\mathbf{H}^3(\Omega))$ and $\boldsymbol{\sigma} \in (\mathbf{H}^2(\Omega))$

$$\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0 \le C\,h^2\|\mathbf{u}\|_3\,, \tag{4.4}$$

$$\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0 + h\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_1 \le Ch^2\|\boldsymbol{\sigma}\|_2\,, \tag{4.5}$$

$$\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_{0,\Gamma^h} \le Ch^{3/2}\|\boldsymbol{\sigma}\|_2\,. \tag{4.6}$$

Note that $A((\boldsymbol{\sigma}-\boldsymbol{\sigma}^h, \mathbf{u}-\mathbf{u}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h))$ in (4.3) can be written as $A((\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h, \mathbf{u}-\tilde{\mathbf{u}}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h)) + A((\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h, \tilde{\mathbf{u}}^h-\mathbf{u}^h), (\boldsymbol{\tau}^h, \mathbf{v}^h))$ by the definition of A. Adding and subtracting $\tilde{\mathbf{u}}^h$, $\tilde{\boldsymbol{\sigma}}^h$ in (4.3) and letting $\boldsymbol{\tau}^h = \tilde{\boldsymbol{\sigma}}^h - \boldsymbol{\sigma}^h$, $\mathbf{v}^h = \tilde{\mathbf{u}}^h - \mathbf{u}^h$, we have

$$\begin{aligned} &A((\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h, \tilde{\mathbf{u}}^h-\mathbf{u}^h), (\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h, \tilde{\mathbf{u}}^h-\mathbf{u}^h)) + \lambda B^h(\mathbf{u}^H, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) \\ &= -A((\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h, \mathbf{u}-\tilde{\mathbf{u}}^h), (\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h, \tilde{\mathbf{u}}^h-\mathbf{u}^h)) - \lambda\Big[B^h(\mathbf{u}-\tilde{\mathbf{u}}^h, \boldsymbol{\sigma}, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) \\ &\quad + B^h(\mathbf{u}-\tilde{\mathbf{u}}^h, \boldsymbol{\sigma}^H-\boldsymbol{\sigma}, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) + B^h(\tilde{\mathbf{u}}^h-\mathbf{u}^h, \boldsymbol{\sigma}^H, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) \\ &\quad + B^h(\mathbf{u}^H, \boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) + B^h(\mathbf{u}-\mathbf{u}^H, \boldsymbol{\sigma}-\boldsymbol{\sigma}^H, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) \\ &\quad + (g_a(\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h, \nabla\mathbf{u}^H), \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) + (g_a(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h, \nabla\mathbf{u}^H), \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) \\ &\quad + (g_a(\boldsymbol{\sigma}^H, \nabla(\mathbf{u}-\tilde{\mathbf{u}}^h), \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) + (g_a(\boldsymbol{\sigma}^H, \nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h), \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) \\ &\quad + (g_a(\boldsymbol{\sigma}-\boldsymbol{\sigma}^H, \nabla(\mathbf{u}-\mathbf{u}^H), \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\Big]. \end{aligned} \tag{4.7}$$

To prove the theorem, we will get a bound for the right-hand side of (4.7) in terms of h, H, $\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0$, $\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0$, $\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0$, and $\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0$. For simplicity we assume that $h < H < 1$ throughout this proof.

(i) *A term.* From the definition of A, and using (4.4), (4.5), and Young's inequality, we have

$$\begin{aligned} &A((\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h, \mathbf{u}-\tilde{\mathbf{u}}^h), (\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h, \tilde{\mathbf{u}}^h-\mathbf{u}^h)) \\ &\quad\le \|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0 + 2\alpha\,\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0 \\ &\qquad + 2\alpha\,\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0 + 4\alpha(1-\alpha)\,\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0 \\ &\quad\le \frac{1}{4\epsilon_1}\,\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0^2 + \epsilon_1\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2 + \frac{(2\alpha)^2}{4\epsilon_2}\,\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0^2 + \epsilon_2\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2 \end{aligned}$$

$$
\begin{aligned}
&+ \frac{(2\alpha)^2}{4\epsilon_3}\,\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0^2 + \epsilon_3\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2 + \frac{(4\alpha(1-\alpha))^2}{4\epsilon_4}\,\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0^2\\
&+ \epsilon_4\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\\
&= \left(\frac{1}{4\epsilon_1}+\frac{\alpha^2}{\epsilon_3}\right)\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0^2 + \left(\frac{\alpha^2}{\epsilon_2}+\frac{4\alpha^2(1-\alpha)^2}{\epsilon_4}\right)\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0^2\\
&\qquad + (\epsilon_1+\epsilon_2)\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2 + (\epsilon_3+\epsilon_4)\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\\
&\le C_1\,M^2\left(\frac{1}{4\epsilon_1}+\frac{\alpha^2}{\epsilon_3}+\frac{\alpha^2}{\epsilon_2}+\frac{4\alpha^2(1-\alpha)^2}{\epsilon_4}\right)h^4 \qquad (4.8)\\
&\qquad + (\epsilon_1+\epsilon_2)\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2 + (\epsilon_3+\epsilon_4)\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\,,
\end{aligned}
$$

where ϵ_i, $i=1,2,3,4$, are positive constants.

(ii) B^h *terms.* First, note that

$$\langle \boldsymbol{\sigma}^+-\boldsymbol{\sigma}^-, {\boldsymbol{\tau}^h}^-\rangle_{h,\mathbf{u}-\tilde{\mathbf{u}}^h} = 0 \qquad \forall \boldsymbol{\tau}^h\in\boldsymbol{\Sigma}^h,$$

since, by continuity, the jump of $\boldsymbol{\sigma}$ across any element boundary is zero. Using (2.5), the embedding of H^1 in L^4, H^2 in L^∞, $W^{2,2}$ in $W^{1,4}$, (2.13), (3.7)–(3.9), (3.11), and (4.4), we obtain a bound for the first and third B^h terms:

$$
\begin{aligned}
&B^h(\mathbf{u}-\tilde{\mathbf{u}}^h,\boldsymbol{\sigma},\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) + B^h(\tilde{\mathbf{u}}^h-\mathbf{u}^h,\boldsymbol{\sigma}^H,\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\\
&\quad\le C_2\|\mathbf{u}-\tilde{\mathbf{u}}^h\|_{0,4}\,\|\nabla\boldsymbol{\sigma}\|_{0,4}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0 + \|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,\|\boldsymbol{\sigma}\|_\infty\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\qquad + \|\tilde{\mathbf{u}}^h-\mathbf{u}^h\|_{0,4}\,\|\nabla\boldsymbol{\sigma}^H\|_{0,4,h}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\qquad + \|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\,\|\boldsymbol{\sigma}^H\|_\infty\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\qquad + h^{-1}\,\|\boldsymbol{\sigma}^H\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,\|\tilde{\mathbf{u}}^h-\mathbf{u}^h\|_\infty\\
&\quad\le C_3\Big[\,\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,\|\boldsymbol{\sigma}\|_2 + \|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\,(h^{-3/2}\,\|\boldsymbol{\sigma}^H\|_0)\\
&\qquad + \|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\,(h^{-1}\,\|\boldsymbol{\sigma}^H\|_0)\\
&\qquad + h^{-1}\,\|\boldsymbol{\sigma}^H\|_0\,(h^{-1/2}\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\,\|_0)\Big]\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,,\\
&\quad\le C_4\left[M^2h^2 + h^{-3/2}\,(M+NH^{3/2})\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\right]\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,. \qquad (4.9)
\end{aligned}
$$

The boundedness of the remaining B^h terms can be shown using interpolates of $\mathbf{u}$. We establish the following two estimates. Let $\hat{\mathbf{u}}$ be the P_2 interpolate of $\mathbf{u}$ on V^h. Then, by interpolation properties and (3.7) [3],

$$
\begin{aligned}
\|\mathbf{u}-\tilde{\mathbf{u}}^h\|_\infty &\le \|\mathbf{u}-\hat{\mathbf{u}}\|_\infty + \|\hat{\mathbf{u}}-\tilde{\mathbf{u}}^h\|_\infty\\
&\le C_5\,(\,h^2\,\|\mathbf{u}\|_3 + h^{-1/2}\,\|\nabla(\hat{\mathbf{u}}-\tilde{\mathbf{u}}^h)\|_0)\\
&\le C_5\,(\,M\,h^2 + h^{-1/2}\,\|\nabla(\hat{\mathbf{u}}-\mathbf{u})\|_0 + h^{-1/2}\,\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,)\\
&\le C_6\,M\,(\,h^2+h^{3/2}\,)\\
&\le C_7\,M\,h^{3/2}\,. \qquad (4.10)
\end{aligned}
$$

Also, by (3.10) and (4.5)–(4.6),

$$
\begin{aligned}
\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_{0,\Gamma^h} &\le \|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_{0,\Gamma^h} + \|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^H\|_{0,\Gamma^h}\\
&\le C_8\left[M\,h^{3/2} + h^{-1/2}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^H\|_0\right]\\
&\le C_8\left[M\,h^{3/2} + h^{-1/2}\,(\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}\|_0 + \|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\,)\right]\\
&\le C_9\left[M\,h^{3/2} + h^{-1/2}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\right]. \qquad (4.11)
\end{aligned}
$$

Then, using (2.6), (3.7)–(3.10), (4.4), (4.10), and (4.11), we obtain a bound for the second B^h term:

$$\begin{aligned}
&B^h(\mathbf{u}-\tilde{\mathbf{u}}^h,\boldsymbol{\sigma}^H-\boldsymbol{\sigma},\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\\
&\quad=-(((\mathbf{u}-\tilde{\mathbf{u}}^h)\cdot\nabla)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}^H-\boldsymbol{\sigma})_h-\frac{1}{2}(\nabla\cdot(\mathbf{u}-\tilde{\mathbf{u}}^h)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}^H-\boldsymbol{\sigma})\\
&\qquad+\langle(\boldsymbol{\sigma}^H-\boldsymbol{\sigma})^-,(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)^--(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)^+\rangle_{h,\mathbf{u}-\tilde{\mathbf{u}}^h}\\
&\qquad\le C_{10}\Big[\|\mathbf{u}-\tilde{\mathbf{u}}^h\|_{0,4}\,\|\nabla(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\|_{0,4,h}\,\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_0\\
&\qquad\quad+\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_\infty\,\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_0\\
&\qquad\quad+\|\mathbf{u}-\tilde{\mathbf{u}}^h\|_\infty\,(\,h^{-1/2}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,)\,\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_{0,\Gamma^h}\Big]\\
&\qquad\le C_{11}\Big[\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_0\,(\,h^{-3/2}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,)\\
&\qquad\quad+\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_0\,(\,h^{-1}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,)\\
&\qquad\quad+M\,h^{-1/2}\,(h^{3/2}\,)\,(\,M\,h^{3/2}+h^{-1/2}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\,)\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\Big]\\
&\qquad\le C_{12}\Big[M\,h^{1/2}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0+M^2\,h^{5/2}\Big]\;\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,. \qquad (4.12)
\end{aligned}$$

Consider the fourth B^h term,

$$\begin{aligned}
&B^h(\mathbf{u}^H,\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h,\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\\
&\qquad=-\,((\mathbf{u}^H\cdot\nabla)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h)_h-\frac{1}{2}(\nabla\cdot\mathbf{u}^H(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h) \qquad (4.13)\\
&\qquad\quad+\langle(\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h)^-,(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)^--(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)^+\rangle_{h,\mathbf{u}^H}
\end{aligned}$$

by (2.6). Since $\nabla\cdot\mathbf{u}=0$, the second term can be written as $\frac{1}{2}(\nabla\cdot(\mathbf{u}^H-\mathbf{u})(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h)$, and using (3.8) and (4.5),

$$\begin{aligned}
\frac{1}{2}(\nabla\cdot(\mathbf{u}^H-\mathbf{u})(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h)\;&\le\;C_{13}\,\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_\infty\,\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0\\
&\le C_{14}\,\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0\,(h^{-1}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0)\,(M\,h^2)\\
&\le C_{14}M\,h\,\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,. \qquad (4.14)
\end{aligned}$$

For the first term in (4.13), let $\check{\mathbf{u}}$ be the P_1 continuous interpolate of $\mathbf{u}$ on $\mathbf{V}^h$. Then, by the imbedding of H^1 in L^4, the Poincaré–Friedrichs inequality, and interpolation properties,

$$\begin{aligned}
\|\mathbf{u}^H-\check{\mathbf{u}}\|_{0,4}\le C_{15}\,\|\nabla(\mathbf{u}^H-\check{\mathbf{u}})\|_0&\le C_{15}(\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0+\|\nabla(\mathbf{u}-\check{\mathbf{u}})\|_0)\\
&\le C_{16}\,(\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0+h\,M)\,. \qquad (4.15)
\end{aligned}$$

Since $\nabla(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)$ is in P_0 on each K, then $(\check{\mathbf{u}}\cdot\nabla)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)$ is in P_1, and thus

$$((\check{\mathbf{u}}\cdot\nabla)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h)=0 \qquad (4.16)$$

since $\tilde{\boldsymbol{\sigma}}^h$ is the L^2 projection of $\boldsymbol{\sigma}$ in $\boldsymbol{\Sigma}^h$. Now, using (3.9), (4.5), (4.15), and (4.16), we have

$$\begin{aligned}
((\mathbf{u}^H\cdot\nabla)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h)_h\;&=\;(((\mathbf{u}^H-\check{\mathbf{u}})\cdot\nabla)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h),\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h)_h\\
&\le C_{17}\|\mathbf{u}^H-\check{\mathbf{u}}\|_{0,4}\,\|\nabla(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\|_{0,4,h}\,\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0\\
&\le C_{18}(\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0+M\,h)\,(h^{-3/2}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0)\,(M\,h^2)\\
&\le C_{18}M\,h^{1/2}(\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0+M\,h)\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,. \qquad (4.17)
\end{aligned}$$

For the third term in (4.13), we use the following result obtained by the imbedding theorem of $W^{1,4}$ in L^∞, (3.6), and (4.4):

$$\begin{aligned}
\|\mathbf{u}^H\|_\infty &\le \|\mathbf{u}\|_\infty + \|\mathbf{u}-\tilde{\mathbf{u}}^h\|_\infty + \|\tilde{\mathbf{u}}^h-\mathbf{u}^H\|_\infty \\
&\le C_{19}\left[M + \|\mathbf{u}-\tilde{\mathbf{u}}^h\|_{1,4} + h^{-1/2}\,\|\tilde{\mathbf{u}}^h-\mathbf{u}^H\|_{0,4}\right] \\
&\le C_{20}\left[M + h\,\|\mathbf{u}\|_{2,4} + h^{-1/2}\,(\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u})\|_0 + \|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0)\right] \\
&\le C_{21}\left[M + M\,h + M\,h^{3/2} + h^{-1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\right] \\
&\le C_{22}\left[M + h^{-1/2}\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\right]. \qquad (4.18)
\end{aligned}$$

Using (4.6) and (4.18), the third term in (4.13) becomes

$$\begin{aligned}
&\langle(\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h)^-, (\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)^- - (\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)^+\rangle_{h,\mathbf{u}^H} \\
&\qquad \le C_{23}\,\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_{0,\Gamma^h}\,(h^{-1/2}\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0)\,\|\mathbf{u}^H\|_\infty \\
&\qquad \le C_{24}\,M\,h\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,\left(M + h^{-1/2}\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\right). \qquad (4.19)
\end{aligned}$$

Therefore, by (4.5), (4.14), (4.17), and (4.19), we obtain

$$\begin{aligned}
&B^h(\mathbf{u}^H, \boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) \\
&\qquad \le C_{25}\,\Big[M\,h^{1/2}\,\left(\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0 + M\,h\right) + M\,h\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0 \\
&\qquad\qquad +M\,h\,\left(M + h^{-1/2}\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\right)\Big]\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,. \qquad (4.20)
\end{aligned}$$

We now estimate the last B^h term. Using $\hat{\mathbf{u}}$, the P_2 interpolate of $\mathbf{u}$ on $\mathbf{V}^h$,

$$\begin{aligned}
\|\mathbf{u}-\mathbf{u}^H\|_\infty &\le \|\mathbf{u}-\hat{\mathbf{u}}\|_\infty + \|\hat{\mathbf{u}}-\mathbf{u}^H\|_\infty \\
&\le C_{26}\,\left(h^2\,\|\mathbf{u}\|_3 + h^{-1/2}\,\|\nabla(\hat{\mathbf{u}}-\mathbf{u}^H)\|_0\right) \\
&\le C_{26}\,\left(M\,h^2 + h^{-1/2}\,\|\nabla(\hat{\mathbf{u}}-\mathbf{u})\|_0 + h^{-1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\right) \\
&\le C_{27}\,\left(M\,h^2 + h^{-1/2}\,(h^2\,M) + h^{-1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\right) \\
&\le C_{28}\,\left(M\,h^{3/2} + h^{-1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\right). \qquad (4.21)
\end{aligned}$$

Then, by (3.7)–(3.9), (4.11), and (4.21),

$$\begin{aligned}
&B^h(\mathbf{u}-\mathbf{u}^H, \boldsymbol{\sigma}-\boldsymbol{\sigma}^H, \tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h) \\
&= -\,((((\mathbf{u}-\mathbf{u}^H)\cdot\nabla)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)), \boldsymbol{\sigma}-\boldsymbol{\sigma}^H)_h - \frac{1}{2}(\nabla\cdot(\mathbf{u}-\mathbf{u}^H)(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h), \boldsymbol{\sigma}-\boldsymbol{\sigma}^H) \\
&\qquad\qquad +\langle(\boldsymbol{\sigma}-\boldsymbol{\sigma}^H)^-, (\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)^- - (\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)^+\rangle_{h,\mathbf{u}-\mathbf{u}^H} \\
&\le C_{29}\,\Big[\|\mathbf{u}-\mathbf{u}^H\|_{0,4}\,\|\nabla(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\|_{0,4,h}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0 \\
&\qquad\qquad + \|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_\infty\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0 \\
&\qquad\qquad + \|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_{0,\Gamma^h}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_{0,\Gamma^h}\,\|\mathbf{u}-\mathbf{u}^H\|_\infty\Big] \\
&\le C_{30}\,\Big[\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,(\,h^{-3/2}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,)\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0
\end{aligned}$$

$$
\begin{aligned}
&+ \|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0 \|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0 \,(h^{-1}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0)\\
&+ (\,M\,h^{3/2}+h^{-1/2}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\,)\,(\,h^{-1/2}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,)\\
&\Big(\,M\,h^{3/2}+h^{-1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,\Big)\Big],
\end{aligned}
$$

which implies

$$
\begin{aligned}
&B^h(\mathbf{u}-\mathbf{u}^H,\boldsymbol{\sigma}-\boldsymbol{\sigma}^H,\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\\
&\quad\le C_{31}\Big[h^{-3/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\\
&\quad\quad+(M\,h+h^{-1}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0)\,(\,M\,h^{3/2}+h^{-1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,)\Big]\;\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,.
\end{aligned}
\tag{4.22}
$$

Therefore, by (4.9), (4.12), (4.20), and (4.22), we have

$$
\begin{aligned}
&\text{Sum of } B^h \text{ terms}\\
&\le C_{32}\Big[M^2\,h^2+h^{-3/2}\,(M+NH^{3/2})\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\\
&\quad+M\,h^{1/2}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0+M^2\,h^{5/2}\\
&\quad+M\,h^{1/2}\,(\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0+M\,h)+M\,h\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\\
&\quad+M\,h\,(M+h^{-1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0)+h^{-3/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\\
&\quad+(M\,h+h^{-1}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0)\,(M\,h^{3/2}+h^{-1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0)\Big]\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&=C_{32}\Big[M^2\,h^2+M^2\,h^{5/2}+M^2\,h^{3/2}+M^2\,h+M^2\,h^{5/2}\\
&\quad+M\,(3\,h^{1/2}+h)\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0+2\,M\,h^{1/2}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\\
&\quad+2\,h^{-3/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\Big]\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\quad+h^{-3/2}\,(M+NH^{3/2})\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\le C_{33}\Big[M^2\,h+M\,h^{1/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0+M\,h^{1/2}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\\
&\quad+h^{-3/2}\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\Big]\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\quad+h^{-3/2}\,(M+NH^{3/2})\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,.
\end{aligned}
$$

We obtain, by Young's inequality, that

$$
\begin{aligned}
\text{Sum of } B^h \text{ terms } \le\; & C_{33}\big[\epsilon_5\,\mathcal{R}^2+\frac{1}{4\epsilon_5}\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2+\frac{1}{4\epsilon_6}\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\\
&+C_{34}\,\epsilon_6\,h^{-3}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2\big],
\end{aligned}
\tag{4.23}
$$

where

$$
\begin{aligned}
\mathcal{R}\le\; & M^2h+Mh^{1/2}(\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0+\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0)\\
&+h^{-3/2}\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\,.
\end{aligned}
$$

(iii) g_a *terms.* Using (2.13)–(2.14), (3.8), and (4.4)–(4.5), we have

$$
\begin{aligned}
&\text{Sum of } g_a \text{ terms}\\
&\le C_{35}\Big[\|\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}^h\|_0\,\|\nabla\mathbf{u}^H\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_\infty+\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,\|\nabla\mathbf{u}^H\|_\infty\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\quad+\|\boldsymbol{\sigma}^H\|_0\,\|\nabla(\mathbf{u}-\tilde{\mathbf{u}}^h)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_\infty+\|\boldsymbol{\sigma}^H\|_\infty\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0
\end{aligned}
$$

$$
\begin{aligned}
&\qquad + \|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_\infty\Big]\\
&\le C_{36}\Big[(M\,h^2)\,(\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0+\|\nabla\mathbf{u}\|_0)\,(h^{-1}\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0)\\
&\qquad + (h^{-1}\|\nabla\mathbf{u}^H\|_0)\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2\\
&\qquad + (\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_0+\|\boldsymbol{\sigma}\|_0)\,(M\,h^2)\,(h^{-1}\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0)\\
&\qquad + (h^{-1}\|\boldsymbol{\sigma}^H\|_0)\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\qquad + \|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,(h^{-1}\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0)\Big]\\
&\le C_{37}\Big[(M+NH^{3/2})\,h^{-1}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2\\
&\qquad + \big(\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0+\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_0+2\,M\big)\,M\,h\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\qquad + h^{-1}\,(M+NH^{3/2})\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\qquad + h^{-1}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\Big]\\
&= C_{37}\Big[h^{-1}\,(M+NH^{3/2})\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2\\
&\qquad + \big(2\,M^2h+M\,h\,(\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0+\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_0)\\
&\qquad + h^{-1}\,\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\,\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\big)\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\\
&\qquad + h^{-1}\,(M+NH^{3/2})\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0\Big]\,.
\end{aligned}
$$

Hence

$$
\begin{aligned}
\text{Sum of } g_a \text{ terms } \le\; & C_{37}\Big[\epsilon_7\mathcal{U}^2+\frac{1}{4\epsilon_7}\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2+\frac{1}{4\epsilon_8}\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\\
&+ C_{38}\,\epsilon_8\,h^{-2}\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2+h^{-1}\,(M+NH^{3/2})\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2\Big]\,,
\end{aligned}
\tag{4.24}
$$

where

$$
\mathcal{U}\le 2\,M^2h+M\,h(\|\nabla(\mathbf{u}^H-\mathbf{u})\|_0+\|\boldsymbol{\sigma}^H-\boldsymbol{\sigma}\|_0)+h^{-1}\|\boldsymbol{\sigma}-\boldsymbol{\sigma}^H\|_0\|\nabla(\mathbf{u}-\mathbf{u}^H)\|_0\,.
$$

(iv) Since $B^h(\mathbf{u}^H,\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h,\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h)\ge 0$, (4.7) and the estimates (4.8), (4.23), and (4.24) imply that

$$
\begin{aligned}
&A((\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h,\tilde{\mathbf{u}}^h-\mathbf{u}^h),(\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h,\tilde{\mathbf{u}}^h-\mathbf{u}^h))\,.\\
&\quad\le C_1\,M^2\,\left(\frac{1}{4\epsilon_1}+\frac{\alpha^2}{\epsilon_3}+\frac{\alpha^2}{\epsilon_2}+\frac{4\alpha^2(1-\alpha)^2}{\epsilon_4}\right)h^4\\
&\qquad + (\epsilon_1+\epsilon_2)\,\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2+(\epsilon_3+\epsilon_4)\,\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\\
&\qquad + \lambda C_{39}\left[\epsilon_5\,\mathcal{R}^2+\left(\frac{1}{4\epsilon_5}+C_{34}\,\epsilon_6\,h^{-3}\right)\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2+\frac{1}{4\epsilon_6}\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\right.\\
&\qquad + \epsilon_7\,\mathcal{U}^2+\left(\frac{1}{4\epsilon_7}+C_{38}\,\epsilon_8\,h^{-2}+h^{-1}\,(M+NH^{3/2})\right)\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2\\
&\qquad \left.+\ \frac{1}{4\epsilon_8}\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\right]\,.
\end{aligned}
$$

Choosing sufficiently small λ and ϵ_i appropriately for $i=1,2,\dots,8$ and using the coercivity of A, we have

$$
\|\tilde{\boldsymbol{\sigma}}^h-\boldsymbol{\sigma}^h\|_0^2+\|\nabla(\tilde{\mathbf{u}}^h-\mathbf{u}^h)\|_0^2\le\overline{C}\,h^4+C\lambda(\mathcal{R}^2+\mathcal{U}^2)\,.
$$

Hence

$$\begin{aligned}\|\tilde{\boldsymbol{\sigma}}^h - \boldsymbol{\sigma}^h\|_0 + \|\nabla(\tilde{\mathbf{u}}^h - \mathbf{u}^h)\|_0 \\ \leq \overline{C}\, h^2 + C\lambda^{1/2} \Big[M^2 h + M\, h^{1/2}(\|\nabla(\mathbf{u} - \mathbf{u}^H)\|_0 + \|\boldsymbol{\sigma} - \boldsymbol{\sigma}^H\|_0) \\ + h^{-3/2}\|\boldsymbol{\sigma} - \boldsymbol{\sigma}^H\|_0 \|\nabla(\mathbf{u} - \mathbf{u}^H)\|_0 \Big],\end{aligned}$$

and we conclude by (4.4)–(4.5) that

$$\begin{aligned}\|\boldsymbol{\sigma} - \boldsymbol{\sigma}^h\|_0 + \|\nabla(\mathbf{u} - \mathbf{u}^h)\|_0 \\ \leq \overline{C}\, h^2 + C\lambda^{1/2} \Big[M^2 h + M\, h^{1/2}(\|\nabla(\mathbf{u} - \mathbf{u}^H)\|_0 + \|\boldsymbol{\sigma} - \boldsymbol{\sigma}^H\|_0) \\ + h^{-3/2}\|\boldsymbol{\sigma} - \boldsymbol{\sigma}^H\|_0 \|\nabla(\mathbf{u} - \mathbf{u}^H)\|_0 \Big]. \qquad \square\end{aligned}$$

REMARK 4.2. *The result in Theorem* 4.1 *is a rough error estimate. It suggests the optimal scaling* $H = h^{5/6}$ *for linear convergence. However, the actual optimal scaling and convergence rate obtained by numerical experiments with* $\lambda = 1$ *are much better than the theoretical ones.*

5. Numerical results. In this section we present the numerical results obtained by multigrid algorithms. The domain is taken to be the unit square $\Omega = [0,1] \times [0,1]$, and the parameters α, a in the model equations are chosen as 0.5 and 0, respectively. Although we assumed that $\mathbf{h} = \mathbf{0}$, $g = 0$, and $\mathbf{u}_\Gamma = \mathbf{0}$ for simplicity of our analysis, it turned out by various precalculations that these conditions are not necessary for computations by the multigrid method. Hence, the right-hand side functions in (1.1)–(1.3) are appropriately given so that the exact solution is

$$\begin{cases} \mathbf{u} = \begin{pmatrix} \sin(\pi x) y(y-1) \\ \sin(x)\,(x-1) y \cos(\pi y/2)) \end{pmatrix}, \\ p = \cos(2\pi x)\, y(y-1), \\ \boldsymbol{\sigma} = 2\alpha\, d(\mathbf{u}). \end{cases}$$

The example we choose for the numerical test satisfies homogeneous boundary condition for $\mathbf{u}$, but $\operatorname{div} \mathbf{u} = g \neq 0$. Note that the example satisfies the compatibility condition

$$\int_\Omega \operatorname{div} \mathbf{u}\, d\Omega = \int_\Gamma \mathbf{u}_\Gamma \cdot \mathbf{n}\, d\Gamma = 0.$$

We first compute the solution to (2.8)–(2.10) with the replacement $(q^h, \nabla \cdot \mathbf{u}^h) = (g, q^h)$ and nonzero right-hand side $(\mathbf{h}, \boldsymbol{\tau}^h)$ in the discrete constitutive equation using a standard one-grid method. For $\lambda = 0.1$, 1, and 2, the nonlinear equation is solved by the Newton iteration with the initial guess $(\mathbf{u}, p, \boldsymbol{\sigma}) = (\mathbf{0}, 0, \mathbf{0})$. We use the stopping criterion defined by

$$\|\text{change in successive values of } \mathbf{u} \text{ and } \boldsymbol{\sigma}\|^2 < 10^{-9}$$

for each mesh size chosen with the maximum number of iteration set at 15. Since we have an exact solution, we compute errors and the experimental rate of convergence computed by comparing the errors on two grids. All computations were performed on a SUN Enterprise 4000 with six processors.

In Table 5.1 we present the results obtained using the one-grid method. It is observed that the number of Newton iterations increases a little for a larger value of λ. The experimental rates of $\mathbf{u}$ and $\boldsymbol{\sigma}$ are very close to theoretical rates when P_2 and P_1 elements are used for an elliptic problem, respectively. In [10], a decoupled algorithm for the same model equation is presented, and the theoretical H^1 and L^2 rates of $\mathbf{u}$ and $\boldsymbol{\sigma}$, respectively, are proved to be 1.5. In fact, the experimental rates

of convergence obtained by the decoupled algorithm are larger than 1.5 but less than the rates presented in Table 5.1. See [8].

In Table 5.2 we present results for the same example using a two-grid method

with $\lambda = 1$, and in Table 5.3 we present results using three- and four-grid methods for the same value of λ. In presenting these computations, we fix the coarse grid H and then vary the fine grid. The full nonlinear problem is solved on the coarse mesh, and then one linearized Newton step is performed on the fine meshes. The rates of convergence in Table 5.2 were obtained by comparing the errors on two consecutive fine grids which used the same initial coarse grid. It is experimentally observed that if a fine grid is fixed, the coarse grid H should be as small as $H \approx h^{2/3}$. For example, when $h = 1/8$, $h^{2/3} = 1/4$, so the two-level method with $H = 1/4$ works as accurately as the one-grid method. However, a choice of $H = 1/3$ yields larger errors, as seen in Table 5.2. Similarly, if $h = 1/12$ or $1/16$, the optimal scaling is $(1/12)^{2/3} \approx 1/5$ or $(1/16)^{2/3} \approx 1/6$.

To compare the accuracy and relative efficiency of the standard one-grid method with the multigrid method, we compare the results generated with a fixed value of h for the one-grid method with the results obtained using a multigrid method where the finest grid has the same mesh spacing h. Table 5.4 summarizes these results by combining the results from Tables 5.1–5.3. It can be easily seen that calculation using the multigrid method gave considerable savings in computational time for similar accuracy. For example, when $h = \frac{1}{16}$, six Newton iterations are needed by the one-grid method, requiring CPU time of 7480.9. The two-grid method with $H = \frac{1}{8}$ and $h = \frac{1}{16}$ required six iterations on H to solve the nonlinear problem and one iteration on h, requiring CPU time of 1723.1. Using the four-grid method with $H = \frac{1}{2}$, $h_1 = \frac{1}{4}$, $h_2 = \frac{1}{8}$, and $h_3 = \frac{1}{16}$, the computational time is reduced to 1337.7, which is 18% of CPU time required for the one-grid method. Note that the finer grid calculations gave more savings in time, and most of the savings are already obtained by using the two-grid method. More savings in time can be obtained by using three- or four-grid methods.

ASYNCHRONOUS FAST ADAPTIVE COMPOSITE-GRID METHODS FOR ELLIPTIC PROBLEMS: THEORETICAL FOUNDATIONS*

BARRY LEE†¶, STEPHEN F. MCCORMICK‡, BOBBY PHILIP§¶, AND DANIEL J. QUINLAN†¶

Abstract. Accurate numerical modeling of complex physical, chemical, and biological systems requires numerical simulation capability over a large range of length scales, with the ability to capture rapidly varying phenomena localized in space and/or time. Adaptive mesh refinement (AMR) is a numerical process for dynamically introducing local fine resolution on computational grids during the solution process, in response to unresolved error in a computation. Fast adaptive composite-grid (FAC) methods are a class of algorithms that exploit the multilevel structure of AMR grids to solve elliptic problems efficiently. This paper develops a theoretical foundation for AFACx, an asynchronous FAC method. A new multilevel condition number estimate establishes that the convergence rate of the AFACx algorithm does not degrade as the number of refinement levels in the AMR hierarchy increases.

1. Introduction.

Adaptive mesh refinement (AMR) is a numerical process for dynamically introducing local fine resolution on computational grids during the solution process in response to unresolved error in a computation. Local fine resolution is achieved by dynamically adapting the existing computational grid based on additional grid points (point-based AMR) or finer local grids (block-structured AMR). AMR approaches are attractive because they often achieve orders of improvement in computational efficiency and memory usage. AMR techniques were first introduced by Brandt [19] in the early 1970s for general problems in a multilevel context and by Berger and Oliger [6] in the 1980s for hyperbolic problems. Since then, AMR research has been pursued by several groups (cf. [1, 2, 5, 29, 42, 43]).

For elliptic problems, when numerical simulations involve a large number of refinement levels and are extremely large, effective parallel methods for AMR must be considered. It is then desirable to develop elliptic solvers that asynchronously process all grids, or at least asynchronously process grids at a fixed refinement level. In addition, as the number of refinement levels increases, the convergence rate should not degrade as a function of the number of refinement levels.

¶The work of these authors was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract W-7405-Eng-48.

The fast adaptive composite-grid (FAC) method was developed in the 1980s [32, 33, 34, 35] to provide more robust discretization and solution methods for elliptic problems on AMR grids. Its strength lies in its ability to use existing single grid solvers on uniform meshes for different refinement levels, with the combined effect of solving a nonuniform composite-grid problem. Though FAC allows for asynchronous processing of disjoint grids at a given refinement level and its convergence rate is bounded independently of the number of refinement levels, the multiplicative way it treats the various refinement levels imposes sequentialness in its processing. For large-scale parallel AMR applications, this sequential nature of FAC, like that of other AMR techniques, represents a serious bottleneck to full scalability.

This difficulty led to the development of the asynchronous version of FAC, called AFAC [28, 33, 36, 37]. AFAC, like FAC, is blessed with level-independent convergence bounds and the convenience of enabling uniform grid solvers. But it has the added advantage of allowing asynchronous processing of all refinement levels. This important asynchronous feature is obtained at the cost of only a modest fixed decrease in convergence rates [33].

Further research into improving computational efficiency associated with the uniform grid solvers on local grid patches led to the development of AFACx [41]. AFACx is very inexpensive because it uses only simple relaxation methods on all but the coarsest grid. Numerical results [39, 41] show that the attendant reduction in computational and communication costs of AFACx comes with no significant degradation in convergence rates compared to AFAC based on multigrid solvers.

Convergence bounds for FAC were established in [32, 38] under certain regularity assumptions. Widlund and Dryja proposed and analyzed variants of FAC [45, 23]. Reusken and Ferket [24] compared FAC with the local defect correction (LDC) method [27] introduced by Hackbusch. AFAC was introduced by Hart and McCormick in [28]. Optimality in the multilevel case for AFAC applied to a model problem was shown in [31]. This was followed by the development of AFACx [41]. Cheng [21, 22] established optimal bounds on the condition number of the multilevel AFAC iteration operator with exact solvers. Moe [39, 7] presented performance results for FAC and AFAC on parallel machines. Quinlan, in his thesis [41], presented a two-level convergence analysis for AFACx assuming a sufficient number of smoothing steps at each level and showed that it is closely related to the convergence rate of AFAC. Shapira [44] compared the performance of AFAC and AFACx. However, a multilevel theory for AFACx remained a gap in the theory of multilevel FAC-type methods.

Closely related to AFACx are the additive preconditioners of Bramble, Pasciak, Xu [16] and Bramble, Pasciak, and Vassilevski [18]. The theoretical framework developed by Bramble, Pasciak, Xu, Wang, Oswald, Griebel, and others [16, 15, 12, 14, 13, 17, 11, 47, 48, 50, 9, 8, 49, 26] presents a powerful tool for analyzing multilevel methods. Relying heavily on this modern multilevel framework for multilevel methods and some of the assumptions therein, we present in this paper a new multilevel condition number estimate for the AFACx operator.

The new theoretical results presented in this paper are strongly backed by numerical evidence [41, 40] and performance results [41]. Recent numerical work [40, 30] shows that AFACx can be applied successfully to elliptic PDE systems arising from first-order system least squares (FOSLS) formulations on adaptively refined curvilinear AMR grids. As increasingly complex PDE systems are simulated and the need for AMR is increasingly crucial, theoretical and computational analyses of fast, parallelizable, and efficient multilevel solvers and preconditioners such as AFACx and BPX [16] become increasingly important for validating the results of complex simulations.

This paper develops new multilevel estimates establishing that the condition number of the AFACx operator, like that for AFAC, is bounded independently of the number of refinement levels. We start by introducing the model problem and necessary preliminaries in section 2. In section 3, we introduce the various FAC-type methods, and finally, in section 4, we establish the theory.

2. Model problem. Consider a linear, self-adjoint, second-order elliptic boundary value problem in $\mathbb{R}^n$, $n = 2, 3$, of the form

$$\left\{ \begin{array}{rl} Lu \equiv -\sum\limits_{i,j=1}^{n} \frac{\partial}{\partial x_i}(a_{ij}(x)\frac{\partial u}{\partial x_j}) = & f \quad \text{in } \Omega, \\ u = & 0 \quad \text{on } \partial\Omega, \end{array} \right. \tag{2.1}$$

where u is the unknown, $f \in L^2(\Omega)$ is the source term, and a_{ij} are appropriate coefficients. Assume that

- domain $\Omega \subset \mathbb{R}^n$ is convex polygonal;
- coefficients $a_{ij}(x) \in C^0(\overline{\Omega}), 1 \le i, j \le n$;
- matrix $[a_{ij}(x)]_{1 \le i,j \le n}$ is symmetric almost everywhere in Ω; and
- operator L is uniformly elliptic in the sense that there exists a constant $\theta > 0$ such that $\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \ge \theta|\xi|^2$ for almost all x in Ω and all ξ in $\mathbb{R}^n$, where $|\cdot|$ is the Euclidean norm.

This section is concerned with the numerical solution of the algebraic equations that arise from discretizing problem (2.1) on adaptively refined curvilinear grids. We focus on the plane $\mathbb{R}^2$ for simplicity.

2.1. Variational formulation. Under the above assumptions, the natural linear space in which to seek a weak solution of (2.1) is $V := H_0^1(\Omega)$, and the variational problem is Find $u \in V$ such that

$$a(u, v) = f(v) \quad \forall v \in V, \tag{2.2}$$

where the respective bilinear and linear forms are

$$a(u, v) = \int_\Omega \sum_{i,j=1}^{n} a_{ij}(x) \frac{\partial u}{\partial x_j} \frac{\partial v}{\partial x_i} \mathrm{d}\Omega, \tag{2.3}$$

$$f(v) = \int_\Omega f v \mathrm{d}\Omega. \tag{2.4}$$

It is known [25] that (2.2) has a unique solution, $u \in V$. Moreover, $a(\cdot, \cdot) : V \times V \to \mathbb{R}$ is symmetric and continuous [25], so uniform ellipticity of L and Poincaré's inequality (cf. [10]) imply that $a(\cdot, \cdot)$ is coercive on V: there exists a constant $\gamma > 0$ such that

$$a(u, u) \ge \gamma \|u\|_V^2 \quad \forall u \in V. \tag{2.5}$$

Coercivity, in turn, implies that $a(\cdot, \cdot)$ defines an equivalent inner product over space V. Furthermore, by the Riesz representation theorem (cf. [10]), $a(\cdot, \cdot)$ induces a bounded linear operator $\mathcal{A} : V \to V$ uniquely determined by

$$a(u, v) = (\mathcal{A}u, v) \quad \forall u, v \in V. \tag{2.6}$$

2.2. Partially refined meshes. To discretize (2.2) on partially refined meshes, we introduce the following notation. Let $\Omega_J \subseteq \Omega_{J-1} \subseteq \cdots \subseteq \Omega_1 \equiv \Omega$ be a nested sequence of nonempty bounded open polygonal Lipschitz domains. Subdomains $\Omega_k,\ k = 2, 3, \ldots, J$, can be viewed as regions where the solution may vary on increasingly finer scales and, hence, regions where local refinement patches are generated during the AMR process. Let $\mathcal{T}_1^c = \{\tau_i^1\}_{i=1}^{N_1}$ be a triangulation of $\Omega_1,\ N_1 \geq 4$, meaning that they cover Ω_1 and do not overlap in the sense that the intersection of any two triangles in the triangulation is either empty, a common vertex, or a common edge. Assume that $\mathcal{T}_1^c$ is quasi-uniform. We assume also that the boundaries of Ω_2 align with the edges of elements in $\mathcal{T}_1^c$, and at least one edge of $\mathcal{T}_1^c$ is contained in Ω_2. Triangulation $\mathcal{T}_k^c = \{\tau_i^k\}_{i=1}^{N_k},\ k = 2, 3, \ldots, J$, of Ω, is obtained from $\mathcal{T}_{k-1}^c$ in the following manner. Since $\Omega_k \subseteq \Omega_{k-1}$ and its boundary aligns with elements of $\mathcal{T}_{k-1}^c$, then there exists a local "coarse" triangulation, $\mathcal{T}_k^{h_{k-1}} = \{\tau_{i_j}^{k-1}\}_{j=1}^{M_k}, M_k \leq N_{k-1}$, consisting of elements of $\mathcal{T}_{k-1}^c$ that cover Ω_k, where h_{k-1} is the length of the longest edge of triangles in $\mathcal{T}_k^{h_{k-1}}$. $\mathcal{T}_k^{h_{k-1}}$ is then a quasi-uniform triangulation of Ω_k. Now we uniformly refine elements of $\mathcal{T}_k^{h_{k-1}}$ by subdividing each triangle into four triangles by connecting the midpoints of the edges. This yields a "fine" local triangulation $\mathcal{T}_k^{h_k}$ of Ω_k, which is regular in the sense of Bank, Dupont, and Yserentant [3]. Elements of $\mathcal{T}_{k-1}^c$ that lie in the complement of Ω_k and the elements of $\mathcal{T}_k^{h_k}$ together form the elements of $\mathcal{T}_k^c = (\mathcal{T}_{k-1}^c \backslash \mathcal{T}_k^{h_{k-1}}) \cup \mathcal{T}_k^{h_k}$. This process leads to a series of nested triangulations $\{\mathcal{T}_k^c\}_{k=1}^J$ of Ω that form partially refined locally quasi-uniform meshes.

2.3. Finite element spaces. Henceforth, we assume that conforming piecewise linear finite elements are used, although our results will clearly apply to more general cases. We thus define $V_k^c \subset H_0^1(\Omega), k = 1, 2, \ldots J$, to be the space spanned by standard piecewise linear nodal basis functions with local support about the nodes of triangulation $\mathcal{T}_k^c$. Because of the conformity of the finite elements, note that there are no degrees of freedom associated with fine nodes that lie on boundary $\partial\Omega_k$. Continuity implies that these "slave" nodes are evaluated simply by interpolation from adjacent coarse nodes. Now, the "fine" local finite element space defined in the interior of domain Ω_k is $V_k^{h_k} = V_k^c \cap H_0^1(\Omega_k)$. By our use of $H_0^1(\Omega_k)$ here, we mean that functions in $V_k^{h_k}$ have support only in the interior of Ω_k. Similarly, we define "coarse" local finite element spaces by $V_k^{h_{k-1}} = V_{k-1}^c \cap H_0^1(\Omega_k), V_k^{h_{k-1}} \subset V_k^{h_k},\ k = 2, \ldots, J$. Note that the local spaces are nested: $V_1^c \subseteq V_2^c \subseteq \cdots \subseteq V_J^c \subset H_0^1(\Omega)$. However, the coarse local spaces are generally nonnested because they typically correspond to increasingly smaller local subdomains.

2.4. The discrete variational problem. Having chosen finite-dimensional composite-grid space V_J^c, the discrete variational problem is Find $u^c \in V_J^c$ such that

$$a(u^c, v) = f(v) \ \ \forall v \in V_J^c. \tag{2.7}$$

This problem is equivalent to solving the linear system

$$A^c u^c = f^c, \tag{2.8}$$

where A^c is a symmetric positive-definite matrix induced by the linear operator $\mathcal{A}^c$ defined over composite-grid space V_J^c. Note that V_J^c is a finite-dimensional subspace of $H_0^1(\Omega)$. For notational convenience, denote spaces V_k^c by $V_k,\ k = 1, 2, \ldots, J$; operator $\mathcal{A}^c$ by A; A-inner product $a(\cdot, \cdot)$ on V_J by $A(\cdot, \cdot)$; and the induced A-norm by $|||\cdot|||$. The L^2 inner product on V_J is denoted by $(\cdot, \cdot)$ and its induced norm by $\|\cdot\|$.

2.5. Stationary linear iteration. A consistent stationary linear iterative process for linear system

$$Au = f$$

can be written in the form

$$u^{n+1} = u^n + B(f - Au^n), \tag{2.9}$$

where B is an approximate inverse of A. Here we are thinking of iteration (2.9) as one of our FAC-type algorithms defined below. If B is symmetric with respect to the A inner product, then the process is said to be symmetric. Letting $e^n = u - u^n$ denote the error in the nth iterate, then (2.9) implies that

$$e^{n+1} = (I - BA)e^n. \tag{2.10}$$

Therefore, for the iteration to converge in general, we must have $\rho(I - BA) < 1$, where $\rho(\cdot)$ denotes the spectral radius. For common multiplicative-type algorithms, it is often easy to establish this condition. However, for additive-type multilevel solvers, typically all that can be shown is that $\kappa(BA)$, the condition number of the operator BA, is independent of the number of levels. Such a result implies that the "damped" linear iteration

$$u^{n+1} = u^n + \omega B(f - Au^n) \tag{2.11}$$

converges for sufficiently small ω. It is this type of a result that we establish for the AFACx algorithm defined below.

To describe the FAC algorithms, we need to define operators that approximate (2.7) at the different refinement levels, projection operators that transfer data from fine to coarse spaces, and smoothing operators on the different spaces, all in terms of the discrete inner products $(\cdot, \cdot)$ and $A(\cdot, \cdot)$.

2.6. Approximating composite-grid operators on coarser levels.

DEFINITION 1. *For $k = 1, 2, \ldots, J$, define operator $A_k : V_k \longrightarrow V_k$ by*

$$(A_k w, \phi) = A(w, \phi) \quad \forall \phi \in V_k.$$

Note that operator A_k is symmetric and positive-definite in inner products $A(\cdot, \cdot)$ and $(\cdot, \cdot)$.

2.7. Projection operators. We introduce the following projection operators typically used in multilevel theory.

DEFINITION 2. *For $k = 1, 2, \ldots, J$, define "elliptic projection" operator $P_k : V_J \longrightarrow V_k$ by*

$$A(P_k w, \phi) = A(w, \phi) \quad \forall \phi \in V_k.$$

DEFINITION 3. *For $k = 1, 2, \ldots, J$, define "L^2 projection" operator $Q_k : V_J \longrightarrow V_k$ by*

$$(Q_k w, \phi) = (w, \phi) \quad \forall \phi \in V_k.$$

It can be shown that P_k and Q_k are orthogonal projection operators satisfying the following basic properties:

- $P_k P_l = P_l$, $P_l P_k = P_l$, $Q_k Q_l = Q_l$, $Q_l Q_k = Q_l$ for $l \leq k$.

Additionally, P_k and Q_k are related according to

$$A_k P_k = Q_k A. \tag{2.12}$$

2.8. Smoothing operators. We can write one step of a general stationary linear smoothing procedure applied to

$$A_k u_k = f_k \tag{2.13}$$

in the form

$$u_k^{n+1} = u_k^n + R_k(f_k - A_k u_k^n), \tag{2.14}$$

where $R_k : V_k \longrightarrow V_k$. Note that (2.14) is of the same form as (2.9), but we use R here and below (possibly with subscripts and hats) to signify smoothing. Now the error, $e_k^n = u_k - u_k^n$, obeys the following propagation equation:

$$e_k^{n+1} = (I - R_k A_k)e_k^n \tag{2.15}$$

or

$$e_k^{n+1} = (I - T_k)e_k^n, \tag{2.16}$$

where $T_k : V_J \longrightarrow V_k$ is defined by $T_k = R_k A_k P_k$. For simplicity, we assume that $R_1 = A_1^{-1}$ and that $R_k,\ k = 2, 3, \ldots, J$, are symmetric with respect to the L^2 inner product. Consider the special case $R_k = \hat{R}_k \equiv \frac{1}{\lambda_k} I$, where λ_k is the spectral radius of A_k. The smoothing process is then just Richardson's iteration defined by

$$u_k^{n+1} = u_k^n + \frac{I}{\lambda_k}(f_k - A_k u_k^n). \tag{2.17}$$

Corresponding to $\hat{R}_k$, we define $\hat{T}_k = \hat{R}_k A_k P_k$.

To further quantify the properties that a simple smoother must satisfy, we make the following assumptions commonly made in modern multilevel analyses. While we do briefly comment on the motivation for each assumption and the conditions under which they hold, we refer the reader to [11, 46, 15, 16, 12, 13, 48, 17, 47, 50] for further details. It suffices to state that the assumptions are valid (cf. [11]) for our model problem with partially refined locally quasi-uniform meshes and simple smoothers like Richardson, damped Jacobi, and symmetric Gauss–Seidel.

The first assumption concerns the Richardson operator, $\hat{R}_k$.

A.1. There exist constants $\epsilon \in (0, 1)$ and $\gamma > 0$ such that

$$A(\hat{T}_k w, w) \le (\gamma \epsilon^{k-l})^2 A(w, w) \quad \forall w \in V_l,\ l \le k, \quad k = 1, 2, \ldots, J. \tag{2.18}$$

Roughly speaking, assumption A.1 asserts that the smoother attenuates "smooth" error components slowly; i.e., energy reduction in "smooth" components (represented by components in subspaces $V_l, l < k$) is small compared to energy reduction in the "oscillatory" components. This assumption is a generalization of the strengthened Cauchy–Schwarz inequalities first introduced by Yserentant [49] for hierarchical bases and used extensively in multilevel theory [47, 14, 11, 48]. Constant γ depends on the ellipticity of the boundary value problem and the variation of the coefficients in (2.1). For our model boundary value problem (2.1) discretized with piecewise linears on simplices, (2.18) has been shown to hold (cf. [14, 48]). However, it is apparently not known whether assumption A.1 holds when the coefficients in (2.1) are not very smooth, e.g., when they are only bounded and measurable (cf. [11]).

The next two assumptions allow for more general smoothers, R_k.

A.2. There exist constants $a_0 \in (0,1)$ and $a_1 > 1$ such that

$$a_0 \frac{\|u\|^2}{\lambda_k} \leq (R_k u, u) \leq a_1 \frac{\|u\|^2}{\lambda_k} \quad \forall u \in V_k, 2 \leq k \leq J. \tag{2.19}$$

Assumption A.2 can also be written in the form

$$a_0(\hat{R}_k u, u) \leq (R_k u, u) \leq a_1(\hat{R}_k u, u) \quad \forall u \in V_k, 2 \leq k \leq J, \tag{2.20}$$

which implies that smoothing operator R_k, $k = 2, 3, \ldots, J$, is spectrally equivalent to the Richardson smoothing operator $\hat{R}_k$. It is easy to see that A.2 implies that

$$a_0\ A(\hat{T}_k u, u) \leq A(T_k u, u) \leq a_1\ A(\hat{T}_k u, u) \quad \forall u \in V_J,\ k = 2, 3, \ldots, J. \tag{2.21}$$

Spectral equivalence of symmetric Gauss–Seidel to the Richardson smoother is shown in [48]. The upper inequality in (2.21) holds in general for point-smoothers (cf. [11]).

A.3. There exists a constant $\theta \in (0, 2)$ such that

$$A(T_k v, T_k v) \leq \theta A(T_k v, v) \quad \forall v \in V_k,\ k = 1, 2, \ldots, J. \tag{2.22}$$

Assumption A.3 is a natural consequence of assuming that operators $I - T_k$ are contractive in the energy norm, i.e.,

$$|||I - T_k||| < 1, \quad k = 1, 2, \ldots, J. \tag{2.23}$$

Note that $\theta = 1$ for Richardson, $\theta < 1$ for under-damped Richardson, and $\theta = 1$ for suitably scaled Jacobi and block Jacobi smoothers. In [13], (2.22) is shown to hold for various line and point-based Jacobi and Gauss–Seidel smoothers.

Assumption A.3 can be derived from assumption A.1 under a suitable assumption on γ and spectral equivalence of the smoothers to Richardson iteration. However, in general, the assumption on γ cannot be established without special scaling of the smoothers, so we choose to state both assumptions separately.

In addition to assumptions A.1–A.3 on smoothers R_k and $\hat{R}_k$, a "weak regularity" assumption is required. This condition replaces the standard full regularity and approximation assumption (cf. [12]) with a weaker assumption on operator A and smoothers $\hat{R}_k, k = 2, 3, \ldots, J$.

A.4. There exists a constant $\eta > 0$ such that

$$A(v, v) \leq \eta \sum_{k=1}^{J} A(\hat{T}_k v, v) \quad \forall v \in V_J. \tag{2.24}$$

Assumption A.4 is shown to hold for our model problem discretization in [11]. However, it is also noted in [11] that, in the application to second-order elliptic equations for coefficients with large jumps, A.4 is not known to hold independent of the size of the jumps.

3. Algorithms. We now describe the FAC, AFAC, and AFACx algorithms and complete the section with a discussion of existing theory.

3.1. FAC. Let $u_c^n \in V_J$ denote the current approximation to the solution of composite-grid equation (2.8).

ALGORITHM 1. *One iteration of the basic FAC algorithm consists of the following steps.*

For $k = 1, 2, \ldots, J$, *do:*
  find $w_k \in V_k^{h_k}$ *such that*
    $a(u_c^{n+(k-1)/J} + w_k, v) = f(v) \quad \forall v \in V_k^{h_k}$;
  set $u_c^{n+k/J} = u_c^{n+(k-1)/J} + w_k$.

As can be seen from this pseudolanguage, FAC involves the solution of the residual equation on all refinement levels. The correction on a coarse level is computed before the correction on the next finer level, thus providing boundary conditions for the finer level equations. FAC is multiplicative, since it can be represented as a product of linear operators. Multiplicative algorithms are inherently sequential because each operation depends on its predecessor, making them less attractive in a parallel environment.

3.2. AFAC. Processing on each level in FAC attempts to resolve all components of the solution to the composite-grid residual equation that are represented on a refinement level and coarser levels. On the other hand, processing of each level by AFAC [33, 36, 37] attempts only to resolve components that can be represented on that refinement level. This objective is not dependent on resolving components of the solution to the residual equation that are represented on coarser or finer levels, so it provides for independent level processing. The principal step in AFAC is resolving solution components on each composite-grid level. Let $u_c^n \in V$ denote the current approximation to the solution of composite-grid equation (2.8).

ALGORITHM 2. *One iteration of the AFAC algorithm consists of the following steps.*

For $k = 1, 2, \ldots, J$, *do:*
  find $w_k^f \in V_k^{h_k}$ *such that*
    $a(u_c^n + w_k^f, v) = f(v) \quad \forall v \in V_k^{h_k}$;
  if $(k > 1)$, *then*
    find $w_k^r \in V_k^{h_{k-1}}$ *such that*
      $a(u_c^n + w_k^r, z) = f(z) \quad \forall z \in V_k^{h_{k-1}}$;
set $w_1^r = 0$;
set $u_c^{n+1} = u_c^n + \sum_{k=1}^{J} (w_k^f - w_k^r)$.

AFAC appears to have optimal or near-optimal complexity in a parallel computing environment because it allows for simultaneous processing of all refinement levels. This is important because the solution process on each grid, even with the most efficient solvers, dominates computational complexity. This is especially true for systems where the solution process is significantly more computationally intensive than the evaluation of the residuals. Coupled with multigrid processing on each level and nested iteration [32] on the composite-grids, the computational cost of AFAC is proportional to the cost of a global-grid solve alone (see Hart and McCormick [28] and McCormick [33] for further details).

The following two-grid result is proved in [32].

THEOREM 3.1. *Suppose* A^c *is positive-definite. Then the spectral radii of the two-level exact solver forms of* $AFAC^c$ *and* FAC^c *satisfy*

$$\rho(AFAC^c) = \rho^{\frac{1}{2}}(FAC^c). \tag{3.1}$$

Here, FAC^c *and* $AFAC^c$ *denote the respective FAC and AFAC error propagation op-*

erators on the composite-grid space, and $\rho(\cdot)$ denotes spectral radius. The convergence factor for one iteration of the two-level exact solver form of AFAC satisfies

$$|||AFAC^c|||| \leq \left(\frac{\delta}{1+\delta}\right)^{\frac{1}{4}}, \tag{3.2}$$

where constant $\delta > 0$ is independent of h but depends on the regularity of (2.1) *and the approximation properties of its discretization (see* [32] *for further details).*

Now, assume for each k, $1 \leq k \leq J$, that there exists a bounded Lipschitz polyhedral region $\hat{\Omega}_k$ such that $\Omega_k \subset \hat{\Omega}_k$, $(\hat{\Omega}_k \setminus \Omega_k) \cap \Omega = \emptyset$, and $\partial\hat{\Omega}_k \cap \Omega_{k+1} = \emptyset$, and that the Lipschitz constants of $\hat{\Omega}_k \setminus \Omega_{k+1}$ are uniformly bounded. In addition, assume there exist constants $\gamma_1 \geq \gamma_0 > 0$ and $q \in (0,1)$ such that $\gamma_0 q^k \leq h_k \leq \gamma_1 q^k$, $k = 1, 2, \ldots, J$. Under these assumptions, the following theorem was proved in [21].

THEOREM 3.2. *The AFAC operator has a condition number that is bounded independent of the number of refinement levels and the number of degrees of freedom.*

It is important to note that the results hold when the exact solvers on each level in FAC and AFAC are replaced by approximate solvers (e.g., multigrid solvers), provided that they give a fixed local error reduction (see [32] and [21]). Note also that in [32], the two-level results do not depend on the refinement ratios (h_{k+1}/h_k).

3.3. AFACx. AFAC removes the sequential nature inherent in the FAC algorithm. However, it is possible to further reduce the computational effort on each level by carefully replacing the local solvers in AFAC with smoothers. AFACx is exactly such an algorithm.

To define this scheme, we introduce auxiliary bilinear forms $b_k^r(\cdot,\cdot) : V_k^{h_{k-1}} \times V_k^{h_{k-1}} \longrightarrow \mathbb{R}$ and $b_k^f(\cdot,\cdot) : V_k^{h_k} \times V_k^{h_k} \longrightarrow \mathbb{R}$. These forms correspond to symmetric positive-definite operators $B_k^r : V_k^{h_{k-1}} \longrightarrow V_k^{h_{k-1}}$ and $B_k^f : V_k^{h_k} \longrightarrow V_k^{h_k}$ that represent the action of smoothers on the "restricted" local coarse grid space $V_k^{h_{k-1}}$ and the local "fine" grid space $V_k^{h_k}$. Let $u_c^n \in V$ denote the current approximation to the solution of composite-grid equation (2.8).

ALGORITHM 3. *One iteration of the AFACx algorithm consists of the following steps.*

For $k = 1, 2, \ldots, J$, do:
  if ($k = 1$), then
    find $u_1^f \in V_1^{h_1}$ such that
      $a(u_c^n + u_1^f, v) = f(v) \ \ \forall v \in V_1^{h_1}$;
  else
    find $w_k^r \in V_k^{h_{k-1}}$ such that
      $b_k^r(w_k^r, z) = f(z) - a(u_c^n, z) \ \ \forall z \in V_k^{h_{k-1}}$;
    find $u_k^f \in V_k^{h_k}$ such that
      $b_k^f(w_k^r + u_k^f, v) = f(v) - a(u_c^n, v) \ \ \forall v \in V_k^{h_k}$;
set $u_c^{n+1} = u_c^n + \sum_{k=1}^J u_k^f$.

The above pseudolanguage shows that AFACx replaces the solves on the local restricted coarse and fine levels in AFAC on all but the coarsest level by smoothing steps. Smoothing is performed on the restricted coarse level to obtain the correction w_k^r on each level k. Smoothing on the fine level with initial guess w_k^r then yields u_k^f, which approximates the component of the correction that is representable only on level k.

AFACx is generally more efficient than AFAC because the various uniform grids (the local fine and restricted coarse refinement levels) are processed only by smoothing, instead of the somewhat more expensive multigrid solvers used in AFAC. This reduction in cost apparently comes with no significant degradation in convergence rates. The following two-level result is due to Quinlan [41].

THEOREM 3.3. *Consider the two-level AFACx algorithm that involves one smoothing step on the fine grid patch and n smoothing steps on the restricted coarse grid. Then, for sufficiently large n, the spectral radius of the AFACx error propagation operator is bounded uniformly by a constant less than one, assuming only that this is true for the AFAC error operator.*

3.4. Symmetric AFACx. The operator corresponding to the AFACx algorithm described above is not symmetric with respect to the A inner product. To facilitate condition number estimates, we work instead with a symmetrized form of AFACx developed as follows. Let $u_c^n \in V$ denote the current approximation to the solution of composite-grid equation (2.8).

ALGORITHM 4. *One iteration of the symmetrized AFACx algorithm consists of the following steps.*

For $k = 1, 2, \ldots, J$, *do:*

if $(k = 1)$, *then*

find $u_1^f \in V_1^{h_1}$ *such that*

$a(u_c^n + u_1^f, v) = f(v) \ \ \forall v \in V_1^{h_1}$;

else

find $w_{k,0}^r \in V_k^{h_{k-1}}$ *such that*

$b_k^r(w_{k,0}^r, z) = f(z) - a(u_c^n, z) \ \ \forall z \in V_k^{h_{k-1}}$;

find $w_{k,0}^f \in V_k^{h_k}$ *such that*

$b_k^f(w_{k,0}^r + w_{k,0}^f, v) = f(v) - a(u_c^n, v) \ \ \forall v \in V_k^{h_k}$;

find $w_{k,1}^f \in V_k^{h_k}$ *such that*

$b_k^f(w_{k,1}^f, v) = f(v) - a(u_c^n, v) \ \ \forall v \in V_k^{h_k}$;

find $w_{k,1}^r \in V_k^{h_{k-1}}$ *such that*

$b_k^r(w_{k,1}^r, z) = f(z) - a(u_c^n + w_{k,1}^f, z) \ \ \forall z \in V_k^{h_{k-1}}$;

set $w_{k,1}^f = w_{k,1}^f + w_{k,1}^r$;

set $w_{k,2}^f = w_{k,1}^f - w_{k,0}^r$;

set $u_k^f = (w_{k,0}^f + w_{k,2}^f)/2$;

set $u_c^{n+1} = u_c^n + \sum_{k=1}^J u_k^f$.

The pseudolanguage above principally involves computing two approximations $w_{k,0}^f$ and $w_{k,2}^f$ and averaging them to form u_k^f at each level k. u_k^f then approximates the component of the composite-grid correction that can be represented at level k. $w_{k,0}^f$ is obtained in the following manner: smooth on the coarse-grid residual equation and interpolate to the local fine level to obtain $w_{k,0}^r$, then smooth on the fine level with initial guess $w_{k,0}^r$ to obtain $w_{k,0}^f$. To compute $w_{k,2}^f$, we first compute $w_{k,1}^f$ by applying a two-level correction scheme (as described in [20, p. 33]) on the local fine and restricted levels. $w_{k,2}^f$ is then set to be the difference $w_{k,1}^f - w_{k,0}^r$. In practice, the unsymmetric form of AFACx is used, while the symmetric form is useful for theoretical analysis.

4. Condition number estimates for AFACx. In this section, a new condition number estimate is developed for the multilevel AFACx algorithm. We show that the condition number of the symmetrized AFACx operator (Algorithm 4) is bounded independently of the number of refinement levels.

The following lemma, which is a generalization of the standard Cauchy–Schwarz inequality, is used extensively in the proofs that follow.

LEMMA 4.1 (see [47]). *Let $T \in \mathcal{L}(W)$ be a nonnegative self-adjoint operator with respect to $\langle \cdot, \cdot \rangle$, where $(W, \langle \cdot, \cdot \rangle)$ is a finite-dimensional inner product space and $\mathcal{L}(W)$ is the space of linear operators that map W into itself. Then*

$$|\langle Tu, v\rangle| \;\leq\; \langle Tu, u\rangle^{\frac{1}{2}} \langle Tv, v\rangle^{\frac{1}{2}} \quad \forall u, v \in W. \tag{4.1}$$

It is easy to show that the following lemma holds for operator $T_k = R_k A_k P_k$.

LEMMA 4.2 (see [11]). *Operator $T_k : V_J \longrightarrow V_J$, $k = 1, 2, \ldots, J$, is nonnegative and self-adjoint with respect to the A inner product on V_J.*

4.1. Full refinement. Consider first the case of full refinement: $\Omega_1 = \Omega_2 = \cdots = \Omega_J$. Note that the "restricted coarse" grid is the entire global coarse grid, so that $V_k^{h_{k-1}} = V_{k-1},\ k = 2, 3, \ldots, J$, and the "local fine" grid is the entire global fine grid, so that $V_k^{h_k} = V_k,\ k = 1, 2, \ldots, J$. Define $R_0 = 0,\ P_0 = 0$, and $Q_0 = 0$. Then the operator corresponding to one iteration of AFACx (Algorithm 3) with a single smoothing step each on the fine grid and the restricted coarse grid can be expressed as

$$B^a = \sum_{k=1}^{J} (R_k Q_k - R_k A_k R_{k-1} Q_{k-1}) A. \tag{4.2}$$

To avoid theoretical complications in satisfying assumption A.3 for $\theta \in (1, 2)$ for general smoothers, we work instead with the operator

$$B^a = \sum_{k=1}^{J} \left(R_k Q_k - \frac{1}{2} R_k A_k R_{k-1} Q_{k-1} \right) A, \tag{4.3}$$

which corresponds to damping the restricted coarse grid smoothing by an additional factor of $\frac{1}{2}$. Using relation (2.12), B^a may be rewritten as

$$B^a = \sum_{k=1}^{J} T_k \left(I - \frac{T_{k-1}}{2} \right), \tag{4.4}$$

where T_0 is identically zero. Expressing P_k as the telescoping series $\sum_{l=1}^{k} (P_l - P_{l-1})$, we can then write

$$B^a = \sum_{k=1}^{J} T_k (P_k - P_{k-1}) + \sum_{k=1}^{J} \sum_{l=1}^{k-1} T_k \left(I - \frac{T_{k-1}}{2} \right) (P_l - P_{l-1}). \tag{4.5}$$

Interchanging the order of summation in the second term in (4.5) allows us to rewrite B^a as

$$B^a = \sum_{l=1}^{J} T_l (P_l - P_{l-1}) + \sum_{l=1}^{J-1} \sum_{k=l+1}^{J} T_k \left(I - \frac{T_{k-1}}{2} \right) (P_l - P_{l-1}). \tag{4.6}$$

4.2. Richardson smoothing. First, consider the case when Richardson iteration is used as the smoother. We then have $R_k = \hat{R}_k$ and $T_k = \hat{T}_k$. Let $P_0 \equiv 0$ and define $w_l = (P_l - P_{l-1})v$, $l = 1, 2, \ldots, J$, for a given $v \in V_J$.

Our next lemma establishes a simple but important approximation property on each level.

LEMMA 4.3. *Let T_k, $k = 2, 3, \ldots, J$, satisfy bound* (2.22). *Then*

$$A\left(T_k\left(I - \frac{T_{k-1}}{2}\right)w_l, \left(I - \frac{T_{k-1}}{2}\right)w_l\right) \leq \left(1 + \frac{\gamma\sqrt{\theta}}{2}\right)^2 (\gamma\epsilon^{k-l})^2 A(w_l, w_l), \quad k = 2, 3, \ldots, J,\ l < k. \tag{4.7}$$

Proof. First, note that

$$A\left(T_k\left(I - \frac{T_{k-1}}{2}\right)w_l, \left(I - \frac{T_{k-1}}{2}\right)w_l\right) \leq A(T_k w_l, w_l) + |A(T_k w_l, T_{k-1} w_l)| + \frac{1}{4}A(T_k T_{k-1} w_l, T_{k-1} w_l). \tag{4.8}$$

Setting $T = T_k$, $u = w_l$, and $v = T_{k-1}w_l$ in Cauchy–Schwarz inequality (4.1), we have

$$|A(T_k w_l, T_{k-1} w_l)| \leq A(T_k w_l, w_l)^{\frac{1}{2}} A(T_k T_{k-1} w_l, T_{k-1} w_l)^{\frac{1}{2}}. \tag{4.9}$$

From (4.8) and (4.9), we thus have

$$A\left(T_k\left(I - \frac{T_{k-1}}{2}\right)w_l, \left(I - \frac{T_{k-1}}{2}\right)w_l\right) \leq \left(A(T_k w_l, w_l)^{\frac{1}{2}} + \frac{1}{2}A(T_k T_{k-1} w_l, T_{k-1} w_l)^{\frac{1}{2}}\right)^2. \tag{4.10}$$

Using assumption A.1 with $w = T_{k-1}w_l$ and applying assumption A.3, we see that the last term in (4.10) is bounded according to

$$A(T_k T_{k-1} w_l, T_{k-1} w_l) \leq (\gamma\epsilon)^2 \theta A(T_{k-1} w_l, w_l). \tag{4.11}$$

Applying assumption A.1 again, we have

$$A(T_{k-1} w_l, w_l) \leq (\gamma\epsilon^{k-l-1})^2 A(w_l, w_l). \tag{4.12}$$

Combining (4.11) and (4.12) yields

$$A(T_k T_{k-1} w_l, T_{k-1} w_l) \leq \gamma^2 \theta (\gamma\epsilon^{k-l})^2 A(w_l, w_l). \tag{4.13}$$

Now, using assumption A.1 to bound the first term on the right-hand side of (4.10) and (4.13) to bound the second term, we have

$$A\left(T_k\left(I - \frac{T_{k-1}}{2}\right)w_l, \left(I - \frac{T_{k-1}}{2}\right)w_l\right) \leq \left(1 + \frac{\gamma\sqrt{\theta}}{2}\right)^2 (\gamma\epsilon^{k-l})^2 A(w_l, w_l). \tag{4.14}$$

∎

Before we prove the main results of this section, we state the following useful identity (cf. [11, 47]).

LEMMA 4.4. *Let* $w_l = (P_l - P_{l-1})v,\ v \in V_J,\ l = 1, 2, \ldots, J$, *with* $P_0 = 0$. *Then*

$$\sum_{l=1}^{J} A(w_l, w_l) = A(v, v). \tag{4.15}$$

The next few lemmas are used to show that a symmetrized version of B^a has a uniformly bounded condition number. We first show that B^a is bounded uniformly in the A-norm.

LEMMA 4.5. *There exists constant* $C_1 > 0$, *independent of the number of levels* J, *such that*

$$A(B^a v, v) \le C_1 A(v, v) \quad \forall v \in V_J.$$

Proof. From (4.6), we have

$$\begin{aligned} A(B^a v, v) &= \sum_{l=1}^{J-1} \sum_{k=l+1}^{J} A\left(T_k \left(I - \frac{T_{k-1}}{2}\right) w_l, v\right) + \sum_{l=1}^{J} A(T_l w_l, v) \\ &= \sum_{l=1}^{J-1} \sum_{k=l+1}^{J} A\left(T_k \left(I - \frac{T_{k-1}}{2}\right) w_l, P_k v\right) + \sum_{l=1}^{J} A(T_l w_l, P_l v). \end{aligned}$$

Expressing P_k as a telescoping series, $P_k = \sum_{j=1}^{k} (P_j - P_{j-1})$, we have

$$\begin{aligned} A(B^a v, v) &= \sum_{l=1}^{J-1} \sum_{k=l+1}^{J} A\left(T_k \left(I - \frac{T_{k-1}}{2}\right) w_l, \sum_{j=1}^{k} (P_j - P_{j-1}) v\right) + \sum_{l=1}^{J} A(T_l w_l, P_l v) \\ &= \sum_{l=1}^{J-1} \sum_{k=l+1}^{J} \sum_{j=1}^{k} A\left(T_k \left(I - \frac{T_{k-1}}{2}\right) w_l, w_j\right) + \sum_{l=1}^{J} A(T_l w_l, P_l v). \end{aligned} \tag{4.16}$$

Now, applying Cauchy–Schwarz inequality (4.1) with $T = T_k,\ u = (I - T_{k-1}) w_l$, and $v = w_j$ yields

$$\begin{aligned} &A\left(T_k \left(I - \frac{T_{k-1}}{2}\right) w_l, w_j\right) \\ &\qquad \le A\left(T_k \left(I - \frac{T_{k-1}}{2}\right) w_l, \left(I - \frac{T_{k-1}}{2}\right) w_l\right)^{\frac{1}{2}} A(T_k w_j, w_j)^{\frac{1}{2}}. \end{aligned} \tag{4.17}$$

Bounding the first factor on the right-hand side of (4.17) using Lemma 4.3 and the second factor using assumption A.1 yields

$$A\left(T_k \left(I - \frac{T_{k-1}}{2}\right) w_l, w_j\right) \le \left(1 + \frac{\gamma\sqrt{\theta}}{2}\right) (\gamma \epsilon^{k-l}) A(w_l, w_l)^{\frac{1}{2}} (\gamma \epsilon^{k-j}) A(w_j, w_j)^{\frac{1}{2}}. \tag{4.18}$$

Finally, applying the arithmetic-geometric mean inequality in (4.18) yields

$$A\left(T_k \left(I - \frac{T_{k-1}}{2}\right) w_l, w_j\right) \le \frac{(1 + \frac{\gamma\sqrt{\theta}}{2}) \gamma^2 \epsilon^{2k-l-j}}{2} (A(w_l, w_l) + A(w_j, w_j)). \tag{4.19}$$

Using bound (4.19) for the individual terms in (4.16), we have

$$A(B^a v, v) \leq \left(\frac{(1+\frac{\gamma\sqrt{\theta}}{2})\gamma^2}{2}\right)\left(\sum_{l=1}^{J-1}\sum_{k=l+1}^{J}\sum_{j=1}^{k}\epsilon^{2k-l-j}(A(w_l,w_l)+A(w_j,w_j))\right)$$

$$+\sum_{l=1}^{J}A(T_l w_l, P_l v). \tag{4.20}$$

We now bound each of the three terms on the right-hand side of (4.20) individually.

Term I. First write

$$S_1 \equiv \sum_{l=1}^{J-1}\sum_{k=l+1}^{J}\sum_{j=1}^{k}\epsilon^{2k-l-j}A(w_l,w_l) = \sum_{l=1}^{J-1}\sum_{k=l+1}^{J}\epsilon^{k-l}A(w_l,w_l)\left(\sum_{j=1}^{k}\epsilon^{k-j}\right).$$

Hence,

$$S_1 \leq \left(\frac{1}{1-\epsilon}\right)\sum_{l=1}^{J-1}A(w_l,w_l)\left(\sum_{k=l+1}^{J}\epsilon^{k-l}\right).$$

Again, bounding terms involving powers of ϵ and applying Lemma 4.4, we have

$$S_1 \leq \frac{\epsilon}{(1-\epsilon)^2}\sum_{l=1}^{J}A(w_l,w_l) = \frac{\epsilon}{(1-\epsilon)^2}A(v,v). \tag{4.21}$$

Term II. Let

$$\begin{aligned} S_2 &\equiv \sum_{l=1}^{J-1}\sum_{k=l+1}^{J}\sum_{j=1}^{k}\epsilon^{2k-l-j}A(w_j,w_j) \\ &= \sum_{l=1}^{J-1}\sum_{k=l+1}^{J}\epsilon^{k-l}\left(\sum_{j=1}^{k}\epsilon^{k-j}A(w_j,w_j)\right). \end{aligned} \tag{4.22}$$

Now, let $\underline{\alpha} = (\alpha_1, \alpha_2, \ldots, \alpha_J)^t$, where $\alpha_j = A(w_j, w_j)$, $j = 1, 2, \ldots, J$. Also, let $\mathcal{E} = (\mathcal{E}_{ij})_{1\leq i,j\leq J}$ denote the $J \times J$ lower triangular matrix with entries given by

$$\mathcal{E}_{ij} = \begin{cases} \epsilon^{i-j} & : \quad i \geq j, \\ 0 & : \quad i < j. \end{cases}$$

Finally, let $\underline{\beta}_l = (\beta_{1l}, \beta_{2l}, \ldots, \beta_{Jl})^t$, $l = 1, 2, \ldots, J$, denote column vectors with entries given by

$$\beta_{il} = \begin{cases} 0 & : \quad i \leq l, \\ \epsilon^{i-l} & : \quad i > l, \end{cases}$$

and define $\tilde{\beta}^t = (1, 1, \ldots, 1)$. Then, (4.22) can be written as

$$S_2 = \sum_{l=1}^{J-1}\sum_{k=1}^{J}\beta_{kl}\left(\sum_{j=1}^{J}\mathcal{E}_{kj}\alpha_j\right) = \sum_{l=1}^{J-1}\underline{\beta}_l^t\,\mathcal{E}\,\underline{\alpha} = \left(\sum_{l=1}^{J-1}\underline{\beta}_l^t\right)\mathcal{E}\,\underline{\alpha}. \tag{4.23}$$

Each entry of the column vector $\sum_{l=1}^{J-1} \underline{\beta}_l^t$ can be bounded by $\frac{\epsilon}{1-\epsilon}$. Since all quantities are nonnegative,

$$S_2 \le \left(\frac{\epsilon}{1-\epsilon}\right) \underline{\tilde{\beta}}^t \mathcal{E}\, \underline{\alpha} = \left(\frac{\epsilon}{1-\epsilon}\right) \sum_{k=1}^{J} \sum_{j=1}^{k} \mathcal{E}_{kj}\alpha_j. \tag{4.24}$$

Interchanging the order of summation and noting that $\mathcal{E}$ is lower triangular, we thus have

$$\begin{aligned} S_2 &\le \left(\frac{\epsilon}{1-\epsilon}\right) \sum_{j=1}^{J} \sum_{k=j}^{J} \mathcal{E}_{kj}\alpha_j \\ &= \left(\frac{\epsilon}{1-\epsilon}\right) \sum_{j=1}^{J} \sum_{k=j}^{J} \epsilon^{k-j} A(w_j, w_j) \\ &= \left(\frac{\epsilon}{1-\epsilon}\right) \sum_{j=1}^{J} A(w_j, w_j) \left(\sum_{k=j}^{J} \epsilon^{k-j}\right) \\ &\le \frac{\epsilon}{(1-\epsilon)^2} \sum_{j=1}^{J} A(w_j, w_j). \end{aligned} \tag{4.25}$$

Applying Lemma 4.4 in (4.25), we therefore have

$$S_2 \le \frac{\epsilon}{(1-\epsilon)^2} A(v, v). \tag{4.26}$$

Term III. Again using the telescoping series $P_k = \sum_{l=1}^{k} (P_l - P_{l-1})$, we have

$$\begin{aligned} S_3 \equiv \sum_{k=1}^{J} A(T_k w_k, P_k v) &= A(P_1 v, P_1 v) + \sum_{k=2}^{J} A(T_k w_k, P_k v) \\ &= A(P_1 v, P_1 v) + \sum_{k=2}^{J} A\left(T_k w_k, \sum_{l=1}^{k} (P_l - P_{l-1}) v\right) \\ &= A(P_1 v, P_1 v) + \sum_{k=2}^{J} \sum_{l=1}^{k} A(T_k w_k, w_l). \end{aligned}$$

Let $\hat{S}_3 = \sum_{k=2}^{J} \sum_{l=1}^{k} A(T_k w_k, w_l)$. Then applying Cauchy–Schwarz inequality (4.1) followed by assumption A.1 yields

$$\begin{aligned} \hat{S}_3 = \sum_{k=2}^{J} \sum_{l=1}^{k} A(T_k w_k, w_l) &\le \sum_{k=2}^{J} \sum_{l=1}^{k} A(T_k w_k, w_k)^{\frac{1}{2}} A(T_k w_l, w_l)^{\frac{1}{2}} \\ &\le \sum_{k=2}^{J} \sum_{l=1}^{k} \gamma A(w_k, w_k)^{\frac{1}{2}} (\gamma \epsilon^{k-l}) A(w_l, w_l)^{\frac{1}{2}} \\ &\le \gamma^2 \sum_{k=1}^{J} \sum_{l=1}^{J} A(w_k, w_k)^{\frac{1}{2}} (\epsilon^{|k-l|}) A(w_l, w_l)^{\frac{1}{2}}. \end{aligned} \tag{4.27}$$

Set $\alpha_k = A(w_k, w_k)^{\frac{1}{2}}$. Then

$$\hat{S}_3 \leq \gamma^2 \sum_{k=1}^{J} \sum_{l=1}^{J} (\epsilon^{|k-l|}) \alpha_k \alpha_l = \gamma^2 \langle\langle \hat{\mathcal{E}} \vec{\alpha}, \vec{\alpha} \rangle\rangle,$$

where $\hat{\mathcal{E}}$ is the $J \times J$ symmetric positive-definite matrix with entries $\epsilon^{|k-l|}$, $\vec{\alpha}$ is the $J \times 1$ column vector with entries α_k, $k = 1, 2, \ldots, J$, and $\langle\langle \cdot, \cdot \rangle\rangle$ is the Euclidean inner product. The largest eigenvalue of $\hat{\mathcal{E}}$ is bounded by its maximal row sum, which in turn is bounded by $\frac{2}{1-\epsilon}$. Therefore,

$$\begin{aligned} \hat{S}_3 &\leq \gamma^2 \left(\frac{2}{1-\epsilon} \right) \langle\langle \vec{\alpha}, \vec{\alpha} \rangle\rangle \\ &= \left(\frac{2\gamma^2}{1-\epsilon} \right) \left(\sum_{k=1}^{J} \alpha_k^2 \right) \\ &= \left(\frac{2\gamma^2}{1-\epsilon} \right) \left(\sum_{k=1}^{J} A(w_k, w_k) \right). \end{aligned} \tag{4.28}$$

From Lemma 4.4 and (4.28), we thus have

$$\begin{aligned} S_3 &= A(P_1 v, P_1 v) + \hat{S}_3 \\ &\leq A(v, v) + \left(\frac{2\gamma^2}{1-\epsilon} \right) A(v, v) \\ &= \left(1 + \frac{2\gamma^2}{1-\epsilon} \right) A(v, v). \end{aligned} \tag{4.29}$$

Substituting (4.21), (4.26), and (4.29) into (4.20), we therefore conclude that

$$A(B^a v, v) \leq \left(\frac{(1 + \frac{\gamma \theta^{\frac{1}{2}}}{2}) \gamma^2 \epsilon}{(1-\epsilon)^2} + 1 + \frac{2\gamma^2}{1-\epsilon} \right) A(v, v), \tag{4.30}$$

which proves the lemma with

$$C_1 = \left(\frac{\left(1 + \frac{\gamma \theta^{\frac{1}{2}}}{2} \right) \gamma^2 \epsilon}{(1-\epsilon)^2} + 1 + \frac{2\gamma^2}{1-\epsilon} \right). \qquad \square$$

The next lemma shows that B^a is coercive in the A inner product.

LEMMA 4.6. *Under assumptions* A.3 *and* A.4, *there exists constant* $C_0 > 0$, *independent of the number of levels* J, *such that*

$$A(B^a v, v) \geq C_0 A(v, v) \quad \forall v \in V_J.$$

Proof. From (4.4), we have that

$$A(B^a v, v) = \sum_{l=1}^{J} A\left(T_l\left(I - \frac{T_{l-1}}{2}\right)v, v\right)$$

$$= \sum_{l=1}^{J} A(T_l v, v) - \sum_{l=1}^{J} \frac{1}{2} A(T_l T_{l-1} v, v) \tag{4.31}$$

$$= \sum_{l=1}^{J} A(T_l v, v) - \sum_{l=1}^{J} \frac{1}{2} A(T_{l-1} v, T_l v). \tag{4.32}$$

Applying the standard Cauchy–Schwarz inequality yields

$$|A(T_{l-1}v, T_l v)| \le A(T_{l-1}v, T_{l-1}v)^{\frac{1}{2}} A(T_l v, T_l v)^{\frac{1}{2}}. \tag{4.33}$$

Applying assumption A.3 to (4.33), we get

$$|A(T_{l-1}v, T_l v)| \le \theta A(T_{l-1}v, v)^{\frac{1}{2}} A(T_l v, v)^{\frac{1}{2}}. \tag{4.34}$$

Hence, using the standard Cauchy–Schwarz inequality and nonnegativeness of operator T_J with respect to the A inner product we have

$$\sum_{l=1}^{J} A(T_l T_{l-1} v, v) \le \theta \sum_{l=1}^{J} A(T_{l-1}v, v)^{\frac{1}{2}} A(T_l v, v)^{\frac{1}{2}}$$

$$\le \theta \left(\sum_{l=1}^{J} A(T_{l-1}v, v)\right)^{\frac{1}{2}} \left(\sum_{l=1}^{J} A(T_l v, v)\right)^{\frac{1}{2}}$$

$$\le \theta \left(\sum_{l=1}^{J} A(T_l v, v)\right). \tag{4.35}$$

Relations (4.32) and (4.35) and assumption A.4 combine to show that

$$A(B^a v, v) \ge \left(1 - \frac{\theta}{2}\right)\left(\sum_{l=1}^{J} A(T_l v, v)\right)$$

$$\ge \frac{1}{2\eta}(2-\theta) A(v, v) \quad \forall v \in V_J. \tag{4.36}$$ ∎

The following theorem is a direct consequence of Lemmas 4.5 and 4.6.

THEOREM 4.7. *There exists constant $C > 0$, independent of the number of levels J, such that*

$$\kappa(B^s) \le C,$$

where $B^s = \frac{1}{2}(B^a + (B^a)^*)$ is the operator corresponding to symmetrized AFACx (Algorithm 4), with $(B^a)^*$ denoting the adjoint of B^a with respect to the A inner product.

4.3. More general smoothers. The estimates established above apply when the smoother used on each level is a Richardson iteration. In practice, simple but more robust smoothers such as damped Jacobi or Gauss–Seidel are usually employed. Assumption A.2 now becomes important in establishing condition number estimates for AFACx with general symmetric smoothers on each level. Lemma 4.3 is restated as follows for general $R_k \neq \hat{R}_k$ that is symmetric in the L^2 inner product.

LEMMA 4.8. *Let T_k satisfy* (2.21). *Then*

$$\begin{aligned} &A\left(T_l\left(I-\frac{T_{l-1}}{2}\right)w_k,\left(I-\frac{T_{l-1}}{2}\right)w_k\right)\\ &\leq a_1\left(1+\frac{\gamma\sqrt{a_1\theta}}{2}\right)^2\left(\gamma\epsilon^{k-l}\right)^2 A(w_k,w_k),\quad l=2,3,\ldots,J,\ k<l. \end{aligned} \tag{4.37}$$

The proof is along the same lines as that for Lemma 4.3.

Also, Lemma 4.5 now reads as follows.

LEMMA 4.9. *We have*

$$A(B^a v,v)\leq C_1 A(v,v)\quad \forall v\in V_J,$$

where

$$C_1=\left(a_1\left(1+\frac{\gamma\sqrt{a_1\theta}}{2}\right)\gamma^2\frac{\epsilon}{(1-\epsilon)^2}+1+\frac{2a_1\gamma^2}{(1-\epsilon)}\right).$$

Lemma 4.6 becomes the following.

LEMMA 4.10. *We have*

$$A(B^a v,v)\geq C_0 A(v,v)\quad \forall v\in V_J,$$

where $C_0=\frac{a_0}{2\eta}(2-\theta)$.

For symmetric smoothers that are spectrally equivalent to Richardson iteration, the condition number of the symmetrized AFACx operator is therefore again bounded independently of the number of levels.

4.4. Partial refinement. For the case of partial refinement, local "restricted coarse" $V_k^{h_{k-1}}$ is a subspace of $V_k^{h_k}\cap V_{k-1}$, and local "fine" $V_k^{h_k}$ is a subspace of V_k, $k=2,3,\ldots,J$. However, spaces $V_k^{h_k}$, $k=2,3,\ldots,J$, need not be nested. To treat this more general setting, we need to define operators at the different levels, projection operators between levels, and smoothing operators. Note that, in what follows, superscripts of "f" and "r" denote linear operators mapping to local "fine" $V_k^{h_k}$ and "restricted coarse" $V_k^{h_{k-1}}$, respectively, for given level k.

DEFINITION 4. *For $k=2,\ldots,J$, define operator $A_k^f: V_k^{h_k}\longrightarrow V_k^{h_k}$ by*

$$(A_k^f w,\phi)=A(w,\phi)\quad \forall\phi\in V_k^{h_k},\ w\in V_k^{h_k}.$$

DEFINITION 5. *For $k=2,\ldots,J$, define operator $A_k^r: V_k^{h_{k-1}}\longrightarrow V_k^{h_{k-1}}$ by*

$$(A_k^r w,\phi)=A(w,\phi)\quad \forall\phi\in V_k^{h_{k-1}},\ w\in V_k^{h_{k-1}}.$$

Orthogonal "elliptic" projection operators P_k^f, $k=1,2,\ldots,J$, and P_k^r, $k=2,3,\ldots,J$, are defined as follows.

DEFINITION 6. $P_k^f : V_J \longrightarrow V_k^{h_k}$ *is defined by*

$$A(P_k^f w, \phi) = A(w, \phi) \quad \forall \phi \in V_k^{h_k},\ w \in V_J.$$

DEFINITION 7. $P_k^r : V_J \longrightarrow V_k^{h_{k-1}}$ *is defined by*

$$A(P_k^r w, \phi) = A(w, \phi) \quad \forall \phi \in V_k^{h_{k-1}},\ w \in V_J.$$

Orthogonal "L^2" projection operators Q_k^f, $k = 1, 2, \ldots, J$, and Q_k^r, $k = 2, 3, \ldots, J$, are defined as follows.

DEFINITION 8. $Q_k^f : V_J \longrightarrow V_k^{h_k}$ *is defined by*

$$(Q_k^f w, \phi) = (w, \phi) \quad \forall \phi \in V_k^{h_k},\ w \in V_J.$$

DEFINITION 9. $Q_k^r : V_J \longrightarrow V_k^{h_{k-1}}$ *is defined by*

$$(Q_k^r w, \phi) = (w, \phi) \quad \forall \phi \in V_k^{h_{k-1}},\ w \in V_J.$$

Symmetric positive-definite smoothing operators $R_k^f : V_k \longrightarrow V_k^{h_k}$ and $R_k^r : V_{k-1} \longrightarrow V_k^{h_{k-1}}$ are also assumed to be defined.

The following relationships hold between the various operators: $Q_k^f A = A_k^f P_k^f$, $Q_k^r A = A_k^r P_k^r$, $R_k^f = R_k^f Q_k^f$, and $R_k^r = R_k^r Q_k^r$, $k = 2, 3, \ldots, J$.

For the case of partial refinement, we present the proof for only the AFACx operator with Richardson iteration as the smoother. It is obvious by now that the case of more general symmetric smoothers that are spectrally equivalent to Richardson iteration is easily handled through conditions like assumption A.2. Henceforth, let $R_1^f = (A_1^f)^{-1}$, $R_k^f = \frac{1}{\lambda_k} I$, $k = 2, 3, \ldots, J$, and $R_k^r = \frac{1}{\lambda_{k-1}} I$, $k = 2, 3, \ldots, J$. Define $T_k^f = R_k^f A_k^f P_k^f$ and $T_k^r = R_k^r A_k^r P_k^r$.

The following lemma is needed for the case of partial refinement.

LEMMA 4.11. *We have*

$$A(T_k^r v, v) \le A(T_{k-1}^f v, v) \quad \forall v \in V_J,\ k = 2, 3, \ldots, J. \tag{4.38}$$

Proof. From the basic properties of the L^2 projection operators listed in section 2.7, we have

$$\begin{aligned}
\|(Q_{k-1}^f - Q_k^r)u\|^2 &= ((Q_{k-1}^f - Q_k^r)u,\ (Q_{k-1}^f - Q_k^r)u) \\
&= \|Q_{k-1}^f u\|^2 + \|Q_k^r u\|^2 - 2(Q_{k-1}^f u, Q_k^r u) \\
&= \|Q_{k-1}^f u\|^2 + \|Q_k^r u\|^2 - 2(Q_{k-1}^f u, (Q_k^r)^2 u) \\
&= \|Q_{k-1}^f u\|^2 + \|Q_k^r u\|^2 - 2(Q_k^r Q_{k-1}^f u, Q_k^r u) \\
&= \|Q_{k-1}^f u\|^2 + \|Q_k^r u\|^2 - 2(Q_k^r u, Q_k^r u) \\
&= \|Q_{k-1}^f u\|^2 - \|Q_k^r u\|^2 \qquad \forall u \in V_J,\ k = 2, 3, \ldots, J. \qquad (4.39)
\end{aligned}$$

Since $\|(Q_{k-1}^f - Q_k^r)u\|^2 \ge 0$, (4.39) implies that

$$\|Q_k^r u\|^2 \le \|Q_{k-1}^f u\|^2 \quad \forall u \in V_J,\ k = 2, 3, \ldots, J. \tag{4.40}$$

Let $u = Av$. Then

$$\begin{aligned}
&\|Q_k^r Av\|^2 \le \|Q_{k-1}^f Av\|^2 \\
\Rightarrow\ &\|A_k^r P_k^r v\|^2 \le \|A_{k-1}^f P_{k-1}^f v\|^2 \\
\Rightarrow\ &\frac{1}{\lambda_{k-1}}(A_k^r P_k^r v, A_k^r P_k^r v) \le \frac{1}{\lambda_{k-1}}(A_{k-1}^f P_{k-1}^f v, A_{k-1}^f P_{k-1}^f v) \\
\Rightarrow\ &(R_k^r A_k^r P_k^r v, A_k^r P_k^r v) \le (R_{k-1}^f A_{k-1}^f P_{k-1}^f v, A_{k-1}^f P_{k-1}^f v) \\
\Rightarrow\ &A(T_k^r v, v) \le A(T_{k-1}^f v, v). \qquad \square
\end{aligned}$$

Assumptions similar to A.1 and A.3 in the previous section are made for the case of partial refinement. We refer to [14] for proof that the assumptions made below are valid in the case of partial refinement.

A.5. There exist constants $\epsilon \in (0,1)$ and $\gamma > 0$ such that

$$A(T_k^f w, w) \le (\gamma \epsilon^{k-l})^2 A(w,w) \quad \forall w \in V_l^{h_l},\ l \le k, \quad k = 1, 2, \ldots, J. \tag{4.41}$$

Then, from Lemma 4.11 and assumption A.5, we have

$$A(T_k^r w, w) \le (\gamma \epsilon^{k-l-1})^2 A(w,w) \quad \forall w \in V_l^{h_l},\ l \le k-1, \quad k = 2, \ldots, J. \tag{4.42}$$

A.6. There exists constant $\theta \in (0,2)$ such that

$$A(T_k^f v, T_k^f v) \le \theta A(T_k^f v, v) \quad \forall v \in V_J \tag{4.43}$$

and

$$A(T_k^r v, T_k^r v) \le \theta A(T_k^r v, v) \quad \forall v \in V_J, \quad k = 1, 2, \ldots, J. \tag{4.44}$$

In addition to the assumptions on the smoothers, a weak regularity assumption analogous to A.4 is also needed.

A.7. There exists a constant $\eta > 0$ such that

$$A(v,v) \le \eta \sum_{k=1}^{J} A(T_k^f v, v) \quad \forall v \in V_J. \tag{4.45}$$

Finally, we make the following assumption.

A.8. $\text{Range}(P_k - P_{k-1}) \subseteq V_k^{h_k}, \quad k = 1, 2, \ldots, J.$

AFACx operator B^a for the case of partial refinement can be written as

$$\begin{aligned}
B^a &= \sum_{k=1}^{J} R_k^f A_k^f P_k^f \left(I - \frac{1}{2} R_k^r A_k^r P_k^r \right) \\
&= \sum_{k=1}^{J} T_k^f \left(I - \frac{T_k^r}{2} \right).
\end{aligned} \tag{4.46}$$

The proofs of the following lemmas are virtually the same as the proofs for Lemmas 4.5 and 4.6, respectively. Assumptions A.5–A.8 and Lemma 4.11 take the place of assumptions A.1, A.3, and A.4.

LEMMA 4.12. *Under assumptions* A.5, A.6, *and* A.8, *there exists a constant* $C_1 > 0$, *independent of the number of levels* J, *such that*

$$A(B^a v, v) \le C_1 A(v,v) \ \ \forall v \in V_J. \tag{4.47}$$

LEMMA 4.13. *Under assumptions* A.5–A.8, *there exists a constant* $C_0 > 0$, *independent of the number of levels* J, *such that*

$$A(B^a v, v) \geq C_0 A(v, v) \quad \forall v \in V_J. \tag{4.48}$$

The following theorem follows immediately from Lemmas 4.12 and 4.13.

THEOREM 4.14. *There exists constant* $C > 0$, *independent of the number of levels* J, *such that*

$$\kappa(B^s) \leq C,$$

where $B^s = \frac{1}{2}(B^a + (B^a)^*)$ *is the operator corresponding to symmetrized AFACx (Algorithm* 4*).*

5. Conclusions. In this paper, we have presented a new multilevel condition number estimate for the AFACx algorithm. This estimate shows that the condition number of the AFACx operator does not degrade as the number of refinement levels in the AMR hierarchy increases. Numerical results supporting these theoretical estimates are presented in a forthcoming paper.

THE HIGH ACCURATE BLOCK-GRID METHOD FOR SOLVING LAPLACE'S BOUNDARY VALUE PROBLEM WITH SINGULARITIES*

A. A. DOSIYEV†

Abstract. A high accurate difference-analytical method is introduced for the solution of the mixed boundary value problem for Laplace's equation on graduated polygons. The polygon can have broken sections and be multiply connected. The uniform estimate of the error of the approximate solution is of order $O(h^6)$, whereas it is of order $O(h^6/r_j^{p-\lambda_j})$ for the errors of p-order derivatives $(p = 1, 2, \dots)$ in a finite neighborhood of reentry vertices; here, h is the mesh step, r_j is the distance from the current point to the vertex in question, $\lambda_j = 1/(a\alpha_j)$, and $a = 1$ or 2 depending on the types of boundary conditions. Further, $\alpha_j\pi$ is the value of the interior angle at the considered vertex. Numerical experiments are illustrated in section 8 to support the analysis made.

Key words. singularity, artificial boundary, block-grid method, matching operator

1. Introduction. As is well known, the use of the classical finite difference method (FDM) or the finite element method (FEM) for the solution of elliptic boundary value problems with singularities proves ineffective. A special construction is usually needed for the numerical scheme near the singularities. Various forms of these methods are often used for both the FDM and the FEM. To start with, (a) the use of a mesh refinement method dealing with the singular points (Volkov [23], [24] and Dosiyev [9] for the FDM; Thatcher [20] for the FEM) and (b) the use of singular terms of the series expansion of the exact solution around the singular points (Motz [16], Fox and Sankar [11], Volkov [25], and Fryazinov [12] in the FDM; Fix [10], Wait and Mitchell [30], Barnhill and Whiteman [5], Blum and Dobrowolski [6], and Olson, Georgiou, and Schultz [17] in the FEM) are two such forms. In the mesh refinement approach, the number of nodes, and consequently the number of unknowns, increase up to $O(h^{-2}\ln h^{-1})$ [9], [23], [24]. The use of the singular term approach, on the other hand, results in a system of ill-conditioned algebraic equations. This is because singular terms with a nonlocal carrier are added to the basic piecewise-polynomial functions with a local carrier, resulting in basic total functions that are "almost" linearly dependent for small h. Other forms also exist: (c) the use of a modified difference approximation in a fixed neighborhood of corners (Babuska and Rosenzweig [3], Andreev [1], [2], and Zenger and Gietl [34]) results in error bounds for a fixed point in the interior of the domain that are of the same order as in the case of smooth solutions but not uniform; and (d) a number of useful combinations of different methods can be used to take into account the differential properties of the solution in different parts of the domain and achieve an effective realization of the resulting system of algebraic equations (see Li [14]).

To elaborate the methods further, Li, Mathon, and Sermer [13] (see also [14]) use piecewise expansions into particular solutions to approximate the boundary conditions

in a least-square sense. In this boundary method, to get high accurate results a large number of particular solutions are needed: in application to the Motz problem, 34 solutions are needed to result in an absolute error in the maximum norm of order $5.47E-9$. This large number of particular solutions may cause serious difficulties due to the ill conditioning of the associated least-squares matrices. Here, the condition number is $3.97E+07$, but it can be decreased to 3617 by dividing the given domain in the Motz problem into three subdomains. Different numbers of particular solutions are then used for each subdomain. However, even when the best combination of these numbers is used, the accuracy is of order $E-06$ only.

The method of auxiliary mapping (MAM) is introduced by Babuska and Oh [4] in the context of the p-version of the FEM to deal with corner singularities. Several extensions of the MAM that include boundary singularities and application to the h-p version of the FEM are given by Lucas and Oh [15]. The best result due to [15] in application to the Motz problem gives an absolute error in the maximum norm as $2.22E-08$ with an optimal mesh refinement when $p=10$. In [15], the results achieved are compared with the extremely accurate results of [13].

A sequence of approximation to the exact boundary conditions at an artificial boundary is given by Wu and Han [33]; exact boundary conditions are obtained around each singular point as a series. The original problem is then reduced to a boundary value problem in a domain away from the singularities; the FEM is applied to the resulting problem. When this method is applied to the Motz problem (see [33]), it is observed that only a few coefficients in the series expansion of the exact solution around the singular points can be approximated. Further, these approximations are not accurate, and increasing the number of terms in the approximation of the exact boundary conditions at an artificial boundary yields no improvement.

Finally, we mention the block method (BM) given by Volkov [26] for solving boundary value problems for Laplace's equation as one that is not a difference method. In the BM, the analytic properties of harmonic functions are most successfully used to construct an approximate solution. The approximate solution is an approximation of the integral representation of the harmonic function in a fixed number of blocks (sectors, semicircles, and circles) covering the given domain. With boundary conditions given by algebraic polynomials or analytic functions, the problem of convergence of the approximate solution and its derivatives of any order is investigated. This method was developed for different problems (see Volkov [29] and references therein). The rates of convergence of the approximate solution and its derivatives of the BM are higher (they converge exponentially with respect to the number of quadrature nodes) than the results obtained in above-mentioned approaches, but the application of the BM becomes restricted when the boundary function on some sides of polygon is given as a nonanalytic function (see Volkov [28]).

In light of the above-reviewed methods, a new difference-analytical method, called the block-grid method (BGM), for the solution of the mixed boundary value problems for Laplace's equation on graduated polygons is introduced. Thus, the proposed method is a combination of two methods which takes only superiorities of each one of them: the BM, which finely takes into account the behavior of the exact solution near the vertices of interior angles $\neq \pi/2$ of the polygon (on the "singular" part), and the FDM, which has a simple structure and high accuracy on square grids of the rectangles covering the remainder, "nonsingular"part of the polygon. A gluing operator of sixth order of accuracy is constructed for gluing together the grids and blocks. Furthermore, the restriction on the boundary functions to be algebraic polynomials is required only

on the sides of interior angles $\neq \pi/2$. The system of finite difference equations on the union of all rectangles may be solved by the alternating method of Schwarz with the number of iterations $O(\ln \varepsilon^{-1})$, where ε is the prescribed accuracy, by solving standard 9-point difference equations of Laplace on the rectangular domain at each iteration. The approximate solution on blocks is defined as a harmonic function, and any order of derivatives can be found by simple differentiation. The uniform estimate of the error of the approximate solution is of order $O(h^6)$, whereas it is of order $O(h^6/r_j^{p-\lambda_j})$ for the errors of p-order derivatives ($p = 1, 2, \dots$) in the "singular" part of the polygon; here r_j is the distance from the current point to the vertex of the block in question, and λ_j depends on the magnitude of the angle at the vertex and the type of boundary conditions on the sides of the considered block. Furthermore, when the boundary conditions are either Dirichlet or mixed type on the sides of interior angles $\neq \pi/2$, then the error of approximate solution on the block sectors decreases as $r_j^{\lambda_j} h^6$, which gives the additional accuracy of this approach near the singular points, with respect to existing FDM or FEM modifications for the singular problems. Finally, we illustrate the effectiveness of the method in solving the problem in L-shaped polygons with the corner and boundary singularities and the well-known Motz problem.

The BGM in the case of the Dirichlet problem on graduated polygons was given in [7], [8].

2. Boundary value problem on polygons. Let G be an open simply connected polygon with sides parallel to the x and y axes, let γ_j, $j = 1, 2, \dots, N$, be its sides, including the ends, enumerated counterclockwise, and let $\alpha_j \pi$, $0 < \alpha_j \leq 2$, be the interior angle formed by its sides γ_{j-1} and γ_j ($\gamma_0 = \gamma_N$). Denote by A_j the vertex of the jth angle, by s the arclength, measured along the boundary of G in the positive direction, and by s_j the value of s at A_j. Let r_j, θ_j be a polar system of coordinates with pole in A_j, where the angle θ_j is taken couterclockwise from the side γ_j, and ν_j is a parameter taking the values 0 or 1; further, $\overline{\nu}_j = 1 - \nu_j$.

We consider the boundary value problem

$$\Delta u = 0 \quad \text{on } G, \tag{2.1}$$

$$\nu_j u + \overline{\nu}_j u_n^{(1)} = \nu_j \varphi_j + \overline{\nu}_j \psi_j \quad \text{on } \gamma_j, \quad j = 1, 2, \dots, N, \tag{2.2}$$

where $\Delta \equiv \partial^2/\partial x^2 + \partial^2/\partial y^2$, $u_n^{(1)}$ is the derivative along the inner normal, φ_j and ψ_j are given functions, and

$$1 \leq \nu_1 + \nu_2 + \cdots + \nu_n \leq N, \tag{2.3}$$

$$\nu_j \varphi_j + \overline{\nu}_j \psi_j \in C_{6,\lambda}(\gamma_j), \quad 0 < \lambda < 1, \quad 1 \leq j \leq N. \tag{2.4}$$

Furthermore, at the vertices A_j for $\alpha_j = 1/2$ the conjugation conditions

$$\nu_j \varphi_j^{(2q+\delta_{\tau-2})} + \overline{\nu}_j \psi_j^{(2q+\delta_\tau)} = (-1)^{q+\delta_\tau+\delta_{\tau-1}} \left(\nu_{j-1} \varphi_{j-1}^{(2q+\delta_{\tau-1})} + \overline{\nu}_{j-1} \psi_{j-1}^{(2q+\delta_\tau)} \right) \tag{2.5}$$

(except maybe for $q = 3$, when $\tau = 3$) are satisfied; $\tau = \nu_{j-1} + 2\nu_j$, $q = 0, 1, \dots, \overline{Q}$, $\overline{Q} = [(6 - \delta_{\tau-1} - \delta_{\tau-2})/2] - \delta_\tau$, and $\delta_w = 1$ when $w = 0$; $\delta_w = 0$ when $w \neq 0$. At the vertices A_j with $\alpha_j \neq 1/2$ no compatibility conditions are required to hold for the boundary conditions; in particular, the values of φ_{j-1} and φ_j at A_j might be different. In addition, we require that when $\alpha_j \neq 1/2$ the boundary functions on γ_{j-1} and γ_j be given as algebraic polynomials of arclength s measured along γ.

We represent the given boundary functions (algebraic polynomials) on γ_{j-1} and γ_j for $\alpha_j \neq 1/2$ in the form

$$\sum_{k=0}^{\tau_{j-1}} a_{jk}^0 r_j^k \quad \text{and} \quad \sum_{k=0}^{\tau_j} b_{jk}^0 r_j^k, \tag{2.6}$$

respectively; here a_{jk}^0 and b_{jk}^0 are numerical coefficients, and τ_{j-1} and τ_j are degrees of those polynomials.

Let $E = \{j : \alpha_j \neq 1/2, j = 1, 2, \dots, N\}$. In the neighborhood of A_j, $j \in E$, we construct two fixed block-sectors $T_j^i = T_j(r_{ji}) \subset G$, $i = 1, 2$, where $0 < r_{j2} < r_{j1} < \min\{s_{j+1} - s_j, s_j - s_{j-1}\}$, $T_j(r) = \{(r_j, \theta_j) : \ 0 < r_j < r, \ 0 < \theta_j < \alpha_j \pi\}$.

On the closed sector $\overline{T}_j^1$, $j \in E$, we consider a function $Q_j(r_j, \theta_j)$ with the following properties:

(i) $Q_j(r_j, \theta_j)$ is harmonic and bounded on the open sector T_j^1;

(ii) continuous on $\overline{T}_j^1$ everywhere, except for the point A_j (the vertex of the sector) for $\nu_j = \nu_{j-1} = 1$ and $a_{j0}^0 \neq b_{j0}^0$, where a_{j0}^0 and b_{j0}^0 are given numbers from (2.6), i.e., for boundary conditions discontinuous at A_j;

(iii) continuously differentiable on $\overline{T}_j^1 \setminus A_j$ and satisfies the boundary conditions (2.2) on $\gamma_{j-1} \cap \overline{T}_j^1$ and $\gamma_j \cap \overline{T}_j^1$, $j \in E$.

For definiteness we assume that $Q_j(r_j, \theta_j)$, with the above properties, has the form (3.2)–(3.9) in [29].

Remark 2.1. For the case of $\nu_{j-1} = \nu_j = 1$, we formally set the value of $Q_j(r_j, \theta_j)$ and the solution u of problem (2.1), (2.2) at the vertex A_j equal to $(a_{j0}^0 + b_{j0}^0)/2$.

We set (see Volkov [26])

$$R(m, m, r, \theta, \eta) = R(r, \theta, \eta) + (-1)^m R(r, \theta, -\eta), \tag{2.7}$$

$$R(1 - m, m, r, \theta, \eta) = R(m, m, r, \theta, \eta) - (-1)^m R(m, m, r, \theta, \pi - \eta), \tag{2.8}$$

where

$$R(r, \theta, \eta) = \frac{1 - r^2}{2\pi(1 - 2r\cos(\theta - \eta) + r^2)} \tag{2.9}$$

is the kernel of the Poisson integral for a unit circle. We specify the kernel

$$R_j(r_j, \theta_j, \eta) = \lambda_j R\left(\nu_{j-1}, \nu_j, \left(\frac{r_j}{r_{j2}}\right)^{\lambda_j}, \lambda_j \theta_j, \lambda_j \eta\right), \quad j \in E, \tag{2.10}$$

where

$$\lambda_j = \frac{1}{(2 - \nu_{j-1}\nu_j - \overline{\nu}_{j-1}\overline{\nu}_j)\alpha_j}. \tag{2.11}$$

The following lemma shows important properties of the solution, which will be used to construct the proposed method.

LEMMA 2.2. *The solution u of the boundary value problem* (2.1), (2.2) *can be represented on $\overline{T}_j^2 \setminus V_j$, $j \in E$ in the form*

$$u(r_j, \theta_j) = Q_j(r_j, \theta_j) + \int_0^{\alpha_j \pi} (u(r_{j2}, \eta) - Q_j(r_{j2}, \eta)) R_j(r_j, \theta_j, \eta) d\eta, \tag{2.12}$$

and the harmonic function $u_n(r_j,\theta_j)$, which is obtained as a result of approximation of the integral in (2.12) *by the composite rectangular formula with n equally spaced nodes, satisfies the inequality*

$$| u - u_n | \le c_j \exp(-d_j n) \quad \text{on } \overline{T}_j^3, \quad 0 < r_{j3} < r_{j2}, \tag{2.13}$$

where V_j is the curvilinear part of the boundary of the sector T_j^2, and c_j and d_j are positive constants independent on n.

The proof of Lemma 2.2 follows from Theorems 3.1 and 5.1 in [29].

Remark 2.3. The constants c_j and d_j in Lemma 2.2 depend on the radius r_{j3} of T_j^3, and the sequence $u_n(r_j,\theta_j)$, $n = 1,2,\dots$, is unbounded in the open sector T_j^2 and hence diverges in T_j^2 in the uniform metric. Therefore, the exponential convergence of $u_n(r_j,\theta_j)$, $n = 1,2,\dots$, is guaranteed only in the sector $\overline{T}_j^3$ with the radius $r_{j3} < r_{j2}$.

3. 9-point solution on rectangles. Let $\Pi = \{(x,y) : 0 < x < a, 0 < y < b\}$ be a rectangle, a/b be rational, γ_j $(j = 1,2,3,4)$ be the sides, including the ends, enumerated counterclockwise starting from the left side ($\gamma_0 \equiv \gamma_4$, $\gamma_5 \equiv \gamma_1$), and let $\gamma = \cup_{j=1}^4 \gamma_j$ be the boundary of Π, let ν_j be a parameter taking the values 0 or 1, and let $\overline{\nu}_j = 1 - \nu_j$.

We consider the boundary value problem (2.1)–(2.5) on $G \equiv \Pi$:

$$\Delta u = 0 \quad \text{on } \Pi, \tag{3.1}$$

$$\nu_j u + \overline{\nu}_j u_n^{(1)} = \nu_j \varphi_j + \overline{\nu}_j \psi_j \quad \text{on } \gamma_j, \quad j = 1,2,3,4. \tag{3.2}$$

Let $h > 0$, with $a/h \ge 2$, $b/h \ge 2$, be integers. We assign Π^h, a square net on Π, with step h, obtained with the lines x, $y = 0, h, 2h, \dots$. Let γ_j^h be a set of nodes on the interior of γ_j, and let

$$\dot{\gamma}_j^h = \gamma_j \cap \gamma_{j+1}, \quad \gamma^h = \bigcup (\gamma_j^h \cup \dot{\gamma}_j^h), \quad \overline{\Pi}^h = \Pi^h \cup \gamma^h.$$

We consider the system of finite difference equations (see [22])

$$u_h = B u_h \quad \text{on } \Pi^h, \tag{3.3}$$

$$u_h = \overline{\nu}_j B_j u_h + E_{jh}(\varphi_j, \psi_j) \quad \text{on } \gamma_j^h, \tag{3.4}$$

$$u_h = \overline{\nu}_j \overline{\nu}_{j+1} \dot{B}_j u_h + \dot{E}_{j,h}(\varphi_j, \varphi_{j+1,}, \psi_j, \psi_{j+1}) \text{ on } \dot{\gamma}_j^h, \quad j = 1,2,3,4, \tag{3.5}$$

where

$$\begin{aligned} Bu(x,y) \equiv {} & (u(x+h,y) + u(x,y+h) + u(x-h,y) \\ & + u(x,y-h))/5 + (u(x+h,y+h) + u(x-h,y+h) \\ & + u(x-h,y-h) + u(x+h,y-h))/20, \end{aligned} \tag{3.6}$$

the operators B_j, E_{jh}, $\dot{B}_j$, $\dot{E}_{jh}$ in the right coordinate system with the axis x_j, directed along γ_{j+1} and the axis y_j, directed along γ_j have the expressions

$$\begin{aligned} B_j u(0,y_j) \equiv {} & (2u(h,y_j) + u(0,y_j+h) + u(0,y_j-h))/5 \\ & + (u(h,y_j+h) + u(h,y_j-h))/10, \end{aligned} \tag{3.7}$$

$$E_{jh}(\varphi_j,\psi_j) \equiv \nu_j \varphi_j - \overline{\nu}_j \left(\frac{3h}{5} \psi_j - \frac{2h^5}{5!5} \psi_j^{(4)} - \frac{2h^7}{7!} \psi_j^{(6)} \right), \tag{3.8}$$

$$\dot{B}_j u(0,0) \equiv (2u(h,0) + 2u(0,h) + u(h,h))/5, \tag{3.9}$$

$$\begin{aligned}\dot{E}_{j,h}(\varphi_j, \varphi_{j+1}, \psi_j, \psi_{j+1}) \equiv \nu_j\varphi_j + \overline{\nu}_j\nu_{j+1}\varphi_{j+1} - \overline{\nu}_j\overline{\nu}_{j+1}\left(\frac{3h}{5}(\psi_j + \psi_{j+1})\right.\\ + \frac{h^2}{5}\psi_{j+1}^{(1)} - \frac{2h^5}{5!5}\left(\psi_j^{(4)} + \psi_{j+1}^{(4)}\right)\\ \left. + \frac{4h^6}{6!5}\left(\psi_j^{(5)} + \psi_{j+1}^{(5)}\right) - \frac{2h^7}{7!}\left(\psi_j^{(6)} + \psi_{j+1}^{(6)}\right)\right).\end{aligned} \tag{3.10}$$

The system of finite difference equations (3.3)–(3.5) which has nonnegative coefficients with the conditions (2.3) is uniquely solvable.

THEOREM 3.1. *Let u be the solution of problem* (3.1), (3.2). *Then*

$$\max_{\overline{\Pi}^h} \mid u_h - u \mid \leq ch^6, \tag{3.11}$$

where u_h is the solution of the system (3.3)–(3.5), *and c is a constant independent of h.*

Proof. Theorem 3.1 is proved in the same way as Theorem 1.1 of [24] except that instead of the function (1.14) of [24] we need to take the function

$$u_j(x,y) = (-1)^j\nu_j\nu_{j+1}\frac{2\left(\widetilde{\varphi}_j^{(6)}(s_{j+1}) + \widetilde{\varphi}_{j+1}^{(6)}(s_{j+1})\right)}{\pi 6!}\operatorname{Im}\{(z-z_j)^6\ln(z-z_j)\}$$

(making the corresponding changes), where $\widetilde{\varphi}_l = \nu_l\varphi_l$, $z = x + iy$, and $z_j = x_j + iy_j$ is the complex coordinate of the vertex $\gamma_j \cap \gamma_{j+1}$. □

4. Description of the block-grid method. Let us consider in addition to the sectors T_j^1, T_j^2, and T_j^3 (see section 2) in the neighborhood of each vertex A_j, $j \in E$, of the polygon G, a sector T_j^4, where $0 < r_{j4} < r_{j3} < r_{j2}$, and let $G^T = G \setminus (\cup_{j\in E}\overline{T}_j^4)$.

The construction of the proposed method can be divided into the following steps.

Step 1. We blockade all singular corners $A_j, j \in E$, by the double sectors $T_j^i = T_j(r_{ji})$, $i = 2,3$, with $r_{j3} < r_{j2}$, $T_k^2 \cap T_l^3 = \emptyset$, $k \neq l$, $k,l \in E$, and cover the given polygon by overlapping rectangles Π_k, $k = 1,2,\ldots,M$, and sectors $T_j^3, j \in E$, such that the distance from $\overline{\Pi}_k$ to the singular point A_j is not less than r_{j4} for all $k = 1,2,\ldots,M$ and $j \in E$ (see Figure 1, in the case when $M = 4$ and $E = \{1\}$; i.e., the singular point is only A_1).

Step 2. On each rectangle Π_k, we use the 9-point scheme for the approximation of Laplace's equation on square grids with the step size $h_k \leq h$, h being the parameter, and as an approximate solution on $\overline{T}_j^3, j \in E$ (in singular parts), we take the harmonic function $u_n(r_j, \theta_j)$, defined in Lemma 2.2 (see also Remark 2.3).

Step 3. We construct the sixth order matching operator to connect the subsystems.

Step 4. We use Schwarz's alternating procedure by solving standard difference equations of Laplace on the rectangular domain at each iteration.

Now we describe the procedure of obtaining the algebraic system of equations for the numerical solution of problem (2.1), (2.2).

Let $\Pi_k \subset G_T$, $k = 1,2,\ldots,M$ $(M < \infty)$ be certain fixed open rectangles with sides a_{1k} and a_{2k} parallel to the x and y axes, with a_{1k}/a_{2k} rational and

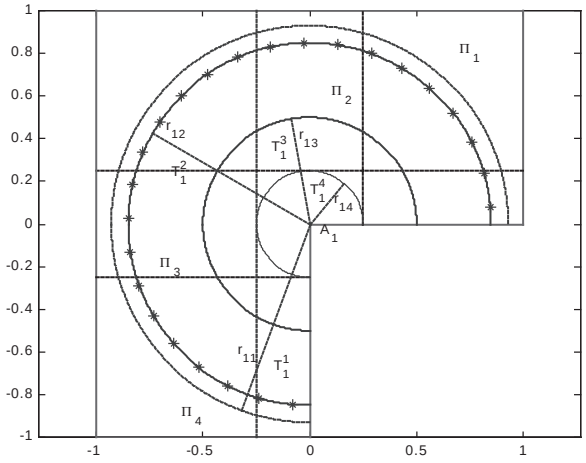

FIG. 1.

$G \subset (\cup_{k=1}^{M} \Pi_k) \cup (\cup_{j \in E} T_j^3) \subset G$. We denote by η_k the boundary of the rectangle Π_k and by V_j the curvilinear part of the boundary of the sector T_j^2, and let $t_j = (\cup_{k=1}^{M} \eta_k) \cap \overline{T}_j^3$. The following general requirement is imposed on the arrangement of the rectangles Π_k, $k = 1, 2, \ldots, M$: any point P lying on $\eta_k \cap G_T$, $1 \le k \le M$, or located on $V_j \cap G$, $j \in E$, falls inside at least one of the rectangles $\Pi_{k(p)}$, $1 \le k(p) \le M$, depending on P, the distance from P to $G_T \cap \eta_{k(p)}$ being not less than some constant κ_0 independent of P.

We will call the quantity κ_0 the *depth* of a gluing of the rectangles Π_k, $k = 1, 2, \ldots, M$. We introduce a parameter $h \in (0, \kappa_0/4]$ and define a square grid on Π_k, $1 \le k \le M$, with maximal possible step $h_k \le \min\{h, \min\{a_{1k}, a_{2k}\}/6\}$ such that the boundary η_k lies entirely on the grid lines. Let Π_k^h be the set of grid nodes on Π_k, let η_k^h be the set of nodes on η_k, and let $\overline{\Pi}_k^h = \Pi_k^h \cup \eta_k^h$. We denote the set of nodes in the closure of $\eta_k \cap G^T$ by η_{k0}^h, the set of nodes on t_j by t_j^h, and the set of remaining nodes on η_k by η_{k1}^h. We also specify a natural number $n \ge [\ln^{1+\varkappa} h^{-1}] + 1$, where $\varkappa > 0$ is a fixed number, and the quantities $n(j) = \max\{4, [\alpha_j n]\}$, $\beta_j = \alpha_j \pi / n(j)$, and $\theta_j^m = (m - 1/2)\beta_j$, $j \in E$, $1 \le m \le n(j)$. On the arc V_j, we choose the points (r_{j2}, θ_j^m), $1 \le m \le n(j)$, and denote the set of these points by V_j^n. Let

$$\omega^{h,n} = \left(\bigcup_{k=1}^{M} \eta_{k0}^h \right) \cup \left(\bigcup_{j \in E} V_j^n \right), \quad \overline{G}_*^{h,n} = \omega^{h,n} \cup \left(\bigcup_{k=1}^{M} \overline{\Pi}_k^h \right).$$

Let φ_j and ψ_j be given functions from the boundary conditions (2.2), and let $\varphi = \{\varphi_j\}_{j=1}^N$ and $\psi = \{\psi_j\}_{j=1}^N$. On the set $\omega^{h,n}$ we introduce the linear matching operator S^6. The value of $S^6(u_h, \varphi, \psi)$ at the point $P \in \omega^{h,n}$ is defined linearly in terms of the values of the function u_h at the nodes of the grid constructed on the rectangle $\Pi_{k(p)} \ni P$ and the assigned boundary values of $\varphi^{(m)}$, $m = 0, 1, \ldots, 5$ (or $\psi^{(q)}$, $q = 0, 1, \ldots, 4$) at a fixed number of points. If there is more than one rectangle containing P, we choose $\Pi_{k(p)}$ such that part of the boundary $\eta_{k(p),0}$ is the maximum distance away from P. The pattern of the operator S^6 lies in a neighborhood $O(h)$ of the point P, and in a uniform metric for $\varphi \equiv 0$ and $\psi \equiv 0$ its norm is not greater than one.

Moreover, $u - S^6(u,\varphi,\psi) = O(h^6)$ uniformly on $\omega^{h,n}$. An operator S^6 with these properties will be constructed in section 5 by developing the method given in [8] for the Dirichlet problem.

Let

$$R_j^{(q)}(r_j,\theta_j) = \frac{R_j(r_j,\theta_j,\theta_j^q)}{\max\left\{1, \beta_j \sum_{p=1}^{n(j)} R_j(r_j,\theta_j,\theta_j^p)\right\}}, \tag{4.1}$$

where $R_j(r,\theta,\eta)$ is the kernel defined by (2.10). It is easy to check that

$$0 \le R_j^{(q)}(r_j,\theta_j) \le R_j(r_j,\theta_j,\theta_j^q), \tag{4.2}$$

where $j \in E$, $0 \le q \le n(j)$. Furthermore, from the estimation (2.29) in [26] follows the existence of the positive constants n_0 and σ such that, for $n \ge n_0$,

$$\max_{(r_j,\theta_j)\in\overline{T}_j^3} \beta_j \sum_{q=1}^{n(j)} R_j(r_j,\theta_j,\theta_j^q) \le \sigma < 1 \tag{4.3}$$

when $\nu_{j-1} + \nu_j \ge 1$, and on the basis of (4.1) and (4.2)

$$0 \le \beta_j \sum_{q=1}^{n(j)} R_j^{(q)}(r_j,\theta_j) \le 1, \ j \in E \tag{4.4}$$

when $\nu_{j-1} = \nu_j = 0$.

Consider the system of linear algebraic equations

$$u_h = Bu_h \ \text{ on } \Pi_k^h, \quad u_h = \bar\nu_m B_m u_h + E_{mh}(\varphi,\psi) \ \text{ on } \eta_{k1}^h \cap \gamma_m, \tag{4.5}$$

$$u_h = \bar\nu_m \bar\nu_{m+1} \dot B_m u_h + \dot E_{mh}(\varphi_m,\varphi_{m+1},\psi_m,\psi_{m+1}) \quad \text{on } \eta_{k1}^h \cap \gamma_m \cap \gamma_{m+1}, \tag{4.6}$$

$$u_h(r_j,\theta_j) = Q_j(r_j,\theta_j) + \beta_j \sum_{q=1}^{n(j)} R_j^{(q)}(r_j,\theta_j)(u_h(r_{j2},\theta_j^q) - Q_j(r_{j2},\theta_j^q)), (r_j,\theta_j) \in t_j^h, \tag{4.7}$$

$$u_h = S^6(u_h,\varphi,\psi) \ \text{ on } \omega^{h,n}, \tag{4.8}$$

where $1 \le m \le N$, $1 \le k \le M$, $j \in E$; B, B_m, $\dot B_m$, E_{mh}, and $\dot E_{mh}$ are defined by the formulas (3.6)–(3.10), respectively; $Q_j(r_j,\theta_j)$ is the harmonic polynomial described in section 2.

Definition 4.1. *The solution of the system* (4.5)–(4.8) *is called a numerical solution of the problem* (2.1), (2.2) *on* $\overline{G}_*^{h,n}$.

Definition 4.2. *Let* u_h *be the solution of the system* (4.5)–(4.8). *The function*

$$U_h(r_j,\theta_j) = Q_j(r_j,\theta_j) + \beta_j \sum_{q=1}^{n(j)} R_j(r_j,\theta_j,\theta_j^q)(u_h(r_{j2},\theta_j^q) - Q_j(r_{j2},\theta_j^q)) \tag{4.9}$$

is called an approximate solution of the problem (2.1), (2.2) *on the closed block* $\overline{T}_j^3$, $j \in E$.

Definition 4.3. *The system* (4.5)–(4.9) *is called the block-grid equations.*

5. Construction of the sixth order matching operator. Let $\Omega = \{(x, y) : x^2 + y^2 < 1\}$ be a unit circle and $u \in C_{6,0}(\overline{\Omega})$ be a harmonic function on Ω. On the basis of Taylor's formula for any point $(x, y) \in \Omega$, we have

$$u(x,y) = \sum_{k=0}^{5} a_k \operatorname{Re}\ z^k + \sum_{k=1}^{5} b_k \operatorname{Im}\ z^k + O(r^6), \tag{5.1}$$

where $r = \sqrt{x^2 + y^2}$,

$$\begin{aligned} &a_0 = u(0,0), \quad a_1 = \frac{\partial u(0,0)}{\partial x}, \quad a_2 = \frac{1}{2}\frac{\partial^2 u(0,0)}{\partial x^2}, \quad a_3 = \frac{1}{3!}\frac{\partial^3 u(0,0)}{\partial x^3}, \\ &a_4 = \frac{1}{4!}\frac{\partial^4 u(0,0)}{\partial x^4}, \quad a_5 = \frac{1}{5!}\frac{\partial^5 u(0,0)}{\partial x^5}; \end{aligned} \tag{5.2}$$

$$\begin{aligned} &b_1 = \frac{\partial u(0,0)}{\partial y}, \quad b_2 = \frac{1}{2}\frac{\partial^2 u(0,0)}{\partial x \partial y}, \quad b_3 = \frac{1}{3!}\frac{\partial^3 u(0,0)}{\partial x^2 \partial y}, \\ &b_4 = \frac{1}{4!}\frac{\partial^4 u(0,0)}{\partial x^3 \partial y}, \quad b_5 = \frac{1}{5!}\frac{\partial^5 u(0,0)}{\partial y^5}. \end{aligned} \tag{5.3}$$

We denote

$$F_5(x,y) = \sum_{k=0}^{5} a_k \operatorname{Re} z^k + \sum_{k=1}^{5} b_k \operatorname{Im} z^k. \tag{5.4}$$

We construct the operator S^6 from the condition that the expression $S^6(F_5, \varphi, \psi)$ gives the exact value of any harmonic polynomial $F_5(x, y)$ defined by the formula (5.4) at each point $P \in \omega^{h,n}$. For simplicity, we will denote the step size of the square grid in the rectangle containing the point $P \in \omega^{h,n}$ by h.

Case 1. The point $P \in \omega^{h,n}$ lies on a grid line. We place the origin of the rectangular system of coordinates at the node P_0 and direct the positive axis of x along the grid line so that $P = P(\delta h, 0)$, $1 \le \delta \le 3/2$. We take points $P_1(2h, 0)$, $P_2(3h, 0)$, $P_3(2h, h)$, $P_4(h, h)$, $P_5(0, h)$. First, we find numerical coefficients λ', λ'_k, $k = 1, \dots, 5$, such that the representation

$$u_0 = \lambda' u + \lambda'_1 u_1 + \lambda'_2 u_2 + \lambda'_3 u_3 + \lambda'_4 u_4 + \lambda'_5 u_5 \tag{5.5}$$

is satisfied for the harmonic polynomials $\operatorname{Re} z^n, n = 0, 1, \dots, 5$, where $u = u(P)$, $u_k = u(P_k)$, $k = 0, 1, \dots, 5$, $z = x + iy$. We then have

$$\begin{aligned} \lambda' + \lambda'_1 + \lambda'_2 + \lambda'_3 + \lambda'_4 + \lambda'_5 &= 1, \\ \delta\lambda' + 2\lambda'_1 + 3\lambda'_2 + 2\lambda'_3 + \lambda'_4 &= 0, \\ \delta^2\lambda' + 4\lambda'_1 + 9\lambda'_2 + 3\lambda'_3 - \lambda'_5 &= 0, \\ \delta^3\lambda' + 8\lambda'_1 + 27\lambda'_2 + 2\lambda'_3 - 2\lambda'_4 &= 0, \\ \delta^4\lambda' + 16\lambda'_1 + 81\lambda'_2 - 7\lambda'_3 - 4\lambda'_4 + \lambda'_5 &= 0, \\ \delta^5\lambda' + 32\lambda'_1 + 243\lambda'_2 - 38\lambda'_3 - 4\lambda'_4 &= 0. \end{aligned} \tag{5.6}$$

Solving system (5.6), we obtain $\lambda' = 1/(1 - \mu_0), \lambda'_q = -\mu_q/(1 - \mu_0), q = 1, \dots, 5$,

where

$$\mu_1 = \delta^2(21 - 34\delta + 21\delta^2 - 4\delta^3)/20, \quad \mu_2 = \delta(\delta - 1)(3\delta^3 - 12\delta^2 + 13\delta - 2)/60,$$
$$\mu_3 = \delta(18 - 87\delta + 153\delta^2 - 87\delta^3 + 15\delta^4)/120, \quad \mu_4 = \delta(6 + \delta - 4\delta^2 + \delta^3)/10,$$
$$\mu_5 = \delta(30 - 49\delta + 31\delta^2 - 9\delta^3 + \delta^4)/40, \quad \mu_0 = \sum_{j=1}^{5} \mu_i.$$

It is easy to check that the inequalities $\lambda' > 0$, $\lambda'_1 < 0$, $\lambda'_2 \le 0$, $\lambda'_3 < 0$, $\lambda'_4 < 0$, $\lambda'_5 < 0$ hold for $1 \le \delta \le 3/2$, with $\lambda'_2 = 0$ only when $\delta = 1$.

Now we take the nodal points $P_6(2h, -h)$, $P_7(h, -h)$, and $P_8(0, -h)$, respectively, symmetric to the points P_3, P_4, and P_5 with respect to the x-axis. Since $\operatorname{Im} z^k = 0$, $k = 0, 1, \dots, 5$, for $y = 0$ and is odd with respect to y, and $\operatorname{Re} z^k$, $k = 0, 1, \dots, 5$, is even with respect to y, from (5.5) we obtain the expression

$$S^6 u \equiv \sum_{k=0}^{8} \lambda_k u_k, \tag{5.7}$$

which gives the exact value of the harmonic polynomial $F_5(x, y)$ at the point P, where

$$\lambda_0 = 1 - \mu_0, \quad \lambda_1 = \mu_1, \quad \lambda_2 = \mu_2, \quad \lambda_{q+3} = \lambda_q = \mu_q/2, \quad q = 3, 4, 5. \tag{5.8}$$

It is easy to check that

$$\lambda_2 \ge 0, \quad \lambda_q > 0, \quad q \ne 2; \quad \sum_{k=0}^{8} \lambda_k = 1, \tag{5.9}$$

and $S^6 u \equiv Bu$ for $\delta = 1$, where B is the operator of (3.6).

Case 2. The point $P \in \omega^{h,n}$ lies inside a grid cell and in the rectangular system of coordinates of Case 1 has coordinates $P = P(\delta h, \mu h)$, $1 \le \delta \le 3/2$, $0 < \mu \le 1/2$. On grid lines we take the additional points $P'_0 = (0, \mu h)$, $P'_1 = (2h, \mu h)$, $P'_2 = (3h, \mu h)$, $P'_3 = (2h, h + \mu h)$, $P'_4 = (h, h + \mu h)$, $P'_5 = (0, h + \mu h)$, $P'_6 = (2h, -h + \mu h)$, $P'_7 = (h, -h + \mu h)$, $P'_8 = (0, -h + \mu h)$. From the values of u at the points P'_k, $k = 0, 1, \dots, 8$, we form the expressions

$$S^6 u \equiv \sum_{k=0}^{8} \lambda_k u'_k,$$

where $u'_k = u(P'_k)$, and λ_k, $k = 0, \dots, 8$, are found from (5.8). Since all the points P'_k, $k = 0, 1, \dots, 8$, lie on grid lines, we express all the values of u'_k, $k = 0, 1, \dots, 8$, in terms of nodal values of the function u by formula (5.7) and finally obtain an expression for $S^6 u$ which gives the exact value of any harmonic polynomial of the fifth degree at the point $P(\delta h, \mu h)$:

$$S^6 u \equiv \sum_{k=0}^{30} \xi_k u_k, \tag{5.10}$$

where

$$\xi_k \ge 0, \quad \sum_{k=0}^{30} \xi_k = 1. \tag{5.11}$$

If any of the points P_k in (5.7) or (5.10) are outside the domain $\overline{G}$, there are two possibilities to consider.

Case 3. The points emerge through the side γ_τ of the boundary γ, where $\tau = j-1$ or $\tau = j$, $j \in E$. Since for $j \in E$ the function φ_τ or ψ_τ is given as an algebraic polynomial of the arclength s, the harmonic function $u - Q_j$, where Q_j is the function defined in section 2, is extendable as an odd function across γ_τ if the boundary condition (2.2) on γ_τ is the Dirichlet type and is extendable as an even function if the boundary condition is the Neumann type. Thus, an operator S^6 has been constructed, as in Cases 1 and 2, but only for the function $u - Q_j$, and $Q_j(P)$ must then be added to the expression $S^6(u - Q_j)$.

Case 4. The points emerge through the side γ_m when φ_m or ψ_m is given as a function of the class $C_{6,\lambda}(\gamma_m)$ only.

Subcase 4a. $\nu_m = 1$; i.e., $u = \varphi_m$ on γ_m and $\varphi_m \in C_{6,\lambda}(\gamma_m)$, $0 < \lambda < 1$. We position the origin of the rectangular system of coordinates on γ_m so that the point P lies on the positive y-axis, and the x-axis is in the direction of the vertex A_{m+1} along γ_m. Since

$$\sum_{k=1}^{5} b_k \operatorname{Im} z^k = 0 \quad \text{if } y = 0, \tag{5.12}$$

by representing the function $\varphi_m \in C_{6,\lambda}(\gamma_m)$ in the neighborhood of $x = 0$ using Taylor's formula, and using (5.2) for the solution of problem (2.1), (2.2) in the neighborhood $|z| \le 4h$, $z = x + iy$, of the origin, we find the coefficients a_k, $k = 0, 1, \dots, 5$, of (5.1) as

$$a_k = \frac{1}{k!} \frac{d^k \varphi_m(0)}{dx^k}.$$

We put

$$\widetilde{u}(x,y) \equiv u(x,y) - \sum_{k=0}^{5} a_k \operatorname{Re} z^k = \sum_{k=1}^{5} b_k \operatorname{Im} z^k + O(h^6)$$

for $y > 0$ and complete the definition with $\widetilde{u}(x,y) = -\widetilde{u}(x,-y)$ for $y < 0$. Obviously, in the given neighborhood $\widetilde{u}(x,y)$ is equal to the harmonic polynomial (5.12) with accuracy $O(h^6)$ by virtue of the fact that this polynomial is odd relative to the x-axis. We then form the expression for $S^6\widetilde{u}$ using (5.7) or (5.10), adding the quantity

$$\left(\sum_{k=0}^{5} a_k \operatorname{Re} z^k \right)(P).$$

Subcase 4b. $\nu_m = 0$; i.e., $u_n^{(1)} = \psi_m$ on γ_m. Let

$$\Pi_\tau = \{(x,y) : -a_{1\tau}/2 < x < a_{1\tau}/2, 0 < y < a_{2\tau}\}$$

be one of the rectangles chosen in section 4 for which $P \in \Pi_\tau$, $(\overline{\Pi}_\tau \cap \gamma) \subseteq \gamma_m$. Since $\psi_m \in C_{6,\lambda}(\gamma_m)$, the solution u of the problem (2.1), (2.2) in any rectangle

$$\Pi'_\tau = \{(x,y) : -a'_{1\tau}/2 < x < a'_{1\tau}/2, 0 < y < a'_{2\tau}\},$$

where $0 < a'_{i\tau} < a_{i\tau}$, $i = 1, 2$, and $P \in \Pi'_\tau$ is

$$u \in C_{7,\lambda}(\overline{\Pi}'_\tau). \tag{5.13}$$

Then in the neigborhood $|z| \le 4h$ of the origin by using Taylor's formula we have

$$\frac{\partial u(x,y)}{\partial y}\Big|_{y=0} = \frac{\partial u(0,0)}{\partial y} + x\frac{\partial^2 u(0,0)}{\partial x \partial y} + \frac{x^2}{2}\frac{\partial^3 u(0,0)}{\partial x^2 \partial y} + \frac{x^3}{3!}\frac{\partial^4 u(0,0)}{\partial x^3 \partial y} + \frac{x^4}{4!}\frac{\partial^5 u(0,0)}{\partial x^4 \partial y}$$
$$+ \frac{x^5}{5!}\frac{\partial^6 u(0,0)}{\partial x^5 \partial y} + O(h^6). \tag{5.14}$$

Furthermore, taking into account the boundary condition $u_n^{(1)} = \psi_m$ we have

$$\frac{\partial u(x,y)}{\partial y}\Big|_{y=0} \equiv \psi_m(x) = \psi_m(0) + x\frac{d\psi_m(0)}{dx} + \frac{x^2}{2}\frac{d^2\psi_m(0)}{dx^2} + \frac{x^3}{3!}\frac{d^3\psi_m(0)}{dx^3}$$
$$+ \frac{x^4}{4!}\frac{d^4\psi_m(0)}{dx^4} + \frac{x^5}{5!}\frac{d^5\psi_m(0)}{dx^5} + O(h^6). \tag{5.15}$$

On the basis of (5.14) and (5.15) we obtain

$$\frac{\partial u(x,y)}{\partial y} = \psi_m(0),\ \frac{\partial^2 u(0,0)}{\partial x \partial y} = \frac{d\psi_m(0)}{\partial x},\ \frac{\partial^3 u(0,0)}{\partial x^2 \partial y} = \frac{d^2\psi_m(0)}{\partial x^2},\ \frac{\partial^4 u(0,0)}{\partial x^3 \partial y} = \frac{d^3\psi_m(0)}{\partial x^3},$$

$$\frac{\partial^5 u(0,0)}{\partial x^4 \partial y} = \frac{d^4\psi_m(0)}{\partial x^4}, \quad \frac{\partial^6 u(0,0)}{\partial x^5 \partial y} = \frac{d^5\psi_m(0)}{\partial x^5}. \tag{5.16}$$

By (5.3) and (5.16), for the coefficients b_k, $k = 1, 2, \dots, 5$, in the representation (5.1), we have

$$b_k = \frac{1}{k!}\frac{d^{k-1}\psi_m(0)}{dx^{k-1}}, \quad k = 1, 2, \dots, 5.$$

We define, for $y > 0$, the function

$$\widetilde{\widetilde{u}}(x,y) \equiv u(x,y) - \sum_{k=1}^{5} b_k \operatorname{Im}\ z^k = \sum_{k=0}^{5} a_k \operatorname{Re}\ z^k + O(h^6)$$

and complete the definition for $y < 0$ with $\widetilde{\widetilde{u}}(x,y) = \widetilde{\widetilde{u}}(x,-y)$. It is evident that in the neighborhood $|z| \le 4h$ the function $\widetilde{\widetilde{u}}(x,y)$ coincides with the harmonic polynomial

$$\sum_{k=0}^{5} a_k \operatorname{Re} z^k$$

with an accuracy $O(h^6)$ by virtue of the fact that this polynomial is even relative to the x-axis. We then form the expression for $S^6\widetilde{\widetilde{u}}$ using (5.7) or (5.10), adding the quantity

$$\left(\sum_{k=1}^{5} b_k \operatorname{Im}\ z^k\right)(P).$$

Remark 5.1. In Cases 1 and 2, it is assumed that all points P_k as well as P are in $\overline{G}_*^{h,n}$. We denote the set of such points P by ω_1^h. Similarly, we denote the set of P in Cases 3 and 4 by ω_2^h and ω_3^h, respectively. Furthermore, let ω_{3a}^h and ω_{3b}^h be the subsets of ω_3^h, which are defined in Subcases 4a and 4b, respectively. It is obvious that $\omega_3^h = \omega_{3a}^h \cup \omega_{3b}^h$ and $\omega_{3a}^h \cap \omega_{3b}^h = \emptyset$. Then the matching operator S^6 can be expressed as follows:

$$S^6(u,\varphi,\psi) = \begin{cases} S^6 u & \text{on} \quad \omega_1^h, \\ S^6(u - Q_j) + Q_j(P) & \text{on} \quad \omega_2^h, \\ S^6\left(u - \sum\limits_{k=0}^{5} a_k \operatorname{Re}\ z^k\right) + \left(\sum\limits_{k=0}^{5} a_k \operatorname{Re}\ z^k\right)(P) & \text{on} \quad \omega_{3a}^h, \\ S^6\left(u - \sum\limits_{k=1}^{5} b_k \operatorname{Im}\ z^k\right) + \left(\sum\limits_{k=1}^{5} b_k \operatorname{Im}\ z^k\right)(P) & \text{on} \quad \omega_{3b}^h. \end{cases}$$

6. Analysis of the block-grid equations.

THEOREM 6.1. *There is a natural number n_0 such that for all $n \geq n_0$ the system of equations* (4.5)–(4.8) *has a unique solution.*

Proof. The proof is obtained on the basis of (4.3), (4.4), (5.7)–(5.11), and Remark 5.1 by analogy with [8]. □

Let

$$\varepsilon_h = u_h - u, \tag{6.1}$$

where u_h is a solution of system (4.5)–(4.8), and u is the trace on $\overline{G}_*^{h,n}$ of the solution of (2.1), (2.2). On the basis of (2.1), (2.2), (4.5)–(4.8), and (6.1) the error ε_h satisfies the system of difference equations

$$\begin{aligned} \varepsilon_h &= B\varepsilon_h + r_h^1 \ \text{ on } \Pi_k^h, \\ \varepsilon_h &= \overline{\nu}_m B_m \varepsilon_h + r_h^2 \ \text{ on } \eta_{k1}^h \cap \gamma_m, \\ \varepsilon_h &= \overline{\nu}_m \overline{\nu}_{m+1} \dot{B}_m \varepsilon_h + r_h^3 \ \text{ on } \eta_{k1}^h \cap \gamma_m \cap \gamma_{m+1}, \\ \varepsilon_h(r_j,\theta_j) &= \beta_j \sum_{q=1}^{n(j)} R_j^{(q)}(r_j,\theta_j)\varepsilon_h(r_{j2},\theta_j^q) + r_{jh}^4, (r_j,\theta_j) \in t_j^h, \\ \varepsilon_h &= S^6\varepsilon_h + r_h^5 \ \text{ on } \omega^{h,n}, \end{aligned} \tag{6.2}$$

where $1 \leq m \leq N$, $1 \leq k \leq M$, $j \in E$,

$$r_h^1 = Bu - u \ \text{ on } \bigcup_{k=1}^{M} \Pi_k^h, \tag{6.3}$$

$$r_h^2 = \overline{\nu}_m B_m u - u + E_{mh}(\varphi_m, \psi_m) \ \text{ on } \gamma_m \cap \left(\bigcup_{k=1}^{M} \eta_{k1}^h\right), \tag{6.4}$$

$$\begin{aligned} r_h^3 &= \overline{\nu}_m \overline{\nu}_{m+1} \dot{B}_m u - u + \dot{E}_{mh}(\varphi_m, \varphi_{m+1}, \psi_m, \psi_{m+1}) \\ &\text{on } \gamma_m \cap \gamma_{m+1} \cap \left(\bigcup_{k=1}^{M} \eta_{k1}^h\right), \end{aligned} \tag{6.5}$$

$$r_{jh}^4 = \beta_j \sum_{q=1}^{n(j)} R_j^{(q)}(r_j,\theta_j)(u(r_{j2},\theta_j^q) - Q_j(r_{j2},\theta_j^q))$$

$$- (u(r_j,\theta_j) - Q_j(r_j,\theta_j)) \ \text{ on } \bigcup_{j\in E} t_j^h, \tag{6.6}$$

$$r_h^5 = \begin{cases} S^6 u - u \ \text{ on } \omega_1^h, \\ S^6(u-Q_j) - (u-Q_j)(P) \ \text{ on } \omega_2^h, \\ S^6\left(u - \sum\limits_{k=0}^{5} a_k \operatorname{Re} z^k\right) - \left(u - \sum\limits_{k=0}^{5} a_k \operatorname{Re} z^k\right)(P) \ \text{ on } \omega_{3a}^h, \\ S^6\left(u - \sum\limits_{k=1}^{5} b_k \operatorname{Im} z^k\right) - \left(u - \sum\limits_{k=1}^{5} b_k \operatorname{Im} z^k\right)(P) \ \text{ on } \omega_{3b}^h. \end{cases} \tag{6.7}$$

In what follows and for simplicity, we will denote constants which are independent of h by c.

LEMMA 6.2. *There exists a natural number n_0 such that for all $n \geq \max\left\{n_0, \left[\ln^{1+\varkappa} h^{-1}\right] + 1\right\}$, $\varkappa > 0$ being a fixed number,*

$$\max_{j\in E} \left|r_{jh}^4\right| \leq ch^6. \tag{6.8}$$

Proof. On the basis of (6.6), Lemma 2.2, (4.1), Lemma 6.5 in [29], and by virtue of $t_j^h \subset \overline{T}_j^3$ and the boundedness of the difference $u(r_{j2},\theta_j^q) - Q_j(r_{j2},\theta_j^q)$, $1 \leq q \leq n(j)$, we obtain

$$\begin{aligned} \left|r_{jh}^4\right| \leq & \left| \beta_j \sum_{q=1}^{n(j)} R_j(r_j,\theta_j,\theta_j^q)(u(r_{j2},\theta_j^q) - Q_j(r_{j2},\theta_j^q)) \right. \\ & \left. - \int_0^{\alpha_j \pi} R_j(r_j,\theta_j,\eta)(u(r_{j2},\eta) - Q_j(r_{j2},\eta))d\eta \right| \\ & + \beta_j \sum_{q=1}^{n(j)} \left|R_j^{(q)}(r_j,\theta_j) - R_j(r_j,\theta_j,\theta_j^q)\right| \left|u(r_{j2},\theta_j^q) - Q_j(r_{j2},\theta_j^q)\right| \\ & \leq c_j^0 \exp\left\{-d_j^0 n\right\}, \quad j \in E, \end{aligned} \tag{6.9}$$

where c_j^0 and $d_j^0 > 0$ are constants independent of n. Putting $c^0 = \max_{j\in E}\left\{c_j^0\right\}$ and $d^0 = \min_{j\in E}\left\{d_j^0\right\}$ from (6.9) we have

$$\max_{j\in E} \left|r_{jh}^4\right| \leq c^0 \exp\left\{-d^0 n\right\}. \tag{6.10}$$

Let n_0 be a natural number to hold the inequality (4.3). Then, for all $n \geq \max\left\{n_0, \left[\ln^{1+\varkappa} h^{-1}\right] + 1\right\}$, where $\varkappa > 0$ is a fixed number, we have the inequality (6.8). □

Since the set of points $\omega^{h,n}$ located from the vertices of the polygon G at the distance exceeding some positive quantity independent of h, then by virtue of (2.4), (2.5), and estimation (4.64) in [21], from (6.7) we obtain

$$\max_{\omega^{h,n}} \left|r_h^5\right| \leq ch^6. \tag{6.11}$$

THEOREM 6.3. *Assume that conditions* (2.3)–(2.5) *hold. Then there exists a natural number* n_0 *such that for all* $n \geq \max\left\{n_0, \left[\ln^{1+\varkappa} h^{-1}\right] + 1\right\}$, $\varkappa > 0$ *being a fixed number,*

$$\max_{\overline{G}_*^{h,n}} |u_h - u| \leq ch^6.$$

Proof. Let us take an arbitrary rectangular grid $\Pi_{k^*}^h$, and let $t_{k^*j}^h = \overline{\Pi}_{k^*}^h \cap t_j^h$. Let $t_{k^*j}^h \neq \emptyset$, and let v_h be a solution of system (6.2) in the case when the discrepancies r_h^1, r_h^2, r_h^3, r_{jh}^4, and r_h^5 in $\overline{\Pi}_{k^*}^h$ are the same as in (6.3)–(6.7) but are zero in $\overline{G}_*^{h,n} \setminus \overline{\Pi}_{k^*}^h$. It is easy to show that

$$W = \max_{\overline{G}_*^{h,n}} |v_h| = \max_{\overline{\Pi}_{k^*}^h} |v_h| . \tag{6.12}$$

We represent the function v_h on $\overline{G}_*^{h,n}$ as

$$v_h = \sum_{\kappa=1}^{4} v_h^\kappa, \tag{6.13}$$

where the functions v_h^κ, $\kappa = 2, 3, 4$, are defined on $\overline{\Pi}_{k^*}^h$ as a solution of the system of equations

$$\begin{aligned}
v_h^\kappa &= Bv_h^\kappa + r^\kappa(h) \ \text{ on } \Pi_{k^*}^h, \\
v_h^\kappa &= \overline{\nu}_m B_m v_h^\kappa + r^\kappa(h) \ \text{ on } \eta_{k^*1}^h \cap \gamma_m, \\
v_h^\kappa &= \overline{\nu}_m \overline{\nu}_{m+1} \dot{B}_m v_h^\kappa + r^\kappa(h) \ \text{ on } \eta_{k^*1}^h \cap \gamma_m \cap \gamma_{m+1}, \\
v_h^\kappa(r_j, \theta) &= r_j^\kappa(h), \quad (r_j, \theta_j) \in t_{k^*j}^h, \\
v_h^\kappa &= r_5^\kappa(h) \ \text{ on } \omega^{h,n};
\end{aligned} \tag{6.14}$$

with

$$v_h^\kappa = 0, \quad \kappa = 2, 3, 4, \ \text{ on } \overline{G}_*^{h,n} \setminus \overline{\Pi}_{k^*}^h, \tag{6.15}$$

$r^\kappa(h) = 0$, $\kappa = 2, 3$; $r_j^\kappa(h) = 0$, $\kappa = 3, 4$, $r_j^2(h) = r_{jh}^4$; $r_5^\kappa(h) = 0$, $\kappa = 2, 4$, $r_5^3(h) = r_h^5$;

$$r^4(h) = \begin{cases} r_h^1 \ \text{ on } \Pi_{k^*}^h, \\ r_h^2 \ \text{ on } \eta_{k^*1}^h \cap \gamma_m, \\ r_h^3 \ \text{ on } \eta_{k^*1}^h \cap \gamma_m \cap \gamma_{m+1}. \end{cases}$$

Hence according to (6.13)–(6.15) the function v_h^1 satisfies the system of equations

$$\begin{aligned}
v_h^1 &= Bv_h^1 \ \text{ on } \Pi_k^h, \\
v_h^1 &= \overline{\nu}_m B_m v_h^1 \ \text{ on } \eta_{k1}^h \cap \gamma_m, \\
v_h^1 &= \overline{\nu}_m \overline{\nu}_{m+1} \dot{B}_m v_h^1 \ \text{ on } \eta_{k1}^h \cap \gamma_m \cap \gamma_{m+1}, \\
v_h^1(r_j, \theta_j) &= \beta_j \sum_{q=1}^{n(j)} R_j^{(q)}(r_j, \theta_j) \sum_{\kappa=1}^{4} v_h^\kappa(r_{j2}, \theta_j^q), (r_j, \theta_j) \in t_{kj}^h, \\
v_h^1 &= S^6 \left(\sum_{\kappa=1}^{4} v_h^\kappa \right) \ \text{ on } \omega^{h,n}, \quad 1 \leq m \leq N, \quad 1 \leq k \leq M, \quad j \in E,
\end{aligned} \tag{6.16}$$

where the functions v_h^κ, $\kappa = 2, 3, 4$, are assumed to be known.

Taking into account (6.8), (6.11), and (6.15), on the basis of the structure of operators B, B_m, and $\dot{B}_m$ and the principle of maximum, we have

$$W_2 = \max_{\overline{G}_*^{h,n}} \left|v_h^2\right| \le ch^6, \tag{6.17}$$

$$W_3 = \max_{\overline{G}_*^{h,n}} \left|v_h^3\right| \le ch^6. \tag{6.18}$$

The function v_h^4 being a solution of the system (6.14), when $\kappa = 4$, with (6.15) is the error function of the finite difference solution, with step $h_{k^*} \le h$, of the boundary value problem (3.1)–(3.2). By virtue of Theorem 3.1 we have

$$W_4 = \max_{\overline{G}_*^{h,n}} \left|v_h^4\right| = \max_{\overline{\Pi}_{k^*}^h} \left|v_h^4\right| \le ch^6. \tag{6.19}$$

We estimate the function v_h^1, which is, according to Theorem 6.1 , the unique solution of system (6.16). On the basis of (4.3), (4.4), (6.16), and the gluing condition of the figures Π_k, $k = 1, 2, \dots, M$, T_j^2, $j \in E$, there exists a real number λ^*, $0 < \lambda^* < 1$, independent of h, such that for all $n \ge \max\left\{n_0, \left[\ln^{1+\varkappa} h^{-1}\right] + 1\right\}$ we have

$$W_1 = \max_{\overline{G}_*^{h,n}} \left|v_h^1\right| \le \lambda^* W + \sum_{i=2}^{4} \max_{\overline{G}_*^{h,n}} \left|v_h^i\right|. \tag{6.20}$$

From (6.12), (6.13), and (6.17)–(6.20) we obtain

$$W = \lambda^* W + 2\sum_{i=2}^{4} W_i \le \lambda^* W + ch^6, \quad 0 < \lambda^* < 1,$$

i.e.,

$$W = \max_{\overline{G}_*^{h,n}} |v_h| \le ch^6. \tag{6.21}$$

In the case when $t_{k^*j}^h \equiv \emptyset$ the function $v_h^2 \equiv 0$ on $\overline{G}_*^{h,n}$ and the inequality (6.21) hold true. Since the number of grid rectangles in $\overline{G}_*^{h,n}$ is finite, for the solution of (6.2) we have

$$\max_{\overline{G}_*^{h,n}} |\varepsilon_h| \le ch^6. \qquad \square$$

Now we consider the question of convergence of function $U_h(r_j, \theta_j)$ defined by the formula (4.9). Taking into account the properties of functions $Q_j(r_j, \theta_j)$, $j \in E$, and the fact that the kernel $R_j(r_j, \theta_j, \eta)$ satisfies the homogeneous boundary condition defined by (2.2) on $(\gamma_{j-1} \cup \gamma_j) \cap \overline{T}_j^2$, the function $U_h(r_j, \theta_j)$ is bounded, harmonic on $T_j^* = T_j(r_j^*)$, $r_j^* = (r_{j2} + r_{j3})/2$, $j \in E$, and continuous up to the boundary of T_j^*, except for the vertex A_j when the specified boundary values are discontinuous at A_j. Moreover, on the rectilinear parts of the boundary of T_j^*, except, maybe, the vertex A_j, the function $U_h(r_j, \theta_j)$ satisfies the boundary conditions defined in (2.2).

THEOREM 6.4. *There is a natural number n_0 such that for all $n \ge \max\left\{n_0, \left[\ln^{1+\varkappa} h^{-1}\right] + 1\right\}$, $\varkappa > 0$ being a fixed number, the following inequalities are valid:*

$$\left|\frac{\partial^p}{\partial x^{p-q} \partial y^q}\left(U_h(r_j, \theta_j) - u(r_j, \theta_j)\right)\right| \le c_p h^6 \quad \text{on } \overline{T}_j^3, \tag{6.22}$$

first, for integer λ_j *and any* ν_{j-1} *and* ν_j *when* $p \geq \lambda_j$ *and, second, for* $\nu_{j-1} = \nu_j = 0$ *and any* λ_j *when* $p = 0$;

$$\left| \frac{\partial^p}{\partial x^{p-q} \partial y^q} (U_h(r_j, \theta_j) - u(r_j, \theta_j)) \right| \leq c_p h^6 / r_j^{p-\lambda_j} \quad \text{on } \overline{T}_j^3, \tag{6.23}$$

for any λ_j, *if* $\nu_{j-1} + \nu_j \geq 1$, $0 \leq p < \lambda_j$ *or* $\nu_{j-1} = \nu_j = 0$, $1 \leq p < \lambda_j$;

$$\left| \frac{\partial^p}{\partial x^{p-q} \partial y^q} (U_h(r_j, \theta_j) - u(r_j, \theta_j)) \right| \leq c_p h^6 / r_j^{p-\lambda_j} \quad \text{on } \overline{T}_j^3 \backslash A_j \tag{6.24}$$

for noninteger λ_j *and any* ν_{j-1} *and* ν_j *when* $p > \lambda_j$. *Everywhere,* $0 \leq q \leq p$, λ_j *is the quantity* (2.11), ν_{j-1} *and* ν_j *are parameters entering into the boundary conditions* (2.2), u *is a solution of the problem* (2.1), (2.2), $c_p, p = 0, 1, \dots$, *are constants independent of* $r_j = r_j(x, y)$, $\theta_j = \theta_j(x, y)$, *and* h.

Proof. On the bases of (4.9) and Lemma 2.2, on the closed block $\overline{T}_j^*$, $j \in E$, we have

$$\begin{aligned} U_h(r_j, \theta_j) - u(r_j, \theta_j) = {} & \beta_j \sum_{q=1}^{n(j)} R_j(r_j, \theta_j, \theta_j^q)(u(r_{j2}, \theta_j^q) - Q_j(r_j, \theta_j^q)) \\ & - \int_0^{\alpha_j \pi} R_j(r_j, \theta_j, \eta)(u(r_{j2}, \eta) - Q_j(r_{j2}, \eta)) d\eta \\ & + \beta_j \sum_{q=1}^{n(j)} R_j(r_j, \theta_j, \theta_j^q)(u_h(r_{j2}, \theta_j^q) - u(r_j, \theta_j^q)). \end{aligned} \tag{6.25}$$

Since $r_j^* = (r_{j2} + r_{j3})/2$ by analogy with the proof of Lemma 6.2 for $n \geq \left[\ln^{1+\varkappa} h^{-1}\right] + 1$, $\varkappa > 0$ being a fixed number, we have

$$\begin{aligned} & \left| \beta_j \sum_{q=1}^{n(j)} R_j(r_j, \theta_j, \theta_j^q)(u(r_{j2}, \theta_j^q) - Q_j(r_j, \theta_j^q)) \right. \\ & \left. - \int_0^{\alpha_j \pi} R_j(r_j, \theta_j, \eta)(u(r_{j2}, \eta) - Q_j(r_{j2}, \eta)) d\eta \right| \\ & \leq c h^6 \quad \text{on } \overline{T}_j^*, \quad j \in E. \end{aligned} \tag{6.26}$$

On the basis of Theorem 6.3 and the boundedness of $\beta_j \sum_{q=1}^{n(j)} R_j(r_j, \theta_j, \theta_j^q)$ for all $n \geq \max\left\{n_0, \left[\ln^{1+\varkappa} h^{-1}\right] + 1\right\}$ we obtain

$$\left| \beta_j \sum_{q=1}^{n(j)} R_j(r_j, \theta_j, \theta_j^q)(u_h(r_{j2}, \theta_j^q) - u(r_j, \theta_j^q)) \right| \leq c h^6 \quad \text{on } \overline{T}_j^*, \quad j \in E. \tag{6.27}$$

From (6.25)–(6.27) for all $n \geq \max\left\{n_0, \left[\ln^{1+\varkappa} h^{-1}\right] + 1\right\}$ we have

$$|U_h(r_j, \theta_j) - u(r_j, \theta_j)| \leq c h^6 \quad \text{on } \overline{T}_j^*, \quad j \in E. \tag{6.28}$$

Since $T_j^3 \subset \overline{T}_j^*$, $j \in E$, then from the inequality (6.28) the proof of (6.22) follows when $p = 0$.

To establish the validity of remainder inequalities of Theorem 6.4 we put

$$\varepsilon_h(r_j,\theta_j) = U_h(r_j,\theta_j) - u(r_j,\theta_j) \ \text{ on } \overline{T}_j^*, \quad j \in E. \tag{6.29}$$

From (4.9), (6.29), and Remark 2.1 it follows that the function $\varepsilon_h(r_j,\theta_j)$ is continuous on $\overline{T}_j^*$ and is a solution of the boundary value problem

$$\begin{aligned} \Delta\varepsilon_h &= 0 \ \text{ on } T_j^*, \\ \nu_m\varepsilon_h + \overline{\nu}_m(\varepsilon_h)'_n &= 0 \ \text{ on } \gamma_m \cap \overline{T}_j^*, \quad m = j-1, j, \\ \varepsilon_h(r_j^*,\theta_j) &= U_h(r_j^*,\theta_j) - u(r_j^*,\theta_j), \quad 0 \le \theta_j \le \alpha_j\pi. \end{aligned} \tag{6.30}$$

Taking into account (6.28)–(6.30), from Lemma 6.12 given by Volkov [29] follows all remainder inequalities of Theorem 6.4. □

Remark 6.5. From the error estimation formula (6.23) of Theorem 6.4 it follows that, when on the sides of interior angles $\neq \pi/2$, the boundary conditions are either Dirichlet or mixed type, then the error of approximate solution on the block sectors decreases as $r_j^{\lambda_j} h^6$, which gives an additional accuracy of the BGM near the singular points, with respect to existing FDM or FEM modifications for the singular problems.

7. The use of Schwarz's alternating method to solve the system of block-grid equations. According to Definitions 4.1–4.3, the approximate solution of problem (2.1), (2.2) must first be found in the domain $\overline{G}_*^{h,n}$ as the solution of the system of difference equations (4.5)–(4.8), and the solution itself and its derivatives of order p, $p = 1, 2, \dots$, at any point of $\overline{T}_j^3$, $j \in E$, except maybe the vertex A_j, can then be found using formula (4.9). Therefore, it is sufficient to justify the possibility of finding a solution of system (4.5)–(4.8) by Schwarz's alternating method.

We denote by γ^D the union of all sides of polygon G on which the boundary condition is Dirichlet type, i.e.,

$$\gamma^D = \bigcup_{j:\nu_j=1} \gamma_j.$$

From (2.3) it follows that $\gamma^D \neq \emptyset$. We define the following classes: Φ_τ, $\tau = 1, 2, \dots, \tau^*$, of rectangles Π_k, $k = 1, 2, \dots, M$ (see [8]). Class Φ_1 includes all rectangles whose intersection with γ^D contains a certain segment of positive length. Class Φ_2 contains all the rectangles which are not in class Φ_1 and whose intersection with rectangles of Φ_1 contains a segment of finite length, and so on. Let Π_{k0}^h be the set of nodes of the grid $\overline{\Pi}_k^h$ which are not less than $l_0 = \min\{\min_{1\le k\le M} \min\{a_{1k}, a_{2k}\}, \kappa_0\}/8$ from the set η_{k0}. Let

$$\Phi_{\tau 0}^h = \bigcup_{k:\Pi_k\in\Phi_\tau} \Pi_{k0}^h, \quad \tau = 1, 2, \dots, \tau^*; \quad G_{*0}^h = \bigcup_{\tau=1}^{\tau^*} \Phi_{\tau 0}^h.$$

Suppose we have a zero approximation $u_h^{(0)}$ to the exact solution u_h of (4.5)–(4.8). Finding $u_h^{(1)}$ on η_{k0} by the formula (4.8) and for all $j \in E$ on t_j^h by (4.7), we solve the system (4.5), (4.6) on each grid $\overline{\Pi}_k^h$ of rectangles, first from class Φ_1, then from class Φ_2, and so on. The next iteration is similar.

Consequently, we have the sequence $u_h^{(1)}, u_h^{(2)}, \dots$, defined as follows:

$$
\begin{aligned}
u_h^{(m)} &= S^6\left(u_h^{(m-1)}, \varphi, \psi\right) \quad \text{on } \omega^{h,n},\\
u_h^{(m)}(r_j,\theta_j) &= Q_j(r_j,\theta_j)\\
&\quad +\beta_j \sum_{q=1}^{n(j)} R_j^{(q)}(r_j,\theta_j)(u^{(m)}(r_{j2},\theta_j^q) - Q_j(r_{j2},\theta_j^q)) \quad \text{on } t_j^h, \qquad (7.1)\\
u_h^{(m)} &= Bu_h^{(m)} \quad \text{on } \Pi_k^h,\\
u_h^{(m)} &= \bar\nu_p B_p u_h^{(m)} + E_{ph}(\varphi,\psi) \quad \text{on } \eta_{k1}^h \cap \gamma_p,\\
u_h^{(m)} &= \bar\nu_p\bar\nu_{p+1}\dot B_p u_h^{(m)} + \dot E_{ph}(\varphi_p,\varphi_{p+1},\psi_p,\psi_{p+1}) \quad \text{on } \eta_{k1}^h \cap \gamma_p \cap \gamma_{p+1},
\end{aligned}
$$

where $1 \le k \le M$, $1 \le p \le N$, $j \in E$, $m = 1, 2, \dots$.

THEOREM 7.1. *For any $n \ge \max\left\{n_0, \left[\ln^{1+\varkappa} h^{-1}\right] + 1\right\}$ the system* (4.5)–(4.8) *can be solved by Schwarz's alternating method with any accuracy $\varepsilon > 0$ in a uniform metric with the number of iterations $O(\ln \varepsilon^{-1})$, independent of h and n, where n_0 and $\varkappa$ mean the same as in Theorem* 6.4.

Proof. Let

$$
\varepsilon^{(m)} = u_h^{(m)} - u_h \quad \text{on } \overline{G}_*^{h,n}, \qquad (7.2)
$$

where u_h is the exact solution of (4.5)–(4.8), and $u_h^{(m)}$ is the mth iteration defined by (7.1), $m = 1, 2, \dots$.

By virtue of (4.5)–(4.8), (7.1), (7.2), and Remark 5.1, for any m, we have

$$
\varepsilon_h^{(m)} = S^6\left(\varepsilon_h^{(m-1)}\right) \quad \text{on } \omega^{h,n}, \qquad (7.3)
$$

$$
\varepsilon_h^{(m)}(r_j,\theta_j) = \beta_j \sum_{q=1}^{n(j)} R_j^{(q)}(r_j,\theta_j)\varepsilon_h^{(m)}(r_{j2},\theta_j^q) \quad \text{on } t_j^h \cap \eta_k, \qquad (7.4)
$$

$$
\varepsilon_h^{(m)} = B\varepsilon_h^{(m)} \quad \text{on } \Pi_k^h, \qquad (7.5)
$$

$$
\varepsilon_h^{(m)} = \bar\nu_p B_p \varepsilon_h^{(m)} \quad \text{on } \eta_{k1}^h \cap \gamma_p, \qquad (7.6)
$$

$$
\varepsilon_h^{(m)} = \bar\nu_p\bar\nu_{p+1}\dot B_p \varepsilon_h^{(m)} \quad \text{on } \eta_{k1}^h \cap \gamma_p \cap \gamma_{p+1}, \qquad (7.7)
$$

where $1 \le k \le M$, $1 \le p \le N$, $j \in E$, $m = 1, 2, \dots$.

We denote

$$
W_h^{(m)} = \max_{\overline{G}_*^{h,n}} \left|\varepsilon_h^{(m)}\right|.
$$

On the basis of (4.3), (4.4), (5.9), (5.11), (7.3), and (7.4) for $n \ge n_0$ we have

$$
\max_{\cup_{k=1}^M \eta_{k,0}^h} \left|\varepsilon_h^{(m)}\right| \le \max_{G_{*0}^h} \left|\varepsilon_h^{(m-1)}\right| \le W_h^{(m-1)}, \qquad (7.8)
$$

$$
\max_{\cup_{j\in E} t_j^h} \left|\varepsilon_h^{(m)}(r_j,\theta_j)\right| \le \max_{G_{*0}^h} \left|\varepsilon_h^{(m-1)}\right| \le W_h^{(m-1)}, \quad m = 1, 2, \dots. \qquad (7.9)
$$

By virtue of (7.8), (7.9), and the maximum principle, from (7.5)–(7.7) we obtain

$$
W_h^{(0)} \ge W_h^{(1)} \ge W_h^{(2)} \ge \cdots, \qquad (7.10)
$$

$$
W_h^{(m)} \le \max_{G_{*0}^h} \left|\varepsilon_h^{(m-1)}\right|, \quad m = 1, 2, \dots. \qquad (7.11)
$$

Taking into account the sequence of calculation over classes Φ_τ, $\tau = 1, 2, \dots, \tau^*$, and the inequalities (7.10) and (7.11), by means of [8], we obtain

$$W_h^{(m+1)} \le \mu_{\tau^*}^m W_h^{(0)}, \quad m = 1, 2, \dots, \tag{7.12}$$

where $\mu_{\tau^*} < 1$ is independent of m and h.

From (7.12) follows the statement of Theorem 7.1. □

8. Numerical examples. We computed two numerical examples in order to test the effectiveness of the BGM. In Example 8.1, the polygon G is L-shaped (Figure 2), and the exact solution is known: it has both the boundary (discontinuity of the boundary functions) and the angle singularities at vertex A_1 of the interior angle ($\alpha_1\pi = 3\pi/2$). In Example 8.2 (Motz problem), the solution has singularities at the vertex A_1, with the interior angle $\alpha_1\pi = \pi$ (Figure 3), caused by abrupt changes in the type of boundary conditions. The exact solution of the Motz problem is unknown, and comparisons are made with the existing best results.

Let us describe the method of realization of Schwarz's iterations defined by (7.1): Let $\Pi = \{(x, y) : 0 < x < a, 0 < y < b\}$, where $a = 2^p h_0$, $b = 2^q h_0$, $h_0 > 0$ is a fixed number, and p and q are integers. We introduce a square grid with the lines $x = ih$, $y = jh$, $h = 2^{-m}h_0$, $m \ge 0$ being an integer, $i = 0, 1, \dots, 2^{p+m}$, $j = 0, 1, \dots, 2^{q+m}$. Let $\Pi_h = \{(x, y) : x = x_i = ih, 0 < i < 2^{p+m}, y = y_j = jh, 0 < j < 2^{q+m}\}$, Γ_h be a set of nodes on Γ (the boundary of Π), $\Gamma_{1h} = \{(x, y) : x = ih, 1 \le i \le 2^{p+m}, y = 0\}$.

We consider the finite difference problem

$$u_h = Bu_h \quad \text{on } \Pi_h, \tag{8.1}$$

$$u_h = \begin{cases} \varphi_h & \text{on } \Gamma_{1h}, \\ 0 & \text{on } \Gamma_h \backslash \Gamma_{1h}, \end{cases} \tag{8.2}$$

where φ_h is a given function on Γ_{1h}.

The solution of (8.1), (8.2) has the representation (see [31], [18])

$$u_h(x, y) = \sum_{n=1}^{2^{p+m}-1} b_n \frac{\sinh(\beta_n(1 - y/b))}{\sinh \beta_n} \sin \frac{n\pi x}{a}, \tag{8.3}$$

where

$$b_n = 2^{1-p-m} \sum_{k=1}^{2^{p+m}-1} \varphi_h(kh) \sin \frac{n\pi kh}{a}, \tag{8.4}$$

$$\beta_n = \frac{2b}{h} \sinh^{-1} \left(\frac{\sin \frac{n\pi h}{2a}}{\sqrt{1 - 2\sin^2(n\pi h/2a)/3}} \right). \tag{8.5}$$

If the boundary condition (8.2) is nonhomogeneous on the whole boundary Γ_h, then we subtract a second order algebraic polynomial which is a solution of (8.1) and with the given values of the boundary function at vertices of Π and then subdivide the given problem into four problems of the type (8.1), (8.2).

In Example 8.1, the four overlapping rectangles and in Example 8.2 three overlapping rectangles are taken, as shown in Figures 2 and 3, respectively. Furthermore,

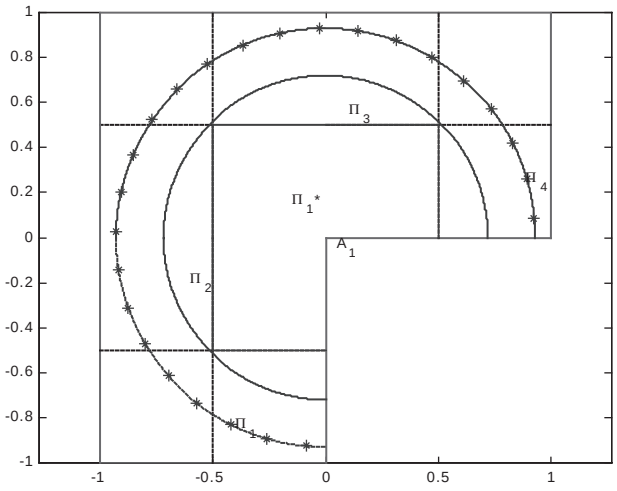

FIG. 2.

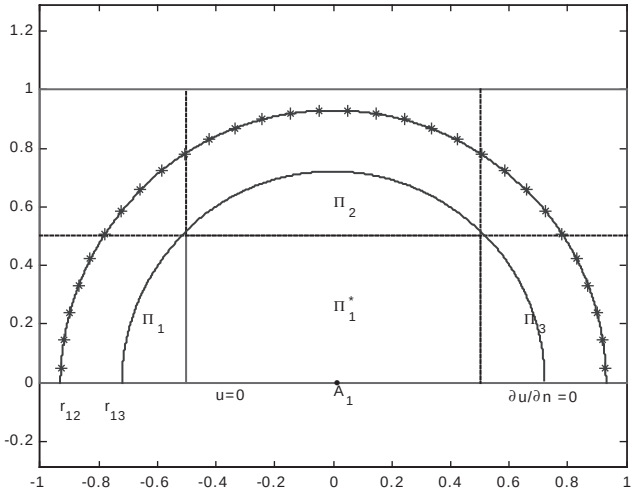

FIG. 3.

according to the boundary conditions on γ_0 and γ_1, $Q_1(r,\theta) = \theta$ is taken for Example 8.1, and $Q_1(r,\theta) = 0$ for Example 8.2. The results of realization of the iteration (7.1) by the formulas (8.3)–(8.5) for the solution of the Dirichlet problem in Example 8.1 are given in Tables 1 and 2. We use the same approach for the problem in Example 8.2 (Motz problem) after reducing the problem for each rectangle Π_k, $k = 1, 2, 3$ (see Figure 3), to the Dirichlet problem by extending the solution through the sides of Π_k as an even function when the homogeneous Neumann condition is given. Using the formulas (8.3)–(8.5) in (7.1) is effective, because the method of discrete fast Fourier transform is applicable for their realization. Some results for the solution of the Motz problem are given in Tables 3 and 4. In both problems, we request the maximum successive error on the sides of overlapping rectangles on G to be reduced by a factor of 10^{-14} as a convergence test for the Schwarz procedure, and all the computations are carried out in double precision. In all computations, we have used the starting

value $u_h^{(0)} = 0$ for the Dirichlet problem on the L-shaped domain and $u_h^{(0)} = 30$ for the Motz problem. Furthermore, for both problems the radius r_{13} of sector T_1^3 is taken 0.72.

In all tables the following notation is used:

$\Pi_1^* = \overline{G} \backslash (\cup_{k=1}^{M} \overline{\Pi}_k)$, $G_{NS} = \overline{G} \backslash \Pi_1^*$ "nonsingular part" of G; $G_S = \overline{G} \cap \Pi_1^*$ "singular part" of G, $G_S^{\varrho} = G_S \cap \{r \leq \varrho\}$, $G_{NS}^{h,n} = G_{NS} \cap \overline{G}_*^{h,n}$, $\|w\|_{C(\Omega)} = \max_{\Omega} |w|$.

EXAMPLE 8.1. *Let G be L-shaped and defined as follows (see Figure 2):*

$$G = \{(x, y) : -1 < x < 1, -1 < y < 1\} \setminus G_1,$$

where $G_1 = \{(x, y) : 0 \leq x \leq 1, -1 \leq y \leq 0\}$. Let γ be the boundary of G. Consider the following problem:

$$\Delta u = 0 \quad on \quad G, \tag{8.6}$$

$$u = v(r, \theta) \quad on \quad \gamma, \tag{8.7}$$

where

$$v(r, \theta) = \theta + r^{\frac{2}{3}} \sin \frac{2\theta}{3} \tag{8.8}$$

is the exact solution of this problem.

In Tables 1 and 2, for the errors $\varepsilon_h = U_h - u$, $\varepsilon_h^{(1)} = r^{\frac{1}{3}}(\frac{\partial U_h}{\partial x} - \frac{\partial u}{\partial x})$, $\varepsilon_h^{(2)} = r^{\frac{4}{3}}(\frac{\partial^2 U_h}{\partial x^2} - \frac{\partial^2 u}{\partial x^2})$ in maximum norm between the block-grid solution U_h and the exact solution u of the problem in Example 8.1 are given.

EXAMPLE 8.2. *(Motz problem). Let* $G = \{(x, y) : -1 < x < 1, 0 < y < 1\}$, *and let* γ *be its boundary (Figure* 3*). We consider the following problem:*

$$\begin{aligned} -\Delta u &= 0 \quad \textit{in } G, \\ u &= 0 \quad \textit{on } y = 0, \quad -1 \le x \le 0, \\ u &= 500 \quad \textit{on } x = 1, \\ \frac{\partial u}{\partial n} &= 0 \quad \textit{on the other boundary segments of } \gamma. \end{aligned}$$

The Motz problem is used [5], [13], [15], [16], [17], [19], [30], [32],[33] as a benchmark in many approaches for the singular problems. An extremely accurate result is obtained in [13], where piecewise expansions into particular solutions are used to approximate the boundary conditions in a least-square sense. To obtain high accurate results (for instance, the maximum error on $x = 1$ is $5.47E-9$) by this boundary method, a large number (34) of particular solutions are needed, and this may result in serious difficulties due to ill conditioning of the associated least-squares matrices (the condition number is $3.97E+07$). To decrease the condition number (down to 3617) in [13], different subdivisions of the given domain into three subdomains are considered. Different numbers of particular solutions are then used for each subdomain. However, even when the best combination of these numbers is used, the accuracy is of order $E-06$ only. Lucas and Oh [15] used the MAM in the context of the *h*-*p* version of the finite element method, and the best result (maximum error is $2.22E-08$) is obtained when $p = 10$. Comparisons in [15] were made with the extremely accurate results obtained in [13].

The results given in Tables 3 and 4 are obtained for the Motz problem. The errors

iter	55	56	61	56	73	61	57

$\varepsilon_h = U_h - v$, $\varepsilon_h^{(1)} = r^{\frac{1}{2}}(\frac{\partial U_h}{\partial x} - \frac{\partial v}{\partial x})$, $\varepsilon_h^{(2)} = r^{\frac{3}{2}}(\frac{\partial^2 U_h}{\partial x^2} - \frac{\partial^2 v}{\partial x^2})$ are defined between the block-grid solution U_h and the extremely accurate solution v ($M = 34$) from [13] after correction of the 31st coefficient (dividing by 10), discovered by Lucas and Oh [15].

The results in Tables 1–4 show that when we decrease the step size h to improve an accuracy of the approximate solution, the number of nodes n of the quadrature formula must be increased (see Theorem 6.3); the results support the theoretical rate $O(h^6)$ for all of (h^{-1}, n). For the Motz problem (the exact solution is unknown), the comparisons are made with the results of Li, Mathon, and Sermer [13], and, as shown in Tables 3 and 4, the errors in nonsingular part are not better than $2.10E-8$ when $(h^{-1}, n) = (32, 80)$, and it is not obvious which approximate solution is better.

In Tables 3 and 4, for the Motz problem some condition numbers of the matrix of the block-grid equations (4.5)–(4.8) are given. They grow slower than $O(h^{-2})$, which is true for the usual FDM. In Table 5, the condition numbers together with the corresponding absolute errors in maximum norm for the BGM and boundary method in [13] are given.

Remark 8.3. As follows from Tables 1–4, the results in the "singular part" for $r_{j2} = 0.93$ are better than for $r_{j2} = 0.87$. Moreover, as shown in Tables 1 and 3, the results get better around the singular point, which support Remark 6.5. Therefore, in applications of the BGM the difference $r_{j2} - r_{j3}$ should be taken not less than some fixed number $k_0 > 0$. To emphasize this important computational aspect, we present the following results obtained when $r_{12} = 0.75$: (i) in the case of Example 8.1 for $(h^{-1}, n) = (32, 80)$, we get $\|\varepsilon_h\|_{C(G_{NS}^{h,n})} = 2.08D-3$, $\|\varepsilon_h\|_{C(G_S)} = 4.27D-3$; (ii) in the case of Example 8.2 for $(h^{-1}, n) = (16, 60)$, we get $\|\varepsilon_h\|_{C(G_{NS}^{h,n})} = 5.34D+1$, $\|\varepsilon_h\|_{C(G_S)} = 4.74D+1$. The explanation of this divergency follows from Remark 2.3, Definition 4.2, and Theorem 6.4. According to the construction of the matching operator (see section 5, Cases 3 and 4), the increase of the difference $r_{12} - r_{j3}$ does not cause any problem.

Remark 8.4. The number of iterations can be decreased if for every Schwarz iteration a few simple subiterations (without using the first and the second equations in (7.1)) are performed to improve the results on the interior boundaries of the rectangles Π_k, $k = 1, 2, \ldots, M$ outside of $\overline{\Pi}_1^*$. The results given in Table 6 are obtained for the Motz problem in the case of $r_{12} = 0.93$, where the five simple subiterations are used. In [14] for the solution of the algebraic system of equations obtained in the combination of the Ritz–Galerkin method and FDM the iterative subtracting method is proposed. This method requires a lower number of iterations.

9. Concluding remarks. In the proposed BGM, by making an artificial boundary, the problem with singularities is reduced to a domain without singularities. Exact boundary conditions on the artificial boundary are the integral representation of the solution in which the composite midpoint rule converges exponentially. To approximate the official boundary condition and Laplace's equation on the obtained domain, the sixth order finite difference schemes are used. On the singular parts (on blocks $\overline{T}_j^3$, $j \in E$), the approximate solution is defined by the formula (4.9), itself being a harmonic function which acquires completely all singularities of the derivatives of the required solution u via the function Q_j, appearing because of the consistency conditions at A_j, $j \in E$, not being fulfilled. The angle singularities are passed on sufficiently exactly to the approximate solution via kernel R_j. Furthermore, to connect the grids and the blocks, the sixth order matching operator is constructed. These properties are a prerequisite for a high rate of convergence established by Theorems 6.3 and 6.4 and by numerical results given in section 8. As it follows from Tables 1–4, the absolute error in the singular part (in G_S) of G is smaller than in the smoother part (in G_{NS}) of G, which agrees with the results obtained in Theorems 6.3 and 6.4 (see Remark 6.5).

If on the sides of the right interior angles of polygon G the boundary functions are given also as an algebraic polynomial of s, then, without conjugate conditions (2.5), the approximate solution in a neighborhood of vertices of these angles can be defined by the formula (4.9), and derivatives of any order can be found by its simple differentiation.

A parallelism of the sides of graduated polygon G to the x- and y-axis is assumed only for simplicity of presentation.

The method and results of this paper are valid for multiply connected graduated polygons.

The sixth order matching operator constructed in section 5 can also be used to build other highly accurate combined or domain decomposition methods.

Acknowledgments. The author thanks Professor E. A. Volkov for his valuable advice and the referee whose appropriate remarks contributed to improve the presentation of the paper. The author also thanks Mrs. S. Cival for her realization of some algorithms in section 8.

GODUNOV-TYPE METHODS FOR CONSERVATION LAWS WITH A FLUX FUNCTION DISCONTINUOUS IN SPACE*

ADIMURTHI†, JÉRÔME JAFFRÉ‡, AND G. D. VEERAPPA GOWDA†

This paper is dedicated to the memory of Jacques-Louis Lions

Abstract. Scalar conservation laws with a flux function discontinuous in space are approximated using a Godunov-type method for which a convergence theorem is proved. The case where the flux functions at the interface intersect is emphasized. A very simple formula is given for the interface flux. A numerical comparison between the Godunov numerical flux and the upstream mobility flux is presented for two-phase flow in porous media. A consequence of the convergence theorem is an existence theorem for the solution of the scalar conservation laws under consideration. Furthermore, for regular solutions, uniqueness has been shown.

Key words. conservation laws, discontinuous coefficients, finite difference, finite volume, flow in porous media

1. Introduction. Let f and g be continuous functions on an interval $I \subset \mathbb{R}$, and define the flux function $F(x,u) = H(x)f(u) + (1-H(x))g(u)$, where $H(x)$ is the Heaviside function. Let $u_0 \in L^\infty(\mathbb{R}, I)$, and consider the following scalar conservation law:

$$\begin{aligned} &\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} F(x,u) = 0 \quad \text{for} \quad x \in \mathbb{R}, \quad t > 0, \\ &u(x,0) = u_0(x), \quad x \in \mathbb{R}. \end{aligned} \tag{1.1}$$

This type of problem appears, for example, in modelling two-phase flow in a porous medium [8, 13], in sedimentation problems [7, 5], and in traffic flow [24].

It is well known that after a finite time (1.1) does not in general possess a continuous solution even if u_0 is sufficiently smooth. Hence by a solution of (1.1) we mean a solution in the weak sense. That is, $u \in L^\infty_{\text{loc}}(\mathbb{R} \times \mathbb{R}_+)$ such that for all $\varphi \in C_0^\infty(\mathbb{R} \times \overline{\mathbb{R}}_+)$

$$\int_{-\infty}^{\infty} \int_0^{\infty} \left(u \frac{\partial \varphi}{\partial t} + F(x,u) \frac{\partial \varphi}{\partial x} \right) dt dx + \int_{-\infty}^{\infty} u_0(x) \varphi(x,0) dx = 0\,. \tag{1.2}$$

Denoting $u_t = \frac{\partial u}{\partial t}$, $u_x = \frac{\partial u}{\partial x}$, then u satisfies (1.2) if and only if in the weak sense u satisfies

$$\begin{aligned} u_t + g(u)_x &= 0, \quad x < 0, \quad t > 0, \\ u_t + f(u)_x &= 0, \quad x > 0, \quad t > 0, \end{aligned} \tag{1.3}$$

and, at $x = 0$, u satisfies the Rankine–Hugoniot condition; namely, for almost all t,

$$f(u^+(t)) = g(u^-(t)), \tag{1.4}$$

where $u^+(t) = \lim_{x \to 0^+} u(x,t), \quad u^-(t) = \lim_{x \to 0^-} u(x,t)\,.$

Because of the discontinuity of the flux F at $x = 0$, the Kruzkov method [19] does not guarantee a weak solution of (1.1), and, even if the solution exists, it may not be unique.

When there is no discontinuity of F at $x = 0$, that is, when $f \equiv g$, the problem has been studied and well understood. In this case, existence of a weak solution was obtained by Kruzkov [19] in the class of functions satisfying the Lax–Oleinik entropy condition [21, 25]. The solution thus obtained can be represented by an L^1-contractive semigroup [18, 19]. The method adopted in this case is that of vanishing viscosity. Furthermore, finite difference schemes are constructed using a numerical flux based on exact or approximate Riemann solvers such as Lax–Friedrich, Godunov, Engquist–Osher, upstream mobility, etc.... Convergence of these schemes is based on the following properties: conservation, consistency, monotonicity, and Lipschitz continuity. Using these properties, one obtains that the finite difference schemes are TVD (total variation diminishing) and satisfy the maximum principle and a numerical entropy condition. This allows one to pass to a limit to obtain a unique weak solution satisfying the Lax–Oleinik entropy condition.

When $f \neq g$, this problem was considered from the theoretical or numerical point of view in several papers [3, 20, 8, 13, 6, 5, 15, 1, 28, 29]. In general, the solution to (1.2) is not unique. To choose a correct solution, in [8] it was suggested to choose a solution which has $|u^+(t) - u^-(t)|$ minimum, but the problem of uniqueness was left open in the case of a general Cauchy problem. Nevertheless, this led to the construction of a numerical flux which was actually the same as the one used in [3, 14]. It turns out that the solution to the Riemann problem and the flux function given in [8] and the numerical scheme given in [3, 14, 28, 29] are correct when assuming that the flux functions f and g are not intersecting, even though this was not stated explicitly. Actually, they may intersect but in such a way that no undercompressive waves are produced, which is not the case when $f' > 0,\ g' < 0$ at the intersection point. It should be noted that in [28, 29] at the intersection points derivatives of fluxes f and g have the same sign. At an intersection point, if the derivative of g is negative and that of f is positive, then the problem becomes more difficult. Later, in [6, 7, 5] the problem was studied in the general case with a source term, and it was suggested to choose a solution with a minimal variation in the x-direction. For this purpose a condition called the Γ-condition was introduced, an explicit formula was given for a solution to the Riemann problem, and uniqueness was proved. Diehl's construction allows undercompressive waves; hence it is not clear that the solution thus obtained can be represented by an L^1-contractive semigroup.

In [15] it was shown that the solution to the Riemann problem with the numerical flux built upon it in [3, 8, 13] was not correct when the flux functions f and g intersect in the undercompressive case, and a correct solution was given for this case. Independently, in [1], the authors asked themselves the following question: "What is an appropriate condition on $x = 0$ so that the solution can be represented by an L^1-contractive semigroup?" Assuming that f and g are strictly convex with superlinear growth, using the Hamilton–Jacobi theory, they constructed an explicit weak solution satisfying an explicit interface entropy condition at $x = 0$, different from the Lax–Oleinik entropy condition satisfied for $x \neq 0$. This interface entropy condition means that it does not allow the undercompressive waves. Furthermore, it was shown that this solution is unique by proving that the solution can be represented by an L^1-contractive semigroup. The solution to the Riemann problem thus obtained is actually the same as in [15], though written in a more compact form. This leads to a very simple

way of calculating the interface flux and to derive its main properties: monotonicity and Lipschitz continuity. One should also note that the solution to the Riemann problem does not satisfy the maximum principle nor is it TVD.

Finally, we mention two papers which recently appeared and also investigate the problem of a nonlinear conservation law with a discontinuous flux function [17, 16].

In this paper, we consider the general case which includes the case where the flux functions are intersecting. Using the solution to the Riemann problem obtain in [15, 1] and the corresponding numerical flux, we study the resulting finite difference scheme and prove its convergence. In section 2 we present the continuous problem, defining in particular an interface entropy condition at $x = 0$, and we state an existence and uniqueness theorem for the solution to the continuous problem. In section 3 we present a Godunov-type method to calculate this solution, and in section 4, the core of this paper, we prove convergence of this numerical scheme. This scheme is conservative and monotone but not consistent in the usual sense. Due to the nonconsistency, it does not satisfy the maximum principle. In spite of this we show that the scheme is L^∞-bounded and L^1-stable. Furthermore, using the singular mapping technique introduced by Temple [27], we show that the scheme converges pointwise to weak solutions. These weak solutions satisfy the Lax–Oleinik entropy condition for $x \neq 0$ and the interface entropy condition at $x = 0$. This ensures the uniqueness of the limit solutions.

In section 5 we study the case of two-phase flow in porous media and introduce the alternative of the upstream mobility numerical flux [2]. One-dimensional numerical experiments are presented in section 6, and a comparison is made between these two numerical fluxes.

A consequence of the convergence theorem proved in section 4 is an existence theorem for the continuous problem for a larger class of functions f and g than the one studied in [1], where they were assumed to be convex. Uniqueness is shown in the appendix by proving that the solutions to the continuous problem form an L^1-contractive semigroup.

2. The continuous problem. Let $s < S$ denote the endpoints of the interval of the definition of f and g. In the following we will assume that f and g are smooth functions with the same endpoints and each one with one global minimum, reached at θ_f and θ_g, respectively, and with no other local minimum (see Figure 1).

Hypotheses. Assume that f, g are Lipschitz continuous functions on $[s, S]$ satisfying

(H_1) $f(s) = g(s), \quad f(S) = g(S),$

(H_2) f and g have one global minimum and no other local minimum in $[s, S]$.

Denote by Lip (f) and Lip (g) the Lipschitz constants of f and g. We will need also the constant

$$M = \max\{\text{Lip}\,(f), \text{Lip}\,(g)\}.$$

In order to state an existence and uniqueness theorem for the continuous problem we need to define regular solutions and entropy conditions. Since the flux function is not continuous, there are actually two different entropy conditions, one in the interior (which is the same as the usual Lax–Oleinik entropy condition) and the other at the interface which was introduced in [1].

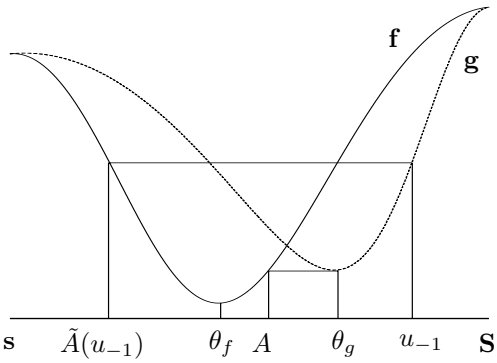

FIG. 1. *Flux functions f and g satisfying hypothesis* (H_2).

Entropy pairs. For $i = 1, 2, (\varphi_i, \psi_i)$ are said to be entropy pairs if φ_i is a convex function on $[s, S]$ and $(\psi_1'(\theta), \psi_2'(\theta)) = (\varphi_1'(\theta) f'(\theta), \varphi_2'(\theta) g'(\theta))$ for $\theta \in [s, S]$.

Let $u_0 \in L^\infty(\mathbb{R})$ be the initial data with $s \le u_0(x) \le S$ for all $x \in \mathbb{R}$, and let u be a weak solution of (1.2) with $s \le u(x,t) \le S$ for all $(x,t) \in \mathbb{R} \times \mathbb{R}_+$.

Interior entropy condition. With u_0 and u as above, u is said to satisfy an interior entropy condition if for any entropy pairs $(\varphi_i, \psi_i), i = 1, 2,$ u satisfies in the sense of distributions

$$\begin{aligned} \frac{\partial \varphi_1(u)}{\partial t} + \frac{\partial \psi_1(u)}{\partial x} &\le 0 \text{ in } x > 0, \quad t > 0, \\ \frac{\partial \varphi_2(u)}{\partial t} + \frac{\partial \psi_2(u)}{\partial x} &\le 0 \text{ in } x < 0, \quad t > 0. \end{aligned} \tag{2.1}$$

Interface entropy condition. With u_0 and u as above, assume that $u^+(t) = \lim_{x \to 0^+} u(x,t)$ and $u^-(t) = \lim_{x \to 0^-} u(x,t)$ exist for almost all $t > 0$, and define

$$L = \left\{ t > 0;\ u^+(t) \in (\theta_f, S], u^-(t) \in [s, \theta_g) \right\},$$
$$U = \left\{ t \in L;\ u^+(t) = u^-(t) = S \right\} \cup \left\{ t \in L;\ u^-(t) = u^+(t) = s \right\}.$$

Then u is said to satisfy the interface entropy condition if

$$\text{meas } \{L \setminus U\} = 0\,. \tag{2.2}$$

This means that the characteristics must connect back to the x-axis on at least one side of the jump in F; i.e., undercompressive waves are not allowed.

Regular solution. u is said to be a regular solution of (1.2) if the discontinuities of u form a discrete set of Lipschitz curves.

We need also an estimator $N(f, g, u_0)$ of the total variation of the flux function evaluated at u_0. This estimator will be defined precisely below at (3.5).

We can now state our existence and uniqueness theorem for the continuous problem.

THEOREM 2.1. *Let $u_0 \in L^\infty(\mathbb{R})$ such that $s \le u_0(x) \le S$ for all $x \in \mathbb{R}$ and $N_h(f, g, u_0) < \infty$. Then there exists a weak solution $u \in L^\infty(\mathbb{R} \times \mathbb{R}_+)$ of* (1.2) *satisfying the following:*

(i) *For almost all $t > 0$ and $x \in \mathbb{R}$, $u(x+, t), u(x-, t)$ exist.*

(ii) *u satisfies the interior entropy condition* (2.1).

(iii) *If u is regular, then it satisfies also the interface entropy condition* (2.2) *and it is unique. Moreover, if $f = g$, then u is the unique entropy solution for the initial value problem studied in* [19].

An existence and uniqueness theorem was proved in [1] for convex functions f and g using arguments from the Hamilton–Jacobi theory. However, functions satisfying hypotheses (H_1) and (H_2) are not necessarily convex, as shown Figure 1, and a consequence of the convergence theorem, Theorem 3.2, proved below is that existence in Theorem 2.1 is valid for such functions. Uniqueness follows by showing that the solutions form an L^1-contractive family, which is done in the appendix.

We remark that a similar analysis to what is done in this paper for f and g satisfying hypothesis (H_2) can be done for the case where f and g satisfy hypothesis (H_3) instead:

(H_3) f and g have one global maximum and no other local maximum in $[s, S]$,

as shown in Figure 2. θ_f and θ_g would denote the points at which the maxima of f and g are reached. In the analysis below only the case where f and g satisfy (H_2) will be considered.

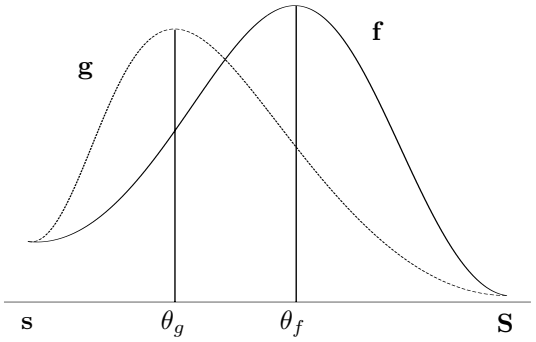

FIG. 2. *Flux functions f and g satisfying hypothesis* (H_3).

3. A Godunov-type finite volume method. Let F be the Godunov numerical flux with respect to f:

$$F(a,b) = \begin{cases} \min\limits_{\theta\in[a,b]} f(\theta) & \text{if} \quad a < b, \\ \max\limits_{\theta\in[b,a]} f(\theta) & \text{if} \quad a \geq b, \end{cases} \tag{3.1}$$

and similarly for the numerical flux G with respect to g.

Taking advantage of hypothesis (H_2), equivalent formulas can be used [1]:

$$\begin{aligned} F(a,b) &= \max\{F(a,S),\ F(s,b)\} = \max\{F(a,\theta_f),\ F(\theta_f,b)\} \\ &= \max\{f(\theta_f)(1-H(a_1)) + f(a)H(a_1), f(\theta_f)H(a_1) + f(b)(1-H(a_1))\} \\ &= \max\{f(\max\{a,\theta_f\}), f(\min\{\theta_f,b\})\}, \end{aligned}$$

where $a_1 = (a-\theta_f)$ and H is the Heaviside function. Note that the last two expressions are much simpler to use in calculations than formula (3.1).

In the case where f satisfies hypothesis (H_3) instead, the equivalent formulas are

$$\begin{aligned} F(a,b) &= \min\{F(a,s),\ F(S,b)\} = \min\{F(a,\theta_f),\ F(\theta_f,b)\} \\ &= \min\{f(\theta_f)H(a_1) + f(a)(1-H(a_1)), f(\theta_f)(1-H(a_1)) + f(b)H(a_1)\} \\ &= \min\{f(\min\{a,\theta_f\}), f(\max\{\theta_f,b\})\}. \end{aligned}$$

Interface flux $\overline{F}$. At the point $x = 0$ where the flux function changes we introduce the numerical flux $\overline{F}$ calculated by using the Riemann problem solution given in [1]:

$$\begin{aligned}\overline{F}(a,b) &= \max\{G(a,S),\ F(s,b)\} = \max\{G(a,\theta_g),\ F(\theta_f,b)\}\\ &= \max\{g(\theta_g)(1-H(a_1)) + g(a)H(a_1),\\ &\qquad\qquad f(\theta_f)H(b_1) + f(b)(1-H(b_1))\}\\ &= \max\{g(\max\{a,\theta_g\}), f(\min\{\theta_f,b\})\},\end{aligned} \tag{3.2}$$

where $a_1 = (a-\theta_g), b_1 = (b-\theta_f)$.

These four expressions of $\overline{F}$ are equivalent, but only the last two are useful for computational purposes. This flux $\overline{F}$ coincides with the one given in [15]. When f and g do not intersect this numerical flux reduces to the one given in [3, 9, 13, 6].

Remark 3.1. In the case where f and g satisfy hypothesis (H_3) the definition of the interface flux should be

$$\begin{aligned}\overline{F}(a,b) &= \min\{G(a,s),\ F(S,b)\} = \min\{G(a,\theta_g),\ F(\theta_f,b)\}\\ &= \min\{g(\theta_g)H(a_1) + g(a)(1-H(a_1)),\\ &\qquad\qquad f(\theta_f)(1-H(b_1)) + f(b)H(b_1)\}\\ &= \min\{g(\min\{a,\theta_g\}), f(\max\{\theta_f,b\})\},\end{aligned} \tag{3.3}$$

where θ_f and θ_g are now the maxima of f and g.

Let $h > 0$ and define the space grid points as follows:

$$x_{-1/2} = x_{1/2} = 0, \quad x_{j+1/2} = j\,h \quad \text{for } j \geq 0, \quad x_{j-1/2} = jh \quad \text{for } j \leq 0.$$

We will also use the midpoints of the intervals:

$$x_j = \left(\frac{2j-1}{2}\right)h \quad \text{for } j \geq 1, \quad x_j = \left(\frac{2j+1}{2}\right)h \quad \text{for } j \leq -1.$$

For time discretization the time step is $\Delta t > 0$, and let $t_n = n\Delta t,\ \lambda = \frac{\Delta t}{h}$.

For an initial data $u_0 \in L^\infty(\mathbb{R})$ we define

$$u^0_{j+1} = \frac{1}{h}\int_{x_{j+1/2}}^{x_{j+3/2}} u_0(x)dx \quad \text{if} \quad j \geq 0, \quad u^0_{j-1} = \frac{1}{h}\int_{x_{j-3/2}}^{x_{j-1/2}} u_0(x)dx \quad \text{if} \quad j \leq 0,$$

$$\begin{aligned}N_h(f,g,u_0) = &\sum_{i<-1} |G(u^0_i, u^0_{i+1}) - G(u^0_{i-1}, u^0_i)| + \sum_{i>1} |F(u^0_i, u^0_{i+1}) - F(u^0_{i-1}, u^0_i)|\\ &+|\overline{F}(u^0_{-1}, u^0_1) - G(u^0_{-2}, u^0_{-1})| + |F(u^0_1, u^0_2) - \overline{F}(u^0_{-1}, u^0_1)|,\end{aligned} \tag{3.4}$$

$$N(f,g,u_0) = \sup_{h>0} N_h(f,g,u_0). \tag{3.5}$$

It is easy to see that if $u_0 \in BV(\mathbb{R})$, then $N(f,g,u_0) \leq C||u_0||_{BV}$, where C is a constant depending only on the Lipschitz constants of f and g.

Now we can define the explicit finite volume scheme $\{u^n_i\}$ inductively as follows:

$$\begin{aligned}u^{n+1}_1 &= u^n_1 - \lambda(F(u^n_1, u^n_2) - \overline{F}(u^n_{-1}, u^n_1)),\\ u^{n+1}_i &= u^n_1 - \lambda(F(u^n_i, u^n_{i+1}) - F(u^n_{i-1}, u^n_i)) \quad \text{if } i > 1,\\ u^{n+1}_{-1} &= u^n_{-1} - \lambda(\overline{F}(u^n_{-1}, u^n_1) - G(u^n_{-2}, u^n_{-1})),\\ u^{n+1}_i &= u^n_i - \lambda(G(u^n_i, u^n_{i+1}) - G(u^n_{i-1}, u^n_i)) \quad \text{if} \quad i < -1.\end{aligned} \tag{3.6}$$

Observe that this is, a Godunov scheme for $i \neq \pm 1$, that is, away from $x = 0$, and that for $i = \pm 1$ the scheme is not consistent; that is, in general $\overline{F}(u, u)$ need not be equal to $f(u)$ or $g(u)$. Because of this, the maximum principle does not hold.

For $u_0 \in L^\infty(\mathbb{R})$ and grid length h and Δt with $\lambda = \frac{\Delta t}{h}$ fixed, define the function $u_h \in L^\infty(\mathbb{R} \times \mathbb{R}_+)$ associated with $\{u_i^n\}$ calculated by the scheme (3.6):

$$u_h(x,t) = u_i^n \quad \text{for } (x,t) \in [x_{i-1/2}, x_{i+1/2}) \times [n\Delta t,\ (n+1)\Delta t), \quad i \neq 0. \tag{3.7}$$

Now we can state the following convergence theorem.

THEOREM 3.2. *Assume that λ, M satisfies the CFL condition $\lambda M \leq 1$. Let $u_0 \in L^\infty(\mathbb{R})$ such that $s \leq u_0(x) \leq S$ for all $x \in \mathbb{R}$ and $N(f, g, u_0) < \infty$. For $h > 0$, let $\lambda = \frac{\Delta t}{h}$ and u_h be the corresponding calculated solution given by* (3.6), (3.7). *Then there exists a subsequence $h_k \to 0$ such that u_{h_k} converges a.e. to a weak solution u of* (1.2) *satisfying interior entropy condition* (2.1). *Suppose the discontinuities of every limit function u of $\{u_h\}$ is a discrete set of Lipschitz curves; then $u_h \to u$ in $L^\infty_{loc}(\mathbb{R}_+, L^1_{loc}(\mathbb{R}))$ as $h \to 0$, and u satisfies the interface entropy condition* (2.2).

The proof of this theorem is the object of the next section.

Remark 3.3. The CFL condition still reads $\lambda M \leq 1$ in the case of a discontinuous flux function.

4. Proof of the convergence theorem, Theorem 3.2.

4.1. Properties of the numerical flux. Before going into the details of the proof, we need to study the properties of the numerical flux F, G, and $\overline{F}$.

From definitions (3.1), (3.2), $F, G, \overline{F}$, are nondecreasing functions in the first variable and nonincreasing functions in the second variable. Furthermore, the functions F, G, and $\overline{F}$ satisfy for any $a, a_1, a_2, b, b_1, b_2 \in [s, S]$

$$\begin{array}{rcl} (|F(a_1,b) - F(a_2,b)|,\ |F(a,b_1) - F(a,b_2)|) & \leq & M(|a_1 - a_2|,\ |b_1 - b_2|), \\ (|G(a_1,b) - G(a_2,b)|,\ |G(a,b_1) - G(a,b_2)|) & \leq & M(|a_1 - a_2|,\ |b_1 - b_2|), \\ (|\overline{F}(a_1,b) - \overline{F}(a_2,b)|,\ |\overline{F}(a,b_1) - \overline{F}(a,b_2)|) & \leq & M(|a_1 - a_2|,\ |b_1 - b_2|). \end{array} \tag{4.1}$$

The following lemma is easy to prove.

LEMMA 4.1. *Let f and g satisfy* (H_1) *and* (H_2). *Then $\overline{F}$ satisfies*

$$\begin{array}{rcl} \overline{F}(s,s) & = & f(s) = g(s), \quad \overline{F}(S,S) = f(S) = g(S), \\ \overline{F}(a,b) & = & F(a,b) \quad \text{if} \quad f \equiv g\,. \end{array}$$

Now we define for $X, Y, Z \in [s, S]$

$$\begin{array}{rcl} H_{-2}(X,Y,Z) & = & Y - \lambda(\overline{F}(Y,Z) - G(X,Y)), \\ H_{-1}(X,Y,Z) & = & Y - \lambda(G(Y,Z) - G(X,Y)), \\ H_1(X,Y,Z) & = & Y - \lambda(F(Y,Z) - F(X,Y)), \\ H_2(X,Y,Z) & = & Y - \lambda(F(Y,Z) - \overline{F}(X,Y)). \end{array}$$

Then we have the following lemma.

LEMMA 4.2. *Let $\lambda M \leq 1$ and $a \in [s, S]$; then we have the following:*

(i) $H_{\pm_1}(a,a,a) = a$, *and* $H_{\pm_2}(s,s,s) = s, H_{\pm_2}(S,S,S) = S$.

(ii) H_i *is nondecreasing in each of its variables.*

(iii) *Let* $\{T_i\}_{i\in z\setminus\{0\}}$ *be a sequence in* $[s,S]$, *and define* $P_i=(T_{i-1},T_i,T_{i+1})$ *if* $|i|\geq 2$, $P_1=(T_{-1},T_1,T_2)$, *and* $P_{-1}=(T_{-2},T_{-1},T_1)$. *Then for* $|i|\geq 3$,

$$\begin{aligned}
\frac{\partial H_1}{\partial X}(P_{i+1}) &+ \frac{\partial H_1}{\partial Y}(P_i) &+ \frac{\partial H_1}{\partial Z}(P_{i-1}) &= 1,\\
\frac{\partial H_{-1}}{\partial X}(P_{i+1}) &+ \frac{\partial H_{-1}}{\partial Y}(P_i) &+ \frac{\partial H_{-1}}{\partial Z}(P_{i-1}) &= 1,\\
\frac{\partial H_1}{\partial X}(P_3) &+ \frac{\partial H_1}{\partial Y}(P_2) &+ \frac{\partial H_2}{\partial Z}(P_1) &= 1,\\
\frac{\partial H_{-2}}{\partial X}(P_{-1}) &+ \frac{\partial H_{-1}}{\partial Y}(P_{-2}) &+ \frac{\partial H_{-1}}{\partial Z}(P_{-3}) &= 1,\\
\frac{\partial H_2}{\partial X}(P_1) &+ \frac{\partial H_{-2}}{\partial Y}(P_{-1}) &+ \frac{\partial H_{-1}}{\partial Z}(P_{-2}) &= 1,\\
\frac{\partial H_1}{\partial X}(P_2) &+ \frac{\partial H_2}{\partial Y}(P_1) &+ \frac{\partial H_{-2}}{\partial Z}(P_{-1}) &= 1.
\end{aligned}$$

Proof. From Lemma 4.1, $\overline{F}(s,s)=f(s)=g(s)$, $\overline{F}(S,S)=f(S)=g(S)$, and for all $a\in[s,S]$, $F(a,a)=f(a), G(a,a)=g(a)$. Hence $H_{\pm1}(a,a,a)=a, H_{\pm2}(s,s,s)=s, H_{\pm2}(S,S,S)=S$. This proves (i). By symmetry it is enough to prove (ii) for H_2. Let (X,Y,Z), $X_1\leq X_2, Y_1\leq Y_2, Z_1\leq Z_2$, be given. Then

$$H_2(X_1,Y,Z)-H_2(X_2,Y,Z)=\lambda(\overline{F}(X_1,Y)-\overline{F}(X_2,Y))\leq 0.$$

Without loss of generality we can assume that $g(\theta_g)=\min g\geq \min f=f(\theta_f)$. For $X\geq\theta_g, Z\leq\theta_f$, define $\tilde{A}(X)\leq\theta_f$ and $\tilde{B}(Z)\geq\theta_f$ by $f(\tilde{A}(X))=g(X)$ and $f(Z)=f(\tilde{B}(Z))$. Then we have by direct calculations

$$I_1=F(Y_1,Z)-F(Y_2,Z)=\begin{cases}
f(\tilde{B}(Z))-f(Y_2) & \text{if } Z\leq\theta_f, \quad Y_1\leq\tilde{B}(Z)\leq Y_2,\\
f(Y_1)-f(Y_2) & \text{if } Z\leq\theta_f, \quad Y_1\geq\tilde{B}(Z)\\
 & \text{or } Z\geq\theta_f, \quad Y_1\geq\theta_f,\\
f(\theta_f)-f(Y_2) & \text{if } Z\geq\theta_f, \quad Y_1\leq\theta_f\leq Y_2,\\
0 & \text{otherwise,}
\end{cases}$$

$$I_2=\overline{F}(X,Y_1)-\overline{F}(X,Y_2)=\begin{cases}
f(Y_1)-f(\min(Y_2,\tilde{A}(X))) & \text{if } X\geq\theta_g, \quad Y_1\leq\tilde{A}(X),\\
f(Y_1)-f(\min(Y_2,\tilde{A}(\theta_g))) & \text{if } X\leq\theta_g, \quad Y_1\leq\tilde{A}(\theta_g),\\
0 & \text{otherwise.}
\end{cases}$$

Let $I=-\lambda(I_1-I_2)$. Then from the above calculation, $I=-\lambda I_1$ if $Y_1\geq\theta_f$ and $I=\lambda I_2$ if $Y_2\leq\theta_f$. In either case we have $|I|\leq\lambda M|Y_1-Y_2|$. Now suppose that $Y_1\leq\theta_f\leq Y_2$; then we have

$$|I|\leq(|I_1|+|I_2|)\leq\lambda M(|Y_2-\theta_f|+|Y_1-\tilde{A}(\theta_g)|)=\lambda M|Y_1-Y_2|.$$

Hence, since F and $\overline{F}$ are nondecreasing in the first variable and nonincreasing in the second variable, we obtain

$$\begin{aligned}
H_2(X,Y_1,Z)-H_2(X,Y_2,Z) &= Y_1-Y_2-\lambda(F(Y_1,Z)-F(Y_2,Z))\\
&\quad +\lambda(\overline{F}(X,Y_1)-\overline{F}(X,Y_2))\\
&= Y_1-Y_2-\lambda(I_1-I_2)\leq Y_1-Y_2+\lambda M|Y_1-Y_2|\\
&\leq (1-\lambda M)(Y_1-Y_2)\leq 0,\\
H_2(X,Y,Z_1)-H_2(X,Y,Z_2) &= -\lambda(F(Y,Z_1)-F(Y,Z_2))\ \leq\ 0.
\end{aligned}$$

This proves (ii).

Let $i \geq 3$; then

$$\frac{\partial H_1}{\partial X}(P_{i+1}) + \frac{\partial H_1}{\partial Y}(P_i) + \frac{\partial H_1}{\partial Z}(P_{i-1}) = \lambda \frac{\partial F}{\partial a}(T_i, T_{i+1}) + 1 - \lambda \left(\frac{\partial F}{\partial a}(T_i, T_{i+1}) - \frac{\partial F}{\partial b}(T_{i-1}, T_i) \right) - \lambda \frac{\partial F}{\partial b}(T_{i-1}, T_i) = 1.$$

This proves the first equality in (iii). The proof is similar for the second equality in (iii). For the third, fourth, fifth, and sixth equalities we have

$$\begin{aligned}
&\frac{\partial H_1}{\partial X}(P_3) + \frac{\partial H_1}{\partial Y}(P_2) + \frac{\partial H_2}{\partial Z}(P_1) = \lambda \frac{\partial F}{\partial a}(T_2, T_3) + 1 \\
&\qquad -\lambda \left(\frac{\partial F}{\partial a}(T_2, T_3) - \frac{\partial F}{\partial b}(T_1, T_2) \right) - \lambda \frac{\partial F}{\partial b}(T_1, T_2) \;=\; 1, \\
&\frac{\partial H_{-2}}{\partial X}(P_{-1}) + \frac{\partial H_{-1}}{\partial Y}(P_{-2}) + \frac{\partial H_{-1}}{\partial Z}(P_3) = \lambda \frac{\partial G}{\partial a}(T_{-2}, T_{-1}) + 1 \\
&\qquad -\lambda \left(\frac{\partial G}{\partial a}(T_{-2}, T_{-1}) - \frac{\partial G}{\partial b}(T_{-3}, T_{-2}) \right) - \lambda \frac{\partial G}{\partial b}(T_{-3}, T_{-2}) \;=\; 1, \\
&\frac{\partial H_2}{\partial X}(P_1) + \frac{\partial H_{-2}}{\partial Y}(P_{-1}) + \frac{\partial H_{-1}}{\partial Z}(P_{-2}) = \lambda \frac{\partial \overline{F}}{\partial a}(T_{-1}, T_1) + 1 \\
&\qquad -\lambda \left(\frac{\partial \overline{F}}{\partial a}(T_{-1}, T_1) - \frac{\partial G}{\partial b}(T_{-2}, T_{-1}) \right) - \lambda \frac{\partial G}{\partial b}(T_{-2}, T_{-1}) \;=\; 1, \\
&\frac{\partial H_1}{\partial X}(P_2) + \frac{\partial H_2}{\partial Y}(P_1) + \frac{\partial H_{-2}}{\partial Z}(P_{-1}) = \lambda \frac{\partial F}{\partial a}(T_1, T_2) + 1 \\
&\qquad -\lambda \left(\frac{\partial F}{\partial a}(T_1, T_2) - \frac{\partial \overline{F}}{\partial b}(T_{-1}, T_1) \right) - \lambda \frac{\partial \overline{F}}{\partial b}(T_{-1}, T_1) \;=\; 1.
\end{aligned}$$

This completes the proof of Lemma 4.2.

4.2. L^∞ and TV bounds. The next lemmas show that the scheme (3.6) is L^1-contractive and the idea of the proof is taken from [11].

LEMMA 4.3. *Let $u_0 \in L^\infty(\mathbb{R}, [s, S])$ be the initial data, and let $\{u_i^n\}$ be the corresponding solution calculated by the finite volume scheme* (3.6)*. When $\lambda M \leq 1$, then*

$$s \leq u_i^n \leq S \quad \forall i, n. \tag{4.2}$$

Proof. Since $s \leq u_0 \leq S$, hence for all i, $s \leq u_i^0 \leq S$. By induction, assume that (4.2) holds for n. Then from (i) and (ii) of Lemma 4.2 we have

$$\begin{aligned}
s &= H_{-1}(s,s,s) \leq H_{-1}(u_{i-1}^n, u_i^n, u_{i+1}^n) = u_1^{n+1} \leq H_{-1}(S,S,S) = S \text{ if } i \leq -2, \\
s &= H_1(s,s,s) \leq H_1(u_{i-1}^n, u_i^n, u_{i+1}^n) = u_i^{n+1} \leq H_1(S,S,S) = S \quad \text{if } i \geq 2, \\
s &= H_{-2}(s,s,s) \leq H_{-2}(u_{-2}^n, u_{-1}^n, u_1^n) = u_{-1}^{n+1} \leq H_{-2}(S,S,S) = S, \\
s &= H_2(s,s,s) \leq H_2(u_{-1}^n, u_1^n, u_2^n) = u_1^{n+1} \leq H_2(S,S,S) = S.
\end{aligned}$$

This proves (4.2).

LEMMA 4.4. *Let $u_0, v_0 \in L^\infty(\mathbb{R},\ [s, S])$ be initial datas, and let $\{u_i^n\}$ and $\{v_i^n\}$ be the corresponding solutions calculated by the finite volume scheme* (3.6)*. Let $\lambda M \leq 1$*

and $i_0 \le j_0$; then

$$\begin{aligned}
\sum_{\substack{i_0 \le i \le j_0 \\ i \neq 0}} |u_i^{n+1} - v_i^{n+1}| &\le \sum_{\substack{i_0 - 1 \le i \le j_0 + 1 \\ i \neq 0}} |u_i^n - v_i^n|, \\
\sum_{i \neq 0} |u_i^{n+1} - u_i^n| &\le \sum_{i \neq 0} |u_i^n - u_i^{n-1}|.
\end{aligned}$$

Lemma 4.4 is a localized version of the Crandall–Tartar lemma [4], which we will prove along the lines of [11].

Proof. The first inequality in Lemma 4.4 will be proved for $i_0 \le -1$ and $j_0 \ge 1$. The other cases follow in the same manner. For $\theta \in [0,1]$, let $p_i^n(\theta) = \theta u_i^n + (1-\theta) v_i^n$ and

$$P_i^n(\theta) = \begin{cases} (p_{i-1}^n(\theta),\ p_i^n(\theta), p_{i+1}^n(\theta)) & \text{if} \quad |i| \ge 2, \\ (p_{-2}^n(\theta),\ p_{-1}^n(\theta), p_1^n(\theta)) & \text{if} \quad i = -1, \\ (p_{-1}^n(\theta),\ p_1^n(\theta),\ p_2^n(\theta)) & \text{if} \quad i = 1. \end{cases}$$

From Lemma 4.3 we have $p_i^n(\theta) \in [s, S]$ for all i, n, and θ. From their definitions, the H_i's are uniformly continuous functions, and from (ii) in Lemma 4.2 a.e. (X, Y, Z), $\frac{\partial H_i}{\partial X} \ge 0$, $\frac{\partial H_i}{\partial Y} \ge 0$, $\frac{\partial H_i}{\partial Z} \ge 0$. Hence from the mean value theorem

$$\begin{aligned}
\sum_{i_0}^{-2} |u_i^{n+1} - v_i^{n+1}| &= \sum_{i_0}^{-2} |H_{-1}(u_{i-1}^n, u_i^n, u_{i+1}^n) - H_{-1}(v_{i-1}^n, v_i^n, v_{i+1}^n)| \\
&\le \sum_{i_0}^{-2} |u_{i-1}^n - v_{i-1}^n| \int_0^1 \frac{\partial H_{-1}}{\partial X}(P_i^n(\theta)) d\theta \\
&+ \sum_{i_0}^{-2} |u_i^n - v_i^n| \int_0^1 \frac{\partial H_{-1}}{\partial Y}(P_i^n(\theta)) d\theta + |u_{i+1}^n - v_{i+1}^n| \int_0^1 \frac{\partial H_{-1}}{\partial Z}(P_i^n(\theta)) d\theta \\
&= |u_{i_0-1}^n - v_{i_0-1}^n| \int_0^1 \frac{\partial H_{-1}}{\partial X}(P_{i_0}^n(\theta)) d\theta \\
&+ \sum_{i_0}^{-3} |u_i^n - v_i^n| \int_0^1 \left(\frac{\partial H_{-1}}{\partial X}(P_{i+1}^n(\theta)) + \frac{\partial H_{-1}}{\partial Y}(P_i^n(\theta)) + \frac{\partial H_{-1}}{\partial Z}(P_{i-1}^n(\theta)) \right) d\theta \\
&+ |u_{-2}^n - v_{-2}^n| \int_0^1 \left(\frac{\partial H_{-1}}{\partial Y}(P_{-2}^n(\theta)) + \frac{\partial H_{-1}}{\partial Z}(P_{-3}^n(\theta)) \right) d\theta \\
&+ |u_{-1}^n - v_{-1}^n| \int_0^1 \frac{\partial H_{-1}}{\partial Z}(P_{-2}^n(\theta)) d\theta.
\end{aligned}$$

Now $\frac{\partial H_{-1}}{\partial X}(X, Y, Z) = \lambda \frac{\partial G}{\partial a}(X, Y) \le \lambda M \le 1$, and from the second equality of (iii) in Lemma 4.2 we obtain

$$\begin{aligned}
\sum_{i_0}^{-2} |u_i^{n+1} - v_i^{n+1}| \le \sum_{i_0 - 1}^{-3} |u_i^n - v_i^n| &+ |u_{-1}^n - v_{-1}^n| \int_0^1 \frac{\partial H_{-1}}{\partial Z}(P_{-2}^n(\theta)) d\theta \\
&+ |u_{-2}^n - v_{-2}^n| \int_0^1 \left(\frac{\partial H_{-1}}{\partial Y}(P_{-2}^n(\theta)) + \frac{\partial H_{-1}}{\partial Z}(P_{-3}^n(\theta)) \right) d\theta.
\end{aligned}$$

Since $\frac{\partial H_1}{\partial Z} = -\lambda \frac{\partial F}{\partial b} \le \lambda M \le 1$, the following inequalities result from the first equality

of (iii) in Lemma 4.2:

$$\begin{aligned}\sum_{2}^{j_0}|u_i^{n+1}-v_i^{n+1}| &\leq \sum_{3}^{j_0+1}|u_i^n-v_i^n|+|u_1^n-v_1^n|\int_0^1\frac{\partial H_1}{\partial X}(P_2^n(\theta))d\theta\\ &\quad+|u_2^n-v_2^n|\int_0^1\left(\frac{\partial H_1}{\partial Y}(P_2^n(\theta))+\frac{\partial H_1}{\partial X}(P_3^n(\theta))\right)d\theta.\end{aligned}$$

Moreover,

$$\begin{aligned}&|u_{-1}^{n+1}-v_{-1}^{n+1}|+|u_1^{n+1}-v_1^{n+1}|\\ &=|H_{-2}(u_{-2}^n,u_{-1}^n,u_1^n)-H_{-2}(v_{-2}^n,v_{-1}^n,v_1^n)|+|H_2(u_{-1}^n,u_1^n,u_2^n)-H_2(v_{-1}^n,v_1^n,v_2^n)|\\ &\leq|u_{-2}^n-v_{-2}^n|\int_0^1\frac{\partial H_{-2}}{\partial X}(P_{-1}^n(\theta))d\theta+|u_{-1}^n-v_{-1}^n|\int_0^1\left(\frac{\partial H_2}{\partial X}(P_1^n(\theta))+\frac{\partial H_{-2}}{\partial Y}(P_{-1}^n(\theta))\right)d\theta\\ &\quad+|u_1^n-v_1^n|\int_0^1\left(\frac{\partial H_2}{\partial Y}(P_1^n(\theta))+\frac{\partial H_{-2}}{\partial Z}(P_{-1}^n(\theta))\right)d\theta+|u_2^n-v_2^n|\int_0^1\frac{\partial H_2}{\partial Z}(P_1^n(\theta))d\theta.\end{aligned}$$

Summing up all the above three inequalities and from the last four equalities of (iii) in Lemma 4.2 we obtain

$$\begin{aligned}\sum_{\substack{i_0\leq i\leq j_0\\ i\neq 0}}|u_i^{n+1}-v_i^{n+1}| &\leq \sum_{i_0-1}^{-3}|u_i^n-v_i^n|+\sum_{3}^{j_0+1}|u_i^n-v_i^n|\\ &\quad+|u_{-2}^n-v_{-2}^n|\int_0^1\left(\frac{\partial H_{-2}}{\partial X}(P_{-1}^n(\theta))+\frac{\partial H_{-1}}{\partial Y}(P_{-2}^n(\theta))+\frac{\partial H_{-1}}{\partial Z}(P_{-3}^n(\theta))\right)d\theta\\ &\quad+|u_{-1}^n-v_{-1}^n|\int_0^1\left(\frac{\partial H_2}{\partial X}(P_1^n(\theta))+\frac{\partial H_{-2}}{\partial Y}(P_{-1}^n(\theta))+\frac{\partial H_{-1}}{\partial Z}(P_{-2}^n(\theta))\right)d\theta\\ &\quad+|u_1^n-v_1^n|\int_0^1\left(\frac{\partial H_1}{\partial X}(P_2^n(\theta))+\frac{\partial H_2}{\partial Y}(P_1^n(\theta))+\frac{\partial H_{-2}}{\partial Z}(P_{-2}^n(\theta))\right)d\theta\\ &\quad+|u_2^n-v_2^n|\int_0^1\left(\frac{\partial H_1}{\partial X}(P_3^n(\theta))+\frac{\partial H_1}{\partial Y}(P_2^n(\theta))+\frac{\partial H_2}{\partial Z}(P_1^n(\theta))\right)d\theta\\ &=\sum_{\substack{i_0-1\leq i\leq j_0+1\\ i\neq 0}}|u_i^n-v_i^n|.\end{aligned}$$

Take the special choice of v_0 by $v_0(x)=u_i^1$ in $[x_{i-1/2},x_{i+1/2})$. Then it follows easily that $v_i^n=u_i^{n+1}$. Now substituting this in the first inequality of the lemma and taking $i_0=-\infty,\ j_0=\infty$ we obtain the second inequality. This completes the proof of Lemma 4.4.

Next we use the singular mapping technique introduced in [27, 23, 22, 28] to obtain TV bounds for the transformed scheme, and this allows us to pass to the limit as $h\to 0$.

Let $k:[s,S]\to\mathbb{R}$ be a Lipschitz continuous function satisfying (H_2), and let K be the corresponding numerical flux as in (3.1). Let θ_k denote the unique minima of k. For $A\in[s,S], a,b\in\mathbb{R},\ \{u_{j-1},u_j,u_{j+1},u_{j+2}\}\subset[s,S]$, define

$$\begin{aligned}\psi_{k,A}(u) &= \int_A^u|k'(\theta)|d\theta, & \chi_-(k'(u)) &= \begin{cases}0 & \text{if} \quad u\in(\theta_k,S],\\ 1 & \text{if} \quad u\in[s,\theta_k],\end{cases}\\ \chi(a,b) &= \begin{cases}1 & \text{if} \quad a\leq b,\\ 0 & \text{if} \quad a>b,\end{cases} & \chi_+(k'(u)) &= \begin{cases}1 & \text{if} \quad u\in[\theta_k,S],\\ 0 & \text{if} \quad u\in[s,\theta_k),\end{cases}\end{aligned}$$

and $H_{i+1/2}=K(u_i,u_{i+1})$ for $j-1\leq i\leq j+1$.

Apart from χ_-, χ_+ we will use the standard notation

$$a_+ = \max(a,0), \quad a_- = \min(a,0), \quad a = a_+ + a_-, \quad |a| = a_+ - a_-.$$

LEMMA 4.5. *With the above notation we have the following inequalities:*

$$-\chi(u_j,u_{j+1}) \int_{u_j}^{u_{j+1}} k'_-(\theta)d\theta \ \le \ \chi_-(k'(u_j))|H_{j+1/2} - H_{j-1/2}|, \tag{4.3}$$

$$\chi(u_j,u_{j+1}) \int_{u_j}^{u_{j+1}} k'_+(\theta)d\theta \le \chi_+(k'(u_{j+1}))|H_{j+3/2} - H_{j+1/2}| \tag{4.4}$$

$$-(\psi_{k,A}(u_j) - \psi_{k,A}(u_{j+1}))_- = \chi(u_j,u_{j+1}) \left\{ \int_{u_j}^{u_{j+1}} k'_+(\theta)d\theta - \int_{u_j}^{u_{j+1}} k'_-(\theta)d\theta \right\}$$

$$\le \chi_-(k'(u_j))|H_{j+1/2} - H_{j-1/2}| + \chi_+(k'(u_{j+1}))|H_{j+3/2} - H_{j+1/2}|. \tag{4.5}$$

The proof of this lemma can be found in [28, Lemma 3.3], just replacing the requirement of a single maximum by a single minimum.

Singular mappings. Let f, g satisfy the hypotheses (H_1) and (H_2). Let θ_f, θ_g be the respective minima for f and g. Define the singular mappings ψ_1, ψ_2 associated with f and g as follows.

Case 1. $f(\theta_f) \le g(\theta_g)$. Choose $A \ge \theta_f$ such that $f(A) = g(\theta_g)$ and for $u \in [s,S]$

$$\psi_1(u) = \psi_{g,\theta_g}(u) = \int_{\theta_g}^{u} |g'(\theta)|d\theta, \quad \psi_2(u) = \psi_{f,A}(u) = \int_{A}^{u} |f'(\theta)|d\theta.$$

Case 2. $f(\theta_f) \ge g(\theta_g)$. Choose $A \le \theta_g$ such that $f(\theta_f) = g(A)$ and for $u \in [s,S]$

$$\psi_1(u) = \psi_{g,A}(u) = \int_{A}^{u} |g'(\theta)|d\theta, \quad \psi_2(u) = \psi_{f,\theta_f}(u) = \int_{\theta_f}^{u} |f'(\theta)|d\theta.$$

In order to obtain TV bounds for the transformed sequence under the singular mappings, we have to estimate the error term E defined as below. This error estimate will be carried out in the next two lemmas.

For $\{u_{-2}, u_{-1}, u_1, u_2\} \subset [s,S]$, define $z_1 = \psi_2(u_1)$, $z_{-1} = \psi_1(u_{-1})$, $H_{3/2} = F(u_1,u_2)$, $H_{1/2} = H_{-1/2} = \overline{F}(u_{-1},u_1)$, $H_{-3/2} = G(u_{-2},u_{-1})$, and

$$E = -(z_{-1} - z_1)_- - \chi(u_1,u_2) \int_{u_1}^{u_2} f'_-(\theta)d\theta + \chi(u_{-2},u_{-1}) \int_{u_{-2}}^{u_{-1}} g'_+(\theta)d\theta$$
$$-|H_{-1/2} - H_{-3/2}| - |H_{3/2} - H_{1/2}|.$$

LEMMA 4.6. *With the above notation, for any sequence* $\{u_{-2}, u_{-1}, u_1, u_2\} \subset [s,S]$, *we have* $E \le 0$.

Proof. Without loss of generality we can assume that $\theta_f \le \theta_g$ and $f(\theta_f) \le g(\theta_g)$ (see Figure 1). Now $\psi_2(S) = f(S) - f(A) = g(S) - g(\theta_g) = \psi_1(S)$ and $\psi_2(s) = -(f(s) - f(\theta_f)) - (f(A) - f(\theta_f)) \le -(f(A) - f(s)) = (g(\theta_g) - g(s)) = \psi_1(s)$. Hence the range of ψ_1 is contained in the range of ψ_2. Therefore for each $u \in [s,S]$ there exists a unique $\rho(u) \in [s,S]$ such that $\psi_1(u) = \psi_2(\rho(u))$ and $u \mapsto \rho(u)$ is an increasing function since ψ_1, ψ_2 are increasing functions.

For $u_{-1} \ge \theta_g$, define $\tilde{A}(u_{-1}) \le \theta_f$ by $f(\tilde{A}(u_{-1})) = g(u_{-1})$ (see Figure 1).

Step 1. Let $u_{-1} \geq \theta_g$, $u_1 \geq \tilde{A}(u_{-1})$.
In this case it is easy to see that $H_{1/2} = H_{-1/2} = \overline{F}(u_{-1}, u_1) = g(u_{-1})$ and

$$\chi(u_{-2}, u_{-1}) \int_{u_{-2}}^{u_{-1}} g'_+(\theta) d\theta = \chi(u_{-2}, u_{-1})(g(u_{-1}) - g(\max(\theta_g, u_{-2}))),$$
$$|H_{-1/2} - H_{-3/2}| = |\overline{F}(u_{-1}, u_1) - G(u_{-2}, u_{-1})| = |g(u_{-1}) - g(\max(\theta_g, u_{-2}))|$$
$$\geq \chi(u_{-2}, u_{-1}) \int_{u_{-2}}^{u_{-1}} g'_+(\theta) d\theta.$$

Hence

$$\chi(u_{-2}, u_{-1}) \int_{u_{-2}}^{u_{-1}} g'_+(\theta) d\theta - |H_{-1/2} - H_{-3/2}| \leq 0. \tag{4.6}$$

Since $u_{-1} \geq \theta_g$ this implies that $0 \leq g(u_{-1}) - g(\theta_g) = \psi_1(u_{-1}) = \psi_2(\rho(u_{-1}))$. Hence $\rho(u_{-1}) \geq A$ and $f(\rho(u_{-1})) = g(u_{-1})$.

Now $(z_{-1} - z_1)_- \neq 0$ if and only if $\psi_2(\rho(u_{-1})) = \psi_1(u_{-1}) < \psi_2(u_1)$. This implies that $\rho(u_{-1}) < u_1$. Therefore for $A \leq \rho(u_{-1}) < u_1$ we have

$$-(z_{-1} - z_1)_- = \psi_2(u_1) - \psi_2(\rho(u_{-1})) = \int_{\rho(u_{-1})}^{u_1} |f'(\theta)| d\theta = f(u_1) - f(\rho(u_{-1})).$$

Hence

$$-(z_{-1} - z_1)_- = \begin{cases} f(u_1) - f(\rho(u_{-1})) & \text{if } A \leq \rho(u_{-1}) < u_1, \\ 0 & \text{otherwise.} \end{cases} \tag{4.7}$$

Now for $\tilde{A}(u_{-1}) \leq u_1$, $0 \leq \overline{F}(u_{-1}, u_1) - g(\theta_g) = g(u_{-1}) - g(\theta_g) = \psi_1(u_{-1}) = \psi_2(\rho(u_{-1})) = f(\rho(u_{-1})) - f(A)$, and therefore $\overline{F}(u_{-1}, u_1) = f(\rho(u_{-1}))$. Hence either $u_1 \leq u_2$ or $\rho(u_{-1}) < u_1$, and for all u_2 we have

$$\begin{aligned} |H_{3/2} - H_{1/2}| &= |F(u_1, u_2) - \overline{F}(u_{-1}, u_1)| = |F(u_1, u_2) - f(\rho(u_{-1}))| \\ &\geq \begin{cases} |f(u_1) - f(\rho(u_{-1}))| & \text{if } u_1 \geq \theta_f, \\ |f(\min(u_2, \theta_f)) - f(\rho(u_{-1}))| & \text{if } u_1 \leq \theta_f, \end{cases} \end{aligned} \tag{4.8}$$

$$-\chi(u_1, u_2) \int_{u_1}^{u_2} f'_-(\theta) d\theta = \begin{cases} 0 & \text{if } u_1 \geq \theta_f, \\ f(u_1) - f(\min(u_2, \theta_f)) & \text{if } u_1 \leq \theta_f. \end{cases} \tag{4.9}$$

Let $E_1 = -(z_{-1} - z_1)_- - \chi(u_1, u_2) \int_{u_1}^{u_2} f'_-(\theta) d\theta - |H_{1/2} - H_{3/2}|$. Suppose $\rho(u_{-1}) < u_1$; then $u_1 \geq \theta_f$, and hence from (4.7), (4.8), and (4.9) we have

$$E_1 \leq f(u_1) - f(\rho(u_{-1})) - |f(u_1) - f(\rho(u_{-1}))| \leq 0.$$

Suppose $u_1 \leq \rho(u_{-1})$; then $(z_{-1} - z_1)_- = 0$. If $\theta_f \leq u_1$, then $E_1 = -|H_{1/2} - H_{3/2}| \leq 0$. Let $\theta_f > u_1 \geq \tilde{A}(u_{-1})$; then by the definition of $\tilde{A}(u_{-1})$ we have $f(\tilde{A}(u_{-1})) = g(u_{-1}) = f(\rho(u_{-1}))$. If $u_2 \leq u_1$, then clearly $E_1 = -|H_{1/2} - H_{3/2}| \leq 0$. Let $u_1 \leq u_2$. Now $f(\tilde{A}(u_{-1})) = g(u_{-1}) = f(\rho(u_{-1}))$, and hence $f(u_1) \leq f(\tilde{A}(u_{-1})) = f(\rho(u_{-1}))$. Hence from (4.7), (4.8), and (4.9),

$$E_1 \leq f(u_1) - f(\min(u_2, \theta_f)) - |f(\rho(u_{-1})) - f(\min(u_2, \theta_f))| \leq 0.$$

This together with (4.6) implies that $E \leq 0$.

Step 2. $u_{-1} \geq \theta_g,\ u_1 < \tilde{A}(u_{-1})$.
In this case $\overline{F}(u_{-1}, u_1) = f(u_1)$ and $g(u_{-1}) \leq f(u_1)$.

$$\begin{aligned} |H_{-1/2} - H_{-3/2}| &= |\overline{F}(u_{-1}, u_1) - G(u_{-2}, u_{-1})| = |f(u_1) - g(\max(u_{-2}, \theta_g))| \\ &\geq \chi(u_{-2}, u_{-1})|g(u_{-1}) - g(\max(u_{-2}, \theta_g))| \\ &\geq \chi(u_{-2}, u_{-1}) \int_{u_{-2}}^{u_{-1}} g'_+(\theta) d\theta, \end{aligned} \tag{4.10}$$

$$\begin{aligned} |H_{3/2} - H_{1/2}| &= |F(u_1, u_2) - \overline{F}(u_{-1}, u_1)| = |f(\min(u_2, \theta_f)) - f(u_1)| \\ &\geq -\chi(u_1, u_2) \int_{u_1}^{u_2} f'_-(\theta) d\theta. \end{aligned} \tag{4.11}$$

From Step 1, $(z_{-1} - z_1)_- \neq 0$ if and only if $A < \rho(u_{-1}) < u_1$. Hence $(z_{-1} - z_1)_- = 0$. Combining this with (4.10) and (4.11) gives $E \leq 0$.

Step 3. $u_{-1} < \theta_g, u_1 \geq \tilde{A}(\theta_g)$ (see Figure 1).

In this case $\overline{F}(u_{-1}, u_1) = f(A) = g(\theta_g)$. Since $u_1 \geq \tilde{A}(\theta_g)$ this implies that $f(u_1) \leq f(A)$ if $u_1 \leq \theta_f$. Let $u_1 \leq u_2$; then

$$-\chi(u_1, u_2) \int_{u_1}^{u_2} f'_-(\theta) - |H_{3/2} - H_{1/2}| \leq \begin{cases} -|f(u_1) - f(A)| & \text{if } u_1 \geq \theta_f, \\ f(u_1) - f(\min(u_2, \theta_f)), & \\ -|f(u_1) - f(\min(u_2, \theta_f))| & \text{if } u_1 \leq \theta_f. \end{cases} \tag{4.12}$$

Since $u_{-1} \leq \theta_g$, hence $\chi(u_{-2}, u_{-1}) \int_{u_{-2}}^{u_{-1}} g'_+(\theta) d\theta = 0$. Let $(z_{-1} - z_1)_- = 0$; then from (4.12) we have $E \leq 0$. Suppose $(z_{-1} - z_1)_- \neq 0$; then $\rho(u_{-1}) \leq u_1$ and

$$\begin{aligned} -(z_{-1} - z_1)_- &= \psi_2(u_1) - \psi_2(\rho(u_{-1})) = \int_{\rho(u_{-1})}^{u_1} |f'(\theta)| d\theta, \\ |H_{-1/2} - H_{-3/2}| &= G(u_{-2}, u_{-1}) - \overline{F}(u_{-1}, u_1) \\ &\geq g(u_{-1}) - g(\theta_g) = -\psi_1(u_{-1}) = -\psi_2(\rho(u_{-1})). \end{aligned}$$

Hence from (4.12) we have

$$E \leq \begin{cases} -(z_{-1} - z_1)_- - |H_{-1/2} - H_{-3/2}| \leq \displaystyle\int_{\rho(u_{-1})}^{u_1} |f'(\theta)| d\theta - \int_{\rho(u_{-1})}^{A} |f'(\theta)| d\theta \leq 0 & \\ \qquad\qquad \text{if } u_1 \leq A, & \\ \displaystyle\int_{\rho(u_{-1})}^{u_1} |f'(\theta)| d\theta - \int_{\rho(u_{-1})}^{A} |f'(\theta)| d\theta - \int_{A}^{u_1} |f'(\theta)| d\theta = 0 \qquad \text{if } u_1 \geq A. \end{cases}$$

Hence in all cases $E \leq 0$.

Step 4. Let $u_{-1} \leq \theta_g,\ u_1 \leq \tilde{A}(\theta_g)$. In this case $\overline{F}(u_{-1}, u_1) = f(u_1)$ and $\chi(u_{-2}, u_{-1}) \int_{u_{-2}}^{u_{-1}} g'_+(\theta) d\theta = 0$. Let $u_1 \leq u_2, u_{-2} \leq u_{-1}$; then

$$\begin{aligned} |H_{3/2} - H_{1/2}| &= |F(u_1, u_2) - \overline{F}(u_{-1}, u_1)| = |f(\min(u_2, \theta_f)) - f(u_1)| \\ &= -\chi(u_1, u_2) \int_{u_1}^{u_2} f'_-(\theta) d\theta. \end{aligned} \tag{4.13}$$

If $u_1 \leq \rho(u_{-1})$, then $(z_{-1} - z_1)_- = 0$, and therefore from (4.13) $E \leq 0$. Hence assume that $\rho(u_{-1}) < u_1$; then $f(\rho(u_{-1})) > f(u_1)$. Since $\psi_2(\rho(u_{-1})) = \psi(u_{-1})$ this

implies that

$$f(\rho(u_{-1})) - f(\theta_f) + f(A) - f(\theta_f) = \int_{\rho(u_{-1})}^{A} |f'(\theta)| d\theta = -\psi_2(\rho(u_{-1}))$$
$$= -\psi_1(u_{-1}) = \int_{u_{-1}}^{\theta_g} |g'(\theta)| d\theta = g(u_{-1}) - g(\theta_g).$$

Hence $f(\rho(u_{-1})) - g(u_{-1}) = 2(f(\theta_f) - f(A)) \leq 0$, and therefore $f(u_1) \leq f(\rho(u_{-1})) \leq g(u_{-1})$. This implies that

$$|H_{-3/2} - H_{-1/2}| = |G(u_{-2}, u_{-1}) - \overline{F}(u_{-1}, u_1)| \geq g(u_{-1})_- f(u_1).$$

Since $f(A) = f(\tilde{A}(\theta_g))$ we have

$$\begin{aligned} E &\leq -(z_{-1} - z_1)_- - |H_{-3/2} - H_{-1/2}| \leq \int_{\rho(u_{-1})}^{u_1} |f'(\theta) d\theta - |g(u_{-1}) - f(u_1)| \\ &= f(\rho(u_{-1})) - g(u_{-1}) \leq 0. \end{aligned}$$

This proves Lemma 4.6.

LEMMA 4.7. *Let $u_0 \in L^\infty(\mathbb{R})$ such that $s \leq u_0(x) \leq S$ for all $x \in \mathbb{R}$ and $N(f, g, u_0) < 0$. Let $\{u_i^n\}$ be the scheme defined as in* (3.6). *Let ψ_1 and ψ_2 be as in Lemma* 4.6. *We introduce the constant*

$$L = \max\{Lip(\psi_1), Lip(\psi_2), \|\psi_1\|_\infty, \|\psi_2\|_\infty\}$$

and define

$$\begin{aligned} z_i^n &= \begin{cases} \psi_2(u_i^n) & \text{if} \quad i \geq 1, \\ \psi_1(u_i^n) & \text{if} \quad i \leq -1, \end{cases} \\ TV(z^n) &= \sum_{i \neq 0, -1} |z_i^n - z_{i+1}^n| + |z_{-1}^n - z_1^n|. \end{aligned} \tag{4.14}$$

Then

$$TV(z^n) \leq 2/\lambda \sum_{i \neq 0} |u_i^{n+1} - u_i^n| \leq 2/\lambda \sum_{i \neq 0} |u_i^1 - u_i^0| = 2N_h(f, g, u_0), \tag{4.15}$$

$$\sum_{i \neq 0} |z_i^n - z_i^m| \leq \lambda L |n - m| N(f, g, P, u_0). \tag{4.16}$$

Proof.

Define $H_{1/2} = H_{-1/2} = \overline{F}(u_{-1}^n, u_1^n)$ and

$$H_{j+1/2} = \begin{cases} F(u_j^n, u_{j+1}^n) & \text{if } j \geq 1, \\ G(u_j^n, u_{j+1}^n) & \text{if } j \leq -2. \end{cases}$$

Since $0 = \sum_{i \neq 0, -1} (z_i^n - z_{i+1}^n) + (z_{-1}^n - z_1^n)$,

$$\begin{aligned} \frac{1}{2} TV(z^n) &= \frac{1}{2} \left(\sum_{i \neq 0, -1} |z_i^n - z_{i+1}^n| + |z_{-1}^n - z_1^n| \right) \\ &= -\left(\sum_{i \neq 0, -1} (z_i^n - z_{i+1}^n)_- + (z_{-1}^n - z_1^n)_- \right) = I_1 + I_2 + I_3, \end{aligned}$$

where

$$\begin{aligned} I_1 &= -\sum_{i\le -3}(z_i^n - z_{i+1}^n)_-, \quad I_2 = -\sum_{i\ge 2}(z_i^n - z_{i+1}^n)_-, \\ I_3 &= -(z_{-2}^n - z_{-1}^n)_- - (z_{-1}^n - z_1^n)_- - (z_1^n - z_2^n)_-. \end{aligned}$$

From (4.3) to (4.5) we have

$$\begin{aligned} I_1 &= -\sum_{i\le -3}(z_i^n - z_{i+1}^n)_- = -\sum_{i\le -3}(\psi_1(u_i^n) - \psi_1(u_{i+1}^n))_- \\ &\le \sum_{i\le -3}\chi_-(g'(u_i^n))|H_{i+1/2} - H_{i-1/2}| + \chi_+(g'(u_{i+1}^n))|H_{i+3/2} - H_{i+1/2}| \\ &\le \sum_{i\le -3}|H_{i+1/2} - H_{i-1/2}| + \chi_+(g'(u_{-2}^n))|H_{-3/2} - H_{-5/2}|, \\ I_2 &= -\sum_{i\ge 2}(z_i^n - z_{i+1}^n)_- = -\sum_{i\ge 2}(\psi_2(u_i^n) - \psi_2(u_{i+1}^n))_- \\ &\le \sum_{i\ge 2}\chi_-(f'(u_i^n))|H_{i+1/2} - H_{i-1/2}| + \chi_+(f'(u_{i+1}^n))|H_{i+3/2} - H_{i+1/2}| \\ &\le \sum_{i\ge 3}|H_{i+1/2} - H_{i-1/2}| + \chi_-(f'(u_2^n))|H_{5/2} - H_{3/2}|, \\ -(z_{-2}^n - z_{-1}^n)_- &= \chi(u_{-2}^n, u_{-1}^n)\left(\int_{u_{-2}^n}^{u_{-1}^n} g'_+(\theta)d\theta - \int_{u_{-2}^n}^{u_{-1}^n} g'_-(\theta)d\theta\right) \\ &\le \chi(u_{-2}^n, u_{-1}^n)\int_{u_{-2}^n}^{u_{-1}^n} g'_+(\theta)d\theta + \chi_-(g'(u_{-2}^n))|H_{-3/2} - H_{-5/2}|, \\ -(z_1^n - z_2^n)_- &= \chi(u_1, u_2)\left(\int_{u_1^n}^{u_2^n} f'_+(\theta)d\theta - \int_{u_1^n}^{u_2^n} f'_-(\theta)d\theta\right) \\ &\le \chi_+(f'(u_2^n))|H_{5/2} - H_{3/2}| - \chi(u_1^n, u_2^n)\int_{u_1^n}^{u_2^n} f'_-(\theta)d\theta. \end{aligned}$$

Combining all the above three inequalities we obtain

$$\begin{aligned} \frac{1}{2}TV(z^n) &\le \sum_{|i|\ge 2}|H_{i+1/2} - H_{i-1/2}| + \chi(u_{-2}^n, u_{-1}^n)\int_{u_{-2}^n}^{u_{-1}^n} g'_+(\theta)d\theta \\ &\quad -\chi(u_1^n, u_2^n)\int_{u_1^n}^{u_2^n} f'_-(\theta)d\theta - (z_{-1}^n - z_1^n)_- \\ &= \sum_{i=-\infty}^{\infty}|H_{i+1/2} - H_{i-1/2}| + E, \end{aligned}$$

where

$$\begin{aligned} E = -(z_{-1}^n - z_1^n)_- - \chi(u_1^n, u_2^n)\int_{u_1^n}^{u_2^n} f'_-(\theta)d\theta + \chi(u_{-2}^n, u_{-1}^n)\int_{u_{-2}^n}^{u_{-1}^n} g'_+(\theta)d\theta \\ - |H_{-1/2} - H_{-3/2}| - |H_{3/2} - H_{1/2}|. \end{aligned}$$

From Lemma 4.6, $E \le 0$; hence from Lemma 4.4

$$\begin{aligned} TV(z^n) &= \sum_{i\ne 0,-1}|z_i^n - z_{i+1}^n| + |z_{-1}^n - z_1^n| \le 2\sum|H_{i+1/2} - H_{i-1/2}| \\ &= \frac{2}{\lambda}\sum_{i\ne 0}|u_i^{n+1} - u_i^n| \le \frac{2}{\lambda}\sum_{i\ne 0}|u_i^1 - u_i^0| = 2N_h(f, g, u_0). \end{aligned}$$

This proves (4.15).

Without loss of generality assume that $n \geq m$; then from Lemma 4.4 we have

$$\begin{aligned}\sum_{i\neq 0}|z_i^n - z_i^m| &= \sum_{i\leq -1}|z_i^n - z_i^m| + \sum_{i\geq 1}|z_i^n - z_i^m| \leq L\sum_{i\neq 0}|u_i^n - u_i^m| \\ &\leq L\sum_{i\neq 0}\sum_{j=0}^{n-m+1}|u_i^{n-j} - u_i^{n-j-1}| \\ &\leq L|n-m|\sum_{i\neq 0}|u_i^1 - u_i^0| = \lambda L|n-m|N_h(f,g,u_0).\end{aligned}$$

This proves (4.16) and hence Lemma 4.7.

The following lemma is the analogue of Lemma 4.7 in terms of functions instead of point values.

LEMMA 4.8. *Let $u_0, v_0 \in L^\infty(\mathbb{R},[s,S])$ such that $N(f,g,u_0) < \infty, N(f,g,v_0) < \infty$ are initial datas, and let u_h and v_h be the corresponding solutions obtained by the finite volume scheme* (3.6) *and defined as in* (3.7). *Let $\{z_i^n\}$ defined as in* (4.14) *for u_0 and z_h be the corresponding function defined as in* (3.7). *Then*

$$s \leq u_h(x,t) \leq S \qquad \forall\ (x,t) \in \mathbb{R}\times\mathbb{R}_+, \tag{4.17}$$

$$||z_h||_\infty \leq L, \qquad TV(z_h(\cdot,t)) \leq 2N_h(f,g,u_0), \tag{4.18}$$

$$\int_{\mathbb{R}}|u_h(x,t) - u_h(x,\tau)|dx \leq N_h(f,g,u_0)(2\Delta t + |t-\tau|), \tag{4.19}$$

$$\int_{\mathbb{R}}|z_h(x,t) - z_h(x,\tau)|dx \leq LN_h(f,g,u_0)(2\Delta t + |t-\tau|). \tag{4.20}$$

Moreover, for $a \leq b$ and $\tau < t$,

$$\int_a^b |u_h(x,t) - v_h(x,t)|dx \leq \int_{a-\frac{1}{\lambda}(t-\tau)}^{b+\frac{1}{\lambda}(t-\tau)} |u_h(x,\tau) - v_h(x,\tau)|dx + 4(S-s)h. \tag{4.21}$$

Proof. Inequalities (4.17) and (4.18) follow from (4.2) and (4.15). For inequality (4.19) let $t_n \leq t < t_{n+1}$ and $t_m \leq \tau < t_{m+1}$ so that

$$|n-m|\Delta t = |t_n - t_m| \leq |t_n - t| + |t-\tau| + |\tau - t_m| \leq 2\Delta t + |t-\tau|.$$

Hence from Lemma 4.2 we obtain

$$\begin{aligned}\int_{\mathbb{R}}|u_h(x,t) - u_h(x,\tau)|dx &= h\sum_{i\neq 0}|u_i^n - u_i^m| \leq h\sum_{i\neq 0}\sum_{j=0}^{n-m+1}|u_i^{n-j} - u_i^{n-j-1}| \\ &\leq h|n-m|\sum_{i\neq 0}|u_i^1 - u_i^0| \leq \frac{\Delta t|n-m|}{\lambda}\sum_{i\neq 0}|u_i^1 - u_i^0| \\ &\leq (2\Delta t + |t-\tau|)N_h(f,g,u_0).\end{aligned}$$

The proof of (4.20) follows from (4.19):

$$\begin{aligned}\int_{\mathbb{R}}|z_h(x,t) - z_h(x,\tau)|dx &\leq h\sum_{i\neq 0}|z_i^n - z_i^m| \leq Lh\sum_{i\neq 0}|u_i^n - u_i^m| \\ &\leq LN_h(f,g,u_0)(2\Delta t + |t-\tau|).\end{aligned}$$

We prove inequality (4.21) for $a < 0,\ b > 0$. The proofs are similar for the other cases. Let

$$\begin{aligned}&x_{i_0-3/2} < a \leq x_{i_0-1/2}, \qquad && x_{j_0+1/2} \leq b < x_{j_0+3/2}, \\ &t_{n+1} \leq t < t_{n+2}, && t_{n-p+1} \leq \tau < t_{n-p+2};\end{aligned}$$

so we have $x_{i_0-p-3/2} \le a - ph \le x_{i_0-p-1/2}$, $x_{j_0+p+1/2} \le b + ph < x_{j_0+p+3/2}$, and $t - \Delta t \le \tau + p\Delta t \le t + \Delta t$. From (4.17) $|u_h - v_h| \le (S - s)$; hence

$$\begin{aligned}\int_a^b |u_h(x,t) - v_h(x,t)|dx &= \int_a^{x_{i_0-1/2}} |u_h(x,t) - v_h(x,t)|dx \\ &+ \int_{x_{i_0-1/2}}^{x_{j_0+1/2}} |u_h(x,t) - v_h(x,t)|dx + \int_{x_{j_0+1/2}}^b |u_h(x,t) - v_h(x,t)|dx \\ &\le 2(S-s)h + h \sum_{\substack{i_0 \le i \le j_0 \\ i \ne 0}} |u_i^{n+1} - v_i^{n+1}|.\end{aligned}$$

Using Lemma 4.4 it follows that

$$\begin{aligned}&\int_a^b |u_h(x,t) - v_h(x,t)|dx \\ &\qquad \le 2(S-s)h + h \sum_{\substack{i_0-p \le i \le j_0+p \\ i \ne 0}} |u_i^{n+1-p} - v_i^{n+1-p}| \\ &\qquad = 2(S-s)h + \int_{x_{i_0-p-1/2}}^{x_{j_0+p+1/2}} |u_h(x,\tau) - v_h(x,\tau)|dx \\ &\qquad = 2(S-s)h + \int_{a-ph}^{b+ph} |u_h(x,\tau) - v_h(x,\tau)|dx \\ &\qquad\quad - \int_{a-ph}^{x_{i_0-p-1/2}} |u_h(x,\tau) - v_h(x,\tau)|dx - \int_{x_{j_0+p+1/2}}^{b+ph} |u_h(x,\tau) - v_h(x,\tau)|dx \\ &\qquad \le 2(S-s)h + \int_{a-\frac{t-\tau}{\lambda}}^{b+\frac{t-\tau}{\lambda}} |u_h(x,\tau) - v_h(x,\tau)|dx \\ &\qquad\quad + \int_{a-\frac{t-\tau}{\lambda}}^{a-ph} |u_h(x,\tau) - v_h(x,\tau)|dx + \int_{b+ph}^{b+\frac{t-\tau}{\lambda}} |u_h(x,\tau) - v_h(x,\tau)|dx \\ &\qquad \le 2(S-s)h + 2|\tfrac{t-\tau}{\lambda} - ph|(S-s) + \int_{a-\frac{t-\tau}{\lambda}}^{b+\frac{t-\tau}{\lambda}} |u_h(x,\tau) - u_h(x,\tau)|dx \\ &\qquad \le 4(S-s)h + \int_{a-\frac{t-\tau}{\lambda}}^{b+\frac{t-\tau}{\lambda}} |u_h(x,\tau) - v_h(x,\tau)|dx\,.\end{aligned}$$

This completes the proof of Lemma 4.8.

4.3. Convergence of a subsequence to the weak solution. From hypotheses (H_1) and (H_2) we will construct a solution to the Riemann problem with under-compressive data which will enable us to prove that the solution satisfies the interface entropy condition (2.2). For $\alpha, \beta \in [s, S]$, let

$$v_0(x,\alpha,\beta) = \begin{cases} \alpha & \text{if} \quad x < 0, \\ \beta & \text{if} \quad x \ge 0\,. \end{cases}$$

Then we have the following lemma.

LEMMA 4.9. *Assume that f, g satisfy hypotheses (H_1) and (H_2). Let $\alpha, \beta \in [s, S]$ be such that $\alpha \le \theta_g$ and $\beta \ge \theta_f$. Let $v_h(x,t,\alpha,\beta)$ be the solution given by the finite volume scheme (3.6) with initial data $v_0(x,\alpha,\beta)$ and $\lambda M \le 1$. Assume that for a subsequence $h_k \to 0$, $v_{h_k}(x,t,\alpha,\beta) \to v(x,t,\alpha,\beta)$ on $L^\infty_{loc}(\mathbb{R}_+, L^1_{loc}(\mathbb{R}))$. Then*

$$\begin{aligned}\lim_{x\to 0^-} v(x,t,\alpha,\beta) &= \theta_g \quad \text{if} \quad \min\ g > \min f, \\ \lim_{x\to 0^+} v(x,t,\alpha,\beta) &= \theta_f \quad \text{if} \quad \min\ g \le \min f.\end{aligned} \tag{4.22}$$

Proof. We will prove the lemma for $\min g > \min f$. The other cases can be proved in a similar manner. Let $A \geq \theta_f$ be such that $f(A) = g(\theta_g)$ (see Figure 1). Since $\alpha \leq \theta_g,\ \beta \geq \theta_f$ it follows from (3.2) that

$$\overline{F}(\alpha, \beta) = \max\{g(\theta_g),\ f(\theta_f)\} = g(\theta_g). \tag{4.23}$$

Then if $\{v_i^n\}$ are the grid values corresponding to the initial data $v_0(x, \alpha, \beta)$,

$$v_i^1 = \begin{cases} \alpha - \lambda(g(\theta_g) - g(\alpha)) & \text{if} \quad i = -1, \\ \alpha & \text{if} \quad i \leq -2, \\ \beta - \lambda(f(\beta) - g(\theta_g)) & \text{if} \quad i = 1, \\ \beta & \text{if} \quad i \geq 2. \end{cases}$$

This implies that $v_{-1}^1 = \alpha - \lambda(g(\theta_g) - g(\alpha))$ and $v_{-1}^1 = \alpha + \lambda(g(\alpha) - g(\theta_g)) \leq \alpha + \lambda M|\alpha - \theta_g| < \alpha + \theta_g - \alpha = \theta_g$. Let $\beta \in [\theta_f, A]$; then $f(\beta) \leq f(A) = g(\theta_g)$, and hence $v_1^1 = \beta - \lambda(f(\beta) - g(\theta_g)) \geq \beta$ and $v_1^1 = \beta + \lambda(g(\theta_g) - f(\beta)) = \beta + \lambda(f(A) - f(\beta)) \leq \beta + (A - \beta) = A$. If $\beta \in [A, S]$, then $f(\beta) > f(A) = g(\theta_g)$, and hence $v_1^1 = \beta - \lambda(f(\beta) - g(\theta_g)) < \beta$ and $v_1^1 = \beta - \lambda(f(\beta) - f(A)) \geq \beta - \lambda M(\beta - A) \geq A$. Hence $\{v_i^1\}$ satisfies

$$\begin{aligned} \alpha &\leq v_{-1}^1 \leq \theta_g, \\ \beta &\leq v_1^1 \leq A \quad \text{if} \quad \beta \in [\theta_f, A], \\ A &\leq v_1^1 \leq \beta \quad \text{if} \quad \beta \in [A, S], \\ v_i^1 &= \begin{cases} \alpha & \text{if} \quad i \leq -2, \\ \beta & \text{if} \quad i \geq 2. \end{cases} \end{aligned} \tag{4.24}$$

Now we claim that $\{v_i^n\}$ satisfies

$$\begin{aligned} \alpha &\leq v_{-n}^n \leq v_{-n+1}^n \leq \cdots \leq v_{-1}^n \leq \theta_g, \\ \beta &\leq v_1^n \leq \cdots \leq v_n^n \leq A \quad \text{if} \quad \beta \in [\theta_f, A], \\ A &\leq v_1^n \leq \cdots \leq v_n^n \leq \beta \quad \text{if} \quad \beta \in [A, S], \\ v_i^n &= \begin{cases} \alpha & \text{if} \quad i \leq -n-1, \\ \beta & \text{if} \quad i \geq n+1. \end{cases} \end{aligned} \tag{4.25}$$

From (4.24) the claim is true for $n = 1$. Assume that it is true up to $n - 1$. Since $v_1^{n-1} \geq \theta_f$ and $v_{-1}^{n-1} \leq \theta_g$, hence as in (4.23) $\overline{F}(v_{-1}^n, v_1^n) = g(\theta_g)$. Hence by the same argument as in (4.24), it follows that $\alpha \leq v_{-1}^n \leq \theta_g,\ \beta \leq v_1^n \leq A$ if $\beta \in [\theta_f, A]$ and $A \leq v_1^n \leq \beta$ if $\beta \in [A, S]$. Now (4.25) follows since the scheme is monotone and consistent for $|i| \geq 2$. This proves (4.25).

From (4.25) it follows that $v(x, t, \alpha, \beta)$ satisfies

$$\begin{aligned} \alpha &\leq v^-(t, \alpha, \beta) = \lim_{x \to 0^-} v(x, t, \alpha_1, \beta) \leq \theta_g, \\ \beta &\leq v^+(t, \alpha, \beta) = \lim_{x \to 0^+} v(x, t, \alpha, \beta) \leq A \quad \text{if} \quad \beta \in [\theta_f, A], \\ A &\leq v^+(t, \alpha, \beta) = \lim_{x \to 0^+} v(x, t, \alpha, \beta) \leq \beta \quad \text{if} \quad \beta \in [A, S]. \end{aligned}$$

From (4.25) and hypothesis (H_2) on the shape of f and g we observe that $\{v_i^{(n)}\}_{i \leq -1}$ is independent of β as long as $\beta \geq \theta_f$. Hence $v^-(t, \alpha, \beta)$ is independent of β, and hence $v^-(t, \alpha, \beta) = v^-(t, \alpha, \theta_f)$. Since $v^+(t, \alpha, \theta_f) \leq A$ and $g(v^-(t, \alpha, \beta)) = f(v^+(t, \alpha, \beta))$, hence $v^-(t, \alpha, \beta) = \theta_g$. This completes the proof of Lemma 4.9.

Proof of Theorem 3.2. Let $\lambda = \frac{\Delta t}{h} \le \frac{1}{M}$ be fixed. Since $N(f,g,u_0) < \infty$, then from Lemma 4.8 and by a standard argument there exists a subsequence $h_k \to 0$ such that z_{h_k} converges to z in $L^\infty(0,T,L^1_{loc}(\mathbb{R}))$ and for almost all fixed t, $z_{h_k}(.,t) \to z(.,t)$ in $L^1_{loc}(\mathbb{R})$. Let

$$u(x,t) = \begin{cases} \psi_2^{-1}(z(x,t)) & \text{if} \quad x > 0, \quad t > 0, \\ \psi_1^{-1}(z(x,t)) & \text{if} \quad x < 0, \quad t > 0. \end{cases}$$

Now for $x > 0, u_{h_k}(x,t) = \psi_2^{-1}(z_{h_k}(x,t))$ and for $x < 0, u_{h_k}(x,t) = \psi_1^{-1}(z_{h_k}(x,t))$ and ψ_1 and ψ_2 are continuous, and therefore for almost all t, $u_{h_k}(.,t) \to u(.,t)$ a.e. in $\mathbb{R}$. From (4.18), for a.e. t, $z(.,t) \in BV(\mathbb{R})$, and hence $z(x+,t), z(x-,t)$ exist for all $x \in \mathbb{R}$. This implies that $u(x+,t), u(x-,t)$ exist for all $x \in \mathbb{R}$ and a.e. t. We will complete the proof of the theorem in two steps.

Step 1. Let us prove that u is a weak solution of (1.2) satisfying the interior entropy condition (2.1). Remember that the scheme is not consistent. However, the proof follows almost as in the Lax–Wendroff theorem [10, Theorem 1.1].

Let $\varphi \in C_0^1(\mathbb{R} \times \mathbb{R}_+)$, and let

$$\varphi_j^n = \varphi(x_j, t_n), \quad j \in Z \setminus (0), \quad n \ge 0\,.$$

Multiplying (3.6) by φ_j^n and summing over j and n we obtain

$$h\sum_{n=1}^{\infty}\sum_{i\neq 0} u_i^n(\varphi_i^{n-1} - \varphi_i^n) + \Delta t\sum_{n=0}^{\infty}\sum_{-\infty}^{-1} G(u_{i-1}^n, u_i^n)(\varphi_{i-1}^n - \varphi_i^n)$$
$$+\Delta t\sum_{n=0}^{\infty}\sum_{2}^{\infty} F(u_{i-1}^n, u_i^n)(\varphi_{i-1}^n - \varphi_i^n) + \Delta t\sum_{n=0}^{\infty}\overline{F}(u_{-1}^n, u_1^n)(\varphi_{-1}^n - \varphi_1^n) - h\sum_{i\neq 0} u_i^0\varphi_i^0 = 0.$$

Let

$$\begin{array}{lll} g_h(x,t) = G(u_{i-1}^n, u_i^n), & i \le -1, \quad x \in (x_{i-1}, x_i], & t \in [n\Delta t, (n+1)\Delta t), \\ f_h(x,t) = F(u_{i-1}^n, u_i^n), & i \ge 2, \quad x \in (x_{i-1}, x_i], & t \in [n\Delta t, (n+1)\Delta t), \\ \overline{F}_h(t) = \overline{F}(u_{-1}^n, u_1^n), & t \in [n\Delta t, (n+1)\Delta t), & \\ \overline{\varphi}_h(t) = \varphi(\frac{h}{2}, n\Delta t) - \varphi(-\frac{h}{2}, n\Delta t), & t \in [n\Delta t, (n+1)\Delta t); & \end{array}$$

then the above equalities read as

$$\int_{-\infty}^{\infty}\int_{\Delta t}^{\infty} u_h(x,t)\left(\frac{\varphi_h(x,t) - \varphi_h(x,t-\Delta t)}{\Delta t}\right)dtdx$$
$$+\int_{-\infty}^{x_{-1}}\int_{0}^{\infty} g_h(x,t)\left(\frac{\varphi_h(x+\frac{h}{2},t) - \varphi_h(x-\frac{h}{2},t)}{h}\right)dtdx$$
$$+\int_{x_1}^{\infty}\int_{0}^{\infty} f_h(x,t)\left(\frac{\varphi_h(x+\frac{h}{2},t) - \varphi_h(x-\frac{h}{2},t)}{h}\right)dtdx$$
$$+\int_0^{\infty}\overline{F}_h(t)\overline{\varphi}_h(t)dt + \int_{-\infty}^{\infty} u_h(x)\varphi_h(x)dx = 0\,.$$

Let $h = h_k$ in the above equation, and by going to a subsequence if necessary, by using by the fact that $|\overline{F}(t)| \le \|F\|_\infty + \|G\|_\infty$ and by the dominated convergence theorem, it follows that as $k \to \infty, u_{h_k} \to u$ in $L^\infty_{loc}(\mathbb{R}, L^1_{loc}(\mathbb{R}))$ and the above equation gives that

$$\int_{-\infty}^{\infty}\int_0^{\infty}\left[u\frac{\partial\varphi}{\partial t} + (H(x)f(u) + (1-H(x))g(u))\frac{\partial\varphi}{\partial x}\right]dtdx + \int_{-\infty}^{\infty} u_0(x)\varphi(x,0)dx = 0,$$

where $H(x)$ is the Heaviside function. This proves that u is a weak solution.

In order to prove the interior entropy condition, for $l \in \mathbb{R}$ define

$$A(a,b) = F(a \wedge l,\ b \wedge l) - F(a \vee l,\ b \vee l), \quad B(a,b) = G(a \wedge l,\ b \wedge l) - G(a \vee l,\ b \vee l),$$
$$A^n_{j+1/2} = A(u^n_j, u^n_{j+1}), \quad B^n_{j+1/2} = B(u^n_j,\ u^n_{j+1}). \tag{4.26}$$

Then as in [4, 10], for $|i| \geq 2$, u^n_i satisfies

$$|u^{n+1}_i - l| \leq |u^n_i - l| - \lambda(A^n_{i+1/2} - A^n_{i-1/2}) \quad \text{if } i \geq 2, \tag{4.27}$$

$$|u^{n+1}_i - l| \leq |u^n_i - l| - \lambda(B^n_{i+1/2} - B^n_{i-1/2}) \quad \text{if } i \leq -2. \tag{4.28}$$

Let $0 \leq \varphi \in C^1_0(\mathbb{R}_+ \times \mathbb{R}_+)$. Then there exists $\alpha > 0$ such that supp $(\varphi) \subset \{(x,t); x > \alpha,\ t > \alpha\}$. Hence for h_k small, $\varphi_{h_k}(x,t) = 0$ for $x \leq x_4,\ t \geq \Delta t$. Let $l \in \mathbb{R}$, A, and $A_{i+1/2}$ be defined as in (4.26). Let $A_h(x,t) = A^n_{i+1/2}$ for $x_i \leq x < x_{i+1},\ t_n \leq t < t_{n+1}$. Then multiplying (4.27) by φ^n_i and summing we obtain

$$\int_0^\infty \int_0^\infty |u_{h_k} - l| \left(\frac{\varphi_{h_k}(x,t) - \varphi_{h_k}(x, t - \Delta t}{\Delta t} \right) + \int_0^\infty \int_{x_3}^\infty A_{h_k}(x,t) \left(\frac{\varphi(x + \frac{h_k}{2}, t) - \varphi(x - \frac{h_k}{2}, t)}{h_k} \right) dx dt \geq 0\,.$$

Now letting $h_k \to 0$ yields $\int_0^\infty \int_0^\infty [\,|u-l| \frac{\partial \varphi}{\partial t} + (f(u) - f(l)) sign(u-l) \frac{\partial \varphi}{\partial x}]\, dx\, dt \geq 0$, and similarly for $x < 0$. Hence u satisfies the interior entropy condition (2.1), and this complete the proof of Step 1.

Step 2. We will now show that if u is the weak solution constructed in Step 1 for some $h_k \to 0$, and assuming that the set of discontinuities of u is a discrete set of Lipschitz curves $\{\Gamma_j\}$, then u satisfies the interface entropy condition (2.2), and the solution thus obtained is unique.

The main ingredient to prove this is the choice of the solution constructed in Lemma 4.9. Without loss of generality we can assume that $\min g \geq \min f$. Since $x \to z(x,t)$ is TV bounded, hence $z(0+,t)$ and $z(0-,t)$ exist. This implies that $u^+(t)$ and $u^-(t)$ exist. Suppose that u does not satisfy the interface entropy condition (2.2). Then $meas\,\{L \setminus U\} \neq 0$. Since for $t \in L \setminus U$ $u^+(t) > \theta_f, u^-(t) < \theta_g$, from hypothesis (H_2) we obtain, for almost all $t \in L \setminus U$ $u^-(t) < S, u^+(t) > s$ and

$$meas\left\{t \in L; u^-(t) < S, u^+(t) > s\right\} \neq 0.$$

Hence from the hypothesis on u and (H_2) we can choose $t_0 \in L \setminus U,\ \alpha, \beta, \varepsilon\ \in \mathbb{R}_+$ such that they satisfy

$$t_0 = n_k \Delta t,\ u_{h_k}(x,t_0) \to u(x,t_0) \text{ in } L^1_{loc}(\mathbb{R}) \text{ and } u^+(t_0) > \theta_f,\ u^-(t_0) < \theta_g, \tag{4.29}$$
$$u \text{ is continuous in } [-\beta, 0) \times [t_0 - \alpha, t_0 + \alpha] \text{ and } (0, \beta] \times [t_0 - \alpha, t_0 + \alpha],$$

$$\begin{array}{ll} u^-(t_0) - \varepsilon \leq u(x,t) \leq u^-(t_0) + \varepsilon < \theta_g & \text{in } \ [-\beta, 0) \times [t_0 - \alpha, t_0 + \alpha], \\ \theta_f < u^+(t_0) - \varepsilon \leq u(x,t) \leq u^+(t_0) + \varepsilon & \text{in } \ (0, \beta] \times [t_0 - \alpha,\ t_0 + \alpha]. \end{array} \tag{4.30}$$

On $\mathbb{R} \times \{t_0\}$, define the functions

$$\begin{aligned} V_k(x,t_0) &= u_{h_k}(x,t_0) \\ V_{k,\varepsilon}(x,t_0) &= \begin{cases} u_{h_k}(x,t_0) & \text{if } \ |x| \geq \beta, \\ \max(u_{h_k}(x,t_0), u^-(t_0) - \varepsilon) & \text{if } \ -\beta \leq x \leq 0, \\ \max\left(u_{h_k}(x,t_0), u^+(t_0) - \varepsilon\right) & \text{if } \ 0 \leq x \leq \beta, \end{cases} \\ V_0 &= \begin{cases} \max(s, u^-(t_0) - \varepsilon) & \text{if } \ x \leq 0, \\ u^+(t_0) - \varepsilon & \text{if } \ x > 0. \end{cases} \end{aligned} \tag{4.31}$$

From (4.29) and (4.30) it follows that as $k \to \infty$, for almost every $x \in \mathbb{R}$

$$V_k(x,t_0) \to u(x,t_0), \quad V_{k,\varepsilon}(x,t_0) \to u(x,t_0). \tag{4.32}$$

With t_0 as the initial time and $h_k,\ \lambda = \frac{\Delta t}{h_k}$, as the grid lengths, let $\tilde{V}_{h_k}, \tilde{V}_{h_{k,\varepsilon}}$, and W_{h_k} be the respective solutions calculated with the finite volume scheme (3.6) for $t \geq t_0$ and associated with $V_k, V_{k,\varepsilon}, V_0$ as initial data at $t = t_0$. Since $V_k, V_{k,\varepsilon}$, and V_0 are such that $N(f,g,V_k), N(f,g,V_{k,\varepsilon}), N(f,g,V_0)$ are bounded, one can extract a subsequence still denoted by h_k such that $\tilde{V}_{h_k}, \tilde{V}_{h_{k,\varepsilon}}, W_{h_k}$ converge to u (since $u_{h_k} = \tilde{V}_{h_k}$), v, w a.e., respectively. Letting $h_k \to 0$ in (4.21) for any $a > 0$, $t > t_0$, we have

$$\int_{-a}^{a} |u(x,t) - v(x,t)|dx \leq \int_{-a-t_0/\lambda}^{a+t_0/\lambda} |u(x,t_0) - v(x,t_0)|dx = 0\,.$$

Hence $u \equiv v$.

From (4.31), $V_0(x,t_0) \leq V_{k,\varepsilon}(x,t_0)$ for $x \in [-\beta,\beta]$. Hence by monotonicity of the scheme (see (ii) of Lemma 4.2), $W_{h_k}(x,t) \leq \tilde{V}_{k,\varepsilon}(x,t) + o(\Delta t)$ for $-\beta + \frac{t-t_0}{\lambda} \leq x \leq \beta - \frac{t-t_0}{\lambda}$, and hence for a.e. (x,t) with $t > t_0$, $-\beta + \frac{t-t_0}{\lambda} \leq x \leq \beta - \frac{t-t_0}{\lambda}$,

$$w(x,t) \leq u(x,t).$$

From this inequality, Lemma 4.9, and (4.30) we have for a.e. $t \in (t_0,\ \min(t_0 + \lambda\beta, t_0 - \alpha))$

$$\theta_g = w^-(t) \leq u^-(t) \leq u^-(t_0) + \varepsilon < \theta_g,$$

which is a contradiction. Hence u satisfies the interface entropy conditions.

Let u, v be two limit points of the scheme $\{u_h\}$ such that u and v have a discrete set of Lipschitz curves as discontinuities. From Steps 1 and 2, u and v satisfy the entropy conditions (2.1) and (2.2), and hence from Lemma A.1, for $b > \overline{M}t$,

$$\int_{-b+\overline{M}t,}^{b+\overline{M}t,} |u(x,t) - v(x,t)|dx \leq \int_{-b}^{b} |u(x,0) - v(x,0)|dx = 0\,.$$

Hence $u \equiv v$. This proves Step 2.

Furthermore, let u and v be the weak solutions of (1.2), constructed in Steps 1 and 2 for the initial data u_0 and v_0, respectively. Then by taking $a = -\infty$, $b = +\infty$, and letting $h \to 0$ in (4.21) we obtain

$$\int_{\mathbb{R}} |u(x,t) - v(x,t)|dx \leq \int_{\mathbb{R}} |u_0(x) - v_0(x)|dx\,.$$

Finally, if $f \equiv g$, then by Lemma 4.1 $\overline{F}(a,b) = F(a,b)$, and hence the scheme is Godunov's scheme. Now Theorem 3.2 follows from Steps 1 to 2.

Note that the scheme defined in (3.6) using the interface flux $\overline{F}$ gives a much stronger bound, i.e., $E \leq 0$. This helps us to extend the result for a flux $F(x,u)$ having more discontinuities in the space variable, as stated in the next remark.

Remark 4.10. The above analysis can be extended readily to the equation

$$u_t + f(k(x),u)_x = 0,$$

where $f(a,b) \in C^1(\mathbb{R} \times \mathbb{R})$ and k is a piecewise smooth function satisfying

(i) $f(a,s) = f(b,s), \quad f(a,S) = f(b,S)$ for all $a, b \in \mathbb{R}$,

(ii) for all a the function $u \longrightarrow f(a,u)$ satisfies (H_2).

Remark 4.11. In a forthcoming paper we will extend the above analysis to all E-schemes, including Engquist–Osher, Lax–Friedrich, etc. The case of the upstream mobility is considered in the next section, where it is compared with scheme (3.6).

5. Two-phase flow in porous media. Capillary-free two-phase incompressible flow in a porous medium with a rock type changing at $x = 0$ is modelled by (1.3), (1.4), where u is the saturation of one of the two phases, say phase 1. Equations (1.3) represent conservation of phase 1 inside each rock type, and (1.4) ensures conservation of the same phase at the interface between the two rock types. The functions f and g are the Darcy velocities (divided by the porosity) of phase 1 in each rock type, and they have the form

$$\begin{aligned} f = f_1 &= \frac{1}{\phi}\,\frac{\lambda_1}{\lambda_1+\lambda_2}[q+(c_1-c_2)\lambda_2] \quad \text{for } x>0,\\ g = g_1 &= \frac{1}{\phi}\,\frac{\mu_1}{\mu_1+\mu_2}[q+(c_1-c_2)\mu_2] \quad \text{for } x<0, \end{aligned} \tag{5.1}$$

where ϕ is the porosity of the rock and q, a constant in space, is the total Darcy velocity, that is, the sum of the Darcy velocities of the two phases, $q = \phi(f_1 + f_2) = \phi(g_1 + g_2)$. The Darcy velocities (divided by the porosity) of phase 2 denoted by f_2, g_2 are given by

$$f_2 = \frac{1}{\phi}\,\frac{\lambda_2}{\lambda_1+\lambda_2}[q+(c_2-c_1)\lambda_1], \quad g_2 = \frac{1}{\phi}\,\frac{\mu_2}{\mu_1+\mu_2}[q+(c_2-c_1)\mu_1].$$

The quantities λ_1, μ_1 and λ_2, μ_2 are the effective mobilities of the two phases. They are functions of u satisfying the following properties:

$$\begin{aligned} &\lambda_1, \mu_1 \text{ are increasing functions of } u, \quad \lambda_1(s) = \mu_1(s) = 0,\\ &\lambda_2, \mu_2 \text{ are decreasing functions of } u, \quad \lambda_2(S) = \mu_2(S) = 0. \end{aligned} \tag{5.2}$$

The gravity constants c_1, c_2 of the phases are proportional to their density.

In such a context the flux functions f and g satisfy hypotheses (H_1), (H_2), or (H_3), and Theorems 2.1, and 3.2 apply, provided that an appropriate CFL condition is satisfied. In numerical computations one can, of course, use the numerical fluxes F, G defined in (3.1) inside the rock types and $\overline{F}$, defined in (3.2) at the interface.

However, petroleum engineers have designed, from simple physical considerations, another numerical flux called the upstream mobility flux. It is an ad hoc flux for two-phase flow in porous media which corresponds to an approximate solution to the Riemann problem. It is given by the following formula:

$$\begin{aligned} &F^{UM}(a,b) = \frac{1}{\phi}\,\frac{\lambda_1^*}{\lambda_1^*+\lambda_2^*}[q+(c_1-c_2)\lambda_2^*],\\ &\lambda_\ell^* = \begin{cases} \lambda_\ell(a) & \text{if } q+(c_\ell-c_i)\lambda_\ell^* > 0, \quad i=1,2, \quad i\neq\ell,\\ \lambda_\ell(b) & \text{if } q+(c_\ell-c_i)\lambda_\ell^* \le 0, \quad i=1,2, \quad i\neq\ell, \end{cases} \qquad \ell = 1,2, \end{aligned} \tag{5.3}$$

and similarly for G^{UM} associated with g. As we can see, the flux is calculated using the mobilities of the phases which are upstream with respect to the flow of the phases. When the two phases are flowing in the same direction, the Godunov flux and the upstream mobility flux give the same answer and coincide with standard upstream weighting, but they differ when the phases are flowing in opposite directions. This flux has been shown to have all the desired properties for convergence of the associated finite difference scheme [26, 2] in the case of a flux function which does not vary with space (one rock type).

The generalization of the upstream mobility flux to the case of two rock types is straightforward, and at the interface the corresponding flux is

$$\begin{aligned} &\overline{F}^{UM}(a,b) = \frac{1}{\phi}\,\frac{\lambda_1^*}{\lambda_1^*+\lambda_2^*}[q+(c_1-c_2)\lambda_2^*], \\ &\lambda_\ell^* = \begin{cases} \mu_\ell(a) & \text{if } q+(c_\ell-c_i)\lambda_\ell^* > 0, \quad i=1,2, \quad i\neq\ell, \\ \lambda_\ell(b) & \text{if } q+(c_\ell-c_i)\lambda_\ell^* \le 0, \quad i=1,2, \quad i\neq\ell, \end{cases} \quad \ell = 1,2. \end{aligned} \tag{5.4}$$

This upstream mobility flux at the interface satisfies the consistency condition of Lemma 4.1:

$$\overline{F}^{UM}(s,s) = f(s) = g(s) = 0, \quad \overline{F}^{UM}(S,S) = f(S) = g(S) = \frac{q}{\phi}.$$

6. Numerical experiments. We consider an idealized experiment in which two phases of different densities are flowing in a vertical closed core. This core is made of two rock types, the top part being associated with the flux function g and the bottom part associated with the function f defined in (5.1). The data associated with the problem are as follows:

$$\begin{aligned} &\phi = 1, \quad q = 0, \quad c_1 = 2, \quad c_2 = 1, \\ &s = 0., \quad S = 1., \quad \lambda_1 = 10u^2, \quad \lambda_2 = 20(1-u)^2, \quad \mu_1 = 50u^2, \quad \mu_2 = 5(1-u)^2, \end{aligned}$$

which gives the flux function f and g represented in Figure 3. Note that we are in the case where f and g satisfy hypothesis (H_3). Phase 1 is the heavy phase, and it moves downwards while phase 2, the light phase, moves upward.

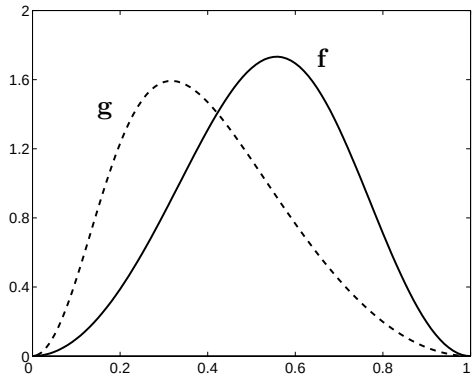

FIG. 3. *The flux functions at the interface for the numerical experiments.*

We present here two simulations which differ by the initial condition. In the first case we start with discontinuous data $u_0(x) = 1$ if $x < 0$, $u_0(x) = 0$ if $x > 0$; that is, at initial time the core is saturated with the heavy fluid (phase 1) in the upper half and with the light fluid (phase 2)in the lower half. The calculated solution is shown in Figure 4. In the second case we start with a constant initial data $u_0 = .5$ which corresponds to a situation where the two phases are "mixed." In this case the solution is shown in Figure 5.

In all figures the top part of the core is on the left of the picture and the bottom part is on the right. As expected, observe as time goes on the heavy fluid moving

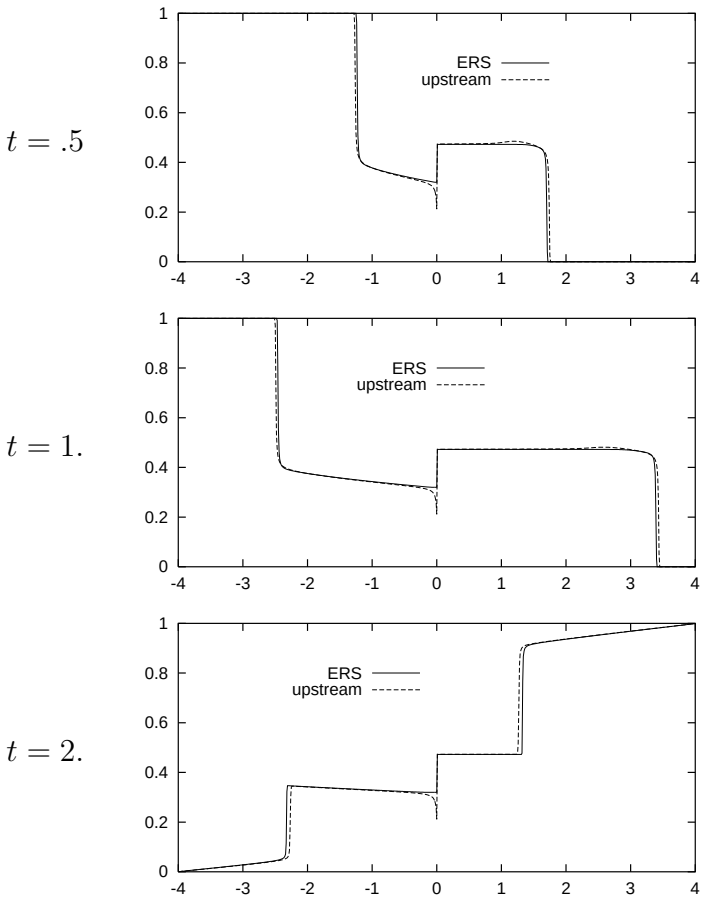

FIG. 4. *Finite difference solutions calculated with numerical flux* (3.1), (3.3) *(ERS) and with the upstream mobility flux* (5.3), (5.4) *at different times for a discontinuous initial data* ($h = 1/100$).

downward which is represented by its saturation u decreasing on the left and increasing on the right. Obviously, in the case of the continuous initial data we reach earlier the stationary state where the heavy phase occupies the bottom half of the core ($u(x) = 0$ if $x < 0, u(x) = 1$ if $x > 0$). However, one can observe the complexity of the solution, which presents several shocks.

In Figures 4 and 5 we compare the finite difference solutions calculated when using the numerical flux based on the exact Riemann solver (ERS) (3.1), (3.3) and the one calculated when using the upstream mobility flux (5.3), (5.4). We can observe that the latter is doing very well even in these complex situations. However, small differences can be seen. In particular, a small boundary layer appears on the left side of the interface. For these numerical examples these differences vanish when $h \to 0$ if they are measured in the L_1 norm.

Finally, in Figure 6 we present the solution given by the numerical flux which was presented in [3, 8, 13, 6] (ERS-NIF) and which is not valid when the flux functions intersect in the undercompressive case, which is our situation. The picture in Figure 6 is to be compared with the bottom picture in Figure 4. As expected, this numerical flux is not able to capture the complexity of the solution.

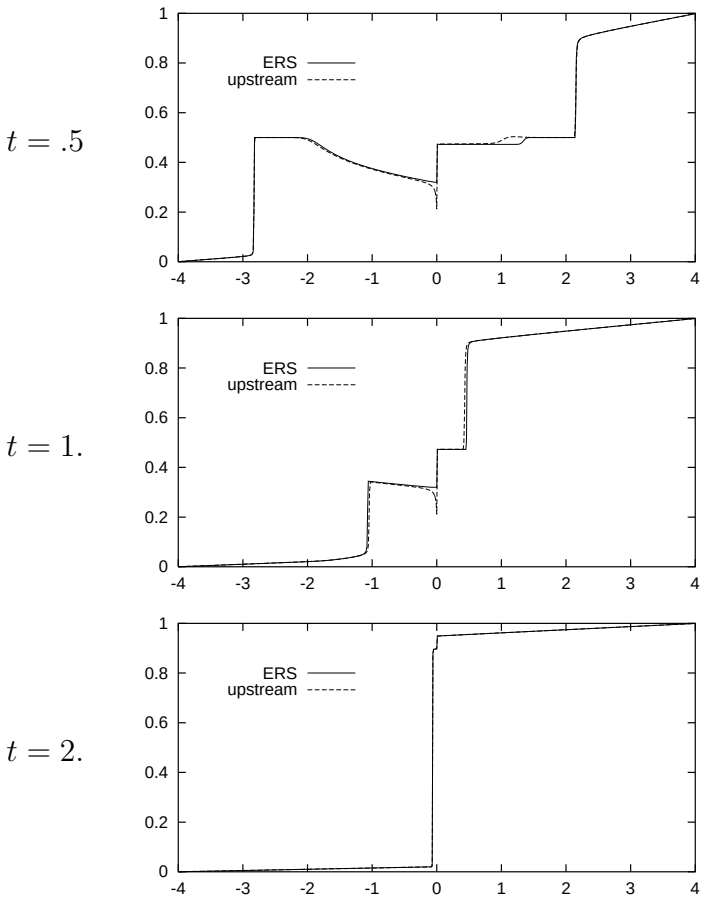

FIG. 5. *Finite difference solutions calculated with numerical flux* (3.1), (3.3) *(ERS) and with the upstream mobility flux* (5.3), (5.4) *at different times for a constant initial data* ($h = 1/100$).

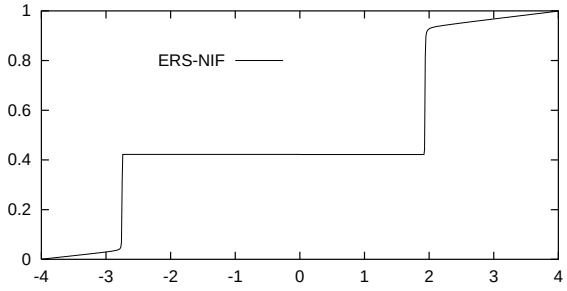

FIG. 6. *Finite difference solution calculated when using the numerical flux for nonintersecting fluxes.*

7. Conclusion. The calculation of the solutions of conservation laws with a flux function discontinuous in space needs appropriate numerical methods. We presented a Godunov method which uses an exact Riemann solver, and we proved convergence of the corresponding numerical scheme. We compared numerically with the upstream

mobility numerical flux used for multiphase flow in porous media, showing that the latter still works well in the case of a discontinuous flux function. A consequence of the proof of the convergence of the numerical scheme is an existence and uniqueness of the solution to the continuous problem.

Appendix A. End of the proof of existence and uniqueness theorem, Theorem 2.1. In this appendix we terminate the proof of Theorem 2.1 for nonconvex functions as in Figure 1. Existence was a consequence of the convergence theorem, Theorem 3.2, and to prove uniqueness we need to show that all solutions of (1.2) satisfying entropy conditions (2.1) and (2.2) can be represented by an L^1-contractive semigroup. The proof is as in [1], so we sketch only the proof. The main idea of this proof goes back to Kruzkov [19].

LEMMA A.1. *Let $u, v \in L^\infty(\mathbb{R}\times\mathbb{R}_+)$ with $s \le u, v \le S$ be two solutions of* (1.2) *with initial data $u_0, v_0 \in L^\infty(\mathbb{R})$, respectively. Assume the following:*

(i) *For almost every t, $u(x+,t), v(x+,t), u(x-,t)$, and $v(x-,t)$ exist.*

(ii) *The set of discontinuities of u and v is a discrete set $\{\Gamma_j\}_{j\in N}$ of Lipschitz curves.*

(iii) *u and v satisfies the entropy conditions* (2.1) *and* (2.2).

Then for any $\overline{M} \ge M$, $a < 0, b > 0$, $b - a \ge 2\overline{M}t$ the function

$$t \mapsto \int_{a+\overline{M}t}^{b-\overline{M}t} |u(x,t) - v(x,t)|dx$$

is nonincreasing.

Proof. The first three steps are exactly as in Kruzkov's proof (see [12, p. 24]), and the interface entropy condition (2.2) is used to prove Step 4.

Step 1. Let $l \in \mathbb{R}$, $\varphi_l(\theta) = |\theta - l|$, $\tilde{f}(\theta, l) = (f(\theta) - f(l))\ \mathrm{sign}\,(\theta - l)$. Let $0 \le \rho \in C_0^\infty(\mathbb{R}\times\mathbb{R}_+)$. Let $\Gamma_j^+ = \Gamma_j \cap \{(x,t) : x > 0, t > 0\}$ and $\nu^j = (\nu_1^j, \nu_2^j)$ be the a.e. normal to Γ_j^+. Then by integration by parts and using the interior entropy condition (2.1) we obtain

$$\begin{aligned}\int_0^\infty \int_0^\infty (\varphi_l(u(x,t))\frac{\partial\rho}{\partial t} + \tilde{f}\,(u(x,t),l)\,\frac{\partial\rho}{\partial x}dxdt \\ = \sum_{j=1}^\infty \int_{\Gamma_j^+} ([\varphi_l(u)]\nu_1^j + [\tilde{f}(u,l)]\nu_2^j)\rho d\sigma - \int_0^\infty \tilde{f}(u^+(t),l)\rho(0,t)dt \\ \ge -\int_0^\infty \tilde{f}(u^+(t),l)\rho(0,t)dt, \qquad \text{(A.1)}\end{aligned}$$

where $[\varphi_l(u)] = \varphi_l(u^-) - \varphi_l(u^+)$, the jump across of Γ_j^+, $[\tilde{f}(u,l)] = \tilde{f}(u^-,l) - \tilde{f}(u^+,l)$, the jump across of Γ_j^+, and $u^+(t) = u(0+,t)$.

Step 2. Let $A(x,t,y,s) = \frac{f(u(x,t))-f(v(y,s))}{u(x,t)-v(y,s)}$, $\alpha \in C_0^1((-1,0)\times(-1,0))$ with $\int_{\mathbb{R}^2}\alpha(z)dz = 1$ and $\beta \in C_0^1(\overline{\mathbb{R}}_+\times\mathbb{R}_+)$. Let $\varepsilon_1 > 0, \varepsilon_2 > 0$, and define

$$\rho_\varepsilon(x,t,y,\tau) = \frac{1}{\varepsilon_1\varepsilon_2}\alpha\left(\frac{x-y}{\varepsilon_1}, \frac{t-\tau}{\varepsilon_2}\right)\beta(y,s).$$

Now taking $l = v(y,\tau)$ and $\rho = \rho_\varepsilon(x,t,y,\tau)$ in (A.1) we integrate with respect to $(y,\tau) \in \mathbb{R}_+\times\mathbb{R}_+$. Then using symmetry and letting $\varepsilon_1 \to 0$, $\varepsilon_2 \to 0$ we obtain

$$\int_0^\infty\int_0^\infty |u(x,t)-v(x,t)|\left\{\frac{\partial\beta}{\partial t} + A(x,t,x,t)\frac{\partial\beta}{\partial x}\right\}dxdt \ge -\int_0^\infty \tilde{f}(u^+(t),v^+(t))\beta(0,t)dt.$$

Step 3. Let $b \geq 0$ and χ_ε be a decreasing smooth function in $(0,\infty)$ converging to $\chi_{[0,b]}$ as $\varepsilon \to 0$. Let $0 \leq \varphi \in C_0^1(\mathbb{R}_+)$, and let $\beta(x,t) = \chi_\varepsilon(|x| + \overline{M}t)\varphi(t)$ in the above equation. Letting $\varepsilon \to 0$ we can write

$$\int_0^\infty \varphi'(t) \int_0^{b-\overline{M}t} |u(x,t) - v(x,t)|dt \geq -\int_0^{b/\overline{M}} \tilde{f}(u^+(t), v^+(t))\varphi(t)dt\,.$$

Similarly for $x \leq 0$,

$$\int_0^\infty \varphi_1(t) \int_{a+\overline{M}t}^0 |u(x,t) - v(x,t)|dt \geq \int_0^{b/\overline{M}} \tilde{g}(u^-(t), v^-(t))\varphi(t)dt.$$

Adding both inequalities we obtain

$$\int_0^\infty \varphi'(t) \int_{a+\overline{M}t}^{b-\overline{M}t} |u(x,t) - v(x,t)|dx \geq \int_0^{b/\overline{M}} (\tilde{g}(u^-(t), v^-(t)) - \tilde{f}(u^+(t), v^+(t))\varphi(t))dt.$$

Step 4. So far, all the above steps are standard, and now we will make use of the interface entropy condition (2.2) to prove Lemma A.1. In order to prove the lemma it is sufficient to show that for almost all $t, I(t) \geq 0$, where

$$I(t) = \tilde{g}(u^-(t), v^-(t)) - \tilde{f}(u^+(t), v^+(t)) = |u^-(t) - v^-(t)|\frac{g(u^-(t)) - g(v^-(t))}{u^-(t) - v^-(t)} - |u^+(t) - v^+(t)|\frac{f(u^+(t)) - f(v^+(t))}{u^+(t) - v^+(t)}.$$

Without loss of generality, we can assume that $u^+(t) > v^+(t)$. If $f(u^+(t)) \leq f(v^+(t))$, then $I(t) \geq 0$. Hence let $f(u^+(t)) > f(v^+(t))$. Since $u^+(t) > v^+(t)$, from hypothesis (H_2) we have $u^+(t) \in (\theta_f, S]$. From the interface entropy condition (2.2) either $u^+(t) = u^-(t) = S$ or $u^-(t) \in (\theta_g, S]$. In the first case, $I(t) = 0$. In the latter case from the Rankine–Hugoniot condition, $g(u^-(t)) > g(v^-(t))$ and from hypothesis (H_2) $u^-(t) > v^-(t)$, and hence $I(t) = 0$. This completes the proof of (A.2) and of Lemma A.1.

Lemma A.1 implies that

$$\int_{a+\overline{M}t}^{b-\overline{M}t} |u(x,t) - v(x,t)|dx \leq \int_a^b |u(x,0) - v(x,0)|dx.$$

Letting $a \to -\infty$, $b \to +\infty$ we obtain the L^1 contractivity and terminate the proof of Theorem 2.1.

Acknowledgment. We would like to thank the referees for their thorough review of our paper and their useful constructive remarks.

ASYMMETRIC CUBATURE FORMULAE WITH FEW POINTS IN HIGH DIMENSION FOR SYMMETRIC MEASURES*

NICOLAS VICTOIR†

Abstract. Let μ be a positive measure on $\mathbb{R}^d$ invariant under the group of reflections and permutations, and let m be a natural number. We describe a method to construct cubature formulae of degree m with respect to μ, with n positive weights and n points in the support of μ and such that n grows at most like d^m with the dimension d. We apply this method to classical measures to explicitly construct cubature formulae of degree 5 with the number of points growing at most like d^3.

Key words. cubature formulae, orthogonal array, t-design

AMS subject classifications. 65D32, 05B15, 51E05

DOI. 10.1137/S0036142902407952

1. Introduction.

We will denote by $\mathbb{R}[X_1, \dots, X_d]$ the space of polynomials in d variables with real coefficients and by $\mathbb{R}_m[X_1, \dots, X_d]$ its subspace made of polynomials of total degree less than or equal to m. Note that $\dim \mathbb{R}_m[X_1, \dots, X_d] = \binom{m+d}{d}$. We will write $\delta_{\mathbf{x}}$ for the Dirac probability at the point $\mathbf{x}$.

DEFINITION 1.1. *Let μ be a positive measure on $\mathbb{R}^d$, $d \geq 1$, and m be a positive integer. We say that the points $\mathbf{x}_1, \dots, \mathbf{x}_n \in \mathbb{R}^d$ and the weights $\lambda_1, \dots, \lambda_n \in \mathbb{R}$ define a cubature formula of degree m, with respect to the measure μ, if*

$$\int_{\mathbb{R}^d} P(z)\mu(dz) = \sum_{k=1}^{n} \lambda_k P(\mathbf{x}_k) \tag{1}$$

holds for all polynomials P in $\mathbb{R}_m[X_1, \dots, X_d]$.

When $d = 1$ people use the term *quadrature* in place of *cubature*.

Remark 1.2. The existence of a cubature formula of degree m is equivalent to the existence of a finite measure ξ (a measure of the form $\xi = \sum_{i=1}^{n} \lambda_i \delta_{\mathbf{x}_i}$) such that, for all polynomials P of degree less than or equal to m, the integral of P with respect to ξ is equal to the integral of P with respect to μ.

Once we have a cubature formula, using the notation of the previous definition, we can approximate the integral of a smooth function f with respect to μ by

$$\sum_{i=1}^{n} \lambda_i f(\mathbf{x}_i).$$

The following theorem was first published by Tchakaloff (in the special case of a compactly supported measure). See [25], [28], [29] for its proof.

THEOREM 1.3. *Let d and m be positive integers and let μ be a positive measure on $\mathbb{R}^d$ with the property that $\int |P(z)|\mu(dz) < \infty$ for all $P \in \mathbb{R}_m[X_1, \dots, X_d]$. Then we can find n points $\mathbf{x}_1, \dots, \mathbf{x}_n$ in the support of μ and n positive real numbers $\lambda_1, \dots, \lambda_n$, with*

$$n \leq \dim \mathbb{R}_m[X_1, \dots, X_d],$$

such that the cubature relation (1) *holds for all* $P \in \mathbb{R}_m[X_1, \dots, X_d]$.

Unfortunately, this is only an existence theorem and does not provide any efficient method to obtain such cubature formulae. Hundreds of papers are devoted to the construction of cubature formulae. See the books [9], [18], [23], [28], the papers [5], [6], [7], [8], and the references therein. In [1], some Gaussian cubature formulae (i.e., cubature formulae with a minimum number of points) were constructed in high dimension. However, the measures considered there are rather artificial and exotic. It seems that no one has constructed explicit cubature formulae for classical measures of degree $m \geq 4$ in high dimension (i.e., in any given dimension) with no more than $\dim \mathbb{R}_m[X_1, \dots, X_d] = \binom{m+d}{m}$ points, despite Tchakaloff's theorem. Stroud, in the introduction of his celebrated book *Approximate Calculation of Multiple Integrals* [28], explains the need to construct such formulae. There exist some cubature formulae of degree 3 with few points, but the degree is not high enough to make the approximation accurate. Few points means, in this paper, that the number of points grows polynomially with the dimension.

Paraphrasing [18], an ideal cubature formula with respect to a positive measure should have points within the domain of integration, as few points as possible (in particular, fewer points than the dimension of the polynomial space $\mathbb{R}_m[X_1, \dots, X_d]$), and positive weights. Also, cubature formulae of higher degree will provide more accurate approximations of integrals. Nonetheless, the "space of cubature formulae is not totally ordered." By this, we mean that a cubature formula of degree 7 with some negative weights and another one of degree 5 with positive weights and with the same number of points cannot really be compared. Indeed, it is easy to find some functions whose integral will be better approximated by the first method and some other functions whose integral will be better approximated by the second method.

In this paper, we describe a method to construct cubature formulae with few points in any given dimension with respect to measures which are invariant under reflection and permutation of the axes. This method works particularly well for cubature formulae of degree 3 (where we get formulae with $O(d)$ points) and 5 (where we get formulae with $O(d^3)$ and even sometimes $O(d^2)$, which is well under the Tchakaloff bound), but we have not yet applied it for higher degrees.

In the next section, we will explain how combinatorics and coding theory help to construct cubature formulae with respect to the finite measure

$$\frac{1}{2^d} \sum_{\mathbf{g} \in \{-1,1\}^d} \delta_{\mathbf{g}}.$$

Formulae of degree $2m+1$ in d dimensions will require only $O(d^m)$ points. Some other combinatorial objects will allow us to construct cubature formulae with few points for measures of the form

$$\frac{1}{|\mathcal{S}_d.\mathbf{x}|} \sum_{\mathbf{y} \in \mathcal{S}_d.\mathbf{x}} \delta_{\mathbf{y}},$$

where we let $\mathcal{S}_d$, the group of permutation of order d, act naturally on $\mathbb{R}^d$. We also let $\mathcal{G}_d \simeq (\{-1,+1\}^d, *)$, the group of reflections of the axes, and $\mathcal{GS}_d$, the group of permutations and reflections of the axes, act naturally on $\mathbb{R}^d$. We will show that for a $\mathcal{GS}_d$-invariant measure μ, there exists a $\mathcal{GS}_d$-invariant cubature formula of degree m,

i.e., a formula of the form

$$\int P(z)\mu(dz) = \sum_{i=1}^{k} \lambda_i \frac{1}{|\mathcal{GS}_d.\mathbf{x}_i|} \sum_{\mathbf{y}\in\mathcal{GS}_d.\mathbf{x}_i} P(\mathbf{y}) \quad \forall P \text{ in } \mathbb{R}_m[X_1,\dots,X_d].$$

In this formula, we can find the points $\mathbf{x}_1,\dots,\mathbf{x}_k$ with the number of points k bounded by a term which depends only on m, the degree of the cubature formula. For example, for a cubature formula of degree 5, this upper bound is equal to 4, and it is possible to find two points that give the formula. Then, using the techniques described in the next two sections, we will construct cubature formulae with respect to $\frac{1}{|\mathcal{GS}_d.\mathbf{x}|}\sum_{\mathbf{y}\in\mathcal{GS}_d.\mathbf{x}}\delta_{\mathbf{y}}$. Those new approximations will give us a cubature formula of degree m with respect to μ and with few points. This explains why we first constructed some cubature formulae with respect to finite measures—that is, why we constructed finite measures approximating some other finite measures! The last section will deal with concrete examples of construction of such cubature formulae of degree 5 with respect to classical measures, such as the Gaussian measure and the Lebesgue measure on the unit hypercube, on the surface of the unit sphere, and on the whole unit sphere. We also include a table of formulae similar to those found in [7], [8].

2. Codes and orthogonal arrays.

2.1. Definitions and link with cubature formulae. In this section, we describe how we can find a cubature formula of degree $2m+1$ with respect to the measure of total mass one which puts equal mass at all of the vertices of a d-dimensional hypercube, i.e., with respect to

$$\delta_{\mathcal{G}_d} = \frac{1}{2^d}\sum_{\mathbf{g}\in\{-1,1\}^d}\delta_{\mathbf{g}}.$$

We will need to define orthogonal arrays. See [14] for a full description of these combinatorial objects.

DEFINITION 2.1. *An $N\times k$ array A with entries from a set S is said to be an orthogonal array with $|S|$ levels, strength t, and index λ (for some t in the range $0\le t\le k$) if every $N\times t$ subarray of A contains each t-uple based on S exactly λ times as a row.*

Such an array will be denoted by $OA(N,k,|S|,t)$. We do not put λ explicitly in this notation, as it is quite easy to see that $\lambda = N/|S|^t$.

THEOREM 2.2. *The points defined to be the rows of an orthogonal array with parameters $OA(N,d,2,2m+1)$ and with entries in $\{-1,1\}$, associated with the constant weight $1/N$, define a cubature formula of degree $2m+1$ with respect to $\delta_{\mathcal{G}_d}$.*

Proof. Let $\mathbf{x}_1,\dots,\mathbf{x}_N$ be the rows of an $OA(N,d,2,2m+1)$ with entries in $\{-1,1\}$. Let P_1 be the square of a monomial with leading coefficient 1. Then, using the particular form of P_1,

$$\sum_{k=1}^{N}\frac{1}{N}P_1(\mathbf{x}_k) = \sum_{k=1}^{N}\frac{1}{N}1 = \int P_1(z)\delta_{\mathcal{G}_d}(dz).$$

Now let $P_2 = Q^2R$, where $R = X_1^{\alpha_1}\dots X_d^{\alpha_d}$, $\alpha_i\in\{0,1\}$ with $1\le\sum_{i=1}^d\alpha_i\le 2m+1$, and Q is any monomial. Then

$$\sum_{k=1}^{N}\frac{1}{N}P_2(\mathbf{x}_k) = \sum_{k=1}^{N}\frac{1}{N}R(\mathbf{x}_k) = \sum_{k=1}^{N}\frac{1}{N}\prod_{i:\ \alpha_i=1}x_k^i.$$

If λ is the index of the orthogonal array $OA(N, d, 2, 2m+1)$, then for any functional Υ, $l \leq 2m+1$ and different indices $i_1, \dots, i_l$,

$$\sum_{k=1}^{N} \Upsilon(x_k^{i_1}, \dots, x_k^{i_l}) = \lambda \sum_{(y^1,\dots,y^l)\in\{-1,1\}^l} \Upsilon(y^1, \dots, y^l).$$

Hence, if $l = \sum_{i=1}^{d} \alpha_i$,

$$\begin{aligned}\sum_{k=1}^{N} \frac{1}{N} \prod_{i:\ \alpha_i=1} x_k^i &= \frac{\lambda}{N} \sum_{(y^1,\dots,y^l)\in\{-1,1\}^l} \prod_{j=1}^{l} y^j \\ &= 0 = \int P(z)\delta_{\mathcal{G}_d}(dz).\end{aligned}$$

We have proved that, for all monomials of degree less than or equal to $2m+1$,

$$\sum_{k=1}^{N} \frac{1}{N} P(\mathbf{x}_k) = \int P(z)\delta_{\mathcal{G}_d}(dz). \qquad \square$$

We are now going to link orthogonal arrays and codes. Let us first give the definition of a code.

DEFINITION 2.3. *Let S be a set of symbols of size s. A code is a collection C of vectors in S^k. These vectors are called codewords. The distance d_C of the code is defined by*

$$d_C = \min_{u,v\in C, u\neq v} card\,\{j \in \{1, \dots, k\}, u^j \neq v^j\}.$$

Such a code will be denoted by $(k, card\ C, d_C)_s$.

DEFINITION 2.4. *Let C be a $(k, N, d_C)_s$ code on S, and assume that S is a finite field. Define the dual code of C by*

$$C^{\perp} = \left\{ v \in S^k, \forall u \in C, uv^{\perp} = \sum_{i=1}^{k} u_i v_i = 0 \right\}.$$

Its distance $d_{C^{\perp}}$ will be called the dual distance of the code C.

The following is due to Delsarte [10].

THEOREM 2.5. *Let A be the $N \times k$ array such that its rows are the codewords of a $(k, N, d)_s$ code over a finite field S, with dual distance $d^{\perp}$. Then A is an $OA(N, k, s, d^{\perp} - 1)$.*

Thus we see that the codewords of a code with parameters $(k, N, d_C)_2$ over $\mathbb{Z}/2\mathbb{Z}$, with dual distance $2m+2$, give us a cubature formula of degree $2m+1$ with respect to $\delta_{\mathcal{G}_d}$. We will now give some examples of such orthogonal arrays.

2.2. Degree 3. We are going to describe the orthogonal arrays with parameters $OA(N, d, 2, 3)$, preferably with N as low as possible. This is closely related to Hadamard matrices. Write I_n for the $n \times n$ identity matrix and A^T for the transpose of a matrix A.

DEFINITION 2.6. *A Hadamard matrix of degree n is a matrix $H \in M_n(\{-1, 1\})$ such that $HH^T = nI_n$.*

PROPOSITION 2.7. *If there exists a Hadamard matrix of degree n, then $n \in \{1, 2\}$ or 4 divides n.*

We can construct an $OA(N,d,2,3)$ in the following way. Consider the least n greater than or equal to d, for which we have a Hadamard matrix A of degree n. Then consider the $2n \times n$ matrix B, such that the rows of B are made of the rows of A and of $-A$. Then delete $n-d$ columns of B. That gives us an $OA(2n,d,2,3)$. The Hadamard matrices have been heavily studied. Hadamard conjectured that if $n \in \{1,2\}$ or if 4 divides n, then a Hadamard matrix exists. It still has not been proved or disproved. Such matrices have been constructed for all $n \leq 1000$, except for $n = 428,668,716,764,892$. Moreover, there exists an easy way to construct them when n is a power of 2.

DEFINITION 2.8. *Let $A = (a_{ij})_{1\leq i,j\leq n} \in M_n(\mathbb{R})$ and $B \in M_m(\mathbb{R})$. Then we define the tensor product of A and B, $A \otimes B$ by the $nm \times nm$ matrix*

$$\begin{pmatrix} a_{11}B & \dots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{n1}B & \dots & a_{nn}B \end{pmatrix}.$$

PROPOSITION 2.9. *Let H_a and H_b be Hadamard matrices of degree a and b. Then $H_a \otimes H_b$ is a Hadamard matrix of degree ab.*

COROLLARY 2.10. *Let $H_1 = (1)$ and $H_2 = \left(\begin{smallmatrix} 1 & 1 \\ -1 & 1 \end{smallmatrix}\right)$. Then define $H_{2^m} = H_1 \otimes (\bigotimes_{i=1}^{m} H_2)$. Then $H_{2^m} \in M_{2^m}(\{-1,1\})$ is a Hadamard matrix.*

These matrices H_{2^m} are called the Hadamard matrices of Sylvester type. There exists an extensive literature (e.g., [12], [14]) on techniques which deal with the construction of Hadamard matrices.

2.3. Degree 5. The arrays we are interested in are $OA(N,d,2,5)$. We saw that we can construct such an array by using the codewords of a code $(d,N,d_C)_2$ with dual distance 6. Lower-dimension constructions are easier.

2.3.1. $d = 5$, $N = 2^d = 32$. The rows of an $OA(N,d,2,5)$ correspond to the $N = 2^d$ points in $\{-1,1\}^d$.

2.3.2. $d = 6,7,8$, $N = 2^{d-1}$. Let A be the $OA(2^d,d,2,5)$ constructed above. Then define $A_{i,d} = \prod_{j=1}^{d-1} A_{i,j}$. That gives us an $OA(2^{d-1},d,2,5)$.

2.3.3. $d = 9$, $N = 128 = 2^{d-2}$. This is the first example of an orthogonal array constructed from a code, a cyclic code. We will describe in this particular case how to construct this array (or those codewords). Let G be the 7×9 matrix in $GF(2)$ (the Galois field with 2 elements, i.e., $\mathbb{Z}/2\mathbb{Z}$):

$$G = \begin{pmatrix} 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \end{pmatrix}.$$

G is called a cyclic generator matrix. Define the set of points C in $GF(2)^9$:

$$C = \{xG, x \in GF(2)^7\},$$

the calculation being done in $GF(2)$. Let

$$\begin{aligned}\Phi_2 : GF(2) &\longrightarrow \{-1,1\},\\ 0 &\mapsto -1,\\ 1 &\mapsto 1.\end{aligned}$$

Now we can construct a matrix A with rows that are the points in $\Phi_2(C) \subset \{-1,1\}^9$. A is an $OA(128, 9, 2, 5)$.

2.3.4. $d = 10, \ldots, 16$, $N = 256$. The $OA(256, 16, 2, 5)$ is constructed using a Nordstrom–Robinson code. Define the generator matrix G in $M_{4,8}(\mathbb{Z}/4\mathbb{Z})$ by

$$G = \begin{pmatrix} 1 & 3 & 1 & 2 & 1 & 0 & 0 & 0\\ 1 & 0 & 3 & 1 & 2 & 1 & 0 & 0\\ 1 & 0 & 0 & 3 & 1 & 2 & 1 & 0\\ 1 & 0 & 0 & 0 & 3 & 1 & 2 & 1 \end{pmatrix}.$$

Define the set of points

$$C = \{xG, x \in (\mathbb{Z}/4\mathbb{Z})^4\},$$

the calculation being done in $\mathbb{Z}/4\mathbb{Z}$. Let us define the Gray map

$$\begin{aligned}\Phi_4 : \mathbb{Z}/4\mathbb{Z} &\longrightarrow \{-1,1\}^2,\\ 0 &\mapsto (-1,-1),\\ 1 &\mapsto (-1,1),\\ 2 &\mapsto (1,1),\\ 3 &\mapsto (1,-1).\end{aligned}$$

Now we can construct a matrix A with rows that are the elements of $\Phi_4(C) \subset \{-1,1\}^{16}$. A is an $OA(256, 16, 2, 5)$. To get an $OA(256, k, 2, 5)$ for $k = 10, \ldots, 15$, we just delete $16 - k$ columns of A.

2.3.5. Higher dimension. $OA(512, 20, 2, 5)$ and $OA(1024, 24, 2, 5)$ are described in [14]. Many more $OA(N, d, 2, 5)$ for higher d are known, in particular with $d = 2^m + 1$ and $N = 2^{2m+1}$ when $m \geq 5$. They come from BCH codes [14], [20]. The X4 construction [14] allows the construction of some $OA(2^{4m+1}, 2^{2m} + 2m, 2, 5)$ for $m \geq 2$. Finally, Kerdock codes ([20] for their original construction or [13] for a simpler one) gives us orthogonal arrays of the form $OA(4^{2m}, 4^m, 2, 5)$ for $m \geq 2$. Those codes allow us to write $N_5(d) = O(d^2)$.

2.4. A notation. We will denote by $\mathcal{G}_d^m$ the set of points of a cubature formula of degree m with respect to $\delta_{\mathcal{G}_d}$ (with points in $\{-1,+1\}^d$), such that we do not know another cubature formula with points in $\{-1,+1\}^d$, of the same degree with respect to the same measure but with fewer points. When $d \geq m$, $\mathcal{G}_d^m$ is described in term of an $OA(|\mathcal{G}_d^m|, d, 2, m)$. $\mathcal{G}_d^m$ can be also seen as a subset of the group $\mathcal{G}_d \simeq (\{-1,+1\}^d, *)$. When $d \leq m$, necessarily, we have $\mathcal{G}_d^m = \mathcal{G}_d$.

Hadamard matrices allow us to write $|\mathcal{G}_d^3| = 2d$ anytime that there exists a Hadamard matrix and $|\mathcal{G}_d^3| = O(d)$. Kerdock and BCH codes allow us to write $|\mathcal{G}_d^5| = O(d^2)$. For a general m, coding theory tells us that $|\mathcal{G}_d^{2m+1}| = O(d^m)$.

3. Permutation sets. Let us consider a point $\mathbf{x} = (x^1, \dots, x^d) \in \mathbb{R}^d$ and the measure of total mass one which puts equal mass at all the points of the form $\sigma.\mathbf{x} = (x^{\sigma(1)}, \dots, x^{\sigma(d)})$ for $\sigma \in \mathcal{S}_d$, i.e.,

$$\delta_{\mathcal{S}_d,\mathbf{x}} = \frac{1}{|\mathcal{S}_d.\mathbf{x}|} \sum_{\mathbf{y}\in\mathcal{S}_d.\mathbf{x}} \delta_{\mathbf{y}}$$

where $\mathcal{S}_d$ denotes the symmetric group. We want to describe a cubature formula of degree m with respect to $\delta_{\mathcal{S}_d,\mathbf{x}}$.

3.1. Block designs. We assume in this subsection that $x^1 = \cdots = x^k = \alpha$ and $x^{k+1} = \cdots = x^d = \beta$, where $\alpha \neq \beta$. Hence, we are looking for a cubature formula of degree t with respect to the measure on $\mathbb{R}^d$:

$$\delta_{\mathcal{S}_d,\mathbf{x}} = \frac{1}{\binom{d}{k}} \sum_{\mathbf{y}\in\mathcal{S}_d.\mathbf{x}} \delta_{\mathbf{y}}.$$

Knowledge of some t-designs will allow us to construct some cubature formulae of degree t.

DEFINITION 3.1. *Let V be a finite set of size v and let B be a collection of k-subsets of V, called blocks. Then (V, B) is a t-design with parameters t-(v, k, λ) if every t-subset of V is in exactly λ blocks.*

The incidence matrix A of a design $(V, B) = (\{1, \dots, v\}, \{B_1, \dots, B_b\})$ is defined, for $i = 1, \dots, b$ and $j = 1, \dots, v$, by

$$A_{i,j} = \mathbf{1}_{\{j\in B_i\}}.$$

It is easily seen that a t-design with parameters (v, k, λ) is a $(t-1)$-design with parameters $(v, k, \lambda\frac{v-(t-1)}{k-(t-1)})$ [2]. Also, every 0-subset (i.e., the empty set) is included in all the blocks, so a t-design with parameters (v, k, λ) is a 0-design with parameters (v, k, b), where $b = |B|$ is the number of blocks of the design. Hence, if a t-design has parameters (v, k, λ) and has b blocks, then

$$\lambda = b\frac{k(k-1)\dots(k-(t-1))}{v(v-1)\dots(v-(t-1))} = b\frac{\binom{k}{t}}{\binom{v}{t}}.$$

A 2-design is usually called a balanced incomplete block design or just a block design. For a block design, if the number of blocks b is equal to v, we say that the design is symmetric (or square for some authors).

Example 3.2. Let q be a prime power, $n \geq 2$ be an integer, and $V(n, q)$ be a n-dimensional vector space over $GF(q)$ (the Galois field of order q). $V(n, q)$ contains q^n vectors. A one-dimensional space is made of $q-1$ nonzero vectors (it is made of the vectors bx, where b ranges over $GF(q) - \{0\}$ and where x is a nonzero vector); hence there are $\frac{q^n-1}{q-1}$ one-dimensional spaces. If $x = (x_1, \dots, x_n)$ is a nonzero vector, then the set of vectors $y = (y_1, \dots, y_n)$ such that

$$x_1y_1 + \cdots + x_ny_n = 0$$

define a subspace of $V(n, q)$ of dimension $n-1$ (a hyperplane), and conversely, for any hyperplane, we can find a vector $x = (x_1, \dots, x_n)$ such that, for each vector $y = (y_1, \dots, y_n)$ of the hyperplane,

$$x_1y_1 + \cdots + x_ny_n = 0.$$

Thus we have $\frac{q^n-1}{q-1}$ hyperplanes. Each hyperplane contains $\frac{q^{n-1}-1}{q-1}$ one-dimensional spaces (itself being a vector space of dimension $n-1$), and the intersection of two hyperplanes is a subspace of $V(n,q)$ of dimension $n-2$, which contains $\frac{q^{n-2}-1}{q-1}$ one-dimensional spaces. Hence, the hyperplanes of $V(n,q)$ as blocks and the one-dimensional spaces of $V(n,q)$ as objects form a symmetric block design $(\frac{q^n-1}{q-1}, \frac{q^{n-1}-1}{q-1}, \frac{q^{n-2}-1}{q-1})$.

We refer to [2], [3], [12] for more details on designs, and for tables of known block designs.

Let $J_{b,d}$ be the $b \times d$ matrix with each entry set to be 1, and we remind the reader that $\mathbf{x}$ is defined in this subsection by $x^1 = \cdots = x^k = \alpha$ and $x^{k+1} = \cdots = x^d = \beta$, with $\alpha \neq \beta$.

THEOREM 3.3. *Let A be the incidence matrix of a t-design with parameters $t-(d,k,\lambda)$ and with b blocks. Let $\mathbf{x}_1, \ldots, \mathbf{x}_b \in \mathbb{R}^d$ be the rows of $(\alpha-\beta)A + \beta J_{b,d}$. Then those points associated to the constant weight $1/b$ (b is the number of blocks of the t-design) define a cubature formula of degree t with respect to $\delta_{\mathcal{S}_d,\mathbf{x}}$.*

Proof. First of all, note that, by considering the polynomials which are products of some $\frac{(X_j-\beta)^k}{(\alpha-\beta)^k}$ in place of the monomials, we see that we may take $\alpha = 1$ and $\beta = 0$. Since for all $k_1, \ldots, k_d \geq 0$, $\int P(z_1^{k_1}, \ldots, z_d^{k_d}) \delta_{\mathcal{S}_d,\mathbf{x}}(dz) = \int P(z_1, \ldots, z_d) \delta_{\mathcal{S}_d,\mathbf{x}}(dz)$, and since permuting the rows of the incidence matrix of a block design gives another block design with the same parameters, we have only to check that

$$\int P(z) \delta_{\mathcal{S}_d,\mathbf{x}}(dz) = \frac{1}{b} \sum_{i=1}^{b} P(\mathbf{x}_i)$$

for the polynomials X_1, X_1X_2, $\ldots$, $X_1 \ldots X_t$. Define $\lambda_t = \lambda$, and for $i < t$, $\lambda_i = \lambda_{i+1}(d-i)/(k-i)$, so that A is the incidence matrix of an $i-(d,k,\lambda_i)$ design, $i = 1, \ldots, t$. Let $P = X_1 \ldots X_i$. Then

$$\frac{1}{b} \sum_{j=1}^{b} P(\mathbf{x}_j) = \frac{\lambda_i}{b} = \frac{\binom{k}{i}}{\binom{d}{i}}.$$

The proof is then finished by noticing that

$$\int P(z) \delta_{\mathcal{S}_d,\mathbf{x}}(dz) = \binom{d-i}{k-i} \Big/ \binom{d}{k} = \frac{\binom{k}{i}}{\binom{d}{i}}. \qquad \square$$

For cubature formulae of degree 2, symmetric block designs will be very interesting, as they provide formulae with the minimum number of points.

3.2. k-homogeneous permutation sets. We now return to the more general case, i.e., we do not assume anything about the structure of the point $\mathbf{x} = (x^1, \ldots, x^d)$, and we recall that we are looking for a cubature formula of degree t with respect to the d-dimensional measure

$$\delta_{\mathcal{S}_d,\mathbf{x}} = \frac{1}{|\mathcal{S}_d.\mathbf{x}|} \sum_{\mathbf{y} \in \mathcal{S}_d.\mathbf{x}} \delta_{\mathbf{y}}.$$

The symmetric group $\mathcal{S}_d$ acts on the set $T = \{1, \ldots, d\}$ and acts naturally on $T^{\{k\}}$, the set of k-element subsets of T. For A, B in $T^{\{k\}}$, $[A;B]$ denotes the subset of $\mathcal{S}_d$

which consists of all permutations that move A to B. A nonempty subset Z_d of $\mathcal{S}_d$ is said to be k-homogeneous on T if the cardinality of $Z_d \cap [A;B]$ is independent of A and B in $T^{\{k\}}$. The cardinality of $Z_d \cap [A;B]$ is called the k-multiplicity of Z_d. When this cardinality is one, we say that Z_d is sharply k-homogeneous on T. If Z_d is k-homogeneous on T, then Z_d is $(k-1)$-homogeneous on T (when $2 \leq k \leq d/2$ [24]). See [4] for the construction of such sets. Particular cases of k-homogeneous sets are k-homogeneous groups [17].

Example 3.4. Let $K = GF(q)$ be the Galois field of order q, where q is a prime power. Let Γ be the group of mappings from K to $K : x \to ax + b$, where $b \in K$ and a is in the group of nonzero square of K. Then Γ is a sharply 2-homogeneous group on K. $|\Gamma| = q(q-1)/2$.

The link with our problem is explained in the following theorem.

THEOREM 3.5. *Let Z_d be a t-homogeneous set on $T = \{1, \ldots, d\}$. Then the set of points $\sigma.\mathbf{x}$, for $\sigma \in Z_d$, with constant weight $1/|Z_d.\mathbf{x}|$ defines a cubature formula of degree t with respect to $\delta_{\mathcal{S}_d,\mathbf{x}}$.*

Proof. It is straightforward to check the cubature relation for all monomials of degree less than or equal to t. ∎

3.3. A notation. We will denote by $\mathcal{S}_d^{m,\mathbf{x}}$ a subset of $\mathcal{S}_d$ such that the probability measure $\frac{1}{|\mathcal{S}_d^{m,x}.\mathbf{x}|}\sum_{\mathbf{y}\in\mathcal{S}_d^{m,x}.\mathbf{x}} \delta_{\mathbf{y}}$ defines a cubature formula of degree m with respect to $\delta_{\mathcal{S}_d,\mathbf{x}}$ (with points inside the support of $\delta_{\mathcal{S}_d,\mathbf{x}}$ and with positive weights) and such that we do not know another formula with fewer points (with points inside the support of $\delta_{\mathcal{S}_d,\mathbf{x}}$ and with positive weights).

4. Invariant cubature formulae. Now that we have constructed some cubature formulae with few points with respect to some discrete measures, we are going to see how these can be useful for the construction of cubature formulae with respect to a "symmetric" measure. First of all, we should remind the reader of the application to cubature of invariant theory. See [18] for a more detailed presentation.

4.1. Invariant theory. Let $\mathcal{G}$ be a group of bijective linear transformations on $\mathbb{R}^d$. A set Ω of $\mathbb{R}^d$ is said to be $\mathcal{G}$-invariant if, for all $\mathbf{g} \in \mathcal{G}$, $\mathbf{g}.\Omega = \Omega$. A function f on Ω is said to be $\mathcal{G}$-invariant if, for all $\mathbf{g} \in \mathcal{G}$, $f \circ \mathbf{g} = f$. Finally, a measure μ is said to be $\mathcal{G}$-invariant if its support is $\mathcal{G}$-invariant and if, for all measurable sets A and for all $\mathbf{g} \in \mathcal{G}$, $\mathbf{g}.A$ is measurable and $\mu(\mathbf{g}.A) = \mu(A)$. We will denote by $\mathbb{R}_m[X_1, \ldots, X_d](\mathcal{G})$ the space of all $\mathcal{G}$-invariant polynomials of maximum degree m.

DEFINITION 4.1. *A cubature formula with points $\mathbf{x}_1, \ldots, \mathbf{x}_n$ and weights $\lambda_1, \ldots, \lambda_n$ is said to be $\mathcal{G}$-invariant if $\{\mathbf{x}_1, \ldots, \mathbf{x}_n\}$ is $\mathcal{G}$-invariant and $\mathbf{g}.\mathbf{x}_i = \mathbf{x}_j$ implies $\lambda_i = \lambda_j$. Equivalently, the cubature formula is $\mathcal{G}$-invariant if $\sum_{i=1}^n \lambda_i \delta_{\mathbf{x}_i}$ is a $\mathcal{G}$-invariant measure.*

$\mathcal{G}.\mathbf{x}_i = \{\mathbf{g}.\mathbf{x}_i, \mathbf{g} \in \mathcal{G}\}$ is called the orbit of the point $\mathbf{x}_i$. All the weights associated with the points inside the same orbit are equal.

A subset $\{\mathbf{x}_{i_1}, \ldots, \mathbf{x}_{i_k}\}$ is called a generator set of the above cubature formula if $\mathcal{G}.\mathbf{x}_{i_1}, \ldots, \mathcal{G}.\mathbf{x}_{i_k}$ forms a partition of $\{\mathbf{x}_1, \ldots, \mathbf{x}_n\}$. We will also say that the collection of orbits $\mathcal{G}.\mathbf{x}_{i_j}$ and weights $\lambda_{i_j}|\mathcal{G}.\mathbf{x}_{i_j}|$, $j = 1, \ldots, k$, generate the above $\mathcal{G}$-invariant cubature formula.

The following theorem is due to Sobolev [26].

THEOREM 4.2. *Let μ be a $\mathcal{G}$-invariant measure. Then the orbits $\mathcal{G}.\mathbf{x}_1, \ldots, \mathcal{G}.\mathbf{x}_k$ and their weights $\lambda_1, \ldots, \lambda_k$ are the generators of a $\mathcal{G}$-invariant cubature formula of degree m with respect to μ if and only if for all $\mathcal{G}$-invariant polynomials P of degree*

less than or equal to m,

$$\int P(z)\mu(dz) = \sum_{i=1}^{k} \lambda_i P(\mathbf{x}_i).$$

From Tchakaloff's theorem and Sobolev's theorem, we obtain the following corollary.

COROLLARY 4.3. *Let d and m be positive integers and let μ be a positive $\mathcal{G}$-invariant measure on $\mathbb{R}^d$ with the property that $\int |P(z)|\mu(dz) < \infty$ for all $P \in \mathbb{R}_m[X_1, \ldots, X_d]$. Then we can find k orbits $\mathcal{G}.\mathbf{x}_1, \ldots, \mathcal{G}.\mathbf{x}_k$ (in the support of μ) and weights $\lambda_1, \ldots, \lambda_k$ that generate a $\mathcal{G}$-invariant cubature formula of degree m with respect to μ with*

$$k \leq \dim \mathbb{R}_m[X_1, \ldots, X_d](\mathcal{G}).$$

Proof. By Tchakaloff's theorem, we can find n points $\widetilde{\mathbf{x}_1}, \ldots, \widetilde{\mathbf{x}_n}$ in the support of μ together with their weights $\widetilde{\lambda_1}, \ldots, \widetilde{\lambda_n}$ that define a cubature formula of degree m with respect to μ. Then the points $\widetilde{\mathbf{x}_{\mathbf{g},i}} = \mathbf{g}.\widetilde{\mathbf{x}}_i$, $\mathbf{g} \in \mathcal{G}$, $i = 1, \ldots, n$, and the weights $\widetilde{\lambda_{\mathbf{g},i}} = \frac{\widetilde{\lambda}_i}{|\mathcal{G}|}$ define a $\mathcal{G}$-invariant cubature formula of degree m with respect to μ. Let $\mathcal{G}.\widehat{\mathbf{x}_1}, \ldots, \mathcal{G}.\widehat{\mathbf{x}_{k'}}$ be some orbits and $\widehat{\lambda_1}, \ldots, \widehat{\lambda_{k'}}$ some weights that generate this $\mathcal{G}$-invariant cubature formula. $\mathcal{G}.\widehat{\mathbf{x}_1}, \ldots, \mathcal{G}.\widehat{\mathbf{x}_{k'}}$ and $\widehat{\lambda_1}, \ldots, \widehat{\lambda_{k'}}$ generate a $\mathcal{G}$-invariant cubature formula of degree m with respect to μ. If $k^{'} > \dim \mathbb{R}_m[X_1, \ldots, X_d](\mathcal{G})$, using the same convex analysis argument as in Tchakaloff's theorem, it is possible to find $k \leq \dim \mathbb{R}_m[X_1, \ldots, X_d](\mathcal{G})$ orbits $\mathcal{G}.\mathbf{x}_1, \ldots, \mathcal{G}.\mathbf{x}_k \in \{\mathcal{G}.\widehat{\mathbf{x}_1}, \ldots, \mathcal{G}.\widehat{\mathbf{x}_{k'}}\}$ and some new weights $\lambda_1, \ldots, \lambda_k$ that generate a $\mathcal{G}$-invariant cubature formula of degree m with respect to μ. ∎

Assume that the orbits $\mathcal{G}.\mathbf{x}_1, \ldots, \mathcal{G}.\mathbf{x}_k$ together with their weights $\lambda_1, \ldots, \lambda_k$ generate a $\mathcal{G}$-invariant cubature formula of degree m with respect to μ. In other words, $\xi = \sum_{i=1}^{k} \lambda_i \xi_{\mathcal{G},\mathbf{x}_i}$, where $\xi_{\mathcal{G},\mathbf{x}_i} = \frac{1}{|\mathcal{G}.\mathbf{x}_i|} \sum_{\mathbf{y} \in \mathcal{G}.\mathbf{x}_i} \delta_{\mathbf{y}}$, is the measure associated with a cubature formula of degree m with respect to μ. Now assume that, for all i, we can find a cubature formula with n_i points and positive weights with respect to the (discrete) measure $\xi_{\mathcal{G},\mathbf{x}_i}$. Let $\widetilde{\xi_{\mathcal{G},\mathbf{x}_i}}$ denote the measures associated with these cubature formulae. Then $\widetilde{\xi} = \sum_{i=1}^{k} \lambda_i \widetilde{\xi_{\mathcal{G},\mathbf{x}_i}}$ is still a measure associated with a cubature formula of degree m with respect to μ. Note that this cubature formula is no longer $\mathcal{G}$-invariant. Its number of points is $\sum_{i=1}^{k} n_i$. We are going to show that, in the case where $\mathcal{G}$ is the group of permutations and reflections of the axes, $\dim \mathbb{R}_m[X_1, \ldots, X_d](\mathcal{G})$ does not depend on the dimension d and that we can find (and construct) cubature formulae with respect to $\xi_{\mathcal{G},\mathbf{x}_i}$ with the number of points bounded by the Tchakaloff bound. Hence, if we have some orbits and weights generating a $\mathcal{G}$-invariant cubature formula with respect to μ, it is possible to find a cubature formula with respect to μ which has a number of points which grows polynomially with the dimension (at least when $\mathcal{G}$ is the group of permutations and reflections of the axes).

4.2. Invariance under reflection. Let us consider a positive measure μ on $\mathbb{R}^d$ invariant with respect to the group of reflections of the axes $\mathcal{G}_d \simeq (\{-1, +1\}^d, *)$. The Lebesgue measure on the hypercube and on the unit sphere and the Gaussian measure on $\mathbb{R}^d$ are examples of such a measure.

$\mathcal{G}_d$ acts on $\mathbb{R}^d$ in a natural way: for a point $\mathbf{x} = (x^1, \ldots, x^d)$ and an element of the group $\mathbf{g} = (g^1, \ldots, g^d)$, we define $\mathbf{g}.\mathbf{x} = (g^1 x^1, \ldots, g^d x^d)$.

For $\mathbf{x} \in \mathbb{R}^d$, $\mathcal{G}_d.\mathbf{x}$ is of cardinality $2^{e(\mathbf{x})}$, where $e(\mathbf{x})$ is the number of nonzero coordinates of $\mathbf{x}$. That allows us to define the action of $\mathcal{G}_{e(\mathbf{x})}$ on $\mathbf{x}$: Assume that $i_1, \ldots, i_{e(\mathbf{x})}$ are the $e(\mathbf{x})$ nonzero coordinates of $\mathbf{x}$; then for $\mathbf{g} \in \mathcal{G}_{e(\mathbf{x})}$, we define the i_l coordinate of $\mathbf{g}.\mathbf{x}$ to be $g^l x^{i_l}$, while the coordinates which are zero remain zero under the action of $\mathbf{g}$. This just means that we consider only the reflection with respect to the ith axis when $x_i \neq 0$. Obviously, $\mathcal{G}_d.\mathbf{x} = \mathcal{G}_{e(\mathbf{x})}.\mathbf{x}$.

Corollary 4.3 tells us that there exists k (with $k \leq \dim \mathbb{R}_m[X_1, \ldots, X_d](\mathcal{G}_d)$) orbits $\mathcal{G}_d.\mathbf{x}_1, \ldots, \mathcal{G}_d.\mathbf{x}_k$ in the support of the measure μ and k weights $\lambda_1, \ldots, \lambda_k$ that generate a $\mathcal{G}_d$-invariant cubature formula of degree m with respect to μ. The measure $\sum_{i=1}^k \lambda_i \xi_{\mathcal{G}_d,\mathbf{x}_i}$, where $\xi_{\mathcal{G}_d,\mathbf{x}_i} = \frac{1}{|\mathcal{G}_d.\mathbf{x}_i|} \sum_{\mathbf{y} \in \mathcal{G}_d.\mathbf{x}_i} \delta_{\mathbf{y}}$, is then associated with a cubature formula of degree m with respect to μ. But the measure

$$\widetilde{\xi_{\mathcal{G}_d,\mathbf{x}_i}} = \frac{1}{2^{e(\mathbf{x}_i)}} \sum_{\mathbf{g} \in \mathcal{G}^m_{e(\mathbf{x}_i)}} \delta_{\mathbf{g}.\mathbf{x}_i}$$

defines a cubature formula of degree m with respect to $\xi_{\mathcal{G}_d,\mathbf{x}_i}$ ($\mathcal{G}^m_{e(\mathbf{x}_i)}$ has been defined in terms of orthogonal arrays in section 2). Hence, the finite measure $\sum_{i=1}^k \lambda_i \widetilde{\xi_{\mathcal{G}_d,\mathbf{x}_i}}$ defines a cubature formula of degree m with respect to μ.

The number of points in this cubature formula is $\sum_{i=1}^k |\mathcal{G}^m_{e(\mathbf{x}_i)}| \leq k|\mathcal{G}^m_d|$. We saw that $|\mathcal{G}^m_d| = O(d^{[m/2]})$. We therefore need to find a way to find k generators, with k growing polynomially with the dimension. First, let us write the problem in equivalent terms.

For $\mathbf{x} \in \mathbb{R}^d$, let us denote

$$\mathbf{x}^2 = \left(\left(x^1\right)^2, \ldots, \left(x^d\right)^2 \right)$$

and

$$\sqrt{\mathbf{x}} = \left(\sqrt{x^1}, \ldots, \sqrt{x^d} \right).$$

We associate with our measure μ the measure $\nu = \mu \circ \sqrt{.}$ with support included in $\mathbb{R}^d_+$, such that, for all integrable functions f,

$$\int f(z^2)\mu(dz) = \int f(z)\nu(dz).$$

Assume that the orbits $\mathcal{G}_d.\mathbf{x}_1, \ldots, \mathcal{G}_d.\mathbf{x}_k$ in the support of the measure μ and the weights $\lambda_1, \ldots, \lambda_k$ generate a $\mathcal{G}_d$-invariant cubature formula of degree m with respect to μ. Then the points $\mathbf{x}_1^2, \ldots, \mathbf{x}_k^2$ and the weights $\lambda_1, \ldots, \lambda_k$ define a $\mathcal{G}_d$-invariant cubature formula of degree $[m/2]$ with respect to ν. Indeed, let P be a polynomial of degree less than or equal to $[m/2]$, and let $Q = P(X^2)$. Then

$$\begin{aligned} \sum_{i=1}^k \lambda_i P(\mathbf{x}_i^2) = \sum_{i=1}^k \lambda_i Q(\mathbf{x}_i) &= \sum_{i=1}^k \lambda_i \frac{1}{2^{e(\mathbf{x}_i)}} \sum_{y \in \mathcal{G}_d.\mathbf{x}_i} Q(y) \\ &= \int Q(z)\mu(dz) = \int P(z)\nu(dz). \end{aligned}$$

It is straightforward to check that, reciprocally, if the points $\mathbf{x}_1, \ldots, \mathbf{x}_k$ in the support of the measure ν and the weights $\lambda_1, \ldots, \lambda_k$ define a cubature formula of degree $[m/2]$

with respect to ν, then the orbits $\mathcal{G}_d.\sqrt{\mathbf{x}_1}, \dots, \mathcal{G}_d.\sqrt{\mathbf{x}_k}$ in the support of the measure μ and the weights $\lambda_1, \dots, \lambda_k$ generate a $\mathcal{G}_d$-invariant cubature formula of degree m with respect to μ.

Therefore, to find these k generators, $\mathcal{G}_d.\mathbf{x}_1, \dots, \mathcal{G}_d.\mathbf{x}_k$ is equivalent to finding a cubature formula of degree $[m/2]$ with respect to $\nu = \mu \circ \sqrt{.}$. We are now going to show that this problem is simpler when ν is invariant with respect to the group of permutation of the axes $\mathcal{S}_d$ (which is equivalent to the fact that μ is invariant with respect to the group of permutation of the axes $\mathcal{S}_d$).

4.3. Invariance under permutation. Let us consider a positive measure ρ on $\mathbb{R}^d$ invariant with respect to the group of permutation of the axes $\mathcal{S}_d$. The Lebesgue measure on the hypercube and on the unit sphere and the Gaussian measure on $\mathbb{R}^d$ are again examples of such a measure.

Corollary 4.3 tells us that there exist k (with $k \leq \dim \mathbb{R}_m[X_1, \dots, X_d](\mathcal{S}_d)$) orbits $\mathcal{S}_d.\mathbf{x}_1, \dots, \mathcal{S}_d.\mathbf{x}_k$ in the support of the measure ρ and k weights $\lambda_1, \dots, \lambda_k$ that generate a $\mathcal{S}_d$-invariant cubature formula of degree m with respect to ρ. Then, by definition, $\sum_{i=1}^k \lambda_i \delta_{\mathcal{S}_d.\mathbf{x}}$, (where $\delta_{\mathcal{S}_d.\mathbf{x}} = \frac{1}{|\mathcal{S}_d.\mathbf{x}|} \sum_{\mathbf{y} \in \mathcal{S}_d.\mathbf{x}} \delta_{\mathbf{y}}$) is the measure associated with a cubature formula of degree m with respect to ρ. But the measure

$$\widetilde{\delta_{\mathcal{S}_d.\mathbf{x}}} = \frac{1}{|\mathcal{S}_d^{m,\mathbf{x}}.\mathbf{x}_i|} \sum_{\sigma \in \mathcal{S}_d^{m,\mathbf{x}_i}} \sigma.\mathbf{x}_i$$

defines a cubature formula of degree m with respect to $\delta_{\mathcal{S}_d.\mathbf{x}}$ ($\mathcal{S}_d^{m,\mathbf{x}}$ has been defined in terms of designs and permutation sets in section 3). Hence, the finite measure $\sum_{i=1}^k \lambda_i \widetilde{\delta_{\mathcal{S}_d.\mathbf{x}}}$ defines a cubature formula of degree m with respect to ρ. This formula has $\sum_{i=1}^k |\mathcal{S}_d^{m,\mathbf{x}_i}|$ points.

$\mathbb{R}_m[X_1, \dots, X_d](\mathcal{GS}_d)$ is generated by $\sum_{\sigma \in \mathcal{S}_d} X_{\sigma(1)}^{p_1} \dots X_{\sigma(d)}^{p_d}$ for $(p_1, \dots, p_d)$ describing $\mathcal{P}_{m,d}$, where

$$\mathcal{P}_{m,d} = \{p = (p_1, \dots, p_d), \quad |p| \leq m, \quad m \geq p_1 \geq p_2 \geq \dots \geq p_d \geq 0\}.$$

For all $d \geq m$, $|\mathcal{P}_{m,d}| = |\mathcal{P}_{m,m}|$. This cardinality can be expressed in terms of number of Young tableaux [19]. The very important point here is that k, the number of generators, is bounded by a term ($|\mathcal{P}_{m,m}|$) which *does not depend on the dimension.* Thus, to get a cubature formula with respect to a symmetric measure with few points, one has to find k generators (and we know that we can do it with k bounded by $|\mathcal{P}_{m,m}|$) and "good" cubature formulae with respect to $\delta_{\mathcal{S}_d.\mathbf{x}}$ (this is a combinatorial problem; we gave some indications on how to do so in section 3).

4.4. Invariance under permutation and reflection. We now put the two previous sections together. Recall that $\mathcal{GS}_d$ is the group generated by all reflections and permutations of the axes. μ will now denote a positive measure on $\mathbb{R}^d$ which is $\mathcal{GS}_d$-invariant. The Lebesgue measure on the hypercube and on the unit sphere and the Gaussian measure on $\mathbb{R}^d$ are, once again, examples of such a measure.

We summarize our technique to find cubature formulae of degree m with respect to our $\mathcal{GS}_d$-invariant measure μ.

1. Find k orbits $\mathcal{GS}_d.\mathbf{x}_1, \dots, \mathcal{GS}_d.\mathbf{x}_k$ (with their elements in the support of μ) and k positive weights $\lambda_1, \dots, \lambda_k$ that generate a $\mathcal{GS}_d$-invariant cubature formula of degree m with respect to μ. This is equivalent to the fact that orbits $\mathcal{S}_d.\mathbf{x}_1^2, \dots, \mathcal{S}_d.\mathbf{x}_k^2$ and the weights $\lambda_1, \dots, \lambda_k$ that generate an $\mathcal{S}_d$-invariant

cubature formula of degree $[m/2]$ with respect to $\nu = \mu \circ \sqrt{.}$. One should be able to find these generators with $k \leq |\mathcal{P}_{[m/2],[m/2]}|$.

2. For all $i = 1, \dots, k$, construct, using the methods of section 3, a cubature formula of degree $[m/2]$ with respect to $\delta_{\mathcal{S}_d,\mathbf{x}}$. Those points are the points in $\mathcal{S}_d^{[m/2],x_i}.\mathbf{x}_i^2 = \{\mathbf{x}_{i,1}^2, \dots, \mathbf{x}_{i,n_i}^2\}$. The points $\mathbf{x}_{i,j}^2$, $i = 1, \dots, k$, $j = 1, \dots, n_i$, with the weights $\frac{\lambda_i}{n_i}$ now define a cubature formula of degree $[m/2]$ with respect to $\mu \circ \sqrt{.}$. Equivalently, the orbits $\mathcal{G}_d.\mathbf{x}_{i,j}$ and the weights $\frac{\lambda_i}{n_i}$ generate a $\mathcal{G}_d$-invariant cubature formula of degree m with respect to μ.
3. The points in $\mathbf{g}.\mathbf{x}_{i,j}$, $i = 1, \dots, k$, $j = 1, \dots, n_i$, $\mathbf{g} \in \mathcal{G}^m_{e(\mathbf{x}_i)}$, with the weights $\frac{\lambda_i}{n_i |\mathcal{G}^m_{e(\mathbf{x}_i)}|}$ define a cubature formula of degree m with respect to μ.

Example 4.4. Consider a $\mathcal{GS}_d$-invariant measure μ_d on $\mathbb{R}^d$ (for example, the Gaussian measure or the Lebesgue measure on the unit cube or on the unit sphere). Let V be the volume of μ_d, and assume that $\mathbf{x} = \sqrt{\frac{1}{V}\int z^2 \mu_d(dz)}$ belongs to the support of μ_d. Then the generator $\mathcal{G}_d.\mathbf{x}$ and its weight V generate a $\mathcal{G}_d$-invariant cubature formula of degree 3 with respect to μ_d (hence it provides a cubature formula with 2^d points). Using our construction, we see that the points $\mathbf{g}.\mathbf{x}$, $\mathbf{g} \in \mathcal{G}_d^3$, with their weight $V/|\mathcal{G}_d^3|$, define a cubature formula of degree 3 with respect to μ_d. It has $|\mathcal{G}_d^3| = O(d)$ points. Recall that $\mathcal{G}_d^3$ was defined in terms of Hadamard matrices and that whenever there exists a Hadamard matrix of degree d, $|\mathcal{G}_d^3| = 2d$ (which is the Möller lower bound [22]).

Let us now construct cubature formula of degree 5 with few points for some classical measures.

5. Application to some classical regions. In this section, we will describe cubature formula of degree 5 for the region C_d, $E_d^{r^2}$, U_d, S_d.

5.1. $E_d^{r^2}$, the Gaussian measure on $\mathbb{R}^d$. Our definition of $E_d^{r^2}$ differs very slightly from the one given by Stroud. We consider the measure on $\mathbb{R}^d$

$$\mu_d(d\mathbf{x}) = \frac{1}{(2\pi)^{d/2}} \exp\left(-\frac{x_1^2 + \cdots + x_d^2}{2}\right) dx_1 \dots dx_d.$$

We choose this definition of $E_d^{r^2}$ so that $\int f(z)\mu_d(z) = \mathbb{E}(f(N))$, where N is a d-dimensional normal random variable. First of all, we write $\nu_d = \mu_d \circ \sqrt{.}$. One can easily see that $\nu_d = \nu_1 \otimes \cdots \otimes \nu_1$ and that

$$\int 1\nu_1(dx) = 1, \quad \int x\nu_1(dx) = 1, \quad \int x^2\nu_1(dx) = 3.$$

We will provide two constructions.

5.1.1. First solution. When the dimension d is of the form $d = 3k - 2$, the orbits $\mathcal{GS}_d.x_0$ and $\mathcal{GS}_d.\mathbf{x}_1$, where

$$\mathbf{x}_0 = (0, \dots, 0), \quad \mathbf{x}_1 = (\sqrt{3}, \dots, \sqrt{3}, 0, \dots, 0)$$

(k coordinates of $\mathbf{x}_1$ are equal to $\sqrt{3}$, $2k-2$ to 0), with the weights

$$\omega_0 = \tfrac{2}{d+2}, \quad \omega_1 = \tfrac{d}{d+2},$$

generate a $\mathcal{GS}_d$-invariant cubature formula of degree 5 with respect to μ_d. Thus we need to find a cubature formula of degree 2 with respect to

$$\delta_{\mathcal{S}_d,\mathbf{x}} = \frac{1}{|\mathcal{S}_d.\mathbf{x}_1|} \sum_{\mathbf{y} \in \mathcal{S}_d.\mathbf{x}_1^2} \delta_{\mathbf{y}}.$$

According to section 3, this can be done by using a 2-design with parameters

$$2-(3k-2,k,\lambda)$$

for a given λ. A few symmetric block designs will give us good answers. There exist symmetric block designs with parameters $(7,3,1)$, $(16,6,2)$, $(25,9,3)$ [3], and $(70,24,8)$ [16] and more generally with parameters $(3^{k+2}-2,3^{k+1},3^k)$ [15], [21] and $(2.9^{k+1}-2,6.9^k,2.9^k)$ [27]. Symmetric design of the form $(9\lambda-2,3\lambda,\lambda)$ do not exist when $\lambda=4,5,6,7$. We give an example of the simplest of these block designs, described by its incidence matrix,

$$A_{7,3,1}=\begin{pmatrix}0&0&0&1&0&1&1\\1&0&0&0&1&0&1\\1&1&0&0&0&1&0\\0&1&1&0&0&0&1\\1&0&1&1&0&0&0\\0&1&0&1&1&0&0\\0&0&1&0&1&1&0\end{pmatrix}. \tag{2}$$

Therefore, assume that there exists a symmetric block design A with parameters $2-(d,(d+2)/3,(d+2)/9)$. Now define $\mathbf{x}_{1,i}$, $i=1,\ldots,d$, to be $\sqrt{3}$ times the ith row of A. Then $\mathbf{x}_{1,1}^2,\ldots,\mathbf{x}_{1,d}^2$ together with equal weights $1/d$ define a cubature formula of degree 2 with respect to $\delta_{\mathcal{S}_d.\mathbf{x}}$. Then the point $\mathbf{x}_0$ with its weight $\frac{2}{d+2}$ and the points $\mathbf{g}.\sqrt{\mathbf{x}_{1,i}}$ for $\mathbf{g}\in\mathcal{G}^5_{(d+2)/3}$, $i=1,\ldots,d$, with their weights equal to $\frac{1}{|\mathcal{G}^5_{(d+2)/3}|(d+2)}$, define a cubature formula of degree 5 with respect to the Gaussian measure μ_d. Thus, every time that there exists a design $(d=9\lambda-2,3\lambda,\lambda)$, we can construct a cubature formula of degree 5 with respect to the d-dimensional Gaussian measure, with the number of points being equal to $d|\mathcal{G}^5_{(d+2)/3}|+1=O(d^3)$. If we want to find a cubature formula for a given dimension for which the above method does not work (as we need the existence of some specific design), we choose the least d' greater than d such that the method works; then we project our points on a d-dimensional subspace of $\mathbb{R}^{d'}$ to get a cubature formula of degree 5 with respect to μ_d. It is interesting to note that, for $\lambda=1$ (hence $d=7$), that leads to a formula with $7|\mathcal{G}^5_3|+1=57$ points, which is exactly the Möller lower bound [22]. Considering that known cubature formulae of degree greater than 4 in dimension greater than 3 attaining the Möller lower bound are quite rare, it is surprising that this formula is actually the second cubature formula (with positive weights) for $E_d^{r^2}$ attaining the Möller lower bound. (See [28] for a description of the first one.)

5.1.2. Second solution. Let

$$\mathbf{x}_0=(r,0,\ldots,0),\quad \mathbf{x}_1=(s,\ldots,s),$$

where

$$r^2=\tfrac{d+2}{2},\quad s^2=\tfrac{d+2}{d-2}.$$

Then the orbits $\mathcal{GS}_d.\mathbf{x}_0$ and $\mathcal{GS}_d.\mathbf{x}_1$, with the weights

$$w_0=\tfrac{8d}{(d+2)^2},\quad w_1=\left(\tfrac{d-2}{d+2}\right)^2,$$

generate a $\mathcal{GS}_d$-invariant cubature formula of degree 5 with respect to μ_d. We denote by (a, b), for $a, b \in \{1, \ldots, d\}$, the permutation which swaps a and b and leaves invariant all the other elements.

Then the points $\pm(1, i).\mathbf{x}_0$, $i = 1, \ldots, d$, with their weights $\frac{w_0}{2d}$ and $\mathbf{g}.\mathbf{x}_1$, $\mathbf{g} \in \mathcal{G}_d^5$, with their weights $\frac{w_1}{|\mathcal{G}_d^5|}$, define a cubature formula of degree 5 with respect to the Gaussian measure μ_d. The formula has $|\mathcal{G}_d^5| + 2d = O(d^2)$ points. The orbits and the weights were obtained from the cubature formula $E_n^{r^2} : 5 - 3$ [28, p. 317].

5.2. C_d, the d-dimensional cube. We place on $[-1, 1]^d$ the measure

$$\mu_d(d\mathbf{x}) = \frac{1}{2^d} dx_1 \ldots dx_d.$$

Thus once again, we want to find a symmetric cubature formula of degree 2 with respect to the measure associated with μ_d. This measure ν_d is actually equal to

$$\nu_d(d\mathbf{x}) = \frac{1}{2^d} \frac{1}{\sqrt{x_1 \ldots x_d}} dx_1 \ldots dx_d.$$

Assume that the dimension d is odd and let

$$\alpha = \sqrt{\tfrac{1}{3} + \tfrac{2}{3\sqrt{5}}}, \quad \beta = \sqrt{\tfrac{1}{3} - \tfrac{2}{3\sqrt{5}}}.$$

Define $\mathbf{x}_0 = (\alpha, \ldots, \alpha)$ and $\mathbf{x}_1 \in \mathbb{R}^d$ such that $\mathbf{x}_1^i = \alpha$ if $i = 1, \ldots, (d-1)/2$ and $\mathbf{x}_1^i = \beta$ if $i = (d+1)/2, \ldots, d$. Then the orbits $\mathcal{GS}_d.x_0$ and $\mathcal{GS}_d.\mathbf{x}_1$, with the weights

$$w_0 = \tfrac{1}{d+1}, \quad w_1 = \tfrac{d}{d+1},$$

generate a $\mathcal{GS}_d$-invariant cubature formula of degree 5 with respect to μ_d. To find a cubature formula with respect to $\delta_{\mathcal{S}_d, \mathbf{x}}$, we need to find a $2 - (d, (d-1)/2, \lambda)$ design.

Symmetric block design with parameter $(4k - 1, 2k - 1, k)$ are called Hadamard designs, and they exist whenever a Hadamard matrix of degree $4k$ exists [2, Chapter I.9]. Indeed, let A be a Hadamard matrix of degree $4k$; we can always take its first column and first row to be full of 1's. Then replace the -1 by 0 and delete the first row and the first column. This gives the incidence matrix B of a 2-$(4k - 1, 2k - 1, k)$ design. Denote by $\mathbf{x}_{1,1}, \ldots, \mathbf{x}_{1,d}$ the d rows of $(\alpha - \beta)B + \beta J_{d,d}$ ($x_{i,j} \in \mathbb{R}^d$). Then $\mathbf{x}_{1,1}^2, \ldots, \mathbf{x}_{1,d}^2$ and the equal weights $\frac{1}{d}$ define a cubature formula of degree 2 with respect to $\delta_{\mathcal{S}_d, \mathbf{x}}$.

This implies that $\mathbf{x}_0^2, \mathbf{x}_{1,1}^2, \ldots, \mathbf{x}_{1,d}^2$ with equal weights $1/(d+1)$ defines a cubature formula of degree 2 with respect to ν_d. To simplify the notation, let $\mathbf{x}_{1,0} = \mathbf{x}_0$. The points $\mathbf{g}.\mathbf{x}_{1,i}$, $i = 0, \ldots, d$, $\mathbf{g} \in \mathcal{G}_d^5$, with equal weights, define a cubature formula of degree 5 with respect to μ_d. This formula has $(d+1)|\mathcal{G}_d^5|$ points when there exists a Hadamard matrix of degree $d + 1$.

If we want to find a cubature formula for a given dimension which is not the degree of a Hadamard matrix minus one, once again we choose the lower d' greater than d such that we know a Hadamard matrix of degree $d + 1$; then we project our points on a d-dimensional subspace of $\mathbb{R}^{d'}$ to get a cubature formula of degree 5 with respect to μ_d. We get once again a formula with $O(d^3)$ points.

We could have described a formula of the same form as that described in section 5.1.2, but that would lead to points outside the hypercube.

5.3. U_d, the surface of the unit sphere. We consider the Lebesgue measure μ_d on the surface of the d-dimensional unit sphere, i.e., the set of points $\mathbf{x} = (x_1, \dots, x_d)$ such that $x_1^2 + \cdots + x_d^2 = 1$. We denote by $V = \int 1 \mu_d(dx)$ the surface of the unit sphere. We propose here a solution comparable to the one proposed in section 5.1.2. Indeed, let

$$\mathbf{x}_0 = (1, 0, \dots, 0), \quad \mathbf{x}_1 = \left(\sqrt{\tfrac{1}{d}}, \dots, \sqrt{\tfrac{1}{d}}\right)$$

and

$$w_0 = \tfrac{2V}{d+2}, \quad w_1 = \tfrac{dV}{d+2}.$$

The orbits $\mathcal{GS}_d.x_0$ and $\mathcal{GS}_d.\mathbf{x}_1$, with the weights w_0 and w_1, generate a $\mathcal{GS}_d$-invariant cubature formula of degree 5 with respect to μ_d. This leads to a cubature formula of degree 5 with respect to the Lebesgue measure on the unit sphere, with $|\mathcal{G}_d^5| + 2d = O(d^2)$ points. The orbits and the weights were obtained from the cubature formula $U_n : 5 - 2$ [28, p. 294].

5.4. S_d, the unit sphere. We consider the Lebesgue measure μ_d on the unit sphere in $\mathbb{R}^d$, i.e., the set of points $\mathbf{x} = (x_1, \dots, x_d)$ such that $x_1^2 + \cdots + x_d^2 \leq 1$. We denote by $V = \int 1 \mu_d(dx)$ the volume of the unit sphere. Let

$$\mathbf{x}_0 = (r, 0, \dots, 0), \quad \mathbf{x}_1 = (s, \dots, s)$$

and

$$w_0 = \tfrac{2dV}{(d+2)(d+4)r^4}, \quad w_1 = \tfrac{V}{(d+2)(d+4)s^4},$$

where

$$r^2 = 1 - \sqrt{\tfrac{2}{d+4}}, \quad s^2 = \tfrac{d(d+4)+2\sqrt{2(d+4)}}{(d^2+2d-4)(d+4)}.$$

The orbits $\mathcal{GS}_d.x_0$ and $\mathcal{GS}_d.\mathbf{x}_1$, with the weights w_0 and w_1, generate a $\mathcal{GS}_d$-invariant cubature formula of degree 5 with respect to μ_d. This leads, once again, to a cubature formula of degree 5 with respect to the Lebesgue measure on the unit sphere, with $|\mathcal{G}_d^5| + 2d = O(d^2)$ points. The orbits and the weights were obtained from the cubature formula $S_n : 5 - 3$ [28, p. 270].

5.5. Tables. In this section, we present some tables of the same type as those found in [7], [8]. PI means that the weights are positive and the points are inside the support of the measure. EI means that the weights are all equal (and positive) with the points inside the support of the measure. We saw that the number of points depends on the existence on some combinatorial objects and thus cannot easily be expressed as a function of the dimension. We make precise for which d our cubature

formulae are very close (or equal) to the Möller lower bound.

Region	Degree	Number of points	Quality	Ref.
$E_d^{r^2}$	3	$\lvert\mathcal{G}_d^3\rvert = O(d)$ $2d$ if $\exists$ Hadamard matrix of degree d	EI	Example 4.4
C_d	3	$\lvert\mathcal{G}_d^3\rvert = O(d)$ $2d$ if $\exists$ Hadamard matrix of degree d	EI	Example 4.4
S_d	3	$\lvert\mathcal{G}_d^3\rvert = O(d)$ $2d$ if $\exists$ Hadamard matrix of degree d	EI	Example 4.4
$E_d^{r^2}$	5	$\lvert\mathcal{G}_d^5\rvert + 2d = O(d^2)$ $d^2 + 2d$ if d is a power of 4	PI	section 5.1.2
$E_d^{r^2}$	5	$O(d^3)$ Möller lower bound for $d = 7$	PI	section 5.1.1
C_d	5	$O(d^3)$	EI	section 5.2
U_d	5	$\lvert\mathcal{G}_d^5\rvert + 2d = O(d^2)$ $d^2 + 2d$ if d is a power of 4	PI	section 5.3
S_d	5	$\lvert\mathcal{G}_d^5\rvert + 2d = O(d^2)$ $d^2 + 2d$ if d is a power of 4	PI	section 5.4

For $d \in \{3, 24\}$, we determine the exact number of points in these formulae, so that one can compare them with the ones in [7], [8]. No other formulae (of degree 5) with quality PI or EI have fewer points when $d \geq 8$.

6. Conclusion. The main but basic idea of this paper is to find some measures $\xi_1, \ldots, \xi_k$ such that their sum provides a cubature formula with respect to a given measure μ and such that it is relatively easy to find cubature formulae with respect to the measures $\xi_1, \ldots, \xi_k$. Here, we have found these measures $\xi_1, \ldots, \xi_k$ using the invariance of μ with respect to some group of symmetries and the cubature formulae with respect to $\xi_1, \ldots, \xi_k$ using some (well-known) combinatorial objects. We believe that many new cubature formulae (with positive weights, points inside the support of μ, and with few points) can be found using this method.

Acknowledgments. I would like to thank Ben Hambly for his support and the two referees for pointing out many references and helping improve the messy presentation of the first draft.

CONVERGENCE OF FINITE VOLUME APPROXIMATIONS FOR A NONLINEAR ELLIPTIC-PARABOLIC PROBLEM: A "CONTINUOUS" APPROACH*

BORIS A. ANDREIANOV†, MICHAËL GUTNIC‡, AND PETRA WITTBOLD‡

Abstract. We study the approximation by finite volume methods of the model parabolic-elliptic problem $b(v)_t = \operatorname{div}(|Dv|^{p-2}Dv)$ on $(0,T)\times\Omega \subset \mathbb{R}\times\mathbb{R}^d$ with an initial condition and the homogeneous Dirichlet boundary condition. Because of the nonlinearity in the elliptic term, a careful choice of the gradient approximation is needed. We prove the convergence of discrete solutions to the solution of the continuous problem as the discretization step h tends to 0, under the main hypotheses that the approximation of the operator $\operatorname{div}(|Dv|^{p-2}Dv)$ provided by the finite volume scheme is still monotone and coercive, and that the gradient approximation is exact on the affine functions of $x \in \Omega$. An example of such a scheme is given for a class of two-dimensional meshes dual to triangular meshes, in particular for structured rectangular and hexagonal meshes. The proof uses the rewriting of the discrete problem under a "continuous" form. This permits us to directly apply the Alt–Luckhaus variational techniques which are known for the continuous case.

Key words. doubly nonlinear elliptic-parabolic equations, finite volume methods, convergence of approximate solutions, continuous approach

1. Introduction.

Let Ω be an open bounded polygonal domain in $\mathbb{R}^d$, $d \geq 1$, and $T > 0$. We consider the initial boundary value problem for a system of nonlinear elliptic-parabolic equations:

$$\left\{\begin{array}{ll} b(v)_t = \operatorname{div} a_p(Dv) & \text{on } Q = (0,T)\times\Omega, \\ v = 0 & \text{on } \Sigma = (0,T)\times\partial\Omega, \\ b(v)(0,\cdot) = u^0 & \text{on } \Omega, \end{array}\right. \tag{1.1}$$

where $1 < p < \infty$ and $\operatorname{div} a_p(Dv) = \operatorname{div}(|Dv|^{p-2}Dv)$ is the N-dimensional p-Laplacian, i.e.,

$$a_p : \xi = (\xi_1,\dots,\xi_N) \in (\mathbb{R}^d)^N \mapsto |\xi|^{p-2}\xi = \left(\sum_{i,j}|\xi_i^j|^2\right)^{p/2-1}(\xi_1,\dots,\xi_N) \in (\mathbb{R}^d)^N.$$

We assume that

$$\left\{\begin{array}{l} b : \mathbb{R}^N \to \mathbb{R}^N \quad \text{is continuous cyclically monotone;} \quad \text{i.e.,} \\ \text{there exists a convex differentiable function } \Phi : \mathbb{R}^N \to \mathbb{R} \ \text{ s.t. } \ b = \nabla\Phi, \end{array}\right. \tag{1.2}$$

normalized by $b(0) = 0$ and $\Phi(0) = 0$. Moreover, we assume

$$u^0 \in L^1(\Omega)^N \quad \text{with} \quad \Psi(u_0) \in L^1(\Omega), \tag{1.3}$$

where Ψ is the Legendre transform of Φ given by

$$\Psi : z \in \mathbb{R}^N \mapsto \sup_{\sigma \in \mathbb{R}^N} \int_0^1 (z - b(s\sigma))\sigma \, ds = \sup_{\sigma \in \mathbb{R}^N} (\sigma z - \Phi(\sigma)).$$

Equations of elliptic-parabolic type (1.1) arise as models of the flow of fluids through porous media (cf., e.g., [6, 12]). They have already been studied extensively in the literature in the last decade from a theoretical point of view (cf., e.g., [1, 21, 22, 12, 7, 26, 8, 10, 2]). Existence of weak solutions of general systems of elliptic-parabolic equations has been proved in [1], using Galerkin approximations and time-discretization. Similar results have been obtained later by other authors using different methods (e.g., using a semigroup approach as in [7, 8] in the case $N = 1$).

In particular, it is known that in the case of the system (1.1), for any u_0 satisfying (1.3), there exists a weak solution of (1.1), where the weak solution is defined as follows. Denote by E the Banach space $L^p(0,T; W_0^{1,p}(\Omega))^N$ and by E' its dual; $E' = L^{p'}(0,T; W^{-1,p'}(\Omega))^N$, where $p' = p/(p-1)$ is the conjugate exponent of p. Denote by $\langle \cdot, \cdot \rangle_{E',E}$ the duality pairing between E' and E.

DEFINITION 1.1. *A function $v \in E$ is a weak solution of the problem (1.1) if $b(v) \in L^\infty(0,T; L^1(\Omega))^N$ and $b(v)_t \in \mathcal{D}'(Q)^N$ can be extended to a functional χ on E satisfying*

$$\langle \chi, \phi \rangle_{E',E} + \iint_Q a_p(Dv) \cdot D\phi = 0 \quad \textit{for all } \phi \in E, \tag{1.4}$$

$$\langle \chi, \xi \rangle_{E',E} = -\iint_Q b(v)\, \xi_t - \int_\Omega u_0(\cdot)\, \xi(0,\cdot) \qquad \begin{array}{l} \textit{for all } \xi \in E \textit{ with} \\ \xi_t \in L^\infty(Q)^N,\ \xi(T,\cdot) = 0. \end{array} \tag{1.5}$$

Note that if v is a weak solution of (1.1), then, by the "chain rule" lemma of [1], one has

$$\begin{array}{l} B(v) \in L^\infty(0,T; L^1(\Omega))^N, \qquad \text{where} \\ B : z \in \mathbb{R}^N \mapsto b(z)z - \Phi(z) \equiv \displaystyle\int_0^1 (b(z) - b(sz))z ds \equiv \Psi(b(z)) \in \mathbb{R}. \end{array} \tag{1.6}$$

From the results of [26, 10] it also follows that, in the scalar case $N = 1$, there is uniqueness of a weak solution of (1.1). To our knowledge, the question of uniqueness is open in the case $N \geq 2$.

In this paper we study the convergence of time-implicit approximations by finite volume numerical schemes for the model nonlinear elliptic-parabolic problem (1.1). Finite volume methods are well suited for numerical simulation of processes where extensive quantities are conserved, and they are popular methods among engineers in hydrology where equations of this type arise. Therefore justification of convergence of this numerical approximation process is of particular interest. In [17] the finite volume method has been studied and convergence of this approximation procedure has been proved for problem (1.1) in the particular case $p = 2$, $N = 1$. The same method has also been studied for this equation (i.e., $p = 2, N = 1$) in the presence of an additional convection term (cf. [18, 14]), and for a nonlinear diffusion problem in [16]. To our knowledge, in the case $p \neq 2$, only the convergence of finite element methods has been studied (cf. [19, 11, 5, 20] and their references).

Let us emphasize that our main object is not only to prove the convergence of some finite volume methods for (1.1), but also to develop a "continuous" approach for this proof. The main idea of this adaptation is to rewrite the discrete finite volume scheme under an equivalent continuous form and to apply known stability techniques for the continuous equation (cf. [1] and [2, Chap. V] for the version we use) in order to get convergence of discrete solutions to a solution of the continuous problem. The "continuous" approach and the convergence result have already been presented in [3].

In section 2, we describe the finite volume schemes and in particular the admissible flux approximations we use. We show the existence and uniqueness of the solution of a finite volume scheme and give some a priori estimates on discrete solutions. Then we state the convergence result. In section 3, we show in Proposition 3.3 that the solution of a finite volume scheme, originally satisfying a discrete system of algebraic equations, also verifies a "continuous" formulation similar to (1.4), (1.5). This representation makes clear in which sense finite volume schemes approximate the elliptic operator in (1.1); we prove that this approximation is consistent. In section 4 we prove the convergence theorem, passing to the limit in the "continuous" formulation of Proposition 3.3. In section 5, we analyze the two admissibility conditions imposed in section 2. For $d = 2$, we propose a scheme on meshes dual to triangular meshes that enters into our framework; in particular, we have the convergence result on structured rectangular and hexagonal meshes.

We consider the p-Laplacian as a prototype of a class of the so-called Leray–Lions-type operators; in [4], we discuss the extension of the techniques presented above to a particular case of the p-Laplacian operator with convection, studied in [12].

In order to simplify the notation, we restrict the exposition to the scalar equation ($N = 1$). The proofs of the auxiliary results used in section 4 can be found in [4].

2. The numerical method. In order to construct approximate solutions to the problem (1.1), we will use the implicit discretization in time and a finite volume scheme in space.

2.1. Finite volume meshes, discrete gradients and finite volume schemes for the problem (1.1). Let Ω be an open bounded polygonal subset of $\mathbb{R}^d$. A finite volume mesh $\mathcal{T}$ of Ω is given by a family of open polygonal convex subsets of Ω with positive measure, called "control volumes," a family of subsets of $\overline{\Omega}$ contained in hyperplanes of $\mathbb{R}^d$, with positive $(d-1)$-measure (these are the interfaces between control volumes), and a family of points of $\overline{\Omega}$, one per control volume (these are the "centers" of the volumes). For a volume K with center $x_K \in \overline{K}$, the interfaces contained in $\partial\Omega$ are considered as additional "boundary" volumes, unless $x_K \in \partial\Omega$.

For the sake of simplicity, we shall denote by $\mathcal{T}$ the family $(K)_{K\in\mathcal{T}}$ of control volumes; $(x_K)_{K\in\mathcal{T}}$ denotes the family of their centers. The set of all volumes K such that $x_K \in \partial\Omega$ is denoted by $\mathcal{T}_{ext}$, and the set of all volumes K with $x_K \in \Omega$ is denoted by $\mathcal{T}_{int}$. The set of interfaces $K|L$ such that K or L or both belong to $\mathcal{T}_{int}$ is denoted by $\mathcal{E}$, and $K|L$ denotes the interface between two neighbors $K, L \in \mathcal{T}$. For all $K|L$, $\widehat{KL}$ denotes the "diamond" over $K|L$, i.e., the smallest convex set of $\mathbb{R}^d$ containing $K|L$, x_K and x_L. Whenever we use K, $K|L$, or n to index objects and make summations, we mean that $K \in \mathcal{T}$, $K|L \in \mathcal{E}$, and $n \in \{1, \dots, [T/k]+1\}$, where k is the time step of the scheme.

Following [15], we give the following definition.

DEFINITION 2.1. *We say that $\mathcal{T}$ is a finite volume mesh of Ω if the following hold:*

(2.1 i) *The closure of the union of all control volumes is $\overline{\Omega}$.*

(2.1 ii) *For any* $(K, L) \in (\mathcal{T})^2$ *with* $K \neq L$, *either the* $(d-1)$*-dimensional measure of* $\overline{K} \cap \overline{L}$ *is* 0 *or* $\overline{K} \cap \overline{L} = \overline{\sigma}$ *for some* $\sigma \in \mathcal{E}$ *(in which case we denote* $\sigma = K|L = L|K$*).*

(2.1 iii) *For any* $K \in \mathcal{T}$, *there exists a subset* $\mathcal{E}_K$ *of* $\mathcal{E}$ *such that* $\partial K = \cup_{\sigma \in \mathcal{E}_K} \overline{\sigma}$. *Furthermore,* $\mathcal{E} = \cup_{K \in \mathcal{T}} \mathcal{E}_K$. *We will denote by* $\mathcal{N}_K$ *the set of volumes adjacent to* K; *i.e.,* $\mathcal{N}_K = \{L \in \mathcal{T},\ K|L \in \mathcal{E}_K\}$.

(2.1 iv) *The family of points* $(x_K)_K$ *is such that* $x_K \in \overline{K}$ *for all* $K \in \mathcal{T}$, *and it is assumed that the straight line joining* x_K *and* x_L *is orthogonal to* $K|L$ *whenever* $L \in \mathcal{N}_K$.

Denote by $\mathfrak{m}(K)$ and $\mathfrak{d}(K)$ the d-dimensional measure and the diameter of $K \in \mathcal{T}$, respectively; and denote by $m(K|L)$ the $(d-1)$-dimensional measure of $K|L \in \mathcal{E}$. A mesh $\mathcal{T}$ is characterized, in particular, by the following numbers:

$$\text{size}(\mathcal{T}) = \max_K \mathfrak{d}(K), \qquad \zeta^*(\mathcal{T}) = \min_K \min_{\sigma \in \mathcal{E}_K} \frac{\text{dist}\,(x_K, \sigma)}{\mathfrak{d}(K)},$$

$$M(\mathcal{T}) = \max_K \text{card}(\mathcal{E}_K), \qquad \zeta_*(\mathcal{T}) = \frac{\min_K \min_{\sigma \in \mathcal{E}_K} \text{dist}\,(x_K, \sigma)}{\text{size}(\mathcal{T})}.$$

A finite volume method for (1.1) requires a family $\left((\mathcal{T}^h, k^h)\right)_h$ of meshes and corresponding time steps $k^h > 0$ such that both the size of the mesh and the time step go to zero. We will assume in our notation that the family is parametrized with h in some subset of $(0, 1)$ whose closure contains zero, and $\text{size}(\mathcal{T}^h) + k^h \leq h$. A couple $(\mathcal{T}^h, k^h)$ will be called a space-time grid.

In relation to a family $\left((\mathcal{T}^h, k^h)\right)_h$, we define the numbers

$$(2.1)\quad M = \sup_h M(\mathcal{T}^h) \in \overline{\mathbb{N}}, \quad \zeta^* = \inf_h \zeta^*(\mathcal{T}^h) \in \mathbb{R}^+, \quad \text{and} \quad \zeta_* = \inf_h \zeta_*(\mathcal{T}^h) \in \mathbb{R}^+.$$

DEFINITION 2.2. *We say that the family of meshes* $(\mathcal{T}^h)_h$ *is weakly proportional if* $M < \infty$ *and* $\zeta^* > 0$. *We say that the family of meshes* $(\mathcal{T}^h)_h$ *is strongly proportional if, in addition,* $\zeta_* > 0$.

Weak proportionality is standard (cf. [18]). Strong proportionality is a technical assumption which ensures that $(\mathcal{T}^h)_h$ has the interpolation property (cf. sections 2.5 and 5.2).

Given a grid $(\mathcal{T}^h, k^h)$, to each time-space volume $Q_K^n = I^n \times K$, $I^n = (k^h(n-1), k^h n)$ one associates an unknown value $v_K^n \in \mathbb{R}^N$. In order to obtain a finite volume scheme for (1.1), one "integrates" the equation in (1.1) over each grid volume Q_K^n. The time derivative in the left-hand side is approximated by the corresponding finite difference. On the right-hand side, one uses the Green formula and then needs to replace the flux on the lateral boundary of Q_K^n by some function of the unknowns $(v_K^n)_{K,n}$. For problem (1.1), this amounts to finding a substitution for Dv in the expression $\int_{I^n \times K|L} a_p(Dv) \cdot \nu_{K,L}$ (where $\nu_{K,L}$ is the unit normal vector to $K|L$ pointing from K into L). We will assume that this substitution is in L^p on each interface $I^n \times K|L$, typically constant in time and piecewise constant in space. We therefore consider "discrete gradient" operators $\mathcal{D}^h$ of the form

$$(2.2)\qquad \begin{cases} \mathcal{D}^h : (v_K^n)_{K,n} \mapsto (D_{K|L}^n)_{K|L,n}, \\ D_{K|L}^n \in L^p(I^n \times K|L) \quad \text{for all } K|L,\ n. \end{cases}$$

It seems natural, though not necessary, to require that $\mathcal{D}^h$ be a linear operator.

A finite volume scheme for (1.1) is defined by a grid $(\mathcal{T}^h, k^h)$ and a discrete gradient $\mathcal{D}^h$ associated with the grid. Finally, a finite volume method for (1.1) is

given by a family $\big((\mathcal{T}^h, k^h, \mathcal{D}^h)\big)_h$ of grids and associated discrete gradient operators $\mathcal{D}^h$. In sections 2.3 and 2.5 we state the admissibility conditions for such methods.

Now we are able to write the equations for a scheme $(\mathcal{T}^h, k^h, \mathcal{D}^h)$:

$$\mathfrak{m}(K)\frac{b(v_K^n)-b(v_K^{n-1})}{k^h} = \sum_{L\in\mathcal{N}_K}\int_{K|L} a_p(D^n_{K|L}(x))dx\cdot\nu_{K,L} \quad \text{for all } K\in\mathcal{T}^h_{int}, \text{ for all } n\in\{1,\dots,[T/k^h]+1\}. \tag{2.3}$$

The homogeneous Dirichlet boundary condition is taken into account by assigning

$$v_K^n = 0 \quad \text{for all } K\in\mathcal{T}^h_{ext}, \quad \text{for all } n\in\{1,\dots,[T/k^h]+1\}. \tag{2.4}$$

The initial condition is given by any values $v_K^0 \in b^{-1}(u_K^0)$, where

$$u_K^0 = \frac{1}{\mathfrak{m}(K)}\int_K u^0 \quad \text{for all } K\in\mathcal{T}^h_{int}. \tag{2.5}$$

We denote by u_0^h the piecewise constant initial function $\sum_K u_K^0 \mathbb{1}_K$, where $\mathbb{1}_K$ is the characteristic function of the set K. Other choices of u_K^0 are possible, provided one has $u_0^h \to u_0$ a.e. on Ω and $\Psi(u_0^h)\to\Psi(u_0)$ in $L^1(\Omega)$ as $h\to 0$, where Ψ is defined in the introduction. These properties hold for u_K^0 given by (2.5), due to the convexity of Ψ.

We denote by $(\mathcal{S}^h)$ the system (2.3), (2.4), (2.5) corresponding to a given finite volume scheme $(\mathcal{T}^h, k^h, \mathcal{D}^h)$.

2.2. Memento on notation. In this section we collect the most used notation related to the finite volume schemes.

$\mathcal{T}$:	a finite volume mesh;
$\mathcal{T}_{ext}, \mathcal{T}_{int}$:	the set of exterior,interior control volumes;
$\mathcal{E}$:	the set of interfaces between control volumes;
K, L:	control volumes of $\mathcal{T}$;
$K\|L$:	the interface between the two neighbors K and L;
$\mathcal{E}_K$:	the set of all interfaces surrounding K;
$\mathcal{N}_K$:	the set of all neighbors of K;
x_K:	the "center" of K;
$d_{K,L}$:	the distance between x_K and x_L, $d_{K,L} = \|x_K - x_L\|$;
$d_{K,K\|L}$:	the distance between x_K and $K\|L$; one has $d_{K,K\|L} + d_{L,K\|L} = d_{K,L}$;
$\nu_{K,L}$:	the unit normal vector to $K\|L$ pointing from K to L;
$\widehat{KL}$:	the smallest convex set of $\mathbb{R}^d$ containing $K\|L, x_K$, and x_L;
$\mathfrak{d}(K), \mathfrak{m}(K)$:	the diameter and the d-dimensional measure of K, respectively;
size$(\mathcal{T})$:	the size of the mesh $\mathcal{T}$, size$(\mathcal{T}) = \max_K \mathfrak{d}(K)$;
$m(K\|L)$:	the $(d-1)$-dimensional measure of $K\|L$;
$\|R\|$:	the $(d+1)$-dimensional measure of a set $R\subset\mathbb{R}^+\times\mathbb{R}^d$;
I^n:	the time interval, $I^n = ((n-1)k, nk)$;
Q_K^n:	the time-space grid element, $Q_K^n = I^n\times K$;
Σ_K^n:	the lateral boundary of Q_K^n, $\Sigma_K^n = I^n\times\partial K$;
$\Upsilon_\varsigma(K)$:	the union of all control volumes of $(\mathcal{T})$ that are separated from K by at most $(\varsigma-1)$ other control volumes;

$\mathbb{1}_A$: the characteristic function of a set A;
$(\mathcal{T}^h, k^h, \mathcal{D}^h)$: a finite volume scheme (mesh, time step, discrete gradient);
$(\mathcal{S}^h)$: the corresponding system of equations (2.3),(2.4),(2.5);
h: the discretization parameter, $h \geq \mathrm{size}(\mathcal{T}^h) + k^h$;
M, ζ^*: the weak proportionality bounds for $(\mathcal{T}^h)_h$,
$M = \sup_h \max_K \mathrm{card}(\mathcal{N}_K)$, and $\zeta^* = \inf_h \min_K \frac{\min_{L\in\mathcal{N}_K} d_{K,K|L}}{\mathfrak{d}(K)}$;
ζ_*: the strong proportionality bound for $(\mathcal{T}^h)_h$,
$\zeta_* = \inf_h \frac{\min_{K,L\in\mathcal{N}_K} d_{K,K|L}}{\mathrm{size}(\mathcal{T})}$;
v_K^n: the unknown of the scheme $(\mathcal{S}^h)$ corresponding to the volume Q_K^n;
$\overline{v}^h$: a discrete solution for the scheme $(\mathcal{T}^h, k^h, \mathcal{D}^h)$, $\overline{v}^h = \sum_{K,n} v_K^n \mathbb{1}_{Q_K^n}$;
u_0^h: the discrete initial data, $u_0^h = \sum_K u_K^0 \mathbb{1}_K$;
$D_{K|L}^n$: the discrete gradient values on $I^n \times K|L$, $D_{K|L}^n \in L^p(I^n \times K|L)$;
$\mathcal{D}^h$: the discrete gradient operator, $\mathcal{D}^h : (v_K^n)_{K,n} \mapsto (D_{K|L}^n)_{K|L,n}$;
$D_{\perp,K|L}^n$: the value $D_{\perp,K|L}^n = \frac{v_L^n - v_K^n}{d_{K,L}}$, featuring in the "discrete $L^p(0,T;W^{1,p}(\Omega))$ norm" of $\overline{v}^h$;
$\mathcal{D}_\perp^h$: the corresponding operator, $\mathcal{D}_\perp^h : (v_K^n)_{K,n} \mapsto (D_{\perp,K|L}^n)_{K|L,n}$.

It is convenient to extend $\mathcal{D}^h$ (as well as $\mathcal{D}_\perp^h$) to an operator acting from E into $L^p(Q)$. Let $\mathcal{P}^h$ be the operator from Ω to $\bigcup_{K|L}$ which projects $x \in K$ on ∂K along the ray joining x_K to x. We define the appropriate lifting operator $\mathcal{L}^h$ and averaging operator $\mathcal{M}^h$ by

$$\mathcal{L}^h\left[(D_{K|L}^n)_{K|L,n}\right](t,x) = \sum_{K|L,n} D_{K|L}^n(\mathcal{P}^h(x))\, \mathbb{1}_{I^n \times \widehat{KL}}(t,x),$$
$$\mathcal{M}^h : \eta \in L^1(Q) \mapsto \mathcal{M}^h[\eta] = (\eta_K^n)_{K,n} \subset \mathbb{R}^N, \quad \eta_K^n = \frac{1}{|Q_K^n|} \iint_{Q_K^n} \eta.$$

We will abusively write $\mathcal{D}^h$ for the operators $\mathcal{D}^h$, $\mathcal{L}^h \circ \mathcal{D}^h$, and $\mathcal{L}^h \circ \mathcal{D}^h \circ \mathcal{M}^h$; and the same for $\mathcal{D}_\perp^h$.

The following notations, specific to the "continuous" approach, are introduced in sections 2.5 and 3.1.

u^h: the continuous in t interpolation of $b(\overline{v}^h)$, affine on each time interval I^n;
v^h: an interpolated solution in E for $\overline{v}^h$ (cf. Definition 2.8);
$\mathcal{G}^h$: the interpolated gradient operator produced by $(\mathcal{T}^h, k^h, \mathcal{D}^h)$ (cf. Definition 3.2);
$\mathcal{A}$: the elliptic operator in (1.1), $\mathcal{A} : \eta \in E \mapsto -\mathrm{div}\, a_p(D\eta) \in E'$;
$\mathcal{A}^h$: the finite volume approximation of $\mathcal{A}$ produced by the scheme $(\mathcal{T}^h, k^h, \mathcal{D}^h)$, given by $\mathcal{A}^h : \eta \in E \mapsto -\mathrm{div}\, a_p(\mathcal{G}^h[\eta]) \in E'$.

2.3. Admissible flux approximations. For simplicity, we consider only the gradients that yield fully implicit schemes; in this case $\mathcal{D}^h, \mathcal{D}_\perp^h$ act independently on each set $\left(v_K^n\right)_K$, and the dependence on n does not matter for their definition.

Let us introduce the operator $\mathcal{D}_\perp^h$, which appears naturally in the a priori estimates of section 2.4:

$$\mathcal{D}_\perp^h : (v_K)_K \mapsto (D_{\perp,K|L})_{K|L}, \qquad D_{\perp,K|L} = \frac{v_L - v_K}{d_{K,L}} \in \mathbb{R}. \tag{2.6}$$

For $\varsigma \in \mathbb{N}$, denote by $\Upsilon_\varsigma(K)$ the union of all control volumes of $\mathcal{T}$ that are separated from K by at most $(\varsigma-1)$ other control volumes; for instance, $\Upsilon_1(K) = \bigcup_{L\in\mathcal{N}_K} L$. The choice of ς corresponds to the choice of control volumes that are really involved in the construction of $\mathcal{D}^h$ on ∂K.

Now we can make precise the assumptions on discrete gradient operators of the form (2.2).

DEFINITION 2.3. *Let $(\mathcal{T}^h, \mathcal{D}^h)_h$ be a family of finite volume meshes and corresponding discrete gradient operators. The gradient approximation provided by $\mathcal{D}^h$ is admissible if the following hold.*

(2.3 i) *$\mathcal{D}^h$ is linear and injective;*

(2.3 ii) *$\mathcal{D}^h$ provides a strictly monotone scheme; i.e., for all $(v_K)_K, (\widetilde{v}_K)_K \subset (\mathbb{R}^d)^N$ that do not coincide,*

$$\frac{1}{d}\sum_{K|L}\Big((v_L - v_K) - (\widetilde{v}_L - \widetilde{v}_K)\Big)\int_{K|L}\Big(a_p(D_{K|L}(x)) - a_p(\widetilde{D}_{K|L}(x))\Big)dx\cdot\nu_{K,L} > 0,$$

where $(D_{K|L})_{K|L} = \mathcal{D}^h\big[(v_K)_K\big]$, $(\widetilde{D}_{K|L})_{K|L} = \mathcal{D}^h\big[(\widetilde{v}_K)_K\big]$;

(2.3 iii) *$\mathcal{D}^h$ provides a scheme coercive at zero; i.e., there exists a constant $C_* > 0$, independent of h, such that for all $(v_K)_K \subset (\mathbb{R}^d)^N$ and $(D_{K|L})_{K|L} = \mathcal{D}^h\big[(v_K)_K\big]$, one has*

$$\frac{1}{d}\sum_{K|L}\Big(v_L - v_K\Big)\int_{K|L} a_p(D_{K|L}(x))dx\cdot\nu_{K,L} \geq C_*\Big\|\mathcal{D}^h_\perp[(v_K)_K]\Big\|^p_{L^p(\Omega)};$$

and there exists $\varsigma \in \mathbb{N}$, independent of h, such that the following hold.

(2.3 iv) *For each h, $\mathcal{D}^h$ is consistent with affine functions. More exactly, assume that, for $K \in \mathcal{T}^h$ given, there exists an affine function w on Ω such that $v_L = \frac{1}{\mathfrak{m}(L)}\int_L w$ whenever $L \subset \Upsilon_\varsigma(K)$. Then $D_{K|L}(x) = Dw = \text{const}$ for all $x \in K|L$ for all $L \in \mathcal{N}_K$.*

(2.3 v) *There exists a constant C^*, independent of h, such that, for all $\widetilde{K} \in \mathcal{T}^h$ and all sets of values $(v_K)_K$ of $\mathbb{R}^N$,*

$$\int_{\widetilde{K}}\Big|\mathcal{D}^h[(v_K)_K]\Big|^p \leq C^*\int_{\Upsilon_\varsigma(\widetilde{K})}\Big|\mathcal{D}^h_\perp[(v_K)_K]\Big|^p.$$

Conditions (2.3 ii) and (2.3 iv) imply strong restrictions on the gradient approximation. We provide some examples of methods with admissible gradient approximation in section 5.1.

2.4. Discrete solutions. Recall that we consider as unknowns the values v_K^n on $K \in \mathcal{T}_{int}$, assigning v_K^n to be zero in $K \in \mathcal{T}_{ext}$. We will repeatedly use the following "summation by parts" formula (cf., e.g., [15]).

Remark 2.4. Let $\mathcal{T}$ be a finite volume mesh of Ω in the sense of Definition 2.1. Let $(v_K)_{K\in\mathcal{T}} \subset \mathbb{R}^N$, $(F_{K,L})_{(K,L)\in\mathcal{T}^2} \subset \mathbb{R}^N$. Assume $v_K = 0$ for all $K \in \mathcal{T}_{ext}$ and $F_{K,L} = -F_{L,K}$ for all $K|L \in \mathcal{E}$. Then

$$\sum_K v_K \sum_{L\in\mathcal{N}_K} F_{K,L} = \sum_{K|L}(v_K - v_L)\,F_{K,L}.$$

If $(v_K^n)_{K,n}$ verifies $(\mathcal{S}^h)$, we say that the function $\overline{v}^h = \sum_{K,n} v_K^n \mathbb{1}_{Q_K^n}$ is the corresponding discrete solution. We prove the discrete version of the $L^p(0,T;W_0^{1,p}(\Omega))$- a priori estimate on $\overline{v}^h$ (which is exactly the estimate on $\mathcal{D}_\perp^h[\overline{v}^h]$ in L^p), and the discrete version of (1.6).

PROPOSITION 2.5. *Let $\big((\mathcal{T}^h, k^h)\big)_h$ be a family of finite volume grids and let $\big(\mathcal{D}^h\big)_h$ be a family of corresponding discrete gradient operators satisfying property* (2.3 iii) *of Definition* 2.3. *Then, for any solution $\overline{v}^h$ of the discrete problem $(\mathcal{S}^h)$, there exists a constant C which depends only on p, d, Ω, T, on C_* in* (2.3 iii), *and on $\|\Psi(u_0)\|_{L^1(\Omega)}$ such that*

$$\text{(i)} \qquad \left\|\mathcal{D}_\perp^h[\overline{v}^h]\right\|_{L^p(Q)}^p = \frac{1}{d}\sum_{K|L,n} m_{(K|L)} d_{K,L}\left|\frac{v_L^n - v_K^n}{d_{K,L}}\right|^p \le C;$$

$$\text{(ii)} \qquad \left\|B(\overline{v}^h)\right\|_{L^\infty(0,T;L^1(\Omega))} = \sup_{n\in\{1,\dots,[T/k^h]+1\}} \sum_K \mathfrak{m}(K)\, B(v_K^n) \le C.$$

Proof. Take $i \in \{1,\dots,[T/k^h]+1\}$ and multiply each term in (2.3) by v_K^i. By (2.3 iii), using Remark 2.4 and (2.4), one gets

$$\sum_K \mathfrak{m}(K)(b(v_K^i) - b(v_K^{i-1}))\, v_K^i + C_* k^h d \int_\Omega \left|\mathcal{D}_\perp^h[\overline{v}^h]\right|^p \le 0.$$

By the convexity of Φ, one has $(b(v_K^i) - b(v_K^{i-1}))\, v_K^i \ge B(v_K^i) - B(v_K^{i-1})$. Summing over i from 1 to $n \in \{1,\dots,[T/k^h]+1\}$ and taking into account the convexity of Ψ, we infer

$$\sum_K \mathfrak{m}(K) B(v_K^n) + C_* d \int_0^{nk^h}\int_\Omega \left|\mathcal{D}_\perp^h[\overline{v}^h]\right|^p \le \sum_K \mathfrak{m}(K)\Psi(u_K^0) = \sum_K \mathfrak{m}(K)\Psi\left(\frac{1}{\mathfrak{m}(K)}\int_K u^0\right) \le \int_\Omega \Psi(u^0). \qquad \square$$

Next, let us prove the discrete version of the Poincaré inequality and of the compact embedding of $W^{1,p}(\Omega)$ in $L^1(\Omega)$. Note that we do not need any proportionality assumptions on the mesh.

LEMMA 2.6. *Let $\Omega \subset \mathbb{R}^d$ be a polygonal domain of diameter $\mathfrak{d}(\Omega)$, and let $\mathcal{T}$ be a finite volume mesh of Ω. Let $\overline{v}^h = \sum_K v_K \mathbb{1}_K$ such that $(v_K)_{K\in\mathcal{T}} \subset \mathbb{R}$ and $v_K = 0$ for all $K \in \mathcal{T}_{ext}$. Then there exists a constant C which depends only on p and d such that*

$$\text{(i)} \qquad \|\overline{v}^h\|_{L^p(\Omega)} \le C\,\mathfrak{d}(\Omega)\left\|\mathcal{D}_\perp^h[\overline{v}^h]\right\|_{L^p(\Omega)};$$

$$\text{(ii)} \qquad \text{for all } \Delta > 0, \quad \sup_{|\Delta x|\le\Delta}\int_{\mathbb{R}^d} |\overline{v}^h(x+\Delta x) - \overline{v}^h(x)|\, dx \le \Delta \times \left\|\mathcal{D}_\perp^h[\overline{v}^h]\right\|_{L^1(\Omega)}.$$

Proof. (i) For $x \in \Omega$, set $\psi_{K|L}(x) = 1$ in the case that the orthogonal projection of $K|L$ on the hyperplane $\{x_1 = 0\}$ contains $(0, x_2, \dots, x_d)$, and set $\psi_{K|L}(x) = 0$ otherwise. One has

$$|\overline{v}^h(x)|^p \le \frac{1}{2}\sum_{K|L}\psi_{K|L}(x)\left||v_L|^p - |v_K|^p\right| \le C\sum_{K|L}\psi_{K|L}(x)\, d_{K,L}\frac{|v_L - v_K|}{d_{K,L}}\Big(|v_K|^{p-1} + |v_L|^{p-1}\Big).$$

Since $\int_\Omega \psi_{K|L}(x)\,dx \le m(K|L)\,\mathfrak{d}(\Omega)$, one has by the Hölder inequality

$$\int_\Omega |\overline{v}^h(x)|^p\,dx \le C\mathfrak{d}(\Omega)\left(\sum_{K|L}\frac{1}{d}\,m(K|L)\,d_{K,L}\Big|\frac{v_L-v_K}{d_{K,L}}\Big|^p\right)^{\frac{1}{p}}\left(\sum_{K|L}\frac{1}{d}\,m(K|L)\,d_{K,L}\big(|v_K|^p+|v_L|^p\big)\right)^{\frac{p-1}{p}}.$$

Denote $h=\mathrm{size}(\mathcal{T})$. Assertion (i) will follow by the Young inequality if we show that

$$\sum_{K|L}\frac{1}{d}\,m(K|L)\,d_{K,L}\big(|v_K|^p+|v_L|^p\big) \le (1+2^p)\sum_K \mathfrak{m}(K)\,|v_K|^p + 2(2h)^p\sum_{K|L}\frac{1}{d}\,m(K|L)\,d_{K,L}\Big|\frac{v_L-v_K}{d_{K,L}}\Big|^p, \tag{2.7}$$

since $h\le\mathfrak{d}(\Omega)$. Denote by R the left-hand side of (2.7). We have $d_{K,L}=d_{K,K|L}+d_{L,K|L}$; thus

$$R=\sum_K \mathfrak{m}(K)|v_K|^p+\sum_{K|L}\frac{1}{d}m(K|L)(|v_K|^p d_{L,K|L}+|v_L|^p d_{K,K|L}).$$

Note that

$$|v_K|^p d_{L,K|L}\le\begin{cases}2^p|v_L|^p d_{L,K|L} & \text{if } |v_K|\le 2|v_L|,\\ (2h)^p\Big|\frac{v_L-v_K}{d_{K,L}}\Big|^p d_{K,L} & \text{otherwise.}\end{cases}$$

Indeed, if $|v_K|>2|v_L|$, one has $|v_L-v_K|>\frac12|v_K|$ so that

$$|v_K|^p d_{L,K|L}\le|v_K|^p d_{K,L}\le 2^p|v_L-v_K|^p d_{K,L}\le 2^p h^p\Big|\frac{v_L-v_K}{d_{K,L}}\Big|^p d_{K,L}.$$

Using the same argument for $|v_L|^p d_{K,K|L}$, we obtain the desired estimate (2.7).

(ii) Now for $x\in\mathbb{R}^d$, set $\overline{\psi}_{K|L}(x)=1$ in the case where the segment $[x,x+\Delta x]$ crosses $K|L$, and set $\overline{\psi}_{K|L}(x)=0$ otherwise. Note that $\int_{\mathbb{R}^d}\overline{\psi}_{K|L}(x)\,dx\le m(K|L)\,\Delta$; hence (ii) follows, since

$$\int_{\mathbb{R}^d}|\overline{v}^h(x)-\overline{v}^h(x+\Delta x)|\,dx\le\int_{\mathbb{R}^d}\sum_{K|L}\overline{\psi}_{K|L}(x)|v_L-v_K|\,dx \le\Delta\sum_{K|L}m(K|L)d_{K,L}\Big|\frac{v_L-v_K}{d_{K,L}}\Big|.$$ ∎

Now we can state the result for existence and uniqueness of a discrete solution.

THEOREM 2.7. *Let $\mathcal{T}^h$ be a finite volume mesh of Ω, $k^h>0$, and let $\mathcal{D}^h$ be a discrete gradient associated to $\mathcal{T}^h$. If $\mathcal{D}^h$ satisfies* (2.3 iii)*, there exists a solution $(v_K^n)_{K,n}$ to the discrete problem $(\mathcal{S}^h)$. If $\mathcal{D}^h$ satisfies* (2.3 ii)*, the solution is unique.*

Proof of Theorem 2.7. Using Remark 2.4 and the coercivity of the scheme, we apply the Brouwer fixed point theorem and get existence. Uniqueness follows from the monotonicity of $b(\cdot)$ and the strict monotonicity of the scheme. See [3] for more detailed proofs. ∎

2.5. Interpolation property and main result. Consider a family of finite volume schemes $\big((\mathcal{T}^h, k^h, \mathcal{D}^h)\big)_h$ such that h tends to 0. Let $(v_K^n)_{K,n}$ be a solution to the scheme $(\mathcal{S}^h)$ and $\overline{v}^h$ the corresponding discrete solution.

We require the existence of what will be called "interpolated solutions" for $\overline{v}^h$, denoted by v^h, such that $v^h \in E$; these should be close to $\overline{v}^h$ (asymptotically as $h \to 0$) and satisfy the a priori estimate in E analogous to the estimate of Proposition 2.5(i) on $\overline{v}^h$. Moreover, the values $(v_K^n)_{K,n}$ should be recoverable from v^h. To this end, we require $\mathcal{M}^h[v^h] = (v_K^n)_{K,n}$.

DEFINITION 2.8. *A family of grids $\big(\mathcal{T}^h, k^h\big)_h$ has the interpolation property in E if, for any family $(\overline{v}^h)_h$ of functions such that $\overline{v}^h|_{Q_K^n} = v_K^n \equiv \text{const}$ for each $K \in \mathcal{T}^h$, $n \in \{1, \dots, [T/k^h]+1\}$, with $v_K^n = 0$ for $K \in \mathcal{T}_{ext}^h$ and with $\big\|\mathcal{D}_\perp^h[\overline{v}^h]\big\|_{L^p(Q)} \le C$ for all h, there exists a family $(v^h)_h \subset E$ such that*

$$\|v^h - \overline{v}^h\|_{L^p(Q)} \to 0 \quad \text{as} \quad h \to 0, \tag{2.8}$$

$$\mathcal{M}^h[v^h] = (v_K^n)_{K,n}, \tag{2.9}$$

$$\|v^h\|_E \le I(C) \quad \text{with some function } I : \mathbb{R}^+ \mapsto \mathbb{R}^+ \text{ independent of } h. \tag{2.10}$$

If $\overline{v}^h$ is a solution to a finite volume scheme, we say that v^h is an interpolated solution for $\overline{v}^h$.

The interpolation property is the main technical assumption required by the "continuous" approach. In section 5.2 we give two conditions ensuring this property. Now let us state the main result of this paper.

THEOREM 2.9. *Let $\big((\mathcal{T}^{h_m}, k^{h_m}, \mathcal{D}^{h_m})\big)_{m\in\mathbb{N}}$ be a sequence of finite volume schemes, where $k^{h_m} + \text{size}(\mathcal{T}^{h_m}) \le h_m \to 0$ as $m \to \infty$. Assume that the family of meshes is weakly proportional, the gradient approximation is admissible, and the interpolation property holds (cf. Definitions* 2.2, 2.3, and 2.8*).*

For $m \in \mathbb{N}$, let $\overline{v}^{h_m}$ be a discrete solution of (S^{h_m}). Then there exists a subsequence $(h_{m_l})_{l\in\mathbb{N}}$ such that $\overline{v}^{h_{m_l}} \rightharpoonup v$ in $L^p(Q)$ as $l \to \infty$, where v is a weak solution of the problem (1.1)*.*

Note that it suffices to strengthen slightly assumption (2.3 ii) of Definition 2.3 in order to get the strong convergence of $\overline{v}^{h_{m_l}}$ to v in $L^p(Q)$ (cf. [4, Corollary 1]). Moreover, in the case when $N = 1$ the whole sequence converges to the unique solution of (1.1). In this case error estimates can be proved (cf., e.g., [15] for the linear case), but this is not the purpose of the present paper.

In what follows, we write k instead of k^h and omit subscripts in sequences (h_m) and(h_{m_l}), simply writing that h tends to zero.

3. The "continuous" approach. Take the discrete solution $\overline{v}^h = \sum_{K,n} v_K^n \mathbb{1}_{Q_K^n}$ produced by the finite volume scheme $(\mathcal{S}^h)$. Let $v^h \in E$ be a corresponding interpolated solution. We will show that there exist functions $u^h \in L^1(Q)$ and $G^h \in L^p(Q)$ such that $u^h(0,\cdot) = u_0^h(\cdot)$ and $u^h{}_t = \operatorname{div} a_p(G^h)$ in the weak sense of Definition 1.1, and the functions u^h, G^h can be recovered from the interpolated solution. More exactly, we prove in Proposition 3.3 below that $u^h{}_t \in \mathcal{D}'$ can be extended to $\chi^h \in E'$ and

$$\langle \chi^h, \phi\rangle_{E',E} + \iint_Q a_p(\mathcal{G}^h[v^h]) \cdot D\phi = 0 \quad \text{for all} \quad \phi \in E, \tag{3.1}$$

$$\langle \chi^h, \xi \rangle_{E',E} = -\iint_Q u^h\, \xi_t - \int_\Omega u_0^h(\cdot)\, \xi(0,\cdot) \qquad \begin{array}{l}\text{for all } \xi \in E \text{ with} \\ \xi_t \in L^\infty(Q)^N,\ \xi(T,\cdot) = 0,\end{array} \tag{3.2}$$

with an operator $\mathcal{G}^h : E \mapsto L^p(Q)$ to be defined.

The analogy of (3.1), (3.2) with (1.4), (1.5) in Definition 1.1 plays the key role in the proof of the convergence result of Theorem 2.9.

3.1. Interpolated gradient and the "continuous" form of the scheme. First define u^h as the piecewise affine in t interpolation of $b(\overline{v}^h)$:

$$u^h = \sum_{K,n} \left(b(v_K^n) + \frac{t - kn}{k} (b(v_K^n) - b(v_K^{n-1})) \right) \mathbb{1}_{Q_K^n}. \tag{3.3}$$

Then (3.2) holds, since $u^h(0,\cdot) = u_0^h(\cdot)$ and the piecewise constant function ${u^h}_t$ extends to $\chi^h \in E'$ by

$$\langle \chi^h, \phi \rangle_{E',E} = \iint_Q {u^h}_t\, \phi \quad \text{for all } \phi \in E. \tag{3.4}$$

Next, note that in $(\mathcal{S}^h)$ the numerical flux is prescribed on the boundary of each control volume; we will extend it to Q as follows. For given $K \in \mathcal{T}^h_{int}$,$n$ and a function $F_K^n : \partial K \mapsto \mathbb{R}$, consider the following Neumann problem in the factor space $\mathcal{W}(K) = W^{1,p}(K)/\mathbb{R}$:

$$\begin{cases} \operatorname{div} a_p(Dw) = \dfrac{1}{\mathfrak{m}(K)} \displaystyle\sum_{K \in \mathcal{N}_K} \int_{K|L} F_K^n \quad \text{on } K, \\ a_p(Dw) \cdot \nu_K|_{\partial K} = F_K^n, \end{cases} \tag{3.5}$$

where ν_K is the exterior unit normal vector to ∂K. For $K \in \mathcal{T}^h_{ext}$ with $\mathfrak{m}(K) > 0$, we drop in (3.5) the Neumann boundary condition on $\partial K \cap \partial\Omega$ and seek $w \in W^{1,p}(K)$ with $w|_{\partial K \cap \partial\Omega} = 0$.

LEMMA 3.1. *Let $F_K^n \in L^{p'}(\partial K)$ ($F_K^n \in L^{p'}(\partial K \setminus \partial\Omega)$, if $K \in \mathcal{T}^h_{ext}$). Then* (3.5) *admits a unique solution.*

The proof is standard, using the coercivity and monotonicity argument [25, Chap. 2, Th. 2.1]. Now we can introduce the interpolated gradient operator.

DEFINITION 3.2. *The interpolated gradient operator $\mathcal{G}^h : E \mapsto L^p(Q)$ maps $\eta \in E$ into $\mathcal{G}^h[\eta]$ given by*

$$\begin{cases} \mathcal{G}^h[\eta] = \sum_{K,n} D\eta_K^n \mathbb{1}_{Q_K^n}, \quad \text{where} \quad \eta_K^n \in \mathcal{W}(K) \ \text{ solves} \\ -\displaystyle\int_K a_p(D\eta_K^n) \cdot D\varphi + \sum_{L \in \mathcal{N}_K} \int_{K|L} \varphi\, a_p(D^n_{K|L}) \cdot \nu_K = \frac{1}{\mathfrak{m}(K)} \int_K \varphi \sum_{L \in \mathcal{N}_K} \int_{K|L} a_p(D^n_{K|L}) \cdot \nu_K \\ \text{for all } \varphi \in W^{1,p}(K) \ (\text{for all } \varphi \in W^{1,p}(K) \text{ with } \varphi|_{\partial K \cap \partial\Omega} = 0, \ \text{in case } K \in \mathcal{T}^h_{ext}) \\ \text{and the values } D^n_{K|L}(x) \text{ are given by } (D^n_{K|L})_{K|L,n} = \mathcal{D}^h[\eta]. \end{cases}$$

If $\overline{v}^h$ solves $(\mathcal{S}^h)$, we set $G^h = \mathcal{G}^h[\overline{v}^h]$. We remark that $G^h = \mathcal{G}^h[v^h]$ by property (2.9) of interpolated solutions v^h. We show that (3.1) follows from (3.4) and the conservation of fluxes.

PROPOSITION 3.3. *Assume that $(v_K^n)_{K,n}$ is a solution of $(\mathcal{S}^h)$. Let v^h be a corresponding interpolated solution, let u^h and χ^h be defined by* (3.3) *and* (3.4)*, respectively,*

and let $\mathcal{G}^h$ be the interpolated gradient operator of Definition 3.2. *Then* (3.1), (3.2) *hold.*

Proof. It remains to check (3.1). By (3.3), for all $K \in \mathcal{T}^h$ and n, we have

$$u^h{}_t - \operatorname{div} a_p(G^h) = \frac{b(v_K^n) - b(v_K^{n-1})}{k} - \frac{1}{\mathfrak{m}(K)} \sum_{L \in \mathcal{N}_K} \int_{K|L} a_p(D^n_{K|L}(x))dx \cdot \nu_{K,L} = 0$$

everywhere on Q_K^n because of (2.3). Therefore, using (3.4) and integrating by parts in each Q_K^n, we have

$$\begin{aligned}\langle \chi^h, \phi\rangle_{E',E} + \int_Q a_p(\mathcal{G}^h[v^h]) \cdot D\phi \iint_Q u^h{}_t \phi + a_p(G^h) \cdot D\phi \\ = \sum_{K,n} \iint_{Q_K^n} (u^h{}_t - \operatorname{div} a_p(G^h))\phi + \sum_{K,n} \sum_{L \in \mathcal{N}_K} \iint_{I^n \times K|L} \phi\, a_p(D^n_{K|L}) \cdot \nu_{K,L} \\ = 0 + \sum_{K|L,n} \iint_{I^n \times K|L} \phi\, a_p(D^n_{K|L}) \cdot (\nu_{K,L} + \nu_{L,K}) = 0. \qquad \square\end{aligned}$$

3.2. Properties of the interpolated gradient and consistency. In view of (3.1) and (1.4), it is natural to compare the elliptic operator in (1.1),

$$\mathcal{A} : \eta \in E \mapsto -\operatorname{div} a_p(D\eta) \in E', \tag{3.6}$$

with the operators

$$\mathcal{A}^h : \eta \in E \mapsto -\operatorname{div} a_p(\mathcal{G}^h[\eta]) \in E'. \tag{3.7}$$

Indeed, $\mathcal{A}^h$ can be considered as the finite volume approximation of $\mathcal{A}$, whence the following definition.

DEFINITION 3.4. *Let $\big((\mathcal{T}^h, k^h, \mathcal{D}^h)\big)_h$ be a family of finite volume schemes for the problem* (1.1), *with* $\operatorname{size}(\mathcal{T}^h) + k^h \le h \to 0$. *We say that the approximation of* (1.1) *by these schemes is consistent if, for all $\eta \in E$, one has $\mathcal{A}^h[\eta] \to A[\eta]$ in E' as $h \to 0$.*

In this section we prove the following result.

THEOREM 3.5. *Let $\big((\mathcal{T}^h, k^h, \mathcal{D}^h)\big)_h$ be a family of finite volume schemes with a weakly proportional family of meshes and an admissible gradient approximation (cf. Definitions* 2.2 *and* 2.3*). Then it provides a consistent approximation of* (1.1), *in the sense of Definition* 3.4.

The proof of Theorem 3.5 is based upon the following properties of the interpolated gradient operator $\mathcal{G}^h$.

PROPOSITION 3.6. *Let $\big((\mathcal{T}^h, k^h, \mathcal{D}^h)\big)_h$ be a family of finite volume schemes with admissible gradient approximation and weakly proportional family of meshes.*

(i) *There exists a constant C such that for all $\eta \in E$ and $H \subset Q$ such that $H = \bigcup_{i=1}^m Q_{K_i}^{n_i}$,*

$$\iint_H \left|\mathcal{G}^h[\eta]\right|^p \le C \iint_{\Upsilon_{\varsigma+1}(H)} |D\eta|^p,$$

where $\Upsilon_{\varsigma+1}(H) = \bigcup_{i=1}^m I^{n_i} \times \Upsilon_{\varsigma+1}(K_i)$. In particular, $\big(\mathcal{G}^h\big)_h$ are uniformly bounded on E and

$$\left\|\mathcal{G}^h[\eta]\right\|_{L^p(Q)} \le C \|\eta\|_E. \tag{3.8}$$

(ii) *The operators $(\mathcal{G}^h)_h$ are locally equicontinuous on E. More exactly, there exists a constant $C(R)$ such that, whenever $\|\eta\|_E \le R$ and $\|\mu\|_E \le R$,*

$$\big\|\mathcal{G}^h[\eta] - \mathcal{G}^h[\mu]\big\|_{L^p(Q)} \le C(R)\big(\|\eta-\mu\|_E\big)^{\min\{p-1,\frac{1}{p-1}\}}, \tag{3.9}$$

$$\big\|a_p(\mathcal{G}^h[\eta]) - a_p(\mathcal{G}^h[\mu])\big\|_{L^{p'}(Q)} \le C(R)\big(\|\eta-\mu\|_E\big)^{\min\{(p-1)^2,\frac{1}{p-1}\}}. \tag{3.10}$$

In the statement above and in the rest of this section, C denotes a generic constant that depends only on p, d, Ω, on M, ζ^* of (2.1), and on C_*, C^*, ς of Definition 2.3, unless the additional dependence on R is specified. The proof uses the standard properties of the function $a_p(\cdot)$ (cf. [19, 12]): for all $y_1, y_2 \in \mathbb{R}^d$,

$$\begin{cases} |a_p(y_1)-a_p(y_2)|^{p'} \le C\,|y_1-y_2|^p, & 1<p\le 2;\\ |a_p(y_1)-a_p(y_2)|^{p'} \le C\,|y_1-y_2|^{p'}\Big(|y_1|^p+|y_2|^p\Big)^{\frac{p-2}{p-1}}, & p\ge 2; \end{cases} \tag{3.11}$$

$$\begin{cases} |y_1-y_2|^p \le C\left[(a_p(y_1)-a_p(y_2))\cdot(y_1-y_2)\right]^{\frac{p}{2}}\Big[|y_1|^p+|y_2|^p\Big]^{\frac{2-p}{2}}, & 1<p\le 2;\\ |y_1-y_2|^p \le C\,(a_p(y_1)-a_p(y_2))\cdot(y_1-y_2), & p\ge 2. \end{cases} \tag{3.12}$$

Before turning to the proofs of Proposition 3.6 and Theorem 3.5, note the following three lemmas.

LEMMA 3.7. *Let $K \subset \mathbb{R}^d$ be a bounded convex domain of $\mathbb{R}^d$ of diameter $\mathfrak{d}(K)$ and d-dimensional measure $\mathfrak{m}(K)$. Assume that K contains a ball of radius $\zeta^*\mathfrak{d}(K) > 0$. Then there exists a constant C such that, assigning $\overline{w} = \frac{1}{\mathfrak{m}(K)}\int_K w$, one has*

$$\int_{\partial K} |w-\overline{w}|^p \le C\,(\mathfrak{d}(K))^{p-1}\int_K |Dw|^p$$

for all $w \in W^{1,p}(K)$, where $w|_{\partial K}$ is understood in the sense of traces.

Proof. Applying, e.g., the proofs of [13, Theorems 59, 60, and 76] with $p=2$ replaced by a general $p \in (1,+\infty)$, we obtain the claim of the lemma with C depending on p, d, and the Lipschitz continuity of ∂K. Due to the convexity of K, C actually depends only on p, d, and ζ^*. ∎

LEMMA 3.8. *Let $(\mathcal{T}^h)_h$ be a weakly proportional family of meshes, and let $(\mathcal{D}^h_\perp)_h$ be the operators defined by* (2.6)*. Then there exists a constant C such that for all K, n for all $\eta \in E$,*

$$\iint_{Q_K^n}\Big|\mathcal{D}^h_\perp[\eta]\Big|^p \le C\iint_{I^n\times\Upsilon_1(K)}|D\eta|^p.$$

Proof. Let $\big(\eta_K^n\big)_{K,n} = \mathcal{M}^h[\eta]$ and $\eta^n_{K|L} = \frac{1}{km(K|L)}\int_{I^n\times K|L}\eta$ in the sense of traces. By definition,

$$\begin{aligned}\iint_{Q_K^n}\Big|\mathcal{D}^h_\perp[\eta]\Big|^p &= \sum_{K|L}\frac{1}{d}\,k\,m(K|L)\,d_{K,K|L}\left|\frac{\eta_L^n-\eta_K^n}{d_{K,L}}\right|^p\\ &\le C\sum_{K|L}\frac{1}{d}\,k\,m(K|L)\,d_{K,K|L}\left(\frac{\big|\eta^n_{K|L}-\eta^n_K\big|^p}{(d_{K,K|L})^p}+\frac{\big|\eta^n_{K|L}-\eta^n_L\big|^p}{d_{K,K|L}\,(d_{L,K|L})^{p-1}}\right)\\ &\le C\sum_{K|L}\frac{1}{d}\,k\,m(K|L)\,d_{K,K|L}\left|\frac{\eta^n_{K|L}-\eta^n_K}{d_{K,K|L}}\right|^p + C\sum_{K|L}\frac{1}{d}\,k\,m(K|L)\,d_{L,K|L}\left|\frac{\eta^n_{K|L}-\eta^n_L}{d_{L,K|L}}\right|^p.\end{aligned}$$

By the convexity of the function $z \mapsto |z|^p$ and Lemma 3.7,

$$k\, m(K|L)\, |\eta^n_{K|L} - \eta^n_K|^p \le \iint_{I^n \times K|L} |\eta - \eta^n_K|^p \le C\, \mathfrak{d}(K)^{p-1} \iint_{Q^n_K} |D\eta|^p,$$

and the same holds if K and L are exchanged. Hence by (2.1) we have

$$\iint_{Q^n_K} \left|\mathcal{D}^h_\perp[\eta]\right|^p \le C \sum_{L \in \mathcal{N}_K} \left(\iint_{Q^n_K} |D\eta|^p + \iint_{Q^n_L} |D\eta|^p \right) \le C \iint_{I^n \times \Upsilon_1(K)} |D\eta|^p. \qquad \square$$

LEMMA 3.9. *Let $\left((\mathcal{T}^h, k^h, \mathcal{D}^h)\right)_h$ be a family of finite volume schemes with a weakly proportional family of meshes and an admissible gradient approximation. Then the following hold:*

(i) *For all $R > 0$ there exists a constant $C(R)$ such that, whenever $\|\eta\|_E \le R$ and $\|\mu\|_E \le R$,*

$$\sum_{K,n} \mathfrak{d}(K) \iint_{\Sigma^n_K} \left| a_p(\mathcal{D}^h[\eta]) - a_p(\mathcal{D}^h[\mu]) \right|^{p'} \le C(R) \Big(\|\eta - \mu\|_E \Big)^{\min\{p,p'\}}.$$

(ii) *There exists a constant C such that for all $\eta \in E$ and $H, \Upsilon_{\varsigma+1}(H)$ as in Proposition 3.6 one has*

$$\sum_{i=1}^m \mathfrak{d}(K_i) \iint_{\Sigma^{n_i}_{K_i}} \left|\mathcal{D}^h[\eta]\right|^p \le C \iint_{\Upsilon_{\varsigma+1}(H)} |D\eta|^p.$$

Proof. First take K and consider $\varphi^K = \left|a_p(\mathcal{D}^h[\eta]) - a_p(\mathcal{D}^h[\mu])\right|^{p'} \in L^1(\partial K)$. Recall that the values of $\mathcal{D}^h$ have been extended from ∂K inside K by means of the projection operator $\mathcal{P}^h$ (cf. section 2.2). Hence by (2.1) we have

$$\begin{aligned} \mathfrak{d}(K) \int_{\partial K} |\varphi^K| &= \mathfrak{d}(K) \sum_{L \in \mathcal{N}_K} \int_{K|L} |\varphi^K| \\ &= d \sum_{L \in \mathcal{N}_K} \frac{\mathfrak{d}(K)}{d_{K,K|L}} \int_{\widehat{KL} \cap K} |\varphi^K \circ \mathcal{P}^h| \le \frac{d}{\zeta^*} \int_K |\varphi^K \circ \mathcal{P}^h|. \end{aligned} \tag{3.13}$$

If $1 < p \le 2$, (3.13) and (3.11) yield

$$\sum_{K,n} \mathfrak{d}(K) \iint_{\Sigma^n_K} \left| a_p(\mathcal{D}^h[\eta]) - a_p(\mathcal{D}^h[\mu]) \right|^{p'} \le C \sum_{K,n} \iint_{Q^n_K} \left| \mathcal{D}^h[\eta] - \mathcal{D}^h[\mu] \right|^p.$$

In turn, (2.3 i), (2.3 iv), Lemma 3.8, and (2.1) imply that

$$\begin{aligned} \sum_{K,n} \iint_{Q^n_K} \left|\mathcal{D}^h[\eta] - \mathcal{D}^h[\mu]\right|^p &\le C \sum_{K,n} \iint_{I^n \times \Upsilon_\varsigma(K)} \left|\mathcal{D}^h_\perp[\eta - \mu]\right|^p \\ &\le C \sum_{K,n} \iint_{I^n \times \Upsilon_{\varsigma+1}(K)} \left|D(\eta - \mu)\right|^p \le C \iint_Q |D\eta - D\mu|^p = C \left(\|\eta - \mu\|_E \right)^p, \end{aligned} \tag{3.14}$$

which was the claim of (i) for $1 < p \le 2$. Furthermore, we remark that (3.14) also holds for $p \ge 2$, in particular with $\eta = 0$ or $\mu = 0$. Therefore for $p \ge 2$, using (3.13), and then (3.11) and the Hölder inequality, we get

$$\sum_{K,n} \mathfrak{d}(K) \iint_{\Sigma^n_K} \left| a_p(\mathcal{D}^h[\eta]) - a_p(\mathcal{D}^h[\mu]) \right|^{p'} \le C \left(\sum_{K,n} \iint_{Q^n_K} \left| \mathcal{D}^h[\eta] - \mathcal{D}^h[\mu] \right|^p \right)^{\frac{p'}{p}} \times \Big(R^p \Big)^{\frac{p-2}{p-1}}.$$

Thus, in the case $p \geq 2$, (i) also follows from (3.14).

The proof of (ii) is similar, using the identity $|a_p(y)|^{p'} = |y|^p$ instead of inequalities (3.11). ∎

Proof of Proposition 3.6. Recalling Definition 3.2, for all $\kappa \in \mathcal{T}_{int}$ and n, denote by η_κ^n (respectively, by μ_κ^n) a function in $W^{1,p}(\kappa)$ that solves (3.5) with $F_\kappa^n(x) = a_p(D_{\kappa|L}^n(x))\cdot\nu_\kappa$ for $x \in \kappa|L \in \mathcal{E}_\kappa$, where $(D_{\kappa|L}^n)_{\kappa|L,n} = \mathcal{D}^h[\eta]$ (respectively, $(D_{\kappa|L}^n)_{\kappa|L,n} = \mathcal{D}^h[\mu]$). In other words, each of $\eta_\kappa^n, \mu_\kappa^n$ verifies the integral identity corresponding to (3.5) with all test functions in $W^{1,p}(\kappa)$. Taking for the test function $(\eta_\kappa^n - \mu_\kappa^n)$, subtracting the two identities, and integrating in $t \in \imath^n$, we obtain

$$\begin{aligned}\iint_{Q_\kappa^n} \Big(a_p(D\eta_\kappa^n) - a_p(D\mu_\kappa^n)\Big)\cdot\Big(D\eta_\kappa^n - D\mu_\kappa^n\Big) \\ = \int_{\imath^n}\int_{\partial\kappa} \Big(\eta_\kappa^n - \mu_\kappa^n - \overline{\eta_\kappa^n - \mu_\kappa^n}\Big)\Big(a_p(\mathcal{D}^h[\eta]) - a_p(\mathcal{D}^h[\mu])\Big)\cdot\nu_\kappa,\end{aligned} \tag{3.15}$$

where $\overline{\eta_\kappa^n - \mu_\kappa^n} = \frac{1}{\mathfrak{m}(\kappa)}\int_\kappa \eta_\kappa^n - \mu_\kappa^n$ for a.a. $t \in \imath^n$. Summing over κ, n, using the Hölder inequality and Lemmas 3.7 and 3.9(i), we have from (3.15)

$$\begin{aligned}&\iint_Q \Big(a_p(\mathcal{G}^h[\eta]) - a_p(\mathcal{G}^h[\mu])\Big)\cdot\Big(\mathcal{G}^h[\eta] - \mathcal{G}^h[\mu]\Big) \\ &\quad\leq \sum_{\kappa,n}\int_{\imath^n}\int_{\partial\kappa} \mathfrak{d}(\kappa)^{\frac{-1}{p'}}\,|\,\eta_\kappa^n - \mu_\kappa^n - \overline{\eta_\kappa^n - \mu_\kappa^n}\,| \\ &\qquad\qquad\times \mathfrak{d}(\kappa)^{\frac{1}{p'}}\Big|a_p(\mathcal{D}^h[\eta]) - a_p(\mathcal{D}^h[\mu])\Big| \\ &\quad\leq \left(\sum_{\kappa,n}\int_{\imath^n} \mathfrak{d}(\kappa)^{1-p}\int_{\partial\kappa} |\,\eta_\kappa^n - \mu_\kappa^n - \overline{\eta_\kappa^n - \mu_\kappa^n}\,|^p\right)^{\frac{1}{p}} \\ &\qquad\qquad\times\left(\sum_{\kappa,n}\mathfrak{d}(\kappa)\iint_{\Sigma_\kappa^n}\Big|a_p(\mathcal{D}^h[\eta]) - a_p(\mathcal{D}^h[\mu])\Big|^{p'}\right)^{\frac{1}{p'}} \\ &\quad\leq \left(\sum_{\kappa,n}\iint_{Q_\kappa^n}|D\eta_\kappa^n - D\mu_\kappa^n|^p\right)^{\frac{1}{p}}\|\eta-\mu\|_E^{\min\{p/p',1\}} \\ &\qquad= \Big\|\mathcal{G}^h[\eta] - \mathcal{G}^h[\mu]\Big\|_{L^p(Q)}\|\eta-\mu\|_E^{\min\{p/p',1\}}.\end{aligned} \tag{3.16}$$

In the same manner, taking $\mu = 0$ and using Lemma 3.9(ii), we get

$$\iint_H \Big|\mathcal{G}^h[\eta]\Big|^p C\,\left(\iint_H\Big|\mathcal{G}^h[\eta]\Big|^p\right)^{\frac{1}{p}}\left(\iint_{\Upsilon_{\varsigma+1}(H)}|D\eta|^p\right)^{\frac{1}{p'}},$$

which proves (i).

Now if $1 < p \leq 2$, (3.12), (3.16), and the Hölder inequality yield

$$\begin{aligned}&\Big\|\mathcal{G}^h[\eta] - \mathcal{G}^h[\mu]\Big\|_{L^p(Q)}^p \\ &\quad\leq C\left(\Big\|\mathcal{G}^h[\eta] - \mathcal{G}^h[\mu]\Big\|_{L^p(Q)}\|\eta-\mu\|_E^{\frac{p}{p'}}\right)^{\frac{p}{2}}\left(\Big\|\mathcal{G}^h[\eta]\Big\|_{L^p(Q)}^p + \Big\|\mathcal{G}^h[\mu]\Big\|_{L^p(Q)}^p\right)^{\frac{2-p}{2}}.\end{aligned}$$

Using (3.8), we obtain (3.9). Now (3.10) follows by (3.11).

If $p \geq 2$, (3.12) and (3.16) readily yield (3.9); hence (3.10) follows by (3.11). ∎

Proof of Theorem 3.5. We have to prove that $\left\|a_p(D\eta) - a_p(\mathcal{G}^h[\eta])\right\|_{L^{p'}(Q)} \to 0$ as $h \to 0$.

Let us first prove the theorem for the case of $\eta \in E$ that is piecewise constant in t and piecewise affine in x. Let $J \subset Q$ be the set of discontinuities of $D\eta$. Clearly, J is of finite d-dimensional Hausdorff measure $\mathcal{H}^d(J)$.

For ς given in Definition 2.3, let us introduce $H^h = \bigcup_{\{K,n \,|\, I^n \times \Upsilon_\varsigma(K) \cap J \neq \emptyset\}} Q_K^n$. Note that $|H^h| \le (\varsigma+1)h\,\mathcal{H}^d(J) \to 0$ as $h \to 0$; likewise, $|\Upsilon_{\varsigma+1}(H^h)| \to 0$ as $h \to 0$. Therefore, by Proposition 3.6(i), we have

$$\iint_{H^h} \left|a_p(D\eta) - a_p(\mathcal{G}^h[\eta])\right|^{p'} \le C \left(\iint_{H^h} |D\eta|^p + \iint_{\Upsilon_{\varsigma+1}(H^h)} |D\eta|^p \right) \to 0$$

as $h \to 0$. Moreover, for all Q_K^n such that $Q_K^n \cap H^h = \emptyset$, we have $\mathcal{G}^h[\eta] \equiv D\eta$ on Q_K^n. Indeed, we have $D[\eta] \equiv \text{const}$ on $\Upsilon_{\varsigma+1}(Q_K^n)$. Therefore $\mathcal{D}^h[\eta]|_{Q_K^n} \equiv D\eta = \text{const}$ by property (2.3 iv) of admissible gradient approximations. Hence $Dw = D\eta$ satisfies the boundary condition in (3.5); the equation is also satisfied, since $\operatorname{div} a_p(D\eta) \equiv 0$ on K and $\frac{1}{\mathfrak{m}(K)} \int_{\partial K} a_p(\mathcal{D}^h[\eta]) \cdot \nu_K = a_p(D\eta) \cdot \int_{\partial K} \nu_K = 0$.

It follows that $\left\|a_p(D\eta) - a_p(\mathcal{G}^h[\eta])\right\|_{L^{p'}(Q)} \to 0$ as $h \to 0$, which was our claim.

Now let us approximate an arbitrary function η in E by functions η_l that are piecewise constant in t and piecewise affine in x. Note that we can always choose this sequence η_l in E such that $\eta_l \to \eta$ in E and a.e. on Q as $l \to \infty$, and $|D\eta_l|^p$ are dominated by an $L^1(Q)$ function independent of l. We have

$$\begin{aligned} \left\|a_p(D\eta) - a_p(\mathcal{G}^h[\eta])\right\|_{L^{p'}(Q)} &\le \left\|a_p(D\eta) - a_p(D\eta_l)\right\|_{L^{p'}(Q)} \\ &+ \left\|a_p(D\eta_l) - a_p(\mathcal{G}^h[\eta_l])\right\|_{L^{p'}(Q)} + \left\|a_p(\mathcal{G}^h[\eta_l]) - a_p(\mathcal{G}^h[\eta])\right\|_{L^{p'}(Q)}. \end{aligned} \tag{3.17}$$

As $l \to 0$, the first term in the right-hand side of (3.17) converges to zero by the Lebesgue dominated convergence theorem, independently of h. The second one converges to zero as $h \to 0$ for all l fixed. Finally, by Proposition 3.6(ii), the third one converges to zero as $l \to \infty$ uniformly in h. Hence the result follows. ∎

4. Proof of Theorem 2.9. In the context of continuous dependence upon the data of weak solutions to "general" elliptic-parabolic problems (cf. [2, Chap.V]), the proof of convergence of weak solutions of approximating problems is based upon the three essential arguments (A), (B), and (C) below.

(A) A priori estimates, using (1.2) and the Alt–Luckhaus chain rule lemma (cf. [1, 26, 10]).

(B) Strong compactness in the parabolic term, using a variant of the Kruzhkov lemma (cf. [23]):

LEMMA 4.1 (cf. [4], [2, Chap. V]). *Let Ω be an open domain in $\mathbb{R}^d$, $Q = (0,T)\times\Omega$, and let the families of functions $(u^h)_h, (F_\alpha^h)_{h,\alpha}$ be bounded in $L^1(Q)$ and satisfy $\frac{\partial}{\partial t} u^h = \sum_{|\alpha| \le m} D^\alpha F_\alpha^h$ in $\mathcal{D}'(Q)$. Assume that u^h can be extended by zero outside Q, and one has*

$$\sup_{|\Delta x| \le \Delta} \iint_{\mathbb{R}^{d+1}} |u^h(t, x+\Delta x) - u^h(t,x)|\, dxdt \le \omega(\Delta), \quad \text{with } \lim_{\Delta \to 0} \omega(\Delta) = 0, \tag{4.1}$$

where $\omega(\cdot)$ does not depend on h. Then $(u^h)_h$ is relatively compact in $L^1(Q)$.

(C) Convergence in the elliptic term, using a variant of the Minty–Browder argument (cf., e.g., [25]).

LEMMA 4.2 (cf. [4], [2, Chap. V]). *Let E be a Banach space, E' its dual and $\langle\cdot,\cdot\rangle_{E',E}$ denote the duality product of elements of E' and E. Let $(v^h)_h \subset E$ and $v^h \rightharpoonup v$ as $h \to 0$. Let $\mathcal{A}^h$ be a sequence of monotone operators from E to E' such that $\mathcal{A}^h[v^h] \overset{*}{\rightharpoonup} -\chi$ for some $\chi \in E'$. Assume that $\mathcal{A}^h$ converge pointwise to some operator $\mathcal{A}$, and $\mathcal{A}$ is hemicontinuous (i.e., continuous in the weak-$*$ topology of E' along each direction). Assume that*

$$\liminf_{h\to 0} \langle \mathcal{A}^h[v^h], v^h\rangle_{E',E} \quad \leq \quad \langle -\chi, v\rangle_{E',E}. \tag{4.2}$$

Then $\chi + \mathcal{A}[v] = 0$, and (4.2) necessarily holds with equality.

Taking advantage of the "continuous" form (3.1), (3.2) of the discrete problem $(\mathcal{S}^h)$, we can prove the convergence of finite volume approximate solutions in the same way, using the discrete a priori estimates shown in Propositions 2.5 and 3.6(i), using next Lemma 4.1, and then using finally Lemma 4.2 together with the essential consistency result of Theorem 3.5.

Proof of Theorem 2.9. Let $\overline{v}^h$ be the solution of $(\mathcal{S}^h)$. Let v^h be a corresponding interpolated solution, and let $\mathcal{A}^h$ be the finite volume approximate of the operator $\mathcal{A}$ in (1.1) (cf. (3.6), (3.7)). Note that all the convergences we state below take place up to extraction of a subsequence.

(A) By Proposition 2.5(i), $\left\|\mathcal{D}^h_\perp[\overline{v}^h]\right\|_{L^p(Q)} \leq$ const uniformly in h so that the family $(v^h)_h$ is bounded in E, by (2.10). Hence there exists a function $v \in E$ such that $v^h \rightharpoonup v$ in E as $h \to 0$. By (2.8), one also has $\overline{v}^h \rightharpoonup v$ in $L^p(Q)$.

(B) We claim that the family $(u^h)_h$ given by (3.3) is relatively compact in $L^1(Q)$. Indeed, let us check the assumptions of Lemma 4.1. We have ${u^h}_t = \operatorname{div} a_p(\mathcal{G}^h[v^h])$ in $\mathcal{D}'(Q)$ by (3.1), (3.2), and the family $\left(a_p(\mathcal{G}^h[v^h])\right)_h$ is bounded in $L^{p'}(Q)$ by Proposition 2.5(i), equation (2.10), and Proposition 3.6(i) (note that $\left(\mathcal{A}^h[v^h]\right)_h$ is thus bounded in E'). Furthermore, (3.3) yields

$$\|u^h\|_{L^1(Q)} \leq 2 \iint_Q |b(\overline{v}^h)| + k^h \sum_K \mathfrak{m}(K)|u^0_K|,$$

and one has $|b(z)| \leq \delta B(z) + \sup_{|\zeta|\leq 1/\delta} |b(\zeta)|$ for all $\delta > 0$ (cf., e.g., [1]). By Proposition 2.5(ii) and since $u^h_0 = \sum_K \mathfrak{m}(K)|u^0_K| \to u_0$ in $L^1(\Omega)$ as $h \to 0$, it follows that $(u^h)_h$ is bounded in $L^1(Q)$.

Finally, by Proposition 2.5(i) and Lemma 2.6(ii), we obtain (4.1) with u^h replaced by $\overline{v}^h$. Hence the estimate (4.1) for u^h follows by (3.3), as in the continuous case (cf. [1]); see [4] for the detailed proof.

Thus the claim of (B) follows, and there exists a function $u \in L^1(Q)$ such that $u^h \to u$ in $L^1(Q)$ and a.e. on Q. In addition, we claim that $u = b(v)$, where v is the weak limit of v^h in E. It suffices to show that $\overline{v}^h \rightharpoonup v$ in $L^1(Q)$ and $b(\overline{v}^h) \to u$ in $L^1(Q)$, and then apply the monotonicity argument of [9]; see [4] for the detailed proof.

(C) By (A), we have $v^h \rightharpoonup v$ in E. We claim that v is a weak solution of (1.1).

By Proposition 3.3, $\chi^h + \mathcal{A}^h[v^h] = 0$ in E' and the initial condition (3.2) is verified for all h. The family $\left(\mathcal{A}^h[v^h]\right)_h$ is bounded in E' (cf. (B)), thus $(\chi^h)_h$ is weak-$*$ relatively compact in E'. By (3.4), (B), and Definition 1.1, we also have $\chi^h = {u^h}_t \to b(v)_t = \chi$ in $\mathcal{D}'(Q)$. Hence $\mathcal{A}^h[v^h] = -\chi^h \overset{*}{\rightharpoonup} -\chi$ in E'.

Moreover, passing to the limit in (3.2), using (B) and the convergence of u_0^h to u_0 in $L^1(\Omega)$, we get (1.5). Consequently, by the chain rule argument [1, Lemma 1.5] we have

$$\langle -\chi, v\rangle_{E',E} = -\int_\Omega \Psi(b(v(T,\cdot))) + \int_\Omega \Psi(u^0). \tag{4.3}$$

On the other hand, by (3.4), (3.3), (2.9), and the monotonicity of $b(\cdot)$, we have

$$\begin{aligned}
\langle -\chi^h, v^h\rangle_{E',E} &= -\frac{1}{k}\sum_{K,n}(b(v_K^n) - b(v_K^{n-1}))\iint_{Q_K^n} v^h \\
&= -\sum_{K,n} \mathfrak{m}(K)(b(v_K^n) - b(v_K^{n-1}))\, v_K^n \\
&\le -\sum_K \mathfrak{m}(K)\Psi(b(v_K^{[T/k^h]+1})) + \sum_K \mathfrak{m}(K)\Psi(u_K^0) \\
&= -\int_\Omega \Psi(b(\overline{v}^h(T,\cdot))) + \int_\Omega \Psi(u_0^h).
\end{aligned}$$

Recall that $\Psi(u_0^h) \to \Psi(u_0)$ in $L^1(\Omega)$. Without loss of generality, we can assume that $\overline{v}^h(T,\cdot) \to v(T,\cdot)$ a.e. on Ω; hence by the Fatou lemma and (4.3) we get (4.2).

Next, the operators $\mathcal{A}^h$ are monotone. Indeed, take $\varphi \in E$ and $(\varphi_K^n)_{K,n} = \mathcal{M}^h[\varphi]$. Arguing as in the proof of Proposition 3.3, integrating by parts in Q_K^n, and cancelling the boundary terms, we get

$$\begin{aligned}
\langle \mathcal{A}^h[\eta], \varphi\rangle_{E',E} &= \iint_Q a_p(\mathcal{G}^h[\eta])\cdot D\varphi = -\sum_{K,n}\iint_{Q_K^n} \varphi \operatorname{div} a_p(\mathcal{G}^h[v^h]) \\
&= -\sum_{K,n}\iint_{Q_K^n} \varphi \times \frac{1}{\mathfrak{m}(K)}\sum_{L\in\mathcal{N}_K}\int_{K|L} a_p(D_{K|L}^n(x))dx\cdot\nu_{K,L} \\
&= -k\sum_{K,n}\varphi_K^n \sum_{L\in\mathcal{N}_K}\int_{K|L} a_p(D_{K|L}^n(x))dx\cdot\nu_{K,L}.
\end{aligned} \tag{4.4}$$

Substituting (4.4) and applying Remark 2.4, we infer by property (2.3 ii) of Definition 2.3 that

$$\begin{aligned}
&\langle \mathcal{A}^h[\eta] - \mathcal{A}^h[\widetilde{\eta}], \eta - \widetilde{\eta}\rangle_{E',E} \\
&\quad = \frac{1}{d}\,k\sum_{K|L,n}\Big((\eta_L^n - \eta_K^n) - (\widetilde{\eta}_L^n - \widetilde{\eta}_K^n)\Big)\int_{K|L}\Big(a_p(D_{K|L}^n(x)) - a_p(\widetilde{D}_{K|L}^n(x))\Big)dx\cdot\nu_{K,L} \ge 0,
\end{aligned}$$

where $(\eta_K^n)_{K,n} = \mathcal{M}^h[\eta]$, $(D_{K|L}^n)_{K|L,n} = \mathcal{D}^h[\eta]$, and the same for $\widetilde{\eta}$.

Finally, by Theorem 3.5, $\mathcal{A}^h$ converge pointwise to the hemicontinuous operator $\mathcal{A}\cdot = -\operatorname{div} a_p(D\,\cdot)$. By Lemma 4.2 we conclude that $\chi + \mathcal{A}[v] = 0$ in E'. Thus (1.4) holds and v is a weak solution of (1.1). ∎

5. Examples of admissible methods. By an admissible method, we mean a method which provides an admissible gradient approximation and weakly proportional meshes satisfying the interpolation property. Recall that in this case, we have the convergence of the finite volume approximation (cf. Theorem 2.9). In this section, we prove that such admissible methods exist.

5.1. On discrete gradients. In this section we construct an admissible gradient for a family $(\mathcal{T}^h)_h$ of finite volume meshes of the Voronoï kind dual to a family $(\widehat{\mathcal{T}}^h)_h$ of triangular meshes.

Let us introduce some notation. We use $\widehat{o}$ to denote a triangle of the mesh $\widehat{\mathcal{T}}^h$; for all $\widehat{o} \in \widehat{\mathcal{T}}^h$, there exist $K, L, M \in \mathcal{T}^h$ such that $\widehat{o} = \Delta x_K x_L x_M$ (the triangle with the corners x_K, x_L, x_M). The three interfaces $K|L$, $L|M$, $M|K$ intersect at point $x_{\widehat{o}}$, which is the center of the circumscribed circle of triangle $\widehat{o}$. We require it to be inside $\widehat{o}$. Let us denote by $S_{\widehat{o}}, S_{K,L}, S_{L,M}$, and $S_{M,K}$ the surfaces of $\Delta x_K x_L x_M, \Delta x_{\widehat{o}} x_K x_L, \Delta x_{\widehat{o}} x_L x_M$, and $\Delta x_{\widehat{o}} x_M x_K$, respectively. One has $S_{\widehat{o}} = S_{K,L} + S_{L,M} + S_{M,K}$.

Recall that $\nu_{K,L} = \overrightarrow{x_K x_L}/d_{K,L}, \nu_{L,M} = \overrightarrow{x_L x_M}/d_{L,M}, \nu_{M,K} = \overrightarrow{x_M x_K}/d_{M,K}$. Note the following elementary lemma.

LEMMA 5.1. *Let $\widehat{o} = \Delta x_K x_L x_M$ be a triangle in $\mathbb{R}^2$, let $x_{\widehat{o}}$ be the center of its circumscribed circle, and let $x_{\widehat{o}} \in \Delta x_K x_L x_M$. With the above notation, for all r in $\mathbb{R}^2$, we have*

$$r = \frac{2}{S_{\widehat{o}}} \Big\{ S_{K,L}(r \cdot \nu_{K,L})\nu_{K,L} + S_{L,M}(r \cdot \nu_{L,M})\nu_{L,M} + S_{M,K}(r \cdot \nu_{M,K})\nu_{M,K} \Big\}.$$

This property can be generalized to any polygon in $\mathbb{R}^2$ which admits the circumscribed circle.

Furthermore, for $\widehat{o} \in \widehat{\mathcal{T}}^h$ such that $\widehat{o} = \Delta x_K x_L x_M$, let ${v^h}_{\widehat{o}}^0 : \mathbb{R}^2 \to \mathbb{R}^N$ be the affine function that takes the values v_K, v_L, v_M at the points x_K, x_L, x_M, respectively. The discrete gradient operator $\mathcal{D}^{h,0} = \mathcal{L}^h \circ \mathcal{D}^{h,0}$ is defined by

$$\mathcal{D}^{h,0} : (v_K)_K \mapsto \sum_{\widehat{o} \in \widehat{\mathcal{T}}^h} D{v^h}_{\widehat{o}}^0(x) \mathbb{1}_{\widehat{o}}(x).$$

In the case of structured hexagonal meshes, as well as that of structured rectangular ones, the family $(\mathcal{D}^{h,0})_h$ is admissible (this will be proved in Proposition 5.2, as a particular case). In general, this construction does not work. Indeed, if the points x_K are not the barycenters of $K \in \mathcal{T}^h$, property (2.3 iv) fails.

This can be overcome, for instance, in the following way. For all $K \in \mathcal{T}^h$, let y_K be the barycenter of K and set $\sigma_K = x_K - y_K$. For $\widehat{o} \in \widehat{\mathcal{T}}^h$ such that $\widehat{o} = \Delta x_K x_L x_M$, let $v^h_{\widehat{o}} : \mathbb{R}^2 \to \mathbb{R}^N$ be the affine function that takes the values v_K, v_L, v_M at the points y_K, y_L, y_M, respectively. The discrete gradient operator $\mathcal{D}^h = \mathcal{L}^h \circ \mathcal{D}^h$ is defined by

$$\mathcal{D}^h : (v_K)_K \mapsto \sum_{\widehat{o} \in \widehat{\mathcal{T}}^h} Dv^h_{\widehat{o}}(x) \mathbb{1}_{\widehat{o}}(x); \tag{5.1}$$

i.e., the affine interpolation over the triangle $\Delta y_K y_L y_M$ is actually used in the triangle $\Delta x_K x_L x_M$.

We will take advantage of considering $\mathcal{D}^h$ as a perturbation of $\mathcal{D}^{h,0}$. For all $\widehat{o} \in \widehat{\mathcal{T}}^h$, let us define the correction operators

$$R_{\widehat{o}} : r \in \mathbb{R}^2 \mapsto \frac{2}{S_{\widehat{o}}} \Bigg\{ S_{K,L} \left(r \cdot \frac{\sigma_L - \sigma_K}{d_{K,L}} \right) \nu_{K,L} + S_{L,M} \left(r \cdot \frac{\sigma_M - \sigma_L}{d_{L,M}} \right) \nu_{L,M} + S_{M,K} \left(r \cdot \frac{\sigma_K - \sigma_M}{d_{M,K}} \right) \nu_{M,K} \Bigg\},$$

with the notation introduced above. We need to guarantee that the Euclidiean norm of $R_{\widehat{O}}$ is less than $\min\{p-1, 1/(p-1)\}$ for all $\widehat{O} \in \mathcal{T}^h$.

PROPOSITION 5.2. *Assume that $(\mathcal{T}^h)_h$ is a family of meshes dual to a family of meshes $(\widehat{\mathcal{T}}^h)_h$ such that all $\widehat{O} \in \widehat{\mathcal{T}}^h$ are triangles with angles less than or equal to $\pi/2$.*

Assume that for all h, for all $\widehat{O} \in \widehat{\mathcal{T}}^h$,

$$\frac{2}{S_{\widehat{O}}}\left\{ S_{K,L}\frac{|\sigma_L - \sigma_K|}{d_{K,L}} + S_{L,M}\frac{|\sigma_M - \sigma_L|}{d_{L,M}} + S_{M,K}\frac{|\sigma_K - \sigma_M|}{d_{M,K}} \right\} < \min\{p-1, 1/(p-1)\},$$

where σ_K is the difference between the "center" x_K of the volume K and its barycenter, etc.

Then the family of discrete gradient operators $(\mathcal{D}^h)_h$ on $(\mathcal{T}^h)_h$ defined by (5.1) *is admissible in the sense of Definition* 2.3.

Proof. Since, for any affine function w on K, one has $\frac{1}{\mathfrak{m}(K)}\int_K w(x)dx = w(y_K)$, where y_K is the barycenter of K, property (2.3 iv) holds for $\mathcal{D}^h$ (with $\varsigma = 1$, by construction). Next, (2.3 i) is clear.

Let us establish the relation between $\mathcal{D}^{h,0}$ and $\mathcal{D}^h$. Denote by $D^0_{\widehat{O}}, D_{\widehat{O}}$ the values on $\widehat{O}$ of $\mathcal{D}^{h,0}[(v_K)_K]$ and $\mathcal{D}^h[(v_K)_K]$, respectively. Let us show that for all $\widehat{O} \in \widehat{\mathcal{T}}^h$,

$$D^0_{\widehat{O}} = (I - R_{\widehat{O}})D_{\widehat{O}}. \tag{5.2}$$

Indeed, if $\widehat{O} = \Delta x_K x_L x_M$, one has

$$\begin{aligned} D_{\widehat{O}} \cdot \nu_{K,L} &= \frac{v^h_{\widehat{O}}(x_L) - v^h_{\widehat{O}}(x_K)}{d_{K,L}} = \frac{(v_L + D_{\widehat{O}} \cdot \sigma_L) - (v_K + D_{\widehat{O}} \cdot \sigma_K)}{d_{K,L}} \\ &= \frac{v_L - v_K}{d_{K,L}} + D_{\widehat{O}} \cdot \frac{\sigma_L - \sigma_K}{d_{K,L}} = D^0_{\widehat{O}} \cdot \nu_{K,L} + D_{\widehat{O}} \cdot \frac{\sigma_L - \sigma_K}{d_{K,L}}. \end{aligned}$$

Writing the same relation for L, M and M, K, from Lemma 5.1, we get $D_{\widehat{O}} - D^0_{\widehat{O}} = R_{\widehat{O}} D_{\widehat{O}}$, whence (5.2) follows.

By Lemma 5.1 and the definition of $\mathcal{D}^h_\perp = \mathcal{L}^h \circ \mathcal{D}^h_\perp$ for all $\widehat{O} \in \widehat{\mathcal{T}}^h$ such that $\widehat{O} = \Delta x_K x_L x_M$ we have

$$\begin{aligned} \int_{\widehat{O}} \left|\mathcal{D}^{h,0}[(v_K)_K]\right|^p &= S_{\widehat{O}} \left|\mathcal{D}^{h,0}[(v_K)_K]\right|^p \\ &\le C^* \left\{ S_{K,L}\left|\frac{v_L - v_K}{d_{K,L}}\right|^p + S_{L,M}\left|\frac{v_M - v_L}{d_{L,M}}\right|^p + S_{M,K}\left|\frac{v_K - v_M}{d_{M,K}}\right|^p \right\} \\ &= C^* \int_{\widehat{O}} \left|\mathcal{D}^h_\perp[(v_K)_K]\right|^p \end{aligned} \tag{5.3}$$

with a constant C^* that depends only on p. Since for given $\widetilde{K} \in \mathcal{T}^h$ and $\widehat{O} \in \widehat{\mathcal{T}}^h$ we have $\widetilde{K} \cap \widehat{O} \neq \emptyset$ if and only if $\widehat{O} \in \Upsilon_1(\widetilde{K})$, it follows that property (2.3 v) holds for the discrete gradient $\mathcal{D}^{h,0}$, with $\varsigma = 1$. Now set $\theta_{\widehat{O}} = \|R_{\widehat{O}}\|$. We have $\theta_{\widehat{O}} < 1$. One has $|D_{\widehat{O}}| \le \|(I - R_{\widehat{O}})^{-1}\|\,|D^0_{\widehat{O}}| \le \frac{1}{1-\theta_{\widehat{O}}}|D^0_{\widehat{O}}|$; therefore (2.3 v) also holds for $\mathcal{D}^h$.

Next, each term in the sum in (2.3 iii) splits into two terms corresponding to the two parts of the interface $K|L$ included in different triangles $\widehat{O}_1, \widehat{O}_2 \in \widehat{\mathcal{T}}^h$. Let us write down all the terms corresponding to the same triangle $\widehat{O} \in \widehat{\mathcal{T}}^h$, $\widehat{O} = \Delta x_K x_L x_M$,

combine them using Lemma 5.1, and estimate using (5.2):

$$\begin{aligned}
&S_{K,L}(a_p(D_{\widehat{o}})\cdot\nu_{K,L})(D^0_{\widehat{o}}\cdot\nu_{K,L}) + S_{L,M}(a_p(D_{\widehat{o}})\cdot\nu_{L,M})(D^0_{\widehat{o}}\cdot\nu_{L,M})\\
&\quad + S_{M,K}(a_p(D_{\widehat{o}})\cdot\nu_{M,K})(D^0_{\widehat{o}}\cdot\nu_{M,K}) = \frac{S_{\widehat{o}}}{2}a_p(D_{\widehat{o}})\cdot D^0_{\widehat{o}}\\
&\qquad = \frac{S_{\widehat{o}}}{2}a_p(D_{\widehat{o}})\cdot(I-R_{\widehat{o}})D_{\widehat{o}} \geq \frac{1-\theta_{\widehat{o}}}{2}S_{\widehat{o}}|D_{\widehat{o}}|^p \geq \frac{1-\theta_{\widehat{o}}}{2(1+\theta_{\widehat{o}})^p}S_{\widehat{o}}|D^0_{\widehat{o}}|^p.
\end{aligned}$$

Property (2.3 iii) for $\mathcal{D}^h$ follows, because one has $|D^0| \geq |D^0_{\widehat{o}}\cdot\nu_{K,L}| = \frac{|v_L - v_K|}{d_{K,L}} = D^h_{\perp,K|L}$ so that

$$\sum_{\widehat{o}\in\widehat{\mathcal{T}}^h} S_{\widehat{o}}|D^0_{\widehat{o}}|^p = \left\|\mathcal{D}^{h,0}[(v_K)_K]\right\|^p_{L^p(\Omega)} \geq \left\|\mathcal{D}^h_\perp[(v_K)]\right\|^p_{L^p(\Omega)}.$$

The proof of (2.3 ii) is similar. Denoting the values $\widetilde{D}^0_{\widehat{o}}, \widetilde{D}_{\widehat{o}}$ of $\mathcal{D}^{h,0}[(\widetilde{v}_K)_K]$ and $\mathcal{D}^h[(\widetilde{v}_K)_K]$, respectively, on $\widehat{o}$, one can rewrite the sum in (2.3 ii) as

$$\begin{aligned}
\sum_{\widehat{o}\in\widehat{\mathcal{T}}^h} \Big\{ & S_{K,L}\Big((a_p(D_{\widehat{o}}) - a_p(\widetilde{D}_{\widehat{o}}))\cdot\nu_{K,L}\Big)\Big((D^0_{\widehat{o}} - \widetilde{D}^0_{\widehat{o}})\cdot\nu_{K,L}\Big)\\
&+ S_{L,M}\Big((a_p(D_{\widehat{o}}) - a_p(\widetilde{D}_{\widehat{o}}))\cdot\nu_{L,M}\Big)\Big((D^0_{\widehat{o}} - \widetilde{D}^0_{\widehat{o}})\cdot\nu_{L,M}\Big)\\
&+ S_{M,K}\Big((a_p(D_{\widehat{o}}) - a_p(\widetilde{D}_{\widehat{o}}))\cdot\nu_{M,K}\Big)\Big((D^0_{\widehat{o}} - \widetilde{D}^0_{\widehat{o}})\cdot\nu_{M,K}\Big)\Big\}\\
&= \frac{1}{2}\sum_{\widehat{o}\in\widehat{\mathcal{T}}^h} S_{\widehat{o}}(a_p(D_{\widehat{o}}) - a_p(\widetilde{D}_{\widehat{o}}))\cdot(D^0_{\widehat{o}} - \widetilde{D}^0_{\widehat{o}}).
\end{aligned}$$

Using (5.2) and denoting by H the Hessian matrix of the function $x \in \mathbb{R}^2 \mapsto \frac{1}{p}|x|^p$, we get

$$\begin{aligned}
&(a_p(D_{\widehat{o}}) - a_p(\widetilde{D}_{\widehat{o}}))\cdot(D^0_{\widehat{o}} - \widetilde{D}^0_{\widehat{o}})\\
&\qquad = (D_{\widehat{o}} - \widetilde{D}_{\widehat{o}})^t\left[\int_0^1 H(\widetilde{D}_{\widehat{o}} + \tau(D_{\widehat{o}} - \widetilde{D}_{\widehat{o}}))\,d\tau\,(I - R_{\widehat{o}})\right](D_{\widehat{o}} - \widetilde{D}_{\widehat{o}}).
\end{aligned}$$

For all $x \in \mathbb{R}^2$, $x \neq 0$, $H(x)$ is a symmetric matrix with positive eigenvalues λ_1, λ_2 such that $\lambda_1/\lambda_2 = p-1$. Thus the condition $\|R_{\widehat{o}}\| < \min\{p-1, 1/(p-1)\}$ ensures that, for all $\tau \in [0,1]$,

$$r^t\left[H(\widetilde{D}_{\widehat{o}} + \tau(D_{\widehat{o}} - \widetilde{D}_{\widehat{o}}))\,(I - R_{\widehat{o}})\right] r \geq a\, r^t\left[H(\widetilde{D}_{\widehat{o}} + \tau(D_{\widehat{o}} - \widetilde{D}_{\widehat{o}}))\right] r > 0$$

for all $r \in \mathbb{R}^2, r \neq 0$, with some constant $a > 0$. Now (2.3 ii) follows. ∎

5.2. On interpolated solutions. First note that it is sufficient to prove the interpolation property in $W^{1,p}_0(\Omega)$ if we require, in addition to the time-independent analogs of (2.8), (2.9) (referred to as (2.8′), (2.9′)), that

$$\|v^h\|_{W^{1,p}_0(\Omega)} \leq c \times \left\|\mathcal{D}^h_\perp[\overline{v}^h]\right\|_{L^p(\Omega)} \tag{2.10′}$$

with a constant c independent of h. We obtain the interpolation property in E with the function $I : C \mapsto c \times C$ by taking v^h constant on each $\imath^n$ and summing in $n \in \{1, \ldots, [T/k^h]+1\}$.

LEMMA 5.3. *Let $(\mathcal{T}^h)_h$ be a strongly proportional family of finite volume meshes of $\Omega \subset \mathbb{R}^d$. Then it has the interpolation property in $W_0^{1,p}(\Omega)$.*

In order to prove the lemma, we first show that the strong proportionality allows us to majorate the L^p norm of the translates of the discrete solutions $\overline{v}^h$ in Lemma 2.6(ii) by $\mathrm{const}\Delta\,(h+\Delta)^{p-1}$. Then we convolute $\overline{v}^h$ with the appropriate mollifier; finally, we restore the average over each mesh volume as in Lemma 5.4 below. The complete proof is given in [4].

Note that the interpolation property can fail on weakly proportional meshes, at least for $p > 2$.

Indeed, consider $\Omega = (0,1)^2$. For $s \geq 2$, let $\mathcal{T}^s$ be the finite volume mesh of Ω such that $\mathcal{T}^s_{int} = \{K^s, L^s\}$, where $K^s = \{(x,y) \in \Omega \,|\, x+y < 1/s\}$ with $x_{K^s} = (\frac{1}{4s}, \frac{1}{4s})$, and L^s is the interior of the complementary of K^s with $x_{L^s} = (\frac{1}{2}, \frac{1}{2})$. Take $\overline{v}^s$ such that $\overline{v}^s \equiv s^{1/p}$ on K^s and $\overline{v}^s \equiv 0$ on L^s. Then $\int_\Omega \left|\mathcal{D}^h_\perp[\overline{v}^s]\right|^p \leq \mathrm{const}$ uniformly in s. If there exist $v^s \in W_0^{1,p}(\Omega)$ interpolated solutions for $\overline{v}^s$, we have $\|v^s\|_{W_0^{1,p}(\Omega)} \leq \mathrm{const}$. Hence by the standard embedding theorem, v^s are uniformly bounded. This contradicts the fact that $\frac{1}{\mathfrak{m}(K^s)}\int_{K^s} v^s = s^{1/p} \to +\infty$ as $s \to +\infty$.

Nevertheless, we have the following result in the situation close to that of Proposition 5.2.

LEMMA 5.4. *Assume that $(\mathcal{T}^h)_h$ is a weakly proportional family of meshes of $\Omega \subset \mathbb{R}^2$ dual to a family of meshes $(\widehat{\mathcal{T}}^h)_h$ such that all $\widehat{o} \in \widehat{\mathcal{T}}^h$ are triangles with angles less than or equal to $\pi/2$. Then $(\mathcal{T}^h)_h$ has the interpolation property in $W_0^{1,p}(\Omega)$.*

Proof. Take discrete solutions $\overline{v}^h = \sum_K v_K \mathbb{1}_K$ on each of $\mathcal{T}^h$ such that, for all h $\left\|\mathcal{D}^h_\perp[\overline{v}^h]\right\|_{L^p(Q)} \leq C$. Denote by c the generic constant that depends only on p and ζ^*. Let $v^{h,0}$ be the continuous piecewise affine function on Ω that interpolates the values v_K, v_L, v_M at the points x_K, x_L, x_M over $\widehat{o}$ for all $\widehat{o} \in \widehat{\mathcal{T}}^h$ (we use the construction and notation of section 5.1). We have $v^{h,0} \in W_0^{1,p}(\Omega)$ and $Dv^{h,0} \equiv \mathcal{D}^{h,0}[\overline{v}^h]$ so that (5.3) yields $\|Dv^{h,0}\|_{L^p(\Omega)} \leq c \times C$. Note that for all $x \in K \in \mathcal{T}^h$,

$$|v^{h,0}(x) - \overline{v}^h(x)| = |v^{h,0}(x) - v^{h,0}(x_K)| \leq \mathfrak{d}(K)\,|Dv^{h,0}(x)|. \tag{5.4}$$

Hence $\|v^{h,0} - \overline{v}^h\|_{L^p(\Omega)} \leq h\,\|Dv^{h,0}\|_{L^p(\Omega)} \to 0$ as $h \to 0$. Now take a continuously differentiable function $\pi : \mathbb{R}^2 \to \mathbb{R}^+$ such that $\operatorname{supp}\pi = \{x \in \mathbb{R}^2 \mid |x| \leq 1\}$ and $\int_{\mathbb{R}^2} \pi = 1$. For all $K \in \mathcal{T}^h_{int}$ set $\varphi_K = \frac{\mathfrak{m}(K)}{(\zeta^*\mathfrak{d}(K))^2}\,\pi\left(\frac{x-x_K}{\zeta^*\mathfrak{d}(K)}\right)$ (for boundary volumes K of nonzero measure; i.e., if $x_K \in \partial\Omega$, an easy modification is needed in order to keep the trace on $\partial\Omega$ equal to zero). Set

$$v^h = v^{h,0} + \sum_K \alpha_K \varphi_K, \qquad \text{with} \quad \alpha_K = v_K - \frac{1}{\mathfrak{m}(K)}\int_K v^{h,0}.$$

Since $\operatorname{supp}\varphi_K \subset K$, by the choice of α_K, the family $(v^h)_h$ verifies (2.9′). Moreover, since $\frac{\mathfrak{m}(K)}{\mathfrak{d}(K)^2} \leq c$ for all $K \in \mathcal{T}^h$, for all h, by the Hölder inequality we get

$$\begin{aligned}
\int_\Omega |v^h - v^{h,0}|^p &= \sum_K |\alpha_K|^p \int_K |\varphi_K|^p \\
&\leq\ c \sum_K \frac{1}{\mathfrak{m}(K)^p}\left|\int_K \overline{v}^h - \int_K v^{h,0}\right|^p \mathfrak{m}(K)\Big(\frac{\mathfrak{m}(K)}{\mathfrak{d}(K)^2}\Big)^p \\
&\leq\ c \sum_K \frac{1}{\mathfrak{m}(K)^p}\mathfrak{m}(K)^{p'/p}\int_K |\overline{v}^h - v^{h,0}|^p \mathfrak{m}(K) = c\int_\Omega |\overline{v}^h - v^{h,0}|^p \to 0
\end{aligned}$$

as $h \to 0$. Thus $(v^h)_h$ satisfies (2.8′). In the same manner, using (5.4) we have

$$\begin{aligned}\int_\Omega |Dv^h - Dv^{h,0}|^p &= \sum_K |\alpha_K|^p \int_K |D\varphi_K|^p \\ &\le \sum_K c \sum_K \frac{1}{\mathfrak{m}(K)^p} \mathfrak{m}(K)^{p'/p} \int_K |\overline{v}^h - v^{h,0}|^p \times \mathfrak{m}(K) \Big(\frac{\mathfrak{m}(K)}{\mathfrak{d}(K)^3}\Big)^p \\ &\le c \sum_K \frac{1}{\mathfrak{d}(K)^p} \int_K |\overline{v}^h - v^{h,0}|^p \le c \sum_K \frac{1}{\mathfrak{d}(K)^p}\, \mathfrak{d}(K)^p \int_K |Dv^{h,0}|^p = c \int_\Omega |Dv^{h,0}|^p.\end{aligned}$$

Hence $\|v^h\|_{W_0^{1,p}(\Omega)} \le c \|v^{h,0}\|_{W_0^{1,p}(\Omega)} \le c \times C$, so $(v^h)_h$ satisfies (2.10′). Thus $(v^h)_h$ can be chosen as interpolated solutions for $(\overline{v}^h)_h$. ∎

ANALYSIS OF A NONSYMMETRIC DISCONTINUOUS GALERKIN METHOD FOR ELLIPTIC PROBLEMS: STABILITY AND ENERGY ERROR ESTIMATES*

MATS G. LARSON† AND A. JONAS NIKLASSON‡

Abstract. In this paper we analyze a nonsymmetric discontinuous Galerkin method for elliptic problems proposed by Oden, Babuška, and Baumann. Our main results are a complete inf-sup stability analysis and, as a consequence, error estimates in a mesh dependent energy norm allowing variable meshsize and order of polynomials. The analysis is carried out in two spatial dimensions on an unstructured triangulation.

Key words. discontinuous Galerkin method, error estimates, stability, energy norm, elliptic problem, nonsymmetric discontinuous Galerkin method

1. Introduction.

The discontinuous Galerkin (dG) method is a classical technique for numerical approximation of partial differential equations which have recently received new interest, motivated by some attractive features including a flexible discretization allowing easy implementation of *h-p* adaptivity, nonmatching grids, and a local conservation property. Of course there are disadvantages too; the number of degrees of freedom is larger (see [8]), and efficient iterative solvers are not yet developed.

In this paper we are concerned with the analytical and numerical study of the recent nonsymmetric dG method for elliptic problems proposed by Oden, Babuška, and Baumann in [12]. This method does not contain the stabilizing (penalty) term as the classical symmetric Nitsche method [11]. Plenty of numerical results were presented in [12], showing that a remarkable stability is hidden in the nonsymmetric form for polynomials of order higher than or equal to two in one and two spatial dimensions. The desire to analytically understand the stability properties of the nonsymmetric dG method is the motivation for the present paper. In an earlier paper [9] Larson and Niklasson showed complete stability estimates for a family of dG methods, including both the nonsymmetric method and the symmetric Nitsche method, in one spatial dimension. These results extended the analytical stability estimates presented by Babuška, Baumann, and Oden in [3] for polynomials of order three or higher in one spatial dimension. The analysis presented in this paper builds on the ideas in [9].

Our main result in this work is a complete discrete stability analysis, where we prove that the method is inf-sup stable with respect to a mesh dependent energy norm for quadratic and higher order polynomials on a general unstructured triangulation

in two spatial dimensions. We present numerical calculations of the inf-sup constant confirming our analytical estimates. Our analytical and numerical results confirm the numerical observations reported in [12]. The case of linear ploynomials is also investigated, and we show that the inf-sup constant either is zero or depends on the meshsize (depending on boundary conditions) if the mesh is of checkerboard type.

From the study of the discrete stability properties we immediately obtain optimal order a priori error estimates in the energy norm, in terms of local meshsize and local degree of polynomials. We present numerical results illustrating our error estimates. In two recent papers, Riviére, Wheeler, and Girault [13], [14], prove an a priori error estimate of the L^2 norm of the gradient of the error for the nonsymmetric dG method by relating it to a method where the discontinuities on each edge have average zero. However, no stability estimate for the nonsymmetric dG method is presented. We also mention the comprehensive overview and analysis of a large class of dG methods by Arnold, Brezzi, Cockburn, and Marini [2].

Key to our analysis is a splitting of the space of all discontinuous piecewise polynomials into a sum of a space of functions with constrained discontinuities, representing continuous scales, and a space of discontinuous functions with small spatial mean value. This splitting, properly constructed, leads to a triangular system which can be analyzed.

The remainder of this paper is organized as follows: in section 2 we introduce the nonsymmetric dG method and the necessary notation; in section 3 we present the splitting of the discontinuous piecewise polynomial space and the two-scale formulation of the dG method; and finally, in section 4 we show the stability estimate and the error estimate in the energy norm.

2. The model problem and the dG method.

2.1. A model problem. Let Ω be a polygonal domain in $\mathbf{R}^2$ with boundary Γ divided into two disjoint parts $\Gamma = \Gamma_N \cup \Gamma_D$. We consider the following linear elliptic model problem: find $u : \Omega \to \mathbf{R}$ such that

$$\begin{aligned} -\nabla \cdot \sigma(u) &= f \quad && \text{in } \Omega, \\ u &= g_D && \text{on } \Gamma_D, \\ \sigma_n(u) &= g_N && \text{on } \Gamma_N. \end{aligned} \tag{2.1}$$

Here the flux $\sigma(u)$ is defined by

$$\sigma(u) = A\nabla u, \tag{2.2}$$

with A a constant (or piecewise constant) symmetric positive definite matrix, and $\sigma_n(u)$ denotes the normal flux

$$\sigma_n(u) = n \cdot A\nabla u, \tag{2.3}$$

where n is the exterior unit normal of Γ. It is well known that there is a unique solution in $H^1(\Omega)$ for $f \in H^{-1}(\Omega)$, $g_D \in H^{1/2}(\Gamma_D)$, and $g_N \in H^{-1/2}(\Gamma_N)$ to (2.1) (see [6]), where $H^s(\omega)$ denote the standard Sobolev spaces on the set ω.

2.2. Discrete spaces. We let $\mathcal{K}$ be a triangulation of Ω into affine triangles K satisfying the minimal angle condition, implying that the trace inequality (2.17) and inverse inequality (2.19) below hold. We denote the set of all edges E by $\mathcal{E}$ and divide $\mathcal{E}$ into three disjoint sets

$$\mathcal{E} = \mathcal{E}_I \cup \mathcal{E}_D \cup \mathcal{E}_N, \tag{2.4}$$

where $\mathcal{E}_I$ is the set of all edges in the interior of Ω, $\mathcal{E}_D$ the edges on the Dirichlet part of the boundary Γ_D, and $\mathcal{E}_N$ the edges on the Neumann part Γ_N. We let $h : \Omega \to \mathbf{R}$ denote the mesh function such that $h|_K = h_K = \operatorname{diam}(K)$ and $h|_E = h_E = \operatorname{diam}(E)$, i.e., the length of the edge E. We let

$$\mathcal{V} = \bigoplus_{K \in \mathcal{K}} \mathcal{P}_p(K), \tag{2.5}$$

where $\mathcal{P}_p(K)$ is the space of all polynomials of degree less than or equal to p defined on K. The degree of polynomials, as well as the meshsize, may vary from element to element so that $p|_K = p_K$, and thus we allow h-p adaptivity.

2.3. The nonsymmetric dG method. In [12] Oden, Babuška, and Baumann proposed the following nonsymmetric dG method: find $u_h \in \mathcal{V}$ such that

$$a(u_h, v) = l(v) \quad \text{for all } v \in \mathcal{V}. \tag{2.6}$$

Here $a(\cdot, \cdot)$ is a bilinear form defined by

$$a(v, w) = a_{\mathcal{K}}(v, w) - a_{\mathcal{E}}(v, w) + a_{\mathcal{E}}(w, v), \tag{2.7}$$

where

$$a_{\mathcal{K}}(v, w) = \sum_{K \in \mathcal{K}} (\sigma(v), \nabla w)_K, \tag{2.8}$$

$$a_{\mathcal{E}}(v, w) = \sum_{E \in \mathcal{E}_I \cup \mathcal{E}_D} (\langle \sigma_n(v) \rangle, [w])_E, \tag{2.9}$$

and $l(\cdot)$ is a linear functional defined by

$$l(v) = (f, v) + \sum_{E \in \mathcal{E}_N} (g_N, v)_E + \sum_{E \in \mathcal{E}_D} (g_D, \langle \sigma_n(v) \rangle)_E. \tag{2.10}$$

We employed the notation

$$\langle v \rangle = \begin{cases} (v^+ + v^-)/2, & E \in \mathcal{E}_I, \\ v^+, & E \in \mathcal{E}_D, \end{cases} \tag{2.11}$$

for the average and

$$[v] = \begin{cases} v^+ - v^-, & E \in \mathcal{E}_I, \\ v^+, & E \in \mathcal{E}_D, \end{cases} \tag{2.12}$$

for the jump at an edge E, where $u^{\pm}(x) = \lim_{t \to 0, t > 0} u(x \mp tn)$, $x \in E$, and n is the exterior unit normal to E for $E \in \mathcal{E}_D \cup \mathcal{E}_N$ and a fixed, but arbitrary, unit normal to E for $E \in \mathcal{E}_I$; see Figure 2.1.

LEMMA 2.1. *If $f \in L^2$, $g_D \in H^{1/2}(\Gamma_D)$, and $g_N \in L^2(\Gamma_N)$, then the linear functional $l(\cdot)$ is bounded on $\mathcal{V}$ and the exact solution u of* (2.1) *satisfies*

$$a(u, v) = l(v) \tag{2.13}$$

for all $v \in \mathcal{V}$.

Proof. The first statement is obvious. For the second we note that the normal trace $\sigma_n(u)$ of $\sigma(u)$ is well defined in $L^2(E)$ on all edges $E \in \mathcal{E}$ since the stability estimate $\|\sigma(u)\| + \|\nabla \cdot \sigma(u)\| \le c(\|f\| + \|g_D\|_{1/2,\Gamma_D} + \|g_N\|_{\Gamma_N})$ holds. ∎

Here and below we let $\|v\|_{s,\omega}$ and $|v|_{s,\omega}$ denote the standard Sobolev norms and seminorms, respectively, for $v \in H^s(\omega)$ on the set $\omega \subset \Omega$. For brevity we write $\|v\|_s = \|v\|_{s,\Omega}$, $\|v\|_\omega = \|v\|_{0,\omega}$, and $\|v\| = \|v\|_{0,\Omega}$ for the L^2 norm.

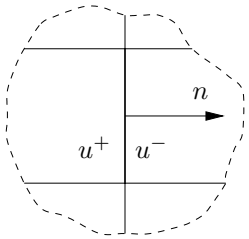

FIG. 2.1. *The plus and minus sides of an edge.*

2.4. The energy norm and some useful inequalities. We equip $\mathcal{V}$ with the mesh dependent energy norm

$$|||v|||^2 = |||v|||_{\mathcal{K}}^2 + \|\langle\sigma_n(v)\rangle\|_{\mathcal{E}}^2 + \|h^{-1}[v]\|_{\mathcal{E}}^2, \tag{2.14}$$

where

$$|||v|||_{\mathcal{K}}^2 = \sum_{K\in\mathcal{K}} (A\nabla v, \nabla v)_K, \tag{2.15}$$

$$\|w\|_{\mathcal{E}}^2 = \sum_{E\in\mathcal{E}_I\cup\mathcal{E}_D} \|h^{1/2}w\|_E^2. \tag{2.16}$$

Next we recall some useful standard inequalities which we will need in our developments. First we have the trace inequality

$$\|v\|_{\partial K}^2 \le c\|v\|_K\left(h_K^{-1}\|v\|_K + \|v\|_{1,K}\right) \quad \text{for } v\in H^1(K), \tag{2.17}$$

where c is a constant independent of h. This inequality follows by mapping to the unit size reference element $\tilde{K}$, employing the trace inequality

$$\|v\|_{\partial\tilde{K}}^2 \le c\|v\|_{\tilde{K}}\|v\|_{1,\tilde{K}} \quad \text{for } v\in H^1(\tilde{K}) \tag{2.18}$$

(see Brenner and Scott [5]) and finally transforming back to K. Furthermore, the following inverse estimate will be useful:

$$\|\langle\sigma_n(v)\rangle\|_{\mathcal{E}} \le C|||v|||_{\mathcal{K}} \quad \text{for } v\in\mathcal{V}, \tag{2.19}$$

with constant C dependent on the degree of polynomials p but not on the meshsize h. This estimate can be shown by scaling; see Thomée [15] for details.

3. A two-scale formulation of the dG method.

3.1. A splitting of $\mathcal{V}$.

THEOREM 3.1. *For $p\ge 2$ there is a decomposition of $\mathcal{V}$ into a direct sum*

$$\mathcal{V} = \mathcal{V}_c + \mathcal{V}_d, \tag{3.1}$$

where

$$\mathcal{V}_d = \{v\in\mathcal{V} : a_{\mathcal{K}}(w,v) - a_{\mathcal{E}}(w,v) = 0 \text{ for all } w\in\mathcal{V}\}, \tag{3.2}$$

$$\mathcal{V}_c = \{v\in\mathcal{V} : a_{\mathcal{E}}(w,v) = 0 \text{ for all } w\in\mathcal{V}_d\}, \tag{3.3}$$

with bilinear forms defined in (2.8) *and* (2.9). *Furthermore, for* $p \geq 2$ *the following norm equivalence holds:*

$$c_1 |||v|||^2 \leq |||v_c|||_{\mathcal{K}}^2 + |||v_d|||_{\mathcal{K}}^2 \leq c_2 |||v|||^2, \tag{3.4}$$

with constants c_1 *and* c_2 *independent of* h *but dependent on* p.

For the proof of Theorem 3.1 we need the following two lemmas.

LEMMA 3.1. *For each edge* $E \in \mathcal{E}_I \cup \mathcal{E}_D$ *there is a function* $\varphi_E \in \mathcal{V}_d$ *such that*

$$[\varphi_E] = 1 \quad \text{on } E, \tag{3.5}$$

$$\int_{E'} [\varphi_E] v = 0 \quad \text{for all } v \in \mathcal{P}_{p-1}(E') \text{ and } E' \in \mathcal{E} \setminus E, \tag{3.6}$$

where $\mathcal{P}_{p-1}(E')$ *denotes the space of polynomials of order* $p-1$ *defined on* E'.

Proof. We consider the case $E \in \mathcal{E}_I$. The case $E \in \mathcal{E}_D$ is similar, and it is also easy to see that the proof does not work out for $E \in \mathcal{E}_N$. We construct φ_E elementwise. Let $K^+, K^- \in \mathcal{K}$ be the triangles which share an interior edge E. Let z denote the coordinate orthogonal to E with positive direction into K^+, let $H^\pm$ be the height of $K^\pm$, and let

$$\varphi_E|_{K^\pm} = \begin{cases} -L_p(2(z/H^\pm) \mp 1)/2, & \text{odd } p, \\ \pm L_p(2(z/H^\pm) \mp 1)/2, & \text{even } p, \end{cases} \tag{3.7}$$

where L_p denotes the Legendre polynomial (see [1]) of order p defined on $[-1, 1]$. We begin by verifying that $\varphi_E \in \mathcal{V}_d$. Note that the condition

$$a_{\mathcal{K}}(w, v) - a_{\mathcal{E}}(w, v) = 0 \tag{3.8}$$

for all $w \in \mathcal{V}$ is equivalent to

$$-(\nabla \cdot \sigma(w), v)_K = (\sigma_n(w), \langle v \rangle)_{\partial K} \tag{3.9}$$

for all $w \in \mathcal{V}_K$ and $K \in \mathcal{K}$. Note that, from the fact that the Legendre polynomial L_p is orthogonal to all polynomials of order $p-1$, it follows that φ_E satisfies

$$-(\nabla \cdot \sigma(w), \varphi_E)_K = 0, \tag{3.10}$$

$$(\sigma_n(w), \langle \varphi_E \rangle)_{\partial K} = 0, \tag{3.11}$$

where in the last equality we also used that $\langle \varphi_E \rangle = 0$ on E. Thus φ_E is in $\mathcal{V}_d$. The properties (3.5) and (3.6) of φ_E are direct consequences of the construction. ∎

LEMMA 3.2. *For* $p \geq 2$ *there is a* $w \in \mathcal{V}_d$ *for each* $v \in \mathcal{V}$ *such that*

$$\|h^{-1} P_0[v]\|_{\mathcal{E}}^2 = \sum_{E \in \mathcal{E}_I \cup \mathcal{E}_D} (\langle \sigma_n(w) \rangle, P_0[v])_E, \tag{3.12}$$

$$|||w|||_{\mathcal{K}} \leq c \|h^{-1} P_0[v]\|_{\mathcal{E}}, \tag{3.13}$$

with constant c *independent of* h *and* p, *and* P_0 *the edgewise* L^2*-projection on constant functions.*

Proof. Let K be a triangle, E one of the edges of K, H the height of K orthogonal to E, and $z \in [0, H]$ the coordinate orthogonal to E. Then the normal derivative of the function $z(z/H - 1)$ is one on E and has average zero on the two other edges.

Based on this observation and the fact that A is positive definite, we conclude that for $p \geq 2$ we can construct a $w' \in \mathcal{V}_d$ for each $v \in \mathcal{V}$ such that

$$\sum_{E \in \mathcal{E}_I \cup \mathcal{E}_D} (\langle \sigma_n(w') \rangle, P_0[v])_E = \|h^{-1} P_0[v]\|_{\mathcal{E}}^2, \tag{3.14}$$

$$|||w'|||_{\mathcal{K}} \leq c \|h^{-1} P_0[v]\|_{\mathcal{E}}. \tag{3.15}$$

Next, for $p \geq 2$, we define $w \in \mathcal{V}_d$ by

$$a_{\mathcal{K}}(w, v) = a_{\mathcal{K}}(w', v) \quad \text{for all } v \in \mathcal{V}_d. \tag{3.16}$$

We note that setting $v = w$ and using the Cauchy–Schwarz inequality give

$$|||w|||_{\mathcal{K}} \leq |||w'|||_{\mathcal{K}}, \tag{3.17}$$

and thus it follows that

$$|||w|||_{\mathcal{K}} \leq c \|h^{-1} P_0[v]\|_{\mathcal{E}}. \tag{3.18}$$

Using the definition of $\mathcal{V}_d$, we get

$$a_{\mathcal{E}}(w, v) = a_{\mathcal{E}}(w', v) \quad \text{for all } v \in \mathcal{V}_d, \tag{3.19}$$

and choosing $v = \varphi_E$ (see Lemma 3.1), we find that

$$P_0 \langle \sigma_n(w) \rangle = P_0 \langle \sigma_n(w') \rangle \quad \text{on } E \tag{3.20}$$

for each edge $E \in \mathcal{E}_I \cup \mathcal{E}_D$. ∎

Remark 3.1. The construction of w' is a consequence of the classical nonconforming quadratic Morley element [10]. The degrees of freedom of the Morley element are the nodal values and the values of the normal derivative at the midpoints of the edges.

LEMMA 3.3. *It holds that*

$$\|h^{-1}(I - P_0)[v]\|_{\mathcal{E}} \leq c |||v|||_{\mathcal{K}} \quad \textit{for all } v \in \mathcal{V}, \tag{3.21}$$

with constant c independent of h and p, and with P_0 the edgewise L^2-projection on constant functions.

Proof. Note that we may subtract the projection of v onto piecewise constants $\pi_0 v$ as follows:

$$\|h^{-1}(I - P_0)[v]\|_{\mathcal{E}}^2 = \|h^{-1}(I - P_0)[v - \pi_0 v]\|_{\mathcal{E}}^2 \tag{3.22}$$

$$\leq c \sum_{K \in \mathcal{K}} h^{-1} \|v - \pi_0 v\|_K \Big(h^{-1} \|v - \pi_0 v\|_K + \|v - \pi_0 v\|_{1,K} \Big) \tag{3.23}$$

$$\leq c |||v|||^2, \tag{3.24}$$

where we finally used the interpolation estimate (4.12) below together with the fact that the H^1 seminorm can be estimated by the energy norm. ∎

Proof of Theorem 3.1. Clearly $\mathcal{V} = \mathcal{V}_c + \mathcal{V}_d$ by the definition. Assume that $v \in \mathcal{V}_c \cap \mathcal{V}_d$. Then we conclude that $a_{\mathcal{K}}(v, v) = 0$, and thus v is a piecewise constant function. It follows that $a_{\mathcal{E}}(w, v) = 0$ for all $w \in \mathcal{V}_d$. Invoking Lemma 3.2, we find that $v = 0$. Therefore, the sum is direct for $p \geq 2$.

Starting with the left inequality in (3.4), we first observe that, using the inverse inequality (2.19) and the triangle inequality, we have

$$\begin{aligned} |||v|||^2 &\le c|||v|||_{\mathcal{K}}^2 + \|h^{-1}[v]\|_{\mathcal{E}}^2 \\ &\le c\Big(|||v_c|||_{\mathcal{K}}^2 + |||v_d|||_{\mathcal{K}}^2\Big) + \|h^{-1}[v]\|_{\mathcal{E}}^2, \end{aligned} \tag{3.25}$$

and thus we need to estimate $\|h^{-1}[v]\|_{\mathcal{E}}^2$. Using the triangle inequality, we have

$$\|h^{-1}[v]\|_{\mathcal{E}} \le \|h^{-1}(I-P_0)[v]\|_{\mathcal{E}} + \|h^{-1}P_0[v]\|_{\mathcal{E}}. \tag{3.26}$$

For the first term on the right-hand side in (3.26) we have, using Lemma 3.3,

$$\|h^{-1}(I-P_0)[v]\|_{\mathcal{E}} \le c|||v|||_{\mathcal{K}} \le c\Big(|||v_d|||_{\mathcal{K}} + |||v_c|||_{\mathcal{K}}\Big). \tag{3.27}$$

Next, for the second, invoking Lemma 3.2 gives

$$\|h^{-1}P_0[v]\|_{\mathcal{E}}^2 = \sum_{E\in\mathcal{E}_I\cup\mathcal{E}_D} (\langle\sigma_n(w)\rangle, P_0[v])_E \tag{3.28}$$

$$= \sum_{E\in\mathcal{E}_I\cup\mathcal{E}_D} (\langle\sigma_n(w)\rangle, [v])_E - \sum_{E\in\mathcal{E}_I\cup\mathcal{E}_D} (\langle\sigma_n(w)\rangle, (I-P_0)[v])_E. \tag{3.29}$$

For the first term on the right-hand side in (3.29) we have the estimate

$$\sum_{E\in\mathcal{E}_I\cup\mathcal{E}_D} (\langle\sigma_n(w)\rangle, [v])_E = \sum_{E\in\mathcal{E}_I\cup\mathcal{E}_D} (\langle\sigma_n(w)\rangle, [v_d])_E \tag{3.30}$$

$$= \sum_{K\in\mathcal{K}} (\sigma(w), \nabla v_d)_K \tag{3.31}$$

$$\le |||w|||_{\mathcal{K}}|||v_d|||_{\mathcal{K}} \tag{3.32}$$

$$\le c\|h^{-1}P_0[v]\|_{\mathcal{E}}|||v_d|||_{\mathcal{K}}, \tag{3.33}$$

where we used the fact that $w\in\mathcal{V}_d$ in (3.30), the definition of $\mathcal{V}_d$ in (3.31), the Cauchy–Schwarz inequality in (3.32), and finally the stability estimate (3.13) in (3.33). For the second term,

$$\sum_{E\in\mathcal{E}_I\cup\mathcal{E}_D} (\langle\sigma_n(w)\rangle, (I-P_0)[v])_E \le \|\langle\sigma_n(w)\rangle\|_{\mathcal{E}}\|(I-P_0)h^{-1}[v]\|_{\mathcal{E}} \tag{3.34}$$

$$\le c|||w|||_{\mathcal{K}}|||v|||_{\mathcal{K}} \tag{3.35}$$

$$\le c\|h^{-1}P_0[v]\|_{\mathcal{E}}|||v|||_{\mathcal{K}}, \tag{3.36}$$

where we used the Cauchy–Schwarz inequality in (3.34), the inverse inequality (2.19) and Lemma 3.3 in (3.35), and finally the stability estimate (3.13) in (3.36).

Starting from (3.29) and using the triangle inequality together with estimates (3.33) and (3.36) and finally dividing with $\|h^{-1}P_0[v]\|_{\mathcal{E}}$ give

$$\|h^{-1}P_0[v]\|_{\mathcal{E}} \le c\Big(|||v_d|||_{\mathcal{K}} + |||v_c|||_{\mathcal{K}}\Big), \tag{3.37}$$

which together with (3.25), (3.26), and (3.27) proves the left inequality in (3.4).

We now turn to the proof of the right inequality in (3.4). Starting from the definition (3.2) of $\mathcal{V}_d$ in Theorem 3.1 and setting $w = v_d$, we get

$$|||v_d|||_{\mathcal{K}}^2 = a_{\mathcal{K}}(v_d, v_d) \tag{3.38}$$

$$= a_{\mathcal{E}}(v_d, v) \tag{3.39}$$

$$\leq \|\langle\sigma_n(v_d)\rangle\|_{\mathcal{E}} \|h^{-1}[v]\|_{\mathcal{E}} \tag{3.40}$$

$$\leq c|||v_d|||_{\mathcal{K}}|||v|||, \tag{3.41}$$

where we used the Cauchy–Schwarz inequality, and, at last, the inverse inequality (2.19) and the obvious fact that $\|h^{-1}[v]\|_{\mathcal{E}} \leq |||v|||$. Finally, dividing by $|||v_d|||_{\mathcal{K}}$ and squaring both sides give

$$|||v_d|||_{\mathcal{K}}^2 \leq c|||v|||^2. \tag{3.42}$$

Next, for v_c we simply have

$$|||v_c|||_{\mathcal{K}}^2 = |||v - v_d|||_{\mathcal{K}}^2 \tag{3.43}$$

$$\leq c\Big(|||v|||_{\mathcal{K}}^2 + |||v_d|||_{\mathcal{K}}^2\Big) \tag{3.44}$$

$$\leq c|||v|||^2, \tag{3.45}$$

which together with (3.42) prove the right inequality in (3.4). At last, tracing constants, we find that both c_1^{-1} and c_2 are of the form $cC^2 + c$, where c denotes constants independent of both h and p, and C is the constant in the inverse inequality (2.19), which depends on p. ∎

3.2. A two-scale formulation of the dG method. Here we shall derive a system of equations corresponding to (2.6) using the splitting given in Theorem 3.1. Writing $u = u_c + u_d$ and $v = v_c + v_d$ and using the identities

$$a(u_c, v_d) = 0, \tag{3.46}$$

$$a(u_d, v_c) = 2a_{\mathcal{K}}(u_d, v_c), \tag{3.47}$$

$$a(u_d, v_d) = a_{\mathcal{K}}(u_d, v_d), \tag{3.48}$$

which are direct consequences of Theorem 3.1, we obtain a triangular system of the following form: find $u = u_c + u_d \in \mathcal{V}_c + \mathcal{V}_d$ such that

$$\begin{aligned} a(u_c, v_c) + 2a_{\mathcal{K}}(u_d, v_c) &= l(v_c), \\ a_{\mathcal{K}}(u_d, v_d) &= l(v_d). \end{aligned} \tag{3.49}$$

We note that, with this particular splitting of $\mathcal{V}$, the discontinuous scales $\mathcal{V}_d$ are in fact not coupled to the continuous scales $\mathcal{V}_c$.

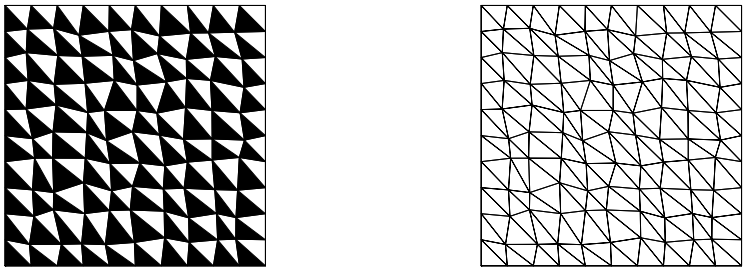
3.3. Checkerboard solutions for $p = 1$. For $p = 1$ the splitting (3.1) in Theorem 3.1 is not direct and the norm equivalence (3.4) does not hold in general. This fact can be seen as follows. Using Green's formula, we have

$$\sum_{K\in\mathcal{K}} (\nabla w, A\nabla v)_K = \sum_{K\in\mathcal{K}} (-\nabla\cdot\nabla w, v)_K + \sum_{E\in\mathcal{E}_I} ([\sigma_n(w)], \langle v\rangle)_E + (\langle\sigma_n(w)\rangle, [v])_E + \sum_{E\in\mathcal{E}_D\cup\mathcal{E}_N} (\sigma_n(w), v)_E.$$

Now if v is a piecewise constant function, then $\nabla v = 0$, and if w is a piecewise linear function, then $-\nabla \cdot A\nabla w = 0$ (recall that A is piecewise constant). Using these facts, we get

$$a_{\mathcal{E}}(w,v) = -\sum_{E\in\mathcal{E}_I} ([\sigma_n(w)], \langle v\rangle)_E - \sum_{E\in\mathcal{E}_N} (\sigma_n(w), v)_E,$$

and thus if $\mathcal{E}_N$ is empty and $\langle v\rangle = 0$ on each edge, then $a_{\mathcal{E}}(w,v) = 0$ for all $w \in \mathcal{V}$. Going back to the splitting $\mathcal{V} = \mathcal{V}_c + \mathcal{V}_d$, in Theorem 3.1 we find that $v \in \mathcal{V}_c \cap \mathcal{V}_d$ and thus the splitting is not direct. Further it is easy to see that $|||v|||_{\mathcal{K}} = 0$, while $|||v|||^2 \neq 0$ and thus c_1 must be zero; i.e., (3.4) does not hold. However, a piecewise constant function v, with $\langle v\rangle = 0$ on each $E \in \mathcal{E}_I$, does exist only on a checkerboard mesh, i.e., a mesh which could be colored as a checkerboard with two colors. In Figure 3.1 we give an example of such a function v on an unstructured checkerboard triangulation of the unit square. In the case when $\mathcal{E}_N$ is not empty but the mesh is a checkerboard mesh, we instead get that $c_1 \to 0$ as $h \to 0$. However, a general unstructured triangulation is usually quite far from being a checkerboard mesh, and in such a situation the norm equivalence will in general hold even for $p = 1$. See the computations of the inf-sup constant presented below.



(a) (b)

FIG. 3.1. (a) *Checkerboard solution with black* $= -1$ *and white* $= 1$ *and* (b) *the corresponding triangulation of the unit square.*

4. Stability analysis and error estimates in the energy norm.

4.1. Stability analysis. Our main result in this section is a proof that the inf-sup constant (see, for instance, [5]) is positive and independent of the meshsize. This stability result is, as is well known, key for proving existence and uniqueness of the discrete solution as well as error estimates in the energy norm.

THEOREM 4.1. *If* $p \geq 2$*, then there is a constant* $m > 0$ *such that*

$$\inf_{u\in\mathcal{V}} \sup_{v\in\mathcal{V}} \frac{a(u,v)}{|||u||| \, |||v|||} \geq m. \tag{4.1}$$

The constant m *is independent of* h *but depends on* p*.*

Proof. Using identities (3.46)–(3.48), we have

$$a(u_c + u_d, v_c + v_d) = a_{\mathcal{K}}(u_c, v_c) + 2a_{\mathcal{K}}(u_d, v_c) + a_{\mathcal{K}}(u_d, v_d). \tag{4.2}$$

Setting

$$v_c + v_d = u_c + \gamma u_d, \tag{4.3}$$

where $\gamma \in \mathbf{R}$ is a parameter, we get

$$a(u_c + u_d, v_c + v_d) = |||u_c|||_{\mathcal{K}}^2 + 2a_{\mathcal{K}}(u_d, u_c) + \gamma|||u_d|||_{\mathcal{K}}^2 \tag{4.4}$$

$$\geq |||u_c|||_{\mathcal{K}}^2 - 2\,|||u_d|||_{\mathcal{K}}|||u_c|||_{\mathcal{K}} + \gamma|||u_d|||_{\mathcal{K}}^2 \tag{4.5}$$

$$\geq (1-\epsilon)|||u_c|||_{\mathcal{K}}^2 + (\gamma - \epsilon^{-1})|||u_d|||_{\mathcal{K}}^2. \tag{4.6}$$

Here we used the Cauchy–Schwarz inequality and the inequality $2ab \leq \epsilon a^2 + \epsilon^{-1}b^2$ for any a, b, and $\epsilon \in \mathbf{R}$ with $\epsilon > 0$. Choosing ϵ such that $1 - \epsilon \geq m'$ and $\gamma \geq 1$ such that $\gamma - \epsilon^{-1} \geq m'$, we get

$$a(u_c + u_d, u_c + \gamma u_d) \geq m'\Big(|||u_c|||_{\mathcal{K}}^2 + |||u_d|||_{\mathcal{K}}^2\Big). \tag{4.7}$$

Next, using the norm equivalence (3.4), we note that, for $\gamma \geq 1$, we have

$$c_1|||u_c + \gamma u_d|||^2 \leq |||u_c|||_{\mathcal{K}}^2 + \gamma^2|||u_d|||_{\mathcal{K}}^2 \tag{4.8}$$

$$\leq \gamma^2\Big(|||u_c|||_{\mathcal{K}}^2 + |||u_d|||_{\mathcal{K}}^2\Big), \tag{4.9}$$

and thus we conclude that

$$|||u_c + u_d|||\;|||u_c + \gamma u_d||| \leq c_1^{-1}\gamma\Big(|||u_c|||_{\mathcal{K}}^2 + |||u_d|||_{\mathcal{K}}^2\Big). \tag{4.10}$$

Combining (4.7) and (4.10), we immediately get the desired inf-sup bound

$$\inf_{u\in\mathcal{V}}\sup_{v\in\mathcal{V}}\frac{a(u,v)}{|||u|||\;|||v|||} \geq \frac{c_1 m'}{\gamma} = m. \qquad \square \tag{4.11}$$

Remark 4.1. In [2] the concept of weak stability $m|||v|||_{\mathcal{K}}^2 \leq a(v,v)$ is discussed. We note that, while weak stability is obvious for the nonsymmetric dG method, it is nontrivial to derive error estimates of $|||u - u_h|||$ since the bilinear form is not bounded with respect to the $|||\cdot|||_{\mathcal{K}}$. Further, $|||\cdot|||_{\mathcal{K}}$ is only a seminorm while $|||\cdot|||$ is a norm.

Example: Computation of the inf-sup constant. We compute the inf-sup constant for the discrete Laplacian defined by (2.6) on the unit square $\Omega = [0,1]^2$ with homogenous Dirichlet conditions on Γ. The triangulations are quasi-uniform unstructured with N elements. For details on such computations we refer to Oden, Babuška, and Baumann [12]. In Table 4.1 we present the inf-sup constant m for a variety of triangulations and $p = 1, \ldots, 4$. We note that the inf-sup constant is independent of the number of elements (or meshsize) and decreases with increasing $p \geq 2$, as expected. Note also that for $p = 1$ the inf-sup constant is indeed strictly positive due to the fact that these computations are done on an unstructured grid in two spatial dimensions, which is typically not close to a checkerboard mesh.

4.2. Error estimates in the energy norm. We first recall that given $u \in H^s(K)$, there is $\pi_K u \in \mathcal{P}_p(K)$ such that the following estimate holds:

$$\|u - \pi_K u\|_{r,K} \leq c p_K^{r-s} h_K^{\mu-r}|u|_{s,K}, \tag{4.12}$$

TABLE 4.1
The inf-sup constant m for different p and meshes with N elements.

N	$p=1$	$p=2$	$p=3$	$p=4$
72	0.054	0.116	0.071	0.047
290	0.022	0.115	0.068	0.044
1300	0.022	0.115	0.067	0.044
2604	0.021	0.116	0.070	–
5366	0.023	0.115	–	–

where $0 \leq r \leq s$, $\mu = \min(p+1, s)$, and c is a constant independent of h and p; see [4]. Further, we let $\pi u \in \mathcal{V}$ be defined by $(\pi v)|_K = \pi_K(v|_K)$. Using (4.12), we get the following lemma.

LEMMA 4.1. *The following interpolation error estimate holds:*

$$|||u - \pi u||| \leq c\left(\sum_{K\in\mathcal{K}} p_K^{-(2s-3)} h_K^{2(\mu-1)} |u|_{s,K}^2\right)^{1/2}. \tag{4.13}$$

Proof. With $\eta = u - \pi u$ we have

$$|||\eta|||^2 = |||\eta|||_{\mathcal{K}}^2 + \|\langle\sigma_n(\eta)\rangle\|_{\mathcal{E}}^2 + \|h^{-1}[\sigma_n(\eta)]\|_{\mathcal{E}}^2.$$

Using the boundedness of A, we get $|||\eta|||_{\mathcal{K}}^2 \leq c\sum_{K\in\mathcal{K}} \|\eta\|_{1,K}^2$. For the second term we invoke the trace inequality (2.17) elementwise to obtain

$$\begin{aligned}\|\langle\sigma_n(\eta)\rangle\|_{\mathcal{E}}^2 &\leq c\sum_{K\in\mathcal{K}} h\|\nabla\eta\|_K\Big(h^{-1}\|\nabla\eta\|_K + \|\nabla\eta\|_{1,K}\Big)\\ &\leq c\sum_{K\in\mathcal{K}} \|\eta\|_{1,K}\Big(\|\eta\|_{1,K} + h\|\eta\|_{2,K}\Big).\end{aligned}$$

For the third term we get in the same way

$$\|h^{-1}[\eta]\|_{\mathcal{E}}^2 \leq c\sum_{K\in\mathcal{K}} h^{-1}\|\eta\|_K\Big(h^{-1}\|\eta\|_K + \|\eta\|_{1,K}\Big).$$

Now (4.13) follows directly from the interpolation error estimate (4.12). ∎

Here we used the multiplicative trace inequality to estimate the edge contributions. We refer to [7] for a discussion of the suboptimality with respect to p resulting from this trace inequality and an alternative estimate.

Using the stability estimate in Theorem 4.1 and the interpolation error estimate in Lemma 4.1, we obtain the following energy norm error estimate using standard arguments. The error estimate is optimal in h but suboptimal in p by a factor $1/2$ modulo the dependence of m on p.

THEOREM 4.2. *The following energy norm error estimate holds:*

$$|||u - u_h|||^2 \leq c(1 + m^{-1})\left(\sum_{K\in\mathcal{K}} p_K^{-(2s-3)} h_K^{2(\mu-1)} |u|_{s,K}^2\right)^{1/2},$$

where c denotes constants independent of h and p. The constant m, defined in Theorem 4.1, is independent of h but depends on p.

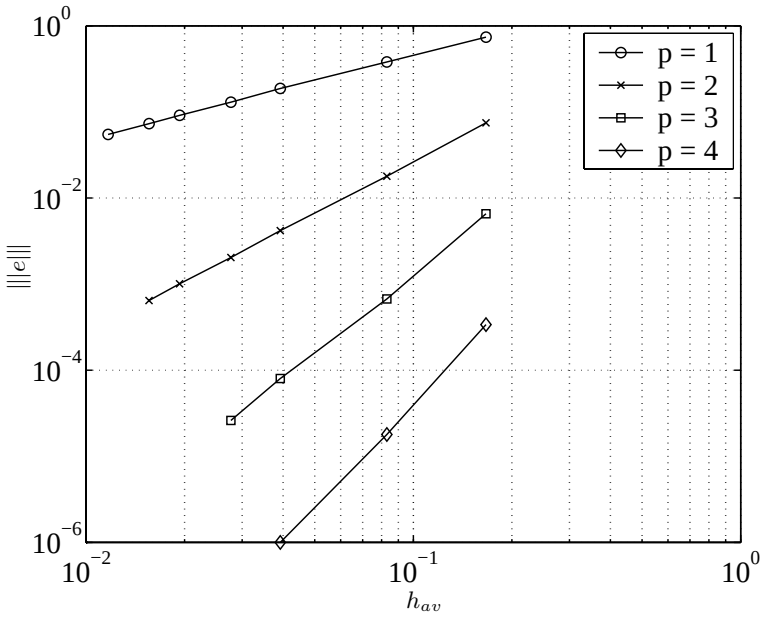


FIG. 4.1. *The energy error as a function of the average meshsize h_{av} for $p = 1, \ldots, 4$.*

Example: The error in the energy norm. We consider the Poisson equation (2.1) on the unit square, $\Omega = [0,1]^2$, with homogeneous Dirichlet boundary conditions, $u = 0$, on the boundary Γ and the right-hand side f chosen so that the exact solution is $u(x,y) = \sin(\pi x)\sin(\pi y)$. The triangulation is unstructured and all triangles are approximately the same size. In Figure 4.1 we plot the error as a function of the average meshsize h_{av} defined by $h_{av} = \sqrt{2N}$, where N is the number of elements. We observe the expected convergence of order $p-1$ for polynomials of order p.

PARALLEL TWO-STEP W-METHODS WITH PEER VARIABLES*

BERNHARD A. SCHMITT† AND RÜDIGER WEINER‡

Abstract. A new class of methods for the solution of stiff initial value problems is introduced that is parallel by design. It has a two-step character and propagates s different "peer" solution variables with essentially identical characteristics from step to step. The main work lies in the solution of s independent linear stage equations which may be solved in parallel. Convergence of order $s-1$ and stability for general stepsize sequences are proved. Conditions for order s and stronger stability criteria are addressed as well. Promising methods up to order 7 are identified by numerical tests with some widely used stiff test problems. Some of these are competitive with existing software even in sequential computations.

Key words. stiff initial value problems, parallel two-step methods, parallel peer W-methods

AMS subject classifications. 65L06, 65Y05

DOI. 10.1137/S0036142902411057

1. Introduction.

Parallel solution methods for large and stiff initial value problems

$$y' = f(t,y), \quad t_0 \le t \le t_e, \quad y(t_0) = y_0 \in \mathbb{R}^n, \tag{1}$$

may be based on many different strategies. In this paper we will consider a new class of time integration schemes with inherent "method parallelism" [8]. This feature is independent of "parallelism across the system" since both kinds of parallelism may be applied simultaneously in many situations. Approaches for method parallelism may start with well-known classical methods and try to parallelize expensive parts of its numerical components, like the solution of the large nonlinear systems in implicit Runge–Kutta methods (e.g., [1]). Similarly, parallel iteration schemes may be applied to classical one-step or multistep methods as in some works of van der Houwen and Sommeijer and van der Houwen and de Swart [11, 12] and Burrage and Suhartanto [3]. For a recent textbook on parallel methods, see [2]. Other approaches are based on new kinds of methods that are parallel by design. Within the wide class of general linear methods (GLMs), the subclass of diagonally implicit multistage integration methods (DIMSIMs) suitable for parallel implementation has been proposed by Butcher [5]. Here, the equations for the internal stages of the GLM may be solved in parallel since the corresponding part of the coefficient matrix is diagonal. The papers [6, 7] are concerned with implementation issues of such methods. Unfortunately, the practical experience with these methods is not overly positive compared to RADAU [10] or parallel software for implicit differential equations (PSIDE) [12].

In order to circumvent some of the theoretical bottlenecks in the structure of classical one-step and multistep methods, the class of linearly implicit *parallel two-step W-methods* (PTSW-methods) has been discussed recently by Podhaisky and the authors [15]. These PTSW-methods are similar to ordinary Rosenbrock–Wanner (ROW)- or

W-methods (cf. [13], [10, IV.7]) but use s stage increments from the previous time step only. So, all s current stages can be processed in parallel. The PTSW-methods are already quite competitive [16, 19] even in sequential computations. They are particularly attractive in very stiff or singularly perturbed problems since they do not suffer an order reduction due to high stage orders. One of their weaknesses, however, is some critical dependence on stepsize ratios in the stiff case.

Literally speaking, many parallel and classical time integration methods have a set of distinguished or "master" variables and compute additional "slave" variables to improve accuracy or stability properties of the masters. In fact, these methods usually employ only one n-dimensional master approximation for the solution in each time interval with distinguished accuracy and stability properties. In contrast to these schemes, we now consider methods having only peer variables sharing the same accuracy and stability properties (with minor modifications). An immediate advantage of this approach is the existence of a continuous extension for these methods by using an interpolating polynomial. In this paper we restrict the discussion to two-step methods that compute several solution approximations Y_{mi}, $i = 1, \dots, s$, associated with a time interval $[t_m, t_{m+1}]$ from the information contained in the variables $Y_{m-1,i}$ from the previous interval. Generalization to methods using even earlier information is obvious but will not be considered here. Moreover, we will concentrate on linearly implicit methods avoiding the solution of nonlinear systems of equations. In parallel "peer" two-step W-methods (PPSW-methods), the solutions Y_{mi}, $i = 1, \dots, s$, are related to points

$$t_{mi} := t_m + h_m c_i, \quad i = 1, \dots, s, \tag{2}$$

associated with the time interval $[t_m, t_{m+1}]$ but not necessarily contained in it. The PPSW-methods are given by

$$\begin{aligned}(I - \gamma_i h_m T_m) Y_{mi} = &\sum_{j=1}^{s} \big(b_{ij} I + h_m \gamma_{ij} T_m\big) Y_{m-1,j} \\ &+ h_m \sum_{j=1}^{s} a_{ij} f\big(t_{m-1,j}, Y_{m-1,j}\big), \quad i = 1, \dots, s.\end{aligned} \tag{3}$$

The terms $\gamma_i > 0$, $b_{ij}, \gamma_{ij}, a_{ij}$ are the parameters of the method. The matrix T_m should be an approximation of the Jacobian $f_y(t_m, y(t_m))$ for stability reasons only. In fact, the accuracy of these methods is derived for arbitrary T_m in the sense of W-methods. In this context it is no essential restriction to consider autonomous problems, and we will do this for simplicity. The subclass of these methods with $\gamma_i = 0$, $\gamma_{ij} = 0$ may also be attractive for nonstiff problems but will not be discussed here.

Introducing the stage vectors $Y_m = (Y_{mi})_{i=1}^{s} \in \mathbb{R}^{sn}$ and coefficient matrices

$$G := \operatorname{diag}(\gamma_i),\ A = (a_{ij}),\ B = (b_{ij}),\ \Gamma = (\gamma_{ij}),\ \beta := A + \Gamma, \tag{4}$$

a more compact version of the PPSW-method is

$$(I - h_m G \otimes T_m) Y_m = (B \otimes I + h_m \Gamma \otimes T_m) Y_{m-1} + h_m (A \otimes I) f(Y_{m-1}). \tag{5}$$

The matrix β introduced in (4) will play an important role in the analysis. In (5) it is easily seen that for methods using $G = \gamma I$ the matrix $I - h_m G \otimes T_m$ commutes with all other matrices in the scheme. Hence the stability analysis simplifies considerably.

Similar to the notion in implicit Runge–Kutta methods, we will also call methods using

$$\gamma_i \equiv \gamma, \quad G = \gamma I \tag{6}$$

singly implicit. We will concentrate on this kind of method in the present paper and display its specific form for ease of reference:

$$\big(I \otimes (I - \gamma h_m T_m)\big) Y_m = (B \otimes I + h_m \Gamma \otimes T_m) Y_{m-1} + h_m (A \otimes I) f(Y_{m-1}). \tag{7}$$

Such methods may be attractive already in a sequential computing environment since the matrix decomposition of $I - \gamma h_m T_m$ may be used in all stages. A situation of interest on parallel machines is the use of expensive parallel preconditioners for this matrix. Still, multi-implicit methods with a general diagonal matrix G offer additional design options and will be discussed in [18].

The emphasis of our discussion lies on higher-order methods with an order near the number of stages s. Here, a critical source of problems is the fact that the coefficients of the methods depend on the current stepsize ratio σ_m defined in (8). Stepsize increases will be restricted by an upper bound

$$\sigma_m := h_m / h_{m-1} \le \bar{\sigma} \tag{8}$$

for all steps, but no lower bound is assumed since this might be a severe restriction in practice. When discussing nonlocal effects we will occasionally add an additional step-index m to the coefficient matrices A, B, Γ, β (see (4)) to indicate this dependence, and the same notation will be used for other quantities. Convergence results are formulated in terms of the maximal stepsize

$$H := \max_{j \ge 0} h_j. \tag{9}$$

Further abbreviations are $\mathbb{1} = (1, \ldots, 1)^{\mathsf{T}}$, e_i for the ith unit vector. The spectral radius of a matrix is denoted by ρ.

After this introduction the paper continues with basic aspects of stability and accuracy of the schemes. Conditions for stability with general stepsizes and the structure of the stability matrix are derived as well as basic order conditions. The conditions for order $s - 1$ lead to explicit representations of the coefficients of the scheme. We concentrate on these high-order schemes in section 3 and identify one class where the general stability conditions from section 2 can be established easily. We also discuss conditions for improving the order to s. For the singly implicit methods in the form (7) it is unlikely that this can be achieved by improving all local errors by one order. However, we show that there is some superconvergence effect for the global error for certain parameter choices. Unfortunately, this effect can be conveniently exploited for constant stepsizes only. In section 4 we finally discuss implementation issues like error estimation and present numerical results with different test problems and methods with up to eight stages.

2. Basic properties.

2.1. Stability issues. Due to the two-step structure of the scheme and the σ-dependence of its coefficients, the stability analysis encounters many of the difficulties of multistep methods. In addition to the step recursion (5), we consider a second one

with additional perturbations $h_m g_m = h_m(g_{mi})_{i=1}^s \in \mathbb{R}^{sn}$ and solutions $Y_m + X_m$. So, for the error X_m we have the recursion

$$(I - h_m G_m \otimes T_m)X_m = (B_m \otimes I + h_m \Gamma_m \otimes T_m)X_{m-1} \tag{10}$$

$$+ h_m(A_m \otimes I)(f(Y_{m-1} + X_{m-1}) - f(Y_{m-1})) + h_m g_m,$$

where the coefficient matrices are supplemented by the step-index m. The stability of the recursion (10) is covered by the theory for multistep methods; see [9]. For ease of reference we formulate it in the following lemma. The crucial assumption (11) will be verified for our methods in section 3.1.

LEMMA 2.1. *Assume that for some fixed $\bar\sigma > 1$ and stepsize sequences with $h_m \le \bar\sigma h_{m-1}$ a uniform bound $\bar b$ exists for all products*

$$\|B_{m+k} \cdots B_{m+1} B_m\| \le \bar b, \quad m, k \ge 0, \tag{11}$$

where $\sum_{j=m}^{m+k} h_j \le t_e - t_0$. Let the maps $X \mapsto (I - h_m G_m \otimes T_m)^{-1}((G_m\beta_m + \Gamma_m) \otimes T_m)X + (A_m \otimes I)(f(Y_{m-1}+X) - f(Y_{m-1}))$ be uniformly Lipschitz continuous in some neighborhood of zero. Then there exists a constant C such that

$$\|X_m\| \le C(\|X_0\| + \max_{j=1}^{m} \|g_j\|) \quad \textit{for} \quad t_0 \le t_m \le t_e.$$

The standard application of this stability lemma concerns the convergence of the scheme, where the "perturbed" solution $Y_m + X_m = y(t_m)$ is the solution of the initial value problem and the perturbations g_m are the corresponding residuals defined in (13). Here, Lemma 2.1 shows that the scheme (3) converges with order p, i.e., $X_m = O(H^p)$, if the local error is of order p too; i.e., $g_m = O(H^p)$. So we do not need to distinguish between the local and global order of the method except in the case of superconvergence; cf. section 3.2.

In the stiff context it is appropriate to consider the linear autonomous problem

$$y' = Jy$$

as a test equation, where the eigenvalues of J lie in the left complex halfplane. With the choice

$$T_m = J$$

the scheme (3) reduces to the recursion (see (4))

$$Y_m = M_m(h_m J)Y_{m-1}, \quad M_m(z) := (I - zG_m)^{-1}(B_m + z\beta_m), \tag{12}$$

where $M_m(\cdot)$ is the stability matrix of the scalar test equation $y' = \lambda y$ and $z = h_m\lambda$. Unfortunately, M_m depends on the current stepsize ratio σ_m, and only for constant stepsizes the spectral radius of M is an appropriate measure for the longtime behavior of the recursion (12). In the case $\sigma \equiv 1$ we may apply some standard stability notions to the scalar function $\rho(M(z))$.

DEFINITION 2.2. *Let $M(.)$ be the stability matrix of a PPSW-method* (3) *as defined in* (12) *with $\sigma = 1$. Then, the method is called* zero-stable *if $\rho(M(0)) = 1$ and the eigenvalues on the unit circle are simple. It is* A*-stable if $\rho(M(z)) < 1$ in the open left complex halfplane, $z \in \mathbb{C}_- := \{z \in \mathbb{C} : \ \mathrm{Re}\ z < 0\}$, and* L*-stable if, additionally, $\rho(M(\infty)) = 0$.*

Remarks. (a) Any consistent method must reproduce constant solutions for $\lambda = 0$. Since this requirement leads to the identity $B\mathbb{1} = \mathbb{1}$, the spectral radius of $M(0) = B$ cannot be smaller than one.

(b) For singly implicit methods (7) we have $M(\infty) = -\frac{1}{\gamma}\beta$, and L-stability requires $\rho(\beta) = 0$.

(c) It is convenient to introduce the variable $w = z/(1-\gamma z)$ satisfying $(1+\gamma w)(1-\gamma z) = 1$. For $z \in \mathbb{C}_-$ the variable w is contained in the circle centered at $-1/(2\gamma)$ and going through the origin. Now, the stability matrix of singly implicit methods (7) is a linear function of w given by

$$M(z) = (1 + \gamma w)B + w\beta = B + w(\gamma B + \beta).$$

This form may be conveniently employed to check the A-stability of the scheme since M has an eigenvalue $\lambda = e^{i\theta}$ on the unit circle if w is an eigenvalue of the generalized eigenvalue problem [17],

$$(e^{i\theta} I - B)x = w(\gamma B + \beta)x, \quad x \in \mathbb{C}^s.$$

A thorough and general analysis of stability properties of our methods is quite difficult since the stability matrix M_m depends on the actual stepsize ratio σ_m for accuracy reasons. However, this is a common problem for multistep methods where even proving zero-stability is nontrivial for general stepsize sequences. For PPSW-methods this case will be dealt with in section 3.1 by verifying (11). A similar result covering the stiff limit $z = h\lambda \to \infty$ for arbitrary stepsize ratios is presented there too. However, stronger z-uniform stability results for these methods with nonconstant stepsize sequences are not yet available.

2.2. Accuracy conditions. The structure of the coefficient matrices is determined to a large extent by accuracy requirements. The accuracy of the PPSW-methods may be analyzed in a standard way by considering the residuals Δ_{mi} obtained when the exact solution is put into the method. From now on we discuss singly implicit methods (7) only. Using the information $f(t_{m-1,j}, y(t_{m-1,j})) = y'(t_{m-1,j})$, we consider

$$h_m\Delta_{mi} := (I - \gamma h_m T_m)y(t_{mi}) - \sum_{j=1}^{s} \big(b_{ij} I + h_m\gamma_{ij} T_m\big)y(t_{m-1,j}) - h_m \sum_{j=1}^{s} a_{ij} y'(t_{m-1,j}), \quad i = 1, \dots, s. \tag{13}$$

We will use Taylor expansion at t_m but write the error in terms of h_{m-1} since σ_m is bounded from above only, so $h_m = O(h_{m-1})$ but not vice versa. Separating the terms depending on T_m from the others, we see that

$$h_m T_m \left(\gamma y(t_{mi}) + \sum_{j=1}^{s} \gamma_{ij} y(t_{m-1,j}) \right) = O(h_{m-1}^{q+1})$$

holds if condition (see (2))

$$\Gamma(q): \quad \gamma c_i^k + \sum_{j=1}^{s} \gamma_{ij}(c_j - 1)^k \sigma_m^{-k} = 0, \quad k = 0, \dots, q-1, \tag{14}$$

is satisfied for a sufficiently smooth solution. Second, it holds that

$$y(t_{mi}) - \sum_{j=1}^{s} b_{ij} y(t_{m-1,j}) - h_m \sum_{j=1}^{s} a_{ij} y'(t_{m-1,j}) = O(h_{m-1}^q)$$

if condition

$$AB(q):\ c_i^k - \sum_{j=1}^{s} b_{ij} \left(\frac{c_j - 1}{\sigma_m}\right)^k - k \sum_{j=1}^{s} a_{ij} \left(\frac{c_j - 1}{\sigma_m}\right)^{k-1} = 0,\ k = 0, \ldots, q-1, \tag{15}$$

is true, where the tacit convention is used that the second sum is not evaluated for $k = 0$ and cancelled by the factor k holds. In both conditions q denotes the number of conditions.

LEMMA 2.3. *If the conditions* $\Gamma(q)$ *and* $AB(q+1)$ *are satisfied with* $q \geq 1$ *and the solution* y *of* (1) *is sufficiently smooth, then the residuals* (13) *for the scheme* (3) *are of order* q*; i.e.,* $\|\Delta_m\| = O(h_{m-1}^q)$.

With respect to the order, the most critical condition seems to be $\Gamma(q)$ in (14) since it depends on the $s^2 + 1$ coefficients γ, γ_{ij} only. In fact, requiring $\Gamma(s)$ leads to the explicit relation

$$\Gamma_m = -\gamma \Theta_m, \quad \Theta_m := V S_m P V^{-1}, \tag{16}$$

with the Vandermonde matrix V and the Pascal matrix P defined by

$$V = \left(c_i^{j-1}\right)_{i,j=1}^{s}, \quad P = \left(\binom{j-1}{i-1}\right)_{i,j=1}^{s}. \tag{17}$$

We also need the diagonal matrices

$$S_m = \operatorname{diag}(1, \sigma_m, \ldots, \sigma_m^{s-1}),\ D := \operatorname{diag}(1, \ldots, s). \tag{18}$$

The matrix Θ_m will be encountered quite often since it describes the polynomial extrapolation from the subgrid $\{t_{m-1} + h_{m-1} c_i,\ i = 1, \ldots, s\}$ to $\{t_m + h_m c_i,\ i = 1, \ldots, s\}$.

In a similar way, explicit solutions for the order conditions (15) may be obtained by requiring $AB(s)$. Here, we note that the matrix $\left(\left(\frac{c_j - 1}{\sigma_m}\right)^{k-1}\right)_{j,k=1}^{s} = V P^{-1} S_m^{-1}$ multiplies B (see (4)) from the right in (15). The corresponding factor for A is obtained from this one by scaling and shifting its columns to the right. The shift is described by the matrix $F_0 = (\delta_{i-1,j})$, which gives rise to the identities

$$P D F_0^{\mathsf{T}} = D F_0^{\mathsf{T}} P, \quad F_0^{\mathsf{T}} S_m = \sigma_m S_m F_0^{\mathsf{T}}, \tag{19}$$

with the matrices defined in (17), (18). The first relation in (19) corresponds to the identity $\binom{j-2}{i-1}(j-1) = i\binom{j-1}{i}$. Now, condition (15) has the matrix form $0 = V - BVP^{-1}S_m^{-1} - AVP^{-1}S_m^{-1}DF_0^{\mathsf{T}}$. Multiplying with $S_m P V^{-1}$ and using the relations (19), we obtain

$$B_m = \Theta_m - \sigma_m A_m V D F_0^{\mathsf{T}} V^{-1}. \tag{20}$$

Since stability properties depend on the matrix $\beta_m = A_m + \Gamma_m$, by (12) it is convenient to replace the coefficient A_m in the last equation by using β_m and the first order condition (14) as well.

LEMMA 2.4. *If the PPSW-method* (7) *satisfies* $AB(s)$ *and* $\Gamma(s-1)$*, then its coefficient matrices* B_m *and* β_m *are related through*

$$B_m = (I+\gamma E)\Theta_m + \sigma_m\beta_m E, \quad E = -VDF_0^{\mathsf{T}}V^{-1}. \tag{21}$$

The matrices E *and* Θ_m *commute for* $\sigma_m = 1$*, since* $E\Theta_m = \sigma_m\Theta_m E$.

Proof. In matrix form the condition $\Gamma(s-1)$ amounts to $\gamma VS_mP + \Gamma_m V = ue_s^{\mathsf{T}}$ with an arbitrary last column u. Using this equation and replacing $A_m = \beta_m - \Gamma_m$ in (20) give

$$B_m = \Theta_m - \sigma_m(\beta_m V + \gamma VS_mP)DF_0^{\mathsf{T}}V^{-1},$$

since the last column of $\Gamma_m V$ drops out after multiplication with the shift matrix F_0^{T}. Combining the two identities in (19) yields $DF_0^{\mathsf{T}}S_mP = \sigma_m S_mPDF_0^{\mathsf{T}}$. So we see that two factorizations $\sigma_m\Theta_m E = \sigma_m VS_mPV^{-1}VDF_0^{\mathsf{T}}V^{-1} = \sigma_m V(S_mPDF_0^{\mathsf{T}})V^{-1} = VDF_0^{\mathsf{T}}S_mPV^{-1} = E\Theta_m$ are possible. ∎

3. High-order methods.

3.1. Convergence for variable stepsize. In the case of one single parameter value γ as considered here, all coefficient matrices have a simpler structure in the monomial basis $(c^{j-1})_{j=1}^s$ contained in the Vandermonde matrix V. The transformed version of the matrix B of (21) is given by (see (16) and (18))

$$\tilde B_m := V^{-1}B_mV = S_mP - \gamma DF_0^{\mathsf{T}}S_mP - \sigma_m\tilde\beta_m DF_0^{\mathsf{T}},\ \tilde\beta_m := V^{-1}\beta_m V. \tag{22}$$

Note that the first column of $\tilde B_m$ is the first unit vector. According to (12), and considering that $G_m = \gamma I$, the stability matrix at infinity is $M_m(\infty) = -\frac{1}{\gamma}\beta_m$, and optimal stiff damping could be obtained by the choice $\beta_m = 0$. However, (22) shows that this choice violates the condition of zero-stability for $\sigma_m \ge 1$ since the leading matrix $S_mP - \gamma DF_0^{\mathsf{T}}S_mP$ is upper triangular and has the eigenvalues σ_m^{i-1}. Hence $\tilde\beta_m$ is needed for the stabilization of B_m. The following theorem provides a convenient compromise between stability for stiff problems and zero-stability.

THEOREM 3.1. *Let the method* (3) *satisfy the conditions* $AB(s)$ *and* $\Gamma(s-1)$ *and use one single* $\gamma = \gamma_i$*,* $i = 1,\dots,s$*. Then, with the choice*

$$\tilde\beta_m = V^{-1}\beta_m V = F_0S_mD^{-1}, \tag{23}$$

the method is both zero-stable and $\mathrm{L}(\alpha)$*-stable if it is* $\mathrm{A}(\alpha)$*-stable. In fact, both matrices* $B_m - 1e_1^{\mathsf{T}}$ *and* β_m *are nilpotent.*

Proof. The only nonzero elements of $\tilde\beta_m$ are $\tilde\beta_{i+1,i} = \frac{1}{i}\sigma_m^{i-1}$, $i = 1,\dots,s-1$. So, clearly, $\tilde\beta_m$ is nilpotent. This choice leads to $\sigma_m\tilde\beta_m DF_0^{\mathsf{T}} = S_mF_0F_0^{\mathsf{T}} = S_m\,\mathrm{diag}(0,1,\dots,1)$ in (22) and cancels the main diagonal of $\tilde B_m$ beyond the first entry. In fact, we have

$$\tilde B_m := V^{-1}B_mV = e_1e_1^{\mathsf{T}} + S_m(P-I) - \gamma DF_0^{\mathsf{T}}S_mP, \tag{24}$$

and $\tilde B_m - e_1u^{\mathsf{T}}$ is nilpotent for any vector u with $u^{\mathsf{T}}e_1 = 1$. So, $V(\tilde B_m - e_1u^{\mathsf{T}})V^{-1} = B_m - \mathbb{1}e_1^{\mathsf{T}}$ is nilpotent with $u = e_1^{\mathsf{T}}V = (1, c_1, \dots)$. ∎

By Theorem 3.1, the transformed coefficient matrix $\tilde B_m$ is fully specified. Due to the upper triangular structure, for any s, this matrix really is part of the large matrix

$$\begin{pmatrix} 1 & 1-\gamma\sigma & 1-2\gamma\sigma & 1-3\gamma\sigma & \cdots \\ & 0 & 2\sigma(1-\gamma\sigma) & 3\sigma(1-2\gamma\sigma) & \cdots \\ & & 0 & 3\sigma^2(1-\gamma\sigma) & \cdots \\ & & & & \ddots \end{pmatrix}. \tag{25}$$

Although the ratio σ (and even γ) may change between intervals, this representation shows that the nilpotency discussed in Theorem 3.1 is structurally stable. It really holds for general stepsize sequences since the Vandermonde transformation used in (24) is the same everywhere.

LEMMA 3.2. *Let the matrices B_m, $m \geq 1$, be given by* (22) *and the matrices β_m be as defined in Theorem* 3.1. *Then each product of at least $s-1$ matrices β_j, respectively, B_j, has rank one at most. In fact, it holds that*

$$\begin{aligned} \beta_m \beta_{m-1} \cdots \beta_{m-k} &= 0, \quad m, k \geq s-1, \\ B_m B_{m-1} \cdots B_{m-k} &= \mathbb{1}\, v^{\mathsf{T}}, \quad m, k \geq s-2, \end{aligned} \tag{26}$$

with $v^{\mathsf{T}}\mathbb{1} = 1$.

Proof. Without restriction we may consider the matrices $\tilde{\beta}_j, \tilde{B}_j$ defined in (22) since they are all transformed by the same matrix V. The result for the matrices $\tilde{\beta}_j$ is trivial due to their common triangular structure. Equation (24) shows that each $\tilde{B}_j$ has the structure

$$\tilde{B}_j = \begin{pmatrix} 1 & v_j^{\mathsf{T}} \\ 0 & \tilde{B}_{22}^{(j)} \end{pmatrix}, \tag{27}$$

where $\tilde{B}_{22}^{(j)}$ is *strictly* upper triangular. Hence $\tilde{B}_{22}^{(m)} \tilde{B}_{22}^{(m-1)} \cdots \tilde{B}_{22}^{(m-k)} = 0$ for $k \geq s-2$ and in the product $\tilde{B}_m \tilde{B}_{m-1} \cdots \tilde{B}_{m-k}$ only the first row is nontrivial and starts with the element 1: let us denote it by w^{T}. Consequently, from (24) it follows that $V^{-1} B_m \cdots B_{m-k} V = e_1 w^{\mathsf{T}}$, and then $B_m \cdots B_{m-k} = \mathbb{1} w^{\mathsf{T}} V^{-1} =: \mathbb{1} v^{\mathsf{T}}$. Finally, $v^{\mathsf{T}}\mathbb{1} = w^{\mathsf{T}} V^{-1} V e_1 = w^{\mathsf{T}} e_1 = 1$. ∎

Remark. We note that the row vector v^{T} in (26) depends on the stepsize ratios of the $s-1$ rightmost matrices in the product. However, since stepsize changes are bounded above by $\bar{\sigma}$, the vector v in (26) is bounded by some fixed power of $\bar{\sigma}$ (and γ).

This verifies the main assumption of the stability Lemma 2.1, and we may summarize most of the previous results in the following theorem.

THEOREM 3.3. *Let a grid $(t_m)_{m \geq 0}$ be given with bounded stepsize changes $\sigma_m \leq \bar{\sigma}$, and let $0 \leq \gamma \leq \bar{\gamma}$. Let the method* (7) *satisfy $AB(s)$ and $\Gamma(s-1)$, and let β_m be chosen by* (23). *If the initial values are accurate, i.e., $\|Y_{0i} - y(t_{0i})\| = O(h_0^{s-1})$, $i = 1, \ldots, s$, then the PPSW-method converges with order $s-1$, i.e.,*

$$\|Y_{mi} - y(t_{mi})\| = O(H^{s-1}), \quad t_0 \leq t_m \leq t_e, \ i = 1, \ldots, s.$$

Proof. For $X_{mi} = y(t_{mi}) - Y_{mi}$ the recursion (10) holds with $g_m = \Delta_m$ defined in (13) which is of order $O(h_{m-1}^{s-1})$ by assumption and Lemma 2.3. Since the main assumption (11) of the stability Lemma 2.1 has been verified in Lemma 3.2, with the present assumptions the assertion follows. ∎

The representations (21) and (24) show that the extrapolation matrix Θ_m defined in (16) is an important contribution in both coefficients B_m and Γ_m (see (21) and (16)). Applying a standard reformulation of W-methods to the scheme (7), avoiding unnecessary multiplications with T_m, reveals a different interpretation. For high-order methods satisfying $\Gamma(s)$ this version reads

$$\begin{aligned} (I - \gamma h_m I \otimes T_m)\big(Y_m - (\Theta_m \otimes I) Y_{m-1}\big) = \big((B_m - \Theta_m) \otimes I\big) Y_{m-1} \\ + h_m (A_m \otimes I) f(Y_{m-1}), \end{aligned} \tag{28}$$

where $A_m = \gamma\Theta_m + \beta_m$ (see (4) and (16)). It may be interpreted as a corrector equation for the predictor $(\Theta_m \otimes I)Y_{m-1}$ obtained by polynomial extrapolation. The implementation of PPSW-methods will be based on this formulation in section 4.

3.2. Superconvergence of PPSW-methods. So far, we have considered methods of order $s-1$ only. It would be of interest, of course, to achieve even higher orders in PPSW-methods. In light of Lemma 2.3, order s requires that the conditions $\Gamma(s)$ and $AB(s+1)$ hold. While the first condition is already satisfied by $\Gamma_m = -\gamma\Theta_m$ defined in (16), the second one, $AB(s+1)$, leads to s additional nonlinear restrictions. Before formulating this result, we point out that the representation (24) of the coefficient matrix B_m may be written as the rule

$$\sum_{j=1}^{s} b_{ij}\psi(c_j) = \psi(1+\sigma_m c_i) - \psi(\sigma_m c_i) + \psi(0) - \gamma\sigma_m\psi'(1+\sigma_m c_i), \tag{29}$$

$i = 1, \dots, s$, for any polynomial ψ of degree $s-1$.

LEMMA 3.4. *Consider the PPSW-method with $\Gamma(s)$ and the coefficients defined in Theorem 3.1, let $\phi(t) := \prod_{i=1}^{s}(t-c_i)$ be the knot polynomial of the scheme, and let the solution y be sufficiently smooth. Then, for each i, $1 \le i \le s$, the condition*

$$\gamma\sigma_m\phi'(1+\sigma_m c_i) = \phi(1+\sigma_m c_i) - \phi(\sigma_m c_i) + (\sigma_m c_i)^s + \phi(0) \tag{30}$$

implies $\Delta_{mi} = O(h_{m-1}^s)$.

Proof. With $\Gamma(s)$ and (24) the residual (13) has the form

$$h_m\Delta_{mi} = \frac{h_{m-1}^s}{s!}\left((1+\sigma_m c_i)^s - \sum_{j=1}^{s} b_{ij}c_j^s - \sigma_m s\sum_{j=1}^{s} a_{ij}c_j^{s-1}\right) y^{(s)}(t_{m-1}) + O(h_{m-1}^{s+1}), \tag{31}$$

where Taylor expansion at t_{m-1} was used for convenience. For the terms (see (4)) $a_{ij}c_j^{s-1} = (\beta_{ij} - \gamma_{ij})c_j^{s-1}$ the condition $\Gamma(s)$ gives $\sum_j \gamma_{ij}c_j^{s-1} = -\gamma(1+\sigma_m c_i)^{s-1}$. Since the last column of $\tilde{\beta}_m$ in Theorem 3.1 is zero, the corresponding contribution $\sum_{j=1}^{s}\beta_{ij}c_j^{s-1} = 0$ is missing. So, the leading bracket in (31) has the form

$$(1+\sigma_m c_i)^s - \sigma_m s\gamma(1+\sigma_m c_i)^{s-1} - \sum_{j=1}^{s} b_{ij}c_j^s =: u_i. \tag{32}$$

By defining the polynomial $\psi(t) := \phi(t) - t^s$, we observe that $\psi(c_j) = -c_j^s$. Moreover, it has degree $s-1$ so that (29) applies. Consequently, from (32) we obtain

$$\begin{aligned} u_i &= (1+\sigma_m c_i)^s - \sigma_m s\gamma(1+\sigma_m c_i)^{s-1} + \sum_{j=1}^{s} b_{ij}\psi(c_j) \\ &= (1+\sigma_m c_i)^s + \psi(1+\sigma_m c_i) - \sigma_m\gamma\big(s(1+\sigma_m c_i)^{s-1} + \psi'(1+\sigma_m c_i)\big) \\ &\quad - \psi(\sigma_m c_i) + \psi(0) \\ &= \phi(1+\sigma_m c_i) - \sigma_m\gamma\phi'(1+\sigma_m c_i) - \psi(\sigma_m c_i) + \psi(0) \\ &= \phi(1+\sigma_m c_i) + (\sigma_m c_i)^s - \phi(\sigma_m c_i) + \phi(0) - \sigma_m\gamma\phi'(1+\sigma_m c_i). \end{aligned} \tag{33}$$

So, $u_i = 0$ implies $\Delta_{mi} = O(h_{m-1}^s)$ in (31). ∎

Since the recursion (10) combines all previous errors, the gain of one order from $s-1$ to s in the global error requires that condition (30) hold for all stages $i = 1,\dots,s$. However, these s conditions are very severe restrictions for the remaining $s+1$ parameters $\gamma, c_1, \dots, c_s$ and are unlikely to be satisfied for some interesting range of σ-values. So, we will not pursue this line of research further. However, later on, we will discuss an application of using one single superconsistency condition (30) in error control. For multi-implicit methods, i.e., methods in the general form (3), the corresponding conditions (30) can easily be satisfied by using different γ_i; see [18].

For some PPSW-methods there is a different global effect leading to order-s convergence in the error. Unfortunately, this superconvergence may be conveniently exploited for constant stepsizes only.

By a careful choice of parameters the structural information (26) may be used to eliminate the leading term in the global error. In fact, adding the error residuals Δ_m from (13), the exact solution $y_m = \big(y(t_{mi})\big)_{i=1}^{s}$ obeys the modified time step recursion

$$I \otimes (I - \gamma h_m T_m) y_m = (B_m \otimes I + h_m \Gamma_m \otimes T_m) y_{m-1} + h_m (A_m \otimes I) f(y_{m-1}) + h_m \Delta_m,$$

and the error $X_m = (Y_{mi} - y(t_{mi}))_{i=1}^{s}$ satisfies (10), which we now write as

$$X_m = (B_m \otimes I + h_m \mathbf{D_m}) X_{m-1} - h_m \big(I \otimes (I - \gamma h_m T_m)^{-1}\big) \Delta_m. \tag{34}$$

The matrix $\mathbf{D_m} = I \otimes (I - \gamma h_m T_m)^{-1}((\Gamma_m + \gamma B_m) \otimes T_m + (A_m \otimes I)\mathbf{J_m})$ is obtained by using the representation

$$f(Y_{mi}) - f(y_{mi}) = \mathbf{J_{mi}}(Y_{mi} - y_{mi}), \quad \mathbf{J_{mi}} = \int_0^1 f'(y_{mi} + t(Y_{mi} - y_{mi}))\, dt$$

with the block diagonal matrix $\mathbf{J_m} = \operatorname{diag}(\mathbf{J_{mi}})$. The structural result in Lemma 3.2 shows that the following computations may still be performed for nonconstant stepsizes. However, the dependence on the different stepsize ratios becomes overly complicated for higher-order methods and may be of no practical use. So we will restrict this discussion to the case $\sigma_m \equiv \sigma = 1$. Then, all matrices B_m are identical and we drop the index. Furthermore, the vector v in (26) is a fixed vector, namely, the left eigenvector of B to the eigenvalue 1 and will be given explicitly below. As a first step we simplify the recursion (34) by assuming $O(\|\mathbf{D_m} X_{m-1}\|) = O(\|X_{m-1}\|)$. Since our main argument is independent of the dimension n, we write only the scalar case $n = 1$ for simplicity. We obtain

$$\begin{aligned}
X_m &= B X_{m-1} - h\Delta_m + O(h\|X_{m-1}\| + h^2\|\Delta_m\|) \\
&= -h \sum_{j=0}^{m-1} B^j \Delta_{m-j} + B^m X_0 + \sum_{j=1}^{m-1} O(h\|X_{m-j}\| + h^2\ \|\Delta_{m-j+1}\|) \\
&= -h \mathbb{1} \sum_{j=s-1}^{m-1} v^{\mathsf{T}} \Delta_{m-j} \\
&\quad - h \sum_{j=0}^{s-2} B^j \Delta_{m-j} + B^m X_0 + \sum_{j=1}^{m} O(h\|X_{m-j}\| + h^2\|\Delta_{m-j+1}\|).
\end{aligned}$$

Now, if the method has order $s-1$ and the initial error X_0 is of appropriate size, all terms in the last equation are of order h^s except the first one, where (26) was used.

However, by an appropriate choice of the vector v in $B^\infty = \mathbb{1}v^\mathsf{T}$ the leading error term in $v^\mathsf{T}\Delta_{m-j}$, $j \ge s-1$, may be eliminated as well.

THEOREM 3.5. *Let the method* (7) *satisfy* $AB(s)$ *and* $\Gamma(s)$*, and use the matrix* β_m *from Theorem* 3.1*. Then, for constant stepsizes the vector* v^T *in* (26) *depends only on* γ *and the knots* c_i*. In fact,* $v^\mathsf{T}V$ *depends on* γ *only and is given by the first* s *components of the vector*

$$\tilde{v}^\mathsf{T} = (1, 1-\gamma, 3-6\gamma+2\gamma^2, 13-39\gamma+30\gamma^2-6\gamma^3, \ldots).$$

If the solution y *of* (1) *is smooth enough, then*

$$v^\mathsf{T}\Delta_m = \tilde{v}_{s+1}\frac{h^{s-1}}{s!}\,y^{(s)}(t_{m-1}) + O(h^s).$$

Proof. Since the stepsize ratio is constant, $\sigma = 1$, the upper triangular matrix $\tilde{B}$ (see (27)) depends on γ only and is explicitly given by the principal submatrix of order s of (25). Hence its left eigenvector $v^\mathsf{T}V$ to the eigenvalue 1 is a function of γ, and its ith component $\tilde{v}_i$ depends on the first i columns of $\tilde{B}$ only. These components may be computed by computer algebra and the first ones are given in the statement. Introducing the s-vector $\varphi = (\phi_0, \ldots, \phi_{s-1})^\mathsf{T}$ of coefficients of the knot polynomial $\phi(t) = (t-c_1)\cdots(t-c_s) = \sum_{k=0}^{s}\phi_k t^k$ defined above, we may write $0 = (\phi(c_i))_{i=1}^s = V\varphi + (c_i^s)_{i=1}^s$. In order to obtain a vector representation of the local residual (31) we introduce additional terms in (33), again canceling the highest power c_i^s. By considering that now $\sigma = 1$, this yields

$$\begin{aligned} u &= \left((1+c_i)^s - \phi(c_i) - s\gamma(1+c_i)^{s-1} + \sum_{j=1}^{s} b_{ij}\big(\phi(c_j) - c_j^s\big)\right)_{i=1}^s \\ &= \left(\sum_{k=1}^{s}\binom{s}{k-1}c_i^{k-1}\right)_{i=1}^s - V\varphi - s\gamma VPe_s + BV\varphi. \end{aligned}$$

Since the coefficient vector φ is multiplied by the matrix $(B-I)V$, it may be observed here that φ drops out in the product $v^\mathsf{T}u$ since v is the left eigenvector of B, and so $v^\mathsf{T}(B-I) = 0$. We show now that the terms

$$V^{-1}(u - (B-I)V\varphi) = \left(\binom{s}{i-1}\right)_{i=1}^s - s\gamma Pe_s$$

are elements of column $s+1$ in (24) if this explicit representation of $\tilde{B}$ is extended to size $(s+1)\times(s+1)$; see also (17), (18). For all these matrices we denote the extended versions by bold face and recall that the main diagonal of the upper triangular matrix $\tilde{\mathbf{B}} - \mathbf{I}$ is -1 below the first row. We obtain

$$\begin{aligned} \begin{pmatrix} V^{-1}u \\ -1 \end{pmatrix} &= \begin{pmatrix} \left(\binom{s}{i-1}\right)_{i=1}^s - \gamma s Pe_s + (\tilde{B}-I)\varphi \\ -1 \end{pmatrix} \\ &= (\mathbf{P} - \mathbf{I} - \gamma\mathbf{D}\mathbf{F}_\mathbf{0}^\mathsf{T}\mathbf{P})e_{s+1} + \begin{pmatrix} (\tilde{B}-I)\varphi \\ -1 \end{pmatrix}, \end{aligned}$$

where sPe_s contains the nontrivial elements of the last column of $\mathbf{D}\mathbf{F}_\mathbf{0}^\mathsf{T}\mathbf{P}$; see (18), (19). Comparing with (24) for dimension $s+1$ and $\sigma = 1$, i.e.,

$$\mathbf{P} - \mathbf{I} - \gamma\mathbf{D}\mathbf{F}_\mathbf{0}^\mathsf{T}\mathbf{P} = \tilde{\mathbf{B}} - \mathbf{e}_1\mathbf{e}_1^\mathsf{T},$$

yields

$$\begin{pmatrix} V^{-1}u \\ -1 \end{pmatrix} = \begin{pmatrix} (\tilde{B}-I)\varphi \\ 0 \end{pmatrix} + (\tilde{\mathbf{B}}-\mathbf{I})\mathbf{e}_{s+1} = (\tilde{\mathbf{B}}-\mathbf{I})\begin{pmatrix} \varphi \\ 1 \end{pmatrix}. \tag{35}$$

Due to the triangular shape of $\tilde{\mathbf{B}}$, its left eigenvector to the eigenvalue 1 has the form $(v^{\mathsf{T}}V, \tilde{v}_{s+1})$ and from (35) follows

$$v^{\mathsf{T}}u - \tilde{v}_{s+1} = (v^{\mathsf{T}}V, \tilde{v}_{s+1})\begin{pmatrix} V^{-1}u \\ -1 \end{pmatrix} = (v^{\mathsf{T}}V, \tilde{v}_{s+1})(\tilde{\mathbf{B}}-\mathbf{I})\begin{pmatrix} \varphi \\ 1 \end{pmatrix} = 0.$$

Recalling that u (see (32)) contains the error constants in (31), the statement follows. ∎

Remark. The theorem shows that the leading error constant of the scheme is a multiple of the component $\tilde{v}_{s+1}$, which itself is a polynomial in the parameter γ. So there are a few exceptional values for γ where the method has global order s for any set of off-step knots c_i. In Table 1 we present explicit formulas for $\tilde{v}_{s+1}(\gamma)$ and some of the parameters $\hat{\gamma}$ with superconvergence, $\tilde{v}_{s+1}(\hat{\gamma}) = 0$, that were used in specific PPSW-methods. The fourth column contains a numerical estimate of the angle of $A(\alpha)$ stability in degrees, and the last column contains the name of the corresponding method consisting of the number of stages and a letter labeling the zero of $\tilde{v}_{s+1}(\gamma)$ ("a" is the leftmost zero). A special name was given only to those methods used in the numerical tests in section 4.

TABLE 1
Superconvergence conditions and name of methods.

The superconvergence property can easily be observed in numerical computations with constant stepsizes. For variable stepsizes a similar effect might still be obtained by clever strategies for a step-dependent choice of the parameter γ. However, for higher-order methods such strategies are probably too complicated to be of practical use. Still, we expect that superconvergence for $\sigma = 1$ has some beneficial effect on the general performance, especially for sharp tolerances where stepsize ratios are clustered around one.

4. Implementation and numerical tests. For practical implementations the form (28) of the PPSW-methods is preferable. Since the coefficients of the method depend on the actual stepsize ratio, they have to be recomputed before (28) can be solved. However, since the expense of these computations is $O(s^3)$ only, it is negligible

compared to the solution of the stage equations for large dimensions n. We also note that in case of a step rejection it is possible to reuse the function evaluations $f(Y_{m-1})$ and the matrix T_m, which is a difference approximation to $f_y(t_{m-1,s}, Y_{m-1,s})$.

Estimates for the local error are required for stepsize selection procedures. As mentioned before, (28) may be interpreted as a corrector equation and its solution $K_m := Y_m - (\Theta_m \otimes I)Y_{m-1}$ is an obvious candidate for an error estimate. Yet, it is of the same order $s-1$ as the error in Y_m that it should estimate. However, this situation can be improved by requiring order s of consistency (30) for one single stage only—for instance, $i = s$. Then, K_{ms} becomes an asymptotically correct order-s estimate for the local error of Y_{ms}. Unfortunately, only for low-order methods ($s \leq 4$) is it possible to find methods satisfying this additional condition and minimal stability requirements, i.e., A(0)-stability for $\sigma = 1$. So, only Method 4a uses this error estimate with the superconvergence value $\gamma = 0.468147$ and knots c_i, yielding (30) for $i = s$ and $\sigma = 1$. In order to obtain a sound error estimate in higher-order methods ($s \geq 5$) too, we compare the latest approximate Y_{ms} with the polynomial predictor of order $s-2$ that ignores $Y_{m-1,1}$ and interpolates the values $Y_{m-1,i}$, $i = 2, \ldots, s$, only.

With the exception of Method 4a, which has a superconsistent stage, the knots are nearly equidistributed in $[-1, 1]$ and $c_s = 1$ was always used. For the sake of completeness we show them in Table 2.

TABLE 2
Knots c_i of specific methods.

Method	c_1	c_2	c_3	c_4	c_5	c_6	c_7	c_8
4a	−1	−0.6779303684	0.5	1				
4b	−1	−0.3	0.7	1				
5b	−1	−0.5	0	0.5	1			
6b, c	−1	−0.5	0	0.4	0.8	1		
7b, c	−1	−0.7	−0.2	0	0.2	0.6	1	
8c	−1	−0.7	−0.3	0	0.3	0.5	0.7	1

Based on the error estimates described above, the new stepsize was computed in a standard manner; cf. [16]. The maximally allowed increase of the stepsize was set to $\sigma_{max} = 1.5$ for all PPSW-methods. Presently the stage equations (28) are solved by LU decomposition. Since this decomposition is the most expensive part and a severe sequential bottleneck for large systems, a remarkable parallel speed-up with PPSW-methods is not likely to be achieved yet. From our experience with PTSW-methods we expect superior parallel performance for large problems only in combination with Krylov solvers for the s independent linear stage systems (see [16, 17]). The first results for Krylov implementations of PPSW methods are reported in the article [20]. We decided to present tests here with sequential computations only, but we compare these with the state-of-the-art linearly implicit one-step code RODAS [10] with the default coefficient set (iwork(2)=1). RODAS was also used to compute the starting values Y_1 for the PPSW-methods. We think that the benchmark with RODAS gives a good insight into basic properties and the potential of these methods and assists in choosing suitable ones. We used Delphi 5 for comfortable programming. Since the reference results have been computed with the original Fortran-code RODAS, we compare the number of steps instead of the computing time. Note that the computational amount of work per step of RODAS is comparable to that of a six-stage PPSW-method in sequential runs. An advantage of our W-type methods over RODAS is that the Jacobian could be kept constant for several steps, but we did not exploit this possibility here.

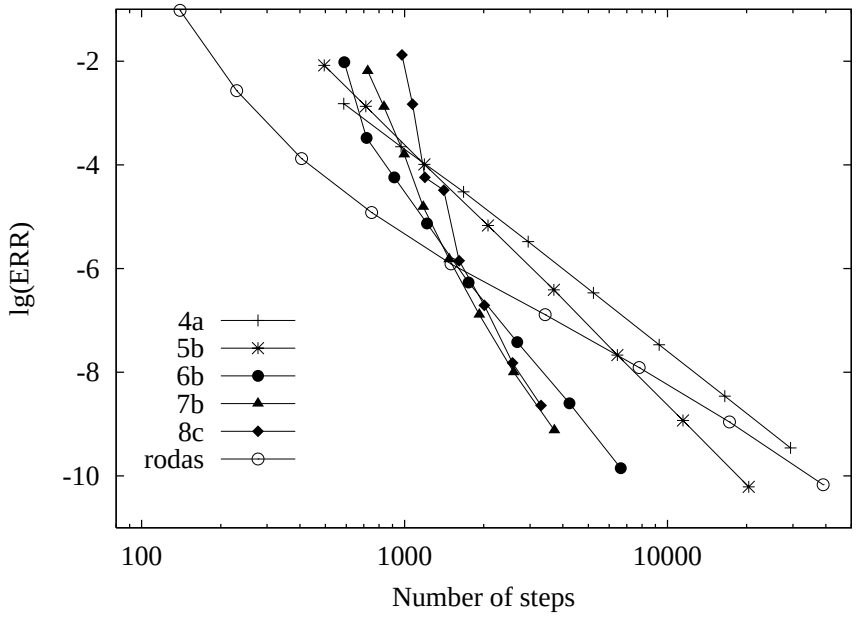

FIG. 1. *Results for OREGO.*

The following stiff test problems from [10] were used in our numerical tests: OREGO with $t_e = 360$, ROBER with $t_e = 10^8$, VDPOL with $t_e = 11$, and PLATE. A problem with a strongly varying Jacobian is KREISS from [14], defined by

$$y' = R(t)\Lambda(\varepsilon)R^{-1}(t), \quad y(0) = \begin{pmatrix} 1 \\ 2.6 \end{pmatrix}, \quad 0 \le t \le 1,$$

$$R(t) = \begin{pmatrix} \cos(-\theta t) & \sin(-\theta t) \\ -\sin(-\theta t) & \cos(-\theta t) \end{pmatrix}, \quad \Lambda(\varepsilon) = \begin{pmatrix} -\frac{1}{\varepsilon} & 0 \\ 0 & -1 \end{pmatrix}.$$

We used $\varepsilon = 10^{-6}$ and $\theta = 1$ here. A reference solution for these problems was computed with RADAU5 [10] and high accuracy. Computations were performed for $atol = rtol = 10^{-2}, \ldots, 10^{-9}$ except for ROBER, where $atol = 10^{-6} rtol$ was set (cf. [10]). In Figures 1–5 we present results for some special methods from Table 1. The logarithm of the final error at the endpoint for Y_{ms} is shown versus the number of steps including the rejected ones. Although the work per step of the methods (7) is one LU decomposition and s function evaluations and back substitutions, we think that this presentation is appropriate for two reasons. First, for larger problems the LU decomposition dominates the computational effort. However, more importantly, we recall that these methods were designed for parallel implementation with s processors.

A general observation for most PPSW-methods is that both the error and the angle α of $L(\alpha)$-stability increase with the parameter γ. So for all examples except PLATE we present the results for the methods with smallest γ from Table 1 since these produced slightly better results. The problem PLATE, however, requires a stability angle $\alpha \ge 71^\circ$ (cf. [10]). Some of the previously mentioned methods had difficulties here, namely, Method 4a for all tolerances and Method 6b for some of

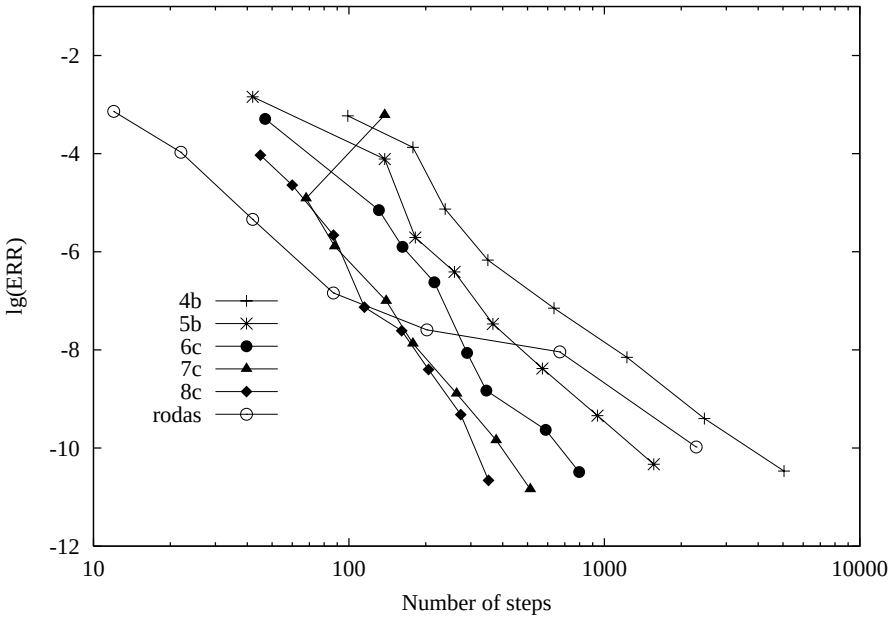

FIG. 2. *Results for PLATE.*

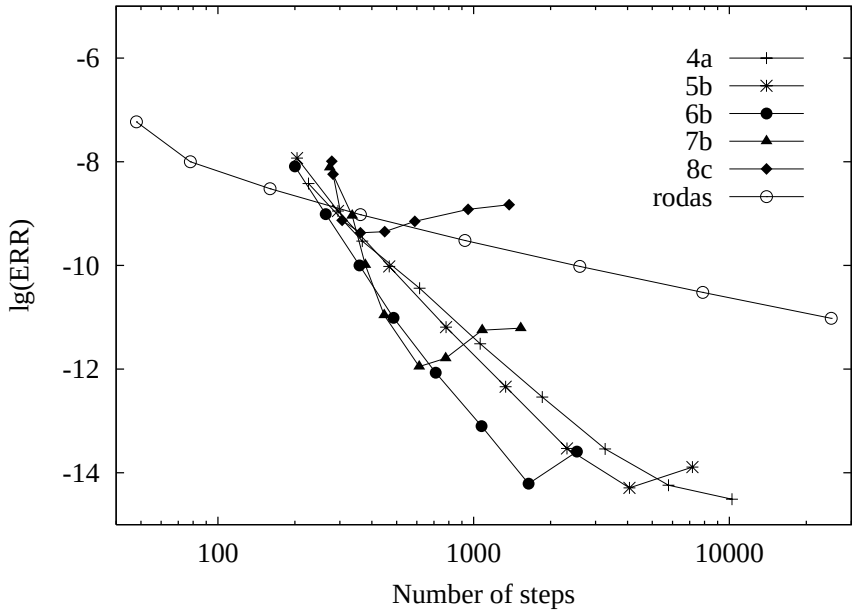

FIG. 3. *Results for ROBER.*

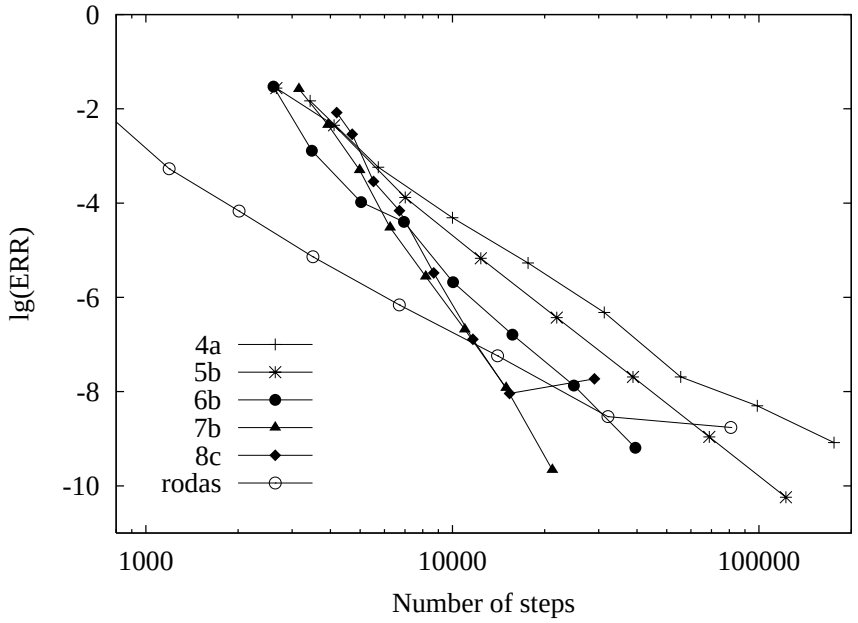

FIG. 4. *Results for VDPOL.*

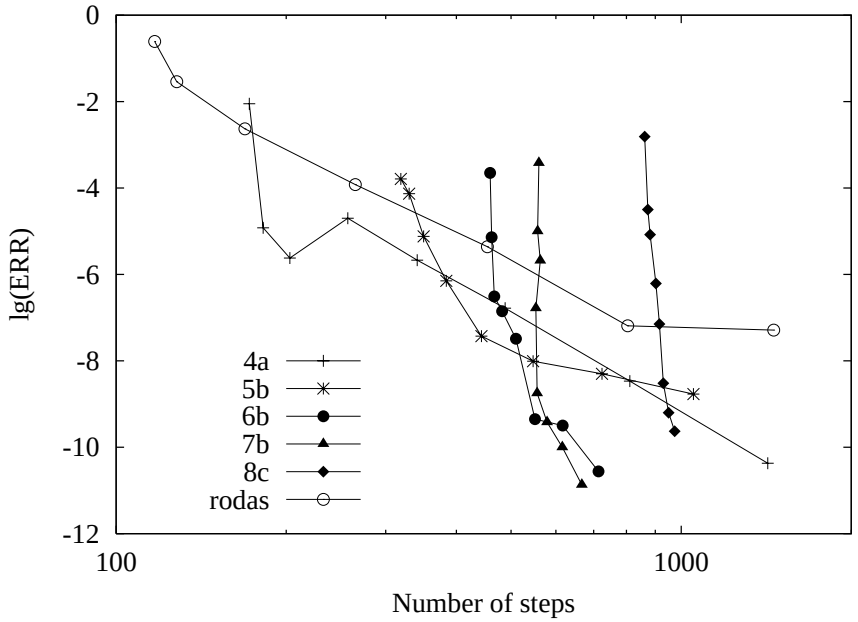

FIG. 5. *Results for the Kreiss problem.*

them. By choosing methods from Table 1 with larger γ and having larger stability angles, suitable PPSW-methods for this problem could be identified, too. Surprisingly, Methods 7b and 8c solved this problem without difficulties for all tolerances.

From these figures it is seen that the presented methods are interesting and have a large potential for stiff equations. The smooth curves show that the stepsize control works reliably but may still be improved. The irregular behavior of the seven- and eight-stage methods in the problem ROBER is an exception that is probably caused by rounding errors due to large values in the coefficients. This problem has been observed with other methods [4] too, and we tried to ameliorate it by distributing the knots c_i over the interval $[-1, 1]$ instead of $[0, 1]$. In comparison to PPSW-methods, RODAS is clearly superior for weak tolerances. This is mainly due to the ability of RODAS to increase the stepsize faster than our methods. Another reason may be that the initial stepsize for the PPSW-methods were too small. However, for medium and stringent tolerances especially, the higher-order PPSW-methods are often superior to RODAS. This is also the case for the six-stage methods whose computational expense is comparable to that of RODAS (in sequential implementations). The choice of the knots c_i is still heuristic, and their influence on accuracy and robustness of the methods needs further research.

5. Conclusions. A new class of linearly implicit methods for stiff initial value problems has been presented with a nearly optimal potential of method parallelism. Its essential new feature is the use of s peer solution variables per time interval. Methods of order $s - 1$ with s stages have been derived possessing good stability properties. The global error improves to order s for special parameter values and constant stepsizes since a certain superconvergence property has been identified. In a sequential implementation using automatic stepsize control and LU-decompositions, several methods with up to $s = 8$ stages have been tested and were found to be competitive with the code RODAS. The full potential of parallelization for PPSW-methods in the solution of large stiff ODEs is expected only in combination with Krylov techniques. Here the use of multi-implicit methods in the general form (3) using different parameters γ_i offers additional options and will be investigated in [18].

A CHARACTERIZATION OF HYBRIDIZED MIXED METHODS FOR SECOND ORDER ELLIPTIC PROBLEMS*

BERNARDO COCKBURN† AND JAYADEEP GOPALAKRISHNAN‡

This paper is dedicated to Jim Douglas, Jr., on the occasion of his 75th birthday

Abstract. In this paper, we give a new characterization of the approximate solution given by hybridized mixed methods for second order self-adjoint elliptic problems. We apply this characterization to obtain an explicit formula for the entries of the matrix equation for the Lagrange multiplier unknowns resulting from hybridization. We also obtain necessary and sufficient conditions under which the multipliers of the Raviart–Thomas and the Brezzi–Douglas–Marini methods of similar order are identical.

Key words. mixed finite elements, hybrid methods, elliptic problems

DOI. 10.1137/S0036142902417893

1. Introduction.

In this paper, we give a new characterization of hybridized mixed methods. This characterization allows us to obtain an explicit formula for the entries of the matrix equation for the so-called Lagrange multipliers. It also allows comparison of hybridized versions of different mixed methods. For example, we give conditions under which the multipliers of the Raviart–Thomas (RT) method and those of the Brezzi–Douglas–Marini (BDM) method of comparable order coincide.

We consider the hybridized version [1] of the standard RT mixed method [13] for the elliptic boundary value problem

$$-\nabla \cdot (a\nabla u) + d\, u = f \qquad \text{in } \Omega \subset \mathbb{R}^2, \tag{1.1}$$

$$u = g \qquad \text{on } \partial\Omega, \tag{1.2}$$

where $a(\boldsymbol{x})$ is a symmetric positive definite matrix-valued function, $d(\boldsymbol{x})$ is a nonnegative function, and Ω is a polygonal domain in $\mathbb{R}^2$. We assume that $a(\boldsymbol{x})$ and $d(\boldsymbol{x})$ are bounded. We consider this a simple setting for transparent presentation of the main ideas. As will be clear later, our techniques can be applied to other hybridized methods and more general second order elliptic problems.

Before describing the results, recall that mixed finite element methods seek approximations $(\boldsymbol{q}_h, u_h)$ to $(-a\,\nabla u, u)$ in appropriate finite element spaces. They give rise to a matrix equation of the form

$$\begin{pmatrix} \mathbb{A} & -\mathbb{B}^t \\ \mathbb{B} & \mathbb{D} \end{pmatrix} \begin{pmatrix} \mathbb{Q} \\ \mathbb{U} \end{pmatrix} = \begin{pmatrix} \mathbb{G} \\ \mathbb{F} \end{pmatrix},$$

where $\mathbb{Q}$ and $\mathbb{U}$ are the vectors of coefficients of $\boldsymbol{q}_h$ and u_h with respect to their corresponding finite element basis, respectively. Since the system is not positive definite,

‡Department of Mathematics, University of Florida, Gainesville, FL 32611–8105 (jayg@math.ufl.edu).

solving for $\mathbb{Q}$ and $\mathbb{U}$ is not always easy. Although one can arrive at a positive definite system by elimination of $\mathbb{Q}$ from the equations, this requires inverting $\mathbb{A}$ and maintaining $\mathbb{A}^{-1}$, which is typically a full matrix. Fortunately, by "hybridizing" the mixed method, this difficulty can be overcome. Let us now briefly recall the hybridization procedure.

First, the so-called Lagrange multiplier λ_h is introduced. This gives rise to a matrix equation of the form

$$\begin{pmatrix} A & -B^t & -C^t \\ B & D & 0 \\ C & 0 & 0 \end{pmatrix} \begin{pmatrix} Q \\ U \\ \Lambda \end{pmatrix} = \begin{pmatrix} \mathcal{G} \\ \mathcal{F} \\ 0 \end{pmatrix}, \tag{1.3}$$

where Λ is the vector of degrees of freedom associated to the multiplier λ_h. We will precisely state the underlying finite element spaces later. As is now well known, the new vectors of degrees of freedom Q and U actually define the *same* approximation $(\boldsymbol{q}_h, u_h)$ as the original mixed method. Moreover, both Q and U can now be easily eliminated to obtain an equation for the multiplier only, namely,

$$\mathbb{E}\,\Lambda = \mathbb{H},$$

where $\mathbb{E}$ and $\mathbb{H}$ are given by

$$\begin{aligned} \mathbb{E} &= CA^{-1}\left(A - B^t(BA^{-1}B^t + D)^{-1}B\right)A^{-1}C^t, \\ \mathbb{H} &= \mathbb{H}_g + \mathbb{H}_f, \\ \mathbb{H}_g &= -CA^{-1}\left(A - B^t(BA^{-1}B^t + D)^{-1}B\right)A^{-1}\mathcal{G}, \\ \mathbb{H}_f &= -CA^{-1}B^t(BA^{-1}B^t + D)^{-1}\,\mathcal{F}. \end{aligned} \tag{1.4}$$

That the inverses taken above exist follows from the properties of the underlying finite element spaces. Considering this matrix equation instead of the previous one has several advantages: (i) the matrix $\mathbb{E}$ is symmetric and positive definite, so it can be numerically inverted by using methods like the conjugate gradient method; (ii) the number of degrees of freedom of the multiplier is remarkably smaller than the number of degrees of freedom of the original mixed method; (iii) once Λ has been obtained, both Q and U can be efficiently computed element by element; and (iv) the multiplier λ_h can actually be used to *improve* the approximation to u by means of a local postprocessing, as shown in [1]. This shows that the use of hybridized mixed methods is indeed very advantageous; however, the complicated relation between the matrices $\mathbb{E}$ and $\mathbb{H}$, and the matrices A, B, C, $\mathcal{F}$ and $\mathcal{G}$, can easily dissuade one from basing an implementation on $\mathbb{E}$ and $\mathbb{H}$.

In this paper, we show that the entries of the matrices $\mathbb{E}$ and $\mathbb{H}$ can be expressed as a weighted L^2-inner product of some *discontinuous* auxiliary functions, the weights being nothing but the matrix a^{-1} and the function d. These auxiliary functions are easily constructed in terms of the geometry of the mesh, the matrix a, the function d, and the spaces of the hybridized mixed finite element method. Their definition induces a natural decomposition of the approximate solution $(\boldsymbol{q}_h, u_h)$ of the form

$$(\boldsymbol{q}_h, u_h) = (\boldsymbol{q}_h, u_h)_{\lambda_h} + (\boldsymbol{q}_h, u_h)_g + (\boldsymbol{q}_h, u_h)_f,$$

where $(\boldsymbol{q}_h, u_h)_{\lambda_h}$ is a *lifting* of the Lagrange multiplier λ_h and $(\boldsymbol{q}_h, u_h)_g$ and $(\boldsymbol{q}_h, u_h)_f$ can be computed *locally* only in terms of the data. The introduction of other discrete

lifting operators has proved useful in another context earlier, namely, the analysis of discontinuous Galerkin methods for elliptic problems [2, 7, 8].

We then present two applications of this result. As a first application, we present a technique to assemble the matrix of the Lagrange multiplier equation using simple local element matrices. Next, we compare the matrices $\mathbb{E}$ and $\mathbb{H}$ of the RT method with those of the BDM method of similar order and give necessary and sufficient conditions for the multipliers to be *exactly* the same. This happens, for example, when $d = 0$ and $f = 0$, a case that occurs in many situations of practical interest.

The paper is organized as follows. In section 2, we introduce the hybridized version of the mixed method of Raviart and Thomas and then state, discuss, and prove the characterization result, Theorem 2.1. In section 3, we show how to assemble the matrices for the multipliers, and in section 4, we compare the matrices of the RT method with those of the BDM method of similar order. Finally, in section 5, we end with some concluding remarks.

2. The main result. We begin this section by introducing the classical mixed method of Raviart and Thomas [13]; then, following [1], we hybridize the method. Finally, we state, discuss, and prove the main result, Theorem 2.1.

2.1. The hybridized mixed method. Given a triangulation of Ω, $\mathcal{T}_h$, made of triangles, the mixed method seeks an approximation $(\boldsymbol{q}_h, u_h)$ to the solution $(\boldsymbol{q}, u)$ of the model problem

$$c\,\boldsymbol{q} = -\nabla u \qquad \text{in } \Omega, \tag{2.1}$$

$$\nabla \cdot \boldsymbol{q} + d\,u = f \qquad \text{in } \Omega, \tag{2.2}$$

$$u = g \qquad \text{on } \partial\Omega, \tag{2.3}$$

where $c = a^{-1}$. The approximation $(\boldsymbol{q}_h, u_h)$ is sought in the finite element space $\mathbb{V}_h \times \mathbb{W}_h$ given by

$$\mathbb{V}_h = \{\boldsymbol{v} \in H(\mathrm{div}, \Omega) : \quad \boldsymbol{v}|_K \in P^k(K) \times P^k(K) + \boldsymbol{x}\,P^k(K) \quad \text{for all } K \in \mathcal{T}_h\},$$

$$\mathbb{W}_h = \{w \in L^2(\Omega) : \quad w|_K \in P^k(K) \quad \text{for all } K \in \mathcal{T}_h\},$$

where $P^k(K)$ denotes the space of polynomials on K of degree at most k, $k \geq 0$, and is defined by requiring that, for all $(\boldsymbol{v}, w) \in V_h \times W_h$,

$$\int_\Omega c\,\boldsymbol{q}_h \cdot \boldsymbol{v}\,dx - \int_\Omega u_h \nabla \cdot \boldsymbol{v}\,dx = -\int_{\partial\Omega} g\,\boldsymbol{v} \cdot \boldsymbol{n}\,ds, \tag{2.4}$$

$$\int_\Omega w \nabla \cdot \boldsymbol{q}_h\,dx + \int_\Omega d\,u_h\,w\,dx = \int_\Omega f\,w\,dx. \tag{2.5}$$

It is easy to see that the above weak formulation gives rise to a system of equations of the form

$$\begin{pmatrix} \mathbb{A} & -\mathbb{B}^t \\ \mathbb{B} & \mathbb{D} \end{pmatrix} \begin{pmatrix} \mathbb{Q} \\ \mathbb{U} \end{pmatrix} = \begin{pmatrix} \mathbb{G} \\ \mathbb{F} \end{pmatrix}.$$

We can try to solve this equation by first eliminating $\mathbb{Q}$ from the equations and then solving the resulting equation for $\mathbb{U}$, namely,

$$\left(\mathbb{B}\,\mathbb{A}^{-1}\mathbb{B}^t + \mathbb{D}\right)\,\mathbb{U} = \mathbb{F} + \mathbb{B}\,\mathbb{A}^{-1}\mathbb{G}.$$

Unfortunately, the matrix $\mathbb{A}$ is not easy to invert since the elements of V_h, being functions in $H(\mathrm{div},\Omega)$, have their normal components continuous across element interfaces. If $\boldsymbol{q}_h$ were totally discontinuous, $\mathbb{A}$ would be block-diagonal and hence easily invertible. The idea of the hybridized mixed methods is to relax this continuity constraint to render $\mathbb{A}$ block-diagonal.

Indeed, it was Fraejis de Veubeque [10], back in 1965, who realized that this can be achieved by introducing additional unknowns λ_h, associated to element interfaces, called Lagrange multipliers. Let $\mathcal{E}_{i,h}$ denote the set of edges of the mesh $\mathcal{T}_h$ that are in the interior of the domain Ω. The multipliers are then nothing but approximations to the trace of u on each $e \in \mathcal{E}_{i,h}$. As we show next, their introduction allows elimination of *both* $\boldsymbol{q}_h$ and u_h and reduction of the system to a single matrix equation for the multipliers.

In our particular case, the hybridized mixed method seeks an approximation $(\boldsymbol{q}_h, u_h, \lambda_h)$ to $(\boldsymbol{q}, u, u|_{\mathcal{E}_{i,h}})$ in the finite element space $V_h \times W_h \times M_h$ given by

$$
\begin{aligned}
V_h &= \{\boldsymbol{v} \in L^2(\Omega)\times L^2(\Omega): \quad \boldsymbol{v}|_K \in P^k(K)\times P^k(K) + \boldsymbol{x}P^k(K) \quad \text{for all } \ K \in \mathcal{T}_h\},\\
W_h &= \{w \in L^2(\Omega): \quad w|_K \in P^k(K) \quad \text{for all } \ K \in \mathcal{T}_h\},\\
M_h &= \{\mu \in L^2(\mathcal{E}_{i,h}): \quad \mu|_e \in P^k(e) \quad \text{for all } \ e \in \mathcal{E}_{i,h}\}.
\end{aligned}
$$

It is defined by requiring that, for all $(\boldsymbol{v}, u, \mu) \in V_h \times W_h \times M_h$,

$$
\int_\Omega c\,\boldsymbol{q}_h\cdot\boldsymbol{v}\,dx - \sum_{K\in\mathcal{T}_h}\int_K u_h\nabla\cdot\boldsymbol{v}\,dx + \sum_{e\in\mathcal{E}_{i,h}}\int_e \lambda_h\,[\![\boldsymbol{v}]\!]\,ds = -\int_{\partial\Omega} g\,[\![\boldsymbol{v}]\!]\,ds, \tag{2.6}
$$

$$
\sum_{K\in\mathcal{T}_h}\int_K w\nabla\cdot\boldsymbol{q}_h\,dx + \int_\Omega d\,u_h\,w\,dx = \int_\Omega f\,w\,dx, \tag{2.7}
$$

$$
\sum_{e\in\mathcal{E}_{i,h}}\int_e \mu\,[\![\boldsymbol{q}_h]\!]\,ds = 0, \tag{2.8}
$$

where $[\![\boldsymbol{v}]\!] = \boldsymbol{v}\cdot\boldsymbol{n}$ on $\partial\Omega$ and $[\![\boldsymbol{v}]\!] = \boldsymbol{v}_e^+\cdot\boldsymbol{n}_e^+ + \boldsymbol{v}_e^-\cdot\boldsymbol{n}_e^-$ on $e \in \mathcal{E}_h$. Here, $\boldsymbol{n}$ denotes the outward unit normal to Ω, $\boldsymbol{n}_e^+ = -\boldsymbol{n}_e^-$ is an arbitrary unit vector normal to the $e \in \mathcal{E}_{i,h}$, and $\boldsymbol{v}_e^\pm(\boldsymbol{x}) = \lim_{\epsilon\downarrow 0}\boldsymbol{v}(\boldsymbol{x} - \epsilon\,\boldsymbol{n}_e^\pm)$.

2.2. Two local mappings. Next, we introduce two mappings in terms of which the characterization result will be expressed. They are defined using (2.6) and (2.7).

The first mapping lifts functions on edges of the triangulation $\mathcal{T}_h$ to functions on Ω. Let $\mathcal{E}_h$ be the set of all edges of the triangulation $\mathcal{T}_h$. Notwithstanding a slight abuse of notation, we shall denote the set of all square integrable functions on the union of all edges of $\mathcal{E}_h$ by $L^2(\mathcal{E}_h)$. The lifting associates to each $\mathsf{m} \in L^2(\mathcal{E}_h)$ the pair of functions $(\boldsymbol{q}_h, u_h)_{\mathsf{m}} \equiv (\boldsymbol{q}_{h,\mathsf{m}}, u_{h,\mathsf{m}}) \in V_h \times W_h$ defined by requiring that

$$
\int_\Omega c\,\boldsymbol{q}_{h,\mathsf{m}}\cdot\boldsymbol{v}\,dx - \sum_{K\in\mathcal{T}_h}\int_K u_{h,\mathsf{m}}\nabla\cdot\boldsymbol{v}\,dx = -\sum_{e\in\mathcal{E}_h}\int_e \mathsf{m}\,[\![\boldsymbol{v}]\!]\,ds, \tag{2.9}
$$

$$
\sum_{K\in\mathcal{T}_h}\int_K w\nabla\cdot\boldsymbol{q}_{h,\mathsf{m}}\,dx + \int_\Omega d\,u_{h,\mathsf{m}}\,w\,dx = 0 \tag{2.10}
$$

hold for all $(\boldsymbol{v}, w) \in V_h \times W_h$.

The second mapping associates to the function $f \in L^2(\Omega)$ the element $(\boldsymbol{q}_h, u_h)_f \equiv (\boldsymbol{q}_{h,f}, u_{h,f}) \in V_h \times W_h$ and is defined by requiring that

$$\int_\Omega c\,\boldsymbol{q}_{h,f} \cdot \boldsymbol{v}\,dx - \sum_{K\in\mathcal{T}_h} \int_K u_{h,f} \nabla\cdot \boldsymbol{v}\,dx = 0, \tag{2.11}$$

$$\sum_{K\in\mathcal{T}_h} \int_K w \nabla\cdot \boldsymbol{q}_{h,f}\,dx + \int_\Omega d\,u_{h,f}\,w\,dx = \int_\Omega f\,w\,dx \tag{2.12}$$

hold for all $(\boldsymbol{v}, w) \in V_h \times W_h$.

Note that these mappings can be computed in an element-by-element fashion. Indeed, they are uniquely defined on each element because of the surjectivity of the map $(\nabla\cdot) : V_h \mapsto W_h$ restricted to an element. Moreover, on each element $K \in \mathcal{T}_h$, the lifting $(\boldsymbol{q}_h, u_h)_{\mathsf{m}}$ can be thought of as a result of a one element discretization of the boundary value problem

$$\begin{aligned} c\,\boldsymbol{q}_{\mathsf{m}} &= -\nabla u_{\mathsf{m}} && \text{in } K,\\ \nabla\cdot\boldsymbol{q}_{\mathsf{m}} + d\,u_{\mathsf{m}} &= 0 && \text{in } K,\\ u_{\mathsf{m}} &= \mathsf{m} && \text{on } \partial K, \end{aligned}$$

and that the mapping $(\boldsymbol{q}_h, u_h)_f$ is an approximation to the solution of

$$\begin{aligned} c\,\boldsymbol{q}_f &= -\nabla u_f && \text{in } K,\\ \nabla\cdot\boldsymbol{q}_f + d\,u_f &= f && \text{in } K,\\ u_f &= 0 && \text{on } \partial K. \end{aligned}$$

2.3. Characterization of the approximate solution. Before stating the result, let us introduce the following convention: The extension by zero of the function $\eta \in L^2(\mathcal{F}_h)$, where $\mathcal{F}_h$ is a subset of $\mathcal{E}_h$, to $\mathcal{E}_h$ is also denoted by η. In this way, if $\mathsf{m} = \lambda_h$ on $\mathcal{E}_{i,h}$ and $\mathsf{m} = g$ on $\partial\Omega$, we simply write $\mathsf{m} = \lambda_h + g$; as a consequence we also write

$$(\boldsymbol{q}_h, u_h)_{\mathsf{m}} = (\boldsymbol{q}_h, u_h)_{\lambda_h} + (\boldsymbol{q}_h, u_h)_g.$$

We now have all that is needed to state the main result.

THEOREM 2.1 (characterization of $(\boldsymbol{q}_h, u_h, \lambda_h)$). *Let $(\boldsymbol{q}_h, u_h, \lambda_h)$ be the solution of the hybridized RT method* (2.6), (2.7), *and* (2.8). *Then*

$$(\boldsymbol{q}_h, u_h) = (\boldsymbol{q}_h, u_h)_{\lambda_h} + (\boldsymbol{q}_h, u_h)_g + (\boldsymbol{q}_h, u_h)_f.$$

The Lagrange multiplier $\lambda_h \in M_h$ is the unique solution of

$$a_h(\lambda_h, \mu) = b_h(\mu) \quad \textit{for all } \mu \in M_h, \tag{2.13}$$

where

$$a_h(\lambda_h, \mu) = \int_\Omega c\,\boldsymbol{q}_{h,\lambda_h} \cdot \boldsymbol{q}_{h,\mu}\,dx + \int_\Omega d\,u_{h,\lambda_h}\,u_{h,\mu}\,dx$$

and

$$b_h(\mu) = \int_{\partial\Omega} g\,[\![\boldsymbol{q}_{h,\mu}]\!]\,ds + \int_\Omega f\,u_{h,\mu}\,dx.$$

Remark 2.1. Although the normal components of the functions $\boldsymbol{q}_{h,g}$, $\boldsymbol{q}_{h,f}$ (which can be computed locally only in terms of the data) and $\boldsymbol{q}_{h,\lambda_h}$ are not necessarily continuous across interelement boundaries, the normal components of their sum, namely, $\boldsymbol{q}_h$, are. Marini [12] pointed out this fact for the lowest order RT method when $d = 0$ and a is a piecewise-constant scalar function.

Remark 2.2. Just as for classical finite element methods, the variational formulation (2.13) gives rise to a matrix equation for the degrees of freedom of the multiplier Λ of the form

$$\mathbb{E}\,\Lambda = \mathbb{H}.$$

Thus the entries of the matrices $\mathbb{E}$ and $\mathbb{H}$ are obtained as a weighted L^2-inner product of discontinuous functions, as claimed in the introduction.

We end this section with a proof of Theorem 2.1.

2.4. Proof of Theorem 2.1. We prove this result in three steps. In the first, we observe some identities that result from the equations of the method. In the next step, we show that the continuity condition on the jumps of the fluxes results in a variational equation for the Lagrange multiplier unknowns. In the last step, we collect these two results and conclude.

2.4.1. Step 1.

LEMMA 2.2 (elementary identities). *We have, for any* $\mathsf{m}, \mu \in L^2(\mathcal{E}_h)$*, and* $f \in L^2(\Omega)$*,*

$$\text{(i)} \; -\sum_{e\in\mathcal{E}_h}\int_e \mu\,[\![\boldsymbol{q}_{h,\mathsf{m}}]\!]\,ds = \int_\Omega c\,\boldsymbol{q}_{h,\mathsf{m}}\cdot\boldsymbol{q}_{h,\mu}\,dx + \int_\Omega d\,u_{h,\mathsf{m}}\,u_{h,\mu}\,dx,$$

$$\text{(ii)} \; \int_\Omega c\,\boldsymbol{q}_{h,f}\cdot\boldsymbol{q}_{h,\mathsf{m}}\,dx + \int_\Omega d\,u_{h,f}\,u_{h,\mathsf{m}}\,dx = 0,$$

$$\text{(iii)} \; -\sum_{e\in\mathcal{E}_h}\int_e \mathsf{m}\,[\![\boldsymbol{q}_{h,f}]\!]\,ds = -\int_\Omega f\,u_{h,\mathsf{m}}\,dx.$$

Proof. Let us begin by proving the identity (i). First, take $\boldsymbol{v} = \boldsymbol{q}_{h,\mu}$ in (2.9). Then, replace m by μ in (2.10) and take $w = u_{h,\mathsf{m}}$. The identity (i) follows by simply adding these two equations.

To prove (ii), simply take $w = u_{h,f}$ in (2.10) and $\boldsymbol{v} = \boldsymbol{q}_{h,\mathsf{m}}$ in (2.11) and add the equations.

Finally, to prove (iii), take $\boldsymbol{v} = \boldsymbol{q}_{h,f}$ in (2.9) and $w = u_{h,\mathsf{m}}$ in (2.12) and add the two equations to obtain

$$-\sum_{e\in\mathcal{E}_h}\int_e \mathsf{m}\,[\![\boldsymbol{q}_{h,f}]\!]\,ds = -\int_\Omega f\,u_{h,\mathsf{m}}\,dx + \Theta,$$

where

$$\Theta = \int_\Omega c\,\boldsymbol{q}_{h,f}\cdot\boldsymbol{q}_{h,\mathsf{m}}\,dx + \int_\Omega d\,u_{h,f}\,u_{h,\mathsf{m}}\,dx.$$

Thus (iii) follows from (ii). This completes the proof. ∎

2.4.2. Step 2. In the following lemma, we explore equivalent characterizations of the continuity requirement on fluxes imposed by the method.

LEMMA 2.3 (jump condition). *Let* $(\boldsymbol{q}_h, u_h, \lambda_h)$ *be the solution of the hybridized RT method* (2.6), (2.7), *and* (2.8), *and let* m *be an arbitrary member of* M_h. *Then the following statements are equivalent:*

1. $\sum_{e\in\mathcal{E}_{i,h}} \int_e \mu\, [\![\boldsymbol{q}_{h,\mathsf{m}} + \boldsymbol{q}_{h,g} + \boldsymbol{q}_{h,f}]\!]\, ds = 0$ *for all* $\mu \in M_h$.
2. $(\boldsymbol{q}_h, u_h) = (\boldsymbol{q}_h, u_h)_{\mathsf{m}} + (\boldsymbol{q}_h, u_h)_g + (\boldsymbol{q}_h, u_h)_f$.
3. $\mathsf{m} = \lambda_h$.
4. $a_h(\mathsf{m}, \mu) = b_h(\mu)$ *for all* $\mu \in M_h$.

Proof. (1) $\Longrightarrow$ (2): Set

$$(\widetilde{\boldsymbol{q}}_h, \widetilde{u}_h) = (\boldsymbol{q}_h, u_h)_{\mathsf{m}} + (\boldsymbol{q}_h, u_h)_g + (\boldsymbol{q}_h, u_h)_f.$$

Then, combining the equations defining the local mappings, we get that

$$\int_\Omega c\, \widetilde{\boldsymbol{q}}_h \cdot \boldsymbol{v}\, dx - \sum_{K\in\mathcal{T}_h} \int_K \widetilde{u}_h \nabla\cdot \boldsymbol{v}\, dx + \sum_{e\in\mathcal{E}_{i,h}} \int_e \mathsf{m}\, [\![\boldsymbol{v}]\!]\, ds = -\int_{\partial\Omega} g\, [\![\boldsymbol{v}]\!]\, ds,$$

$$\sum_{K\in\mathcal{T}_h} \int_K w \nabla\cdot \widetilde{\boldsymbol{q}}_h\, dx + \int_\Omega d\, \widetilde{u}_h\, w\, dx = \int_\Omega f\, w\, dx$$

for all $(\boldsymbol{v}, w) \in V_k \times W_h$. Therefore, whenever (1) holds, $\widetilde{\boldsymbol{q}}_h$ and $\widetilde{u}_h$ satisfy all the equations of the hybridized RT method. By uniqueness of solutions of the method, $\widetilde{\boldsymbol{q}}_h = \boldsymbol{q}_h$ and $\widetilde{u}_h = u_h$, so (2) follows.

(2) $\Longrightarrow$ (3): By linear superposition, $\boldsymbol{q}_h = \boldsymbol{q}_{h,\lambda_h} + \boldsymbol{q}_{h,g} + \boldsymbol{q}_{h,f}$. Moreover, $\int_e \mu [\![\boldsymbol{q}_h]\!]\, ds = 0$ for all $e \in \mathcal{E}_{i,h}$. From the implication (1) $\Longrightarrow$ (2), it follows that

$$(\boldsymbol{q}_h, u_h) = (\boldsymbol{q}_h, u_h)_{\lambda_h} + (\boldsymbol{q}_h, u_h)_g + (\boldsymbol{q}_h, u_h)_f.$$

Consequently, (2) implies that

$$(\boldsymbol{q}_h, u_h)_{\mathsf{m}-\lambda_h} = 0,$$

from which it follows that $\mathsf{m} - \lambda_h = 0$.

(3) $\Longrightarrow$ (4): Now we observe that the following identity holds for any $\mathsf{m} \in M_h$:

$$\begin{aligned} -\int_\Omega c\, \boldsymbol{q}_{h,\mathsf{m}} \cdot \boldsymbol{q}_{h,\mu}\, dx - \int_\Omega d\, u_{h,\mathsf{m}}\, u_{h,\mu}\, dx + \int_{\partial\Omega} g\, [\![\boldsymbol{q}_{h,\mu}]\!]\, ds + \int_\Omega f\, u_{h,\mu}\, dx \\ = \sum_{e\in\mathcal{E}_h} \int_e \mu\, [\![\boldsymbol{q}_{h,\mathsf{m}} + \boldsymbol{q}_{h,g} + \boldsymbol{q}_{h,f}]\!]\, ds \quad \text{for all } \mu \in M_h. \end{aligned} \tag{2.14}$$

This equality follows from the identities of Lemma 2.2. Moreover, whenever $\mathsf{m} = \lambda_h$, the last equation of the hybridized mixed method asserts that the right-hand side of (2.14) is zero. From the definition of the forms a_h and b_h in Theorem (2.1), we see that (4) follows.

(4) $\Longrightarrow$ (1): We apply (2.14) again. Whenever (4) holds, the left-hand side of (2.14) is zero. Therefore, (1) follows. This completes the proof. ∎

2.4.3. Step 3. To conclude the proof of Theorem 2.1 observe that the first assertion of the theorem follows from the equivalence of the identities (1) and (2) of Lemma 2.3. The second assertion of the theorem follows again from Lemma 2.3, this time from the equivalence of (3) and (4). This completes the proof of Theorem 2.1.

Remark 2.3. The characterization theorem we just proved states that the solution $(\boldsymbol{q}_h, u_h)$ is the sum of the lifting of $\mathsf{m} = \lambda_h + g$, $(\boldsymbol{q}_h, u_h)_{\mathsf{m}}$ and the contribution from f, $(\boldsymbol{q}_h, u_h)_f$. By the identity (ii) of Lemma 2.2, we see that these two are orthogonal with respect to the bilinear form on $(V_h \times W_h)^2$ defined by

$$\langle\!\langle\, (\boldsymbol{q}_1, u_1), (\boldsymbol{q}_2, u_2)\,\rangle\!\rangle = \int_\Omega c\,\boldsymbol{q}_1 \cdot \boldsymbol{q}_2\,dx + \int_\Omega d\,u_1\,u_2\,dx.$$

3. The matrix entries.

3.1. The local matrices. To compute the matrices $\mathbb{E}$ and $\mathbb{H}$, we can proceed in the traditional finite element way. Let e denote an interior edge of the mesh $\mathcal{T}_h$, and let $\{\, L_{e,\ell}\,\}_{\ell=0}^k$ denote a basis for the set of polynomials of degree at most k on e. For example, we can choose properly scaled Legendre polynomials. Then, we set

$$(\boldsymbol{q}_{e,\ell}, u_{e,\ell}) = (\boldsymbol{q}_h, u_h)_{L_{e,\ell}}.$$

Now, for each element K, we compute the so-called local matrices, whose entries are

$$\begin{aligned}
\mathbb{E}_{K;e,\ell;e',\ell'} &= \int_K c\,\boldsymbol{q}_{e,\ell} \cdot \boldsymbol{q}_{e',\ell'}\,dx + \int_K d\,u_{e,\ell}\,u_{e',\ell'}\,dx,\\
\mathbb{H}_{g\,K;e,\ell} &= \int_{\partial K \cap \partial\Omega} g\,\boldsymbol{q}_{e,\ell} \cdot \boldsymbol{n}\,dx,\\
\mathbb{H}_{f\,K;e,\ell} &= \int_K u_{e,\ell}\,f\,dx.
\end{aligned}$$

Then the global matrices can be easily assembled by noting that

$$\begin{aligned}
\Lambda_{e,\ell}^t \mathbb{E}\,\Lambda_{e',\ell'} &= \sum_{K\in\mathcal{T}_h} \mathbb{E}_{K;e,\ell;e',\ell'},\\
\Lambda_{e,\ell}^t\,\mathbb{H}_g &= \sum_{K\in\mathcal{T}_h} \mathbb{H}_{g\,K;e,\ell},\\
\Lambda_{e,\ell}^t\,\mathbb{H}_f &= \sum_{K\in\mathcal{T}_h} \mathbb{H}_{f\,K;e,\ell}.
\end{aligned}$$

Since the lifting $(\boldsymbol{q}_{e,\ell}, u_{e,\ell})$ is supported only on the triangles sharing the edge e, to compute the local matrices, we have to provide only the numbers $\mathbb{E}_{K;e,\ell;e',\ell'}$, $\mathbb{H}_{g\,K;e,\ell}$, and $\mathbb{H}_{f\,K;e,\ell}$ for any two edges e and e' of K and any two integers ℓ and ℓ' between 0 and k; all the remaining entries are equal to zero. This also implies that the matrix $\mathbb{E}$ is a matrix of $(k+1)\times(k+1)$ blocks which has *at most four* off-diagonal blocks in each block column.

3.2. An example. The above computations can easily be carried out for the hybridized version of the RT method of lowest order. In this example, as the subscript ℓ in $\boldsymbol{q}_{e,\ell}$ and $u_{e,\ell}$ is superfluous, we drop it.

We begin by computing the lifting $\mathsf{m} \mapsto (\boldsymbol{q}_h, u_h)_{\mathsf{m}}$. Let m take the constant value λ_i on the edge e_i of the triangle K, $i = 1, 2, 3$. Then, on K,

$$(\boldsymbol{q}_h, u_h)_{\mathsf{m}} = \sum_{i=1}^{3} (\boldsymbol{q}_{e_i}, u_{e_i})\,\lambda_i,$$

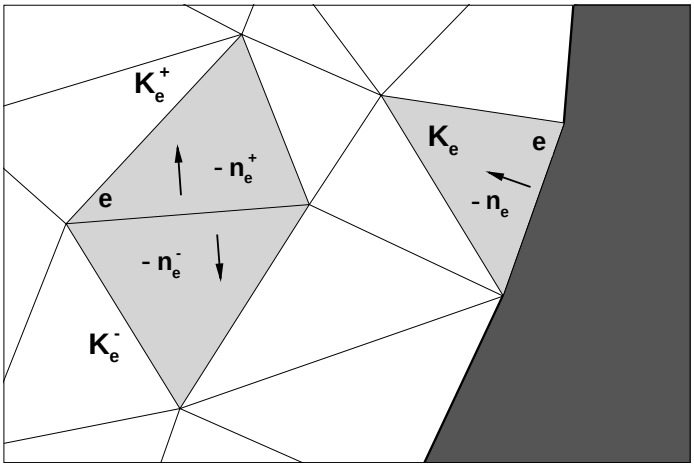

FIG. 1. *A representation of the lifting* $\boldsymbol{q}_{h,\mathsf{m}}$ *when* $\mathsf{m} = \chi_e$ *for interior and boundary edges* e. *In this case, we have taken* $d = 0$ *and* $c = Id$.

where, for $\boldsymbol{x} \in K$ and $i = 1, 2, 3$,

$$\boldsymbol{q}_{e_i}(\boldsymbol{x}) = -\frac{|\, e_i \,|}{|\, K \,|}\,(\bar{c})^{-1}\boldsymbol{n}_i - \frac{1}{2}\left(\frac{\bar{d}\,\rho_i}{1+\bar{d}\,\mathsf{h}^2}\right)(\boldsymbol{x}-\boldsymbol{B}), \qquad u_{e_i}(\boldsymbol{x}) = \frac{\rho_i}{1+\bar{d}\,\mathsf{h}^2},$$

and

$$\bar{c} = \frac{1}{|\, K \,|}\int_K c\,dx, \qquad \bar{d} = \frac{1}{|\, K \,|}\int_K d\,dx, \qquad \rho_i = \frac{|\, e_i \,|\,(\boldsymbol{m}_i - \boldsymbol{B})\cdot\boldsymbol{n}_i}{2\,|\, K \,|},$$
$$\mathsf{h}^2 = \frac{1}{4\,|\, K \,|}\int_K c\,(\boldsymbol{x}-\boldsymbol{B})\cdot(\boldsymbol{x}-\boldsymbol{B})\,dx, \qquad \boldsymbol{B} = (\bar{c})^{-1}\frac{\int_K c\,\boldsymbol{x}\,dx}{|\, K \,|}.$$

Here $\boldsymbol{m}_i$ denotes the midpoint of the edge e_i and $\boldsymbol{n}_i$ its outward unit normal. Note that if c is the identity, $\boldsymbol{B}$ is the barycenter of the triangle; if, moreover, K is an equilateral triangle of diameter h, then $\rho_i = 1/3$ and $\mathsf{h}^2 = h^2/48$. The case of c equaling the 2×2 identity and vanishing d is illustrated in Figure 1.

Now, it is easy to compute the entries of the local matrices:

$$\mathbb{E}_{K;e_i;e_j} = \frac{|\, e_i \,|\,|\, e_j \,|}{|\, K \,|}\,\boldsymbol{n}_j\cdot(\bar{c})^{-1}\boldsymbol{n}_j + \frac{\bar{d}\,|\, K \,|}{1+\bar{d}\,\mathsf{h}^2}\,\rho_i\,\rho_j,$$
$$\mathbb{H}_{g\,K;e_i} = -\sum_{e_j\subset\partial K\cap\partial\Omega}\left(\frac{|\, e_i \,|}{|\, K \,|}(\bar{c})^{-1}\boldsymbol{n}_i\cdot\boldsymbol{n}_j + \frac{|\, K \,|}{|\, e_j \,|}\left(\frac{\bar{d}}{1+\bar{d}\,\mathsf{h}^2}\right)\rho_i\,\rho_j\right)\int_{e_j} g(s)\,ds,$$
$$\mathbb{H}_{f\,K;e_i} = \frac{\rho_i}{1+\bar{d}\,\mathsf{h}^2}\int_K f(x)\,dx.$$

3.3. The reference element. A convenient implementation results if the local matrices for the multiplier can be computed by using quadratures on a reference element alone.

To achieve it, we need to define local mappings on the reference element and map spaces on the reference element $\widehat{K}$ to corresponding ones on any triangle K. Let $\widehat{K}$ be mapped one-to-one onto K by the standard affine mapping

$$\boldsymbol{x} = D_K\,\widehat{\boldsymbol{x}} + b_K,$$

and let us set

$$\widehat{u}(\widehat{\boldsymbol{x}}) \equiv u(\boldsymbol{x}), \quad \widehat{\boldsymbol{q}}(\widehat{\boldsymbol{x}}) \equiv |\det D_K|\, D_K^{-1}\, \boldsymbol{q}(\boldsymbol{x})$$

for scalar-valued functions u and vector-valued functions $\boldsymbol{q}$, respectively. Finally, set

$$\begin{aligned}
\widehat{V} &= P^k(\widehat{K}) \times P^k(\widehat{K}) + \boldsymbol{x}\, P^k(\widehat{K}),\\
\widehat{W} &= P^k(\widehat{K}),\\
\widehat{M} &= \{\widehat{\mathsf{m}} \in L^2(\partial\widehat{K}) : \quad \widehat{\mathsf{m}}|_{\widehat{e}} \in P^k(\widehat{e}) \quad \text{for all } \ \widehat{e} \in \partial\widehat{K}\}.
\end{aligned}$$

Now, suppose we are given a symmetric positive definite 2×2 matrix function $\widehat{C}$ and a scalar nonnegative function $\widehat{D}$ on $\widehat{K}$. For each $\widehat{\mathsf{m}}$ in $\widehat{M}$, we define the element $(\widehat{\boldsymbol{Q}}_{\widehat{\mathsf{m}}}, \widehat{U}_{\widehat{\mathsf{m}}}) \in \widehat{V} \times \widehat{W}$ by requiring that

$$\begin{aligned}
&\int_{\widehat{K}} \widehat{C}\, \widehat{\boldsymbol{Q}}_{\widehat{\mathsf{m}}} \cdot \boldsymbol{V}\, d\widehat{\boldsymbol{x}} - \int_{\widehat{K}} \widehat{U}_{\widehat{\mathsf{m}}} \widehat{\nabla} \cdot \boldsymbol{V}\, d\widehat{\boldsymbol{x}} = -\sum_{\widehat{e}\in\partial\widehat{K}} \int_{\widehat{e}} \widehat{\mathsf{m}}\, [\![\boldsymbol{V}]\!]\, d\widehat{s},\\
&\int_{\widehat{K}} W \widehat{\nabla} \cdot \widehat{\boldsymbol{Q}}_{\widehat{\mathsf{m}}}\, d\widehat{\boldsymbol{x}} + \int_{\widehat{K}} \widehat{D}\, \widehat{U}_{\widehat{\mathsf{m}}}\, W\, d\widehat{\boldsymbol{x}} = 0
\end{aligned}$$

hold for all $(\boldsymbol{V}, W) \in \widehat{V} \times \widehat{W}$. Then, we have the following result.

PROPOSITION 3.1. *Let K be any triangle and e be one of its edges. Set*

$$\widehat{C}(\widehat{\boldsymbol{x}}) = |\det D_K|^{-1}\, D_K^t\, c(\boldsymbol{x})\, D_K \quad \textit{and} \quad \widehat{D}(\widehat{\boldsymbol{x}}) = |\det D_K|\, d(\boldsymbol{x}).$$

Then, the lifting $(\boldsymbol{q}_{e,\ell}, u_{e,\ell})$ on K when mapped to $\widehat{K}$ satisfies

$$\widehat{\boldsymbol{q}}_{e,\ell} = \widehat{\boldsymbol{Q}}_{\widehat{L_{e,\ell}}} \qquad \textit{and} \qquad \widehat{u}_{e,\ell} = \widehat{U}_{\widehat{L_{e,\ell}}}.$$

Moreover,

$$\begin{aligned}
\mathbb{E}_{K;e,\ell;e',\ell'} &= -\int_{\widehat{e}} \widehat{L_{e,\ell}}\, \widehat{\boldsymbol{Q}}_{\widehat{L_{e',\ell'}}} \cdot \widehat{\boldsymbol{n}}\, d\widehat{s},\\
\mathbb{H}_{g\,K;e,\ell} &= \int_{\widehat{e}} \widehat{g}\, \widehat{\boldsymbol{Q}}_{\widehat{L_{e,\ell}}} \cdot \widehat{\boldsymbol{n}}\, d\widehat{s},\\
\mathbb{H}_{f\,K;e,\ell} &= \int_{\widehat{K}} \widehat{U}_{\widehat{L_{e,\ell}}}\, \widehat{f}\, |\det D_K|\, d\widehat{\boldsymbol{x}}.
\end{aligned}$$

This result can be easily proved by a straightforward change of variables and application of Lemma 2.2. Note that if the functions $\widehat{C}$ and $\widehat{D}$ are constant, there is no need to use quadrature rules to find the matrix entries.

4. Comparison with the hybridized BDM method. Now we compare the multipliers given by the hybridized version of the RT method and those given by the hybridized version of the corresponding BDM method.

4.1. Statement of the results. To state our comparison results, we first introduce the hybridized BDM method. The approximate solution given by this method, $(\boldsymbol{q}_h^{\mathrm{BDM}}, u_h^{\mathrm{BDM}}, \lambda_h^{\mathrm{BDM}})$, is sought in the finite element space $V_h^{\mathrm{BDM}} \times W_h^{\mathrm{BDM}} \times M_h$ given by

$$\begin{aligned}
V_h^{\mathrm{BDM}} &= \{\boldsymbol{v} \in L^2(\Omega)\times L^2(\Omega) : \quad \boldsymbol{v}|_K \in P^k(K)\times P^k(K) \quad \text{for all } \ K \in \mathcal{T}_h\},\\
W_h^{\mathrm{BDM}} &= \{w \in L^2(\Omega) : \quad w|_K \in P^{k-1}(K) \quad \text{for all } \ K \in \mathcal{T}_h\},
\end{aligned}$$

where $k \geq 1$, and is defined by requiring that, for all $(\boldsymbol{v}, u, \mu) \in V_h^{\mathrm{BDM}} \times W_h^{\mathrm{BDM}} \times M_h$,

$$\int_\Omega c\, \boldsymbol{q}_h^{\mathrm{BDM}} \cdot \boldsymbol{v}\, dx - \sum_{K \in \mathcal{T}_h} \int_K u_h^{\mathrm{BDM}} \nabla \cdot \boldsymbol{v}\, dx + \sum_{e \in \mathcal{E}_{i,h}} \int_e \lambda_h^{\mathrm{BDM}} [\![\boldsymbol{v}]\!]\, ds = -\int_{\partial\Omega} g\, [\![\boldsymbol{v}]\!]\, ds,$$

$$\sum_{K \in \mathcal{T}_h} \int_K w \nabla \cdot \boldsymbol{q}_h^{\mathrm{BDM}}\, dx + \int_\Omega d\, u_h^{\mathrm{BDM}}\, w\, dx = \int_\Omega f\, w\, dx,$$

$$\sum_{e \in \mathcal{E}_{i,h}} \int_e \mu\, [\![\boldsymbol{q}_h^{\mathrm{BDM}}]\!]\, ds = 0.$$

Note that the approximate solution of the BDM method satisfies exactly the same weak formulation as the approximate solution of the RT method; the only difference is the choice of the finite element spaces. As a consequence, the characterization theorem (Theorem 2.1) holds for the hybridized version of the BDM method. This is the key fact that allows us to compare the hybridized versions of the RT and the BDM methods.

In comparing the RT and BDM methods, for the sake of readability, we shall superscript the notation previously introduced in connection with the RT method by "RT." When superscripted by "BDM," such notation is to be understood as defined exactly as before except that the RT spaces are replaced by the BDM spaces. For example, $(\boldsymbol{q}_h, u_h)_{\mathsf{m}}^{\mathrm{BDM}} \equiv (\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}, u_{h,\mathsf{m}}^{\mathrm{BDM}}) \in V_h^{\mathrm{BDM}} \times W_h^{\mathrm{BDM}}$ is defined by requiring that

$$\int_\Omega c\, \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}} \cdot \boldsymbol{v}\, dx - \sum_{K \in \mathcal{T}_h} \int_K u_{h,\mathsf{m}}^{\mathrm{BDM}} \nabla \cdot \boldsymbol{v}\, dx = -\sum_{e \in \mathcal{E}_h} \int_e \mathsf{m}\, [\![\boldsymbol{v}]\!]\, ds,$$

$$\sum_{K \in \mathcal{T}_h} \int_K w \nabla \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\, dx + \int_\Omega d\, u_{h,\mathsf{m}}^{\mathrm{BDM}}\, w\, dx = 0$$

hold for all $(\boldsymbol{v}, w) \in V_h^{\mathrm{BDM}} \times W_h^{\mathrm{BDM}}$.

To state our first comparison theorem, we need the following additional notation: Denote by $\mathcal{P}_k$ the L^2-orthogonal projection into the space of functions which are piecewise polynomials of degree k on each triangle $K \in \mathcal{T}_h$. Let $\mathcal{R}f = \mathcal{P}_k f - \mathcal{P}_{k-1} f$ for all $f \in L^2(\Omega)$. Define the form

$$b_{h,\mathcal{R}f}^{\mathrm{RT}}(\mu) = \int_\Omega \mathcal{R}f\, u_{h,\mu}^{\mathrm{RT}}\, dx \quad \text{for all } \mu \in M_h$$

and the function $\rho_h \equiv \rho_h(\mathcal{R}f) \in M_h$ by

$$a_h^{\mathrm{RT}}(\rho_h, \mu) = b_{h,\mathcal{R}f}^{\mathrm{RT}}(\mu) \quad \text{for all } \mu \in M_h.$$

Also set

$$\Psi(\mu, g, f) = (\mathbf{0}, \mathcal{R}u_{h,\mu}^{\mathrm{RT}}) + (\mathbf{0}, \mathcal{R}u_{h,g}^{\mathrm{RT}}) + (\mathbf{0}, \mathcal{R}u_{h,\mathcal{P}_{k-1}f}^{\mathrm{RT}}) \quad \text{and}$$
$$\Upsilon(\mathcal{R}f) = (\boldsymbol{q}_h, u_h)_{\rho_h}^{\mathrm{RT}} + (\boldsymbol{q}_h, u_h)_{\mathcal{R}f}^{\mathrm{RT}}.$$

Now we can state the theorem.

THEOREM 4.1 (comparison of the RT and BDM methods for $d = 0$).
Assume that $d(\boldsymbol{x}) = 0$ almost everywhere in Ω.

1. *Suppose $f \in L^2(\Omega)$ is such that $(\mathcal{P}_k - \mathcal{P}_{k-1})f = 0$. Then, the Lagrange multiplier components of the RT and BDM solutions coincide:*

$$\lambda_h^{\mathrm{RT}} = \lambda_h^{\mathrm{BDM}}.$$

2. *If $f \in L^2(\Omega)$ is arbitrary, then the following statements hold:*

$$
\begin{aligned}
&(\alpha) \quad a_h^{\mathrm{RT}}(\mathsf{m},\mu) = a_h^{\mathrm{BDM}}(\mathsf{m},\mu) && \text{for all } \mathsf{m},\mu \in L^2(\mathcal{E}_h).\\
&(\beta) \quad b_h^{\mathrm{RT}}(\mu) = b_h^{\mathrm{BDM}}(\mu) + b_{h,\mathcal{R}f}^{\mathrm{RT}}(\mu) && \text{for all } \mu \in L^2(\mathcal{E}_h).\\
&(\gamma) \quad \lambda_h^{\mathrm{RT}} = \lambda_h^{\mathrm{BDM}} + \rho_h(\mathcal{R}f).\\
&(\delta) \quad (\boldsymbol{q}_h^{\mathrm{RT}}, u_h^{\mathrm{RT}}) = (\boldsymbol{q}_h^{\mathrm{BDM}}, u_h^{\mathrm{BDM}}) + \Psi(\lambda_h^{\mathrm{BDM}}, g, f) + \Upsilon(\mathcal{R}f).
\end{aligned}
$$

Before proving the theorem, let us discuss the result and some of its consequences.

Remark 4.1. Statements (α) and (β) can be easily rewritten in matrix form as follows:

$$
\begin{aligned}
&(\alpha') \quad \mathbb{E}^{\mathrm{RT}} = \mathbb{E}^{\mathrm{BDM}},\\
&(\beta') \quad \mathbb{H}^{\mathrm{RT}} = \mathbb{H}^{\mathrm{BDM}} + \mathbb{H}_{\mathcal{R}f}^{\mathrm{RT}},
\end{aligned}
$$

where the matrix $\mathbb{E}^{\mathrm{N}}$ is the stiffness matrix associated to the bilinear form $a_h^{\mathrm{N}}(\cdot,\cdot)$, and the matrix $\mathbb{H}^{\mathrm{N}}$ is the right-hand side matrix associated to the linear form $b_h^{\mathrm{N}}(\cdot)$ for $\mathrm{N} \in \{\mathrm{RT}, \mathrm{BDM}\}$. The matrix $\mathbb{H}_{\mathcal{R}f}^{\mathrm{RT}}$ is, of course, the right-hand side matrix associated to the linear form $b^{\mathrm{RT}}(\cdot)_{h,\mathcal{R}f}$. This means that, when $d = 0$, the stiffness matrices of the multipliers of both methods *coincide*. However, the right-hand side matrices differ. But they differ by a matrix which vanishes when $\mathcal{R}f = 0$—hence the coincidence of the Lagrange multipliers whenever $\mathcal{R}f = 0$.

Remark 4.2. The coincidence of Lagrange multipliers asserted by the theorem in the case $\mathcal{R}f = 0$ (and $d = 0$) appears to have gone unnoticed hitherto even numerically. This case occurs, e.g., when f is a polynomial of degree $k-1$ on every element of the mesh and in several applications of practical interest, e.g., incompressible flow in porous media (where $f = 0$ usually). The condition $\mathcal{R}f = 0$ is not only sufficient but also necessary for such a coincidence: From the characterization theorem, it is clear that the only part of f that determines λ_h^{RT} is $\mathcal{P}_k f$, while the only part of f that determines λ_h^{BDM} is $\mathcal{P}_{k-1} f$. Therefore, setting f to a polynomial of degree k for which $0 = \mathcal{P}_{k-1} f \neq \mathcal{P}_k f$, we can make $\lambda_h^{\mathrm{RT}} \neq \lambda_h^{\mathrm{BDM}}$.

Remark 4.3. Statement (δ) of the theorem shows how the solution components other than the multipliers are related. Obviously, $\Upsilon(\mathcal{R}f)$ depends linearly on $\mathcal{R}f$. Therefore, when $\mathcal{R}f = 0$, the solution $(\boldsymbol{q}_h^{\mathrm{RT}}, u_h^{\mathrm{RT}})$ differs from $(\boldsymbol{q}_h^{\mathrm{BDM}}, u_h^{\mathrm{BDM}})$ only by $\Psi(\lambda_h^{\mathrm{BDM}}, g, f)$, a function that can be computed locally element by element. In particular, this means that it is possible to implement the less expensive BDM method and locally recover the RT solution u_h^{RT}, which is one order higher in accuracy (under certain regularity assumptions). In this sense, (δ) can be thought of as yielding a postprocessing technique. Of course, one can then further postprocess the RT solution by the technique of [1] and gain one further order in accuracy.

Remark 4.4. It is well known that the Lagrange multiplier of both the RT and the BDM methods approximates the traces of the exact solution u on mesh edges. Specifically, under certain regularity assumptions, [5, Lemma 4.1] asserts that when $\mathcal{T}_h$ is a quasi-uniform mesh with mesh size h, as $h \to 0$,

$$
\|\lambda_h^{\mathrm{BDM}} - \mathcal{P}_{M_h} u\|_{\mathcal{E}_h} = O(h^{k+3/2-\delta_{k1}}), \tag{4.1}
$$

where $\mathcal{P}_{M_h}$ denotes the L^2-orthogonal projection onto M_h, $\|\cdot\|_{\mathcal{E}_h}$ denotes the $L^2(\mathcal{E}_h)$-norm, and δ_{k1} is zero for all k except for $k = 1$, in which case it equals one. The analogous estimate for the RT method [1, Corollary 1.5] is

$$
\|\lambda_h^{\mathrm{RT}} - \mathcal{P}_{M_h} u\|_{\mathcal{E}_h} = O(h^{k+3/2}).
$$

However, obviously whenever $\lambda_h^{\mathrm{RT}} = \lambda_h^{\mathrm{BDM}}$, there can be no difference in the convergence rates. Therefore, when $k = 1$ and $\mathcal{R}f = 0$, by virtue of Theorem 4.1, we conclude that although (4.1) provides for only $O(h^{3/2})$-convergence, in fact the convergence rate is at least $O(h^{5/2})$.

When $d \neq 0$, the liftings $\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}}$ and $\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}$ are no longer divergence-free on each element, in general. In fact, as we show later, there are multipliers m for which $\mathcal{R}u_{h,\mathsf{m}}^{\mathrm{RT}} \neq 0$. This property implies that the statements of Theorem 4.1 do not hold in general. In particular, the following theorem provides a case wherein statement (α) does not hold. Obviously, whenever statement (α) fails to hold, one cannot expect coincidence of RT and BDM Lagrange multipliers.

THEOREM 4.2 (comparison of the RT and BDM methods for $d \geq 0$). *Assume that $c(\boldsymbol{x})$ and $d(\boldsymbol{x})$ are constant on each element of the mesh. Then, whenever $d(\boldsymbol{x})$ is positive on at least one element, statement (α) of Theorem 4.2 does not hold.*

Now, we prove Theorems 4.1 and 4.2.

4.2. Proof of Theorem 4.1. The proof proceeds by establishing a connection between the BDM and RT liftings and applying the characterization theorem. Two properties of the finite element spaces of the RT and BDM methods play a crucial role. The first is simply that the multipliers of both methods share the same space. The second is that the elements of V_h^{RT} whose divergence on each element is a polynomial of degree $k-1$ also belong to the space V_h^{BDM}. Let us begin by proving the latter property.

LEMMA 4.3. *The following containment holds:*

$$\{\boldsymbol{q}_h \in V_h^{\mathrm{RT}} : \nabla \cdot \boldsymbol{q}_h|_K \in P^{k-1}(K) \ \text{ for all } \ K \in \mathcal{T}_h\} \subset V_h^{\mathrm{BDM}}.$$

Proof. If $\boldsymbol{q}_h \in V_h^{\mathrm{RT}}$, then $\boldsymbol{q}_h|_K = \boldsymbol{v}_k + \boldsymbol{x}\widetilde{p}_k$ for some $\boldsymbol{v}_k \in P^k(K) \times P^k(K)$ and some homogeneous polynomial $\widetilde{p}_k(\boldsymbol{x})$ of degree k on K. Taking the divergence, we find that

$$\nabla \cdot (\boldsymbol{q}_h|_K) = \nabla \cdot \boldsymbol{v}_k + (k+2)\widetilde{p}_k.$$

Therefore, $\nabla \cdot (\boldsymbol{q}_h|_K) \in P^{k-1}(K)$ implies that $\widetilde{p}_k = 0$, and consequently $\boldsymbol{q}_h|_K \in P^k(K) \times P^k(K)$. Hence $\boldsymbol{q}_h \in V_h^{\mathrm{BDM}}$. This completes the proof. ∎

The next result uses the above lemma and the definition of the local mappings to establish key relations between the local mappings of the RT and BDM methods.

LEMMA 4.4. *Assume that $d = 0$. Then, for all $\mathsf{m} \in L^2(\mathcal{E}_h)$ and $f \in L^2(\Omega)$,*

$$\begin{aligned} &\text{(i)} \quad \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} = \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}, && u_{h,\mathsf{m}}^{\mathrm{RT}} = u_{h,\mathsf{m}}^{\mathrm{BDM}} + \mathcal{R}u_{h,\mathsf{m}}^{\mathrm{RT}}, \\ &\text{(ii)} \quad \boldsymbol{q}_{h,f}^{\mathrm{RT}} = \boldsymbol{q}_{h,f}^{\mathrm{BDM}} + \boldsymbol{q}_{h,\mathcal{R}f}^{\mathrm{RT}}, && u_{h,f}^{\mathrm{RT}} = u_{h,f}^{\mathrm{BDM}} + \mathcal{R}u_{h,\mathcal{P}_{k-1}f}^{\mathrm{RT}} + u_{h,\mathcal{R}f}^{\mathrm{RT}}. \end{aligned}$$

Proof. Let us begin by proving (i). From (2.9), we have

$$\int_\Omega c\,(\,\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} - \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\,) \cdot \boldsymbol{v}\,dx - \sum_{K\in\mathcal{T}_h} \int_K (\,u_{h,\mathsf{m}}^{\mathrm{RT}} - u_{h,\mathsf{m}}^{\mathrm{BDM}}\,)\,\nabla\cdot\boldsymbol{v}\,dx = 0 \quad \text{for all } \ \boldsymbol{v} \in V_h^{\mathrm{BDM}},$$

and from (2.10), $\nabla \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}}|_K = 0$ and $\nabla \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}|_K = 0$ for all $K \in \mathcal{T}_h$. Since by Lemma 4.3 $\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} \in V_h^{\mathrm{BDM}}$, we can take $\boldsymbol{v} = \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} - \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}$ in the first equation of this proof to get that $\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} = \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}$. It immediately follows that

$$-\sum_{K\in\mathcal{T}_h} \int_K (\,u_{h,\mathsf{m}}^{\mathrm{RT}} - u_{h,\mathsf{m}}^{\mathrm{BDM}}\,)\,\nabla\cdot\boldsymbol{v}\,dx = 0 \qquad \text{for all } \ \boldsymbol{v} \in V_h^{\mathrm{BDM}},$$

which implies that $\mathcal{P}_{k-1}\,u_{h,\mathsf{m}}^{\mathrm{RT}} = u_{h,\mathsf{m}}^{\mathrm{BDM}}$. This proves (i).

Now, let us prove (ii). It suffices to show that for $p = \mathcal{P}_{k-1} f$,

$$\boldsymbol{q}_{h,p}^{\mathrm{RT}} = \boldsymbol{q}_{h,p}^{\mathrm{BDM}} \quad \text{and} \quad u_{h,p}^{\mathrm{RT}} = u_{h,p}^{\mathrm{BDM}} + \mathcal{R} u_{h,p}^{\mathrm{RT}}. \tag{4.2}$$

Indeed, once we have (4.2), by linearity and the obvious equality

$$(\boldsymbol{q}_h, u_h)^{\mathrm{BDM}}_{\mathcal{P}_{k-1} f} = (\boldsymbol{q}_h, u_h)^{\mathrm{BDM}}_{f},$$

we get that

$$\begin{aligned}(\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{f} &= (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{p} + (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{\mathcal{R} f} \\ &= (\boldsymbol{q}_h, u_h)^{\mathrm{BDM}}_{p} + (\boldsymbol{0}, \mathcal{R} u_{h,p}^{\mathrm{RT}}) + (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{\mathcal{R} f},\end{aligned}$$

and (ii) follows. To show (4.2), first observe that since $p|_K = (\mathcal{P}_{k-1} f)|_K \in P^{k-1}(K)$, (2.12) implies that

$$\nabla \cdot \boldsymbol{q}_{h,p}^{\mathrm{RT}}|_K = p \quad \text{and} \quad \nabla \cdot \boldsymbol{q}_{h,p}^{\mathrm{BDM}}|_K = p \quad \text{for all } \ K \in \mathcal{T}_h.$$

Therefore, using Lemma 4.3 again, $\boldsymbol{q}_{h,p}^{\mathrm{RT}} \in V_h^{\mathrm{BDM}}$. Now, (2.11) yields

$$\int_\Omega c \, \big(\boldsymbol{q}_{h,p}^{\mathrm{RT}} - \boldsymbol{q}_{h,p}^{\mathrm{BDM}} \big) \cdot \boldsymbol{v} \, dx - \sum_{K \in \mathcal{T}_h} \int_K \big(u_{h,p}^{\mathrm{RT}} - u_{h,p}^{\mathrm{BDM}} \big) \nabla \cdot \boldsymbol{v} \, dx = 0 \quad \text{for all } \ \boldsymbol{v} \in V_h^{\mathrm{BDM}}.$$

Since we have shown that $\boldsymbol{q}_{h,p}^{\mathrm{RT}} \in V_h^{\mathrm{BDM}}$, we can choose $\boldsymbol{v} = \boldsymbol{q}_{h,p}^{\mathrm{RT}} - \boldsymbol{q}_{h,p}^{\mathrm{BDM}}$ above. Then the first equality of (4.2), namely, $\boldsymbol{q}_{h,p}^{\mathrm{RT}} = \boldsymbol{q}_{h,p}^{\mathrm{BDM}}$, immediately follows. The second equality of (4.2) also follows, because by (i) we have $\mathcal{P}_{k-1} \, u_{h,p}^{\mathrm{RT}} = u_{h,p}^{\mathrm{BDM}}$. This completes the proof. ∎

We are now ready to prove Theorem 4.1.

Proof of Theorem 4.1. First, observe that the first conclusion of the theorem, namely, $\lambda_h^{\mathrm{RT}} = \lambda_h^{\mathrm{BDM}}$ whenever $\mathcal{R} f = 0$, follows from statement (γ), because $\rho_h(\mathcal{R} f)$ depends linearly on $\mathcal{R} f$. Therefore, we shall prove only statements (α)–(δ).

Applying the characterization theorem with $d = 0$, we find that

$$a_h^{\mathrm{N}}(\mathsf{m}, \mu) = \int_\Omega c \, \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{N}} \cdot \boldsymbol{q}_{h,\mu}^{\mathrm{N}} \quad \text{for } {}_{\mathrm{N}} \in \{{}_{\mathrm{RT}}, {}_{\mathrm{BDM}}\},$$

so the equality of (α) follows from the first equality of Lemma 4.4(i). Similarly, since

$$b_h^{\mathrm{N}}(\mu) = \int_{\partial\Omega} g \, [\![\boldsymbol{q}_{h,\mu}^{\mathrm{N}}]\!] \, ds + \int_\Omega f \, u_{h,\mu}^{\mathrm{N}} \, dx \quad \text{for } {}_{\mathrm{N}} \in \{{}_{\mathrm{RT}}, {}_{\mathrm{BDM}}\},$$

the second equality, namely, (β), also follows from Lemma 4.4(i). Now, statement (γ) obviously follows from (α), (β), and the definitions of the multipliers.

To prove statement (δ), we start again from the characterization theorem, apply statement (γ), and use the identities of Lemma 4.4 in succession:

$$\begin{aligned}(\boldsymbol{q}_h^{\mathrm{RT}}, u_h^{\mathrm{RT}}) &= (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{\lambda_h^{\mathrm{RT}}} + (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{g} + (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{f} \\ &= (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{(\lambda_h^{\mathrm{BDM}} + \rho_h)} + (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{g} + (\boldsymbol{q}_h, u_h)^{\mathrm{RT}}_{f} \\ &= (\boldsymbol{q}_h, u_h)^{\mathrm{BDM}}_{\lambda_h^{\mathrm{BDM}}} + (\boldsymbol{0}, \mathcal{R} u_{h,\lambda_h^{\mathrm{BDM}}}^{\mathrm{RT}} + u_{h,\rho_h}^{\mathrm{RT}}) + (\boldsymbol{q}_{h,g}^{\mathrm{BDM}}, u_{h,g}^{\mathrm{BDM}} + \mathcal{R} u_{h,g}^{\mathrm{RT}}) \\ &\qquad + (\boldsymbol{q}_{h,f}^{\mathrm{BDM}} + \boldsymbol{q}_{h,\mathcal{R} f}^{\mathrm{RT}}, \ u_{h,f}^{\mathrm{BDM}} + \mathcal{R} u_{h,\mathcal{P}_{k-1} f}^{\mathrm{RT}} + u_{h,\mathcal{R} f}^{\mathrm{RT}}) \\ &= (\boldsymbol{q}_h, u_h)^{\mathrm{BDM}}_{\lambda_h^{\mathrm{BDM}}} + (\boldsymbol{q}_h, u_h)^{\mathrm{BDM}}_{g} + (\boldsymbol{q}_h, u_h)^{\mathrm{BDM}}_{f} \\ &\qquad + \Psi(\lambda_h^{\mathrm{BDM}}, g, f) + \Upsilon(\mathcal{R} f).\end{aligned}$$

The first three terms on the right-hand side of the last equality sum to the BDM solution. This completes the proof of Theorem 4.1. ∎

4.3. Proof of Theorem 4.2. To prove this result, we begin by studying the local spaces of the RT method, namely,

$$\begin{aligned} V_K^{\mathrm{RT}} &= P^k(K) \times P^k(K) + \boldsymbol{x}\, P^k(K), \\ W_K^{\mathrm{RT}} &= P^k(K), \\ M_K^{\mathrm{RT}} &= \{\mu \in L^2(\partial K) : \mu|_e \in P^k(e) \text{ for each edge of } K\}. \end{aligned}$$

It turns out that, when $d > 0$, the lifting maps induce a natural orthogonal decomposition of the local space V_K^{RT}, namely,

$$V_K^{\mathrm{RT}} = V_K^0 \oplus V_K^{\perp},$$

where

$$\begin{aligned} V_K^0 &= \{\boldsymbol{v} \in V_K^{\mathrm{RT}} : \boldsymbol{v} \cdot \boldsymbol{n}_e = 0 \text{ on each edge } e \text{ of } K\}, \\ V_K^{\perp} &= \{\boldsymbol{v} \in V_K^{\mathrm{RT}} : (\!(\boldsymbol{v}, \boldsymbol{q})\!) = 0 \ \text{ for all } \boldsymbol{q} \in V_K^0\}, \end{aligned}$$

and

$$(\!(\boldsymbol{v}_1, \boldsymbol{v}_2)\!) = \int_K c\, \boldsymbol{v}_1 \cdot \boldsymbol{v}_2 \, dx + \int_K \frac{1}{d} \nabla \cdot \boldsymbol{v}_1 \, \nabla \cdot \boldsymbol{v}_2 \, dx.$$

Indeed, the following result states that the local space $V_K^{\perp}$ is nothing but the image of the lifting map $\mathsf{m} \mapsto \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}}$.

LEMMA 4.5. *Assume that $d(\boldsymbol{x})$ is a positive constant on an element $K \in \mathcal{T}_h$, and let $\{\mathsf{m}_i\}_{i=1}^{3(k+1)}$ be a basis of M_K^{RT}. Then, $\{\boldsymbol{q}_{h,\mathsf{m}_i}^{\mathrm{RT}}\}_{i=1}^{3(k+1)}$ is a basis of $V_K^{\perp}$.*

Proof. By (2.10), we have for any $\mathsf{m} \in M_K^{\mathrm{RT}}$

$$u_{h,\mathsf{m}}^{\mathrm{RT}} = -\frac{1}{d} \nabla \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}}. \tag{4.3}$$

Substituting this expression for $u_{h,\mathsf{m}}^{\mathrm{RT}}$ into (2.9), we see that (2.9) can be rewritten as follows:

$$(\!(\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}}, \boldsymbol{v})\!) = -\sum_{e \in \partial K} \int_e \mathsf{m}\, [\![\boldsymbol{v}]\!]\, ds.$$

As a consequence

$$\{\boldsymbol{q}_{h,\mathsf{m}_i}^{\mathrm{RT}}\}_{i=1}^{3(k+1)} \subset V_K^{\perp}.$$

Since the dimension of $V_K^{\perp}$ is $3(k+1)$, it remains only to show that the elements of the set $\{\boldsymbol{q}_{h,\mathsf{m}_i}^{\mathrm{RT}}\}_{i=1}^{3(k+1)}$ are linearly independent. So, assume that there are scalars α_i such that

$$\sum_{i=1}^{3(k+1)} \alpha_i\, \boldsymbol{q}_{h,\mathsf{m}_i}^{\mathrm{RT}} = 0.$$

By the linearity of the lifting, this implies that $\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} = 0$, where

$$\mathsf{m} = \sum_{i=1}^{3(k+1)} \alpha_i\, \mathsf{m}_i.$$

However, since by (4.3)

$$u_{h,\mathsf{m}}^{\mathrm{RT}} = -\frac{1}{d}\nabla \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} = 0,$$

we have that the lifting $(\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}}, u_{h,\mathsf{m}}^{\mathrm{RT}})$ is zero. Consequently, $\mathsf{m} = 0$. Since $\{\mathsf{m}_i\}_{i=1}^{3(k+1)}$ is a basis for M_K^{RT}, it follows that $\alpha_i = 0$ for all $i = 1, \ldots, 3(k+1)$. This completes the proof. ∎

Now, we use the above result to show that the lifting $u_{h,\mathsf{m}}^{\mathrm{RT}}$ is not always a polynomial of degree at most $k-1$ on all the elements of the triangulation.

LEMMA 4.6. *Assume that $c(\boldsymbol{x})$ is constant on an element $K \in \mathcal{T}_h$. Also assume that $d(\boldsymbol{x})$ is a positive constant on K. Then there is a function $\mathsf{m} \in M_K^{\mathrm{RT}}$ such that*

$$\mathcal{R} u_{h,\mathsf{m}}^{\mathrm{RT}} \neq 0 \qquad \text{on } K.$$

Proof. Since by (4.3)

$$u_{h,\mathsf{m}}^{\mathrm{RT}} = -\frac{1}{d}\nabla \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}},$$

an application of Lemma 4.3 shows that $\mathcal{R} u_{h,\mathsf{m}}^{\mathrm{RT}} = 0$ if and only if

$$\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} \in P^k(K) \times P^k(K) \quad \text{for all } \mathsf{m} \in M_K^{\mathrm{RT}}. \tag{4.4}$$

We claim that this is not possible for all $\mathsf{m} \in M_K^{\mathrm{RT}}$. Indeed, if this were the case, $V_K^{\perp} \subset P^k(K) \times P^k(K)$. This implies that the orthogonal complement of $P^k(K) \times P^k(K)$ in V_K^{RT} with respect to the inner product $(\!(\cdot,\cdot)\!)$, which we denote by W_K, satisfies

$$W_K \subset V_K^0. \tag{4.5}$$

However, as we shall now see, this implies that $W_K = \{\mathbf{0}\}$, which is a contradiction.

In the orthogonality relation

$$\int_K c\boldsymbol{\phi} \cdot \boldsymbol{v}\, dx + \frac{1}{d}\int_K (\nabla \cdot \boldsymbol{\phi})(\nabla \cdot \boldsymbol{v})\, dx = 0 \quad \text{for all } \boldsymbol{v} \in P^k(K) \times P^k(K),$$

let us choose $\boldsymbol{v} = c^{-T}\nabla\eta$ for some $\eta \in P^{k+1}(K)$ (where c^{-T} denotes the inverse of the transpose of c):

$$\int_K \boldsymbol{\phi} \cdot \nabla\eta\, dx + \frac{1}{d}\int_K (\nabla \cdot \boldsymbol{\phi})(\nabla \cdot c^{-T}\nabla\eta)\, dx = 0. \tag{4.6}$$

By (4.5) and integration by parts

$$\int_K \boldsymbol{\phi} \cdot \nabla\eta\, dx + \int_K \eta \nabla \cdot \boldsymbol{\phi}\, dx = \int_{\partial K} \eta(\boldsymbol{\phi} \cdot \boldsymbol{n})\, ds = 0. \tag{4.7}$$

Subtracting (4.6) from (4.7), we have

$$\int_K \left(\eta - \frac{1}{d}\nabla \cdot c^{-T}\nabla\eta\right)(\nabla \cdot \boldsymbol{\phi})\, dx = 0 \quad \text{for all } \eta \in P^{k+1}(K). \tag{4.8}$$

Now we show that (4.8) implies that $\nabla \cdot \boldsymbol{\phi} = 0$. Choosing $\eta \in P^1(K)$ in (4.8), we conclude that $\nabla \cdot \boldsymbol{\phi}$ is $L^2(K)$-orthogonal to $P^1(K)$. For $k \geq 2$, if $\nabla \cdot \boldsymbol{\phi}$ is $L^2(K)$-orthogonal to $P^{k-1}(K)$, then choosing $\eta \in P^k(K)$ we find that $\nabla \cdot \boldsymbol{\phi}$ is $L^2(K)$-orthogonal to $P^k(K)$ as well, because $\nabla \cdot (c^{-T}\nabla\eta) \in P^{k-2}(K)$. Thus, by induction, $\nabla \cdot \boldsymbol{\phi}$ is zero.

It follows from $\nabla \cdot \boldsymbol{\phi} = 0$ that $\boldsymbol{\phi} = 0$: Indeed, any $\boldsymbol{\phi} \in W$ can be written as $\boldsymbol{\phi}(\boldsymbol{x}) = \boldsymbol{x}\widetilde{p}_k - \mathcal{Q}_k(\boldsymbol{x}\widetilde{p}_k)$, where $\mathcal{Q}_k$ is the orthogonal projection onto $P^k(K) \times P^k(K)$ in the $(\!(\cdot,\cdot)\!)$-inner product, and $\widetilde{p}_k$ is a homogeneous polynomial of degree k. Therefore,

$$0 = \nabla \cdot \boldsymbol{\phi} = (k+2)\widetilde{p}_k - \nabla \cdot \mathcal{Q}_k(\boldsymbol{x}\widetilde{p}_k).$$

Since the latter term is in $P^{k-1}(K)$, we conclude that $\widetilde{p}_k = 0$, so $\boldsymbol{\phi} = \mathbf{0}$. Thus (4.4) does not hold, and the lemma is proved. ∎

The next result establishes an equivalent criterion for statement (α) of Theorem 4.1 in terms of the liftings.

LEMMA 4.7. *Assume that $d(\boldsymbol{x})$ is constant on every element of the mesh. Let $\mathsf{m} \in L^2(\partial K)$. Then*

$$a_h^{\mathrm{RT}}(\mathsf{m},\mathsf{m}) = a_h^{\mathrm{BDM}}(\mathsf{m},\mathsf{m})$$

if and only if

(i) $\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} = \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}$ *on Ω and*

(ii) $u_{\mathsf{m}}^{\mathrm{RT}} = u_{\mathsf{m}}^{\mathrm{BDM}}$ *on all elements $K \in \mathcal{T}_h$, where $d > 0$.*

Proof. Set $\mathbb{J}(\mathsf{m}) = a_h^{\mathrm{RT}}(\mathsf{m},\mathsf{m}) - a_h^{\mathrm{BDM}}(\mathsf{m},\mathsf{m})$. Since, by Theorem 2.1, we have, for $\mathrm{N} \in \{\mathrm{RT}, \mathrm{BDM}\}$,

$$a_h^{\mathrm{N}}(\mathsf{m},\mathsf{m}) = \int_\Omega c\,\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{N}} \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{N}}\,dx + \int_\Omega d\,u_{h,\mathsf{m}}^{\mathrm{N}}\,u_{h,\mathsf{m}}^{\mathrm{N}}\,dx,$$

a straightforward use of the identity $a^2 - b^2 = (a-b)^2 + 2\,b\,(a-b)$ allows us to write $\mathbb{J}(\mathsf{m}) = \Theta(\mathsf{m}) + \mathbb{D}(\mathsf{m})$, where

$$\Theta(\mathsf{m}) = \int_\Omega c\,(\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} - \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}) \cdot (\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} - \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}})\,dx + \int_\Omega d\,(u_{\mathsf{m}}^{\mathrm{RT}} - u_{\mathsf{m}}^{\mathrm{BDM}})^2\,dx$$

and

$$\mathbb{D}(\mathsf{m}) = 2\int_\Omega c\,\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}} \cdot \left(\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} - \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\right)\,dx + 2\int_\Omega d\,u_{h,\mathsf{m}}^{\mathrm{BDM}}\left(u_{h,\mathsf{m}}^{\mathrm{RT}} - u_{h,\mathsf{m}}^{\mathrm{BDM}}\right)\,dx.$$

We will now show that $\mathbb{D}(\mathsf{m}) = 0$. Consider the first term in the definition of $\mathbb{D}(\mathsf{m})$. By (2.9),

$$\begin{aligned}\int_\Omega c\,\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}} \cdot \left(\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} - \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\right)\,dx &= \int_\Omega c\,\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\,dx - \int_\Omega c\,\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}} \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\,dx \\ &= -\sum_{K\in\mathcal{T}_h}\int_K \left(u_{h,\mathsf{m}}^{\mathrm{RT}} - u_{h,\mathsf{m}}^{\mathrm{BDM}}\right)\,\nabla \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\,dx.\end{aligned}$$

Hence, using also (2.10), we have

$$\begin{aligned}\int_\Omega c\,\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}} \cdot \left(\boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{RT}} - \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\right)\,dx &= -\sum_{K\in\mathcal{T}_h}\int_K \left(\mathcal{P}_{k-1}u_{h,\mathsf{m}}^{\mathrm{RT}} - u_{h,\mathsf{m}}^{\mathrm{BDM}}\right)\,\nabla \cdot \boldsymbol{q}_{h,\mathsf{m}}^{\mathrm{BDM}}\,dx \\ &= -\int_\Omega d\,u_{h,\mathsf{m}}^{\mathrm{BDM}}\left(\mathcal{P}_{k-1}u_{h,\mathsf{m}}^{\mathrm{RT}} - u_{h,\mathsf{m}}^{\mathrm{BDM}}\right)\,dx.\end{aligned}$$

Inserting this expression in the definition of $\mathbb{D}$, we get

$$\mathbb{D}(\mathsf{m}) = 2\int_\Omega d\, u_{h,\mathsf{m}}^{\mathrm{BDM}} \left(u_{h,\mathsf{m}}^{\mathrm{RT}} - \mathcal{P}_{k-1} u_{h,\mathsf{m}}^{\mathrm{RT}} \right) dx = 0,$$

because d is constant on each element of the mesh. In other words, $\mathbb{J}(\mathsf{m}) = \Theta(\mathsf{m})$.

This implies that $\mathbb{J}(\mathsf{m}) = 0$ if and only if $\Theta(\mathsf{m}) = 0$. The lemma follows from the definition of $\Theta(\mathsf{m})$ and the fact that $c(\boldsymbol{x})$ is positive definite. ∎

We are now ready to prove Theorem 4.2.

Proof of Theorem 4.2. Since there is at least one element $K \in \mathcal{T}_h$ wherein d is a positive constant, Lemma 4.6 asserts the existence of at least one function $\mathsf{m} \in M_K^{\mathrm{RT}}$ for which $\mathcal{R} u_{h,\mathsf{m}}^{\mathrm{RT}} \neq 0$ on K. This implies that $u_{h,\mathsf{m}}^{\mathrm{RT}} \neq u_{h,\mathsf{m}}^{\mathrm{BDM}}$ on K. Therefore, by Lemma 4.7, for any $\mu \in M_h$ such that $\mu|_{\partial K} = \mathsf{m}$, we have $a_h^{\mathrm{RT}}(\mu,\mu) \neq a_h^{\mathrm{BDM}}(\mu,\mu)$. Consequently, statement (α) of Theorem 4.1 does not hold. This completes the proof. ∎

5. Concluding remarks. The characterization theorem obtained in this paper for the hybridized RT method on triangular meshes also holds for various other methods. For example, it holds for the RT method on simplicial meshes in any space dimension as well as on rectangular and cubic meshes. It also holds for the hybridized versions of the mixed methods of Brezzi, Douglas, and Marini [5, 6] on rectangles, the method of Brezzi et al. [3] on tetrahedra and bricks, and the method of Brezzi et al. [4] on triangles, rectangles, tetrahedra, and bricks.

As a consequence, the matrix entries for the multipliers of all of the above-mentioned methods can be computed as described in section 3. Moreover, a result similar to the comparison theorem (Theorem 4.1) holds for the RT and BDM methods on multidimensional simplices. However, when the elements are rectangles or bricks, the subspace of divergence-free members of the RT and BDM spaces on an element are not identical. Therefore, in general, we cannot expect a result analogous to Theorem 4.1 to hold in this case.

Other applications of the characterization theorem are studied elsewhere. Indeed, in [11] it is shown how to use the characterization theorem to construct a Schwarz preconditioner for the multiplier equation of the RT and BDM hybridized mixed methods of *any* order. Such preconditioners were known only for the lowest order hybridized RT method. Also, in a forthcoming paper, we show how to use the characterization result to obtain error estimates for the multipliers *without* relying on error estimates on the other variables, as is customarily done.

Finally, let us briefly comment on the relation between the hybridized mixed methods and the discontinuous Galerkin methods. It is not difficult to see that the counterpart of the multiplier λ_h is nothing but the so-called numerical trace of the approximation u_h given by the discontinuous Galerkin method. How to exploit this link to achieve a better theoretical understanding of *both* methods remains a challenging open problem; see [9].

Acknowledgment. The authors would like to thank Wolfgang Dahmen, whose stimulating visit to the I.M.A., University of Minnesota, in the Spring of 2001, prompted them to explore ways of characterizing stiffness matrices of mixed methods by using discontinuous test functions. This paper is the unexpected outcome of such exploration.

ADJOINT-BASED ITERATIVE METHOD FOR ROBUST CONTROL PROBLEMS IN FLUID MECHANICS*

T. TACHIM MEDJO† AND L. R. TCHEUGOUE TEBOU†

Abstract. In this article we study the convergence of an adjoint-based iterative method recently proposed in [T. R. Bewley, R. Temam, and M. Ziane, *Phys. D*, 138 (2000), pp. 360–392] for the numerical solution of a class of nonlinear robust control problems in fluid mechanics. Under weaker assumptions than those of [T. Tachim Medjo, *Numer. Funct. Anal. Optim.*, 23 (2002), pp. 849–873], we prove the convergence of the algorithm, and we obtain an estimate of the convergence rate. Numerical solutions of a robust control problem related to data assimilation in oceanography are presented to illustrate the method.

Key words. robust control, fluid mechanics, Navier–Stokes, iterative methods

1. Introduction.

Optimal control of fluid flows such as those governed by the Navier–Stokes equations has long been the subject of extensive studies, and applications to engineering and sciences are tremendous. In recent years, the control of fluid flows has also become the subject of intense study in the mathematical community. Due to advances in computer technology, the application of optimal control theory to complex phenomena such as weather forecasting and oceanography is becoming a reality [1, 2, 6, 9, 11, 14, 15, 16, 17, 25, 26, 27, 28]. A classical control problem arising in meteorology and oceanography, and related to *data assimilation*, is the adjustment of initial conditions in order to obtain a flow that agrees with the observations. This has been the subject of extensive studies in the past, and a lot of progress has been made both mathematically and computationally to understand the subject [1, 2, 6, 9, 11, 14, 15, 16, 17, 25, 26, 27, 28].

In general, the application of optimal control theory to complex problems in fluid mechanics has proven to be quite effective when complete state information from high resolution numerical simulations is available [6]. As suggested in [6], in order to extend this infinite-dimensional optimization approach to control externally disturbed flows in which the controls must be determined based on limited noisy flow measurements alone, it is necessary that the controls computed be insensitive to both state disturbances and measurement noise.

As described in [6], robust control theory, which generalizes optimal control theory, can be represented as a differential game between an engineer seeking the "best" control that stabilizes the flow perturbation with limited control effort and, simultaneously, nature seeking the "maximally malevolent" disturbance that destabilizes the flow perturbation with limited disturbance magnitude. In [6], the authors present a general framework for robust control problems in fluid mechanics. Given a fairly general cost functional $\mathcal{J} = \mathcal{J}(\psi, \phi)$, the authors in [6] proved the existence of a saddle point $(\bar{\psi}, \bar{\phi})$, which maximizes $\mathcal{J}$ with respect to the disturbance ψ and minimizes $\mathcal{J}$ with respect to the control ϕ, subject to the Navier–Stokes equations. Chaotic prob-

lems, such as weather systems, are highly susceptible to the small disturbances present in all physical systems. The robust control framework presented in [6] should help to reduce the component of the initial state most susceptible to external disturbance and therefore to improve the accuracy of the forecast. Numerical solutions of linear robust control problems of small state dimension can be accurately obtained using traditional methods such as the Riccati solver [5]. However, for linear problems with large state dimension or nonlinear problems in fluid mechanics, methods that require the storage of a large quantity of fields become less appropriate; as suggested in [1], iterative methods seem to be very attractive for these types of problems. Iterative methods based on repeated computations of the adjoint flow have been proven to be very successful in numerical solutions of optimal control problems [1, 15, 17, 18]. The analysis of stability and convergence of a class of such methods is given in [17, 18, 28]. In [6], the authors proposed some iterative algorithms based on repeated computations of the adjoint flow for the numerical solution of a class of robust control problems. In [22], the author proved the convergence of the iterative methods proposed in [6] for the linearized problems. The nonlinear problem was considered in [21], in which the author proved the convergence of the iterative methods proposed in [6] when the cost parameters (γ, l) are large enough and for only one particular choice of the iteration parameter. Although the result of [21] is interesting because the iteration parameters are given explicitly, it is not physically reasonable that the condition (γ, l) be large enough. In fact, let us recall that l large enough corresponds to prohibitive control. In this article, we revisit the method in [21], and we prove the convergence of the adjoint-based iterative method of [6] for γ large enough and $l > 0$.

The article is divided as follows. In the next section, we present the mathematical models. The third section recalls from [6] the robust control problems and proves the existence and uniqueness of their solutions using a contraction mapping argument. This section ends by proving the convergence of the algorithm of [6] under a weaker assumption than those in [21]. The fourth section presents some numerical simulations of a robust control problem related to data assimilation in oceanography in order to illustrate the algorithm.

2. Governing equations and mathematical setting.

2.1. Governing equations. Hereafter, Ω is an open domain in R^2. The flow U and the forcing F satisfy the Navier–Stokes equations in $\Omega \times (0, \infty)$ given by

$$\begin{cases} \dfrac{\partial U}{\partial t} - \nu \Delta U + (U \cdot \nabla) U + \nabla P = F, \\ \text{div } U = 0, \\ U = 0 \text{ on } \partial\Omega, \\ U = U_0 \text{ at } t = 0. \end{cases} \tag{2.1}$$

A stationary or nonstationary solution U with the corresponding forcing F will be referred to as target flow for the control problem. If no target flow is given, U and F are taken as zero. We are interested in the robust regulation of the deviation of the flow from the target (U, F). As in [6], we will consider the control of the linearized equation, which models small perturbations (u, f) to the target flow (U, F) with Dirichlet boundary conditions and known initial conditions such that, in $\Omega \times (0, \infty)$, we have

$$\frac{\partial u}{\partial t} - \nu \Delta u + (u \cdot \nabla) U + (U \cdot \nabla) u + \nabla p = f, \quad u = 0 \text{ on } \partial\Omega, \ u = g \text{ at } t = 0. \tag{2.2}$$

We will also consider the control of the full nonlinear equation which models large perturbations (u, f) to the target flow (U, F) such that, in $\Omega \times (0, \infty)$, we have

(2.3)
$$\frac{\partial u}{\partial t} - \nu\Delta u + (u \cdot \nabla)U + (U \cdot \nabla)u + (u \cdot \nabla)u + \nabla p = f, \quad u = 0 \text{ on } \partial\Omega, \ u = g \text{ at } t = 0.$$

We will generalize our results to control problems related to data assimilation in oceanography.

2.2. Mathematical setting. Let Ω be a bounded open set of R^2 with boundary $\partial\Omega$, and let $\vec{n}$ be the unit outward normal vector to $\partial\Omega$. We denote by $H^s(\Omega)$, for $s \in R$, the Sobolev spaces constructed on $L^2(\Omega)$, and by $H_0^s(\Omega)$, for $s > 1/2$, the closure of $C_0^\infty(\Omega)$ in $H^s(\Omega)$. As in [6, 30], we set $M = \{u \in (C_0^\infty)^2;\ \text{div } u = 0\}$ and denote by H (resp., V) the closure of M in $(L^2(\Omega))^2$ (resp., $(H^1(\Omega))^2$); we have

$$H = \{u \in (L^2(\Omega))^2;\ \text{div } u = 0 \text{ in } \Omega,\ u \cdot \vec{n} = 0 \text{ on } \partial\Omega\}$$

and

$$V = \{u \in (H_0^1(\Omega))^2;\ \text{div } u = 0 \text{ in } \Omega\},$$

where $\vec{n}$ denotes the outward normal vector to $\partial\Omega$. The scalar product in H is denoted by $(u, v) = \int_\Omega u \cdot v dx$, that on V is denoted by $((u, v)) = \int_\Omega \nabla u \cdot \nabla v dx$, and the associated norms are denoted by $|\cdot|$ and $\|\cdot\|$, respectively. Hereafter, if Z is any other Hilbert space, we will denote by $\langle\cdot,\cdot\rangle_Z$ the scalar product in Z and by $\|\cdot\|_Z$ the associated norm. We also set $Y = L^2(0, T; V)$ and $W = \{u \in L^2(0, T; V), \frac{du}{dt} \in L^2(0, T; V')\}$ endowed with the norm

$$\|u\|_W = \left(\|u\|^2_{L^2(0,T;V)} + \left\| \frac{du}{dt} \right\|^2_{L^2(0,T;V')} \right)^{\frac{1}{2}}.$$

We denote by A the Stokes operator, defined as an isomorphism from V onto the dual V' of V such that, for $u \in V$, Au is defined by

$$\langle Au, v\rangle_{V',V} = ((u, v)) \quad \forall u, v \in V,$$

where $\langle\cdot,\cdot\rangle_{V',V}$ is the duality bracket between V' and V. The operator A is extended to H as a linear unbounded operator with domain $D(A) = (H^2(\Omega))^2 \cap V$ when $\partial\Omega$ is a C^2 surface. We also denote by $\mathcal{P}$ the Leray–Hopf projector, which is the orthogonal projector of the space $\mathbf{L}^2(\Omega) \equiv (L^2(\Omega))^2$ onto the divergence-free space H. The Stokes operator is related to $\mathcal{P}$ by

$$Au = -\mathcal{P}(\Delta u) \quad \forall u \in D(A).$$

We also define the bilinear mapping B by

$$B(u, v) = \mathcal{P}\left((u \cdot \nabla)v\right) \quad \forall u, v \in V,$$

which is a bilinear mapping from V into V'. To simplify the notation, we define the nonlinear application B from V into V' by

$$B(u) = B(u, u) \quad \forall u \in V. \tag{2.4}$$

Then B is differentiable, and we have

$$B'(u)v = B(u,v) + B(v,u) \quad \forall u, v \in V. \tag{2.5}$$

We will denote by $B'(u)^*$ the adjoint operator of $B'(u)$ for the duality between V and V'. Define a continuous trilinear form b on V such that, with $u, v, w \in (H^1(\Omega))^2$, we have

$$b(u,v,w) = \langle B(u,v), w\rangle_{V',V} = \int (u \cdot \nabla)v \cdot w dx. \tag{2.6}$$

Then the following properties hold true (see [6]):

$$\begin{aligned}
&b(u,v,v) = 0 \quad \forall u \in V, v \in V,\\
&|b(u,v,w)| \le c|u|_{L^2}^{\frac{1}{2}}\|u\|^{\frac{1}{2}}\|v\|^{\frac{1}{2}}|Av|_{L^2}^{\frac{1}{2}}|w|_{L^2} \quad \forall u \in V, v \in D(A), w \in H,\\
&|b(u,v,w)| \le c|u|_{L^2}^{\frac{1}{2}}|Au|_{L^2}^{\frac{1}{2}}\|v\||w|_{L^2} \quad \forall u \in D(A), v \in V, w \in H,\\
&|b(u,v,w)| \le c|u|_{L^2}^{\frac{1}{2}}\|u\|^{\frac{1}{2}}\|v\||w|_{L^2}^{\frac{1}{2}}\|w\|^{\frac{1}{2}} \quad \forall u \in V, v \in V, w \in V,
\end{aligned} \tag{2.7}$$

where $c = c(\Omega)$ is a constant depending only on Ω. The estimates developed in this work involve integration by parts and the following inequalities, which are repeated here for the sake of clarity: the Cauchy–Schwarz inequality $|\langle u, v\rangle| \le |u|_{L^2}|v|_{L^2}$; Hölder's inequality

$$\int fg dx \le \left(\int |f|^p\right)^{\frac{1}{p}} \left(\int |g|^q\right)^{\frac{1}{q}}, \qquad \frac{1}{p} + \frac{1}{q} = 1; \tag{2.8}$$

the Poincaré inequality $|u|_{L^2} \le c\|u\|$; Young's inequality

$$ab \le \frac{\epsilon}{p}a^p + \frac{\epsilon^{-q/p}}{q}b^q, \qquad 1 < p < \infty,\ \frac{1}{p} + \frac{1}{q} = 1; \tag{2.9}$$

and Gronwall's lemma

$$\begin{aligned}
&\frac{dy}{dt} \le gy + h \quad \forall t \ge 0\\
&\quad \Longrightarrow y(t) \le y(0)\exp\left(\int_0^t g(\tau)d\tau\right) + \int_0^t h(s)\exp\left(\int_s^t g(\tau)d\tau\right)ds \quad \forall t \ge 0.
\end{aligned} \tag{2.10}$$

Using the operators A and B, the linearized Navier–Stokes equations (2.2) become

$$\begin{cases}
\dfrac{du}{dt} + \nu Au + B(U,u) + B(u,U) = \mathcal{P}f,\\
u \in V,\\
u = g \text{ at } t = 0,
\end{cases} \tag{2.11}$$

where the regularity required on f, g is

$$f \in L^2(0,T;\mathbf{L}^2(\Omega)) \quad \forall T > 0,\ g \in V; \quad U \in L^\infty(0,T;V) \cap L^2(0,T;D(A)). \tag{2.12}$$

Similarly, application of the Leray projector to the fully nonlinear problem (2.3) gives (with $\tau = 1$)

$$\begin{cases} \dfrac{du}{dt} + \nu Au + B(U,u) + B(u,U) + \tau B(u,u) = \mathcal{P}f, \\ u \in V, \\ u = g \text{ at } t = 0. \end{cases} \tag{2.13}$$

Hereafter, $\tau \in R$ is a nondimensional parameter.

3. Robust control.

3.1. Body force control framework. Following the framework presented in [6], the interior forcing f is decomposed into a disturbance $\psi \in L^2(0,T;\mathbf{L}^2(\Omega))$ and a control $\phi \in L^2(0,T;\mathbf{L}^2(\Omega))$, with $T > 0$. Thus, we write

$$f = B_1\psi + B_2\phi,$$

where B_1 and B_2 are bounded operators on $(L^2(\Omega))^2$. We will also write

$$\mathcal{P}f = \mathcal{B}_1\psi + \mathcal{B}_2\phi,$$

where $\mathcal{B}_1 = \mathcal{P}B_1$ and $\mathcal{B}_2 = \mathcal{P}B_2$ are mappings from $\mathbf{L}^2(\Omega)$ to H. In this section, the cost functional is given by

$$\begin{aligned} \mathcal{J}(\psi,\phi) = {} & \frac{1}{2}\int_0^T |\mathcal{C}_1 u|_{L^2}^2\, dt + \frac{1}{2}\,|\mathcal{C}_2 u(T)|_{L^2}^2 - \frac{1}{2}\int_0^T \left\langle \mathcal{C}_3 \nu \frac{\partial u}{\partial n}, \vec{r} \right\rangle_{\mathbf{L}^2(\partial\Omega)} dt \\ & + \frac{1}{2}\int_0^T \left[l^2\,|\phi|_{L^2}^2 - \gamma^2\,|\psi|_{L^2}^2 \right] dt, \end{aligned} \tag{3.1}$$

where the scalar control parameters γ and l are given, $\vec{r}$ is a known vector field on $\partial\Omega$, $\vec{n}$ is the unit normal vector to $\partial\Omega$, and $\mathcal{C}_3^*\vec{r}\cdot\vec{n} = 0$. The operators $\mathcal{C}_1$ and $\mathcal{C}_2$ are unbounded linear operators on $\mathbf{L}^2(\Omega)$ satisfying

$$|\mathcal{C}_i v|_{\mathbf{L}^2(\Omega)} \le c\|v\| \quad \text{for } i = 1,2, \quad \forall v \in V, \tag{3.2}$$

and $\mathcal{C}_3$ is a bounded linear operator of $\mathbf{L}^2(\partial\Omega)$. The reader is referred to [6] for more details. Some particular interesting cases are

- $\mathcal{C}_1 = d_1 I$ and $\mathcal{C}_2 = \mathcal{C}_3 = 0 \Longrightarrow$ regulation of the turbulent kinetic energy;
- $\mathcal{C}_1 = d_2\nabla\times$ and $\mathcal{C}_2 = \mathcal{C}_3 = 0 \Longrightarrow$ regulation of the square of the vorticity;
- $\mathcal{C}_2 = d_3 I$ and $\mathcal{C}_1 = \mathcal{C}_3 = 0 \Longrightarrow$ terminal control of the turbulent kinetic energy;
- $\mathcal{C}_3 = d_4 I$ and $\mathcal{C}_1 = \mathcal{C}_2 = 0 \Longrightarrow$ minimization of the time-average skin-friction in the direction of the vector $\vec{r}$ integrated over the boundary of the domain.

We consider the following robust control problem, referred to as Problem I.

Problem I. Find $(\bar{\psi},\bar{\phi}) \in L^2(0,T;\mathbf{L}^2(\Omega)) \times L^2(0,T;\mathbf{L}^2(\Omega))$ such that

$$\mathcal{J}(\bar{\psi},\bar{\phi}) = \min_{\phi\in D}\sup_{\psi\in X} \mathcal{J}(\psi,\phi) = \max_{\psi\in X}\inf_{\phi\in D} \mathcal{J}(\psi,\phi),$$

subject to the Navier–Stokes equations (2.13), where $X = D = L^2(0,T;\mathbf{L}^2(\Omega))$. With Problem I we associate the following coupled system (3.3)–(3.5):

$$\begin{cases} \dfrac{du}{dt} + \nu Au + B(U,u) + B(u,U) + \tau B(u,u) = \mathcal{B}_1\psi + \mathcal{B}_2\phi, \\ u \in V, \\ u = g \text{ at } t = 0, \end{cases} \tag{3.3}$$

$$\text{(3.4)}\quad \begin{cases} -\dfrac{d\tilde{u}}{dt} + \nu A^*\tilde{u} + B'(U)^*\tilde{u} + \tau B'(u)^*\tilde{u} = \mathcal{C}_1^*\mathcal{C}_1 u, \\ \tilde{u}(t) \in V_r = \left\{ v \in (H^1(\Omega))^2;\ \text{div } v = 0 \text{ in } \Omega,\ v = \mathcal{C}_3^*\vec{r} \text{ on } \partial\Omega \right\},\ t < T, \\ \tilde{u}(T) = \mathcal{C}_2^*\mathcal{C}_2 u(T) \in H, \end{cases}$$

$$\text{(3.5)}\quad \begin{cases} \gamma^2\psi - \mathcal{B}_1^*\tilde{u} = 0, \\ l^2\phi + \mathcal{B}_2^*\tilde{u} = 0, \end{cases}$$

where A^* is the unbounded operator on $H \cap (H^1(\Omega))^2$ defined by

$$\text{(3.6)}\quad \langle u', A^*\tilde{u}\rangle = \langle Au', \tilde{u}\rangle + \left\langle \frac{\partial u'}{\partial n}, \tilde{u} \right\rangle_{\mathbf{L}^2(\partial\Omega)} \quad \text{for } u' \in D(A),\ \tilde{u} \in H \cap (H^1(\Omega))^2.$$

In [6], the authors proposed an iterative method for the numerical solution of Problem I. This method is based on a repeated computation of the state equation (3.3) and the adjoint equation (3.4). The purpose of this article is to prove the convergence of the algorithm proposed in [6]. To achieve that goal, we rewrite the system (3.3)–(3.5) as a fixed-point problem. Then, using a contraction mapping argument, we prove the convergence of the algorithm, and we obtain its rate of convergence as well.

Linear case. Hereafter, we assume that $\mathcal{C}_3 = 0$. We consider the problem (3.3)–(3.5) in which $\tau = 0$. For $\tau = 0$ and $\mathcal{C}_3 = 0$, we obtain the following system:

$$\text{(3.7)}\quad \begin{cases} \dfrac{du}{dt} + \nu Au + B(U,u) + B(u,U) = \mathcal{B}_1\psi + \mathcal{B}_2\phi, \\ u \in V, \\ u = g \text{ at } t = 0, \end{cases}$$

$$\text{(3.8)}\quad \begin{cases} -\dfrac{d\tilde{u}}{dt} + \nu A^*\tilde{u} + B'(U)^*\tilde{u} = \mathcal{C}_1^*\mathcal{C}_1 u, \\ \tilde{u}(t) \in V,\ t < T, \\ \tilde{u}(T) = \mathcal{C}_2^*\mathcal{C}_2 u(T) \in H, \end{cases}$$

$$\text{(3.9)}\quad \begin{cases} \gamma^2\psi - \mathcal{B}_1^*\tilde{u} = 0, \\ l^2\phi + \mathcal{B}_2^*\tilde{u} = 0. \end{cases}$$

The following result was proven in [6].

PROPOSITION 3.1. *If γ is large enough, then* (3.7)–(3.9) *has a unique solution.*

The purpose of this part is to prove the existence and uniqueness of solutions to (3.7)–(3.9) using a contraction mapping method, and therefore we derive an iterative method (fixed-point iteration method) for the numerical solution of (3.7)–(3.9). Let $\rho > 0$ be a constant, and consider the operator G defined from $\mathbf{Z} \equiv L^2(0,T;\mathbf{L}^2(\Omega)) \times L^2(0,T;\mathbf{L}^2(\Omega))$ into itself by

$$\text{(3.10)}\quad G(\psi,\phi) = (\psi,\phi) - \rho\,(\gamma^2\psi - \mathcal{B}_1^*\tilde{u}, l^2\phi + \mathcal{B}_2^*\tilde{u}),$$

where $\tilde{u}$ is given by (3.7)–(3.8). It is easy to check that (ψ,ϕ) is a fixed point of G if and only if (ψ,ϕ) solves (3.7)–(3.8). The following result holds true.

PROPOSITION 3.2. *Assume that γ is large enough. Then there exists $\rho_0 > 0$ such that G is a contraction from $\mathbf{Z}$ into itself for $\rho < \rho_0$.*

Proof. Let $(\psi_i, \phi_i) \in \mathbf{Z} = L^2(0,T;\mathbf{L}^2(\Omega)) \times L^2(0,T;\mathbf{L}^2(\Omega))$, $i = 1, 2$. Let $(\psi, \phi) = (\psi_1, \phi_1) - (\psi_2, \phi_2)$, $u = u_1 - u_2$, $\tilde{u} = \tilde{u}_1 - \tilde{u}_2$. Then we have

$$\begin{cases} \dfrac{du}{dt} + \nu Au + B(u,U) + B(U,u) = \mathcal{B}_1\psi + \mathcal{B}_2\phi, \\ u \in V, \\ u = 0 \text{ at } t = 0, \end{cases} \tag{3.11}$$

$$\begin{cases} -\dfrac{d\tilde{u}}{dt} + \nu A^*\tilde{u} + B'(U)^*\tilde{u} = \mathcal{C}_1^*\mathcal{C}_1 u, \\ \tilde{u}(t) \in V,\ t < T, \\ \tilde{u}(T) = \mathcal{C}_2^*\mathcal{C}_2 u(T) \in H. \end{cases} \tag{3.12}$$

If we set $G(\psi,\phi) = G(\psi_1,\phi_1) - G(\psi_2,\phi_2)$, then we have

$$\begin{aligned} \|G(\psi,\phi)\|_{\mathbf{Z}}^2 = {} & \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds - 2\rho\gamma^2 \int_0^T |\psi(s)|^2 ds - 2\rho l^2 \int_0^T |\phi(s)|^2 ds \\ & + 2\rho \int_0^T (\psi, \mathcal{B}_1^*\tilde{u}) ds - 2\rho \int_0^T (\phi, \mathcal{B}_2^*\tilde{u}) ds + \rho^2 \int_0^T |\gamma^2\psi - \mathcal{B}_1^*\tilde{u}|^2 ds \\ & + \rho^2 \int_0^T |l^2\phi + \mathcal{B}_2^*\tilde{u}|^2 ds. \end{aligned} \tag{3.13}$$

Thanks to (3.11) and (3.12), we have

$$-2\rho \int_0^t (\phi, \mathcal{B}_2^*\tilde{u}) ds = 2\rho \int_0^t (\psi, \mathcal{B}_1^*\tilde{u}) ds - 2\rho \int_0^t |\mathcal{C}_1 u(s)|^2 ds - 2\rho |\mathcal{C}_2 u(T)|^2. \tag{3.14}$$

Reporting (3.14) in (3.13), we get

$$\begin{aligned} \|G(\psi,\phi)\|_{\mathbf{Z}}^2 = {} & \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds - 2\rho\gamma^2 \int_0^T |\psi(s)|^2 ds - 2\rho l^2 \int_0^T |\phi(s)|^2 ds \\ & + 4\rho \int_0^T (\psi, \mathcal{B}_1^*\tilde{u}) ds - 2\rho \int_0^T |\mathcal{C}_1 u(s)|^2 ds \\ & - 2\rho |\mathcal{C}_2 u(T)|^2 + \rho^2 \int_0^T |\gamma^2\psi - \mathcal{B}_1^*\tilde{u}|^2 ds + \rho^2 \int_0^T |l^2\phi + \mathcal{B}_2^*\tilde{u}|^2 ds. \end{aligned} \tag{3.15}$$

Using Young's inequality and the continuity of the operators $\mathcal{B}_1^*$ and $\mathcal{B}_2^*$ in (3.15), we obtain the estimate

$$\begin{aligned} \|G(\psi,\phi)\|_{\mathbf{Z}}^2 \le {} & (1 - 2\rho\gamma^2 + \tfrac{2\rho}{\varepsilon} + 2\rho^2\gamma^4) \int_0^T |\psi(s)|^2 ds + 2\rho c_1 \varepsilon \int_0^T |\tilde{u}(s)|^2 ds \\ & + (1 - 2\rho l^2 + 2\rho^2 l^4) \int_0^T |\phi(s)|^2 ds + 4\rho^2 c_1 \int_0^T |\tilde{u}(s)|^2 ds - 2\rho \int_0^T |\mathcal{C}_1 u(s)|^2 ds \\ & - 2\rho |\mathcal{C}_2 u(T)|^2, \end{aligned} \tag{3.16}$$

where here and in what follows, c_1 denotes different positive constants depending only on Ω, U, and T.

To complete the proof of this proposition, it remains to conveniently estimate the integrals involving $\tilde{u}$.

From (3.12), by applying the Cauchy–Schwarz, Poincaré, and Young's inequalities, we obtain that

$$\begin{aligned} -\tfrac{1}{2}\tfrac{d}{dt}|\tilde{u}|^2 + \nu\|\tilde{u}\|^2 &\le |b(\tilde{u},U,\tilde{u})| + c|\mathcal{C}_1 u|\|\tilde{u}\| \\ &\le c|\mathcal{C}_1 u|^2 + \tfrac{\nu}{4}\|\tilde{u}\|^2 + c\|U\||\tilde{u}|\|\tilde{u}\|, \end{aligned} \tag{3.17}$$

which gives

$$-\tfrac{1}{2}\tfrac{d}{dt}|\tilde{u}|^2 + \nu\|\tilde{u}\|^2 \le c|\mathcal{C}_1 u|^2 + \tfrac{\nu}{2}\|\tilde{u}\|^2 + c\|U\|^2|\tilde{u}|^2. \tag{3.18}$$

Gronwall's inequality gives

$$\begin{aligned} |\tilde{u}(t)|^2 &\le e^{N_0(t)}|\tilde{u}(T)|^2 + ce^{N_0(t)}\int_t^T |\mathcal{C}_1 u(s)|^2 ds \\ &\le c_1|\mathcal{C}_2 u(T)|^2 + c_1\int_0^T |\mathcal{C}_1 u(s)|^2 ds, \end{aligned} \tag{3.19}$$

where $N_0(t) = c\int_t^T \|U(s)\|^2 ds$ and c is a constant depending only on Ω.

From (3.11), we also have (see [6])

$$\begin{aligned} |u(t)|^2 &\le ce^{M_0(t)}\int_0^t \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds \\ &\le c_1\int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds, \end{aligned} \tag{3.20}$$

where $M_0(t) = c\int_0^t \|U(s)\|^2 ds$. Thanks to (3.20) and the continuity of the operators $\mathcal{C}_1$ and $\mathcal{C}_2$, we derive from (3.19) that

$$|\tilde{u}(t)|^2 \le c_1\int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds. \tag{3.21}$$

Reporting (3.19) and (3.21) in (3.16), we find

$$\begin{aligned} \|G(\psi,\phi)\|_{\mathbf{Z}}^2 &\le (1 - 2\rho\gamma^2 + \tfrac{2c_1\rho}{\varepsilon} + 2\rho^2\gamma^4)\int_0^T |\psi(s)|^2 ds + 2\rho c_1\varepsilon\int_0^T |\mathcal{C}_1 u(s)|^2 ds \\ &+ 2\rho c_1\varepsilon|\mathcal{C}_2 u(T)|^2 + (1 - 2\rho l^2 + 2\rho^2 l^4)\int_0^T |\phi(s)|^2 ds + 4\rho^2 c_1\int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds \\ &- 2\rho\int_0^T |\mathcal{C}_1 u(s)|^2 ds - 2\rho|\mathcal{C}_2 u(T)|^2. \end{aligned} \tag{3.22}$$

Choosing $\varepsilon = c_1^{-1}$ in (3.22) yields

$$\begin{aligned} \|G(\psi,\phi)\|_{\mathbf{Z}}^2 &\le (1 - 2\rho\gamma^2 + 2c_1\rho + 2\rho^2(\gamma^4 + 2c_1))\int_0^T |\psi(s)|^2 ds \\ &\quad + (1 - 2\rho l^2 + 2\rho^2(l^4 + 2c_1))\int_0^T |\phi(s)|^2 ds \\ &\le \max\{1 - 2\rho\gamma^2 + 2c_1\rho + 2\rho^2(\gamma^4 + 2c_1), 1 - 2\rho l^2 + 2\rho^2(l^4 + 2c_1)\} \\ &\quad \times \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds. \end{aligned} \tag{3.23}$$

It is then obvious to check that G is a contraction if γ is large enough and $\rho < \min\{\frac{\gamma^2-c_1}{\gamma^4+2c_1}, \frac{l^2}{l^4+2c_1}\}$; this completes the proof of Proposition 3.2. ∎

Nonlinear case. In this part we study the nonlinear problem, that is (3.3)–(3.5) with $\tau = 1$. For $(\psi, \phi) \in \mathbf{Z} \equiv L^2(0,T;\mathbf{L}^2(\Omega)) \times L^2(0,T;\mathbf{L}^2(\Omega))$, we set

$$G(\psi,\phi) = (\psi,\phi) - \rho\,(\gamma^2\psi - \mathcal{B}_1^*\tilde{u}, l^2\phi + \mathcal{B}_2^*\tilde{u}), \tag{3.24}$$

where $\rho > 0$ is a constant and $\tilde{u}$ is given by (3.3)–(3.4). We will prove that G is a contraction defined on an appropriate subset $\mathcal{X}$ of $\mathbf{Z}$.

Some a priori estimates. Now let $R > 0$ and

$$\mathcal{X}(R) = \left\{(\psi,\phi) \in \mathbf{Z};\ \int_0^T (|\psi(s)|_{L^2}^2 + |\phi(s)|_{L^2}^2)ds \le R^2\right\}.$$

Hereafter we will denote by c_1 a positive constant that depends on Ω, T, and U and whose values may be different in each inequality. Multiplying $(3.3)_1$ by u and applying the Cauchy–Schwarz, Poincaré, and Young's inequalities, we obtain (see [6])

$$\begin{aligned} &|u(t)|_{L^2}^2 \le e^{M_0(t)}|u_0|_{L^2}^2 + ce^{M_0(t)}\int_0^t (|\psi(s)|_{L^2}^2 + |\phi|_{L^2}^2)ds,\\ &\frac{1}{t}\int_0^t \|u(s)\|ds \le \frac{1}{t}e^{M_0(t)}|g|_{L^2}^2 + \frac{1}{t}e^{M_0(t)}\int_0^t (|\psi(s)|_{L^2}^2 + |\phi|_{L^2}^2)ds, \end{aligned} \tag{3.25}$$

where

$$M_0(t) = c\int_0^t \|U\|^2 d\tau \le c_1. \tag{3.26}$$

Now, multiplying $(3.4)_1$ by $\tilde{u}$ and applying the Cauchy–Schwarz, Poincaré, and Young's inequalities, we obtain

$$\begin{aligned} -\tfrac{1}{2}\tfrac{d}{dt}|\tilde{u}|_{L^2}^2 + \nu\|\tilde{u}\|^2 &\le |b(\tilde{u},U+u,\tilde{u})| + |b(U+u,\tilde{u},\tilde{u})| + c|\mathcal{C}_1 u|_{L^2}\|\tilde{u}\|\\ &\le c|\mathcal{C}_1 u|^2 + \tfrac{\nu}{4}\|\tilde{u}\|^2 + c|\tilde{u}|_{L^2}\|\tilde{u}\|\|U+u\|\\ &\le c|\mathcal{C}_1 u|^2 + \tfrac{\nu}{2}\|\tilde{u}\|^2 + c(\|U\|^2 + \|u\|^2)|\tilde{u}|^2, \end{aligned} \tag{3.27}$$

from which we derive

$$\begin{aligned} |\tilde{u}(t)|_{L^2}^2 &\le e^{N_0(t)}|\tilde{u}(T)|_{L^2}^2 + e^{N_0(t)}\int_t^T |u(s)|_{L^2}^2 ds\\ &\le c_1|\mathcal{C}_2 u(T)|_{L^2}^2 + c_1\int_0^T |\mathcal{C}_1 u(s)|_{L^2}^2 ds, \end{aligned} \tag{3.28}$$

where $N_0(t) = c\int_t^T (\|U(s)\|^2 + \|u(s)\|^2)ds \le c_1$.

PROPOSITION 3.3. *Assume that γ is large enough and that R and $|g|_{L^2}$ are small enough. Then there exists $\rho_1 > 0$ such that G maps $\mathcal{X}(R)$ into $\mathcal{X}(R)$ for $\rho \le \rho_1$.*

Proof. Let $(\psi,\phi) \in \mathcal{X}(R)$. We shall prove that $G(\psi,\phi) \in \mathcal{X}(R)$ for γ large enough, R, $|g|_{L^2}$, and ρ small enough. As in the linear case, it is easy to check that

(3.29)
$$\begin{aligned}\|G(\psi,\phi)\|_{\mathbf{Z}}^2 = &\int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds - 2\rho\gamma^2 \int_0^T |\psi(s)|^2 ds - 2\rho l^2 \int_0^T |\phi(s)|^2 ds \\ &+ 2\rho \int_0^T (\psi, \mathcal{B}_1^* \tilde{u}) ds - 2\rho \int_0^T (\phi, \mathcal{B}_2^* \tilde{u}) ds + \rho^2 \int_0^T |\gamma^2 \psi - \mathcal{B}_1^* \tilde{u}|^2 ds \\ &+ \rho^2 \int_0^T |l^2 \phi + \mathcal{B}_2^* \tilde{u}|^2 ds.\end{aligned}$$

It follows from (3.3) and (3.4) that

$$\begin{aligned}-2\rho \int_0^T (\phi, \mathcal{B}_2^* \tilde{u}) ds = &2\rho \int_0^T (\psi, \mathcal{B}_1^* \tilde{u}) ds - 2\rho \int_0^T |\mathcal{C}_1 u(s)|^2 ds - 2\rho |\mathcal{C}_2 u(T)|^2 \\ &+ 2\rho (g, \tilde{u}(0)) + 2\rho \int_0^T b(u,u,\tilde{u}) ds.\end{aligned} \tag{3.30}$$

Reporting (3.30) in (3.29), we get

(3.31)
$$\begin{aligned}\|G(\psi,\phi)\|_{\mathbf{Z}}^2 = &\int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds - 2\rho\gamma^2 \int_0^T |\psi(s)|^2 ds - 2\rho l^2 \int_0^T |\phi(s)|^2 ds \\ &+ 4\rho \int_0^T (\psi, \mathcal{B}_1^* \tilde{u}) ds - 2\rho \int_0^T |\mathcal{C}_1 u(s)|^2 ds + 2\rho \int_0^T b(u,u,\tilde{u}) ds \\ &- 2\rho |\mathcal{C}_2 u(T)|^2 + \rho^2 \int_0^T |\gamma^2 \psi - \mathcal{B}_1^* \tilde{u}|^2 ds + \rho^2 \int_0^T |l^2 \phi + \mathcal{B}_2^* \tilde{u}|^2 ds + 2\rho (g, \tilde{u}(0)).\end{aligned}$$

Thanks to the continuity of the operators $\mathcal{B}_1^*$ and $\mathcal{B}_2^*$, we have

$$\int_0^T |\mathcal{B}_i^* \tilde{u}(s)|^2 ds \le c \int_0^T |\tilde{u}(s)|^2 ds \le c_1 \int_0^T |\mathcal{C}_1 u(s)|^2 ds + c_1 |\mathcal{C}_2 u(T)|^2. \tag{3.32}$$

On the other hand, (2.7), (3.25), and (3.28) show that

$$\int_0^T |b(u,u,\tilde{u})| ds \le c_1 \{|g|^2 + R^2\} \left\{ \int_0^T |\mathcal{C}_1 u(s)|^2 ds + |\mathcal{C}_2 u(T)|^2 \right\}^{\frac{1}{2}}. \tag{3.33}$$

Using Young's inequality as well as (3.32) and (3.33) in (3.31), we find

(3.34)
$$\begin{aligned}\|G(\psi,\phi)\|_{\mathbf{Z}}^2 \le &\left(1 - 2\rho\gamma^2 + \frac{2c_1\rho}{\varepsilon} + 2\rho^2\gamma^4\right) \int_0^T |\psi(s)|^2 ds + 2\rho\varepsilon \int_0^T |\mathcal{C}_1 u(s)|^2 ds \\ &+ 2\rho\varepsilon |\mathcal{C}_2 u(T)|^2 + (1 - 2\rho l^2 + 2\rho^2 l^4) \int_0^T |\phi(s)|^2 ds \\ &+ 4\rho^2 c_1 \left\{ \int_0^T |\mathcal{C}_1 u(s)|^2 ds + |\mathcal{C}_2 u(T)|^2 \right\} \\ &+ \rho\eta \left\{ \int_0^T |\mathcal{C}_1 u(s)|^2 ds + |\mathcal{C}_2 u(T)|^2 \right\} + \frac{\rho}{\eta} c_1 |g|^2 \\ &+ \rho\delta \left\{ \int_0^T |\mathcal{C}_1 u(s)|^2 ds + |\mathcal{C}_2 u(T)|^2 \right\} + \frac{\rho}{\delta} c_1 (|g|^2 + R^2)^2 \\ &- 2\rho \int_0^T |\mathcal{C}_1 u(s)|^2 ds - 2\rho |\mathcal{C}_2 u(T)|^2 \quad \forall \varepsilon, \eta, \delta > 0.\end{aligned}$$

Choosing $\varepsilon = \eta = \delta = \frac{1}{4}$ and

$$\rho \leq \frac{1}{4c_1} \tag{3.35}$$

in (3.34), it follows that

(3.36)

$$\|G(\psi,\phi)\|_{\mathbf{Z}}^2 \leq (1 - 2\rho\gamma^2 + 8c_1\rho + 2\rho^2\gamma^4)\int_0^T |\psi(s)|^2 ds + 4\rho c_1|g|^2 + 4\rho c_1(|g|^2 + R^2)^2 + (1 - 2\rho l^2 + 2\rho^2 l^4)\int_0^T |\phi(s)|^2 ds.$$

We notice that, for the inequality $\|G(\psi,\phi)\|_{\mathbf{Z}} \leq R$ to hold, we shall have

$$1 - 2\rho\gamma^2 + 8c_1\rho + 2\rho^2\gamma^4 + 4\rho c_1\left\{\frac{|g|^2 + (|g|^2 + R^2)^2}{R^2}\right\} \leq 1 \tag{3.37}$$

and

$$1 - 2\rho l^2 2\rho^2 l^4 + 4\rho c_1\left\{\frac{|g|^2 + (|g|^2 + R^2)^2}{R^2}\right\} \leq 1. \tag{3.38}$$

It is obvious that, for γ large enough, (3.37) holds true with

$$\rho \leq \frac{\gamma^2 - 4c_1 - 2c_1\left\{\frac{|g|^2 + (|g|^2 + R^2)^2}{R^2}\right\}}{\gamma^4}. \tag{3.39}$$

As for (3.38), the inequality holds for l large enough; however, choosing l large enough makes the control very expensive, so for practical reasons, we will avoid this choice. The price to pay is to choose R and g small enough. We now make precise what we mean by choosing R and g small. Let $\theta \in (0,1)$, and assume that $|g|^2 \leq R^{2+\theta}$. Then (3.38) holds true, provided

$$-2l^2 + 2\rho l^4 + 4c_1\left\{R^\theta + R^2(R^\theta + 1)^2\right\} \leq 0. \tag{3.40}$$

For (3.40) to hold, it is enough to choose R and ρ so that

$$\begin{aligned} &-l^2 + 4c_1\left\{R^\theta + R^2(R^\theta + 1)^2\right\} \leq 0, \\ &-l^2 + 2\rho l^4 \leq 0. \end{aligned} \tag{3.41}$$

Since we may choose R as small as we want, this completes the proof. ∎

PROPOSITION 3.4. *Assume that γ is large enough and that R and $|g|_{L^2}$ are small enough. Then there exists $\rho_2 > 0$ such that G is a contraction from $\mathcal{X}(R)$ into $\mathcal{X}(R)$ for $\rho < \rho_2$.*

Proof. Let $(u_i, \tilde{u}_i)$ be the solution of (3.3)–(3.4) with (ψ,ϕ) replaced by (ψ_i,ϕ_i), $i = 1,2$. Let $u = u_1 - u_2$, $\psi = \psi_1 - \psi_2$, and $\phi = \phi_1 - \phi_2$. Then $(u, \tilde{u}, \psi, \phi)$ satisfies

$$\begin{cases} \dfrac{du}{dt} + \nu Au + B(u,U) + B(U,u) + B(u_1,u) + B(u,u_2) = \mathcal{B}_1\psi + \mathcal{B}_2\phi, \\ u \in V, \\ u = 0 \text{ at } t = 0, \end{cases} \tag{3.42}$$

$$\begin{cases} -\dfrac{d\tilde{u}}{dt} + \nu A^*\tilde{u} + B'(U+u_1)^*\tilde{u} + B'(u)^*\tilde{u}_2 = \mathcal{C}_1^*\mathcal{C}_1 u, \\ \tilde{u}(t) \in V,\ t < T, \\ \tilde{u}(T) = \mathcal{C}_2^*\mathcal{C}_2 u(T) \in H, \end{cases} \tag{3.43}$$

$$\begin{cases} \gamma^2\psi - \mathcal{B}_1^*\tilde{u} = 0, \\ l^2\phi + \mathcal{B}_2^*\tilde{u} = 0. \end{cases} \tag{3.44}$$

Now set $G(\psi,\phi) = G(\psi_1,\phi_1) - G(\psi_2,\phi_2)$, where G is given as in (3.24). We shall prove that G is a contraction on $\mathcal{X}(R)$. To this end, it suffices to show that $\|G(\psi,\phi)\|_{\mathbf{Z}} \le k\|(\psi,\phi)\|_{\mathbf{Z}}$ for some $0 < k < 1$. For this purpose we need some estimates on u and $\tilde{u}$.

Multiplying $(3.42)_1$ by u, we derive

$$\begin{aligned} &|u(t)|_{L^2}^2 \le e^{M_1(t)} \int_0^t (|\psi(s)|_{L^2}^2 + |\phi|_{L^2}^2)ds, \\ &\frac{1}{t}\int_0^t \|u(s)\|^2 ds \le \frac{1}{t} e^{M_1(t)} \int_0^t (|\psi(s)|_{L^2}^2 + |\phi|_{L^2}^2)ds, \end{aligned} \tag{3.45}$$

where

$$M_1(t) = c\int_0^t (\|U(s)\|^2 + \|u_2(s)\|^2)ds \le c_1. \tag{3.46}$$

Let us notice that

$$\begin{aligned} \langle B'(U+u_1)^*\tilde{u} + B'(u)^*\tilde{u}_2, \tilde{u}\rangle_{V',V} &= b(U+u_1,\tilde{u},\tilde{u}) \\ &\quad + b(\tilde{u},U+u_1,\tilde{u}) + b(u,\tilde{u},\tilde{u}_2) + b(\tilde{u},u,\tilde{u}_2). \end{aligned} \tag{3.47}$$

Moreover,

$$\begin{aligned} |b(\tilde{u},U+u_1,\tilde{u})| &\le c|\tilde{u}|_{L^2}\|\tilde{u}\|(\|U\| + \|u_1\|) \\ &\le \tfrac{\nu}{8}\|\tilde{u}\|^2 + c(\|U\|^2 + \|u_1\|^2)|\tilde{u}|_{L^2}^2, \end{aligned} \tag{3.48}$$

$$\begin{aligned} |b(u,\tilde{u},\tilde{u}_2)| &\le c|u|_{L^2}^{\frac{1}{2}}\|u\|^{\frac{1}{2}}\|\tilde{u}\||\tilde{u}_2|_{L^2}^{\frac{1}{2}}\|\tilde{u}_2\|^{\frac{1}{2}} \\ &\le \tfrac{\nu}{8}\|\tilde{u}\|^2 + c|u|_{L^2}\|u\||\tilde{u}_2|_{L^2}\|\tilde{u}_2\|, \end{aligned} \tag{3.49}$$

$$\begin{aligned} |b(\tilde{u},u,\tilde{u}_2)| &\le c|\tilde{u}|_{L^2}^{\frac{1}{2}}\|\tilde{u}\|^{\frac{1}{2}}\|u\||\tilde{u}_2|_{L^2}^{\frac{1}{2}}\|\tilde{u}_2\|^{\frac{1}{2}} \\ &\le \tfrac{\nu}{8}\|\tilde{u}\|^2 + c|\tilde{u}|_{L^2}^{\frac{2}{3}}\|u\|^{\frac{4}{3}}|\tilde{u}_2|_{L^2}^{\frac{2}{3}}\|\tilde{u}_2\|^{\frac{2}{3}} \\ &\le \tfrac{\nu}{8}\|\tilde{u}\|^2 + c\|u\|^2|\tilde{u}_2|_{L^2} + c|\tilde{u}|_{L^2}^2\|\tilde{u}_2\|^2. \end{aligned} \tag{3.50}$$

Multiplying $(3.43)_1$ by $\tilde{u}$ and using (3.47)–(3.50), we obtain

$$\begin{aligned} -\tfrac{1}{2}\tfrac{d}{dt}|\tilde{u}|_{L^2}^2 + \nu\|\tilde{u}\|^2 &\le c|\mathcal{C}_1 u|_{L^2}^2 + \tfrac{\nu}{2}\|\tilde{u}\|^2 + c\|u\|^2|\tilde{u}_2|_{L^2} + c(\|U\|^2 + \|u_1\|^2)|\tilde{u}|_{L^2}^2 \\ &\quad + c|u|_{L^2}\|u\||\tilde{u}_2|_{L^2}\|\tilde{u}_2\| + c|\tilde{u}|_{L^2}^2\|\tilde{u}_2\|^2, \end{aligned} \tag{3.51}$$

from which we derive (using (3.45))

(3.52)
$$
\begin{aligned}
|\tilde{u}(t)|^2_{L^2} &+ \int_t^T \|\tilde{u}(s)\|^2 ds \leq e^{N_1(t)}|\mathcal{C}_2 u(T)|^2_{L^2} + e^{N_1(t)}\int_t^T |\mathcal{C}_1 u(s)|^2_{L^2} ds \\
&+ e^{N_1(t)}\int_t^T (\|u\|^2 |\tilde{u}_2|_{L^2} + |u(s)|_{L^2}\|u(s)\||\tilde{u}_2|_{L^2}\|\tilde{u}_2(s)\|) ds \\
&\leq e^{N_1(t)}|\mathcal{C}_2 u(T)|^2_{L^2} + e^{N_1(t)}\int_t^T |\mathcal{C}_1 u(s)|^2_{L^2} ds + e^{N_1(t)}\int_t^T \|u\|^2 |\tilde{u}_2|_{L^2} ds \\
&+ e^{N_1(t)} \sup_{s\in[0,T]} |u(s)|_{L^2} \int_t^T |\tilde{u}_2(s)|_{L^2} \left(\int_t^T \|u(s)\|^2 ds\right)^{\frac{1}{2}} \left(\int_t^T \|\tilde{u}_2(s)\|^2 ds\right)^{\frac{1}{2}} \\
&\leq c_1\big((R^2+|g|^2)^{\frac{1}{2}} + R^2 + |g|^2\big)\int_0^T (|\psi(s)|^2_{L^2} + |\phi(s)|^2_{L^2}) ds \\
&+ c_1 \int_0^T |\mathcal{C}_1 u(s)|^2 ds + c_1 |\mathcal{C}_2 u(T)|^2,
\end{aligned}
$$

where $N_1(t) = c\int_t^T (\|U(s)\|^2 + \|u_1(s)\|^2 + \|\tilde{u}_2(s)\|^2) ds \leq c_1$.

Now, proceeding as in the proof of Proposition 3.3, we get

(3.53)
$$
\begin{aligned}
\|G(\psi,\phi)\|^2_{\mathbf{Z}} &= \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds - 2\rho\gamma^2 \int_0^T |\psi(s)|^2 ds - 2\rho l^2 \int_0^T |\phi(s)|^2 ds \\
&+ 4\rho \int_0^T (\psi, \mathcal{B}_1^* \tilde{u}) ds - 2\rho \int_0^T |\mathcal{C}_1 u(s)|^2 ds + 2\rho \int_0^T b(u,u,\tilde{u}) ds + 4\rho \int_0^T b(u,u,\tilde{u}_2) ds \\
&- 2\rho |\mathcal{C}_2 u(T)|^2 + \rho^2 \int_0^T |\gamma^2 \psi - \mathcal{B}_1^* \tilde{u}|^2 ds + \rho^2 \int_0^T |l^2 \phi + \mathcal{B}_2^* \tilde{u}|^2 ds.
\end{aligned}
$$

Thanks to Young's inequality and the continuity of the operators $\mathcal{B}_1^*$ and $\mathcal{B}_2^*$, it follows from (3.53) that

(3.54)
$$
\begin{aligned}
\|G(\psi,\phi)\|^2_{\mathbf{Z}} &\leq \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds - 2\rho\gamma^2 \int_0^T |\psi(s)|^2 ds - 2\rho l^2 \int_0^T |\phi(s)|^2 ds \\
&+ \tfrac{4\rho c_1}{\varepsilon} \int_0^T |\psi|^2 ds + (\varepsilon\rho + 4\rho^2 c_1) \int_0^T |\tilde{u}|^2 ds - 2\rho \int_0^T |\mathcal{C}_1 u(s)|^2 ds + 2\rho \int_0^T b(u,u,\tilde{u}) ds \\
&+ 4\rho \int_0^T b(u,u,\tilde{u}_2) ds - 2\rho |\mathcal{C}_2 u(T)|^2 + 2\rho^2\gamma^4 \int_0^T |\psi|^2 ds \\
&+ 2\rho^2 l^4 \int_0^T |\phi|^2 ds.
\end{aligned}
$$

On the other hand, using (3.45) and (3.52), we get

(3.55)
$$
\begin{aligned}
\int_0^T |b(u,u,\tilde{u})| ds &\leq c_1 \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds \Bigg\{ \int_0^T |\mathcal{C}_1 u(s)|^2 ds + |\mathcal{C}_2 u(T)|^2 \\
&\qquad + \left[(R^2+|g|^2) + (R^2+|g|^2)^{\frac{1}{2}}\right] \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds \Bigg\}^{\frac{1}{2}} \\
&\leq c_1 R \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds \quad \text{for } R \text{ small enough.}
\end{aligned}
$$

Similarly, one can show that

$$\int_0^T |b(u,u,\tilde{u}_2)|ds \le c_1 R \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds. \tag{3.56}$$

Reporting (3.55) and (3.56) in (3.53), using (3.52), and choosing $\varepsilon = \frac{2}{c_1}$, we find

(3.57)

$$\begin{aligned}\|G(\psi,\phi)\|_{\mathbf{Z}}^2 \le & \int_0^T \left(|\psi(s)|^2 + |\phi(s)|^2\right) ds \\ & + (-2\rho\gamma^2 + 2\rho c_1 + \tfrac{2\rho}{c_1}R + 2\rho^2\gamma^4 + 4\rho^2 c_1 + 6\rho R c_1) \int_0^T |\psi(s)|^2 ds \\ & + (-2\rho l^2 + 2\rho^2 l^4 + 4\rho^2 c_1 + \tfrac{2\rho}{c_1}R + 6\rho R c_1) \int_0^T |\phi(s)|^2 ds.\end{aligned}$$

One easily derives from (3.57) that, for G to be a contraction, one shall have

$$1 - 2\rho\gamma^2 + 2\rho c_1 + \frac{2\rho}{c_1}R + 2\rho^2\gamma^4 + 4\rho^2 c_1 + 6\rho R c_1 < 1 \tag{3.58}$$

and

$$1 - 2\rho l^2 + 2\rho^2 l^4 + 4\rho^2 c_1 + \frac{2\rho}{c_1}R + 6\rho R c_1 < 1. \tag{3.59}$$

It is obvious that, for γ large enough, (3.58) holds true with

$$\rho < \frac{\gamma^2 - c_1 - 3c_1 R - \frac{R}{c_1}}{\gamma^4 + 2c_1}. \tag{3.60}$$

As for (3.59), it is easily seen that it holds for R and ρ satisfying

$$\rho < \frac{l^2}{2(l^4 + 2c_1)}, \qquad R < \frac{l^2}{2(3c_1 + \frac{2}{c_1})}, \tag{3.61}$$

which completes the proof of Proposition 3.4. ∎

PROPOSITION 3.5. *Under the hypotheses of Propositions* 3.3 *and* 3.4*, the system* (3.3)–(3.5) *has a unique solution* $(u,\tilde{u},\psi,\phi)$ *for which* $(\psi,\phi) \in \mathcal{X}(R)$.

Proof. It follows from Propositions 3.3 and 3.4 and the fact that if (ψ,ϕ) is a fixed point of G, then $(u,\tilde{u},\psi,\phi)$ is a solution to (3.3)–(3.5), where $(u,\tilde{u})$ is given by (3.3)–(3.4). ∎

3.2. Data assimilation. A classical control problem arising in meteorology and oceanography in relation to data assimilation is the adjustment of initial conditions in order to obtain a flow that agrees with a desired target flow (i.e., the observations). Chaotic problems, such as weather system, are highly susceptible to the small disturbance present in all physical systems. Given a set of measurements of some actual flow $\mathbf{v}$ on $[0,T]$, the problem is to determine a "best" estimate as to the initial state of the model u that leads to the observed system behavior, while simultaneously forcing the model with the worst-case disturbance which perturbs u away from the observed system behavior $\mathbf{v}$. Define $w = u - \mathbf{v}$ as the amount by which the estimated flow

u differs from the observed flow $\mathbf{v}$. The cost function considered for this problem is given by

$$\begin{aligned}\mathcal{J}(\psi,\phi) = \frac{1}{2}\int_0^T |\mathcal{C}_1 w|_{L^2}^2\,dt + \frac{1}{2}\,|\mathcal{C}_2 w(T)|_{L^2}^2 + \frac{1}{2}\int_0^T \left\|\mathcal{C}_3\nu\frac{\partial w}{\partial n}\right\|_{\mathbf{L}^2(\partial\Omega)}^2 dt \\ + \frac{l^2}{2}\,|\phi|_{L^2}^2 - \gamma^2\int_0^T |\psi|_{L^2}^2\,dt,\end{aligned} \tag{3.62}$$

where $\mathcal{C}_3^*\mathcal{C}_3\nu(\partial w/\partial n)\cdot\vec{n} = 0$. The measurements of the actual flow $\mathcal{C}_1\mathbf{v}$, $\mathcal{C}_2\mathbf{v}(T)$, and $\mathcal{C}_3\nu(\partial\mathbf{v}/\partial n)|_{\partial\Omega}$ are assumed to be given. More detail on the functional $\mathcal{J}$ is given in [6]. The results given in this subsection are generalizations of the ones given in the previous subsection; therefore we will omit the proofs. We consider the following robust control problem, related to data assimilation and referred to as Problem II.

Problem II. Find $(\bar{\psi},\bar{\phi}) \in L^2(0,T;\mathbf{L}^2(\Omega)) \times \mathbf{L}^2(\Omega)$ such that

$$\mathcal{J}(\bar{\psi},\bar{\phi}) = \min_{\phi\in D}\sup_{\psi\in X}\mathcal{J}(\psi,\phi) = \max_{\psi\in X}\inf_{\phi\in D}\mathcal{J}(\psi,\phi),$$

subject to the Navier–Stokes equation

$$\begin{cases} \dfrac{du}{dt} + \nu Au + B(U,u) + B(u,U) + \tau B(u,u) = \mathcal{B}_1\psi, \\ u \in V, \\ u = \mathcal{B}_2\phi \text{ at } t = 0, \end{cases} \tag{3.63}$$

where $X = L^2(0,T;\mathbf{L}^2(\Omega))$ and $D = \mathbf{L}^2(\Omega)$. Hereafter, we assume that $\mathcal{C}_3 \equiv 0$. To Problem II we associate the following coupled system:

$$\begin{cases} \dfrac{du}{dt} + \nu Au + B(U,u) + B(u,U) + \tau B(u,u) = \mathcal{B}_1\psi, \\ u \in V, \\ u = \mathcal{B}_2\phi \text{ at } t = 0, \end{cases} \tag{3.64}$$

$$\begin{cases} -\dfrac{d\tilde{u}}{dt} + \nu A\tilde{u} + B'(U)^*\tilde{u} + \tau B'(u)^*\tilde{u} = \mathcal{C}_1^*\mathcal{C}_1(u-\mathbf{v}), \\ \tilde{u}(t) \in V,\ t < T, \\ \tilde{u}(T) = \mathcal{C}_2^*\mathcal{C}_2(u-\mathbf{v})(T) \in H, \end{cases} \tag{3.65}$$

$$\begin{cases} \gamma^2\psi - \mathcal{B}_1^*\tilde{u} = 0, \\ l^2\phi + \mathcal{B}_2^*\tilde{u}(0) = 0, \end{cases} \tag{3.66}$$

where A^* is defined by

$$\langle u', A^*\tilde{u}\rangle = \langle Au', \tilde{u}\rangle \quad \text{for } u' \in D(A) \text{ and } \tilde{u} \in V, \tag{3.67}$$

and $\mathcal{B}_2$ is a mapping from $\mathbf{L}^2(\Omega)$ to V. For the data assimilation (3.64)–(3.66), the operator G is defined from $\mathbf{Z} \equiv L^2(0,T;\mathbf{L}^2(\Omega)) \times \mathbf{L}^2(\Omega)$ into itself by

$$G(\psi,\phi) = (\psi,\phi) - \rho\left(\gamma^2\psi - \mathcal{B}_1^*\tilde{u}, l^2\phi + \mathcal{B}_2^*\tilde{u}(0)\right), \tag{3.68}$$

where ρ is a positive constant and $\tilde{u}$ is given by (3.64)–(3.65). The results obtained for the body force control extend to the data assimilation problem. In particular, if we set

$$\chi(R) = \{(\psi, \phi) \in \mathbf{Z}, \|(\psi, \phi)\|_{\mathbf{Z}} \leq R\},$$

then we have the following result.

PROPOSITION 3.6. *Assume that γ is large enough and that ρ, $\mathbf{v}$, and R are small enough. Then G is a strict contraction from $\mathcal{X}(R)$ into itself.*

Proof. The proof is completely similar to that of Proposition 3.4. ∎

3.3. Iterative method. In this section, we study an iterative method for the numerical solution of the robust control problems presented in this article. This method was proposed in [6] for the numerical solution of Problems I and II. Hereafter, we prove the convergence of the algorithm and we obtain an estimate to the convergence rate. We restrict ourselves to the nonlinear body force control problem (3.3)–(3.5), although the method also applies to the data assimilation problem (3.64)–(3.66). For the sake of clarity, we recall the algorithm proposed in [6].

ALGORITHM.

(1) Initialize $k = 0$ and $(\psi^0, \phi^0) = 0$ on $t \in [0, T]$, where k is the iteration index and (ψ^k, ϕ^k) is the numerical approximation of the disturbance and the control at the kth iteration of the algorithm.

(2) Determine the state u^k on $[0, T]$ from the state equation based on the initial conditions g with the forcing (ψ^k, ϕ^k).

(3) Determine the state $\tilde{u}^k$ on $[0, T]$ from the adjoint equation based on the state u^k.

(4) Determine the local expression of the gradients

$$\frac{\mathrm{D}\mathcal{J}}{\mathrm{D}\psi}(\psi^k, \phi^k) \quad \text{and} \quad \frac{\mathrm{D}\mathcal{J}}{\mathrm{D}\phi}(\psi^k, \phi^k).$$

(5) Determine the updated disturbance ψ^{k+1} with

$$\psi^{k+1} = \psi^k + \alpha^k \frac{\mathrm{D}\mathcal{J}}{\mathrm{D}\psi}(\psi^k, \phi^k),$$

where $0 < M_1 \leq \alpha^k \leq M_2 < 1$, where M_1 and M_2 depend on the second derivative of $\mathcal{J}$.

(6) Determine the updated control ϕ^{k+1} with

$$\phi^{k+1} = \phi^k - \beta^k \frac{\mathrm{D}\mathcal{J}}{\mathrm{D}\phi}(\psi^k, \phi^k),$$

where $0 < M_1 \leq \beta^k \leq M_2 < 1$.

(7) Increment index: $k = k + 1$. Repeat from step (2) until convergence.

Hereafter, we will prove the convergence of the previous algorithm when the iteration parameters α^k and β^k are constant and small enough.

To proceed, set

$$\mathcal{Y} = \begin{cases} L^2(0, T; L^2(\Omega)) & \text{for the linear case,} \\ \mathcal{X}(R) & \text{for the nonlinear case.} \end{cases} \tag{3.69}$$

Propositions 3.2, 3.4, and 3.6 prove that, under certain conditions, G is a strict contraction from $\mathcal{Y}$ into $\mathcal{Y}$. From the contraction mapping principle, G has a unique fixed point $(\psi, \phi) \in \mathcal{Y}$, which is a solution to the robust control problem (3.3)–(3.5). To approximate the solution (ψ, ϕ), we consider the following well known fixed-point iterative method:

$$\begin{aligned} &\text{Choose } (\psi^0, \phi^0) \in \mathcal{Y}, \\ &(\psi^{k+1}, \phi^{k+1}) = G(\psi^k, \phi^k) \quad \text{for } k \geq 0. \end{aligned} \tag{3.70}$$

Then the following results hold true.

PROPOSITION 3.7. *For γ and l large enough, the sequence (ψ^k, ϕ^k) defined by* (3.70) *converges to the unique solution $(\psi, \phi) \in \mathcal{Y}$ of the robust control problem* (3.3)–(3.5) *given by Proposition* 3.5. *Moreover, we have the following estimate of the convergence rate:*

$$\left(\|\psi^k - \psi\|_Y^2 + \|\phi^k - \phi\|_Y^2\right)^{\frac{1}{2}} \leq Q^k (1-Q)^{-1} \left(\|\psi^0 - \psi\|_Y^2 + \|\phi^0 - \phi\|_Y^2\right)^{\frac{1}{2}}, \tag{3.71}$$

where $0 < Q < 1$, with

$$Q^2 = \begin{cases} \max\{1 - 2\rho\gamma^2 + 2c_1\rho + 2\rho^2(\gamma^4 + 2c_1), 1 - 2\rho l^2 + 2\rho^2(l^4 + 2c_1)\} \\ \qquad \textit{for the linear case}, \\ \max\{1 - 2\rho\gamma^2 + 2\rho c_1 + \frac{2\rho}{c_1}R + 2\rho^2\gamma^4 + 4\rho^2 c_1 + 6\rho R c_1, \\ \qquad 1 - 2\rho l^2 + 2\rho^2 l^4 + 4\rho^2 c_1 + \frac{2\rho}{c_1}R + 6\rho R c_1\} \textit{ for the nonlinear case}, \end{cases} \tag{3.72}$$

where γ is large enough and ρ and R are small enough.

Proof. Notice that

$$\|G(\psi_1, \phi_1) - G(\psi_2, \phi_2)\|_{\mathbf{Z}} \leq Q \left(\|\psi_1 - \psi_2\|_X^2 + \|\phi_1 - \phi_2\|_X^2\right)^{\frac{1}{2}}$$

for all $(\psi_1, \phi_1), (\psi_2, \phi_2) \in \mathcal{Y}$. Therefore the proof follows directly from the contraction mapping theory [17]. ∎

Remark 3.1. Let us notice that $(\psi^{k+1}, \phi^{k+1}) = G(\psi^k, \phi^k)$ is computed as

$$\begin{cases} \dfrac{du^k}{dt} + \nu A u^k + B(U, u^k) + B(u^k, U) + B(u^k, u^k) = \mathcal{B}_1 \psi^k + \mathcal{B}_2 \phi^k, \\ u^k \in V, \\ u^k = g \text{ at } t = 0, \end{cases} \tag{3.73}$$

$$\begin{cases} -\dfrac{d\tilde{u}^k}{dt} + \nu A^* \tilde{u}^k + B'(U + u^k)^* \tilde{u}^k = \mathcal{C}_1^* \mathcal{C}_1 u^k, \\ \tilde{u}^k(t) \in V, \ t < T, \\ \tilde{u}^k(T) = \mathcal{C}_2^* \mathcal{C}_2 u^k(T) \in H, \end{cases} \tag{3.74}$$

$$\begin{cases} \psi^{k+1} = \psi^k - \rho(\gamma^2 \psi^k - \mathcal{B}_1^* \tilde{u}^k), \\ \phi^{k+1} = \phi^k - \rho(l^2 \phi^k + \mathcal{B}_2^* \tilde{u}^k). \end{cases} \tag{3.75}$$

Since (see [6])

$$\frac{DJ}{D\psi}(\psi^k, \phi^k) = \mathcal{B}_1^* \tilde{u}^k - \gamma^2 \psi^k \quad \text{and} \quad \frac{DJ}{D\phi}(\psi^k, \phi^k) = \mathcal{B}_2^* \tilde{u}^k + l^2 \phi^k, \tag{3.76}$$

it follows that (3.75) can be rewritten as

$$\left\{\begin{array}{l} \psi^{k+1} = \psi^k + \rho \frac{DJ}{D\psi}(\psi^k, \phi^k), \\ \phi^{k+1} = \phi^k - \rho \frac{DJ}{D\phi}(\psi^k, \phi^k), \end{array}\right. \tag{3.77}$$

which is exactly steps (5) and (6) of the algorithm proposed in [6]. The first to fourth steps are given by (3.73)–(3.75). Therefore, the fixed-point iteration method (3.70) is a particular case of the algorithm proposed in [6] with $\beta^k = \rho$ and $\alpha^k = \rho$. This proves the convergence of the aforementioned iterative method. Moreover, Proposition 3.7 gives an estimate of the convergence rate.

4. Numerical results. In this section, we present some numerical solutions of the data assimilation problem (3.64)–(3.66) obtained using the fixed-point iteration method described in the previous section. A major advantage of the algorithm is that it requires less storage of the fields than do conventional methods such as the Riccati solver. The method is based on repeated computations of the adjoint field (which is just as complicated as the state field). The equations considered in this section are the quasi-geostrophic equations of the ocean given by

$$\left\{\begin{array}{l} \dfrac{\partial \omega}{\partial t} - \nu \Delta \omega + J(\psi, \omega) + \beta \dfrac{\partial \psi}{\partial x} = f, \\ \omega = 0 \text{ on } \partial\Omega, \\ \omega(x, 0) = \omega_0, \end{array}\right. \tag{4.1}$$

where ψ is defined by

$$\left\{\begin{array}{l} \Delta \psi = \omega, \\ \psi = 0 \text{ on } \partial\Omega. \end{array}\right. \tag{4.2}$$

The unknown function ω represents the vorticity of the fluid, and the function ψ is the streamfunction. The constant $\beta > 0$ is the meridional gradient of the Coriolis parameter, and $\nu > 0$ is a constant. The Jacobian operator J is defined by

$$J(u, v) = \frac{\partial u}{\partial x}\frac{\partial v}{\partial y} - \frac{\partial u}{\partial y}\frac{\partial v}{\partial x}.$$

The system (4.1)–(4.2) has been extensively used in analytical and numerical study of ocean models [4, 7, 8, 10, 24]. This system is relatively simple as compared to other ocean models such as the primitive equations of the ocean [12, 13] or the multilayer shallow water equations in [29], but we prefer to emphasize in this article the control aspects and do not look for the most involved ocean model. Another advantage of the system (4.1)–(4.2) is that it captures the key features of large scale oceanic circulation and filters out undesired fast (high frequency) oscillations, which are not easy to handle numerically. Using the notation of [20], we can rewrite the quasi-geostrophic equations into the form

$$\left\{\begin{array}{l} \dfrac{d\omega}{dt} + \nu A\omega + B(\omega, \omega) + E\omega = f, \\ \omega \in V, \\ \omega = \omega_0 \text{ at } t = 0. \end{array}\right. \tag{4.3}$$

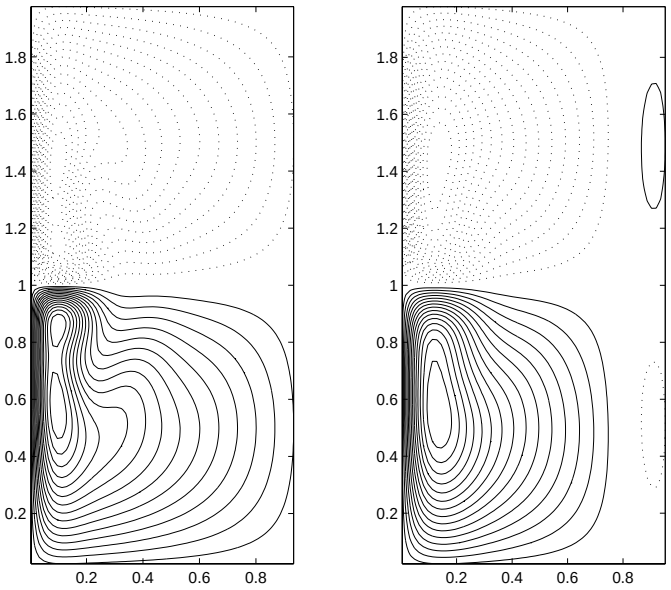

FIG. 1. *Target (streamfunction) flow and state (streamfunction) flow at* $t = T = 0.1$*, for* $\nu = 0.1$*,* $\gamma = 20.0$*,* $l = 20.0$*.*

Define $w = \omega - \mathbf{v}$ as the amount by which the estimated flow ω differs from the observed flow $\mathbf{v}$. The cost function considered in this section is given by (3.62). For simplification, the linear operators $\mathcal{C}_1$, $\mathcal{C}_2$, and $\mathcal{C}_3$ are chosen as $\mathcal{C}_1 w = d_1 w$, $\mathcal{C}_2 w = d_2 w$, and $\mathcal{C}_3 = 0$, where d_1 and d_2 are constants. The functional $\mathcal{J}(f_1, f_2)$ measures the errors $\mathcal{C}_1 w$ and $\mathcal{C}_2 w$ on the interior and at the final time, respectively. To find the best estimate ω of the actual flow $\mathbf{v}$, we seek the best initial condition f_2 subject to the worst-case disturbance forcing f_1 such that $\mathcal{J}$ is minimized with respect to f_1 and maximized with respect to f_1, where ω is a solution of the quasi-geostrophic equations (4.3). More detail on the numerical results presented hereafter will appear elsewhere.

Experiment. The focus of this numerical experiment is to apply the algorithm described previously to approximate the solutions of the data assimilation problem (3.64)–(3.66). In our simulations, the (nondimensional) domain is the rectangular basin $[0, 1] \times [0, 2]$. In order to compute the solutions of (3.64)–(3.66), we need to discretize the problem in both time and space. For the time discretization, the numerical scheme presented in [19] is used for the time integration of the state and the adjoint equation. For the space discretization, we use a centered finite-difference scheme of order 2. For the Jacobian operator, we use Arakawa's method [3]. The total (nondimensional) integration time is $T = 0.1$, and the time step $\Delta t = 1.10^{-4}$ in our computations. The total number of grid points is 60×120 (i.e., $\Delta x = \Delta y = \frac{1}{60}$). For the iteration parameters, we set $\rho = 10^{-2}$ in the computations presented in this article. In all the computations presented hereafter, the observed (vorticity) flow $\mathbf{v}$ is obtained by running the quasi-geostrophic model (4.1) with the forcing $f = -\Gamma \sin \pi y$ and the initial conditions $\omega(0) = 0$ until steady state is reached. We then use the results as given data. For the values of the (nondimensional) viscosity ν used in our computations, the observed flow is time-independent, and it is obtained as a steady state of the quasi-geostrophic equation (4.1). The purpose of our simulations is to re-

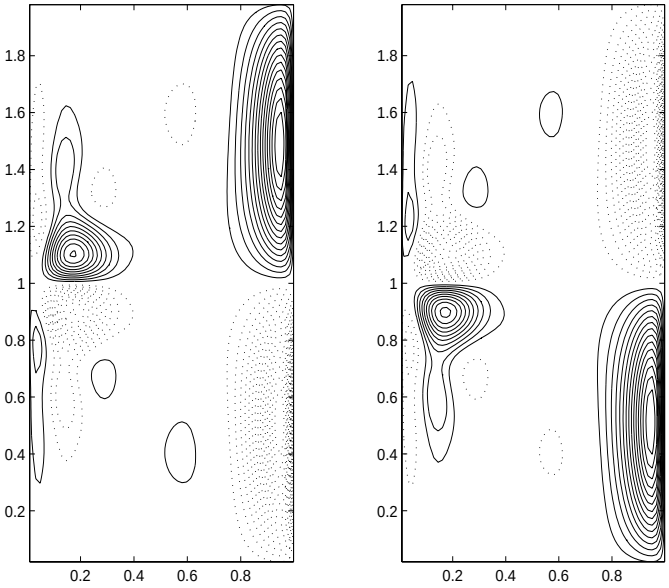

FIG. 2. *Control ϕ and disturbance ψ at $t = T = 0.1$, for $\nu = 0.1$, $\gamma = 20.0$, $l = 20.0$.*

construct the observed flow using the robust control model (3.64)–(3.66). To achieve that, we apply the fixed-point iteration method described in the previous section until convergence is reached. The criterion for the termination of the algorithm is given by

$$\left(\frac{|\psi_{k+1} - \psi_k|^2 + |\phi_{k+1} - \phi_k|^2}{|\psi_{k+1}|^2 + |\phi_{k+1}|^2} \right)^{\frac{1}{2}} < \epsilon, \tag{4.4}$$

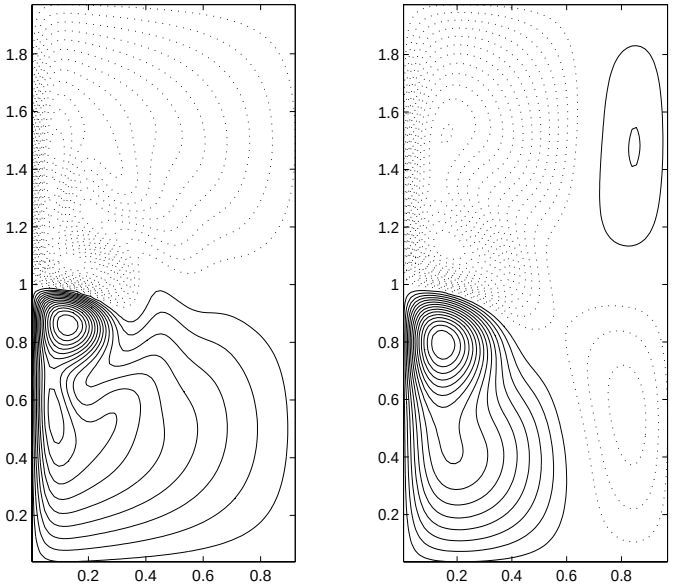

FIG. 4. *Target (streamfunction) flow and state (streamfunction) flow at* $t = T = 0.3$*, for* $\nu = 0.05$*,* $\gamma = 1.0$*,* $l = 10.0$*.*

where $\epsilon = h^2$, h is the space step in the finite-difference approximation, and $|\cdot|$ is a finite-difference approximation of the $L^2(0,T;\mathbf{L}^2(\Omega))$-norm. The following figures present the numerical results obtained from the simulations at time $t = T$ for different values of the "cost" parameter (γ, l) and (nondimensional) viscosity number ν. Figure 1 presents the target (streamfunction) flow at $t = T$, the state (streamfunction) flow at $t = T$ for the (nondimensional) viscosity number $\nu = 0.1$, and the cost

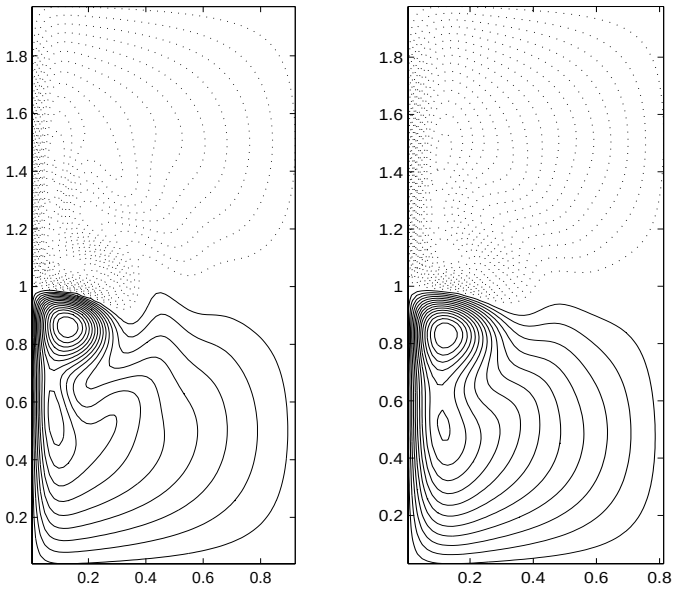

FIG. 6. *Target (streamfunction) flow and state (streamfunction) flow at* $t = T = 0.1$, *for* $\nu = 0.05$, $\gamma = 10.0$, $l = 10.0$.

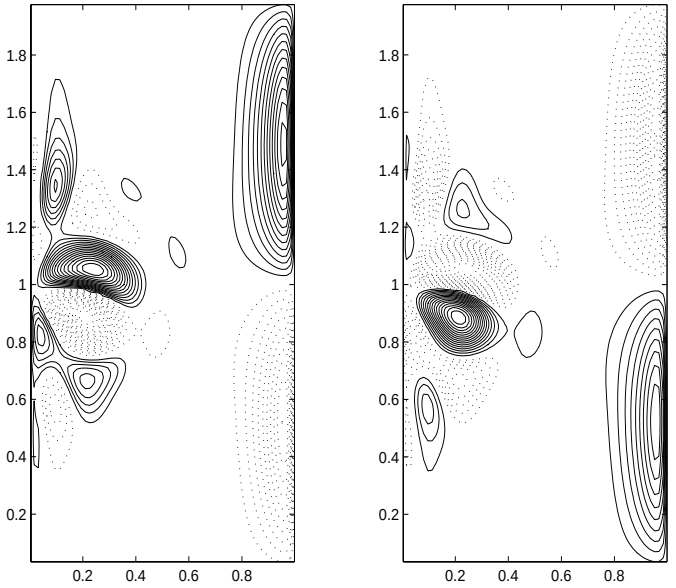

FIG. 7. *Control* ϕ *and disturbance* ψ *at* $t = T = 0.1$, *for* $\nu = 0.05$, $\gamma = 10.0$, $l = 10.0$.

parameter $(\gamma, l) = (20.0, 20.0)$. Figure 2 presents the perturbation ψ at $t = T$ and the control ϕ for the (nondimensional) viscosity number $\nu = 0.1$ and the cost parameter $(\gamma, l) = (20.0, 20.0)$. For these parameters, the state flow accurately approximates the target flow. In fact, as for the target flow, the state flow is characterized by two gyres, one cyclonic in the northern part of the basin and one anticyclonic in the southern part. The two gyres are separated by a meandering jet [23, 24]. As shown in Figure 2,

the contour lines for the control and the disturbances are the same in shape except that they have opposite signs. This suggests that the algorithm has converged to a saddle point of the functional $\mathcal{J}$. In fact, a saddle point must satisfy the condition (3.66) and in our simulations $\mathcal{B}_i = d_i I$, where I is the identity operator and $d_i > 0$ is a constant. This is also confirmed by the convergence rate given in Figure 3. A similar phenomenon appears in Figures 4–5 and Figures 6–7, for which the parameters (ν, γ, l) are $(0.05, 1.0, 10.0)$ and $(0.05, 10.0, 10.0)$, respectively. More numerical simulations will be presented elsewhere.

ERROR ANALYSIS FOR MAPPED LEGENDRE SPECTRAL AND PSEUDOSPECTRAL METHODS*

JIE SHEN† AND LI-LIAN WANG‡

Abstract. A general framework is introduced to analyze the approximation properties of mapped Legendre polynomials and of interpolations based on mapped Legendre–Gauss–Lobatto points. Optimal error estimates featuring explicit expressions on the mapping parameters for several popular mappings are derived. These results not only play an important role in numerical analysis of mapped Legendre spectral and pseudospectral methods for differential equations but also provide quantitative criteria for the choice of parameters in these mappings.

Key words. spectral approximation, mapped Legendre polynomials, interpolation, orthogonal system

1. Introduction.

In a spectral method, global polynomials are used as trial functions to approximate solutions of partial differential equations (PDEs); if the underlying solutions are smooth throughout the domain, the spectral method will provide very accurate approximations with significantly fewer degrees of freedom when compared with finite difference or finite element methods (cf. [13, 8, 7]). However, if the solutions of PDEs exhibit localized rapid variations such as spikes, sharp interfaces, or internal layers, standard spectral methods usually fail to produce accurate approximations with a reasonable number of degrees of freedom, for the grid is fixed in a standard spectral method and does not take into account the localized solution behaviors. Thus, for problems with localized rapid variations, it is advisable to use a grid adapted to the localized solution behaviors rather than a standard fixed grid.

However, unlike in a finite difference or finite element method, spectral methods cannot gracefully handle an arbitrarily locally refined grid, for the spectral accuracy will usually be lost due to the fact that the locally refined grid cannot, in general, be "smoothly" mapped to the standard spectral grid. Thus the adaptivity for spectral methods is best realized through a "smooth" map which transforms a function having sharp interfaces in the physical domain to a slow varying function on the computational domain. Hence two questions need to be addressed: (i) what is the influence of the mapping on the accuracy of the spectral methods? (ii) how do we adaptively determine a suitable mapping? In this paper, we aim to provide a complete answer to the first question, which is a first step toward a long-term goal of designing a robust adaptive spectral method for solving PDEs.

In general, a coordinate transformation takes the form

$$x = g(y;\lambda), \qquad y \in [-1,1], \quad \lambda \in D_\lambda, \tag{1.1}$$

such that

$$g'(y;\lambda) > 0, \qquad g(\pm 1,\lambda) = \pm 1, \qquad \lambda \in D_\lambda, \tag{1.2}$$

where λ is a parameter vector and D_λ is the feasible domain of λ, and $'$ denotes the derivative with respect to y so (1.1) maps the interval $[-1,1]$ univalently onto itself. Without loss of generality, we assume that the mapping (1.1) is explicitly invertible and denote

$$y = g^{-1}(x;\lambda) := h(x;\lambda), \qquad x, y \in [-1,1], \qquad \lambda \in D_\lambda.$$

Several interesting mappings have been proposed and implemented in practice. In particular, Kosloff and Tal-Ezer [20] introduced the one-parameter mapping

$$x = g(y;\lambda) = \frac{\arcsin(\lambda y)}{\arcsin\lambda}, \qquad 0 < \lambda < 1. \tag{1.3}$$

This mapping stretches the Chebyshev–Gauss–Lobatto grid toward a uniform grid as $\lambda \to 1^-$. Bayliss et al. [3] used a mapped Chebyshev method to treat the boundary layer problem with the mapping

$$x = g(y;\lambda) = (4/\pi)\arctan(\tan(\pi(y-1)/4)/\lambda) + 1, \qquad \lambda > 0. \tag{1.4}$$

The mapping clusters more and more points near $x = -1$ (resp., $x = 1$) as $\lambda \to 0^+$ (resp., as $\lambda \to +\infty$). Bayliss and Turkel [4] introduced a two-parameter mapping

$$x = g(y;\lambda) = \lambda_2 + \tan(a_1(y - a_0))/\lambda_1, \qquad \lambda_1 > 0, \quad -1 \le \lambda_2 < 1, \tag{1.5}$$

where a_0 and a_1 are chosen to satisfy (1.2). Here, as λ_1 increases, more and more points are clustered near $x = \lambda_2$. These mappings have been successfully used to treat some practical problems with localized rapid variations. We note that in [1], the authors used properties special to Chebyshev polynomials to derive some error estimates on projection and interpolation errors of the mapped Chebyshev methods with the mapping (1.3). However, as far as we know, there is neither a systematic framework for analyzing the mapped spectral methods for solving PDEs nor a precise rigorous analysis on how the mapping parameter(s) would affect the accuracy. For example, there have been controversies as to whether λ (with λ close to 1) in [20] would degrade the accuracy [20, 9, 1, 23].

The main purposes of this paper are: (i) to establish a general framework for analyzing the mapped Legendre spectral methods as a first step toward an efficient adaptive spectral method; (ii) to provide precise information on how the mapping parameters affect the accuracy of the mapped spectral method.

For a given mapping, there are essentially two approaches to implement (and analyze) a mapped spectral method. In the first approach, we use $x = g(y;\lambda)$ to transform the original equation (with localized rapid variations in x) to a mapped equation (with smooth behaviors in y), and then apply a standard spectral method (in y) to the mapped equation (see, for instance, [14, 17]). The main advantage of this approach is that standard spectral approximation results can be used for the analysis, but its main disadvantage is that the mapped equation is usually very complicated and its analysis is often cumbersome. In the second approach, we do not transform the equation, but we approximate its solution using a new family of orthogonal functions $\{p_k(h(x;\lambda))\}$, which are obtained by applying the mapping $y = h(x;\lambda)$ to classical

orthogonal polynomials $\{p_k(y)\}$ (see, for instance, [6, 18, 16]) and which are suitable for capturing the localized rapid variations in the solution of the given problem. The analysis of this approach will require approximation results by using the new family of orthogonal functions. The advantage of this approach is that once these approximation results are established, it can be directly (i.e., without using a transform) applied to a large class of problems. We shall take the second approach and establish approximation results for the mapped Legendre polynomials. We emphasize that the two approaches will yield essentially the same approximate solutions (although the two implementations can be quite different). Hence the dependence of the error estimates on the mapping parameters established here for the second approach is essentially valid for the first approach.

The remainder of the paper is organized as follows. In the next section, we introduce the general framework for the mapped Legendre spectral and pseudospectral approximations. In section 3, we apply our general results to the specific mappings (1.3)–(1.5). In section 4, we consider the mapped Legendre approximations for a model problem and present some illustrative numerical results. Some concluding remarks are given in section 5.

2. The general framework. In this section, we introduce a general framework for the error analysis of Legendre spectral methods using mapping (1.1) with (1.2). We assume that for a certain positive integer $r \geq 1$,

$$h(x;\lambda) \in C^r((-1,1)), \qquad \lambda \in D_\lambda. \tag{2.1}$$

2.1. Preliminaries. We first introduce some notation. Let $I = (-1,1)$, and let $\chi(x) > 0$ be a given weight function on I. We define

$$L^2_\chi(I) = \{v \mid v \text{ is measurable on } I \text{ and } \|v\|_\chi < \infty\},$$

equipped with the following inner product and norm:

$$(u,v)_\chi = \int_I u(x)v(x)\chi(x)dx, \qquad \|v\|_\chi = (v,v)_\chi^{\frac{1}{2}}.$$

The weighted Sobolev spaces $H^m_\chi(I)$ and $H^m_{0,\chi}(I)$ are defined as usual. The norm of $H^m_\chi(I)$ is defined as

$$\|v\|_{m,\chi} = \left(\sum_{k=0}^m \|\partial_x^k v\|_\chi^2\right)^{\frac{1}{2}}.$$

In case $\chi(x) \equiv 1$, we shall drop the subscript χ in the notation for the sake of simplicity.

Let $\omega^{\alpha,\beta}(x) = (1-x)^\alpha(1+x)^\beta$ be the Jacobi weight function and $\mathbb{N}$ be the set of all nonnegative integers. For any $m \in \mathbb{N}$, we define the nonuniformly weighted Hilbert space

$$A^m(I) = \{v \mid \partial_x^k v \in L^2_{\omega^{k,k}}(I),\ 0 \leq k \leq m\} \tag{2.2}$$

equipped with the inner product, the seminorm, and the norm as follows:

$$(u,v)_{m,A} = \sum_{k=0}^m (\partial_x^k u, \partial_x^k v)_{\omega^{k,k}}, \quad |v|_{m,A} = \|\partial_x^m v\|_{\omega^{m,m}}, \quad \|v\|_{m,A} = (v,v)_{m,A}^{\frac{1}{2}}.$$

For any real $r > 0$, we define the space $A^r(I)$ and its norm by space interpolation.

We shall use the expression $A \lesssim B$ to mean that there exist a generic positive constant c, independent of any function, N, and the parameters of the mappings, such that $A \leq cB$.

Let $L_l(y)$ be the Legendre polynomial of degree l, which is the eigenfunction of the Sturm–Liouville problem

$$\partial_y((1-y^2)\partial_y v(y)) + \mu v(y) = 0, \qquad y \in I, \tag{2.3}$$

with the corresponding eigenvalues $\mu_l = l(l+1),\ l = 0, 1, 2, \ldots$. We have $L_l(\pm 1) = (\pm 1)^l$ and the following recurrence relations:

$$L_{l+1}(y) = \frac{2l+1}{l+1} y L_l(y) - \frac{l}{l+1} L_{l-1}(y), \qquad l \geq 1, \tag{2.4}$$

$$(2l+1)L_l(y) = \partial_y L_{l+1}(y) - \partial_y L_{l-1}(y), \qquad l \geq 1. \tag{2.5}$$

The set of Legendre polynomials forms an $L^2(I)$-orthogonal system, i.e.,

$$\int_I L_l(y) L_m(y) dy = \gamma_l \delta_{l,m}, \qquad \text{with} \quad \gamma_l = \frac{2}{2l+1}. \tag{2.6}$$

For any $v \in L^2(I)$, we write

$$v(y) = \sum_{l=0}^{\infty} \hat{v}_l L_l(y), \quad \text{with} \quad \hat{v}_l = \frac{1}{\gamma_l}(v, L_l).$$

We have the following equivalence (see [17]):

$$\|\partial_y^r v\|_{\omega^{r,r}} \sim \left(\sum_{l=r}^{\infty} \mu_l^r \hat{v}_l^2 \gamma_l \right)^{\frac{1}{2}} \quad \forall v \in A^r(I). \tag{2.7}$$

We now recall some results on the Legendre spectral approximations. Let $\mathcal{P}_N$ be the set of all polynomials of degree less than or equal to N and $\mathcal{P}_N^0 = \{\phi \in \mathcal{P}_N : \phi(\pm 1) = 0\}$. We define $\widehat{P}_N : L^2(I) \to \mathcal{P}_N$ the $L^2(I)$-orthogonal projector by

$$(\widehat{P}_N v - v, \phi) = 0 \qquad \forall \phi \in \mathcal{P}_N. \tag{2.8}$$

The following result was proved in [11] (see also [2, 15]).

LEMMA 2.1.

$$\|\partial_y^\mu (\widehat{P}_N v - v)\|_{\omega^{\mu,\mu}} \lesssim N^{\mu - r} \|\partial_y^r v\|_{\omega^{r,r}}, \qquad 0 \leq \mu \leq r,\ v \in A^r(I). \tag{2.9}$$

We define the $H^1(I)$-orthogonal projector $\widehat{P}_N^1 : H^1(I) \to \mathcal{P}_N$ by

$$(\widehat{P}_N^1 v - v, \phi)_1 = 0 \qquad \forall \phi \in \mathcal{P}_N \tag{2.10}$$

and the $H_0^1(I)$-orthogonal projector $\widehat{P}_N^{1,0} : H_0^1(I) \to \mathcal{P}_N^0$ by

$$(\partial_y(\widehat{P}_N^{1,0} v - v), \partial_y \phi) = 0 \qquad \forall \phi \in \mathcal{P}_N^0. \tag{2.11}$$

As two special cases of Theorem 3.1 and Theorem 3.4 in Guo and Wang [19], we have the following lemma.

LEMMA 2.2. *If $v \in H^1(I)$ and $\partial_y^r v \in L^2_{\omega^{r-1,r-1}}(I)$, then*

$$\|\widehat{P}^1_N v - v\|_\mu \lesssim N^{\mu-r}\|\partial_y^r v\|_{\omega^{r-1,r-1}}, \quad 0 \le \mu \le 1 \le r. \tag{2.12}$$

If $v \in H^1_0(I)$ and $\partial_y^r v \in L^2_{\omega^{r-1,r-1}}(I)$, then

$$\|\widehat{P}^{1,0}_N v - v\|_\mu \lesssim N^{\mu-r}\|\partial_y^r v\|_{\omega^{r-1,r-1}}, \quad 0 \le \mu \le 1 \le r. \tag{2.13}$$

Next, let $\zeta_{N,j},\ 0 \le j \le N$, be the Legendre–Gauss–Lobatto (LGL) points, which are the zeros of $(1-y^2)\partial_y L_N(y)$. We assume that they are arranged in ascending order. There exists a unique set of Christoffel numbers $\{\omega_{N,j}\}$ such that

$$\int_I \phi(y)dy = \sum_{j=0}^{N} \phi(\zeta_{N,j})\omega_{N,j} \qquad \forall \phi \in \mathcal{P}_{2N-1}. \tag{2.14}$$

In fact, we have

$$\omega_{N,0} = \omega_{N,N} = \frac{2}{N(N+1)},\ \ \omega_{N,j} = \frac{2}{N(N+1)}(L_N(\zeta_{N,j}))^{-2},\ \ 1 \le j \le N-1. \tag{2.15}$$

We define the discrete inner product and discrete norm as

$$(u,v)_N = \sum_{j=0}^{N} u(\zeta_{N,j})v(\zeta_{N,j})\omega_{N,j}, \quad \|v\|_N = (v,v)_N^{\frac{1}{2}}.$$

Note that we have (see, for instance, formula (21.8) of Bernardi and Maday [5])

$$\|\phi\| \le \|\phi\|_N \le \sqrt{2+N^{-1}}\|\phi\| \quad \forall \phi \in \mathcal{P}_N. \tag{2.16}$$

On the other hand, we also have (see Theorem 4.9 of Guo and Wang [15])

$$\|v\|_N \lesssim \|v\| + N^{-1}\|\partial_y v\|_{\omega^{1,1}} \qquad \forall v \in H^1_0(I). \tag{2.17}$$

2.2. Mapped Legendre orthogonal approximations. For a given mapping $y = h(x;\lambda)$, we define the mapped Legendre polynomials by

$$\mathcal{L}_l^{(\lambda)}(x) = L_l(y) = L_l(h(x;\lambda)), \qquad l = 0,1,2,\ldots. \tag{2.18}$$

Due to $h(\pm 1;\lambda) = \pm 1$, we have $\mathcal{L}_l^{(\lambda)}(\pm 1) = (\pm 1)^l$. We denote the weight function

$$\omega_\lambda(x) := h'(x;\lambda) = \frac{1}{g'(y;\lambda)}. \tag{2.19}$$

Thanks to (2.5), we have the recurrence relation

$$(2l+1)\omega_\lambda(x)\mathcal{L}_l^{(\lambda)}(x) = \partial_x \mathcal{L}_{l+1}^{(\lambda)}(x) - \partial_x \mathcal{L}_{l-1}^{(\lambda)}(x), \qquad l \ge 1. \tag{2.20}$$

By virtue of (2.6), the set $\{\mathcal{L}_l^{(\lambda)}\}_{l=0}^{\infty}$ forms a complete orthogonal system in $L^2_{\omega_\lambda}(I)$, and consequently, for any $v \in L^2_{\omega_\lambda}(I)$, we can write

$$v(x) = \sum_{l=0}^{\infty} \hat{v}_l^{(\lambda)} \mathcal{L}_l^{(\lambda)}(x), \qquad \text{with} \qquad \hat{v}_l^{(\lambda)} = \frac{1}{\gamma_l}(v, \mathcal{L}_l^{(\lambda)})_{\omega_\lambda}. \tag{2.21}$$

Moreover, $\mathcal{L}_l^{(\lambda)}$ is the eigenfunction of the Sturm–Liouville problem

$$w_\lambda^{-1}(x)\partial_x(\tilde{\omega}_\lambda(x)\partial_x \mathcal{L}_l^{(\lambda)}(x)) + \mu_l \mathcal{L}_l^{(\lambda)}(x) = 0, \quad x \in I,$$

with $\tilde{\omega}_\lambda(x) = (1-h^2(x;\lambda))\omega_\lambda^{-1}(x)$. This implies that $\{\partial_x \mathcal{L}_l^{(\lambda)}\}_{l=1}^{\infty}$ forms an orthogonal system in $L^2_{\tilde{\omega}_\lambda}(I)$, i.e.,

$$\int_I \partial_x \mathcal{L}_l^{(\lambda)}(x)\partial_x \mathcal{L}_m^{(\lambda)}(x)\tilde{\omega}_\lambda(x)dx = \mu_l \gamma_l \delta_{l,m}. \tag{2.22}$$

We now consider error estimates for approximations using the orthogonal system $\{\mathcal{L}_l^{(\lambda)}\}_{l=0}^{\infty}$. For $\lambda \in D_\lambda$, we set $\mathcal{V}_{N,\lambda} = \text{span}\{\mathcal{L}_0^{(\lambda)}, \mathcal{L}_1^{(\lambda)}, \dots, \mathcal{L}_N^{(\lambda)}\}$. Let $P_{N,\lambda} : L^2_{\omega_\lambda}(I) \to \mathcal{V}_{N,\lambda}$ be the $L^2_{\omega_\lambda}(I)$-orthogonal projector defined by

$$(P_{N,\lambda}v - v, \phi)_{\omega_\lambda} = 0 \qquad \forall \phi \in \mathcal{V}_{N,\lambda}. \tag{2.23}$$

For clarity, the following notation will be used in what follows:

$$V_\lambda(y) = v \circ g(y;\lambda) = v(x), \;\; \Phi_\lambda(y) = \phi \circ g(y;\lambda) = \phi(x), \;\; x, y \in I, \;\; \lambda \in D_\lambda. \tag{2.24}$$

For $\lambda \in D_\lambda$ and $r \in \mathbb{N}$, we define

$$A_\lambda^r(I) = \{v \in L^2_{\omega_\lambda}(I) \mid |v|_{A_\lambda^r} = \|(1-y^2)^{\frac{r}{2}}\partial_y^r V_\lambda\| < \infty, \; y = h(x;\lambda)\} \tag{2.25}$$

and

$$B_\lambda^r(I) = \{v \in L^2_{\omega_\lambda}(I) \mid |v|_{B_\lambda^r} = \|(1-y^2)^{\frac{r-1}{2}}\partial_y^r V_\lambda\| < \infty, \; y = h(x;\lambda)\}. \tag{2.26}$$

The following is a fundamental result for the mapped Legendre spectral approximations.

THEOREM 2.1. *For any $v \in A_\lambda^r(I)$, $\lambda \in D_\lambda$, and $r \geq 1$,*

$$\|\partial_x(P_{N,\lambda}v - v)\|_{\tilde{\omega}_\lambda} + N\|P_{N,\lambda}v - v\|_{\omega_\lambda} \lesssim N^{1-r}|v|_{A_\lambda^r}. \tag{2.27}$$

Moreover, for $r > 1$,

$$|P_{N,\lambda}v(\pm 1) - v(\pm 1)| \lesssim N^{1-r}|v|_{A_\lambda^r}. \tag{2.28}$$

Proof. For $v \in L^2_{\omega_\lambda}(I)$, we have $V_\lambda \in L^2(I)$, so we can write

$$v(x) = \sum_{l=0}^{\infty} \hat{v}_l^{(\lambda)} \mathcal{L}_l^{(\lambda)}(x) = \sum_{j=0}^{\infty} \widehat{V}_l^{(\lambda)} L_l(y) = V_\lambda(y) \tag{2.29}$$

with

$$\hat{v}_l^{(\lambda)} = \frac{1}{\gamma_l}(v, \mathcal{L}_l^{(\lambda)})_{\omega_\lambda} = \frac{1}{\gamma_l}(V_\lambda, L_l) = \widehat{V}_l^{(\lambda)}. \tag{2.30}$$

Let $\widehat{P}_N$ and $P_{N,\lambda}$ be the projectors defined in (2.8) and (2.23). We derive from (2.30) and Lemma 2.1 with $\mu = 0$ that

$$\begin{aligned}\|P_{N,\lambda}v - v\|^2_{\omega_\lambda} &= \sum_{l=N+1}^{\infty} (\hat{v}_l^{(\lambda)})^2\gamma_l = \sum_{l=N+1}^{\infty} (\widehat{V}_l^{(\lambda)})^2\gamma_l = \|\widehat{P}_N V_\lambda - V_\lambda\|^2 \\ &\lesssim N^{-2r}\|(1-y^2)^{\frac{r}{2}}\partial_y^r V_\lambda\|^2 = N^{-2r}|v|^2_{A^r_\lambda}.\end{aligned} \tag{2.31}$$

On the other hand, since $\{\partial_y L_l\}$ is $L^2_{\omega^{1,1}}(I)$-orthogonal, we derive from (2.22), (2.30), and Lemma 2.1 with $\mu = 1$ that

$$\begin{aligned}\|\partial_x(P_{N,\lambda}v - v)\|^2_{\tilde{\omega}_\lambda} &= \sum_{l=N+1}^{\infty} \mu_l\gamma_l(\hat{v}_l^{(\lambda)})^2 = \sum_{l=N+1}^{\infty} \mu_l\gamma_l(\widehat{V}_l^{(\lambda)})^2 \\ &= \|\partial_y(\widehat{P}_N V_\lambda - V_\lambda)\|^2_{\omega^{1,1}} \lesssim N^{2(1-r)}|v|^2_{A^r_\lambda}.\end{aligned}$$

Next, since $|\mathcal{L}_l^{(\lambda)}(\pm 1)| = 1$, we derive from (2.7), (2.29), and (2.30) that

$$\begin{aligned}|P_{N,\lambda}v(\pm 1) - v(\pm 1)| &\le \sum_{l=N+1}^{\infty} |\widehat{V}_l^{(\lambda)}| \le C_{N,r}\left(\sum_{l=N+1}^{\infty} \mu_l^r(\widehat{V}_l^{(\lambda)})^2\gamma_l\right)^{\frac{1}{2}} \\ &\lesssim C_{N,r}\|\partial_y^r V_\lambda\|_{\omega^{r,r}} \lesssim C_{N,r}|v|_{A^r_\lambda},\end{aligned}$$

where for $r > 1$,

$$C_{N,r} = \left(\sum_{l=N+1}^{\infty} \mu_l^{-r}\gamma_l^{-1}\right)^{\frac{1}{2}} \lesssim \left(\sum_{l=N+1}^{\infty} l^{1-2r}\right)^{\frac{1}{2}} \lesssim \left(\int_N^{\infty} x^{1-2r}dx\right)^{\frac{1}{2}} \lesssim N^{1-r}.$$

The proof is complete. ∎

When analyzing mapped Legendre spectral methods for numerical solutions of PDEs, we often need to consider the $H^1_{\omega_\lambda}(I)$-orthogonal projection $P^1_{N,\lambda} : H^1_{\omega_\lambda}(I) \to \mathcal{V}_{N,\lambda}$ defined by

$$(P^1_{N,\lambda}v - v, \phi)_{1,\omega_\lambda} = 0 \qquad \forall \phi \in \mathcal{V}_{N,\lambda}.$$

THEOREM 2.2. *For any $v \in H^1_{\omega_\lambda}(I) \cap B^r_\lambda(I)$, $\lambda \in D_\lambda$, and $r \ge 1$,*

$$\|P^1_{N,\lambda}v - v\|_{1,\omega_\lambda} \lesssim (d_{\lambda,1}+1)N^{1-r}|v|_{B^r_\lambda}, \tag{2.32}$$

where $d_{\lambda,1} = \max_{x\in\bar{I}} |\omega_\lambda(x)|$.

Proof. By (2.19) and (2.24),

$$\begin{aligned}\|\phi - v\|^2_{1,\omega_\lambda} &= \int_I (\partial_y(\Phi_\lambda(y) - V_\lambda(y)))^2\Big(\frac{dy}{dx}\Big)^2 dy + \int_I (\Phi_\lambda(y) - V_\lambda(y))^2 dy \\ &\le (d_{\lambda,1}+1)^2\|\Phi_\lambda - V_\lambda\|^2_1.\end{aligned} \tag{2.33}$$

Next, we take $\phi(x) = \Phi_\lambda(y) = \widehat{P}^1_N V_\lambda(y)$ in (2.33), where $\widehat{P}^1_N$ is defined in (2.10), and we obtain from the projection theorem and Lemma 2.2 that

$$\begin{aligned}\|P^1_{N,\lambda}v - v\|_{1,\omega_\lambda} &= \inf_{\phi\in\mathcal{V}_{N,\lambda}} \|\phi - v\|_{1,\omega_\lambda} \le (d_{\lambda,1}+1)\|\widehat{P}^1_N V_\lambda - V_\lambda\|_1 \\ &\lesssim (d_{\lambda,1}+1)N^{1-r}\|\partial_y^r V_\lambda\|_{\omega^{r-1,r-1}} \lesssim (d_{\lambda,1}+1)N^{1-r}|v|_{B^r_\lambda}.\end{aligned}$$ ∎

Next, we consider the bilinear form

$$a_{\omega_\lambda}^{(\nu)}(u,v)=\nu_1(\partial_x u,\partial_x(v\omega_\lambda))+\nu_2(u,v)_{\omega_\lambda}$$

(where $\nu=(\nu_1,\nu_2)$ and $\nu_i>0, i=1,2$) associated to the mapped Legendre spectral approximation of the model elliptic equation

$$-\mu_1 v_{xx}+\mu_2 v=f,\quad v(\pm 1)=0. \tag{2.34}$$

Due to the nonuniform weight function $\omega_\lambda(x)$, the bilinear form $a_{\omega_\lambda}^{(\nu)}(u,v)$ is not symmetric. We first study its continuity and coercivity.

LEMMA 2.3. *For any $u,v\in H^1_{\omega_\lambda}(I)$,*

$$a_{\omega_\lambda}^{(\nu)}(u,v)\le \nu_1(d_{\lambda,2}+1)|u|_{1,\omega_\lambda}\|v\|_{1,\omega_\lambda}+\nu_2\|u\|_{\omega_\lambda}\|v\|_{\omega_\lambda}, \tag{2.35}$$

where

$$d_{\lambda,2}=\max_{x\in\bar I}|\omega_\lambda^{-1}(x)\partial_x\omega_\lambda(x)|. \tag{2.36}$$

For any $v\in H^1_{0,\omega_\lambda}(I)$,

$$a_{\omega_\lambda}^{(\nu)}(v,v)\ge \nu_1|v|^2_{1,\omega_\lambda}+\Big(\nu_2-\frac{\nu_1}{2}d_{\lambda,3}\Big)\|v\|^2_{\omega_\lambda}, \tag{2.37}$$

where

$$d_{\lambda,3}=\max_{x\in\bar I}\{\omega_\lambda^{-1}(x)\partial_x^2\omega_\lambda(x)\}. \tag{2.38}$$

Proof. By the Cauchy inequality,

$$\begin{aligned}a_{\omega_\lambda}^{(\nu)}(u,v)&\le \nu_1|(\partial_x u,\partial_x v)_{\omega_\lambda}+(\partial_x u,v\partial_x\omega_\lambda)|+\nu_2|(u,v)_{\omega_\lambda}|\\&\le \nu_1(|u|_{1,\omega_\lambda}|v|_{1,\omega_\lambda}+\max_{x\in\bar I}|\omega_\lambda^{-1}(x)\partial_x\omega_\lambda(x)||u|_{1,\omega_\lambda}\|v\|_{\omega_\lambda})+\nu_2\|u\|_{\omega_\lambda}\|v\|_{\omega_\lambda}\\&\le \nu_1(d_{\lambda,2}+1)|u|_{1,\omega_\lambda}\|v\|_{1,\omega_\lambda}+\nu_2\|u\|_{\omega_\lambda}\|v\|_{\omega_\lambda}.\end{aligned}$$

On the other hand,

$$\begin{aligned}a_{\omega_\lambda}^{(\nu)}(v,v)&=\nu_1|v|^2_{1,\omega_\lambda}+\nu_2\|v\|^2_{\omega_\lambda}+\frac{\nu_1}{2}\int_I\partial_x(v^2(x))\partial_x\omega_\lambda(x)dx\\&=\nu_1|v|^2_{1,\omega_\lambda}+\nu_2\|v\|^2_{\omega_\lambda}-\frac{\nu_1}{2}\int_I v^2(x)\partial_x^2\omega_\lambda(x)dx \qquad (2.39)\\&\ge \nu_1|v|^2_{1,\omega_\lambda}+\Big(\nu_2-\frac{\nu_1}{2}d_{\lambda,3}\Big)\|v\|^2_{\omega_\lambda}.\end{aligned}$$

∎

This lemma indicates that if $\nu_2>\frac{\nu_1}{2}d_{\lambda,3}$, then $|||v|||_{1,\omega_\lambda}:=\sqrt{a_{\omega_\lambda}^{(\nu)}(v,v)}$ is a norm for the space $H^1_{0,\omega_\lambda}(I)$.

Next, we set $\mathcal{V}^0_{N,\lambda}=H^1_{0,\omega_\lambda}(I)\cap\mathcal{V}_{N,\lambda}$ and define the orthogonal projector $P^{1,0}_{N,\lambda}: H^1_{0,\omega_\lambda}(I)\to\mathcal{V}^0_{N,\lambda}$ by

$$a_{\omega_\lambda}^{(\nu)}(P^{1,0}_{N,\lambda}v-v,\phi)=0\qquad\forall\phi\in\mathcal{V}^0_{N,\lambda}. \tag{2.40}$$

THEOREM 2.3. *If* $\nu_2 > \frac{\nu_1}{2} d_{\lambda,3}$, *then for any* $v \in H^1_{0,\omega_\lambda}(I) \cap B^r_\lambda(I)$, $\lambda \in D_\lambda$, *and* $r \geq 1$,

$$|||P^{1,0}_{N,\lambda} v - v|||_{1,\omega_\lambda} \lesssim (\nu_1^{\frac{1}{2}}(d_{\lambda,1}+1)(d_{\lambda,2}+1)^{\frac{1}{2}} + \nu_2^{\frac{1}{2}} N^{-1}) N^{1-r} |v|_{B^r_\lambda}, \tag{2.41}$$

where $d_{\lambda,i}, i = 1, 2, 3$, *are the same as before.*

Proof. By the projection theorem, (2.33), and (2.35),

$$\begin{aligned} |||P^{1,0}_{N,\lambda} v - v|||^2_{1,\omega_\lambda} &= \inf_{\phi \in \mathcal{V}^0_{N,\lambda}} |||\phi - v|||^2_{1,\omega_\lambda} \\ &\leq \nu_1 (d_{\lambda,2}+1) |\phi - v|_{1,\omega_\lambda} \|\phi - v\|_{1,\omega_\lambda} + \nu_2 \|\phi - v\|^2_{\omega_\lambda} \\ &\leq \nu_1 (d_{\lambda,1}+1)^2 (d_{\lambda,2}+1) \|\Phi_\lambda - V_\lambda\|^2_1 + \nu_2 \|\Phi_\lambda - V_\lambda\|^2. \end{aligned} \tag{2.42}$$

Let $\widehat{P}^{1,0}_N$ be the $H^1_0(I)$-orthogonal projection as in Lemma 2.2. Hence, by taking $\phi(x) = \Phi_\lambda(y) = \widehat{P}^{1,0}_N V_\lambda(y)$ in (2.42), where $\widehat{P}^{1,0}_N$ is defined in (2.11), we can obtain the desired result thanks to Lemma 2.2. ∎

2.3. Mapped Legendre pseudospectral approximations. In this subsection, we consider the interpolation operator based on the mapped Legendre–Gauss–Lobatto (MLGL) points.

Let $\{\zeta_{N,j}\}_{j=0}^N$ and $\{\omega_{N,j}\}_{j=0}^N$ be the LGL points and weights. The MLGL points and weights are defined by

$$\xi^{(\lambda)}_{N,j} = g(\zeta_{N,j}; \lambda), \quad \omega^{(\lambda)}_{N,j} = \omega_{N,j}, \quad 0 \leq j \leq N, \ \ \lambda \in D_\lambda. \tag{2.43}$$

It is clear that $\xi^{(\lambda)}_{N,0} = -1$ and $\xi^{(\lambda)}_{N,N} = 1$, and thanks to (2.14),

$$\int_I \phi(x) \omega_\lambda(x) dx = \int_I \phi(g(y;\lambda)) dy = \sum_{j=0}^N \phi(\xi^{(\lambda)}_{N,j}) \omega^{(\lambda)}_{N,j} \qquad \forall \phi \in \mathcal{V}_{2N-1,\lambda}. \tag{2.44}$$

Let the discrete inner product and discrete norm be defined as

$$(u,v)_{\omega_\lambda,N} = \sum_{j=0}^N u(\xi^{(\lambda)}_{N,j}) v(\xi^{(\lambda)}_{N,j}) \omega^{(\lambda)}_{N,j}, \qquad \|v\|_{\omega_\lambda,N} = (v,v)^{\frac{1}{2}}_{\omega_\lambda,N}.$$

We have from (2.16) that

$$\|\phi\|_{\omega_\lambda} \leq \|\phi\|_{\omega_\lambda,N} \leq \Big(2 + \frac{1}{N}\Big)^{\frac{1}{2}} \|\phi\|_{\omega_\lambda} \qquad \forall \phi \in \mathcal{V}_{N,\lambda}. \tag{2.45}$$

Let $\mathcal{I}_{N,\lambda} v$ be the interpolation of $v(x)$ in $\mathcal{V}_{N,\lambda}$ at points $\xi^{(\lambda)}_{N,j}$. We first establish a result on the stability of $\mathcal{I}_{N,\lambda}$.

LEMMA 2.4. *For any* $v \in L^2_{\omega_\lambda}(I) \cap H^1_{\tilde{\omega}_\lambda}(I)$ *and* $\lambda \in D_\lambda$,

$$\|\mathcal{I}_{N,\lambda} v\|_{\omega_\lambda} \lesssim \|v\|_{\omega_\lambda} + N^{-1}(|v(1)| + |v(-1)| + |v|_{1,\tilde{\omega}_\lambda}). \tag{2.46}$$

Proof. By (2.15), (2.43), and (2.45),

$$\begin{aligned} \|\mathcal{I}_{N,\lambda} v\|^2_{\omega_\lambda} \leq \|\mathcal{I}_{N,\lambda} v\|^2_{\omega_\lambda,N} &= \frac{2}{N(N+1)}(v^2(-1) + v^2(1)) + \sum_{j=1}^{N-1} v^2(\xi^{(\lambda)}_{N,j}) \omega^{(\lambda)}_{N,j} \\ &= \frac{2}{N(N+1)}(v^2(-1) + v^2(1)) + \sum_{j=1}^{N-1} V^2_\lambda(\zeta_{N,j}) \omega_{N,j}. \end{aligned} \tag{2.47}$$

Thanks to (2.17), we have from (2.24) that

$$\sum_{j=1}^{N-1} V_\lambda^2(\zeta_{N,j})\omega_{N,j} \le \|V_\lambda\|_N^2 \lesssim \|V_\lambda\|^2 + N^{-2}\|\partial_y V_\lambda\|_{\omega^{1,1}}^2 \lesssim \|v\|_{\omega_\lambda}^2 + N^{-2}|v|_{1,\tilde{\omega}_\lambda}^2. \tag{2.48}$$

This completes the proof. ∎

Remark 2.1. For the treatment of nonlinear problems, we often need to estimate the terms such as $\mathcal{I}_{N,\lambda}\phi$ with $\phi \in \mathcal{V}_{M,\lambda}^0, M > N$. By the formula (5.9) in [5], we have the following inverse inequality:

$$|\phi|_{1,\tilde{\omega}_\lambda} = |\Phi_\lambda|_{1,\omega^{1,1}} \le \sqrt{2}N\|\Phi_\lambda\| = \sqrt{2}N\|\phi\|_{\omega_\lambda} \quad \forall \phi \in \mathcal{V}_{N,\lambda}. \tag{2.49}$$

So we obtain from (2.46) that for any $\phi \in \mathcal{V}_{M,\lambda}^0$ and $\psi \in \mathcal{V}_{L,\lambda}^0$,

$$\|\mathcal{I}_{N,\lambda}\phi\|_{\omega_\lambda} \lesssim \|\phi\|_{\omega_\lambda} + N^{-1}|\phi|_{1,\tilde{\omega}_\lambda} \lesssim \Big(1 + \frac{M}{N}\Big)\|\phi\|_{\omega_\lambda}. \tag{2.50}$$

On the other hand, by (2.45),

$$\begin{aligned} |(\phi,\psi)_{\omega_\lambda,N}| &= |(\mathcal{I}_{N,\lambda}\phi, \mathcal{I}_{N,\lambda}\psi)_{\omega_\lambda,N}| \le \|\mathcal{I}_{N,\lambda}\phi\|_{\omega_\lambda,N}\|\mathcal{I}_{N,\lambda}\psi\|_{\omega_\lambda,N} \\ &\le \Big(2 + \frac{1}{N}\Big)\|\mathcal{I}_{N,\lambda}\phi\|_{\omega_\lambda}\|\mathcal{I}_{N,\lambda}\psi\|_{\omega_\lambda} \\ &\lesssim \Big(1 + \frac{M}{N}\Big)\Big(1 + \frac{L}{N}\Big)\|\phi\|_{\omega_\lambda}\|\psi\|_{\omega_\lambda}. \end{aligned} \tag{2.51}$$

The following is the main result on the MLGL interpolation.

THEOREM 2.4. *For any* $v \in A_\lambda^r(I)$, $\lambda \in D_\lambda$, *and* $r > 1$,

$$\|\partial_x(\mathcal{I}_{N,\lambda}v - v)\|_{\tilde{\omega}_\lambda} + N\|\mathcal{I}_{N,\lambda}v - v\|_{\omega_\lambda} \lesssim N^{1-r}|v|_{A_\lambda^r}. \tag{2.52}$$

Proof. By (2.27), (2.28), and (2.46),

$$\begin{aligned} \|\mathcal{I}_{N,\lambda}v - P_{N,\lambda}v\|_{\omega_\lambda} &= \|\mathcal{I}_{N,\lambda}(P_{N,\lambda}v - v)\|_{\omega_\lambda} \\ &\lesssim \|P_{N,\lambda}v - v\|_{\omega_\lambda} + N^{-1}(|P_{N,\lambda}v(1) - v(1)| \\ &\quad + |P_{N,\lambda}v(-1) - v(-1)| + \|\partial_x(P_{N,\lambda}v - v)\|_{\tilde{\omega}_\lambda}) \\ &\lesssim N^{-r}|v|_{A_\lambda^r}. \end{aligned} \tag{2.53}$$

Due to (2.49), we obtain from (2.53) that

$$|\mathcal{I}_{N,\lambda}v - P_{N,\lambda}v|_{1,\tilde{\omega}_\lambda} \lesssim N\|\mathcal{I}_{N,\lambda}v - P_{N,\lambda}v\|_{\omega_\lambda} \lesssim N^{1-r}|v|_{A_\lambda^r}.$$

We then derive from (2.27) that

$$\begin{aligned} |\mathcal{I}_{N,\lambda}v - v|_{1,\tilde{\omega}_\lambda} + N\|\mathcal{I}_{N,\lambda}v - v\|_{\omega_\lambda} &\le |\mathcal{I}_{N,\lambda}v - P_{N,\lambda}v|_{1,\tilde{\omega}_\lambda} + N\|\mathcal{I}_{N,\lambda}v - P_{N,\lambda}v\|_{\omega_\lambda} \\ &\quad + |P_{N,\lambda}v - v|_{1,\tilde{\omega}_\lambda} + N\|P_{N,\lambda}v - v\|_{\omega_\lambda} \lesssim N^{1-r}|v|_{A_\lambda^r}. \end{aligned}$$

∎

Remark 2.2. As a direct consequence, we can estimate the difference between the continuous and discrete inner products. In fact, we deduce from (2.27), (2.44), (2.45), and (2.52) that for any $v \in A_\lambda^r(I)$ and $\phi \in \mathcal{V}_{N,\lambda}$ with $r > 1$ and $\lambda \in D_\lambda$,

$$\begin{aligned} &|(v,\phi)_{\omega_\lambda} - (v,\phi)_{\omega_\lambda,N}| \\ &\quad \le |(v,\phi)_{\omega_\lambda} - (P_{N-1,\lambda}v, v)_{\omega_\lambda}| + |(P_{N-1,\lambda}v,\phi)_{\omega_\lambda,N} - (\mathcal{I}_{N,\lambda}v,\phi)_{\omega_\lambda,N}| \\ &\quad \le \|P_{N-1,\lambda}v - v\|_{\omega_\lambda}\|\phi\|_{\omega_\lambda} + \|P_{N-1,\lambda}v - \mathcal{I}_{N,\lambda}v\|_{\omega_\lambda,N}\|\phi\|_{\omega_\lambda,N} \\ &\quad \lesssim N^{-r}|v|_{A_\lambda^r}\|\phi\|_{\omega_\lambda}. \end{aligned} \tag{2.54}$$

3. The upper bounds of $|v|_{A^r_\lambda}$ and $|v|_{B^r_\lambda}$. In this section, we provide upper bounds of $|v|_{A^r_\lambda}$ and $|v|_{B^r_\lambda}$ in terms of derivatives of $v(x)$ for the mappings (1.3)–(1.5). We also derive explicit bounds on the positive constants $d_{\lambda,i}$ $(i = 1, 2, 3)$ defined in the previous section. These bounds provide, in particular, explicit information on how the mapping parameters affect the accuracy of the mapped Legendre approximation.

3.1. The mapping (1.3). In this case, we have $D_\lambda = (0, 1)$. The inverse of the mapping (1.3) is

$$y = h(x;\lambda) = \frac{\sin(ax)}{\lambda}, \qquad a = \arcsin\lambda, \quad \lambda \in (0,1). \tag{3.1}$$

Moreover,

$$\omega_\lambda(x) = \frac{dy}{dx} = \frac{a}{\lambda}\cos(ax) = \Big(\frac{dx}{dy}\Big)^{-1} = \frac{a}{\lambda}\sqrt{1-\lambda^2y^2}. \tag{3.2}$$

Since $a \to \lambda$ as $\lambda \to 0$, $\frac{\lambda}{a}$ is uniformly bounded for $\lambda \in (0, 1)$. For clarity, let $Q_l(y;\lambda)$ be a polynomial of degree l with respect to y. Then for any integer $k \geq 1$,

$$\begin{aligned}
\frac{d^kx}{dy^k} &= \frac{\lambda}{a}\sum_{j=0}^{k-1}\binom{k-1}{j}\Big((1-\lambda y)^{-\frac12}\Big)^{(j)}\Big((1+\lambda y)^{-\frac12}\Big)^{(k-j-1)}\\
&= \sum_{j=0}^{k-1}E_j^k(\lambda)(1-\lambda y)^{-\frac12-j}(1+\lambda y)^{\frac12+j-k}\\
&= (1-\lambda^2y^2)^{\frac12-k}\sum_{j=0}^{k-1}E_j^k(\lambda)(1-\lambda y)^{k-1-j}(1+\lambda y)^j\\
&= (1-\lambda^2y^2)^{\frac12-k}Q_{k-1}(y;\lambda),
\end{aligned} \tag{3.3}$$

where $E_j^k(\lambda)$ is a constant in terms of j, k, and λ. By direct calculations,

$$\begin{aligned}
\partial_yV_\lambda(y) &= \partial_xv(x)\frac{dx}{dy} = (1-\lambda^2y^2)^{-\frac12}Q_0(y;\lambda)\partial_xv(x),\\
\partial_y^2V_\lambda(y) &= \partial_x^2v(x)\Big(\frac{dx}{dy}\Big)^2 + \partial_xv(x)\frac{d^2x}{dy^2}\\
&= (1-\lambda^2y^2)^{-1}Q_0(y;\lambda)\partial_x^2v(x) + (1-\lambda^2y^2)^{-\frac32}Q_1(y;\lambda)\partial_xv(x),\\
\partial_y^3V_\lambda(y) &= \partial_x^3v(x)\Big(\frac{dx}{dy}\Big)^3 + 3\partial_x^2v(x)\frac{dx}{dy}\frac{d^2x}{dy^2} + \partial_xv(x)\frac{d^3x}{dy^3}\\
&= (1-\lambda^2y^2)^{-\frac32}Q_0(y;\lambda)\partial_x^3v(x) + (1-\lambda^2y^2)^{-2}Q_1(y;\lambda)\partial_x^2v(x)\\
&\quad + (1-\lambda^2y^2)^{-\frac52}Q_2(y;\lambda)\partial_xv(x).
\end{aligned} \tag{3.4}$$

Thus an induction argument leads to

$$\partial_y^kV_\lambda(y) = \sum_{j=1}^{k}(1-\lambda^2y^2)^{\frac{j}{2}-k}Q_{k-j}(y;\lambda)\partial_x^jv(x), \qquad k \geq 1, \tag{3.5}$$

where $Q_l(y;\lambda)$ $(0 \leq l \leq k)$ are uniformly bounded for all $y \in \bar I$ and $\lambda \in (0, 1)$. Then, by the definition of $|v|_{A^r_\lambda}$, we derive from (3.5) that for $r \geq 1$,

$$|v|^2_{A^r_\lambda} = \|\partial_y^rV_\lambda\|^2_{\omega^{r,r}} \lesssim \sum_{j=1}^{r}\int_I(1-\lambda^2y^2)^{j-2r}(1-y^2)^r(\partial_x^jv(x))^2\omega_\lambda(x)dx, \tag{3.6}$$

where $y = g(x;\lambda) \in \bar{I}$. Since $1-y^2 \le 1-\lambda^2 y^2$ and $A^0_\lambda(I) = L^2_{\omega_\lambda}(I)$, we conclude that

$$|v|_{A^r_\lambda} \lesssim (1-\lambda^2)^{\frac{1}{2}-\frac{r}{2}} \|v\|_{r,\omega_\lambda}, \quad r \ge 0, \ \ \lambda \in (0,1). \tag{3.7}$$

Similarly, we derive from by the definition of $B^r_\lambda(I)$ that

$$|v|_{B^r_\lambda} \lesssim (1-\lambda^2)^{-\frac{r}{2}} \|v\|_{r,\omega_\lambda}, \quad r \ge 1, \ \ \lambda \in (0,1). \tag{3.8}$$

Next, we derive from (3.1) and (3.2) that the values of $d_{\lambda,i}, 1 \le i \le 3$, in (2.32), (2.35), and (2.38) are

$$d_{\lambda,1} = \frac{a}{\lambda}, \qquad d_{\lambda,2} = \frac{a\lambda}{\sqrt{1-\lambda^2}}, \qquad d_{\lambda,3} = -a^2. \tag{3.9}$$

In summary, we have proved the following results.

COROLLARY 3.1. *For any $v \in H^r_{\omega_\lambda}(I)$, $\lambda \in (0,1)$, and $r \ge 1$,*

$$\|\partial_x(P_{N,\lambda}v - v)\|_{\tilde{\omega}_\lambda} + N\|P_{N,\lambda}v - v\|_{\omega_\lambda} \lesssim (1-\lambda^2)^{\frac{1}{2}-\frac{r}{2}} N^{1-r} \|v\|_{r,\omega_\lambda}, \tag{3.10}$$

$$\|P^1_{N,\lambda}v - v\|_{1,\omega_\lambda} \lesssim (1-\lambda^2)^{-\frac{r}{2}} N^{1-r} \|v\|_{r,\omega_\lambda}, \tag{3.11}$$

and for $r > 1$,

$$\|\partial_x(\mathcal{I}_{N,\lambda}v - v)\|_{\tilde{\omega}_\lambda} + N\|\mathcal{I}_{N,\lambda}v - v\|_{\omega_\lambda} \lesssim (1-\lambda^2)^{\frac{1}{2}-\frac{r}{2}} N^{1-r} \|v\|_{r,\omega_\lambda}. \tag{3.12}$$

If $\nu_1, \nu_2 > 0$ and $v \in H^1_{0,\omega_\lambda}(I) \cap H^r_{\omega_\lambda}(I)$ with $r \ge 1$, then

$$|||P^{1,0}_{N,\lambda}v - v|||_{1,\omega_\lambda} \lesssim (\nu_1^{\frac{1}{2}}(1-\lambda^2)^{-\frac{1}{4}} + \nu_2^{\frac{1}{2}} N^{-1})(1-\lambda^2)^{-\frac{r}{2}} N^{1-r} \|v\|_{r,\omega_\lambda}. \tag{3.13}$$

Remark 3.1. For $\lambda = 0$, (1.3) becomes the identity map. So we obtain the same results as in the standard Legendre case, i.e.,

$$|v|_{A^r_\lambda} \lesssim \|(1-x^2)^{\frac{r}{2}} \partial^r_x v\|, \qquad |v|_{B^r_\lambda} \lesssim \|(1-x^2)^{\frac{r-1}{2}} \partial^r_x v\|, \qquad \lambda \to 0.$$

Remark 3.2. For $\lambda = 1$, (1.3) becomes $y = \sin(\pi x/2)$. This mapping has singularities at $x = \pm 1$, and therefore, (3.7)–(3.8) are no longer valid. However, we find from (3.1), (3.2), and (3.6) that

$$\begin{aligned} |v|_{A^r_1} &\lesssim \left(\sum_{j=1}^r \int_I (1-y^2)^{j-r} (\partial^j_x v(x))^2 \omega_\lambda(x) dx \right)^{\frac{1}{2}} \\ &\lesssim \left(\sum_{j=1}^r \int_I (1-x^2)^{j-r+\frac{1}{2}} (\partial^j_x v(x))^2 dx \right)^{\frac{1}{2}}. \end{aligned}$$

This implies that $|v|_{A^r_1}$ is bounded if $v \in H^r(I)$ and for some $\sigma < 1$,

$$(1-x^2)^{j-r+\frac{1}{2}} (\partial^j_x v(x))^2 \lesssim \frac{1}{(1-x^2)^\sigma} \quad \text{as} \quad |x| \to 1, \quad 1 \le j \le r. \tag{3.14}$$

In particular, one can verify that (3.14) is satisfied if

$$\partial^j_x v(\pm 1) = 0, \qquad 1 \le j \le r-2, \ v \in H^r(I). \tag{3.15}$$

Indeed, by the Hardy's inequality (see [12]), we have that for $\alpha < 1$,

$$\int_I u^2(x)(1-x^2)^{\alpha-1}dx \lesssim \int_I u^2(x)(1-x^2)^{\alpha-2}dx \lesssim \int_I (\partial_x u(x))^2(1-x^2)^{\alpha}dx,$$

provided that $u(\pm 1) = 0$ and the right-hand side of the inequality is finite. Using this equality and the condition (3.15), we have for $1 \le j \le r-2$,

$$\begin{aligned}\int_I (\partial_x^j v(x))^2\ (1-x^2)^{j-r+\frac{1}{2}}dx &\lesssim \int_I (\partial_x^{j+1} v(x))^2(1-x^2)^{j-r+\frac{3}{2}}dx\\ &\lesssim \cdots \lesssim \int_I (\partial_x^{r-1} v(x))^2(1-x^2)^{-\frac{1}{2}}dx.\end{aligned}$$

Then, by the inequality (13.5) in [5], we have that for $\alpha > 1$,

$$\int_I u^2(x)(1-x^2)^{\alpha-2}dx \lesssim \int_I ((\partial_x u(x))^2 + u^2(x))(1-x^2)^{\alpha}dx,$$

which implies that

$$\int_I (\partial_x^{r-1} v(x))^2(1-x^2)^{-\frac{1}{2}}dx \lesssim \int_I ((\partial_x^r v(x))^2 + (\partial_x^{r-1} v(x))^2)(1-x^2)^{\frac{3}{2}}dx.$$

A combination of the above estimates show that under the condition (3.15), we have

$$|v|_{A_1^r} \lesssim (\|(1-x^2)^{\frac{3}{4}}\partial_x^{r-1} v\| + \|(1-x^2)^{\frac{1}{4}}\partial_x^r v\|). \tag{3.16}$$

Similar results can also be derived for $|v|_{B_1^r}$. The estimates indicate, in particular, that, for the mapping (1.3) with $\lambda = 1$, the convergence rate of the mapped Legendre method is of order r if (3.15) is satisfied. In particular, only a second-order convergence rate can be expected if the function does not vanish at the end-points.

Remark 3.3. If the parameter λ was chosen as (cf. [1] and [10])

$$\lambda = \lambda(N,\epsilon) = \operatorname{sech}\Big(\frac{|\ln\epsilon|}{N}\Big) = \frac{2}{\epsilon^{1/N} + \epsilon^{-1/N}} \sim 1 - \frac{1}{2}(\ln^2\epsilon)N^{-2} \quad \text{for } N \gg 1, \tag{3.17}$$

where ϵ is the desired accuracy, then we find from (3.7) and (3.8) that for any $v \in H_{\omega_\lambda}^r(I)$,

$$|v|_{A_\lambda^r} \sim (|\ln\epsilon|)^{1-r}N^{r-1}, \quad |v|_{B_\lambda^r} \sim (|\ln\epsilon|)^{-r}N^r,$$

which, along with Corollary 3.1, implies that

$$\|P_{N,\lambda}v - v\|_{\omega_\lambda} \sim |\ln\epsilon|^{1-r}N^{-1}, \quad \|P_{N,\lambda}^1 v - v\|_{1,\omega_\lambda} \sim |\ln\epsilon|^{-r}N.$$

Thus a lower order ($< r$) of accuracy is expected by choosing (3.17), except when ϵ and N are such that $\epsilon \lesssim \exp(-\gamma N)$, $\gamma > 0$.

3.2. The mapping (1.4). In this case, $D_\lambda = \{\lambda \mid \lambda > 0\}$, and (1.4) is

$$y = h(x;\lambda) = (4/\pi)\arctan(\lambda\tan(\pi(x-1)/4)) + 1, \qquad \lambda > 0, \tag{3.18}$$

$$\omega_\lambda(x) = \frac{dy}{dx} = \frac{\lambda}{1 + (\lambda^2-1)\sin^2(\pi(x-1)/4)}. \tag{3.19}$$

In particular, $h(x;\lambda)=x$ and $\omega_\lambda(x)=1$ for $\lambda=1$.

Let us denote

$$C_\lambda=\begin{cases}\lambda^{-1}, & 0<\lambda\le 1,\\ \lambda, & \lambda>1,\end{cases}\quad C_1=\begin{cases}1, & 0<\lambda\le 1,\\ \lambda^{-2}, & \lambda>1,\end{cases}\quad C_2=\begin{cases}\lambda^2, & 0<\lambda\le 1,\\ 1, & \lambda>1.\end{cases}$$

We have $C_1,\ C_2\le 1$ for $\lambda>0$, and by (3.19),

$$\begin{aligned}\frac{dx}{dy}&=(\cos^2(\pi(x-1)/4)+\lambda^2\sin^2(\pi(x-1)/4))/\lambda\\ &=C_\lambda(C_1\cos^2(\pi(x-1)/4)+C_2\sin^2(\pi(x-1)/4)).\end{aligned}\tag{3.20}$$

We set

$$\mathcal{T}_l=\operatorname{span}\{\cos(k\pi(x-1)/4),\ \sin(k\pi(x-1)/4),\ 1\le k\le l\},\quad l\in\mathbb{N}.$$

For $j\ge 1$, we denote by $T_{k,j}(x)$ some functions in $\mathcal{T}_l$ with coefficients in terms of C_1 and C_2. Then, by (3.18) and (3.20),

$$\begin{aligned}\partial_y V_\lambda(y)&=\partial_x v(x)\frac{dx}{dy}=C_\lambda T_{2,1}(x)\partial_x v(x),\\ \partial_y^2 V_\lambda(y)&=\frac{d(\partial_y V_\lambda(y))}{dx}\frac{dx}{dy}=C_\lambda^2(T_{4,2}(x)\partial_x^2 v(x)+T_{4,1}(x)\partial_x v(x)).\end{aligned}$$

Hence, by an induction argument, we find that for $k\ge 1$,

$$\partial_y^k V_\lambda(y)=C_\lambda^k\sum_{j=1}^{k}T_{k,j}(x)\partial_x^j v(x),\tag{3.21}$$

where $T_{k,j}(x)$ $(1\le j\le k)$ are uniformly bounded for all $x\in\bar I$ and $\lambda>0$. Let

$$\omega_\lambda^{(r)}(x):=\omega_\lambda(x)(1-y^2)^r=\omega_\lambda(x)(1-h^2(x;\lambda))^r\ (\lesssim\omega_\lambda(x),\quad x\in I,\ \lambda>0).$$

By (3.18) and (3.20),

$$\lim_{x\to 1}\frac{1-h(x;\lambda)}{1-x}=\lambda,\qquad \lim_{x\to -1}\frac{1+h(x;\lambda)}{1+x}=\lambda^{-1}.$$

By virtue of (3.21) and the definitions of $|v|_{A_\lambda^r}$ and $|v|_{B_\lambda^r}$, we derive that

$$|v|_{A_\lambda^r}\lesssim C_\lambda^r\|v\|_{r,\omega_\lambda^{(r)}},\qquad |v|_{B_\lambda^r}\le C_\lambda^r\|v\|_{r,\omega_\lambda^{(r-1)}},\quad \lambda>0.\tag{3.22}$$

Next, we deduce from (3.18)–(3.20) that the values of the constants $d_{\lambda,i},\ 1\le i\le 3$, are

$$d_{\lambda,1}=C_\lambda,\quad d_{\lambda,2}=\frac{\pi/4|\lambda^2-1|\,|\sin(\pi(x-1)/2)|}{\cos^2(\pi(x-1)/4)+\lambda^2\sin^2(\pi(x-1)/4)}\le\frac{\pi|\lambda^2-1|}{4\lambda},$$

$$d_{\lambda,3}=\begin{cases}\max\{\frac{\pi^2}{8}(1-\lambda^2),S_\lambda(z_0)\} & \text{if}\quad 0<\lambda\le e_0,\\ \frac{\pi^2}{8}(1-\lambda^2) & \text{if}\quad e_0<\lambda\le 1,\\ \frac{\pi^2(\lambda^2-1)}{8\lambda^2} & \text{if}\quad 1<\lambda\le e_1,\\ \max\{\frac{\pi^2(\lambda^2-1)}{8\lambda^2},S_\lambda(z_0)\} & \text{if}\quad \lambda>e_1,\end{cases}\tag{3.23}$$

where $e_0 = \sqrt{\frac{\sqrt{97}-5}{6}}, e_1 = \sqrt{\frac{5}{3}}, z_0 = \frac{5\lambda^2-3}{3(1-\lambda^4)}$, and

$$S_\lambda(z) = \frac{\pi^2 b(-2bz^2 + (3b-2)z + 1)}{8(1-bz)^2}, \quad \text{with} \quad b = 1-\lambda^2.$$

The estimate on $d_{\lambda,2}$ is derived using a simple inequality $a^2 + b^2 \geq 2ab$. The estimate on $d_{\lambda,3}$ is nontrivial and its derivation is given in Appendix A.

In summary, we obtained the following approximation results for mapping (1.4).

COROLLARY 3.2. *For any $v \in H^r_{\omega_\lambda^{(r)}}(I)$, $\lambda \in (0,1)$, and $r \geq 1$,*

$$\|\partial_x(P_{N,\lambda}v - v)\|_{\tilde{\omega}_\lambda} + N\|P_{N,\lambda}v - v\|_{\omega_\lambda} \lesssim C_\lambda^r N^{1-r}\|v\|_{r,\omega_\lambda^{(r)}}, \tag{3.24}$$

and for $r > 1$,

$$\|\partial_x(\mathcal{I}_{N,\lambda}v - v)\|_{\tilde{\omega}_\lambda} + N\|\mathcal{I}_{N,\lambda}v - v\|_{\omega_\lambda} \lesssim C_\lambda^r N^{1-r}\|v\|_{r,\omega_\lambda^{(r)}}, \tag{3.25}$$

while for any $v \in H^r_{\omega_\lambda^{(r-1)}}(I)$ and $r \geq 1$,

$$\|P^1_{N,\lambda}v - v\|_{1,\omega_\lambda} \lesssim C_\lambda^{r+1} N^{1-r}\|v\|_{r,\omega_\lambda^{(r-1)}}. \tag{3.26}$$

If, in addition, $\nu_2 > \frac{\nu_1}{2} d_{\lambda,3}$ and $v \in H^1_{0,\omega_\lambda}(I)$, then

$$|||P^{1,0}_{N,\lambda}v - v|||_{1,\omega_\lambda} \lesssim (\nu_1^{\frac{1}{2}}(d_{\lambda,1}+1)(d_{\lambda,2}+1)^{\frac{1}{2}} + \nu_2^{\frac{1}{2}}N^{-1})N^{1-r}\|v\|_{r,\omega_\lambda^{(r-1)}}, \tag{3.27}$$

where $d_{\lambda,i}, i = 1,2,3$ are given in (3.23).

3.3. The mapping (1.5). In this case, $\lambda = (\lambda_1, \lambda_2)$ and $D_\lambda = \{(\lambda_1, \lambda_2) \mid \lambda_1 > 0, \ -1 \leq \lambda_2 < 1\}$. The mapping (1.5) is explicitly invertible:

$$y = h(x;\lambda) = a_0 + \arctan(\lambda_1(x - \lambda_2))/a_1. \tag{3.28}$$

The values of a_0 and a_1 are

$$a_0 = a_0(\lambda) = \frac{\kappa_1 - \kappa_2}{\kappa_1 + \kappa_2}, \qquad a_1 = a_1(\lambda) = \frac{\kappa_1 + \kappa_2}{2}, \tag{3.29}$$

where

$$\kappa_1 = \arctan(\lambda_1(1+\lambda_2)), \qquad \kappa_2 = \arctan(\lambda_1(1-\lambda_2)). \tag{3.30}$$

With the above choice, we find that

$$-1 \leq a_0 < 1, \qquad 0 < a_1 < \frac{\pi}{2}. \tag{3.31}$$

The weight functions are

$$\omega_\lambda(x) = \frac{dy}{dx} = \frac{\lambda_1}{a_1(1+\lambda_1^2(x-\lambda_2)^2)} = \Big(\frac{dx}{dy}\Big)^{-1} = \frac{\lambda_1}{a_1}\cos^2(a_1(y-a_0)), \tag{3.32}$$

$$\tilde{\omega}_\lambda(x) = a_1^{-1}\lambda_1^{-1}(\kappa_1 - q(x;\lambda))(\kappa_2 + q(x;\lambda))(1+\lambda_1^2(x-\lambda_2)^2), \tag{3.33}$$

where $q(x;\lambda) = \arctan(\lambda_1(x-\lambda_2))$.

For simplicity, we rewrite (3.32) as

(3.34)
$$\frac{dx}{dy} = \frac{a_1(\lambda_1+1)^2}{\lambda_1}\left(\frac{1}{(\lambda_1+1)^2} + \frac{\lambda_1^2}{(\lambda_1+1)^2}(x-\lambda_2)^2\right) := C_\lambda(D_1 + D_2(x-\lambda_2)^2).$$

Since $a_1 \to \lambda_1$ as $\lambda_1 \to 0$, we have that for all $\lambda \in D_\lambda$,

$$C_\lambda \lesssim \lambda_1 + 1, \qquad 0 < C_\lambda^{-1}, D_1, D_2 \le 1. \tag{3.35}$$

Let us denote by $Q_l(x-\lambda_2)$ a polynomial of degree l with respect to $x-\lambda_2$ with coefficients in terms of D_1, D_2, and C_λ^{-1}. Then, by (3.28) and (3.34),

$$\partial_y V_\lambda(y) = \partial_x v(x)\frac{dx}{dy} = C_\lambda Q_2(x-\lambda_2)\partial_x v(x),$$
$$\partial_y^2 V_\lambda(y) = \frac{d(\partial_y V_\lambda(y))}{dx}\frac{dx}{dy} = C_\lambda^2(Q_4(x-\lambda_2)\partial_x^2 v(x) + Q_3(x-\lambda_2)\partial_x v(x)).$$

Hence, by an induction argument, we find that for $k \ge 1$,

$$\partial_y^k V_\lambda(y) = C_\lambda^k \sum_{j=1}^{k} Q_{k+j}(x-\lambda_2)\partial_x^j v(x), \tag{3.36}$$

where $Q_{k+j}(x-\lambda_2)$ $(1 \le j \le k)$ are uniformly bounded for all $x \in \bar{I}$ and $\lambda \in D_\lambda$. Let us denote

(3.37)
$$S_\lambda(x;r) := (1-y^2)^r = \frac{1}{a_1^{2r}}\Big(\kappa_2 - \arctan(\lambda_1(x-\lambda_2))\Big)^r\Big(\kappa_1 + \arctan(\lambda_1(x-\lambda_2))\Big)^r.$$

We have $S_\lambda(x;r) \le 1$, and

$$\lim_{x\to 1}\frac{\kappa_2 - \arctan(\lambda_1(x-\lambda_2))}{1-x} = \frac{\lambda_1}{1+\lambda_1^2(1-\lambda_2)^2},$$

$$\lim_{x\to -1}\frac{\kappa_1 + \arctan(\lambda_1(x-\lambda_2))}{1+x} = \frac{\lambda_1}{1+\lambda_1^2(1+\lambda_2)^2}.$$

Consequently,

(3.38)
$$\lim_{|x|\to 1} S_\lambda(x;r) = G_\lambda^r(1-x^2)^r \quad \text{with} \quad G_\lambda = \frac{\lambda_1^2}{a_1^{2r}(1+\lambda_1^2(1-\lambda_2)^2)(1+\lambda_1^2(1+\lambda_2)^2)}.$$

Next, let

$$\varpi_\lambda^{(r)}(x) := \omega_\lambda(x)S_\lambda(x;r) \lesssim \omega_\lambda(x), \quad x \in I,\ \lambda \in D_\lambda.$$

By the definition of $|v|_{A_\lambda^r}$ and (3.35),

$$|v|_{A_\lambda^r} \lesssim (\lambda_1+1)^r \|v\|_{r,\varpi_\lambda^{(r)}}, \qquad r \ge 0, \quad \lambda \in D_\lambda. \tag{3.39}$$

Similarly, we deduce that

$$|v|_{B^r_\lambda} \lesssim (\lambda_1+1)^r \|v\|_{r,\varpi^{(r-1)}_\lambda}, \qquad r\geq 1, \quad \lambda\in D_\lambda. \tag{3.40}$$

Remark 3.4. We find from (3.28)–(3.30) and (3.32) that

$$a_0\to\lambda_2, \quad a_1\to 1, \quad h(x;\lambda)\to x, \quad \omega_\lambda(x)\to 1, \quad \text{as} \quad \lambda_1\to 0.$$

So we have the same estimate as for the standard Legendre case:

$$|v|_{A^r_\lambda} \lesssim \|(1-x)^{\frac{r}{2}}\partial_x^r v\|, \qquad |v|_{B^r_\lambda} \lesssim \|(1-x)^{\frac{r-1}{2}}\partial_x^r v\|.$$

Remark 3.5. We observe from the derivation of (3.36) that if the function v possesses certain special properties as specified below, more precise estimates can be derived. For instance, if the rapid variational region of $v(x)$ is contained in $O_\varepsilon(\lambda_2) := (\lambda_2-\varepsilon,\lambda_2+\varepsilon)$ for some $\varepsilon>0$, we can assume

$$\sup_{x\in I_\epsilon} |\partial_x^j v(x)| \leq \delta(\varepsilon) C_\lambda^{-r}, \qquad 0\leq j\leq r,$$

where $I_\varepsilon = \bar I \setminus O_\varepsilon(\lambda_2)$, and $\delta(\varepsilon)$ is a small positive number corresponding to ε. Then

$$|v|_{A^r_\lambda} \lesssim \Big(\delta(\varepsilon) + a_1^r\lambda_1^{-r}(1+\lambda_1^2\varepsilon^2)^r \|v\|_{H^r_{\omega^{(r)}_\lambda}(O_\varepsilon(\lambda_2))}\Big).$$

In particular, if

$$\mathrm{supp}\{\partial_x^j v(x)\} \subseteq \overline{O_\varepsilon(\lambda_2)} \subseteq [-1,1], \qquad 0\leq j\leq r,$$

then we have

$$|v|_{A^r_\lambda} \lesssim \Big(a_1^r\lambda_1^{-r}(1+\lambda_1^2\varepsilon^2)^r \|v\|_{H^r_{\omega^{(r)}_\lambda}(O_\varepsilon(\lambda_2))}\Big).$$

The above analysis is also valid for $|v|_{B^r_\lambda}$.

Next, we compute the values of $d_{\lambda,i}, i=1,2,3$. Using (3.28) and (3.32) yields

$$d_{\lambda,1} = a_1\lambda_1^{-1}, \quad d_{\lambda,2} = \max_{x\in\bar I} \frac{2\lambda_1^2|x-\lambda_2|}{1+\lambda_1^2(x-\lambda_2)^2} \leq \lambda_1, \quad d_{\lambda,3} \leq \frac{3}{2}\lambda_1^2. \tag{3.41}$$

The derivation of $d_{\lambda,3}$ is a little complicated, so we defer it to Appendix B.

A combination of Theorems 2.1–2.4 and the above estimates leads to the following approximation results.

COROLLARY 3.3. *For any $v\in H^r_{\varpi^{(r)}_\lambda}(I)$, $\lambda\in D_\lambda$, and $r\geq 1$,*

$$\|\partial_x(P_{N,\lambda}v-v)\|_{\tilde\omega_\lambda} + N\|P_{N,\lambda}v-v\|_{\omega_\lambda} \lesssim (\lambda_1+1)^r N^{1-r}\|v\|_{r,\varpi^{(r)}_\lambda}, \tag{3.42}$$

and for $r>1$,

$$\|\partial_x(\mathcal{I}_{N,\lambda}v-v)\|_{\tilde\omega_\lambda} + N\|\mathcal{I}_{N,\lambda}v-v\|_{\omega_\lambda} \lesssim (\lambda_1+1)^r N^{1-r}\|v\|_{r,\varpi^{(r)}_\lambda}, \tag{3.43}$$

while for any $v\in H^r_{\varpi^{(r-1)}_\lambda}(I)$ and $r\geq 1$,

$$\|P^1_{N,\lambda}v-v\|_{1,\omega_\lambda} \lesssim (\lambda_1+1)^r N^{1-r}\|v\|_{r,\varpi^{(r-1)}_\lambda}. \tag{3.44}$$

If, in addition, $\nu_2 > \frac{\nu_1}{2}d_{\lambda,3}$ and $v\in H^1_{0,\omega_\lambda}(I)$, then

$$|||P^{1,0}_{N,\lambda}v-v|||_{1,\omega_\lambda} \lesssim (\nu_1^{\frac12}(d_{\lambda,1}+1)(d_{\lambda,2}+1)^{\frac12} + \nu_2^{\frac12}N^{-1})N^{1-r}\|v\|_{r,\varpi^{(r-1)}_\lambda}, \tag{3.45}$$

where $d_{\lambda,i}, i=1,2,3$, are given in (3.41).

3.4. Some other mappings. We consider here several useful mappings which do not quite fit into our framework.

Let us consider first the mapping

$$C(s) = (1-b)\frac{\sinh(\theta s)}{\sinh(\theta)} + b\frac{\tanh(\theta(s+1/2)) - \tanh(\theta/2)}{2\tanh(\theta/2)}, \quad s \in [-1,0], \tag{3.46}$$

which was first introduced by Song and Haidvogel [26] as part of the so-called s-coordinates in their ocean circulation model. The two parameters $0 \le \theta \le 20$ and $0 \le b \le 1$ are used to fit the surface and bottom topography.

In order to apply our general framework, we set $s = \frac{y-1}{2}$, $x = 2C(s)+1$, $\lambda_1 = \theta$, and $\lambda_2 = b$ in (3.46) to get

$$x = g(y;\lambda) = 2(1-\lambda_2)\frac{\sinh(\lambda_1(y-1)/2)}{\sinh(\lambda_1)} + \lambda_2\frac{\tanh(\lambda_1 y/2) - \tanh(\lambda_1/2)}{\tanh(\lambda_1/2)} + 1, \tag{3.47}$$
$$y \in [-1,1], \quad \lambda_1 \ge 0, \quad 0 \le \lambda_2 \le 1.$$

Clearly, it maps the interval $[-1,1]$ univalently onto itself with $g(\pm 1;\lambda) = \pm 1$, and it is an identity mapping when $\lambda_1 = 0$. However, this mapping is not explicitly invertible. For simplicity, we consider only the special case $\lambda_2 = 0$ and denote $\lambda := \lambda_1$. In this case, the weight function is

$$\omega_\lambda(x) = \Big(\frac{dx}{dy}\Big)^{-1} = \frac{\sinh\lambda}{\lambda}\mathrm{sech}(\lambda(y-1)/2) > 0, \quad x, y \in I,\ \lambda > 0. \tag{3.48}$$

One can verify readily that

$$\frac{\tanh\lambda}{\lambda} \le \omega_\lambda(x) \le \frac{\sinh\lambda}{\lambda}, \quad x \in I,\ \lambda > 0.$$

To estimate the corresponding upper bounds of $|v|_{A^r_\lambda}$ and $|v|_{B^r_\lambda}$ (cf. section 2), we can follow the same procedure as for the mapping (1.3). Since

$$\frac{d^k x}{dy^k} = \frac{2}{\sinh\lambda}\Big(\frac{\lambda}{2}\Big)^k \begin{cases} \sinh(\lambda(y-1)/2) & \text{if } k \text{ is even,} \\ \cosh(\lambda(y-1)/2) & \text{if } k \text{ is odd,} \end{cases}$$

we find

$$\Big|\frac{d^k x}{dy^k}\Big| \lesssim \lambda^k \coth\lambda, \quad x \in \bar{I},\ \lambda > 0,\ k \ge 1.$$

As in the derivations of (3.4)–(3.6), we obtain that for any $v \in H^r_{\omega_\lambda}(I)$,

$$|v|_{A^r_\lambda},\ |v|_{B^r_\lambda} \lesssim \lambda^r (\coth\lambda)^r ||v||_{r,\omega_\lambda}. \tag{3.49}$$

In view of the facts

$$\coth\lambda \sim \lambda^{-1} \text{ if } \lambda \ll 1, \quad \coth\lambda \sim 1 \text{ if } \lambda \gg 1,$$

we conclude that for small λ, this mapping is close to the identity mapping, while for large λ, an extra factor λ^r appears in the error estimates.

The mapping techniques have been successfully used in spectral methods to resolve boundary layers. For instance, the following mapping is used in [21] and [22]:

(3.50)
$$x = g(y;m) = -1 + \sigma_m \int_{-1}^{y} (1-t^2)^m dt, \ \text{ with } \sigma_m = 2\Big/\int_{-1}^{1}(1-y^2)^m dy, \ \ m \in \mathbb{N}.$$

Clearly, we have $g(\pm 1;m) = \pm 1$, and

$$\omega_m(x) = \sigma_m^{-1}(1-y^2)^{-m}, \quad x, y \in I. \tag{3.51}$$

As m increases, more and more Gauss-type collocation points are clustered near the end-points ± 1 so it is suitable for resolving very thin boundary layers. However, the mapping is singular at the end-points, which implies in particular that $d_{\lambda,1} = \infty$. The same is true for the iterated mappings introduced by Tang and Trummer [27],

$$x_0 = y, \quad x_m = \sin\Big(\frac{\pi}{2}x_{m-1}\Big), \quad m \geq 1, \tag{3.52}$$

which are very effective mappings for problems with thin boundary layers. Hence we cannot directly apply our general framework to these mappings. Although it is possible to derive some special estimates as we did in Remark 3.2, the computations would be very tedious. However, we shall consider in a forthcoming paper the mapped Jacobi method in which we will be able to handle mappings with singularities at the end-points.

4. The mapped Legendre methods for a model equation. To illustrate how the results we developed in previous sections can be applied to analyze the mapped Legendre spectral and pseudospectral methods for PDEs, we consider the following model equation:

$$\begin{cases} -\varepsilon\partial_x^2 u(x) + u(x) = f(x), & x \in I, \\ u(\pm 1) = 0. \end{cases} \tag{4.1}$$

Let $\nu_1 = \varepsilon$ and $\nu_2 = 1$ and $\omega_\lambda(x)$, $a^{(\nu)}_{\omega_\lambda}(\cdot,\cdot)$ be the same as in section 2. A weighted variational formulation for (4.1) is to find $u \in H^1_{0,\omega_\lambda}(I)$ such that

$$a^{(\nu)}_{\omega_\lambda}(u,v) = (f,v)_{\omega_\lambda} \qquad \forall v \in H^1_{0,\omega_\lambda}(I). \tag{4.2}$$

It is clear from Lemma 2.3 that, if $\varepsilon d_{\lambda,3} < 2$ and $f \in L^2_{\omega_\lambda}(I)$, (4.2) admits a unique solution.

4.1. Error estimates. The mapped Legendre spectral approximation for (4.2) is to find $u_N \in \mathcal{V}^0_{N,\lambda}$ such that

$$a^{(\nu)}_{\omega_\lambda}(u_N, v_N) = (f, v_N)_{\omega_\lambda} \qquad \forall v_N \in \mathcal{V}^0_{N,\lambda}. \tag{4.3}$$

Let $P^{1,0}_{N,\lambda}$ be the projector as in Theorem 2.3. Then, by (2.40), (4.2), and (4.3),

$$a^{(\nu)}_{\omega_\lambda}(u - u_N, v_N) = a^{(\nu)}_{\omega_\lambda}(P^{1,0}_{N,\lambda}u - u_N, v_N) = 0 \qquad \forall v_N \in \mathcal{V}^0_{N,\lambda}.$$

As a consequence of Theorem 2.3, we have the following theorem.

THEOREM 4.1. *Let u and u_N be, respectively, the solutions of* (4.2) *and* (4.3). *If* $\varepsilon d_{\lambda,3} < 2$, $u \in H^1_{0,\omega_\lambda}(I) \cap B^r_\lambda(I)$, $\lambda \in D_\lambda$, *and* $r \geq 1$, *then*

$$|||u - u_N|||_{1,\omega_\lambda} \lesssim (\varepsilon^{\frac{1}{2}}(d_{\lambda,1}+1)(d_{\lambda,2}+1)^{\frac{1}{2}} + N^{-1})N^{1-r}|u|_{B^r_\lambda}, \tag{4.4}$$

where $d_{\lambda,i}, i = 1, 2, 3$, *are the same as in Theorem* 2.3. *For the mappings* (1.3)–(1.5), *the upper bound of* $|u|_{B^r_\lambda}$ *and the values of* $d_{\lambda,i}, i = 1, 2, 3$, *are given in section* 3.

Unlike in the standard Legendre–Galerkin method, where the linear system can be made sparse by choosing suitable basis functions [24], the linear system associated to (4.3) is in general full (unless a very special mapping is used), and furthermore, it is very costly to evaluate the entries of the linear system. Hence it is often convenient to use the mapped Legendre collocation method: find $u_N \in \mathcal{V}^0_{N,\lambda}$ such that

$$-\varepsilon\partial_x^2 u_N(\xi^{(\lambda)}_{N,j}) + u_N(\xi^{(\lambda)}_{N,j}) = f(\xi^{(\lambda)}_{N,j}), \qquad 1 \leq j \leq N-1, \tag{4.5}$$

where $\{\xi^{(\lambda)}_{N,j}\}_{j=0}^N$ are the mapped LGL points defined in (2.43). Taking the discrete inner product of (4.5) with any $v_N \in \mathcal{V}^0_{N,\lambda}$, thanks to (2.44), we find that (4.5) is equivalent to the following: find $u_N \in \mathcal{V}^0_{N,\lambda}$ such that

$$\varepsilon(\partial_x u_N, \partial_x(\omega_\lambda v_N)) + (u_N, v_N)_{\omega_\lambda,N} = (f, v_N)_{\omega_\lambda,N} \qquad \forall v_N \in \mathcal{V}^0_{N,\lambda}. \tag{4.6}$$

We note that the linear system associated with the above formulation is full and ill conditioned. However, as demonstrated in [24, 25], it can be efficiently solved by using a preconditioned conjugate gradient–type iterative method with the standard Legendre–Galerkin method for (4.1) as a preconditioner. Note that with the collocation approach, there is no additional cost involved if the original PDE (4.1) has variable coefficients.

THEOREM 4.2. *Let u and u_N be, respectively, the solutions of* (4.2) *and* (4.6). *If* $\varepsilon d_{\lambda,3} < 2$, $u \in H^1_{0,\omega_\lambda}(I) \cap B^r_\lambda(I)$, *and* $f \in A^s_\lambda(I), \lambda \in D_\lambda$ *with* $r \geq 1$ *and* $s > 1$, *then*

$$|||u - u_N|||_{1,\omega_\lambda} \lesssim (\varepsilon^{\frac{1}{2}}(d_{\lambda,1}+1)(d_{\lambda,2}+1)^{\frac{1}{2}} + N^{-1})N^{1-r}|u|_{B^r_\lambda} + N^{-s}|f|_{A^s_\lambda}, \tag{4.7}$$

where $d_{\lambda,i}, i = 1, 2, 3$, *are the same as in Theorem* 2.3. *For the mappings* (1.3)–(1.5), *the upper bounds of* $|u|_{B^r_\lambda}, |f|_{A^s_\lambda}$ *and the values of* $d_{\lambda,i}, i = 1, 2, 3$, *are given in section* 3.

Proof. Let $U_N = P^{1,0}_{N,\lambda}u$ and $\hat{e}_N = U_N - u_N$. Then by (2.40), (4.2), and (4.6),

$$\begin{aligned} \varepsilon(\partial_x \hat{e}_N, \partial_x(\omega_\lambda v_N)) + (\hat{e}_N, v_N)_{\omega_\lambda,N} &= (U_N, v_N)_{\omega_\lambda,N} - (U_N, v_N)_{\omega_\lambda} \\ &\quad + (f, v_N)_{\omega_\lambda} - (f, v_N)_{\omega_\lambda,N} \qquad \forall v_N \in \mathcal{V}^0_{N,\lambda}. \end{aligned} \tag{4.8}$$

Taking $v_N = \hat{e}_N$ in (4.8), we have from (2.45) that

$$\begin{aligned} a^{(\nu)}_\lambda(\hat{e}_N, \hat{e}_N) &\leq \varepsilon(\partial_x \hat{e}_N, \partial_x(\omega_\lambda \hat{e}_N)) + \|\hat{e}_N\|^2_{\omega_\lambda,N} \\ &\leq |(U_N, \hat{e}_N)_{\omega_\lambda,N} - (U_N, \hat{e}_N)_{\omega_\lambda}| + |(f, \hat{e}_N)_{\omega_\lambda} - (f, \hat{e}_N)_{\omega_\lambda,N}|. \end{aligned} \tag{4.9}$$

By Remark 2.3,

$$|(f, \hat{e}_N)_{\omega_\lambda} - (f, \hat{e}_N)_{\omega_\lambda,N}| \lesssim N^{-s}|f|_{A^s_\lambda}\|\hat{e}_N\|_{\omega_\lambda}.$$

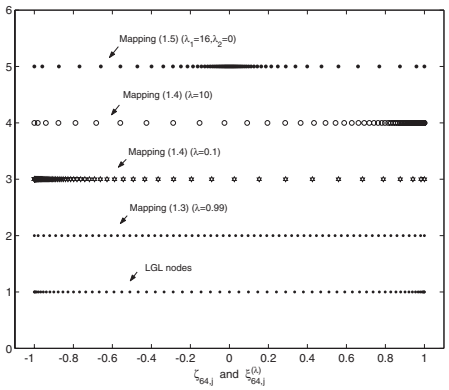

FIG. 1. *LGL vs. MLGL points.*

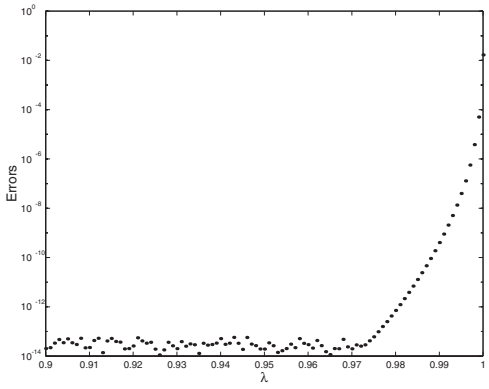

FIG. 2. *Errors for mapping* (1.3).

Moreover, by (2.44), (2.45), and Theorem 2.3,

$$\begin{aligned}|(U_N,\hat{e}_N)_{\omega_\lambda,N}-(U_N,\hat{e}_N)_{\omega_\lambda}| &\le |(U_N-P^{1,0}_{N-1,\lambda}u,\hat{e}_N)_{\omega_\lambda,N}|+|(U_N-P^{1,0}_{N-1,\lambda}u,\hat{e}_N)_{\omega_\lambda}|\\ &\lesssim \|U_N-P^{1,0}_{N-1,\lambda}u\|_{\omega_\lambda}\|e_N\|_{\omega_\lambda}\lesssim (|||U_N-u|||_{1,\omega_\lambda}+|||P^{1,0}_{N-1,\lambda}u-u|||_{1,\omega_\lambda})\|\hat{e}_N\|_{\omega_\lambda}\\ &\lesssim (\varepsilon^{\frac{1}{2}}(d_{\lambda,1}+1)(d_{\lambda,2}+1)^{\frac{1}{2}}+N^{-1})N^{1-r}|u|_{B^r_\lambda}\|\hat{e}_N\|_{\omega_\lambda}.\end{aligned}$$

The desired results follow from the above estimates. □

4.2. Numerical results. We now present some numerical results with emphasis on how the accuracy depends on the choice of the parameters in the mappings (1.3)–(1.5).

We first illustrate the effects of the parameters on the distributions of the MLGL points. In Figure 1, we plot the LGL points vs. the MLGL points ($N = 64$) with several typical parameters. It is clear that the mapping (1.3) stretches the grid evenly as $\lambda \to 1$; the mapping (1.4) clusters the points to $x = -1$ (resp., $x = 1$) for $\lambda < 1$ (resp., $\lambda > 1$); and the mapping (1.5) clusters the points to $x = \lambda_2$ for $\lambda_1 > 1$.

Example 1. We consider (4.1) with the exact solution

$$u(x) = \frac{e^{(1+x)/\sqrt{\varepsilon}} - e^{-(1+x)/\sqrt{\varepsilon}}}{e^{2/\sqrt{\varepsilon}} - e^{-2/\sqrt{\varepsilon}}} - \frac{1+x}{2}.$$

This solution exhibits a boundary layer of width $O(\sqrt{\varepsilon})$ at $x = -1$.

We first take $\varepsilon = 0.1$ so the solution is smoothly varying throughout the domain. We use (4.5) with the mapping (1.3) and $N = 100$ to approximate (4.1). In Figure 2, we plot the maximum absolute errors between u and u_N at the MLGL points with $\lambda \in [0.9, 1]$. We see that the error increases very quickly as $\lambda \to 1$, which is in agreement with the theoretic analysis in Corollary 3.1 and Theorem 4.2. Hence it is not advisable to use mapping (1.3) with λ close to 1.

Next we take $\varepsilon = 10^{-8}$ so the solution has a thin boundary layer at $x = -1$, and we use (4.5) with the mapping (1.4) and $N = 100$ to approximate (4.1). We plot in Figure 3 the errors with $\lambda \in [20, 200]$. The results indicate that the errors grow as λ increases, as predicted by Corollary 3.2 and Theorem 4.2.

Example 2. We take $u(x) = \tanh(ax)$ with $a = 150$. This solution has a large derivative at $x = 0$; see Figure 4. We use (4.5) with mapping (1.5) and $N = 100$. In

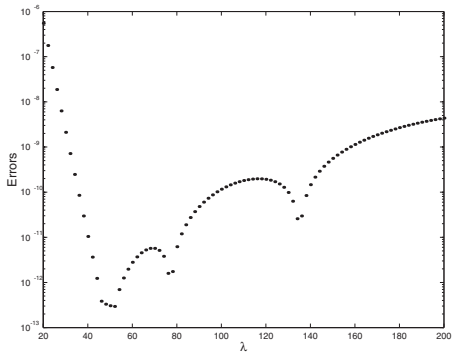

FIG. 3. *Errors for mapping* (1.4).

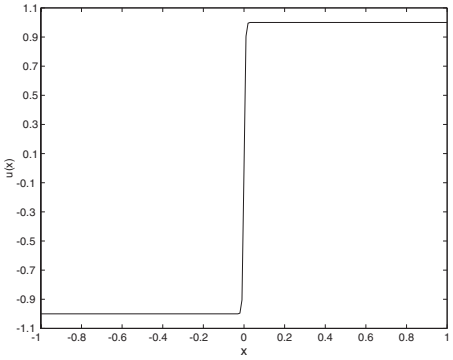

FIG. 4. *Solution in Example* 2.

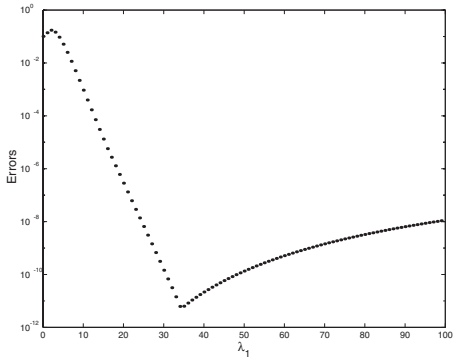

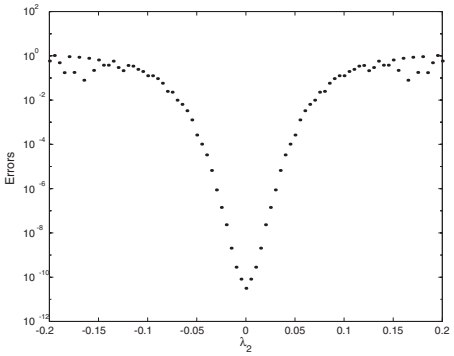

FIG. 5. *Errors for mapping* (1.5) *with* $\lambda_2 = 0$ *and various* λ_1 *(left), and with* $\lambda_1 = 51$ *and various* λ_2 *(right).*

Figure 5, we plot the maximum absolute errors at the MLGL points with $\lambda_2 = 0$ and various λ_1 (left panel) and with $\lambda_1 = 51$ and different λ_2 (right panel). Note that the accuracy is very sensitive to the choice of the parameter λ_2, which should be at the location of large variation, but less sensitive to the values of λ_1, which represents the intensity of the mapping at $x = \lambda_2$. Again, the numerical results are in agreement with Corollary 3.3 and Theorem 4.2.

5. Concluding remarks. We presented a general framework for analyzing the approximation properties of mapped Legendre polynomials and of interpolations based on MLGL points and derived optimal error estimates for general mappings. More precisely, we introduced a new family of orthogonal functions which are obtained by applying the mapping to Legendre polynomials, and we analyzed various projection and interpolation operators based on these mapped Legendre functions.

As an application of our general results, we considered the popular mappings (1.3)–(1.5) introduced in [20, 3, 4] and derived error estimates featuring explicit expressions on the mapping parameters. We used a model equation to show that these results not only play an important role in numerical analysis of mapped Legendre spectral and pseudospectral methods for differential equations but also provide quantitative criteria for the choice of parameters in these mappings.

This paper is a first step toward a long-term goal of designing a robust adaptive spectral method for solving PDEs.

Appendix A. The derivation of $d_{\lambda,3}$ in (3.23). For $\lambda = 1$, we have $d_{\lambda,3} \equiv 0$. We next consider $\lambda \neq 1$. For simplicity, let $z = \sin^2(\pi(x-1)/4)$ and $b = 1 - \lambda^2$. By (3.19) and a direct calculation, we find that

$$S_\lambda(z) := \omega_\lambda^{-1}(x)\partial_x^2\omega_\lambda(x) = \frac{\pi^2 b(-2bz^2 + (3b-2)z + 1)}{8(1-bz)^2}$$

and

$$S'_\lambda(z) = \frac{\pi^2 b(3b(b-2)z + 5b - 2)}{8(1-bz)^3}.$$

Let us denote

$$z_0 = -\frac{5b-2}{3b(b-2)} = \frac{5\lambda^2 - 3}{3(1-\lambda^4)}, \quad e_0 = \sqrt{\frac{\sqrt{97}-5}{6}}, \quad e_1 = \sqrt{\frac{5}{3}}.$$

We find that

$$\text{if } \ 0 < \lambda \le e_0 \quad \text{or} \quad \lambda \ge e_1, \ \text{ then } |z_0| \le 1.$$

Hence

$$\begin{aligned} d_{\lambda,3} &= \max_{z\in[0,1]} S_\lambda(z) = \max\{S_\lambda(0), S_\lambda(z_0), S_\lambda(1)\} \\ &= \begin{cases} \max\{\frac{\pi^2}{8}(1-\lambda^2), S_\lambda(z_0)\} & \text{if} \quad 0 < \lambda \le e_0, \\ \frac{\pi^2}{8}(1-\lambda^2) & \text{if} \quad e_0 < \lambda \le 1, \\ \frac{\pi^2(\lambda^2-1)}{8\lambda^2} & \text{if} \quad 1 < \lambda \le e_1, \\ \max\{\frac{\pi^2(\lambda^2-1)}{8\lambda^2}, S_\lambda(z_0)\} & \text{if} \quad \lambda > e_1. \end{cases} \end{aligned}$$

Appendix B. The derivation of $d_{\lambda,3}$ in (3.41). By (3.28), (3.32), and a direct calculation, we find

$$W_\lambda(x) := \omega_\lambda^{-1}(x)\partial_x^2\omega_\lambda(x) = \frac{2\lambda_1^2(3\lambda_1^2(x-\lambda_2)^2 - 1)}{(1+\lambda_1^2(x-\lambda_2)^2)^2}$$

and

$$\partial_x W_\lambda(x) = \frac{4\lambda_1^2(x-\lambda_2)(5 - 3\lambda_1^2(x-\lambda_2)^2)}{(1+\lambda_1^2(x-\lambda_2)^2)^3}.$$

Clearly, $W_\lambda(\lambda_2) = -2\lambda_1^2$, and if x is such that $\lambda_1^2(x-\lambda_2)^2 = \frac{5}{3}$, we have $W_\lambda(x) = \frac{9}{8}\lambda_1^2$. Hence

$$W_\lambda(\lambda_2) \le W_\lambda(\pm 1) = \frac{2\lambda_1^2(3\lambda_1^2(\pm 1 - \lambda_2)^2 - 1)}{(1+\lambda_1^2(\pm 1-\lambda_2)^2)^2} \le 6\lambda_1^2\Big(\frac{\lambda_1|\pm 1 - \lambda_2|}{1+\lambda_1^2(\pm 1-\lambda_2)^2}\Big)^2 \le \frac{3}{2}\lambda_1^2.$$

Therefore,

$$-2\lambda_1^2 \le W_\lambda(x) \le \frac{3}{2}\lambda_1^2, \qquad x \in \bar{I}.$$

This completes the proof. ∎

CONVERGENCE OF A SEMI-LAGRANGIAN SCHEME FOR THE ONE-DIMENSIONAL VLASOV–POISSON SYSTEM*

NICOLAS BESSE†

Abstract. A semi-Lagrangian scheme is proposed for solving the periodic one-dimensional Vlasov–Poisson system in phase space on unstructured meshes. The distribution function $f(t, x, v)$ and the electric field $E(t, x)$ are shown to converge to the exact solution values in the L^∞ norm. The rate of convergence is in $O(h^{4/3})$.

Key words. Vlasov–Poisson system, semi-Lagrangian methods, convergence analysis

AMS subject classifications. 65M12, 82D10

DOI. 10.1137/S0036142902410775

1. Introduction.

The numerical resolution of the Vlasov equation is usually performed by Lagrangian methods like particles-in-cell methods (PIC), which consist of approximating the plasma by a finite number of macroparticles. The trajectories of these particles are computed from the characteristic curves given by the Vlasov equation, whereas self-consistent fields are computed by gathering the charge and current densities of the particles on a mesh of the physical space (see Birdsall and Langdon [10] for more details). Although this method allows us to obtain satisfying results with a small number of particles, it is well known that the numerical noise inherent to the particle method becomes too large to allow a precise description of the tail of the distribution function, which plays an important role in charged particle beams. To remedy this problem, Eulerian methods have been proposed which consist of discretizing the Vlasov equation on a mesh of phase space. For example, finite volume schemes, which are known to be robust and computationally cheap, have been implemented by Boris and Book [11], Cheng and Knorr [13], and more recently Mineau [32], Fijalkow [19], and Filbet, Sonnendrücker, and Bertrand [21]. Nevertheless, finite volume schemes are low order, too dissipative, and restricted by a CFL condition.

Other kinds of Eulerian method are the semi-Lagrangian methods which, in some particular cases, can be regarded as local versions of characteristic Galerkin methods [3, 4], which have been used in convection-diffusion problems [17, 35, 25]. Semi-Lagrangian methods were introduced at the beginning of the 1980s for the time-advection of various atmospheric and fluid dynamics models [43, 42, 37], which can be formulated as abstract Liouville systems (ALS). Semi-Lagrangian advection attempts to combine the advantages of both Eulerian and Lagrangian advection schemes while ameliorating their drawbacks. Eulerian advection schemes have good resolution properties, but CFL condition number, which is a necessary condition for achieving numerical stability, often leads to overly restrictive time steps. On the other hand, Lagrangian advection schemes allow one to use larger time steps, but, at later times, Lagrangian distortion (an initial regularly spaced set of particles will generally become highly irregularly spaced over long times) implies that important features of the flow

may not be well described. A semi-Lagrangian method uses a regular Cartesian mesh and different sets of particles. At each time step the set of particles is chosen such that they arrive exactly at the points of the mesh at the end of the time step, and is advected by the characteristic curves of the ALS. More precisely, the method consists of directly computing the distribution function of the ALS on a fixed Cartesian grid of phase space, by integrating (or following) the characteristic curves backward (from the end of the characteristic, which is a point of the fixed mesh, to the beginning of characteristic, during a time step) at each time step and interpolating the value at the base of the characteristics. In recent applications of semi-Lagrangian methods to lower-dimensional relativistic Vlasov–Maxwell (RVM) calculations [1, 2, 40], cubic splines are used for the interpolation scheme, linear interpolation being too dissipative. Semi-Lagrangian methods have been efficiently implemented using parallel computers [41] and give considerable promise for displaying the detailed structure of distribution functions in weak density regions.

The author extends semi-Lagrangian schemes on unstructured meshes with a different kind of high order local interpolation operator and with the possibility of having a positive and conservative method by introducing a linear combination of low order solutions and high order solutions tempered by a limiter coefficient (cf. [9]). Here we present the convergence of the method for the simplest interpolation operator, that is, the Lagrange first order interpolation operator. The scheme preserves positivity because the basis functions associated with the Lagrange first order interpolation operator are always positive. Additionally, the scheme is not limited by a CFL condition. More complicated interpolation on a triangle, which involves knowledge of the gradient of the distribution function, has been implemented successfully (cf. [9]), but it seems to be a challenge to show the convergence of these methods because we advect not only the distribution function f but also its gradients. A first result on the convergence analysis of semi-Lagrangian methods with propagation of gradients is stated in [8].

Let us note that a first work on convergence of one-dimensional particle methods is [33], where Neunzert and Wick consider nonuniform initial loadings of particles asymptotically distributed with respect to initial data. Cottet and Raviart [16] present a mathematical analysis of the particle method for solving the one-dimensional Vlasov–Poisson system, where uniform initial loadings of particles are considered. A number of additional authors have studied the convergence of particle methods for the multidimensional Vlasov–Poisson system [22, 45, 46, 49]. They have also proved convergence results on random and deterministic particle methods for the Vlasov–Poisson–Fokker–Planck kinetic equations [26, 27]. Finally, Glassey and Schaeffer have done the convergence analysis of a particle method for the RVM system [24]. Schaeffer [39] has also proved the convergence of a finite difference scheme for the one-dimensional Vlasov–Poisson–Fokker–Planck system, and Filbet [20] has shown the convergence of a finite volume scheme for the one-dimensional Vlasov–Poisson system.

Although a number of papers present satisfactory numerical results using semi-Lagrangian methods [43, 13, 40, 1, 2, 18, 9], few rigorous mathematical results on convergence analysis of semi-Lagrangian methods have been stated. Although interesting a priori estimates have been pointed out (cf. [4, 5, 18]), a lot of work still remains to give complete and rigorous results in more general situations. The more difficult step in the convergence analysis of semi-Lagrangian methods is obtaining a stability result for the interpolation operators. If stability results in the L^∞ norm seem inaccessible for high order interpolation operators because of the Runge phenomena (artificial os-

cillations, whose amplitude increases with the degree of the polynomial in the case of Lagrange interpolation, appear at the edges of finite elements), a more appropriate mathematical framework is L^2 stability. If Fourier analysis tools as Fourier series are useful for proving L^2 stability in the case of grids, convenient mathematical tools are lacking for unstructured meshes such as triangulation and have to be developed in the future. Nevertheless new results on the convergence analysis of classes of high order schemes can be found in [7, 8, 6].

This paper is organized as follows. In the first part we present the continuous problem. In the second part we expose the discrete problem and the numerical scheme to solve it. Then we study the convergence of our numerical scheme. In the last section we give refined convergence results.

2. The continuous problem. We consider a noncollisional plasma of charged particles (electrons and ions) in one dimension. We take into account the electrostatic forces and neglect the magnetic effects. Due to the great inertia of the ions compared to the electrons, we assume that the ions form a neutralizing uniform background.

Denoting by $f(t,x,v) \geq 0$ the distribution function of electrons in phase space (with mass normalized to one, the charge to plus one), and by $E(t,x)$ the self-consistent electric field, the adimensional Vlasov–Poisson system reads

$$\frac{\partial f}{\partial t} + v\frac{\partial f}{\partial x} + E(t,x)\frac{\partial f}{\partial v} = 0, \tag{2.1}$$

$$\frac{dE}{dx}(t,x) = \rho(t,x) = \int_{-\infty}^{+\infty} f(t,x,v)dv - 1. \tag{2.2}$$

We consider a periodic plasma of period L. Hence in (2.1) and (2.2) we have $x \in [0,L]$, $v \in \mathbb{R}$, $t \geq 0$, and the functions f and E satisfy the periodic boundary conditions

$$f(t,0,v) = f(t,L,v), \quad v \in \mathbb{R}, \quad \mathrm{t} \geq 0, \tag{2.3}$$

and

$$E(t,0) = E(t,L) \Longleftrightarrow \frac{1}{L}\int_0^L \int_{-\infty}^{+\infty} f(t,x,v)dvdx = 1, \quad t \geq 0, \tag{2.4}$$

which means that the plasma is globally neutral. In order to have a well-posed problem, we add to (2.1)–(2.4) a zero-mean electrostatic condition,

$$\int_0^L E(t,x)dx = 0, \quad t \geq 0, \tag{2.5}$$

and an initial condition,

$$f(0,x,v) = f_0(x,v), \quad x \in [0,L],\ v \in \mathbb{R}. \tag{2.6}$$

If we introduce the electrostatic potential $\phi = \phi(t,x)$ such that

$$E(t,x) = -\frac{\partial \phi}{\partial x}(t,x),$$

and if we denote by $G = G(x,y)$ the Green function associated with our problem—that is to say, for $y \in]0,L[$, $G(.,y)$ is the solution of

$$-\frac{\partial^2 G}{\partial x^2}(x,y) = \delta(x-y), \quad x \in [0,L], \quad G(0,y) = G(L,y),$$

where δ is the Dirac distribution—then $G(x,y)$ and $K(x,y) = -\partial_x G(x,y)$ are given by

$$G(x,y) = \begin{cases} x\left(1-\dfrac{y}{L}\right), & 0 \le x \le y, \\ y\left(1-\dfrac{x}{L}\right), & y \le x \le L, \end{cases} \qquad K(x,y) = \begin{cases} \left(\dfrac{y}{L}-1\right), & 0 \le x < y, \\ \dfrac{y}{L}, & y < x \le L. \end{cases}$$

Therefore ϕ is given by

$$\phi(t,x) = \int_0^L G(x,y)\left(\int_{-\infty}^{+\infty} f(t,y,v)dv - 1\right)dy,$$

and E can be rewritten as

$$E(t,x) = \int_0^L K(x,y)\left(\int_{-\infty}^{+\infty} f(t,y,v)dv - 1\right)dy. \tag{2.7}$$

In addition, assuming that the electric field E is smooth enough, we can solve (2.1), (2.3), and (2.6) in the classical sense as follows. For the existence, uniqueness, and regularity of the solutions of the following differential system we refer the reader to [12] and [36].

We consider the first order differential system

$$\begin{aligned} &\frac{dX}{dt}(t;s,x,v) = V(t;s,x,v), \\ &\frac{dV}{dt}(t;s,x,v) = E(t,X(t;s,x,v)) \end{aligned} \tag{2.8}$$

and denote by $t \to (X(t;s,x,v), V(t;s,x,v))$ the characteristic curves, which are the solution of (2.8) with the initial conditions

$$X(s;s,x,v) = x, \qquad V(s;s,x,v) = v. \tag{2.9}$$

Then the solution of problem (2.1), (2.6) is given by

$$f(t,x,v) = f_0(X(0;t,x,v), V(0;t,x,v)), \quad x,v \in \mathbb{R},\ \ t \ge 0. \tag{2.10}$$

We note that the periodicity in x of $f_0(x,v)$ and $E(t,x)$ implies the periodicity in x of $f(t,x,v)$. Moreover, as

$$\left|\frac{\partial(X,V)}{\partial(x,v)}\right| = 1,$$

we get

$$\frac{1}{L}\int_0^L \int_{-\infty}^{+\infty} f(t,x,v)dvdx = \frac{1}{L}\int_0^L \int_{-\infty}^{+\infty} f_0(x,v)dvdx = 1.$$

Therefore, according to the previous considerations, an equivalent form of the Vlasov–Poisson periodic problem is to find a pair (f,E), smooth enough, periodic with respect to x, with period L, and solving (2.7), (2.8), (2.9), and (2.10).

2.1. Definitions and notation. We now introduce basic notation. If $\mathbb{N}$ denotes the set of nonnegative integers, a multi-index α is an n-tuple of nonnegative integers $\alpha := (\alpha_1, \ldots, \alpha_n)$, $\alpha_i \in \mathbb{N}$, $i = 1, \ldots, n$. We have the following definitions:

$$|\alpha| = \alpha_1 + \cdots + \alpha_n,$$

$$D^\alpha = \partial_{x_1}^{\alpha_1} \ldots \partial_{x_n}^{\alpha_n}.$$

Let Ω be a domain in $\mathbb{R}^n$. For any nonnegative integer m let $\mathscr{C}^m(\Omega)$ be the vector space consisting of all functions ϕ that, together with all their partial derivatives $D^\alpha\phi$ of orders $|\alpha| \leq m$, are continuous on Ω.

We define the vector space $\mathscr{C}_b^m(\Omega)$ of all functions $\phi \in \mathscr{C}^m(\Omega)$ for which $D^\alpha\phi$ is bounded and uniformly continuous on Ω for $0 \leq |\alpha| \leq m$. $\mathscr{C}_b^m(\Omega)$ is a Banach space with the norm given by

$$||\phi||_{\mathscr{C}_b^m(\Omega)} = \max_{0 \leq |\alpha| \leq m} \sup_{z \in \Omega} |D^\alpha\phi(z)|.$$

We define $\mathscr{C}_c^m(\Omega)$ as the subspace of $\mathscr{C}_b^m(\Omega)$ consisting of those functions ϕ for which, for $0 \leq |\alpha| \leq m$, $D^\alpha\phi$ has compact support in Ω.

If $0 < \lambda \leq 1$, we define $\mathscr{C}^{m,\lambda}(\Omega)$ to be the subspace of $\mathscr{C}_b^m(\Omega)$ consisting of those functions ϕ for which, for $0 \leq |\alpha| \leq m$, $D^\alpha\phi$ satisfies in Ω a Hölder condition of exponent λ; that is, there exists a constant K such that

$$|D^\alpha\phi(x) - D^\alpha\phi(y)| \leq K|x - y|^\lambda, \quad x, y \in \Omega.$$

$\mathscr{C}^{m,\lambda}(\Omega)$ is a Banach space with norm given by

$$||\phi||_{\mathscr{C}^{m,\lambda}(\Omega)} = ||\phi||_{\mathscr{C}_b^m(\Omega)} + \max_{0 \leq |\alpha| \leq m} \sup_{\substack{x,\, y \,\in\, \Omega \\ x \neq y}} \frac{|D^\alpha\phi(x) - D^\alpha\phi(y)|}{|x - y|^\lambda}.$$

For all $\phi : \mathbb{R}^n \longrightarrow \mathbb{R}$ we let

$$\mathrm{Lip}(\phi) = \sup_{\substack{x,\, y \,\in\, \Omega \\ x \neq y}} \frac{|\phi(x) - \phi(y)|}{|x - y|}.$$

Furthermore,

$$\mathrm{Lip}(\Omega) = \{\phi : \mathbb{R}^n \longrightarrow \mathbb{R} \mid \ \mathrm{Lip}(\phi) < \infty\}$$

is a Banach space with the norm given by

$$||\phi||_{\mathrm{Lip}(\Omega)} = ||\phi||_{\mathscr{C}^{0,1}(\Omega)}.$$

We define $\mathscr{C}_{b,per_{x_i}}^m(\Omega_{x_i} \times \Omega_{n-1})$ as the subspace of $\mathscr{C}_b^m(\Omega)$ consisting of those functions ϕ which are periodic with respect to the variable x_i and bounded with respect to other variables. We also define $\mathscr{C}_{c,per_{x_i}}^m(\Omega_{x_i} \times \Omega_{n-1})$ as the subspace of $\mathscr{C}_c^m(\Omega)$ consisting of those functions ϕ which are periodic with respect to the variable x_i and compactly supported with respect to the other variables.

We denote by $L^p(\Omega)$, $1 \le p \le \infty$, the space of all equivalence classes of real-valued Lebesgue-measurable functions. $L^p(\Omega)$ is a Banach space with the norm given by

$$||\phi||_{L^p(\Omega)} = \left\{ \int_\Omega |\phi|^p d\Omega \right\}^{1/p}, \quad 1 \le p < \infty,$$
$$||\phi||_{L^\infty(\Omega)} = \text{ess } \sup_{z\in\Omega} |\phi(z)|.$$

We define $W^{m,p}(\Omega)$ to be the Sobolev space consisting of all functions ϕ which, together with all their partial derivatives $D^\alpha\phi$ taken in the sense of distribution of orders $|\alpha| \le m$, belong to the $L^p(\Omega)$ space. If we define the seminorm as

$$|\phi|_{W^{k,p}(\Omega)} = \left\{ \sum_{|\alpha|=k} |D^\alpha\phi|^p_{L^p(\Omega)} \right\}^{1/p}, \quad 1 \le p < \infty,$$
$$|\phi|_{W^{k,\infty}(\Omega)} = \max_{|\alpha|=m} \text{ ess } \sup_{z\in\Omega} |D^\alpha\phi(z)|,$$

then we provide $W^{m,p}(\Omega)$ with the norm

$$||\phi||_{W^{m,p}(\Omega)} = \left\{ \sum_{k=0}^{m} |\phi|^p_{W^{k,p}(\Omega)} \right\}^{1/p}, \quad 1 \le p < \infty,$$
$$||\phi||_{W^{m,\infty}(\Omega)} = \max_{0\le k\le m} |\phi|_{W^{k,\infty}(\Omega)}.$$

Let X be a Banach space with norm $||\cdot||_X$. We denote by $\mathscr{C}^m(0,T;X)$, $0 < T < +\infty$, the space of m-times continuously differentiable functions from $(0,T)$ into X, and by $L^p(0,T;X)$ the space of all strongly measurable functions $\phi : t \longrightarrow \phi(t)$ from $(0,T)$ into X. The following norms are defined:

$$||\phi||_{\mathscr{C}(0,T;X)} = \sup_{t\in[0,T]} ||\phi(t)||_X,$$

$$||\phi||_{\mathscr{C}^m(0,T;X)} = \sum_{k=0}^{m} \left\| \frac{d^k\phi}{dt^k} \right\|_{\mathscr{C}(0,T;X)},$$

$$||\phi||_{L^p(0,T;X)} = \left\{ \int_0^T ||\phi(t)||^p_X dt \right\}^{1/p}, \quad 1 \le p < \infty,$$

$$||\phi||_{L^\infty(0,T;X)} = \text{ess } \sup_{0<t<T} ||\phi(t)||_X.$$

Finally, we introduce the space $\ell^\infty(0,T;X)$ defined by

$$\ell^\infty(0,T;X) := \left\{ f : \{t^0,\dots,t^M\} \to X \mid \ ||f||_{\ell^\infty(0,T;X)} = \max_{1\le n\le M} ||f(t^n)||_X < \infty \right\},$$

where X denotes a functional space (in our context X should be L^p, $p \in [1,\infty]$), and the space $L^{1,\infty}$ defined by

$$L^{1,\infty} = \left\{ f \in L^1 \cap L^\infty \mid \ \|f\|_{L^{1,\infty}} < \infty \right\},$$

where

$$\|f\|_{L^{1,\infty}} = \|f\|_{L^1} + \|f\|_{L^\infty}.$$

2.2. Existence, uniqueness, and regularity of the solution of the continuous problem. In this section we recall a theorem of existence of a classical solution for the Vlasov–Poisson system. The following theorem gives the existence, uniqueness, and regularity of the classical solutions, global in time, of the Vlasov–Poisson periodic system in one dimension.

THEOREM 2.1. *Assuming $f_0 \in \mathscr{C}^1_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)$, positive, periodic with respect to the variable x with period L, and $Q(0) \leq R$ with $R > 0$ and $Q(t)$ defined as*

$$Q(t) = 1 + \sup\{|v| : \exists x \in [0, L], \quad \tau \in [0, t] \mid f(\tau, x, v) \neq 0\}$$

and

$$\frac{1}{L}\int_0^L \int_{-\infty}^{+\infty} f_0(x, v) dv dx = 1,$$

then the periodic Vlasov–Poisson system has a unique classical solution (f, E), periodic in x, with period L, for all time t in $[0, T]$, such that

$$f \in \mathscr{C}^1_b\left(0, T; \mathscr{C}^1_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)\right),$$
$$E \in \mathscr{C}^1_b\left(0, T; \mathscr{C}^1_{b,per_x}(\mathbb{R})\right),$$

and there exists a constant $C = C(R, f_0)$ dependent on R and f_0 such that

$$Q(T) \leq CT.$$

Moreover, if we assume $f_0 \in \mathscr{C}^m_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)$, then $(f, E) \in \mathscr{C}^m_b(0, T; \mathscr{C}^m_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)) \times \mathscr{C}^m_b(0, T; \mathscr{C}^m_{b,per_x}(\mathbb{R}))$ for all finite time T.

Proof. We do not write out the proof because it is a straightforward adaptation of the proof done by Schaeffer in [38]. We refer the reader to the articles [34, 28, 29, 23, 15, 30, 31]. ∎

2.3. Regularity assumptions for the continuous problem. For our purpose, we first suppose that $f_0(x, v)$ satisfies the following regularity assumptions:

$$f_0 \in \mathscr{C}^2_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v).$$

Then, as is proven in Glassey [23], if f_0 is smooth and compactly supported, the solution of the Vlasov–Poisson system remains smooth and compactly supported for all time. Theorem 2.1 gives the existence and uniqueness of the solution (f, E) such that

$$f \in \mathscr{C}^2_b\left(0, T; \mathscr{C}^2_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)\right), \tag{2.11}$$

$$E \in \mathscr{C}^2_b\left(0, T; \mathscr{C}^2_{b,per_x}(\mathbb{R})\right). \tag{2.12}$$

Further, we prove that we still have convergence under weaker regularity assumptions.

3. The discrete problem.

3.1. Space of approximation and the interpolation operator. Let $Q = [0, L] \times \mathbb{R}$, $\Omega = [0, L] \times [-R, R]$ with $R > 0$, and $\mathcal{T}_h$ be a triangulation of Q.

Before going further we impose some regularity assumptions on the triangulation $\mathcal{T}_h$ as follows:

(H1) The triangulation $\mathcal{T}_h$ is regular; that is to say, there exists a constant σ such that

$$\frac{h_T}{\rho_T} \leq \sigma \quad \forall T \in \mathcal{T}_h,$$

and the quantity $h = \max_{\{T \in \mathcal{T}_h\}} h_T$ approaches zero, where h_T and ρ_T denote, respectively, the exterior and the interior diameter of a finite element T.

(H2) All the finite elements (T, P_T, Σ_T), $T \in \mathcal{T}_h$, are affine equivalent to a single reference finite element $(\widehat{T}, \widehat{P}, \widehat{\Sigma})$ (see [14]).

Let P_m be the space Lagrange polynomial of degree less than or equal to m, and let X_h be the space defined by

$$X_h = \{g \in W^{1,\infty} \cap W^{1,p}(Q),\ g_{|_T} \in P_m\ \forall T \in \mathcal{T}_h\}.$$

Let π_h be a continuous linear interpolation operator from $W^{m+1,\infty} \cap W^{m+1,p}(Q)$, $1 \leq p < \infty$, onto X_h. The interpolation error estimations in Sobolev spaces (see [14]) give, with $k \in \{0, 1\}$ and $q \in \{p, \infty\}$,

$$||f - \pi_h f||_{W^{k,q}(Q)} \leq C h^{m+1-k} |f|_{W^{m+1,q}} \quad \forall f \in W^{m+1,\infty} \cap W^{m+1,q}(Q). \tag{3.1}$$

The space X_h is characterized by its basis functions, denoted by $\{\psi_k\}$.

3.2. Transport operators. Now we introduce some transport operators. Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be the operators defined as

$$\mathcal{T}_1 g(t, x, v) = g\left(t, x - v\frac{\Delta t}{2}, v\right),$$

$$\mathcal{T}_2 g(t, x, v) = g(t, x, v - \Delta t \widetilde{E}(t, x)),$$

where $\widetilde{E}(t, x)$ is the solution of the following problem:

$$\begin{cases} \dfrac{d\widetilde{E}}{dx}(t, x) = \displaystyle\int_v \mathcal{T}_1 g(t, x, v) dv - 1, \\ \displaystyle\int_0^L \widetilde{E}(t, x) dx = 0. \end{cases} \tag{3.2}$$

Let $\widetilde{\mathcal{T}}_1$ be the transport operator defined as

$$\widetilde{\mathcal{T}}_1 g(t, x, v) = \pi_h g\left(t, x - v\frac{\Delta t}{2}, v\right),$$

where

$$\pi_h g(t, x, v) = \sum_k g(t, x_k, v_k) \psi_k(x, v),$$

and let $\widetilde{\mathcal{T}}_2$ be defined as

$$\widetilde{\mathcal{T}}_2 g(t, x, v) = \pi_h g(t, x, v - \Delta t \widetilde{E}(t, x)).$$

Finally we introduce

$$\widetilde{\mathcal{T}}_2^{\star} g(t,x,v) = \pi_h g(t,x,v - \Delta t E_h(t,x)),$$

where $E_h(t,x)$ is the solution of the following problem:

$$\begin{cases} \dfrac{dE_h}{dx}(t,x) = \displaystyle\int_v \widetilde{\mathcal{T}}_1 g(t,x,v)dv - 1, \\ \displaystyle\int_0^L E_h(t,x)dx = 0. \end{cases} \tag{3.3}$$

Notice that (2.7) implies that $\widetilde{E}(t,x)$ and $E_h(t,x)$ are respectively given by

$$\widetilde{E}(t,x) = \int_0^L K(x,y) \left(\int_{-\infty}^{+\infty} \mathcal{T}_1 g(t,y,v)dv - 1 \right) dy$$

and

$$E_h(t,x) = \int_0^L K(x,y) \left(\int_{-\infty}^{+\infty} \widetilde{\mathcal{T}}_1 g(t,y,v)dv - 1 \right) dy.$$

4. The numerical scheme. We suppose that we know $f_h(t^n)$ defined on $\mathcal{T}_h$. Therefore the numerical scheme which allows us to go from time t^n to t^{n+1} and compute $f_h(t^{n+1})$ can be described in four steps:

- (A1) We evaluate the distribution at time t^n at the foot of the field-free characteristics starting at (x,v) at time $t^{n+1/2}$ using a Lagrange interpolation operator. This action is described by the transport operator $\widetilde{\mathcal{T}}_1$.
- (A2) The output from (A1) is integrated with respect to velocity to provide an approximation for the density at time $t^{n+1/2}$, which is then substituted into the Poisson equation (3.3) to compute the approximation of the electric field at time $t^{n+1/2}$.
- (A3) The result obtained from (A1) is evaluated at the foot of the velocity characteristic starting at (x,v) at time t^{n+1} with the acceleration field found in (A2) using a Lagrange interpolation operator. This action is described by the transport operator $\widetilde{\mathcal{T}}_2^{\star}$
- (A4) Between time $t^{n+1/2}$ and t^{n+1}, we apply step (A1) to the output from (A3). This action is described by the transport operator $\widetilde{\mathcal{T}}_1$. Then we obtain $f_h(t^{n+1})$, which is the new initial data for the algorithm (A1)–(A4).

Using transport operators defined above in section 3.2, the numerical scheme can be written as

$$f_h(t^{n+1},x,v) = \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^{\star} \circ \widetilde{\mathcal{T}}_1 f_h(t^n,x,v),$$

where $f_h(0,x,v) = \pi_h f_0(x,v)$ is a discretization of f_0 for the initial data,

$$f_h(t^n, x+L, v) = f_h(t^n,x,v) \quad \forall |v| \leq Q(T)$$

is the boundary condition in x, and

$$f_h(t^n,x,v) = 0 \quad \forall |v| > Q(T),\ \forall x \in [0,L]$$

is the boundary condition in v.

5. Convergence analysis.

5.1. Main theorem. We next give the convergence theorem.

THEOREM 5.1. *Assuming $f_0 \in \mathscr{C}^2_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)$, positive, periodic with respect to the variable x with period L, then the numerical solution of the Vlasov–Poisson system (f_h, E_h), computed by the numerical scheme exposed in section 4, converges toward the solution (f, E) of the periodic Vlasov–Poisson system, and there exists a constant $C = C(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))})$ independent of Δt, h such that*

$$||f - f_h||_{\ell^\infty(0,T;L^\infty(Q))} \leq C\left(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\left(\Delta t^2 + h^2 + \frac{h^2}{\Delta t}\right)$$

and

$$||E - E_h||_{\ell^\infty(0,T;L^\infty([0,L]))} \leq C\left(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\left(\Delta t^2 + h^2 + \frac{h^2}{\Delta t}\right).$$

Remark 5.2. In Theorem 5.1 we have a lot of choices for the time step. We note that the convergence rate is slightly better than first order: If we make the choice $\Delta t = h^{2/3}$, then the error estimate involves $h^{4/3}$ rather than h to the first power. Therefore we see that the main reason for using semi-Lagrangian schemes in lieu of particle schemes comes from the nice flexibility of the error estimates stated in Theorem 5.1, because they allow us to choose larger time steps and get convergence rates higher than one.

5.2. Idea of the proof. We want to evaluate the global error at time t^{n+1}:

$$e^{n+1} = ||f(t^{n+1}, x, v) - f_h(t^{n+1}, x, v)||_{L^\infty(Q)}.$$

Therefore we decompose $f(t^{n+1}, x, v) - f_h(t^{n+1}, x, v)$ as

$$\begin{aligned} f(t^{n+1}, x, v) - f_h(t^{n+1}, x, v) = {} & f(t^{n+1}, x, v) - \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n, x, v) \\ & + \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n, x, v) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n, x, v) \\ & + \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n, x, v) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 f(t^n, x, v) \\ & + \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 (f(t^n, x, v) - f_h(t^n, x, v)). \end{aligned}$$

In order to estimate e^{n+1} we will estimate the four terms on the right-hand side of this equation. These estimations are described in the following section.

5.3. A priori estimates. We begin with the following lemma, which gives an estimate of the time discretization error.

LEMMA 5.3. *Assume that $f \in \mathscr{C}^2_b(0,T;\mathscr{C}^2_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$; then there exists a constant C such that*

$$\left\| f(t^{n+1}) - \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) \right\|_{L^\infty(Q)} \leq C\left(\|f\|_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\Delta t^3.$$

Proof. As f is constant along the characteristic curves, we have

$$\begin{aligned} f(t^{n+1}, x, v) &= f(t^{n+1}, X(t^{n+1}; t^{n+1}, x, v), V(t^{n+1}; t^{n+1}, x, v)) \\ &= f(t^n, X(t^n; t^{n+1}, x, v), V(t^n; t^{n+1}, x, v)) \\ &= f(t^n, X(t^n), V(t^n)), \end{aligned}$$

where $X(t^n) = X(t^n; t^{n+1}, x, v)$ and $V(t^n) = V(t^n; t^{n+1}, x, v)$. On the other hand, we have

$$\begin{aligned}
\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) &= \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n, x, v) \\
&= \mathcal{T}_1 \circ \mathcal{T}_2 f\Big(t^n, x - v\tfrac{\Delta t}{2}, v\Big) \\
&= \mathcal{T}_1 f\left(t^n, x - v\tfrac{\Delta t}{2} + \tfrac{\Delta t^2}{2}\widetilde{E}(t^{n+1/2}, x), v - \Delta t \widetilde{E}(t^{n+1/2}, x)\right) \\
&= f\Big(t^n, x - v\Delta t + \tfrac{\Delta t^2}{2}\widetilde{E}\Big(t^{n+1/2}, x - v\tfrac{\Delta t}{2}\Big), v - \Delta t \widetilde{E}\Big(t^{n+1/2}, x - v\tfrac{\Delta t}{2}\Big)\Big) \\
&= f(t^n, \widetilde{X}(t^n; t^{n+1}, x, v), \widetilde{V}(t^n; t^{n+1}, x, v)) \\
&= f(t^n, \widetilde{X}(t^n), \widetilde{V}(t^n)),
\end{aligned}$$

where

$$\widetilde{X}(t^n) = x - v\Delta t + \frac{\Delta t^2}{2}\widetilde{E}\left(t^{n+1/2}, x - v\frac{\Delta t}{2}\right)$$

and

$$\widetilde{V}(t^n) = v - \Delta t \widetilde{E}\left(t^{n+1/2}, x - v\frac{\Delta t}{2}\right).$$

In order to justify the following Taylor expansion, we remember that assumption (2.12) gives $E \in \mathscr{C}^2_b(0, T; \mathscr{C}^2_{b,per_x}(\mathbb{R}))$. We notice that $\widetilde{E}$ has the same regularity in space as E, as the source terms in Poisson equations (3.2) and (2.2) also have the same regularity.

Hence a Taylor expansion gives

$$\begin{aligned}
X(t^{n+1/2}) - \big(x - v\tfrac{\Delta t}{2}\big) &= X(t^{n+1/2}) - \big(X(t^{n+1}) - V(t^{n+1})\tfrac{\Delta t}{2}\big) \\
&= X(t^{n+1/2}) - \big(X(t^{n+1}) - \tfrac{\Delta t}{2}\dot{X}(t^{n+1})\big) \\
&= O(\Delta t^2).
\end{aligned} \tag{5.1}$$

As $f \in \mathscr{C}^2_b(0, T; \mathscr{C}^2_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$, we have

$$\begin{aligned}
\frac{f(t^{n+1/2}, x, v) - f\big(t^n, x - v\frac{\Delta t}{2}, v\big)}{\frac{\Delta t}{2}} &= \partial_t f(t^{n+1/2}, x, v) + v\partial_x f(t^{n+1/2}, x, v) + O(\Delta t) \\
&= -E(t^{n+1/2}, x)\partial_v f(t^{n+1/2}, x, v) + O(\Delta t).
\end{aligned} \tag{5.2}$$

Then, using (2.7) and (5.2), we get

$$\begin{aligned}
&E(t^{n+1/2}, x) - \widetilde{E}(t^{n+1/2}, x) \\
&\quad = \int_0^L K(x, y)\left(\int_{-\infty}^{+\infty}\Big[f(t^{n+1/2}, y, v) - f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big)\Big]dv\right)dy \\
&\quad \leq C\left(\|f\|_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\Delta t^2.
\end{aligned} \tag{5.3}$$

Using (5.1) and (5.3), we obtain

$$\begin{aligned}
V(t^n) - \widetilde{V}(t^n) &= V(t^n) - \Big(V(t^{n+1}) - \Delta t \widetilde{E}\Big(t^{n+1/2}, X(t^{n+1}) - V(t^{n+1})\tfrac{\Delta t}{2}\Big)\Big) \\
&= V(t^n) - \Big(V(t^{n+1}) - \Delta t \widetilde{E}\left(t^{n+1/2}, X(t^{n+1/2}) + O(\Delta t^2)\right)\Big) \\
&= V(t^n) - \left(V(t^{n+1}) - \Delta t E\left(t^{n+1/2}, X(t^{n+1/2}) + O(\Delta t^2)\right)\right) \\
&\quad + \Delta t \Big(\widetilde{E}\ \left(t^{n+1/2}, X(t^{n+1/2}) + O(\Delta t^2)\right) \\
&\qquad - E\left(t^{n+1/2}, X(t^{n+1/2}) + O(\Delta t^2)\right)\Big) \\
&= V(t^n) - \left(V(t^{n+1}) - \Delta t E(t^{n+1/2}, X(t^{n+1/2}))\right) + O(\Delta t^3) \\
&= V(t^n) - V(t^{n+1}) + \Delta t \dot{V}(t^{n+1/2}) + O(\Delta t^3) \\
&\le C\left(\|f\|_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\Delta t^3
\end{aligned}$$

and

$$\begin{aligned}
X(t^n) - \widetilde{X}(t^n) &= X(t^n) - \Big(X(t^{n+1}) - \Delta t V(t^{n+1}) \\
&\qquad + \tfrac{\Delta t^2}{2}\widetilde{E}\Big(t^{n+1/2}, X(t^{n+1}) - V(t^{n+1})\tfrac{\Delta t}{2}\Big)\Big) \\
&= X(t^n) - \Big(X(t^{n+1}) - \Delta t V(t^{n+1}) \\
&\qquad + \tfrac{\Delta t^2}{2}\widetilde{E}\big(t^{n+1/2}, X(t^{n+1/2}) + O(\Delta t^2)\big)\Big) \\
&= X(t^n) - \Big(X(t^{n+1}) - \Delta t V(t^{n+1}) \\
&\qquad + \tfrac{\Delta t^2}{2}E\big(t^{n+1/2}, X(t^{n+1/2}) + O(\Delta t^2)\big)\Big) \\
&\quad - \tfrac{\Delta t^2}{2}\Big(\widetilde{E}(t^{n+1/2}, X(t^{n+1/2}) + O(\Delta t^2)) \\
&\qquad - E(t^{n+1/2}, X(t^{n+1/2}) + O(\Delta t^2))\Big) \\
&= X(t^n) - \Big(X(t^{n+1}) - \Delta t V(t^{n+1}) \\
&\qquad + \tfrac{\Delta t^2}{2}E(t^{n+1/2}, X(t^{n+1/2}))\Big) + O(\Delta t^4) \\
&= X(t^n) - \Big(X(t^{n+1}) - \Delta t \dot{X}(t^{n+1}) + \tfrac{\Delta t^2}{2}\ddot{X}(t^{n+1/2})\Big) + O(\Delta t^4) \\
&= X(t^n) - \Big(X(t^{n+1}) - \Delta t \dot{X}(t^{n+1}) + \tfrac{\Delta t^2}{2}\ddot{X}(t^{n+1})\Big) + O(\Delta t^3) \\
&\le C\left(\|f\|_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\Delta t^3.
\end{aligned}$$

Finally, we deduce that

$$\begin{aligned}
\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) &= f(t^n, X(t^n) + O(\Delta t^3), V(t^n) + O(\Delta t^3)) \\
&= f(t^n, X(t^n), V(t^n)) + \nabla f(t^n, X(t^n), V(t^n)) \cdot O(\Delta t^3) \\
&= f(t^{n+1}, X(t^{n+1}), V(t^{n+1})) + \nabla f(t^n, X(t^n), V(t^n)) \cdot O(\Delta t^3) \\
&= f(t^{n+1}, x, v) + \nabla f(t^n, X(t^n), V(t^n)) \cdot O(\Delta t^3)
\end{aligned}$$

and

$$||f(t^{n+1}) - \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n)||_{L^p(Q)} \leq C \left(\|f\|_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))} \right) ||\nabla f||_{L^\infty([0,T]\times Q)} \Delta t^3. \qquad \square$$

We continue with the following result.

PROPOSITION 5.4. *Assume that* $f \in L^\infty(0,T;\mathscr{C}^{m+1}_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$, $m \geq 0$, *and* π_h *is a continuous linear interpolation operator from* $W^{m+1,\infty}(Q)$ *onto* X_h; *then there exists a constant* C *such that for* $i = 1, 2$, $1 \leq p \leq \infty$,

$$||\mathcal{T}_i f||_{L^\infty(0,T;W^{m+1,p}(Q))} \leq C||f||_{L^\infty(0,T;W^{m+1,p}(Q))}, \tag{5.4}$$

$$||\widetilde{\mathcal{T}}_i f||_{L^\infty(0,T;L^p(Q))} \leq C||f||_{L^\infty(0,T;W^{m+1,p}(Q))}, \tag{5.5}$$

and

$$\|(\mathcal{T}_i - \widetilde{\mathcal{T}}_i)f\|_{L^\infty(0,T;L^p(Q))} \leq Ch^{m+1}||f||_{L^\infty(0,T;W^{m+1,p}(Q))}. \tag{5.6}$$

Proof. It is obvious that

$$\left\| f\left(t, x - v\tfrac{\Delta t}{2}, v\right) \right\|_{L^\infty(0,T;L^p(Q))} = \|f\|_{L^\infty(0,T;L^p(Q))} \tag{5.7}$$

and

$$\|f(t,x,v - \widetilde{E}(t,x)\Delta t)\|_{L^\infty(0,T;L^p(Q))} = \|f\|_{L^\infty(0,T;L^p(Q))}. \tag{5.8}$$

On one side the gradient of $f(t, x - v\Delta t/2, v)$ gives

$$\left\| \partial_x \left(f\left(t, x - v\tfrac{\Delta t}{2}, v\right) \right) \right\|_{L^\infty(0,T;L^p(Q))} = \|\partial_x f\|_{L^\infty(0,T;L^p(Q))}$$

and

$$\left\| \partial_v \left(f(t, x - v\tfrac{\Delta t}{2}, v) \right) \right\|_{L^\infty(0,T;L^p(Q))} \leq \tfrac{\Delta t}{2} \|\partial_x f\|_{L^\infty(0,T;L^p(Q))} + \|\partial_v f\|_{L^\infty(0,T;L^p(Q))}.$$

Hence

$$\left\| f\left(t, x - v\tfrac{\Delta t}{2}, v\right) \right\|_{L^\infty(0,T;W^{1,p}(Q))} \leq C \|f\|_{L^\infty(0,T;W^{1,p}(Q))}.$$

In the same way we get

$$\left\| f\left(t, x - v\tfrac{\Delta t}{2}, v\right) \right\|_{L^\infty(0,T;W^{m+1,p}(Q))} \leq C \|f\|_{L^\infty(0,T;W^{m+1,p}(Q))}.$$

On the other side the gradient of $f(t,x,v - \widetilde{E}(t,x)\Delta t)$ gives

$$\begin{aligned} &\|\partial_x(f(t,x,v - \widetilde{E}(t,x)\Delta t))\|_{L^\infty(0,T;L^p(Q))} \\ &\quad \leq \|\partial_x f\|_{L^\infty(0,T;L^p(Q))} + \Delta t||\partial_x \widetilde{E}||_{L^\infty([0,T]\times[0,L])} \|\partial_v f\|_{L^\infty(0,T;L^p(Q))} \end{aligned}$$

and

$$\|\partial_v(f(t,x,v - \widetilde{E}(t,x)\Delta t))\|_{L^\infty(0,T;L^p(Q))} \leq \|\partial_v f\|_{L^\infty(0,T;L^p(Q))}.$$

Hence

$$\begin{aligned}\|f(t,x,v-\widetilde{E}(t,x)\Delta t)\|_{L^\infty(0,T;W^{1,p}(Q))} &\le (1+C\Delta t)\,\|f\|_{L^\infty(0,T;W^{1,p}(Q))}\\ &\le C\,\|f\|_{L^\infty(0,T;W^{1,p}(Q))}.\end{aligned}$$

In the same way, as $\widetilde{E}\in L^\infty(0,T;\mathscr{C}^{m+1}_{b,per_x}(\mathbb{R}))$, we get

$$\|f(t,x,v-\widetilde{E}(t,x)\Delta t)\|_{L^\infty(0,T;W^{m+1,p}(Q))} \le C\,\|f\|_{L^\infty(0,T;W^{m+1,p}(Q))},$$

which completes the proof of (5.4).

π_h is an interpolation operator which is characterized by the basis functions $\{\psi_k\}$. Then $\pi_h f$ can be written as follows:

$$\pi_h f(t,x,v)=\sum_k f(t,x_k,v_k)\psi_k(x,v)=\sum_k f_k(t)\psi_k(x,v).$$

As any $\psi_k\in L^\infty(Q)$ and has compact support, there exists a constant M such that

$$\begin{aligned}\left\|\sum_k|\psi_k(x,v)|\right\|_{L^\infty(Q)} &\le \sup_{T\in\mathcal{T}_h}\left\|\sum_k|\psi_k(x,v)|\right\|_{L^\infty(T)}\\ &\le \mathrm{card}(\Sigma_T)\sup_{T\in\mathcal{T}_h}\max_{(x,v)\in T}|\psi_k(x,v)|\\ &\le M,\end{aligned}$$

where Σ_T is the set of degrees of freedom on the triangle T.

- L^∞ case:

$$\|\pi_h f\|_{L^\infty(Q)}\le\|f\|_{L^\infty(Q)}\sum_k|\psi_k(x,v)|\le M\,\|f\|_{L^\infty(Q)}.$$

- L^1 case:

$$\int_Q|\pi_h f(t)|dvdx\le\sum_k|f_k(t)|\int_Q|\psi_k|dxdv\le M\sum_k|f_k(t)|\mathrm{meas}\,(\mathcal{S}_k),$$

where $\mathcal{S}_k$ is the support of ψ_k. Let $\mathcal{A}_k$ be the geometrical area associated with the node $N_k=(x_k,v_k)$, obtained by joining the barycenter of the triangles that have the vertex N_k in common to the middle of the edges of the triangles; then there exists a constant $K>0$ independent of h such that $(1/K)\mathrm{meas}(\mathcal{S}_k)\le\mathrm{meas}(\mathcal{A}_k)<\mathrm{meas}(\mathcal{S}_k)$. Then we obtain

$$\|\pi_h f(t)\|_{L^1(Q)}\le CMK\sum_k|f_k(t)|\mathrm{meas}\,(\mathcal{A}_k)\le C\,\|f(t)\|_{L^1(Q)}$$

and

$$\|\pi_h f\|_{L^\infty([0,T],L^1(Q))}\le C\,\|f\|_{L^\infty([0,T],L^1(Q))}.$$

- L^p case:

$$\int_Q|\pi_h f(t)|^p dvdx\le\int_Q\left(\sum_k|f_k(t)|\,|\psi_k|\right)^p dvdx.$$

Thanks to the Hölder inequality, we get

$$\int_Q |\pi_h f(t)|^p \leq \int_Q \left(\sum_k |f_k(t)|^p |\psi_k|\right) \left(\sum_k |\psi_k|\right)^{p/p^*} dvdx,$$

with $p^* = p/(p-1)$. Then we get

$$\begin{aligned}
\|\pi_h f(t)\|^p_{L^p(Q)} &\leq M^{p/p^*} \sum_k |f_k(t)|^p \int_Q |\psi_k| dxdv \\
&\leq K M^{p/p^*+1} \sum_k |f_k(t)|^p \text{meas}\,(\mathcal{A}_k) \\
&\leq C \|f\|^p_{L^p(Q)}
\end{aligned}$$

and finally

$$\|\pi_h f\|_{L^\infty(0,T;L^p(Q))} \leq C \|f\|_{L^\infty(0,T;L^p(Q))}.$$

Hence, as $f \in L^\infty(0,T;\mathscr{C}^{m+1}_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$, then

$$\begin{aligned}
\left\|\pi_h f\Big(t, x - v\tfrac{\Delta t}{2}, v\Big)\right\|_{L^\infty(0,T;L^p(Q))} &\leq C \left\|f\Big(t, x - v\tfrac{\Delta t}{2}, v\Big)\right\|_{L^\infty(0,T;L^p(Q))} \\
&\leq C||f||_{L^\infty(0,T;L^p(Q))} \\
&\leq C||f||_{L^\infty(0,T;W^{m+1,p}(Q))}
\end{aligned}$$

and

$$\begin{aligned}
\|\pi_h f(t,x,v - \widetilde{E}(t,x)\Delta t)\|_{L^\infty(0,T;L^p(Q))} &\leq C \|f(t,x,v - \widetilde{E}(t,x)\Delta t)\|_{L^\infty(0,T;L^p(Q))} \\
&\leq C||f||_{L^\infty(0,T;L^p(Q))} \\
&\leq C||f||_{L^\infty(0,T;W^{m+1,p}(Q))},
\end{aligned}$$

which completes the proof of (5.5). Finally, thanks to inequality (3.1), we obtain

$$\begin{aligned}
&\left\|f\Big(t, x - v\tfrac{\Delta t}{2}, v\Big) - \pi_h f\Big(t, x - v\tfrac{\Delta t}{2}, v\Big)\right\|_{L^\infty(0,T;L^p(Q))} \\
&\qquad \leq C h^{m+1} \left\|f\Big(t, x - v\tfrac{\Delta t}{2}, v\Big)\right\|_{L^\infty(0,T;W^{m+1,p}(Q))} \\
&\qquad \leq C h^{m+1} ||f||_{L^\infty(0,T;W^{m+1,p}(Q))}
\end{aligned}$$

and

$$\begin{aligned}
&\|f(t,x,v - \widetilde{E}(t,x)\Delta t) - \pi_h f(t,x,v - \widetilde{E}(t,x)\Delta t)\|_{L^\infty(0,T;L^p(Q))} \\
&\qquad \leq C h^{m+1} ||f(t,x,v - \widetilde{E}(t,x)\Delta t)||_{L^\infty(0,T;W^{m+1,p}(Q))} \\
&\qquad \leq C h^{m+1} ||f||_{L^\infty(0,T;W^{m+1,p}(Q))},
\end{aligned}$$

which completes the proof of the proposition. □

The next lemma gives an estimate of the space discretization error.

LEMMA 5.5. *Assume that* $f \in L^\infty(0,T;\mathscr{C}^{m+1}_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$ *and that* π_h *is a continuous linear interpolation operator from* $W^{m+1,\infty}(Q)$ *onto* X_h*; then there exists a constant* C *such that*

$$\|\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^\infty(Q)} \leq Ch^{m+1}||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))}.$$

Proof. We begin with the following decomposition:

$$\begin{aligned}\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n) &= (\mathcal{T}_1 - \widetilde{\mathcal{T}}_1) \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) \\ &\quad + \widetilde{\mathcal{T}}_1 \circ (\mathcal{T}_2 - \widetilde{\mathcal{T}}_2) \circ \mathcal{T}_1 f(t^n) \\ &\quad + \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ (\mathcal{T}_1 - \widetilde{\mathcal{T}}_1) f(t^n).\end{aligned} \tag{5.9}$$

Using (5.4), (5.5), and (5.6), the decomposition (5.9) gives for the first term

$$\begin{aligned}||(\mathcal{T}_1 - \widetilde{\mathcal{T}}_1) \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n)||_{L^\infty(\Omega)} &\leq Ch^{m+1}|\mathcal{T}_2 \circ \mathcal{T}_1 f(t^n)|_{W^{m+1,\infty}(Q)} \\ &\leq Ch^{m+1}|\mathcal{T}_1 f(t^n)|_{W^{m+1,\infty}(Q)} \\ &\leq Ch^{m+1}|f(t^n)|_{W^{m+1,\infty}(Q)} \\ &\leq Ch^{m+1}||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))},\end{aligned}$$

for the second term of (5.9)

$$\begin{aligned}||\widetilde{\mathcal{T}}_1 \circ (\mathcal{T}_2 - \widetilde{\mathcal{T}}_2) \circ \mathcal{T}_1 f(t^n)||_{L^\infty(Q)} &\leq C||(\mathcal{T}_2 - \widetilde{\mathcal{T}}_2) \circ \mathcal{T}_1 f(t^n)||_{L^\infty(Q)} \\ &\leq Ch^{m+1}|\mathcal{T}_1 f(t^n)|_{W^{m+1,\infty}(Q)} \\ &\leq Ch^{m+1}||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))},\end{aligned}$$

and for the third term of (5.9)

$$\begin{aligned}||\widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ (\mathcal{T}_1 - \widetilde{\mathcal{T}}_1) f(t^n)||_{L^\infty(Q)} &\leq C||(\mathcal{T}_1 - \widetilde{\mathcal{T}}_1) f(t^n)||_{L^\infty(Q)} \\ &\leq Ch^{m+1}||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))},\end{aligned}$$

which proves the lemma. ∎

We continue with the proof of another lemma that gives an estimate of a coupling error between the resolution of the Vlasov and the Poisson equations.

LEMMA 5.6. *Assume that* $f \in L^\infty(0,T;\mathscr{C}^{m+1}_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v))$ *and that* π_h *is a continuous linear interpolation operator from* $W^{m+1,\infty}(Q)$ *onto* X_h*; then there exists a constant* C *such that*

$$\|\widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^\infty(Q)} \leq C\Delta t \left(e^n + h^{m+1}\right) ||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))},$$

where

$$e^n = \|f(t^n) - f_h(t^n)\|_{L^\infty(Q)}.$$

Proof. On the one hand, we have

$$(\widetilde{\mathcal{T}}_2 - \widetilde{\mathcal{T}}_2^\star)g(t^n) = \pi_h\left(g(t^n, x, v - \Delta t\widetilde{E}^{n+1/2}(x)) - g(t^n, x, v - \Delta t E_h^{n+1/2}(x))\right).$$

On the other hand, we have

$$\begin{aligned}|g(t^n, x, v- &\ \Delta t\widetilde{E}^{n+1/2}(x)) - g(t^n, x, v - \Delta t E_h^{n+1/2}(x))| \\ &\leq \Delta t|\widetilde{E}^{n+1/2}(x) - E_h^{n+1/2}(x)|\,\|\nabla g(t^n)\|_{L^\infty(Q)},\end{aligned}$$

where $\widetilde{E}^{n+1/2}(x)$ and $E_h^{n+1/2}(x)$ can be written as follows:

$$\widetilde{E}^{n+1/2}(x) = \int_0^L K(x,y)\left(\int_{\mathbb{R}} \mathcal{T}_1 f(t^n,y,v)dv - 1\right)dy,$$
$$E_h^{n+1/2}(x) = \int_0^L K(x,y)\left(\int_{\mathbb{R}} \widetilde{\mathcal{T}}_1 f_h(t^n,y,v)dv - 1\right)dy.$$

Then we can write

$$\begin{aligned}
E_h^{n+1/2}(x) - \widetilde{E}^{n+1/2}(x) &= \int_0^L K(x,y)\left(\int_{\mathbb{R}} \left[\widetilde{\mathcal{T}}_1 f_h(t^n,y,v) - \mathcal{T}_1 f(t^n,y,v)\right]dv\right)dy,\\
&= \int_0^L K(x,y)\left(\int_{|v|\le Q(T)} \pi_h\Big[f_h\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) - f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big)\Big]dv\right)dy\\
&\quad + \int_0^L \int_{|v|\le Q(T)} K(x,y)\Big(\pi_h f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) - f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big)\Big)dvdy,
\end{aligned}$$

so that we get

$$\begin{aligned}
&\|E_h^{n+1/2} - \widetilde{E}^{n+1/2}\|_{L^\infty([0,L])}\\
&\qquad \le LQ(T)||K||_{L^\infty}\left\|\pi_h\Big[f_h\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) - f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big)\Big]\right\|_{L^\infty(Q)}\\
&\qquad\quad + LQ(T)||K||_{L^\infty}\left\|\pi_h f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) - f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big)\right\|_{L^\infty(Q)},
\end{aligned} \tag{5.10}$$

and using (5.4), (5.5), and (5.6),

$$\begin{aligned}
\|E_h^{n+1/2} - \widetilde{E}^{n+1/2}\|_{L^\infty([0,L])} &\le LQ(T)||K||_{L^\infty}||\pi_h||_{L^\infty}\,\|f_h(t^n) - f(t^n)\|_{L^\infty(Q)}\\
&\quad + CLQ(T)||K||_{L^\infty}h^{m+1}||f(t^n)||_{W^{m+1,\infty}(Q)}.
\end{aligned} \tag{5.11}$$

Finally, we obtain

$$\|E_h^{n+1/2} - \widetilde{E}^{n+1/2}\|_{L^\infty([0,L])} \le C\left(e^n + h^{m+1}\right)$$

and, as a consequence,

$$\|(\widetilde{\mathcal{T}}_2 - \widetilde{\mathcal{T}}_2^\star)g(t^n)\|_{L^\infty(Q)} \le C\Delta t\left(e^n + h^{m+1}\right)\|\nabla g(t^n)\|_{L^\infty(Q)}. \tag{5.12}$$

Then, using (5.4) and (5.12),

$$\begin{aligned}
\|\widetilde{\mathcal{T}}_1 \circ (\widetilde{\mathcal{T}}_2 - \widetilde{\mathcal{T}}_2^\star) \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^\infty(Q)} &\le C\|(\widetilde{\mathcal{T}}_2 - \widetilde{\mathcal{T}}_2) \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^\infty(Q)}\\
&\le C\Delta t\left(e^n + h^{m+1}\right)\|\nabla(\widetilde{\mathcal{T}}_1 f(t^n))\|_{L^\infty(Q)}.
\end{aligned}$$

Now we estimate the term $\|\nabla(\widetilde{\mathcal{T}}_1 f(t^n))\|_{L^\infty(Q)}$. We can do this in the following way. Using (3.1), we get

$$\begin{aligned}
\|\nabla(\widetilde{\mathcal{T}}_1 f(t^n))\|_{L^\infty(Q)} &\le \left\|\nabla\Big(\pi_h f\Big(t^n, x - v\tfrac{\Delta t}{2}, v\Big)\Big)\right\|_{L^\infty(Q)} \\
&\le \left\|\nabla\Big[(\pi_h f - f)\Big(t^n, x - v\tfrac{\Delta t}{2}, v\Big)\Big]\right\|_{L^\infty(Q)} \\
&\qquad + \left\|\nabla\Big(f\Big(t^n, x - v\tfrac{\Delta t}{2}, v\Big)\Big)\right\|_{L^\infty(Q)} \\
&\le Ch^m ||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))} + ||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))} \\
&\le C||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))}.
\end{aligned}$$

In fact, this estimation is due to the continuity of π_h from $W^{m+1,\infty}(Q)$ onto X_h. Then we finally obtain

$$\|\widetilde{\mathcal{T}}_1 \circ (\widetilde{\mathcal{T}}_2 - \widetilde{\mathcal{T}}_2^\star) \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^\infty(Q)} \le C\Delta t \left(e^n + h^{m+1}\right) ||f||_{L^\infty(0,T;W^{m+1,\infty}(Q))},$$

which completes the proof. ∎

We now state the last lemma, which gives information about the stability of the numerical scheme.

LEMMA 5.7. *Let π_h be the interpolation operator from $W^{2,\infty}(Q)$ onto X_h with $P_m = P_1$; then we have*

$$\|\widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 (f(t^n) - f_h(t^n))\|_{L^\infty(Q)} \le e^n. \tag{5.13}$$

Proof. As π_h is a linear interpolation operator, the basis functions satisfy

$$0 \le \psi_k \le 1$$

and

$$\sum_k \psi_k = 1,$$

and therefore we have

$$\|\pi_h\|_{L^\infty} = \sup_{\substack{f \in L^\infty \\ f \neq 0}} \frac{\|\pi_h f\|_{L^\infty(Q)}}{\|f\|_{L^\infty(Q)}} \le 1.$$

Indeed we have

$$\begin{aligned}
|\pi_h g| &= \left|\sum_k g(x_k, v_k)\psi_k(x, v)\right| \\
&\le \sum_k |g_k|\psi_k(x, v) \\
&\le \|g\|_{L^\infty} \sum_k \psi_k = \|g\|_{L^\infty}.
\end{aligned}$$

As a consequence we obviously obtain

$$\begin{aligned}
\|\widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 (f(t^n) - f_h(t^n))\|_{L^\infty(Q)} &\le \|\widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 (f(t^n) - f_h(t^n))\|_{L^\infty(Q)} \\
&\le \|\widetilde{\mathcal{T}}_1 (f(t^n) - f_h(t^n))\|_{L^\infty(Q)} \\
&\le \|f(t^n) - f_h(t^n)\|_{L^\infty(Q)},
\end{aligned}$$

which completes the proof. ∎

Now we can return to the proof of the main theorem.

Proof of the main theorem. We want to evaluate the global error at time t^{n+1}:

$$e^{n+1} = ||f(t^{n+1},x,v) - f_h(t^{n+1},x,v)||_{L^\infty(Q)}.$$

We decompose $f(t^{n+1},x,v) - f_h(t^{n+1},x,v)$ as

$$\begin{aligned} f(t^{n+1},x,v) - f_h(t^{n+1},x,v) = {} & f(t^{n+1},x,v) - \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n,x,v) \\ & + \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n,x,v) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n,x,v) \\ & + \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n,x,v) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 f(t^n,x,v) \\ & + \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 (f(t^n,x,v) - f_h(t^n,x,v)). \end{aligned} \tag{5.14}$$

Finally if we put together Lemmas 5.3, 5.5, 5.6, 5.7, we obtain the following estimation:

$$e^{n+1} \leq (1 + C\Delta t)e^n + C\left(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\left(\Delta t^3 + h^2 + h^2\Delta t\right).$$

A discrete Gronwall inequality enables us to get

$$e^{n+1} \leq \exp(CT)e^0 + C\left(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\left(\Delta t^2 + \frac{h^2}{\Delta t} + h^2\right).$$

As e^0 is only a fixed interpolation error, we obtain

$$e^n \leq C\left(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\left(\Delta t^2 + \frac{h^2}{\Delta t} + h^2\right).$$

In order to prove the convergence of the electric field, we estimate

$$||E(t^{n+1/2}) - E_h^{n+1/2}||_{L^\infty([0,L])}.$$

To estimate this term we proceed as in the proof of Lemmas 5.6 and 5.3. Then we obtain

$$||\widetilde{E}(t^{n+1/2}) - E_h^{n+1/2}||_{L^\infty([0,L])} \leq C\left(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\left(\Delta t^2 + h^2 + \frac{h^2}{\Delta t}\right)$$

and

$$||E(t^{n+1/2}) - \widetilde{E}(t^{n+1/2})||_{L^\infty([0,L])} \leq C\left(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\Delta t^2$$

so that

$$||E(t^{n+1/2}) - E_h^{n+1/2}||_{L^\infty([0,L])} \leq C\left(||f||_{\mathscr{C}^2(0,T;W^{2,\infty}(Q))}\right)\left(\Delta t^2 + h^2 + \frac{h^2}{\Delta t}\right). \qquad \square$$

5.4. Other results. We can prove the convergence of our numerical scheme under weaker regularity assumptions. Following the proof of existence and uniqueness of the solutions of the Cauchy problem for the Vlasov–Maxwell system in one dimension made by Cooper and Klimas [15], if we take f_0 such that

$$f_0 \in \mathscr{C}_{b,per_x} \cap W_c^{1,\infty}(\mathbb{R}_x \times \mathbb{R}_v),$$

the Vlasov–Poisson periodic system given by (2.7), (2.8), (2.9), and (2.10) has a unique solution (f, E) such that

$$f \in \mathscr{C}_b\left(0,T;\mathscr{C}_{b,per_x} \cap W_c^{1,\infty}(\mathbb{R}_x \times \mathbb{R}_v)\right),$$

$$\partial_t f \in L^\infty\left(0,T;L_c^\infty(\mathbb{R}_x \times \mathbb{R}_v)\right),$$

where the derivative is taken in the sense of distribution, and

$$E \in \mathscr{C}^1\left(0,T;\mathscr{C}^1_{b,per_x}(\mathbb{R}_x)\right).$$

Now we state the theorem.

THEOREM 5.8. *Assume that* $f_0 \in \mathscr{C}_{b,per_x} \cap W_c^{1,\infty}(\mathbb{R}_x \times \mathbb{R}_v)$. *Let* $\alpha > 0$, $h \sim \Delta t^{1/\varepsilon}$, *with* $0 < \varepsilon < 1$; *then* (f_h, E_h), *the numerical solution of the periodic Vlasov–Poisson system, converges towards* (f, E), *and there exists a constant* $C = C(\|f\|_{\mathscr{C}_b(0,T;W^{1,\infty}(Q))}, \|\partial_t f\|_{L^\infty(0,T;L^\infty(Q))})$ *independent of* Δt *and* h *such that*

$$||f - f_h||_{\ell^\infty(0,T;L^\infty(Q))} \leq C\left(\Delta t + h + h^{1-\varepsilon}\right)$$

and

$$||E - E_h||_{\ell^\infty(0,T;L^\infty([0,L]))} \leq C\left(\Delta t + h + h^{1-\varepsilon}\right).$$

Proof. In order to prove Theorem 5.8 we have to examine how Lemmas 5.3, 5.5, 5.6, 5.7 and Proposition 5.4 can be adapted to the new regularity assumptions.

We begin with Lemma 5.3. Now we cannot apply Taylor expansion, since the solution is not regular enough. Thus we have to rewrite all the estimates. First we have

$$\begin{aligned} X(t^{n+1/2}) - (x - v\Delta t/2) &= X(t^{n+1/2}) - \left(X(t^{n+1}) - V(t^{n+1})\tfrac{\Delta t}{2}\right) \\ &= \int_{t^{n+1}}^{t^{n+1/2}} \left(V(t) - V(t^{n+1})\right) dt \\ &= \int_{t^{n+1}}^{t^{n+1/2}} \int_{t^{n+1}}^{t} E\left(\tau, X(\tau)\right) d\tau dt \\ &\leq C\Delta t^2 \left\|E\right\|_{L^\infty(0,T;L^\infty([0,L]))} \\ &\leq C\Delta t^2. \end{aligned} \tag{5.15}$$

Next we note that we have the following decomposition:

$$f(t^{n+1/2}, y, v) - f\left(t^n, y - v\tfrac{\Delta t}{2}, v\right) = \int_{t^n}^{t^{n+1/2}} \partial_t f(t, y, v) dt + \int_{y - v\Delta t/2}^{y} \partial_x f(t^n, x, v) dx.$$

As $f \in \mathscr{C}_b(0,T;{W_c}^{1,\infty}(Q))$ and $\partial_t f \in L^\infty\left(0,T;L_c^\infty(Q)\right)$, integrating the previous decomposition, we obtain

$$\begin{aligned} &\int_0^L \int_{\mathbb{R}_v} \left| f(t^{n+1/2}, y, v) - f\left(t^n, y - v\tfrac{\Delta t}{2}, v\right)\right| dy dv \\ &\quad \leq \int_0^L \int_{\mathbb{R}_v} \int_{t^n}^{t^{n+1/2}} \left|\partial_t f\left(t, y, v\right)\right| dt dv dy + \int_0^L \int_{\mathbb{R}_v} \int_{y - v\Delta t/2}^{y} \left|\partial_x f\left(t^n, x, v\right)\right| dx dv dy, \end{aligned}$$

and then

$$\int_0^L \int_{\mathbb{R}_v} \left| f(t^{n+1/2}, y, v) - f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) \right| dydv$$
$$\leq CLQ^2(T)\Delta t \left(\|\partial_t f\|_{L^\infty(0,T,L^\infty(Q))} + \|\partial_x f\|_{L^\infty(0,T;L^\infty(Q))} \right)$$
$$\leq C\Delta t, \tag{5.16}$$

so that, using (2.7),

$$|E(t^{n+1/2}, x) - \widetilde{E}(t^{n+1/2}, x)| \leq C\Delta t. \tag{5.17}$$

Then we have

$$V(t^n) - \widetilde{V}(t^n) = \int_{t^{n+1}}^{t^n} E\left(t, X(t)\right) dt + \Delta t \widetilde{E}\Big(t^{n+1/2}, x - v\tfrac{\Delta t}{2}\Big)$$
$$= \int_{t^{n+1}}^{t^n} \left(E\left(t, X(t)\right) - E(t^{n+1/2}, X(t))\right) dt$$
$$+ \int_{t^{n+1}}^{t^n} \left(E(t^{n+1/2}, X(t)) - E(t^{n+1/2}, X(t^{n+1/2}))\right) dt$$
$$+ \Delta t \Big\{ E\Big(t^{n+1/2}, X(t^{n+1}) - V(t^{n+1})\tfrac{\Delta t}{2}\Big) - E(t^{n+1/2}, X(t^{n+1/2})) \Big\}$$
$$+ \Delta t \Big\{ \widetilde{E}\Big(t^{n+1/2}, X(t^{n+1}) - V(t^{n+1})\tfrac{\Delta t}{2}\Big)$$
$$- E\Big(t^{n+1/2}, X(t^{n+1}) - V(t^{n+1})\tfrac{\Delta t}{2}\Big) \Big\}.$$

As $E \in \mathscr{C}^1(0,T;\mathscr{C}^1_{b,per_x}(\mathbb{R}_x))$, we obtain

$$\sup \left\{ \left| V(t^n; t^{n+1}, x, v) - \widetilde{V}(t^n; t^{n+1}, x, v) \right| \mid \forall (x,v) \in [0,L] \times \mathbb{R} \right\}$$
$$\leq C\Delta t^2 \mathrm{Lip}\left(E(.,x)\right) + CQ(T)\Delta t^2 \mathrm{Lip}\left(E(t,.)\right) + C\Delta t^3 \mathrm{Lip}\left(E(t,.)\right) + C\Delta t^2$$
$$\leq C\Delta t^2. \tag{5.18}$$

We go on with the estimate of $X(t^n) - \widetilde{X}(t^n)$. We have

$$X(t^n) - \widetilde{X}(t^n) = \int_{t^{n+1}}^{t^n} \int_{t^{n+1}}^{t} E\left(\tau, X(\tau)\right) d\tau dt - \tfrac{\Delta t^2}{2} \widetilde{E}\Big(t^{n+1/2}, X(t^{n+1}) - V(t^{n+1})\tfrac{\Delta t}{2}\Big)$$

so that

$$\sup \left\{ \left| X(t^n) - \widetilde{X}(t^n) \right| \mid \forall (x,v) \in [0,L] \times \mathbb{R} \right\} \leq C\Delta t^2 \left(\|E\|_{L^\infty} + \|\widetilde{E}\|_{L^\infty} \right) \leq C\Delta t^2. \tag{5.19}$$

Now we use the estimates (5.18) and (5.19) in order to bound the quantity

$$\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - f\left(t^{n+1}, x, v\right) = f(t^n, \widetilde{X}(t^n), \widetilde{V}(t^n)) - f\left(t^n, X(t^n), V(t^n)\right)$$

in the L^∞ norm. As we have the continuous embedding $W^{1,\infty} \hookrightarrow \mathscr{C}^{0,1}$, then

$$\begin{aligned} \left\|\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - f\left(t^{n+1}\right)\right\|_{L^\infty(Q)} &\leq C\mathrm{Lip}\left(f(t^n, ., .)\right)\Delta t^2, \\ &\leq C \sup_{t\in[0,T]} \mathrm{Lip}\left(f(t, ., .)\right)\Delta t^2, \\ &\leq C\Delta t^2. \end{aligned} \tag{5.20}$$

Following the proof of Proposition 5.4, if we take $f \in \mathscr{C}_b(0, T; W^{1,\infty}_c(Q))$, $E \in \mathscr{C}^1(0, T; \mathscr{C}^1_{b,per_x}(\mathbb{R}))$, and if we take the derivative in the sense of distribution, then, using (3.1), we still have (with $m \in \{0, 1\}$)

$$||\mathcal{T}_i f||_{L^\infty(0,T;W^{m,\infty}(Q))} \leq C||f||_{L^\infty(0,T;W^{m,\infty}(Q))}, \tag{5.21}$$

$$||\widetilde{\mathcal{T}}_i f||_{L^\infty(0,T;L^\infty(Q))} \leq C||f||_{L^\infty(0,T;W^{m,\infty}(Q))}, \tag{5.22}$$

and

$$\|(\mathcal{T}_i - \widetilde{\mathcal{T}}_i)f\|_{L^\infty(0,T;L^\infty(Q))} \leq Ch||f||_{L^\infty(0,T;W^{1,\infty}(Q))}. \tag{5.23}$$

As a consequence, Lemma 5.5 supplies the estimate

$$\|\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^\infty(Q)} \leq Ch.$$

The estimate of Lemma 5.6 has to be replaced by

$$\|\widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^\infty(Q)} \leq C\Delta t\left(e^n + h\right).$$

In order to justify this inequality we just have to show that $\mathrm{Lip}(\widetilde{\mathcal{T}}_1 f(t^n))$ is bounded. Indeed we have

$$\mathrm{Lip}(\widetilde{\mathcal{T}}_1 f(t^n)) = \mathrm{Lip}\Big(\pi_h f\Big(t^n, x - v\tfrac{\Delta t}{2}, v\Big)\Big) \leq \|\pi_h\|_{L^\infty}\mathrm{Lip}\left(f(t^n, ., .)\right) < +\infty.$$

Finally, we get all the desired a priori estimates by seeing that the stability result (5.13) still holds. Then the proof of the theorem is the same as that for Theorem 5.1, and we get

$$||f - f_h||_{\ell^\infty(0,T;L^\infty(Q))} \leq C\left(\Delta t + h + \frac{h}{\Delta t}\right)$$

and

$$||E - E_h||_{\ell^\infty(0,T;L^\infty([0,L]))} \leq C\left(\Delta t + h + \frac{h}{\Delta t}\right).$$

Now if we take $\Delta t \sim h^\varepsilon$ with $0 < \varepsilon < 1$, we get the desired result. In fact the best ε to choose is $1/2$ so that convergence holds with order $1/2$. ∎

Remark 5.9. Under the regularity assumptions $f_0 \in \mathscr{C}^{m+1}_{c,per_x}(\mathbb{R}_x \times \mathbb{R}_v)$, if there exists an interpolation operator π_h that satisfies both a consistency condition such as

$$\|f - \pi_h f\|_{L^\infty(0,T;L^p(Q))} \leq Ch^{m+1}||f||_{L^\infty(0,T;W^{m+1,p}(Q))} \tag{5.24}$$

and a stability condition such as

$$\|\pi_h f\|_{L^\infty(0,T;L^p(Q))} \leq (1+Ch)||f||_{L^\infty(0,T;L^p(Q))}, \tag{5.25}$$

then our method can easily be applied to prove the convergence of high order schemes in the L^p norm and to find error estimates such as

$$||f - f_h||_{\ell^\infty(0,T;L^p(Q))} \leq C\left(||f||_{\mathscr{C}^2(0,T;W^{m+1,p}(Q))}\right)\left(\Delta t^2 + h^{m+1} + \frac{h^{m+1}}{\Delta t}\right)$$

and

$$||E - E_h||_{\ell^\infty(0,T;L^\infty([0,L]))} \leq C\left(||f||_{\mathscr{C}^2(0,T;W^{m+1,p}(Q))}\right)\left(\Delta t^2 + h^{m+1} + \frac{h^{m+1}}{\Delta t}\right).$$

Unfortunately Lagrange interpolations of high order do not satisfy the stability condition (5.25). Besides, it seems difficult but not impossible to build interpolation operators π_h which satisfy both conditions (5.24) and (5.25).

If we use a Lagrange interpolation operator of high order, the discrete solution $f_h(t^n)$ belongs to $W^{1,p}(Q)$. The numerical scheme consists of a succession of transport and projection on the finite element space generated by the Lagrange finite element of high order. The transport operation leaves the norm of the solution unchanged. Then the scheme is stable if the interpolation operator π_h is stable, i.e., $\|\pi_h\|_{L^p} \leq 1 + \varepsilon(h)$ with $\lim_{h\to 0}\varepsilon(h) = 0$. Unfortunately Lagrange interpolation does not have nice properties of stability. Let $\tau_{h,\xi}$ be a translation operator such that $\tau_{z,\xi}f_h(t^n,x,v) = f_h(t^n,x-z,v-\xi) = g_h(t^n,x,v)$. Therefore $g_h(t^n) \in W^{1,p}(Q)$, and we have

$$\begin{aligned}
\|\pi_h \circ \tau_{z,\xi} f_h(t^n)\|_{L^p(Q)} &= \|\pi_h g_h(t^n)\|_{L^p(Q)} \\
&\leq \|g_h(t^n)\|_{L^p(Q)} + \|\pi_h g_h(t^n) - g_h(t^n)\|_{L^p(Q)} \\
&\leq \|g_h(t^n)\|_{L^p(Q)} + Ch\,|g_h(t^n)|_{W^{1,p}(Q)} \\
&\leq \|g_h(t^n)\|_{L^p(Q)} + C,
\end{aligned}$$

since $|g_h(t^n)|_{W^{1,p}(Q)} \sim O(h^{-1})$ and with C independent of h and such that $C > 1$.

We can also prove the convergence of our numerical scheme with noncompactly supported initial data. If we take f_0 such that

$$f_0 \in \mathscr{C}_{b,per_x} \cap W^{1,\infty} \cap W^{1,1}(\mathbb{R}_x \times \mathbb{R}_v),$$

$$0 < f_0 \leq (1+|v|)^{-\lambda}, \quad v\nabla f_0 \in L^\infty_x\left(L^1_v\right),$$

and if we suppose that there exists a constant $R > 0$ such that

$$\mathcal{L}(f_0,R)(\xi) = \sup\left\{ \frac{|f_0(x,v) - f_0(y,w)|}{\|(x,v)-(y,w)\|_2} \;\middle|\; x,y \in [0,L],\ v,w \in \mathbb{R},\right.$$
$$\left.(x,v) \neq (y,w),\ |v-\xi| \leq R,\ |w-\xi| \leq R\right\}(1+|\xi|) \in L^\infty \cap L^1(\mathbb{R}_\xi), \tag{5.26}$$

where $(x,v) \in [0,L] \times \mathbb{R}$ and $\|(x,v)\|_2 = \sqrt{x^2+v^2}$, the periodic Vlasov–Poisson system given by (2.7), (2.8), (2.9), and (2.10) has a unique solution (f,E) such that

$$0 < f(t,x,v) \le (1+|v|)^{-\lambda}, \tag{5.27}$$

$$f \in \mathscr{C}_b\left(0,T;\mathscr{C}_{b,per_x} \cap W^{1,\infty} \cap W^{1,1}(\mathbb{R}_x \times \mathbb{R}_v)\right),$$

$$v\nabla f,\ \partial_t f \in L^\infty\left(0,T;L^\infty_x\left(L^1_v\right)\right),$$

where the derivative is taken in the sense of distribution and

$$E \in \mathscr{C}^1\left(0,T;\mathscr{C}^1_{b,per_x}(\mathbb{R}_x)\right).$$

In addition, there exists a constant $C(T) > 0$ such that $\forall t \in [0,T]$,

$$\begin{aligned}
&\mathcal{L}(f(t), R + C(T))(\xi) \\
&\quad = \sup\left\{ \frac{|f(t,x,v) - f(t,y,w)|}{\|(x,v)-(y,w)\|_2} \;\middle|\; x,y \in [0,L],\ v,w \in \times\mathbb{R},\right. \\
&\qquad\qquad \left.(x,v) \neq (y,w),\ |v-\xi| \le R + C(T),\ |w-\xi| \le R + C(T)\right\}(1+|\xi|) \\
&\quad \in L^\infty \cap L^1(\mathbb{R}_\xi).
\end{aligned}$$

Now we state the theorem.

THEOREM 5.10. *Assume that $f_0 \in \mathscr{C}_{b,per_x} \cap W^{1,\infty} \cap W^{1,1}(\mathbb{R}_x \times \mathbb{R}_v)$, $0 \le f_0 \le (1+|v|)^{-\lambda}$, $\forall \lambda > 1$ and that f_0 satisfies (5.26). Let α be such that $0 < \alpha < \lambda$, and suppose that the bound of velocity support R evolves as $h^{-1/\alpha}$. Then (f_h, E_h), the numerical solution of the periodic Vlasov–Poisson system, converges towards (f,E), and there exists a positive function μ such that $\lim_{h\to 0}\mu(h) = 0$, and a constant $C = C(\|f\|_{L^\infty(0,T;W^{1,\infty}(Q))}, \|f\|_{L^\infty(0,T;W^{1,1}(Q))}, \|\partial_t f\|_{L^\infty(0,T;L^\infty_x(L^1_v))}, \|v\nabla f\|_{L^\infty(0,T;L^\infty_x(L^1_v))})$ independent of Δt, h such that*

$$||f - f_h||_{\ell^\infty(0,T;L^{1,\infty}(Q))} \le C\left(\Delta t + h + (h+\mu(h))^{1-1/\sigma} + h^{\lambda/\alpha}\right)$$

and

$$||E - E_h||_{\ell^\infty(0,T;L^\infty([0,L]))} \le C\left(\Delta t + h + (h+\mu(h))^{1-1/\sigma} + h^{\lambda/\alpha}\right),$$

where $\Delta t \sim (h+\mu(h))^{1/\sigma}$, with $\sigma > 1$.

Before giving the proof of Theorem 5.10, we need to establish the L^1 stability of π_h by proving the following two lemmas.

LEMMA 5.11. *Assume that $0 \le f_0(x,v) \le \zeta(x,v) \sim (1+|v|)^{-\lambda}$, for $\lambda > 1$. Then there exists a constant C, depending only on T, L, and f_0, such that*

$$0 \le f_h(t,x,v) \le C\zeta_h(x,v), \quad t \in [0,T], \quad (x,v) \in Q, \tag{5.28}$$

where

$$\zeta_h(x,v) = \sum_k \frac{1}{(1+|v_k|)^\lambda}\psi_k(x,v).$$

There also exists a constant $C > 0$ such that

$$||f_h(t)||_{L^1(Q)} \le C, \quad t \in [0,T]. \tag{5.29}$$

Proof. We begin with the transport in x. Let us notice that there exists a constant R independent of h such that for every triangle T_m of the triangulation $\mathcal{T}_h$ there exists a ball $B(a_m, Rh)$ of center a_m and radius Rh which contains T_m. Let N_k be a vertex of triangle T_m. If we consider transport in x, the origin of the characteristic, $x_k^\star = x_k - v_k\Delta t/2$, which ends at N_k, belongs to a triangle $T_m^\star$. Let $\mu(h)$ be a positive function such that $\lim_{h\to 0}\mu(h) = 0$. If N_o, N_p, and N_q are the vertices of the triangle $T_m^\star$, we have

$$|v_k - v_o| \leq 2Rh \leq 2R(h + \mu(h)) \leq 2R\varepsilon(h),$$

$$|v_k - v_p| \leq 2Rh \leq 2R(h + \mu(h)) \leq 2R\varepsilon(h),$$

and

$$|v_k - v_q| \leq 2Rh \leq 2R(h + \mu(h)) \leq 2R\varepsilon(h),$$

where $\varepsilon(h) = h + \mu(h)$. On the other hand, we note that

$$\frac{\zeta_h(x_j, v_j)}{\zeta_h(x_k, v_k)} = \frac{(1 + |v_k|)^\lambda}{(1 + |v_j|)^\lambda} \leq 1 + C_1(\lambda, R)\varepsilon(h), \quad j = \{o, p, q\}. \tag{5.30}$$

Now, if we consider the transport in v, the origin of the characteristic $v_k^* = v_k - E_h(t^{n+1/2})\Delta t$ which ends at N_k belongs to a triangle T_m^*. If N_i, N_s, and N_l are the vertices of a triangle T_m^*, as $\|E_h\|_{\ell^\infty(0,T;L^\infty([0,L]))}$ is bounded we have

$$|v_k - v_i| \leq C\Delta t, \quad |v_k - v_s| \leq C\Delta t, \quad \text{and } |v_k - v_l| \leq C\Delta t,$$

and then we have

$$\frac{\zeta_h(x_j, v_j)}{\zeta_h(x_k, v_k)} = \frac{(1 + |v_k|)^\lambda}{(1 + |v_j|)^\lambda} \leq 1 + C_2(\lambda, R)\Delta t, \quad j = \{i, s, l\}. \tag{5.31}$$

If we set $b_1 = 1 + C_1(\lambda, R)\varepsilon(h)$, $b_2 = 1 + C_2(\lambda, R)\Delta t$, and $b = b_1 b_2 b_1$, then we have

$$f_h(0, x_k, v_k) \leq \frac{1}{(1 + |v_k|)^\lambda} \leq \frac{b^0}{(1 + |v_k|)^\lambda}$$

and consequently

$$f_h(0, x, v) \leq b^0 \zeta_h(x, v).$$

If we assume that

$$f_h(t^n, x_k, v_k) \leq b^n \zeta_h(x_k, v_k)$$

and consequently

$$f_h(t^n, x, v) \leq b^n \zeta_h(x, v),$$

the numerical scheme gives for the first half advection with the respect to the variable x

$$f_h(t^{n+1/2}, x_k, v_k) = \sum_l f_h(t^n, x_l, v_l)\psi_l\left(x_k - v_k\frac{\Delta t}{2}, v_k\right).$$

Let $T_m^\star$ be the triangle which contains the origin of the characteristic coming from the node N_k. Let N_o, N_p, and N_q be the three vertices of $T_m^\star$. Then we can write

$$\frac{f_h(t^{n+1/2}, x_k, v_k)}{\zeta_h(x_k, v_k)} = \lambda_o\frac{f_{h,o}^n}{\zeta_h(x_k, v_k)} + \lambda_p\frac{f_{h,p}^n}{\zeta_h(x_k, v_k)} + \lambda_q\frac{f_{h,q}^n}{\zeta_h(x_k, v_k)},$$

where

$$\lambda_l = \psi_l\left(x_k - v_k\frac{\Delta t}{2}, v_k\right)$$

and

$$f_{h,l}^n = f_h(t^n, x_l, v_l).$$

Using the property (5.30) of ζ_h and the property

$$\lambda_o + \lambda_p + \lambda_q = 1,$$

we obtain

$$\frac{f_h(t^{n+1/2}, x_k, v_k)}{\zeta_h(x_k, v_k)} \le b^n\lambda_o\frac{\zeta_h(x_o, v_o)}{\zeta_h(x_k, v_k)} + b^n\lambda_p\frac{\zeta_h(x_p, v_p)}{\zeta_h(x_k, v_k)} + b^n\lambda_q\frac{\zeta_h(x_q, v_q)}{\zeta_h(x_k, v_k)} \le b_1 b^n.$$

In the same way for the two other advections we finally obtain

$$\frac{f_h(t^{n+1}, x_k, v_k)}{\zeta_h(x_k, v_k)} \le b^{(n+1)} \quad \forall\ N_k \in \mathcal{T}_h.$$

For a finite time T and $\forall n \in \{0, \dots, T/\Delta t\}$, if we consider $\varepsilon(h) \le \Delta t$, we have $b \le 1 + C(C_1, C_2)\Delta t$, $b^{(n+1)} \le \exp(C(C_1, C_2)T)$, and as in the continuous case there exists a majorizing function of the discrete distribution

$$f_h(t, x, v) \le C\zeta_h(x, v) \quad \forall t \in [0, T], \quad \forall (x, v) \in Q.$$

In order to prove (5.29), we note that

$$\begin{aligned}\int_{\mathbb{R}\zeta_h(x,v)dxdv} &= \sum_k \frac{1}{(1 + |v_k|)^\lambda}\int_{\mathbb{R}} \psi_k(x, v)dxdv \\ &= \sum_k \frac{\text{meas}(\mathcal{A}_k)}{(1 + |v_k|)^\lambda} \\ &\le C\int_{\mathbb{R}} \frac{1}{(1 + |v|)^\lambda} < +\infty. \qquad \square\end{aligned}$$

Let $\mathcal{A}_k$ be the area associated with the node N_k and $\psi_k \in P_1$; then we have

$$\text{meas}(\mathcal{A}_k) = \int_{\mathbb{R}} \psi_k(x, v)dxdv = \frac{|\text{supp}\psi_k|}{3}.$$

We introduce χ_k, the characteristic function defined as follows:

$$\chi_k(x,v) = \begin{cases} 1 \text{ if } (x,v) \in \mathcal{A}_k, \\ 0 \text{ otherwise.} \end{cases}$$

Then we introduce the function $g_h^n(x,v)$ defined by

$$g_h^n(x,v) = \sum_k g_h^n(x_k,v_k)\chi_k(x,v),$$

with

$$g_h^n(x_k,v_k) = f_h(t^n,x_k,v_k).$$

We note that

$$||f_h(t^n)||_{L^1(Q)} = ||g_h^n||_{L^1(Q)}.$$

Moreover, as for the proof of the Lemma 5.11, we can prove that

$$0 \leq g_h^n(x,v) \leq C\gamma_h(x,v) \ \ \forall n \in [0,N], \ N = \left[\frac{T}{\Delta t}\right], \ \ (x,v) \in Q,$$

where

$$\gamma_h(x,v) = \sum_k \frac{1}{(1+|v_k|)^\lambda}\chi_k(x,v).$$

We notice that there exists another constant C independent of h such that

$$0 < \gamma_h \leq C(1+|v|)^{-\lambda}.$$

Now we state the lemma which shows the L^1 stability of the interpolation operator π_h.

LEMMA 5.12. *Let $g \in \mathscr{C}_b \cap L^1(Q)$ and $0 < g \leq C(1+|v|)^{-\lambda}$; then there exists a positive function μ, where $\lim_{h\to 0}\mu(h) = 0$, such that*

$$||\pi_h g||_{L^1(Q)} \leq ||g||_{L^1(Q)} + \mu(h).$$

Proof. We have

$$\begin{aligned} ||\pi_h g||_{L^1(Q)} &= \sum_k g_k \int_{\mathbb{R}}\int_0^L \psi_k(x,v)dxdv = \sum_k g_k \text{meas}(\mathcal{A}_k) \\ &= \sum_k g_k \int_Q \chi_k(x,v)dxdv = \int_Q \sum_k g_k\chi_k(x,v)dxdv \\ &= ||g_h||_{L^1(Q)}. \end{aligned}$$

As

$$g_h(x,v) \leq C(1+|v|)^{-\lambda}$$

and

$$\lim_{h\to 0} g_h = g \quad \text{a.e.},$$

the dominated convergence theorem asserts that

$$\lim_{h\to 0} \int_Q |g_h - g|\, dxdv = 0,$$

and as a consequence there exists a positive function μ with $\lim_{h\to 0} \mu(h) = 0$ such that

$$\int_Q |g_h - g|\, dxdv \le \mu(h).$$

Then we deduce that

$$\left| \|\pi_h g\|_{L^1(Q)} - \|g\|_{L^1(Q)} \right| = \left| \|g_h\|_{L^1(Q)} - \|g\|_{L^1(Q)} \right| \le \int_Q |g_h - g|\, dxdv \le \mu(h).$$

Finally we deduce that

$$||\pi_h g||_{L^1(Q)} \le ||g||_{L^1(Q)} + \mu(h). \qquad \square$$

Now we can return to the proof of Theorem 5.10.

Proof of Theorem 5.10. In order to prove the theorem we have to see how the a priori estimates (5.16), (5.17), (5.18), (5.19), and (5.20) are modified and obtain the same kind of a priori estimates in the L^1 norm.

As $v\nabla f,\ \partial_t f \in L^\infty(0,T; L^\infty_x(L^1_v))$ the estimate (5.16) becomes

$$\begin{aligned}\int_0^L \int_{\mathbb{R}_v} |f(t^{n+1/2}, y, v) - f\left(t^n, y - v\Delta t/2, v\right)| dydv \\ &\le CL\Delta t \left(\|\partial_t f\|_{L^\infty(0,T,L^\infty_x(L^1_v))} + \|v\partial_x f\|_{L^\infty(0,T;L^\infty_x(L^1_v))} \right) \\ &\le C\Delta t,\end{aligned}$$

so that we still have

$$|E(t^{n+1/2}, x) - \widetilde{E}(t^{n+1/2}, x)| \le C\Delta t.$$

The estimate (5.19) still holds, but the estimate (5.18) changes into

$$|V(t^n) - \widetilde{V}(t^n)| \le C(1 + |v|)\Delta t^2.$$

Then the estimate (5.20) becomes

$$\begin{aligned}\left\| \mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - f\left(t^{n+1}\right) \right\|_{L^\infty(Q)} &\le \sup_{v\in\mathbb{R}} \left\{ \mathcal{L}(f(t^n), C(T))(v) \right\} \Delta t^2 \\ &\le C\Delta t^2,\end{aligned}$$

and in the L^1 norm we have

$$
\begin{aligned}
&\left\|\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - f\left(t^{n+1}\right)\right\|_{L^1(Q)} \\
&\leq \int_0^L \int_{\mathbb{R}} \Big| f\left(t^n, \widetilde{X}(t^n; t^{n+1}, x, v), \widetilde{V}(t^n; t^{n+1}, x, v)\right) \\
&\qquad\qquad - f\left(t^n, X(t^n; t^{n+1}, x, v), V(t^n; t^{n+1}, x, v)\right)\Big| dvdx \\
&\leq \int_0^L \int \sup\Big\{ \|(\chi,\xi)-(y,w)\|_2^{-1} \cdot |f(t^n,\chi,\xi) - f(t^n,y,w)| \ \Big| \\
&\qquad\qquad (\chi,\xi),(y,w) \in [0,L]\times\mathbb{R},\ (\chi,\xi)\neq(y,w), |\xi - v|, |w-v| \leq C(T)\Big\} \\
&\qquad\qquad \times \left\|\left(\widetilde{X}(t^n; t^{n+1}, x, v), \widetilde{V}(t^n; t^{n+1}, x, v)\right)\right. \\
&\qquad\qquad\quad \left. - \left(X(t^n; t^{n+1}, x, v), V(t^n; t^{n+1}, x, v)\right)\right\|_2 dvdx \\
&\leq \Delta t^2 \int_0^L \int_{\mathbb{R}} \mathcal{L}(f(t^n), C(T))(v) dvdx \\
&\leq C\Delta t^2,
\end{aligned}
$$

where

$$
\begin{aligned}
\sup\left\{\left|V(t^n; t^{n+1}, x, v) - v\right| \mid x \in [0,L], v \in \mathbb{R}\right\} &\leq \int_{t^n}^{t^{n+1}} \|E(\tau,.)\|_{L^\infty} dt \\
&\leq T\,\|E\|_{L^\infty(0,T;L^\infty)} \leq C(T) < +\infty.
\end{aligned}
$$

Then we conclude that the estimate of Lemma 5.3 has to be replaced by

$$
\left\|\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - f\left(t^{n+1}\right)\right\|_{L^{1,\infty}(Q)} \leq C\Delta t^2.
$$

Following the proof of Proposition 5.4, if we take $f \in \mathscr{C}_b(0,T; W^{1,\infty} \cap W^{1,1}(Q))$ and $E \in \mathscr{C}^1(0,T; \mathscr{C}^1_{b,per_x}(\mathbb{R}))$, then using (3.1) and taking the derivative in the sense of distribution, we still have (with $m \in \{0,1\}$, $p \in \{1,\infty\}$)

$$
||\mathcal{T}_i f||_{L^\infty(0,T;W^{m,p}(Q))} \leq C||f||_{L^\infty(0,T;W^{m,p}(Q))},
$$

$$
||\widetilde{\mathcal{T}}_i f||_{L^\infty(0,T;L^p(Q))} \leq C||f||_{L^\infty(0,T;W^{m,p}(Q))},
$$

and

$$
\|(\mathcal{T}_i - \widetilde{\mathcal{T}}_i) f\|_{L^\infty(0,T;L^p(Q))} \leq Ch||f||_{L^\infty(0,T;W^{1,p}(Q))}.
$$

As a consequence, Lemma 5.5 supplies the estimate

$$
\|\mathcal{T}_1 \circ \mathcal{T}_2 \circ \mathcal{T}_1 f(t^n) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^{1,\infty}(Q)} \leq Ch.
$$

The estimate of Lemma 5.6 has to be replaced by

(5.32)
$$\|\widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2 \circ \widetilde{\mathcal{T}}_1 f(t^n) - \widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 f(t^n)\|_{L^{1,\infty}(Q)} \leq C\Delta t \left(e^n + \frac{1}{(1+R)^\lambda} + h \right),$$

where

$$e^n = \|f(t^n) - f_h(t^n)\|_{L^{1,\infty}(Q)}.$$

The proof of Lemma 5.6 holds, except for the estimate of $E_h^{n+1/2}(x) - \widetilde{E}^{n+1/2}(x)$ that we slightly modify as follows. We rewrite

$$\begin{aligned}
&E_h^{n+1/2}(x) - \widetilde{E}^{n+1/2}(x) \\
&\quad = \int_0^L K(x,y) \left(\int_{\mathbb{R}} \left[\widetilde{\mathcal{T}}_1 f_h(t^n, y, v) - \mathcal{T}_1 f(t^n, y, v) \right] dv \right) dy \\
&\quad = \int_0^L K(x,y) \left(\int_{|v|\leq R} \pi_h \Big[f_h\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) - f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) \Big] dv \right) dy \\
&\qquad + \int_0^L \int_{|v|>R} K(x,y) f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) dv dy \\
&\qquad + \int_0^L \int_{|v|\leq R} K(x,y) \Big(\pi_h f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) - f\Big(t^n, y - v\tfrac{\Delta t}{2}, v\Big) \Big) dv dy,
\end{aligned}$$

so that we get

$$\begin{aligned}
\|E_h^{n+1/2} - \widetilde{E}^{n+1/2}\|_{L^\infty([0,L])} \leq\ & ||K||_{L^\infty} ||\pi_h||_{L^\infty} \|f_h(t^n) - f(t^n)\|_{L^{1,\infty}(Q)} \\
& + ||K||_{L^\infty} ||f(t^n)||_{L^1(Q\setminus\Omega)} \\
& + C||K||_{L^\infty} h ||f(t^n)||_{W^{1,1}(Q)}.
\end{aligned} \tag{5.33}$$

Thanks to assumption (5.27), for the second term of (5.33) we obtain

$$\left\| E_h^{n+1/2} - \widetilde{E}^{n+1/2} \right\|_{L^\infty([0,L])} \leq C \left(e^n + \frac{1}{(1+R)^\lambda} + h \right).$$

In order to finish justifying the inequality (5.32), we now just have to show that $\mathcal{L}(\widetilde{\mathcal{T}}_1 f(t^n, C(T)))(\xi)$ belongs to $L^\infty \cap L^1$. Indeed we have

$$\begin{aligned}
\mathcal{L}(\widetilde{\mathcal{T}}_1 f(t^n, C(T)))(\xi) &= \mathcal{L}\Big(\pi_h f\Big(t^n, x - v\tfrac{\Delta t}{2}, v\Big), C(T) \Big)(\xi) \\
&\leq \|\pi_h\|_{L^\infty} \mathcal{L}\left(f(t^n), C(T) \right)(\xi) \in L^\infty \cap L^1.
\end{aligned}$$

Finally, thanks to Lemma 5.12, we get the $L^{1,\infty}$ stability of the interpolation operator π_h; that is to say, there exists a constant C such that

$$||\pi_h f||_{L^{1,\infty}} \leq ||f||_{L^{1,\infty}} + \mu(h) \quad \forall f \in \mathscr{C}_b\left(0, T; \mathscr{C}_{b,per_x} \cap L^1(\mathbb{R}_x \times \mathbb{R}_v)\right).$$

Then it is obvious that the estimate of Lemma 5.7 becomes

$$\|\widetilde{\mathcal{T}}_1 \circ \widetilde{\mathcal{T}}_2^\star \circ \widetilde{\mathcal{T}}_1 (f(t^n) - f_h(t^n))\|_{L^{1,\infty}(Q)} \leq e^n + 3\mu(h).$$

As in the proof of the main theorem, a discrete Gronwall inequality enables us to get

$$e^{n+1} \leq \exp(CT)e^0 + C\left(\Delta t + h + \frac{h+\mu(h)}{\Delta t} + \frac{1}{(1+R)^\lambda}\right).$$

If we suppose that $R = \frac{1}{h^{1/\alpha}}$, $\alpha > 0$, and since e^0 is only a fixed interpolation error, we obtain

$$e^{n+1} \leq C\left(\Delta t + h + \frac{h+\mu(h)}{\Delta t} + h^{\lambda/\alpha}\right).$$

Then the end of the proof is the same as the proof of the main Theorem 5.1, and we get

$$||f - f_h||_{\ell^\infty(0,T;L^{1,\infty}(Q))} \leq C\left(\Delta t + h + \frac{h+\mu(h)}{\Delta t} + h^{\lambda/\alpha}\right)$$

and

$$||E - E_h||_{\ell^\infty(0,T;L^\infty([0,L]))} \leq C\left(\Delta t + h + \frac{h+\mu(h)}{\Delta t} + h^{\lambda/\alpha}\right).$$

If we choose $\Delta t \sim (h+\mu(h))^{1/\sigma}$, $\sigma > 1$, we get the estimates of Theorem 5.1. □

EXCLUSION REGIONS FOR SYSTEMS OF EQUATIONS*

HERMANN SCHICHL† AND ARNOLD NEUMAIER†

Abstract. Branch and bound methods for finding all zeros of a nonlinear system of equations in a box frequently have the difficulty that subboxes containing no solution cannot be easily eliminated if there is a nearby zero outside the box. This has the effect that near each zero many small boxes are created by repeated splitting, whose processing may dominate the total work spent on the global search.

This paper discusses the reasons for the occurrence of this so-called cluster effect and how to reduce the cluster effect by defining exclusion regions around each zero found that are guaranteed to contain no other zero and hence can safely be discarded.

Such exclusion regions are traditionally constructed using uniqueness tests based on the Krawczyk operator or the Kantorovich theorem. These results are reviewed; moreover, refinements are proved that significantly enlarge the size of the exclusion region. Existence and uniqueness tests are also given.

Key words. zeros, system of equations, validated enclosure, existence test, uniqueness test, inclusion region, exclusion region, branch and bound, cluster effect, Krawczyk operator, Kantorovich theorem, backboxing, affine invariant

1. Introduction.

Branch and bound methods for finding all zeros of a nonlinear system of equations in a box [10, 23] frequently have the difficulty that subboxes containing no solution cannot be easily eliminated if there is a nearby zero outside the box. This has the effect that near each zero many small boxes are created by repeated splitting, whose processing may dominate the total work spent on the global search.

This paper discusses in section 3 the reasons for the occurrence of this so-called cluster effect and how to reduce the cluster effect by defining exclusion regions around each zero found that are guaranteed to contain no other zero and hence can safely be discarded. Such exclusion boxes (possibly first used by Jansson [4]) are the basis for the backboxing strategy by van Iwaarden [24] (see also Kearfott [8, 9]) that eliminates the cluster effect near well-conditioned zeros.

Exclusion regions are traditionally constructed using uniqueness tests based on the Krawczyk operator (see, e.g., Neumaier [16, Chapter 5]) or the Kantorovich theorem (see, e.g., Ortega and Rheinboldt [19, Theorem 12.6.1]); both provide existence and uniqueness regions for zeros of systems of equations. Shen and Neumaier [22] proved that the Krawczyk operator with slopes always provides an existence region which is at least as large as that computed by Kantorovich's theorem. Deuflhard and Heindl [2] proved an affine invariant version of the Kantorovich theorem.

In section 2, these results are reviewed, together with recent works on improved preconditioning by Hansen [3] and on Taylor models by Berz and Hoefkens [1] that are related to our present work. In sections 4–7, we discuss componentwise and affine invariant existence, uniqueness, and nonexistence regions given a zero or any other

point of the search region. They arise from a more detailed analysis of the properties of the Krawczyk operator with slopes used in [22].

Numerical examples given in section 8 show that the refinements introduced in this paper significantly enlarge the sizes of the exclusion regions.

In the following, the notation is as in the book [17]. In particular, inequalities are interpreted componentwise, I denotes the identity matrix, intervals and boxes (= interval vectors) are in boldface, and $\operatorname{rad}\mathbf{x} = \frac{1}{2}(\overline{x} - \underline{x})$ denotes the radius of a box $\mathbf{x} = [\underline{x}, \overline{x}] \in \mathbb{IR}^n$. The interior of a set $S \subseteq \mathbb{R}^n$ is denoted by $\operatorname{int}(S)$ and the interval hull by $\Box S$.

We consider the nonlinear system of equations

$$F(x) = 0, \tag{1}$$

where $F : D \subseteq \mathbb{R}^n \to \mathbb{R}^n$ is twice continuously differentiable in a convex domain D. (For some results, weaker conditions suffice; it will be clear from the arguments used that continuity and the existence of the quantities in the hypothesis of the theorems are sufficient.)

Since F is twice continuously differentiable, we can always (e.g., using the mean value theorem) write

$$F(x) - F(z) = F[z, x](x - z) \tag{2}$$

for any two points x and z with a suitable matrix $F[z, x] \in \mathbb{R}^{n\times n}$, continuously differentiable in x and z; any such $F[z, x]$ is called a *slope matrix* for F. While (in dimension $n > 1$) $F[z, x]$ is not uniquely determined, we always have (by continuity)

$$F[z, z] = F'(z). \tag{3}$$

Thus $F[z, x]$ is a slope version of the Jacobian. There are recursive procedures to calculate a slope $F[z, x]$, given x and z; see Krawczyk and Neumaier [14], Rump [20], and Kolev [13]; a Matlab implementation is in Intlab [21].

Since the slope matrix $F[z, x]$ is continuously differentiable, we can write similarly

$$F[z, x] = F[z, z'] + \sum (x_k - z'_k) F_k[z, z', x] \tag{4}$$

with *second order slope matrices* $F_k[z, z', x]$, continuous in z, z', x. Here, as throughout this paper, the summation extends over $k = 1, \ldots, n$. Second order slope matrices can also be computed recursively; see Kolev [13]. Moreover, if F is quadratic, the slope is linear in x and z, and the coefficients of x determine constant second order slope matrices without any work.

If $z = z'$ the formula above somewhat simplifies, because of (3), to

$$F[z, x] = F'(z) + \sum (x_k - z_k) F_k[z, z, x]. \tag{5}$$

Throughout the paper we shall make the following assumption, without mentioning it explicitly.

Assumption A. The point z and the convex subset X lie in the domain of definition of F. The center, $z \in X$, and the second order slope (5) are fixed. Moreover, for a fixed preconditioning matrix $C \in \mathbb{R}^{m\times n}$, the componentwise bounds

$$\begin{aligned} \overline{b} &\geq |CF(z)| \geq \underline{b}, \\ B_0 &\geq |CF'(z) - I|, \\ B'_0 &\geq |CF'(z)|, \\ B_k(x) &\geq |CF_k[z, z, x]| \quad (k = 1, \ldots, n) \end{aligned} \tag{6}$$

are valid for all $x \in X$.

Example 1.1. We consider the system of equations

$$\begin{aligned} x_1^2 + x_2^2 &= 25, \\ x_1 x_2 &= 12. \end{aligned} \tag{7}$$

The system has the form (1) with

$$F(x) = \begin{pmatrix} x_1^2 + x_2^2 - 25 \\ x_1 x_2 - 12 \end{pmatrix}. \tag{8}$$

With respect to the center $z = \binom{3}{4}$, we have

$$F(x) - F(z) = \begin{pmatrix} x_1^2 - 3^2 + x_2^2 - 4^2 \\ x_1 x_2 - 3 \cdot 4 \end{pmatrix} = \begin{pmatrix} (x_1 + 3)(x_1 - 3) + (x_2 + 4)(x_2 - 4) \\ x_2(x_1 - 3) + 3(x_2 - 4) \end{pmatrix}$$

so that we can take

$$F[z, x] = \begin{pmatrix} x_1 + 3 & x_2 + 4 \\ x_2 & 3 \end{pmatrix}$$

as a slope. (Note that other choices would be possible.) The interval slope $F[z, \mathbf{x}]$ in the box $\mathbf{x} = [2, 4] \times [3, 5]$ is then

$$F[z, x] = \begin{pmatrix} [5, 7] & [7, 9] \\ [3, 5] & 3 \end{pmatrix}.$$

The slope can be put in form (5) with

$$F'(z) = \begin{pmatrix} 6 & 8 \\ 4 & 3 \end{pmatrix}, \quad F_1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad F_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

and we obtain

$$B_1 = \frac{1}{14} \begin{pmatrix} 3 & 0 \\ 4 & 0 \end{pmatrix}, \qquad B_2 = \frac{1}{14} \begin{pmatrix} 8 & 3 \\ 6 & 4 \end{pmatrix}.$$

Since we calculated without rounding errors and z happens to be a zero of F, both B_0 and $\bar{b}$ vanish.

2. Known results. The oldest semilocal existence theorem for zeros of systems of equations is due to Kantorovich [7], who obtained as a by-product of a convergence guarantee for Newton's method (which is not of interest in our context) the following result.

THEOREM 2.1 (Kantorovich). *Let z be a vector such that $F'(z)$ is invertible, and let α and β be constants with*

$$\|F'(z)^{-1}\|_\infty \le \alpha, \qquad \|F'(z)^{-1} F(z)\|_\infty \le \beta. \tag{9}$$

Suppose further that $z \in \mathbf{x}$ and that there exists a constant $\gamma > 0$ such that for all $x \in \mathbf{x}$,

$$\max_i \sum_{j,k} \left| \frac{\partial^2 F_i(x)}{\partial x_j \partial x_k} \right| \le \gamma. \tag{10}$$

If $2\alpha\beta\gamma < 1$, then $\Delta := \sqrt{1 - 2\alpha\beta\gamma}$ is real and we have the following:

1. *There is no zero $x \in \mathbf{x}$ with*

$$\underline{r} < \|x - z\|_\infty < \overline{r},$$

where

$$\underline{r} = \frac{2\beta}{1+\Delta}, \qquad \overline{r} = \frac{1+\Delta}{\alpha\gamma}.$$

2. *At most one zero x is contained in $\mathbf{x}$ with*

$$\|x - z\|_\infty < \frac{2}{\alpha\gamma}.$$

3. *If*

$$\max_{x\in\mathbf{x}} \|x - z\|_\infty < \overline{r},$$

then there is a unique zero $x \in \mathbf{x}$, and this zero satisfies

$$\|x - z\|_\infty \le \underline{r}.$$

The affine invariant version of the Kantorovich theorem given in Deuflhard and Heindl [2] essentially amounts to applying the theorem to $F'(z)^{-1}F(x)$ in place of $F(x)$. In practice, rounding errors in computing $F'(z)^{-1}$ are made, which requires the use of a preconditioning matrix $C \approx F'(z)^{-1}$ and $CF(x)$ in place of $F(x)$ to get the benefits of affine invariance in floating point computations.

Kahan [5] used the Krawczyk operator, which needs only first order slopes, to make existence statements. Together with later improvements using slopes, his result is contained in the following statement.

THEOREM 2.2 (Kahan). *Let $z \in \mathbf{z} \subseteq \mathbf{x}$. If there is a matrix $C \in \mathbb{R}^{n\times n}$ such that the Krawczyk operator*

$$K(\mathbf{z}, \mathbf{x}) := z - CF(z) - (CF[\mathbf{z}, \mathbf{x}] - I)(\mathbf{x} - z) \tag{11}$$

satisfies $K(\mathbf{z}, \mathbf{x}) \subseteq \mathbf{x}$, then $\mathbf{x}$ contains a zero of (1). *Moreover, if $K(\mathbf{x}, \mathbf{x}) \subseteq \operatorname{int}(\mathbf{x})$, then $\mathbf{x}$ contains a unique zero of* (1).

Shen and Neumaier [22] proved that the Krawczyk operator with slopes always provides existence regions which are at least as large as those computed by Kantorovich's theorem, and, since the Krawczyk operator is affine invariant, this also covers the affine invariant Kantorovich theorem.

Recent work by Hansen [3] shows that there is scope for gain in Krawczyk's method by improved preconditioning; but he gives only heuristic recipes for how to proceed. For quadratic problems, where the slope is linear in x, his recipe suggests evaluating $CF[z, x]$ term by term before substituting intervals. Indeed, by subdistributivity, we always have

$$CA_0 + \sum CA_k(\mathbf{x}_k - \mathbf{z}_k) \subseteq C\Big(A_0 + \sum A_k(\mathbf{x}_k - \mathbf{z}_k)\Big)$$

so that, for quadratic functions, Hansen's recipe is never worse than the traditional recipe. We adapt it as follows to general functions, using second order slopes; in the general case, the preconditioned slope takes the form

$$CF[z, x] = CF[z, z'] + \sum (x_k - z'_k) CF_k[z, z', x] \tag{12}$$

or, with $z = z'$, as we use it most of the time,

$$CF[z,x] = CF'(z) + \sum (x_k - z_k) CF_k[z,z,x]. \tag{13}$$

In the following, the consequences of this formulation, combined with ideas from Shen and Neumaier [22], are investigated in detail.

Recent work on Taylor models by Berz and Hoefkens [1] (see also Neumaier [18]) uses expansions to even higher than second order, although at a significantly higher cost. This may be of interest for systems suffering a lot from cancellation, where using low order methods may incur much overestimation, leading to tiny inclusion regions. Another recent paper on exclusion boxes is Kalovics [6].

3. The cluster effect. As explained by Kearfott and Du [11], many branch and bound methods used for global optimization suffer from the so-called *cluster effect*. As is apparent from the discussion below, this effect is also present for branch and bound methods using constraint propagation methods to find and verify *all* solutions of nonlinear systems of equations. (See, e.g., Van Hentenryck, Michel, and Deville [23] for constraint propagation methods.)

The cluster effect consists of excessive splitting of boxes close to a solution and failure to remove many boxes not containing the solution. As a consequence, these methods slow down considerably once they reach regions close to the solutions. The mathematical reason for the cluster effect and how to avoid it will be investigated in this section.

Let us assume that for arbitrary boxes $\mathbf{x}$ of maximal width ε the computed expression $F(\mathbf{x})$ overestimates the range of F over $\mathbf{x}$ by $O(\varepsilon^k)$:

$$F(\mathbf{x}) \in (1 + C\varepsilon^k) \square \{F(x) \mid x \in \mathbf{x}\} \tag{14}$$

for $k \leq 2$ and ε sufficiently small. The exponent k depends on the method used for the computation of $F(\mathbf{x})$.

Let x^* be a regular solution of (1) (so that $F'(x^*)$ is nonsingular), and assume (14). Then any box of diameter ε that contains a point x with

$$\|F'(x^*)(x - x^*)\|_\infty \leq \Delta = C\varepsilon^k \tag{15}$$

might contain a solution. Therefore, independent of the pruning scheme used in a branch and bound method, no box of diameter ε can be eliminated. The inequality (15) describes a parallelepiped of volume

$$V = \frac{\Delta^n}{\det F'(x^*)}.$$

Thus, any covering of this region by boxes of diameter ε contains at least V/ε^n boxes.

The number of boxes of diameter ε which cannot be eliminated is therefore proportional to at least

$$\frac{C^n}{\det F'(x^*)} \quad \text{if } k = 1,$$

$$\frac{(C\varepsilon)^n}{\det F'(x^*)} \quad \text{if } k = 2.$$

For $k = 1$ this number grows exponentially with the dimension, with a growth rate determined by the relative overestimation C and a proportionality factor related to the condition of the Jacobian.

In contrast, for $k = 2$ the number is guaranteed to be small for sufficiently small ε. The size of ε, the diameter of the boxes most efficient for covering the solution, is essentially determined by the nth root of the determinant, which, for a well-scaled problem, reflects the condition of the zero. However, for ill-conditioned zeros (with a tiny determinant in naturally scaled coordinates), one already needs quite narrow boxes before the cluster effect subsides.

So, to avoid the cluster effect, we need at least the quadratic approximation property $k = 2$. Hence, Jacobian information is essential, as well as techniques to discover the shape of the uncertainty region.

A comparison of the typical techniques used for box elimination shows that constraint propagation techniques lead to overestimation of order $k = 1$; hence they suffer from the cluster effect. Centered forms using first order information (Jacobians) as in Krawczyk's method provide estimates with $k = 2$ and are therefore sufficient to avoid the cluster effect, except near ill-conditioned or singular zeros. Second order information as used, e.g., in the theorem of Kantorovich still provides only $k = 2$ in estimate (15); the cluster effect is avoided under the same conditions.

For singular (and hence for sufficiently ill-conditioned) zeros, the argument does not apply, and no technique is known to remove the cluster effect in this case. A heuristic that limits the work in this case by retaining a single but *larger* box around an ill-conditioned approximate zero is described in Algorithm 7 (Step 4(c)) of Kearfott [10].

4. Componentwise exclusion regions close to a zero. Suppose that x^* is a solution of the nonlinear system of equations (1). We want to find an *exclusion region* around x^* with the property that in the interior of this region x^* is the only solution of (1). Such an exclusion region need not be further explored in a branch and bound method for finding all solutions of (1); hence we get the name.

In this section we take an approximate zero z of F, and we choose C to be an approximation of $F'(z)^{-1}$. Suitable candidates for z can easily be found within a branch and bound algorithm by trying Newton steps from the midpoint of each box, iterating while x^ℓ remains in a somewhat enlarged box and either $\|x^{\ell+1} - x^\ell\|$ or $\|F(x^\ell)\|$ decreases by a factor of, say, 1.5 below the best previous value in the iteration. This works locally well even at nearly singular zeros and gives a convenient stop in case no nearby solution exists.

PROPOSITION 4.1. *For every solution $x \in X$ of* (1)*, the deviation*

$$s := |x - z|$$

satisfies

$$0 \le s \le \Big(B_0 + \sum s_k B_k(x)\Big)s + \bar{b}. \tag{16}$$

Proof. By (2) we have $F[z, x](x - z) = F(x) - F(z) = -F(z)$, because x is a zero. Hence, using (5), we compute

$$\begin{aligned} -(x - z) &= -(x - z) + C(F[z, x](x - z) + F(z) + F'(z)(x - z) - F'(z)(x - z)) \\ &= C(F[z, x] - F'(z))(x - z) + (CF'(z) - I)(x - z) + CF(z) \\ &= \Big(CF'(z) - I + \sum (x_k - z_k)CF_k[z, z, x]\Big)(x - z) + CF(z). \end{aligned}$$

Now we take absolute values, use (6), and get

$$\begin{aligned} s = |x - z| &\le \Big(|CF'(z) - I| + \sum |x_k - z_k|\,|CF_k[z, z, x]|\Big)\,|x - z| + |CF(z)| \\ &\le \Big(B_0 + \sum s_k B_k(x)\Big)\,s + \bar{b}. \qquad \square \end{aligned}$$

Using this result we can give a first criterion for existence regions.

THEOREM 4.2. *Let $0 < u \in \mathbb{R}^n$ be such that*

$$\Big(B_0 + \sum u_k \overline{B}_k\Big)u + \bar{b} \le u \tag{17}$$

with $B_k(x) \le \overline{B}_k$ for all $x \in M_u$, where

$$M_u := \{x \mid |x - z| \le u\} \subseteq X. \tag{18}$$

Then (1) *has a solution $x \in M_u$.*

Proof. For arbitrary x in the domain of definition of F we define

$$K(x) := x - CF(x).$$

Now take any $x \in M_u$. We get

$$\begin{aligned} K(x) = x - CF(x) &= z - CF(z) - (CF[z, x] - I)(x - z) \\ &= z - CF(z) - \Big(C\Big(F'(z) + \sum F_k[z, z, x](x_k - z_k)\Big) - I\Big)\,(x - z); \end{aligned}$$

hence

$$K(x) = z - CF(z) - \Big(CF'(z) - I + \sum CF_k[z, z, x](x_k - z_k)\Big)\,(x - z). \tag{19}$$

Taking absolute values we find

$$\begin{aligned} |K(x) - z| &= \Big|-CF(z) - \Big(CF'(z) - I + \sum CF_k[z, z, x](x_k - z_k)\Big)\,(x - z)\Big| \\ &\le |CF(z)| + \Big(|CF'(z) - I| + \sum |CF_k[z, z, x]|\,|x_k - z_k|\Big)\,|x - z| \qquad (20) \\ &\le \bar{b} + \Big(B_0 + \sum u_k \overline{B}_k\Big)\,u. \end{aligned}$$

Now assume (17). Then (20) gives

$$|K(x) - z| \le u,$$

which implies by Theorem 2.2 that there exists a solution of (1) which lies in M_u. $\square$

Note that (17) implies $B_0 u \le u$; thus the spectral radius $\rho(B_0) \le 1$. In the applications, we can make both B_0 and $\bar{b}$ very small by choosing z as an approximate zero and C as an approximate inverse of $F'(z)$.

Now the only thing that remains is the construction of a suitable vector u for Theorem 4.2.

THEOREM 4.3. *Let $S \subseteq X$ be any set containing z, and take*

$$\overline{B}_k \ge B_k(x) \quad \textit{for all } x \in S. \tag{21}$$

For $0 < v \in \mathbb{R}^n$, set

$$w := (I - B_0)v, \qquad a := \sum v_k \overline{B}_k v. \tag{22}$$

We suppose that

$$D_j = w_j^2 - 4a_j\overline{b}_j > 0 \tag{23}$$

for all $j = 1, \ldots, n$, and we define

$$\lambda_j^e := \frac{w_j + \sqrt{D_j}}{2a_j}, \qquad \lambda_j^i := \frac{\overline{b}_j}{a_j \lambda_j^e}, \tag{24}$$

$$\lambda^e := \min_{j=1,\ldots,n} \lambda_j^e, \qquad \lambda^i := \max_{j=1,\ldots,n} \lambda_j^i. \tag{25}$$

If $\lambda^e > \lambda^i$, then there is at least one zero x^* of (1) in the (inclusion) region

$$R^i := [z - \lambda^i v, z + \lambda^i v] \cap S. \tag{26}$$

The zeros in this region are the only zeros of F in the interior *of the (exclusion) region*

$$R^e := [z - \lambda^e v, z + \lambda^e v] \cap S. \tag{27}$$

Proof. Let $0 < v \in \mathbb{R}^n$ be arbitrary, and set $u = \lambda v$. We check for which λ the vector u satisfies property (17) of Theorem 4.2. The requirement

$$\begin{aligned} \lambda v &\geq \Big(B_0 + \sum u_k \overline{B}_k\Big)u + \overline{b} = \Big(B_0 + \sum \lambda v_k \overline{B}_k\Big)\lambda v + \overline{b} \\ &= \overline{b} + \lambda B_0 v + \lambda^2 \sum v_k \overline{B}_k v = \overline{b} + \lambda(v - w) + \lambda^2 a \end{aligned}$$

leads to the sufficient condition $\lambda^2 a - \lambda w + \overline{b} \leq 0$. The jth component of this inequality requires that λ lies between the solutions of the quadratic equation $\lambda^2 a_j - \lambda w_j + \overline{b}_j = 0$, which are λ_j^i and λ_j^e. Hence, for every $\lambda \in [\lambda^i, \lambda^e]$ (this interval is nonempty by assumption), the vector u satisfies (17).

Now assume that x is a solution of (1) in $\operatorname{int}(R^e) \setminus R^i$. Let λ be minimal with $|x - z| \leq \lambda v$. By construction, $\lambda^i < \lambda < \lambda^e$. By the properties of the Krawczyk operator, we know that $x = K(z, x)$; hence

$$\begin{aligned} |x - z| &\leq |CF(z)| + \Big(|CF'(z) - I| + \sum |CF_k[z, z, x]|\,|x_k - z_k|\Big)|x - z| \\ &\leq \overline{b} + \lambda B_0 v + \lambda^2 \sum v_k \overline{B}_k v < \lambda v, \end{aligned} \tag{28}$$

since $\lambda > \lambda^i$. But this contradicts the minimality of λ. So there are indeed no solutions of (1) in $\operatorname{int}(R^e) \setminus R^i$. ∎

This is a componentwise analogue of the Kantorovich theorem. We show in Example 8.1 that it is best possible in some cases.

We observe that the inclusion region from Theorem 4.3 can usually be further improved by noting that $x^* = K(z, x^*)$ and (19) imply

$$\begin{aligned} x^* &\in K(z, \mathbf{x}^i) \\ &= z - CF(z) - \Big(CF'(z) - I + \sum CF_k[z, z, \mathbf{x}^i](\mathbf{x}_k^i - z_k)\Big)\,(\mathbf{x}^i - z) \\ &\subset \operatorname{int}(\mathbf{x}^i). \end{aligned}$$

An important special case is when $F(x)$ is quadratic in x. For such a function $F[z,x]$ is linear in x, and therefore all $F_k[z,z,x]$ are constant in x. This, in turn, means that $B_k(x) = B_k$ is constant as well. So we can set $\overline{B}_k = B_k$, and the estimate (21) becomes valid everywhere.

COROLLARY 4.4. *Let F be a quadratic function. For arbitrary $0 < v \in \mathbb{R}^n$ define*

$$w := (I - B_0)v, \qquad a := \sum v_k B_k v. \tag{29}$$

We suppose that

$$D_j = w_j^2 - 4a_j\overline{b}_j > 0 \tag{30}$$

for all $j = 1, \ldots, n$, and we set

$$\lambda_j^e := \frac{w_j + \sqrt{D_j}}{2a_j}, \qquad \lambda_j^i := \frac{\overline{b}_j}{a_j \lambda_j^e}, \tag{31}$$

$$\lambda^e := \min_{j=1,\ldots,n} \lambda_j^e, \qquad \lambda^i := \max_{j=1,\ldots,n} \lambda_j^i. \tag{32}$$

If $\lambda^e > \lambda^i$, then there is at least one zero x^* of (1) in the (inclusion) box

$$\mathbf{x}^i := [z - \lambda^i v, z + \lambda^i v]. \tag{33}$$

The zeros in this region are the only zeros of F in the interior *of the (exclusion) box*

$$\mathbf{x}^e := [z - \lambda^e v, z + \lambda^e v]. \tag{34}$$

The examples later will show that the choice of v greatly influences the quality of the inclusion and exclusion regions. The main difficulty for choosing v is the positivity requirement for every D_j. In principle, a vector v, if it exists, could be found by local optimization. A method worth trying could be to choose v as a local optimizer of the problem

$$\begin{aligned} &\max n \log \lambda^e + \sum_{j=1}^{n} \log v_j \\ &\text{s.t. } D_j \geq \eta \quad (j = 1, \ldots, n), \end{aligned}$$

where η is the smallest positive machine number. This maximizes locally the volume of the excluded box. However, since λ^e is nonsmooth, solving this needs a nonsmooth optimizer (such as SolvOpt [15]).

The $\overline{B}_k$ can be constructed using interval arithmetic for a given reference box $\mathbf{x}$ around z. Alternatively, they could be calculated once in a bigger reference box $\mathbf{x}_{\text{ref}}$ and later reused on all subboxes of $\mathbf{x}_{\text{ref}}$. Saving the $\overline{B}_k$ (which needs the storage of n^3 numbers per zero) provides a simple exclusion test for other boxes. This takes $O(n^3)$ operations, while recomputing the $\overline{B}_k$ costs $O(n^4)$ operations.

5. Exclusion polytopes. Instead of boxes, we can use more general polytopes to describe exclusion and inclusion regions. With the notation as in the introduction, we assume the upper bounds

$$\overline{B}_k \geq |B_k(x)| \qquad \text{for all } x \in X. \tag{35}$$

THEOREM 5.1. *For $0 \le v \le w \in \mathbb{R}^n$, define*

$$P(w) = (\overline{B}_1{}^T w, \ldots, \overline{B}_n{}^T w) \in \mathbb{R}^{n\times n}, \tag{36}$$

$$\Pi^i = \{x \in \mathbb{R}^n \mid (w-v)^T|x-z| \le \bar{b}^T w\}. \tag{37}$$

Then any zero $x \in X$ of (1) contained in the polytope

$$\Pi^e = \{x \in \mathbb{R}^n \mid P(w)|x-z| + B_0^T w \le v\} \tag{38}$$

lies already in Π^i.

Proof. Suppose $x \in \Pi^e$ satisfies $F(x) = 0$. By Proposition 4.1, $s = |x-z|$ satisfies

$$\begin{aligned} s^T w &\le s^T\Big(B_0^T w + \sum s_k \overline{B}_k{}^T w\Big) + \bar{b}^T w \\ &= s^T(B_0^T w + P(w)s) + \bar{b}^T w \\ &\le s^T v + \bar{b}^T w. \end{aligned}$$

Hence $s^T(w-v) \le \bar{b}^T w$, giving

$$(w-v)^T|x-z| \le \bar{b}^T w; \tag{39}$$

hence $x \in \Pi^i$. ∎

COROLLARY 5.2. *Let $\mathbf{x} \subseteq X$ be a box and $z \in \mathbf{x}$ be an approximate zero. If there is a vector $0 \le w \in \mathbb{R}^n$ with*

$$v := P(w)u + B_0^T w \le w, \tag{40}$$

where $u := |\mathbf{x} - z|$, then all solutions $x \in \mathbf{x}$ of (1) satisfy (39), and, in particular,

$$|x-z|_i \le \bar{b}^T w\,(w_i - v_i)^{-1} \quad \text{for all } i \text{ with } w_i > v_i. \tag{41}$$

Proof. Let $x \in \mathbf{x}$ be a solution of (1). Then $x \in \Pi^e$ by (40), and, due to Theorem 5.1, $\mathbf{x} \in \Pi^i$. Therefore (39) holds. In particular, $(w-v)_i|x-z|_i \le \bar{b}^T w$. This implies the result. ∎

In contrast to (32), the test (40) needs only $O(n^2)$ operations (once $P(w)$ is computed) and the storage of n^2+n numbers per zero. Since $P(w)$ can be calculated columnwise, it is not even necessary to keep all $\overline{B}_k$ in store.

Since B_0 and $\bar{b}$ usually are very tiny (they contain only roundoff errors), this is a powerful box reduction technique if we can find a suitable vector w.

The result is most useful, of course, if $w > v$, but in some cases this is not possible. In these cases boxes are at least reduced in some components.

A suitable choice for w may be an approximation $w > 0$ to a Perron eigenvector [16, section 3.2] of the nonnegative matrix

$$M = \sum_k u_k \overline{B}_k{}^T,$$

where $u > 0$ is proportional to the width of the box of interest. Then

$$\lambda w = Mw = \sum u_k \overline{B}_k{}^T w = P(w)u.$$

If

$$\frac{\max(B_0^T w)_i}{w_i} < \alpha < 1, \qquad \mu := (1-\alpha)\lambda^{-1},$$

we can conclude from Corollary 5.2 (with μu in place of u) that the box $[z-\mu u, z+\mu u]$ can be reduced to $[z-\hat{u}, z+\hat{u}]$, where (with $c/0 = \infty$)

$$\hat{u}_i := \min\left(\mu u_i, \frac{\overline{b}^T w}{\max(0, \alpha w_i - (B_0^T w))_i}\right).$$

6. Uniqueness regions. Regions in which there is a unique zero can be found most efficiently as follows. First, one verifies as in the previous sections an exclusion box $\mathbf{x}^e$ which contains no zero except in a much smaller inclusion box $\mathbf{x}^i$. The inclusion box can usually be refined further by some iterations with Krawczyk's method, which generally converges quickly if the initial inclusion box is already verified. Thus we may assume that $\mathbf{x}^i$ is really tiny, with width determined by rounding errors only.

Clearly, $\mathrm{int}(\mathbf{x}^e)$ contains a unique zero iff $\mathbf{x}^i$ contains at most one zero. Thus it suffices to have a condition under which a tiny box contains at most one zero. This can be done even in fairly ill-conditioned cases by the following test.

THEOREM 6.1. *Take an approximate solution $z \in X$ of (1), and let B be a matrix such that*

$$|CF[z,\mathbf{x}] - I| + \sum |\mathbf{x}_k - z_k|\,|CF_k[\mathbf{x}, z, \mathbf{x}]| \le B. \tag{42}$$

If $\|B\| < 1$ for some monotone norm, then $\mathbf{x}$ contains at most one solution x of (1).

Proof. Assume that x and x' are two solutions. Then we have

$$0 = F(x') - F(x) = F[x,x'](x'-x) = \Big(F[x,z] + \sum (x'_k - z_k)F_k[x,z,x']\Big)(x'-x). \tag{43}$$

Using an approximate inverse C of $F'(z)$ we further get

$$x - x' = \Big((CF[z,x] - I) + \sum (x'_k - z_k)CF_k[x,z,x']\Big)(x'-x). \tag{44}$$

Applying absolute values, and using (42), we find

$$|x'-x| \le \Big(|CF[z,x]-I| + \sum |CF_k[x,z,x']|\,|x'_k - z_k|\Big)|x'-x| \le B|x'-x|. \tag{45}$$

This, in turn, implies $\|x'-x\| \le \|B\|\,\|x'-x\|$. If $\|B\| < 1$ we immediately conclude $\|x'-x\| \le 0$; hence $x = x'$. ∎

Since B is nonnegative, $\|B\| < 1$ holds for some norm iff the spectral radius of B is less than one (see, e.g., Neumaier [16, Corollary 3.2.3]); a necessary condition for this is that $\max B_{kk} < 1$, and a sufficient condition is that $|B|u < u$ for some vector $u > 0$.

So one first checks whether $\max B_{kk} < 1$. If this holds, one checks whether $\|B\|_\infty < 1$; if this fails, one computes an approximate solution u of $(I-B)u = e$, where e is the all-one vector, and checks whether $u > 0$ and $|B|u < u$. If this fails, the spectral radius of B is very close to 1 or larger. (Essentially, this amounts to testing $I - B$ for being an H-matrix; cf. [16, Proposition 3.2.3].)

We can find a matrix B satisfying (42) by computing $\hat{B}_k \geq |CF_k[\mathbf{x}, z, \mathbf{x}]|$, for example by interval evaluation, using (5), and observing

$$\begin{aligned}|CF[z,\mathbf{x}] - I| &\leq |CF'(z) - I| + \sum |\mathbf{x}_k - z_k|\,|CF_k[z,z,\mathbf{x}]| \\ &\leq |CF'(z) - I| + \sum |\mathbf{x}_k - z_k|\,|CF_k[\mathbf{x},z,\mathbf{x}]|.\end{aligned}$$

Then, using (6), we get

$$|CF[z,\mathbf{x}] - I| + \sum |\mathbf{x}_k - z_k|\,|CF_k[\mathbf{x},z,\mathbf{x}]| \leq B_0 + 2\sum |\mathbf{x}_k - z_k|\,\hat{B}_k =: B, \tag{46}$$

where B can be computed using rounding towards $+\infty$.

If F is quadratic, the results simplify again. In this case all $F_k[x', z, x] =: F_k$ are constant, and we can replace $\hat{B}_k$ by $B_k := |CF_k|$. Hence (46) becomes

$$B = B_0 + 2\sum |\mathbf{x}_k - z_k| B_k.$$

7. Componentwise exclusion regions around arbitrary points. In a branch–and–bound-based method for finding all solutions to (1), we not only need to exclude regions close to zeros but also boxes far away from all solutions. This is usually done by interval analysis on the range of F, by constraint propagation methods (see, e.g., Van Hentenryck, Michel, and Deville [23]), or by Krawczyk's method or preconditioned Gauss–Seidel iteration (see, e.g., [16]). An affine invariant, componentwise version of the latter is presented in this section.

Let z be an arbitrary point in the region of definition of F. Throughout this section, $C \in \mathbb{R}^{m\times n}$ denotes an arbitrary rectangular matrix. M_u is as in (18).

THEOREM 7.1. *Let $0 < u \in \mathbb{R}^n$, and take $\overline{B}_k \geq B_k(x)$ for all $x \in M_u$. If there is an index $i \in \{1,\dots,n\}$ such that the inequality*

$$\underline{b}_i - (B_0'u)_i - \sum u_k(\overline{B}_k u)_i > 0 \tag{47}$$

is valid, then (1) *has no solution $x \in M_u$.*

Proof. We set $\mathbf{x} = [z-u, z+u]$. For a zero $x \in M_u$ of F, we calculate, using (5), similar to the proof of Theorem 4.2,

(48)
$$\begin{aligned}0 = |K(x) - x| &= \Big| - CF(z) - \Big(CF'(z) - \sum CF_k[z,z,x](x_k - z_k)\Big)(x-z)\Big| \\ &\geq |CF(z)| - \Big|(CF'(z) - I)(x-z) + \sum (x_k - z_k) CF_k[z,z,x](x-z)\Big|.\end{aligned}$$

Now we use (6) and (47) to compute

$$\begin{aligned}|CF(z)|_i \geq \underline{b}_i &> (B_0'u)_i + \sum (u_k \overline{B}_k u)_i \\ &\geq \Big(|CF'(z)|u\Big)_i + \sum \Big(u_k |CF_k[z,z,x]\,|u\Big)_i \\ &\geq \Big|CF'(z)(x-z)\Big|_i + \sum \Big|(x_k - z_k)CF_k[z,z,x](x-z)\Big|_i \\ &\geq \Big|(CF'(z) - I)(x-z) + \sum (x_k - z_k) CF_k[z,z,x](x-z)\Big|_i .\end{aligned}$$

This calculation and (47) imply

$$\begin{aligned}|CF(z)|_i - \Big|CF'(z)(x-z) + \sum (x_k - z_k) CF_k[z,z,x](x-z)\Big|_i \\ \geq \underline{b}_i - (B_0'u)_i - \sum (u_k \overline{B}_k u)_i > 0,\end{aligned}$$

contradicting (48). ∎

Again, we need a method to find good vectors u satisfying (47). The following theorem provides that.

THEOREM 7.2. *Let $S \subseteq X$ be a set containing z, and take $\overline{B}_k \geq B_k(x)$ for all $x \in S$. If for any $0 < v \in \mathbb{R}^n$ we define*

$$\begin{aligned} w^\times &:= B_0' v, \\ a^\times &:= \sum v_k \overline{B}_k v, \\ D_i^\times &:= {w_i^\times}^2 + 4\underline{b}_i a_i^\times, \\ \lambda_i^\times &:= \frac{\underline{b}_i}{w_i^\times + \sqrt{D_i^\times}}, \\ \lambda^\times &:= \max_{i=1,\ldots,n} \lambda_i^\times, \end{aligned} \tag{49}$$

then F has no zero in the interior of the exclusion region

$$R^\times := [z - \lambda^\times v, z + \lambda^\times v] \cap S. \tag{50}$$

Proof. We set $u = \lambda v$ and check the result (47) of Theorem 7.1:

$$0 < \underline{b}_i - (B_0' u)_i - \sum (u_k \overline{B}_k u)_i = \underline{b}_i - \lambda (B_0' v)_i - \lambda^2 \sum (v_k \overline{B}_k v)_i.$$

This quadratic inequality has to be satisfied for some $i \in \{1, \ldots, n\}$. The ith inequality is true for all $\lambda \in [0, \lambda_i^\times[$, so we can take the maximum of all these numbers and still have the inequality satisfied for at least one i. Bearing in mind that the estimates are only true in the set S, the result follows from Theorem 7.1. ∎

As in the last section, a vector v could be calculated by local optimization, e.g., as a local optimizer of the problem

$$\max n \log \lambda^\times + \sum_{j=1}^{n} \log v_j.$$

This maximizes locally the volume of the excluded box. Solving this also needs a nonsmooth optimizer since $\lambda^\times$ is nonsmooth like λ^e. However, in contrast to the v needed in Theorem 4.3, there is no positivity requirement which has to be satisfied. In principle, every choice of v leads to some exclusion region.

Finding a good choice for C is a subtle problem and could be attacked by methods similar to Kearfott, Hu, and Novoa [12]. Example 8.3 below shows that a pseudoinverse of $F'(z)$ usually yields reasonable results. However, improving the choice of C sometimes widens the exclusion box by a considerable amount.

Again, for quadratic F the result can be made global, due to the fact that the $F_k[z, z, x]$ are independent of x.

COROLLARY 7.3. *Let F be quadratic, and $0 < v \in \mathbb{R}^n$. Choose $\overline{B}_k \geq |CF_k|$, $w_i^\times$, $a_i^\times$, $D_i^\times$, $\lambda_i^\times$, and $\lambda^\times$ as in Theorem 7.2. Then F has no zero in the interior of the exclusion box*

$$\mathbf{x}^\times := [z - \lambda^\times v, z + \lambda^\times]. \tag{51}$$

Proof. This is a direct consequence of Theorem 7.2 and the fact that all $F_k[z, z, x]$ are constant in x. ∎

Results analogous to Theorems 4.3, 5.1, 6.1, and 7.2 can be obtained for exclusion regions in global optimization problems by applying the above techniques to the first order optimality conditions. Since nothing new happens mathematically, we refrain from giving details.

8. Examples. We illustrate the theory with a few examples.

Example 8.1. We continue Example 1.1, doing all calculations symbolically, hence free of rounding errors, assuming a known zero. (This idealizes the practically relevant case where a good approximation of a zero is available from a standard zero-finder.)

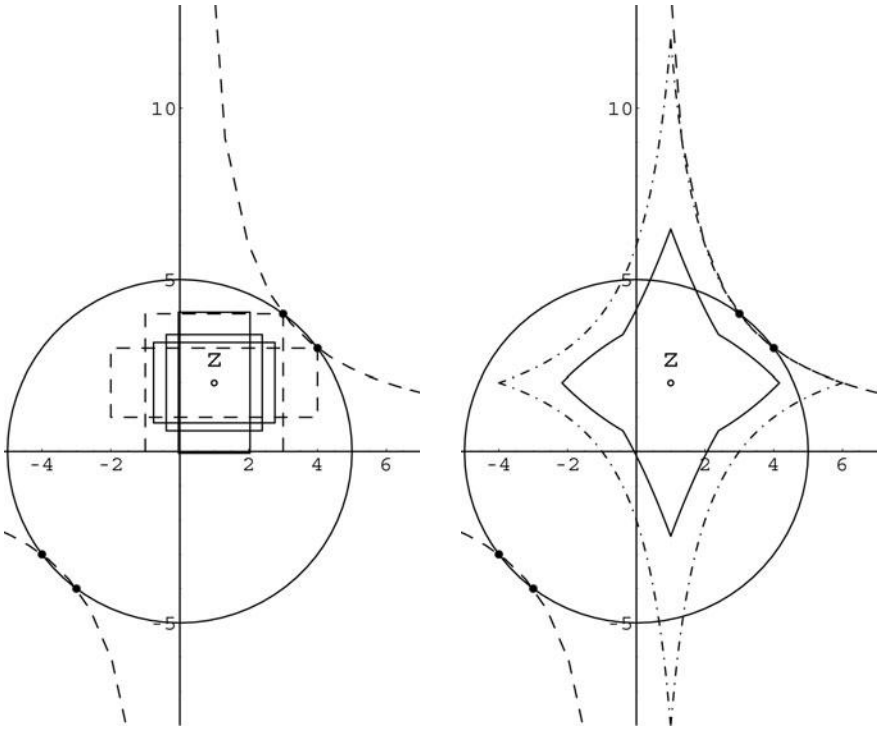

FIG. 1. *Maximal exclusion boxes around* $\binom{1}{2}$ *and the total excluded region for Example* 8.1.

We consider the system of equations (7), which has the four solutions $\pm\binom{3}{4}$ and $\pm\binom{4}{3}$; cf. Figure 1. The system has the form (1) with F given by (8). If we take the solution $x^* = \binom{3}{4}$ as center z, we can use the slope calculations from the introduction. From (29) we get

$$w_j = v_j, \qquad D_j = v_j^2 \quad (j = 1, 2),$$

$$a_1 = \tfrac{1}{14}(3v_1^2 + 8v_1v_2 + 3v_2^2), \qquad a_2 = \tfrac{1}{14}(4v_1^2 + 6v_1v_2 + 4v_2^2),$$

and, for the particular choice $v = \binom{1}{1}$, we get from (31)

$$\lambda^i = 0, \qquad \lambda^e = 1. \tag{52}$$

Thus, Corollary 4.4 implies that the interior of the box

$$[x^* - v, x^* + v] = \begin{pmatrix} [2,4] \\ [3,5] \end{pmatrix}$$

contains no solution apart from $\binom{3}{4}$. This is best possible, since there is another solution $\binom{4}{3}$ at a vertex of this box. The choice $v = \binom{1}{2}$, $\omega(v) = \frac{8}{7}$, gives another exclusion box, neither contained in nor containing the other box.

If we consider the point $z = \binom{1}{2}$, we find

$$F(z) = \begin{pmatrix} -20 \\ -10 \end{pmatrix}, \quad F'(z) = \begin{pmatrix} 2 & 4 \\ 2 & 1 \end{pmatrix}, \quad C = \frac{1}{6}\begin{pmatrix} -1 & 4 \\ 2 & -2 \end{pmatrix},$$

$$\underline{b} = \frac{10}{3}\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad B_0 = 0, \quad B_1 = \frac{1}{6}\begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix}, \quad B_2 = \frac{1}{6}\begin{pmatrix} 4 & 1 \\ 2 & 2 \end{pmatrix},$$

$$w^\times = v, \qquad a^\times = \frac{1}{6}\begin{pmatrix} v_1^2 + 4v_1v_2 + v_2^2 \\ 2v_1^2 + 2v_1v_2 + 2v_2^2 \end{pmatrix},$$

$$D_1^\times = \frac{1}{9}(29v_1^2 + 80v_1v_2 + 20v_2^2), \qquad D_2^\times = \frac{1}{9}(40v_1^2 + 40v_1v_2 + 49v_2^2).$$

Since everything is affine invariant and $v > 0$, we can set $v = (1, v_2)$, and we compute

$$\lambda^\times = \begin{cases} \frac{20}{3v_2 + \sqrt{40 + 40v_2 + 49v_2^2}} & \text{if } v_2 \le 1, \\ \frac{30}{3 + \sqrt{29 + 80v_2 + 20v_2^2}} & \text{if } v_2 > 1. \end{cases}$$

Depending on the choice of v_2, the volume of the exclusion box varies. There are three locally best choices $v_2 \approx 1.97228$, $v_2 \approx 0.661045$, and $v_2 = 1$, the first providing the globally maximal exclusion box.

For any two different choices of v_2 the resulting boxes are never contained in one another. Selected maximal boxes are depicted in Figure 1 (left) in solid lines; the total region which can be excluded by Corollary 7.3 is shown in solid lines in the right part of the figure.

The optimal preconditioner for exclusion boxes, however, does not need to be an approximate inverse to $F'(z)$. In this case, it turns out that $C = (0\ 1)$ is optimal for every choice of v. Two clearly optimal boxes and the total excluded region for every possible choice of v with $C = (0\ 1)$ can be found in Figure 1 in dashed lines.

Example 8.2. The system of equations (1) with

$$F(x) = \begin{pmatrix} x_1^2 + x_1x_2 + 2x_2^2 - x_1 - x_2 - 2 \\ 2x_1^2 + x_1x_2 + 3x_2^2 - x_1 - x_2 - 4 \end{pmatrix} \tag{53}$$

has the solutions $\binom{1}{1}$, $\binom{1}{-1}$, $\binom{-1}{1}$; cf. Figure 2. It is easily checked that

$$F[z, x] = \begin{pmatrix} x_1 + x_2 + z_1 - 1 & 2x_2 + z_1 + 2z_2 - 1 \\ 2x_1 + x_2 + 2z_1 - 1 & 3x_2 + z_1 + 3z_2 - 1 \end{pmatrix}$$

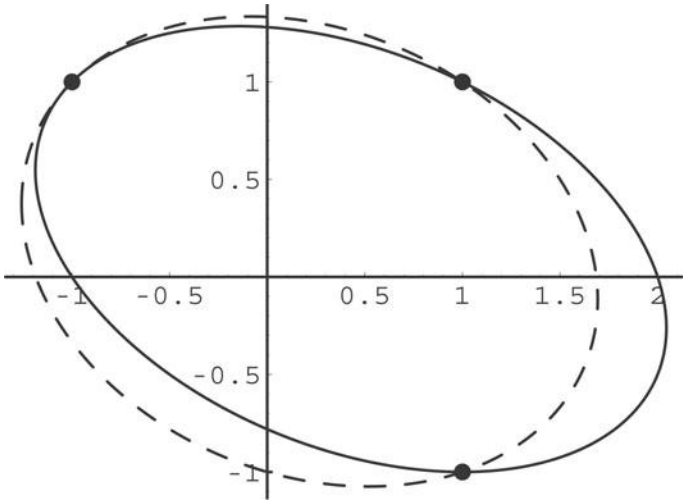

FIG. 2. *Two quadratic equations in two variables; Example* 8.2.

satisfies (2). Thus (5) holds with

$$F'(z) = \begin{pmatrix} 2z_1 + z_2 - 1 & z_1 + 4z_2 - 1 \\ 4z_1 + z_2 - 1 & z_1 + 6z_2 - 1 \end{pmatrix}, \qquad F_1 = \begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix}, \qquad F_2 = \begin{pmatrix} 1 & 2 \\ 1 & 3 \end{pmatrix}.$$

We consider boxes centered at the solution $z = x^* = \binom{1}{1}$. For

$$\mathbf{x} = [x^* - \varepsilon u, x^* + \varepsilon u] = \begin{pmatrix} [1-\varepsilon, 1+\varepsilon] \\ [1-\varepsilon, 1+\varepsilon] \end{pmatrix},$$

we find

$$F'[x^*, \mathbf{x}] = \begin{pmatrix} [2-2\varepsilon, 2+2\varepsilon] & [4-2\varepsilon, 4+2\varepsilon] \\ [4-3\varepsilon, 4+3\varepsilon] & [6-3\varepsilon, 6+3\varepsilon] \end{pmatrix},$$

$$F'(\mathbf{x}) = \begin{pmatrix} [2-3\varepsilon, 2+3\varepsilon] & [4-5\varepsilon, 4+5\varepsilon] \\ [4-5\varepsilon, 4+5\varepsilon] & [6-7\varepsilon, 6+7\varepsilon] \end{pmatrix}.$$

The midpoint of $F'(\mathbf{x})$ is here $F'(z)$, and the optimal preconditioner is

$$C := F'(x^*)^{-1} = \begin{pmatrix} -1.5 & 1 \\ 1 & -0.5 \end{pmatrix};$$

from this, we obtain

$$B_1 = \begin{pmatrix} 0.5 & 0 \\ 0 & 0 \end{pmatrix}, \qquad B_2 = \begin{pmatrix} 0.5 & 0 \\ 0.5 & 0.5 \end{pmatrix}.$$

The standard uniqueness test checks for a given box $\mathbf{x}$ whether the matrix $F'(\mathbf{x})$ is strongly regular (Neumaier [16]). But given the zero x^* (or, in finite precision

calculations, a tiny enclosure for it), it suffices to show strong regularity of $F[x^*, \mathbf{x}]$. We find

$$|I - CF'(\mathbf{x})| = \frac{\varepsilon}{2}\begin{pmatrix} 19 & 29 \\ 11 & 17 \end{pmatrix},$$

with spectral radius $\varepsilon(9 + 4\sqrt{5}) \approx 17.944\varepsilon$. Thus $F'(\mathbf{x})$ is strongly regular for $\varepsilon < 1/17.944 = 0.0557$. The exclusion box constructed from slopes is better, since

$$|I - CF[x^*, \mathbf{x}]| = \varepsilon\begin{pmatrix} 6 & 6 \\ 3.5 & 3.5 \end{pmatrix}$$

has spectral radius 9.5ε. Thus $F[x^*, \mathbf{x}]$ is strongly regular for $\varepsilon < 1/9.5$, and we get an exclusion box of radius $1/9.5$.

The Kantorovich theorem, Theorem 2.1, yields the following results:

$$\begin{aligned} &F'' = \left(\begin{pmatrix} 2 & 1 \\ 4 & 1 \end{pmatrix} \quad \begin{pmatrix} 4 & 1 \\ 1 & 6 \end{pmatrix}\right), \\ &\alpha = 2.5, \quad \beta = 0, \quad \gamma = 12, \quad \Delta = 1, \\ &\underline{r} = 0, \qquad \overline{r} = \frac{2}{2.5 \cdot 12} = \frac{1}{15}; \end{aligned}$$

hence it provides an even smaller (i.e., inferior) exclusion box of radius $\frac{1}{15}$.

If we apply Kahan's theorem, Theorem 2.2, with $F'(\mathbf{x})$, we have to check that $K(\mathbf{x}, \mathbf{x}) \subseteq \operatorname{int}(\mathbf{x})$. Now

$$K(\mathbf{x}, \mathbf{x}) = \begin{pmatrix} 1 \\ 1 \end{pmatrix} - \frac{\varepsilon}{2}\begin{pmatrix} 19 & 29 \\ 11 & 17 \end{pmatrix}\begin{pmatrix} [-\varepsilon, \varepsilon] \\ [-\varepsilon, \varepsilon] \end{pmatrix}$$

is in $\operatorname{int}(\mathbf{x})$ if

$$\begin{pmatrix} [1 - 24\varepsilon^2, 1 + 24\varepsilon^2] \\ [1 - 14\varepsilon^2, 1 + 14\varepsilon^2] \end{pmatrix} \subseteq \begin{pmatrix} [1 - \varepsilon, 1 + \varepsilon] \\ [1 - \varepsilon, 1 + \varepsilon] \end{pmatrix},$$

which holds for $\varepsilon < 1/24$. This result can be improved if we use slopes instead of interval derivatives. Indeed,

$$K(z, \mathbf{x}) = \begin{pmatrix} 1 \\ 1 \end{pmatrix} - \varepsilon\begin{pmatrix} 6 & 6 \\ 3.5 & 3.5 \end{pmatrix}\begin{pmatrix} [-\varepsilon, \varepsilon] \\ [-\varepsilon, \varepsilon] \end{pmatrix}$$

is in $\operatorname{int}(\mathbf{x})$ if

$$\begin{pmatrix} [1 - 12\varepsilon^2, 1 + 12\varepsilon^2] \\ [1 - 7\varepsilon^2, 1 + 7\varepsilon^2] \end{pmatrix} \subseteq \begin{pmatrix} [1 - \varepsilon, 1 + \varepsilon] \\ [1 - \varepsilon, 1 + \varepsilon] \end{pmatrix},$$

i.e., for $\varepsilon < 1/12$.

Now we consider the new results. From (31) we get

$$\lambda^e = \frac{2}{v_1 + v_2}. \tag{54}$$

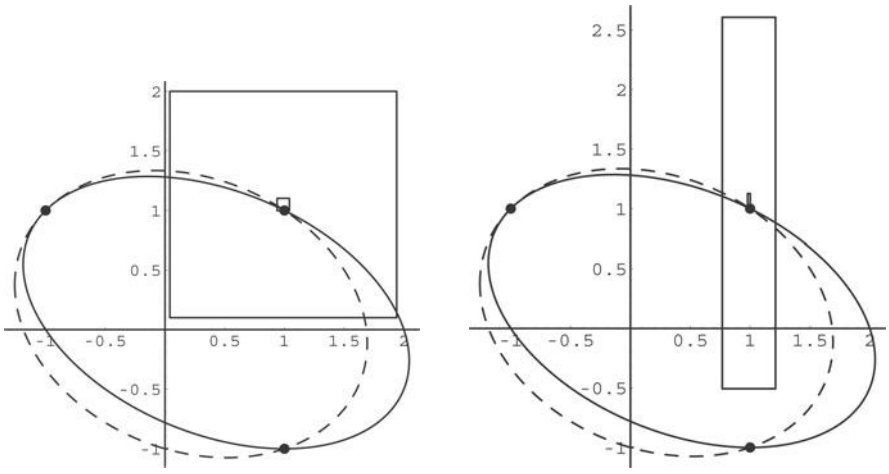

FIG. 3. $\mathbf{x}^e$ *and* $\mathbf{x}^i$ *calculated for Example* 8.2 *with three significant digits for* $v = (1, 1)$ *and* $v = (1, 7)$ *at* $z = (0.99, 1.05)$.

In exact arithmetic, we find $\lambda^e = 1$ so that Corollary 4.4 implies that the interior of the box

$$[x^* - v, x^* + v] = \begin{pmatrix} [0, 2] \\ [0, 2] \end{pmatrix} \tag{55}$$

contains no solution apart from z. In this example, the box is not as large as desirable, since in fact the larger box

$$[x^* - 2v, x^* + 2v] = \begin{pmatrix} [-1, 3] \\ [-1, 3] \end{pmatrix}$$

contains no other solution. However, *the box* (55) *is still one order of magnitude larger than that obtained from the standard uniqueness tests or the Kantorovich theorem.*

If we use inexact arithmetic (we used Mathematica with three significant digits, using this artificially low precision to make the inclusion regions visible in the pictures) and only approximative zeros, the results do not change too much, which can be seen in the pictures of Figure 3.

Corollary 7.3 also gives very promising results. The size of the exclusion boxes again depends on the center z and the vector v. The results for various choices can be found in Figure 4.

To utilize Corollary 5.2 at the exact zero $z = \binom{1}{1}$ we first choose for $u = \binom{1}{1}$ the Perron eigenvector $w_p = \binom{1}{0}$. Its eigenvalue is $\lambda = 1$, and, since $B_0 = 0$ and $\overline{b} = 0$, we conclude that Corollary 5.2 reduces the *first* component of every box $\mathbf{x}$ in the parallelogram P,

$$|x_1 - 1| + |x_2 - 1| < 2, \tag{56}$$

to the thin value $[1, 1]$. That the second component is not reduced is caused by the degeneracy of u. If we choose instead a positive approximation $w = \binom{1}{\varepsilon}$ to w_p and consider any box $\mathbf{x} \subseteq P$, there is $\alpha < 1$ with

$$|x_1 - 1| + |x_2 - 1| < 2\alpha < 2,$$

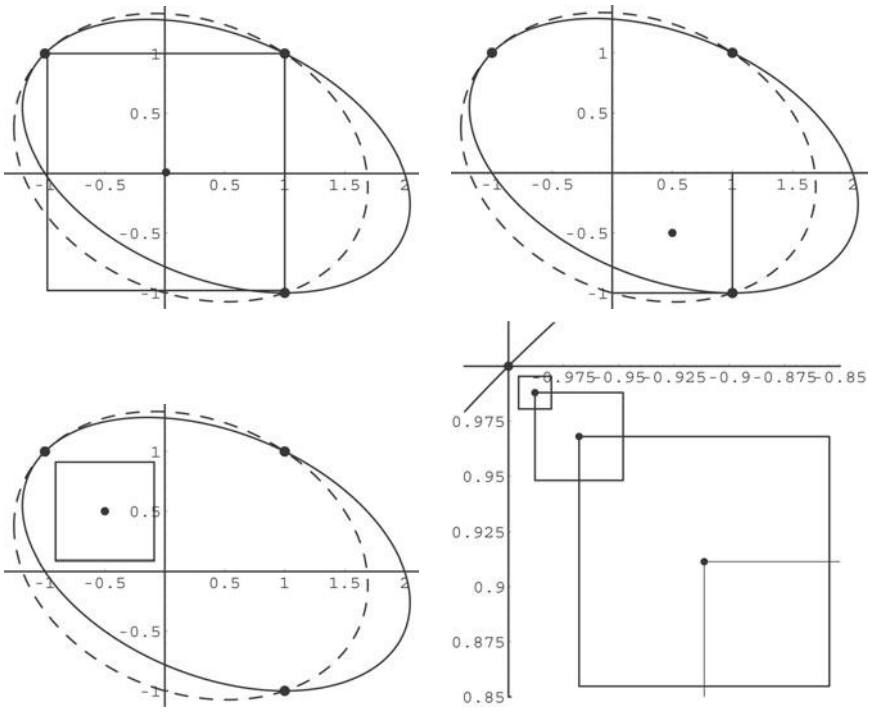

FIG. 4. $\mathbf{x}^\times$ *for Example* 8.2 *and various choices of* z *and* $v = (1, 1)$.

because $\mathbf{x}$ is compact. For $\varepsilon \le 1/\alpha - 1$, we therefore get

$$v = \frac{1}{2}\begin{pmatrix} |x_1 - 1| + (1+\varepsilon)|x_2 - 1| \\ \varepsilon|x_2 - 1| \end{pmatrix} \le \frac{1}{2}\begin{pmatrix} (1+\varepsilon)(|x_1 - 1| + |x_2 - 1|) \\ \varepsilon|x_2 - 1| \end{pmatrix} < w.$$

Then Corollary 5.2 implies that $|x_i - 1| \le 0$ for $i = 1, 2$.

The parallelogram P is best possible in the sense that it contains the other two solutions on its boundary. (But, for general systems, the corresponding maximal exclusion set need not reach another zero and has no simple geometric shape.)

For a nonquadratic polynomial function, all calculations become more complex, and the exclusion sets found are usually far from optimal, though still much better than those from the traditional methods. The $F_k[z, z, x]$ are no longer independent of x, so Theorems 4.3 and 7.2 have to be applied. This involves the computation of a suitable upper bound $\overline{B}_k$ of $F_k[z, z, x]$ by interval arithmetic.

Example 8.3. Figure 5 displays the following system of equations $F(x) = 0$ in two variables, with two polynomial equations of degree 2 and 8:

(57)

$$\begin{aligned} F_1(x) &= x_1^2 + 2x_1x_2 - 2x_2^2 - 2x_1 - 2x_2 + 3, \\ F_2(x) &= x_1^4x_2^4 + x_1^3x_2^4 + x_1^4x_2^3 + 15x_1^2x_2^4 - 8x_1^3x_2^3 + 10x_1^4x_2^2 + 3x_1x_2^4 + 5x_1^2x_2^3 \\ &\quad + 7x_1^3x_2^2 + x_1^4x_2 - 39x_2^4 + 32x_1x_2^3 - 57x_1^2x_2^2 + 21x_1^3x_2 - 17x_1^4 - 27x_2^3 - 17x_1x_2^2 \\ &\quad - 8x_1^2x_2 - 18x_1^3 - 478x_2^2 + 149x_1x_2 - 320x_1^2 - 158x_2 - 158x_1 + 1062. \end{aligned}$$

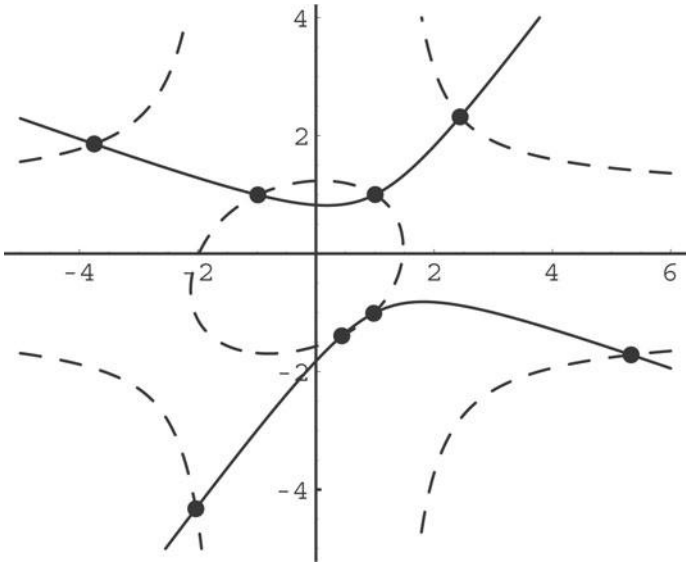

FIG. 5. *Two polynomial equations in two variables; Example* 8.3.

The system (57) has 8 solutions, at approximately

$$\begin{pmatrix}1.0023149901708083\\1.0011595047756938\end{pmatrix},\quad \begin{pmatrix}0.4378266929701329\\-1.3933047617799774\end{pmatrix},\quad \begin{pmatrix}0.9772028387127761\\-1.0115934531170049\end{pmatrix},$$

$$\begin{pmatrix}-0.9818234823156266\\0.9954714636375825\end{pmatrix},\quad \begin{pmatrix}-3.7502535429488344\\1.8585101451403585\end{pmatrix},\quad \begin{pmatrix}2.4390986061035260\\2.3174396617957018\end{pmatrix},$$

$$\begin{pmatrix}5.3305903297000243\\-1.7161362016394848\end{pmatrix},\quad \begin{pmatrix}-2.0307311621763933\\-4.3241016906293375\end{pmatrix}.$$

We consider the approximate solution $z = \binom{0.99}{1.01}$. For the set S we choose the box $[z-u, z+u]$ with $u = \binom{1}{1}$. In this case we have

$$F(z) \approx \begin{pmatrix}-0.0603\\-1.170\end{pmatrix},\qquad F'(z) \approx \begin{pmatrix}2 & -4.06\\-717.55 & -1147.7\end{pmatrix},$$

$$F_1[z,z,x] = \begin{pmatrix}1 & 0\\f_1 & 0\end{pmatrix},\qquad F_2[z,z,x] = \begin{pmatrix}2 & -2\\f_2 & f_3\end{pmatrix},$$

where

$$\begin{aligned}f_1 \approx &-405.63 - 51.66x_1 - 17x_1^2 + 36.52x_2 + 23x_1x_2 + x_1^2x_2\\ &- 13.737x_2^2 + 26.8x_1x_2^2 + 10x_1^2x_2^2 - 7.9x_2^3 - 6.02x_1x_2^3 + x_1^2x_2^3\\ &+ 19.92x_2^4 + 2.98x_1x_2^4 + x_1^2x_2^4,\\ f_2 \approx &\quad 191.04 - 7.6687x_2 + 62.176x_2^2 + 39.521x_2^3,\\ f_3 \approx &-588.05 - 36.404x_2 - 19.398x_2^2.\end{aligned}$$

We further compute

$$C = \begin{pmatrix} 0.22035 & -0.00077947 \\ -0.13776 & -0.00038397 \end{pmatrix},$$

$$B_0 = 10^{-5}\begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \quad \overline{B}_1 = \begin{pmatrix} 1.0636 & 0 \\ 0.5027 & 0 \end{pmatrix}, \quad \overline{B}_2 = \begin{pmatrix} 0.3038 & 0.1358 \\ 0.5686 & 0.5596 \end{pmatrix}, \quad \overline{b} = \begin{pmatrix} 0.0124 \\ 0.0088 \end{pmatrix}.$$

If we use Theorem 4.3 for $v = \binom{1}{1}$, we get

$$w = \begin{pmatrix} 0.99999 \\ 0.99998 \end{pmatrix}, \quad a = \begin{pmatrix} 1.5032 \\ 1.6309 \end{pmatrix}, \quad D = \begin{pmatrix} 0.925421 \\ 0.942575 \end{pmatrix},$$

$$\lambda^i = 0.0126403, \qquad \lambda^e = 0.604222,$$

so we may conclude that there is exactly one zero in the box

$$\mathbf{x}^i = \begin{pmatrix} [0.97736, 1.00264] \\ [0.99736, 1.02264] \end{pmatrix},$$

and this zero is the only zero in the interior of the exclusion box

$$\mathbf{x}^e = \begin{pmatrix} [0.385778, 1.59422] \\ [0.405778, 1.61422] \end{pmatrix}.$$

In Figure 6 the two boxes are displayed.

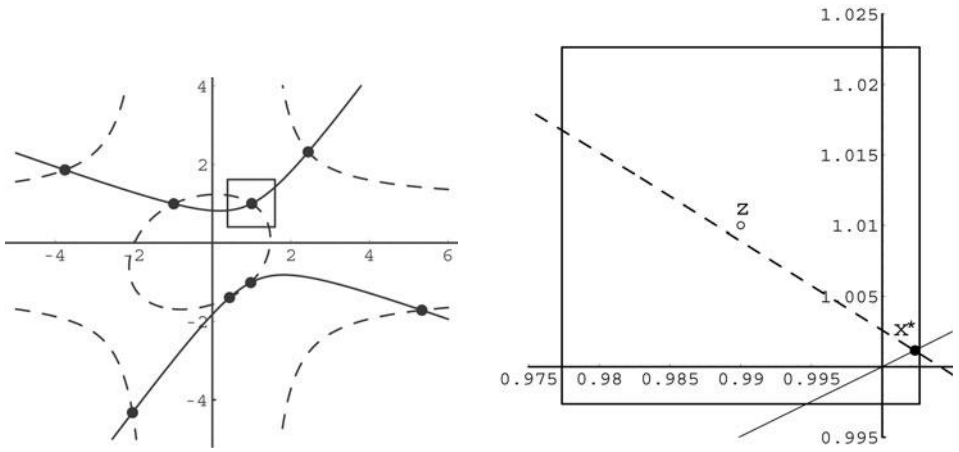

FIG. 6. *Exclusion and inclusion boxes for Example* 8.3 *at* $z = (0.99, 1.01)$.

Next we consider the point $z = \binom{1.5}{-1.5}$ to test Theorem 7.2. We compute

$$F(z) \approx \begin{pmatrix} -3.75 \\ -1477.23 \end{pmatrix}, \qquad F_1[z, z, x] \approx \begin{pmatrix} 1 & 0 \\ g_1 & 0 \end{pmatrix},$$

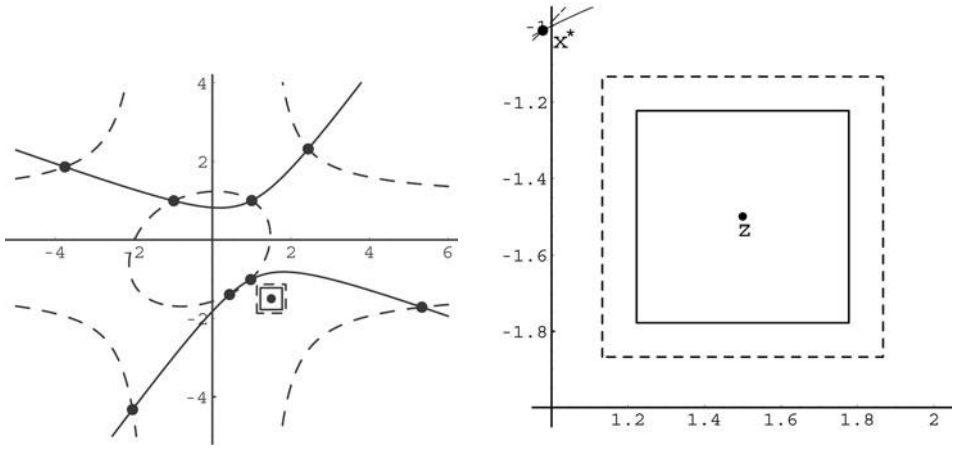

FIG. 7. *Exclusion boxes for Example* 8.3 *at* $z = (1.5, -1.5)$.

$$F'(z) \approx \begin{pmatrix} -2 & 7 \\ -1578.73 & 1761.77 \end{pmatrix}, \qquad F_2[z,z,x] = \begin{pmatrix} 2 & -2 \\ g_2 & g_3 \end{pmatrix},$$

with

$$\begin{aligned} g_1 \approx & -488.75 - 69x_1 - 17x_1^2 + 61.75x_2 + 24x_1x_2 + x_1^2x_2 \\ & + 31.5x_2^2 + 37x_1x_2^2 + 10x_1^2x_2^2 - 12.25x_2^3 - 5x_1x_2^3 + x_1^2x_2^3 \\ & + 24.75x_2^4 + 4x_1x_2^4 + x_1^2x_2^4, \\ g_2 \approx & \quad 73.1563 + 138.063x_2 - 95.875x_2^2 + 68.25x_2^3, \\ g_3 \approx & -536.547 - 12.75x_2 + 7.6875x_2^2. \end{aligned}$$

Performing the necessary computations, we find for $\mathbf{x} = [z-u, z+u]$ with $u = \frac{1}{2}\binom{1}{1}$

$$F'(z)^{-1} \approx \begin{pmatrix} 0.234 & -0.00093 \\ 0.21 & -0.000266 \end{pmatrix}, \qquad \underline{b} = \begin{pmatrix} 0.496 \\ 0.3939 \end{pmatrix},$$

$$\overline{B}_1 = \begin{pmatrix} 1.2895 & 0 \\ 0.5113 & 0 \end{pmatrix}, \quad B_0' = \begin{pmatrix} 1 & 10^{-5} \\ 10^{-5} & 1.00001 \end{pmatrix}, \quad \overline{B}_2 = \begin{pmatrix} 1.5212 & 0.0215 \\ 0.7204 & 0.2919 \end{pmatrix}.$$

Now we use Theorem 7.2 for $v = \binom{1}{1}$ and $C = F'(z)^{-1}$ and get

$$w^\times = \begin{pmatrix} 1.00001 \\ 1.00002 \end{pmatrix}, \quad a^\times = \begin{pmatrix} 2.8322 \\ 1.5236 \end{pmatrix}, \quad D^\times = \begin{pmatrix} 6.6191 \\ 3.4006 \end{pmatrix}, \quad \lambda^\times = 0.277656;$$

so we conclude that there are no zeros of F in the interior of the exclusion box

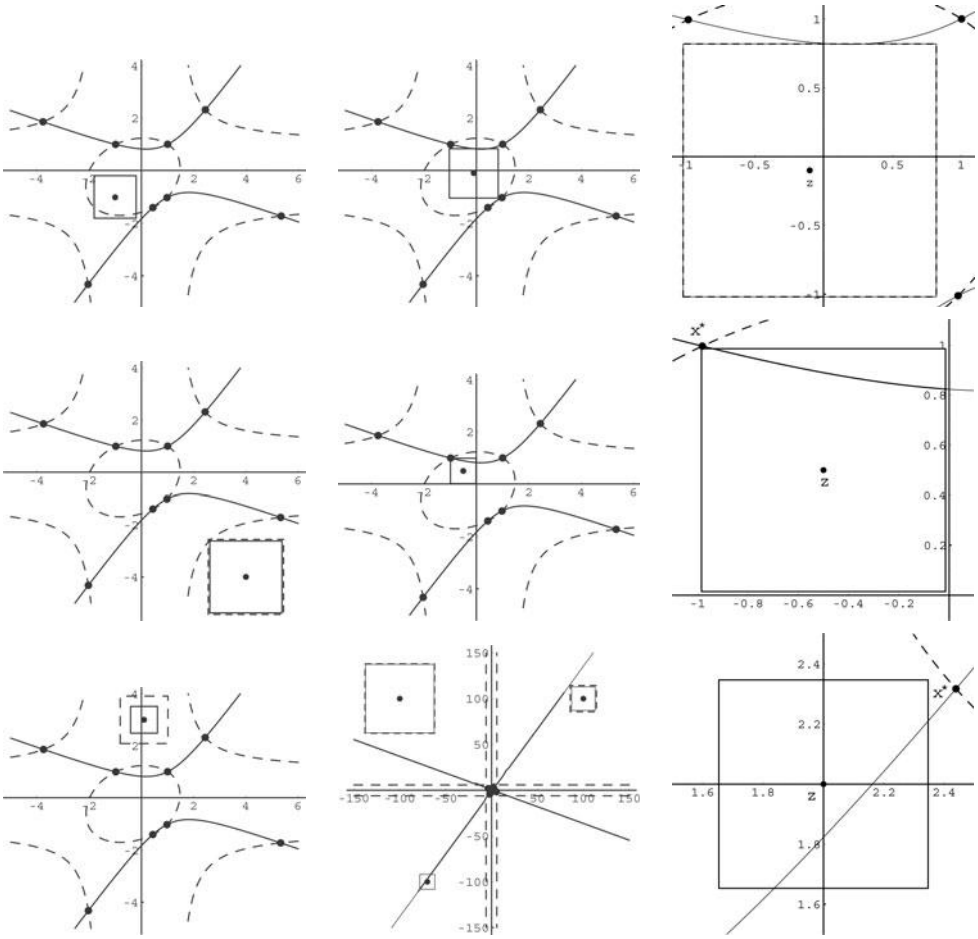

FIG. 8. *Exclusion boxes for Example* 8.3 *in various regions of* $\mathbb{R}^2$.

$$\mathbf{x}^{\times} = \begin{pmatrix} [1.22234, 1.77766] \\ [-1.77766, -1.22234] \end{pmatrix}.$$

However, the choice $C = F'(z)^{-1}$ is not best possible in this situation. If we take

$$C = \begin{pmatrix} 1 & 0.002937 \end{pmatrix},$$

we compute $\lambda^{\times} = 0.367223$ and find the considerably larger exclusion box

$$\mathbf{x}^{\times} = \begin{pmatrix} [1.13278, 1.86722] \\ [-1.86722, -1.13278] \end{pmatrix}.$$

Figure 7 shows both boxes, the bigger one in dashed lines.

Finally, Figure 8 shows various exclusion boxes for nonzeros, and Figure 9 contains exclusion boxes and some inclusion boxes for all of the zeros of F.

While the previous examples were low dimensional, our final example shows that the improvements over traditional results may even be more pronounced for higher dimensional problems with poorly conditioned zeros.

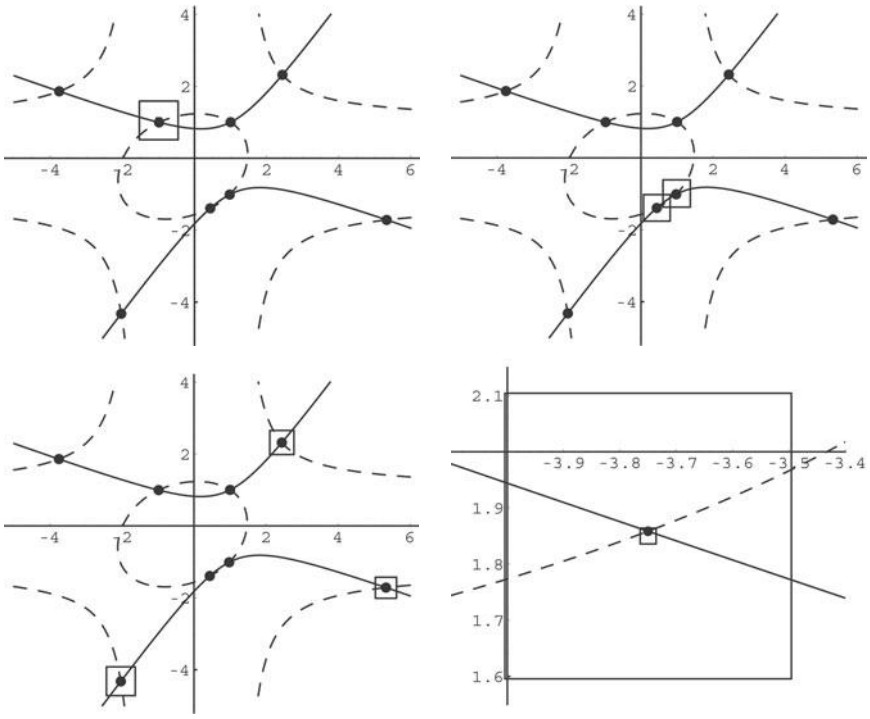

FIG. 9. *Exclusion boxes for all zeros of F in Example* 8.3.

Example 8.4. We consider the set of equations

$$\sum_{k=1}^{n} x_k^i = H(n,-i) \quad \text{for } i = 1,\dots,n,$$

where the *harmonic numbers* $H(n,m)$ are defined as

$$H(n,m) := \sum_{k=1}^{n} k^{-m}.$$

Clearly, $x_k^* = k$ is a solution, and the complete set of solutions is given by all permutations of this vector.

We compare the results provided by Theorem 4.3 with the exclusion box obtained by strong regularity of the slope $F[z,\mathbf{x}]$ (which in the previous examples was the best among the traditional choices). The vector v needed in Theorem 4.3 was chosen as the all-one vector e. All numerical calculations were performed in double precision arithmetic.

The results are collected in Table 1; R denotes the radius of the exclusion box computed by Theorem 4.3, r the radius of the exclusion box implied by strong regularity of $F[z,\mathbf{x}]$, and κ the condition number of $F'(x^*)$. All numbers are approximate.

From the logarithmic plot in Figure 10, we see that the radii of the exclusion boxes decrease in both cases exponentially with n. However, the quotient of the two radii increases exponentially with n. This shows that our new method suffers much less from the double deterioration due to the increase of both dimension and the Jacobian condition number at the zero.

PERFECTLY MATCHED LAYERS FOR THE CONVECTED HELMHOLTZ EQUATION*

E. BÉCACHE†, A.-S. BONNET-BEN DHIA‡, AND G. LEGENDRE§

Abstract. In this paper, we propose and analyze perfectly matched absorbing layers for a problem of time-harmonic acoustic waves propagating in a duct in the presence of a uniform flow. The absorbing layers are designed for the pressure field, satisfying the convected scalar Helmholtz equation. A difficulty, compared to the Helmholtz equation, comes from the presence of so-called inverse upstream modes which become unstable, instead of evanescent, with the classical Bérenger's perfectly matched layers (PMLs). We investigate here a PML model, recently introduced for time-dependent problems, which makes all outgoing waves evanescent. We then analyze the error due to the truncation of the domain and prove that the convergence is exponential with respect to the size of the layers for both the classical and the new PML models. Numerical validations are finally presented.

Key words. acoustic waves, convected Helmholtz equation, duct modes, absorbing layers, perfectly matched layer, instabilities

DOI. 10.1137/S0036142903420984

1. Introduction.

Perfectly matched layers (PMLs) were introduced by Bérenger [3] in order to design efficient numerical absorbing boundary conditions (more precisely, absorbing layers) for the computation of time-dependent solutions of Maxwell's equations in unbounded domains. They have since been used for numerous applications, mostly in the time domain [4, 28, 5, 23] but also for time-harmonic wave-like equations [27, 15].

In particular, PMLs have been used for the solution in the time domain of the linearized Euler equations [19, 13, 16, 26], which model acoustic propagation in the presence of a flow. In this case, it has been observed that PMLs can lead to instabilities, due to the presence of waves whose phase and group velocities have opposite signs [26] (see [2] for a general analysis of this phenomenon). Some techniques have been developed to overcome this difficulty, making the layers stable but, unfortunately, no longer perfectly matched [16, 1]. More recently, ideas for designing stable PMLs for this problem have emerged from several teams independently. These new approaches, which seem to be very closely related, have been developed for time-dependent applications in [20, 11, 14] and for time-harmonic applications in the present paper. These different works all deal with the case of a parallel flow, which is orthogonal to the layers.

We are concerned with the propagation of acoustic waves in a duct in the presence of a uniform flow. For such a mean flow, thetime-harmonic linearized Euler equations reduce into a scalar convected Helmholtz equation for the pressure. In this particular case, one could, of course, use a Dirichlet-to-Neumann (DtN) operator to obtain an equivalent problem in a bounded domain. However, the PMLs, being local, are easier to implement, and we intend to extend this method to vectorial cases, involving more general flows in a forthcoming paper.

When applying the *classical* (i.e., Bérenger's) PMLs to the convected Helmholtz equation in a duct, a simple modal analysis shows that the presence of the so-called inverse upstream modes produces an exponential blow-up of the solution in the space variable. This is easy to see, remembering the interpretation of the PMLs as a complex change of variable [8, 24, 10, 9]. This change of variable corresponds to a similarity applied on the axial wave numbers of the modes. For the classical Helmholtz equation, this similarity makes all outgoing modes become evanescent. But in the presence of a flow, the transformation sends the inverse upstream modes into the "bad" part of the complex plane, leading to the instabilities observed in the time domain.

The idea proposed here, which is similar to those developed independently in [20, 14] for time domain applications, consists of applying a translation before the similarity to the axial wave numbers. This removes the unstable modes. We will call the PMLs thus obtained *new* PMLs.

The object of this paper is the analysis of the convergence of both PML models as the thickness of the sponge layer tends to infinity. Similar convergence analyses have already been carried out for the Helmholtz equation, via boundary integral equation techniques in [21] or using the pole condition in [18]. Surprisingly, we prove that, for the convected Helmholtz equation, the two models always converge. In other words, contrary to time domain applications, the presence of unstable modes does not affect the efficiency of the classical PMLs.

Finally, let us emphasize that in most papers concerning PMLs for time-harmonic applications, coefficients are designed in order to satisfy requirements established for time domain applications. We show that this choice is too restrictive: for instance, the particular dependence of these coefficients regarding the frequency has no more justification for the present case.

The outline of this paper is as follows: the equations of the scattering problem are presented in section 2. A formulation in a bounded domain is given, involving DtN conditions on the fictitious boundaries, which are known explicitly through modal expansions. Finally, the well posedness is proven using Fredholm theory.

Classical and new PML techniques, with constant coefficients, are described in section 3. A modal analysis indicates that these layers are "perfectly matched." Besides, they are absorbing, except the classical PMLs in the presence of the so-called inverse upstream modes.

Section 4 is devoted to the analysis of the error due to the truncation of the layers. An equivalent formulation of the problem with PMLs is written in the physical domain, the thickness of the layers appearing in the expression of the DtN maps. In this way, we prove that both PML models converge to the physical solution, as the length of the layers tends to infinity. More precisely, the error in the physical domain does not depend on the PML model under consideration and decreases exponentially fast for both models. Note, however, that classical PMLs lead to an exponentially large solution in the layers, whereas the solution computed with new PMLs is evanescent in the layers.

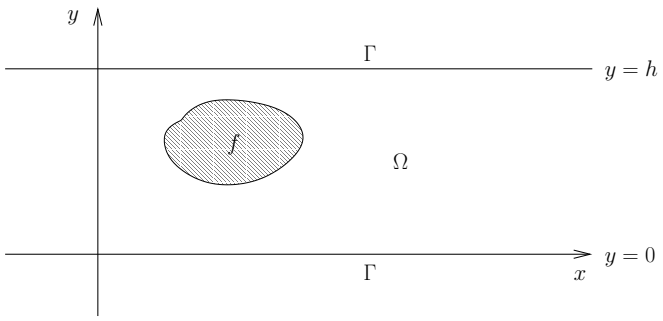

FIG. 1. *The infinite duct.*

Extension to the case of layers with spatially varying coefficients is discussed in section 5, and numerical illustrations are given in the last section.

2. The physical and the mathematical models.

2.1. The problem in the infinite duct. We consider an infinite rigid duct carrying a mean fluid flow; see Figure 1. The problem is two-dimensional, set in the xy-plane, where the x- (resp., y-) axis is parallel (resp., normal) to the walls of the duct. Mathematically, the duct is defined by the unbounded domain $\Omega = \mathbb{R} \times [0, h]$, where h denotes the distance between the rigid walls.

To describe the propagation of acoustic waves in the duct, we assume the following approximations to be valid:

- The fluid is homogeneous, nonviscous, and nonheat conductive.
- The thermodynamic processes are adiabatic.
- The mean velocity v_0 is subsonic and uniform.
- The perturbations are small, and equations are linear in the acoustic quantities.
- A harmonic time dependence $\exp(-i\omega t)$, $\omega > 0$ being the pulsation, is assumed (although this factor is suppressed throughout).

The acoustic pressure field $p(x, y)$ then satisfies the convected Helmholtz equation in the infinite duct:

$$(1 - M^2)\,\frac{\partial^2 p}{\partial x^2} + \frac{\partial^2 p}{\partial y^2} + 2ikM\,\frac{\partial p}{\partial x} + k^2\,p = f \quad \text{in } \Omega, \tag{2.1}$$

where $f \in L^2(\Omega)$ is a compactly supported function and $M = v_0/c_0$ and $k = \omega/c_0$ are, respectively, the Mach number ($-1 < M < 1$) and the wave number, c_0 being the sound velocity in the fluid. In addition to (2.1), the pressure satisfies the Neumann homogeneous boundary condition on the two rigid walls of the duct:

$$\frac{\partial p}{\partial y} = 0 \quad \text{on } \Gamma = \partial\Omega. \tag{2.2}$$

To obtain a well-posed problem, a "radiation condition," which selects the "outgoing" waves, needs to be defined at infinity. This condition is nonlocal and is given in terms of the DtN operator. This requires the introduction of the so-called modes of the duct, which are the solutions of (2.1)–(2.2) in the absence of a source ($f = 0$) and with separated variables. These are given by

$$p_n^{\pm}(x, y) = e^{i\beta_n^{\pm} x}\,\varphi_n(y),$$

where

$$\varphi_0(y) = \sqrt{\frac{1}{h}}, \quad \varphi_n(y) = \sqrt{\frac{2}{h}}\,\cos\Big(\frac{n\pi y}{h}\Big), \quad n \in \mathbb{N}^*, \tag{2.3}$$

and where the axial wave numbers $\beta_n^{\pm}$ are the solutions of

$$-(1-M^2)\,\beta^2 - 2kM\,\beta + k^2 = \frac{n^2\pi^2}{h^2}, \quad n \in \mathbb{N}.$$

Let us introduce

$$K_0 = \frac{kh}{\pi\sqrt{1-M^2}}, \tag{2.4}$$

and let $N_0 = [K_0]$ denote the integer part of K_0. If $n \le N_0$, $\beta_n^{\pm}$ is real and equal to

$$\beta_n^{\pm} = \frac{-kM \pm \sqrt{k^2 - \frac{n^2\pi^2}{h^2}(1-M^2)}}{1-M^2}. \tag{2.5}$$

In this case, $p_n^{\pm}$ is called a propagative mode. The number of propagative modes is an increasing function of the Mach number M, which is assumed to be positive. Simple calculations show that the group velocity $\frac{\partial\omega}{\partial\beta}$ is positive for the p_n^+ modes and negative for the p_n^- modes. A well-known effect of the presence of flow is the existence, when

$$\sqrt{1-M^2}\,\frac{n\pi}{h} < k < \frac{n\pi}{h},$$

of modes p_n^+ which have a negative phase velocity $\frac{\omega}{\beta}$ and a positive group velocity. These are called inverse upstream modes.

The axial wave number $\beta_n^{\pm}$ is complex if $n > N_0$:

$$\beta_n^{\pm} = \frac{-kM \pm i\sqrt{\frac{n^2\pi^2}{h^2}(1-M^2) - k^2}}{1-M^2}. \tag{2.6}$$

In this case, $p_n^{\pm}$ is exponentially decreasing when $x \to \pm\infty$ and is called an evanescent mode.

2.2. Reduction to a bounded domain. We now want to select the outgoing solution (2.1)–(2.2), which corresponds to a superposition of p_n^+ (resp., p_n^-) modes when $x \to +\infty$ (resp., $x \to -\infty$), i.e., either to the propagative modes with a positive (resp., negative) group velocity or to the evanescent modes.

To derive the appropriate DtN boundary condition, we introduce the bounded domain Ω_b, located in between two boundaries $\Sigma_{\pm}$, respectively, located at $x = x_-$ and $x = x_+$ (see Figure 2), such that the support of the source f is included in Ω_b:

$$\Omega_b = \{(x,y) \in \Omega,\ x_- \le x \le x_+\}.$$

We set $\Omega_{\pm}$ the complementary domains

$$\Omega_- = \{(x,y) \in \Omega,\ x < x_-\} \quad \text{and} \quad \Omega_+ = \{(x,y) \in \Omega,\ x > x_+\}.$$

The solution p of (2.1) then satisfies the homogeneous equation

$$(1-M^2)\,\frac{\partial^2 p}{\partial x^2} + 2ikM\,\frac{\partial p}{\partial x} + \frac{\partial^2 p}{\partial y^2} + k^2\,p = 0 \quad \text{in } \Omega_{\pm} \tag{2.7}$$

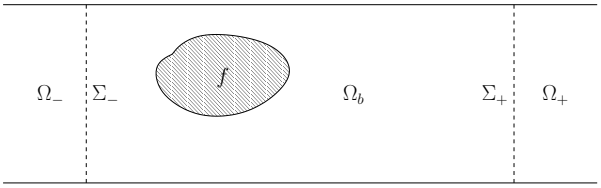

FIG. 2. *The bounded domain.*

and therefore can be decomposed on the modes. Consequently, in Ω_-, i.e., for $x < x_-$, we have

$$p(x,y) = \sum_{n=0}^{+\infty} \left(p(x_-,.),\varphi_n\right)_{L^2(\Sigma_-)}\ \varphi_n e^{i\beta_n^-(x-x_-)},$$

and in Ω_+, i.e., for $x > x_+$,

$$p(x,y) = \sum_{n=0}^{+\infty} \left(p(x_+,.),\varphi_n\right)_{L^2(\Sigma_+)}\ \varphi_n e^{i\beta_n^+(x-x_+)},$$

where $(\cdot,\cdot)_{L^2(\Sigma_+)}$ (resp., $(\cdot,\cdot)_{L^2(\Sigma_-)}$) denotes the $L^2(\Sigma_+)$ (resp., $L^2(\Sigma_-)$) inner product for scalar functions:

$$(u,v)_{L^2(\Sigma_\pm)} \equiv \int_{\Sigma_\pm} u(y)\overline{v}(y)\,\mathrm{d}y.$$

The DtN operators $T_\pm$ can then be defined as

$$\begin{aligned} T_\pm :\ H^{1/2}(\Sigma_\pm) &\to H^{-1/2}(\Sigma_\pm), \\ \phi &\mapsto \mp\sum_{n=0}^{+\infty} i\beta_n^\pm\ (\phi,\varphi_n)_{L^2(\Sigma_\pm)}\ \varphi_n(y), \end{aligned} \tag{2.8}$$

and we have the following boundary conditions on $\Sigma_\pm$ for the solution of (2.1):

$$\frac{\partial p}{\partial \boldsymbol{n}} = -T_\pm p \quad \text{on } \Sigma_\pm, \tag{2.9}$$

where the vector $\boldsymbol{n}$ denotes the unit outward normal to $\Sigma_\pm$.

Having established exact boundary conditions satisfied by p, we can now define a problem in the bounded domain Ω_b: find $p \in H^1(\Omega_b)$ such that

$$\begin{cases} (1-M^2)\,\dfrac{\partial^2 p}{\partial x^2} + 2ikM\,\dfrac{\partial p}{\partial x} + \dfrac{\partial^2 p}{\partial y^2} + k^2\,p = f & \text{in } \Omega_b, \\ \dfrac{\partial p}{\partial y} = 0 & \text{on } \Gamma \cap \partial\Omega_b, \\ \dfrac{\partial p}{\partial \boldsymbol{n}} = -T_\pm p & \text{on } \Sigma_\pm. \end{cases} \tag{2.10}$$

The fact that f is compactly supported in Ω_b shows clearly that problems (2.10) and (2.1)–(2.2) are equivalent in the sense of the following proposition.

PROPOSITION 2.1. *If p is a solution of system* (2.1)–(2.2)*, then $p_{|\Omega_b}$ is a solution of* (2.10)*. Conversely, if $\widetilde{p}$ is a solution of* (2.10)*, then $\widetilde{p}$ can be extended in a unique way to a solution of* (2.1)–(2.2)*.*

2.3. Well posedness. Formulation (2.10) has two main advantages. First, from a theoretical point of view, it provides a result of existence and uniqueness of the solution. Second, it can be used to obtain numerical solutions, since it is posed in a bounded domain.

An equivalent weak form of system (2.10) can then be written as follows: find $p \in H^1(\Omega_b)$ such that

$$a_{\Omega_b}(p,q) = -\int_{\Omega_b} f\overline{q}\,\mathrm{d}x\,\mathrm{d}y \quad \forall q \in H^1(\Omega_b), \tag{2.11}$$

where the sesquilinear form $a_{\Omega_b}(\cdot\,,\cdot)$ is defined by

$$a_{\Omega_b}(p,q) = b(p,q) + c(p,q), \tag{2.12}$$

with

$$b(p,q) = \int_{\Omega_b} \left((1-M^2)\,\frac{\partial p}{\partial x}\frac{\partial \overline{q}}{\partial x} + \frac{\partial p}{\partial y}\frac{\partial \overline{q}}{\partial y} + p\overline{q} \right) \mathrm{d}x\,\mathrm{d}y + \langle T_+ p, q\rangle_{\Sigma_+} + \langle T_- p, q\rangle_{\Sigma_-}\,, \tag{2.13}$$

where the brackets $\langle\cdot,\cdot\rangle_{\Sigma_+}$ (resp., $\langle\cdot,\cdot\rangle_{\Sigma_-}$) denote the natural duality pairing between $H^{-1/2}(\Sigma_+)$ and $H^{1/2}(\Sigma_+)$ (resp., $H^{-1/2}(\Sigma_-)$ and $H^{1/2}(\Sigma_-)$), and

$$c(p,q) = \int_{\Omega_b} \left(-2ikM\,\frac{\partial p}{\partial x}\overline{q} - (1+k^2)\,p\overline{q} \right) \mathrm{d}x\,\mathrm{d}y. \tag{2.14}$$

It was shown in [6] that this problem is of Fredholm type. By the Fredholm alternative, problem (2.11) is well posed if and only if the homogeneous problem has no solution except the trivial one, $p = 0$.

THEOREM 2.2. *The problem is well posed if and only if*

$$k \neq \sqrt{1-M^2}\,\frac{n\pi}{h} \quad \forall n \in \mathbb{N}. \tag{2.15}$$

Proof. Suppose that p is a solution of (2.1)–(2.2) with $f = 0$. Then there are complex constants A_n^+ and A_n^- such that

$$p(x,y) = \sum_{n=0}^{+\infty} \left(A_n^+\, e^{i\beta_n^+ x} + A_n^-\, e^{i\beta_n^- x} \right) \varphi_n(y),$$

with definitions (2.3) through (2.6). Boundary condition (2.9) then gives

$$A_n^-(\beta_n^- - \beta_n^+) = A_n^+(\beta_n^- - \beta_n^+) = 0$$

so that p vanishes identically if $\beta_n^+ \neq \beta_n^-$ or, likewise, if $k^2 \neq (1-M^2)\,\frac{n^2\pi^2}{h^2}$.

Suppose conversely that $k = \sqrt{1-M^2}\,\frac{n\pi}{h}$; then

$$\beta_n^+ = \beta_n^- = -\frac{kM}{1-M^2},$$

and $\varphi_n(y)\,e^{i\beta_n^+ x}$ is a nontrivial solution of the homogeneous problem. ∎

In what follows, we assume the problem is well posed, which means that (2.15) is satisfied.

3. The PML model. The PML model introduced by Bérenger for the time-dependent Maxwell equations can be constructed using a complex change of variable in the frequency domain, as shown in [8, 10, 9]. We use this same approach in the present paper. This is closely related to the technique known as dilation analyticity for the study of resonances [17].

In this section, we briefly recall some properties of the classical PML formulation for the Helmholtz equation. Note that in the context of propagation in a waveguide the interpretation of the method relies on the modal approach instead of the usual plane wave approach. This modal analysis allows us to point out the origin of the instabilities in the presence of flow and leads naturally to the introduction of a new model of PMLs as a remedy.

3.1. Modal analysis of Bérenger's model in a waveguide. The purpose of the method is to provide a fictitious, absorbing medium such that its interface with the "physical" bounded domain does not reflect any outgoing mode. Transposing Bérenger's formulation in the frequency domain from its original setting in the time domain consists of making the following substitution:

$$\frac{\partial}{\partial x} \longrightarrow \alpha \, \frac{\partial}{\partial x}, \tag{3.1}$$

where α is a complex function taken to be

$$\alpha(x) = \frac{-i\omega}{-i\omega + \sigma(x)} \tag{3.2}$$

with $\sigma(x)$ a real, positive function such as $\sigma(x) = 0$ (and therefore $\alpha(x) = 1$) in Ω_b, the derivative with respect to y being left unchanged.

In the case of the Helmholtz equation, we obtain

$$\alpha(x) \, \frac{\partial}{\partial x} \left(\alpha(x) \, \frac{\partial p}{\partial x} \right) + \frac{\partial^2 p}{\partial y^2} + k^2 \, p = f \quad \text{in } \Omega. \tag{3.3}$$

Note that the writing of this equation in the weak sense implies the following jump conditions at the interfaces between Ω_b and the PMLs:

$$[p(x,y)] = 0 \quad \text{and} \quad \left[\alpha(x) \, \frac{\partial p}{\partial x}(x,y) \right] = 0. \tag{3.4}$$

For the modal analysis in the waveguide, we now assume that $\alpha(x)$ is a constant in $\Omega \setminus \Omega_b$, which we still denote by α for the sake of simplicity. In other words,

$$\alpha(x) = \begin{cases} 1 & \text{if } x_- \leq x \leq x_+, \\ \alpha & \text{otherwise.} \end{cases} \tag{3.5}$$

For any α, the interface between the PML and the physical domain is perfectly transparent, and we will see that if α is well chosen, the transmitted waves decrease exponentially in the layer.

Classically, the modes in a waveguide are given by

$$p_n^{\pm}(x,y) = e^{\pm i \beta_n x} \varphi_n(y), \quad n \in \mathbb{N}, \tag{3.6}$$

where functions φ_n, for all $n \in \mathbb{N}$, are defined by (2.3) and axial wave numbers β_n are solutions of the dispersion equation

$$\beta_n{}^2 = k^2 - \frac{n^2 \pi^2}{h^2}, \quad n \in \mathbb{N},$$

such that $\beta_n > 0$ for the propagative modes and $\mathrm{Im}(\beta_n) > 0$ for the evanescent modes. Referring to subsection 2.1, note that

$$\beta_n = \beta_n^+ = -\beta_n^-,$$

with the Mach number M taken equal to zero in the definitions (2.5) and (2.6) of $\beta_n^\pm$. In the same manner, one can define the modes in the PML as

$$p_{n,\alpha}^\pm(x,y) = e^{\pm i\beta_{n,\alpha}x}\varphi_n(y), \quad n \in \mathbb{N}, \tag{3.7}$$

with

$$\beta_{n,\alpha} = \frac{\beta_n}{\alpha}.$$

If α satisfies the hypotheses

$$\mathrm{Re}(\alpha) > 0, \quad \mathrm{Im}(\alpha) < 0, \tag{3.8}$$

then $p_{n,\alpha}^\pm$ is exponentially decreasing as $x \to \pm\infty$ for any n corresponding either to a propagative or to an evanescent mode. It is now straightforward to show that an incident mode p_n^+ generates an evanescent transmitted mode $p_{n,\alpha}^+$ in Ω_+ and no reflection at the interface Σ_+. Let us stress that assumption (3.8) is the only requirement on α to obtain a PML. Surprisingly, the fairly restrictive choice (3.2) seems to be used in most time-harmonic applications.

3.2. The new PML formulation for the convected Helmholtz equation. A natural idea for designing a PML for the convected Helmholtz equation, already used in the literature for applications in the time domain, is to apply the technique described in the previous subsection. It has been observed by several authors that this approach leads to instabilities in the time domain [19, 13, 16, 26]. The presence of instabilities have been explained in [2], thanks to an analysis via group velocities. In the context of a duct, this phenomenon can be easily understood using the modal approach.

As in the no-flow case, the axial wave numbers $\beta_{n,\alpha}^\pm$ of the modes $p_{n,\alpha}^\pm$ in the PML are given by

$$\beta_{n,\alpha}^\pm = \frac{\beta_n^\pm}{\alpha}, \quad n \in \mathbb{N}.$$

This can be illustrated by representing the $\beta_n^\pm$ and $\beta_{n,\alpha}^\pm$ in the complex plane. We clearly notice in Figures 3 and 4 that the transformation

$$\begin{array}{rccc} S_\alpha & : & \mathbb{C} & \to & \mathbb{C}, \\ & & z & \mapsto & \dfrac{z}{\alpha}, \end{array}$$

due to the change of variable used in the PML, is a similarity of ratio $\frac{1}{|\alpha|}$ and angle $\arg\left(\frac{1}{\alpha}\right) = -\arg(\alpha)$ around the origin in the complex plane. The main difference between the equation considered here and the Helmholtz equation is the possible existence of inverse upstream modes. Indeed, if p_n^+ is an inverse upstream mode (as defined in subsection 2.1), the corresponding β_n^+ is negative so that $\mathrm{Im}(\frac{\beta_n^+}{\alpha})$ becomes negative for any α satisfying assumption (3.8). This is illustrated in Figure 5, the third propagative downstream mode of the case presented being an inverse upstream

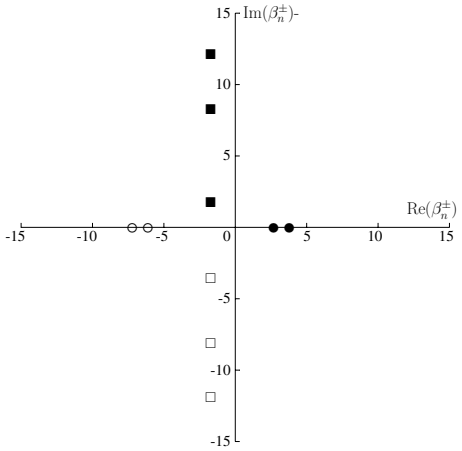

FIG. 3. *First axial wave numbers of the modes for the convected Helmholtz equation ($k = 5$, $M = 0.3$, and $h = 1$). Circles and squares are respectively associated with propagative and evanescent modes, while filled and empty symbols, respectively, refer to downstream and upstream modes.*

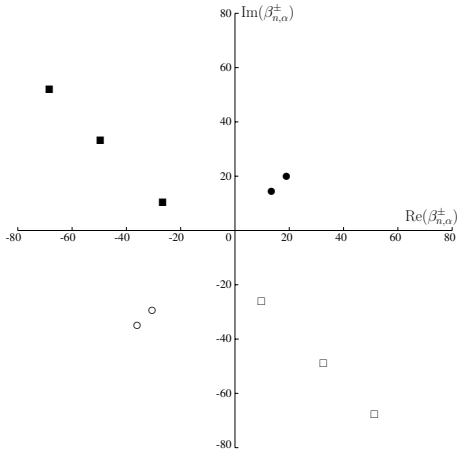

FIG. 4. *Effect of the similarity S_α ($\alpha = 0.1(1-i)$) on the first axial wave numbers of the modes for the convected Helmholtz equation ($k = 5$, $M = 0.3$, and $h = 1$).*

mode. This leads us to the conclusion that the PML model does not produce any unstable (i.e., exponentially growing in the layer) modes if all the axial wave numbers $\beta_{n,\alpha}$ for the propagative downstream (resp., upstream) modes are strictly located in the upper (resp., lower) half of the complex plane.

Guided by the previous geometrical interpretation, we apply a translation in the complex plane prior to the similarity which moves all the $\beta_{n,\alpha}^{+}$'s corresponding to the inverse upstream modes in the right half-plane and keeps the $\beta_{n,\alpha}^{-}$'s associated with propagative modes in the left one. Such a transformation is equivalent to the following substitution in (2.1):

$$\frac{\partial}{\partial x} \longrightarrow \alpha \frac{\partial}{\partial x} + i\lambda$$

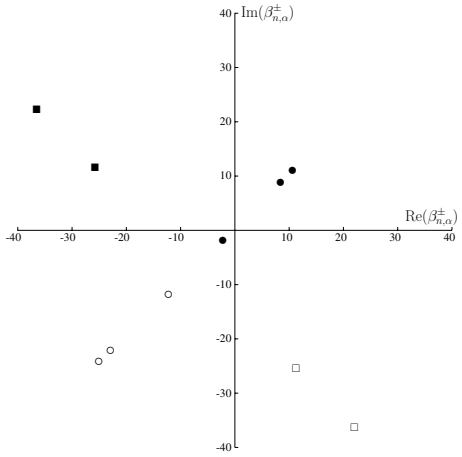

FIG. 5. *Effect of the similarity S_α ($\alpha = 0.2(1-i)$) on the first axial wave numbers of the modes for the convected Helmholtz equation in presence of an inverse upstream mode ($k = 6$, $M = 0.4$, and $h = 1$).*

with $\lambda \in \mathbb{R}$. The resulting axial wave numbers are now given by

$$\beta^{\pm}_{n,\alpha,\lambda} = \frac{\beta^{\pm}_n - \lambda}{\alpha}, \quad n \in \mathbb{N}. \tag{3.9}$$

Although λ could be chosen from among several values, the most appropriate choice is the following:

$$\lambda^* = -\frac{kM}{1-M^2}. \tag{3.10}$$

This value corresponds to the real part of the wave number of each evanescent mode, and, for any α satisfying assumption (3.8), the $\beta^{\pm}_{n,\alpha,\lambda^*}$'s are well located. Other choices for λ would require further restrictions on α in order to ensure that the β_n's associated with evanescent modes also stay in the "good side" of the complex plane (see Figure 6).

We denote in the following by $\lambda(x)$ the function defined by

$$\lambda(x) = \begin{cases} 0 & \text{if } x_- \le x \le x_+, \\ \lambda & \text{otherwise.} \end{cases} \tag{3.11}$$

Finally, the equation in the new PML medium can be written as

$$\left(1-M^2\right)\left(\alpha(x)\,\frac{\partial}{\partial x} + i\lambda(x)\right)^2 p \,+\, \frac{\partial^2 p}{\partial y^2} \,+\, 2ikM\left(\alpha(x)\,\frac{\partial}{\partial x} + i\lambda(x)\right) p \,+\, k^2 p = f \quad \text{in } \Omega, \tag{3.12}$$

where the function $\alpha(x)$ (resp., $\lambda(x)$) is defined in (3.5) (resp., in (3.11)) with $\lambda \in \mathbb{R}$ and $\alpha \in \mathbb{C}$ satisfying assumption (3.8). Writing this equation in a weak sense implies jump conditions at the interfaces between Ω_b and the layers:

$$[p(x,y)] = 0 \quad \text{and} \quad \left[\alpha(x)\,\frac{\partial p}{\partial x}(x,y) + i\lambda(x)\,p(x,y)\right] = 0. \tag{3.13}$$

Remark. This new change of variable can also be used to derive stable PMLs in the time domain, as is done in [20, 14].

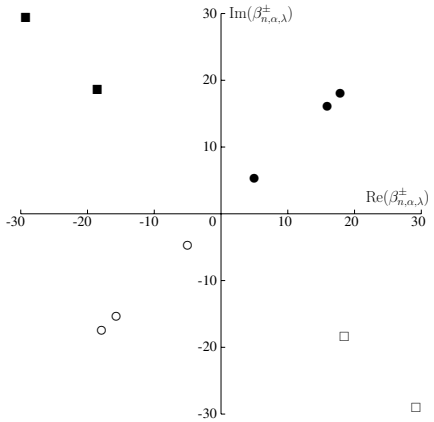

FIG. 6. *Effect of the new transformation (translation prior to similarity S_α) on the first axial wave numbers of the modes for the convected Helmholtz equation in the presence of an inverse upstream mode ($k = 6$, $M = 0.4$, and $h = 1$), $\alpha = 0.2(1 - i)$, and $\lambda = -\frac{kM}{1-M^2}$.*

4. PML truncation. Error estimates.

4.1. Truncation of the absorbing layer and well posedness. Until now, we have considered an absorbing layer of infinite length. In practice, one has to bound the computational domain and layers are of finite length L in this section.

We denote by Ω^L the truncated domain and by $\Sigma^L_\pm$ the external boundaries, presented in Figure 7. For simplicity, we choose to use homogeneous Dirichlet boundary conditions on these boundaries, but the analysis done in the following would still be valid for the natural boundary conditions $\alpha \frac{\partial p}{\partial x} + i\lambda\, p = 0$. Let p^L denote the solution in the truncated domain, satisfying

$$\begin{cases} \left(1 - M^2\right)\left(\alpha(x)\,\dfrac{\partial}{\partial x} + i\lambda(x)\right)^2 p + \dfrac{\partial^2 p}{\partial y^2} \\ \quad + 2ikM\left(\alpha(x)\,\dfrac{\partial}{\partial x} + i\lambda(x)\right) p + k^2\, p = f & \text{in } \Omega^L, \\ \dfrac{\partial p^L}{\partial y} = 0 & \text{on } \Gamma \cap \partial\Omega^L, \\ p^L = 0 & \text{on } \Sigma^L_\pm. \end{cases} \tag{4.1}$$

Denoting $V_L = \left\{q \in H^1(\Omega^L) \mid q = 0 \text{ on } \Sigma^L_\pm\right\}$, a variational formulation of (4.1) can be written as follows: find $p^L \in V_L$ such that

$$a_{\Omega^L}(p^L, q) = -\int_{\Omega^L} \frac{1}{\alpha}\, f\overline{q}\,\mathrm{d}x\,\mathrm{d}y \;\forall q \in V_L, \tag{4.2}$$

where the sesquilinear form $a_{\Omega^L}(\cdot\,,\cdot)$ is defined by

$$a_{\Omega^L}(p, q) = b_L(p, q) + c_L(p, q),$$

with

$$b_L(p, q) = \int_{\Omega^L} \left((1 - M^2)\alpha\,\frac{\partial p}{\partial x}\frac{\partial \overline{q}}{\partial x} + \frac{1}{\alpha}\,\frac{\partial p}{\partial y}\frac{\partial \overline{q}}{\partial y} + p\overline{q}\right) \mathrm{d}x\,\mathrm{d}y$$

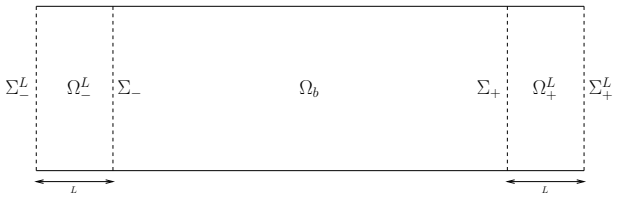

FIG. 7. *The truncated domain* Ω^L.

and

$$\begin{aligned} c_L(p,q) &= \int_{\Omega^L} i\left(\left((M^2-1)\lambda - 2kM\right)\frac{\partial p}{\partial x}\overline{q} + (1-M^2)\lambda\, p\frac{\partial \overline{q}}{\partial x}\right)\mathrm{d}x\,\mathrm{d}y \\ &\quad + \int_{\Omega^L}\left((1-M^2)\frac{\lambda^2}{\alpha} + 2kM\frac{\lambda}{\alpha} - \frac{k^2}{\alpha} - 1\right)p\overline{q}\,\mathrm{d}x\,\mathrm{d}y. \end{aligned}$$

THEOREM 4.1. *If* α *satisfies* (3.8)*, then problem* (4.2) *is of Fredholm type.*

Proof. The bounded operator C_L on $H^1(\Omega^L)$, defined by the Riesz representation theorem as

$$(C_L p, q)_{H^1(\Omega^L)} = c_L(p,q)\ \forall (p,q) \in H^1(\Omega^L)^2,$$

is clearly compact (from the compactness of the embedding of $H^1(\Omega^L)$ into $L^2(\Omega^L)$). On the other hand, the sesquilinear form $b_L(\cdot\,,\cdot)$ is coercive on V_L. To check this, it suffices to take the real part of $b_L(q,q)$:

$$\begin{aligned} \mathrm{Re}\,(b_L(q,q)) &= \int_{\Omega^L}\left(\mathrm{Re}(\alpha)(1-M^2)\left|\frac{\partial q}{\partial x}\right|^2 + \mathrm{Re}\left(\frac{1}{\alpha}\right)\left|\frac{\partial q}{\partial y}\right|^2 + |q|^2\right)\mathrm{d}x\,\mathrm{d}y \\ &\geq C\,\|q\|^2_{H^1(\Omega^L)}, \end{aligned}$$

where, because of assumption (3.8), C is a strictly positive constant depending on the complex constant α and the Mach number M:

$$C = \inf\left((1-M^2)\mathrm{Re}(\alpha), \mathrm{Re}\left(\frac{1}{\alpha}\right), 1\right). \qquad \square$$

4.2. Reduction to a problem posed in Ω_b. Remember that our original problem (2.1)–(2.2) has been proved in section 2.2 to be equivalent to the problem (2.10) posed in Ω_b. Having in mind the comparison between the solution p^L of problem (4.1), posed in the truncated domain, and the solution p of the original problem, we first reformulate (4.1) as a problem posed only in Ω_b. Consider the following problem: find $p_b^L \in H^1(\Omega_b)$ such that

$$\text{(4.3)} \qquad \begin{cases} (1-M^2)\,\dfrac{\partial^2 p_b^L}{\partial x^2} + 2ikM\,\dfrac{\partial p_b^L}{\partial x} + \dfrac{\partial^2 p_b^L}{\partial y^2} + k^2\,p_b^L = f & \text{in } \Omega_b, \\ \dfrac{\partial p_b^L}{\partial y} = 0 & \text{on } \Gamma \cap \partial\Omega_b, \\ \dfrac{\partial p_b^L}{\partial \boldsymbol{n}} = -T_\pm^L p_b^L & \text{on } \Sigma_\pm, \end{cases}$$

where $T_\pm^L$ are operators defined as follows:

$$\begin{aligned} T_\pm^L :\ H^{1/2}(\Sigma_\pm) &\to H^{-1/2}(\Sigma_\pm), \\ \phi &\mapsto \mp \sum_{n=0}^{+\infty} i\nu_n^\pm(L)\ (\phi,\varphi_n)_{L^2(\Sigma_\pm)}\ \varphi_n(y), \end{aligned} \tag{4.4}$$

with

$$\nu_n^\pm(L) = \beta_n^\pm + \frac{\beta_n^\mp - \beta_n^\pm}{1 - e^{i(\beta_n^- - \beta_n^+)L/\alpha}}. \tag{4.5}$$

Note that values $\nu_n^\pm(L)$ are well defined, because of assumption (2.15).

PROPOSITION 4.2. *If p^L is a solution of* (4.1)*, then $p^L{}_{|\Omega_b}$ is a solution of* (4.3)*. Conversely, if p_b^L is a solution of* (4.3)*, then it can be extended in a unique way to a solution of* (4.1)*.*

Proof. The key idea for reformulating the problem as a problem posed in Ω_b is to write an exact boundary condition satisfied by the solution on the boundaries $\Sigma_\pm$. We define the complementary domains $\Omega_\pm^L$ by

$$\Omega_-^L = \left\{(x,y)\in\Omega^L,\ x_- - L < x < x_-\right\} \quad \text{and} \quad \Omega_+^L = \left\{(x,y)\in\Omega^L,\ x_+ < x < x_+ + L\right\}.$$

Since $p_\pm^L = p^L{}_{|\Omega_\pm^L}$ satisfies a homogeneous equation in these domains, it can be given as a modal expansion. Consider, for instance, the solution in the right domain Ω_+^L. Using the Dirichlet boundary condition on the external layer boundary Σ_+^L, the solution can be written as

$$p_+^L(x,y) = \sum_{n=0}^{+\infty} \left(p_+^L(x_+,.),\varphi_n\right)_{L^2(\Sigma_+)} \left(A_n^+\, e^{i\gamma_n^+(x-x_+)} + A_n^-\, e^{i\gamma_n^-(x-x_+)}\right) \varphi_n(y),$$

where we have denoted $\gamma_n^\pm = \beta_{n,\alpha,\lambda}^\pm$, for the sake of clarity, and

$$A_n^\pm = \mp \frac{e^{i\gamma_n^\mp L}}{e^{i\gamma_n^+ L} - e^{i\gamma_n^- L}}.$$

We check easily that these quantities are always defined. Actually, the denominator would vanish if there existed an integer n for which $(\gamma_n^+ - \gamma_n^-)L \in 2\pi\mathbb{Z}$, which means that $(\beta_n^+ - \beta_n^-)L/\alpha \in 2\pi\mathbb{Z}$. If $k^2 \neq (1-M^2)\,\frac{n^2\pi^2}{h^2}$, the quantity $\beta_n^+ - \beta_n^-$ is never zero. Furthermore, with α satisfying assumption (3.8), $(\beta_n^+ - \beta_n^-)L/\alpha$ always has a nonzero imaginary part and thus cannot belong to $2\pi\mathbb{Z}$. We then write an exact boundary condition satisfied by p_+^L on Σ_+:

$$\left(\frac{\partial p_+^L}{\partial x}\right)_{|\Sigma_+} = \sum_{n=0}^{+\infty} \left(p_+^L(x_+,.),\varphi_n\right)_{L^2(\Sigma_+)} \left(A_n^+\, i\gamma_n^+ + A_n^-\, i\gamma_n^-\right) \varphi_n(y).$$

Using the jump conditions (3.13) and relation (3.9), this yields an exact boundary condition satisfied in the interior by p_b^L:

$$\begin{aligned} \left(\frac{\partial p_b^L}{\partial x}\right)_{|\Sigma_+} &= \alpha \left(\frac{\partial p_+^L}{\partial x}\right)_{|\Sigma_+} + i\lambda\, p_{+|\Sigma_+}^L \\ &= i \sum_{n=0}^{+\infty} \left(p_b^L(x_+,.),\varphi_n\right)_{L^2(\Sigma_+)} \left(A_n^+\beta_n^+ + A_n^-\beta_n^-\right) \varphi_n(y). \end{aligned}$$

Setting $\nu_n^+(L) = A_n^+\beta_n^+ + A_n^-\beta_n^-$, this can also be written as

$$\left(\frac{\partial p_b^L}{\partial x}\right)_{|\Sigma_+} = -T_+^L(p_b^L)_{|\Sigma_+},$$

where T_+^L denotes the operator defined in (4.4). ∎

Remark. It clearly appears in the expression (4.5) that operators $T_\pm^L$, and thus problem (4.3), do not depend on λ. In fact, the computed solution p^L depends on λ only in the layers.

4.3. Convergence and error estimates. We have shown that the original system (2.1)–(2.2) and system (4.1) with absorbing layers of finite length are both equivalent to problems posed only in Ω_b (respectively, (2.10) and (4.3)). We are now able to compare the solutions of these two problems, which are solutions of the following variational formulations:

For the original problem (2.10): find $p_b \in H^1(\Omega_b)$ such that

$$a_{\Omega_b}(p_b, q) = -\int_{\Omega_b} f\overline{q}\,\mathrm{d}x\,\mathrm{d}y \;\forall q \in H^1(\Omega_b), \tag{4.6}$$

where the sesquilinear form $a_{\Omega_b}(\cdot\,,\cdot)$ is given by (2.12) and can be written as

$$a_{\Omega_b}(p, q) = (Ap, q)_{H^1(\Omega_b)} + \langle T_+ p, q\rangle_{\Sigma_+} + \langle T_- p, q\rangle_{\Sigma_-}\,, \tag{4.7}$$

with A the bounded linear operator on $H^1(\Omega_b)$ defined by

$$(Ap, q)_{H^1(\Omega_b)} = \int_{\Omega_b}\left(\left(1-M^2\right)\frac{\partial p}{\partial x}\frac{\partial \overline{q}}{\partial x} + \frac{\partial p}{\partial y}\frac{\partial \overline{q}}{\partial y} - 2ikM\,\frac{\partial p}{\partial x}\overline{q} - k^2\,p\overline{q}\right)\mathrm{d}x\,\mathrm{d}y. \tag{4.8}$$

For the problem with absorbing layers of finite length (4.3): find $p_b^L \in H^1(\Omega_b)$ such that

$$a_{\Omega_b}^L(p_b^L, q) = -\int_{\Omega_b} f\overline{q}\,\mathrm{d}x\,\mathrm{d}y \;\forall q \in H^1(\Omega_b), \tag{4.9}$$

where the sesquilinear form $a_{\Omega_b}^L(\cdot\,,\cdot)$ can be written as

$$a_{\Omega_b}^L(p, q) = (Ap, q)_{H^1(\Omega_b)} + \left\langle T_+^L p, q\right\rangle_{\Sigma_+} + \left\langle T_-^L p, q\right\rangle_{\Sigma_-}\,, \tag{4.10}$$

the operator A being defined in (4.8).

To prove convergence and get error estimates, we follow an idea developed in [25], which has also been used in [12].

LEMMA 4.3. *Suppose that assumptions* (2.15) *and* (3.8) *hold. Then there exist strictly positive constants* $\mathcal{C} = \mathcal{C}(k, M)$ *and* $\eta = \eta(\theta, k, h, M)$ *(where* θ *denotes the argument of* α*) such that, for all* $(p, q) \in \left(H^1(\Omega_b)\right)^2$*, we have*

$$\left|a_{\Omega_b}(p, q) - a_{\Omega_b}^L(p, q)\right| \le \mathcal{C}e^{-\eta L/|\alpha|}\,\|p\|_{H^1(\Omega_b)}\,\|q\|_{H^1(\Omega_b)}\,. \tag{4.11}$$

More precisely, the constant η *is determined by*

$$\eta = \frac{2k}{1-M^2}\,\min\left(-\sin(\theta)\sqrt{1-\frac{{N_0}^2}{{K_0}^2}},\ \cos(\theta)\sqrt{\frac{(N_0+1)^2}{{K_0}^2}-1}\right), \tag{4.12}$$

where K_0 *is defined in* (2.4).

Proof. From expressions (4.7) and (4.10), we have

$$a_{\Omega_b}(p,q) - a^L_{\Omega_b}(p,q) = \left(\langle T_+ p, q\rangle_{\Sigma_+} - \langle T^L_+ p, q\rangle_{\Sigma_+}\right) + \left(\langle T_- p, q\rangle_{\Sigma_-} - \langle T^L_- p, q\rangle_{\Sigma_-}\right).$$

Let us focus on the first term in the right-hand side, the estimation of the second one being analogous. From the definitions (2.8) and (4.4) of operators T_+ and T^L_+, we have, for any $\phi \in H^{1/2}(\Sigma_+)$,

$$\left(T_+ - T^L_+\right)\phi = -\sum_{n=0}^{+\infty} i\left(\beta^+_n - \nu^+_n(L)\right)\,\phi_n\,\varphi_n(y) \quad \text{with } \phi_n = (\phi,\varphi_n)_{L^2(\Sigma_+)}.$$

Therefore, for any $(\phi,\psi) \in (H^{1/2}(\Sigma_+))^2$,

$$\left\langle (T_+ - T^L_+)\phi, \psi\right\rangle_{\Sigma_+} = -\sum_{n=0}^{+\infty} i(\beta^+_n - \nu^+_n(L))\,\phi_n\,\overline{\psi}_n,$$

with $\phi_n = (\phi,\varphi_n)_{L^2(\Sigma_+)}$ and $\psi_n = (\psi,\varphi_n)_{L^2(\Sigma_+)}$. This implies the following estimate:

$$\left|\left\langle \left(T_+ - T^L_+\right)\phi, \psi\right\rangle_{\Sigma_+}\right| \le \sum_{n=0}^{+\infty} \left|\beta^+_n - \nu^+_n(L)\right|\,\left|\phi_n\overline{\psi}_n\right|. \tag{4.13}$$

From (4.5), we have

$$\left|\beta^+_n - \nu^+_n(L)\right| = \frac{|\beta^+_n - \beta^-_n|}{\left|1 - e^{i(\beta^-_n - \beta^+_n)L/\alpha}\right|}.$$

Noticing that, for any $z \in \mathbb{C}$,

$$\left|1 - e^{iz}\right| \ge \left|e^{-\mathrm{Im}(z)} - 1\right|$$

so that, if $\mathrm{Im}(z) < 0$ and $|\mathrm{Im}(z)|$ is large enough, we conclude that this quantity is larger than

$$\left|1 - e^{iz}\right| \ge \left|e^{-\mathrm{Im}(z)} - 1\right| \ge \frac{1}{2}\,e^{-\mathrm{Im}(z)}.$$

We can easily check, using assumption (3.8), that we have $\mathrm{Im}\left((\beta^-_n - \beta^+_n)\,L/\alpha\right) < 0$ for all $n \in \mathbb{N}$ so that, for L large enough, the previous estimate gives us

$$\left|\beta^+_n - \nu^+_n(L)\right| \le 2\left|\beta^+_n - \beta^-_n\right|\,e^{\mathrm{Im}\left((\beta^-_n - \beta^+_n)L/\alpha\right)}. \tag{4.14}$$

Let us now distinguish the two cases.

The propagative modes $n \le N_0$. From (2.5), we have

$$\beta^+_n - \beta^-_n = \frac{2k}{1-M^2}\sqrt{1 - \frac{n^2}{{K_0}^2}} = \delta_n > 0.$$

Noting that

$$\delta_{N_0} \le \delta_n \le \frac{2k}{1-M^2},$$

we derive from estimate (4.14)

$$\left|\beta^+_n - \nu^+_n(L)\right| \le 2\delta_n\,e^{-\delta_{N_0} L\,\mathrm{Im}(1/\alpha)} \le \frac{4k}{1-M^2}\,e^{-\delta_{N_0} L\,\mathrm{Im}(1/\alpha)}. \tag{4.15}$$

The evanescent modes $n \geq N_0 + 1$. From (2.6), we have

$$\beta_n^+ - \beta_n^- = \frac{2ik}{1-M^2}\sqrt{\frac{n^2}{{K_0}^2} - 1} = i\delta_n, \quad \delta_n > 0.$$

This time, δ_n is increasing and $\sqrt{\frac{n^2}{{K_0}^2} - 1} \leq \frac{n}{K_0}$. Estimate (4.14) thus yields

$$\left|\beta_n^+ - \nu_n^+(L)\right| \leq \frac{4k}{1-M^2}\frac{n}{K_0}\, e^{-\delta_{N_0+1} L \,\mathrm{Re}(1/\alpha)}. \tag{4.16}$$

By substituting these estimates into (4.13), we see that

$$\begin{aligned}\left|\left\langle \left(T_+ - T_+^L\right)\phi, \psi\right\rangle_{\Sigma_+}\right| \;\leq\; & \frac{4k}{1-M^2}\left(\sum_{n=0}^{N_0} e^{-\delta_{N_0} L \,\mathrm{Im}(1/\alpha)}\, \left|\phi_n\, \overline{\psi}_n\right| \right. \\ & \left. + \sum_{n=N_0+1}^{+\infty} \frac{n}{K_0}\, e^{-\delta_{N_0+1} L \,\mathrm{Re}(1/\alpha)}\, \left|\phi_n \overline{\psi}_n\right|\right).\end{aligned}$$

Setting $\eta = |\alpha| \min(\delta_{N_0} \,\mathrm{Im}(1/\alpha), \delta_{N_0+1}\,\mathrm{Re}(1/\alpha))$, we then have

$$\begin{aligned}\left|\left\langle \left(T_+ - T_+^L\right)\phi, \psi\right\rangle_{\Sigma_+}\right| \;&\leq\; \frac{4k}{1-M^2}\, e^{-\eta L/|\alpha|} \sum_{n=0}^{+\infty}\left(1 + \frac{n^2}{{K_0}^2}\right)^{1/2} \left|\phi_n\, \overline{\psi}_n\right| \\ &\leq\; \mathcal{C}\, e^{-\eta L/|\alpha|}\, |\phi|_{H^{1/2}(\Sigma_+)}\, |\psi|_{H^{1/2}(\Sigma_+)}.\end{aligned}$$

The trace theorem now yields, for any $(p,q) \in \left(H^1(\Omega_b)\right)^2$,

$$\left|\left\langle (T_+ - T_+^L)p, q\right\rangle_{\Sigma_+}\right| \leq \mathcal{C}\, e^{-\eta L/|\alpha|}\, \|p\|_{H^1(\Omega_b)}\, \|q\|_{H^1(\Omega_b)}.$$

One can obviously obtain the same estimate on Σ_- and thus conclude the proof of claim (4.11). ∎

Setting $V = H^1(\Omega_b)$, we introduce linear operators $\mathcal{A}$ and $\mathcal{A}^L$ in $\mathcal{L}(V, V')$, respectively, associated with the sesquilinear forms $a_{\Omega_b}(\cdot\,,\cdot)$ and $a^L_{\Omega_b}(\cdot\,,\cdot)$: for all $(p,q) \in V^2$,

$$\langle \mathcal{A}p, q\rangle_{V',V} = a_{\Omega_b}(p,q) \quad \text{and} \quad \left\langle \mathcal{A}^L p, q\right\rangle_{V',V} = a^L_{\Omega_b}(p,q).$$

Obviously estimate (4.11) implies

$$\left\|\mathcal{A} - \mathcal{A}^L\right\|_{\mathcal{L}(V,V')} \leq \mathcal{C}\, e^{-\eta L/|\alpha|}. \tag{4.17}$$

Problems (4.6) and (4.9) can both be written in terms of these operators:

$$\mathcal{A}p_b = -f, \tag{4.18}$$

$$\mathcal{A}^L p_b^L = -f. \tag{4.19}$$

It follows from taking the difference between (4.18) and (4.19) that the error $p_b - p_b^L$ satisfies the following equation:

$$\mathcal{A}^L\left(p_b - p_b^L\right) = \left(\mathcal{A}^L - \mathcal{A}\right) p_b. \tag{4.20}$$

Using estimate (4.17), we are now able to show the following result.

THEOREM 4.4. *Suppose that assumptions* (3.8) *and* (2.15) *hold. There exists* $L_1 > 0$ *such that for all* $L \geq L_1$, $\mathcal{A}^L$ *is an isomorphism on* $H^1(\Omega_b)$ *and the solution* p_b^L *of problem* (4.3) *converges to the solution* p_b *of problem* (2.10). *Furthermore, there exists a constant* $\mathcal{C}$ *depending on* M *and* k *such that*

$$\left\|p_b - p_b^L\right\|_V \leq \mathcal{C}\, e^{-\eta L/|\alpha|} \left\|p_b\right\|_V , \tag{4.21}$$

with η *being defined in* (4.12).

Proof. For $g \in V'$, we consider the following problem: find $u \in V$ such that

$$\mathcal{A}^L u = g. \tag{4.22}$$

We can rewrite the operator $\mathcal{A}^L$ as $\mathcal{A}^L = \mathcal{A} + \left(\mathcal{A}^L - \mathcal{A}\right)$ and, using that $\mathcal{A}$ is an isomorphism on V,

$$\mathcal{A}^L = \mathcal{A}\left(I + \mathcal{A}^{-1}\left(\mathcal{A}^L - \mathcal{A}\right)\right).$$

Problem (4.22) thus becomes

$$\left(I + \mathcal{A}^{-1}\left(\mathcal{A}^L - \mathcal{A}\right)\right) u = \mathcal{A}^{-1} g.$$

Applying the Banach fixed point theorem, this problem admits a unique solution if

$$\left\|\mathcal{A}^{-1}\left(\mathcal{A}^L - \mathcal{A}\right)\right\|_{\mathcal{L}(V,V')} < 1,$$

which is satisfied as soon as

$$\left\|\mathcal{A}^L - \mathcal{A}\right\|_{\mathcal{L}(V,V')} < \left\|\mathcal{A}^{-1}\right\|^{-1}_{\mathcal{L}(V,V')}.$$

This can be achieved for L large enough, that is, $L \geq L_1$, since $\left\|\mathcal{A}^L - \mathcal{A}\right\|_{\mathcal{L}(V,V')}$ tends to zero as L tends to infinity, because of (4.17). Moreover, we have

$$\left\|\left(I + \mathcal{A}^{-1}\left(\mathcal{A}^L - \mathcal{A}\right)\right)^{-1}\right\|_{\mathcal{L}(V,V')} < \frac{1}{1 - \left\|\mathcal{A}^{-1}\left(\mathcal{A}^L - \mathcal{A}\right)\right\|_{\mathcal{L}(V,V')}},$$

which implies the following estimate:

$$\left\|u\right\|_V < \frac{\left\|\mathcal{A}^{-1} g\right\|_V}{1 - \left\|\mathcal{A}^{-1}(\mathcal{A}^L - \mathcal{A})\right\|_{\mathcal{L}(V,V')}}.$$

Applying this result to the error, the solution of problem (4.20) yields

$$\begin{aligned}\left\|p_b - p_b^L\right\|_V &< \frac{\left\|\mathcal{A}^{-1}\left(\mathcal{A}^L - \mathcal{A}\right) p_b\right\|_V}{1 - \left\|\mathcal{A}^{-1}\left(\mathcal{A}^L - \mathcal{A}\right)\right\|_{\mathcal{L}(V,V')}} \\ &\leq \frac{\left\|\mathcal{A}^{-1}\right\|_{\mathcal{L}(V,V')} \left\|\mathcal{A}^L - \mathcal{A}\right\|_{\mathcal{L}(V,V')} \left\|p_b\right\|_V}{1 - \left\|\mathcal{A}^{-1}\right\|_{\mathcal{L}(V,V')} \left\|\mathcal{A}^L - \mathcal{A}\right\|_{\mathcal{L}(V,V')}}.\end{aligned}$$

When $\left\|\mathcal{A}^L - \mathcal{A}\right\|_{\mathcal{L}(V,V')}$ is small enough, the quantity in the right-hand side can be bounded by

$$\left\|p_b - p_b^L\right\|_V \leq 2 \left\|\mathcal{A}^{-1}\right\|_{\mathcal{L}(V,V')} \left\|\mathcal{A}^L - \mathcal{A}\right\|_{\mathcal{L}(V,V')} \left\|p_b\right\|_V \leq 2\mathcal{C}\, e^{-\eta} \left\|p_b\right\|_V ,$$

the last inequality coming from (4.17). ∎

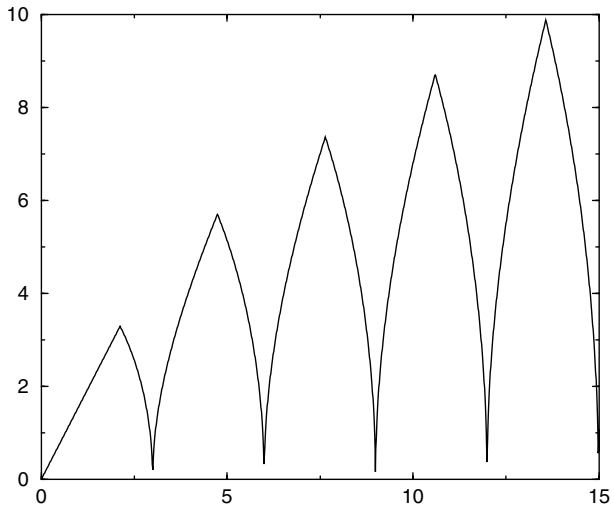

FIG. 8. *Coefficient η plotted as a function of wave number k for $M = 0.3$, $h = 1$, and $\theta = -\frac{\pi}{4}$.*

Remarks. 1. We emphasize that error estimate (4.21) of Theorem 4.4 does not depend on the parameter λ. As a consequence, exponential convergence is obtained for both the classical and the new PML models. This is the main difference between the behavior of the new PMLs and that of the classical PMLs in the time domain, as in that case the layers lead to instabilities in the presence of inverse upstream modes [19, 26, 1, 2].

2. Note that estimate (4.21) also proves that convergence holds when the length of the layers L is fixed and $|\alpha|$ tends to 0. This is useful in practice for numerical computations. Indeed, L has to be small in order to reduce the number of degrees of freedom. Moreover, it is more convenient to change the value of parameter α than the length of the layers, which requires a new mesh of the computational domain.

3. The value of η is strongly related to the position of wave number k with respect to the cut-off frequencies. More precisely, for a given value of the argument θ of coefficient α, the accuracy deteriorates when k is close to a cut-off wave number (see Figure 8).

5. Varying coefficients. In practical computations, it is very common to use a spatially varying coefficient $\alpha(x)$ in the layers. Actually, it has been proven for finite difference schemes that discontinuities in α through the boundaries $\Sigma_\pm$ generate spurious reflections after discretization [10]. In this section, we show that the analysis done previously for constant coefficients α and λ can be easily extended to varying coefficients. Let us point out, however, that the numerical results presented in the next section are obtained with constant coefficients and that no significant effects due to the discontinuities have been observed.

Let α and λ be two functions of the coordinate x, defined from $\mathbb{R}$ to $\mathbb{C}$, such that

$$\alpha(x) = 1 \quad \text{and} \quad \lambda(x) = 0 \quad \text{for } x \in [x_-, x_+].$$

We assume, moreover, that $\alpha(x)$ satisfies (3.8) for all $x > x_+$ or $x < x_-$. Let us consider once more problem (4.1). Since the proof of Theorem 4.1 does not use the fact that α and λ are constant in the layers, the theorem still holds, and the problem is of Fredholm type.

To establish a convergence result with respect to the size of the layers, we follow the steps of sections 4.2 and 4.3. The main point is that the modal solutions in the right-hand side layer, for instance, are now

$$p_n^{\pm}(x,y) = \psi_n^{\pm}(x)\varphi_n(y), \quad n \in \mathbb{N},$$

where φ_n is given by (2.3) and $\psi_n^{\pm}$ is defined by

$$\begin{cases} \left(\alpha(x)\dfrac{d}{dx} + i\lambda(x)\right)\psi_n^{\pm} = i\beta_n^{\pm}\psi_n^{\pm}, \\ \psi_n^{\pm}(x_+) = 1. \end{cases}$$

It then follows from straightforward calculations that problem (4.1) is equivalent to problem (4.3) set in domain Ω_b, with the following new definition for the coefficient $\nu_n^+(L)$:

$$\nu_n^+(L) = \beta_n^+ + \frac{\beta_n^- - \beta_n^+}{1 - \dfrac{\psi_n^-(x_+ + L)}{\psi_n^+(x_+ + L)}}. \tag{5.1}$$

and a similar definition for $\nu_n^-(l)$. Note, moreover, that

$$\frac{\psi_n^-(x_+ + L)}{\psi_n^+(x_+ + L)} = e^{i(\beta_n^- - \beta_n^+)} \int_{x_+}^{x_+ + L} \frac{1}{\alpha(x)}\,\mathrm{d}x$$

so that again the coefficients $\nu_n^{\pm}(L)$ do not depend on λ.

The final result then reads as follows.

THEOREM 5.1. *Problem* (4.1) *is well posed, and the solution* p_b^L *of problem* (4.3)*, with* $\nu_n^{\pm}(L)$ *defined above, exists and converges to the solution* p_b *of problem* (2.10) *as* $L \to +\infty$*. Furthermore, there exist three constants* $\mathcal{C} = \mathcal{C}(k, M)$ *and* $\tau_{\pm} = \tau_{\pm}(k, M, \alpha, L)$ *such that*

$$\left\|p_b - p_b^L\right\|_V \leq \mathcal{C}\,\left(e^{-\tau_+} + e^{-\tau_-}\right)\|p_b\|_V\,,$$

with

$$\tau_{\pm} = \frac{2k}{1 - M^2}\,\min\left(\mathrm{Im}(I_{\pm})\sqrt{1 - \frac{{N_0}^2}{{K_0}^2}},\ \mathrm{Re}(I_{\pm})\sqrt{\frac{(N_0+1)^2}{{K_0}^2} - 1}\right),$$

where $I\pm = \pm\int_{x_\pm}^{x_\pm \pm L} \frac{1}{\alpha(x)}\,\mathrm{d}x$*,* K_0 *is defined in* (2.4)*, and* N_0 *denotes the integer part of* K_0*.*

6. Numerical results. In order to illustrate the conclusions previously drawn concerning the PML models, numerical examples are presented. The following configuration is considered: the computational domain is the same as the one presented in Figure 7, extending from $x = -0.2$ to $x = 2.2$ and $y = 0$ to $y = 1$. The layers occupy the region from $x = -0.2$ to $x = 0$ in the downstream direction and from $x = 2$ to $x = 2.2$ in the upstream direction, the thickness L of the layers then being fixed and equal to 10% of the length of domain Ω_b. A compactly supported source f is given by

$$f = \begin{cases} 1 \text{ if } (x-1)^2 + (y-0.7)^2 \leq 0.04, \\ 0 \text{ elsewhere.} \end{cases}$$

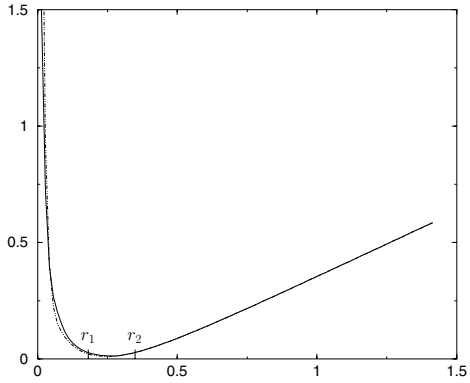

FIG. 9. *Relative error* $\frac{\|p-p_{\rm ref}\|_{H^1(\Omega_b)}}{\|p_{\rm ref}\|_{H^1(\Omega_b)}}$ *as a function of* $|\alpha|$, $k = 10$, *and* $M = 0.3$. *The solid line is the result for the new PML model, while the dotted line refers to the classical PML model.*

The numerical solution of problem (4.2) posed in the domain bounded with PMLs is compared to the computed solution (which is called the *reference solution*) of problem (2.11) posed in the domain bounded with DtN operators. Both approximations are done with a finite element method. The DtN map, usually expressed through an infinite series expansion, is here approximated by truncating the series.

All the simulations have been conducted with the same unstructured mesh, whose mesh size is linked to the problem via a resolution of approximately 20 nodal points per wavelength when using second-order triangular (P_2) Lagrange finite elements. For the computation of the reference solution, the number of terms in the truncated DtN map is 8, which is sufficient for accuracy in each of the cases tested. The coefficient α is chosen to be a complex constant in the layers, whose argument is taken to be equal to $-\frac{\pi}{4}$, and coefficient λ of the new PML model takes the value λ^* defined in (3.10). Homogeneous Dirichlet boundary conditions are imposed on the outer boundaries of the layers. The computations are done with the finite element library MÉLINA [22].

6.1. The no inverse upstream mode case. In this first simulation, we choose $k = 10$ and $M = 0.3$. For such values of the wave number and the Mach number, four modes are propagative, and there is no inverse upstream mode. The solution in the layers is then exponentially decaying for both the classical (i.e., $\lambda = 0$) and new PML models.

In Figure 9, the relative error to the reference solution in the $H^1(\Omega_b)$ norm is plotted as a function of the modulus of α for the two models. We observe no noticeable discrepancy between the classical and new PML models, which behave similarly in this case. Both curves present a minimum plateau, and we can roughly distinguish three zones, as indicated in Figure 9:

• $|\alpha| \in [r_1, r_2]$. A very good agreement between the DtN and the PML solutions, for the classical and new PML models, is obtained for a large range of values of $|\alpha|$ corresponding to the plateau seen in Figure 9. The real part of the corresponding solution is shown in Figure 10. We also observe in this figure the effect of the flow on the propagation of sound, as the wavelength of the solution is longer downstream from the source than upstream.

• $|\alpha| > r_2$. For larger values of $|\alpha|$, the layer is insufficiently absorbing, and a reflection occurs at the end of the layers, as shown in Figure 11.

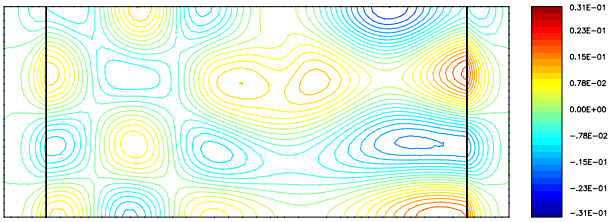

FIG. 10. *Real part of the pressure field;* $k = 10$ *and* $M = 0.3$, $\alpha = .19(1 - i)$, *and* $\lambda = -\frac{kM}{1-M^2}$.

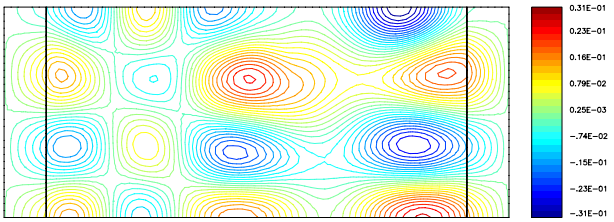

FIG. 11. *Real part of the pressure field;* $k = 10$ *and* $M = 0.3$, $\alpha = 1 - i$, *and* $\lambda = -\frac{kM}{1-M^2}$.

• $|\alpha| < r_1$. For small values of $|\alpha|$, the absorption in the layers is high, but the mesh resolution becomes too coarse to correctly represent modes in the PML medium, thus producing spurious numerical errors, as seen in Figure 12.

We want to confirm the convergence estimate of Theorem 4.4, which implies that

$$-\ln\left(\frac{\left\|p_b - p_b^L\right\|_V}{\|p_b\|_V}\right) \geq \frac{\eta L}{|\alpha|} - \ln(\mathcal{C}).$$

To this end, the opposite of the logarithm of the relative error in $H^1(\Omega_b)$ norm is plotted as a function of the inverse of $|\alpha|$ for both PML models. The exponential convergence of the method, which can be deduced from the slope of curves in Figure 13, agrees satisfactorily with the estimation given by the theory for both PML models, as the two curves coincide for this case.

6.2. The inverse upstream mode case. For the choice of $k = 9$ and $M = 0.4$, the last of the four propagative downstream modes (i.e., $n = 3$) has a negative phase velocity and is therefore called an inverse upstream mode. The solution in the downstream layer is then exponentially decreasing or increasing with the distance, depending on the applied PML model. Results for this case are shown in Figures 14 and 15, where the relative error in the $H^1(\Omega_b)$ norm and the opposite of its logarithm, respectively, are shown.

As one can observe in the zoom in Figure 14, the curves of the relative error have again a minimum plateau for both PML models. This time, the size of the plateau is smaller for the classical PML and the error for this model has a rather erratic behavior for small values of $|\alpha|$. The convergence of the method is nonetheless achieved for both models, with the predicted exponential rate (see Figure 15). However, the new PML model seems better suited to practical computations, as one can choose an appropriate and optimal value of α for convergence more conveniently.

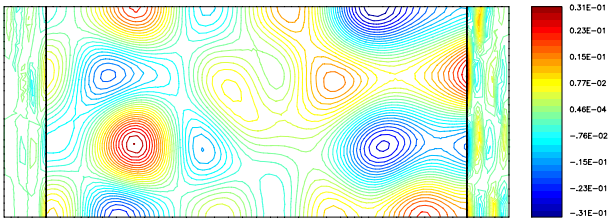

FIG. 12. *Real part of the pressure field;* $k = 10$ *and* $M = 0.3$, $\alpha = .02(1 - i)$, *and* $\lambda = -\frac{kM}{1-M^2}$.

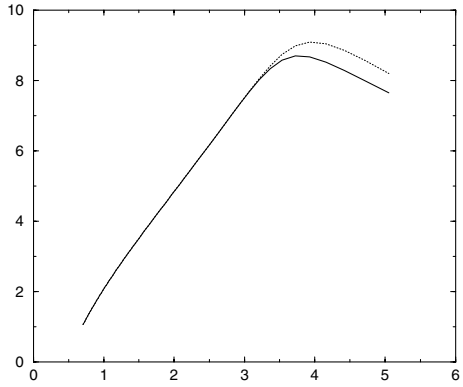

FIG. 13. $-\ln(\frac{\|p-p_{\text{ref}}\|_{H^1(\Omega_b)}}{\|p_{\text{ref}}\|_{H^1(\Omega_b)}})$ *as a function of* $\frac{1}{|\alpha|}$, $k = 10$, *and* $M = 0.3$. *The solid and dotted lines, respectively, refer to results for the new and classical PML models.*

To conclude, Figures 16 and 17, respectively, show the solutions for the new and classical models, the value of $|\alpha|$ for this case corresponding to the minimum of the curves in Figure 14. Note that whatever the behavior of the solution in the layers, the solution in the "physical" domain remains almost the same.

6.3. Some practical remarks on the use of PMLs for time-harmonic problems. We would like to point out that the numerical analysis which has been carried out in this section was based on the knowledge of a reference solution. In practice, it would be useful to have a posteriori criteria which indicate whether the numerical solution is satisfactory or not. In transient applications, the quality of the PML model is ensured as soon as the reflections produced at the interface between the physical and the absorbing layer can be neglected. In particular, if the excitation is a pulse localized in time, the exact solution should vanish after a large time, which gives a criterion for evaluating the efficiency of the absorbing layer. The situation is completely different in time-harmonic applications. For instance, we have the following:

- The notion of reflection is more difficult to exploit: as illustrated in the previous numerical results, it is not clear how to distinguish a "reflected" wave from an "incident" wave.
- The experiment of a pulse localized in time has no counterpart in time-harmonic applications.
- A good choice of the absorbing layer parameters allows one to select the outgoing solution of the problem. A bad choice ($\text{Im}(\alpha) > 0$) would select

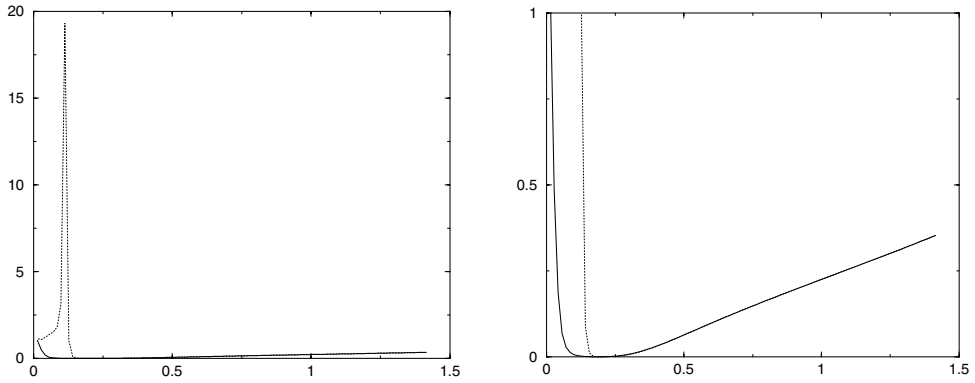

FIG. 14. *Left: relative error* $\frac{\|p-p_{\rm ref}\|_{H^1(\Omega_b)}}{\|p_{\rm ref}\|_{H^1(\Omega_b)}}$ *as a function of* $|\alpha|$, $k = 9$, *and* $M = 0.4$*; right: zoom on the zone of interest. The solid line is the result for the new PML model, while the dotted line refers to the classical PML model.*

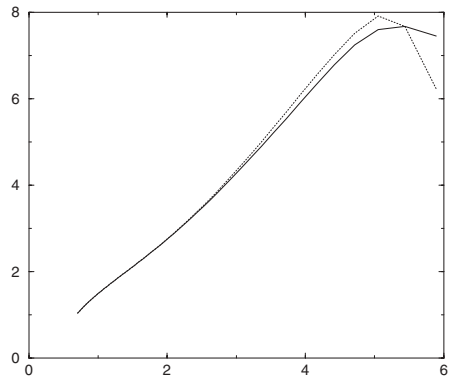

FIG. 15. $-\ln(\frac{\|p-p_{\rm ref}\|_{H^1(\Omega_b)}}{\|p_{\rm ref}\|_{H^1(\Omega_b)}})$ *as a function of* $\frac{1}{|\alpha|}$, $k = 9$, *and* $M = 0.4$. *The solid and dotted lines, respectively, refer to results for the new and classical PML models.*

the ingoing solution, which is difficult to detect when one does not know the exact solution.

- However, one can note that when $|\alpha|$ is too small, spurious numerical errors are observed. They can be removed by refining the mesh in the layer.

7. Conclusion. In this paper, we have studied PMLs for the convected Helmholtz equation. In the presence of inverse upstream modes, the solution can have arbitrarily large values in the classical PMLs, thus causing the instabilities observed in time domain applications. We have investigated a new PML model which always leads to an exponentially decreasing solution in the layer, even in the presence of inverse upstream modes. The error analysis surprisingly showed the convergence for both the classical and new models. Nevertheless, numerical results seem to indicate that the error is best controlled with the new model when inverse upstream modes are present. In order to understand the different numerical behaviors of the two models, there remains to analyze the convergence of the solution of the discretized PML models with respect to both the finite element mesh size and the layer parameters α and L.

This is a preliminary step in dealing with more complex time-harmonic problems.

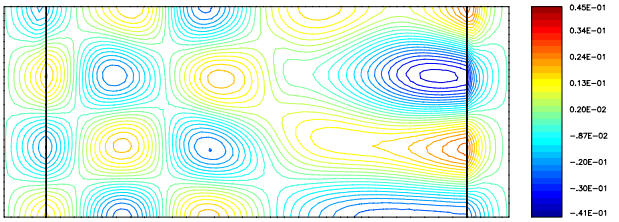

FIG. 16. *Real part of the pressure field;* $k = 9$ *and* $M = 0.4$, $\alpha = .14(1 - i)$, *and* $\lambda = -\frac{kM}{1-M^2}$.

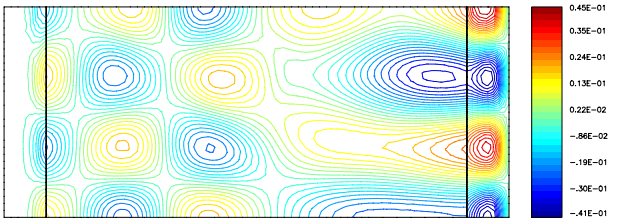

FIG. 17. *Real part of the pressure field;* $k = 9$ *and* $M = 0.4$, $\alpha = .14(1 - i)$, *and* $\lambda = 0$.

In particular, it would be interesting to extend the present method to nonuniform flows. This gives rise to several difficulties. First, even for a parallel flow, the problem can no longer be reduced to a simple scalar equation and has to be modeled with a vectorial model, for instance linearized Euler equations or Galbrun's equation [7]. Furthermore, a modal analysis cannot be done so easily, since the orthogonality of the modes is lost and their completeness is an open question. Finally, for some flows, there exist physical outgoing unstable modes which have to be adequately treated by the absorbing model.

MIXED DISCONTINUOUS GALERKIN APPROXIMATION OF THE MAXWELL OPERATOR*

PAUL HOUSTON†, ILARIA PERUGIA‡, AND DOMINIK SCHÖTZAU§

Abstract. We introduce and analyze a discontinuous Galerkin discretization of the Maxwell operator in mixed form. Here, all the unknowns of the underlying system of partial differential equations are approximated by discontinuous finite element spaces of the same order. For piecewise constant coefficients, the method is shown to be stable and optimally convergent with respect to the mesh size. Numerical experiments highlighting the performance of the proposed method for problems with both smooth and singular analytical solutions are presented.

Key words. discontinuous Galerkin methods, mixed methods, Maxwell operator

1. Introduction.

The origins of discontinuous Galerkin (DG) methods can be traced back to the 1970s, where they were proposed for the numerical solution of the neutron transport equation, as well as for the weak enforcement of continuity in Galerkin methods for elliptic and parabolic problems; see [11] for a historical review. In the meantime, these methods have undergone quite a remarkable development and are used in a wide range of applications; see the recent survey articles [10, 12, 13] and the references cited therein. The main advantages of DG methods lie in their robustness, conservation properties, and great flexibility in the mesh design. Indeed, being based on completely discontinuous finite element spaces, these methods can easily handle elements of various types and shapes, nonmatching grids, and local spaces of different polynomial orders; thus, they are ideal for *hp*-adaptivity.

In recent years, DG methods have begun to find their way into computational electromagnetics. Here, we mention the work in [17], where the full Maxwell system is discretized using unstructured spectral elements in space together with a suitable low-storage Runge–Kutta time stepping scheme; similar spectral DG methods were proposed in [22]. The study of DG methods applied to the time-harmonic Maxwell equations in electric field-based formulation was initiated in [24]; here, a local discontinuous Galerkin (LDG) method was proposed for the low-frequency problem, covering the cases of heterogeneous media and topologically nontrivial domains. The numerical experiments in [19] have confirmed the *hp*-convergence rates proved in [24] for smooth solutions and indicate that DG methods can be effective in a wide range of low-frequency applications where the bilinear forms are coercive.

On the other hand, one of the main difficulties in the numerical solution of Maxwell's equations consists of dealing with divergence-free constraints that need

to be imposed on the fields, especially in cases where the analytical solutions exhibit strong singularities. Several approaches have been proposed in the literature: we mention here the (weighted) regularization methods studied in [1, 14], the singular field approach of [6], and the Lagrange multiplier techniques used in [9, 15, 26], for example. The methods studied in [24, 19] are DG versions of the regularization approach of [1] and, for singular solutions, were shown to suffer from similar drawbacks as their conforming counterparts. A mixed discontinuous Galerkin approach was recently adopted in [25], where a stabilized interior penalty discretization was proposed for the high-frequency time-harmonic Maxwell equations. For smooth material coefficients, optimal convergence of the method was proved by employing a duality approach, provided that appropriate stabilization terms were included in the method.

In this paper, we introduce and analyze a new mixed DG formulation for the Maxwell operator (consisting of the curl-curl operator subject to a divergence-free constraint). Although this formulation is based on the same mixed approach as the one proposed in [25], here the amount of numerical stabilization is drastically reduced. In particular, we abandon all the volume stabilization terms from [25] and achieve well-posedness of the formulation through a suitable definition of the numerical fluxes. We present a numerical analysis of this method for piecewise constant material coefficients and obtain a priori error bounds in the associated energy norm that are optimal in the mesh size if both the field and the Lagrange multiplier related to the divergence constraint are approximated with piecewise polynomials of the same degree. Here, we consider both the case where the underlying analytical solution is smooth and where only minimal regularity assumptions are assumed. The method proposed in this paper is tested on a set of numerical examples that confirm the convergence rates predicted in the theoretical analysis for both smooth and singular solutions on regular and irregular meshes. The method is also tested within an adaptive procedure on affine quadrilateral meshes where hanging nodes are introduced during the course of the refinement. The numerical results indicate that singularities present in the analytical solution are correctly captured by the proposed scheme.

The stability analysis of the mixed DG formulation is carried out along the following lines. First, we rewrite the mixed system in an augmented form by introducing auxiliary variables, giving rise to a standard mixed saddle point problem with nonconsistent forms. Then we establish coercivity of the curl-curl operator on a suitable kernel. Finally, we prove the inf-sup stability condition for the form related to the divergence constraint. The proof of this result makes use of ideas developed in [8] for the analysis of stabilized mixed methods and relies on a decomposition of the discontinuous Galerkin finite element space for the Lagrange multiplier into the direct sum of its largest conforming (stable) subspace and a corresponding complement. The control over functions in the complement is then ensured by a crucial norm equivalence property that we establish by using an approximation result from [21, section 2.1].

The outline of the paper is as follows. In section 2 we introduce our mixed DG method for the Maxwell operator. Our main theoretical results are the a priori error bounds presented in section 3. Their proofs are carried out in the following sections, where we introduce an auxiliary mixed formulation (section 4), establish the continuity and stability properties of the forms involved (section 5), and, finally, derive the actual error estimates (section 6). The numerical performance of the method is tested in section 7. Concluding remarks are presented in section 8.

2. Model problem and discretization. In this section, we introduce a mixed DG discretization of the curl-curl operator subject to a divergence-free constraint.

2.1. Notation. We start by introducing the notation and function spaces that will be used throughout this paper. Given a bounded domain D in $\mathbb{R}^2$ or $\mathbb{R}^3$, we denote by $H^s(D)$ the standard Sobolev space of functions with the integer or fractional regularity exponent $s \geq 0$ and by $\|\cdot\|_{s,D}$ its norm. We also write $\|\cdot\|_{s,D}$ to denote the norms in the spaces $H^s(D)^d$, $d = 2, 3$. We set $L^2(D) = H^0(D)$. Furthermore, $L^\infty(D)$ is the space of bounded functions on D. Given $D \subset \mathbb{R}^3$ and a positive weight function $w \in L^\infty(D)$, $H(\mathrm{curl}_w; D)$ and $H(\mathrm{div}_w; D)$ are the spaces of vector fields $\boldsymbol{u} \in L^2(D)^3$ with $\nabla \times (w\boldsymbol{u}) \in L^2(D)^3$ and $\nabla \cdot (w\boldsymbol{u}) \in L^2(D)$, respectively, endowed with their corresponding graph norms. $H(\mathrm{curl}^0_w; D)$ and $H(\mathrm{div}^0_w; D)$ are the subspaces of $H(\mathrm{curl}_w; D)$ and $H(\mathrm{div}_w; D)$, respectively, of functions with zero (weighted) curl and divergence, respectively. For $w \equiv 1$, we omit the subscript and write $H(\mathrm{curl}; D)$ and $H(\mathrm{div}; D)$, respectively. We denote by $H^1_0(D)$, $H_0(\mathrm{curl}; D)$, and $H_0(\mathrm{div}; D)$ the subspaces of $H^1(D)$, $H(\mathrm{curl}; D)$, and $H(\mathrm{div}; D)$, respectively, of functions with zero trace, tangential trace, and normal trace, respectively.

2.2. Model problem. Let Ω be a bounded Lipschitz polyhedron in $\mathbb{R}^3$, with $\boldsymbol{n}$ denoting the outward normal unit vector to its boundary $\Gamma = \partial\Omega$. We assume that the domain Ω is simply connected and that Γ is connected. We consider the following mixed model problem: find the vector field $\boldsymbol{u}$ and the scalar field p such that

$$\begin{aligned} \nabla \times (\mu^{-1} \nabla \times \boldsymbol{u}) - \varepsilon \nabla p &= \boldsymbol{j} \quad \text{in } \Omega, \\ \nabla \cdot (\varepsilon \boldsymbol{u}) &= 0 \quad \text{in } \Omega, \\ \boldsymbol{n} \times \boldsymbol{u} &= \boldsymbol{g} \quad \text{on } \Gamma, \\ p &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{2.1}$$

Here, the right-hand side $\boldsymbol{j} \in L^2(\Omega)^3$ is an external source field, and the Dirichlet datum $\boldsymbol{g}$ is a prescribed tangential trace which we assume belongs to $L^2(\Gamma)^3$. The coefficients $\mu = \mu(\boldsymbol{x})$ and $\varepsilon = \varepsilon(\boldsymbol{x})$ are real functions in $L^\infty(\Omega)$ that satisfy

$$0 < \mu_* \leq \mu(\boldsymbol{x}) \leq \mu^* < \infty, \qquad 0 < \varepsilon_* \leq \varepsilon(\boldsymbol{x}) \leq \varepsilon^* < \infty, \quad \text{a.e. } \boldsymbol{x} \in \overline{\Omega}. \tag{2.2}$$

For simplicity, we assume that μ and ε are piecewise constant with respect to a partition of the domain Ω into Lipschitz polyhedra.

REMARK 2.1. *Problem* (2.1) *describes the principal operator of the time-harmonic Maxwell equations in a heterogeneous insulating medium (i.e., with electric conductivity* $\sigma = 0$*). The coefficients* μ *and* ε *are the magnetic permeability and the electric permittivity of the medium, respectively. The divergence constraint is incorporated by means of the Lagrange multiplier* p*; see, e.g.,* [15, 25, 26] *and the references cited therein. Problem* (2.1) *is also a formulation of the magnetostatic problem in terms of the vector potential* $\boldsymbol{u}$ *and with Coulomb's gauge* $\nabla \cdot \boldsymbol{u} = 0$ *(*$\varepsilon \equiv 1$ *in this case).*

REMARK 2.2. *In the discontinuous Galerkin context, the Dirichlet boundary condition* $\boldsymbol{n} \times \boldsymbol{u} = \boldsymbol{g}$ *on* Γ *is enforced weakly by so-called interior penalty stabilization terms. In order to make these terms well defined for each boundary face of a grid on* Ω*, we use the regularity assumption* $\boldsymbol{g} \in L^2(\Gamma)^3$*, which is slightly stronger than the natural assumption for* $\boldsymbol{g}$*. For less regular boundary data, the interior penalty terms need to be defined as suitable duality pairings over the whole boundary* Γ*.*

Setting $\boldsymbol{V} = \{\boldsymbol{v} \in H(\mathrm{curl}; \Omega) : (\boldsymbol{n} \times \boldsymbol{v})|_\Gamma \in L^2(\Gamma)^3\}$ and $Q = H^1_0(\Omega)$, the variational form of (2.1) is as follows: find $\boldsymbol{u} \in \boldsymbol{V}$, with $\boldsymbol{n} \times \boldsymbol{u} = \boldsymbol{g}$ on Γ, and $p \in Q$ such that

$$a(\boldsymbol{u},\boldsymbol{v}) + b(\boldsymbol{v},p) = \int_\Omega \boldsymbol{j}\cdot\boldsymbol{v}\,d\boldsymbol{x}, \tag{2.3}$$

$$b(\boldsymbol{u},q) = 0 \tag{2.4}$$

for all $(\boldsymbol{v},q) \in H_0(\mathrm{curl};\Omega)\times Q$, where the forms a and b are given, respectively, by

$$a(\boldsymbol{u},\boldsymbol{v}) = \int_\Omega \mu^{-1}\nabla\times\boldsymbol{u}\cdot\nabla\times\boldsymbol{v}\,d\boldsymbol{x}, \qquad b(\boldsymbol{v},p) = -\int_\Omega \varepsilon\boldsymbol{v}\cdot\nabla p\,d\boldsymbol{x}.$$

Well-posedness of the formulation (2.3)–(2.4) follows from the standard theory of mixed problems [7], since a is bilinear, continuous, and coercive on the kernel of b, and b is linear and continuous, and satisfies the inf-sup condition; see, e.g., [26] for details.

2.3. Meshes, finite element spaces, and traces. Throughout, we consider shape regular and affine meshes $\mathcal{T}_h$ that partition the domain Ω into tetrahedra and/or parallelepipeds, with possible hanging nodes; we always assume that the meshes are aligned with any discontinuities in the coefficients μ and ε. We denote by h_K the diameter of the element $K\in\mathcal{T}_h$ and set $h=\max_K h_K$. An interior face of $\mathcal{T}_h$ is defined as the (nonempty) two-dimensional interior of $\partial K^+\cap\partial K^-$, where K^+ and K^- are two adjacent elements of $\mathcal{T}_h$, not necessarily matching. A boundary face of $\mathcal{T}_h$ is defined as the (nonempty) two-dimensional interior of $\partial K\cap\Gamma$, where K is a boundary element of $\mathcal{T}_h$. We denote by $\mathcal{F}_h^{\mathcal{I}}$ the union of all interior faces of $\mathcal{T}_h$, $\mathcal{F}_h^{\mathcal{D}}$ the union of all boundary faces of $\mathcal{T}_h$, and set $\mathcal{F}_h=\mathcal{F}_h^{\mathcal{I}}\cup\mathcal{F}_h^{\mathcal{D}}$.

Given a nonnegative integer ℓ and an element $K\in\mathcal{T}_h$, we define $\mathcal{S}^\ell(K)$ as the space $\mathcal{P}^\ell(K)$ of polynomials of degree at most ℓ in K, if K is a tetrahedron, or the space $\mathcal{Q}^\ell(K)$ of polynomials of degree at most ℓ in each variable in K, if K is a parallelepiped. Similarly, for a face $f\subset\mathcal{F}_h$, we write $\mathcal{S}^\ell(f)$ for the space $\mathcal{P}^\ell(f)$ of polynomials of degree at most ℓ in f, if f is a triangle, and the space $\mathcal{Q}^\ell(f)$ of polynomials of degree at most ℓ in each variable in f, if f is a parallelogram. Then the generic finite element space of discontinuous piecewise polynomials is given by

$$S^\ell(\mathcal{T}_h) = \{u\in L^2(\Omega):\, u|_K\in\mathcal{S}^\ell(K)\ \ \forall K\in\mathcal{T}_h\}.$$

For piecewise smooth vector- and scalar-valued functions $\boldsymbol{v}$ and q, respectively, we introduce the following trace operators. Let $f\subset\mathcal{F}_h^{\mathcal{I}}$ be an interior face shared by two neighboring elements K^+ and K^-; we write $\boldsymbol{n}^\pm$ to denote the outward normal unit vectors to the boundaries $\partial K^\pm$, respectively. Denoting by $\boldsymbol{v}^\pm$ and $q^\pm$ the traces of $\boldsymbol{v}$ and q on $\partial K^\pm$ taken from within $K^\pm$, respectively, we define the jumps across f by $[\![\boldsymbol{v}]\!]_T=\boldsymbol{n}^+\times\boldsymbol{v}^+ + \boldsymbol{n}^-\times\boldsymbol{v}^-$, $[\![\boldsymbol{v}]\!]_N=\boldsymbol{v}^+\cdot\boldsymbol{n}^+ + \boldsymbol{v}^-\cdot\boldsymbol{n}^-$, and $[\![q]\!]_N=q^+\boldsymbol{n}^+ + q^-\boldsymbol{n}^-$ and the averages by $\{\!\{\boldsymbol{v}\}\!\}=(\boldsymbol{v}^+ + \boldsymbol{v}^-)/2$ and $\{\!\{q\}\!\}=(q^+ + q^-)/2$. On a boundary face $f\subset\mathcal{F}_h^{\mathcal{D}}$, we set $[\![\boldsymbol{v}]\!]_T=\boldsymbol{n}\times\boldsymbol{v}$, $[\![q]\!]_N=q\,\boldsymbol{n}$, $\{\!\{\boldsymbol{v}\}\!\}=\boldsymbol{v}$, and $\{\!\{q\}\!\}=q$.

2.4. DG discretization. We wish to approximate problem (2.1) by discrete functions $\boldsymbol{u}_h$ and p_h in the finite element spaces $\boldsymbol{V}_h=S^\ell(\mathcal{T}_h)^3$ and $Q_h=S^\ell(\mathcal{T}_h)$, respectively, for a given partition $\mathcal{T}_h$ of Ω and an approximation order $\ell\ge 1$.

To this end, we consider the following DG method: find $(\boldsymbol{u}_h,p_h)\in\boldsymbol{V}_h\times Q_h$ such that

$$a_h(\boldsymbol{u}_h,\boldsymbol{v}) + b_h(\boldsymbol{v},p_h) = f_h(\boldsymbol{v}), \tag{2.5}$$

$$b_h(\boldsymbol{u}_h,q) - c_h(p_h,q) = 0 \tag{2.6}$$

for all $(\boldsymbol{v},q) \in \boldsymbol{V}_h \times Q_h$, where the discrete forms a_h, b_h, and c_h and the linear functional f_h are given, respectively, by

$$
\begin{aligned}
a_h(\boldsymbol{u},\boldsymbol{v}) &= \int_\Omega \mu^{-1}\nabla_h \times \boldsymbol{u} \cdot \nabla_h \times \boldsymbol{v}\, d\boldsymbol{x} - \int_{\mathcal{F}_h} [\![\boldsymbol{u}]\!]_T \cdot \{\!\{\mu^{-1}\nabla_h \times \boldsymbol{v}\}\!\}\, ds \\
&\quad - \int_{\mathcal{F}_h} [\![\boldsymbol{v}]\!]_T \cdot \{\!\{\mu^{-1}\nabla_h \times \boldsymbol{u}\}\!\}\, ds + \int_{\mathcal{F}_h} \mathtt{a}\, [\![\boldsymbol{u}]\!]_T \cdot [\![\boldsymbol{v}]\!]_T\, ds + \int_{\mathcal{F}_h^{\mathcal{I}}} \mathtt{b}\, [\![\varepsilon\boldsymbol{u}]\!]_N [\![\varepsilon\boldsymbol{v}]\!]_N\, ds, \\
b_h(\boldsymbol{v},p) &= -\int_\Omega \varepsilon\boldsymbol{v} \cdot \nabla_h p\, d\boldsymbol{x} + \int_{\mathcal{F}_h} \{\!\{\varepsilon\boldsymbol{v}\}\!\} \cdot [\![p]\!]_N\, ds, \qquad c_h(p,q) = \int_{\mathcal{F}_h} \mathtt{c}[\![p]\!]_N \cdot [\![q]\!]_N\, ds, \\
f_h(\boldsymbol{v}) &= \int_\Omega \boldsymbol{j} \cdot \boldsymbol{v}\, d\boldsymbol{x} - \int_{\mathcal{F}_h^{\mathcal{D}}} \boldsymbol{g} \cdot \mu^{-1}\nabla_h \times \boldsymbol{v}\, ds + \int_{\mathcal{F}_h^{\mathcal{D}}} \mathtt{a}\, \boldsymbol{g} \cdot (\boldsymbol{n} \times \boldsymbol{v})\, ds.
\end{aligned}
$$

Here, ∇_h denotes the elementwise ∇ operator. The form a_h corresponds to the interior penalty discretization of the curl-curl operator [19, 25], with the addition of a normal jump term; the form b_h discretizes the divergence operator in a DG fashion; and the form c_h is a stabilization form that penalizes the jumps of p_h. The parameters $\mathtt{a}$, $\mathtt{b}$, and $\mathtt{c}$ are positive stabilization parameters that will be chosen later on, depending on the mesh size and the coefficients μ and ε. Note that a similar discretization has been investigated in [25] for a time-harmonic high-frequency model of Maxwell's equations; we point out that the additional stabilization forms that have been added there become obsolete with the analysis presented in this paper.

As in [24, Remark 3.2] or [25, Proposition 4], it can be readily seen that the analytical solution $(\boldsymbol{u},p) \in \boldsymbol{V} \times Q$ satisfies (2.5)–(2.6) for all $(\boldsymbol{v},q) \in \boldsymbol{V}_h \times Q_h$.

REMARK 2.3. *All the interface contributions arising in the forms in* (2.5)–(2.6) *can easily be obtained by rewriting the problem* (2.1) *as a first-order system and introducing so-called* numerical fluxes *in the sense of* [5]. *Thus, all the stabilization terms in* (2.5)–(2.6) *are* local, consistent, *and* conservative. *To see this, we rewrite* (2.1) *as*

$$
\boldsymbol{s} - \mu^{-1}\nabla \times \boldsymbol{u} = 0, \qquad \nabla \times \boldsymbol{s} - \varepsilon\nabla p = \boldsymbol{j}, \qquad \nabla \cdot (\varepsilon\boldsymbol{u}) = 0 \qquad \text{in } \Omega,
$$

subject to the boundary conditions $\boldsymbol{n} \times \boldsymbol{u} = \boldsymbol{g}$ *and* $p = 0$ *on* Γ. *Then we consider the following discretization: find* $(\boldsymbol{s}_h, \boldsymbol{u}_h, p_h) \in \boldsymbol{V}_h \times \boldsymbol{V}_h \times Q_h$ *such that*

$$
\begin{aligned}
&\int_K \boldsymbol{s}_h \cdot \boldsymbol{t}\, d\boldsymbol{x} - \int_K \mu^{-1}\nabla \times \boldsymbol{t} \cdot \boldsymbol{u}_h\, d\boldsymbol{x} + \int_{\partial K} \mu^{-1}\boldsymbol{t} \cdot \widehat{\boldsymbol{u}}_h \times \boldsymbol{n}\, ds = 0, \\
&\int_K \boldsymbol{s}_h \cdot \nabla \times \boldsymbol{v}\, d\boldsymbol{x} - \int_{\partial K} \boldsymbol{v} \cdot \widehat{\boldsymbol{s}}_h \times \boldsymbol{n}\, ds + \int_K p_h\, \nabla \cdot (\varepsilon\boldsymbol{v})\, d\boldsymbol{x} \\
&\qquad\qquad - \int_{\partial K} \widehat{p}_h\, \varepsilon\boldsymbol{v} \cdot \boldsymbol{n}\, ds = \int_K \boldsymbol{j} \cdot \boldsymbol{v}\, d\boldsymbol{x}, \\
&\int_K \varepsilon\boldsymbol{u}_h \cdot \nabla q\, d\boldsymbol{x} - \int_{\partial K} q\, \widehat{\varepsilon\boldsymbol{u}}_h \cdot \boldsymbol{n}\, ds = 0
\end{aligned}
\tag{2.7}
$$

for all $(\boldsymbol{t},\boldsymbol{v},q) \in \boldsymbol{V}_h \times \boldsymbol{V}_h \times Q_h$ *and for all elements* K *in the partition* $\mathcal{T}_h$. *In* (2.7), *the traces of* $\boldsymbol{u}_h$, $\boldsymbol{s}_h$, p_h, *and* $\varepsilon\boldsymbol{u}_h$ *on* ∂K *are approximated by the numerical fluxes*

$$
\begin{aligned}
\widehat{\boldsymbol{u}}_h &= \{\!\{\boldsymbol{u}_h\}\!\}, & \widehat{\boldsymbol{s}}_h &= \{\!\{\mu^{-1}\nabla_h \times \boldsymbol{u}_h\}\!\} - \mathtt{a}[\![\boldsymbol{u}_h]\!]_T, \\
\widehat{p}_h &= \{\!\{p_h\}\!\} - \mathtt{b}[\![\varepsilon\boldsymbol{u}_h]\!]_N, & \widehat{\varepsilon\boldsymbol{u}}_h &= \{\!\{\varepsilon\boldsymbol{u}_h\}\!\} - \mathtt{c}[\![p_h]\!]_N,
\end{aligned}
$$

respectively (these definitions are for interior faces; they must be suitably adapted for

boundary faces). By integration by parts, the first equation of (2.7) *reads as*

$$\int_K \boldsymbol{s}_h \cdot \boldsymbol{t}\, d\boldsymbol{x} = \int_K \mu^{-1} \nabla \times \boldsymbol{u}_h \cdot \boldsymbol{t}\, d\boldsymbol{x} + \int_{\partial K} \mu^{-1} \boldsymbol{t} \cdot (\boldsymbol{u}_h - \widehat{\boldsymbol{u}}_h) \times \boldsymbol{n}\, ds. \tag{2.8}$$

As the numerical flux $\widehat{\boldsymbol{u}}_h$ *is independent of* $\boldsymbol{s}_h$*, the auxiliary variable* $\boldsymbol{s}_h$ *can be locally expressed in terms of* $\boldsymbol{u}_h$ *by inverting the local mass matrix* $\int_K \boldsymbol{s}_h \cdot \boldsymbol{t}\, d\boldsymbol{x}$ *in* (2.8)*. By substituting the resulting expression for* $\boldsymbol{s}_h$ *into the second equation of* (2.7)*, one obtains an elemental formulation for the unknowns* $\boldsymbol{u}_h$ *and* p_h *only. Finally, summing over all elements* $K \in \mathcal{T}_h$ *gives the formulation* (2.5)–(2.6)*. We refer the reader to* [5] *and* [24] *for further details on the formalization of this elimination process.*

3. Main results. In this section, we state our main results for the mixed DG method in (2.5)–(2.6); the proofs of these a priori error bounds will be given in sections 4, 5, and 6.

3.1. Stabilization parameters and DG-norms. We start by defining the stabilization parameters $\mathtt{a}$, $\mathtt{b}$, and $\mathtt{c}$ appearing in (2.5)–(2.6) and introduce the norms employed in the proceeding error analysis. To this end, we first define the function $\mathtt{h}$ in $L^\infty(\mathcal{F}_h)$, representing the local mesh size, as $\mathtt{h}(\boldsymbol{x}) = \min\{h_K, h_{K'}\}$, if $\boldsymbol{x}$ is in the interior of $\partial K \cap \partial K'$ for two neighboring elements in the mesh $\mathcal{T}_h$, and $\mathtt{h}(\boldsymbol{x}) = h_K$ if $\boldsymbol{x}$ is in the interior of $\partial K \cap \Gamma$. Similarly, we define the functions $\mathtt{m}$ and $\mathtt{e}$ in $L^\infty(\mathcal{F}_h)$ by $\mathtt{m}(\boldsymbol{x}) = \min\{\mu_K, \mu_{K'}\}$ and $\mathtt{e}(\boldsymbol{x}) = \max\{\varepsilon_K, \varepsilon_{K'}\}$, if $\boldsymbol{x}$ is in the interior of $\partial K \cap \partial K'$, and $\mathtt{m}(\boldsymbol{x}) = \mu_K$ and $\mathtt{e}(\boldsymbol{x}) = \varepsilon_K$, if $\boldsymbol{x}$ is in the interior of $\partial K \cap \Gamma$, with μ_K and ε_K denoting the restrictions of μ and ε to the element K, respectively. With this notation, we choose the stabilization parameters as follows:

$$\mathtt{a} = \alpha\, \mathtt{m}^{-1}\mathtt{h}^{-1}, \qquad \mathtt{b} = \beta\, \mathtt{e}^{-1}\mathtt{h}, \qquad \mathtt{c} = \gamma\, \mathtt{e}\mathtt{h}^{-1}, \tag{3.1}$$

where α, β, and γ are positive parameters, independent of the mesh size and the coefficients μ and ε.

Further, we set $\boldsymbol{V}(h) = (\boldsymbol{V} \cap H(\mathrm{div}_\varepsilon; \Omega)) + \boldsymbol{V}_h$ and $Q(h) = Q + Q_h$ and define

$$\begin{aligned}
|\boldsymbol{v}|^2_{\boldsymbol{V}(h)} &= \|\mu^{-\frac{1}{2}} \nabla_h \times \boldsymbol{v}\|^2_{0,\Omega} + \|\mathtt{m}^{-\frac{1}{2}} \mathtt{h}^{-\frac{1}{2}} [\![\boldsymbol{v}]\!]_T\|^2_{0,\mathcal{F}_h} + \|\mathtt{e}^{-\frac{1}{2}} \mathtt{h}^{\frac{1}{2}} [\![\varepsilon \boldsymbol{v}]\!]_N\|^2_{0,\mathcal{F}_h^{\mathcal{I}}}, \\
\|\boldsymbol{v}\|^2_{\boldsymbol{V}(h)} &= \|\varepsilon^{\frac{1}{2}} \boldsymbol{v}\|^2_{0,\Omega} + |\boldsymbol{v}|^2_{\boldsymbol{V}(h)}, \\
\|q\|^2_{Q(h)} &= \|\varepsilon^{\frac{1}{2}} \nabla_h q\|^2_{0,\Omega} + \|\mathtt{e}^{\frac{1}{2}} \mathtt{h}^{-\frac{1}{2}} [\![q]\!]_N\|^2_{0,\mathcal{F}_h}.
\end{aligned}$$

We also introduce the space $H^s(\mathcal{T}_h) = \{v \in L^2(\Omega) : v|_K \in H^s(K),\ K \in \mathcal{T}_h\}$, endowed with the norm $\|v\|^2_{s,\mathcal{T}_h} = \sum_{K \in \mathcal{T}_h} \|v\|^2_{s,K}$. On the boundary, we define $H^s(\mathcal{F}_h^{\mathcal{D}}) = \{v \in L^2(\mathcal{F}_h^{\mathcal{D}}) : v|_f \in H^s(f),\ f \subset \mathcal{F}_h^{\mathcal{D}}\}$, equipped with the norm $\|v\|^2_{s,\mathcal{F}_h^{\mathcal{D}}} = \sum_{f \subset \mathcal{F}_h^{\mathcal{D}}} \|v\|^2_{s,f}$.

3.2. Existence and uniqueness. Next, we show that the discrete problem in (2.5)–(2.6) is uniquely solvable, provided that α is sufficiently large. To this end, we first recall the following well-known coercivity result, valid in view of the choice of $\mathtt{a}$ and the assumptions on the meshes; see [5, 19, 25] for details.

LEMMA 3.1. *There exists a parameter* $\alpha_{\min} > 0$*, independent of the mesh size and the coefficients* μ *and* ε*, such that for* $\alpha \geq \alpha_{\min}$ *and* $\beta > 0$ *we have*

$$a_h(\boldsymbol{v}, \boldsymbol{v}) \geq C |\boldsymbol{v}|^2_{\boldsymbol{V}(h)} \quad \forall \boldsymbol{v} \in \boldsymbol{V}_h,$$

with a constant $C > 0$ *independent of the mesh size and the coefficients* μ *and* ε*.*

The condition $\alpha \geq \alpha_{\min} > 0$ is a restriction that is typically encountered with symmetric interior penalty methods and may be omitted by using other DG discretizations of the curl-curl operator, such as the nonsymmetric interior penalty or the LDG method; see, e.g., [5, 24] for details.

PROPOSITION 3.2. *For $\alpha \geq \alpha_{\min}$, $\beta > 0$, and $\gamma > 0$, the mixed DG method* (2.5)–(2.6) *possesses a unique solution.*

Proof. It is enough to show that $\boldsymbol{j} = \mathbf{0}$ and $\boldsymbol{g} = \mathbf{0}$ imply $\boldsymbol{u}_h = \mathbf{0}$ and $p_h = 0$. To this end, take $\boldsymbol{v} = \boldsymbol{u}_h$ in (2.5) and $q = p_h$ in (2.6); then subtract (2.6) from (2.5). With the coercivity of a_h in Lemma 3.1, it follows that $\nabla_h \times \boldsymbol{u}_h = \mathbf{0}$, $[\![\boldsymbol{u}_h]\!]_T = \mathbf{0}$ on $\mathcal{F}_h$, $[\![\varepsilon \boldsymbol{u}_h]\!]_N = 0$ on $\mathcal{F}_h^{\mathcal{I}}$, and $[\![p_h]\!]_N = \mathbf{0}$ on $\mathcal{F}_h$; i.e., $\boldsymbol{u}_h \in H(\mathrm{curl}^0;\Omega) \cap H_0(\mathrm{curl};\Omega)$, $\boldsymbol{u}_h \in H(\mathrm{div}_\varepsilon;\Omega)$, and $p_h \in H_0^1(\Omega)$. Integrating by parts, (2.6) becomes $\int_\Omega q\, \nabla \cdot (\varepsilon \boldsymbol{u}_h)\, d\boldsymbol{x} = 0$, for any $q \in Q_h$, and then, since ε is piecewise constant, $\nabla \cdot (\varepsilon \boldsymbol{u}_h) = 0$. Therefore, $\boldsymbol{u}_h$ also belongs to $H(\mathrm{div}_\varepsilon^0;\Omega)$, which, owing to our assumptions on Ω, implies that $\boldsymbol{u}_h = \mathbf{0}$; cf. [16, section 4]. Equation (2.5) becomes $\int_\Omega \varepsilon \boldsymbol{v} \cdot \nabla p_h\, d\boldsymbol{x} = 0$, for any $\boldsymbol{v} \in V_h$, and then $\nabla p_h = \mathbf{0}$. Since $p_h = 0$ on Γ, we conclude that $p_h = 0$. ∎

For the rest of this article, we shall assume that the hypotheses on the stabilization parameters in the statement of Proposition 3.2 hold.

3.3. A priori error estimates. First, we establish optimal error estimates for smooth solutions on possibly nonconforming meshes subject to the following restrictions: (i) any interior face $f \subset \mathcal{F}_h^{\mathcal{I}}$ has to be an *entire* elemental face of at least one of the two adjacent elements sharing f; (ii) the number of interior faces contained in an elemental face is uniformly bounded with respect to the mesh size h. This implies bounded variation of the local mesh size; i.e., whenever K and K' share a common face and $h_K \geq h_{K'}$, we have $h_K \leq C h_{K'} \leq C h_K$, for a constant $C > 0$, independent of the mesh size. The reason for this restriction is related to the validity of the norm equivalence result of Theorem 5.3.

THEOREM 3.3. *Let $(\boldsymbol{u}, p)$ be the analytical solution of* (2.1) *satisfying $\boldsymbol{u} \in H^{s+1}(\mathcal{T}_h)^3$ and $p \in H^{s+1}(\mathcal{T}_h)$ for a regularity exponent $s > \frac{1}{2}$. Let $(\boldsymbol{u}_h, p_h)$ be the mixed DG approximation obtained by* (2.5)–(2.6) *on possibly nonconforming meshes that satisfy restrictions* (i) *and* (ii) *above. Then we have the a priori error bound*

$$\|\boldsymbol{u} - \boldsymbol{u}_h\|_{\boldsymbol{V}(h)} + \|p - p_h\|_{Q(h)} \leq C\, h^{\min\{s,\ell\}} \Big[\|\boldsymbol{u}\|_{s+1,\mathcal{T}_h} + \|p\|_{s+1,\mathcal{T}_h} \Big],$$

with $C > 0$ depending on the bounds (2.2) *on the coefficients μ and ε, the shape-regularity and bounded variation properties of the mesh, the stabilization parameters α, β, and γ, and the polynomial degree ℓ but independent of the mesh size h.*

While the bound in Theorem 3.3 guarantees optimal convergence in the mesh size h with respect to the polynomial degree used in the approximation, the smoothness assumptions on the analytical solution are not minimal. In fact, for $\varepsilon = \mu = 1$ and a homogeneous Dirichlet datum $\boldsymbol{g} \equiv \mathbf{0}$, from the regularity results in [3], it follows that one has only $\boldsymbol{u} \in H^s(\Omega)^3$ and $\nabla \times \boldsymbol{u} \in H^s(\Omega)^3$ for a regularity exponent $s = s(\Omega) > \frac{1}{2}$ (the same actually holds for smooth coefficients ε and μ; see [25, section 2.2]). As far as the assumption $p \in H^{s+1}(\Omega)$ is concerned, although it does not seem to hold for general source terms $\boldsymbol{j}$ in $L^2(\Omega)^3$, it is trivially satisfied in the physically most relevant case of divergence-free source terms $\boldsymbol{j}$, where $p \equiv 0$.

For these reasons, we state a second result under weaker smoothness assumptions for the component $\boldsymbol{u}$ of the analytical solution. In order to do this, we restrict ourselves to the case of conforming meshes (i.e., meshes with no hanging nodes); this restriction is necessary, since the proof requires the use of $H(\mathrm{curl};\Omega)$-conforming projections.

Note that, since the boundary datum $\boldsymbol{g}$ is the tangential trace on Γ of a function in $H(\mathrm{curl};\Omega)$, its restriction to each $f \subset \mathcal{F}_h^{\mathcal{D}}$ is a two-dimensional vector field which lies on the same plane as f. Hence, we can understand $\boldsymbol{g}$ as a function in $L^2(\Gamma)^2$.

THEOREM 3.4. *Let $(\boldsymbol{u},p)$ be the analytical solution of (2.1) satisfying $\varepsilon\boldsymbol{u} \in H^s(\mathcal{T}_h)^3$, $\mu^{-1}\nabla\times\boldsymbol{u} \in H^s(\mathcal{T}_h)^3$, $p \in H^{s+1}(\mathcal{T}_h)$, and $\boldsymbol{g} \in H^{s+\frac{1}{2}}(\mathcal{F}_h^{\mathcal{D}})^2$ for a regularity exponent $s > \frac{1}{2}$. Let $(\boldsymbol{u}_h,p_h)$ be the mixed DG approximation obtained by (2.5)–(2.6) on conforming meshes. Then we have the a priori error bound*

$$\begin{aligned}&\|\boldsymbol{u}-\boldsymbol{u}_h\|_{\boldsymbol{V}(h)} + \|p-p_h\|_{Q(h)}\\ &\qquad \le C\,h^{\min\{s,\ell\}}\Big[\|\varepsilon\boldsymbol{u}\|_{s,\mathcal{T}_h} + \|\mu^{-1}\nabla\times\boldsymbol{u}\|_{s,\mathcal{T}_h} + \|p\|_{s+1,\mathcal{T}_h} + \|\boldsymbol{g}\|_{s+\frac{1}{2},\mathcal{F}_h^{\mathcal{D}}}\Big],\end{aligned}$$

with $C > 0$ depending on the bounds (2.2) on the coefficients μ and ε, the shape-regularity of the mesh, the stabilization parameters α, β, and γ, and the polynomial degree ℓ but independent of the mesh size h.

REMARK 3.5. *The numerical results reported in section 7 show that, on a two-dimensional L-shaped domain, the above convergence rates are obtained also on nonconforming affine meshes for the strongest corner singularities.*

The mixed method in (2.5)–(2.6) enforces the divergence constraint in a weak sense only; nevertheless, the convergence rate of the error in the (elementwise) divergence might be of interest. Our last result addresses this issue and proves a rate that is of one order lower than the error measured in the DG-norm. This result is numerically observed to be sharp on conforming finite element meshes; cf. section 7.

THEOREM 3.6. *Let $(\boldsymbol{u},p)$ be the analytical solution of (2.1) and $(\boldsymbol{u}_h,p_h)$ be the mixed DG approximation obtained by (2.5)–(2.6) on a possibly nonconforming mesh satisfying restrictions* (i) *and* (ii) *above. Then we have*

$$\sum_{K\in\mathcal{T}_h} h_K^2\|\nabla\cdot(\varepsilon(\boldsymbol{u}-\boldsymbol{u}_h))\|_{0,K}^2 \le C\left[\|\mathtt{h}^{\frac{1}{2}}[\![\varepsilon\boldsymbol{u}-\varepsilon\boldsymbol{u}_h]\!]_N\|_{\mathcal{F}_h^{\mathcal{I}}}^2 + \|\mathtt{e}^{\frac{1}{2}}\mathtt{h}^{-\frac{1}{2}}[\![q-q_h]\!]_N\|_{0,\mathcal{F}_h}^2\right],$$

with $C > 0$ depending on the shape-regularity and bounded variation properties of the mesh, the stabilization parameter γ, and the polynomial degree ℓ but independent of the mesh size h.

REMARK 3.7. *Under the assumptions of both Theorem 3.3 and Theorem 3.4, the estimate in Theorem 3.6 implies that $[\sum_{K\in\mathcal{T}_h} h_K^2\|\nabla\cdot(\varepsilon(\boldsymbol{u}-\boldsymbol{u}_h))\|_{0,K}^2]^{\frac{1}{2}} \le C\,h^{\min\{s,\ell\}}$, with $C > 0$ independent of the mesh size.*

The proofs of Theorems 3.3, 3.4, and 3.6 are carried out in the next sections and concluded in sections 6.2 and 6.3.

4. Auxiliary mixed formulation. In order to facilitate the error analysis, we rewrite the discrete formulation (2.5)–(2.6) in a different (and perturbed) form by introducing the jumps of p_h as auxiliary unknowns and by employing lifting operators as in [5, 24]. In this way, the resulting bilinear forms have suitable continuity and coercivity properties so that the method can be analyzed using the classical theory of mixed finite methods. We begin by introducing the lifting operators $\mathcal{L}$ and $\mathcal{M}$. For $\boldsymbol{v}$ belonging to $\boldsymbol{V}(h)$ and $q \in Q(h)$, we define $\mathcal{L}(\boldsymbol{v}) \in \boldsymbol{V}_h$ and $\mathcal{M}(q) \in Q_h$ by

$$\int_\Omega \mathcal{L}(\boldsymbol{v})\cdot\boldsymbol{w}\,d\boldsymbol{x} = \int_{\mathcal{F}_h} [\![\boldsymbol{v}]\!]_T\cdot\{\!\{\boldsymbol{w}\}\!\}\,ds, \qquad \int_\Omega \mathcal{M}(q)\cdot\boldsymbol{w}\,d\boldsymbol{x} = \int_{\mathcal{F}_h}\{\!\{\boldsymbol{w}\}\!\}\cdot[\![q]\!]_N\,ds$$

for all $\boldsymbol{w} \in \boldsymbol{V}_h$. We then define the perturbed forms

$$\widetilde{a}_h(\boldsymbol{u},\boldsymbol{v}) = \int_\Omega \mu^{-1}\nabla_h \times \boldsymbol{u} \cdot \nabla_h \times \boldsymbol{v}\, d\boldsymbol{x} - \int_\Omega \mathcal{L}(\boldsymbol{u}) \cdot (\mu^{-1}\nabla_h \times \boldsymbol{v})\, d\boldsymbol{x} - \int_\Omega \mathcal{L}(\boldsymbol{v}) \cdot (\mu^{-1}\nabla_h \times \boldsymbol{u})\, d\boldsymbol{x} + \int_{\mathcal{F}_h} \mathtt{a}\, [\![\boldsymbol{u}]\!]_T \cdot [\![\boldsymbol{v}]\!]_T\, ds + \int_{\mathcal{F}_h^{\mathcal{I}}} \mathtt{b}\, [\![\varepsilon \boldsymbol{u}]\!]_N [\![\varepsilon \boldsymbol{v}]\!]_N\, ds,$$

$$\widetilde{b}_h(\boldsymbol{v},p) = -\int_\Omega \varepsilon \boldsymbol{v} \cdot \big[\nabla_h p - \mathcal{M}(p)\big]\, d\boldsymbol{x}.$$

Note that $a_h = \widetilde{a}_h$ in $\boldsymbol{V}_h \times \boldsymbol{V}_h$ and $b_h = \widetilde{b}_h$ in $\boldsymbol{V}_h \times Q_h$, although this is no longer true in $\boldsymbol{V}(h) \times \boldsymbol{V}(h)$ and $\boldsymbol{V}(h) \times Q(h)$, respectively.

Next, we define the discrete space

$$M_h = \{\lambda \in L^2(\mathcal{F}_h)^3 : \lambda|_f \in \mathcal{S}^\ell(f)^3 \quad \forall f \subset \mathcal{F}_h\},$$

endowed with the norm $\|\eta\|_{M_h} = \|\mathtt{e}^{\frac{1}{2}}\mathtt{h}^{-\frac{1}{2}}\eta\|_{0,\mathcal{F}_h}$, and consider the following auxiliary mixed formulation: find $(\boldsymbol{u}_h, \lambda_h, p_h) \in \boldsymbol{V}_h \times M_h \times Q_h$ such that

$$A_h(\boldsymbol{u}_h,\lambda_h;\boldsymbol{v},\eta) + B_h(\boldsymbol{v},\eta;p_h) = f_h(\boldsymbol{v}) \qquad \forall (\boldsymbol{v},\eta) \in \boldsymbol{V}_h \times M_h, \tag{4.1}$$

$$B_h(\boldsymbol{u}_h,\lambda_h;q) = 0 \qquad \forall q \in Q_h, \tag{4.2}$$

with forms A_h and B_h given, respectively, by

$$A_h(\boldsymbol{u},\lambda;\boldsymbol{v},\eta) = \widetilde{a}_h(\boldsymbol{u},\boldsymbol{v}) + \int_{\mathcal{F}_h} \mathtt{c}\lambda \cdot \eta\, ds, \quad B_h(\boldsymbol{v},\eta;p) = \widetilde{b}_h(\boldsymbol{v},p) - \int_{\mathcal{F}_h} \mathtt{c}[\![p]\!]_N \cdot \eta\, ds.$$

PROPOSITION 4.1. *Problem* (4.1)–(4.2) *admits a unique solution* $(\boldsymbol{u}_h, \lambda_h, p_h) \in \boldsymbol{V}_h \times M_h \times Q_h$, *with* $(\boldsymbol{u}_h, p_h)$ *the solution to* (2.5)–(2.6), *and* $\lambda_h = [\![p_h]\!]_N$.

Proof. By choosing test functions $(\boldsymbol{0}, \eta)$ in (4.1), we have

$$\int_{\mathcal{F}_h} \mathtt{c}\lambda_h \cdot \eta\, ds = \int_{\mathcal{F}_h} \mathtt{c}[\![p_h]\!]_N \cdot \eta\, ds \qquad \forall \eta \in M_h.$$

Since $\mathtt{c}$ is constant on each $f \in \mathcal{F}_h$, we have that $\lambda_h = [\![p_h]\!]_N$. Then (4.1) and (4.2) coincide with (2.5) and (2.6), respectively. Therefore, if $(\boldsymbol{u}_h, \lambda_h, p_h) \in \boldsymbol{V}_h \times M_h \times Q_h$ is a solution to (4.1)–(4.2), then $\lambda_h = [\![p_h]\!]_N$ and $(\boldsymbol{u}_h, p_h)$ is (the unique) solution to (2.5)–(2.6), which proves uniqueness of the solution. Existence follows from uniqueness. ∎

Finally, we introduce the space $\boldsymbol{W}(h) = \boldsymbol{V}(h) \times M_h$ and set

$$|(\boldsymbol{v},\eta)|^2_{\boldsymbol{W}(h)} = |\boldsymbol{v}|^2_{\boldsymbol{V}(h)} + \|\eta\|^2_{M_h}, \qquad \|(\boldsymbol{v},\eta)\|^2_{\boldsymbol{W}(h)} = \|\boldsymbol{v}\|^2_{\boldsymbol{V}(h)} + \|\eta\|^2_{M_h}.$$

The proofs of Theorems 3.3, 3.4, and 3.6 are now carried out by analyzing the auxiliary mixed formulation (4.1)–(4.2). In section 5 we prove the continuity of A_h and B_h, the ellipticity of A_h on the kernel of B_h, as well as the inf-sup condition for B_h. In the proof of the inf-sup condition, we employ a norm equivalence property. Then the error estimates of Theorems 3.3, 3.4, and 3.6 are obtained in section 6.

5. Continuity and stability. In this section, we prove continuity properties of the forms A_h and B_h, the ellipticity of A_h on the kernel of B_h, as well as the inf-sup condition for B_h.

5.1. Continuity properties. The following continuity properties hold.

PROPOSITION 5.1. *There exist constants $a_1 > 0$ and $a_2 > 0$, independent of the mesh size and the coefficients μ and ε, such that*

$$|A_h(\boldsymbol{u},\lambda;\boldsymbol{v},\eta)| \le a_1\,\|(\boldsymbol{u},\lambda)\|_{\boldsymbol{W}(h)}\|(\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)}, \qquad (\boldsymbol{u},\lambda),(\boldsymbol{v},\eta)\in\boldsymbol{W}(h),$$
$$|B_h(\boldsymbol{v},\eta;q)| \le a_2\,\|(\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)}\|q\|_{Q(h)}, \qquad (\boldsymbol{v},\eta)\in\boldsymbol{W}(h),\ q\in Q(h).$$

The linear functional $f_h : \boldsymbol{V}_h \to \mathbb{R}$ on the right-hand side of (4.1) *satisfies*

$$|f_h(\boldsymbol{v})| \le C\big[\varepsilon_*^{-\frac12}\|\boldsymbol{j}\|_{0,\Omega} + \|\mathtt{m}^{-\frac12}\mathtt{h}^{-\frac12}\boldsymbol{g}\|_{0,\Gamma}\big]\|\boldsymbol{v}\|_{\boldsymbol{V}(h)}, \qquad \boldsymbol{v}\in\boldsymbol{V}_h,$$

with a constant $C > 0$, independent of the mesh size and the coefficients μ and ε.

Proof. Proceeding as in [24, Proposition 4.2] or [25, Proposition 12], we have the following stability estimates for $\mathcal{L}$ and $\mathcal{M}$:

$$\|\mu^{-\frac12}\mathcal{L}(\boldsymbol{v})\|_{0,\Omega} \le C\|\mathtt{m}^{-\frac12}\mathtt{h}^{-\frac12}[\![\boldsymbol{v}]\!]_T\|_{0,\mathcal{F}_h}, \qquad \|\varepsilon^{\frac12}\mathcal{M}(q)\|_{0,\Omega} \le C\|\mathtt{e}^{\frac12}\mathtt{h}^{-\frac12}[\![q]\!]_N\|_{0,\mathcal{F}_h},$$

for any $\boldsymbol{v}\in\boldsymbol{V}(h)$, $q\in Q(h)$, with a constant $C > 0$ that is independent of the mesh size and the coefficients μ and ε. With these stability estimates, the continuity of A_h and B_h follows from the Cauchy–Schwarz inequality and the choice of the stabilization parameters in (3.1). The continuity of f_h is obtained by using similar arguments; see [24, Corollary 4.15] for details. ∎

5.2. Ellipticity on the kernel. Define the discrete kernel

$$\mathrm{Ker}(B_h) = \{(\boldsymbol{u},\lambda)\in\boldsymbol{W}_h : B_h(\boldsymbol{u},\lambda;p) = 0 \ \ \forall p\in Q_h\}.$$

PROPOSITION 5.2. *For $\alpha \ge \alpha_{\min}$, $\beta > 0$, $\gamma > 0$, there is a constant $b > 0$, independent of the mesh size, such that*

$$A_h(\boldsymbol{u},\lambda;\boldsymbol{u},\lambda) \ge b\,\|(\boldsymbol{u},\lambda)\|^2_{\boldsymbol{W}(h)} \quad \forall(\boldsymbol{u},\lambda)\in\mathrm{Ker}(B_h).$$

Proof. Throughout the proof, we denote by C any constant independent of the mesh size and the coefficients μ and ε and by C_m any constant that depends on the bounds (2.2) on the coefficients μ and ε but is independent of the mesh size.

From Lemma 3.1, we immediately have

$$A_h(\boldsymbol{u},\lambda;\boldsymbol{u},\lambda) \ge C\,|(\boldsymbol{u},\lambda)|^2_{\boldsymbol{W}(h)}, \qquad (\boldsymbol{u},\lambda)\in\boldsymbol{W}_h. \tag{5.1}$$

Now fix $(\boldsymbol{u},\lambda)\in\mathrm{Ker}(B_h)$, and let $(\boldsymbol{z},\psi)$ be the solution of the auxiliary problem

$$\nabla\times(\mu^{-1}\nabla\times\boldsymbol{z}) - \varepsilon\nabla\psi = \varepsilon\boldsymbol{u}, \qquad \nabla\cdot(\varepsilon\boldsymbol{z}) = 0 \qquad \text{in } \Omega,$$

subject to the boundary conditions $\boldsymbol{n}\times\boldsymbol{z} = \boldsymbol{0}$ and $\psi = 0$ on Γ. Thereby,

$$\begin{aligned}\|\mu^{-\frac12}\nabla\times\boldsymbol{z}\|_{0,\Omega} + \|\varepsilon^{\frac12}\boldsymbol{z}\|_{0,\Omega} + \|\nabla\times(\mu^{-1}\nabla\times\boldsymbol{z})\|_{0,\Omega}\\ + \|\varepsilon^{\frac12}\nabla\psi\|_{0,\Omega} + \|\varepsilon^{\frac12}\psi\|_{0,\Omega} \le C_m\|\varepsilon^{\frac12}\boldsymbol{u}\|_{0,\Omega}.\end{aligned} \tag{5.2}$$

Set $\boldsymbol{w} = \mu^{-1}\nabla\times\boldsymbol{z}$; clearly, $\boldsymbol{w}\in H(\mathrm{curl};\Omega)$. Therefore, from [16, Corollary 7.2], there exists $\boldsymbol{w}_0\in H^1(\Omega)^3$ such that

$$\nabla\times\boldsymbol{w}_0 = \nabla\times\boldsymbol{w}, \qquad \|\boldsymbol{w}_0\|_{1,\Omega} \le C\|\boldsymbol{w}\|_{H(\mathrm{curl};\Omega)} \le C_m\|\varepsilon^{\frac12}\boldsymbol{u}\|_{0,\Omega}. \tag{5.3}$$

Multiplying the first equation of the auxiliary problem by $\boldsymbol{u}$ and integrating by parts over each element, we get

$$\|\varepsilon^{\frac{1}{2}}\boldsymbol{u}\|_{0,\Omega}^2 = \int_\Omega \boldsymbol{w}_0 \cdot \nabla_h \times \boldsymbol{u}\, d\boldsymbol{x} - \int_{\mathcal{F}_h} \boldsymbol{w}_0 \cdot [\![\boldsymbol{u}]\!]_T\, ds + \int_\Omega \psi \nabla_h \cdot (\varepsilon \boldsymbol{u})\, d\boldsymbol{x} - \int_{\mathcal{F}_h^{\mathcal{I}}} \{\!\{\psi\}\!\} [\![\varepsilon \boldsymbol{u}]\!]_N\, ds.$$

Since $(\boldsymbol{u}, \lambda) \in \mathrm{Ker}(B_h)$, we have $B_h(\boldsymbol{u}, \lambda; \psi_h) = 0$ for any $\psi_h \in Q_h$ and obtain, from integration by parts and the fact that $[\![\psi]\!]_N = 0$ on $\mathcal{F}_h$,

$$\|\varepsilon^{\frac{1}{2}}\boldsymbol{u}\|_{0,\Omega}^2 = \int_\Omega \boldsymbol{w}_0 \cdot \nabla_h \times \boldsymbol{u}\, d\boldsymbol{x} - \int_{\mathcal{F}_h} \boldsymbol{w}_0 \cdot [\![\boldsymbol{u}]\!]_T\, ds + \int_\Omega (\psi - \psi_h) \nabla_h \cdot (\varepsilon \boldsymbol{u})\, d\boldsymbol{x} - \int_{\mathcal{F}_h^{\mathcal{I}}} \{\!\{\psi - \psi_h\}\!\} [\![\varepsilon \boldsymbol{u}]\!]_N\, ds - \int_{\mathcal{F}_h} \mathtt{eh}^{-1} \lambda \cdot [\![\psi - \psi_h]\!]_N\, ds.$$

Using (2.2) and (5.3), we have

$$\left| \int_\Omega \boldsymbol{w}_0 \cdot \nabla_h \times \boldsymbol{u}\, d\boldsymbol{x} \right| \le C_m \|\boldsymbol{w}_0\|_{1,\Omega} \|\mu^{-\frac{1}{2}} \nabla_h \times \boldsymbol{u}\|_{0,\Omega} \le C_m \|\varepsilon^{\frac{1}{2}}\boldsymbol{u}\|_{0,\Omega} |\boldsymbol{u}|_{\boldsymbol{V}(h)}.$$

Furthermore, using trace inequalities, (2.2) and (5.3), we obtain

$$\begin{aligned}\left| \int_{\mathcal{F}_h} \boldsymbol{w}_0 \cdot [\![\boldsymbol{u}]\!]_T\, ds \right| &\le C \left(\sum_{K \in \mathcal{T}_h} h_K \mu_K \|\boldsymbol{w}_0\|_{0,\partial K}^2 \right)^{\frac{1}{2}} \|\mathtt{m}^{-\frac{1}{2}} \mathtt{h}^{-\frac{1}{2}} [\![\boldsymbol{u}]\!]_T\|_{0,\mathcal{F}_h} \\ &\le C_m \|\boldsymbol{w}_0\|_{1,\Omega} \|\mathtt{m}^{-\frac{1}{2}} \mathtt{h}^{-\frac{1}{2}} [\![\boldsymbol{u}]\!]_T\|_{0,\mathcal{F}_h} \le C_m \|\varepsilon^{\frac{1}{2}}\boldsymbol{u}\|_{0,\Omega} |\boldsymbol{u}|_{\boldsymbol{V}(h)}.\end{aligned}$$

For the other terms, we choose ψ_h as the L^2-projection of ψ on Q_h. Since ε is piecewise constant, we have $\int_\Omega (\psi - \psi_h) \nabla_h \cdot (\varepsilon \boldsymbol{u})\, d\boldsymbol{x} = 0$. Then, using the Cauchy–Schwarz inequality, the definition of $\mathtt{e}$, and standard approximation properties of the L^2-projection, we obtain

$$\begin{aligned}\left| \int_{\mathcal{F}_h^{\mathcal{I}}} \{\!\{\psi - \psi_h\}\!\} [\![\varepsilon \boldsymbol{u}]\!]_N\, ds \right| &\le C \left(\sum_{K \in \mathcal{T}_h} \varepsilon_K h_K^{-1} \|\psi - \psi_h\|_{0,\partial K}^2 \right)^{\frac{1}{2}} |\boldsymbol{u}|_{\boldsymbol{V}(h)} \\ &\le C \left(\sum_{K \in \mathcal{T}_h} \varepsilon_K \|\nabla \psi\|_{0,K}^2 + \varepsilon_K \|\psi\|_{0,K}^2 \right)^{\frac{1}{2}} |\boldsymbol{u}|_{\boldsymbol{V}(h)} \le C_m \|\varepsilon^{\frac{1}{2}}\boldsymbol{u}\|_{0,\Omega} |\boldsymbol{u}|_{\boldsymbol{V}(h)}.\end{aligned}$$

Similarly,

$$\begin{aligned}\left| \int_{\mathcal{F}_h} \mathtt{eh}^{-1} \lambda \cdot [\![\psi - \psi_h]\!]_N\, ds \right| &\le C \left(\sum_{K \in \mathcal{T}_h} \varepsilon_K h_K^{-1} \|\psi - \psi_h\|_{0,\partial K}^2 \right)^{\frac{1}{2}} \left(\int_{\mathcal{F}_h} \mathtt{eh}^{-1} \lambda^2\, ds \right)^{\frac{1}{2}} \\ &\le C_m \|\varepsilon^{\frac{1}{2}}\boldsymbol{u}\|_{0,\Omega} \|\lambda\|_{M_h}.\end{aligned}$$

The above computations show that $\|\varepsilon^{\frac{1}{2}}\boldsymbol{u}\|_{0,\Omega} \le C_m\, |(\boldsymbol{u}, \lambda)|_{\boldsymbol{W}(h)}$. Combining this with (5.1) and the definition of $\|(\boldsymbol{u}, \lambda)\|_{\boldsymbol{W}(h)}$ completes the proof. ∎

5.3. Inf-sup condition. In this section, we prove the inf-sup condition for the form B_h. Our proof is inspired by recent ideas from [8] used in the analysis of stabilized mixed methods. We will make use of the following crucial norm equivalence result. To this end, let Q_h^c be the subspace $Q_h \cap H_0^1(\Omega)$ of Q_h, and let $Q_h^\perp$ be the orthogonal complement in Q_h of Q_h^c, with respect to the norm $\|\cdot\|_{Q(h)}$. We observe that $\|q\|_{Q_h^\perp} = \|\mathtt{e}^{\frac{1}{2}}\mathtt{h}^{-\frac{1}{2}}[\![q]\!]_N\|_{0,\mathcal{F}_h}$ is a norm on $Q_h^\perp$. Indeed, if $q \in Q_h^\perp$ and $\|q\|_{Q_h^\perp} = 0$, then $q \in Q_h^\perp \cap Q_h^c = \{0\}$. The norms $\|\cdot\|_{Q_h^\perp}$ and $\|\cdot\|_{Q(h)}$ are equivalent in $Q_h^\perp$.

THEOREM 5.3. *There are positive constants C_1 and C_2, independent of the mesh size and the coefficients μ and ε, such that $C_1\,\|q\|_{Q(h)} \le \|q\|_{Q_h^\perp} \le C_2\,\|q\|_{Q(h)}$ for any $q \in Q_h^\perp$.*

Proof. Step 1. The following approximation result holds: for any $q \in Q_h$,

$$\inf_{q^c \in Q_h^c} \|\varepsilon^{\frac{1}{2}}\nabla_h(q - q^c)\|_{0,\Omega} \le C\|\mathtt{e}^{\frac{1}{2}}\mathtt{h}^{-\frac{1}{2}}[\![q]\!]_N\|_{0,\mathcal{F}_h}, \tag{5.4}$$

with a constant $C > 0$ independent of the mesh size and the coefficients μ and ε. This result has been proved in [21, Theorems 2.2 and 2.3] for simplicial meshes. The proof there can be easily generalized to the meshes considered in this paper and readily gives the independence of the constant on the coefficients μ and ε; we refer the reader to [18, Appendix A] for these technical details.

Step 2. The inequality on the right-hand side of the norm equivalence is trivially satisfied with $C_2 = 1$. To show the bound on the left-hand side, let $P_h : Q_h \to Q_h^\perp$ denote the $Q(h)$-orthogonal projection. For $q \in Q_h$, we then have $\|P_h q\|_{Q(h)} = \inf_{\overline{q} \in Q_h^c} \|q - \overline{q}\|_{Q(h)} \le C\|P_h q\|_{Q_h^\perp}$. Here, we have used properties of orthogonal projections, the approximation result (5.4), the fact that $[\![q]\!]_N = [\![P_h q]\!]_N$, and the definition of $\|\cdot\|_{Q_h^\perp}$. Since P_h is surjective, the equivalence follows. ∎

Our main result of this section is the following inf-sup condition.

PROPOSITION 5.4. *We have*

$$\inf_{0 \ne q \in Q_h} \sup_{\mathbf{0} \ne (\boldsymbol{v},\nu) \in \boldsymbol{W}_h} \frac{B_h(\boldsymbol{v}, \nu; q)}{\|q\|_{Q(h)}\|(\boldsymbol{v},\nu)\|_{\boldsymbol{W}(h)}} \ge \kappa > 0,$$

for a constant κ, independent of the mesh size and the coefficients μ and ε.

Proof. Fix $0 \ne q \in Q_h$ arbitrary and consider its $Q(h)$-orthogonal decomposition as $q = q_0 \oplus q_1$, with $q_0 \in Q_h^c$ and $q_1 \in Q_h^\perp$. By choosing $\boldsymbol{v}_0 = -\nabla q_0 \in \boldsymbol{V}_h \cap H(\mathrm{curl}^0;\Omega) \cap H_0(\mathrm{curl};\Omega)$, we have

$$B_h(\boldsymbol{v}_0, 0; q_0) = \|\varepsilon^{\frac{1}{2}}\nabla q_0\|_{0,\Omega}^2 = \|q_0\|_{Q(h)}^2. \tag{5.5}$$

Furthermore, by the definition of $\mathtt{e}$,

$$\begin{aligned} \|(\boldsymbol{v}_0, 0)\|_{\boldsymbol{W}(h)}^2 &= \|\mathtt{e}^{-\frac{1}{2}}\mathtt{h}^{\frac{1}{2}}[\![\varepsilon \boldsymbol{v}_0]\!]_N\|_{0,\mathcal{F}_h^{\mathcal{I}}}^2 + \|\varepsilon^{\frac{1}{2}}\boldsymbol{v}_0\|_{0,\Omega}^2 \\ &\le C \sum_{K \in \mathcal{T}_h} \varepsilon_K h_K \|\nabla q_0\|_{0,\partial K}^2 + \|\varepsilon^{\frac{1}{2}}\nabla q_0\|_{0,\Omega}^2 \le C\|\varepsilon^{\frac{1}{2}}\nabla q_0\|_{0,\Omega}^2 = C\|q_0\|_{Q(h)}^2. \end{aligned} \tag{5.6}$$

Here, we have used the discrete trace inequality $\|\nabla\varphi\|_{0,\partial K} \le C h_K^{-\frac{1}{2}}\|\nabla\varphi\|_{0,K}$, valid for polynomials $\varphi \in \mathcal{S}^\ell(K)$, with a constant $C > 0$ that is independent of the local mesh size h_K. Next, setting $\nu_1 = -[\![q_1]\!]_N$ gives

$$B_h(\mathbf{0}, \nu_1; q_1) = \gamma \int_{\mathcal{F}_h} \mathtt{e}\mathtt{h}^{-1}[\![q_1]\!]_N^2\, ds \ge \gamma C_1^2 \|q_1\|_{Q(h)}^2, \quad \|(\mathbf{0}, \nu_1)\|_{\boldsymbol{W}(h)} \le C_2\|q_1\|_{Q(h)}, \tag{5.7}$$

where C_1 and C_2 are the constants in the norm equivalence of Theorem 5.3.

Then we set $(\boldsymbol{v},\nu) = (\boldsymbol{v}_0,0)+\delta(\boldsymbol{0},\nu_1)$, with a parameter $\delta>0$ still at our disposal. Since $B_h(\boldsymbol{0},\nu_1;q_0)=0$, we obtain from (5.5) and (5.7)

$$\begin{aligned} B_h(\boldsymbol{v},\nu;q) &= B_h(\boldsymbol{v}_0,0;q_0) + B_h(\boldsymbol{v}_0,0;q_1) + \delta B_h(\boldsymbol{0},\nu_1;q_1) \\ &\geq \|q_0\|^2_{Q(h)} + \delta\gamma C_1^2 \|q_1\|^2_{Q(h)} - |B_h(\boldsymbol{v}_0,0;q_1)|. \end{aligned}$$

Combining the continuity of B_h (see Proposition 5.1) with a weighted Cauchy–Schwarz inequality and (5.6), we obtain, for any $\zeta>0$,

$$|B_h(\boldsymbol{v}_0,0;q_1)| \leq C\zeta \|\boldsymbol{v}_0\|^2_{\boldsymbol{V}(h)} + \frac{C}{\zeta}\|q_1\|^2_{Q(h)} \leq C\zeta\|q_0\|^2_{Q(h)} + \frac{C}{\zeta}\|q_1\|^2_{Q(h)}.$$

Hence, by suitably choosing δ and ζ, we have

$$B_h(\boldsymbol{v},\nu;q) \geq \kappa_1\big[\|q_0\|^2_{Q(h)} + \|q_1\|^2_{Q(h)}\big] = \kappa_1\|q\|^2_{Q(h)}, \tag{5.8}$$

where we used the orthogonality of the decomposition of q. From (5.6) and (5.7),

$$\|(\boldsymbol{v},\nu)\|_{\boldsymbol{W}(h)} \leq \kappa_2\|q\|_{Q(h)}. \tag{5.9}$$

The constants κ_1 and κ_2 in (5.8) and (5.9) are independent of the mesh size and the coefficients μ and ε. The proposition follows from (5.8) and (5.9), with $\kappa=\kappa_1/\kappa_2$. ∎

6. Error estimates. In this section, we prove the error estimates stated in Theorems 3.3, 3.4, and 3.6.

6.1. Abstract error estimates. We start by deriving abstract error bounds. To this end, for the analytical solution $(\boldsymbol{u},p)$ to (2.3)–(2.4), we define the residuals

$$R^1_h(\boldsymbol{u},p;\boldsymbol{v},\nu) = A_h(\boldsymbol{u},0;\boldsymbol{v},\nu) + B_h(\boldsymbol{v},\nu;p) - f_h(\boldsymbol{v}) \quad \text{and} \quad R^2_h(\boldsymbol{u};q) = B_h(\boldsymbol{u},0;q)$$

for all $(\boldsymbol{v},\nu)\in\boldsymbol{W}_h$ and $q\in Q_h$ and set

$$\mathcal{R}^1_h(\boldsymbol{u},p) = \sup_{\boldsymbol{0}\neq(\boldsymbol{v},\nu)\in\boldsymbol{W}_h} \frac{|R^1_h(\boldsymbol{u},p;\boldsymbol{v},\nu)|}{\|(\boldsymbol{v},\nu)\|_{\boldsymbol{W}(h)}}, \qquad \mathcal{R}^2_h(\boldsymbol{u}) = \sup_{0\neq q\in Q_h} \frac{|R^2_h(\boldsymbol{u};q)|}{\|q\|_{Q(h)}}.$$

In the following theorem we present abstract error estimates for our DG method. These error bounds are obtained by extending the standard conforming mixed finite element theory [7] to the setting considered here and taking into account the residual terms arising from the nonconsistency of the perturbed formulation.

THEOREM 6.1. *There exist positive constants C such that*

$$\begin{aligned} \|(\boldsymbol{u}-\boldsymbol{u}_h,\lambda_h)\|_{\boldsymbol{W}(h)} \leq C\max\{1,b^{-1}\}\Big[&\inf_{\boldsymbol{v}\in\boldsymbol{V}_h}\|\boldsymbol{u}-\boldsymbol{v}\|_{\boldsymbol{V}(h)} \\ &+ \inf_{q\in Q_h}\|p-q\|_{Q(h)} + \mathcal{R}^1_h(\boldsymbol{u},p) + \mathcal{R}^2_h(\boldsymbol{u})\Big], \\ \|p-p_h\|_{Q(h)} \leq C\Big[&\inf_{q\in Q_h}\|p-q\|_{Q(h)} + \|(\boldsymbol{u}-\boldsymbol{u}_h,\lambda_h)\|_{\boldsymbol{W}(h)} + \mathcal{R}^1_h(\boldsymbol{u},p)\Big]. \end{aligned}$$

Here, b, the ellipticity constant from Proposition 5.2*, depends on the bounds in* (2.2) *but is independent of the mesh size. The constants C depend on the continuity constants a_1 and a_2 in Proposition* 5.1 *and the inf-sup constant κ from Proposition* 5.4 *but are independent of the mesh size and the coefficients μ and ε.*

Proof. By the triangle inequality and the definition of $\|(\cdot,\cdot)\|_{\boldsymbol{W}(h)}$, we have

$$\|(\boldsymbol{u}-\boldsymbol{u}_h,\lambda_h)\|_{\boldsymbol{W}(h)} \le \|(\boldsymbol{u}-\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)} + \|(\boldsymbol{v}-\boldsymbol{u}_h,\eta-\lambda_h)\|_{\boldsymbol{W}(h)} \tag{6.1}$$

for any $(\boldsymbol{v},\eta)\in\boldsymbol{W}_h$. First, we take $(\boldsymbol{v},\eta)\in\mathrm{Ker}(\mathrm{B_h})$. Since $(\boldsymbol{v}-\boldsymbol{u}_h,\eta-\lambda_h)\in\mathrm{Ker}(\mathrm{B_h})$, employing the ellipticity property of Proposition 5.2 and the definition of R_h^1, we have

$$\begin{aligned} b\|(\boldsymbol{v}-\boldsymbol{u}_h,\eta-\lambda_h)\|^2_{\boldsymbol{W}(h)} &\le A_h(\boldsymbol{v}-\boldsymbol{u}_h,\eta-\lambda_h;\boldsymbol{v}-\boldsymbol{u}_h,\eta-\lambda_h)\\ &= A_h(\boldsymbol{v}-\boldsymbol{u},\eta;\boldsymbol{v}-\boldsymbol{u}_h,\eta-\lambda_h)\\ &\quad - B_h(\boldsymbol{v}-\boldsymbol{u}_h,\eta-\lambda_h;p-q) + R_h^1(\boldsymbol{u},p;\boldsymbol{v}-\boldsymbol{u}_h,\eta-\lambda_h) \end{aligned}$$

for any $q\in Q_h$. From the continuity properties of Proposition 5.1, the definition of the norm $\|(\cdot,\cdot)\|_{\boldsymbol{W}(h)}$, and (6.1), we have

$$\begin{aligned} \|(\boldsymbol{u}-\boldsymbol{u}_h,\lambda_h)\|_{\boldsymbol{W}(h)} &\le \Big(1+\frac{a_1}{b}\Big)\inf_{(\boldsymbol{v},\eta)\in\mathrm{Ker}(\mathrm{B_h})}\|(\boldsymbol{u}-\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)}\\ &\quad + \frac{a_2}{b}\inf_{q\in Q_h}\|p-q\|_{Q(h)} + \frac{1}{b}\mathcal{R}_h^1(\boldsymbol{u},p). \end{aligned} \tag{6.2}$$

Next, we prove that

$$\inf_{(\boldsymbol{v},\eta)\in\mathrm{Ker}(\mathrm{B_h})}\|(\boldsymbol{u}-\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)} \le \Big(1+\frac{a_2}{\kappa}\Big)\inf_{(\boldsymbol{v},\eta)\in\boldsymbol{W}_h}\|(\boldsymbol{u}-\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)} + \frac{1}{\kappa}\mathcal{R}_h^2(\boldsymbol{u}). \tag{6.3}$$

To this end, let $(\boldsymbol{v},\eta)$ be any element of $\boldsymbol{W}_h$, and consider the following problem: find $(\boldsymbol{w},\nu)\in\boldsymbol{W}_h$ such that

$$B_h(\boldsymbol{w},\nu;q) = B_h(\boldsymbol{u}-\boldsymbol{v},-\eta;q) - R_h^2(\boldsymbol{u},q) \qquad \forall q\in Q_h. \tag{6.4}$$

Problem (6.4) admits solutions in $\boldsymbol{W}_h$ that are unique up to elements in the kernel of B_h. The discrete inf-sup condition of Proposition 5.4 guarantees the existence of a solution $(\boldsymbol{w},\nu)$ satisfying

$$\begin{aligned} \|(\boldsymbol{w},\nu)\|_{\boldsymbol{W}(h)} &\le \frac{1}{\kappa}\Big[\sup_{q\in Q_h}\frac{|B_h(\boldsymbol{u}-\boldsymbol{v},-\eta;q)|}{\|q\|_{Q(h)}} + \sup_{q\in Q_h}\frac{|R_h^2(\boldsymbol{u},q)|}{\|q\|_{Q(h)}}\Big]\\ &\le \frac{a_2}{\kappa}\|(\boldsymbol{u}-\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)} + \frac{1}{\kappa}\mathcal{R}_h^2(\boldsymbol{u}), \end{aligned} \tag{6.5}$$

where we have used the continuity of B_h, the definition of the norm $\|(\cdot,\cdot)\|_{\boldsymbol{W}(h)}$, and the definition of $\mathcal{R}_h^2$. From (6.4), $B_h(\boldsymbol{w}+\boldsymbol{v},\nu+\eta;q)=0$, for any $q\in Q_h$, so that $(\boldsymbol{w}+\boldsymbol{v},\nu+\eta)\in\mathrm{Ker}(B_h)$. Therefore, since

$$\|(\boldsymbol{u}-(\boldsymbol{v}+\boldsymbol{w}),\eta+\nu)\|_{\boldsymbol{W}(h)} \le \|(\boldsymbol{u}-\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)} + \|(\boldsymbol{w},\nu)\|_{\boldsymbol{W}(h)},$$

for any $(\boldsymbol{v},\eta)\in\boldsymbol{W}_h$, taking into account (6.5), we obtain (6.3). This, together with (6.2), yields

$$\begin{aligned} \|(\boldsymbol{u}-\boldsymbol{u}_h,\lambda_h)\|_{\boldsymbol{W}(h)} \le C\max\{1,b^{-1}\}\Big[&\inf_{(\boldsymbol{v},\eta)\in\boldsymbol{W}_h}\|(\boldsymbol{u}-\boldsymbol{v},\eta)\|_{\boldsymbol{W}(h)}\\ &+ \inf_{q\in Q_h}\|p-q\|_{Q(h)} + \mathcal{R}_h^1(\boldsymbol{u},p) + \mathcal{R}_h^2(\boldsymbol{u})\Big], \end{aligned}$$

where the constant C depends on a_1, a_2, and κ. Choosing $\eta = 0$ gives the error bound for $(\boldsymbol{u} - \boldsymbol{u}_h, \lambda_h)$.

We now turn to the bound for $p - p_h$. Again by the triangle inequality, we have

$$\|p - p_h\|_{Q(h)} \leq \|p - q\|_{Q(h)} + \|q - p_h\|_{Q(h)} \tag{6.6}$$

for any $q_h \in Q_h$. Since

$$A_h(\boldsymbol{u} - \boldsymbol{u}_h, -\lambda_h; \boldsymbol{v}, \eta) + B_h(\boldsymbol{v}, \eta; p - q) + B_h(\boldsymbol{v}, \eta; q - p_h) = R_h^1(\boldsymbol{u}, p; \boldsymbol{v}, \eta),$$

for any $(\boldsymbol{v}, \eta) \in \boldsymbol{W}_h$, the discrete inf-sup condition of Proposition 5.4 gives

$$\begin{aligned}
\|q - p_h\|_{Q(h)} &\leq \frac{1}{\kappa} \sup_{(\boldsymbol{0},0) \neq (\boldsymbol{v},\eta) \in \boldsymbol{W}_h} \frac{B_h(\boldsymbol{v}, \eta; q - p_h)}{\|(\boldsymbol{v}, \eta)\|_{\boldsymbol{W}(h)}} \\
&= \frac{1}{\kappa} \sup_{(\boldsymbol{0},0) \neq (\boldsymbol{v},\eta) \in \boldsymbol{W}_h} \frac{-A_h(\boldsymbol{u} - \boldsymbol{u}_h, -\lambda_h; \boldsymbol{v}, \eta) - B_h(\boldsymbol{v}, \eta; p - q) + R_h^1(\boldsymbol{u}, p; \boldsymbol{v}, \eta)}{\|(\boldsymbol{v}, \eta)\|_{\boldsymbol{W}(h)}} \\
&\leq \frac{a_1}{\kappa} \|(\boldsymbol{u} - \boldsymbol{u}_h, \lambda_h)\|_{\boldsymbol{W}(h)} + \frac{a_2}{\kappa} \|p - q\|_{Q(h)} + \frac{1}{\kappa} \mathcal{R}_h^1(\boldsymbol{u}, p).
\end{aligned}$$

This, together with (6.6), gives the bound for $p - p_h$. ∎

6.2. Proof of Theorems 3.3 and 3.4. We are now ready to prove our main results by making explicit the abstract error estimates of Theorem 6.1. First, we derive bounds on the residuals; we note that the residuals are optimally convergent on possibly nonconforming meshes under minimal smoothness assumptions as in Theorem 3.4, thereby covering both the cases of Theorems 3.3 and 3.4.

PROPOSITION 6.2. *Let $\mathcal{T}_h$ be a possibly nonconforming mesh satisfying restrictions* (i) *and* (ii) *in section* 3.3. *Assume the analytical solution $(\boldsymbol{u}, p)$ of* (2.1) *satisfies $\varepsilon \boldsymbol{u} \in H^s(\mathcal{T}_h)^3$ and $\mu^{-1} \nabla \times \boldsymbol{u} \in H^s(\mathcal{T}_h)^3$ for $s > \frac{1}{2}$. Then we have*

$$\mathcal{R}_h^1(\boldsymbol{u}, p) + \mathcal{R}_h^2(\boldsymbol{u}) \leq C h^{\min\{s, \ell+1\}} \big[\|\varepsilon \boldsymbol{u}\|_{s, \mathcal{T}_h} + \|\mu^{-1} \nabla \times \boldsymbol{u}\|_{s, \mathcal{T}_h} \big],$$

with a constant $C > 0$, independent of the mesh size.

Proof. First, for $\boldsymbol{v} \in \boldsymbol{V}_h$, $\eta \in M_h$, we have

$$|R_h^1(\boldsymbol{u}, p; \boldsymbol{v}, \eta)| = \left| \int_{\mathcal{F}_h} \{\!\{ \mu^{-1} \nabla \times \boldsymbol{u} - \boldsymbol{\Pi}_{\boldsymbol{V}_h} (\mu^{-1} \nabla \times \boldsymbol{u}) \}\!\} \cdot [\![\boldsymbol{v}]\!]_T \, ds \right|,$$

with $\boldsymbol{\Pi}_{\boldsymbol{V}_h}$ denoting the L^2-projection onto $\boldsymbol{V}_h$. This can be easily proved by employing integration by parts, the properties of the L^2-projection, and taking into account the first equation in (2.1). From the Cauchy–Schwarz inequality and standard approximation properties, we obtain

$$\begin{aligned}
|R_h^1(\boldsymbol{u}, \lambda, p; \boldsymbol{v}, \eta)| &\leq C \left(\sum_{K \in \mathcal{T}_h} h_K \|\mu^{-1} \nabla \times \boldsymbol{u} - \boldsymbol{\Pi}_{\boldsymbol{V}_h} (\mu^{-1} \nabla \times \boldsymbol{u})\|_{0, \partial K}^2 \right)^{\frac{1}{2}} \|(\boldsymbol{v}, \eta)\|_{\boldsymbol{W}(h)} \\
&\leq C h^{\min\{s, \ell+1\}} \|\mu^{-1} \nabla \times \boldsymbol{u}\|_{s, \mathcal{T}_h} \|(\boldsymbol{v}, \eta)\|_{\boldsymbol{W}(h)}.
\end{aligned}$$

Furthermore, for $q \in Q_h$,

$$|R_h^2(\boldsymbol{u}; q)| = \left| \int_{\mathcal{F}_h} \{\!\{ \varepsilon \boldsymbol{u} - \boldsymbol{\Pi}_{\boldsymbol{V}_h} (\varepsilon \boldsymbol{u}) \}\!\} \cdot [\![q]\!]_N \, ds \right|.$$

Hence,

$$|R_h^2(\boldsymbol{u};q)| \le C\left(\sum_{K\in\mathcal{T}_h} h_K \|\varepsilon\boldsymbol{u} - \boldsymbol{\Pi}_{\boldsymbol{V}_h}(\varepsilon\boldsymbol{u})\|_{0,\partial K}^2\right)^{\frac{1}{2}} \|q\|_{Q(h)} \le C h^{\min\{s,\ell+1\}} \|\varepsilon\boldsymbol{u}\|_{s,\mathcal{T}_h} \|q\|_{Q(h)}.$$

This completes the proof (the constant C in these estimates actually depends on the bound (2.2) on the coefficients μ and ε). ∎

Next, we prove the result of Theorems 3.3 and 3.4.

Proof of Theorem 3.3. Let $(\boldsymbol{u}_h, p_h, \lambda_h)$ be the solution of the auxiliary mixed system in (4.1)–(4.2). We apply Theorem 6.1 and bound all the terms in the abstract error bounds there. To this end, we set $\boldsymbol{v} = \boldsymbol{\Pi}_{\boldsymbol{V}_h}\boldsymbol{u}$ and $q = \Pi_{Q_h} p$, with $\boldsymbol{\Pi}_{\boldsymbol{V}_h}$ and Π_{Q_h} denoting the L^2-projections onto $\boldsymbol{V}_h$ and Q_h, respectively. Standard approximation properties, together with the bounded variation of the mesh size, give $\|\boldsymbol{u} - \boldsymbol{\Pi}_{\boldsymbol{V}_h}\boldsymbol{u}\|_{\boldsymbol{V}(h)} \le C\, h^{\min\{s,\ell\}} \|\boldsymbol{u}\|_{s+1,\mathcal{T}_h}$. The additional smoothness assumption on $\boldsymbol{u}$ made in this case is required for the estimate of the term containing the tangential jumps. Similarly, we have $\|p - \Pi_{Q_h} p\|_{Q(h)} \le C\, h^{\min\{s,\ell\}} \|p\|_{s+1,\mathcal{T}_h}$. The constants C in the previous estimates depend on the bounds (2.2) on the coefficients μ and ε. Inserting these estimates, together with the residual estimates of Proposition 6.2, in Theorem 6.1 gives the result. ∎

Proof of Theorem 3.4. Let $(\boldsymbol{u}_h, p_h, \lambda_h)$ be the solution of the auxiliary mixed system in (4.1)–(4.2). As in the proof of Theorem 3.3, we apply Theorem 6.1. On conforming meshes, we can choose $\boldsymbol{v} = \boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u} \in H(\mathrm{curl};\Omega)$ as the standard conforming Nédélec interpolant of $\boldsymbol{u}$ of the second type; see [23]. Thereby, we have $[\![\boldsymbol{v}]\!]_T = \boldsymbol{0}$ on $\mathcal{F}_h^{\mathcal{I}}$, and from the approximation results proved in [2] for tetrahedra, but also valid for parallelepipeds, we get

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u}\|_{0,K} + \|\nabla\times(\boldsymbol{u} - \boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u})\|_{0,K} \le C\, h_K^{\min\{s,\ell\}} \big[\|\boldsymbol{u}\|_{s,K} + \|\nabla\times\boldsymbol{u}\|_{s,K}\big].$$

Hence,

$$\begin{aligned}\|\varepsilon^{\frac{1}{2}}(\boldsymbol{u} - \boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u})\|_{0,\Omega} + \|\mu^{-\frac{1}{2}}\nabla\times(\boldsymbol{u} - \boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u})\|_{0,\Omega} \\ \le\ C\, h^{\min\{s,\ell\}} \big[\|\varepsilon\boldsymbol{u}\|_{s,\mathcal{T}_h} + \|\mu^{-1}\nabla\times\boldsymbol{u}\|_{s,\mathcal{T}_h}\big],\end{aligned} \tag{6.7}$$

with C also depending on the bounds (2.2) on the coefficients μ and ε. On a boundary face $f \subset \mathcal{F}_h^{\mathcal{D}}$, the tangential field $\boldsymbol{n}\times\boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u}$ coincides with $\boldsymbol{\Pi}_{\mathrm{div}}(\boldsymbol{n}\times\boldsymbol{u})$, where $\boldsymbol{\Pi}_{\mathrm{div}}$ is the two-dimensional $H(\mathrm{div})$-conforming Nédélec interpolation operator of the second type. In particular, $\boldsymbol{\Pi}_{\mathrm{div}}$ reproduces polynomial tangential fields of degree ℓ on f; see [23] for details. From a standard scaling argument, we obtain

$$\|\boldsymbol{n}\times(\boldsymbol{u} - \boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u})\|_{0,f} \le C\, \mathtt{h}_{|f}^{\min\{s,\ell\}+\frac{1}{2}} \|\boldsymbol{g}\|_{s+\frac{1}{2},f}.$$

Therefore, summing over all faces yields

$$\|\mathtt{m}^{-\frac{1}{2}}\mathtt{h}^{-\frac{1}{2}}(\boldsymbol{n}\times\boldsymbol{u} - \boldsymbol{\Pi}_{\mathrm{curl}}(\boldsymbol{n}\times\boldsymbol{u}))\|_{0,\mathcal{F}_h^{\mathcal{D}}} \le C\, h^{\min\{s,\ell\}} \|\boldsymbol{g}\|_{s+\frac{1}{2},\mathcal{F}_h^{\mathcal{D}}}. \tag{6.8}$$

Moreover, since $\boldsymbol{u} \in H(\mathrm{div}_\varepsilon^0;\Omega)$, we have for an interior face f, shared by K_f and K_f',

$$\|\mathtt{e}^{-\frac{1}{2}}\mathtt{h}^{\frac{1}{2}}[\![\varepsilon(\boldsymbol{u} - \boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u})]\!]_N\|_{0,f} \le C\, h^{\min\{s,\ell\}} \big[\|\boldsymbol{u}\|_{s,K_f\cup K_f'} + \|\nabla\times\boldsymbol{u}\|_{s,K_f\cup K_f'}\big].$$

This bound follows from [25, Lemma 23]. Hence,

$$\|\mathtt{e}^{-\frac{1}{2}}\mathtt{h}^{\frac{1}{2}}[\![\varepsilon(\boldsymbol{u} - \boldsymbol{\Pi}_{\mathrm{curl}}\boldsymbol{u})]\!]_N\|_{0,\mathcal{F}_h^{\mathcal{I}}} \le C\, \big[\|\varepsilon\boldsymbol{u}\|_{s,\mathcal{T}_h} + \|\mu^{-1}\nabla\times\boldsymbol{u}\|_{s,\mathcal{T}_h}\big]. \tag{6.9}$$

Moreover, choosing $q = \Pi_{H^1} p$ in Theorem 6.1, where Π_{H^1} is a standard H^1-projector, we have $[\![q]\!]_N = 0$ on $\mathcal{F}_h$ and

$$\|p - \Pi_{H^1} p\|_{Q(h)} \leq C\, h^{\min\{s,\ell\}} \|p\|_{s+1,\mathcal{T}_h}. \tag{6.10}$$

Combining (6.7)–(6.10) with the residual estimates in Proposition 6.2 yields

$$\begin{aligned}\inf_{\boldsymbol{v}\in\boldsymbol{V}_h} \|\boldsymbol{u}-\boldsymbol{v}\|_{\boldsymbol{V}(h)} + \inf_{q\in Q_h} \|p-q\|_{Q(h)} + \mathcal{R}_h^1(\boldsymbol{u},p) + \mathcal{R}_h^2(\boldsymbol{u}) \\ \leq C\, h^{\min\{s,\ell\}} \left[\|\varepsilon\boldsymbol{u}\|_{s,\mathcal{T}_h} + \|\mu^{-1}\nabla\times\boldsymbol{u}\|_{s,\mathcal{T}_h} + \|p\|_{s+1,\mathcal{T}_h} + \|\boldsymbol{g}\|_{s+\frac{1}{2},\mathcal{F}_h^{\mathcal{D}}}\right],\end{aligned}$$

with C also depending on the bounds (2.2) on the coefficients μ and ε. Combining these estimates with the residual estimates of Proposition 6.2 gives the result. ∎

6.3. Proof of Theorem 3.6. To prove Theorem 3.6, we first recall that

$$B_h(\boldsymbol{u}_h, \lambda_h; q) = 0 \qquad \forall q \in Q_h.$$

Note that $\lambda_h = [\![p]\!]_N$ (cf. Proposition 4.1); thereby, for an element $K \in \mathcal{T}_h$, we have

$$-\int_K \varepsilon\boldsymbol{u}_h \cdot \nabla q \, d\boldsymbol{x} + \int_{\partial K} \{\!\{\varepsilon\boldsymbol{u}_h\}\!\} \cdot (q\boldsymbol{n}_K)\, ds - \gamma \frac{\mathtt{e}}{\mathtt{h}} \int_{\partial K} [\![p_h]\!] \cdot (q\boldsymbol{n}_K)\, ds = 0 \tag{6.11}$$

for all $q \in \mathcal{S}^\ell(K)$. Employing integration by parts and the identity (6.11), we get, after some elementary manipulations, the following:

$$\begin{aligned} h_K \int_K \nabla\cdot(\varepsilon\boldsymbol{u}_h) q \, d\boldsymbol{x} &= -h_K \int_K \varepsilon\boldsymbol{u}_h \cdot \nabla q \, d\boldsymbol{x} + h_K \int_{\partial K} \varepsilon\boldsymbol{u}_h \cdot (q\boldsymbol{n}_K)\, ds \\ &= \frac{1}{2} h_K \int_{\partial K^0} [\![\varepsilon\boldsymbol{u}_h]\!]_N q \, ds + h_K \gamma \frac{\mathtt{e}}{\mathtt{h}} \int_{\partial K} [\![p_h]\!] \cdot (q\boldsymbol{n}_K)\, ds, \end{aligned}$$

for $q \in \mathcal{S}^\ell(K)$, where $\partial K^0 = \partial K \cap \mathcal{F}_h^{\mathcal{I}}$. The Cauchy–Schwarz inequality gives

$$\left| h_K \int_K \nabla\cdot(\varepsilon\boldsymbol{u}_h) q \, d\boldsymbol{x} \right| \leq C h_K^{\frac{1}{2}} \|q\|_{0,\partial K} \left(\int_{\partial K^0} \mathtt{h} [\![\varepsilon\boldsymbol{u}_h]\!]_N^2 \, ds + \int_{\partial K} \frac{\mathtt{e}}{\mathtt{h}} [\![p_h]\!]_N^2 \, ds \right)^{\frac{1}{2}},$$

with a constant $C > 0$, independent of the mesh size. Here, we used shape-regularity and bounded variation properties of the mesh. Employing the discrete trace inequality $\|q\|_{0,\partial K} \leq C h_K^{-\frac{1}{2}} \|q\|_{0,K}$ for all $q \in \mathcal{S}^\ell(K)$ and the characterization

$$h_K \|\nabla\cdot(\varepsilon\boldsymbol{u}_h)\|_{0,K} = \sup_{q\in\mathcal{S}^\ell(K)} \frac{h_K \int_K \nabla\cdot(\varepsilon\boldsymbol{u}_h) q \, d\boldsymbol{x}}{\|q\|_{0,K}},$$

we obtain

$$h_K^2 \|\nabla\cdot(\varepsilon\boldsymbol{u}_h)\|_{0,K}^2 \leq C \left(\int_{\partial K^0} \mathtt{h} [\![\varepsilon\boldsymbol{u}_h]\!]_N^2 \, ds + \int_{\partial K} \frac{\mathtt{e}}{\mathtt{h}} [\![p_h]\!]_N^2 \, ds \right).$$

Summing over all elements and taking into account that the analytical solution satisfies $[\![\varepsilon\boldsymbol{u}]\!]_N = 0$ on $\mathcal{F}_h^{\mathcal{I}}$ and $[\![p]\!]_N = \boldsymbol{0}$ on $\mathcal{F}_h$ completes the proof. ∎

7. Numerical experiments. In this section, we present a series of numerical experiments to illustrate the a priori error estimates derived for the mixed DG method introduced in section 2. Here, we restrict ourselves to two-dimensional model problems with constant coefficients $\mu \equiv \varepsilon \equiv 1$. In this case, by identifying two-dimensional vector fields $\boldsymbol{u}(x,y) = (u_1(x,y), u_2(x,y))$ in $\mathbb{R}^2$ with their three-dimensional extensions $\boldsymbol{u}(x,y,z) = (u_1(x,y,0), u_2(x,y,0), 0)$ in $\mathbb{R}^3$, we deduce that

$$\nabla \times (\nabla \times \boldsymbol{u}) = \left(\frac{\partial}{\partial y} \left(\frac{\partial u_2}{\partial x} - \frac{\partial u_1}{\partial y} \right), -\frac{\partial}{\partial x} \left(\frac{\partial u_2}{\partial x} - \frac{\partial u_1}{\partial y} \right) \right).$$

On the boundary, we have $\boldsymbol{n} \times \boldsymbol{u} = \boldsymbol{u} \cdot \boldsymbol{t}$, where $\boldsymbol{t}$ is the counterclockwise oriented tangential unit vector; i.e., if $\boldsymbol{n} = (n_1, n_2)$, then $(t_1, t_2) = (-n_2, n_1)$. Hence, the Dirichlet boundary datum given in (2.1) is a scalar function g. Similarly, the tangential jumps are scalar quantities defined as $[\![\boldsymbol{u}]\!]_T = \boldsymbol{u}^+ \cdot \boldsymbol{t}^+ + \boldsymbol{u}^- \cdot \boldsymbol{t}^-$.

We shall restrict our attention to meshes consisting of quadrilateral elements only. In this case the finite element space $S^\ell(\mathcal{T}_h)$ is constructed by mapping the reference element $\hat{K} = (-1,1)^2$ onto each element K in the computational mesh $\mathcal{T}_h$ via the standard bilinear mapping $F_K : \hat{K} \mapsto K$. Thereby, discrete functions, restricted to a given element K, are defined as $u \circ F_K = \hat{u}$, where $\hat{u} \in \mathcal{Q}^\ell(\hat{K})$. We point out that meshes obtained with nonaffine mappings F_K are not rigorously covered by our analysis, and the underlying stability and approximation properties need to be further investigated; see [4] for related work on the approximation properties of bilinearly mapped quadrilateral elements. Finally, we note that throughout this section we select the constants appearing in the stabilization parameters defined in (3.1) as follows: $\alpha = 10\,\ell^2$, $\beta = 1$, and $\gamma = 1$. We remark that the dependence of α on the polynomial degree ℓ has been formally chosen in order to guarantee the coercivity property in Lemma 3.1 of the underlying DG form a_h independently of ℓ; cf. [19], for example.

7.1. Example 1. Here, we let Ω be the L-shaped domain $(-1,1)^2 \backslash [0,1) \times (-1,0]$; further, we choose $\boldsymbol{j}$ and g so that the analytical solution to the two-dimensional analogue of (2.1) with $\mu \equiv \varepsilon \equiv 1$ is given by

$$\begin{pmatrix} u_1 \\ u_2 \\ p \end{pmatrix} = \begin{pmatrix} -\exp(x)(y\cos(y) + \sin(y)) \\ \exp(x) y \sin(y) \\ \sin(\pi(x-1)/2)\sin(\pi(y-1)/2) \end{pmatrix}; \tag{7.1}$$

this is a variant of the model problem considered in [19]. We investigate the asymptotic behavior of the errors of the mixed DG method (2.5)–(2.6) on a sequence of successively finer square and quadrilateral meshes for different values of the polynomial degree ℓ. In each case we consider two types of quadrilateral meshes which are constructed from a uniform square mesh by (i) randomly perturbing each of the interior nodes by up to 10% of the local mesh size (cf. Figure 1(a)) and (ii) randomly *splitting* each of the interior nodes by a displacement of up to 10% of the local mesh size (cf. Figure 1(b)). The latter meshes are constructed so that all the nodes in the interior of Ω are irregular (i.e., hanging); cf. [20].

In Figure 2 we first present a comparison of the DG-norm $\|\cdot\|_{\boldsymbol{V}(h)}$ of the error in the approximation to $\boldsymbol{u}$ with the mesh function h for $1 \le \ell \le 4$. For consistency, $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{\boldsymbol{V}(h)}$ is plotted against h_u for each mesh type, where h_u denotes the mesh size of the uniform square mesh; this ensures that a fair comparison between the error per degree of freedom for each mesh type can be made. Here, we observe that $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{\boldsymbol{V}(h)}$ converges to zero, for each fixed ℓ, at the rate $\mathcal{O}(h^\ell)$ as the mesh is

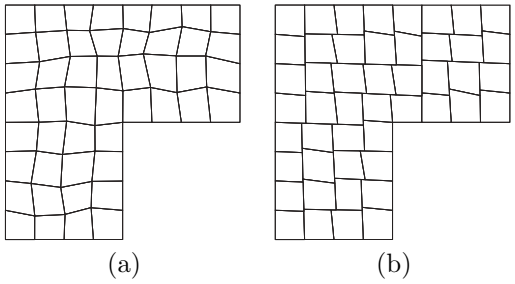

FIG. 1. *Example* 1. (a) *quadrilateral mesh* (i)*;* (b) *quadrilateral mesh* (ii).

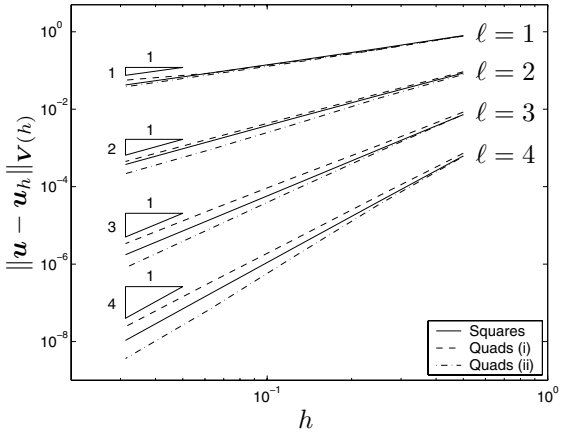

FIG. 2. *Example* 1. *Convergence of* $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{\boldsymbol{V}(h)}$ *with h-refinement.*

refined, thereby confirming Theorem 3.3. In particular, we observe that while the error on the square mesh is smaller than on the randomly generated quadrilateral mesh (i), as we would expect, the error is consistently smaller when the irregular quadrilateral mesh is employed. As in [20], we attribute this improvement in $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{\boldsymbol{V}(h)}$ to the increase in interelement communication on the meshes (ii); when no hanging nodes are present in the mesh, elements may communicate only with their four immediate neighbors. On the other hand, on irregular meshes elements may now communicate with all of their neighbors which share a common node; cf. [20].

Second, in Figure 3 we plot the DG-norm $\|\cdot\|_{Q(h)}$ of the error in approximating p by p_h as the mesh size tends to zero. As for the approximation to $\boldsymbol{u}$, we again observe that $\|p - p_h\|_{Q(h)}$ converges to zero, for each fixed ℓ, at the rate $\mathcal{O}(h^\ell)$ as the mesh is refined; cf. Theorem 3.3. However, in contrast to the approximation to $\boldsymbol{u}$, both the conforming and nonconforming quadrilateral meshes lead to a slight degradation in the size of the error in the approximation to p for each mesh and each polynomial degree employed, though in almost all cases the error in the numerical solution computed on the meshes (ii) was observed to be slightly smaller than the corresponding quantity computed on the meshes (i). Thereby, the increase in interelement communication arising when the meshes (ii) are employed no longer leads to the improvement in the size of the approximation error observed above for $\boldsymbol{u}$ as well as in [20].

The increase in the quality of the numerical approximation $\boldsymbol{u}_h$ to $\boldsymbol{u}$ when the nonconforming meshes (ii) are employed becomes even more apparent when the error

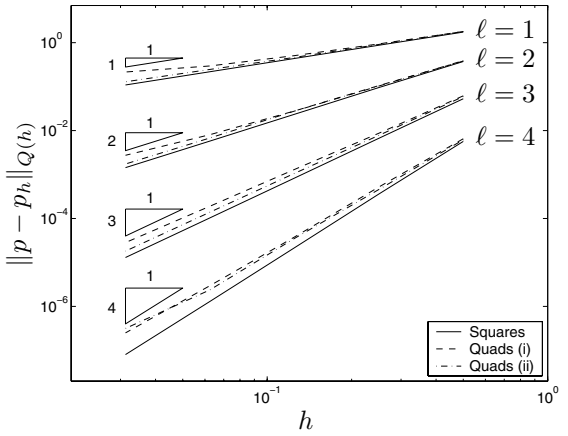

FIG. 3. *Example* 1. *Convergence of* $\|p - p_h\|_{Q(h)}$ *with h-refinement.*

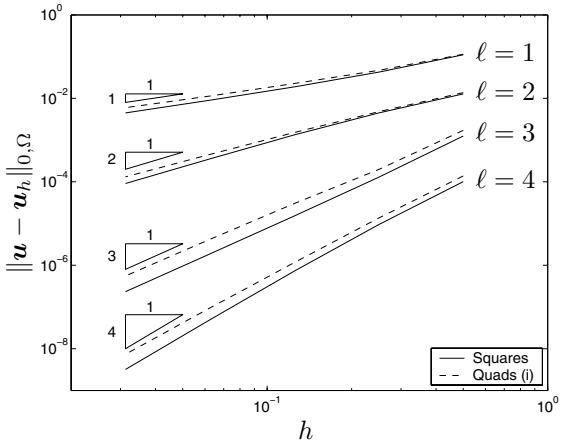

FIG. 4. *Example* 1. *Convergence of* $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{0,\Omega}$ *with h-refinement.*

$\boldsymbol{u} - \boldsymbol{u}_h$ is measured in terms of the $L^2(\Omega)$-norm. To this end, in Figure 4, we first plot $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{0,\Omega}$ against h for $1 \leq \ell \leq 4$ using the uniform square and randomly generated quadrilateral meshes (i). As predicted by Theorem 3.3, we observe that $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{0,\Omega}$ converges to zero, for each fixed ℓ, at the rate $\mathcal{O}(h^\ell)$ as the mesh is refined. While this rate of convergence is one order less than we would expect when using discontinuous piecewise polynomials of degree at most ℓ in each coordinate direction, the numerical results clearly verify the sharpness of the a priori error analysis. However, in contrast, when the nonconforming quadrilateral meshes (ii) are employed, the order of convergence increases by a full power of h; thereby, in this case $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{0,\Omega}$ now converges to zero, for each fixed ℓ, at the rate $\mathcal{O}(h^{\ell+1})$ as h tends to zero; cf. Figure 5. Analogous behavior is also observed when the $L^2(\Omega)$-norm of the error in the approximation to the divergence of $\boldsymbol{u}$ is computed. Indeed, from Figure 6, we observe that $\|h\,\nabla_h \cdot \boldsymbol{e}_h\|_{0,\Omega}$ converges to zero at the rate $\mathcal{O}(h^\ell)$ as h tends to zero when the uniform and randomly generated quadrilateral meshes (i) are employed, thereby confirming Theorem 3.6 and Remark 3.7. On the other hand, when the nonconforming quadrilateral meshes (ii) are employed, this rate of convergence increases to $\mathcal{O}(h^{\ell+1})$

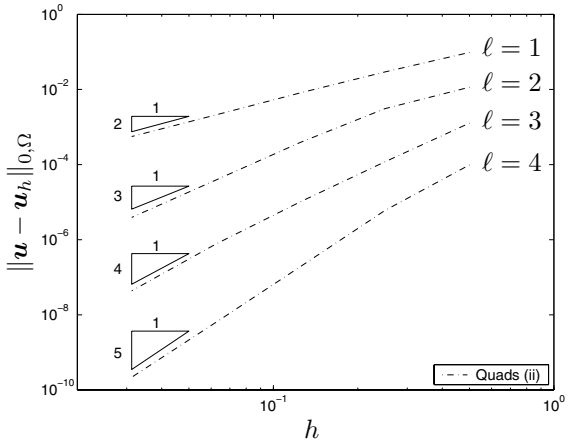

FIG. 5. *Example* 1. *Convergence of* $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{0,\Omega}$ *with h-refinement.*

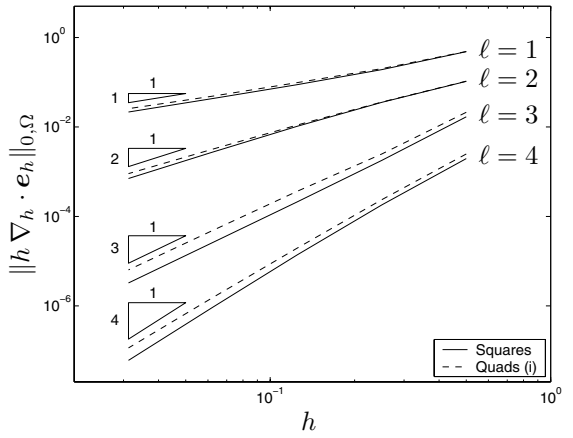

FIG. 6. *Example* 1. *Convergence of* $\|h\,\nabla_h \cdot \boldsymbol{e}_h\|_{0,\Omega}$ *with h-refinement.*

as h tends to zero; cf. Figure 7.

As a final remark, we note that on all the meshes employed, the $L^2(\Omega)$-norm of the error in the approximation to p converges to zero, for each fixed ℓ, at the (optimal) rate $\mathcal{O}(h^{\ell+1})$ as the mesh is refined. As for the DG-norm of $p - p_h$, both the conforming and nonconforming quadrilateral meshes lead to a slight degradation in the size of $\|p - p_h\|_{0,\Omega}$ for each mesh and each polynomial degree employed, though the error in the numerical solution computed on the meshes (ii) was observed to be slightly smaller than the corresponding quantity computed on the meshes (i); for brevity, these results have been omitted.

7.2. Example 2. In this second example, we investigate the performance of the mixed DG method (2.5)–(2.6) for a problem with a corner singularity in $\boldsymbol{u}$. To this end, we again let Ω be the same L-shaped domain as in the first example; here, we set $\boldsymbol{j} = \boldsymbol{0}$, and g is chosen so that the analytical solution $\boldsymbol{u}$ to the two-dimensional analogue of (2.1) with $\mu \equiv \varepsilon \equiv 1$ is given, in terms of the polar coordinates (r, ϑ), by $\boldsymbol{u}(x, y) = \nabla S(r, \vartheta)$, where $S(r, \vartheta) = r^{2/3} \sin(2\vartheta/3)$; thereby, $p \equiv 0$. The analytical solution $\boldsymbol{u}$ contains a singularity at the corner located at the origin of Ω; here, we

have only $\boldsymbol{u} \in H^{2/3-\varepsilon}(\Omega)^2$, $\varepsilon > 0$.

In this example, let us first confine ourselves to uniform square meshes; we shall return to the more general meshes considered in the previous example later. To this end, in Tables 1 and 2 we present a comparison of the DG-norms of the error in the approximation to both $\boldsymbol{u}$ and p, respectively, with the mesh function h on a sequence of uniform square meshes for $1 \leq \ell \leq 3$. In each case we show the number of elements in the computational mesh, the corresponding DG-norm of the error, and the computed rate of convergence k. Here, we observe that (asymptotically) both $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{\boldsymbol{V}(h)}$ and $\|p - p_h\|_{Q(h)}$ converge to zero at the optimal rate $\mathcal{O}(h^{\min(2/3-\varepsilon,\ell)})$ as h tends to zero, predicted by Theorem 3.4.

Next, in Table 3 we present a comparison of the $L^2(\Omega)$-norm of the error in the numerical approximation to $\boldsymbol{u}$ with h. On the basis of Theorem 3.4, we expect that $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{0,\Omega}$ should tend to zero at the rate $\mathcal{O}(h^{\min(2/3-\varepsilon,\ell)})$ as h tends to zero. However, from Table 3, we observe that for $\ell = 1, 2, 3$, the rate of convergence of the

$L^2(\Omega)$-norm of the error in the approximation to $\boldsymbol{u}$ is slightly higher than predicted, although, asymptotically, we expect these convergence rates to slowly tend to the optimal one. Additionally, in Table 4 we show the convergence of $\|h\nabla_h\cdot\boldsymbol{e}_h\|_{0,\Omega}$ with respect to h; here, we again observe that, asymptotically, the rate of convergence tends to the one predicted in Theorem 3.6; cf. Remark 3.7. Finally, in Table 5 we show $\|p-p_h\|_{0,\Omega}$ for $\ell=1,2,3$, based on employing uniform square meshes. In comparison with Table 3, Table 5 indicates that the rate of convergence of $\|p-p_h\|_{0,\Omega}$ is almost twice the optimal rate of $\|\boldsymbol{u}-\boldsymbol{u}_h\|_{0,\Omega}$; indeed, asymptotically, we observe that k is tending towards $4/3$ as the mesh is uniformly refined.

We remark that analogous convergence rates to those reported in Tables 1–5 are also observed when the numerical approximation is computed on the conforming quadrilateral meshes (i); for brevity, these results are omitted. However, convergence of the mixed DG method was *not* observed on the quadrilateral meshes (ii). We recall that the convergence proof presented in the case of weak smoothness assumptions for the component $\boldsymbol{u}$ of the analytical solution (cf. Theorem 3.4) precludes the presence of hanging nodes in the mesh $\mathcal{T}_h$ and, as in the case of smooth analytical solutions, assumes that the elements in $\mathcal{T}_h$ are affine. As noted above, optimal rates of convergence are still observed computationally when the quadrilateral meshes (i), which are conforming, but nonaffine, are employed. In order to test the method in the case when $\mathcal{T}_h$ contains hanging nodes, but the elements are affine, we consider the performance of the mixed DG method (2.5)–(2.6) on a sequence of adaptively refined square

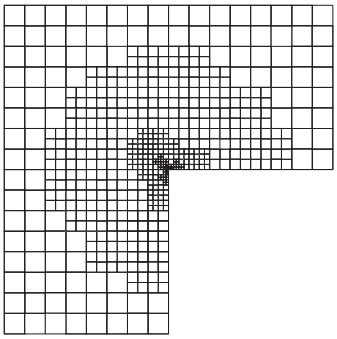

FIG. 8. *Example* 2. *Computational mesh after* 9 *adaptive refinement steps, with* 721 *nodes and* 618 *elements and* $\ell = 1$.

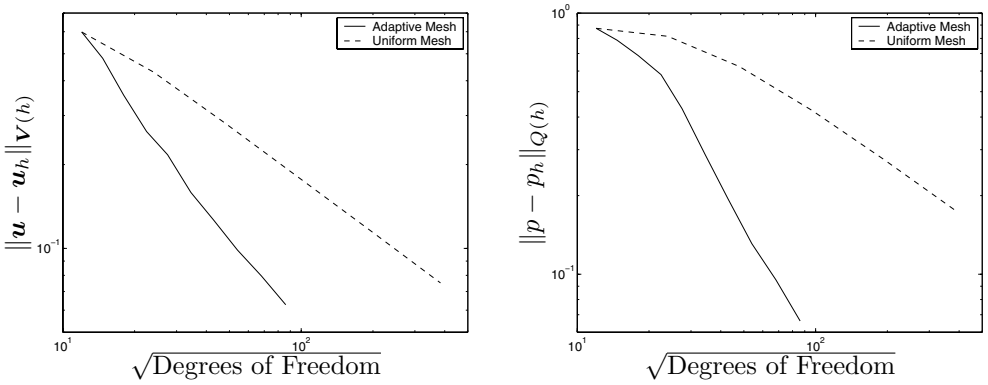

FIG. 9. *Example* 2. *Comparison of adaptive and uniform* h*-refinement.*

meshes. Here, the adaptive meshes are constructed by employing the fixed fraction strategy (with refinement and derefinement fractions set to 25% and 0%, respectively) with a simple error indicator η_K based on the gradient of the numerical approximation. More precisely, given K in $\mathcal{T}_h$, we set $\eta_K = (\|h_K \nabla \boldsymbol{u}_h\|^2_{0,K} + \|h_K \nabla p_h\|^2_{0,K})^{1/2}$. More sophisticated error indicators may be appropriate for this problem; here, we are simply interested in generating a sequence of adaptive meshes (containing hanging nodes) in which to test the hypotheses of our a priori error analysis. A typical mesh generated with this adaptive algorithm is shown in Figure 8.

In Figure 9, we present a comparison of $\|\boldsymbol{u} - \boldsymbol{u}_h\|_{\boldsymbol{V}(h)}$ and $\|p - p_h\|_{Q(h)}$ with the (square root of the) number of degrees of freedom in $\boldsymbol{V}_h \times Q_h$ for $\ell = 1$ on the sequence of adaptively refined meshes generated as above, as well as on a sequence of uniform square meshes; cf. Tables 1 and 2 above, respectively. Here, we clearly observe that the error in the mixed DG discretization of (2.1) converges to zero as the finite element space $\boldsymbol{V}_h \times Q_h$ is enriched, even when the mesh contains hanging nodes; indeed, we see that the adaptively refined meshes lead to a general improvement in the error when compared to the uniform square meshes. In summary, in the case of weak Sobolev regularity assumptions on $\boldsymbol{u}$, the mixed DG method (2.5)–(2.6) is observed (numerically) to be optimally convergent on both conforming and nonconforming affine square meshes as well as on conforming nonaffine meshes; however, convergence is not observed when the mesh contains hanging nodes *and* the elements are not affine.

8. Conclusions. In this paper, we have presented a new mixed discontinuous Galerkin method for the discretization of the time-harmonic Maxwell operator. This method is based on equal-order finite element spaces, where all the unknowns are approximated with piecewise discontinuous polynomials of the same degree. When compared to the numerical scheme proposed in [25], the amount of numerical stabilization here is drastically reduced. Our error analysis and numerical results show that the method is optimally convergent in the energy norms for smooth as well as for singular solutions. In the latter case, the theoretical analysis is restricted to regular meshes without hanging nodes. However, numerical experiments for a problem with a strongly singular solution have demonstrated that the application of the method within an adaptive procedure on affine quadrilateral meshes, where hanging nodes are introduced during the course of the refinement, still leads to a convergent numerical approximation as the finite element space is enriched. A more delicate issue seems to be the one related to nonaffine meshes. Indeed, our tests seem to indicate that the assumption of affineness on the meshes cannot be eliminated when meshes containing hanging nodes are employed. Future work will be devoted to the study of variants of the proposed method which deliver optimal rates of convergence when the error in the approximation to the vector field $\boldsymbol{u}$ is measured in the $L^2(\Omega)$-norm.

Acknowledgments. The numerical experiments in this paper were performed using the University of Leicester Mathematical Modelling Centre's supercomputer, which was purchased through the EPSRC Strategic Equipment Initiative.

FIRST-ORDER SYSTEM LEAST SQUARES AND ELECTRICAL IMPEDANCE TOMOGRAPHY*

H. R. MACMILLAN†, T. A. MANTEUFFEL‡, AND S. F. MCCORMICK†

Abstract. Electrical impedance tomography (EIT) belongs to a family of imaging methods that employ boundary measurements to distinguish interior spatial variation of an electromagnetic parameter. The associated inverse problem is notoriously ill-posed, due to diffusive effects in the quasi-static regime, when electrical impedance reduces to its real part, resistivity. The standard approach to EIT is output least squares (OLS). For a set of applied normal boundary currents, one minimizes the defect between the measured and computed boundary voltages associated, respectively, with the exact impedance and its approximation. In minimizing a boundary functional, OLS implicitly imposes the governing Poisson equation as an optimization constraint. To reconstruct resistivity or, equivalently, conductivity, we introduce a new first-order system least-squares (FOSLS) formulation that incorporates the elliptic PDE as an interior functional in a global unconstrained minimization scheme. We then establish equivalence of our functional to OLS and to an existing interior least-squares functional due to Kohn and Vogelius [*Comm. Pure Appl. Math*, 37 (1984), pp. 289–298]. That the latter may be viewed as a special dual approach (FOSLL*) is an interesting attribute of this equivalence. Because the FOSLS functional implicitly reflects the inherent loss of resolution away from the boundary, relative to the set of applied boundary tests, the need for artificial regularization may be avoided.

Key words. first-order system least squares, electrical impedance tomography

1. Introduction.

Electrical impedance tomography (EIT) belongs to a family of imaging methods based on distinguishing interior spatial variation of an electromagnetic parameter. The basic principle is to approximate this parameter in a manner consistent with given pairings of boundary current and boundary voltage data. In mathematical parlance, given boundary data represents discrete knowledge of the Dirichlet-to-Neumann map associated with the unknown parameter's effect on diffusion. The broad scope of EIT's application, ranging from biomedical imaging [8, 10, 4] to geophysical prospecting [34, 28, 37, 12] to industrial process tomography [31, 14, 15], implies the importance of different parameter regimes and boundary data protocols. Thus, it is reasonable to expect efficient and effective algorithms to be highly problem specific, according to prior information and measurement techniques. In this paper, we discuss the governing equations, the standard least-squares approach, and established theoretical insights, but we do not conduct a comprehensive study of a myriad of practical concerns. Our focus is, instead, on proving equivalence of three least-squares formulations: output least squares [8], a formulation due to Kohn and Vogelius [23], and a new first-order system least-squares (FOSLS) formulation. That the Kohn and Vogelius functional may be viewed as a first-order system LL* (FOSLL* [6]) formulation, combined with the equivalence results, suggests a unifying framework for future

studies of EIT. It is our conviction that the ultimate goal of such studies is to quantify the sense in which the notoriously ill-posed problem can be posed well. This is in line with not only classical Backus and Gilbert theory on geophysical inverse problems [1] but also with recent analysis of probabilistic approaches [26]. The equivalence results of this paper, by establishing common ground, set the stage for investigations of the uncertainty inherent in posing least-squares formulations of EIT.

1.1. Mathematical setting. The development of a mathematical model for the EIT inverse problem begins with Maxwell's equations in a source-free, closed, and simply connected domain, which we denote Ω with boundary Γ. A series of assumptions (see [8, 30] and the references therein), including negligible magnetic permeability and quasi-static periodic time variation, leads to a Poisson equation for complex-valued voltage p:

$$\nabla \cdot \gamma \nabla p = 0, \tag{1.1}$$

where $\gamma = \sigma + i\omega\epsilon$ is the admittance. EIT refers to the reconstruction of this parameter, since electrical impedance is defined as $1/\gamma$. Here we make the electrostatic assumption, $\omega = 0$. Thus, the quantities in (1.1) are real-valued, and the aim is reconstruction of the conductivity, σ, based on its associated Dirichlet and Neumann boundary data. This is equivalent to reconstructing resistivity, $1/\sigma$. The electrostatic assumption is an important first principle since the lack of resolution with quasi-static fields, and thus EIT, is attributed to the conductivity term. Extension to electromagnetic fields varying slowly in time remains a future work.

Remark 1. We refer to the process of reconstructing conductivity given Dirichlet and Neumann data as electrical conductivity tomography (ECT) and remark that in the literature it is also known as the DC resistivity problem, applied potential tomography, electric current computed tomography, and electrical resistance tomography.

In what follows, we adopt the usual Sobolev spaces, $\mathrm{L}^2(\Omega)$ and $\mathrm{H}^1(\Omega)$, including the dual boundary spaces, $\mathrm{H}^{1/2}(\Gamma)$ and $\mathrm{H}^{-1/2}(\Gamma)$ [11]. We assume that the boundary, Γ, is Lipschitz and note that the normal current flux is the scaled Neumann data, $\mathbf{n} \cdot \sigma \nabla p$, where $\mathbf{n}$ denotes the outward unit normal. Also, the boundary voltage distribution is the Dirichlet data, $p_{|\Gamma}$. It is practical to impose the normal current and measure the resulting voltage data, and we choose this perspective in the presentation of our theory. Hence, considering the Neumann problem

$$\begin{aligned} \nabla \cdot \sigma \nabla p &= 0 \qquad \text{in } \Omega, \\ \mathbf{n} \cdot \sigma \nabla p &= h \qquad \text{on } \Gamma, \end{aligned} \tag{1.2}$$

where the normal current $h \in \mathrm{H}^{-1/2}(\Gamma)$ satisfies $\int_\Gamma h \, ds = 0$, one may view coefficient σ as determining a Neumann-to-Dirichlet map, i.e., as determining the trace of voltage $p_{|\Gamma} \in \mathrm{H}^{1/2}(\Gamma)$ on the boundary (up to a constant). An alternative and likely more realistic mathematical model uses Robin boundary conditions in place of the Dirichlet conditions as the measured data [8, 40]. However, since the Neumann data is in each case given, such measurements are equivalent to discrete knowledge of the Neumann-to-Dirichlet map. At this stage we assume the most general Sobolev setting and defer addressing practical issues regarding boundary data to a future work [25].

Several definitions associated with system (1.2) now follow to facilitate formally stating the inverse problem of ECT.

DEFINITION 1.1. *Denote* $\mathrm{L}^\infty_+(\Omega) := \{\sigma \in \mathrm{L}^\infty(\Omega) : \sigma > 0\}$. *Also, let*

$$\mathrm{H}^{1/2}_0(\Gamma) := \left\{ g \in \mathrm{H}^{1/2}(\Gamma) : \int_\Gamma g \, d\tau = 0 \right\},$$
$$\mathrm{H}^{-1/2}_0(\Gamma) := \left\{ h \in \mathrm{H}^{-1/2}(\Gamma) : \int_\Gamma h \, d\tau = 0 \right\}.$$

A given conductivity, $\sigma \in \mathrm{L}^\infty_+(\Omega)$, *induces a bounded linear map,*

$$\mathcal{R}_\sigma : \mathrm{H}^{-1/2}_0(\Gamma) \longrightarrow \mathrm{H}^{1/2}_0(\Gamma),$$

from the imposed normal current to the resulting boundary voltage. This map is defined by

$$\mathcal{R}_\sigma(h) := p_{|\Gamma},$$

where p *solves* (1.2), *and we call* $\mathcal{R}_\sigma$ *the Neumann-to-Dirichlet map (NtD map) associated with* σ.

Remark 2. Function space $\mathrm{L}^\infty_+(\Omega)$ is used for admissible conductivity since it is the least restrictive for which the NtD map associated with (1.2) can be defined. However, uniquely defining the NtD map requires further restriction [17]. Regarding the boundary spaces, a compatibility condition on (1.2) implies that we must have $\int_\Gamma h \, d\tau = 0$. Similarly, p is determined by (1.2) only up to a constant, so we are permitted to impose the condition $\int_\Gamma g \, d\tau = 0$.

DEFINITION 1.2. *We say that* $\{p, \mathcal{R}_\sigma(h), h\} \in \mathrm{H}^1(\Omega) \times \mathrm{H}^{1/2}_0(\Gamma) \times \mathrm{H}^{-1/2}_0(\Gamma)$ *is a Dirichlet–Neumann triple (DN triple) for* σ *if* (1.2) *holds. Also, we shall refer to* $\{\mathcal{R}_\sigma(h), h\}$ *as a DN pair.*

Remark 3. The NtD map, $\mathcal{R}_\sigma$, is self-adjoint in the L^2-inner-product. This is apparent since for DN triples $\{p_1, \mathcal{R}_\sigma(h_1), h_1\}$ and $\{p_2, \mathcal{R}_\sigma(h_2), h_2\}$, integration by parts leads to

$$\langle h_1, \mathcal{R}_\sigma(h_2) \rangle_{0,\Gamma} = \int_\Omega \sigma \nabla p_1 \cdot \nabla p_2 \, dx = \langle \mathcal{R}_\sigma(h_1), h_2 \rangle_{0,\Gamma}.$$

Finally, we have the notation to define the inverse problem of ECT.

DEFINITION 1.3. *The inverse problem of ECT is to approximate the exact conductivity,* σ^*, *according to a given graph of measured DN data* $\{g_i, h_i\}_{i=1}^L$, *where* $g_i \approx \mathcal{R}_{\sigma^*}(h_i)$.

Stated otherwise, the inverse problem of ECT is to approximately invert the nonlinear mapping $\sigma \longrightarrow \mathcal{R}_\sigma$. The approximate nature of this inversion is due to the preimposed discreteness of having finite data, the inexactness of this data, and the need to choose a discrete approximation space for conductivity. Next, we give background on these issues as they affect our ability to solve the inverse problem.

1.2. Theoretical background. Classical discussion of existence and uniqueness of the inverse problem is hindered by several concerns. First, assuming exact boundary data is the same as assuming the existence of a conductivity consistent with the boundary data. However, given the intrinsic error in the measurements of the data, it is likely that there is no such consistent conductivity. As for uniqueness, progressively refined results have been established, with a focus on achieving a uniqueness result for piecewise continuous conductivity [21, 22, 35, 27, 17]. The techniques used in theoretical uniqueness results, however, rely on complete and precise

boundary information and cannot accommodate the reality of only a finite number of approximate DN pairs. As such, they do not provide insight into how inexact and incomplete boundary data unleash error in σ that cannot be confidently eliminated. Toward such an understanding, it is instructive to consider Calderon's initial analysis [7]. Let $\delta \in \mathrm{L}^1(\Omega)$ be a perturbation of a background conductivity, σ. For DN triples $\{p_i, \mathcal{R}_\sigma(h_i), h_i\}$ and $\{p_j, \mathcal{R}_\sigma(h_j), h_j\}$, he observes that

$$\langle h_i, \mathcal{R}_{\sigma+\delta}(h_j) - \mathcal{R}_\sigma(h_j)\rangle_{0,\Gamma} = \int_\Omega \delta\, \nabla p_i \cdot \nabla p_j \, dx \; + \; O(\delta^2). \tag{1.3}$$

This classical expansion displays how perturbations in the interior can be practically undetectable at the boundary. For example, observe that, with σ constant, the distribution of voltage, p, is increasingly smooth away from the boundary. Thus, the product of the gradients of solutions to the Laplace equation places decreasing weight on perturbations of conductivity according to distance into the interior. Notably, this weighting appears within the FOSLS formulation when updating the approximate conductivity.

In a now classical work, Backus and Gilbert [1] introduce the notion of "inference" for studying a wide class of geophysical inverse problems, not just ECT. Parker [29] has applied this theory to ECT, considering the linearized one-dimensional problem of determining the conductive layers of stratified earth. Independently, Seagar, Yeo, and Bates [32, 33] assess the "visibility" of circular disks of constant conductivity as perturbations of a background constant conductivity in a two-dimensional circular domain by using conformal mapping techniques. Finally, to determine whether the effect of a certain error can be detected on the boundary, Isaacson [16] introduces "distinguishability." As is observed in each analysis of resolution, the best test to apply in order to detect a specific error, $\sigma - \sigma^*$, is that which attains the operator norm of the defect in the NtD maps, i.e., that which attains the sup in

$$\|\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*}\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{1/2}(\Gamma))} := \sup_{h\in\mathrm{H}_0^{-1/2}(\Gamma)} \frac{\|(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})h\|_{1/2,\Gamma}}{\|h\|_{-1/2,\Gamma}}. \tag{1.4}$$

Thus, given complete and exact boundary data, the natural functional to minimize is the operator norm in (1.4). Of course, with finite data, the sup can be taken only over a finite-dimensional subspace, $span\{h_i\}_{i=1}^L \subset \mathrm{H}_0^{-1/2}(\Gamma)$, where L is the number of available DN data. Despite the preimposed discreteness of this data and its inevitable error, we hope to still recover meaningful components of σ^*.

1.3. Output least squares. In analogy to the Frobenius norm of matrix algebra, a natural alternative to minimizing the sup over the span of the boundary data is to minimize the output least-squares (OLS) functional,

$$\mathcal{F}(\sigma; \{g_i, h_i\}_{i=1}^L) := \sum_{i=1}^{L} \|\mathcal{R}_\sigma(h_i) - g_i\|_{1/2,\Gamma}^2. \tag{1.5}$$

This formulation is an example of unconstrained least-squares optimization and is the standard approach throughout the wide range of EIT applications [3, 8, 12, 40]. It should be noted that the L^2-norm, rather than $\mathrm{H}^{1/2}$-norm, is typically enforced. However, in this work we preserve the most general Sobolev space setting. This top-down approach should prove more beneficial, as future work in computational electromagnetics leads to a better understanding of the fields impinging a given domain, thereby leading to a more accurate representation of the boundary data.

To minimize $\mathcal{F}$ in (1.5), the first variation of the NtD map with respect to σ enables a standard Newton quadraticization. The first-order term in (1.3) is used to represent this variation, determining the effect on the boundary of changing a given degree of freedom for σ. Once the linear system, involving the "sensitivity matrix," is solved to obtain a new approximation, the L forward problems are solved, and the process is repeated (see [8] and the references therein). The physics at the source of EIT's difficulty is manifested by the extremely high condition number of the sensitivity matrix when a uniform grid for σ is chosen. This is consistent with what the physics suggests: an increasingly coarse representation of conductivity should be used to extend the grid into the interior. Typically, some form of regularization is instead performed to ensure that the Hessian is sufficiently positive definite.

Regularization is, in essence, the process of posing an inverse problem well [36], and it has taken several forms in application to EIT. A regularization operator, $\mathcal{B}$, can be incorporated into the OLS functional as an additional least-squares term so that (1.5) is replaced by

$$\mathcal{F}(\sigma; \{g_i, h_i\}_{i=1}^{L}) := \left(\sum_{i=1}^{L} \|\mathcal{R}_\sigma(h_i) - g_i\|_{0,\Gamma}^2 \right) + \alpha \|\mathcal{B}\sigma\|_{0,\Omega}^2, \tag{1.6}$$

where α is a regularization parameter that is usually chosen empirically to balance resolution and computability in some sense. The most common regularization is a penalty on the H^1-seminorm of σ [8], wherein $\mathcal{B} = \nabla$. When piecewise constant basis functions are used in the discrete representation of σ, one can impose a penalty on the jumps between each element [9]. Of course, the resulting reconstruction is artificially smoothed, especially near the boundary where one ought to be able to recover high frequency components. However, the technique has been actively researched for many years, and ways of reducing the artificial smoothness have been developed, including the recent multilevel approach of Borcea [3]. The theory we develop suggests that the FOSLS formulation inherently imposes a smoothing of the conductivity estimate that is relative to both the distance from the boundary and prior information about σ. Indeed, the FOSLS formulation may likewise benefit from an empirical process of determining ideal weightings on each term in the functional, analogous to determining α in (1.6). These present potential directions for future research.

An alternative regularization scheme, referred to as a statistical or Bayesian approach, is implemented by Vauhkonen et al. [39] and Kaipio et al. [18, 19] to penalize the orthogonal complement of an operator which represents prior information. The penalty thus serves to steer the approximation toward an expected solution. A related method, that of basis constraints [38], builds the subspace of admissible conductivity, which may in practice be of very low dimension, by using basis functions selected according to prior information. Though we encourage the use of basis constraints to incorporate what is already known into the solution process, the prevailing conviction is that such information should not serve to "regularize" the inverse problem. Rather, one must accept and account for the inherent lack of resolution [1, 26, 13]. We feel that FOSLS offers a natural foundation for projecting this conviction.

2. FOSLS framework. We now prove equivalence of the OLS formulation to two interior least-squares functionals. To represent Dirichlet data, we write $\mathcal{R}_{\sigma^*}(h)$ instead of g to stress the present assumption on zero error in the data, as well as the dependence on σ^*. Finally, we develop the framework explicitly for two dimensions and anticipate that the setting generalizes to three dimensions, although we

draw attention to those points in the development for which the three-dimensional generalization is not obvious.

2.1. Kohn and Vogelius. The first interior least-squares formulation we address was introduced by Kohn and Vogelius [23] and Kohn and McKenney [20] and is closely related to the original interior functional proposed for ECT by Wexler, Fry, and Neumann [41]. We now review their formulation in two dimensions before proving its equivalence to OLS.

2.1.1. Formulation. To begin, we recall the interior partial differential equation (PDE) and boundary conditions associated with the exact, albeit unknown, conductivity, σ^*:

$$\begin{aligned} \nabla \cdot \sigma^* \nabla p &= 0 && \text{in } \Omega, \\ \mathbf{n} \cdot \sigma^* \nabla p &= h && \text{on } \Gamma, \\ p &= \mathcal{R}_{\sigma^*}(h) && \text{on } \Gamma. \end{aligned}$$

Letting $\nabla^\perp = (-\partial_y, \partial_x)^t$, and recalling that Ω is simply connected, then the divergence-free condition on $\sigma^* \nabla p$ asserted in this PDE implies the existence of $s \in \mathrm{H}^1(\Omega)$, depending on σ^*, h, and Ω, such that

$$\sigma^* \nabla p = \nabla^\perp s.$$

On Γ, we have

$$\mathbf{n} \cdot \sigma^* \nabla p = \mathbf{n} \cdot \nabla^\perp s = \boldsymbol{\tau} \cdot \nabla s = h,$$

where $\boldsymbol{\tau}$ denotes the clockwise unit tangent vector. Note that s satisfies

$$\begin{aligned} \nabla \cdot \frac{1}{\sigma^*} \nabla s = \nabla \times \frac{1}{\sigma^*} \nabla^\perp s &= 0 && \text{in } \Omega, \\ s &= \int_\Gamma h \, d\gamma && \text{on } \Gamma. \end{aligned}$$

To assess the validity of an approximate conductivity, the Kohn and Vogelius (KV) functional is based on defining two separate sets of Dirichlet problems: given $\{\mathcal{R}_{\sigma^*}(h_i), h_i\}_{i=1}^L$, find $p_i \in \mathrm{H}^1(\Omega)$ such that

$$\begin{aligned} \nabla \cdot \sigma \nabla p_i &= 0 && \text{in } \Omega, \\ p_i &= \mathcal{R}_{\sigma^*}(h_i) && \text{on } \Gamma, \end{aligned} \tag{2.1}$$

and find $s_i \in \mathrm{H}^1(\Omega)$ such that

$$\begin{aligned} \nabla \times \frac{1}{\sigma} \nabla^\perp s_i &= 0 && \text{in } \Omega, \\ s_i &= \int_\Gamma h_i \, d\gamma && \text{on } \Gamma. \end{aligned} \tag{2.2}$$

Now, if $\sigma = \sigma^*$, then

$$\| \sigma \nabla p_i - \nabla^\perp s_i \|_{0,\Omega} = 0 \qquad \forall \, i \in \{1, 2, \ldots, L\}. \tag{2.3}$$

With a complete set of boundary data associated with σ^*, the converse statement, which confirms uniqueness, is also true: if (2.1)–(2.3) are satisfied for every DN pair $\{\mathcal{R}_{\sigma^*}(h), h\}$, then $\sigma = \sigma^*$.

The statement in (2.3) suggests minimizing the functional

$$\mathcal{F}_{KV}(\sigma;\{\mathcal{R}_{\sigma^*}(h_i),h_i\}_{i=1}^L) := \sum_{i=1}^{L}\left(\min_{p_i,s_i\,\in\,\mathrm{H}^1(\Omega)} \|\sigma^{1/2}\nabla p_i - \sigma^{-1/2}\nabla^{\perp}s_i\|_{0,\Omega}^2\right), \tag{2.4}$$

where, for each $i = 1, 2, \ldots, L$, we define

$$\begin{aligned} p_{i|_\Gamma} &:= \mathcal{R}_{\sigma^*}(h_i),\\ s_{i|_\Gamma} &:= \int_\Gamma h_i\, d\gamma\,. \end{aligned} \tag{2.5}$$

The rescaling of conductivity used in (2.4) is chosen so that, for a fixed approximation, σ, the minimizations in (2.4) can be conducted separately. This fact is shown explicitly in Lemma 2.2 below.

The scaling of conductivity used in (2.4) also benefits the updating process for conductivity. For a fixed set of approximations, $\{p_i, s_i\}_{i=1}^L$, it is shown in [20] that the best conductivity is determined pointwise to be

$$\sigma = \left(\sum_{i=1}^{L} |\ \nabla^{\perp}s_i\ |^2\right)^{1/2}\left(\sum_{i=1}^{L} |\ \nabla p_i\ |^2\right)^{-1/2}.$$

This sets up a natural minimization process of alternating between the subspace for σ and those for $\{p_i, s_i\}_{i=1}^L$. Indeed, this alternating process is the design of the proof of the equivalence result. In numerical studies of the KV functional in [20], minimization in σ is incorporated explicitly, and, instead of the natural alternating scheme, a Newton quadraticization is used.

2.1.2. Equivalence to OLS. Here we establish equivalence of the KV functional to that of OLS. Because the line of proof follows for each DN pair, it is convenient to denote

$$\mathrm{F}(\sigma,p,s) := \|\sigma^{1/2}\nabla p - \sigma^{-1/2}\nabla^{\perp}s\|_{0,\Omega}.$$

Also, we observe that, for any DN pair $\{\mathcal{R}_{\sigma^*}(h),h\}$, the exact conductivity generates solutions p^* and s^* to (2.1) and (2.2), respectively, such that $\mathrm{F}(\sigma^*,p^*,s^*) = 0$. For any arbitrary $p\,, s \in \mathrm{H}^1(\Omega)$ satisfying (2.5), we can interpret $\mathrm{F}(\sigma,p,s)$ as an expression of error in each variable. Thus, letting $\mathrm{H}_0^1(\Omega) := \{q \in \mathrm{H}^1(\Omega) : q = 0 \text{ on } \Gamma\}$, it is useful to define

$$\begin{aligned} \delta p &:= p - p^* \in \mathrm{H}_0^1(\Omega),\\ \delta s &:= s - s^* \in \mathrm{H}_0^1(\Omega). \end{aligned}$$

Note that since δp and δs are zero on the boundary, we preserve the boundary values of p^* and s^*, as required by the functional, and we can rewrite (2.4) subject to (2.5) as

$$\mathcal{F}_{KV}(\sigma;\{\mathcal{R}_{\sigma^*}(h_i),h_i\}_{i=1}^L) = \sum_{i=1}^{L}\left(\min_{\delta p_i,\delta s_i\,\in\,\mathrm{H}_0^1(\Omega)} \mathrm{F}(\sigma,p_i^*+\delta p_i,s_i^*+\delta s_i)\right). \tag{2.6}$$

The equivalence relation we seek, Corollary 2.3 below, follows from a generalized ellipticity property for functional term $\mathrm{F}(\sigma,p^*+\delta p,s^*+\delta s)$. As already mentioned, this

property of the functional is established in Lemma 2.2. Essentially, in the following theorem we establish that $\mathrm{F}(\sigma, p^*+\delta p, s^*+\delta s)$ is equivalent to an expression of specific quantities $\mathcal{R}_\sigma(h) - \mathcal{R}_{\sigma^*}(h)$, $\delta p - \delta p_D$, and $\delta s - \delta s_D$, where

$$\begin{aligned} \delta p_D &:= \arg \min_{\delta p \,\in\, \mathrm{H}^1_0(\Omega)} \|\sigma^{1/2}\nabla(p^* + \delta p)\|_{0,\Omega}, \\ \delta s_D &:= \arg \min_{\delta s \,\in\, \mathrm{H}^1_0(\Omega)} \|\sigma^{-1/2}\nabla^\perp(s^* + \delta s)\|_{0,\Omega} \end{aligned} \tag{2.7}$$

come from the minimizations in (2.6). Hence by design, proceeding to conduct the minimizations in (2.6) leads to lower and upper bounds for $\mathcal{F}_{KV}(\sigma; \{\mathcal{R}_{\sigma^*}(h_i), h_i\}_{i=1}^L)$ in terms of the defect in the NtD map.

THEOREM 2.1. *Suppose that $\sigma \in \mathrm{L}^\infty_+(\Omega)$ satisfies $\sigma = \sigma^*$ on Γ. Suppose also that $s^* \in \mathrm{H}^1(\Omega)$ is such that $\mathrm{F}(\sigma^*, p^*, s^*) = 0$ for DN triple $\{p^*, \mathcal{R}_{\sigma^*}(h), h\}$ associated with σ^*, where $h \in \mathrm{H}^{-1/2}_0(\Gamma)$. Finally, let δp_D and δs_D be as defined in* (2.7). *Then there exist positive constants c_0 and c_1 such that*

$$\begin{aligned} c_0\|(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})h\|^2_{1/2,\Gamma} + \|\sigma^{1/2}\nabla(\delta p - \delta p_D)\|^2_{0,\Omega} + \|\sigma^{-1/2}\nabla^\perp(\delta s - \delta s_D)\|^2_{0,\Omega} \\ \le F(\sigma, p^* + \delta p, s^* + \delta s) \\ \le c_1\|(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})h\|^2_{1/2,\Gamma} + \|\sigma^{1/2}\nabla(\delta p - \delta p_D)\|^2_{0,\Omega} + \|\sigma^{-1/2}\nabla^\perp(\delta s - \delta s_D)\|^2_{0,\Omega}, \end{aligned} \tag{2.8}$$

where c_0 depends on Ω and $\min_\Omega |\sigma|$, $c_1 = \|\mathcal{R}_\sigma^{-1}\|_{\mathcal{L}(\mathrm{H}^{1/2}_0(\Gamma), \mathrm{H}^{-1/2}_0(\Gamma))}$, and each multiply only the first terms.

Proof. The optimality of δp_D and δs_D, characterized in (2.7), leads to the orthogonality conditions

$$\begin{aligned} \langle \sigma\nabla(p^* + \delta p_D), \nabla\delta p\rangle_{0,\Omega} = 0 \qquad \forall\, \delta p \in \mathrm{H}^1_0(\Omega), \\ \langle \sigma^{-1}\nabla^\perp(s^* + \delta s_D), \nabla^\perp\delta s\rangle_{0,\Omega} = 0 \qquad \forall\, \delta s \in \mathrm{H}^1_0(\Omega). \end{aligned} \tag{2.9}$$

Note that the Neumann data for δp_D and δs_D are generally not zero and that, in preserving the Dirichlet data, the strong form of the first equation in (2.9) means that $\{p^* + \delta p_D, \mathcal{R}_\sigma(h), h\}$ is a DN triple. Now we expand the terms of the functional, use (2.9), and note that all but one cross term vanishes upon integrating by parts:

$$\begin{aligned} F(\sigma, p^* + \delta p, s^* + \delta s) \\ &= \|\sigma^{1/2}\nabla(p^* + \delta p_D + \delta p - \delta p_D) - \sigma^{-1/2}\nabla^\perp(s^* + \delta s_D + \delta s - \delta s_D)\|^2_{0,\Omega} \\ &= \|\sigma^{1/2}(\nabla p^* + \delta p_D)\|^2_{0,\Omega} + \|\sigma^{1/2}\nabla(\delta p - \delta p_D)\|^2_{0,\Omega} - 2\langle \nabla p^*, \nabla^\perp s^*\rangle_{0,\Omega} \\ &\quad + \|\sigma^{-1/2}\nabla^\perp(s^* + \delta s_D)\|^2_{0,\Omega} + \|\sigma^{-1/2}\nabla^\perp(\delta s - \delta s_D)\|^2_{0,\Omega}. \end{aligned} \tag{2.10}$$

By assumption, $\sigma^*\nabla p^* = \nabla^\perp s^*$, so we may split the lone cross term in (2.10) to write

$$\begin{aligned} F(\sigma, p^* + \delta p, s^* + \delta s) = \|\sigma^{1/2}\nabla(p^* + \delta p_D)\|^2_{0,\Omega} - \|\sigma^{*1/2}\nabla p^*\|^2_{0,\Omega} \\ + \|\sigma^{-1/2}\nabla^\perp(s^* + \delta s_D)\|^2_{0,\Omega} - \|\sigma^{*-1/2}\nabla^\perp s^*\|^2_{0,\Omega} \\ + \|\sigma^{1/2}\nabla(\delta p - \delta p_D)\|^2_{0,\Omega} + \|\sigma^{-1/2}\nabla^\perp(\delta s - \delta s_D)\|^2_{0,\Omega}. \end{aligned} \tag{2.11}$$

With the last two terms as desired, consider the other four. The second equation in (2.9) implies that $\sigma^{-1}\nabla^\perp(s^*+\delta s_D)$ is equal to a grad. Thus, there exists a $\delta p_N \in \mathrm{H}^1(\Omega)$ such that

$$\sigma\nabla(p^* + \delta p_N) = \nabla^\perp(s^* + \delta s_D).$$

Together with the Dirichlet data for $s = s^* + \delta s_D$ in (2.5), we have

$$\mathbf{n} \cdot \sigma \nabla (p^* + \delta p_N) = \mathbf{n} \cdot \nabla^\perp (s^* + \delta s_D) = h. \tag{2.12}$$

In other words, we may think of $\{p^* + \delta p_N, \mathcal{R}_\sigma(h), h\}$ as a DN triple for σ. This allows us to write (2.11) as

$$\begin{aligned} F(\sigma, p^* + \delta p, s^* + \delta s) = {} & \|\sigma^{1/2} \nabla (p^* + \delta p_D)\|_{0,\Omega}^2 - \|\sigma^{*1/2} \nabla p^*\|_{0,\Omega}^2 \\ & + \|\sigma^{1/2} \nabla (p^* + \delta p_N)\|_{0,\Omega}^2 - \|\sigma^{*1/2} \nabla p^*\|_{0,\Omega}^2 \\ & + \|\sigma^{1/2} \nabla (\delta p - \delta p_D)\|_{0,\Omega}^2 + \|\sigma^{-1/2} \nabla^\perp (\delta s - \delta s_D)\|_{0,\Omega}^2. \end{aligned} \tag{2.13}$$

Next, integration by parts yields the following relations:

$$\begin{aligned} \langle \mathcal{R}_{\sigma^*}(h), h \rangle_{0,\Gamma} &= \|\sigma^{*1/2} \nabla p^*\|_{0,\Omega}^2, \\ \langle \mathcal{R}_{\sigma}(h), h \rangle_{0,\Gamma} &= \|\sigma^{1/2} \nabla (p^* + \delta p_N)\|_{0,\Omega}^2, \\ \left\langle \mathcal{R}_{\sigma^*}^{-1}(\mathcal{R}_{\sigma^*}(h)), \mathcal{R}_{\sigma^*}(h) \right\rangle_{0,\Gamma} &= \|\sigma^{*1/2} \nabla p^*\|_{0,\Omega}^2, \\ \left\langle \mathcal{R}_{\sigma}^{-1}(\mathcal{R}_{\sigma^*}(h)), \mathcal{R}_{\sigma^*}(h) \right\rangle_{0,\Gamma} &= \|\sigma^{1/2} \nabla (p^* + \delta p_D)\|_{0,\Omega}^2. \end{aligned} \tag{2.14}$$

Thus, (2.13) becomes

$$\begin{aligned} F(\sigma, p^* + \delta p, s^* + \delta s) = {} & \left\langle (\mathcal{R}_\sigma^{-1} - \mathcal{R}_{\sigma^*}^{-1}) \mathcal{R}_{\sigma^*}(h), \mathcal{R}_{\sigma^*}(h) \right\rangle_{0,\Gamma} + \langle (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h), h \rangle_{0,\Gamma} \\ & + \|\sigma^{1/2} \nabla (\delta p - \delta p_D)\|_{0,\Omega}^2 + \|\sigma^{-1/2} \nabla^\perp (\delta s - \delta s_D)\|_{0,\Omega}^2. \end{aligned} \tag{2.15}$$

Since $\mathcal{R}_\sigma$ and $\mathcal{R}_{\sigma^*}$ are self-adjoint, we may combine the first two terms:

$$\begin{aligned} & \left\langle (\mathcal{R}_\sigma^{-1} - \mathcal{R}_{\sigma^*}^{-1}) \mathcal{R}_{\sigma^*}(h), \mathcal{R}_{\sigma^*}(h) \right\rangle_{0,\Gamma} + \langle (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h), h \rangle_{0,\Gamma} \\ & \quad = \left\langle (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*} + \mathcal{R}_{\sigma^*} \mathcal{R}_\sigma^{-1} \mathcal{R}_{\sigma^*} - \mathcal{R}_{\sigma^*})(h), h \right\rangle_{0,\Gamma} \\ & \quad = \left\langle (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*}) \mathcal{R}_\sigma^{-1} (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h), h \right\rangle_{0,\Gamma} \\ & \quad = \left\langle \mathcal{R}_\sigma^{-1} (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h), (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h) \right\rangle_{0,\Gamma}. \end{aligned} \tag{2.16}$$

Also, since

$$\begin{aligned} & \langle \mathcal{R}_\sigma^{-1} (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h), (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*}) h \rangle_{0,\Gamma} \\ & \qquad \leq \|\mathcal{R}_\sigma^{-1}\|_{\mathcal{L}(\mathrm{H}_0^{1/2}(\Gamma), \mathrm{H}_0^{-1/2}(\Gamma))} \|(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h)\|_{1/2,\Gamma}^2, \end{aligned}$$

we may combine (2.15) and (2.16) to arrive at the desired upper bound:

$$\begin{aligned} \mathrm{F}(\sigma, p^* + \delta p, s^* + \delta s) \leq {} & \|\mathcal{R}_\sigma^{-1}\|_{\mathcal{L}(\mathrm{H}_0^{1/2}(\Gamma), \mathrm{H}_0^{-1/2}(\Gamma))} \|\mathcal{R}_\sigma(h) - \mathcal{R}_{\sigma^*}(h)\|_{1/2,\Gamma}^2 \\ & + \|\sigma^{1/2} \nabla (\delta p - \delta p_D)\|_{0,\Omega}^2 + \|\sigma^{-1/2} \nabla^\perp (\delta s - \delta s_D)\|_{0,\Omega}^2. \end{aligned}$$

To achieve the lower bound, we recall (2.7) and observe that

$$(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h) = \delta p_{N|\Gamma} \in \mathrm{H}_0^{-1/2}(\Gamma)$$

by definition of δp_N. Hence, we may now consider the $\tilde{p} \in \mathrm{H}^1(\Omega)$ that solves

$$\begin{aligned} \nabla \cdot \sigma \nabla \tilde{p} &= 0 && \text{in } \Omega, \\ \tilde{p} &= \delta p_N && \text{on } \Gamma. \end{aligned}$$

Appealing to (2.14) and the trace theorem [11], we have

$$\begin{aligned}\langle \mathcal{R}_\sigma^{-1}(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h), (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h)\rangle_{0,\Gamma} &= \|\sigma^{1/2}\nabla\tilde{p}\|_{0,\Omega}^2 \\ &\geq c\,\|\nabla\tilde{p}\|_{0,\Omega}^2 \\ &\geq c_0\,\|\delta p_N\|_{1/2,\Gamma}^2 \\ &= c_0\|(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h)\|_{1/2,\Gamma}^2, \end{aligned} \tag{2.17}$$

where c_0 depends on the smoothness of the boundary and $\min_\Omega |\sigma|$. Finally, incorporating (2.17) with (2.16) into (2.6) establishes the lower bound:

$$\begin{aligned}\mathrm{F}(\sigma, p^* + \delta p, s^* + \delta s) \geq c_0\|(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h)\|_{1/2,\Gamma}^2 \\ +\|\sigma^{1/2}\nabla(\delta p - \delta p_D)\|_{0,\Omega}^2 + \|\sigma^{-1/2}\nabla^\perp(\delta s - \delta s_D)\|_{0,\Omega}^2. \end{aligned}$$ ∎

To make use of the above equivalence, we establish the following lemma using the constructs of the theorem to reassert the ability to minimize the functional in (2.4) for s_i and p_i separately.

LEMMA 2.2. *Suppose that $\sigma = \sigma^*$ on Γ. Also, for each $h \in \mathrm{H}_0^{-1/2}(\Gamma)$, let $\{p^*, \mathcal{R}_{\sigma^*}(h), h\}$ be a DN triple for σ^* and define*

$$\begin{aligned}\delta p_D &:= \arg \min_{\delta p \,\in\, \mathrm{H}_0^1(\Omega)} \|\sigma^{1/2}\nabla(p^* + \delta p)\|_{0,\Omega}, \\ \delta s_D &:= \arg \min_{\delta s \,\in\, \mathrm{H}_0^1(\Omega)} \|\sigma^{-1/2}\nabla^\perp(s^* + \delta s)\|_{0,\Omega}. \end{aligned} \tag{2.18}$$

Then

$$\mathrm{F}(\sigma, p^* + \delta p_D, s^* + \delta s_D) = \min_{\delta p, \delta s \,\in\, \mathrm{H}_0^1(\Omega)} \mathrm{F}(\sigma, p^* + \delta p, s^* + \delta s). \tag{2.19}$$

Proof. From (2.10) and the boundary data for p^* and s^*, we have

$$\begin{aligned} F(\sigma, p^* + \delta p, s^* + \delta s) \\ &= \|\sigma^{1/2}(\nabla p^* + \delta p_D)\|_{0,\Omega}^2 + \|\sigma^{1/2}\nabla(\delta p - \delta p_D)\|_{0,\Omega}^2 - 2\langle \nabla p^*, \nabla^\perp s^*\rangle_{0,\Omega} \\ &\quad + \|\sigma^{-1/2}\nabla^\perp(s^* + \delta s_D)\|_{0,\Omega}^2 + \|\sigma^{-1/2}\nabla^\perp(\delta s - \delta s_D)\|_{0,\Omega}^2 \\ &= \|\sigma^{1/2}(\nabla p^* + \delta p_D)\|_{0,\Omega}^2 + \|\sigma^{1/2}\nabla(\delta p - \delta p_D)\|_{0,\Omega}^2 - 2\langle \mathcal{R}_{\sigma^*}(h), h\rangle_{0,\Gamma} \\ &\quad + \|\sigma^{-1/2}\nabla^\perp(s^* + \delta s_D)\|_{0,\Omega}^2 + \|\sigma^{-1/2}\nabla^\perp(\delta s - \delta s_D)\|_{0,\Omega}^2. \end{aligned}$$

The conclusion is apparent since the boundary term is a known fixed quantity. ∎

A direct result of this lemma and Theorem 2.1 is the following corollary.

COROLLARY 2.3. *For any $h \in \mathrm{H}_0^{-1/2}(\Gamma)$, there exist positive constants c_0 and c_1 such that*

$$\begin{aligned} c_0\|\mathcal{R}_\sigma(h) - \mathcal{R}_{\sigma^*}(h)\|_{1/2,\Gamma}^2 \\ &\leq \min_{p,s \,\in\, \mathrm{H}^1(\Omega)} \|\sigma^{1/2}\nabla p - \sigma^{-1/2}\nabla^\perp s\|_{0,\Omega}^2 \\ &\leq c_1\|\mathcal{R}_\sigma(h) - \mathcal{R}_{\sigma^*}(h)\|_{1/2,\Gamma}^2, \end{aligned} \tag{2.20}$$

where c_0 depends on Ω and $\min_\Omega |\sigma|$, $c_1 = \|\mathcal{R}_\sigma^{-1}\|_{\mathcal{L}(\mathrm{H}_0^{1/2}(\Gamma), \mathrm{H}_0^{-1/2}(\Gamma))}$, and where p and s are subject to the boundary data in (2.5).

It is also clear from Lemma 2.2, as a generalization of the above corollary, that the KV formulation is equivalent to the OLS formulation. We state this formally in the following corollary.

COROLLARY 2.4. *With $\mathcal{F}_{KV}$ defined in* (2.4) *subject to* (2.5)*, there exist positive constants c_0 and c_1 such that*

$$\begin{aligned} c_0 \sum_{i=1}^{L} \|\mathcal{R}_\sigma(h_i) - \mathcal{R}_{\sigma^*}(h_i)\|^2_{1/2,\Gamma} & \\ \leq \mathcal{F}_{KV}(\sigma; \{\mathcal{R}_{\sigma^*}(h_i), h_i\}_{i=1}^{L}) & \\ \leq c_1 \sum_{i=1}^{L} \|\mathcal{R}_\sigma(h_i) - \mathcal{R}_{\sigma^*}(h_i)\|^2_{1/2,\Gamma}, & \end{aligned} \tag{2.21}$$

where $c_1 = \|\mathcal{R}_\sigma^{-1}\|_{\mathcal{L}(\mathrm{H}_0^{1/2}(\Gamma),\mathrm{H}_0^{-1/2}(\Gamma))}$ and c_0 depends on Ω and $\min_\Omega |\sigma|$.

Remark 4. As a final remark, consider (2.20) under the assumption of complete knowledge of the NtD map. Taking the sup over all $h \in \mathrm{H}_0^{-1/2}(\Gamma)$ of each quantity and scaling appropriately then leads to the idealized equivalence result:

$$\begin{aligned} c_0 \|\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*}\|^2_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{1/2}(\Gamma))} & \\ \leq \sup_{h \in \mathrm{H}_0^{-1/2}(\Gamma)} \frac{\left(\min_{p,s \,\in\, \mathrm{H}^1(\Omega)} \|\sigma^{1/2}\nabla p - \sigma^{-1/2}\nabla^\perp s\|^2_{0,\Omega}\right)}{\|h\|_{-1/2,\Gamma}} & \\ \leq c_1 \|\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*}\|^2_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{1/2}(\Gamma))}, & \end{aligned}$$

where, again, p and s are subject to the boundary data in (2.5) for a given h. This suggests a sup version, rather than least-squares version, of the KV functional that is equivalent to the operator norm of the defect in the NtD maps.

2.2. FOSLS. We now present a FOSLS formulation for ECT. The first-order system we use may be viewed as a rescaled version of the Maxwell equations. We will show that the FOSLS formulation not only provides the ability to solve forward problems efficiently but also yields an insightful process for updating the approximate conductivity. Again, the result is a natural alternating minimization scheme. We present the FOSLS formulation and provide an equivalence result akin to that of the previous section.

2.2.1. Formulation. To derive the FOSLS formulation for ECT, define $q := \frac{1}{2}\log(\sigma)$ so that $e^{2q} := \sigma$. This is natural thing to do for deeper reasons than the positivity of conductivity, since the reciprocal of conductivity, resistivity, is also of interest. It is therefore seemingly arbitrary whether one considers an error in conductivity, $\sigma - \sigma^*$, or the associated error in resistivity, $1/\sigma - 1/\sigma^*$. However, by defining error in terms of q, such an inconsistency is avoided since

$$|q - q^*| = \frac{1}{2}\left|\log\left(\frac{\sigma}{\sigma^*}\right)\right| = \frac{1}{2}\left|\log\left(\frac{1/\sigma}{1/\sigma^*}\right)\right|. \tag{2.22}$$

Proceeding with the formulation, we now let $\mathbf{u} := e^q \nabla p$. Then, with $\{p, \mathcal{R}_\sigma(h), h\}$ a DN triple for σ, $\mathbf{u}$ solves the first-order system

$$\begin{aligned} e^{-q}\nabla \cdot e^q \mathbf{u} &= 0 && \text{in } \Omega, \\ e^q \nabla \times e^{-q}\mathbf{u} &= 0 && \text{in } \Omega, \\ \mathbf{n} \cdot e^q \mathbf{u} &= h && \text{on } \Gamma. \end{aligned} \tag{2.23}$$

We may think of (2.23) as determining the tangential current

$$\mathbf{n} \times e^{-q}\mathbf{u} = (\mathbf{n} \times \nabla)\mathcal{R}_\sigma(h) \in (\mathrm{H}_0^{-1/2}(\Gamma))^{n-1}.$$

When $n = 2$, we write $(\boldsymbol{\tau}\cdot)$ in lieu of $(\mathbf{n}\times)$. Practically speaking, deriving tangential current data from voltage data is problematic at best, since simply differentiating noisy data is an unstable process. Though there may be future innovations that enable direct assessment of tangential current, we defer discussion of this important matter to future research.

We now make our first definition regarding the FOSLS formulation.

DEFINITION 2.5. *First-order system* (2.23) *defines the normal-to-tangential current map (NtT map),* $\mathcal{P}_q : \mathrm{H}_0^{-1/2}(\Gamma) \longrightarrow (\mathrm{H}_0^{-1/2}(\Gamma))^{n-1}$, *where*

$$\mathcal{P}_q(h) = \mathbf{n} \times e^{-q}\mathbf{u} = (\mathbf{n} \times \nabla)\mathcal{R}_\sigma(h).$$

We also define the following variations on $\mathrm{H}(\mathrm{div}, \Omega)$ and $\mathrm{H}(curl, \Omega)$.

DEFINITION 2.6. *For* $q \in \mathrm{L}^\infty(\Omega)$, *let* $\mathrm{W}_q = \mathrm{H}(\mathrm{div}\, e^q, \Omega) \cap \mathrm{H}(curl\, e^{-q}, \Omega)$, *where*

$$\mathrm{H}(\mathrm{div}\, e^q, \Omega) = \{\mathbf{u} \in (\mathrm{L}^2(\Omega))^n : \nabla \cdot e^q\mathbf{u} \in \mathrm{L}^2(\Omega)\},$$
$$\mathrm{H}(curl\, e^{-q}, \Omega) = \left\{\mathbf{u} \in (\mathrm{L}^2(\Omega))^n : \nabla \times e^{-q}\mathbf{u} \in (\mathrm{L}^2(\Omega))^{2n-3}\right\},$$

for $n = 2, 3$.

Finally, it is convenient to introduce an analogy to the DN-triple notation.

DEFINITION 2.7. *In the FOSLS setting, if* $\mathbf{u}$ *solves* (2.23) *with boundary data* h, *then we refer to* $\{\mathbf{u}, h, \mathcal{P}_{q^*}(h)\}$ *as a normal-tangential triple (NT triple) for* q *and to* $\{h, \mathcal{P}_{q^*}(h)\}$ *as an NT pair.*

Given the boundary data, $\{h_i, \mathcal{P}_{q^*}(h_i)\}_{i=1}^L$, associated with an unknown q^*, we approximate q^* by minimizing the FOSLS functional

$$\mathcal{F}_{OSLS}(q; \{h_i, \mathcal{P}_{q^*}(h_i)\}_{i=1}^L) = \sum_{i=1}^{L} \left(\min_{\mathbf{u}_i \in \mathrm{W}_q} \mathrm{F}(q, \mathbf{u}_i; h_i, \mathcal{P}_{q^*}(h_i)) \right), \tag{2.24}$$

where

$$\begin{aligned} \mathrm{F}(q, \mathbf{u}_i; h_i, \mathcal{P}_{q^*}(h_i)) &:= \|e^{-q}\nabla \cdot e^q\mathbf{u}_i\|_{0,\Omega}^2 + \|e^q\nabla \times e^{-q}\mathbf{u}_i\|_{0,\Omega}^2 \\ &\quad + \|\mathbf{n} \cdot e^q\mathbf{u}_i - h_i\|_{-1/2,\Gamma}^2 + \|\mathbf{n} \times e^{-q}\mathbf{u}_i - \mathcal{P}_{q^*}(h_i)\|_{-1/2,\Gamma}^2. \end{aligned} \tag{2.25}$$

To minimize $\mathcal{F}_{OSLS}$, first note that, for a fixed approximation, q, each $\mathbf{u}_i$ can be numerically approximated with optimal efficiency [5]. Furthermore, if we assume $q \in \mathrm{H}^1(\Omega)$ and $\mathbf{u} \in \mathrm{W}_0 = \mathrm{H}(\mathrm{div}, \Omega) \cap \mathrm{H}(curl, \Omega)$, then for fixed $\mathbf{u}_i \in (\mathrm{H}^1(\Omega))^n$, with $i = 1, \ldots, L$, we also have an elliptic problem to improve approximation $q \in \mathrm{H}^1(\Omega)$. Taking the first variation in q of $\mathcal{F}_{OSLS}$ for a fixed set, $\{\mathbf{u}_i \in (\mathrm{H}^1(\Omega))^2\}_{i=1}^L$, reveals that the best $q \in \mathrm{H}^1(\Omega)$ satisfies the weak form

$$\langle A\nabla q, \nabla r\rangle_{0,\Omega} = f(r) \qquad \forall\, r \in \mathrm{H}^1(\Omega), \tag{2.26}$$

where

$$A = 2\sum_{i=1}^{L} |\mathbf{u}_i|^2 \tag{2.27}$$

and $f \in \mathrm{H}^{-1}(\Omega)$, for $n = 2$ for example, is given by

$$\langle f, r\rangle_{0,\Omega} = \sum_{i=1}^{L} \left(\langle \nabla \cdot \mathbf{u}_i, \nabla r \cdot \mathbf{u}_i \rangle_{0,\Omega} + \langle \nabla \times \mathbf{u}_i, \nabla^{\perp} r \cdot \mathbf{u}_i \rangle_{0,\Omega} \right),$$

using $(\boldsymbol{\tau}\cdot)$ in lieu of $(\mathbf{n}\times)$ and $(\nabla^{\perp}\cdot)$ in lieu of $(\nabla\times)$.

These properties suggest that we can employ an alternating subspace minimization scheme. Furthermore, it is remarkable that the minimization associated with the weak form in (2.26) incorporates inner products of interior current as a weighting on the components of q, just as it appears in Calderdon's linearization. Thus, the FOSLS functional appears to reduce error in q according to naturally weighted H^1-seminorms. Note that prior information about σ^*, manifested as an improved approximation σ, is reflected in this weighting. Because requiring $q \in \mathrm{H}^1(\Omega)$ is quite restrictive, the OLS or KV approach may be better suited for many applications. However, given the above insights, the role of FOSLS as a framework for EIT is compelling.

2.2.2. Equivalence to OLS. As with the KV functional, we demonstrate equivalence for $n = 2$. To show that the FOSLS functional in (2.24) is equivalent to OLS, we first establish several lemmas and some useful notation. In the first lemma, we relate $\mathcal{P}_q$ to $\mathcal{R}_\sigma$ in two dimensions. Generalization of this lemma to the three-dimensional problem is not obvious, and not addressed in this study. In three dimesions, complications arise since $\mathcal{P}_q$ is then a 2-vector, whereas $\mathcal{R}_\sigma(h)$ remains a scalar quantity. However, the increased dimensionality of the data in three dimensions can be expected to improve the quality of the reconstruction.

LEMMA 2.8. *Let $\sigma = \sigma^*$ on Γ and $n = 2$. Then*

$$\|\mathcal{P}_q - \mathcal{P}_{q^*}\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{-1/2}(\Gamma))} = \|\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*}\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{1/2}(\Gamma))}. \tag{2.28}$$

Proof. We wish to show that

$$\sup_{h\in\mathrm{H}_0^{-1/2}(\Gamma)} \frac{\|(\mathcal{P}_q - \mathcal{P}_{q^*})(h)\|_{-1/2,\Gamma}}{\|h\|_{-1/2,\Gamma}} = \sup_{h\in\mathrm{H}_0^{-1/2}(\Gamma)} \frac{\|(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h)\|_{1/2,\Gamma}}{\|h\|_{-1/2,\Gamma}}.$$

Since $(\mathcal{P}_q - \mathcal{P}_{q^*})(h) = (\boldsymbol{\tau}\cdot\nabla)(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h)$, it suffices to show that

$$\|(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h)\|_{1/2,\Gamma} = \|(\boldsymbol{\tau}\cdot\nabla)(\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})(h)\|_{-1/2,\Gamma}.$$

Noting that there is a $g \in \mathrm{H}^{1/2}(\Gamma)$ such that $g = (\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*})h$, then this reduces to

$$\|g\|_{1/2,\Gamma} = \left\| \frac{dg}{d\tau} \right\|_{-1/2,\Gamma}. \tag{2.29}$$

We now show that this holds for any $g \in \mathrm{H}_0^{1/2}(\Gamma)$ by appealing to the representation of the $\mathrm{H}^{1/2}$- and $\mathrm{H}^{-1/2}$-norms using the Fourier transform. Defining $\hat{g}(\omega)$ as the transform of g, we have [24]

$$\|g\|_{1/2,\Gamma} = \|\omega^{1/2}\hat{g}\|_{0,\Gamma},$$
$$\|h\|_{-1/2,\Gamma} = \|\omega^{-1/2}\hat{h}\|_{0,\Gamma}.$$

Hence, (2.29) follows from

$$\|g\|_{1/2,\Gamma} = \|\omega^{1/2}\hat{g}\|_{0,\Gamma} = \|\omega^{-1/2}\omega\hat{g}\|_{0,\Gamma} = \|\omega^{-1/2}\hat{g'}\|_{0,\Gamma} = \left\| \frac{dg}{d\tau} \right\|_{-1/2,\Gamma}. \qquad \square$$

Remark 5. An alternative proof may be preferable in which (2.29) is derived by interpolating from an analogous statement of integer index.

It is convenient to isolate the interior and boundary functional terms of the FOSLS functional in (2.24) and write

$$\begin{aligned}
\mathrm{F}(q,\mathbf{u}_i;h,\mathcal{P}_{q^*}(h_i)) &:= \mathrm{F_I}(q,\mathbf{u}_i) + \mathrm{F_B}(q,\mathbf{u}_i;h_i,\mathcal{P}_{q^*}(h_i)),\\
\mathrm{F_I}(q,\mathbf{u}_i) &:= \|e^{-q}\nabla\cdot e^{q}\mathbf{u}_i\|^2_{0,\Omega} + \|e^{q}\nabla\times e^{-q}\mathbf{u}_i\|^2_{0,\Omega},\\
\mathrm{F_B}(q,\mathbf{u}_i;h_i,\mathcal{P}_{q^*}(h_i)) &:= \|\mathbf{n}\cdot e^{q}\mathbf{u}_i - h_i\|^2_{-1/2,\Gamma} + \|\boldsymbol{\tau}\cdot e^{-q}\mathbf{u}_i - \mathcal{P}_{q^*}(h_i)\|^2_{-1/2,\Gamma}.
\end{aligned} \tag{2.30}$$

The following lemmas set the stage for stating and proving the equivalence results. The first establishes a useful equivalence relation between F and the norm defined on $\mathrm{W}_q(\Omega)$ by

$$\|\mathbf{w}\|^2_{\mathrm{W}_q} := \|\mathbf{w}\|^2_{0,\Omega} + \|e^{-q}\nabla\cdot e^{q}\mathbf{w}\|^2_{0,\Omega} + \|e^{q}\nabla\times e^{-q}\mathbf{w}\|^2_{0,\Omega}.$$

LEMMA 2.9. *Let* $\mathbf{w}\in\mathrm{W}_q(\Omega)$. *Then there exists a constant, c, depending on q and* Ω, *such that*

$$\frac{1}{c}\|\mathbf{w}\|^2_{\mathrm{W}_q} \le \mathrm{F}(q,\mathbf{w};0,0) \le c\|\mathbf{w}\|^2_{\mathrm{W}_q}. \tag{2.31}$$

Proof. The upper bound in (2.31) follows directly from the trace theorem [11]. For the lower bound, it suffices to show there is a c such that

$$\begin{aligned}
&\|\mathbf{w}\|^2_{0,\Omega}\\
&\quad\le c\left(\|e^{-q}\nabla\cdot e^{q}\mathbf{w}\|^2_{0,\Omega} + \|e^{q}\nabla\times e^{-q}\mathbf{w}\|^2_{0,\Omega} + \|\mathbf{n}\cdot e^{q}\mathbf{w}\|^2_{-1/2,\Gamma} + \|\boldsymbol{\tau}\cdot e^{-q}\mathbf{w}\|^2_{-1/2,\Gamma}\right).
\end{aligned}$$

To this end, we use a scaled Helmholtz decomposition [11]: $\forall\ \mathbf{v}\in(\mathrm{L}^2(\Omega))^2$, there exist $\phi\in\mathrm{H}^1_0(\Omega)$ and $\psi\in\mathrm{H}^1(\Omega)/\mathbb{R}$ such that

$$\mathbf{v} = e^{q}\nabla\phi + e^{-q}\nabla^{\perp}\psi.$$

The logic leading to this representation is to choose ϕ so that $\nabla\cdot e^{2q}\nabla\phi = \nabla\cdot e^{q}\mathbf{v}$ and to similarly choose ψ to satisfy $\nabla\times e^{-2q}\nabla^{\perp}\psi = \nabla\times e^{-q}\mathbf{v}$. The choice of boundary conditions on ϕ and ψ enables us to eliminate the cross term that would otherwise appear below and to use a Poincaré–Friedrichs inequality. With this decomposition, we write

$$\begin{aligned}
\|\mathbf{w}\|_{0,\Omega} &= \sup_{\mathbf{v}\in(\mathrm{L}^2(\Omega))^2} \frac{\langle\mathbf{w},\mathbf{v}\rangle_{0,\Omega}}{\|\mathbf{v}\|_{0,\Omega}}\\
&= \sup_{\phi,\psi\in\mathrm{H}^1(\Omega)} \frac{\langle\mathbf{w},e^{q}\nabla\phi + e^{-q}\nabla^{\perp}\psi\rangle_{0,\Omega}}{\|e^{q}\nabla\phi + e^{-q}\nabla^{\perp}\psi\|_{0,\Omega}}\\
&\le \sup_{\phi\in\mathrm{H}^1(\Omega)} \frac{\langle\mathbf{w},e^{q}\nabla\phi\rangle_{0,\Omega}}{\|e^{q}\nabla\phi\|_{0,\Omega}} + \sup_{\psi\in\mathrm{H}^1(\Omega)} \frac{\langle\mathbf{w},e^{-q}\nabla^{\perp}\psi\rangle_{0,\Omega}}{\|e^{-q}\nabla^{\perp}\psi\|_{0,\Omega}}\\
&= \frac{\langle\mathbf{w},e^{q}\nabla\phi^*\rangle_{0,\Omega}}{\|e^{q}\nabla\phi^*\|_{0,\Omega}} + \frac{\langle\mathbf{w},e^{-q}\nabla^{\perp}\psi^*\rangle_{0,\Omega}}{\|e^{-q}\nabla^{\perp}\psi^*\|_{0,\Omega}}.
\end{aligned} \tag{2.32}$$

Applying Green's theorem to the first term, we have

$$\begin{aligned}
&\frac{\langle \mathbf{w}, e^q\nabla\phi^*\rangle_{0,\Omega}}{\|e^q\nabla\phi^*\|_{0,\Omega}} \\
&\quad\le \frac{|\langle e^{-q}\nabla\cdot e^q\mathbf{w}, e^q\phi^*\rangle_{0,\Omega}| + |\langle \mathbf{n}\cdot e^q\mathbf{w}, \phi^*\rangle_{0,\Gamma}|}{\|e^q\nabla\phi^*\|_{0,\Omega}} \\
&\quad\le \frac{\|e^{-q}\nabla\cdot e^q\mathbf{w}\|_{0,\Omega}\|e^q\phi^*\|_{0,\Omega} + \|\mathbf{n}\cdot e^q\mathbf{w}\|_{-1/2,\Gamma}\|\phi^*\|_{1/2,\Gamma}}{\|e^q\nabla\phi^*\|_{0,\Omega}} \\
&\quad\le \left(\|e^{-q}\nabla\cdot e^q\mathbf{w}\|_{0,\Omega}^2 + \|\mathbf{n}\cdot e^q\mathbf{w}\|_{-1/2,\Gamma}^2\right)^{1/2}\left(\frac{\|e^q\phi^*\|_{0,\Omega}^2 + \|\phi^*\|_{1/2,\Gamma}^2}{\|e^q\nabla\phi^*\|_{0,\Omega}^2}\right)^{1/2}. \qquad (2.33)
\end{aligned}$$

The term in (2.33) that does not involve $\mathbf{w}$ may be bounded by a constant depending on q and Ω. To see this, note that we can use the Poincaré–Friedrichs inequality [11] to write

$$\frac{\|e^q\phi^*\|_{0,\Omega}^2 + \|\phi^*\|_{1/2,\Gamma}^2}{\|e^q\nabla\phi^*\|_{0,\Omega}^2} \le \frac{\max_\Omega\{e^{2q},1\}}{\min_\Omega e^{2q}}\frac{(\|\phi^*\|_{0,\Omega}^2 + \|\phi^*\|_{1/2,\Gamma}^2)}{\|\nabla\phi^*\|_{0,\Omega}^2} \le c(q),$$

where

$$c(q) = c\frac{\max_\Omega\{e^{2q},1\}}{\min_\Omega e^{2q}}. \qquad (2.34)$$

Thus, (2.33) becomes

$$\frac{\langle \mathbf{w}, e^q\nabla\phi^*\rangle_{0,\Omega}}{\|e^q\nabla\phi^*\|_{0,\Omega}} \le c_1(q)\left(\|e^{-q}\nabla\cdot e^q\mathbf{w}\|_{0,\Omega}^2 + \|\mathbf{n}\cdot e^q\mathbf{w}\|_{-1/2,\Gamma}^2\right)^{1/2}. \qquad (2.35)$$

Similarly, there is a $c_2(q)$ such that

$$\frac{|\,\langle \mathbf{w}, e^{-q}\nabla^\perp\psi^*\rangle_{0,\Omega}\,|}{\|e^{-q}\nabla^\perp\psi^*\|_{0,\Omega}} \le c_2(q)\left(\|e^q\nabla\times e^{-q}\mathbf{w}\|_{0,\Omega}^2 + \|\boldsymbol{\tau}\cdot e^{-q}\mathbf{w}\|_{-1/2,\Gamma}^2\right)^{1/2}. \qquad (2.36)$$

Therefore, combining inequalities (2.35) and (2.36) and choosing c appropriately proves the lemma. ∎

We also make use of the next lemma to relate the FOSLS functional directly to the NtT map.

LEMMA 2.10. *Let* $\mathbf{w}\in \mathrm{W}_q(\Omega)$, *and suppose* $\mathbf{n}\cdot e^q\mathbf{w} = h$ *on* Γ. *If* $\mathbf{w}_h$ *satisfies*

$$\begin{aligned}
e^{-q}\nabla\cdot e^q\mathbf{w}_h &= 0 && \text{in } \Omega,\\
e^q\nabla\times e^{-q}\mathbf{w}_h &= 0 && \text{on } \Gamma,\\
\mathbf{n}\cdot e^q\mathbf{w}_h &= h && \text{on } \Gamma, \qquad (2.37)
\end{aligned}$$

then there exists a constant, c, depending only on Ω *and* $\max_\Omega e^q$, *such that* $\boldsymbol{\tau}\cdot e^{-q}(\mathbf{w}-\mathbf{w}_h)$ *satisfies*

$$\|\boldsymbol{\tau}\cdot e^{-q}(\mathbf{w}-\mathbf{w}_h)\|_{-1/2,\Gamma}^2 \le c\,\mathrm{F}_I(q,\mathbf{w}). \qquad (2.38)$$

Proof. We have from the trace theorem [11] that

$$\begin{aligned}
\|\boldsymbol{\tau}\cdot e^{-q}(\mathbf{w}-\mathbf{w}_h)\|_{-1/2,\Gamma}^2 &\le c\left(\|\nabla\times e^{-q}(\mathbf{w}-\mathbf{w}_h)\|_{0,\Omega}^2 + \|e^{-q}(\mathbf{w}-\mathbf{w}_h)\|_{0,\Omega}^2\right)\\
&\le c\left(\|\nabla\times e^{-q}(\mathbf{w}-\mathbf{w}_h)\|_{0,\Omega}^2 + \|e^{q}(\mathbf{w}-\mathbf{w}_h)\|_{0,\Omega}^2\right),
\end{aligned}$$

where c depends on Ω and $\max_\Omega e^q$. Since, by assumption, $\mathbf{n} \cdot e^q(\mathbf{w} - \mathbf{w}_h) = 0$ on the boundary, we may bound the L^2-term above using a Poincaré–Friedrichs-like inequality of the form [2]

$$\|e^q(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega}^2 \leq c \left(\|\nabla \times e^{-q}(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega}^2 + \|\nabla \cdot e^q(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega}^2 \right), \tag{2.39}$$

where c depends on Ω and $\max_\Omega e^q$. We therefore have

$$\begin{aligned} \|\boldsymbol{\tau} \cdot e^{-q}(\mathbf{w} - \mathbf{w}_h)\|_{-1/2,\Gamma}^2 &\leq c \left(\|\nabla \times e^{-q}(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega}^2 + \|\nabla \cdot e^q(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega}^2 \right) \\ &\leq c\, \mathrm{F}_I(q, \mathbf{w}), \end{aligned}$$

where, again, c depends on Ω and $\max_\Omega e^q$. ∎

The above lemmas now allow us to establish a lower bound for the FOSLS functional in terms of the defect in the ND map. In analogy to the equivalence established for the KV formulation, the line of proof follows for each NT pair. To begin, let $\{\mathbf{u}^*, h, \mathcal{P}_{q^*}(h)\}$ be an NT triple for unknown $\sigma^* = e^{2q^*}$. This implies that $\mathrm{F}(q^*, \mathbf{u}^*; h, \mathcal{P}_{q^*}(h)) = 0$. For arbitrary $q \in \mathrm{H}^1(\Omega)$, provided $q_{|\Gamma} = q^*_{|\Gamma}$, and arbitrary $\mathbf{u} \in \mathrm{W}_q(\Omega)$, we wish to interpret how $\mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h))$ expresses errors $q - q^*$ and $\mathbf{u} - \mathbf{u}^*$. To facilitate this analysis, we write the perturbed functional as

$$\mathrm{F}(q, \mathbf{u}^* + \delta\mathbf{u}; h, \mathcal{P}_{q^*}(h)),$$

where $\delta\mathbf{u} \in \mathrm{W}_q(\Omega)$. It is convenient to make the following definition.

Definition 2.11. *Denote*

$$\mathrm{S}_q := \{\mathbf{u} \in \mathrm{W}_q(\Omega) \,:\, \mathrm{F}_\mathrm{I}(q, \mathbf{u}) = 0\},$$

the space of F_I*-harmonic functions relative to* q*.*

Before addressing arbitrary $\mathbf{u} \in \mathrm{W}_q(\Omega)$, and thus arbitrary $\delta\mathbf{u} \in \mathrm{W}_q(\Omega)$, we first consider perturbations $\delta\mathbf{u}$ such that $\mathbf{u} \in \mathrm{S}_q$.

Lemma 2.12. *Let* $\mathbf{u} \in \mathrm{S}_q$*. Then*

$$\frac{1}{c} \|\mathcal{P}_q(h) - \mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma}^2 \leq \mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \qquad \forall\, h \in \mathrm{H}_0^{-1/2}(\Gamma),$$

where $c = 1 + \|\mathcal{P}_q\|^2_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma), \mathrm{H}_0^{-1/2}(\Gamma))}$.

Proof. Since $\mathbf{u} \in \mathrm{S}_q$, we immediately have that $\mathrm{F}_I(q, \mathbf{u}) = 0$. Also, writing $\mathbf{n} \cdot e^q \mathbf{u} = f$, we have that $\boldsymbol{\tau} \cdot e^{-q}\mathbf{u} = \mathcal{P}_q(f)$, and the remaining part of the functional is the boundary term:

$$\begin{aligned} \mathrm{F}_B(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) &= \|f - h\|_{-1/2,\Gamma}^2 + \|\mathcal{P}_q(f) - \mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma}^2 \\ &= \|f - h\|_{-1/2,\Gamma}^2 + \|\mathcal{P}_q(f) - \mathcal{P}_q(h) + \mathcal{P}_q(h) - \mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma}^2 \\ &= \|f - h\|_{-1/2,\Gamma}^2 + \|\mathcal{P}_q(f) - \mathcal{P}_q(h)\|_{-1/2,\Gamma}^2 + \|\mathcal{P}_q(h) - \mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma}^2 \\ &\quad + 2\langle \mathcal{P}_q(f) - \mathcal{P}_q(h), \mathcal{P}_q(h) - \mathcal{P}_{q^*}(h) \rangle_{-1/2,\Gamma}. \end{aligned} \tag{2.40}$$

Now, since $\mathcal{P}_q$ is linear, we have

$$\|\mathcal{P}_q\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma), \mathrm{H}_0^{-1/2}(\Gamma))} \geq \frac{\|\mathcal{P}_q(f) - \mathcal{P}_q(h)\|_{-1/2,\Gamma}}{\|f - h\|_{-1/2,\Gamma}}.$$

Denoting $\zeta = \|\mathcal{P}_q\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{-1/2}(\Gamma))}$, we may write

$$\|f-h\|_{-1/2,\Gamma} \geq \frac{1}{\zeta}\|\mathcal{P}_q(f)-\mathcal{P}_q(h)\|_{-1/2,\Gamma}$$

so that (2.40) becomes

$$\begin{aligned}\mathrm{F}_B(q,\mathbf{u};h,\mathcal{P}_{q^*}(h)) \geq \left(1+\frac{1}{\zeta^2}\right)\|\mathcal{P}_q(f)-\mathcal{P}_q(h)\|^2_{-1/2,\Gamma} + \|\mathcal{P}_q(h)-\mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}\\ -2\|\mathcal{P}_q(f)-\mathcal{P}_q(h)\|_{-1/2,\Gamma}\|\mathcal{P}_q(h)-\mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma}.\end{aligned}$$

Using an ϵ-inequality, $\forall\,\epsilon>0$ we have

$$\begin{aligned}&\mathrm{F}_B(q,\mathbf{u};h,\mathcal{P}_{q^*}(h))\\ &\quad\geq \left(1+\frac{1}{\zeta^2}-\epsilon\right)\|\mathcal{P}_q(f)-\mathcal{P}_q(h)\|^2_{-1/2,\Gamma} + \left(1-\frac{1}{\epsilon}\right)\|\mathcal{P}_q(h)-\mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}.\end{aligned}$$

Choosing $\epsilon = 1+\frac{1}{\zeta^2}$ leads to

$$\mathrm{F}(q,\mathbf{u};h,\mathcal{P}_{q^*}(h)) \geq \left(\frac{1}{1+\zeta^2}\right)\|\mathcal{P}_q(h)-\mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}. \qquad \square$$

We now have all the necessary tools and notation to establish the main theorem, associated with the lower bound in the equivalence we seek. We write an arbitrary $\mathbf{u}\in(\mathrm{H}^1(\Omega))^2$ as $\mathbf{u}^*+\delta\mathbf{u}$ and consider its projection onto space S_q.

THEOREM 2.13. *Assume that q^* and $\mathbf{u}^*$ are such that $\mathrm{F}(q^*,\mathbf{u}^*;h,\mathcal{P}_{q^*}(h))=0$, and consider $\mathrm{F}(q,\mathbf{u};h,\mathcal{P}_{q^*}(h))$, where q and $\mathbf{u}$ are arbitrary insofar as $q-q^*\in\mathrm{H}_0^1(\Omega)$ and $\mathbf{u}\in\mathrm{W}_q(\Omega)$. Also, let $\delta\mathbf{u}_s$ satisfy*

$$\mathbf{u}^*+\delta\mathbf{u}_s = \arg\min_{\mathbf{u}^*+\delta\mathbf{u}'\in\mathrm{S}_q}\mathrm{F}(q,\mathbf{u}^*+\delta\mathbf{u}';h,\mathcal{P}_{q^*}(h)), \tag{2.41}$$

and define $\delta\mathbf{u}=\mathbf{u}-\mathbf{u}^*$. Then there exists a positive constant, c, depending on Ω and $\|\mathcal{P}_q\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{-1/2}(\Gamma))}$, such that

$$\mathrm{F}(q,\mathbf{u};h,\mathcal{P}_{q^*}(h)) \geq c\left(\|\delta\mathbf{u}-\delta\mathbf{u}_s\|^2_{\mathrm{W}_q(\Omega)} + \|\mathcal{P}_q(h)-\mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}\right).$$

Proof. First, $\mathbf{u}^*+\delta\mathbf{u}_s\in\mathrm{S}_q$ implies that

$$\begin{aligned}\mathrm{F}(q,\mathbf{u}^*+\delta\mathbf{u};h,\mathcal{P}_{q^*}(h)) &= \mathrm{F}(q,\mathbf{u}^*+\delta\mathbf{u}_s+\delta\mathbf{u}-\delta\mathbf{u}_s;h,\mathcal{P}_{q^*}(h))\\ &= \mathrm{F}_I(q,\delta\mathbf{u}-\delta\mathbf{u}_s)+\mathrm{F}_B(q,\mathbf{u}^*+\delta\mathbf{u}_s+\delta\mathbf{u}-\delta\mathbf{u}_s;h,\mathcal{P}_{q^*}(h)).\end{aligned} \tag{2.42}$$

On the boundary, we denote

$$\begin{aligned}\mathbf{n}\cdot(e^q(\mathbf{u}^*+\delta\mathbf{u}_s)) &= h_s,\\ \boldsymbol{\tau}\cdot(e^{-q}(\mathbf{u}^*+\delta\mathbf{u}_s)) &= \mathcal{P}_q(h_s)\end{aligned}$$

and

$$\begin{aligned}\mathbf{n}\cdot(e^q(\delta\mathbf{u}-\delta\mathbf{u}_s)) &= \delta h,\\ \boldsymbol{\tau}\cdot(e^{-q}(\delta\mathbf{u}-\delta\mathbf{u}_s)) &= \delta f.\end{aligned} \tag{2.43}$$

Then (2.42) becomes

$$\begin{aligned}\mathrm{F}(q, \mathbf{u}^* + \delta\mathbf{u}; h, \mathcal{P}_{q^*}(h)) = \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) + \langle h_s - h + \delta h, h_s - h + \delta h\rangle_{-1/2,\Gamma} \\ + \langle \mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h) + \delta f, \mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h) + \delta f\rangle_{-1/2,\Gamma}.\end{aligned} \tag{2.44}$$

Next, expanding the terms in (2.44) leads to

$$\begin{aligned}&\mathrm{F}(q, \mathbf{u}^* + \delta\mathbf{u}; h, \mathcal{P}_{q^*}(h)) \\ &\quad = \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) + \|h_s - h\|^2_{-1/2,\Gamma} + \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma} \\ &\qquad + \|\delta h\|^2_{-1/2,\Gamma} + \|\delta f\|^2_{-1/2,\Gamma} + 2\langle h_s - h, \delta h\rangle_{-1/2,\Gamma} + 2\langle \mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h), \delta f\rangle_{-1/2,\Gamma}.\end{aligned} \tag{2.45}$$

To address the cross terms, we must use the orthogonality statement associated with (2.41). First, note that there exists a $\widehat{\delta\mathbf{u}}$ such that $\{\mathbf{u}^* + \widehat{\delta\mathbf{u}}, h + \delta h, \mathcal{P}_q(h + \delta h)\}$ is an NT triple. We may therefore speak of $\mathcal{P}_q(h + \delta h) = \mathcal{P}_q(h) + \mathcal{P}_q(\delta h)$ and of an orthogonality condition for $\mathbf{u}^* + \delta\mathbf{u}_s$:

$$\langle h_s - h, \delta h\rangle_{-1/2,\Gamma} + \langle \mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h), \mathcal{P}_q(\delta h)\rangle_{-1/2,\Gamma} = 0 \qquad \forall\ \delta h \in \mathrm{H}_0^{-1/2}(\Gamma). \tag{2.46}$$

We can now use (2.46) to add and subtract some helpful terms so that, for any $\epsilon \in (0, 1)$, equation (2.45) becomes

$$\begin{aligned}&\mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \\ &\quad = \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) + \|h_s - h\|^2_{-1/2,\Gamma} + \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma} + \|\delta h\|^2_{-1/2,\Gamma} \\ &\qquad + \|\delta f\|^2_{-1/2,\Gamma} + 2\epsilon\langle \mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h), \delta f - \mathcal{P}_q(\delta h)\rangle_{-1/2,\Gamma} \\ &\qquad + 2(1-\epsilon)\langle h_s - h, \delta h\rangle_{-1/2,\Gamma} + 2(1-\epsilon)\langle \mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h), \delta f\rangle_{-1/2,\Gamma} \\ &\quad \geq \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) + \|h_s - h\|^2_{-1/2,\Gamma} + \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma} + \|\delta h\|^2_{-1/2,\Gamma} \\ &\qquad + \|\delta f\|^2_{-1/2,\Gamma} - 2\epsilon\|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma}\|\delta f - \mathcal{P}_q(\delta h)\|_{-1/2,\Gamma} \\ &\qquad - 2(1-\epsilon)\left|\langle h_s - h, \delta h\rangle_{-1/2,\Gamma}\right| - 2(1-\epsilon)\left|\langle \mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h), \delta f\rangle_{-1/2,\Gamma}\right|.\end{aligned} \tag{2.47}$$

Focusing on the $(1-\epsilon)$ terms, by Cauchy–Schwarz we have

$$\begin{aligned}2\left|\langle h_s - h, \delta h\rangle_{-1/2,\Gamma}\right| &\leq \|h_s - h\|^2_{-1/2,\Gamma} + \|\delta h\|^2_{-1/2,\Gamma}, \\ 2\left|\langle \mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h), \delta f\rangle_{-1/2,\Gamma}\right| &\leq \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma} + \|\delta f\|^2_{-1/2,\Gamma}.\end{aligned}$$

Applying these bounds to (2.47), we have

$$\begin{aligned}&\mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \\ &\quad \geq \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) - 2\epsilon\|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma}\|\delta f - \mathcal{P}_q(\delta h)\|_{-1/2,\Gamma} \\ &\qquad + \epsilon\left(\|h_s - h\|^2_{-1/2,\Gamma} + \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma} + \|\delta h\|^2_{-1/2,\Gamma} + \|\delta f\|^2_{-1/2,\Gamma}\right).\end{aligned} \tag{2.48}$$

Now, as a direct application of Lemma 2.10, there exists a constant c_1 such that

$$\|\delta f - \mathcal{P}_q(\delta h)\|^2_{-1/2,\Gamma} \leq c_1\, \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s). \tag{2.49}$$

To see this, first note that $\exists\,\tilde{\mathbf{u}} \in \mathrm{W}_q(\Omega)$ such that $\{\tilde{\mathbf{u}}, h_s + \delta h, \mathcal{P}_q(h_s) + \mathcal{P}_q(\delta h)\}$ is an NT triple for q. Then observe that if we let $\mathbf{w}_h = \tilde{\mathbf{u}}$ and $\mathbf{w} = \mathbf{u}^* + \delta\mathbf{u}_s + \delta\mathbf{u} - \delta\mathbf{u}_s$, we may write

$$\boldsymbol{\tau} \cdot (e^{-q}(\mathbf{w} - \mathbf{w}_h)) = \delta f - \mathcal{P}_q(\delta h). \tag{2.50}$$

Therefore, applying Lemma 2.10, we have

$$\begin{aligned} \|\delta f - \mathcal{P}_q(\delta h)\|^2_{-1/2,\Gamma} &\le c\,\mathrm{F}_I(q, \mathbf{w} - \mathbf{w}_h) \\ &\le c\,\mathrm{F}_I(q, \mathbf{w}) \\ &\le c_1\,\mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s). \end{aligned} \tag{2.51}$$

As a direct result of (2.51), we may write (2.48) as

$$\begin{aligned} \mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \ge\ & \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) + \epsilon\|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma} \\ & - 2\epsilon c_1 \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma} \left(\mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s)\right)^{1/2} \\ & + \epsilon\left(\|h_s - h\|^2_{-1/2,\Gamma} + \|\delta h\|^2_{-1/2,\Gamma} + \|\delta f\|^2_{-1/2,\Gamma}\right). \end{aligned} \tag{2.52}$$

Next, we use an ϵ-inequality, with η in place of ϵ, to rewrite the first three terms: For any $\eta > 0$,

$$\begin{aligned} -2\epsilon c_1 \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|_{-1/2,\Gamma} (\mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s))^{1/2} & \\ \ge -\epsilon c_1^2 \eta \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) - \frac{\epsilon}{\eta}\|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}, & \end{aligned} \tag{2.53}$$

and (2.52) becomes

$$\begin{aligned} \mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \ge\ & (1 - \epsilon c_1^2\eta)\mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) + \epsilon\left(1 - \frac{1}{\eta}\right)\|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma} \\ & + \epsilon\left(\|h_s - h\|^2_{-1/2,\Gamma} + \|\delta h\|^2_{-1/2,\Gamma} + \|\delta f\|^2_{-1/2,\Gamma}\right). \end{aligned}$$

Choosing $0 < \epsilon < 1$ and $\eta > 1$ so that $(1 - \epsilon c_1^2\eta) = \epsilon(1 - 1/\eta)$ and ϵ is as large as possible, we have

$$\begin{aligned} \mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \ge\ & \epsilon\left(1 - \frac{1}{\eta}\right)\left(\mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) + \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}\right) \\ & + \epsilon\left(\|\delta h\|^2_{-1/2,\Gamma} + \|\delta f\|^2_{-1/2,\Gamma} + \|h_s - h\|^2_{-1/2,\Gamma}\right). \end{aligned} \tag{2.54}$$

Note that this is always possible since $\epsilon = \left(c_1^2\eta + (1 - 1/\eta)\right)^{-1}$. Now we use

$$\mathrm{F}(q, \delta\mathbf{u} - \delta\mathbf{u}_s; 0, 0) = \mathrm{F}_I(q, \delta\mathbf{u} - \delta\mathbf{u}_s) + \|\delta h\|^2_{-1/2,\Gamma} + \|\delta f\|^2_{-1/2,\Gamma}$$

so that we may write

$$\begin{aligned} \mathrm{F}(q, \mathbf{u}; h, & \mathcal{P}_{q^*}(h)) \\ & \ge c_2\left(\mathrm{F}(q, \delta\mathbf{u} - \delta\mathbf{u}_s; 0, 0) + \|h_s - h\|^2_{-1/2,\Gamma} + \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}\right), \end{aligned}$$

where $c_2 := \epsilon(1 - 1/\eta)$. Next, we recall that

$$\begin{aligned} \mathrm{F}(q, \mathbf{u}^* + \delta\mathbf{u}_s; h, \mathcal{P}_{q^*}(h)) &= \mathrm{F}_B(q, \mathbf{u}^* + \delta\mathbf{u}_s; h, \mathcal{P}_{q^*}(h)) \\ &= \|h_s - h\|^2_{-1/2,\Gamma} + \|\mathcal{P}_q(h_s) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}, \end{aligned}$$

since $\mathbf{u}^* + \delta\mathbf{u}_s \in \mathrm{S}_q$. Therefore, we may apply Lemma 2.12 to arrive at

$$\mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \;\geq\; c\left(\mathrm{F}(q, \delta\mathbf{u} - \delta\mathbf{u}_s; 0, 0) + \|\mathcal{P}_q(h) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma}\right).$$

Finally, by Lemma 2.9, we have the desired coercive bound. ∎

We now state an equivalence result for a fixed NT pair, $\{h, \mathcal{P}_{q^*}(h)\}$, which immediately follows from Theorem 2.13 and a simple derivation of the upper bound.

COROLLARY 2.14. *Let $h \in \mathrm{H}_0^{-1/2}(\Gamma)$, and recall that $\sigma = e^{2q}$ and $\sigma^* = e^{2q^*}$. Then there exists a positive constant, c, depending only on Ω and $\|\mathcal{P}_q\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{-1/2}(\Gamma))}$, such that*

$$\begin{aligned} c\|\mathcal{R}_\sigma(h) - \mathcal{R}_{\sigma^*}(h)\|^2_{1/2,\Gamma} & \\ &\leq \min_{\mathbf{u}\,\epsilon\,\mathrm{W}_q(\Omega)} \mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \\ &\leq \|\mathcal{R}_\sigma(h) - \mathcal{R}_{\sigma^*}(h)\|^2_{1/2,\Gamma}. \end{aligned} \tag{2.55}$$

Proof. The lower bound follows immediately from applying Lemma 2.8 to the statement in Theorem 2.13 and performing the minimization in (2.24). To show continuity, we simply restrict the space over which the minimization is conducted and use the definition of S_q to see that

$$\begin{aligned} \min_{\mathbf{u}\,\epsilon\,\mathrm{W}_q(\Omega)} \mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) &\leq \min_{\mathbf{u}\in\mathrm{S}_q} \mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \\ &\leq \min_{\{\mathbf{u}\in\mathrm{S}_q : \mathbf{n}\cdot\mathbf{u} = h\}} \mathrm{F}_B(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h)) \\ &= \|\mathcal{P}_q(h) - \mathcal{P}_{q^*}(h)\|^2_{-1/2,\Gamma} \end{aligned} \tag{2.56}$$

for any $h \in \mathrm{H}_0^{-1/2}(\Gamma)$. Hence, again appealing to Lemma 2.8 to relate $\mathcal{P}$ to $\mathcal{R}$ proves the upper bound in (2.55). ∎

The above corollary immediately leads to the equivalence of the OLS and FOSLS functionals, which we now state formally.

COROLLARY 2.15. *With $\mathcal{F}_{OSLS}$ defined in* (2.24)*, there exists a positive constant, c, depending only on Ω and $\|\mathcal{P}_q\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{-1/2}(\Gamma))}$, such that*

$$\begin{aligned} c\sum_{i=1}^{L} \|\mathcal{R}_\sigma(h_i) - \mathcal{R}_{\sigma^*}(h_i)\|^2_{1/2,\Gamma} & \\ &\leq \mathcal{F}_{OSLS}(q; \{h_i, \mathcal{P}_{q^*}(h_i)\}_{i=1}^{L}) \\ &\leq \sum_{i=1}^{L} \|\mathcal{R}_\sigma(h_i) - \mathcal{R}_{\sigma^*}(h_i)\|^2_{1/2,\Gamma}. \end{aligned} \tag{2.57}$$

As in the previous section, we can also state the equivalence of a sup version of the FOSLS functional and the operator norm of the defect in the NtD maps. For $c > 0$ depending only on Ω and $\|\mathcal{P}_q\|_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{-1/2}(\Gamma))}$, we may write

$$\begin{aligned} c\|\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*}\|^2_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{1/2}(\Gamma))} & \\ &\leq \sup_{h\in\mathrm{H}_0^{-1/2}(\Gamma)} \frac{\left(\min_{\mathbf{u}\,\epsilon\,\mathrm{W}_q(\Omega)} \mathrm{F}(q, \mathbf{u}; h, \mathcal{P}_{q^*}(h))\right)}{\|h\|_{-1/2,\Gamma}} \\ &\leq \|\mathcal{R}_\sigma - \mathcal{R}_{\sigma^*}\|^2_{\mathcal{L}(\mathrm{H}_0^{-1/2}(\Gamma),\mathrm{H}_0^{1/2}(\Gamma))}. \end{aligned}$$

3. Unifying FOSLS framework. Beyond their equivalence, another connection between the KV and FOSLS functionals can be made. Considering a single DN pair, the FOSLS interior functional may be written as

$$\left\| \begin{pmatrix} e^{-q}\nabla \cdot e^{q} \\ e^{q}\nabla \times e^{-q} \end{pmatrix} \mathbf{u} \right\|_{0,\Omega}^{2} := \|\mathcal{L}\mathbf{u}\|_{0,\Omega}^{2}.$$

Alternatively, one can arrive at the KV functional using a generalized Helmholtz decomposition for $\mathbf{u}$, leading to

$$\begin{aligned} \mathbf{u} &= e^{q}\nabla e^{-q} r - e^{-q}\nabla^{\perp} e^{q} t \\ &= \mathcal{L}^{*} \begin{pmatrix} r \\ t \end{pmatrix}, \end{aligned}$$

for some $r, t \in \mathrm{H}^{1}(\Omega)$. The KV functional in this context, for a single DN pair, may be written as

$$\|e^{q}\nabla p - e^{-q}\nabla^{\perp} s\|_{0,\Omega}^{2} = \left\| \mathcal{L}^{*} \begin{pmatrix} e^{q} p \\ e^{-q} s \end{pmatrix} \right\|_{0,\Omega}^{2}$$

and may thus be viewed as a first-order system LL* (FOSLL*) formulation [6]. Indeed, in being adjoint formulations, the $\mathcal{L}$ in FOSLS has overspecified boundary conditions, while the corresponding $\mathcal{L}^{*}$ has no boundary conditions. FOSLL* is in its formative stages as a viable methodology for the solution of PDEs, yet it may prove particularly effective in the forward solution of Maxwell's equations, for which regularity requirements of standard FOSLS are often too stringent. As such, the KV formulation represents an interesting connection between FOSLL* and the inverse problem.

4. Conclusion. We have presented a new FOSLS formulation for the reconstruction of conductivity or, equivalently, resistivity, given knowledge of the corresponding NtD map. Moreover, we have established its equivalence to two existing approaches, including the standard constrained minimization, OLS. Further analysis of many practical concerns is needed before this novel approach moves beyond theory to actually impact imaging technology. Here we have established the common ground from which to conduct such analysis and only begun to explore the role FOSLS can play in determining the sense in which the inverse problem of EIT can be posed well.

AN EXPLICIT A PRIORI ESTIMATE FOR A FINITE VOLUME APPROXIMATION OF LINEAR ADVECTION ON NON-CARTESIAN GRIDS*

BRUNO DESPRÉS†

Abstract. We propose an elementary proof of strong convergence for a finite volume approximation of nonstationary linear advection on arbitrary grids in two space dimensions. This proof is elementary in the sense that the basic a priori estimate uses only some discrete integrations by parts and the Cauchy–Schwarz inequality. Numerical results show that the estimate is probably nonoptimal.

Key words. nonstationary linear advection, finite volume schemes, optimal rate of convergence

AMS subject classifications. 65M12, 65M15

DOI. 10.1137/S0036142901394558

1. Introduction.

Let us consider the following nonstationary linear advection model problem:

$$\begin{cases} \partial_t u + \vec{a}.\vec{\nabla} u = 0, & (t,\vec{x}) \in [0,T] \times \Omega, \\ u(t=0,\vec{x}) = u_0(\vec{x}), & \vec{x} \in \partial\Omega. \end{cases} \tag{1.1}$$

For the sake of simplicity we consider the two-dimensional case:

$$\vec{x} = (x_1, x_2) \in \Omega = [0,1] \times [0,1] \subset \mathbb{R}^2; \tag{1.2}$$

assume that $\vec{a} \neq 0$ is constant in space and time, and supplement (1.1) with periodic boundary conditions

$$\begin{cases} u(t,0,x_2) = u(t,1,x_2), & (t,x_2) \in [0,T] \times [0,1], \\ u(t,x_1,0) = u(t,x_1,1), & (t,x_1) \in [0,T] \times [0,1]. \end{cases} \tag{1.3}$$

Taking in account the periodicity of boundary conditions the exact solution is

$$u(t,\vec{x}) = u_0(\vec{x} - \vec{a}t). \tag{1.4}$$

In this work we address the standard finite volume numerical approximation of (1.1). Even if finite volume methods in conjunction with high order methods are widely used in practice for industrial problems (see [20, 12, 11, 4, 3, 21, 30] and the references therein), mathematical open problems still exist around these techniques. This has been reported, for instance, in [15] and [16]: in particular, explicit and simple estimates of the error between the exact solution of (1.1) and various lowest order finite volume approximations are not so simple to obtain. What we really intend to show in this work is that a complete understanding of the accuracy of nonstationary linear advection on non-Cartesian grids is still an open problem.

In their seminal work [24], Lesaint and Raviart address L^2-based approaches for transport with absorption such as

$$\partial_t u + \vec{a}.\vec{\nabla} u + cu - d\Delta u = 0, \quad \text{with } c > 0 \quad \text{and } d = 0. \tag{1.5}$$

Other L^2-based approaches with either diffusion or absorption (i.e., $c > 0$ or $d > 0$) may be found in [7, 8, 17, 18, 28] in the context of discontinuous Galerkin methods and also in [23] in the context of the Friedrichs systems.

Proof of convergence and estimate of convergence for finite volume methods applied to nonlinear problems is a subject that has already been considered by many authors. A nonexhaustive list of references is as follows: [31], based on [14], for a use of the measure value solution technique to give the first proof of convergence for transport on general meshes; [2], which uses the kinetic approach [22, 14]; [6, 15] about the Kuznetsov error approach [19]. Other references may be found in [15] and [16]. See also [13] for an approach with nonlinear schemes. Most proofs of convergence on arbitrary grids (at least all proofs we are aware of) are based on some mathematical notions which were designed mainly to tackle nonlinear problems or to tackle coercive-diffusive transport. The one proposed here, L^2-based, gives an explicit bound of the error in function of the solution for the case $c = d = 0$. To our knowledge, all L^2-based estimates given in [24, 7, 8] and [28] blow up when $c \to 0^+$ or $d \to 0^+$.

The central part of this paper addresses a new L^2-based a priori estimate for the numerical error concerning the problem (1.1) (i.e., (1.5) with $c = d = 0$): see inequality (4.21) of Theorem 2. The interest of this estimate is that it gives an explicit bound of the numerical error in terms of the solution only:

$$\|u^n - \mathbf{u}^n\|_2 \leq F(u(n\Delta t), u((n-1)\Delta t), \ldots, u(0)), \tag{1.6}$$

where $u(., j\Delta t)$ is the solution at $T = j\Delta t$, and F is some functional. A consequence is a proof of convergence for a standard upwind finite volume approximation of (1.1) on a regular (we will make this clearer in the following) arbitrary grid, due to

$$F(u(n\Delta t), u((n-1)\Delta t), \ldots, u(0)) \leq C(T, ||\nabla u_0||_{L^2}, ||\nabla^2 u_0||_{L^2})\Delta x^{\frac{1}{2}}, \tag{1.7}$$

where we assume that $u_0 \in H^2(\Omega)$ and that the mesh is a general triangular or quadrangular mesh: u^n is the numerical solution and $\mathbf{u}^n = \frac{1}{s_j}\int_{\Omega_j} u(n\Delta t, \vec{x})dx$ is the cell-averaged exact solution in cell Ω_j. A corollary is convergence of the upwind finite volume scheme for linear advection on regular grids in L^1 and L^2.

Estimate (1.7) displays a fractional order of convergence $C\Delta x^{\frac{1}{2}}$, even for a H^2 solution. It has to be compared with the standard estimate [29] of convergence $C\Delta x$, true for the numerical approximation on a Cartesian grid of the smooth solution of (1.1) (actually numerical results clearly indicate that the numerical rate of convergence is $C\Delta x$, even for non-Cartesian grids). It is still an open question to decide whether the fractional order of convergence $C\Delta x^{\frac{1}{2}}$ is optimal on arbitrary non-Cartesian grids or not. The reason why we obtain only a fractional order of convergence in our proof is that finite volume methods on general meshes are nonconsistent in the finite difference sense. To deal with the formal nonconsistency of finite volume techniques, which is here the real difficulty, we introduce an approximate and global cell-averaged solution $\mathbf{v}^n \approx \mathbf{u}^n$ and prove various but basic a priori estimates about this approximate solution. The interest of this approximate solution is that it is consistent, while the projection of the exact solution is nonconsistent. These a priori estimates give the $C\Delta x^{\frac{1}{2}}$ order of convergence. An important difference with previous works about the

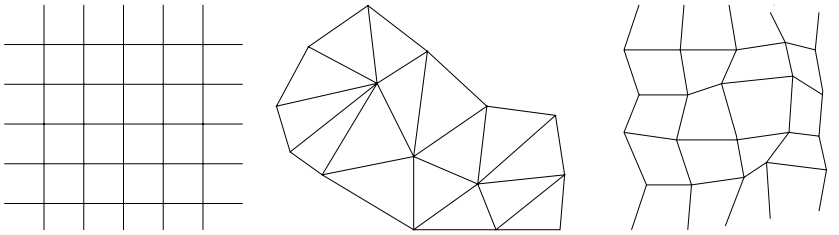

FIG. 1. *Some meshes.*

L^2 analysis (see, for example, [24, 26], in connection with analysis of discontinuous Galerkin methods) is that the keystone of our analysis is the construction of this approximate solution, which helps to give a direct analysis of the scheme in terms of the truncation error: actually we prove that the approximate solution is close to the exact solution and is consistent; the analysis of [26] is for the stationary equation, never explains anything about the consistency discrepancy of the scheme, is in some sense global, and does not help to get the error at time T, which is what one is really interested in for nonstationary problems.

The paper is organized as follows. In section 2, we introduce some notation and define the standard finite volume approximation of (1.1). Then, in section 3, we recall the basic definition of the stability of the finite volume discretization. In section 4, we introduce new material, define what we call the approximate solution $\mathbf{v}$, and prove various a priori estimates for this $\mathbf{v}$. Then, in section 5, we prove the convergence in L^2 of the finite volume scheme on arbitrary grids with a rate $C\Delta x^{\frac{1}{2}}$. In section 6, we give a counterexample of why $C\Delta x^{\frac{1}{2}}$ proofs of convergence via total variation bounded estimates are not possible. Finally, we give some numerical results in section 7.

2. Notation. From now on, we consider only the discretization of (1.1). Let $(\Omega_j)_{j\in[1,..,J]}$ be a finite mesh of Ω:

$$\left\{ \begin{array}{ll} \Omega_j \cap \Omega_k = \emptyset & \forall j,k, \quad j \neq k, \\ \bigcup\limits_{j\in[1,..,J]} \bar{\Omega}_j = \bar{\Omega} = \Omega. & \end{array} \right. \tag{2.1}$$

J is the number of cells. The shape of any cell is arbitrary. Most usual cases are square cells (finite difference) and triangle or distorted quadrangular cells (finite volume); see Figure 1. Other meshes can be constructed; see Figure 5. Two cells are neighboring cells if and only if they have an edge in common (taking into account periodic boundary conditions). Each cell has a finite number of neighbors: $I(j)$ is the set of the neighbors of cell j. The outgoing normal from Ω_j on the edge $\partial\Omega_j \cap \partial\Omega_k$ is denoted as $\vec{n}_{jk}$. Of course, the outgoing normal from Ω_j is the opposite of the outgoing normal from Ω_k for $k \in I(j)$:

$$\vec{n}_{jk} + \vec{n}_{kj} = 0. \tag{2.2}$$

We introduce some very natural notation:

$$\left\{ \begin{array}{ll} l_{jk} = l_{kj} = \mathbb{R}\text{-Lebesgue measure of } \partial\Omega_j \cap \partial\Omega_k, & \text{a length}, \\ s_j = \mathbb{R}^2\text{-Lebesgue measure of } \Omega_j, & \text{a surface}. \end{array} \right. \tag{2.3}$$

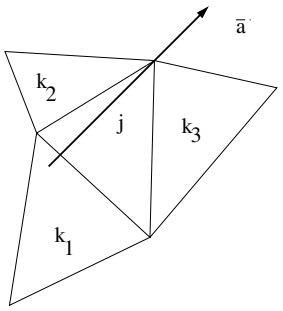

FIG. 2. $I^+(j) = \{k_2, k_3\}$, $I^-(j) = \{k_1\}$.

We also define

$$\left\{ \begin{array}{l} I^+(j) = \{k \in I(j); (\vec{a}, \vec{n}_{jk}) > 0\}, \\ I^0(j) = \{k \in I(j); (\vec{a}, \vec{n}_{jk}) = 0\}, \\ I^-(j) = \{k \in I(j); (\vec{a}, \vec{n}_{jk}) < 0\} \end{array} \right. \tag{2.4}$$

and

$$m_{jk} = m_{kj} = l_{jk} |(\vec{a}, \vec{n}_{jk})|. \tag{2.5}$$

$(.,.)$ denotes the standard scalar product. $I^+(j)$ (resp., $I^-(j)$) is the set of outgoing (resp., incoming) cells from Ω_j. An example with a triangular mesh is given in Figure 2. With all this notation the standard upwind finite volume-like method together with a constant mass initial condition is (2.6)–(2.7):

$$s_j \frac{u_j^{n+1} - u_j^n}{\Delta t} + \sum_{k \in I^+(j)} m_{jk} u_j^n - \sum_{k \in I^-(j)} m_{jk} u_k^n = 0 \quad \forall j \in [1, ., J], \quad \forall n \geq 0, \tag{2.6}$$

$$u_j^0 = \frac{1}{s_j} \int_{\Omega_j} u_0(x) \ \ \forall j \in [1, ., J]. \tag{2.7}$$

The following formula will play an important role in the analysis.

LEMMA 1. *One has the equality*

$$\sum_{k \in I^+(j)} m_{jk} = \sum_{k \in I^-(j)} m_{jk} \ \ \forall j. \tag{2.8}$$

It is a well-known consequence of the divergence theorem:

$$0 = \int_{\Omega_j} \mathbf{div}\ \vec{a} = \int_{\partial \Omega_j} (\vec{a}, \vec{n}_{jk}) = \sum_{k \in I^+(j)} m_{jk} - \sum_{k \in I^-(j)} m_{jk}.$$

Taking into account periodic boundary conditions, the scheme is conservative since

$$\sum_j s_j u_j^{n+1} = \sum_j \left(s_j u_j^n - \Delta t \sum_{k \in I^+(j)} m_{jk} u_j^n - \sum_{k \in I^-(j)} m_{jk} u_k^n \right)$$

$$= \sum_j s_j u_j^n + \left(-\Delta t \sum_j \sum_{k \in I^+(j)} m_{jk} u_j^n + \Delta t \sum_j \sum_{k \in I^-(j)} m_{jk} u_k^n \right)$$
$$= \sum_j s_j u_j^n.$$

Since (2.8) proves that $\sum_j \sum_{k \in I^-(j)} m_{jk} u_k^n = \sum_k [\sum_{j \in I^+(k)} m_{jk}] u_k^n$, then the term between parentheses in the right-hand side of the above expression is zero. It shows the conservativity of the scheme.

3. Stability. In order to investigate the convergence of the scheme we equip the space $\mathbb{R}^J$ with either the standard L^2, L^1, or L^∞ norm.

DEFINITION 1. *The standard L^2, L^1, and L^∞ discrete norms are*

$$\|\mathbf{w}\|_2 = \left(\sum_j s_j (\mathbf{w}_j)^2 \right)^{\frac{1}{2}}, \quad \|\mathbf{w}\|_1 = \sum_j s_j |\mathbf{w}_j|, \quad \|\mathbf{w}\|_\infty = \max_j (|\mathbf{w}_j|). \tag{3.1}$$

Now we consider $\mathbf{w} = (\mathbf{w}_j)_{j \in [1,.,J]}$ an arbitrary vector $\mathbf{w} \in \mathbb{R}^J$ and define the iteration operator.

DEFINITION 2. *The linear iteration operator $A : \mathbb{R}^J \to \mathbb{R}^J$ extracted from* (2.6) *is defined by*

$$(A\mathbf{w})_j = \mathbf{w}_j - \frac{\Delta t}{s_j} \left(\sum_{k \in I^+(j)} m_{jk} \mathbf{w}_j - \sum_{k \in I^-(j)} m_{jk} \mathbf{w}_k \right) \quad \forall j \in [1,.,J]. \tag{3.2}$$

This iteration operator is stable in the following sense.

LEMMA 2. *Let us assume the CFL condition*

$$\frac{\sum_{k \in I^+(j)} m_{jk}}{s_j} \Delta t \leq 1 \quad \forall j \in [1,.,J]. \tag{3.3}$$

Then

$$\|A\mathbf{w}\|_2 \leq \|\mathbf{w}\|_2, \quad \|A\mathbf{w}\|_1 \leq \|\mathbf{w}\|_1, \quad \|A\mathbf{w}\|_\infty \leq \|\mathbf{w}\|_\infty. \tag{3.4}$$

The proof is completely standard.

A problem is that the scheme (2.6) is not consistent, at least in the finite difference sense and for general grids in several space dimensions: this has been reported, for instance, in [16, 2, 15, 6] and the references therein. To understand more precisely this property of nonconsistency, we consider the exact solution of (1.1), $u(t, \vec{x})$, and define $\mathbf{u}_j^n$ to be the mean value of the exact solution:

$$\mathbf{u}_j^n = \frac{1}{s_j} \int_{\Omega_j} u(n\Delta t, \vec{x}) dx \quad \forall j, n. \tag{3.5}$$

DEFINITION 3. *The truncation error $\mathbf{R}^n = (\mathbf{R}_j^n) \in \mathbb{R}^J$ is*

$$\mathbf{R}_j^n = \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t} + \frac{1}{s_j} \left(\sum_{k \in I^+(j)} m_{jk} \mathbf{u}_j^n - \sum_{k \in I^-(j)} m_{jk} \mathbf{u}_k^n \right). \tag{3.6}$$

The following result is referred to as the Lax theorem in the literature. We state it using the L^2 norm, but it is possible to use other norms as the L^1 or L^∞ norm.

THEOREM 1 (Lax theorem). *Assuming the CFL condition* (3.3)*, the numerical error* $\|u^n - \mathbf{u}^n\|_2$ *is bounded:*

$$\|u^n - \mathbf{u}^n\|_2 \leq \Delta t \sum_{p=0}^{n-1} \|\mathbf{R}^p\|_2. \tag{3.7}$$

The numerical error is $\mathbf{e}^n = u^n - \mathbf{u}^n$: using the definition of the scheme, the definition of the iteration operator A and the definition of the truncation error $\mathbf{R}$, one has

$$\mathbf{e}^{n+1} = A\mathbf{e}^n - \Delta t \mathbf{R}^n.$$

Due to the CFL condition we have $\|\mathbf{e}^{n+1}\|_2 \leq \|\mathbf{e}^n\|_2 + \Delta t \|\mathbf{R}^n\|_2$, which implies

$$\|\mathbf{e}^n\|_2 \leq \|\mathbf{e}^0\|_2 + \Delta t \sum_{p=0}^{n-1} \|\mathbf{R}^p\|_2.$$

Since $\mathbf{e}^0 = u^0 - \mathbf{u}^0 = 0$ by definition of u^0 (2.7), it gives (3.7). Assuming enough regularity of the initial data, and assuming that the mesh is Cartesian, simple Taylor expansions prove that

$$\|\mathbf{R}^n\|_2 = O(\Delta x, \Delta t). \tag{3.8}$$

Due to the CFL inequality (3.3), equation (3.8) implies $\|\mathbf{R}^n\|_2 = O(\Delta x)$.

However, the mesh might not have such a structure (a general triangular mesh with no particular symmetry is an example; see Figure 1). Then (3.9) is replaced by

$$\|\mathbf{R}^n\|_2 = O(1). \tag{3.9}$$

Using such a general mesh there is no way for $\mathbf{R}_j^n$ to be bounded like (3.8). The reason why we have only (3.9) is that

$$\frac{1}{s_j}\left(\sum_{k\in I^+(j)} m_{jk}\mathbf{u}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{u}_k^n\right) = \frac{1}{s_j}\int_{\Omega_j} \vec{a}.\nabla u(n\Delta t, \vec{x})dx + O(1) \tag{3.10}$$

on arbitrary grids for the exact solution. As a consequence of this lack of consistency (3.9), it is not possible to rely on the Lax theorem (3.7) to prove the convergence of the scheme.

4. The approximate solution. In order to circumvent this problem we consider that the difficulty comes from the numerical approximation of the gradient of the solution, which is expressed in (3.10). First we remark that the left-hand side of (3.10) may be rewritten as (4.1):

$$\begin{aligned}\frac{1}{s_j}&\left(\sum_{k\in I^+(j)} m_{jk}\mathbf{u}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{u}_k^n\right)\\ &= \frac{1}{s_j}\left(\sum_{k\in I^+(j)} m_{jk}\mathbf{u}_{jk}^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{u}_{jk}^n\right) + O(1),\end{aligned} \tag{4.1}$$

where $\mathbf{u}_{jk}^n$ is the mean value of the exact solution on the edges:

$$\mathbf{u}_{jk}^n = \mathbf{u}_{kj}^n = \frac{1}{l_{jk}} \int_{\partial\Omega_j \cap \partial\Omega_k} u(n\Delta t, \vec{x}) d\sigma \quad \forall j,k,n. \tag{4.2}$$

Second, it suggests that we may define a new approximate solution, denoted as $\mathbf{v}_j^n$, in order to get rid of this consistency problem.

DEFINITION 4. *Let $\sigma > 0$. Assuming that u is C^0 (so that (4.2) makes sense), the approximate solution $\mathbf{v}^n \in \mathbb{R}^J$ is defined as the solution of the following linear system:*

$$\begin{aligned} &\sigma s_j(\mathbf{v}_j^n - \mathbf{u}_j^n) + \sum_{k\in I^+(j)} m_{jk}\mathbf{v}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{v}_k^n \\ &\quad = \sum_{k\in I^+(j)} m_{jk}\mathbf{u}_{jk}^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{u}_{jk}^n \quad \forall j \in [1,.,J], \quad n \geq 0. \end{aligned} \tag{4.3}$$

Here σ is a kind of penalization parameter. If we take $\sigma = 0$, then the numerical flux of the approximate solution satisfies

$$\frac{1}{s_j}\left(\sum_{k\in I^+(j)} m_{jk}\mathbf{v}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{v}_k^n\right) = \frac{1}{s_j}\left(\sum_{k\in I^+(j)} m_{jk}\mathbf{u}_{jk}^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{u}_{jk}^n\right),$$

which is a better approximation of $\vec{a}.\nabla u(n\Delta t, \vec{x})$ than (4.1). For technical reasons which will appear clearly in (4.5), it is better to consider $\sigma > 0$. This parameter will be set to the optimal value $\sigma \approx 1$ at the end of the proof. In complete rigor, we should write this approximate solution as $\mathbf{v} = \mathbf{v}(u, \sigma)$. However, we prefer to save notation, still working with the simplified notation $\mathbf{v}$. Let us point to an originality of the approximate solution: $\mathbf{v}$ is defined globally; that is, $\mathbf{v}_j^n$ is a function of $\mathbf{u}_i^n$ and $\mathbf{u}_{ik}^n \; \forall$ $i \in [1,.,J]$. To our knowledge, such a global definition has rarely been considered before. It is a simple exercise to check that

$$\sum_j s_j \mathbf{v}_j^n = \sum_j s_j \mathbf{u}_j^n. \tag{4.4}$$

The terminology *approximate solution* is justified, at least by the fact that $\sigma = +\infty$ implies $\mathbf{v} = \mathbf{u}$. The interest of definition (4.3) relies principally on the following a priori estimate.

LEMMA 3. *Let $\mathbf{v}^n \in \mathbb{R}^J$ be a solution of (4.3). Then*

(a) *one has the a priori estimate*

$$\sigma \|\mathbf{v}^n - \mathbf{u}^n\|_2^2 \leq \frac{1}{2}\sum_j \sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_j^n)^2; \tag{4.5}$$

(b) *$\forall \sigma > 0$ the linear system (4.3) is invertible; that is, the approximate solution $\mathbf{v}^n \in \mathbb{R}^J$ is well defined and unique;*

(c) *the discrete derivative in time is bounded:*

$$\begin{aligned} &\sigma \left\| \frac{\mathbf{v}^{n+1} - \mathbf{v}^n}{\Delta t} - \frac{\mathbf{u}^{n+1} - \mathbf{u}^n}{\Delta t} \right\|_2^2 \\ &\quad \leq \frac{1}{2}\sum_j \sum_{k\in I^+(j)} m_{jk}\left(\frac{\mathbf{u}_{jk}^{n+1} - \mathbf{u}_{jk}^n}{\Delta t} - \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t}\right)^2. \end{aligned} \tag{4.6}$$

In the next section, we prove that the right-hand sides of (4.5) and (4.6) are bounded by $C\Delta x$ for a smooth solution u. So (4.5) and (4.6) prove that $\mathbf{v}^n$ is indeed an approximate numerical solution of (1.1) at time step n. We split the proof of this lemma in three steps.

(a) The a priori estimate (4.5) is actually the key to the approach developed in this paper. The proof is simple and uses basic discrete integrations by parts and the Cauchy–Schwarz inequality. We define $\mathbf{w}_j^n = \mathbf{v}_j^n - \mathbf{u}_j^n$ and rewrite (4.3) as

$$\begin{aligned}(4.7)\qquad & \sigma s_j \mathbf{w}_j^n + \sum_{k\in I^+(j)} m_{jk}\mathbf{w}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{w}_k^n \\ & = \sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_j^n) - \sum_{k\in I^-(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_k^n) \ \ \forall j \in [1,.,J].\end{aligned}$$

So $\mathbf{w}^n$ is a solution of the nonhomogeneous system.

We multiply by $\mathbf{w}_j^n$ and sum with respect to j. Thus

$$\begin{aligned}(4.8)\qquad & \sigma\|\mathbf{w}^n\|_2^2 + \sum_j \left(\sum_{k\in I^+(j)} m_{jk}\mathbf{w}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{w}_k^n \right) \mathbf{w}_j^n \\ & = \sum_j \left(\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_j^n) - \sum_{k\in I^-(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_k^n) \right) \mathbf{w}_j^n.\end{aligned}$$

We use Lemma 1 to get

$$\begin{aligned}(4.9)\qquad & \left(\sum_{k\in I^+(j)} m_{jk}\mathbf{w}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{w}_k^n \right) \mathbf{w}_j^n \\ & = \sum_{k\in I^-(j)} m_{jk} \left(\frac{1}{2}(\mathbf{w}_j^n)^2 - \frac{1}{2}(\mathbf{w}_k^n)^2 + \frac{1}{2}(\mathbf{w}_j^n - \mathbf{w}_k^n)^2 \right).\end{aligned}$$

So we deduce from (4.9) that

$$\begin{aligned}(4.10)\qquad & \sigma\|\mathbf{w}^n\|_2^2 + \frac{1}{2}\sum_j \left(\sum_{k\in I^-(j)} m_{jk}(\mathbf{w}_j^n - \mathbf{w}_k^n)^2 \right) \\ & + \frac{1}{2}\sum_j \left(\sum_{k\in I^-(j)} m_{jk} \right) (\mathbf{w}_j^n)^2 - \frac{1}{2}\sum_j \left(\sum_{k\in I^-(j)} m_{jk}(\mathbf{w}_k^n)^2 \right) \\ & = \sum_j \left(\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_j^n) - \sum_{k\in I^-(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_k^n) \right) \mathbf{w}_j^n.\end{aligned}$$

We reorganize the last term in the left-hand side and get

$$(4.11)\qquad \sum_j \sum_{k\in I^-(j)} m_{jk}\mathbf{w}_k^2 = \sum_j \left(\sum_{k\in I^+(j)} m_{jk} \right) \mathbf{w}_j^2.$$

Thus one has

$$\sum_{j\in[1,.,J]}\left(\sum_{k\in I^-(j)} m_{jk}(\mathbf{w}_k^n)^2\right)=\sum_{k\in[1,.,J]}\left(\sum_{j;k\in I^-(j)} m_{jk}\right)(\mathbf{w}_k^n)^2 \tag{4.12}$$
$$=\sum_{k\in[1,.,J]}\left(\sum_{j;j\in I^+(k)} m_{kj}\right)(\mathbf{w}_k^n)^2=\sum_{j\in[1,.,J]}\left(\sum_{k;k\in I^-(j)} m_{jk}\right)(\mathbf{w}_j^n)^2.$$

So we rewrite (4.8) as

$$\sigma\|\mathbf{w}^n\|_2^2+\frac{1}{2}\sum_j\left(\sum_{k\in I^-(j)} m_{jk}(\mathbf{w}_j^n-\mathbf{w}_k^n)^2\right)$$
$$=\sum_j\left(\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n-\mathbf{u}_j^n)-\sum_{k\in I^-(j)} m_{jk}(\mathbf{u}_{jk}^n-\mathbf{u}_k^n)\right)\mathbf{w}_j^n.$$

Using a discrete integration by part we transform the right-hand side:

$$\sigma\|\mathbf{w}^n\|_2^2+\frac{1}{2}\sum_j\left(\sum_{k\in I^-(j)} m_{jk}(\mathbf{w}_j^n-\mathbf{w}_k^n)^2\right) \tag{4.13}$$
$$=\sum_j\left(\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n-\mathbf{u}_j^n)(\mathbf{w}_j^n-\mathbf{w}_k^n)\right).$$

The Cauchy–Schwarz inequality applied to this right-hand side gives

$$\left|\sum_j\left(\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n-\mathbf{u}_j^n)(\mathbf{w}_j^n-\mathbf{w}_k^n)\right)\right|$$
$$\le\left(\sum_j\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n-\mathbf{u}_j^n)^2\right)^{\frac{1}{2}}\times\left(\sum_j\sum_{k\in I^+(j)} m_{jk}(\mathbf{w}_j^n-\mathbf{w}_k^n)^2\right)^{\frac{1}{2}}$$
$$\le\frac{1}{2}\sum_j\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n-\mathbf{u}_j^n)^2+\frac{1}{2}\sum_j\left(\sum_{k\in I^+(j)} m_{jk}(\mathbf{w}_j^n-\mathbf{w}_k^n)^2\right)$$
$$\le\frac{1}{2}\sum_j\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n-\mathbf{u}_j^n)^2+\frac{1}{2}\sum_j\left(\sum_{k\in I^-(j)} m_{jk}(\mathbf{w}_j^n-\mathbf{w}_k^n)^2\right).$$

Together with (4.13) it turns into $\sigma\|\mathbf{w}^n\|_2^2\le\frac{1}{2}\sum_j\sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n-\mathbf{u}_j^n)^2$, which gives point (a) of the lemma.

(b) To prove the well posedness of the linear system (4.3) we consider the homogeneous linear system:

$$\sigma s_j\mathbf{v}_j+\sum_{k\in I^+(j)} m_{jk}\mathbf{v}_j-\sum_{k\in I^-(j)} m_{jk}\mathbf{v}_k=0\ \ \forall j\in[1,.,J].$$

Inequality (4.5) applied to this homogeneous linear system gives

$$\sigma\|\mathbf{v}\|_2^2 + \frac{1}{2}\sum_j \left(\sum_{k\in I^-(j)} m_{jk}(\mathbf{v}_j - \mathbf{v}_k)^2 \right) = 0. \tag{4.14}$$

Using now $\sigma > 0$ we obtain $\mathbf{v} = 0$. It proves the well posedness of the definition of $\mathbf{v}$.

(c) Finally, we turn to (4.6). Let us define

$$\mathbf{z}^n = \frac{\mathbf{w}^{n+1} - \mathbf{w}^n}{\Delta t}.$$

This definition is equivalent to

$$\mathbf{z}_j^n = \frac{\mathbf{w}_j^{n+1} - \mathbf{w}_j^n}{\Delta t} = \frac{\mathbf{v}_j^{n+1} - \mathbf{v}_j^n}{\Delta t} - \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t} \quad \forall j \in [1,.,J].$$

Combining (4.7) with the same definition at time step $^{n+1}$, we obtain

$$\begin{aligned} &\sigma s_j \mathbf{z}_j^n + \sum_{k\in I^+(j)} m_{jk}\mathbf{z}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{z}_k^n \\ &\quad = \sum_{k\in I^+(j)} m_{jk}\left(\frac{\mathbf{u}_{jk}^{n+1} - \mathbf{u}_{jk}^n}{\Delta t} - \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t} \right) \\ &\quad\quad - \sum_{k\in I^-(j)} m_{jk}\left(\frac{\mathbf{u}_{jk}^{n+1} - \mathbf{u}_{jk}^n}{\Delta t} - \frac{\mathbf{u}_k^{n+1} - \mathbf{u}_k^n}{\Delta t} \right) \quad \forall j \in [1,.,J]. \end{aligned} \tag{4.15}$$

This equality has exactly the same structure as (4.8). Thus we obtain a very similar inequality:

$$\sigma\|\mathbf{z}^n\|_2^2 \le \frac{1}{2}\sum_j \left(\sum_{k\in I^+(j)} m_{jk}\left(\frac{\mathbf{u}_{jk}^{n+1} - \mathbf{u}_{jk}^n}{\Delta t} - \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t} \right)^2 \right),$$

which is exactly (4.6).

DEFINITION 5. *We define the truncation error* $\mathbf{S}^n = (\mathbf{S}_j^n) \in \mathbb{R}^J$,

$$\mathbf{S}_j^n = \frac{\mathbf{v}_j^{n+1} - \mathbf{v}_j^n}{\Delta t} + \frac{1}{s_j}\left(\sum_{k\in I^+(j)} m_{jk}\mathbf{v}_j^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{v}_k^n \right), \quad n \ge 0, \tag{4.16}$$

and the truncation error $\mathbf{T}^n = (\mathbf{T}_j^n) \in \mathbb{R}^J$,

$$\mathbf{T}_j^n = \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t} + \frac{1}{s_j}\left(\sum_{k\in I^+(j)} m_{jk}\mathbf{u}_{jk}^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{u}_{jk}^n \right), \quad n \ge 0. \tag{4.17}$$

LEMMA 4. *The truncation error* $\mathbf{S}^n$ *is bounded by*

$$\|\mathbf{S}^n\|_2 \le \sigma\|\mathbf{v}^n - \mathbf{u}^n\|_2 + \left\| \frac{\mathbf{v}^{n+1} - \mathbf{v}^n}{\Delta t} - \frac{\mathbf{u}^{n+1} - \mathbf{u}^n}{\Delta t} \right\|_2 + \|\mathbf{T}^n\|_2 \quad \forall n \ge 0. \tag{4.18}$$

The truncation error is $\mathbf{S}^n = a^n + b^n + c^n$, where

$$a_j^n = \frac{\mathbf{v}_j^{n+1} - \mathbf{v}_j^n}{\Delta t} - \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t}, \quad b_j^n = -\sigma(\mathbf{v}_j^n - \mathbf{u}_j^n),$$

and due to the definition of $\mathbf{v}$ in (4.3),

$$c_j^n = \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t} + \frac{1}{s_j}\left(\sum_{k\in I^+(j)} m_{jk}\mathbf{u}_{jk}^n - \sum_{k\in I^-(j)} m_{jk}\mathbf{u}_{jk}^n\right) = \mathbf{T}_j^n.$$

Thus $\|\mathbf{S}^n\|_2 \le \|a^n\|_2 + \|b^n\|_2 + \|c^n\|_2$, which is exactly (4.18).

It remains to express some bounds between the numerical solution and the approximate or exact solution. Inequality (4.20) has to be compared with (3.7): the interest is that even if the right-hand side of (3.7) is $O(1)$ on arbitrary grids, the right-hand side of (4.20) will be proved to be $O(\Delta x^{\frac{1}{2}})$ on arbitrary grids at least when the exact solution is H^2.

THEOREM 2. *Assuming the CFL condition* (3.3)*, one has some a priori estimates:*

$$\|u^n - \mathbf{v}^n\|_2 \le \|\mathbf{u}^0 - \mathbf{v}^0\|_2 + \Delta t \sum_{p=0}^{n-1} \|\mathbf{S}^p\|_2 \quad \forall n \ge 0 \tag{4.19}$$

and

$$\begin{aligned}\|u^n - \mathbf{u}^n\|_2 \le{}& \|\mathbf{v}^n - \mathbf{u}^n\|_2 + \|\mathbf{u}^0 - \mathbf{v}^0\|_2 + \sigma\Delta t \sum_{p=0}^{n-1} \|\mathbf{v}^p - \mathbf{u}^p\|_2 \\ &+ \Delta t \sum_{p=0}^{n-1} \left\| \frac{\mathbf{v}^{p+1} - \mathbf{v}^p}{\Delta t} - \frac{\mathbf{u}^{p+1} - \mathbf{u}^p}{\Delta t} \right\|_2 + \Delta t \sum_{p=0}^{n-1} \|\mathbf{T}^p\|_2 \quad \forall n \ge 0,\end{aligned} \tag{4.20}$$

which implies

$$\begin{aligned}\|u^n - \mathbf{u}^n\|_2 \le{}& \left(\frac{1}{2\sigma}\sum_j \sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_j^n)^2\right)^{\frac{1}{2}} \\ &+ \left(\frac{1}{2\sigma}\sum_j \sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^0 - \mathbf{u}_j^0)^2\right)^{\frac{1}{2}} \\ &+ \sigma\Delta t \sum_{p=0}^{n-1} \left(\frac{1}{2\sigma}\sum_j \sum_{k\in I^+(j)} m_{jk}(\mathbf{u}_{jk}^p - \mathbf{u}_j^p)^2\right)^{\frac{1}{2}} \\ &+ \Delta t \sum_{p=0}^{n-1} \left(\frac{1}{2\sigma}\sum_j \sum_{k\in I^+(j)} m_{jk}\left(\frac{\mathbf{u}_{jk}^{p+1} - \mathbf{u}_{jk}^p}{\Delta t} - \frac{\mathbf{u}_j^{p+1} - \mathbf{u}_j^p}{\Delta t}\right)^2\right)^{\frac{1}{2}} \\ &+ \Delta t \sum_{p=0}^{n-1} \|\mathbf{T}^p\|_2 \quad \forall n \ge 0,\end{aligned} \tag{4.21}$$

where T^p is explicitly given in (4.17) *in terms of the solution u. The interest of inequality* (4.21) *is that the numerical error is explicitly bounded by a discrete quantity which is a function of the solution u only.*

To prove (4.19) we consider the numerical error between the numerical solution u^n and the approximate solution $\mathbf{v}^n$: $\mathbf{f}^n = u^n - \mathbf{v}^n$. Using the definition of the scheme, the definition of the iteration operator A and the definition of the truncation error $\mathbf{S}$, one has $\mathbf{f}^{n+1} = A\mathbf{f}^n - \Delta t \mathbf{S}^n$. One uses the CFL condition $\|\mathbf{f}^{n+1}\|_2 \leq \|\mathbf{f}^n\|_2 + \Delta t \|\mathbf{S}^n\|_2$ which proves (4.19). Next, the triangular inequality gives

$$\|u^n - \mathbf{u}^n\|_2 \leq \|u^n - \mathbf{v}^n\|_2 + \|\mathbf{v}^n - \mathbf{u}^n\|_2 \leq \|\mathbf{u}^0 - \mathbf{v}^0\|_2 + \Delta t \sum_{p=0}^{p=n-1} \|\mathbf{S}^p\|_2 + \|\mathbf{v}^n - \mathbf{u}^n\|_2.$$

Using (4.18), (4.5), and (4.6) we obtain (4.20) and (4.21).

5. Convergence. We need some regularity assumptions on the mesh. In the following we assume that the mesh is triangular, but this is only for the sake of simplicity; many other meshes can be considered as in Figures 1 and 5. We also assume that there exists two constants $c_1 > 0$ and $c_2 > 0$ such that

$$c_1 \Delta x^2 \leq s_j \leq c_2 \Delta x^2, \tag{5.1}$$

where Δx is a characteristic length of the mesh. A well-known consequence of (5.1) is

$$\exists c_3 = c_3(c_2) > 0, \quad l_{jk} \leq c_3 \Delta x \quad \forall j, k \in [1, ., J]. \tag{5.2}$$

DEFINITION 6. *A sequence of triangular meshes such that $\Delta x \to 0$ and such that* (5.1) *is true with uniform c_1 and c_2 is called a uniformly regular sequence of triangular meshes. Since $c_3 = c_3(c_2)$, a consequence of this property of uniform regularity is that c_3 is also uniform. We refer the reader to* [5] *for more definitions and properties about such uniformly regular meshes.*

Using the above material, it is easy to get an explicit bound of the numerical error. This bound is a theorem of convergence.

THEOREM 3. *We assume that the initial condition u_0 of* (1.1) *is $H^2(\Omega)$, so the solution u is $H^2([0,T] \times \Omega)$. Consider the numerical solution given by* (2.6)–(2.7) *on a sequence of triangular uniformly regular meshes. Then $\exists C > 0$ such that $\forall T > 0$, $\forall n \leq \frac{T}{\Delta t}$, and $\forall \Delta x \leq 1$,*

$$\|u^n - \mathbf{u}^n\|_2 \leq \left(C(T+2) \max(||\nabla u_0||_{L^2}, ||\nabla^2 u_0||_{L^2})\right) \Delta x^{\frac{1}{2}}, \tag{5.3}$$

where $C = C(c_1, c_2)$ is a constant which depends only on the parameters of the mesh.

The proof is, of course, based on inequalities (4.20), (4.5), and (4.6). First, we need to estimate $\|\mathbf{v}^n - \mathbf{u}^n\|_2$. Due to (4.5), one has

$$\|\mathbf{v}^n - \mathbf{u}^n\|_2^2 \leq \frac{1}{2\sigma} \sum_j \sum_{k \in I^+(j)} m_{jk} (\mathbf{u}_{jk}^n - \mathbf{u}_j^n)^2. \tag{5.4}$$

We split the rest of the proof in five steps. The first step is very classical in the framework of finite elements and is given here for the sake of the completeness of this work.

Step 1: *Study of* $|\mathbf{u}_{jk}^n - \mathbf{u}_j^n|$**.** In the next we will drop the superscript ^{n} and use $|\mathbf{u}_{jk} - \mathbf{u}_j|$ instead of $|\mathbf{u}_{jk}^n - \mathbf{u}_j^n|$.

We define the affine mapping of the plane $F_j : \mathbb{R}^2 \to \mathbb{R}^2$ such that a given triangle (denoted as Ω_j) is transformed into the reference triangle (denoted as T); see Figure 3. This mapping is well known in the theory of finite elements [5].

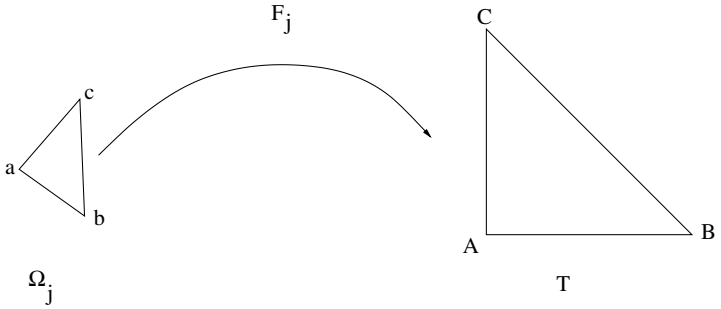

FIG. 3. *The mapping F_j.*

The coordinates of all these points are $a^j = (x_a^j, y_a^j)$, $b^j = (x_b^j, y_b^j)$, and $c^j = (x_c^j, y_c^j)$, together with $A = (0,0)$, $B = (1,0)$, and $C = (0,1)$. The mapping is $(\bar{x}, \bar{y}) = F_j(x,y)$:

$$\left\{ \begin{array}{l} \bar{x} = \alpha^j (x - x_a^j) + \beta^j (y - y_a^j), \\ \bar{y} = \gamma^j (x - x_a^j) + \delta^j (y - y_a^j), \end{array} \right. \tag{5.5}$$

with $D^j = (x_b^j - x_a^j)(y_c^j - y_a^j) - (x_c^j - x_a^j)(y_b^j - y_a^j)$, $\alpha^j = \frac{y_c^j - y_a^j}{D^j}$, $\beta^j = -\frac{x_c^j - x_a^j}{D^j}$, $\gamma^j = -\frac{y_b^j - y_a^j}{D^j}$, and $\delta^j = \frac{x_b^j - x_a^j}{D^j}$. The inverse mapping is defined by

$$\left\{ \begin{array}{l} x = \bar{\alpha}^j \bar{x} + \bar{\beta}^j \bar{y}, \\ y = \bar{\gamma}^j \bar{x} + \bar{\delta}^j \bar{y}, \end{array} \right. \tag{5.6}$$

where $\bar{\alpha}^j = x_b^j - x_a^j$, $\bar{\beta}^j = x_c^j - x_a^j$, $\bar{\gamma}^j = y_b^j - y_a^j$, and $\bar{\delta}^j = y_c^j - y_a^j$. Note that $|D^j| = \text{meas}(\Omega_j) = s_j$. Due to (5.1)

$$|D^j| \geq c_1 \Delta x^2. \tag{5.7}$$

Next, we define $u^j(\bar{x}, \bar{y}) = u(F_j^{-1}(x,y))$. Assuming now that $\mathbf{u}_{jk}$ (resp., $\mathbf{u}_j$) is the edge- (resp., cell-) averaged value of u on (a^j, b^j) (resp., Ω_j), we get that

$$\mathbf{u}_{jk} - \mathbf{u}_j = \int_{(A,B)} u^j(\bar{x}, \bar{y}) d\bar{x} - \int_T u^j(\bar{x}, \bar{y}) d\bar{x}\, d\bar{y}. \tag{5.8}$$

It is useful to introduce the reference square and to extend the function u^j by symmetry with respect to the (B,C) edge of the reference triangle T; see Figure 4. So (5.8) turns into

$$\mathbf{u}_{jk} - \mathbf{u}_j = \int_{(A,B)} u^j(\bar{x}, \bar{y}) d\bar{x} - \int_S u^j(\bar{x}, \bar{y}) d\bar{x}\, d\bar{y}. \tag{5.9}$$

It is then an easy matter to get an upper estimate of the right-hand side. It proves

$$\exists C > 0, \quad |\mathbf{u}_{jk} - \mathbf{u}_j|^2 \leq C ||\nabla u||^2_{L^2(\Omega_j)} \ \forall j, k. \tag{5.10}$$

This inequality is uniform with respect to the index of the triangle j and uniform with respect to the mesh size Δx.

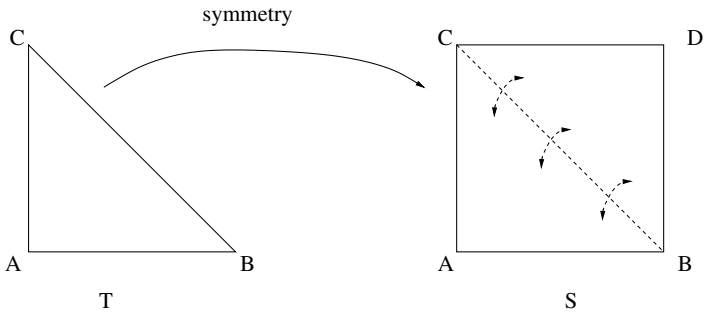

FIG. 4. *Symmetry.*

Step 2: *Bounds for* $\|\mathbf{v}^n - \mathbf{u}^n\|_2$**.** Since $m_{jk} = l_{jk}|(\vec{a}, \vec{n}_{jk})| \leq c_3|\vec{a}|\Delta x$, we get

$$\sum_j \sum_{k \in I^+(j)} m_{jk}(\mathbf{u}_{jk}^n - \mathbf{u}_j^n)^2 \leq (c_3|\vec{a}|\Delta x) \sum_j \left(3C \int_{\Omega_j} |\nabla u|^2 \right)$$
$$\leq (c_3|\vec{a}|3C\Delta x)||\nabla u||^2_{L^2(\Omega)}.$$

Here 3 is the maximal number of edges per triangle. So

$$\|\mathbf{v}^n - \mathbf{u}^n\|_2 \leq C_1||\nabla u||_{L^2(\Omega)} \left(\frac{\Delta x}{\sigma} \right)^{\frac{1}{2}}, \tag{5.11}$$

where the constant C_1 is a function only of (c_1, c_2, c_3).

Step 3: *Bounds for* $\|\frac{\mathbf{v}^{n+1}-\mathbf{v}^n}{\Delta t} - \frac{\mathbf{u}^{n+1}-\mathbf{u}^n}{\Delta t}\|_2$**.** Of course, we use (4.6). With respect to what has already been done for (5.11), the extra work concerns only the evaluation of

$$\frac{\mathbf{u}_{jk}^{n+1} - \mathbf{u}_{jk}^n}{\Delta t} - \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t}. \tag{5.12}$$

Defining $w(n\Delta t) = \frac{u((n+1)\Delta) - u(n\Delta t)}{\Delta t}$, we remark that all terms in (5.12) may be reinterpreted as averages of w:

$$\frac{\mathbf{u}_{jk}^{n+1} - \mathbf{u}_{jk}^n}{\Delta t} - \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t} = \mathbf{w}_{jk}^n - \mathbf{w}_j^n, \tag{5.13}$$

where $\mathbf{w}_{jk}^n$ (resp., $\mathbf{w}_j^n$) is the edge (resp., cell) average of $w(n\Delta t)$. So if we prove that $\nabla w(n\Delta t)$ is bounded in $L^2(\Omega)$, then it is sufficient to use Step 2, applied to this $w(n\Delta t)$ function. Since $w(n\Delta t) = \int_{n\Delta t}^{(n+1)\Delta t} \frac{\partial u}{\partial t} dt = -\vec{a}(\int_{n\Delta t}^{(n+1)\Delta t} \nabla u dt)$, then $\nabla w(n\Delta t) = -(\int_{n\Delta t}^{(n+1)\Delta t} \nabla^2 u dt)\vec{a}$, so $\exists \tilde{c} > 0$ such that

$$||\nabla w(n\Delta t)||_{L^2(\Omega)} \leq \tilde{c}||\nabla^2 u(n\Delta t)||_{L^2(\Omega)} = \tilde{c}||\nabla^2 u_0||_{L^2(\Omega)}.$$

So we have

$$\left\| \frac{\mathbf{v}^{n+1} - \mathbf{v}^n}{\Delta t} - \frac{\mathbf{u}^{n+1} - \mathbf{u}^n}{\Delta t} \right\|_2 \leq C_2||\nabla^2 u_0||_{L^2(\Omega)} \left(\frac{\Delta x}{\sigma} \right)^{\frac{1}{2}}, \tag{5.14}$$

where the constant $C_2 > 0$ is a function only of (c_1, c_2, c_3).

Step 4: *Estimate of* $\mathbf{T}^n$**.** Concerning $\mathbf{T}^n$, we have

$$\mathbf{T}_j^n = \frac{\mathbf{u}_j^{n+1} - \mathbf{u}_j^n}{\Delta t} + \frac{1}{s_j}\left(\sum_{k \in I^+(j)} m_{jk} \mathbf{u}_{jk}^n - \sum_{k \in I^-(j)} m_{jk} \mathbf{u}_{jk}^n \right).$$

By definition of $\mathbf{u}_{jk}^n$ in (4.2)

$$\begin{aligned}
\mathbf{T}_j^n &= \frac{1}{s_j} \int_{\Omega_j} \frac{u((n+1)\Delta t, \vec{x}) - u(n\Delta t, \vec{x})}{\Delta t} + \frac{1}{s_j} \int_{\Omega_j} \vec{a} \nabla u(n\Delta t, \vec{x}) \\
&= \frac{1}{s_j} \int_{\Omega_j} \int_{n\Delta t}^{(n+1)\Delta t} (\partial_t u(s, \vec{x}) - \partial_t u(n\Delta t, \vec{x})) ds\, dx \\
&= \frac{1}{\Delta t} \frac{1}{s_j} \int_{\Omega_j} \int_{n\Delta t}^{(n+1)\Delta t} \int_{n\Delta t}^{s} \partial_t^2 u(\tau, \vec{x}) d\tau\, ds\, dx.
\end{aligned}$$

Using the Cauchy–Schwarz inequality we get that

$$\begin{aligned}
|\mathbf{T}_j^n| &\le \frac{1}{\Delta t} \frac{1}{s_j} \left(\int_{n\Delta t}^{(n+1)\Delta t} \int_{n\Delta t}^{s} \int_{\Omega_j} \partial_t^2 u(\tau, \vec{x})^2 dx\, d\tau\, ds \right)^{\frac{1}{2}} \\
&\quad \times \left(\int_{n\Delta t}^{(n+1)\Delta t} \int_{n\Delta t}^{s} \int_{\Omega_j} dx\, d\tau\, ds \right)^{\frac{1}{2}} \\
&\le \frac{1}{s_j^{\frac{1}{2}}} \left(\int_{n\Delta t}^{(n+1)\Delta t} \int_{n\Delta t}^{s} \int_{\Omega_j} (\partial_t^2 u(\tau, \vec{x}))^2 dx\, d\tau\, ds \right)^{\frac{1}{2}}.
\end{aligned}$$

So finally we obtain the estimate

$$\|\mathbf{T}^n\|_2^2 = \sum_j s_j |\mathbf{T}_j^n|^2 \le \int_{n\Delta t}^{(n+1)\Delta t} \int_{n\Delta t}^{s} \left(\int_{\Omega} (\partial_t^2 u(\tau, \vec{x}))^2 dx \right) d\tau\, ds.$$

As a consequence $\exists \tilde{C}_3 > 0$ and $\exists C_3 > 0$ such that

$$\|\mathbf{T}^n\|_2^2 \le \tilde{C}_3 \Delta t^2 ||\partial_t^2 u||_{L^2(\Omega)}^2 \le C_3^2 \Delta x^2 ||\nabla^2 u_0||_{L^2(\Omega)}^2,$$

that is,

$$\|\mathbf{T}^n\|_2 \le C_3 \Delta x ||\nabla^2 u_0||_{L^2(\Omega)}. \tag{5.15}$$

Step 5: *End of the proof.* Finally, we use (5.11)–(5.15) in (4.20) and get

$$\begin{aligned}
\|u^n - \mathbf{u}^n\|_2 &\le (2 + \sigma n \Delta t) C_1 ||\nabla u_0|| \left(\frac{\Delta x}{\sigma} \right)^{\frac{1}{2}} \\
&\quad + (n\Delta t) C_2 ||\nabla^2 u_0|| \left(\frac{\Delta x}{\sigma} \right)^{\frac{1}{2}} + (n\Delta t) C_3 ||\nabla^2 u_0|| \Delta x.
\end{aligned}$$

The coefficient $2 + \sigma n \Delta t \le 2 + \sigma T$ is simply the multiplicative factor, equal to the number of terms like $\|\mathbf{v}^p - \mathbf{u}^p\|$ in the sum. Finally, we optimize the parameter σ and choose $\sigma = 1$. Be careful that we really need to optimize σ since it appears both in

the numerator $\sigma\frac{1}{\sigma^{\frac{1}{2}}}\times\ldots$ and in the denominator $\frac{1}{\sigma^{\frac{1}{2}}}\times\ldots$. Since $\Delta x\le 1$ we bound $\Delta x\le\Delta x^{\frac{1}{2}}$. It gives (5.3) and finishes the proof.

COROLLARY 1. *We assume that the initial condition u_0 of (1.1) is in $L^1(\Omega)$ (resp., $L^2(\Omega)$), so the solution u is $L^1([0,T]\times\Omega)$ (resp., $L^2([0,T]\times\Omega)$). Consider the numerical solution given by (2.6)–(2.7) on a sequence of triangular uniformly regular meshes, and assume a CFL inequality (3.3). Then $\forall T>0$ and $\forall n\le\frac{T}{\Delta t}$,*

$$u^n\to\mathbf{u}^n \text{ as } \Delta x\to 0 \text{ in } L^1(\Omega) \text{ (resp., } L^2(\Omega)). \tag{5.16}$$

This is straightforward and is a mere consequence of the stability of the iteration operator for the L^1 and L^2 norms.

6. A remark about convergence via bounded variation estimates. Nonlinear techniques applied to the study of the convergence of the scheme have been used in various works. Let us mention [4, 3, 15, 6], where a $\Delta x^{\frac{1}{4}}$ rate of convergence in L^1 for a initial data in $L^1\cap BV$ is proved; see also [25]. In [9, 10] it is proved that the scheme converges with a $\Delta x^{\frac{1}{2}}$ rate in L^1 for a initial data in $L^1\cap BV$, provided the numerical solution is bounded in $L^\infty([0,T]\times BV)$. Many numerical experiments show that this hypothesis—the numerical solution is bounded in $L^\infty([0,T]\times BV)$—is very reasonable. Unfortunately, it is false without additional hypotheses, as is shown in the proof of the next lemma.

LEMMA 5. *There exist meshes such that the numerical solution is not bounded in $L^\infty([0,T]\times BV)$ (with a initial data in $L^1\cap BV$, of course).*

Actually the total variation of these numerical solutions blows up like $\Delta x^{-\frac{1}{2}}$. The construction is very simple. Let us consider the almost Cartesian mesh represented in Figure 5. The mesh is made of squares, but the size of each square is either Δx or $\frac{\Delta x}{2}$. On each "line" all squares have the same size. So we distinguish all cells on "large" lines, referred to as $(2p,j)$ cells, and all cells on "small" line, referred to as $(2p+1,j)$ cells. Thus $2p$ (resp., $2p+1$) is the index of the line, while j is the index of the cell inside its line. Just be careful that there are twice as many cells on a $2p+1$ line than on a $2p$ line. The index of the column is $j=0$ for the first square on the positive half-plane $x>0$. Here P is the number of "large" lines: provided there are exactly the same number of large and small lines, one has

$$P=\frac{1}{\frac{3\Delta x}{2}}=\frac{2}{3\Delta x}. \tag{6.1}$$

Let us solve the problem with periodic boundary conditions:

$$\begin{cases}\partial_t u+\partial_x u=0, & -1\le x,\quad y\le 1,\\ u_0(x,y)=0 \text{ for } x<\frac{1}{2}, & u_0(x,y)=1 \text{ for } x>\frac{1}{2}.\end{cases} \tag{6.2}$$

This is a one-dimensional problem on each line. But since the size of each square is not the same, the CFL number is not the same on lines made with Δx "large" squares and lines made with $\frac{\Delta x}{2}$ "small" squares. Let us consider for the sake of simplicity that the CFL number is exactly one for the "small" squares $\Delta t=\frac{\Delta x}{2}$. It means that the scheme is the one-dimensional exact linear scheme on "small" lines,

$$u^{n+1}_{2p+1,j}=u^n_{2p+1,j-1},\quad u^0_{2p,j}=1 \quad\text{for}\quad j\ge 0,\quad u^0_{2p,j}=0 \quad\text{for}\quad j<0, \tag{6.3}$$

and is the one-dimensional nonexact linear scheme on "large" lines,

$$u^{n+1}_{2p,j}=\frac{1}{2}(u^n_{2p,j}+u^n_{2p,j-1}),\quad u^0_{2p,j}=1 \quad\text{for}\quad j\ge 0,\quad u^0_{2p,j}=0 \quad\text{for}\quad j<0. \tag{6.4}$$

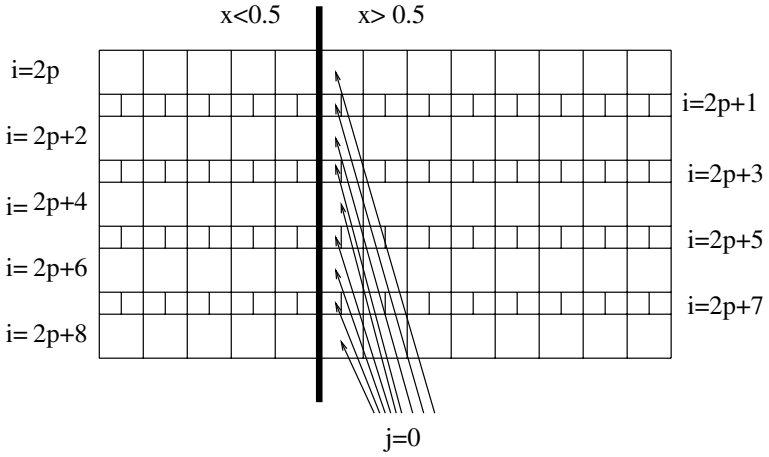

FIG. 5. *An almost Cartesian mesh.*

The solution of (6.3) is, of course, the exact solution $u^n_{2p+1,j} = u^0_{2p+1,j-n}$. It is a classroom exercise to check that the solution of (6.4) is $u^n_{2p,j} = \frac{1}{2^n}\sum_{q\le j}\binom{q}{n}$, where $\binom{q}{n} = \frac{n!}{q!(n-q)!}$ is the binomial coefficient: $\binom{q}{n} = 0$ for $q < 0$ and $q > n$. The L^1 difference between the exact the the numerical solution on "large" lines is

$$\sum_j |u^{2k}_{2p,j} - u_{\text{exact}}(2k\Delta t)| = \sum_{0\le j\le k-1} |u^{2k}_{2p,j}| + \sum_{k\le j\le 2k-1} |u^{2k}_{2p,j} - 1|.$$

Let us get a lower bound for $\sum_{0\le j\le k-1} |u^{2k}_{2p,j}|$. One has

$$\begin{aligned}\sum_{0\le j\le k-1} |u^{2k}_{2p,j}| &= \frac{1}{2^{2k}} \sum_{0\le j\le k-1}\sum_{q\le j}\binom{q}{2k} \\ &= \frac{1}{2^{2k}} \sum_{0\le q\le k-1} (k-q)\binom{q}{2k} = A - B.\end{aligned} \tag{6.5}$$

The right-hand side is the difference between

$$A = \frac{1}{2^{2k}}\frac{k}{2}\left(2\sum_{0\le q\le k-1}\binom{q}{2k}\right) = \frac{1}{2^{2k}}\frac{k}{2}\left(2^{2k} - \binom{k}{2k}\right) = \frac{k}{2}\left(1 - \frac{\binom{k}{2k}}{2^{2k}}\right)$$

and

$$\begin{aligned}B &= \frac{1}{2^{2k}}\sum_{0\le q\le k-1} q\binom{q}{2k} = \frac{k}{2^{2k}}\left(2\sum_{q\le k-1}\binom{q-1}{2k-1}\right) \\ &= \frac{k}{2^{2k}}\left(2^{2k-1} - 2\binom{k-1}{2k-1}\right) = \frac{k}{2}\left(1 - 4\frac{\binom{k-1}{2k-1}}{2^{2k}}\right) \\ &= \frac{k}{2}\left(1 - 2\frac{\binom{k}{2k}}{2^{2k}}\right).\end{aligned}$$

Thus

$$A - B = \frac{k}{2}\frac{\binom{k}{2k}}{2^{2k}} = \frac{\sqrt{k}}{2\sqrt{2\pi}} + o(\sqrt{k}) \tag{6.6}$$

from the standard Stirling approximation of the factorial $q! \approx \sqrt{2\pi q}\left(\frac{q}{e}\right)^q$; see [1]. Now going back to (6.5) we get that

$$\Delta x \sum_j |u^{2k}_{2p,j} - u_{\text{exact}}(2k\Delta t)| \geq \Delta x \left(\frac{\sqrt{k}}{2\sqrt{2\pi}} + o(\sqrt{k})\right).$$

But $2k$ is the iteration number and corresponds to the time $T = 2k\Delta t = k\Delta x$. Then $\Delta x\sqrt{k} = \sqrt{\Delta x}\sqrt{\Delta x k} = \sqrt{\Delta x}\sqrt{T}$. Then we get that $\Delta x \sum_j |u^{2k}_{2p,j} - u_{\text{exact}}(2k\Delta t)| \geq C\Delta x^{\frac{1}{2}} + o(\Delta x^{\frac{1}{2}})$, $C = \frac{\sqrt{T}}{2\sqrt{2\pi}}$. Let us now get a lower bound of the total variation in two dimensions of the numerical solution. Since the two-dimensional total variation is by definition the sum on all edges of the absolute value of the difference of the numerical solution on both sides, multiplied by the length of the edge, then we get that

$$\begin{aligned} |u^{2k}|_{BV} &\geq 2\Delta x \sum_{p=1}^{P} \left(\sum_j |u^{2k}_{2p,j} - u_{\text{exact}}(2k\Delta t)|\right) \\ &= P\frac{\sqrt{T}}{\sqrt{2\pi}}(\Delta x^{\frac{1}{2}} + o(\Delta x^{\frac{1}{2}})). \end{aligned} \tag{6.7}$$

Then we get from (6.1) that

$$|u^{2k}|_{BV} \geq \frac{2\sqrt{T}}{3\sqrt{2\pi}}\Delta x^{-\frac{1}{2}} + o(\Delta x^{-\frac{1}{2}}). \tag{6.8}$$

Here $T = 2k\Delta t$. It ends the proof of the lemma.

7. Numerical order of convergence. However, very simple numerical experiments show that the $\Delta x^{\frac{1}{2}}$ order of convergence proved in this work for twice differentiable initial data is probably not optimal. The initial data is

$$u_0(x, y) = \sin(2\pi(x + y)) \in H^2_{\text{per}}([0, 1]^2).$$

Indeed, the experimental order of convergence is clearly ≈ 1 $\forall L^p$ norms, $p = 1,\ 2,\ \infty$.

In Figure 6 is plotted the type of mesh one usually gets with a standard mesh generator. Here we have used the Freefem++ mesh generator [27], but it is very reasonable to think that similar conclusions can be drawn with other mesh generators. In Table 1 we give the experimental relative error which is defined by

$$e_p = \frac{||u(n\Delta t) - u^{n\Delta t}||_p}{||u(n\Delta t)||_p}, \tag{7.1}$$

where $u(n\Delta t)$ (resp., $u^{n\Delta t}$) is the exact (resp., numerical) solution at time $n\Delta t$. Here we took $n\Delta t = 1$. The equation is (1.1) with $\vec{a} = (1, 1)$. There are many possibilities to define the characteristic length of the mesh. We use

$$h = \max(\text{edge's length}). \tag{7.2}$$

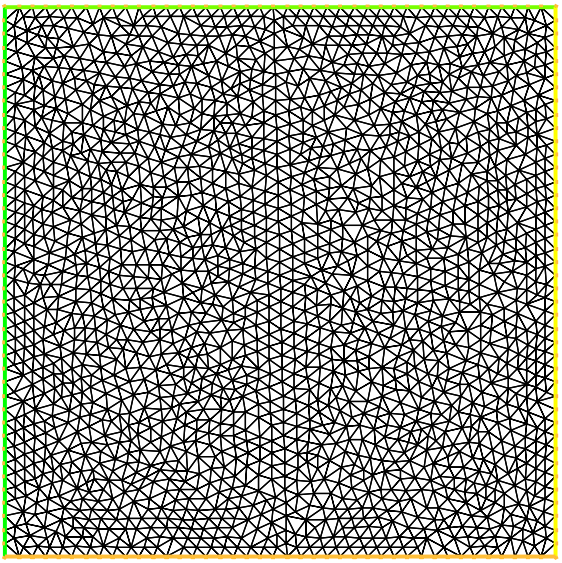

FIG. 6. *From Freefem++.*

TABLE 1
Errors with respect to the size of the mesh.

Triangular mesh	Points	Cells	h	L^1	L^2	L^∞
	2034	3902	0.0408	0.3967	0.3967	0.4102
	4488	8730	0.0276	0.2828	0.2828	0.2933
	7873	15420	0.0216	0.2173	0.2179	0.2308
	17756	35026	0.0147	0.1554	0.1553	0.1675
	31232	61818	0.0114	0.1207	0.1206	0.1290
Order				0.9939	0.9946	1.027

Cartesian mesh	Points	Cells	h	L^1	L^2	L^∞
	40^2	40^2	0.025	0.3964	0.3973	0.3961
	60^2	60^2	0.01666	0.2849	0.2852	0.2848
	80^2	80^2	0.0125	0.2187	0.2187	0.2187
	120^2	120^2	0.00833	0.1538	0.1539	0.1538
	160^2	160^2	0.00625	0.1160	0.1160	0.1160
Order				0.9818	0.9840	0.981

By inspection of the table one finds that the rate of convergence is very close to one. We use the approximate formula for the order of convergence:

$$\text{order}_{\text{triangle}} = \frac{\log \frac{e_p(0.0147)}{e_p(0.00114)}}{\log \frac{0.0147}{0.00114}} \quad \text{and} \quad \text{order}_{\text{square}} = \frac{\log \frac{e_p(0.025)}{e_p(0.00625)}}{\log \frac{0.025}{0.00625}}. \tag{7.3}$$

In each case, the formula is a function of the error for the two finest meshes.

8. Conclusion. In this paper we give an elementary proof of convergence for linear advection on arbitrary grids in several space dimensions, based on an explicit and

new a priori estimate. It is possible to take into account other boundary conditions. To our knowledge it is still an open problem to explain the one order of convergence for the linear advection discretized with finite volume methods on non-Cartesian meshes.

Acknowledgment. The author thanks both referees for their help in the improvement of the quality of this paper.

ADAPTIVE APPROXIMATION OF YOUNG MEASURE SOLUTIONS IN SCALAR NONCONVEX VARIATIONAL PROBLEMS*

SÖREN BARTELS†

Abstract. This paper addresses the numerical approximation of Young measures appearing as generalized solutions to scalar nonconvex variational problems. We prove a priori and a posteriori error estimates for a macroscopic quantity, the stress. For a scalar three-well problem we show convergence of other quantities such as Young measure support and microstructure region. Numerical experiments indicate that the computational effort in the solution of the large optimization problem is significantly reduced by using an adaptive mesh refinement strategy based on a posteriori error estimates in combination with an active set strategy due to Carstensen and Roubíček [*Numer. Math.*, 84 (2000), pp. 395–414].

Key words. nonconvex variational problems, microstructure, finite elements, error estimation, adaptivity, multiple scales

1. Introduction.

A scalar model example in the context of phase transitions in crystalline solids reads

$$\text{(P)} \quad \begin{cases} \text{Seek } u \in \mathcal{A} := \{v \in W^{1,2}(\Omega) : v|_{\Gamma_D} = u_D\} \\ \text{such that } I(u) = \inf\limits_{v\in\mathcal{A}} I(v). \end{cases}$$

Here, $\Omega \subseteq \mathbb{R}^n$ is a bounded Lipschitz domain, $\Gamma_D \subseteq \partial\Omega$ a closed subset of $\partial\Omega$ with positive surface measure, and $u_D \in W^{1/2,2}(\Gamma_D)$ is the trace of some function $\tilde{u}_D \in W^{1,2}(\Omega)$. The energy functional $I : \mathcal{A} \to \mathbb{R}$ is for $v \in \mathcal{A}$ defined by

$$\begin{aligned} I(v) := &\int_\Omega W(\nabla v(x))dx + \alpha \int_\Omega |u_0(x) - v(x)|^2 dx \\ &- \int_\Omega f(x)v(x)dx - \int_{\Gamma_N} g(x)v(x)ds_x, \end{aligned}$$

where $u_0, f \in L^2(\Omega)$, $g \in L^2(\Gamma_N)$ for $\Gamma_N := \partial\Omega\backslash\Gamma_D$, and $\alpha \geq 0$. An energy density W that can be derived from a three-dimensional model with one-dimensional symmetry [2] is given by $N+1$ wells $s_0, \dots, s_N \in \mathbb{R}^n$ and numbers $s_0^0, \dots, s_N^0 \in \mathbb{R}$ and reads

$$W(s) = \min_{j=0,\dots,N} \left(|s - s_j|^2 + s_j^0\right) \quad \forall s \in \mathbb{R}^n. \tag{1.1}$$

This function W serves as a model energy density, but more generally we will consider mappings $W : \mathbb{R}^n \to \mathbb{R}$ which are continuous and satisfy quadratic growth conditions.

The contributions in I which involve f and g represent outer body forces, while the integral of $W(\nabla v)$ measures the stored energy in Ω. A mechanical interpretation

of the term $\alpha\|u_0 - v\|^2_{L^2(\Omega)}$ may be obtained from a model of a thin crystal plate glued to a rigid substrate [12]. Similar scalar minimization problems arise in optimal control theory [27]. For ease of presentation, we restrict the analysis to quadratic growth conditions ($p = 2$) but stress that the estimates can easily be generalized to other growth conditions ($2 \le p < \infty$).

It is well known that existence of solutions for (P) depends on convexity properties of W: If W is convex, then there exists a solution which is unique, provided W is strictly convex or $\alpha > 0$. In case that W fails to be convex, then I is not weakly lower semicontinuous and solutions may not exist. In the latter case, infimizing sequences are generically enforced to develop oscillations and therefore do not converge to a global minimizer of I. To be able to deal with this phenomenon, we will consider appropriate (weak*) limits of infimizing sequences for (P) which contain the most important information and which show where infimizing sequences develop oscillations. Those limits are measure-valued functions called Young measures and arise as solutions for an extended problem (EP). We refer the reader to [23, 26, 27] for details on the mathematical analysis of (P). The numerical approximation of the extended problem has been proposed in [24, 27, 17, 8, 25, 28] and in [18] for a nonconvex variational problem in the theory of micromagnetics. It is our aim to establish error estimates for the numerical treatment of the extended problem. We note, however, that our analysis is restricted to scalar problems. The practically more relevant case of nonconvex vectorial variational problems requires an efficient characterization of gradient Young measures and is excluded from our considerations. The alternative approach of directly minimizing I is discussed in [7, 9, 21].

The idea for the derivation of a priori and a posteriori error estimates is that the discretized extended problem may be regarded as a perturbation of a discretization of a relaxed (convexified) problem which has been analyzed in [7]. This perturbation consists of the difference between the convex hull of the energy density itself and the convex hull of a discrete approximation of the energy density. Employing the concept of subdifferentials in the theory of nonsmooth optimization we show that a dual variable, occurring in the discretized extended problem, converges to a macroscopic quantity of the relaxed problem and prove related error estimates. Moreover, we prove computable error estimates that allow for adaptive mesh refinement and which characterize a reliable relation between the two scales involved.

The "active set strategy" of [8] to solve a discretization of (EP) efficiently for a fixed triangulation of Ω is a multilevel scheme and depends on a good guess of a solution. Based on our error estimates we propose the embedding of that scheme into an adaptive mesh refining algorithm. We report the performance of the resulting algorithm for two examples. Our overall observation is that the algorithm performs very efficiently but depends on a good solver for large optimization problems. For a two-dimensional problem a numerical experiment indicates linear complexity of our solving strategy.

The outline of the rest of this paper is as follows. We state the extended problem in section 2 and proceed in section 3 with some notation, a construction of discrete Young measures, and the formulation of the discrete problem. Section 4 gives the announced error analysis as the main contribution of this work. Section 5 is devoted to the analysis of convergence of various quantities in a scalar three-well problem. The "active set strategy" of [8] and its embedding into an adaptive mesh refinement algorithm are given in section 6. Finally, in section 7, we report on numerical results for two specifications of (P) which illustrate the theoretical results of this article.

2. Young measures and the extended problem. In this section we recall the notion of Young measures which are mappings from Ω into the space of probability measures on $\mathbb{R}^n$ and allow for the computation of certain limits of weakly* convergent sequences in Lebesgue spaces.

DEFINITION 2.1. *Let $\mathcal{M}(\mathbb{R}^n)$ be the set of all signed Radon measures on $\mathbb{R}^n$, and let $PM(\mathbb{R}^n)$ be the subset of probability measures on $\mathbb{R}^n$, i.e., the set of all nonnegative Radon measures $\mu \in \mathcal{M}(\mathbb{R}^n)$ satisfying $\int_{\mathbb{R}^n} \mu(ds) = 1$. The set of L^2-*Young measures $\mathcal{Y}_2(\Omega;\mathbb{R}^n)$ *is defined as*

$$\mathcal{Y}_2(\Omega;\mathbb{R}^n) := \Big\{ \nu \in L^\infty_w(\Omega;\mathcal{M}(\mathbb{R}^n)) : \nu_x \in PM(\mathbb{R}^n) \text{ for a.a. } x \in \Omega, \int_\Omega \int_{\mathbb{R}^n} |s|^2 \nu_x(ds)dx < \infty \Big\}.$$

Here $\nu_x := \nu(x)$ for $x \in \Omega$, and $L^\infty_w(\Omega;\mathcal{M}(\mathbb{R}^n))$ consists of those mappings $\nu \in L^\infty(\Omega;\mathcal{M}(\mathbb{R}^n))$ for which the mapping $x \mapsto \int_{\mathbb{R}^n} v(s)\,\nu_x(ds)$ is measurable whenever $v \in C(\mathbb{R}^n)$ satisfies $\lim_{|s|\to\infty} v(s) = 0$.

Infimizing sequences for (P) generate Young measures in the sense of the following statement, which is a consequence of the fundamental theorem on Young measures [30, 1, 16, 27]. Throughout this paper we assume that there exist constants $c_1, c_2 > 0$ such that

$$c_1|s|^2 - c_2 \le W(s) \le c_2(1 + |s|^2) \quad \forall s \in \mathbb{R}^n. \tag{2.1}$$

LEMMA 2.2 (see [26, Lemma 4.3]). *Let $(u_j) \subseteq \mathcal{A}$ be an infimizing sequence for (P), i.e., $I(u_j) \to \inf_{v\in\mathcal{A}} I(v)$. Then there exist $u \in \mathcal{A}$, $\nu \in \mathcal{Y}_2(\Omega;\mathbb{R}^n)$, and a subsequence (u_k) such that $u_k \rightharpoonup u$ (weakly) in $W^{1,2}(\Omega)$,*

$$\int_\Omega W(\nabla u_k(x))dx \to \int_\Omega \int_{\mathbb{R}^n} W(s)\,\nu_x(ds)dx,$$

and, for almost all $x \in \Omega$, there holds $\nabla u(x) = \int_{\mathbb{R}^n} s\,\nu_x(ds)$.

The Young measure ν generated by the gradients of an infimizing sequence (u_j) for (P) describes oscillations in that sequence in a statistical way [1]. Together with the weak limit u, we obtain the most relevant information about (P). If we express the limit of $I(u_j)$ in terms of u and ν we obtain the extended problem (EP).

$$\text{(EP)} \quad \begin{cases} \text{Seek } (u,\nu) \in \mathcal{B} := \Big\{ (v,\mu) \in W^{1,2}(\Omega) \times \mathcal{Y}_2(\Omega;\mathbb{R}^n) : \\ \qquad v|_{\Gamma_D} = u_D, \nabla v(x) = \displaystyle\int_{\mathbb{R}^n} s\,\mu_x(ds) \text{ for a.a. } x \in \Omega \Big\} \\ \text{such that } \overline{I}(u,\nu) = \displaystyle\inf_{(v,\mu)\in\mathcal{B}} \overline{I}(v,\mu). \end{cases}$$

The extended energy functional $\overline{I}$ is for $(v,\mu) \in \mathcal{B}$ defined by

$$\overline{I}(v,\mu) := \int_\Omega \int_{\mathbb{R}^n} W(s)\,\mu_x(ds)dx + \alpha \int_\Omega |u_0 - v|^2 dx - \int_\Omega fv dx - \int_{\Gamma_N} gv ds_x.$$

The following theorem shows that (EP) is a correct extension of (P). Limits in $\mathcal{B}$ refer to the (weak, weak*)-topology in $W^{1,2}(\Omega) \times \mathcal{Y}_2(\Omega;\mathbb{R}^n)$ (cf. [27] for details).

Via the mapping $\iota : \mathcal{A} \to \mathcal{B}$, $u \mapsto (u, \delta_{\nabla u})$, where for almost all $x \in \Omega$ and all $v \in C(\mathbb{R}^n)$ with $\lim_{|s|\to\infty} v(s) = 0$ the Dirac measure $\delta_{\nabla u(x)} \in PM(\mathbb{R}^n)$ is defined by $\int_{\mathbb{R}^n} v(s)\,\delta_{\nabla u(x)}(ds) = v(\nabla u(x))$, $\mathcal{A}$ can be embedded continuously into $\mathcal{B}$.

THEOREM 2.3 (see [27, Proposition 5.2.1]). (i) (EP) *admits a solution.*

(ii) $\inf_{v\in\mathcal{A}} I(v) = \min_{(w,\mu)\in\mathcal{B}} \overline{I}(w,\mu)$.

(iii) *The embedding $\iota : \mathcal{A} \to \mathcal{B}$ of each infimizing sequence for* (P) *has a convergent subsequence whose limit is a solution to* (EP).

(iv) *Each solution to* (EP) *is the limit of the embedding $\iota : \mathcal{A} \to \mathcal{B}$ of an infimizing sequence for* (P).

Carathéodory's theorem implies that there exist solutions $(u, \nu) \in \mathcal{B}$ to (EP) such that for almost all $x \in \Omega$ the probability measure ν_x is a convex combination of at most $n + 1$ Dirac measures (cf. [27, Corollary 5.3.3]). This fact motivates the discretization of (EP) introduced in section 3 and the algorithm of [8] to efficiently approximate (EP).

3. Discretization of (EP). This section is devoted to the construction of a discrete subspace of $\mathcal{B}$.

3.1. Finite element spaces and notation. Let $\mathcal{T}$ be a regular triangulation of Ω into triangles ($n = 2$) or tetrahedra ($n = 3$) in the sense of [10], i.e., there are no hanging nodes; the domain is matched exactly, i.e., $\overline{\Omega} = \cup_{T\in\mathcal{T}} T$; and $\mathcal{T}$ satisfies the maximum angle condition. Therefore, $\partial\Omega$ is assumed to be polygonal. The extremal points of $T \in \mathcal{T}$ are called nodes, and $\mathcal{N}$ denotes the set of all such nodes. Let $\mathcal{K} := \mathcal{N} \setminus \Gamma_D$ be the subset of free nodes. The set of edges (respectively, faces if $n = 3$) $E = \operatorname{conv}\{z_1, \dots, z_n\} \subseteq \partial T$ for pairwise distinct $z_1, \dots, z_n \in \mathcal{N}$ and $T \in \mathcal{T}$ is denoted as $\mathcal{E}$. A partition $\mathcal{E} = \mathcal{E}_\Omega \cup \mathcal{E}_D \cup \mathcal{E}_N$ is given by $\mathcal{E}_N := \{E \in \mathcal{E} : E \subseteq \overline{\Gamma}_N\}$, $\mathcal{E}_D := \{E \in \mathcal{E} : E \subseteq \Gamma_D\}$, and $\mathcal{E}_\Omega := \mathcal{E} \setminus (\mathcal{E}_D \cup \mathcal{E}_N)$. The set

$$\mathcal{L}^k(\mathcal{T}) := \{v_h \in L^\infty(\Omega) : \forall T \in \mathcal{T},\ v_h|_T \in P_k(T)\}$$

consists of all (possibly discontinuous) $\mathcal{T}$-elementwise polynomials of degree at most k. Define

$$\mathcal{S}^1(\mathcal{T}) := \mathcal{L}^1(\mathcal{T}) \cap C(\overline{\Omega}) \quad \text{and} \quad \mathcal{S}^1_D(\mathcal{T}) := \{u_h \in \mathcal{S}^1(\mathcal{T}) : u_h|_{\Gamma_D} = 0\} \subseteq W^{1,2}_D(\Omega),$$

where $W^{1,2}_D(\Omega) := \{v \in W^{1,2}(\Omega) : v|_{\Gamma_D} = 0\}$. Let $(\varphi_z : z \in \mathcal{N})$ be the nodal basis of $\mathcal{S}^1(\mathcal{T})$; i.e., $\varphi_z \in \mathcal{S}^1(\mathcal{T})$ satisfies $\varphi_z(x) = 0$ if $x \in \mathcal{N} \setminus \{z\}$ and $\varphi_z(z) = 1$. A function $h_\mathcal{T} \in \mathcal{L}^0(\mathcal{T})$ is defined by $h_\mathcal{T}|_T = h_T := \operatorname{diam}(T)$ for all $T \in \mathcal{T}$. Moreover, let $h_\mathcal{E} \in L^\infty(\cup\mathcal{E})$ be defined by $h_\mathcal{E}|_E = h_E := \operatorname{diam}(E)$ for all $E \in \mathcal{E}$.

The nodal interpolation operator associated with a triangulation $\mathcal{T}$ is denoted by $P_\mathcal{T}$. If τ is a triangulation of a convex domain $\omega \subseteq \mathbb{R}^n$ and $v \in C(\overline{\omega})$ we extend $P_\tau v$ to $\mathbb{R}^n$ by setting $P_\tau v(s) = P_\tau v(\mathcal{P}_\omega(s))$, where $\mathcal{P}_\omega$ denotes the orthogonal projection onto $\overline{\omega}$.

Suppose $g \in L^2(\Gamma_N)$ is such that $g|_E \in W^{1,2}(E)$ for all $E \in \mathcal{E}_N$ and, for each node $z \in \mathcal{N} \cap \overline{\Gamma}_N$ where the outer unit normal n_{Γ_N} on Γ_N is continuous, g is continuous. We set

$$\mathcal{S}^1_N(\mathcal{T}, g) := \{\tau_h \in \mathcal{S}^1(\mathcal{T})^n : \forall E \in \mathcal{E}_N\ \forall z \in E \cap \mathcal{N},\ \tau_h(z) \cdot n_{\Gamma_N}|_E = g(z)\} \tag{3.1}$$

and note that $\mathcal{S}^1_N(\mathcal{T}, g) \neq \emptyset$ if $n = 2$. We will assume that $\mathcal{S}^1_N(\mathcal{T}, g) \neq \emptyset$ if $n = 3$.

Throughout this article $c, C > 0$ denote mesh-size independent, generic constants. For $1 \le p \le \infty$ and an integer $\ell > 0$, $\|\cdot\|_{L^p(\Omega)}$ stands for $\|\cdot\|_{L^p(\Omega;\mathbb{R}^\ell)}$, and $\|\cdot\|$ abbreviates $\|\cdot\|_{L^2(\Omega)}$. The operator $\partial_\mathcal{E}\cdot/\partial s$ denotes the edgewise derivative along (subsets of) $\partial\Omega$.

3.2. Discrete Young measures. We define a convex, discrete (i.e., finite-dimensional) subset of the set of L^2-Young measures $\mathcal{Y}_2(\Omega;\mathbb{R}^n)$ following ideas of [27, 8, 22].

DEFINITION 3.1 (see [27, Example 3.5.4]). *Given a convex polygonal set $\omega \subseteq \mathbb{R}^n$ and regular triangulations τ of ω with nodes $\mathcal{N}_\tau$ and $\mathcal{T}$ of Ω we set*

$$YM_{d,h}(\Omega;\mathbb{R}^n) := \Bigg\{ \nu_{d,h} \in \mathcal{Y}_2(\Omega;\mathbb{R}^n) : \forall z \in \mathcal{N}_\tau \ \exists a_z \in \mathcal{L}^0(\mathcal{T}),\, a_z \geq 0 \text{ and} \\ \sum_{z\in\mathcal{N}_\tau} a_z(x) = 1 \text{ a.e. in } \Omega,\, \nu_{d,h,x} = \sum_{z\in\mathcal{N}_\tau} a_z(x)\delta_z \text{ for a.e. } x \in \Omega \Bigg\},$$

where δ_z denotes the Dirac measure supported in the atom $z \in \mathbb{R}^n \cap \mathcal{N}_\tau$. *By d and h we denote the maximal mesh-size in τ and $\mathcal{T}$, respectively, and refer to τ and $\mathcal{T}$ through these quantities.*

3.3. Discretized extended problem. For regular triangulations $\mathcal{T}$ of Ω and τ of a convex Lipschitz domain $\omega \subseteq \mathbb{R}^n$ and an approximation $u_{D,h} \in \mathcal{S}^1(\mathcal{T})|_{\Gamma_D}$ of u_D we consider the following discrete problem ($\mathrm{EP}_{d,h}$):

$$(\mathrm{EP}_{d,h}) \quad \begin{cases} \text{Seek } (u_{d,h},\nu_{d,h}) \in \mathcal{B}_{d,h} := \Big\{ (v_h,\mu_{d,h}) \in \mathcal{S}^1(\mathcal{T}) \times YM_{d,h}(\Omega;\mathbb{R}^n) : \\ \qquad v_h|_{\Gamma_D} = u_{D,h}, \nabla v_h(x) = \displaystyle\int_{\mathbb{R}^n} s\,\mu_{d,h,x}(ds) \text{ for a.e. } x \in \Omega \Big\}, \\ \text{such that } \overline{I}(u_{d,h},\nu_{d,h}) = \displaystyle\inf_{(v_h,\mu_{d,h})\in\mathcal{B}_{d,h}} \overline{I}(v_h,\mu_{d,h}). \end{cases}$$

An existence result for ($\mathrm{EP}_{d,h}$) follows as for (EP).

PROPOSITION 3.2 (see [27, Proposition 5.5.1]). *If $\mathcal{B}_{d,h} \neq \emptyset$, then* ($\mathrm{EP}_{d,h}$) *admits a solution.*

Remarks. (i) There holds $\mathcal{B}_{d,h} \neq \emptyset$ if the diameter of ω is large enough.

(ii) For efficient approximations one has to assume a uniform bound on the gradient of a solution for (EP). Based on the optimality conditions stated below one may, however, enlarge ω successively to obtain a correct discrete solution. Therefore, no a priori bound on the gradient of an exact solution for (EP) will be assumed.

(iii) For a triangulation $\mathcal{T}$ of Ω with N^n free nodes and a triangulation τ of ω with N^n atoms the number of degrees of freedom in ($\mathrm{EP}_{d,h}$) is N^{2n} if $h \approx d \approx 1/N$.

3.4. Optimality conditions. The following lemma describes optimality conditions for ($\mathrm{EP}_{d,h}$) which are key ingredients for the subsequent analysis.

LEMMA 3.3 (see [8, Proposition 4.3]). *Assume $\omega = \mathbb{R}^n$. The pair $(u_{d,h},\nu_{d,h}) \in \mathcal{B}_{d,h}$ is a solution for* ($\mathrm{EP}_{d,h}$) *if and only if there exists $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^n$ such that, for almost all $x \in \Omega$, we have*

$$\max_{s\in\omega} \mathcal{H}_{\lambda_{d,h}}(x,s) = \int_{\mathbb{R}^n} \mathcal{H}_{\lambda_{d,h}}(x,s)\,\nu_{d,h,x}(ds),$$

where $\mathcal{H}_{\lambda_{d,h}}(x,s) := \lambda_{d,h}(x)\cdot s - P_\tau W(s)$, and, for all $v_h \in \mathcal{S}^1_D(\mathcal{T})$, there holds

$$\int_\Omega \lambda_{d,h}\cdot\nabla v_h dx = 2\alpha\int_\Omega (u_0 - u_{d,h})v_h dx + \int_\Omega f v_h dx + \int_{\Gamma_N} g v_h ds_x.$$

Remark. The elementwise constant function $\lambda_{d,h}$ is the Lagrange multiplier for the constraint $\nabla u_{d,h}|_T = \int_{\mathbb{R}^n} s\,\nu_{d,h}|_T(ds)$, $T \in \mathcal{T}$, in $(\mathrm{EP}_{d,h})$.

For the practical implementation a bounded domain ω and a finite discretization of ω has to be chosen. We formulate appropriate computable conditions that imply Lemma 3.3.

LEMMA 3.4. *Assume that ω is bounded and $B_{r_0}(0) := \{s \in \mathbb{R}^n : |s| < r_0\} \subseteq \omega$ for some $r_0 > 0$. Let $(u_{d,h}, \nu_{d,h}) \in \mathcal{B}_{d,h}$, $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^n$, and assume*

$$\int_\Omega \lambda_{d,h} \cdot \nabla v_h dx = 2\alpha \int_\Omega (u_0 - u_{d,h}) v_h dx + \int_\Omega f v_h dx + \int_{\Gamma_N} g v_h ds_x.$$

If for almost all $x \in \Omega$ the mapping $s \mapsto \lambda_{d,h}(x) \cdot s - P_\tau W(s)$, $s \in \overline{\omega}$, attains its maximum in some $s_x^* \in \overline{B_{r_0}(0)}$, if $2r_0 c_1 \geq \|\lambda\|_{L^\infty(\Omega)}$, and if for almost all $x \in \Omega$

$$r_0 \|\lambda\|_{L^\infty(\Omega)} - c_1 r_0^2 + c_2 \leq \lambda_{d,h}(x) \cdot s_x^* - W(s_x^*), \tag{3.2}$$

then the conditions of Lemma 3.3 are satisfied; i.e., $(u_{d,h}, \nu_{d,h})$ is a solution for $(\mathrm{EP}_{d,h})$.

Proof. It suffices to show that for almost all $x \in \Omega$, any extension $\tilde{\tau}$ of τ to $\mathbb{R}^n$, and all $s \in \mathcal{N}_{\tilde{\tau}} \setminus \overline{B_{r_0}(0)}$ there holds $\lambda_{d,h}(x) \cdot s - P_{\tilde{\tau}} W(s) \leq \mathcal{H}_{\lambda_{d,h}}(x, s_x^*)$ since then the optimality conditions of Lemma 3.3 are satisfied (with $\tilde{\omega} = \mathbb{R}^n$ and $\tilde{\tau}$). In view of (2.1) there holds

$$\lambda_{d,h}(x) \cdot s - P_{\tilde{\tau}} W(s) \leq \|\lambda_{d,h}\|_{L^\infty(\Omega)} |s| - c_1 |s|^2 + c_2.$$

Since $2r_0 c_1 \geq \|\lambda\|_{L^\infty(\Omega)}$ the mapping $t \mapsto \|\lambda_{d,h}\|_{L^\infty(\Omega)} t - c_1 t^2 + c_2$, $t \geq r_0$, is monotonically decreasing and since $\|\lambda_{d,h}\|_{L^\infty(\Omega)} r_0 - c_1 r_0^2 + c_2 \leq \mathcal{H}_{\lambda_{d,h}}(x, s_x^*)$ we have $\lambda_{d,h}(x) \cdot s - P_{\tilde{\tau}} W(s) \leq \mathcal{H}_{\lambda_{d,h}}(x, s_x^*)$ for all $s \in \mathcal{N}_{\tilde{\tau}} \setminus \overline{B_{r_0}(0)}$, which implies the same estimate for all $s \in \mathbb{R}^n \setminus \overline{B_{r_0}(0)}$. ∎

4. Error estimates for $(\mathrm{EP}_{d,h})$. We now turn to the formulation of error estimates for solutions for $(\mathrm{EP}_{d,h})$. We prove that the Lagrange multiplier $\lambda_{d,h}$ converges to a macroscopic quantity, the stress, that appears naturally in (P) and also in the convexified problem (P**). To estimate the distance between $\lambda_{d,h}$ and the exact stress we will regard $(\mathrm{EP}_{d,h})$ as a perturbation of a discretization of (P**).

$$(\mathrm{P}^{**}) \quad \text{Seek } u \in \mathcal{A} \text{ such that } I^{**}(u) = \inf_{v \in \mathcal{A}} I^{**}(v).$$

Here, the energy functional I^{**} is defined for $v \in \mathcal{A}$ and the convex envelope W^{**} of W by

$$I^{**}(v) := \int_\Omega W^{**}(\nabla v(x)) dx + \alpha \int_\Omega |u_0 - v|^2 dx - \int_\Omega f v dx - \int_{\Gamma_N} g v ds_x.$$

DEFINITION 4.1. *For a solution $u \in \mathcal{A}$ for* (P**) *we define the* stress $\sigma := DW^{**}(\nabla u) \in L^2(\Omega)^n$.

THEOREM 4.2 (see [7, Theorem 2]). (P**) *admits a solution $u \in \mathcal{A}$ such that*

$$\int_\Omega DW^{**}(\nabla u) \cdot \nabla v dx - 2\alpha \int_\Omega (u_0 - u) v dx - \int_\Omega f v dx - \int_{\Gamma_N} g v ds_x = 0 \tag{4.1}$$

for all $v \in W_D^{1,2}(\Omega)$. *If* DW^{**} *satisfies, for all* $F, G \in \mathbb{R}^n$,

$$|DW^{**}(F) - DW^{**}(G)|^2 \le C\,(DW^{**}(F) - DW^{**}(G)) \cdot (F - G), \tag{4.2}$$

then for two solutions $u, w \in \mathcal{A}$ *for* (P**) *there holds* $DW^{**}(\nabla u) = DW^{**}(\nabla w)$; *i.e.,* σ *is unique. If in addition to* (4.2) $\alpha > 0$ *or* W^{**} *is strictly convex, then* $u = w$.

Remarks. (i) If W is as in (1.1), then DW^{**} satisfies (4.2).

(ii) For a solution $(u, \nu) \in \mathcal{B}$ for (EP) and a solution w for (P**) we have, provided $W, W^{**} \in C^1(\mathbb{R}^n)$, for almost all $x \in \Omega$ [14, 16],

$$\int_{\mathbb{R}^n} DW(s)\,\nu_x(ds) = DW^{**}(\nabla w(x)).$$

(iii) A result in [6] shows $\sigma \in W^{1,2}_{loc}(\Omega)$.

In order to obtain a version of (4.1) in the discrete setting (EP$_{d,h}$) we need to differentiate the nonsmooth convexification of $P_\tau W$. To do this we apply the concept of subdifferentials.

DEFINITION 4.3. *For a convex function* $V : \mathbb{R}^n \to \mathbb{R}$ *and* $\varsigma \in \mathbb{R}^n$ *the* subdifferential *of* V *at* ς *is defined by*

$$\partial V(\varsigma) := \{\xi \in \mathbb{R}^n : V(\varsigma + \zeta) - V(\varsigma) \ge \zeta \cdot \xi \ \forall \zeta \in \mathbb{R}^n\}.$$

Remarks (see [11]). (i) V has a minimum in $\varsigma \in \mathbb{R}^n$ if and only if $0 \in \partial V(\varsigma)$.

(ii) If V is Gâteaux differentiable in $\varsigma \in \mathbb{R}^n$, then $\partial V(\varsigma) = \{\nabla V(\varsigma)\}$.

The following lemma shows that the finite-dimensional minimization problem (EP$_{d,h}$) may be seen as a perturbation of a discretization of (P**).

LEMMA 4.4. *Let* $W_d^{cx} := ((P_\tau W)|_{\overline{\omega}})^{**}$ *denote the convexification of the restriction of* $P_\tau W$ *to* $\overline{\omega}$. *Assume that* $(u_{d,h}, \nu_{d,h}) \in \mathcal{B}_{d,h}$ *and* $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^n$ *satisfy the conditions of Lemma* 3.4. *Then* $(u_{d,h}, \nu_{d,h})$ *minimizes the modified energy functional*

$$\begin{aligned}\overline{I}'(v_h, \mu_{d,h}) := &\int_\Omega \int_{\mathbb{R}^n} W_d^{cx}(s)\,\mu_{d,h,x}(ds)dx \\ &+ \alpha \int_\Omega |u_0 - v_h|^2 dx - \int_\Omega f v_h dx - \int_{\Gamma_N} g v_h ds_x,\end{aligned}$$

among all $(v_h, \mu_{d,h}) \in \mathcal{B}_{d,h}$. *Moreover,* $\lambda_{d,h}(x) \in \partial W_d^{cx}(\nabla u_{d,h}(x))$ *for a.e.* $x \in \Omega$.

Proof. For $s \in \omega$ we have by Carathéodory's theorem [27],

$$W_d^{cx}(s) = ((P_\tau W)|_{\overline{\omega}})^{**}(s) = \inf_{\substack{s_1,\dots,s_{n+1} \in \overline{\omega},\\ \theta_1,\dots,\theta_{n+1} \in [0,1],\\ \sum_{i=1}^{n+1} \theta_i = 1,\, \sum_{i=1}^{n+1} \theta_i s_i = s}} \sum_{i=1}^{n+1} \theta_i P_\tau W(s_i).$$

Since $P_\tau W|_{\overline{\omega}}$ is τ-elementwise affine, it suffices to use the nodal values of $P_\tau W$ in the calculation of W_d^{cx}, i.e.,

$$W_d^{cx}(s) = ((P_\tau W)|_{\overline{\omega}})^{**}(s) = \inf_{\substack{\theta_z \in [0,1],\\ \sum_{z \in \mathcal{N}_\tau} \theta_z = 1,\\ \sum_{z \in \mathcal{N}_\tau} \theta_z z = s}} \sum_{z \in \mathcal{N}_\tau} \theta_z P_\tau W(z). \tag{4.3}$$

Assume that there exists $s \in \operatorname{conv}\{z_1, \dots, z_{n+1}\} = t \in \tau$, $z_1, \dots, z_{n+1} \in \mathcal{N}_\tau$, such that $s = \sum_{i=1}^{n+1} \alpha_i z_i$ but $W_d^{cx}(s) \ne \sum_{i=1}^{n+1} \alpha_i W_d^{cx}(z_i)$ with $\alpha_i \in [0,1]$, $\sum_{i=1}^{n+1} \alpha_i = 1$.

If $W_d^{cx}(s) > \sum_{i=1}^{n+1} \alpha_i W_d^{cx}(z_i)$, then $W_d^{cx}(s)$ was not convex. In case that $W_d^{cx}(s) < \sum_{i=1}^{n+1} \alpha_i W_d^{cx}(z_i)$, then W_d^{cx} was not the largest convex function satisfying $W_d^{cx} \le P_\tau W|_{\overline{\omega}}$. Therefore, $W_d^{cx}(s) = \sum_{i=1}^{n+1} \alpha_i W_d^{cx}(z_i)$ so that W_d^{cx} is τ-elementwise affine and $P_\tau W_d^{cx}|_{\overline{\omega}} = W_d^{cx}$. To prove that $(u_{d,h}, \nu_{d,h})$ minimizes the functional $\overline{I}'$ it suffices to verify the optimality conditions from Lemma 3.4 with $P_\tau W$ replaced by $P_\tau W_d^{cx}$. For this it is sufficient to show that, for almost all $x \in \Omega$, there holds

$$\max_{s\in\omega}(\lambda_{d,h}(x)\cdot s - P_\tau W(s)) = \max_{s\in\omega}(\lambda_{d,h}(x)\cdot s - W_d^{cx}(s)) \tag{4.4}$$

and

$$\int_{\mathbb{R}^n} (\lambda_{d,h}(x)\cdot s - W_d^{cx}(s))\,\nu_{d,h,x}(ds) = \int_{\mathbb{R}^n} (\lambda_{d,h}(x)\cdot s - P_\tau W(s))\,\nu_{d,h,x}(ds). \tag{4.5}$$

Since $W_d^{cx} \le P_\tau W(s)|_{\overline{\omega}}$, we have to show only that

$$\max_{s\in\omega}(\lambda_{d,h}(x)\cdot s - P_\tau W(s)) \ge \max_{s\in\omega}(\lambda_{d,h}(x)\cdot s - W_d^{cx}(s))$$

and

$$\int_{\mathbb{R}^n} W_d^{cx}(s)\,\nu_{d,h,x}(ds) \ge \int_{\mathbb{R}^n} P_\tau(s)\,\nu_{d,h,x}(ds).$$

Let $\overline{s} \in \overline{\omega}$ be maximizing in the right-hand side of (4.4), i.e.,

$$\lambda_{d,h}(x)\cdot\overline{s} - W_d^{cx}(\overline{s}) = \max_{s\in\omega}(\lambda_{d,h}(x)\cdot s - W_d^{cx}(s)).$$

By definition of W_d^{cx} there exist $\theta_1,\dots,\theta_{n+1} \in [0,1]$, $\sum_{i=1}^{n+1}\theta_i = 1$, and $z_1,\dots,z_{n+1} \in \mathcal{N}_\tau$ such that $\sum_{i=1}^{n+1}\theta_i z_i = \overline{s}$ and $W_d^{cx}(\overline{s}) = \sum_{i=1}^{n+1}\theta_i P_\tau W(z_i)$. By linearity of $s \mapsto \lambda_{d,h}(x)\cdot s$ we have

$$\begin{aligned}
\lambda_{d,h}(x)\cdot\overline{s} - W_d^{cx}(\overline{s}) &= \sum_{i=1}^{n+1}\theta_i(\lambda_{d,h}(x)\cdot z_i - P_\tau W(z_i)) \\
&\le \sum_{i=1}^{n+1}\theta_i \max_{s\in\omega}(\lambda_{d,h}(x)\cdot s - P_\tau W(s)) \\
&= \max_{s\in\omega}(\lambda_{d,h}(x)\cdot s - P_\tau W(s)),
\end{aligned}$$

which proves (4.4). If $\int_{\mathbb{R}^n} W_d^{cx}(s)\,\nu_{d,h,x}(ds) < \int_{\mathbb{R}^n} P_\tau W(s)\,\nu_{d,h,x}(ds)$, the explicit representation of W_d^{cx} contradicts the fact that $(u_{d,h},\nu_{d,h})$ is minimal for $\overline{I}$. We have thus shown (4.5), which yields the optimality conditions. The maximum principle of Lemma 3.3, the convexity of the mapping $s \mapsto W_d^{cx}(s) - \lambda_{d,h}(x)\cdot s$ together with Jensen's inequality, and the identity $\nabla u_{d,h}(x) = \int_{\mathbb{R}^n} s d\nu_{d,h,x}(s)$ yield, for almost all $x \in \Omega$,

$$\begin{aligned}
\max_{s\in\omega}(\lambda_{d,h}(x)\cdot s - W_d^{cx}(s)) &= \int_{\mathbb{R}^n} (\lambda_{d,h}(x)\cdot s - W_d^{cx}(s))\,\nu_{d,h,x}(ds) \\
&\le \lambda_{d,h}(x)\cdot\nabla u_{d,h}(x) - W_d^{cx}(\nabla u_{d,h}(x)).
\end{aligned}$$

Therefore, for almost all $x \in \Omega$, we have $0 \in -\lambda_{d,h}(x) + \partial W_d^{cx}(\nabla u_{d,h}(x))$. ∎

Another definition is needed for the a priori and a posteriori error estimates. It concerns the approximation of DW^{**} by the multivalued mapping ∂W_d^{cx}.

DEFINITION 4.5. *For $A \subseteq \mathbb{R}^n$ and a multivalued mapping $S : A \to 2^{\mathbb{R}^n}$, where $2^{\mathbb{R}^n}$ denotes the power set of $\mathbb{R}^n$, let*

$$\|S\|_{L^\infty(A;2^{\mathbb{R}^n})} := \sup_{t\in A} \sup_{s\in S(t)} |s|.$$

4.1. A priori error estimates. The following theorem shows that the multiplier $\lambda_{d,h}$ for a solution $(u_{d,h}, \nu_{d,h}) \in \mathcal{B}_{d,h}$ for $(\mathrm{EP}_{d,h})$ approximates the unique quantity $\sigma = DW^{**}(\nabla u)$ for a solution $u \in \mathcal{A}$ for (P^{**}).

THEOREM 4.6. *Assume that DW^{**} satisfies (4.2) and $u \in \mathcal{A}$ solves (P^{**}). Assume that $(u_{d,h}, \nu_{d,h}) \in \mathcal{B}_{d,h}$ and $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^n$ satisfy the conditions of Lemma 3.3. There holds*

$$\begin{aligned}\|\sigma - \lambda_{d,h}\| + \alpha\|u - u_{d,h}\| \le C \inf_{(v_h,\mu_{d,h})\in\mathcal{B}_{d,h}} \big(\|\nabla(u - v_h)\| + \alpha\|u - v_h\|\big)\\ + C\|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}\\ + |\Omega|\sqrt{C'}\|\partial W_d^{cx} - DW^{**}\|^{1/2}_{L^\infty(\omega;2^{\mathbb{R}^n})}.\end{aligned}$$

Proof. The triangle inequality and estimate (4.2) show

$$\begin{aligned}\frac{1}{2}\|\sigma - \lambda_{d,h}\|^2 &\le \|\sigma - DW^{**}(\nabla u_{d,h})\|^2 + \|DW^{**}(\nabla u_{d,h}) - \lambda_{d,h}\|^2\\ &\le C\int_\Omega (DW^{**}(\nabla u) - DW^{**}(\nabla u_{d,h}))\cdot\nabla(u - u_{d,h})dx\\ &\quad + \|DW^{**}(\nabla u_{d,h}) - \lambda_{d,h}\|^2.\end{aligned}$$

Hölder's inequality yields

$$\begin{aligned}\frac{1}{2}\|\sigma - \lambda_{d,h}\|^2 &\le C\int_\Omega (DW^{**}(\nabla u) - \lambda_{d,h})\cdot\nabla(u - u_{d,h})dx\\ &\quad + C\int_\Omega (\lambda_{d,h} - DW^{**}(\nabla u_{d,h}))\cdot\nabla(u - u_{d,h})dx\\ &\quad + \|\lambda_{d,h} - DW^{**}(\nabla u_{d,h})\|^2\\ &\le C\int_\Omega (DW^{**}(\nabla u) - \lambda_{d,h})\cdot\nabla(u - u_{d,h})dx\\ &\quad + C\|\lambda_{d,h} - DW^{**}(\nabla u_{d,h})\|\|\nabla(u - u_{d,h})\|\\ &\quad + \|\lambda_{d,h} - DW^{**}(\nabla u_{d,h})\|^2.\end{aligned}$$

The Euler–Lagrange equations (4.1) for u and Lemma 3.3 yield, for all $w_h \in \mathcal{S}^1_D(\mathcal{T})$,

$$\int_\Omega (\sigma - \lambda_{d,h})\cdot\nabla w_h dx + 2\alpha\int_\Omega (u - u_{d,h})w_h dx = 0.$$

We thus have

$$\begin{aligned}\int_\Omega (\sigma-\lambda_{d,h})\cdot\nabla(u-u_{d,h})dx+2\alpha\int_\Omega (u-u_{d,h})^2dx\\ =\int_\Omega (\sigma-\lambda_{d,h})\cdot\nabla(u-u_{d,h}-w_h)dx+2\alpha\int_\Omega (u-u_{d,h})(u-u_{d,h}-w_h)dx\\ \le \|\sigma-\lambda_{d,h}\|\|\nabla(u-u_{d,h}-w_h)\|+2\alpha\|u-u_{d,h}\|\|u-u_{d,h}-w_h\|.\end{aligned}$$

The combination of the last two estimates shows, after absorption of $\|\sigma-\lambda_{d,h}\|$ and $\|u-u_{d,h}\|$,

$$\begin{aligned}\|\sigma-\lambda_{d,h}\|^2+\alpha\|u-u_{d,h}\|^2\le C\big(&\|\nabla(u-u_{d,h}-w_h)\|^2+\alpha\|u-u_{d,h}-w_h\|^2\\ &+\|\lambda_{d,h}-DW^{**}(\nabla u_{d,h})\|\|\nabla(u-u_{d,h})\|\\ &+\|\lambda_{d,h}-DW^{**}(\nabla u_{d,h})\|^2\big).\end{aligned}$$

Lemma 4.4 ensures $\lambda_{d,h}(x)\in\partial W_d^{cx}(\nabla u_{d,h}(x))$, and, by construction of $\mathcal{B}_{d,h}$ we have $\nabla u_{d,h}(x)\in\omega$ for almost all $x\in\Omega$. This implies

$$\begin{aligned}\|\lambda_{d,h}-DW^{**}(\nabla u_{d,h})\|^2&\le\int_\Omega \sup_{s\in\partial W_d^{cx}(\nabla u_{d,h}(x))-DW^{**}(\nabla u_{d,h})}|s|^2dx\\ &\le|\Omega|\sup_{t\in\omega}\sup_{s\in\partial W_d^{cx}(t)-DW^{**}(t)}|s|^2\\ &=|\Omega|\|\partial W_d^{cx}-DW^{**}\|^2_{L^\infty(\omega;2^{\mathbb{R}^n})}.\end{aligned}$$

Letting $w_h=v_h-u_{d,h}$ for arbitrary $(v_h,\mu_{d,h})\in\mathcal{B}_{d,h}$ and estimating $\|\nabla(u-u_{d,h})\|\le C$ (which follows from growth conditions (2.1)) we verify the assertion of the theorem. □

For a given energy density W and an appropriate triangulation τ of ω the term $\|\partial W_d^{cx}-DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}$ can be estimated by the mesh-size of the discretization τ of ω. We refer the reader to Theorem 5.1 below for an estimate for a three-well energy density.

Remarks. (i) Theorem 4.6, Theorem 5.1 below, and density of finite element spaces in $\mathcal{A}$ prove $\lambda_{d,h}\to\sigma$ in $L^2(\Omega)$ for $(d,h_{\mathcal{T}})\to 0$, and, if $\alpha>0$, we also have $u_{d,h}\to u$ in $L^2(\Omega)$. If $u\in C(\overline{\Omega})$ we may choose v_h in Theorem 4.6 as the nodal interpolant of u, and then we can estimate the error in powers of the mesh-size depending on smoothness properties of u. Since, in general, u has no higher regularity properties, computable error bounds are needed.

(ii) Owing to the nonuniqueness of u and degeneracy of (EP) we cannot expect strong convergence $u_{d,h}\to u$ in $W^{1,2}$.

4.2. A posteriori error estimates. In this section two a posteriori error estimates, which are computable bounds for the error $\|\sigma-\lambda_{d,h}\|$, are given. The first error estimate is similar to classical residual based a posteriori error estimates for elliptic partial differential equations [29] and employs jumps of normal components of $\lambda_{d,h}$ across edges. Recall from the definition of $(\mathrm{EP}_{d,h})$ that ω is a fixed convex subset of $\mathbb{R}^n$.

DEFINITION 4.7. *For $E\in\mathcal{E}_\Omega$ and $T_1,T_2\in\mathcal{T}$ with $E=T_1\cap T_2$ let n_E be the unit vector normal to E, pointing from T_1 into T_2. For $\lambda_{d,h}\in\mathcal{L}^0(\mathcal{T})^n$ define*

$$[\lambda_{d,h}\cdot n_E] := \begin{cases} (\lambda_{d,h}|_{T_2} - \lambda_{d,h}|_{T_1})\cdot n_E & \text{for } E\in\mathcal{E}_\Omega,\ T_1,T_2\in\mathcal{T},\ E=T_1\cap T_2,\\ g-\lambda_{d,h}|_T\cdot n_{\Gamma_N}|_E & \text{for } E\in\mathcal{E}_N,\ T\in\mathcal{T},\ E\subseteq\partial T.\end{cases}$$

THEOREM 4.8. *Assume that DW^{**} satisfies* (4.2) *and $u\in\mathcal{A}$ solves* (P^{**}). *Let $(u_{d,h},\nu_{d,h})\in\mathcal{B}_{d,h}$ and $\lambda_{d,h}\in\mathcal{L}^0(\mathcal{T})^n$ satisfy the conditions of Lemma* 3.3. *Then*

$$\begin{aligned}&\|\sigma-\lambda_{d,h}\|^2+\alpha\|u-u_{d,h}\|^2\\ &\quad\le C\Bigg\{\left(\sum_{T\in\mathcal{T}} h_T^2\|(f+\operatorname{div}\lambda_{d,h}+2\alpha(u_0-u_{d,h}))\|^2_{L^2(T)}\right)^{1/2}\\ &\qquad+\left(\sum_{E\in\mathcal{E}_\Omega\cup\mathcal{E}_N} h_E\|[\lambda_{d,h}\cdot n_E]\|^2_{L^2(E)}\right)^{1/2}+\|\partial W_d^{cx}-DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}\\ &\qquad+\left\|h_{\mathcal{E}}^{3/2}\partial^2_{\mathcal{E}}u_D/\partial s^2\right\|_{L^2(\Gamma_D)}\Bigg\}+|\Omega|\|\partial W_d^{cx}-DW^{**}\|^2_{L^\infty(\omega;2^{\mathbb{R}^n})}.\end{aligned}$$

Proof. Recall from the proof of Theorem 4.6 that, for $w\in W^{1,2}(\Omega)$ satisfying $w|_{\Gamma_D}=u_D-u_{D,h}$ and $v_h\in\mathcal{S}^1_D(\mathcal{T})$, there holds

$$\begin{aligned}C\|\sigma-\lambda_{d,h}\|^2+2\alpha\|u-u_{d,h}\|^2 \le{}& \int_\Omega (DW^{**}(\nabla u)-\lambda_{d,h})\cdot\nabla(u-u_{d,h}-w-v_h)dx\\ &+2\alpha\int_\Omega (u-u_{d,h})(u-u_{d,h}-w-v_h)dx\\ &+|\Omega|\|\partial W_d^{cx}-DW^{**}\|^2_{L^\infty(\omega;2^{\mathbb{R}^n})}\\ &+C|\Omega|\|\partial W_d^{cx}-DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}\\ &+\|\sigma-\lambda_{d,h}\|\|\nabla w\|+2\alpha\|u-u_{d,h}\|\|w\|.\end{aligned}$$

We employ the weak approximation operator $\mathcal{J}: W^{1,2}_D(\Omega)\to\mathcal{S}^1_D(\mathcal{T})$ of [4, 5] and set $v_h:=\mathcal{J}v$. We then have (cf. [5, Theorem 2.1])

$$\|\nabla v_h\|+\|h_{\mathcal{T}}^{-1}(v-v_h)\|+\|h_{\mathcal{E}}^{-1/2}(v-v_h)\|_{L^2(\cup\mathcal{E})}\le C\|\nabla v\| \tag{4.6}$$

The Euler–Lagrange equations (4.1) for u, an elementwise integration by parts, and (4.6) show for $v:=u-u_{d,h}-w\in W^{1,2}_D(\Omega)$

$$\begin{aligned}&\int_\Omega (DW^{**}(\nabla u)-\lambda_{d,h})\cdot\nabla(v-\mathcal{J}v)dx+2\alpha\int_\Omega (u-u_{d,h})(v-\mathcal{J}v)dx\\ &\quad=\sum_{T\in\mathcal{T}}\int_T (f+\operatorname{div}\lambda_{d,h})(v-\mathcal{J}v)dx+2\alpha\int_\Omega (u_0-u_{d,h})(v-\mathcal{J}v)dx\\ &\qquad+\sum_{E\in\mathcal{E}_\Omega\cup\mathcal{E}_N}\int_E[\lambda_{d,h}\cdot n_E](v-\mathcal{J}v)ds_x\\ &\quad\le C\Bigg(\left(\sum_{T\in\mathcal{T}} h_T^2\|(f+\operatorname{div}\lambda_{d,h}+2\alpha(u_0-u_{d,h}))\|^2_{L^2(T)}\right)^{1/2}\\ &\qquad+\left(\sum_{E\in\mathcal{E}_\Omega\cup\mathcal{E}_N} h_E\|[\lambda_{d,h}\cdot n_E]\|^2_{L^2(E)}\right)^{1/2}\Bigg)\|\nabla v\|.\end{aligned}$$

The combination of the last two estimates, together with the estimates $\|\nabla v\| \le \|\nabla(u-u_{d,h})\| + \|\nabla w\| \le C$, $\min_{w|_{\Gamma_D}=u_D-u_{D,h}} \|w\|_{W^{1,2}(\Omega)} \le C\|h_{\mathcal{E}}^{3/2}\partial_{\mathcal{E}}^2 u_D/\partial s^2\|_{L^2(\Gamma_D)}^2$ (cf. [3, Lemma 3.1]), shows the assertion after absorption of $\|\sigma-\lambda_{d,h}\|$ and $\|u-u_{d,h}\|$. ∎

Remarks. (i) The term $\|h_{\mathcal{E}}^{3/2}\partial_{\mathcal{E}}^2 u_D/\partial s^2\|_{L^2(\Gamma_D)}$ is of higher order.

(ii) The terms $\|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}^2$ and $\|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}$ are of higher order, provided $d \ll h_{\mathcal{T}}$ (cf. Theorem 5.1). It will be shown later in section 6 that the assumption $d \ll h_{\mathcal{T}}$ does not lead to inefficiency of our numerical schemes.

(iii) The a priori error estimate of Theorem 4.6 and the a posteriori error estimate of Theorem 4.8 yield a gap between reliability and efficiency of the error estimates with respect to the discretization parameter h. While the a priori estimate gives optimal convergence results (for smooth solutions) we face a loss of a factor $h_{\mathcal{T}}^{1/2}$ in the a posteriori estimate due to degeneracy of the problem.

Our second error estimate is related to Zienkiewicz–Zhu error estimators (see, e.g., [5]) for elliptic partial differential equations.

THEOREM 4.9. *Assume that DW^{**} satisfies* (4.2) *and $u \in \mathcal{A}$ solves* (P**). *Let $(u_{d,h},\nu_{d,h}) \in \mathcal{B}_{d,h}$ and $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^n$ satisfy the conditions of Lemma* 3.3. *If $\alpha = 0$ and $f \in W^{1,2}(\Omega)$, then*

$$\begin{aligned}\|\sigma-\lambda_{d,h}\|^2 \le C\Big\{ &\min_{\tau_h\in\mathcal{S}_N^1(\mathcal{T},g)} \|\lambda_{d,h}-\tau_h\| + \|h_{\mathcal{T}}^2\nabla f\| + \|h_{\mathcal{E}}^{3/2}\partial_{\mathcal{E}}^2 u_D/\partial s^2\|_{L^2(\Gamma_D)} \\ &+ \big\|h_{\mathcal{E}}^{3/2}\partial_{\mathcal{E}} g/\partial s\big\|_{L^2(\Gamma_N)} + \|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}\Big\} \\ &+ |\Omega|\|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}^2.\end{aligned}$$

Proof. As in the proof of Theorem 4.6 we have, for $w \in W^{1,2}(\Omega)$ with $w|_{\Gamma_D} = u_D - u_{D,h}$ and $v_h \in \mathcal{S}_D^1(\mathcal{T})$,

$$\begin{aligned}C\|\sigma-\lambda_{d,h}\|^2 \le &\int_\Omega (DW^{**}(\nabla u)-\lambda_{d,h})\cdot\nabla(u-u_{d,h}-w-v_h)dx \\ &+ |\Omega|\|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}^2 \\ &+ C|\Omega|\|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})} + \|\sigma-\lambda_{d,h}\|\|\nabla w\|.\end{aligned}$$

Letting $\tau_h \in \mathcal{S}_N^1(\mathcal{T},g)$ and writing $v := u-u_{d,h}-w \in W_D^{1,2}(\Omega)$ and $v_h := \mathcal{J}v \in \mathcal{S}_D^1(\mathcal{T})$ we verify, using $\operatorname{div}\lambda_{d,h}|_T = 0$, the Euler–Lagrange equation (4.1), an integration by parts, and Hölder's inequality,

$$\begin{aligned}&\int_\Omega (DW^{**}(\nabla u)-\lambda_{d,h})\cdot\nabla(v-\mathcal{J}v)dx \\ &\quad\le \int_\Omega f(v-\mathcal{J}v)dx + \sum_{T\in\mathcal{T}}\int_T \operatorname{div}(\tau_h-\lambda_{d,h})(v-\mathcal{J}v)dx \\ &\qquad + \int_{\Gamma_N}(g-\tau_h\cdot n_{\Gamma_N})(v-\mathcal{J}v)ds_x + \|\tau_h-\lambda_{d,h}\|\|\nabla(v-\mathcal{J}v)\|.\end{aligned}$$

The estimate (cf. [5, Theorem 2.1]) $\int_\Omega f(v-\mathcal{J}v)dx \le C\|\nabla v\|\,\|h_{\mathcal{T}}^2\nabla f\|$ and (4.6) yield

$$\begin{aligned}\int_\Omega &(DW^{**}(\nabla u)-\lambda_{d,h})\cdot\nabla(v-\mathcal{J}v)dx\\ &\le C\Bigg\{\|h_{\mathcal{T}}^2\nabla f\|+\bigg(\sum_{T\in\mathcal{T}}h_T^2\|\operatorname{div}(\tau_h-\lambda_{d,h})\|_{L^2(T)}^2\bigg)^{1/2}\\ &\qquad+\big\|h_{\mathcal{E}}^{3/2}\partial_{\mathcal{E}}g/\partial s\big\|_{L^2(\Gamma_N)}+\|\tau_h-\lambda_{d,h}\|\Bigg\}\|\nabla v\|.\end{aligned}$$

Choosing w as in [3] and employing elementary results about nodal interpolation on Γ_N we infer

$$\|w\|_{W^{1,2}(\Omega)}+\|g-\tau_h\cdot n_{\Gamma_N}\|_{L^2(\Gamma_N)}\le C\Big(\big\|h_{\mathcal{E}}^{3/2}\partial_{\mathcal{E}}^2u_D/\partial s^2\big\|_{L^2(\Gamma_D)}+\big\|h_{\mathcal{E}}^{3/2}\partial_{\mathcal{E}}g/\partial s\big\|_{L^2(\Gamma_N)}\Big),$$

and using an elementwise inverse estimate of the form

$$h_T\|\operatorname{div}(\tau_h-\lambda_{d,h})\|_{L^2(T)}\le C\|\tau_h-\lambda_{d,h}\|_{L^2(T)}\quad\forall T\in\mathcal{T}$$

we verify the assertion as in the proof of the preceding theorem. ∎

Remarks. (i) Terms including derivatives of u_D, g, or f are of higher order. Moreover, remarks (ii) and (iii) below Theorem 4.8 are valid here as well.

(ii) Theorem 4.9 shows, up to higher order terms, reliability of the error estimate $\|\lambda_{d,h}-\lambda_{d,h}^*\|$ for any choice of a smooth approximation $\lambda_{d,h}^*\in\mathcal{S}_N^1(\mathcal{T},g)$ to $\lambda_{d,h}$.

(iii) A triangle inequality proves an inverse, efficiency estimate of Theorem 4.9 which holds up to higher order terms, provided σ is smooth but with different exponents,

$$\min_{\tau_h\in\mathcal{S}_N^1(\mathcal{T},g)}\|\lambda_{d,h}-\tau_h\|\le\|\sigma-\lambda_{d,h}\|+\min_{\tau_h\in\mathcal{S}_N^1(\mathcal{T},g)}\|\sigma-\tau_h\|.$$

This efficiency estimate can be made rigorous but then without explicit constants.

5. Convergence of other quantities. In this section we present an estimate for $DW^{**}-\partial W_d^{cx}$ and results concerning the convergence behavior of other quantities such as Young measure support and microstructure region in a three-well problem. Ideas behind the proofs are adapted from [7, 14].

5.1. Approximation of DW^{**}. We first state an approximation result for W^{**}.

THEOREM 5.1. *For $W:\mathbb{R}^2\to\mathbb{R}$, $s\mapsto\min_{j=0,1,2}|s-s_j|^2$ with $s_0=(0,0)$, $s_1=(1,0)$, and $s_2=(0,1)$ and $\omega=(-m,m)^2$, $m\ge1$, there exists a triangulation τ of ω with maximal mesh-size $d=1/k$, k a positive integer, of ω such that*

$$\|\partial W_d^{cx}-DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^n})}\le Cd\,\|D^2W^{**}\|_{L^\infty(\omega)}.$$

Moreover, the mapping DW^{**} satisfies (4.2).

Proof. A careful analysis shows that $W^{**}\in C^1(\mathbb{R}^n)$ satisfies (4.2) and is for $F=(f_1,f_2)\in\mathbb{R}^2$ given by

$$W^{**}(F) = \begin{cases} 0, & F \in X_I, \\ W(F), & F \in X_{II} \cup X_{III} \cup X_{IV}, \\ f_2^2, & F \in X_V, \\ f_1^2, & F \in X_{VI}, \\ \frac{1}{2}(f_1+f_2-1)^2, & F \in X_{VII}. \end{cases}$$

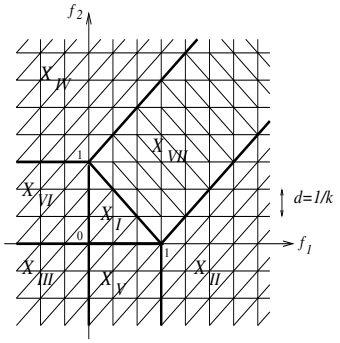

FIG. 1. *W^{**} and the triangulation of $\omega \subseteq \mathbb{R}^2$ to resolve the discontinuities of D^2W^{**}.*

For $d = 1/k$, k a positive integer, choose τ as in Figure 1. Since W_d^{cx} is affine on each $t \in \tau$ we have $\partial W_d^{cx}(s) = \operatorname{conv}\{DW_d^{cx}|_t : t \in \tau, s \in t\}$. Since DW^{**} is continuous and τ-elementwise differentiable it therefore suffices to show for each $t \in \tau$

$$\|DW_d^{cx} - DW^{**}\|_{L^\infty(t)} \le d\|D^2W^{**}\|_{L^\infty(t)}.$$

Letting $W_d^{**} = P_\tau W^{**}$ denote the nodal interpolant of W^{**} we have by standard interpolation results

$$\begin{aligned} \|DW_d^{cx} - DW^{**}\|_{L^\infty(t)} &\le \|DW_d^{cx} - DW_d^{**}\|_{L^\infty(t)} + \|DW_d^{**} - DW^{**}\|_{L^\infty(t)} \\ &\le \|DW_d^{cx} - DW_d^{**}\|_{L^\infty(t)} + Cd\,\|D^2W^{**}\|_{L^\infty(t)}. \end{aligned} \tag{5.1}$$

For each $k \in \tau$ we define an affine function $a_k : \mathbb{R}^2 \to \mathbb{R}$ such that, for all $x \in \mathbb{R}^2$, there holds

$$W_d^{cx}(x) = \sup_{k \in \tau} a_k(x) \tag{5.2}$$

and $W_d^{cx}|_k = a_k$. If $k \subseteq X_I \cup X_{II} \cup X_{III} \cup X_{IV} \cup X_V \cup X_{VI}$ we define a_k such that $a_k(z) = W^{**}(z)$ for all $z \in k \cap \mathcal{N}_\tau$. If $k \subseteq X_{VII}$ and there exists $y = (y_1, y_2) \in k$ with $y_1 + y_2 \in 1 + 2d[j, j+1)$, $j \ge 0$, then we define

$$\begin{aligned} a_k(x) = W(1+jd, jd) &+ (x_1 - 1 - jd, x_2 - jd) \cdot (1,1) \\ &\times \frac{W(1+(j+1)d, (j+1)d) - W(1+jd, jd)}{2d}. \end{aligned}$$

Then $\sup_{k\in\tau} a_k$ is convex, as it is the supreme of countably many affine functions. A proof for (5.2) then follows as above for the convexification of W. Note that W_d^{cx} is mesh dependent. We now prove the remaining estimates. For $k \subset X_I \cup X_{II} \cup \cdots \cup X_{VI}$ we have $DW_d^{cx}|_k = DW_d^{**}|_k$ so that the asserted estimate follows from (5.1). For $k \subseteq X_{VII}$ such that $k \subseteq A_j = \{(x_1, x_2) \in \mathbb{R}^2 : x_1 - x_2 \in [-1, 1], x_1 + x_2 \in 1 + 2d[j, j+1)\}$, $j \ge 0$, there holds $W_d^{cx} = W^{**}$ on ∂A_j, and W_d^{cx} is affine on A_j. Therefore, W_d^{cx} interpolates W^{**} along each line segment in A_j parallel to $(1, 1)$. The estimate

$$\begin{aligned} \|DW_d^{cx} - DW_d^{**}\|_{L^\infty(t)} &\le \|DW_d^{cx} - DW^{**}\|_{L^\infty(t)} + \|DW^{**} - DW_d^{**}\|_{L^\infty(t)} \\ &\le Cd\,\|D^2W^{**}\|_{L^\infty(t)} \end{aligned}$$

follows from the fact that the line segments have a length d. ∎

5.2. Convergence of Young measure support. We employ the following definition in order to prove convergence for the support of the discrete Young measure solution to the support of an exact solution.

DEFINITION 5.2. *For $A, B \subseteq \mathbb{R}^n$ let* $\operatorname{dist}(A,B) := \inf_{(a,b)\in A\times B} |a-b|$. *We write* $\operatorname{Lim\,sup}_{\rho\to\rho_0} A_\rho \subseteq A$ *(i.e., A is the upper Kuratowski limit of A_ρ, cf.* [19, 20]*) if*

$$\forall \varepsilon > 0\, \exists \delta > 0\ \forall \rho, \quad |\rho - \rho_0| \le \delta\ \forall x \in A_\rho, \quad \operatorname{dist}(x, A) \le \varepsilon.$$

THEOREM 5.3. *Let W be as in Theorem* 5.1*, $u \in \mathcal{A}$ a solution for* (P**)*, and $(u_j)_{j>0}$ an infimizing sequence for* (P)*. Let $(u_{d,h}, \nu_{d,h}) \in \mathcal{B}_{d,h}$ and $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^n$ satisfy the conditions of Lemma* 3.3*. Assume that a subsequence of $(u_j)_{j>0}$ converges weakly to u and generates the Young measure ν. Then there exists a mapping $S : \mathbb{R}^2 \to 2^{\mathbb{R}^2}$ such that*

$$\operatorname{dist}(S(\lambda_{d,h}(x)), \operatorname{supp}\nu_x) \to 0$$

if $x \in \Omega$ and $\lambda_{d,h}(x) \to \sigma(x)$. If for all $T \in \mathbb{R}^2$ there holds

$$\begin{aligned}(5.3)\quad &\operatorname{Lim\,sup}_{d\to 0}\{F \in \mathbb{R}^2 : \exists G,\ S \in \mathbb{R}^2,\ \{S,T\} \subseteq \partial W_d^{cx}(G),\ S \in \partial W_d^{cx}(F)\}\\ &\qquad \subseteq \{F \in \mathbb{R}^2 : T = DW^{**}(F)\},\end{aligned}$$

then we also have, if $x \in \Omega$ and $\lambda_{d,h}(x) \to \sigma(x)$,

$$\operatorname{Lim\,sup}_{\lambda_{d,h}(x)\to\sigma(x)}\ \operatorname{conv}\operatorname{supp}\nu_{d,h,x} \subseteq \operatorname{conv} S(\sigma(x)).$$

Remark. If W_d^{cx} is continuously differentiable, then

$$\begin{aligned}&\{F \in \mathbb{R}^2 : \exists G,\ S \in \mathbb{R}^2,\ \{S,T\} \subseteq \partial W_d^{cx}(G),\ S \in \partial W_d^{cx}(F)\}\\ &\quad = \{F \in \mathbb{R}^2 : T = DW_d^{cx}(F)\}.\end{aligned}$$

Proof. Define $\mu : \mathbb{R}^2 \to PM(\mathbb{R}^2)$ by

$$F \mapsto \begin{cases} (1-f_1-f_2)\delta_{(0,0)} + f_1\delta_{(1,0)} + f_2\delta_{(0,1)} & \text{for } F \in X_I,\\ \delta_F & \text{for } F \in X_{II} \cup X_{III} \cup X_{IV},\\ (1-f_1)\delta_{(0,f_2)} + f_1\delta_{(1,f_2)} & \text{for } F \in X_V,\\ (1-f_2)\delta_{(f_1,0)} + f_2\delta_{(f_1,1)} & \text{for } F \in X_{VI},\\ \dfrac{1}{2}(f_1-f_2+1)\delta_{\frac{1}{2}(f_1+f_2+1,f_1+f_2-1)} & \\ \quad +\dfrac{1}{2}(1-f_1+f_2)\delta_{\frac{1}{2}(f_1+f_2-1,f_1+f_2+1)} & \text{for } F \in X_{VII}. \end{cases}$$

Since W^{**} is affine on $\operatorname{conv}\operatorname{supp}\nu_x$, $\int_{\mathbb{R}^2} s\,d\nu_x = \nabla u(x)$, and $\operatorname{supp}\nu_x \subseteq \{E \in \mathbb{R}^2 : W(E) = W^{**}(E)\}$ for almost all $x \in \Omega$ [7, 14], one can show $\nu_x = \mu(\nabla u(x))$ for almost all $x \in \Omega$. For $S : \mathbb{R}^2 \to 2^{\mathbb{R}^2}$ defined by

$$(t_1,t_2) \mapsto \begin{cases} \{(0,0),(1,0),(0,1)\} & \text{for } (t_1,t_2) = (0,0),\\ \{(t_1+2,t_2)/2\} & \text{for } t_1 > 0 \text{ and } t_2 < t_1,\\ \{(t_1,t_2)/2\} & \text{for } t_1 < 0 \text{ and } t_2 < 0,\\ \{(t_1,t_2+2)/2\} & \text{for } t_2 > 0 \text{ and } t_1 < t_2,\\ \{(0,t_2)/2,(2,t_2)/2\} & \text{for } t_1 = 0,\\ \{(t_1,0)/2,(t_1,2)/2\} & \text{for } t_2 = 0,\\ \{(t_1,t_2+2)/2,(t_1+2,t_2)/2\} & \text{for } t_1 = t_2 \text{ and } t_1 > 0, \end{cases}$$

the explicit representation of W^{**} shows

$$\operatorname{supp}\mu(F) = S(DW^{**}(F))$$

so that $\operatorname{supp}\nu_x = S(\sigma(x))$ for a.e. $x \in \Omega$. Hence

$$\operatorname{conv} S(T) = \{E \in \mathbb{R}^2 : T = DW^{**}(E)\}. \tag{5.4}$$

Moreover, for each $\Sigma \in \mathbb{R}^2$ the mapping $\operatorname{dist}(S(\cdot),\Sigma) : \mathbb{R}^2 \to \mathbb{R}$ is continuous, and therefore

$$\operatorname{dist}(S(\lambda_{d,h}(x)), \operatorname{supp}\nu_x) = \operatorname{dist}(S(\lambda_{d,h}(x)), S(\sigma(x))) \to 0$$

if $x \in \Omega$ and $\lambda_{d,h}(x) \to \sigma(x)$. Because of (5.3), (5.4) and since $\operatorname{Lim\,sup}_{\rho\to\rho_0} B_\rho \subseteq A$ if $\operatorname{Lim\,sup}_{\rho\to\rho_0} A_\rho \subseteq A$ and $B_\rho \subseteq A_\rho$ for all ρ, we have to show only that for $T = \lambda_{d,h}(x)$

$$\operatorname{conv}\operatorname{supp}\nu_{d,h,x} \subseteq \{F \in \mathbb{R}^2 : \exists G,\ S \in \mathbb{R}^2,\ \{S,T\} \subseteq \partial W_d^{cx}(G),\ S \in \partial W_d^{cx}(F)\}$$

in order to prove the second assertion. The set

$$M_1 := \{G \in \mathbb{R}^2 : \exists S \in \partial W_d^{cx}(\nabla u_{d,h}),\ S \in \partial W_d^{cx}(G)\}$$

contains each subset $A \subseteq \mathbb{R}^2$ with

$$W_d^{cx} \quad \text{affine on } A \text{ and } \nabla u_{d,h}(x) \in A.$$

Since W_d^{cx} is affine $\operatorname{conv}\operatorname{supp}\nu_{d,h,x}$ and $\nabla u_{d,h}(x) \in \operatorname{conv}\operatorname{supp}\nu_{d,h,x}$ we conclude that $\operatorname{conv}\operatorname{supp}\nu_{d,h,x} \subseteq M_1$. The inclusion $\lambda_{d,h}(x) \in \partial W_d^{cx}(\nabla u_{d,h}(x))$ and the choice $G = \nabla u_{d,h}(x)$ yield

$$M_1 \subseteq \{F \in \mathbb{R}^2 : \exists G,\ S \in \mathbb{R}^2,\ \{S,T\} \subseteq \partial W_d^{cx}(G),\ S \in \partial W_d^{cx}(F)\},$$

which concludes the proof. □

5.3. Convergence of the microstructure region. The microstructure region is that subset of Ω in which the exact Young measure solution is not a single Dirac measure. In this part of Ω infimizing sequences for (P) develop oscillations.

DEFINITION 5.4. *Let $\overline{M}$ denote the closure of $M := \{F \in \mathbb{R}^n : W(F) \neq W^{**}(F)\}$. For a solution $u \in \mathcal{A}$ for the convexified problem* (P**) *and a solution $(u_{d,h},\nu_{d,h}) \in \mathcal{B}_{d,h}$ for* (EP$_{d,h}$) *the* microstructure region $\Omega_{ms} \subseteq \Omega$ *and the* discrete microstructure region $\Omega_{ms,h} \subseteq \Omega$ *are defined by*

$$\Omega_{ms} := \{x \in \Omega : \nabla u(x) \in \overline{M}\} \qquad \textit{and} \qquad \Omega_{ms,h} := \{x \in \Omega : \nabla u_{d,h}(x) \in \overline{M}\},$$

respectively.

The following theorem shows that Ω_{ms} is uniquely defined and that an appropriate approximation $\tilde{\Omega}_{m,h}$ of $\Omega_{ms,h}$ converges to Ω_{ms}.

THEOREM 5.5. *Let W be as in Theorem* 5.1*, and let u solve* (P**)*. There exists a Lipschitz-continuous mapping $\xi : \mathbb{R}^2 \to \mathbb{R}$ such that, for almost all $x \in \Omega$, we have*

$$x \in \Omega_{ms} \Longleftrightarrow \xi(\sigma(x)) = 0.$$

If $v \in \mathcal{A}$ is another solution for (P**)*, then $\xi(DW^{**}(\nabla u)) = \xi(DW^{**}(\nabla v))$ a.e. in Ω. For a solution $(u_{d,h},\nu_{d,h}) \in \mathcal{B}_{d,h}$ for* (EP$_{d,h}$) *with multiplier $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^2$ let*

$$\tilde{\Omega}_{m,h} := \{x \in \Omega : \xi(\lambda_{d,h}(x)) = 0\}.$$

We then have

$$\|\xi(\sigma) - \xi(\lambda_{d,h})\| \le C\|\sigma - \lambda_{d,h}\| \tag{5.5}$$

and

$$x \in \tilde{\Omega}_{m,h} \quad \Longrightarrow \quad \operatorname{dist}(\nabla u_{d,h}(x), \overline{M}) \le C'\|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^2})}.$$

Conversely, there holds

$$x \in \Omega_{ms,h} \quad \Longrightarrow \quad |\xi(\lambda_{d,h}(x))| \le \|\partial W_d^{cx} - DW^{**}\|_{L^\infty(\omega;2^{\mathbb{R}^2})}.$$

Proof. The explicit representation of W^{**} in the proof of Theorem 5.1 shows, for almost all $x \in \Omega$, with $(s_1, s_2) = \sigma(x)$ and $F = \nabla u(x)$

$$\begin{aligned} x \in \Omega_{ms} &\iff F \in \overline{X}_I \cup \overline{X}_V \cup \overline{X}_{VI} \cup \overline{X}_{VII} \\ &\iff (s_1 = 0 \wedge s_2 \le 0) \vee (s_2 = 0 \wedge s_1 \le 0) \vee (s_1 = s_2 \wedge s_1 \ge 0). \end{aligned} \tag{5.6}$$

The mapping $\xi : \mathbb{R}^2 \to \mathbb{R}_{\ge 0}$ defined by

$$(s_1, s_2) \mapsto \min\{|s_1| - \min\{-s_2, 0\}, |s_2| - \min\{-s_1, 0\}, |s_1 - s_2| - \min\{s_1, 0\}\}$$

is Lipschitz continuous with bounded Lipschitz constant $C > 0$ and satisfies because of (5.6) the equivalence

$$\xi(\sigma(x)) = 0 \iff x \in \Omega_{ms}$$

for almost all $x \in \Omega$. Since the quantity $\sigma := DW^{**}(\nabla u)$ is independent of the choice of a solution (cf. Theorem 4.2) we have uniqueness of Ω_{ms}. The Lipschitz continuity of ξ implies the estimate (5.5). Let $x \in \Omega$ be such that $\xi(\lambda_{d,h}(x)) = 0$. The Lipschitz continuity of ξ and the inclusion $\lambda_{d,h}(x) \in \partial W_d^{cx}(\nabla u_{d,h}(x))$ show

$$\begin{aligned} \xi(DW^{**}(\nabla u_{d,h}(x))) &= |\xi(DW^{**}(\nabla u_{d,h}(x))) - \xi(\lambda_{d,h}(x))| \\ &\le C|DW^{**}(\nabla u_{d,h}(x)) - \lambda_{d,h}(x)| \\ &\le C\|DW^{**} - \partial W_d^{cx}\|_{L^\infty(\omega;2^{\mathbb{R}^2})}. \end{aligned}$$

To prove the asserted estimate for $\operatorname{dist}(\nabla u_{d,h}(x), \overline{M})$ it now suffices to prove

$$\operatorname{dist}(F, \overline{M}) \le c\xi(DW^{**}(F))$$

for a constant $c > 0$ and all $F \in \mathbb{R}^2$. The assertion is obvious if $F \in X_I \cup X_V \cup X_{VI} \cup X_{VII}$. We prove the case $F \in X_{II}$; the remaining cases $F \in X_{III}$, X_{IV} follow analogously. Let $F = (f_1, f_2) \in X_{II}$. Then $f_1 - 1 \ge 0$ and $f_1 - 1 \ge f_2$. A short calculation shows $\operatorname{dist}(F, \overline{M}) = \min\{f_1 - 1, (f_1 - f_2 - 1)/\sqrt{2}\}$. Since $DW^{**}(F) = 2(f_1 - 1, f_2)$ we have $\xi(DW^{**}(F)) = 2\min\{f_1 - 1 - \min\{-f_2, 0\}, |f_2| + f_1 - 1, f_1 - f_2 - 1\}$. If $f_2 \le 0$, then this term can be simplified to $\xi(DW^{**}(F)) = \min\{f_1 - 1, f_1 - f_2 - 1\}$, and the assertion follows. If $f_2 \ge 0$ we have

$$\begin{aligned} \xi(DW^{**}(F)) &= \min\{f_1 - 1 + f_2, f_1 - f_2 - 1\} = f_1 - f_2 - 1 \\ &\ge (f_1 - f_2 - 1)/\sqrt{2} = \min\{f_1 - 1, (f_1 - f_2 - 1)/\sqrt{2}\} \\ &= \operatorname{dist}(F, \overline{M}). \end{aligned}$$

To prove the inverse implication let $x \in \Omega_{ms,h}$, i.e., $\nabla u_{d,h}(x) \in X_I \cup X_V \cup X_{VI} \cup X_{VII}$. Since $\lambda_{d,h}(x) \in \partial W_d^{cx}(\nabla u_{d,h}(x))$ and since $\partial W_d^{cx}(\nabla u_{d,h}) = \operatorname{conv}\{DW_d^{cx}|_t : t \in \tau, \nabla u_{d,h}(x) \in t\}$, there exist $t_1, \dots, t_{n+1} \in \tau$ and $\varrho_i \in [0,1]$, $\sum_{i=1}^{n+1} \varrho_i = 1$, such that $\lambda_{d,h}(x) = \sum_{i=1}^{n+1} \varrho_i DW_d^{cx}|_{t_i}$. The identities

$$\lambda_{d,h}(x) = \sum_{i=1}^{n+1} \varrho_i DW_d^{cx}|_{t_i} = \sum_{i=1}^{n+1} \varrho_i (DW_d^{cx}|_{t_i} - DW^{**}(\nabla u_{d,h})) + DW^{**}(\nabla u_{d,h})$$

and $\xi(DW^{**}(\nabla u_{d,h})) = 0$ combined with the Lipschitz continuity of ξ show

$$\begin{aligned}
&|\xi(\lambda_{d,h}(x))| \\
&\quad = \left| \xi\left(\sum_{i=1}^{n+1} \varrho_i (DW_d^{cx}|_{t_i} - DW^{**}(\nabla u_{d,h})) + DW^{**}(\nabla u_{d,h}) \right) - \xi(DW^{**}(\nabla u_{d,h})) \right| \\
&\quad \le C \left| \sum_{i=1}^{n+1} \varrho_i (DW_d^{cx}|_{t_i} - DW^{**}(\nabla u_{d,h})) \right| \le C \|W^{**} - \partial W_d^{cx}\|_{L^\infty(\omega;2^{\mathbb{R}^2})}. \qquad \square
\end{aligned}$$

6. Combination of a multilevel scheme and adaptive mesh refinement. In this section we propose an iterative, adaptive strategy to efficiently approximate the extended problem (EP).

6.1. Active set strategy due to Carstensen and Roubíček. The identity

$$\max_{s\in\omega} \mathcal{H}_{\lambda_{d,h}}(x,s) = \int_{\mathbb{R}^n} \mathcal{H}_{\lambda_{d,h}}(x,s)\, \nu_{d,h,x}(ds)$$

in Lemma 3.3 for a solution $(u_{d,h}, \nu_{d,h}) \in \mathcal{B}_{d,h}$ for $(\mathrm{EP}_{d,h})$ with multiplier $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^n$ states that for almost each $x \in \Omega$ the probability measure $\nu_{d,h,x}$ is supported in those atoms $z \in \mathcal{N}_\tau$ for which $\mathcal{H}_{\lambda_{d,h}}(x,\cdot)$ attains its maximum. Typically, these are only a few atoms.

If the support of the Young measure $\nu_{d,h}$,

$$\operatorname{Supp}(\nu_{d,h}) := \{(x,z) \in \Omega \times \mathcal{N}_\tau : z \in \operatorname{supp}(\nu_{d,h,x})\},$$

where $\operatorname{supp}(\nu_{d,h,x}) \subseteq \mathbb{R}^n$ is the support of the Radon measure $\nu_{d,h,x}$, was known a priori, we could set $A := \operatorname{Supp}(\nu_{d,h})$ and seek $(u_{d,h}, \nu_{d,h})$ as a solution of the following lower-dimensional problem $(\mathrm{EP}_{d,h,A})$:

$$(\mathrm{EP}_{d,h,A}) \quad \begin{cases} \text{Seek } (u_{d,h}, \nu_{d,h}) \in \mathcal{B}_{d,h} \text{ such that } \operatorname{Supp}(\nu_{d,h}) \subseteq A \\ \text{and } \overline{I}(u_{d,h}, \nu_{d,h}) = \inf\limits_{(v_h,\mu_{d,h})\in\mathcal{B}_{d,h}} \overline{I}(v_h, \mu_{d,h}). \end{cases}$$

Proposition 5.4 in [8] gives a necessary condition on A which ensures that $(\mathrm{EP}_{d,h,A})$ is a correct reduction of $(\mathrm{EP}_{d,h})$. Conversely, Lemma 3.4 states a sufficient criterion for a solution of $(\mathrm{EP}_{d,h,A})$ to solve $(\mathrm{EP}_{d,h})$.

Given an approximation $\tilde{h}$ of $\mathcal{H}_{\lambda_{d,h}}$ we define a set of active atoms, called the *active set*, by

$$A = \Big\{(x,z) \in \Omega \times \mathcal{N}_\tau : \tilde{h}(x,z) \ge \max_{s\in\omega} \tilde{h}(x,s) - \varepsilon(x)\Big\}, \tag{6.1}$$

where $\varepsilon \in \mathcal{L}^0(\mathcal{T})$, $\varepsilon > 0$ a.e. in Ω, is a given tolerance. If ε is large enough, then any solution for $(\mathrm{EP}_{d,h,A})$ with A as in (6.1) is a solution for $(\mathrm{EP}_{d,h})$.

LEMMA 6.1. *Let $(u_{d,h}, \nu_{d,h})$ be a solution for $(\mathrm{EP}_{d,h})$ with corresponding multiplier $\lambda_{d,h}$ and $\mathcal{H}_{\lambda_{d,h}}(x,s) = \lambda_{d,h}(x)\cdot s - P_\tau W(s)$. Moreover, let $\tilde{h} : \Omega \times \mathbb{R}^n \to \mathbb{R}$ and $\varepsilon \in \mathcal{L}^0(\mathcal{T})$, $\varepsilon > 0$ a.e. in Ω, be such that, for each $T \in \mathcal{T}$,*

$$\|\mathcal{H}_{\lambda_{d,h}} - \tilde{h}\|_{L^\infty(T\times S_T)} \le \varepsilon|_T,$$

with $S_T \subseteq \mathbb{R}^n$ such that, for almost all $x \in T$, we have

$$\Big\{s \in \omega : \mathcal{H}_{\lambda_{d,h}}(x,s) = \max_{\tilde{s}\in\overline{\omega}} \mathcal{H}_{\lambda_{d,h}}(x,\tilde{s})\Big\} \cup \Big\{s \in \omega : \tilde{h}(x,s) = \max_{\tilde{s}\in\overline{\omega}} \tilde{h}(x,\tilde{s})\Big\} \subseteq S_T.$$

If A is defined by (6.1)*, then any solution for $(\mathrm{EP}_{d,h,A})$ is a solution for $(\mathrm{EP}_{d,h})$.*

Proof. The proof follows the arguments of [8]. □

The idea to guess the support of a Young measure solution in a multilevel scheme, together with Lemma 6.1, motivates the following algorithm, in which a sequence of refining triangulations, elementwise constant tolerances, and an initial guess $\tilde{h}_0$ for $\mathcal{H}_{\lambda_{d,h}}$, e.g., $\tilde{h}_0 = 0$, are given. Figure 2 includes a flow chart of the algorithm.

Algorithm ($A^{\textit{active set}}$). Let $\tau_1, \tau_2, \dots, \tau_J$ be triangulations of ω, $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_J > 0$ be elementwise constant, and $\tilde{h}_0 \in L^1(\Omega; C(\mathbb{R}^n))$.

(1) Set $\varepsilon := \varepsilon_1$, $\tilde{h} := \tilde{h}_0$, $\tau := \tau_1$, and $j := 1$.

(2) Compute A from (6.1).

(3) Compute a solution $(u_{d,h}, \nu_{d,h}) \in \mathcal{B}_{d,h,A}$ for $(\mathrm{EP}_{d,h,A})$ and the multiplier $\lambda_{d,h} \in \mathcal{L}^0(\mathcal{T})^n$.

(4) If the conditions of Lemma 3.4 are satisfied, then go to (6); otherwise, proceed with (5).

(5) Increase m if necessary. Enlarge ε by $\varepsilon|_T := 2\varepsilon|_T$ if for some $x_T \in T$

$$\max_{z\in\mathcal{N}_\tau} \mathcal{H}_{\lambda_{d,h}}(x_T, z) > \int_{\mathbb{R}^n} \mathcal{H}_{\lambda_{d,h}}(x_T, s)\, \nu_{h,x_T}(ds),$$

and set $\varepsilon|_T := \varepsilon|_T$ otherwise. Go to (2).

(6) If $j < J$ proceed with (7); otherwise, terminate.

(7) Set $j := j + 1$, $\tilde{h}(x,s) := \lambda_{d,h}(x)\cdot s - P_\tau W(s)$, $\varepsilon := \varepsilon_j$, and go to (2).

Remarks. (i) The approximation $\tilde{h}_0$ may initially be chosen as $\tilde{h}_0 = 0$, and then all atoms are activated in (6.1) or $\tilde{h}_0$ is defined through the solution on a coarser triangulation $\mathcal{T}'$.

(ii) Since the tolerance ε is increased successively the optimality conditions of Lemma 6.1 are satisfied after a finite number of iterations.

6.2. Adaptive mesh refinement. Theorems 4.8 and 4.9 allow the introduction of local refinement indicators which may be used for automatic mesh refinement. Let $(u_{d,h}, \nu_{d,h})$ be a solution for $(\mathrm{EP}_{d,h})$ with corresponding multiplier $\lambda_{d,h}$.

Theorem 4.8 motivates the elementwise contributions, for $T \in \mathcal{T}$,

$$\eta_R(T)^2 := h_T^2 \|f + \operatorname{div}\lambda_{d,h} + 2\alpha(u_0 - u_{d,h})\|^2_{L^2(T)} + \sum_{\substack{E\in\mathcal{E}_\Omega\cup\mathcal{E}_N \\ E\subseteq\partial T}} h_E \|[\lambda_{d,h}\cdot n_E]\|^2_{L^2(E)}.$$

In regard to Theorem 4.9 we employ the operator $\bar{\mathcal{A}} : L^2(\Omega)^n \to \mathcal{S}^1_N(\mathcal{T}; g)$ of [5], which is for $\Gamma_N = \emptyset$ and $p \in L^2(\Omega)^n$ given by

$$\bar{\mathcal{A}}p = \sum_{z\in\mathcal{N}} p_z\varphi_z, \quad \text{for } p_z = \int_{\varphi_z>0} p dx \Big/ \int_{\varphi_z>0} 1 dx,$$

to define, for $T \in \mathcal{T}$,

$$\eta_Z(T) := \|\lambda_{d,h} - \bar{\mathcal{A}}\lambda_{d,h}\|_{L^2(T)}.$$

With these definitions we have

$$\|\sigma - \lambda_{d,h}\|^2 \le C\left(\sum_{T\in\mathcal{T}} \eta(T)^2\right)^{1/2} + \text{h.o.t.},$$

where $\eta(T) = \eta_Z(T)$ or $\eta(T) = \eta_R(T)$ and the higher order terms depend on the mesh-size of the triangulation τ which are of higher order, provided $d \ll h_{\mathcal{T}}$, and on the smoothness of given right-hand sides. We set

$$\eta_R := \left(\sum_{T\in\mathcal{T}} \eta_R(T)^2\right)^{1/4} \quad \text{and} \quad \eta_{Z,R} := \left(\sum_{T\in\mathcal{T}} \eta_Z(T)^2\right)^{1/4}.$$

Remark (iii) below Theorem 4.9 states

$$\eta_{Z,E} := \left(\sum_{T\in\mathcal{T}} \eta_Z(T)^2\right)^{1/2} \le \|\sigma - \lambda_{d,h}\| + \text{h.o.t.}$$

The following algorithm generates the triangulations in the numerical examples of the subsequent section. The parameter Θ allows us to use the algorithm for uniform mesh refinement, which corresponds to $\Theta = 0$, and adaptive mesh refinement, where $\Theta = 1/2$. For details on adaptive mesh refinement we refer the reader to [29]. A schematical flow chart for the combination of the active set strategy with the adaptive mesh refinement algorithm is shown in Figure 2.

Algorithm ($A_\Theta^{adaptive}$). (1) Start with a coarse triangulation $\mathcal{T}_1$ of Ω and set $\omega := (-m,m)^n$, $\ell = 1$, and $\tilde{\lambda}_\ell = 0$.

(2) Compute a discrete solution $(u_\ell, \nu_\ell, \lambda_\ell)$ with Algorithm ($A^{active\,set}$) and starting values $\tilde{h}_0(x,s) := \tilde{\lambda}_\ell(x)\cdot s - P_\tau W(s)$, $J = 2$, $d_j = 2^{j-1}/k$, $k = \lfloor 4m\, 2^{-J}\, \mathrm{card}(\mathcal{N}_{\mathcal{T}_\ell})^{3/2n} \rfloor$ ($\lfloor s \rfloor$ is the largest integer $\le s$), $\varepsilon_j := 2^{-\ell-j}\, 10^{-4}$ for $j = 1, \dots, J$ ($\varepsilon_1 := \infty$ if $\ell = 1$ to activate *all* atoms), and a triangulation τ_j of ω with maximal mesh-size d_j.

(3) For each $T \in \mathcal{T}_\ell$ compute refinement indicators $\eta_Z(T)$ and $\eta_R(T)$.

(4) Mark the element T for red-refinement if

$$\eta_R(T) \ge \Theta \max_{T'\in\mathcal{T}_\ell} \eta_R(T').$$

(5) Mark further elements (*red-blue-green-refinement*) to avoid hanging nodes. Terminate if the stopping criterion is satisfied, generate a new triangulation $\mathcal{T}_{\ell+1}$, define $\tilde{\lambda}_{\ell+1} := \lambda_\ell$, increment ℓ, and go to (2) otherwise.

Remarks. (i) We chose k such that $d \propto h^{3/2}$ so that $\|DW^{**} - \partial W_d^{cx}\|_{L^\infty(\Omega;2^{\mathbb{R}^n})}$ is of the same order as the presumed higher order terms involving g and u_D in Theorems 4.8 and 4.9.

(ii) Since $\lambda_\ell \to DW^{**}(\nabla u)$ in $L^2(\Omega)$ for a solution $u \in \mathcal{A}$ for (P**), λ_ℓ is a Cauchy sequence, and therefore λ_ℓ is a good approximation for $\lambda_{\ell+1}$ if ℓ is large enough.

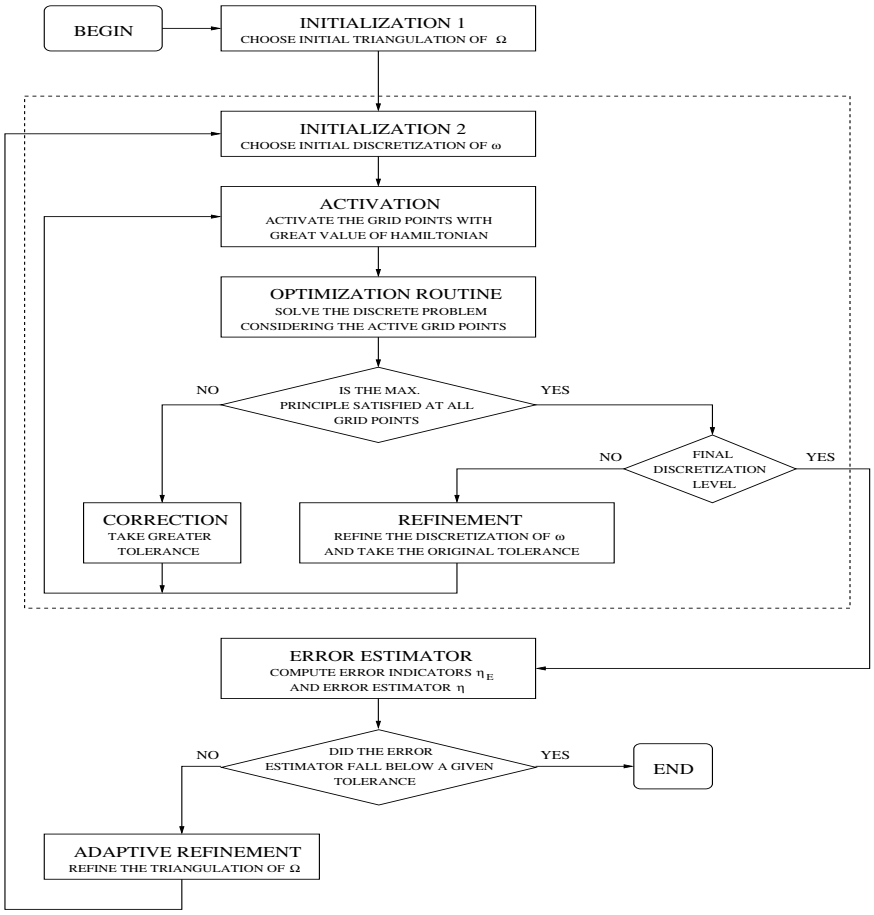

FIG. 2. *Flow chart for the combination of the active set strategy (as in* [8]*, inside the dashed box) with adaptive mesh refinement.*

7. Numerical experiments. In this section we present numerical results for two specifications of (P). The first example has been investigated in [8] and is modified here to obtain quadratic growth conditions. The second example is a two-dimensional problem that reveals limitations of our approach to solve (P) but thereby underlines the necessity of the design of efficient algorithms for the solution for ($\mathrm{EP}_{d,h}$).

The implementation of the algorithms was performed in Matlab as described in [8] for the part concerning the active set strategy. We solved the linear optimization problems with the interior point linear program solver HOPDM [15].

Example 7.1 (one-dimensional two-well problem). Let $n = 1$, $\Omega = (0,1)$, $\Gamma_D = \{0,1\}$, $\alpha = 0$, $\Gamma_N = \emptyset$, and $W(s) = \min\{(s-1)^2, (s+1)^2\}$. The right-hand sides are defined by

$$f(x) = \begin{cases} 0 & \text{for } x \le x_b, \\ \gamma(x - x_b)/2 & \text{for } x \ge x_b \end{cases}$$

and

$$u_D(0) = 3x_b^5/128 + x_b^3/3 \qquad \text{and} \qquad u_D(1) = \gamma(1 - x_b)^3/24 + 1 - x_b,$$

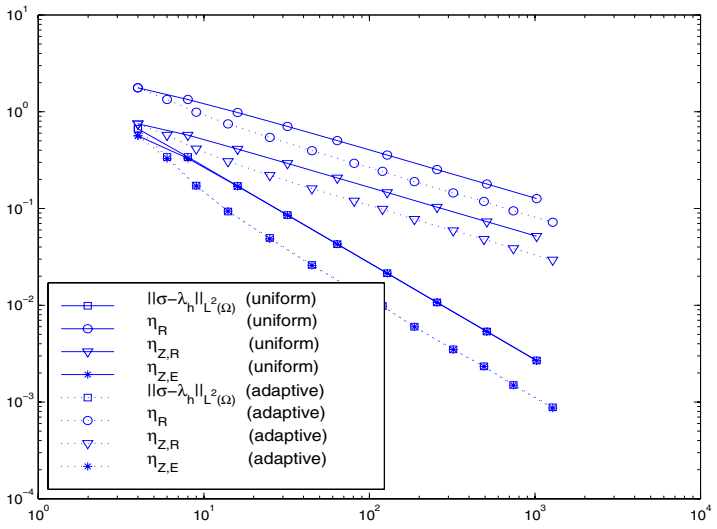

FIG. 3. *Error and error estimators in Example* 7.2 *for uniform and adaptive mesh refinement.*

where $\gamma = 100$ and $x_b = \pi/6$. A solution for (P**) is then given by

$$u(x) = \begin{cases} -3(x-x_b)^5/128 - (x-x_b)^3/3 & \text{for } x \le x_b, \\ \gamma(x-x_b)^3/24 + x - x_b & \text{for } x \ge x_b \end{cases}$$

and allows us to compute the unique quantity $\sigma := DW^{**}(u')$. The microstructure region is $(0, x_b)$ in which $\sigma = 0$ and u' lies between the wells -1 and 1; i.e., $u'(x) \in (-1, 1)$ for $x \in (0, x_b)$. A Young measure corresponding to u is given by

$$\nu_x = \begin{cases} \dfrac{1-u'(x)}{2}\delta_{-1} + \dfrac{1+u'(x)}{2}\delta_{+1} & \text{for } x \le x_b, \\ \delta_{u'(x)} & \text{for } x > x_b. \end{cases}$$

For Algorithm $(A_\Theta^{adaptive})$ we used $m = 4$ and

$$\mathcal{T}_1 = \{[0, 1/4], [1/4, 1/2], [1/2, 3/4], [3/4, 1]\}.$$

Note that the weighted jumps $h_E\|[\lambda_{d,h} \cdot n_E]\|^2_{L^2(E)}$ of $\lambda_{d,h}$ across edges $E \in \mathcal{E}_\Omega$ are in the one-dimensional situation given by

$$\max\{h_{T_1}, h_{T_2}\}(\lambda_{d,h}|_{T_1} - \lambda_{d,h}|_{T_2})^2$$

for $z \in \mathcal{K}$, $T_1, T_2 \in \mathcal{T}$ such that $z = T_1 \cap T_2$.

We ran Algorithm $(A_0^{adaptive})$ and $(A_{1/2}^{adaptive})$ in Example 7.2. The obtained error estimators η_R, $\eta_{Z,R}$, and $\eta_{Z,E}$ and the exact error $\|\sigma - \lambda_{d,h}\|$ for each triangulation are plotted against the degrees of freedom in $\mathcal{T}$ in Figure 3 with a logarithmic scaling used for both axes. Both uniform and adaptive refinement strategies yield the same experimental convergence rates, but the adaptive scheme yields a comparable error reduction at similar numbers of degrees of freedom. The error estimators η_R and $\eta_{Z,R}$ converge much slower than the error itself, while the efficient error estimator $\eta_{Z,E}$ approximates the error very well and converges with the same order.

TABLE 1
Possible and active atoms per element on uniform meshes.

# active atoms	7.9	10.7	9.6	17.4	46.3	64.5	127.1

TABLE 2
Possible and active atoms per element on adapted meshes.

Triangulation	7	8	9	10	11	12	13
# elements	81	120	187	321	492	741	1,280
# atoms	11,881	21,297	41,244	92,450	175,143	323,390	733,574
# active atoms	7.4	11.6	38.9	31.2	29.6	27.4	30.7

In Tables 1 and 2 we displayed for uniform and adapted meshes, respectively, the number of possible atoms per element and the average number of active atoms per element selected by ($A^{active\ set}$). We observe that the numbers of atoms is significantly reduced by the active set strategy. Moreover, the average number of active atoms seems to be bounded or maybe grows very slowly on the adapted meshes, while on the uniform meshes the number of active atoms grows linearly.

Example 7.2 (two-dimensional, scalar three-well problem). Let $n = 2$, $\Omega = (0,1)^2$, W as in Theorem 5.1, $\alpha = 0$, $\Gamma_D = \partial\Omega$, and, for $(x,y) \in \overline{\Omega}$, $u_D(x,y) = v(x) + v(y)$, where, for $t \in [0,1]$,

$$v(t) = \begin{cases} (t-1/4)^3/6 + (t-1/4)/8 & \text{for } t \le 1/4, \\ -(t-1/4)^5/40 - (t-1/4)^3/8 & \text{for } t \ge 1/4. \end{cases}$$

Setting $f := -\operatorname{div} DW^{**}(\nabla u_D)$, i.e., for $(x,y) \in (0,1)^2$,

$$f(x,y) = \begin{cases} 0 & \text{for } x \le 1/4 \text{ and } y \le 1/4, \\ -2\,v''(y) & \text{for } x \le 1/4 \text{ and } 1/4 \le y, \\ -2\,v''(x) & \text{for } 1/4 \le x \text{ and } y \le 1/4, \\ -2\,(v''(x) + v''(y)) & \text{for } 1/4 \le x \text{ and } 1/4 \le y, \end{cases}$$

we have that $u = u_D$ is the weak limit of an infimizing sequence for (P). If u_x and u_y abbreviate $\partial u/\partial x$ and $\partial u/\partial y$, respectively, then for

$$\nu_{(x,y)} := \begin{cases} (1 - u_x(x,y) - u_y(x,y))\delta_{(0,0)} & \\ \quad + u_x(x,y)\delta_{(1,0)} + u_y(x,y)\delta_{(0,1)} & \text{for } x \le 1/4,\ y \le 1/4, \\ (1 - u_x(x,y))\delta_{(0,u_y(x,y))} + u_x(x,y)\delta_{(1,u_y(x,y))} & \text{for } x \le 1/4,\ 1/4 \le y, \\ (1 - u_y(x,y))\delta_{(u_x(x,y),0)} + u_y(x,y)\delta_{(u_x(x,y),1)} & \text{for } 1/4 \le x,\ y \le 1/4, \\ \delta_{\nabla u(x,y)} & \text{for } 1/4 \le x,\ 1/4 \le y, \end{cases}$$

the pair (u,ν) is a solution for (EP). The coarsest triangulation $\mathcal{T}_1$ consists of 32 triangles, which are halved squares, and we set $m = 1.5$.

Our numerical results in Example 7.2 are not as satisfying as those for Example 7.1. The Lagrange multiplier provided by the linear program solver did not satisfy the optimality conditions even when m was large and all atoms were activated. We suspect

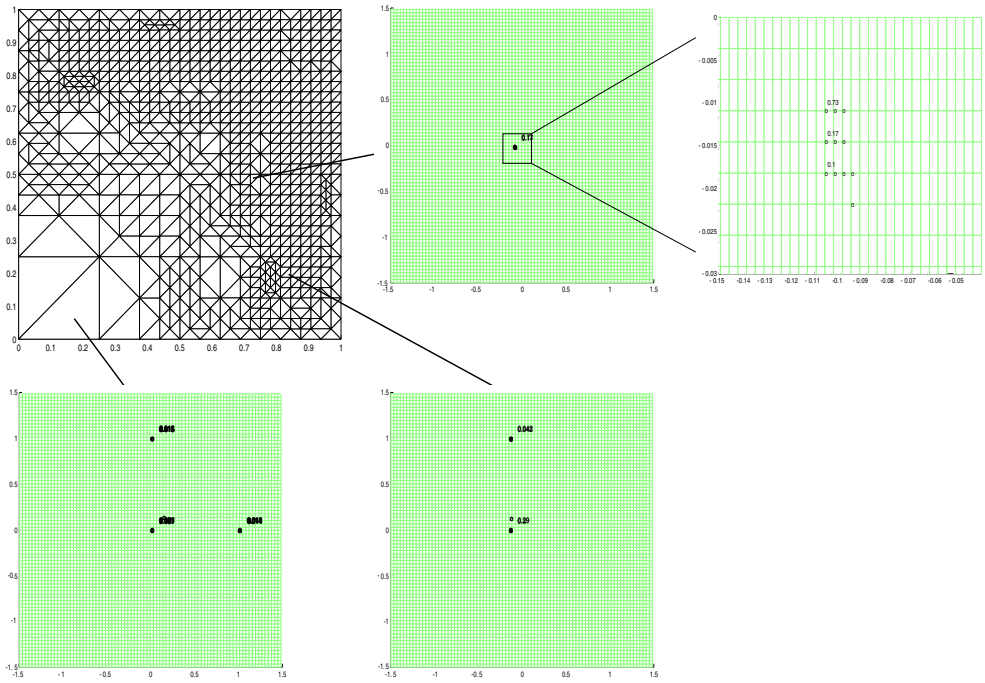

FIG. 4. *Adaptively generated mesh and Young measure restricted to three different elements in Example* 7.1.

TABLE 3
CPU-times for $(\mathrm{EP}_{d,h})$ *on adaptively refined meshes in Example* 7.1.

Dof	9	35	70	162	255	492
CPU-time [s]	11.7	269.0	830.7	5,792.7	9,797.4	24,317.5

that this is caused by the huge complexity of the problem. Other solvers for the linear programming problem did not find a solution when the problem became large. This indicates that efficient methods for the solution of $(\mathrm{EP}_{d,h})$ are very important. We found, however, that the quantity $DW^{**}(\nabla u_{d,h})$ satisfied the maximum principle and the equilibrium equation up to an absolute error of about 0.05 in Example 7.2 so that we used this quantity to activate atoms in Algorithm $(A^{active\,set})$ and to calculate error indicators η_R, $\eta_{Z,R}$, and $\eta_{Z,E}$ in order to refine the mesh and to estimate the error in Algorithm $(A^{adaptive}_{1/2})$.

Figure 4 shows the adaptively generated mesh $\mathcal{T}_6$ and the support of the discrete Young measure solution and the corresponding volume fractions restricted to three different elements. The three meshes show every tenth atom in τ, and circles indicate that an atom is active. Numbers next to circles are volume fractions, provided they are larger than 0.01. We observe that the discrete Young measure approximates the Young measure solution ν from Example 7.2 very well. Moreover, the adaptive algorithm refines the mesh in those regions where the stress is large. Since the error estimators and the active set strategy show the same behavior as in the previous example we omit the corresponding plots and tables here.

Table 3 displays the CPU-time needed to solve $(\mathrm{EP}_{d,h})$ in Example 7.2 on a

sequence of adaptively refined triangulations against the number of degrees of freedom in $\mathcal{T}_k$, $k = 1, \ldots, 6$. The numerical solutions were obtained on a SUN Enterprise with 14 processors and 14 GB RAM, and the numbers suggest that the CPU-time depends linearly on the number of degrees of freedom.

Acknowledgment. The author wishes to thank Professor C. Carstensen for stimulating discussions.

ON THE NUMERICAL INTEGRATION OF ORDINARY DIFFERENTIAL EQUATIONS BY PROCESSED METHODS*

S. BLANES†, F. CASAS†, AND A. MURUA‡

Abstract. We provide a theoretical analysis of the processing technique for the numerical integration of ODEs. We get the effective order conditions for processed methods in a general setting so that the results obtained can be applied to different types of numerical integrators. We also propose a procedure to approximate the postprocessor such that its evaluation is virtually cost-free. The analysis is illustrated for a particular class of composition methods.

Key words. effective order, processing technique, cheap postprocessor, initial value problems

1. Introduction.

Given the ODE

$$x' = f(x), \qquad x_0 = x(t_0) \in \mathbb{R}^D, \tag{1.1}$$

with $f : \mathbb{R}^D \to \mathbb{R}^D$ and associated vector field (or Lie operator associated with f)

$$F = \sum_{i=1}^{D} f_i(x) \frac{\partial}{\partial x_i}, \tag{1.2}$$

a one-step numerical *integrator* for a time step h, $\psi_h : \mathbb{R}^D \to \mathbb{R}^D$, can be seen as a smooth family of maps with parameter h such that ψ_0 is the identity map. The integrator ψ_h is said to have order of consistency $\geq q$ (or, equivalently, to be of order $\geq q$) if

$$\psi_h = \varphi_h + \mathcal{O}(h^{q+1}), \tag{1.3}$$

where φ_h is the h-flow of the ODE (1.1). Then an approximation to the exact solution $x(h)$ is given by

$$x_h = \psi_h(x_0) = \varphi_h(x_0) + \delta_{h,q}(x_0),$$

where $\delta_{h,q}(x_0) = \mathcal{O}(h^{q+1})$ denotes the local truncation error. The efficiency of the integrator (when compared with methods of the same order and family) depends both on its computational cost and the magnitude of the error term.

In this work we discuss the class of methods obtained by enhancing an integrator ψ_h with processing. The idea of processing can be traced back to the work of Butcher

[7] in 1969, where it is considered in the context of Runge–Kutta methods, and is summarized in [12, 19]. Essentially, it consists of obtaining a new (hopefully better) integrator of the form

$$\hat{\psi}_h = \pi_h \circ \psi_h \circ \pi_h^{-1}. \tag{1.4}$$

The method ψ_h is referred to as the *kernel* and the parametric map $\pi_h : \mathbb{R}^D \to \mathbb{R}^D$ as the *postprocessor* or *corrector*. Application of n steps of the integrator $\hat{\psi}_h$ leads to

$$\hat{\psi}_h^n = \pi_h \circ \psi_h^n \circ \pi_h^{-1},$$

which can be considered as a change of coordinates in phase space. Thus, it is not required that the kernel ψ_h used to propagate the numerical solution be a *good* integrator. It is sufficient, using dynamical system terminology, that ψ_h be *conjugate* to a good integrator.

Usually one is interested in the case where $\pi_0 = \mathrm{id}$, the identity map; i.e., π_h is also a near-identity map, although it is not intended to approximate the h-flow φ_h. The *preprocessor* π_h^{-1} is applied only once so that its computational cost may be ignored; then the kernel ψ_h acts once per step, and, finally, the action of the postprocessor π_h is evaluated only when output is required. Processing is advantageous if $\hat{\psi}_h$ is a more accurate method than ψ_h and the cost of π_h is negligible: it provides the accuracy of $\hat{\psi}_h$ at the cost of the less accurate method ψ_h.

Although initially intended for Runge–Kutta methods, the processing technique did not become significant in practice, probably due to the difficulties of coupling processing with classical strategies of variable step-sizes. It has been only recently that this idea has proved its usefulness in the context of geometric integration, where constant step-sizes are widely employed.

The aim of geometric integration is to construct numerical schemes for discretizing the differential equation (1.1) while preserving certain geometric properties of the vector field F. It is generally recognized that this class of numerical algorithms (the so-called *geometric integrators*) provide a better description of the system (1.1) than standard methods, both with respect to the preservation of invariants and also in the accumulation of numerical errors along the evolution [12, 22].

A typical procedure in geometric integration is to consider one or more low order methods and compose them with appropriately chosen weights to achieve higher order schemes. The resulting composition method inherits the relevant properties that the basic integrator shares with the exact solution, provided these properties are preserved by composition [16].

It has been precisely in this context where the application of processing has proved to be a very powerful tool, allowing one to build numerical schemes with both the kernel and the postprocessor taken as compositions of basic integrators. In particular, highly efficient processed composition methods have been proposed in the last few years, both in the separable case [3] (including families of Runge–Kutta–Nyström class of methods [5, 14, 15]) and also for slightly perturbed systems [4, 17, 24].

The method ψ_h is of *effective order* q if a postprocessor π_h exists for which $\hat{\psi}_h$ is of (conventional) order q [7], that is,

$$\pi_h \circ \psi_h \circ \pi_h^{-1} = \varphi_h + \mathcal{O}(h^{q+1}). \tag{1.5}$$

When analyzing the order conditions $\hat{\psi}_h$ has to verify to be a method of order q, it has been shown that many of them can be satisfied by using π_h [1, 3, 8] so that ψ_h must

fulfill a much reduced set of constraints. Furthermore, the error term $\delta_{h,q}(x_0)$ depends on both ψ_h and π_h, and additional conditions can be imposed on the postprocessor in order to reduce its magnitude. This allows one, on the one hand, to consider kernels involving fewer evaluations and, on the other hand, to analyze and obtain new and efficient composition methods of high order [5].

In this paper we develop a general theory of the processing technique as applied to the numerical integration of differential equations and derive, under very general assumptions, the conditions to be satisfied by the kernel and the postprocessor to attain a given order of consistency. The analysis can be directly applied to different types of numerical methods, including families of composition integrators and Runge–Kutta-type methods.

For processed methods whose postprocessor is itself constructed as a composition of basic integrators, it turns out that the computational cost of evaluating π_h is usually higher than of ψ_h so that their use is restricted (in sequential computer environments) to situations where intermediate results are not frequently required. Otherwise the overall efficiency of the methods is highly deteriorated.

Another goal of this work is precisely to show how to avoid this situation, i.e., how to obtain approximations to the postprocessor virtually cost-free and without loss of accuracy. The key point is a generalization of a procedure outlined in [14]: π_h is replaced by a new integrator $\hat{\pi}_h \simeq \pi_h$ obtained from the intermediate stages in the computation of ψ_h.

The plan of the paper is as follows. In section 2 we provide a general analysis of processed methods, obtaining the order conditions to be verified by the kernel and the postprocessor. In section 3 we propose a cheap alternative for approximating the postprocessor, study the corresponding order conditions, and examine the propagation of the error that results from replacing the optimal postprocessor by the cheap alternative. Section 4 is concerned with numerical examples, and section 5 contains some concluding remarks.

2. Analysis of processed methods.

2.1. Order of consistency of numerical integrators. Let ψ_h be an integrator that approximates the h-flow φ_h of the system (1.1). It is well known that, for each $g \in C^\infty(\mathbb{R}^D, \mathbb{R})$ (i.e, each infinitely differentiable map $g : \mathbb{R}^D \to \mathbb{R}$), $g(\varphi_h(x))$ admits an expansion of the form [21]

$$g(\varphi_h(x)) = \exp(hF)[g](x) = g(x) + \sum_{k\geq 1} \frac{h^k}{k!} F^k[g](x), \quad x \in \mathbb{R}^D,$$

where F is the vector field (1.2). Let us assume that, for each $g \in C^\infty(\mathbb{R}^D, \mathbb{R})$, $g(\psi_h(x))$ admits an expansion of the form

$$g(\psi_h(x)) = g(x) + h\Psi_1[g](x) + h^2\Psi_2[g](x) + \cdots,$$

where each Ψ_k is a linear differential operator, and let Ψ_h denote the series of differential operators

$$\Psi_h = I + \sum_{k\geq 1} h^k \Psi_k$$

so that, formally, $g \circ \psi_h = \Psi_h[g]$. Clearly, (1.3) is then equivalent to

$$\Psi_k = \frac{1}{k!} F^k, \quad 1 \leq k \leq q. \tag{2.1}$$

Alternatively, let us consider the series

$$F_h = \log(\Psi_h) = \sum_{m\geq 1} \frac{(-1)^{m+1}}{m}(\Psi_h - I)^m$$

so that, formally, $\Psi_h = \exp(F_h)$ and

$$F_h = \sum_{k\geq 1} h^k F_k, \quad \text{with } F_k = \sum_{m\geq 1} \frac{(-1)^{m+1}}{m} \sum_{j_1+\cdots+j_m=k} \Psi_{j_1}\cdots\Psi_{j_m}. \tag{2.2}$$

It can be shown that the algebraic properties of the linear differential operators Ψ_k imply that such F_h is a series of vector fields. This means the well-known fact that the integrator ψ_h can be formally interpreted as the exact 1-flow of the modified vector field F_h [12]. Then condition (2.1) is equivalent to

$$F_1 = F, \qquad F_k = 0 \quad \text{for } 2 \leq k \leq q. \tag{2.3}$$

It is worth noticing that characterizations (2.1) and (2.3) for the order conditions of the integrator ψ_h are written, in contrast with (1.3), in a way that it is straightforward to extend them to integrators on smooth manifolds so that we need not restrict ourselves to integrators on $\mathbb{R}^D$. In fact, the theory of the present paper remains true in a coordinate-free setting, where F_k are vector fields (sections of the tangent bundle) on a finite-dimensional smooth manifold.

2.2. Graded Lie algebra of vector fields. We have observed that numerical integrators can be expanded as exponentials of series of vector fields, and these can be used to compare with the exact flow of the system to be integrated numerically. In section 3 we will consider expansions of linear combinations of vector fields, which lie in the associative algebra $\mathcal{B}$ of linear differential operators generated by concatenation of smooth vector fields on $\mathbb{R}^D$, with the identity operator I as the unit element. At this point it seems appropriate to briefly review the main concepts of the theory of Lie algebras in this setting. They will prove to be very useful in the subsequent analysis.

As any associative algebra, the algebra $\mathcal{B}$ has structure of Lie algebra with the commutator $[a, b] = ab - ba$ as the Lie bracket. In other words, the commutator $[a, b]$ is a bilinear operator satisfying

- skew-symmetry: $[a, b] = -[b, a]$;
- the Jacobi identity: $[a, [b, c]] + [b, [c, a]] + [c, [a, b]] = 0$.

The vector fields on $\mathbb{R}^D$ form a subspace of $\mathcal{B}$ that is closed under commutation; i.e., $[F, G]$ is a smooth vector field, provided that both F, G are also smooth vector fields.

From (2.2) one has $F_h = hF_1 + h^2F_2 + h^3F_3 + \cdots$, where each F_k is a vector field and h is a symbol that corresponds to the parameter present in the definition of the integrator ψ_h. The set of series of this form inherits a Lie algebra structure from the Lie algebra structure of the set of vector fields if there is a sequence of vector subspaces $\mathcal{L}_k$, $k \geq 1$, of the Lie algebra of vector fields such that $F_k \in \mathcal{L}_k$ for each series $\sum_{k\geq 1} h^k F_k$ and

$$[\mathcal{L}_n, \mathcal{L}_m] \subset \mathcal{L}_{n+m} \quad \text{for each } n, m \geq 1. \tag{2.4}$$

In this way the concept of *graded Lie algebra* naturally arises. A graded Lie algebra $\mathcal{L}$ can be defined as a Lie algebra together with a sequence of subspaces $\{\mathcal{L}_1, \mathcal{L}_2, \mathcal{L}_3, \ldots\}$ of $\mathcal{L}$ such that $\mathcal{L} = \bigoplus_{k\geq 1} \mathcal{L}_k$ and (2.4) holds. The vector spaces $\mathcal{L}_k$ in the graded Lie algebra $\mathcal{L}$ are called *homogeneous components* of $\mathcal{L}$.

Also the notion of *free Lie algebra* is very useful in this setting [23]. Roughly speaking, a Lie algebra $\mathcal{L}$ is free if there exists a set $S \subset \mathcal{L}$ such that (i) any element in $\mathcal{L}$ can be written as a linear combination of nested brackets of elements in S and (ii) the only linear dependencies among such nested brackets are due to the skew-symmetry property and the Jacobi identity of brackets (see [20] for more details on the theory of free Lie algebras in the context of numerical integration).

Given a Lie algebra $\mathcal{L}$ of vector fields one may consider the associative algebra generated by $\mathcal{L}$ (which is a subalgebra of $\mathcal{B}$). There exists an associative algebra $\mathcal{A} = U(\mathcal{L})$, called the *universal enveloping algebra* [23] of the Lie algebra $\mathcal{L}$ and a unique algebra homomorphism σ of $\mathcal{A}$ onto the algebra of linear differential operators generated by the vector fields in $\mathcal{L}$. That is, any such linear differential operator can be represented as an element of $\mathcal{A}$.

The Poincaré–Birkhoff–Witt theorem [23] allows one to construct a basis of the universal enveloping algebra $\mathcal{A}$ of $\mathcal{L}$ in terms of a basis of $\mathcal{L}$. More specifically, if $\{L_i\}$ denotes a basis of $\mathcal{L}$, each element of the basis of $\mathcal{A}$ is associated with a family $\{L_{i_1}, \dots, L_{i_k}\}$ of (possibly repeated) elements of the basis of $\mathcal{L}$, and it is the sum of all possible concatenations of basic vector fields $L_{j_1} \cdots L_{j_k}$ such that $(j_1, \dots, j_k)$ is obtained by reordering $(i_1, \dots, i_k)$. When $\mathcal{L}$ is a graded Lie algebra $\mathcal{L} = \bigoplus_{k\geq 1} \mathcal{L}_k$, then $\mathcal{A}$ also admits a graded associative algebra structure, with $\mathcal{A} = \bigoplus_{k\geq 0} \mathcal{A}_k$, where $\mathcal{A}_0 = \operatorname{span}(I)$ (that is, $\mathcal{A}_n \mathcal{A}_m \subset \mathcal{A}_{n+m}$). Given a basis $\{E_{k,j}\}_{j=1}^{n_k}$ in $\mathcal{L}_k$ for each $k \geq 1$ with $n_k = \dim \mathcal{L}_k$, this procedure leads to a basis $\{D_{k,j}\}_{j=1}^{m_k}$ in $\mathcal{A}_k$ for $k \geq 1$ with $m_k = \dim \mathcal{A}_k$. In particular, this allows one to obtain m_k in terms of the dimensions $n_1, \dots, n_k$.

2.3. Effective order conditions. Let us consider now a mapping π_h close to the identity as a postprocessor for the integrator ψ_h. Our aim is to obtain characterizations for the order of consistency of the resulting processed integrator (1.4).

As before, let

$$\Pi_h = I + \sum_{k\geq 1} h^k \Pi_k, \qquad \hat{\Psi}_h = I + \sum_{k\geq 1} h^k \hat{\Psi}_k$$

be the series of differential operators such that, formally, $g \circ \pi_h = \Pi_h[g]$ and $g \circ \hat{\psi}_h = \hat{\Psi}_h[g]$, respectively. Then $\hat{\Psi}_h = \Pi_h^{-1} \Psi_h \Pi_h$, where Π_h^{-1} can be expanded using the same differential operators as in Π_h, and the processed integrator $\hat{\psi}_h$ has order of consistency $\geq q$ if

$$\Psi_h \Pi_h = \Pi_h \exp(hF) + \mathcal{O}(h^{q+1}). \tag{2.5}$$

It is important to notice that different postprocessors may result in the same processed integrator so that it is useful to consider the following definition.

DEFINITION 2.1. *Two postprocessors π_h and $\bar{\pi}_h$ are said to be equivalent with respect to the kernel ψ_h if they give rise to the same processed integrator, i.e., if $\pi_h \circ \psi_h \circ \pi_h^{-1} = \bar{\pi}_h \circ \psi_h \circ \bar{\pi}_h^{-1}$ or, in terms of their respective series of differential operators, if*

$$\Pi_h^{-1} \Psi_h \Pi_h = \bar{\Pi}_h^{-1} \Psi_h \bar{\Pi}_h. \tag{2.6}$$

Remark. Clearly, Π_h and $\bar{\Pi}_h$ are equivalent with respect to the kernel $\Psi_h = \exp(F_h)$ if and only if the vector field $S_h = \log(\Pi_h \bar{\Pi}_h^{-1})$ commutes with F_h, for (2.6) can be written as $\exp(F_h) = \Pi_h \bar{\Pi}_h^{-1} \exp(F_h)(\Pi_h \bar{\Pi}_h^{-1})^{-1}$ or $\exp(F_h)\exp(S_h) =$

$\exp(S_h)\exp(F_h)$, and this is true if and only if $[F_h, S_h] = 0$. In particular, given a postprocessor Π_h and a kernel $\Psi_h = \exp(F_h)$, Π_h is equivalent to $\bar{\Pi}_h = \exp(\lambda F_h)\Pi_h$ for an arbitrary $\lambda \in \mathbb{R}$.

For a given family of integrators $\mathcal{G}$, the effective order conditions are equations on the parameters of the family that indicate the effective order of a particular integrator ψ_h in $\mathcal{G}$. Such effective order conditions can be directly derived from (2.5) for each family of integrators. For instance, for Runge–Kutta methods, (2.5) is equivalent to considering composition of B-series, which is the usual procedure to study the effective order conditions in that setting [8]. However, a general treatment, including the study of the generic number of order conditions, seems difficult with this approach: it would require making specific assumptions on the structure and properties of the series of linear differential operators Ψ_h and Π_h. Instead we propose an alternative based on the vector fields

$$F_h = \sum_{k\geq 1} h^k F_k = \log(\Psi_h), \qquad \hat{F}_h = \sum_{k\geq 1} h^k \hat{F}_k = \log(\hat{\Psi}_h),$$
$$P_h = \sum_{k\geq 1} h^k P_k = \log(\Pi_h).$$

In principle, given a kernel $\Psi_h = \exp(\sum h^k F_k)$, one might look for the best possible postprocessor $\Pi_h = \exp(P_h)$ among all possible series of vector fields $P_h = \sum h^k P_k$. However, if F_k is known to belong (for each $k \geq 1$) to a certain Lie algebra $\mathcal{L}$ of vector fields and it is desired that the vector fields $\hat{F}_k$ associated with $\hat{\psi}_h$ also belong to $\mathcal{L}$, then it seems natural to restrict oneself to the case $P_k \in \mathcal{L}$ (this is particularly true if no additional assumptions are made for F_k). We will say that a processed integrator $\hat{\psi}_h$ has order $p \geq q$ in $\mathcal{L}$ if there exist vector fields $P_k \in \mathcal{L}$, $k \geq 1$, such that (2.5) holds with $\Pi_h = \exp(\sum h^k P_k)$.

THEOREM 2.2. *An integrator ψ_h has effective order $p \geq q$ in $\mathcal{L}$ if and only if there exist vector fields $P_1, \ldots, P_{q-1} \in \mathcal{L}$ such that*

$$\begin{aligned} F_1 &= F, \\ [P_{k-1}, F] &= F_k + R_k(P_1, \ldots, P_{k-2}, F_1, \ldots, F_{k-1}), \quad 1 < k \leq q, \end{aligned} \tag{2.7}$$

holds, where

$$R_k = -\sum_{j=1}^{k-2} [P_j, F_{k-j}] + \sum_{l\geq 2} \frac{(-1)^l}{l!} \sum_{j_1+\cdots+j_{l+1}=k} [P_{j_1}, [P_{j_2}, \ldots [P_{j_l}, F_{j_{l+1}}] \ldots]]. \tag{2.8}$$

Proof. The equality $\hat{\Psi}_h = \Pi_h^{-1}\Psi_h\Pi_h$ can be written in terms of the respective vector fields as $\exp(\hat{F}_h) = \exp(-P_h)\exp(F_h)\exp(P_h)$. Formal application of the logarithm in both sides of this expression leads to [23]

$$\hat{F}_h = \exp(-P_h)F_h\exp(P_h) = \exp(\mathrm{ad}_{-P_h})F_h = \sum_{k=0}^{\infty} \frac{(-1)^k}{k!} \mathrm{ad}_{P_h}^k F_h,$$

where $\mathrm{ad}_A B = [A, B]$. Therefore

$$\hat{F}_h = F_h - [P_h, F_h] + \frac{1}{2!}[P_h, [P_h, F_h]] - \frac{1}{3!}[P_h, [P_h, [P_h, F_h]]] + \cdots,$$

which implies

$$\begin{aligned} \hat{F}_1 &= F_1, \\ \hat{F}_k &= F_k + [F_1, P_{k-1}] + R_k, \quad k > 1, \end{aligned} \tag{2.9}$$

where $R_2 = 0$, and for $k > 2$, R_k is given by (2.8). Condition (2.5) reads $\hat{F}_1 = F$, $\hat{F}_k = 0$ for $2 \le k \le q$, which is equivalent to (2.7). ∎

In order to proceed further, we adopt the following assumption.

Assumption 1. The kernels ψ_h under consideration in this work are such that their associated vector fields $F_k \in \mathcal{L}_k$, $k \ge 1$, where $\{\mathcal{L}_n\}_{n\ge 1}$ is a sequence of subspaces of a certain graded Lie algebra $\mathcal{L}$ of vector fields satisfying (2.4).

In typical situations in numerical integration $\mathcal{L}$ is a graded free Lie algebra, and $n_k = \dim \mathcal{L}_k$ corresponds to the number of order conditions at order k for nonprocessed methods. The values of n_k, $k \ge 1$, can often be computed by using Witt's formula and their generalizations (see [19] and references therein).

Example 2.3. Let us now consider some particular cases which illustrate Assumption 1 and the context where the results of this paper can be applied.

(1.a) First assume that ODE (1.1) can be written as $x' = f_a(x) + f_b(x)$ and the vector field F is split accordingly as $F = F_a + F_b$. Suppose that the corresponding h-flows $\varphi_h^{[a]}$ and $\varphi_h^{[b]}$ can be exactly computed. Then it is useful to consider numerical integrators of the form

$$\psi_h = \varphi^{[b]}_{\alpha_{2s}h} \circ \varphi^{[a]}_{\alpha_{2s-1}h} \circ \cdots \circ \varphi^{[b]}_{\alpha_2 h} \circ \varphi^{[a]}_{\alpha_1 h}, \tag{2.10}$$

with $\alpha_i \in \mathbb{R}$; i.e., ψ_h is taken as a composition of basic flows. Now Assumption 1 holds for ψ_h with

$$\mathcal{L}_1 = \operatorname{span}(\{F_a, F_b\}), \qquad \mathcal{L}_k = \operatorname{span}\left(\bigcup_{l+m=k} [\mathcal{L}_l, \mathcal{L}_m] \right), \quad k \ge 2. \tag{2.11}$$

If one is interested in obtaining results that are valid for all pairs F_a, F_b of arbitrary vector fields, then one must assume that the only linear dependencies among nested commutators of F_a and F_b can be derived from the skew-symmetry and the Jacobi identity of commutators. In other words, $\mathcal{L} = \bigoplus_{k\ge 1} \mathcal{L}_k$ is the graded free Lie algebra generated by the symbolic vector fields F_a, F_b, where both have degree one. In particular, the dimensions n_k of the first homogeneous components $\mathcal{L}_k$ are $n_k = 2, 1, 2, 3, 6, 9, 18, 30, 56, 99$.

(1.b) Let us consider the generalized harmonic oscillator with Hamiltonian function

$$H(\mathbf{q}, \mathbf{p}) = \frac{1}{2}\mathbf{p}^T M^{-1} \mathbf{p} + \frac{1}{2}\mathbf{q}^T S \mathbf{q}. \tag{2.12}$$

Here $\mathbf{q}, \mathbf{p} \in \mathbb{R}^d$ and M, S are constant symmetric matrices, M being invertible. This Hamiltonian (with $S = M^{-1}$) appears in the matrix representation of the time-dependent Schrödinger equation [10], where $\mathbf{q}$ and $\mathbf{p}$ represent the real and imaginary parts of the vector describing the state of the system. With $x = (\mathbf{q}, \mathbf{p})$, $D = 2d$, the corresponding equations of motion can be written as in (1.a) with $f_a(x) = (M^{-1}\mathbf{p}, \mathbf{0})$, $f_b(x) = (\mathbf{0}, -S\mathbf{q})$. Then the Hamiltonian vector field is decomposed as $F = F_a + F_b$, with

$$F_a = \sum_{i=1}^{d} (M^{-1}\mathbf{p})_i \frac{\partial}{\partial q_i}, \qquad F_b = \sum_{i=1}^{d} (-S\mathbf{q})_i \frac{\partial}{\partial p_i}.$$

Now Assumption 1 holds with $\mathcal{L}_k$ given by (2.11). In this case, not all the nested commutators are independent. For instance, $[F_a,[F_a,[F_a,F_b]]] = [F_b,[F_b,[F_b,F_a]]] = 0$. In fact, all nested commutators with an even number of operators F_a, F_b are either zero or a vector field F_C associated with the Hamiltonian $\mathbf{q}^T C\mathbf{p}$, where C is a polynomial matrix function of SM^{-1}. In consequence, $[F_a, F_C]$ is associated with a Hamiltonian function quadratic in $\mathbf{p}$, $[F_a,[F_a,F_C]] = 0$, and, similarly, $[F_b,[F_b,F_C]] = 0$. In addition, $[F_a,[F_b,F_C]] = [F_b,[F_a,F_C]]$ is also associated with a Hamiltonian function of the form $\mathbf{q}^T C_1\mathbf{p}$. As a result, $n_{2k} = 1$ and $n_{2k+1} = 2$ for all k.

(1.c) *Near-integrable system.* It corresponds to the problem $x' = f_a(x) + \varepsilon f_b(x)$ with $|\varepsilon| \ll 1$, which is a particular case of (1.a). The vector field associated with composition (2.10) takes the form $F_h = \sum_{k\geq 1}\sum_{i=1}^{k-1} h^k \varepsilon^i F_{k,i}$ so that we consider a bigraded Lie algebra with

$$F_a \in \mathcal{L}_{1,0}, \qquad F_b \in \mathcal{L}_{1,1}, \qquad [\mathcal{L}_{k,i}, \mathcal{L}_{m,j}] \subset \mathcal{L}_{k+m,i+j}, \tag{2.13}$$

and $\mathcal{L}_k = \bigoplus_{i=1}^{k-1} \mathcal{L}_{k,i}$ for $k \geq 2$. We denote $n_{k,i} = \dim \mathcal{L}_{k,i}$ so that obviously $n_k = \sum_{i=1}^{k-1} n_{k,i}$. An explicit formula for the $n_{k,i}$ can be found, in particular, in [16]: for instance, $n_{k,1} = n_{k,k-1} = 1$, $k > 1$, $n_{k,2} = n_{k,k-2} = \lfloor \frac{1}{2}(k-1)\rfloor$, $k > 2$, and $n_{k,3} = n_{k,k-3} = \lfloor \frac{1}{6}(k-1)(k-2)\rfloor$, $k > 3$ [19]. Here $\lfloor x\rfloor$ denotes the integer part of x.

(1.d) If $\mathcal{S}_h : \mathbb{R}^D \to \mathbb{R}^D$ is a second order time-symmetric integrator for (1.1), then we can consider integrators of the form [16]

$$\psi_h = \mathcal{S}_{\alpha_s h} \circ \cdots \circ \mathcal{S}_{\alpha_1 h}, \quad (\alpha_1, \ldots, \alpha_s) \in \mathbb{R}^s. \tag{2.14}$$

It can be shown (see Appendix A) that for such integrators Assumption 1 holds for the graded Lie algebra $\mathcal{L} = \bigoplus_{k\geq 1} \mathcal{L}_k$ generated by certain vector fields $\{Y_1, Y_3, Y_5, \ldots\}$ such that $Y_{2k-1} \in \mathcal{L}_{2k-1}$, $k \geq 1$. The dimensions n_k of the first homogeneous components $\mathcal{L}_k$ for $k \geq 1$ are $n_k = 1, 0, 1, 1, 2, 2, 4, 5, 8, 11, 18$ (see, for example, [19, 20]).

(1.e) *Runge–Kutta-type methods.* The set of rooted trees plays a fundamental role in the standard order theory of Runge–Kutta integrators applied to (1.1) (see, for instance, [6, 11, 12]). A similar role is played by certain sets of colored rooted trees in the case of other families of Runge–Kutta-type integrators such as Runge–Kutta–Nyström, partitioned Runge–Kutta, and additive Runge–Kutta methods. Let us generically denote as $\mathcal{T}$ the set of trees corresponding to a family of Runge–Kutta-type integrators and as $\mathcal{T}_k$ the set of trees in $\mathcal{T}$ with k vertices. For each family of methods, the parameters of any particular qth order integrator must satisfy $n_1 + \cdots + n_q$ algebraic equations, where n_k is the cardinal of $\mathcal{T}_k$. In the standard theory of order conditions, each tree $u \in \mathcal{T}$ is associated with an *elementary differential*, which is a map $F(u) : \mathbb{R}^D \to \mathbb{R}^D$ defined in terms of the map f in (1.1) and its partial derivatives. Now it can be seen that for each family of Runge–Kutta-type integrators considered above, Assumption 1 holds with

$$\mathcal{L}_k = \operatorname{span}\left(\sum_{i=1}^{D} (F(u))_i \frac{\partial}{\partial y_i} : u \in \mathcal{T}_k\right), \quad k \geq 1.$$

The dimensions n_k of the first homogeneous components $\mathcal{L}_k$ for $k \geq 1$ are $n_k = 1, 1, 2, 4, 9, 20, 48, 115, 286, 719$ [11].

As we have mentioned before, given a kernel of effective order q, the vector fields P_k satisfying (2.7) are not unique. This nonuniqueness is intimately related to the fact that the Lie subalgebra $\mathcal{L}^0 = \{G \in \mathcal{L} : [F, G] = 0\}$, i.e., the kernel of ad_F, is nonempty

(obviously, $F \in \mathcal{L}^0$). From this perspective, it is useful to choose a direct complement $\mathcal{L}^*$ of $\mathcal{L}^0$ with respect to $\mathcal{L}$ so that $\mathcal{L}$ is decomposed as a direct sum of two subspaces $\mathcal{L} = \mathcal{L}^0 \oplus \mathcal{L}^*$. For each k, we denote $\mathcal{L}_k^0 = \mathcal{L}^0 \cap \mathcal{L}_k$, $\mathcal{L}_k^* = \mathcal{L}^* \cap \mathcal{L}_k$, and n_k^* the dimension of $\mathcal{L}_k^*$ or, equivalently, $n_k^* = \dim[F, \mathcal{L}_k]$, where $[F, \mathcal{L}_k] = [F, \mathcal{L}_k^*]$ is a subspace of $\mathcal{L}_{k+1}$. In general, *if $\mathcal{L}$ is a graded free Lie algebra, then* $\dim[F, \mathcal{L}_k] = \dim \mathcal{L}_k$, $k > 1$, *i.e.,* $n_k^* = n_k$, $k > 1$, *and* $n_1^* = n_1 - 1$.

LEMMA 2.4. *Let $F_k, P_k \in \mathcal{L}_k$ for each $k \geq 1$, with $F_1 = F$. There exist unique $P_k^* \in \mathcal{L}_k^*$, $k \geq 1$, such that the postprocessors* $\exp(\sum_{k\geq 1} h^k P_k^*)$ *and* $\exp(\sum_{k\geq 1} h^k P_k)$ *are equivalent with respect to the kernel* $\Psi_h = \exp(\sum_{k\geq 1} h^k F_k)$.

Proof. By induction on n, it is sufficient to prove that if, in addition to the assumptions of Lemma 2.4, $P_1, \ldots, P_{n-1} \in \mathcal{L}^*$ and $P_n \notin \mathcal{L}_n^*$, then there exists a unique $P_n^* \in \mathcal{L}_n^*$ such that $\exp(hP_1 + \cdots + h^{n-1}P_{n-1} + h^n P_n^* + h^{n+1}Q_{n+1} + h^{n+2}Q_{n+2} + \cdots)$ is equivalent to $\exp(\sum h^k P_k)$ with certain $Q_k \in \mathcal{L}_k$, $k > n$.

One first proves that, for arbitrary $P_n^0 \in \mathcal{L}_n^0$, there exists a unique sequence $S_k^* \in \mathcal{L}_k^*$, $k \geq n+1$ such that $S_h = -h^n P_n^0 + \sum_{k\geq n+1} h^k S_k^*$ commutes with F_h. One considers $P_n^0 \in \mathcal{L}_n^0$, $P_n^* \in \mathcal{L}_n^*$ such that $P_n = P_n^0 + P_n^*$, and observe that, by choosing S_h as above, $\exp(\sum h^k P_k)$ is equivalent to

$$\exp\left(-h^n P_n^0 + \sum_{k\geq n+1} h^k S_k^*\right) \exp\left(\sum_{k\geq 1} h^k P_k\right) = \exp\left(\sum_{k=1}^{n-1} h^k P_k + h^n P_n^* + \cdots\right).$$

The uniqueness of P_n^* directly follows from (2.9). ∎

In other words, Lemma 2.4 shows that we can take into account only postprocessors such that $P_k \in \mathcal{L}_k^*$ without restricting the choice of the processed integrator. In addition, ψ_h has effective order $p \geq q$ in $\mathcal{L}$ if and only if there exist vector fields $P_k \in \mathcal{L}_k^*$, $k \leq q-1$, such that (2.7) hold. Moreover, such vector fields are unique in $\mathcal{L}^*$.

On the other hand, equations (2.9) lead directly to the following result.

LEMMA 2.5. *If the vector fields $F_k, \hat{F}_k \in \mathcal{L}_k$, $P_k \in \mathcal{L}_k^*$, $k \geq 1$, are associated with the kernel ψ_h, the processed method $\hat{\psi}_h$, and the postprocessor π_h, respectively, it follows that*

(a) *if ψ_h is a method of order d, then $\pi_h = \mathrm{id} + \mathcal{O}(h^d)$ or, equivalently,*

$$F_k = \hat{F}_k = 0, \quad 2 \leq k \leq d \quad \Longrightarrow \quad P_k = 0, \quad 1 \leq k \leq d-1;$$

(b) *provided the kernel is such that $\psi_{-h} = \psi_h^{-1} + \mathcal{O}(h^{2d+2})$, then it holds that $\hat{\psi}_{-h} = \hat{\psi}_h^{-1} + \mathcal{O}(h^{2d+2})$ if and only if $\pi_{-h} = \pi_h + \mathcal{O}(h^{2d+1})$. In terms of vector fields,*

$$F_{2k} = \hat{F}_{2k} = 0, \quad 1 \leq k \leq d \quad \Longleftrightarrow \quad F_{2k} = P_{2k-1} = 0, \quad 1 \leq k \leq d.$$

Next we rewrite the order conditions (2.7) for the processed integrator as a system of (polynomial) equations in the coefficients of the vector fields F_k in a basis $\{E_{k,i}\}_{i=1}^{n_k}$ of $\mathcal{L}_k$, $k \geq 1$. Such conditions take a very simple form if the basis of $\mathcal{L}_{k+1}$ ($k \geq 1$) includes a basis of $[F, \mathcal{L}_k] = [F, \mathcal{L}_k^*]$. This can be done, for instance, as follows. First, choose a basis $\{E_{k,i}^*\}_{i=1}^{n_k^*}$ of $\mathcal{L}_k^*$ (of course, such a basis of $\mathcal{L}_k^*$ can always be chosen as a subset of the basis $\{E_{k,i}\}_{i=1}^{n_k}$ of $\mathcal{L}_k$). Then take

$$E_{k+1,n_{k+1}-n_k^*+i} = [F, E_{k,i}^*], \quad \text{for } i = 1, \ldots, n_k^*, \tag{2.15}$$

and complete the basis of $\mathcal{L}_{k+1}$ by choosing $n_{k+1} - n_k^*$ elements of $\mathcal{L}_{k+1}$, say $E_{k+1,i}$, $i = 1, \ldots, n_{k+1} - n_k^*$, such that $\{E_{k+1,i}\}_{i=1}^{n_{k+1}}$ spans $\mathcal{L}_{k+1}$.

From now on, we assume that the bases of $\mathcal{L}_k$ and $\mathcal{L}_k^*$ have been constructed in such a way that (2.15) holds. Let us write

$$F_k = \sum_{i=1}^{n_k} f_{k,i} E_{k,i}, \qquad R_k = \sum_{i=1}^{n_k} r_{k,i} E_{k,i}, \qquad P_{k-1} = \sum_{i=1}^{n_{k-1}^*} p_{k-1,i} E_{k-1,i}^*. \tag{2.16}$$

The effective order conditions (2.7) are then expressed in terms of the coefficients $f_{k,i}$, $r_{k,i}$, and $p_{k-1,i}$ as follows.

THEOREM 2.6. *The scheme ψ_h, satisfying Assumption 1, has effective order $p \geq q$ if and only if*

$$f_{k,i} = -r_{k,i}, \qquad 1 \leq i \leq l_k := n_k - n_{k-1}^*, \tag{2.17}$$

$$p_{k-1,i} = -f_{k,l_k+i} - r_{k,l_k+i}, \quad 1 \leq i \leq n_{k-1}^*, \tag{2.18}$$

for $1 < k \leq q$. If, in addition, ψ_h is time-symmetric (i.e., if $\psi_{-h} \circ \psi_h = \mathrm{id}$), then, for even values of k, conditions (2.17) *are automatically satisfied and equations* (2.18) *reduce to $p_{k-1,i} = 0$.*

Proof. Assumption 1 implies that each R_k in (2.9) belongs to $\mathcal{L}_k$ and thus expressions (2.16) hold, where each $r_{k,i}$ is a polynomial in the coefficients $f_{l,j}$, $p_{l-1,j}$, $l = 2, \ldots, k-1$ (as R_k in (2.9) is a Lie polynomial in F_l, P_{l-1}, $l \leq k-1$). Conditions (2.7) together with (2.15) then lead to (2.17) and (2.18).

In the particular case of a time-symmetric kernel, $F_{2i} = 0$. The conclusion readily follows from Lemma 2.5. ∎

COROLLARY 2.7. *A total number of*

$$s(q) \equiv \sum_{k=1}^{q} n_k - \sum_{k=1}^{q-1} n_k^* = n_q + \sum_{k=1}^{q-1} (n_k - n_k^*)$$

conditions have to be satisfied by a given kernel ψ_h of effective order $p \geq q > 1$. If $\mathcal{L}$ is a graded free Lie algebra, this number is $s(q) = n_q + 1$. If ψ_h is time-symmetric, then the total number of effective order conditions reduces to $\bar{s}(2) = n_1$ and $\bar{s}(2n) = n_1 + \sum_{k=2}^{n} (n_{2k-1} - n_{2k-2}^*)$.

Proof. Equations (2.18) hold for any kernel, provided the postprocessor is appropriately chosen, and equations (2.17) give $l_k = n_k - n_{k-1}^*$ conditions for each $k = 2, \ldots, q$. This, together with the n_1 consistency conditions corresponding to $F_1 = F$, leads to $s(q)$ equations on the coefficients $f_{k,i}$. On the other hand, if the graded Lie algebra is free, then $n_k^* = n_k$, $k > 1$, and $n_1^* = n_1 - 1$. Finally, if ψ_h is time-symmetric, one has to count only the number of conditions for odd values of k. ∎

Remark. For any kernel, each $r_{k,i}$ is a polynomial in $f_{l,j}$, $p_{l-1,j}$, $l = 2, \ldots, k-1$. Recursive substitution of (2.17)–(2.18) in such polynomials $r_{k,i}$ leads to an equivalent system of equations of the form (2.17)–(2.18), where now each $r_{k,i}$ is a polynomial in the coefficients $f_{l,j}$, $l = 2, \ldots, k-1$, $j = n_l - n_{l-1}^* + 1, \ldots, n_l$.

Example 2.8. Next we provide the total number of order conditions for the particular cases collected in Example 2.3.

(2.a) For the composition methods of example (1.a), $\mathcal{L}^0 = \mathrm{span}(\{F\})$. Therefore $n_1^* = n_1 - 1 = 1$, and, among the different choices for $\mathcal{L}_1^*$, one can take, for instance, $\mathcal{L}_1^* = \mathrm{span}(\{F_a\})$, $\mathcal{L}_1^* = \mathrm{span}(\{F_b\})$, or $\mathcal{L}_1^* = \mathrm{span}(\{F_a - F_b\})$. For each $k \geq 2$, $\mathcal{L}_k \cap \mathcal{L}^0 = \{\emptyset\}$ so that $\mathcal{L}_k^* = \mathcal{L}_k$, $n_k^* = n_k$, and one can choose $E_{k,i}^* = E_{k,i}$. According to Corollary 2.7, the total number of effective order conditions is then $s(q) = n_q + 1$, a result already obtained in [3].

(2.b) For the harmonic oscillator (2.12) considered in example (1.b), the number of effective order conditions $s(q)$ is substantially reduced. As we have seen, $n_{2k-1} = 2$ and $n_{2k} = 1$ for each $k \geq 1$. The basis elements can recursively be built, for example, as follows: $E_{1,1} = F = F_a + F_b$, $E_{1,2} = F_a - F_b$, and for $k \geq 1$, $E_{2k,1} = [F, E_{2k-1,2}]$, $E_{2k+1,1} = [F_a - F_b, E_{2k,1}]$, $E_{2k+1,2} = [F, E_{2k,1}]$, with $\mathcal{L}_{2k} = \operatorname{span}(\{E_{2k,1}\})$ and $\mathcal{L}_{2k+1} = \operatorname{span}(\{E_{2k+1,1}, E_{2k+1,2}\})$. From example (1.b), we have that $[F_a, [F_a, E_{2k,1}]] = [F_b, [F_b, E_{2k,1}]] = 0$ and $[F, E_{2k+1,1}] = -[F, E_{2k+1,2}]$ so that

$$n^*_{2k} = \dim[F, \mathcal{L}_{2k}] = \dim \operatorname{span}(\{[F, E_{2k,1}]\}) = 1,$$
$$n^*_{2k+1} = \dim[F, \mathcal{L}_{2k+1}] = \dim \operatorname{span}(\{[F, E_{2k+1,1}], [F, E_{2k+1,2}]\}) = 1,$$

i.e., $n^*_k = 1$ for all k, and thus $s(q) = \lfloor (q+1)/2 \rfloor + 1$ (or $s(2n-1) = s(2n) = n+1$). Counting the number of effective order conditions and the number of variables from the composition (2.10) we observe that if the equations have real solutions, in principle methods of effective order $4s-2$ can be obtained. Furthermore, an interesting feature of schemes (2.10) applied to the generalized harmonic oscillator (2.12) is that for any kernel of the form (2.10), a postprocessor exists such that the processed integrator is time-symmetric. This is a consequence of the fact that $l_{2k} := n_{2k} - n^*_{2k-1} = 0$ for all k, and therefore $\hat{F}_{2k} = 0$ if the postprocessor is appropriately chosen (i.e., if $p_{2k-1,1} = -f_{2k,2} - r_{2k,2}$).

(2.c) Since the near-integrable problem is a particular case of (1.a), we can build a basis of $\mathcal{L}_k$ and then, by taking into account that $\mathcal{L}_k = \bigoplus_{i=1}^{k-1} \mathcal{L}_{k,i}$, obtain a basis of each $\mathcal{L}_{k,i}$. According to (2.a), $\mathcal{L}_k = \mathcal{L}^*_k$ and $\mathcal{L}_{k,i} = \mathcal{L}^*_{k,i}$ for $k > 1$, $i = 1, \ldots, k-1$. If we take $\mathcal{L}^0_1 = \operatorname{span}(\{F_a\})$, then $n_{1,0} = n_{1,1} = 1$ and $n^*_{1,0} = 0$, $n^*_{1,1} = 1$.

Usually, one is interested in designing methods such that [4]

$$F_h - F = \mathcal{O}(\varepsilon h^{s_1+1} + \varepsilon^2 h^{s_2+1} + \varepsilon^3 h^{s_3+1} + \cdots). \tag{2.19}$$

A method which satisfies this condition is said to be of order $(s_1, s_2, s_3, \ldots, s_q = q)$. We are interested in the case where $s_i \geq s_{i+1}$ and the list terminates with $\varepsilon^q h^{q+1}$, q being the standard order of consistency of the method. Observe that s_1 is the order of consistency the method would have in the limit $\varepsilon \to 0$.

To count the number of order conditions one has to consider each power of ε separately. In a nonprocessed method this number is $n_{1,0} + n_{1,1} + \sum_{i=1}^{q-1} \sum_{k=i+1}^{s_i} n_{k,i}$, whereas in the processed case this number reduces to (applying Corollary 2.7 to each power of ε separately)

$$s(s_1, \ldots, q) = 1 + \sum_{i=1}^{q-1} n_{s_i,i}.$$

Since $n_{s_1,1} = 1$, the number of order conditions is independent of s_1, and $(s_1, 2)$ methods can be obtained just with a consistent kernel (a first order method) [24]. If $s_1 = \cdots = s_q = q$, the result of Corollary 2.7 is recovered.

(2.d) For kernels constructed as compositions of a basic second order symmetric integrator (2.14), $\mathcal{L}^0 = \mathcal{L}_1 = \operatorname{span}(\{F\})$. Whence $n^*_1 = n_1 - 1 = 0$, and for each $k \geq 2$, $\mathcal{L}_k \cap \mathcal{L}^0 = \{\emptyset\}$ so that $\mathcal{L}^*_k = \mathcal{L}_k$, $n^*_k = n_k$. The total number of effective order conditions is then $s(q) = n_q + 1$.

(2.e) For the family of Runge–Kutta methods, the situation is very similar to (2.d). Now $n_1 = 1$, $n^*_1 = 0$, and $n^*_k = n_k$ for $k \geq 2$, and thus the number of conditions

to have effective order conditions q is $s(q) = n_q + 1$, that is, the number of rooted trees with q vertices plus one. This result was obtained by Butcher and Sanz-Serna in [8]. As for Runge–Kutta–Nyström methods, the situation is similar to (2.a), with $n_1 = 1$, $n_1^* = 0$, and $n_k^* = n_k$ for $k \geq 2$, and Corollary 2.7 again leads to $s(q) = n_q + 1$.

For a kernel of effective order q (i.e., satisfying equations (2.17) for $k \leq q$ but not for $k = q+1$), one could in principle determine a postprocessor such that (2.18) *holds also for all* $k > q$. From now on we shall refer to that postprocessor as *optimal*, as it causes many terms of each $\hat{F}_k = \sum_{i=1}^{n_k} \hat{f}_{k,i} E_{k,i}$ of the processed method $\hat{\psi}_h$ to cancel ($\hat{f}_{k,i} = 0$ for $i = n_k - n_{k-1}^* + 1, \ldots, n_k$).

Remark. This optimal postprocessor is not uniquely defined, and it depends on the way a basis of $[F, \mathcal{L}_{k-1}]$ ($k \geq 2$) is completed to get a basis of $\mathcal{L}_k$ (i.e., on the choice of the direct complement $\bar{\mathcal{L}}_k := \mathrm{span}(\{E_{k,i}\}_{i=1}^{n_k - n_{k-1}^*})$ of $[F, \mathcal{L}_{k-1}]$ with respect to $\mathcal{L}_k$). In fact, we are determining the optimal P_h by requiring that the vector field $\hat{F}_h$ belongs to $\bar{\mathcal{L}} := \bigoplus_{k \geq 1} \bar{\mathcal{L}}_k$ (i.e., that the projection onto $[F, \mathcal{L}]$ parallel to $\bar{\mathcal{L}}$ is canceled). This obviously depends on the choice of $\bar{\mathcal{L}}$. We will, nevertheless, still use the term "optimal postprocessor" by implicitly assuming that this refers to a prescribed decomposition $\mathcal{L} = \bar{\mathcal{L}} \oplus [F, \mathcal{L}]$.

DEFINITION 2.9. *We denote by* $\mathbb{P}_k$ *the set of maps* $\pi_h : \mathbb{R}^D \to \mathbb{R}^D$ *whose Taylor expansion is identical to the optimal postprocessor up to order* k *(i.e., their difference is* $\mathcal{O}(h^{k+1})$*).*

Thus, we have a qth order processed integrator $\hat{\psi}_h$ if the kernel ψ_h has effective order q and the postprocessor π_h is in $\mathbb{P}_{q-1}$. If, in addition, $\pi_h \in \mathbb{P}_q$, then the leading term of the resulting vector field $\hat{F}_h - hF$ coincides with the leading term of the optimal postprocessor.

3. Cheap postprocessing. In most cases the optimal postprocessor can be accurately approximated, but it usually turns into a scheme which is (at least) as expensive to evaluate as the kernel. Since the preprocessor is evaluated only once, it makes sense to use this (typically) expensive approximation. On the contrary, using the more accurate approximation to the postprocessor for obtaining intermediate results along the numerical integration process may deteriorate the efficiency of the method, especially if output is frequently required as occurs, for instance, in the calculation of Lyapunov exponents and the computation of Poincaré maps in dynamical systems. It is then reasonable to look for an approximation $\hat{\pi}_h$ to the optimal postprocessor as cheap to compute as possible. Usually, such a cheap postprocessor $\hat{\pi}_h$ will be a less accurate approximation to the optimal postprocessor, but the error $\hat{\pi}_h(y_n) - \pi_h(y_n)$ thus introduced will not be propagated: as we shall see in section 3.2, such an error eventually is overtaken by the global error of the underlying processed integrator in typical situations (where the global error grows at least linearly in time).

Computationally cheap approximations to the optimal postprocessor can be obtained by applying different techniques. Here we present an approach which can be considered cost-free. In essence, π_h is approximated by reusing intermediate calculations obtained in the evaluation of the kernel ψ_h.

More precisely, let $x(t_0) = x_0$ be the initial value of the problem, and $y_n = \psi_h^n(\pi_h^{-1}(x_0))$. Then we approximate $x_n = \pi_h(y_n)$ as the linear combination

$$x_n \approx \sum_{i=-s}^{s} w_i Y_i \tag{3.1}$$

of intermediate values $Y_i \in \mathbb{R}^D$ computed when evaluating $y_n = \psi_h(y_{n-1})$ and $y_{n+1} =$

$\psi_h(y_n)$. Here we consider only intermediate values from two steps, although more could also be used. There is no loss of generality though, since using $2m$ steps is equivalent to using two steps of the kernel ψ_h^m.

To proceed further, the existence of such intermediate values has to be guaranteed.

Assumption 2. After evaluating $y_{n+1} = \psi_h(y_n)$ with a kernel ψ_h satisfying Assumption 1, the intermediate values Y_i, $i = 1, \dots, s$, are available. These can be interpreted as $Y_i = \phi_h^{(i)}(y_n)$ for suitable integrators $\phi_h^{(i)}$ satisfying Assumption 1.

3.1. Conditions on the cheap postprocessor. Under Assumption 2, we consider (3.1) with $Y_0 = y_n$, and $Y_{-i} = \phi_h^{(s-i)}(y_{n-1})$, $i = 1, \dots, s$, that is, $Y_{-i} = \phi_h^{(-i)}(y_n)$, where $\phi_h^{(-i)} = \phi_h^{(s-i)} \circ \psi_h^{-1}$. Thus, (3.1) can be rewritten as

$$x_n \approx \hat{\pi}_h(y_n), \quad \text{where } \hat{\pi}_h(y) = \sum_{i=-s}^{s} w_i \phi_h^{(i)}(y) \tag{3.2}$$

and each $\phi_h^{(i)}(y)$, $-s \le i \le s$, is an integrator satisfying Assumption 1.

Example 3.1. We illustrate Assumption 2 in some particular cases.

(3.a) For kernels of the form (2.10), Assumption 2 holds for the intermediate values $Y_j = \phi_h^{(j)}(y_n)$ ($-2s \le j \le 2s$, because we have $2s$ intermediate stages per step), where

$$\begin{aligned} Y_{2i-1} &= \varphi^{[a]}_{\alpha_{2i-1}h} \circ \cdots \circ \varphi^{[a]}_{\alpha_1 h}(y_n), & Y_{2i} &= \varphi^{[b]}_{\alpha_{2i}h} \circ \cdots \circ \varphi^{[a]}_{\alpha_1 h}(y_n), \\ Y_{-2i+1} &= \varphi^{[a]}_{\alpha_{2s-2i+1}h} \circ \cdots \circ \varphi^{[a]}_{\alpha_1 h}(y_{n-1}), & Y_{-2i} &= \varphi^{[b]}_{\alpha_{2s-2i}h} \circ \cdots \circ \varphi^{[a]}_{\alpha_1 h}(y_{n-1}), \end{aligned}$$

and $-s \le i \le s$.

(3.b) For kernels of the form (2.14), Assumption 2 holds for the intermediate values $Y_i = \phi_h^{(i)}(y_n)$ ($-s \le i \le s$), where

$$Y_i = \mathcal{S}_{\alpha_i h} \circ \cdots \circ \mathcal{S}_{\alpha_1 h}(y_n), \qquad Y_{-i} = \mathcal{S}_{\alpha_{s-i} h} \circ \cdots \circ \mathcal{S}_{\alpha_1 h}(y_{n-1}). \tag{3.3}$$

(3.c) Recall that a Runge–Kutta integrator ψ_h for the system (1.1) reads as

$$\psi_h(y) = y + h \sum_{i=1}^{s} b_i f(Y_i), \quad Y_i = y + h \sum_{j=1}^{s} a_{ij} f(Y_j), \quad i = 1, \dots s, \tag{3.4}$$

where b_i, a_{ij} are parameters of the method. Clearly, Assumption 2 holds for the intermediate stages Y_i ($1 \le i \le s$), since each Y_i defines a Runge–Kutta scheme. The internal stages of other Runge–Kutta-type families of integrators can be similarly seen to satisfy Assumption 2.

Next we study the conditions the coefficients w_i must satisfy so that $\hat{\pi}_h \in \mathbb{P}_l$ with l as high as possible. In fact, this is guaranteed for a given $l \ge 1$ if

$$\hat{\Pi}_h := \sum_{i=-s}^{s} w_i \Phi_h^{(i)} = \Pi_h + \mathcal{O}(h^{l+1}), \tag{3.5}$$

where $\Phi_h^{(i)}$ ($-s < i \le s$) is the series of differential operators $\Phi_h^{(i)} = I + \sum_{j \ge 1} h^j \Phi_j^{(i)}$ such that, formally, $g \circ \phi_h^{(i)} = \Phi_h^{(i)}[g]$. From Assumption 2 we have that $\Phi_h^{(i)} = \exp(F_h^{(i)})$, where $F_h^{(i)} = \sum_{k \ge 1} h^k F_k^{(i)}$ and $F_k^{(i)} \in \mathcal{L}_k$, $k \ge 1$.

Observe that $\hat{\pi}_h$ cannot be interpreted as the exact 1-flow of a formal vector field in the Lie algebra $\mathcal{L}$, that is, $\log(\hat{\Pi}_h) \notin \mathcal{L}$. However, since $\hat{\Pi}_h$ is defined as a linear combination of exponentials of (formal) vector fields in $\mathcal{L}$, it is clear that $\hat{\Pi}_h$ is a formal series of elements in the associative algebra of linear differential operators generated by the vector fields in $\mathcal{L}$, and therefore, as noted in subsection 2.2, the series $\hat{\Pi}_h$ can be appropriately represented by using the universal enveloping algebra $\mathcal{A}$ of $\mathcal{L}$.

According to that discussion, Π_h and each Φ_h^i (hence $\hat{\Pi}_h$) can be expressed as

$$\Pi_k = \sum_{j=1}^{m_k} \pi_{k,j} D_{k,j}, \qquad \Phi_k^{(i)} = \sum_{j=1}^{m_k} \phi_{k,j}^{(i)} D_{k,j}, \quad -s \le i \le s, \tag{3.6}$$

where $\pi_{k,j}, \phi_{k,j}^{(i)} \in \mathbb{R}$, and $\{D_{k,j}\}_{j=1}^{m_k}$ is a basis of the kth homogeneous component $\mathcal{A}_k$ of $\mathcal{A}$, constructed, for instance, at the end of subsection 2.2. In particular, since $\Phi_h^{(i)} = \exp(F_h^{(i)})$ with $F_h^{(i)} = \sum_{k\ge 1} h^k F_k^{(i)}$, $F_k^{(i)} = \sum_{j=1}^{n_k} f_{k,j}^{(i)} E_{k,j}$, we have that each $\phi_{k,j}^{(i)}$ in (3.6) is a polynomial function of $f_{l,r}^{(i)}$, $l \le k$, $r \le n_l$. The same is true for the coefficients $\pi_{k,j}$ and the coefficients $p_{k,j}$ in $P_k = \sum_{j=1}^{n_k} p_{k,j} E_{k,j}$. Hence, (3.5) is equivalent to a system of linear equations on the unknowns w_i, i.e.,

$$\sum_{i=-s}^{s} w_i \phi_{k,j}^{(i)} = \pi_{k,j}, \quad 1 \le j \le m_k, \ 0 \le k \le l. \tag{3.7}$$

In particular, $\hat{\pi}_h \in \mathbb{P}_0$ is equivalent to $\sum_{i=-s}^{s} w_i = 1$, and the number of equations (3.7) required for $\hat{\pi}_h \in \mathbb{P}_l$ is then $1 + m_1 + \cdots + m_l$.

When the number of unknowns w_i in (3.1) is larger than the number of equations (3.7) required so that $\hat{\pi}_h \in \mathbb{P}_l$ for a given l, then one can use this freedom to minimize the difference with the optimal postprocessor at higher orders.

3.1.1. Cheap postprocessing for time-symmetric kernels. In the important case of time-symmetric kernels, $\Pi_k = 0$ for odd indices k. In addition, it is typically the case that $\Phi_h^{(-i)} = \Phi_{-h}^{(i)}$ for $-s \le i \le s$. The choice $w_{-i} = w_i$ for all i in (3.1) then makes sense, that is,

$$\hat{\pi}_h = w_0 \,\mathrm{id} + \sum_{i=1}^{s} w_i (\phi_h^{(i)} + \phi_h^{(-i)}), \tag{3.8}$$

so that ($w_0 = 1 - 2\sum_{i=1}^{s} w_i$)

$$\hat{\Pi}_h = w_0 I + \sum_{i=1}^{s} w_i (\Phi_h^{(i)} + \Phi_{-h}^{(i)}) = I + 2 \sum_{r\ge 1} h^{2r} \left(\sum_{i=1}^{s} w_i \Phi_{2r}^{(i)} \right).$$

This guarantees that equations (3.7) are automatically satisfied for odd values of k, and the equations for even values of k are of the form

$$2 \sum_{i=1}^{s} w_i \phi_{k,j}^{(i)} = \pi_{k,j}, \quad 1 \le j \le m_k. \tag{3.9}$$

Hence, the number of equations that remain to be satisfied by the unknowns $w_1, \ldots, w_s$ so that $\hat{\pi}_h \in \mathbb{P}_{2r-1}$ is $m_2 + \cdots + m_{2r-2}$.

Example 3.2. A kernel of the form (2.14) is time-symmetric if $\alpha_{s-i+1} = \alpha_i$ for each i. We already know that in that case, $f_{2i,j} = 0$, $p_{2i-1,j} = 0$. In addition, one has $\phi_h^{(-i)} = \phi_{-h}^{(i)}$ for the intermediate values (3.3) to be used for the cheap postprocessor. Hence, we take $w_{-i} = w_i$ $(1 \le i \le s)$ in (3.2). Thus, in particular, a total number of $m_2 + m_4 = 1 + 3 = 4$ linear equations (3.9) have to be satisfied in order that $\hat{\pi}_h \in \mathbb{P}_5$. In Appendix A these equations are written explicitly in terms of the coefficients α_i of the kernel.

3.1.2. Improved specialized cheap postprocessors. As we have seen, condition (3.5) is sufficient for a cheap postprocessor (3.2) to belong to $\mathbb{P}_l$. However, this is not necessary in general. In fact, (3.5) means that

$$\sum_{i=-s}^{s} w_i g(\phi^{(i)}(y)) = g(\pi_h(y)) + \mathcal{O}(h^{l+1}) \tag{3.10}$$

for any $g \in C^\infty(\mathbb{R}^D, \mathbb{R})$, $y \in \mathbb{R}^D$, but in order that $\hat{\pi}_h \in \mathbb{P}_l$, (3.10) has to be imposed only for $g = g_j$, $j = 1, \dots, D$, where g_j is the projection onto the jth coordinate. As we will see, this observation leads in certain cases to a reduction in the number of conditions required.

Example 3.3. Consider again the family of Runge–Kutta schemes (3.4). Recall that in that case, n_k is the number of rooted trees with k vertices, and it is not difficult to show that $m_k = n_{k+1}$ for each $k \ge 1$. Now the integrator $\hat{\pi}_h$ in (3.2) is itself a Runge–Kutta method (provided that $\sum w_i = 1$), and standard Runge–Kutta theory can be used to show that $1 + n_1 + \cdots + n_l$ conditions on the parameters w_i are sufficient for $\hat{\pi}_h \in \mathbb{P}_l$, instead of the $1 + m_1 + \cdots + m_l = 1 + n_1 + \cdots + n_{l+1}$ conditions obtained from (3.5).

One could also consider the use of cheap postprocessors with different sets of values of the parameters w_i for different components of y. In that case, one needs only to impose (3.10) for the projection onto the corresponding component. Under certain assumptions, this also leads to a reduction in the number of conditions to be satisfied by the coefficients w_i. To be more specific, let us consider the following assumptions.

Assumption 3. For a certain j, there exists $r_j \in C^\infty(\mathbb{R}^D, \mathbb{R})$ such that for any $k \ge 1$ and $\Phi_k \in \mathcal{A}_k$, $\Phi_k[g_j]$ can be written as a linear combination of elements in $\mathcal{A}_{k-1}$ acting on r_j.

One can show that, under Assumption 3, $2 + (m_1 + \cdots + m_{l-1})$ conditions on the parameters w_i guarantee that (3.10) holds for $g = g_j$ (such conditions are independent of the actual function r_j).

Assumption 3 holds, in particular, for every component for Runge–Kutta methods, that is, for the graded free Lie algebra associated with the set of rooted trees considered in example (1.e). It also holds for the case of integrators in example (1.d), provided the basic second order symmetric method $\mathcal{S}_h$ is the implicit trapezoidal rule.

Assumption 4. For a certain j, there exists $r_j \in C^\infty(\mathbb{R}^D, \mathbb{R})$ such that for any $k \ge 2$ and $\Phi_k \in \mathcal{A}_k$, $\Phi_k[g_j]$ can be written as a linear combination of elements in $\mathcal{A}_{k-2}$ acting on r_j.

In a similar way, it can be shown that, under Assumption 4, $1 + m_1 + (1 + m_1 + \cdots + m_{l-2})$ conditions on the parameters w_i are sufficient for (3.10) to hold with $g = g_j$.

It can be seen that when $\mathcal{L}$ is the Lie algebra corresponding to Runge–Kutta–Nyström methods (example (1.e)), Assumption 4 holds for the components corre-

sponding to positions, while Assumption 3 holds for the velocity components.

For the case of integrators in example (1.d), if the basic second order symmetric method $\mathcal{S}_h$ is the Störmer–Verlet method, then again Assumption 3 holds for velocities, while Assumption 4 holds for positions.

3.2. Error propagation. Our purpose now is to analyze the propagation of the global error when the postprocessor is approximated by the linear combination $\hat{\pi}_h$ of intermediate values obtained in the computation of the kernel. As a general rule, the precision of the final results is not conditioned by the use of a very accurate postprocessor, whereas the error introduced by replacing the preprocessor π_h^{-1} by $\hat{\pi}_h^{-1}$ can grow significantly along the integration.

To justify this assertion, let us consider a postprocessor π_h in $\mathbb{P}_l$, with $l \geq q$, and q is the order of the processed integrator $\hat{\psi}_h$. After n steps we have

$$x_n = \hat{\psi}_h^n(x_0) = \pi_h \circ \psi_h^n \circ \pi_h^{-1}(x_0) = x(t_n) + e_{h,q}(n, x_0),$$

where $t_n = nh$ and $e_{h,q}(n, x_0)$ is the global error of the method. If $\hat{\pi}_h \in \mathbb{P}_k$, with $k < q$, is used as the postprocessor, then

$$\tilde{x}_n \equiv \hat{\pi}_h \circ \psi_h^n \circ \pi_h^{-1}(x_0) = \hat{\pi}_h \circ \pi_h^{-1} \circ \hat{\psi}_h^n(x_0) = x(t_n) + e_{h,q}(n, x_0) + \hat{\delta}_{h,k}(x_n).$$

Here $\hat{\delta}_{h,k} \equiv \hat{\pi}_h \circ \pi_h^{-1} - \mathrm{id} = \mathcal{O}(h^{k+1})$ is an error of local nature which in general can be bounded independently of n, while the global error typically grows as n increases. On the other hand, if $\hat{\pi}_h^{-1}$ is used as the preprocessor, then

$$\begin{aligned}\hat{x}_n &\equiv \pi_h \circ \psi_h^n \circ \hat{\pi}_h^{-1}(x_0) = \hat{\psi}_h^n \circ \pi_h \circ \hat{\pi}_h^{-1}(x_0) = \hat{\psi}_h^n(x_0 + \tilde{\delta}_{h,k}(x_0)) \\ &= x(t_n) + e_{h,q}(n, x_0) + \tilde{e}_{h,k}(n, x_0),\end{aligned}$$

where $\tilde{e}_{h,k}$ corresponds to the propagation of the initial error $\tilde{\delta}_{h,k} \equiv \pi_h \circ \hat{\pi}_h^{-1} - \mathrm{id} = \mathcal{O}(h^{k+1})$. Now the error term $\tilde{e}_{h,k}$ is not of local character and can grow significantly as n increases.

It is important to notice that when the kernel approximately preserves an integral of motion I and $\hat{\pi}_h$ is used as the postprocessor, the accuracy in the value of I can be reduced. Nevertheless, one must keep in mind that this corresponds to a local error which is not propagated and that, if required, one can always use a more precise approximation to the postprocessor at selected times.

4. Numerical experiments. In this section we examine how the processing technique with a cheap postprocessor behaves in practice. Our purpose, rather than providing a complete analysis of different processed methods, is just to illustrate the previous theoretical analysis on some specific examples. We consider a kernel with effective order six of the form (2.14) with $s = 11$ constructed and studied in [18, 19]. Its coefficients $\alpha_i = \alpha_{12-i}$ are collected in Table 4.1. Next we construct an approximation $\pi_h^{(c)} \in \mathbb{P}_6$ to the postprocessor π_h also as a composition of the second order integrator $\mathcal{S}_h$ at different stages. In particular, we take

$$\pi_h^{(c)} = \omega_h \circ \omega_{-h} \simeq \pi_h, \quad \text{with } \omega_h = \mathcal{S}_{\gamma_6 h} \circ \cdots \circ \mathcal{S}_{\gamma_1 h} \tag{4.1}$$

and coefficients γ_i, $i = 1, \ldots, 6$, given in Table 4.1. Finally, we consider the intermediate values (3.3) and solve equations (A.2) for the cheap postprocessor $\hat{\pi}_h \in \mathbb{P}_5$. The corresponding solution obtained by taking w_1, w_5, w_6, w_7 (in addition to w_0) as the nonzero coefficients is also collected in Table 4.1.

TABLE 4.1

Coefficients for the sixth order processed method with kernel ψ_h of the form (2.14) ($s = 11$) and postprocessors π_h and $\hat{\pi}_h$ given by (4.1) and (3.8), respectively.

$P_{11}6$		
$\alpha_1 = 0.1705768865009222157$	$\gamma_6 = -0.1$	$w_0 = 1 - 2(w_1 + w_5 + w_6 + w_7)$
$\alpha_2 = \alpha_1$	$\gamma_5 = 0.24687306977659$	$w_1 = 0.35601475536028$
$\alpha_3 = \alpha_1$	$\gamma_4 = 0.09086982276241$	$w_5 = 0.12246549694690$
$\alpha_4 = \alpha_1$	$\gamma_3 = 0.23651387483203$	$w_6 = 0.00415291514453$
$\alpha_5 = -0.4233661408926580 48$	$\gamma_2 = -0.20621953139126$	$w_7 = -0.20658995116781$
$\alpha_6 = 1 - 2(\alpha_1 + \cdots + \alpha_5)$	$\gamma_1 = -(\gamma_2 + \cdots + \gamma_6)$	

We recall that both $\pi_h^{(c)}$ and $\hat{\pi}_h$ are approximations to the postprocessor π_h. The map $\pi_h^{(c)}$ is built as a composition of the basic integrator $\mathcal{S}_h$ so that $\log(\pi_h^{(c)}) \in \mathcal{L}$, and $\hat{\pi}_h$ is taken as a linear combination of intermediate values used in the calculation of the kernel. From (4.1) we observe that the computational cost of $\pi_h^{(c)}$ is similar to that of the kernel, whereas $\hat{\pi}$ can be considered cost-free.

We compare this sixth order test integrator with other standard nonprocessed composition methods of the same family. In particular, we consider the well-known sixth order seven stages method "A" ($Y_7 6$) built by Yoshida [25] and the optimized sixth order nine stages method ($SS, m = 9$) of McLachlan [16] ($M_9 6$) (similar results are obtained with the sixth order nine stages method proposed by Kahan and Li [13]).

Numerical example 1. To illustrate how the error is propagated along the evolution when different approximations to the postprocessor are considered, we take the simple Lotka–Volterra problem

$$u' = u(v-2), \qquad v' = v(1-u), \tag{4.2}$$

which admits as first integral $I(u,v) = \ln(uv^2) - (u+v)$. Using logarithmic scale ($q = \ln v,\ p = \ln u$) the system becomes Hamiltonian with $H = p - e^p + 2q - e^q = T(p) + V(q)$. Equations (4.2) can be written as $x' = f_a(x) + f_b(x)$ with $x = (u,v)$, $f_a = (u(v-2), 0)$, $f_b = (0, v(1-u))$ so that the corresponding h-flows $\varphi_h^{[a]}$ and $\varphi_h^{[b]}$ can be exactly computed. We choose as second order time-symmetric integrator the composition $\mathcal{S}_h = \varphi_{h/2}^{[a]} \circ \varphi_h^{[b]} \circ \varphi_{h/2}^{[a]}$.

In the region $0 < u, v$ the system has periodic trajectories around $(u,v) = (1,2)$. We take $(u_0, v_0) = (1,1)$, integrate up to $t = 100 \times 2\pi$, and get outputs at $t = i \times 2\pi$, $i = 1, \ldots, 100$. In Figure 4.1(a) we present the global error for the processed schemes both using the accurate postprocessor $\pi_h^{(c)}$ of (4.1) (method $P_{11}6$) and the cheap approximation $\hat{\pi}_h$ ($P_{11}6C$) only for output. The results obtained are compared with $Y_7 6$ and $M_9 6$. The time steps selected are $h = \frac{1}{14}, \frac{1}{11}, \frac{1}{9}$, for $Y_7 6$, $M_9 6$, and $P_{11}6$, respectively, so that all methods require approximately the same number of evaluations. Figure 4.1(b) shows the error in the first integral $I(u,v)$ for $P_{11}6$ and $P_{11}6C$. In this case, for $1.9 < \log(t) \le 2$ the cheap postprocessor $\hat{\pi}_h$ is replaced by $\pi_h^{(c)}$ just to clearly show that this higher accuracy can always be recovered. If $P_{11}6C$ is started with $(\hat{\pi}_h)^{-1}$ instead of $(\pi_h^{(c)})^{-1}$, this accuracy would not have been restored.

From the figures we observe the following: (a) the processed integrator is clearly more accurate; (b) the results for the global error obtained using $\hat{\pi}_h$ approach asymptotically those given by $\pi_h^{(c)}$; (c) the error in $I(u,v)$ is higher when $\hat{\pi}_h$ is used, but it does not grow with time, and the more accurate results can always be retrieved using $\pi_h^{(c)}$ when desired.

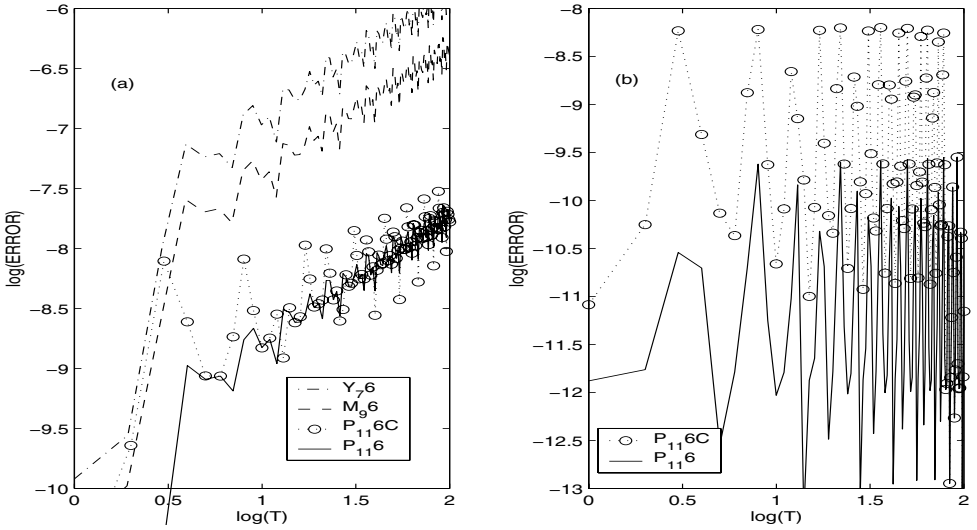

FIG. 4.1. (a) *Error in position and* (b) *error in the first integral* $I(u,v)$ *as functions of time for the Lotka–Volterra problem. The time step is chosen such that all methods require the same number of evaluations (this number corresponds to the kernel for the processed integrators).*

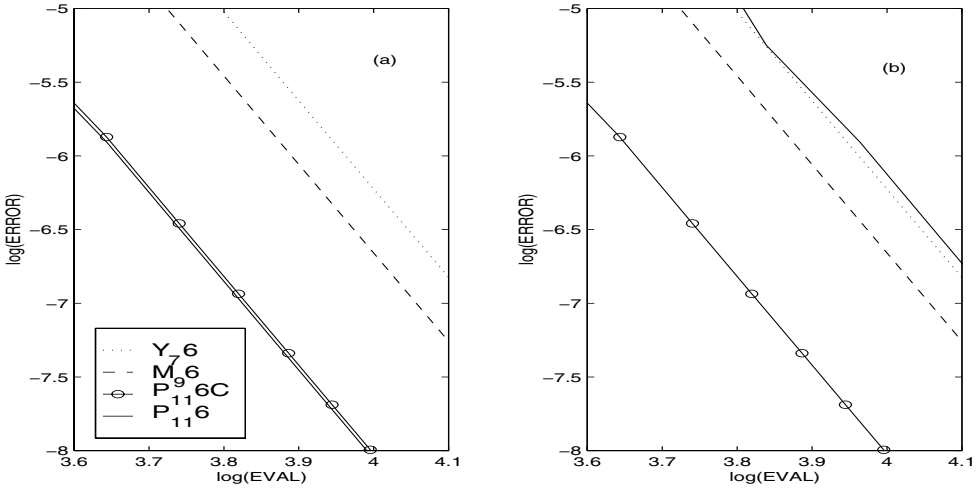

FIG. 4.2. *Average error in position versus number of evaluations for the first example* (a) *when the output is not frequent and* (b) *when the output is required at each step.*

Next we measure the average relative error in position versus the number of evaluations for different time steps and methods. Figure 4.2 shows the results (a) when the output is required only occasionally and (b) when it is required at each step. From this figure the importance of using a cheap postprocessor when the output is desired frequently is clear.

Numerical example 2. Let us consider now the ABC-flow [12], whose equations are given by

$$x' = B\cos y + C\sin z,$$

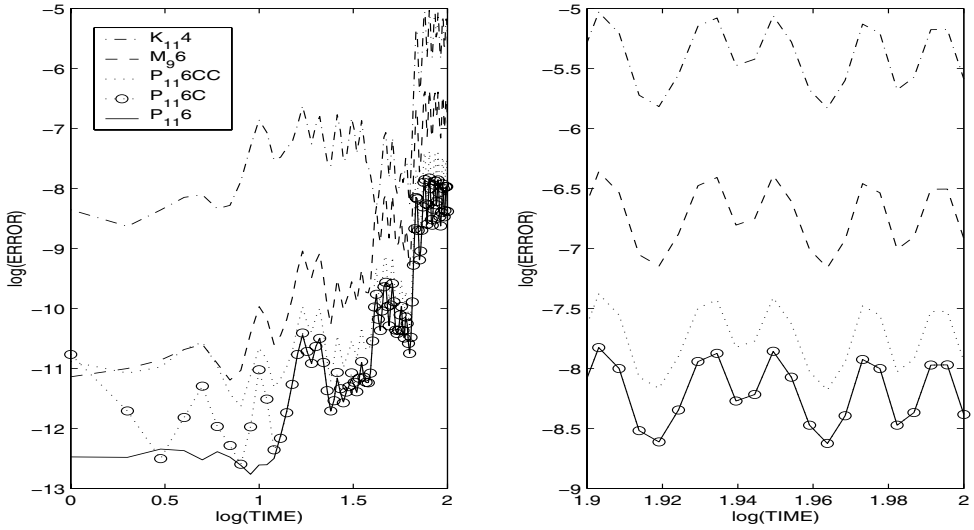

FIG. 4.3. *Error growth in position for the ABC-flow problem using a kernel* (2.14) *with coefficients in Table* 4.1 *and different pre- and postprocessors. The results obtained with the nonprocessed integrator* $\mathrm{M}_9 6$ *are also shown. The picture to the right is an enlargement of the rectangle* $[1.9, 2] \times [-9, -5]$ *in the left-hand picture.*

$$
\begin{aligned}
y' &= C\cos z + A\sin x,\\
z' &= A\cos x + B\sin y,
\end{aligned}
\tag{4.3}
$$

and the vector field is separable in three solvable parts, i.e.,

$$f = f_a + f_b + f_c = A(0, \sin x, \cos x) + B(\cos y, 0, \sin y) + C(\sin z, \cos z, 0).$$

We take as initial condition $(x_0, y_0, z_0) = (3.14, 2.77, 0)$, take as parameters $A = B = C = 1$, and integrate the system until $t = 100$. We choose as the basic symmetric second order integrator $\mathcal{S}_h = \chi_{h/2} \circ \chi^*_{h/2}$, where $\chi_h = \varphi_h^{[a]} \circ \varphi_h^{[b]} \circ \varphi_h^{[c]}$ and $\chi_h^* = \varphi_h^{[c]} \circ \varphi_h^{[b]} \circ \varphi_h^{[a]}$. In Figure 4.3 we show the error growth in the Euclidean norm when the following integrators based on $\mathrm{P}_{11}6$ are considered:

- ψ_h: only the kernel without the pre- and postprocessor (dash-dotted line, $\mathrm{K}_{11}4$);
- $\hat{\pi}_h \circ \psi_h \circ \hat{\pi}_h^{-1}$: the cheap pre- and postprocessors are employed (dotted line, $\mathrm{P}_{11}6\mathrm{CC}$);
- $\hat{\pi}_h \circ \psi_h \circ (\pi_h^{(c)})^{-1}$: we use the accurate preprocessor and the cheap postprocessor (circles joined by dotted lines, $\mathrm{P}_{11}6\mathrm{C}$);
- $\pi_h^{(c)} \circ \psi_h \circ (\pi_h^{(c)})^{-1}$: the accurate pre- and postprocessors are used (solid line, $\mathrm{P}_{11}6$).

We also include the results obtained using $\mathrm{M}_9 6$ (dashed line), choosing the time step such that the number of evaluations is the same as for the kernel. From the figure, it is clear that the kernel by itself is not good enough for giving accurate results (it is only a fourth order integrator). In addition we see that, at least for this problem, it is important to start the computation using a good preprocessor (some accuracy is lost when using $\hat{\pi}_h^{-1}$). Finally, we observe that after some time the results obtained using the cheap and the composition postprocessors agree up to drawing accuracy, but the former is faster to compute.

5. Concluding remarks. We have presented a general study of the processing technique which can be readily applied in several contexts. We obtain the number of order conditions and indicate how to find them explicitly in a systematic way. We have also presented a technique to find postprocessors virtually cost-free, just using intermediate results from the kernel. From the error propagation analysis we conclude that it is important to start the computation with an accurate preprocessor (even if it is expensive) and that, in general, a computationally cheap postprocessor can be safely used for ordinary intermediate output, although a more expensive postprocessor may be used, if required, to compute more accurate results at selected times.

An important application of the results contained in this paper is the construction of processed methods whose kernel is a composition of low order basic integrators. In that case, by analyzing the structure of the corresponding Lie algebra $\mathcal{L}$, it is possible to obtain approximations to the postprocessor either as a composition of basic methods or as a linear combination of intermediate stages of the kernel. In [2] this analysis is pursued in more detail for different families of composition methods, and new high order schemes are constructed which prove to be more efficient than other composition integrators available in the literature.

In practice, the efficient integration of systems of ODEs often requires the use of some step-size changing strategy. In principle, two possibilities can be contemplated. (i) Reparameterize the time variable in such a way that, with the new independent variable, a constant step-size can be used [12]. This is a familiar approach in geometric integration, and the theory developed here applies directly. (ii) Consider the problem of adapting the step-size in general terms, i.e., to construct processed methods whose step-size h changes to ρh, with $\rho \in [\rho_{\min}, \rho_{\max}]$ chosen according to some sort of local error estimation technique. This is the usual approach for general purpose integrators such as those based on explicit Runge–Kutta methods, and it is not suitable for geometric integration, as such standard variable step-size implementation destroys the geometric nature of the integration [22]. Although recently an adaptation of processing techniques to standard variable step-size strategies has been proposed in the Runge–Kutta context [9], this is largely an open problem which deserves further research.

Appendix A. Here we derive explicitly the effective order conditions up to order 6 for methods with kernel (2.14) and obtain the corresponding linear equations (3.9) for the cheap postprocessor (3.2). The series $S_h = I + \sum_{k\geq 1} h^k S_k$ of differential operators associated with the second order time-symmetric integrator $\mathcal{S}_h : \mathbb{R}^D \longrightarrow \mathbb{R}^D$ for (1.1) can be written as $S_h = \exp(Y_h)$, where $Y_h = hY_1 + h^3 Y_3 + h^5 Y_5 + \cdots$, and $Y_1 = F$. Then

$$\Psi_h = \exp(Y_{h\alpha_1}) \cdots \exp(Y_{h\alpha_s}). \tag{A.1}$$

By repeated application of the Baker–Campbell–Hausdorff formula one arrives at an expansion of $F_h = \log(\Psi_h) = hF_1 + h^3 F_3 + h^4 F_4 + \cdots$, with $h^k F_k \in \mathcal{L}_k$ for the graded Lie algebra $\mathcal{L} = \bigoplus_{k\geq 1} \mathcal{L}_k$ generated by the vector fields $\{Y_1, Y_3, Y_5, \ldots\}$. Here $n_1 = 1$, $n_2 = 0$, $n_k^* = n_k$ for $k \geq 2$, whence, according to Lemma 2.5, $F_2 = 0$, $P_1 = P_2 = 0$. A basis of $\mathcal{L}$ is given in Table A.1 up to $k = 6$.

The order conditions for the kernel and postprocessor up to order six in this basis read as

$$\begin{gathered} f_{1,1} = 1, \qquad f_{3,1} = 0, \qquad f_{5,1} = 0, \\ p_{4,1} = -f_{5,2}, \qquad p_{1,1} = p_{3,1} = p_{5,1} = p_{5,2} = 0. \end{gathered}$$

TABLE A.1
Basis of $\mathcal{L} = \bigoplus_{k\geq 1} \mathcal{L}_k$, the free Lie algebra generated by $\{hY_1, h^3Y_3, h^5Y_5, \ldots\}$.

	Basis of $\mathcal{L}$	
$\mathcal{L}_1$	$E_{1,1} = Y_1 = F$	
$\mathcal{L}_3$	$E_{3,1} = Y_3$	
$\mathcal{L}_4$	$E_{4,1} = [F, E_{3,1}]$	
$\mathcal{L}_5$	$E_{5,1} = Y_5$	$E_{5,2} = [F, E_{4,1}]$
$\mathcal{L}_6$	$E_{6,1} = [F, E_{5,1}]$	$E_{6,2} = [F, E_{5,2}]$

The basis for $\mathcal{L}_k$ presented in Table A.1 leads to the following basis in the universal enveloping algebra:

$$\begin{aligned}
&\mathcal{A}_1 : D_{1,1} = E_{1,1}, \qquad \mathcal{A}_2 : D_{2,1} = \frac{1}{2}E_{1,1}^2,\\
&\mathcal{A}_3 : D_{3,1} = E_{3,1}, \quad D_{3,2} = \frac{1}{3!}E_{1,1}^3,\\
&\mathcal{A}_4 : D_{4,1} = E_{4,1}, \quad D_{4,2} = \frac{1}{4!}E_{1,1}^4, \quad D_{4,3} = \frac{1}{2}(E_{1,1}E_{3,1} + E_{3,1}E_{1,1}).
\end{aligned}$$

The series of vector fields Π_h corresponding to the optimal processor is

$$\Pi_h = \exp(P_h) = \exp(h^4 p_{4,1}E_{4,1} + \mathcal{O}(h^6)) = I + h^4 p_{4,1}D_{4,1} + \mathcal{O}(h^6).$$

For the intermediate stages of the cheap approximation we take (3.3), or, equivalently,

$$\Phi_h^{(i)} = \exp(Y_{h\alpha_1}) \cdots \exp(Y_{h\alpha_i}) = \exp(hf_{1,1}^{(i)}E_{1,1} + h^3 f_{3,1}^{(i)}E_{3,1} + h^4 f_{4,1}^{(i)}E_{4,1} + \mathcal{O}(h^5)).$$

Then $\Phi_h^{(i)} + \Phi_h^{(-i)} = 2(I + \Phi_2^{(i)}h^2 + \Phi_4^{(i)}h^4 + \mathcal{O}(h^6))$, with

$$\Phi_2^{(i)} = \phi_{2,1}^{(i)}D_{2,1}, \qquad \Phi_4^{(i)} = (\phi_{4,1}^{(i)}D_{4,1} + \phi_{4,2}^{(i)}D_{4,2} + \phi_{4,3}^{(i)}D_{4,3}).$$

Here

$$\phi_{2,1}^{(i)} = (f_{1,1}^{(i)})^2, \qquad \phi_{4,1}^{(i)} = f_{4,1}^{(i)}, \qquad \phi_{4,2}^{(i)} = (f_{1,1}^{(i)})^4, \qquad \phi_{4,3}^{(i)} = f_{1,1}^{(i)}f_{3,1}^{(i)},$$

and

$$f_{1,1}^{(i)} = \sum_{j=1}^{i} \alpha_j; \qquad f_{3,1}^{(i)} = \sum_{j=1}^{i} \alpha_j^3; \qquad f_{4,1}^{(i)} = \frac{1}{2}\left(\sum_{j=1}^{i-1} \alpha_j \sum_{k=1}^{j} \alpha_k^3 - \sum_{j=1}^{i-1} \alpha_j^3 \sum_{k=1}^{j} \alpha_k\right)$$

with $f_{4,1}^{(1)} = 0$. Finally, (3.9) for $k = 2, 4$ leads to the following linear system of equations:

$$\text{(A.2)} \quad \sum_{i=1}^{s} \phi_{2,1}^{(i)} w_i = 0; \quad \sum_{i=1}^{s} \phi_{4,1}^{(i)} w_i = \frac{1}{2}p_{4,1}; \quad \sum_{i=1}^{s} \phi_{4,2}^{(i)} w_i = 0; \quad \sum_{i=1}^{s} \phi_{4,3}^{(i)} w_i = 0$$

so that $\hat{\pi}_h \in \mathbb{P}_5$.

DISCRETE DISPERSION RELATION FOR *hp*-VERSION FINITE ELEMENT APPROXIMATION AT HIGH WAVE NUMBER*

MARK AINSWORTH†

Dedicated to Professor Ian H. Sloan on the occasion of his sixty-fifth birthday

Abstract. The dispersive properties of high order finite element schemes are analyzed in the setting of the Helmholtz equation, and an explicit form of the discrete dispersion relation is obtained for elements of arbitrary order. It is shown that the numerical dispersion displays three different types of behavior, depending on the size of the order of the method relative to the mesh-size and the wave number. Quantitative estimates are obtained for the behavior and rates of decay of the dispersion error in the differing regimes. All estimates are fully explicit and are shown to be sharp. Limits are obtained, where transitions between the different regimes occur, and used to provide guidelines for the selection of the mesh-size and the polynomial order in terms of the wave number so that the dispersion error is controlled.

Key words. discrete dispersion relation, high wave number, *hp*-finite element method

1. Introduction.

Wave propagation phenomena arising in practical applications typically require large wave number (or frequency) ω. Accurate numerical simulation of such applications is thwarted by a number of issues, perhaps the most acute of which is numerical dispersion. This refers to the effect whereby the numerical scheme fails to propagate waves at the correct speed, resulting in a phase lead or lag in the numerical approximation. Numerical dispersion is often responsible not only for poor resolution but also for approximations that are even qualitatively incorrect.

Finite elements are often the method of choice for engineers interested in problems of continuum mechanics posed over complicated domains. It is therefore not surprising that finite elements are frequently used in numerical wave propagation [3]. The importance of numerical dispersion is widely recognized and is often used in assessing the quality of a numerical scheme and as a basis for ranking different finite element methods. For instance, Harari [16, 17], Harari and Avraham [18], and Harari and Hughes [19] consider the use of stabilized and Galerkin least squares finite element formulations for combatting the problem of dispersion in the solution of acoustic scattering problems, typically in the context of low order finite elements. Abboud and Pinsky [1] and Oberai and Pinsky [25] also study the discrete dispersive properties of various lower order finite element methods (such as the 8-node trilinear element, 20-node serendipity, 27-node triquadratic element) for the approximation of the scalar wave equation in three dimensions. More recently, Christon [6] considered the dispersive behavior of a variety of finite element schemes for the second order wave equation and performed a computational study of the discrete phase and group velocities.

The work of this author was supported in part by the Engineering and Physical Sciences Research Council of Great Britain under grant GR/M59426. This work was completed while the author was visiting the Newton Institute for Mathematical Sciences, Cambridge, UK.

The advantages of using higher order elements have also been widely recognized. For example, Harari and Avraham [18] compare the efficiency of first and second order elements for the solution of acoustic scattering problems and view their work as justifying the extension of the ideas to higher order (p-version) finite elements. Thompson and Pinsky [29] study the dispersive and attenuation properties of finite elements up to fifth order for the one-dimensional scalar Helmholtz equation and, on the basis of numerical evidence, conjecture that elements of degree p provide a $2p$th order accurate approximation of the dispersion relation in the limit where ωh tends to zero.

Applications are not confined to applications in acoustic scattering; for instance, Dyson [12] proposes the use of high (up to fifteenth) order schemes for propagation of waves for Euler equations. Cohen and Monk [7], Cohen [9], and Monk and Parrott [24] have considered the dispersive behavior of lower order finite element methods for Maxwell's equations. The use of high order finite element and spectral element schemes for the approximation of Maxwell's equations has attracted much interest [10, 20].

The first systematic study of the properties of finite element methods for high wave number applications was carried out in a series of papers by Babuška and Ihlenburg. In [4, 21], the convergence properties in the H^1-norm of first order finite elements for the one-dimensional model Helmholtz problem are studied working under the assumption that $\omega h < 1$. These ideas are extended to higher dimensions by Deraemaeker, Babuška, and Bouillard [11], who undertake a numerical study of the dispersive behavior for various finite element formulations in higher dimensions that allow one to include topological effects of the meshes, while Gerdes and Ihlenburg [14] study convergence of an h-version Galerkin finite element method for a three-dimensional problem of rigid scattering with mesh refinement in the radial direction and show that the error bound contains pollution effects similar to those observed in the one-dimensional analysis. A detailed study of the dispersion and approximation behavior of hp-finite elements for the Helmholtz equation in one dimension is undertaken by Ihlenburg and Babuška [22].

Despite extensive investigations, several important issues concerning the dispersive properties of standard finite element schemes remain unresolved, particularly in the context of high order elements. The aim of the present work is to give a sharp analysis of the dispersive properties of high order finite element schemes in the setting of the Helmholtz equation, to identify thresholds (relating the order p of the method and the mesh-size h to the wave number ω) where the dispersion error begins to decay, and to obtain sharp quantitative estimates on the rates of decay of the error in the differing regimes. A clear understanding of the dispersive properties of a scheme is not only of academic interest. Accurate quantitative information on the dispersion effects can serve as a practical guideline for the construction of a mesh and a polynomial order that will lead to a reasonable first approximation.

The analysis hinges on knowledge of an explicit form for the discrete dispersion relation valid for elements of arbitrary order. This is obviously a valuable tool for the study of numerical dispersion and, to the best of our knowledge, has not been obtained before. We derive a neat closed form expression for the discrete dispersion relation for elements of arbitrary order in terms of Padé approximants.

We study the behavior of the error in the discrete dispersion relation in two important limits: (i) in the small wave number limit, where $\omega h \ll 1$, where we provide a confirmation of the conjecture of Thompson and Pinsky [29]; and (ii) in the important practical case of high wave number, where $\omega h \gg 1$. The analysis provides a concrete guideline for choosing the order p of the elements and the mesh-size h in

order that the dispersion error is virtually eliminated:

$$p + \frac{1}{2} > \frac{\omega h}{2} + C(\omega h)^{1/3}, \tag{1.1}$$

where C is a constant which may in practice be chosen to be unity. In fact, when p is increased in this regime, the error decays at a superexponential rate, and an explicit expression for the error is given. In the limit where p is much larger than $\omega h/2$, the expression decays as $(\omega he/2(2p+1))^{2p+1}$, which is compatible with the upper bounds derived by Ihlenburg and Babuška [22]. More importantly, criterion (1.1) is shown to be sharp in the sense that if p does not satisfy (1.1), i.e., if

$$p + \frac{1}{2} < \frac{\omega h}{2} - o(\omega h)^{1/3},$$

then the dispersion error will not decay and may even increase significantly as the order p is increased. These results show that there is essentially no preasymptotic error reduction, which one might have expected based on the analysis for the positive definite case [28]. Strictly speaking, the error does begin to decay when p enters the transition zone:

$$p + \frac{1}{2} \in \left(\frac{\omega h}{2} - o(\omega h)^{1/3}, \frac{\omega h}{2} + o(\omega h)^{1/3} \right).$$

However, it is shown that the decay in this phase is only algebraic: $\mathcal{O}(p^{-1/3})$, and the comparatively narrow transition zone means that the preasymptotic decay is too short-lived to be of any real practical significance.

The results obtained here improve on the upper bounds given in [22]. In particular, all estimates are given explicitly and do not involve generic constants. This enables us to show that these estimates are the best ones possible. Our analysis is restricted to schemes of uniform order on tensor product meshes. Nevertheless, this type of scheme is used locally in regions remote from the scatterer, where the main issue is to control numerical dispersion. Equally well, our analysis deals only with the issue of numerical dispersion. The actual accuracy of the approximation is a separate issue which is considered by Ihlenburg and Babuška [22], where it is shown that the accuracy of the finite element approximation error in the H^1-norm will be quasi-optimal only if $\omega^{2p+1}h^{2p}$ is sufficiently small.

The remainder of this article is organized as follows. First, we review the standard framework leading to the derivation of the discrete dispersion relation in the setting of the wave equation in one dimension and describe the relevance of this to the multidimensional case, where tensor product meshes are used. The main results are outlined in the following section. The remaining sections deal with the technical details and proofs of the results.

2. The discrete dispersion relation.

2.1. The setting. It is well known that the general solution of the homogeneous wave equation in one space dimension,

$$\frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial x^2} = 0,$$

can be expressed as a superposition of plane waves in the form

$$u(x,t) = \int_{\mathbb{R}} \left[a(k)e^{i(kx+\omega t)} + b(k)e^{i(kx-\omega t)} \right] \mathrm{d}k$$

for suitable functions a and b, where ω and k are related by the *dispersion relation*

$$\omega^2 = k^2.$$

Suppose that a uniform grid of size $h > 0$ is placed on the real line with nodes located at $h\mathbb{Z}$, and let V_h denote the set of continuous piecewise linear functions relative to the grid. By analogy with the continuous problem, we may seek solutions of the form

$$u_h(x,t) = e^{i\omega t} U_h(x) \tag{2.1}$$

so that $U_h \in V_h$ must satisfy

$$B_\omega(U_h, v_h) = 0 \quad \forall v_h \in V_h, \tag{2.2}$$

where

$$B_\omega(U_h, v_h) = (U_h', v_h') - \omega^2 (U_h, v_h)$$

and $(\cdot,\cdot)$ denotes the L_2-inner product on $\mathbb{R}$.

The invariance of the grid under translation by h prompts us to seek Bloch wave [26] solutions of the homogeneous (2.2) in the form

$$U_h(x) = \alpha \sum_{m\in\mathbb{Z}} e^{imkh} \theta_m(x), \tag{2.3}$$

where α and k are constants to be determined. Here, θ_m are the usual piecewise linear hat functions defined by

$$\theta_m(nh) = \delta_{mn}, \quad m, n \in \mathbb{Z}. \tag{2.4}$$

The translation invariance of the grid means that

$$\theta_m(x + nh) = \theta_{m-n}(x), \quad x \in \mathbb{R},\ n \in \mathbb{Z},$$

which in turn implies that U_h has the characteristic property of a Bloch wave: for each $n \in \mathbb{Z}$,

$$U_h(x + nh) = e^{iknh} U_h(x), \quad x \in \mathbb{R}. \tag{2.5}$$

This means that (2.2) is equivalent to the condition

$$B_\omega(U_h, \theta_0) = 0,$$

or, inserting the expression (2.3) for U_h,

$$\alpha \sum_{m\in\mathbb{Z}} e^{imkh} B_\omega(\theta_m, \theta_0) = 0.$$

Hence, a nontrivial Bloch wave exists, provided that

$$\sum_{m\in\mathbb{Z}} e^{imkh} B_\omega(\theta_m, \theta_0) = 0.$$

This expression may be simplified further using properties of the hat functions giving

$$e^{-ikh} B_\omega(\theta_{-1}, \theta_0) + B_\omega(\theta_0, \theta_0) + e^{ikh} B_\omega(\theta_1, \theta_0) = 0,$$

and, again by exploiting translation invariance of the grid, we obtain the *discrete dispersion relation*

$$2\cos(kh)B_\omega(\theta_1,\theta_0)+B_\omega(\theta_0,\theta_0)=0. \tag{2.6}$$

We refer to (2.6) as the dispersion relation for the following reason. For the first order standard Galerkin scheme considered above, we find that

$$B_\omega(\theta_0,\theta_0)=\frac{2}{h}\left(1-\frac{1}{3}\omega^2h^2\right),\qquad B_\omega(\theta_1,\theta_0)=-\frac{1}{h}\left(1+\frac{1}{6}\omega^2h^2\right),$$

and the discrete dispersion relation simplifies to give the well-known result,

$$kh=\cos^{-1}\left(\frac{6-2\omega^2h^2}{6+\omega^2h^2}\right)=\omega h-\frac{1}{24}(\omega h)^3+\cdots.$$

Here, we have adopted the common practice whereby kh is compared directly with ωh. However, examining (2.5) reveals that the value of $\exp(ikh)$ compared with $\exp(i\omega h)$ is actually of more physical relevance in the study of phase lag or lead. Of course, if both kh and ωh are small, then $\exp(ikh)-\exp(i\omega h)$ is closely related to $kh-\omega h$, and it makes sense to compare k and ω directly. However, we shall later be concerned with the regime $\omega h\gg 1$, and we shall therefore seek to compare $\exp(ikh)$ with $\exp(i\omega h)$. More precisely, we shall derive estimates for the difference $\cos(kh)-\cos(\omega h)$.

2.2. Extension to high order schemes. The discrete dispersion relation for higher order schemes may be obtained by modifying the previous arguments. Let V_{hp} denote the set of continuous piecewise polynomials of degree p on the grid $h\mathbb{Z}$, and let $V_{hp}^\flat$ denote the subspace

$$V_{hp}^\flat=\{v_{hp}\in V_{hp}: v_{hp}(mh)=0,\ m\in\mathbb{Z}\}.$$

As before, we seek a Bloch wave solution $U_{hp}\in V_{hp}$ satisfying

$$B_\omega(U_{hp},v_{hp})=0\quad\forall v_{hp}\in V_{hp}.$$

Accordingly, we write U_{hp} in the form

$$U_{hp}(x)=\sum_{m\in\mathbb{Z}}e^{ikmh}[\alpha\theta_m^{(p)}(x)+\beta\psi^{(p)}(x-mh)], \tag{2.7}$$

where α and β are constants, and $\psi^{(p)}\in V_{hp}^\flat$ is supported on $(0,h)$. By analogy with (2.4), the function $\theta_m^{(p)}\in V_{hp}$ has nodal values given by

$$\theta_m^{(p)}(nh)=\delta_{mn},\quad m,n\in\mathbb{Z}, \tag{2.8}$$

but is instead extended to the element interiors as a polynomial of degree p by requiring that

$$B_\omega(\theta_m^{(p)},v_{hp})=0\quad\forall v_{hp}\in V_{hp}^\flat. \tag{2.9}$$

This amounts to a decoupling of the nodal and interior degrees of freedom through Gaussian elimination or static condensation.

If ω does not correspond to a discrete eigenvalue, then $\theta_m^{(p)}$ is uniquely defined by this condition. It is not difficult to show that the function U_{hp} satisfies the Bloch wave condition: for all $n \in \mathbb{Z}$,

$$U_{hp}(x + nh) = e^{iknh} U_{hp}(x), \quad x \in \mathbb{R}.$$

Consequently, exploiting translation invariance of the grid, it suffices to require

$$\left.\begin{aligned} B_\omega(U_{hp}, \theta_0^{(p)}) &= 0 \\ B_\omega(U_{hp}, \psi^{(p)}) &= 0 \end{aligned}\right\}.$$

By inserting the expression (2.7) for U_{hp} into the latter equation, using (2.9) and the fact that ω does not correspond to a discrete eigenvalue, we conclude that $\psi^{(p)}$ must vanish identically. Consequently, the expression (2.7) collapses to the form considered in the case of first order schemes,

$$U_{hp}(x) = \alpha \sum_{m \in \mathbb{Z}} e^{ikmh} \theta_m^{(p)}(x), \tag{2.10}$$

and, by analogy with (2.6), the higher order discrete dispersion relation assumes the form

$$2\cos(kh) B_\omega(\theta_1^{(p)}, \theta_0^{(p)}) + B_\omega(\theta_0^{(p)}, \theta_0^{(p)}) = 0. \tag{2.11}$$

The same expression was obtained by Babuška and Ihlenburg [4] and Ihlenburg and Babuška [22]. A detailed study of the discrete dispersion relation for higher order elements is postponed until the next section.

2.3. Relevance to multidimensional problems. Information on the discrete dispersion relation for the scalar Helmholtz equation in one dimension may be used to derive explicit forms for the discrete dispersion relation for finite element approximation of problems in higher dimensions on tensor product meshes. Here, we describe the case of the wave equation in detail. An extension of the argument to the approximation of Maxwell equations using Nédélec elements may be found in [2].

Consider the wave equation in d-dimensions,

$$\frac{1}{c^2} \frac{\partial^2 u}{\partial t^2} - \Delta u = 0,$$

and assume that a tensor product grid $h\mathbb{Z}^d$ is introduced on $\mathbb{R}^d$. Let V_{hp} denote the space of piecewise polynomials of total degree p in each variable on the grid; then seeking a discrete solution of the form (2.1) leads to the problem of determining $U_{hp} \in V_{hp}^{(d)}$ such that

$$\sum_{r=1}^{d} \left(\frac{\partial U_{hp}}{\partial x_r}, \frac{\partial v_{hp}}{\partial x_r} \right) - \kappa^2 (U_{hp}, v_{hp}) = 0 \quad \forall v_{hp} \in V_{hp}^{(d)}.$$

The tensor product structure prompts us to seek a solution of the form

$$U_{hp}(x_1, \ldots, x_d) = \alpha \prod_{r=1}^{d} X_p(k_r; x_r),$$

where α is a constant, and

$$X_p(k;s) = \sum_{m\in\mathbb{Z}} e^{imkh}\phi_m^{(p)}(s), \tag{2.12}$$

with $\phi_m^{(p)}$ defined as above. In particular, we recall that $X_p(k_r) \in V_{hp}$ satisfies

$$(X_p'(k_r), v') - \kappa_r^2(X_p(k_r), v) = 0 \quad \forall v \in V_{hp}, \tag{2.13}$$

where κ_r is related to k_r by the discrete dispersion relation (2.11).

Choosing the test function v_{hp} to be a product of one-dimensional functions $\prod v_r$ leads to the following necessary condition for the existence of nontrivial solutions:

$$\sum_{q=1}^{d}(\Phi_p'(k_q), v_q')\prod_{r\neq q}(X_p(k_r), v_r) - \kappa^2\prod_{r=1}^{d}(X_p(k_r), v_r) = 0.$$

Therefore, in view of (2.13), we obtain

$$\left(\sum_{r=1}^{d}\kappa_r^2 - \kappa^2\right)\prod_{q=1}^{d}(X_p(k_q), v_q) = 0,$$

and it follows that the discrete dispersion relation for the multidimensional scheme is given by

$$\sum_{r=1}^{d}\kappa_r^2 = \kappa^2, \tag{2.14}$$

where κ_r is related to k_r by the discrete dispersion relation (2.11). An alternative proof of this result for Gauss point mass lumped finite element schemes may be found in [9, p. 228]. The above argument extends immediately to these schemes.

3. Higher order discrete dispersion relation. An explicit expression for the higher order dispersion relation could, at least in principle, be derived by proceeding directly as in the first order case. Unfortunately, such a direct computation rapidly becomes intractable with increasing order, as pointed out in [9], and the general result might seem to be unattainable. In section 4, we prove that the discrete dispersion relation is given explicitly in terms of Padé approximants [5].

THEOREM 3.1. *Suppose $p \in \mathbb{N}$, and define set $N_e = \lfloor p/2\rfloor$ and $N_o = \lfloor (p+1)/2\rfloor$. Let $[2N_e + 2/2N_e]_{\kappa\tan\kappa}$ and $[2N_o/2N_o - 2]_{\kappa\cot\kappa}$ denote the Padé approximants to $\kappa\tan\kappa$ and $\kappa\cot\kappa$, respectively. Then the discrete dispersion relation is given by*

$$\cos(kh) = R_p(h\omega), \tag{3.1}$$

where R_p is the rational function

$$R_p(2\kappa) = \frac{[2N_o/2N_o - 2]_{\kappa\cot\kappa} - [2N_e + 2/2N_e]_{\kappa\tan\kappa}}{[2N_o/2N_o - 2]_{\kappa\cot\kappa} + [2N_e + 2/2N_e]_{\kappa\tan\kappa}}. \tag{3.2}$$

Despite the apparent simplicity, this result has been hitherto unknown in the literature, although special cases for lower order elements can be found in many sources. Table 3.1 shows the discrete dispersion relation and the leading term in the error in

TABLE 3.1
Discrete dispersion relation $\cos(kh) = R_p(\omega h)$ *for order* p *approximation given in Theorem* 3.1. *The leading term in the series expansion for the error when* $\Omega \ll 1$ *(see Theorem* 3.2*) is also indicated.*

Order p	$R_p(\Omega)$	$\cos^{-1} R_p(\Omega) - \Omega$
1	$\dfrac{-2\Omega^2+6}{\Omega^2+6}$	$-\dfrac{\Omega^3}{24}$
2	$\dfrac{3\Omega^4-104\Omega^2+240}{\Omega^4+16\Omega^2+240}$	$-\dfrac{\Omega^5}{1440}$
3	$\dfrac{-4\Omega^6+540\Omega^4-11520\Omega^2+25200}{\Omega^6+30\Omega^4+1080\Omega^2+25200}$	$-\dfrac{\Omega^6}{201600}$
4	$\dfrac{5\Omega^8-1800\Omega^6+134064\Omega^4-2378880\Omega^2+5080320}{\Omega^8+48\Omega^6+3024\Omega^4+161280\Omega^2+5080320}$	$-\dfrac{\Omega^7}{50803200}$

the dispersion relation for methods of order $p = 1$ to $p = 4$. For example, in the case of first order approximation $p = 1$,

$$\cos(kh) = R_1(\omega h) = \frac{6 - 2\omega^2 h^2}{6 + \omega^2 h^2},$$

which agrees with the result obtained for first order approximation in the previous section.

3.1. Accuracy at small wave numbers. The following general result for the leading term for the error in the dispersion relation, valid for wave numbers satisfying $\omega h \ll 1$, is proved in section 4.

THEOREM 3.2. *Let* $p \in \mathbb{N}$. *Then the error in the discrete dispersion relation is given by*

$$\cos kh - \cos \omega h = \frac{1}{2}\left[\frac{p!}{(2p)!}\right]^2 \frac{(\omega h)^{2p+2}}{2p+1} + \mathcal{O}(\omega h)^{2p+4} \tag{3.3}$$

or, if kh *is sufficiently small,*

$$kh - \omega h = -\frac{1}{2}\left[\frac{p!}{(2p)!}\right]^2 \frac{(\omega h)^{2p+1}}{2p+1} + \mathcal{O}(\omega h)^{2p+3}. \tag{3.4}$$

The result implies that

$$\frac{k}{\omega} - 1 = \mathcal{O}\left(\omega h\right)^{2p}, \tag{3.5}$$

meaning that the dispersion relation for a pth order scheme is accurate to order $2p$. This is consistent with the conjecture made by Thompson and Pinsky [29, eq. (41)] on the basis of numerical evidence in the particular cases of elements of order $p = 1$ to $p = 5$.

3.2. Accuracy at large wave numbers. While error estimates for small values of ωh are not without interest, the most interesting case in practice is the high wave number limit, where the practical limitations on the size of mesh means that product ωh is large even though h is small. The next result describes the behavior of the error as the order of approximation p is increased so that both p and ωh are large.

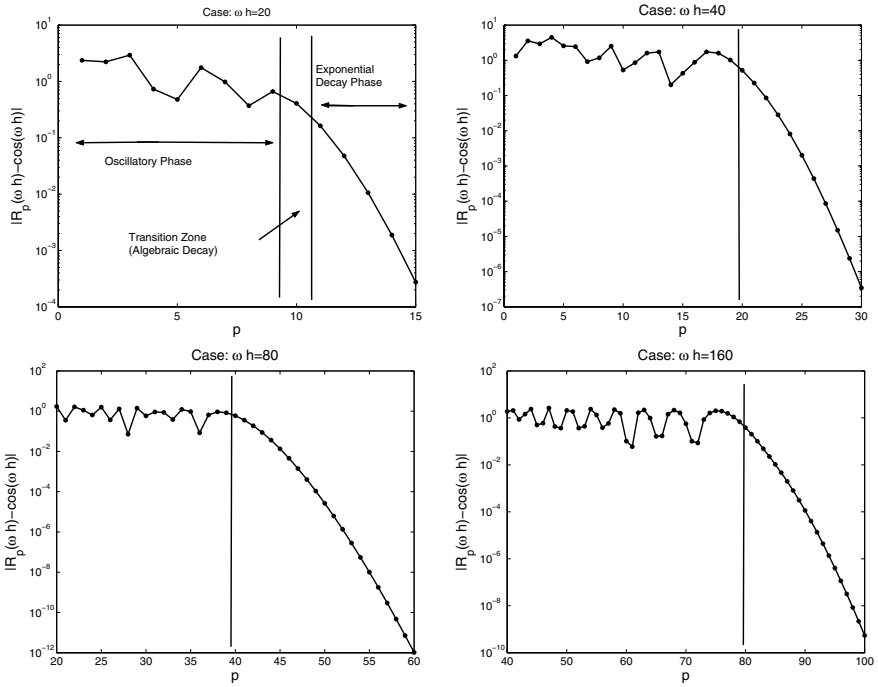

FIG. 3.1. *Behavior of error in the discrete dispersion relation for high wave numbers $\omega h \gg 1$ as the order p is increased. The transition region between the oscillatory phase and the superexponential decay of the error is indicated in each case (cf. Theorem* 3.3*).*

THEOREM 3.3. *Suppose that $\omega h \gg 1$. Then the error $\mathcal{E}^p = \cos kh - \cos \omega h$ in the discrete dispersion relation passes through three distinct phases as the order $p \in \mathbb{N}$ is increased*:

1. *Oscillatory phase: For $2p+1 < \omega h - o(\omega h)^{1/3}$, $\mathcal{E}^p$ oscillates, but does not decay, as p is increased.*

2. *Transition zone: For $\omega h - o(\omega h)^{1/3} < 2p+1 < \omega h + o(\omega h)^{1/3}$, the error $\mathcal{E}^p$ decays algebraically at a rate $\mathcal{O}(p^{-1/3})$.*

3. *Superexponential decay: For $2p+1 > \omega h + o(\omega h)^{1/3}$, $\mathcal{E}^p$ decreases at a superexponential rate:*

$$\mathcal{E}^p \approx \frac{\sin(\omega h)}{2} f(\sqrt{1-(\omega h/(2p+1))^2})^{p+1/2}, \tag{3.6}$$

where $f : w \to (1-w)/(1+w)\exp(2w)$, so that in the case where $2p+1 > \omega he/2$ with $e = \exp(1)$,

$$\mathcal{E}^p \approx \frac{\sin(\omega h)}{2}\left[\frac{\omega he}{2(2p+1)}\right]^{2p+1}. \tag{3.7}$$

Observe that the term appearing in parentheses in (3.6) has a magnitude less than unity, which follows from the fact that the function $f : w \to (1-w)/(1+w)\exp(2w)$ is nonnegative and monotonic decreasing on $[0,1]$ and the observation that $f(0) = 1$.

Figure 3.1 shows the behavior of the actual error as the order p is increased for a range of values of ωh. The oscillatory region and the transition to the superexponential decay in the error described in Theorem 3.3 can be clearly discerned.

Theorem 3.3 provides clear guidelines for the construction of meshes and the choice of order for the numerical resolution of waves using finite elements. In order to ensure that the dispersion error is for all practical purposes virtually eliminated, it is desirable that we work in the superexponential regime. For this reason, it is recommended to choose the order p and the mesh-size h so that

$$2p + 1 > \omega h + C(\omega h)^{1/3}, \tag{3.8}$$

where C is some fixed constant, which may be chosen to be unity in practice. The numerical results shown in Figure 3.1 support this criterion. It is interesting that the same type of criterion is arrived at for the choice of the number of terms to be used in the implementation of the fast multipole method for scattering problems [23, eq. (3.38)].

4. Proofs of the results.

4.1. Basic polynomials.

Let $\widehat{B}$ denote the bilinear form

$$\widehat{B}(u, v) = \int_{-1}^{1} \left(u'v' - \kappa^2 uv \right) \, \mathrm{d}s,$$

where $\kappa > 0$ is a constant. We introduce the basic polynomials, Φ_o^p and Φ_e^p, of degree at most $p \in \mathbb{N}$ satisfying

$$\Phi_e^p(\pm 1) = 1 : \quad \widehat{B}(\Phi_e^p, v) = 0 \quad \forall v \in \mathbb{P}_p \cap H_0^1(-1, 1) \tag{4.1}$$

and

$$\Phi_o^p(\pm 1) = \pm 1 : \quad \widehat{B}(\Phi_o^p, v) = 0 \quad \forall v \in \mathbb{P}_p \cap H_0^1(-1, 1). \tag{4.2}$$

Throughout, it will be assumed that κ does not coincide with an eigenvalue for this problem so that the polynomials are defined uniquely by these conditions.

It is easy to see that Φ_o^p and Φ_e^p are odd and even functions, respectively. The first result gives explicit closed forms for the expressions $\widehat{B}(\Phi_o^p, \Phi_o^p)$ and $\widehat{B}(\Phi_e^p, \Phi_e^p)$, which will be needed later.

THEOREM 4.1. *Let $p \in \mathbb{N}$ satisfy $p \geq 2$. Then*

1. *if $\kappa \neq (m + 1/2)\pi$ for all $m \in \mathbb{Z}$,*

$$\widehat{B}(\Phi_e^p, \Phi_e^p) = 2\kappa \frac{J_{2N+3/2}(\kappa) \cos \kappa + Y_{2N+3/2}(\kappa) \sin \kappa}{J_{2N+3/2}(\kappa) \sin \kappa - Y_{2N+3/2}(\kappa) \cos \kappa}, \tag{4.3}$$

where J and Y are cylindrical Bessel functions of the first and second kind, $N = \lfloor p/2 \rfloor$, and $\lfloor \cdot \rfloor$ denotes the integer part;

2. *if $\kappa \neq m\pi$ for all $m \in \mathbb{Z}$,*

$$\widehat{B}(\Phi_o^p, \Phi_o^p) = -2\kappa \frac{J_{2N+1/2}(\kappa) \sin \kappa - Y_{2N+1/2}(\kappa) \cos \kappa}{J_{2N+1/2}(\kappa) \cos \kappa + Y_{2N+1/2}(\kappa) \sin \kappa}, \tag{4.4}$$

where $N = \lfloor (p + 1)/2 \rfloor$.

Proof. Symmetry arguments reveal that the function Φ_e^p is an even order polynomial of degree $2N$, where $N = \lfloor p/2 \rfloor$. For the remainder of the proof superscripts will

be omitted since no confusion is likely to arise. Using definition (4.1) and integrating by parts shows that

$$\int_{-1}^{1} \left(\Phi_e'' + \kappa^2 \Phi_e\right) v \, \mathrm{d}x = 0 \quad \forall v \in \mathbb{P}_{2N} \cap H_0^1(-1,1).$$

The term in parentheses is a polynomial of degree $2N$, which may be written in the form

$$\Phi_e'' + \kappa^2 \Phi_e = \sum_{k=1}^{2N+1} \mu_k L_k'(x)$$

for suitable scalars μ_k, where L_k is the Legendre polynomial [15] of degree k. Inserting $v = (1-x^2)L_k'(x)$, with $j = 1, 2, \ldots, 2N-1$, and recalling the orthogonality property [15]

$$\int_{-1}^{1} (1-x^2) L_j'(x) \, L_k'(x) \, \mathrm{d}x = 0 \quad \text{for } j \neq k,$$

leads to the conclusion $\mu_j = 0$ for $j = 1, 2, \ldots, 2N-1$. Furthermore, the fact that L_{2N}' is an odd function and a parity argument shows that $\mu_{2N} = 0$. Hence,

$$\Phi_e'' + \kappa^2 \Phi_e = \mu_{2N+1} L_{2N+1}'. \tag{4.5}$$

It is not difficult to verify that the function w_{2N} defined by

$$w_{2N}(x) = \sum_{j=0}^{N} \left(-\frac{1}{\kappa^2}\right)^{j+1} L_{2N+1}^{(2j+1)}(x) \tag{4.6}$$

is a polynomial of degree $2N$ satisfying

$$w_{2N}'' + \kappa^2 w_{2N} = -L_{2N+1}'.$$

Consequently, Φ_e may be written in the form

$$\Phi_e(x) = \frac{w_{2N}(x)}{w_{2N}(1)},$$

provided that $w_{2N}(1)$ is nonzero, and, moreover, inserting this form into (4.5) reveals that

$$\mu_{2N+1} = -1/w_{2N}(1).$$

With the aid of these results, we obtain

$$\begin{aligned}
\widehat{B}(\Phi_e, \Phi_e) &= \left[\Phi_e' \Phi_e\right]_{-1}^{1} - \int_{-1}^{1} \Phi_e \left(\Phi_e'' + \kappa^2 \Phi_e\right) \mathrm{d}x \\
&= 2\Phi_e'(1) - \mu_{2N+1} \int_{-1}^{1} \Phi_e L_{2N+1}' \, \mathrm{d}x \\
&= 2\Phi_e'(1) - \mu_{2N+1} \left[\Phi_e L_{2N+1}\right]_{-1}^{1} \\
&= 2\left(\Phi_e'(1) - \mu_{2N+1}\right) \\
&= \frac{2}{w_{2N}(1)} \left(1 + w_{2N}'(1)\right),
\end{aligned}$$

where standard properties of Legendre polynomials have been used, such as the fact that L_{2N+1} is orthogonal to any polynomial of lower degree with respect to the $L_2(-1,1)$ inner product and that $L_{2N+1}(\pm 1) = \pm 1$. The values of w and its derivative at $x = 1$ are given by the following formula, which is obtained using $(8.910)_2$ in [15]:

$$L_n^{(d)}(\pm 1) = \begin{cases} \dfrac{(n+d)!}{d!(n-d)!}\dfrac{(\pm 1)^{d+n}}{2^d} & \text{for } d = 0, \dots, n, \\ 0 & \text{otherwise,} \end{cases} \tag{4.7}$$

giving, after some manipulation,

$$1 + w'_{2N}(1) = a_{2N+1} \tag{4.8}$$

and

$$w_{2N}(1) = -b_{2N+1}/\kappa. \tag{4.9}$$

Here, a_n and b_n are the expressions defined, for nonnegative integers n, by

$$a_n = \sum_{k=0}^{\lfloor n/2 \rfloor} \frac{(-1)^k}{(2k)!}\frac{(n+2k)!}{(n-2k)!}\frac{1}{(2\kappa)^{2k}} \tag{4.10}$$

and

$$b_n = \sum_{k=0}^{\lfloor (n-1)/2 \rfloor} \frac{(-1)^k}{(2k+1)!}\frac{(n+2k+1)!}{(n-2k-1)!}\frac{1}{(2\kappa)^{2k+1}}. \tag{4.11}$$

These series appear in formulas (8.461) and (8.465) of [15] and satisfy the identity

$$\begin{bmatrix} \sin(\kappa - \pi n/2) & \cos(\kappa - \pi n/2) \\ \cos(\kappa - \pi n/2) & -\sin(\kappa - \pi n/2) \end{bmatrix} \begin{bmatrix} a_n \\ b_n \end{bmatrix} = \sqrt{\frac{\pi\kappa}{2}} \begin{bmatrix} J_{n+1/2}(\kappa) \\ (-1)^{n-1} Y_{n+1/2}(\kappa) \end{bmatrix}, \tag{4.12}$$

where $J_{n+1/2}$ and $Y_{n+1/2}$ again denote cylindrical Bessel functions of the first and second kind, respectively. Equation (4.12) may be rearranged to obtain expressions for the series a_n and b_n, leading to the conclusion,

$$\widehat{B}(\Phi_e, \Phi_e) = -2\kappa\frac{a_{2N+1}}{b_{2N+1}} = 2\kappa\frac{J_{2N+3/2}(\kappa)\cos\kappa + Y_{2N+3/2}(\kappa)\sin\kappa}{J_{2N+3/2}(\kappa)\sin\kappa - Y_{2N+3/2}(\kappa)\cos\kappa}, \tag{4.13}$$

which completes the proof in the even case.

The proof of the odd order case follows similar lines, leading to the following analogue of (4.13):

$$\widehat{B}(\Phi_o, \Phi_o) = -2\kappa\frac{a_{2N}}{b_{2N}}, \tag{4.14}$$

where $N = \lfloor (p+1)/2 \rfloor$. Inserting expressions for the series a_{2N} and b_{2N} and simplifying leads to the result claimed. □

Equations (4.3) and (4.4) provide compact representations for the terms $\widehat{B}(\Phi_e^p, \Phi_e^p)$ and $\widehat{B}(\Phi_o^p, \Phi_o^p)$ but hide the fact that they are actually rational functions of κ. Interestingly enough, the expressions are actually certain types of Padé approximants [5].

THEOREM 4.2. *Let $p \in \mathbb{N}$ satisfy $p \geq 2$. Then we have the following:*

1. *$\widehat{B}(\Phi_e^p, \Phi_e^p)$ is the $[2N+2/2N]$-Padé approximant of $-2\kappa\tan\kappa$, where $N = \lfloor p/2 \rfloor$. Furthermore, if $\kappa \neq (m+1/2)\pi$, $m \in \mathbb{Z}$, then*

$$\begin{aligned} \mathcal{E}_e^p(\kappa) &= \widehat{B}(\Phi_e^p, \Phi_e^p) + 2\kappa\tan\kappa \\ &= \frac{1}{2}\left[\frac{(2N+1)!}{(4N+2)!}\right]^2 \frac{(2\kappa)^{4N+4}}{4N+3} + \mathcal{O}(\kappa^{4N+6}). \end{aligned} \tag{4.15}$$

2. *$\widehat{B}(\Phi_o^p, \Phi_o^p)$ is the $[2N/2N-2]$-Padé approximant of $2\kappa\cot\kappa$, where $N = \lfloor (p+1)/2 \rfloor$. If $\kappa \neq m\pi$, $m \in \mathbb{Z}$, then*

$$\begin{aligned} \mathcal{E}_o^p(\kappa) &= \widehat{B}(\Phi_o^p, \Phi_o^p) - 2\kappa\cot\kappa \\ &= 2\left[\frac{(2N)!}{(4N)!}\right]^2 \frac{(2\kappa)^{4N}}{4N+1} + \mathcal{O}(\kappa^{4N+2}). \end{aligned} \tag{4.16}$$

Proof. First, (4.13) shows that $\widehat{B}(\Phi_e^p, \Phi_e^p)$ is given by $-2\kappa a_{2N+1}/b_{2N+1}$, where a_{2N+1} and b_{2N+1} are defined in (4.10)–(4.11). It is not difficult to see that $\kappa^{2N+1}a_{2N+1}$ and $\kappa^{2N+1}b_{2N+1}$ are polynomials in κ of degree $2N+1$ and $2N$, respectively. Hence, $\widehat{B}(\Phi_e^p, \Phi_e^p)$ is a rational function of degree $[2N+2/2N]$. Straightforward manipulation beginning with the expression (4.3) gives

$$\widehat{B}(\Phi_e^p, \Phi_e^p) + 2\kappa\tan\kappa = -\frac{2\kappa}{\cos^2\kappa} Q_{2N+3/2}(\kappa)\left(1 - Q_{2N+3/2}(\kappa)\tan\kappa\right)^{-1}, \tag{4.17}$$

where

$$Q_{2N+3/2}(\kappa) = \frac{J_{2N+3/2}(\kappa)}{Y_{2N+3/2}(\kappa)}.$$

The behavior of $Q_{2N+3/2}(\kappa)$ is studied in the appendix, where the following estimate is proved in Lemma A.1:

$$Q_{2N+3/2}(\kappa) = -\frac{1}{2}\left[\frac{(2N+1)!}{(4N+2)!}\right]^2 \frac{(2\kappa)^{4N+3}}{4N+3} + \cdots.$$

With the aid of this estimate, we obtain that

$$\widehat{B}(\Phi_e^p, \Phi_e^p) + 2\kappa\tan\kappa = \frac{1}{2}\left[\frac{(2N+1)!}{(4N+2)!}\right]^2 \frac{(2\kappa)^{4N+4}}{4N+3} + \cdots$$

as claimed. Summarizing, we have shown that $\widehat{B}(\Phi_e^p, \Phi_e^p)$ is the rational function of degree $[2N+2/2N]$ which approximates $-2\kappa\tan\kappa$ to order $4N+4$. Consequently, $\widehat{B}(\Phi_e^p, \Phi_e^p)$ is the $[2N+2/2N]$-Padé approximant of $-2\kappa\tan\kappa$.

The assertions concerning $\widehat{B}(\Phi_o^p, \Phi_o^p)$ are proved in a similar fashion. In particular, using (4.14) it is easy to see that $\widehat{B}(\Phi_o^p, \Phi_o^p)$ is a rational function of type $[2N/2N-2]$. With the aid of (4.4), we derive

$$\widehat{B}(\Phi_o^p, \Phi_o^p) - 2\kappa\cot\kappa = -\frac{2\kappa}{\sin^2\kappa} Q_{2N+1/2}(\kappa)\left(1 + Q_{2N+1/2}(\kappa)\cot\kappa\right)^{-1}, \tag{4.18}$$

where

$$Q_{2N+1/2}(\kappa) = \frac{J_{2N+1/2}(\kappa)}{Y_{2N+1/2}(\kappa)},$$

and then, applying Lemma A.1, we deduce that

$$\widehat{B}(\Phi_o^p, \Phi_o^p) - 2\kappa \cot \kappa = 2 \left[\frac{(2N)!}{(4N)!}\right]^2 \frac{(2\kappa)^{4N}}{4N+1} + \cdots$$

as claimed. It follows that $\widehat{B}(\Phi_o^p, \Phi_o^p)$ is the $[2N/2N-2]$-Padé approximant of $2\kappa \cot \kappa$. ∎

4.2. Proof of Theorem 3.1. We are now in a position to present the proof of Theorem 3.1.

Proof. Fix $\kappa = \omega h/2$. First, we claim that for $x \in (0,h)$, the function $\theta_m^{(p)}$ defined in (2.8)–(2.9) may be expressed in terms of the basic polynomials as follows:

$$\theta_0^{(p)}(x) = \frac{1}{2}[\Phi_e^p(s) - \Phi_o^p(s)]$$

and

$$\theta_1^{(p)}(x) = \frac{1}{2}[\Phi_e^p(s) + \Phi_o^p(s)],$$

where $s = 2x/h - 1 \in (-1,1)$. It is easy to verify that the expression for $\theta_0^{(p)}$ takes the correct values at the endpoints $x = 0$ and $x = h$. Moreover, since Φ_e^p is a polynomial of degree p (in both x and s), it suffices to show that the orthogonality condition (2.9) is satisfied. Let $v_{hp} \in V_{hp}^\flat$ be supported on $(0,h)$, and define $V \in \mathbb{P} \cap H_0^1(-1,1)$ by $V(s) = v_{hp}(x)$, $x \in (0,h)$. A simple change of variable reveals that

$$B_\omega(\theta_0^{(p)}, v_{hp}) = h^{-1}\widehat{B}(\Phi_e^p - \Phi_o^p, V),$$

and conditions (4.1)–(4.2) show that this vanishes. Similar arguments may be applied in the case of $\theta_1^{(p)}$.

It is clear from symmetry considerations that $\theta_0^{(p)}$ is an even function. This fact, combined with a simple change of variable, shows that, since $\omega h = 2\kappa$,

$$B_\omega(\theta_0^{(p)}, \theta_0^{(p)}) = h^{-1}\widehat{B}(\Phi_e^p - \Phi_o^p, \Phi_e^p - \Phi_o^p);$$

then, exploiting the parities of Φ_e^p and Φ_o^p, we obtain

$$B_\omega(\theta_0^{(p)}, \theta_0^{(p)}) = h^{-1}[\widehat{B}(\Phi_e^p, \Phi_e^p) + \widehat{B}(\Phi_o^p, \Phi_o^p)].$$

Similar arguments reveal that

$$B_\omega(\theta_0^{(p)}, \theta_1^{(p)}) = (2h)^{-1}[\widehat{B}(\Phi_e^p, \Phi_e^p) - \widehat{B}(\Phi_o^p, \Phi_o^p)].$$

Substituting these results into (2.11) gives

$$\cos(kh) = \frac{\widehat{B}(\Phi_o^p, \Phi_o^p) + \widehat{B}(\Phi_e^p, \Phi_e^p)}{\widehat{B}(\Phi_o^p, \Phi_o^p) - \widehat{B}(\Phi_e^p, \Phi_e^p)}. \tag{4.19}$$

Theorem 4.2 identifies the terms appearing in this quotient as Padé approximants, and substituting for these expressions leads to the result claimed in Theorem 3.1. ∎

4.3. Error for small ωh. The general result for the leading term given in Theorem 3.2 for the error in the dispersion relation for the small wave number is proved using Theorem 4.2 as follows.

Proof. Fix $\kappa = \omega h/2 \ll 1$, and let $\mathcal{E}_e^p(\kappa)$ and $\mathcal{E}_o^p(\kappa)$ be defined as in Theorem 4.2. By writing $\widehat{B}(\Phi_e^p, \Phi_e^p)$ and $\widehat{B}(\Phi_o^p, \Phi_o^p)$ in terms of $\mathcal{E}_e^p$ and $\mathcal{E}_o^p$, respectively, substituting into (4.19), followed by a lengthy but otherwise straightforward computation, one arrives at the following expression for the error in the discrete dispersion relation:

$$\begin{aligned}(4.20)\qquad &\cos kh - \cos \omega h \\ &\quad = \frac{\sin \omega h}{\omega h}\left\{\mathcal{E}_o^p \sin^2\left(\frac{\omega h}{2}\right) + \mathcal{E}_e^p \cos^2\left(\frac{\omega h}{2}\right)\right\}\left\{1 + \frac{\sin \omega h}{2\omega h}(\mathcal{E}_o^p - \mathcal{E}_e^p)\right\}^{-1}.\end{aligned}$$

(Here, the argument κ of $\mathcal{E}_e^p$ and $\mathcal{E}_o^p$ has been suppressed.) In particular, for small argument, Theorem 4.2 implies that

$$\mathcal{E}_o^p = 2\left[\frac{(2N_o)!}{(4N_o)!}\right]^2 \frac{(\omega h)^{4N_o}}{4N_o + 1} + \cdots,$$

where $N_o = \lfloor (p+1)/2 \rfloor$, and

$$\mathcal{E}_e^p = \frac{1}{2}\left[\frac{(2N_e+1)!}{(4N_e+2)!}\right]^2 \frac{(\omega h)^{4N_e+4}}{4N_e + 3} + \cdots,$$

where $N_e = \lfloor p/2 \rfloor$. It then follows that

$$\cos kh - \cos \omega h = \left(\frac{\omega h}{2}\right)^2 \mathcal{E}_o^p + \mathcal{E}_e^p + \cdots,$$

where

$$\left(\frac{\omega h}{2}\right)^2 \mathcal{E}_o^p = \frac{1}{2}\left[\frac{(2N_o)!}{(4N_o)!}\right]^2 \frac{(\omega h)^{4N_o+2}}{4N_o + 1} + \cdots,$$

and $\mathcal{E}_e^p$ is given above. There are two cases, depending on the parity of the polynomial order p:

- If p is even, then $2N_e = 2N_o = p$, and the term involving $\mathcal{E}_o^p$ dominates the error, giving

$$\cos kh - \cos \omega h = \frac{1}{2}\left[\frac{p!}{(2p)!}\right]^2 \frac{(\omega h)^{2p+2}}{2p+1} + \cdots.$$

- If p is odd, then $2N_e = p - 1$ and $2N_o = p + 1$, and the term involving $\mathcal{E}_e^p$ now dominates the error, giving

$$\cos kh - \cos \omega h = \frac{1}{2}\left[\frac{p!}{(2p)!}\right]^2 \frac{(\omega h)^{2p+2}}{2p+1} + \cdots.$$

This concludes the proof of (3.3). Estimate (3.4) then follows immediately from (3.3) using the approximation

$$\cos kh - \cos \omega h = -(kh - \omega h)\sin \omega h + \cdots,$$

valid for small $kh - \omega h$. ∎

In examining this proof, we observe that the leading term in the remainder is the same, regardless of the parity of the polynomial order p. This effect occurs despite terms of different parities alternately dominating the error.

4.4. Error for large ωh. Now fix $\kappa = \omega h/2 \gg 1$. Equation (4.17) implies that, with $\kappa = \omega h/2$,

$$\mathcal{E}_e^p(\kappa)\frac{\cos^2(\omega h/2)}{\omega h} = -Q_{2N_e+3/2}(\kappa)\left\{1 - Q_{2N_e+3/2}(\kappa)\tan\kappa\right\}^{-1}, \tag{4.21}$$

while (4.18) implies that

$$\mathcal{E}_o^p(\kappa)\frac{\sin^2(\omega h/2)}{\omega h} = -Q_{2N_o+1/2}(\kappa)\{1 + Q_{2N_o+1/2}(\kappa)\cot\kappa\}^{-1}. \tag{4.22}$$

Theorem 3.3 is proved using the foregoing results along with estimates for the behavior of the quotient Q_m studied in Theorem A.2 of the appendix.

Proof. First, consider the preasymptotic regime where $2p+1 < \omega h - o(\omega h)^{1/3}$. For p in this range, neither $2N_e$ nor $2N_o$ exceeds $\kappa - o(\kappa^{1/3})$, where $\kappa = \omega h/2$. Therefore, we are in the situation covered by the first part of Theorem A.2, where both $Q_{2N_o+1/2}(\kappa)$ and $Q_{2N_e+3/2}(\kappa)$ oscillate but do not decay. Consequently, with the aid of the identities (4.21)–(4.22) and the expression for the error given in (4.20), we are led to the conclusion that $\mathcal{E}^p$ oscillates, but does not decay, as p is increased in this range.

For p in the transition region where $\omega h - o(\omega h)^{1/3} < 2p+1 < \omega h + o(\omega h)^{1/3}$, it follows that both $2N_e$ and $2N_o$ lie in the transition region $[\kappa - o(\kappa^{1/3}), \kappa + o(\kappa^{1/3})]$ dealt with in the second part of Theorem A.2. Here, the term appearing in the denominator of (4.20) is $\mathcal{O}(1)$ for $\omega h \gg 1$. The identities (4.21)–(4.22) show that the error in the dispersion relation is dictated by the behavior of the sum of $Q_{2N_e+3/2}(\kappa)$ and $Q_{2N_o+1/2}(\kappa)$. Applying Theorem A.2, we conclude that the error decays algebraically at a rate $\mathcal{O}(p^{-1/3})$.

The proof in the case where $2p+1 > \omega h + o(\omega h)^{1/3}$ follows along the same lines as the argument used in the transition region and will not be elaborated upon further. ∎

Appendix A. Behavior of $Q_m(\kappa)$. The quotient Q_m defined by

$$Q_m(\kappa) = \frac{J_m(\kappa)}{Y_m(\kappa)}, \quad m = \text{integer} + \frac{1}{2}, \tag{A.1}$$

appears in the expression for the error in the Padé approximants considered in section 4. The following estimate, valid for small values of κ, was used in the proof of Theorem 4.2.

LEMMA A.1. *Let $m = \text{integer} + 1/2$, and let Q_m be defined as above. Then, for $\kappa \ll 1$,*

$$Q_m(\kappa) = -\frac{1}{2}\left[\frac{(m-\frac{1}{2})!}{(2m-1)!}\right]^2 \frac{(2\kappa)^{2m}}{2m} + \cdots. \tag{A.2}$$

Proof. Write $m = n + 1/2$, where $n \in \mathbb{Z}$. For small κ, identity (8.440) of [15] gives

$$J_{n+1/2}(\kappa) = \frac{1}{\Gamma(3/2+n)}\left(\frac{\kappa}{2}\right)^{n+1/2} + \cdots,$$

while combining identities $(8.465)_1$ and (8.440) of [15] gives

$$Y_{n+1/2}(\kappa) = (-1)^{n-1}J_{-n-1/2}(\kappa) = \frac{(-1)^{n-1}}{\Gamma(1/2-n)}\left(\frac{\kappa}{2}\right)^{-n-1/2} + \cdots,$$

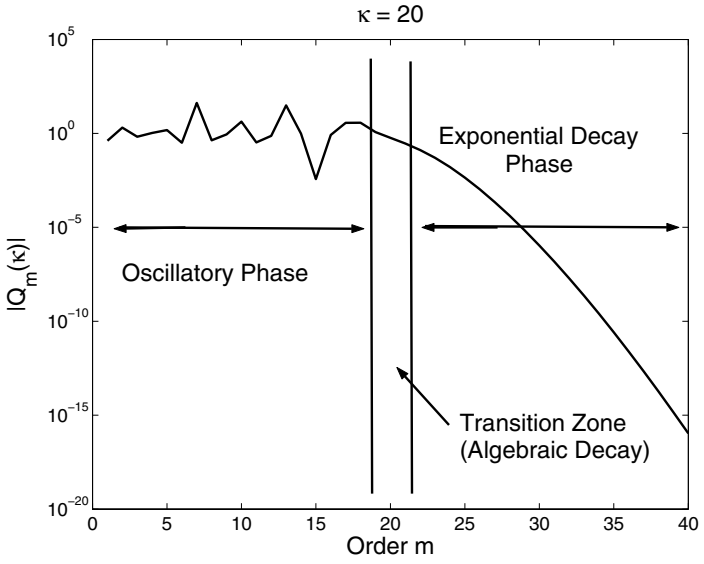

FIG. A.1. *Graph showing the three phases in the behavior of* $|Q_m(\kappa)|$ *for* $\kappa = 20$ *as the order* m *is increased.*

where Γ denotes the gamma function. Therefore, using formulas (8.339) of [15] gives, after some simplification,

$$Q_m(\kappa) = -\frac{1}{2}\left[\frac{n!}{(2n)!}\right]^2 \frac{(2\kappa)^{2n+1}}{2n+1} + \cdots,$$

and rewriting in terms of m gives the result claimed. □

Lemma A.1 shows that $Q_m(\kappa)$ decays algebraically as κ becomes small. However, it will be useful to consider the ratio in the regime $\kappa \gg 1$, with particular attention to the behavior as the order m of the Bessel functions becomes large. Figure A.1 shows the behavior of $Q_m(\kappa)$ when $\kappa = 20$ as the order m is increased. It is found that there are three distinct phases, depending on the size of the order m. Initially, $Q_m(\kappa)$ oscillates around unity. As the order m passes through κ, there is a relatively short-lived transition zone where $Q_m(\kappa)$ begins to decay at an algebraic rate as m is increased. Finally, as m is increased further, $Q_m(\kappa)$ decays at an exponential rate.

Our objective in the remainder of this section will be to show that the behavior observed in this particular case is typical. The following result provides sharp estimates for the values at which the different phases occur and quantifies the rates of decay.

THEOREM A.2. *Let* Q_m *be defined as above, and* $m = \text{integer} + 1/2$. *Then, as* m *is increased,* $Q_m(\kappa)$ *passes through three phases*:

1. *For* $m < \kappa - o(\kappa^{1/3})$, $Q_m(\kappa)$ *oscillates around unity but does not decay as* m *is increased.*

2. *For* $\kappa - o(\kappa^{1/3}) < m < \kappa + o(\kappa^{1/3})$, $Q_m(\kappa)$ *decays algebraically at a rate* $\mathcal{O}(m^{-1/3})$. *More precisely,*

$$Q_m(\kappa) \approx -\frac{1}{\sqrt{3}} - \frac{1}{\pi}\Gamma\left(\frac{2}{3}\right)^2 (\kappa - m)\left(\frac{6}{m}\right)^{1/3} + \cdots. \tag{A.3}$$

3. *For $m > \kappa + o(\kappa^{1/3})$, $Q_m(\kappa)$ decays at a superexponential rate:*

$$Q_m(\kappa) \approx -\frac{1}{2}\left[\frac{1-\sqrt{1-\kappa^2/m^2}}{1+\sqrt{1-\kappa^2/m^2}}e^{2\sqrt{1-\kappa^2/m^2}}\right]^m \tag{A.4}$$

so that, for $m \gg \kappa$,

$$Q_m(\kappa) \approx -\frac{1}{2}\left[\frac{\kappa e}{2m}\right]^{2m}. \tag{A.5}$$

The proof of this result is divided into four distinct cases covered in the following sections.

A.1. Preasymptotic regime: $m < \kappa$. We start by discussing the behavior of $Q_m(\kappa)$ in the preasymptotic regime, where the value of the argument κ exceeds the order m of the Bessel functions. Langer's formulas [13, sect. 7.13.4] provide uniform asymptotic expansions for Bessel functions of large order and large argument, and they give

$$Q_m(\kappa) = \frac{J_{1/3}(z)\cos(\pi/6) - Y_{1/3}(z)\sin(\pi/6) + \mathcal{O}(m^{-4/3})}{J_{1/3}(z)\sin(\pi/6) + Y_{1/3}(z)\cos(\pi/6) + \mathcal{O}(m^{-4/3})}, \tag{A.6}$$

where

$$z = m(w - \tan^{-1} w) \qquad \text{and} \qquad w = \sqrt{\kappa^2/m^2 - 1}.$$

Bounds on the accuracy of the approximation obtained when the higher order terms are dropped in (A.6) could be obtained using the uniform asymptotic expansions with the remainder given in Olver [27]. However, we shall content ourselves with making the approximation

$$Q_m(\kappa) \approx \frac{J_{1/3}(z)\cos(\pi/6) - Y_{1/3}(z)\sin(\pi/6)}{J_{1/3}(z)\sin(\pi/6) + Y_{1/3}(z)\cos(\pi/6)}. \tag{A.7}$$

A.1.1. Oscillatory phase: $m < \kappa - o(\kappa^{1/3})$. In the preasymptotic range where m is small relative to κ, the ratio $Q_m(\kappa)$ tends to oscillate and has magnitude of order unity. While it is difficult to make quantitative statements concerning the erratic behavior observed in Figure A.1, it is possible to give a qualitative explanation. When m is small relative to κ, the argument z of the Bessel functions appearing in (A.7) will be large and positive. Asymptotic expansions for Bessel functions of large argument are given in $(8.440)_1$ of [15]:

$$J_\nu(z) \sim \left(\frac{\pi z}{2}\right)^{-1/2}\cos\left(z - \frac{1}{2}\nu\pi - \frac{\pi}{4}\right)$$

and in $(8.440)_2$ of [15]:

$$Y_\nu(z) \sim \left(\frac{\pi z}{2}\right)^{-1/2}\sin\left(z - \frac{1}{2}\nu\pi - \frac{\pi}{4}\right).$$

Together with (A.7), these expressions show that $Q_m(\kappa)$ will tend to oscillate without a decay in the magnitude as m is increased. Indeed, inserting these expressions into the right-hand side of (A.7) and simplifying gives

$$\cot\left(z - \frac{\pi}{4}\right). \tag{A.8}$$

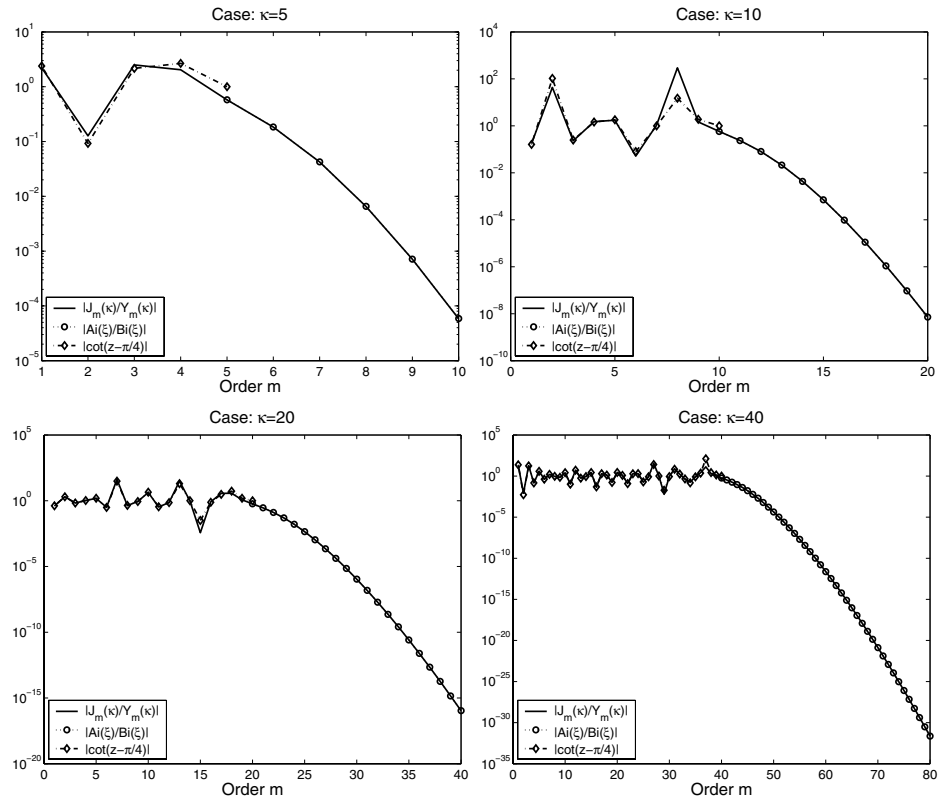

FIG. A.2. *Graphs of* $|Q_m(\kappa)|$ *in* (A.1) *for* $m = 1, \ldots, 2\kappa$, $|\cot(z - \pi/4)|$ *in* (A.8) *for* $m = 1, \ldots, \kappa$ *and* $|\operatorname{Ai}(\xi)/\operatorname{Bi}(\xi)|$ *in* (A.11) *for* $m = \kappa + 1, \ldots, 2\kappa$. *Values of* $\kappa = 5$, 10, 20, *and* 40 *are shown. Observe the oscillatory behavior of* $|Q_m|$ *and the good qualitative agreement provided by the cotangent in the preasymptotic regime* $m < \kappa$. *Furthermore, note the quantitative agreement between* $|Q_m|$ *and* $|\operatorname{Ai}(\xi)/\operatorname{Bi}(\xi)|$ *in the asymptotic regime* $m > \kappa$.

Of course, we would not expect this expression to necessarily agree closely with $Q_m(\kappa)$. Nevertheless, this expression actually provides a surprisingly good representation of the qualitative behavior in the preasymptotic regime even in the case of relatively modest values of κ, as shown in Figure A.2.

A.1.2. Transition zone: $\kappa - o(\kappa^{1/3}) < m < \kappa$. We consider the behavior in the zone where m approaches κ from below. For m in this range,

$$1 < \frac{\kappa}{m} < 1 + o(m^{-2/3})$$

so that

$$w \approx \left[\frac{\kappa - m}{(m/2)}\right]^{1/2} = o(1),$$

and therefore

$$z \approx \frac{1}{3} m w^3 \approx \frac{2}{3}\left[\frac{\kappa - m}{(m/2)^{1/3}}\right]^{3/2} = o(1).$$

Using the series representations for Bessel functions [15, eq. (8.440)], we obtain

$$Q_m(\kappa) \approx -\frac{1}{\sqrt{3}} - \frac{3}{\pi}\Gamma\left(\frac{2}{3}\right)^2\left(\frac{z}{2}\right)^{2/3} + \cdots,$$

and, by substituting for z and simplifying, we arrive at the conclusion:

$$Q_m(\kappa) \approx -\frac{1}{\sqrt{3}} - \frac{1}{\pi}\Gamma\left(\frac{2}{3}\right)^2(\kappa - m)\left(\frac{6}{m}\right)^{1/3} + \cdots, \tag{A.9}$$

valid for $\kappa - o(\kappa^{1/3}) < m < \kappa$. As a matter of fact, this result could also have been obtained formally using Nicholson's formulas [13, sect. 7.13.3].

A.2. Asymptotic regime: $m > \kappa$. We now study the behavior in the regime where the order of the Bessel functions exceeds the argument. Langer's formulas [13, sect. 7.13.4] imply that

$$Q_m(\kappa) = -\frac{\pi^{-1}K_{1/3}(z) + \mathcal{O}(m^{-4/3})}{I_{1/3}(z) + I_{1/3}(z) + \mathcal{O}(m^{-4/3})}, \tag{A.10}$$

where, in this case,

$$z = m\left(\tanh^{-1} w - w\right) \quad \text{and} \quad w = \sqrt{1 - \kappa^2/m^2}.$$

As before, it is possible to use the results of Olver [27] to obtain bounds on the accuracy of the approximation obtained when the higher order terms are dropped in (A.10), although we will not pursue this further here. Writing $z = \frac{2}{3}\xi^{3/2}$ and using formulas (11.1.04) and (11.1.12) from [27] gives

$$Q_m(\kappa) \approx -\frac{\pi^{-1}K_{1/3}(z)}{I_{1/3}(z) + I_{1/3}(z)} = -\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)}, \tag{A.11}$$

where Ai and Bi denote Airy functions of the first and second kinds, respectively [15]. The accuracy of this approximation is indicated in Figure A.2.

The behavior of the ratio of Airy functions for positive ξ may be deduced from the results quoted in Olver [27, pp. 392–393]. However, the following simple approximations will suffice for present purposes. For small argument $\xi \le 2$,

$$\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)} \approx \frac{1}{\sqrt{3}}\frac{1 - 3^{5/6}\Gamma\left(\frac{2}{3}\right)^2\frac{\xi}{2\pi} + \frac{\xi^3}{12}}{1 + 3^{5/6}\Gamma\left(\frac{2}{3}\right)^2\frac{\xi}{2\pi} + \frac{\xi^3}{12}}, \tag{A.12}$$

while for larger arguments where $\xi > 2$,

$$\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)} \approx \frac{e^{-2z}}{2}\frac{1 - \frac{15}{216z}}{1 + \frac{15}{216z}}, \quad z = \frac{2}{3}\xi^{3/2}. \tag{A.13}$$

Here Γ denotes the gamma function [15]. Together, these approximations provide an accurate picture of the behavior of the ratio throughout the full range of argument, as indicated in Figure A.3. In particular, it is observed that the ratio initially decays linearly,

$$\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)} \approx \frac{1}{\sqrt{3}} - \frac{3^{1/3}}{\pi}\Gamma\left(\frac{2}{3}\right)^2\xi, \tag{A.14}$$

before undergoing a rapid transition to an exponential rate of decay given by

$$\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)} \approx \frac{e^{-2z}}{2}. \tag{A.15}$$

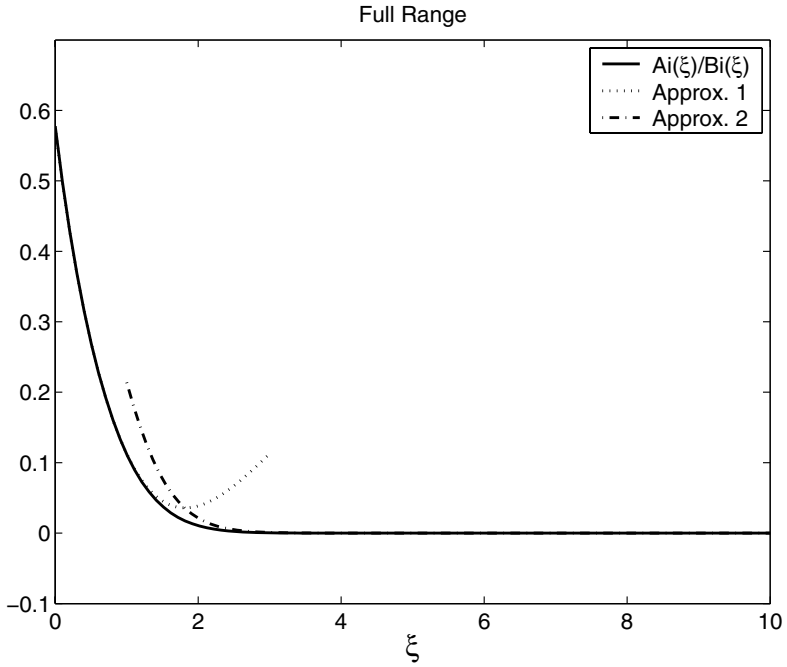

FIG. A.3. *Graph showing the ratio* $\mathrm{Ai}(\xi)/\mathrm{Bi}(\xi)$ *compared with the approximations for small and large arguments given in* (A.12) *and* (A.13)*, respectively.*

A.2.1. Transition zone: $\kappa < m < \kappa + o(\kappa^{1/3})$. As the order m passes through κ, we have

$$1 - o(m^{-2/3}) < \frac{\kappa}{m} < 1,$$

and, using similar arguments to those used before, we obtain

$$z \simeq \frac{1}{3} m w^3 \simeq \frac{2}{3} \left[\frac{m-\kappa}{(m/2)^{1/3}} \right]^{3/2}$$

or, equally well,

$$\xi \simeq \left(\frac{2}{m} \right)^{1/3} (m - \kappa).$$

Since $m - \kappa = o(\kappa^{1/3}) = o(m^{1/3})$, it follows that $\xi = o(1)$ and, using (A.14), we obtain

$$Q_m(\kappa) \approx -\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)} \simeq -\frac{1}{\sqrt{3}} + \frac{1}{\pi} \Gamma \left(\frac{2}{3} \right)^2 (m-\kappa) \left(\frac{6}{m} \right)^{1/3} + \cdots, \tag{A.16}$$

valid for $\kappa < m < \kappa + o(\kappa^{1/3})$. This form agrees with the result (A.9) obtained when m lies in the transition region to the left of κ.

A.2.2. Exponential decay phase: $m > \kappa + o(\kappa^{1/3})$. If m exceeds $\kappa + o(\kappa^{1/3})$, then w is no longer small, and, in turn, z and ξ will be large. By substituting for

z in terms of w in the expression (A.15) and applying elementary manipulations, we arrive at

$$\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)} \approx \frac{1}{2}\left[\frac{1-w}{1+w}e^{2w}\right]^m$$

or, substituting for w,

$$\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)} \approx \frac{1}{2}\left[\frac{1-\sqrt{1-\kappa^2/m^2}}{1+\sqrt{1-\kappa^2/m^2}}e^{2\sqrt{1-\kappa^2/m^2}}\right]^m.$$

The function $f : w \to (1-w)/(1+w)\exp(2w)$ is monotonic decreasing on $[0,1]$ from 1 to 0. Therefore, the term in parentheses is less than unity, and we have an exponential rate of decay when m is close to κ. This rate of decay increases as m becomes even larger relative to κ, and in the limiting case we find that

$$f\left(\sqrt{1-\kappa^2/m^2}\right) \simeq \left[\frac{\kappa e}{2m}\right]^2.$$

Therefore, when $m > \kappa e/2$, we obtain a superexponential rate of decay:

$$\frac{\mathrm{Ai}(\xi)}{\mathrm{Bi}(\xi)} \approx \frac{1}{2}\left[\frac{\kappa e}{2m}\right]^{2m}.$$

ANALYSIS OF A TWO-SCALE, LOCALLY CONSERVATIVE SUBGRID UPSCALING FOR ELLIPTIC PROBLEMS*

TODD ARBOGAST†

Abstract. We present a two-scale theoretical framework for approximating the solution of a second order elliptic problem. The elliptic coefficient is assumed to vary on a scale that can be resolved on a fine numerical grid, but limits on computational power require that computations be performed on a coarse grid. We consider the elliptic problem in mixed variational form over $W \times \mathbf{V} \subset L^2 \times H(\mathrm{div})$. We base our scale expansion on local mass conservation over the coarse grid. It is used to define a direct sum decomposition of $W \times \mathbf{V}$ into coarse and "subgrid" subspaces $W_c \times \mathbf{V}_c$ and $\delta W \times \delta \mathbf{V}$ such that (1) $\nabla \cdot \mathbf{V}_c = W_c$ and $\nabla \cdot \delta \mathbf{V} = \delta W$, and (2) the space $\delta \mathbf{V}$ is locally supported over the coarse mesh. We then explicitly decompose the variational problem into coarse and subgrid scale problems. The subgrid problem gives a well-defined operator taking $W_c \times \mathbf{V}_c$ to $\delta W \times \delta \mathbf{V}$, which is localized in space, and it is used to upscale, that is, to remove the subgrid from the coarse-scale problem. Using standard mixed finite element spaces, two-scale mixed spaces are defined. A mixed approximation is defined, which can be viewed as a type of *variational multiscale method* or a *residual-free bubble technique*. A numerical Green's function approach is used to make the approximation to the subgrid operator efficient to compute. A mixed method π-operator is defined for the two-scale approximation spaces and used to show optimal order error estimates.

1. Introduction.

Many mathematical models and numerical schemes have appeared in the literature that can capture fine-scale phenomena on coarse scales or grids. This is the essence of *upscaling*. The change-of-scale problem goes back to the beginning of mathematical modeling; however, research on it has recently seen a renewed and widespread resurgence.

Among many approaches, numerical techniques have been developed and exploited. For second order elliptic equations, a certainly not exhaustive list includes the multiscale finite element method [20], the residual-free bubble techniques [9], certain domain-decomposition techniques [27, 31], the two-grid techniques [30, 18], and a posteriori modeling techniques [25, 26]. A scheme related directly to the work here is the variational multiscale finite element method [21, 22, 23]. Each scheme can be viewed as a subgrid technique in the sense that each attempts to resolve scales below the coarse grid scale by incorporating local computations into a global problem defined only on a coarse grid.

A new subgrid technique for upscaling an elliptic partial differential equation based on a certain combination of low order mixed finite elements was introduced in [5] and [1]. It involves the decomposition of the solution operator into two parts, one representing the coarse scale and the other representing the subgrid scale. The method is described in general terms, and numerical tests are given that demonstrate

the overall speed and convergence properties of the method in [5, 1]. Applications to groundwater contaminant transport and petroleum simulation are given in [3, 4], wherein it is shown that the method has great potential to resolve fine-scale effects in practical problems. Complete details of implementation are presented in [2], as well as additional and more stringent numerical tests that apply the technique to two-phase porous medium problems with significant heterogeneity and wells. An advantage of this subgrid technique is that it needs no assumptions about the underlying physics. The data used in the simulation is to be provided directly on the fine scale.

The goals of this paper are threefold. First, we present a theoretical framework within which to understand the upscaling process. We achieve upscaling *without* the need for an explicit closure assumption or a restrictive assumption such as periodicity or the like. In general, it is difficult to analyze the errors introduced by a closure assumption; however, this problem does *not* arise here. Rather the ability of the upscaled model to capture fine-scale features in the solution becomes a question of approximation theory: how well do we approximate the upscaled model? Second, we generalize the mixed finite element technique of [5, 1] to essentially arbitrary choices of mixed spaces. Because of the upscaling framework, these methods can be implemented very efficiently and require the solution of a global problem defined only on the coarse grid. Finally, we provide an error analysis showing optimal order approximation.

Both an outline of the paper and a brief summary of results follow. After presenting in the next section the elliptic problem in mixed variational form posed in $W \times \mathbf{V} \subset L^2 \times H(\mathrm{div})$, we then proceed in section 3 to define our framework within which we upscale the differential problem. We define the coarse grid we can ultimately compute over and use it to define a direct sum decomposition of $W \times \mathbf{V}$ into coarse and subgrid subspaces $W_c \times \mathbf{V}_c$ and $\delta W \times \delta \mathbf{V}$ such that (1) the divergence constraints $\nabla \cdot \mathbf{V}_c = W_c$ and $\nabla \cdot \delta \mathbf{V} = \delta W$, needed for local mass conservation over the coarse and subgrid scales, and (2) the space $\delta \mathbf{V}$ is locally supported over the coarse mesh, which is needed for upscaling the subgrid. This then leads to a decomposition of the variational problem into coarse and subgrid scale problems, with solutions in $W_c \times \mathbf{V}_c$ and $\delta W \times \delta \mathbf{V}$, although the two problems remain coupled.

We define in section 4 the δ-solution operator as the solution of the subgrid problem. It is used to relate the subgrid to the coarse solution, and it is a well-defined operator that takes $W_c \times \mathbf{V}_c$ to $\delta W \times \delta \mathbf{V}$. Since this operator is localized in space, it can be used to control the fine scales. We use it in the coarse problem to remove direct reference to the subgrid, resulting in the upscaled problem involving only the coarse-scale solution.

In section 5 we exploit the two-scale structure of the solution to define an efficient mixed finite element method. We use any of the usual mixed elements to approximate the δ-solution operator and also any choice of mixed spaces to approximate the upscaled coarse solution. This defines many families of two-scale, mixed spaces. Our approximation can be viewed as a type of variational multiscale method [21, 22] or a residual-free bubble technique [9]. A numerical Green's function approach makes the approximation to the subgrid operator efficient to compute.

In section 6 we analyze the approximation error. We show optimal order a priori error estimates. Care must be taken, as the two-scale decomposition depends on the coarse grid. We therefore analyze the combined system, showing approximation of the full solution. The key development here is the definition of a suitable mixed method π-operator that preserves the L^2-projection of the discrete divergence and approximates

well in the two-scale context. Finally, in section 7 we apply the convergence theory to the special cases defined in [5] and [1].

2. A second order elliptic equation. Let $\Omega \subset \mathbb{R}^n$, $n = 2$ or 3, be a convex polygonal domain. Throughout the paper, for domain ω, we denote by $L^p(\omega)$ the usual Lebesgue space of index p, $1 \le p \le \infty$, and by $W^{k,p}(\omega)$ the usual Sobolev space of k weak derivatives in $L^p(\omega)$. We denote by $(\cdot,\cdot)_\omega$ the $L^2(\omega)$-inner product (i.e., Lebesgue integration over ω). Moreover, $\|\cdot\|_{k,\omega}$ is the norm of $H^k(\omega) \equiv W^{k,2}(\omega)$. In the notation we may suppress ω when it is Ω.

Decompose $\partial\Omega = \bar{\Gamma}_N \cup \bar{\Gamma}_R$, where Γ_N and Γ_R are disjoint open sets in $\partial\Omega$, and let ν be the outer unit normal vector. The problem is to find the unknown functions p (pressure) and $\mathbf{u}$ (velocity) satisfying

$$ap + \nabla \cdot \mathbf{u} = b \qquad \text{in } \Omega, \tag{2.1}$$

$$\mathbf{u} = -d(\nabla p - c) \quad \text{in } \Omega, \tag{2.2}$$

$$\mathbf{u} \cdot \nu = g_N \qquad \text{on } \Gamma_N, \tag{2.3}$$

$$\alpha \mathbf{u} \cdot \nu = p - g_R \quad \text{on } \Gamma_R, \tag{2.4}$$

wherein $a \in L^\infty(\Omega)$ is nonnegative, $b \in L^2(\Omega)$, $c \in (L^2(\Omega))^n$, and d is a second order uniformly positive definite symmetric tensor in $(L^\infty(\Omega))^{n\times n}$ (i.e., d and d^{-1} are both uniformly elliptic and uniformly bounded). The boundary conditions represent Neumann and Robin (and Dirichlet, if $\alpha = 0$) conditions for suitably nice functions g_N, g_R, and $\alpha \ge 0$. We assume that a unique and sufficiently regular solution to this system exists and that the coefficients are sufficiently regular for the error analysis to follow.

A special case arises if a vanishes identically on all of Ω and $\Gamma_N = \partial\Omega$. Then it is well known and follows from the divergence theorem that solvability requires the compatibility condition

$$\int_\Omega b(x)\,dx = \int_{\partial\Omega} g_N(x)\,ds(x). \tag{2.5}$$

In this case, we obtain p only up to an arbitrary constant.

To enforce conservation of mass (2.1) locally, we base our method on a mixed variational formulation. Let

$$H(\mathrm{div};\Omega) = \{\mathbf{v} \in (L^2(\Omega))^n : \nabla \cdot \mathbf{v} \in L^2(\Omega)\}$$

denote the usual space, with the inner product

$$(\mathbf{v}_1, \mathbf{v}_2)_{H(\mathrm{div})} = (\mathbf{v}_1, \mathbf{v}_2) + (\nabla \cdot \mathbf{v}_1, \nabla \cdot \mathbf{v}_2)$$

and norm $\|\mathbf{v}\|_{H(\mathrm{div})} = (\mathbf{v},\mathbf{v})^{1/2}_{H(\mathrm{div})}$, and let

$$\mathbf{V} = \{\mathbf{v} \in H(\mathrm{div};\Omega) : \mathbf{v} \cdot \nu = 0 \text{ on } \Gamma_N\},$$

which is a closed subspace. To impose the Neumann boundary condition, we need to extend g_N to some fixed vector $\mathbf{v}_{g_N} \in H(\mathrm{div};\Omega)$ such that

$$\mathbf{v}_{g_N} \cdot \nu = g_N \text{ on } \Gamma_N \quad \text{and} \quad \mathbf{v}_{g_N} \cdot \nu = 0 \text{ on } \Gamma_R.$$

Finally, let $W = L^2(\Omega)$, or let $W = L^2(\Omega)/\mathbb{R} = \{w \in L^2(\Omega) : \int_\Omega w(x)\,dx = 0\}$ if p will be defined only up to a constant.

The mixed variational problem equivalent to (2.1)–(2.4) is to find $\mathbf{u} \in \mathbf{V} + \mathbf{v}_{g_N}$ and $p \in W$ such that

$$(ap, w) + (\nabla \cdot \mathbf{u}, w) = (b, w) \qquad \forall\, w \in W, \tag{2.6}$$

$$(d^{-1}\mathbf{u}, \mathbf{v}) + (\alpha \mathbf{u} \cdot \nu, \mathbf{v} \cdot \nu)_{\Gamma_R} - (p, \nabla \cdot \mathbf{v}) = (c, \mathbf{v}) - (g_R, \mathbf{v} \cdot \nu)_{\Gamma_R} \quad \forall\, \mathbf{v} \in \mathbf{V}. \tag{2.7}$$

Note that (2.3) is imposed as an essential condition and (2.4) is imposed weakly as a natural boundary condition.

3. Separation of scales. We recall that a Hilbert space H is the direct sum of M and N if $H = M + N$ and M and N are closed subspaces that intersect only at the zero vector. We denote this fact by $H = M \oplus N$. In this case, given $x \in H$, there is some unique $m \in M$ and $n \in N$ such that $x = m + n$. We note the following result, which is an exercise in the application of the closed graph theorem [29].

PROPOSITION 3.1. *If H is a Hilbert space and $H = M \oplus N$, then the operator $\tilde{\mathcal{P}}_M : H \to M$ defined for $x \in H$ by $\tilde{\mathcal{P}}_M x = m$, where $x = m + n$, $m \in M$ and $n \in N$, is a bounded linear (but possibly nonorthogonal) projection.*

We expand functions in $W \times \mathbf{V}$ uniquely according to a direct sum decomposition of the spaces. We base our decomposition on our two primary requirements: that the finer (i.e., "subgrid") scales be localized and that mass conservation is maintained. To do so we choose a coarse mesh partition $\mathcal{T}_H$ of Ω of a finite number of convex elements over which we will decompose the solution into coarse and local (i.e., "subgrid") pieces. The choice is mostly arbitrary at this point, but later the mesh will be used as the coarse mesh we compute on. We do, however, need a nondegeneracy condition. We assume that there is some universal fixed constant $\gamma > 0$ such that any choice of $\mathcal{T}_H$ satisfies

$$\mathrm{msr}(E_c) \geq \gamma(\mathrm{diam}(E_c))^n \quad \forall E_c \in \mathcal{T}_H, \tag{3.1}$$

where $\mathrm{msr}(E_c)$ is the measure of E_c and $\mathrm{diam}(E_c)$ is its diameter.

3.1. A two-scale decomposition of $W \times \mathbf{V}$. As is well known, the divergence operator maps $\mathbf{V}$ onto W. The range of the divergence operator must be decomposed into a direct sum decomposition $W = W_c \oplus \delta W$ of closed subspaces. For our purposes, the decomposition is arbitrary, except that we must insist on two properties. First,

$$\delta W \subset (W_c^1)^\perp, \quad W_c^1 = \{w_c \in W : w_c \text{ is constant } \forall \text{ coarse elements } E_c \in \mathcal{T}_H\},$$

with respect to the $L^2(\Omega)$-inner product.

Second, we insist that there is a uniformity in the separation of W_c and δW. We define the possibly nonorthogonal projections

$$\tilde{\mathcal{P}}_{W_c} : W \to W_c \quad \text{and} \quad \tilde{\mathcal{P}}_{\delta W} : W \to \delta W \tag{3.2}$$

with respect to the direct sum decomposition. By Proposition 3.1, these operators are bounded but not necessarily uniformly so with respect to the coarse mesh $\mathcal{T}_H$ selected. Our requirement is that in fact these are bounded uniformly: there is some universal constant C, independent of the coarse mesh $\mathcal{T}_H$, such that

$$\|w_c\|_0 + \|\delta w\|_0 \leq C\|w\|_0, \tag{3.3}$$

where $w = w_c + \delta w \in W_c \oplus \delta W$. We can easily achieve this property if, for example, $W_c \subset W$ such that $W_c^1 \subset W_c$ is given arbitrarily and $\delta W = W_c^\perp$. However, we maintain flexibility by not assuming strict orthogonality.

To obtain a decomposition of $\mathbf{V}$, we first define

$$\mathbf{V}_c^1 = \{\mathbf{v} \in \mathbf{V} : \nabla \cdot \mathbf{v} \in W_c\},$$
$$\delta\mathbf{V}^1 = \{\delta\mathbf{v} \in \mathbf{V} : \nabla \cdot \delta\mathbf{v} \in \delta W \text{ and } \delta\mathbf{v} \cdot \nu = 0 \text{ on } \partial E_c \ \forall\ E_c \in \mathcal{T}_H\}.$$

PROPOSITION 3.2. *It follows that*
(a) $\mathbf{V}_c^1$ *and* $\delta\mathbf{V}^1$ *are closed subspaces of* $\mathbf{V}$*;*
(b) $\mathbf{V} = \mathbf{V}_c^1 + \delta\mathbf{V}^1$*;*
(c) $\mathbf{V}_c^1 \cap \delta\mathbf{V}^1 = \{\mathbf{v} \in \mathbf{V} : \nabla \cdot \mathbf{v} = 0$ *and* $\mathbf{v} \cdot \nu = 0$ *on* $\partial E_c \ \forall\ E_c \in \mathcal{T}_H\}$*;*
(d) $\nabla \cdot \mathbf{V}_c^1 = W_c$ *and* $\nabla \cdot \delta\mathbf{V}^1 = \delta W$.

Proof. For (a), first note that each space is a linear subspace. The divergence operator is continuous on $\mathbf{V}$, so $\mathbf{V}_c^1$ is closed. Finally, we note that $\delta\mathbf{V}^1$ is the intersection of a closed subspace of $\mathbf{V}$ (the vectors $\delta\mathbf{v}$ with $\nabla \cdot \delta\mathbf{v} \in \delta W$) and the kernel of a finite number of normal trace operators, so $\delta\mathbf{V}^1$ is also closed.

To see (d), we consider an auxiliary elliptic problem. Given $\delta w \in \delta W$, on each $E_c \in \mathcal{T}_H$ let $\varphi \in H^1(E_c)$ solve the linear problem

$$\Delta\varphi = \delta w \qquad \text{in } E_c, \tag{3.4}$$
$$\nabla\varphi \cdot \nu = 0 \qquad \text{on } \partial E_c. \tag{3.5}$$

This problem is solvable because $\delta w \perp W_c^1$, so δw satisfies the compatibility condition. Set $\delta\mathbf{v} = \nabla\varphi$. It is easy to conclude that $\delta\mathbf{v} \in \mathbf{V}$, since the normal traces match (in fact vanish) on each side of $\partial E_c \cap \Omega\ \forall E_c \in \mathcal{T}_H$. Thus we conclude that $\delta\mathbf{v} \in \delta\mathbf{V}^1$, and so $\delta W \subset \nabla \cdot \delta\mathbf{V}^1$. The opposite inclusion holds by definition, so $\nabla \cdot \delta\mathbf{V}^1 = \delta W$. Similarly, given $w_c \in W_c$, let $\psi \in H^1(\Omega)$ solve the linear problem

$$\Delta\psi = w_c \qquad \text{in } \Omega, \tag{3.6}$$
$$\nabla\psi \cdot \nu = 0 \qquad \text{on } \Gamma_N, \tag{3.7}$$
$$\psi = 0 \qquad \text{on } \Gamma_R. \tag{3.8}$$

Then $\mathbf{v}_c = \nabla\psi \in \mathbf{V}_c^1$ allows us to conclude that $\nabla \cdot \mathbf{V}_c^1 = W_c$.

For (b), we know that $\mathbf{V} \supset \mathbf{V}_c^1 + \delta\mathbf{V}^1$, so consider any $\mathbf{v} \in \mathbf{V}$ and decompose $\nabla \cdot \mathbf{v} = w_c + \delta w$ for $w_c \in W_c$ and $\delta w \in \delta W$. Construct φ and $\delta\mathbf{v} = \nabla\varphi$ from δw as in (3.4)–(3.5) above. Then we conclude that $\mathbf{v}_c = \mathbf{v} - \delta\mathbf{v} \in \mathbf{V}_c^1$, and so $\mathbf{V} \subset \mathbf{V}_c^1 + \delta\mathbf{V}^1$.

Finally, (c) follows trivially from (d), since $W_c \cap \delta W = \{0\}$. ∎

The proof above suggests the following Helmholtz decomposition. Let

$$\mathbf{V}_c^p = \{\mathbf{v}_c^p \in \mathbf{V}_c^1 : \mathbf{v}_c^p = \nabla\psi \text{ for some } w_c \in W_c \text{ and } \psi \text{ satisfying (3.6)–(3.8)}\},$$
$$\mathbf{V}^s = \{\mathbf{v}^s \in \mathbf{V} : \nabla \cdot \mathbf{v}^s = 0\} \subset \mathbf{V}_c^1.$$

These spaces are clearly closed subspaces, and we claim that $\mathbf{V}_c^p \cap \mathbf{V}^s = \{0\}$. Let $\mathbf{v}$ be a member of both. Then there is some scalar potential function ψ such that $\mathbf{v} = \nabla\psi$, and $\nabla \cdot \mathbf{v} = \Delta\psi = 0$. Moreover, the boundary conditions from $\mathbf{V}_c^p$ imply that ψ is constant (zero if $\Gamma_R \neq \emptyset$), and so $\mathbf{v} = 0$. Thus we conclude that in fact

$$\mathbf{V}_c^1 = \mathbf{V}_c^p \oplus \mathbf{V}^s$$

is a direct sum of potential and solenoidal vector fields. Similarly, we have the closed subspace

$$\delta\mathbf{V}^p = \{\delta\mathbf{v}^p \in \delta\mathbf{V}^1 : \delta\mathbf{v}^p = \nabla\varphi \text{ for some } \delta w \in \delta W \text{ and } \varphi \text{ satisfying (3.4)–(3.5)}\}$$

and the direct sum

$$\delta\mathbf{V}^1 = \delta\mathbf{V}^p \oplus \delta\mathbf{V}^s, \quad \text{where} \quad \delta\mathbf{V}^s = \mathbf{V}^s \cap \delta\mathbf{V}^1.$$

By similar reasoning, we conclude from $W_c \cap \delta W = \{0\}$ that $\mathbf{V}_c^p \cap \delta\mathbf{V}^p = \{0\}$, and thus

$$\mathbf{V} = \mathbf{V}_c^p \oplus \delta\mathbf{V}^p \oplus \mathbf{V}^s. \tag{3.9}$$

THEOREM 3.3. *There is some constant C, independent of $\mathcal{T}_H$, and there exist closed subspaces $\mathbf{V}_c$ and $\delta\mathbf{V}$ of $\mathbf{V}$ such that*

(a) $\mathbf{V} = \mathbf{V}_c \oplus \delta\mathbf{V}$;
(b) $\nabla \cdot \mathbf{V}_c = W_c$ *and* $\nabla \cdot \delta\mathbf{V} = \delta W$;
(c) $\delta\mathbf{V} \subset \delta\mathbf{V}^1 = \{\delta\mathbf{v} \in \mathbf{V} : \nabla \cdot \delta\mathbf{v} \in \delta W$ *and* $\delta\mathbf{v} \cdot \nu = 0$ *on* $\partial E_c \ \forall\ E_c \in \mathcal{T}_H\}$;
(d) *for* $\mathbf{v} = \mathbf{v}_c + \delta\mathbf{v} \in \mathbf{V}_c \oplus \delta\mathbf{V}$ *given,*

$$\|\mathbf{v}_c\|_{H(div)} + \|\delta\mathbf{v}\|_{H(div)} \le C\|\mathbf{v}\|_{H(div)}. \tag{3.10}$$

Moreover, a choice exists such that also the potential vector fields

(e) $\mathbf{V}_c^p \subset \mathbf{V}_c$ *and* $\delta\mathbf{V}^p \subset \delta\mathbf{V}$.

That is, (d) says that the projection operators defined by the direct sum,

$$\tilde{\mathcal{P}}_{\mathbf{V}_c} : \mathbf{V} \to \mathbf{V}_c \quad \text{and} \quad \tilde{\mathcal{P}}_{\delta\mathbf{V}} : \mathbf{V} \to \delta\mathbf{V}, \tag{3.11}$$

are bounded independently of $\mathcal{T}_H$.

Proof. The troublesome part of (3.9) are the solenoidal fields $\mathbf{V}^s$. With respect to the $H(\mathrm{div})$-inner product, let

$$\mathbf{V}_c^s = (\delta\mathbf{V}^s)^\perp \cap \mathbf{V}^s = \{\mathbf{v}_c^s \in \mathbf{V}^s : \mathbf{v}_c^s \perp \delta\mathbf{V}^s\}.$$

Then $\mathbf{V}^s = \mathbf{V}_c^s \oplus \delta\mathbf{V}^s$, and we can define

$$\mathbf{V}_c = \mathbf{V}_c^p \oplus \mathbf{V}_c^s \quad \text{and} \quad \delta\mathbf{V} = \delta\mathbf{V}^p \oplus \delta\mathbf{V}^s,$$

satisfying (a)–(c) and (e).

We need to examine the construction more carefully to conclude (d). Let $\mathbf{v} \in \mathbf{V}$ be given, and decompose

$$\nabla \cdot \mathbf{v} = w_c + \delta w = \tilde{\mathcal{P}}_{W_c} \nabla \cdot \mathbf{v} + \tilde{\mathcal{P}}_{\delta W} \nabla \cdot \mathbf{v} \in W_c \oplus \delta W.$$

We then construct $\delta\mathbf{v}^p = \nabla\varphi \in \delta\mathbf{V}^p$ from (3.4)–(3.5) using the given δw and note that standard elliptic energy estimates show that on each $E_c \in \mathcal{T}_H$,

$$\begin{aligned}\|\delta\mathbf{v}^p\|_{0,E_c}^2 &= \|\nabla\varphi\|_{0,E_c}^2 = (\tilde{\mathcal{P}}_{\delta W}\nabla \cdot \mathbf{v}, \varphi)_{E_c} \\ &\le \|\tilde{\mathcal{P}}_{\delta W}\nabla \cdot \mathbf{v}\|_{0,E_c}\|\varphi\|_{0,E_c} \le C\|\tilde{\mathcal{P}}_{\delta W}\nabla \cdot \mathbf{v}\|_{0,E_c}\|\nabla\varphi\|_{0,E_c},\end{aligned}$$

where C is the Poincaré inequality constant [17] for E_c, which is proportional to $\frac{\mathrm{diam}(E_c)^n}{\mathrm{msr}(E_c)^{1-1/n}}$ and therefore universally bounded by the nondegeneracy assumption (3.1). Thus, from (3.3),

$$\|\delta\mathbf{v}^p\|_{H(\mathrm{div})} \le C\|\tilde{\mathcal{P}}_{\delta W}\nabla \cdot \mathbf{v}\|_0 \le C\|\mathbf{v}\|_{H(\mathrm{div})}.$$

Similarly, we construct $\mathbf{v}_c^p = \nabla\psi \in \mathbf{V}_c^p$ from (3.6)–(3.8) using the given w_c and conclude that

$$\|\mathbf{v}_c^p\|_{H(\mathrm{div})} \le C\|\mathbf{v}\|_{H(\mathrm{div})}.$$

Now $\mathbf{v} = \mathbf{v}_c^p + \delta\mathbf{v}^p + \mathbf{v}^s \in \mathbf{V}_c^p \oplus \delta\mathbf{V}^p \oplus \mathbf{V}^s$ by (3.9), and $\mathbf{v}^s = \mathbf{v}_c^s + \delta\mathbf{v}^s \in \mathbf{V}_c^s \oplus \delta\mathbf{V}^s$, which is an orthogonal decomposition, so

$$\|\mathbf{v}_c^s\|_{H(\mathrm{div})}^2 + \|\delta\mathbf{v}^s\|_{H(\mathrm{div})}^2 = \|\mathbf{v}^s\|_{H(\mathrm{div})}^2 = \|\mathbf{v} - \mathbf{v}_c^p - \delta\mathbf{v}^p\|_{H(\mathrm{div})}^2 \le C\|\mathbf{v}\|_{H(\mathrm{div})}^2.$$

Finally,

$$\begin{aligned}\|\mathbf{v}_c\|_{H(\mathrm{div})} &= \|\mathbf{v}_c^p + \mathbf{v}_c^s\|_{H(\mathrm{div})} \le C\|\mathbf{v}\|_{H(\mathrm{div})},\\ \|\delta\mathbf{v}\|_{H(\mathrm{div})} &= \|\delta\mathbf{v}^p + \delta\mathbf{v}^s\|_{H(\mathrm{div})} \le C\|\delta\mathbf{v}\|_{H(\mathrm{div})},\end{aligned}$$

and the proof is complete. ∎

Thus (a) gives us a unique decomposition of vectors in $\mathbf{V}$, (b) allows us to enforce mass conservation over $\mathcal{T}_H$ on both the coarse and subgrid scales, (c) gives us a locality property of the space $\delta\mathbf{V}$ that we can exploit later, and (d) gives us a uniformity property of the decomposition independent of $\mathcal{T}_H$. The specific choice of decomposition appears to be unimportant for our purposes, although we will revisit this question later in section 5.1. In what follows, we fix a choice of $\mathbf{V}_c$ and $\delta\mathbf{V}$ satisfying the properties (a)–(d) of the theorem.

3.2. Separation of scales in the equations. Recall that $\mathbf{v}_{g_N} \in H(\mathrm{div};\Omega)$ satisfies the Neumann boundary condition. Decompose the solution

$$\begin{aligned}p &= p_c + \delta p \in W_c \oplus \delta W,\\ \mathbf{u} &= \mathbf{u}_c + \delta\mathbf{u} + \mathbf{v}_{g_N} \in \mathbf{V}_c \oplus \delta\mathbf{V} + \mathbf{v}_{g_N}.\end{aligned}$$

Then we decompose (2.6)–(2.7) by choosing test functions restricted to the spaces $W_c \times \mathbf{V}_c$ or $\delta W \times \delta\mathbf{V}$. This results in an equivalent system of the four equations (3.12)–(3.15) below. For convenience, let

$$\begin{aligned}b^* &= b - \nabla\cdot\mathbf{v}_{g_N},\\ c^* &= c - d^{-1}\mathbf{v}_{g_N}.\end{aligned}$$

Coarse-scale equations. Find $\mathbf{u}_c \in \mathbf{V}_c$ and $p_c \in W_c$ such that

$$(a(p_c+\delta p), w_c) + (\nabla\cdot(\mathbf{u}_c+\delta\mathbf{u}), w_c) = (b^*, w_c) \qquad \forall\ w_c \in W_c, \tag{3.12}$$

$$\begin{aligned}&(d^{-1}(\mathbf{u}_c+\delta\mathbf{u}), \mathbf{v}_c) + (\alpha\mathbf{u}_c\cdot\nu, \mathbf{v}_c\cdot\nu)_{\Gamma_R} - (p_c+\delta p, \nabla\cdot\mathbf{v}_c)\\ &\quad = (c^*, \mathbf{v}_c) - (g_R, \mathbf{v}_c\cdot\nu)_{\Gamma_R} \qquad \forall\ \mathbf{v}_c \in \mathbf{V}_c.\end{aligned} \tag{3.13}$$

Subgrid δ-scale equations. Find $\delta\mathbf{u} \in \delta\mathbf{V}$ and $\delta p \in \delta W$ such that

$$(a(p_c+\delta p), \delta w) + (\nabla\cdot(\mathbf{u}_c+\delta\mathbf{u}), \delta w) = (b^*, \delta w) \quad \forall\ \delta w \in \delta W, \tag{3.14}$$

$$(d^{-1}(\mathbf{u}_c+\delta\mathbf{u}), \delta\mathbf{v}) - (p_c+\delta p, \nabla\cdot\delta\mathbf{v}) = (c^*, \delta\mathbf{v}) \quad \forall\ \delta\mathbf{v} \in \delta\mathbf{V}. \tag{3.15}$$

4. The δ-solution operator and upscaling. The systems (3.12)–(3.13) and (3.14)–(3.15) are coupled together, and as written they do not allow us to exploit the locality of $\delta\mathbf{V}$. Our goal now is to rewrite (3.12)–(3.13) independently of δp and $\delta\mathbf{u}$. To do so, we need to write these quantities in terms of p_c and $\mathbf{u}_c$.

4.1. Solvability of the subgrid scale equations.

LEMMA 4.1. *Given* $(p_c, \mathbf{u}_c) \in W_c \times \mathbf{V}_c$, *there exists a unique solution* $(\delta p, \delta \mathbf{u}) \in \delta W \times \delta \mathbf{V}$ *to* (3.14)–(3.15). *Moreover, there is some constant* C, *independent of the coarse mesh* $\mathcal{T}_H$ *and the specific decomposition of* $W \times \mathbf{V}$ *selected, such that*

$$\|\delta p\|_0 + \|\delta \mathbf{u}\|_{H(div)} \leq C\{\|b\|_0 + \|c\|_0 + \|\mathbf{v}_{g_N}\|_{H(div)} + \|p_c\|_0 + \|\mathbf{u}_c\|_{H(div)}\}.$$

We can prove Lemma 4.1 using the theory of saddle point problems [6, 8, 13, 7]. We need a generalization of the theory developed in, e.g., [13]. Consider the following abstract problem: Find $\check{p} \in \check{W}$ and $\check{\mathbf{u}} \in \check{\mathbf{V}}$ such that

$$\check{c}(\check{p}, \check{w}) + (\nabla \cdot \check{\mathbf{u}}, \check{w}) = F(\check{w}) \quad \forall\ \check{w} \in \check{W}, \tag{4.1}$$

$$\check{a}(\check{\mathbf{u}}, \check{\mathbf{v}}) - (\check{p}, \nabla \cdot \check{\mathbf{v}}) = G(\check{\mathbf{v}}) \quad \forall\ \check{\mathbf{v}} \in \check{\mathbf{V}}, \tag{4.2}$$

where $\check{W} \subset L^2(\Omega)$ and $\check{\mathbf{V}} \subset H(\mathrm{div}; \Omega)$ are Hilbert spaces. The following result is a simple corollary of the more general theory [13, pp. 44–47].

THEOREM 4.2. *Suppose that* $\check{W} \subset L^2(\Omega)$ *and* $\check{\mathbf{V}} \subset H(\mathrm{div}; \Omega)$ *are Hilbert spaces such that* $\nabla \cdot \check{\mathbf{V}} = \check{W}$. *Suppose that* $\check{a}$ *and* $\check{c}$ *are continuous, symmetric, positive semidefinite bilinear forms on* $\check{\mathbf{V}} \times \check{\mathbf{V}}$ *and* $\check{W} \times \check{W}$, *respectively, and that* $\check{a}$ *is coercive on* $\check{\mathbf{V}} \cap \ker(\nabla \cdot)$, $G \in \check{\mathbf{V}}'$, $F \in \check{W}'$, *and there exists* $\beta > 0$ *such that*

$$\inf_{\check{w} \in \check{W}} \sup_{\check{\mathbf{v}} \in \check{\mathbf{V}}} \frac{(\nabla \cdot \check{\mathbf{v}}, \check{w})}{\|\check{\mathbf{v}}\|_{H(div)} \|\check{w}\|_0} \geq \beta > 0. \tag{4.3}$$

Then there exists a unique solution $(\check{p}, \check{\mathbf{u}}) \in \check{W} \times \check{\mathbf{V}}$ *to* (4.1)–(4.2), *and there is a constant* C *such that*

$$\|\check{p}\|_0 + \|\check{\mathbf{u}}\|_{H(div)} \leq C\{\|F\| + \|G\|\},$$

where C *is a nonlinear function of* $\|\check{a}\|$, $\|\check{c}\|$, *the reciprocal of the coercivity bound for* $\check{a}$, *and* $1/\beta$ *that is bounded on bounded subsets.*

The key result is to prove the celebrated inf-sup condition (4.3). This condition is known to hold over $W \times \mathbf{V}$, and the following corollary is well known and uses the fact that for $\mathbf{v} \in \mathbf{V}$,

$$(g_R, \mathbf{v} \cdot \nu)_{\Gamma_R} = (g_R, \mathbf{v} \cdot \nu)_{\partial\Omega} \leq C\|g_R\|_{1/2,\partial\Omega}\|\mathbf{v}\|_{H(\mathrm{div})},$$

where g_R on $\partial\Omega$ is any fixed bounded extension.

COROLLARY 4.3. *There exists a unique solution to* (2.6)–(2.7), *and there is some constant* C *depending on* a, d, *and the inf-sup bound such that*

$$\|p\|_0 + \|\mathbf{u}\|_{H(div)} \leq C\{\|b\|_0 + \|c\|_0 + \|\mathbf{v}_{g_N}\|_{H(div)} + \|g_R\|_{1/2,\partial\Omega}\}.$$

LEMMA 4.4. *The inf-sup condition holds over both* $W_c \times \mathbf{V}_c$ *and* $\delta W \times \delta \mathbf{V}$, *with constants independent of the coarse mesh* $\mathcal{T}_H$ *and the specific decomposition of* $W \times \mathbf{V}$ *selected.*

Proof. For $W_c \times \mathbf{V}_c$, we have the following argument. Given $w_c \in W_c$, solve for $\psi \in H^1(\Omega)$ satisfying (3.6)–(3.8), with $\int_\Omega \psi\, dx = 0$ if $\Gamma_N = \partial\Omega$. Set $\mathbf{v} = \nabla\psi$. Then

$$\|\mathbf{v}\|_0^2 = \|\nabla\psi\|_0^2 = (w_c, \psi) \leq \|w_c\|_0\|\psi\|_0 \leq C\|w_c\|_0\|\nabla\psi\|_0,$$

by Poincaré's inequality [17], so $\|\mathbf{v}\|_{H(\mathrm{div})} \le C\|w_c\|_0$. Let $\mathbf{v} = \hat{\mathbf{v}}_c + \delta\mathbf{v}$, where $\hat{\mathbf{v}}_c \in \mathbf{V}_c$ and $\delta\mathbf{v} \in \delta\mathbf{V}$. We note that $w_c = \nabla\cdot\mathbf{v} = \nabla\cdot\hat{\mathbf{v}}_c \in W_c$. Moreover,

$$\|\hat{\mathbf{v}}_c\|_{H(\mathrm{div})} = \|\tilde{\mathcal{P}}_{\mathbf{V}_c}\mathbf{v}\|_{H(\mathrm{div})} \le C\|\mathbf{v}\|_{H(\mathrm{div})} \le C\|w_c\|_0.$$

Thus

$$\begin{aligned}\inf_{w_c\in W_c}\sup_{\mathbf{v}_c\in\mathbf{V}_c}\frac{(\nabla\cdot\mathbf{v}_c, w_c)}{\|\mathbf{v}_c\|_{H(\mathrm{div})}\,\|w_c\|_0} &\ge \inf_{w_c\in W_c}\frac{(\nabla\cdot\hat{\mathbf{v}}_c, w_c)}{\|\hat{\mathbf{v}}_c\|_{H(\mathrm{div})}\,\|w_c\|_0}\\ &= \inf_{w_c\in W_c}\frac{\|w_c\|_0}{\|\hat{\mathbf{v}}_c\|_{H(\mathrm{div})}} \ge \frac{1}{C} > 0.\end{aligned}$$

The proof for $\delta W\times\delta\mathbf{V}$ is entirely similar and omitted. ∎

Proof of Lemma 4.1. We can rewrite the subgrid δ-scale equations (3.14)–(3.15) in the form of the abstract problem (4.1)–(4.2) by taking $\check{\mathbf{V}} = \delta\mathbf{V}$ and $\check{W} = \delta W$ and by defining

$$\begin{aligned}&\check{c}(\delta w_1, \delta w_2) = (a\delta w_1, \delta w_2),\\ &\check{a}(\delta\mathbf{v}_1, \delta\mathbf{v}_2) = (d^{-1}\delta\mathbf{v}_1, \delta\mathbf{v}_2),\\ &F(\delta w) = (b^* - ap_c - \nabla\cdot\mathbf{u}_c, \delta w),\\ &G(\delta\mathbf{v}) = (c^* - d^{-1}\mathbf{u}_c, \delta\mathbf{v}) + (p_c, \nabla\cdot\delta\mathbf{v}).\end{aligned}$$

Easily, the bilinear forms $\check{a}$ and $\check{c}$ are continuous, symmetric, and nonnegative on $\delta\mathbf{V}$, and $\check{a}$ is coercive on $\delta\mathbf{V}\cap\ker(\nabla\cdot)$, with constants depending on the coefficients a, c, and d. Moreover, F and G are continuous linear functionals. Lemma 4.4 gives us the inf-sup condition (4.3), so the hypotheses required by Theorem 4.2 are satisfied by the system, and so the conclusions follow. ∎

4.2. The δ-solution operator. Lemma 4.1 allows us to define the solution operator of the subgrid δ-scale equations (3.14)–(3.15) in terms of the coarse-scale solution. It is in fact an affine operator with constant and linear parts.

Constant part of the δ-solution operator. Find $\delta\bar{p}\in\delta W$ and $\delta\bar{\mathbf{u}}\in\delta\mathbf{V}$ such that

$$(a\delta\bar{p}, \delta w) + (\nabla\cdot\delta\bar{\mathbf{u}}, \delta w) = (b^*, \delta w) \quad \forall\ \delta w\in\delta W, \tag{4.4}$$

$$(d^{-1}\delta\bar{\mathbf{u}}, \delta\mathbf{v}) - (\delta\bar{p}, \nabla\cdot\delta\mathbf{v}) = (c^*, \delta\mathbf{v}) \quad \forall\ \delta\mathbf{v}\in\delta\mathbf{V}. \tag{4.5}$$

W_c-linear part of the δ-solution operator. For $w_c\in W_c$, find $\delta\tilde{p}\in\delta W$ and $\delta\tilde{\mathbf{u}}\in\delta\mathbf{V}$ such that

$$(a(w_c + \delta\tilde{p}), \delta w) + (\nabla\cdot\delta\tilde{\mathbf{u}}, \delta w) = 0 \quad \forall\ \delta w\in\delta W, \tag{4.6}$$

$$(d^{-1}\delta\tilde{\mathbf{u}}, \delta\mathbf{v}) - (w_c + \delta\tilde{p}, \nabla\cdot\delta\mathbf{v}) = 0 \quad \forall\ \delta\mathbf{v}\in\delta\mathbf{V}. \tag{4.7}$$

$\mathbf{V}_c$-linear part of the δ-solution operator. For $\mathbf{v}_c\in\mathbf{V}_c$, find $\delta\hat{p}\in\delta W$ and $\delta\hat{\mathbf{u}}\in\delta\mathbf{V}$ such that

$$(a\delta\hat{p}, \delta w) + (\nabla\cdot(\mathbf{v}_c + \delta\hat{\mathbf{u}}), \delta w) = 0 \quad \forall\ \delta w\in\delta W, \tag{4.8}$$

$$(d^{-1}(\mathbf{v}_c + \delta\hat{\mathbf{u}}), \delta\mathbf{v}) - (\delta\hat{p}, \nabla\cdot\delta\mathbf{v}) = 0 \quad \forall\ \delta\mathbf{v}\in\delta\mathbf{V}. \tag{4.9}$$

The theory of saddle point problems allows us to conclude the solvability and boundedness of each system, so we have the following result.

THEOREM 4.5. *There exist bounded linear operators*

$$\delta\tilde{p} : W_c \to \delta W \quad \text{and} \quad \delta\tilde{\mathbf{u}} : W_c \to \delta\mathbf{V},$$
$$\delta\hat{p} : \mathbf{V}_c \to \delta W \quad \text{and} \quad \delta\hat{\mathbf{u}} : \mathbf{V}_c \to \delta\mathbf{V},$$

bounded independent of the coarse mesh $\mathcal{T}_H$ and the specific decomposition of $W \times \mathbf{V}$ selected, defined by (4.6)–(4.9)*, and functions $\delta\bar{p} \in \delta W$ and $\delta\bar{\mathbf{u}} \in \delta\mathbf{V}$ defined by* (4.4)–(4.5) *such that*

$$\delta p = \delta\tilde{p}(p_c) + \delta\hat{p}(\mathbf{u}_c) + \delta\bar{p},$$
$$\delta\mathbf{u} = \delta\tilde{\mathbf{u}}(p_c) + \delta\hat{\mathbf{u}}(\mathbf{u}_c) + \delta\bar{\mathbf{u}}.$$

Moreover, there is some constant C such that

$$\|\delta\bar{p}\|_0 + \|\delta\bar{\mathbf{u}}\|_{H(div)} \le C\{\|b\|_0 + \|c\|_0 + \|\mathbf{v}_{g_N}\|_{H(div)}\}.$$

Because $\delta\mathbf{V} \cdot \nu = 0$ on each ∂E_c for $E_c \in \mathcal{T}_H$, $\delta\tilde{p}$, $\delta\tilde{\mathbf{u}}$, $\delta\hat{p}$, and $\delta\hat{\mathbf{u}}$ are locally defined operators. That is, the restriction to E_c of the result is given by evaluating the restricted operators, which are defined by restricting the integrals to E_c in (4.6)–(4.9). Symbolically, we might write

$$\delta\tilde{p}(p_c)|_{E_c} = \delta\tilde{p}|_{E_c}(p_c|_{E_c}) \quad \text{and} \quad \delta\tilde{\mathbf{u}}(p_c)|_{E_c} = \delta\tilde{\mathbf{u}}|_{E_c}(p_c|_{E_c}),$$
$$\delta\hat{p}(\mathbf{u}_c)|_{E_c} = \delta\hat{p}|_{E_c}(\mathbf{u}_c|_{E_c}) \quad \text{and} \quad \delta\hat{\mathbf{u}}(\mathbf{u}_c)|_{E_c} = \delta\hat{\mathbf{u}}|_{E_c}(\mathbf{u}_c|_{E_c}).$$

These operators are well defined, linear, and bounded uniformly with respect to $\mathcal{T}_H$ and the decomposition of $W \times \mathbf{V}$ selected.

In upscaling theory, results like Theorem 4.5 allow one to *close* the equations. That is, the fine scale is represented as an operator of the coarse scale. However, usually such a result is either *assumed* or additional assumptions are added to restrict the nature of the problem (such as assuming some kind of periodicity or ergodicity). Hence such results are often called *closure assumptions*. We have closed our system without the need of any additional assumptions.

4.3. The upscaled equation. If we substitute the δ-solution operator into the coarse-scale equations (3.12)–(3.13), we obtain the following problem.

Asymmetric upscaled equations. Find $p_c \in W_c$ and $\mathbf{u}_c \in \mathbf{V}_c$ such that

$$\begin{aligned}
&(a(p_c + \delta\tilde{p}(p_c) + \delta\hat{p}(\mathbf{u}_c)), w_c) \\
&\quad + (\nabla \cdot (\mathbf{u}_c + \delta\tilde{\mathbf{u}}(p_c) + \delta\hat{\mathbf{u}}(\mathbf{u}_c)), w_c) \\
&\quad = (b^* - a\delta\bar{p} - \nabla \cdot \delta\bar{\mathbf{u}}, w_c) \qquad \forall\ w_c \in W_c, \qquad (4.10)\\
&(d^{-1}(\mathbf{u}_c + \delta\tilde{\mathbf{u}}(p_c) + \delta\hat{\mathbf{u}}(\mathbf{u}_c)), \mathbf{v}_c) \\
&\quad + (\alpha\mathbf{u}_c \cdot \nu, \mathbf{v}_c \cdot \nu)_{\Gamma_R} - (p_c + \delta\tilde{p}(p_c) + \delta\hat{p}(\mathbf{u}_c), \nabla \cdot \mathbf{v}_c) \\
&\quad = (c^* - d^{-1}\delta\bar{\mathbf{u}}, \mathbf{v}_c) + (\delta\bar{p}, \nabla \cdot \mathbf{v}_c) - (g_R, \mathbf{v}_c \cdot \nu)_{\Gamma_R} \qquad \forall\ \mathbf{v}_c \in \mathbf{V}_c. \qquad (4.11)
\end{aligned}$$

This system is posed entirely with respect to coarse-scale functions, so we say that it has been *upscaled* from the fine scale. However, this system is not symmetric, even though the original fine-scale system is symmetric. We can remedy this by noting several equivalences. First, note that from (4.6) and then (4.7),

$$\begin{aligned}
(a(p_c + \delta\tilde{p}(p_c)), \delta\tilde{p}(w_c)) &= -(\nabla \cdot \delta\tilde{\mathbf{u}}(p_c), \delta\tilde{p}(w_c)) \\
&= -(d^{-1}\delta\tilde{\mathbf{u}}(w_c), \delta\tilde{\mathbf{u}}(p_c)) + (w_c, \nabla \cdot \delta\tilde{\mathbf{u}}(p_c)),
\end{aligned}$$

and similarly from (4.9) and then (4.8),

$$\begin{aligned}(d^{-1}(\mathbf{u}_c+\delta\hat{\mathbf{u}}(\mathbf{u}_c)),\delta\hat{\mathbf{u}}(\mathbf{v}_c)) &= (\delta\hat{p}(\mathbf{u}_c),\nabla\cdot\delta\hat{\mathbf{u}}(\mathbf{v}_c))\\ &= -(a\delta\hat{p}(\mathbf{v}_c),\delta\hat{p}(\mathbf{u}_c))-(\nabla\cdot\mathbf{v}_c,\delta\hat{p}(\mathbf{u}_c)).\end{aligned}$$

We also apply (4.9), (4.6), (4.7), and then (4.8) to obtain

$$\begin{aligned}(d^{-1}\delta\tilde{\mathbf{u}}(p_c),\mathbf{v}_c) &= (\delta\hat{p}(\mathbf{v}_c),\nabla\cdot\delta\tilde{\mathbf{u}}(p_c))-(d^{-1}\delta\hat{\mathbf{u}}(\mathbf{v}_c),\delta\tilde{\mathbf{u}}(p_c))\\ &= -(a(p_c+\delta\tilde{p}(p_c)),\delta\hat{p}(\mathbf{v}_c))-(d^{-1}\delta\hat{\mathbf{u}}(\mathbf{v}_c),\delta\tilde{\mathbf{u}}(p_c))\\ &= -(a(p_c+\delta\tilde{p}(p_c)),\delta\hat{p}(\mathbf{v}_c))-(p_c+\delta\tilde{p}(p_c),\nabla\cdot\delta\hat{\mathbf{u}}(\mathbf{v}_c))\\ &= -(ap_c,\delta\hat{p}(\mathbf{v}_c))-(p_c,\nabla\cdot\delta\hat{\mathbf{u}}(\mathbf{v}_c))+(\nabla\cdot\mathbf{v}_c,\delta\tilde{p}(p_c)).\end{aligned}$$

Combining, we obtain a symmetric form for our system.

Symmetric upscaled equations. Find $p_c\in W_c$ and $\mathbf{u}_c\in\mathbf{V}_c$ such that

$$\begin{aligned}&(a(p_c+\delta\tilde{p}(p_c)),w_c+\delta\tilde{p}(w_c))+(d^{-1}\delta\tilde{\mathbf{u}}(p_c),\delta\tilde{\mathbf{u}}(w_c))\\ &\quad+(\nabla\cdot(\mathbf{u}_c+\delta\hat{\mathbf{u}}(\mathbf{u}_c)),w_c)+(a\delta\hat{p}(\mathbf{u}_c),w_c)\\ &\quad=(b^*-a\delta\bar{p}-\nabla\cdot\delta\bar{\mathbf{u}},w_c)\qquad\forall\ w_c\in W_c,\end{aligned}\tag{4.12}$$

$$\begin{aligned}&(d^{-1}(\mathbf{u}_c+\delta\hat{\mathbf{u}}(\mathbf{u}_c)),\mathbf{v}_c+\delta\hat{\mathbf{u}}(\mathbf{v}_c))\\ &\quad+(a\delta\hat{p}(\mathbf{u}_c),\delta\hat{p}(\mathbf{v}_c))+(\alpha\mathbf{u}_c\cdot\nu,\mathbf{v}_c\cdot\nu)_{\Gamma_R}\\ &\quad-(p_c,\nabla\cdot(\mathbf{v}_c+\delta\hat{\mathbf{u}}(\mathbf{v}_c)))-(ap_c,\delta\hat{p}(\mathbf{v}_c))\\ &\quad=(c^*-d^{-1}\delta\bar{\mathbf{u}},\mathbf{v}_c)+(\delta\bar{p},\nabla\cdot\mathbf{v}_c)-(g_R,\mathbf{v}_c\cdot\nu)_{\Gamma_R}\qquad\forall\ \mathbf{v}_c\in\mathbf{V}_c.\end{aligned}\tag{4.13}$$

The final solution is given then by

$$p=p_c+\delta\tilde{p}(p_c)+\delta\hat{p}(\mathbf{u}_c)+\delta\bar{p},\tag{4.14}$$

$$\mathbf{u}=\mathbf{u}_c+\delta\tilde{\mathbf{u}}(p_c)+\delta\hat{\mathbf{u}}(\mathbf{u}_c)+\delta\bar{\mathbf{u}}+\mathbf{v}_{g_N}.\tag{4.15}$$

It remains to show that indeed (4.10)–(4.11) or, equivalently, (4.12)–(4.13) has a unique solution from which to construct the solution p and $\mathbf{u}$.

THEOREM 4.6. *There exists a unique solution to* (4.10)–(4.11) *or, equivalently, to* (4.12)–(4.13). *Moreover, there is some constant C, independent of the coarse mesh $\mathcal{T}_H$ and the specific decomposition of $W\times\mathbf{V}$ selected, such that*

$$\|p_c\|_0+\|\mathbf{u}_c\|_{H(div)}\le C\{\|b\|_0+\|c\|_0+\|\mathbf{v}_{g_N}\|_{H(div)}+\|g_R\|_{1/2,\partial\Omega}\}.$$

Proof. Rather than trying to show the inf-sup condition for the system (4.12)–(4.13) with its bilinear form $(\nabla\cdot(\mathbf{v}_c+\delta\hat{\mathbf{u}}(\mathbf{v}_c)),w_c)+(a\delta\hat{p}(\mathbf{v}_c),w_c)$, we use a more direct route. From Corollary 4.3, we have $(p,\mathbf{u})\in W\times(\mathbf{V}+\mathbf{v}_{g_N})$ solving the original system. We uniquely decompose $p=p_c+\delta p\in W_c\oplus\delta W$ and $\mathbf{u}-\mathbf{v}_{g_N}=\mathbf{u}_c+\delta\mathbf{u}\in\mathbf{V}_c\oplus\delta\mathbf{V}$. By construction, $(p_c,\mathbf{u}_c)\in W_c\times\mathbf{V}_c$ is a solution to (4.12)–(4.13).

To demonstrate the uniqueness of the solution, consider the difference of two solutions, which is equivalent to setting all constant terms to zero and showing that there is only the trivial solution. Take the test functions $w_c=p_c$ and $\mathbf{v}_c=\mathbf{u}_c$ and sum the equations to conclude that $\mathbf{u}_c+\delta\hat{\mathbf{u}}(\mathbf{u}_c)=\delta\tilde{\mathbf{u}}(p_c)=0$ and, by the uniqueness of the decomposition $\mathbf{V}_c\oplus\delta\mathbf{V}$, that $\mathbf{u}_c=0$ and thus also $\delta\hat{p}(\mathbf{u}_c)=0$. Since $\nabla\cdot\mathbf{V}=W$, equations (4.7) and (4.11) imply that $p_c+\delta\tilde{p}(p_c)=0$, and thus $p_c=0$ and uniqueness is established.

We use (3.3) and (3.10) to bound

$$\|p_c\|_0\le C\|p\|_0\quad\text{and}\quad\|\mathbf{u}_c\|_{H(\mathrm{div})}\le C\|\mathbf{u}\|_{H(\mathrm{div})}.$$

Finally, Corollary 4.3 bounds these terms as required. ∎

5. Numerical approximation. In the previous section, we demonstrated that the δ-problems (4.4)–(4.9) and the upscaled problem (4.12)–(4.13) are well-posed, uniformly with respect to $\mathcal{T}_H$. In this section, we construct an efficient computational algorithm, exploiting the structure exposed in the previous two sections. Namely, we exploit that the δ-problems are local and thus easily solved computationally and that the global upscaled problem on $\mathcal{T}_H$ is relatively small compared to the full fine-scale problem (2.6)–(2.7) itself.

We present a class of discretizations based on standard mixed spaces. Our class of discretizations includes the particularly pertinent low order discretization described in [1, 2] and later in section 7.

We now consider $\mathcal{T}_H$ as a coarse mesh. For approximation purposes, we assume that it is chosen of conforming simplexes, rectangular parallelepipeds, or prisms such that, for simplicity, $\bar{\Gamma}_N$ is the union of coarse edges or faces. Let

$$H = \max_{E_c \in \mathcal{T}_H} \operatorname{diam}(E_c).$$

On each $E_c \in \mathcal{T}_H$, let $\mathcal{T}_h(E_c)$ be a fine mesh sufficient to resolve the coefficients of the problem, and define

$$h = \max_{E_c \in \mathcal{T}_H} \max_{\delta E \in \mathcal{T}_h(E_c)} \operatorname{diam}(\delta E).$$

Then $\mathcal{T}_{H,h} = \cup_{E_c \in \mathcal{T}_H} \mathcal{T}_h(E_c)$ is the full fine mesh. The meshes need not match across boundaries of coarse elements.

5.1. Two-scale conforming approximation spaces. From among any of the usual mixed finite element spaces for second order elliptic equations, such as those of [28, 24, 12, 10, 11, 14, 13], we select the coarse space $W_H^* \times \mathbf{V}_H^* \subset W \times \mathbf{V}$ on the mesh $\mathcal{T}_H$, with $\mathbf{V}_H^*$ satisfying the homogeneous Neumann boundary condition on Γ_N. In all the usual spaces,

$$\nabla \cdot \mathbf{V}_H^* = W_H^*$$

and piecewise discontinuous constants $W_c^1 \subset W_H^*$.

On each coarse element $E_c \in \mathcal{T}_H$, we similarly select from among any of the usual mixed finite element spaces the δ-space $\delta W_h(E_c) \times \delta \mathbf{V}_h(E_c) \subset (W \times \mathbf{V})|_{E_c}$ on the mesh $\mathcal{T}_h(E_c)$, with $\delta W_h(E_c) \perp 1$ and $\delta \mathbf{V}_h(E_c)$ satisfying the homogeneous Neumann boundary condition on ∂E_c. Merging these spaces results in $\delta W_h \times \delta \mathbf{V}_h$ over the entire domain Ω. Then $\delta W_h \perp W_c^1$ and

$$\nabla \cdot \delta \mathbf{V}_h = \delta W_h.$$

For simplicity, we take the same mixed space for each coarse element, although this assumption could be relaxed.

The overall two-scale mixed spaces are then defined to be

$$W_{H,h} = W_H^* + \delta W_h \quad \text{and} \quad \mathbf{V}_{H,h} = \mathbf{V}_H^* + \delta \mathbf{V}_h.$$

However, it is possible for general combinations of mixed spaces that the coarse and δ-spaces are not linearly independent. The following construction suffices to rectify the problem. First, complete a basis for $\delta W_h \cap W_H^*$ to a basis for W_H^* and then define W_H as the span of the extra vectors. Similarly, we complete a basis for $\delta \mathbf{V}_h \cap \mathbf{V}_H^*$ to a basis for $\mathbf{V}_H^*$ and use the extra vectors to define $\mathbf{V}_H$.

To summarize our construction, our two-scale finite element spaces are and satisfy

$$W_{H,h} = W_H^* + \delta W_h = W_H \oplus \delta W_h \subset W,$$
$$\mathbf{V}_{H,h} = \mathbf{V}_H^* + \delta \mathbf{V}_h = \mathbf{V}_H \oplus \delta \mathbf{V}_h \subset \mathbf{V},$$

where

$$\nabla \cdot \delta \mathbf{V}_h = \delta W_h \quad \text{and} \quad \nabla \cdot \mathbf{V}_{H,h} = W_{H,h}.$$

Our spaces are conforming in the sense that both W_H and δW_h are subspaces of W, and $\mathbf{V}_H$ and $\delta \mathbf{V}_h$ are subspaces of $\mathbf{V}$ and $\delta \mathbf{V}^1$, respectively, and thus have the required $H(\mathrm{div})$ smoothness and satisfy the requisite boundary conditions.

However, it is not necessarily the case that $W_H \subset W_c$ and $\delta W_h \subset \delta W$ nor that $\mathbf{V}_H \subset \mathbf{V}_c$ and $\delta \mathbf{V}_h \subset \delta \mathbf{V}$. In section 3.1, we made a few arbitrary choices. We could, for example, have chosen $W_H = W_c$ and then defined δW in such a way that both $\delta W_h \subset \delta W$ and (3.3) hold, perhaps after assuming the restriction on the grid mentioned in section 6. We might similarly be able to decompose $\mathbf{V}^s$ in such a way that $\mathbf{V}_H \subset \mathbf{V}_c$ and $\delta \mathbf{V}_h \subset \delta \mathbf{V}$. Then the mixed spaces would be fully conforming in the two-scale sense. However, there appears to be no advantage to such a construction, so we will not attempt it here.

5.2. The discrete equations in computable form. The key to efficient implementation is to determine the δ-operators' actions only on the finite element basis for $\mathbf{V}_H$. We call such solutions *numerical Green's functions*, since they give the response of the system to a "unit" disturbance, which on the numerical level is a coarse-scale basis function.

Let $\{w_{H,i}\}_i$ and $\{\mathbf{v}_{H,j}\}_j$ be finite element bases for W_H and $\mathbf{V}_H$, respectively. One property of a finite element basis is that the support of any basis function is relatively small. Expand

$$p_H = \sum_i p_i w_{H,i} \quad \text{and} \quad \mathbf{u}_H = \sum_j u_j \mathbf{v}_{H,j}. \tag{5.1}$$

Then to compute, for example,

$$\delta \hat{\mathbf{u}}(\mathbf{u}_H) = \sum_j u_j \delta \hat{\mathbf{u}}(\mathbf{v}_{H,j})$$

requires only the numerical Green's functions $\delta \hat{\mathbf{u}}(\mathbf{v}_{H,j})$ for each j.

The numerical scheme has three main steps. The first step is to compute the solutions to the following problems.

Constant part of the approximate δ-solution operator. Find $\delta \bar{p}_h \in \delta W_h$ and $\delta \bar{\mathbf{u}}_h \in \delta \mathbf{V}_h$ such that

$$(a \delta \bar{p}_h, \delta w_h) + (\nabla \cdot \delta \bar{\mathbf{u}}_h, \delta w_h) = (b^*, \delta w_h) \qquad \forall\, \delta w_h \in \delta W_h, \tag{5.2}$$

$$(d^{-1} \delta \bar{\mathbf{u}}_h, \delta \mathbf{v}_h) - (\delta \bar{p}_h, \nabla \cdot \delta \mathbf{v}_h) = (c^*, \delta \mathbf{v}_h) \quad \forall\, \delta \mathbf{v}_h \in \delta \mathbf{V}_h. \tag{5.3}$$

W_H-linear part of the approximate δ-solution operator. For $w_{H,i}$ in a basis for W_H, find $\delta \tilde{p}_{h,i} \in \delta W_h$ and $\delta \tilde{\mathbf{u}}_{h,i} \in \delta \mathbf{V}_h$ such that

$$(a(w_{H,i} + \delta \tilde{p}_{h,i}), \delta w_h) + (\nabla \cdot \delta \tilde{\mathbf{u}}_{h,i}, \delta w_h) = 0 \quad \forall\, \delta w_h \in \delta W_h, \tag{5.4}$$

$$(d^{-1} \delta \tilde{\mathbf{u}}_{h,i}, \delta \mathbf{v}_h) - (w_{H,i} + \delta \tilde{p}_{h,i}, \nabla \cdot \delta \mathbf{v}_h) = 0 \quad \forall\, \delta \mathbf{v}_h \in \delta \mathbf{V}_h. \tag{5.5}$$

$\mathbf{V}_H$-linear part of the approximate δ-solution operator. For $\mathbf{v}_{H,j}$ in a basis for $\mathbf{V}_H$, find $\delta\hat{p}_{h,j} \in \delta W_h$ and $\delta\hat{\mathbf{u}}_{h,j} \in \delta\mathbf{V}_h$ such that

$$(a\delta\hat{p}_{h,j}, \delta w_h) + (\nabla\cdot(\mathbf{v}_{H,j} + \delta\hat{\mathbf{u}}_{h,j}), \delta w_h) = 0 \qquad \forall\, \delta w_h \in \delta W_h, \tag{5.6}$$

$$(d^{-1}(\mathbf{v}_{H,j} + \delta\hat{\mathbf{u}}_{h,j}), \delta\mathbf{v}_h) - (\delta\hat{p}_{h,j}, \nabla\cdot\delta\mathbf{v}_h) = 0 \quad \forall\, \delta\mathbf{v}_h \in \delta\mathbf{V}_h. \tag{5.7}$$

These problems are quick and efficient to solve, since they are relatively quite small due to their local nature. That is, we actually solve them on each coarse element independently. For example, we know that for the standard mixed spaces, $\mathbf{v}_{H,j}$ is supported on at most two coarse elements, E_c^1 and E_c^2. Thus, to evaluate $\delta\hat{\mathbf{u}}(\mathbf{v}_{H,j})$, we solve (5.6)–(5.7) twice, with all spaces and integrals restricted to E_c^k for $k = 1, 2$. Then in fact $\delta\hat{\mathbf{u}}(\mathbf{v}_{H,j})$ is the combination of the two solutions $\delta\hat{\mathbf{u}}|_{E_c^k}(\mathbf{v}_{H,j}|_{E_c^k})$ on E_c^k, $k = 1, 2$. On each coarse element, each linear system in (5.2)–(5.7) has the same matrix, and only the so-called right-hand side vector varies. Thus it is reasonable to use a direct solver for these problems. Moreover, they parallelize trivially. Since these are square linear systems, existence and uniqueness of a solution follow from uniqueness, which follow in the usual way from the fact that $\nabla\cdot\delta\mathbf{V}_h = \delta W_h$.

Then we have the implicit expressions

$$\delta p_h = \delta\tilde{p}_h(p_H) + \delta\hat{p}_h(\mathbf{u}_H) + \delta\bar{p}_h = \sum_i p_i\delta\tilde{p}_{h,i} + \sum_j u_j\delta\hat{p}_{h,j} + \delta\bar{p}_h, \tag{5.8}$$

$$\delta\mathbf{u}_h = \delta\tilde{\mathbf{u}}_h(p_H) + \delta\hat{\mathbf{u}}_h(\mathbf{u}_H) + \delta\bar{\mathbf{u}}_h = \sum_i p_i\delta\tilde{\mathbf{u}}_{h,i} + \sum_j u_j\delta\hat{\mathbf{u}}_{h,j} + \delta\bar{\mathbf{u}}_h, \tag{5.9}$$

since at this stage of the computation p_i and u_j are not known.

The second main step is to compute the solution to the upscaled equation. We approximate (4.12)–(4.13) in the symmetric case by restricting to the finite element basis: Find $p_H \in W_H$ and $\mathbf{u}_H \in \mathbf{V}_H$ such that

$$\begin{aligned}
&(a(p_H + \delta\tilde{p}(p_H)), w_H + \delta\tilde{p}(w_H)) + (d^{-1}\delta\tilde{\mathbf{u}}(p_H), \delta\tilde{\mathbf{u}}(w_H)) \\
&\quad + (\nabla\cdot(\mathbf{u}_H + \delta\hat{\mathbf{u}}(\mathbf{u}_H)), w_H) + (a\delta\hat{p}(\mathbf{u}_H), w_H) \\
&\quad = (b^* - a\delta\bar{p}_h - \nabla\cdot\delta\bar{\mathbf{u}}_h, w_H) \qquad \forall\, w_H \in W_H,
\end{aligned} \tag{5.10}$$

$$\begin{aligned}
&(d^{-1}(\mathbf{u}_H + \delta\hat{\mathbf{u}}(\mathbf{u}_H)), \mathbf{v}_H + \delta\hat{\mathbf{u}}(\mathbf{v}_H)) \\
&\quad + (a\delta\hat{p}(\mathbf{u}_H), \delta\hat{p}(\mathbf{v}_H)) + (\alpha\mathbf{u}_H\cdot\nu, \mathbf{v}_H\cdot\nu)_{\Gamma_R} \\
&\quad - (p_H, \nabla\cdot(\mathbf{v}_H + \delta\hat{\mathbf{u}}(\mathbf{v}_H))) - (ap_H, \delta\hat{p}(\mathbf{v}_H)) \\
&\quad = (c^* - d^{-1}\delta\bar{\mathbf{u}}_h, \mathbf{v}_H) - (\delta\bar{p}_h, \nabla\cdot\mathbf{v}_H) - (g_R, \mathbf{v}_H\cdot\nu)_{\Gamma_R} \quad \forall\, \mathbf{v}_H \in \mathbf{V}_H.
\end{aligned} \tag{5.11}$$

By following the computations in section 4.3, we easily see that a similar finite element approximation of the asymmetric formulation (4.10)–(4.11) is equivalent to (5.10)–(5.11). Either problem is the same size as a full finite element approximation of (2.6)–(2.7) over the *coarse* space $W_H \times \mathbf{V}_H$.

The final main step is to construct the solution using (5.8)–(5.9):

$$p_h = p_H + \delta p_h \in W_{H,h}, \tag{5.12}$$

$$\mathbf{u}_h = \mathbf{u}_H + \delta\mathbf{u}_h + \mathbf{v}_{g_N} \in \mathbf{V}_{H,h} + \mathbf{v}_{g_N}. \tag{5.13}$$

5.3. An equivalent form for the discrete equations. It should be noted that our procedure is an efficient implementation of the algebraically equivalent mixed

finite element method corresponding to (2.6)–(2.7), which is to find $\mathbf{u}_h \in \mathbf{V}_{H,h} + \mathbf{v}_{g_N}$ and $p_h \in W_{H,h}$ such that

$$(ap_h, w_h) + (\nabla \cdot \mathbf{u}_h, w_h) = (b, w_h) \qquad \forall\ w_h \in W_{H,h}, \tag{5.14}$$

$$\begin{aligned}(d^{-1}\mathbf{u}_h, \mathbf{v}_h) + (\alpha \mathbf{u}_h \cdot \nu, \mathbf{v}_h \cdot \nu)_{\Gamma_R} - (p_h, \nabla \cdot \mathbf{v}_h) \\ = (c, \mathbf{v}_h) - (g_R, \mathbf{v}_h \cdot \nu)_{\Gamma_R} \qquad \forall\ \mathbf{v}_h \in \mathbf{V}_{H,h}.\end{aligned} \tag{5.15}$$

Existence and uniqueness of a solution follow from uniqueness, which follows from the linear independence of $W_H \times \mathbf{V}_H$ and $\delta W_h \times \delta \mathbf{V}_h$ and the fact that $\nabla \cdot \mathbf{V}_{H,h} = W_{H,h}$.

From (5.14)–(5.15), we can conclude existence and uniqueness of (5.10)–(5.11), since $p_h = p_H + \delta p_h$ and $\mathbf{u}_h = \mathbf{u}_H + \delta \mathbf{u}_h$ give p_H and $\mathbf{u}_H$, which satisfy the system.

6. Analysis of the approximation error. We begin this section with some notation. For M, a subspace of L^2, we denote by $\mathcal{P}_M : L^2 \to M$ the orthogonal L^2-projection, based on the decomposition $L^2 = M \oplus M^\perp$. We contrast this with $\tilde{\mathcal{P}}_M : L^2 \to M$ from Proposition 3.1, which was based on a possibly nonorthogonal decomposition $L^2 = M \oplus N$.

At this point, we require some uniformity of the discrete decomposition. Let $\tilde{\mathcal{P}}_{W_H} : W_{H,h} \to W_H$ and $\tilde{\mathcal{P}}_{\delta W_h} : W_{H,h} \to \delta W_h$ be the projections associated with the decomposition $W_{H,h} = W_H \oplus \delta W_h$. We assume that there is a constant C such that

$$\|\tilde{\mathcal{P}}_{\delta W_h}\| \le C. \tag{6.1}$$

Note that then also

$$\|\tilde{\mathcal{P}}_{W_H}\| = \|I - \tilde{\mathcal{P}}_{\delta W_h}\| \le 1 + C. \tag{6.2}$$

It is not difficult to ensure (6.1). The simplest possibility is that $W_H \perp \delta W_h$ so that $\tilde{\mathcal{P}}_{\delta W_h} = \mathcal{P}_{\delta W_h}$ and we can take $C = 1$. This holds for certain choices of mixed spaces but not for others. Another possibility is to enforce uniformity on the two-scale mesh $\mathcal{T}_{H,h}$. Suppose that as $H \to 0$, we insist that H/h remains fixed. If we also assume that the coarse and fine element shapes remain fixed, then it is clear by a scaling argument that (6.1) will hold on each coarse element and thus globally. Moreover, we can even allow the element shapes to change as long as they do not change too badly, such as being the images of a reference element under a uniformly bounded family of affine maps with uniformly bounded inverses.

Let $K \ge 1$ and $L \ge 1$ denote the approximation orders of the coarse spaces $\mathbf{V}_H^*$ and W_H^*, respectively. That is, for some constant C and for any $\mathbf{v} \in \mathbf{V}$ and $w \in W$,

$$\inf_{\mathbf{v}_H \in \mathbf{V}_H^*} \|\mathbf{v} - \mathbf{v}_H\|_0 \le C \|\mathbf{v}\|_m\, H^m, \quad 0 \le m \le K, \tag{6.3}$$

$$\inf_{w_H \in W_H^*} \|w - w_H\|_0 \le C \|w\|_i\, H^i, \quad 0 \le i \le L. \tag{6.4}$$

For all the usual mixed spaces, $L = K$ or $L = K - 1$. It is also true that

$$\inf_{\mathbf{v}_H \in \mathbf{V}_H^*} \|(\mathbf{v} - \mathbf{v}_H) \cdot \nu\|_{0,\Gamma_R} \le C \|\mathbf{v} \cdot \nu\|_{m,\Gamma_R} H^m, \quad 0 \le m \le K. \tag{6.5}$$

Similarly, let $k \ge 1$ and $\ell \ge 1$ denote the approximation orders of the δ-spaces $\delta \mathbf{V}_h$ and δW_h, respectively.

LEMMA 6.1. *Given any $w \in W$,*

$$\|w - \mathcal{P}_{W_{H,h}} w\|_0 \le C \|w\|_{i+j} H^i h^j, \quad 0 \le i \le \max(0, L - j),\ 0 \le j \le \ell. \tag{6.6}$$

Proof. For each $E_c \in \mathcal{T}_H$, we note that in all the usual mixed spaces W_H^* restricted to E_c consists of polynomials of full degree at least $L-1$ that are discontinuous across ∂E_c. Thus from standard polynomial approximation results, we compute

$$\begin{aligned}\|w - \mathcal{P}_{W_{H,h}} w\|_{0,E_c} &= \inf_{w_H \in W_H^*} \inf_{\delta w_h \in \delta W_h} \|w - w_H - \delta w_h\|_{0,E_c} \\ &\le C \inf_{w_H \in W_H^*} \|w - w_H\|_{j,E_c} h^j \\ &\le C \|w\|_{i+j,E_c} H^i h^j,\end{aligned}$$

wherein $0 \le j \le \ell$ and then $0 \le i \le \max(0, L-j)$. ∎

Approximation in $\mathbf{V}_{H,h}$ is more delicate, as we need to preserve divergence properties.

6.1. A mixed method π-operator. All the usual mixed spaces $\check{W}_\eta \times \check{\mathbf{V}}_\eta$ have projection operators $\check{\pi} : \mathbf{V} \cap H^1(\Omega) \to \check{\mathbf{V}}_\eta$ such that

$$\begin{aligned}&\nabla \cdot \check{\pi}\mathbf{v} = \mathcal{P}_{\check{W}_\eta} \nabla \cdot \mathbf{v}, \\ &\|\mathbf{v} - \check{\pi}\mathbf{v}\| \le C \|\mathbf{v}\|_i \eta^i, \quad 1 \le i \le m,\end{aligned}$$

where C is a constant independent of the mesh spacing η and m is the approximation order of the space $\check{\mathbf{V}}_\eta$. Moreover, on $\partial\Omega$,

$$\check{\pi}\mathbf{v} \cdot \nu = \mathcal{P}_{\check{\mathbf{V}}_\eta \cdot \nu} \mathbf{v} \cdot \nu. \tag{6.7}$$

We have the associated operators

$$\begin{aligned}&\pi_H : \mathbf{V} \cap H^1(\Omega) \to \mathbf{V}_H^*, \\ &\delta\pi_{E_c,h} : \delta\mathbf{V}(E_c) \cap H^1(E_c) \to \delta\mathbf{V}_h(E_c) \quad \forall\, E_c \in \mathcal{T}_H,\end{aligned}$$

and also $\delta\pi_h$, defined by combining the $\delta\pi_{E_c,h}$. Then for any $\mathbf{v} \in \mathbf{V}$ and $\delta\mathbf{v} \in \delta\mathbf{V}^1$,

$$\begin{aligned}&\nabla \cdot \pi_H \mathbf{v} = \mathcal{P}_{W_H^*} \nabla \cdot \mathbf{v}, \\ &\nabla \cdot \delta\pi_h \delta\mathbf{v} = \mathcal{P}_{\delta W_h} \nabla \cdot \delta\mathbf{v}.\end{aligned}$$

Our goal now is to define a similar operator for the two-scale space $W_{H,h} \times \mathbf{V}_{H,h}$. Let $\mathbf{v} \in \mathbf{V} \cap H^1(\Omega)$. On each $E_c \in \mathcal{T}_H$, let

$$\delta w = \tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v}.$$

Define $\delta\mathbf{v}^p = \nabla\varphi$, where $\varphi \in H^1(E_c)$ satisfies (3.4)–(3.5) with the given δw. Then, because of (3.1), the Poincaré inequality constant is independent of H and h, so elliptic regularity [19] gives us the bound

$$\|\varphi\|_{2,E_c} \le C \|\tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v}\|_{0,E_c},$$

where a simple scaling argument shows that C depends on the shape of E_c but not on its size. Thus also

$$\|\delta\mathbf{v}^p\|_{1,E_c} \le C \|\tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v}\|_{0,E_c}, \tag{6.8}$$

and we conclude that we can apply $\delta\pi_h$ to $\delta\mathbf{v}^p$.

DEFINITION 6.2. *Let $\pi : \mathbf{V} \cap H^1(\Omega) \to \mathbf{V}_{H,h} = \mathbf{V}_H^* + \delta\mathbf{V}_h$ be defined by*

$$\pi\mathbf{v} = \pi_H(\mathbf{v} - \delta\mathbf{v}^p) + \delta\pi_h \delta\mathbf{v}^p,$$

where $\delta\mathbf{v}^p = \nabla\varphi$ and φ satisfies (3.4)–(3.5) *with $\delta w = \tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v}$.*

This operator, while well defined, is *not* a projection.

PROPOSITION 6.3. *It follows that*

$$\begin{aligned} &\nabla \cdot \pi \mathbf{v} = \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v} \quad &&\text{on } \Omega, \\ &\pi \mathbf{v} \cdot \nu = \pi_H \mathbf{v} \cdot \nu &&\text{on } \partial\Omega. \end{aligned}$$

Proof. Since $\mathcal{P}_{W_{H,h}} = (\tilde{\mathcal{P}}_{W_H} + \tilde{\mathcal{P}}_{\delta W_h})\mathcal{P}_{W_{H,h}}$ and $\mathcal{P}_{W_H^*}\mathcal{P}_{W_{H,h}} = \mathcal{P}_{W_H^*}$, we compute

$$\begin{aligned} \nabla \cdot \pi \mathbf{v} &= \nabla \cdot \pi_H(\mathbf{v} - \delta \mathbf{v}^p) + \nabla \cdot \delta \pi_h \delta \mathbf{v}^p \\ &= \mathcal{P}_{W_H^*} \nabla \cdot (\mathbf{v} - \delta \mathbf{v}^p) + \mathcal{P}_{\delta W_h} \nabla \cdot \delta \mathbf{v}^p \\ &= \mathcal{P}_{W_H^*} \nabla \cdot \mathbf{v} - \mathcal{P}_{W_H^*} \tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v} + \mathcal{P}_{\delta W_h} \tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v} \\ &= \mathcal{P}_{W_H^*} \nabla \cdot \mathbf{v} - \mathcal{P}_{W_H^*} (I - \tilde{\mathcal{P}}_{W_H}) \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v} + \tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v} \\ &= (\tilde{\mathcal{P}}_{W_H} + \tilde{\mathcal{P}}_{\delta W_h}) \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v} \\ &= \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v}. \end{aligned}$$

By (6.7), we see that

$$\pi \mathbf{v} \cdot \nu = \pi_H(\mathbf{v} - \delta \mathbf{v}^p) \cdot \nu + \delta \pi_h \delta \mathbf{v}^p \cdot \nu = \pi_H \mathbf{v} \cdot \nu,$$

since $\delta \mathbf{v}^p \cdot \nu = 0$ on $\partial\Omega$. ∎

LEMMA 6.4. *If* (3.1) *and* (6.1) *hold, then for* $\mathbf{v} \in \mathbf{V} \cap H^1(\Omega)$,

$$\begin{aligned} &\|\mathbf{v} - \pi \mathbf{v}\|_0 \le C \|\mathbf{v}\|_m H^m, \quad 1 \le m \le K, \\ &\|(\mathbf{v} - \pi \mathbf{v}) \cdot \nu\|_{0,\Gamma_R} \le C \|\mathbf{v} \cdot \nu\|_{m,\Gamma_R} H^m, \quad 0 \le m \le K. \end{aligned}$$

Proof. We construct $\delta \mathbf{v}^p \in \delta \mathbf{V}^p$ as in the definition of π. Then for $1 \le m \le K$,

$$\begin{aligned} \|\mathbf{v} - \pi \mathbf{v}\|_0 &= \|\mathbf{v} - \pi_H \mathbf{v} + \pi_H \delta \mathbf{v}^p - \delta \pi_h \delta \mathbf{v}^p\|_0 \\ &\le \|\mathbf{v} - \pi_H \mathbf{v}\|_0 + \|\pi_H \delta \mathbf{v}^p - \delta \mathbf{v}^p\|_0 + \|\delta \mathbf{v}^p - \delta \pi_h \delta \mathbf{v}^p\|_0 \\ &\le C \left\{ \|\mathbf{v}\|_m H^m + \sum_{E_c \in \mathcal{T}_H} (\|\delta \mathbf{v}^p\|_{1,E_c} H + \|\delta \mathbf{v}^p\|_{1,E_c} h) \right\} \\ &\le C \{ \|\mathbf{v}\|_m H^m + \|\tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v}\|_0 H \}, \end{aligned}$$

by (6.8). The Bramble–Hilbert lemma [15, 7] implies that for any $0 \le i \le L$,

$$\|\tilde{\mathcal{P}}_{\delta W_h} \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v}\|_0 = \|(I - \tilde{\mathcal{P}}_{W_H}) \mathcal{P}_{W_{H,h}} \nabla \cdot \mathbf{v}\|_0 \le C \|\nabla \cdot \mathbf{v}\|_i H^i,$$

since the operator $(I - \tilde{\mathcal{P}}_{W_H})\mathcal{P}_{W_{H,h}}$ is uniformly bounded by (6.1), and it preserves polynomials of the appropriate degree. With $i = m - 1$, i is in the range $0 \le i \le L$ ($L = K$ or $L = K - 1$), and we obtain the required first estimate.

The second estimate follows from Proposition 6.3 and its approximation properties, (6.7) and (6.5). ∎

6.2. Error analysis. The equation for the error is given by (2.6)–(2.7) with test functions in $W_{H,h} \times \mathbf{V}_{H,h}$ minus (5.14)–(5.15), which is

$$(a(p - p_h), w) + (\nabla \cdot (\mathbf{u} - \mathbf{u}_h), w) = 0 \qquad \forall\, w \in W_{H,h}, \tag{6.9}$$

$$(d^{-1}(\mathbf{u} - \mathbf{u}_h), \mathbf{v}) + (\alpha(\mathbf{u} - \mathbf{u}_h) \cdot \nu, \mathbf{v} \cdot \nu)_{\Gamma_R} = (p - p_h, \nabla \cdot \mathbf{v}) \quad \forall\, \mathbf{v} \in \mathbf{V}_{H,h}. \tag{6.10}$$

THEOREM 6.5. *If* (3.1) *and* (6.1) *hold, and* $a \in W^{1,\infty}(\Omega)$*, then the two-scale approximation satisfies the error bounds*

$$\begin{aligned}
&\|\sqrt{a}(\mathcal{P}_{W_{H,h}}p - p_h)\|_0 + \|\mathbf{u} - \mathbf{u}_h\|_0 + \|\sqrt{\alpha}(\mathbf{u} - \mathbf{u}_h)\cdot\nu\|_{0,\Gamma_R} \\
&\quad \le C\{\|p\|_{i+j}H^i h^{j+1} + (\|\mathbf{u} - \mathbf{v}_{g_N}\|_m + \|(\mathbf{u} - \mathbf{v}_{g_N})\cdot\nu\|_{m,\Gamma_R})H^m\}, \\
&\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 \le C\{\|\mathbf{u} - \mathbf{u}_h\|_0 + \|\sqrt{\alpha}(\mathbf{u} - \mathbf{u}_h)\cdot\nu\|_{0,\Gamma_R}\}, \\
&\|p - p_h\|_0 \le C\{\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 + \|p\|_{i+j}H^i h^j\}, \\
&\|\nabla\cdot(\mathbf{u} - \mathbf{u}_h)\|_0 \le C\{\|\sqrt{a}(\mathcal{P}_{W_{H,h}}p - p_h)\|_0 + \|p\|_{i+j}H^i h^{j+1} + \|\nabla\cdot\mathbf{u}\|_{i+j}H^i h^j\},
\end{aligned}$$

wherein $0 \le i \le \max(0, L-j)$*,* $0 \le j \le \ell$*, and* $1 \le m \le K$*. Moreover, if* $\alpha = 0$ *or* $\Gamma_R = \emptyset$*, and if* h *is sufficiently small, then*

$$\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 \le C\{\|\nabla\cdot(\mathbf{u} - \mathbf{u}_h)\|_0 h + \|p\|_{i+j}H^i h^{j+1} + \|\mathbf{u} - \mathbf{u}_h\|_0 H\}.$$

Note that these are optimal order estimates, since $L = K$ or $L = K-1$. Moreover, $\|\mathcal{P}_{W_{H,h}}p - p_h\|_0$ is superconvergent if $\alpha = 0$ or $\Gamma_R = \emptyset$ and h is sufficiently small.

Proof. For notational convenience, let us define

$$\pi\mathbf{u} \equiv \pi(\mathbf{u} - \mathbf{v}_{g_N}) + \mathbf{v}_{g_N}.$$

The sum of the equations (6.9)–(6.10) with

$$w = \mathcal{P}_{W_{H,h}}p - p_h \in W_{H,h} \quad \text{and} \quad \mathbf{v} = \pi\mathbf{u} - \mathbf{u}_h \in \mathbf{V}_{H,h},$$

because of Proposition 6.3 and the fact that $\nabla\cdot\mathbf{V}_{H,h} = W_{H,h}$, results in

$$\begin{aligned}
&(a(\mathcal{P}_{W_{H,h}}p - p_h), \mathcal{P}_{W_{H,h}}p - p_h) + (d^{-1}(\mathbf{u} - \mathbf{u}_h), \mathbf{u} - \mathbf{u}_h) \\
&\qquad + (\alpha(\mathbf{u} - \mathbf{u}_h)\cdot\nu, (\mathbf{u} - \mathbf{u}_h)\cdot\nu)_{\Gamma_R} \\
&\quad = (a(\mathcal{P}_{W_{H,h}}p - p), \mathcal{P}_{W_{H,h}}p - p_h) + (d^{-1}(\mathbf{u} - \mathbf{u}_h), \mathbf{u} - \pi\mathbf{u}) \\
&\qquad + (\alpha(\mathbf{u} - \mathbf{u}_h)\cdot\nu, (\mathbf{u} - \pi\mathbf{u})\cdot\nu)_{\Gamma_R}.
\end{aligned}$$

If $\bar{a} \in W_{H,h}$ is the piecewise discontinuous constant average of a over the fine mesh $\mathcal{T}_{H,h}$, then

$$\begin{aligned}
&(a(\mathcal{P}_{W_{H,h}}p - p), \mathcal{P}_{W_{H,h}}p - p_h) = ((a - \bar{a})(\mathcal{P}_{W_{H,h}}p - p), \mathcal{P}_{W_{H,h}}p - p_h) \\
&\quad \le C\|a\|_{W^{1,\infty}(\Omega)}h\,\|\mathcal{P}_{W_{H,h}}p - p\|_0\|\mathcal{P}_{W_{H,h}}p - p_h\|_0.
\end{aligned}$$

Thus for any $\epsilon > 0$,

$$\begin{aligned}
&\|\sqrt{a}(\mathcal{P}_{W_{H,h}}p - p_h)\|_0 + \|\mathbf{u} - \mathbf{u}_h\|_0 + \|\sqrt{\alpha}(\mathbf{u} - \mathbf{u}_h)\cdot\nu\|_{0,\Gamma_R} \\
&\quad \le C_\epsilon\{\|p - \mathcal{P}_{W_{H,h}}p\|_0 h + \|\mathbf{u} - \pi\mathbf{u}\|_0 + \|(\mathbf{u} - \pi\mathbf{u})\cdot\nu\|_{0,\Gamma_R}\} + \epsilon\|\mathcal{P}_{W_{H,h}}p - p_h\|_0.
\end{aligned}$$

Standard elliptic lift arguments can be used to estimate $\mathcal{P}_{W_{H,h}}p - p_h$. That is, we solve (3.6)–(3.8) for ψ with w_c replaced by $\mathcal{P}_{W_{H,h}}p - p_h$ and take $\mathbf{v} = \pi\nabla\psi$. Then $\nabla\cdot\mathbf{v} = \mathcal{P}_{W_{H,h}}p - p_h$ and

$$\begin{aligned}
&\|\mathbf{v}\|_0 \le \|\nabla\psi\|_0 + \|\nabla\psi - \pi\nabla\psi\|_0 \le C\|\psi\|_2 \le C\|\mathcal{P}_{W_{H,h}}p - p_h\|_0, \\
&\|\mathbf{v}\cdot\nu\|_{0,\Gamma_R} \le \|\nabla\psi\cdot\nu\|_{0,\Gamma_R} + \|(\nabla\psi - \pi_H\nabla\psi)\cdot\nu\|_{0,\Gamma_R} \\
&\quad \le C\|\psi\|_2 \le C\|\mathcal{P}_{W_{H,h}}p - p_h\|_0,
\end{aligned}$$

using (6.7). Then (6.10) implies that

$$\begin{aligned}\|\mathcal{P}_{W_{H,h}}p - p_h\|_0^2 &= (d^{-1}(\mathbf{u}-\mathbf{u}_h),\mathbf{v}) + (\alpha(\mathbf{u}-\mathbf{u}_h)\cdot\nu,\mathbf{v}\cdot\nu)_{\Gamma_R}\\ &\le C\{\|\mathbf{u}-\mathbf{u}_h\|_0\|\mathbf{v}\|_0 + \|\sqrt{\alpha}(\mathbf{u}-\mathbf{u}_h)\cdot\nu\|_{0,\Gamma_R}\|\mathbf{v}\cdot\nu\|_{0,\Gamma_R}\\ &\le C\{\|\mathbf{u}-\mathbf{u}_h\|_0 + \|\sqrt{\alpha}(\mathbf{u}-\mathbf{u}_h)\cdot\nu\|_{0,\Gamma_R}\}\|\mathcal{P}_{W_{H,h}}p - p_h\|_0,\end{aligned}$$

and, with Lemmas 6.1 and 6.4, the first three estimates of the theorem follow.

If $\alpha = 0$ or $\Gamma_R = \emptyset$, we replace (3.6)–(3.8) by

$$a\psi - \nabla\cdot d\nabla\psi = \mathcal{P}_{W_{H,h}}p - p_h \qquad \text{in } \Omega, \tag{6.11}$$

$$-d\nabla\psi\cdot\nu = 0 \qquad \text{on } \Gamma_N, \tag{6.12}$$

$$\psi = 0 \qquad \text{on } \Gamma_R, \tag{6.13}$$

and we modify the argument as follows [16]:

$$\begin{aligned}\|\mathcal{P}_{W_{H,h}}p - p_h\|_0^2 &= (\mathcal{P}_{W_{H,h}}p - p_h, a\psi - \nabla\cdot d\nabla\psi)\\ &= (a(\mathcal{P}_{W_{H,h}}p - p_h),\psi) - (\mathcal{P}_{W_{H,h}}p - p_h, \nabla\cdot\pi d\nabla\psi),\end{aligned}$$

and, using (6.10),

$$\begin{aligned}(\mathcal{P}_{W_{H,h}}p - p_h, \nabla\cdot\pi d\nabla\psi) &= (d^{-1}(\mathbf{u}-\mathbf{u}_h),\pi d\nabla\psi)\\ &= (\mathbf{u}-\mathbf{u}_h,\nabla\psi) - (d^{-1}(\mathbf{u}-\mathbf{u}_h), d\nabla\psi - \pi d\nabla\psi)\\ &= -(\nabla\cdot(\mathbf{u}-\mathbf{u}_h),\psi) - (d^{-1}(\mathbf{u}-\mathbf{u}_h), d\nabla\psi - \pi d\nabla\psi),\end{aligned}$$

and, for $w \in W_{H,h}$ arbitrary, by (6.9),

$$\begin{aligned}(\nabla\cdot(\mathbf{u}-\mathbf{u}_h),\psi) &= (\nabla\cdot(\mathbf{u}-\mathbf{u}_h),\psi - w) - (a(\mathcal{P}_{W_{H,h}}p - p_h), w)\\ &\quad - (a(p - \mathcal{P}_{W_{H,h}}p), w)\\ &= (\nabla\cdot(\mathbf{u}-\mathbf{u}_h),\psi - w) - (a(\mathcal{P}_{W_{H,h}}p - p_h),\psi)\\ &\quad - (a(\mathcal{P}_{W_{H,h}}p - p_h), w - \psi) - ((a-\bar{a})(p - \mathcal{P}_{W_{H,h}}p), w).\end{aligned}$$

Since a good choice of w implies

$$\|w - \psi\|_0 \le C|\psi|_1 h \quad \text{and} \quad \|w\|_0 \le C|\psi|_1,$$

we have that

$$\begin{aligned}\|\mathcal{P}_{W_{H,h}}p - p_h\|_0^2 &\le C\{(\|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)\|_0 + \|\mathcal{P}_{W_{H,h}}p - p_h\|_0 + \|p - \mathcal{P}_{W_{H,h}}p\|_0)|\psi|_1 h\\ &\quad + \|\mathbf{u}-\mathbf{u}_h\|_0|\psi|_2 H\}\\ &\le C\{(\|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)\|_0 + \|\mathcal{P}_{W_{H,h}}p - p_h\|_0 + \|p - \mathcal{P}_{W_{H,h}}p\|_0)h\\ &\quad + \|\mathbf{u}-\mathbf{u}_h\|_0 H\}\|\mathcal{P}_{W_{H,h}}p - p_h\|_0,\end{aligned}$$

and the final result of the theorem follows for h sufficiently small.

Finally, (6.9) with $w = \nabla\cdot(\pi\mathbf{u} - \mathbf{u}_h) \in W_{H,h}$ implies that

$$\begin{aligned}\|\nabla\cdot(\pi\mathbf{u} - \mathbf{u}_h)\|_0^2 &= -(a(\mathcal{P}_{W_{H,h}}p - p_h), \nabla\cdot(\pi\mathbf{u} - \mathbf{u}_h))\\ &\quad - ((a-\bar{a})(p - \mathcal{P}_{W_{H,h}}p), \nabla\cdot(\pi\mathbf{u} - \mathbf{u}_h)).\end{aligned}$$

Since $\nabla\cdot(\mathbf{u} - \pi\mathbf{u}) = (I - \mathcal{P}_{W_{H,h}})\nabla\cdot\mathbf{u}$, which approximates as in (6.6), the divergence estimate of the theorem follows. ∎

In the special case $a = \alpha = 0$, we obtain optimality of the finite element approximation $\mathbf{u}_h$ to $\mathbf{u}$ in the energy norm subject to the appropriate divergence constraint.

THEOREM 6.6. *If $a = \alpha = 0$ and (3.1) and (6.1) hold, then*

$$\|d^{-1/2}(\mathbf{u}-\mathbf{u}_h)\|_0 \leq \inf_{\substack{\mathbf{v}_h\in\mathbf{V}_{H,h}\\ \nabla\cdot\mathbf{v}_h=\mathcal{P}_{W_{H,h}}\nabla\cdot(\mathbf{u}-\mathbf{v}_{g_N})}} \|d^{-1/2}(\mathbf{u}-\mathbf{v}_{g_N}-\mathbf{v}_h)\|_0 \leq C\|\mathbf{u}-\mathbf{v}_{g_N}\|_m H^m,$$

$$\nabla\cdot\mathbf{u}_h = \mathcal{P}_{W_{H,h}}\nabla\cdot\mathbf{u},$$

$$\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 \leq C\|\mathbf{u}-\mathbf{u}_h\|_0,$$

$$\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 \leq C\{\|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)\|_0 h + \|\mathbf{u}-\mathbf{u}_h\|_0 H\},$$

$$\|p-p_h\|_0 \leq C\{\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 + \|p\|_{i+j}H^i h^j\},$$

wherein $0 \leq i \leq \max(0, L-j)$, $0 \leq j \leq \ell$, and $1 \leq m \leq K$.

Proof. For any $\mathbf{v}_h \in \mathbf{V}_{H,h}$ such that $\nabla\cdot\mathbf{v}_h = \mathcal{P}_{W_{H,h}}\nabla\cdot(\mathbf{u}-\mathbf{v}_{g_N})$, take

$$w = \mathcal{P}_{W_{H,h}}p - p_h \in W_{H,h},$$
$$\mathbf{v} = (\mathbf{u}-\mathbf{u}_h) - (\mathbf{u}-\mathbf{v}_{g_N}-\mathbf{v}_h) \in \mathbf{V}_{H,h}$$

in (6.9)–(6.10). Then with $a = \alpha = 0$, the sum of the equations implies that

$$\begin{aligned}(d^{-1}(\mathbf{u}-\mathbf{u}_h), \mathbf{u}-\mathbf{u}_h) &= (d^{-1}(\mathbf{u}-\mathbf{u}_h), \mathbf{u}-\mathbf{v}_{g_N}-\mathbf{v}_h)\\ &\leq \|d^{-1/2}(\mathbf{u}-\mathbf{u}_h)\|_0 \|d^{-1/2}(\mathbf{u}-\mathbf{v}_{g_N}-\mathbf{v}_h)\|_0\end{aligned}$$

so that

$$\|d^{-1/2}(\mathbf{u}-\mathbf{u}_h)\|_0 \leq \inf_{\mathbf{v}_h}\|d^{-1/2}(\mathbf{u}-\mathbf{v}_{g_N}-\mathbf{v}_h)\|_0 \leq C\|\mathbf{u}-\mathbf{v}_{g_N}-\pi(\mathbf{u}-\mathbf{v}_{g_N})\|_0,$$

since $\pi(\mathbf{u}-\mathbf{v}_{g_N})$ satisfies the divergence constraint by Proposition 6.3. Lemma 6.4 gives the required approximation result for the first estimate of the theorem.

Now $a = 0$ and (6.9) imply that $\nabla\cdot\mathbf{u}_h = \mathcal{P}_{W_{H,h}}\nabla\cdot\mathbf{u}$, giving the second result of the theorem. The final estimates follow as in the previous proof. ∎

The underlying assumption in the error analysis, and the tacit assumption in all similar subgrid methods mentioned in the introduction, is that the finest grid, scale h, resolves the fine-scale details of the solution. We see this here in the Sobolev norms appearing in the error estimates. If h does not resolve the subgrid problems, then we cannot expect a good approximation.

Under this tacit assumption, we proved two main results. First, in Theorem 6.6, the solution is optimally approximated in the finite element space subject to the fine-scale divergence constraint. Thus the approximation is no worse than using only a coarse-scale approximation (up to questions of the scale of the divergence constraint). It is presumably much better, as numerical results show [1, 2, 4]. Second, the pressure is approximated on the finest scale, up to a higher order coarse H error term. This is a strict improvement over merely solving on the coarse scale. Moreover, these improvements are achieved for negligible additional numerical cost compared to the coarse-scale solution and much less cost than the fine-scale solution itself [1, 4].

The error estimates of this subsection appear to explain the numerical results that have appeared elsewhere: that they are amazingly accurate for reasonable problems where the fine grid resolves the coefficients of the problem [1, 2, 4]. The error estimates also explain why numerical results break down in certain difficult cases in which h does not resolve the problem well. If h and H are relatively large compared to the Sobolev norms of the solution, the method is not expected to work well. This appears to be the main factor limiting the utility of the method in practice. As an example, in [2], a numerical test was presented involving Darcy flow in a porous medium with a long thin high permeability streak. This is a very difficult problem to resolve numerically on a coarse grid. The streak introduces channelized flow, which means that the derivatives of the solution are large, and so by Theorem 6.5 or 6.6, we neither expect nor see good results. (It should be noted, however, that the upscaling technique of this paper is not entirely unsuccessful in resolving the solution of even this very difficult problem.)

7. Two special cases. A particularly pertinent choice of spaces was studied numerically in [1, 2]. On the coarse mesh, we approximate $(p_c, \mathbf{u}_c)$ in the two-dimensional BDM-1 or three-dimensional BDDF-1 mixed finite element spaces [12, 10]. The space of scalars W_H^* consists of piecewise discontinuous constants, and the space of vectors $\mathbf{V}_H^*$ is second order accurate and has linear fluxes on the edges or faces of coarse elements.

On each coarse element $E_c \in \mathcal{T}_H$, we approximate $(\delta\bar{p}, \delta\bar{\mathbf{u}})$, $(\delta\tilde{p}, \delta\tilde{\mathbf{u}})$, and $(\delta\hat{p}, \delta\hat{\mathbf{u}})$ in the RT-0 spaces [28]. These approximate with piecewise discontinuous constants for $\delta W_h(E_c)$ and with constant fluxes on each interior edge or face for $\delta\mathbf{V}_h(E_c)$.

In this case, $\mathbf{V}_H^* \cap \delta\mathbf{V}_h = \{0\}$, so $\mathbf{V}_H = \mathbf{V}_H^*$ requires no attention. Also, $W_{H,h} = W_h^*$, the space of piecewise discontinuous constants over the fine mesh $\mathcal{T}_{H,h}$. We note that $W_H^* \perp \delta W_h$, so $W_H = W_H^*$ and condition (6.1) holds. However, it is not so simple to compute with $\delta W_h(E_c)$, since such functions are supported in all of E_c. Fortunately, a careful implementation of the scheme [2] allows one to avoid working over $\delta W_h(E_c)$ and instead work over the full space $\delta W_h(E_c) + \operatorname{span}\{1\}$ of piecewise discontinuous constants over $\mathcal{T}_h(E_c)$. Now $K = 2$ and $L = k = \ell = 1$, so Theorem 6.5 takes the following simple form.

THEOREM 7.1. *If $a \in W^{1,\infty}(\Omega)$ and (3.1) holds, the BDDF-1(BDM-1)/RT-0 two-scale approximation satisfies the error bounds*

$$\begin{aligned}
&\|\sqrt{a}(\mathcal{P}_{W_{H,h}}p - p_h)\|_0 + \|\mathbf{u} - \mathbf{u}_h\|_0 + \|\sqrt{\alpha}(\mathbf{u} - \mathbf{u}_h)\cdot\nu\|_{0,\Gamma_R} \\
&\quad \le C\{\|p\|_1 h^2 + (\|\mathbf{u} - \mathbf{v}_{g_N}\|_2 + \|(\mathbf{u} - \mathbf{v}_{g_N})\cdot\nu\|_{2,\Gamma_R})H^2\} \le CH^2, \\
&\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 \le C\{\|\mathbf{u} - \mathbf{u}_h\|_0 + \|\sqrt{\alpha}(\mathbf{u} - \mathbf{u}_h)\cdot\nu\|_{0,\Gamma_R}\} \le CH^2, \\
&\|p - p_h\|_0 \le C\{\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 + \|p\|_1 h\} \le C(H^2 + h), \\
&\|\nabla\cdot(\mathbf{u} - \mathbf{u}_h)\|_0 \le C\{\|\sqrt{a}(\mathcal{P}_{W_{H,h}}p - p_h)\|_0 + \|p\|_1 h^2 + \|\nabla\cdot\mathbf{u}\|_1 h\} \le C(H^2 + h).
\end{aligned}$$

Moreover, if $\alpha = 0$ or $\Gamma_R = \emptyset$, and h is sufficiently small, then

$$\|\mathcal{P}_{W_{H,h}}p - p_h\|_0 \le C\{\|\nabla\cdot(\mathbf{u} - \mathbf{u}_h)\|_0 h + \|p\|_1 h^2 + \|\mathbf{u} - \mathbf{u}_h\|_0 H\} \le C(H^3 + h^2).$$

If $H^2 \sim h$ as $H \to 0$, then p and $\mathbf{u}$ are resolved on the fine scale to order h. Hence relatively good numerical approximation results have been obtained [1, 3, 4, 2].

A second special choice is to use RT-0 spaces on both scales. In this case, $K = L = k = \ell = 1$, and Theorem 6.5 would suggest that p and $\mathbf{u}$ are approximated only on the coarse scale to order H. Although we retain the optimality of the solution

in the energy norm under the appropriate conditions, the numerical approximation results are not nearly as good as in the previous special case (see [5]).

A GRID-BASED BOUNDARY INTEGRAL METHOD FOR ELLIPTIC PROBLEMS IN THREE DIMENSIONS*

J. THOMAS BEALE†

Abstract. We develop a simple, efficient numerical method of boundary integral type for solving an elliptic partial differential equation in a three-dimensional region using the classical formulation of potential theory. Accurate values can be found near the boundary using special corrections to a standard quadrature. We treat the Dirichlet problem for a harmonic function with a prescribed boundary value in a bounded three-dimensional region with a smooth boundary. The solution is a double layer potential, whose strength is found by solving an integral equation of the second kind. The boundary surface is represented by rectangular grids in overlapping coordinate systems, with the boundary value known at the grid points. A discrete form of the integral equation is solved using a regularized form of the kernel. It is proved that the discrete solution converges to the exact solution with accuracy $O(h^p)$, $p < 5$, depending on the smoothing parameter. Once the dipole strength is found, the harmonic function can be computed from the double layer potential. For points close to the boundary, the integral is nearly singular, and accurate computation is not routine. We calculate the integral by summing over the boundary grid points and then adding corrections for the smoothing and discretization errors using formulas derived here; they are similar to those in the two-dimensional case given by [J. T. Beale and M.-C. Lai, *SIAM J. Numer. Anal.*, 38 (2001), pp. 1902–1925]. The resulting values of the solution are uniformly of $O(h^p)$ accuracy, $p < 3$. With a total of N points, the calculation could be done in essentially $O(N)$ operations if a rapid summation method is used.

Key words. boundary integral methods, nearly singular integrals, potential theory, Dirichlet problem, overlapping grids

1. Introduction.

In this paper we develop a simple, direct numerical method of boundary integral type for the solution of an elliptic boundary value problem in a three-dimensional (3D) region with a smooth boundary. We emphasize the Dirichlet problem for an interior harmonic function, although a larger class of problems can be treated. We assume the boundary surface is represented by several overlapping grids, each rectangular in some coordinate system. Values of the solution are to be found at arbitrary points in space (typically, those on a regular 3D grid), some of which will be close to the surface. We do not assume any relationship between the coordinate grids on the surface and the interior grid. We use the classical formulation of the Dirichlet problem in potential theory: The solution can be written as a double layer potential, or dipole layer, with an unknown strength. This dipole strength is determined by a Fredholm integral equation of the second kind on the surface. We solve a discretized form of this integral equation at the coordinate grid points on the surface, replacing the Green's function in the layer potential with a regularized version and the integral with a sum over grid points. We prove that the solution of the numerical integral equation converges to the exact solution with order h^p, for any $p < 5$, depending on the choice of the smoothing parameter relative to h, and that it can be found by a simple iteration. Once the dipole strength is found, the value of the harmonic function at any point is given by the double layer potential. For points away from

the boundary, the surface integral can be computed in a standard way, but, at points near the boundary, the integral is nearly singular, and accurate computation is not routine. We find the integral in this case by starting with a standard quadrature, again regularized, and then adding corrections. These corrections account for the errors introduced by the smoothing, or regularization, and by discretization. They are derived by local analysis near the singularity, extending the treatment for a two-dimensional (2D) region given in [3]. With grid spacing h on the boundary, the resulting values are accurate to $O(h^p)$ for $p < 3$, again depending on smoothing.

Boundary integral formulations of the Laplace or Helmholtz equation in three dimensions are widely used in engineering, especially electromagnetics. They are most often solved numerically by the boundary element method; the surface is triangulated, and the equation holds at collocation points (see, e.g., [2, 15]). The integration of the kernel times a basis function at a point in its support often uses a change of variables or a product integration rule. Special care is also needed for points near the support. High order accuracy can be achieved [2, section 9.2], and the method can be accurate for piecewise smooth surfaces. More direct quadrature, or Nyström, methods have not been widely used. Such a method for polyhedral surfaces, summing over centroids in a triangulation, was shown to converge by Rathsfeld [23]. In [24] he showed that a simple quadrature over a triangulation of a smooth surface gives almost $O(h^2)$ convergence with singularity subtraction, and this can be improved to higher order using product integration. Recently, practical methods of this type have been developed. Canino et al. [8] use a triangulation with quadrature based on a local correction method of Strain, an alternative to product integration. Bruno and Kunyansky [7] use overlapping grids and a partition of unity, as in the present work, but they integrate the singularity by a change of variables. Other current approaches include use of wavelets (see, e.g., [19]) or spherical polynomials (see, e.g., [13]). The difficulty of calculating nearly singular integrals for the field at points near the boundary is well recognized [2, section 7.2.1], but very few works have treated it; two recent approaches are given in [17, 25].

While there are many choices of numerical methods for elliptic problems, with boundary integrals or otherwise, the present approach has several advantages for some applications. The data structure needed to represent the surface is minimal, and calculations on the surface are done in the rectangular grids, with the dependence on the surface reduced to coordinate functions. The integration requires no extra work at the singularity while solving the integral equation. Finally, values of the field near the surface can be found by direct integration, adding the corrections presented here. These attributes may be especially important for a time-dependent calculation with a moving boundary. For viscous, incompressible fluid flow, pressure terms due to a boundary could be found as nearly singular integrals [3]. The linear system resulting from the integral equation is well conditioned. With n boundary points, the direct solution of the linear system would require about $O(n^2)$ operations, but this could be reduced to about $O(n)$ using a rapid summation method such as the fast multipole method of Greengard and Rokhlin [14]. Similarly, fast summation could be used to produce the values of the harmonic function. Another way to produce the interior solution, as observed by Mayo [21] (see also [1]), is to find values near the boundary, compute a discrete Laplacian, extend it by zero to a computational box including the original region, and then invert using a fast Poisson solver to produce values at grid points. This approach was used in the 2D case in [3, section 4]. Either way, the operation count with a total of N points could be reduced to about $O(N)$. We assume here that the surface and functions are smooth, i.e., have several derivatives

to justify various Taylor expansions; this method would not be valid for a boundary with corners and edges without further modification.

We now summarize the method and results. We consider the Dirichlet problem for a bounded domain $\Omega \subseteq \mathbf{R}^3$ with smooth boundary $\mathcal{S}$. Given a function g on $\mathcal{S}$ we want to find a function u on Ω such that

$$\Delta u = 0 \quad \text{on } \Omega, \qquad u = g \quad \text{on } \mathcal{S}. \tag{1.1}$$

The solution can be written as a double layer potential

$$u(y) = \int_{\mathcal{S}} \frac{\partial}{\partial n(x)} G(x-y) f(x)\, dS(x) \tag{1.2}$$

for some dipole strength f, determined by g, where $n(x)$ is the unit outward normal at $x \in \mathcal{S}$, G is the Green's function for Δ in $\mathbf{R}^3$, $G(x) = -1/4\pi|x|$, and

$$\frac{\partial}{\partial n(x)} G(x-y) \;=\; n(x) \cdot \nabla G(x-y) \;=\; \frac{n(x)\cdot(x-y)}{4\pi|x-y|^3}. \tag{1.3}$$

The unknown f is the solution of the integral equation on the surface $\mathcal{S}$:

$$\frac{1}{2} f(x) + \int_{\mathcal{S}} K(x,x') f(x')\, dS(x') \;=\; g(x), \qquad K(x,x') = \frac{\partial}{\partial n(x)} G(x'-x), \tag{1.4}$$

or $f + 2Tf = 2g$, where T is the integral operator with kernel K. It is known (see, e.g., [18, section 10.5]) that the iterates f^n defined by

$$f^{n+1} = (1-\beta) f^n - 2\beta T f^n + 2\beta g \tag{1.5}$$

converge to the solution of (1.4), provided $0 < \beta < 1$.

To describe the numerical formulation of the problem (1.4) for f, we suppose the surface $\mathcal{S}$ is covered by several coordinate patches $X^\sigma : U_\sigma \to \mathcal{S}$, where U_σ is an open subset of $\mathbf{R}^2$. We assume each $X^\sigma : U_\sigma \to \mathbf{R}^3$ is smooth and nondegenerate; i.e., $\partial X^\sigma(\alpha)/\partial\alpha$ has rank 2 at each point, with $\alpha = (\alpha_1, \alpha_2)$. In order to write the integral as a sum of integrals in coordinates, we introduce a partition of unity, that is, a collection of smooth functions $\{\psi^\sigma\} : \mathcal{S} \to \mathbf{R}$ such that ψ^σ is zero outside a compact subset of U_σ, called the support of ψ^σ, and $\sum_\sigma \psi^\sigma(x) = 1$ for each $x \in \mathcal{S}$. (See section 5 for typical choices.) We can now write the integral of a function F on $\mathcal{S}$ as

$$\int_{\mathcal{S}} F(x')\, dS(x') \;=\; \sum_\sigma \int_{U_\sigma} F(X^\sigma(\alpha)) \psi^\sigma(X^\sigma(\alpha)) A^\sigma(\alpha) d\alpha, \tag{1.6}$$

where $A^\sigma(\alpha)d\alpha$ is the element of surface area in the σth patch. In solving (1.4) it is helpful to use the familiar identity

$$\int_{\mathcal{S}} K(x,x')\, dS(x') = \frac{1}{2} \tag{1.7}$$

to reduce the order of the singularity; we rewrite (1.4) as

$$f(x) + \int_{\mathcal{S}} K(x,x')[f(x') - f(x)]\, dS(x') \;=\; g, \qquad x \in S. \tag{1.8}$$

Since $K = O(1/r)$ on $\mathcal{S}$, the resulting integrand is bounded, although not smooth. We will write the integral in (1.8) as in (1.6), replacing K by a regularized version K_δ, with a shape factor s and a smoothing parameter δ to be chosen:

(1.9)
$$K_\delta(x,x') = n(x') \cdot \nabla G_\delta(x'-x), \qquad \nabla G_\delta(x'-x) = \nabla G(x'-x) s(|x-x'|/\delta).$$

With the natural choice $G_\delta(x) = G(x)\,\mathrm{erf}(|x|/\delta) = -\,\mathrm{erf}(|x|/\delta)/4\pi|x|$, we have

$$s(r) = \mathrm{erf}(r) - (2/\sqrt{\pi}) r e^{-r^2}, \tag{1.10}$$

where erf is the usual error function

$$\mathrm{erf}(r) = \frac{2}{\sqrt{\pi}} \int_0^r e^{-t^2}\, dt. \tag{1.11}$$

In section 2 we find that this choice of smoothing leads to an $O(\delta^3)$ error to the integral in (1.8). Moreover, this can be improved to $O(\delta^5)$ with a slight change to

$$s(r) = \mathrm{erf}(r) - (2/\sqrt{\pi})(r - 2r^3/3) e^{-r^2}. \tag{1.12}$$

We can now give the discrete form of (1.8). Suppose a grid spacing h is chosen for the coordinate patches, and the σth patch has grid points $x_i^\sigma = X^\sigma(ih)$ for $i \in Z^2$ such that $x_i^\sigma \in V_\sigma$, where V_σ is the interior of the support of ψ^σ. We assume the specified function g is known at these points, say, $g_i^\sigma = g(x_i^\sigma)$. Then

$$f_i^\sigma + \sum_{j,\tau} K_{ij}^{\sigma\tau} \psi_j^\tau [f_j^\tau - f_i^\sigma] A_j^\tau\, h^2 \;=\; g_i^\sigma \tag{1.13}$$

is the discrete analogue of (1.8), where

$$K_{ij}^{\sigma\tau} = K_\delta(x_i^\sigma, x_j^\tau), \quad \psi_j^\tau = \psi^\tau(x_j^\tau), \quad A_j^\tau = A^\tau(jh). \tag{1.14}$$

We choose δ in terms of h so that $\delta \to 0$ as $h \to 0$, but, for some constant ρ_0,

$$\rho \;=\; \delta/h \geq \rho_0 > 0. \tag{1.15}$$

We can find the solution f_i^σ as the limit of the iteration corresponding to (1.5),

$$f_i^{\sigma,n+1} \;=\; (1-2\beta) f_i^{\sigma,n} - 2\beta \sum_{j,\tau} K_{ij}^{\sigma\tau} \psi_j^\tau [f_j^{\tau,n} - f_i^{\sigma,n}] A_j^\tau\, h^2 \;+\; 2\beta g_i^\sigma. \tag{1.16}$$

The following theorem assures the validity of this procedure.

THEOREM 1.1. *For the interior Dirichlet problem* (1.1)*, with $\mathcal{S}$ and g smooth, suppose that the grid size h and the smoothing radius δ are chosen sufficiently small subject to the condition* (1.15)*. Then the discrete integral equation* (1.13)*, using the regularization* (1.9)*,* (1.12)*, has a unique solution f_i^σ, which converges uniformly to the exact solution f of* (1.4) *or* (1.8) *as $h \to 0$, $\delta \to 0$, with the estimate*

$$|f_i^\sigma - f(x_i^\sigma)| \;\leq\; C_1 \delta^5 + C_2 h^2 e^{-c_0 (\delta/h)^2}. \tag{1.17}$$

Here c_0 depends only on the coordinate patches, but C_1, C_2 depend on bounds for derivatives of f. For $0 < \beta < 1$, the iterates defined by (1.16) *converge uniformly to the discrete solution f_i^σ, with a rate independent of h and δ.*

The convergence proof must take into account the agreement of function values where the grids overlap. This is done using a discrete Hölder norm. The error from the smoothing gives the first term in (1.17); the discretization contributes the second term, plus a remainder smaller than the first. The second term is dominated by the first if $\rho = \delta/h$ grows slowly as $h, \delta \to 0$. For example, if we choose $\delta = ch^q$, with $q < 1$, the error is $O(\delta^5) = O(h^{5q})$. Similarly, if we use the simpler choice of smoothing (1.10) we obtain almost $O(h^3)$ convergence. The constant c_0 is $\pi^2\gamma^2/2$, where γ, given by (3.19), depends on g^{ij}; see (3.25).

After solving the discrete integral equation for the dipole strength f at the coordinate grid points x_i^σ, we now want to find the values of the solution u of (1.1) from the double layer representation (1.2). For a point y away from the surface we can discretize the integral routinely, since the integrand is smooth. For y near the surface, however, the integral is nearly singular, and accurate calculation requires more care. In contrast to the case $y \in \mathcal{S}$, $n(x) \cdot \nabla G(x-y) = O(|x-y|^{-2})$. Given y near $\mathcal{S}$, there is a point x_0 on the surface so that y is on the normal line through x_0; i.e., $y = x_0 + bn_0$, for some b, where n_0 is the outward unit normal at x_0. We can use Green's identity to replace (1.2) with a subtracted form

$$u(y) = \int_{\mathcal{S}} \frac{\partial}{\partial n(x)} G(x-y)[f(x) - f(x_0)]\, dS(x) + f(x_0), \qquad y \in \Omega. \tag{1.18}$$

We can approximate the integral above by the sum

$$S = \sum_{\sigma,j} n(x_j^\sigma) \cdot \nabla G_\delta(x_j^\sigma - y)[f(x_j^\sigma) - f(x_0)]\psi_j^\sigma A_j^\sigma h^2. \tag{1.19}$$

We use the simpler regularization (1.10); it seems that higher order smoothing cannot be incorporated in the modified kernel for the nearly singular case. This sum typically has a large error for y near S. We can think of the error in two parts: the smoothing error from replacing ∇G by ∇G_δ and the discretization error from replacing the integral with ∇G_δ by the sum or, briefly,

$$\sum_\delta - \int = \left(\int_\delta - \int\right) + \left(\sum_\delta - \int_\delta\right). \tag{1.20}$$

The analysis of the following sections shows that these errors, uniform with respect to y near $\mathcal{S}$, are $O(\delta^2)$ and $O(h)$, respectively. However, the largest errors can be removed by corrections which we now describe. They are derived in sections 2 and 3 and are analogous to those found in the 2D case in [3].

The corrections involve the geometry of the surface near x_0. There is at least one σ so that x_0 is in the σth patch; i.e., $x_0 = X^\sigma(\alpha_0)$ for some $\alpha_0 \in U^\sigma$. Let T_i be the tangent vector $(\partial X^\sigma/\partial\alpha_i)(\alpha_0)$ at x_0, $i = 1, 2$. We use the metric tensor $g_{ij} = T_i \cdot T_j$; its determinant $g = \det(g_{ij})$; the inverse $g^{ij} = (g_{ij})^{-1}$; and the surface Laplacian

$$\Delta f = \sum_{i,j=1}^{2} \frac{1}{\sqrt{g}} \frac{\partial}{\partial\alpha_j} \left(\sqrt{g}\, g^{ij} \frac{\partial(f \circ X^\sigma)}{\partial\alpha_i}\right). \tag{1.21}$$

If the grid points $\{x_j^\sigma\}$ and values f_j^σ are known, these quantities can be found at α_0 by interpolation. The smoothing correction derived in section 2 is, with $\lambda = b/\delta$,

$$\mathcal{T}_1 = \delta^2(\Delta f(x_0))(\lambda/4)(|\lambda| \operatorname{erfc}|\lambda| - e^{-\lambda^2}/\sqrt{\pi}). \tag{1.22}$$

The discretization correction comes from the Poisson summation formula applied to the regularized kernel. It uses the function

$$E(p,q) = e^{2pq}\operatorname{erfc}(p+q) + e^{-2pq}\operatorname{erfc}(-p+q), \tag{1.23}$$

where erfc $= 1 -$ erf is the complementary error function. The point x_0 may be in more than one coordinate patch, and a correction term is needed for each. In the σth patch, $x_0 = X^\sigma(\alpha_0)$ for some α_0 depending on σ. We can write $\alpha_0 = ih + \nu h$ for some $i \in Z^2$ and $\nu = (\nu_1, \nu_2)$, with $0 \le \nu_s \le 1$, $s = 1, 2$. The correction for the σth patch is

$$\mathcal{T}_2^\sigma = -h \sum_{r=1}^{2} c_r \psi^\sigma(\alpha_0) \frac{\partial (f \circ X^\sigma)}{\partial \alpha_r}(\alpha_0), \tag{1.24}$$

$$c_r = \frac{\rho\lambda}{2} \sum_{s=1}^{2} \sum_{n \in Q} a(n,s) \sin(2\pi n \cdot \nu) \frac{g^{rs} n_s}{\|n\|} E(\lambda, \pi\rho\|n\|). \tag{1.25}$$

Here $Q = \{n = (n_1, n_2) \in \mathbf{Z}^2 : n_2 \ge 0, n \ne 0\}$; $\|n\| = \sqrt{g^{ij} n_i n_j}$; $a(n,s) = 1/2$ when $s = 1$ and $n_2 = 0$, and $a(n,s) = 1$ otherwise.

The following theorem summarizes the error estimates for the computed value of $u(y)$ in (1.2), starting with the sum (1.19) and adding corrections.

THEOREM 1.2. *For $y \in \Omega$, let $u(y)$ be the exact solution of* (1.1)*, given by* (1.2)*, assuming f and $\mathcal{S}$ are smooth. Let $\tilde{u}(y)$ be the value computed as the sum*

$$\tilde{u}(y) \;=\; S \;+\; f(x_0) \;+\; \mathcal{T}_1 \;+\; \sum_\sigma \mathcal{T}_2^\sigma, \tag{1.26}$$

with $S, \mathcal{T}_1, \mathcal{T}_2^\sigma$ given by (1.19)*,* (1.10)*,* (1.21)*–*(1.25)*, subject to* (1.15)*. Then the error has the form $\tilde{u}(y) - u(y) = \varepsilon_1 + \varepsilon_2$, where the smoothing error ε_1 and the discretization error ε_2 can be estimated as follows, uniformly for y near $\mathcal{S}$, with c_0 as before:*

$$|\varepsilon_1| \le C_1 \delta^3, \qquad |\varepsilon_2| \le C_2 h^2 e^{-c_0(\delta/h)^2} + C_3 h^3. \tag{1.27}$$

Again we can choose δ so that $\rho = \delta/h$ grows slowly and the error is almost $O(h^3)$. Thus, for $\delta = ch^q$ with $q < 1$, the error is $O(\delta^3) = O(h^{3q})$. The sum in (1.25) is infinite, but the terms decay at a Gaussian rate, independent of y, and only a few terms are needed; see Lemma 3.3. It decreases rapidly as ρ is increased, as does the main term in the estimate for ε_2; see (3.20).

Related problems for harmonic functions can be treated; correction formulas for the single layer potential in the nearly singular case will be given elsewhere. Similar methods should apply to the Helmholtz equation since the leading singularities are the same. This approach in two dimensions [3] was applied to the Stokes equations of viscous fluid flow by Cortez [10], and 3D applications should be possible as well. Regularized kernels have long been used for fluid flow in vorticity formulation (see, e.g., [16, 6]), as well as other physical contexts, and discretization corrections of the present type have also been used in fluid problems [20, 22, 4].

In section 2 we analyze the smoothing error, derive the correction (1.22), and show that (1.12) has $O(\delta^5)$ error on the surface. We begin section 3 with a general lemma about the quadrature of nearly singular integrals with a homogeneous kernel. This is used to derive the correction (1.24), (1.25) and the estimates for the remaining discretization error. Sections 2 and 3 together prove Theorem 1.2 and the consistency part of Theorem 1.1. The rest of the proof of Theorem 1.1 is given in section 4. In section 5 we present numerical examples, with $\mathcal{S}$ a sphere or ellipsoid, illustrating the general principles.

2. The smoothing error. In this section we find the first correction to the error in the double layer potential, evaluated at a point near the surface, resulting from the smoothing in the simplest regularized Green's function

$$G_\delta(x) = -\frac{1}{4\pi}\frac{\operatorname{erf}(r/\delta)}{r} = G(x)\operatorname{erf}(r/\delta), \qquad r = |x|. \tag{2.1}$$

The correction is $O(\delta^2)$ and leaves an error of $O(\delta^3)$. We also derive the fifth order kernel (1.9), (1.12) for points on the surface.

The smoothing error for a point y near the surface is localized, and we can assume the function f is zero outside one coordinate patch. We can write the error as an integral in this patch, regarding f as a function of α,

$$\varepsilon = \int [\nabla G_\delta(x(\alpha) - y) - \nabla G(x(\alpha) - y)] \cdot n(\alpha) f(\alpha)\, dS(\alpha). \tag{2.2}$$

For simplicity, we will assume that $x(0) = 0$ and y is along the normal line from $x(0)$ so that $y = bn_0$ for some b, where n_0 is the unit normal at $x(0)$. Since we always subtract out the principal singularity, we also assume $f(0) = 0$. Now

$$\frac{\partial}{\partial r}(G_\delta - G) = \frac{1}{4\pi r^2}\,\phi(r/\delta), \tag{2.3}$$

$$\phi(\rho) = -\operatorname{erfc}(\rho) + \rho \operatorname{erfc}'(\rho) = -\operatorname{erfc}(\rho) - (2/\sqrt{\pi})\rho e^{-\rho^2}. \tag{2.4}$$

Thus, with $r = |x(\alpha) - y|$,

$$\varepsilon = \frac{1}{4\pi}\int \frac{(x(\alpha) - y)\cdot n(\alpha)}{r^3}\phi(r/\delta) f(\alpha)\, dS(\alpha). \tag{2.5}$$

We will find the largest contribution to ε using Taylor expansions at $\alpha = 0$. To simplify the calculations we first assume the α-coordinate system is specially chosen and then extend the result to a general system. With $T_j = \partial x/\partial \alpha_j$ the tangent vectors to surface, $j = 1, 2$, we assume that the metric tensor $g_{ij} = T_i \cdot T_j$ is the identity at $\alpha = 0$ and, furthermore, that $\partial g_{ij}/\partial \alpha_k = 0$ at $\alpha = 0$, $i, j, k = 1, 2$. The latter is equivalent to assuming that the Christoffel symbols vanish at $\alpha = 0$. We also assume, rotating if necessary, that T_1, T_2 have the directions of principal curvature at $\alpha = 0$. We then have simple expansions for $x(\alpha)$ and $n(\alpha)$:

$$x(\alpha) = T_1(0)\alpha_1 + T_2(0)\alpha_2 + \tfrac{1}{2}\kappa_1 n_0 \alpha_1^2 + \tfrac{1}{2}\kappa_2 n_0 \alpha_2^2 + O(|\alpha|^3), \tag{2.6}$$

$$n(\alpha) = n_0 - \kappa_1 T_1(0)\alpha_1 - \kappa_2 T_2(0)\alpha_2 + O(|\alpha|^2), \tag{2.7}$$

where κ_1, κ_2 are the principal curvatures. Thus

$$r^2 = |x - bn_0|^2 = |\alpha|^2 + b^2 - b\kappa_1\alpha_1^2 - b\kappa_2\alpha_2^2 + O(|\alpha|^4) + O(|\alpha|^3 b).$$

We make a further coordinate change $\alpha \mapsto \xi$ to simplify the dependence of r in the integral. We define ξ_1, ξ_2 by requiring $\xi_j/|\xi| = \alpha_j/|\alpha|$ and $|\xi|^2 + b^2 = r^2$, or

$$|\xi|^2 = |\alpha|^2 - b\kappa_1\alpha_1^2 - b\kappa_2\alpha_2^2 + O(|\alpha|^4) + O(|\alpha|^3 b) \tag{2.8}$$

so that

$$|\xi| = |\alpha|\left(1 - \frac{1}{2}b\kappa_1\frac{\alpha_1^2}{|\alpha|^2} - \frac{1}{2}b\kappa_2\frac{\alpha_2^2}{|\alpha|^2}\right) + O(|\alpha|^3) + O(b^3). \tag{2.9}$$

For α near 0, we can solve for $|\alpha|$ to get $|\alpha| = |\xi|(1 + bq/2) + O(|\xi|^3 + b^3)$ and then

$$\alpha_j = (\xi_j/|\xi|)|\alpha| = (1 + bq/2)\xi_j + O(|\xi|^3) + O(b^3), \tag{2.10}$$

$$q = \kappa_1 \xi_1^2/|\xi|^2 + \kappa_2 \xi_2^2/|\xi|^2. \tag{2.11}$$

We can now write the smoothing error in the form

$$\varepsilon = \frac{1}{4\pi} \int \frac{\phi(\sqrt{|\xi|^2 + b^2}/\delta)}{(|\xi|^2 + b^2)^{3/2}} w(\xi, b)\, d\xi \tag{2.12}$$

with the nonradial factors combined into

$$w(\xi, b) = [(x - y) \cdot n] f \left| \frac{\partial \alpha}{\partial \xi} \right| |T_1 \times T_2|. \tag{2.13}$$

Next we approximate each of these factors. First, using the expressions above for $x(\alpha)$ and $n(\alpha)$ we find, with $y = bn_0$,

$$(x(\alpha) - y) \cdot n(\alpha) = -b - \tfrac{1}{2}\kappa_j \alpha_j^2 + O(|\alpha|^3) + O(b^3),$$

summed over j, and, since $\alpha_j = \xi_j + O(b)$,

$$(x - y) \cdot n = -b - \tfrac{1}{2} q|\xi|^2 + O(|\xi|^3) + O(b^3). \tag{2.14}$$

Next, with α-derivatives of f at $\alpha = 0$ denoted by f_i or f_{ij}, we have

$$f = f_j \alpha_j + \tfrac{1}{2} f_{ij} \alpha_i \alpha_j + O(|\alpha|^3)\,,$$

since $f(0) = 0$, with sums over i and j, or

$$f = f_j \left(1 + \frac{bq}{2}\right) \xi_j + \frac{1}{2} f_{ij} \xi_i \xi_j + O(|\xi|^3) + O(b^3). \tag{2.15}$$

For the Jacobian, since q depends only on $\xi/|\xi|$, we find from (2.10) that

$$\det(\partial \alpha/\partial \xi) = 1 + bq + O(|\xi|^2) + O(b^2). \tag{2.16}$$

Finally, from (2.6) we have $T_j(\alpha) = T_j(0) + \kappa_j \alpha_j n_0$, and, since $T_j(0) \perp n(0)$,

$$|T_1 \times T_2| = 1 + O(|\alpha|^2) = 1 + O(|\xi|^2). \tag{2.17}$$

To approximate (2.12), we now substitute (2.14)–(2.17) into (2.13) and obtain

$$w(\xi, b) = -b\xi_j f_j - (3q/2) b^2 \xi_j f_j - (q/2)|\xi|^2 \xi_j f_j - (b/2) f_{ij} \xi_i \xi_j + R(\xi, b), \tag{2.18}$$

where $R = O(|\xi|^4 + b^4)$. The first three terms are odd in ξ and will contribute zero to the integral (2.12). We check that the remainder R is negligible: With the change of variables $\xi = \delta\zeta$, $b = \delta\lambda$, we can write $R(\xi, b) = \delta^4 \tilde{R}(\zeta, \lambda)$ for some bounded function $\tilde{R}$. Then the contribution to (2.12) from the remainder R in w is

$$(4\pi)^{-1} \delta^{-3+4+2} \int \frac{\phi(\sqrt{|\zeta|^2 + \lambda^2})}{(|\zeta|^2 + \lambda^2)^{3/2}} \tilde{R}(\zeta, \lambda)\, d\xi \;=\; O(\delta^3).$$

We are now left with only the fourth term in (2.18). Because of symmetry, only the terms with $i = j$ contribute, and the integral with ξ_j^2 reduces to a radial one. Again with $\xi = \delta\zeta$, $b = \delta\lambda$, and $s = |\zeta|$, (2.12) is now

$$\varepsilon = -\delta^2 \frac{\lambda}{8}(f_{11} + f_{22}) \int_0^\infty \frac{\phi(\sqrt{s^2+\lambda^2})}{(s^2+\lambda^2)^{3/2}} s^3\, ds \,+\, O(\delta^3).$$

To evaluate the integral, let

$$I(\lambda) = \int_0^\infty (G_1(r) - G(r)) s^3\, ds, \qquad r^2 = s^2 + \lambda^2;$$

then $dI/d\lambda$ is similar to the above:

$$I'(\lambda) = \frac{\lambda}{4\pi} \int_0^\infty \frac{\phi(r)}{4\pi r^3} s^3\, ds.$$

Changing the variable of integration to r, we have

$$I(\lambda) = \int_{|\lambda|}^\infty (G_1(r) - G(r)) s^2 r\, dr = (4\pi)^{-1} \int_{|\lambda|}^\infty \operatorname{erfc}(r)(r^2 - \lambda^2)\, dr,$$
$$I'(\lambda) = -(2\pi)^{-1}\lambda \int_{|\lambda|}^\infty \operatorname{erfc}(r)\, dr = (2\pi)^{-1}\lambda\,(|\lambda| \operatorname{erfc}|\lambda| - e^{-\lambda^2}/\sqrt{\pi}),$$

and, finally,

$$\varepsilon = -\delta^2(f_{11} + f_{22})(\lambda/4)(|\lambda| \operatorname{erfc}|\lambda| - e^{-\lambda^2}/\sqrt{\pi}) \,+\, O(\delta^3). \tag{2.19}$$

We have now obtained the smoothing correction with derivatives expressed in the special coordinates. To restate the answer in a general coordinate system, we have only to note the invariant form of the Laplacian on the surface, given by (1.21). It reduces to $f_{11} + f_{22}$ at $\alpha = 0$ in the special case above. Therefore it is also the correct expression in arbitrary coordinates. Thus $\varepsilon = -\mathcal{T}_1 + O(\delta^3)$, with $\mathcal{T}_1$ given by (1.22), justifying the stated correction and smoothing error.

The fifth order kernel. In view of the above analysis, we can identify the source of the $O(\delta^3)$ error in the special case when the point y is on the surface. We can then modify the choice of G_δ to remove this error, resulting in smoothing that is $O(\delta^5)$ accurate on the surface. With y on the surface, the smoothing error ε is given by (2.12) with $b = 0$. From (2.18) we see that the terms in the expansion of $w(\xi, 0)$ up to order 3 make no contribution. The fourth order terms will give an error proportional to

$$\int \phi(|\xi|/\delta)|\xi|^{-3}|\xi|^4\, d\xi \;=\; \delta^3 \int \phi(|\zeta|)|\zeta| d\zeta \;=\; 2\pi\delta^3 \int_0^\infty \phi(r) r^2\, dr.$$

The fifth order terms will lead to odd integrands, and thus the remaining error is $O(\delta^5)$. To eliminate the $O(\delta^3)$ error, we simply have to change the choice of G_δ, and therefore ϕ, so that the last integral is zero. Our new choice of G_δ will be so that $\phi(r)$ is replaced by $\phi_5(r) = \phi(r) + ar\phi'(r)$ with a a constant. It is easy to see from an integration by parts that the integral above is zero, with ϕ_5 in place of ϕ, provided we take $a = 1/3$. Thus $\phi_5(r) = \operatorname{erf}(r) - 1 - (2/\sqrt{\pi})(r - 2r^3/3)e^{-r^2}$, and the modification of ∇G is $\nabla G_\delta(x) = \nabla G(x)[1 + \phi_5(|x|/\delta)]$ as given by (1.9), (1.12).

3. The discretization error. We begin with a general principle, Lemma 3.1, for the quadrature of nearly singular integrals. We apply this to a local approximation of the double layer potential in Lemma 3.3, obtaining the corrections (1.24), (1.25). We then compare with the exact potential, verifying the discretization estimate of Theorem 1.2, and find an improved estimate needed for Theorem 1.1.

Our treatment of the discretization error is based on a lemma describing the quadrature error for the integral of a regularized homogeneous function K_δ, times a smooth function f, over a plane displaced from the origin. This lemma is similar to Lemma 3.1 of [3], except that we do not assume here that the smoothing radius δ is proportional to the grid size h; we allow $\rho = \delta/h$ unbounded as $h \to 0$. Let K be a homogeneous function of $(x, y) \in \mathbf{R}^d \times \mathbf{R}$ with degree m, that is,

$$K(ax, ay) = a^m K(x, y)\,, \qquad a > 0\,, \quad (x, y) \neq 0. \tag{3.1}$$

We choose a regularization of the form

$$K_\delta(x, y) = K(x, y)s(x/\delta, y/\delta), \qquad (x, y) \in \mathbf{R}^d \times \mathbf{R}, \tag{3.2}$$

where s is a specified shape function such that $s \to 1$ rapidly at infinity. It follows that $K_\delta(x, y) = \delta^m K_1(x/\delta, y/\delta)$. The lemma concerns the integral of $K_\delta f$ over x with y fixed. We allow the singularity to be misaligned from the grid points in x-space.

LEMMA 3.1. *Let K_δ be a smooth function on $\mathbf{R}^{d+1}$ with the form* (3.2) *such that K and s are smooth for $(x, y) \neq 0$; K is homogeneous of degree m with $-d \leq m \leq 0$; $s(x, y) \to 1$ as $(x, y) \to \infty$; and $|D^\beta s(x, y)| \leq C_\beta |(x, y)|^{-|\beta|}$ for $|(x, y)| \geq 1$ and for each multi-index β. Let f be a smooth function on $\mathbf{R}^d$ such that f and its derivatives are rapidly decreasing. Suppose, for each $h > 0$, that δ is chosen so that $\rho = \delta/h \geq \rho_0$ for some fixed $\rho_0 > 0$. Assume $\nu \in \mathbf{R}^d$ with $0 \leq \nu_j \leq 1$ for $1 \leq j \leq d$. Let $\eta = y/h$. Then the error in replacing the integral I by the sum S,*

$$I = \int_{\mathbf{R}^d} K_\delta(x, y) f(x)\, dx = \int_{\mathbf{R}^d} K(x, y) s(x/\delta, y/\delta) f(x)\, dx, \tag{3.3}$$

$$S = \sum_{n \in \mathbf{Z}^d} K_\delta(nh - \nu h, y) f(nh - \nu h)\, h^d, \tag{3.4}$$

has the form

$$S - I = h^{d+m} \left(c_0 f(0) + C_1 h + C_2 h^2 + \cdots + C_\ell h^\ell \right) + O(\delta^{d+m+\ell+1}), \tag{3.5}$$

$$c_0 = (2\pi)^{d/2} \sum_{0 \neq n \in \mathbf{Z}^d} e^{-2\pi i n \nu} \hat{K}_\rho(2\pi n, \eta). \tag{3.6}$$

Here $\hat{K}_\rho(\cdot, \eta)$ is the Fourier transform of $K_\rho(\cdot, \eta)$, and ℓ depends on the smoothness of K, s, f. The leading constant c_0 is uniformly bounded in η, ρ, ν. The C_j, for $j \geq 1$, and the error term are uniformly bounded in η, ρ, ν, depending on f.

The value of c_0 is derived from the Poisson summation formula applied to K_ρ. The sum (3.6) converges rapidly. We write the Fourier transform as

$$\hat{F}(k) \,=\, (2\pi)^{-d/2} \int F(x) e^{-ikx}\, dx.$$

The proof is a modification of that for Lemma 3.1 in [3] and related to ones in [4, 12].

When we apply this lemma to the double layer potential, evaluated at a point y near the surface, the leading error comes from the part of the surface close to y,

and we begin with a simplified approximation for the potential. Suppose $y = bn_0$, where n_0 is the unit normal to a point $x(\alpha_0)$ on the surface. For convenience, we take $\alpha_0 = 0$ and $x(\alpha_0) = 0$. With T_j, g_{ij}, g^{ij} as defined earlier, at $\alpha = 0$, let $\tau = |T_1 \times T_2|$ so that $\det g_{ij} = \tau^2$. Also let $J = \partial x(0)/\partial\alpha$ so that $J\alpha = T_1\alpha_1 + T_2\alpha_2$. For α near 0, we can approximate $x(\alpha)$ by its projection $J\alpha$ in the tangent plane and the double layer kernel $n(\alpha) \cdot \nabla G_\delta(x(\alpha), y)$ by

$$K_\delta^{(0)}(\alpha, b) = n_0 \cdot \nabla G_\delta(J\alpha - bn_0) = -(\partial/\partial b)G_\delta(J\alpha - bn_0). \tag{3.7}$$

The surface area $dS(\alpha)$ is $\tau\, d\alpha$ to first approximation. We subtract out the singularity in the double layer potential, and the leading contribution to $f(\alpha) - f(0)$ will be $(\alpha_1\partial_1 f + \alpha_2\partial_2 f)\zeta(\alpha)$ with $\partial_r f = \partial_r f(0)$ for some cut-off function ζ, $\zeta = 1$ near $\alpha = 0$. Thus we actually apply the lemma to the kernel

$$K_\delta^{(r)}(\alpha, b) = K_\delta^{(0)}(\alpha, b)\alpha_r, \qquad r = 1, 2. \tag{3.8}$$

We first show that this simplified case gives the $O(h)$ error stated in (1.24), (1.25).

LEMMA 3.2. *With the notation above, let*

$$I = \int_{R^2} n_0 \cdot \nabla G_\delta(J\alpha - bn_0)(\alpha_1\partial_1 f + \alpha_2\partial_2 f)\zeta(\alpha)\tau\, d\alpha \tag{3.9}$$

and S be the corresponding sum with $\alpha = jh - \nu h$. Then $S - I = (c_1\partial_1 f + c_2\partial_2 f)h + O(h^p)$ for large p, where c_1, c_2 are given by (1.25).

Proof. Our main task is to find the Fourier transform of $K_\rho^{(r)}(\alpha, b)$ in α alone. We begin with the 3D Fourier transform of $G_\rho(x) = -\operatorname{erf}(|x|/\rho)/4\pi|x|$,

$$\hat{G_\rho}(k) = -(2\pi)^{-3/2}|k|^{-2}e^{-\rho^2|k|^2/4}, \qquad k = (k_1, k_2, k_3) \in \mathbf{R}^3. \tag{3.10}$$

We interpret $G_\rho(J\alpha - bn_0)$ as a composition: Since G_ρ is radial, it depends on α only through $|J\alpha|^2 = |B\alpha|^2$, where $B = (J^*J)^{1/2}$; note $|B\alpha|^2 = J^*J\alpha \cdot \alpha = \sum_{ij} g_{ij}\alpha_i\alpha_j$. Thus $G_\rho(J\alpha - bn_0) = (G_\rho \circ M)(\alpha, b)$, where $M(\alpha, b) = (B\alpha, b)$. The 3D transform of $G_\rho \circ M$, as a function of (α, b), is then

$$(G_\rho \circ M)\hat{}(k) = |\det M|^{-1}\hat{G_\rho}((M^*)^{-1}k) = \tau^{-1}\hat{G_\rho}(B^{-1}(k_1, k_2), k_3), \tag{3.11}$$

and, since $\hat{G_\rho}$ is radial and $B^{-2} = (J^*J)^{-1}$,

$$(G_\rho \circ M)\hat{}(k) = \tau^{-1}\hat{G_\rho}(\ell, k_3), \qquad \ell^2 = \sum_{i,j=1}^{2} g^{ij}k_ik_j. \tag{3.12}$$

Now

$$\hat{K}_\rho^{(0)}(k) = (-(\partial/\partial b)G_\rho \circ M)\hat{}(k) = -ik_3\,\tau^{-1}\hat{G_\rho}(\ell, k_3), \tag{3.13}$$

and the transform of $K_\rho^{(0)}(\alpha, b)$ in α alone is

$$\begin{aligned} K_\rho^{(0)}(\cdot, b)\hat{}(k_1, k_2) &= (2\pi)^{-1/2}\int_{-\infty}^{\infty} \hat{K}_\rho^{(0)}(k_1, k_2, k_3)e^{ik_3b}\, dk_3 \\ &= (2\pi)^{-2}\tau^{-1}\frac{\partial}{\partial b}\int_{-\infty}^{\infty}\frac{1}{\ell^2 + k_3^2}e^{-\rho^2(\ell^2+k_3^2)/4}e^{ik_3b}\, dk_3. \end{aligned} \tag{3.14}$$

This is similar to (3.29) in [3]; we find

$$K_\rho^{(0)}(\cdot,b)\hat{}(k_1,k_2) = (8\pi\tau)^{-1}\left[e^{\ell b}\operatorname{erfc}(b/\rho+\ell\rho/2) - e^{-\ell b}\operatorname{erfc}(-b/\rho+\ell\rho/2)\right]. \tag{3.15}$$

Next, since $K_\rho^{(r)} = K_\rho^{(0)}\alpha_r$, $\hat{K}_\rho^{(r)}(k_1,k_2,b)$ is given by

$$\hat{K}_\rho^{(r)} = i(\partial/\partial k_r)\hat{K}_\rho^{(0)} = i(\partial\ell/\partial k_r)(\partial/\partial\ell)\hat{K}_\rho^{(0)} = i(g^{rs}k_s/\ell)(\partial/\partial\ell)\hat{K}_\rho^{(0)}, \tag{3.16}$$

summed over s. After differentiating and canceling we get

$$\hat{K}_\rho^{(r)}(k_1,k_2,b) = \frac{ib}{8\pi\tau}\sum_{s=1}^{2}\frac{g^{rs}k_s}{\ell}E\left(\frac{b}{\rho},\frac{\ell\rho}{2}\right) \tag{3.17}$$

with $E(p,q)$ given by (1.23). We are now ready to apply Lemma 3.1 to the simplified integral (3.9). The kernel $K_\rho^{(r)}(\alpha,b)$ is homogeneous with degree $m=-1$, and, according to the lemma, $S-I = \varepsilon h + O(h^p)$, with

$$\varepsilon = 2\pi\tau\sum_{r=1}^{2}\sum_{n\neq 0}e^{-2\pi i n\nu}(\partial_r f)\hat{K}_\rho^{(r)}(2\pi n, b/h),$$

and, using (3.17), with $\lambda = b/\delta$ and $\|n\| = \sqrt{g^{ij}n_in_j}$,

$$\varepsilon = \frac{i\rho\lambda}{4}\sum_{r,s=1}^{2}\sum_{n\neq 0}e^{-2\pi i n\nu}(\partial_r f)\frac{g^{rs}n_s}{\|n\|}E(\lambda,\pi\rho\|n\|).$$

Combining terms for n and $-n$, we find $\varepsilon = c_1\partial_1 f + c_2\partial_2 f$, with c_1, c_2 expressed as in (1.25), and the lemma is proved. ∎

To understand the dependence of the errors on $\rho = \delta/h$, we will use the following lemma concerning the size of the function E of (1.23).

LEMMA 3.3. *With E as in* (1.23)*, we have for $q \geq q_0 > 0$ and any p,*

$$E(p,q) \leq C_0\exp(-q_0 p - q^2), \tag{3.18}$$

where C_0 depends on q_0.

Proof. Since E is even in p we assume $p \geq 0$. Call the two terms T_1 and T_2. Since $\operatorname{erfc} a \leq C\exp(-a^2)$ for $a \geq 0$, $T_1 \leq C\exp(2pq-(p+q)^2) = C\exp(-p^2-q^2)$. If $q \geq p$, then $T_2 \leq C\exp(-p^2-q^2)$ in the same way. If $q \leq p$, then $T_2 \leq 2\exp(-2pq) = 2\exp(-pq)\exp(-pq) \leq 2\exp(-pq)\exp(-q^2)$. Thus in any case $E \leq \left[C\exp(-p^2) + 2\exp(-q_0 p)\right]\exp(-q^2)$, and the result follows from this. ∎

Suppose now that we assume a lower bound for the matrix g^{ij},

$$\|k\|^2 \equiv \sum_{ij} g^{ij}k_ik_j \geq \gamma^2|k|^2, \tag{3.19}$$

for some $\gamma > 0$. Then applying (3.18) to ε above, we have $\rho|\lambda|E(\lambda,\pi\rho\|n\|) \leq C\rho\exp(-\pi^2\rho^2\gamma^2|n|^2)$, and, after summing,

$$|c_r| \leq C\rho\exp(-\pi^2\rho^2\gamma^2), \qquad r = 1,2. \tag{3.20}$$

We can now complete the discretization error estimate in Theorem 1.2. With $\alpha = 0$, $x(0) = 0$ as before, and assuming $f(0) = 0$ for simplicity, we compare

$$I = \int n(\alpha) \cdot \nabla G_\delta(x(\alpha) - y) f(\alpha) dS(\alpha), \tag{3.21}$$

$$S = \sum_j n(\alpha_j) \cdot \nabla G_\delta(x(\alpha_j) - y) f(\alpha_j) A_j \, h^2, \tag{3.22}$$

where $\alpha_j = jh - \nu h$ and $A_j \, d\alpha = dS(\alpha_j)$. We will show that, assuming (3.19),

$$S - I = (c_1 \partial_1 f + c_2 \partial_2 f)h + O(h^2 \rho^3 \exp(-\pi^2 \gamma^2 \rho^2)) + O(h^3) \tag{3.23}$$

with errors uniform in b, ρ, ν. The estimate in (1.27) follows, with $c_0 = \pi^2 \gamma^2 / 2$. We need to show that the error from replacing (3.21) by the simplified version (3.9) is bounded by the remainder in (3.23). This is the quadrature error for the integral of

$$n(\alpha) \nabla G_\delta(x(\alpha) - bn_0) f(\alpha) A(\alpha) - n_0 \nabla G_\delta(J\alpha - bn_0)[\alpha_1 \partial_1 f(0) + \alpha_2 \partial_2 f(0)] A(0). \tag{3.24}$$

We can suppose f is zero outside a neighborhood of $\alpha = 0$, since the outer part is smooth and gives a high order error. We can add and subtract to write (3.24) as a sum of terms, each a regularized homogeneous function in (α, b) of degree 0, times a smooth function, as in Lemma 3.1, plus a higher degree remainder. For the remainder we can show the quadrature error is $O(h^3)$ as in the end of the proof of Lemma 3.1 in [3]. The degree 0 terms are similar to the main term treated in Lemma 3.2; they involve ∇G_δ or $D^2 G_\delta$ and up to two more factors of α. By Lemma 3.1, the $O(h^2)$ errors resulting from these terms are given by expressions like those in Lemma 3.2. The Fourier transform of the kernel is very similar to that case, with a second α-derivative leading to a factor of k in the transform. An α-factor corresponds to a k-derivative, leading to an extra factor of ρ in the estimate like (3.20). Otherwise the $O(h^2)$ correction term is bounded as in (3.20), and the estimate (3.23) results.

Finally, we discuss the special case with y on the surface to obtain an improved estimate needed for the discretization error in (1.17) of Theorem 1.1. In this case $b = 0$, $\lambda = 0$, and the $O(h)$ correction term in (3.23) is zero. The expansion in the proof of (3.23) can be continued further, with successive regularized homogeneous terms of degree ≤ 2 and an $O(h^5)$ remainder. In this way we find, for y on the surface, $S - I = O(h^2 \rho^k \exp(-\pi^2 \gamma^2 \rho^2)) + O(h^5)$ for some integer k. The fifth order kernel used in solving the integral equation has an added term; it has Gaussian form, and the last estimate applies as well with this new term. Finally, since $\rho^k \exp(-\pi^2 \gamma^2 \rho^2 / 2)$ is bounded we can write

$$S - I = O(h^2 \exp(-\pi^2 \gamma^2 \rho^2 / 2)) + O(h^5). \tag{3.25}$$

This estimate is used in section 4 to prove (1.17) with $c_0 = \pi^2 \gamma^2 / 2$.

4. The integral equation. In this section we prove the assertions about the numerical solution of the integral equation in Theorem 1.1. The exact integral equation, for unknown f on the surface $\mathcal{S}$, with g prescribed on $\mathcal{S}$, has the form

$$\tfrac{1}{2} f + Tf = g, \qquad (Tf)(x) = \int_{\mathcal{S}} K(x, x') f(x') \, dS(x'), \tag{4.1}$$

where T is the double layer potential, with kernel $K(x,x') = n(x') \cdot \nabla G(x'-x)$. We can use the coordinate patches to write the integral operator as

$$Tf(x) = \sum_\sigma \int K(x, X^\sigma(\alpha)) \psi^\sigma(X^\sigma(\alpha)) f(X^\sigma(\alpha)) A^\sigma(\alpha) d\alpha. \tag{4.2}$$

Subtracting $f(x)$ inside the integral, we convert (4.1) to the equivalent form (1.8). We are concerned with the discrete version (1.13), (1.14) of (1.8).

We can regard T as a bounded operator on $L^p(\mathcal{S})$ for any p with $2 \le p < \infty$. From potential theory we know that $\frac{1}{2} + T$ has kernel $\{0\}$ in $C(\mathcal{S})$; the same is true in $L^2(\mathcal{S})$ (see, e.g., [11, Prop. 3.13]) and then also in $L^p(\mathcal{S})$, $p \ge 2$. Thus, from Fredholm theory, $\frac{1}{2} + T$ has a bounded inverse on $L^p(\mathcal{S})$ for $2 \le p < \infty$, and (4.1) has a unique solution $f \in L^p$ for each $g \in L^p$, with $\|f\|_p \le C\|g\|_p$. We will argue that the discrete problem can be solved by regarding it as a perturbation of the exact problem, making a sequence of steps from (4.1) to (1.13). This is the stability part of the proof; the consistency part has been done in sections 2 and 3. We always assume (1.15). When we say a discrete operator is bounded, we mean bounded uniformly with respect to h.

4.1. The smoothing. The regularized kernel K_δ has the form $K_\delta(x,x') = K(x,x')s(|x-x'|/\delta)$, where $s(x) \to 1$, $Ds(x) \to 0$ rapidly as $x \to \infty$. Using the smoothness of K_δ and s, we note the pointwise estimates

$$|K_\delta(x,x')| \le Cr^{-1}, \quad r \ge \delta; \qquad |K_\delta(x,x')| \le C\delta^{-1}, \quad r \le \delta; \tag{4.3}$$

$$|DK_\delta(x,x')| \le Cr^{-2}, \quad r \ge \delta; \qquad |DK_\delta(x,x')| \le C\delta^{-2}, \quad r \le \delta, \tag{4.4}$$

where $r = |x-x'|$ and D denotes an α-derivative, with either $x = X^\sigma(\alpha)$ or $x' = X^\sigma(\alpha)$. We assume here that x, x' are in a bounded set such as $\mathcal{S}$.

To see the effect of the smoothing, we can estimate, as in section 2,

$$\int_S |K_\delta(x,x') - K(x,x')|\, dS \le C_1 \int_0^\infty r^{-1} |s(r/\delta) - 1|\, r\, dr = C_2 \delta$$

uniformly for $x \in S$; the same holds with x, x' reversed. In general, for any integral operator $\mathcal{A}$ on $\mathcal{S}$ with kernel $\mathcal{K}$, if we have uniform estimates

$$\int_{\mathcal{S}} |\mathcal{K}(x,x')|\, dS(x') \le M, \qquad \int_{\mathcal{S}} |\mathcal{K}(x,x')|\, dS(x) \le M, \tag{4.5}$$

it follows that $\mathcal{A}$ is a bounded operator on $L^p(\mathcal{S})$ with $\|\mathcal{A}\| \le M$ (see, e.g., [11, Prop. 0.10]). In our case we conclude that the operator on $L^p(\mathcal{S})$ with kernel $K_\delta - K$ has norm $O(\delta)$. Thus, since the operator $\frac{1}{2} + T$ is invertible, the same is true for $\frac{1}{2} + T_\delta$, for δ small enough, where T_δ is the operator as in (4.1) with K_δ in place of K.

4.2. A discretized kernel. Next we modify the kernel K_δ so that it acts in a natural way on discrete functions. We work with grid functions f_i^σ, defined at each grid point $x_i^\sigma = X^\sigma(ih)$, $ih \in V_\sigma$, for each σ. If $x_i^\sigma = x_j^\tau$ for some i, j with $\sigma \ne \tau$, we require $f_i^\sigma = f_j^\tau$; this property is preserved by the discrete operators. Let Q_i be the grid square in the α-plane $Q_i = \{\alpha = (\alpha_1, \alpha_2) : -h/2 < \alpha_\nu - i_\nu h \le h/2, \nu = 1,2\}$, and let $\chi_i^\sigma(x) = 1$ for $x = X^\sigma(\alpha)$, with $\alpha \in Q_i$, and $\chi_i^\sigma(x) = 0$ otherwise; i.e., χ_i^σ is the characteristic function of the set $X^\sigma(Q_i)$. Given any grid function f_i^σ, we can associate a function Bf on $\mathcal{S}$ defined by

$$(Bf)(x) = \sum_{\sigma,i} \psi_i^\sigma \chi_i^\sigma(x) f_i^\sigma. \tag{4.6}$$

The part of Bf from one σ is piecewise constant, but Bf is not, since the parts overlap. Recalling (1.14), we define a modified kernel $\tilde{K}$ and operator $\tilde{T}$ on $L^p(\mathcal{S})$ as

$$\tilde{K}(x,x') = \sum_{i,\sigma,j,\tau} K_{ij}^{\sigma\tau}\psi_i^\sigma\psi_j^\tau\chi_i^\sigma(x)\chi_j^\tau(x')A_j^\tau \;=\; B\Big(\sum_{j,\tau} K_{ij}^{\sigma\tau}\psi_j^\tau\chi_j^\tau(x')A_j^\tau\Big), \tag{4.7}$$

$$\tilde{T}f(x) = \sum_\tau \int \tilde{K}(x, X^\tau(\alpha))f(X^\tau(\alpha))\,d\alpha. \tag{4.8}$$

We write $K_\delta(x,x')$ as $\sum_{\sigma,\tau} K_\delta(x,x')\psi^\sigma(x)\psi^\tau(x')$; for each σ,τ,i,j we have replaced $K^{\sigma\tau} \equiv K_\delta\psi^\sigma\psi^\tau A^\tau$ on $X^\sigma(Q_i)\times X^\tau(Q_j)$ with the constant $\tilde{K}^{\sigma\tau} \equiv K_\delta(x_i^\sigma, x_j^\tau)\psi_i^\sigma\psi_j^\tau A_j^\tau$. Then for each σ,τ and each $x \in X^\sigma(U^\sigma)$ we estimate

$$\int_{U_\tau} |\tilde{K}^{\sigma\tau}(x, X^\tau(\alpha)) - K^{\sigma\tau}(x, X^\tau(\alpha))|\,d\alpha \;\le\; Ch\sum_j M_{ij}^{\sigma\tau}\,h^2, \tag{4.9}$$

where i is such that $x \in X^\sigma(Q_i)$. Here $M_{ij}^{\sigma\tau}$ is a bound for $|DK^{\sigma\tau}|$ within radius $O(h)$ of (x_i^σ, x_j^τ). Using (4.4) we have $|M_{ij}^{\sigma\tau}| \le C|x_i^\sigma - x_j^\tau|^{-2}$ for $|x_i^\sigma - x_j^\tau| > C_0\delta$ and $|M_{ij}^{\sigma\tau}| \le C\delta^{-2}$ otherwise. Since $c_1|\alpha-\alpha'| \le |X^\tau(\alpha) - X^\tau(\alpha')| \le c_2|\alpha-\alpha'|$, we can bound (4.9) as follows, replacing the sum for $|x_i^\sigma - x_j^\tau| \ge O(\delta)$ by an α-integral:

$$C_1h\delta^{-2}(\delta/h)^2h^2 + C_2h\int_{C_3\delta}^{C_4} r^{-2}r\,dr \;\le\; C_5h(1+|\log\delta|) \;\le\; C_6h(1+|\log h|) \tag{4.10}$$

(cf. [5, Lemma 3.2] or [16, Lemma 5] for arguments of this type). This gives the first of two estimates of form (4.5), with $\mathcal{K} = \tilde{K} - K_\delta$, and the second is similar. Thus we can conclude that the norm of $\tilde{T} - T$, as an operator on $L^p(\mathcal{S})$, is $O(h|\log h|)$. Since the operator $\frac{1}{2} + T_\delta$ is invertible, the nearby operator $\frac{1}{2} + \tilde{T}$ is also invertible.

4.3. Discrete functions. Next we pass from functions of continuous $x \in \mathcal{S}$ to discrete functions. For a grid function f_i^σ we use the L_h^p norm, defined by

$$\|f\|_{L_h^p}^p = \sum_{\sigma,i} |f_i^\sigma|^p\,h^2. \tag{4.11}$$

The operator B of (4.6) is bounded from L_h^p to L^p. Now, given a grid function $g \in L_h^p$, we have $Bg \in L^p(\mathcal{S})$, and from the result above there is a unique $F \in L^p(\mathcal{S})$ depending boundedly on $Bg \in L^p(S)$ so that $\frac{1}{2}F + \tilde{T}F = Bg$, or, in view of (4.7), $F = -2Bw + 2Bg$, where

$$w_i^\sigma = \sum_{j,\tau} K_{ij}^{\sigma\tau}\psi_j^\tau A_j^\tau \int_{Q_j} F(X^\tau(\alpha))\,d\alpha. \tag{4.12}$$

Now we can define a discrete function f so that $F = Bf$:

$$f_i^\sigma = -2w_i^\sigma + 2g_i^\sigma. \tag{4.13}$$

This can be rewritten as

$$\tfrac{1}{2}f_i^\sigma + (T_h(\mathcal{M}f))_i^\sigma = g_i^\sigma, \qquad (\mathcal{M}f)_j^\tau = h^{-2}\int_{Q_j} F(X^\tau(\alpha))\,d\alpha, \qquad F = Bf, \tag{4.14}$$

where T_h is the discrete integral operator from L^p_h to L^p_h defined by

$$(T_h \bar f)^\sigma_i = \sum_{j,\tau} K^{\sigma\tau}_{ij} \psi^\tau_j \bar f^\tau_j A^\tau_j \, h^2. \tag{4.15}$$

Equation (4.14) resembles the desired discrete integral equation (1.13) but has $(\mathcal{M}f)^\tau_j$ rather than f^τ_j inside the integral operator. It is easy to check that the mapping $F \mapsto \mathcal{M}f$ is bounded from L^p to L^p_h, and thus $f \mapsto Bf = F \mapsto \mathcal{M}f$ is bounded from L^p_h to L^p_h. We can see that the discrete operator T_h is bounded on L^p_h using the pointwise estimate (4.3) and an argument similar to that for $\tilde K - K$ in (4.9), (4.10). We can now check that the discrete solution f of (4.14) depends boundedly on g: Given $g \in L^p_h$, $F \in L^p$, as determined by the equation $(\frac12 + \tilde T)F = Bg$, depends boundedly on $Bg \in L^p$ and therefore on $g \in L^p_h$. Then, using the boundedness of T_h, the discrete function f, defined by (4.12), (4.13), depends boundedly in L^p_h on g. The solution f of (4.14) is unique since the corresponding solution F of $(\frac12 + \tilde T)F = Bg$ is unique. We have shown that the operator $\mathcal{A}$ has a bounded inverse on L^p_h, where

$$\mathcal{A}f \;=\; \tfrac12 f + T_h \mathcal{M} f. \tag{4.16}$$

4.4. Boundedness in the Hölder norm. We will now improve the solvability estimate for $\mathcal{A}$ to a higher norm in order to measure the agreement of values on overlapping grids. For $0 < \lambda < 1$, we define the discrete Hölder norm as

$$\|f\|_{C^\lambda_h} = \sup_{\sigma,i} |f^\sigma_i| + \sup_{\sigma,i,\sigma',i'} |f^\sigma_i - f^{\sigma'}_{i'}| / |x^\sigma_i - x^{\sigma'}_{i'}|^\lambda, \tag{4.17}$$

excluding pairs with $x^\sigma_i = x^{\sigma'}_{i'}$ in the latter sup. Similarly, C^0_h will be the space with the supremum norm. We first consider the operator $\mathcal{A}$ on C^0_h. From (4.3) we see that, for $q < 2$, $\sum_j |K^{\sigma\tau}_{ij}|^q h^2 \le C$. Then, from Hölder's inequality, T_h is bounded from L^p_h to C^0_h, provided $p > 2$. Now if $\frac12 f + T_h \mathcal{M} f = g$, we have $\|T_h \mathcal{M} f\|_{C^0_h} \le C_1 \|g\|_{L^p_h} \le C_2 \|g\|_{C^0_h}$, and so $\|f\|_{C^0_h} \le C_3 \|g\|_{C^0_h}$. Thus $\mathcal{A}$ has a bounded inverse on C^0_h.

Next we check that T_h is bounded from C^0_h to C^λ_h. For arbitrary grid points x^σ_i and $x^{\sigma'}_{i'}$, let $d = |x^\sigma_i - x^{\sigma'}_{i'}|$. We need to verify that (with τ fixed)

$$d^{-\lambda} \sum_j \left[K^{\sigma\tau}_{ij} - K^{\sigma'\tau}_{i'j} \right] \psi^\tau_j f^\tau_j A^\tau_j \, h^2 \tag{4.18}$$

is bounded, assuming f bounded in C^h_0. We use the estimates (4.3), (4.4) to bound

$$K^{\sigma\tau}_{ij} - K^{\sigma'\tau}_{i'j} = K_\delta(x^\sigma_i, x^\tau_j) - K_\delta(x^{\sigma'}_{i'}, x^\tau_j). \tag{4.19}$$

As in classical arguments, we split the sum into two parts. For j in the set J_1 such that $|x^\sigma_i - x^\tau_j| \le 2d$, we apply (4.3) to the two terms separately. If $d < \delta$ we have

$$\sum_{j \in J_1} |K^{\sigma\tau}_{ij}| h^2 \le C_1 \delta^{-1} (d/h)^2 h^2 \le C_2 d,$$

and similarly for $K^{\sigma'\tau}_{i'j}$, whereas, for larger d, the sum is bounded by

$$C_3 \delta^{-1} (\delta/h)^2 h^2 + C_4 \int_{C_5\delta}^{C_6 d} r^{-1} r \, dr \le C_7 \delta + C_8 d \le C_9 d.$$

For the remaining sum over the set J_2 with $|x_i^\sigma - x_j^\tau| > 2d$, we bound (4.19) by d times $DK(z, x_j^\tau)$, with z along the line from x_i^σ to $x_{i'}^{\sigma'}$. With $r = |x_j^\tau - x_i^\sigma|$, we have $|x_j^\tau - z| \geq r - d \geq r/2$. Thus (4.19) is bounded by Cdr^{-2} for $r > \delta$ or $Cd\delta^{-2}$ otherwise, using (4.4). Now if $d \geq \delta$ we get

$$\sum_{j \in J_2} |K_{ij}^{\sigma\tau} - K_{i'j}^{\sigma'\tau}| h^2 \;\leq\; C_1 d \int_{C_2 d}^{C_3} r^{-2} r \, dr \;\leq\; C_4 d(1 + |\log d|),$$

and otherwise we have this plus an additional term $C_5 d\delta^{-2}(\delta/h)^2 h^2 \leq C_6 d$. We conclude that the Hölder quotient (4.18) is bounded by

$$C_1 d^{1-\lambda}(|\log d| + 1)\|f\|_{C_h^0} \leq C_2 \|f\|_{C_h^0}, \tag{4.20}$$

and, consequently, for any $f \in C_h^0$, $\|T_h f\|_{C_h^\lambda} \leq C_3 \|f\|_{C_h^0}$ as claimed.

We have already shown that the operator $\mathcal{A}$ has a bounded inverse on C_h^0; we can now show the same is true for C_h^λ. If $\frac{1}{2} f + T_h \mathcal{M} f = g$ with $g \in C_h^\lambda$, then $\|\mathcal{M} f\|_{C_h^0} \leq C_1 \|f\|_{C_h^0} \leq C_2 \|g\|_{C_h^0}$, and thus $\|T_h \mathcal{M} f\|_{C_h^\lambda} \leq C_3 \|g\|_{C_h^0} \leq C_3 \|g\|_{C_h^\lambda}$. Since $f = 2g - 2T_h \mathcal{M} f$, it follows that $\|f\|_{C_h^\lambda} \leq C \|g\|_{C_h^\lambda}$.

4.5. Correcting the discrete equation. Next, in order to compare the operator $T_h \mathcal{M}$ with T_h, we show that $\mathcal{M} f$, as defined in (4.14), is close to f in C_h^0, relative to the C_h^λ-norm of f, for small h. Given a grid function f and $x \in \mathcal{S}$, suppose $x \in X^\tau(Q_j)$ for some τ, j so that $|x - x_j^\tau| \leq Ch$. If also $x \in X^\sigma(Q_i)$, then $|x - x_i^\sigma| \leq Ch$ so that $|x_i^\sigma - x_j^\tau| \leq 2Ch$. Thus $|f_i^\sigma - f_j^\tau| \leq C_1 h^\lambda \|f\|_{C_h^\lambda}$. Similarly, $\psi_i^\sigma - \psi^\sigma(x) = O(h)$. Applying this to the definition of Bf, we find $|(Bf)(x) - f_j^\tau| \leq C_2 h^\lambda \|f\|_{C_h^\lambda}$ uniformly for $x \in X^\tau(Q_j)$. Then since $(\mathcal{M} f)_j^\tau$ is an average of Bf over this set,

$$|(\mathcal{M} f)_j^\tau - f_j^\tau| \leq C_2 h^\lambda \|f\|_{C_h^\lambda}. \tag{4.21}$$

The last result has an important consequence: Since $\mathcal{M}$ is close to the identity as an operator from C_h^λ to C_h^0, and since T_h is bounded from C_h^0 to C_h^λ, the operators $f \mapsto \frac{1}{2} f + T_h \mathcal{M} f$ and $f \mapsto \frac{1}{2} f + T_h f$, acting on C_h^λ, are close when h is small. Since the first has a bounded inverse on C_h^λ, the second does as well. That is, we have a bounded solution operator on C_h^λ for the equation $\frac{1}{2} f + T_h f = g$. This equation is the analogue of (1.13) without the subtracted term.

4.6. The subtraction. Now let $z_i^\sigma = T_h \cdot 1$. The sum z_i^σ approximates an integral which, according to (1.7), is identically $\frac{1}{2}$. We check that $\|z_i^\sigma - \frac{1}{2}\|_{C_h^\lambda} \to 0$ as $h, \delta \to 0$: The estimates of sections 2 and 3 show that $|z_i^\sigma - \frac{1}{2}| \leq C(h + \delta)$ uniformly in i, σ. As for the Hölder quotient, we see from (4.20) that it is small for d small, say, $d \leq d_0$, with d_0 independent of h. But for $d \geq d_0$ it is bounded by $Ch\, d_0^{-\lambda}$, which is small when h is small enough. As a consequence, the operators $f \mapsto \frac{1}{2} f + T_h f$ and $f \mapsto f + T_h f - zf$ on C_h^λ are close for h small. As before, we conclude that the new operator has a bounded inverse. This is exactly the statement that the discrete integral equation (1.13) is solvable, with solution bounded in C_h^λ, that is, $\|f\|_{C_h^\lambda} \leq C \|g\|_{C_h^\lambda}$.

We wish to show that the solution of (1.13) is also bounded on C_h^0, since this norm is more convenient for comparing with the exact solution. We can write the equation as $(1 - z) f + T_h f = g$ or $f + \zeta T_h f = \zeta g$, where $\zeta = 1/(1 - z)$. Since $z \approx \frac{1}{2}$ in C_h^λ, $\zeta \approx 2$ in C_h^λ. Rearranging the terms, we have $(1 - z)(f - \zeta g) + T_h(f - \zeta g) = -T_h(\zeta g)$.

Now, using our last result, with $f-\zeta g$ in place of f, and the bound for $T_h : C_h^0 \to C_h^\lambda$, we find $\|f-\zeta g\|_{C_h^\lambda} \le C_1\|T_h(\zeta g)\|_{C_h^\lambda} \le C_2\|g\|_{C_h^0}$ from which it follows that

$$\|f\|_{C_h^0} \le C\|g\|_{C_h^0}, \qquad f = ((1-z)I + T_h)^{-1}g. \tag{4.22}$$

4.7. The error estimate. Having established the bounded solvability (4.22) for the discrete integral equation (1.13), we can easily estimate the error when the exact solution is smooth. Suppose f, g are smooth functions on $\mathcal{S}$ satisfying (4.1). (If g is smooth, it follows that f is smooth.) Let g_i^σ be the grid function taking values $g_i^\sigma = g(x_i^\sigma)$, and let f_i^σ be the solution of (1.13). Define $e_i^\sigma = f_i^\sigma - f(x_i^\sigma)$. Subtracting, we get the error equation

$$e_i^\sigma + \sum_{j,\tau} K_{ij}^{\sigma\tau}\psi_j^\tau[e_j^\tau - e_i^\sigma]A_j^\tau\, h^2 + r_i^\sigma, \tag{4.23}$$

$$r_i^\sigma = \int K(x_i^\sigma, x')[f(x') - f(x_i^\sigma)]\,dx' - \sum_{j,\tau} K_{ij}^{\sigma\tau}\psi_j^\tau[f(x_j^\tau) - f(x_i^\sigma)]A_j^\tau\, h^2. \tag{4.24}$$

The $O(\delta^5)$ smoothing estimate of section 2 and the discretization estimate (3.25) apply to r_i^σ, since f is smooth, and we have $|r_i^\sigma| \le \varepsilon(h,\delta)$, uniformly in i, σ, where $\varepsilon(h,\delta)$ is the right side of (1.17). A similar estimate follows for e_i^σ, after applying (4.22) to the error equation (4.23), and we have $|f_i^\sigma - f(x_i^\sigma)| \le \varepsilon(h,\delta)$. Thus we have proved the error estimate (1.17) of Theorem 1.1.

4.8. The iteration. Finally, we discuss the convergence of the iterates (1.16) to the solution of the discrete integral equation (1.13). It is a fact of potential theory that the operator T has spectrum in the interval $-\frac{1}{2} < \lambda \le \frac{1}{2}$ (see, e.g., [18, section 10.5] or [9, section 5.1]). Then, for $0 < \beta < 1$, the related operator $(1-\beta)I - 2\beta T$ has spectral radius < 1, and the convergence of (1.5) follows. For the discrete case we can argue that the approximations to T above perturb this spectral radius only slightly, and thus the discrete iteration (1.16) also converges. We omit the details.

5. Numerical examples. We present the results of three test problems illustrating the solution of the integral equation and the subsequent calculation of the solution of the Dirichlet problem (1.1) at points near the surface. The results generally verify the predictions of the theory.

For our first two examples the surface $\mathcal{S}$ is the unit sphere $x_1^2 + x_2^2 + x_3^2 = 1$. We cover the sphere with two stereographic projections. The projection on the equatorial plane by rays through the south pole $(0,0,-1)$ gives the first coordinate system, $X^1 : \mathbf{R}^2 \to U^1 = S - \{(0,0,-1)\}$:

$$x_1 = \frac{2\alpha_1}{1+|\alpha|^2}, \quad x_2 = \frac{2\alpha_2}{1+|\alpha|^2}, \quad x_3 = \frac{1-|\alpha|^2}{1+|\alpha|^2}. \tag{5.1}$$

Similarly, projecting from the north pole gives a second system $X^2 : \mathbf{R}^2 \to U^2 = S - \{(0,0,1)\}$ as in (5.1) but with $x_3 \to -x_3$. Each system maps the unit disk in the plane to a hemisphere; we use disks of radius 1.25 so that the two systems overlap. To define the partition of unity $\{\psi^1, \psi^2\}$, we first set $\phi^\sigma(X^\sigma(\alpha)) = \exp(-1.25^2/(1.25^2 - |\alpha|^2))$ for $|\alpha| \le 1.25$ and $\phi^\sigma = 0$ otherwise; then ϕ^σ is a smooth function with support $\{X^\sigma(\alpha) : |\alpha| \le 1.25\}$. We then define $\psi^\sigma(x) = \phi^\sigma(x)/(\phi^1(x) + \phi^2(x))$. Grid points $\alpha_i = ih$ are introduced with $X^\sigma(\alpha_i) \in V^\sigma$, where V^σ is the interior of the support of ψ^σ. These sets are $V^1 = \mathcal{S} \cap \{x_3 > -9/41\}$, $V^2 = \mathcal{S} \cap \{x_3 < 9/41\}$, corresponding

to $|\alpha| < 1.25$. The metric tensor in each patch is $g_{ij} = 4(|\alpha|^2 + 1)^{-2}\delta_{ij}$, and the area factor $A = \sqrt{g}$ is $4(|\alpha|^2+1)^{-2}$. The surface Laplacian is $\frac{1}{4}(|\alpha|^2+1)^2(\partial_{11}+\partial_{22})$. These quantities could be computed from the points $\{X^\sigma(\alpha_i)\}$, but we used analytical values in our computations.

Our first example is based on a spherical harmonic, so that the solution for the integral equation is known, as well as for the boundary value problem. We define

$$f(x) = 1.75(y_1 - 2y_2)(7.5y_3^2 - 1.5), \qquad y = Mx,$$

with $M = (1/\sqrt{6})(\sqrt{2}(1,1,1)^T, \sqrt{3}(0,1,-1)^T, (-2,1,1)^T)$, an orthogonal matrix. We use M to avoid rectangular symmetry in the test problem. The functions $f(x/r)r^3$ and $f(x/r)/r^4$, $r = |x|$, are both harmonic. The double layer potential u due to f is determined by the jump in u and the fact that $\partial u/\partial n$ is continuous. It is

$$u(x) = (4/7)f(x/r)r^3, \quad r < 1; \qquad u(x) = (-3/7)f(x/r)/r^4, \quad r > 1. \tag{5.2}$$

Thus if we set $g(x) = (4/7)f(x)$ on $\mathcal{S}$, the solution of the Dirichlet problem (1.1) is u, as defined above for $r < 1$, and the solution of the integral equation (1.4) is f.

We solved the discrete form (1.13) of the exact integral equation (1.4) using 12 iterations of (1.16) with $\beta = .7$. We tested the third order kernel (1.10) as well as the fifth order one (1.12) to check the order of accuracy. The results are reported in Tables 1 and 2. A grid size h in the coordinate systems and the total number of grid points are displayed. Each coordinate patch is a disk with $5/2h$ points along a diameter. We choose the smoothing radius δ proportional to h^q, $q = 2/3$ or 1. The relative error displayed is the maximum error divided by $\max_{\mathcal{S}} f \approx 8.1$. The computed order of accuracy is found from two successive cases. With the third order kernel, the expected order of accuracy $3q$ is clearly visible in Table 1. The errors shown in Table 2 for the fifth order kernel are much smaller. With $q = 2/3$ the predicted order $10/3$ is less evident, but it appears to take over in the second case, with the larger δ. With $q = 1$, $\delta = 2h$, the order is at first near 5 but deteriorates as h is decreased, as we should expect from the analysis.

After solving the integral equation with a choice of h and δ, using the fifth order kernel, we then computed the solution u at points near $\mathcal{S}$ with the same h and δ. To select a set of points, we cover $\mathbf{R}^3$ with a 3D mesh of spacing h; it is an arbitrary

choice to use the same h in $\mathbf{R}^3$ as on $\mathcal{S}$. We select the set of "irregular" points (i_1h, i_2h, i_3h) inside $\mathcal{S}$ for which the stencil of the five-point discrete Laplacian crosses the surface; i.e., the two points obtained by displacement of $\pm h$ in some coordinate are on different sides of $\mathcal{S}$. All such points are within h of $\mathcal{S}$, and, for h small, all points within ch of $\mathcal{S}$ have this property if $c < 1/\sqrt{3}$. Thus they provided a good sample of 3D grid points near $\mathcal{S}$. These are the interior points needed to form the discrete Laplacian of u in order to recover the values elsewhere; cf. [21] or [3].

For each selected point y we find the closest point x_0 on $\mathcal{S}$. We need f and the first two derivatives at x_0 for the subtraction and corrections. We find these from the computed values of f at the grid points by Lagrange interpolation. We compute the sum (1.19) and add the smoothing and discretization corrections (1.21)–(1.25). Table 3 gives the number of irregular points; the relative error, found as the maximum error divided by $\max_{\mathcal{S}} g \approx 4.6$; and the computed order of accuracy. With $\delta = ch^q$, $q = 2/3$ or 1, we see the expected order $3q = 2$ or 3.

Our second test problem, still with the unit sphere, is the harmonic function

$$u(x) = \exp(y_1 + 2y_2)\cos\sqrt{5}y_3, \qquad y = Mx, \tag{5.3}$$

with M as before. We prescribe $g(x) = u(x)$ on $\mathcal{S}$ and solve the integral equation within an error tolerance, again with $\beta = .7$. In this case we do not know the solution f of the integral equation; however, we use the computed f to find u at the irregular points, as before, and compare with the exact solution in (5.3). Results are reported in Table 4. Again the predicted order of accuracy is evident as h decreases. The error displayed is the maximum error divided by $\max_{\mathcal{S}} g \approx 9.4$.

For our third problem the surface $\mathcal{S}$ is the ellipsoid $x_1^2 + x_2^2 + x_3^2/2 = 1$. We use coordinate systems similar to those for the sphere, with x_3 in (5.1) multiplied by $\sqrt{2}$. As the test problem we take the same harmonic function u in (5.3). The coordinate systems are symmetric, but the functions are not, because of the rotation by M. The needed geometric quantities can be found analytically in this case. The coordinates are not orthogonal, as they were for the sphere, so that the formulas are tested in a more general setting. We solve the integral equation as before. We then select the set of irregular points by the same criterion and compute the solution u on this set as a double layer potential, with corrections, using the solution f of the integral equation.

For each irregular point y we need to find the point x_0 on the surface so that y is along the normal from x_0, as well as the distance; we do this using Newton's method. The results, displayed in Table 5, are similar to those for the sphere. Again the relative error is the maximum error divided by $\max_{\mathcal{S}} g \approx 9.4$.

For the last problem we show in Table 6 the results of computing the solution at the irregular points using various choices of the smoothing parameter δ. We first solve the integral equation with $h = 1/32$ and $\delta = 2h$. We then compute the values at the irregular points, chosen with $h = 1/32$, for various values of δ/h, to verify the effects of the two corrections. For small δ/h, the discretization correction is dominant; when δ/h is extremely small, more terms are needed in the sum (1.25). For larger δ/h the smoothing correction is important, and the discretization correction is negligible. As δ/h increases, the remaining smoothing error becomes significant.

A COERCIVE COMBINED FIELD INTEGRAL EQUATION FOR ELECTROMAGNETIC SCATTERING*

A. BUFFA† AND R. HIPTMAIR‡

Abstract. Many boundary integral equation methods used in the simulation of direct electromagnetic scattering of a time-harmonic wave at a perfectly conducting obstacle break down when applied at frequencies close to a resonant frequency of the obstacle. A remedy is offered by special indirect boundary element methods based on the so-called combined field integral equation. However, hitherto no theoretical results about the convergence of discretized combined field integral equations have been available.

In this paper we propose a new combined field integral equation, convert it into variational form, establish its coercivity in the natural trace spaces for electromagnetic fields, and conclude existence and uniqueness of solutions for any frequency. Moreover, a conforming Galerkin discretization of the variational equations by means of div_Γ-conforming boundary elements can be shown to be asymptotically quasi-optimal. This permits us to derive quantitative convergence rates on sufficiently fine, uniformly shape-regular sequences of surface triangulations.

Key words. electromagnetic scattering, combined field integral equations, coercivity, boundary element methods, Galerkin scheme

1. Introduction.

The numerical simulation of direct scattering at a perfect conductor, the so-called scatterer, is a central task in computational electromagnetism. The scatterer occupies a bounded domain $\Omega \subset \mathbb{R}^3$. In general, Ω will have Lipschitz-continuous boundary $\Gamma := \partial\Omega$, which can be equipped with an exterior unit normal vector field $\mathbf{n} \in \boldsymbol{L}^\infty(\Gamma)$. With boundary element methods in mind, we do not lose generality by admitting only scatterers Ω that are polyhedra with flat faces and a Lipschitz-continuous boundary. We emphasize that the extension of the results to curvilinear faces is straightforward.

Electromagnetic waves propagate outside the scatterer in the "air region" $\Omega' := \mathbb{R}^3 \setminus \Omega$. From an electrodynamic point of view, Ω' is filled with a homogeneous, isotropic, and linear material. Excitation is provided by the electric field $\mathbf{e}_i$ of an incident (plane) wave of angular frequency $\omega > 0$. Hence, we can switch to the frequency domain and are left with complex amplitudes (phasors) as unknown spatial functions. After suitable scaling, the complex amplitude $\mathbf{e}$ of the scattered field satisfies the following exterior Dirichlet problem for the *electric wave equation* [23, Chap. 6]:

$$\mathbf{curl}\,\mathbf{curl}\,\mathbf{e} - \kappa^2\mathbf{e} = 0 \quad \text{in } \Omega', \tag{1.1}$$

$$\mathbf{e} \times \mathbf{n} = g := \mathbf{e}_i \times \mathbf{n} \quad \text{on } \Gamma. \tag{1.2}$$

The constant $\kappa := \omega\sqrt{\epsilon_0\mu_0} > 0$ is called the *wave number*, because $\kappa/2\pi$ tells us the number of wavelengths per unit length. Henceforth, κ will stand for a fixed

positive wave number. These equations have to be supplemented with the *Silver–Müller radiation conditions*

$$\int_{\partial B_r} |\mathbf{curl}\,\mathbf{e} \times \mathbf{n} + i\kappa(\mathbf{n} \times \mathbf{e}) \times \mathbf{n}|^2 \, \mathrm{d}S \to 0 \quad \text{for } r \to \infty, \tag{1.3}$$

where B_r is a ball around 0 with radius $r > 0$. Existence and uniqueness of solutions of (1.1) and (1.3) can be inferred from Rellich's lemma [18, 42].

Integral equation methods are a natural choice for the discretization of the direct electromagnetic scattering problem, which is posed on an unbounded domain. Prominent examples are the electric field integral equation (EFIE) and magnetic field integral equation; see [42, sect. 5.6] or [18, Chap. 3]. These indirect methods display a worrisome instability when κ^2 coincides with a Dirichlet or Neumann eigenvalue (resonant frequency) of the **curl curl**-operator inside Ω; then the integral equation may not have a solution. After discretization this manifests itself in extreme ill-conditioning of the resulting linear systems of equations if κ is close to a resonant frequency [20].

Two classes of integral equation methods are known to avoid this difficulty. The first is the method proposed in [26] and examined for electromagnetism in [30]. However, it entails constructing an auxiliary surface and can be haunted by stability problems, too. The second, vastly more popular class of methods are approaches based on combined field integral equations (CFIEs), as introduced in [3] and [17]. A particular representative will be the focus of this paper.

CFIEs owe their name to the presence of both single and double layer potentials in the ansatz for the electric field in Ω'. As a theoretical tool they were pioneered for acoustic scattering in [3] and for electromagnetics in [43]. These methods are widely used in computational electromagnetism [47]. For acoustics, existence and uniqueness of solutions can be shown for smooth scatterers [23]. Yet, in the case of electromagnetism even this remains elusive. Hence, mainly for the sake of theoretical treatment, regularized formulations have been introduced by Kress in [36]. However, the idea is applicable only for scattering at smooth objects, and it is not suitable for numerical implementation.

In this article we hark back to the idea of regularization in a different way. Based on recent advances in the understanding of boundary integral operators of electromagnetic scattering achieved in [15, 32, 33], we apply regularization to the double layer part of the integral operator. Reformulation as a mixed problem and subsequent Galerkin discretization pave the way to a practical computational scheme. It is the first method based on an electromagnetic CFIE that can be proven to converge quasi-optimally in relevant trace norms. Related techniques for the Helmholtz equation of acoustic scattering are covered in [14].

The developments in this paper rest on a huge body of previous work. We will restate the most important results. However, in order to maintain a reasonable length we cannot elaborate on most of the existing theory of boundary integral equations for electromagnetic scattering. However, we will try to give comprehensive references for all results we rely upon.

The plan of the paper is as follows: the next section will give a concise survey of relevant function spaces and trace theorems and prove some new results which are needed in the rest of the paper. Then we briefly recall the crucial integral operators of electromagnetic scattering. In the fourth section we will present and analyze the new CFIE and the variational problem associated with it. The fifth section will be devoted to proving the asymptotic quasi optimality of a Galerkin discretization. Based on it, the final section will give quantitative convergence estimates.

2. Function spaces and traces. Let $\Omega \subseteq \mathbb{R}^3$ be any of the sets $\Omega, \Omega', \mathbb{R}^3$. We define the Fréchet space $\boldsymbol{L}^2_{\rm loc}(\Omega) = \{\mathbf{u}_{|\Omega} : \mathbf{u} \in \mathbf{L}^2_{\rm loc}(\mathbb{R}^3)\}$, where $\boldsymbol{L}^2_{\rm loc}(\mathbb{R}^3)$ is the space of complex, vector-valued, locally square-integrable functions on $\mathbb{R}^3$. In a similar way, we define the Sobolev spaces $\boldsymbol{H}^s_{\rm loc}(\Omega)$, $s \geq 0$ (see, e.g., [1] for definitions), with the convention $\boldsymbol{H}^0 \equiv \boldsymbol{L}^2$. The subscript $_{\rm loc}$ will be dropped whenever Ω is bounded: in this case, $\boldsymbol{H}^s(\Omega)$ is a Hilbert space endowed with the natural graph norm $\|\mathbf{u}\|_{\boldsymbol{H}^s(\Omega)}$ and seminorm $|\mathbf{u}|_{\boldsymbol{H}^s(\Omega)}$, respectively [1]. Parentheses will consistently be used to express inner products.

With D a first order differential operator, for any $s \geq 0$ we define

$$\boldsymbol{H}^s_{\rm loc}(D,\Omega) := \{\mathbf{u} \in \boldsymbol{H}^s_{\rm loc}(\Omega) :\ D\mathbf{u} \in \boldsymbol{H}^s_{\rm loc}(\Omega)\}, \tag{2.1}$$

$$\boldsymbol{H}^s_{\rm loc}(D0,\Omega) := \{\mathbf{u} \in \boldsymbol{H}^s_{\rm loc}(\Omega) :\ D\mathbf{u} = 0\}. \tag{2.2}$$

When $s = 0$, we simplify the notation by setting $\boldsymbol{H}^0 = \boldsymbol{H}$. If Ω is bounded, $\boldsymbol{H}^s_{\rm loc}(D,\Omega)$ is endowed with the graph norm $\|\cdot\|^2_{\boldsymbol{H}^s(D,\Omega)} := \|\cdot\|^2_{\boldsymbol{H}^s(\Omega)} + \|D\cdot\|^2_{\boldsymbol{H}^s(\Omega)}$ and seminorm $|\cdot|^2_{\boldsymbol{H}^s(D,\Omega)} := |\cdot|^2_{\boldsymbol{H}^s(\Omega)} + |D\cdot|^2_{\boldsymbol{H}^s(\Omega)}$. This defines the spaces $\boldsymbol{H}^s(\mathbf{curl},\Omega)$, $\boldsymbol{H}^s(\mathrm{div},\Omega)$ and $\boldsymbol{H}^s(\mathbf{curl}\,0,\Omega)$, $\boldsymbol{H}^s(\mathrm{div}\,0,\Omega)$, for which [28, Chap. 1] is the main reference.

The integration by parts formulae for the operators **curl** and div suggest that we define the tangential trace mapping $\gamma_{\mathbf{t}} : \mathbf{u} \mapsto \mathbf{u}_{|\Gamma} \times \mathbf{n}$ and the normal component trace $\gamma_{\mathbf{n}} : \mathbf{u} \mapsto \mathbf{u}_{|\Gamma} \cdot \mathbf{n}$. To begin with, they are defined for $\mathbf{u} \in C^\infty(\overline{\Omega})^3$.

The trace theorem for $\boldsymbol{H}^1(\Omega)$ [29, Thm. 1.5.1.1] shows that the tangential trace $\gamma_{\mathbf{t}} : \boldsymbol{C}^\infty(\bar{\Omega}) \mapsto \boldsymbol{L}^\infty(\Gamma)$ and the normal trace $\gamma_{\mathbf{n}} : \boldsymbol{C}^\infty(\bar{\Omega}) \mapsto L^\infty(\Gamma)$ are continuous as mappings $\boldsymbol{H}(\mathbf{curl};\Omega) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\Gamma)$ and $\boldsymbol{H}(\mathrm{div};\Omega) \mapsto H^{-\frac{1}{2}}(\Gamma)$, respectively. Here, $H^{-\frac{1}{2}}(\Gamma)$ and $\boldsymbol{H}^{-\frac{1}{2}}(\Gamma)$ are the dual spaces of $H^{\frac{1}{2}}(\Gamma)$ and $\boldsymbol{H}^{\frac{1}{2}}(\Gamma) := (H^{\frac{1}{2}}(\Gamma))^3$, respectively, with respect to the pivot spaces $L^2(\Gamma)$ and $\boldsymbol{L}^2(\Gamma)$. Consequently, the traces can be extended to $\boldsymbol{H}(\mathbf{curl};\Omega)$ and $\boldsymbol{H}(\mathrm{div};\Omega)$, respectively. Moreover, if we define the antisymmetric pairing

$$\langle \boldsymbol{\mu}, \boldsymbol{\eta} \rangle_{\boldsymbol{\tau},\Gamma} := \int_\Gamma (\boldsymbol{\mu} \times \mathbf{n}) \cdot \boldsymbol{\eta}\, \mathrm{d}S, \qquad \boldsymbol{\mu}, \boldsymbol{\eta} \in \boldsymbol{L}^2_{\mathbf{t}}(\Gamma) := \{\mathbf{u} \in (L^2(\Gamma))^3,\ \mathbf{u} \cdot \mathbf{n} = 0\}, \tag{2.3}$$

then we can state the integration by parts formula for the **curl**-operator as [9, sect. 4]

$$\int_\Omega (\mathbf{curl}\,\mathbf{u} \cdot \mathbf{v} - \mathbf{u} \cdot \mathbf{curl}\,\mathbf{v})\, \mathrm{d}\mathbf{x} = \langle \gamma_{\mathbf{t}}\mathbf{v}, \gamma_{\mathbf{t}}\mathbf{u} \rangle_{\boldsymbol{\tau},\Gamma}. \tag{2.4}$$

A meaningful strong form of the electric wave equation (1.1) has to rely on yet another space: from the fact that a field $\mathbf{u}$ is a locally square-integrable function satisfying $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u} - \mathbf{u} = 0$ we can conclude that $\mathbf{curl}\,\mathbf{curl}\,\mathbf{u}$ is locally square-integrable, too. Hence, the space

$$\boldsymbol{H}_{\rm loc}(\mathbf{curl}^2,\Omega) := \{\mathbf{u} \in \boldsymbol{H}_{\rm loc}(\mathbf{curl};\Omega),\ \mathbf{curl}\,\mathbf{curl}\,\mathbf{u} \in \boldsymbol{L}^2_{\rm loc}(\Omega)\}$$

will play the role of the natural space for solutions of the electric wave equation with constant coefficients.

Trace spaces for electromagnetic fields are essential for stating the boundary integral equations and, in particular, their variational formulations. The corresponding results on nonsmooth boundaries are fairly recent: we refer the reader to [6, 9, 10] for the treatment of Lipschitz polyhedra. The issue of traces of $\boldsymbol{H}(\mathbf{curl};\Omega)$ for general Lipschitz domains was settled in [13]. The results are summarized in the survey article [7].

DEFINITION 2.1. *We introduce the Hilbert spaces* $\boldsymbol{H}^s_\times(\Gamma) := \gamma_{\mathbf{t}}(\boldsymbol{H}^{s+1/2}(\Omega))$, $s \in (0,1)$, *equipped with an inner product that renders* $\gamma_{\mathbf{t}} : \boldsymbol{H}^{s+1/2}(\Omega) \mapsto \boldsymbol{H}^s_\times(\Gamma)$ *continuous and surjective. For* $s = 0$ *we set* $\mathbf{H}^0_\times(\Gamma) := \mathbf{L}^2_t(\Gamma)$. *The dual spaces with respect to the pairing* $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$ *are denoted by* $\boldsymbol{H}^{-s}_\times(\Gamma)$.

REMARK 1. *When* $s = 1$, *the standard trace operator* γ *fails to map* $H^{3/2}(\Omega)$ *to* $H^1(\Gamma)$, *although* $H^1(\Gamma)$ *is well defined on the boundary* Γ. *In this case, we adopt the definition* $\mathbf{H}^1_\times(\Gamma) := \gamma_{\mathbf{t}}(\gamma^{-1}H^1(\Gamma)^3)$, *where* γ^{-1} *represents any continuous lifting from* $H^1(\Gamma)$ *to* $H^{3/2}(\Omega)$ *(see* [35]*).*

Next, we introduce the surface divergence operator div_Γ; cf. [9, sect. 2.1].

Let $\{\Gamma_1,\dots,\Gamma_P\}$, $P \in \mathbb{N}$, stand for the set of open flat faces of Γ, and write Σ_{ij} for the straight edge $\partial\Gamma_j \cap \partial\Gamma_i$. The vector $\boldsymbol{\nu}^{ij}$ lies in the plane of Γ_j, is perpendicular to Σ_{ij}, and points into the exterior of Γ_j. Then for $\mathbf{u} \in C^\infty(\overline{\Omega})$ we set

$$\mathrm{div}_\Gamma \gamma_{\mathbf{t}}\mathbf{u} := \begin{cases} \mathrm{div}_j(\gamma_{\mathbf{t}}\mathbf{u}_{|\Gamma_j}) & \text{on } \Gamma^j, \\ \left((\gamma_{\mathbf{t}}\mathbf{u}_{|\Gamma_j})\cdot\boldsymbol{\nu}^{ij} + (\gamma_{\mathbf{t}}\mathbf{u}_{|\Gamma_i})\cdot\boldsymbol{\nu}^{ji}\right)\delta_{ij} & \text{on } \overline{\Gamma^j}\cap\overline{\Gamma^i}, \end{cases} \tag{2.5}$$

where δ_{ij} is the delta distribution (in local coordinates) whose support is the edge $\overline{\Gamma^j}\cap\overline{\Gamma^i}$ and div_j denotes the two-dimensional divergence computed on the face Γ^j. By density, this differential operator can be extended to less regular distributions and, in particular, to functionals in $\boldsymbol{H}^{-\frac{1}{2}}_\times(\Gamma)$. We set

$$\boldsymbol{H}^s_\times(\mathrm{div}_\Gamma,\Gamma) := \{\boldsymbol{\mu} \in \boldsymbol{H}^s_\times(\Gamma),\ \mathrm{div}_\Gamma\boldsymbol{\mu} \in H^s(\Gamma)\}, \qquad s \in [-1/2, 0].$$

Finally, we denote by $\mathbf{curl}_\Gamma$ the operator adjoint to div_Γ with respect to the pairing $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$, i.e.,

$$\langle\mathbf{curl}_\Gamma q, \mathbf{p}\rangle_{\boldsymbol{\tau},\Gamma} = \langle\mathrm{div}_\Gamma\mathbf{p}, q\rangle_{\frac{1}{2},\Gamma}, \quad \mathbf{p} \in \boldsymbol{H}^{-\frac{1}{2}}_\times(\mathrm{div}_\Gamma,\Gamma), \quad q \in H^{\frac{1}{2}}(\Gamma). \tag{2.6}$$

It is known [7, sect. 1.2] that $\mathbf{curl}_\Gamma : H^s(\Gamma) \to \boldsymbol{H}^{s-1}_\times(\Gamma)$ is continuous for every s, $1/2 \le s \le 1$. The spaces just defined turn out to be the desired trace spaces; see [9, Prop. 1.7], [10, Thm. 5.4], and [13, sect. 2].

THEOREM 2.2. *The operator* $\gamma_{\mathbf{t}} : \boldsymbol{H}(\mathbf{curl};\Omega) \mapsto \boldsymbol{H}^{-\frac{1}{2}}_\times(\mathrm{div}_\Gamma,\Gamma)$ *is continuous, is surjective, and possesses a continuous right inverse.*

The following self-duality of the electromagnetic trace space will be the foundation of weak formulations. The result was first given in [10].

THEOREM 2.3. *The pairing* $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$ *can be extended to a continuous bilinear form on* $\boldsymbol{H}^{-\frac{1}{2}}_\times(\mathrm{div}_\Gamma,\Gamma)$. *With respect to* $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$ *the space* $\boldsymbol{H}^{-\frac{1}{2}}_\times(\mathrm{div}_\Gamma,\Gamma)$ *becomes its own dual.*

Piecewise smooth scatterers offer the possibility that some considerations can be done locally on the faces and thus become essentially two-dimensional. To provide a framework for such considerations we introduce the spaces $\boldsymbol{H}^s_\times(\Gamma_j)$, $s \ge 0$, defined locally on a face Γ_j in a straightforward fashion, and we denote by $\boldsymbol{H}^{-s}_\times(\Gamma_j)$, $s \in (0, \frac{1}{2})$, their duals (note that we adopt the notion introduced in [39] and not the one used in [29]).

In addition, we define the localized spaces $\boldsymbol{H}_{\times 0}(\mathrm{div}_\Gamma,\Gamma_j) := \{\mathbf{u} \in \boldsymbol{L}^2_{\mathbf{t}}(\Gamma_j) : \widetilde{\mathbf{u}} \in \boldsymbol{H}_\times(\mathrm{div}_\Gamma,\Gamma)\}$, where $\widetilde{\ }$ denotes the trivial extension by zero to all of Γ. These spaces will be combined to

$$\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma) := \prod_{j=1}^P \boldsymbol{H}_{\times 0}(\mathrm{div}_\Gamma,\Gamma_j).$$

LEMMA 2.4. *The space* $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$ *is dense in* $\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$.

Proof. Let us adopt the notation Σ for the skeleton of the polyhedron, that is, the union of all edges Σ_{ij}, $1 \le i,j \le P$. Then we recall that regular functions compactly supported in $\bar{\Omega} \setminus \Sigma$ are dense in $H^1(\Omega)$ [41]. Of course, also the inclusion $\boldsymbol{H}^1(\Omega) \subset \boldsymbol{H}(\mathbf{curl},\Omega)$ is dense. By continuity of the tangential trace operator $\gamma_\mathbf{t}$, we deduce that tangential vector fields in $\boldsymbol{H}_\times^{1/2}(\Gamma)$ compactly supported in $\Gamma \setminus \Sigma$ are dense in $\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$. Since the set of fields in $\boldsymbol{H}_\times^{1/2}(\Gamma)$ compactly supported in $\Gamma \setminus \Sigma$ is a subset of $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$, the statement is proved. ∎

LEMMA 2.5. *The embedding* $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma) \hookrightarrow \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ *is compact.*

Proof. To begin with, since $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma) \subset \boldsymbol{H}_\times(\mathrm{div}_\Gamma,\Gamma)$, we need to prove only that the injection $\boldsymbol{H}_\times(\mathrm{div}_\Gamma,\Gamma) \subset \boldsymbol{H}_\times^{-1/2}(\mathrm{div}_\Gamma,\Gamma)$ is compact.

Let $\{\mathbf{u}_n\}_{n\in\mathbb{N}} \subset \boldsymbol{H}_\times(\mathrm{div}_\Gamma,\Gamma)$ be a sequence such that $\|\mathbf{u}_n\|_{\boldsymbol{H}_\times(\mathrm{div}_\Gamma,\Gamma)} < 1$ for all n. Then, owing to the compact embedding $\mathbf{L}_\mathbf{t}^2(\Gamma) \hookrightarrow \boldsymbol{H}_\times^{-1/2}(\Gamma)$, there exists a subsequence $\mathbf{u}_{n_k}$ of $\mathbf{u}_n$ and a $\mathbf{u} \in \boldsymbol{H}_\times^{-1/2}(\Gamma)$ such that $\mathbf{u}_{n_k} \to \mathbf{u}$ strongly in $\boldsymbol{H}_\times^{-1/2}(\Gamma)$. The operator $\mathrm{div}_\Gamma : \boldsymbol{H}_\times^{-1/2}(\Gamma) \mapsto H^{-3/2}(\Gamma)$ is continuous (see [9] for a proof and the definition of $H^{-3/2}(\Gamma)$). Hence, $\mathrm{div}_\Gamma \mathbf{u}_{n_k} \to \mathrm{div}_\Gamma \mathbf{u}$ strongly in $H^{-3/2}(\Gamma)$.

On the other hand, we also know that $\|\mathrm{div}_\Gamma \mathbf{u}_{n_k}\|_{L^2(\Gamma)} < 1$, which implies that up to extraction of a subsequence $\mathrm{div}_\Gamma \mathbf{u}_{n_k}$ is strongly converging to an element in $H^{-1/2}(\Gamma)$. By uniqueness of the limit, we deduce that $\mathrm{div}_\Gamma \mathbf{u} \in H^{-1/2}(\Gamma)$, and, up to selecting a subsequence, $\mathbf{u}_{n_k} \to \mathbf{u} \in \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ strongly. ∎

When we want to examine the convergence of boundary element methods quantitatively, extra smoothness of the functions to be approximated is indispensable. A convenient gauge for smoothness is offered by scales of Sobolev spaces. Again, localization is a handy tool: for any $s > \frac{1}{2}$, we define $\mathbf{H}_-^s(\Gamma) := \{\mathbf{u} \in \mathbf{L}_\mathbf{t}^2(\Gamma) : \mathbf{u}_{|\Gamma^j} \in \boldsymbol{H}_\mathbf{t}^s(\Gamma^j)\}$. The corresponding space of scalar functions will be denoted by $H_-^s(\Gamma)$. Then, for $s \ge 1$, we set $\boldsymbol{H}_\times^s(\Gamma) := \boldsymbol{H}_\times^{\frac{1}{2}}(\Gamma) \cap \mathbf{H}_-^s(\Gamma)$.

To characterize extra smoothness of traces we resort to the family of Hilbert spaces

$$\boldsymbol{H}_\times^s(\mathrm{div}_\Gamma,\Gamma) := \begin{cases} \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) & \text{if } s = -\frac{1}{2}, \\ \{\boldsymbol{\mu} \in \boldsymbol{H}_\times^s(\Gamma),\ \mathrm{div}_\Gamma \boldsymbol{\mu} \in H^s(\Gamma)\} & \text{if } -\frac{1}{2} < s < \frac{1}{2}, \\ \{\boldsymbol{\mu} \in \boldsymbol{H}_\times^s(\Gamma),\ \mathrm{div}_\Gamma \boldsymbol{\mu} \in H_-^s(\Gamma)\} & \text{if } s \ge \frac{1}{2}. \end{cases}$$

The following trace theorem has been proved in the appendix of [8].

THEOREM 2.6. *Let* $\sigma \in \mathbb{R}$ *be the maximum real number such that* $\{p \in H^1(\Omega) : \Delta p \in L^2(\Omega),\ (\partial_\mathbf{n} p)_{|\Gamma} = 0\} \subset H^{1+\sigma'}(\Omega)$ *for all* $\sigma' < \sigma$. *For all* $0 \le s < \min\{\sigma, 1\}$ *the tangential trace mapping* $\gamma_\mathbf{t}$ *can be extended to a continuous and surjective mapping* $\gamma_\mathbf{t} : \boldsymbol{H}^s(\mathbf{curl},\Omega) \mapsto \boldsymbol{H}_\times^{s-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$, *which possesses a continuous right inverse.*

3. Potentials and integral operators. Here we define the boundary integral operators relevant for electromagnetic scattering and recall a few of their properties. More details can be found in [42, Chap. 5], [23, Chap. 6], [15, sect. 3], and [34].

DEFINITION 3.1. *A distribution* $\mathbf{e} \in \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2,\Omega)$ *is called a* Maxwell solution *on some generic domain* Ω, *if it satisfies* (1.1) *in* Ω, *and the Silver–Müller radiation conditions at* ∞ *if* Ω *is not bounded.*

As far as the differential operator $\mathbf{curl}\,\mathbf{curl} - \kappa^2\,\mathrm{Id}$ is concerned, the integration by parts formula (2.4) suggests the distinction between *Dirichlet trace* $\gamma_\mathbf{t}$ and *Neumann*

trace $\gamma_N := \kappa^{-1}\gamma_{\mathbf{t}} \circ \mathbf{curl}$. The trace γ_N can be labelled "magnetic," because it actually retrieves the tangential trace of the magnetic field solution. From the trace theorem, Theorem 2.2, we see that γ_N is meaningful on $\boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega \cup \Omega')$.

LEMMA 3.2. *The trace* $\gamma_N : \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega' \cup \Omega) \to \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ *is a continuous and surjective operator.*

The integral representation for Maxwell solutions relies on the famous Stratton–Chu representation formula for the electric field in $\Omega \cup \Omega'$ [46]. To state it we rely on the notion of a jump $[\cdot]_\Gamma$ across Γ defined by $[\gamma]_\Gamma := \gamma^+ - \gamma^-$ for some trace γ onto Γ. Here, superscripts $-$ and $+$ tag traces onto Γ from Ω and $\Omega' := \mathbb{R}^3 \setminus \bar{\Omega}$, respectively. For notational simplicity, it is also useful to resort to the average $\{\gamma\}_\Gamma = \frac{1}{2}(\gamma^+ + \gamma^-)$. Both operators can be applied only to functions defined in $\Omega \cup \Omega'$.

As elaborated in [23, sect. 6.2], [42, sect. 5.5], and [18, Chap. 3, sect. 1.3.2], any Maxwell solution in $\Omega \cup \Omega'$ satisfies

$$\mathbf{u}(\mathbf{x}) = -\boldsymbol{\Psi}^\kappa_{DL}([\gamma_{\mathbf{t}}]_\Gamma(\mathbf{u}))(\mathbf{x}) - \boldsymbol{\Psi}^\kappa_{SL}([\gamma_N]_\Gamma(\mathbf{u}))(\mathbf{x}), \qquad \mathbf{x} \in \Omega \cup \Omega', \tag{3.1}$$

where we have introduced the (electric) *Maxwell single layer potential*

$$\boldsymbol{\Psi}^\kappa_{SL}(\boldsymbol{\mu})(\mathbf{x}) := \kappa \boldsymbol{\Psi}^\kappa_{\mathbf{A}}(\boldsymbol{\mu})(\mathbf{x}) + \frac{1}{\kappa}\,\mathbf{grad}_{\mathbf{x}}\, \Psi^\kappa_V(\mathrm{div}_\Gamma \boldsymbol{\mu})(\mathbf{x}), \qquad \mathbf{x} \notin \Gamma, \tag{3.2}$$

and the (electric) *Maxwell double layer potential*

$$\boldsymbol{\Psi}^\kappa_{DL}(\boldsymbol{\mu})(\mathbf{x}) := \mathbf{curl}_{\mathbf{x}}\, \boldsymbol{\Psi}^\kappa_{\mathbf{A}}(\boldsymbol{\mu})(\mathbf{x}), \qquad \mathbf{x} \notin \Gamma. \tag{3.3}$$

Here, Ψ^κ_V and $\boldsymbol{\Psi}^\kappa_{\mathbf{A}}$ are the scalar and the vectorial single layer potentials for the Helmholtz kernel $E_\kappa(\mathbf{x}) := \exp(i\kappa|\mathbf{x}|)/4\pi|\mathbf{x}|$, whose integral representation is given by ($\mathbf{x} \notin \Gamma$)

$$\Psi^\kappa_V(\phi)(\mathbf{x}) := \int_\Gamma \phi(\mathbf{y}) E_\kappa(\mathbf{x} - \mathbf{y})\, dS(\mathbf{y}), \qquad \boldsymbol{\Psi}^\kappa_{\mathbf{A}}(\boldsymbol{\mu})(\mathbf{x}) := \int_\Gamma \boldsymbol{\mu}(\mathbf{y}) E_\kappa(\mathbf{x} - \mathbf{y})\, dS(\mathbf{y}).$$

Both potentials $\boldsymbol{\Psi}^\kappa_{SL}$ and $\boldsymbol{\Psi}^\kappa_{DL}$ are Maxwell solutions; that is, for $\boldsymbol{\mu} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$, they fulfill

$$(\mathbf{curl}\,\mathbf{curl} - \kappa^2\,\mathrm{Id})\boldsymbol{\Psi}^\kappa_{SL}(\boldsymbol{\mu}) = 0, \qquad (\mathbf{curl}\,\mathbf{curl} - \kappa^2\,\mathrm{Id})\boldsymbol{\Psi}^\kappa_{DL}(\boldsymbol{\mu}) = 0 \tag{3.4}$$

off the boundary Γ in a pointwise sense. In addition, they comply with the Silver–Müller radiation conditions.

From the well-known mapping properties of Ψ^κ_V and $\boldsymbol{\Psi}^\kappa_{\mathbf{A}}$ it is easy to get those for $\boldsymbol{\Psi}^\kappa_{SL}$ and $\boldsymbol{\Psi}^\kappa_{DL}$; see, e.g., [15, sect. 3].

THEOREM 3.3. *The following mappings are continuous:*

$$\begin{aligned}
\boldsymbol{\Psi}^\kappa_{SL} &: \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega \cup \Omega') \cap \boldsymbol{H}_{\mathrm{loc}}(\mathrm{div}\,0; \Omega \cup \Omega'),\\
\boldsymbol{\Psi}^\kappa_{DL} &: \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega \cup \Omega') \cap \boldsymbol{H}_{\mathrm{loc}}(\mathrm{div}\,0; \Omega \cup \Omega').
\end{aligned}$$

The fact that $\mathbf{curl} \circ \boldsymbol{\Psi}^\kappa_{SL} = \kappa\, \boldsymbol{\Psi}^\kappa_{DL}$ and $\mathbf{curl} \circ \boldsymbol{\Psi}^\kappa_{DL} = \kappa\, \boldsymbol{\Psi}^\kappa_{SL}$ implies

$$\gamma_N^\pm \boldsymbol{\Psi}^\kappa_{SL} = \gamma_{\mathbf{t}}^\pm \boldsymbol{\Psi}^\kappa_{DL}, \qquad \gamma_N^\pm \boldsymbol{\Psi}^\kappa_{DL} = \gamma_{\mathbf{t}}^\pm \boldsymbol{\Psi}^\kappa_{SL}. \tag{3.5}$$

This means that the following two *boundary integral operators* are sufficient for electromagnetic scattering:

$$\mathsf{S}_\kappa := \{\gamma_{\mathbf{t}}\}_\Gamma \circ \boldsymbol{\Psi}^\kappa_{SL} = \{\gamma_N\}_\Gamma \circ \boldsymbol{\Psi}^\kappa_{DL}, \qquad \mathsf{C}_\kappa := \{\gamma_{\mathbf{t}}\}_\Gamma \circ \boldsymbol{\Psi}^\kappa_{DL} = \{\gamma_N\}_\Gamma \circ \boldsymbol{\Psi}^\kappa_{SL}.$$

The continuity of S_κ and C_κ is immediate from Theorem 3.3, in conjunction with Lemma 3.2 and Theorem 2.2.

COROLLARY 3.4. *The operators* $\mathsf{S}_\kappa, \mathsf{C}_\kappa : \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ *are continuous.*

A fundamental tool for deriving boundary integral equations are *jump relations* describing the behavior of the potentials across Γ. For the Maxwell single and double layer potentials they closely resemble those for conventional single and double layer potentials for second order elliptic operators [40, Chap. 6]. For smooth domains these results are contained in [23, Thm. 6.11], [42, Thm. 5.5.1], and [45].

THEOREM 3.5. *The interior and exterior Dirichlet and Neumann traces of the potentials* $\boldsymbol{\Psi}_{SL}^\kappa$ *and* $\boldsymbol{\Psi}_{DL}^\kappa$ *are well defined and, on* $\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$*, satisfy*

$$[\gamma_{\mathbf{t}}]_\Gamma \circ \boldsymbol{\Psi}_{SL}^\kappa = [\gamma_N]_\Gamma \circ \boldsymbol{\Psi}_{DL}^\kappa = 0, \qquad [\gamma_N]_\Gamma \circ \boldsymbol{\Psi}_{SL}^\kappa = [\gamma_{\mathbf{t}}]_\Gamma \circ \boldsymbol{\Psi}_{DL}^\kappa = -\,\mathrm{Id}\,.$$

As auxiliary boundary integral operators, which supply building blocks for S_κ and C_κ, we introduce the two single layer boundary integral operators

$$\mathsf{V}_\kappa := \{\gamma\}_\Gamma \circ \Psi_V^\kappa, \qquad \mathsf{A}_\kappa := \{\gamma_{\mathbf{t}}\}_\Gamma \circ \boldsymbol{\Psi}_{\mathbf{A}}^\kappa.$$

By inspecting the potential $\boldsymbol{\Psi}_{SL}^\kappa$ and recalling $\gamma_{\mathbf{t}} \circ \mathbf{grad} = \mathbf{curl}_\Gamma \circ \gamma$, it is clear that we can write

$$\mathsf{S}_\kappa = \kappa\, \mathsf{A}_\kappa + \kappa^{-1} \mathbf{curl}_\Gamma \circ \mathsf{V}_\kappa \circ \mathrm{div}_\Gamma. \tag{3.6}$$

It is easy to see that the bilinear form associated with S_κ is given by

$$\langle \mathsf{S}_\kappa \boldsymbol{\mu}, \boldsymbol{\xi} \rangle_{\boldsymbol{\tau},\Gamma} = \frac{1}{\kappa} \langle \mathrm{div}_\Gamma \boldsymbol{\mu}, \mathsf{V}_\kappa \mathrm{div}_\Gamma \boldsymbol{\mu} \rangle_{\frac{1}{2},\Gamma} - \kappa \langle \boldsymbol{\mu}, \mathsf{A}_\kappa \boldsymbol{\xi} \rangle_{\boldsymbol{\tau},\Gamma}\,. \tag{3.7}$$

Obviously, it involves two parts of different order, neither of which is a compact perturbation of the other. In recent years a very successful approach to variational problems of this kind has emerged; see [31, sect. 5.1], [15], and [8]. The idea is to consider the above bilinear form separately on the components of a suitable splitting

$$\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) = \boldsymbol{\mathcal{X}}(\Gamma) \oplus \boldsymbol{\mathcal{N}}(\Gamma), \tag{3.8}$$

where $\boldsymbol{\mathcal{N}}(\Gamma) = \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma 0; \Gamma)$, and $\boldsymbol{\mathcal{X}}(\Gamma) \subset \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ is a closed subspace such that

1. the splitting (3.8) is direct, that is, $\boldsymbol{\mathcal{X}}(\Gamma) \cap \boldsymbol{\mathcal{N}}(\Gamma) = \emptyset$;
2. the embedding $\boldsymbol{\mathcal{X}}(\Gamma) \hookrightarrow \boldsymbol{H}_\times^{-\frac{1}{2}}(\Gamma)$ is compact.

Note that div_Γ has closed range in $\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$, and this implies that

$$\|\boldsymbol{\mu}\|_{\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \leq C \, \|\mathrm{div}_\Gamma \boldsymbol{\mu}\|_{H^{-\frac{1}{2}}(\Gamma)} \qquad \forall \boldsymbol{\mu} \in \boldsymbol{\mathcal{X}}(\Gamma).$$

By R^Γ and Z^Γ we denote the projectors onto $\boldsymbol{\mathcal{X}}(\Gamma)$ and $\boldsymbol{\mathcal{N}}(\Gamma)$, respectively, that are associated with the splitting (3.8). Examples of splittings satisfying these requirements are given by the "$\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$-orthogonal" Hodge decomposition [10] and the "projected regular splitting" [32, sect. 7].

To establish a generalized Gårding inequality for S_κ we employ the direct splitting (3.8) and two auxiliary lemmata; see [33, Lem. 3.2] and [12, Prop. 4.1].

LEMMA 3.6. *The integral operators* $\delta\mathsf{V}_\kappa := \mathsf{V}_\kappa - \mathsf{V}_0 : H^{-\frac{1}{2}}(\Gamma) \mapsto H^{\frac{1}{2}}(\Gamma)$ *and* $\delta\mathsf{A}_\kappa := \mathsf{A}_\kappa - \mathsf{A}_0 : \boldsymbol{H}_\times^{-\frac{1}{2}}(\Gamma) \mapsto \boldsymbol{H}_\times^{\frac{1}{2}}(\Gamma)$ *are compact.*

LEMMA 3.7. *The operators* V_0 *and* A_0 *are continuous, are self-adjoint with respect to the bilinear pairings* $\langle\cdot,\cdot\rangle_{\frac{1}{2},\Gamma}$ *and* $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$*, respectively, and satisfy*

$$\langle\mu, \mathsf{V}_0\overline{\mu}\rangle_{\frac{1}{2},\Gamma} \geq C\,\|\mu\|^2_{H^{-\frac{1}{2}}(\Gamma)} \qquad \forall\mu \in H^{-\frac{1}{2}}(\Gamma),$$

$$\langle\boldsymbol{\mu}, \mathsf{A}_0\overline{\boldsymbol{\mu}}\rangle_{\boldsymbol{\tau},\Gamma} \geq C\,\|\boldsymbol{\mu}\|^2_{\boldsymbol{H}_\times^{-\frac{1}{2}}(\Gamma)} \qquad \forall\boldsymbol{\mu} \in \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma 0;\Gamma),$$

with constants $C > 0$ *depending only on* Γ.

The main result will be a generalized Gårding inequality for S_κ that involves the isomorphism

$$\mathsf{X}_\Gamma = \mathsf{R}^\Gamma - \mathsf{Z}^\Gamma : \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \mapsto \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma). \tag{3.9}$$

LEMMA 3.8 (cf. [12, 33]). *There is a compact bilinear form* $c_\Gamma : \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \times \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \mapsto \mathbb{C}$ *and a constant* $C > 0$ *such that*

$$|\,\langle\mathsf{S}_\kappa\boldsymbol{\mu}, \mathsf{X}_\Gamma\overline{\boldsymbol{\mu}}\rangle_{\boldsymbol{\tau},\Gamma} + c_\Gamma(\boldsymbol{\mu},\overline{\boldsymbol{\mu}})| \geq C\,\|\boldsymbol{\mu}\|^2_{\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \qquad \forall\boldsymbol{\mu} \in \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma).$$

Remember that S_κ is the integral operator underlying the EFIE. Lemma 3.8 tells us that $\mathsf{S}_\kappa : \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \mapsto \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ is a Fredholm operator of index 0. This will ensure surjectivity as soon as injectivity holds. However, the very problem of instability at resonant frequencies is due to the failure of S_κ to be injective for certain discrete values of κ; see, e.g., [18], [42], or [15, sect. 5.2].

4. The CFIE. The CFIEs arise from an indirect approach which aims to exploit that both $\boldsymbol{\Psi}^\kappa_{SL}$ and $\boldsymbol{\Psi}^\kappa_{DL}$ yield Maxwell solutions; see (3.4). The crudest variant starts from the trial expression

$$\mathbf{e} = -i\eta\boldsymbol{\Psi}^\kappa_{SL}(\boldsymbol{\zeta}) - \boldsymbol{\Psi}^\kappa_{DL}(\boldsymbol{\zeta}), \tag{4.1}$$

with some parameter $\eta > 0$. By the jump relations, taking the exterior Dirichlet trace $\gamma^+_{\mathbf{t}}$ results in the boundary integral equation

$$-i\eta\mathsf{S}_\kappa(\boldsymbol{\zeta}) + (\tfrac{1}{2}\,\mathrm{Id} - \mathsf{C}_\kappa)(\boldsymbol{\zeta}) = \gamma^+_{\mathbf{t}}\mathbf{e}_i, \tag{4.2}$$

which is generically posed in $\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$. At least on smooth surfaces the operator $\mathsf{C}_\kappa : \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \mapsto \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ is compact [42, sect. 5.5] and a generalized Gårding inequality for the sum $-i\eta\mathsf{S}_\kappa + \frac{1}{2}\,\mathrm{Id}$ is available. However, on nonsmooth surfaces C_κ cannot be dismissed as compact perturbation.

The bottom line is that existence of solutions of (4.2) cannot be established on nonsmooth surfaces, let alone any theory about discrete approximations. This dire state led Kress to propose the introduction of a smoothing operator into (4.1) in [36]. His analysis was set in Hölder spaces, and he targeted the single layer potential $\boldsymbol{\Psi}^\kappa_{SL}$, because, working on smooth surfaces, he could rely on the compactness of C_κ.

We cannot make this assumption, but we are aware of Lemma 3.8. This means that the Fredholm operator S_κ is not the problem, but it is the innocent looking

identity Id in (4.2). Therefore, Kress's policy should be turned upside down, and regularization has to be aimed at the double layer potential $\mathbf{\Psi}^{\kappa}_{DL}$.

The crucial device for regularization is a *compact* "smoothing operator"

$$\mathsf{M} : \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma) \mapsto \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$$

that satisfies

$$\boldsymbol{\mu} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma) : \langle \mathsf{M}\boldsymbol{\mu}, \overline{\boldsymbol{\mu}} \rangle_{\boldsymbol{\tau},\Gamma} > 0 \quad \Leftrightarrow \quad \boldsymbol{\mu} \neq 0.$$

According to the strategy outlined above it will enter the contribution of the double layer potential to the representation formula: we get the trial expression

$$\mathbf{e} = -i\eta \mathbf{\Psi}^{\kappa}_{SL}(\boldsymbol{\zeta}) - \mathbf{\Psi}^{\kappa}_{DL}(\mathsf{M}\boldsymbol{\zeta}), \tag{4.3}$$

where $\boldsymbol{\zeta} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$, $\eta > 0$. By (3.4), this field is a Maxwell solution in $\Omega \cup \Omega'$. As above, the exterior Dirichlet trace applied to (4.3) results in the *new CFIE*

$$-i\eta \mathsf{S}_{\kappa}(\boldsymbol{\zeta}) + (\tfrac{1}{2}\,\mathrm{Id} - \mathsf{C}_{\kappa})(\mathsf{M}\boldsymbol{\zeta}) = \gamma_{\mathbf{t}}^{+}\mathbf{e}_i. \tag{4.4}$$

Since it is set in $\boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$, Theorem 2.3 hints at how to cast it into a variational form: find $\boldsymbol{\zeta} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$ such that for all $\boldsymbol{\mu} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$,

$$-i\eta \left\langle \mathsf{S}_{\kappa}(\boldsymbol{\zeta}), \boldsymbol{\mu} \right\rangle_{\boldsymbol{\tau},\Gamma} + \left\langle (\tfrac{1}{2}\,\mathrm{Id} - \mathsf{C}_{\kappa})(\mathsf{M}\boldsymbol{\zeta}), \boldsymbol{\mu} \right\rangle_{\boldsymbol{\tau},\Gamma} = \left\langle \gamma_{\mathbf{t}}^{+}\mathbf{e}_i, \boldsymbol{\mu} \right\rangle_{\boldsymbol{\tau},\Gamma}. \tag{4.5}$$

It shares the crucial uniqueness of solutions with other CFIEs.

THEOREM 4.1. *For all $\eta \neq 0$ and wave numbers $\kappa > 0$, the boundary integral equation* (4.5) *has a unique solution $\boldsymbol{\zeta} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$.*

Proof. To demonstrate uniqueness, we assume that $\boldsymbol{\zeta} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$ solves

$$-i\eta \mathsf{S}_{\kappa}(\boldsymbol{\zeta}) + (\tfrac{1}{2}\,\mathrm{Id} - \mathsf{C}_{\kappa})(\mathsf{M}\boldsymbol{\zeta}) = 0. \tag{4.6}$$

It is immediate from the jump relations that $\mathbf{e}$ given by (4.3) is an exterior Maxwell solution with $\gamma_{\mathbf{t}}^{+}\mathbf{e} = 0$. By their uniqueness we infer that $\mathbf{e} = 0$ in Ω'. Appealing to the jump relations from Theorem 3.5 once more, we find

$$\gamma_{\mathbf{t}}^{-}\mathbf{e} = -\mathsf{M}\boldsymbol{\zeta}, \qquad \gamma_{N}^{-}\mathbf{e} = -i\eta\boldsymbol{\zeta}.$$

Next, we use (2.4) and see that

$$i\mathbb{R} \ni i\eta \left\langle \boldsymbol{\zeta}, \overline{\mathsf{M}\boldsymbol{\zeta}} \right\rangle_{\boldsymbol{\tau},\Gamma} = \left\langle \gamma_{N}^{-}\mathbf{e}, \overline{\gamma_{\mathbf{t}}^{-}\mathbf{e}} \right\rangle_{\boldsymbol{\tau},\Gamma} = \int_{\Omega} \frac{1}{\kappa} |\,\mathbf{curl}\,\mathbf{e}|^2 \,\mathrm{d}\mathbf{x} - \kappa|\mathbf{e}|^2 \,\mathrm{d}\mathbf{x} \in \mathbb{R}.$$

Necessarily, $\left\langle \boldsymbol{\zeta}, \overline{\mathsf{M}\boldsymbol{\zeta}} \right\rangle_{\boldsymbol{\tau},\Gamma} = 0$ so that the requirements on M imply $\boldsymbol{\zeta} = 0$, which settles the issue of uniqueness.

Next, we know from Corollary 3.4 that $\mathsf{C}_{\kappa} : \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma) \mapsto \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$ is continuous so that $(\frac{1}{2}\,\mathrm{Id} - \mathsf{C}_{\kappa}) \circ \mathsf{M} : \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma) \mapsto \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$ turns out to be compact. Eventually, we conclude from Lemma 3.8 that the bilinear form of (4.5) satisfies a generalized Gårding inequality. Thus, a Fredholm alternative argument gives existence of a solution from its uniqueness. ∎

A simple eligible operator M can be introduced through a variational definition: for $\boldsymbol{\zeta} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ and all $\mathbf{q} \in \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$, $\mathsf{M}\boldsymbol{\zeta} \in \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$ is to satisfy

$$(\mathsf{M}\boldsymbol{\zeta},\mathbf{q})_{0;\Gamma} + (\mathrm{div}_\Gamma \mathsf{M}\boldsymbol{\zeta}, \mathrm{div}_\Gamma \mathbf{q})_{0;\Gamma} = \langle \mathbf{q}, \boldsymbol{\zeta}\rangle_{\boldsymbol{\tau},\Gamma}\,, \tag{4.7}$$

where $(\cdot,\cdot)_{0;\Gamma}$ denotes the standard $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$ scalar product. It becomes obvious that $\mathsf{M} : \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \mapsto \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$ is a continuous linear operator. To prove injectivity, let $\boldsymbol{\zeta}$ be such that $\mathsf{M}\boldsymbol{\zeta} = 0$, and let $\boldsymbol{\eta} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ be the vector verifying

$$\langle \boldsymbol{\eta}, \boldsymbol{\zeta}\rangle_{\boldsymbol{\tau},\Gamma} = \|\boldsymbol{\zeta}\|^2_{\boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}.$$

Due to Lemma 2.4, there exists a sequence $\{\boldsymbol{\eta}_\ell\}_{\ell\in\mathbb{N}} \subset \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$ converging to $\boldsymbol{\eta}$. Now choosing $\boldsymbol{\eta}_\ell$ as the test function in (4.7) and passing to the limit for $\ell \to \infty$, we obtain $\boldsymbol{\zeta} = 0$. The injectivity of M immediately implies

$$\big\langle \mathsf{M}\boldsymbol{\zeta}, \overline{\boldsymbol{\zeta}}\big\rangle_{\boldsymbol{\tau},\Gamma} = \|\mathsf{M}\boldsymbol{\zeta}\|^2_{\boldsymbol{H}_\times(\mathrm{div}_\Gamma,\Gamma)} > 0 \quad \Leftrightarrow \quad \boldsymbol{\zeta} \neq 0.$$

In addition, M inherits compactness from the embedding $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma) \hookrightarrow \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$; see Lemma 2.5: it meets all requirements listed above.

The composition of the integral operator C_κ and the smoothing operator M in (4.5) is not problematic. However, it cannot be handled in the context of Galerkin discretization, which we intend to apply; we have to find an equivalent weak form that can be discretized easily.

The usual trick to avoid operator products is to switch to a mixed formulation. Here, this amounts to introducing the new unknown $\mathbf{p} := \mathsf{M}\boldsymbol{\zeta}$. If we use the particular smoothing operator from (4.7), we get $\mathbf{p} \in \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$ and may simply incorporate (4.7) into the eventual mixed variational problem: find $\boldsymbol{\zeta} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$, $\mathbf{p} \in \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$ such that for all $\boldsymbol{\mu} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$, $\mathbf{q} \in \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$,

$$\begin{array}{rcrcl} -i\eta\,\langle \mathsf{S}_\kappa\boldsymbol{\zeta},\boldsymbol{\mu}\rangle_{\boldsymbol{\tau},\Gamma} & + & \big\langle (\tfrac{1}{2}\,\mathrm{Id} - \mathsf{C}_\kappa)\mathbf{p},\boldsymbol{\mu}\big\rangle_{\boldsymbol{\tau},\Gamma} & = & \big\langle \gamma_{\mathbf{t}}^+ \mathbf{e}_i,\boldsymbol{\mu}\big\rangle_{\boldsymbol{\tau},\Gamma}\,, \\ \langle \mathbf{q},\boldsymbol{\zeta}\rangle_{\boldsymbol{\tau},\Gamma} & - & (\mathbf{p},\mathbf{q})_{0;\Gamma} - (\mathrm{div}_\Gamma\mathbf{p},\mathrm{div}_\Gamma\mathbf{q})_{0;\Gamma} & = & 0. \end{array} \tag{4.8}$$

The next lemma tells us that we need not worry about Id in (4.8).

LEMMA 4.2. *The bilinear forms* $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$ *and* / $\langle \mathsf{C}_\kappa\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$ *are compact as mapping* $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma) \times \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \mapsto \mathbb{C}$.

Proof. It is enough to note that $\langle\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$ / $\langle \mathsf{C}_\kappa\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma} : \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)\times\boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \to \mathbb{C}$ are continuous and the injection $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma) \hookrightarrow \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ is compact due to Lemma 2.5. ∎

As an immediate consequence of this result we note that the off-diagonal terms in (4.8) represent compact bilinear forms. It remains to investigate the diagonal terms. First, $(\mathbf{p},\mathbf{q})_{0;\Gamma} + (\mathrm{div}_\Gamma\mathbf{p},\mathrm{div}_\Gamma\mathbf{q})_{0;\Gamma}$ is clearly elliptic in $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$, because it gives rise to its inner product. Second, the other bilinear form $\langle \mathsf{S}_\kappa\boldsymbol{\zeta},\boldsymbol{\mu}\rangle_{\boldsymbol{\tau},\Gamma}$ has been found to verify a generalized Gårding inequality; see Lemma 3.8.

Let us summarize what we know about the entire variational problem (4.8). For the sake of brevity we write $\mathfrak{V} := \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \times \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$ and denote by $\|\cdot\|_{\mathfrak{V}}$ its natural graph norm. We use the symbols $\mathfrak{u},\mathfrak{v},\mathfrak{w},\ldots$ for pairs of functions in $\mathfrak{V}$. Let $\widetilde{a} : \mathfrak{V}\times\mathfrak{V} \mapsto \mathbb{C}$ be the bilinear form associated with (4.8). As an immediate

consequence of the preceding considerations, it will also fulfill a generalized Gårding inequality. It can be stated using the isomorphism

$$\mathbb{X}_\Gamma : \mathfrak{V} \mapsto \mathfrak{V}, \qquad \mathbb{X}_\Gamma \begin{pmatrix} \boldsymbol{\mu} \\ \mathbf{q} \end{pmatrix} := \begin{pmatrix} \mathsf{X}_\Gamma \boldsymbol{\mu} \\ \mathbf{q} \end{pmatrix}.$$

COROLLARY 4.3. *There is a compact bilinear form* $\widetilde{c} : \mathfrak{V} \times \mathfrak{V} \mapsto \mathbb{C}$ *and a constant* $C_G > 0$ *such that*

$$|\widetilde{a}(\mathbb{X}_\Gamma \mathfrak{v}, \overline{\mathfrak{v}}) + \widetilde{c}(\mathfrak{v}, \overline{\mathfrak{v}})| \geq C_G \, \|\mathfrak{v}\|_{\mathfrak{V}}^2 \qquad \forall \mathfrak{v} \in \mathfrak{V}.$$

Since we have confirmed the uniqueness of solutions of (4.8), a Fredholm alternative argument shows that $\widetilde{a}$ induces an isomorphism, in particular that the inf-sup condition

$$\sup_{\mathfrak{v} \in \mathfrak{V}} \frac{|\widetilde{a}(\mathfrak{u}, \mathfrak{v})|}{\|\mathfrak{v}\|_{\mathfrak{V}}} \geq C_S \, \|\mathfrak{u}\|_{\mathfrak{V}} \tag{4.9}$$

holds with $C_S > 0$ independent of $\mathfrak{u} \in \mathfrak{V}$.

REMARK 2. *Many choices of smoothing operators* M *are conceivable. For the following reasons we opted for the definition* (4.7).

First, the operator M *is the inverse of* $-\mathbf{grad}_\Gamma \operatorname{div}_\Gamma + \mathrm{Id}$ *with Dirichlet boundary conditions on the skeleton* Σ. *We are anxious to use the inverse of a proper differential operator, because any nonlocal operator in the definition of* M *will be awkward to deal with in an implementation. We also aimed at making* M *local on each face of the polyhedron, which is satisfied by the concrete choice, since surface vector fields* $\boldsymbol{H}_\Sigma(\operatorname{div}_\Gamma, \Gamma)$ *have no flux across any edge in* Σ.

Second, we have to take great pains to ensure sufficient regularity of the solution for the new unknown $\mathbf{p}$. *If, in* (4.7), *we used* $\boldsymbol{H}_\times(\operatorname{div}_\Gamma, \Gamma)$ *trial and test function spaces instead of* $\boldsymbol{H}_\Sigma(\operatorname{div}_\Gamma, \Gamma)$, *then the regularity of* $\mathbf{p}$ *would be impaired, because Laplace–Beltrami singularities* [12, *sect.* 5.2.1] *would sneak into* $\mathbf{p}$ *through the associated smoothing operator. We are going to resume the discussion at the end of section* 6.

5. Galerkin discretization. We equip the piecewise smooth compact two-dimensional surface Γ with an oriented triangulation Γ_h. This means that all its edges are endowed with a direction. We assume a perfect resolution of Γ; that is, $\Gamma = \bar{K}_1 \cup \cdots \cup \bar{K}_N$, where $\mathcal{K}_h := \{K_1, \ldots, K_N\}$ is the set of mutually disjoint open cells of Γ_h. Moreover, no cell may straddle boundaries of the smooth faces Γ^j of Γ. We will admit triangular and quadrilateral cells only: for each $K \in \mathcal{K}_h$ there is a diffeomorphism $\boldsymbol{\Phi}_K : \widehat{K} \mapsto \bar{K}$, where $\widehat{K}$ is the "unit triangle" or unit square in $\mathbb{R}^2$, depending on the shape of K [19, sect. 5].

This paves the way for a parametric construction of boundary elements: to begin with, choose finite-dimensional local spaces $\boldsymbol{\mathcal{W}}(\widehat{K}) \subset (C^\infty(\widehat{K}))^2$ of polynomial vector fields, together with a dual basis of so-called local degrees of freedom (d.o.f.). Possible choices for $\boldsymbol{\mathcal{W}}(\widehat{K})$ and related d.o.f. abound [5, Chap. III]: we may use the classical triangular Raviart–Thomas (RT_p) elements of polynomial order $p \in \mathbb{N}_0$ [44] that use

$$\boldsymbol{\mathcal{W}}(\widehat{K}) := \{\mathbf{x} \mapsto \mathbf{p}_1(\mathbf{x}) + p_2(\mathbf{x}) \cdot \mathbf{x}, \, \mathbf{x} \in \widehat{K}, \, \mathbf{p}_1 \in (\mathcal{P}_p(\widehat{K}))^2, \, p_2 \in \mathcal{P}_p(\widehat{K})\},$$

where $\mathcal{P}_p(\widehat{K})$ is the space of two-variable polynomials of total degree $\leq p$. Possible alternatives are the triangular BDM_p elements of degree p [4], $p \in \mathbb{N}_0$, which rely

on $\boldsymbol{\mathcal{W}}(\widehat{K}) := (\mathcal{P}_{p+1}(\widehat{K}))^2$. In both cases, the usual d.o.f. involve certain polynomial moments of normal components on edges, together with interior vectorial moments for $p > 0$. For instance, in the case of RT_0, edge fluxes are the appropriate d.o.f.:

$$\boldsymbol{\mu}_h \in \boldsymbol{\mathcal{W}}(\widehat{K}) \mapsto \int_{\widehat{e}} \boldsymbol{\mu}_h \cdot \widehat{\mathbf{n}} \,\mathrm{d}S, \qquad \widehat{e} \text{ edge of } \widehat{K}.$$

Similar local spaces and d.o.f. are available for the unit square.

Using the pullback of 1-forms the local spaces can be lifted to the cells of Γ_h. In terms of vector fields this is equivalent to the *Piola transformation*

$$(\mathfrak{F}_K\boldsymbol{\mu})(\mathbf{x}) := \sqrt{\det(\mathrm{G})}\,\mathrm{G}^{-1}\, D\boldsymbol{\Phi}_K^T(\widehat{\mathbf{x}})\boldsymbol{\mu}(\widehat{\mathbf{x}}), \tag{5.1}$$

where $\mathrm{G} := D\boldsymbol{\Phi}(\widehat{\mathbf{x}})^T D\boldsymbol{\Phi}(\widehat{\mathbf{x}})$, $\mathbf{x} = \boldsymbol{\Phi}_K(\widehat{\mathbf{x}})$, $\widehat{\mathbf{x}} \in \widehat{K}$. Thus, we can introduce the global boundary element space

$$\boldsymbol{\mathcal{W}}_h := \{\boldsymbol{\mu} \in \boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma) : \boldsymbol{\mu}_{|K} \in \mathfrak{F}_K(\boldsymbol{\mathcal{W}}(\widehat{K}))\, \forall K \in \mathcal{K}_h\}. \tag{5.2}$$

In practice, $\boldsymbol{\mathcal{W}}_h \subset \boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$ is ensured by a suitable choice of d.o.f. Remember that d.o.f. have to be associated with individual edges of $\widehat{K}$ or the interior of $\widehat{K}$. It is crucial that the normal component of any $\widehat{\boldsymbol{\mu}}_h \in \boldsymbol{\mathcal{W}}(\widehat{K})$ on any edge $\widehat{e}$ of $\widehat{K}$ vanishes if and only if $\widehat{\boldsymbol{\mu}}_h$ belongs to the kernel of all local d.o.f. associated with $\widehat{e}$. In light of (2.5), this ensures $\boldsymbol{\mathcal{W}} \subset \boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$. In the rest of the paper $\boldsymbol{\mathcal{W}}_h$ will designate a generic $\boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$-conforming boundary element space. It may arise from the RT_p family of elements, $p \in \mathbb{N}_0$, the BDM_p family, or a combination of both.

Based on the d.o.f. we can introduce *local interpolation operators* $\Pi_h : \mathrm{Dom}(\Pi_h) \mapsto \boldsymbol{\mathcal{W}}_h$. They are projectors onto $\boldsymbol{\mathcal{W}}_h$ and enjoy the fundamental *commuting diagram property* [5, Chap. III, sect. 3]

$$\mathrm{div}_\Gamma \circ \Pi_h = \mathsf{Q}_h \circ \mathrm{div}_\Gamma \quad \text{on } \boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma) \cap \mathrm{Dom}(\Pi_h). \tag{5.3}$$

Here, Q_h is the $L^2(\Gamma)$-orthogonal projection onto a suitable space Q_h of Γ_h-piecewise polynomial discontinuous functions. It must be emphasized that the interpolation operators Π_h fail to be bounded on $\boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$; slightly more regularity of tangential vector fields in $\mathrm{Dom}(\Pi_h)$ is required [33, Lem. 5.1].

Next, we turn our attention to asymptotic properties of the boundary element spaces, in particular to estimates of interpolation errors and best approximation errors. We restrict ourselves to the h-version of boundary elements, which relies on uniformly shape-regular families $\{\Gamma_h\}_{h\in\mathbb{H}}$ of triangulations of Γ [22, Chap. 3, sect. 3.1]. Here, $\mathbb{H}$ stands for a decreasing sequence of meshwidths, and $\mathbb{H}$ is assumed to converge to zero.

By means of transformation to reference elements, the commuting diagram property, and Bramble–Hilbert arguments, interpolation error estimates can easily be obtained [5, Chap. III, sect. 3.3].

LEMMA 5.1 (interpolation error estimate). *For $0 < s \le p+1$ we find constants $C > 0$, depending only on the shape regularity of the meshes, s and p, such that for all $\boldsymbol{\mu} \in \boldsymbol{H}^s_\times(\Gamma) \cap \boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$, $h \in \mathbb{H}$,*

$$\|\boldsymbol{\mu} - \Pi_h\boldsymbol{\mu}\|_{\boldsymbol{L}^2(\Gamma)} \le Ch^s \left(\|\boldsymbol{\mu}\|_{\boldsymbol{H}^s_\times(\Gamma)} + \|\mathrm{div}_\Gamma\boldsymbol{\mu}\|_{L^2(\Gamma)}\right),$$

and such that for all $\boldsymbol{\mu} \in \boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$, $\mathrm{div}_\Gamma\boldsymbol{\mu} \in H^s_-(\Gamma)$,

$$\|\mathrm{div}_\Gamma(\boldsymbol{\mu} - \Pi_h\boldsymbol{\mu})\|_{L^2(\Gamma)} \le Ch^s \|\mathrm{div}_\Gamma\boldsymbol{\mu}\|_{H^s_-(\Gamma)}.$$

COROLLARY 5.2. *The union of all boundary element spaces* $\boldsymbol{\mathcal{W}}_h$, $h \in \mathbb{H}$, *is dense in* $\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$.

A particular variant of the above interpolation error estimate addresses vector fields with discrete surface divergence; cf. [33, Lem. 6.2].

LEMMA 5.3. *If* $\boldsymbol{\mu} \in \boldsymbol{H}_\times^s(\Gamma)$, $0 < s \leq 1$, *and* $\mathrm{div}_\Gamma \boldsymbol{\mu} \in Q_h$, *then*

$$\|\boldsymbol{\mu} - \Pi_h \boldsymbol{\mu}\|_{\boldsymbol{L}_\mathbf{t}^2(\Gamma)} \leq C h^s \|\boldsymbol{\mu}\|_{\boldsymbol{H}_\times^s(\Gamma)},$$

where the constant $C > 0$ *depends only on the shape regularity of the meshes and the polynomial degree* p.

From the interpolation error estimates we instantly get best approximation estimates in terms of the $\boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$-norm. Yet, what we actually need is a result about approximation in the "energy norm" (trace norm) of the form

$$\inf_{\boldsymbol{\xi}_h} \|\boldsymbol{\mu}_h - \boldsymbol{\xi}_h\|_{\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \leq C h^{s+\frac{1}{2}} \|\boldsymbol{\mu}\|_{\boldsymbol{H}_\times^s(\mathrm{div}_\Gamma,\Gamma)}. \tag{5.4}$$

The estimate in $\boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$ does not directly provide (5.4). The question of obtaining (5.4) has been addressed in [8, sect. 4.4.2], and the idea is to use the duality argument face by face (each one seen as a regular open manifold), relying on the continuity of the normal components of vector fields in $\boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$. At the end of a technical procedure we obtain the following result [8, Thm. 4.9].

THEOREM 5.4. *Let* $\mathcal{P}_h : \boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \to \boldsymbol{\mathcal{W}}_h$ *be the orthogonal projection with respect to the* $\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ *inner product. Then for any* $-\frac{1}{2} \leq s \leq p+1$ *we have*

$$\|\boldsymbol{\mu} - \mathcal{P}_h \boldsymbol{\mu}\|_{\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \leq C h^{s+\frac{1}{2}} \|\boldsymbol{\mu}\|_{\boldsymbol{H}_\times^s(\mathrm{div}_\Gamma,\Gamma)} \qquad \forall \boldsymbol{\mu} \in \boldsymbol{H}_\times^s(\mathrm{div}_\Gamma, \Gamma). \tag{5.5}$$

This theorem tells us that we can expect good approximation properties, much better than the estimates for the local interpolation error.

A finite-dimensional subspace of $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma, \Gamma)$ is easily obtained from $\boldsymbol{\mathcal{W}}_h$ by setting all d.o.f. associated with edges on the skeleton Σ to zero. Let us write $\boldsymbol{\mathcal{W}}_{\Sigma,h}$ for the resulting space. By construction the estimates of Lemma 5.1 will carry over to $\boldsymbol{H}_\times^s(\Gamma) \cap \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma, \Gamma)$ and $\boldsymbol{\mathcal{W}}_{\Sigma,h}$.

Based on the boundary element spaces $\boldsymbol{\mathcal{W}}_h$ and $\boldsymbol{\mathcal{W}}_{\Sigma,h}$, which are contained in $\boldsymbol{H}_\times^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ and $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma, \Gamma)$, respectively, we pursue a standard Galerkin discretization of (4.8). Writing $\mathfrak{V}_h = \boldsymbol{\mathcal{W}}_h \times \boldsymbol{\mathcal{W}}_{\Sigma,h}$, we end up with the following discrete problem:

$$\text{Find } \mathfrak{u}_h \in \mathfrak{V}_h \ : \ \widetilde{a}(\mathfrak{u}_h, \mathfrak{v}_h) = \left\langle \begin{pmatrix} \gamma_\mathbf{t}^+ \mathbf{e} \\ 0 \end{pmatrix}, \mathfrak{v}_h \right\rangle_{\boldsymbol{\tau},\Gamma} \qquad \forall\, \mathfrak{v}_h \in \mathfrak{V}_h. \tag{5.6}$$

We aim at establishing a *uniform discrete inf-sup condition* of the following form: there exists $C_D > 0$ such that

$$\sup_{\mathfrak{v}_h \in \mathfrak{V}_h} \frac{|\widetilde{a}(\mathfrak{u}_h, \mathfrak{v}_h)|}{\|\mathfrak{v}_h\|_\mathfrak{V}} \geq C_D \|\mathfrak{u}_h\|_\mathfrak{V} \qquad \forall \mathfrak{u}_h \in \mathfrak{V}_h, \qquad h \in \mathbb{H}. \tag{5.7}$$

According to [48] this guarantees existence of discrete solutions $\mathfrak{u}_h := (\boldsymbol{\zeta}_h, \mathbf{p}_h) \in \mathfrak{V}_h$ of (5.6) and translates into their quasi-optimal behavior:

$$\|\mathfrak{u} - \mathfrak{u}_h\|_\mathfrak{V} \leq C_D^{-1} C_{\widetilde{a}} \inf_{\mathfrak{v}_h \in \mathfrak{V}_h} \|\mathfrak{u} - \mathfrak{v}_h\|_\mathfrak{V} \qquad \forall h \in \mathbb{H}, \tag{5.8}$$

where $C_{\widetilde{a}} > 0$ is the operator norm of $\widetilde{a}(\cdot,\cdot)$. We follow lines of reasoning laid out in [8, 15, 33]. As a first step towards a discrete inf-sup condition (5.7), we have to find a suitable candidate for $\mathfrak{v}$ in (4.9). To that end, introduce the operator $\mathsf{T} : \mathfrak{V} \mapsto \mathfrak{V}$ through

$$\widetilde{a}(\mathfrak{v}, \mathsf{T}\mathfrak{w}) = \widetilde{c}(\mathfrak{w}, \mathfrak{v}) \qquad \forall \mathfrak{v} \in \mathfrak{V},\, \mathfrak{w} \in \mathfrak{V},$$

where $\widetilde{c}$ is the compact bilinear form specified in Corollary 4.3. Owing to (4.9) this is a valid definition of a compact operator T. It is immediate from (4.9) and Lemma 3.8 that

$$|\widetilde{a}(\mathfrak{w}, (\mathbb{X}_\Gamma + \mathsf{T})\overline{\mathfrak{w}})| = |\widetilde{a}(\mathfrak{w}, \mathbb{X}_\Gamma\overline{\mathfrak{w}}) + c_\Gamma(\mathfrak{w}, \overline{\mathfrak{w}})| \geq C_G \, \|\mathfrak{w}\|^2_{\mathfrak{V}} \tag{5.9}$$

for all $\mathfrak{w} \in \mathfrak{V}_h$. Consequently, the choice $\mathfrak{v} := (\mathbb{X}_\Gamma + \mathsf{T})\overline{\mathfrak{w}}$ will make (4.9) hold with $C_S = C_G$.

Let $\mathfrak{w}_h \in \mathfrak{V}_h$, and $\mathfrak{v} := (\mathbb{X}_\Gamma + \mathsf{T})\mathfrak{w}_h$. In general, $\mathfrak{v} \notin \mathfrak{V}_h$ so that we have to use a projection. Write $\mathsf{P}_h : \boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{\mathcal{W}}_{\Sigma,h}$ for the $\boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$-orthogonal projection and introduce

$$\mathbb{P} : \mathfrak{V} \mapsto \mathfrak{V}_h, \qquad \mathbb{P}\begin{pmatrix}\boldsymbol{\mu}\\ \mathbf{q}\end{pmatrix} := \begin{pmatrix}\mathcal{P}_h\boldsymbol{\mu}\\ \mathsf{P}_h\mathbf{q}\end{pmatrix}.$$

Then a promising candidate for the discrete inf-sup condition is the vector $\mathfrak{v}_h := \mathbb{P}_h\mathfrak{v} = (\mathbb{P}_h\mathbb{X}_\Gamma + \mathbb{P}_h\mathsf{T})\overline{\mathfrak{w}}_h$. The triangle inequality

$$|\widetilde{a}(\mathfrak{w}_h, \mathfrak{v}_h)| \geq |\widetilde{a}(\mathfrak{w}_h, \mathfrak{v})| - C_{\mathfrak{b}}\|\mathfrak{w}_h\|_{\mathfrak{V}}\|\mathfrak{v} - \mathfrak{v}_h\|_{\mathfrak{V}} \tag{5.10}$$

shows that (strong) convergence $\|\mathfrak{v} - \mathfrak{v}_h\|_{\mathfrak{V}} \to 0$ is needed. First, $\|(I - \mathbb{P}_h)\mathsf{T}\mathfrak{w}_h\|_{\mathfrak{V}} \to 0$ uniformly for all $\mathfrak{w}_h \in \mathfrak{V}_h$, since the composition of pointwise convergent and compact operators gives uniform convergence in operator norms [37, Cor. 10.4]. Second, it is important to note that X_Γ leaves the div_Γ of its argument function invariant, which means that the first component of $\mathbb{X}_\Gamma\mathfrak{w}_h$ has a surface divergence in a space of Γ_h-piecewise polynomials. This enables us to invoke Lemma 5.3, and we obtain (see [15, sect. 4.2]) that there exists an $s > 0$ such that

$$\|(I - \mathcal{P}_h)\mathbb{X}_\Gamma\mathfrak{w}_h\|_{\mathfrak{V}} \leq \|(\mathrm{Id} - \Pi_h)\mathsf{X}_\Gamma\boldsymbol{\mu}_h\|_{\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)} \leq Ch^s \, \|\mathrm{div}_\Gamma\mathsf{X}_\Gamma\boldsymbol{\mu}_h\|_{H^{-\frac{1}{2}}(\Gamma)},$$

where $\boldsymbol{\mu}_h \in \boldsymbol{\mathcal{W}}_h$ stands for the first component of $\mathfrak{w}_h$.

Using these estimates in (5.10) and recalling that, by definition of $\mathfrak{v}$, $|\widetilde{a}(\mathfrak{w}_h, \mathfrak{v})| \geq C_G\|\mathfrak{w}_h\|^2_{\mathfrak{V}}$, we easily deduce the following theorem.

THEOREM 5.5. *There is an $h^* > 0$, depending on the parameters of the continuous problem and the shape regularity of the triangulation, such that a unique solution $\mathfrak{u}_h \in \mathfrak{V}_h$ of the discretized problem* (5.6) *exists, provided that $h < h_*$. It supplies an asymptotically optimal approximation to the continuous solution $\mathfrak{u} = (\boldsymbol{\zeta}, \mathbf{p})$ of* (4.8) *in the sense of* (5.8).

After choosing local bases of $\boldsymbol{\mathcal{W}}_h$ and $\boldsymbol{\mathcal{W}}_{\Sigma,h}$, we end up with a linear system of equations of the form

$$\begin{pmatrix} i\eta S & \frac{1}{2}B - C\\ B^T & -D\end{pmatrix}\begin{pmatrix}\underline{\zeta}\\ \underline{\mathbf{p}}\end{pmatrix} = \begin{pmatrix}\underline{\mathbf{g}}\\ 0\end{pmatrix}. \tag{5.11}$$

Here S and C will be dense square matrices arising from the discretized boundary integral operators S_κ and C_κ. The sparse, skew-symmetric matrix B is related to

$\langle\cdot,\cdot\rangle_{\boldsymbol{\tau},\Gamma}$, whereas the s.p.d. matrix D corresponds to the $\boldsymbol{H}_\Sigma(\mathrm{div}_\Gamma,\Gamma)$-inner product. The other symbols have obvious meanings.

Note that D is even block-diagonal with one sparse block for each face Γ_j, $j = 1,\ldots,P$. Using advanced sparse Cholesky factorization techniques, it may be feasible to compute the application of D^{-1} to a vector directly. Then we face the linear system of equations

$$(i\eta S + (\tfrac{1}{2}B - C)D^{-1}B^T)\underline{\zeta} = \underline{\mathbf{g}}. \tag{5.12}$$

It can be solved only iteratively, because the actual matrix D^{-1} is not available. Besides, iterative solvers allow the use of fast summation techniques (multipole, $\mathcal{H}^2$-matrices) for the approximate application of S and C to a vector.

REMARK 3. *Of course, $\boldsymbol{\zeta}$ and $\mathbf{p}$ can be approximated in completely different boundary element spaces, as long as these are contained in $\boldsymbol{H}_\times(\mathrm{div}_\Gamma,\Gamma)$. The analysis can immediately be extended to this case.*

REMARK 4. *The iterative solution of* (5.12) *(e.g., by means of GMRES) requires a preconditioner, because the principal part of the related boundary integral operator is given by S_κ. As pointed out in* [21] *the condition number of S will deteriorate on fine meshes. Yet, the fact that S is related to the principal part also means that preconditioning needs only to target this matrix, which is the same matrix as in the Galerkin discretization of the EFIE. An elaborate preconditioning strategy has been devised in* [21].

Yet, if κ is close to a resonant frequency, S will become nearly singular, and preconditioning might suffer. This requires further investigation, which is beyond the scope of this paper.

REMARK 5. *The choice of η is another issue which has eluded theory so far. It is clear that η has a major impact on the spectral properties of the final linear system* (5.12)*, but it is not clear how to choose η to achieve good properties of the discrete problem. This situation is commonly faced with CFIE approaches. Some investigations in the case of two-dimensional acoustic scattering can be found in* [38]*; see also* [27, *sect.* 2.4.1] *and* [16].

REMARK 6. *For reasons explained in Remark* 2*, we have decided to use a localized version of M. One could argue that localization could be carried further by considering split faces. Of course, the theory will cover this, but it is important to keep in mind that the result of Theorem* 5.5 *is asymptotic in nature. The choice of M will affect the threshold h^*, and it may well be that certain choices of M will delay the onset of asymptotic convergence until unreasonably fine meshes. We acknowledge that this might also be true for our choice of M.*

6. Convergence estimates. In light of the asymptotic quasi optimality of the conforming Galerkin solutions expressed in Theorem 5.5, we have to investigate how well the solution $(\boldsymbol{\zeta},\mathbf{p})$ of (4.8) can be approximated in $\mathfrak{V}_h$. This entails knowledge about the regularity of both $\boldsymbol{\zeta}$ and $\mathbf{p}$.

Thanks to the localization of M onto the faces of Γ, studying the smoothness of $\mathbf{p}$ can chiefly rely on two-dimensional considerations.

LEMMA 6.1. *For a Lipschitz domain $\omega \subset \mathbb{R}^2$ we denote by α the maximum regularity exponent for the Laplace problem with Dirichlet or Neumann boundary conditions; i.e., if $\Delta u \in H^{\alpha-1}(\omega)$ and u verifies either the Dirichlet or Neumann homogeneous boundary condition, then $u \in H^{\alpha+1}(\omega)$.*

Let $\mathbf{f} \in (H^\sigma(\omega))^2$ and $\mathrm{curl}_{2D}\,\mathbf{f} \in H^\sigma(\omega)$, $\sigma \geq 0$. If $\mathbf{p} \in \boldsymbol{H}_0(\mathrm{div};\omega)$ satisfies

$$(\mathrm{div}\,\mathbf{p},\mathrm{div}\,\mathbf{v})_{0;\omega} + (\mathbf{p},\mathbf{v})_{0;\omega} = (\mathbf{f},\mathbf{v})_{0;\omega} \qquad \forall \mathbf{v} \in \boldsymbol{H}_0(\mathrm{div};\omega),$$

then $\mathbf{p} \in H^{\min\{\alpha,\sigma+1\}}(\omega)$ *and* $\operatorname{div}\mathbf{p} \in H^{\min\{\alpha+1,1+\sigma\}}(\omega)$.

Proof. It goes without saying that $\mathbf{p}$ is well defined. The main tool for the proof of the asserted regularity properties will be $\boldsymbol{L}^2(\omega)$-orthogonal Helmholtz decompositions (see [28, Chap. 1])

$$\begin{aligned}\boldsymbol{L}^2(\omega) &= \mathbf{curl}_{2D}\, H^1_0(\omega) \oplus \mathbf{grad}\, H^1(\omega),\\ \boldsymbol{H}_0(\operatorname{div};\omega) &= \mathbf{curl}_{2D}\, H^1_0(\omega) \oplus \mathbf{grad}\, H_0(\Delta,\omega),\end{aligned}$$

where

$$H_0(\Delta,\omega) := \left\{\psi \in H^1(\omega):\ \Delta\psi \in L^2(\omega),\ \frac{\partial\psi}{\partial\mathbf{n}} = 0 \text{ on } \partial\omega\right\}.$$

Accordingly, we decompose

$$\mathbf{p} = \mathbf{curl}_{2D}\,\varphi_1 + \mathbf{grad}\,\varphi_2, \qquad \mathbf{f} = \mathbf{curl}_{2D}\,\phi_1 + \mathbf{grad}\,\phi_2,$$

with $\varphi_1,\phi_1 \in H^1_0(\omega)$, $\varphi_2 \in H_0(\Delta,\omega)$, $\phi_2 \in H^1(\omega)$. A closer scrutiny reveals that

$$\operatorname{curl}_{2D}\mathbf{curl}_{2D}\,\phi_1 = -\Delta\phi_1 = \operatorname{curl}_{2D}\mathbf{f} \in H^\sigma(\omega) \quad\Rightarrow\quad \phi_1 \in H^{\min\{1+\alpha,2+\sigma\}}(\omega),$$

because of the $1+\alpha$-regularity of the Laplacian. Testing with $\mathbf{curl}_{2D}\,\nu$, $\nu \in H^1_0(\omega)$, in the definition of $\mathbf{p}$, we immediately see that $\varphi_1 = \phi_1$.

For $\nu_2 \in H_0(\Delta,\omega)$ we deduce from the variational equation that

$$(\operatorname{div}\mathbf{p}, \operatorname{div}\mathbf{grad}\,\nu_2)_{0;\omega} + (\mathbf{p}, \mathbf{grad}\,\nu_2)_{0;\omega} = (\mathbf{f}, \mathbf{grad}\,\nu_2)_{0;\omega}.$$

After integrating by parts, this means

$$(\operatorname{div}\mathbf{p}, \Delta\nu_2 - \nu_2)_{0;\omega} = (\mathbf{f}, \mathbf{grad}\,\nu_2)_{0;\omega}. \tag{6.1}$$

Now consider $\zeta \in H^1(\omega)$, solving

$$(\mathbf{grad}\,\zeta, \mathbf{grad}\,\nu)_{0;\omega} + (\zeta,\nu)_{0;\omega} = (\mathbf{f}, \mathbf{grad}\,\nu)_{0;\omega} \qquad \forall\nu \in H^1(\omega). \tag{6.2}$$

The regularity assumption implies that $\zeta \in H^{\min\{1+\alpha,1+\sigma\}}(\omega)$. We can pick $\nu \in H_0(\Delta,\omega)$ in this equation, carry out integration by parts, and subtract the result from (6.1). We end up with

$$(\operatorname{div}\mathbf{p} - \zeta, -\Delta\nu + \nu)_{0;\omega} = 0.$$

Since $(-\Delta + Id)(H_0(\Delta,\omega)) = L^2(\omega)$, we infer that $\operatorname{div}\mathbf{p} = \zeta$, i.e., $\operatorname{div}\mathbf{p} \in H^{\min\{1+\alpha,1+\sigma\}}(\omega)$. ∎

We point out that for a polygon ω the exponent α is directly related to the angles θ_i, $i = 1,\ldots,n_c$, at its corners:

$$\alpha = \min\{1, \pi/\theta_i, i = 1,\ldots,n_c\} \geq \tfrac{1}{2}.$$

This lemma can instantly be applied to all the smooth faces of Γ and supplies lifting properties of M, because there is no coupling between the faces.

COROLLARY 6.2. *If* $\boldsymbol{\mu} \in \boldsymbol{H}^\sigma_\times(\operatorname{div}_\Gamma,\Gamma)$, $\sigma \geq 0$, *then* $\mathsf{M}\boldsymbol{\mu} \in \boldsymbol{H}^{\min\{\alpha,\sigma+1\}}_\times(\operatorname{div}_\Gamma,\Gamma)$, *where* α *is the minimum of the* $\Delta_{\mathrm{Dir}}/\Delta_{\mathrm{Neu}}$*-regularity exponents on the flat faces* Γ_j, $j = 1,\ldots,P$.

Assume that $\boldsymbol{\zeta} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ is the unique solution of (4.5), and denote by $\mathbf{e} \in \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega \cup \Omega')$ the Maxwell solution according to (4.3):

$$\mathbf{e} = -i\eta \boldsymbol{\Psi}_{SL}^{\kappa}(\boldsymbol{\zeta}) - \boldsymbol{\Psi}_{DL}^{\kappa}(\mathsf{M}\boldsymbol{\zeta}).$$

To study the regularity it is essential to recall that by the jump relations

$$\gamma_{\mathbf{t}}^{-}\mathbf{e} = -\mathsf{M}\boldsymbol{\zeta} - \mathbf{g}, \qquad \gamma_{N}^{-}\mathbf{e} = i\eta\boldsymbol{\zeta} - \mathbf{h}, \tag{6.3}$$

where we wrote $\mathbf{h} := \gamma_N^+\mathbf{e} \in \boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ for the exterior Neumann data of the scattered field. As $\mathbf{g} := \gamma_{\mathbf{t}}^{+}\mathbf{e}_i$ is the tangential trace of an incident wave, it will belong to $\boldsymbol{H}_{\times}^{s}(\mathrm{div}_\Gamma, \Gamma)$ for all $s > 0$. Additional information can be gleaned only from lifting properties of the Maxwell operator. Its regularity theory, elaborated in [25], justifies the following assumption.

ASSUMPTION 6.2.1. *There are two regularity indices $\sigma^-, \sigma^+ > \frac{1}{2}$ such that*

1. *any field $\mathbf{u} \in \boldsymbol{H}(\mathbf{curl}^2, \Omega)$ solving*

$$\mathbf{curl}\,\mathbf{curl}\,\mathbf{u} - \mathbf{grad}\,\mathrm{div}\,\mathbf{u} - \kappa^2\mathbf{u} = \mathbf{f} \quad \text{in } \Omega, \quad \gamma_{\mathbf{t}}^{-}\mathbf{u} = 0, \quad \text{or} \quad \gamma_N^{-}\mathbf{u} = 0$$

   belongs to $\boldsymbol{H}^{\sigma}(\mathbf{curl}, \Omega)$ for all $\sigma \le \sigma^-$ if $\mathbf{f} \in H^{\sigma-1}(\Omega)$;
2. *any field $\mathbf{u} \in \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega')$ satisfying the radiation condition and*

$$\mathbf{curl}\,\mathbf{curl}\,\mathbf{u} - \mathbf{grad}\,\mathrm{div}\,\mathbf{u} - \kappa^2\mathbf{u} = \mathbf{f} \quad \text{in } \Omega', \quad \gamma_{\mathbf{t}}^{+}\mathbf{u} = 0, \quad \text{or} \quad \gamma_N^{+}\mathbf{u} = 0$$

   lies in $\boldsymbol{H}_{\mathrm{loc}}^{\sigma}(\mathbf{curl}, \Omega')$ for all $\sigma < \sigma^+$ if $\mathbf{f} \in H^{\sigma-1}(\Omega')$.

Owing to the trace theorem, Theorem 2.6, this assumption implies that $\mathbf{h} \in \boldsymbol{H}_{\times}^{\sigma^+ - \frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$. Then we can resort to a "bootstrap argument."

Step 1. We remember a result by Costabel [24] confirming the existence of a constant $c > 0$ that depends only on Ω such that for all $\mathbf{u} \in \boldsymbol{H}(\mathrm{div}; \Omega) \cap \boldsymbol{H}(\mathbf{curl}; \Omega)$,

$$\left\|\gamma_{\mathbf{n}}^{-}\mathbf{u}\right\|_{L^2(\Gamma)} \le c\left\{\left\|\gamma_{\mathbf{t}}^{-}\mathbf{u}\right\|_{\boldsymbol{L}^2(\Gamma)} + \|\mathbf{u}\|_{\boldsymbol{L}^2(\Omega)} + \|\mathbf{curl}\,\mathbf{u}\|_{\boldsymbol{L}^2(\Omega)} + \|\mathrm{div}\,\mathbf{u}\|_{L^2(\Omega)}\right\}, \tag{6.4}$$

$$\left\|\gamma_{\mathbf{t}}^{-}\mathbf{u}\right\|_{\boldsymbol{L}^2(\Gamma)} \le c\left\{\left\|\gamma_{\mathbf{n}}^{-}\mathbf{u}\right\|_{L^2(\Gamma)} + \|\mathbf{u}\|_{\boldsymbol{L}^2(\Omega)} + \|\mathbf{curl}\,\mathbf{u}\|_{\boldsymbol{L}^2(\Omega)} + \|\mathrm{div}\,\mathbf{u}\|_{L^2(\Omega)}\right\}. \tag{6.5}$$

Since $\mathbf{e}$ is a Maxwell solution in Ω, these estimates combined with Theorem 3.3 give

$$\begin{aligned}\left\|\gamma_N^{-}\mathbf{e}\right\|_{\boldsymbol{L}^2(\Gamma)} &\le C\left\{\left\|\gamma_{\mathbf{n}}^{-}\,\mathbf{curl}\,\mathbf{e}\right\|_{L^2(\Gamma)} + \kappa^2\left\|\mathbf{e}\right\|_{\boldsymbol{L}^2(\Omega)} + \|\mathbf{curl}\,\mathbf{e}\|_{\boldsymbol{L}^2(\Omega)}\right\}\\ &\le C\left\{\left\|\mathrm{div}_\Gamma\gamma_{\mathbf{t}}^{-}\mathbf{e}\right\|_{L^2(\Gamma)} + \|\boldsymbol{\zeta}\|_{\boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} + \|\mathsf{M}\boldsymbol{\zeta}\|_{\boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}\right\}.\end{aligned}$$

Similarly, we can use (6.4) and get

$$\begin{aligned}\left\|\mathrm{div}_\Gamma\gamma_N^{-}\mathbf{e}\right\|_{L^2(\Gamma)} = \kappa^2\left\|\gamma_{\mathbf{n}}^{-}\mathbf{e}\right\|_{L^2(\Gamma)} &\le C\left\{\left\|\gamma_{\mathbf{t}}^{-}\mathbf{e}\right\|_{\boldsymbol{L}^2(\Gamma)} + \|\mathbf{curl}\,\mathbf{e}\|_{\boldsymbol{L}^2(\Omega)} + \|\mathbf{e}\|_{\boldsymbol{L}^2(\Omega)}\right\}\\ &\le C\left\{\left\|\gamma_{\mathbf{t}}^{-}\mathbf{e}\right\|_{\boldsymbol{L}^2(\Gamma)} + \|\boldsymbol{\zeta}\|_{\boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} + \|\mathsf{M}\boldsymbol{\zeta}\|_{\boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}\right\}.\end{aligned}$$

The generic constants $C > 0$ may depend on Ω, κ, and η. The combined estimate reads

$$\left\|\gamma_N^{-}\mathbf{e}\right\|_{\boldsymbol{H}_{\times}(\mathrm{div}_\Gamma,\Gamma)} \le C\left\{\left\|\gamma_{\mathbf{t}}^{-}\mathbf{e}\right\|_{\boldsymbol{H}_{\times}(\mathrm{div}_\Gamma,\Gamma)} + \|\boldsymbol{\zeta}\|_{\boldsymbol{H}_{\times}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}\right\},$$

which means $\gamma_N^- \mathbf{e} \in \boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$.

Step 2. Next, from (6.3) we infer that $\boldsymbol{\zeta} \in \boldsymbol{H}_\times(\mathrm{div}_\Gamma, \Gamma)$. Now, we can apply Corollary 6.2, we get $\mathsf{M}\boldsymbol{\zeta} \in \boldsymbol{H}_\times^{\min\{1,\alpha\}}(\mathrm{div}_\Gamma, \Gamma)$, and (6.3) gives us $\gamma_{\mathbf{t}}^- \mathbf{e} \in \boldsymbol{H}_\times^{\min\{1,\alpha\}}(\mathrm{div}_\Gamma, \Gamma)$. Now, since $\mathbf{e}$ is a Maxwell solution verifying $\gamma_{\mathbf{t}}^- \mathbf{e} \in \boldsymbol{H}_\times^{\min\{1,\alpha\}}(\mathrm{div}_\Gamma, \Gamma)$, using Theorem 2.6 and Assumption 6.2.1, we have that $\mathbf{e}, \mathbf{curl}\,\mathbf{e} \in \boldsymbol{H}^{\min\{\sigma^-,1\}}(\mathbf{curl}, \Omega)$, i.e., $\gamma_N^- \mathbf{e} \in \boldsymbol{H}_\times^{\min\{\sigma^- - \frac{1}{2}, \frac{1}{2}\}}(\mathrm{div}_\Gamma, \Gamma)$.
