The result in Corollary 5.6 shows that the H^1-norm of errors close to the inflow boundary can be made arbitrarily small if the right-hand side is zero on a sufficiently

large subdomain $(\Omega \setminus \Omega_\eta)$ that is adjacent to this inflow boundary. In the proof of the approximation property in section 10 we will need these estimates for the case $\xi = h_k$ and $p = \frac{1}{2}$. Hence we take $\eta = 4h_k|\ln h_k| + h_k$. Note that for the results in the previous corollaries to be applicable we need right-hand side functions f_k which are zero in $\Omega \setminus \Omega_\eta$. For technical reasons we take Ω_η such that the right boundary of the domain $\Omega \setminus \Omega_\eta$ coincides with a grid line. We use $|\ln h_k| = k \ln 2$ and thus $4h_k|\ln h_k| + h_k \leq (3k+1)h_k$ and introduce the following auxiliary domains for each grid level:

$$\Omega_k^{in} := \{\, (x,y) \in \Omega \mid x < (3k+1)h_k \,\}. \tag{5.18}$$

As a direct consequence of the previous corollary we then obtain the following.

COROLLARY 5.7. *Consider $f_k \in \mathbb{V}_k$ such that f_k is zero on the subdomain Ω_k^{in}. Let u and u_k be the solutions of* (2.7) *and* (2.8)*, respectively. Then for $e_k = u - u_k$ we have*

$$\|(e_k)_x\|_{L_2(\Omega_{h_k})} \leq c\, h_k^{\frac{1}{2}} \|f_k\|, \tag{5.19}$$

$$\|(e_k)_y\|_{L_2(\Omega_{h_k})} \leq c\, \frac{h_k}{\sqrt{\varepsilon}} \|f_k\|. \tag{5.20}$$

6. Multigrid method and convergence analysis. In this section we describe the multigrid method for solving a problem of the form $A_k x = \hat{b}$ with the stiffness matrix A_k from section 2 and present a convergence analysis.

For the prolongation and restriction in the multigrid algorithm we use the canonical choice:

$$p_k : \mathrm{X}_{k-1} \to \mathrm{X}_k, \quad p_k = P_k^{-1} P_{k-1}, \quad r_k = \frac{1}{4} p_k^T. \tag{6.1}$$

Let $W_k : \mathrm{X}_k \to \mathrm{X}_k$ be a nonsingular matrix. We consider a smoother of the form

$$x^{\mathrm{new}} = \mathcal{S}_k(x^{\mathrm{old}}, \hat{b}) = x^{\mathrm{old}} - \omega_k W_k^{-1}(A_k x^{\mathrm{old}} - \hat{b}) \quad \text{for } x^{\mathrm{old}}, \hat{b} \in \mathrm{X}_k, \tag{6.2}$$

with corresponding iteration matrix denoted by

$$S_k = I - \omega_k W_k^{-1} A_k. \tag{6.3}$$

The preconditioner W_k we use is of line-Jacobi type:

$$W_k = \frac{4\varepsilon}{h_k^2} I + D_x \ . \tag{6.4}$$

Note that W_k is a blockdiagonal matrix with diagonal blocks that are $n_k \times n_k$ bidiagonal matrices. A suitable choice for the parameter ω_k follows from the analysis below.

Remark 6.1. In the literature it is often recommended to apply a so-called *robust smoother* for solving singularly perturbed elliptic problem using multigrid. Such a smoother should have the property that it becomes a direct solver if the singular perturbation parameter tends to zero (cf. [9], chapter 10). In the formulation (6.2) one then must have a splitting such that $A_k - W_k = \mathcal{O}(\varepsilon)$ (the constant in $\mathcal{O}$ may depend on k). Such robust smoothers are well known for some anisotropic problems. For anisotropic problems in which the anisotropy is *aligned with the gridlines* one

can use a line (Jacobi or Gauss–Seidel) method or an ILU factorization as a robust smoother. Theoretical analyses of these methods can be found in [29, 30, 34].

If the convection-diffusion problem (1.2) is discretized using standard finite differences it is easy to see that an appropriate line solver yields a robust smoother. However, in the finite element setting such line methods do *not yield a robust smoother*. This is clear from the stencil in (3.3). For $\varepsilon \to 0$ the diffusion part yields an x-line difference operator which can be represented exactly by an x-line smoother, but in the convection stencil the $[0 \ -\frac{1}{6} \ \frac{1}{6}]$ and $[-\frac{1}{6} \ \frac{1}{6} \ 0]$ parts of the difference operator are not captured by such a smoother. It is not clear to us how for the finite element discretization, with a stencil as in (3.3), a robust smoother can be constructed.

In multigrid analyses for reaction-diffusion or anisotropic diffusion problems one usually observes a ε^{-1} dependence in the standard approximation property that is then compensated by an ε factor from the smoothing property (cf. [21, 22, 29, 30, 34]). However, we cannot apply a similar technique, due to the fact that for our problem class a robust smoother is not available. Instead, we use another splitting of the iteration matrix of the two-grid method, leading to modified (ε-independent) smoothing and approximation properties. ∎

We consider a standard multigrid method with pre- and postsmoothers of the form as in (6.2), (6.4). In the analysis we will need different damping parameters for the pre- and postsmoother. Thus we introduce

$$S_{k,pr} := I - \omega_{k,pr} W_k^{-1} A_k, \quad S_{k,po} := I - \omega_{k,po} W_k^{-1} A_k.$$

We also define the transformed iteration matrices

$$\tilde{S}_{k,pr} := A_k S_{k,pr} A_k^{-1}, \quad \tilde{S}_{k,po} := A_k S_{k,po} A_k^{-1}.$$

We will analyze a standard two-grid method with iteration matrix

$$T_k = S_{k,po}^{\nu_k} \big(I - p_k A_{k-1}^{-1} r_k A_k\big) S_{k,pr}^{\mu_k}. \tag{6.5}$$

For the corresponding multigrid W-cycle the iteration matrix (cf. [10]) is given by

$$M_0^{\mathrm{mgm}} := 0, \quad M_k^{\mathrm{mgm}} = T_k + S_{k,po}^{\nu_k} p_k (M_{k-1}^{\mathrm{mgm}})^2 A_{k-1}^{-1} r_k A_k S_{k,pr}^{\mu_k}, \quad k > 1. \tag{6.6}$$

In the convergence analysis of this method the auxiliary inflow domain Ω_k^{in} defined in (5.18) plays a crucial role. As in the analysis of the upstream influence in section 5 we will use a cut-off function in the x-direction. We define diagonal matrices $\hat{\Phi}_k$, Φ_k as follows:

$$\xi := (3k+1)h_k, \quad \hat{\Phi}_k := \mathrm{diag}(\phi_1^\xi, \dots, \phi_{n_k}^\xi), \quad \Phi_k := I_{n_k - 1} \otimes \hat{\Phi}_k; \tag{6.7}$$

here ϕ_i^ξ is the cut-off function defined in (5.14) with $\xi = (3k+1)h_k$. For notational simplicity we drop the superscript ξ in ϕ_i^ξ in the remainder. Note that the diagonal matrix Φ_k is positive definite.

For any symmetric positive definite matrix $C \in \mathbb{R}^{m \times m}$ we define

$$\langle x, y \rangle_C := x^T C y, \quad \|x\|_C^2 := \langle x, x \rangle_C, \quad \|B\|_C := \|C^{\frac{1}{2}} B C^{-\frac{1}{2}}\|$$

with $x, y \in \mathbb{R}^m$, $B \in \mathbb{R}^{m \times m}$. Note that if $C = E^T E$ for some nonsingular matrix E then $\|B\|_C = \|EBE^{-1}\|$.

The convergence analysis is based on the following splitting, with $A := A_k$:

$$\begin{aligned}
\|T_k\|_{A^TA} &= \|S_{k,po}^{\nu_k}(I - p_k A_{k-1}^{-1} r_k A_k) S_{k,pr}^{\mu_k}\|_{A^TA} \\
&= \|S_{k,po}^{\nu_k}(A_k^{-1} - p_k A_{k-1}^{-1} r_k)\big((I - \Phi_k^{\frac{1}{2}}) + \Phi_k^{\frac{1}{2}}\big) A_k S_{k,pr}^{\mu_k}\|_{A^TA} \\
&\le \|S_{k,po}^{\nu_k}(A_k^{-1} - p_k A_{k-1}^{-1} r_k)(I - \Phi_k^{\frac{1}{2}}) A_k S_{k,pr}^{\mu_k}\|_{A^TA} \\
&\quad + \|S_{k,po}^{\nu_k}(A_k^{-1} - p_k A_{k-1}^{-1} r_k)\Phi_k^{\frac{1}{2}} A_k S_{k,pr}^{\mu_k}\|_{A^TA} \\
&\le \|\tilde{S}_{k,po}^{\nu_k} A_k W_k^{-1}\| \|W_k(A_k^{-1} - p_k A_{k-1}^{-1} r_k)(I - \Phi_k^{\frac{1}{2}})\| \|\tilde{S}_{k,pr}^{\mu_k}\| \\
&\quad + \|\tilde{S}_{k,po}^{\nu_k}\| \|I - A_k p_k A_{k-1}^{-1} r_k\| \|\Phi_k^{\frac{1}{2}} \tilde{S}_{k,pr}^{\mu_k}\|.
\end{aligned} \tag{6.8}$$

Remark 6.2. Note that the splitting in (6.8) differs from the usual splitting that is used in the theory based on the smoothing and approximation property introduced by Hackbusch (cf. [10]). In this theory the approximation property of the form $\|A_k^{-1} - p_k A_{k-1}^{-1} r_k\| \le C_A\, g(h_k, \varepsilon)$ is combined with a smoothing property of the form $\|A_k S_{k,po}^{\mu_k}\| \le \eta(\mu_k)\, g(h_k, \varepsilon)^{-1}$ with some $\eta(\mu_k)$ such that $\eta(\mu_k) \to 0,\ \mu_k \to \infty$ uniformly with respect to h_k and ε. In numerical experiments we observed that bounds of this type are not likely to be valid. Due to the fact that the smoother is not an exact solver for $\varepsilon \downarrow 0$ (cf. Remark 6.1), it is essential to have the preconditioner W_k as part of the approximation property. Furthermore, it turns out that for obtaining an appropriate bound for $\|W_k(A_k^{-1} - p_k A_{k-1}^{-1} r_k) f_k\|$ the right-hand side function f_k must vanish near the inflow boundary. We illustrate this by numerical experiments in section 11. This motivates the introduction of the "cut-off" matrix Φ_k in the decomposition.

We now formulate the main results on which the convergence analysis will be based. The proofs of these results will be given further on.

THEOREM 6.1. *The following holds:*

$$W_k A_k^{-1} \ge \frac{1}{8} I \quad \text{for} \quad k = 1, 2, \ldots . \tag{6.9}$$

Proof. The proof is given in section 7. ∎

LEMMA 6.2. *From* (6.9) *it follows that*

$$\|I - \omega A_k W_k^{-1}\| \le 1 \quad \text{for all} \ \ \omega \in \left[0, \frac{1}{4}\right].$$

Proof. The proof is elementary. ∎

Assumption 6.1. In the postsmoother $S_{k,po}$ we take $\omega_{k,po} := \frac{1}{8}$.

We note that the analysis below applies for any fixed $\omega_{k,po} \in (0, \frac{1}{8}]$. We obtain the following smoothing property.

COROLLARY 6.1. *There exists a constant c_1 independent of k and ε such that*

$$\|\tilde{S}_{k,po}^{\nu_k} A_k W_k^{-1}\| \le \frac{c_1}{\sqrt{\nu_k}}. \tag{6.10}$$

Proof. Follows from Lemma 6.2 and Theorem 10.6.8 in [10] (or results in [12, 24]). The result holds with $c_1 = \frac{32}{\sqrt{2\pi}}$. ∎

We now turn to the presmoother.

THEOREM 6.3. *There exist constants $d_1 > 0, d_2 > 0$ independent of k and ε such that*

$$\left\| \Phi_k^{\frac{1}{2}} \Big(I - \frac{d_1}{k^2} A_k W_k^{-1} \Big) \Phi_k^{-\frac{1}{2}} \right\| \leq 1 - \frac{d_2}{k^4}. \tag{6.11}$$

Proof. The proof is given in section 8. ∎

Assumption 6.2. In the presmoother $S_{k,pr}$ we take $\omega_{k,pr} := \min\{ \frac{1}{4}, \frac{d_1}{k^2} \}$.

Remark 6.3. The result in (6.11) can be written as $\|I - \frac{d_1}{k^2} A_k W_k^{-1}\|_{\Phi_k} \leq 1 - \frac{d_2}{k^4}$. Hence, we have a contraction result in the almost degenerated norm $\|\cdot\|_{\Phi_k}$. This norm, however, coincides with the Euclidean one for the vectors that have a support only in Ω_k^{in}. Hence the result in (6.11) indicates that the presmoother is a fast solver *near the inflow boundary* (cf. section 11).

Concerning the approximation property the following result holds.

THEOREM 6.4. *There exists a constant c_2 independent of k and ε such that*

$$\|W_k(A_k^{-1} - p_k A_{k-1}^{-1} r_k)(I - \Phi_k^{\frac{1}{2}})\| \leq c_2 \quad \textit{for} \quad k = 2, 3, \ldots . \tag{6.12}$$

Proof. The proof is given in section 10. ∎

Finally, we present two results related to stability of the coarse-grid correction. It is well known that for the canonical restriction operator the inequality

$$\|r_k\| \leq c_r$$

holds with a constant c_r independent of k. The second stability result is the following.

THEOREM 6.5. *There exists a constant c_3 independent of k and ε such that*

$$\|A_k p_k A_{k-1}^{-1}\| \leq c_3 \quad \textit{for} \quad k = 2, 3, \ldots . \tag{6.13}$$

Proof. The proof is given in section 9. ∎

We now obtain a two-grid convergence result.

THEOREM 6.6. *For the two-grid method we then have*

$$\|T_k\|_{A^T A} \leq \frac{c_1 c_2}{\sqrt{\nu_k}} + (1 + c_r c_3) \left(1 - \frac{d_2}{k^4} \right)^{\mu_k}.$$

Proof. The proof is based on results from (6.9), (6.11), (6.12), and (6.13). We use the splitting in (6.8). From the Assumptions 6.1 and 6.2 and Lemma 6.2 it follows that $\|\tilde{S}_{k,pr}\| \leq 1$ and $\|\tilde{S}_{k,po}\| \leq 1$. From Assumption 6.2, Theorem 6.3, and $\|\Phi_k\| \leq 1$ we obtain

$$\|\Phi_k^{\frac{1}{2}} \tilde{S}_{k,pr}^{\mu_k}\| \leq \|(\Phi_k^{\frac{1}{2}} \tilde{S}_{k,pr} \Phi_k^{-\frac{1}{2}})^{\mu_k}\| \|\Phi_k^{\frac{1}{2}}\| \leq \left(1 - \frac{d_2}{k^4} \right)^{\mu_k}$$

Combine these bounds with the results in Corollary 6.1 and Theorems 6.4 and 6.5. ∎

Using the two-grid result of Theorem 6.6 we derive a multigrid W-cycle convergence result based on standard arguments.

THEOREM 6.7. *In addition to the assumptions of Theorem* 6.6 *we assume that the number of smoothing steps on every grid level is sufficiently large:*

$$\nu_k \geq c_{po}, \quad \mu_k \geq c_{pr}\, k^4$$

with suitable constants c_{po}, c_{pr}. Then for the contraction number of the multigrid W-cycle the inequality

$$\|M_k^{\mathrm{mgm}}\|_{A^TA} \leq \xi^* \tag{6.14}$$

holds, with a constant $\xi^* < 1$ independent of k and ε.

Proof. Define $\xi_k := \|M_k^{\mathrm{mgm}}\|_{A_k^TA_k}$. Using the recursion relation (6.6) for M_k^{mgm} it follows that

$$\begin{aligned}\xi_k &\leq \|T_k\|_{A_k^TA_k} + \|\tilde{S}_{k,po}\|^{\nu_k}\|A_kp_kA_{k-1}^{-1}\|\xi_{k-1}^2\|r_k\|\|\tilde{S}_{k,pr}\|^{\mu_k} \\ &\leq \|T_k\|_{A_k^TA_k} + c_3c_r\xi_{k-1}^2.\end{aligned}$$

Now use the two-grid bound given in Theorem 6.6 and a fixed point argument. ∎

Remark 6.4. We briefly discuss the arithmetic work needed in one W-cycle iteration. The arithmetic work for a matrix vector multiplication on level k is of order $\mathcal{O}(N_k) = \mathcal{O}(n_k^2)$. The work needed in one smoothing iteration is of order $\mathcal{O}(N_k)$. The number of smoothings behaves like $\nu_k + \mu_k \sim k^4$. Using a standard recursive argument it follows that for a multigrid W-cycle iteration the arithmetic complexity is of the order $N_k(\ln N_k)^4$. Hence this multigrid method has suboptimal complexity.

7. Proof of Theorem 6.1. We recall the representation of the stiffness matrix in (3.4)

$$A_k = \left(\varepsilon + \left(\bar{\delta} - \frac{1}{3}\right)h_k\right)A_x + \varepsilon A_y + \frac{1}{6}BD_x.$$

We will need the following lemma:

LEMMA 7.1. *The inequality $BD_x \geq 0$ holds.*

Proof. The matrix $\frac{1}{6}BD_x - \frac{1}{3}h_kA_x$ is the stiffness matrix corresponding to the bilinear form $(u,v) \to \int_\Omega u_xv\,dxdy$. For any $x \in X_k$ we get

$$\frac{1}{6}\langle BD_xx,x\rangle_k - \frac{1}{3}\langle h_kA_xx,x\rangle_k = \int_\Omega (P_kx)_x(P_kx)\,dxdy = \frac{1}{2}\int_{\Gamma_E}(P_kx)^2\,dxdy \geq 0.$$

Since the matrix A_x is symmetric positive definite the result now follows. ∎

We now consider the preconditioner $W_k = \frac{4\varepsilon}{h_k^2}I + D_x$, as in (6.4).

THEOREM 7.2 (=Theorem 6.1). *The inequality $W_kA_k^{-1} \geq \frac{1}{8}I$ holds.*

Proof. First note that

$$h_k\hat{D}_x\hat{D}_x^T = \hat{D}_x + \hat{D}_x^T - \frac{1}{h_k}(1,0,\ldots,0)^T(1,0,\ldots,0) \leq \hat{D}_x + \hat{D}_x^T$$

and thus $h_k\hat{D}_x^T\hat{D}_x\hat{D}_x^T\hat{D}_x \leq \hat{D}_x^T(\hat{D}_x + \hat{D}_x^T)\hat{D}_x$ holds. Using $\hat{A}_x = \hat{D}_x^T\hat{D}_x$ this results in $h_k\hat{A}_x^2 \leq 2\hat{D}_x^T\hat{A}_x$ and thus

$$\frac{1}{2}h_kA_x^2 \leq D_x^TA_x. \tag{7.1}$$

Note that the following inequality holds for any $a,b,c \in \mathbb{R}$ and $\sigma_1,\sigma_2,\sigma_3 > 0$:

$$(a+b+c)^2 \leq (1+\sigma_2+\sigma_3^{-1})a^2 + (1+\sigma_3+\sigma_1^{-1})b^2 + (1+\sigma_1+\sigma_2^{-1})c^2.$$

We apply this inequality with $\sigma_2 = 2, \sigma_1 = \sigma_3 = 1$. Also using $\|A_y\| \leq 4h_k^{-2}$ and $\|B\| \leq 6$ we get for any $x \in \mathrm{X}_k$

$$\begin{aligned}\|A_k x\|^2 &\leq 4\varepsilon^2 \|A_y x\|^2 + 3\bar{\varepsilon}_k^2 \|A_x x\|^2 + \frac{5}{2}\left\|\frac{1}{6} B D_x x\right\|^2 \\ &\leq 16\left(\frac{\varepsilon}{h_k}\right)^2 \langle A_y x, x\rangle_k + 3\bar{\varepsilon}_k^2 \|A_x x\|^2 + \frac{5}{2}\|D_x x\|^2.\end{aligned} \tag{7.2}$$

We recall that $\bar{\varepsilon}_k = \varepsilon_k - \bar{\delta} h_k \leq \frac{7}{6} h_k$. Now apply the result (7.1) and the estimates in Lemmas 3.1 and Lemma 7.1 to obtain

$$\begin{aligned}\langle W_k x, A_k x\rangle_k &= \left\langle \frac{4\varepsilon}{h_k^2} x + D_x x\,,\, \varepsilon A_y x + \bar{\varepsilon}_k A_x x + \frac{1}{6} B D_x x \right\rangle_k \\ &\geq 4\left(\frac{\varepsilon}{h_k}\right)^2 \langle A_y x, x\rangle_k + \bar{\varepsilon}_k \langle D_x x, A_x x\rangle_k + \left\langle D_x x, \frac{1}{6} B D_x x\right\rangle_k \\ &\geq 4\left(\frac{\varepsilon}{h_k}\right)^2 \langle A_y x, x\rangle_k + \frac{3}{7}\bar{\varepsilon}_k^2 \|A_x x\|^2 + \frac{1}{3}\|D_x x\|^2 \\ &= \frac{1}{8}\left(32\left(\frac{\varepsilon}{h_k}\right)^2 \langle A_y x, x\rangle_k + \frac{24}{7}\bar{\varepsilon}_k^2 \|A_x x\|^2 + \frac{8}{3}\|D_x x\|^2\right) \\ &\geq \frac{1}{8}\left(16\left(\frac{\varepsilon}{h_k}\right)^2 \langle A_y x, x\rangle_k + 3\bar{\varepsilon}_k^2 \|A_x x\|^2 + \frac{5}{2}\|D_x x\|^2\right).\end{aligned}$$

Combination of this with the inequality in (7.2) proves the theorem. ∎

8. Proof of Theorem 6.3. We start with an elementary known result on the convergence of basic iterative methods.

LEMMA 8.1. *Assume $C, A, W \in \mathbb{R}^{n\times n}$ with C symmetric positive definite. If there are constants $c_0 > 0$, c_1 such that*

$$c_0 \langle Ay, Ay\rangle_C \leq \langle Wy, Wy\rangle_C \leq c_1 \langle Wy, Ay\rangle_C \quad \text{for all } y \in \mathbb{R}^n \tag{8.1}$$

then for arbitrary $d \in [0,1]$ we have

$$\|I - \alpha \frac{c_0}{c_1} A W^{-1}\|_C \leq \sqrt{1 - d\frac{c_0}{c_1^2}} \quad \text{if} \quad 1 - \sqrt{1-d} \leq \alpha \leq 1 + \sqrt{1-d}.$$

Proof. Let $D := AW^{-1}$. From (8.1) we get

$$\langle Dy, y\rangle_C \geq c_1^{-1} \langle y, y\rangle_C\,, \quad \langle Dy, Dy\rangle_C \leq c_0^{-1} \langle y, y\rangle_C \quad \text{for all } y.$$

Note that

$$\begin{aligned}\left\|\left(I - \alpha \frac{c_0}{c_1} A W^{-1}\right) y\right\|_C^2 &= \langle y, y\rangle_C - 2\alpha \frac{c_0}{c_1}\langle Dy, y\rangle_C + \alpha^2 \frac{c_0^2}{c_1^2}\langle Dy, Dy\rangle_C \\ &\leq \left(1 - 2\alpha \frac{c_0}{c_1^2} + \alpha^2 \frac{c_0}{c_1^2}\right)\|y\|_C^2 = \left(1 - (2\alpha - \alpha^2)\frac{c_0}{c_1^2}\right)\|y\|_C^2\end{aligned}$$

and $2\alpha - \alpha^2 \geq d$ if $1 - \sqrt{1-d} \leq \alpha \leq 1 + \sqrt{1-d}$. ∎

Below we use the scalar product $\langle \cdot,\cdot\rangle_\Phi := \langle \Phi_k \cdot,\cdot\rangle_k$ with Φ_k defined in (6.7). We recall the result proved in Lemma 5.3,

$$\langle A_k x, D_x x\rangle_\Phi \geq c\,\|D_x x\|_\Phi^2 \quad \text{for all} \;\; x \in X_k \tag{8.2}$$

with $c > 0$ independent of k and of ε.

We introduce the diagonal projection matrix $J_k := I_{n_k-1} \otimes \hat{J}_k$ with $\hat{J}_k$ the $n_k \times n_k$ diagonal matrix with $(\hat{J}_k)_{i,i} = 1$ if $(\hat{\Phi}_k)_{i,i} = 1$ and $(\hat{J}_k)_{i,i} = 0$ otherwise.

LEMMA 8.2. *There exists a constant $c > 0$ independent of k and ε such that*

$$\|W_k x\|_\Phi^2 \leq ck^2 \left(\frac{\varepsilon}{h_k^3} \|(I - J_k)x\|_\Phi^2 + \|D_x x\|_\Phi^2 \right) \quad \textit{for all} \;\; x \in X_k.$$

Proof. Note that

$$\begin{aligned} \|J_k x\|_\Phi &= \|J_k D_x^{-1} J_k D_x x\|_\Phi \leq \|J_k D_x^{-1} J_k\|_\Phi \|D_x x\|_\Phi \\ &= \|J_k D_x^{-1} J_k\| \|D_x x\|_\Phi \leq (3k+1) h_k \|D_x x\|_\Phi. \end{aligned}$$

And thus, using $\varepsilon \leq \frac{1}{2} h_k$ we get

$$\begin{aligned} \|W_k x\|_\Phi &= \left\| \frac{4\varepsilon}{h_k^2} x + D_x x \right\|_\Phi \leq \frac{4\varepsilon}{h_k^2} \|(I - J_k)x\|_\Phi + \frac{4\varepsilon}{h_k^2} \|J_k x\|_\Phi + \|D_x x\|_\Phi \\ &\leq \frac{4\varepsilon}{h_k^2} \|(I - J_k)x\|_\Phi + ck \|D_x x\|_\Phi \leq ck \left(\frac{4\varepsilon}{h_k^2} \|(I - J_k)x\|_\Phi + \|D_x x\|_\Phi \right). \end{aligned}$$

Squaring this result and using $(\frac{\varepsilon}{h_k^2})^2 \leq \frac{1}{2} \frac{\varepsilon}{h_k^3}$ completes the proof. ∎

We define $\hat{\Phi}_x := \frac{1}{h_k} \mathrm{diag}(\phi_i - \phi_{i+1})_{1 \leq i \leq n_k}$ with $\phi_i = \phi_i^\xi$ as in (6.7). Consider the diagonal matrix $\Phi_x := I_{n_k-1} \otimes \hat{\Phi}_x$. Note that $\Phi_x \geq 0$.

LEMMA 8.3. *The following estimate holds:*

$$\langle A_k x, x\rangle_\Phi \geq \frac{1}{30} \|\Phi_x^{\frac{1}{2}} x\|^2 \quad \textit{for all} \;\; x \in X_k.$$

Proof. Recall

$$A_k = \bar{\varepsilon}_k A_x + \varepsilon A_y + \frac{1}{6} B D_x. \tag{8.3}$$

Note that

$$\Phi_k A_y = (I_{n_k-1} \otimes \hat{\Phi}_k)(\hat{A}_y \otimes \hat{J}) = \hat{A}_y \otimes \hat{\Phi}_k \hat{J} \geq 0. \tag{8.4}$$

We consider the term $\bar{\varepsilon}_k \Phi_k A_x = \bar{\varepsilon}_k (I_{n_k-1} \otimes \hat{\Phi}_k \hat{A}_x)$. Note that $\hat{\Phi}_k \hat{A}_x = \hat{\Phi}_k \hat{D}_x^T \hat{D}_x$. A simple computation yields $\hat{\Phi}_k \hat{D}_x^T - \hat{D}_x^T \hat{\Phi}_k = -\hat{\Phi}_x \hat{T}$, with $\hat{T} := \mathrm{tridiag}(0,0,1)$, and thus

$$\bar{\varepsilon}_k \hat{\Phi}_k \hat{A}_x = \bar{\varepsilon}_k \hat{D}_x^T \hat{\Phi}_k \hat{D}_x - \bar{\varepsilon}_k \hat{\Phi}_x \hat{T} \hat{D}_x. \tag{8.5}$$

From the Cauchy–Schwarz inequality it follows that

$$\bar{\varepsilon}_k \langle \hat{\Phi}_x \hat{T} \hat{D}_x y, y\rangle \leq \bar{\varepsilon}_k^2 \frac{9}{4} \|\hat{\Phi}_x^{\frac{1}{2}} \hat{T} \hat{D}_x y\|^2 + \frac{1}{9} \|\hat{\Phi}_x^{\frac{1}{2}} y\|^2 \quad \text{for all} \;\; y \in \mathbb{R}^{n_k}. \tag{8.6}$$

Using the property (5.15) we get

$$\hat{T}^T\hat{\Phi}_x\hat{T} \le \bar{\varepsilon}_k^{-1}c_0\hat{\Phi}_k. \tag{8.7}$$

Combination of the results in (8.5), (8.6), (8.7) and using $c_0 \le \frac{4}{9}$ yields

$$\begin{aligned}\bar{\varepsilon}_k\langle\hat{\Phi}_k\hat{A}_x y, y\rangle &\ge \bar{\varepsilon}_k\|\hat{D}_x y\|^2_{\hat{\Phi}_k} - \bar{\varepsilon}_k\frac{9}{4}c_0\|\hat{D}_x y\|^2_{\hat{\Phi}_k} - \frac{1}{9}\|\hat{\Phi}_x^{\frac{1}{2}}y\|^2\\ &\ge -\frac{1}{9}\|\hat{\Phi}_x^{\frac{1}{2}}y\|^2 \quad \text{for all} \quad y\in\mathbb{R}^{n_k}.\end{aligned}$$

And thus

$$\bar{\varepsilon}_k\Phi_k A_x \ge -\frac{1}{9}\Phi_x \tag{8.8}$$

holds. Finally we consider the term $\frac{1}{6}\langle BD_x x, x\rangle_\Phi$. First we note

$$BD_x = \text{blocktridiag}(\hat{D}_x, 4\hat{D}_x, \hat{S}_x), \quad \hat{S}_x := \frac{1}{h_k}\begin{pmatrix}-1 & 1 & & \\ & \ddots & \ddots & \\ & & -1 & 1\\ & & & 0\end{pmatrix} \in \mathbb{R}^{n_k\times n_k}$$

and thus $K := \frac{1}{6}\Phi_k BD_x = \frac{1}{6}\text{blocktridiag}(\hat{\Phi}_k\hat{D}_x, 4\hat{\Phi}_k\hat{D}_x, \hat{\Phi}_k\hat{S}_x)$. Hence

$$\frac{1}{2}(K+K^T) = \frac{1}{12}\text{blocktridiag}\big(\hat{\Phi}_k\hat{D}_x + \hat{S}_x^T\hat{\Phi}_k, 4(\hat{\Phi}_k\hat{D}_x + \hat{D}_x^T\hat{\Phi}_k), \hat{\Phi}_k\hat{S}_x + \hat{D}_x^T\hat{\Phi}_k\big).$$

A simple computation yields

$$\hat{\Phi}_k\hat{D}_x + \hat{D}_x^T\hat{\Phi}_k = \hat{\Phi}_x + \frac{1}{h_k}\text{tridiag}(-\phi_i, \phi_i+\phi_{i+1}, -\phi_{i+1})_{1\le i\le n_k} =: \hat{\Phi}_x + R \tag{8.9}$$

and $\hat{\Phi}_k\hat{S}_x + \hat{D}_x^T\hat{\Phi}_k = \hat{\Phi}_x\hat{T} + \frac{1}{h_k}\phi_n e_n e_n^T$, with $n := n_k$ and e_n the nth basis vector in $\mathbb{R}^n$. Thus we obtain

$$\begin{aligned}\frac{1}{2}(K+K^T) &= \frac{1}{12}\text{blocktridiag}\big(\hat{T}^T\hat{\Phi}_x, 4\hat{\Phi}_x, \hat{\Phi}_x\hat{T}\big)\\ &\quad + \frac{1}{12}\text{blocktridiag}\left(\frac{1}{h_k}\phi_n e_n e_n^T, 4R, \frac{1}{h_k}\phi_n e_n e_n^T\right)\\ &\ge \frac{1}{12}\text{blocktridiag}\big(\hat{T}^T\hat{\Phi}_x, 4\hat{\Phi}_x, \hat{\Phi}_x\hat{T}\big).\end{aligned}$$

By $\hat{\Phi}_x^{-1}$ (Φ_x^{-1}) we denote the pseudoinverse of $\hat{\Phi}_x$ (Φ_x). We then have

$$\frac{1}{2}\Phi_x^{-\frac{1}{2}}(K+K^T)\Phi_x^{-\frac{1}{2}} \ge \frac{1}{12}\text{blocktridiag}\big(\hat{\Phi}_x^{-\frac{1}{2}}\hat{T}^T\hat{\Phi}_x^{\frac{1}{2}}, 4I, \hat{\Phi}_x^{\frac{1}{2}}\hat{T}\hat{\Phi}_x^{-\frac{1}{2}}\big).$$

Note that

$$\|\hat{\Phi}_x^{-\frac{1}{2}}\hat{T}^T\hat{\Phi}_x^{\frac{1}{2}}\|_\infty = \|\hat{\Phi}_x^{\frac{1}{2}}\hat{T}\hat{\Phi}_x^{-\frac{1}{2}}\|_\infty = \max_{i\ge 3k+2}\left(\frac{\phi_{i-1}-\phi_i}{\phi_i-\phi_{i+1}}\right)^{\frac{1}{2}} = e^{\frac{1}{8}}.$$

And thus we get $\frac{1}{2}\Phi_x^{-\frac{1}{2}}(K+K^T)\Phi_x^{-\frac{1}{2}} \ge \frac{1}{12}(4-2e^{\frac{1}{8}})I$. Hence

$$\frac{1}{6}\Phi_k BD_x = K \ge \frac{1}{6}(2-e^{\frac{1}{8}})\Phi_x. \tag{8.10}$$

Combination of the results in (8.3), (8.4), (8.8), and (8.10) yields

$$\Phi_k A_k \geq \left(-\frac{1}{9} + \frac{1}{6}(2 - e^{\frac{1}{8}}) \right) \Phi_x > \frac{1}{30}\Phi_x. \qquad \square$$

Using the previous two lemmas we can show a result as in the second inequality in (8.1).

THEOREM 8.4. *There exists a constant c_1 independent of k and ε such that*

$$\langle W_k x, W_k x\rangle_\Phi \leq c_1 k^2 \langle W_k x, A_k x\rangle_\Phi \quad \textit{for all } \; x \in X_k.$$

Proof. From Lemma 8.3 and (8.2) we get

$$\begin{aligned} \langle W_k x, A_k x\rangle_\Phi &= \frac{4\varepsilon}{h_k^2}\langle x, A_k x\rangle_\Phi + \langle D_x x, A_k x\rangle_\Phi \\ &\geq c\left(\frac{\varepsilon}{h_k^2}\langle \Phi_x x, x\rangle_k + \|D_x x\|_\Phi^2 \right) \end{aligned} \tag{8.11}$$

with $c > 0$ independent of k and ε. Using $\phi_i - \phi_{i+1} = (1 - e^{-\frac{1}{4}})\phi_i \geq \frac{1}{5}\phi_i$ for $i \geq 3k+1$ we get

$$\langle \Phi_x x, x\rangle_k \geq \frac{1}{5} h_k^{-1} \langle (I - J_k)\Phi_k x, x\rangle_k = \frac{1}{5} h_k^{-1} \|(I - J_k)x\|_\Phi^2. \tag{8.12}$$

From (8.11) and (8.12) we obtain

$$\langle W_k x, A_k x\rangle_\Phi \geq c\left(\frac{\varepsilon}{h_k^3}\|(I - J_k)x\|_\Phi^2 + \|D_x x\|_\Phi^2 \right)$$

Now combine this with the result in Lemma 8.2. $\square$

We now consider the first inequality in (8.1).

THEOREM 8.5. *There exists a constant $c_0 > 0$ independent of k and ε such that*

$$c_0 \langle A_k x, A_k x\rangle_\Phi \leq \langle W_k x, W_k x\rangle_\Phi \quad \textit{for all } \; x \in X_k.$$

Proof. The constants c that appear in the proof are all strictly positive and independent of k and ε. First note that $\|A_k x\|_\Phi \leq \bar{\varepsilon}_k \|A_x x\|_\Phi + \varepsilon \|A_y x\|_\Phi + \frac{1}{6}\|B D_x x\|_\Phi$. We have

$$\|A_y\|_\Phi = \|(I_{n_k - 1} \otimes \hat{\Phi}_k^{\frac{1}{2}})(\hat{A}_y \otimes \hat{J})(I_{n_k - 1} \otimes \hat{\Phi}_k^{-\frac{1}{2}})\| = \|\hat{A}_y \otimes \hat{J}\| \leq \frac{4}{h_k^2}.$$

Note that $|\phi_i \phi_{i+1}^{-1}| \leq e^{\frac{1}{4}}$ and thus $\|\hat{\Phi}_k^{\frac{1}{2}} \hat{D}_x^T \hat{\Phi}_k^{-\frac{1}{2}}\| \leq c h_k^{-1}$ holds. From this it follows that $\|D_x^T\|_\Phi \leq c h_k^{-1}$ holds. With a similar argument we get $\|B\|_\Phi \leq c$. Thus we obtain, using $\bar{\varepsilon}_k \leq \frac{3}{2} h_k$,

$$\begin{aligned} \|A_k x\|_\Phi &\leq \bar{\varepsilon}_k \|D_x^T\|_\Phi \|D_x x\|_\Phi + \frac{4\varepsilon}{h_k^2}\|x\|_\Phi + c\|D_x x\|_\Phi \\ &\leq c\left(\frac{\varepsilon}{h_k^2}\|x\|_\Phi + \|D_x x\|_\Phi \right). \end{aligned} \tag{8.13}$$

From (8.9) it follows that $\langle D_x x, x\rangle_\Phi \geq 0$ holds. Using this we get

$$\begin{aligned}\|W_k x\|_\Phi^2 &= \frac{16\varepsilon^2}{h_k^4}\|x\|_\Phi^2 + \frac{16\varepsilon}{h_k^2}\langle D_x x, x\rangle_\Phi + \|D_x x\|_\Phi^2 \\ &\geq c\left(\frac{\varepsilon^2}{h_k^4}\|x\|_\Phi^2 + \|D_x x\|_\Phi^2\right).\end{aligned} \tag{8.14}$$

Now combine (8.13) with (8.14). ∎

Combination of the results of Theorems 8.4 and 8.5 with the second result in Lemma 8.1 shows that Theorem 6.3 holds.

9. Proof of Theorem 6.5. Let $\mathrm{g}_{k-1} \in X_{k-1}$ be given and define $g_{k-1} := (P_{k-1}^*)^{-1}\mathrm{g}_{k-1} \in \mathbb{V}_{k-1}$. Let $u_{k-1} \in \mathbb{V}_{k-1}$ be such that

$$a_{k-1}(u_{k-1}, v_{k-1}) = (g_{k-1}, v_{k-1}) \quad \text{for all} \quad v_{k-1} \in \mathbb{V}_{k-1}.$$

Then $A_{k-1}^{-1}\mathrm{g}_{k-1} = P_{k-1}^{-1}u_{k-1}$ holds. The corresponding continuous solution $u \in \mathbf{V}$ satisfies $a_{k-1}(u, v) = (g_{k-1}, v)$ for all $v \in \mathbf{V}$. Now note that

$$\begin{aligned}\|A_k p_k A_{k-1}^{-1}\mathrm{g}_{k-1}\| &= \max_{y\in X_k}\frac{\langle A_k p_k P_{k-1}^{-1}u_{k-1}, y\rangle_k}{\|y\|} \leq c\max_{v_k\in\mathbb{V}_k}\frac{a_k(u_{k-1}, v_k)}{\|v_k\|} \\ &\leq c\max_{v_k\in\mathbb{V}_k}\frac{a_{k-1}(u_{k-1}, v_k)}{\|v_k\|} + c\max_{v_k\in\mathbb{V}_k}\frac{a_k(u_{k-1}, v_k) - a_{k-1}(u_{k-1}, v_k)}{\|v_k\|}.\end{aligned} \tag{9.1}$$

Define $e_{k-1} := u - u_{k-1}$. For the first term in (9.1) we get, using the results of Lemma 4.3,

$$\begin{aligned}a_{k-1}(u_{k-1}, v_k) &\leq |a_{k-1}(e_{k-1}, v_k)| + |a_{k-1}(u, v_k)| \\ &\leq ch_k\|(e_{k-1})_x\|\|(v_k)_x\| + \varepsilon\|(e_{k-1})_y\|\|(v_k)_y\| + \|(e_{k-1})_x\|\|v_k\| + |(g_{k-1}, v_k)| \\ &\leq c\left(\|(e_{k-1})_x\| + \frac{\varepsilon}{h_k}\|(e_{k-1})_y\|\right)\|v_k\| + \|g_{k-1}\|\|v_k\| \\ &\leq c\|g_{k-1}\|\|v_k\| \leq c\|\mathrm{g}_{k-1}\|\|v_k\|.\end{aligned} \tag{9.2}$$

For the second term in (9.1) we have, using Lemma 4.2,

$$\begin{aligned}|a_k(u_{k-1}, v_k) - a_{k-1}(u_{k-1}, v_k)| &= \bar{\delta}h_k|((u_{k-1})_x, (v_k)_x)| \\ &\leq c\|(u_{k-1})_x\|\|v_k\| \\ &\leq c\|g_{k-1}\|\|v_k\| \leq c\|\mathrm{g}_{k-1}\|\|v_k\|.\end{aligned} \tag{9.3}$$

Combination of the results in (9.1), (9.2), and (9.3) yields $\|A_k p_k A_{k-1}^{-1}\mathrm{g}_{k-1}\| \leq c\|\mathrm{g}_{k-1}\|$ and thus the result in Theorem 6.5 holds. ∎

10. Proof of Theorem 6.4. We briefly comment on the idea of the proof. As usual to prove an estimate for the error in the L^2-norm we use a duality argument. However, the formal dual problem has poor regularity properties, since in this dual problem Γ_E is the "inflow" boundary and Γ_W is the "outflow" boundary. Thus Dirichlet outflow boundary conditions would appear and we obtain poor estimates due to the poor regularity. To avoid this, we consider a dual problem with Neumann outflow and Dirichlet inflow conditions. To be able to deal with the inconsistency caused by these "wrong" boundary conditions we *assume* the right-hand side is zero

near the boundary Γ_W. In order to satisfy this assumption we use the cut-off operator with matrix Φ_k.

A further problem we have to deal with is the fact that due to the level dependent stabilization term we have to treat k-dependent bilinear forms.

We introduce the space

$$\mathbb{V}_k^0 := \{ v_k \in \mathbb{V}_k \mid v_k(x) = 0 \quad \text{for all} \quad x \in \Omega_k^{in} \}.$$

Let $\hat{b}_k \in X_k$ be given. In view of Theorem 6.4 we must prove an estimate $\|W_k(A_k^{-1} - p_k A_{k-1}^{-1} r_k)(I - \Phi_k)\hat{b}_k\| \leq c\|\hat{b}_k\|$ with a constant c that is independent of k, ε, and $\hat{b}_k$. Note that $(P_k^*)^{-1}(I - \Phi_k^{\frac{1}{2}})\hat{b}_k =: f_k \in \mathbb{V}_k^0$ holds. For this $f_k \in \mathbb{V}_k^0$ we define corresponding discrete solutions and continuous solutions as follows:

$$\begin{aligned}
u_k \in \mathbb{V}_k : &\quad a_k(u_k, v_k) = (f_k, v_k) && \text{for all} \quad v_k \in \mathbb{V}_k, \\
u \in \mathbf{V} : &\quad a_k(u, v) = (f_k, v) && \text{for all} \quad v \in \mathbf{V}, \\
u_{k-1} \in \mathbb{V}_{k-1} : &\quad a_{k-1}(u_{k-1}, v_{k-1}) = (f_k, v_{k-1}) && \text{for all} \quad v_{k-1} \in \mathbb{V}_{k-1}, \\
\tilde{u} \in \mathbf{V} : &\quad a_{k-1}(\tilde{u}, v) = (f_k, v) && \text{for all} \quad v \in \mathbf{V}.
\end{aligned} \tag{10.1}$$

In the proof of Lemma 4.2 we showed that $\|v_x\| = \|D_x P_k^{-1} v\|$ holds for all $v \in \mathbb{V}_k$. We use that $W_k = \frac{4\varepsilon}{h_k^2} I + D_x$ and obtain

$$\begin{aligned}
\|W_k(A_k^{-1} - p_k A_{k-1}^{-1} r_k)(I - \Phi_k^{\frac{1}{2}})\hat{b}_k\| &\leq \frac{4\varepsilon}{h_k^2} \|(A_k^{-1} - p_k A_{k-1}^{-1} r_k)(I - \Phi_k^{\frac{1}{2}})\hat{b}_k\| \\
&\quad + \|D_x A_k^{-1}(I - \Phi_k^{\frac{1}{2}})\hat{b}_k\| + \|D_x p_k A_{k-1}^{-1} r_k (I - \Phi_k^{\frac{1}{2}})\hat{b}_k\| \\
&\leq c \left(\frac{\varepsilon}{h_k^2} \|u_k - u_{k-1}\| + \|(u_k)_x\| + \|(u_{k-1})_x\| \right) \\
&\leq c \left(\frac{\varepsilon}{h_k^2} \big(\|u - u_k\| + \|\tilde{u} - u_{k-1}\| + \|u - \tilde{u}\| \big) + \|(u_k)_x\| + \|(u_{k-1})_x\| \right).
\end{aligned} \tag{10.2}$$

From Lemma 4.2 we get

$$\|(u_k)_x\| + \|(u_{k-1})_x\| \leq c\|f_k\|. \tag{10.3}$$

From the result in Theorem 10.1 below it follows that

$$\|u_k - u\| + \|u_{k-1} - \tilde{u}\| \leq c \, \frac{h_k^2}{\varepsilon} \, \|f_k\|. \tag{10.4}$$

Finally, from Theorem 10.4 we have

$$\|u - \tilde{u}\| \leq c \, h_k \|f_k\|. \tag{10.5}$$

If we insert the results (10.3),(10.4), and (10.5) in (10.2) we get

$$\|W_k(A_k^{-1} - p_k A_{k-1}^{-1} r_k)(I - \Phi_k^{\frac{1}{2}})\hat{b}_k\| \leq c\|f_k\| \leq c\|(P_k^*)^{-1}\| \|I - \Phi_k^{\frac{1}{2}}\| \|\hat{b}_k\| \leq c\|\hat{b}_k\|$$

and thus the result of Theorem 6.4 is proved. It remains to prove the results in Theorems 10.1 and 10.4.

THEOREM 10.1. *For $f_k \in \mathbb{V}_k^0$ let u and u_k be as defined in* (10.1). *Then*

$$\|u - u_k\| \leq c \, \frac{h_k^2}{\varepsilon} \, \|f_k\| \tag{10.6}$$

holds.

Proof. Define $e_k := u - u_k$. Let $w \in H^2(\Omega)$ be such that

$$-\varepsilon w_{yy} - \varepsilon_k w_{xx} - w_x = e_k \tag{10.7}$$

with

$$w_x = 0 \text{ on } \Gamma_W \ , \quad w = 0 \text{ on } \Gamma \setminus \Gamma_W. \tag{10.8}$$

Note that for this problem Γ_E is the "inflow" boundary and Γ_W is the "outflow" boundary. We multiply (10.7) with e_k and integrate by parts to get

$$\begin{aligned}\|e_k\|^2 &= \varepsilon((e_k)_y, w_y) + \varepsilon_k((e_k)_x, w_x) - \varepsilon_k \int_{\Gamma_E} w_x e_k \, dy + ((e_k)_x, w) \\ &= a_k(e_k, w) - \varepsilon_k \int_{\Gamma_E} w_x e_k \, dy.\end{aligned}$$

We use (4.6) with w and e_k instead of u and f, respectively, and (4.12) to estimate

$$\left|\varepsilon_k \int_{\Gamma_E} w_x e_k \, dy\right| \le \varepsilon_k^{\frac{1}{2}} \left(\varepsilon_k \int_{\Gamma_E} w_x^2 \, dy\right)^{\frac{1}{2}} \left(\int_{\Gamma_E} e_k^2 \, dy\right)^{\frac{1}{2}} \le c\, h_k^{\frac{1}{2}} \|e_k\| \frac{h_k}{\sqrt{\varepsilon}} \|f_k\|. \tag{10.9}$$

From this estimate and the Galerkin orthogonality for the error it follows that for any $v_k \in \mathbb{V}_k$

$$\begin{aligned}\|e_k\|^2 \le{}& \varepsilon\, ((e_k)_y, (w - v_k)_y) + \varepsilon_k\, ((e_k)_x, (w - v_k)_x) \\ &+ ((e_k)_x, w - v_k) + c\, \|e_k\| \frac{h_k^{\frac{3}{2}}}{\sqrt{\varepsilon}} \|f_k\|.\end{aligned} \tag{10.10}$$

Let $\Omega_h := \Omega_{h_k}$ be as defined in (5), i.e., Ω_h is the set of triangles with at least one vertex on Γ_W. In the remainder of the domain, $\omega = \Omega \backslash \Omega_h$, we take v_k as a nodal interpolant to w and we put $v_k = 0$ on Γ_W to ensure $v_k \in \mathbb{V}_k$. Note that v_k is a proper interpolant of w everywhere in Ω except in Ω_h. Therefore we will estimate scalar products in (10.10) over ω and Ω_h, separately. We continue (10.10) with

$$\begin{aligned}\|e_k\|^2 &\le c\, \varepsilon\, h_k \|(e_k)_y\|_\omega \|w\|_{H^2(\omega)} + c\, \varepsilon_k\, h_k \|(e_k)_x\|_\omega \|w\|_{H^2(\omega)} \\ &\quad + c\, h_k^2 \|(e_k)_x\|_\omega \|w\|_{H^2(\omega)} + c\, \|e_k\| \frac{h_k^{\frac{3}{2}}}{\sqrt{\varepsilon}} \|f_k\| + \mathrm{I}_{\Omega_h} \\ &\le c\, h_k^2 \|f_k\| \frac{1}{\varepsilon} \|e_k\| + \mathrm{I}_{\Omega_h}.\end{aligned} \tag{10.11}$$

The term I_{Ω_h} collects integrals over Ω_h:

$$\mathrm{I}_{\Omega_h} = \varepsilon\, ((e_k)_y, (w - v_k)_y)_{\Omega_h} + \varepsilon_k\, ((e_k)_x, (w - v_k)_x)_{\Omega_h} + ((e_k)_x, w - v_k)_{\Omega_h}\,.$$

To estimate I_{Ω_h} we use Corollary 5.7 and the following auxiliary estimate for the interpolant $v_k \in \mathbb{V}_k$ of w, with $\omega_h = \{(x, y) \in \Omega : x \in (h_k, 2h_k)\}$:

$$\begin{aligned}\|v_k\|_{\Omega_h} &\le c\|v_k\|_{\omega_h} \le c(\|w\|_{\omega_h} + \|v_k - w\|_\omega) \\ &= c\left(\left(\int_0^1 \int_{h_k}^{2h_k} \left[w(0, y) + \int_0^x w_\eta(\eta, y)\, d\eta \right]^2 dx\, dy \right)^{\frac{1}{2}} + \|v_k - w\|_\omega \right) \\ &\le c\left(h_k^{\frac{1}{2}} \left(\int_{\Gamma_W} w^2 \, dy \right)^{\frac{1}{2}} + h_k \|w_x\| + h_k^2 \|w\|_{H^2(\omega)} \right) \le c \left(h_k^{\frac{1}{2}} + \frac{h_k^2}{\varepsilon} \right) \|e_k\|.\end{aligned}$$

We proceed estimating terms from I_{Ω_h}, where we use the previous result:

$$\begin{aligned}
\varepsilon\,((e_k)_y,(w-v_k)_y)_{\Omega_h} &\le \varepsilon\|(e_k)_y\|_{\Omega_h}\,(\|w_y\|+\|(v_k)_y\|_{\Omega_h})\\
&\le c\,\varepsilon^{\frac12}h_k\|f_k\|\,(\varepsilon^{-\frac12}\|e_k\|+h_k^{-1}\|v_k\|_{\Omega_h})\\
&\le c\,\varepsilon^{\frac12}h_k\|f_k\|\left(\varepsilon^{-\frac12}+h_k^{-\frac12}+\frac{h_k}{\varepsilon}\right)\|e_k\|\le c\left(h_k+\frac{h_k^2}{\sqrt{\varepsilon}}\right)\|f_k\|\|e_k\|,\\
\varepsilon_k\,((e_k)_x,(w-v_k)_x)_{\Omega_h} &\le \varepsilon_k\|(e_k)_x\|_{\Omega_h}\,(\|w_x\|+\|(v_k)_x\|_{\Omega_h})\\
&\le c\,h_k^{\frac12}\varepsilon_k\|f_k\|\,(\|e_k\|+h_k^{-1}\|v_k\|_{\Omega_h})\le c\left(h_k+\frac{h_k^{\frac52}}{\varepsilon}\right)\|f_k\|\|e_k\|,\\
((e_k)_x,w-v_k)_{\Omega_h} &\le \|(e_k)_x\|_{\Omega_h}(\|w\|_{\Omega_h}+\|v_k\|_{\Omega_h})\\
&\le c\,h_k^{\frac12}\|f_k\|\left(h_k^{\frac12}\left(\int_{\Gamma_W}w^2\,dy\right)^{\frac12}+h_k\|w_x\|_{\Omega_h}+\|v_k\|_{\Omega_h}\right)\\
&\le c\left(h_k+\frac{h_k^{\frac52}}{\varepsilon}\right)\|f_k\|\|e_k\|.
\end{aligned}$$

Inserting these estimates into (10.11) and using $\varepsilon\le\frac12 h_k$ we obtain

$$\|e_k\|^2\le c\,\frac{h_k^2}{\varepsilon}\|f_k\|\|e_k\|+c\left(h_k+\frac{h_k^2}{\sqrt{\varepsilon}}+\frac{h_k^{\frac52}}{\varepsilon}\right)\|f_k\|\|e_k\|\le c\,\frac{h_k^2}{\varepsilon}\|f_k\|\|e_k\|.$$

and thus the theorem is proved. ∎

For the proof of Theorem 10.4 we first formulate two lemmas.

LEMMA 10.2. *Consider a function $g\in\mathrm{H}^1(\Omega)$. The solution of*

$$-\varepsilon_k u_{xx}-\varepsilon u_{yy}+u_x=g_x \tag{10.12}$$

with boundary conditions as in (1.2) *satisfies*

$$\int_{\Gamma_E}u^2\,dy\le c\left(h_k^{-1}\,\|g\|^2+\int_{\Gamma_E}g^2\,dy+h_k\,\|g_x\|^2\right). \tag{10.13}$$

Proof. We multiply (10.12) with u and integrate by parts to get

$$\varepsilon_k\|u_x\|^2+\varepsilon\|u_y\|^2+\frac12\int_{\Gamma_E}u^2\,dy=-(g,u_x)+\int_{\Gamma_E}g\,u\,dy. \tag{10.14}$$

For the right-hand side in (10.14) we have

$$|(g,u_x)|\le\|g\|\|u_x\|\le c\,\|g\|\|g_x\|\le c\,\left(h_k^{-1}\,\|g\|^2+h_k\|g_x\|^2\right)$$

and

$$\int_{\Gamma_E}g\,u\,dy\le\int_{\Gamma_E}g^2\,dy+\frac14\int_{\Gamma_E}u^2\,dy.$$

Combining these estimates and (10.14) the lemma is proved. ∎

LEMMA 10.3. *Assume $g \in H^1$ and $g|_{\Gamma_E} = 0$, let u be the corresponding solution of* (10.12). *Then the following holds:*

$$\|u\| \le c \left(\|g\| + h_k \|g_x\| + \left(\int_{\Gamma_W} g^2 \, dy \right)^{\frac{1}{2}} + h_k \left(\int_{\Gamma_W} u_x^2 \, dy \right)^{\frac{1}{2}} \right). \tag{10.15}$$

(Note that the standard a priori estimates would give only $\|u\| \le c \|g_x\|$.)

Proof. Consider the auxiliary function $v(x,y) := \int_0^x u(\xi, y) \, d\xi$. It satisfies

$$-\varepsilon_k v_{xx} - \varepsilon v_{yy} + v_x = g + \varepsilon_k u_{in} + g_{in}, \tag{10.16}$$

with $u_{in}(x,y) = u_x(0,y)$ and $g_{in} = g(0,y)$. The corresponding boundary conditions are

$$v_x = u(1,y) \text{ on } \Gamma_E \,, \qquad v = 0 \text{ on } \partial\Omega \setminus \Gamma_E. \tag{10.17}$$

Then the estimate (10.15) is equivalent to

$$\|v_x\| \le c \left(\|g\| + h_k \|g_x\| + \left(\int_{\Gamma_W} g^2 \, dy \right)^{\frac{1}{2}} + h_k \left(\int_{\Gamma_W} u_x^2 \, dy \right)^{\frac{1}{2}} \right). \tag{10.18}$$

The estimate (10.18) is proved by the following arguments. We multiply (10.16) with v_x and integrate by parts to obtain

$$\begin{aligned} &\|v_x\|^2 + \frac{\varepsilon}{2} \int_{\Gamma_E} (v_y)^2 \, dy + \frac{\varepsilon_k}{2} \int_{\Gamma_W} (v_x)^2 \, dy \\ &\qquad = (g, v_x) + \varepsilon_k (u_{in}, v_x) + (g_{in}, v_x) + \frac{\varepsilon_k}{2} \int_{\Gamma_E} (v_x)^2 \, dy. \end{aligned} \tag{10.19}$$

Since $g|_{\Gamma_E} = 0$ the estimate (10.13) yields

$$\int_{\Gamma_E} (v_x)^2 \, dy = \int_{\Gamma_E} u^2 \, dy \le c \left(h_k^{-1} \|g\|^2 + h_k \|g_x\|^2 \right). \tag{10.20}$$

Now (10.18) follows from (10.19) by applying the Cauchy inequality and estimate (10.20). ∎

Using these lemmas we can prove the final result we need.

THEOREM 10.4. *For $f \in \mathbb{V}_k^0$ let u and $\tilde{u}$ be the continuous solutions defined in* (10.1). *Then the following holds:*

$$\|u - \tilde{u}\| \le c \, h_k \|f_k\|. \tag{10.21}$$

Proof. The difference $e := u - \tilde{u}$ solves the equation

$$-\varepsilon_k e_{xx} - \varepsilon e_{yy} + e_x = g_x, \tag{10.22}$$

with $g = -\bar{\delta} h_k \tilde{u}_x$ and boundary conditions as in (1.2). Now the result of Lemma 10.3 can be applied. We obtain

$$\begin{aligned} \|e\| &\le c \left(\|g\| + h_k \|g_x\| + \left(\int_{\Gamma_W} g^2 \, dy \right)^{\frac{1}{2}} + h_k \left(\int_{\Gamma_W} e_x^2 \, dy \right)^{\frac{1}{2}} \right) \\ &\le c \, h_k \left(\|\tilde{u}_x\| + h_k \|\tilde{u}_{xx}\| + \left(\int_{\Gamma_W} u_x^2 \, dy \right)^{\frac{1}{2}} + \left(\int_{\Gamma_W} \tilde{u}_x^2 \, dy \right)^{\frac{1}{2}} \right). \end{aligned}$$

To estimate the norms $\|\tilde{u}_x\|$ and $\|\tilde{u}_{xx}\|$ we use a priori bounds from Theorem 4.1. Further we use the fact that $f_k = 0$ in Ω_k^{in}. Due to the choice of Ω_k^{in} (cf. (5.18)) we can apply Corollary 5.2 with $\xi = h_k$, $\eta = \varepsilon_k |\ln h_k| + h_k$, and $p = \frac{1}{2}$. Using (5.5) and $\varepsilon_k \geq \frac{1}{3} h_k$ we get $\int_{\Gamma_W} u_x^2 \, dy \leq c \, \|f_k\|^2$. The same estimate holds for $\int_{\Gamma_W} \tilde{u}_x^2 \, dy$. Thus we obtain $\|e\| \leq c \, h_k \|f_k\|$. ∎

11. Numerical experiments. In this section we present results of a few numerical experiments to illustrate that in a certain sense our analysis is sharp. In particular it will be shown that the nonstandard splitting in (6.8) which forms the basis of our convergence analysis reflects some important phenomena.

In the experiments we use the following parameters. For $\bar{\delta}$ in (2.4) we take $\bar{\delta} = \frac{1}{2}$. The pre- and postsmoother are as in (6.2), (6.4) with $\omega_k = 1$. We take a random right-hand side vector and a starting vector equal to zero. For the stopping criterion we take a reduction of the relative residual by a factor 10^9 . Thus in the tables below convergence is measured in the norm $\|\cdot\|_{A^T A}$. We use the notation $Pe_h := \frac{h}{2\varepsilon}$.

First we present results for a standard V-cycle with $\mu_k = \nu_k = 2$. In Table 11.1 we give the number of iterations needed to satisfy the stopping criterion and (between brackets) the average residual reduction per iteration. These results clearly show robustness of the multigrid solver. For a W-cycle we also observed robust results.

TABLE 11.1
Multigrid convergence: V-cycle with $\nu_k = \nu_k = 2$.

	h			
Pe_h	1/8	1/32	1/128	1/512
1	**8**(0.06)	**10**(0.12)	**11**(0.13)	**11**(0.13)
10	**7**(0.04)	**8**(0.07)	**8**(0.07)	**8**(0.07)
1e+3	**8**(0.05)	**11**(0.14)	**11**(0.14)	**11**(0.14)
1e+5	**7**(0.04)	**11**(0.14)	**11**(0.14)	**11**(0.14)

Number of iterations and average reduction factor.

If we consider only the smoother and do not use a coarse grid correction, then for $\varepsilon \approx h$ this method has an h-dependent convergence rate. This is illustrated in Table 11.2.

We consider the standard splitting in the convergence analysis based on the smoothing and approximation property. For $\varepsilon = h^2$ some results are presented in Table 11.3. The estimates that are given in this table result from the computation of

$$\frac{\|(A_h^{-1} - p A_{2h}^{-1} r)\hat{f}\|}{\|\hat{f}\|} \quad \text{and} \quad \frac{\|(A_h S_h^2)\hat{f}\|}{\|\hat{f}\|}$$

TABLE 11.2
h-dependence of convergence of the smoothing iterations.

	h			
Pe_h	1/8	1/32	1/128	1/512
1	**119**(0.83)	**244**(0.91)	**533**(0.94)	**1495**(0.986)
10	**26**(0.44)	**51**(0.61)	**66**(0.72)	**173**(0.88)

Number of iterations and average reduction factor.

with $\hat{f} \in \mathbb{V}_h$ a discrete point source in the grid point $(\frac{1}{2}, \frac{1}{2})$. These results indicate $\mathcal{O}(h^{-1})$ behavior for the smoothing property (as expected) and $\mathcal{O}(\sqrt{h})$ behavior for the approximation property. Hence this splitting is not satisfactory for proving a robustness result.

TABLE 11.3
Standard splitting for approximation and smoothing properties.

	h			
Estimates for	1/8	1/32	1/128	1/512
$\|A_h^{-1} - pA_{2h}^{-1}r\|$	8.4e-2	5.0e-2	2.7e-2	1.4e-2
$\|A_h S_h^2\|$	1.25	4.48	17.7	70.8

The proof of the modified approximation property is based on the result in Theorem 10.1. In that theorem a $\frac{h_k^2}{\varepsilon}$ bound is proved *provided the right-hand side function f_k is zero close to the inflow boundary.* We performed an experiment with a function f_k which has values equal to one in all grid points $(h_k, jh_k),\ j = 1, \ldots, n_k$, and zero elsewhere. Results are given in Table 11.4. We observe an $h_k^{-\frac{1}{2}}$ effect. This justifies the splitting using the cut-off operator Φ_k.

TABLE 11.4
Approximation property if f_k has support near inflow.

	h			
Pe_h	1/8	1/32	1/128	1/512
1	0.31	0.60	1.23	2.53
10	0.07	0.17	0.23	0.46

Values of $\frac{\varepsilon}{h^2}\|(A_h^{-1} - pA_{2h}^{-1}r)f\|/\|f\|$.

Finally we performed a numerical experiment related to the result in Theorem 6.3. For the smoother we computed residual reduction factors in the almost degenerated norm $\|\Phi_k^{\frac{1}{2}} \cdot\|$ with $\Phi_k := I_{n_{k-1}} \otimes \mathrm{diag}(\phi)$ and

$$\phi_i = \begin{cases} 1 & \text{for } 1 \le i < 5, \\ \exp(4-i) & \text{for } 5 \le i \le n_k. \end{cases}$$

For the relaxation parameter ω in the smoother we take the value $\omega = 1.2$. The results in Table 11.5 show h-independent and "fast" convergence of the smoother in this norm.

TABLE 11.5
Residual reduction of the smoother in the $\|\Phi^{\frac{1}{2}} \cdot\|$-norm.

DIFFERENCE APPROXIMATIONS OF THE NEUMANN PROBLEM FOR THE SECOND ORDER WAVE EQUATION*

HEINZ-OTTO KREISS†, N. ANDERS PETERSSON‡, AND JACOB YSTRÖM§

Abstract. Stability theory and numerical experiments are presented for a finite difference method that directly discretizes the Neumann problem for the second order wave equation. Complex geometries are discretized using a Cartesian embedded boundary technique. Both second and third order accurate approximations of the boundary conditions are presented. Away from the boundary, the basic second order method can be corrected to achieve fourth order spatial accuracy. To integrate in time, we present both a second order and a fourth order accurate explicit method. The stability of the method is ensured by adding a small fourth order dissipation operator, locally modified near the boundary to allow its application at all grid points inside the computational domain. Numerical experiments demonstrate the accuracy and long-time stability of the proposed method.

1. Introduction.

There are many methods to solve the wave equation numerically. Methods based on variational principles [1] have the advantage that the energy is conserved, but they are not as efficient as difference methods. On the other hand, difference methods are prone to instabilities. To avoid these one often has to add dissipative terms, and the energy is not conserved. Luckily, the instabilities are often weak and caused by high frequency waves which are not accurately represented anyway. Therefore, one constructs the dissipation in such a way that it acts mainly only on these frequencies. We feel that the fixation on energy conservation often goes too far. Large phase-errors can destroy the solution as well.

In this paper we continue the development of numerical methods that directly discretize the second order wave equation without first rewriting it as a system of first order equations. In particular, we want to discuss the kind of instabilities that can arise and how to control them. Since we treated the Dirichlet problem in [9], we consider here only the Neumann problem

$$\begin{aligned} u_{tt} &= \Delta u + F(\boldsymbol{x},t), \quad \boldsymbol{x}\in\Omega,\ t>0,\\ \frac{\partial u}{\partial n}(\boldsymbol{x},t) &= f(\boldsymbol{x},t), \quad \boldsymbol{x}\in\Gamma,\ t>0,\\ u(\boldsymbol{x},0) = u_0(\boldsymbol{x}), &\quad u_t(\boldsymbol{x},0) = u_1(\boldsymbol{x}), \quad \boldsymbol{x}\in\Omega, \end{aligned} \tag{1.1}$$

where Ω is a bounded one- or two-dimensional domain with boundary Γ.

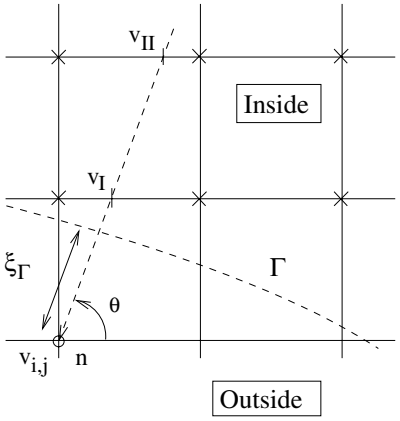

FIG. 1. *The points used for discretizing the Neumann boundary condition.*

We will discretize (1.1) on a Cartesian embedded boundary grid. The embedded boundary technique for discretizing partial differential equations dates back to the first order technique by Weller and Shortley [15] and the higher order generalizations of Collatz [3]. More recently, several embedded boundary methods have been presented for various types of partial differential equations. For example, Pember et al. [12] used a Cartesian grid method for solving the time-dependent equations of gas dynamics. Zhang and LeVeque [16] solved the acoustic wave equation with discontinuous coefficients written as a first order system. They derived special difference stencils that satisfy the jump conditions at the interior interfaces, where the coefficients are discontinuous. A staggered grid method was used by Ditkowski, Dridi, and Hesthaven [4] for solving Maxwell's equations on a Cartesian grid. The methods described in these papers all solve first order systems (in time). For Poisson's equation with Dirichlet boundary conditions, Johansen and Colella [6] derived an embedded boundary technique based on the finite volume method combined with multigrid.

We proceed by presenting the highlights of our proposed method. The domain Ω is covered by a Cartesian grid with step size h where the grid points are located at $\boldsymbol{x}_{i,j} = (x_i, y_j)^T = (ih, jh)^T$, and the boundary Γ is allowed to cut through the grid in an arbitrary manner; see Figure 1. Let $t_n = nk$, $k = 0, 1, 2, \ldots$, denote the time-discretization with step size k, and let $v_{i,j}^n$ be the difference approximation of $u(x_i, y_j, t_n)$. A second order accurate approximation of the Laplacian of u is given by

$$\Delta_h v_{i,j}^n =: \frac{1}{h^2}(v_{i+1,j}^n + v_{i-1,j}^n + v_{i,j+1}^n + v_{i,j-1}^n - 4v_{i,j}^n). \tag{1.2}$$

To be able to evaluate $\Delta_h v_{i,j}^n$ at all grid points inside Ω, we use ghost points just outside the domain. Consider the case in Figure 1 where the grid point $\boldsymbol{x}_{i,j}$ is outside of Ω, but $\boldsymbol{x}_{i,j+1}$ is inside. To aid in the approximation of the Neumann boundary condition, we construct a third order accurate interpolant between three points along the normal: $(0, v_{i,j}^n)$, (ξ_I, v_I^n), (ξ_{II}, v_{II}^n). Here ξ_I and $\xi_{II} = 2\xi_I$ are the distances between $\boldsymbol{x}_{i,j}$, along the normal going through that point, and the horizontal grid lines y_{j+1} and y_{j+2}, respectively. After differentiating the interpolant, we get a second order accurate approximation of the (outward) normal derivative

$$D_n^{(2)} v_{i,j}^n =: g_0 v_{i,j}^n + g_I v_I^n + g_{II} v_{II}^n = \frac{\partial v}{\partial n}(\boldsymbol{x}_{i,j}^\Gamma, t_n) + O(h^2), \tag{1.3}$$

where $\boldsymbol{x}_{i,j}^{\Gamma}$ is the intersection point between the boundary and the normal going through $\boldsymbol{x}_{i,j}$. The coefficients g_j are given by

$$g_0 = \frac{3\xi_I - 2\xi_\Gamma}{2\xi_I^2}, \quad g_I = \frac{2\xi_\Gamma - 2\xi_I}{\xi_I^2}, \quad g_{II} = \frac{\xi_I - 2\xi_\Gamma}{2\xi_I^2}, \tag{1.4}$$

where ξ_Γ is the distance between $\boldsymbol{x}_{i,j}$ and the boundary. Since the coefficients $g_j = \mathcal{O}(1/h)$, we need to use third order accurate approximations for v_I^n and v_{II}^n. Here we use Lagrangian interpolation along the grid lines y_{j+1} and y_{j+2}:

$$\begin{aligned} v_I^n &= c_0 v_{i,j+1}^n + c_1 v_{i+1,j+1}^n + c_2 v_{i+2,j+1}^n, \\ v_{II}^n &= c_3 v_{i,j+2}^n + c_4 v_{i+1,j+2}^n + c_5 v_{i+2,j+2}^n. \end{aligned}$$

The resulting formula for $D_n^{(2)} v_{i,j}$ holds when the angle θ between the x-axis and the normal satisfies $\pi/4 \le \theta \le \pi/2$. When $0 \le \theta \le \pi/4$, the horizontal interpolations to obtain v_I and v_{II} are replaced by corresponding interpolations in the vertical direction. The expressions in the remaining three quadrants are simply obtained by reflections in index space, leading to a total of eight different cases to treat all possible directions of the boundary.

The second order boundary condition formula results in an overall second order scheme, but since the boundary condition is discretized using one-sided differences, the truncation error will be larger at the boundary than in the interior, where a centered scheme is used. We can easily modify the above technique to construct a third order accurate formula $D_n^{(3)} v_{i,j}$ to make the coefficient in front of the leading second order truncation error term smaller. In this case, three interior values v_I, v_{II}, and v_{III} are interpolated using fourth order Lagrangian interpolation along three contiguous grid lines. Hence this stencil involves 12 interior points. The third order boundary condition formula works nicely for well-resolved geometries where there are enough interior points. For less resolved geometries, or for very thin regions where two parts of the boundary are close to each other, we will use the second order boundary condition formula.

All ghost point values in (1.2) can be eliminated using formulas of the type (1.3). The discrete approximation of the Laplacian of u (for functions subject to the boundary condition $\partial u/\partial n = f(\boldsymbol{x}^{\Gamma}, t)$) can then be written in matrix form:

$$\Delta u = A\boldsymbol{v} + \boldsymbol{b}(t) + O(h^2). \tag{1.5}$$

Here the array $\boldsymbol{v}$ contains the solution at all grid points inside Ω, and $\boldsymbol{b}(t)$ is the discrete counterpart of the boundary forcing $f(\boldsymbol{x}_\Gamma, t)$.

Because of the discretized form of the Neumann boundary condition, the matrix A will not be symmetric. As a result, the basic scheme proposed in [9],

$$\frac{\boldsymbol{v}^{n+1} - 2\boldsymbol{v}^n + \boldsymbol{v}^{n-1}}{k^2} = A\boldsymbol{v}^n + \boldsymbol{b}(t_n) + \boldsymbol{F}(t_n),$$

suffers from a weak instability (here $\boldsymbol{F}(t_n)$ is the discretized version of the internal forcing $F(\boldsymbol{x}, t_n)$). The definition of a weak instability will be given in section 4. To understand the loss of stability, we analyze a number of model problems. We start with the one-dimensional half-plane (section 2) and strip (section 3) problems, proving that the difference approximation is stable in these cases, without damping. The two-dimensional case is analyzed in sections 4–6, where we show that the tangential

derivatives that occur in the truncation error of the boundary condition can lead to instabilities, both for the half-plane and strip problems. We also show that our scheme can be stabilized by a small fourth order artificial dissipation of the type $h^3\Delta^2\boldsymbol{v}_t$. However, a centered finite difference stencil such as $\Delta_h^2\boldsymbol{v}_t$ is wider than the discretized Laplacian, so it is not possible to use this damping term all the way up to the boundary (without adding extra numerical boundary conditions). Instead, we suggest using the discrete operator $h^3A^T(A(\boldsymbol{v}^n-\boldsymbol{v}^{n-1})/k)$ which *can* be applied all the way up to the boundary. Away from the boundary, it is equivalent to $\Delta_h^2(\boldsymbol{v}^n-\boldsymbol{v}^{n-1})/k$. For the general case with inhomogeneous boundary conditions and internal forcing, the proposed scheme becomes

$$\frac{\boldsymbol{v}^{n+1}-2\boldsymbol{v}^n+\boldsymbol{v}^{n-1}}{k^2} = A\boldsymbol{v}^n+\boldsymbol{b}(t_n)+\boldsymbol{F}(t_n) - \alpha h^3A^T\left(A(\boldsymbol{v}^n-\boldsymbol{v}^{n-1})/k+\frac{d\boldsymbol{b}}{dt}(t_n)\right). \tag{1.6}$$

We note that the sparse structure of A can be used to efficiently evaluate both $A\boldsymbol{v}$ and $A^T\boldsymbol{v}$, without the need to store the matrix explicitly; see Appendix A.

In section 7.1, we will demonstrate that this discretization does not suffer from the "small cell" stiffness problem that commonly is encountered when the finite volume method is used on a Cartesian grid with an embedded boundary; cf. [2]. We will also show that the damping term inflicts an $\mathcal{O}(h^2)$ perturbation of the undamped scheme (section 7.2), and by numerical experiments in section 8 we will demonstrate that it suffices to take α very small (of the order $\mathcal{O}(10^{-3})$). Hence, the resulting numerical solution will be second order accurate, and the scheme is well suited for long-time calculations where it is important to keep damping to a minimum. In section 7.3, we also present correction terms that optionally can be added to make the scheme fourth order accurate in time and space (away from the boundary). A number of numerical examples are presented in section 8 to assess the accuracy and long-time stability of the method with and without fourth order corrections, both for smooth boundaries and in the presence of corners. The proposed method is finally used for a resonance analysis of wave propagation in a harbor.

2. The one-dimensional half-plane problem. We start with the half-plane problem

$$\begin{gathered} u_{tt}=u_{xx},\quad 0\le x<\infty,\ t\ge 0,\\ u(x,0)=f(x),\end{gathered} \tag{2.1}$$

with boundary conditions

$$u_x(0,t)=0,\qquad \lim_{x\to\infty}u(x,t)=0. \tag{2.2}$$

Let $x_\nu=\nu h$, $h>0$, denote the grid points, $v(x_\nu,t)$ be a grid function, and $D_+v(x_\nu,t)=(v(x_{\nu+1},t)-v(x_\nu,t))/h$ represent the usual forward difference operator. We want to solve (2.1), (2.2) by the simplest central difference approximation

$$\begin{gathered} v_{tt}(x_\nu,t)=D_+D_-v(x_\nu,t),\quad \nu=1,2,\dots,\\ v(x_\nu,0)=f(x_\nu),\end{gathered} \tag{2.3}$$

with boundary conditions

$$D_+v(0,t)+\alpha hD_+^2v(0,t)+\beta h^2D_+^3v(0,t)=0,\qquad \lim_{x_\nu\to\infty}v(x_\nu,t)=0. \tag{2.4}$$

If we set $\alpha = \beta = 0$ or $\alpha = -\frac{1}{2},\ \beta = 0$, we obtain a first order or second order accurate approximation, respectively. In these cases we can prove stability by energy estimates; see [9]. If $\alpha = -\frac{1}{2}$ and $\beta = \frac{1}{3}$, we obtain the third order accurate approximation

$$D_+ v(0,t) - \frac{1}{2} h D_+^2 v(0,t) + \frac{1}{3} h^2 D_+^3 v(0,t) = 0. \tag{2.5}$$

In this case, we do not know how to prove stability by energy estimates. Instead, we will use mode analysis.

For simplicity, we keep time continuous. In actual calculations we use the method of lines. In [10] we have shown that the stability of the semidiscrete approximation implies the stability of the totally discretized method for most standard methods of lines.

By stability we mean here that there are no exponentially growing solutions. Therefore, a test for stability is that (2.3), (2.4) has no solutions of type

$$v(x_\nu, t) = e^{st} \varphi(x_\nu), \quad |\varphi(x_\nu)| \leq \text{const} \tag{2.6}$$

for $\operatorname{Re} s > 0$, satisfying the boundary condition (2.4). Introducing (2.6) into (2.3) gives us

$$h^2 s^2 \varphi(x_\nu) = h^2 D_+ D_- \varphi(x_\nu) = \varphi(x_\nu + h) - 2\varphi(x_\nu) + \varphi(x_\nu - h). \tag{2.7}$$

Since (2.7) is a difference equation with constant coefficients, its general solution is of the form

$$\varphi(x_\nu) = \sigma_1 \kappa_1^\nu + \sigma_2 \kappa_2^\nu, \tag{2.8}$$

where κ_1, κ_2 are solutions of the characteristic equation

$$(\kappa - 1)^2 - h^2 s^2 \kappa = 0. \tag{2.9}$$

We have $\kappa_2 = \kappa_1^{-1}$, and we simplify the notation by removing the index of the roots and set $\kappa_1 = \kappa$, $\kappa_2 = \kappa^{-1}$.

LEMMA 2.1. *For $|hs| \ll 1$, the roots of* (2.9) *are of the form*

$$\begin{aligned} \kappa &= 1 - hs + \frac{h^2 s^2}{2} + \mathcal{O}(h^3 s^3) = e^{-hs(1+\mathcal{O}(h^2 s^2))}, \\ \kappa^{-1} &= 1 + hs + \frac{h^2 s^2}{2} + \mathcal{O}(h^3 s^3) = e^{hs(1+\mathcal{O}(h^2 s^2))}. \end{aligned} \tag{2.10}$$

Also, for $\operatorname{Re} s > 0$, (2.9) *has no root with $|\kappa| = 1$ and exactly one root κ with $|\kappa| < 1$.*

Proof. Equation (2.10) follows by asymptotic expansion of the roots. (It is not surprising: The corresponding solutions of (2.1) are e^{-sx}, e^{sx}, and (2.3) is second order accurate.)

Assume that (2.9) has a solution

$$|\kappa| = 1, \quad \text{i.e.,} \quad \kappa = e^{i\tau},\ \tau \text{ real},$$

for some s with $\operatorname{Re} s > 0$. Then (2.9) becomes

$$-4 \sin^2(\tau/2) = h^2 s^2.$$

Therefore, $\operatorname{Re} s = 0$, which is a contradiction.

For $hs \to \infty$, $s > 0$ real, the solutions of (2.9) satisfy

$$\lim_{hs\to\infty} \kappa = 0, \qquad \lim_{hs\to\infty} \kappa^{-1} = \infty.$$

Since the roots are smooth functions of s and $|\kappa| \neq 1$ for $\operatorname{Re} s > 0$, we always have $|\kappa| < 1$, $|\kappa^{-1}| > 1$. This proves the lemma. □

The lemma shows that the solution can only stay bounded in space if $\sigma_2 = 0$, so

$$\varphi(x_\nu) = \sigma_1 \kappa^\nu, \quad |\kappa| < 1. \tag{2.11}$$

Introducing (2.11) into the boundary condition (2.4) gives us

$$(\kappa - 1)(1 + \alpha(\kappa - 1) + \beta(\kappa - 1)^2) = 0. \tag{2.12}$$

The cubic equation (2.12) has three roots $\kappa = \kappa_j$, $j = 1, 2, 3$, which lead to possible solutions of (2.6). We obtain the corresponding s from the characteristic equation (2.9), i.e.,

$$hs = \pm\sqrt{\frac{(\kappa - 1)^2}{\kappa}} = \pm(\kappa^{1/2} - \kappa^{-1/2}). \tag{2.13}$$

The first root, $\kappa_1 = 1$, does not generate a growing solution. In fact, any root with $|\kappa| = 1$ has this property, since inserting $\kappa = e^{i\xi}$ into (2.13) yields

$$hs = \pm 2i \sin\frac{\xi}{2}, \quad \text{i.e.,} \quad \operatorname{Re} s = 0. \tag{2.14}$$

Roots with $|\kappa| > 1$ are not permissible because $\varphi(x_\nu) = \sigma\kappa^\nu$ becomes unbounded as $\nu \to \infty$ and violates the boundary condition (2.4). However, solutions of the type $\kappa = e^{i\xi - \eta}$, ξ, η real, $\eta > 0$, correspond to

$$h\operatorname{Re} s = \pm(e^{-\eta/2} - e^{\eta/2}) \cos\frac{\xi}{2},$$

which grows rapidly in time if $\xi \neq \pi + 2n\pi$, $n = 0, 1, 2, \ldots$. These solutions decay rapidly away from the boundary, and we therefore denote these solutions as *boundary layer instabilities*.

Often one tries to stabilize numerical methods by adding a dissipative term to the difference equation. Instead of (2.3), we then consider

$$v_{tt} = D_+ D_- v + \sigma h D_+ D_- v_t.$$

For boundary layer instabilities, this does not work. If the boundary layer is oscillatory, then one can stabilize the method, but the amount of necessary dissipation is, in general, too large for accuracy reasons. Therefore, the only useful boundary condition approximations are those where $|\kappa_2| > 1$, $|\kappa_3| > 1$. While this condition is violated for general coefficients α, β, it is easy to see that the third order approximation (2.5) satisfies the requirement. That approximation has $\alpha = -\frac{1}{2}$, $\beta = \frac{1}{3}$, and (2.12) has the solutions

$$\kappa_1 = 1, \quad \kappa_{2,3} = \frac{7}{4} \pm i\sqrt{3 - \frac{9}{16}}, \quad |\kappa_{2,3}| = \frac{\sqrt{88}}{4} > \frac{9}{4}. \tag{2.15}$$

3. The one-dimensional strip problem. We consider now the wave equation (2.1) for $0 \le x \le 1$, $t \ge 0$. As boundary conditions we use

$$u_x(0,t) = 0, \qquad u(1,t) = 0. \tag{3.1}$$

We approximate the continuous problem by

$$\begin{aligned} v_{tt}(x_\nu,t) = D_+D_-v(x_\nu,t), \quad \nu = 1,2,\dots,N-1, \quad Nh = 1, \\ v(x_\nu,0) = f(x_\nu), \end{aligned} \tag{3.2}$$

with boundary conditions

$$\begin{aligned} L_hv =: D_+v(0,t) - \frac{1}{2}hD_+^2v(0,t) + \frac{1}{3}h^2D_+^3v(0,t) = 0, \\ v(1,t) = 0. \end{aligned} \tag{3.3}$$

For the analytic problem (2.1), (3.1) there is an energy estimate. Also, we can represent the solution by an eigenfunction expansion

$$u(x,t) = \sum_{j=0}^{\infty} e^{\lambda_j t}\psi_j(x).$$

The eigenvalues λ_j are purely imaginary and are solutions of the eigenvalue problem

$$\lambda^2\psi = \psi_{xx}, \qquad \psi_x(0) = \psi(1) = 0. \tag{3.4}$$

Again we want to investigate whether (3.2), (3.3) has exponentially growing solutions. We make the ansatz (2.6) and obtain

$$\begin{aligned} h^2s^2\varphi(x_\nu) = h^2D_+D_-\varphi(x_\nu), \\ L_h\varphi = 0, \quad \varphi(1) = 0, \end{aligned} \tag{3.5}$$

and start our discussion with the case that $|sh| \ll 1$. The discretized eigenvalue problem (3.5) is an approximation of the continuous problem (3.4), and since the difference stencil is compact, solutions of (3.5) with $|sh| \ll 1$ are close to solutions of the continuous problem; see Kreiss [7]. The question is whether the eigenvalues also are purely imaginary.

The general solution of (3.5) is

$$\varphi(x_\nu) = \sigma_1\kappa_1^\nu + \sigma_2\kappa_2^\nu, \tag{3.6}$$

where κ_j, $j = 1,2$, are the solutions of the characteristic equation (2.9)

$$\kappa^2 - (2 + h^2s^2)\kappa + 1 = 0.$$

Therefore, $\kappa_1\kappa_2 = 1$, i.e., $\kappa_2 = \kappa_1^{-1}$. By (2.10) we can write

$$\kappa_1 = e^{h\tilde{s}}, \quad \kappa_2 = e^{-h\tilde{s}}, \quad \tilde{s} =: s(1 + \mathcal{O}(h^2s^2)),$$

and

$$\varphi(x) = \sigma_1e^{\tilde{s}x} + \sigma_2e^{-\tilde{s}x}, \quad x = x_\nu,\ \nu = 0,1,2,\dots,N, \quad Nh = 1.$$

For smooth functions $w(x)$,

$$L_h w = w_x(0) + \gamma_4 h^3 w_{xxxx}(0) + \gamma_5 h^4 w_{xxxxx}(0) + \mathcal{O}(h^5).$$

Therefore, introducing (3.6) into the boundary conditions gives us

$$\sigma_1(1 + \tilde{\gamma}_4 h^3 \tilde{s}^3 + \tilde{\gamma}_5 h^4 \tilde{s}^4) - \sigma_2(1 - \tilde{\gamma}_4 h^3 \tilde{s}^3 + \tilde{\gamma}_5 h^4 \tilde{s}^4) = 0, \tag{3.7}$$

$$\sigma_1 e^{\tilde{s}} + \sigma_2 e^{-\tilde{s}} = 0. \tag{3.8}$$

Here

$$\tilde{\gamma}_4 = \gamma_4 + \gamma_{41}\tilde{s}^2 h^2 + \cdots, \quad \tilde{\gamma}_5 = \gamma_5 + \gamma_{51}\tilde{s}^2 h^2 + \cdots$$

account for the higher order terms.

There is a nontrivial solution of (3.7), (3.8) if and only if

$$\frac{\sigma_2}{\sigma_1} = -e^{2\tilde{s}} = \frac{1 + \tilde{\gamma}_5 h^4 \tilde{s}^4 + \tilde{\gamma}_4 h^3 \tilde{s}^3}{1 + \tilde{\gamma}_5 h^4 \tilde{s}^4 - \tilde{\gamma}_4 h^3 \tilde{s}^3}.$$

If $|sh| \ll 1$, then the eigenvalues of (3.5) converge to the eigenvalues $\lambda_n = i(\frac{\pi}{2} + n\pi)$ of (3.4) where $|h\lambda_n| \ll 1$. Thus we make the ansatz

$$h\tilde{s} = h\lambda_n + ih\tau = ih\mu_n + ih\tau, \quad \mu_n = \frac{\pi}{2} + n\pi,$$

and obtain

$$e^{2i\tau} = \frac{1 + \tilde{\gamma}_5((\mu_n + \tau)h)^4 - i\tilde{\gamma}_4((\mu_n + \tau)h)^3}{1 + \tilde{\gamma}_5((\mu_n + \tau)h)^4 + i\tilde{\gamma}_4((\mu_n + \tau)h)^3} =: S. \tag{3.9}$$

Since $\tilde{\gamma}_4$, $\tilde{\gamma}_5$ are real and bounded and μ_n is real, an asymptotic expansion of $|S|$ in h yields

$$|S| = 1 + \mathcal{O}(|\tau|^3 h^3) = e^{2i\tau}.$$

Hence, τ must be real-valued; that is, $\tilde{s}$ must be purely imaginary. By the above expansion, it follows that there is a unique solution close to λ_n with

$$i\tau = i\tilde{\gamma}_4(\mu_n h)^3 + \mathcal{O}((\mu_n h)^4), \ \tau \text{ real}.$$

Thus the eigenvalues of the discrete problem are purely imaginary, provided $|sh| \ll 1$.

Now we consider the case that $|sh| \geq \tilde{\delta} > 0$. The characteristic equation (2.9) implies

$$|\kappa - 1|^2 = |sh|^2|\kappa| \geq \tilde{\delta}^2|\kappa|.$$

Hence, when $|\kappa| \geq 1/2$,

$$|\kappa - 1| \geq \tilde{\delta}/\sqrt{2} = \delta > 0.$$

Furthermore, when $|\kappa| \leq 1/2$, the triangle inequality gives $|1 - \kappa| \geq 1 - |\kappa| \geq 1/2$. Thus κ cannot be arbitrarily close to 1 when $|sh| \geq \tilde{\delta} > 0$.

In the following, we use the representation

$$\varphi(x_\nu) = \sigma_1 \kappa^{+\nu} + \sigma_2 \kappa^{-\nu}, \quad |\kappa| \geq 1.$$

The discrete eigenvalue problem (3.5) has a nontrivial solution if and only if

$$\sigma_1 P_h(\kappa - 1) + \sigma_2 P_h(\kappa^{-1} - 1) = 0, \qquad \sigma_1 \kappa^N + \sigma_2 \kappa^{-N} = 0,$$

i.e.,

$$\kappa^N P_h(\kappa^{-1} - 1) - \kappa^{-N} P_h(\kappa - 1) = 0, \tag{3.10}$$

has a nontrivial solution. Here

$$P_h(y) = y - \frac{1}{2}y^2 + \frac{1}{3}y^3 \equiv y(y - y_2)(y - y_3), \quad y_{2,3} = \frac{3}{4} \pm i\sqrt{3 - \frac{9}{16}}. \tag{3.11}$$

LEMMA 3.1. *There is a constant $C > 0$ such that* (3.10) *has no solution for*

$$|\kappa| \geq e^{Ch}.$$

Proof. Assume that $|\kappa| = e^{Ch}$. By (3.11), the zeros of $P_h(y)$ are $y = 0$ and $y = y_{2,3}$ with $\operatorname{Re} y_{2,3} = 3/4$. For $|\kappa - 1| \geq \delta$ and $|\kappa| \geq 1$, κ^{-1} is inside the unit circle but bounded away from 1. Therefore, $\kappa^{-1} - 1$ is inside a unit circle centered at -1 but bounded away from zero. There are no zeros of P_h in this region, and we have

$$\min_{|\kappa|\geq 1,\, |\kappa - 1| \geq \delta} |P_h(\kappa^{-1} - 1)| \geq d > 0.$$

Since $|\kappa|^N = e^C$, and $\kappa^{-3} P_h(\kappa - 1) \leq \text{const}$ for $|\kappa| \geq 1$,

$$|\kappa^{-N} P_h(\kappa - 1)| = |\kappa^{-N+3}|\, |\kappa^{-3} P_h(\kappa - 1)| \leq \text{const}\ e^{-C},$$
$$|\kappa^N P_h(\kappa^{-1} - 1)| \geq d e^C.$$

Hence, (3.10) has no solution if C is sufficiently large, and the lemma follows. ∎

We can now prove the following theorem.

THEOREM 3.2. *For sufficiently small h, all eigenvalues s of* (3.5) *are purely imaginary and the discrete problem* (3.2), (3.3) *is stable.*

Proof. We have already shown that all eigenvalues with $|sh| \ll 1$ are purely imaginary. For $|sh| \geq \tilde{\delta}$, the eigenvalue problem (3.5) has a solution if and only if (3.10) has a solution with $|\kappa| \geq 1$ and $|\kappa - 1| \geq \delta$. We can write (3.10) in the form

$$Q(\kappa) =: \frac{P_h(\kappa^{-1} - 1)}{P_h(\kappa - 1)} = \kappa^{-2N}. \tag{3.12}$$

By noting that $\overline{P_h(y)} = P_h(\overline{y})$ and that $\overline{e^{i\xi} - 1} = e^{-i\xi} - 1$, it is easy to see that

$$|Q(e^{i\xi})| = 1, \quad |(e^{i\xi})^{-2N}| = 1.$$

Now consider $\kappa = e^{i\xi + \eta h}$, $0 \leq \eta \leq C$. Then,

$$|Q(e^{i\xi+\eta h})| = 1 + \mathcal{O}(\eta h), \quad \text{but } |(e^{i\xi+\eta h})^{-2N}| = e^{-2\eta}. \tag{3.13}$$

For sufficiently small h, (3.12) can only have solutions for $\eta = 0$ since only the left-hand side of (3.13) scales with h. Lemma 3.1 tells us that (3.10) has no solution for $|\kappa| \geq e^{Ch}$, and we conclude that all solutions of (3.10) must have $|\kappa| = 1$. By solving the characteristic equation (2.9) for s and setting $\kappa = e^{i\xi}$, we get (2.14) which shows that all eigenvalues are purely imaginary.

Since we can represent the solution of the discrete problem (3.2), (3.3) in an eigenfunction expansion where all eigenvalues are purely imaginary, there can be no exponentially growing solutions, and we conclude that the discrete problem is stable. ∎

4. A continuous two-dimensional model problem. We now start our discussion of two-dimensional problems. The results from the one-dimensional model seem to indicate that we need only to avoid boundary instabilities. However, there are also highly oscillatory instabilities which can be controlled by small amounts of dissipation. As will be demonstrated in section 5, our embedded boundary approximation of the Neumann condition in general two-dimensional domains introduces truncation errors in both the tangential and normal directions. To illustrate the type of instabilities that the tangential terms can give, we study the solutions of the wave equation with perturbed Neumann conditions. We start with the half-plane problem

$$\begin{aligned} u_{tt} &= u_{xx} + u_{yy}, \quad 0 \le x < \infty,\ -\infty < y < \infty,\ t \ge 0, \\ u_x(0, y, t) &= \epsilon u_y(0, y, t), \end{aligned} \tag{4.1}$$

where ϵ is a real parameter. It turns out the size of ϵ is of minor importance, and we will for simplicity consider the case $\epsilon = 1$. Corresponding to section 2, the problem is unstable if we can find exponentially growing solutions of the type

$$u = e^{st + i\omega y}\varphi(x), \quad \operatorname{Re} s > 0,\ |\varphi(x)| \le \text{const},\ \omega \text{ real}. \tag{4.2}$$

Introducing (4.2) into (4.1) gives us the eigenvalue problem for s:

$$\begin{aligned} \varphi_{xx} &= (s^2 + \omega^2)\varphi, \\ \varphi_x(0) &= i\omega\varphi(0), \quad |\varphi(x)| \le \text{const}. \end{aligned} \tag{4.3}$$

Since (4.3) is a differential equation with constant coefficients, its general solution is

$$\varphi(x) = \sigma_1 e^{\lambda x} + \sigma_2 e^{-\lambda x}, \quad \lambda = \sqrt{s^2 + \omega^2},\ \operatorname{Re}\lambda \ge 0. \tag{4.4}$$

Clearly, $\operatorname{Re}\lambda > 0$ for $\operatorname{Re} s > 0$. Therefore, $|\varphi(x)| \le \text{const}$ if and only if $\sigma_1 = 0$, i.e.,

$$\varphi(x) = \sigma_2 e^{-\lambda x}, \quad \operatorname{Re}\lambda > 0. \tag{4.5}$$

Introducing (4.5) into the boundary condition gives us

$$-\lambda = i\omega.$$

Since $\operatorname{Re}\lambda > 0$, there are no solutions of type (4.2). However, let $s = i\sqrt{2}\,\omega + \eta$, $\eta > 0$. Solving (4.4) for λ gives

$$\lim_{\eta \to 0} \lambda = i|\omega|.$$

Thus, for $\omega < 0$, there is a solution of type (4.2) but with $\operatorname{Re} s = 0$,

$$u = e^{i\sqrt{2}\,\omega t - i|\omega|(x+y)}. \tag{4.6}$$

There is no exponential growth in time and, for large ω, the solutions are highly oscillatory in space. Furthermore, there is no decay in the x-direction. Hence, $s = i\sqrt{2}\omega$ is a generalized eigenvalue (see [5] for a definition) which forecasts instabilities for the corresponding problem on a bounded domain.

To demonstrate these instabilities, we next consider the strip problem,

$$\begin{aligned} u_{tt} &= u_{xx} + u_{yy}, \quad 0 \le x \le 1,\ -\infty < y < \infty,\ t \ge 0, \\ u_x(0,y,t) &= u_y(0,y,t), \qquad u_x(1,t) = 0. \end{aligned} \tag{4.7}$$

Again, we construct solutions of the type (4.2). Instead of (4.3), we now obtain the eigenvalue problem

$$\begin{aligned} \varphi_{xx} &= (s^2 + \omega^2)\varphi, \\ \varphi_x(0) &= i\omega\varphi(0), \quad \varphi_x(1) = 0. \end{aligned} \tag{4.8}$$

Introducing the general solution (4.4) into the boundary conditions shows that (4.8) has a solution if

$$\frac{\lambda - i\omega}{\lambda + i\omega} = e^{2\lambda}. \tag{4.9}$$

THEOREM 4.1. *The strip problem* (4.7) *is unstable. For large* $|\omega|$ *there are solutions of the type* (4.2) *with*

$$\operatorname{Re} s \approx \frac{1}{\sqrt{8}} \log(2|\omega|), \quad \textit{i.e.}, \quad e^{(\operatorname{Re} s)t} = (2|\omega|)^{t/\sqrt{8}}. \tag{4.10}$$

Proof. Let

$$\lambda = \lambda_r + i\lambda_i,$$

and assume that

$$\lambda_i = -\omega, \quad |\omega| \gg 1.$$

By (4.9),

$$\frac{\lambda_r - 2i\omega}{\lambda_r} = e^{2\lambda_r} e^{-2i\omega}. \tag{4.11}$$

Take $|\omega|$ large and $\arg\omega$ such that the arguments of the left- and right-hand sides of (4.11) match. The modulus matches if

$$\frac{\lambda_r^2 + 4\omega^2}{\lambda_r^2} = e^{4\lambda_r},$$

i.e., to the highest order in ω,

$$\lambda_r \approx \frac{1}{2} \log(2|\omega|).$$

Thus,

$$s = \pm\sqrt{-\omega^2 + \lambda^2} \approx \pm\sqrt{-2\omega^2 - i\omega\, \log(2|\omega|)},$$

and (4.10) follows. ∎

The above example shows that the stability of the left and right half-plane problems is not enough to ensure stability for the strip problem. The reason is that the generalized eigenfunctions (4.6) do not decay in space but are reflected back and forth between the boundaries at $x = 0, 1$, respectively. Every time they hit the left boundary they are amplified. These are highly oscillatory instabilities, and we will see that they can easily be controlled by small amounts of dissipation. This example also illustrates that nondissipative difference methods of our type are prone to weak instabilities, i.e., instabilities that grow only algebraically in time (see (4.10)). Note that a weak instability also occurs if the tangential derivative in (4.1) is replaced by a higher order, odd, tangential derivative.

To demonstrate a strong instability, we study the half-plane problem where the boundary condition in (4.1) is replaced by

$$u_x = \beta u_{yy}, \quad x = 0, \tag{4.12}$$

where β is a constant. As before, we look for solutions of the type (4.2), and using the same arguments as above, we know the solution must have the form (4.5). Inserting this ansatz into the boundary condition (4.12) gives

$$-\lambda = -\beta\omega^2. \tag{4.13}$$

Since $\operatorname{Re}\lambda > 0$, there are no solutions with $\operatorname{Re} s > 0$ when $\beta < 0$. Next we investigate if there are any generalized eigenvalues. Setting $s = i\tau$ yields $\lambda = \sqrt{-\tau^2 + \omega^2}$, so $-\lambda$ is either real and negative or purely imaginary. When $\beta < 0$, the right-hand side of (4.13) is always real and positive, and we conclude that there are not any generalized eigenvalues either. Hence, the case $\beta < 0$ is stable.

When $\beta > 0$ and ω is large, (4.13) is solved by

$$s \approx \beta\omega^2,$$

and inserting (4.13) into (4.5) gives

$$u = e^{\beta\omega^2 t - \beta\omega^2 x + i\omega y}, \quad \omega \text{ large}, \ \beta > 0.$$

Hence, these solutions have a thin boundary layer in space and grow exponentially in time. This is a strong instability. As we shall see in section 5, this type of instability can only be controlled by dissipation when the coefficient β is small. Perturbing the Neumann condition by a higher order, even, tangential derivative results in the same behavior; i.e., the stability depends on the sign of the coefficient.

5. The discrete half-plane problem in two dimensions. We consider next the two-dimensional half-plane problem for

$$u_{tt} = u_{xx} + u_{yy}, \quad 0 \le x < \infty, \ -\infty < y < \infty, \ t \ge 0, \tag{5.1}$$

with the boundary condition

$$u_x(0, y, t) = 0, \quad |u(x, y, t)| \le \text{const}, \tag{5.2}$$

and approximate it by

$$v_{tt} = (D_{+x}D_{-x} + D_{+y}D_{-y})v, \tag{5.3}$$

with the third order accurate boundary condition (2.5)

$$L_h v(0,y,t) = 0, \quad |v(x,y,t)| \le \text{const.} \tag{5.4}$$

Here v is a discrete function varying on a grid

$$\{x_\nu = \nu h,\ y_\mu = \mu h\}, \quad \nu = 0,1,2,\dots,\ \mu = 0,\pm 1,\pm 2,\dots.$$

We Fourier-transform the difference equation with respect to y and obtain

$$\begin{aligned} &\hat{v}_{tt} = \left(D_{+x}D_{-x} - \frac{4}{h^2}\sin^2(\omega h/2)\right)\hat{v}, \\ &L_h\hat{v}(0,\omega,t) = 0, \quad |\hat{v}(x,\omega,t)| \le \text{const.} \end{aligned} \tag{5.5}$$

Thus, we obtain a one-dimensional problem for every fixed ω and can apply mode analysis as before. Then

$$\hat{v}(x_\nu,t) = e^{st}\varphi(x_\nu), \quad \operatorname{Re} s > 0,$$

is a solution of (5.5) if there are solutions $\varphi(x_\nu)$ of the eigenvalue problem

$$\left(s^2 + \frac{4}{h^2}\sin^2(\omega h/2)\right)\varphi = D_{+x}D_{-x}\varphi, \tag{5.6}$$

$$L_h\varphi = 0, \quad |\varphi(x)| \le \text{const}, \tag{5.7}$$

with $\operatorname{Re} s > 0$. The eigenvalue problem (5.6), (5.7) is of the same type as for the one-dimensional half-plane problem in section 2. In particular, the general solution has the form (2.8), where κ now is a solution of the two-dimensional characteristic equation

$$(\kappa - 1)^2 - (s^2h^2 + 4\sin^2(\omega h/2))\kappa = 0. \tag{5.8}$$

It is straightforward to show that this characteristic equation has the same essential properties as in the one-dimensional case. To be precise, we have the following lemma.

LEMMA 5.1. *For $|hs| \ll 1$ and $|h\omega| \ll 1$, the roots of* (5.8) *are of the form*

$$\begin{aligned} \kappa &= 1 - h\lambda + \frac{h^2\lambda^2}{2} + \mathcal{O}(h^3\lambda^3) = e^{-h\lambda(1+\mathcal{O}(h^2\lambda^2))}, \\ \kappa^{-1} &= 1 + h\lambda + \frac{h^2\lambda^2}{2} + \mathcal{O}(h^3\lambda^3) = e^{h\lambda(1+\mathcal{O}(h^2\lambda^2))}, \end{aligned}$$

where $\lambda = \sqrt{s^2+\omega^2}$, $\operatorname{Re}\lambda > 0$, for $\operatorname{Re} s > 0$. Also, for each fixed ω and for $\operatorname{Re} s > 0$, (5.8) *has no root with $|\kappa| = 1$ and exactly one root κ with $|\kappa| < 1$.*

Proof. The proof follows by straightforward generalization of Lemma 2.1. ∎

Since the boundary conditions are the same as in the one-dimensional case, we can use the same arguments as in section 2 to show that there are no solutions of (5.6), (5.7) for $\operatorname{Re} s > 0$, which implies that there are no exponentially growing solutions of (5.5). Note that for the Neumann boundary condition approximation (5.4), the boundary normal is aligned with the x-direction.

Our goal is to construct stable difference approximations for general domains. In this case the boundary condition for the differential equation is

$$\partial u/\partial n = 0, \quad \partial/\partial n: \text{ derivative normal to the boundary}, \tag{5.9}$$

and in general the normal is not aligned with the mesh. In the following, we will study the continuous boundary conditions perturbed by the leading truncation error terms. In the literature this technique is often used for the Cauchy or spatially periodic problems, and the truncation terms appear only in the differential equation. The obtained equation is often called the "modified equation"; see, for example, [14] or [11]. Here we use the technique to analyze the influence of truncation errors in the boundary conditions. The modified equation is a more accurate description of the discretized problem than the continuous problem. Or rephrased, the numerical solution approximates the modified equation to a higher order of accuracy than the continuous problem. However, the modified equation can only model low and intermediate frequencies in the discrete solution, and we rely on the dissipation to control the highest frequencies.

In section 4 we have discussed half-plane and strip problems. The reason is this: For analytic initial boundary value problems where there are no direct energy estimates, the study of wellposedness can be reduced to the study of half-plane and strip problems. This is done in the following way. In the neighborhood of every boundary point P with tangent T_g we use a locally smooth map to transform the curved boundary locally onto T_g. Then we study the half-plane problem with T_g as the boundary. After freezing the variable coefficients we can solve the problem by Fourier–Laplace transform. If for all these half-plane problems there are no eigenvalues or generalized eigenvalues s with $\operatorname{Re} s \geq 0$, then the original problem is well posed; see Kreiss and Lorenz [8].

We shall now apply this technique to analyze the stability of the discrete problem. Let the angle θ between the outward normal and the x-axis be defined as in Figure 1. We consider the differential equation on the half-plane $\boldsymbol{n} \cdot \boldsymbol{x} \leq 0$, i.e.,

$$x \cos\theta + y \sin\theta \geq 0. \tag{5.10}$$

To be able to calculate the truncation error of the discrete boundary condition we assume that the solution u of the differential equation is smooth and decays rapidly to zero for $x^2 + y^2 \to \infty$, in the half-plane (5.10). Also, we extend it smoothly beyond the boundary such that the extended u decays rapidly to zero for $x^2 + y^2 \to \infty$ in the whole plane.

The truncation error in the third order Neumann boundary condition satisfies ($\pi/4 \leq \theta \leq \pi/2$)

$$D_n^{(3)} u(x_i, y_j) = \frac{\partial u}{\partial n}(\boldsymbol{x}_{i,j}^{\Gamma}) + C_1 h^4 \frac{\partial^5 u}{\partial n^5}(\boldsymbol{x}_{i,j}^{\Gamma}) + C_2 h^3 \frac{\partial^4 u}{\partial n^4}(\boldsymbol{x}_{i,j}^{\Gamma}) + h^4 R_1 + h^3 R_2 + O(h^5).$$

Here,

$$R_1 = \sum_{\nu=1}^{3} C_{1\nu} \frac{\partial^5 u(\tilde{x}_\nu, y_{j+\nu})}{\partial x^5}, \quad R_2 = \sum_{\nu=1}^{3} C_{2\nu} \frac{\partial^4 u(\tilde{x}_\nu, y_{j+\nu})}{\partial x^4}.$$

The terms in R_1, R_2 originate from interpolation errors in v_I, v_{II}, and v_{III}, respectively.

Derivatives with respect to x and y can be related to normal ($\partial/\partial n$) and tangential ($\partial/\partial \sigma$) derivatives. We have

$$\frac{\partial}{\partial x} = -\sin\theta \frac{\partial}{\partial \sigma} - \cos\theta \frac{\partial}{\partial n}, \qquad \frac{\partial}{\partial y} = \cos\theta \frac{\partial}{\partial \sigma} - \sin\theta \frac{\partial}{\partial n}.$$

We can also use Taylor expansions to express derivatives at $(\tilde{x}_\nu, y_{j+\nu})$ in terms of derivatives at the boundary point x_{ij}^Γ. After some calculations we obtain

$$D_n^{(3)} u(x_i, y_j) = (1+R)\frac{\partial u}{\partial n} - \left(h^4 \beta_1 \frac{\partial^5 u}{\partial \sigma^5} + h^3 \beta_2 \frac{\partial^4 u}{\partial \sigma^4} \right) + \mathcal{O}\left(h^5 \frac{\partial^6 u}{\partial n^{6-j} \partial \sigma^j} \right).$$

Here R is an operator of the form

$$R = \sum_{p+q \geq 3} \beta_{pq} h^{p+q} \frac{\partial^{p+q}}{\partial n^p \partial \sigma^q}.$$

We can write the half-plane problem for the differential equation in the form

$$\frac{\partial^2 u}{\partial t^2} = \frac{\partial^2 u}{\partial n^2} + \frac{\partial^2 u}{\partial \sigma^2}, \quad n \geq 0, \ -\infty < \sigma < \infty,$$
$$\frac{\partial u}{\partial n} = 0 \quad \text{for } n = 0.$$

After Fourier-transforming with respect to σ and Laplace-transforming with respect to t, we obtain

$$\frac{\partial^2 \hat{u}}{\partial n^2} = (s^2 + \omega^2)\hat{u}.$$

Thus,

$$\hat{u} = e^{-\sqrt{s^2+\omega^2}\, n} u_0(s, \omega), \quad \frac{\partial \hat{u}}{\partial n} = -\sqrt{s^2+\omega^2}\hat{u},$$

and the Fourier–Laplace transform of $\partial/\partial n$ is $-\sqrt{s^2+\omega^2}$. After freezing the coefficients, we Fourier–Laplace-transform the truncation error and obtain

$$\hat{D}_n^{(3)} = -(1+\hat{R})\sqrt{s^2+\omega^2} - (i\beta_1 h^4 \omega^5 + \beta_2 h^3 \omega^4) + \mathcal{O}((|\omega| + |s|)^6 h^5).$$

Here,

$$\hat{R} = \sum_{p+q \geq 3} \beta_{pq} (-\sqrt{(hs)^2 + (h\omega)^2})^p (ih\omega)^q = \mathcal{O}((|hs| + |h\omega|)^3).$$

For $|hs| + |h\omega|$ sufficiently small, $\|\hat{R}\| \leq 1/2$, and we can write

$$\begin{aligned} \hat{D}_n^{(3)} &= (1+\hat{R}) \left(-\sqrt{s^2+\omega^2} - \frac{i\beta_1 h^4 \omega^5 + \beta_2 h^3 \omega^4}{1+\hat{R}} \right) + \mathcal{O}((|\omega| + |s|)^6 h^5) \\ &= (1+\hat{R})(-\sqrt{s^2+\omega^2} - (i\beta_1 h^4 \omega^5 + \beta_2 h^3 \omega^4)) + \mathcal{O}((|\omega| + |s|)^6 h^5). \end{aligned}$$

By neglecting the $\mathcal{O}(h^5)$ term and transforming back to physical space, the boundary condition $D_n^{(3)} u = 0$ corresponds to

$$(1+R)\left(\frac{\partial u}{\partial n} - \beta_1 h^4 \frac{\partial^5 u}{\partial \sigma^5} - \beta_2 h^3 \frac{\partial^4 u}{\partial \sigma^4} \right) = 0.$$

By assumption, $\|R\|$ is small and the boundary condition can only be satisfied if the term following $(1+R)$ is zero. After changing spatial variables, $n \to x$ and $\sigma \to y$,

we arrive at the modified equation model corresponding to the discrete half-plane problem (5.3)–(5.4) in domains where the normal is not aligned with the mesh:

$$u_{tt} = u_{xx} + u_{yy} - \alpha h^3 u_{tyyyy}, \quad \alpha \geq 0,\ x \geq 0,\ -\infty < y < \infty, \tag{5.11}$$

$$u_x = \beta_1 h^4 u_{yyyyyy} + \beta_2 h^3 u_{yyyy}, \quad x = 0,\ |u| \leq \text{const}. \tag{5.12}$$

We have added a dissipation term to the differential equation because we shall need it later. Note that we have only added dissipation in the tangential direction, to avoid having to add any extra boundary conditions.

After Fourier-transforming in y and Laplace-transforming in t, we obtain

$$\hat{u}_{xx} = (s^2 + \omega^2)\hat{u} + sa\hat{u}, \quad a = \alpha h^3 \omega^4,\ \operatorname{Re} s > 0, \tag{5.13}$$

with boundary conditions

$$\hat{u}_x(0) = b\hat{u}(0), \quad |\hat{u}| \leq \text{const},\ b = i\beta_1 \omega^5 h^4 + \beta_2 \omega^4 h^3. \tag{5.14}$$

As $|\omega|$ gets larger, the Fourier symbol of the second divided difference, $-\frac{4}{h^2}\sin^2(\frac{\omega h}{2})$, deviates more and more from the Fourier symbol of a second derivative, $-\omega^2$. In particular, for the highest frequency on the mesh ($\omega h = \pi$), the symbol of the second divided difference is $-4/h^2$, while the symbol of the second derivative is $-\pi^2/h^2$. Hence, the highest frequencies on the mesh are not accurately modeled by the modified equation. We therefore restrict the following analysis to $|\omega h| \leq 1$.

The general solution of (5.13) is given by

$$\hat{u} = \sigma_1 e^{\lambda x} + \sigma_2 e^{-\lambda x}, \tag{5.15}$$

where λ now satisfies

$$\lambda = \sqrt{s^2 + \omega^2 + sa}, \quad \operatorname{Re}\lambda \geq 0. \tag{5.16}$$

Since $\operatorname{Re}\lambda > 0$ for $\operatorname{Re} s > 0$, the boundary conditions are satisfied if and only if

$$\sigma_1 = 0, \qquad \lambda = -b = -(i\beta_1 \omega^5 h^4 + \beta_2 \omega^4 h^3). \tag{5.17}$$

There are two possibilities:

1. If $\beta_2 \geq 0$, then there are no solutions of (5.17) with $\operatorname{Re} s > 0$ since $\operatorname{Re}\lambda > 0$, but $\operatorname{Re}(-b) \leq 0$. Furthermore, when the dissipation coefficient $\alpha > 0$, $\operatorname{Re}\lambda > 0$ also for $\operatorname{Re} s = 0$, $\omega \neq 0$. Hence, there are no generalized eigenvalues when $\alpha > 0$, and we conclude that the half-plane problem is stable.

2. If $\beta_2 < 0$, then the problem can be unstable. We want to show that if $|\beta_1|$ and $|\beta_2|$ are small, the problem can be stabilized by a small $\alpha > 0$.

THEOREM 5.2. *If $\beta_2 < 0$, $|\beta_2| \ll 1$, $|\beta_1| \ll 1$, and $\alpha \geq K|\beta_1\beta_2|$, $K = \text{const}$, the modified half-plane problem* (5.11)–(5.12) *is stable; i.e., the eigenvalue problem* (5.13)–(5.14) *has no solutions with* $\operatorname{Re} s > 0$ *and no generalized eigenvalues* $\operatorname{Re} s = 0$ *for* $\omega \neq 0$.

Proof. Introducing (5.17) into (5.16) gives

$$s^2 + sa + \omega^2 - b^2 = 0.$$

Since $|\omega h| \leq 1$, $|a| \leq |\alpha||\omega|$. If we assume $0 \leq \alpha \leq 1$, we have $|a| \leq |\omega|$ and $\omega^2 - a^2/4 \geq 3\omega^2/4$. Therefore,

$$s = -\frac{a}{2} \pm i\sqrt{\left(\omega^2 - \frac{a^2}{4}\right)}\sqrt{1 - \frac{b^2}{\omega^2 - a^2/4}}. \tag{5.18}$$

By assumption $|b^2| \ll \omega^2$. We can therefore expand the square root and conclude that

$$s = -\frac{a}{2} \pm \left(i\sqrt{\left(\omega^2 - \frac{a^2}{4}\right)} - \frac{ib^2}{2\sqrt{\omega^2 - a^2/4}} + \cdots \right).$$

Hence,

$$\operatorname{Re} s \approx -\frac{\alpha}{2} h^3 \omega^4 \pm \frac{\operatorname{Im} b^2}{2\sqrt{\omega^2 - a^2/4}} = -\frac{\alpha}{2} h^3 \omega^4 \pm \frac{\beta_1 \beta_2 (\omega h)^7 \omega^2}{\sqrt{\omega^2 - a^2/4}} < 0$$

for $\alpha \geq 4|\beta_1 \beta_2|/\sqrt{3}$. ∎

We have numerically computed the truncation error coefficients β_1 and β_2 for our boundary condition approximation. To conserve space, we will only report the result of these computations here. For all possible directions of the boundary normal and all permissible distances between the ghost point and the boundary, we found that $-0.065 < \beta_2 < 0.015$ and $-0.063 < \beta_1 < 0.063$. It is critical that $|\beta_2|$ is small since the case $\beta_2 < 0$, $|\beta_2| = \mathcal{O}(1)$ cannot be stabilized by adding a dissipative term to the differential equation. In earlier versions of our numerical code we added a tangential smoothing operator to the boundary condition approximation. In terms of the modified problem this means that $\beta_2 > 0$. The dissipation operator proposed in section 1 seems to be so efficient that this extra smoothing operator is not needed.

6. The two-dimensional strip problem. Here we generalize the modified equation approach to study the stability of solutions on a bounded domain,

$$u_{tt} = u_{xx} + u_{yy} - \alpha h^3 u_{tyyyy}, \quad \alpha \geq 0,\ 0 \leq x \leq 1,\ -\infty < y < \infty, \tag{6.1}$$

$$u_x = \beta_1 h^4 u_{yyyyy} + \beta_2 h^3 u_{yyyy}, \quad x = 0,\ u_x = 0,\ x = 1. \tag{6.2}$$

Remark. In reality the boundary condition at $x = 1$ also contains truncation order terms, but the results are the same.

After Fourier- and Laplace-transforming the problem, (6.1)–(6.2) becomes

$$s^2 \hat{u} = \hat{u}_{xx} - (\omega^2 + as)\hat{u}, \quad a = \alpha h^3 \omega^4, \tag{6.3}$$

$$\hat{u}_x(0) = b\hat{u}(0), \quad \hat{u}_x(1) = 0, \quad b = i\beta_1 \omega^5 h^4 + \beta_2 \omega^4 h^3. \tag{6.4}$$

The general solution of (6.3) now has the form

$$\hat{u} = \sigma_1 e^{\lambda x} + \sigma_2 e^{-\lambda x}, \tag{6.5}$$

where λ is the solution of (5.16), i.e., $\operatorname{Re} \lambda > 0$ for $\operatorname{Re} s > 0$. Introducing (6.5) into (6.4) shows that there is a nontrivial solution if and only if

$$\frac{\lambda - b}{\lambda + b} = e^{2\lambda}. \tag{6.6}$$

We have already studied the corresponding half-plane problem and shown that for $\beta_2 \geq 0$, there are no eigenvalues s, with $\operatorname{Re} s > 0$, and that there are no generalized eigenvalues when $\alpha > 0$. For $\beta_2 < 0$, Theorem 5.2 shows when the half-plane problem is stable. Hence, it can be expected that the strip problem also is stable. In Appendix B, we perform a detailed calculation to verify the stability of the strip problem. From this calculation, we can also read off the order of magnitude of the dissipation coefficient α that is necessary for stability. The results are summarized in the following theorem.

THEOREM 6.1. *If the half-plane problem* (5.11)–(5.12) *is stable, the modified strip problem* (6.1)–(6.2) *is stable for* $\alpha > 0$, $\alpha = \mathcal{O}(h^{3/4})$.

7. General two-dimensional domains. In this section, we will add some details to our proposed scheme that were left out of the general description in section 1.

7.1. Near boundary behavior of the discretized Laplacian. The discretized Neumann boundary condition (1.3) can be used to eliminate all ghost point values in the discretized Laplacian (1.2). Referring to the case shown in Figure 1, we get at the point $(i, j+1)$,

$$\begin{aligned}\Delta_h v^n_{i,j+1} = {} & \frac{1}{h^2}(v^n_{i+1,j+1} + v^n_{i-1,j+1} + v^n_{i,j+2} - 4v^n_{i,j+1}) \\ & - \frac{g_I}{h^2 g_0}(c_0 v^n_{i,j+1} + c_1 v^n_{i+1,j+1} + c_2 v^n_{i+2,j+1}) \\ & - \frac{g_{II}}{h^2 g_0}(c_3 v^n_{i,j+2} + c_4 v^n_{i+1,j+2} + c_5 v^n_{i+2,j+2}) + \frac{f(\boldsymbol{x}^\Gamma_{i,j}, t_n)}{h^2 g_0},\end{aligned} \tag{7.1}$$

assuming that (i, j) is the only nearest neighbor of $(i, j+1)$ that is outside of Ω. If additional points are outside, other formulas of the type (1.3) would be used to eliminate those points as well. The coefficients g_0, g_I, g_{II} are given by (1.4). Since $0 \le \xi_\Gamma \le \xi_I$ and $h \le \xi_I \le \sqrt{2}h$, the denominator g_0 satisfies

$$\frac{1}{2\sqrt{2}h} \le \frac{1}{2\xi_I} \le |g_0| \le \frac{3}{2\xi_I} \le \frac{3}{2h}.$$

Because the coefficient g_0 in (7.1) is bounded away from zero, we conclude that this discretization of the Laplacian does *not* suffer from the "small cell" stiffness problem.

7.2. Accuracy of the damped scheme. For simplicity, let the grid function $\boldsymbol{v}$ satisfy the semidiscrete problem, where time is left continuous,

$$\boldsymbol{v}_{tt} = A\boldsymbol{v} + \boldsymbol{b} + \boldsymbol{F} - \alpha h^3 A^T(A\boldsymbol{v}_t + \boldsymbol{b}_t).$$

Let the error in the discrete solution be $\boldsymbol{e} = u - \boldsymbol{v}$, where u is the solution of the continuous problem (1.1) evaluated on the grid. We have

$$\begin{aligned}\boldsymbol{e}_{tt} &= \Delta u - A\boldsymbol{v} - \boldsymbol{b} + \alpha h^3 A^T(A(\boldsymbol{v}_t + u_t - u_t) + \boldsymbol{b}_t) \\ &= \Delta u - Au - \boldsymbol{b} + A\boldsymbol{e} - \alpha h^3 A^T A\boldsymbol{e}_t + \alpha h^3 A^T(Au_t + \boldsymbol{b}_t).\end{aligned}$$

We split the error according to $\boldsymbol{e} = \boldsymbol{e}^I + \boldsymbol{e}^{II}$ and let $\boldsymbol{e}^I$ satisfy

$$A\boldsymbol{e}^I = -\alpha h^3 A^T(Au_t + \boldsymbol{b}_t). \tag{7.2}$$

Now, $Au_t + \boldsymbol{b}_t$ is a second order accurate approximation of Δu_t evaluated on the grid. Furthermore, away from the boundary, $A^T\Delta u_t$ is a second order approximation of $\Delta^2 u_t$, but near the boundary $A^T\Delta u_t = \mathcal{O}(\Delta u_t/h^2)$. Hence the right-hand side of (7.2) is $\mathcal{O}(h)$ near the boundary but $\mathcal{O}(h^3)$ in the interior. Due to the smoothing properties of the elliptic operator A (see Figure 2 and Table 1 for a numerical example), we gain one order of magnitude when solving for $\boldsymbol{e}^I$, resulting in

$$\boldsymbol{e}^I = \mathcal{O}(h^2).$$

Since the right-hand side of (7.2) is smooth in time, we also have $\boldsymbol{e}^I_{tt} = \mathcal{O}(h^2)$ and $A\boldsymbol{e}^I_t = \mathcal{O}(h)$. The equation for $\boldsymbol{e}^{II}$ is

$$\boldsymbol{e}^{II}_{tt} = A\boldsymbol{e}^{II} - \alpha h^3 A^T A\boldsymbol{e}^{II}_t - \boldsymbol{e}^I_{tt} - \alpha h^3 A^T A\boldsymbol{e}^I_t + \Delta u - (Au + \boldsymbol{b}).$$

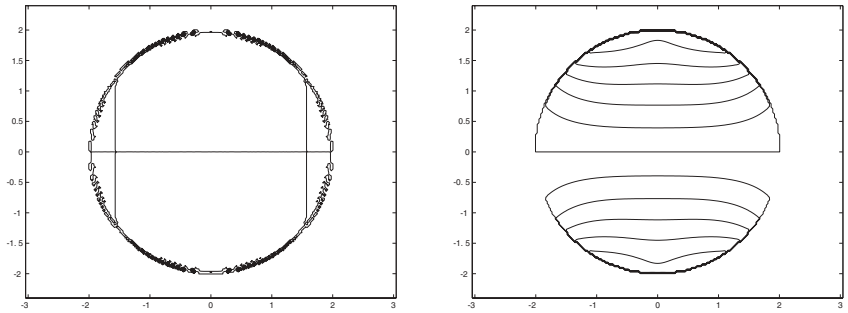

FIG. 2. *Numerical test of the smoothing properties of* $A\boldsymbol{e}^I = h^3 A^T \boldsymbol{u}$. *The left figure shows a contour plot of the right-hand side* $h^3 A^T \boldsymbol{u}$, *and the right figure shows the solution* $\boldsymbol{e}^I$ *for* $N = 171$; *see Table* 1 *for quantitative information. In this case, the computational domain was a circle with unit radius and the test function was* $\boldsymbol{u}_{i,j} = \cos(x_i)\sin(y_j)$. *The problem was solved using the conjugated gradient algorithm.*

TABLE 1

Smoothing properties of the operator A investigated by solving $A\boldsymbol{e}^I = h^3 A^T \boldsymbol{u}$ *for different grid sizes for the case shown in Figure* 2. *Clearly,* $\boldsymbol{e}^I = \mathcal{O}(h^2)$ *while* $h^3 A^T \boldsymbol{u} = \mathcal{O}(h)$.

N	$\|\boldsymbol{e}^I\|_\infty$	$\|h^3 A^T \boldsymbol{u}\|_\infty$	h
171	3.43×10^{-4}	4.36×10^{-2}	2.82×10^{-2}
341	9.21×10^{-5}	2.20×10^{-2}	1.41×10^{-2}
681	2.40×10^{-5}	1.20×10^{-2}	7.06×10^{-3}

Because $Au + \boldsymbol{b}$ is a second order accurate approximation of Δu and $h^3 A^T A \boldsymbol{e}_t^I = \mathcal{O}(h^2)$, all forcing terms are of the order $\mathcal{O}(h^2)$. Hence

$$\boldsymbol{e}^{II} = \mathcal{O}(h^2),$$

which shows that the damped scheme is second order accurate.

7.3. Fourth order corrections. To reduce the phase-error away from the boundary, we can optionally add a fourth order correction term,

$$\Delta_{h,4} v_{i,j}^n = -\frac{h^2}{12}(D_+^x D_-^x \gamma_{i,j} D_+^x D_-^x + D_+^y D_-^y \gamma_{i,j} D_+^y D_-^y) v_{i,j}^n,$$

to our second order accurate approximation of the Laplacian. Clearly, this stencil is too wide to be evaluated all the way up to the boundary, so the grid function $\gamma_{i,j}$ must be identically zero in a band near the boundary. Away from the boundary we want $\gamma_{i,j} \equiv 1$ to make the correction term cancel the second order truncation error in $\Delta_h v_{i,j}$. To aid in the construction of $\gamma_{i,j}$, we initially compute a smoothed distance function $d_{i,j} \geq 0$ using the technique described in [13]. The value of the distance function at a grid point approximately equals the distance between that grid point and the nearest boundary. Hence, the distance function is zero on the boundary and increases monotonically away from the boundary, making it straightforward to construct a smooth $\gamma_{i,j}$ that is zero near the boundary ($d_{i,j} \leq \epsilon_1$) and one away from the boundary ($d_{i,j} \geq \epsilon_2$). In all numerical examples presented below, we used $\epsilon_1 = 3h$ and $\epsilon_2 = 13h$. The resulting scheme can be written in semidiscrete form as

$$\boldsymbol{v}_{tt} = A\boldsymbol{v} + B\boldsymbol{v} + \boldsymbol{F} + \boldsymbol{b} - \alpha h^3 A^T \left(A\boldsymbol{v}_t + \frac{d\boldsymbol{b}}{dt}(t_n) \right), \tag{7.3}$$

where B represents the fourth order correction term. The symmetry of B and the smoothness of the distance function of $\gamma_{i,j}$ seem to give stability. A heuristic argument for this is that B cannot generate any boundary layer instability, since this type of instability decays rapidly away from the boundary and in this region $\Delta_{h,4} v_{i,j}^n$ is arbitrarily small. And the other type of instability discussed above, highly oscillatory in the whole domain, is effectively stabilized by our damping term. The smoothness of the distance function implies that no new spurious solutions are generated. The smoothness furthermore guarantees accuracy of order two in the transition region. Hence, the resulting scheme will only be second order accurate. The main benefit of the fourth order spatial correction will be a reduced phase-error away from the boundary. For this reason we will call the resulting scheme the "internally fourth order" method.

We can also improve the basic second order time-integration method by using a fourth order accurate Taylor series method. Consider the second order system of ordinary differential equations

$$\boldsymbol{w}_{tt} = C\boldsymbol{w} + \boldsymbol{F},$$

where C is a symmetric negative semidefinite matrix. A fourth order time-discretization is given by

$$\frac{\boldsymbol{w}^{n+1} - 2\boldsymbol{w}^n + \boldsymbol{w}^{n-1}}{k^2} = C\boldsymbol{w}^n + \boldsymbol{F}^n + \frac{k^2}{12}(C(C\boldsymbol{w}^n + \boldsymbol{F}^n) + \boldsymbol{F}_{tt}^n), \tag{7.4}$$

and it is stable for

$$\max_j (-\lambda_j) k^2 < 12,$$

where λ_j are the real-valued nonpositive eigenvalues of C. The scheme (7.4) can be formulated in predictor-corrector form,

$$\tilde{\boldsymbol{w}}^{n+1} = 2\boldsymbol{w}^n - \boldsymbol{w}^{n-1} + k^2 C\boldsymbol{w}^n + k^2 \boldsymbol{F}^n, \tag{7.5}$$

$$\boldsymbol{w}^{n+1} = \tilde{\boldsymbol{w}}^{n+1} + \frac{k^2}{12}(C(\tilde{\boldsymbol{w}}^{n+1} - 2\boldsymbol{w}^n + \boldsymbol{w}^{n-1}) + k^2 \boldsymbol{F}_{tt}^n). \tag{7.6}$$

Hence, the predictor step (7.5) is simply the second order time-integration scheme presented above. The discrete damping term is added to the predictor-corrector scheme in the same way as in (1.6). For the spatially fourth order method, we take $C = A + B$; otherwise $C = A$. We note that the corrector step (7.6) needs only a second order accurate approximation of $\boldsymbol{w}_{tt}$. Hence, from an accuracy standpoint we can omit the correction term and always take $C = A$ in this step. Numerical experiments (see section 8) indicate that the resulting scheme is stable.

We start the time-integration at $n = 0$. For the fourth order time-discretization, we take $v_{i,j}^0 = u_0(x_i, y_j)$ and need to use a fifth order accurate approximation of $u(x_i, y_j, -k)$ for $v_{i,j}^{-1}$. This is achieved by using the differential equation to

approximate higher order time derivatives,

$$
\begin{aligned}
v_{i,j}^{-1} = {} & u_0(x_i,y_j) - ku_1(x_i,y_j) + \frac{k^2}{2}(D_+^xD_-^x + D_+^yD_-^y)u_0(x_i,y_j) + \frac{k^2}{2}F(\boldsymbol{x}_{i,j},0) \\
& -\frac{k^3}{6}(D_+^xD_-^x + D_+^yD_-^y)u_1(x_i,y_j) - \frac{k^3}{6}F_t(\boldsymbol{x}_{i,j},0) \\
& -\frac{k^2h^2}{24}((D_+^xD_-^x)^2 - (D_+^yD_-^y)^2)u_0(x_i,y_j) \\
& +\frac{k^4}{24}(D_+^xD_-^x + D_+^yD_-^y)^2u_0(x_i,y_j) + \frac{k^4}{24}F_{tt}(\boldsymbol{x}_{i,j},0).
\end{aligned} \tag{7.7}
$$

Note that the last three lines can be omitted for the second order time-discretization.

8. Numerical examples. In this section we numerically solve (1.1) with the schemes described above. For the cases where an analytical solution is known, we use this solution to initialize the computation at time levels $t = -k$ and $t = 0$. For the cases where an analytical solution is not known we use the initialization (7.7).

We will denote the CFL-number by $\mathrm{CFL} \equiv k/h$. Note that for a two-dimensional periodic domain, our second order time-integration scheme (1.6) is stable for CFL $\leq 1/\sqrt{2} \approx 0.71$, while the fourth order predictor-corrector scheme (7.5), (7.6) is stable for $\mathrm{CFL} \leq \sqrt{3/2} \approx 1.22$. Also note that all errors are measured in max-norm.

In all examples presented below, the fourth order predictor-corrector time-integrator (7.5), (7.6) is used together with the internally fourth order spatial correction. The second order scheme (1.6) is always used together with the second order spatial discretization. Unless otherwise noted, the Neumann boundary condition is discretized using the third order accurate formula to reduce the constant in the second order truncation error, as was mentioned in the introduction.

To evaluate the accuracy of the method, the forcing function is chosen such that the exact solution is the trigonometric traveling wave:

$$
u(x,y,t) = \sin(\omega(x-t))\sin(\omega y), \quad \omega = 4\pi. \tag{8.1}
$$

The domain Ω is taken to be an ellipse centered at the origin with semiaxes $x_s = 1$ and $y_s = 0.75$. The Cartesian grid covers the rectangle $-1.1 \leq x \leq 1.1$, $-0.85 \leq y \leq 0.85$. In Table 2, we present a grid refinement study for the second order scheme (1.6) and the internally fourth order predictor-corrector scheme (7.5), (7.6). The fourth order correction applies only in the interior of the domain, and the second order errors near the boundary clearly dominate the total error. Hence, in this case, there is no apparent benefit of using the internally fourth order method. The time step can be taken twice as large, but this gain is balanced by having to evaluate the Laplacian twice instead of once per time step. Also note that the influence of the damping term is so small that it changes only the last digit in the error in one of these runs.

To more clearly illustrate the benefits of using a fourth order correction away from the boundary, we select the forcing function F and boundary data f such that the exact solution is a spatially localized, outwardly traveling wave,

$$
u(x,y,t) = \phi(\sqrt{x^2+y^2} - t), \qquad \phi(\xi) = \frac{1}{2}\left(1 + \tanh\frac{\xi-\xi_0}{\epsilon}\right)\left(1 - \tanh\frac{\xi-\xi_1}{\epsilon}\right). \tag{8.2}
$$

Note that such waves are exact solutions to the unforced wave equation in one and three space dimensions, but not in the two-dimensional case. The domain Ω is taken

to be the circle, $|r| \leq 1.5$, and the Cartesian grid covers the square $-1.6 \leq x \leq 1.6$, $-1.6 \leq y \leq 1.6$. The parameters in ϕ are taken to be

$$\xi_0 = 0.3, \quad \xi_1 = 0.5, \quad \epsilon = 0.07.$$

The wave reaches the boundary at $t \approx 0.8$. In Table 3 we see that for the internally fourth order method, the error is at least one order of magnitude smaller and the convergence rate is much higher before the wave hits the boundary. No such distinction can be made for the second order method, where the errors grow more gradually in time. Furthermore, the errors in the internally fourth order method are substantially smaller than those of the second order method, especially before the wave hits the boundary.

We proceed by investigating the long-time stability properties of the method. We take the domain to be the same ellipse used above and take the forcing functions such that the exact solution is the trigonometric traveling wave (8.1). In Figure 3, we show the error in the solution as a function of time for different values of α and for different grid sizes. We conclude that it is sufficient to take $\alpha = 2 \times 10^{-3}$ for both the second order and the predictor-corrector scheme. Note that these computations integrated the solution for long times. In particular, the second order scheme on the finer grid ($N = 401$) required 66,666 time steps to reach $t = 200$. Also note that there is no long-time increase in the error, which indicates that the damping is very mild.

We next study the homogeneous problem

$$F(\boldsymbol{x}, t) \equiv 0, \quad f(\boldsymbol{x}, t) \equiv 0,$$

in a domain bounded by an ellipse centered at the origin, with semiaxes $x_s = 2.0$ and $y_s = 2.54$. The Cartesian grid covers the square $-2.1 \leq x \leq 2.1$, $-2.64 \leq y \leq 2.64$.

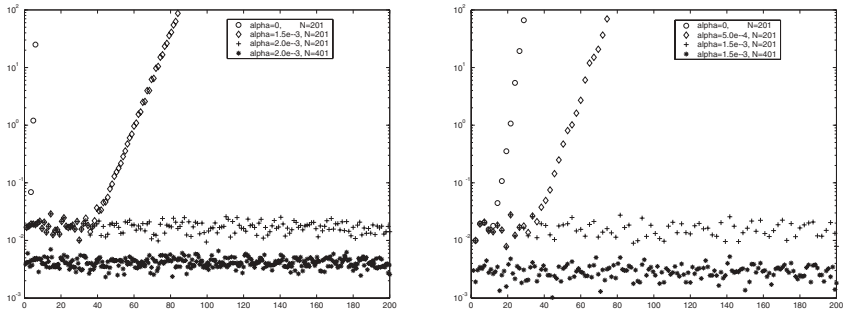

FIG. 3. *The max-norm of the error in the solution as a function of time. The second order scheme* (1.6) *was run at CFL* $= 0.5$ *(left), and the predictor-corrector method* (7.5), (7.6) *was run at CFL* $= 1.0$ *(right). Note that to stabilize the solution, the damping coefficient had to be slightly larger for the second order scheme* (2×10^{-3}) *than for the predictor-corrector method* (1.5×10^{-3}).

We take initial data to be

$$u_0(x, y) = \phi(\sqrt{x^2 + (y - y_F)^2}),$$

where $\phi(\xi)$ is given by (8.2). The upper focal point is located at $y_F = \sqrt{y_s^2 - x_s^2} \approx 1.56$ and

$$u_1(\boldsymbol{x}) = -\phi'(\sqrt{x^2 + (y - y_F)^2}).$$

The parameters in $\phi(\xi)$ are

$$\xi_0 = 0.2, \quad \xi_1 = 0.4, \quad \epsilon = 0.035.$$

Note that the initial data is chosen such that the wave is essentially traveling radially outwardly from the focal point $(0, y_F)$. By making a ray-tracing argument, we see that a high frequency wave should reflect the boundary and refocus at the other focal point $(0, -y_F)$. This was verified for the Dirichlet problem in [9] (Figure 6). For the Neumann boundary condition, we should get a similar behavior, except that the solution should have the opposite phase compared to the Dirichlet case. This is confirmed in Figure 4, where we show a well-resolved calculation using the predictor-corrector scheme with $N = 801$ and $CFL = 1.0$. It is interesting to use this calculation as a yard-stick to compare the quality of the solutions from both schemes at a lower resolution, $N = 401$; see Figures 5 and 6. Observe the more pronounced over- and undershoots for the second order method in comparison to the predictor-corrector method, indicating that the phase-error dominates at the time of comparison. In all these calculations, the damping coefficient was $\alpha = 0.001$.

While all theory and all numerical experiments up to this point have been presented for the third order accurate discretization of the boundary conditions, our practical experience with the second order boundary condition stencil is at least as good. The advantage of the second order stencil is that it uses fewer internal points, which becomes important for thin or marginally resolved geometries. However, near true corners, the second order boundary condition needs to be modified to avoid using grid points where the solution is undefined; see Figure 7. To avoid this problem, all grid points are first scanned in a preprocessing step to detect interior points within $\sqrt{2}h$ of corners. All such points that also have at least two exterior nearest neighbors

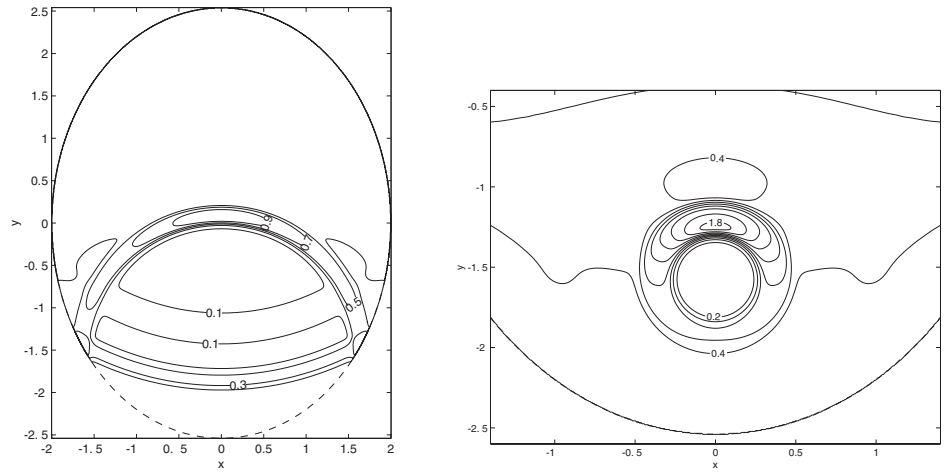

FIG. 4. *Contours of the bouncing wave solution to the Neumann problem. Here a reference solution is produced with the predictor-corrector scheme,* $CFL = 1.0, N = 801$, $t = 3.12$ *(left), and* $t = 4.41$ *(right). The dashed line is the boundary and the contour spacing is* 0.2.

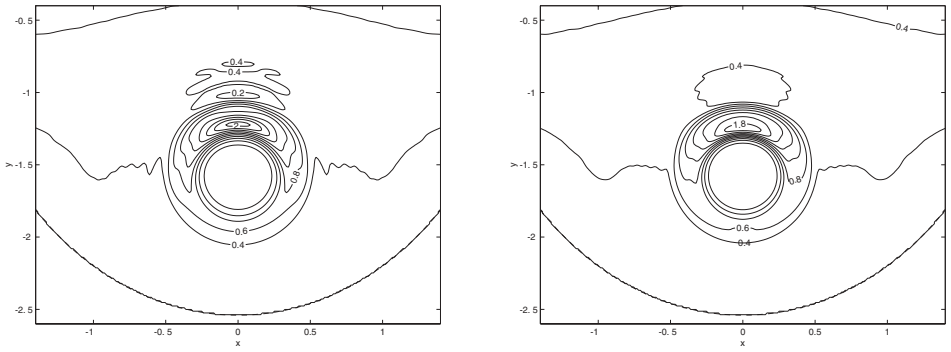

FIG. 5. *Contours of the bouncing wave solution to the Neumann problem. The second order scheme is used with* $CFL = 0.5$ *(left) and the predictor-corrector scheme is used with* $CFL = 1.0$ *(right). Here* $N = 401$, $t = 4.41$, *and the contour spacing is* 0.2.

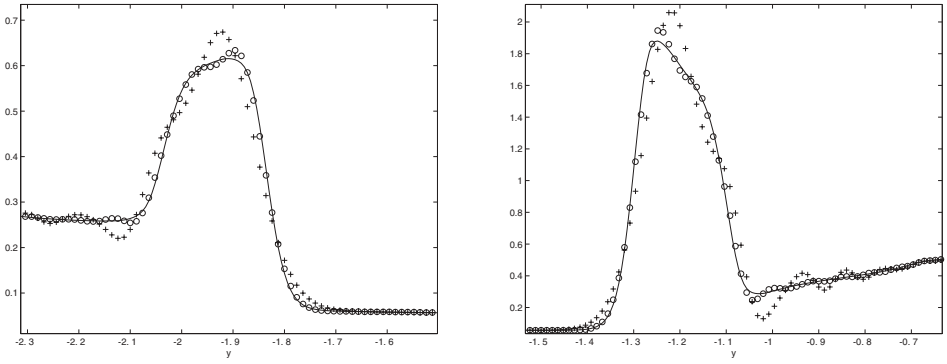

FIG. 6. *Comparison of the bouncing wave solution for the Neumann problem at* $t = 4.41$ *along the line* $x = 0$ *centered around* $y = -2.0$ *(left) and* $y = -1.2$ *(right). The reference solution is for* $N = 801$ *(solid), the second order scheme is for* $N = 401$, $CFL = 0.5$(“+”), *and the predictor-corrector scheme is for* $N = 401$, $CFL = 1.0$(“o”).

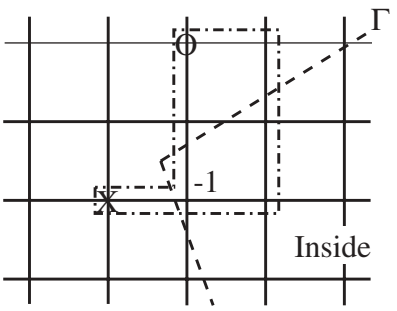

FIG. 7. *The standard second order boundary condition stencil (outlined with a dash-dotted line) for the ghost point at "X" involves the point "O", where the solution is undefined due to the corner. In this case, the boundary stencil at "X" is reduced to a divided difference between the solution at "−1" and "X."*

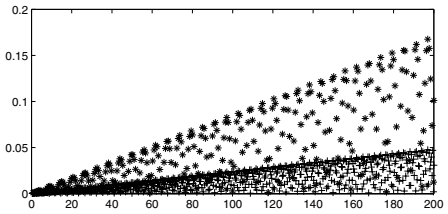

FIG. 8. *The max-norm of the error for a rotated square domain, as a function of time. The "∗" correspond to the grid size $h = 1.417 \times 10^{-2}$, and the "+" represent the grid size $h = 7.087 \times 10^{-3}$. The damping coefficient was $\alpha = 2 \times 10^{-3}$.*

get marked with a "−1." The boundary condition stencil at ghost points neighboring a "−1" point is then modified to be a divided difference between the ghost point and the "−1" point; i.e., the direction of the normal is locally changed to be either vertical or horizontal. As a consequence, no undefined points are involved in the boundary stencil near the corner, and the resulting contribution to the discretized Laplace operator (the matrix A) will be locally symmetric.

While the modified boundary condition approximation will be at most first order accurate near each corner, it is not clear what impact that truncation error has on the accuracy of the solution. We are also interested in the long-time stability of the resulting scheme. To investigate these issues, we take the domain to be a square with side length 2, rotated 10 degrees relative to the grid directions. In rotated coordinates $\tilde{x} = x\cos(\theta) + y\sin(\theta)$, $\tilde{y} = -x\sin(\theta) + y\cos(\theta)$, $\theta = 10\pi/180$, an exact solution of the homogeneous wave equation can be constructed using Fourier expansion. Here we take

$$u(\tilde{x}, \tilde{y}, t) = \sin\left(\frac{\pi\tilde{x}}{2}\right)\sin\left(\frac{3\pi\tilde{y}}{2}\right)\cos(\omega t), \quad \omega = \frac{\pi\sqrt{10}}{2},$$

which satisfies homogeneous Neumann conditions along $\tilde{x} = \pm 1$ and $\tilde{y} = \pm 1$, respectively. The errors in the computed solutions on two grid sizes are reported in Figure 8, indicating that the solution is almost second order accurate despite the corners. However, for reasons not currently understood, the errors accumulate and seem to grow linearly in time.

In our last numerical example, we use the numerical method to compute the

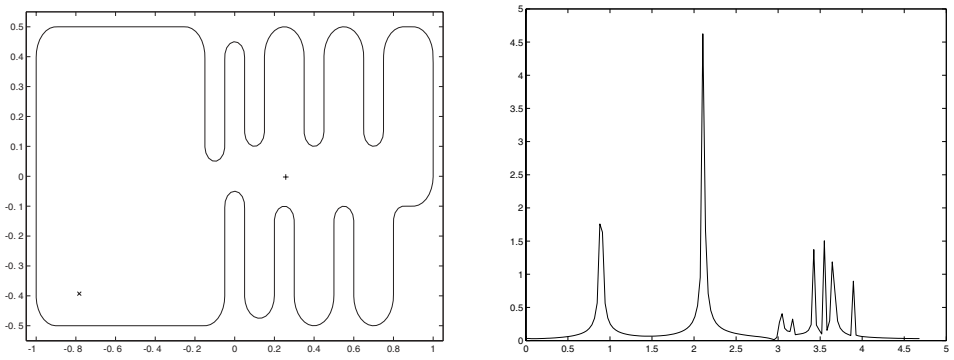

FIG. 9. *The geometry for the harbor model (left). The computational grid covered* $-1.05 \le x \le 1.05$, $-0.55 \le y \le 0.55$ *and had* 801×401 *grid points corresponding to the grid size* $h = 2.6 \times 10^{-3}$. *The forcing is located at the "*x*" and the signal is recorded at the "+." The right figure shows the lowest modes in the discrete Fourier transform of the recorded signal, as a function of the frequency. The spikes indicate eigenfrequencies.*

eigenfrequencies and eigenmodes of the domain shown in Figure 9. Since the wave equation models the propagation of small amplitude water waves, we may think of this geometry as representing a simple harbor. Even though the grid is rather fine, the wide stencil used by the third order boundary condition couples the solution at some ghost points near the ends of the convex fingers protruding into the domain. By coupling we mean that at least one of the interior points in one boundary condition stencil is also a ghost point. Satisfying the boundary conditions at all ghost points would then require an iteration over the ghost point values. To avoid this iterative procedure, we will instead use the second order boundary condition, which uses fewer interior points in its stencil. For this case, the solution does not get coupled at any ghost points. To estimate the eigenfrequencies, we apply a forcing to two consecutive points in space,

$$F(x_{i,j}, y_{i,j}, t) = \begin{cases} Ke^{-(t-t_0)^2/\varepsilon_1^2}, & i = I_1,\ j = J_1, \\ -Ke^{-(t-t_0)^2/\varepsilon_1^2}, & i = I_1 + 1,\ j = J_1, \\ 0, & \text{otherwise.} \end{cases}$$

Here $K = 10^5$, $\varepsilon_1 = 0.07$, $t_0 = 1.0$. We choose this forcing since it is likely to have a component along each eigenmode, except the constant mode corresponding to the zero eigenvalue, which is present due to the Neumann boundary condition. We start the computation from rest and integrate up to time $T = 200$. During the computation, the solution is recorded at another point (I_r, J_r). This signal is then Fourier-transformed in time, after which the eigenfrequencies of the domain appear as spikes in the spectrum; see Figure 9. Note that the frequency resolution is limited by $2\pi/T$, so a longer computation leads to a more accurate estimate of the eigenfrequencies. Also note that the eigenvalues of

$$\begin{aligned} \Delta u &= \lambda u \quad \text{in } \Omega, \\ \frac{\partial u}{\partial n} &= 0 \quad \text{on } \Gamma \end{aligned}$$

are related to the eigenfrequencies ω through $\lambda = -\omega^2$.

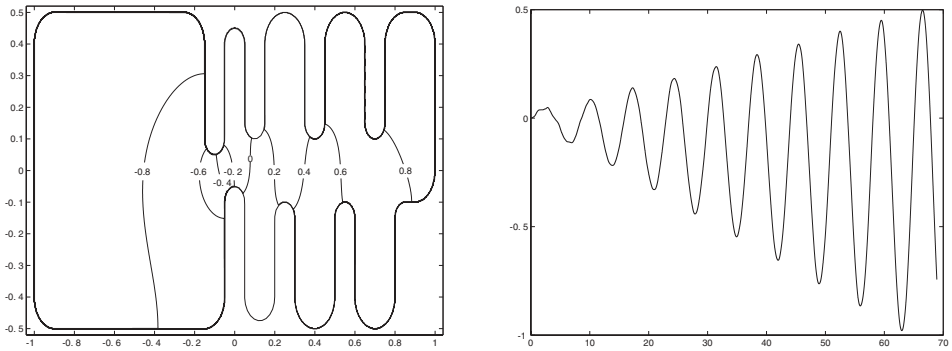

FIG. 10. *A contour plot of the solution at $t = 62.4$ approximating the eigenmode corresponding to the eigenfrequency $\omega_r = 0.90$ (left). Here, the contour levels are equally spaced between -0.8 and 0.8. The right figure shows the time-history of the solution at the point $(x, y) = (-0.6526, -0.1976)$. Because of resonance, the amplitude grows linearly in time.*

To compute the corresponding eigenmode, we perform a second computation, where the forcing is taken to be

$$F(x, y, t) = \sin(\omega_r t)\gamma'(x - x_0)\gamma(y), \quad \gamma(\xi) = e^{-\xi^2/\varepsilon_2^2}, \quad x_0 = -0.6,\ \varepsilon_2 = 0.2.$$

The frequency of the time-harmonic forcing is chosen to obtain resonance. In this computation, we take $\omega_r = 0.90$, which is the approximate location of the first spike in the spectrum; see Figure 9. Due to resonance, the solution will be more and more dominated by the corresponding eigenmode as time increases, assuming that the forcing is not orthogonal to that mode. The resulting eigenmode is shown in Figure 10 together with the time-history of the solution in one point, which demonstrates the expected linear growth in amplitude.

9. Conclusions. We have presented stability theory and numerical examples for a Cartesian embedded boundary scheme which directly discretizes the second order wave equation subject to Neumann boundary conditions, without rewriting the problem as a system of first order equations. Since the discrete approximation of the Laplacian subject to the Neumann boundary condition leads to a matrix A that is not symmetric, the stability theory developed in [9] does not directly apply. Indeed, numerical experiments in two-dimensional domains indicate that the basic undamped scheme is unstable. In the one-dimensional case, we prove that the semidiscrete scheme is stable, thus indicating that the instability is due to two-dimensional effects. In two dimensions, tangential derivatives are present in the truncation error of the boundary condition, when the boundary is not aligned with the mesh. A two-dimensional stability theory is presented that first is used to show the destabilizing effect of perturbing a Neumann boundary condition by tangential derivatives. The stability theory also predicts that a small fourth order dissipative term $h^3\Delta^2 u_t$ can control the destabilizing effects of high order tangential derivatives. The discrete stabilization term $h^3 A^T A(u^n - u^{n-1})/k$ is proposed for the practical computation. This term can be evaluated all the way up to the boundary so no extra numerical boundary conditions are necessary. After discretization in space, the system of second order ordinary differential equations is integrated in time using a second or fourth order explicit method. Improved spatial accuracy can be achieved away from the boundary by adding a fourth order spatial correction term. Our numerical examples indicate

that the resulting scheme is second order accurate measured in max-norm and that the time step can be chosen independently of small grid cells near the boundary. Numerical experiments also show that the amount of dissipation needed to stabilize the scheme is very small and, for smooth boundaries, long-time computations do not show any accumulation of the error. A simple modification of the scheme in the vicinity of corners is proposed, but more work is needed to fully understand its implications.

Work is underway to generalize the proposed method to Maxwell's equations written as a system of second order wave equations, which requires more complicated boundary conditions to be satisfied. Further work is also planned to extend the method to three space dimensions.

Appendix A. Computing $\boldsymbol{A^T u}$. Using standard notation for an $N \times N$ matrix $\mathcal{A}$ and vectors $\boldsymbol{u}$ and $\boldsymbol{v}$, the most straightforward way of computing $\boldsymbol{v} = \mathcal{A}^T \boldsymbol{u}$ might be

$$v_i = \sum_{j=1}^{N} \mathcal{A}_{j,i} u_j.$$

However, when the matrix is sparse, it is inefficient to store all matrix elements explicitly. If we let $\boldsymbol{a}_i^T$ denote the ith row of $\mathcal{A}$, we can write $\mathcal{A}$ in row form,

$$\mathcal{A} = \begin{pmatrix} \boldsymbol{a}_1^T \\ \boldsymbol{a}_2^T \\ \vdots \\ \boldsymbol{a}_N^T \end{pmatrix}, \quad \mathcal{A}^T = (\boldsymbol{a}_1, \boldsymbol{a}_2, \ldots, \boldsymbol{a}_N), \tag{A.1}$$

and $\boldsymbol{v} = \mathcal{A}^T \boldsymbol{u} = \sum_{j=1}^{N} \boldsymbol{a}_j u_j$. Hence, another way of computing $\mathcal{A}^T \boldsymbol{u}$ is by accumulating the contributions from each column of $\mathcal{A}^T$, i.e., each row of $\mathcal{A}$:

1. $\boldsymbol{v} = 0$;
2. for $j = 1, 2, \ldots, N$ do $\boldsymbol{v} += \boldsymbol{a}_j u_j$.

Here the operator $+=$ means evaluate the right-hand side and add the result to the left-hand side (as it is defined in the "C" programming language).

Next consider the particular form of the matrix $\mathcal{A} = A$ that arises in our embedded boundary discretization. Away from the boundary, A is defined by (1.2). Near the boundary, outside points in the stencil get eliminated using the discretized Neumann boundary condition, resulting in a stencil of the type (7.1). In general, each row of A will only have a few nonzero entries. To simplify the notation, we define $u(k,l) =: u_{k,l}$. Each row of the matrix can then be written in sparse form as

$$A\boldsymbol{u}|_{i,j} =: \sum_{k=1}^{NZ_{i,j}} a_{i,j}^{(k)} u(I_{i,j}^{(k)}, J_{i,j}^{(k)}), \tag{A.2}$$

where $NZ_{i,j}$ is the number of nonzero entries for the row corresponding to grid point (i,j), and $(I_{i,j}^{(k)}, J_{i,j}^{(k)})$ is the grid point index of the kth contribution to $A\boldsymbol{u}$ in that row.

Equation (A.2) represents the matrix A in a sparse row form corresponding to (A.1). The operation $\boldsymbol{v} = A^T \boldsymbol{u}$ can therefore be computed using the above accumulation algorithm,

1. $\boldsymbol{v} = 0$;
2. for all grid points (i,j) inside Ω do
   for $k = 1, 2, \ldots, NZ_{i,j}$ do

$$v(I_{i,j}^{(k)}, J_{i,j}^{(k)}) += a_{i,j}^{(k)} u(i,j).$$

We note that it is only necessary to form the sparse representation of A at interior points where some neighbors are outside Ω. If all neighbors of (i,j) are interior, the "for k"-loop in the second step in the accumulation algorithm can be replaced by

$$v(i+1,j) += \frac{u(i,j)}{h^2}, \quad v(i-1,j) += \frac{u(i,j)}{h^2}, \quad v(i,j) += -\frac{4u(i,j)}{h^2},$$
$$v(i,j-1) += \frac{u(i,j)}{h^2}, \quad v(i,j+1) += \frac{u(i,j)}{h^2}.$$

Appendix B. Proof of Theorem 6.1. The proof is divided into three cases: $|\lambda| \gg |b|$, $|\lambda| \ll 1$, and $|\lambda| \leq C|b|$.

Case 1, $|\lambda| \gg |b|$. We have $(\lambda - b)/(\lambda + b) \sim 1$. To make the modulus of the right-hand side of (6.6) be close to one,

$$\lambda = Ni\pi + \tilde{\lambda}, \quad |\tilde{\lambda}| \ll 1, \ N \geq 1 \text{ integer}.$$

(Note that $N = 0$; i.e., $|\lambda| \ll 1$ is treated in Case 2 below.) To first approximation in $\tilde{\lambda}$,

$$\frac{\tilde{\lambda} + iN\pi - b}{\tilde{\lambda} + iN\pi + b} = 1 + 2\tilde{\lambda}.$$

Therefore,

$$\tilde{\lambda} + iN\pi - b = \tilde{\lambda} + iN\pi + b + 2\tilde{\lambda}^2 + 2iN\pi\tilde{\lambda} + 2b\tilde{\lambda}$$

or

$$\tilde{\lambda}^2 + (iN\pi + b)\tilde{\lambda} + b = 0.$$

Since $|\lambda| \gg |b|$, $|b| \ll N\pi$, and we can expand the roots of $\tilde{\lambda}$ in the small parameter $\epsilon = b/N\pi$, $|\epsilon| \ll 1$,

$$\begin{aligned}\tilde{\lambda} &= -\frac{iN\pi + b}{2} \pm i\frac{N\pi}{2}\sqrt{1 - \frac{4b}{N\pi}\left(\frac{i}{2} - \frac{1}{N\pi} + \frac{b}{4N\pi}\right)} \\ &= -\frac{iN\pi + b}{2} \pm \left(\frac{iN\pi + b}{2} + \frac{ib}{N\pi} + \mathcal{O}(\epsilon^2)\right).\end{aligned}$$

Only the plus sign gives $|\tilde{\lambda}| \ll 1$, and we have

$$\lambda = iN\pi + \tilde{\lambda} \approx iN\pi + \frac{ib}{N\pi}.$$

By solving the characteristic equation (5.16) for s and inserting the above expression for λ,

$$s = -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - \omega^2 - N^2\pi^2 - 2b - \frac{b^2}{(N\pi)^2}}. \tag{B.1}$$

We assume that

$$0 \le \alpha \le 1. \tag{B.2}$$

Since $|\omega h| \le 1$, we have that

$$|a| \le |\omega|, \tag{B.3}$$

so $N^2\pi^2 + \omega^2 - a^2/4$ is real and positive. Because $|b|/N\pi \ll 1$, we can expand the roots of (B.1),

$$\begin{aligned} s &= -\frac{a}{2} \pm i\sqrt{\left(N^2\pi^2 + \omega^2 - \frac{a^2}{4}\right)}\sqrt{1 + \frac{2b}{N^2\pi^2 + \omega^2 - a^2/4}\left(1 + \frac{b}{2N^2\pi^2}\right)} \\ &= -\frac{a}{2} \pm \left(i\sqrt{\left(N^2\pi^2 + \omega^2 - \frac{a^2}{4}\right)} + \frac{ib}{\sqrt{N^2\pi^2 + \omega^2 - a^2/4}} + \cdots\right). \end{aligned}$$

We have $ib = -\beta_1\omega^5h^4 + i\beta_2\omega^4h^3$, and $N^2\pi^2 + \omega^2 - a^2/4 \ge 3\omega^2/4$, so

$$\operatorname{Re} s \approx -\frac{1}{2}\alpha h^3\omega^4 \mp \frac{\beta_1\omega^5h^4}{\sqrt{N^2\pi^2 + \omega^2 - a^2/4}} \le -\frac{1}{2}\alpha h^3\omega^4 + \frac{2|\beta_1|\omega^4h^4}{\sqrt{3}}. \tag{B.4}$$

Therefore, $\operatorname{Re} s < 0$ for $\alpha \ge 4|\beta_1|h/\sqrt{3}$, and we conclude that there can be no exponentially growing solutions with $|\lambda| \gg |b|$, when α exceeds that value.

Case 2, $|\lambda| \ll 1$. If $|\lambda| \ll 1$, we can replace (6.6) by

$$\frac{\lambda - b}{\lambda + b} = 1 + 2\lambda,$$

i.e.,

$$\lambda^2 = -b + \mathcal{O}(b^{3/2}). \tag{B.5}$$

Then (5.16) gives us

$$s = -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - \omega^2 + \lambda^2} \approx -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - \omega^2 - i\beta_1\omega^5h^4 - \beta_2\omega^4h^3}, \tag{B.6}$$

and by making the same expansion as above we obtain

$$\operatorname{Re} s \approx -\frac{1}{2}\alpha h^3\omega^4 \pm \frac{|\beta_1|\omega^4h^4}{\sqrt{3}}.$$

Hence, in this case, $\operatorname{Re} s < 0$ for $\alpha > 2|\beta_1|h/\sqrt{3}$, and there can be no exponentially growing solutions with $|\lambda| \ll 1$ when α satisfies that inequality. Note that (B.5) implies that $|b| \ll 1$ when $|\lambda| \ll 1$.

Case 3, $|\lambda| \le C|b|$. From Case 2 above, we know that $|b| \ll 1$ when $|\lambda| \ll 1$. We can therefore assume that $|b| \ge \delta_1 > 0$. Since $|b| = \omega^4h^3\sqrt{\beta_2^2 + \beta_1^2\omega^2h^2}$ and $|\omega h| \le 1$,

$$c_1h^{-3/4} \le |\omega| \le h^{-1}. \tag{B.7}$$

Let us define a complex number ρ such that

$$\lambda + b = \rho b, \tag{B.8}$$

that is, $|\rho - 1| \leq C$. There are two possibilities:

$$\text{(a)} \quad |\rho| \geq \delta > 0, \quad \text{(b)} \quad |\rho| \leq \epsilon \ll 1.$$

For possibility (a), we start by deriving a bound for $\operatorname{Re}\lambda$. Let $\lambda_r = \operatorname{Re}\lambda$ and $\lambda_i = \operatorname{Im}\lambda$. From (6.6)

$$e^{2\lambda_r} = \left|\frac{\lambda + b - 2b}{\lambda + b}\right| \leq 1 + \left|\frac{2b}{\lambda + b}\right| = 1 + \frac{2}{|\rho|} \leq 1 + \frac{2}{\delta},$$

and therefore

$$\lambda_r \leq \frac{1}{2}\log\left(1 + \frac{2}{\delta}\right) = c_2. \tag{B.9}$$

By solving the characteristic equation (5.16) for s, we have

$$s = -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - \omega^2 - \lambda_i^2 + 2i\lambda_i\lambda_r + \lambda_r^2}.$$

Since (B.7) bounds $|\omega|$ from below, $\lambda_r^2 \ll \omega^2$. Hence, we can neglect this term, expand the roots of s as before, and use (B.9) to get

$$\operatorname{Re} s \leq -\frac{1}{2}\alpha h^3\omega^4 + \frac{c_2|\lambda_i|}{\sqrt{\frac{3}{4}\omega^2 + \lambda_i^2}}.$$

Let $\rho_r = \operatorname{Re}\rho$ and $\rho_i = \operatorname{Im}\rho$. The relation (B.8) gives $\lambda_i = \xi\omega^4h^3$, where the real-valued coefficient $\xi = \rho_i\beta_2 + (\rho_r - 1)\beta_1\omega h$. Clearly, for all $|\rho| \geq \delta$ and $|\omega h| \leq 1$,

$$\frac{|\lambda_i|}{\sqrt{\frac{3}{4}\omega^2 + \lambda_i^2}} = \frac{|\xi||\omega h|^3}{\sqrt{\frac{3}{4} + \xi^2\omega^6h^6}} \leq c_3|\omega h|^3.$$

Since $|\omega|$ is bounded from below by (B.7), $\operatorname{Re} s < 0$ for $\alpha > 2c_2c_3c_1^{-1}h^{3/4}$.

For possibility (b), we exploit that $\operatorname{Re}\lambda > 0$ for $\operatorname{Re} s > 0$. We have

$$\lambda = -b(1 - \rho), \quad |\rho| \ll 1. \tag{B.10}$$

When $\rho = 0$, this case reverts to (5.17) and the half-plane problem. For $\beta_2 > 0$, $\operatorname{Re}(-b) = -\beta_2\omega^4h^3 < 0$, but $\operatorname{Re}\lambda > 0$ for $\operatorname{Re} s > 0$, which is contradicted by (B.10). Hence there are no solutions with $\operatorname{Re} s > 0$ when $\beta_2 > 0$. When $\beta_2 < 0$, $\beta_1 \ll 1$, and $|\beta_2| \ll 1$, Theorem 5.2 applies and the problem can be stabilized by a small amount of dissipation $\alpha \geq K|\beta_1\beta_2|$.

For the perturbed case, $|\rho| = \epsilon$, $\epsilon \ll 1$, a simple computation yields

$$\operatorname{Re}(-b + \rho b) = (-1 + \rho_r)\beta_2\omega^4h^3 - \rho_i\beta_1\omega^5h^4,$$

and $\operatorname{Re}(-b + \rho b) < 0$ if $(-1 + \rho_r)\beta_2 + |\rho_i\beta_1| < 0$, i.e.,

$$\beta_2 > \frac{|\rho_i|}{1 - \rho_r}|\beta_1| \approx \epsilon|\beta_1|. \tag{B.11}$$

Hence, when $|\rho| \leq \epsilon$, there cannot be any solutions with $\operatorname{Re} s > 0$ when (B.11) is satisfied. For $\beta_2 < \epsilon|\beta_1|$, we can apply the same expansion as in Theorem 5.2 for the half-plane problem. Since λ is perturbed by $\rho b = \mathcal{O}(\epsilon)$, the roots of s can only be perturbed by $\mathcal{O}(\epsilon)$, and the amount of dissipation necessary to stabilize the problem remains essentially the same.

This concludes the proof of Theorem 6.1.

A FINITE ELEMENT APPROXIMATION OF A VARIATIONAL INEQUALITY FORMULATION OF BEAN'S MODEL FOR SUPERCONDUCTIVITY*

C. M. ELLIOTT†, D. KAY†, AND V. STYLES†

Abstract. We introduce a finite element approximation of a variational formulation of Bean's model for the physical configuration of an infinitely long cylindrical superconductor subject to a transverse magnetic field. We prove an error between the exact solution and the approximate solution for the current density and the magnetic field in appropriate norms of order $h^{1/2} + \Delta t$. Numerical simulations for a variety of applied magnetic fields are also presented.

Key words. finite elements, variational inequalities, superconductors

DOI. 10.1137/S0036142902412324

1. Introduction. In this paper we consider the numerical approximation of an evolutionary variational inequality arising from a critical state model for a type-II superconductor. The physical setting is that of an infinitely long cylinder of type-II superconducting material subject to an applied transverse magnetic field. We take the cylindrical superconductor to occupy the region $D = \Omega \times \mathbb{R}$, where $\Omega \subset \mathbb{R}^2$, a bounded, simply connected domain in $\mathbb{R}^2$, is the cross section of the superconductor. The physical vector fields that are relevant are the current density $\mathbf{J} = (0, 0, J(\underline{x}, t))$, which is parallel to the axis of the cylinder, and the magnetic field $\mathbf{H} = (\underline{H}(\underline{x}, t), 0)$, which is orthogonal to the cylinder's axis, for $\underline{x} \in \mathbb{R}^2$. The well-known Bean critical state model can be formulated as an evolutionary variational inequality for $J(\underline{x}, t)$ of the form (see [10]):

(**P**) Find $J(\cdot, t) \in K$ for a.e. $t \geq 0$ such that $J(\cdot, 0) = J_0 \in K$ and

$$\left(\frac{\partial GJ}{\partial t}, \eta - J\right) \geq (f, \eta - J) \quad \forall\, \eta \in K. \tag{1.1}$$

Here $(\cdot, \cdot)$ denotes the standard L^2 inner product over Ω,

$$\mathcal{V} := \left\{\eta \in L^2_{\mathrm{loc}}(\mathbb{R}^2) : \nabla\eta \in L^2(\mathbb{R}^2),\ (\eta, 1) = 0\right\},$$

$$K = \left\{\eta \in \mathcal{V} : \eta = 0 \ \text{ on } \mathbb{R}^2/\overline{\Omega}, |\eta| \leq J_c, \ \ (\eta, 1) = 0\right\}$$

and $G : \mathcal{V}' \to \mathcal{V}$ is the "inverse Laplacian" operator defined by the solution to the following variational problem:

Given $v \in \mathcal{V}'$, find $Gv \in \mathcal{V}$ such that

$$(\nabla Gv, \nabla\eta)_{\mathbb{R}^2} = \langle v, \eta\rangle \quad \forall\, \eta \in \mathcal{V} \tag{1.2}$$

with $\langle\cdot,\cdot\rangle$ denoting the duality pairing between $\mathcal{V}'$ and $\mathcal{V}$. For $v \in \mathcal{F} \subset \mathcal{V}'$ we have

$$\langle v, \eta\rangle = (v, \eta) \quad \forall\ \eta \in \mathcal{V},$$

where

$$\mathcal{F} := \Big\{\eta \in \mathcal{V}' : \eta \in L^2_{\rm loc}(\mathbb{R}^2) :\ \eta = 0 \text{ on } \mathbb{R}^2/\overline{\Omega}\Big\}.$$

Setting

$$\mathcal{F}_0 := \Big\{\eta \in \mathcal{F} : (\eta, 1) = 0\Big\},$$

we have the following for all $v \in \mathcal{F}_0$:

$$-\Delta Gv = v \quad \text{in } \mathbb{R}^2, \qquad \int_\Omega Gv\ d\underline{x} = 0, \qquad \text{and} \qquad \nabla Gv \sim 0 \quad \text{at } \infty, \tag{1.3}$$

and Gv is unique.

Throughout the remaining sections we assume that

$$f \in L^2(0,T; H^2(\Omega)), \quad f_t \in L^2(0,T; H^1(\Omega)). \tag{1.4}$$

It follows from the classical theory of evolutionary variational inequalities that (**P**) has a unique solution; see [10, 5].

2. Derivation of the model and reduction to a bounded domain.

2.1. Derivation of the model. We suppose that all field variables depend only on t and $\underline{x} \in \mathbb{R}^2$, and that there is a prescribed, time dependent, smooth magnetic field $\mathbf{H}^a = (\underline{H}^a(\underline{x}, t), 0)$ applied at infinity and a prescribed, bounded current density $\mathbf{J}^a = J^a(\underline{x}, t)\mathbf{e}_3$, exterior to the superconductor, such that the compatibility condition

$$\mathbf{J}^a - \operatorname{curl} \mathbf{H}^a \to 0 \quad \text{as } |\underline{x}| \to \infty$$

is satisfied. Then Maxwell's equations, neglecting displacement current, are

$$\begin{aligned} \frac{\partial \mathbf{H}}{\partial t} + \operatorname{curl} \mathbf{E} &= \mathbf{0} \qquad \text{in } \mathbb{R}^2, \\ \operatorname{curl} \mathbf{H} &= \mathbf{J} \qquad \text{in } \mathbb{R}^2, \\ \nabla \cdot \mathbf{H} &= 0 \qquad \text{in } \mathbb{R}^2, \end{aligned}$$

where $\mathbf{E}$ is the electric field; see [10]. Note we have taken the magnetic permeability equal to 1 for simplicity.

The critical state model assumes the following nonlinear Ohm's law in the superconductor,

$$\mathbf{E} \ = \ \rho\mathbf{J} \qquad \text{in } \Omega$$

with

$$|\mathbf{J}| \ \le \ J_c \qquad \text{in } \Omega,$$

and the effective resistivity ρ achieves the constraint on $|\mathbf{J}|$ by the relation $\rho \in \beta(|\mathbf{J}|)$, where β is a multivalued map given by the graph

$$\beta(r) = \begin{cases} (-\infty, 0] & \text{if} \quad r = -J_c, \\ 0 & \text{if} \quad |r| < J_c, \\ [0, \infty) & \text{if} \quad r = J_c. \end{cases}$$

We assume that exterior to the superconductor the current is prescribed so

$$\mathbf{J} = \mathbf{J}^a \qquad \text{in } \mathbb{R}^2/\overline{\Omega}.$$

To complete this set of equations we require initial and boundary conditions for the magnetic field given, respectively, by

$$\mathbf{H}(\underline{x}, 0) \;=\; \mathbf{H}_0(\underline{x})$$

and

$$\mathbf{H} \;\to\; \mathbf{H}^a \quad \text{as } |\underline{x}| \to \infty.$$

On the boundary of the superconductor, $\partial\Omega$, we have that

$$[\mathbf{H}_\tau] = [\mathbf{H}_\nu] = 0,$$

where $[\mathbf{H}_\tau]$ and $[\mathbf{H}_\nu]$ denote the jumps in the tangential and normal components, respectively, of $\mathbf{H}$ across $\partial\Omega$.

In order to consider homogeneous boundary conditions at infinity, it is convenient to introduce a current density $\mathbf{J}^e$ defined by

$$\mathbf{J}^e \;= \begin{cases} \mathbf{0} & \text{in } \Omega, \\ \mathbf{J}^a & \text{in } \mathbb{R}^2/\overline{\Omega}. \end{cases}$$

Associated with $\mathbf{J}^e$ is the magnetic field $\mathbf{H}^e$ such that

$$\begin{aligned} \operatorname{curl} \mathbf{H}^e &= \mathbf{J}^e \quad \text{in } \mathbb{R}^2, \\ \nabla \cdot \mathbf{H}^e &= 0 \quad \text{in } \mathbb{R}^2, \\ \mathbf{H}^e &\to \mathbf{H}^a \quad \text{as } |\underline{x}| \to \infty. \end{aligned}$$

Finally, we use the shift

$$\hat{\mathbf{J}} = \mathbf{J} - \mathbf{J}^e \quad \text{and} \quad \hat{\mathbf{H}} = \mathbf{H} - \mathbf{H}^e$$

to give the problem

$$\frac{\partial \hat{\mathbf{H}}}{\partial t} + \operatorname{curl}(\rho \hat{\mathbf{J}}) = -\frac{\partial \mathbf{H}^e}{\partial t} \qquad \text{in } \Omega, \tag{2.1}$$

$$\operatorname{curl} \hat{\mathbf{H}} = \hat{\mathbf{J}} \qquad \text{in } \mathbb{R}^2, \tag{2.2}$$

$$\nabla \cdot \hat{\mathbf{H}} = 0 \qquad \text{in } \mathbb{R}^2, \tag{2.3}$$

$$|\hat{\mathbf{J}}| \le J_c \qquad \text{in } \Omega \tag{2.4}$$

together with the boundary condition

$$\hat{\mathbf{H}} \to \mathbf{0} \text{ as } |\underline{x}| \to \infty.$$

Note that interpreting (2.2), (2.3) in conservation form yields the compatibility boundary conditions

$$\left[\hat{\mathbf{H}}_\nu\right] = \left[\hat{\mathbf{H}}_\tau\right] = 0 \quad \text{on } \partial\Omega.$$

It follows by the assumption $\mathbf{J}^a = J^a(\underline{x}, t)\mathbf{e}_3$ and the definitions of $\mathbf{J}$ and $\mathbf{J}^e$ that $\hat{\mathbf{J}} = (0, 0, J)$, where $J \in K$. From this last set of equations and using the assumption that $\hat{\mathbf{H}}$ lies in the (x_1, x_2) plane, we see that there exists a scalar potential $q(\underline{x}, t)$, $\underline{x} \in \mathbb{R}^2$, for $\hat{\mathbf{H}}$ such that $\hat{\mathbf{H}} = (\nabla^\perp q, 0)$.

Furthermore, q satisfies

$$-\Delta q = J \quad \text{in } \mathbb{R}^2 \tag{2.5a}$$

and

$$|\nabla^\perp q| \to 0 \quad \text{as } |\underline{x}| \to \infty. \tag{2.5b}$$

Imposing the condition

$$\int_\Omega q d\underline{x} = 0, \tag{2.5c}$$

the problem (2.5a)–(2.5c) is known to have a unique solution, which we denote by

$$q = GJ.$$

Similarly, there exists a scalar potential q^e for $\mathbf{H}^e$, unique up to a constant function in time, such that

$$\mathbf{H}^e = (\nabla^\perp q^e, 0), \quad \nabla^\perp q^e \to \underline{H}^a \quad \text{as } |\underline{x}| \to \infty.$$

We may rewrite (2.1) in the form

$$\nabla^\perp \left(\frac{\partial q}{\partial t} + \rho J \right) = -\nabla^\perp \frac{\partial q^e}{\partial t}$$
$$\Rightarrow \nabla^\perp \left(\frac{\partial GJ}{\partial t} + \rho J \right) = -\nabla^\perp \frac{\partial q^e}{\partial t}.$$

Hence, fixing q^e, we obtain

$$\frac{\partial GJ}{\partial t} + \rho J - \lambda(t) = -\frac{\partial q^e}{\partial t} := f,$$

where λ is an arbitrary function of time.

Multiplying the above equation by $\eta - J$ for $\eta \in K$, integrating over Ω, and using the fact that $(1, \eta - J) = 0$, we have

$$\left(\frac{\partial GJ}{\partial t}, \eta - J \right) = (f, \eta - J) - (\rho J, \eta - J).$$

Since $\rho(r) \in \beta(|J|)$ and $|\eta| \le J_c$, we have

$$(\rho J, \eta - J) \le 0.$$

Hence, we obtain problem (**P**).

The above formulation of Bean's model is the basis of the numerical algorithm proposed by Prigozhin in [9, 11] using an explicit formula for the integral operator G. The discretization is then based upon piecewise constant finite elements. This approach leads to a dense matrix. In the following we use the finite element method to approximate G but never form the matrix associated with this finite element approximation. Whenever G is required we use an elliptic solve. In this paper an error bound is proved and an iterative method is proposed for the resulting discrete variational inequality. For an engineering application of (**P**), see [2, 3].

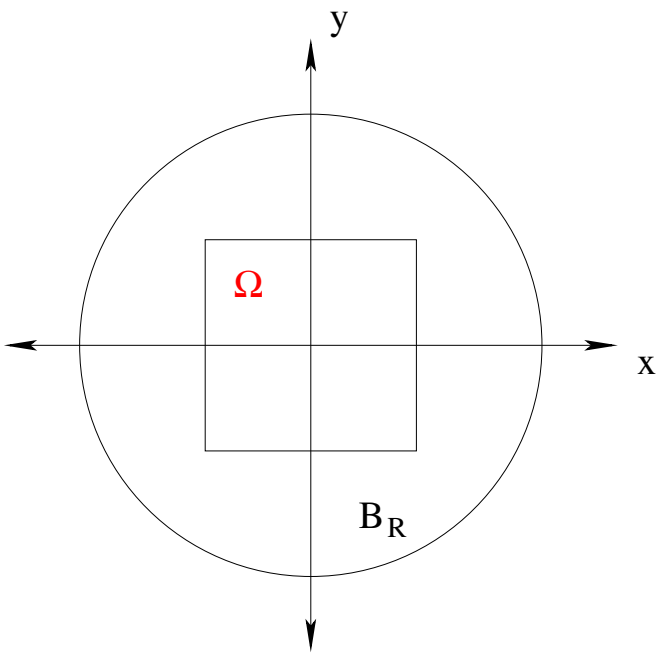

FIG. 2.1. *Reduction in the domain of the problem.*

2.2. Reduction to a bounded domain. From a computational viewpoint, discretizing the whole of $\mathbb{R}^2$ in order to find the operator G is not practical. A natural approach is to restrict the problem to a large bounded region B_R containing Ω and to write an exact boundary condition for Gv on ∂B_R.

Consider the situation where Ω is embedded in a large circle B_R of radius R; see Figure 2.1.

We consider a Dirichlet-to-Neumann mapping which relies on the harmonic property of Gv outside B_R and the boundedness of $\nabla^\perp Gv$ in $L^2(\mathbb{R}^2)$. This method of truncating a problem defined on an infinite domain to one defined on a finite domain is described in [6]. An overview is given here.

For $w \in H^{1/2}(\partial B_R)$ let z solve

$$-\Delta z = 0 \quad \text{in} \quad \mathbb{R}^2 \backslash \overline{B_R}, \tag{2.6}$$

$$z = w \quad \text{on} \quad \partial B_R, \tag{2.7}$$

$$\nabla z \in L^2(\mathbb{R}^2 \backslash \overline{B_R}). \tag{2.8}$$

It follows that we have a Fourier expansion

$$z(r,\theta) = \frac{a_0}{2} + \sum_{k=1}^{\infty} (a_k \cos(k\theta) + b_k \sin(k\theta)) R^k r^{-k},$$

where a_k, b_k are the Fourier coefficients for $w = w(\theta)$ on ∂B_R.

Differentiating with respect to r and letting $r \to R$ gives

$$\frac{\partial z}{\partial r}(R,\theta) = -\sum_{k=1}^{\infty} \frac{k}{R}(a_k \cos(k\theta) + b_k \sin(k\theta)). \tag{2.9}$$

Since

$$a_k = -\frac{1}{k\pi}\int_0^{2\pi} \frac{\partial w}{\partial \varphi}\sin(k\varphi)d\varphi \quad \text{and} \quad b_k = \frac{1}{k\pi}\int_0^{2\pi} \frac{\partial w}{\partial \varphi}\cos(k\varphi)d\varphi,$$

substituting into (2.9) gives the relation

$$\left.\frac{\partial z}{\partial r}\right|_{\partial B_R}(\theta) = \mathcal{B}(w)(\theta) := -\sum_{k=1}^{\infty}\frac{1}{R\pi}\int_0^{2\pi}\frac{\partial w}{\partial \varphi}\sin(k(\varphi-\theta))d\varphi. \tag{2.10}$$

Let z be a solution of (2.6)–(2.8) for w being the trace of Gv on ∂B_R. Taking $\mathcal{B}(\cdot)$ to be defined as above, it follows that Gv solves the following Neumann problem defined on B_R:

$$-\Delta Gv = v \quad \text{in } B_R, \frac{\partial Gv}{\partial \nu} = \mathcal{B}(Gv) \quad \text{on } \partial B_R. \tag{2.11}$$

Multiplying (2.11) by a test function $\eta \in H^1(B_R)$, integrating over B_R, and then integrating by parts yield the equivalent variational problem:

For $v \in \mathcal{F}_0$, find $Gv \in H^1(B_R)$ such that

$$(Gv, 1) = 0, \quad a(Gv,\eta) + b(Gv,\eta) = (v,\eta) \quad \forall\ \eta \in H^1(B_R), \tag{2.12}$$

where for $\xi, \eta \in H^1(B_R)$,

$$a(\xi,\eta) := \int_{B_R}\nabla\xi\cdot\nabla\eta\ d\underline{x} \quad \text{and} \quad b(\xi,\eta) := \int_{\partial B_R}\mathcal{B}(\xi)\eta\ dS.$$

The existence of a unique solution Gv to this variational problem is easily proved.

We define

$$A(\xi,\eta) := a(\xi,\eta) + b(\xi,\eta) \quad \forall\ \xi,\eta \in H^1(B_R) \tag{2.13}$$

together with the seminorm and norm

$$|\eta|_A^2 := A(\eta,\eta) \quad \forall\ \eta \in H^1(B_R), \quad ||\eta||_{A^{-1}}^2 := |G\eta|_A^2 \quad \forall\ \eta \in \mathcal{F}_0. \tag{2.14}$$

Henceforth we define the L^2 norm and the H^1 norm and seminorm over X respectively by

$$||\eta||_{0,X}^2 = \int_X |\eta|^2 d\underline{x}, \quad ||\eta||_{1,X}^2 = \int_X (|\eta|^2 + |\nabla\eta|^2)d\underline{x} \quad \text{and} \quad |\eta|_{1,X}^2 = \int_X |\nabla\eta|^2 d\underline{x}.$$

From [6] we have that A is continuous with respect to the H^1 norm; that is, for all $\xi, \eta \in H^1(B_R)$

$$|A(\xi,\eta)| \ \le\ C||\xi||_{1,B_R}||\eta||_{1,B_R}. \tag{2.15}$$

Using (2.12)–(2.15), we have the following useful result:

$$(\xi,\eta) = A(G\xi,\eta) \le |G\xi|_A|\eta|_A \le C||\xi||_{A^{-1}}||\eta||_{1,B_R} \quad \forall\ \eta \in H^1(B_R),\ \xi \in \mathcal{F}_0. \tag{2.16}$$

3. Finite element approximation. In this section we consider a finite element approximation of (**P**) under the following assumptions on the partitioning:

(A) Let Ω be a polygon and let T_h^1 be a quasi-uniform partitioning of Ω into disjoint open simplices κ with $h_\kappa := \operatorname{diam}(\kappa)$ and $h := \max_{\kappa\in T_h^1} h_\kappa$, so that $\overline{\Omega} = \cup_{\kappa\in T_h^1}\overline{\kappa}$.

(B) Let T_h^2 be a partitioning of B_R into disjoint open elements $\kappa \in T_h^2$ such that
- $\cup_{\kappa\in T_h^2}\overline{\kappa} = \overline{B}_R$,
- either $\kappa \cap \Omega$ is empty or $\kappa \in T_h^1$,
- if $\overline{\kappa} \cap \partial B_R = \emptyset$, or a point, then κ is a simplex; otherwise, κ is a three-sided element with a curved edge on ∂B_R.

Associated with T_h^1 is the finite element space of continuous piecewise linear functions on Ω such that

$$S_h^1 = \left\{\chi \in C(\overline{\Omega}) : \chi|_\kappa \quad \text{is linear } \forall\ \kappa \in T_h^1\right\} \subset H^1(\Omega).$$

Similarly associated with T_h^2 is the finite element space of continuous functions on B_R such that

$$S_h^2 = \left\{\chi \in C(\overline{B_R}) : \chi|_\kappa \quad \text{is linear } \ \forall\ \kappa \in T_h^2\right\} \subset H^1(B_R).$$

The discrete inner product $(\cdot,\cdot)^h$ is defined by numerical integration in the following way.

Associated with each node $\underline{x}_i$, $i = 1, 2, \dots, M$, of S_h^1 we have a lumped mass matrix value $\mathcal{M}_i > 0$. We now introduce a discrete semi-inner product on $L^2(\Omega)$, defined by

$$(\eta_1, \eta_2)^h := \int_\Omega \Pi^h(\eta_1\eta_2)d\underline{x} = \sum_{i=1}^{M} \mathcal{M}_i(\eta_1\eta_2)(\underline{x}_i), \tag{3.1}$$

where $\Pi^h : C(\overline{\Omega}) \to S_h^1$ is the standard linear interpolation operator.

We introduce the $L^2(\Omega)$ projection operator $Q^h : L^2(\Omega) \to S_h^1$ such that

$$\left(Q^h\eta, \chi\right)^h = (\eta, \chi) \quad \forall\ \chi \in S_h^1. \tag{3.2}$$

Similar to (2.12) we introduce the operator $G^h : \mathcal{F}_0 \to \mathcal{V}_h := \{v_h \in S_h^2 : (v_h, 1) = 0\}$ such that

$$A(G^h\xi, \chi) = (Q^h\eta, \chi)^h \quad \forall\ \xi \in \mathcal{F}_0,\ \chi \in S_h^2, \tag{3.3}$$

and we define the norm

$$||\eta||^2_{A^{-h}} := \left|G^h\eta\right|^2_A \quad \forall \eta \in \mathcal{F}_0.$$

It follows from (3.2) and (3.3) similarly to (2.16) that

$$(\xi, \chi) \ \le\ C||\xi||_{A^{-h}}||\chi||_{1,B_R} \quad \forall\ \chi \in S_h^2,\ \xi \in \mathcal{F}_0. \tag{3.4}$$

From [6] we have the following useful results:

$$\left\|(G - G^h)\eta\right\|_{0,B_R} \ \le\ C_R h^2 \left\|\eta\right\|_{0,\Omega} \qquad \forall\ \eta \in \mathcal{F}_0, \tag{3.5}$$

$$\left|(G-G^h)\eta\right|_{1,B_R} \;\le\; C_R h\,\|\eta\|_{0,\Omega} \qquad \forall\ \eta\in\mathcal{F}_0, \tag{3.6}$$

$$\left|G^h\chi\right|_A \;\le\; |G\chi|_A \qquad \forall\ \chi\in S_h^1, \tag{3.7}$$

and using (3.6) it follows that

$$|G\chi|_A \le C\left|G^h\chi\right|_A \qquad \forall\ \chi\ \in S_h^1. \tag{3.8}$$

Lastly from (2.16) and an inverse inequality we have the following for all $\chi\in\mathcal{F}_0\cap S_h^2$:

$$\|\chi\|_{0,\Omega}^2 \;\le C\ |G\chi|_A||\chi||_{1,\Omega} \;\le\; Ch^{-1}|G\chi|_A\,\|\chi\|_{0,\Omega}$$

$$\Rightarrow \|\chi\|_{0,\Omega}\le Ch^{-1}|G\chi|_A. \tag{3.9}$$

LEMMA 3.1. *We have*

$$\left|G(\eta-Q^h\eta)\right|_A \le Ch\,\|\eta\|_{0,\Omega} \qquad \forall\ \eta\in\mathcal{F}_0. \tag{3.10}$$

Proof. Using (2.12), (3.2), (3.3), (3.5), Hölder's inequality, and the well-known estimate

$$\left|(\xi,\eta)-(\xi,\eta)^h\right| \le Ch^2|\xi|_{1,\Omega}|\eta|_{1,\Omega}\le Ch|\xi|_{1,\Omega}\,\|\eta\|_{0,\Omega} \quad \forall\ \xi,\eta\in S_h^1, \tag{3.11}$$

we have the following for all $\eta\in\mathcal{F}_0$:

$$\begin{aligned}
\left|G(\eta-Q^h\eta)\right|_A^2 &= A(G(\eta-Q^h\eta),G(\eta-Q^h\eta))\\
&= (G(\eta-Q^h\eta),\eta-Q^h\eta)\\
&= ((G-G^h)(\eta-Q^h\eta),\eta-Q^h\eta)\\
&\quad +(G^h(\eta-Q^h\eta),Q^h\eta)^h-(G^h(\eta-Q^h\eta),Q^h\eta)\\
&\le \left\|(G-G^h)(\eta-Q^h\eta)\right\|_{0,\Omega}\left\|\eta-Q^h\eta\right\|_{0,\Omega}\\
&\quad +Ch\left|G^h(\eta-Q^h\eta)\right|_{1,\Omega}\left\|Q^h\eta\right\|_{0,\Omega}\\
&\le Ch^2\left\|\eta-Q^h\eta\right\|_{0,\Omega}^2+Ch\left|G^h(\eta-Q^h\eta)\right|_A\left\|Q^h\eta\right\|_{0,\Omega}.
\end{aligned}$$

The result follows by noting (3.7) and using Young's inequality. ∎

Finally we introduce a finite element approximation of (**P**):

(**P**$_h$) Find $J_h\in K_h$ such that $J_h(\cdot,0)=Q^hJ_0$ and

$$\left(\frac{\partial}{\partial t}G^hJ_h,\chi-J_h\right)\ge(f,\chi-J_h) \qquad \forall\ \chi\in K_h, \tag{3.12}$$

where

$$K_h:=\Big\{\chi\in S_h^1:|\chi|\le J_c,\ \ (\chi,1)=0\Big\}.$$

Remark 3.1. Let the assumptions (A) hold. Then there exists a unique solution J_h to (**P**$_h$) such that

$$||J_h||_{L^\infty(0,T;L^\infty(\Omega))}+\left\|\frac{\partial}{\partial t}GJ_h\right\|_{L^\infty(0,T;A)}\le C. \tag{3.13}$$

LEMMA 3.2. *The unique solutions of* $(\mathbf{P}_h)$ *and* $(\mathbf{P}_h)$ *satisfy*

$$||J - J_h||^2_{L^\infty(0,T;A^{-1})} \leq Ch. \tag{3.14}$$

Proof. Since $J_h \in K$ using (1.1), (2.16), and (3.12) we have

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}\|J - J_h\|^2_{A^{-1}} &= \left(\frac{\partial}{\partial t}G(J - J_h), J - J_h\right) \\
&\leq (f, J - J_h) - \left(\frac{\partial}{\partial t}GJ_h, J - J_h\right) \\
&= (f, J - J_h) - \left(\frac{\partial}{\partial t}G^hJ_h, Q^hJ - J_h\right) - \left(\frac{\partial}{\partial t}G^hJ_h, J - Q^hJ\right) \\
&\quad -\left(\frac{\partial}{\partial t}(G - G^h)J_h, J - J_h\right) \\
&\leq (f, J - J_h) - \left(f, Q^hJ - J_h\right) - \left(\frac{\partial}{\partial t}G^hJ_h, J - Q^hJ\right) \\
&\quad -\left(\frac{\partial}{\partial t}(G - G^h)J_h, J - J_h\right) \\
&= \left(f - \frac{\partial}{\partial t}G^hJ_h, J - Q^hJ\right) - \left(\frac{\partial}{\partial t}(G - G^h)J_h, J - J_h\right) \\
&\leq \left|f - \frac{\partial}{\partial t}G^hJ_h\right|_A \|J - Q^hJ\|_{A^{-1}} + \left\|\frac{\partial}{\partial t}(G - G^h)J_h\right\|_{0,\Omega} \|J - J_h\|_{0,\Omega}.
\end{aligned}$$

Using the above inequality together with (1.4), (3.9), (3.5), (3.10), and (3.13) yields

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}\|J - J_h\|^2_{A^{-1}} &\leq Ch + Ch^2\left\|\frac{\partial}{\partial t}J_h\right\|_{0,\Omega}\|J - J_h\|_{0,\Omega} \\
&\leq Ch + Ch\left|\frac{\partial}{\partial t}GJ_h\right|_A.
\end{aligned}$$

Integrating from 0 to t and using (3.13) gives the required result. ∎

Remark 3.2. This is a suboptimal error bound because of the error term $(f - \frac{\partial}{\partial t}G^hJ_h, J - P^hJ)$, arising due to the variational inequality, which only gives $\mathcal{O}(h)$ because of the lack of H^1 regularity of J.

4. Fully discrete model. In this section we consider a fully discrete discretization of $(\mathbf{P})$. Setting $N\Delta t = T$ and $t_n : n\Delta t$ for $n = 0 \to N$ and for any $\chi_h \in S^1_h$, $n = 0, 1, \ldots,$ we set

$$\delta_t\chi^n = \frac{\chi^n - \chi^{n-1}}{\Delta t}.$$

We consider the following fully discrete discretization of $(\mathbf{P})$:

$(\mathbf{P}_{h,\Delta t})$ For $n = 1 \to N$, find $J^n_h \in K_h$ such that $J^0_h = Q^hJ_0$ and

$$\left(G^h(\delta_tJ^n_h), \chi - J^n_h\right) \geq (f^n, \chi - J^n_h) \quad \forall\ \chi\ \in K_h, \tag{4.1}$$

where $f^n := f(\cdot, t_n)$.

LEMMA 4.1. *Let the assumptions* (A) *hold. Then for* $n = 1 \to N$ *there exists a unique solution* J_h^n *to* $(\mathbf{P}_{h,\Delta t})$ *such that*

$$\max_{n=1\to N} ||\delta_t J_h^n||_{A^{-h}}^2 \le C. \tag{4.2}$$

Proof. Existence and uniqueness for (4.1) are standard. Setting $\chi = J_h^{n-1}$ in (4.1), dividing by Δt, and noting (1.4) and (3.4) gives

$$\left(G^h \delta_t J_h^n, \delta_t J_h^n\right) \le (f^n, \delta_t J_h^n)$$

$$\Rightarrow ||\delta_t J_h^n||_{A^{-h}}^2 \le ||f^n||_{1,B_R} ||\delta_t J_h^n||_{A^{-h}}$$

which together with (1.4) yields (4.2). ∎

Before we derive an error bound on the solutions of $(\mathbf{P}_h)$ and $(\mathbf{P}_{h,\Delta t})$ we introduce some useful notation. For $n \ge 1$ we set

$$J_{h,\Delta t}(t) := \frac{t - t_{n-1}}{\Delta t} J_h^n + \frac{t_n - t}{\Delta t} J_h^{n-1}, \quad f_{\Delta t}(t) := \frac{t - t_{n-1}}{\Delta t} f^n + \frac{t_n - t}{\Delta t} f^{n-1} \quad \forall t \in [t_{n-1}, t_n], \tag{4.3}$$

and

$$\hat{J}_{h,\Delta t}(t) := J_h^n, \quad \hat{f}_{\Delta t}(t) := f^n \quad \forall\, t \in (t_{n-1}, t_n]. \tag{4.4}$$

From (4.3) and (4.4) it follows that for a.e. $t \in (0, T)$,

$$J_{h,\Delta t} - \hat{J}_{h,\Delta t} = -(t_n - t)\frac{\partial}{\partial t} J_{h,\Delta t}, \quad f_{\Delta t} - \hat{f}_{\Delta t} = -(t_n - t)\frac{\partial}{\partial t} f_{\Delta t}. \tag{4.5}$$

We also introduce for $t \in (0, T)$,

$$\mathcal{R}(t) := \left(\hat{f}_{\Delta t} - \frac{\partial}{\partial t} G^h J_{h,\Delta t}, \hat{J}_{h,\Delta t} - J_{h,\Delta t}\right)$$

$$= (t_n - t)\left(\hat{f}_{\Delta t} - \frac{\partial}{\partial t} G^h J_{h,\Delta t}, \frac{\partial}{\partial t} J_{h,\Delta t}\right), \quad t \in (t_{n-1}, t_n], \tag{4.6}$$

and for $t \in (0, T]$,

$$\mathcal{D}(t) := \mathcal{D}^n := -\left(G^h(\delta_t J_h^n), \delta_t J_h^n\right) + \left(G^h(\delta_t J_h^{n-1}), \delta_t J_h^n\right), \quad t \in (t_{n-1}, t_n], \tag{4.7}$$

with J_h^{-1} satisfying (4.1) and

$$\left|\left|\frac{J^0 - J^{-1}}{\Delta t}\right|\right|_{A^{-h}}^2 = \left(G^h(\delta_t J_h^0), \delta_t J_h^0\right) \le C. \tag{4.8}$$

LEMMA 4.2. *For a.e.* $t \in (0, T)$ *we have that*

$$\mathcal{R}(t) \le (t_n - t)\left[\mathcal{D}(t) + \Delta t\left(\frac{\partial}{\partial t} f_{h,\Delta t}, \frac{\partial}{\partial t} J_{h,\Delta t}\right)\right], \quad t \in (t_{n-1}, t_n], \tag{4.9}$$

and

$$\int_0^T \mathcal{R}(t)dt \le C(\Delta t)^2. \tag{4.10}$$

Proof. Setting $\chi = J_h^n$ in (4.1) for $n = n-1$ and using the definitions of $\mathcal{D}(t)$ and $\mathcal{R}(t)$, we have

$$\begin{aligned}\mathcal{R}(t) &= -(t_n - t)\left(\frac{\partial}{\partial t}G^h J_{h,\Delta t}, \frac{\partial}{\partial t}J_{h,\Delta t}\right) + (t_n - t)\left(\hat{f}_{\Delta t}(t) - \hat{f}_{\Delta t}(t-\Delta t), \frac{\partial}{\partial t}J_{h,\Delta t}\right)\\ &\quad +(t_n - t)\left(\hat{f}_{\Delta t}(t-\Delta t), \frac{\partial}{\partial t}J_{h,\Delta t}\right)\\ &\le (t_n - t)\mathcal{D}^n + (t_n - t)\left(\hat{f}_{\Delta t}(t) - \hat{f}_{\Delta t}(t-\Delta t), \frac{\partial}{\partial t}J_{h,\Delta t}\right),\end{aligned}$$

and (4.9) follows by using (4.3). We now integrate (4.9) from 0 to t and use (1.4), (3.4), and (4.2) to obtain

$$\int_0^T \mathcal{R}(t)dt = \sum_{n=1}^N \mathcal{D}^n \int_{t_{n-1}}^{t_n} (t_n - t)dt + \int_0^T \Delta t\left(\frac{\partial}{\partial t}f_{\Delta t}, \frac{\partial}{\partial t}J_{h,\Delta t}\right)(t_n - t)dt$$

$$\le \sum_{n=1}^N \frac{(\Delta t)^2}{2}\mathcal{D}^n + (\Delta t)^2 \int_0^T \left|\left|\frac{\partial}{\partial t}f_{\Delta t}\right|\right|_{1,B_R}\left|\left|\frac{\partial}{\partial t}J_{h,\Delta t}\right|\right|_{A^{-h}} dt \tag{4.11}$$

$$\le \sum_{n=1}^N \frac{(\Delta t)^2}{2}\mathcal{D}^n + C(\Delta t)^2. \tag{4.12}$$

To bound the first term on the right-hand side we use the identity

$$2\big(G^h(a-b), a\big) = \big(G^h a, a\big) - \big(G^h b, b\big) + \big(G^h(a-b), a-b\big)$$

to obtain

$$2\mathcal{D}^n \le \big(G^h(\delta_t J_h^{n-1}), \delta_t J_h^{n-1}\big) - \big(G^h(\delta_t J_h^n), \delta_t J_h^n\big).$$

Summing the above inequality from $n = 1 \to N$ and using (3.4) and (4.8), we have

$$\begin{aligned}2\sum_{n=1}^N \mathcal{D}^n &\le \big(G^h(\delta_t J_h^0), \delta_t J_h^0\big) - \big(G^h(\delta_t J_h^N), \delta_t J_h^N\big)\\ &\le \big(G^h(\delta_t J_h^0), \delta_t J_h^0\big) \le C.\end{aligned} \tag{4.13}$$

Using (4.13) in (4.12), we conclude (4.10). ∎

LEMMA 4.3. *The unique solutions of* $(\mathbf{P}_h)$ *and* $(\mathbf{P}_{h,\Delta t})$ *satisfy*

$$||J_h - J_{h,\Delta t}||_{L^\infty(0,T;A^{-1})} \le C\Delta t. \tag{4.14}$$

Proof. Setting $\chi = J_h$ in (4.1) and $\chi = J_{h,\Delta t}$ in (3.12) and adding the resulting inequalities gives

$$\left(\frac{\partial}{\partial t}G^h(J_{h,\Delta t} - J_h), J_{h,\Delta t} - J_h\right) \le \left(\hat{f}_{\Delta t} - f, J_{h,\Delta t} - J_h\right) + \left(\frac{\partial}{\partial t}G^h J_{h,\Delta t} - \hat{f}_{\Delta t}, J_{h,\Delta t} - \hat{J}_{h,\Delta t}\right).$$

Noting (3.4) and (4.6), we obtain

$$\frac{1}{2}\frac{\partial}{\partial t}||J_{h,\Delta t} - J_h||^2_{A^{-h}} \le \left|\left|\hat{f}_{\Delta t} - f\right|\right|_{1,B_R} ||J_{h,\Delta t} - J_h||_{A^{-h}} + \mathcal{R}.$$

From Lemma 3.6 in [8] we conclude that

$$\max_{t\in[0,T]} ||J_{h,\Delta t} - J_h||_{A^{-h}} \le \left(||J_{h,\Delta t}(0) - J_h(0)||^2_{A^{-h}} + \int_0^T \mathcal{R}(t)dt\right)^{1/2} + \int_0^T \left|\left|\hat{f}_{\Delta t} - f\right|\right|_{1,B_R} dt,$$

and noting (1.4), (3.8), (4.4), and (4.10) yields the required result. ∎

Finally we have our main result.

THEOREM 4.4. *Let the assumptions* (A) *hold. Then the unique solutions* $\{J_h^n\}_{n=0}^N$ *to* $(\mathbf{P}_{h,\Delta t})$ *and* J *to* $(\mathbf{P})$ *satisfy*

$$||J - J_{h,\Delta t}||_{L^\infty(0,T;A^{-1})} \le C(T)(h^{1/2} + \Delta t).$$

Proof. The desired result follows directly from (3.14) and (4.14). ∎

Recalling that $\underline{\hat{H}} = \nabla^\perp GJ$ and setting $\underline{\hat{H}}_h^n = \underline{\hat{H}}_h(t_n) := \nabla^\perp G^h J_h(t_n)$ and $\underline{\hat{H}}_{h,\Delta t}$ as in (4.3), we conclude the following.

COROLLARY 4.1. *The error between the magnetic field* $\underline{H}$ *and its approximation* $\underline{H}_{h,\Delta t}$ *is*

$$\left\|\underline{H} - \underline{H}_{h,\Delta t}\right\|_{L^\infty(0,T;L^2(B_R))} \le C(T)(h^{1/2} + \Delta t).$$

5. Algorithm for solving $(\widehat{\mathbf{P}}_{\mathbf{h},\Delta\mathbf{t}})$. In the numerical simulations presented in section 6 we solve the following approximation of $(\widehat{\mathbf{P}}_{h,\Delta t})$:

$(\widehat{\mathbf{P}}_{h,\Delta t})$ For $n = 1 \to N$, find $J_h^n \in K_h$ such that $J_h^0 = Q^h J_0$ and

$$\left(\hat{G}^h\left(\delta_t \widehat{J}_h^n\right), \chi - \widehat{J}_h^n\right)^h \ge \left(f^n, \chi - \widehat{J}_h^n\right)^h \quad \forall\, \chi \in K_h, \tag{5.1}$$

where $f^n := f(\cdot, t_n)$ and the operator $\hat{G}^h : \mathcal{V}_h \to \mathcal{V}_h$ is such that

$$A(\hat{G}^h\xi, \chi) = (\xi, \chi)^h \quad \forall\, \xi \in \mathcal{V}_h, \chi \in S_h^2.$$

Below we give an algorithm for solving $(\widehat{\mathbf{P}}_{h,\Delta t})$. See [5] for an account of iterative methods for solving discrete variational inequalities.

Reformulating $(\widehat{\mathbf{P}}_{h,\Delta t})$ gives the following problem:

Given $J_h^0 = P^h J_0$, for $n = 1 \to N$, find $J_h^n \in K_h$ and $\lambda^n \in \mathbb{R}$ such that $|J_h^n| \le J_c$, $(J_h^n, 1)^h = 0$, and

$$\left(\hat{G}^h \widehat{J}_h^n, \chi - \widehat{J}_h^n\right)^h \ge \left(\Delta t f^n + \lambda^n + \hat{G}^h \widehat{J}_h^{n-1}, \chi - \widehat{J}_h^n\right)^h \quad \forall\, \chi \in S_h^1 \text{ such that } |\chi| \le J_c.$$

Setting $\Lambda_h^n := \Delta t f^n + \hat{G}^h \widehat{J}_h^{n-1}$, the above problem is equivalent to the following problem:

Find $\widehat{J}_h^n \in S_h^1$ such that $(J_h^n, 1)^h = 0$ and

$$\hat{G}^h \widehat{J}_h^n - \Lambda_h^n - \lambda^n + \beta_h^n = 0$$

$$\Leftrightarrow \frac{1}{\mu}\widehat{J}_h^n + \hat{G}^h \widehat{J}_h^n - \lambda^n + \beta_h^n = \Lambda_h^n + \frac{1}{\mu}\widehat{J}_h^n, \tag{5.2}$$

where $\beta_h^n(\underline{x}_i) \in \beta(J_h^n(\underline{x}_i))$.

We solve (5.2) iteratively using a splitting algorithm of Lions and Mercier [7]. Let $\widehat{J}_h^0$ be given; for fixed μ we construct $J_h^{n,k+1}$, $\beta_h^{n,k+1}$, and $\lambda^{n,k+1}$ iteratively by solving for $k \ge 0$:

$$\frac{1}{\mu}\widehat{J}_h^{n,k+1/2} + \hat{G}^h \widehat{J}_h^{n,k+1/2} = \Lambda_h^n + \frac{1}{\mu}\widehat{J}_h^{n,k} - \beta_h^{n,k} + \lambda^{n,k} := \tilde{\Lambda}_h^{n,k}, \tag{5.3}$$

$$\frac{1}{\mu}\widehat{J}_h^{n,k+1} - \lambda^{n,k+1} + \beta_h^{n,k+1} = \Lambda_h^n + \frac{1}{\mu}\widehat{J}_h^{n,k+1/2} - \hat{G}^h \widehat{J}_h^{n,k+1/2} := F^{n,k+1/2}, \tag{5.4}$$

$$(J_h^{n,k+1}, 1)^h = 0,$$

where $\beta_h^{n,k+1}(\underline{x}_i) \in \beta(J_h^{n,k+1}(\underline{x}_i))$. To solve (5.3) we use (3.3) to rewrite

$$\frac{1}{\mu}\left(\bar{J}_h^{k+1/2}, \chi\right)^h + \left(\hat{G}^h \bar{J}_h^{k+1/2}, \chi\right)^h = \left(\tilde{\Lambda}_h^{n,k}, \chi\right)^h$$

as

$$\frac{1}{\mu}A(\hat{G}^h \bar{J}_h^{k+1/2}, \chi) + \left(\hat{G}^h \bar{J}_h^{k+1/2}, \chi\right)^h = \left(\tilde{\Lambda}_h^{n,k}, \chi\right)^h, \tag{5.5}$$

where $\bar{J}_h^{k+1/2} = \widehat{J}_h^{k+1/2} - f^n$.

At the ith node we may rewrite (5.4) using the projection

$$J_i^{n,k+1} = P(\mu(F_i^{n,k+1/2} + \lambda^{n,k+1})), \tag{5.6}$$

where

$$P(r) = \begin{cases} J_c & \text{if} \quad r \ge J_c, \\ r & \text{if} \quad |r| < J_c, \\ -J_c & \text{if} \quad r \le -J_c. \end{cases}$$

Noting that $(J_h^{n,k+1}, 1)^h = 0$, $\lambda^{n,k+1}$ solves the equation

$$g(\lambda) = \sum_i \mathcal{M}_i P(\mu(F_i^{n,k+1/2} + \lambda)) = 0. \tag{5.7}$$

To obtain the solution at the $(k+1)$th time step we proceed as follows:

Step 1. Solve (5.5) to obtain $\hat{G}^h \bar{J}_h^{k+1/2}$.

Step 2. Set $\hat{G}^h J_h^{n,k+1/2} = \hat{G}^h \bar{J}_h^{k+1/2} + f^n$.

Step 3. Use (5.3) to obtain $\widehat{J}_h^{n,k+1/2}$.

Step 4. Solve (5.6) and (5.7) to obtain $\widehat{J}_h^{n,k+1}$.

Step 5. Use (5.4) to obtain $\beta_h^{n,k+1}$.

Step 6. If $|\widehat{J}_h^{n,k+1} - \widehat{J}_h^{n,k}| \leq \text{tol}$, then set $\widehat{J}_h^n = \widehat{J}_h^{n,k+1}$; else set $\widehat{J}_h^{n,k} = \widehat{J}_h^{n,k+1/2}$ and go to Step 1.

The above procedure is relatively cheap apart from Step 1, which involves the solution of a large sparse matrix problem,

$$A\mathbf{x} = \mathbf{f}, \quad A \in \mathbb{R}^{N \times N}.$$

In general N is required to be large, so that interfaces between critical current and noncritical current can be captured.

Since the matrix A remains fixed throughout time, we could calculate the inverse, or an LU decomposition, of A at the beginning. Due to the nonlocal boundary condition the LU decomposition of this matrix produces $O(N^{3/2})$ entries, and thus, for large problems this is not practical.

Since Step 1 is part of an iteration, we need not solve this problem exactly. In the following section ten or fewer preconditioned GMRES iterations (see [12]) are used with an ILU decomposition used as a preconditioner. This allows large problems to be solved and accurate solutions to be obtained.

Note that Step 4 is well defined for $J_h^{n,k+1}$. It is easily seen that the function g is continuous and monotone piecewise linear which takes negative values for sufficiently negative λ and positive values for sufficiently positive λ, and hence (5.7) has a solution. Furthermore it has only a nonunique solution when $g(\lambda) = 0$ in an interval and in such an interval we observe that $P(F_i^{n,k+1/2} + \lambda)$ is constant for each i; hence the solution of (5.6) is unique. A solution of (5.7) can be found by efficiently by using the bisection method.

In [9, 11] Prigozhin solves the discrete variational inequality associated with the full matrix approximation of G using a projected SOR algorithm. We avoid doing this by using the splitting algorithm defined above in which it is not necessary to form the solution operator G explicitly but its action is calculated by the use of an elliptic solve. That is, (5.3) is implemented using elliptic solve (5.5). The constraint condition is then handled by (5.4), which is easily solved by the projection (5.6) and the Lagrange multiplier equation (5.7).

In practice we do not actually compute $G^h J_h$. Instead we approximate it by replacing the nonlocal boundary inner product $b(\cdot,\cdot)$ with a truncated version $b_M(\cdot,\cdot)$, where

$$b_M(\xi,\eta) = \int_{\partial\Omega} \mathcal{B}_M(\xi)\eta dS$$

with

$$\mathcal{B}_M(w)(\theta) := \int_{\partial\Omega} \sum_{k=1}^{M} \frac{1}{R\pi} \int_0^{2\pi} \frac{\partial w}{\partial \varphi} \sin\left(k(\varphi - \theta)\right) d\varphi.$$

Error analysis for this approximation can be found in [6].

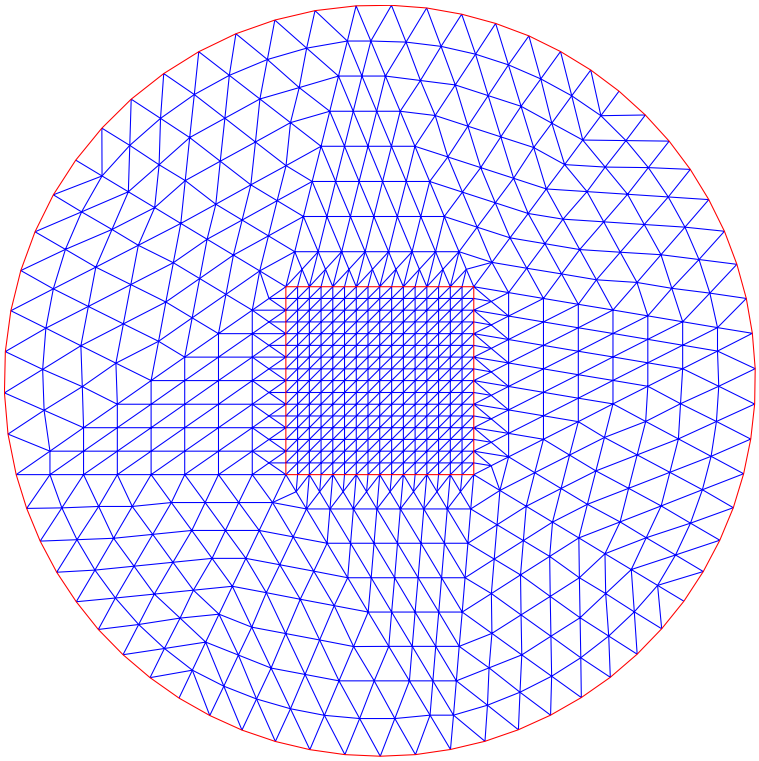

FIG. 6.1. *A typical mesh used for numerical simulations.*

6. Numerical results. In this section we present three sets of computational simulations. All results are calculated on domains of the form seen in Figure 6.1, where the superconductor is located in the square region $(-0.5, 0.5) \times (-0.5, 0.5)$. For all simulations the critical current density is taken to be $J_c = 1$ and the truncated sum for the nonlocal boundary inner product has $M = 5$.

In the first set (Figure 6.2) we take an applied magnetic field

$$\mathbf{H}^a = (0, \min\{t, H_{max}\}, 0)^T$$

for four values of H_{max}. For each value of H_{max} we display steady state solutions of the current density J_h. We see that while the applied magnetic field is increasing, the region in which the current takes critical values also increases.

In the second set of results (Figure 6.3) we apply an oscillating magnetic field of the form

$$\mathbf{H}^a = \left(0, 0.14 \sin \frac{\pi t}{2}, 0\right)^T, \tag{6.1}$$

and we display plots of the current density J_h at times $t = 1, 1.5, 2$, and 2.5.

In Table 6.1 we display the calculated error

$$\left\| \tilde{J}(\cdot, t^*) - J_{h,\Delta t}(\cdot, t^*) \right\|_{A^{-1}}$$

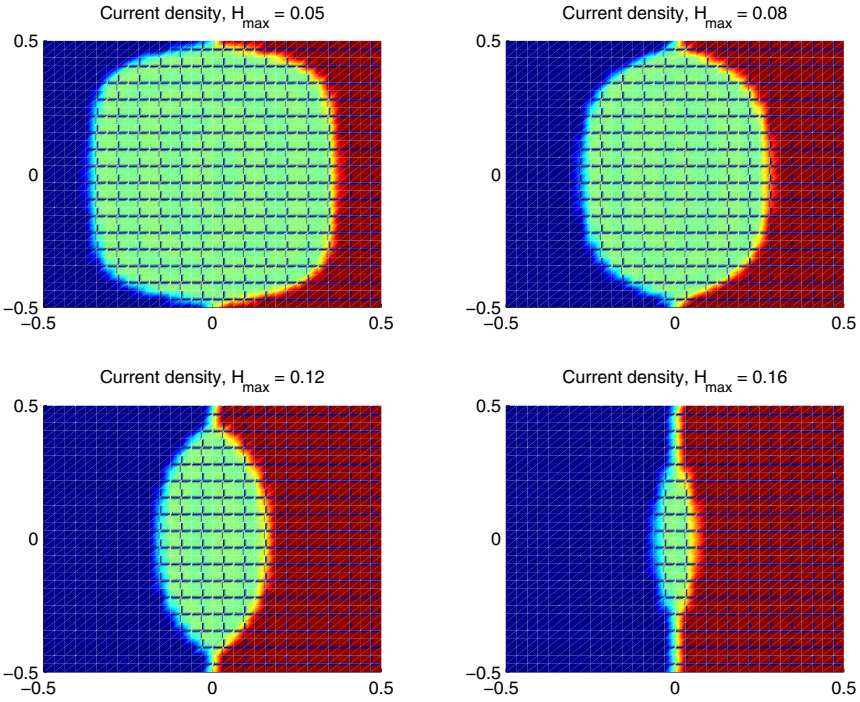

FIG. 6.2. *Steady state solutions:* $\mathbf{H}^a = (0, \min\{t, H_{max}\}, 0)^T$.

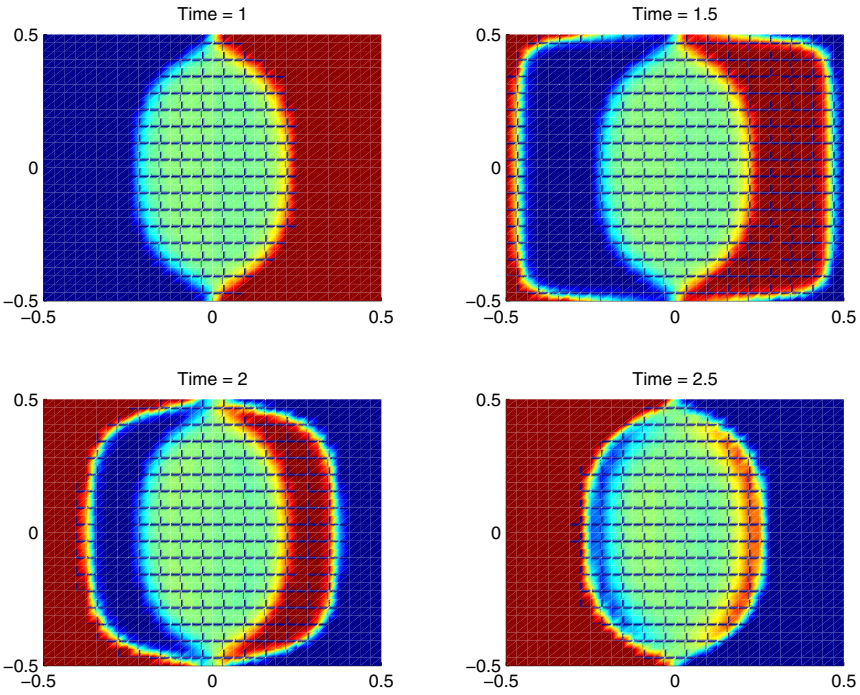

FIG. 6.3. *Current density for oscillating problem:* $\mathbf{H}^a = (0, 0.14 \sin \frac{\pi t}{2}, 0)^T$.

TABLE 6.1
Estimated errors for varying times and meshes.

	$t^* = 1.0$	$t^* = 2.0$	$t^* = 3.0$
$h = 1/8,\ \Delta t = 1/16$	0.0236	0.0255	0.0236
$h = 1/16,\ \Delta t = 1/64$	0.0126	0.0130	0.0126
$h = 1/32,\ \Delta t = 1/256$	0.0063	0.0068	0.0063

MULTILEVEL SOLVERS FOR A FINITE ELEMENT DISCRETIZATION OF A DEGENERATE PROBLEM*

SVEN BEUCHLER†

Abstract. In this paper, finite element discretizations of the degenerate operator $-\omega^2(y)u_{xx} - \omega^2(x)u_{yy} = g$ in the unit square are investigated, where the weight function satisfies $\omega(\xi) > 0$ for $\xi \in (0,1]$ and is monotonically increasing. We propose two multilevel methods in order to solve the resulting system of linear algebraic equations. The first method is a multigrid algorithm with line smoother. A proof of the smoothing property is given. The second method is a Bramble–Pasciak–Xu-like preconditioner with line smoother which we call multiple tridiagonal scaling Bramble–Pasciak–Xu preconditioner.

Key words. multigrid, preconditioning

1. Introduction.

In this paper, we consider the following problem: Find $u \in H^1_{0,\omega}(\Omega)$ such that

$$a(u,v) := \int_\Omega (\omega(y))^2 u_x v_x + (\omega(x))^2 u_y v_y = \int_\Omega gv =: \langle g, v\rangle \quad \forall v \in H^1_{0,\omega}(\Omega), \tag{1.1}$$

where $H^1_{0,\omega}(\Omega) = \{u \in L^2(\Omega), \omega(x)u_y, \omega(y)u_x \in L^2(\Omega), u \mid_{\partial\Omega} = 0\}$. The domain $\Omega = (0,1)^2$ is the unit square.

Assumption 1.1. The weight function $\omega(\xi) \in L^\infty((0,1))$ is assumed to be monotonically increasing and satisfies $\omega(\xi) > 0$ for $\xi \in (0,1]$.

Remark 1.1. If $\omega(0) = 0$, then the differential operator in (1.1) is not uniformly elliptic in the Sobolev space $H^1_0(\Omega)$, and an estimate of the type

$$a(u,u) \geq \gamma \parallel u \parallel^2_{H^1(\Omega)} \quad \forall u \in H^1_0(\Omega) \tag{1.2}$$

with a constant $\gamma > 0$ is not satisfied.

The integrand on the left-hand side in (1.1) is of the type $(\nabla u)^T D(x,y)\nabla v$ with the diffusion tensor

$$D(x,y) = \begin{bmatrix} \omega^2(y) & 0 \\ 0 & \omega^2(x) \end{bmatrix}. \tag{1.3}$$

Therefore, the matrix D is symmetric and positive definite for all $(x,y) \in \Omega$ but not uniformly positive definite if $\omega(0) = 0$. Moreover, the matrix D is bounded for each $(x,y) \in \Omega$. Such problems are called degenerate problems. In the past, degenerate problems have been considered relatively rarely. One reason is the unphysical behavior of the PDE which is quite unusual in technical applications. One work focusing on this type of PDE is the book of Kufner and Sändig [17]. Nowadays, problems of this type have become more and more popular because there are stochastic PDEs which

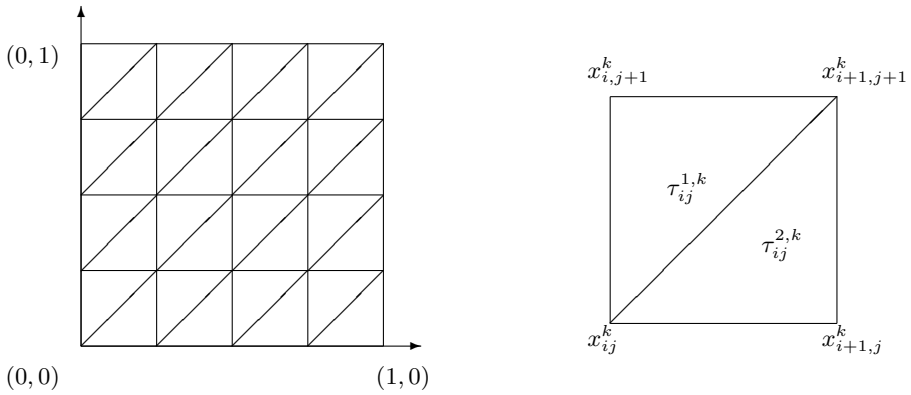

FIG. 1.1. *Mesh for the finite element method (left). Notation within a macroelement $\mathcal{E}^k_{ij}$ (right).*

have a similar structure. An example of a degenerate stochastic PDE is the Black–Scholes PDE in [21]. Moreover, the solver related to the problem of the subdomains embedded in a domain decomposition preconditioner for the p-version of the finite element method can be interpreted as an h-version fem-discretization matrix of (1.1) in the case of the weight function $\omega(\xi) = \xi$. We refer to [6] and [7] for more details.

We discretize problem (1.1) by finite elements. For this purpose, some notation is introduced. Let k be the level of approximation and $n = 2^k$. Let $x^k_{ij} = (\frac{i}{n}, \frac{j}{n})$, where $i, j = 0, \ldots, n$. The domain Ω is divided into congruent, isosceles, right-angled triangles $\tau^{s,k}_{ij}$, where $0 \le i, j < n$ and $s = 1, 2$ (see Figure 1.1). The triangle $\tau^{1,k}_{ij}$ has the three vertices $x^k_{ij}, x^k_{i+1,j+1}$, and $x^k_{i,j+1}$, $\tau^{2,k}_{ij}$ has the three vertices $x^k_{ij}, x^k_{i+1,j+1}$, and $x^k_{i+1,j}$ (see Figure 1.1). Furthermore, let $\mathcal{E}^k_{ij} = \overline{\tau^{1,k}_{ij} \cup \tau^{2,k}_{ij}}$ be the macroelement $\left[\frac{i}{n}, \frac{i+1}{n}\right] \times \left[\frac{j}{n}, \frac{j+1}{n}\right]$. Piecewise linear finite elements are used on the mesh $T_k = \{\tau^{s,k}_{ij}\}^{n-1,n-1,2}_{i=0,j=0,s=1}$. The subspace of piecewise linear functions ϕ^k_{ij} with

$$\phi^k_{ij} \in H^1_0(\Omega),\ \phi^k_{ij}\,|_{\tau^{s,k}_{lm}} \in \mathbb{P}_1(\tau^{s,k}_{lm})$$

is denoted by $\mathbb{V}_k$, where $\mathbb{P}_1$ is the space of polynomials of degree ≤ 1. A basis of $\mathbb{V}_k$ is the system of the usual hat-functions $\{\phi^k_{ij}\}^{n-1}_{i,j=1}$ uniquely defined by

$$\phi^k_{ij}(x^k_{lm}) = \delta_{il}\delta_{jm}$$

and $\phi^k_{ij} \in \mathbb{V}_k$, where δ_{il} is the Kronecker delta. Now, we can formulate the discretized problem.

Find $u^k \in \mathbb{V}_k$ such that

$$a(u^k, v^k) = \langle g, v^k \rangle \quad \forall v^k \in \mathbb{V}_k \tag{1.4}$$

holds. Problem (1.4) is equivalent to solving the system of linear algebraic equations

$$K_{\omega,k}\underline{u}_k = \underline{g}_k, \tag{1.5}$$

where $K_{\omega,k} = \left[a(\phi^k_{ij}, \phi^k_{lm})\right]^{n-1}_{i,j,l,m=1}$, $\underline{u}_k = [u_{ij}]^{n-1}_{i,j=1}$, and $\underline{g}_k = \left[\langle g, \phi^k_{lm}\rangle\right]^{n-1}_{l,m=1}$. The index ω denotes the weight function ω. Then, $u^k = \sum^{n-1}_{i,j=1} u_{ij}\phi^k_{ij}$ is the solution of

(1.4). In this paper, we will derive fast solution methods for (1.5). Because of the right-angled triangles $\tau_{ij}^{s,k}$, and the diagonal matrix $D(x,y)$ in (1.3), the matrix $K_{\omega,k}$ is a sparse matrix with 5-point stencil structure and $\mathcal{O}(n^2)$ nonzero matrix entries. Therefore, it is important to find a method which solves (1.5) in $\mathcal{O}(n^2)$ arithmetical operations. Using direct methods, an additional memory requirement is necessary. Moreover, the arithmetical cost is at least $\mathcal{O}(n^3)$ (see [13] and [14]).

Using iterative methods, no additional memory requirement is necessary in order to save the matrix $K_{\omega,k}$.

However, efficient preconditioners are needed. For systems of finite element equations arising from the discretization of boundary value problems as, for example, $-u_{xx} - u_{yy} = f$, efficient solution techniques have been developed in the last two decades. Examples for such solvers are the preconditioned conjugate gradient (PCG) method with Bramble–Pasciak–Xu preconditioners (see [11]), or hierarchical basis preconditioners (see [26]), and multigrid methods (see [15] and [16]).

However, the differential operator in (1.1) is not spectrally equivalent to the Laplacian. It is an elliptic, but not uniformly elliptic, differential operator (cf. (1.2)). In a certain way, this differential operator can be interpreted as an operator with local anisotropies, where the range of anisotropy ε goes to zero, if the discretization parameter h tends to zero.

A typical anisotropic model problem considered in the literature (see [15]) is

$$-\frac{\partial^2 u}{\partial x^2} - \varepsilon \frac{\partial^2 u}{\partial y^2} = f, \quad \varepsilon \text{ small.}$$

One iterative method with a rate of convergence independent of the choice of ε is the multigrid algorithm with a line Gauss–Seidel (GS) smoother (cf. [16]). Bramble and Zhang [12] considered multigrid methods for a more general case than the Laplace equation. Using a line Jacobi or GS smoother in the x-direction, they proved multigrid convergence for differential operators of the type $-(f(x,y)u_x)_x - (g(x,y)u_y)_y$, where $0 < g(x,y) \leq g_{\max}$ and $0 < f_{\min} < f(x,y) < f_{\max}$, i.e., one of the coefficients can be arbitrarily small. However, both coefficients can be arbitrarily small in (1.1). So a modified smoother handling changing types of anisotropies has to be used. The papers [2], [19], and [1] propose algebraic multilevel iteration (AMLI) preconditioners. In the case of piecewise constant functions $f(x,y)$ and $g(x,y)$, the optimality and robustness of the methods can be shown, i.e., these methods can handle changing types of anisotropies. In our paper, the coefficients are not piecewise constant.

In [6], the special case of the singular weight function $\omega(\xi) = \xi$ in (1.1) is considered. Using the techniques of Braess [10], Schieweck [22], and Pflaum [20], a mesh-size independent multigrid convergence rate $\rho < 1$ has been shown. Moreover, numerical experiments (see [9]) for discretizations of differential operators as (1.1) indicate a mesh-size independent convergence rate $\rho < 1$ for multigrid algorithms with semicoarsening and line smoother. In [5], a BPX-like preconditioner which we call the multiple tridiagonal scaling BPX (MTS-BPX) preconditioner $\hat{C}_{\xi,k}$ for $K_{\xi,k}$ is proposed (i.e., $\omega(\xi) = \xi$). Numerical experiments indicate a small increasing condition number of $\hat{C}_{\xi,k}^{-1} K_{\xi,k}$.

The aim of this paper is to extend the MTS-BPX preconditioner of [5] and the multigrid algorithm of [6] to the more general problem of $K_{\omega,k}\underline{w} = \underline{r}$, where $\omega(\xi)$ satisfies Assumption 1.1.

This paper is organized as follows. In section 2, the multigrid algorithm is considered. We state the main assumptions required for the algebraic convergence theory,

the constant in the strengthened Cauchy inequality, and the smoothing property. Then, the definition of the smoother in [6] for $K_{\xi,k}$ is generalized to a smoother for $K_{\omega,k}$. Moreover, a proof of the smoothing property is given. In section 3, the MTS-BPX preconditioner $\hat{C}_{\omega,k}$ for $K_{\omega,k}$ is defined. Finally, the upper eigenvalue estimate of $\hat{C}_{\omega,k}^{-1}K_{\omega,k}$ is proved and some numerical experiments are given.

Throughout this paper, $\omega(\xi)$ describes the weight function in (1.1). Moreover, the lowest and largest eigenvalues of the matrix A are denoted by $\lambda_{\min}(A)$ and $\lambda_{\max}(A)$, respectively. The integer k is the level number for the refinement of the finite element mesh and $n = 2^k$.

2. Multigrid for degenerate problems. In the typical multigrid proofs (cf. [15]), one splits the multigrid operator into a product of two operators, $\mathcal{A}$ and $\mathcal{B}$. One proves a smoothing property for the operator $\mathcal{A}$, whereas an approximation property has to be shown for $\mathcal{B}$. Helpful tools for this aim are the approximation theorems for finite elements such as the Aubin–Nitsche trick. In order to prove such a result, the boundedness and the uniform ellipticity of the bilinear form are required in the Sobolev space $H^1(\Omega)$. However, the uniform ellipticity of the bilinear form (1.1) cannot be guaranteed (cf. relation (1.2)).

Another technique in order to prove a mesh-size independent convergence rate has been introduced by Braess [10]. In this method, the approximation space $\mathbb{V}_k$ is split into a direct sum of the space $\mathbb{V}_{k-1}$ and a complementary space $\mathbb{W}_k$. One obtains a multiplicative solver for the problem on $\mathbb{V}_k$ by solving the problems on $\mathbb{V}_{k-1}$ and $\mathbb{W}_k$. Schieweck [22] and Pflaum [20] have extended this technique. This method does not require regularity assumptions to the bilinear form. Moreover, for triangulations of simple geometry as for (1.4), the required assumptions are quite simple to handle.

Remark 2.1. Note that the bilinear form $a(\cdot,\cdot)$ is positive definite on the space $\mathbb{V}_k$ (cf. Assumption 1.1).

2.1. Multigrid algorithm and convergence theory. In this subsection, the multigrid algorithm in order to solve (1.5) is introduced. The space $\mathbb{V}_k$ is represented as the direct sum

$$\mathbb{V}_k = \mathbb{V}_{k-1} \oplus \mathbb{W}_k, \quad \text{where} \quad \mathbb{W}_k = \operatorname{span}\{\phi_{ij}^k\}_{(i,j)\in N_k}$$

(see, e.g., [18], [10], [22], [23], and [24]). The index subset $N_k \subset \mathbb{N}^2$ contains the indices of the new nodes on level k and is given by

$$N_k := \{(i,j) \in \mathbb{N}^2, 1 \le i,j \le n-1, i = 2m-1 \text{ or } j = 2m-1, m \in \mathbb{N}\}. \tag{2.1}$$

Let $u_0 \in \mathbb{V}_k$ be the initial guess, and let $\|\cdot\|_a^2 := a(\cdot,\cdot)$ be the energy norm. One step of the multigrid algorithm $u_1 = MULT(k, u_0, g)$ is defined recursively as follows.

ALGORITHM 2.1 ($MULT$). Set $l = k$.

- If $l > 1$, then do
  1. Projection onto $\mathbb{W}_l$: Determine $\tilde{w}_1 \in \mathbb{W}_l$ such that $\| \tilde{w}_1 - w_1 \|_a \le \rho_1 \| w_1 \|_a$, where $w_1 \in \mathbb{W}_l$ is the unique solution of

     $$a(w_1, v) = \langle g, v\rangle - a(u_0, v) = \langle r_1, v\rangle \quad \forall v \in \mathbb{W}_l. \tag{2.2}$$

     Set $u_0^1 = u_0 + \tilde{w}_1$.
  2. Projection onto $\mathbb{V}_{l-1}$ (coarse grid correction): Determine the approximation $\tilde{w}_2 \in \mathbb{V}_{l-1}$ to $w_2 \in \mathbb{V}_{l-1}$ using μ_l steps of the algorithm $MULT(l-1, 0, r_2)$, where w_2 is the unique solution of

     $$a(w_2, v) = \langle g, v\rangle - a(u_0^1, v) = \langle r_2, v\rangle \quad \forall v \in \mathbb{V}_{l-1}.$$

Set $u_0^2 = u_0^1 + \tilde{w}_2$.

3. Projection onto $\mathbb{W}_l$: Determine $\tilde{w}_3 \in \mathbb{W}_l$ such that $\| \tilde{w}_3 - w_3 \|_a \leq \rho_1 \| w_3 \|_a$, where $w_3 \in \mathbb{W}_l$ is the unique solution of

$$a(w_3, v) = \langle g, v \rangle - a(u_0^2, v) = \langle r_3, v \rangle \quad \forall v \in \mathbb{W}_l. \tag{2.3}$$

Set $u_0^3 = u_0^2 + \tilde{w}_3$.

- else
  - Solve $a(w, v) = \langle g, v \rangle$ for all $v \in \mathbb{V}_l$ exactly and set $u_1 = w$.
- end-if.

The algorithm can be interpreted as an approximate alternate projection with respect to $a(\cdot, \cdot)$ onto the subspaces $\mathbb{V}_{k-1}$ and $\mathbb{W}_k$. The exact projections are denoted by w_j, the approximate projections by $\tilde{w}_j$, $j = 1, 2, 3$. For the projection onto $\mathbb{V}_{k-1}$, we apply μ iterations of the algorithm 2.1. For the exact projection onto $\mathbb{W}_k$, we have to solve a system with the matrix

$$K_{\mathbb{W}_k} = \left[a(\phi_{lm}^k, \phi_{ij}^k) \right]_{(i,j),(l,m) \in N_k} \tag{2.4}$$

(compare (2.1)–(2.3) and (1.5)), i.e., the stiffness matrix $K_{\omega,k}$ restricted to the space $\mathbb{W}_k$. In the case of the potential equation, i.e., $\omega(\xi) = 1$, the condition number of $K_{\mathbb{W}_k}$ is bounded independently of the mesh-size h. Hence, in order to solve (2.2), ν iterations $\tilde{w}_{1,0} = 0$, $\tilde{w}_{1,j} = \mathcal{S}\tilde{w}_{1,j-1} + (I - \mathcal{S})w_1$, $j = 1, \ldots, \nu$ of a simple iterative method, i.e., the Jacobi smoother, can be done, where $\mathcal{S}$ denotes the error propagation operator of this method. In each iteration step, the relative error in the energy norm is reduced up to a factor of ρ, where ρ is bounded by $\rho_0 < 1$ from above for all $k \in \mathbb{N}$. So, for all $k \in \mathbb{N}$, it suffices to use $\nu = 1 + \left[\frac{\ln \rho_1}{\ln \rho_0} \right]$ iterations with a Jacobi smoother in order to satisfy $\| \tilde{w}_1 - w_1 \|_a \leq \rho_1 \| w_1 \|_a$ in the case of $\omega(x) = 1$. However, in the case of a general weight function ω, the constant ρ cannot be bounded by $\rho_0 < 1$ independent of k if the Jacobi smoother is used. Then, the main aim of this section is to define a more appropriate preconditioned Richardson iteration, in order to solve (2.2) and (2.3), such that the error propagation operator $\mathcal{S}$ satisfies the estimate

$$\| \mathcal{S}^\nu w \|_a \leq \rho^\nu \| w \|_a \quad \forall w \in \mathbb{W}_k, \nu \in \mathbb{N}. \tag{2.5}$$

The constant ρ in (2.5) is bounded by $\rho_0 < 1$ from above independent of k. Then, the νth iterate of the process $\tilde{w}_{1,0} = 0$, $\tilde{w}_{1,j} = \mathcal{S}\tilde{w}_{1,j-1} + (I - \mathcal{S})w_1$, $j = 1, \ldots, \nu$ satisfies

$$\begin{aligned} \| \tilde{w}_{1,\nu} - w_1 \|_a &= \| \mathcal{S}(\tilde{w}_{1,\nu-1} - w_1) \|_a \\ &\leq \rho \| \tilde{w}_{1,\nu-1} - w_1 \|_a \leq \cdots \leq \rho^\nu \| \tilde{w}_{1,0} - w_1 \|_a = \rho^\nu \| w_1 \|_a . \end{aligned}$$

This means that (2.2), or (2.3), can be solved with a relative accuracy of ρ_1 by a number of ν smoothing steps, where ν is bounded independently of the mesh-size h, i.e., it suffices to verify relation (2.5).

Note that the exact solution w_1 does not have to be determined in order to compute $\tilde{w}_{\nu,1}$ if the smoother is a preconditioned Richardson iteration (cf. (2.20)).

In order to prove the convergence of the multigrid algorithm 2.1 for (1.5), the following convergence theorem is known (see [20] and [22]).

THEOREM 2.1. *Let us assume that the following assumptions are fulfilled.*

- *Let $a(\cdot, \cdot)$ be a symmetric and positive definite bilinear form on $\mathbb{V}_k$.*
- *Let $\mathcal{S}$ be the error propagation operator of a simple iterative method in order to solve* (2.2) *and* (2.3) *which satisfies the estimate* (2.5) *with $0 \leq \rho \leq \rho_0 < 1$ independent of k.*

- *There is a constant* $0 \le \gamma < 1$ *independent of* k *such that*

$$(a(v,w))^2 \le \gamma^2 a(v,v)a(w,w) \quad \forall w \in \mathbb{W}_k, \forall v \in \mathbb{V}_{k-1} \tag{2.6}$$

  holds.
- *Let* $u_{j+1,k} = MULT(k, u_{j,k}, g)$, *let* u^* *be the exact solution of* (1.5), *and let*

$$\sigma_k = \sup_{u_{j,k}-u^* \in \mathbb{V}_\neg} \frac{\| u_{j+1,k} - u^* \|_a}{\| u_{j,k} - u^* \|_a}$$

  be the convergence rate of $MULT$ *in the energy norm with* ν *smoothing operations.*

Then, the recursion formula

$$\sigma_k \le \sigma_{k-1}^{\mu_{k-1}} + (1 - \sigma_{k-1}^{\mu_{k-1}})(\rho^\nu + (1-\rho^\nu)\gamma)^2 \tag{2.7}$$

is valid.

Proof. This theorem has been proved by Schieweck, in Theorem 2.2 of [22], with $\rho^\nu = \rho_1 = \rho_3$, and Pflaum, in Theorem 4 of [20]. □

The following lemma gives conditions on ρ, ν, and γ such that the estimate $\sigma_k < \sigma < 1$ is valid.

LEMMA 2.2. *Let us assume that the assumptions of Theorem* 2.1 *hold. Let* $\kappa^2 = (\rho^\nu + (1-\rho^\nu)\gamma)^2 < \frac{\mu-1}{\mu}$ *with* $\mu = \mu_l$. *If* $\gamma^2 < \frac{\mu-1}{\mu}$, *one has* $\sigma_k < \sigma < 1$ *for*

$$\nu > \ln \frac{\sqrt{\frac{\mu-1}{\mu}} - \gamma}{1-\gamma} / \ln \rho.$$

Proof. The proof is standard (see, e.g., [22]). □

By Remark 2.1, the first assumption of Theorem 2.1 is satisfied for the bilinear form $a(\cdot,\cdot)$ (1.1).

In Theorem 2.2 of [6] we have proved $(a(v,w))^2 \le \frac{95}{176} a(v,v)a(w,w)$ for all $v \in \mathbb{V}_k$ and for all $w \in \mathbb{W}_{k+1}$ for the bilinear form $a(\cdot,\cdot)$ (1.1) with the weight function $\omega(\xi) = \xi$. The techniques described there can be extended to other weight functions. Table 2.1 gives estimates of the strengthened Cauchy inequalities for several weight functions of the type $\omega(\xi) = \xi^\alpha$, $\alpha \ge 0$. For $\alpha = 10$, the constant γ^2 of the strengthened Cauchy inequality is very close to 1. In the cases $\alpha = \frac{1}{2}, 1, 2$, the estimate $\frac{1}{2} < \gamma^2 < \frac{2}{3}$ is valid. Thus, we can prove a mesh-size independent multigrid convergence rate $\sigma_k < 1$ for $\mu = 3$, if $\tilde{w}_1$ and $\tilde{w}_3$ are close to w_1 and w_3 in Algorithm 2.1 (cf. (2.2) and (2.3)), i.e., $\nu > \ln \frac{\sqrt{2/3}-\gamma}{1-\gamma} / \ln \rho$.

TABLE 2.1
Estimates of the constant in strengthened Cauchy inequality for several weight functions.

weight function	$\omega = 1$	$\omega(\xi) = \sqrt{\xi}$	$\omega(\xi) = \xi$	$\omega(\xi) = \xi^2$	$\omega(\xi) = \xi^{10}$
γ^2 in (2.6)	$\frac{1}{2}$	$\frac{81}{158}$	$\frac{95}{176}$	$\frac{2195375}{3508896}$	≈ 0.9929

In subsection 2.3, we define an iterative method with an error propagation operator $\mathcal{S}$ satisfying relation (2.5) with $\rho < \rho_0 < 1$ for more general weight functions as in [6]. It will be shown that the constant ρ in (2.5) is independent of the choice of the weight function.

Therefore, the stiffness matrices restricted to the elements $\tau_{ij}^{1,k}$ and $\tau_{ij}^{2,k}$ are required. This is done in subsection 2.2.

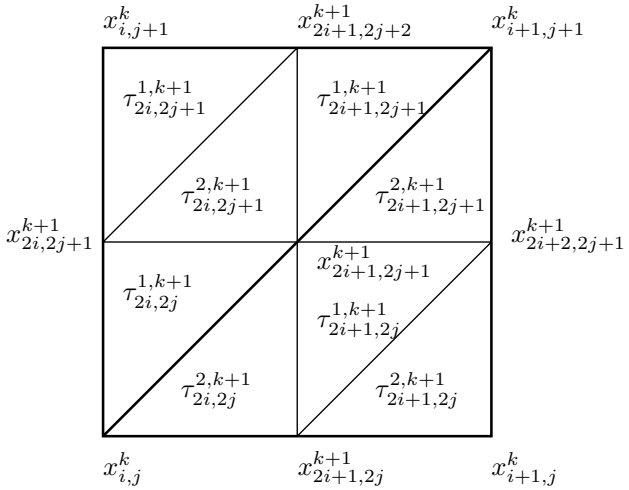

FIG. 2.1. *Local numbering of the nodes and subtriangles of* $\mathcal{E}^k_{ij}$.

2.2. Calculation of the macroelement stiffness matrices. In this subsection, we determine the stiffness matrix on the macroelements $\mathcal{E}^k_{ij}$ with respect to the basis functions of $\mathbb{W}_{k+1}\,|_{\mathcal{E}^k_{ij}}$. We start with the introduction of the basis functions on $\mathcal{E}^k_{ij}$. Note that the triangle $\tau^{2,k}_{ij}$ is the union of the triangles $\tau^{2,k+1}_{2i,2j}$, $\tau^{1,k+1}_{2i+1,2j}$, $\tau^{2,k+1}_{2i+1,2j}$, and $\tau^{2,k+1}_{2i+1,2j+1}$, and the triangle $\tau^{1,k}_{ij}$ is the union of the triangles $\tau^{1,k+1}_{2i,2j}$, $\tau^{1,k+1}_{2i,2j+1}$, $\tau^{2,k+1}_{2i,2j+1}$, and $\tau^{1,k+1}_{2i+1,2j+1}$. The nodes x^k_{ij}, $x^k_{i,j+1}$, $x^k_{i+1,j}$, and $x^k_{i+1,j+1}$ are the coarse grid nodes, the nodes $x^{k+1}_{2i+1,2j}$, $x^{k+1}_{2i,2j+1}$, $x^{k+1}_{2i+2,2j+1}$, $x^{k+1}_{2i+1,2j+2}$, and $x^{k+1}_{2i+1,2j+1}$ are new in level $k+1$ (cf. Figure 2.1). Using this notation, we have

$$\mathbb{W}_{k+1}\,|_{\mathcal{E}^k_{ij}} = \operatorname{span}\{\phi^{k+1}_{lm}\}_{(l,m)\in N^{\mathbb{W}_{k+1}}_{ij}}. \tag{2.8}$$

For reasons of simplicity, we write only ϕ^{k+1}_{lm} instead of $\phi^{k+1}_{lm}\,|_{\mathcal{E}^k_{ij}}$ for the restriction of ϕ^{k+1}_{lm} on $\mathcal{E}^k_{ij}$. The index set in (2.8) is given by

$$N^{\mathbb{W}_{k+1}}_{ij} = N_{k+1} \cap \{(l,m) \in \mathbb{N}_0^2, 2i \le l \le 2i+2, 2j \le m \le 2j+2\},$$

where N_{k+1} was defined in (2.1). Since $\mathbb{V}_k \subset H^1_0(\Omega)$, some modifications are necessary for boundary macroelements $\mathcal{E}^k_{ij}$, i.e., with $i=0$, $j=0$, $i=n-1$, or $j=n-1$.

On the elements $\tau^{s,k}_{ij}$, $s=1,2$, we introduce the matrices

$$J_{s,ij} := \left[a^{\tau^{s,k}_{ij}}(\phi^{k+1}_{lm}, \phi^{k+1}_{rq})\right]_{(r,q),(l,m)\in N^{s,\mathbb{W}_{k+1}}_{ij}}$$

with $N^{s,\mathbb{W}_{k+1}}_{ij} := T^s_{ij} \cap N^{\mathbb{W}_{k+1}}_{ij}$, where $T^1_{ij} := \{(l,m) \in \mathbb{N}_0^2, l-m \le i-j\}$ and $T^2_{ij} := \{(l,m) \in \mathbb{N}_0^2, l-m \ge i-j\}$. Namely, we obtain

$$N^{2,\mathbb{W}_{k+1}}_{ij} = \{(2i+1,2j),(2i+2,2j+1),(2i+1,2j+1)\} \quad \text{and}$$
$$N^{1,\mathbb{W}_{k+1}}_{ij} = \{(2i,2j+1),(2i+1,2j+2),(2i+1,2j+1)\}.$$

The entries of the matrices $J_{q,ij}$ can be determined by a straightforward calculation. We compute those for the case of a general weight function $\omega(\xi)$. The following

positive parameters depending on the integer j are introduced:

$$d_j = \frac{1}{4}\int_{\tau_{2i,2j}^{1,k+1}\cup\tau_{2i,2j+1}^{2,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y), \quad e_j = \frac{1}{4}\int_{\tau_{2i,2j}^{2,k+1}\cup\tau_{2i+1,2j}^{2,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y),$$

$$f_j = \frac{1}{4}\int_{\tau_{2i,2j+1}^{1,k+1}\cup\tau_{2i+1,2j+1}^{1,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y). \tag{2.9}$$

Note that d_j, e_j, and f_j are independent of the integer i. The values d_i, e_i, and f_i are defined by a permutation of x with y, and of each triangle $\tau_{ij}^{2,k}$ with $\tau_{ji}^{1,k}$ in (2.9). One obtains the following proposition.

PROPOSITION 2.3. *Let $0 \le i < n-1$ and $0 < j \le n-1$. Then, one has*

$$J_{2,ij} = 4\begin{bmatrix} d_i+e_j & 0 & -d_i \\ 0 & f_i+d_j & -d_j \\ -d_i & -d_j & d_i+d_j \end{bmatrix}. \tag{2.10}$$

Due to the boundary condition $u\,|_{\partial\Omega} = 0$, the second row and column of $J_{2,ij}$ has to be canceled for $i = n-1$, whereas the first row and column in $J_{2,ij}$ has to be canceled for $j = 0$ in (2.10).

By exchanging the indices i and j in (2.10), one derives the matrices $J_{1,ij} = J_{2,ji}$.

2.3. Construction of the smoother. In order to apply multigrid to the linear system (1.5), we need an efficient smoother. This smoother will be constructed by the local behavior of the differential operator. An idea of Axelsson and Padiy [2] (see also [19]) for anisotropic problems is extended to bilinear forms as in problem (1.1). This smoother operates only on the space $\mathbb{W}_{k+1}$.

Consider the triangle $\tau_{ij}^{s,k}$. For our discussion, only the submatrices $J_{s,ij}$, where $0 \le i,j \le n-1$, and $s = 1,2$, are required which correspond to the nodal basis functions on $\mathbb{W}_{k+1}$. The two cases $i < j$ and $i \ge j$ are discussed. We start with $i < j$ and $s = 2$. By Proposition 2.3,

$$J_{2,ij} = 4\begin{bmatrix} d_i+e_j & 0 & -d_i \\ 0 & f_i+d_j & -d_j \\ -d_i & -d_j & d_i+d_j \end{bmatrix}.$$

The index k is omitted. For $i < j$, the matrix

$$M_{2,ij} = 4\begin{bmatrix} d_i+e_j & 0 & 0 \\ 0 & f_i+d_j & -d_j \\ 0 & -d_j & d_i+d_j \end{bmatrix} \tag{2.11}$$

is introduced. In the matrix $M_{2,ij}$, we set all off-diagonal entries of $J_{2,ij}$ to 0 which have relatively small absolute values in comparison to the corresponding main diagonal entries. Since ω is monotonically increasing, the relation $d_i < d_j$ is valid for $i < j$. Thus, we set the $-d_i$ entries of $J_{2,ij}$ in $M_{2,ij}$ to 0. We now prove the following lemma.

LEMMA 2.4. *For $0 \le i < j < n$, the eigenvalue estimates*

$$\lambda_{\min}\left({M_{2,ij}}^{-1}J_{2,ij}\right) \ge 1 - \frac{1}{2}\sqrt{2} \quad \textit{and} \quad \lambda_{\max}\left({M_{2,ij}}^{-1}J_{2,ij}\right) \le 1 + \frac{1}{2}\sqrt{2}$$

hold.

Proof. Let $\beta = d_i f_i + d_i d_j + f_i d_j$. Then, we have

$$M_{2,ij}^{-1} J_{2,ij} = \begin{bmatrix} 1 & 0 & \frac{-d_i}{d_i+e_j} \\ \frac{-d_i d_j}{\beta} & 1 & 0 \\ \frac{-d_i f_i - d_i d_j}{\beta} & 0 & 1 \end{bmatrix}.$$

This matrix has the characteristic polynomial

$$\det(\lambda I - M_{2,ij}^{-1} J_{2,ij}) = (\lambda - 1)\left((1-\lambda)^2 - \frac{d_i}{d_i+e_j}\frac{d_i f_i + d_i d_j}{d_i f_i + d_i d_j + f_i d_j}\right).$$

The roots λ_i, $i = 1, 2, 3$, of this polynomial are $\lambda_1 = 1$ and $\lambda_{2,3} = 1 \pm \sqrt{\rho}$, where

$$\rho = \frac{d_i}{d_i+e_j}\frac{d_i f_i + d_i d_j}{d_i f_i + d_i d_j + f_i d_j}. \tag{2.12}$$

Note that for all i and j, the values d_j, e_j, and f_j are mean values of the positive function $(\omega(y))^2$ over the union of two triangles having a volume of $\frac{1}{8n^2}$. By $i \le j-1$ and the monotonicity of the weight function, one has $\omega(x) \le \omega(y)$ for all $x, y \in \tau_{ij}^{2,k}$. Thus, by integration over subtriangles of $\tau_{ij}^{2,k}$ with volume $\frac{1}{8n^2}$ (cf. Figure 2.1),

$$d_i = \frac{1}{4}\int_{\tau_{2i,2j}^{2,k+1} \cup \tau_{2i+1,2j}^{1,k+1}} (\omega(x))^2 \,\mathrm{d}(x,y) \le \frac{1}{4}\int_{\tau_{2i,2j}^{2,k+1} \cup \tau_{2i+1,2j}^{2,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y) = e_j,$$

$$\text{or} \quad \frac{d_i}{d_i+e_j} \le \frac{1}{2}.$$

Since $d_i, d_j, f_i, f_j > 0$ (the weight function is positive), we have

$$\frac{d_i fi + d_i d_j}{d_i f_i + d_i d_j + f_i d_j} < 1. \tag{2.13}$$

Inserting the above estimates into (2.12), one has

$$1 - \sqrt{\frac{1}{2}} \le \lambda_2 \le \lambda_1 \le \lambda_3 \le 1 + \sqrt{\frac{1}{2}}.$$

Hence, the assertion follows immediately. ∎

Remark 2.2. The estimate (2.13) is not sharp. With $f_i \le d_j$ and $d_i < d_j$, one can show the stronger estimate $\frac{d_i f_i + d_i d_j}{d_i f_i + d_i d_j + f_i d_j} < \frac{2}{3}$ (cf. [8]).

Now, consider the case $i \ge j$. Introducing the matrix

$$M_{2,ij} = 4\begin{bmatrix} d_i + e_j & 0 & -d_i \\ 0 & f_i + d_j & 0 \\ -d_i & 0 & d_i + d_j \end{bmatrix}, \tag{2.14}$$

we will show that $\kappa\left({M_{2,ij}}^{-1} J_{2,ij}\right) \le c$ independent of the parameters j, i, and n.

LEMMA 2.5. *For $0 \le j \le i < n$, one has*

$$\lambda_{\min}\left({M_{2,ij}}^{-1} J_{2,ij}\right) \ge 1 - \frac{1}{2}\sqrt{2} \quad \textit{and} \quad \lambda_{\max}\left({M_{2,ij}}^{-1} J_{2,ij}\right) \le 1 + \frac{1}{2}\sqrt{2}.$$

Proof. We start with the case $i < n-1$ and $j > 0$. The proof is similar to the proof of Lemma 2.4. A short calculation yields

$$\det(\lambda I - M_{2,ij}^{-1} J_{2,ij}) = (\lambda - 1)\left((\lambda - 1)^2 - \frac{d_j}{d_j + f_i}\frac{d_i d_j + e_j d_j}{d_i e_j + d_i d_j + e_j d_j}\right).$$

By $i \geq j$ and the monotonicity of the weight function ω, we have

$$\begin{aligned}\int_{\tau_{2i+1,2j}^{2,k+1}} (\omega(x))^2 \,\mathrm{d}(x,y) &= \int_{\tau_{2i+1,2j+1}^{2,k+1}} (\omega(x))^2 \,\mathrm{d}(x,y)\\ &\geq \int_{\tau_{2j+1,2i}^{2,k+1}} (\omega(x))^2 \,\mathrm{d}(x,y)\\ &= \int_{\tau_{2i,2j+1}^{1,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y) \geq \int_{\tau_{2i+1,2j}^{1,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y). \end{aligned} \tag{2.15}$$

For the same reason,

$$\int_{\tau_{2i,2j}^{2,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y) \leq \int_{\tau_{2i+1,2j}^{1,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y). \tag{2.16}$$

Using (2.15) and (2.16), we have

$$f_i = \int_{\tau_{2i+1,2j}^{2,k+1} \cup \tau_{2i+1,2j+1}^{2,k+1}} (\omega(x))^2 \,\mathrm{d}(x,y) \geq \int_{\tau_{2i,2j}^{2,k+1} \cup \tau_{2i+1,2j}^{1,k+1}} (\omega(y))^2 \,\mathrm{d}(x,y) = d_j$$
$$\text{and} \quad \frac{d_j}{d_j + f_i} \leq \frac{1}{2}.$$

Together with $e_j d_j + d_j d_i < e_j d_i + e_j d_j + d_j d_i$, the assertion follows as in the proof of Lemma 2.4.

Consider now $i = n-1$. Then, the second row and column of $M_{2,ij}$ and $J_{2,ij}$ has to be canceled. Thus, $M_{2,n-1,j} = J_{2,n-1,j}$ and

$$\lambda_1(M_{2,n-1,j}^{-1} J_{2,n-1,j}) = \lambda_2(M_{2,n-1,j}^{-1} J_{2,n-1,j}) = 1.$$

The last case is $j = 0$. We have to omit the first row and column in $M_{2,i,0}$ and $J_{2,i,0}$. By a short calculation the estimates $\frac{1}{2} \leq \lambda_2 < \lambda_1 \leq \frac{3}{2}$ are obtained for the roots of the characteristic polynomial of the matrix $M_{2,i,0}^{-1} J_{2,i,0}$ (cf. [8]). ∎

In (2.11) and (2.14), we have defined a local preconditioner $M_{2,ij}$ for the element stiffness matrix $J_{2,ij}$ corresponding to the triangle $\tau_{ij}^{2,k}$. On the triangles $\tau_{ij}^{1,k}$, we define matrices $M_{1,ij}$ in the same way as $M_{2,ij}$ for $\tau_{ij}^{2,k}$:

$$M_{1,ij} = \begin{cases} 4\begin{bmatrix} e_i + d_j & 0 & -d_j \\ 0 & d_i + f_j & 0 \\ -d_j & 0 & d_i + d_j \end{bmatrix} & \text{for} \quad i \leq j, \\ 4\begin{bmatrix} e_i + d_j & 0 & 0 \\ 0 & d_i + f_j & -d_i \\ 0 & -d_i & d_i + d_j \end{bmatrix} & \text{for} \quad i > j. \end{cases}$$

Remark 2.3. By the symmetry of the differential operator with respect to the variables x and y, we obtain the same results for the triangles $\tau_{ij}^{1,k}$ as in Lemmas 2.4 and 2.5.

Following [6], a global preconditioner $M_{\mathbb{W}_{k+1}}$ for $K_{\mathbb{W}_{k+1}}$ (2.4) is defined using the local matrices $M_{s,ij}$, where $0 \le i,j \le n-1$, $s = 1,2$. The matrix $K_{\mathbb{W}_{k+1}}$ is the result of assembling the local stiffness matrices $J_{s,ij}$, $s = 1,2$, and $i,j = 0,\dots,n-1$, i.e.,

$$K_{\mathbb{W}_{k+1}} = \sum_{s=1}^{2} \sum_{i,j=0}^{n-1} L_{s,ij}^T J_{s,ij} L_{s,ij}. \tag{2.17}$$

The matrices $L_{s,ij} \in \mathbb{R}^{3\times 3\cdot 4^{k-1}-2^k}$ are the usual finite element connectivity matrices.

DEFINITION 2.6. *We define the matrix* $M_{\mathbb{W}_{k+1}}$ *by*

$$M_{\mathbb{W}_{k+1}} = \sum_{s=1}^{2} \sum_{i,j=0}^{n-1} L_{s,ij}^T M_{s,ij} L_{s,ij}. \tag{2.18}$$

Because of the properties of the local preconditioners $M_{s,ij}$, the matrix $M_{\mathbb{W}_{k+1}}$ is a good preconditioner for $K_{\mathbb{W}_{k+1}}$. This result is stated as the main theorem of this subsection.

THEOREM 2.7. *Let* $\omega(\xi)$ *satisfy Assumption* 1.1*, let* $M_{\mathbb{W}_{k+1}}$ *and* $K_{\mathbb{W}_{k+1}}$ *be defined in* (2.18) *and* (2.17)*, respectively. Then, one obtains*

$$\lambda_{\min}\left((M_{\mathbb{W}_{k+1}})^{-1} K_{\mathbb{W}_{k+1}}\right) \ge 1 - \frac{1}{2}\sqrt{2}, \quad \lambda_{\max}\left((M_{\mathbb{W}_{k+1}})^{-1} K_{\mathbb{W}_{k+1}}\right) \le 1 + \frac{1}{2}\sqrt{2}.$$

In order to prove the assertion, we use the following result (cf. Lemma 2.5 of [6]; see also [2], [25]).

LEMMA 2.8. *Let* $\{A_i \in \mathbb{R}^{m_i,m_i}\}_{i=1}^s$ *be a finite set of symmetric positive definite matrices. Let* $A = \sum_{i=1}^s L_i^T A_i L_i$*, where* $L_i \in \mathbb{R}^{m_i,m}$ *and* $A \in \mathbb{R}^{m,m}$*. Furthermore, let* C_i *be a preconditioner for the matrix* A_i*, i.e., for all* $\underline{w} \in \mathbb{R}^{m_i}$ *the relations*

$$\underline{\lambda}_i (C_i \underline{w}, \underline{w}) \le (A_i \underline{w}, \underline{w}) \le \overline{\lambda}^i (C_i \underline{w}, \underline{w}) \tag{2.19}$$

with $0 < \overline{\lambda^i}$ *and* $0 \le \underline{\lambda_i}$ *hold. Let* $C = \sum_{i=1}^s L_i^T C_i L_i$*. Then,* $\forall \underline{v} \in \mathbb{R}^m$

$$\underline{\lambda}(C\underline{v}, \underline{v}) \le (A\underline{v}, \underline{v}) \le \overline{\lambda}(C\underline{v}, \underline{v})$$

is valid with

$$\underline{\lambda} = \min_i \underline{\lambda}_i, \quad \overline{\lambda} = \max_i \overline{\lambda}^i.$$

Proof of Theorem 2.7. By Lemmas 2.4 and 2.5 and Remark 2.3, the assumptions (2.19) are satisfied. Using Lemma 2.8, the assertions follow. ∎

Applying Theorem 2.7, a preconditioned Richardson iteration can be built as a preconditioned simple iteration method. The error propagation operator $\mathcal{S}_{\omega,k+1}$ of this method is defined by

$$S_{\omega,k+1} = I - \zeta (M_{\mathbb{W}_{k+1}})^{-1} K_{\mathbb{W}_{k+1}}, \tag{2.20}$$

where $S_{\omega,k+1}$ denotes the matrix representation of $\mathcal{S}_{\omega,k+1}$ by the usual fem-isomorphism. This smoother $\mathcal{S} = \mathcal{S}_{\omega,k+1}$ can be used for Algorithm 2.1.

COROLLARY 2.9. *Let* $\| w \|_a^2 = a(w,w)$ *be the energy norm of the bilinear form* a*. Then, for all* $w \in \mathbb{W}_{k+1}$*,*

$$\| \mathcal{S}_{\omega,k+1}^{\nu} w \|_a \le \rho^{\nu} \| w \|_a$$

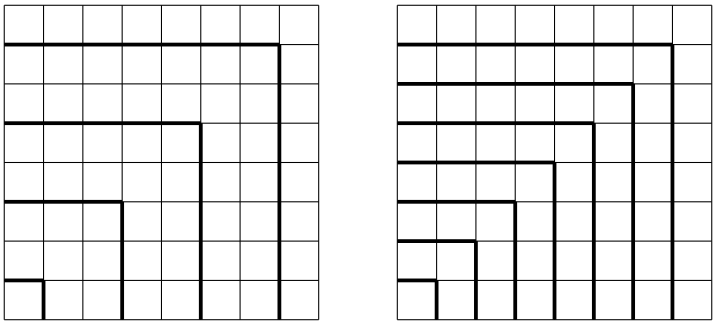

FIG. 2.2. *Lines of the smoothers $S_{\omega,k}$ (left) and $\tilde{S}_{\omega,k}$ (right).*

holds, where $\zeta = 1$ and $\rho = \frac{1}{2}\sqrt{2}$.

Proof. The proof is similar to the proof of Corollary 2.3 in [6]. ∎

The smoother $S_{\omega,k+1}$ can be interpreted as a line smoother (see [6] and the left-hand picture of Figure 2.2). Then, using Cholesky or Crout decomposition, the operation $S_{\omega,k}\underline{w} = \underline{r}$ can be done in $\mathcal{O}(m_k)$ arithmetical operations, where m_k is the number of unknowns on level k.

Additionally, we build a smoother $\tilde{S}_{\omega,k} = I - \zeta L_{\omega,k}^{-1} K_{\omega,k}$ which uses the ideas of (2.20). This smoother operates on the space $\mathbb{V}_k$. Let

(2.21)
$$L_{\omega,k} = \operatorname{diag}(K_{\omega,k}) + \tilde{R}, \quad \text{where} \quad \tilde{R} = \left[\tilde{b}(\phi_{ij}^k, \phi_{lm}^k) + \tilde{b}(\phi_{lm}^k, \phi_{ij}^k)\right]_{(i,j),(l,m)=(1,1)}^{(n-1,n-1)}$$

with the bilinear form $\tilde{b} : \mathbb{V}_k \times \mathbb{V}_k \to \mathbb{R}$,

$$\tilde{b}(\phi_{ij}^k, \phi_{lm}^k) = \begin{cases} a(\phi_{ij}^k, \phi_{lm}^k) & \text{if} \quad \begin{array}{lll} i = l = r, & j = 2, \dots, i, & m = j-1, \\ \text{or} \quad j = m = r, & i = 2, \dots, j, & l = i-1, \end{array} \\ 0 & \text{otherwise} \end{cases}$$

for $r = 1, \dots, n-1$. As well as $S_{\omega,k}$ (2.20), $\tilde{S}_{\omega,k}$ is a line smoother (cf. [6] and the right-hand picture of Figure 2.2). Analogous to $S_{\omega,k}$, the operation $\tilde{S}_{\omega,k}\underline{w} = \underline{r}$ can be done in $\mathcal{O}(n^2)$ flops using Cholesky or Crout decomposition.

3. BPX preconditioner. Recall the finite element discretization of problem (1.1).

Find $u \in \mathbb{V}_k$ such that

$$\int_\Omega \left(\omega^2(y) u_x v_x + \omega^2(x) u_y v_y\right) \, \mathrm{d}(x,y) = \int_\Omega f v \, \mathrm{d}(x,y) \tag{3.1}$$

holds for all $v \in \mathbb{V}_k$ with a weight function $\omega(\xi)$ satisfying Assumption 1.1.

For the efficient solution of systems of linear equations arising from discretizations of uniformly elliptic problems by finite elements, Bramble, Pasciak, and Xu [11] have developed a preconditioner which has been called the BPX preconditioner. For this preconditioner, the spectral equivalence to the original stiffness matrix can be shown. Later, this preconditioner has been improved by the multiple diagonal scaling version (see [27]). As mentioned in [4], a BPX preconditioner with multiple diagonal scaling

does not show good numerical results in order to solve $K_{\omega,k}\underline{u} = \underline{g}_k$, the system of linear algebraic equations resulting from the finite element discretization of (3.1). One reason is that this preconditioner cannot handle the anisotropies resulting from the degenerate elliptic operator. However, with a modification, the so-called MTS-BPX, this behavior of the BPX preconditioner can be improved (see [5]).

In subsection 2.3, the smoother $\tilde{S}_{\omega,k} = I - \zeta L_{\omega,k}^{-1} K_{\omega,k}$ has been considered as smoother for $K_{\omega,k}$. In this smoother, the matrix $L_{\omega,k}$ is a preconditioner for $K_{\omega,k}$ which can handle anisotropies. The idea now is to apply the matrix $L_{\omega,k}$ as "scaling" on each level instead of a diagonal scaling. We expect a stabilization of the BPX preconditioner. The following MTS-BPX preconditioner is now defined. Let Q_l^k, $l = 0, \ldots, k$ be the basis interpolation matrix from the basis $\{\phi_{ij}^l\}_{i,j}^{n_l-1} \in \mathbb{V}_l$ to the basis $\{\phi_{ij}^k\}_{i,j=1}^{n_k-1} \in \mathbb{V}_k$, where $n_j = 2^j$. Let Q_k^l be the transposed matrix. Furthermore, let $L_{\omega,k}$ be the matrix in (2.21). Then, we define the preconditioner

$$\hat{C}_{\omega,k}^{-1} = \sum_{l=1}^{k} Q_l^k L_{\omega,l}^{-1} Q_k^l. \tag{3.2}$$

This preconditioner is called the MTS-BPX preconditioner for $K_{\omega,k}$. In the case of $\omega(\xi) = \xi$, this definition corresponds to the definition of the MTS-BPX preconditioner given in [5].

Concerning the quality of $\hat{C}_{\omega,k}$ as preconditioner for $K_{\omega,k}$, the following result has been proved in [8].

LEMMA 3.1. *The eigenvalue estimate* $\lambda_{\max}\left(\hat{C}_{\omega,k}^{-1} K_{\omega,k}\right) \leq 2\,k$ *for the MTS-BPX preconditioner* (3.2) *is valid.*

For the MTS-BPX preconditioner $\hat{C}_{\omega,k}$ (3.2), Table 3.1 gives the lower and upper

constants for the spectral equivalence relations

$$\underline{c}\left(\hat{C}_{\omega,k}\underline{v},\underline{v}\right) \leq (K_{\omega,k}\underline{v},\underline{v}) \leq \overline{c}\left(\hat{C}_{\omega,k}\underline{v},\underline{v}\right) \quad \forall \underline{v},$$

computed by a vector iteration and inverse vector iteration for the corresponding matrices and the weight functions $\omega(\xi) = \xi^\alpha$, $(\alpha = 0, \frac{1}{2}, 1, 2, 10)$. One can see that the constant $\overline{c}$ is proportional to the level number for all considered weight functions which indicates that the estimate of Lemma 3.1 is sharp. The lower constant $\underline{c}$ seems to be bounded from below by a constant of about 0.488 uniformly with respect to α. However, we cannot prove the boundedness of $\underline{c}$ from below.

4. Concluding remarks. In this paper, we have proposed two methods in order to solve the system $K_{\omega,k}\underline{u}_k = \underline{g}_k$ (1.5). The first method is the multigrid algorithm $MULT$ with an appropriate line smoother $\mathcal{S}$. We have given the proof of the smoothing property (2.5) for a general class of weight functions ω. Together with the estimate for the constant γ^2 of the strengthened Cauchy inequality, the constant lies between $\frac{1}{2}$ and $\frac{2}{3}$ for $\omega(x) = x^\alpha$, $\alpha = 0.5, 1, 2$, and we can prove a mesh-size independent convergence rate for $\mu \geq 3$. Hence, the proposed method solves (1.5) in $\mathcal{O}(n^2)$ operations if $\gamma^2 < \frac{2}{3}$. If $\gamma^2 > \frac{2}{3}$, one can obtain an optimal method with two modified approaches. On the one hand, a multigrid with varying μ_l can be used, i.e., $\mu_l = 3$ if l is even and $\mu_l = 4$ if l is odd. On the other hand, a PCG method with AMLI preconditioner $C_{am,k,\omega}$ is used. Then, using the ingredients of the multigrid algorithm, i.e., $M_{\mathbb{W}_{k+1}}$ (2.17) as preconditioner for $K_{\mathbb{W}_{k+1}}$, and a polynomial iteration of degree $\mu = 3$, one can prove that the condition number of $C^{-1}_{am,k,\omega}K_{\omega,k}$ is bounded independently of the mesh-size h (see [7] for the special case $\omega(\xi) = \xi$, if $\gamma^2 < \frac{8}{9}$; cf. [3]). The second method is the PCG method with the MTS-BPX preconditioner. Due to Lemma 3.1, this method is not optimal. However, the numerical experiments indicate that we obtain a robust fast solver for weight functions as, e.g., $\omega(\xi) = \xi^{10}$ as well.

STABILITY AND CONVERGENCE OF A CLASS OF FINITE ELEMENT SCHEMES FOR HYPERBOLIC SYSTEMS OF CONSERVATION LAWS*

CHRISTOS ARVANITIS†, CHARALAMBOS MAKRIDAKIS‡, AND ATHANASIOS E. TZAVARAS§

Abstract. We propose a class of finite element schemes for systems of hyperbolic conservation laws that are based on finite element discretizations of appropriate relaxation models. We consider both semidiscrete and fully discrete finite element schemes and show that the schemes are stable and, when the compensated compactness theory is applicable, do converge to a weak solution of the hyperbolic system. The schemes use piecewise polynomials of arbitrary degree and their consistency error is of high order. We also prove that the rate of convergence of the relaxation system to a smooth solution of the conservation laws is of order $O(\varepsilon)$.

Key words. stability and convergence, finite element schemes, hyperbolic conservation laws, adaptive schemes

1. Introduction.

The problem of numerical approximation of nonlinear hyperbolic systems of conservation laws,

$$\begin{aligned} &\partial_t u + \sum_{j=1}^{d} \partial_{x_j} F_j(u) = 0, \quad x \in \mathbb{R}^d, \;\; u = u(x,t) \in \mathbb{R}^n, \quad t > 0\,, \\ &u(\cdot,0) = u_0(\cdot), \end{aligned} \tag{1.1}$$

is a challenging area testing the performance of various numerical methods. Such methods need to resolve accurately the shock regions and at the same time approximate with high accuracy the smooth parts of the solution.

It is a widely held belief that to achieve this goal one has to impose extraneous stabilization mechanisms, such as shock capturing terms or limiters (depending on the parameters of the problem, on the order of the method, on the particular form of the system, etc.). This approach seems to hold for those finite element or high-order finite volume methods previously developed [21, 10, 19, 11]. We refer to [11] for a comprehensive review of the current state of the art on the high-order finite difference, finite volume, and finite element methods for hyperbolic conservation laws; see also [17, 26].

§Department of Mathematics, University of Wisconsin, Madison, WI 53706, and Institute of Applied and Computational Mathematics, FORTH, 71110 Heraklion, Crete, Greece (tzavaras@math.wisc.edu, http://www.math.wisc.edu/~tzavaras).

Our motivation is to consider schemes designed to be used in conjunction with appropriate mesh refinement. It is conceivable that successful adaptive schemes may not need to be stabilized by using extra stabilization operators (such as limiters or shock capturing terms) accounting in turn for stabilization by the natural diffusion or relaxation mechanisms of the problem plus an appropriate mesh selection. A successful application of this idea requires one to have at hand a stable, robust, and flexible method. Indeed, toward this goal finite elements are a natural choice, since the development of supportive structures (finite element spaces of any order, flexibility in mesh construction, etc.) in adaptive finite element literature and software implementation is at a remarkable level.

In this article we propose a class of finite element methods based on relaxation models and address stability and convergence issues. For these relaxation finite element schemes the stabilization mechanisms are the regularization by wave operators (coming from the relaxation model) and appropriate mesh refinement in the shock areas. Our adaptive finite element schemes are of the general type introduced in [4] and further developed in [2, 3]. There, alternative methods and mesh refinement strategies are extensively tested computationally. Preliminary results indicate that the adaptive relaxation finite element schemes are a robust and reliable alternative for shock computations.

1.1. Relaxation finite element approximations. Relaxation models that approximate (1.1) are the basis of our schemes. In particular, the model suggested in [20],

$$\begin{aligned} &\partial_t\, u \;+\sum_{j=1}^{d}\partial_{x_j} v_j \;=\; 0,\\ &\partial_t\, v_i \;+A_i\,\partial_{x_i}\, u \;=\; -\frac{1}{\varepsilon}\big(v_i - F_i(u)\big), \quad i=1,\dots,d, \end{aligned} \tag{1.2}$$

corresponds to the regularization of (1.1) by a wave operator of order ε. Here A_i are symmetric, positive definite matrices with constant coefficients that are selected to satisfy certain stability conditions, *the subcharacteristic conditions*; see [20, 43] and the next sections. This relaxation model induces a regularization mechanism with *finite speed of propagation* that results in a partial differential equation with linear principal part. In return, the number of unknowns is increased. Nevertheless, in schemes based on the discretization of (1.2) the extra cost is compensated for by the simplicity and the natural implicit-explicit discretization that this model admits. The relaxation finite element schemes are based on the direct finite element approximation of (1.2).

Let $\mathcal{T}_h = \{K\}$ be a decomposition of $\mathbb{R}^d$ into elements with the usual properties [7]. We use the notation $h_K = \operatorname{diam}(K)$, $h = \sup_{K\in\mathcal{T}_h} h_K < 1$, and $\underline{h} = \min_{K\in\mathcal{T}_h} h_K$. The standard conforming finite element space S_k is defined by

$$S_k = \{\phi \in C^0\,(\mathbb{R}^d)^n \;:\; \phi\,|_K \in \mathbb{P}_k,\; K\in\mathcal{T}_h,\;\; \phi\,|_{\Omega^C} \equiv\; 0\}. \tag{1.3}$$

Here we assume that the initial values have compact support and thus, for all $t\in[0,T]$, our solution will vanish outside some compact set $\Omega\subset\mathbb{R}^n$. Clearly, $S_k \subset H_0^1(\Omega)$; see [7] for the approximation properties of S_k into Sobolev spaces. Further, we introduce a finite element space consisting of piecewise discontinuous polynomials:

$$V_{k-1} = \{\psi \in L^2(\mathbb{R}^d)^n \;:\; \psi\,|_K \in \mathbb{P}_{k-1},\; K\in\mathcal{T}_h,\;\; \psi\,|_{\Omega^C} \equiv\; 0\}. \tag{1.4}$$

By construction $\partial_{x_i}\phi \in V_{k-1}$ for all $\phi\in S_k$.

The schemes under consideration are obtained by a direct discretization (without adding additional diffusion terms) of (1.2). The approximation of u is sought in the space S_k and the approximations of the relaxation variables v_i in V_{k-1}; that is, find $(u_h, v_{h,1}, \dots, v_{h,d}) : (0,T] \to S_k \times (V_{k-1})^d$ such that

(1.5)
$$\begin{aligned}
&(\partial_t\, u_h, \phi) \;-\sum_{j=1}^{d} (v_{h,j}, \partial_{x_j}\, \phi) \;=\; 0 \quad \forall\, \phi \in S_k,\\
&(\partial_t\, v_{h,i}, \psi) \;+\; (A_i\, \partial_{x_i}\, u_h, \psi) \;=\; -\frac{1}{\varepsilon}\big(v_{h,i} - F_i(u_h), \psi\big) \quad \forall\, \psi \in V_{k-1}, i = 1, \dots, d,
\end{aligned}$$

with initial conditions $u_h(0) = \Pi_S u_0$ and $v_{h,i}(0) = \Pi_V F_i(u_0)$, where Π_S and Π_V are nodal interpolants on S_k and V_{k-1}, respectively. We note that (1.5) is a semidiscrete scheme since we have discretized only the spatial variable, in the sense that for any fixed $t \in [0,T]$, $u_h(\cdot, t) \in S_k$. In section 2 we show that if u_h solves (1.5), then it satisfies

(1.6)
$$\begin{aligned}
&(\partial_t\, u_h, \phi) + \sum_{i=1}^{d} \big(\partial_{x_i} F_i(u_h), \phi\big)\\
&\qquad +\; \varepsilon\, \left((\partial_{tt}\, u_h, \phi) + \sum_{i=1}^{d} (A_i\, \partial_{x_i}\, u_h, \partial_{x_i}\, \phi) \right) \;= 0 \quad \forall \phi \in S_k.
\end{aligned}$$

In the stability analysis we work with (1.6) but note that (1.5) is better suited to explicit-implicit one-step discretizations in time. Time discretizations based on (1.6) are also possible; see section 3.

The method is comparable, in terms of computational performance, with the fully conforming discretization of the relaxation model considered in [4]: find $(u_h, v_{h,1}, \dots, v_{h,d}) : (0,T] \to (S_k)^{d+1}$ such that

(1.7)
$$\begin{aligned}
&(\partial_t\, u_h, \phi) \;-\sum_{j=1}^{d} (v_{h,j}, \partial_{x_j}\, \phi) \;=\; 0 \quad \forall\, \phi \in S_k,\\
&(\partial_t\, v_{h,i}, \psi) \;+\; (A_i\, \partial_{x_i}\, u_h, \psi) \;=\; -\frac{1}{\varepsilon}\big(v_{h,i} - F_i(u_h), \psi\big) \quad \forall\, \psi \in S_k, i = 1, \dots, d.
\end{aligned}$$

The corresponding one field equation to (1.7) takes the form

(1.8)
$$\begin{aligned}
&(\partial_t\, u_h, \phi) + \sum_{i=1}^{d} \big(\partial_{x_i} P\, F_i(u_h), \phi\big),\\
&\qquad +\; \varepsilon\, \left((\partial_{tt}\, u_h, \phi) + \sum_{i=1}^{d} (A_i\, P\, \partial_{x_i}\, u_h, P\, \partial_{x_i}\, \phi) \right) \;= 0 \quad \forall \phi \in S_k,
\end{aligned}$$

where P is the L^2-projection operator onto S_k. Note that, when discretizing (1.7) in time with an explicit scheme, the computation of u_h will require the inversion of $d+1$ systems with the same mass matrix. The same procedure in (1.5) will require only the inversion of one mass matrix.

Based on the semidiscrete schemes one can devise various one-step implicit-explicit Runge–Kutta time discretizations [40, 4, 2, 3]. In the following sections we analyze the stability properties of semidiscrete as well as fully discrete schemes.

1.2. Stabilization by mesh refinement. Schemes (1.5) and (1.7) are indeed simple, but the relaxation mechanism alone does not provide the necessary stabilization required in the shock regions. Indeed, this is confirmed by coarse mesh numerical experiments; see section 6 and [4]. This also becomes evident by further examination of properties of the schemes. Consider the one-space dimensional ($d = 1$) system

$$\begin{aligned} &\partial_t u + \partial_x F(u) = 0, \quad x \in \mathbb{R},\ t > 0,\ \ u = u(x,t) \in \mathbb{R}^n, \\ &u(\cdot, 0) = u_0(\cdot) \end{aligned} \tag{1.9}$$

with u_0 of compact support and the associated finite element relaxation scheme. Following the argument in [4], it is seen that the effective equation of both schemes (1.5) and (1.7) in the case $n = 1,\ d = 1,\ q = 1$ is

$$\partial_t u + F(u)_x + \varepsilon\big[\partial_{tt} u - A\partial_{xx} u\big] + \beta\, h_{\mathrm{loc}}^2 F(u)_{xxx} = 0 \tag{1.10}$$

for some positive constant β. As expected, the finite element discretization induces a dispersion term which is linear in the flux variable. Applying the Chapman–Enskog expansion to (1.10) we obtain

$$\partial_t u + F(u)_x - \varepsilon\partial_x\big((c^2 - F'(u)^2)\,\partial_x u\big) + \beta\, h_{\mathrm{loc}}^2 F(u)_{xxx} = 0.$$

It is evident that to exclude approximations with oscillatory character near shocks or to avoid computing nonentropic solutions, the diffusion term should be dominant; see the relevant numerical example in section 6 and the literature on diffusion-dispersion approximations of conservation laws [28, 29]. This will enforce a condition of the form

$$h_{\mathrm{loc}} < o(\varepsilon), \tag{1.11}$$

where h_{loc} is the local mesh size close to the shock. On the other hand, the theoretical analysis in sections 2–4 provides convergence results under the slightly weaker condition

$$h_{\mathrm{loc}} < \gamma\,\varepsilon \tag{1.12}$$

for some constant γ. That is, the convergence results include even certain cases pertaining to nonclassical shocks. However, in practice typically mesh adaptivity selects the entropic solution, since it applies mesh refinement in a neighborhood of the shock. The extensive numerical experiments in [4, 2] and section 6 show that appropriate mesh refinement indeed stabilizes in a robust way the finite element relaxation schemes. Since the focus of this paper is the theoretical justification of the above schemes, we will not insist on the important problem of identifying appropriate mesh refinement strategies and refer to [4, 2, 3].

1.3. Stability and related properties. In what follows, we investigate the theoretical properties of the relaxation finite element schemes (1.5). It is shown that for a wide class of one-dimensional but also of multidimensional systems (1.1), the schemes are stable in the sense that they satisfy certain strong dissipation estimates; see Propositions 2.1, 2.3, 2.6, 3.1, 3.3, and 3.5. Similar estimates are satisfied by the relaxation model (1.2) [43, 18]. The strong dissipation estimates for relaxation approximations introduced in [43] are a basic tool in our analysis. In addition, nonstandard stability estimates for appropriate finite element projections are used in an essential way. The stability results are of interest since they justify the dissipative character of our schemes.

The stability estimates will also be used in conjunction with the compensated compactness framework to derive compactness conditions. Recall that a pair of functions $\eta = \eta(u)$, $q = q(u)$ are called an entropy-entropy flux pair (or entropy pair for short) if (η, q) solve the linear hyperbolic system

$$\nabla q = \nabla \eta \cdot \nabla F.$$

The existence and properties of entropy pairs have been extensively investigated (e.g., [15, 38]), and entropy pairs are used to describe the compactness properties of approximate solutions for certain one-dimensional systems of two conservation laws [42, 15, 38, 37].

In fact, we show that for the finite element relaxation scheme (1.5) with $d = 1$, the approximations u_h satisfy

$$\partial_t \eta(u_h) + \partial_x q(u_h) \subset \text{ compact set of } H^{-1}_{\text{loc}}(\mathcal{O}).$$

This condition suffices to apply the compensated compactness program for certain one-dimensional equations and systems (see section 4) and to obtain convergence for semidiscrete or fully discrete finite element schemes. Similar results appear to hold for the fully conforming methods (1.7), (1.8), but their verification requires additional technical estimations. This is largely because the presence of the projection P in the one field equation (1.8) will result in extra error terms in the stability analysis. This case will not be pursued here.

The estimates derived in the following sections are rather complicated. To focus on the ideas and to present the material in a readable way, we have chosen to work step by step to distinguish the cases:

- semidiscrete schemes with symmetric flux F',
- semidiscrete schemes and the system admits a convex entropy function,
- fully discrete schemes with symmetric flux F',
- fully discrete schemes and the system admits a convex entropy function, and
- semidiscrete and fully discrete schemes for multidimensional systems that admit a convex entropy function.

In summary, the results provide theoretical support to the use of finite element relaxation schemes by establishing stability for a wide class of systems and convergence in various cases.

1.4. Error estimates for smooth solutions. Since the schemes are based on the discretization of model (1.2), in section 5 we address the problem of error estimates for relaxation approximations. We consider a system endowed with a convex entropy. Let u be a smooth solution of (1.1) defined on a maximal interval of existence, and let U_ε be the smooth solution of the relaxation approximation (1.2). We show that

$$\|U_\varepsilon(t) - u(t)\|_{L^2} \le C(t,u)\,\varepsilon, \tag{1.13}$$

where the constant $C(t,u)$ depends on a strong norm of u and blows up at the critical time. The proof is based on a novel application of an idea of Dafermos [14, Thm. 5.2.1] to an error estimation. The difficulty posed by the relaxation approximation is handled by introducing a modified functional, corresponding to the relative entropy

$$H_R(u, U_\varepsilon) = \eta\big(U_\varepsilon + \varepsilon\partial_t(U_\varepsilon - u)\big) - \eta(u) - \eta'(u)\big(U_\varepsilon - u + \varepsilon\partial_t(U_\varepsilon - u)\big) \tag{1.14}$$

in the place of

$$H(u,w) = \eta(w) - \eta(u) - \eta'(u)(w-u) \tag{1.15}$$

used in [14]; see section 5 for details.

The finite element relaxation schemes are related to the central difference schemes of [33, 27]. One of their main common properties is that both schemes are Riemann solvers free and thus they combine high accuracy with simplicity. Finite element methods for hyperbolic conservation laws were considered in [21, 39, 22, 23, 19, 12, 10]. The theoretical properties of the streamline diffusion method were analyzed extensively (convergence, error estimates) in the scalar case [21, 39, 9]. The case of systems admitting entropy pairs is considered in [23] and it is shown that, for a streamline diffusion shock capturing method defined using the entropy variables, the bounded a.e. converging limits of approximations are weak entropy solutions of the system.

Finite element methods with discontinuous elements were proposed in [19] and [12]. In [12] stabilization is enforced by applying projection operators based on limiters. The above methods use piecewise polynomials of arbitrary degree and are formally of high order. Adaptive finite element methods based on a posteriori estimates have been considered in [22] for the ϵ-viscous approximation of one-dimensional systems of conservation laws. There exists a large literature on finite difference relaxation schemes; see, e.g., [20, 1, 25, 18] and [24] for relaxation schemes on unstructured grids.

The article is organized as follows. In section 2 we consider semidiscrete schemes and show stability and compactness of the dissipation measure for (i) case $d = 1$, F' is symmetric; (ii) case $d = 1$ and the system admits a convex entropy; and (iii) the multidimensional case. Section 3 is devoted to the analysis of implicit-explicit fully discrete schemes. The proofs are presented in a compact way, avoiding repetition of arguments already used in the semidiscrete case. In section 4 we discuss issues related to the application of compensated compactness to certain specific systems in order to conclude convergence of the schemes to a weak solution of (1.1). Section 5 is devoted to the error estimation between a smooth solution of (1.1) and the relaxation model (1.2). We conclude in section 6 with a discussion of implementation issues and present indicative examples reflecting the numerical performance of the method in two test cases.

2. Semidiscrete schemes: Stability estimates. We start by showing that the scheme (1.5) admits a field equation that is in fact a standard finite element discretization of the conservation law perturbed by a wave operator.

LEMMA 2.1. *If u_h solves* (1.5)*, then it satisfies* (1.6).

Proof. Select $\psi = \partial_{x_i}\phi, \quad \phi \in S_k$ in (1.5). Since $\psi \in V_{k-1}$ we have on summing with respect to $i,\ i = 1, \dots, d$,

$$\sum_{i=0}^{d}(\partial_t\, v_{h,i}, \partial_{x_i}\, \phi)\ +\ \sum_{i=1}^{d}(A_i\, \partial_{x_i}\, u_h, \partial_{x_i}\, \phi) = \ -\frac{1}{\varepsilon}\sum_{i=0}^{d}(v_{h,i} - F_i(u_h), \partial_{x_i}\, \phi).$$

Differentiating the first equation of (1.5) with respect to t we get

$$(\partial_{tt}\, u_h, \phi) - \ \sum_{j=1}^{d}(\partial_t v_{h,j},\ \partial_{x_j}\phi)\ =\ 0.$$

Hence,

$$\varepsilon(\partial_{tt}\, u_h, \phi)\ +\ \varepsilon\ \sum_{i=1}^{d}(A_i\, \partial_{x_i}\, u_h, \partial_{x_i}\, \phi) + \ \sum_{i=1}^{d}(v_{h,i}, \partial_{x_i}\, \phi)\ -\ \sum_{i=1}^{d}\big(F_i(u_h), \partial_{x_i}\, \phi\big)\ =\ 0.$$

Then by (1.5) we get the desired relation. □

In what follows, we establish stability properties for the finite element scheme (1.6). The stability estimates are proved consecutively for (i) case $d = 1$, F', symmetric; (ii) case $d = 1$, and the system admits a convex entropy; and (iii) the multidimensional case.

The one-dimensional semidiscrete finite element scheme takes the form

$$(\partial_t\, u_h, \phi) - \big(F(u_h), \partial_x \phi\big) + \varepsilon \Big((\partial_{tt}\, u_h, \phi) + (A\partial_x u_h, \partial_x\, \phi)\Big) = 0 \quad \forall \phi \in S_k. \tag{2.1}$$

For (2.1), we also prove compactness of the dissipation measure so as to apply the compensated compactness program and deduce convergence of the scheme in section 4. In the proof we use Murat's lemma [32].

LEMMA 2.2 (see Murat [32]). *Let $\mathcal{O}$ be an open subset of $\mathbb{R}^m$ and $\{\phi_j\}$ a bounded sequence of $W^{-1,p}(\mathcal{O})$ for some $p > 2$. In addition let $\phi_j = \chi_j + \psi_j$, where $\{\chi_j\}$ belongs in a compact set of $H^{-1}(\mathcal{O})$ and $\{\psi_j\}$ belongs in a bounded set of the space of measures $M(\mathcal{O})$. Then $\{\phi_j\}$ belongs in a compact set of $H^{-1}(\mathcal{O})$.*

2.1. The case $d = 1$ and F' is symmetric. Let $\phi = u_h$ in (2.1) and use $\big(F(u_h), \partial_x u_h\big) = 0$ to get

$$\partial_t \left[\int_\Omega \left(\frac{1}{2}|u_h|^2 + \varepsilon\, u_h\, \partial_t u_h\right) dx\right] + \varepsilon \int_\Omega [A\partial_x\, u_h \cdot \partial_x\, u_h - (\partial_t u_h)^2] dx = 0. \tag{2.2}$$

To estimate $\varepsilon \int_\Omega (\partial_t u_h)^2 dx$ let $\phi = \partial_t u_h$ in (2.1). Then,

$$\begin{aligned} &\|\partial_t\, u_h\|_{L^2}^2 + (F'(u_h)\, \partial_x\, u_h, \partial_t\, u_h) \\ &\qquad + \varepsilon \frac{1}{2} \partial_t \|\partial_t\, u_h\|_{L^2}^2 + \varepsilon \frac{1}{2} \partial_t (A\partial_x\, u_h, \partial_x\, u_h) = 0. \end{aligned} \tag{2.3}$$

Adding (2.2) with 2ε times (2.3) yields

$$\begin{aligned} &\frac{1}{2}\, \partial_t\, \|u_h + \varepsilon \partial_t\, u_h\|_{L^2}^2 + \varepsilon\, (A\partial_x\, u_h, \partial_x\, u_h) + 2\varepsilon (F'(u_h)\, \partial_x\, u_h, \partial_t\, u_h) \\ &\qquad + \varepsilon\, \|\partial_t\, u_h\|_{L^2}^2 + \frac{1}{2}\, \varepsilon^2\, \partial_t \Big\{\|\partial_t\, u_h\|_{L^2}^2 + 2(A\partial_x\, u_h, \partial_x\, u_h)\Big\} = 0. \end{aligned}$$

Since F' is symmetric, we have

$$\|\partial_x F(u_h)\|_{L^2}^2 = \big({F'}^2(u_h) \partial_x u_h, \partial_x u_h\big),$$

and we obtain

$$\begin{aligned} &\frac{1}{2}\, \partial_t \Big\{\|u_h + \varepsilon \partial_t\, u_h\|_{L^2}^2 + \varepsilon^2 \|\partial_t u_h\|_{L^2}^2 + 2\varepsilon^2 (A\partial_x\, u_h, \partial_x\, u_h)\Big\} \\ &\qquad + \varepsilon \|\partial_t\, u_h + \partial_x F(u_h)\|_{L^2}^2 + \varepsilon \big([A - {F'}^2(u_h)] \partial_x u_h, \partial_x u_h\big) = 0. \end{aligned}$$

We conclude with the following.

PROPOSITION 2.1. *Assume that $F'(u), A$ are symmetric and satisfy for some $\nu > 0$*

$$A - F'(u)^2 \geq \nu\, I, \qquad u \in \mathbb{R}^n. \tag{2.4}$$

Then the finite element approximation (2.1) *satisfies*

$$\begin{aligned}\int_\Omega \Big(|u_h + \varepsilon\, \partial_t\, u_h|^2 \;+\; \varepsilon^2 |\partial_t\, u_h|^2 \;+\; 2\varepsilon^2 A\partial_x\, u_h \;\cdot\; \partial_x\, u_h\Big)\\ + 2\int_0^t \int_\Omega \Big(\varepsilon|\partial_t u_h + F'(u_h)\partial_x\, u_h|^2 \;+\; \varepsilon\,\nu|\partial_x\, u_h|^2\Big)\\ \leq \int_\Omega |u_h^0 + \varepsilon\,\partial_t\, u_h(0)|^2 + \;\varepsilon^2|\partial_t\, u_h(0)|^2 + \;2\varepsilon^2 A\partial_x\, u_h^0 \cdot \partial_x\, u_h^0 \;=: C(u_h^0).\end{aligned}$$

In what follows we prove the next proposition.

PROPOSITION 2.2. *Let (η, q) be an entropy pair satisfying*

$$\|\eta\|_{L^\infty},\ \|q\|_{L^\infty},\ \|\eta'\|_{L^\infty},\ \|\eta''\|_{L^\infty} \;\leq\; C.$$

Then, for $h \leq \gamma\,\varepsilon$, there holds

$$\eta(u_h)_t \;+\; q(u_h)_x \text{ lies in a compact set of } H^{-1}_{loc}(\mathbb{R}\times\mathbb{R}^+).$$

Proof. Let (η, q) be an entropy pair and $\phi \in C_c^\infty(\mathbb{R}\times[0,\infty))$ a test function, and $\operatorname{supp}\phi \subset \tilde\Omega \times [0,\tilde T] =: Q$. We denote by $\Pi : L^2(\Omega) \to S_k$ a projection operator onto the finite element space of u_h to be determined later. Using the definition of the scheme we have

$$\begin{aligned}\Big(\eta(u_h)_t \;+\; q(u_h)_x, \phi\Big) &= \Big(\eta'(u_h)\big[u_{h,t} \;+\; F'(u_h)u_{h,x}\big], \phi\Big)\\ &= \Big(\big[u_{h,t} + F'(u_h)u_{h,x}\big], \Pi\big(\eta'(u_h)\,\phi\big)\Big)\\ &\quad + \Big(\big[u_{h,t} + F'(u_h)u_{h,x}\big], \eta'(u_h)\phi \;-\; \Pi(\eta'(u_h)\phi)\Big)\\ &= -\,\varepsilon\Big(A\partial_x\, u_h, \big[\Pi\big(\eta'(u_h)\phi\big)\big]_x\Big) - \varepsilon\Big(u_{h,tt}, \Pi\big(\eta'(u_h)\phi\big)\Big)\\ &\quad + \Big(\big[u_{h,t} + F'(u_h)u_{h,x}\big],\ \eta'(u_h)\phi - \Pi\big(\eta'(u_h)\phi\big)\Big).\end{aligned} \tag{2.5}$$

We select now $\Pi : L^2(\Omega) \to S_k$ to be the L^2-projection onto S_k. Π satisfies

$$(\Pi\omega, \phi) \;=\; (\omega, \phi) \qquad \forall \phi \in S_k,\ \omega \in L^2(\Omega), \tag{2.6}$$

$$\|\Pi\omega - \omega\|_{L^2(\Omega)} \;=\; \inf_{\chi\in S_k} \|\omega - \chi\|_{L^2(\Omega)} \;\leq\; C\,h\,\|\omega_x\|_{L^2(\Omega)}, \quad \omega \in H^1(\Omega), \tag{2.7}$$

as well as the stability estimate [13]

$$\|(\Pi\omega)_x\|_{L^2(\Omega)} \;\leq\; C\|\omega_x\|_{L^2(\Omega)}, \quad \omega \in H^1(\Omega). \tag{2.8}$$

We are ready to bound the terms in the right-hand side of (2.5). Indeed, (2.8) implies

$$\begin{aligned}&\varepsilon\Big|\Big(A\,u_{h,x}, \big[\Pi\big(\eta'(u_h)\phi\big)\big]_x\Big)\Big| \leq \varepsilon\, C\|u_{h,x}\|_{L^2(\Omega)}\,\|\big(\eta'(u_h)\phi\big)_x\|_{L^2(\Omega)}\\ &\leq C\Big(\varepsilon\int_\Omega |u_{h,x}|^2\Big)\|\eta''\|_{L^\infty(\Omega)}\|\phi\|_{C^0(\Omega)} + \varepsilon^{1/2}C\Big(\varepsilon\int_\Omega |u_{h,x}|^2\Big)^{1/2}\|\eta'\|_{L^\infty(\Omega)}\|\phi_x\|_{L^2(\Omega)}.\end{aligned} \tag{2.9}$$

Next, since $u_{h,tt} \in S_k$ and by (2.6),

$$
\begin{aligned}
&- \varepsilon \int_0^t \int_\Omega u_{h,tt}\, \Pi\Big(\eta'(u_h)\phi\Big) dxds \;=\; -\varepsilon \int_0^t \int_\Omega u_{h,tt}\, \eta'(u_h)\phi dxds \\
&= \varepsilon \int_0^t \int_\Omega u_{h,t}\big(\eta'(u_h)\phi\big)_t dxds + \varepsilon \int_\Omega u_{h,t}\, \eta'(u_h)\phi\Big|_{s=0} dx - \varepsilon \int_\Omega u_{h,t}\, \eta'(u_h)\phi\Big|_{s=t} dx.
\end{aligned}
$$

By Proposition 2.1 we have

(2.10)
$$
\varepsilon\Big|\int_\Omega u_{h,t}\, \eta'(u_h)\phi(t)dx\Big| \le \varepsilon\Big(\int_\Omega u_{h,t}^2\Big)^{1/2} \|\eta'\|_{L^\infty(\Omega)}\, \|\phi\|_{C^0(\Omega)}\, m(\Omega)^{1/2} \le \; C_\Omega \|\phi\|_{C^0(\Omega)},
$$

and as before

(2.11)
$$
\begin{aligned}
\varepsilon\Big|\int_0^t \int_\Omega u_{h,t}\big(\eta'(u_h)\phi\big)_t dxdt\Big| \;\le\; & C\Big(\varepsilon \int_0^t \int_\Omega |u_{h,t}|^2\Big)\|\eta''\|_{L^\infty(Q)}\, \|\phi\|_{C^0(Q)} \\
& + \; \varepsilon^{1/2}\Big(\varepsilon \int_0^t \int_\Omega |u_{h,t}|^2\Big)^{1/2} \|\eta'\|_{L^\infty(Q)}\, \|\phi_t\|_{L^2(Q)}.
\end{aligned}
$$

To estimate the last term in (2.5), note that $\eta'(u_h)\phi \in H^1(\Omega)$ and thus

$$
\begin{aligned}
\|\eta'(u_h)\phi - \Pi\big(\eta'(u_h)\phi\big)\|_{L^2(\Omega)} \;&\le Ch\|\big(\eta'(u_h)\phi\big)_x\|_{L^2(\Omega)} + Ch\|\eta'(u_h)\phi_x\|_{L^2(\Omega)} \\
&\le Ch\|\eta''\|_{L^\infty(\Omega)}\, \|u_{h,x}\|_{L^2(\Omega)}\, \|\phi\|_{C^0(\Omega)} + Ch\|\eta'\|_{L^\infty(\Omega)}\, \|\phi_x\|_{L^2(\Omega)}.
\end{aligned}
$$

By (2.4) we have $\|F'(u_h)^2\|_{L^\infty(\Omega)} \le C$; therefore

$$
\begin{aligned}
&\Big|\Big(\big[u_{h,t} + F'(u_h)u_{h,x}\big],\, \eta'(u_h)\phi - \Pi\big(\eta'(u_h)\phi\big)\Big)\Big| \\
&\qquad \le\; C\Big(h \int_\Omega (|u_{h,t}|^2 dx \;+\; |\partial_x u_h|^2) dx\Big)\|\phi\|_{C^0(\Omega)} \\
&\qquad\quad + h\,\Big(\int_\Omega (|u_{h,t}|^2 \;+\; |\partial_x u_h|^2)\, dx\Big)^{1/2} \|\phi_x\|_{L^2(\Omega)}.
\end{aligned} \tag{2.12}
$$

Combining (2.9)–(2.12) and using Murat's Lemma 2.2 (in our case, $\chi_h \to 0$ in H^{-1} and is thus precompact in H^{-1}), we complete the proof. ∎

2.2. The case $d = 1$, and the system admits a convex entropy. The case that F' is not necessarily symmetric but the system is equipped with a convex entropy η is examined next. In this case the system is symmetrizable. The finite element approximations (1.5) enjoy the same a priori bounds with the continuous solution of the relaxation model considered in [43]. Indeed, the following proposition holds.

PROPOSITION 2.3. *Let* (1.9) *be equipped with a strictly convex entropy* $\eta(u)$ *satisfying for some* $\alpha > 0$

$$
\frac{1}{\alpha} I \le \eta''(u) \le \alpha\, I, \quad u \in \mathbb{R}^n. \tag{2.13}
$$

Assume for some $M > 0$ *we have* $|F'(u)| \le M$ *for* $u \in \mathbb{R}^n$ *and that the positive definite, symmetric matrix* A *is selected to satisfy, for* $\overline{\alpha} = 2\alpha \max\{\beta, 1\}$, β *as in* (2.22) *and some* $\nu > 0$,

$$
\frac{1}{2}\big((\eta''(u)A)^T + \eta''(u)A\big) - \overline{\alpha} F'(u)^T F'(u) \ge \nu\, I \qquad \text{for } u \in \mathbb{R}^n. \tag{2.14}
$$

Then there is $\gamma = \gamma(\alpha, \beta, M, \nu) > 0$ *such that, for*

$$h \leq \gamma\, \varepsilon \tag{2.15}$$

and for some positive constants c_1, c_2, *and* c_3, *the finite element approximation* (2.1) *satisfies the stability estimate*

$$\begin{aligned}
&\int_\Omega \Big(\eta(u_h + \varepsilon\, \partial_t\, u_h) + \varepsilon^2 c_1 \big[|\partial_t\, u_h|^2 + A\partial_x\, u_h\, \cdot\, \partial_x\, u_h\big]\Big) dx \\
&\quad + \varepsilon c_2 \int_0^t \int_\Omega \Big(|\partial_t u_h + F'(u_h)\partial_x\, u_h|^2 + |\partial_x\, u_h|^2 + |\partial_t u_h|^2\Big) dx dt \\
&\quad \leq \int_\Omega \Big(\eta(u_h^0 + \varepsilon\, \partial_t\, u_h(0)) + \varepsilon^2 c_3 \big[|\partial_t\, u_h(0)|^2 + A\partial_x\, u_h^0 \cdot \partial_x\, u_h^0\big]\Big) dx.
\end{aligned} \tag{2.16}$$

Remark 2.1. We are interested here in data and associated finite element approximations u_h that are of compact support. It is thus natural to normalize η so that $\eta(0) = 0$ and $\eta'(0) = 0$. This can always be achieved, because if (η, q) is an entropy pair, then

$$\eta(u) - \eta(0) - \eta'(0)u, \quad q(u) - q(0) - \eta'(0)(F(u) - F(0))$$

is also an entropy pair. In view of (2.13), the normalized η is equivalent to the Euclidean norm, $\eta(u) \sim |u|^2$. Thus the stability framework in Proposition 2.3 is that of L^2.

Using the stability estimate, it is easy to see that strong convergence of the finite element approximations gives a weak solution that satisfies the integral version of the entropy inequality.

PROPOSITION 2.4. *Under the hypotheses of Proposition* 2.3, *if*

$$u_h \to u \quad \text{in } L^2_{x,t} \text{ and a.e.,} \tag{2.17}$$

then u *is a weak solution of* (1.9) *that satisfies*

$$\int_\Omega \eta(u(x,t))dx \leq \int_\Omega \eta(u^0(x))dx \qquad \text{for a.e. } t. \tag{2.18}$$

Proof. We assume with no loss of generality that $F(0) = 0$ and note that $|F(u)| \leq M|u|$. Let $u^0 \in H_0^1$ and be of compact support, let $v^0 = F(u^0) \in H_0^1$ and be of compact support, and define the approximations $u_h^0 \in S_k$ and $v_h^0 \in V_{k-1}$ defined by $v_h^0 = \Pi_{V_{k-1}} F(u_h^0)$ with $\Pi_{V_{k-1}}$ the L^2-projection. Let $u_h = u_h(x,t)$, $v_h = v_h(x,t)$ be the solution of the semidiscrete scheme. Note that $\partial_t u_h(0) = \Pi_{S_k} \partial_x F(u_h^0)$, where Π_{S_k} is the L^2-projection onto S_k.

For $\phi(x) \in S_k$ and $\theta(t) \in C_c^\infty([0,\infty))$ we have

$$\begin{aligned}
&-\int_0^t \int_\Omega [u_h \phi \partial_t \theta + F(u_h)\partial_x \phi\theta - \epsilon A \partial_x u_h \cdot \partial_x \phi\theta + \epsilon \partial_t u_h \cdot \phi \partial_t \theta] dx dt \\
&\quad - \int_\Omega (u_h^0 \phi\theta(0) + \epsilon \partial_t u_h(0) \phi\theta(0)) dx = 0.
\end{aligned} \tag{2.19}$$

Note that

$$\begin{aligned}
&u_h \to u, \;\; F(u_h) \to F(u) \quad \text{in } L^2_{x,t} \text{ and a.e.,} \\
&u_h^0 \to u^0, \;\; \varepsilon \partial_t u_h(0) \to 0 \quad \text{in } L^2_x \text{ and (along a subsequence) a.e.,} \\
&\varepsilon^{\frac{1}{2}} \|\partial_x u_h\|_{L^2_{x,t}} + \varepsilon^{\frac{1}{2}} \|\partial_t u_h\|_{L^2_{x,t}} \leq O(1).
\end{aligned}$$

Using that tensor products $\phi(x) \otimes \theta(t)$, $\phi \in S_k$, $\theta \in C_c^\infty([0,\infty))$ are dense as $h \to 0$ in $C^2(\bar{\Omega})$ for Ω bounded, we pass to the limit in (2.19) and obtain that u is a weak solution of (1.9). Using Fatou's lemma, we pass to the limit ε, $h \to 0$ in (2.16) to deduce

$$\int_\Omega \eta(u(x,t))\,dx \le \liminf_{h\to 0,\,\varepsilon\to 0} \int_\Omega \eta(u_h + \varepsilon \partial_t u_h)\,dx \le \int_\Omega \eta(u_0(x))\,dx$$

and conclude. ∎

To show the stability estimate we use the elliptic projection operator onto S_k and its approximation and stability properties. To this end let $P_1 : H_0^1 \to S_k$ be the Ritz (elliptic) projection defined by

$$(A\partial_x\, P_1 v, \partial_x \phi) = (A\partial_x\, v, \partial_x \phi) \qquad \forall \phi \in S_k,\ v \in H_0^1. \tag{2.20}$$

It is a standard result that P_1 satisfies

$$\begin{aligned} \|P_1\omega - \omega\|_{L^2(\Omega)} &\le C\,h\,\|\omega_x\|_{L^2(\Omega)}, \quad \omega \in H_0^1, \\ \|(P_1\omega)_x\|_{L^2(\Omega)} &\le C\|\omega_x\|_{L^2(\Omega)}, \quad \omega \in H_0^1. \end{aligned} \tag{2.21}$$

The second bound is a direct consequence of the definition and the first is obtained by a standard duality argument using once more the second bound (see [7, Thm. 5.4.8]). The following nonstandard stability property of P_1 will be crucial in the proof of Proposition 2.3. It uses in an essential way the stability analysis of the finite element method by mesh-dependent norms due to Babuška and Osborn [5].

LEMMA 2.3. *Let η be a strictly convex entropy and $v_h \in S_k$. Under hypothesis* (2.13)*, there exists a positive constant β such that*

$$(v_h, P_1\,[\,\eta''(w)(v_h)\,]\,) \le \beta\,\|\eta''(w)\|_{L^\infty(\Omega)}\,\|v_h\|^2_{L^2(\Omega)} \quad \forall w \in S_k. \tag{2.22}$$

Proof. It is known that P_1 is not stable with respect to $L^2(\Omega)$ [5]. Its stability with respect to the mesh-dependent L^2-like norm

$$\|v\|_{0,h,\Omega} = \left(\|v\|^2_{L^2(\Omega)} + \sum_j \delta_j |v(x_j)|^2 \right)^{1/2}, \tag{2.23}$$

where x_j are the nodes of the partition and $\delta_j = (x_{j+1} - x_{j-1})/2$ is as shown in [5], and

$$\|P_1\,v\|_{0,h,\Omega} \le \beta_1 \|v\|_{0,h,\Omega}, \tag{2.24}$$

where β_1 is a positive constant independent of h. Thus, (2.24) implies

$$\|P_1\,[\,\eta''(w)(v_h)\,]\,\|_{L^2(\Omega)} \le \beta_1 \|\eta''(w)\|_{L^\infty(\Omega)}\,\|v_h\|_{0,h,\Omega}. \tag{2.25}$$

But in the finite element space local inverse inequalities imply

$$\|v_h\|_{0,h,\Omega} \le \beta_2 \|v_h\|_{L^2(\Omega)} \qquad \forall v_h \in S_k, \tag{2.26}$$

with β_2 independent of h [7, 5]. Therefore, (2.22) follows with $\beta = \beta_1\,\beta_2$. ∎

Proof of Proposition 2.3. The finite element approximation u_h satisfies (2.1). Setting $\phi = P_1\,\eta'(u_h)$ and using (2.20), we obtain after a rearrangement

$$\begin{aligned}(\partial_t\, u_h, \eta'(u_h))+\big(\partial_x F(u_h), \eta'(u_h)\big) + \varepsilon(\partial_{tt} u_h, P_1\eta'(u_h)) + \varepsilon(A\partial_x u_h, \partial_x \eta'(u_h))\\ = (\partial_t\, u_h, \eta'(u_h) - P_1\,\eta'(u_h))+\big(\partial_x F(u_h), \eta'(u_h) - P_1\,\eta'(u_h)\big)\\ =: Z_1 + Z_2.\end{aligned} \tag{2.27}$$

The terms in the right-hand side will be estimated in what follows. First we examine the stability properties of the left-hand side. Since P_1 commutes with time differentiation,

$$\begin{aligned}\varepsilon(\partial_{tt}\, u_h, P_1\,\eta'(u_h)) &= \varepsilon\partial_t\,(\partial_t\, u_h, P_1\,\eta'(u_h)) - \varepsilon(\partial_t\, u_h, P_1\,[\,\eta''(u_h)\partial_t\, u_h\,])\\ &= \varepsilon\partial_t\,(\partial_t\, u_h, \eta'(u_h)) - \varepsilon(\partial_t\, u_h, P_1\,[\,\eta''(u_h)\partial_t\, u_h\,])\\ &\quad - \varepsilon\partial_t\,(\partial_t\, u_h, \eta'(u_h) - P_1\eta'(u_h)).\end{aligned} \tag{2.28}$$

We thus have

$$\begin{aligned}\partial_t \int_\Omega \eta(u_h)+ \int_\Omega \partial_x q(u_h) + \varepsilon\partial_t\,(\partial_t\, u_h, \eta'(u_h))\\ +\varepsilon(A\partial_x\, u_h, \eta''(u_h)\partial_x\, u_h) - \varepsilon(\partial_t\, u_h, P_1\,[\,\eta''(u_h)\partial_t\, u_h\,])\\ = Z_1 + Z_2 + Z_3,\end{aligned} \tag{2.29}$$

where the new term Z_3 is given by

$$Z_3 = \varepsilon\partial_t\,(\partial_t\, u_h, \eta'(u_h) - P_1\eta'(u_h)) = \varepsilon\partial_t Z_1. \tag{2.30}$$

As in [43] the following identity will be important:

$$\begin{aligned}\int_\Omega \eta(u_h + \varepsilon\partial_t\, u_h)dx = \int_\Omega \eta(u_h)dx + \varepsilon(\eta'(u_h), \partial_t\, u_h)\\ + \varepsilon^2\left(\partial_t\, u_h, \left\{\int_0^1\int_0^s \eta''(u_h + \varepsilon\,\tau\partial_t\, u_h)d\tau ds\right\}\partial_t\, u_h\right).\end{aligned} \tag{2.31}$$

It is evident that we need to estimate $\varepsilon(\partial_t u_h, P_1[\,\eta''(u_h)\partial_t u_h\,])$. This is done by Lemma 2.3, which gives

$$\varepsilon|(\partial_t\, u_h, P_1\,[\,\eta''(u_h)\partial_t\, u_h\,])| \le \varepsilon\beta\,\|\eta''(u_h)\|_{L^\infty(\Omega)}\,\|\partial_t\, u_h\|^2_{L^2(\Omega)}. \tag{2.32}$$

We proceed to handle $\varepsilon\int_\Omega(\partial_t u_h)^2dx$. Observe that setting $\phi = \partial_t u_h$ in (2.1) gives

$$\|\partial_t\, u_h\|^2_{L^2(\Omega)} + (F'(u_h)\partial_x\, u_h, \partial_t\, u_h) + \varepsilon\frac{1}{2}\partial_t\|\partial_t\, u_h\|^2_{L^2(\Omega)} + \varepsilon\frac{1}{2}\partial_t(A\partial_x\, u_h, \partial_x\, u_h) = 0. \tag{2.33}$$

Next, define

$$\begin{aligned}\overline{\beta} &= \beta\,\|\eta''(u_h)\|_{L^\infty(\Omega)},\\ \overline{\eta''} &= \left\{\int_0^1\int_0^s \eta''(u_h + \varepsilon\,\tau\partial_t\, u_h)d\tau ds\right\},\\ \overline{\alpha} &= \max\{2\overline{\beta}, 2\alpha\}\end{aligned} \tag{2.34}$$

and note that $\overline{\beta} = \beta\alpha$, $\overline{\alpha} = 2\alpha \max\{1, \beta\}$. After summing (2.29) with $2\varepsilon\,\overline{\alpha}$ times (2.33), we arrive at

(2.35)
$$\begin{aligned}\partial_t \int_\Omega \Big(\eta(u_h + \varepsilon\partial_t u_h) + \varepsilon^2 \partial_t u_h \cdot \{\overline{\alpha}\, I - \overline{\eta''}\}\partial_t u_h + \varepsilon^2 \overline{\alpha} A\partial_x\, u_h \cdot \partial_x u_h\Big) dx - \varepsilon \partial_t Z_1 \\ + \varepsilon\,(\overline{\alpha} - \overline{\beta})\|\partial_t\, u_h\|^2_{L^2(\Omega)} + \varepsilon\overline{\alpha}\|\partial_t\, u_h\|^2_{L^2(\Omega)} + 2\varepsilon\overline{\alpha}(F'(u_h)\partial_x u_h, \partial_t u_h\,) \\ + \varepsilon(A\partial_x\, u_h, \eta''(u_h)\partial_x\, u_h) \le Z_1 + Z_2.\end{aligned}$$

But since

$$\begin{aligned}&\|\partial_t\, u_h\|^2_{L^2(\Omega)} + 2(F'(u_h)\;\partial_x\, u_h, \partial_t\, u_h\,) \\ &\quad = \|\partial_t u_h + F'(u_h)\partial_x u_h\|^2_{L^2(\Omega)} - (F'(u_h)^T F'(u_h)\partial_x u_h, \partial_x\, u_h)\end{aligned} \tag{2.36}$$

and

$$(A\partial_x\, u_h, \eta''(u_h)\partial_x\, u_h) = \frac{1}{2}\,\big((\eta''(u_h)A + (\eta''(u_h)A)^T\big)\partial_x\, u_h, \partial_x\, u_h\big),$$

we conclude by (2.13) and (2.14) that

(2.37)
$$\begin{aligned}\partial_t\Big\{ \int_\Omega \eta(u_h + \varepsilon\partial_t u_h)dx + \varepsilon^2\overline{\alpha}\|\partial_t u_h\|^2_{L^2(\Omega)} + \varepsilon^2\overline{\alpha}(A\partial_x u_h, \partial_x u_h) - \varepsilon Z_1\Big\} \\ + \varepsilon\overline{\beta}\|\partial_t\, u_h\|^2_{L^2(\Omega)} + \varepsilon\,\overline{\alpha}\,\|\partial_t\, u_h + F'(u_h)\;\partial_x\, u_h\|^2_{L^2(\Omega)} + \varepsilon\nu\;\|\partial_x\, u_h\|^2_{L^2(\Omega)} \\ \le Z_1 + Z_2.\end{aligned}$$

At this point $\overline{\alpha}$, $\overline{\beta}$, and ν are fixed. We now turn to the estimation of the Z_i. Observe that, by (2.13) and (2.21),

$$\begin{aligned}Z_1 &= (\partial_t\, u_h, \eta'(u_h) - P_1\,\eta'(u_h)) \\ &\le C\,h\,\|\partial_t\, u_h\|_{L^2(\Omega)}\;\|\partial_x\,\eta'(u_h)\|_{L^2(\Omega)} \\ &\le C\,h\,\|\partial_t\, u_h\|_{L^2(\Omega)}\;\|\eta''(u_h)\|_{L^\infty(\Omega)}\;\|\partial_x\, u_h\|_{L^2(\Omega)} \\ &\le Ch\,\alpha\,\|\partial_t\, u_h\|_{L^2(\Omega)}\;\|\partial_x\, u_h\|_{L^2(\Omega)},\end{aligned} \tag{2.38}$$

while

$$\begin{aligned}Z_2 &= \big(\partial_x F(u_h), \eta'(u_h) - P_1\,\eta'(u_h)\big) \\ &\le C\,h\,\|\partial_x\, u_h\|_{L^2(\Omega)}\;\|F'(u_h)\|_{L^\infty(\Omega)}\;\;\|\eta''(u_h)\|_{L^\infty(\Omega)}\;\|\partial_x\, u_h\|_{L^2(\Omega)} \\ &\le C\,h\,\alpha\,M\,\|\partial_x\, u_h\|^2_{L^2(\Omega)}.\end{aligned} \tag{2.39}$$

Next, we select h so that (i) the quadratic form in the first term of (2.37) is positive definite, and (ii) the terms Z_1 and Z_2 on the right of (2.37) can be absorbed to the left. This can be done provided $h \le \gamma\varepsilon$ for some $\gamma = \gamma(\alpha, \beta, M, \nu)$ positive and small. This gives (2.16) and concludes the proof. ∎

The compactness of the dissipation measure for the scheme is obtained by an argument similar to that in the symmetric case.

PROPOSITION 2.5. *For entropy pairs (η, q) satisfying*

$$\|\eta\|_{L^\infty},\ \|q\|_{L^\infty},\ \|\eta'\|_{L^\infty},\ \|\eta''\|_{L^\infty}\ \le\ C \tag{2.40}$$

and for $h \le \gamma\,\varepsilon$,

$$\eta(u_h)_t + q(u_h)_x \quad \textit{lies in a compact set of } H^{-1}_{loc}(\mathbb{R}\times\mathbb{R}^+). \tag{2.41}$$

Remark 2.2. Proposition 2.5 and the analogous statement for the symmetric case (Proposition 2.2) state that for entropy pairs satisfying (2.40) the entropy dissipation measure is controlled. They are used in section 4 to prove compactness of relaxation finite element approximations for the system (4.1). We note that entropy pairs (η, q) that satisfy (2.40) are constructed in [38] for the system (4.1) under hypotheses (4.3)–(4.4).

2.3. The multidimensional case. Next we consider multidimensional systems (1.1) for which the system is endowed with a uniformly convex entropy η. Let $(q_1,\dots,q_d)$ be the associated entropy flux, and

$$\begin{aligned} &q_i'(u) = \eta'(u)\,F_i'(u), \quad i=1,\dots,d,\\ &\eta''(u)\,F_i'(u) = F_i'(u)^T\,\eta''(u), \quad i=1,\dots,d. \end{aligned} \tag{2.42}$$

Still, in this case the finite element approximations (1.5) satisfy similar a priori bounds with the one-dimensional case, provided that each A_i is chosen to satisfy certain subcharacteristic conditions.

PROPOSITION 2.6. *Assume that* (1.1) *is equipped with a strictly convex entropy* $\eta(u)$ *that satisfies for some* $\alpha > 0$

$$\frac{1}{\alpha}\,I \le \eta''(v) \le \alpha\,I, \quad v\in\mathbb{R}^n; \tag{2.43}$$

let $\overline{\alpha} = 2\alpha\max\{1,\beta\}$ *with* β *as in* (2.46), *and assume that the symmetric, positive definite matrices* A_i *satisfy, for some* $\nu > 0$,

$$\sum_{j=1}^d \frac{1}{2}\big(A_j\eta''(v) + (A_j\eta''(v))^T\big)\xi_j\cdot\xi_j - \overline{\alpha}\left|\sum_{j=1}^d F_j'(v)\xi_j\right|^2 \ge \nu\sum_{j=1}^d|\xi_j|^2 \tag{2.44}$$
$$\forall \xi_1,\dots,\xi_d\in\mathbb{R}^n,\ v\in\mathbb{R}^n.$$

If $h \le \gamma\varepsilon$ *for some* $\gamma > 0$, *then the finite element approximations* (1.5) *satisfy, for some* $c_1,\ c_2 > 0$, *the stability estimate*

$$\begin{aligned} &\int_\Omega\left(\eta(u_h+\varepsilon\partial_t u_h) + \varepsilon^2 c_1\left[|\partial_t u_h|^2 + \sum_{i=1}^d A_i\partial_{x_i}u_h\cdot\partial_{x_i}u_h\right]\right)\\ &\qquad + \varepsilon c_2\int_0^t\int_\Omega\left(\left|\partial_t u_h + \sum_{i=1}^d F_i'(u_h)\partial_x u_h\right|^2 + \sum_{i=1}^d|\partial_{x_i}u_h|^2 + |\partial_t u_h|^2\right)\\ &\qquad \le C(u_h^0, \partial_t u_h(0)\,). \end{aligned}$$

The proof is entirely similar to the one-dimensional case presented before and therefore it will be omitted. Still, an essential tool in the analysis will be the elliptic projection $P_1 : H^1 \to S_k$ defined by

$$\sum_{i=1}^d(A_i\partial_{x_i}\,P_1 v, \partial_{x_i}\phi) = \sum_{i=1}^d(A_i\partial_{x_i}\,v, \partial_{x_i}\phi) \qquad \forall\phi\in S_k. \tag{2.45}$$

The multidimensional analogue of Lemma 2.3 still holds:

$$(v_h, P_1\,[\,\eta''(u_h)(v_h)\,]\,) \;\le\; \beta\,\|\eta''(w)\|_{L^\infty(\Omega)}\,\|v_h\|^2_{L^2(\Omega)}. \tag{2.46}$$

Its proof is based on the stability analysis of the finite element method by mesh-dependent norms [6]; see [16] for related results on stability of the elliptic projection in $L^2(\Omega)$. The quasi-uniformity assumption on the mesh in [6] needed to verify (2.24) can be relaxed along the lines of arguments presented in [16].

3. Fully discrete schemes. There are many alternative ways to perform the time discretization of (1.5) at the discrete time nodes $0, \kappa, 2\kappa, \dots$. In this section we consider a simple implicit-explicit time discretization. Seek $(u_h^n, v_{h,1}^n, \dots, v_{h,d}^n) \in S_k \times V_{k-1}^d$, $n = 0, 1, \dots$,

$$\begin{aligned}
&\left(\frac{u_h^{n+1} - u_h^n}{\kappa},\ \phi\right) - \sum_{i=1}^{d}(v_{h,i}^n,\ \partial_{x_i}\phi) = 0 \quad \forall \phi \in S_k,\\
&\left(\frac{v_{h,i}^{n+1} - v_{h,i}^n}{\kappa},\ \psi\right) + (A_i \partial_{x_i} u_h^{n+1},\ \psi) = -\frac{1}{\varepsilon}\big(v_{h,i}^{n+1} - F_i(u_h^{n+1}),\ \psi\big),\\
&\qquad\qquad \forall \psi \in V_{k-1}, \quad i = 1, \dots, d,
\end{aligned} \tag{3.1}$$

where $u_h^0 = u_0,\ v_{h,i}^0 = F_i(u_0)$, and $i = 1, \dots, d$.

When $d = 1$, the scheme takes the form

$$\begin{aligned}
&\left(\frac{u_h^{n+1} - u_h^n}{\kappa},\ \phi\right) - (v_h^n,\ \partial_x \phi) = 0 \quad \forall \phi \in S_k,\\
&\left(\frac{v_h^{n+1} - v_h^n}{\kappa},\ \psi\right) + (A \partial_x u_h^{n+1},\ \psi) = -\frac{1}{\varepsilon}\big(v_h^{n+1} - F(u_h^{n+1}),\ \psi\big) \quad \forall \psi \in V_{k-1}.
\end{aligned} \tag{3.2}$$

3.1. Properties of the scheme. For any sequence $\{\,Y^n\} \subset L^2(\Omega)$, define the operators $\overline{\partial}_t,\ \overline{\partial}_{tt}$:

$$\overline{\partial}_t Y^n := \frac{1}{\kappa}(Y^{n+1} - Y^n), \qquad \overline{\partial}_{tt} Y^n := \overline{\partial}_t \overline{\partial}_t Y^n.$$

Then the centered difference quotient that corresponds to the second time derivative at t^n is

$$\overline{\partial}_{tt} Y^{n-1} = \frac{1}{\kappa^2}(Y^{n+1} - 2Y^n + Y^{n-1}).$$

The following properties will prove useful (L^2 stands for $L^2(\Omega)$):

$$\begin{aligned}
(\overline{\partial}_t Y^n,\ Y^{n+1}) &= \frac{1}{2\kappa}\big[\,\|\,Y^{n+1}\|^2_{L^2} - \|\,Y^n\|^2_{L^2} + \|\,Y^{n+1} - Y^n\|^2_{L^2}\big]\\
&= \frac{1}{2}\big[\,\overline{\partial}_t\|\,Y^n\|^2_{L^2} + \kappa\|\,\overline{\partial}_t Y^n\|^2_{L^2}\big],
\end{aligned} \tag{3.3}$$

$$(\overline{\partial}_t Y^n,\ Y^n) = \frac{1}{2}\big[\,\overline{\partial}_t\|\,Y^n\|^2_{L^2} - \kappa\|\,\overline{\partial}_t Y^n\|^2_{L^2}\big], \tag{3.4}$$

$$\begin{aligned}
(\overline{\partial}_{tt} Y^n,\ \overline{\partial}_t Y^{n+1}) &= (\overline{\partial}_t W^n,\ W^{n+1}), \qquad W^n := \overline{\partial}_t Y^n,\ n = 0, 1, 2, \dots,\\
&= \frac{1}{2}\big[\,\overline{\partial}_t\|\,\overline{\partial}_t Y^n\|^2_{L^2} + \kappa\|\,\overline{\partial}_{tt} Y^n\|^2_{L^2}\big].
\end{aligned} \tag{3.5}$$

In addition one can verify that

$$
\begin{aligned}
(\overline{\partial}_{tt}Y^{n-1},\ Y^{n+1}) = \kappa(\overline{\partial}_{tt}Y^{n-1},\ \overline{\partial}_t Y^n) \\
+\overline{\partial}_t(\overline{\partial}_t Y^{n-1},\ Y^n)\ - \|\ \overline{\partial}_t Y^n\|^2_{L^2}.
\end{aligned} \tag{3.6}
$$

Now we have the following lemma.

LEMMA 3.1. *If u_h^n solves* (3.1)*, then it satisfies*

$$
(\overline{\partial}_t u_h^n,\ \phi) - \sum_{i=1}^d (F_i(u_h^n),\ \partial_{x_i}\phi) + \varepsilon\left((\overline{\partial}_{tt}u_h^{n-1},\ \phi) + \sum_{i=1}^d (A_i\partial_{x_i}u_h^n,\ \partial_{x_i}\phi)\right) = 0. \tag{3.7}
$$

Proof. For $\phi\in S_k$, we see that the solution of (3.1) satisfies

$$
\begin{aligned}
\sum_{i=1}^d (\overline{\partial}_t v_{h,i}^{n-1},\ \partial_{x_i}\phi) &= \sum_{i=1}^d \left(\frac{v_{h,i}^n - v_{h,i}^{n-1}}{\kappa},\ \partial_{x_i}\phi\right) \\
&\overset{(3.1)}{=} \left(\frac{\overline{\partial}_t u_h^n - \overline{\partial}_t u_h^{n-1}}{\kappa},\ \phi\right) = (\overline{\partial}_{tt}u_h^{n-1},\ \phi).
\end{aligned}
$$

Next, summing $i = 1,\dots,d$, (3.1), and using that $\partial_{x_i}\phi\in V_{k-1}$, we get

$$
\begin{aligned}
0 =& \sum_{i=1}^d (v_{h,i}^n,\ \partial_{x_i}\phi) - \sum_{i=1}^d (F_i(u_h^n),\ \partial_{x_i}\phi) + \varepsilon\sum_{i=1}^d (\overline{\partial}_t v_{h,i}^{n-1} + A_i\partial_{x_i}u_h^n,\ \partial_{x_i}\phi) \\
&\overset{(3.1)}{=} (\overline{\partial}_t u_h^n,\ \phi) - \sum_{i=1}^d (F_i(u_h^n),\ \partial_{x_i}\phi) + \varepsilon\sum_{i=1}^d (\overline{\partial}_t v_{h,i}^{n-1} + A_i\partial_{x_i}u_h^n,\ \partial_{x_i}\phi)
\end{aligned} \tag{3.8}
$$

and the result follows. ∎

In the case $d = 1$, we have

$$
(\overline{\partial}_t v_h^n,\ \partial_x\phi) = (\overline{\partial}_{tt}u_h^n,\ \phi), \tag{3.9}
$$

$$
(\overline{\partial}_t u_h^n,\ \phi) - (F(u_h^n),\ \partial_x\phi) + \varepsilon\big((\overline{\partial}_{tt}u_h^{n-1},\ \phi) + (A\partial_x u_h^n,\ \partial_x\phi)\big) = 0. \tag{3.10}
$$

3.2. The case $d = 1$ and F' symmetric. Let $\phi = 2u_h^{n+1} + 4\varepsilon\ \overline{\partial}_t u_h^n,$ in (3.10). Then

$$
\begin{aligned}
0 &= 2(\overline{\partial}_t u_h^n,\ u_h^{n+1})\ + 2(\partial_x F(u_h^n),\ u_h^{n+1}) \\
&+ 2\varepsilon(\overline{\partial}_{tt}u_h^{n-1},\ u_h^{n+1})\ + 2\varepsilon(A\ \partial_x u_h^n,\ \partial_x u_h^{n+1}) \\
&+ 4\varepsilon(\overline{\partial}_t u_h^n,\ \overline{\partial}_t u_h^n)\ + 4\varepsilon(\partial_x F(u_h^n),\ \overline{\partial}_t u_h^n) \\
&+ 4\varepsilon^2(\overline{\partial}_{tt}u_h^{n-1},\ \overline{\partial}_t u_h^n)\ + 4\varepsilon^2(A\ \partial_x u_h^n,\ \partial_x\overline{\partial}_t u_h^n).
\end{aligned} \tag{3.11}
$$

Using the properties of the discrete time operators listed above, the terms of (3.11) are handled as follows. First note

$$
2(\overline{\partial}_t u_h^n,\ u_h^{n+1}) = \overline{\partial}_t\|\ u_h^n\|^2_{L^2} + \kappa\|\ \overline{\partial}_t u_h^n\|^2_{L^2}.
$$

Also,

$$
2(\partial_x F(u_h^n),\ u_h^{n+1})\ = 2\ \kappa(F'(u_h^n)\ \partial_x u_h^n,\ \overline{\partial}_t u_h^n).
$$

The next term is estimated as

$$2\varepsilon(\overline{\partial}_{tt}u_h^{n-1},\ u_h^{n+1}) \overset{(3.6)}{=} 2\varepsilon\overline{\partial}_t(\overline{\partial}_t u_h^{n-1},\ u_h^n)\ - 2\varepsilon\|\overline{\partial}_t u_h^n\|_{L^2}^2\ + 2\varepsilon\kappa(\overline{\partial}_{tt}u_h^{n-1},\ \overline{\partial}_t u_h^n)$$
$$\geq 2\varepsilon\overline{\partial}_t(\overline{\partial}_t u_h^{n-1},\ u_h^n) - 2\varepsilon\|\overline{\partial}_t u_h^n\|_{L^2}^2 - 2\varepsilon^2\kappa\|\overline{\partial}_{tt}u_h^{n-1}\|_{L^2}^2 - \frac{\kappa}{2}\|\overline{\partial}_t u_h^n\|_{L^2}^2.$$

In addition,

$$2\varepsilon(A\ \partial_x u_h^n,\ \partial_x u_h^{n+1})\ = 2\varepsilon(A\ \partial_x u_h^n,\ \partial_x u_h^n)\ + 2\varepsilon\ \kappa(A\ \partial_x u_h^n,\ \partial_x\overline{\partial}_t u_h^n).$$

For the terms with coefficient 4ε we first note

$$4\varepsilon^2(\overline{\partial}_{tt}u_h^{n-1},\ \overline{\partial}_t u_h^n) \overset{(3.5)}{=} 2\varepsilon^2\ \overline{\partial}_t\|\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2 + 2\varepsilon^2\ \kappa\|\ \overline{\partial}_{tt}u_h^{n-1}\|_{L^2}^2$$

and

$$4\varepsilon^2(A\ \partial_x u_h^n,\ \partial_x\overline{\partial}_t u_h^n)\ = 4\varepsilon^2(W^n,\ \overline{\partial}_t W^n), \qquad W^n := A^{1/2}\partial_x u_h^n,\ n = 0, 1, 2, \dots,$$
$$\overset{(3.4)}{=} 2\varepsilon^2\ \overline{\partial}_t\|\ W^n\|_{L^2}^2 - 2\varepsilon^2\ \kappa\|\ \overline{\partial}_t W^n\|_{L^2}^2$$
$$= 2\varepsilon^2\ \overline{\partial}_t(A\ \partial_x u_h^n,\ \partial_x u_h^n)\ - 2\varepsilon^2\ \kappa(A\ \partial_x\overline{\partial}_t u_h^n,\ \partial_x\overline{\partial}_t u_h^n).$$

Summarizing, the terms with discrete time derivative that will appear in (3.11) are

$$\overline{\partial}_t\Big[\|\ u_h^n\|_{L^2}^2\ + 2\varepsilon(\overline{\partial}_t u_h^{n-1},\ u_h^n)\ + 2\varepsilon^2\|\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ + 2\varepsilon^2(A\ \partial_x u_h^n,\ \partial_x u_h^n)\Big]$$
$$= \overline{\partial}_t\Big[\|\ u_h^n\ + \varepsilon\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ + \varepsilon^2\|\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ + 2\varepsilon^2(A\ \partial_x u_h^n,\ \partial_x u_h^n)\Big].$$

In addition, the following calculation is useful:

$$2\varepsilon\|\overline{\partial}_t u_h^n\|_{L^2}^2 + 4\varepsilon(\partial_x F(u_h^n),\ \overline{\partial}_t u_h^n)$$
$$= \varepsilon\|\overline{\partial}_t u_h^n\|_{L^2}^2 + 2\varepsilon\|\ \frac{1}{\sqrt{2}}\ \overline{\partial}_t u_h^n + \sqrt{2}\ F'(u_h^n)\ \partial_x u_h^n\|_{L^2}^2$$
$$- 4\varepsilon((F'(u_h^n))^2\ \partial_x u_h^n,\ \partial_x u_h^n).$$

We conclude, therefore, that

$$\begin{aligned}
&\overline{\partial}_t\Big[\ \|\ u_h^n\ + \varepsilon\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ + \varepsilon^2\|\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ + 2\varepsilon^2(A\ \partial_x u_h^n,\ \partial_x u_h^n)\Big] \\
&\quad + \varepsilon\|\overline{\partial}_t u_h^n\|_{L^2}^2 + \frac{\kappa}{2}\|\overline{\partial}_t u_h^n\|_{L^2}^2\ + 2\varepsilon((A - 2(F'(u_h^n))^2)\ \partial_x u_h^n,\ \partial_x u_h^n) \\
&\quad \leq |2\kappa(\partial_x F(u_h^n),\ \overline{\partial}_t u_h^n)| + |2\varepsilon\ \kappa(A\ \partial_x u_h^n,\ \partial_x\overline{\partial}_t u_h^n)| \\
&\quad + 2\varepsilon^2\ \kappa(A\ \partial_x\overline{\partial}_t u_h^n,\ \partial_x\overline{\partial}_t u_h^n).
\end{aligned} \tag{3.12}$$

Next,

$$|2\kappa(\partial_x F(u_h^n),\ \overline{\partial}_t u_h^n)| \leq 4\kappa((F'(u_h^n))^2\ \partial_x u_h^n,\ \partial_x u_h^n) + \frac{\kappa}{4}\|\overline{\partial}_t u_h^n\|_{L^2}^2.$$

We will use the inverse inequality in S_k [7],

$$\|\partial_x\varphi\|_{L^2} \leq C_I\underline{h}^{-1}\|\varphi\|_{L^2} \qquad \forall\varphi \in S_k, \tag{3.13}$$

to obtain

$$|2\varepsilon\ \kappa(A\ \partial_x u_h^n,\ \partial_x \overline{\partial}_t u_h^n)| \le \varepsilon\ C_I\ \|A\|\ \frac{\kappa}{\underline{h}}\ \|\partial_x u_h^n\|_{L^2}^2 + \varepsilon\ C_I\ \|A\|\ \frac{\kappa}{\underline{h}}\ \|\overline{\partial}_t u_h^n\|_{L^2}^2,$$

$$2\varepsilon^2\ \kappa(A\ \partial_x \overline{\partial}_t u_h^n,\ \partial_x \overline{\partial}_t u_h^n) \le \varepsilon\ \frac{\varepsilon}{\underline{h}}\ \left(C_I^2\ \|A\|\ \frac{\kappa}{\underline{h}}\right)\ \|\overline{\partial}_t u_h^n\|_{L^2}^2.$$

Multiplying (3.12) by κ, and summing we finally conclude with the following proposition.

PROPOSITION 3.1. *We assume that $F'(u)$ is symmetric and that for given $\tilde{\beta}$ there holds*

$$\kappa \le \tilde{\beta}\varepsilon. \tag{3.14}$$

Assume further that we can choose A symmetric so that for some ν,

$$A - (\,2 + 4\tilde{\beta}\,)\,F'(u)^2 \ge \nu\ I \quad \textit{for}\ \ u \in \mathbb{R}^n. \tag{3.15}$$

Let $\gamma_{CFL} = C_I^2\,\|A\|\frac{\kappa}{\underline{h}}$ and assume that γ_{CFL} is sufficiently small and that

$$\varepsilon \le\ \frac{1}{2\,\gamma_{CFL}}\ \underline{h}.$$

Then the approximations of the fully discrete schemes satisfy the stability estimate

$$\begin{aligned}\|\ u_h^n\ &+\varepsilon\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ +\varepsilon^2\|\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ + 2\varepsilon^2(A\ \partial_x u_h^n,\ \partial_x u_h^n)\\ &+\sum_{j=1}^{n-1}\varepsilon\ \kappa\|\,\overline{\partial}_t u_h^j\|_{L^2}^2 + \sum_{j=1}^{n-1}\kappa^2\|\,\overline{\partial}_t u_h^j\|_{L^2}^2\ + \sum_{j=1}^{n-1}\varepsilon\ \kappa\ \|\partial_x u_h^j\|_{L^2}^2\ \le\ C(u_h^0).\end{aligned}$$

In what follows we study the compactness properties of the dissipation measure associated to the scheme. To this end we use the notation

$$\begin{aligned}&u_h \quad \text{denotes the piecewise linear in time}\\ &\quad\ \text{function such that}\quad u_h(t^n) = u_h^n,\\ &\overline{u}_h \quad \text{denotes the piecewise constant in time}\\ &\quad\ \text{function such that}\quad \overline{u}_h(t^n) = u_h^n,\ I_n\ =\ (t^n, t^{n+1}].\end{aligned} \tag{3.16}$$

PROPOSITION 3.2. *Under the assumptions of Proposition* 3.1*, for entropy pairs (η, q) such that*

$$\|\eta\|_{L^\infty},\ \|q\|_{L^\infty},\ \|\eta'\|_{L^\infty},\ \|\eta''\|_{L^\infty}\ \le\ C$$

and for $h\ \le\ C\,\varepsilon$ there holds

$$\eta(u_h)_t\ +\ q(u_h)_x \quad \textit{lies in a compact set of}\ H_{loc}^{-1}(\mathbb{R}\times\mathbb{R}^+), \tag{3.17}$$

where u_h is defined by (3.16).

Proof. Let (η, q) be an entropy pair and $\phi \in C_c^\infty(\mathbb{R}\times[0,\infty))$ a test function, and $\operatorname{supp}\phi \subset \tilde{\Omega}\times[0,\tilde{T}] =: Q$. Without loss of generality assume that $\tilde{T} = t^{m+1}$. Let

$\Pi : H^1 \to S_k$ be the L^2-projection onto the finite element space defined in (2.6). Then using the definition of the scheme we obtain

(3.18)
$$\begin{aligned}\int_0^{\tilde{T}} \Big(\partial_t \eta(u_h) \,+\, \partial_x q(u_h), \phi\Big) dt \;&=\; \int_0^{\tilde{T}} \Big(\eta'(u_h)\big[\partial_t u_h \,+\, \partial_x F'(u_h) u_h\big], \phi\Big) dt \\ &= -\varepsilon \sum_{j=0}^{j=m} \int_{I_j} \Big\{ \Big(A \partial_x\, u_h^j, \partial_x \big[\Pi\big(\eta'(u_h)\phi\big)\big]\Big) + \Big(\overline{\partial}_{tt} u_h^{j-1}, \Pi\big(\eta'(u_h)\phi\big)\Big)\Big\} dt \\ &+ \sum_{j=0}^{j=m} \int_{I_j} \Big\{ \Big(\big[\,\overline{\partial}_t u_h^j \,+\, \partial_x F'(\overline{u}_h)\big],\; \eta'(u_h)\phi - \Pi\big(\eta'(u_h)\phi\big)\Big) \\ &+ \Big(\eta'(u_h)\partial_x\big[\,F(u_h) - F(\overline{u}_h)\big], \phi\Big)\Big\} dt.\end{aligned}$$

Note here that for notational simplicity when we use $\overline{\partial}_t u_h^j, u_h^j, \overline{\partial}_{tt} u_h^{j-1}$ we mean the piecewise constant (with respect to t) functions that have these values in I_j. To proceed with the estimates, note that using (2.8) one obtains

(3.19)
$$\begin{aligned}&\varepsilon \sum_{j=0}^{j=m} \int_{I_j} \Big|\, \Big(A \partial_x\, u_h^j, \partial_x \big[\Pi\big(\eta'(u_h)\phi\big)\big]\Big) \,\Big| \, dt \\ &\qquad \le \varepsilon\, C \left(\kappa \sum_{j=0}^{m} \|\partial_x\, u_h^j\|^2_{L^2(\Omega)} \right)^{1/2} \|\partial_x\, \big(\eta'(u_h)\phi\big)\|_{L^2(Q)} \\ &\qquad \le C \left(\varepsilon\, \kappa \sum_{j=0}^{m} \|\partial_x\, u_h^j\|^2(\Omega) \right) \cdot \|\eta''\|_{L^\infty}\, \|\phi\|_{C^0(Q)} \\ &\qquad\quad + \varepsilon^{1/2}\, C \left(\varepsilon\, \kappa \sum_{j=0}^{m} \|\partial_x\, u_h^j\|^2(\Omega) \right)^{1/2} \|\eta\|_{L^\infty}\, \|\partial_x \phi\|_{L^2(Q)}.\end{aligned}$$

In addition, using the notation

$$\overline{v}_j = \kappa^{-1} \int_{I_j} v\, dt,$$

we have by (2.6),

(3.20)
$$\begin{aligned}-\varepsilon \sum_{j=0}^{m} \int_{I_j} \int_\Omega \overline{\partial}_{tt} u_h^{j-1}\, \Pi\Big(\eta'(u_h)\phi\Big) \;&=\; -\varepsilon \sum_{j=0}^{m} \int_{I_j} \overline{\partial}_{tt} u_h^{j-1} \int_\Omega \eta'(u_h)\phi \\ &= -\varepsilon \int_\Omega \sum_{j=0}^{m} \big(\overline{\partial}_t u_h^j - \overline{\partial}_t u_h^{j-1}\big)\, \overline{(\eta'(u_h)\phi)}_j \\ &= \varepsilon \int_\Omega \sum_{j=0}^{m-1} \overline{\partial}_t u_h^j \,\big(\, \overline{(\eta'(u_h)\phi)}_{j+1} - \overline{(\eta'(u_h)\phi)}_j \,\big) - \varepsilon \int_\Omega \overline{\partial}_t u_h^m \int_\Omega \overline{(\eta'(u_h)\phi)}_m.\end{aligned}$$

The stability in Proposition 3.1 implies, since $|\overline{v}_j| \le \| v \|_\infty$,

$$\begin{aligned} \varepsilon\Big|\int_\Omega \overline{\partial}_t u_h^m \, \overline{(\eta'(u_h)\phi)}_m \Big| &\le \varepsilon \, \|\overline{\partial}_t u_h^m\|_{L^2(\Omega)} \, \|\eta'\|_{L^\infty} \, \|\phi\|_{C^0(\Omega)} \, m(\Omega)^{1/2} \\ &\le C_\Omega \|\phi\|_{C^0(Q)}. \end{aligned} \tag{3.21}$$

Observing that $|\overline{v}_{j+1} - \overline{v}_j| = \frac{1}{\kappa} \left|\int_{I_j} \int_t^{t+\kappa} v_t \, ds \, dt\right| \le \int_{t_j}^{t_{j+2}} |\, v_t \,| \, dt$, we conclude

$$\begin{aligned} &\varepsilon\left|\int_\Omega \sum_{j=0}^{m-1} \overline{\partial}_t u_h^j \, (\overline{(\eta'(u_h)\phi)}_{j+1} - \overline{(\eta'(u_h)\phi)}_j)\right| \\ &\qquad \le C\left(\varepsilon\,\kappa \sum_{j=0}^{m} \|\overline{\partial}_t \, u_h^j\|^2_{L^2(\Omega)}\right)\|\eta''\|_{L^\infty} \, \|\phi\|_{C^0(Q)} \\ &\qquad + \varepsilon^{1/2}\left(\varepsilon\,\kappa \sum_{j=0}^{m} \|\overline{\partial}_t \, u_h^j\|^2_{L^2(\Omega)}\right)^{1/2} \|\eta'\|_{L^\infty} \, \|\partial_t\phi\|_{L^2(Q)}. \end{aligned} \tag{3.22}$$

Next,

$$\begin{aligned} &\|\eta'(u_h)\phi - \Pi\big(\eta'(u_h)\phi\big)\|_{L^2(\Omega)} \\ &\qquad \le Ch\|\eta''\|_{L^\infty} \, \|\partial_x u_h\|_{L^2(\Omega)} \, \|\phi\|_{C^0(\Omega)} + Ch\|\eta'\|_{L^\infty} \, \|\partial_x\phi\|_{L^2(\Omega)} \end{aligned}$$

and $\|F'(u)^2\|_{L^\infty} \le C$ (see (2.4)); therefore,

$$\begin{aligned} &\sum_{j=0}^{m} \int_{I_j} \Big|\Big(\big[\,\overline{\partial}_t u_h^j \;+\; F'(\overline{u}_h)\partial_x\overline{u}_h\big],\; \eta'(u_h)\phi - \Pi\big(\eta'(u_h)\phi\big)\Big)\Big| \\ &\qquad \le C\left(h\,\kappa \sum_{j=0}^{m} \|\overline{\partial}_t \, u_h^j\|^2_{L^2(\Omega)} + \|\partial_x \, u_h^j\|^2_{L^2(\Omega)}\right)\|\phi\|_{C^0(Q)} \\ &\qquad + h\left(\kappa \sum_{j=0}^{m} \|\overline{\partial}_t \, u_h^j\|^2_{L^2(\Omega)} + \|\partial_x \, u_h^j\|^2_{L^2(\Omega)}\right)^{1/2} \|\partial_x\phi\|_{L^2(Q)}. \end{aligned} \tag{3.23}$$

Finally, using the fact that $|u_h - \overline{u}_h| \le C\kappa|\partial_t u_h| = C\kappa|\overline{\partial}_t \, u_h^n|$, we have by using (3.14) and (3.15),

(3.24)

$$\begin{aligned} \sum_{j=0}^{m} \int_{I_j} \Big(\eta'(u_h)\partial_x\big[\,F(u_h) - F(\overline{u}_h)\big], \phi\Big) &= -\sum_{j=0}^{m} \int_{I_j} \Big(\big[\,F(u_h) - F(\overline{u}_h)\big], \partial_x(\eta'(u_h)\,\phi)\Big) \\ &\le C\left(\varepsilon\,\kappa \sum_{j=0}^{m} \|\overline{\partial}_t \, u_h^j\|^2_{L^2(\Omega)} + \|\partial_x \, u_h^j\|^2_{L^2(\Omega)}\right)\|\phi\|_{C^0(Q)} \\ &+ \varepsilon\left(\kappa \sum_{j=0}^{m} \|\overline{\partial}_t \, u_h^j\|^2_{L^2(\Omega)} + \|\partial_x \, u_h^j\|^2_{L^2(\Omega)}\right)^{1/2} \|\partial_x\phi\|_{L^2(Q)}. \end{aligned}$$

Combining (3.19)–(3.24), we obtain the desired result in view of Lemma 2.2. ∎

3.3. The case $d = 1$, and the system admits a convex entropy. The case that F' is not necessarily symmetric but the system is equipped with a convex entropy η will be briefly examined here. The analysis in this case mainly uses a combination of arguments from the corresponding semidiscrete case and the analysis of the fully discrete scheme in the symmetric case. For this reason we will present briefly the basic steps of the proof, explaining only the new estimates. The following proposition holds.

PROPOSITION 3.3. *Assume that* (1.9) *admits a convex entropy* $\eta(u)$ *satisfying* (2.13), *and the symmetric, positive definite matrix* A *satisfies* (2.14) *for some* $\nu > 0$ *where the constant* $\overline{\alpha}$ *depends on* α, β, *and* $\tilde{\beta}$; *see* (2.13), (2.22), *and* (3.14). *Under similar conditions on* κ, ε, h *as in Proposition* 3.1 *(with possibly different constants), and if* $h \le \gamma\,\varepsilon$ *for some* $\gamma > 0$, *the fully discrete finite element approximations satisfy*

$$\begin{aligned} &\| u_h^n + \varepsilon\,\overline{\partial}_t u_h^{n-1}\|_{L^2}^2 + \varepsilon^2 \| \overline{\partial}_t u_h^{n-1}\|_{L^2}^2 + 2\varepsilon^2 (A\,\partial_x u_h^n,\ \partial_x u_h^n) \\ &\quad + \sum_{j=1}^{n-1} \varepsilon\,\kappa \| \overline{\partial}_t u_h^j\|_{L^2}^2 + \sum_{j=1}^{n-1} \kappa^2 \| \overline{\partial}_t u_h^j\|_{L^2}^2 + \sum_{j=1}^{n-1} \varepsilon\,\kappa\,\|\partial_x u_h^j\|_{L^2}^2 \ \le\ C(u_h^0). \end{aligned} \tag{3.25}$$

Proof. The fully discrete finite element approximation u_h^n satisfies

$$(\overline{\partial}_t u_h^n,\ \phi) - (F(u_h^n),\ \partial_x \phi) + \varepsilon\big((\overline{\partial}_{tt} u_h^{n-1},\ \phi) + (A \partial_x u_h^n,\ \partial_x \phi)\big) = 0. \tag{3.26}$$

Let $\phi = P_1\,\eta'(u_h^{n+1})$ in (3.26), where $P_1 : H^1 \to S_k$ is the elliptic projection defined in (2.20). Then

$$\begin{aligned} &(\overline{\partial}_t u_h^n, \eta'(u_h^{n+1})) + \big(\partial_x F(u_h^n), \eta'(u_h^{n+1})\big) \\ &\quad + \varepsilon(\overline{\partial}_{tt} u_h^{n-1}, P_1, \eta'(u_h^{n+1})) + \varepsilon(A \partial_x\, u_h^n, \partial_x \eta'(u_h^{n+1})) \\ &\quad = (\overline{\partial}_t u_h^n, \eta'(u_h^{n+1}) - P_1\,\eta'(u_h^{n+1})) \\ &\quad + \big(\partial_x F(u_h^n), \eta'(u_h^{n+1}) - P_1\,\eta'(u_h^{n+1})\big) =: Z_1 + Z_2. \end{aligned} \tag{3.27}$$

The terms in the right-hand side will be estimated as in the semidiscrete case. We start by examining the stability that is inherited in the left-hand side. In a way similar to (3.6) one can show

$$\begin{aligned} (\overline{\partial}_{tt} Y^{n-1},\ W^{n+1}) &= \kappa(\overline{\partial}_{tt} Y^{n-1},\ \overline{\partial}_t W^n) \\ &\quad + \overline{\partial}_t(\overline{\partial}_t Y^{n-1},\ W^n) - (\overline{\partial}_t Y^n,\ \overline{\partial}_t W^n). \end{aligned} \tag{3.28}$$

Therefore,

$$\begin{aligned} &\varepsilon(\overline{\partial}_{tt} u_h^{n-1}, P_1\,\eta'(u_h^{n+1})) \\ &\quad = \varepsilon\kappa(\overline{\partial}_{tt} u_h^{n-1},\ \overline{\partial}_t P_1\,\eta'(u_h^n)) + \varepsilon\overline{\partial}_t(\overline{\partial}_t u_h^{n-1},\ P_1\,\eta'(u_h^n)) - \varepsilon(\overline{\partial}_t u_h^n,\ \overline{\partial}_t P_1\,\eta'(u_h^n)) \\ &\quad = \varepsilon\overline{\partial}_t(\overline{\partial}_t u_h^{n-1},\ \eta'(u_h^n)) + \varepsilon\kappa(\overline{\partial}_{tt} u_h^{n-1},\ \overline{\partial}_t P_1\,\eta'(u_h^n)) \\ &\qquad - \varepsilon(\overline{\partial}_t u_h^n,\ \overline{\partial}_t P_1\,\eta'(u_h^n)) + \varepsilon\overline{\partial}_t(\overline{\partial}_t u_h^{n-1},\ P_1\,\eta'(u_h^n) - \eta'(u_h^n)). \end{aligned} \tag{3.29}$$

Taylor's formula implies

$$\begin{aligned} \int_\Omega \eta(u_h^n)dx &= \int_\Omega \eta(u_h^{n+1})dx - \kappa(\eta'(u_h^{n+1}), \overline{\partial}_t u_h^n) \\ &\quad + \kappa^2 \left(\overline{\partial}_t u_h^n, \left\{ \int_0^1 \int_0^s \eta''(u_h^{n+1} - \kappa\,\tau \overline{\partial}_t u_h^n) d\tau ds \right\} \overline{\partial}_t u_h^n \right), \end{aligned} \tag{3.30}$$

i.e.,

$$
\begin{aligned}
(\overline{\partial}_t u_h^n, \eta'(u_h^{n+1})) &= \overline{\partial}_t \int_\Omega \eta(u_h^n) dx \\
&\quad + \kappa \left(\overline{\partial}_t u_h^n, \left\{ \int_0^1 \int_0^s \eta''(u_h^{n+1} - \kappa\, \tau \overline{\partial}_t u_h^n) d\tau ds \right\} \overline{\partial}_t u_h^n \right).
\end{aligned} \tag{3.31}
$$

Further, since (η, q) is an entropy pair,

$$
\begin{aligned}
(F'(u_h^n)\, \partial_x u_h^n,\ \eta'(u_h^{n+1})) &= (F'(u_h^n)\, \partial_x u_h^n,\ \eta'(u_h^n)) \\
&\quad + (F'(u_h^n)\, \partial_x u_h^n,\ \eta'(u_h^{n+1}) - \eta'(u_h^n)) \\
&= \kappa (F'(u_h^n)\, \partial_x u_h^n,\ \overline{\partial}_t \eta'(u_h^n)).
\end{aligned}
$$

Hence

$$
\begin{aligned}
&\overline{\partial}_t \int_\Omega \eta(u_h^n) dx + \varepsilon \overline{\partial}_t (\overline{\partial}_t u_h^{n-1},\ \eta'(u_h^n)) \\
&\qquad + \varepsilon (A \partial_x\, u_h^n, \eta''(u_h) \partial_x\, u_h^n) - \varepsilon (\overline{\partial}_t\, u_{h^n}, P_1\, \overline{\partial}_t \eta'(u_h^n)) \\
&\qquad + \kappa \left(\overline{\partial}_t u_h^n, \left\{ \int_0^1 \int_0^s \eta''(u_h^{n+1} - \kappa\, \tau \overline{\partial}_t u_h^n) d\tau ds \right\} \overline{\partial}_t u_h^n \right) \\
&\qquad = Z_1 + Z_2 + Z_3,
\end{aligned} \tag{3.32}
$$

where the new term Z_3 is given by

$$
\begin{aligned}
Z_3 = &- \varepsilon \kappa (\overline{\partial}_{tt} u_h^{n-1},\ \overline{\partial}_t P_1\, \eta'(u_h^n)) \\
&- \varepsilon \overline{\partial}_t (\overline{\partial}_t u_h^{n-1},\ P_1\, \eta'(u_h^n) - \eta'(u_h^n)) - \kappa (F'(u_h^n)\, \partial_x u_h^n,\ \overline{\partial}_t \eta'(u_h^n)).
\end{aligned} \tag{3.33}
$$

Using once more Taylor's formula we obtain,

$$
\begin{aligned}
\int_\Omega \eta(u_h^n + \varepsilon \overline{\partial}_t u_h^{n-1}) dx &= \int_\Omega \eta(u_h^n) dx + \varepsilon \overline{\partial}_t (\overline{\partial}_t u_h^{n-1},\ \eta'(u_h^n)) \\
&\quad + \varepsilon^2 \left(\overline{\partial}_t u_h^{n-1}, \left\{ \int_0^1 \int_0^s \eta''(u_h^n + \varepsilon\, \tau \overline{\partial}_t u_h^{n-1}) d\tau ds \right\} \overline{\partial}_t u_h^{n-1} \right).
\end{aligned} \tag{3.34}
$$

By a slight modification of the proof of Lemma 2.3 we have

$$
\varepsilon |(\overline{\partial}_t\, u_h^n, P_1\, \overline{\partial}_t \eta'(u_h^n))| \le \beta\, \|\eta''\|_{L^\infty}\, \|\overline{\partial}_t\, u_h^n\|^2_{L^2(\Omega)}. \tag{3.35}
$$

Essentially what remains now is an estimate of $\|\overline{\partial}_t\, u_h^n\|_{L^2(\Omega)}$. As in the symmetric case we use the test function $\phi = \overline{\partial}_t\, u_h^n$ and we conclude the proof by combining arguments from the semidiscrete case (see (2.33)–(2.37)), and the fully discrete case with symmetric F' (cf. the terms with coefficient $4\varepsilon^2$), and by estimating of course the terms Z_i. It is to be noted, finally, the essential role of the estimate

$$
\begin{aligned}
&\kappa \left(\overline{\partial}_t u_h^n, \left\{ \int_0^1 \int_0^s \eta''(u_h^{n+1} - \kappa\, \tau \overline{\partial}_t u_h^n) d\tau ds \right\} \overline{\partial}_t u_h^n \right) \\
&\qquad \ge \mu \kappa \|\overline{\partial}_t u_h^n\|^2_{L^2}, \qquad \mu > 0,
\end{aligned} \tag{3.36}
$$

in the stability analysis. ∎

Remark 3.1 (mesh conditions). Proposition 3.3 holds under the assumptions for the mesh stated in Proposition 3.1, assuming in addition that $h \leq \gamma\varepsilon$. Combining these conditions we conclude that we need to have a CFL condition with small constant γ_{CFL} and in addition $h \leq \frac{\gamma}{2\gamma_{CFL}}\underline{h}$. This last relation is a quasi-uniformity condition on the mesh, the constant of which depends on how strong the CFL condition is. It seems that it is a weakness of our proof to assume $h \leq \gamma\varepsilon$ rather than $h_{\text{loc}} \leq \gamma\varepsilon$, where h_{loc} is the local mesh size close to the shock; see section 1.2. If this were the case this would not be a restriction since h_{loc} is naturally of the order of $\underline{h}$. Nevertheless, the above conditions provide enough room for computations compatible with the principle to have finer mesh in the shock areas and coarser mesh in the smooth parts of the solution. See also the related discussion in section 6.

We conclude with the following proposition.

PROPOSITION 3.4. *For entropy pairs* (η, q) *such that*

$$\|\eta\|_{L^\infty},\ \|q\|_{L^\infty},\ \|\eta'\|_{L^\infty},\ \|\eta''\|_{L^\infty}\ \leq\ C$$

and under the hypotheses of Proposition 3.3*, we have*

$$\eta(u_h)_t\ +\ q(u_h)_x\ \subset\ \textit{lies in a compact set of } H^{-1}_{loc}(\mathbb{R}\times\mathbb{R}^+),$$

where u_h *and* u_h^n *are related by* (3.16).

3.4. Estimates in the multidimensional case. Let (1.1) be endowed with a uniformly convex entropy η; the fluxes q_i are given by (2.42) [14, sec. IV.4.3]. The finite element approximations defined by (3.1) satisfy similar a priori bounds with the one-dimensional case. The matrices A_i should now satisfy the analogue of (2.44). We state the stability estimate; its proof is a modification of the proof of Proposition 3.3 and is omitted.

PROPOSITION 3.5. *Assume that* (1.1) *is equipped with a convex entropy* $\eta(u)$ *satisfying* (2.6)*. If the symmetric, positive definite matrices* A_i *satisfy* (2.44)*, then, under similar conditions on* κ, ε, h *as in Proposition* 3.1 *(with possibly different constants), and for* $h \leq \gamma\varepsilon$ *for some* $\gamma > 0$*, the fully discrete finite element approximations* (3.1) *satisfy*

$$\begin{aligned}\|\ u_h^n\ +\varepsilon\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ +\varepsilon^2\|\ \overline{\partial}_t u_h^{n-1}\|_{L^2}^2\ +2\varepsilon^2\sum_{i=1}^{d}(A_i\ \partial_{x_i}u_h^n,\ \partial_{x_i}u_h^n)\\ +\sum_{j=1}^{n-1}\varepsilon\ \kappa\|\overline{\partial}_t u_h^j\|_{L^2}^2+\sum_{j=1}^{n-1}\kappa^2\|\overline{\partial}_t u_h^j\|_{L^2}^2+\sum_{j=1}^{n-1}\varepsilon\ \kappa\ \sum_{i=1}^{d}\|\partial_{x_i}u_h^j\|_{L^2}^2\ \leq\ C(u_h^0).\end{aligned}$$

4. Convergence of finite element schemes for one-dimensional systems. The compactness of the dissipation measure (2.41) or (3.17) is central in establishing compactness of approximate solutions for systems of conservation laws via the program of compensated compactness. Such results are available (in a one-dimensional context) for the scalar conservation law, the equations of elastodynamics, the equations of isentropic gas dynamics, and the class of rich systems (see [42, 15] and the references in [14, Chap. XV]). One difficulty in applying the compensated compactness framework is that, while several of the existing compactness theorems are valid in the presence of uniform L^∞-estimates, the available estimates in applications are often just in the energy norm. In particular, this is the case for the approximations arising via semidiscrete (2.1) or fully discrete (3.2) finite element schemes. Note that

under the additional hypothesis of uniform L^∞ bounds for the approximations, one would conclude directly convergence toward a weak solution for all the aforementioned systems.

Our results can be applied to systems where the compensated compactness program has been carried out in the energy-norm framework. Such results are available for the scalar conservation law in the L^p framework (e.g., [35], [34, Thm. 2.3]) and for the equations of one-dimensional elasticity,

$$\begin{aligned} u_{1,t} - u_{2,x} &= 0, \\ u_{2,t} - \sigma(u_1)_x &= 0, \end{aligned} \tag{4.1}$$

in the energy norm [31, 38, 37]. In both cases one can deduce compactness of semidiscrete or fully discrete finite element schemes and conclude with a convergence result.

We consider here as a paradigm the system (4.1). For $\sigma'(u_1) > 0$, it is strictly hyperbolic with wave speeds $\lambda_{1,2} = \pm\sqrt{\sigma'(u_1)}$. It admits an infinite number of entropy pairs, of which the special pair

$$\eta = \frac{1}{2}u_2^2 + \int_0^{u_1} \sigma(\tau)d\tau, \quad q = -u_2\sigma(u_1) \tag{4.2}$$

is associated with the mechanical energy and the work of contact forces, and η is strictly convex. We assume that σ satisfies the subcharacteristic condition

$$0 < s \le \sigma'(u) \le S, \quad u \in \mathbb{R}, \tag{4.3}$$

with s, S positive constants. One easily checks that the matrix A can be selected so that all conditions in Propositions 2.3 and 3.3 hold.

We need a second hypothesis on σ that allows us to apply the results of [38, 37]. We assume either that (4.1) is genuinely nonlinear with

$$\sigma''(u) \neq 0 \quad \text{and} \quad \sigma'', \sigma''' \in L^2 \cap L^\infty(\mathbb{R}) \tag{4.4}$$

or that σ has precisely one inflection point at u_0 with

$$\begin{aligned} &(u - u_0)\sigma''(u) \neq 0 \quad \text{for } u \neq u_0 \\ &\quad \text{and } \ \sigma'', \sigma''' \in L^2 \cap L^\infty(\mathbb{R}). \end{aligned} \tag{4.5}$$

We then have the following theorem.

THEOREM 4.1. *Let $\sigma \in C^3$ satisfy hypotheses* (4.3), (4.4) *(or* (4.3), (4.5)*). Let $(u_1^{\varepsilon,h}, u_2^{\varepsilon,h})$ be a family of solutions of* (2.1)*, and let A be a symmetric, positive definite matrix satisfying* (2.14)*. Then, for $h \le \gamma\varepsilon$ (with γ as in Proposition* 2.3*) and along a subsequence,*

$$u_{1,h} \to u_1\,, \quad u_{2,h} \to u_2\,, \quad \text{a.e. } (x,t) \text{ and in } L^p_{loc}(\mathbb{R}\times(0,T)) \text{ for } p < 2,$$

and (u_1, u_2) is a weak solution of (4.1)*.*

Proof. The proof uses the theory of compensated compactness and proceeds by controlling the dissipation measure

$$\partial_t\eta(u_1^{\varepsilon,h}, u_2^{\varepsilon,h}) + \partial_x q(u_1^{\varepsilon,h}, u_2^{\varepsilon,h}) \quad \text{lies in a compact of } H^{-1}_{loc}, \tag{4.6}$$

for entropy pairs $(\eta(u,v)\,,\, q(u,v))$ for the equations of elasticity. In the presence of uniform L^∞-bounds, the theorem of DiPerna [15] would guarantee compactness of

approximate solutions and imply that, along a subsequence, $u_1^{\varepsilon,h} \to u_1$ and $u_2^{\varepsilon,h} \to u_2$ a.e. (x,t).

In the current case, uniform L^∞-estimates are not available and the natural stability framework is in the energy norm (see Proposition 2.3). Nevertheless, under hypothesis (4.3) and by Proposition 2.5, the dissipation measure is controlled for a class of entropy-flux pairs $(\eta(u,v)\,,\, q(u,v))$ satisfying the growth restrictions

$$\eta,\ q,\ \eta_u,\ \eta_v,\ \eta_{uu},\ \eta_{uv},\ \eta_{vv} \in L^\infty(\mathbb{R}^2). \tag{4.7}$$

This class of entropy pairs contains sufficient test pairs in order to achieve the reduction of the generalized Young measure to a point mass and to show strong convergence in L^p_{loc} for $p < 2$. The hypotheses (4.3)–(4.4) allow us to apply the result of Shearer [38], where the reduction is performed for the genuine nonlinear case, while the hypotheses (4.3)–(4.5) allow us to apply the corresponding reduction in Serre and Shearer [37] applicable to the case of elasticity with one inflection point. □

In a similar manner we can prove convergence of fully discrete finite element approximations (3.2) for the equations (4.1).

THEOREM 4.2. *Let σ be as in Theorem* 4.1 *and let A satisfy the hypotheses of Proposition* 3.3. *Let $(u_{1,h}, u_{2,h})$ be the fully discrete finite element approximations defined in* (3.16). *If the parameters κ, h, and ε are restricted by* (3.14) *and $h \le \gamma\varepsilon$ for some $\gamma > 0$, then along a subsequence*

$$u_{1,h} \to u_1, \quad u_{2,h} \to u_2, \quad \text{a.e. } (x,t) \text{ and in } L^p_{loc}(\mathbb{R}\times(0,T)) \text{ for } p<2,$$

and (u,v) is a weak solution of (4.1).

5. Error estimates for smooth solutions. In this section we consider the system of conservation laws

$$\partial_t u + \partial_x F(u) = 0 \tag{5.1}$$

and assume that (5.1) is endowed with a convex entropy $\eta(u)$. We let u be a classical solution of (5.1) defined on a maximal interval of existence and let U_ε be the smooth solution of the relaxation approximation

$$\partial_t U_\varepsilon + \partial_x F(U_\varepsilon) = \varepsilon A \partial_{xx} U_\varepsilon - \varepsilon \partial_{tt} U_\varepsilon\,. \tag{5.2}$$

We show

$$\|U_\varepsilon(t) - u(t)\|_{L^2} \le C(t,u)\,\varepsilon\,, \tag{5.3}$$

where the constant $C(t,u)$ depends on a strong norm of u and blows up at the critical time.

5.1. Motivation. It was established in Theorem 5.2.1 of [14] that the classical solution of (1.1) is unique among the class of admissible weak solutions in the case where the system admits a convex entropy. The result follows by showing a stability estimate in L^2:

$$\|u(t) - w(t)\|_{L^2} \le C(t,u)\,\|u(0) - w(0)\|_{L^2}. \tag{5.4}$$

Here u is the classical and w an admissible weak solution of (1.1). The main idea of the proof is to control the spatial integral of the quadratic in the $u - w$ function

$$H(u,w) = \eta(w) - \eta(u) - \eta'(u)(w-u). \tag{5.5}$$

This is made possible by the observation that certain quantities arising in the proof vanish when u is a classical solution and thus satisfies the entropy inequality as equality. Our idea is to use a similar approach to show the error estimate (5.3). A difficulty arises (except for handling the error terms in an appropriate way) that it is no longer possible to work with the same function H as in (5.5). On the other hand, the estimates in [43] and in section 2 suggest that when the system admits a convex entropy, we are able to control the quantity

$$\int \eta(U_\varepsilon + \varepsilon \partial_t U_\varepsilon) dx.$$

Motivated by these considerations, we introduce the functions

$$H_R(u, U_\varepsilon) = \eta\big(U_\varepsilon + \varepsilon \partial_t (U_\varepsilon - u)\big) - \eta(u) - \eta'(u)\big(U_\varepsilon - u + \varepsilon \partial_t (U_\varepsilon - u)\big), \tag{5.6}$$

$$Q\,(u, U_\varepsilon) = q(U_\varepsilon) \;-\; q(u) - \eta'(u)\;(F(U_\varepsilon) - F(u)). \tag{5.7}$$

The function H_R is the relaxational correction of (5.5) and is of quadratic order in the quantity $\big(U_\varepsilon - u + \varepsilon \partial_t (U_\varepsilon - u)\big)$. Control of $\|u(t) - U_\varepsilon(t)\|^2_{L^2}$ is achieved through the additional control of $\varepsilon^2 \|\partial_t\,(U_\varepsilon - u)\|^2_{L^2}$ that is obtained from a separate estimate natural for approximations by wave equation (5.2).

5.2. The decay functional. The first objective is to establish that H_R is a Lyapunov functional. We begin with the derivation of the main decay identity.

Let η be the convex entropy with q the corresponding flux. The classical solution u satisfies

$$\partial_t \eta(u) + \partial_x q(u) = 0.$$

The approximate solution of (5.2) will henceforth be denoted by $U \equiv U_\varepsilon$. It satisfies the identities

$$\begin{aligned}
&\partial_t (U - u) + \partial_x (F(U) - F(u)) = \varepsilon A U_{xx} - \varepsilon U_{tt},\\
&\partial_t \eta'(u)(U - u) + \partial_x \eta'(u)(F(U) - F(u))\\
&\quad = \eta''(u) u_x \cdot [F(U) - F(u) - F'(u)(U - u)] + \varepsilon \eta'(u) \cdot A U_{xx} - \varepsilon \eta'(u) \cdot U_{tt},
\end{aligned}$$

where we use (5.1) and the fact that η is an entropy if and only if $(\eta'' F')^T = \eta'' F'$; see (2.42). Combining the above, we deduce

$$\begin{aligned}
&\partial_t [\eta(U) - \eta(u) - \eta'(u)(U - u)] + \partial_x [q(U) - q(u) - \eta'(u)(F(U) - F(u))]\\
&\qquad = -\eta''(u) u_x \cdot [F(U) - F(u) - F'(u)(U - u)]\\
&\qquad\quad + \varepsilon\big(\eta'(U) - \eta'(u)\big) \cdot A U_{xx} - \varepsilon\big(\eta'(U) - \eta'(u)\big) \cdot U_{tt}.
\end{aligned} \tag{5.8}$$

We now use (5.8) in conjunction with the identities

$$\begin{aligned}
(\eta'(U) - \eta'(u)) \cdot U_{tt} &= \partial_t [(\eta'(U) - \eta'(u)) \cdot (U_t - u_t)] - \eta''(U)(U_t - u_t) \cdot (U_t - u_t)\\
&\quad - (\eta''(U) - \eta''(u)) u_t \cdot (U_t - u_t) + (\eta'(U) - \eta'(u)) \cdot u_{tt},\\
(\eta'(U) - \eta'(u)) \cdot A U_{xx} &= \partial_x [(\eta'(U) - \eta'(u)) \cdot A (U - u)_x]\\
&\quad - \eta''(U)(U - u)_x \cdot A (U - u)_x\\
&\quad - (\eta''(U) - \eta''(u)) u_x \cdot A (U - u)_x + (\eta'(U) - \eta'(u)) \cdot A u_{xx}
\end{aligned}$$

and

$$\eta\big(U+\varepsilon\partial_t(U-u)\big)=\eta(U)+\eta'(U)\varepsilon\partial_t(U-u)+\varepsilon^2\partial_t(U-u)\cdot\overline{\eta''}\partial_t(U-u)$$
$$\text{with}\quad \overline{\eta''}=\int_0^1\int_0^s \eta''(U+\varepsilon\,\tau\partial_t\,(U-u))d\tau ds$$

to conclude

(5.9)
$$\begin{aligned}&\partial_t\{\eta(U+\varepsilon\partial_t(U-u))-\eta(u)-\eta'(u)[U-u+\varepsilon\partial_t(U-u)]\\&\qquad\qquad-\varepsilon^2\partial_t(U-u)\cdot\overline{\eta''}\partial_t(U-u)\}\\&\quad+\partial_x\{q(U)-q(u)-\eta'(u)(F(U)-F(u))\}\\&\quad+\varepsilon\{\eta''(U)(U-u)_x\cdot A(U-u)_x-\eta''(U)(U-u)_t\cdot(U-u)_t\}\\&=\partial_x\{\varepsilon(\eta'(U)-\eta'(u))\cdot A(U-u)_x\}-\eta''(u)u_x\cdot[F(U)-F(u)-F'(u)(U-u)]\\&\quad+a_{1t}+a_{2t}+b_{1x}+b_{2x}.\end{aligned}$$

The error terms a_{1t}, a_{2t}, b_{1x}, and b_{2x} are defined by

$$\begin{aligned}a_{1t}&=\varepsilon\big(\eta''(U)-\eta''(u)\big)u_t\cdot(U_t-u_t),\\a_{2t}&=-\varepsilon\big(\eta'(U)-\eta'(u)\big)\cdot u_{tt},\\b_{1x}&=-\varepsilon\big(\eta''(U)-\eta''(u)\big)u_x\cdot A(U-u)_x,\\b_{2x}&=\varepsilon\big(\eta'(U)-\eta'(u)\big)\cdot Au_{xx}\end{aligned}\tag{5.10}$$

and will be estimated in what follows.

Identity (5.9) is supplemented by a correction accounting for the fact that the third term is indefinite. The correcting identity is obtained by multiplying the equation

$$(U-u)_t+F'(U)(U-u)_x=\varepsilon A(U-u)_{xx}-\varepsilon(U-u)_{tt}+\varepsilon(Au_{xx}-u_{tt})-(F'(U)-F'(u))u_x$$

by $(U-u)_t$ and integrating by parts to deduce

$$\begin{aligned}&\partial_t\Big\{\frac{1}{2}\varepsilon|U_t-u_t|^2+\frac{1}{2}\varepsilon(U-u)_x\cdot A(U-u)_x\Big\}+|(U-u)_t|^2\\&\qquad+F'(U)(U-u)_x\cdot(U-u)_t=\partial_x\Big\{\varepsilon A(U-u)_x\cdot(U-u)_t\Big\}+c_{1t}+c_{2t},\end{aligned}\tag{5.11}$$

where c_{1t}, c_{2t} are given by

$$\begin{aligned}c_{1t}&=\varepsilon(Au_{xx}-u_{tt})\cdot(U-u)_t,\\c_{2t}&=-(F'(U)-F'(u))u_x\cdot(U-u)_t.\end{aligned}\tag{5.12}$$

Next, we multiply (5.11) by $2\alpha\varepsilon$, add the resulting identity to (5.9), and use (5.6)

and (5.7) to arrive at

$$
\begin{aligned}
&\partial_t \mathcal{G}(u,U) + \partial_x Q(u,U) + \alpha\varepsilon\Big|(U-u)_t + F'(U)(U-u)_x\Big|^2 \\
&\quad + \varepsilon\Big\{\eta''(U)(U-u)_x \cdot A(U-u)_x - \alpha F'(U)(U-u)_x \cdot F'(U)(U-u)_x\Big\} \\
&\quad + \varepsilon\Big\{\big(\alpha I - \eta''(U)\big)(U-u)_t \cdot (U-u)_t\Big\} \\
&= \partial_x\Big\{\varepsilon(\eta'(U)-\eta'(u)\big)\cdot A(U-u)_x + 2\alpha\varepsilon^2 A(U-u)_x \cdot (U-u)_t\Big\} \\
&\quad - \eta''(u)u_x \cdot \Big[F(U) - F(u) - F'(u)(U-u)\Big] \\
&\quad + a_{1t} + a_{2t} + b_{1x} + b_{2x} + 2\alpha\varepsilon(c_{1t}+c_{2t}),
\end{aligned}
\tag{5.13}
$$

where

$$
\begin{aligned}
\mathcal{G}(u,U) &= H_R(u,U) \\
&\quad + \varepsilon^2\big[\alpha I - \overline{\eta''}\,\big](U-u)_t \cdot (U-u)_t + \varepsilon^2\alpha A(U-u)_x \cdot (U-u)_x.
\end{aligned}
\tag{5.14}
$$

5.3. The error estimate. Equation (5.13) is the basic decay identity. We see below that, under certain conditions on the entropy η, the quantity $\mathcal{G}(u,U)$ becomes a Lyapunov functional and leads to an error estimate.

PROPOSITION 5.1. *Assume that* (5.1) *is equipped with a strictly convex entropy* η *that satisfies, for some* $\alpha > 0$,

$$
\frac{1}{\alpha}\, I \le \eta''(u) \le \alpha\, I, \quad u \in \mathbb{R}^n,
\tag{5.15}
$$

and the positive definite, symmetric matrix A *can be selected so that for some* $\nu > 0$ *we have*

$$
\frac{1}{2}\big((\eta''(u)A)^T + \eta''(u)A\big) - \alpha F'^T(u)F'(u) \ge \nu I, \quad u \in \mathbb{R}^n.
\tag{5.16}
$$

Let u *be a smooth solution of* (5.1), *let* U_ε *be a smooth solution of* (5.2), *and suppose that both* u, U_ε *decay sufficiently fast at infinity.*

(i) *Then* $\mathcal{G}(u,U)$ *is positive definite and*

$$
\begin{aligned}
&\frac{d}{dt}\int_{\mathbb{R}} \mathcal{G}(u,U_\varepsilon)dx + \frac{1}{c}\varepsilon\int_{\mathbb{R}} |(U_\varepsilon-u)_x|^2 + |(U_\varepsilon-u)_t|^2 dx \\
&\le \int_{\mathbb{R}} \Big\{|\eta''(u)u_x\big(F(U_\varepsilon) - F(u) - F'(u)(U_\varepsilon-u)\big)| \\
&\qquad\qquad + |a_{1t} + a_{2t} + b_{1x} + b_{2x} + 2\alpha\varepsilon(c_{1t}+c_{2t})|\Big\}dx
\end{aligned}
\tag{5.17}
$$

for some constant c *independent of* ε.

(ii) *If in addition for some* $M > 0$

$$
|F''(u)| \le M, \quad |\eta'''(u)| \le M, \quad u \in \mathbb{R}^n,
\tag{5.18}
$$

then

$$
\begin{aligned}
&\|(U_\varepsilon - u)(t)\|_{L^2} + \varepsilon\|(\partial_x U_\varepsilon - \partial_x u)(t)\|_{L^2} + \varepsilon\|(\partial_t U_\varepsilon - \partial_t u)(t)\|_{L^2} \\
&\quad \le C(t,u)(\|(U_\varepsilon - u)(0)\|_{L^2} + \varepsilon\|(\partial_x U_\varepsilon - \partial_x u)(0)\|_{L^2} + \varepsilon\|(\partial_t U_\varepsilon - \partial_t u)(0)\|_{L^2} + \varepsilon),
\end{aligned}
\tag{5.19}
$$

where $C(t,u)$ is a constant depending on t and norms of the smooth solution u.

Proof. Integrating (5.13) over $\mathbb{R}$ and using the hypotheses (5.15) and (5.16), we obtain (5.17). By (5.15),

$$\alpha I - \overline{\eta''} = \alpha I - \int_0^1 \int_0^s \eta''(U + \varepsilon\,\tau\partial_t\,(U-u))d\tau ds \geq \frac{1}{2}\alpha I.$$

Moreover, the function $H_R(u,U)$ defined in (5.6) is strictly convex and thus $\mathcal{G}(u,U)$ in (5.14) is positive definite.

Under (5.15), (5.18) and for

$$\varphi(t) = \int_{\mathbb{R}} |U-u|^2 + \varepsilon^2|U_t - u_t|^2 + \varepsilon^2|U_x - u_x|^2 dx,$$

we have

$$\frac{1}{C}\varphi(t) \leq \int_{\mathbb{R}} \mathcal{G}(u,U)dx \leq C\varphi(t)\,.$$

The error terms in (5.10) are estimated by

$$\|a_{1t}\|_{L^1} \leq \varepsilon C\|u_t\|_{L^\infty}\|U-u\|_{L^2}\|U_t-u_t\|_{L^2}, \qquad \|a_{2t}\|_{L^1} \leq \varepsilon C\|u_{tt}\|_{L^2}\|U-u\|_{L^2},$$
$$\|b_{1x}\|_{L^1} \leq \varepsilon C\|u_x\|_{L^\infty}\|U-u\|_{L^2}\|U_x-u_x\|_{L^2}, \qquad \|b_{2x}\|_{L^1} \leq \varepsilon C\|u_{xx}\|_{L^2}\|U-u\|_{L^2},$$

while the ones in (5.12) are estimated by

$$\|\varepsilon c_{1t}\|_{L^1} \leq \varepsilon^2 C\big(\|u_{tt}\|_{L^2} + \|u_{xx}\|_{L^2}\big)\|U_t-u_t\|_{L^2},$$
$$\|\varepsilon c_{2t}\|_{L^1} \leq \varepsilon C\|u_x\|_{L^\infty}\|U-u\|_{L^2}\|U_t-u_t\|_{L^2},$$

where C is a generic constant depending on α, M, and norms of u.

From (5.17) we obtain

(5.20)
$$\begin{aligned}
&\frac{d}{dt}\int_{\mathbb{R}} \mathcal{G}(u,U_\varepsilon)dx + \frac{1}{C}\varepsilon\left(\|U_t-u_t\|_{L^2}^2 + \|U_x-u_x\|_{L^2}^2\right)\\
&\leq C(\|U-u\|_{L^2}^2 + \varepsilon\|U-u\|_{L^2}(1 + \|U_t-u_t\|_{L^2} + \|U_x-u_x\|_{L^2}) + \varepsilon^2\|U_t-u_t\|_{L^2})\\
&\leq C(\|U-u\|_{L^2}^2 + \varepsilon^2\|U_t-u_t\|_{L^2}^2 + \varepsilon^2\|U_x-u_x\|_{L^2}^2 + \varepsilon^2).
\end{aligned}$$

This in turn gives

$$\varphi(t) \leq \varphi(0) + \varepsilon^2 Ct + C\int_0^t \varphi(s)ds$$

and we conclude from Gronwall's inequality that

$$\varphi(t) \leq C(t,u)\big(\varphi(0) + \varepsilon^2\big). \tag{5.21}$$

Then (5.19) follows. ∎

Remark 5.1. As an example where Proposition 5.1 applies, consider the equations of elastodynamics (4.1). This system admits the entropy pair (4.2). One checks that if

$$0 < s \leq \sigma'(u) \leq S, \quad |\sigma''(u)| \leq M,$$

for some constants s, S, and $M > 0$, then (5.15), (5.16), and (5.18) are fulfilled and we obtain the relevant stability estimate.

Remark 5.2. Proposition 5.1 can be extended for multidimensional hyperbolic systems. In this case, condition (5.16) should be replaced by the analogue of (2.44).

6. Implementation issues. We include here a short discussion on the implementation of the schemes and we present indicative numerical examples that relate to our results.

Adaptivity and mesh reconstruction. The basic principles of our mesh reconstruction policy are

(a) locate the regions of space where increased accuracy is demanded, through a positive functional g;

(b) find a partition of space with predefined constant cardinality and density that follows the estimator function g; and

(c) reconstruct the solution on the finite element space which corresponds to that partition and advance to the next time step by applying the finite element scheme.

These steps are studied, introducing appropriate estimator functions for finite element methods of systems of hyperbolic conservation laws. Among others, estimator functions g are proposed which are based on a posteriori estimates or on the curvature of the approximate solution [4, 2, 3]. This approach yields a dynamic mesh construction which is combined with finite element schemes in what follows, but the mesh selection according to the basic properties of the solution is independent of the particular method used.

Mesh conditions. The mesh conditions needed in the stability analysis in section 3 are somewhat restrictive regarding the flexibility in the selection of the mesh, especially for small values of ε. The main reason is that the time step κ should be chosen very small if ε is very small. (The restrictions on the spatial mesh discussed in Remark 3.1 are not present in the numerical experiments.) In fact, the computational examples show that certain mesh conditions that relate the mesh size and ε are indeed needed and thus for fixed number of spatial mesh points and fixed κ we cannot take ε close to zero; see the following examples and [2, 3].

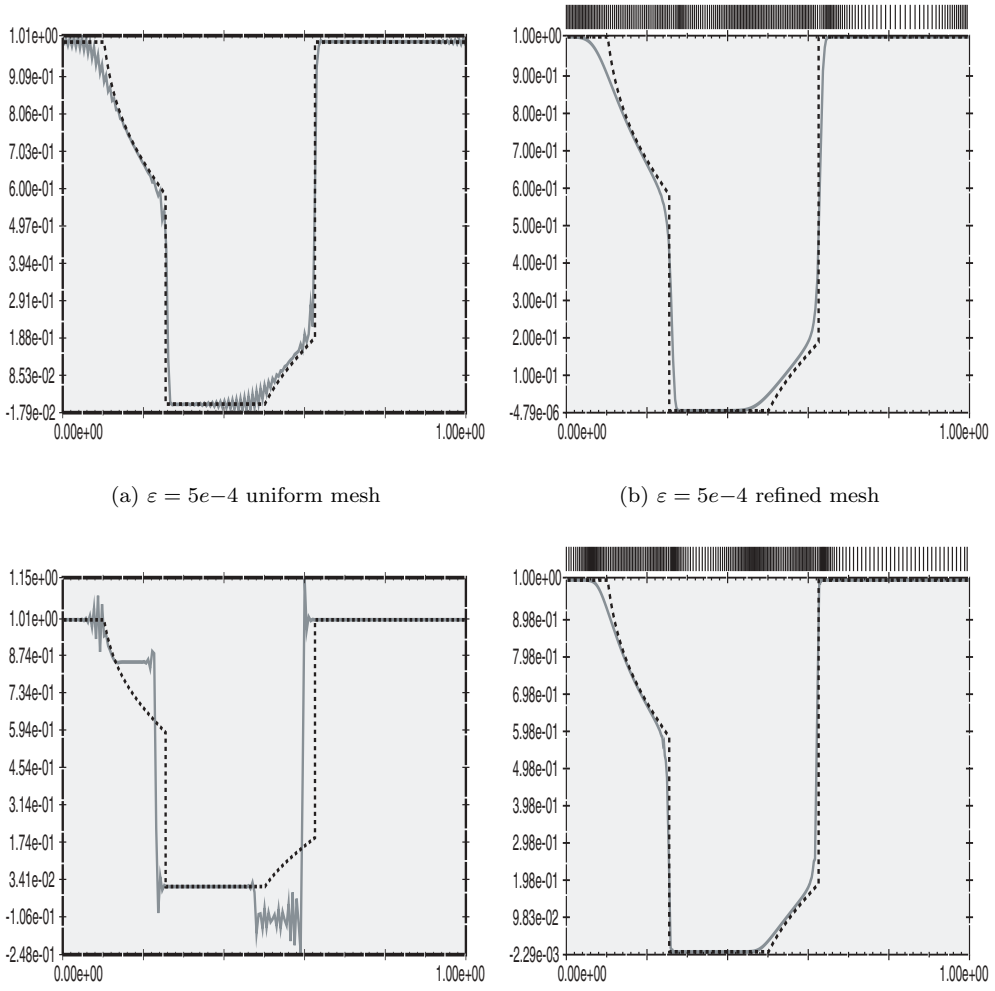
An alternative that completely bypasses this problem is provided by a modification of the finite element relaxation schemes developed in [2, 3]. The alternative is a class of finite element schemes based on the finite element discretization of a modified model with *switched relaxation.* These are schemes in which the application of a Runge–Kutta scheme uses the relaxation finite element model (1.5) for the calculation of the intermediate stages and of u_h^{n+1} and then $v_{h,i}^{n+1}$ is calculated as $v_{h,i}^{n+1} = \Pi F_i(u_h^{n+1})$. This enforces the projection to the equilibrium manifold $v = F(u)$ in each time step. The resulting schemes (switched relaxation finite element schemes) show remarkable stability even for extremely small values of ε. This is illustrated in the examples presented below.

CFL conditions. A common problem in explicit schemes with mesh refinement is to require strong CFL conditions, reflecting the relation of the time step κ to the minimum spatial mesh size $\underline{h}$. This problem appears in the computational examples of [4, 2, 3] but it is not very essential. A computationally more attractive idea would be to use time steps variable with x, or space-time elements, but this will remain for a future work.

Two-phase flow scalar problem. As a scalar example we chose the Buckley–Leverett equation [30] as a model of a two-phase flow in a porous medium. Here the flux F is not convex and is given by

$$F(u) = \frac{u^2}{u^2 + 0.5(1-u)^2}. \tag{6.1}$$

We compute the (periodic) Riemann problem in $[0,1]$ with $u_0 = 1$ on $[0, 0.1] \cup [0.5, 1]$



(a) $\varepsilon = 5e{-}4$ uniform mesh

(b) $\varepsilon = 5e{-}4$ refined mesh

(c) $\varepsilon = 5e{-}6$ uniform mesh

(d) $\varepsilon = 5e{-}6$ refined mesh

FIG. 1. *Buckley–Leverett two-phase flow problem:* 200 *nodes on* $[0,1]$. *The effect of the relationship of* h *and* ε *and of the stabilization by mesh refinement. Dotted line: exact solution; gray line: approximation. The distribution of the nodes in the refined mesh is displayed at top in* (b) *and* (d).

and $u_0 = 0$ on $(0.1, 0.5)$. In Figure 1 we display the results of application of our schemes in this problem for 200 nodes in $[0,1]$ with and without mesh refinement. For $\varepsilon = 5e-4$ the uniform mesh approximation has oscillations, while the corresponding approximation with mesh refinement provides an acceptable solution free of oscillations. Next for $\varepsilon = 5e-6$ the uniform mesh finite element solution seems to approximate a nonclassical weak solution. Thus the restrictions in our stability results on the relationship of h and ε are necessary. In this case the corresponding finite element approximation with mesh refinement not only eliminates the oscillations but resumes into the approximation of the entropy solution.

It is interesting to note that the method with uniform mesh, although oscillatory, seems to converge (weakly) as $h \to 0$. Moreover, this is also true in the example above where a nonclassical shock for (6.1) is captured. This is an indication that relaxation finite element schemes may conceivably be used to compute nonclassical shocks; compare to [29]. This interesting issue will be examined in a forthcoming work.

For 200 points we cannot take ε smaller unless we use the modified method based on the switched relaxation parameter. In Figure 2 we display the switched relaxation finite element schemes mentioned above. (Here the parameter $\varepsilon = \varepsilon(t)$ is a function of time that vanishes only on discrete time steps and elsewhere has a constant value ε.) Now we can have acceptable approximations for extremely small values of ε. This is a further indication of the strong regularization inherited by the adaptive mesh refinement.

System of elastodynamics. The one-dimensional system of elastodynamics is a particular case where all the results of this paper apply. We consider

$$\begin{aligned} u_{1,t} - u_{2,x} &= 0, \\ u_{2,t} - \sigma(u_1)_x &= 0 \end{aligned}$$

with $\sigma(v) = v + v^3$. We compute the relaxation finite element approximations with Riemann data $u_1(0) = 2$ on $[0, 1/4] \cup [3/4, 1]$ and $u_1(0) = 1$ on $[1/4, 3/4]$ and $u_2(0) = 2$ on $[0, 1]$ extended periodically. Figure 3 displays the approximations for 200 nodes in $[0, 1]$ with mesh refinement for $\varepsilon = 5e-5$. As before we use the modified method with switched relaxation parameter to compute the approximations still with 200 nodes but taking much smaller ε; Figure 4 displays the corresponding results. Figure 5 shows the improvement of the approximations if we use 400 points. In Figure 6 we see the dramatic difference of the approximations with uniform mesh and adaptive mesh refinement still with 400 nodes in $[0, 1]$. For further numerical results and detailed discussion on the adaptive mesh refinement strategies and on implementation issues for the schemes, see [4, 2, 3].

A LOCAL A POSTERIORI ERROR ESTIMATOR BASED ON EQUILIBRATED FLUXES*

R. LUCE† AND B. I. WOHLMUTH‡

Abstract. We present and analyze a new a posteriori error estimator for lowest order conforming finite elements. It is based on Raviart–Thomas finite elements and can be obtained locally by a postprocessing technique involving for each vertex a local subproblem associated with a dual mesh. Under certain regularity assumptions on the right-hand side, we obtain an error estimator where the constant in the upper bound for the true error tends to one. Replacing the conforming finite element solution by a postprocessed one, the error estimator is asymptotically exact. The local equivalence between our estimator and the standard residual-based error estimator is established. Numerical results illustrate the performance of the error estimator.

Key words. a posteriori error estimator, adaptive refinement, Raviart–Thomas finite elements

DOI. 10.1137/S0036142903433790

1. Introduction.

Many efficient numerical algorithms for the solution of partial differential equations are based on adaptive techniques. Here, we consider conforming finite elements for the numerical solution of scalar second order elliptic partial differential equations. A posteriori error estimators are very often used to control the adaptive refinement process of the triangulations. Moreover, upper bounds for the discretization error in terms of the error estimator can be obtained. The quality of the error estimator depends highly on the constants in the upper and lower bounds. Unfortunately, the reliability and efficiency constants very often can be quite large. Here, we propose a new approach such that the discretization error is bounded by our a posteriori error estimator. We refer to [3, 8, 33] for a good overview and some recent techniques and ideas.

There are many different possibilities for constructing locally defined error estimators. One possibility is to use residual-type error estimators which measure locally the jump of the discrete flux; see, e.g., [4, 5, 6, 7, 11, 31, 32]. A different approach is to solve local subproblems by using higher order finite elements, e.g., [9, 12, 18, 20, 25]. The starting point for the construction of these hierarchical error estimators is a saturation assumption. Very simple and extremely cheap a posteriori error estimators can be based on averaging techniques; see, e.g., [14, 29, 34, 35]. Error estimators for more general norms are very often based on duality techniques [10, 26]. Convergent adaptive algorithms without explicit knowledge of constants are proposed and analyzed in [19, 23].

Here, we propose a new approach which can be interpreted as a combination of equilibration and averaging techniques. The error estimator can be obtained locally and is based on a local subproblem for the flux. On each patch, we compute a

Raviart–Thomas finite element approximation. The error estimator is then defined in terms of the L^2-norm of the difference between the discrete flux approximation and the Raviart–Thomas finite element solution.

We consider the following elliptic second order boundary value problem with homogeneous Dirichlet boundary conditions on $\partial\Omega$:

$$-\text{div}\,(a\nabla p) = f \quad \text{on} \quad \Omega, \tag{1.1}$$

where $\Omega \subset \mathbb{R}^2$ is a bounded polygonal domain. The symmetric tensor a is assumed to be uniformly positive definite and $f \in L^2(\Omega)$. Associated with (1.1) is the symmetric bilinear form $a(p,q) := \int_\Omega \nabla q \cdot a\nabla p\, dx$.

To discretize (1.1), we use conforming finite elements of lowest order on a shape regular family of simplicial triangulations $\mathcal{T}_h$. We use standard nodal hat functions ϕ_x associated with the vertices of $\mathcal{T}_h$ to define V_h. Then, the hat functions associated with the interior vertices of $\mathcal{T}_h$ form a basis of the finite element space $V_h \subset H_0^1(\Omega)$. The weak solution of (1.1) is denoted by $p \in H_0^1(\Omega)$ and the discrete weak solution by $p_h \in V_h$. We assume that the tensor a restricted to $T \in \mathcal{T}_h$ is constant, and $a_D \in \mathbb{R}$ stands for the lower bound of the eigenvalues of a restricted to the subdomain $D \subset \Omega$. The space of polynomials of order less than or equal to $k \geq 0$ on D is denoted by $P_k(D)$. In the following the generic constants $0 < c, C < \infty$ do not depend on the mesh size but only on the shape regularity of the triangulations and possibly on the variation of the tensor a restricted to suitable local patches. We use the notation $y \equiv z$ as the abbreviation for the equivalence $cy \leq z \leq Cz$.

The rest of this paper is organized as follows. In section 2, we define a Raviart–Thomas finite element by solving local systems, and we introduce our a posteriori error estimator. Global upper and local lower bounds are established for the discretization error in the energy norm in section 3, where we also show the local equivalence with the jump term of the standard residual-based error estimator. In section 4, we introduce a postprocessed flux approximation. It can be shown that our error estimator is asymptotically exact for this discrete flux. Finally, in section 5, we provide some numerical results illustrating the performance of our approach.

2. An a posteriori error estimator. In this section, we introduce our a posteriori error estimator. It is based on a postprocessing of the finite element solution p_h. We consider a dual mesh $\mathcal{K}_h$ which is defined by the centers of gravity of the triangles and the midpoints of the edges; see Figure 2.1.

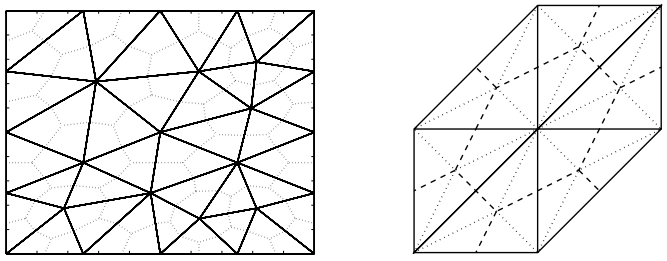

FIG. 2.1. *Primal $\mathcal{T}_h$ and dual $\mathcal{K}_h$ mesh (left) and local construction of the fine mesh $\mathcal{S}_h$ (right).*

The number of elements in the dual mesh $\mathcal{K}_h$ is equal to the number of vertices in the primal mesh $\mathcal{T}_h$. We denote the set of vertices of the primal mesh by $\mathcal{X}_h$. The left picture in Figure 2.1 shows the primal (solid lines) and the dual mesh (dashed

lines). We note that each $K \in \mathcal{K}_h$ is associated with one center vertex $x_K \in \mathcal{X}_h$. The corners of an element K of the dual mesh are the midpoints of the edges of the primal mesh which have the vertex x_K as an endpoint and the centers of gravity of all triangles $T \in \mathcal{T}_h$ with x_K as vertex. This dual mesh is well known and widely used in the context of finite volume methods, e.g., [24]. The intersection of the primal $\mathcal{T}_h$ and the dual $\mathcal{K}_h$ mesh yields a third mesh. To obtain a simplicial triangulation $\mathcal{S}_h$, we have to introduce additional edges. The elements $t \in \mathcal{S}_h$ are subtriangles of the elements $T \in \mathcal{T}_h$. Each element $T \in \mathcal{T}_h$ is decomposed into six subtriangles, as follows. The center of gravity of T is connected with the three vertices and with the three midpoints of the edges of T, yielding six subelements; see the right picture of Figure 2.1. By construction the area of each subelement t of T is equal, and thus $|t| = |T|/6$. Moreover, the number of elements of $\mathcal{S}_h$ is $6n_T$, where n_T is the number of elements in $\mathcal{T}_h$. The shape regularity of $\mathcal{S}_h$ follows from the shape regularity of $\mathcal{T}_h$. We note that the primal $\mathcal{T}_h$ and the fine $\mathcal{S}_h$ mesh are simplicial triangulations but that the dual mesh $\mathcal{K}_h$ is not. Figure 2.2 illustrates the construction of an element $K \in \mathcal{K}_h$.

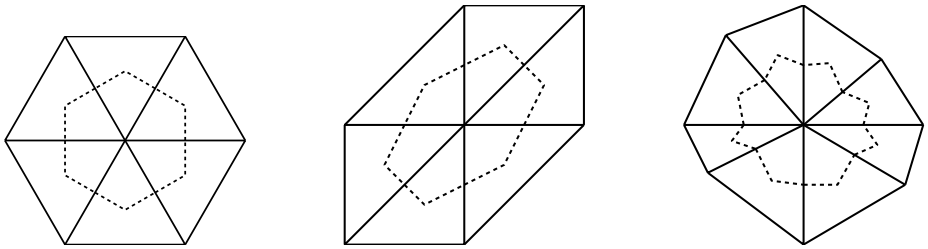

FIG. 2.2. *Different examples for an element* $K \in \mathcal{K}_h$.

We now can introduce a new finite element space U_h associated with the fine mesh $\mathcal{S}_h$. This new space is a subspace of $H(\text{div};\Omega) := \{v \in (L^2(\Omega))^2,\ \text{div}\ v \in L^2(\Omega)\}$ and is based on mixed finite elements. We denote by $RT_0(t)$ the local space of Raviart–Thomas finite elements of lowest order on t and by $RT_h \subset H(\text{div};\Omega)$ the global space of Raviart–Thomas finite elements of lowest order associated with the fine triangulation $\mathcal{S}_h$; see, e.g., [13, 27]. Locally the elements of RT_h can be written as $v_{|_t} = (a_t, b_t)^T + c_t(x, y)^T$ with some constants $a_t, b_t, c_t \in \mathbb{R}$, $t \in \mathcal{S}_h$. The finite element space U_h is defined by

$$U_h := \{v_h \in RT_h;\ \text{div}\ v_h \in Q_h\} \subset RT_h,$$

where $Q_h := \{v \in L^2(\Omega);\ v_{|_K} \in P_0(K), K \in \mathcal{K}_h\} \subset W_h := \{v \in L^2(\Omega);\ v_{|_t} \in P_0(t), t \in \mathcal{S}_h\}$. We denote by $\mathcal{E}_h$ the set of edges of the fine triangulation $\mathcal{S}_h$ which belong to the boundary ∂K of at least one element $K \in \mathcal{K}_h$, and we denote by $\mathcal{K}_h^0 \subset \mathcal{K}_h$ the subset of elements $K \in \mathcal{K}_h$ such that $\partial K \cap \partial\Omega = \emptyset$. Associated with the edge e is the unit vector n_e, which is orthogonal on e. The orientation is arbitrary but should be fixed. We define two local spaces $RT_K := \{v_h \in RT_h;\ \text{supp}\ v_h \subset \bar{K}\}$ and $W_K := \{w_h \in W_h;\ \text{supp}\ w_h \subset \bar{K}, \int_K w_h\, dx = 0\}$, $K \in \mathcal{K}_h$. Then it is well known that the differential operator $Lv := \text{div}\ v$ is a surjective mapping from RT_K onto W_K; see, e.g., [13]. Moreover, the dimension of its kernel is equal to one if $K \in \mathcal{K}_h^0$ and to zero if $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$. For each $K \in \mathcal{K}_h^0$, we set $w_K := \beta_K \text{curl}\ \psi_K$, where ψ_K is the nodal P1 conforming basis function associated with the vertex x_K and the fine triangulation $\mathcal{S}_h$, and the scaling parameter β_K is given by $\beta_K := (\text{curl}\ \psi_K, \text{curl}\psi_K)_0^{-0.5}$. It is easy

to verify that the support of w_K is K, div $w_K = 0$ and $(w_K, w_K)_0 = 1$. Given w_K, we define $w_e \in U_h$, $e \in \mathcal{E}_h$, by

$$w_e n_{\hat{e}|_{\hat{e}}} = \frac{1}{h_e}\delta_{e\hat{e}},\ \hat{e} \in \mathcal{E}_h, \quad \text{and} \quad (w_e, w_K)_0 = 0,\ K \in \mathcal{K}_h^0, \tag{2.1}$$

where h_e denotes the length of the edge e. We note that each $w_e \in U_h$ is uniquely defined by (2.1). Let $v_h^1, v_h^2 \in U_h$ satisfy (2.1); then $\Delta v_h := v_h^1 - v_h^2$ can be written as a linear combination of elements in RT_K, $K \in \mathcal{K}_h$, i.e.,

$$\Delta v_h = \sum_{K \in \mathcal{K}_h} v_K, \quad v_K \in RT_K.$$

Observing that $\mathrm{div} v_K \in P_0(K)$ and $\int_K \mathrm{div} v_K\, dx = 0$, we find that $\mathrm{div} v_K = 0$. The orthogonality on w_K yields $v_K = 0$. The existence follows now from the uniqueness and the dimension of the space. For each inner edge, we find that supp $w_e = \overline{K}_1 \cup \overline{K}_2$, $K_1, K_2 \in \mathcal{K}_h$ such that $e = \partial K_1 \cap \partial K_2$.

It is easy to see that w_e, $e \in \mathcal{E}_h$ and w_K, $K \in \mathcal{K}_h^0$ form a set of linear independent functions. Let w_h be an element of U_h; then $v_h := w_h - \sum_{e \in \mathcal{E}_h} \beta_e w_e \in U_h$ with $\beta_e := h_e w_h n_{e|_e}$. Moreover, by definition $v_h n_{e|_e} = 0$, $e \in \mathcal{E}_h$ and thus div $v_h = 0$. Observing that $v_{h|_K} \in U_h$, we find that $v_h \in$ span $\{w_K, K \in \mathcal{K}_h^0\}$. Thus w_e, $e \in \mathcal{E}_h$ and w_K, $K \in \mathcal{K}_h^0$ form a basis of U_h and

$$U_h = \sum_{e \in \mathcal{E}_h} \text{span } \{w_e\} \oplus \sum_{K \in \mathcal{K}_h^0} \text{span } \{w_K\}.$$

To introduce our error estimator, we define $u_h \in U_h$ in terms of p_h and f. Each element $u_h \in U_h$ can be written as a linear combination of the given basis functions, i.e., $u_h = \sum_{e \in \mathcal{E}_h} \alpha_e w_e + \sum_{K \in \mathcal{K}_h^0} \alpha_K w_K$. We set α_e and α_K,

$$\alpha_e := \int_e a \nabla p_h n_e\, d\sigma + \hat{\alpha}_{K_e}, \quad \alpha_K := \int_K a \nabla p_h\ w_K\ dx, \tag{2.2}$$

where $\hat{\alpha}_{K_e} := 0$ if $e \not\subset \partial\Omega$. Otherwise, we set

$$\hat{\alpha}_{K_e} := \frac{1}{2}\left(\int_\Omega -f \phi_{x_{K_e}}\ dx - \int_{\partial K_e} a \nabla p_h n_{K_e}\ d\sigma \right), \tag{2.3}$$

where K_e is the unique element of the dual mesh such that $e \subset \partial K_e \cap \partial\Omega$. By using the orthogonality between w_e and w_K and definition (2.2), we find

$$\int_K u_h w_K\ dx = \int_K a \nabla p_h w_K\ dx, \quad K \in \mathcal{K}_h^0. \tag{2.4}$$

The analysis of the properties of u_h is based on two operators P_Q and I_Q. For each $K \in \mathcal{K}_h$, we introduce two sets of edges $\mathcal{E}_K$, $\mathcal{E}_K^x$ and a set of triangles $\mathcal{S}_K := \{t \in \mathcal{S}_h;\ t \subset K\}$. The set of edges $\mathcal{E}_K$ contains all edges of the triangulation $\mathcal{S}_h$ which are in the interior of K, and the set of $\mathcal{E}_K^x$ is the union of all edges of the primal triangulation $\mathcal{T}_h$ having x_K as a vertex; see Figure 2.3. The edges in $\mathcal{E}_K^x$ are marked by dashed lines and the elements in $\mathcal{E}_K$ by solid lines.

We remark that the number of elements in $\mathcal{S}_K$ and $\mathcal{E}_K$ is the same for $K \in \mathcal{K}_h^0$. By definition, the divergence of u_h is constant on each element $K \in \mathcal{K}_h$. Moreover, it

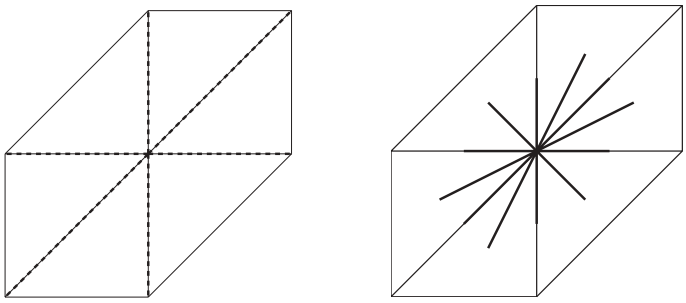

FIG. 2.3. *The two sets of edges $\mathcal{E}_K^x$ (left) and $\mathcal{E}_K$ (right).*

depends only on the right-hand side and can be obtained as a weighted mean value of f. To see this, we introduce two quasi-interpolants. The first, $P_Q : L^2(\Omega) \longrightarrow Q_h$, is defined in terms of a weighted mean value of v on K,

$$P_Q v_{|_K} := \frac{1}{|K|} \int_\Omega v \phi_{x_K} \, dx, \quad v \in L^2(\Omega),$$

where ϕ_{x_K} is the nodal P1 conforming basis function associated with the vertex x_K and the primal triangulation $\mathcal{T}_h$. If v is constant on each element $T \in \mathcal{T}_h$, then $P_Q v = \Pi_Q v$, where Π_Q denotes the L^2-projection on Q_h. The second, $I_Q : C(\Omega) \longrightarrow Q_h$, is given in terms of a nodal value,

$$I_Q v_{|_K} := v(x_K), \quad v \in C(\Omega).$$

It is easy to verify that

$$\int_\Omega w v_h \, dx = \int_\Omega P_Q w \; I_Q v_h \, dx, \quad v_h \in V_h, w \in L^2(\Omega). \tag{2.5}$$

Furthermore, we have the orthogonality relation

$$\int_\Omega q_h (I_Q - \mathrm{Id}) v_h \, dx = 0, \quad q_h \in W_h, v_h \in V_h, \tag{2.6}$$

where $W_h := \{v \in L^2(\Omega);\ v_{|_T} \in P_0(T), T \in \mathcal{T}_h\}$. This results from the fact that $|T \cap K| = 1/3|T|$ for each T such that $T \cap K$ has a nonzero measure. Additionally, the operators P_Q, I_Q satisfy a local approximation property in the L^2-norm,

$$\begin{aligned} \|v - I_Q v\|_{0;K} &\le C h_K |v|_{1;K}, \quad v \in V_h, \\ \|v - P_Q v\|_{0;K} &\le C h_K |v|_{1;\omega_K}, \quad v \in H^1(\Omega), \end{aligned}$$

where ω_K is the union of all elements $T \in \mathcal{T}_h$ such that K and T have a nonempty intersection. The first inequality results from a discrete norm equivalence. We next observe that $P_Q v = v$ on K if v is constant on ω_K. The second inequality is then a consequence of the L^2-stability of P_Q. In terms of P_Q, we find a relation between the divergence of u_h and f.

LEMMA 2.1. $\operatorname{div} u_h = -P_Q f$.

Proof. In a first step, we consider a $K \in \mathcal{K}_h^0$. The definition of the basis functions of U_h and (2.2) yield

$$\begin{aligned}\int_K \operatorname{div} u_h \, dx &= \int_{\partial K} u_h n_K \, d\sigma = \int_{\partial K} a\nabla p_h n_K \, d\sigma \\ &= \sum_{t\in\mathcal{S}_K} \int_{\partial t} a\nabla p_h n_t \, d\sigma - \sum_{e\in\mathcal{E}_K} \int_e [a\nabla p_h n_e] \, d\sigma,\end{aligned}$$

where the jump on e is defined by $[a\nabla p_h n_e] := (a\nabla p_{h|_{t_1}} - a\nabla p_{h|t_2})n_e$ and $\partial t_1 \cap \partial t_2 = e$ such that n_e is the outer unit normal on ∂t_1 and n_t is the outer unit normal on ∂t and n_K on ∂K. The first term on the right side is zero. Using the observation that $[a\nabla p_h n_e] = 0$ for each e which is an interior edge of a primal element $T \in \mathcal{T}_h$ and that the jump of the discrete flux is constant on each edge, we get

$$\begin{aligned}\int_K \operatorname{div} u_h \, dx &= -\frac{1}{2} \sum_{E\in\mathcal{E}_K^x} \int_E [a\nabla p_h n_E] \, d\sigma = - \sum_{E\in\mathcal{E}_K^x} \int_E [a\nabla p_h n_E]\phi_{x_K} \, d\sigma \\ &= - \sum_{T\in\mathcal{T}_K} \int_{\partial T} a\nabla p_h n_T \phi_{x_K} \, d\sigma = - \sum_{T\in\mathcal{T}_K} \int_T a\nabla p_h \nabla \phi_{x_K} \, dx \\ &= - \sum_{T\in\mathcal{T}_K} \int_T f\phi_{x_K} \, dx = - \int_\Omega f\phi_{x_K} \, dx = - \int_K P_Q f \, dx,\end{aligned}$$

where $\mathcal{T}_K$ contains all elements of $\mathcal{T}_h$ such that $K \cap T \neq \emptyset$. Using the definition (2.3), the assertion follows for $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$ from

$$\int_K \operatorname{div} u_h \, dx = \int_{\partial K} a\nabla p_h n_K \, d\sigma + 2\hat{\alpha}_K. \qquad \square$$

We define our a posteriori error estimator in terms of u_h. For each element K in $\mathcal{K}_h$, the local contribution is given by

$$\eta_K^2 := \|a^{-\frac{1}{2}}(u_h - a\nabla p_h)\|_{0;K}^2, \tag{2.7}$$

and the global error estimator is defined as $\eta^2 := \sum_{K\in\mathcal{K}_h} \eta_K^2$. This error estimator is related to averaging techniques, to the equilibrated residual method, and to a better flux approximation; see, e.g., [2, 3, 22, 28, 30]. It can be evaluated easily and is cheap. The coefficients of u_h with respect to the basis functions w_e and w_K are defined by scalar equations. To obtain the basis functions w_e, we have to solve low dimensional local systems on K.

However, it is more efficient to compute u_h directly as an element in RT_h. Working with a scaled nodal basis for Raviart–Thomas finite elements of lowest order, the coefficients of u_h can be obtained locally by solving for each K a low dimensional system. We denote by q_e the scaled nodal basis function of RT_h associated with the edge e. The scaling is done such that q_e satisfies, for all edges $\hat{e}$ of the fine triangulation $\mathcal{S}_h$,

$$(q_e n_{\hat{e}})_{|\hat{e}} = \frac{\delta_{e\hat{e}}}{h_e}.$$

The values of $u_h n_K$ on ∂K in combination with $\operatorname{div} u_h \in P_0(K)$ define u_h on $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$ uniquely. Moreover, for $K \in \mathcal{K}_h^0$, these properties define u_h up to a term

of the form $c_K \mathrm{curl}\, \psi_{x_K}$. Using the definition of the scaled nodal basis functions q_e and of w_e and $U_h \subset RT_h$, we find that u_h restricted to K can be written as $u_h = \sum_{e\subset\partial K} \alpha_e q_e + \sum_{e\in\mathcal{E}_K} \beta_e q_e$, where α_e is defined by (2.2). The coefficients β_e can now be obtained from the fact that div u_h is constant on K and from (2.4). We enumerate the small triangles and the edges in K clockwise. Let m_K be the number of triangles in $\mathcal{S}_K$. The edges on $\partial K \setminus \partial\Omega$ are denoted by $\hat{e}_i$ and the edges in the interior of K or on $\partial K \cap \partial\Omega$ by e_i. For $K \in \mathcal{K}_h$, t_i has the edges $\hat{e}_i$, e_i, and e_{i+1}, $1 \le i \le m_K$, where $e_{m_K+1} := e_1$ for $K \in \mathcal{K}_h^0$; see Figure 2.4. The orientation of the normals is chosen such that $-n_{e_i}$ is the outer normal on t_i and $n_{\hat{e}_i}$ is the outer normal on K.

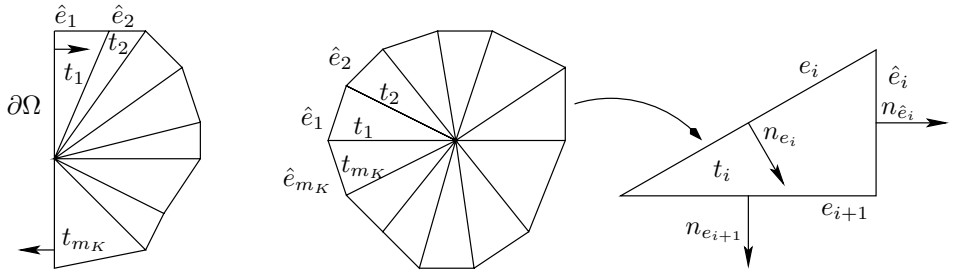

FIG. 2.4. *An element $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$ (left) and an element $K \in \mathcal{K}_h^0$ (right).*

In the case of $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$, we have to find β_{e_i}, $2 \le i \le m_K$, and for $K \in \mathcal{K}_h^0$, we have to find β_{e_i}, $1 \le i \le m_K$. In a first step, we define coefficients γ_i, $2 \le i \le m_K$, such that

$$\begin{pmatrix} 1 & 0 & \cdots & \cdots & \cdots & 0 \\ -1 & 1 & 0 & \cdots & \cdots & 0 \\ 0 & -1 & 1 & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & \ddots & \ddots & \\ 0 & \ddots & & \ddots & \ddots & 0 \\ 0 & \cdots & \cdots & 0 & -1 & 1 \end{pmatrix} \begin{pmatrix} \gamma_2 \\ \gamma_3 \\ \vdots \\ \vdots \\ \vdots \\ \gamma_{m_K} \end{pmatrix} = \begin{pmatrix} b_1 \\ b_2 \\ \vdots \\ \vdots \\ \vdots \\ b_{m_K-1} \end{pmatrix},$$

where the right side b depends only on p_h and f. We set

$$b_i := -P_Q f(x_K)|t_i| - \alpha_{\hat{e}_i} + d_K \delta_{i1} \alpha_{e_1},$$

where $d_K = 0$ if $K \in \mathcal{K}_h^0$ and $d_K = 1$ if $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$. For this choice, we find div u_h = div $\tilde{u}_h$, where $\tilde{u}_h := \sum_{i=1}^{m_K} \alpha_{\hat{e}_i} q_{\hat{e}_i} + \sum_{i=2}^{m_K} \gamma_i q_{e_i} + d_K(\alpha_{e_1} q_{e_1} + \alpha_{e_{m_K+1}} q_{e_{m_K+1}})$, and $\tilde{u}_h n_K = u_h n_K$ restricted on ∂K. We recall that Lemma 2.1 yields $\sum_{i=1}^{m_K} \alpha_{\hat{e}_i} = -P_Q f(x_K)|K|$, $K \in \mathcal{K}_h^0$, and $\sum_{i=1}^{m_K} \alpha_{\hat{e}_i} - \alpha_{e_1} + \alpha_{e_{m_K+1}} = -P_Q f(x_K)|K|$, $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$. Due to the uniqueness of u_h, we get that $u_h = \tilde{u}_h$ on $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$ and $u_h = \tilde{u}_h + \gamma_K w_K$ on $K \in \mathcal{K}_h^0$, where γ_K is given by

$$\gamma_K := \int_K (a\nabla p_h - \tilde{u}_h) w_K \, dx.$$

Remark 2.2. We note that in the more general case of Neumann boundary conditions with data g_N, we have to add the term $h_e/a_{t_e} \|a\nabla p_h - g_N\|_{0;e}^2$, where $e = t_e \cap \partial\Omega$ to our estimator. This term is well known for the standard residual-based error estimator.

3. Upper and lower bounds for the discretization error. In this section, we establish upper and lower bounds for the discretization error in terms of the error estimator. The following theorem provides an upper bound for the error in the energy norm in terms of the error estimator. To start, we introduce a higher order term

$$\xi^2 := \sum_{K\in\mathcal{K}_h} \frac{h_K^2}{a_K}\|f - P_Q f\|_{0;K}^2 + \sum_{T\in\mathcal{T}_h} \frac{h_T^2}{a_T}\|f - \Pi_W f\|_{0;T}^2,$$

where Π_W denotes the L^2-projection on W_h.

THEOREM 3.1. *The error in the energy norm is bounded by*

$$|\!|\!| e_h |\!|\!| := a(p - p_h, p - p_h)^{\frac{1}{2}} \le \eta + C\xi.$$

Proof. Integration by parts and Lemma 2.1 yield for the error in the energy norm

$$\begin{aligned}
|\!|\!| e_h |\!|\!|^2 &= \int_\Omega (a\nabla p - u_h + u_h - a\nabla p_h)(\nabla p - \nabla p_h)\ dx \\
&= \int_\Omega \operatorname{div}\ (a\nabla p - u_h)(p_h - p)\ dx + \int_\Omega (u_h - a\nabla p_h)(\nabla p - \nabla p_h)\ dx \\
&\le \|a^{-\frac{1}{2}}(u_h - a\nabla p_h)\|_0 |\!|\!| e_h |\!|\!| + \int_\Omega (f - P_Q f)(p - p_h)\ dx.
\end{aligned}$$

We now have to consider the second term on the right side in more detail. Using the projection operator P_h of Scott and Zhang [21] and the identity (2.5), we find

$$\begin{aligned}
\int_\Omega (f - P_Q f)(p - p_h)\ dx &= \int_\Omega (f - P_Q f)(p - p_h - P_h(p - p_h))\ dx \\
&\quad + \int_\Omega (f - P_Q f) P_h(p - p_h)\ dx \\
&\le C \sum_{K\in\mathcal{K}_h} h_K \|f - P_Q f\|_{0;K} \|\nabla p - \nabla p_h\|_{0;\tilde{\omega}_K} \\
&\quad + \int_\Omega P_Q f (I_Q - \mathrm{Id}) P_h(p - p_h)\ dx,
\end{aligned}$$

where $\tilde{\omega}_K$ is a suitable local neighborhood of K. The number of elements $T \subset \tilde{\omega}_K$ is bounded independently of the mesh size. In terms of the orthogonality (2.6), the second term can be bounded by

$$\begin{aligned}
\int_\Omega P_Q f (I_Q - \mathrm{Id}) P_h(p - p_h)\ dx &= \int_\Omega (P_Q f - \Pi_W f)(I_Q - \mathrm{Id}) P_h(p - p_h)\ dx \\
&\le \sum_{K\in\mathcal{K}_h} h_K \|\Pi_W f - P_Q f\|_{0;K} |P_h(p - p_h)|_{1;K}.
\end{aligned}$$

The definition of the energy norm and the H^1-stability of P_h yield

$$|\!|\!| e_h |\!|\!| \le \eta + C\left(\sum_{K\in\mathcal{K}_h} \frac{h_K^2}{a_K}\|f - P_Q f\|_{0;K}^2 + \sum_{T\in\mathcal{T}_h} \frac{h_T^2}{a_T}\|f - \Pi_W f\|_{0;T}^2\right)^{\frac{1}{2}}.$$

We remark that ξ is a higher order term and can be neglected asymptotically. ∎

For a reliable and efficient error estimator, it is not sufficient to guarantee a global upper bound for the discretization error. Additionally, we have to consider the local contributions of the error estimator. We define for each edge $e \in \mathcal{E}_K$ the coefficient a_e by $a_e := 0.5(a_{t_1} + a_{t_2})$ if $e = \partial t_1 \cap \partial t_2$, $t_1, t_2 \in \mathcal{S}_h$ and $a_e := a_t$ if $e = \partial t \cap \partial\Omega$, $t \in \mathcal{S}_h$.

LEMMA 3.2. *The local contribution η_K, $K \in \mathcal{K}_h^0$, of the error estimator is equivalent to the jump of the discrete flux $a\nabla p_h$, i.e.,*

$$c \sum_{e \in \mathcal{E}_K} \frac{h_e}{a_e} \|[a\nabla p_h]\|_{0;e}^2 \le \eta_K^2 \le C \sum_{e \in \mathcal{E}_K} \frac{h_e}{a_e} \|[a\nabla p_h]\|_{0;e}^2, \quad K \in \mathcal{K}_h^0.$$

Proof. To obtain the lower bound, we use a discrete norm equivalence for lowest order Raviart–Thomas finite elements. The L^2-norm of $v \in RT_0(t)$ on $t \in \mathcal{S}_h$ is equivalent to a weighted L^2-norm on ∂t of the normal component

$$c\|v\|_{0,t}^2 \le \sum_{e \subset \partial t} h_e \|v n_e\|_{0;e}^2 \le C\|v\|_{0,t}^2, \quad v \in RT_0(t). \tag{3.1}$$

Using this norm equivalence and observing that locally $a\nabla p_{h|_t}$ is in $RT_0(t)$, we find for $K \in \mathcal{K}_h$

$$\begin{aligned}
\eta_K^2 &= \sum_{t \in \mathcal{S}_K} \|a^{-\frac{1}{2}}(u_h - a\nabla p_h)\|_{0;t}^2 \equiv \sum_{t \in \mathcal{S}_K} \frac{h_t}{a_t} \|(u_h - a\nabla p_h) n_t\|_{0;\partial t}^2 \\
&\equiv \sum_{e \in \mathcal{E}_K} \frac{h_e}{a_e} \left(\|[(u_h - a\nabla p_h) n_e]\|_{0;e}^2 + \|\{u_h - a\nabla p_h\} n_e\|_{0;e}^2 \right) \\
&\quad + \sum_{e \subset \partial K} \frac{h_e}{a_e} \|(u_h - a\nabla p_h) n_K\|_{0;e}^2,
\end{aligned}$$

where $[\cdot]$ denotes the jump and $\{\cdot\}$ denotes the average over the edge e. The orientation is arbitrary but should be fixed. By definition, $u_h n_K = a\nabla p_h n_K$ on $\partial K \setminus \partial\Omega$. Thus, in the second term on the right-hand side, we can replace the sum by $\sum_{e \subset \partial K \cap \partial\Omega}$. Observing that $u_h \in H(\mathrm{div}\,;\Omega)$ results in $[u_h n_e] = 0$, we find

$$\eta_K^2 \equiv \sum_{e \in \mathcal{E}_K} \frac{h_e}{a_e} \left(\|[a\nabla p_h n_e]\|_{0;e}^2 + \|\{u_h - a\nabla p_h\} n_e\|_{0;e}^2 \right) + \frac{\hat{\alpha}_K^2}{a_K}. \tag{3.2}$$

This norm equivalence guarantees the lower bound for η_K^2. To establish the upper bound, it is sufficient to bound $\hat{\alpha}_K$ and $\|\{u_h - a\nabla p_h\} n_e\|_{0;e}$. Let K be in $\mathcal{K}_h^0$; then $\partial K \cap \partial\Omega = \emptyset$ and $\hat{\alpha}_K = 0$. In a first step, we introduce $w_h \in RT_h$ locally on K by

$$w_h n_K = a\nabla p_h n_K \quad \text{on} \quad \partial K, \quad w_h n_e = \{a\nabla p_h n_e\} \quad \text{on} \quad e \in \mathcal{E}_K.$$

Then, in general, div w_h is not constant on K and thus $w_h \notin U_h$. We can now decompose u_h restricted to K in terms of w_h by $u_h = w_h + v_h$ and find

$$\sigma_{\text{average}}^2 := \sum_{e \in \mathcal{E}_K} \frac{h_e}{a_e} \|\{u_h - a\nabla p_h\} n_e\|_{0;e}^2 = \sum_{e \in \mathcal{E}_K} \frac{h_e}{a_e} \|v_h n_e\|_{0;e}^2 \le C\|a^{-\frac{1}{2}} v_h\|_{0;K}^2.$$

The number of elements t in K is bounded independently of the mesh size. The bound depends only on the shape regularity of the triangulation. A generalized Poincaré–

Friedrichs-type inequality for Raviart–Thomas elements yields

$$\|a^{-\frac{1}{2}} v_h\|_{0;K}^2 \le C \sum_{t\in\mathcal{S}_K} \frac{|t|}{a_t} \|\text{div } v_h\|_{0;t}^2 + \frac{C}{a_K} \left(\int_K v_h w_K \, dx \right)^2$$
$$= C \sum_{t\in\mathcal{S}_K} \frac{|t|}{a_t} \|\text{div } (u_h - w_h)\|_{0;t}^2 + \frac{C}{a_K} \left(\int_K v_h w_K \, dx \right)^2.$$

To obtain the first inequality, we used $v_h n_K = 0$ on ∂K. In a next step, we consider the two terms on the right-hand side separately. We start with the second term and find

$$\left(\int_K v_h w_K \, dx \right)^2 = \left(\int_K (a\nabla p_h - w_h) w_K \, dx \right)^2 \le \|a\nabla p_h - w_h\|_{0;K}^2.$$

Using the definition of w_h, we obtain that $(a\nabla p_h - w_h)_{|t} \in RT_0(t)$ and that the normal component depends only on the jump of $a\nabla p_h n$. Thus, the L^2-norm of $a\nabla p_h - w_h$ can be bounded by the jump, and we get

$$\frac{1}{a_K} \left(\int_K v_h w_K \, dx \right)^2 \le C \sum_{e\in\mathcal{E}_K} \frac{h_e}{a_e} \|[a\nabla p_h n_e]\|_{0;e}^2.$$

We note that each element $t \in \mathcal{S}_K$ has at least one edge such that $[a\nabla p_h n_e] = 0$. This results from the fact that p_h is linear on the triangles of the primal mesh. Let $e_1 := \partial t \cap \partial K$, e_3 stands for the edge of t which is a subset of an edge in $\mathcal{E}_K^p$, and e_2 is the edge of ∂t in the interior of a $T \in \mathcal{T}_h$; see Figure 3.1.

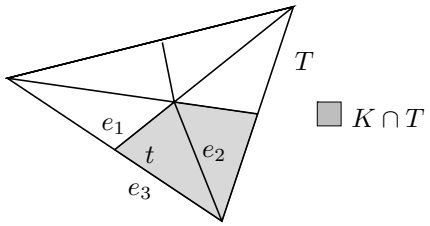

FIG. 3.1. *Numeration of the three edges of ∂t.*

We then get for the divergence of w_h on t,

$$|t| \, \|\text{div } w_h\|_{0;t}^2 = \left(\int_t \text{div } w_h \, dx \right)^2 = \left(\sum_{i=1}^3 \int_{e_i} w_h n_t \, d\sigma \right)^2$$
$$= \left(\int_{e_1} a\nabla p_h n_t \, d\sigma + \int_{e_2} a\nabla p_h n_t \, d\sigma + \int_{e_3} \{a\nabla p_h n_t\} \, d\sigma \right)^2$$
$$= \left(\int_{\partial t} a\nabla p_h n_t \, d\sigma - \frac{1}{2} \int_{e_3} [a\nabla p_h n_t] \, d\sigma \right)^2 = \frac{h_{e_3}}{4} \|[a\nabla p_h n_{e_3}]\|_{0;e_3}^2.$$

In terms of the jump and the divergence of u_h, we can now bound $\sigma^2_{\text{average}}$ by

$$\sigma^2_{\text{average}} \le C \left(\sum_{t\in\mathcal{S}_K} \frac{|t|}{a_t} \|\text{div } u_h\|_{0;t}^2 + \sum_{e\in\mathcal{E}_K} \frac{h_e}{a_e} \|[a\nabla p_h n_e]\|_{0;e}^2 \right).$$

In a last step, we have to consider the divergence of u_h in more detail. To bound div u_h, we use the proof of Lemma 2.1 and the fact that it is constant on K. We find that

$$\sum_{t\in\mathcal{S}_K}\frac{|t|}{a_t}\|\text{div } u_h\|^2_{0;t} \le \sum_{t\in\mathcal{S}_K}\frac{1}{a_t}\left(\int_K \text{div } u_h\, dx\right)^2$$
$$\le C\sum_{t\in\mathcal{S}_K}\frac{1}{a_t}\left(\sum_{e\in\mathcal{E}_K}\int_e [a\nabla p_h n_e]\, d\sigma\right)^2 \le C\sum_{e\in\mathcal{E}_K}\frac{h_e}{a_e}\|[a\nabla p_h n_e]\|^2_{0;e}. \square$$

We note that the jump of the discrete flux $a\nabla p_h n_e$ is one component of the standard residual-based error estimator; see, e.g., [33]. In particular, this term can be bounded locally by the exact error and a higher order term. Moreover, we find that $\eta_K = 0$, $K \in \mathcal{K}_h^0$ if and only if p_h is linear on K. The second term in the standard residual error estimator is a weighted L^2-norm of $\Pi_W f$. An inverse estimate for Raviart–Thomas finite elements yields

$$\eta_K^2 \ge C\sum_{t\in\mathcal{S}_K}\frac{h_t^2}{a_t}\|\text{div } (u_h - a\nabla p_h)\|^2_{0;t} \ge C\frac{h_K^2}{a_K}\|P_Q f\|^2_{0;K}.$$

By means of Lemma 3.2, we find that $h_K^2/a_K\|P_Q f\|^2_{0;K}$, $K \in \mathcal{K}_h^0$, is bounded by the jump of the discrete flux approximation $a\nabla p_h$. We cannot establish this result for an element $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$. The following lemma provides an equivalence for these elements of the dual mesh.

LEMMA 3.3. *The local contribution η_K, $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$, of the error estimator is equivalent to*

$$c\eta_K^2 \le \frac{h_K^2}{a_K}\|P_Q f\|^2_{0;K} + \sum_{e\in\mathcal{E}_K}\frac{h_e}{a_e}\|[a\nabla p_h n_e]\|^2_{0;e} \le C\eta_K^2, \quad K \in \mathcal{K}_h \setminus \mathcal{K}_h^0.$$

Proof. The starting point for the lower bound is the norm equivalence (3.1). We recall that if $w_h \in U_h$ and div $w_h = 0$ on $K \in \mathcal{K}_h \setminus \mathcal{K}_h^0$ and $w_h n_K = 0$ on ∂K, then $w_h = 0$. Due to the shape regularity, the number of elements t in K is bounded, and thus we obtain

$$\eta_K^2 \le C\sum_{t\in\mathcal{S}_K}\frac{1}{a_t}\|u_h - a\nabla p_h\|^2_{0;t}$$
$$\le C\left(\sum_{t\in\mathcal{S}_K}\frac{h_t^2}{a_t}\|\text{ div } u_h\|^2_{0;t} + \sum_{e\in\mathcal{E}_K}\frac{h_e}{a_e}\|[a\nabla p_h n_e]\|^2_{0;e} + \frac{\hat{\alpha}_K^2}{a_K}\right)$$
$$\le C\left(\frac{h_K^2}{a_K}\|P_Q f\|^2_{0;K} + \sum_{e\in\mathcal{E}_K}\frac{h_e}{a_e}\|[a\nabla p_h n_e]\|^2_{0;e} + \frac{\hat{\alpha}_K^2}{a_K}\right).$$

We now have to consider $\hat{\alpha}_K$ in more detail:

$$\begin{aligned}\hat{\alpha}_K^2 &\le \left(\int_K P_Q f \; dx + \int_{\partial K} a\nabla p_h n_K \; d\sigma\right)^2 \\ &= \left(\int_K P_Q f \; dx + \sum_{t\in\mathcal{S}_K}\int_{\partial t} a\nabla p_h n_t \; d\sigma - \sum_{e\in\mathcal{E}_K}\int_e [a\nabla p_h n_e] \; d\sigma\right)^2 \\ &\le C\left(h_K^2\|P_Q f\|_{0;K}^2 + \sum_{e\in\mathcal{E}_K} h_e\|[a\nabla p_h n_e]\|_{0;e}^2\right).\end{aligned}$$

The upper bound can be easily established by using the norm equivalence (3.2), the definition (2.3), and the observation that $\int_{\partial K} a\nabla p_h n_K \; d\sigma$ is bounded by the jump. As a consequence, we find that the weighted L^2-norm of $P_Q f$ on K can be bounded by a weighted sum of the boundary term $|\hat{\alpha}_K|$ and the jump. ∎

By using Lemmas 3.2 and 3.3, we find that our error estimator can be bounded locally, up to higher order terms, by the discretization error.

THEOREM 3.4. *The local contribution η_K of the error estimator can be bounded locally by the exact discretization error*

$$\eta_K \le C\left(|\!|\!| e_h |\!|\!|_K + \frac{h_K^2}{a_K}\|f - P_Q f\|_{0;K}\right).$$

Proof. We do not provide details. Using Lemmas 3.2 and 3.3, it is sufficient to bound the jump terms and $P_Q f$. This can be done by standard techniques; see, e.g., [3, 8, 33]. To get the local bound on K for the jump, we have to use quadratic edge bubble functions associated with the small edges $e \in \mathcal{E}_K$. ∎

Remark 3.5. Although the starting point for the construction of our error estimator is quite different from an equilibrated error estimator, we can interpret our estimator in that framework. In the case of an equilibrated error estimator, a linear approximation of the flux is locally computed in a postprocessing step on each edge. This can be done by using biorthogonal basis functions and solving, for each vertex, a low dimensional system; see, e.g., [30]. Here, we use an approximation of the flux by Raviart–Thomas elements. Each edge of the primal triangulation is decomposed into two subedges, and for each subedge we compute a constant approximation of the flux. As in the equilibrated situation, we have two degrees of freedom per edge and the arising linear system has the same algebraic structure.

4. A postprocessed flux approximation. In this section, we introduce a postprocessing step. To start, we define an approximation of the flux by

$$u_h^p := \frac{a\nabla p_h + u_h}{2}. \tag{4.1}$$

The following theorem guarantees that our error estimator is asymptotically exact for the flux u_h^p.

THEOREM 4.1. *There exists a constant $0 < C < \infty$ independent of the mesh size such that for all $\epsilon > 0$*

$$\frac{1}{4}(1-\epsilon)\eta^2 - C\left(1+\frac{1}{\epsilon}\right)\xi^2 \le \|a^{\frac{1}{2}}\nabla p - a^{-\frac{1}{2}}u_h^p\|_0^2 \le \frac{1}{4}(1+\epsilon)\eta^2 + C\left(1+\frac{1}{\epsilon}\right)\xi^2.$$

Proof. We start with the definition of the approximation u_h^p and set $u := a\nabla p$,

$$\begin{aligned} 4\|a^{\frac{1}{2}}\nabla p - a^{-\frac{1}{2}}u_h^p\|_0^2 &= \|a^{\frac{1}{2}}(\nabla p - \nabla p_h) + a^{-\frac{1}{2}}(u - u_h)\|_0^2 \\ &= \|a^{\frac{1}{2}}(\nabla p - \nabla p_h)\|_0^2 + \|a^{-\frac{1}{2}}(u - u_h)\|_0^2 + 2(\nabla p - \nabla p_h, u - u_h)_0 \\ &= \|a^{\frac{1}{2}}\nabla p_h - a^{-\frac{1}{2}}u_h\|_0^2 + 4(\nabla p - \nabla p_h, u - u_h)_0 \\ &= \eta^2 + 4\int_\Omega (f - P_Q f)(p - p_h)\, dx. \end{aligned}$$

Using Theorem 3.1 and the results of its proof, the second term on the right side can be bounded by

$$-C(\eta + C\xi)\xi \le 4\int_\Omega (f - P_Q f)(p - p_h)\, dx \le C(\eta + C\xi)\xi.$$

Young's inequality provides upper and lower bounds,

$$\eta^2 - \epsilon\eta^2 - 4C\left(1 + \frac{1}{\epsilon}\right)\xi^2 \le 4\|a^{\frac{1}{2}}\nabla p - a^{-\frac{1}{2}}u_h\|_0^2 \le \eta^2 + \epsilon\eta^2 + 4C\left(1 + \frac{1}{\epsilon}\right)\xi^2. \qquad \square$$

We note that ξ, compared to η, is a higher order term which can be neglected asymptotically. If $f \in H^s(\Omega)$, $0 < s \le 1$, we find that ξ is of order h^{1+s}. Setting $\epsilon = h^s$ and assuming $\eta \ge ch$, we obtain

$$1 - \mathcal{O}(h^s) \le \frac{4\|a^{\frac{1}{2}}\nabla p - a^{-\frac{1}{2}}u_h^p\|_0^2}{\eta^2} \le 1 + \mathcal{O}(h^s).$$

Remark 4.2. The term $a_e/h_e\|p_h - g_D\|_{0;e}^2$, $e \subset \partial\Omega$, enters into the a posteriori estimates, in the case of nonhomogeneous Dirichlet boundary conditions g_D. If the boundary data is smooth enough, this is also a higher order term which can be neglected asymptotically.

Figure 4.1 illustrates the postprocessing in the case that $P_Q f = f$ and homogeneous Dirichlet boundary conditions. In that case, we have $2\|a^{\frac{1}{2}}\nabla p - a^{-\frac{1}{2}}u_h^p\|_0 = \eta$.

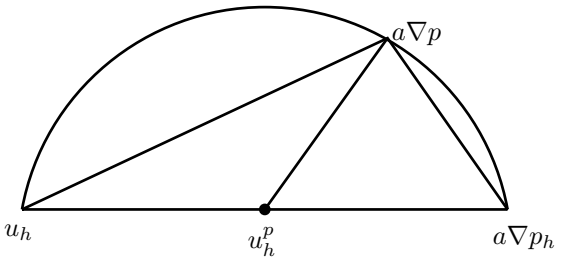

FIG. 4.1. *The discrete flux u_h and the postprocessed flux u_h^p.*

We note that our approach is not restricted to conforming finite elements of lowest order in two dimensions. It can be extended to higher order elements by using higher order Raviart–Thomas finite elements, to the three-dimensional situation and to nonconforming finite elements. However, the construction is then more technical. Nonconforming Crouzeix–Raviart elements are of special interest. Residual- and averaging-based a posteriori error estimators for nonconforming finite elements can

be found in [15, 16, 17]. We do not work out all the details but only point out the basic ideas. In this situation, the construction of a dual mesh is very simple. Each edge of the primal mesh is associated with an element of the dual mesh; see Figure 4.2. The elements of the primal mesh are marked by solid lines and those of the dual and fine mesh by dashed lines, respectively. The shadowed region in the left picture shows an element of the dual mesh.

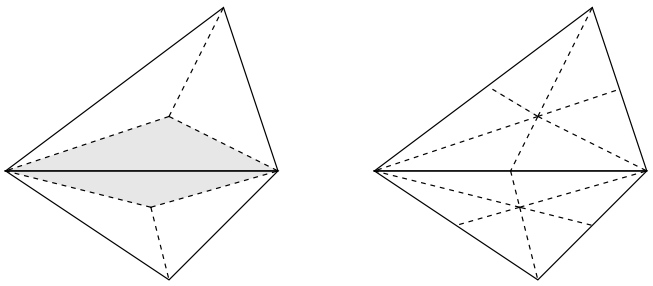

FIG. 4.2. *Primal and dual mesh (left) and primal and fine mesh (right).*

Proceeding as in the conforming setting yields a locally defined Raviart–Thomas finite element of lowest order. However, there is one essential difference. In contrast to conforming finite elements, the Crouzeix–Raviart finite element solution p_h is, in general, not continuous. Thus, applying integration by parts produces an additional term. This term reflects the nonconformity of the finite element solution and can be bounded by the weighted L^2-norm of the jump of p_h. As a consequence, we find that the discretization error cannot be bounded by $\|a^{-\frac{1}{2}}(u_h - a\nabla p_h)\|_0^2$. We must add one term to bound the discretization error from above and below, and we can define the local component of the error estimator on K by

$$\|a^{-\frac{1}{2}}(u_h - a\nabla p_h)\|_{0;K}^2 + \frac{a_{e_K}}{h_{e_K}}\|[p_h]\|_{0;e_K}^2,$$

where e_k is the edge of the primal triangulation which is associated with K. Upper and lower bounds with constants independent of the mesh size can be established. Unfortunately, we cannot guarantee that the upper constant in the bound is one. However, a sharper result can be found in [1]. Here, the same patch as in the conforming situation is used to construct a local error estimator. To estimate the nonconformity, a smoothing step must be carried out; see [1] for details. It can be easily verified that the difference between the nonconforming finite element solution p_h and the smoothed solution is locally equivalent to the jump of p_h on the edges.

5. Numerical results. In this section, we show some numerical results illustrating the efficiency of our error estimator. We provide the global ratio between the exact discretization error and the error estimator for different test examples. Additionally, we consider the local ratio on each element of the dual mesh. The adaptive refinement process is controlled by a standard mean value strategy. We start with an initial coarse triangulation and show the adaptively generated triangulations. We denote the square of the different error components by

$$e_p := \left\|a^{\frac{1}{2}}(\nabla p - \nabla p_h)\right\|_0^2, \quad e_{p;K} := \left\|a^{\frac{1}{2}}(\nabla p - \nabla p_h)\right\|_{0,K}^2,$$
$$e_u := \left\|a^{\frac{1}{2}}\nabla p - a^{-\frac{1}{2}}u_h^p\right\|_0^2, \quad e_{u,K} := \left\|a^{\frac{1}{2}}\nabla p - a^{-\frac{1}{2}}u_h^p\right\|_{0,K}^2.$$

In the case of inhomogeneous Dirichlet boundary conditions, we set

$$e_\Gamma := \sum_{e\in\partial\Omega} \frac{a_e}{h_e} \|p - p_h\|^2_{0;e}\,.$$

To compute the error contributions, we use on each element of the fine triangulation $\mathcal{S}_h$ a Gaussian quadrature formula of higher order or a semianalytical integration scheme if ∇p has a singularity. We note that asymptotically the quadrature error can be neglected. To illustrate the performance of the a posteriori error estimator, we consider the ratio between the exact and the estimated error. We set $\sigma_p := \sqrt{e_p}/\eta$ and $\sigma_u := 2\sqrt{e_u}/\eta$.

In our first example, Table 5.1, we use $\Omega := (0,1)^2$, $a = 1$. The source term and the boundary condition are chosen to match the exact solution:

$$p(x,y) = x(x-1)y(y-1)\exp\left(-100\left(x-\frac{1}{2}\right)^2 - 100\left(y-\frac{117}{1000}\right)^2\right).$$

We observe that σ_u tends asymptotically to one, as predicted by our theory. The ratio between η and $\sqrt{e_p}$ is asymptotically ≈ 0.80. We remark that on the coarse levels, the error e_p is underestimated by the error estimator. This is because the higher order term ξ^2 is dominant at the beginning. The last column of the table shows that ξ^2 can be neglected asymptotically. We recall that ξ^2 measures the quality of the approximation of the right-hand side by the triangulation and has to be controlled during the adaptive refinement process.

Figure 5.1 shows the local distribution of the different error terms and the adaptively generated triangulations on level six. The left and middle pictures have the same scaling and compare the local contribution between η_K^2 and $4e_{u,K}$. To compare η_K^2 and $e_{p,K}$, a rescaling is carried out. It shows that our error estimator captures the local distribution of the error very well.

In the second example, we use an L-shaped domain and set the exact solution of the inhomogeneous Dirichlet problem to be $p = r^{2/3}\sin(2/3\theta)$, where (r,θ) are the polar coordinates and the center is located at the corner of the L-shaped domain. Here, the geometry of the domain and the singularity of the solution at the corner dominate the adaptive refinement process. We note that the higher order term ξ^2 is

18942	$8.830\ 10^{-5}$	$5.066\ 10^{-5}$	0.758	$2.208\ 10^{-5}$	1.000	$1.096\ 10^{-7}$

zero but that we have a nontrivial boundary contribution e_Γ due to the inhomogeneous Dirichlet boundary condition.

Table 5.2 reports the values of the different error terms. Since $f = 0$ and thus $\xi^2 = 0$, we show the influence of the inhomogeneous Dirichlet condition in the last column of Table 5.2. We note that e_Γ does not decrease if no element touching the boundary is refined in the next adaptive step. Compared to η^2, the boundary term e_Γ is of smaller magnitude. The ratio between e_Γ and η^2 tends slowly to zero with the increasing number of refinement steps. During the adaptive refinement process, we have to control this additional term.

From the beginning, σ_u is close to one. The ratio between e_p and η^2 is increasing but it is bounded by one. In this example the asymptotic rate starts late and cannot be observed. We note that the asymptotic ratio σ_u is independent of the problem setting, whereas σ_p depends on the given data. Our theoretical results yield that asymptotically $0 < c \leq \sigma_p \leq 1$.

In Figure 5.2, the local distribution of the errors is given for Example 2. As expected, the highest value is located at the corner singularity. In the case of η_K^2 and $4e_{u,K}$ the scaling is the same, and the local values are quite close.

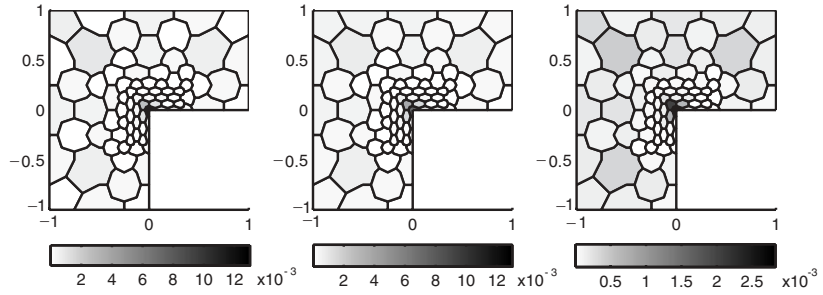

FIG. 5.2. *Example* 2: *Local contributions of the error estimator* η_K^2 *(left), the postprocessed error* $4e_{u,K}$ *(middle), and the error* $e_{p,K}$ *(right).*

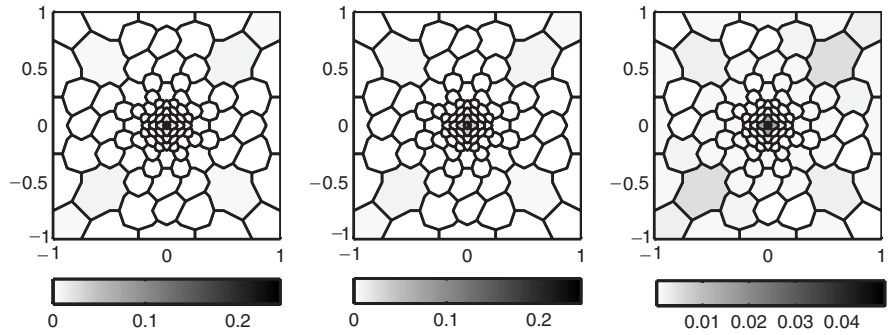

FIG. 5.3. *Example* 3: *Local contributions of the error estimator* η_K^2 *(left), the postprocessed error* $4e_{u,K}$ *(middle), and the error* $e_{p,K}$ *(right).*

In the following example, we use a discontinuous coefficient. The domain Ω is decomposed into four subdomains, $\Omega_{ij} := (-i, -i+1) \times (-j, -j+1)$, $0 \le i, j \le 1$. On each subdomain a constant coefficient a_{ij} is used. We set $a_{10} := a_{01}$, $a_{00} := a_{11}$ and assume that the analytical solution has the form $p = r^\alpha(\beta_{ij}\sin(\alpha\theta)+\gamma_{ij}\cos(\alpha\theta))$, where (r, θ) are the polar coordinates in Ω and β_{ij}, γ_{ij} are constants depending on the subdomains Ω_{ij}. The interface conditions $[p] = 0$ and $[a\nabla p] = 0$ yield $-\mathrm{div}(a\nabla p) = 0$. The coefficients α, β_{ij}, γ_{ij} are uniquely defined in terms of a_{01} and a_{00}. In the case $a_{01} := 1$, $a_{00} := 5$, we find $\alpha = 0.53544094560$, $\beta_{10} = -0.7453559925$, $\gamma_{10} = 2.333333333$, $\beta_{00} = 0.4472135955$, $\gamma_{00} = 1$, $\beta_{11} = -0.9441175905$, $\gamma_{11} = 0.555555556$, $\beta_{01} = -2.401702643$, and $\gamma_{01} = -0.4814814815$.

We report the numerical results for e_p, e_u, and e_Γ in Table 5.3. The ratio σ_u tends asymptotically to one as in the other examples. In contrast to our first example, it is close to one from the first step on. This is due to the fact that $\xi = 0$ and that e_Γ is of smaller magnitude.

Figure 5.3 shows that the local error estimator captures very well the location and the amplitude of the singularity. The isolines of the solution are given in the right picture of Figure 5.4.

In all our examples the local contributions of $4e_{u,K}$ and η_K^2 are quite close; see Figures 5.1–5.3. The error estimator captures the local contributions of $e_{u,K}$ better than the ones of $e_{p,K}$. We note that we compare the local contributions on the dual mesh and not on the primal triangulation.

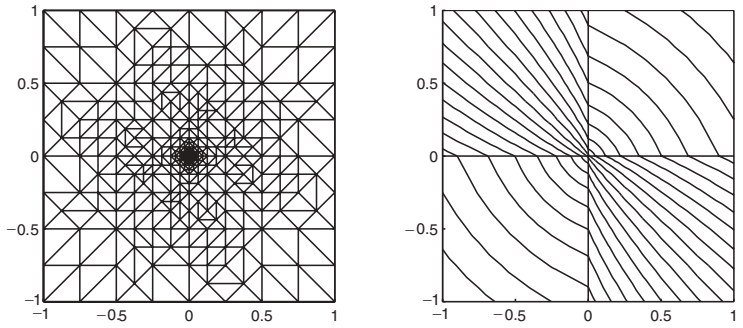

FIG. 5.4. *Example* 3: *Adaptively generated mesh (step* 6*) and isolines of* p_h.

We compare the standard residual-based error estimator with our estimator. Figure 5.5 shows the errors e_p and e_u with respect to the number of unknowns. In the two left pictures, we use $a_{01} := 1$ and $a_{00} := 5$. The two right pictures show the results for $a_{01} := 1$ and $a_{00} := 100$. The efficiency of both error estimators is almost the same for the first setting. Increasing a_{00} from 5 to 100 demonstrates the quality of our error estimator. We note that in the pictures the discretization errors are shown, not the error estimators. In the case $a_{00} = 100$, the solution has a higher singularity at the center and our new error estimator yields better results than the standard residual-based estimator. To obtain the same accuracy, considerably more degrees of freedom are required if the adaptive refinement process is controlled by the residual-based error estimator. We remark that in contrast to the residual-based error estimator, the tensor a enters by the bilinear form $a(\cdot,\cdot)$ in the calculation of η.

In our next example, we consider the domain Ω defined in Figure 5.6. Ω is decomposed into three subdomains Ω_i, $0 \le i \le 2$. On each subdomain a constant coefficient a_i is used. We set $a_2 = a_0$, $a_1 = 1$ and $f = 100$.

Figure 5.7 shows the adaptive meshes on levels three and four. For $a_0 = 10$, there is no significant difference in the mesh size on the three different subdomains. As a_0 increases, we observe stronger adaptive refinement in Ω_1. In the case $a_0 = 1000$, the mesh size is considerably smaller in the subdomain Ω_1 than in Ω_0 and Ω_2.

TENSORIAL RATIONAL SURFACES WITH BASE POINTS VIA MASSIC VECTORS*

OLIVIER GIBARU†

Abstract. Let S be a tensorial rational surface defined by a rational function from $[0,1]^2$ onto $\mathbb{R}^3$ with a base point at $(u,v)=(0,0)$. We demonstrate that the image of this base point is a set of rational curves; a base point is a parameter value for which the rational parametrization takes the value $(\frac{0}{0},\frac{0}{0},\frac{0}{0})$. This result was established by Clebsch [*Ueber die abbildung algebraischer flächen, insbesondere der vierten und fünften ordnung,* Math. Ann., 1 (1869), pp. 253–316]. Base points were first introduced in the context of geometric design by Chionh [*Base Points, Resultants and the Implicit Representation of Rational Surfaces,* Ph.D. thesis, Department of Computer Science, University of Waterloo, Waterloo, Ontario, 1990] and Manocha and Canny [*Implicitizing Rational Parametric Surfaces*, Tech. report 90/592, Computer Science Division, University of California, Berkeley, 1990] and were used by Warren [*ACM Trans. Graphics,* 11 (1992), pp. 127–139] to define multisided rational Bézier patches. We give here a constructive approach of this result to exploit it directly in the industrial scope of computer aided design. We show that these rational curves are placed end to end by using the formalism of massic vectors introduced by Fiorot and Jeannin [*Courbes et Surfaces Rationnelles. Applications à la CAO*, R.M.A. 12, Masson, Paris, 1989]. Furthermore, we give the relations between the massic vectors which define these curves and the massic vectors which define S. Finally, we give an algorithm to draw on a computer a surface having base points.

Key words. base point, Newton polygon, SBR-surfaces, BR-curves, blow up, blow down

1. Introduction.

The aim of this article is to study the image of the base points of rational surfaces put on the form of SBR-surfaces (see [11], [10], [24]). The representation of tensor product rational surfaces in the SBR-form is quite relevant. Indeed, the control of the classical rational Bézier surfaces (see [9]) is obtained only via weighted points where the masses of the points are positive reals. Hence, there is no identity between rational surfaces and rational Bézier surfaces. This is why Fiorot and Jeannin introduced the massic vector space to control any rational surfaces. In addition, they showed that one needs pure vectors and weighted points with negative masses to obtain this identity with rational surfaces. The elements of the massic vector space are called massic vectors; they are either weighted points or pure vectors.

For applications, rational surfaces are usually defined on the square domain $[0,1]^2$. Therefore, we shall state some results on the images of base points which are located on the vertices of $[0,1]^2$. The formalism of massic vectors will help us to obtain these images more precisely. We shall demonstrate that the image of a base point of a rational surface is a set of rational curves whose massic vectors are obtained from the massic vectors of the initial SBR-surface.

We shall see that this type of singularity, which one wishes to avoid in general, is very useful for applications in computer aided geometric design.

Indeed, the users of computer aided design systems are often faced with the problem of filling in a many-sided hole, for example, when trying to define the body of a car or joint surface of a mould in smelting.

Given an n-sided hole left by n contiguous connecting surfaces, either along a common boundary curve or by a point, our aim is to build a surface, called a filling surface, to fill in this hole. The surfaces needed are either Bézier–de Casteljau [1], [7] polynomial surfaces or SBR-surfaces (see [11], [10]). In this case we have to define an n-sided filling SBR-surface to join these n given surfaces along the curves which surround the hole. In [31] and [30], Warren used base points to create n-sided rational Bézier patches. Consequently, to create such a filling surface as a single entity we need to introduce base points at the vertices of the parameter domain $[0,1]^2$ of a rational surface to obtain this n-sided SBR-surface ($n \geq 5$). The additional boundary curves resulting from the images of these base points are obtained by the use of the fundamental Theorem 3.5. As a consequence, this filling n-sided SBR-surface will be defined in one piece on $[0,1]^2$.

In [22], the author introduced another approach via toric patches associated to lattice polygon to deal with this problem of multisided patches (see [20] for related algorithms). Nevertheless, this model of surface takes into account only positive weights.

In section 2, we recall some results concerning massic vectors which allow us to control rational curves or rational surfaces, as was done with points by Bézier–de Casteljau for polynomial curves or surfaces [1], [7]. We give the explicit form of the rational curves and surfaces in terms of massic vectors. The main theorem demonstrated in section 3 is that the image of a base point of a rectangular SBR-surface is a set of rational curves. This result was established by Clebsch in [5] and mentioned in [27]. We state this result via the formalism of massic vectors. Therefore, we consider a more general framework than did Warren. Furthermore, we need to define the Newton polygon of an SBR-surface from the set of indices of the nonzero massic vectors. We show that the massic vectors of the BR-curve images of a base point are those (within a constant) which belong to boundaries of this Newton polygon. With an assumption on the masses of the massic vectors we demonstrate that the curves are placed end to end. A corollary to this theorem is that the image of a base point may be either a curve or reduced to a point. In section 4 we shall examine the problem of drawing rectangular SBR-surfaces with base points at corners on a computer. In [22], the author used the concept of facet variables (see [6]) associated to the lattice polygon of a toric patch (which is in fact the Newton polygon of the patch) to draw it. The method is based on a subdivision process where an n-sided patch is divided into n adjacent tensor product rational Bézier surfaces. Contrary to this strategy (under the conditions of Theorem 3.5), we propose to draw the surface by also using the properties of the Newton polygon of the surface, but we apply successive quadratic changes of variables to obtain n rectangular SBR surfaces without base points. It should be noted that in [24], [25], and [23], the authors used implicit representation to represent a tensor product rational surface. They developed a simple algorithm for implicitizing a rational surface with base points based on perturbation and symbolic manipulation. As we can see, the Newton polygon plays a key role for drawing a rational surface with base points and multisided toric patches. It is also the key for other problems like the efficient computation of sparse mixed resultants (see [2]).

In section 5, we construct from a given set of seven rational BR-curves a seven-sided SBR-surface defined via a rectangular one containing one base point at $(0,0)$. We get three consecutive rational curves arbitrarily taken among the set of given curves as the image of this base point.

2. BR-form and SBR-form of rational curves and surfaces. We know that any rational curve of an affine space in three dimensions (respectively, n), denoted $\mathcal{E}$, is the conic projection of a polynomial curve of an affine space $\mathcal{F}$ in fourth dimension (respectively, $(n+1)$th). The latter can be expressed as a polynomial Bézier–de Casteljau curve. The conic projection of the affine space $\mathcal{F}$ onto $\mathcal{E}$ of a polynomial Bézier–de Casteljau curve whose control points are projected to a finite distance is a rational Bézier–de Casteljau curve controlled by weighted points. A particular problem arises when certain control points of the polynomial Bézier–de Casteljau curve of $\mathcal{F}$ are projected to infinity. In this case, it is necessary to add vectors of $\vec{\mathcal{E}}$ (the vector space associated with the affine space $\mathcal{E}$) to the weighted points to control any rational curve of $\mathcal{E}$. We call massic vectors either weighted points of $\mathcal{E}$ or vectors of $\vec{\mathcal{E}}$. They lead to the BR-form of any rational curve.

To understand these notions, according to [11], we recall some basic definitions and results concerning the representation of rational curves (respectively, rational surfaces) by BR-curves (respectively, SBR-surfaces).

Let us define $\mathcal{E}$ (respectively, $\mathcal{F}$) a real affine space, $\vec{\mathcal{E}}$ (respectively, $\vec{\mathcal{F}}$) its associated linear vector space such that $\mathcal{E}$ (respectively, $\vec{\mathcal{E}}$) is a hyperplane of $\mathcal{F}$ (respectively, $\vec{\mathcal{F}}$), and $\widetilde{\mathcal{E}}$ the projective completion of $\mathcal{E}$. Let Ω be a point of $\mathcal{F}$ not belonging to $\mathcal{E}$.

We define the linear vector space $\widehat{\mathcal{E}} = (\mathcal{E} \times \mathbb{R}^*) \cup \vec{\mathcal{E}}$ called the massic vector space : $\theta \in \widehat{\mathcal{E}}$ is called a massic vector; it is either a weighted point of $\mathcal{E}$ denoted by the couple (P, α), where $P \in \mathcal{E}$ and $\alpha \in \mathbb{R}^*$, or a pure vector, denoted by $\vec{u} \in \vec{\mathcal{E}}$. The one-to-one map $\widehat{\Omega} : \widehat{\mathcal{E}} \to \vec{\mathcal{F}}$ defined by $\widehat{\Omega}(P, \alpha) = \alpha.\overrightarrow{\Omega P}$, $\widehat{\Omega}(\vec{u}) = \vec{u}$ induces an addition operator and an external multiplication in $\widehat{\mathcal{E}}$, respectively denoted $\oplus$ and $*$, such that $\widehat{\mathcal{E}}$ is a linear space and $\widehat{\Omega}$ is an isomorphism.

For any $\theta, \theta' \in \widehat{\mathcal{E}}$ and $\lambda \in \mathbb{R}^* : \theta \oplus \theta' = \widehat{\Omega}^{-1}(\widehat{\Omega}(\theta) + \widehat{\Omega}(\theta'))$ and $\lambda * \theta = \widehat{\Omega}^{-1}(\lambda.\widehat{\Omega}(\theta))$. These operations on massic vectors were first introduced by Grassmann in [21]; see also the survey by Cartan in [3] and the book by Goldman [20].

We shall define the linear form $\chi : \widehat{\mathcal{E}} \to \mathbb{R}$; $\chi(P, \alpha) = \alpha$, $\chi(\vec{u}) = 0$. $\chi(\theta)$ is called the mass of θ. Let $\Pi\Omega : \vec{\mathcal{F}} \backslash \{\vec{0}\} \to \widetilde{\mathcal{E}}$ be the conic projection of apex Ω and $\Pi : \widehat{\mathcal{E}} \backslash \{\vec{0}\} \to \widetilde{\mathcal{E}}$ the natural projection : $\Pi(P, \alpha) = P$, $\Pi(\vec{u}) = (\vec{u})_\infty$, where $(\vec{u})_\infty$ designates the point at infinity of $\mathcal{E}$ along the direction $\vec{u}$. These projections are linked by the relation $\Pi = \Pi\Omega \circ \widehat{\Omega}$. We have $\Pi(\lambda * \theta) = \Pi(\theta)$ for all $\lambda \in \mathbb{R}^*$. We can now define a BR-curve.

DEFINITION 2.1. *Let $\theta_0, \theta_1, \ldots, \theta_n$ be $n+1$ massic vectors not simultaneously null ; a BR-curve of $\widetilde{\mathcal{E}}$, of controlling massic polygon $\theta = \{\theta_i, 0 \leqslant i \leqslant n\}$, denoted by* $\mathrm{BR}[\theta_0, \theta_1, \ldots, \theta_n]$ *or* $\mathrm{BR}[\theta]$*, is parametrized by*

$$\mathrm{BR}[\theta](t) = \Pi(\mathrm{BP}[\theta_0, \theta_1, \ldots, \theta_n; [0,1]](t)),$$

where $BP[\theta_0, \theta_1, \ldots, \theta_n; [0,1]](t) = \sum_{i=0}^{n} B_i^n(t) * \theta_i$ is the Bézier–de Casteljau curve in $\widehat{\mathcal{E}}$, n is called the length of the BR-curve.

For $i = 0, \ldots, n$, the $B_i^n(t) = \binom{n}{i}(1-t)^{n-i} t^i$ are Bernstein's polynomials of degree n relative to $[0,1]$ where $\binom{n}{i} = \frac{n!}{(n-i)!i!}$ denotes the binomial coefficients.

PROPOSITION 2.2. *Let $\theta = (\theta_i)_{0 \leq i \leq n}$ be a set of massic vectors which define a BR-curve. Let us define the sets $I := \{i : \theta_i = (P_i, \beta_i) \in \mathcal{E} \times \mathbb{R}^*\}$ and $\bar{I} := \{i : \theta_i = \vec{U}_i \in \vec{\mathcal{E}}\}$ such that $I \cup \bar{I} = \{0, 1, \ldots, n\}$ and $I \cap \bar{I} = \emptyset$ and the mass of the curve denoted by $\beta(t) = \sum_{i \in I} \beta_i B_i^n(t)$. Hence the explicit form of this BR-curve is*

(a) *if* $\beta(t) \neq 0$, *then*

$$\mathrm{BR}[\theta](t) = \frac{\sum_{i\in I}\beta_i B_i^n(t) P_i}{\beta(t)} + \frac{\sum_{i\in \bar{I}} B_i^n(t)\vec{U}_i}{\beta(t)};$$

(b) *if* $\beta(t) = 0$ *and* $\vec{V}(t) = \sum_{i\in I}\beta_i B_i^n(t) P_i + \sum_{i\in\bar{I}} B_i^n(t)\vec{U}_i \neq \vec{0}$, *then* $\mathrm{BR}[\theta](t)$ *defined the point at infinity*

$$\mathrm{BR}[\theta](t) = \left(\sum_{i\in I}\beta_i B_i^n(t) P_i + \sum_{i\in\bar{I}} B_i^n(t)\vec{U}_i\right)_\infty$$

along the direction given by the vector $\sum_{i\in I}\beta_i B_i^n(t) P_i + \sum_{i\in\bar{I}} B_i^n(t)\vec{U}_i$;

(c) *if* $\vec{V}(t_0) = \vec{0}$ (*hence* $\beta(t_0) = 0$), *then* $\mathrm{BR}[\theta](t_0) = \lim_{t\to t_0}\mathrm{BR}[\theta](t)$.

Proof. For the proof, see Proposition 1.3 in [11]. □

DEFINITION 2.3. *Let* $\theta = (\theta_{ij})_{\substack{0\le i\le n\\ 0\le j\le p}}$ *be a set of massic vectors. A rectangular SBR-surface, denoted by* $\mathrm{SBR}[\theta]$, *is defined by*

$$\mathrm{SBR}[\theta](u,v) = \Pi\left(\sum_{i=0}^{n}\sum_{j=0}^{p} B_i^n(u) B_j^p(v) * \theta_{ij}\right) \text{ for all } (u,v)\in[0,1]^2.$$

This SBR-surface is said to be of length n *and of width* p.

THEOREM 2.4. *There is an identity between the set of rational surfaces (respectively, rational curves) and rectangular SBR-surfaces (respectively, BR-curves).*

Proof. For the proof, see Propositions 2.2.2.2 and 6.3.1.3 in [11]. □

PROPOSITION 2.5. *Let* $\theta = (\theta_{ij})_{\substack{0\le i\le n\\ 0\le j\le p}}$ *be a set of massic vectors which define a SBR-surface. Let us define* $I := \{(i,j) : \theta_{ij} = (P_{ij}, \beta_{ij}) \in \mathcal{E}\times\mathbb{R}^*\}$, $\bar{I} := \{(i,j) : \theta_{ij} = \vec{U}_{ij} \in \vec{\mathcal{E}}\}$, *and*

$$\beta(u,v) := \chi\left(\sum_{i=0}^{n}\sum_{j=0}^{p} B_i^n(u) B_j^p(v) * \theta_{ij}\right) = \sum_{(i,j)\in I} B_i^n(u) B_j^p(v)\beta_{ij}$$

the mass of S. *The explicit form of this rectangular SBR-surface is*

(a) *if* $\beta(u,v) \neq 0$, *then*

$$\mathrm{SBR}[\theta](u,v) = \frac{\sum_{(i,j)\in I}\beta_{ij} B_i^n(u) B_j^p(v) P_{ij}}{\beta(u,v)} + \frac{\sum_{(i,j)\in\bar{I}} B_i^n(u) B_j^p(v)\vec{U}_{ij}}{\beta(u,v)};$$

(b) *if* $\beta(u,v) = 0$ *and* $\vec{V}(u,v) = \sum_{(i,j)\in I}\beta_{ij} B_i^n(u) B_j^p(v) P_{ij} + \sum_{(i,j)\in\bar{I}} B_i^n(u) B_j^p(v)\vec{U}_{ij} \neq \vec{0}$, *then* $\mathrm{SBR}[\theta](u,v)$ *defines the point at infinity*

$$\left(\sum_{(i,j)\in I}\beta_{ij} B_i^n(u) B_j^p(v) P_{ij} + \sum_{(i,j)\in\bar{I}} B_i^n(u) B_j^p(v)\vec{U}_{ij}\right)_\infty;$$

(c) *if* $\vec{V}(u_0,v_0) = \vec{0}$ (*hence* $\beta(u_0,v_0) = 0$), *then* $\mathrm{SBR}[\theta](u_0,v_0)$ *is not defined.* $\mathrm{SBR}[\theta](u,v)$ *takes on the value* $\left(\frac{0}{0},\frac{0}{0},\frac{0}{0}\right)$ *and we say that the SBR-surface has a base point at* $(u,v) = (u_0,v_0)$.

Proof. For the proof, see Proposition 6.3.1.5 in [11]. □

From now on, we assume that the base point is at $(u,v) = (0,0)$. If this is not the case, we apply an affine change of variables to make it so.

LEMMA 2.6. *Let $\hat{f}:[0,1]^2 \to \widehat{\mathcal{E}}$ be a polynomial function defined by*

$$\hat{f}(u,v) = \sum_{i=0}^{n}\sum_{j=0}^{p} B_i^n(u)\, B_j^p(v) * \theta_{ij}, \tag{2.1}$$

where $\theta = (\theta_{ij})_{\substack{0\le i\le n\\ 0\le j\le p}}$ is a set of massic vectors. Then we have $\vec{V}(0,0) = \vec{0} \Leftrightarrow \hat{f}(0,0) = \vec{0} \Leftrightarrow \theta_{00} = \vec{0}$.

Proof. We remark that $\vec{V}(u,v) = \widehat{\Omega}(\hat{f}(u,v))$ and that $\hat{f}(0,0) = \theta_{00}$. □

The main subject of this paper is to handle this singularity as thoroughly as possible for further applications in the industrial scope of computer aided design.

3. Image of a rectangular SBR-surface base point. The aim of this section is to show that there is a deep connection between the lattice polytope (see [6]), here defined by the indices of the nonzero massic vectors of a rectangular SBR-surface, and the image of its base points.

The following theorem highlights the link between the null derivatives of $\hat{f}$ defined by (2.1) at a base point $(u,v) = (0,0)$ (i.e., $\hat{f}(u,v) = \vec{0}$) of the rational surface issued from the Π-projection of $\hat{f}$ and the null massic vectors of $\hat{f}$ in the vicinity of $\theta_{00} = \vec{0}$.

THEOREM 3.1. *Let $\hat{S}$ be a polynomial surface of $\widehat{\mathcal{E}}$ defined by (2.1). Consider $n_0 < n$ and let $q(0) \ge q(1) \ge \cdots \ge q(n_0) \ge 0$ be n_0+1 given integers with $p > q(0)$. Hence, $\partial^{k+l}\hat{f}(0,0)/\partial u^k \partial v^l = \vec{0}$ for $k = 0,\dots,n_0$ and $l = 0,\dots,q(k)$ if and only if $\theta_{kl} = \vec{0}$ for $k = 0,\dots,n_0$ and $l = 0,\dots,q(k)$.*

Moreover, if we put $\hat{f}$ in the monomial form as $\hat{f}(u,v) = \sum_{i=0}^{n}\sum_{j=0}^{p} u^i v^j * \alpha_{ij}$, we obtain that $\alpha_{kl} = \vec{0}$ for $k = 0,\dots,n_0$ and $l = 0,\dots,q(k)$ if and only if $\theta_{kl} = \vec{0}$ for $k = 0,\dots,n_0$ and $l = 0,\dots,q(k)$.

Proof. We shall use the following relation: for any $(k,l) \in \mathbb{R}^2$ we have

$$\frac{\partial^{k+l}\hat{f}(0,0)}{\partial u^k \partial v^l} = \frac{n!p!}{(n-k)!\,(p-l)!} * \Delta^{kl}\theta_{00}, \tag{3.1}$$

where $\Delta^{kl}\theta_{00}$ is the forward difference operator defined by

$$\Delta^{kl}\theta_{00} = \sum_{i=0}^{k}\sum_{j=0}^{l}\binom{k}{i}\binom{l}{j}(-1)^{k+l-i-j} * \theta_{ij}. \tag{3.2}$$

We shall demonstrate the necessary condition by induction on k. Assuming that $\partial^{k+l}\hat{f}(0,0)/\partial u^k \partial v^l = \vec{0}$, it follows from (3.1) that $\Delta^{kl}\theta_{00} = \vec{0}$. For $k = 0$ and $l = 0,\dots,q(0)$, the set of relations $\Delta^{0l}\theta_{00} = \vec{0}$ is a triangular linear system which directly gives $\theta_{00} = \theta_{01} = \cdots = \theta_{0q(0)} = \vec{0}$. Assuming that $\theta_{jl} = \vec{0}$ for $j = 0,\dots,k$ ($k < n_0$) and $l = 0,\dots,q(j)$, then the conditions $\Delta^{k+1,l}\theta_{00} = \vec{0}$ for $l = 0,\dots,q(k+1)$ with $q(k+1) \le q(k) \le \cdots \le q(0)$ imply that $\theta_{k+1,l} = \vec{0}$ for $l = 0,\dots,q(k+1)$, so completing the induction proof. The sufficient condition is obvious via (3.1) and (3.2). The previous result and the relation $\alpha_{ij} = \binom{n}{i}\binom{p}{j} * \Delta^{ij}\theta_{00}$ enable us to conclude the proof. □

Remark. Obviously, in the previous theorem we may change the role of k and l.

Let us consider the following grid of massic vectors:

θ_{0p}	$\cdots$	$\cdots$	$\cdots$	$\cdots$	θ_{np}
$\vdots$					$\vdots$
θ_{03}	θ_{13}				$\vdots$
$\vec{0}$	$\vec{0}$	θ_{22}			$\vdots$
$\vec{0}$	$\vec{0}$	θ_{21}			$\vdots$
$\vec{0}$	$\vec{0}$	$\vec{0}$	θ_{30}	$\cdots$	θ_{n0}

,

where at least $\theta_{00} = \vec{0}$. Following the previous theorem for $k = 0, 1, 2$ and $l = 0, \ldots, q(k)$ with $q(0) = q(1) = 2$, $q(2) = 0$, we have $\partial^{k+l}\hat{f}(0,0)/\partial u^k \partial v^l = \vec{0}$. Of course, partial derivatives of $\hat{f}$ can be equal to zero for orders (k, l) different from those above given by the theorem; for instance, we may have $\partial^4 \hat{f}(0,0)/\partial u^2 \partial v^2 = \vec{0}$ if $\theta_{22} = 2 * \theta_{21}$.

As we shall see later, knowing the minimum orders of the nonzero partial derivatives of $\hat{f}$ at a base point is not sufficient to determine the images of this base point. In the previous example the minimum orders are $(k, q(k) + 1)$, $k = 0, 1, 2$. If $\chi(\theta_{03}) > 0$, $\chi(\theta_{30}) > 0$, and $\chi(\theta_{21}) \geq 0$, then we shall show that the image of the base point $(u, v) = (0, 0)$ is the rational cubic defined by the massic vectors θ_{03}, $\theta_{12} = \vec{0}$, θ_{21}, θ_{30} (we have, respectively, $\partial^3 \hat{f}(0,0)/\partial v^3 \neq \vec{0}$, $\partial^3 \hat{f}(0,0)/\partial u \partial v^2 = \vec{0}$, $\partial^3 \hat{f}(0,0)/\partial u^2 \partial v \neq \vec{0}$, $\partial^3 \hat{f}(0,0)/\partial u^3 \neq \vec{0}$); θ_{13} corresponding to $\partial^3 \hat{f}(0,0)/\partial u^1 \partial v^3 \neq \vec{0}$ is not concerned.

Consider a rational surface defined by $\theta = (\theta_{ij})_{\substack{0 \leq i \leq n \\ 0 \leq j \leq p}}$, a set of massic vectors.

Assumption 1. We assume that at least $\theta_{00} = \vec{0}$ and among the massic vectors θ_{i0}, $i \in \{1, \ldots, n\}$ (respectively, among the massic vectors θ_{0j}, $j \in \{1, \ldots, p\}$), there exists at least a nonzero massic vector.

We define the set $\mathcal{A} := \{p_{ij} = (i, j) \in \mathbb{R}^2 : \theta_{ij} \neq \vec{0}\}$ so as to create the Newton polygon of an SBR-surface.

DEFINITION 3.2. *The point $Q \in \mathcal{A}$ is an extreme point if it does not exist two different points q_1 and q_2 belonging to $\mathcal{A}$ such that $Q \in]q_1, q_2[$.*

DEFINITION 3.3. *Let $Q_0, Q_1, \ldots, Q_l$ be the extreme points of $\mathcal{A}$. The convex hull of $\mathcal{A}$ is defined by* $\mathrm{Conv}(\mathcal{A}) := \{\lambda_0 Q_0 + \cdots + \lambda_l Q_l,\ \lambda_i \in \mathbb{R}^+ : \sum_{i=0}^{l} \lambda_i = 1\} \subset \mathbb{R}^2$.

DEFINITION 3.4. *The Newton polygon (see* [29], [8], [28], [6]*) of the rectangular SBR-surface* $\mathrm{SBR}[\theta]$*, denoted by Newton* $(\mathrm{SBR}[\theta])$*, is defined as the convex hull of $\mathcal{A}$. We denote by $\{\mathcal{P}_0, \mathcal{P}_1, \ldots, \mathcal{P}_q\}$ the set of extreme points of* $\mathrm{Conv}(\mathcal{A})$ *$(q \leq l)$. These points are included in the set $\{Q_0, Q_1, \ldots, Q_l\}$ of the extreme points of $\mathcal{A}$.*

We denote by (α_i, β_i) the integer coordinates of the point $\mathcal{P}_i$ for $i = 0, \ldots, q$. Let us assume that $\mathcal{P}_0 = (\alpha_0 \neq 0, \beta_0 = 0)$ is the point such that α_0 is the lowest value with $y = 0$ and $\mathcal{P}_m = (\alpha_m = 0, \beta_m \neq 0)$ is the point such that β_m is the lowest value with $x = 0$. This implies that $\frac{\beta_{i+1} - \beta_i}{\alpha_i - \alpha_{i+1}} > \frac{\beta_i - \beta_{i-1}}{\alpha_{i-1} - \alpha_i}$ for $i = 1, \ldots, m-1$, where $\alpha_i > \alpha_{i+1}$ and $\beta_{i+1} > \beta_i$ for $i = 0, \ldots, m-1$. We need to define the complement of the Newton polygon with respect to the positive orthant in $\mathbb{R}^2$ which contains the point $(0, 0)$, denoted $\overline{\mathrm{Newton}}^{00}(\mathrm{SBR}[\theta])$.

Notice that each edge $[\mathcal{P}_k, \mathcal{P}_{k+1}]$, for $k = 0, \ldots, m-1$, of $\mathrm{Conv}(\mathcal{A})$ has a normal vector $\vec{n}_k$ such that it is inwardly oriented and it is taken as the shortest vector in this direction with integer coordinates. Actually, the coordinates of $\vec{n}_k$ are $(\frac{\beta_k - \beta_{k+1}}{d_k}, \frac{\alpha_{k+1} - \alpha_k}{d_k})$, where d_k is the greatest common divisor of the integers $\beta_{k+1} - \beta_k$

and $\alpha_k - \alpha_{k+1}$. It is observed that $d_k + 1$ is the number of integer points which belong to the segment $[\mathcal{P}_k, \mathcal{P}_{k+1}]$.

Assumption 2. *We assume that the mass of* $\theta_{ij} \geq 0$ *for all* $(i,j) \in \mathcal{A}$ *except for the* $(i,j) \in \{\mathcal{P}_0, \mathcal{P}_1, \ldots, \mathcal{P}_q\}$, *where the mass of* $\theta_{ij} > 0$.

We come to the fundamental theorem.

THEOREM 3.5. *With Assumptions* 1 *and* 2 *we obtain that the image of the base point* $(u,v) = (0,0)$ *of the rational surface*

$$\begin{aligned} &\mathrm{SBR}\,[\theta] : [0,1]^2 / D \to \tilde{\mathcal{E}} \\ &(u,v) \mapsto \mathrm{SBR}\,[\theta]\,(u,v) = \Pi\left(\sum_{i=0}^{n}\sum_{j=0}^{p} B_i^n\,(u)\,B_j^p\,(v) * \theta_{ij}\right) \end{aligned} \tag{3.3}$$

is m *consecutive rational curves (*D *being the points of* $[0,1]^2$ *where* $\mathrm{SBR}\,[\theta]$ *is not defined). They are respectively defined by the massic vectors* θ_{ij} *whose indices* (i,j) *respectively belong to the* m *segments* $[\mathcal{P}_k, \mathcal{P}_{k+1}]$ *for* $k = 0, \ldots, m-1$. *More precisely, these* m *BR-curves are defined by* $\mathrm{BR}\left[\tau^{(k+1)}\right](t) = \Pi(\sum_{i=0}^{d_k} B_i^{d_k}\,(t) * \tau_i^{(k+1)})$, *where the massic vectors* $\tau_i^{(k+1)}$ *of these rational curves are defined via the massic vectors of* $\mathrm{SBR}\,[\theta]$ *as follows:*

$$\tau_i^{(k+1)} = \frac{\dbinom{n}{\alpha_k - i\frac{\alpha_k - \alpha_{k+1}}{d_k}}\dbinom{p}{\beta_k + i\frac{\beta_{k+1} - \beta_k}{d_k}}}{\dbinom{d_k}{i}} * \theta_{\alpha_k - i\frac{\alpha_k - \alpha_{k+1}}{d_k},\, \beta_k + i\frac{\beta_{k+1} - \beta_k}{d_k}}. \tag{3.4}$$

Proof. We use fractional changes of variables to obtain any image curve directly without having to apply successive changes of variables, as is usually done in algebraic geometry [26]. For each value of k in $\{0, \ldots, m-1\}$ we apply the change of variables

$$\varphi_k\,(r,t) = \left(u = r^{(\beta_{k+1} - \beta_k)}\,(1-t)^{\frac{d_k}{\alpha_k - \alpha_{k+1}}}, v = r^{(\alpha_k - \alpha_{k+1})} t^{\frac{d_k}{\beta_{k+1} - \beta_k}}\right)$$

to the function $\mathrm{SBR}\,[\theta]$. Therefore we have

$$\begin{aligned} &\mathrm{SBR}\,[\theta]\,(\varphi_k\,(r,t)) \\ &= \Pi\left(\sum_{(i,j)\in\mathcal{A}} \tbinom{n}{i}\tbinom{p}{j}\left(1 - r^{(\beta_{k+1} - \beta_k)}\,(1-t)^{\frac{d_k}{\alpha_k - \alpha_{k+1}}}\right)^{n-i} \times \left(1 - r^{(\alpha_k - \alpha_{k+1})} t^{\frac{d_k}{\beta_{k+1} - \beta_k}}\right)^{p-j}\right. \\ &\quad \left. \times\, r^{i(\beta_{k+1} - \beta_k) + j(\alpha_k - \alpha_{k+1})}\,(1-t)^{\frac{i d_k}{\alpha_k - \alpha_{k+1}}}\, t^{\frac{j d_k}{\beta_{k+1} - \beta_k}} * \theta_{ij}\right) \text{ for all } (r,t) \in [0,1]^2. \end{aligned}$$

Pairs (i,j) of integers belonging to $[\mathcal{P}_k, \mathcal{P}_{k+1}]$ satisfy $i\,(\beta_{k+1} - \beta_k) + j\,(\alpha_k - \alpha_{k+1}) = \alpha_k\beta_{k+1} - \alpha_{k+1}\beta_k$. Consequently for all $(i,j) \in \mathcal{A}$ we have $i\,(\beta_{k+1} - \beta_k) + j\,(\alpha_k - \alpha_{k+1}) \geq \alpha_k\beta_{k+1} - \alpha_{k+1}\beta_k$. Therefore in the previous sum we factorize with $r^{(\alpha_k\beta_{k+1} - \alpha_{k+1}\beta_k)}$, which is eliminated by a property of the Π-projection (see section 2). Finally, with the assumption on the masses it is possible to set $r = 0$. It gives

$$\mathrm{SBR}\,[\theta]\,(\varphi_k\,(0,t)) = \Pi\left(\sum_{(i,j)\in[\mathcal{P}_k,\mathcal{P}_{k+1}]\cap\mathcal{A}} \binom{n}{i}\binom{p}{j}\,(1-t)^{\frac{i d_k}{\alpha_k - \alpha_{k+1}}}\, t^{\frac{j d_k}{\beta_{k+1} - \beta_k}} * \theta_{ij}\right).$$

Actually, pairs (i,j) of integers belonging to $[\mathcal{P}_k,\mathcal{P}_{k+1}]$ are given by $i=\alpha_k-l\frac{\alpha_k-\alpha_{k+1}}{d_k}$ and $j=\beta_k+l\frac{\beta_{k+1}-\beta_k}{d_k}$ for $l=0,\ldots,d_k$. Again via the Π-projection we simplify with $(1-t)^{\frac{\alpha_{k+1}d_k}{\alpha_k-\alpha_{k+1}}}\,t^{\frac{\beta_k d_k}{\beta_{k+1}-\beta_k}}$ in the previous relation.

We have

$$\begin{aligned}&\mathrm{SBR}\,[\theta]\,(\varphi_k\,(0,t))\\&=\Pi\left(\sum_{l=0}^{d_k}\binom{n}{\alpha_k-l\frac{\alpha_k-\alpha_{k+1}}{d_k}}\binom{p}{\beta_k+l\frac{\beta_{k+1}-\beta_k}{d_k}}(1-t)^{d_k-l}\,t^l\right.\\&\qquad\left.*\,\theta_{\alpha_k-l\frac{\alpha_k-\alpha_{k+1}}{d_k},\beta_k+l\frac{\beta_{k+1}-\beta_k}{d_k}}\right).\end{aligned}$$

Therefore we obtain for $k=0,\ldots,m-1$ the following BR-curves:

$$\mathrm{SBR}\,[\theta]\,(\varphi_k\,(0,t))=\Pi\left(\sum_{i=0}^{d_k}B_i^{d_k}\,(t)*\tau_i^{(k+1)}\right),\ t\in[0,1]\,,$$

where

$$\tau_i^{(k+1)}=\frac{\binom{n}{\alpha_k-i\frac{\alpha_k-\alpha_{k+1}}{d_k}}\binom{p}{\beta_k+i\frac{\beta_{k+1}-\beta_k}{d_k}}}{\binom{d_k}{i}}*\theta_{\alpha_k-i\frac{\alpha_k-\alpha_{k+1}}{d_k},\beta_k+i\frac{\beta_{k+1}-\beta_k}{d_k}}.$$

As we have $\tau_{d_{k-1}}^{(k)}=\tau_0^{(k+1)}$ for $k=1,\ldots,m-1$, it comes that the BR-curves images of the base point are consecutive. Hence, the image of the base point $(u,v)=(0,0)$ is a set made of these m consecutive rational curves whose massic vectors are defined by (3.4). □

Since Clebsch [5], it has been known that the image of a base point can be blown up into a set of rational curves. The main result of this theorem is that via relation (3.4) we explicitly give the link between the massic vectors defining this set of rational curves and those of indices belonging to $\mathrm{Newton}\,(\mathrm{SBR}\,[\theta])\cap\overline{\mathrm{Newton}}^{00}\,(\mathrm{SBR}\,[\theta])$. Moreover, we point out that these BR-curves are placed end to end, which is very important for applications in geometric design.

In Figure 1, the image of the base point $(u,v)=(0,0)$ is represented by two consecutive rational curves respectively defined up to multiplicative constants by the massic vectors: $\theta_{8,0}$, $\theta_{3,2}$; and $\theta_{3,2}$, $\theta_{2,4}$, $\theta_{1,6}$, $\theta_{0,8}$.

Remark. The assumption that $\chi\,(\theta_{ij})\geq 0$ for all $(i,j)\in\mathcal{A}$ except for $(i,j)\in\{\mathcal{P}_0,\mathcal{P}_1,\ldots,\mathcal{P}_q\}$ where $\chi\,(\theta_{ij})>0$ prevents the SBR-surface from having base points elsewhere than at the vertices of each definition domains obtained after applying changes of variables to the surface. We could have admitted negative and positive masses but the image curves of the base point $(u,v)=(0,0)$ of $\mathrm{SBR}\,[\theta]$ are not necessarily given by the massic vectors whose indices belong to $\mathrm{Newton}\,(\mathrm{SBR}\,[\theta])\cap\overline{\mathrm{Newton}}^{00}\,(\mathrm{SBR}\,[\theta])$. Moreover, they are not necessarily end to end and their number can be greater than the number of edges of $\mathrm{Newton}\,(\mathrm{SBR}\,[\theta])\cap\overline{\mathrm{Newton}}^{00}\,(\mathrm{SBR}\,[\theta])$. For instance, in Figure 2 the image of the base point $(0,0)$ is two orthogonal segments. In a future work, we shall tackle this difficult problem.

If we want the image of the base point $(u,v)=(0,0)$ to be a unique rational curve or a point then we have the following.

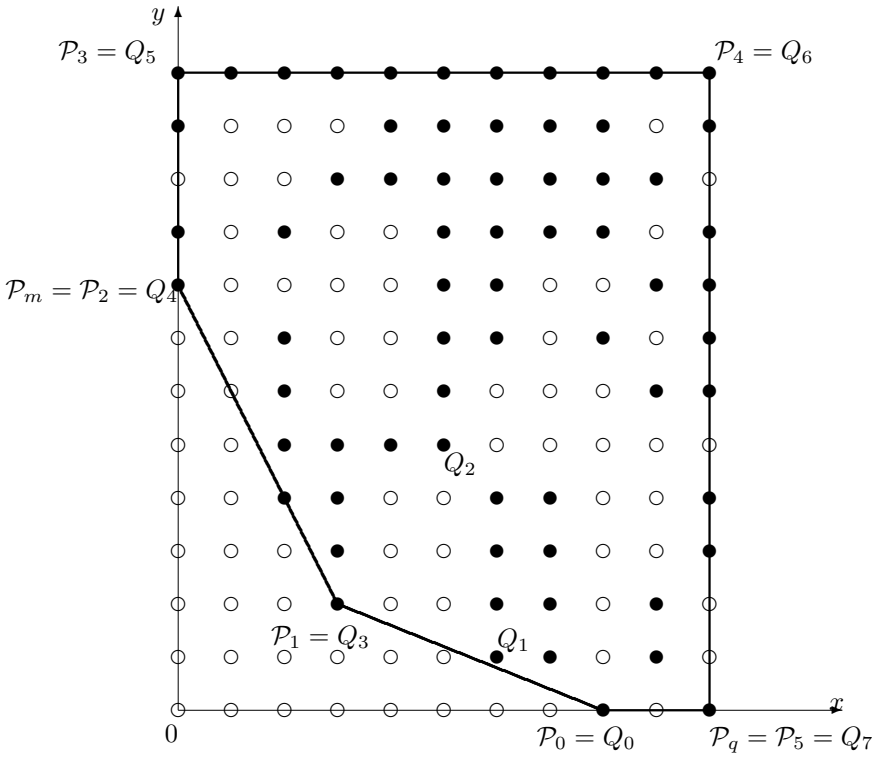

FIG. 1. *An example of a convex hull of a set of integer points associated with the nonzero massic vectors of an SBR-surface.* • *(respectively,* ○*) denotes integer points* (i,j) *such that* $\theta_{ij} \neq \vec{0}$ *(respectively,* $\theta_{ij} = \vec{0}$*);* Q_i *= extreme points of* $\mathcal{A}$*;* $\mathcal{P}_i$ *= extreme points of* $\mathrm{Conv}(\mathcal{A})$.

COROLLARY 3.6. *Let* S *be a SBR-surface defined by* (3.3) *where* $\chi(\theta_{ij}) \geq 0$ *for all* $(i,j) \in \mathcal{A}$ *except for* $(i,j) \in \{\mathcal{P}_0, \mathcal{P}_1, \ldots, \mathcal{P}_q\}$ *where* $\chi(\theta_{ij}) > 0$*. If* $\mathcal{P}_0 = (\alpha_0, 0)$ *and* $\mathcal{P}_1 = (0, \beta_1)$ $(\alpha_0 < n$ *and* $\beta_1 < p)$ *such that* $\theta_{ij} = \vec{0}$ *for all* $(i,j) \in \mathbb{R}^2$ *with* $i\beta_1 + j\alpha_0 < \alpha_0\beta_1$*, then the image of the base point* $(u,v) = (0,0)$ *is the BR-curve defined by*

$$\Pi\left(\sum_{i=0}^{d_0=\gcd(\alpha_0,\beta_1)} B_i^{d_0}(t)\, \frac{\binom{n}{\alpha_0 - i\frac{\alpha_0}{d_0}}\binom{p}{i\frac{\beta_1}{d_0}}}{\binom{d_0}{i}} * \theta_{\alpha_0 - i\frac{\alpha_0}{d_0}, i\frac{\beta_1}{d_0}}\right) \text{ for all } t \in [0,1]. \tag{3.5}$$

Furthermore, if $\Pi(\theta_{\alpha_0,0}) = \Pi(\theta_{0,\beta_1})$ $\left(\text{where } \Pi(\theta_{0,\beta_1}) = P \in \mathbb{R}^3\right)$ *and either* $\Pi(\theta_{\alpha_0 - i\frac{\alpha_0}{d_0}, i\frac{\beta_1}{d_0}}) = P$ *or* $\theta_{\alpha_0 - i\frac{\alpha_0}{d_0}, i\frac{\beta_1}{d_0}} = \vec{0}$ *for* $i = 1, \ldots, d_0 - 1$*, then* $\mathrm{SBR}[\theta]$ *is continuous at* $(0,0)$.

Proof. Relation (3.5) follows from the application of the previous theorem with $\mathcal{P}_0 = (\alpha_0, 0)$ and $\mathcal{P}_1 = (0, \beta_1)$. The assumption on the masses compels us to demonstrate the continuity of $\mathrm{SBR}[\theta]$ at $(0,0)$. Let us define the sets $I = \{(i,j) : \theta_{ij} =$

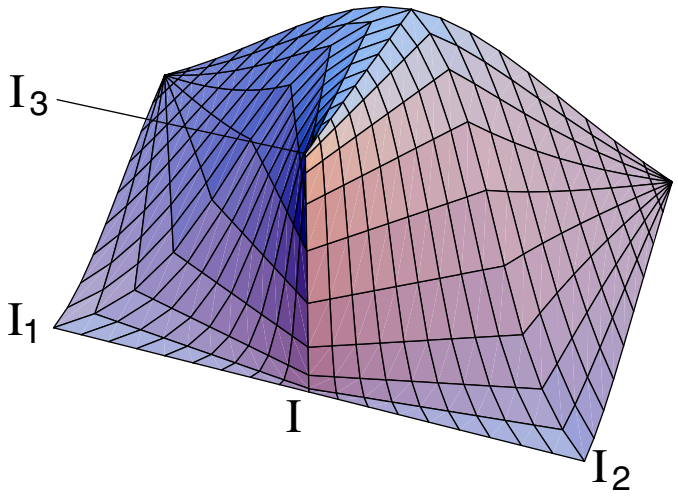

FIG. 2. *The image of the base point is the two orthogonal segments* $[I_1, I_2]$ *and* $[I, I_3]$ *which intersect at the point* I.

$(P_{ij}, \beta_{ij}) \in \mathcal{E} \times \mathbb{R}^*\}$ and $\bar{I} = \{(i,j) : \theta_{ij} = \vec{U}_{ij} \in \vec{\mathcal{E}}\}$; then we obtain via the explicit form of an SBR-surface (see Proposition 2.5(a)) that for all $(u,v) \in [0,1]^2$,

$$\mathrm{SBR}\,[\theta]\,(u,v) - P = \frac{\sum_{(i,j)\in I} \beta_{ij} B_i^n(u) B_j^p(v).(P_{ij}-P) + \sum_{(i,j)\in \bar{I}} B_i^n(u) B_j^p(v).\vec{U}_{ij}}{\sum_{(i,j)\in I} \beta_{ij} B_i^n(u) B_j^p(v)}.$$

When applying the change of variables $u = r^{\beta_1}(1-t)^{\frac{d_0}{\alpha_0}}$, $v = r^{\alpha_0} t^{\frac{d_0}{\beta_1}}$ (with $r \geq 0$ and $t \in [0,1]$) to the right side of the previous expression and symplifying by $r^{\alpha_0\beta_1}$ it follows that

$$\begin{aligned}
&\mathrm{SBR}\,[\theta]\,(u,v) - P \\
&= \frac{\sum_{(i,j)\in I} \binom{n}{i}\binom{p}{j} r^{i\beta_1 + j\alpha_0 - \alpha_0\beta_1} \beta_{ij} . \left(1 - r^{\beta_1}(1-t)^{\frac{d_0}{\alpha_0}}\right)^{n-i} \left(1 - r^{\alpha_0} t^{\frac{d_0}{\beta_1}}\right)^{p-j} (1-t)^{i\frac{d_0}{\alpha_0}} t^{j\frac{d_0}{\beta_1}} (P_{ij}-P)}{\sum_{(i,j)\in I} \binom{n}{i}\binom{p}{j} r^{i\beta_1 + j\alpha_0 - \alpha_0\beta_1} \beta_{ij} . \left(1 - r^{\beta_1}(1-t)^{\frac{d_0}{\alpha_0}}\right)^{n-i} \left(1 - r^{\alpha_0} t^{\frac{d_0}{\beta_1}}\right)^{p-j} (1-t)^{i\frac{d_0}{\alpha_0}} t^{j\frac{d_0}{\beta_1}}} \\
&\quad + \frac{\sum_{\substack{(i,j)\in \bar{I} \\ i+j>m}} \binom{n}{i}\binom{p}{j} r^{i\beta_1 + j\alpha_0 - \alpha_0\beta_1} \left(1 - r^{\beta_1}(1-t)^{\frac{d_0}{\alpha_0}}\right)^{n-i} \left(1 - r^{\alpha_0} t^{\frac{d_0}{\beta_1}}\right)^{p-j} (1-t)^{i\frac{d_0}{\alpha_0}} t^{j\frac{d_0}{\beta_1}} . \vec{U}_{ij}}{\sum_{(i,j)\in I} \binom{n}{i}\binom{p}{j} r^{i\beta_1 + j\alpha_0 - \alpha_0\beta_1} \beta_{ij} . \left(1 - r^{\beta_1}(1-t)^{\frac{d_0}{\alpha_0}}\right)^{n-i} \left(1 - r^{\alpha_0} t^{\frac{d_0}{\beta_1}}\right)^{p-j} (1-t)^{i\frac{d_0}{\alpha_0}} t^{j\frac{d_0}{\beta_1}}}.
\end{aligned} \tag{3.6}$$

The assumption on the masses of the massic vectors implies that the denominator is strictly greater than zero for all $r \geq 0$ and $t \in [0,1]$. Consequently as $P_{i,j} = P$ for all $(i,j) \in I$ such that $i\beta_1 + j\alpha_0 = \alpha_0\beta_1$ we can factorize the numerator of (3.6) by r and we obtain

$$\|\mathrm{SBR}\,[\theta]\,(u,v) - P\| = \mathcal{O}(r).$$

θ_{05}	θ_{15}	θ_{25}	θ_{35}	θ_{45}
θ_{04}	$\vec{0}$	$\vec{0}$	$\vec{0}$	θ_{44}
θ_{03}	$\vec{0}$	$\vec{0}$	$\vec{0}$	θ_{43}
$\vec{0}$	θ_{12}	$\vec{0}$	$\vec{0}$	θ_{42}

FIG. 3. *An SBR-surface with a corner of null massic vectors.*

Hence,

$$\lim_{\substack{(u,v)\to(0,0)\\(u,v)\in[0,1]^2}} \mathrm{SBR}\left[\theta\right](u,v) = P$$

and the continuity of $\mathrm{SBR}\left[\theta\right]$ at $(0,0)$ holds. □

Figure 3 illustrates the case of an SBR-surface having a base point at $(u,v)=(0,0)$ whose image is a unique rational boundary curve of S. This image is the segment defined by the massic vectors θ_{03} and θ_{20}.

Remark. If

$$\lim_{\substack{(u,v)\to(0,0)\\(u,v)\in[0,1]^2}} \mathrm{SBR}\left[\theta\right](u,v) = P$$

we say that the image of the base point $(u,v)=(0,0)$ blows down into a point.

4. Algorithm for drawing a rectangular SBR-surface with base points. To draw a rectangular SBR-surface S which is the image of $[0,1]^2$, where S has a base point at $(u,v)=(0,0)$ whose image is m consecutive rational curves, we may apply a finite number of quadratic changes of variables of type $u=r(1-t), v=rt$ to the function $\mathrm{SBR}\left[\theta\right]$ (see [29]). Another strategy is to apply the same kind of change of variables as in the proof of Theorem 3.5. In each case, we clearly show the m additional boundary curves of S. Assuming that we apply the first strategy, the drawing of S will be a set of SBR-surfaces without any base point. We shall not apply the second strategy. Indeed, in that case, the regular SBR-surfaces we obtain by this method overlap, which is unsatisfactory for applications. The following proposition will help us to highlight the image curves of a base point.

PROPOSITION 4.1. *Let S be an SBR-surface defined by* (3.3). *Hence, by applying the change of variables $u=r(1-t), v=rt$ to function* $\mathrm{SBR}\left[\theta\right]$ *we obtain*

$$\mathrm{SBR}\left[\theta\right](u(r,t),v(r,t)) = \Pi\left(\sum_{k=0}^{n+pn+p}\sum_{l=0} B_k^{n+p}(r)\, B_l^{n+p}(t) * \omega_{kl}\right),$$

where for all $(k,l)\in\{0,\ldots,n+p\}^2$

$$\omega_{kl} = \sum_{i=0}^{k}\sum_{j=\max(0,i-n)}^{\min(i,p)} \frac{\binom{k}{i}\binom{n}{i-j}\binom{p}{j}\binom{n+p-i}{l-j}}{\binom{n+p}{i}\binom{n+p}{l}} * \Delta^{i-j,j}\theta_{00} \ \textit{if } n\le p,$$

$$\omega_{kl} = \sum_{i=0}^{k}\sum_{j=\max(0,i-p)}^{\min(i,n)} \frac{\binom{k}{i}\binom{n}{j}\binom{p}{i-j}\binom{n+p-i}{l-j}}{\binom{n+p}{i}\binom{n+p}{l}} * \Delta^{j,i-j}\theta_{00} \ \textit{else.}$$

Proof. We can write $\mathrm{SBR}\,[\theta]$ in the following monomial form:

$$\mathrm{SBR}\,[\theta]\,(u,v)=\Pi\left(\sum_{i=0}^{n}\sum_{j=0}^{p}\binom{n}{i}\binom{p}{j}u^{i}v^{j}*\Delta^{ij}\theta_{00}\right).$$

With the assumption that $n\leq p$, letting $u=r\,(1-t)\,,v=rt$, and $k=i+j$, we obtain

$$\mathrm{SBR}\,[\theta]\,(u\,(r,t)\,,v\,(r,t))=\Pi\left(\sum_{k=0}^{n+p}\sum_{j=\max(0,k-n)}^{\min(k,p)}r^{k}B_{j}^{k}\,(t)\,\frac{\binom{n}{k-j}\binom{p}{j}}{\binom{k}{j}}*\Delta^{k-j,j}\theta_{00}\right).$$

To provide the expression of $\mathrm{SBR}\,[\theta]$ in the Bernstein polynomial bases of degree $n+p$ in t, one can apply $n+p-k$ degree of elevations in t (see [9]), which gives

$$\begin{aligned}&\mathrm{SBR}\,[\theta]\,(u\,(r,t)\,,v\,(r,t))\\&\quad=\Pi\left(\sum_{k=0}^{n+p}\sum_{l=0}^{n+p}r^{k}B_{l}^{n+p}\,(t)\sum_{j=\max(0,k-n)}^{\min(k,p)}\frac{\binom{n}{k-j}\binom{p}{j}\binom{n+p-k}{l-j}}{\binom{n+p}{l}}*\Delta^{k-j,j}\theta_{00}\right).\end{aligned}$$

We are now able to write $\mathrm{SBR}\,[\theta]\,(u\,(r,t)\,,v\,(r,t))$ in the Bernstein polynomial bases of degree $n+p$ in r as follows:

$$\mathrm{SBR}\,[\theta]\,(u\,(r,t)\,,v\,(r,t))=\Pi\left(\sum_{k=0}^{n+p}\sum_{l=0}^{n+p}B_{k}^{n+p}\,(r)\,B_{l}^{n+p}\,(t)\,\omega_{kl}\right),$$

where $\Delta^{k0}\omega_{0l}=\sum_{j=\max(0,k-n)}^{\min(k,p)}\frac{\binom{n}{k-j}\binom{p}{j}\binom{n+p-k}{l-j}}{\binom{n+p}{k}\binom{n+p}{l}}*\Delta^{k-j,j}\theta_{00}$. Moreover, as we have $\omega_{kl}=\sum_{i=0}^{k}\binom{k}{i}*\Delta^{i0}\omega_{0l}$, then for all $(k,l)\in\{0,\ldots,n+p\}^{2}$,

$$\omega_{kl}=\sum_{i=0}^{k}\sum_{j=\max(0,i-n)}^{\min(i,p)}\frac{\binom{k}{i}\binom{n}{i-j}\binom{p}{j}\binom{n+p-i}{l-j}}{\binom{n+p}{i}\binom{n+p}{l}}*\Delta^{i-j,j}\theta_{00}.$$

The case $n>p$ is obtained by replacing n by p and conversely replacing $\Delta^{i-j,j}$ by $\Delta^{j,i-j}$. ∎

Remark. We can use this proposition for any base point at the corners of the definition domain. It suffices to apply an affine change of variables to the function (3.3).

The application of a quadratic change of variables to a rational surface with a base point at $(0,0)$ provides a new SBR-surface with certain complete lines of zero massic vectors which come from the diagonal lines of null massic vectors of the initial rectangular SBR-surface. Therefore, the aim of Proposition 4.2 is to eliminate these complete lines of null massic vectors.

PROPOSITION 4.2. *Let S be an* SBR*-surface defined by* (3.3)*, where for any given integers k_0,k_1,l_0,l_1 such that $n-k_0-k_1\geq 0$ and $p-l_0-l_1\geq 0$, we have $\theta_{ij}=\vec{0}$ for all $(i,j)\in\{0,\ldots,k_0-1\}\times\{0,\ldots,l_0-1\}$ and for all $(i,j)\in\{n-k_1+1,\ldots,n\}\times\{p-l_1+1,\ldots,p\}$. Then we have*

$$\mathrm{SBR}\,[\theta]\,(u,v)=\Pi\left(\sum_{i=0}^{n-k_0-k_1}\sum_{j=0}^{p-l_0-l_1}B_{i}^{n-k_0-k_1}\,(u)\,B_{j}^{p-l_0-l_1}\,(v)*\omega_{ij}\right),$$

where $\omega_{ij} = \frac{\binom{n}{i+k_0}\binom{p}{j+l_0}}{\binom{n-k_0-k_1}{i}\binom{p-l_0-l_1}{j}} * \theta_{i+k_0,j+l_0}$ *for all* $(i,j) \in \{0,\ldots,n-k_0-k_1\} \times \{0,\ldots,p-l_0-l_1\}$.

Proof. With these assumptions we have

$$\begin{aligned}&\mathrm{SBR}\,[\theta]\,(u,v)\\ &= \Pi\left(\sum_{j=0}^{p} B_j^p\,(v)\left(\binom{n}{k_0}(1-u)^{n-k_0}\,u^{k_0} * \theta_{k_0,j} \oplus \cdots \oplus (1-u)^{k_1}\,u^{n-k_1} * \theta_{n-k_1,j}\right)\right).\end{aligned}$$

Consequently, we can factorize by $u^{k_0}\,(1-u)^{k_1}$ and write $\mathrm{SBR}\,[\theta]$ in the following form:

$$\mathrm{SBR}\,[\theta]\,(u,v) = \Pi\left(\sum_{i=0}^{n-k_0-k_1}\sum_{j=0}^{p} B_i^{n-k_0-k_1}\,(u)\,B_j^p\,(v)\,\frac{\binom{n}{i+k_0}}{\binom{n-k_0-k_1}{i}} * \theta_{i+k_0,j}\right).$$

Again we factorize by $v^{l_0}\,(1-v)^{l_1}$ and we obtain the result. □

To draw on a computer a rectangular SBR-surface S having a base point at $(0,0)$ which satisfies the assumptions of Theorem 3.5, we need to remove the singularity. This can be done via the use of quadratic changes of variables and a subdivision process. Hence, the initial singular rectangular SBR-surface will be drawn by a net of regular SBR-surfaces defined by massic vectors. To do so, we define the following algorithm:

Step 0: Initialize the set C to $\{S\}$

Step 1: Do while there is a null massic vector either in the top left corner or in the bottom left corner of one rectangular SBR-surface of C

If there is a null massic vector at the two left corners of a surface of C then

- Subdivide the set of the massic vectors of this surface into four sets of massic vectors via the use of the algorithm of de Casteljau for SBR-surfaces [10] evaluated with the following parameters: $\left(\frac{1}{2},\frac{1}{2}\right)$.
- Remove the surface from C
- Add the two right regular surfaces to C
- Apply four quadratic changes of variables (see Propositions 4.1 and 4.2) to the two left surfaces:
  - For the bottom left SBR-surface, one at $(0,0)$ and one at $(1,1)$ (see Figure 5)
  - For the top left SBR-surface, one at $(0,1)$ and one at $(1,0)$
- Add these four new surfaces to C

End if

If there is only a null massic vector at the top left corner of a surface of C, then

- Remove the surface from C
- Apply two quadratic changes of variables to this surface, one at $(0,1)$ and one at $(1,0)$
- Add the two resulting sets of massic vectors to C

End if

If there is only a null massic vector at the bottom left corner of a surface of C, then

- Remove the surface from C
- Apply two quadratic changes of variables to this surface, one at $(0,0)$ and one at $(1,1)$
- Add the two resulting sets of massic vectors to C

End if

Step 2: Draw all the regular SBR-surfaces to the set C.

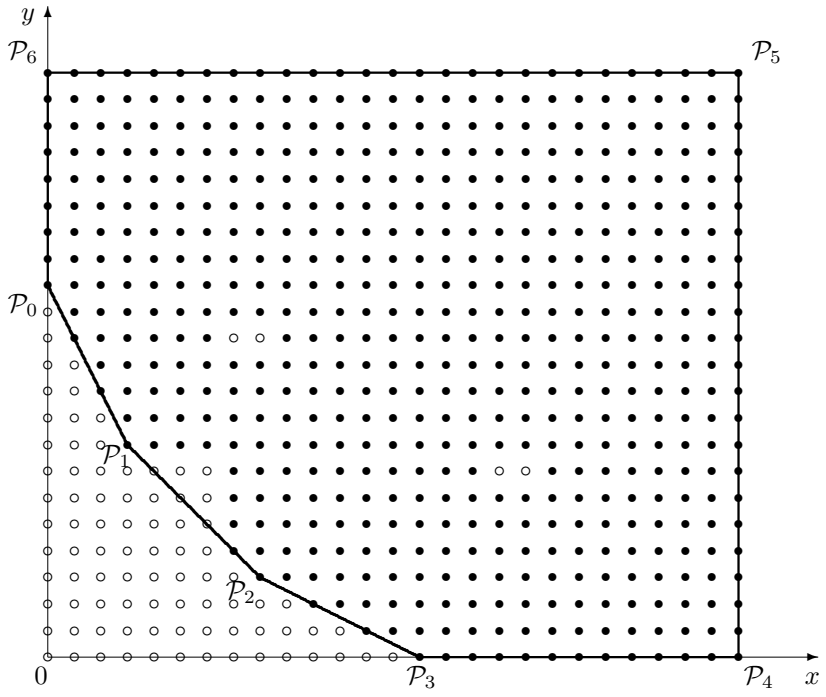

FIG. 4. *Example of a rectangular SBR-surface with a base point at* $(0,0)$. $\circ$ *denotes points associated with null massic vectors;* $\bullet$ *denotes points associated with non-zero massic vectors.*

For instance, in the case of Figure 4, we first apply the change of variables $u = r(1-t), v = rt$ to $\mathrm{SBR}[\theta]$ (see Figure 5). Thus, we divide the domain $[0,1]^2$ into two triangles. The upper triangle defines the domain of the surface SBR-surface called S_1 which does not have any base points at corners. The image of the lower one is, in variables (r,t), the square $[0,1]^2$, where the image of $(u,v) = (0,0)$ is $(0,t)$ for all $t \in [0,1]$. As the SBR-surface image of this domain has two base points (one at $t=0$ and the other one at $t=1$), we subdivide it into four SBR-patches by applying the classical algorithm of de Casteljau [7], [11], [10] at $(r,t) = \left(\frac{1}{2}, \frac{1}{2}\right)$ so that two of them (S_4 and S_5) are free from base points at corners. However, the two other do have a base point. By applying again a quadratic change of variables, $r = r_1(1-t_1)$, $t = r_1 t_1$ and $r = r_2(1-t_2)$, $t = 1 - r_2 t_2$, we obtain two additional SBR-patches S_6 and S_7, which do not present any base points on $[0,1]^2$. This method is illustrated by Figure 5.

5. Example of a seven-sided SBR-surface. We are now able to construct an n-sided SBR-surface which interpolates n given consecutive rational curves via the introduction of base points at the vertices of the definition domain of a rectangular SBR-surface. This can be done via relation (3.4), which gives the relations between the massic vectors whose indices belong to $\mathrm{Newton}(\mathrm{SBR}[\theta]) \cap \overline{\mathrm{Newton}}^{00}(\mathrm{SBR}[\theta])$ of the initial SBR-surface, and the massic vectors of the given BR-curves. Naturally, the massic vectors whose indices are inside points of the Newton polygon can be chosen arbitrarily with positive or null masses. This brings new possibilities to control the form of surfaces. The framework thus considered is more significant than that

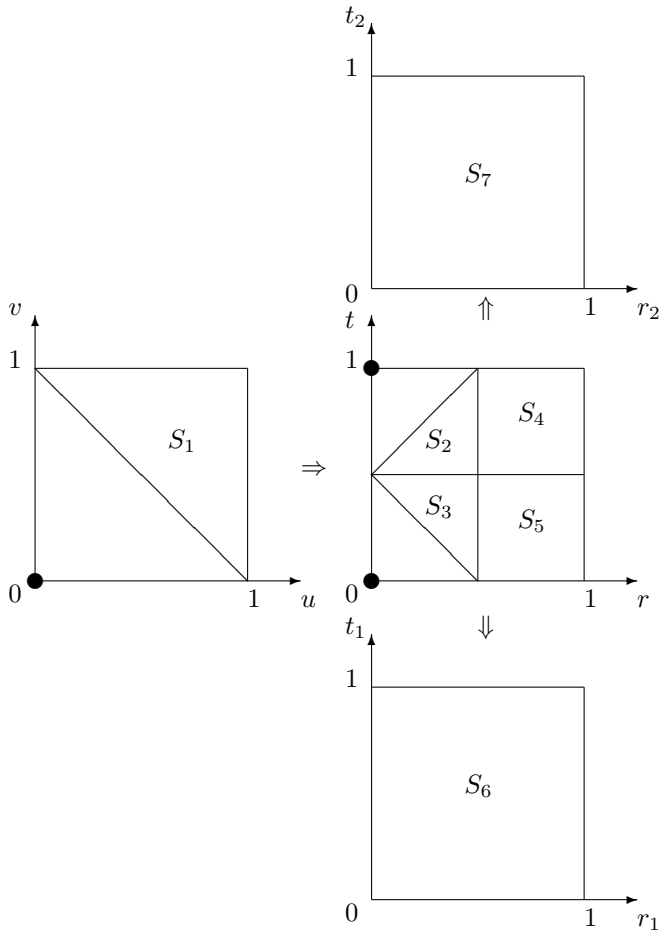

FIG. 5. *The diagram of the consecutive change of variables.*

considered in [30] and [31]. We shall now study an example with seven BR-curves.

Let $(\Omega, \vec{i}, \vec{j}, \vec{k})$ be a Cartesian frame. Let us consider the seven following BR-curves which create a hole (see Figure 6):

$$\Gamma_1(t) = BR[\tau_0^1 = (A_1; 1), \tau_1^1 = 2\vec{k}, \tau_2^1 = (A_2; 1)](t),$$

$$\Gamma_2(t) = BR[\tau_0^2 = (A_2; 1), \tau_1^2 = -2\vec{k}, \tau_2^2 = (A_3; 1)](t),$$

$$\Gamma_3(t) = BR[\tau_0^3 = (A_3; 1), \tau_1^3 = (A_4; 1)](t),$$

$$\Gamma_4(t) = BR\left[\tau_0^4 = (A_4; 1), \tau_1^4 = \left(\begin{pmatrix} 12.5 \\ 0 \\ -4 \end{pmatrix}; 2\right), \tau_2^4 = (A_5; 1)\right](t),$$

$$\Gamma_5(t) = BR\left[\tau_0^5 = (A_5; 1), \tau_1^5 = (A_6; 1)\right](t),$$

$$\Gamma_6(t) = BR\left[\tau_0^5 = (A_6; 1), \tau_1^5 = (A_7; 1)\right](t),$$

$$\Gamma_7(t) = BR[\tau_0^4 = (A_7; 1), \tau_1^4 = -2\vec{k}, \tau_2^4 = (A_1; 1)](t),$$

where

$$A_1 = \begin{pmatrix} -5 \\ 10 \\ 0 \end{pmatrix},\ A_2 = \begin{pmatrix} -3 \\ 5 \\ 0 \end{pmatrix},\ A_3 = \begin{pmatrix} 0 \\ 3 \\ 1 \end{pmatrix},\ A_4 = \begin{pmatrix} 10 \\ 0 \\ 0 \end{pmatrix},$$

$$A_5 = \begin{pmatrix} 15 \\ 0 \\ 0 \end{pmatrix},\ A_6 = \begin{pmatrix} 15 \\ 15 \\ 1 \end{pmatrix},\ A_7 = \begin{pmatrix} -5 \\ 15 \\ 0 \end{pmatrix}.$$

As $\chi\left(\tau_1^1\right)^2 - \chi\left(\tau_0^1\right)\chi\left(\tau_2^1\right) < 0$, $\chi\left(\tau_1^2\right)^2 - \chi\left(\tau_0^2\right)\chi\left(\tau_2^2\right) < 0$, and $\chi\left(\tau_1^7\right)^2 - \chi\left(\tau_0^7\right)\chi\left(\tau_2^7\right) < 0$, we can conclude via Proposition 5.1.6 in [11] that Γ_1, Γ_2, and Γ_7 are arcs of ellipses. As $\chi\left(\tau_1^4\right)^2 - \chi\left(\tau_0^4\right)\chi\left(\tau_2^4\right) > 0$ via the same proposition, we conclude that Γ_4 is a hyperbolic arc.

Moreover, we can show that Γ_1, Γ_2 join C^1 at A_2 and Γ_1, Γ_7 join C^1 at A_1 via Proposition 4.1.6 in [11].

We can now construct the grid of massic vectors of a rectangular SBR-surface, denoted by S, which fills the previous hole. We have to satisfy some relations so that the given BR-curves are the boundary curves of this surface. We arbitrarily choose to define the massic vectors of S as follows.

The massic vectors θ_{i9}, $i = 0, \ldots, 8$ (respectively, θ_{8j}, $j = 0, \ldots, 9$), are obtained from seven (respectively, eight) elevations of the length of the BR-curve Γ_6 (respectively, Γ_5). This allows us to obtain a better parametrization of the surface.

We are now searching for the relations between the massic vectors of the rectangular SBR-surface and the massic vectors of the boundary BR-curves Γ_1, Γ_2, Γ_3 so that they are the image of the base point at $(0,0)$. With that aim in view, we use the relation (3.4) and we obtain

$$\text{for } \Gamma_1\colon \theta_{07} = \frac{\binom{2}{2}}{\binom{8}{0}\binom{9}{7}} * (A_1;1), \quad \theta_{15} = \frac{\binom{2}{1}}{\binom{8}{1}\binom{9}{5}} 2\vec{k}, \quad \theta_{23} = \frac{\binom{2}{0}}{\binom{8}{2}\binom{9}{3}} * (A_2;1)\,;$$

$$\text{for } \Gamma_2\colon \theta_{23} = \frac{\binom{2}{2}}{\binom{8}{2}\binom{9}{3}} * (A_2;1), \quad \theta_{32} = -\frac{\binom{2}{1}}{\binom{8}{3}\binom{9}{2}} 2\vec{k}, \quad \theta_{41} = \frac{\binom{2}{0}}{\binom{8}{4}\binom{9}{1}} * (A_3;1)\,;$$

$$\text{for } \Gamma_3\colon \theta_{41} = \frac{\binom{1}{1}}{\binom{8}{4}\binom{9}{1}} * (A_3;1), \quad \theta_{60} = \frac{\binom{1}{0}}{\binom{8}{6}\binom{9}{0}} * (A_4;1)\,.$$

Moreover, Γ_4 (respectively, Γ_7) has to be the image of $(u,0)$, $u \in [0,1]$ (respectively, of $(0,v)$, $v \in [0,1]$). So we have

$$\text{for } \Gamma_4\colon \theta_{60} = \frac{\binom{2}{2}}{\binom{8}{6}} * (A_4;1), \quad \theta_{70} = \frac{\binom{2}{1}}{\binom{8}{7}} * \left(\begin{pmatrix} 12.5 \\ 0 \\ -4 \end{pmatrix};2\right), \quad \theta_{80} = \frac{\binom{2}{0}}{\binom{8}{8}} * (A_5;1)\,;$$

$$\text{for } \Gamma_7\colon \theta_{07} = \frac{\binom{2}{2}}{\binom{9}{7}} * (A_1;1), \quad \theta_{08} = -\frac{\binom{2}{1}}{\binom{9}{8}} 2\vec{k}, \theta_{09} = \frac{\binom{2}{0}}{\binom{9}{9}} * (A_7;1)\,.$$

As these relations are compatible, we have Figure 8.

FIG. 7. *A grid of the massic vectors of S.*

To draw this seven-sided SBR-surface S we use the results of the previous section. It is composed of seven SBR-surfaces which join each other naturally with the G^∞-continuity. Notice that the C^1-continuity of Γ_7 and Γ_1 at A_1 (respectively, the C^1-continuity of Γ_1 and Γ_2 at A_2) is satisfied and the null massic vectors whose indices are in the interior of $\mathrm{Conv}(\mathcal{A})$ (see Figure 7) induce a tension effect on the surface.

This seven-sided SBR-surface could have been defined with a base point, for instance, at $(0,0)$, $(1,0)$, $(1,1)$, with the constraint that the image of each base point is a unique BR-curve.

For instance, in the case of a five-sided filling surface we use the grid of massic vectors defined in Figure 3. The image curve of the base point is given by the massic vectors,

$$\theta_{20} = \left(\begin{pmatrix} 5 \\ 0 \\ 0 \end{pmatrix} ; 1 \right), \theta_{03} = \left(\begin{pmatrix} 0 \\ 5 \\ 0 \end{pmatrix} ; 1 \right)$$

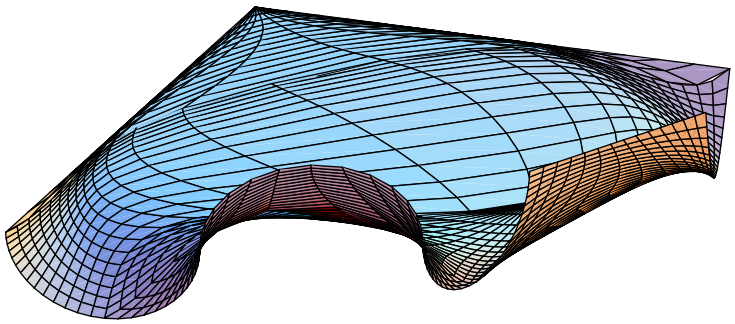

FIG. 8. *A seven sided SBR-surface defined from a rectangular one with a base point.*

(see Corollary 3.6), and the other boundaries are defined via the following four arcs of ellipses:

$$\theta_{20},\theta_{30}=\vec{k},\theta_{40}=\left(\begin{pmatrix}10\\0\\0\end{pmatrix};1\right);$$

$$\theta_{40},\ \theta_{41}=\left(\begin{pmatrix}10\\0\\\frac{2}{3}\end{pmatrix};\frac{3}{5}\right),\ \theta_{42}=\left(\begin{pmatrix}10\\\frac{5}{2}\\\\\frac{3}{2}\end{pmatrix};\frac{2}{5}\right),\ \theta_{43}=\left(\begin{pmatrix}10\\\frac{15}{2}\\\\\frac{3}{2}\end{pmatrix};\frac{3}{5}\right),$$

$$\theta_{44}=\left(\begin{pmatrix}10\\10\\\frac{2}{3}\end{pmatrix};\frac{3}{5}\right),\ \theta_{45}=\left(\begin{pmatrix}10\\10\\0\end{pmatrix};1\right);$$

$$\theta_{03},\theta_{04}=\vec{k},\theta_{05}=\left(\begin{pmatrix}0\\10\\0\end{pmatrix};1\right);$$

$$\theta_{05},\theta_{15}=\left(\begin{pmatrix}0\\10\\\frac{1}{2}\end{pmatrix};\frac{1}{2}\right),\ \theta_{25}=\left(\begin{pmatrix}5\\10\\1\end{pmatrix};\frac{1}{3}\right),\ \theta_{35}=\left(\begin{pmatrix}10\\10\\\frac{1}{2}\end{pmatrix};\frac{1}{2}\right),\ \theta_{45};$$

where the vector

$$\vec{k}=\begin{pmatrix}0\\0\\1\end{pmatrix}$$

and the massic vectors $\theta_{12}=\theta_{21}=\frac{1}{4}\vec{k}$.

If we modify θ_{12} and θ_{21}, the surface preserves its boundaries but the shape of the surface is modified (see Figures 9 and 10).

In a future work, we will apply the previous results to define an n-sided filling SBR-surface which joins G^1 or G^2 continuously with n given polynomial or rational surfaces. More generally (see [12], [13], [15], [14], [17], [16], [19]), we have dealt with

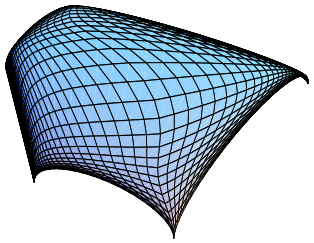

FIG. 9. *A five-sided rational surface where the segment is the image of the base point.*

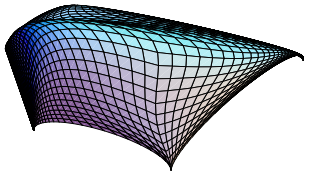

FIG. 10. *A five-sided rational surface with* $\theta_{12} = \vec{0}$ *and* $\theta_{21} = 2\vec{k}$.

this n-sided filling problem with parametric pole-functions of two variables where the image of a base point is several parametric boundary curves.

Acknowledgments. The author is grateful to Professor J. C. Fiorot for his valuable comments and suggestions. He would also like to thank A. Massabo for having brought to his attention the significance of base points for the applications.

A POSTERIORI ESTIMATION OF DIMENSION REDUCTION ERRORS FOR ELLIPTIC PROBLEMS ON THIN DOMAINS*

SERGEY REPIN†, STEFAN SAUTER‡, AND ANTON SMOLIANSKI‡

Abstract. A new a posteriori error estimator is presented for the verification of the dimensionally reduced models stemming from the elliptic problems on thin domains. The original problem is considered in a general setting, without any specific assumptions on the domain geometry, coefficients, and the right-hand sides. For the energy norm of the error of the zero-order dimension reduction method, the proposed estimator is shown to always provide a guaranteed upper bound. In the case when the original domain has constant thickness (but, possibly, nonplane upper and lower faces), the estimator demonstrates the optimal convergence rate as the thickness tends to zero. It is also flexible enough to successfully cope with infinitely growing right-hand sides in the equation when the domain thickness tends to zero. The numerical tests indicate the efficiency of the estimator and its ability to accurately represent the local error distribution needed for an adaptive improvement of the reduced model.

Key words. dimension reduction, thin domain, a posteriori error estimate, reliability, efficiency, local error distribution

DOI. 10.1137/030602381

1. Introduction.

The method of dimension reduction is a popular approach frequently used by engineers for the approximate solution of the problems posed in *thin* domains. The term "thin" means that the size of the original physical domain along one coordinate direction is much smaller than along the others; this allows us to make some simplifying assumptions on the behavior of the exact solution and to replace the original high-dimensional problem with a lower-dimensional one. For instance, such a situation arises if a three-dimensional problem is analyzed with the help of a two-dimensional model. It is, however, clear that the solution of the new, "reduced" problem will, in general, differ from the solution to the original high-dimensional problem. Thus, the dimension reduction method unavoidably produces an error that can be referred to as the dimension reduction or the *modeling error*. The essential part of the model verification is, hence, a reliable *a posteriori* control of the dimension reduction error.

Despite the practical importance of the topic, only a few a posteriori estimators for the dimension reduction error have been introduced so far. In [15] and [3] (see also [2]) the residual-type estimators were proposed and proved reliable and efficient under the assumptions that the right-hand side of the given equation is zero and the original domain is a plate with plane parallel faces. In [5] and [12] the implicit estimators based on the solution of local three-dimensional Neumann problems were developed for the hierarchical modeling of complex elastic plates. In [1] the estimator of Babuška and Schwab (see [2], [3]) was extended to take into account the discretization error stemming from the approximate solution of the reduced problem. In this respect, we

‡Institute of Mathematics, Zurich University, Winterthurerstrasse 190, CH-8057 Zurich, Switzerland (stas@amath.unizh.ch, antsmol@amath.unizh.ch).

have to notice that the present work is focused on the estimation of the modeling error; i.e., we assume, exactly as in [2], [3], that the error of discretizing the reduced problem is negligible. The work on the simultaneous a posteriori estimation of both the modeling error and the discretization error will be reported in a forthcoming paper.

In this work we propose a reliable and efficient a posteriori estimator for the dimension reduction error in the energy norm, having no specific assumptions on the right-hand side of the given equation and considering a general geometry of the given domain. In contrast to the above-mentioned papers, which deal with the hierarchical modeling of the problems in thin domains, we consider only the so-called *zero-order method* of dimension reduction that is, however, very popular owing to its simplicity and purely two-dimensional formulation. At the same time, this method forms a basis for the hierarchical modeling of three-dimensional plates (see, e.g., [14], [3], [12]). It is also worth noting that the zero-order method of dimension reduction does not cover the important Kirchhoff plate model in linear elasticity. The presented approach can, however, be extended to this case; the work on this subject is underway.

We advocate the functional-type a posteriori error estimation approach (see [7], [8], [9], [10]) that essentially differs from the approaches taken in the aforementioned articles; however, surprisingly enough, it is possible to show that Babuška and Schwab's estimator for the zero-order reduced problem can be obtained as a particular case of our estimator when the right-hand side of the equation is zero and the original domain is a plate with plane parallel faces. It must also be noticed that the treatment of the case with nonzero right-hand side may require special care, as we are about to see in one of the numerical examples; the presented estimator exhibits sufficient flexibility to remain efficient in this case.

The paper is set out as follows. Section 2 contains the geometric definitions and the problem statement. In section 3 we derive the reduced problem. Section 4 is devoted to the derivation of the a posteriori error estimate, while in section 5 we consider two particular cases and analyze the behavior of the estimator. The numerical examples are considered in section 6, and we draw the conclusions in section 7.

2. Problem setting. We consider three-dimensional Lipschitz domains, which can be given in the form

$$\Omega := \{x \in \mathbb{R}^3 \mid (x_1, x_2) \in \widehat{\Omega}\,,\ d_\ominus(x_1, x_2) < x_3 < d_\oplus(x_1, x_2)\}\,,$$

where $\widehat{\Omega} \subset \mathbb{R}^2$ is the orthogonal projection of Ω on the (x_1, x_2)-plane ($\widehat{\Omega}$ has the Lipschitz boundary $\widehat{\Gamma}$) and $d_\ominus$ and $d_\oplus$ are Lipschitz continuous functions defined on $\overline{\widehat{\Omega}}$. The lower and upper faces of Ω are denoted by

$$\Gamma_\ominus := \{x \in \mathbb{R}^3 \mid (x_1, x_2) \in \widehat{\Omega}\,,\ x_3 = d_\ominus(x_1, x_2)\}$$

and

$$\Gamma_\oplus := \{x \in \mathbb{R}^3 \mid (x_1, x_2) \in \widehat{\Omega}\,,\ x_3 = d_\oplus(x_1, x_2)\}\,;$$

the lateral boundary by

$$\Gamma_0 := \{x \in \mathbb{R}^3 \mid (x_1, x_2) \in \widehat{\Gamma}\,,\ d_\ominus(x_1, x_2) < x_3 < d_\oplus(x_1, x_2)\}$$

(see Figure 1).

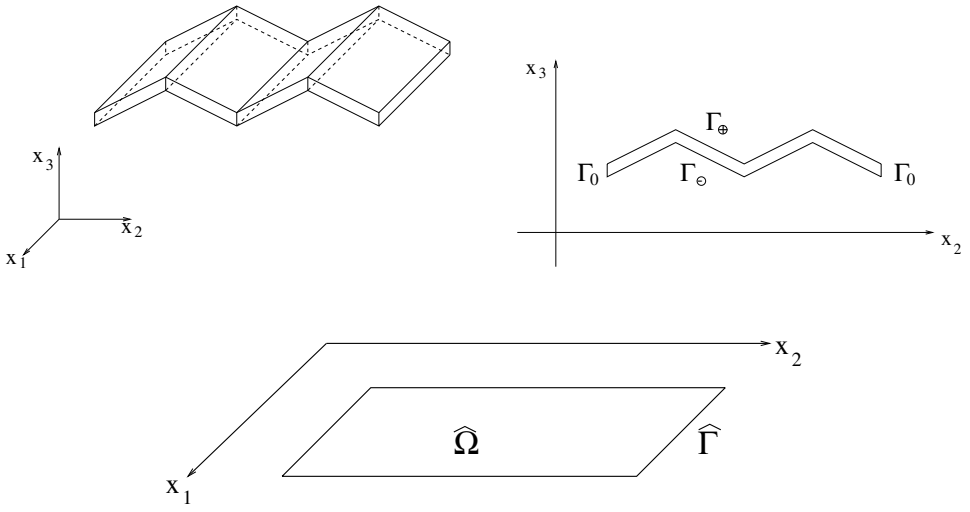

FIG. 1. *Sketch of the domain geometry.*

Remark 2.1. We consider $d_\ominus$ and $d_\oplus$ as explicit functions of (x_1, x_2)-coordinates only for the sake of simplicity. The generalization of the theory to the case of an arbitrary Lipschitz domain Ω presents no difficulty from the conceptional point of view.

The assumption that the given domain Ω is "thin" can now be written as

$$\operatorname{diam}\widehat{\Omega} \gg \max_{(x_1,x_2)\in\overline{\widehat{\Omega}}} d\,(x_1, x_2)\,, \tag{2.1}$$

where $d = d_\oplus - d_\ominus$ is the domain thickness, $d\,(x_1, x_2) \geq d_* > 0 \;\; \forall (x_1, x_2) \in \overline{\widehat{\Omega}}$. Although the assumption is of a purely qualitative nature, it will motivate the derivation of the corresponding two-dimensional reduced model in the next section. We also have to notice that Figure 1 depicts a simplified case; in the geometrical definitions we do not assume the domain thickness $d\,(x_1, x_2)$ to be a constant.

In the domain Ω we consider a model elliptic problem

$$-\operatorname{Div}(\mathbf{A}\nabla u) = f \quad \text{in } \Omega\,, \tag{2.2}$$

$$u = 0 \quad \text{on } \Gamma_0\,, \tag{2.3}$$

$$\mathbf{A}\nabla u \cdot \boldsymbol{\nu}_\ominus = F_\ominus \text{ on } \Gamma_\ominus\,, \tag{2.4}$$

$$\mathbf{A}\nabla u \cdot \boldsymbol{\nu}_\oplus = F_\oplus \text{ on } \Gamma_\oplus\,, \tag{2.5}$$

where $f \in L_2(\Omega)$, $F_\ominus \in L_2(\Gamma_\ominus)$, $F_\oplus \in L_2(\Gamma_\oplus)$, and $\boldsymbol{\nu}_\ominus$ and $\boldsymbol{\nu}_\oplus$ are outward normal vectors at $\Gamma_\ominus$ and $\Gamma_\oplus$, respectively. The matrix $\mathbf{A} = (a_{ij}(x))_{i,j=\overline{1,3}}$ with the components from $L_\infty(\Omega)$ is symmetric and uniformly positive definite; i.e., there exist constants $0 < c < C < \infty$ such that

$$c|\xi|^2 \leq \mathbf{A}(x)\xi \cdot \xi \leq C|\xi|^2 \quad \forall \xi \in \mathbb{R}^3, \text{ a.e. in } \Omega. \tag{2.6}$$

If the space of admissible functions is denoted by

$$V_0 := \{v \in H^1(\Omega) \mid v = 0 \text{ on } \Gamma_0\}\,, \tag{2.7}$$

the weak form of problem (2.2)–(2.5) reads as follows.

Problem (P). Find $u \in V_0$ such that

$$\int_\Omega \mathbf{A}\nabla u \cdot \nabla w \, dx = \int_\Omega f\, w \, dx + \int_{\Gamma_\ominus} F_\ominus \, w \, ds + \int_{\Gamma_\oplus} F_\oplus \, w \, ds \qquad \forall w \in V_0 \,. \tag{2.8}$$

From now on we will frequently use the notation $\widehat{x} = (x_1, x_2)$, $\widehat{x} \in \widehat{\Omega}$, and all functions depending only on (x_1, x_2) will be marked by $\widehat{\ }$; in addition, we will distinguish between the three- and two-dimensional divergence operators:

$$\mathrm{Div}\, \boldsymbol{\tau} = \frac{\partial \boldsymbol{\tau}_1}{\partial x_1} + \frac{\partial \boldsymbol{\tau}_2}{\partial x_2} + \frac{\partial \boldsymbol{\tau}_3}{\partial x_3} \,, \quad \mathrm{div}\, \widehat{\boldsymbol{\tau}} = \frac{\partial \widehat{\boldsymbol{\tau}}_1}{\partial x_1} + \frac{\partial \widehat{\boldsymbol{\tau}}_2}{\partial x_2} \,.$$

We also denote $\widehat{F}_\ominus(\widehat{x}) := F_\ominus(\widehat{x}, d_\ominus(\widehat{x}))$, $\widehat{F}_\oplus(\widehat{x}) := F_\oplus(\widehat{x}, d_\oplus(\widehat{x}))$ for any $\widehat{x} \in \widehat{\Omega}$. Finally, we define the energy norm

$$|||v||| := \left(\int_\Omega \mathbf{A}(x) \nabla v \cdot \nabla v \, dx \right)^{1/2} \qquad \forall v \in V_0 \,. \tag{2.9}$$

3. The reduced problem. In view of (2.1), it is reasonable to consider the hypothesis that

(3.1) the exact solution u is almost *constant* with respect to the x_3-coordinate.

This gives rise to the so-called *zero-order reduced model* for the original problem (2.8). The model is very popular due to its simplicity and purely two-dimensional formulation. A discussion on the hierarchy of reduced models of different orders can be found in, e.g., [14], [3].

With (3.1) in mind, one can expect that the exact solution u may be well approximated by the functions from the subspace

(3.2)
$$\widehat{V}_0 := \{ v \in V_0 \mid \exists\, \widehat{v} \in H^1_0(\widehat{\Omega}) \text{ such that } v(x) = \widehat{v}(\widehat{x}) \text{ for a.e. } x = (\widehat{x}, x_3) \in \Omega \} \,.$$

Thus, any function from $\widehat{V}_0$ can be identified with the corresponding function $\widehat{v} \in H^1_0(\widehat{\Omega})$ (and vice versa: for any $\widehat{v} \in H^1_0(\widehat{\Omega})$ one can reconstruct $v \in \widehat{V}_0 \subset V_0$ by the constant extension as in the definition of $\widehat{V}_0$). Then, the energy-norm projection of u onto the subspace $\widehat{V}_0$ yields the following *reduced problem* (the zero-order reduced model).

Problem ($\widehat{P}$). Find $\widehat{u} \in \widehat{V}_0$ such that

$$\int_\Omega \mathbf{A}\nabla \widehat{u} \cdot \nabla \widehat{w} \, dx = \int_\Omega f\, \widehat{w} \, dx + \int_{\Gamma_\ominus} F_\ominus \, \widehat{w} \, ds + \int_{\Gamma_\oplus} F_\oplus \, \widehat{w} \, ds \qquad \forall \widehat{w} \in \widehat{V}_0 \,. \tag{3.3}$$

Now we can define the dimension reduction error (the *modeling error*) as the difference $e := u - \widehat{u}$ between the solution to the original problem (2.8) and the solution to the reduced problem (3.3).

Remark 3.1. It may be noticed that assumption (2.1) (and, consequently, (3.1)) serves only as an intuitive motivation for the introduction of the approximation subspace $\widehat{V}_0$ and the reduced problem (3.3). Since the assumption cannot be quantified,

the real error of "replacing" u with $\widehat{u}$ may be large; a robust a posteriori error estimator should, however, measure this error sufficiently accurately even in the cases when assumption (2.1) is virtually unsatisfied.

Remark 3.2. The asymptotic behavior of the modeling error e was analyzed in [14] (see also [2]) for the case of a plate with plane parallel faces $\Gamma_\ominus$ and $\Gamma_\oplus$ (i.e., when $d_\ominus = -\frac{d_0}{2}$, $d_\oplus = \frac{d_0}{2}$, $d_0 = \text{const} > 0$ is the plate thickness) and $f = 0$. It was proved that

$$|||e||| \le C\, d_0^{1/2} \left(\|\widehat{F}_\ominus\|_{L_2(\widehat{\Omega})} + \|\widehat{F}_\oplus\|_{L_2(\widehat{\Omega})} \right) \quad \text{as } d_0 \to 0\,.$$

Remark 3.3. We have to note that the third component of the vector $\nabla\widehat{u}$ is zero (since $\widehat{u}$ does not depend on x_3) and, thus, the vector will sometimes be considered as a two-component vector when no confusion is possible.

In order to see that the reduced problem (3.3) is, in fact, a two-dimensional problem, we define the operation $(\widetilde{\ })$ of averaging in the x_3-direction as follows:

$$\forall g \in L_1(\Omega)\ : \quad \widetilde{g}(\widehat{x}) := \frac{1}{d\,(\widehat{x})} \int_{d_\ominus(\widehat{x})}^{d_\oplus(\widehat{x})} g(\widehat{x}, x_3)\, dx_3 \ \text{ for a.e. } \widehat{x} \in \widehat{\Omega}\,,$$

and, having noticed that

$$\int_{\Gamma_\ominus} F_\ominus\, \widehat{w}\, ds = \int_{\widehat{\Omega}} \widehat{F}_\ominus\,(\widehat{x})\, \widehat{w}\,(\widehat{x}) \sqrt{1 + |\nabla d_\ominus(\widehat{x})|^2}\, d\widehat{x} \quad \left(\text{analogously for } \int_{\Gamma_\oplus} F_\oplus\, \widehat{w}\, ds \right),$$

we can rewrite problem (3.3) as follows.

Find $\widehat{u} \in \widehat{V}_0$ such that

$$\int_{\widehat{\Omega}} d\,(\widehat{x}) \widetilde{\mathbf{A}}_p(\widehat{x}) \nabla\widehat{u} \cdot \nabla\widehat{w}\, d\widehat{x} = \int_{\widehat{\Omega}} d\,(\widehat{x}) \widehat{f}(\widehat{x}) \widehat{w}\, d\widehat{x} \quad \forall \widehat{w} \in \widehat{V}_0\,. \tag{3.4}$$

Here $\widetilde{\mathbf{A}}_p(\widehat{x}) = (\widetilde{a}_{ij}(\widehat{x}))_{i,j=\overline{1,2}}$ is the averaged "plane" part $\mathbf{A}_p(x)$ $(\mathbf{A}_p(x) = (a_{ij}(x))_{i,j=\overline{1,2}})$ of the matrix $\mathbf{A}$ and

$$\widehat{f}(\widehat{x}) = \widetilde{f}(\widehat{x}) + \frac{\widehat{F}_\ominus(\widehat{x}) \sqrt{1 + |\nabla d_\ominus(\widehat{x})|^2} + \widehat{F}_\oplus(\widehat{x}) \sqrt{1 + |\nabla d_\oplus(\widehat{x})|^2}}{d\,(\widehat{x})}\,.$$

It is clear that problem (3.4) is a two-dimensional elliptic problem with the homogeneous Dirichlet boundary condition

$$-\mathrm{div}\,(d(\widehat{x})\, \widetilde{\mathbf{A}}_p(\widehat{x}) \nabla\widehat{u}) = d(\widehat{x})\, \widehat{f}(\widehat{x}) \quad \text{in } \widehat{\Omega}, \tag{3.5}$$

$$\widehat{u} = 0 \quad \text{on } \widehat{\Gamma}\,. \tag{3.6}$$

4. A posteriori estimation of the modeling error. In order to control the dimension reduction error, we apply the functional-type a posteriori error estimate derived in [10] (see also [7] and [9]) to the original three-dimensional problem (2.8). The estimate reads as follows.

For all $\gamma > 0$, $\delta > 0$, and $y^* \in H_*(\Omega, \mathrm{Div})$ there holds

$$\begin{aligned} |||u - v|||^2 \le{}& (1+\gamma)\, M_1^2\,(v, y^*) + \left(1 + \frac{1}{\gamma}\right)(1+\delta)\, C_\Omega^2\, M_2^2\,(y^*) \\ &+ \left(1 + \frac{1}{\gamma}\right)\left(1 + \frac{1}{\delta}\right) C_\Gamma^2 (1 + C_\Omega^2)\, M_3^2\,(y^*), \end{aligned} \tag{4.1}$$

where v is any function from the energy space V_0, C_Ω is the constant from Friedrichs' inequality,

$$C_\Omega^{-2} = \inf_{w \in V_0 \setminus \{0\}} \frac{|||w|||^2}{\|w\|^2_{L_2(\Omega)}}\,, \tag{4.2}$$

C_Γ is the constant from the trace inequality,

$$C_\Gamma^2 = \sup_{w \in V_0 \setminus \{0\}} \frac{\|w\|^2_{L_2(\Gamma_\oplus)} + \|w\|^2_{L_2(\Gamma_\ominus)}}{|||w|||^2 + \|w\|^2_{L_2(\Omega)}}\,, \tag{4.3}$$

the space $H_*(\Omega, \mathrm{Div})$ is defined as

$$H_*(\Omega, \mathrm{Div}) := \{y^* \in L_2(\Omega, \mathbb{R}^3) \mid \mathrm{Div}\, y^* \in L_2(\Omega)\,,\ y^* \cdot \boldsymbol{\nu}_\ominus \in L_2(\Gamma_\ominus)\,,\ y^* \cdot \boldsymbol{\nu}_\oplus \in L_2(\Gamma_\oplus)\}\,,$$

and the functionals $M_1^2\,(v, y^*)$, $M_2^2\,(y^*)$, $M_3^2\,(y^*)$ are defined by

$$\begin{aligned}
M_1^2\,(v, y^*) &:= \int_\Omega (\nabla v - \mathbf{A}^{-1} y^*) \cdot (\mathbf{A}\nabla v - y^*)\, dx\,,\\
M_2^2\,(y^*) &:= \|\mathrm{Div}\, y^* + f\|^2_{L_2(\Omega)}\,,\\
M_3^2\,(y^*) &:= \|F_\ominus - y^* \cdot \boldsymbol{\nu}_\ominus\|^2_{L_2(\Gamma_\ominus)} + \|F_\oplus - y^* \cdot \boldsymbol{\nu}_\oplus\|^2_{L_2(\Gamma_\oplus)}\,.
\end{aligned}$$

In what follows, we will denote the functionals simply by M_1^2, M_2^2, M_3^2. Since estimate (4.1) holds true for any "approximate solution" v from V_0 and since the solution $\widehat{u}$ of the reduced problem is in $\widehat{V}_0 \subset V_0$, we can simply plug $\widehat{u}$ into estimate (4.1) to obtain an upper bound of the modeling error. We also emphasize that the estimate is valid for any positive numbers γ and δ and for any vector-function y^* from the space $H_*(\Omega, \mathrm{Div})$. While the best possible option would be to take as y^* the exact flux $\mathbf{A}\nabla u$ (then M_2 and M_3 would vanish and M_1 would give us the energy norm of the exact error), we have to restrict ourselves to choosing some computable quantity, i.e., not containing the unknown exact solution u. We approximate the flux by

$$y^* = \widetilde{\mathbf{A}}_p \nabla \widehat{u} + \boldsymbol{\tau}^*\,, \tag{4.4}$$

with $\boldsymbol{\tau}^* = \{0\,,\ 0\,,\ \psi(x)\}^T$. Here ψ is the auxiliary function from $L_2(\Omega)$ satisfying the conditions $\frac{\partial \psi}{\partial x_3} \in L_2(\Omega)\,$, $\psi \in L_2(\Gamma_\ominus)$, and $\psi \in L_2(\Gamma_\oplus)$. The concrete form of the function ψ will be given later. Its meaning becomes clear in the case of the Poisson equation (i.e., if $\mathbf{A}$ is the identity matrix), where ψ should, obviously, approximate the derivative $\frac{\partial u}{\partial x_3}$ of the exact solution in the x_3-direction. Using (3.5), it is easy to verify that y^* from (4.4) belongs to $H_*(\Omega, \mathrm{Div})$.

Remark 4.1. If in (4.1) we take y^* from the set

$$Q^*_{f,F} := \{q^* \in L_2(\Omega, \mathbb{R}^3) \mid \mathrm{Div}\, q^* = -f \text{ in } \Omega\,,\ q^* \cdot \boldsymbol{\nu}_{\ominus,\oplus} = F_{\ominus,\oplus} \text{ on } \Gamma_{\ominus,\oplus}\}\,,$$

we obtain the dual-formulation-based error estimate of [4] (see also [6] and [13]). Since it is not easy to satisfy the constraints of the set $Q^*_{f,F}$, the estimate (4.1) with y^* from $H_*(\Omega, \mathrm{Div})$ seems to be more practical. In particular, for the estimation of the modeling error under consideration we essentially exploit the freedom of choosing y^* in the whole space $H_*(\Omega, \mathrm{Div})$.

Remark 4.2. The estimate (4.1) possesses the property of asymptotic exactness (see [10]) but, if we choose y^* as in (4.4), this property might be lost, since the

only remaining "degree of freedom" is the function ψ and the approximate plane flux $\widetilde{\mathbf{A}}_p\nabla\widehat{u}$ may not sufficiently represent the first two components of the exact flux $\mathbf{A}\nabla u$. On the other hand, if we did not fix the first two components of y^*, the process of estimation would require the minimization of the right-hand side of (4.1) with respect to those components, which is, in principle, equivalent to solving a three-dimensional problem. However, our goal is to avoid any truly three-dimensional calculations in the evaluation of the error estimator (this process should not be more expensive than the solution of the reduced problem). Fortunately, in most of the situations, $\widetilde{\mathbf{A}}_p\nabla\widehat{u}$ is a good approximation to the "plane" part of the exact flux, and the modeling-error estimate with y^* as in (4.4) exhibits both efficiency and flexibility, as the numerical tests of section 6 show.

In order to rewrite estimate (4.1) in a more convenient form, we introduce the notation

$$\mathbf{B} := \mathbf{A}^{-1} \quad (\mathbf{B}(x) = (b_{ij}(x))_{i,j=\overline{1,3}}\,,\ \ \mathbf{B} = \mathbf{B}^T)\,, \tag{4.5}$$

$$\mathbf{B}_p := (b_{ij})_{i,j=\overline{1,2}}\,, \tag{4.6}$$

$$\mathbf{b}_3 := \{b_{31}\,,\ b_{32}\}^T\,. \tag{4.7}$$

The term M_1^2 with $v = \widehat{u}$ reads

$$M_1^2 = \int_\Omega (\nabla\widehat{u} - \mathbf{B}y^*)\cdot(\mathbf{A}\nabla\widehat{u} - y^*)\,dx = \int_\Omega (\mathbf{A}\nabla\widehat{u}\cdot\nabla\widehat{u} - 2y^*\cdot\nabla\widehat{u} + \mathbf{B}y^*\cdot y^*)\,dx\,. \tag{4.8}$$

For the first term in (4.8), one immediately obtains

$$\int_\Omega \mathbf{A}\nabla\widehat{u}\cdot\nabla\widehat{u}\,dx = \int_{\widehat{\Omega}} d\,(\widehat{x})\widetilde{\mathbf{A}}_p(\widehat{x})\nabla\widehat{u}\cdot\nabla\widehat{u}\,d\widehat{x}\,. \tag{4.9}$$

The second term in (4.8) can be further rewritten if one notices that (recall $\frac{\partial\widehat{u}}{\partial x_3} = 0$)

$$y^*\cdot\nabla\widehat{u} = (\widetilde{\mathbf{A}}_p\nabla\widehat{u} + \tau^*)\cdot\nabla\widehat{u} = \widetilde{\mathbf{A}}_p\nabla\widehat{u}\cdot\nabla\widehat{u}\,.$$

Thus,

$$\int_\Omega y^*\cdot\nabla\widehat{u}\,dx = \int_{\widehat{\Omega}} d\,(\widehat{x})\widetilde{\mathbf{A}}_p(\widehat{x})\nabla\widehat{u}\cdot\nabla\widehat{u}\,d\widehat{x}\,. \tag{4.10}$$

For the third term in (4.8) we have

$$\begin{aligned}\mathbf{B}y^*\cdot y^* &= (\mathbf{B}\widetilde{\mathbf{A}}_p\nabla\widehat{u} + \mathbf{B}\tau^*)\cdot(\widetilde{\mathbf{A}}_p\nabla\widehat{u} + \tau^*) = \mathbf{B}\widetilde{\mathbf{A}}_p\nabla\widehat{u}\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u} + \mathbf{B}\widetilde{\mathbf{A}}_p\nabla\widehat{u}\cdot\tau^*\\ &\quad + \mathbf{B}\tau^*\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u} + \mathbf{B}\tau^*\cdot\tau^* = \mathbf{B}_p\widetilde{\mathbf{A}}_p\nabla\widehat{u}\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u} + 2(\mathbf{b}_3\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u})\psi + b_{33}\psi^2\end{aligned}$$

that yields

$$\int_\Omega \mathbf{B}y^*\cdot y^*\,dx = \int_{\widehat{\Omega}} d\,(\widehat{x})\widetilde{\mathbf{B}}_p\widetilde{\mathbf{A}}_p\nabla\widehat{u}\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u}\,d\widehat{x} + \int_\Omega (b_{33}\psi(x)^2 + 2(\mathbf{b}_3\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u})\psi(x))\,dx\,, \tag{4.11}$$

where $\widetilde{\mathbf{B}}_p$ is the averaged "plane" part $\mathbf{B}_p(x)$ of the matrix $\mathbf{B}(x)$.

Substituting (4.9), (4.10), and (4.11) into (4.8), one obtains

(4.12)
$$M_1^2 = \int_{\widehat{\Omega}} d\,(\widehat{x})\,(\widetilde{\mathbf{B}}_p\widetilde{\mathbf{A}}_p - \mathbf{I})\nabla\widehat{u}\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u}\,d\widehat{x} + \int_\Omega (b_{33}\psi(x)^2 + 2(\mathbf{b}_3\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u})\psi(x))\,dx\,,$$

where $\mathbf{I}$ is the identity (2×2)-matrix. It is interesting to note that the first integral in (4.12) represents the error in averaging the coefficient matrix $\mathbf{A}(x)$; this becomes fully transparent in the case of a block-diagonal matrix $\mathbf{A}$, i.e., when $a_{31} = a_{32} = 0$ (then $\mathbf{B}_p = \mathbf{A}_p^{-1}$ and, without the averaging, the integral would be identically zero).

The functional M_2^2 of (4.1) also can be rearranged if one takes y^* as in (4.4). First, note that

$$\operatorname{Div} y^* = \operatorname{div}\widetilde{\mathbf{A}}_p\nabla\widehat{u} + \frac{\partial\psi}{\partial x_3}\,.$$

From (3.5) one can deduce

$$\operatorname{div}\widetilde{\mathbf{A}}_p\nabla\widehat{u} = -\widehat{f} - \frac{\nabla d}{d}\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u}\,.$$

Hence,

(4.13)
$$M_2^2 = \left\| f - \widetilde{f} - \frac{\widehat{F}_\ominus\sqrt{1+|\nabla d_\ominus|^2} + \widehat{F}_\oplus\sqrt{1+|\nabla d_\oplus|^2}}{d} - \frac{\nabla d}{d}\cdot\widetilde{\mathbf{A}}_p\nabla\widehat{u} + \frac{\partial\psi}{\partial x_3}\right\|^2_{L_2(\Omega)}\,.$$

The term M_3^2 with y^* from (4.4) reads

(4.14)
$$M_3^2 = \|F_\ominus - \widetilde{\mathbf{A}}_p\nabla\widehat{u}\cdot\boldsymbol{\nu}_\ominus - \psi\nu_{\ominus 3}\|^2_{L_2(\Gamma_\ominus)} + \|F_\oplus - \widetilde{\mathbf{A}}_p\nabla\widehat{u}\cdot\boldsymbol{\nu}_\oplus - \psi\nu_{\oplus 3}\|^2_{L_2(\Gamma_\oplus)}\,,$$

where $\widetilde{\mathbf{A}}_p\nabla\widehat{u}$ is considered as a vector in $\mathbb{R}^3$ with the third component equal to zero, and

$$\nu_{\ominus 3} = \frac{-1}{\sqrt{1+|\nabla d_\ominus|^2}}\,,\quad \nu_{\oplus 3} = \frac{1}{\sqrt{1+|\nabla d_\oplus|^2}}$$

are the third components of the normal vectors $\boldsymbol{\nu}_\ominus$ and $\boldsymbol{\nu}_\oplus$.

Now we can write the general a posteriori estimate for dimension reduction error as follows.

For all $\gamma > 0$ and $\delta > 0$ there holds

(4.15)
$$|||u-\widehat{u}|||^2 \le (1+\gamma)\,M_1^2 + \left(1+\frac{1}{\gamma}\right)(1+\delta)\,C_\Omega^2\,M_2^2 + \left(1+\frac{1}{\gamma}\right)\left(1+\frac{1}{\delta}\right)C_\Gamma^2(1+C_\Omega^2)\,M_3^2\,,$$

where the constants C_Ω and C_Γ are as above (see (4.2) and (4.3)) and the functionals M_1^2, M_2^2, and M_3^2 are given by (4.12), (4.13), and (4.14).

In estimate (4.15) we still have the freedom of choosing the auxiliary function ψ. The simplest choice is to take such a ψ so that the term M_3 (i.e., the residual on the

Neumann boundary condition) would be identically zero. To do so, we first rewrite the L_2-norms on $\Gamma_{\oplus,\ominus}$ in (4.14) as the integrals over $\widehat{\Omega}$:

$$\begin{aligned}&\| F_{\ominus} - \widetilde{\mathbf{A}}_p \nabla \widehat{u} \cdot \boldsymbol{\nu}_{\ominus} - \psi \nu_{\ominus 3} \|^2_{L_2(\Gamma_{\ominus})} \\ &\quad = \int_{\widehat{\Omega}} (\widehat{F}_{\ominus}(\widehat{x}) - \widetilde{\mathbf{A}}_p \nabla \widehat{u} \cdot \boldsymbol{\nu}_{\ominus} - \psi(\widehat{x}, d_{\ominus}(\widehat{x})) \nu_{\ominus 3})^2 \sqrt{1 + |\nabla d_{\ominus}|^2}\, d\widehat{x}\end{aligned}$$

(analogously for the norm in $L_2(\Gamma_{\oplus})$). Then, we denote

$$\widehat{G}_{\oplus,\ominus} := \widehat{F}_{\oplus,\ominus} - \widetilde{\mathbf{A}}_p \nabla \widehat{u} \cdot \boldsymbol{\nu}_{\oplus,\ominus}$$

and set

$$\psi_1(x) = \widehat{\alpha}(\widehat{x})\, x_3 + \widehat{\beta}(\widehat{x})\,, \tag{4.16}$$

where the functions $\widehat{\alpha}$ and $\widehat{\beta}$ ($\widehat{\alpha}\,,\ \widehat{\beta} \in L_2(\widehat{\Omega})$) are chosen so that

$$\psi_1 \nu_{\oplus 3} = \widehat{G}_{\oplus} \ \text{ at } \ x_3 = d_{\oplus}\,, \quad \psi_1 \nu_{\ominus 3} = \widehat{G}_{\ominus} \ \text{ at } \ x_3 = d_{\ominus}\,. \tag{4.17}$$

As $\nu_{\ominus 3}$, $\nu_{\oplus 3}$ belong to $L_\infty(\widehat{\Omega})$ and cannot be zero in $\widehat{\Omega}$, the functions $\widehat{\alpha}$ and $\widehat{\beta}$ are uniquely defined by conditions (4.17):

$$\widehat{\alpha} = \frac{1}{d}\left(\frac{\widehat{G}_{\oplus}}{\nu_{\oplus 3}} - \frac{\widehat{G}_{\ominus}}{\nu_{\ominus 3}}\right), \tag{4.18}$$

$$\widehat{\beta} = \frac{1}{d}\left(\frac{\widehat{G}_{\ominus}}{\nu_{\ominus 3}}\, d_{\oplus} - \frac{\widehat{G}_{\oplus}}{\nu_{\oplus 3}}\, d_{\ominus}\right). \tag{4.19}$$

It is obvious that the function ψ_1, as well as its derivative in the x_3-direction, belongs to $L_2(\Omega)$, and ψ_1 belongs to $L_2(\Gamma_{\oplus})$ and $L_2(\Gamma_{\ominus})$ (since $\psi_1\big|_{x_3 = d_{\oplus,\ominus}(\widehat{x})} \in L_2(\widehat{\Omega})$). Moreover, with such a function ψ the term M_3 becomes zero.

Remark 4.3. One can also consider a quadratic (with respect to x_3) function

$$\psi_2(x) = \psi_1(x) + \widehat{\eta}(\widehat{x})(x_3 - d_{\oplus}(\widehat{x}))(x_3 - d_{\ominus}(\widehat{x}))$$

with $\widehat{\eta}$ being an arbitrary function from $L_2(\widehat{\Omega})$. The substitution of ψ_2 instead of ψ into (4.14) will evidently imply $M_3 = 0$. In the second numerical example of section 6 we will use ψ_2 because of the freedom in the choice of the function $\widehat{\eta}$. It is clear that one can quite analogously construct the functions $\{\psi_m\}$, $m = 3, 4, \dots$, which would make the M_3-term vanish and could, possibly, allow us to approximate the third component of the exact flux $\mathbf{A}\nabla u$ with a higher accuracy.

Having chosen the function ψ such that $M_3 = 0$, one can obtain from (4.15) the following estimate for the squared energy norm of the modeling error:

$$|||u - \widehat{u}|||^2 \le (1 + \gamma)\, M_1^2 + \left(1 + \frac{1}{\gamma}\right) C_\Omega^2\, M_2^2\,, \tag{4.20}$$

where γ is any positive number, C_Ω is the Friedrichs constant, and M_1^2 and M_2^2 are given by (4.12) and (4.13). Minimizing the right-hand side of (4.20) with respect to the scalar parameter $\gamma > 0$, we immediately arrive at the estimate for the energy norm of the modeling error,

$$|||u - \widehat{u}||| \le M := M_1 + C_\Omega\, M_2, \tag{4.21}$$

with M_1 and M_2 defined by (4.12) and (4.13).

The rest of the paper will be devoted to the analysis of the properties of estimates (4.20), (4.21).

5. Particular cases. The error majorant M in (4.21) has been derived for quite general geometry of Ω and coefficient matrix $\mathbf{A}(x)$; to make the estimate more transparent, we consider two particular cases.

5.1. Plate of constant thickness. We assume that

$$d_\oplus = d_\ominus + d_0 \quad (d_0 = \text{const} > 0) \tag{5.1}$$

and, in addition, that

$$\mathbf{A} = \mathbf{A}(\widehat{x}) \ \text{ (this immediately implies } \mathbf{B} = \mathbf{B}(\widehat{x})\text{)}, \tag{5.2}$$

$$a_{31} = a_{32} = 0 \ \text{ (this yields } \mathbf{B}_p = \mathbf{A}_p^{-1},\ b_{33} = a_{33}^{-1},\ b_{31} = b_{32} = 0\text{)}. \tag{5.3}$$

With these assumptions and the choice $\psi = \psi_1$ (see (4.16)) the terms M_1 and M_2 in estimate (4.21) become simpler:

$$M_1 = \left(\int_\Omega a_{33}^{-1} \psi_1^2 \, dx \right)^{1/2}, \quad M_2 = \|f - \widetilde{f}\|_{L_2(\Omega)}. \tag{5.4}$$

One may notice that the integral in the first term M_1 of the error majorant M can be rewritten as

$$\int_\Omega a_{33}^{-1} \psi_1^2 \, dx = d_0 \cdot \int_{\widehat{\Omega}} a_{33}^{-1} \left(\widehat{\alpha}^2 \frac{d_\oplus^2 + d_\oplus d_\ominus + d_\ominus^2}{3} + \widehat{\alpha}\widehat{\beta}(d_\oplus + d_\ominus) + \widehat{\beta}^2 \right) d\widehat{x},$$

which means that the term M_1 is of order $\mathcal{O}(d_0^{1/2})$ when the plate thickness d_0 tends to zero. If $f \in L_\infty(\Omega)$, the second term M_2 is obviously of the same order $\mathcal{O}(d_0^{1/2})$; i.e., the whole estimator M converges to zero with the rate $\mathcal{O}(d_0^{1/2})$ as $d_0 \to 0$. This is the optimal convergence rate for the modeling error e in the energy norm, as was shown in [14] for the simpler case of a plate with plane parallel faces and $f = 0$ (see Remark 3.2). It is worth noting that, if $f \in C^1(\Omega)$, the second term in M is of higher order $\mathcal{O}(d_0^{3/2})$ as compared to the first term.

5.2. Plate with plane parallel faces. If in addition to (5.2), (5.3) we strengthen assumption (5.1) by replacing it with

$$d_\oplus = \frac{d_0}{2},\ d_\ominus = -\frac{d_0}{2} \quad (d_0 = \text{const} > 0), \tag{5.5}$$

then the function ψ_1 takes the simple form

$$\psi_1(x) = \frac{\widehat{F}_\oplus(\widehat{x}) + \widehat{F}_\ominus(\widehat{x})}{d_0} \, x_3 + \frac{\widehat{F}_\oplus(\widehat{x}) - \widehat{F}_\ominus(\widehat{x})}{2}$$

and the error estimate (4.21) reduces to

$$|||u - \widehat{u}||| \le \sqrt{\frac{d_0}{3}} \left(\int_{\widehat{\Omega}} a_{33}^{-1} (\widehat{F}_\oplus^2 + \widehat{F}_\ominus^2 - \widehat{F}_\oplus \widehat{F}_\ominus) \, d\widehat{x} \right)^{1/2} + C_\Omega \, \|f - \widetilde{f}\|_{L_2(\Omega)}. \tag{5.6}$$

If we set here $f = 0$, $a_{33} = 1$, and $\widehat{F}_\oplus = \widehat{F}_\ominus = \widehat{F}$, we obtain

$$|||u - \widehat{u}||| \le \sqrt{\frac{d_0}{3}} \, \|\widehat{F}\|_{L_2(\widehat{\Omega})}, \tag{5.7}$$

which is exactly the estimator of Babuška and Schwab (see [2]) for the zero-order reduced model. Thus, the latter estimator can be obtained as a particular case of the error majorant (4.21) if one makes the assumptions (5.2), (5.3), (5.5) and sets $f = 0$. This fact is especially interesting, since we advocate the estimation approach (see the details in [10]) that is completely different from the one utilized in [2].

Remark 5.1. The error estimate (4.21) contains the Friedrichs constant C_Ω that must be, in general, evaluated numerically. The constant depends solely on the geometry of the domain Ω and can be computed as $1/\sqrt{\lambda}$, where λ is the minimal eigenvalue of the elliptic operator $-\mathrm{Div}\,(\mathbf{A}\nabla\cdot\,)$ equipped with the homogeneous Dirichlet condition on Γ_0 and homogeneous Neumann conditions on $\Gamma_{\oplus,\ominus}$ (see (4.2)). It is clear that, in the case of a plate with plane parallel faces, C_Ω can be easily estimated from above if one computes the Friedrichs constant in a larger domain obtained by embedding the cross section $\widehat{\Omega}$ of Ω into some rectangle; the faces of this larger domain are then obtained by the extension of plane faces of Ω. Yet a simpler, but rougher, upper estimate for C_Ω in the case of a plate with plane parallel faces is given by $(\mathrm{diam}\,\widehat{\Omega})/c$, where c is the lower bound of the minimal eigenvalue of the matrix $\mathbf{A}(x)$ in Ω (see (2.6)). It is worth noticing that the constant C_Ω multiplies in the majorant the term M_2, which is often of higher order as compared to the first term M_1 (it is so, for example, in the particular cases considered above, when the function f is smooth). Then, the possible error of overestimation of C_Ω is harmless for the majorant accuracy.

6. Numerical examples.

6.1. Numerical test 1. In order to analyze the performance of the proposed error estimator, we consider a two-dimensional test problem in the "sine-shape" domain (see Figure 2 (left)) whose upper and lower faces are given by

$$d_{\oplus,\ominus}(x) = \sin(k\pi x) \pm \frac{d_0}{2}\,, \quad k = 1, 2, \dots\,,$$

where $d_0 > 0$ is the domain thickness. In this example, $\widehat{\Omega} = (0, 1)$ and $\Omega = \{(x, y) \in \mathbb{R}^2 \mid x \in \widehat{\Omega}\,,\ d_\ominus(x) < y < d_\oplus(x)\}$. The considered problem is

$$\begin{aligned} -\Delta u &= f && \text{in } \Omega\,,\\ u &= 0 && \text{at } x = 0 \text{ and } x = 1\,,\\ \nabla u \cdot \boldsymbol{\nu}_{\oplus,\ominus} &= F_{\oplus,\ominus} && \text{at } y = d_{\oplus,\ominus}\,, \end{aligned}$$

and the right-hand sides of the equation and of the boundary condition are computed using the exact solution

$$u(x, y) = \sin(\pi x) \cdot y^m \quad (m = 1, 2, \dots).$$

The reduced problem (3.3) is, in this case, a one-dimensional Dirichlet problem that, of course, can be solved very accurately (in the present work, we address the estimation of the modeling error only, assuming that the discretization error stemming from the solution of the reduced problem is negligible). The Friedrichs constant C_Ω was evaluated by computing the minimal eigenvalue of the Laplace operator with the corresponding homogeneous Dirichlet/Neumann boundary conditions (see Remark 5.1). We found that, for each $k = 1, 2, \dots$, C_Ω is an increasing function of the thickness d_0 as $d_0 \to 0$. There always exists, however, a clear upper bound for C_Ω; in particular, the estimates $C_\Omega \le \sqrt{2}$ for $k = 2$ and $C_\Omega \le 3$ for $k = 4$ hold true.

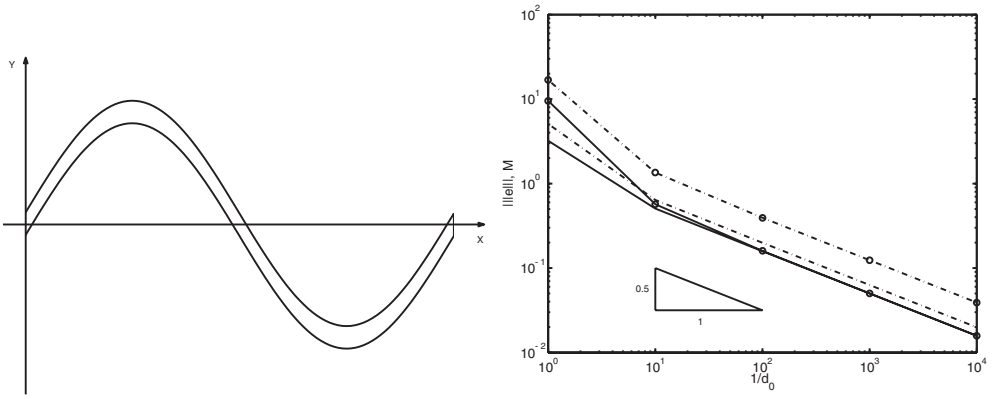

FIG. 2. *Left: The domain geometry. Right: Convergence rate of the exact modeling error and of the error majorant, $k = 2$, $m = 4$ (solid lines) and $m = 5$ (dash-dot lines). The majorant is indicated by "$\circ$."*

TABLE 1

Convergence of the exact modeling error in the energy norm ($|||e|||$) and of the error majorant (M) as $d_0 \to 0$ ($k = 2$); the results are rounded up to 10^{-4}.

Figure 2 (right) shows the convergence rates of the exact modeling error in the energy norm ($|||e|||$) and of the error majorant (M) as the domain thickness d_0 tends to zero (the analysis here corresponds to the case $k = 2$, when the domain Ω has the shape depicted in Figure 2 (left)). It is clear that both the exact error and the majorant vanish with the theoretically predicted, optimal rate $\mathcal{O}(d_0^{1/2})$. However, the behavior of the majorant is different for even and odd values of degree m determining the polynomial growth of the exact solution u in the y-direction. The typical picture corresponding to an even value of the parameter m is well represented by the case $m = 4$ in Figure 2 (right); in this case, the majorant M demonstrates the asymptotic exactness, and, moreover, the *effectivity index* $\frac{M}{|||e|||}$ behaves like $1 + \mathcal{O}(d_0)$ (see Table 1). In the case of an odd value of m (represented by $m = 5$ in Figure 2 (right)), the majorant loses the property of asymptotic exactness, although the effectivity index remains stable and behaves, approximately, like $1.963 + \mathcal{O}(d_0)$ (see Table 1). This problem was addressed in Remark 4.1 and is caused by the fact that the approximate flux computed in the reduced model does not provide sufficient information on the corresponding components of the exact flux. We may note, however, that the effectivity index is still quite acceptable in this case. Finally, it is worth noticing that the presented error estimator provides a reliable upper bound for the exact error at any positive values of the domain thickness d_0, i.e., also in the cases when the domain is not "thin" at all.

The local error distributions provided by the exact error and by the first M_1-term of the majorant M (see (5.4)) are depicted in Figure 3 (here we consider the

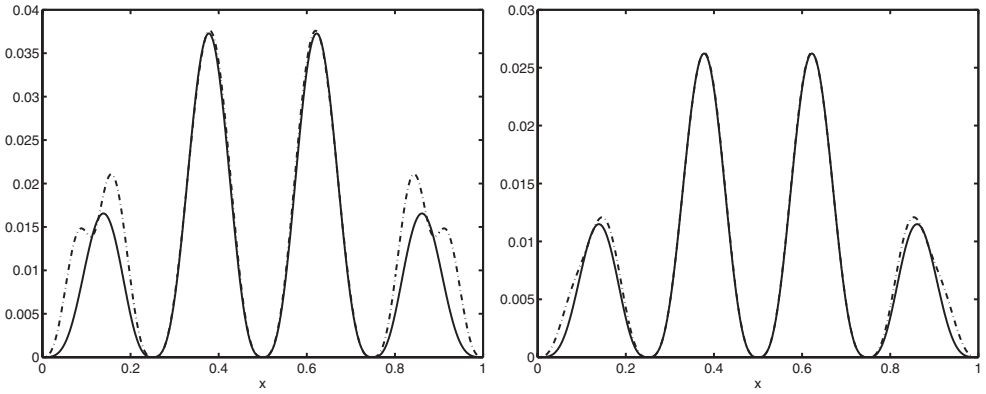

FIG. 3. *Local error distribution provided by the exact modeling error (solid line) and by the M_1-term of the majorant (dash-dot line), $k = 4$, $m = 4$. Left: $d_0 = 0.1$. Right: $d_0 = 0.05$.*

case $k = 4$, when the functions $d_{\oplus,\ominus}$ defining the shape of the domain have 4 extrema). The figure shows that already for rather large values of the domain thickness $d_0 = 0.1$ the majorant delivers sufficiently accurate information on the location of the regions of the biggest modeling error, while for $d_0 = 0.05$ the exact and the estimated error distributions are practically coincident.

6.2. Numerical test 2. The previous test shows that in the standard situations the proposed error estimator performs well. The example in this section demonstrates the performance of the estimator in a relatively difficult case when the right-hand side of the equation grows infinitely as the domain thickness tends to zero.

In this test, we consider a very simple geometry (see Figure 4 (left)), namely

$$d_{\oplus,\ominus} = \pm\frac{d_0}{2}\,,$$

where $d_0 > 0$ is the given thickness of the domain, $\widehat{\Omega} = (0,1)$ and $\Omega = \{(x,y) \in \mathbb{R}^2 \mid x \in \widehat{\Omega}\,,\ -\frac{d_0}{2} < y < \frac{d_0}{2}\}$. The considered problem reads

$$\begin{aligned} -\Delta u &= f && \text{in } \Omega\,,\\ u &= 0 && \text{at } x = 0 \text{ and } x = 1\,,\\ \frac{\partial u}{\partial y} &= \pm F_{\oplus,\ominus} && \text{at } y = \pm\frac{d_0}{2}\,, \end{aligned}$$

and the right-hand sides of the equation and of the boundary condition are computed using the exact solution

$$u(x,y) = \sin(\pi x)\cdot\frac{y^m}{d_0^{m-1}} \quad (m = 1, 2, \dots).$$

The scaling factor d_0^{m-1} makes this test essentially different from the previous one: while the Neumann boundary data $F_{\oplus,\ominus}$ remain of order $\mathcal{O}(1)$ as $d_0 \to 0$, the right-hand side of the equation f exhibits the behavior $f \sim \mathcal{O}(d_0) + \mathcal{O}\big(\frac{1}{d_0}\big)$, i.e., unboundedly grows when d_0 tends to zero. The unbounded growth of f may yield serious problems for an a posteriori error estimator, as we are about to see. We also note that the

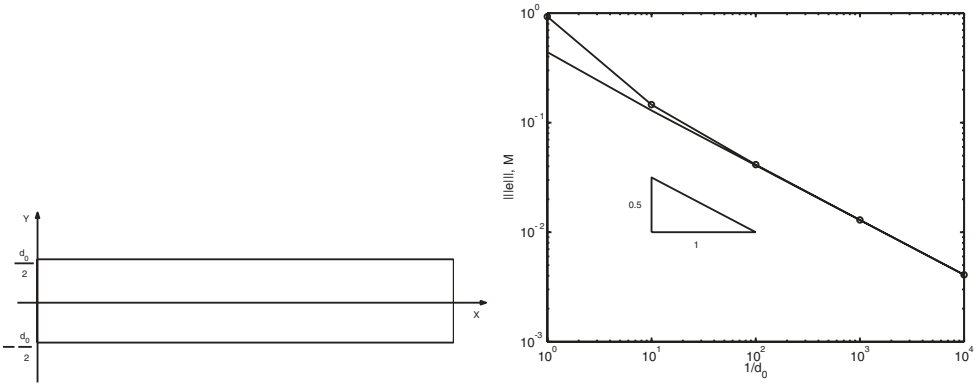

FIG. 4. *Left: The domain geometry. Right: Convergence rate of the exact modeling error and of the error majorant, $m = 2$; the majorant is indicated by* "$\circ$."

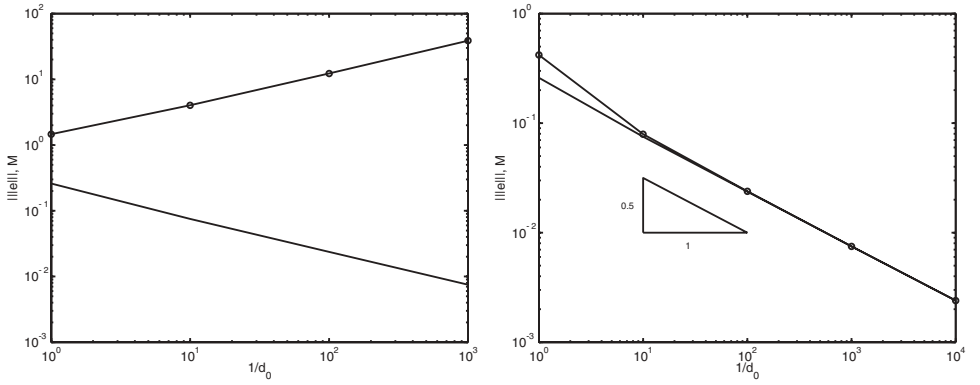

FIG. 5. *The case $m = 3$. Left: Divergence of the majorant $M(\psi_1)$ as $d_0 \to 0$. Right: Convergence of the improved majorant $M(\psi_2)$.*

constant C_Ω can be computed exactly in this example: $C_\Omega = \frac{1}{\pi}$ for all values of the thickness d_0.

First, we take $m = 2$ and observe the convergence of the exact modeling error in the energy norm and of the error majorant as d_0 tends to zero; see Figure 4 (right). As in the preceding example, the error majorant provides a reliable upper bound for the exact error at any values of the thickness d_0, both the exact error and the majorant demonstrate the optimal convergence rate $\mathcal{O}(d_0^{1/2})$ and, moreover, the error majorant shows the asymptotic exactness in this case (the effectivity index $\frac{M}{|||e|||} = 1 + \mathcal{O}(d_0)$; see the column under "$m = 2$, $M(\psi_1)$," in Table 2). However, if we set $m = 3$, the second term of the majorant M (i.e., $\|f - \widetilde{f}\|_{L_2(\Omega)}$, see (5.6)) becomes dominant and the whole estimator grows unboundedly, as can be seen in Figure 5 (left). The estimator becomes, of course, useless as it dramatically overestimates the exact error for small values of d_0. It is rather clear that the problem originates from the poor choice of the auxiliary function ψ that is supposed to approximate $\frac{\partial u}{\partial y}$; for $m = 3$ the derivative is quadratic and cannot be adequately represented by the linear function ψ_1.

The situation may be improved by invoking the quadratic function $\psi = \psi_2$ (see Remark 4.3), $\psi_2(x,y) = \psi_1(x,y) + \widehat{\eta}(x)\,(y^2 - \frac{d_0^2}{4})$, where $\widehat{\eta}$ is an arbitrary function from $L_2(\widehat{\Omega})$. The possibility of choosing a suitable $\widehat{\eta}$ enables us to suppress the unbounded growth of f in the M_2-term of the majorant and makes the majorant flexible enough to efficiently reproduce the behavior of the exact error.

If we plug ψ_2 into the estimate (4.20), we obtain

$$|||u - \widehat{u}|||^2 \le M^2(\widehat{\eta}, \gamma) \qquad \forall \widehat{\eta} \in L_2(\widehat{\Omega})\,,\ \forall \gamma > 0\,, \tag{6.1}$$

where

$$\begin{aligned} M^2(\widehat{\eta},\gamma) :&= (1+\gamma)\|\psi_2\|^2_{L_2(\Omega)} + \left(1 + \frac{1}{\gamma}\right) C_\Omega^2 \left\| f - \widetilde{f} + \frac{\partial \psi_2}{\partial y} \right\|^2_{L_2(\Omega)} \\ &= (1+\gamma) \int_\Omega \left(\psi_1(x,y) + \widehat{\eta}(x)\,\left(y^2 - \frac{d_0^2}{4}\right)\right)^2 dxdy \\ &\quad + \left(1 + \frac{1}{\gamma}\right) C_\Omega^2 \int_\Omega (f(x,y) - \widetilde{f}(x) + \widehat{\eta}(x)\cdot 2y)^2\, dxdy\,. \end{aligned}$$

Since estimate (6.1) is valid for any $\gamma > 0$ and $\widehat{\eta}$ from $L_2(\widehat{\Omega})$, one can minimize the functional $M^2(\widehat{\eta},\gamma)$ with respect to these parameters. In particular, one can set $\gamma = \gamma_* < 1$ (the concrete value of γ_* does not matter, as the numerical experiments show; we used the value $\gamma_* = 0.5$) and find $\widehat{\eta}_{\min}$ as the minimizer of $M^2(\widehat{\eta},\gamma_*)$ over the space S of piecewise-constant functions defined on some finite subdivision of $\widehat{\Omega}$ (obviously, $S \subset L_2(\widehat{\Omega})$). The minimization problem is just an L_2-projection onto the space of functions defined on $\widehat{\Omega}$ and amounts to the solution of a linear system with the diagonal matrix.

The properties of the improved majorant $M(\psi_2) = M_1(\psi_2) + C_\Omega\, M_2(\psi_2)$, where

$$\begin{aligned} M_1(\psi_2) &:= \left\| \psi_1 + \widehat{\eta}_{\min}\,\left(y^2 - \frac{d_0^2}{4}\right) \right\|_{L_2(\Omega)}\,, \\ M_2(\psi_2) &:= \|f - \widetilde{f} + \widehat{\eta}_{\min}\cdot 2y\|_{L_2(\Omega)}, \end{aligned}$$

can be observed in Figure 5 (right). We see that the improved majorant vanishes with the optimal rate $\mathcal{O}(d_0^{1/2})$ as $d_0 \to 0$, remains a reliable upper bound for the exact error at any values of the thickness d_0, and even demonstrates the asymptotic exactness with the effectivity index behaving like $1 + \mathcal{O}(d_0)$ (see Table 2).

We may note that in the case of larger values of m ($m > 3$) the higher degree function ψ_{m-1} might be needed (see Remark 4.3); the function will contain several free parameters which are the functions from $L_2(\widehat{\Omega})$, and, hence, the minimization should be performed with respect to all of them. However, as this always remains a least-squares minimization problem, the total complexity for the moderate values of m will not be greater than the complexity of solving the reduced problem. In general, if the right-hand side f exhibits an unbounded growth for $d_0 \to 0$ and no a priori information on the behavior of the exact solution is available, one has to choose the function ψ in an adaptive way; i.e., starting with ψ_1, increase the polynomial degree of the function until the difference between the two successive majorants $M(\psi_{n-1})$ and $M(\psi_n)$ becomes small enough.

7. Conclusions. For the zero-order dimension reduction method, the new a posteriori error estimator has been derived in a general geometrical setting of the problem and without any specific assumptions on the given data. In particular, the estimator reduces to the Babuška–Schwab estimator when the physical domain Ω is a plate with plane parallel faces and the equation has zero right-hand side. It has been demonstrated, both theoretically and numerically, that also in a more complicated case of a plate having constant thickness but nonplane faces and for a general right-hand side $f \in L_\infty(\Omega)$ the proposed estimator vanishes with the optimal rate $\mathcal{O}(d_0^{1/2})$ as the plate thickness d_0 tends to zero. Since the estimator always provides an upper bound for the exact modeling error, the latter convergence result can be considered as the generalization of the result on the convergence of the dimension reduction error proved in [14] (see also [2]) for the case of a plate with plane parallel faces and zero right-hand side f.

The presented estimator cannot, however, be considered as just a generalization of the explicit residual-type error estimator to the case of more complicated geometry, coefficients, and right-hand side. As numerical test 2 shows, in the problem with the right-hand side f infinitely growing as the plate thickness tends to zero, some additional "degree of freedom" should be introduced into the estimator to suppress the unbounded growth of f. Thus, it seems that any error estimator that cannot be adjusted to the particular problem will fail in such a case. The proposed estimator is sufficiently flexible to allow the modification necessary for capturing the behavior of the exact error. The recovered efficiency of the estimator manifests itself in the asymptotics of the effectivity index $\frac{M}{|||e|||} = 1 + \mathcal{O}(d_0)$ when d_0 tends to zero. We have to note that such an asymptotics may not always be observed if the domain Ω has nonplane faces; however, even in the latter case, the effectivity index of the estimator remains stable (i.e., does not grow with the decreasing domain thickness) and stays at the acceptable level.

The computational cost of evaluating the presented error majorant is typically smaller than or, in the worst case, of the same order as the cost of solving the reduced, lower-dimensional problem. Finally, the numerical results show that the proposed estimator is capable of an accurate indication of the local error distribution and, hence, may be utilized not only for the verification of the dimensionally reduced model but also for its adaptive improvement.

ORDER OF CONVERGENCE ESTIMATES FOR AN EULER IMPLICIT, MIXED FINITE ELEMENT DISCRETIZATION OF RICHARDS' EQUATION*

FLORIN RADU†, IULIU SORIN POP‡, AND PETER KNABNER†

Abstract. We analyze a discretization method for a class of degenerate parabolic problems that includes the Richards' equation. This analysis applies to the pressure-based formulation and considers both variably and fully saturated regimes. To overcome the difficulties posed by the lack in regularity, we first apply the Kirchhoff transformation and then integrate the resulting equation in time. We state a conformal and a mixed variational formulation and prove their equivalence. This will be the underlying idea of our technique to get error estimates.

A regularization approach is combined with the Euler implicit scheme to achieve the time discretization. Again, equivalence between the two formulations is demonstrated for the semidiscrete case. The lowest order Raviart–Thomas mixed finite elements are employed for the discretization in space. Error estimates are obtained, showing that the scheme is convergent.

Key words. error estimates, Euler implicit scheme, mixed finite elements, regularization, degenerate parabolic problems, porous media, Richards' equation

1. Introduction.

A commonly accepted mathematical model of water flow in porous media is the Richards' equation, a nonlinear, possibly degenerate, parabolic differential equation. In the pressure formulation, Richards' equation [5] is expressed as

$$\partial_t \Theta(\psi) - \nabla \cdot K(\Theta)\nabla(\psi + z) = 0, \tag{1.1}$$

where ψ is the pressure head, Θ the saturation, K the conductivity, and z the height against the gravitational direction. The equation (1.1) models the flow of a wetting fluid (water) in a porous media in the presence of a nonwetting fluid (air) supposed to be at constant pressure, 0. In the saturated region (where only water is present) we have $\psi \geq 0$, while $\psi < 0$ in the unsaturated domain. Different functional dependencies (retention curves) between ψ, K and Θ are proposed in the literature. These are provided essentially by soil particularities and allow reducing all the unknowns in the above equation to a single one. Here we are interested in both partially saturated and saturated flow, therefore we retain the pressure ψ as primary unknown.

As suggested in [1], applying the Kirchhoff transformation

$$\begin{aligned} \mathcal{K} : \mathbb{R} &\longrightarrow \mathbb{R}, \\ \psi &\longmapsto \int_0^{\psi} K(\Theta(s))\, ds \end{aligned} \tag{1.2}$$

leads to unknowns that are more regular. Since $K(\Theta(s))$ is positive, this transformation can be inverted and equation (1.1) can be rewritten in terms of a new variable, $u := \mathcal{K}(\psi)$. Now defining

$$\begin{aligned} b(u) &:= \Theta \circ \mathcal{K}^{-1}(u), \\ k(b(u)) &:= K \circ \Theta \circ \mathcal{K}^{-1}(u) \end{aligned} \tag{1.3}$$

and letting e_z denote the vertical unit vector, (1.1) becomes

$$\partial_t b(u) - \nabla \cdot (\nabla u + k(b(u))\ e_z) = 0 \quad \text{in} \quad (0,T] \times \Omega. \tag{1.4}$$

By the above transformation, diffusion becomes linear in equation (1.1). However, the problem may still remain degenerate, leading to solutions lacking regularity. Since this equation models important practical problems, several papers are dealing with analysis and numerical methods for it. Euler methods are often employed for the discretization in time. Adaptive time stepping is studied in [25], [14], or [28]. In case of an implicit discretization, iterative methods are considered (see, for example, [16], [8], whose method was already proposed in [12] and used also in [15], and [14]).

For the spatial discretization, mixed finite elements or finite volumes provide a good approximation of the solution [17], [4], [6], [10]. The most comprehensive algorithmic approach has been presented in the thesis [25], where hybrid mixed finite elements and an implicit Euler discretization are used. The set of nonlinear equations is solved by a Newton/multigrid method, while time and space adaptive strategies are constructed on the basis of rigorous error indicators. However, most of the authors are mainly interested in computational aspects and less concerned with rigorous convergence results. With respect to this last aspect we mention [2], where a model nonlinear, degenerate, advection-diffusion equation is considered. Through time integration a mixed variational formulation respecting the known minimal regularity of the solution is obtained. Raviart–Thomas lowest order finite elements are used. A priori error estimates are derived for the time integral of the flux and for the saturation. The estimates are optimal for the semidiscrete (continuous in time), noncomputable scheme. In the degenerate case, an explicit order of convergence for the fully discrete scheme can be deduced only by assuming extra (nonrealistic) regularity for the solution. Using similar techniques, [26] proved also some a priori error estimates for a mixed finite element discretization of Richards' equation. Unfortunately, again an explicit order of convergence for the scheme can be derived only in the nondegenerate case. Another important paper is [21], which deals with a class of multidimensional degenerate parabolic equations, including Richards' equation. A fully discrete scheme based on C^0 piecewise linear finite elements in space and a semi-implicit discretization in time is proposed and analyzed. An explicit order of convergence $(\tau^{1/2} + h)$ is proved. The techniques used here to cope with degenerate parabolic equations, which have been not used so far for discretizations based on mixed finite element method, will permit us to extend the results in [2] to the general, degenerate case. As in [26], error bounds for the time integral of the pressure will be also derived. We note also the recent paper [29], where the techniques from [2] are used for the numerical analysis of an expanded mixed finite element discretization of the Richards' equation. Also employed here are the Raviart–Thomas lowest order finite elements. Convergence rates depending on the Hölder continuity of the capacity term are derived for the entire regime of fully saturated to fully unsaturated flow. Nevertheless, the expanded mixed finite element method is not equivalent with the standard mixed finite element method and their results cannot be simply transferred to our method. Finally, we

mention also [10] (where convergence of an implicit finite volume method is proven by compactness arguments), [13] (for a relaxation scheme that applies to this equation too), and [23] (where error estimates are obtained for the unsaturated regime).

Here we consider an increasing and Lipschitz continuous b. Nevertheless, $b'(u)$ may be 0 for some values of u (not necessary isolated). Our numerical approach employs the lowest order Raviart–Thomas finite elements in space and Euler implicit in time, together with a regularization step. Specifically, with $N > 0$ integer, set $\tau = T/N$ and let $\mathcal{T}_h$ be a decomposition of Ω into closed d-simplices; h stands for the mesh-size. In a formal writing, the numerical scheme under consideration reads as

$$\begin{aligned} b_\epsilon(p_h^n) + \tau \nabla \cdot q_h^n &= b_\epsilon(p_h^{n-1}), \\ q_h^n + \nabla p_h^n + k(b(p_h^n))e_z &= 0 \end{aligned}$$

for $n = \overline{1, N}$; p_h^0 approximates u^0 in the finite dimensional approximation space. The term ∇p_h^n should be understood in a weak sense. Here b_ϵ is a regular approximation of b depending on the small parameter $\epsilon > 0$. By p_h^n we denote a piecewise constant approximation of u and q_h^n is a Raviart–Thomas (RT_0) approximation of the flux $-(\nabla u + k(b(u))e_z)$, based on $\mathcal{T}_h$, both at $t = n\tau$.

As suggested in [2], to overcome the difficulties posed by the lack in regularity, equation (1.4) is first integrated in time. For the resulting problem a mixed variational formulation is stated.

Convergence is shown by obtaining first error estimates for the time discrete scheme, by following the ideas in [21]. Since we work in a slightly more general framework, we include for completeness the proof for the conformal formulation. Next, using the procedure described in [2, 26], error estimates for the fully discrete scheme are obtained. In this setting, the equivalence between the mixed and conformal formulations becomes essential since, in this way, results obtained for one case can be transferred to the other one.

The outline of the paper is as follows. First, we state the main assumptions and notations used throughout the paper, define the problem to be solved, and discuss questions regarding existence and regularity of a solution. In section 2 the equivalence between a conformal and a mixed variational formulations is proved, for the continuous case as well as for the time discrete one. In section 3 we investigate the stability of the numerical scheme, while error estimates are derived in section 4.

1.1. Notations and assumptions. In what follows we let Ω be a domain in $\mathbb{R}^d$ (with $d = 1, 2,$ or 3). Let $J = (0, T]$ be a finite time interval. We are interested in solving (1.4) endowed with initial and boundary conditions,

$$\begin{aligned} \partial_t b(u) - \nabla \cdot (\nabla u + k(b(u))e_z) &= 0 \qquad \text{in} \quad J \times \Omega, \\ u &= u^0 \qquad \text{in} \quad 0 \times \Omega, \\ u &= 0 \qquad \text{on} \quad J \times \Gamma. \end{aligned} \tag{1.5}$$

Throughout this paper we make use of the following assumptions.

(A1) $\Omega \subset \mathbb{R}^d$ is bounded with Lipschitz continuous boundary.

(A2) $b \in C^1$ is nondecreasing and Lipschitz continuous.

(A3) $k(b(z))$ is continuous and bounded in z and satisfies, for all $z_1, z_2 \in \mathbb{R}$, $| k(b(z_2)) - k(b(z_1)) |^2 \leq C_k(b(z_2) - b(z_1))(z_2 - z_1)$.

(A4) $b(u_0)$ is essentially bounded (by 0 and 1) in Ω and $u_0 \in L^2(\Omega)$.

REMARK 1.1. *By* (A3)*, the convection term is bounded. This restriction is not unrealistic since, for Richards' equation, k stands for the conductivity of the medium.*

This assumption makes our analysis easier, but can be avoided. Moreover, the growth condition on $k(b(\cdot))$ (see also [11], [27], [30], *or* [23]*) relaxes the more often assumed Lipschitz continuity of k (see, e.g.,* [21], [2]*). It gives uniqueness for the weak solution, as shown in* [1]*. In addition, source terms can also be considered here, provided that they satisfy a similar growth condition as $k(b(u))$.*

REMARK 1.2. *In the transformed version, Richards' equation fits in our framework. However, since b is Lipschitz, a vanishing permeability in* (1.1) *is not allowed, meaning that our analysis is valid in the variably saturated to fully saturated flow regimes, but not in the completely air saturated one.*

REMARK 1.3. *For the sake of simplicity, we deal with homogeneous Dirichlet boundary conditions. More general situations can be included in a straightforward manner, with similar results. Here nonlinearities depend only on the unknown u, not on x and t. For more general situations, techniques developed in* [2] *can be employed.*

Because of its degenerate character, we do not expect smooth solutions for problem (1.5). For defining a solution in a weak sense we let $(\cdot,\cdot)$ stand for the inner product on $L^2(\Omega)$ or the duality pairing between $H_0^1(\Omega)$ and $H^{-1}(\Omega)$, $\|\cdot\|$ for the norm in $L^2(\Omega)$, and $\|\cdot\|_1$ and $\|\cdot\|_{-1}$ for the norms in $H^1(\Omega)$ and $H^{-1}(\Omega)$, respectively. We use analogous notations for the inner product and the corresponding norm on $L^2(J;\mathcal{H})$, with $\mathcal{H}$ being either $L^2(\Omega)$, $H^1(\Omega)$, or $H^{-1}(\Omega)$. In addition, we often write u or $u(t)$ instead of $u(t,x)$ and use C to denote a generic positive constant, not depending on the discretization or regularization parameters.

A weak solution for problem (1.5) is defined as follows.

DEFINITION 1.4. *A function u is called a weak solution for equation* (1.5) *iff $b(u) \in H^1(J;H^{-1}(\Omega))$, $u \in L^2(J;H_0^1(\Omega))$, $u(0) = u_0$ (in H^{-1} sense), and for all $\varphi \in L^2(J;H_0^1(\Omega))$ it holds that*

$$\int_0^T (\partial_t b(u(t)),\varphi(t)) \;+\; (\nabla u(t) + k(b(u(t)))e_z, \nabla\varphi(t))dt = 0. \tag{1.6}$$

Existence, uniqueness, and essential bounds for a weak solution of the above problem are studied in several papers (see, for example, [1], [22], [27] and the references therein). In [1] the following regularity result is obtained:

$$b(u) \in L^\infty(J;L^1(\Omega)), \tag{1.7}$$

$$q := -(\nabla u + k(b(u))e_z) \in L^2(J;(L^2(\Omega))^d). \tag{1.8}$$

Here $b(u)$ models the water content, hence it is natural to assume that, after scaling, it lies between 0 and 1 for almost every $(t,x) \in J \times \Omega$. For the same reason, in (A4) similar restrictions are imposed to the initial data. Such essential estimates can be shown, for example, if b and k do not depend explicitly on x, or if $k(b(u))$ is constant for $u = 0$ and $u = 1$. Moreover, $u \in L^2(J;H_0^1(\Omega))$ yields $b(u) \in L^2(J;H_0^1(\Omega))$ due to the Lipschitz continuity of b. Since $b(u) \in H^1(J;H^{-1}(\Omega))$ we have $b(u) \in C([0,T];L^2(\Omega))$ (see [20, Chapter I]), allowing a simplified mixed variational formulation. Following [2] or [29] we integrate (1.5) in time and obtain, for every $t \in J$,

$$b(u(t)) + \nabla \cdot \int_0^t q\ (s)\, ds = b(u^0) \tag{1.9}$$

in L^2 sense. It follows (see [2] or [25]) that the flux $\vec{q}$ defined in (1.8) satisfies

$$\int_0^t q\, d\tau \in H^1(J;(L^2(\Omega))^d) \cap L^2(J;(H^1(\Omega))^d) =: X. \tag{1.10}$$

2. Equivalent formulations. In this section we give the mixed variational formulations and study the equivalence with the conformal ones in both continuous and time discrete cases.

2.1. The continuous case. Integrated in time, problem (1.5) becomes the following.

Problem 1. Find $u \in L^2(J, H_0^1(\Omega))$ such that $b(u) \in L^\infty(J \times \Omega)$, and for all $t \in J$ and $\phi \in H_0^1(\Omega)$ it holds that

$$(b(u(t)) - b(u^0), \phi) + \int_0^t (\nabla u(s) + k(b(u(s)))e_z, \nabla\phi)ds = 0. \tag{2.1}$$

As mentioned in the previous section, this stronger formulation makes sense since $b(u) \in C(J; L^2(\Omega))$.

A mixed formulation for problem (1.5) reads as follows.

Problem 2. Find $(p, \tilde{q}) \in L^2(J \times \Omega)) \times X$ such that $b(p) \in L^\infty(J \times \Omega)$ and for all $t \in J$ the equations

$$(b(p(t)) - b(p^0), w) + (\nabla \cdot \tilde{q}(t), w) = 0, \tag{2.2}$$

$$(\tilde{q}(t), v) - \int_0^t (p(s), \nabla v)ds + \int_0^t (k(b(p(s)))e_z, v)ds = 0 \tag{2.3}$$

hold for all $w \in L^2(\Omega)$ and $v \in H(\mathrm{div}, \Omega)$, with $p^0 = u^0 \in L^2(\Omega)$.

The two problems are equivalent, as shown in Proposition 2.2. In the proof we use the following lemma [7, p. 91].

LEMMA 2.1. *Let $v \in H(\mathrm{div}, \Omega)$ and $\vec{n}$ denote the outer normal to Γ. Then $v \cdot \vec{n}$ is defined in $H^{-1/2}(\Gamma)$ (in the sense of traces) and Green's formula applies for all $p \in H^1(\Omega)$*

$$\int_\Omega \nabla \cdot v \; p \; dx + \int_\Omega v \cdot \; \nabla p \; dx = \int_\Gamma \vec{n} \cdot v \; p \; ds. \tag{2.4}$$

PROPOSITION 2.2. *$u \in L^2(J, H_0^1(\Omega))$ solves Problem 1 iff $(p, \tilde{q}) \in L^2(J \times \Omega)) \times X$ defined as*

$$(p, \tilde{q}) = \left(u, -\int_0^t (\nabla u(s) + k(b(u(s)))e_z)ds\right) \tag{2.5}$$

solves Problem 2. Moreover, in this case we have $p \in L^2(J, H_0^1(\Omega))$.

Proof. We use some ideas from [18].

"$\Rightarrow$" Let $u \in L^2(J, H_0^1(\Omega))$ be a solution of Problem 1 and $(p, \tilde{q})$ defined in (2.5). By (1.10) we have $(p, \tilde{q}) \in L^2(J, H_0^1(\Omega)) \times X$. Fixing now $t > 0$, for any $v \in H(\mathrm{div}, \Omega)$, using Green's formula we get

$$\begin{aligned}(\tilde{q}(t), v) &= -\int_0^t (\nabla u(s) + k(b(u(s)))e_z, v)ds \\ &= \int_0^t (p(s), \nabla v) - (k(b(p(s)))e_z, v)ds,\end{aligned}$$

so (2.3) is proven.

Next, taking any $\phi \in C_0^\infty(\Omega)$ in (2.1) yields

$$(b(u(t)) - b(u^0), \phi) = -\left(\int_0^t (\nabla u(s) + k(b(u(s)))e_z)ds, \nabla\phi\right)$$
$$= (\tilde{q}(t), \nabla\phi) = -(\nabla \cdot \tilde{q}(t), \phi).$$

However, for any $t > 0$, both $b(u(t)) - b(u^0)$ and $\nabla \cdot \tilde{q}(t)$ lie in $L^2(\Omega)$, so the above relations still hold for $\phi \in L^2(\Omega)$, implying (2.2).

"$\Leftarrow$" Let $(p, \tilde{q}) \in L^2(J \times \Omega) \times X$ solving Problem 2 and set $u = p \in L^2(J \times \Omega)$. Taking $v \in (C_0^\infty(\Omega))^d \subset H(\mathrm{div}, \Omega)$ arbitrary, by differentiating (2.3) we get for almost all $t > 0$

$$(\partial_t \tilde{q}(t), v) + (k(b(p(t)))e_z, v) = (p(t), \nabla \cdot v) = -(\nabla p(t), v), \tag{2.6}$$

so $\nabla p = -\partial_t \tilde{q} - k(b(p))e_z$ in a distributional sense. Since both $\partial_t \tilde{q}$ and $k(b(p))e_z$ are in $L^2(J \times \Omega)$, the same holds for ∇p, so $u = p \in L^2(J, H^1(\Omega))$.

Taking now $v \in H(\mathrm{div}, \Omega)$ in (2.3) gives, for every $t \in J$,

$$-\int_0^t (\nabla p, v) \overset{(2.6)}{=} (\tilde{q}(t), v) + \int_0^t (k(b(p))e_z, v) \overset{(2.3)}{=} \int_0^t (p, \nabla \cdot v).$$

In this way, using (2.4) we get

$$\int_0^t \int_\Gamma pv \cdot \vec{n} ds = \int_0^t (\nabla p, v) + \int_0^t (p, \nabla \cdot v) = 0.$$

Here v was chosen arbitrary, so the trace of p on Γ is zero. Thus $p \in L^2(J, H_0^1(\Omega))$ and the same holds for u.

Moreover, taking any $\phi \in H_0^1(\Omega)$ yields, for all $t > 0$,

$$\big(b(u(t)) - b(u^0), \phi\big) \overset{(2.2)}{=} -(\nabla \cdot \tilde{q}(t), \phi) = (\tilde{q}(t), \nabla\phi)$$
$$\overset{(2.3)}{=} -\int_0^t (\nabla u(s) + k(b(u(s)))e_z, \nabla\phi)ds,$$

so u solves (2.1). ∎

2.2. The semidiscrete case. As mentioned in the introduction, for overcoming difficulties due to degeneracy, we first perturb the original equation to obtain a regular parabolic one. Such a technique has been successfully applied in the analysis of degenerate problems and also allows developing effective numerical schemes (see, e.g., [21]).

In problem (1.5) degeneracy appears due to the vanishing of b'. Therefore we approximate this nonlinearity by b_ϵ, with $\epsilon > 0$ a small perturbation parameter. A possible choice reads as

$$b_\epsilon(u) = b(u) + \epsilon u. \tag{2.7}$$

Obviously, b_ϵ is Lipschitz continuous (with the same Lipschitz constant as b, if ϵ is small enough), strictly increasing and its derivative is bounded from below by ϵ. The regularized problem becomes

$$\begin{aligned} \partial_t b_\epsilon(u) - \nabla \cdot (\nabla u + k(b(u))e_z) &= 0 \quad && \text{in} \quad (0;T] \times \Omega, \\ u &= u^0 \quad && \text{in} \quad \Omega, \\ u &= 0 \quad && \text{on} \quad J \times \Gamma. \end{aligned} \tag{2.8}$$

We let $N > 1$ be an integer giving a time step $\tau = T/N$, with $t_n = n\tau$. The regularized semidiscrete conformal problem reads

Problem 3. Let $n = \overline{1, N}$ and u^{n-1} be given. Find $u^n \in H_0^1(\Omega)$ such that, for all $\phi \in H_0^1(\Omega)$,

$$(b_\epsilon(u^n) - b_\epsilon(u^{n-1}), \phi) + \tau(\nabla u^n + k(b(u^n))e_z, \nabla\phi) = 0. \tag{2.9}$$

However, our final aim is a mixed discretization. The time discrete regularized mixed problem becomes the following.

Problem 4. Let $n = \overline{1, N}$ and p^{n-1} given. Find $(p^n, q^n) \in L^2(\Omega) \times H(\mathrm{div}, \Omega)$ such that

$$(b_\epsilon(p^n) - b_\epsilon(p^{n-1}), w) + \tau(\nabla \cdot q^n, w) = 0, \tag{2.10}$$

$$(q^n, v) - (p^n, \nabla v) + (k(b(p^n))e_z, v) = 0, \tag{2.11}$$

for all $w \in L^2(\Omega)$, respectively, $v \in H(\mathrm{div}, \Omega)$, with $p^0 = u^0 \in L^2(\Omega)$.

As in the continuous case, the two problems above are equivalent.

PROPOSITION 2.3. *Let $n = \overline{1, N}$ be fixed and assume $u^{n-1} = p^{n-1}$. Then $u^n \in H_0^1(\Omega)$ solves Problem* 3 *iff $(p^n, q^n) \in L^2(\Omega) \times H(\mathrm{div}, \Omega)$ defined as*

$$(p^n, q^n) = (u^n, -(\nabla u^n + k(b(u^n))e_z)) \tag{2.12}$$

solve Problem 4. *Moreover, we have $p^n \in H_0^1(\Omega)$.*

Proof. "⇒" Let $u^n \in H_0^1(\Omega)$ be a solution of Problem 3 and (p^n, q^n) be defined in (2.12). For all $v \in H(\mathrm{div}, \Omega)$ we have

$$(q^n, v) = -(\nabla u^n + k(b(u^n))e_z, v) = (p^n, \nabla v) - (k(b(p^n))e_z, v),$$

so (p^n, q^n) verify (2.11).

Next, for all $\phi \in C_0^\infty(\Omega)$ (which is dense in $H_0^1(\Omega)$) we get

$$\begin{aligned}(b_\epsilon(p^n) - b_\epsilon(p^{n-1}), \phi) &\overset{(2.9)}{=} -\tau(\nabla u^n + k(b(u^n))e_z, \nabla\phi) = \tau(q^n, \nabla\phi)\\ &= -\tau(\nabla \cdot q^n, \phi).\end{aligned}$$

But $b_\epsilon(p^n) - b_\epsilon(p^{n-1}) \in L^2(\Omega)$, so $\nabla \cdot q^n \in L^2(\Omega)$, implying $q^n \in H(\mathrm{div}, \Omega)$ and that (2.10) holds by density arguments.

"⇐" Let $(p^n, q^n) \in L^2(\Omega) \times H(\mathrm{div}, \Omega)$ be a solution of Problem 4 and $u^n = p^n \in L^2(\Omega)$. For any $v \in (C_0^\infty(\Omega))^d \subset H(\mathrm{div}, \Omega)$ we have

$$\begin{aligned}(q^n, v) &\overset{(2.11)}{=} (p^n, \nabla v) - (k(b(p^n))e_z, v)\\ &= -(\nabla p^n, v) - (k(b(p^n))e_z, v),\end{aligned}$$

implying

$$\nabla p^n + k(b(p^n))e_z = -q^n$$

in distributional sense. Since both q^n and $k(b(p^n))$ are $L^2(\Omega)$ functions it follows that $p^n \in H^1(\Omega)$. As for the continuous case, using Green's formula (2.4), we get actually $u^n = p^n \in H_0^1(\Omega)$.

Finally, (2.9) results by taking any $\phi \in H_0^1(\Omega)$ in (2.10),

$$\begin{aligned}(b_\epsilon(u^n) - b_\epsilon(u^{n-1}), \phi) &= -\tau(\nabla \cdot q^n, \phi) = \tau(q^n, \nabla\phi)\\ &= -\tau((\nabla p^n + k(b(p^n))e_z), \nabla\phi).\end{aligned}$$

□

As resulting from the equivalencies proven above, stability and error estimates for the time discrete mixed formulation can be obtained by analyzing the Euler implicit scheme applied to Problem 3. This is the underlying idea in the forthcoming section.

3. Stability estimates. In this section we investigate the stability of our numerical approach. We make use of the lemmas below.

LEMMA 3.1. *For any vectors* $a_k, b_k \in \mathbb{R}^q$ $(k = \overline{1,N}, q \geq 1)$ *we have*

$$2\sum_{n=1}^{N} a_n \sum_{k=1}^{n} a_k = \left(\sum_{n=1}^{N} a_n\right)^2 + \sum_{n=1}^{N} (a_n)^2, \tag{3.1}$$

$$2\sum_{n=1}^{N} (a_n - a_{n-1}, a_n) = |a_N|^2 - |a_0|^2 + \sum_{n=1}^{N} |a_n - a_{n-1}|^2, \tag{3.2}$$

$$\sum_{n=1}^{N} (a_n - a_{n-1}, b_n) = a_N b_N - a_0 b_0 - \sum_{n=1}^{N} (b_n - b_{n-1}, a_{n-1}). \tag{3.3}$$

LEMMA 3.2. *Under the assumption* (A1)*, for any real sequence* x^j*,* $j = \overline{1,n}$ *we have*

$$\sum_{j=1}^{n} (b_\epsilon(x^j) - b_\epsilon(x^{j-1}))\ x^j \geq -C|x^0|^2 + \frac{\epsilon}{2}|x^n|^2. \tag{3.4}$$

Proof. Since $b'_\epsilon \geq \epsilon$, one has, for any reals x and y,

$$((b_\epsilon(x) - b_\epsilon(y))x \geq \int_y^x s b'_\epsilon ds \quad \text{and} \quad \int_0^x s b'_\epsilon(s) ds \geq \frac{\epsilon}{2} x^2.$$

Furthermore,

$$\begin{aligned}\sum_{j=1}^{n} (b_\epsilon(x^j) - b_\epsilon(x^{j-1}))x^j &\geq \sum_{j=1}^{n} \int_{x^{j-1}}^{x^j} s b'_\epsilon(s) ds \\ &= \int_0^{x^n} s b'_\epsilon(s) ds - \int_0^{x^0} s b'_\epsilon(s) ds \geq -C|x^0|^2 + \frac{\epsilon}{2}|x^n|^2,\end{aligned}$$

where the constant C is half of the Lipschitz constant of b. ∎

3.1. Stability in the time discrete conformal case.

PROPOSITION 3.3. *Assume* (A1)–(A4)*. If* u^n *solves Problem* 3 *(*$n = \overline{1,N}$*), we have*

$$\tau \sum_{n=1}^{N} \|u^n\|_1^2 \leq C. \tag{3.5}$$

Proof. Taking $\phi = u^n$ in (2.9) and summing up for $n = \overline{1,N}$ give

$$\sum_{n=1}^{N} \left(b_\epsilon(u^n) - b_\epsilon(u^{n-1}), u^n\right) + \sum_{n=1}^{N} \tau \|\nabla u^n\|^2 + \sum_{n=1}^{N} \tau \left(k(b(u^n))e_z, \nabla u^n\right) = 0. \tag{3.6}$$

Now we estimate the terms on the left in the above. By (3.4), since $u^0 \in L^2(\Omega)$,

$$\sum_{n=1}^{N} \left(b_\epsilon(u^n) - b_\epsilon(u^{n-1}), u^n\right) \geq -C.$$

The second term needs no further treatment. Finally, since k is bounded, applying the Cauchy–Schwarz inequality, we get

$$\tau \sum_{n=1}^{N} |(k(b(u^n))e_z, \nabla u^n)| \leq \frac{\tau}{2} \sum_{n=1}^{N} \|k(b(u^n))e_z\|^2 + \frac{\tau}{2} \sum_{n=1}^{N} \|\nabla u^n\|^2$$

$$\leq C + \frac{\tau}{2} \sum_{n=1}^{N} \|\nabla u^n\|^2 .$$

Inserting the last inequalities into (3.6) and using the inequality of Poincaré gives (3.5). ∎

3.2. Stability for the time discrete mixed formulation. By the equivalence of Problems 3 and 4, Proposition 3.3 provides stability for the time discrete solutions p^n and q^n.

PROPOSITION 3.4. *Assuming* (A1)–(A4)*, if, for any* $n = \overline{1, N}$*,* (p^n, q^n) *solve Problem* 4*, we have*

$$\tau \sum_{n=1}^{N} \|p^n\|_1^2 + \tau \sum_{n=1}^{N} \|q^n\|^2 \leq C. \tag{3.7}$$

Proof. The estimate for p^n is a direct consequence of (3.5). Next, taking $w = p^n$ in (2.10) and $v = \tau q^n$ in (2.11) yields

$$(b_\epsilon(p^n) - b_\epsilon(p^{n-1}), p^n) + \tau(\nabla \cdot q^n, p^n) = 0,$$
$$(q^n, \tau q^n) - (p^n, \tau \nabla \cdot q^n) + (k(b(p^n))e_z, \tau q^n) = 0.$$

Adding these two equations and summing up for $n = 1$ to N give

$$\sum_{n=1}^{N} (b_\epsilon(p^n) - b_\epsilon(p^{n-1}), p^n) + \tau \sum_{n=1}^{N} \|q^n\|^2 + \tau \sum_{n=1}^{N} (k(b(p^n))e_z, q^n) = 0,$$

and the rest of the proof follows exactly as in the previous proposition. ∎

Other stability estimates can be obtained defining an initial flux $q^0 \in [L^2(\Omega)]^d$. In doing so we take $\rho \in C_0^\infty(B_d(0,1))$ ($B_d(0,1)$ being the unit ball in $\mathbb{R}^d$) so that $\int_{B_d(0,1)} \rho(x)dx = 1$ and consider the mollifier sequence $\{\rho_\mu(x) = \frac{1}{\mu^d}\rho(\frac{x}{\mu})\}_{1>>\mu>0}$. Defining q^0 as

$$q^0 = -\nabla(\rho_\mu * p^0) - k(b(p^0))e_z, \tag{3.8}$$

with μ to be chosen further and $*$ denoting the convolution operator, for any $v \in H(\mathrm{div}, \Omega)$ we have

$$(q^0, v) - (\rho_\mu * p^0, \nabla \cdot v) + (k(b(p^0))e_z, v) = 0. \tag{3.9}$$

A mollifying of p^0 in the above is necessary for having $q^0 \in [L^2(\Omega)]^d$. However, since $p^0 \in L^2(\Omega)$, $\|p^0 - \rho_\mu * p^0\|$ goes to 0 as $\mu \searrow 0$, so $\|q^0\|$ is uniformly bounded with respect to μ. Now the following estimates can be obtained.

PROPOSITION 3.5. *Assuming* (A1)–(A4)*, if, for all* $n = \overline{1, N}$*,* (p^n, q^n) *solve Problem* 4*, for any* $k > 0$ *we have*

$$\sum_{n=1}^{k} (b_\epsilon(p^n) - b_\epsilon(p^{n-1}), p^n - p^{n-1}) + \tau\|q^k\|^2 + \tau \sum_{n=1}^{k} \|q^n - q^{n-1}\|^2 \leq C\tau. \tag{3.10}$$

Proof. First we take $w = p^n - p^{n-1} \in L^2(\Omega)$ in (2.10) and subtract equation (2.11) at time step $n-1$ from the one at time step n. Testing with $v = \tau q^n$ in the resulting equality yields

$$(b_\epsilon(p^n) - b_\epsilon(p^{n-1}), p^n - p^{n-1}) + \tau(\nabla \cdot q^n, p^n - p^{n-1}) = 0,$$
$$\tau(q^n - q^{n-1}, q^n) - \tau(p^n - p^{n-1}, \nabla \cdot q^n) + \tau((k(b(p^n)) - k(b(p^{n-1})))e_z, q^n) = 0.$$

For $n = 1$ the second equation above reads as

$$\tau(q^1 - q^0, q^1) - \tau(p^1 - p^0, \nabla \cdot q^1) + \tau((k(b(p^1)) - k(b(p^0)))e_z, q^1) = \tau(p^0 - \rho_\mu * p^0, \nabla \cdot q^1).$$

Adding the above pairs of equalities and summing the result up for $n = \overline{1,k}$ yields

$$\begin{aligned} &\sum_{n=1}^{k}(b_\epsilon(p^n) - b_\epsilon(p^{n-1}), p^n - p^{n-1}) + \tau\sum_{n=1}^{k}(q^n - q^{n-1}, q^n) \\ &\quad + \tau\sum_{n=1}^{k}((k(b(p^n)) - k(b(p^{n-1})))e_z, q^n) = \tau(p^0 - \rho_\mu * p^0, \nabla \cdot q^1). \end{aligned} \tag{3.11}$$

Denoting the terms above by $T_1, \dots, T_4$, we first notice that T_1 is positive by the monotonicity of b_ϵ. Next, by (3.2),

$$\begin{aligned} T_2 &= \tau\sum_{n=1}^{k}(q^n - q^{n-1}, q^n) \\ &= \frac{\tau}{2}\|q^k\|^2 - \frac{\tau}{2}\|q^0\|^2 + \frac{\tau}{2}\sum_{n=1}^{k}\|q^n - q^{n-1}\|^2. \end{aligned}$$

Recalling (A3) and the Cauchy–Schwarz inequality, for T_3 we get

$$\begin{aligned} |T_3| &\le \frac{\delta_1}{2}\sum_{n=1}^{k}\|(k(b(p^n)) - k(b(p^{n-1})))e_z\|^2 + \frac{\tau^2}{2\delta_1}\sum_{n=1}^{k}\|q^n\|^2 \\ &\le \frac{\delta_1 C_k}{2}\sum_{n=1}^{k}(b(p^n) - b(p^{n-1}), p^n - p^{n-1}) + \frac{\tau^2}{2\delta_1}\sum_{n=1}^{k}\|q^n\|^2. \end{aligned}$$

Estimating T_4 follows as before,

$$|T_4| \le \tau\|p^0 - \rho_\mu * p^0\|\|\nabla \cdot q^1\| \le \delta_2\|p^0 - \rho_\mu * p^0\|^2 + \frac{\tau^2}{4\delta_2}\|\nabla \cdot q^1\|^2.$$

To estimate $\|\nabla \cdot q^1\|$ we use (2.10) for $n = 1$, test with $w = \nabla \cdot q^1 \in L^2(\Omega)$ and obtain

$$\tau\|\nabla \cdot q^1\|^2 \le \|b_\epsilon(p^1) - b_\epsilon(p^0)\|\|\nabla \cdot q^1\| \le \frac{C}{2\tau}\left(b_\epsilon(p^1) - b_\epsilon(p^0), p^1 - p^0\right) + \frac{\tau}{2}\|\nabla \cdot q^1\|^2$$

by the Lipschitz continuity of b_ϵ. In this way we get

$$\tau\|\nabla \cdot q^1\|^2 \le \tfrac{C}{\tau}(b_\epsilon(p^1) - b_\epsilon(p^0), p^1 - p^0).$$

Using these estimates in (3.11) and choosing the δ's properly give

$$\begin{aligned} &\sum_{n=1}^{k}(b_\epsilon(p^n) - b_\epsilon(p^{n-1}), p^n - p^{n-1}) + \tau\|q^k\|^2 + \tau\sum_{n=1}^{k}\|q^n - q^{n-1}\|^2 \\ &\quad \le C_1\tau + C_2\|p^0 - \rho_\mu * p^0\|^2 + C_3\tau^2\sum_{n=1}^{k}\|q^n\|^2. \end{aligned}$$

We still have to choose μ in (3.8). Since $\|p^0 - \rho_\mu * p^0\|$ converges to 0, taking μ sufficiently small, the right term in the above becomes

$$C_4\tau + C_3\tau^2 \sum_{n=1}^{k} \|q^n\|^2.$$

Now (3.10) follows by the discrete Gronwall lemma. ∎

REMARK 3.6. *If $p^0 \in H^1(\Omega)$, q^0 can be defined without using a mollifier,*

$$q^0 = -\nabla p^0 - k(b(p^0))e_z. \tag{3.12}$$

Then $T_4 = 0$ in (3.11)*, without changing* (3.10).

A direct consequence of the stability estimates above follows.

PROPOSITION 3.7. *In the setting of Proposition* 3.5 *we have*

$$\sum_{n=1}^{N} \tau\|\nabla \cdot q^n\|^2 \le C. \tag{3.13}$$

Proof. Taking $w = \nabla \cdot q^j$ in equation (2.10) and applying the Cauchy–Schwarz inequality one gets

$$\tau\|\nabla \cdot q^j\|^2 \le \frac{1}{2\tau}\|b_\epsilon(p^j) - b_\epsilon(p^{j-1})\|^2 + \frac{\tau}{2}\|\nabla \cdot q^j\|^2,$$

so

$$\tau\|\nabla \cdot q^j\|^2 \le \frac{1}{\tau}\|b_\epsilon(p^j) - b_\epsilon(p^{j-1})\|^2.$$

Summing up the above for $j = \overline{1,N}$, using the Lipschitz continuity of b_ϵ and (3.10) leads to (3.13). ∎

4. Error estimates. In this section we obtain a priori error estimates for both time discrete scheme, as well as for the fully discrete one.

4.1. Error estimates for the semidiscrete approximation. To obtain error estimates for the time discrete scheme we employ techniques developed in [21] and make use of the Green operator $G : H^{-1}(\Omega) \to H_0^1(\Omega)$ defined as

$$(\nabla(G\psi), \nabla\phi) = (\psi, \phi) \quad \text{for all} \quad \phi \in H_0^1(\Omega). \tag{4.1}$$

Obviously, G is linear and self-adjoint. Moreover, by the Cauchy–Schwarz inequality, using (3.3) yields the following lemma.

LEMMA 4.1. *For all $f, f_k \in H^{-1}(\Omega)$ $(k = \overline{1,N})$ and $g \in H^1(\Omega)$ we have*

$$(f, g) \le \|f\|_{-1}\|\nabla g\|,$$

$$\|\nabla Gf\|^2 = (f, Gf) = \|f\|_{-1}^2,$$

$$2\sum_{k=1}^{N}(f_k - f_{k-1}, Gf_k) = \|f_k\|_{-1,\Omega}^2 - \|f_0\|_{-1,\Omega}^2 + \sum_{k=1}^{N}\|f_k - f_{k-1}\|_{-1,\Omega}^2.$$

Further, we use the notations

$$\begin{aligned} \overline{u}^n &= \frac{1}{\tau}\int_{t_{n-1}}^{t_n} u(t)dt, \\ u_\Delta(t) &= u^n \quad \text{for} \quad t \in (t_{n-1}, t_n], \\ e_b(u) &= b(u) - b_\epsilon(u_\Delta), \end{aligned} \tag{4.2}$$

where $n = \overline{1, N}$ and $\overline{u}^0 = u^0$.

It is worth pointing out here that, by Propositions 2.2 and 2.3, estimates obtained for the conformal discretization can be transferred to the mixed case.

PROPOSITION 4.2. *Assuming* (A1)–(A4)*, if* u *is the weak solution of Problem* 1 *and* u^n *solves, for each* $n = \overline{1, N}$*, Problem* 3*, then*

$$\begin{aligned} \max_{n=\overline{1,N}} \left\| \overline{e_b(u)}^n \right\|_{-1}^2 + \|e_b(u)\|_{L^2(J\times\Omega)}^2 + \int_0^T (b_\epsilon(u(t)) - b_\epsilon(u_\Delta), u(t) - u_\Delta)dt \\ \le C\,(\tau + \epsilon). \end{aligned} \tag{4.3}$$

Proof. Subtracting (2.1) at $t = t_{j-1}$ from the one at $t = t_j$ and then subtracting (2.9) with $n = j$ from the result give

$$\begin{aligned} &(b(u(t_j)) - b(u(t_{j-1})) - b_\epsilon(u^j) + b_\epsilon(u^{j-1}), \phi) \\ &\quad + \tau(\nabla(\overline{u}^j - u^j), \nabla\phi) + \tau((\overline{k(b(u))}^j - k(b(u^j)))e_z, \nabla\phi) = 0. \end{aligned}$$

Taking $\phi = G\overline{e_b(u)}^j \in H_0^1(\Omega)$ into above and summing up for $j = \overline{1, n}$ (with $n \le N$) yield

$$\begin{aligned} &\sum_{j=1}^n (b(u(t_j)) - b(u(t_{j-1})) - b_\epsilon(u^j) + b_\epsilon(u^{j-1}), G\overline{e_b(u)}^j) \\ &\quad + \sum_{j=1}^n \tau(\nabla\overline{u}^j - \nabla u^j, \nabla G\overline{e_b(u)}^j) \\ &\quad + \sum_{j=1}^n \tau((\overline{k(b(u))}^j - k(b(u^j)))e_z, \nabla G\overline{e_b(u)}^j) = 0. \end{aligned} \tag{4.4}$$

We estimate now each of terms in (4.4), denoted by T_1, T_2, and T_3:

$$\begin{aligned} T_1 &= \sum_{j=1}^n (b(u(t_j)) - \overline{b(u)}^j - b(u(t_{j-1})) + \overline{b(u)}^{j-1}, G\overline{e_b(u)}^j) \\ &\quad + \sum_{j=1}^n (\overline{b(u)}^j - b_\epsilon(u^j) - \overline{b(u)}^{j-1} + b_\epsilon(u^{j-1}), G\overline{e_b(u)}^j) \\ &=: T_{11} + T_{12}. \end{aligned}$$

Further, by (3.3) and recalling that $b(u(0)) = \overline{b(u)}^0$ we have

$$\begin{aligned} T_{11} &= \sum_{j=1}^n (b(u(t_j)) - \overline{b(u)}^j - b(u(t_{j-1})) + \overline{b(u)}^{j-1}, G\overline{e_b(u)}^j) \\ &= (b(u(t_n)) - \overline{b(u)}^n, G\overline{e_b(u)}^n) \end{aligned}$$

$$
\begin{aligned}
&-\sum_{j=1}^{n}(b(u(t_{j-1}))-\overline{b(u)}^{j-1},G\overline{e_b(u)}^{j}-G\overline{e_b(u)}^{j-1})\\
&=: T_{111}-T_{112}.
\end{aligned}
$$

For T_{111} we make use of Lemma 4.1 and obtain

$$
\begin{aligned}
|T_{111}| &\le \frac{1}{\tau}\int_{t_{n-1}}^{t_n}|(b(u(t_n))-b(u(t)),G\overline{e_b(u)}^{n})|dt\\
&\le \frac{1}{\tau}\int_{t_{n-1}}^{t_n}\int_{t}^{t_n}|(\partial_s b(u(s)),G\overline{e_b(u)}^{n})|dsdt\\
&\le \frac{1}{\tau}\int_{t_{n-1}}^{t_n}\sqrt{\tau}\,\|\partial_t b(u)\|_{L^2(t_{n-1},t_n;H^{-1})}\,\|\overline{e_b(u)}^{n}\|_{-1}dt \qquad (4.5)\\
&\le \sqrt{\tau}\,\|\partial_s b(u)\|_{L^2(t_{n-1},t_n;H^{-1})}\,\|\overline{e_b(u)}^{n}\|_{-1}\\
&\le \tau\,\|\partial_s b(u)\|^2_{L^2(t_{n-1},t_n;H^{-1})}+\frac{1}{4}\|\overline{e_b(u)}^{n}\|^2_{-1}.
\end{aligned}
$$

Proceeding as before, T_{112} can be estimated as

$$
|T_{112}|\le \tau\,\|\partial_t b(u)\|^2_{L^2(0,t_n;H^{-1})}+\frac{1}{4}\sum_{j=1}^{n}\|\overline{e_b(u)}^{j}-\overline{e_b(u)}^{j-1}\|^2_{-1}. \qquad (4.6)
$$

Using Lemma 4.1 again, since $\overline{e_b(u)}^{0}=0$, T_{12} gives

$$
\begin{aligned}
T_{12} &= \sum_{j=1}^{n}(\overline{b(u)}^{j}-b_\epsilon(u^j)-\overline{b(u)}^{j-1}+b_\epsilon(u^{j-1}),G\overline{e_b(u)}^{j}))\\
&= \frac{1}{2}(\overline{e_b(u)}^{n},G\overline{e_b(u)}^{n}) \qquad (4.7)\\
&\quad+\frac{1}{2}\sum_{j=1}^{n}(\overline{e_b(u)}^{j}-\overline{e_b(u)}^{j-1},G\overline{e_b(u)}^{j}-G\overline{e_b(u)}^{j-1})\\
&= \frac{1}{2}\|\overline{e_b(u)}^{n}\|^2_{-1}+\frac{1}{2}\sum_{j=1}^{n}\|\overline{e_b(u)}^{j}-\overline{e_b(u)}^{j-1}\|^2_{-1}.
\end{aligned}
$$

For T_2 we have

$$
\begin{aligned}
T_2 &= \sum_{j=1}^{n}\tau(\nabla\overline{u}^{j}-\nabla u^j,\nabla G\overline{e_b(u)}^{j})\\
&= \tau\sum_{j=1}^{n}\left(\frac{1}{\tau}\int_{t_{j-1}}^{t_j}(u(t)-u^j)dt,\frac{1}{\tau}\int_{t_{j-1}}^{t_j}(b(u(s))-b_\epsilon(u^j))ds\right)\\
&= \sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\big(u(t)-u^j,b(u(t))-b_\epsilon(u^j)\big)\,dt\\
&\quad+\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\left(u(t)-u^j,\frac{1}{\tau}\int_{t_{j-1}}^{t_j}(b(u(s))-b(u(t)))ds\right)dt\\
&=: T_{21}+T_{22}.
\end{aligned}
$$

T_{21} can be decomposed as follows:

$$T_{21} = \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \big(u(t) - u^j, b(u(t)) - b_\epsilon(u(t))\big)\, dt$$
$$+ \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \big(u(t) - u^j, b_\epsilon(u(t)) - b_\epsilon(u^j)\big)\, dt \;=: T_{211} + T_{212}.$$

The definition of b_ϵ in (2.7) gives

$$|T_{211}| = \left| \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \big(u(t) - u^j, \epsilon\, u(t)\big)\, dt \right|$$
$$\leq \epsilon \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \big\|u(t) - u^j\big\|\, \|u(t)\|\, dt \tag{4.8}$$
$$\leq \frac{\epsilon}{4} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \big\|u(t) - u^j\big\|^2\, dt + \epsilon\, \|u\|^2_{L^2(0,t_n;L^2(\Omega))}.$$

Since b_ϵ is monotone, T_{212} is positive; moreover, it holds

$$T_{212} \geq \frac{1}{2} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \big(u(t) - u^j, b_\epsilon(u(t)) - b_\epsilon(u^j)\big)\, dt$$
$$+ \frac{\epsilon}{2} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \big\|u(t) - u^j\big\|^2\, dt. \tag{4.9}$$

Proceeding as for T_{111} and recalling the a priori estimates in Proposition 3.3, since $b(u) \in H^1(J; H^{-1})$ and $u \in L^2(J; H^1)$ we obtain

$$T_{22} = \frac{1}{\tau} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \int_{t_{j-1}}^{t_j} \big(u(t) - u^j, b(u(s)) - b(u(t))\big)\, ds dt$$
$$= \frac{1}{\tau} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \int_{t_{j-1}}^{t_j} \left(\int_t^s (u(t) - u^j, \partial_r b(u)) dr \right) ds dt$$
$$\leq \frac{1}{\tau} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \int_{t_{j-1}}^{t_j} \int_t^s \|\nabla(u(t) - u^j)\| \|\partial_r b(u)\|_{-1} dr ds dt \tag{4.10}$$
$$\leq \frac{\tau}{2} \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \big\|\nabla(u(t) - u^j)\big\|^2 + \frac{\tau}{2} \|\partial_r b(u)\|^2_{L^2(0,t_n;H^{-1})}$$
$$\leq C\, \tau.$$

For the T_3 we proceed as follows:

$$|T_3| \leq \frac{\tau}{4\delta} \sum_{j=1}^{n} \|\overline{k(b(u))}^j - k(b(u^j))\|^2 + \delta\tau \sum_{j=1}^{n} \|\overline{e_b(u)}^j\|^2_{-1}$$
$$= T_{31} + \delta\tau \sum_{j=1}^{n} \|\overline{e_b(u)}^j\|^2_{-1}.$$

Applying (A3) and taking $\delta = C_k$ gives

$$
\begin{aligned}
|T_{31}| &= \frac{\tau}{4\delta}\frac{1}{\tau^2}\sum_{j=1}^{n}\int_\Omega\left(\int_{t_{j-1}}^{t_j}(k(b(u))-k(b(u^j)))dt\right)^2 dx\\
&\le \frac{1}{4\delta\tau}\sum_{j=1}^{n}\int_\Omega \tau\int_{t_{j-1}}^{t_j}(k(b(u))-k(b(u^j)))^2 dtdx\\
&\le \frac{1}{4}\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\left(b(u)-b(u^j),u-u^j\right)dt \qquad (4.11)\\
&\le \frac{1}{4}\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\left(b_\epsilon(u)-b_\epsilon(u^j),u-u^j\right)dt.
\end{aligned}
$$

Since $b(u)\in H^1(J;H^{-1})$ and $u\in L^2(J;H^1(\Omega))$, inserting (4.5)–(4.11) into (4.4) yields

$$
\begin{aligned}
&\|\overline{e_b(u)}^n\|_{-1}^2+\sum_{j=1}^{n}\|\overline{e_b(u)}^j-\overline{e_b(u)}^{j-1}\|_{-1}^2+\epsilon\int_{t_{j-1}}^{t_j}\left\|u(t)-u^j\right\|^2dt\\
&\quad+\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}\left(u(t)-u^j,b_\epsilon(u(t))-b_\epsilon(u^j)\right)dt\\
&\quad\le C(\tau+\epsilon)+4C_k\tau\sum_{j=1}^{n}\|\overline{e_b(u)}^j\|_{-1}^2,
\end{aligned}
$$

and (4.3) is a direct consequence of the discrete Gronwall lemma. □

Using the above result an error estimate for the L^2 norm of the time integrated gradient can be obtained. Such an estimate is essential for our analysis because it provides also an error estimate for the time integral of the flux in the mixed formulation.

PROPOSITION 4.3. *Under the assumptions in Proposition* 4.2 *we have*

$$
\left\|\int_0^T(u(t)-u_\Delta(t))dt\right\|_1^2\le C\,(\tau+\epsilon). \qquad (4.12)
$$

Proof. Following the ideas in [21], we first add (2.9) for $n=1$ to N, subtract the result from (2.1) at $t=t_N=T$ and end up with

$$
\begin{aligned}
&\left(b(u(T))-b_\epsilon(u^N),\phi\right)-\left(b(u(t_0))-b_\epsilon(u^0),\phi\right)\\
&\quad+\left(\sum_{j=1}^{N}\int_{t_{j-1}}^{t_j}\nabla(u(t)-u^j)dt,\nabla\phi\right)\\
&\quad+\left(\sum_{j=1}^{N}\int_{t_{j-1}}^{t_j}(k(b(u))-k(b(u^j)))e_z dt,\nabla\phi\right)=0
\end{aligned}
$$

for all $\phi\in H_0^1(\Omega)$. Now taking $\phi=\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)$ into the total above gives

$$
\begin{aligned}
&\left(b(u(T))-b_\epsilon(u^N),\tau\sum_{j=1}^{N}\left(\overline{u}^j-u^j\right)\right)\\
&-\left(\epsilon u^0,\tau\sum_{j=1}^{N}\left(\overline{u}^j-u^j\right)\right)+\left\|\tau\sum_{j=1}^{N}\nabla\left(\overline{u}^j-u^j\right)\right\|^2\\
&+\left(\sum_{j=1}^{N}\int_{t_{j-1}}^{t_j}(k(b(u))-k(b(u^j)))e_z,\nabla\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)\right)=0.
\end{aligned}
\tag{4.13}
$$

Denoting the terms in (4.13) by T_1, T_2, T_3, and T_4, we proceed by estimating each of them separately. T_1 yields

$$
T_1=\left(b(u(T))-\overline{b(u)}^N+\overline{b(u)}^N-b_\epsilon(u^N),\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)\right)=:T_{11}+T_{12}.
$$

As in (4.5), since $\partial_t b(u)\in L^2(J;H^{-1})$, T_{11} gives

$$
\begin{aligned}
|T_{11}|&\le\frac{1}{\tau}\int_{t_{N-1}}^{t_N}\int_{t}^{t_N}\left|\left(\partial_s b(u),\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)\right)\right|dsdt\\
&\le\frac{C_{11}}{2\delta_{11}}\tau+\frac{\delta_{11}}{2}\left\|\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)\right\|_1^2.
\end{aligned}
\tag{4.14}
$$

Applying the Cauchy–Schwarz inequality, for T_{12} we obtain

$$
|T_{12}|\le\frac{1}{2\delta_{12}}\left\|\overline{e_b(u)}^N\right\|_{-1}^2+\frac{\delta_{12}}{2}\left\|\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)\right\|_1^2.
\tag{4.15}
$$

Analogously, T_2 gives

$$
|T_2|\le\frac{1}{2\delta_2}\epsilon\left\|u^0\right\|^2+\frac{\delta_2}{2}\left\|\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)\right\|_1^2.
\tag{4.16}
$$

For T_3 we recall the inequality of Poincaré:

$$
T_3=\left\|\sum_{j=1}^{N}\tau\nabla\left(\overline{u}^j-u^j\right)\right\|^2\ge C\left\|\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)\right\|_1^2.
\tag{4.17}
$$

Analogously, T_4 can be estimated as

$$
|T_4|\le\frac{1}{2\delta_4}\left\|\sum_{j=1}^{N}\int_{t_{j-1}}^{t_j}(k(b(u))-k(b(u^j)))e_z dt\right\|^2+\frac{\delta_4}{2}\left\|\nabla\sum_{j=1}^{N}\tau\left(\overline{u}^j-u^j\right)\right\|^2.
$$

For the first term above—denoted by T_{41}—we get, by (A3),

$$
\begin{aligned}
T_{41}&\le N\sum_{j=1}^{N}\tau\int_{t_{j-1}}^{t_j}\|k(b(u))-k(b(u^j))\|^2dt\\
&\le TC_k\sum_{j=1}^{N}\int_{t_{j-1}}^{t_j}\left(b(u(t))-b(u^j),u(t)-u^j\right).
\end{aligned}
\tag{4.18}
$$

Inserting (4.14)–(4.18) into (4.13), choosing the $\delta's$ properly and recalling the estimates in Proposition 4.2 we obtain (4.12). ∎

Propositions 4.2 and 4.3 can be summarized in the following.

THEOREM 4.4. *If u is the solution of Problem 1 and u^n solves Problem 3 ($n = \overline{1,N}$), we have*

$$\max_{n=\overline{1,N}} \|\overline{e_b(u)}^n\|_{-1}^2 + \|e_b(u)\|_{L^2(J\times\Omega)}^2 + \left\|\int_0^T (u(t)-u_\Delta(t))dt\right\|_1^2 + \int_0^T (b_\epsilon(u(t))-b_\epsilon(u_\Delta(t)), u(t)-u_\Delta(t))dt \le C(\tau+\epsilon). \tag{4.19}$$

REMARK 4.5. *The estimates above do not change if we replace the last term on the left by $\int_0^T (b(u(t))-b(u_\Delta(t)), u(t)-u_\Delta(t))dt$.*

Since Problems 3 and 4 are equivalent we immediately obtain the following theorem.

THEOREM 4.6. *In the setting of Theorem 4.4, if (p^n, q^n) solve Problem 4 ($n = \overline{1,N}$), we get*

$$\begin{aligned}&\sum_{n=1}^N \int_{t_{n-1}}^{t_n} (b_\epsilon(u(t))-b_\epsilon(p^n), u(t)-p^n)dt \\ &+ \left\|\sum_{n=1}^N \int_{t_{n-1}}^{t_n} (u(t)-p^n)dt\right\|_1^2 + \left\|\tilde{q}(T) - \tau\sum_{n=1}^N q^n\right\|^2 \\ &\le C(\tau+\epsilon).\end{aligned} \tag{4.20}$$

REMARK 4.7. *As in Remark 4.5, we can replace the scalar product in (4.20) by $\int_0^T (b(u(t))-b(u_\Delta(t)), u(t)-u_\Delta(t))dt$. This immediately implies an error estimate for the saturation,*

$$\sum_{n=1}^N \int_{t_{n-1}}^{t_n} \|b(u(t))-b(p^n)\|^2 dt \le C(\tau+\epsilon).$$

4.2. Error estimates for the fully discrete mixed discretization. The next step in our analysis is proving error estimates for the fully discrete approximation. We first estimate the error for the flux variable and then proceed with estimates for the p unknowns.

In doing so we denote by W and V the spaces $L^2(\Omega)$ and $H(\mathrm{div},\Omega)$. Let $\mathcal{T}_h$ be a regular decomposition of $\Omega \subset \mathbb{R}^d$ into closed d-simplices; h stands for the mesh-size (see [9]). Here we assume $\overline{\Omega} = \cup_{T\in\mathcal{T}_h} T$, hence Ω is polygonal. Thus we neglect the errors caused by an approximation of a nonpolygonal domain, avoiding an excess of technicalities (a complete analysis in this sense can be found in [21]).

The discrete subspaces $W_h \times V_h \subset W \times V$ are defined as

$$\begin{aligned}W_h &:= \{p \in W |\ p \text{ is constant on each element } T \in \mathcal{T}_h\}, \\ V_h &:= \{\overrightarrow{q} \in V |\ \overrightarrow{q}_{|T} = \overrightarrow{a} + b\overrightarrow{x} \ \text{ for all } T \in \mathcal{T}_h\}.\end{aligned} \tag{4.21}$$

So W_h denotes the space of piecewise constant functions, while V_h is the RT_0 space (see [7]). Further we make use of the usual L^2 projector

$$P_h : L^2(\Omega) \to W_h, \quad ((P_h w - w), w_h) = 0 \qquad \forall w_h \in W_h. \tag{4.22}$$

Taking a $\widetilde{V}$ slightly better than V (for example, $V \cap (L^s(\Omega))^d$ with an $s > 2$), a projector Π_h can be defined as (see [7, p. 131])

$$\Pi_h : \widetilde{V} \to V_h, \quad (\nabla \cdot (\Pi_h v - v), w_h) = 0 \tag{4.23}$$

for all $w_h \in W_h$. With $r \in (0, 1]$, for the operators defined above we have

$$\begin{aligned} \|w - P_h w\| &\le C h^r \|w\|_r, \\ \|v - \Pi_h v\| &\le C h^r \|v\|_r \end{aligned} \tag{4.24}$$

for any $w \in H^r(\Omega)$ and $v \in (H^r(\Omega))^d$.

The following technical lemma is proven in [25].

LEMMA 4.8. *Assuming* (A1)*, taking $f_h \in W_h$, a $v_h \in V_h$ exists so that*

$$\begin{aligned} \nabla \cdot v_h &= f_h, \\ \|v_h\| &\le C \|\nabla \cdot v_h\|, \end{aligned}$$

$C > 0$ being a generic constant not depending on h, f_h, or v_h.

Before proceeding with the fully discrete approximation scheme, we rewrite Problem 4 (continuous in space) as

Problem 5. Let $n = \overline{1, N}$. Find $(p^n, q^n) \in W \times V$ such that

$$(b_\epsilon(p^n), w) - (b_\epsilon(p^0), w) + \tau \left(\sum_{j=1}^{n} \nabla \cdot q^j, w \right) = 0, \tag{4.25}$$

$$(q^n, v) - (p^n, \nabla \cdot v) + (k(b(p^n))e_z, v) = 0 \tag{4.26}$$

for all $w \in W$ and $v \in V$, with $p^0 = u^0$.

The fully discrete mixed finite element approximation reads the following.

Problem 6. Let $n = \overline{1, N}$. Find $(p_h^n, q_h^n) \in W_h \times V_h$ such that

$$(b_\epsilon(p_h^n), w_h) + \tau \left(\sum_{j=1}^{n} \nabla \cdot q_h^j, w_h \right) = (b_\epsilon(p_h^0), w_h), \tag{4.27}$$

$$(q_h^n, v_h) - (p_h^n, \nabla \cdot v_h) + (k(b(p_h^n))e_z, v_h) = 0 \tag{4.28}$$

for all $w_h \in W_h$ and $v_h \in V_h$.

Initially we take $p_h^0 = b_\epsilon^{-1}(P_h b_\epsilon(u^0))$. Since $P_h b_\epsilon(u^0)$ is constant on any $T \in \mathcal{T}_h$, the same holds for $b_\epsilon^{-1}(P_h b_\epsilon(u^0))$, so $p_h^0 \in W_h$. Moreover, with this choice, for all $w_h \in W_h$, we obtain

$$(b_\epsilon(p_h^0), w_h) = (b_\epsilon(u^0), w_h) = (b_\epsilon(p^0), w_h).$$

We start with some stability estimates for the fully discrete case.

PROPOSITION 4.9. *Assuming* (A1)–(A4)*, if (p_h^n, q_h^n) solve Problem* 6 *($n = \overline{1, N}$), we have*

$$\begin{aligned} \|p_h^n\|^2 + \|q_h^n\|^2 &\le C, \\ \sum_{k=1}^{n} (b_\epsilon(p_h^k) - b_\epsilon(p_h^{k-1}), p_h^k - p_h^{k-1}) &\le C\tau. \end{aligned} \tag{4.29}$$

Proof. Applying the arguments used in Propositions 3.4 and 3.7 we immediately obtain the estimates (4.29), excepting the one for $\|p_h^n\|$. To complete the proof we apply Lemma 4.8. Consequently, there exists a $v_h \in V_h$ such that $\nabla \cdot v_h = p_h^n$ and $\|v_h\| \leq C\|p_h^n\|$. Using this as a test function in (4.28) gives

$$\|p_h^n\|^2 = (q_h^n, v_h) + (k(b(p_h^n))e_z, v_h) \leq C(\|q_h^n\| + \|k(b(p_h^n))\|)\|p_h^n\|,$$

and the estimate follows from the estimates for $\|q_h^n\|$ and the boundedness of k. ∎

Applying now techniques developed in [2] we estimate the errors induced by the spatial discretization.

PROPOSITION 4.10. *Let $n = \overline{1,N}$. If $(p^n, q^n) \in W \times V$, $(p_h^n, q_h^n) \in W_h \times V_h$ solve Problem 5, respectively 6, assuming* (A1)–(A4) *yields*

$$\sum_{n=1}^{N} \left\{ (b_\epsilon(p^n) - b_\epsilon(p_h^n), p^n - p_h^n) + \tau \|\Pi_h q^n - q_h^n\|^2 \right\} + \tau \left\| \sum_{n=1}^{N} (\Pi_h q^n - q_h^n) \right\|^2$$

$$\leq C \sum_{n=1}^{N} \{ \|q^n - \Pi_h q^n\|^2 + \|P_h p^n - p^n\|^2 \}. \tag{4.30}$$

Proof. Subtracting (4.27) from (4.25) and (4.28) from (4.26) gives

$$(b_\epsilon(p^n) - b_\epsilon(p_h^n), w_h) + \tau \left(\sum_{j=1}^{n} \nabla \cdot (q^j - q_h^j), w_h \right) = 0,$$

$$(q^n - q_h^n, v_h) - (p^n - p_h^n, \nabla \cdot v_h) + ((k(b(p^n)) - k(b(p_h^n)))e_z, v_h) = 0.$$

Taking $w_h = P_h p^n - p_h^n \in W_h$ and $v_h = \tau \sum_{j=1}^{n} (\Pi_h q^j - q_h^j) \in V_h$ into the above leads to

$$(b_\epsilon(p^n) - b_\epsilon(p_h^n), P_h p^n - p_h^n) + \tau \left(\sum_{j=1}^{n} \nabla \cdot (\Pi_h q^j - q_h^j), P_h p^n - p_h^n \right) = 0,$$

$$\tau \left(q^n - q_h^n, \sum_{j=1}^{n} (\Pi_h q^j - q_h^j) \right) - \tau \left(P_h p^n - p_h^n, \nabla \cdot \sum_{j=1}^{n} (\Pi_h q^j - q_h^j) \right)$$

$$+ \tau \left((k(b(p^n)) - k(b(p_h^n)))e_z, \sum_{j=1}^{n} (\Pi_h q^j - q_h^j) \right) = 0.$$

Adding these equalities and summing the result up from 1 to N yields

$$\sum_{n=1}^{N} (b_\epsilon(p^n) - b_\epsilon(p_h^n), P_h p^n - p_h^n) + \sum_{n=1}^{N} \left(q^n - q_h^n, \sum_{j=1}^{n} \tau (\Pi_h q^j - q_h^j) \right)$$

$$+ \sum_{n=1}^{N} \left((k(b(p^n)) - k(b(p_h^n)))e_z, \sum_{j=1}^{n} \tau (\Pi_h q^j - q_h^j) \right) = 0. \tag{4.31}$$

We estimate now each of the terms above, denoted by T_1, T_2, and T_3:

$$T_1 = \sum_{n=1}^{N} (b_\epsilon(p^n) - b_\epsilon(p_h^n), p^n - p_h^n)$$

$$+\sum_{n=1}^{N}(b_\epsilon(p^n)-b_\epsilon(p_h^n),P_hp^n-p^n)=:T_{11}+T_{12}. \tag{4.32}$$

By (A2) and the definition (2.7) of b_ϵ, a $C>0$ independent of τ and h exists such that

$$\begin{aligned}T_{11}&\geq\frac{1}{2}\sum_{n=1}^{N}(b_\epsilon(p^n)-b_\epsilon(p_h^n),p^n-p_h^n)\\&\quad+C\left(\sum_{n=1}^{N}\|b_\epsilon(p^n)-b_\epsilon(p_h^n)\|^2+\epsilon\sum_{n=1}^{N}\|p^n-p_h^n\|^2\right).\end{aligned} \tag{4.33}$$

Applying the inequality of Cauchy T_{12} yields

$$|T_{12}|\leq\frac{\mu}{2}\sum_{n=1}^{N}\|b_\epsilon(p^n)-b_\epsilon(p_h^n)\|^2+\frac{1}{2\mu}\sum_{n=1}^{N}\|P_hp^n-p^n\|^2. \tag{4.34}$$

Rewriting T_2 as

$$\begin{aligned}T_2&=\sum_{n=1}^{N}\left(q^n-\Pi_hq^n,\sum_{j=1}^{n}\tau(\Pi_hq^j-q_h^j)\right)\\&\quad+\sum_{n=1}^{N}\left(\Pi_hq^n-q_h^n,\sum_{j=1}^{n}\tau(\Pi_hq^j-q_h^j)\right)=:T_{21}+T_{22},\end{aligned} \tag{4.35}$$

we estimate T_{21} and T_{22}. For T_{21} we get

$$|T_{21}|\leq\frac{1}{2}\sum_{n=1}^{N}\|q^n-\Pi_hq^n\|^2+\frac{\tau^2}{2}\sum_{n=1}^{N}\left\|\sum_{j=1}^{n}(\Pi_hq^j-q_h^j)\right\|^2, \tag{4.36}$$

while for T_{22} we use (3.1) to obtain

$$T_{22}=\frac{\tau}{2}\left\|\sum_{n=1}^{N}(\Pi_hq^n-q_h^n)\right\|^2+\frac{\tau}{2}\sum_{n=1}^{N}\|\Pi_hq^n-q_h^n\|^2. \tag{4.37}$$

Using (A3), T_3 gets

$$\begin{aligned}|T_3|&\leq\frac{\delta}{2}\sum_{n=1}^{N}\|k(b(p^n))-k(b(p_h^n))\|^2+\frac{\tau^2}{2\delta}\sum_{n=1}^{N}\left\|\sum_{j=1}^{n}(\Pi_hq^j-q_h^j)\right\|^2\\&\leq\frac{C_k\delta}{2}\sum_{n=1}^{N}(b(p^n)-b(p_h^n),p^n-p_h^n)+\frac{\tau^2}{2\delta}\sum_{n=1}^{N}\left\|\sum_{j=1}^{n}(\Pi_hq^j-q_h^j)\right\|^2.\end{aligned} \tag{4.38}$$

Inserting (4.32)–(4.38) into (4.31) and choosing μ and δ properly gives

$$\begin{aligned}&\sum_{n=1}^{N}\{(b_\epsilon(p^n)-b_\epsilon(p_h^n),p^n-p_h^n)+\tau\|\Pi_hq^n-q_h^n\|^2\}+\tau\left\|\sum_{n=1}^{N}(\Pi_hq^n-q_h^n)\right\|^2\\&\quad\leq C\sum_{n=1}^{N}\left\{\|q^n-\Pi_hq^n\|^2+\|P_hp^n-p^n\|^2+\tau^2\left\|\sum_{j=1}^{n}(\Pi_hq^j-q_h^j)\right\|^2\right\}.\end{aligned}$$

Finally, (4.30) follows applying the discrete Gronwall lemma. ∎

REMARK 4.11. *By the equivalence proven in Proposition* 2.3, $p^n \in H^1(\Omega)$ *for all* n. *Now using* (4.24) *and* (3.7) *we get*

$$\sum_{n=1}^{N} \|P_h p^n - p^n\|^2 \le Ch^2 \sum_{n=1}^{N} \|p^n\|_1^2 \le C\frac{h^2}{\tau},$$

and the estimates (4.30) *can be modified accordingly.*

Similar estimates can be obtained for the p-unknowns.

PROPOSITION 4.12. *Under the assumptions of Proposition* 4.10 *we have*

$$\tau \left\| \sum_{n=1}^{N} (P_h p^n - p_h^n) \right\|^2 \le C \Bigg\{ \sum_{n=1}^{N} (b_\epsilon(p^n) - b_\epsilon(p_h^n), p^n - p_h^n) + \tau \left\| \sum_{n=1}^{N} (\Pi_h q^n - q_h^n) \right\|^2 + \sum_{n=1}^{N} \|q^n - \Pi_h q^n\|^2 \Bigg\}. \tag{4.39}$$

Proof. Subtracting (4.28) from (4.26), recalling the definition of P_h, and summing up for $n = 1$ to N yield

$$\left(\sum_{n=1}^{N} (q^n - q_h^n), v_h \right) - \left(\sum_{n=1}^{N} (P_h p^n - p_h^n), \nabla \cdot v_h \right) + \left(\sum_{n=1}^{N} \tau (k(b(p^n)) - k(b(p_h^n)))e_z, v_h \right) = 0 \tag{4.40}$$

for any $v_h \in V_h$. Using now Lemma 4.8, a $v_h \in V_h$ exists such that

$$\nabla \cdot v_h = \sum_{n=1}^{N} \tau (P_h p^n - p_h^n) \tag{4.41}$$

and $\|v_h\| < C\|\tau \sum_{n=1}^{N} (P_h p^n - p_h^n)\|$. In this case (4.40) gives

$$\tau \left\| \sum_{n=1}^{N} (P_h p^n - p_h^n) \right\|^2 = \left(\sum_{n=1}^{N} (q^n - q_h^n), v_h \right) + \left(\sum_{n=1}^{N} (k(b(p^n)) - k(b(p_h^n)))e_z, v_h \right). \tag{4.42}$$

Denoting by T_1 and T_2 the terms on the right into above, applying the inequality of Cauchy and recalling the estimates on $\|v_h\|$ leads to

$$|T_1| \le \frac{\tau}{2\delta_1} \left\| \sum_{n=1}^{N} (q_h^n - q^n) \right\|^2 + \frac{\delta_1}{2\tau} \|v_h\|^2$$

$$\le \frac{\tau}{2\delta_1} \left\| \sum_{n=1}^{N} (q_h^n - q^n) \right\|^2 + \frac{C\tau\delta_1}{2} \left\| \sum_{n=1}^{N} (p_h^n - P_h p_h^n) \right\|^2. \tag{4.43}$$

Similarly, by (A3) we obtain

$$|T_2| \le \frac{\tau}{2\delta_2}\left\|\sum_{n=1}^{N}(k(b(p_h^n))-k(b(p^n)))\right\|^2 + \frac{\delta_2}{2\tau}\|v_h\|^2$$

$$\le \frac{C}{2\delta_2}\sum_{n=1}^{N}(b(p_h^n)-b(p^n),p_h^n-p^n) + \frac{C\tau\delta_2}{2}\left\|\sum_{n=1}^{N}(p_h^n-P_hp_h^n)\right\|^2. \tag{4.44}$$

Choosing δ_1 and δ_2 properly, (4.42)–(4.44) gives

$$\tau\left\|\sum_{n=1}^{N}(P_hp^n-p_h^n)\right\|^2$$

$$\le C\left\{\sum_{n=1}^{N}(b_\epsilon(p^n)-b_\epsilon(p_h^n),p^n-p_h^n)+\tau\left\|\sum_{n=1}^{N}(q^n-q_h^n)\right\|^2\right\}.$$

The last term above can be rewritten as

$$\tau\left\|\sum_{n=1}^{N}(q^n-q_h^n)\right\|^2 \le \tau\left\|\sum_{n=1}^{N}(\Pi_hq^n-q_h^n)\right\|^2+\tau\left\|\sum_{n=1}^{N}(q^n-\Pi_hq^n)\right\|^2$$

$$\le \tau\left\|\sum_{n=1}^{N}(\Pi_hq^n-q_h^n)\right\|^2+T\sum_{n=1}^{N}\|q^n-\Pi_hq^n\|^2,$$

which completes the proof. □

The following is a direct consequence of Propositions 4.10 and 4.12.

THEOREM 4.13. *Assuming* (A1)–(A4), *if* $(p^n,q^n)\in W\times V$, $(p_h^n,q_h^n)\in W_h\times V_h$ *solve, for* $n=\overline{1,N}$, *Problems* 5 *and* 6, *we obtain*

$$\sum_{n=1}^{N}(b_\epsilon(p^n)-b_\epsilon(p_h^n),p^n-p_h^n)+\tau\sum_{n=1}^{N}\|\Pi_hq^n-q_h^n\|^2$$

$$+\tau\left\|\sum_{n=1}^{N}(q^n-q_h^n)\right\|^2+\tau\left\|\sum_{n=1}^{N}(p^n-p_h^n)\right\|^2 \tag{4.45}$$

$$\le C\left(\sum_{n=1}^{N}\|q^n-\Pi_hq^n\|^2+\sum_{n=1}^{N}\|P_hp^n-p^n\|^2\right).$$

Combining the estimates in Theorems 4.6 and 4.13 and recalling Remark 4.11 we get, for the fully discrete scheme, the following.

THEOREM 4.14. *Assuming* (A1)–(A4), *we get*

$$\left\|\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(u(t)-p_h^n)dt\right\|^2+\left\|\tilde{q}(T)-\tau\sum_{n=1}^{N}q_h^n\right\|^2$$

$$\le C\left(\tau+\epsilon+h^2+\tau\sum_{n=1}^{N}\|q^n-\Pi_hq^n\|^2\right). \tag{4.46}$$

Proof. Let T_1 and T_2 denote the terms on the left in (4.46). For T_1, by the properties of norms we have

$$T_1 \le 2\left\|\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(u(t)-p^n)dt\right\|^2 + 2\tau^2\left\|\sum_{n=1}^{N}(p^n-p_h^n)\right\|^2.$$

Estimates (4.20) in Theorem 4.4 give

$$\left\|\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(u(t)-p^n)dt\right\|^2 \le C(\tau+\epsilon),$$

which, together with (4.45), imply

$$T_1 \le C(\tau+\epsilon). \tag{4.47}$$

Analogously, for T_2 we obtain

$$\begin{aligned} T_2 &\le 2\left\|\tilde{q}(T)-\tau\sum_{n=1}^{N}q^n\right\|^2 + 2\tau^2\left\|\sum_{n=1}^{N}(q^n-q_h^n)\right\|^2 \\ &\le C_1(\tau+\epsilon) + C_2\left(\tau+\epsilon+h^2+\tau\sum_{n=1}^{N}\|q^n-\Pi_h q^n\|^2\right) \end{aligned} \tag{4.48}$$

by the arguments above. Now (4.46) follows from (4.47) and (4.48). ∎

COROLLARY 4.15. *Under the assumptions of Theorem* 4.14*, for the scalar product we have*

$$\begin{aligned} &\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(b_\epsilon(u(t))-b_\epsilon(p_h^n),u(t)-p_h^n)dt \\ &\quad\le C\left(\tau^{\frac12}+\epsilon^{\frac12}+h^2/\tau^{\frac12}+\tau^{\frac12}\sum_{n=1}^{N}\|q^n-\Pi_h q^n\|^2\right). \end{aligned} \tag{4.49}$$

Proof. We decompose the scalar product as follows:

$$\begin{aligned} &\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(b_\epsilon(u(t))-b_\epsilon(p_h^n),u(t)-p_h^n)dt \\ &\quad=\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(b_\epsilon(u(t))-b_\epsilon(p^n),u(t)-p_h^n)dt \\ &\qquad+\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(b_\epsilon(p^n)-b_\epsilon(p_h^n),u(t)-p_h^n)dt =: T_1+T_2. \end{aligned}$$

Applying Cauchy's inequality T_1 yields

$$\begin{aligned} |T_1| &\le \sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}\|b_\epsilon(u(t))-b_\epsilon(p^n)\|\|u(t)-p_h^n\|dt \\ &\le \frac{1}{4\delta_1}\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}\|b_\epsilon(u(t))-b_\epsilon(p^n)\|^2dt + \delta_1\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}\|u(t)-p_h^n\|^2dt. \end{aligned}$$

Since b_ϵ is Lipschitz, using (4.20), the first sum gives

$$\begin{aligned}
&\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}\|b_\epsilon(u(t))-b_\epsilon(p^n)\|^2dt\\
&\quad\le C\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(b_\epsilon(u(t))-b_\epsilon(p^n),u(t)-p^n)dt\\
&\quad\le C(\tau+\epsilon).
\end{aligned}$$

Having $u\in L^2(J\times\Omega)$, by (4.29) we get

$$\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}\|u(t)-p_h^n\|^2dt\le C.$$

In this way, choosing $\delta_1=(\tau+\epsilon)^{\frac12}$ yields

$$|T_1|\le C(\tau+\epsilon)^{\frac12}\le C(\tau^{\frac12}+\epsilon^{\frac12}). \tag{4.50}$$

For T_2 we obtain

$$\begin{aligned}
|T_2|&\le\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}\|b_\epsilon(p^n)-b_\epsilon(p_h^n)\|\|u(t)-p_h^n\|dt\\
&\le\frac{\tau^{\frac12}}{4}\sum_{n=1}^{N}\|b_\epsilon(p^n)-b_\epsilon(p_h^n)\|^2+\tau^{\frac12}\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}\|u(t)-p_h^n\|^2dt.
\end{aligned}$$

As before, the second sum above is uniformly bounded, while for the first one we write

$$\sum_{n=1}^{N}\|b_\epsilon(p^n)-b_\epsilon(p_h^n)\|^2\le C\sum_{n=1}^{N}(b_\epsilon(p^n)-b_\epsilon(p_h^n),p^n-p_h^n).$$

Using (4.45) gives

$$\sum_{n=1}^{N}\|b_\epsilon(p^n)-b_\epsilon(p_h^n)\|^2\le C\left(h^2/\tau+\sum_{n=1}^{N}\|q^n-\Pi_hq^n\|^2\right),$$

so T_2 is bounded by

$$|T_2|\le C\left(\tau^{\frac12}+h^2/\tau^{\frac12}+\tau^{\frac12}\sum_{n=1}^{N}\|q^n-\Pi_hq^n\|^2\right). \tag{4.51}$$

The result follows now from (4.50) and (4.51). ∎

Assuming additionally

(A5) $q^n\in H^1(\Omega)^d$ for all $n=\overline{1,N}$,

using (4.24) and the estimates in Theorem 4.14 and Corollary 4.15 we obtain the following theorem.

THEOREM 4.16. *Assuming* (A1)–(A5) *we have*

$$\left\|\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(u(t)-p_h^n)dt\right\|^2+\left\|\tilde{q}(T)-\tau\sum_{n=1}^{N}q_h^n\right\|^2\le C(\tau+\epsilon+h^2),$$

$$\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}(b_\epsilon(u(t))-b_\epsilon(p_h^n),u(t)-p_h^n)dt\le C(\tau^{\frac{1}{2}}+\epsilon^{\frac{1}{2}}+h^2/\tau^{\frac{1}{2}}). \tag{4.52}$$

REMARK 4.17. *Obviously* (A5) *is fulfilled in one spatial dimension, since then* $H(\mathrm{div},\Omega)$ *and* $H^1(\Omega)$ *coincide. Assumption* (A5) *also holds in the multidimensional case, provided* $\partial\Omega$ *is smooth enough and* k *is differentiable. Using* (A2) *and* (A3)*, since* $k(b(\cdot))\in C^1(0,1)$ *we have*

$$|\partial_u k(b(u))|\le\lim_{\delta\to 0}\left|\frac{k(b(u+\delta))-k(b(u))}{\delta}\right|\le\sqrt{C_k\frac{b(u+\delta)-b(u)}{\delta}}\le C.$$

Following [19, *Chapter* 4, *Theorems* 5.1 *and* 5.2]*, for any* $n=\overline{1,N}$*,* u^n *solving Problem* 3 *is in* $H^2(\Omega)$ *and the corresponding norm is bounded uniformly in* n *by a constant that, nevertheless, may depend on* τ*. Therefore* $q^n\in H^1(\Omega)$ *for all* $n\ge 1$ *and* $\|q^n\|_1\le C(\tau)$.

To confirm our theoretical results we present a numerical test. We consider a problem allowing for a travel wave solution, as proposed in [12] which refers to the Richards' equation in its form after the Kirchhoff transformation (1.4), without gravitation term and with

$$b(u)=\begin{cases}\frac{\pi^2}{2}-\frac{u^2}{2} & \text{for} \quad u\le 0,\\ \frac{\pi^2}{2} & \text{for} \quad u>0.\end{cases}$$

For this problem an exact solution is known:

$$u_{\mathrm{ex}}(t,x,y)=\begin{cases}\frac{-2(e^s-1)}{e^s+1} & \text{for} \quad s\ge 0,\\ -s & \text{for} \quad s<0,\end{cases}$$

where $s=x-y-t$. The equation has been solved in the unit square Ω, with Dirichlet boundary condition given by $u=u_{\mathrm{ex}}$ on $\partial\Omega$ and initial value u_{ex} at $t=0$. For mixed finite element discretizations the emerging system of equations is difficult to solve due to being the solution of a saddle point problem. A common implementation trick is to enlarge the system by adding Lagrange multipliers on edges (hybridization of the method). Briefly, within one timestep the resulting algorithm reads as follows: first the flux variable is eliminated on each element; then the continuity equation is locally solved for pressure by a variably damped Newton's method. The global system is set for the Lagrange multipliers and solved using the Newton method and a multigrid solver for the linear subproblems in the Newton iterations (for details see [25]). An alternative linearization approach is discussed in [24]. The implementation is based on the package UG (version 3.8, see also [3]), and the computations have been done on a SUN workstation.

To verify the theoretical estimates, we have started performing computations on a uniform triangular mesh with $h=0.25$, and a time step $\tau=0.04$. Then τ and h^2 are successively halved, up to $\tau=0.000625$ and $h=0.03125$. The final time was set

TABLE 4.1
Numerical results.

to be 1.0 for all the computations. Knowing the exact solution, the square of the total error (as written in (4.52)) is given by

$$E_{tot}^2 = \left\| \sum_{n=1}^{N} \int_{t_{n-1}}^{t_n} (u_{\mathrm{ex}}(t) - p_h^n)\, dt \right\|^2 + \left\| \tilde{q}_{\mathrm{ex}}(T) - \tau \sum_{n=1}^{N} q_h^n \right\|^2,$$

where $\tilde{q}_{\mathrm{ex}}(T) = \int_0^T \nabla\, u_{\mathrm{ex}}(t)\, dt$ is the exact flux. The order of convergence (for the squared error) is estimated by dividing the errors above, computed for two sets of parameters (refined according to the procedure mentioned above). Dividing the natural logarithm of the result by the natural logarithm of the refinement ratio yields an approximation of the convergence order. Results are displayed in Table 4.1. As predicted by Theorem 4.14, the order of E_{tot}^2 is between 0.8 and 1.1. Thus we can conclude that the numerical results are in concordance with our theoretical analysis, in particular confirming the convergence of the scheme.

Acknowledgments. We would like to thank Prof. C. J. van Duijn and Dr. E. F. Kaasschieter for useful discussions and suggestions.

ADAPTIVE WAVELET GALERKIN METHODS FOR LINEAR INVERSE PROBLEMS*

ALBERT COHEN†, MARC HOFFMANN‡, AND MARKUS REIß§

Abstract. We introduce and analyze numerical methods for the treatment of inverse problems, based on an adaptive wavelet Galerkin discretization. These methods combine the theoretical advantages of the wavelet-vaguelette decomposition (WVD) in terms of optimally adapting to the unknown smoothness of the solution, together with the numerical simplicity of Galerkin methods. In a first step, we simply combine a thresholding algorithm on the data with a Galerkin inversion on a fixed linear space. In a second step, a more elaborate method performs the inversion by an adaptive procedure in which a smaller space adapted to the solution is iteratively constructed; this leads to a significant reduction of the computational cost.

Key words. statistical inverse problems, Galerkin methods, wavelets and nonlinear methods, Besov spaces, minimax estimation

1. Introduction.

1.1. Statistical model. We want to recover a function f in $L^2(\Omega_X)$, where Ω_X is a certain bounded domain in $\mathbb{R}^d$, but we are able to observe data about Kf only, where $K : L^2(\Omega_X) \to L^2(\Omega_Y)$ is a compact linear operator and Ω_X and Ω_Y are two bounded domains in $\mathbb{R}^d$ and $\mathbb{R}^q$, respectively. In the following, when mentioning L^2 or more general function spaces, we shall omit the domain Ω_X or Ω_Y when this information is obvious from the context.

We are interested in the statistical formulation of linear inverse problems: we assume that the data are noisy, so that we observe

$$g_\varepsilon = Kf + \varepsilon \dot{W}, \tag{1.1}$$

where $\dot{W}$ is a white noise and ε a noise level. In rigorous probabilistic terms, we observe a Gaussian measure on L^2 with drift Kf and intensity ε^2 (see, e.g., [20]). Observable quantities take the form

$$\langle g_\varepsilon, v\rangle = \langle Kf, v\rangle + \varepsilon\, \eta(v),$$

where $v \in L^2$ is a test function and $\eta(v)$ is a Gaussian centered random variable with variance $\|v\|_{L^2}^2$. For $v_1, v_2 \in L^2$ the covariance between $\eta(v_1)$ and $\eta(v_2)$ is given by the scalar product $\langle v_1, v_2\rangle$. In particular, if v_1 and v_2 are orthogonal, the random variables $\eta(v_1)$ and $\eta(v_2)$ are stochastically independent. The cognitive value of the white noise model (1.1) is discussed in detail in [4], [26] and the references therein.

If $f_\varepsilon \in L^2$ is an estimator of f, that is a measurable quantity w.r.t. the data g_ε, we measure its accuracy by the mean-square error $E(\|f_\varepsilon - f\|_{L^2}^2)$ as $\varepsilon \to 0$, with $E(\cdot)$ denoting the expectation operator.

1.2. SVD and Galerkin projection. Among the most popular regularization methods, let us first mention the *singular value decomposition* (SVD); see, e.g., [21], [22], and [24]. Although very attractive theoretically, the SVD suffers from two limitations. First, the singular basis functions may be difficult to determine and manipulate numerically. Second, while these bases are fully adapted to describe the action of K, they might not be appropriate for the accurate description of the solution with a small number of parameters (see, e.g., [16]). Concerning numerical simplicity, *projection methods* are more appealing. Given finite dimensional subspaces $X_h \subset L^2(\Omega_X)$ and $Y_h \subset L^2(\Omega_Y)$ with $\dim(X_h) = \dim(Y_h)$, one defines the approximation f_ε as the solution in X_h of the problem

$$\langle K f_\varepsilon, g_h \rangle = \langle g, g_h \rangle \quad \text{for all} \quad g_h \in Y_h, \tag{1.2}$$

which amounts to solving a linear system (see [25] for a general approach to projection methods). In the case where $\Omega_X = \Omega_Y$ and K is a self-adjoint positive definite operator, we choose $Y_h = X_h$ and the linear system is particularly simple to solve since the corresponding discretized operator K_h is symmetric positive definite: this is the so-called *Galerkin method*. In the case of general $\Omega_X \neq \Omega_Y$ and injective K, one may choose $Y_h := K(X_h)$ and we are led back to the Galerkin method applied to the least squares equation $K^*Kf = K^*g$ with data K^*g_ε, where K^* denotes the adjoint of K. The numerical simplicity of projection methods comes from the fact that X_h and Y_h are typically finite element spaces equipped with standard local bases. As in the SVD method, the discretization parameter h has to be properly chosen. The choice of finite element spaces for X_h and Y_h is also beneficial with respect to the second limitation of SVD, since the approximation properties of finite elements can be exploited when the solution has some smoothness.

However, the Galerkin projection method suffers from two drawbacks which are encountered in all *linear* estimation methods, including, in particular, the SVD. First, the choice of h with respect to the noise level ε depends on the regularity of the solution which is almost always unknown in advance. Second, the use of a finite element space X_h with a fixed uniform mesh size h does not provide any spatial adaptation.

1.3. Wavelet-vaguelette decomposition. In recent years, *nonlinear* methods have been developed, with the objective of automatically adapting to unknown smoothness and locally singular behavior of the solution. In the case of simple denoising, i.e., when K is the identity, wavelet thresholding is probably one of the most attractive nonlinear methods, since it is both numerically straightforward and asymptotically optimal for a large variety of Sobolev or Besov classes as models for the unknown smoothness of the solution; see, e.g., [18]. This success strongly exploits the fact that wavelets provide unconditional bases for such smoothness spaces. In order to adapt this approach to the framework of ill-posed inverse problems, Donoho introduced in [16] a wavelet-like decomposition which is specifically adapted to describe the action of K, the so-called *wavelet-vaguelette decomposition* (WVD), and proposed applying a thresholding algorithm on this decomposition. In [1] Donoho's method was compared with the similar *vaguelette-wavelet decomposition* (VWD) algorithm. Both methods rely on an orthogonal wavelet basis (ψ_λ) and associated Riesz bases of

"vaguelettes" defined as

$$v_\lambda = \beta_\lambda K^{-1}\psi_\lambda \text{ and } u_\lambda = \beta_\lambda (K^*)^{-1}\psi_\lambda, \tag{1.3}$$

where the scaling coefficients β_λ typically depend on the order of ill-posedness of K. We thus have the WVD and VWD decompositions

$$f = \sum_\lambda \beta_\lambda^{-1}\langle Kf, u_\lambda\rangle\psi_\lambda = \sum_\lambda \beta_\lambda^{-1}\langle Kf, \psi_\lambda\rangle v_\lambda. \tag{1.4}$$

The WVD and VWD estimation methods amount to estimating the coefficients in these expansions from the observed data and applying a thresholding procedure. On a theoretical level, similarly to wavelet thresholding in the case of simple denoising, both WVD and VWD allow recovery at the same rate as the projection method, under weaker smoothness conditions, a fact that reflects their ability for spatial adaptivity.

On a more applied level, numerical implementations in [1] and [15] have illustrated the efficiency of both WVD and VWD methods, in the case of operators that behave like integration $Kf(x) = \int_0^x f(t)dt$. For more general operators, however, the assumption that $K^{-1}\psi_\lambda$ or $(K^*)^{-1}\psi_\lambda$ are known for all indices λ may simply result in putting forward the inversion problem: if an integral operator has a kernel with a complicated structure (see [5]), or if this kernel is itself derived from observations (see [27]), this inversion has to be done numerically with additional computational cost and error. In other words, the vaguelettes u_λ and v_λ might be difficult to handle numerically (similar to the SVD functions), and in particular they are not ensured to have compact support.

1.4. Our approach: Adaptive wavelet Galerkin. In this context, a natural goal is to build a method which combines the numerical simplicity of linear Galerkin projection methods with the optimality of adaptive wavelet thresholding methods. This is the goal of the paper.

Adaptive Galerkin methods are well established in the context of solving operator equations *without noise*; typically, the finite element space is locally refined based on *a-posteriori error analysis* of the current numerical solution. Such adaptive algorithms were recently extended to the context of wavelet discretizations, exploiting both the characterization of function spaces and the sparse representation of the operator by wavelet bases; see, e.g., [8]. Our goal is to introduce and analyze similar adaptive wavelet Galerkin algorithms in the context of statistical inverse problems. Such adaptive algorithms involve only the wavelet system (ψ_λ) and are therefore often easier to handle numerically than WVD and VWD. On the other hand, their optimality will essentially rely on the assumption that K has certain mapping properties with respect to the relevant function spaces, a fact which is also implicitly used in the WVD and VWD approaches. Last but not least, one can exploit the fact that the Galerkin discretization of K in the wavelet basis might be sparse even for nonlocal integral operators, in order to improve the computational efficiency of our estimator.

Concerning the organization of the paper, we progressively develop our methodology. In section 2, we introduce general assumptions on model (1.1), in terms of mapping properties of the operator K between smoothness spaces. After a brief recall of the analysis of the linear Galerkin method using a wavelet multiresolution space V_j in section 3.1, a first nonlinear method is proposed in section 3.2, which initially operates in a way similar to the VWD, by thresholding the wavelet coefficients $g_\lambda^\varepsilon := \langle g_\varepsilon, \psi_\lambda\rangle$ with λ restricted up to a maximal scale level $j = j(\varepsilon)$, and then

applies a linear Galerkin inversion of these denoised data on the multiresolution space V_j. As ε decreases, the scale level $j(\varepsilon)$ grows and the Galerkin approximation thus becomes computationally heavy, while the solution could still be well represented by a small adaptive set of wavelets within V_j. Therefore, we propose in section 4 an adaptive algorithm which iteratively produces such a set together with the corresponding Galerkin estimator. This algorithm intertwines the process of thresholding with an iterative resolution of the Galerkin system, and it exploits, in addition, the sparse representation of K in the wavelet basis. As we completed the revision of this paper, we became aware of a related approach recently proposed in [13], based on least squares minimization with a nonquadratic penalization term in a deterministic setting, which results in a similar combination of gradient iteration with a thresholding procedure, yet operating in infinite dimension. Both methods in sections 3.2 and 4 are proved to achieve the same minimax rate as WVD and VWD under the same general assumptions on the operator K. We eventually compare the different estimators in section 5 numerically on the example of a singular integral equation of the first kind. For simplicity, we present our methods and results in the case where K is elliptic and self-adjoint. The extension to more general operators, via a least squares approach, is the object of Appendix A. We also discuss in Appendix B several properties of multiresolution spaces which are used throughout the paper.

2. Assumptions on the operator K. The ill-posed nature of the problem comes from the assumption that K is compact and therefore its inverse is not L^2-continuous. This is expressed by a smoothing action: K typically maps L^2 into H^t for some $t > 0$. More generally we say that K has the smoothing property of order t with respect to some smoothness space H^s (resp., W_p^s, $B_{p,q}^s$) if this space is mapped onto H^{s+t} (resp., W_p^{s+t}, $B_{p,q}^{s+t}$).

The estimator f_ε will be searched within a finite dimensional subspace V of $L^2(\Omega_X)$ based on the projection method. In the case where $\Omega_X = \Omega_Y = \Omega$ and K is self-adjoint positive definite, we shall use the Galerkin method, that is,

$$\text{find } f_\varepsilon \in V \text{ such that } \langle Kf_\varepsilon, v\rangle = \langle g_\varepsilon, v\rangle \text{ for all } v \in V. \tag{2.1}$$

The smoothing property of order t will be expressed by the ellipticity property

$$\langle Kf, f\rangle \sim \|f\|^2_{H^{-t/2}}, \tag{2.2}$$

where $H^{-t/2}$ stands for the dual space of the Sobolev space $H^{t/2}$ appended with boundary conditions that might vary depending on the considered problem (homogeneous Dirichlet, periodic, and so on). The symbol $a \sim b$ means that there exists $c > 0$ independent of f such that $c^{-1}b \le a \le cb$.

In the case where $\Omega_X \neq \Omega_Y$ or when K is not self-adjoint positive definite, we shall consider the least squares method, that is,

$$\text{find } f_\varepsilon \in V \text{ which minimizes } \|Kv - g_\varepsilon\|^2_{L^2} \text{ among all } v \in V. \tag{2.3}$$

As already remarked, this amounts to applying the Galerkin method on the equation $K^*Kf = K^*g$ with data K^*g_ε and trial space $K(V)$. The smoothing property of order t will then be expressed by the ellipticity property

$$\|Kf\|^2_{L^2} = \langle K^*Kf, f\rangle \sim \|f\|^2_{H^{-t}}. \tag{2.4}$$

We shall only deal with this general situation in Appendix A, and we therefore assume for the next sections that K is self-adjoint positive definite and satisfies (2.2).

3. Nonlinear estimation by linear Galerkin. Wavelet bases have been documented in numerous textbooks and survey papers (see [12] for a general treatment). With a little effort, they can be adapted to fairly general domains $\Omega \subset \mathbb{R}^d$ (see [7] for a survey of these adaptations as well as a discussion of the characterizations of function spaces on Ω by wavelet coefficients).

The wavelet decomposition of a function $f \in L^2$ takes the form

$$f = \sum_{\lambda \in \Gamma_{j_0}} \alpha_\lambda \varphi_\lambda + \sum_{j \geq j_0} \sum_{\lambda \in \nabla_j} f_\lambda \psi_\lambda, \tag{3.1}$$

where $(\varphi_\lambda)_{\lambda \in \Gamma_j}$ is the scaling function basis spanning the approximation at level j with appropriate boundary modification, and $(\psi_\lambda)_{\lambda \in \nabla_j}$ is the wavelet basis spanning the details at level j. The index λ concatenates the usual scale and space indices j and k. The coefficients of f can be evaluated according to

$$\alpha_\lambda = \langle f, \tilde{\varphi}_\lambda \rangle \text{ and } f_\lambda = \langle f, \tilde{\psi}_\lambda \rangle,$$

where $\tilde{\varphi}_\lambda$ and $\tilde{\psi}_\lambda$ are the corresponding dual scaling functions and wavelets. In what follows, we shall (merely for notational convenience) always take $j_0 := 0$. To simplify notation even more, we incorporate the first layer of scaling functions $(\varphi_\lambda)_{\lambda \in \Gamma_0}$ into the wavelet layer $(\psi_\lambda)_{\lambda \in \nabla_0}$ and define $\nabla = \cup_{j \geq 0} \nabla_j$, so that, if we write $|\lambda| = j$ if $\lambda \in \nabla_j$, we simply have

$$f = \sum_{\lambda \in \nabla} f_\lambda \psi_\lambda = \sum_{j=0}^{\infty} \sum_{|\lambda| = j} f_\lambda \psi_\lambda.$$

3.1. Preliminaries: Linear estimation by linear Galerkin. We first recall some classical results on the linear Galerkin projection method. For some scale $j > 0$ to be chosen further, let V_j be the linear space spanned by $(\varphi_\lambda)_{\lambda \in \Gamma_j}$. We define our first estimator $f_\varepsilon = \sum_{\gamma \in \Gamma_j} f_{\varepsilon,\gamma} \varphi_\gamma \in V_j$ as the unique solution of the finite dimensional linear problem

$$\text{find } f_\varepsilon \in V_j \text{ such that } \langle K f_\varepsilon, v \rangle = \langle g_\varepsilon, v \rangle \text{ for all } v \in V_j. \tag{3.2}$$

Defining the data vector $G_\varepsilon := (\langle g_\varepsilon, \varphi_\gamma \rangle)_{\gamma \in \Gamma_j}$ and the Galerkin stiffness matrix $K_j := (K\varphi_\gamma, \varphi_\mu\rangle)_{\gamma,\mu \in \Gamma_j}$, the coordinate vector $F_\varepsilon := (f_{\varepsilon,\gamma})_{\gamma \in \Gamma_j}$ of f_ε is therefore the solution of the linear system

$$K_j F_\varepsilon = G_\varepsilon. \tag{3.3}$$

The analysis of the method is summarized in the following classical result; see, for instance, [21], [22], [25], [15], and the references therein.

PROPOSITION 3.1. *Assuming that f belongs to the Sobolev ball $B := \{f \in H^s \,;\, \|f\|_{H^s} \leq M\}$ and choosing $j = j(\varepsilon)$ with $2^{-j(\varepsilon)} \sim \varepsilon^{2/(2s+2t+d)}$, we have*

$$\sup_{f \in B} E(\|f - f_\varepsilon\|_{L^2}^2) \lesssim \varepsilon^{4s/(2s+2t+d)},$$

and this rate is minimax over the class B.

The symbol $\lesssim$ means that the left-hand side is bounded by a constant multiple of the right-hand side where the constant possibly depends on s and M, but not on

ε. In order to be self contained, we give a proof of Proposition 3.1. The techniques we use here will prove helpful in the sequel.

Proof. The analysis of this method can be done by decomposing f_ε according to

$$f_\varepsilon = f_j + h_\varepsilon, \tag{3.4}$$

where the terms f_j and h_ε are, respectively, solutions of (3.2) with Kf and $\varepsilon\dot{W}$ in place of g_ε as the right-hand side. This gives the classical decomposition of the estimation error into a bias and variance term

$$E(\|f - f_\varepsilon\|_{L^2}^2) = \|f - f_j\|_{L^2}^2 + E(\|h_\varepsilon\|_{L^2}^2). \tag{3.5}$$

Both terms are estimated by inverse and direct estimates with respect to Sobolev spaces, which are recalled in Appendix B. The variance term can be estimated as follows: we first use the ellipticity property (2.2), which gives

$$\|h_\varepsilon\|_{H^{-t/2}}^2 \lesssim \langle Kh_\varepsilon, h_\varepsilon\rangle = \varepsilon\langle \dot{W}, h_\varepsilon\rangle \le \varepsilon\|P_j\dot{W}\|_{L^2}\|h_\varepsilon\|_{L^2}. \tag{3.6}$$

Using the inverse inequality $\|g\|_{L^2} \lesssim 2^{tj/2}\|g\|_{H^{-t/2}}$ for all $g \in V_j$ and dividing by $\|h_\varepsilon\|_{L^2}$, we obtain

$$\|h_\varepsilon\|_{L^2} \lesssim \varepsilon 2^{tj}\|P_j\dot{W}\|_{L^2}, \tag{3.7}$$

and therefore

$$E(\|h_\varepsilon\|_{L^2}^2) \lesssim \varepsilon^2 2^{2tj}\dim(V_j) \lesssim \varepsilon^2 2^{(2t+d)j}. \tag{3.8}$$

For the bias term, we take an arbitrary $g_j \in V_j$ and write

$$\begin{aligned}\|f - f_j\|_{L^2} &\le \|f - g_j\|_{L^2} + \|f_j - g_j\|_{L^2}\\ &\lesssim \|f - g_j\|_{L^2} + 2^{tj/2}\|f_j - g_j\|_{H^{-t/2}}\\ &\lesssim \|f - g_j\|_{L^2} + 2^{tj/2}\|f - g_j\|_{H^{-t/2}},\end{aligned}$$

where we have again used the inverse inequality and the fact that the Galerkin projection satisfies $\|f - f_j\|_{H^{-t/2}} \lesssim \|f - g_j\|_{H^{-t/2}}$ for any $g_j \in V_j$. It follows that

$$\|f - f_j\|_{L^2} \lesssim \inf_{g_j\in V_j}[\|f - g_j\|_{L^2} + 2^{tj/2}\|f - g_j\|_{H^{-t/2}}]. \tag{3.9}$$

Assuming that f belongs to B we obtain the direct estimate

$$\inf_{g_j\in V_j}[\|f - g_j\|_{L^2} + 2^{tj/2}\|f - g_j\|_{H^{-t/2}}] \lesssim 2^{-sj}, \tag{3.10}$$

and therefore

$$\|f - f_j\|_{L^2}^2 \lesssim 2^{-2sj}. \tag{3.11}$$

Balancing the bias and variance terms gives the optimal choice of resolution

$$2^{-j(\varepsilon)} \sim \varepsilon^{2/(2s+2t+d)}, \tag{3.12}$$

and the rate of convergence

$$E(\|f - f_\varepsilon\|_{L^2}^2) \lesssim \varepsilon^{4s/(2s+2t+d)}, \tag{3.13}$$

which ends the proof of Proposition 3.1. □

3.2. Nonlinear estimation by linear Galerkin. Our first nonlinear estimator f_ε simply consists of applying a thresholding algorithm on the observed data before performing the linear Galerkin inversion which was described in the previous section: for some $j \geq 0$ to be chosen later, we define $f_\varepsilon = \sum_{|\lambda|<j} f_{\varepsilon,\lambda}\psi_\lambda \in V_j$ such that

$$\langle Kf_\varepsilon, \psi_\lambda\rangle = T_\varepsilon(\langle g_\varepsilon, \psi_\lambda\rangle) \tag{3.14}$$

for all $|\lambda| < j$. Here T_ε is the hard thresholding operator

$$T_\varepsilon(x) = x\chi(|x| \geq t(\varepsilon)) \tag{3.15}$$

(where $\chi(P)$ is 1 if P is true and 0 otherwise), and the threshold $t(\varepsilon)$ has the usual size

$$t(\varepsilon) := 8\varepsilon\sqrt{|\log\varepsilon|}. \tag{3.16}$$

Defining the data vector $G_\varepsilon := (\langle g_\varepsilon, \psi_\lambda\rangle)_{|\lambda|<j}$, and the Galerkin stiffness matrix $K_j := (\langle K\psi_\lambda, \psi_\mu\rangle)_{|\lambda|,|\mu|<j}$, the coordinate vector $F_\varepsilon := (f_{\varepsilon,\lambda})_{|\lambda|<j}$ of f_ε in the wavelet basis $(\psi_\lambda)_{|\lambda|<j}$ is the solution of the linear system

$$K_j F_\varepsilon = T_\varepsilon(G_\varepsilon), \tag{3.17}$$

where $T_\varepsilon(G_\varepsilon) := (T_\varepsilon(\langle g_\varepsilon, \psi_\lambda\rangle))_{|\lambda|<j}$. Note that such an estimator can be viewed as a variant of the vaguelette-wavelet estimator truncated at level j. Such an estimator would indeed be given (in the case where (ψ_λ) is an orthonormal basis) by

$$f_\varepsilon := \sum_{|\lambda|<j} T_\varepsilon(\langle g_\varepsilon, \psi_\lambda\rangle)K^{-1}\psi_\lambda. \tag{3.18}$$

The solution f_ε of (3.14) has a similar form with the vaguelettes $K^{-1}\psi_\lambda$ replaced by their Galerkin approximations $u_\lambda^j \in V_j$ such that

$$\langle Ku_\lambda^j, v\rangle = \langle \psi_\lambda, v\rangle \text{ for all } v \in V_j. \tag{3.19}$$

We therefore expect that this estimator behaves in the same optimal way as the VWD estimator provided that j is large enough. The following theorem shows that this is indeed true if $2^{-j} \leq \varepsilon^{1/t}$ where t is the degree of ill-posedness of the operator. It should be noted that the lower bound on j does not depend on the unknown smoothness of f, in contrast to the classical thresholding for signal denoising.

THEOREM 3.2. *Assume that f belongs to $B := \{f\ ;\ \|f\|_{B^s_{p,p}} \leq M\}$ with $s > 0$ and $1/p = 1/2 + s/(2t + d)$. Assume in addition that K is an isomorphism between L^2 and H^t and that it has the smoothing property of order t with respect to the space $B^s_{p,p}$. Then the estimator from equation* (3.14) *satisfies the minimax rate*

$$\sup_{f\in B} E(\|f - f_\varepsilon\|_{L^2}^2) \lesssim [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)}, \tag{3.20}$$

provided that j is such that $2^{-j} \leq \varepsilon^{1/t}$.

Proof. We write again $f_\varepsilon = f_j + h_\varepsilon$, where $f_j \in V_j$ is the solution of the linear problem with data g_ε

$$\text{find } f_j \in V_j \text{ such that } \langle Kf_j, v\rangle = \langle g, v\rangle \text{ for all } v \in V_j, \tag{3.21}$$

where $g = Kf$. Correspondingly, the term h_ε represents the solution of the linear problem with the thresholding error as data, in other words $h_\varepsilon \in V_j$ such that

$$\langle Kh_\varepsilon, \psi_\lambda\rangle = T_\varepsilon(\langle g_\varepsilon, \psi_\lambda\rangle) - \langle g, \psi_\lambda\rangle \tag{3.22}$$

for all $|\lambda| < j$. Similarly to the analysis described in the previous section, we need to estimate $\|f - f_j\|_{L^2}^2$ and $E(\|h_\varepsilon\|_{L^2}^2)$. For the deterministic term, we remark that the space $B_{p,p}^s$ is continuously imbedded in H^α whenever

$$\alpha \le s + d/2 - d/p = 2ts/(2t+d). \tag{3.23}$$

By the same arguments as in the previous section we obtain

$$\|f - f_j\|_{L^2}^2 \lesssim 2^{-4sj\frac{t}{d+2t}}. \tag{3.24}$$

This gives the optimal order $\varepsilon^{4s/(2s+2t+d)}$ if j is large enough so that

$$2^{-j} \le \varepsilon^{\frac{d+2t}{t(2s+2t+d)}}. \tag{3.25}$$

We have $\varepsilon^{1/t} \le \varepsilon^{\frac{d+2t}{t(2s+2t+d)}}$ for all $s \ge 0$. Therefore the choice $2^{-j} \le \varepsilon^{1/t}$ yields

$$\|f - f_j\|_{L^2}^2 \lesssim \varepsilon^{4s/(2s+2t+d)}. \tag{3.26}$$

We next turn to the stochastic term $E(\|h_\varepsilon\|_{L^2}^2)$. If H_ε is the coordinate vector of h_ε in the basis $(\psi_\lambda)_{|\lambda|<j}$, we want to estimate $E(\|H_\varepsilon\|_{\ell^2}^2)$. We write

$$H_\varepsilon = K_j^{-1}(T_\varepsilon(G_\varepsilon) - G_j) \tag{3.27}$$

and remark that $T_\varepsilon(G_\varepsilon) - G_j$ is exactly the error when estimating G_j by the thresholding procedure on the data G_ε. We shall take into account the action of K_j^{-1} by measuring this error in the wavelet version of the H^t norm

$$\|U\|_{h^t}^2 := \sum_{|\lambda|<j} 2^{2t|\lambda|}|u_\lambda|^2. \tag{3.28}$$

Indeed, we shall see that the stability property

$$\|K_j^{-1}U\|_{\ell^2} \lesssim \|U\|_{h^t} \tag{3.29}$$

holds under the assumption that K^{-1} maps H^t onto L^2. Our result will therefore follow from

$$E(\|T_\varepsilon(G_\varepsilon) - G_j\|_{h^t}^2) \lesssim [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)}. \tag{3.30}$$

Such a rate is a particular case of classical results on wavelet thresholding, using the fact that g belongs to a Besov ball $\tilde{B} = \{g \in B_{p,p}^{s+t}\ ;\ \|g\|_{B_{p,p}^{s+t}} \le \tilde{M}\}$. For this model, (3.30) follows, e.g., from Theorem 4 in [10]. We are thus left with proving the stability property (3.29). To do so, we remark that if

$$K_j^{-1}U = V = (v_\lambda)_{|\lambda|<j}, \tag{3.31}$$

then the function $v = \sum_{|\lambda|<j} v_\lambda \psi_\lambda$, is the Galerkin approximation of $K^{-1}u$, where u is the function defined by

$$U = (\langle u, \psi_\lambda \rangle)_{|\lambda|<j} \text{ and } \langle u, \psi_\lambda \rangle = 0 \text{ if } |\lambda| \geq j. \tag{3.32}$$

It follows that

$$\|K^{-1}u - v\|_{H^{-t/2}} \lesssim 2^{-jt/2}\|K^{-1}u\|_{L^2} \lesssim 2^{-jt/2}\|u\|_{H^t}. \tag{3.33}$$

For the projection $P_j K^{-1}u$, we also have the error estimate

$$\|K^{-1}u - P_j K^{-1}u\|_{H^{-t/2}} \lesssim 2^{-jt/2}\|K^{-1}u\|_{L^2} \lesssim 2^{-jt/2}\|u\|_{H^t}. \tag{3.34}$$

It follows that

$$\|v - P_j K^{-1}u\|_{H^{-t/2}} \lesssim 2^{-jt/2}\|u\|_{H^t}. \tag{3.35}$$

Using the inverse estimate, we obtain

$$\|v - P_j K^{-1}u\|_{L^2} \lesssim \|u\|_{H^t}, \tag{3.36}$$

so that

$$\|v\|_{L^2} \lesssim \|u\|_{H^t} + \|P_j K^{-1}u\|_{L^2} \lesssim \|u\|_{H^t} + \|K^{-1}u\|_{L^2} \lesssim \|u\|_{H^t}. \tag{3.37}$$

Using the wavelet characterization of L^2 and H^t, this yields (3.29). □

Remark. The assumption that K^{-1} maps H^t into L^2 which we are using in the above result is also implicit in the vaguelette-wavelet method when assuming that the vaguelettes

$$v_\lambda = \beta_\lambda K^{-1}\psi_\lambda = 2^{-t|\lambda|}K^{-1}\psi_\lambda \tag{3.38}$$

constitute a Riesz basis of L^2.

4. Nonlinear estimation by adaptive Galerkin. The main defect of the method described in the previous section remains its computational cost: the dimension of V_j is of order $N_j = 2^{dj} \sim \varepsilon^{-d/t}$ and might therefore be quite large. Moreover, in the case of an integral operator the stiffness matrix K_j might be densely populated. In this section we shall try to circumvent this problem by replacing the full Galerkin inversion by an adaptive algorithm which operates only in subspaces of V_j generated by appropriate wavelets and which exploits, in addition, the possibility of compressing the matrix K_j when discretized in the wavelet basis. Our estimator f_ε will therefore belong to an adaptive subspace of V_j

$$V_{\Lambda_\varepsilon} = \text{Span}\{\psi_\lambda \,;\, \lambda \in \Lambda_\varepsilon\}, \tag{4.1}$$

where Λ_ε is a data-driven subset of $\{|\lambda| < j\}$. A first intuitive guess for Λ_ε is the set obtained by the thresholding procedure applied on g_ε in the previous section, namely

$$\Lambda_\varepsilon := \{|\lambda| < j \,;\, |\langle g_\varepsilon, \psi_\lambda \rangle| \geq t(\varepsilon)\}. \tag{4.2}$$

It would thus be tempting to define $f_\varepsilon \in V_{\Lambda_\varepsilon}$ by applying the Galerkin inversion in this adaptive subspace:

$$\langle f_\varepsilon, \psi_\lambda \rangle = \langle g_\varepsilon, \psi_\lambda \rangle \text{ for all } \lambda \in \Lambda_\varepsilon. \tag{4.3}$$

However, it is by no means ensured that such an estimator f_ε will achieve the optimal convergence rate in the case of nonlocal operators K. Indeed, there are many instances of operator equations $Kf = g$ where the adapted wavelet set for the solution f differs significantly from the adapted set for the data g.

In order to build a better adapted set of wavelets, we shall introduce a level dependent thresholding operator S_ε to be applied in the solution domain (in contrast to T_ε which operates in the observation domain) according to

$$S_\varepsilon(u_\lambda) = u_\lambda \chi(|u_\lambda| \geq 2^{t|\lambda|} t(\varepsilon)). \tag{4.4}$$

The role of the weight $2^{t|\lambda|}$ is to take into account the amplification of the noise by the inversion process. The L^2-approximation error obtained by such level dependent thresholding procedures is well understood; see, in particular, Theorem 7.1 in [9], which implies that for $f = \sum_{\lambda \in \nabla} f_\lambda \psi_\lambda \in B^s_{p,p}$, with $s > 0$ and $1/p = 1/2 + s/(2t+d)$ and $S_\varepsilon(f) = \sum_{\lambda \in \nabla} S_\varepsilon(f_\lambda)\psi_\lambda$ we have

$$\begin{aligned} \|f - S_\varepsilon(f)\|^2_{L^2} &\sim \sum_{|f_\lambda| < 2^{t|\lambda|} t(\varepsilon)} |f_\lambda|^2 \\ &\lesssim \|f\|^2_{B^s_{p,p}} t(\varepsilon)^{2-p} = \|f\|^2_{B^s_{p,p}} t(\varepsilon)^{4s/(2s+2t+d)}. \end{aligned} \tag{4.5}$$

Our first result shows that S_ε is well adapted to build an adaptive solution of the inverse problem in the following sense: if we apply S_ε to the coordinates of the estimator f_ε defined in the previous section by (3.14), then the resulting estimator

$$S_\varepsilon(f_\varepsilon) := \sum_{|\lambda| < j} S_\varepsilon(f_{\varepsilon,\lambda})\psi_\lambda \tag{4.6}$$

still satisfies the optimal convergence rate.

THEOREM 4.1. *Let us assume that f belongs to $B := \{f \ ; \ \|f\|_{B^s_{p,p}} \leq M\}$ with $s > 0$ and $1/p = 1/2 + s/(2t+d)$. Then, we have the estimate*

$$\sup_{f \in B} E(\|f_\varepsilon - S_\varepsilon(f_\varepsilon)\|^2_{L^2}) \ \lesssim \ [\varepsilon \sqrt{|\log \varepsilon|}]^{4s/(2s+2t+d)}. \tag{4.7}$$

It follows that the adaptive estimator $S_\varepsilon(f_\varepsilon) = \sum_{|\lambda|<j} S_\varepsilon(f_{\varepsilon,\lambda})\psi_\lambda$ is also rate-optimal.

Proof. We want to estimate the expectation of

$$\|f_\varepsilon - S_\varepsilon(f_\varepsilon)\|^2_{L^2} \ \lesssim \sum_{|\lambda|<j, |f_{\varepsilon,\lambda}| < 2^{t|\lambda|} t(\varepsilon)} |f_{\varepsilon,\lambda}|^2. \tag{4.8}$$

Using the fact that if $|a| \leq \eta$ we have for all real b

$$|a| \leq |a - b\chi(|b| \geq 2\eta)|, \tag{4.9}$$

we derive

$$\begin{aligned} \|f_\varepsilon - S_\varepsilon(f_\varepsilon)\|^2_{L^2} &\lesssim \textstyle\sum_{\lambda \in \nabla} |f_{\varepsilon,\lambda} - f_\lambda \chi(|f_\lambda| \geq 2^{t|\lambda|+1} t(\varepsilon))|^2 \\ &\lesssim \|f - f_\varepsilon\|^2_{L^2} + \textstyle\sum_{|f_\lambda| < 2^{t|\lambda|+1} t(\varepsilon)} |f_\lambda|^2 \\ &\lesssim \|f - f_\varepsilon\|^2_{L^2} + [\varepsilon \sqrt{|\log \varepsilon|}]^{4s/(2s+2t+d)}. \end{aligned}$$

Taking the expectation, we obtain (4.7) and

$$E(\|f - S_\varepsilon(f_\varepsilon)\|_{L^2}^2) \lesssim [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)} \tag{4.10}$$

follows by the triangle inequality. □

Of course, computing $S_\varepsilon(f_\varepsilon)$ is more costly than computing f_ε, and we cannot be satisfied with this new estimator. However, it shows us that the level-dependent thresholding operator S_ε maintains optimality. Based on this observation we now build an adaptive procedure which aims at reducing the computational cost. Let us note that many numerical methods are available in order to solve the system

$$K_j F_\varepsilon = T_\varepsilon(G_\varepsilon) \tag{4.11}$$

with the optimal cost $\mathcal{O}(N_j)$, where $N_j = \dim(V_j) \sim 2^{dj}$. In particular, one can rely on multigrid methods [3] in the case of local elliptic operators and fast multipole or wavelet [2] methods in the case of integral operators. However, our goal here is to reduce further the computational cost to the order of the dimension of the compressed solution, i.e., the number of nonzero coefficients in $S_\varepsilon(f_\varepsilon)$. Therefore, we shall rather be inspired by the approach introduced in [8] for adaptively solving operator equations *without noise*: consider a simple method for solving

$$K_j F_\varepsilon = T_\varepsilon(G_\varepsilon), \tag{4.12}$$

namely the fixed step gradient iteration $F_\varepsilon^0 = 0$ and

$$F_\varepsilon^n = F_\varepsilon^{n-1} + \tau(T_\varepsilon(G_\varepsilon) - K_j F_\varepsilon^{n-1}) \tag{4.13}$$

with a sufficiently small enough relaxation parameter $\tau > 0$. The convergence rate of F_ε^n to F_ε might deteriorate for large j due to the bad condition number of K_j. Wavelet discretization is well adapted to circumvent this problem, when using the preconditioned iteration

$$F_\varepsilon^n = F_\varepsilon^{n-1} + \tau D_j^{-1}(T_\varepsilon(G_\varepsilon) - K_j F_\varepsilon^{n-1}), \tag{4.14}$$

where $D_j = \mathrm{Diag}(2^{-t|\lambda|})$. From the ellipticity of K and the wavelet characterization of $H^{-t/2}$, it follows that the condition number $\kappa(D_j^{-1}K_j)$ remains bounded independently of j, so that a proper choice of τ will ensure a fixed error reduction rate

$$\|F_\varepsilon - F_\varepsilon^n\|_{\ell^2} \le \rho\|F_\varepsilon - F_\varepsilon^{n-1}\|_{\ell^2}, \tag{4.15}$$

with $\rho \in]0,1[$ independent of j. The idea is now to perturb this iteration by the thresholding operator S_ε, i.e., define

$$F_\varepsilon^n = S_\varepsilon[F_\varepsilon^{n-1} + \tau D_j^{-1}(T_\varepsilon(G_\varepsilon) - K_j F_\varepsilon^{n-1})]. \tag{4.16}$$

At each step n, the vector $F_\varepsilon^n = (f_{\varepsilon,\lambda}^n)$ is supported on an adaptive index set Λ_ε^n. The corresponding estimator for f is given as

$$f_\varepsilon^n = \sum_{\lambda\in\Lambda_\varepsilon^n} f_{\varepsilon,\lambda}^n \psi_\lambda. \tag{4.17}$$

When comparing (4.16) with (4.14), we observe a first obvious gain in computational time: the cost of the matrix-vector multiplication $K_j F_\varepsilon^{n-1}$ in (4.16) is of

order $(\dim(V_j))^2 \sim 2^{2dj}$, while the cost of the matrix-vector multiplication $K_j F_\varepsilon^{n-1}$ in (4.16) is of order $\dim(V_j) \times \#(\Lambda_\varepsilon^n) \sim 2^{dj}\#(\Lambda_\varepsilon^n)$. Additional computational time can be gained using the fact that for many relevant instances of operators K, the matrix K_j can be compressed by discarding most of its entries. Such instances include in particular pseudodifferential operators and singular integral operators with Calderon–Zygmund-type kernel; see, e.g., Chapter 4 in [7] and [8]. For such operators, the entries $K_j(\lambda,\mu)$ can be estimated a priori, allowing us to predict in advance those coefficients in $F_\varepsilon^{n-1} + \tau D_j^{-1}(T_\varepsilon(G_\varepsilon) - K_j F_\varepsilon^{n-1})$ which will be thresholded by S_ε and to avoid their exact computation. With such an approach, the cost of each iteration (4.16) can therefore be pushed down to the order $\#(\Lambda_\varepsilon^n)^2$, and even to $\#(\Lambda_\varepsilon^n)$ using a fast matrix vector multiplication; see Chapter 4 in [7] and [8].

We shall now prove that after a sufficient number of iterations independent of the unknown smoothness, the estimator f_ε^n attains the optimal rate of convergence.

THEOREM 4.2. *Let us assume that f belongs to $B := \{f\ ;\ \|f\|_{B^s_{p,p}} \le M\}$ with $s > 0$ and $1/p = 1/2 + s/(2t+d)$. For $n \ge \log(\varepsilon)/\log(\rho)$, we have*

$$\sup_{f\in B} E(\|f_\varepsilon - f_\varepsilon^n\|_{L^2}^2) \ \lesssim\ [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)}. \tag{4.18}$$

It follows that the adaptive estimator f_ε^n is also rate-optimal.

Proof. The result will follow from the reduction estimate

$$E(\|F_\varepsilon - F_\varepsilon^n\|_{\ell^2}^2) \le \tilde\rho^2 E(\|F_\varepsilon - F_\varepsilon^{n-1}\|_{\ell^2}^2) + C[\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)} \tag{4.19}$$

for any $\tilde\rho > \rho$, where C depends of the closeness of $\tilde\rho$ to ρ. Indeed, assuming this estimate to hold, from

$$E(\|F_\varepsilon - F_\varepsilon^0\|_{\ell^2}^2) = E(\|F_\varepsilon\|_{\ell^2}^2) \ \lesssim\ \|F\|_{\ell^2}^2 \le C \tag{4.20}$$

we obtain after n steps

$$E(\|F_\varepsilon - F_\varepsilon^n\|_{\ell^2}^2) \ \lesssim\ \max\{\tilde\rho^{2n}, [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)}\}. \tag{4.21}$$

Since $4s/(2s+2t+d) < 2$, we have

$$\tilde\rho^{2\log(\varepsilon)/\log(\rho)} = \varepsilon^{2\log(\tilde\rho)/\log(\rho)} \ \lesssim\ [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)} \tag{4.22}$$

if $\tilde\rho$ is chosen close enough to ρ, and (4.18) follows. In order to prove (4.19), we introduce the intermediate vector

$$F_\varepsilon^{n-1/2} = F_\varepsilon^{n-1} + \tau D_j^{-1}(T_\varepsilon(G_\varepsilon) - K_j F_\varepsilon^{n-1}), \tag{4.23}$$

for which we have

$$\|F_\varepsilon - F_\varepsilon^{n-1/2}\|_{\ell^2} \le \rho\|F_\varepsilon - F_\varepsilon^n\|_{\ell^2}. \tag{4.24}$$

We can then write

$$\|F_\varepsilon - F_\varepsilon^n\|_{\ell^2}^2 = \sum_{|\lambda|<j} |f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}\chi(|f_{\varepsilon,\lambda}^{n-1/2}| \ge 2^{t|\lambda|}t(\varepsilon))|^2. \tag{4.25}$$

Denoting by $K > 1$ a constant to be fixed later, we split the above sum into three parts Σ_1, Σ_2, and Σ_3, respectively corresponding to the index sets

$$\begin{aligned}
I_1 &:= \{|\lambda| < j\ ;\ |f_{\varepsilon,\lambda}^{n-1/2}| < 2^{t|\lambda|}t(\varepsilon) \text{ and } |f_{\varepsilon,\lambda}| < K2^{t|\lambda|}t(\varepsilon)\},\\
I_2 &:= \{|\lambda| < j\ ;\ |f_{\varepsilon,\lambda}^{n-1/2}| \ge 2^{t|\lambda|}t(\varepsilon)\},\\
I_3 &:= \{|\lambda| < j\ ;\ |f_{\varepsilon,\lambda}^{n-1/2}| < 2^{t|\lambda|}t(\varepsilon) \text{ and } |f_{\varepsilon,\lambda}| \ge K2^{t|\lambda|}t(\varepsilon)\}.
\end{aligned}$$

If $\lambda \in I_1$, we have $|f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}\chi(|f_{\varepsilon,\lambda}^{n-1/2}| \geq 2^{t|\lambda|}t(\varepsilon))| = |f_{\varepsilon,\lambda}|$. Using again the fact that if $|a| \leq \eta$ we have $|a| \leq |a - b\chi(|b| \geq 2\eta)|$ for all b, we can write

$$\begin{aligned} |f_{\varepsilon,\lambda}| &\leq |f_{\varepsilon,\lambda} - f_\lambda \chi(|f_\lambda| \geq 2K2^{t|\lambda|}t(\varepsilon))| \\ &\leq |f_{\varepsilon,\lambda} - f_\lambda| + |f_\lambda - f_\lambda\chi(|f_\lambda| \geq 2K2^{t|\lambda|}t(\varepsilon))|. \end{aligned}$$

It follows that

$$\begin{aligned} \Sigma_1 &= 2\|f_\varepsilon - f\|_{L^2}^2 + 2\textstyle\sum_{|f_\lambda| \leq 2K2^{t|\lambda|}t(\varepsilon)} |f_\lambda|^2 \\ &\lesssim \|f_\varepsilon - f\|_{L^2}^2 + [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)}, \end{aligned}$$

so that

$$E(\Sigma_1) \lesssim [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)}. \tag{4.26}$$

If $\lambda \in I_2$, we have

$$|f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}\chi(|f_{\varepsilon,\lambda}^{n-1/2}| \geq 2^{t|\lambda|}t(\varepsilon))| = |f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}|, \tag{4.27}$$

so that

$$\Sigma_2 = \|F_\varepsilon - F_\varepsilon^{n-1/2}\|_{\ell^2(\Lambda_1).}^2 \tag{4.28}$$

If $\lambda \in I_3$, we have $|f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}\chi(|f_{\varepsilon,\lambda}^{n-1/2}| \geq 2^{t|\lambda|}t(\varepsilon))| = |f_{\varepsilon,\lambda}|$ and

$$|f_{\varepsilon,\lambda}| \leq |f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}| + |f_{\varepsilon,\lambda}^{n-1/2}| \leq |f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}| + 2^{t|\lambda|}t(\varepsilon). \tag{4.29}$$

On the other hand, since $|f_{\varepsilon,\lambda}| > K2^{t|\lambda|}t(\varepsilon)$ and $|f_{\varepsilon,\lambda}^{n-1/2}| < 2^{t|\lambda|}t(\varepsilon)$, we also have

$$|f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}| \geq (K-1)2^{t|\lambda|}t(\varepsilon). \tag{4.30}$$

It follows that

$$|f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}\chi(|f_{\varepsilon,\lambda}^{n-1/2}| \geq 2^{t|\lambda|}t(\varepsilon))| < \tfrac{K}{K-1}|f_{\varepsilon,\lambda} - f_{\varepsilon,\lambda}^{n-1/2}|, \tag{4.31}$$

so that

$$\Sigma_3 \leq (\tfrac{K}{K-1})^2\|F_\varepsilon - F_\varepsilon^{n-1/2}\|_{\ell^2(\Lambda_3)}^2. \tag{4.32}$$

Combining (4.28) and (4.32), we obtain

$$\Sigma_2 + \Sigma_3 \leq (\tfrac{K}{K-1})^2\|F_\varepsilon - F_\varepsilon^{n-1/2}\|_{\ell^2}^2 \leq (\tfrac{K}{K-1})^2\rho^2\|F_\varepsilon - F_\varepsilon^{n-1}\|_{\ell^2}^2. \tag{4.33}$$

Combined with (4.26), this yields the claimed estimate (4.19) with $\tilde{\rho} = \frac{K}{K-1}\rho$, which can be made arbitrarily close to ρ by taking K large enough, up to enlarging the constant C which comes from the estimation of Σ_1. □

Remark. As was already explained, the cost of each iteration can be, at most, pushed down to $\mathcal{O}(\#(\Lambda_\varepsilon^n))$, which allows the estimate of the computational cost of the algorithm by

$$\mathcal{C}(\varepsilon) \leq \sum_{n \leq \log(\varepsilon)/\log(\rho)} \#(\Lambda_\varepsilon^n). \tag{4.34}$$

In addition, a rough estimate of $\#(\Lambda_\varepsilon^n)$ can be obtained from the smoothness of f, assuming that the number of coefficients retained at each thresholding step is of the same order as the number of coefficients which would be retained when applying S_ε to the exact f. In order to estimate this number, we note that if f belongs to $B := \{f\ ;\ \|f\|_{B^s_{p,p}} \le M\}$ with $s > 0$ and $1/p = 1/2 + s/(2t+d)$, it also belongs to $\tilde{B} := \{f\ ;\ \|f\|_{B^s_{q,q}} \le M\}$ with $1/q = 1/2 + (s+t)/d$ (since $q \le p$), or equivalently

$$\sum \|f_\lambda \psi_\lambda\|_{H^{-t}}^q \sim \sum |f_\lambda 2^{-t|\lambda|}|^q \le M^q. \tag{4.35}$$

It follows that

$$\#(\Lambda_\varepsilon^n) \ \lesssim\ t(\varepsilon)^{-q} \sim [\varepsilon\sqrt{|\log\varepsilon|}]^{-\frac{2d}{d+2s+2t}}, \tag{4.36}$$

and therefore

$$\mathcal{C}(\varepsilon) \ \lesssim\ [\varepsilon\sqrt{|\log\varepsilon|}]^{-\frac{2d}{d+2s+2t}} \log(\varepsilon)/\log(\rho). \tag{4.37}$$

In contrast, the cost of a nonadaptive inversion of (4.11) when using an optimal solver is of order

$$\mathcal{C}(\varepsilon) \sim \dim(V_j) \sim 2^{dj} \ \lesssim\ \varepsilon^{-d/t}. \tag{4.38}$$

Since $\frac{2d}{d+2s+2t} < \frac{d}{t}$, we see that (4.37) always improves (4.38). Let us insist on the fact that this improvement relies on the compressibility of the stiffness matrix in the sense that the adaptive matrix-vector multiplication involved in the iteration only costs $\mathcal{O}(\#(\Lambda_\varepsilon^n))$ operations. For arbitrary noncompressible matrices, this cost should be multiplied by 2^{jd}. Note also that the cost for nonadaptive inversion may then also be substantially higher than $\dim(V_j)$.

Note also that, in addition to the fact that the algorithm adapts to unknown smoothness, its practical computational cost also decreases as the amount of smoothness increases.

5. A numerical example. We focus on a simple example of a logarithmic potential kernel in dimension one and a single test function. The relatively simple analytical form of this operator gives the ability to approximate reasonably well its singular values. Therefore, the SVD method is feasible and can be compared with the Galerkin approach with reasonable accuracy. Our goals are the following:

1. To illustrate on a specific test case that (1) the oracle-SVD and the oracle linear Galerkin methods are comparable; (2) the nonlinear Galerkin method of section 4, obtained by thresholding the data in the image domain, achieves comparable numerical results as the oracle-SVD and the oracle linear Galerkin estimators.
2. To verify on an example that the empirical L^2 error stabilizes beyond a certain resolution level j, which is related to the noise level ε and the degree of ill-posedness of the operator. In theory, we know that the condition $2^{-j} \ \lesssim\ \varepsilon^{1/t}$ is sufficient to obtain optimality and that there is no gain in increasing j further.
3. To verify on an example that if we threshold further by S_ε the estimator obtained by the nonlinear Galerkin inversion of section 4, we still have a good estimator, as predicted by our Theorem 4.1. This suggests that the iterative adaptive Galerkin method described in Theorem 4.2 shall be effective when dealing with more precise numerical studies.

A logarithmic potential integral operator. We consider a single-layer logarithmic potential operator that relates the density of electric charge on an infinite cylinder of a given radius $r > 0$: $\{(z, re^{i2\pi x}), z \in \mathbb{R}, x \in [0,1]\}$ to the induced potential on the same cylinder, when both functions are independent of the variable z. The associated kernel $k(x,y)$ of the operator that we take is

$$Kf(x) = \int_0^1 k(x,y)f(y)dy, \quad k(x,y) = -\log\left(r|e^{i2\pi x} - e^{i2\pi y}|\right) \tag{5.1}$$

for some $r > 0$. We choose $r = \frac{1}{4}$ and we rewrite (5.1) as

$$k(x,y) = -\log\left[\tfrac{1}{2}|\sin\pi(y-x)|\right], \quad x, y \in [0,1], \tag{5.2}$$

so that $k(x,y) \geq 0$ on the unit square. It is singular on the diagonal $\{x = y\}$ but integrable. The single layer potential is known to be an elliptic operator of order -1, which maps $H^{-1/2}$ into $H^{1/2}$ (see [7]). So the assumptions on K are satisfied with $t = 1$.

For the maximal resolution level $J \leq 15$ we discretize K by computing the matrix K_J with entries

$$(K_J)_{m,n=0,\dots,2^J-1} = (\langle K_J\varphi_{J,m}, \varphi_{J,n}\rangle)_{m,n=0,\dots,2^J-1},$$

where the $\varphi_{J,m} = 2^{J/2}1_{[m2^{-J},(m+1)2^{-J})}$ are the Haar functions. Each

$$\langle K_J\varphi_{J,m}, \varphi_{J,n}\rangle = \int_0^1\int_0^1 k(x,y)\varphi_{J,m}(x)\varphi_{J,n}(y)dxdy$$

is computed by midpoint rule at scale 2^{-18}. It is noteworthy that k is a periodic convolution kernel. In turn the discretization K_{15} of K is a Toeplitz cyclic matrix, of the form $K_J(m,n) = K_J\big((m-n)[\mathrm{mod}\ 2^J]\big)$. As a consequence, the fast Fourier transform diagonalizes the matrix K_J, which makes the computation of its singular values an easy numerical task. We take K_{15} as a proxy for K and let the level of analysis of our method vary for $j = 1, \dots, 15$. We consider the test function f, defined for $x \in [0,1]$ by

$$f(x) = \max\{1 - |30(x - \tfrac{1}{2})|, 0\}.$$

The piky function f is badly approximated by the singular functions of K, but it has a sparse representation in a wavelet basis, so the Galerkin method shall be more effective for the estimation problem.

Methodology. We first pick the maximal resolution level $J := 12$, a noise level $\varepsilon := 2 \cdot 10^{-4}$, and a single typical sample of a white noise process $w_{12} = (w_{k,12})_{k=0,\dots,2^{12}-1}$. This means that the $w_{k,12}$ are outcomes of independent identically distributed standard Gaussian random variables that contaminate the action of K_{12} on f, up to the noise level $\varepsilon = 2 \cdot 10^{-4}$. Figure 1 shows the true signal f (dash-dotted) together with the data process.

Let us recall that given a family of estimators $\hat{f}_j$ depending on a tuning constant $j = 1, \dots, j_{max}$ (here, $\hat{f}_j$ is constructed with the SVD or the linear Galerkin method, and j varies from level 1 to level 12), the oracle estimator $\hat{f}^*$ is defined as $\hat{f}^* = \hat{f}_{j_*}$, where

$$j_* := \mathrm{argmin}_{j=1,\dots,j_{max}}\|\hat{f}_j - f\|_{L^2}.$$

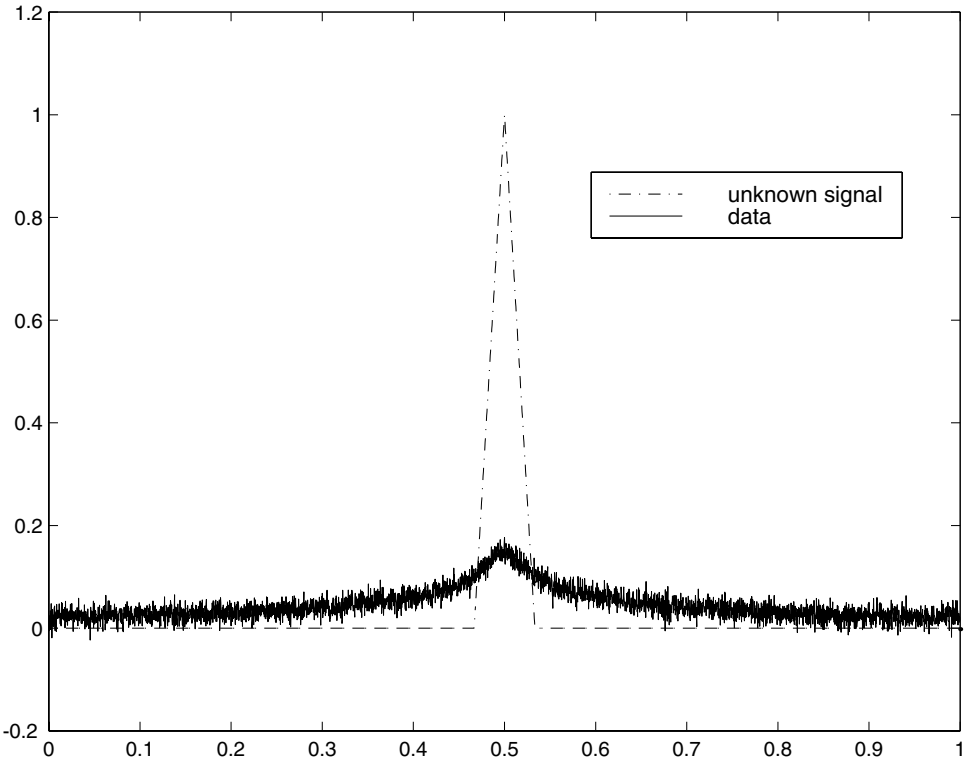

FIG. 1. *True function f and noisy signal.*

TABLE 1

	SVD oracle		Linear Galerkin		Nonlinear Galerkin
	j_*	L^2-error	j_*	L^2-error	L^2-error
f	5	$5.66 \cdot 10^{-4}$	5	$5.31 \cdot 10^{-4}$	$3.75 \cdot 10^{-4}$

Note that, strictly speaking, $\hat{f}^*$ is not an estimator (the ideal level j_* depends on the unknown) and appears as a benchmark for the method at hand. For technical reasons, we have replaced the L^2-risk by its empirical version.

Numerical results. The oracle estimator $\hat{f}^*$, for the SVD is displayed in Figure 2 and the oracle linear Galerkin estimator is displayed in Figure 3. In Figure 4, we show the performance of the nonlinear Galerkin estimator (Method 3), when applying a threshold $T_\varepsilon(\cdot)$ in the observation domain, specified with $t(\varepsilon) := 8 \cdot 10^{-4}$. We take a wavelet filter corresponding to compactly supported Daubechies wavelets of order 14. The numerical results of the three methods are summarized in Table 1.

Compression rate and approximation results. In the same context, we next investigate (see Figure 5) the performance of the nonlinear Galerkin estimator when applying further the level dependent thresholding operator $S_\varepsilon(\cdot)$, recall (4.4), with $t(\varepsilon) := 8 \cdot 10^{-4}$. We also indicate the number of wavelet coefficients put to zero divided by the total number of coefficients. The very high compression rate (see Table 2) that still ensures a small estimation error advocates in favor of the iterative adaptive scheme of section 4.

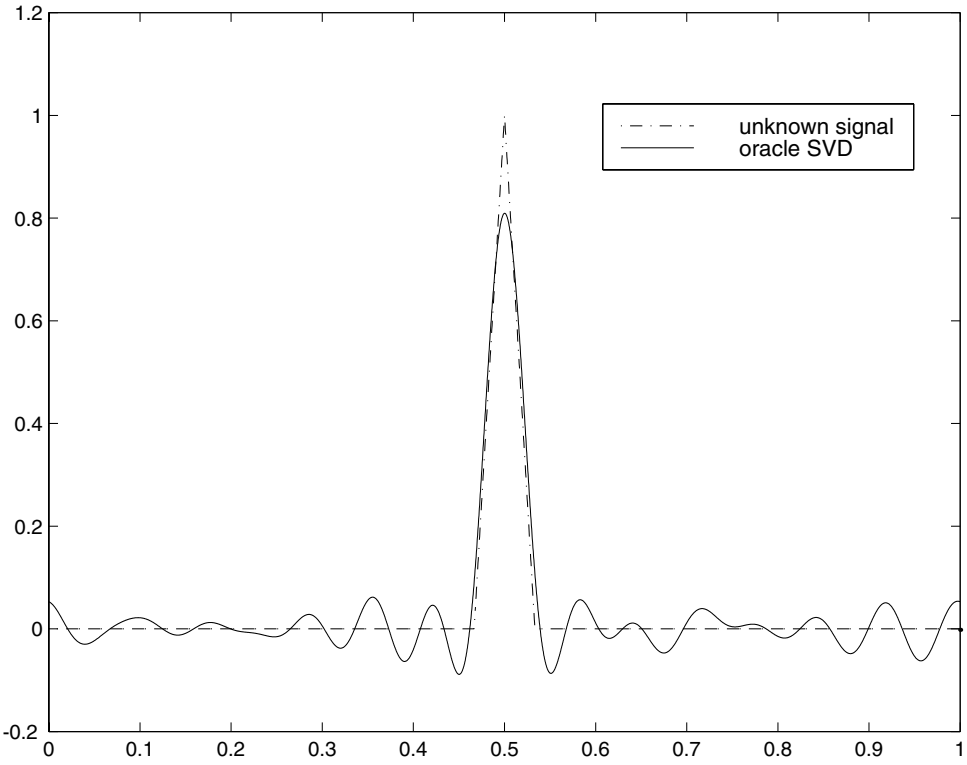

FIG. 2. *Oracle SVD.*

TABLE 2

	L^2-error, T_ε only	L^2-error, T_ε and S_ε	comp. rate
f	$3.75 \cdot 10^{-4}$	$4.12 \cdot 10^{-4}$	0.996

On a visual level, we observe that the nonlinear methods avoid the persistence of high oscillations far away from the singularity, in contrast to the linear methods. However, we still observe an artifact on the right side of the central peak. We hope to remedy this defect by (i) using biorthogonal spline wavelets instead of Daubechies orthogonal wavelets and (ii) apply a translation-invariant processing as introduced in [11] for denoising.

Appendix A. Extension to nonelliptic operators. In this appendix, we shall briefly explain how the methods and results that we have presented throughout can be extended by the mean-square approach to the case where K is not an elliptic operator. Here, the smoothing property of order t is expressed by the ellipticity property of the normal operator

$$\|Kf\|_{L^2}^2 = \langle K^*Kf, f\rangle \sim \|f\|_{H^{-t}}^2. \tag{A.1}$$

We discuss the adaptation of sections 3 and 4 to this more general context.

Linear Galerkin estimation. The method becomes the Galerkin projection

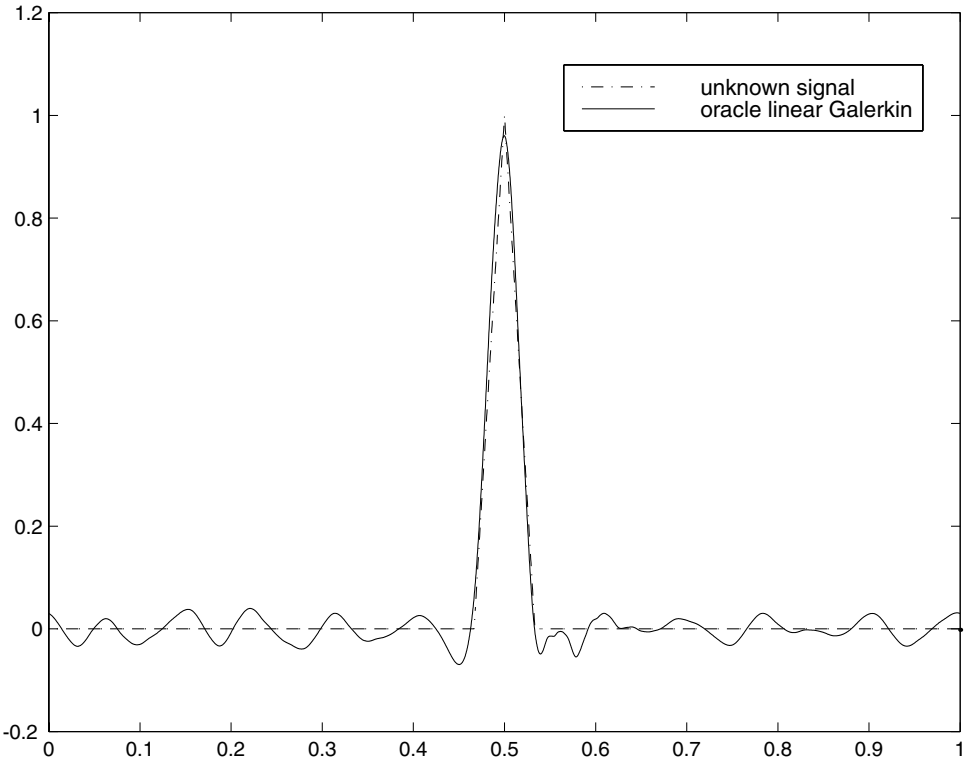

FIG. 3. *Oracle linear Galerkin method.*

method applied to the normal equation $K^*Kf = K^*g$. It therefore reads as follows:

$$\text{find } f_\varepsilon \in V_j \text{ such that } \langle Kf_\varepsilon, Kv\rangle = \langle g_\varepsilon, Kv\rangle \text{ for all } v \in V_j. \tag{A.2}$$

As in the elliptic case, we can use the decomposition $f_\varepsilon = f_j + h_\varepsilon$ in order to estimate the mean-square error according to

$$E(\|f - f_\varepsilon\|_{L^2}^2) \lesssim \|f - f_j\|_{L^2}^2 + E(\|h_\varepsilon\|_{L^2}^2). \tag{A.3}$$

For the variance term, we write

$$\begin{aligned}\|h_\varepsilon\|_{H^{-t}}^2 &\sim \langle K^*Kh_\varepsilon, h_\varepsilon\rangle = \varepsilon\langle \dot{W}, Kh_\varepsilon\rangle \\ &\le \varepsilon\|P_j^K\dot{W}\|_{L^2}\|Kh_\varepsilon\|_{L^2} \lesssim \varepsilon\|P_j^K\dot{W}\|_{L^2}\|h_\varepsilon\|_{H-t},\end{aligned}$$

where P_j^K is the orthogonal projector onto KV_j. Using the inverse inequality which states that $\|h_\varepsilon\|_{L^2} \lesssim 2^{tj}\|h_\varepsilon\|_{H^{-t}}$, we therefore obtain

$$\|h_\varepsilon\|_{L^2} \lesssim \varepsilon 2^{tj}\|P_j^K\dot{W}\|_{L^2}, \tag{A.4}$$

and therefore

$$E(\|h_\varepsilon\|_{L^2}^2) \lesssim \varepsilon^2 2^{2tj}\dim(KV_j) \lesssim \varepsilon^2 2^{(2t+d)j}. \tag{A.5}$$

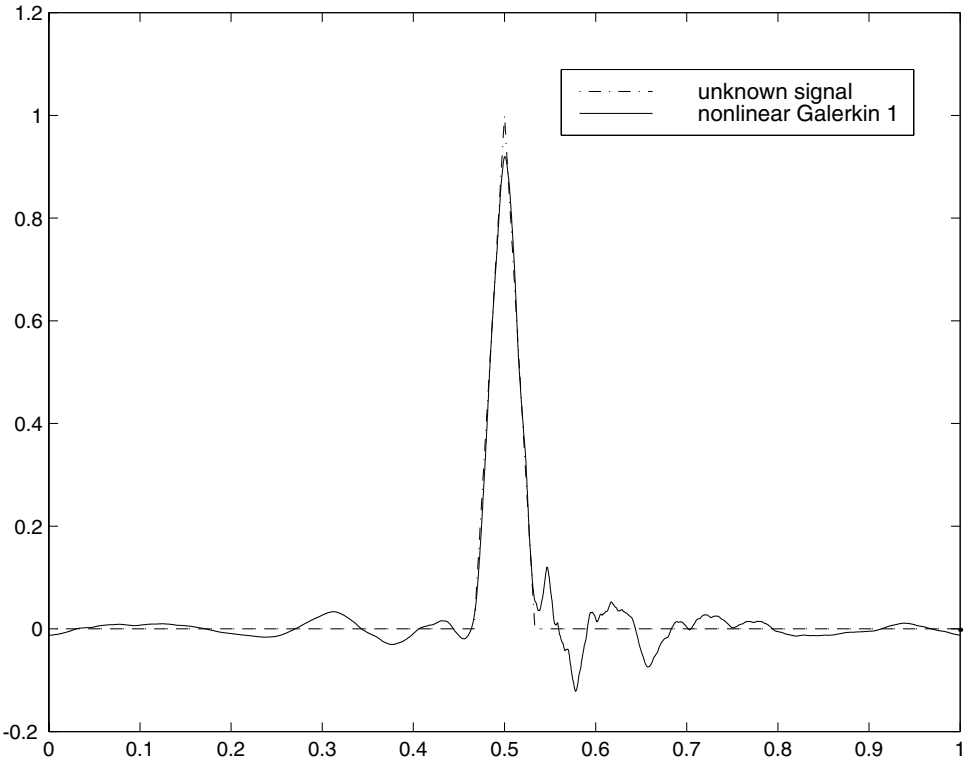

FIG. 4. *Nonlinear Galerkin estimator, thresholding in the image domain.*

For the bias term, we take any $g_j \in V_j$ and write

$$\begin{aligned} \|f - f_j\|_{L^2} &\lesssim \|f - g_j\|_{L^2} + 2^{tj}\|f_j - g_j\|_{H^{-t}} \\ &\lesssim \|f - g_j\|_{L^2} + 2^{tj}\|f - g_j\|_{H^{-t}}, \end{aligned}$$

where we have used the inverse inequality and Galerkin orthogonality. Assuming that f belongs to a Sobolev ball $B := \{f \in H^s \ ; \ \|f\|_{H^s} \leq M\}$, we obtain from approximation theory the direct estimate

$$\|f - f_j\|_{L^2}^2 \lesssim \inf_{g_j \in V_j} [\|f - g_j\|_{L^2} + 2^{tj}\|f - g_j\|_{H^{-t}}] \lesssim 2^{-sj}. \tag{A.6}$$

Proceeding as in section 3, we therefore achieve the same estimate for $E(\|f - f_\varepsilon\|_{L^2}^2)$ under the same assumptions as in the elliptic case.

Nonlinear estimation by linear Galerkin. The method becomes the Galerkin projection applied to the normal equation after thresholding the observed data. It therefore reads as follows: find $f_\varepsilon = \sum_{|\lambda|<j} f_{\varepsilon,\lambda}\psi_\lambda \in V_j$ such that

$$\langle Kf_\varepsilon, K\psi_\lambda\rangle = \tilde{T}_\varepsilon(\langle g_\varepsilon, K\psi_\lambda\rangle) \tag{A.7}$$

for all $|\lambda| < j$. Here the thresholding operator $\tilde{T}_\varepsilon$ differs from T_ε since it is applied to the wavelet coefficients of $K^* g_\varepsilon$. More precisely, we define

$$\tilde{T}_\varepsilon(d_\lambda) = d_\lambda \chi(|d_\lambda| \geq 2^{-t|\lambda|} t(\varepsilon)) = 2^{-t|\lambda|} T_\varepsilon(2^{t|\lambda|} d_\lambda), \tag{A.8}$$

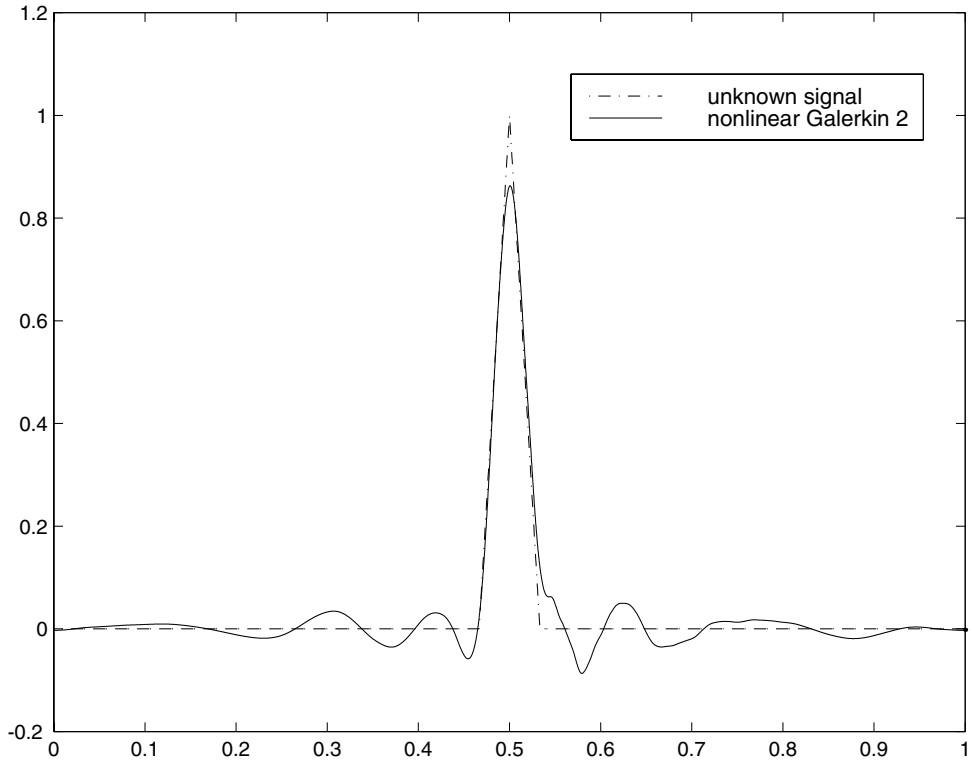

FIG. 5. *Nonlinear Galerkin estimator, thresholding in the image and solution domain.*

again with $t(\varepsilon) = C\varepsilon\sqrt{|\log\varepsilon|}$. With this method, Theorem 3.2 can be extended to the nonelliptic case, provided that we now use the assumption that K^*K is an isomorphism from L^2 to H^{2t} and has the smoothing property of order $2t$ with respect to the space $B^s_{p,p}$. For the proof of this result, we again write $f_\varepsilon = f_j + h_\varepsilon$, where the term h_ε now represents the solution of the linear problem with the thresholding error as data. By the same analysis as in the proof of Theorem 3.2, we obtain

$$\|f - f_j\|^2_{L^2} \lesssim \varepsilon^{4s/(2s+2t+d)} \tag{A.9}$$

if j is large enough so that $2^{-j} \le \varepsilon^{1/t}$. For the stochastic term, if H_ε is the coordinate vector of h_ε in the basis $(\psi_\lambda)_{|\lambda|<j}$, we write

$$H_\varepsilon = L_j^{-1} D_j (T_\varepsilon(\tilde{G}_\varepsilon) - \tilde{G}_j), \tag{A.10}$$

where $L_j := (\langle K\psi_\lambda, K\psi_\mu\rangle)_{|\lambda|,|\mu|<j}$ is now the Galerkin matrix for the least-squares formulation, $\tilde{G}_j := (2^{t|\lambda|}\langle K^*g, \psi_\lambda\rangle)_{|\lambda|<j}$, $\tilde{G}_\varepsilon := (2^{t|\lambda|}\langle K^*g_\varepsilon, \psi_\lambda\rangle)_{|\lambda|<j}$, and again $D_j := \mathrm{Diag}(2^{-t|\lambda|})$. In this case, we invoke the stability property

$$\|L_j^{-1}U\|_{\ell^2} \lesssim \|U\|_{h^{2t}}, \tag{A.11}$$

which is proved by similar argument as in the proof of Theorem 3.2. Since D_j is an i somorphism from h^t to h^{2t}, we are therefore left to prove that

$$E(\|T_\varepsilon(\tilde{G}_\varepsilon) - \tilde{G}_j\|^2_{h^t}) \lesssim [\varepsilon\sqrt{|\log\varepsilon|}]^{4s/(2s+2t+d)}. \tag{A.12}$$

The components of $\tilde{G}_\varepsilon$ are related to those of $\tilde{G}_j$ by

$$\tilde{g}_{\varepsilon,\lambda} := 2^{t|\lambda|}\langle K^*Kf, \psi_\lambda\rangle + \varepsilon\langle \dot{W}, 2^{t|\lambda|}K\psi_\lambda\rangle = \tilde{g}_{j,\lambda} + \varepsilon\eta_\lambda, \tag{A.13}$$

where the η_λ are normalized Gaussian variables since

$$\|2^{t|\lambda|}K\psi_\lambda\|_{L^2} \sim 2^{t|\lambda|}\|\psi_\lambda\|_{H^{-t}} \sim 1. \tag{A.14}$$

Therefore, the estimate (A.12) again follows from classical results on wavelet thresholding such as Theorem 4 in [10] using the fact that K^*Kf belongs to a Besov ball $\tilde{B} = \{h \in B^{s+2t}_{p,p}\ ;\ \|h\|_{B^{s+2t}_{p,p}} \le \tilde{M}\}$.

Nonlinear estimation by adaptive Galerkin. The iterative method becomes

$$F^n_\varepsilon = S_\varepsilon[F^{n-1}_\varepsilon + \tau D_j^{-1}(\tilde{T}_\varepsilon(G_\varepsilon) - L_jF^{n-1}_\varepsilon)], \tag{A.15}$$

and the statements of Theorems 4.1 and 4.2 remain valid with the same proof.

Appendix B. Direct and inverse inequalities for multiresolution spaces. Direct and inverse inequalities are a key ingredient in multiresolution approximation theory. In their simplest form, the direct inequality reads as follows:

$$\inf_{g_j\in V_j} \|f - g_j\|_{L^2} \lesssim 2^{-sj}|f|_{H^s}, \tag{B.1}$$

and the inverse estimate states that for all $g_j \in V_j$

$$|g_j|_{H^s} \lesssim 2^{sj}\|g_j\|_{L^2}. \tag{B.2}$$

The proof of such estimates is quite classical and we refer the reader to Chapter 3 in [7]. Basically, the validity of the direct inequality requires that the spaces V_j have enough approximation power, in the sense that polynomials of degree m are contained in V_j for all $m < s$. On the other hand, the validity of the inverse estimate requires that the functions of V_j have enough smoothness in the sense that they are contained in H^s. The direct and inverse estimate which have been used in section 3 are less standard since they involve the Sobolev space of negative order $H^{-t/2}$, and we shall therefore briefly discuss their validity. The inverse estimate states that for all $g_j \in V_j$,

$$\|g_j\|_{L^2} \lesssim 2^{tj/2}\|g_j\|_{H^{-t/2}}. \tag{B.3}$$

We prove it by a duality argument:

$$\begin{aligned}\|g_j\|_{L^2} &= \sup_{f_j\in V_j, \|f_j\|_{L^2}=1} |\langle g_j, f_j\rangle| \\ &\lesssim \sup_{f_j\in V_j, \|f_j\|_{L^2}=1} \|g_j\|_{H^{-t/2}}\|f_j\|_{H^{t/2}} \\ &\lesssim 2^{tj/2}\|g_j\|_{H^{-t/2}},\end{aligned}$$

where we have used the standard inverse estimate (B.2) with $s = t/2$. The direct estimate states that

$$\inf_{g_j\in V_j} [\|f - g_j\|_{L^2} + 2^{tj/2}\|f - g_j\|_{H^{-t/2}}] \lesssim 2^{-sj}\|f\|_{H^s}. \tag{B.4}$$

In order to prove it, we take $g_j = P_jf$ where P_j is the L^2-orthogonal projector onto V_j. Clearly the first part $\|f - P_jf\|_{L^2} \lesssim 2^{-sj}\|f\|_{H^s}$ is simply the standard direct

estimate (B.1). For the second part, we write

$$\begin{aligned}\|f - P_j f\|_{H^{-t/2}} &= \sup_{\|g\|_{H^{t/2}}=1} |\langle f - P_j f, g\rangle| \\ &= \sup_{\|g\|_{H^{t/2}}=1} |\langle f - P_j f, g - P_j g\rangle| \\ &= \|f - P_j f\|_{L^2} \sup_{\|g\|_{H^{t/2}}=1} \|g - P_j g\|_{L^2} \\ &\sim 2^{-sj}\|f\|_{H^s} 2^{-tj/2},\end{aligned}$$

where we have used the fact that $(I - P_j)^2 = (I - P_j)^*(I - P_j) = I - P_j$ and the standard direct estimate (B.1) both for H^s and $H^{t/2}$.

Remark. The type of duality argument that we have used in order to prove both (B.3) and (B.4) can be generalized in such a way that the standard direct and inverse estimate between L^2 and $H^{t/2}$ are invoked for a dual space $\tilde{V}_j$ which might differ from V_j. For the direct estimate, this means that we take for P_j a more general biorthogonal projector, such that P_j^* is a projector onto $\tilde{V}_j$ (see [7] for examples of dual spaces and biorthogonal projectors), so that we are led to apply a standard direct inequality of the type

$$\|g - P_j^* g\|_{L^2} \lesssim 2^{-tj/2}\|g\|_{H^{t/2}} \tag{B.5}$$

which only requires polynomial exactness up to order $t/2$ for $\tilde{V}_j$. For the inverse estimate, we can also use the space $\tilde{V}_j$ in order to evaluate the L^2 norm according to

$$\|g_j\|_{L^2} \lesssim \sup_{\tilde{f}_j \in \tilde{V}_j, \|\tilde{f}_j\|_{L^2}=1} |\langle g_j, \tilde{f}_j\rangle| \lesssim \sup_{\tilde{f}_j \in \tilde{V}_j, \|\tilde{f}_j\|_{L^2}=1} \|g_j\|_{H^{-t/2}} \|\tilde{f}_j\|_{H^{t/2}}, \tag{B.6}$$

so that we are led to apply a standard inverse inequality of the type

$$\|\tilde{f}_j\|_{H^{t/2}} \lesssim 2^{tj/2}\|\tilde{f}_j\|_{L^2}, \tag{B.7}$$

which only requires that the space $\tilde{V}_j$ has $H^{t/2}$ smoothness. This last point is practically important, since it means that we are not enforced to use multiresolution spaces V_j consisting of smooth functions, neither are we forced to use smooth wavelets in the nonlinear methods. In contrast, it is crucial that the spaces V_j have enough polynomial reproduction ($\Pi_m \subset V_j$ for all $m < s$) in order to apply the direct estimate for H^s, and it is crucial for the nonlinear method that the wavelets ψ_λ have enough vanishing moments ($\int x^m \psi_\lambda = 0$ for all $m < s + t$) in order to apply the results on wavelet thresholding such as (3.30).

ANALYSIS OF FINITE ELEMENT APPROXIMATION OF EVOLUTION PROBLEMS IN MIXED FORM*

DANIELE BOFFI† AND LUCIA GASTALDI‡

Abstract. This paper deals with the finite element approximation of evolution problems in mixed form. Following [D. Boffi, F. Brezzi, and L. Gastaldi, *Math. Comp.*, 69 (2000), pp. 121–140], we handle separately two types of problems. A model for the first case is the heat equation in mixed form, while the time dependent Stokes problem fits within the second one. For either case, we give sufficient conditions for a good approximation in the natural functional spaces. The results are not obvious in the first situation. In this case, the well-known conditions for the well posedness and convergence of the corresponding steady problem are not sufficient for the good approximation of the time dependent problem. This issue is demonstrated with a numerical (counter-) example and justified analytically.

Key words. mixed finite element, evolution problem, Stokes problem, Laplace problem in mixed form

AMS subject classifications. 65N30, 65M60

DOI. 10.1137/S0036142903431821

1. Introduction.

Mixed finite elements often are used in engineering applications, and their analysis has been considered in several papers, starting from the 1970s (see [10, 3, 13]), mainly for the approximation of steady source problems. For the reader's convenience, we recall here what we mean by a general standard mixed problem. We consider a pair of Hilbert spaces Φ and Ξ and denote by Φ' and Ξ' their dual spaces. Given two data $f \in \Phi'$ and $g \in \Xi'$, a general (steady) mixed problem reads as follows: Find $\psi \in \Phi$ and $\chi \in \Xi$ such that

$$\begin{aligned} a(\psi,\varphi) + b(\varphi,\chi) &= {}_{\Phi'}\!< f, \chi >_{\Phi} \quad && \forall \varphi \in \Phi, \\ b(\psi,\xi) &= {}_{\Xi'}\!< g, \xi >_{\Xi} && \forall \xi \in \Xi, \end{aligned} \tag{1}$$

where $a : \Phi \times \Phi \to \mathbb{R}$ and $b : \Phi \times \Xi \to \mathbb{R}$ are continuous bilinear forms.

When a finite element approximation to problem (1) is considered, it is well known that the necessary and sufficient condition for the well posedness, stability, and convergence of the scheme (for any given data) is that two inf-sup constants are bounded below away from zero independently of the meshsize parameter.

In the 1980s the use of mixed finite elements has been considered also for the approximation of eigenvalue problems (see [18, 4]), and only fairly recently it has been understood (see [8, 7]) that the inf-sup conditions are not the main assumptions in this context. It has been observed that, in most cases, we can distinguish between two families of mixed problems, depending on the role played by the two equations which define the mixed problem itself, and it has been proved that suitable conditions have to be considered in either case for the good convergence of the computed eigenvalues. Namely, we can consider $\binom{f}{0}$-type problems, when in (1) $g = 0$ and $\binom{0}{g}$-type problems when the opposite situation occurs, i.e., $f = 0$. For instance, the Stokes problem

belongs to the first family and the standard mixed formulation for the Laplace problem to the second one.

In this paper, we want to consider the finite element approximation of evolution problems in mixed form. The mathematical literature on this field is mainly related to the approximation of the heat equation by means of Raviart–Thomas (RT) elements (see, e.g., [16]); mixed finite element schemes have been used extensively for the approximation of evolution problems, in particular in fluid dynamic applications (see [14, 15]).

It is not an unexpected result that the theoretical analysis of such approximations strongly relies on the behavior of the corresponding eigenvalue approximations. For this reason, we consider separately the $\binom{0}{g}$- and $\binom{f}{0}$-type formulations. Actually, it is not completely true that, for instance, in the mixed form of the heat equation f has to vanish, being possibly related to some nonhomogeneous boundary conditions. However, in this paper, we shall consider only truly $\binom{0}{g}$ and $\binom{f}{0}$ problems; in the case of the heat equation, for instance, we can reduce the problem into this form via a suitable extension of the boundary trace.

The outline of the paper is as follows. In the next section we recall some known results about the standard Galerkin space semidiscretization of parabolic problems. In section 3 we introduce the problems we are dealing with and present some examples. We are going to use a different notation than the one introduced in (1). In particular, we want to adapt our notation to the mixed Laplace equation for the $\binom{0}{g}$-type system and to the Stokes problem when dealing with the $\binom{f}{0}$ problem. In section 4, we report on some numerical experiments. In particular, we construct test cases and approximating spaces in such a way that the inf-sup conditions hold true (hence the corresponding steady problems are well approximated) but for which we observe that the evolution problem is not well approximated. These results show the need for an accurate analysis of the evolution case, which is not a straightforward extension of the standard steady state analysis. In the next two sections, where the main results of this paper are stated and proved, we give sufficient conditions for the convergence of the approximation of evolution problems of $\binom{0}{g}$- and $\binom{f}{0}$-type, respectively. The last section contains additional remarks related to the counterexample presented in section 4. It follows, in particular, that, if the data are smooth enough, the solution can be accurately approximated even with the scheme used for our counterexample.

2. Galerkin semidiscretization of parabolic problems. In this section we collect some known results on the semidiscrete approximation to parabolic problems with the aim of introducing some basic estimates and of comparing them with those obtained in the case of mixed formulations. The interested reader is referred to, e.g., [23] for a more detailed analysis of the problem under consideration in this section.

We consider two Hilbert spaces V and H, $V \subseteq H$, V dense in H. We identify H with its dual space H'. Let $a : V \times V \to \mathbb{R}$ be a continuous bilinear form, satisfying the following coercivity condition: There exist $\alpha > 0$ and $\mu \geq 0$ such that $a(v,v) + \mu||v||_H^2 \geq \alpha||v||_V^2$ for all $v \in V$. The variational formulation of the parabolic problem (denoting by $(\cdot,\cdot)$ the scalar product in H) reads as follows: Given $T > 0$, $f :]0,T[\to V'$, and $u_0 \in H$, for almost every $t \in]0,T[$ find $u(t) \in V$ such that

$$\frac{d}{dt}(u(t),v) + a(u(t),v) = {}_{V'}\!< f(t), v >_V \quad \forall v \in V; \qquad u(0) = u_0. \tag{2}$$

The following existence and uniqueness theorem for problem (2) is well known (see, e.g., [17]).

THEOREM 1. *Assume that the bilinear form a is continuous and coercive on $V \times V$. Then, given $f \in L^2(]0,T[;V')$ and $u_0 \in H$, there exists a unique solution $u \in L^2(]0,T[;V) \cap C^0([0,T];H)$ to (2), with $\partial u/\partial t \in L^2(]0,T[;V')$. Moreover, the following energy estimate holds true:*

$$\max_{t\in[0,T]} ||u(t)||_H^2 + \alpha \int_0^T ||u||_V^2 \, dt \le ||u_0||_H^2 + C \int_0^T ||f||_{V'}^2 \, dt.$$

A suitable shift reduces our problem to the case $\mu = 0$; for this reason we consider this case in detail.

If the bilinear form a is symmetric and the embedding of V in H is compact, then, for every $f \in L^2(]0,T[;H)$, the solution to (2) can be represented with the following series:

$$u(t) = \sum_{i=1}^{\infty} \left((u_0, w_i) e^{-\lambda_i t} + \int_0^t (f(s), w_i) e^{-\lambda_i (t-s)} \, ds \right) w_i. \tag{3}$$

Here, $\lambda_i \in \mathbb{R}$ and $w_i \in V$, with $w_i \neq 0$, are eigenvalues and eigenvectors of the bilinear form a; that is, for each i they satisfy $a(w_i, v) = \lambda_i (w_i, v)$ for all $v \in V$.

Example 1 (the heat equation). The standard example is given by the following heat equation: Ω is a polygon in $\mathbb{R}^2$ or a Lipschitz polyhedron in $\mathbb{R}^3$, $H = L^2(\Omega)$, $V = H_0^1(\Omega)$, and $a(u,v) = \int_\Omega \operatorname{grad} u \cdot \operatorname{grad} v \, dx$. Clearly, in this case, the coercivity assumption is valid with $\mu = 0$ for the Poincaré inequality.

Approximating the space V by a finite dimensional subspace V_h provides a space semidiscretization of the variational formulation (2). Given $f \in L^2(]0,T[;H)$ and $u_{0,h} \in V_h$, for each $t \in [0,T]$ find $u_h(t) \in V_h$ such that

$$\frac{d}{dt}(u_h(t), v) + a(u_h(t), v) = {}_{V'}\!< f(t), v >_V \quad \forall v \in V_h; \qquad u_h(0) = u_{0,h}. \tag{4}$$

Subtracting (4) from (2), we obtain the error equation

$$\frac{d}{dt}(u(t) - u_h(t), v) + a(u(t) - u_h(t), v) = 0 \quad \forall v \in V_h.$$

Then we can derive the following estimate for all $v_h \in V_h$:

$$\begin{aligned} \max_{t\in[0,T]} ||u(t) - u_h(t)||_H^2 + \alpha \int_0^T ||u(t) - u_h(t)||_V^2 &\le ||u_0 - u_{0,h}||_H^2 \\ + \int_0^T \left(\left(\frac{\partial}{\partial t}(u(t) - u_h(t)), u(t) - v_h \right) + a(u(t) - u_h(t), u(t) - v_h) \right) dt. \end{aligned} \tag{5}$$

Let us try to get some error estimates from (5) in the case of the finite element approximation of the heat equation (see Example 1). If we take $v_h = u^I(t)$, the interpolant of $u(t)$ in V_h, then we get

$$\begin{aligned} \max_{t\in[0,T]} ||u(t) - u_h(t)||_H^2 + \alpha \int_0^T ||u(t) - u_h(t)||_V^2 &\le ||u_0 - u_{0,h}||_H^2 \\ + \int_0^T \left(\left(\left\| \frac{\partial u}{\partial t}(t) \right\|_H + \left\| \frac{\partial u_h}{\partial t}(t) \right\|_H \right) \|u(t) - u^I(t)\|_H + C\|u(t) - u^I(t)\|_V^2 \right) dt. \end{aligned}$$

If V_h is the space of continuous piecewise linear functions and $u_{0,h}$ is the interpolant of u_0, then we have the optimal convergence (with the obvious modifications in the case of nonconvex domains)

$$||u-u_h||_{L^\infty(L^2)}+\alpha||u-u_h||_{L^2(H^1)}\le Ch\left(||u_0||_{H^1}+||f||_{L^2(L^2)}\right). \tag{6}$$

Unfortunately, the generalization of (6) to higher order approximations is not optimal; when kth order elements are used, (5) gives only $O(h^{(k+1)/2})$. On the other hand, we can take in (5) $v_h = Pu(t)$, the L^2-projection of $u(t)$ into V_h. Now the first term in the integral on the right-hand side of (5) reads

$$\begin{aligned}\left(\frac{\partial}{\partial t}u(t)-\frac{\partial}{\partial t}u_h(t),u(t)-Pu(t)\right)&=\left(\frac{\partial}{\partial t}u(t)-P\frac{\partial}{\partial t}u(t),u(t)-Pu(t)\right)\\&=\frac{1}{2}\frac{d}{dt}||u(t)-Pu(t)||_H^2,\end{aligned}$$

since $\partial u_h(t)/\partial t \in V_h$, P is the L^2-projection onto V_h, and P commutes with the time derivative. Moreover, the estimate of the second term in the integral on the right-hand side of (5) involves the term $||u(t)-Pu(t)||_{H^1}$. If V_h is the space of continuous piecewise polynomials of degree k, and if we assume that the mesh is such that we can use an *inverse estimate*, then we can obtain

$$||u-u_h||_{L^\infty(L^2)}+\alpha||u-u_h||_{L^2(H^1)}\le Ch^k\left(||u_0||_{H^k}+||u||_{L^\infty(H^k)}+||u||_{L^2(H^{k+1})}\right). \tag{7}$$

If, instead of using (5), we introduce the *elliptic projection* operator Π defined as

$$\Pi w\in V_h,\quad a(\Pi w,v)=a(w,v)\quad \forall v\in V_h,$$

for each $w\in V$, then the following error estimate holds true:

$$\begin{aligned}&\max_{t\in[0,T]}||u(t)-u_h(t)||_H^2+\alpha\int_0^T||u(t)-u_h(t)||_V^2\,dt\le||u_0-u_{0,h}||_H^2\\&+\max_{t\in[0,T]}||u(t)-\Pi u(t)||_H^2+C\int_0^T\left(\left\|\frac{\partial}{\partial t}\Big(u(t)-\Pi u(t)\Big)\right\|_{V'}^2+||u(t)-\Pi u(t)||_V^2\right)dt.\end{aligned}$$

In the case of the heat equation, the last equation, together with the usual error estimates for elliptic problems, leads to an estimate similar to (7) but without using the inverse inequality (see, e.g., [23, 20]).

3. Setting of the problem.

3.1. $\binom{0}{g}$-type problems. We consider two Hilbert spaces Σ and V and a third Hilbert space H (which will be identified with its dual space H') such that the following standard inclusions hold with dense and continuous embedding: $V\subseteq H\simeq H'\subseteq V'$. When referring to the inner product of H, we shall omit the reference to the space; in the main application we have in mind, H is simply L^2. A model $\binom{0}{g}$-type evolution problem reads as follows: Given $T>0$, $g:\,]0,T[\,\to V'$, and $u_0\in H$, for almost every $t\in\,]0,T[$ find $\sigma(t)\in\Sigma$ and $u(t)\in V$ such that

$$\begin{aligned}&a(\sigma(t),\tau)+b(\tau,u(t))=0 && \forall\tau\in\Sigma,\\&b(\sigma(t),v)-\frac{d}{dt}(u(t),v)=-{}_{V'}\!<g(t),v>_V && \forall v\in V,\\&u(0)=u_0,\end{aligned} \tag{8}$$

where the first two equations are defined in the sense of distributions in $]0,T[$. We make the following assumptions on the involved bilinear forms $a : \Sigma \times \Sigma \to \mathbb{R}$ and $b : \Sigma \times V \to \mathbb{R}$:

$$\begin{array}{l} a(\cdot,\cdot) \text{ and } b(\cdot,\cdot) \text{ are continuous; that is,} \\ \exists M_a > 0 : \forall \sigma, \tau \in \Sigma \; a(\sigma,\tau) \le M_a ||\sigma||_\Sigma ||\tau||_\Sigma, \\ \exists M_b > 0 : \forall \sigma \in \Sigma, \forall v \in V \; b(\sigma, v) \le M_b ||\sigma||_\Sigma ||v||_V. \end{array}$$

We also assume that $a(\cdot,\cdot)$ is symmetric and positive semidefinite and set

$$|\tau|_a := (a(\tau,\tau))^{1/2}.$$

It is immediate to check that $|\cdot|_a$ is a seminorm on Σ and that for all $\sigma, \tau \in \Sigma$ we have

$$a(\sigma,\tau) \le |\sigma|_a |\tau|_a.$$

We suppose that problem (8) is well posed and that the following a priori estimates hold true:

$$\max_{t\in[0,T]} ||u(t)||_H^2 + \int_0^T ||u(t)||_V^2 \, dt \le ||u_0||_H^2 + C \int_0^T ||g(t)||_{V'}^2 \, dt, \tag{9}$$

$$\int_0^T \mu^2(t) ||\sigma(t)||_\Sigma^2 \, dt \le C \left(||u_0||_H^2 + \int_0^T ||g(t)||_{V'}^2 \, dt \right), \tag{10}$$

where $\mu(t)$ is a suitably chosen weight function which might tend to zero as t goes to zero.

Let Σ_h and V_h be finite dimensional subspaces of Σ and V, respectively. The space semidiscretization of problem (8) reads as follows: For almost every $t \in]0,T[$, find $\sigma_h(t) \in \Sigma_h$ and $u_h(t) \in V_h$ such that

$$\begin{array}{ll} a(\sigma_h(t),\tau) + b(\tau, u_h(t)) = 0 & \forall \tau \in \Sigma_h, \\ b(\sigma_h(t), v) - \dfrac{d}{dt}(u_h(t), v) = -_{V'}\!< g(t), v >_V & \forall v \in V_h, \\ u_h(0) = u_{0,h}, & \end{array} \tag{11}$$

where $u_{0,h} \in V_h$ is a suitable approximation of u_0.

Example 2 (the heat equation in mixed form). Let Ω be an open Lipschitz polygon in $\mathbb{R}^2$ or polyhedron in $\mathbb{R}^3$. Setting $\Sigma = H(\mathrm{div};\Omega)$, $V = H = V' = L^2(\Omega)$, the formulation given in (8) is a weak form of the heat equation ($\boldsymbol{\sigma}(t) = \operatorname{grad} u(t)$) with the choices

$$a(\boldsymbol{\sigma}, \boldsymbol{\tau}) = (\boldsymbol{\sigma}, \boldsymbol{\tau}), \qquad b(\boldsymbol{\tau}, v) = (\operatorname{div} \boldsymbol{\tau}, v).$$

It can be directly checked that the a priori estimates (10) hold with $\mu(t) = t$. The estimates can be improved to get $\mu(t) = 1$ if more regularity is assumed on u_0, namely $u_0 \in H_0^1(\Omega)$ or, analogously, $\boldsymbol{\sigma}_0 = \operatorname{grad} u_0 \in L^2(\Omega)$.

For the mixed spatial semidiscretization of the heat equation we construct two sequences of finite element spaces $\Sigma_h \subset H(\mathrm{div};\Omega)$ and $V_h \subset L^2(\Omega)$ and consider

the following discrete problem: For almost every $t \in]0,T[$, find $\boldsymbol{\sigma}_h(t) \in \Sigma_h$ and $u_h(t) \in V_h$ such that

$$
\begin{aligned}
&(\boldsymbol{\sigma}_h(t), \boldsymbol{\tau}) + (\operatorname{div} \boldsymbol{\tau}, u_h(t)) = 0 && \forall \boldsymbol{\tau} \in \Sigma_h,\\
&(\operatorname{div} \boldsymbol{\sigma}_h(t), v) - \frac{d}{dt}(u_h(t), v) = -(g(t), v) && \forall v \in V_h,\\
&u_h(0) = u_{0,h}.
\end{aligned} \tag{12}
$$

Several possible choices for the spaces Σ_h and V_h have been presented in the literature for the corresponding source problem. For instance, in the case of triangular or tetrahedral meshes, we can choose as Σ_h the spaces of the RT elements introduced in [21, 19] or the Brezzi–Douglas–Marini (BDM) and Brezzi–Douglas–Fortin–Marini (BDFM) elements introduced in [12, 11] (see [13] for a unified presentation; see also [16] for the use of RT elements in the context of parabolic problems in mixed form). In all these cases V_h is equal to $\operatorname{div} \Sigma_h$. On quadrilaterals or hexahedrons the situation is more complicated; a two-dimensional theory has been developed recently in [1], showing that the standard families just listed do not achieve optimal approximation properties in $H(\operatorname{div}; \Omega)$ for general quadrilateral meshes. There, a new Arnold–Boffi–Falk (ABF) family has been proposed by adding internal degrees of freedom to the RT elements in order to recover the optimal accuracy. In this case, the inclusion $\operatorname{div} \Sigma_h \subseteq V_h$ is no longer valid (see [1] for the details about the definition of V_h).

All these spaces satisfy the conditions for the well posedness of the steady problem, namely, there exist two positive constants α and β such that

$$
(\boldsymbol{\tau}, \boldsymbol{\tau}) \geq \alpha ||\boldsymbol{\tau}||^2_{H(\operatorname{div};\Omega)} \quad \forall \boldsymbol{\tau} \in \Sigma_h \text{ with } (\operatorname{div} \boldsymbol{\tau}, v) = 0 \quad \forall v \in V_h, \tag{13}
$$

$$
\sup_{\boldsymbol{\tau} \in \Sigma_h} \frac{(\operatorname{div} \boldsymbol{\tau}, v)}{||\boldsymbol{\tau}||_{H(\operatorname{div};\Omega)}} \geq \beta ||v||_{L^2(\Omega)} \quad \forall v \in V_h. \tag{14}
$$

In section 4 we shall test the lowest order RT element for the approximation of the heat equation, together with another less standard element which also satisfies (13) and (14).

3.2. $\binom{f}{0}$-type problems. We consider three Hilbert spaces V, H, and Q such that $V \subseteq H \simeq H' \subseteq V'$ with dense and continuous inclusions. As in the previous section, we shall refer to the scalar product of H with $(\cdot, \cdot)$. A model $\binom{f}{0}$-type evolution problem reads as follows: Given $T > 0$, $f :]0,T[\to V'$, and $u_0 \in H$, for almost every $t \in]0,T[$ find $u(t) \in V$ and $p(t) \in Q$ such that

$$
\begin{aligned}
&\frac{d}{dt}(u(t), v) + a(u(t), v) + b(v, p(t)) = {}_{V'}\!< f, v >_V && \forall v \in V,\\
&b(u(t), q) = 0 && \forall q \in Q,\\
&u(0) = u_0,
\end{aligned} \tag{15}
$$

where the first two equations are defined in the sense of distributions in $]0,T[$. We recall the definitions of the bilinear forms $a : V \times V \to \mathbb{R}$ and $b : V \times Q \to \mathbb{R}$ and make the following standard hypotheses:

$a(\cdot, \cdot)$ and $b(\cdot, \cdot)$ are continuous; that is,
$\exists M_a > 0 : \forall u, v \in V \; a(u, v) \leq M_a ||u||_V ||v||_V$,
$\exists M_b > 0 : \forall v \in V, \forall q \in Q \; b(v, q) \leq M_b ||v||_V ||q||_Q$.

Moreover, we assume that the form a is coercive on the kernel of B,

$$K = \{v \in V : b(v,q) = 0 \ \forall q \in Q\},$$

i.e., there exists $\alpha > 0$ such that

$$a(v,v) \geq \alpha ||v||_V^2 \quad \forall v \in K. \tag{16}$$

A weaker ellipticity could be considered when dealing with parabolic problems. However, it can be reduced to (16) with a change of variables. We suppose that problem (15) is well posed and that the following a priori estimates hold true:

$$\max_{t\in[0,T]} ||u(t)||_H^2 + \alpha \int_0^T ||u(t)||_V^2 \, dt \leq ||u_0||_H^2 + C \int_0^T ||f(t)||_{V'}^2 \, dt, \tag{17}$$

$$\int_0^T ||p(t)||_Q^2 \, dt \leq C \left(||u_0||_H^2 + \int_0^T ||f(t)||_{V'}^2 \, dt \right). \tag{18}$$

Let V_h and Q_h be finite dimensional subspaces of V and Q; then the Galerkin space semidiscretization of problem (15) reads as follows: For almost every $t \in]0,T[$, find $u_h(t) \in V_h$ and $p_h(t) \in Q_h$ such that

$$\begin{aligned} &\frac{d}{dt}(u_h(t), v) + a(u_h(t), v) + b(v, p_h(t)) = {}_{V'}\!< f, v >_V \quad && \forall v \in V_h, \\ &b(u_h(t), q) = 0 && \forall q \in Q_h, \\ &u_h(0) = u_{0,h}, \end{aligned} \tag{19}$$

where $u_{0,h} \in V_h$ is an approximation of u_0.

Example 3 (the Stokes equations). Let Ω be an open Lipschitz polyhedron in $\mathbb{R}^n$ (with $n = 2$ or 3); then the Stokes equations fit in a natural way within our setting with the following definitions:

$$\begin{gathered} V = (H_0^1(\Omega))^n, \quad Q = L^2(\Omega)/\mathbb{R}, \quad H = (L^2(\Omega))^n, \\ a(\mathbf{u}, \mathbf{v}) = (\boldsymbol{\varepsilon}(\mathbf{u}) : \boldsymbol{\varepsilon}(\mathbf{v})), \qquad b(\mathbf{v}, q) = (\operatorname{div} \mathbf{v}, q), \end{gathered}$$

where $\boldsymbol{\varepsilon}$ is, as usual, the linearized strain tensor. It is known (see, for instance, [22]) that estimates (17) and (18) hold true in this case. Moreover, whenever Ω is convex (with the usual modifications for the nonconvex case), if $f \in L^2(]0,T[\,; H)$ and $u_0 \in K$, then $u \in L^2(]0,T[\,; (H^2(\Omega))^n)$, $\partial u/\partial t \in L^2(]0,T[\,; H)$, and $p \in L^2(]0,T[\,; H^1(\Omega))$.

For the discretization of the steady problem, we refer to [13]. We shall see at the end of section 6 that a good approximation of the steady Stokes equations provides a convergent approximation to the time dependent problem also.

4. Numerical investigations. In this section we report on some numerical tests for various mixed discretization to the heat equation presented in Example 2. The discrete problem we are dealing with is the one presented in (12). We consider two possible choices for the discrete spaces Σ_h and V_h. Given $\Omega =]0,\pi[^2$ and a triangular mesh, the first method consists in choosing Σ_h as the lowest order RT element (see [21]) and as V_h the space of piecewise constant functions. We shall refer to this choice as the RT method. In the second method, which has been analyzed in [8], the space Σ_h consists of continuous piecewise linear (in each component) vector fields and V_h is simply defined as $V_h = \operatorname{div} \Sigma_h$ and turns out to be a subset of the space of piecewise constant functions. We shall refer to this example as the P1 method.

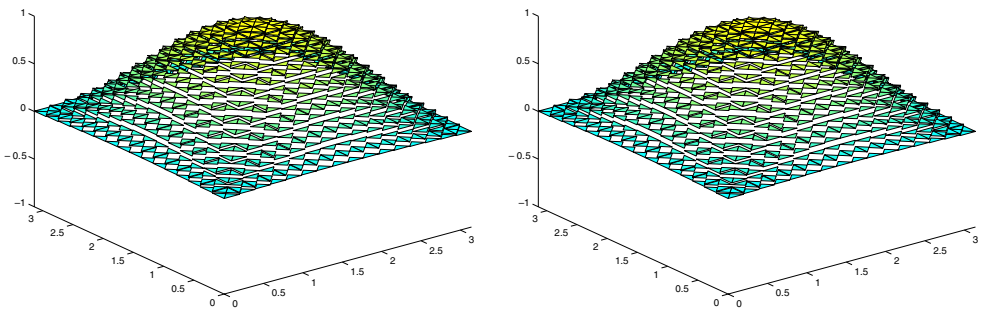

FIG. 1. $u(10)$ *on* 16*-by-*16 *criss-cross mesh computed with the RT (left) and* $P1$ *(right) methods with* $g = 2 \sin x \sin y$.

The RT method is well known to be stable (see [21]), when applied to the steady problem (see (13) and (14)). The P1 method has been introduced in [8] in order to construct a counterexample for the approximation of eigenvalue problems. It has been shown to be stable on a special mesh sequence of the square which is built of uniform subsquares, each of them subdivided into four triangles (criss-cross mesh). In this section, we shall denote by N the number of subdivisions of each side of Ω, so that a criss-cross mesh contains $4N^2$ triangles. On general triangular meshes, the P1 element does not satisfy the inf-sup condition (14) in the sense that the inf-sup constant β tends to zero as h goes to zero.

If not otherwise indicated, we take $T = 10$ and advance in time using an implicit Euler scheme with step $dt = 0.1$.

In all our tests, g does not depend on t and $u_0 \equiv 0$, so that the solution $(\boldsymbol{\sigma}(t), u(t))$ asymptotically tends to the solution $(\boldsymbol{\sigma}_\infty, u_\infty) \in H(\mathrm{div}; \Omega) \times L^2(\Omega)$ of the steady problem

$$\begin{aligned} &(\boldsymbol{\sigma}_\infty, \boldsymbol{\tau}) + (\mathrm{div}\, \tau, u_\infty) = 0 \quad && \forall \boldsymbol{\tau} \in H(\mathrm{div}; \Omega), \\ &(\mathrm{div}\, \boldsymbol{\sigma}_\infty, v) = -(g, v) && \forall v \in L^2(\Omega). \end{aligned}$$

In our first test, we choose $g(x, y) = 2 \sin x \sin y$, so that $u_\infty(x, y) = \sin x \sin y$. In Figure 1 the component $u(t)$ of the solution at time $T = 10$ is plotted for both methods on a criss-cross mesh with $N = 16$. The results look quite similar; the $L^2(\Omega)$ norms of the solution are 1.5725 and 1.5674 (the reference value is $\pi/2 = 1.57079\ldots$) for the RT and P1 methods, respectively, and the corresponding solution values at the center are 0.9957 and 0.9925 (the reference value is 1.0). In the second test, considering again criss-cross meshes, we take the function $g = c(h)$ depending on the meshsize h as a checkerboard function with values ± 1 on the underlying mesh of subsquares. For example, the case $N = 4$ is plotted in Figure 2. Let $u_\infty(h)$ be the asymptotic solution of our problem with datum $g = c(h)$. As h goes to zero, the function $c(h)$ tends weakly to zero in $L^2(\Omega)$, so that, for the compactness of the inverse Laplace operator, we have that $u_\infty(h)$ tends to zero strongly in $L^2(\Omega)$. We expect a good numerical method to provide a solution $u_h(t) \in V_h$ tending to zero as h goes to zero. We explicitly observe that our expectation is related to a sort of uniform convergence, since the solution is computed, for each h, with respect to a different right-hand side. On the other hand, this kind of convergence is what we usually obtain from the error estimates (see (27) and (36)).

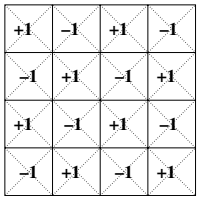

FIG. 2. *The checkerboard $c(h)$ for $N = 4$.*

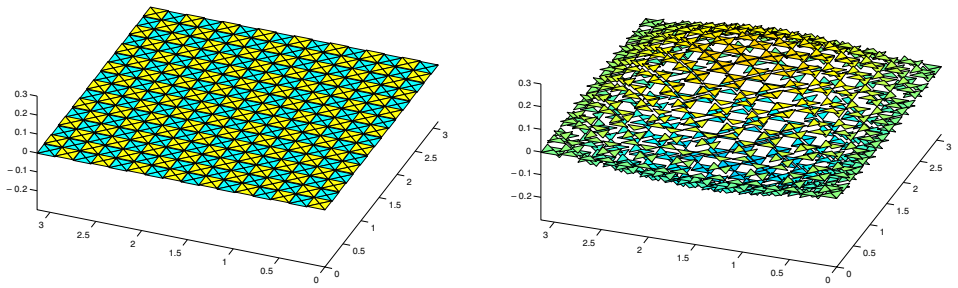

FIG. 4. *$u(10)$ on 16-by-16 criss-cross mesh computed with the RT (left) and P1 (right) methods when g is a checkerboard.*

In Table 1 we report the L^2 norm of $u_h(10)$ for various values of N computed with RT and P1 methods. It is evident that the solution computed with the P1 method does not go to zero. This fact clearly indicates a different behavior for the two methods. In particular, it is evident that the stability of the steady problem (see (13) and (14)) is not sufficient for the good approximation of the evolution problem in mixed form. Here, by *good approximation* we mean a convergence like it comes from estimates (27) or (36). In Table 1 we also show that the bad behavior of the P1 approximation is not related to a poor time discretization. Indeed, a refinement in t does not produce any improvement. At the end of section 5, we shall come back to this example and analyze more deeply the differences between the two methods. In Figure 4 we show the solution $u_h(10)$ computed with the two methods. The resonance induced by the checkerboard in the case of the P1 scheme can be observed. This will

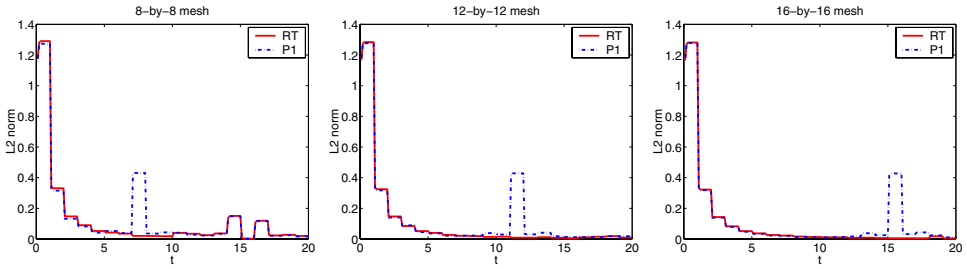

FIG. 5. L^2 *norm of* $u_h(t)$ *for* $t \in [0, 20]$ *with* $g(t)$ *equal to* $N(t)$*-by-*$N(t)$ *checkerboard function and Dirichlet (natural) boundary conditions.*

be related to the presence of spurious eigenvalues (see [8]) at the end of section 5. On the other hand, if we keep g fixed and let h go to zero, then we observe that the solution computed with the P1 method is similar to the one obtained with the RT method (see Table 2), the only exception being when the mesh is the one underlying the structure of g.

We introduce now another example, in which the P1 method is not converging as h goes to zero in the $L^\infty(L^2)$ norm. The load term g is now a function of t; namely, at time t, $g(t)$ is the $N(t)$-by-$N(t)$ checkerboard function with $N(t) = \lceil t \rceil$. The norm of the solution $u(t)$, computed with RT and P1 methods using three different meshes ($N = 8, 12, 16$), is plotted in Figure 5. We notice that, when the P1 method is used, there is a pick with constant height appearing at an increasing value of t as h decreases. This happens when the structure of g *resonates* with the mesh and cannot be avoided even if the mesh is refined.

5. Convergence analysis for the $\binom{0}{g}$-type evolution problems. In this section we shall develop two different error estimates. The first one, stated in Theorem 3, is new and is based on the compatibility assumption (23). This assumption is satisfied for most standard finite elements used for the approximation of the heat equation. The second estimate, given in Theorem 5, is basically equivalent to the one given in Theorem 2.1 of [16]. Our proof is new, and we explicitly observe that, in this case, the regularity hypothesis (34) has to be made.

We start this section by recalling the continuous problem (8) and its space semidiscretization (11). The hypotheses on the involved bilinear forms have been made explicit in section 3.1. Given $T > 0$, $g :]0, T[\to V'$, and $u_0 \in H$, for almost every $t \in]0, T[$ we look for $\sigma(t) \in \Sigma$ and $u(t) \in V$ such that

$$\begin{aligned} &a(\sigma(t), \tau) + b(\tau, u(t)) = 0 && \forall \tau \in \Sigma, \\ &b(\sigma(t), v) - \frac{d}{dt}(u(t), v) = -_{V'}\!< g(t), v >_V && \forall v \in V, \\ &u(0) = u_0. \end{aligned}$$

The semidiscrete counterpart reads as follows: For almost every $t \in]0, T[$, find $\sigma_h(t) \in \Sigma_h$ and $u_h(t) \in V_h$ such that

$$\begin{aligned} &a(\sigma_h(t), \tau) + b(\tau, u_h(t)) = 0 && \forall \tau \in \Sigma_h, \\ &b(\sigma_h(t), v) - \frac{d}{dt}(u_h(t), v) = -_{V'}\!< g(t), v >_V && \forall v \in V_h, \\ &u_h(0) = u_{0,h}. \end{aligned}$$

The error equations are

$$a(\sigma(t)-\sigma_h(t),\tau)+b(\tau,u(t)-u_h(t))=0 \quad \forall \tau\in\Sigma_h,$$
$$b(\sigma(t)-\sigma_h(t),v)-\frac{d}{dt}(u(t)-u_h(t),v)=0 \quad \forall v\in V_h.$$

Given two linear operators $\Pi:\Sigma\to\Sigma_h$ and $P:H\to V_h$, and taking $\tau=\Pi\sigma(t)-\sigma_h(t)$, $v=Pu(t)-u_h(t)$ in the error equations we get, after summation,

(20)
$$\begin{aligned}\left(\frac{\partial}{\partial t}\Big(Pu(t)-u_h(t)\Big),Pu(t)-u_h(t)\right)&+a(\Pi\sigma(t)-\sigma_h(t),\Pi\sigma(t)-\sigma_h(t))\\ &=b(\sigma(t)-\Pi\sigma(t),Pu(t)-u_h(t))-\left(\frac{\partial}{\partial t}\Big(u(t)-Pu(t)\Big),Pu(t)-u_h(t)\right)\\ &\quad-a(\sigma(t)-\Pi\sigma(t),\Pi\sigma(t)-\sigma_h(t))-b(\Pi\sigma(t)-\sigma_h(t),u(t)-Pu(t)).\end{aligned}$$

Let us now take Π as a Fortin operator and P as the H projection onto V_h, namely,

(21)
$$\begin{aligned}&\Pi:\Sigma\to\Sigma_h,\\ &b(\tau-\Pi\tau,v)=0 \quad \forall v\in V_h,\end{aligned}$$

and

$$\begin{aligned}&P:H\to V_h,\\ &(w-Pw,v)=0 \quad \forall v\in V_h.\end{aligned}$$

Then, (20) reduces to

(22)
$$\begin{aligned}\left(\frac{\partial}{\partial t}\Big(Pu(t)-u_h(t)\Big),Pu(t)-u_h(t)\right)&+a(\Pi\sigma(t)-\sigma_h(t),\Pi\sigma(t)-\sigma_h(t))\\ &=a(\sigma(t)-\Pi\sigma(t),\Pi\sigma(t)-\sigma_h(t))-b(\Pi\sigma(t)-\sigma_h(t),u(t)-Pu(t)),\end{aligned}$$

where we used the fact that Π is a Fortin operator (see (21)) and that the projection P commutes with the time derivative.

In several interesting applications, the last term in the right-hand side of (22) vanishes. Let $B:\Sigma\to V'$ denote the canonical operator defined by ${}_{V'}\!<B\sigma,v>_V=b(\sigma,v)$ for all $\sigma\in\Sigma$ and $v\in V$; if

(23)
$$B(\Sigma_h)\subseteq V_h,$$

then we can show that, for any $v\in V$,

$$b(\tau,v-Pv)=0 \quad \forall \tau\in\Sigma_h.$$

Indeed, in this case, $b(\tau,v-Pv)={}_{V'}\!<B\tau,v-Pv>_V=(B\tau,v-Pv)=0$, due to the identification $H\simeq H'$.

Hence, we can easily obtain the following result.

LEMMA 2. *Let (σ,u) and (σ_h,u_h) be the solutions of problems* (8) *and* (11)*, respectively. If the inclusion* (23) *holds, then the following error estimate is true:*

$$\begin{aligned}&\max_{t\in[0,T]}||u(t)-u_h(t)||_H^2+\int_0^T|\sigma(t)-\sigma_h(t)|_a^2\,dt\\ &\qquad\le||Pu_0-u_{0,h}||_H^2+\max_{t\in[0,T]}||u(t)-Pu(t)||_H^2+2\int_0^T|\sigma(t)-\Pi\sigma(t)|_a^2\,dt.\end{aligned}$$

In order to obtain a convergence result, we need some assumptions on the operators P and Π. Let us denote by V^+ a subspace of V such that the second component of the solution u belongs to $L^2(]0,T[;V^+)$ whenever $g \in L^2(]0,T[;H)$ and denote by Σ^+ a space such that the first component of the solution σ belongs to $L^2(]0,T[;\Sigma^+)$ whenever $g \in L^2(]0,T[;H)$. Moreover, let us assume that the following estimate holds:

$$\|\sigma\|_{L^2(\Sigma^+)} + \|u\|_{L^2(V^+)} \le C\|g\|_{L^2(H)}. \tag{24}$$

Then we assume that there exists $\rho_1(h)$, tending to zero as h goes to zero, such that for every $u \in V^+$ it holds that

$$||u - Pu||_H \le \rho_1(h)||u||_{V^+}. \tag{25}$$

In general, estimate (25) can be achieved if P is a suitable approximation operator. As far as the operator Π is concerned, in the spirit of [7], we make the following assumption: There exists $\rho_2(h)$, tending to zero as h goes to zero, such that

$$|\sigma - \Pi\sigma|_a \le \rho_2(h)||\sigma||_{\Sigma^+}. \tag{26}$$

The following theorem summarizes the results obtained so far.

THEOREM 3. *Let (σ,u) and (σ_h,u_h) be the solutions of problems* (8) *and* (11)*, respectively, and suppose that the inclusion* (23) *holds true. If there exist P and Π satisfying* (25) *and* (26)*, then we have the following estimate:*

$$\begin{aligned} ||u(t) - u_h(t)||_{L^\infty(H)} + \left(\int_0^T |\sigma(t) - \sigma_h(t)|_a^2\, dt\right)^{1/2} \\ \le C||Pu_0 - u_{0,h}||_H + C(\rho_1(h) + \rho_2(h))||g||_{L^2(H)}. \end{aligned} \tag{27}$$

A different estimate, which does not require the inclusion (23), but for which some more regularity assumption on the solution is required, can be obtained by using the approach of the *elliptic projection* (see section 2). Let us consider the steady problem associated to (8): Given $g \in V'$, find $(\sigma,u) \in \Sigma \times V$ such that

$$\begin{aligned} a(\sigma,\tau) + b(\tau,u) &= 0 \qquad \forall \tau \in \Sigma, \\ b(\sigma,v) &= -{}_{V'}\!< g, v >_V \quad \forall v \in V, \end{aligned} \tag{28}$$

and the corresponding discrete problem: Find $(\sigma_h,u_h) \in \Sigma_h \times V$ such that

$$\begin{aligned} a(\sigma_h,\tau) + b(\tau,u_h) &= 0 \qquad \forall \tau \in \Sigma_h, \\ b(\sigma_h,v) &= -{}_{V'}\!< g, v >_V \quad \forall v \in V_h. \end{aligned} \tag{29}$$

We make the assumption that (28) and (29) are well posed. Then, given $(\sigma,u) \in \Sigma \times V$ solution of (28), we can define $\Pi\sigma \in \Sigma_h$ and $P\sigma \in V_h$ as the solution of (29) with right-hand side ${}_{V'}\!< g, v >_V = -b(\sigma,v)$, namely,

$$\begin{aligned} a(\Pi\sigma,\tau) + b(\tau,P\sigma) &= 0 \quad \forall \tau \in \Sigma_h, \\ b(\Pi\sigma,v) &= b(\sigma,v) \qquad \forall v \in V_h. \end{aligned} \tag{30}$$

We observe that, thanks to the well posedness of problem (28), the continuous solution of (30) is (σ,u). Since, basically, Π and P depend explicitly only on σ, we omit u from the notation for simplicity. It should be remembered, however, that $P\sigma$ is a

discrete counterpart to u. Moreover, the operator $\Pi : \Sigma \to \Sigma_h$ defined in (30) is a Fortin operator in the sense of (21). Inserting now the *elliptic projections* Π and P defined in (30) into (20), we obtain

$$\left(\frac{\partial}{\partial t}\Big(P\sigma(t)-u_h(t)\Big), P\sigma(t)-u_h(t)\right) + a(\Pi\sigma(t)-\sigma_h(t), \Pi\sigma(t)-\sigma_h(t)) = -\left(\frac{\partial}{\partial t}\Big(u(t)-P\sigma(t)\Big), P\sigma(t)-u_h(t)\right),$$

where we made use of the fact that Π is a Fortin operator and we took advantage of the following error equation:

$$a(\sigma(t)-\Pi\sigma(t),\tau) + b(\tau, u(t)-P\sigma(t)) = 0 \quad \forall \tau \in \Sigma_h.$$

Hence, using standard arguments and Gronwall's lemma, we obtain the following result.

LEMMA 4. *Let (σ, u) and (σ_h, u_h) be the solutions of problems* (8) *and* (11)*, respectively. Let $\Pi : \Sigma \to \Sigma_h$ and $P : V \to V_h$ be defined as in* (30)*. Suppose, moreover, that u_0 is in V and is such that there exists $\sigma_0 \in \Sigma$ with (σ_0, u_0) solution to* (28) *for a suitable $g \in V'$. Then the following error estimate is true:*

$$\max_{t\in[0,T]} ||u(t)-u_h(t)||_H^2 + \int_0^T |\sigma(t)-\sigma_h(t)|_a^2\, dt \le ||P\sigma_0 - u_{0,h}||_H^2 + \max_{t\in[0,T]} ||u(t)-P\sigma(t)||_H^2 + 2\int_0^T |\sigma(t)-\Pi\sigma(t)|_a^2\, dt + C\int_0^T \left\|\frac{\partial}{\partial t}(u(t)-P\sigma(t))\right\|_H^2 dt.$$

In order to get the convergence estimate from the previous lemma, we make the following assumptions. First, we assume that there exists $\omega_1(h)$, going to zero as h goes to zero, such that

$$||u-P\sigma||_H \le \omega_1(h)||u||_{V^+}. \tag{31}$$

Then, we need an estimate for $||\sigma(t)-\Pi\sigma(t)||_a$. In analogy to (26), we suppose that there exists $\omega_2(h)$, going to zero as h goes to zero, such that

$$|\sigma-\Pi\sigma|_a \le \omega_2(h)||\sigma||_{\Sigma^+}. \tag{32}$$

Finally, we suppose the existence of $\omega_3(h)$, going to zero as h goes to zero, such that

$$\left\|\frac{\partial}{\partial t}(u-P\sigma)\right\|_{L^2(H)} \le \omega_3(h)\left\|\frac{\partial u}{\partial t}\right\|_{L^2(V^+)}. \tag{33}$$

Remark 1. We explicitly notice that estimate (33) is not an immediate consequence of (31) unless the operator P commutes with the time derivative. Actually, this property is true provided some regularity assumption is made. Indeed, we need to assume

$$\frac{\partial \sigma}{\partial t} \in L^2(]0,T[;\Sigma) \tag{34}$$

in order to define $P(\partial\sigma(t)/\partial t) \in V_h$, according to (30):

$$\begin{aligned} a\left(\Pi\frac{\partial\sigma(t)}{\partial t},\tau\right) + b\left(\tau, P\frac{\partial\sigma(t)}{\partial t}\right) &= 0 \quad \forall \tau \in \Sigma_h, \\ b\left(\Pi\frac{\partial\sigma(t)}{\partial t}, v\right) &= b\left(\frac{\partial\sigma(t)}{\partial t}, v\right) \quad \forall v \in V_h. \end{aligned}$$

Differentiating (30) with respect to t, we get

$$\begin{aligned} a\left(\frac{\partial\Pi\sigma(t)}{\partial t},\tau\right) + b\left(\tau, \frac{\partial P\sigma(t)}{\partial t}\right) &= 0 \quad \forall \tau \in \Sigma_h, \\ b\left(\frac{\partial\Pi\sigma(t)}{\partial t}, v\right) &= b\left(\frac{\partial\sigma(t)}{\partial t}, v\right) \quad \forall v \in V_h. \end{aligned}$$

Comparing the last two equations, and using the uniqueness hypothesis on problem (29), we finally obtain

$$P\frac{\partial\sigma(t)}{\partial t} = \frac{\partial P\sigma(t)}{\partial t} \quad \text{for a.e. } t \in]0,T[\,. \tag{35}$$

Relation (35), which relies on the regularity assumption (34), can be used to get the estimate

$$\left\| \frac{\partial}{\partial t}(u - P\sigma) \right\|_{L^2(H)} \leq \omega_1(h) \left\| \frac{\partial u}{\partial t} \right\|_{L^2(V^+)}.$$

Assumptions (31), (32), and (33) allow us to state the following theorem.

THEOREM 5. *Let (σ, u) and (σ_h, u_h) be the solutions of problems* (8) *and* (11)*, respectively. Let Π and P be the two components of the elliptic projection* (30)*, and let σ_0 be as in Lemma* 4*. If* (31)*,* (32)*, and* (33) *are satisfied, then we have the following estimate:*

$$\begin{aligned} &||u(t) - u_h(t)||_{L^\infty(H)} + \left(\int_0^T |\sigma(t) - \sigma_h(t)|_a^2 \, dt \right)^{1/2} \\ &\quad \leq C||P\sigma_0 - u_{0,h}||_H + C(\omega_1(h) + \omega_2(h))||g||_{L^2(H)} + C\omega_3(h) \left\| \frac{\partial u}{\partial t} \right\|_{L^2(V^+)}. \end{aligned} \tag{36}$$

Example 4 (convergence analysis for the mixed approximation to the heat equation). We review here the numerical examples presented in section 4. We start with the analysis of the RT, BDM, and BDFM methods for mesh of triangles, tetrahedrons, rectangles, and parallelepipeds. In these cases, Theorem 3 gives the optimal kth order rate of convergence (see [13, 8]).

On general quadrilateral meshes, we can use the ABF family introduced in [1]. In this case we cannot use Theorem 3, since the inclusion (23) is not satisfied. However, we can invoke Theorem 5 and conclude with the optimal estimate, provided some extra regularity on the time derivative of u is assumed.

On the other hand, the P1 scheme does not fit within our results. Indeed, it has been proved in [8] that (32) does not hold. We shall make it clear how things might go wrong (as shown numerically in Figure 4) with the following considerations. In [8] it has been shown that the P1 element, when applied to the mixed eigenvalue problem associated with the Laplace operator, presents spurious eigenvalues. Let Ω be the square of side length π, and define f^h as the eigenfunction associated to the first spurious eigenvalue $\bar{\lambda}_h$. We normalize f^h so that $||f^h||_{L^2} = 1$. This function, in particular, has a clear checkerboard pattern, and numerical evidence shows that $\bar{\lambda}_h$ tends to a number close to six (see [8] and section 7 of this paper). Take $u_0 = 0$, then the continuous solution u^h to the heat equation is (see (3))

$$u^h(t) = \sum_{i=1}^{\infty} w_i \int_0^t (f^h, w_i) e^{\lambda_i (s-t)}\, ds.$$

Let us consider the discrete eigenmodes $\lambda_{i,h} \in \mathbb{R}$ and $w_{i,h} \in V_h$, $\sigma_{i,h} \in \Sigma_h$, $i = 1, \dots, \mathcal{N}(h)$, (where $\mathcal{N}(h)$ is the dimension of V_h) satisfying

$$\begin{aligned} &(\boldsymbol{\sigma}_{i,h}, \boldsymbol{\tau}) + (\operatorname{div} \boldsymbol{\tau}, w_{i,h}) = 0 \quad && \forall \boldsymbol{\tau} \in \Sigma_h, \\ &(\operatorname{div} \boldsymbol{\sigma}_{i,h}, v) = -\lambda_{i,h} (w_{i,h}, v) \quad && \forall v \in V_h. \end{aligned}$$

With this notation, a solution expansion also holds at the discrete level, namely,

$$u_h^h(t) = \sum_{i=1}^{\mathcal{N}(h)} w_{i,h} \int_0^t (f^h, w_{i,h}) e^{\lambda_{i,h}(s-t)}\, ds = \sum_{i=1}^{\mathcal{N}(h)} w_{i,h} (f^h, w_{i,h}) \frac{1 - e^{-\lambda_{i,h} t}}{\lambda_{i,h}}. \tag{37}$$

Since f^h tends to zero weakly in $L^2(\Omega)$, the continuous asymptotic solution u_∞^h tends to zero strongly in $L^2(\Omega)$. On the other hand, from (37) we get

$$u_h^h(t) = f^h \frac{1 - e^{-\bar{\lambda}_h t}}{\bar{\lambda}_h} \quad \text{and} \quad ||u_h^h||_{L^\infty(L^2)} = \frac{1 - e^{-\bar{\lambda}_h T}}{\bar{\lambda}_h}.$$

This last relation implies that an estimate like (27) cannot hold for the P1 method if we can show that $||u^h||_{L^\infty(L^2)}$ tends to zero as h goes to zero. Indeed, we can split u^h as the sum of u_1 and u_2 defined as follows:

$$\begin{aligned} &\frac{\partial u_1}{\partial t} - \Delta u_1 = f^h \quad \text{in } \Omega \times]0, T[\,, && \qquad \frac{\partial u_2}{\partial t} - \Delta u_2 = 0 \quad \text{in } \Omega \times]0, T[\,, \\ &u_1(0) = u_\infty^h \quad \text{in } \Omega, && \qquad u_2(0) = -u_\infty^h \quad \text{in } \Omega. \end{aligned}$$

It is clear that $u_1(t) = u_\infty^h$ for all t, so that

$$||u^h||_{L^\infty(L^2)} \le ||u_1||_{L^\infty(L^2)} + ||u_2||_{L^\infty(L^2)} \le 2||u_\infty^h||_{L^2}.$$

6. Convergence analysis for the $\binom{f}{0}$-type evolution problems. Also in this section we present two different error estimates. In the first one, we shall make the hypothesis that the bilinear form a is coercive on the whole space V (see Theorem 9). This estimate applies, for instance, to the Stokes problem introduced in Example 3 and in this case provides the optimal rate of convergence only when the lowest order elements are used. In the second estimate, presented in Theorem 11, we only assume the ellipticity in the kernel (16), but, in order to get the result, we require an additional approximation property. If applied to the Stokes problem, this estimate turns out to be optimal also for higher order schemes.

We recall the continuous problem (15) and its space semidiscretization (19). The hypotheses on the forms, in particular the ellipticity in the kernel (16), have been made in section 3.2. Given $T > 0$, $f :]0,T[\to V'$, and $u_0 \in H$, for almost every $t \in]0,T[$ find $u(t) \in V$ and $p(t) \in Q$ such that

$$\begin{aligned} &\frac{d}{dt}(u(t),v) + a(u(t),v) + b(v,p(t)) = {}_{V'}\!< f, v >_V \quad && \forall v \in V, \\ &b(u(t),q) = 0 && \forall q \in Q, \\ &u(0) = u_0. \end{aligned}$$

The discrete counterpart reads as follows: For almost every t, find $u_h(t) \in V_h$ and $p_h(t) \in Q_h$ such that

$$\begin{aligned} &\frac{d}{dt}(u_h(t),v) + a(u_h(t),v) + b(v,p_h(t)) = {}_{V'}\!< f, v >_V \quad && \forall v \in V_h, \\ &b(u_h(t),q) = 0 && \forall q \in Q_h, \\ &u_h(0) = u_{0,h}, \end{aligned}$$

where $u_{0,h} \in V_h$ is an approximation of u_0. The error equations are as follows:

$$\begin{aligned} \frac{d}{dt}(u(t) - u_h(t), v) + a(u(t) - u_h(t), v) + b(v, p(t) - p_h(t)) = 0 \quad \forall v \in V_h, \\ b(u(t) - u_h(t), q) = 0 \quad \forall q \in Q_h. \end{aligned}$$

In the next lemma, we shall use the kernel of the discrete operator associated to b, namely, $K_h = \{v_h \in V_h : b(v_h, q_h) = 0 \ \forall q_h \in Q_h\}$.

LEMMA 6. *Let us suppose that the form a is elliptic in V, that is,* (16) *holds for any $v \in V$. Let (u,p) and (u_h,p_h) be the solutions of problems* (15) *and* (19)*, respectively. If the time derivatives of u and u_h are bounded in $L^2(]0,T[;H)$, then the following estimate holds true:*

$$\begin{aligned} \max_{t\in[0,T]} ||u(t) - u_h(t)||_H^2 + \alpha \int_0^T ||u(t) - u_h(t)||_V^2 &\le ||u_0 - u_{0,h}||_H^2 \\ &+ C\left(\int_0^T ||u(t) - \Pi u(t)||_H^2 \, dt\right)^{1/2} + C\int_0^T ||u(t) - \Pi u(t)||_V^2 \, dt \\ &+ \int_0^T b(\Pi u(t) - u_h(t), p(t)) \, dt, \end{aligned} \tag{38}$$

where Π is an operator from V^+ to the discrete kernel K_h.

Proof. From the ellipticity and the error equations we get

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}||u(t) - u_h(t)||_H^2 + \alpha||u(t) - u_h(t)||_V^2 \\ &\quad = \left(\frac{\partial}{\partial t}\Big(u(t) - u_h(t)\Big), u(t) - u_h(t)\right) + a(u(t) - u_h(t), u(t) - u_h(t)) \\ &\quad = \left(\frac{\partial}{\partial t}\Big(u(t) - u_h(t)\Big), u(t) - \Pi u(t)\right) + a(u(t) - u_h(t), u(t) - \Pi u(t)) \\ &\qquad - b(\Pi u(t) - u_h(t), p(t) - p_h(t)). \end{aligned} \tag{39}$$

From our assumption on the time derivative of u and u_h and the fact that $\Pi u(t) \in K_h$, we easily get the result integrating from 0 to T. ∎

Remark 2. From the previous proof it follows that the first constant C appearing on the right-hand side of (38) is related to the bound of the time derivatives of u and u_h in $L^2(]0,T[;H)$. This is a regularity assumption which is in general not too strong if $f \in L^2(]0,T[;H)$. On the other hand, if the time derivatives of u and u_h are only in $L^2(]0,T[;V')$, then a result similar to (38) can be obtained but with the V norm instead of the H one in the second term in the right-hand side.

In order to obtain a rate of convergence from the previous lemma, we consider $V^+ \subseteq V$ and $Q^+ \subseteq Q$ such that the solution to (15) satisfies $u \in L^2(]0,T[;V^+)$ and $p \in L^2(]0,T[;Q^+)$ if $f \in L^2(]0,T[;H)$ with the a priori estimate $\|u\|_{L^2(V^+)} + \|p\|_{L^2(Q^+)} \leq C\|f\|_{L^2(H)}$. Then we introduce the following definitions (see [7]).

DEFINITION 7. *We say that the* weak approximability *property of the space Q^+ holds, if there exists $\rho_1(h)$, tending to zero as h goes to zero, such that*

$$\sup_{v_h \in K_h} \frac{b(v_h,p)}{||v_h||_V} \leq \rho_1(h)||p||_{Q^+} \quad \forall p \in Q^+.$$

Moreover, we also need an approximability property of the kernel; hence, we define the following *strong approximability* of V^+.

DEFINITION 8. *The* strong approximability *of V^+ with respect to Π is satisfied if there exists $\rho_2(h)$ tending to zero as h goes to zero, such that for all $u \in V^+$ it holds that*

$$\|u - \Pi u_h\|_V \leq \rho_2(h)\|u\|_{V^+}.$$

If the above definitions are fulfilled, then the following theorem holds true.

THEOREM 9. *Let us assume that the form a is elliptic in V and that Definitions 7 and 8 hold true. Moreover, let us denote by $\rho_3(h)$ a function going to zero as h tends to zero such that $||u - \Pi u||_H \leq \rho_3(h)||u||_{V^+}$. Let (u,p) and (u_h,p_h) be the solutions of problems* (15) *and* (19)*, respectively. If the time derivatives of u and u_h are bounded in $L^2(]0,T[;H)$, then we have the following error estimate:*

$$\begin{aligned} ||u-u_h||_{L^\infty(H)} + ||u-u_h||_{L^2(V)} &\leq ||u_0 - u_{0,h}||_H \\ &\quad + C\left(\sqrt{\rho_3(h)||f||_{L^2(H)}} + (\rho_1(h)+\rho_2(h))\,||f||_{L^2(H)}\right). \end{aligned} \tag{40}$$

Remark 3. Since $V \subseteq H$ with continuous embedding, we could take $\rho_3(h) = \rho_2(h)$ in the previous theorem. However, we prefer to keep separated the two functions, since in general the approximation in H might be of higher order than in V.

From estimate (40), it is clear that, in order to derive an optimal order of convergence, we need a good balance among the ρ_i, $i = 1,2,3$. We shall discuss this issue in more detail in Example 5.

Going back to the proof of the previous theorem, we notice that, taking in (39) Π as the H projection onto the discrete kernel K_h, we obtain the following different estimate, provided u belongs to $L^\infty(V)$ (see [14] for a similar approach to the analysis of the Navier–Stokes equations):

$$\begin{aligned} &||u-u_h||_{L^\infty(H)} + ||u-u_h||_{L^2(V)} \\ &\qquad \leq ||u_0 - u_{0,h}||_H + C\left(\rho_4(h)||u||_{L^\infty(V)} + \rho_2(h)\|u\|_{L^2(V^+)} + \rho_1(h)||p||_{L^2(Q^+)}\right), \end{aligned} \tag{41}$$

where $\rho_4(h)$, going to zero as h tends to zero, is such that

$$||u - \Pi u||_H \leq \rho_4(h)||u||_V. \tag{42}$$

We notice that this estimate is not fully satisfactory either. Indeed, in some cases, in order to get a good bound for $\rho_4(h)$, one should use an inverse inequality, leading to stronger assumptions on the mesh sequence.

We are now ready to present the second estimate of this section. Let $\Pi : V^+ \times Q^+ \to K_h$ and $P : V^+ \times Q^+ \to Q_h$ denote the elliptic projections; that is, for $u \in V^+$ and $p \in Q^+$,

$$\begin{array}{ll} a(\Pi(u,p),v) + b(v,P(u,p)) = a(u,v) + b(v,p) & \forall v \in V_h, \\ b(\Pi(u,p),q) = 0 & \forall q \in Q_h. \end{array} \tag{43}$$

In order to give sense to (43), we make the assumption that the approximation to the steady equation associated with problem (15) is stable in the sense of [13].

LEMMA 10. *Let (u,p) and (u_h,p_h) be the solutions of problems* (15) *and* (19)*, respectively. Assume that the form a is uniformly elliptic in the discrete kernel; that is,* (16) *is satisfied for any $v \in K_h$ with α independent of h. Then we have*

$$\begin{aligned} &\max_{t\in[0,T]} ||u(t)-u_h(t)||_H^2 + \alpha \int_0^T ||u(t)-u_h(t)||_V^2 \, dt \le ||\Pi(u_0,0)-u_{0,h}||_H^2 \\ &\quad + \max_{t\in[0,T]} ||u(t)-\Pi(u(t),p(t))||_H^2 \\ &\quad + \int_0^T \left(\left\| \frac{\partial}{\partial t}(u(t)-\Pi(u(t),p(t))) \right\|_H^2 + ||u(t)-\Pi(u(t),p(t))||_V^2 \right) dt, \end{aligned} \tag{44}$$

where Π is the elliptic projector mapping $V^+ \times Q^+$ into K_h (see (43)*).*

Proof. Using the ellipticity in the discrete kernel we have

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}||\Pi(u(t),p(t))-u_h(t)||_H^2 + \alpha||\Pi(u(t),p(t))-u_h(t)||_V^2 \\ \le -\left(\frac{\partial}{\partial t}\Big(u(t)-\Pi(u(t),p(t))\Big), \Pi(u(t),p(t))-u_h(t)\right) \\ - a(u(t)-\Pi(u(t),p(t)), \Pi(u(t),p(t))-u_h(t)) \\ - b(\Pi(u(t),p(t))-u_h(t), p(t)-p_h(t)). \end{aligned}$$

In the last term, p_h can be replaced by $P(u,p) \in Q_h$, since $\Pi(u(t),p(t)) - u_h(t) \in K_h$. Then, using the definition of the elliptic projections (see (43)), we get the desired estimate. ∎

The following theorem gives the convergence result.

THEOREM 11. *Let the hypotheses of Lemma* 10 *be satisfied, and suppose that the* strong approximability *property (see Definition* 8*) is fulfilled. Then, we have the estimate*

$$\begin{aligned} &||u-u_h||_{L^\infty(H)} + \alpha||u-u_h||_{L^2(V)} \\ &\quad \le ||\Pi(u_0,0)-u_{0,h}||_H + \rho_4(h)\left(||u||_{L^\infty(V)} + \left\| \frac{\partial u}{\partial t} \right\|_{L^2(V)} \right) + \rho_2(h)||u||_{L^2(V^+)}, \end{aligned} \tag{45}$$

where $\rho_4(h)$ has been introduced in (42).

Proof. The proof easily follows from the previous lemma, by noticing that the elliptic projection operator Π commutes with the time derivative. ∎

We now present an estimate for the pressure.

THEOREM 12. *Let (u,p) and (u_h,p_h) be the solutions of problems* (15) *and* (19)*, respectively. Let the hypotheses of Lemma* 10 *be satisfied, and suppose that the following discrete inf-sup condition holds with $\beta>0$ independent of h:*

$$\inf_{q_h\in Q_h}\sup_{v_h\in V_h}\frac{b(v_h,q_h)}{||v_h||_V||q_h||_Q}\geq\beta.$$

If there exists $\rho_5(h)$ going to zero as h tends to zero such that

$$||p-P(u,p)||_Q\leq\rho_5(h)||p||_{Q^+}\quad\forall q\in Q^+,$$

then we have the following estimate:

(46)
$$||p-p_h||_{L^2(Q)}\leq C\left(\rho_5(h)||p||_{L^2(Q^+)}+\rho_4(h)\left\|\frac{\partial u}{\partial t}\right\|_{L^2(V)}+||\Pi(u_0,0)-u_{0,h}||_V\right).$$

Proof. For almost any t we have

$$\begin{aligned}\beta||P(u(t),p(t))-p_h(t)||_Q&\leq\sup_{v_h\in V_h}\frac{b(v_h,P(u(t),p(t))-p_h(t))}{||v_h||_V}\\&=\sup_{v_h\in V_h}\frac{b(v_h,P(u(t),p(t))-p(t))-\left(\frac{\partial}{\partial t}\Big(u(t)-u_h(t)\Big),v_h\right)-a(u(t)-u_h(t),v_h)}{||v_h||_V}\\&\leq||p(t)-P(u(t),p(t))||_Q+\left\|\frac{\partial}{\partial t}\Big(u(t)-u_h(t)\Big)\right\|_{V'}+||u(t)-u_h(t)||_V.\end{aligned}$$

In order to conclude the proof we need to estimate the second term. We subtract from the first equation in (43) the first equation in (19) and, taking $v_h\in K_h$, we get

$$\begin{aligned}\left(\frac{\partial}{\partial t}\Big(\Pi(u(t),p(t))-u_h(t)\Big),v_h\right)+a(\Pi(u(t),p(t))-u_h(t),v_h)\\=-\left(\frac{\partial}{\partial t}\Big(u(t)-\Pi(u(t),p(t))\Big),v_h\right).\end{aligned}$$

We take $v_h=\partial(\Pi(u(t),p(t))-u_h(t))/\partial t\in K_h$, and we have

$$\begin{aligned}\left\|\frac{\partial}{\partial t}\Big(\Pi(u(t),p(t))-u_h(t)\Big)\right\|_H^2+\frac{1}{2}\frac{d}{dt}a(\Pi(u(t),p(t))-u_h(t),\Pi(u(t),p(t))-u_h(t))\\\leq\left\|\frac{\partial}{\partial t}\Big(u(t)-\Pi(u(t),p(t))\Big)\right\|_H\left\|\frac{\partial}{\partial t}\Big(\Pi(u(t),p(t))-u_h(t)\Big)\right\|_H.\end{aligned}$$

Integrating over $[0,T]$, we obtain the result in a standard way. ∎

Example 5 (convergence analysis for the approximation to the evolution Stokes problem). Estimate (40) can be used when lowest order elements are used. For instance, if we consider the MINI element (see [2]); then we have $\rho_2(h)=Ch$, $\rho_3(h)=Ch^2$, and $\rho_1(h)$ can be bounded by Ch in a standard way as follows:

$$\sup_{\mathbf{v}_h\in K_h}\frac{b(\mathbf{v}_h,p)}{||\mathbf{v}_h||_{H^1}}=\sup_{\mathbf{v}_h\in K_h}\frac{b(\mathbf{v}_h,p-p^I)}{||\mathbf{v}_h||_{H^1}}\leq Ch||p||_{H^1},$$

where p^I is an approximation of p satisfying $\|p-p^I\|_{L^2} \le Ch\|p\|_{H^1}$. Then, Theorem 9 gives a first order convergence estimate.

Estimate (45) can be used to analyze higher order methods. For instance, when using generalized kth order Hood–Taylor schemes (see [5] and [6]), we have $||\mathbf{u} - \Pi(\mathbf{u},p)||_{L^2} + h||\mathbf{u} - \Pi(\mathbf{u},p)||_{H^1} \le Ch^{k+1}|\mathbf{u}|_{H^{k+1}}$ and Theorem 11 gives a kth order estimate, provided suitable regularity on the solution is assumed, in particular on the time derivative of $\mathbf{u}$. An alternative estimate can be obtained from (41) with no regularity assumptions on $\partial u/\partial t$ but with the need for an inverse inequality. As far as the approximation of the pressure is concerned, the conclusions of Theorem 12 are that $||p - p_h||_{L^2(L^2)}$ is $O(h^k)$, as expected, provided the solution is smooth enough (see (46)).

7. Further considerations on the heat equation in mixed form. In this section we study in more detail the numerical results reported at the end of section 4. We introduce a modified P1 element on criss-cross meshes, which we call P1*, following the notation of [8], and which has a behavior similar to the P1 element with respect to the convergence of eigenmodes. We recall that the criss-cross mesh is constructed by dividing Ω into N-by-N subsquares (macroelements) which are then partitioned into four subtriangles by their diagonals. The elements P1 and P1* present different definitions of both spaces Σ_h and V_h. For the P1* approximation, the space of scalars V_h is made of piecewise constants on the square macroelements and the number of degrees of freedom in Σ_h has been reduced by eliminating the ones corresponding to the centers of the macroelements. The elimination is performed in such a way that the divergences of the elements in Σ_h are constant on each macroelement. We refer the reader to [8] for more details on how to perform the elimination of such degrees of freedom.

To get started, we recall the mixed formulation of the Laplace eigenproblem: Find $\lambda \in \mathbb{R}$ such that there exist $w \in V = L^2_0(\Omega)$ and $\boldsymbol{\sigma} \in \Sigma = H_0(\mathrm{div};\Omega)$ with $w \not\equiv 0$ satisfying

$$\begin{aligned} &(\boldsymbol{\sigma},\boldsymbol{\tau}) + (\mathrm{div}\,\boldsymbol{\tau}, w) = 0 \quad \forall \boldsymbol{\tau} \in \Sigma, \\ &(\mathrm{div}\,\boldsymbol{\sigma}, v) = -\lambda(w,v) \qquad \forall v \in V, \end{aligned} \tag{47}$$

and its numerical approximation with the P1* method: Find $\lambda_h \in \mathbb{R}$ such that there exist $w_h \in V_h$ and $\boldsymbol{\sigma}_h \in \Sigma_h$ with $w_h \not\equiv 0$ satisfying

$$\begin{aligned} &(\boldsymbol{\sigma}_h,\boldsymbol{\tau}) + (\mathrm{div}\,\boldsymbol{\tau}, w_h) = 0 \quad \forall \boldsymbol{\tau} \in \Sigma_h, \\ &(\mathrm{div}\,\boldsymbol{\sigma}_h, v) = -\lambda_h(w_h,v) \quad \forall v \in V_h. \end{aligned} \tag{48}$$

It can be easily shown (in (48), set $w_h = -1/\lambda_h \,\mathrm{div}\,\boldsymbol{\sigma}_h$, which comes from the second equation, into the first equation) that the eigenvalues of (48) correspond to the non-vanishing ones of the following problem: Find $\lambda_h \in \mathbb{R}$ such that there exists $\boldsymbol{\sigma}_h \in \Sigma$ with $\boldsymbol{\sigma}_h \not\equiv 0$ satisfying

$$(\mathrm{div}\,\boldsymbol{\sigma}_h, \mathrm{div}\,\boldsymbol{\tau}) = \lambda_h(\boldsymbol{\sigma}_h,\boldsymbol{\tau}) \quad \forall \boldsymbol{\tau} \in \Sigma_h. \tag{49}$$

In [8] it has been proved and numerically demonstrated that this method does not work. Namely, some *spurious* solutions appear which pollute the numerical spectrum. Here we present the following new result which shows that the only pathology of the method under consideration is the presence of spurious modes; namely, all continuous eigenmodes are correctly approximated.

Let $\Omega =]0,\pi[\times]0,\pi[$; then by separation of variable it is easy to obtain the exact solution to (47):

$$\begin{aligned}\lambda^{mn} &= m^2+n^2, \quad m,n\in\mathbb{N},\ n+m\neq 0,\\ \boldsymbol{\sigma}^{mn}(x,y) &= (m\sin(mx)\cos(ny), n\cos(mx)\sin(nx)),\\ w^{mn} &= -\cos(mx)\cos(ny).\end{aligned}$$

The following proposition and the next corollary give the expressions of the discrete solutions to (49) and (48).

PROPOSITION 13. *Given $N\in\mathbb{N}$, and defined*

$$\begin{aligned}h=\pi/N,\quad \mathrm{cm}=\cos(mh),\quad \mathrm{cn}=\cos(nh),\\ A=(1+1/3\cos(mh)+1/3\cos(nh)+1/3\cos(mh)\cos(nh))(\cos(nh)-\cos(mh)),\\ B_1=\sin(mh)\sin(nh)(4/3+2/3\cos(mh)),\\ B_2=\sin(mh)\sin(nh)(4/3+2/3\cos(nh)),\end{aligned}$$

for $m,n=0,\dots,N-1$, the eigenvalues of scheme (49) *are given by $\lambda_h^{00}=0$,*

(50)
$$\lambda_h^{m0}=\frac{6}{h^2}\frac{1-\cos(mh)}{2+\cos(mh)},\qquad \lambda_h^{0n}=\frac{6}{h^2}\frac{1-\cos(nh)}{2+\cos(nh)},$$
$$\lambda_h^{mn}=\frac{2}{h^2}\frac{4+\mathrm{cm}+\mathrm{cn}-(\mathrm{cm}+\mathrm{cn})^2-\mathrm{cm}\,\mathrm{cn}(\mathrm{cm}+\mathrm{cn})+3\sqrt{A^2+B_1B_2}}{(1+\mathrm{cm}/3+\mathrm{cn}/3+\mathrm{cm}\,\mathrm{cn}/3)(4+\mathrm{cm}+\mathrm{cn})-\sqrt{A^2+B_1B_2}},\qquad mn>0.$$

Setting for $mn>0$,

$$\overline{m}=\sqrt{\frac{A+\sqrt{A^2+B_1B_2}}{B_2}}\sqrt{nm},\qquad \overline{n}=\sqrt{\frac{-A+\sqrt{A^2+B_1B_2}}{B_1}}\sqrt{nm},\tag{51}$$

the eigenfunctions corresponding to (50) *are*

$$\boldsymbol{\sigma}_h^{mn}(x_i,y_j)=\begin{cases}(m\sin(mx_i),0) & \text{if } n=0,\\ (0,n\sin(ny_j)) & \text{if } m=0,\\ (\overline{m}\sin(mx_i)\cos(ny_j),\overline{n}\cos(mx_i)\sin(ny_j)) & \text{if } mn>0.\end{cases}\tag{52}$$

Proof. We provide a sketch of the proof which is mainly a tedious calculation. Considering the reference criss-cross macroelement (based on the square $[0,1]\times[0,1]$), we denote by $\varphi_i(\hat{x},\hat{y})$, $i=1,\dots,5$, the standard continuous piecewise linear functions associated to the nodes represented in Figure 3. It turns out that the eight basis functions for the space Σ_h are

$$\begin{aligned}\psi_1(\hat{x},\hat{y})&=(\varphi_1(\hat{x},\hat{y})+\varphi_5(\hat{x},\hat{y})/4,\varphi_5(\hat{x},\hat{y})/4),\\ \psi_2(\hat{x},\hat{y})&=(\varphi_5(\hat{x},\hat{y})/4,\varphi_1(\hat{x},\hat{y})+\varphi_5(\hat{x},\hat{y})/4),\\ \psi_3(\hat{x},\hat{y})&=(\varphi_2(\hat{x},\hat{y})+\varphi_5(\hat{x},\hat{y})/4,-\varphi_5(\hat{x},\hat{y})/4),\\ \psi_4(\hat{x},\hat{y})&=(-\varphi_5(\hat{x},\hat{y})/4,\varphi_2(\hat{x},\hat{y})+\varphi_5(\hat{x},\hat{y})/4),\\ \psi_5(\hat{x},\hat{y})&=(\varphi_3(\hat{x},\hat{y})+\varphi_5(\hat{x},\hat{y})/4,\varphi_5(\hat{x},\hat{y})/4),\\ \psi_6(\hat{x},\hat{y})&=(\varphi_5(\hat{x},\hat{y})/4,\varphi_3(\hat{x},\hat{y})+\varphi_5(\hat{x},\hat{y})/4),\\ \psi_7(\hat{x},\hat{y})&=(\varphi_4(\hat{x},\hat{y})+\varphi_5(\hat{x},\hat{y})/4,-\varphi_5(\hat{x},\hat{y})/4),\\ \psi_8(\hat{x},\hat{y})&=(-\varphi_5(\hat{x},\hat{y})/4,\varphi_4(\hat{x},\hat{y})+\varphi_5(\hat{x},\hat{y})/4),\end{aligned}$$

where the numbering is taken such that $\psi_{2i-1}(\hat{x},\hat{y})$ and $\psi_{2i}(\hat{x},\hat{y})$ are the two shape functions associated with node i ($i = 1,\dots,4$). Taking $\boldsymbol{\sigma}_h$ as given by (52), it is easy (even if long) to check that the expression for λ_h is the one reported in (50). We acknowledge that, in order to guess the correct expression for (52), we have used Mathematica (see [24]). ∎

COROLLARY 14. *With the same notation as in Proposition* 13*, the solutions* $(\lambda_h, \boldsymbol{\sigma}_h, w_h)$ *of* (48) *are given by* (50), (52)*, and by the following expressions:*

(53)

$$w_h^{m0}|_{K_{ij}} = -\frac{2}{h\lambda_h^{m0}} m \sin\Big(m\frac{h}{2}\Big)\cos\big(mx_{i+\frac{1}{2}}\big),$$

$$w_h^{0n}|_{K_{ij}} = -\frac{2}{h\lambda_h^{0n}} n \sin\Big(n\frac{h}{2}\Big)\cos\big(ny_{j+\frac{1}{2}}\big),$$

$$w_h^{mn}|_{K_{ij}}$$

$$= -\frac{2}{h\lambda_h^{mn}}\Big(\overline{m}\sin\Big(m\frac{h}{2}\Big)\cos\Big(n\frac{h}{2}\Big) + \overline{n}\sin\Big(n\frac{h}{2}\Big)\cos\Big(m\frac{h}{2}\Big)\Big)\cos\big(mx_{i+\frac{1}{2}}\big)\cos\big(ny_{j+\frac{1}{2}}\big),$$

where the last term in (53) *holds for* $mn > 0$ *and* $x_{i+1/2} = x_i + h/2$, $y_{j+1/2} = y_i + h/2$, *and* K_{ij} *is the square of vertices* (x_i, y_j), (x_{i+1}, y_j), (x_{i+1}, y_{j+1}), *and* (x_i, y_{j+1}).

Proof. The proof follows from the expressions for λ_h and $\boldsymbol{\sigma}_h$ given in Proposition 13 and from the formula $w_h = -\operatorname{div}\boldsymbol{\sigma}_h/\lambda_h$. ∎

Let m and n be fixed; then from (50) and (51) we have

$$\lim_{h\to 0}\lambda_h^{mn} = m^2 + n^2 \quad \text{and} \quad \lim_{h\to 0}\overline{m} = m, \quad \lim_{h\to 0}\overline{n} = n,$$

so that it is evident that all continuous eigensolutions are approximated by a suitably chosen discrete one. On the other hand, if we take $m = n = N - 1 = \pi/h - 1$, then

$$\lim_{h\to 0}\lambda_h^{N-1,N-1} = 6,$$

which does not correspond to any continuous eigenvalue of (47). This result is in agreement with the numerical experiments presented in [8], where, in particular, the presence of a sequence of spurious eigenvalues converging to 6 was apparent. For a better understanding of the behavior of the discrete eigenvalues, in Figure 6 we present the graph of λ_h^{mn} as a function of m, n when $N = 100$. The obtained surface is similar to the one obtained in [9] in an analogue situation. We now present the main result of this section, which is closely related to the numerical tests reported in section 4. In that section, we showed two examples in order to demonstrate that the P1 method provides results which are acceptable in one case (*regular* right-hand side) and awful in the other (oscillatory right-hand side). Here we theoretically substantiate those tests, proving that, in general, the P1* methods works if the right-hand side is regular enough. Our theorem is proved under the general hypothesis that any continuous eigensolution to (47) is well approximated by the numerical scheme, no matter whether other spurious solutions are present. For this reason we analyze the P1* method, since to our best knowledge estimates like (50), (52), and (53) are not available for the P1 method. On the other hand, we chose to perform the numerical tests using the P1 method (which seems more natural), even though the P1* method would behave similarly.

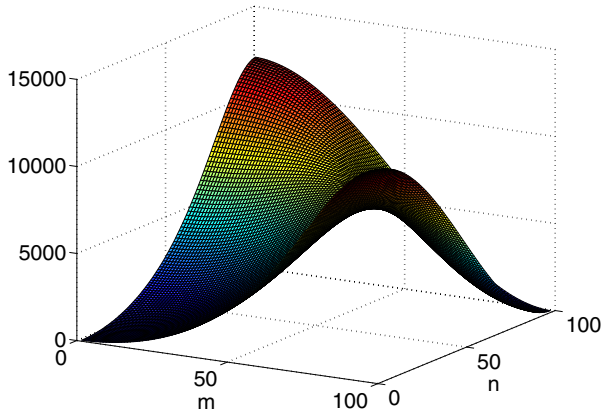

FIG. 6. *Eigenvalues corresponding to formula* (50) *as functions of* m *and* n *when* $N = 100$.

THEOREM 15. *Let us consider the* $P1^*$ *element for the approximation of the heat equation as in scheme* (12)*, and let* $g \in L^\infty(]0,T[;L^2(\Omega))$ *and* $u_0 \in L^2(\Omega)$.

Then, if $(\boldsymbol{\sigma}, u)$ *is the continuous solution and* $(\boldsymbol{\sigma}_h, u_h)$ *the discrete one, we have that* u_h *converges to* u *in* $L^\infty([0,T];L^2(\Omega))$.

Proof. The regularity assumptions on g and u_0 can be written in a more convenient way as follows: For any $\varepsilon > 0$ there exists N such that

$$\sum_{i>N}(g(t),w_i)^2 < \varepsilon, \quad \forall t \in [0,T], \qquad \sum_{i>N}(u_0,w_i)^2 < \varepsilon, \tag{54}$$

where w_i denote the eigenfunctions of problem (47).

The following structure for the continuous and discrete solutions of the mixed heat equation holds:

$$\begin{aligned} u(t) &= \sum_{i=1}^{\infty}\left((u_0,w_i)e^{-\lambda_i t} + \int_0^t (g(s),w_i)e^{-\lambda_i(t-s)}\,ds\right)w_i, \\ u_h(t) &= \sum_{i=1}^{\infty}\left((u_0,w_{i_h})e^{-\lambda_{i,h} t} + \int_0^t (g(s),w_{i,h})e^{-\lambda_{i,h}(t-s)}\,ds\right)w_{i,h}, \end{aligned} \tag{55}$$

where λ_i and w_i (resp., $\lambda_{i,h}$ and $w_{i,h}$ for $i = 1,\ldots,\mathcal{N}(h)$) denote continuous (resp., discrete) eigensolutions of problem (47) (resp., (48)). According to the analysis presented at the beginning of this section (see, in particular, (50) and (53)), they can be ordered in such a way that for any i,

$$\lambda_{i,h} \to \lambda_i \quad \text{and} \quad w_{i,h} \to w_i \quad \text{pointwise in } \Omega \tag{56}$$

as h goes to zero. We explicitly note that in the previous notation we have associated with any eigenvalue λ_i (resp., $\lambda_{i,h}$) a one-dimensional eigenspace spanned by the eigenfunction w_i (resp., $w_{i,h}$); this means in particular that it might be $\lambda_i = \lambda_j$ (and/or, resp., $\lambda_{i,h} = \lambda_{j,h}$) for some $i \neq j$. Moreover, we shall use the orthogonalities $(w_i, w_j) = 0$ (resp., $(w_{i,h}, w_{j,h})$) for $i \neq j$.

The aim of our proof is to show that for any $\varepsilon > 0$ we have $||u(t) - u_h(t)||_0 < \varepsilon$ for any $t \in [0,T]$ when h is small enough. Using (55), we have

$$||u(t) - u_h(t)||_0^2 \leq T_1 + T_2 + T_3 + T_4$$

with

$$T_1 = \sum_{i=N+1}^{\infty} \left((u_0, w_i)^2 e^{-2\lambda_i t} + \int_0^t (g(s), w_i)^2 e^{-2\lambda_i (t-s)}\, ds \right),$$

$$T_2 = \sum_{i=N+1}^{\mathcal{N}(h)} \left((u_0, w_{i,h})^2 e^{-2\lambda_{i,h} t} + \int_0^t (g(s), w_{i,h})^2 e^{-2\lambda_{i,h} (t-s)}\, ds \right),$$

$$T_3 = \left\| \sum_{i=1}^{N} \left((u_0, w_i) w_i e^{-\lambda_i t} - (u_0, w_{i,h}) w_{i,h} e^{-\lambda_{i,h} t} \right) \right\|_0^2,$$

$$T_4 = \int_0^t \left\| \sum_{i=1}^{N} \left((g(s), w_i) w_i e^{-\lambda_i (t-s)} - (g(s), w_{i,h}) w_{i,h} e^{-\lambda_{i,h} (t-s)} \right) \right\|_0^2 ds.$$

Given $\varepsilon > 0$, thanks to the regularity hypotheses (54), we can choose N such that $T_1 < \varepsilon$. The convergence of the eigenvalues and eigenvectors (56) gives that, for h small enough, we also have $T_3 < \varepsilon$ and $T_4 < \varepsilon$. It remains to estimate T_2, which we do now. We shall show that $\sum_{i>N} (u_0, w_{i,h})^2$ can be bounded by 2ε if h is small enough. The term involving $g(s)$ can be handled in the same way and, putting things together, this is what we need in order to get $T_2 < \varepsilon$. The term $\sum_{i>N} (u_0, w_{i,h})^2$ can indeed be estimated in the following way. We have

$$\sum_{i=1}^{N} (u_0, w_{i,h})^2 + \sum_{i=N+1}^{\mathcal{N}(h)} (u_0, w_{i,h})^2 = \sum_{i=1}^{\mathcal{N}(h)} (u_0, w_{i,h})^2$$
$$\leq \sum_{i=1}^{\infty} (u_0, w_i)^2 = \sum_{i=1}^{N} (u_0, w_i)^2 + \sum_{i=N+1}^{\infty} (u_0, w_i)^2 \leq \sum_{i=1}^{N} (u_0, w_i)^2 + \varepsilon.$$

From the convergence of the eigenvectors (56), we have, for h small enough,

$$\sum_{i=1}^{N} (u_0, w_{i,h})^2 - \sum_{i=1}^{N} (u_0, w_i)^2 \leq \varepsilon, \qquad \text{and the bound} \qquad \sum_{i=N+1}^{\mathcal{N}(h)} (u_0, w_{i,h})^2 \leq 2\varepsilon. \qquad \square$$

Remark 4. The proof of the previous theorem strongly relies on (54) and (56). In particular, it shows that any scheme which provides convergent eigenmodes for problem (47) (no matter whether spurious solutions are present) can be successfully applied to the approximation of the heat equation in the case of smooth data (in the sense of (54)).

DESIGN OF ABSORBING BOUNDARY CONDITIONS FOR SCHRÖDINGER EQUATIONS IN $\mathbb{R}^{d*}$

JÉRÉMIE SZEFTEL†

Abstract. We construct a family of absorbing boundary conditions for the linear Schrödinger equation on curved boundaries in any dimension which are local both in space and time. We give a convergence result and show that the corresponding initial boundary value problems are well posed. We also prove the nonlinear Schrödinger equation with the absorbing boundary conditions of the linearized problem to be well posed. We finally present numerical results both for the linear and the nonlinear case.

Key words. Schrödinger equation, transparent operator, pseudodifferential calculus, absorbing boundary conditions, well-posedness

1. Introduction.

The Schrödinger equation on the whole space arises in particular in quantum mechanics and, with some additional nonlinear term, models the propagation of a laser beam. Numerical computations of this equation are therefore often needed. Although the problem is defined in the whole space, it is often sufficient to know the solution only on a bounded domain: the domain of interest. An artificial domain which includes this region of interest is then defined. Inside the domain the equations are discretized in the usual way but there remains the question of the choice of reliable boundary conditions on the artificial boundary. To reduce the computational cost, the numerical domain must be chosen to be slightly larger than the region of interest. Thus the boundary conditions have to be well posed and accurate to be able to approximate the restriction of the solution to the domain of interest.

Several strategies have been developed to find boundary conditions that minimize the reflection of the solution at the artificial boundary. These absorbing boundary conditions have been constructed for hyperbolic problems [12] and parabolic problems [14] with success using pseudodifferential calculus. This is the strategy we develop in this paper for the linear Schrödinger equation.

Engquist and Majda [12] first found a sequence of absorbing boundary conditions for the case of the wave equation in a half space which implies the convergence toward the restriction to this half-space of the solution in the whole space. They also implemented a strategy based on a pseudodifferential factorization of the operator allowing them to derive absorbing boundary conditions for linear hyperbolic equations with variable coefficients.

For linear parabolic equations, Halpern and Rauch [14] also used a pseudodifferential factorization of the operator to construct a family of absorbing boundary conditions on a curved boundary, and they identified the various terms geometrically. In [10], Dubach implemented these boundary conditions in $\mathbb{R}^2$ on a disk.

In the case of the reaction diffusion equations, we used the conditions designed for the linearized heat equation, we proved them to be well posed for the nonlinear

problem and, through numerical experiments, that they were well suited for reaction-diffusion equations (see [27]).

In the case of the linear Schrödinger equation, several authors [6], [8], [25], [4], [5], [22], [3] approximated the transparent condition (the boundary condition satisfied by the exact solution) with a finite difference scheme in one space dimension. The authors in [26], [17], [9], [13], and [1] constructed absorbing boundary conditions for the half-space case, and the author in [9] proved with the Laplace transform in time and Fourier transform in the directions of the boundary that they are well posed. Antoine and Besse [2] wrote absorbing boundary conditions involving the nonlocal operator in time $\sqrt{\partial_t}$ in the case of a curved boundary in two dimensions, and they identified the various terms geometrically. In [7], the authors tested numerically some qualitative properties of absorbing boundary conditions designed for the linear Schrödinger equation on a nonlinear Schrödinger equation.

We extend here all these works for the linear and nonlinear Schrödinger equations. As in [12], we rely on the theory of reflection of singularities we derived in a related paper [28]. The present work consists of two parts. First, we study the linear Schrödinger equation. We recall the expression of the transparent operator obtained in [28] through a result of reflection of singularities for the Schrödinger equation, and we identify geometrically the first two terms in the asymptotic expansion. The transparent condition is not very manageable for numerical simulation and we approximate it with absorbing boundary conditions that are easy to implement. We justify the choice of these absorbing boundary conditions in the case of the half-space with a convergence result and we generalize these conditions for open sets with curved boundary. Then we show the Schrödinger equation to be well posed with these conditions. Finally, we present numerical results in the linear case relying on the optimization of the reflection coefficient.

Second, we study the application to the nonlinear case. We prove the well-posedness of the nonlinear problem with the boundary conditions of the linear one: these boundary conditions have never been studied in the Schrödinger literature. We define an iterative scheme, and we use the estimates of the linear nonhomogeneous problem to show the convergence of the scheme. We finally present numerical results related to the propagation of solitons.

2. The linear Schrödinger equation. We try to approximate the restriction to a bounded region of the solution u_{ex} of the Cauchy problem for the Schrödinger operator:

$$\begin{cases} (i\partial_t + \Delta)u_{ex} = 0 \quad \text{in } \mathbb{R}_t^+ \times \mathbb{R}^d, \\ u_{ex}|_{t=0} = u_0. \end{cases} \tag{2.1}$$

2.1. Absorbing boundary conditions for the Schrödinger equation.

2.1.1. The transparent operator for the Schrödinger equation. We adapt to the Schrödinger equation the work of Engquist and Majda on absorbing boundary conditions for hyperbolic equations [12] and the work of Halpern and Rauch on absorbing boundary conditions for parabolic equations [14]. We first factorize the Schrödinger operator near the boundary of the numerical domain through Nirenberg's method, as in the case of hyperbolic [12] and parabolic [14] equations. We deduce the transparent operator from this factorization using a result of reflection of singularities. This is an important result in itself and was addressed in a separate paper [28].

Let Ω be a bounded convex open subset of $\mathbb{R}^d$ which together with its boundary S is an embedded smooth submanifold with boundary. Let $L = i\partial_t + \Delta$ be the

Schrödinger operator on $\mathbb{R}^d$, u_0 be in $L^2(\mathbb{R}^d)$ with compact support in Ω, and u_{ex} in $C^0(\mathbb{R}_t^+, L^2(\mathbb{R}^d))$ be the unique solution of (2.1).

We consider the Dirichlet problem for L. Let h be in $C_0^\infty(\mathbb{R}\times S)$ so that $h\equiv 0$ for $t\le 0$, and let v be the unique solution of

$$\begin{cases} Lv = 0 \text{ in } \mathbb{R}\times\Omega, \\ v|_{\mathbb{R}\times S} = h, \\ v = 0 \text{ for } t\le 0 \text{ in } \Omega. \end{cases} \tag{2.2}$$

Let ν_Ω be the unit outward pointing normal. We call $N_\Omega : h \to \partial_{\nu_\Omega} v|_S$ the Dirichlet-to-Neumann map for the open set Ω and the operator L.

In $\widetilde{\Omega} = \text{ext}(\Omega)$, u_{ex} is a solution of

$$\begin{cases} Lu_{ex} = 0 \text{ in } \mathbb{R}\times\widetilde{\Omega}, \\ u_{ex} = 0 \text{ for } t\le 0. \end{cases} \tag{2.3}$$

The definition of $N_{\tilde\Omega}$ therefore implies $\partial_{\nu_\Omega} u_{ex} = -N_{\tilde\Omega}(u_{ex}|_{\mathbb{R}\times S})$. Thus u_{ex} is a solution of

$$\begin{cases} Lu_{ex} = 0 \text{ in } \mathbb{R}^+\times\Omega, \\ \partial_{\nu_\Omega} u_{ex} = -N_{\tilde\Omega} u_{ex} \text{ in } \mathbb{R}^+\times S, \\ u_{ex} = u_0 \text{ at } t = 0. \end{cases} \tag{2.4}$$

As in [21], for any even integer r, we define the inhomogeneous Sobolev space,

$$\begin{aligned} H^{r,\frac{r}{2}}(]0,T[\times\Omega) = \{u\in\mathcal{D}'(]0,T[\times\Omega)/\partial_t^l\partial_x^\alpha u \in L^2(]0,T[\times\Omega) \\ \forall(l,\alpha), 2l+|\alpha|\le r\}, \end{aligned} \tag{2.5}$$

and extend it for $r\ge 0$ by interpolation. $u_{ex}|_{\mathbb{R}^+\times\Omega}$ is the unique solution of (2.4).

LEMMA 1. *Let u_0 be in $H^4(\mathbb{R}^d)$ with compact support in Ω and $T>0$. There exists a unique solution w of* (2.4) *in $H^{4,2}(]0,T[\times\Omega)$.*

Proof. The extension of u_0 by 0 outside Ω is in $H^4(\mathbb{R}^d)$ and we still call it u_0. The solution u_{ex} of (2.1) is in $H^{4,2}(]0,T[\times\mathbb{R}^d)$ and taking $w = u_{ex}|_{\mathbb{R}^+\times\Omega}$ imply the existence.

Let w be a solution of (2.4) in $H^{4,2}(]0,T[\times\Omega)$ and let $h = w|_{\mathbb{R}^+\times S}$. The results in [21] imply that h is in $H^{7/2,7/4}(]0,T[\times S)$ and satisfies $h|_{t=0} = \partial_t h|_{t=0} = 0$, and that there exists a unique solution v in $H^{2,1}(]0,T[\times\widetilde{\Omega})$ of (2.2), where $\widetilde{\Omega}$ replaces Ω. Multiplying (2.2) by $\hat v$, taking the imaginary part, and integrating on $\widetilde{\Omega}$ in space and on $]0,T'[$ in time,

$$\|v(T',.)\|^2_{L^2(\Omega)} + \int_0^{T'} [\partial_{\nu_{\tilde\Omega}} v, v] = 0, \tag{2.6}$$

where $0\le T'\le T$, and $[.,.]$ denotes the Hermitian product in $L^2(S)$. Multiplying (2.4) by $\hat w$, taking the imaginary part, and integrating on Ω in space and on $]0,T'[$ in time,

$$\|w(T',.)\|^2_{L^2(\Omega)} - \|u_0\|^2_{L^2(\Omega)} - \int_0^{T'} [N_{\tilde\Omega} w, w] = 0. \tag{2.7}$$

As $w|_{\mathbb{R}^+\times S} = w|_{\mathbb{R}^+\times S} = h$ and $\partial_{\nu_{\tilde\Omega}} v = N_{\tilde\Omega} h$ by definition of $N_{\tilde\Omega}$,

$$\int_0^{T'} [\partial_{\nu_{\tilde\Omega}} v, v] = \int_0^{T'} [N_{\tilde\Omega} w, w],$$

and thus $\int_0^{T'} [N_{\tilde\Omega} w, w] \leq 0$ by (2.6), which implies for all $0 \leq T' \leq T$

$$\|w(T', .)\|^2_{L^2(\Omega)} \leq \|u_0\|^2_{L^2(\Omega)} \tag{2.8}$$

in view of (2.7). (2.8) implies the uniqueness result. □

We first show that $N_{\tilde\Omega}$ is a pseudodifferential operator and compute the first two terms of its symbol. For this we use a change of coordinates which splits the normal coordinate from the tangential ones in L. We recall the expression of the Laplace–Beltrami operator for the Riemannian metric $g = \sum g_{ij} dx_i \otimes dx_j$,

$$\Delta_g v = \sum_{i,j} (\det g)^{-\frac{1}{2}} \partial_{x_i} ((\det g)^{\frac{1}{2}} g^{ij} \partial_{x_j} v),$$

where $g^{ij} = (g^{-1})_{i,j}$. Therefore $L = i\partial_t + \Delta_g$ with g being the canonical scalar product on $\mathbb{R}^d$. In geodesic normal coordinates, g has the form

$$g = (dx_d)^2 + \sum_{\alpha,\beta=1}^{d-1} g_{\alpha\beta} dx_\alpha dx_\beta$$

(i.e., $g_{id} = 0$ for $i = 1, \ldots, d-1$, and $g_{dd} = 1$), and

$$\Delta_g v = \rho^{-1} \partial_{x_d} (\rho \partial_{x_d} v) + \sum_{\alpha,\beta=1}^{d-1} \rho^{-1} \partial_{x_\alpha} (\rho g^{\alpha\beta} \partial_{x_\beta} v),$$

where $\rho = (\det g)^{1/2}$ (with the analyst's sign convention for Δ_g). With the standard notation $D \equiv -i\nabla \equiv (D_1, \ldots, D_d) \equiv (D', D_d)$, the operator L takes the form

$$L = -D_d^2 + i\rho^{-1} \partial_{x_d} \rho D_d + \sum_{\alpha,\beta=1}^{d-1} \rho^{-1} \partial_\alpha (\rho g^{\alpha\beta}) i D_\beta - \sum_{\alpha,\beta=1}^{d-1} g^{\alpha\beta} D_\alpha D_\beta - D_t.$$

Lascar [18] introduces a pseudodifferential algebra well suited to the Schrödinger equation. The symbol class $S^m_{Sch}(\mathbb{R}_t \times \mathbb{R}^d_x)$ is defined by

$$|\partial^\alpha_{t,x} \partial^\beta_{\tau,\xi} p(t, x, \tau, \xi)| \leq C_{\alpha,\beta} (1 + \tau^2 + |\xi|^4)^{\frac{m - 2\beta_\tau - |\beta_\xi|}{4}}. \tag{2.9}$$

Remark. Antoine and Besse [2] use this algebra to compute N_Ω.

We will give an approximation of N_Ω by an operator of $OpS^1_{Sch}(\mathbb{R}_t \times S)$.

Let I be the first fundamental form for the metric g restricted to S. I is given by

$$I(x')(\xi', \xi') = \sum_{\alpha,\beta=1}^{d-1} g_{\alpha\beta} \xi_\alpha \xi_\beta.$$

We define the glancing region $\mathcal{G}$, the hyperbolic region $\mathcal{H}$, and the elliptic region $\mathcal{E}$:

$$\mathcal{G} = \{(t, (x', 0), \tau, \xi') \in T^*(\mathbb{R}_t \times S)/\tau + I(x')(\xi', \xi') = 0\}, \tag{2.10}$$

$$\mathcal{H} = \{(t,(x',0),\tau,\xi') \in T^*(\mathbb{R}_t \times S)/\tau + I(x')(\xi',\xi') < 0\}, \tag{2.11}$$

$$\mathcal{E} = \{(t,(x',0),\tau,\xi') \in T^*(\mathbb{R}_t \times S)/\tau + I(x')(\xi',\xi') > 0\}. \tag{2.12}$$

The following result is proved in [28] using Nirenberg's procedure of factorization (see [23]).

PROPOSITION 1. *Suppose geodesic normal coordinates are introduced as above. Then there are tangential pseudodifferential operators $A(x,D_t,D_{x'})$ and $B(x,D_t,D_{x'})$ in $C^\infty(]-\varepsilon,\varepsilon[_{x_d}, OpS^1_{Sch}(T^*(\mathbb{R}_t\times S)\backslash\mathcal{G}))$ with symbols*

$$A(x,\tau,\xi') \sim \sum_{j\geq 0} A_{1-j}(x,\tau,\xi'),$$
$$B(x,\tau,\xi') \sim \sum_{j\geq 0} B_{1-j}(x,\tau,\xi')$$

with A_k and B_k satisfying $A_k(x,\lambda^2\tau,\lambda\xi') = \lambda^k A_k(x,\tau,\xi')$ and $B_k(x,\lambda^2\tau,\lambda\xi') = \lambda^k B_k(x,\tau,\xi')$ for all $\lambda > 0$ such that

$$\begin{aligned} &L = -(D_{x_d}+A)(D_{x_d}+B) \ \textit{mod}\ C^\infty(]-\varepsilon,\varepsilon[_{x_d}: OpS^{-\infty}_{Sch}(T^*(\mathbb{R}_t\times S)\backslash\mathcal{G})),\\ &B_1 \in i\mathbb{R}^+ \textit{ in } \mathcal{E} \textit{ and } B_1 \in \mathbb{R}^+ \textit{ in } \mathcal{H}. \end{aligned} \tag{2.13}$$

We compute B_1 and B_0:

$$\begin{aligned}(D_{x_d}+A)(D_{x_d}+B) &= D^2_{x_d} + (A+B)D_{x_d} + AB + [D_{x_d},B]\\ &\sim D^2_{x_d} + (A+B)D_{x_d} - i\frac{\partial B}{\partial x_d} + \sum(\partial^\alpha_{\tau,\xi'}A)(D^\alpha_{t,x'}B)/\alpha!.\end{aligned}$$

Comparing with the expression of L, we identify

$$\begin{aligned} B_1 &= \left(-\tau - \sum_{\alpha,\beta} g^{\alpha\beta}\xi_\alpha\xi_\beta\right)^{\frac{1}{2}},\\ B_0 &= -i\frac{\rho^{-1}\partial_{x_d}\rho}{2} + \frac{i\sum \rho^{-1}\partial_\alpha(\rho g^{\alpha\beta})\xi_\beta + D_{x_d}B_1 - \sum \partial_{\xi_\alpha}B_1 D_{x_\alpha}B_1}{2B_1}. \end{aligned} \tag{2.14}$$

The following proposition allows us to compute the Dirichlet-to-Neumann map. It is proved in [28] using a result of reflection of singularities for Schrödinger's equation.

PROPOSITION 2. *Let $N_{\tilde\Omega}$ be the Dirichlet-to-Neumann map for the open set $\widetilde\Omega$ and let B be the operator appearing in* (2.13). *If Ω is convex, then $N_{\tilde\Omega} = -iB + OpS^{-\infty}_{Sch}(T^*(\mathbb{R}_t\times S)\backslash\mathcal{G})$.*

Remark. Antoine and Besse [2] proved the previous factorization in the two-dimensional case, and they formally wrote $N_{\tilde\Omega} = -iB$.

Proposition 2 shows that $N_{\tilde\Omega}$ is a pseudodifferential operator, and we computed the first two terms of its symbol. Consider the Schrödinger operator L_0 on the Riemannian product manifold $S\times\mathbb{R}^+_{x_d}$ with metric equal to $g_S + g_{\mathbb{R}} = g_S + (dx_d)^2$. Then $L_0 = i\partial_t + \Delta_S + \partial^2_d$. For this operator, $N_0^2 = -i\partial_t - \Delta_S$, where N_0 is the Dirichlet-to-Neumann map for L_0 and $S\times\mathbb{R}^+_{x_d}$. (2.14) gives a pseudodifferential asymptotic expansion of N_0:

$$\sigma((-i\partial_t - \Delta_S)^{\frac{1}{2}}) = \sigma(N_0) = -iB_1 + \frac{\sum \rho^{-1}\partial_\alpha(\rho g^{\alpha\beta})\xi_\beta + i\sum \partial_{\xi_\alpha}B_1 D_{x_\alpha}B_1}{2B_1} + S^{-1}_{Sch};$$

thus we obtain

$$\sigma(N_{\tilde{\Omega}}) = \sigma((-i\partial_t - \Delta_S)^{\frac{1}{2}}) - i\frac{D_{x_d}B_1}{2B_1} - \frac{\rho^{-1}\partial_{x_d}\rho}{2} + S_{Sch}^{-1}. \tag{2.15}$$

The geometrical interpretation in [14] remains. Let H be the mean curvature, and let I and II be the two first fundamental forms for the metric g restricted to S. H and II are given by

$$H = \frac{1}{d-1}\rho^{-1}\partial_d\rho, \text{ and } II(\xi',\xi') = -\frac{1}{2}\sum_{\alpha,\beta=1}^{d-1}\partial_{x_d}g^{\alpha\beta}\xi_\alpha\eta_\beta.$$

Then the proposition follows.

PROPOSITION 3. *The symbol of $N_{\tilde{\Omega}}$ is given by*

$$\sigma(N_{\tilde{\Omega}}) = \sigma((-i\partial_t - \Delta_S)^{\frac{1}{2}}) - \frac{d-1}{2}H + \frac{II(\xi',\xi')}{2(\tau + I(\xi',\xi'))} + S_{Sch}^{-1}.$$

Remark. This is a generalization of the result obtained by Antoine and Besse [2] in two dimensions.

2.1.2. A sequence of absorbing boundary conditions for the half-space. Having in mind (2.4), we solve the problem

$$\begin{cases} Lu_{app} = 0 & \text{in } \mathbb{R}^+ \times \Omega, \\ \partial_{\nu_\Omega} u_{app} = F u_{app} & \text{in } \mathbb{R}^+ \times S, \\ u_{app} = u_0 & \text{at } t = 0, \end{cases} \tag{2.16}$$

where the operator F is an approximation of $-N_{\tilde{\Omega}}$ in a sense that we will make more precise later. We may keep only the first terms in the asymptotic expansion of $N_{\tilde{\Omega}}$ so that we let the singular part of the solution leave the domain. (We will keep B_1 or $B_1 + B_0$ in what follows.) But $(-i\partial_t - \Delta_S)^{\frac{1}{2}}$ is nonlocal in space and time and thus is not practical for numerical computations. We need to approximate it with operators local in space and time leading to well-posed initial boundary value problems.

Here we adapt to Schrödinger's equation the strategy used in [12] for the wave equation.

Let d be an integer, $d \geq 2$, and h be a function in $H^{7/2,7/4}(\mathbb{R}_t^+ \times \mathbb{R}_{x'}^{d-1})$. We assume that $h|_{t=0} = 0$ and $\partial_t h|_{t=0} = 0$. For all $T > 0$, there exists a unique solution $\tilde{u}$ in $H^{2,1}(]0,T[\times\mathbb{R}_+^{d-1})$ (see [21]) of (2.2) in the half space $x \geq 0$:

$$\begin{cases} i\partial_t\tilde{u} + \Delta\tilde{u} = 0, \ t \geq 0, \ \ y \in \mathbb{R}^{d-1}, \ \ x \geq 0, \\ \tilde{u} = 0 \text{ for } t \leq 0, \\ \tilde{u}(0,y,t) = h(y,t). \end{cases} \tag{2.17}$$

Remark. Taking $h = u_{ex}|_{x=0}$ and u_0 with support in $x < 0$, we see from (2.3) that $\tilde{u} = u_{ex}|_{x>0}$.

Let $\delta > 0$ be an acceptable error, let T be a strictly positive time, and let a_0 be a strictly positive real number. We look for a boundary operator F on the hyperplane

$x = a$, with $a \geq a_0$ as close to a_0 as possible, such that if u is the solution of

$$\begin{cases} i\partial_t u + \Delta u = 0, \ t \geq 0, \ \ y \in \mathbb{R}^{d-1}, \ \ 0 < x < a, \\ u = 0 \ \text{ for } \ t \leq 0, \\ u(0, y, t) = h(y, t), \\ \partial_x u(a, y, t) = Fu(a, y, t), \end{cases} \tag{2.18}$$

then u satisfies

$$\left(\int_0^T \int_{\mathbb{R}^{d-1}} \int_0^{a_0} |\tilde{u} - u|^2 dx dy dt \right)^{\frac{1}{2}} \leq \delta. \tag{2.19}$$

Moreover, we seek F as a local operator in space and time leading to a well-posed problem for the Schrödinger operator. As in [12], to get (2.19) we will minimize the amplitude of the reflected waves.

Given $\eta > 0$, the Laplace transform in t and the Fourier transform in y are defined for w such that $e^{-\eta t} w$ is in $L^2(]0, +\infty[_t \times \mathbb{R}^{d-1})$ by:

$$\mathcal{L}w(s, \omega) = \frac{1}{(2\pi)^{\frac{d}{2}}} \int_0^{+\infty} \int_{\mathbb{R}^{d-1}} \exp(-(\eta + i\tau)t - i\omega y) w(t, y) dt dy,$$

where $s = \eta + i\tau$. For all $\eta > 0$, $e^{-\eta t}\tilde{u}(x, .)$ is in $L^2(\mathbb{R}_t^+ \times \mathbb{R}^{d-1})$ for almost all $x > 0$, and its Fourier–Laplace transform satisfies the following ordinary differential equation:

$$\frac{d^2}{dx^2} \mathcal{L}\tilde{u} - (-is + |\omega|^2) \mathcal{L}\tilde{u} = 0.$$

The Fourier–Laplace transform of $\tilde{u}$ is not more than slowly increasing because it is a tempered distribution. Therefore, $\mathcal{L}\tilde{u} = \exp(-\varrho x)\mathcal{L}h$, where $\varrho = (-is + |\omega|^2)^{1/2}$, and we choose the square root branch well defined for $-\pi < \arg(z) < \pi$. At $x = a$, $\mathcal{L}\tilde{u}$ satisfies

$$\frac{d}{dx} \mathcal{L}\tilde{u} + \varrho \mathcal{L}\tilde{u} = 0.$$

We will thus seek a sequence of local operator F_m such that its symbol approximates $-\varrho$.

To write absorbing boundary conditions for the heat equation on a half-space, Joly used the following sequence of rational functions in [16]:

$$\begin{aligned} f_{m+1}(z) &= 1 + \frac{z}{1 + f_m(z)}, \\ f_0(z) &= 0. \end{aligned} \tag{2.20}$$

In the following lemma, we group together the properties that will be used in what follows.

LEMMA 2. *Let Δ be the set of all real numbers smaller than -1. For all complex numbers z in $\mathbb{C} \setminus \Delta$ we have the equality*

$$\frac{f_m(z) - (1+z)^{\frac{1}{2}}}{f_m(z) + (1+z)^{\frac{1}{2}}} = -\left(\frac{1 - (1+z)^{\frac{1}{2}}}{1 + (1+z)^{\frac{1}{2}}} \right)^m. \tag{2.21}$$

In particular, we have for any set K in $\mathbb{C}\backslash\Delta$

$$\sup_{z\in K}\left|\frac{f_m(z)-(1+z)^{\frac{1}{2}}}{f_m(z)+(1+z)^{\frac{1}{2}}}\right|\leq\gamma(K)^m$$

with $\gamma(K)=\sup_{z\in K}\left|\frac{1-(1+z)^{\frac{1}{2}}}{1+(1+z)^{\frac{1}{2}}}\right|\leq 1$. If K is a compact subset of $\mathbb{C}\backslash\Delta$, then $\gamma(K)<1$. Finally, we have for all integer m

$$f_{2m}(z)=\frac{1}{m}\sum_{k=0}^{m-1}\frac{(z+1)\ \cos^2\left(\frac{(2k+1)\pi}{4m}\right)}{z+1+\tan^2\left(\frac{(2k+1)\pi}{4m}\right)}. \tag{2.22}$$

As $\varrho=(-is+|\omega|^2)^{1/2}=-i(is-|\omega|^2)^{1/2}$ we may approximate it by $\varrho_m=-if_{2m}(is-|\omega|^2-1)$. It is the same as approximating the transparent operator by the operator F_m which symbol is $if_{2m}(is-|\omega|^2-1)$. Using Lemma 2, we can rewrite the symbol of F_m as

$$\sigma(F_m)=i\beta_m+i\sum_{k=0}^{m-1}\frac{a_{km}(is-|\omega|^2)}{is-|\omega|^2+d_{km}}, \tag{2.23}$$

where $\beta_m=0$, $a_{km}=1/\cos^2(\frac{(2k+1)\pi}{4m})$, and $d_{km}=\tan^2(\frac{(2k+1)\pi}{4m})$. In particular, $\beta_m\geq 0$, $a_{km}>0$, and $d_{km}>0$. Following Lindmann [19], we introduce the auxiliary functions φ_{km} defined in the Fourier–Laplace domain by

$$\mathcal{L}\varphi_{km}=\frac{\mathcal{L}v}{is-|\omega|^2+d_{km}}.$$

F_m is then defined by

$$F_mv=i\beta_mv+i\sum_{k=0}^{m-1}a_{km}(i\partial_t+\Delta_y)\varphi_{km},$$

where φ_{km} is defined by

$$\begin{cases}(i\partial_t+\Delta_y+d_{km})\varphi_{km}=v\ \text{ in }\ \mathbb{R}_t^+\times\mathbb{R}_{x'}^{d-1},\\ \varphi_{km}=0\ \text{ at }\ t=0.\end{cases}$$

F_m is therefore local in space and time.

We will show the well-posedness of Schrödinger's equation with boundary conditions F_m in Proposition 6. (We prove it for a bounded domain but it extends easily to the half-space case.) We show here that the solution u_m of (2.18) with $F=F_m$ satisfies (2.19) for sufficiently large m. We have the following proposition.

PROPOSITION 4. *Let δ be an acceptable error, let a_0 be a strictly positive real number, let T be a strictly positive time, let h be in $H^{7/2,7/4}(\mathbb{R}_t^+\times\mathbb{R}_{x'}^{d-1})$ so that $h|_{t=0}=0$ and $\partial_t h|_{t=0}=0$, and let u_m be the solution of* (2.18) *with $F=F_m$. Then u_m is in $H^{2,1}(]0,T[\times\mathbb{R}_+^d)$ and there exists $a\geq a_0$ and an integer m so that u_m satisfies* (2.19).

Proof. We use the results in [21] for the nonhomogeneous Dirichlet condition at $x = 0$ and Proposition 6 for the absorbing boundary conditions at $x = a$ to prove the existence and the regularity of u_m. $e^{-\eta t}\tilde{u}$ and $e^{-\eta t}u_m$ are in $L^2(\mathbb{R}_t^+ \times \mathbb{R}_{x'}^{d-1}\times]0,a[)$ because h is in $H^{7/2,7/4}(\mathbb{R}_t^+ \times \mathbb{R}_{x'}^{d-1})$. Using the Parseval equality,

$$\int_0^T \int_{\mathbb{R}^{d-1}} \int_0^{a_0} |e^{-\eta t}\tilde{u} - e^{-\eta t}u|^2 dx dy dt \le \int_{\mathbb{R}^d} \int_0^{a_0} |\mathcal{L}\tilde{u} - \mathcal{L}u|^2 dx d\omega d\tau. \tag{2.24}$$

The map taking $h \in H^{7/2,7/4}(]0,T[\times\mathbb{R}_{x'}^{d-1})$ to $\tilde{u} \in H^{2,1}(]0,T[\times\mathbb{R}_+^d)$ is continuous. It is therefore sufficient to prove the proposition for h in a dense subset of $H^{7/2,7/4}(]0,T[\times\mathbb{R}_{x'}^{d-1})$. We may assume there exists a real number $0 < \varepsilon < 1$ such that the support of $\mathcal{L}h$ is included in $\{(\tau,\omega)/|\tau + |\omega|^2| \ge \varepsilon \text{ and } \tau + |\omega|^2 \ge -1/\varepsilon\}$.

As $\mathcal{L}\tilde{u}$, $\mathcal{L}u_m$ satisfies a second-order ordinary differential equation with constant coefficients. We compute $\mathcal{L}u_m$ explicitly using boundary conditions at $x = 0$ and $x = a$. We obtain

$$\mathcal{L}u_m - \mathcal{L}\tilde{u} = (\exp(\varrho x) - \exp(-\varrho x))\frac{R_m}{R_m - \exp(2\varrho a)}\mathcal{L}h, \tag{2.25}$$

where R_m is the reflection coefficient defined by

$$R_m(s,i\omega) = \frac{-(-is + |\omega|^2)^{\frac{1}{2}} - if_{2m}(is - |\omega|^2 - 1)}{(-is + |\omega|^2)^{\frac{1}{2}} - if_{2m}(is - |\omega|^2 - 1)}.$$

Lemma 2 implies that $|R_m(s,i\omega)| < 1$ for all $\eta > 0$. We define the following three regions of $\mathbb{R}^d$:

$$\begin{aligned} G_1 &= \{(\tau,\omega)/|\tau + |\omega|^2| \le \varepsilon \text{ or } \tau + |\omega|^2 \le -\tfrac{1}{\varepsilon}\},\\ G_2 &= \{(\tau,\omega)/ -\tfrac{1}{\varepsilon} \le \tau + |\omega|^2 \le -\varepsilon\},\\ G_3 &= \{(\tau,\omega)/\tau + |\omega|^2 \ge \varepsilon\}. \end{aligned}$$

In G_1, $\mathcal{L}(u_n - \tilde{u}) = 0$.

Let γ_ε be equal to $\sup_{z\in K_\varepsilon}\left|\frac{1-(1+z)^{\frac{1}{2}}}{1+(1+z)^{\frac{1}{2}}}\right|$, where K_ε is the compact set of $\mathbb{C} \setminus \Delta$ defined by $\{\theta + i\eta/\varepsilon - 1 \le \theta \le 1/\varepsilon - 1,\ 0 \le \eta \le 1\}$. $0 < \gamma_\varepsilon < 1$ by Lemma 2 and (2.25) implies the following inequality in G_2:

$$|\mathcal{L}u_m - \mathcal{L}\tilde{u}| \le \frac{2\gamma_\varepsilon^{2m}}{1 - \gamma_\varepsilon}|\mathcal{L}h|.$$

In G_3, we have the inequality

$$|\mathcal{L}u_m - \mathcal{L}\tilde{u}| \le \frac{\exp(\sqrt{\varepsilon}(a_0 - 2a))|\mathcal{L}h|}{1 - \exp(-2a_0\sqrt{\varepsilon})}.$$

Summing up, we finally get

$$\begin{aligned} \int_0^{a_0}\int_{\mathbb{R}^+}\int_{\mathbb{R}^{d-1}} |\mathcal{L}u_m - \mathcal{L}\tilde{u}|^2 &= \int_0^{a_0}\int_{G_2} |\mathcal{L}u_m - \mathcal{L}\tilde{u}|^2 + \int_0^{a_0}\int_{G_3} |\mathcal{L}u_m - \mathcal{L}\tilde{u}|^2\\ &\le \frac{4a_0\gamma_\varepsilon^{4m}}{(1-\gamma_\varepsilon)^2}\int_{G_2}|\mathcal{L}h|^2 + \frac{\exp(2\sqrt{\varepsilon}(a_0 - 2a))a_0}{(1 - \exp(-2a_0\sqrt{\varepsilon}))^2}\int_{G_3}|\mathcal{L}h|^2. \end{aligned}$$

We choose m such that $\frac{4a_0\gamma_\varepsilon^{4m}}{(1-\gamma_\varepsilon)^2}\int_{G_2}|\mathcal{L}h|^2 \leq \frac{\delta}{2}$ and a such that

$$\frac{\exp(2\sqrt{\varepsilon}(a_0-2a))a_0}{(1-\exp(-2a_0\sqrt{\varepsilon}))^2}\int_{G_3}|\mathcal{L}h|^2 \leq \frac{\delta}{2}.$$

Using (2.24), we obtain (2.19) by letting η converge toward 0. □

2.1.3. Absorbing boundary conditions in the general case. The study in section 2.1.2 suggests the following approximation of $(-i\partial_t - \Delta_S)^{1/2}$:

$$(-i\partial_t - \Delta_S)^{\frac{1}{2}} \approx i\beta + i\sum_{k=1}^{m} a_k(i\partial_t + \Delta_S)(i\partial_t + \Delta_S + d_k)^{-1},$$

where $\beta \geq 0$, $a_k > 0$, and $d_k > 0$ again. The term $(i\partial_t + \Delta_S + d_k)^{-1}$ can again be handled with auxiliary functions:

$$\begin{cases}(i\partial_t + \Delta_S + d_k)\varphi_k = u \text{ in } \mathbb{R}^+ \times S,\\ \varphi_k = 0 \text{ at } t = 0.\end{cases} \tag{2.26}$$

Remark. In the case of the half-space, the conditions on β, a_k, and d_k imply that the reflection coefficient $R(\eta + i\tau, \omega)$ is less than one when $\eta = 0$ and holomorphic when $\eta > 0$. Thus, the maximum principle implies that $|R| < 1$ when $\eta > 0$ as in the proof of Proposition 4.

If we keep only $B_1 + B_0$ in the pseudodifferential expansion, we approximate $N_{\tilde{\Omega}}$ by $-F$ with F defined by

$$F = i\beta u + i\sum_{k=1}^{m} a_k(i\partial_t + \Delta_S)\varphi_k - \frac{d-1}{2}H_{\tilde{\Omega}}u + \frac{II(D',D')}{2}\varphi_0, \tag{2.27}$$

where

$$\begin{cases}(i\partial_t + \Delta_S)\varphi_0 = u \text{ in } \mathbb{R}^+ \times S,\\ \varphi_0 = 0 \text{ at } t = 0.\end{cases} \tag{2.28}$$

2.2. The linear problem with absorbing boundary conditions.

2.2.1. Properties of the boundary operator F. The auxiliary functions are defined by (2.26) and (2.28). F is the operator defined by

$$F : u \to i\beta u + i\sum_{k=1}^{m} a_k(u - d_k\varphi_k) - \frac{d-1}{2}H_\Omega u + II(D',D')\frac{\varphi_0}{2}.$$

Let η be a strictly positive real number. We introduce the following auxiliary functions:

$$\begin{cases}(i\partial_t + \Delta_S + i\eta + d_k)\varphi_{\eta k} = u \text{ in } \mathbb{R}^+ \times S,\\ \varphi_{\eta k} = 0 \text{ at } t = 0.\end{cases} \tag{2.29}$$

F_η is the operator defined by

$$F_\eta : u \to i\beta u + i\sum_{k=1}^{m} a_k(u - d_k\varphi_{\eta k}) - \frac{d-1}{2}H_\Omega u + II(D',D')\frac{\varphi_{\eta 0}}{2}.$$

Remark. F equals F_η when $\eta = 0$.

Let b be the continuous bilinear form on $H^1(S) \times H^1(S)$ such that

$$\left[-\frac{II(D', D')v}{2}, w\right] = b(v, w) \ \ \forall v \in H^2(S) \quad \forall w \in H^1(S).$$

To obtain energy estimates, we assume that Ω is convex. Therefore, H_Ω is nonnegative on S and b is a nonnegative bilinear form in this case.

Remark. We did not need this additional hypothesis for the heat equation (see [27]) due to the more favorable estimates derived in that case. In any case, the convexity hypothesis has been used to compute the transparent operator (see Proposition 2).

PROPOSITION 5. *Let T be any strictly positive time, let s be any real number, and let u be in $H^1(]0, T[, H^s(S))$. For all $\eta \geq 0$, there exist functions $\varphi_{\eta k}$ in $L^\infty(]0, T[, H^{s+2}(S)) \cap W^{1,\infty}(]0, T[, H^s(S))$ for $k = 0, \ldots, m$ solutions of (2.29). Moreover, F_η satisfies the following inequalities in $\mathcal{D}'(0, T)$:*

$$Im\,([F_\eta u, u]) \geq \frac{1}{2}\frac{d}{dt} b(\varphi_{\eta 0}, \varphi_{\eta 0}) + \eta b(\varphi_{\eta 0}, \varphi_{\eta 0}) - C\|u\|^2_{L^2(S)} \tag{2.30}$$

and

$$Re\,([F_\eta u, \partial_t u]) \leq C(\|u\|^2_{L^2(S)} + \|\partial_t u\|^2_{L^2(S)}). \tag{2.31}$$

Finally, if $\eta > d_k$ for $k = 1, \ldots, m$ we define $c_\eta = \sum_{k=1}^m a_k(1 - d_k/\eta)$. Then $c_\eta > 0$ and F_η satisfies the following inequality:

$$\int_0^T Im\,([F_\eta u, u]) \geq (\beta + c_\eta) \int_0^T \|u\|^2_{L^2(S)} + \frac{1}{2} b(\varphi_{\eta 0}(T), \varphi_{\eta 0}(T)) + \int_0^T \eta b(\varphi_{\eta 0}, \varphi_{\eta 0}). \tag{2.32}$$

Proof. We first prove the existence and regularity of $\varphi_{k\eta}$. We prove it in the case $s = 0$. The case where s is an integer follows by iteration differentiating the equation along any C^∞ vector field on S. The case where s is a nonnegative real number follows by interpolation. (See [27] in the case of the heat equation.)

Let d be a nonnegative real number and let u be in $H^1(]0, T[, L^2(S))$. We will prove the existence and uniqueness of φ_η in $W^{1,\infty}(]0, T[, L^2(S)) \cap L^\infty(]0, T[, H^2(S))$ solution of

$$\begin{cases} \forall \psi \in H^1(S), \\ i\frac{d}{dt}[\varphi_\eta, \psi] - [\nabla_S \varphi_\eta, \nabla_S \psi] + (d + i\eta)[\varphi_\eta, \psi] = [u, \psi] \ \text{ in } \ \mathcal{D}'(0, T), \\ \varphi_\eta = 0 \ \text{ at t = 0.} \end{cases} \tag{2.33}$$

Multiplying the equation by $\overline{\varphi_\eta}$, integrating it in space, and taking the imaginary part, we obtain a first a priori estimate:

$$\frac{1}{2}\frac{d}{dt}\|\varphi_\eta\|^2_{L^2(S)} + \eta\|\varphi_\eta\|^2_{L^2(S)} \leq \frac{1}{2}\|\varphi_\eta\|^2_{L^2(S)} + \frac{1}{2}\|u\|^2_{L^2(S)}. \tag{2.34}$$

Multiplying the equation by $\overline{\partial_t \varphi_\eta}$, integrating it in space, and taking the real part, we obtain a second a priori estimate:

$$\frac{1}{2}\frac{d}{dt}\|\nabla_S \varphi_\eta\|^2_{L^2(S)} \leq C(\|\varphi_\eta\|^2_{L^2(S)} + \|\partial_t \varphi_\eta\|^2_{L^2(S)} + \|u\|^2_{L^2(S)}). \tag{2.35}$$

Differentiating in time the equation satisfied by φ_η, multiplying it by $\overline{\partial_t\varphi_\eta}$, integrating it in space, and taking the imaginary part, we obtain a third a priori estimate:

$$\frac{1}{2}\frac{d}{dt}\|\partial_t\varphi_\eta\|^2_{L^2(S)} + \eta\|\partial_t\varphi_\eta\|^2_{L^2(S)} \leq \frac{1}{2}\|\partial_t\varphi_\eta\|^2_{L^2(S)} + \frac{1}{2}\|\partial_t u\|^2_{L^2(S)}. \tag{2.36}$$

We deduce from these three energy estimates and Galerkin's method the existence and uniqueness of φ_η in $W^{1,\infty}(]0,T[,L^2(S)) \cap L^\infty(]0,T[,H^1(S))$ solution of (2.33).

Since $\Delta_S\varphi_\eta = -i\partial_t\varphi_\eta + u$, $\Delta_S\varphi_\eta$ is in $L^\infty(]0,T[,L^2(S))$. Thus φ_η belongs to $L^\infty(]0,T[,H^2(S))$ by using the regularity of weak solutions of second-order elliptic equations on a manifold, and we obtain the following estimate:

$$\|\varphi_\eta\|_{L^\infty(]0,T[,H^2(S))} \leq C(\|\varphi_\eta\|_{W^{1,\infty}(]0,T[,L^2(S))} + \|u\|_{H^1(]0,T[,L^2(S))}). \tag{2.37}$$

The estimates (2.34), (2.36), and (2.37) and Gronwall's lemma yield

$$\|\varphi_\eta\|_{L^\infty(]0,T[,H^2(S))} + \|\varphi_\eta\|_{W^{1,\infty}(]0,T[,L^2(S))} \leq C\|u\|_{H^1(]0,T[,L^2(S))}. \tag{2.38}$$

It remains to prove (2.30), (2.31), and (2.32). We first recall the following lemma (see [20]).

LEMMA 3. *Let V, H, and V' be three Hilbert spaces such that $V \subset H \subset V'$ and V' is the dual space of V. If φ is in $L^2(]0,T[,V)$ and φ' is in $L^2(]0,T[,V')$, then φ equals almost everywhere a continuous function from $[0,T]$ to H and $\frac{d}{dt}\|\varphi\|^2_H = 2Re < \varphi', \varphi >$.*

Using the previous lemma with $H = H^1(S)$, $V = H^2(S)$ and $V' = H^{-2}(S)$, we obtain $\frac{d}{dt}b(\varphi_{\eta 0},\varphi_{\eta 0}) = 2\mathrm{Re}\, b(\varphi_{\eta 0},\partial_t\varphi_{\eta 0})$. Using the regularity of u and $\varphi_{\eta k}$, we have

$$\begin{aligned}
\mathrm{Im}\,([F_\eta u,u]) &= \beta\|u\|^2_{L^2(S)} + \sum_{k=1}^m a_k \mathrm{Re}\,([u-d_k\varphi_{\eta k},u]) \\
&\quad + \mathrm{Im}\left(\left[II(D',D')\frac{\varphi_{\eta 0}}{2}, i\partial_t\varphi_{\eta 0} + \Delta_S\varphi_{\eta 0} + i\eta\varphi_{\eta 0}\right]\right) \\
&\geq \frac{1}{2}\frac{d}{dt}b(\varphi_{\eta 0},\varphi_{\eta 0}) + \eta b(\varphi_{\eta 0},\varphi_{\eta 0}) + \beta\|u\|^2_{L^2(S)} \\
&\quad - \sum_{k=1}^m a_k\|u-d_k\varphi_{\eta k}\|_{L^2(S)}\|u\|_{L^2(S)},
\end{aligned}$$

which yields (2.30). Then, let e be equal to $\frac{d-1}{2}\|H_\Omega\|_{L^\infty(S)}$:

$$\begin{aligned}
\mathrm{Re}\,([F_\eta u,\partial_t u]) &= -\beta\mathrm{Im}\,([u,\partial_t u]) + \sum_{k=1}^m \mathrm{Re}\,(ia_k[u-d_k\varphi_{\eta k},\partial_t u]) \\
&\quad - \frac{d-1}{2}\mathrm{Re}\,([H_\Omega u,\partial_t u]) + \mathrm{Re}\left(\left[II(D',D')\frac{\varphi_{\eta 0}}{2},\partial_t u\right]\right) \\
&\leq \left(\frac{d-1}{2}\|H_\Omega\|_{L^\infty(S)} + \beta\right)\|u\|_{L^2(S)}\|\partial_t u\|_{L^2(S)} \\
&\quad + \sum_{k=1}^m a_k\|u-d_k\varphi_{\eta k}\|_{L^2(S)}\|\partial_t u\|_{L^2(S)} + C\|\varphi_{\eta 0}\|_{H^2(S)}\|\partial_t u\|_{L^2(S)},
\end{aligned}$$

which yields (2.31) by using (2.38). Finally we have

$$\begin{aligned}\mathrm{Im}\left([F_\eta u,u]\right) &= \beta\|u\|^2_{L^2(S)} + \sum_{k=1}^m a_k \mathrm{Re}\left([u-d_k\varphi_{\eta k},u]\right)\\ &\quad + \mathrm{Im}\left(\left[II(D',D')\frac{\varphi_{\eta 0}}{2}, i\partial_t\varphi_{\eta 0} + \Delta_S\varphi_{\eta 0} + i\eta\varphi_{\eta 0}\right]\right)\\ &\geq \left(\beta + \sum_{k=1}^m a_k\right)\|u\|^2_{L^2(S)} + \frac{1}{2}\frac{d}{dt}b(\varphi_{\eta 0},\varphi_{\eta 0}) + \eta b(\varphi_{\eta 0},\varphi_{\eta 0})\\ &\quad - \sum_{k=1}^m a_k d_k \|\varphi_{\eta k}\|_{L^2(S)}\|u\|_{L^2(S)}.\end{aligned} \tag{2.39}$$

Moreover, we may generalize (2.34) for all $C>0$ to

$$\frac{1}{2}\frac{d}{dt}\|\varphi_\eta\|^2_{L^2(S)} + \eta\|\varphi_\eta\|^2_{L^2(S)} \leq C\|\varphi_\eta\|^2_{L^2(S)} + \frac{1}{4C}\|u\|^2_{L^2(S)}.$$

Taking $C=\eta/2$, we obtain

$$\eta^2\int_0^T \|\varphi_\eta\|^2_{L^2(S)} \leq \int_0^T \|u\|^2_{L^2(S)}, \tag{2.40}$$

and if $\eta > d_k$ for all $k=1,\dots,m$, (2.39) and (2.40) yield (2.32). □

2.2.2. Existence and uniqueness results. We try to approximate the restriction of the solution u_{ex} of (2.1) to the open set Ω. We introduce the following problem:

$$\begin{cases} Lu = 0 & \text{in } \mathbb{R}^+\times\Omega,\\ \partial_{\nu_\Omega}u = Fu & \text{in } \mathbb{R}^+\times S,\\ u = u_0 & \text{at } t=0,\end{cases} \tag{2.41}$$

where F is defined by (2.27).

PROPOSITION 6. *Let g be in $H^1(]0,T[,L^2(\Omega))$ and u_0 be in $H^2(\Omega)$ such that*

$$\partial_{\nu_\Omega}u_0|_S = -\left(i\beta + ia_1 + \cdots + ia_m - \frac{d-1}{2}H_\Omega\right)u_0|_S. \tag{2.42}$$

There exists a unique solution u in the space $W^{1,\infty}(]0,T[,L^2(\Omega))\cap H^1(]0,T[,L^2(S))\cap L^\infty(]0,T[,H^1(\Omega))$ of the following variational problem:

$$\begin{cases}\forall v\in H^1(\Omega):\\ i\frac{d}{dt}(u,v) - (\nabla u,\nabla v) + [Fu,v] = (g,v) \text{ in } \mathcal{D}'(0,T),\end{cases} \tag{2.43}$$

where (u,v) denotes the Hermitian product in $L^2(\Omega)$.

Moreover, suppose g is in $H^2(]0,T[,L^2(\Omega))$ and Δu_0 and $g(0)$ are in $H^2(\Omega)$ and satisfy (2.42). Then u belongs to $W^{2,\infty}(]0,T[,L^2(\Omega))\cap W^{1,\infty}(]0,T[,H^1(\Omega))\cap L^\infty(]0,T[,H^2(\Omega))$ and satisfies the estimate

$$\begin{aligned}\|u\|^2_{L^\infty(]0,T[,H^2(\Omega))} &\leq C(\|u_0\|^2_{H^2(\Omega)} + \|\Delta u_0\|^2_{H^2(\Omega)} + \|g(0)\|^2_{H^2(\Omega)}\\ &\quad + \|\partial_t g(0)\|^2_{L^2(\Omega)} + \|g\|^2_{H^2(]0,T[,L^2(\Omega))}).\end{aligned} \tag{2.44}$$

Remark. If u_0 has compact support in Ω as in section 2.1.1, then u_0 satisfies (2.42).

Remark. The existence result of Proposition 6 with $g = 0$ implies the well-posedness of problem (2.41). The regularity result of Proposition 6 will be used to define and show the convergence of the iterative scheme in section 3.1.2

Proof. Let η be equal to $\max_{1\leq k\leq m}(d_k) + 1$; then $\eta > d_k$ for $k = 1, \dots, m$. Let $g_\eta = \exp(-\eta t)g$ and u_η be equal to $\exp(-\eta t)u$. u is the unique solution in $W^{1,\infty}(]0,T[, L^2(\Omega)) \cap H^1(]0,T[, L^2(S)) \cap L^\infty(]0,T[, H^1(\Omega))$ of (2.43) if and only if u_η is the unique solution in $W^{1,\infty}(]0,T[, L^2(\Omega)) \cap H^1(]0,T[, L^2(S)) \cap L^\infty(]0,T[, H^1(\Omega))$ of the following variational problem:

$$\begin{cases} \forall v \in H^1(\Omega) : \\ i\frac{d}{dt}(u_\eta, v) + i\eta(u_\eta, v) - (\nabla u_\eta, \nabla v) + [F_\eta u_\eta, v] = (g_\eta, v) \text{ in } \mathcal{D}'(0,T). \end{cases} \tag{2.45}$$

We will prove the existence and uniqueness of u_η in the space $W^{1,\infty}(]0,T[, L^2(\Omega)) \cap H^1(]0,T[, L^2(S)) \cap L^\infty(]0,T[, H^1(\Omega))$ solution of (2.45). Multiplying the equation by $\overline{u_\eta}$, integrating it in space, and taking imaginary part yields

$$\frac{d}{dt}\|u_\eta\|^2_{L^2(\Omega)} + 2\eta\|u_\eta\|^2_{L^2(\Omega)} + 2\mathrm{Im}\,([F_\eta u_\eta, u_\eta]) = 2\mathrm{Im}\,(g_\eta, u_\eta). \tag{2.46}$$

Multiplying the equation by $\overline{\partial_t u_\eta}$, integrating it in space, and taking the real part yields

$$\frac{d}{dt}\|\nabla u_\eta\|^2_{L^2(\Omega)} \leq 2\mathrm{Re}\,([F_\eta u_\eta, \partial_t u_\eta]) + \eta\|\partial_t u_\eta\|^2_{L^2(\Omega)} + \eta\|u_\eta\|^2_{L^2(\Omega)} - 2\mathrm{Re}\,(g_\eta, \partial_t u_\eta). \tag{2.47}$$

Differentiating the equation satisfied by u_η in time, multiplying it by $\overline{\partial_t u_\eta}$, integrating it in space, and taking the imaginary part yields

$$\frac{d}{dt}\|\partial_t u_\eta\|^2_{L^2(\Omega)} + 2\eta\|\partial_t u_\eta\|^2_{L^2(\Omega)} + 2\mathrm{Im}\,([F_\eta \partial_t u_\eta, \partial_t u_\eta]) = 2\mathrm{Im}\,(\partial_t g_\eta, \partial_t u_\eta). \tag{2.48}$$

By (2.32), (2.46), and Gronwall's lemma we obtain the following a priori estimate:

$$\|u_\eta\|^2_{L^\infty(]0,T[,L^2(\Omega))} + \|u_\eta\|^2_{L^2(]0,T[,L^2(S))} \leq C(\|u_0\|^2_{L^2(\Omega)} + \|g_\eta\|^2_{L^2(]0,T[,L^2(\Omega))}), \tag{2.49}$$

where $C = \max(1, (2(\beta + c_\eta))^{-1})$. In what follows, we do not make this dependence on η precise because η is fixed. By an inequality similar to (2.32), (2.48), and Gronwall's lemma we obtain the following a priori estimate:

$$\|\partial_t u_\eta\|^2_{L^\infty(]0,T[,L^2(\Omega))} + \|\partial_t u_\eta\|^2_{L^2(]0,T[,L^2(S))} \leq C(\|\partial_t u(0)\|^2_{L^2(\Omega)} + \|\partial_t g_\eta\|^2_{L^2(]0,T[,L^2(\Omega))}). \tag{2.50}$$

We shall find a bound on $\|\partial_t u_\eta(0)\|^2_{L^2(\Omega)}$. Multiplying the equation by $\overline{\partial_t u_\eta}$ and taking the imaginary part, we obtain after an integration by part in space

$$\begin{aligned} &\|\partial_t u_\eta\|^2_{L^2(\Omega)} + \eta\mathrm{Re}\,(u_\eta, \partial_t u_\eta) + \mathrm{Im}\,(\Delta u_\eta, \partial_t u_\eta) \\ &\qquad + \mathrm{Im}\,[F_\eta u_\eta - \partial_{\nu_\Omega} u_\eta, \partial_t u_\eta] = \mathrm{Re}\,(g_\eta, \partial_t u_\eta). \end{aligned} \tag{2.51}$$

By (2.42), $F_\eta u_\eta(0) - \partial_{\nu_\Omega} u_\eta(0) = (i\beta + i\sum_{k=1}^m a_k - (d-1)/2H_\Omega)u_0 - \partial_{\nu_\Omega} u_0 = 0$. Thus, taking $t = 0$ in (2.51),

$$\|\partial_t u_\eta(0)\|_{L^2(\Omega)} \leq \eta\|u_0\|_{L^2(\Omega)} + \|\Delta u_0\|_{L^2(\Omega)} + \|g_\eta(0)\|_{L^2(\Omega)}. \tag{2.52}$$

Remark. We do not use the equality $i\partial_t u_\eta(0) = g(0) - i\eta u_0 - \Delta u_0$ to give a bound on $\|\partial_t u_\eta(0)\|^2_{L^2(\Omega)}$. We rather use the variational formulation so that the estimates remain valid for approximate solutions of Galerkin's method. In fact, we may take initial conditions of these approximate solutions satisfying (2.42) as in [27]. Then, these approximate solutions satisfy (2.52).

Finally, (2.50) and (2.52) yield

$$\begin{aligned}\|\partial_t u_\eta\|^2_{L^\infty(]0,T[,L^2(\Omega))} + \|\partial_t u_\eta\|^2_{L^2(]0,T[,L^2(S))}\\ \le C(\|u_0\|^2_{H^2(\Omega)} + \|g_\eta(0)\|^2_{L^2(\Omega)} + \|\partial_t g_\eta\|^2_{L^2(]0,T[,L^2(\Omega))}).\end{aligned} \tag{2.53}$$

Equations (2.31) and (2.47) yield the following energy estimate:

$$\begin{aligned}\|\nabla u_\eta\|^2_{L^\infty(]0,T[,L^2(\Omega))} \le C(\|u_0\|^2_{H^1(\Omega)} + \|g_\eta\|^2_{L^2(]0,T[,L^2(\Omega))}\\ + \|u_\eta\|^2_{H^1(]0,T[,L^2(\Omega))} + \|u_\eta\|^2_{H^1(]0,T[,L^2(S))}.\end{aligned} \tag{2.54}$$

Thus (2.49) and (2.53) yield

$$\begin{aligned}\|\partial_t u_\eta\|^2_{L^\infty(]0,T[,L^2(\Omega))} + \|\partial_t u_\eta\|^2_{L^2(]0,T[,L^2(S))}\\ \le C(\|u_0\|^2_{H^2(\Omega)} + \|g_\eta(0)\|^2_{L^2(\Omega)} + \|\partial_t g_\eta\|^2_{L^2(]0,T[,L^2(\Omega))}).\end{aligned} \tag{2.55}$$

From the energy estimates (2.49), (2.53), and (2.55) we deduce by using Galerkin's method the existence and uniqueness of u_η in $W^{1,\infty}(]0,T[,L^2(\Omega))\cap H^1(]0,T[,L^2(S))\cap L^\infty(]0,T[,H^1(\Omega))$ solution of (2.45). Therefore, we have proved the existence and uniqueness of u in $W^{1,\infty}(]0,T[,L^2(\Omega))\cap H^1(]0,T[,L^2(S))\cap L^\infty(]0,T[,H^1(\Omega))$ solution of (2.43). Moreover, estimates (2.49), (2.53), and (2.55) remain valid for u (with different constants C).

Moreover, we suppose that g is in $H^2(]0,T[,L^2(\Omega))$ and Δu_0 and $g(0)$ are in $H^2(\Omega)$ and satisfy (2.42). The previous estimates are valid for $\partial_t u$ which is like u in $W^{1,\infty}(]0,T[,L^2(\Omega)) \cap H^1(]0,T[,L^2(S)) \cap L^\infty(]0,T[,H^1(\Omega))$. In particular, u is in $W^{2,\infty}(]0,T[,L^2(\Omega)) \cap W^{1,\infty}(]0,T[,H^1(\Omega))$ and we have a similar estimate to (2.55) for $\partial_t u$:

$$\begin{aligned}\|\nabla\partial_t u\|^2_{L^\infty(]0,T[,L^2(\Omega))} \le C(\|\Delta u_0\|^2_{H^2(\Omega)} + \|g(0)\|^2_{H^2(\Omega)}\\ + \|\partial_t g(0)\|^2_{L^2(\Omega)} + \|\partial_t g\|^2_{H^1(]0,T[,L^2(\Omega))}).\end{aligned} \tag{2.56}$$

It remains to show that u belongs to $L^\infty(]0,T[,H^2(\Omega))$. As g and $\partial_t u$ belong to $L^\infty(]0,T[,L^2(\Omega))$, Δu belongs also to $L^\infty(]0,T[,L^2(\Omega))$. Moreover, u belongs to $W^{1,\infty}(]0,T[,H^1(\Omega))$, and thus Fu belongs to $L^\infty(]0,T[,H^{\frac12}(S))$ according to Proposition 5. This proves that $\partial_{\nu_\Omega} u$ is in $L^\infty(]0,T[,H^{\frac12}(S))$. Standard results for elliptic boundary value problems (see, for example, [21]) imply that u is in $L^\infty(]0,T[,H^2(\Omega))$ and satisfies the following estimate:

$$\begin{aligned}\|u\|^2_{L^\infty(]0,T[,H^2(\Omega))} \le C\big(\|u\|^2_{L^\infty(]0,T[,L^2(\Omega))} + \|\Delta u\|^2_{L^\infty(]0,T[,L^2(\Omega))}\\ + \|\partial_{\nu_\Omega} u\|^2_{L^\infty(]0,T[,H^{\frac12}(S))}\big).\end{aligned} \tag{2.57}$$

Since $\partial_{\nu_\Omega} u = Fu$, Proposition 5 yields

$$\|\partial_{\nu_\Omega} u\|^2_{L^\infty(]0,T[,H^{\frac12}(S))} \le C\|u\|^2_{H^1(]0,T[,H^{\frac12}(S))} \le C\|u\|^2_{H^1(]0,T[,H^1(\Omega))}, \tag{2.58}$$

$$\|g\|_{L^\infty(]0,T[,L^2(\Omega))} \le \|g(0)\|_{L^2(\Omega)} + C\|\partial_t g\|_{L^2(]0,T[,L^2(\Omega))}.$$

Therefore, using $\Delta u = g - i\partial_t u$ we get

(2.59)
$$\|\Delta u\|_{L^\infty(]0,T[,L^2(\Omega))} \leq \|g(0)\|_{L^2(\Omega)} + C\|\partial_t g\|_{L^2(]0,T[,L^2(\Omega))} + \|\partial_t u\|_{L^\infty(]0,T[,L^2(\Omega))}.$$

(2.49), (2.53), (2.55), (2.56), (2.57), (2.58), and (2.59) imply (2.44). □

Remark. We can prove the half-space case in a similar way (see section 2.1.2). Moreover, we could prove a similar result replacing the operator $-\Delta$ by the elliptic operator $-\sum_{i,j=1}^{d} \partial_{x_i} a^{ij}(t,x)\partial_{x_j}$, where a^{ij} are in $C^1(\mathbb{R}\times\bar{\Omega})$ (as in [14] for parabolic operators). Finally, we may prove Schrödinger's equation with the absorbing boundary conditions of Di Menza [9] to be well posed in a similar way. (Di Menza gives a proof in a half-space through a Laplace transform.)

2.3. Numerical results.

2.3.1. The frame. We test our absorbing boundary conditions in the one-dimensional and two-dimensional cases.

In the one-dimensional case, we take $\Omega =]-5,5[$ as computational domain and $]-4.98,4.98[$ as domain of interest. The boundary S reduces then to two points. We compare the solution of (2.41) to the explicit solution of (2.1):

$$u_{ex}(t,x) = \frac{\exp(-i\pi/4)}{\sqrt{4t-i}} \exp\left(\frac{ix^2-6x-36t}{4t-i}\right).$$

This solution is a good test because it has almost compact support in $]-5,5[$ at $t=0$ (it remains under 10^{-10} on the boundary) and crosses the boundary $x=-5$ between $t=0$ and $t=1$. We take the time step $\delta t = 10^{-3}$ and the space step $h = 10^{-2}$. (δt is small compared to h to avoid numerical instabilities pointed out in [1].) We use three auxiliary functions ($m=3$), and the coefficients β, a_k, and d_k are given in section 2.3.2. We use a finite difference scheme with $N = 10/h$, $x_j = jh$ for $0 \leq j \leq N$, and $t_n = n\delta t$. u_j^n approximates $u(t_n,x_j)$, $\varphi_{k,1}^n$ approximates $\varphi_k(t_n,x_1)$, and $\varphi_{k,2}^n$ approximates $\varphi_k(t_n,x_{N-1})$. Inside the computational domain we use Crank–Nicolson's scheme

$$i\frac{u_j^{n+1}-u_j^n}{\delta t} + \frac{u_{j+1}^{n+1/2} - 2u_j^{n+1/2} + u_{j-1}^{n+1/2}}{h^2} = 0,$$

where $u_j^{n+1/2} = (u_j^{n+1}+u_j^n)/2$. The boundary conditions are approximated by

$$\frac{u_0^{n+1/2}-u_2^{n+1/2}}{2h} = i\beta u_1^{n+1/2} + i\sum_{k=1}^{m} a_k(u_1^{n+1/2} - d_k\varphi_{k,1}^{n+1/2}),$$

$$\frac{u_N^{n+1/2}-u_{N-2}^{n+1/2}}{2h} = i\beta u_{N-1}^{n+1/2} + i\sum_{k=1}^{m} a_k(u_{N-1}^{n+1/2} - d_k\varphi_{k,2}^{n+1/2}),$$

$$i\frac{\varphi_{k,1}^{n+1}-\varphi_{k,1}^n}{\delta t} + d_k\varphi_{k,1}^{n+1/2} = u_1^{n+1/2},\ k=1,\dots,m,$$

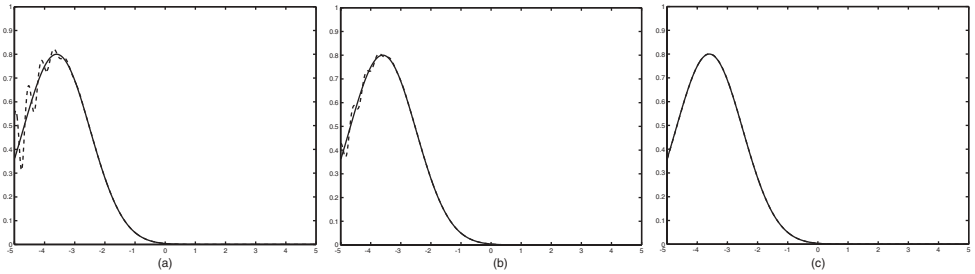

FIG. 1. *The exact solution* (*solid*) *and the approximate ones* (*dashed*) *at* $t = 0.3$, *one-dimensional case.* (*a*) *ABC in* [9], (*b*) *Padé,* (*c*) *present method.*

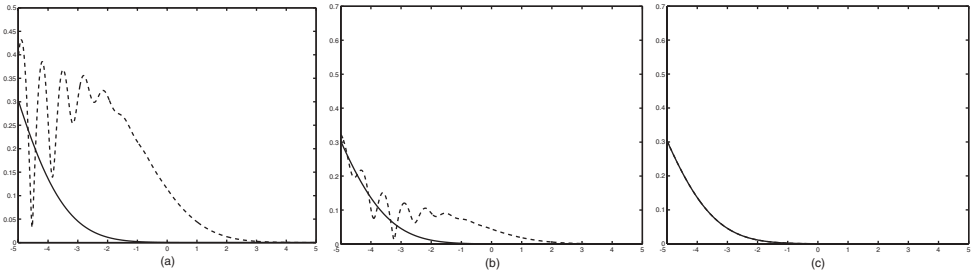

FIG. 2. *The exact solution* (*solid*) *and the approximate ones* (*dashed*) *at* $t = 0.6$, *one-dimensional case.* (*a*) *ABC in* [9], (*b*) *Padé,* (*c*) *present method.*

and

$$i\frac{\varphi_{k,2}^{n+1} - \varphi_{k,2}^{n}}{\delta t} + d_k \varphi_{k,2}^{n+1/2} = u_{N-1}^{n+1/2},\ k = 1, \ldots, m.$$

We give a snapshot of the solution at time $t = 0.3$ and $t = 0.6$ computed, respectively, with the ABC of Di Menza [9] with $m = 3$ (Figures 1(a) and 2(a)), the ABC with the coefficient of (2.23) and $m = 3$, which will be called Padé in what follows (Figures 1(b) and 2(b)), and our method with $m = 3$ (Figures 1(c) and 2(c)) and compared to the exact solution. We give the relative error in L^2 norm on $]-4.98, 4.98[$ as a function of time computed, respectively, with the ABC of Fevens and Jiang [13] with $p = 3$ (Figure 3(a)), the TBC of Arnold and Ehrhardt [5] (Figure 3(b)), and our method with $m = 3$ (Figure 4). We take this time $\delta t = 2.10^{-4}$ and $h = 2.10^{-3}$ (otherwise we compute the errors of the scheme instead of the errors due to our absorbing boundary conditions).

Remark. The TBC of Arnold and Ehrhardt [5] is the only boundary condition we tried that gives results of the same order as our method. However, we must store the boundary values at all previous times and do discrete convolution in time to implement the transparent boundary conditions of [5] (see (3.6)). It is much less costly to approximate the solution with our absorbing boundary conditions.

In the two-dimensional case, we take the disk with radius 1.1 as computational domain and the disk with radius 0.9 as domain of interest. We take the time step $\delta t = 10^{-3}$ and we mesh the two disks with Freefem+ [15] taking 200 points on the boundary of each disk. We use Crank–Nicolson's scheme for the time discretization and for the space discretization P1 finite elements based on the following weak formulation:

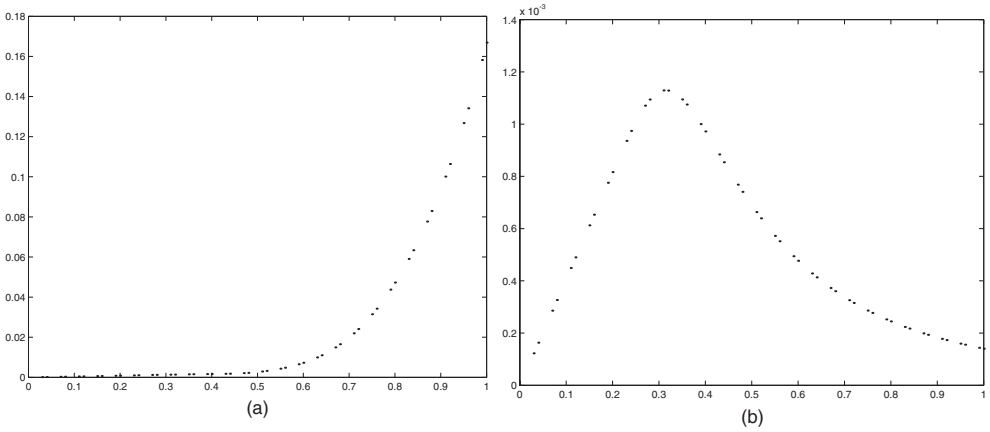

FIG. 3. *Linear case on* $]-4.98, 4.98[$. *Relative error in the* L^2 *norm as a function of time.* (*a*) *ABC in* [13], (*b*) *TBC in* [5].

$$i\left(\frac{u^{n+1}-u^n}{\delta t}, v\right) - (\nabla u^{n+1/2}, \nabla v) + i\beta[u^{n+1/2}, v] + i\sum_{k=1}^{m} a_k[u^{n+1/2} - d_k\varphi_k^{n+1/2}, v]$$
$$- \frac{1}{2}[Hu^{n+1/2}, v] + \left[\frac{II(D', D')}{2}u^{n+1/2}, v\right] = 0$$

and

$$i\left[\frac{\varphi_k^{n+1}-\varphi_k^n}{\delta t}, \theta_k\right] - [\nabla_S\varphi_k^{n+1/2}, \nabla_S\theta_k] + d_k[\varphi_k^{n+1/2}, \theta_k] = [u^{n+1/2}, \theta_k],\ k = 1, \ldots, m,$$

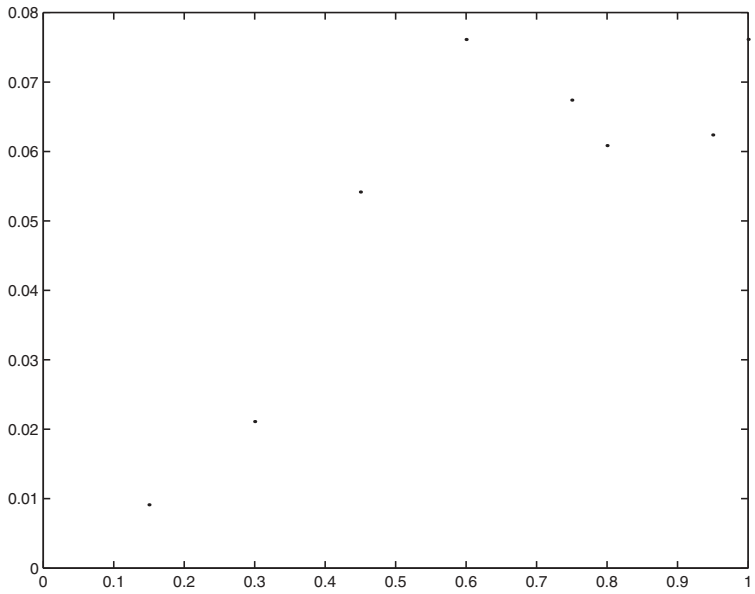

FIG. 5. *Linear case on the disk of radius* 0.9*, relative error in the* L^2 *norm as a function of time.*

TABLE 1
Maximum of the relative error in L^2 *norm for Padé ABC with increasing* m*.*

m	3	5	7	10	12	15
Padé	7.0737	1.9673	0.5647	0.0846	0.0200	0.0085

where $u^{n+1/2} = (u^{n+1} + u^n)/2$, $\varphi_k^{n+1/2} = (\varphi_k^{n+1} + \varphi_k^n)/2$, $k = 1, \ldots, m$, and where v and θ_k, $k = 1, \ldots, m$, are test functions. We compare the solution of (2.41) to the explicit solution of (2.1):

$$u_{ex}(t, x_1, x_2) = \frac{-i}{4t\gamma - i} \exp\left(\frac{i\gamma|x|^2 - \sqrt{\gamma}x_1 - \gamma t}{4t\gamma - i}\right),$$

where $\gamma = 24$ so that the initial condition has almost compact support in Ω (it remains under 10^{-10} on the boundary). This solution crosses the boundary between $t = 0$ and $t = 1$. Figure 5 gives the relative error in L^2 norm on the disk of radius 0.9 as a function of time. We take three auxiliary functions ($m = 3$), and the coefficients β, a_k, and d_k are given in section 2.3.2.

2.3.2. Optimization of the reflection coefficient. *The one-dimensional case.* We proved in section 2.1.2 the convergence of the problem with absorbing boundary conditions (2.18) to the problem (2.17). This happens for a special choice of the coefficients β_m, a_{km}, and d_{km} when letting m converge toward infinity. (See Table 1 for a numerical verification.) However, we are not interested in the case where m is large. In fact, one goal of this work is to reduce the numerical cost as much as possible. Thus we try for a given small m to optimize the absorbing boundary conditions.

Section 2.1.2 emphasized the role of the reflection coefficient. m being fixed, we optimize it for $\beta \geq 0$, $a_k > 0$, and $d_k > 0$, where $k = 1, \ldots, m$. In the one-dimensional case, the reflection coefficient is

$$R(\tau) = \frac{-\sqrt{\tau} - i\beta - i\sum_{k=1}^{m} \frac{a_k(-\tau)}{-\tau+d_k}}{\sqrt{\tau} - i\beta - i\sum_{k=1}^{m} \frac{a_k(-\tau)}{-\tau+d_k}}, \ \tau \in \mathbb{R}.$$

As in section 2.1.2, $|R| = 1$ when $\tau \geq 0$ and $|R| < 1$ when $\tau < 0$ for all $\beta \geq 0$, $a_k > 0$, and $d_k > 0$. We optimize the reflection coefficient in the region $\tau < 0$ (which corresponds to the hyperbolic region G_2 in section 2.1.2) and more precisely in $[-2\pi/\delta t, -2\pi/T]$ to stay in the range of the numerical frequencies. Moreover, we optimize in the L^2 norm with the weight $d\tau/(1+\tau^2)$. Because δt is small we optimize with the simplex method for $r = -1/\tau$ in $[0, T/2\pi]$ the integral

$$\int_0^{T/2\pi} \left| \frac{\sqrt{r} - \beta r - \sum_{k=1}^{m} \frac{a_k r}{1+d_k r}}{\sqrt{r} + \beta r + \sum_{k=1}^{m} \frac{a_k r}{1+d_k r}} \right|^2 \frac{dr}{1+r^2},$$

which is computed with the Weddle–Hardy method. Figure 4 shows the result obtained in the case $m = 3$. The error remains under 0.2% for times between 0 and 1, which is very satisfactory.

The coefficients that allowed us to obtain these results are $\beta = 7.269284.10^{-1}$, $a_1 = 2.142767$, $a_2 = 5.742223$, $a_3 = 4.658032.10^1$, $d_1 = 6.906263$, $d_2 = 6.582243.10^1$, and $d_3 = 1.124376.10^3$.

The two-dimensional case. In the case of the disk of radius $\kappa = 1.1$, the reflection coefficient is

$$R(\tau, \omega) = \frac{-\sqrt{\tau + (\frac{\omega}{\kappa})^2} - i\beta - i\sum_{k=1}^{m} \frac{a_k(-\tau-(\frac{\omega}{\kappa})^2)}{-\tau-(\frac{\omega}{\kappa})^2+d_k}}{\sqrt{\tau + (\frac{\omega}{\kappa})^2} - i\beta - i\sum_{k=1}^{m} \frac{a_k(-\tau-(\frac{\omega}{\kappa})^2)}{-\tau-(\frac{\omega}{\kappa})^2+d_k}}.$$

We optimize the reflection coefficient in the region $\tau + (\frac{\omega}{\kappa})^2 < 0$ (which corresponds to the hyperbolic region G_2 in section 2.1.2). More precisely, we optimize in L^2 norm on $s = -\tau - (\frac{\omega}{\kappa})^2$ in $[b, +\infty[$ with the weight $ds/(1+s^2)$ where $b > 0$. Because the interval is large we optimize for $r = 1/s$ the integral

$$\int_0^{1/b} \left| \frac{\sqrt{r} - \beta r - \sum_{k=1}^{m} \frac{a_k r}{1+d_k r}}{\sqrt{r} + \beta r + \sum_{k=1}^{m} \frac{a_k r}{1+d_k r}} \right|^2 \frac{dr}{1+r^2}.$$

We obtained our best results with $b = 0.5$. Figure 5 shows the results obtained in the case $m = 3$. The error remains under 8% for times between 0 and 1. (The solution computed with Dirichlet conditions on the circle of radius 1.1 gives 2000% error at time $t = 1$.)

Remark. We could use more terms in the asymptotic expansion of the Dirichlet-to-Neumann map $N_{\tilde{\Omega}}$ to improve these results. (We used only two terms in this study.)

The coefficients that allowed us to obtain those results are $\beta = 2.241274.10^{-1}$, $a_1 = 7.062909.10^{-1}$, $a_2 = 2.057994$, $a_3 = 1.705610.10^1$, $d_1 = 6.941414.10^{-1}$, $d_2 = 7.496463$, and $d_3 = 1.449250.10^2$.

3. The nonlinear problem with the absorbing boundary conditions of the linear problem. We wrote absorbing boundary conditions for the linear Schrödinger's equation. The numerical tests were convincing. In the case of the heat equation, we used absorbing boundary conditions of the linear problem for nonlinear ones and the results were also very good (see [27]). Similarly, we will try for nonlinear Schrödinger's equations the absorbing boundary conditions designed for the linear problem.

3.1. Existence results for nonlinear approximate problems.

3.1.1. The exact problem and the approximate problems. We fix an integer d so that $1 \leq d \leq 3$ and let f be a C^2 function from $\mathbb{C}$ to $\mathbb{C}$ (as a function from $\mathbb{R}^2$ to $\mathbb{R}^2$). The operator $-\Delta$ is the generator of a semigroup of contraction on $H^2(\mathbb{R}^d)$ and f is locally Lipschitzian from $H^2(\mathbb{R}^d)$ into itself. Thus (see [24]), for all u_0 in $H^2(\mathbb{R}^d)$, there is a time $T > 0$ and a unique solution u_{ex} in $C([0,T], H^2(\mathbb{R}^d))$ of the problem

$$\begin{cases} Lu_{ex} = f(u_{ex}),\ ]0,T[\times \mathbb{R}^d, \\ u_{ex} = u_0 \ \text{ at } \ t = 0, \end{cases} \tag{3.1}$$

We want to approximate the restriction of u_{ex} to the open set Ω. To generalize problem (2.16), we introduce the following problem:

$$\begin{cases} Lu = f(u) & \text{in } \mathbb{R}^+ \times \Omega, \\ \partial_{\nu_\Omega} u = Fu & \text{in } \mathbb{R}^+ \times S, \\ u = u_0 & \text{at } t = 0, \end{cases} \tag{3.2}$$

where F is an operator equal to the right-hand side of (2.27) in what follows.

We define the solution of (3.2) via the following variational formulation:

$$\begin{cases} u \in L^\infty(]0,T[, L^2(\Omega)) \cap L^2(]0,T[, H^1(\Omega)), \quad f(u) \in L^\infty(]0,T[, L^2(\Omega)), \\ \forall v \in H^1(\Omega), \\ i\frac{d}{dt}(u,v) - (\nabla u, \nabla v) + [Fu, v] = (f(u), v) \ \text{ in } \ \mathcal{D}'(0,T). \end{cases} \tag{3.3}$$

THEOREM 1. *Suppose Ω is convex. For any u_0 in $H^4(\Omega)$ with compact support in Ω, there exists a time $T > 0$ such that problem (3.3) has a unique solution u in $W^{2,\infty}(]0,T[, L^2(\Omega)) \cap W^{1,\infty}(]0,T[, H^1(\Omega)) \cap L^\infty(]0,T[, H^2(\Omega))$.*

Remark. We have already used the compactness of the support of u_0 in Ω to obtain our absorbing boundary conditions (see 2.1.1).

3.1.2. The iterative scheme. First, we define u_{l+1} from u_l, as the solution of the linear problem with the right-hand side $f(u_l)$. Then we prove that for sufficiently small $T > 0$, (u_l) is bounded in the space $W^{2,\infty}(]0,T[, L^2(\Omega)) \cap W^{1,\infty}(]0,T[, H^1(\Omega)) \cap L^\infty(]0,T[, H^2(\Omega))$. Finally, we show that (u_l) is a Cauchy sequence in $C^0(0,T; L^2(\Omega))$ and that the limit u satisfies the nonlinear problem.

To define (u_l), we need the following lemma.

LEMMA 4. *Let v belong to the space $L^\infty(]0,T[, H^2(\Omega)) \cap W^{1,\infty}(]0,T[, H^1(\Omega)) \cap W^{2,\infty}(]0,T[, L^2(\Omega))$, and $g = f(v)$. Then g belongs to $H^2(]0,T[, L^2(\Omega))$ and satisfies the inequality*

$$\|g\|^2_{H^2(]0,T[,L^2(\Omega))} \leq T\theta(\|v\|^2_{L^\infty(]0,T[,H^2(\Omega))}+\|v\|^2_{W^{1,\infty}(]0,T[,H^1(\Omega))}+\|v\|^2_{W^{2,\infty}(]0,T[,L^2(\Omega))}),$$

where θ is a continuous increasing function.

The proof of this lemma relies on the injection of $H^2(\Omega)$ in $L^\infty(\Omega)$, the injection of $H^1(\Omega)$ in $L^4(\Omega)$, and the fact that f is C^2.

Proposition 6, Lemma 4, and Gronwall's lemma yield the following.

COROLLARY 1. *Let v belong to $L^\infty(]0,T[,H^2(\Omega)) \cap W^{1,\infty}(]0,T[,H^1(\Omega)) \cap W^{2,\infty}(]0,T[,L^2(\Omega))$ such that $v(0) = u_0$ and $i\partial_t v(0) = -\Delta u_0 + f(u_0)$, where u_0 is in $H^4(\Omega)$ with compact support in Ω. Let w be the unique solution of Proposition 6 with $g = f(v)$. Then w satisfies following estimate:*

$$\begin{aligned}\|w\|^2_{W^{2,\infty}(]0,T[,L^2(\Omega))} + \|w\|^2_{W^{1,\infty}(]0,T[,H^1(\Omega))} + \|w\|^2_{L^\infty(]0,T[,H^2(\Omega))} \leq e^{CT}(\theta(\|u_0\|_{H^4(\Omega)})\\ + T\theta(\|v\|^2_{W^{2,\infty}(]0,T[,L^2(\Omega))} + \|v\|^2_{W^{1,\infty}(]0,T[,H^1(\Omega))}\\ + \|v\|^2_{L^\infty(]0,T[,H^2(\Omega))})),\end{aligned}$$

where C depends only on Ω, θ and the function f.

Remark. We suppose that u_0 has compact support which is stronger than (2.42). In fact, (2.42) is not preserved under the action of a nonlinear function f.

Now we set $C_1 = \max(\|u_0\|_{H^2(\Omega)}, \theta(\|u_0\|_{H^4(\Omega)}))$ and $T_1 > 0$ so that we have $e^{CT_1}(C_1 + T_1\theta(2C_1)) \leq 2C_1$. Set $C_2 = \sup_{|s|\leq 4C_1} |f'(s)|$ and $T_2 > 0$ so that $CC_2T_2 \leq \frac{1}{2}$.

DEFINITION 1. *Let $T > 0$ be such that $T \leq \max(T_1, T_2)$. We define the sequence (u^l) in $W^{2,\infty}(]0,T[,L^2(\Omega)) \cap W^{1,\infty}(]0,T[,H^1(\Omega)) \cap L^\infty(]0,T[,H^2(\Omega))$ by induction. u^0 is constant in time and is equal to u_0 on $[0,T]$. Suppose u^l is defined in $W^{2,\infty}(]0,T[,L^2(\Omega)) \cap W^{1,\infty}(]0,T[,H^1(\Omega)) \cap L^\infty(]0,T[,H^2(\Omega))$; then $f(u^l)$ is in $H^2(]0,T[,L^2(\Omega))$ by Lemma 4: we may thus define u^{l+1} as the unique solution of problem (2.43) with the right-hand side $f(u^l)$.*

Corollary 1 and the energy estimates of Proposition 6 yield the following.

LEMMA 5. *The sequence (u^l) is bounded in the space $W^{2,\infty}(]0,T[,L^2(\Omega)) \cap W^{1,\infty}(]0,T[,H^1(\Omega)) \cap L^\infty(]0,T[,H^2(\Omega))$ and is a Cauchy sequence in $C([0,T],L^2(\Omega))$.*

The end of the proof of the existence of u is classical (see, for example, [20]). The limit u of the Cauchy sequence (u^l) satisfies the variational formulation (3.3) by using the strong convergence in $C([0,T],L^2(\Omega))$ and the boundedness in $L^\infty(]0,T[,H^2(\Omega))$ for the nonlinear term. The uniqueness follows from the energy estimate (2.49) and the fact that u belongs to $L^\infty(]0,T[,H^2(\Omega))$.

3.2. Numerical results. We test our absorbing boundary conditions in the one-dimensional case. In fact, we will see that the numerical results are poor in this case. It is therefore useless to implement higher-dimensional cases.

3.2.1. The frame. We take $\Omega =]-5,5[$ as computational domain and $]-4.98,4.98[$ as domain of interest. We take the time step $\delta t = 10^{-3}$ and the space step $h = 10^{-2}$. We compare the solution of (3.2) to the soliton solution of (3.1) with $f(u) = -|u|^2u$:

$$u_{ex}(t,x) = \sqrt{2a}\,\mathrm{sech}(\sqrt{a}(x-ct))\exp\left(i\frac{c}{2}(x-ct)+i\theta_0\right)\exp\left(i\left(a+\frac{c^2}{4}\right)t\right),$$

where $a = 27$, $c = 15$, and $\theta_0 = \pi/4$. This solution is a good test because it has almost compact support in $]-5,5[$ at $t = 0$ (it remains under 10^{-10} on the boundary), and it crosses the boundary $x = 5$ between $t = 0$ and $t = 1$.

We use Durán and Sanz-Serna's scheme [11], where the semidiscrete form is

$$\frac{U^{n+1}-U^n}{\delta t} = i\partial_{xx}^2 U^{n+\frac{1}{2}} + if(U^{n+\frac{1}{2}}), \tag{3.4}$$

where $U^{n+1/2} = (U^{n+1}+U^n)/2$ and $n = 0,\dots,T/\delta t - 1$. We solve the nonlinear system with a fixed-point method giving $U^{n+1/2}$:

$$Z = \left(1 - i\frac{\delta t}{2}\partial_{xx}^2\right)^{-1}\left(U^n + i\frac{\delta t}{2}f(Z)\right).$$

We initialize the fixed-point method with U^n. Then $U^{n+1} = 2Z - U^n$.

3.2.2. The discrete transparent operator for the linear case. We approximate (3.2) with the following problem:

$$\begin{cases} Lu = f(u) & \text{in } \mathbb{R}^+ \times \Omega, \\ \partial_{\nu_\Omega} u = Tu & \text{in } \mathbb{R}^+ \times S, \\ u = u_0 & \text{at } t = 0, \end{cases} \tag{3.5}$$

where T is the transparent operator for the linear case (the Dirichlet-to-Neumann map of section 2.1.1). In [5], Arnold and Ehrhardt discretize T (here at $x = -5$) as

$$u_1^{n+1} - s^0 u_0^{n+1} = \sum_{l=1}^{n} s^{n+1-k} u_0^k - u_1^n, \tag{3.6}$$

where $(s^k)_{k\geq 0}$ is computed through a recurrence formula (see Theorem 3.8 of [5]). We implement the solution of (3.5) with the scheme (3.4).

Figure 6 shows that (3.2) approximates (3.5), but not very well. In fact, the error reaches 37% at time 1. In any case, Figure 7 shows that (3.5) does not approximate (3.1) at all. In fact, the soliton leaves Ω, which is not the case of the solution of (3.5). Therefore, the use of any choice of absorbing boundary conditions of the linearized problem does not allow one to approximate the solution of the nonlinear Schrödinger's equation.

Remark. This strategy (to approximate the nonlinear equation with the absorbing boundary conditions of the linearized problem) is efficient in the case of reaction-diffusion equations (see [27]).

Remark. In [7], the authors show that the solution of (3.1) and of (3.5) share some qualitative properties (blow-up, filamentation, etc.). However, Figure 7 shows that the two solutions are quantitatively very different.

4. Conclusion. Our absorbing boundary conditions give an accurate method with which to approximate the solution of Schrödinger's equation on the whole space with a low numerical cost. In the case of curved boundaries, we could still improve our results by computing more terms in the asymptotic expansion of the Dirichlet-to-Neumann map. (we used only two terms in this study.)

Regarding the nonlinear problem, we have proved an existence and uniqueness result for the problem with nonclassical boundary conditions, which is a new result. Our absorbing boundary conditions for the linearized problem allow us to approximate the problem with the transparent boundary conditions for the linearized problem as shown by our numerical computations. However, the nonlinear problem with the transparent boundary conditions of the linearized problem does not approximate the nonlinear problem on the whole space. We should develop a purely nonlinear strategy.

HOMOTOPIES FOR INTERSECTING SOLUTION COMPONENTS OF POLYNOMIAL SYSTEMS*

ANDREW J. SOMMESE†, JAN VERSCHELDE‡, AND CHARLES W. WAMPLER§

Abstract. We show how to use numerical continuation to compute the intersection $C = A \cap B$ of two algebraic sets A and B, where A, B, and C are numerically represented by witness sets. En route to this result, we first show how to find the irreducible decomposition of a system of polynomials restricted to an algebraic set. The intersection of components A and B then follows by considering the decomposition of the diagonal system of equations $u - v = 0$ restricted to $\{u, v\} \in A \times B$. An offshoot of this new approach is that one can solve a large system of equations by finding the solution components of its subsystems and then intersecting these. It also allows one to find the intersection of two components of the two polynomial systems, which is not possible with any previous numerical continuation approach.

Key words. components of solutions, embedding, generic points, homotopy continuation, irreducible components, numerical algebraic geometry, polynomial system

1. Introduction.

In a series of papers [12, 13, 14, 15, 16, 17], we proposed numerical continuation algorithms that use witness sets as the basic construct for representing solution components of a system of polynomial equations on $\mathbb{C}^N$. Witness sets are the central concept of a young subject that we call numerical algebraic geometry, which uses numerical continuation [1, 2] and generalizes earlier work in computing isolated solutions of polynomial systems [8, 9]. The main concern of this paper is to provide an algorithm for computing the intersection of two solution components A, B from two possibly identical polynomial systems f, g, whose witness sets have been given. It is important to realize that naively combining f, g into one system $h = \{f, g\}$ is not sufficient, even if we were willing to put aside the potentially prohibitive size of the combined system. For example, suppose A is the line $x_2 = 0$ as a solution component of $f(x) = x_1 x_2$ and B is the line $x_1 - x_2 = 0$ as a solution component of $g(x) = x_1(x_1 - x_2)$. Then, $A \cap B$, which is the isolated point $(0, 0)$, does not appear as an irreducible component of the system $h = \{f, g\}$.

Questions involving intersection of components arise naturally in applications. Just as a single polynomial in one variable has multiple roots, a system of polynomial equations in several variables can have multiple solution components; these compo-

nents can even appear at different dimensions (points, curves, surfaces, etc.) from the same set of equations. We may wish to find the intersection of just one of those components with another algebraic set. In our new approach, only the degrees of the components being intersected come into play in the determination of the number of paths followed by the homotopies that we use. This is important since the degree of a component of a given system of polynomials is typically much less than the number of paths required to find even all isolated solutions of the given system.

Viewed another way, the intersection operation is required for a Boolean algebra of constructible algebraic sets; a complete Boolean algebra also requires the operations of union and complement. Suppose W is a witness set for a component X. There are several probability-one algorithms for deciding if a point $x \in \mathbb{C}^N$ is a member of X, using numerical continuation and the data in W. (We review witness sets and membership tests in section 2.) The complement operation is just the logical inversion of a membership test, and the union operation is just a union of witness sets, utilizing membership tests to eliminate duplications. However, the operation of intersection is more difficult.

In our previous work, we showed how to find the solution set of a system of polynomial equations as a union of witness sets, and, further, we showed how to decompose these into witness sets for the irreducible components. Said another way, this solves the problem of intersecting a collection of hypersurfaces defined by polynomial equations. But this does not give us an effective means of computing the intersection of two components represented by witness sets.

Our first step in creating an algorithm for the intersection of components is to generalize an earlier algorithm for generating the witness sets for the solution set of a system of polynomial equations on $\mathbb{C}^N$. The generalization instead considers the polynomial equations restricted to an algebraic set. The intersection of components A and B then follows by considering the decomposition of the diagonal system of equations $u - v = 0$ restricted to $\{u, v\} \in A \times B$. Hence, we call the intersection algorithm the diagonal homotopy.

This paper is organized as follows. First, in section 2, we review the definition of a witness set and its role in finding the numerical irreducible decomposition of the solution set of a system of polynomial equations. In section 3 we introduce a slight generalization of the randomization procedure of [17], and in section 4 we give a general construction of homotopies. These sections give the basic definitions and results that will be needed later in the article.

The original algorithm for constructing witness supersets was given in [17]. A much more efficient algorithm for constructing witness supersets was given in [12] by means of an embedding theorem. In section 5, we show how to carry out the generalization of [12] to the case of a system of polynomials on a pure N-dimensional algebraic set $X \subset \mathbb{C}^m$, i.e., an algebraic subset of $\mathbb{C}^m$ all of whose irreducible components are N-dimensional. We call this the abstract embedding theorem because it does not rely on any specific numerical description of X. In this generality we lose some control of multiplicities. However, since our main objective is to find the underlying reduced algebraic solution components, this loss of multiplicity information is of minor importance.

In section 6 we show how to implement the abstract embedding theorem numerically. We need only the information about X that would be produced by the algorithm for the numerical irreducible decomposition of a polynomial system f, for which X is an irreducible component of the solution set of f.

In section 7 we specialize to the situation in which we have two polynomial systems

f and g on $\mathbb{C}^N$ and we wish to describe the irreducible decompositions of $A \cap B$ where A is an irreducible component of $V(f)$ and B is an irreducible component of $V(g)$. Computational experiments are discussed in section 8.

In Appendix A, we give some further discussion of the method of constructing homotopies described in section 4.

In Appendix B, we give the proof of Theorem 5.1.

2. Witness sets. We begin by reviewing the basics of numerical algebraic geometry, wherein the most fundamental concept is a witness set. See [13, 15, 17] for details on irreducible components, the irreducible decomposition, and reduced algebraic sets.

Given a system of polynomials on $\mathbb{C}^N$

$$f(x) := \begin{bmatrix} f_1(x) \\ \vdots \\ f_n(x) \end{bmatrix}, \tag{2.1}$$

we denote the underlying point set $\{x \in \mathbb{C}^N \mid f(x) = 0\}$ by $V(f)$, i.e., the algebraic set $f^{-1}(0)$ (with all multiplicity information that comes with $f^{-1}(0)$ ignored). A pure i-dimensional algebraic subset X of $V(f)$ is a subset $X \subset V(f)$ equal to the closure of a union of i-dimensional connected components of the smooth points of $V(f)$. We emphasize that X is reduced, i.e., that we are ignoring the multiplicity of X within $f^{-1}(0)$. We represent X numerically by a witness set, defined as follows.

DEFINITION 2.1. *A witness set for a pure i-dimensional algebraic set $X \subset V(f) \in \mathbb{C}^N$ consists of*

1. *the dimension, i, of X;*
2. *the polynomial system $f(x)$;*
3. *a general $(N-i)$-dimensional affine linear subspace $L_{N-i} \subset \mathbb{C}^N$; and*
4. *the set of $\deg X$ distinct points $\mathcal{X} = L_{N-i} \cap X$.*

In other words, a witness set W for X is the ordered set $W = \{i, f, L_{N-i}, \mathcal{X}\}$. We use the notation $V(W)$ to denote the component represented by W; in the current context $V(W) = X$.

This definition is useful because it allows us to numerically represent and manipulate the irreducible decomposition of the solution set of a polynomial system. Let us quickly review that concept before describing our new results. Everything we say is over the complex numbers, e.g., even if the polynomials have real coefficients, we always deal with the sets of solutions on complex Euclidean space.

We start with a system of polynomials f on $\mathbb{C}^N$ as in (2.1). Let $V(f)$ denote the set of solutions of f on $\mathbb{C}^N$, i.e., the set of points $x \in \mathbb{C}^N$ such that $f(x) = 0$. The set $Z := V(f)$ is an affine algebraic set and decomposes into a union of distinct irreducible components. Recall that an algebraic set X is irreducible if and only if the Zariski open dense subset of manifold points on X is connected. We have the decomposition

$$Z = \bigcup_{i=1}^{\dim Z} Z_i = \bigcup_{i=1}^{\dim Z} \left(\bigcup_{j \in \mathcal{I}_i} Z_{i,j} \right), \tag{2.2}$$

where

1. for each i, $Z_i := (\cup_{j \in \mathcal{I}_i} Z_{i,j})$;
2. the sets $\mathcal{I}_i$ are finite and each $Z_{i,j}$ is irreducible of dimension i; and

3. $Z_{i,j}$ is not contained in a union of a collection of the $Z_{a,b}$ unless $Z_{i,j}$ occurs in the collection.

Any collection of irreducible components $Z_{i,j}$ having the same dimension, i, can be numerically represented by a witness set. A numerical irreducible decomposition is a list having one witness set $W_{i,j}$ for the reduction of each irreducible component $Z_{i,j}$.

In a series of papers [12, 13, 14, 15, 16, 17], we showed how to compute a numerical irreducible decomposition of $Z := V(f)$. The approach is to intertwine two numerical algorithms: a witness generating algorithm, which finds a superset of witness points for each pure-dimensional algebraic set Z_i, and a decomposition algorithm, which eliminates spurious points from the superset and breaks it into irreducible components. To be more precise, at each dimension $i = 0, \ldots, \dim Z$, the witness generating algorithm gives a finite set of points $\widehat{W}_i$ satisfying $L_{N-i} \cap Z_i \subset \widehat{W}_i \subset L_{N-i} \cap (\cup_{j \geq i} Z_j)$, where $L_{N-i} \subset \mathbb{C}^N$ is a general $(N-i)$-dimensional affine linear subspace. The second algorithm decomposes the $\widehat{W}_i$. Precisely,

1. $\widehat{W}_i$ decomposes into the disjoint union

$$J_i \cup \left(\bigcup_{j \in \mathcal{I}_i} \mathcal{Z}_{i,j} \right), \tag{2.3}$$

where $J_i \subset \cup_{k>i} Z_k$ and $\mathcal{Z}_{i,j}$ consists of the $\deg Z_{i,j}$ points of $L_{N-i} \cap Z_{i,j}$; and

2. $J_{\dim Z} = \emptyset$.

The points $\mathcal{Z}_{i,j}$, along with the dimension i, the system of equations f, and the linear subspace L_{N-i}, form a witness set for the irreducible component $Z_{i,j}$.

The key theoretical advance of this paper is to observe that the previous algorithms for numerical irreducible decomposition still work with restrictions of a polynomial system to a pure-dimensional algebraic set. Only the first algorithm constructing the witness point supersets $\widehat{W}_i$ needs to be generalized. The decomposition algorithms starting with the witness point supersets $\widehat{W}_i$ are proved in [13, 14, 15] in sufficient generality to cover the present situation.

The above implicitly assumes that the components $Z_{i,j}$ are reduced, i.e., of multiplicity one in $f^{-1}(0)$. The algorithms in [12, 17] in fact produce sets $\mathcal{Z}_{i,j}$ consisting of $\deg Z_{i,j}$ distinct points each repeated $\mu_{i,j}$ times, where $\mu_{i,j}$ is greater than or equal to the multiplicity of $Z_{i,j}$ in $f^{-1}(0)$. Moreover the multiplicity of $Z_{i,j}$ is one if and only if $\mu_{i,j} = 1$. Unfortunately, in the algorithm in this article we can assert only that $\mu_{i,j} > 0$ for any irreducible component $Z_{i,j}$.

As mentioned in the introduction, an important aspect of a witness set $\mathcal{X}$ is that we can use it to test a point for membership in the algebraic set $X = V(\mathcal{X})$ that $\mathcal{X}$ represents. This stems from the fact that we can sample X by continuously perturbing the linear slice and numerically tracking its intersection with X, starting from the witness points in $\mathcal{X}$. Several different membership tests can be employed. At one expensive extreme, by sampling and fitting, we might compute a set of polynomials, whose set of common zeros is exactly X. A much more efficient probability-one test for a point $x \in \mathbb{C}^N$ to be in X is whether the pullback from $\mathbb{C}^{\dim X+1}$ of a $\deg X$ defining polynomial for $\pi(X) \subset \mathbb{C}^{\dim X+1}$ is zero on x, where π is a general linear projection from $\mathbb{C}^N$ to $\mathbb{C}^{\dim X+1}$. Finally, a very different sort, and quite efficient test, for $x \in \mathbb{C}^N$ to be in X is to see whether x is one of the images of the set $\mathcal{X}$ under the homotopy taking L_{N-i} to a general $(N-i)$-dimensional linear subspace of $\mathbb{C}^N$ that contains x. This test depends on the real-one-dimensional path

between the general linear subspaces to remain general, which occurs with probability one.

3. Randomizing systems. Randomization is a key element of our approach. This section introduces some notation for randomized systems and gives a lemma describing their most important properties. Given a system of n equations defined on $\mathbb{C}^N$, as in (2.1), and a positive integer k, we define a randomization operation

$$\mathfrak{R}(f(x);k) := \Lambda f(x), \quad \Lambda \in \mathbb{C}^{k\times n}, \tag{3.1}$$

where Λ is chosen generically from $\mathbb{C}^{k\times n}$. Note that k does not have to equal n. Gaussian elimination does not change the ideal generated by $\Lambda f(x)$. Therefore, when $k \geq n$, $\Lambda f(x)$ is equivalent to the system consisting of $f(x)$ plus $k-n$ identically zero equations. For the same reason, when $k \leq n$, $\Lambda f(x)$ is equivalent to the system

$$\left[\begin{array}{cc} I_k & R \end{array}\right] f(x), \quad R \in \mathbb{C}^{k\times(n-k)}, \tag{3.2}$$

where I_k is the $k\times k$ identity matrix. Consequently, we may without loss of generality assume that $\mathfrak{R}(f(x);k)$ is of the form of (3.2) with a generic choice of $R \in \mathbb{C}^{k\times(n-k)}$. This form allows us to take some advantage of the original equations. For example, if $k = N$ and the original equations had total degrees $d_1 \geq d_2 \geq \cdots \geq d_n$, then the total degree of the original form of $\mathfrak{R}(f(x);N)$ is d_1^N, but the total degree of the modified form is $d_1 d_2 \cdots d_N$.

The following lemma gives the main properties of randomization.

LEMMA 3.1. *Let*

$$f(x) := \left[\begin{array}{c} f_1(x) \\ \vdots \\ f_n(x) \end{array}\right] \tag{3.3}$$

be a system of restrictions of n polynomials on $\mathbb{C}^m$ to a pure N-dimensional affine algebraic set $X \subset \mathbb{C}^m$. Assume that $k \leq \min\{n, N\}$. Assume that f does not vanish on any component of X. These conclusions follow:

1. *The dimension of any component of $V(\mathfrak{R}(f(x);k))$ is $\geq N-k$.*
2. *The irreducible components of $V(\mathfrak{R}(f(x);k))$ and $V(f)$ of dimension greater than $N-k$ are the same, and the irreducible $(N-k)$-dimensional components of $V(f)$ are components of $V(\mathfrak{R}(f(x);k))$.*

Proof. This variant of Bertini's theorem follows by the same type of reasoning as the analogous result in [12, 17] for systems of N polynomials on $\mathbb{C}^N$. For the convenience of the reader, we give a proof.

The first conclusion is simply [11, Corollary 3.14].

Since $V(f) \subset V(\mathfrak{R}(f(x);k))$, the second conclusion will follow if we show that all irreducible components $V(\mathfrak{R}(f(x);k)) \cap (X \setminus V(f))$ have dimension $N-k$. Thus it suffices to show that if $V(f)$ is empty, it follows that all irreducible components $V(\mathfrak{R}(f(x);k))$ have dimension $N-k$. This is immediate from Theorem B.1. ∎

4. Construction of homotopies. Our algorithm for intersecting algebraic varieties is based on constructing homotopies to solve a system of polynomial equations restricted to an algebraic set. This is a generalization of existing homotopies, which have until now always worked on complex Euclidean space, $\mathbb{C}^m$. Accordingly, in this section we give a very general construction for homotopies on varieties.

Let $X \subset \mathbb{C}^m$ be an irreducible N-dimensional affine algebraic set and let Y be an irreducible r-dimensional smooth algebraic set with $r \geq 1$. Let

$$f(x,y) = \begin{bmatrix} f_1(x,y) \\ \vdots \\ f_N(x,y) \end{bmatrix} = 0 \tag{4.1}$$

be a system of N algebraic functions on $X \times Y$. In practice, Y is a parameter space defining a family of systems of interest, and for any one member of the family, we wish to find its solution points in X.

More precisely, suppose we have some parameter value $y^* \in Y$ for which we want to find a finite set $\mathcal{F}^*$ of solutions of the system $f(x,y^*) = 0$, such that all the isolated solutions of $f(x,y^*) = 0$ are contained in $\mathcal{F}^*$. A procedure to do this proceeds in a number of steps in the same manner as if Y is $\mathbb{C}^N$:

1. Choose a point $y' \in Y$ for which we can find the isolated solutions $\mathcal{F}'$ of $f(x,y') = 0$, and the number of isolated solutions is the maximum number D for any system $f(x,y) = 0$ as a system in the x variables. We assume here that $y' \neq y^*$, since otherwise we are done.
2. Construct a smooth connected algebraic curve $B \subset Y$ which contains y^* and y'. (Typically Y is a Euclidean space and we choose B equal to the complex line joining the points y^* and y'.)
3. Construct a differentiable mapping $c : [0,1] \times \Gamma \to B$, where Γ is an interval or the unit circle, $c(0,\Gamma) = y^*$, $c(1,\Gamma) = y'$, and where there is a positive integer K such that given any point $y'' \in c([0,1] \times \Gamma)$ not equal to y^* or y', it follows that $c^{-1}(y'')$ has at most K inverse images.
4. Choose a random $\gamma \in \Gamma$ and starting with the isolated solutions $\mathcal{F}'$ of $f(x,y') = 0$ use homotopy continuation of the system $f(x,c(t,\gamma)) = 0$ to continue from the solutions $\mathcal{F}'$ at $t = 1$ to solutions $\mathcal{F}^*$ at $t = 0$.

Let us show that if we can make the choices specified by this procedure, we will find a finite set $\mathcal{F}^*$ of solutions of the system $f(x,y^*) = 0$, such that all the isolated solutions of $f(x,y^*) = 0$ are contained in $\mathcal{F}^*$. In Appendix A we show how to relax item 2 so that the procedure can be carried in all situations where Y is irreducible.

It may happen that the solution sets of $f(x,y) = 0$ for some or all the $y \in Y$ also contain positive dimensional solution components. Nevertheless, the number D in item 1 exists and is finite by general results, e.g., [10]. Now choose B as in item 2. Lemma A.1 guarantees that for all but a finite number of points $\hat{y} \in B$, $f(x,\hat{y}) = 0$ has D isolated solutions and that the closure of the union of the isolated solutions of $f(x,\hat{y}) = 0$ as $\hat{y}$ runs over B is an algebraic curve $\mathcal{B}$ which surjects generically D-to-one onto B. Since the set of points in B over which this mapping is not a covering is an algebraic set and hence finite, the procedure is seen to work.

Remark 4.1. Algebraic functions on an affine algebraic set $X \subset \mathbb{C}^m$ are the restrictions of polynomials from $\mathbb{C}^m$. If by $\deg f_i$ we denote a degree of a polynomial on $\mathbb{C}^m$ restricting to X, it follows that the number D above is at most $\deg X \times \Pi_{i=1}^N \deg f_i$. From this it further follows that if we can find a y' such that $f(x,y') = 0$ has $\deg X \times \Pi_{i=1}^N \deg f_i$ nonsingular isolated solutions, we can use y'.

Remark 4.2. Lemma A.1, which justifies the above procedure, is strong enough to yield the algorithms we need to construct witness points. However, the lemma is too weak to relate the multiplicity of the points as they appear in these algorithms to the multiplicity of the components that they represent. See Appendix A for more details.

5. An abstract embedding theorem. The object of this section is to present Theorem 5.1, a generalization of the main theorem of [12]. We are aiming for the same results as in that article except that $\mathbb{C}^N$ is replaced by a pure N-dimensional affine algebraic set X. We call the generalization in this section abstract because we do not specify an explicit description of X; a numerical version is the topic of the next section. Since the proof of Theorem 5.1 follows the same line of reasoning of [12], we only state and discuss the parts of that article that need changes. Before we can state the theorem, we need some notation.

5.1. Definitions. Let $X \subset \mathbb{C}^m$ be a reduced pure N-dimensional affine algebraic set, i.e., an affine algebraic subset of $\mathbb{C}^m$, all of whose irreducible components are of multiplicity one and dimension N. We assume that we have a system of restrictions of polynomials on $\mathbb{C}^m$ to X,

$$f(x) := \begin{bmatrix} f_1(x) \\ \vdots \\ f_N(x) \end{bmatrix}. \tag{5.1}$$

We assume that f does not vanish identically on any irreducible component of X. We will occasionally abuse notation and use the same notation f_i to denote the polynomial on $\mathbb{C}^m$ and its restriction to X. In line with this abuse, we let

$$x := \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix} \tag{5.2}$$

denote both the coordinates on $\mathbb{C}^m$ and the restrictions of the coordinates to X.

Let $\mathcal{Y}$ denote the matrix space $\mathbb{C}^{N\times(1+m+N)}$, with submatrices denoted as

$$\begin{bmatrix} \mathcal{A}_0 & \mathcal{A}_1 & \mathcal{A}_2 \end{bmatrix}, \tag{5.3}$$

where $\mathcal{A}_0 \in \mathbb{C}^{N\times 1}$, $\mathcal{A}_1 \in \mathbb{C}^{N\times m}$, and $\mathcal{A}_2 \in \mathbb{C}^{N\times N}$. We have the stratification of $\mathcal{Y}$,

$$\mathcal{Y}_0 \subset \mathcal{Y}_1 \subset \cdots \subset \mathcal{Y}_N, \tag{5.4}$$

where $\mathcal{Y}_i$ is the subspace of $\mathcal{Y}$ obtained by setting the last $N-i$ rows of $\mathcal{Y}$ equal to 0, and we define $\pi_i : \mathcal{Y} \to \mathcal{Y}_i$ as the corresponding projection. Note in particular that $\mathcal{Y}_N$ is $\mathcal{Y}$, whereas $\mathcal{Y}_0$ is an $N \times (1+m+N)$ matrix of zeros. Defining e_i as the $N \times N$ matrix of all zeros except a 1 in the ith diagonal element and letting $P_i = \sum_{j=1}^{i} e_j$, we can explicitly write $\pi_i(Y) = P_i Y$. We define P_0 to be the $N \times N$ matrix with all entries zero. This notation will be useful in defining a homotopy.

We let

$$z := \begin{bmatrix} z_1 \\ \vdots \\ z_N \end{bmatrix} \tag{5.5}$$

denote coordinates on $\mathbb{C}^N$.

5.2. Embedding and cascade. For $Y = (\mathcal{A}_0, \mathcal{A}_1, \mathcal{A}_2) \in \mathcal{Y}$, we define the system

$$\mathcal{E}(f)(x, z, Y) := \begin{bmatrix} f(x) + \mathcal{A}_2^T z \\ z - \mathcal{A}_0 - \mathcal{A}_1 x \end{bmatrix}, \tag{5.6}$$

which admits the embeddings

$$\mathcal{E}_i(f)(x, z, Y) = \mathcal{E}(x, z, \pi_i(Y)) = \mathcal{E}(x, z, P_i Y). \tag{5.7}$$

We often refer to $\mathcal{E}_i(f)(x, z, Y)$ by $\mathcal{E}_i$ or $\mathcal{E}_i(f)$. We regard $\mathcal{E}_i$ as a family of systems of equations on $X \times \mathbb{C}^N$ parameterized by $\mathcal{Y}_i$. Note that

1. the $\mathcal{E}_i$ are the restrictions of systems $\mathcal{E}_N$ to $\mathcal{Y}_i$; and
2. the $\mathcal{E}_i$ can be identified with systems on $X \times \mathbb{C}^i$ with coordinates $z_1, \ldots, z_i$ on $\mathbb{C}^i$. (This is because $z_j = 0$ for $j > i$.) Thus, $\mathcal{E}_0$ is naturally identified with the system f.

For i from 1 to N and $\gamma_i \in \{\gamma \in \mathbb{C} \mid |\gamma| = 1\}$, we define a cascade of homotopies that connect the embedded systems:

$$\mathcal{H}_i(x, z, t, Y, \gamma_i) := \begin{bmatrix} f(x) + \mathcal{A}_2^T z \\ P_{i-1}(z - \mathcal{A}_0 - \mathcal{A}_1 x) \\ \qquad + e_i((1-t)z + \gamma_i t(z - \mathcal{A}_0 - \mathcal{A}_1 x)) \\ \qquad + (I_N - P_i)z \end{bmatrix}. \tag{5.8}$$

The nonzero parts of the three terms in the lower block of this expression occupy separate rows, with only the ith row depending on t. At $t = 1$, $\mathcal{H}_i(x, z, 1, Y, \gamma_i)$ is equivalent to $\mathcal{E}_i(x, z, Y)$ (they differ only in that the ith row of the lower block has been scaled by γ_i), and at $t = 0$, $\mathcal{H}_i(x, z, 0, Y, \gamma_i) = \mathcal{E}_{i-1}(x, z, Y)$. Homotopy $\mathcal{H}_i$ allows us to compute solutions to the embedded systems by continuation, as described in the next paragraph.

For i from 1 to N, $\mathcal{F}_i$ denotes the solutions to $\mathcal{E}_i = 0$ with $z \neq 0$. In the case of $i = 0$, we make the convention that $\mathcal{F}_0$ is the empty set. Of course, like $\mathcal{E}_i$, $\mathcal{F}_i$ depends on $Y \in \mathcal{Y}$. We do not emphasize the dependence since the thrust of the main result is that a generic choice of Y, which is done once and for all using a random number generator in implementations, has a number of nice properties:

1. The solutions $\mathcal{F}_i$ of $\mathcal{E}_i = 0$ are nonsingular and isolated and equal to the set of solutions of $\mathcal{E}_i = 0$ with $z_i \neq 0$.
2. The solutions of $\mathcal{E}_i = 0$ equal $\mathcal{F}_i$ for $i > \dim V(f)$.
3. For all $u \in \mathcal{F}_i$ and but a finite number of γ_i, there is a unique continuous map $s_u(t) : [0, 1] \to X \times \mathbb{C}^i$ such that
   (a) $s_u(1) = u$;
   (b) $\mathcal{H}_i(s_u(t), t, Y, \gamma_i) = 0$; and
   (c) the Jacobian of $\mathcal{H}_i(x, z, t, Y, \gamma_i)$ with respect to (x, z) is invertible at $(s_u(t), t)$ for $t \in (0, 1]$.
4. The limits of the functions $s_u(t)$ as $t \to 0$, which exist by the last properties, consist of the set $\mathcal{F}_{i-1}$ plus a finite set $\widehat{W}_{i-1}$.

The collection of sets $\widehat{W}_i$ for $i = 1, \ldots, N$ contains the witness points for the irreducible decomposition of $f^{-1}(0)$. This is stated formally in the following theorem, a generalization of the main theorem of [12].

THEOREM 5.1. *Let f be the restriction of a system of N polynomials on $\mathbb{C}^m$ to a pure N-dimensional affine algebraic set $X \subset \mathbb{C}^m$. Assume that f is not identically*

zero on any irreducible component of X and that $(\mathcal{A}_0, \mathcal{A}_1, \mathcal{A}_2)$ is chosen generically. If j is the largest integer with $\widehat{W}_j$ nonempty, then the dimension of $f^{-1}(0)$ is j. Moreover, given any irreducible component W of $f^{-1}(0)$ of dimension $i \leq j$, then the finite set $\widehat{W}_i$ contains $\deg(W_{\rm red})$ *generic points of $W_{\rm red}$, each counted ν_W times, where ν_W is a positive integer, and $W_{\rm red}$ is the reduction of W. The remaining points $J_i \subset \widehat{W}_i$ lie on components of $f^{-1}(0)$ of dimension $> i$.*

Theorem 5.1 is a consequence of Lemma A.1 and Lemmas B.2 and B.4.

6. Numerical embedding. In this section we show how to numerically implement the algorithm of section 5. We assume that we have f and $X \subset \mathbb{C}^m$ as in Theorem 5.1. We assume that we have a system of polynomials on $\mathbb{C}^m$

$$g(x) := \begin{bmatrix} g_1(x) \\ \vdots \\ g_n(x) \end{bmatrix} \tag{6.1}$$

such that X is a union of dimension N irreducible components of $V(g)$. Once and for all choose a randomized system of $m - N$ polynomials $G(x) := \mathfrak{R}(g(x); m - N)$. By Lemma 3.1 we know that X is a union of dimension N irreducible components of $V(G)$.

We further assume that we begin with a witness set for X; that is, we know its dimension N and have found the $\deg X$ smooth isolated witness points $W = \mathcal{L}_{m-N} \cap X$ for a general linear subspace $\mathcal{L}_{m-N}$ of dimension $m - N$. (This will be on hand after computing the numerical irreducible decomposition of $g(x) = 0$.)

To convert the abstract systems of the previous section to systems we can compute with, we append G. Thus regarding the f_i as polynomials on $\mathbb{C}^m$, we replace $\mathcal{E}_i(f)$ by

$$\begin{bmatrix} G(x) \\ \mathcal{E}_i(f)(x, z) \end{bmatrix}, \tag{6.2}$$

which by abuse we still call $\mathcal{E}_i(f)$. We let $\widetilde{\mathcal{E}}_i(f)$ denote the original $\mathcal{E}_i(f)$ without the $G(x)$; we use this only in (6.6) and (6.7).

To start the algorithm we need to solve $\mathcal{E}_N(f) = 0$. Assume the total degree of f_i as a polynomial on $\mathbb{C}^m$ is d_i for each i.

Choosing $d_1 + \cdots + d_N$ general linear forms

$$L_{1,1}(x), \ldots, L_{1,d_1}(x), \ldots, L_{N,1}(x), \ldots, L_{N,d_N}(x) \tag{6.3}$$

on $\mathbb{C}^m$, we want them to have the good property that for any choice of integers i_j in $1, \ldots, d_j$ for each j in $1, \ldots, N$, the solution set $\mathcal{S}_{i_1,\ldots,i_N}$ of the system of restrictions to X of the linear equations

$$\begin{aligned} L_{1,i_1}(x) &= 0 \\ &\vdots \\ L_{N,i_N}(x) &= 0 \end{aligned} \tag{6.4}$$

consists of $\deg X$ nonsingular isolated solutions, and moreover $\mathcal{S}_{i_1,\ldots,i_N} \cap \mathcal{S}_{k_1,\ldots,k_N} = \emptyset$ unless $(i_1, \ldots, i_N) = (k_1, \ldots, k_N)$. Let $\pi : \mathbb{C}^m \to \mathbb{C}^N$ denote a general linear projection. As discussed in [14], π_X is proper and $(\deg X)$-to-one. Let B be the proper algebraic subset such that π_X is an unramified cover when restricted to $X \backslash \pi^{-1}(B)$. By

composing with π we have reduced to the straightforward observation that choosing $d_1+\cdots+d_N$ general linear functions L_i on $\mathbb{C}^N$ for i from 1 to $d_1+\cdots+d_N$, it follows that

1. the unique zero of the linear functions $L_{i_1},\ldots,L_{i_N}$ for distinct $i_1,\ldots,i_N$ between 1 and $d_1+\cdots+d_N$ vanishes at a general point of $\mathbb{C}^N\setminus B$; and
2. given any $N+1$ of the $d_1+\cdots+d_N$ linear functions, there are no solutions on $\mathbb{C}^N$.

The system

$$\widehat{L}(x)=\begin{bmatrix} L_{1,1}(x)\cdots L_{1,d_1}(x)\\ \vdots\\ L_{N,1}(x)\cdots L_{N,d_N}(x)\end{bmatrix}=0 \tag{6.5}$$

has $d_1\cdots d_N\cdot\deg X$ nonsingular isolated solutions w_α contained in X_{reg}, the Zariski open set of smooth points of X. By homotopy continuation tracking from $\mathcal{L}_{m-N}$ to each of the $d_1\cdots d_N$ linear systems that occur in the system $\widehat{L}(x)$, we can compute all the solutions w_α of $\widehat{L}(x)=0$.

Fix the homotopy

$$H(x,z,t):=\begin{bmatrix} G(x)\\ (1-t)\widetilde{\mathcal{E}}_N(f)(x,z)+t\gamma\begin{bmatrix}\widehat{L}(x)\\ z\end{bmatrix}\end{bmatrix}=0, \tag{6.6}$$

where γ is any of all but a finite number of norm one complex numbers. The solutions of $\mathcal{E}_N(f)=0$ are the nonsingular limits as $t\to 0$ on X of paths starting at $t=1$ with the w_α and $z_i=0$ for all i.

Remark 6.1. In practice we often have some estimate, say, $\mathcal{N}-1$, of the largest dimension of any component of the solution set of f on X. This will happen, for example, in section 7. In such a situation we need only start with $\mathcal{E}_{\mathcal{N}}$. In this case we can replace the homotopy (6.6) with

$$H(x,z,t):=\begin{bmatrix} G(x)\\ (1-t)\widetilde{\mathcal{E}}_{\mathcal{N}}(f)(x,z)+t\gamma\begin{bmatrix}\widehat{L}(x)\\ z\end{bmatrix}\end{bmatrix}=0. \tag{6.7}$$

Note that the smooth nonsingular solutions of $\mathcal{E}_i(f)$ on X are generic. Thus they miss $E:=\overline{(G^{-1}(0)\setminus X)}\cap X$ except for a proper algebraic set of parameter values. Thus for a Zariski open dense set of the homotopy parameters the homotopies with G compute the abstract homotopies. Although E may contain the limits of a homotopy, the value of the limit is not influenced by G.

It is important to realize that serious numerical difficulties can arise, even when we are dealing with a smooth reduced component $\mathcal{C}$ of the system f on X. These occur if $\mathcal{C}$ is contained in a component of $V(g)$ other than those in X. If this happens, path tracking to decompose the witness point superset containing generic points of $\mathcal{C}$ will be singular and require the path tracker used in [15].

7. Diagonal homotopies. Assume that A is an irreducible component of the solution set of polynomial system $f_A(u)=0$ in $u\in\mathbb{C}^k$ of dimension $a>0$ and that B is an irreducible component of the solution set of polynomial system $f_B(v)=0$ in $v\in\mathbb{C}^k$ of dimension $b>0$. An important special case of this is when f_A and f_B are the same system and A and B are distinct irreducible components. After renaming if

necessary, we assume $a \geq b$. Moreover, we assume that B is not contained in A, since we would check this at the start of the algorithm and terminate if B was contained in A. Thus all components of $A \cap B$ are of dimension at most $b-1$.

We wish to compute the irreducible decomposition of $A \cap B$. Note that the product $X := A \times B \subset \mathbb{C}^{2k}$ is irreducible of dimension $a+b$. The theory of the preceding sections applies with $m = 2k$ and $N = a+b$. The intersection of A and B can be identified, e.g., [4, Example 13.15], with $X \cap \Delta$, where Δ is the diagonal of $\mathbb{C}^{2k}$ defined by the system on X,

$$\delta(u,v) := \begin{bmatrix} u_1 - v_1 \\ \vdots \\ u_k - v_k \end{bmatrix} = 0. \tag{7.1}$$

Remark 7.1. Notice that $\delta(u,v)$ plays the role of f in (5.1).

If $a+b \geq k$, set $D(u,v)$ equal to $\delta(u,v)$ with $a+b-k$ identically zero equations adjoined. If $k < a+b$, fix a randomization $D(u,v) := \mathfrak{R}(\delta(u,v); a+b)$ once and for all. Note that the smallest dimensional nonempty component of $A \cap B$ is of dimension at least $\max\{0, a+b-k\}$. Thus by Lemma 3.1, we can find the irreducible decomposition of $A \cap B$ by finding the irreducible decomposition of $D(u,v) = 0$ on X.

Fix randomizations $F_A(u) := \mathfrak{R}(f_A(u); k-a)$ and $F_B(v) := \mathfrak{R}(f_B(v); k-b)$ once and for all. We assume that we have already processed f_A and f_B through our numerical irreducible decomposition. Thus our data for A consist of a generic system $L_A(u) = 0$ of $a = \dim A$ linear equations and the $\deg A$ solutions $\{\alpha_1, \ldots, \alpha_{\deg A}\} \in \mathbb{C}^k$ of the system

$$\begin{bmatrix} F_A(u) \\ L_A(u) \end{bmatrix} = 0, \tag{7.2}$$

and the data for B consist of a generic system $L_B(v) = 0$ of $b = \dim B$ linear equations and the $\deg B$ solutions $\{\beta_1, \ldots, \beta_{\deg B}\} \in \mathbb{C}^m$ of the system

$$\begin{bmatrix} F_B(v) \\ L_B(v) \end{bmatrix} = 0. \tag{7.3}$$

Remark 7.2. We are not assuming that A and B occur with multiplicity one. If the multiplicity is greater than one, we must use a singular path tracker [15].

Note that $A \times B$ is an irreducible component of the solution set of the system

$$\mathcal{F}(u,v) := \begin{bmatrix} F_A(u) \\ F_B(v) \end{bmatrix} = 0. \tag{7.4}$$

In the following paragraphs, we write $z_{h:k}$ to mean the column vector of variables $z_h, \ldots, z_k$.

Since we know that all components of $A \cap B$ are of dimension at most $b-1$, the first system of the cascade of homotopies is

$$\mathcal{E}_b(u,v,z_{1:b}) = \begin{bmatrix} \mathcal{F}(u,v) \\ \mathfrak{R}(D(u,v), z_1, \ldots, z_b; a+b) \\ z_{1:b} - \mathfrak{R}(1,u,v;b) \end{bmatrix} = 0. \tag{7.5}$$

This system consists of $k-a+k-b+a+b+b = 2k+b$ equations in $2k+b$ variables.

To start the cascade, we must find the solutions of (7.5). Recall $a \geq b$. Specializing the system from the end of section 6, we have the homotopy

$$\left[\begin{array}{c} \mathcal{F}(u,v) \\ (1-t) \left[\begin{array}{c} \mathfrak{R}(D(u,v), z_1, \ldots, z_b; a+b) \\ z_{1:b} - \mathfrak{R}(1,u,v;b) \end{array} \right] + t\gamma \left[\begin{array}{c} L_A(u) \\ L_B(v) \\ z_{1:b} \end{array} \right] \end{array} \right] = 0. \tag{7.6}$$

At $t = 1$, solution paths start at the $\deg A \times \deg B$ nonsingular solutions

$$\{(\alpha_1, \beta_1), \ldots, (\alpha_{\deg A}, \beta_{\deg B})\} \subset \mathbb{C}^{2k} \tag{7.7}$$

obtained by combining the witness points for A and B. At $t = 0$, the solution paths terminate at the desired start solutions for (7.5).

Since $A \cap B \neq \emptyset$ implies that

$$\dim A \cap B \geq a + b - k, \tag{7.8}$$

we see that when $a + b \geq k$, we do not have to continue the cascade beyond level $a + b - k$. We can codify this into the numerics by noting that the system $\mathcal{E}_b$ is, with probability one, the same as the system

$$\widehat{\mathcal{E}}_b(u, v, z_{b-\bar{a}+1}, \ldots, z_b) = \left[\begin{array}{l} \mathcal{F}(u,v) \\ \mathfrak{R}(\delta(u,v), z_{b-\bar{a}+1}, \ldots, z_b; k) \\ \mathfrak{R}(1,u,v;b-\bar{a}) \\ z_{(b-\bar{a}+1):b} - \mathfrak{R}(1,u,v;\bar{a}) \end{array} \right] = 0, \tag{7.9}$$

where $\bar{a} = k - a$. This system has $(k-a)+(k-b)+k+(k-a)+(a+b-k) = 3k-a$ equations in $3k-a$ variables. Notice that $a + b \geq k$ implies $3k - a \leq 2k + b$. To appreciate this, consider the case when a and b are both $k-1$ and f_A and f_B are each a single equation. In this case the first system of the cascade is

$$\widehat{\mathcal{E}}_1(u, v, z_1) = \left[\begin{array}{r} f_A(u) \\ f_B(v) \\ u - v + R_{k\times 1} z_1 \\ \mathfrak{R}(1,u,v;k-2) \\ z_1 - \mathfrak{R}(1,u,v;1) \end{array} \right] = 0, \tag{7.10}$$

where $R_{k\times 1}$ is a generic complex k-vector.

In the important case when $a + b \geq k$, we want to compute the start solutions for (7.9). Then, letting $\bar{a} = k - a$, the homotopy (7.6) reduces with probability one to

$$\left[\begin{array}{c} \mathcal{F}(u,v) \\ (1-t) \left[\begin{array}{c} \mathfrak{R}(\delta(u,v), z_{b-\bar{a}+1}, \ldots, z_b; k) \\ \mathfrak{R}(1,u,v;b-\bar{a}) \\ z_{(b-\bar{a}+1):b} - \mathfrak{R}(1,u,v;\bar{a}) \end{array} \right] + t\gamma \left[\begin{array}{c} L_A(u) \\ L_B(v) \\ z_{(b-\bar{a}+1):b} \end{array} \right] \end{array} \right] = 0. \tag{7.11}$$

8. Computational experiments. The diagonal homotopies are implemented in the software package PHCpack [18], recently upgraded to deal with positive dimensional solution components. The software is available at http://www.math.uic.edu/~jan.

To compute witness points on all positive dimensional components of the intersection, we distinguish three stages:

1. Given witness points on the two components, construct the top dimensional system in the cascade and the start system to start the cascade.
2. Use polynomial continuation to compute the solutions at the start of the cascade.
3. Follow all paths defined by the cascade, in b stages, until all slack variables in $z_{1:b}$ are eliminated or until no more paths are left to trace. When $a+b \geq k$, we need work only with $z_{(b-\bar{a}+1):b}$.

The complexity of this procedure thus depends on

1. the number of variables (and equations) in the top dimensional system in the cascade,
2. the number of paths it takes to compute the solutions at the start of the cascade, and
3. the number of paths defined by the cascade.

Although we mention timings of runs done on a 2.4 Ghz Linux machine, the numbers describing the complexity are less transient.

8.1. An illustrative example. Consider the following example:

$$f(x,y,z,w) = \begin{bmatrix} xz \\ xw \\ yz \\ yw \end{bmatrix} = 0. \tag{8.1}$$

There are two solution components of dimension two, characterized by the equations $\{x=0, y=0\}$ and $\{z=0, w=0\}$. Pretending we do not know the two components intersect in the origin, we will set up a cascade of homotopies to compute the intersection of the two components.

Since we start out with four variables ($k=4$) and work with two-dimensional components ($a=b=2$), the total number of variables at the start of the cascade is $2k+b=10$. The components are characterized by one witness point each, so there is only one path to trace. Tracing one path to start the cascade takes only 80 milliseconds of CPU time and gives a point with $z_2 \neq 0$, $z_1 \neq 0$. In the first stage of the cascade, we take z_2 to zero, but z_1 remains nonzero, showing that there is not a one-dimensional component. The second stage of the cascade takes z_1 to zero and yields the origin as the point of intersection of the two components, as expected. The two stages of the cascade together take just 30 milliseconds.

8.2. Intersection of a cylinder with a sphere. In Figure 8.1 we see a sphere intersected by a cylinder. The curve C defined by this intersection is

$$C := \{\ (x,y,z) \mid x^2+y^2-1=0\ \cap\ (x+0.5)^2+y^2+z^2-1=0\ \}. \tag{8.2}$$

The total user CPU time of all path tracking is about a tenth of a second. First we track two paths to find a witness set for the cylinder, which takes 20 milliseconds. Then it also takes 20 milliseconds to compute a witness set for the sphere. We have $a=b=2$ and $k=3$; thus $a+b>k$ and the diagonal homotopy requires seven variables, as $7=3k-a$. Tracking the 2×2 paths defined by the diagonal homotopy takes 70 milliseconds of CPU time. At the end of the paths we find four points in the witness set for the curve C.

We may now move the slicing plane of the witness set to find the intersection of C with any desired plane. For example, to find the points on C of the form (x,x,z), we move the slice in a continuous fashion to $x-y=0$. Tracking the four solutions in

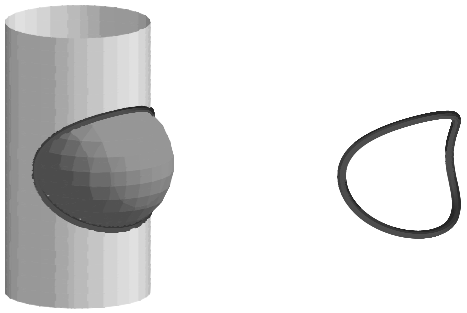

FIG. 8.1. *Intersection of a sphere with a cylinder. At the right we see the curve of degree four defined by the intersection.*

the witness set to this special plane takes only 10 milliseconds of CPU time and gives two real and two complex-conjugate solutions.

8.3. Adding an extra leg to a moving platform. In this section we give an application of the important case where one of the components is a hypersurface. We consider a special case of a Stewart–Gough platform proposed by Griffis and Duffy [6]. When further specialized to have equilateral upper and lower triangles connected by six legs in cyclic fashion from a vertex of one triangle to a midpoint of an edge of the other triangle, and vice versa, the platform permits motion. This property was first identified and analyzed by Husty and Karger [7] and subsequently reexamined in [15].

When the legs of the mechanism described above have general lengths, a formulation of the kinematic equations using Study coordinates has one curve of degree 28 and 12 lines [15]. The lines are mechanically irrelevant, so we ignore them. Suppose we form a tetrahedron by adding a fourth point in general position to the base triangle and similarly for the upper triangle and then add a seventh leg of known length connecting these two points. The condition for assembling the mechanism is equivalent to intersecting the motion curve of degree 28 for the first six legs with a quadratic hypersurface that equates the length of the seventh leg to the distance between its points of connection. This hypersurface is of the same form as the main equations in the system defining the curve. With the addition of the seventh leg, the platform will no longer move but instead will have a finite number of fixed postures.

The number of variables and equations in the original system is eight ($k = 8$). We intersect a one-dimensional component with a hypersurface; for $k = 8$, this hypersurface is of dimension seven. Since $a \geq b$, we have $a = 7$ and $b = 1$. Thus the cascade starts with 17 variables, as $2k + b = 2 \times 8 + 1 = 17$. The hypersurface is represented by two witness points and the curve we intersect has 28 witness points. To start the cascade, we trace $2 \times 28 = 56$ paths in dimension 17, using 20.3 seconds of CPU time. The cascade just has to remove one hyperplane to arrive at the 40 intersection points (16 of the 56 paths diverge), which requires 14.4 seconds of CPU time. Interestingly, a general Stewart–Gough platform also has 40 solution points.

Finally, we point out that the CPU time spent on the diagonal homotopy is considerably less than for solving the system directly. For the direct approach the input is a system in nine equations and eight variables. Before giving it to the blackbox solver of PHCpack, we add to every equation one monomial, which is a new slack variable multiplied with a random constant. The mixed volume of this new nine-dimensional system is 164. The computation of the mixed volume and tracking of all 164 paths

takes 108.5 seconds (1.8 minutes) of CPU time. At the end we find the same 40 intersection points; the other 124 paths diverged to infinity. Notice that in the diagonal homotopy, only 16 paths diverged.

9. Conclusions. In this paper, we extend the cascade of [12] to compute witness points on all components of the intersection of two irreducible varieties. This is done by computing the irreducible decomposition of the diagonal of the product of the two irreducible varieties, and so we call the new procedure a diagonal homotopy. The procedure is justified as a special case of a method, also described herein, for the irreducible decomposition of the solution set of any polynomial system restricted to an irreducible algebraic set.

The diagonal homotopy given here always has at least twice the number of variables as the ambient space of the varieties being intersected. In a sequel to this paper, we will describe a modification to the diagonal homotopy that avoids the explicit doubling of the system, which leads to more efficient computation.

Appendix A. Homotopy on an algebraic set. In section 4, we give a procedure for constructing homotopies to solve a system of parameterized polynomials restricted to an algebraic set. In that procedure, Y is the parameter space and B is a smooth curve in Y, and we compute solution paths along a one-real-dimensional curve in B. Both Y and B are irreducible algebraic sets.

While choosing a smooth B is a difficulty when Y is irreducible and singular, it is always easy to find an irreducible curve B that contains y' and y^* with $y' \notin B_{\text{Sing}}$. If y' is not in the singular set Y_{Sing} of Y, then B is not contained in Y_{Sing}. This is more than enough for the procedure to find a finite set $\mathcal{F}^*$ of solutions of the system $f(x, y^*) = 0$, such that all the isolated solutions of $f(x, y^*) = 0$ are contained in $\mathcal{F}^*$.

In fact, the procedure given in section 4 works with item 2 of that procedure relaxed to the condition of constructing an irreducible curve B containing y' and y^* such that

1. B is not contained in the singular set Y_{Sing} of Y, and
2. $y' \notin B_{\text{Sing}}$.

That the procedure finds a finite set $\mathcal{F}^*$ of solutions of the system $f(x, y^*) = 0$, such that all the isolated solutions of $f(x, y^*) = 0$ are contained in $\mathcal{F}^*$, may be shown by reducing to the nonsingular case:

1. Desingularize Y, i.e., let $\pi : \overline{Y} \to Y$ denote a surjective birational morphism which gives an isomorphism from $\overline{Y} \setminus \pi^{-1}(Y_{\text{Sing}})$ to $Y \setminus Y_{\text{Sing}}$.
2. Note that since $B \not\subset Y_{\text{Sing}}$, there is an algebraic curve $B' \subset \overline{Y}$ that maps generically one to one and onto B. By using embedded resolution of $\overline{Y}$, it can be further assumed that B' is smooth.
3. By composition with π we get algebraic functions f_i' on $X \times \overline{Y}$.
4. Note that given $y^* \in B \subset Y$, there is a point $y'^* \subset B'$ that maps onto y^*.
5. Note that the result shown holds for $X, \overline{Y}, f', B'$ and that (with the obvious identifications) the system $f(x, y^*) = 0$ on $X \times \{y^*\}$ is identical to the system $f'(x, y'^*)$ on $X \times \{y'^*\}$.

The lemma which justifies the homotopy is as follows.

LEMMA A.1. *Let $X \subset \mathbb{C}^m$ be an irreducible N-dimensional affine algebraic set and let Y be an irreducible smooth algebraic set. Let*

$$f(x, y) = \begin{bmatrix} f_1(x, y) \\ \vdots \\ f_N(x, y) \end{bmatrix} = 0 \tag{A.1}$$

be a system of N algebraic functions on $X \times Y$. Let x^* be an isolated solution of $f(x, y^*) = 0$ for a fixed value $y^* \in Y$, i.e., assume that there is an open set $\mathcal{O} \subset X$ containing x^* with x^* the only solution of $f(x, y^*) = 0$ on $\mathcal{O}$. Then there exists a neighborhood V of $y^* \in Y$ such that for any $y \in V$ there exists at least one isolated solution of $x \in \mathcal{O}$ of $f(x, y) = 0$.

Proof. This result is a special case of a basic general result from complex algebraic geometry, e.g., [11, (3.10)]. Any irreducible component of $f(x, y) = 0$ is of dimension $\geq \dim Y$. Choose such a component C through (x^*, y^*). Consider $\overline{C} \subset \overline{X} \times Y$, where we close up X within $\mathbb{P}^m$. Since the induced projection $\pi : \overline{C} \to Y$ is proper, and there is a Euclidean neighborhood $\mathcal{O}$ of x^* as in the lemma with $\pi_{\mathcal{O}}^{-1}(y^*) = x^*$, we conclude that there is a neighborhood $V \subset Y$ of y^* such that $\pi_{C \cap (\mathcal{O} \times V)} : C \cap (\mathcal{O} \times V) \to V$ is proper. By the proper mapping theorem the image is an algebraic subset, and by the upper semicontinuity of fiber dimension it must be surjective. This proves the lemma. □

We conclude this appendix with a few remarks on multiplicity. Lemma A.1 is strong enough to yield the algorithms we need to construct witness points but unfortunately too weak for us to relate the multiplicity of x^* as a solution of $f(x, y^*) = 0$ to the multiplicity of the projection map from C to Y at (x^*, y^*). If X were a local complete intersection, then it would follow that C was Cohen–Macaulay in a neighborhood of (x^*, y^*), and we could use the stronger result [12, Lemma 6], conclude the two multiplicities are the same, and thus have the same multiplicity statements as in [12, Theorem 3].

When we apply Lemma A.1, we know a bit more information, i.e., that for a general point y' near y^*, the solutions of $f(x, y') = 0$ near (x^*, y') are nonsingular. It is worth noting in this case, e.g., using [11, Appendix to Chapter 6] that when we choose a sufficiently generic smooth curve in Y through y^*, e.g., a generic line through y^* when Y is Euclidean space, the number of paths coming into (x^*, y^*) is the multiplicity of the local ring of X at x^* with respect to the ideal generated by the functions $f_i(x, y^*)$. Unfortunately, this multiplicity is in general bounded only by the multiplicity of (x^*, y^*) as a solution of $f(x, y^*) = 0$.

Appendix B. Proof of the main theorem. For algebraic sets, there is a very strong version of Sard's theorem, e.g., [11, Theorem 3.7]. This result has a large number of consequences, going under the name Bertini's theorem, asserting that the zero set of a suitably general function inherits properties of the set the function is defined on. For the convenience of the reader we collect in one place a Bertini theorem of sufficient generality to cover the needs of this article. Given a complex vector space V, we let V^r denote the Cartesian product of V with itself r times, i.e., the space of r-tuples of elements of V. V^r has a natural vector space structure given by addition of r-tuples and multiplication of an r-tuple by a complex number being defined as the r-tuple obtained by componentwise multiplication of elements of the r-tuple by the complex number. V^r with this vector space structure is denoted by $V^{\oplus r}$. In the following theorem, we use notation close to that of Fulton [5, Lemma B.9.1].

THEOREM B.1 (Bertini's theorem). *Let X denote an irreducible algebraic subset of $\mathbb{C}^k$. Let $Z_1, \ldots, Z_q$ denote a finite number of irreducible algebraic subsets of X (with one of the X_i possibly equal to X). Let $\mathbb{V}$ denote a finite dimensional vector space of polynomial functions on $\mathbb{C}^k$. Assume that for each point of X at least one element of $\mathbb{V}$ does not evaluate to zero. Then for any integer $r > 0$, there is a Zariski open dense set $U \subset \mathbb{V}^r$ such that for $f := (f_1, \ldots, f_r) \in U$ it follows for each Z_i*

that

1. *if* $V(f) \cap Z_i$ *is nonempty, then* $\dim V(f) \cap Z_i = \dim Z_i - r$, *and*
2. *letting* $\mathrm{Sing}(Z_i)$ *denote the singular set of* Z_i, $V(f) \cap (Z_i \setminus \mathrm{Sing}(Z_i))$ *is smooth.*

Proof. We first apply [5, Lemma B.9.1]. For the vector bundle E in [5, Lemma B.9.1] take $X \times \mathbb{C}^r$; take $p = 1$ with $C_1 = X \times \{0\}$; for Γ take $\mathbb{V}^{\oplus r}$, i.e., take $\mathbb{V}^r$. The conclusion from [5, Lemma B.9.1] is the existence of a Zariski open dense set Γ^o of Γ such that for $f := (f_1, \ldots, f_s) \in \Gamma^o$, it follows that if $V(f) \cap Z_i$ is nonempty, then

$$\dim(V(f) \cap Z_i) \leq \dim Z_i - r.$$

The opposite inequality is a property of zero sets of functions, e.g., [11, Corollary 3.14].

Since the intersection of a finite number of Zariski open and dense sets is Zariski open and dense, it suffices to show that there is a Zariski open dense set $U_i \subset \mathbb{V}^{\oplus r}$ such that for $f \in U_i$, $V(f) \cap (Z_i \setminus \mathrm{Sing}(Z_i))$ is smooth. For this we use [3, Theorem 1.7.1.1]. Restricting to $(Z_i \setminus \mathrm{Sing}(Z_i))$, we conclude from [3, Theorem 1.7.1.1] that there is a Zariski open dense set $\mathcal{O}_1 \subset \mathbb{V}$ such that for $f_1 \in \mathcal{O}_1$ we have that $V(f_1) \cap (Z_i \setminus \mathrm{Sing}(Z_i))$ is smooth and if nonempty of dimension $\dim Z_i - 1$. Applying [3, Theorem 1.7.1.1] to the restriction of $\mathbb{V}$ to $V(f_1) \cap (Z_i \setminus \mathrm{Sing}(Z_i))$, we conclude that there is a Zariski open dense set $\mathcal{O}_2 \subset \mathbb{V}$ such that for $f_2 \in \mathcal{O}_2$ we have that $V(f_1, f_2) \cap (Z_i \setminus \mathrm{Sing}(Z_i))$ is smooth and if nonempty of dimension $\dim Z_i - 2$. Proceeding this way for j going to r, $U_i := \mathcal{O}_1 \times \cdots \times \mathcal{O}_r \subset \mathbb{V}^{\oplus r}$ is the desired Zariski open dense set. ∎

LEMMA B.2. *Let* f *and* X *be as in Theorem* 5.1. *Assume further that* Z *is an algebraic subset of* X *of dimension* $< N$. *Assume that* f *does not vanish on any component of* X *or of* Z. *There is a Zariski open and dense set* $U \subset \mathcal{Y} = \mathbb{C}^{N \times (1+m+N)}$ *such that*

1. *the solutions* $\mathcal{F}_i$ *of the system* $\mathcal{E}_i(f)(x, z, Y)$ *for* $Y \in U$ *with* $z \neq 0$ *are isolated nonsingular solutions and lie in the set* $(X \setminus Z) \times \mathbb{C}^i$;
2. $U \cap \mathcal{Y}_i$ *is Zariski open and dense for each* $i < N$; *and*
3. *the solutions of* $\mathcal{E}_i(f)(x, z, Y)$ *for* $Y \in U$ *with* $z \neq 0$ *are the same as those with* $z_i \neq 0$.

Proof. Since the following result follows almost verbatim from the reasoning in the first half of the proof of [12, Lemma 2], we give only a brief sketch of the proof. As discussed in section 5, we regard $\mathcal{E}_i$ as a system on $X \times \mathbb{C}^i$.

Consider the vector space V_1 of functions on $X \times \mathbb{C}^i$ generated by

$$f_1, \ldots, f_N, z_1, \ldots, z_i.$$

The common zeros of the functions in V_1 are the points

$$V(V_1) := \left\{(x, 0) \in X \times \mathbb{C}^i | f(x) = 0\right\}.$$

From this we conclude, using Theorem B.1, that for a choice of a system $\mathcal{S}$ in a nonempty Zariski open set of the vector space $V_1^{\oplus N}$, it follows that the common zeros $Z_{\mathcal{S}}$ of $\mathcal{S}$ on $X \times \mathbb{C}^i \setminus V(V_1)$ are pure i-dimensional with singular set of dimension $\leq i-1$. Similarly, $Z_{\mathcal{S}}$ meets $Z \times \mathbb{C}^i \setminus V(V_1)$ in a set of dimension at most $\dim Z + i - N \leq i - 1$.

Now let V_2 be the vector space of functions on $X \times \mathbb{C}^i$ generated by

$$1, x_1, \ldots, x_m, z_1, \ldots, z_i.$$

Since $1 \in V_2$, there are no common zeros of the functions in V_2. Using Theorem B.1 again, we conclude that for a generic choice of a system $\mathcal{S}'$ in a nonempty Zariski

open set of the vector space $V_2^{\oplus i}$, it follows that the common zeros of $\mathcal{S}'$ on $Z_{\mathcal{S}}$ with $z \neq 0$ are a finite set of isolated smooth points not contained in $Z \times \mathbb{C}^i$. The above system

$$\begin{bmatrix} \mathcal{S} \\ \mathcal{S}' \end{bmatrix} = 0 \tag{B.1}$$

of $N + i$ equations is of the form

$$\begin{aligned} B \begin{bmatrix} f_1(x) \\ \vdots \\ f_N(x) \end{bmatrix} + C \begin{bmatrix} z_1 \\ \vdots \\ z_i \end{bmatrix} = 0, \\ D + E \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix} + F \begin{bmatrix} z_1 \\ \vdots \\ z_i \end{bmatrix} = 0, \end{aligned} \tag{B.2}$$

where B is an $N \times N$ complex matrix, C is an $N \times i$ complex matrix, D is an $i \times 1$ complex matrix, E is an $i \times m$ complex matrix, and F is an $i \times i$ complex matrix. The above Bertini type results show that the set of

$$(B, C, D, E, F) \in \mathbb{C}^{N \times (N+i) + i \times (1+m+i)}$$

giving rise to systems of the form (B.2) with only isolated nonsingular solutions on $X \times \mathbb{C}^i \setminus X \times \{0\}$ is dense in $\mathbb{C}^{N \times (N+i) + i \times (1+m+i)}$ with respect to the usual Euclidean topology. The set of such (B, C, D, E, F) such that the maximal number of isolated solutions of the associated system (B.2) on $X \times \mathbb{C}^i \setminus X \times \{0\}$ occurs is a dense constructible set and thus by Chevalley's theorem, e.g., [11, Proposition 2.31], contains a dense Zariski open set $\mathcal{O}$. Moreover, we know that the systems of the form (B.2) with only isolated solutions on $X \times \mathbb{C}^i \setminus X \times \{0\}$ form a constructible set $\mathcal{C}$ of (B, C, D, E, F). By the density of the systems (B.1) in the usual Euclidean topology, we conclude that $\mathcal{C}$ is a dense Zariski constructible set and thus contains a dense Zariski open set $\mathcal{O}'$. The systems arising with parameters from the set $U_i' = \mathcal{O} \cap \mathcal{O}'$ have the properties required for the first assertion of the lemma. The matrices (B, C, D, E, F) giving rise to systems with the desired properties are invariant under the action

$$G_1 \times G_2 \times (B, C, D, E, F) \to (G_1^{-1}B, G_1^{-1}C, G_2^{-1}D, G_2^{-1}E, G_2^{-1}F),$$

where G_1 is an invertible $N \times N$ complex matrix and G_2 is an invertible $i \times i$ complex matrix. Thus we can assume that U_i' is invariant under this action. Since the matrices (B, C, D, E, F) with B and F invertible form a Zariski open dense set invariant under the same action, we can assume that the Zariski open set U_i' is chosen so that all (B, C, D, E, F) in the set have B and F invertible. Since $(I_N, B^{-1}C, F^{-1}D, F^{-1}E, I_i)$ is in U_i', we see that the set

$$U_i := U_i' \cap \{(B, C, D, E, F) | B \text{ and } F \text{ invertible}\}$$

is the desired set for conclusion 1 of the lemma.

We have natural projections $\pi_i : \mathcal{Y} \to \mathcal{Y}_i$ obtained by setting the last $N - i$ rows of an element of $\mathcal{Y}$ to 0. The set $U := \cap_{i=1}^N \pi^{-1}(U_i)$ is Zariski open and dense. Noting that since the maps π_i are surjective, the images are Zariski dense constructible sets, we have, on redefining $U_i := U \cap \mathcal{Y}_i$, the first two assertions of the lemma.

For the last assertion we can assume without loss of generality that $i \geq 2$. The desired assertion will follow if we show that the set of $Y \in U$ for which there are solutions of $\mathcal{E}_i(f)(x,z,Y)$ with $z_i = 0$ but $z \neq 0$ is not Zariski dense. Assume it is Zariski dense. Then, for a general $Y \in U$ and a general $(a_i, a_{1,1}, \ldots, a_{i,N}) \in \mathbb{C}^{N+1}$, the system

$$\begin{bmatrix} \mathcal{E}_{i-1}(f)(x,z,Y) \\ a_i + a_{i,1}x_1 + \cdots + a_{i,m}x_m \end{bmatrix} = 0$$

has a solution with $(z_1, \ldots, z_{i-1}) \neq 0$. This is absurd, since we have already shown that for a general $Y \in U$, there are only a finite number of solutions of $\mathcal{E}_{i-1}(f)(x,z,Y)$ with $(z_1, \ldots, z_{i-1}) \neq 0$. ∎

Remark B.3. The condition in Lemma B.2 that the $\mathcal{F}_i$ lie in $(X - Z) \times \mathbb{C}^i$ is important because we typically will not have defining polynomials for X but know only that X is an irreducible component of $V(g)$ for a system of polynomials g. Taking Z equal to the union of the intersections of X with other components of $V(g)$ guarantees with probability one that g will be a set of defining equations for X on a Zariski open set large enough so that all the homotopy continuations that are given in this article will be well defined.

We need some information about the isolated solutions of $\mathcal{E}_i(f)(x,z,Y)$ with $z = 0$. This is the generalization of the last assertion of [12, Lemma 2].

LEMMA B.4. *There is a Zariski open and dense set $U \subset \mathcal{Y} = \mathbb{C}^{N\times(1+m+N)}$ such that the solutions of the system $\mathcal{E}_i(f)(x,z,Y)$ for $Y \in U$ with $z = 0$ consist of*

1. *positive dimensional components all contained in components of $V(f)$ of dimension greater than i, plus*
2. *for each dimension i irreducible component W of $f^{-1}(0)$, isolated solutions consisting of $\deg(W_{\mathrm{red}})$ generic points of W_{red}, the reduction of W, each occurring the same number of times.*

Proof. When $z = 0$, the system $\mathcal{E}_i(f)(x,z,Y)$ reduces to

$$\begin{bmatrix} f(x) \\ \mathcal{A}_0 + \mathcal{A}_1 \cdot x \end{bmatrix}. \tag{B.3}$$

The assertion is contained in the discussion in [17]. ∎

The remaining result from [12] that needs modification is the local extension lemma [12, Lemma 6]. We use Lemma A.1 in its place.

Acknowledgment. We would like to thank the referees for their helpful suggestions.

FINITE ELEMENT METHODS FOR A MODIFIED REISSNER–MINDLIN FREE PLATE MODEL*

L. BEIRÃO DA VEIGA†

Abstract. The solution of the Reissner–Mindlin plate problem with free boundary conditions presents a strong layer effect near the free edges. As a consequence, the solution is not even uniformly bounded even in $H^{3/2}$, which implies that at most an $O(h^{1/2})$ uniform convergence rate can be reached by finite element methods in the H^1 norm. Following instead the modified free boundary model presented by Beirão da Veiga and Brezzi, which gives more regular solutions, better error estimates can be obtained in principle. In this paper we present and analyze the extension of different families of well-known optimal plate methods to this new model. All the modified methods presented are proved to be optimal and free of locking.

1. Introduction.

The history of finite element methods for Reissner–Mindlin plates is strictly tied to the well-known shear locking phenomena. This numerical effect, which arises from the natural constraint enforced in the problem when the thickness of the plate tends to zero, can severely deteriorate the convergence of the method at small thicknesses.

Numerous finite element schemes that are completely free of locking are available in the literature. Most of these methods hold a rate of convergence to the continuous solution which is independent of the plate thickness and optimal with respect to the polynomial degree of the discrete spaces and the regularity required for the solution.

On the other hand, this last point introduces another issue which is fundamental in the numerical analysis of plates—the presence of boundary layers. As a consequence of this phenomena, even the solution of Reissner–Mindlin plate problems with C^∞ loads can hold (as the thickness tends to zero) a Sobolev regularity which is not much higher than H^1, the minimum required for the variational problem formulation.

In particular, as proved in [4], even with smooth loads the maximum (uniform in t) H^s regularity which can be expected for the rotations is

$$s < \frac{7}{2} \qquad \text{soft clamped plates,}$$

$$s < \frac{5}{2} \qquad \text{hard clamped, hard supported plates,}$$

$$s < \frac{3}{2} \qquad \text{soft supported, free plates.}$$

This low solution regularity, especially because it is coupled with the locking phenomena, clearly hinders the approximation capabilities of numerical methods on the whole

plate domain (unless some ad hoc mesh refinement is introduced). For example, for the hard clamped plate there are only a few elements (for instance, the nonconforming element of [5] and the MITC4 of Bathe and Dvorkin as proved in [17]) which give an uniform $O(h)$ rate of convergence adopting a basic polynomial degree equal to one and using a solution regularity which satisfies the bounds above. The effect of the boundary layer is particularly severe in the case of soft supported and free plates, where at most an $O(h^{1/2})$ uniform convergence rate can be reached in the H^1 norm. In the case of the supported plates, as there is no clear physical reason whether to use the soft or hard version, this can be avoided using the latter one. This is not true for free plates, where no other immediate choice seems to be viable.

In [9] the authors proposed a new way to model the free plate boundary condition which, holding a deeper consistency with the limit Kirchhoff model, gives a Sobolev order of regularity of up to 5/2. The idea is to minimize the usual Reissner–Mindlin energy functional under the additional condition that the tangential component of the rotations equals the tangential derivative of the transversal displacements on the free edge. Roughly speaking, this additional constraint generates free boundary conditions which are more consistent than the original ones with those of the limit (thickness $= 0$) Kirchhoff model; as a consequence, the respective boundary layer is weaker and the solution gains more regularity.

On the other hand, this new free boundary condition cannot in general be directly enforced in the discrete space (as is done for the clamped and supported conditions) without spoiling its approximation properties. Therefore it may not be immediate to derive a finite element method which shows optimal error bounds. In [9] an optimal finite element method, which was an adaptation of the Duran–Libermann element (see [18]), was presented. The aim of this contribution is to show that several families of finite elements present in the literature can be adapted to efficiently treat this model.

The outline of the paper is as follows. In section 2 we present the problem and the new free boundary model of [9]. In section 3 we treat the discretization of the problem following the Helmholtz decomposition finite element philosophy (see, for example, [11, 12]), which for instance covers well-known plate elements as the MITC. The additional boundary constraint above is here imposed in a relaxed way that involves use of the projection operator already present in this method. We also introduce a new first order nonconforming element and its adaptation to the new model. In section 4 we present the extension of the linked interpolation plate methods (see, for example, [6, 7, 21]). The projection operator which is hidden in the linked formulation is not suitable to directly enforce the free boundary constraint in a relaxed way, as done in section 3. On the other hand, we show that the particular approximation properties of this finite element allow one to enforce this condition by penalization.

For all the extensions presented we prove that the same uniform and optimal approximation properties of the original methods continue to hold. Considering the solution regularity of the modified model, this means that $O(h)$ (respectively, $O(h^{3/2})$) uniform error estimates are provided for all the first order (respectively, higher order) methods analyzed. This is to be compared with an $O(h^{1/2})$ convergence rate, which is the best that can be reached using the original free plate model.

2. The Reissner–Mindlin plate model. We start by introducing the equations in strong form for the Reissner–Mindlin plate model. Let Ω be an open bounded domain in $\mathbb{R}^2$ representing the plate and let g be an assigned sufficiently regular load. Then $(\boldsymbol{\theta}, w, \boldsymbol{\gamma})$, respectively, the rotation, transversal displacements, and scaled shear

stresses, must satisfy the scaled equations

$$-\operatorname{div}\mathbf{C}\,\varepsilon(\boldsymbol{\theta})-\boldsymbol{\gamma}=\mathbf{0}\quad\text{in }\Omega, \tag{2.1}$$

$$-\operatorname{div}\boldsymbol{\gamma}=g\quad\text{in }\Omega, \tag{2.2}$$

$$\boldsymbol{\gamma}=\lambda t^{-2}(\boldsymbol{\nabla}w-\boldsymbol{\theta})\quad\text{in }\Omega. \tag{2.3}$$

In (2.1)–(2.3), $\mathbf{C}$ is the tensor of bending moduli, ε is the usual symmetric gradient operator, $\lambda(=5/6)$ is the shear correction factor, and t is the thickness.

The boundary conditions to be coupled with the above system clearly depend on the physical constraints imposed at the edges of the plate.

We first introduce the operators (defined on any rotation $\boldsymbol{\varphi}$ sufficiently regular)

$$\mathbf{M}[\boldsymbol{\varphi}]:=\mathbf{C}\,\varepsilon(\boldsymbol{\varphi}),\quad \mathbf{M}_{\mathbf{n}}[\boldsymbol{\varphi}]:=\mathbf{M}[\boldsymbol{\varphi}]\cdot\mathbf{n}, \tag{2.4}$$

and

$$M_{nn}[\boldsymbol{\varphi}]:=\mathbf{M}_{\mathbf{n}}[\boldsymbol{\varphi}]\cdot\mathbf{n},\quad M_{ns}[\boldsymbol{\varphi}]:=\mathbf{M}_{\mathbf{n}}[\boldsymbol{\varphi}]\cdot\mathbf{s}, \tag{2.5}$$

where $\mathbf{n}$ and $\mathbf{s}$ are, respectively, the outward unit normal and counterclockwise unit tangent vector to $\partial\Omega$. Here and in what follows, whenever the above operators are applied on the solution $\boldsymbol{\theta}$, this will not be written explicitly; for example, by M_{nn} we intend $M_{nn}[\boldsymbol{\theta}]$.

We also need the following notation: for every vector valued function $\boldsymbol{\eta}$ and for every scalar function v, we will write

$$\eta_n:=\boldsymbol{\eta}\cdot\mathbf{n},\quad \eta_s:=\boldsymbol{\eta}\cdot\mathbf{s},\quad v_{/n}:=\frac{\partial v}{\partial\mathbf{n}},\quad v_{/s}:=\frac{\partial v}{\partial\mathbf{s}}. \tag{2.6}$$

We now assume that the boundary $\partial\Omega$ is the union of three nonoverlapping parts $\partial\Omega=\Sigma_c\cup\Sigma_s\cup\Sigma_f$, corresponding to clamped, (hard) simply supported, and free boundary conditions. More precisely, we require (formally)

$$\boldsymbol{\theta}=\mathbf{0},\qquad w=0\qquad\text{on }\Sigma_c, \tag{2.7}$$

$$\theta_s=0,\quad w=0,\quad M_{nn}=0\qquad\text{on }\Sigma_s, \tag{2.8}$$

and

$$M_{nn}=0,\quad M_{ns}=0,\quad \gamma_n\equiv-(\operatorname{div}\mathbf{M})_n=0\qquad\text{on }\Sigma_f. \tag{2.9}$$

We make also the minimal requirement that every part of $\partial\Omega$ is the union of a finite number of connected components and that every rigid movement $\mathbf{r}$ satisfying $\mathbf{r}=\mathbf{0}$ on Σ_c and $r_s=0$ on Σ_s is necessarily $\mathbf{0}$. This, together with the usual ellipticity assumptions on $\mathbf{C}$, will grant the well-known Korn inequality: there exists a constant $\alpha>0$ such that for every $\boldsymbol{\eta}\in(H^1(\Omega))^2$ satisfying $\boldsymbol{\eta}=\mathbf{0}$ on Σ_c and $\eta_s=0$ on Σ_s we have

$$\alpha\|\boldsymbol{\eta}\|^2_{(H^1(\Omega))^2}\le\int_\Omega\mathbf{C}\,\varepsilon(\boldsymbol{\eta}):\varepsilon(\boldsymbol{\eta})\mathrm{d}x. \tag{2.10}$$

It is well known that, as the thickness $t \to 0$, the solution $(\boldsymbol{\theta}^t, w^t, \boldsymbol{\gamma}^t)$ of the Reissner–Mindlin plate model tends to a finite limit which is the solution of the Kirchhoff model with the corresponding boundary conditions; on the other side, this convergence is well known to take place only in Sobolev spaces of low order. In particular, in [4] it is proved that if $\Sigma_f = \emptyset$, then $\|\boldsymbol{\theta}(t)\|_s$ remains bounded as $t \to 0$ at least for all $s < 5/2$ while, if some free boundary conditions are present ($\Sigma_f \neq \emptyset$), the solution stays uniformly bounded only up to $s < 3/2$.

This additional irregularity of the $\Sigma_f \neq \emptyset$ case is clearly of great hindrance when t-uniform error estimates for finite element methods are sought. It is easily seen that, unless some particular technique is applied to treat the corresponding boundary layer, an error estimate of order no better than $h^{1/2}$ can be obtained in the natural norms of the problem.

This is the reason why in [9] a modified set of conditions to model the plate free boundaries was proposed; the idea is to change (2.9) with a set of boundary conditions holding deeper consistency with the limit Kirchhoff model:

$$\theta_s = w_{/s}, \quad M_{nn} = 0, \quad \text{and} \quad M_{ns/s} - \gamma_n = 0 \quad \text{on } \Sigma_f. \tag{2.11}$$

Introducing the spaces

$$\boldsymbol{\Theta} = \{\boldsymbol{\varphi} \in [H^1(\Omega)]^2 \,:\, \boldsymbol{\varphi} = 0 \text{ on } \Sigma_c,\ \boldsymbol{\varphi}_s = 0 \text{ on } \Sigma_s\}, \tag{2.12}$$

$$W = \{w \in [H^1(\Omega)] \,:\, w = 0 \text{ on } \Sigma_c \cup \Sigma_s\}, \tag{2.13}$$

$$\mathcal{V} = \{(\boldsymbol{\theta}, w) \in \boldsymbol{\Theta} \times W \text{ such that } \theta_s = w_{/s} \text{ on } \Sigma_f\}, \tag{2.14}$$

classical arguments give the following result (see [9]).

PROPOSITION 2.1. *For every $t > 0$, any smooth solution of* (2.1)–(2.3) *with the boundary conditions* (2.7), (2.8), *and* (2.11) *coincides with the unique minimizing argument on $\mathcal{V}$ of the functional*

$$J^t(\boldsymbol{\eta}, v) = \frac{1}{2} a(\boldsymbol{\eta}, \boldsymbol{\eta}) + \frac{\lambda t^{-2}}{2} ||\boldsymbol{\nabla} v - \boldsymbol{\eta}||^2_{0,\Omega} - (g, v), \tag{2.15}$$

where

$$a(\boldsymbol{\theta}, \boldsymbol{\eta}) := \int_\Omega \mathbf{C}\, \varepsilon(\boldsymbol{\theta}) : \varepsilon(\boldsymbol{\eta}) \mathrm{d}x \equiv \int_\Omega \mathbf{M} : \varepsilon(\boldsymbol{\eta}) \mathrm{d}x. \tag{2.16}$$

Conversely, the unique minimizing argument of (2.15) *satisfies* (2.1)–(2.3) *in the distributional sense, and if it is smooth enough it also satisfies the boundary conditions* (2.7), (2.8), *and* (2.11).

Concerning the t-uniform regularity of the solution for this new problem, we have the following.

PROPOSITION 2.2. *Assume, for simplicity, that the material is homogeneous (and hence the system has constant coefficients), that the load g is in $C^\infty(\bar{\Omega})$, and that Ω is a polygon (or that the boundary $\partial\Omega$ is piecewise C^∞). Let D be any open subset of Ω such that $\overline{D}$ that does not contain any vertex or points where the boundary conditions change from one type to another. Then there exists a constant c, independent of t, such that*

$$\|\boldsymbol{\theta}\|_{r+2,D} + t\|\boldsymbol{\gamma}\|_{r+1,D} + \|\boldsymbol{\gamma}\|_{r,D} + \|\mathrm{div}\boldsymbol{\gamma}\|_{r,D} \le c\|g\|_r \quad \forall\ -1 \le r < \frac{1}{2}, \tag{2.17}$$

$$\|w\|_{\rho+2,D} \le \|g\|_\rho \qquad \forall \rho \ge -1. \tag{2.18}$$

Proof. The proof can be easily obtained by adapting the analysis of [4] to the present situation near Σ_f. We see that the most irregular term in the expansion of the solution (as computed by [4]) drops, leaving for $\boldsymbol{\theta}$ a limit regularity of order $s < 5/2$. □

Consequently, following this new model, $\|\boldsymbol{\theta}(t)\|_{s,D}$ stays uniformly bounded for any $s < 5/2$. As addressed in [9], taking the steps from Proposition 2.2 it is not unrealistic to assume

$$\|\boldsymbol{\theta}\|_{r+2,\Omega} + \|w\|_{r+2,\Omega} + t\|\boldsymbol{\gamma}\|_{r+1,\Omega} + \|\boldsymbol{\gamma}\|_{r,\Omega} + \|\mathrm{div}\boldsymbol{\gamma}\|_{r,\Omega} \le c \quad \forall r < 1/2, \tag{2.19}$$

as we will do in what follows. In light of (2.18), it will also be realistic to require (as we will need for the linked interpolation elements) the additional uniform regularity

$$\|w\|_{s,\Omega} \le c \quad \forall s < 7/2. \tag{2.20}$$

This improved uniform regularity of the solution allows in principle a t-independent error estimate of up to order $h^{3/2}$ in the natural norms of the problem. The difficulty here is that the additional constraint $\theta_s = w_{/s}$ on Σ_f appearing in $\mathcal{V}$ cannot in general be directly enforced in the discrete problem (as is done for the clamped and hard simply supported conditions) without spoiling its approximation properties. Therefore it may not be immediate to derive a finite element method which shows the aforementioned optimal error bounds. In [9] an optimal finite element method, which was an adaptation of the Duran–Libermann element (see [18]), was analyzed. The aim here is to show that several families of finite elements present in the literature can be adapted to efficiently treat this model; in particular we will consider all those methods pertaining to the Helmholtz decomposition (see, for instance, [11, 12]) and the linked interpolation (see, for example, [6, 7, 21]) philosophies.

3. Model discretization following the P1–P5 philosophy. In this section we discretize and derive (uniform and optimal) error estimates for our free plate model, taking the steps from the plate finite element methods proposed in [11, 12].

Let $\mathcal{T}_h$ be a regular mesh on Ω (see, for example, [10, 14]) and h the maximum diameter of its elements. Then, we start with three conforming piecewise polynomial spaces on this grid,

$$\boldsymbol{\Theta}_h \subset \boldsymbol{\Theta}, \quad W_h \subset W, \quad \boldsymbol{\Gamma}_h \subset H(\mathrm{rot};\Omega), \tag{3.1}$$

approximating, respectively, the space of rotations, deflections, and shear stresses.

To relax the shear stress constraint, we introduce as usual a linear reduction operator Π_h,

$$\Pi_h \,:\, H(\mathrm{rot};\Omega) \longrightarrow \boldsymbol{\Gamma}_h, \tag{3.2}$$

which is the identity when restricted to $\boldsymbol{\Gamma}_h$.

At this stage we require that our operator Π_h satisfies the approximation property

$$\|\boldsymbol{\varphi} - \Pi_h\boldsymbol{\varphi}\|_0 \le c\,h\|\boldsymbol{\varphi}\|_1, \tag{3.3}$$

which in particular implies continuity as an application from $H^1(\Omega)$ to $L^2(\Omega)$.

Given the spaces $\boldsymbol{\Theta}_h, W_h$ and the operator Π_h above, we set

$$\mathcal{V}_h := \{(\boldsymbol{\eta}_h, v_h) \in \boldsymbol{\Theta}_h \times W_h \text{ such that } (\Pi_h\boldsymbol{\eta}_h)_s = (v_h)_{/s} \text{ on } \Sigma_f\}, \tag{3.4}$$

where we remark that the boundary conditions on Σ_c, Σ_s are already included in (3.1).

We can now define the discrete solution $(\boldsymbol{\theta}_h, w_h)$ as the unique minimizer of the relaxed functional

$$J_h^t(\boldsymbol{\eta}_h, v_h) = \frac{1}{2}a(\boldsymbol{\eta}_h, \boldsymbol{\eta}_h) + \frac{\lambda t^{-2}}{2}||\boldsymbol{\nabla} v_h - \Pi_h \boldsymbol{\eta}_h||^2_{0,\Omega} - (g, v_h) \tag{3.5}$$

over the discrete space $\mathcal{V}_h$. It is then easily seen that, setting

$$\boldsymbol{\gamma}_h := \lambda t^{-2}(\boldsymbol{\nabla} w_h - \Pi_h \boldsymbol{\theta}_h), \tag{3.6}$$

the triple $(\boldsymbol{\theta}_h, w_h, \boldsymbol{\gamma}_h)$ coincides with the unique solution of the variational problem

$$\begin{cases} \text{Find } ((\boldsymbol{\theta}_h, w_h), \boldsymbol{\gamma}_h) \in \mathcal{V}_h \times \boldsymbol{\Gamma}_h \text{ such that} \\ a(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) - (\boldsymbol{\gamma}_h, \Pi_h \boldsymbol{\eta}_h - \boldsymbol{\nabla} v_h) = (g, v_h), \qquad (\boldsymbol{\eta}_h, v_h) \in \mathcal{V}_h, \\ \lambda^{-1} t^2 (\boldsymbol{\gamma}_h, \boldsymbol{\delta}_h) - (\boldsymbol{\nabla} w_h, \boldsymbol{\delta}_h) + (\Pi_h \boldsymbol{\theta}_h, \boldsymbol{\delta}_h) = 0, \qquad \boldsymbol{\delta}_h \in \boldsymbol{\Gamma}_h. \end{cases} \tag{3.7}$$

Now let $Q_h \subset L^2_0(\Omega)$ be an auxiliary finite element space such that the five properties introduced in [12] hold for the choice of spaces $(\boldsymbol{\Theta}_h, W_h, \boldsymbol{\Gamma}_h, Q_h)$:

P1. $\boldsymbol{\nabla} W_h \subset \boldsymbol{\Gamma}_h$;

P2. $\operatorname{rot} \boldsymbol{\Gamma}_h \subset Q_h$;

P3. $\operatorname{rot} \Pi_h \boldsymbol{\varphi} = P_h \operatorname{rot} \boldsymbol{\varphi}$, $\boldsymbol{\varphi} \in [H^1_0]^2$, where $P_h : L^2_0 \to Q_h$ denotes the L^2 projection;

P4. $\{\mathbf{s} \in \boldsymbol{\Gamma}_h \ : \ \operatorname{rot} \mathbf{s} = 0\} = \boldsymbol{\nabla} W_h$; and

P5. $(\boldsymbol{\Theta}_h, Q_h)$ is a stable pair of spaces for the Stokes problem.

We also assume the following:

P6. If $\gamma \in H(\operatorname{rot}; \Omega)$ is such that $\gamma_s = 0$ on Σ_f, then the same is true for $\Pi_h \gamma$.

Then we have the following crucial lemma.

LEMMA 3.1. *Consider the couple $(\boldsymbol{\theta}, w) \in \mathcal{V}$. Let the properties* P1 *to* P6 *be satisfied. Then there exists a couple of interpolants $(\boldsymbol{\theta}_I, w_I) \in \mathcal{V}_h$ such that*

$$\Pi_h(\boldsymbol{\nabla} w_I - \boldsymbol{\theta}_I) = \Pi_h(\boldsymbol{\nabla} w - \boldsymbol{\theta}) \tag{3.8}$$

with

$$\| \boldsymbol{\theta} - \boldsymbol{\theta}_I \|_1 \leq c \inf_{\boldsymbol{\varphi} \in \boldsymbol{\Theta}_h} \| \boldsymbol{\theta} - \boldsymbol{\varphi} \|_1, \tag{3.9}$$

$$\| w - w_I \|_1 \leq c \inf_{\boldsymbol{\varphi} \in \boldsymbol{\Theta}_h} \| \boldsymbol{\theta} - \boldsymbol{\varphi} \|_1 + \| \boldsymbol{\nabla} w - \Pi_h(\boldsymbol{\nabla} w) \|_0. \tag{3.10}$$

Proof. A similar proof can be found in [18]. Due to property P5, it follows easily (see [11]) that there exists $\theta_I \in \boldsymbol{\Theta}_h$ such that

$$\int_\Omega \operatorname{rot}(\boldsymbol{\theta} - \boldsymbol{\theta}_I) q = 0 \qquad \forall q \in Q_h \tag{3.11}$$

and (3.9) holds.

From (3.11) and P3 we have

$$0 = P_h \operatorname{rot}(\boldsymbol{\theta} - \boldsymbol{\theta}_I) = \operatorname{rot} \Pi_h(\boldsymbol{\theta} - \boldsymbol{\theta}_I), \tag{3.12}$$

which, recalling P4, grants the existence of $w_1 \in W_h$ such that $\Pi_h(\boldsymbol{\theta} - \boldsymbol{\theta}_I) = \boldsymbol{\nabla} w_1$.

With similar steps, starting from the obvious statement $\mathrm{rot}(\boldsymbol{\nabla} w) = 0$ we obtain $\mathrm{rot}\,\Pi_h(\boldsymbol{\nabla} w) = 0$ and finally the existence of a $w_2 \in W_h$ such that $\Pi_h(\boldsymbol{\nabla} w) = \boldsymbol{\nabla} w_2$. Setting $w_I = w_2 - w_1$ and remembering that, due to P1, $\Pi_h v_h = v_h$ for all $v_h \in W_h$, we immediately have (3.8).

Using the Poincaré inequality and the triangle inequality and recalling the definition of w_1, w_2, it follows that

$$\begin{aligned} &\| w - w_I \|_1 \le c \| \boldsymbol{\nabla} w - \boldsymbol{\nabla} w_I \|_0 \le c(\| \boldsymbol{\nabla} w - \boldsymbol{\nabla} w_2 \|_0 + \| \boldsymbol{\nabla} w_1 \|_0) \\ &= c(\| \boldsymbol{\nabla} w - \Pi_h \boldsymbol{\nabla} w \|_0 + \| \Pi_h(\boldsymbol{\theta} - \boldsymbol{\theta}_I) \|_0). \end{aligned} \tag{3.13}$$

Recalling the continuity observed for Π_h, statements (3.13) and (3.9) immediately give estimate (3.10).

What remains to check is that the couple $(\boldsymbol{\theta}_I, w_I) \in \mathcal{V}_h$, in other words, that it satisfies the boundary condition on Σ_f. But this follows easily if we remember that $(\boldsymbol{\theta}, w) \in \mathcal{V}$, using first P6 on $(\boldsymbol{\nabla} w - \boldsymbol{\theta})$ and then (3.8). □

Under the above hypothesis we have uniform error estimates, as shown in the following proposition.

PROPOSITION 3.2. *Let $((\boldsymbol{\theta}, w), \boldsymbol{\gamma})$ be the solution of the continuous problem (see section 2) while $((\boldsymbol{\theta}_h, w_h), \boldsymbol{\gamma}_h)$ is the solution of the discrete problem* (3.7). *Let the approximating spaces satisfy properties* P1 *to* P6. *Then we have the following error estimates:*

$$\begin{aligned} &\|\boldsymbol{\theta} - \boldsymbol{\theta}_h\|_1 + t\|\boldsymbol{\gamma} - \boldsymbol{\gamma}_h\|_0 + \|\boldsymbol{\nabla}(w - w_h)\|_0 \\ &\le c \left(\inf_{\boldsymbol{\varphi} \in \boldsymbol{\Theta}_h} \| \boldsymbol{\theta} - \boldsymbol{\varphi} \|_1 + t\|\boldsymbol{\gamma} - \Pi_h \boldsymbol{\gamma}\|_0 + \| \boldsymbol{\nabla} w - \Pi_h \boldsymbol{\nabla} w \|_0 + h\, A_1 + h^{1/2}\, A_2 \right), \end{aligned} \tag{3.14}$$

where

$$A_1 = \sup_{\boldsymbol{\varphi} \in \boldsymbol{\Theta}_h} \frac{(\boldsymbol{\gamma}, (I - \Pi_h)\boldsymbol{\varphi})}{\|(I - \Pi_h)\boldsymbol{\varphi}\|_0}, \tag{3.15}$$

$$A_2 = \sup_{\boldsymbol{\varphi} \in \boldsymbol{\Theta}_h} \frac{\int_{\Sigma_f} M_{ns}(I - \Pi_h)\boldsymbol{\varphi}_s \, ds}{\|(I - \Pi_h)\boldsymbol{\varphi}_s\|_{0,\Sigma_f}}. \tag{3.16}$$

Proof. Using statement (3.8) it follows immediately that

$$\boldsymbol{\gamma}_I := \lambda t^{-2}(\Pi_h \boldsymbol{\nabla} w_I - \Pi_h \boldsymbol{\theta}_I) = \lambda t^{-2}(\Pi_h \boldsymbol{\nabla} w - \Pi_h \boldsymbol{\theta}) \equiv \Pi_h \boldsymbol{\gamma}, \tag{3.17}$$

which will play a fundamental role in our proof.

Before deriving the error equations we first notice that the space $\mathcal{V}_h$, as defined in (3.4), is not a subspace of $\mathcal{V}$, defined in (2.14). As a consequence, for $(\boldsymbol{\eta}, v) \in \mathcal{V}_h$ we have, integrating by parts and using (2.1) and (2.2), using boundary conditions (2.7), (2.8), then using (2.11), and finally (3.4),

(3.18)

$$\begin{aligned} a(\boldsymbol{\theta}, \boldsymbol{\eta}) + (\boldsymbol{\gamma}, \boldsymbol{\nabla} v - \boldsymbol{\eta}) - (g, v) &= \int_{\Sigma_f} M_{ns}\eta_s + \boldsymbol{\gamma}_n v \, \mathrm{d}s \\ &= \int_{\Sigma_f} M_{ns}(\eta_s - v_{/s}) \, \mathrm{d}s = \int_{\Sigma_f} M_{ns}(\eta - \Pi_h \eta)_s \, \mathrm{d}s. \end{aligned}$$

Comparing (3.18) with the first equation of (3.7) we obtain, for $(\boldsymbol{\eta}, v) \in \mathcal{V}_h$, the error equation

$$a(\boldsymbol{\theta} - \boldsymbol{\theta}_h, \boldsymbol{\eta}) + (\boldsymbol{\gamma}, \boldsymbol{\nabla} v - \boldsymbol{\eta}) - (\boldsymbol{\gamma}_h, \boldsymbol{\nabla} v - \Pi_h \boldsymbol{\eta}) = \int_{\Sigma_f} M_{ns}(\eta - \Pi_h \eta)_s \, \mathrm{d}s, \tag{3.19}$$

which can also be rewritten as

$$a(\boldsymbol{\theta} - \boldsymbol{\theta}_h, \boldsymbol{\eta}) + (\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\nabla} v - \Pi_h \boldsymbol{\eta}) = (\boldsymbol{\gamma}, (I - \Pi_h)\boldsymbol{\eta}) + \int_{\Sigma_f} M_{ns}((I - \Pi_h)\eta)_s \, \mathrm{d}s. \tag{3.20}$$

Using the Korn inequality and adding and subtracting $\boldsymbol{\theta}$ and $\boldsymbol{\gamma}$ we have

$$\begin{aligned} \alpha \|\boldsymbol{\theta}_I - \boldsymbol{\theta}_h\|_1^2 + \lambda^{-1} t^2 \|\boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h\|_0^2 &\le a(\boldsymbol{\theta}_I - \boldsymbol{\theta}_h, \boldsymbol{\theta}_I - \boldsymbol{\theta}_h) + \lambda^{-1} t^2 (\boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h, \boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h) \\ &= a(\boldsymbol{\theta}_I - \boldsymbol{\theta}, \boldsymbol{\theta}_I - \boldsymbol{\theta}_h) + a(\boldsymbol{\theta} - \boldsymbol{\theta}_h, \boldsymbol{\theta}_I - \boldsymbol{\theta}_h) \\ &\quad + \lambda^{-1} t^2 (\boldsymbol{\gamma}_I - \boldsymbol{\gamma}, \boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h) + \lambda^{-1} t^2 (\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h). \end{aligned} \tag{3.21}$$

On the other hand, as $\boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h = \lambda t^{-2}(\boldsymbol{\nabla}(w_I - w_h) - \Pi_h(\boldsymbol{\theta}_I - \boldsymbol{\theta}_h))$, it follows from the error equation (3.20) (tested with $\eta = \boldsymbol{\theta}_I - \boldsymbol{\theta}_h$ and $v = w_I - w_h$) that

$$\begin{aligned} &a(\boldsymbol{\theta} - \boldsymbol{\theta}_h, \boldsymbol{\theta}_I - \boldsymbol{\theta}_h) + \lambda^{-1} t^2 (\boldsymbol{\gamma} - \boldsymbol{\gamma}_h, \boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h) \\ &\quad = (\boldsymbol{\gamma}, (I - \Pi_h)(\boldsymbol{\theta}_I - \boldsymbol{\theta}_h)) + \int_{\Sigma_f} M_{ns}(I - \Pi_h)(\theta_I - \theta_h)_s \, \mathrm{d}s. \end{aligned} \tag{3.22}$$

Combining (3.21) and (3.22) we then have

$$\alpha \|\boldsymbol{\theta}_I - \boldsymbol{\theta}_h\|_1^2 + \lambda^{-1} t^2 \|\boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h\|_0^2 = T_1 + T_2 + T_3 + T_4, \tag{3.23}$$

where

$$T_1 = a(\boldsymbol{\theta}_I - \boldsymbol{\theta}, \boldsymbol{\theta}_I - \boldsymbol{\theta}_h), \tag{3.24}$$

$$T_2 = \lambda^{-1} t^2 (\boldsymbol{\gamma}_I - \boldsymbol{\gamma}, \boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h), \tag{3.25}$$

$$T_3 = (\boldsymbol{\gamma}, (I - \Pi_h)(\boldsymbol{\theta}_I - \boldsymbol{\theta}_h)), \tag{3.26}$$

$$T_4 = \int_{\Sigma_f} M_{ns}(I - \Pi_h)(\theta_I - \theta_h)_s \, \mathrm{d}s, \tag{3.27}$$

which we shall bound separately.

By continuity (and remembering (3.17)),

$$T_1 \le c \, \|\boldsymbol{\theta} - \boldsymbol{\theta}_I\|_1 \, \|\boldsymbol{\theta}_I - \boldsymbol{\theta}_h\|_1, \tag{3.28}$$

$$T_2 \le c \, t \, \|\boldsymbol{\gamma} - \Pi_h \boldsymbol{\gamma}\|_0 \, t \, \|\boldsymbol{\gamma}_I - \boldsymbol{\gamma}_h\|_0. \tag{3.29}$$

For the third term, dividing and multiplying by $\|(I - \Pi_h)(\boldsymbol{\theta}_I - \boldsymbol{\theta}_h)\|_0$, using property (3.3), and finally bounding with the supremum, we obtain

$$T_3 \le c \, h \frac{(\boldsymbol{\gamma}, (I - \Pi_h)(\boldsymbol{\theta}_I - \boldsymbol{\theta}_h))}{\|(I - \Pi_h)(\boldsymbol{\theta}_I - \boldsymbol{\theta}_h)\|_0} \|\boldsymbol{\theta}_I - \boldsymbol{\theta}_h\|_1 \le c \, h \sup_{\boldsymbol{\varphi} \in \boldsymbol{\Theta}_h} \frac{(\boldsymbol{\gamma}, (I - \Pi_h)\boldsymbol{\varphi})}{\|(I - \Pi_h)\boldsymbol{\varphi}\|_0} \|\boldsymbol{\theta}_I - \boldsymbol{\theta}_h\|_1. \tag{3.30}$$

To bound the last term, we first recall the well-known Agmon inequality [1]: if e is an edge of a triangle T (with the usual minimum angle condition), $\varphi \in H^1(T)$, and h_T is the diameter of T, then we have

$$\|\varphi\|_{0,e} \le c\,(h_T^{-1/2}\|\varphi\|_{0,T} + h_T^{1/2}\|\varphi\|_{1,T}). \tag{3.31}$$

With the same arguments used in (3.30) we obtain, for any $e \in \Sigma_f$,

$$\int_e M_{ns}(I-\Pi_h)(\theta_I-\theta_h)_s\,\mathrm{d}s \le c \sup_{\boldsymbol{\varphi}\in\boldsymbol{\Theta}_h} \frac{\int_e M_{ns}(I-\Pi_h)\boldsymbol{\varphi}_s\,\mathrm{d}s}{\|(I-\Pi_h)\boldsymbol{\varphi}_s\|_{0,e}}\,\|(I-\Pi_h)(\theta_I-\theta_h)_s\|_{0,e}. \tag{3.32}$$

Using (3.31) and (3.3), from (3.32) we have

$$T_4 \le c\,h^{1/2} \sup_{\boldsymbol{\varphi}\in\boldsymbol{\Theta}_h} \frac{\int_{\Sigma_f} M_{ns}(I-\Pi_h)\boldsymbol{\varphi}_s\,\mathrm{d}s}{\|(I-\Pi_h)\boldsymbol{\varphi}_s\|_{0,\Sigma_f}}\,\|\boldsymbol{\theta}_I-\boldsymbol{\theta}_h\|_1. \tag{3.33}$$

Finally, inserting (3.28)–(3.30) and (3.33) in (3.23), and from the usual arithmetic-geometric inequality, we have

$$\alpha\|\boldsymbol{\theta}_I-\boldsymbol{\theta}_h\|_1^2 + \lambda^{-1}t^2\|\boldsymbol{\gamma}_I-\boldsymbol{\gamma}_h\|_0^2 \le c\,(\,\|\boldsymbol{\theta}-\boldsymbol{\theta}_I\|_1^2 + t^2\|\boldsymbol{\gamma}-\Pi_h\boldsymbol{\gamma}\|_0^2 + h^2\,A_1^2 + h\,A_2^2\,), \tag{3.34}$$

where we recall that A_1 and A_2 are defined in (3.15) and (3.16).

From (3.34) we can then easily obtain an estimate for $\boldsymbol{\nabla}(w_I - w_h)$:

$$\|\boldsymbol{\nabla}(w_I-w_h)\|_0 \le \lambda^{-1}t^2\,\|\boldsymbol{\gamma}_I-\boldsymbol{\gamma}_h\|_0 + \|\boldsymbol{\theta}_I-\boldsymbol{\theta}_h\|_0. \tag{3.35}$$

The proposition is finally proved using (3.34), (3.35), (3.9), (3.10) and the triangle inequality and absorbing λ in the constants. □

3.1. Examples of finite elements. The above analysis works essentially with all the plate finite elements following the P1–P5 philosophy (see [11, 12]).

To fix the ideas, we will apply Proposition 3.2 to one of the two main elements of [11], the MITC7. Then we will show briefly how the same arguments can be applied to the general families of [11, 12]; finally, an adaptation to a new low order nonconforming element will be presented.

3.1.1. The MITC7 element. We quickly present the second order triangular mixed interpolation of tensorial components plate element, MITC7. We assume that we are given a triangulation (into triangles T) of Ω (see, for instance, [10, 14]). We introduce, on every T, the space

$$S_7(T) = P_2(T) \oplus B(T), \tag{3.36}$$

where here and in what follows P_k represents the polynomials of order k, and $B = \lambda_1\lambda_2\lambda_3$ is the cubic bubble on T.

Let also

$$RT_k(T) = [P_k]^2 \oplus P_k\,(y, -x)^T \tag{3.37}$$

be the rotated Raviart–Thomas space of order k ($k \in \mathbf{N}$; see [20]).

The discretization spaces for our problem are

$$\boldsymbol{\Theta}_h = \{\boldsymbol{\varphi} \,:\, \boldsymbol{\varphi} \in \boldsymbol{\Theta},\ \boldsymbol{\varphi}|_T \in S_7(T)\ \forall\, T\}, \tag{3.38}$$

$$W_h = \{v \,:\, v \in W,\ v|_T \in P_2(T)\ \forall\, T\}, \tag{3.39}$$

$$\boldsymbol{\Gamma}_h = \{\boldsymbol{\delta} \,:\, \boldsymbol{\delta} \in H(\mathrm{rot};\Omega),\ \boldsymbol{\delta}|_T \in RT_1(T)\ \forall\, T\}, \tag{3.40}$$

where we note that requiring $\boldsymbol{\delta} \in H(\mathrm{rot};\Omega)$ in (3.40) is equivalent to the continuity of the tangential components at the interelement boundaries.

The approximating space $\mathcal{V}_h$ therefore will be as described in (3.4); we observe that, given the degrees of freedom of the spaces above, the additional condition on the free boundary is indeed quite easy to implement.

We now introduce the reduction operator Π_h. Given a smooth $\boldsymbol{\delta}$ defined on Ω, $\Pi_h\boldsymbol{\delta}$ is the unique element of $\boldsymbol{\Gamma}_h$ such that, on every triangle T,

$$\int_e (\boldsymbol{\delta} - \Pi_h\boldsymbol{\delta})_s p_1(s)\,\mathrm{d}s = 0 \quad \forall e \text{ edge of } T,\ \forall p_1(s) \in P_1(e), \tag{3.41}$$

$$\int_T (\boldsymbol{\delta} - \Pi_h\boldsymbol{\delta})\,\mathrm{d}x\,\mathrm{d}y = \mathbf{0}. \tag{3.42}$$

From (3.41) and (3.42) it can be seen that Π_h is indeed uniquely defined (see, for example, [20]) and with image in $\boldsymbol{\Gamma}_h$. Also, the approximation property (3.3) follows from classical results (see again [20]).

For these elements, it is proved in [11] that, choosing Q_h as the piecewise linear a priori discontinuous functions, properties P1–P5 hold; on the other side, from the definition of Π_h, it can be easily checked that P6 also holds.

Applying the general Proposition 3.2 we then have the following.

PROPOSITION 3.3. *Let $((\boldsymbol{\theta}_h, w_h), \boldsymbol{\gamma}_h)$ be the solution of the discrete problem* (3.7) *using the MITC7 finite element spaces already introduced, while $((\boldsymbol{\theta}, w), \boldsymbol{\gamma})$ is the solution of the continuous problem (see section* 2*). Then, for $1 \le s \le 2$,*

$$\|\boldsymbol{\theta} - \boldsymbol{\theta}_h\|_1 + t\|\boldsymbol{\gamma} - \boldsymbol{\gamma}_h\|_0 + \|\boldsymbol{\nabla}(w - w_h)\|_0 \le c\,h^s(\,\|\,\boldsymbol{\theta}\,\|_{s+1} + t\|\boldsymbol{\gamma}\|_s + \|\boldsymbol{\gamma}\|_{s-1}\,), \tag{3.43}$$

which, recalling (2.19)*, gives an error estimate of order $O(h^s)$ for $s < 3/2$ on the full domain.*

Proof. We start applying Proposition 3.2. The bounds for the first three addenda in the left member of (3.14) follow from classical polynomial interpolation theory (see, for instance, [10, 14]). We have

$$\inf_{\boldsymbol{\varphi}\in\boldsymbol{\Theta}_h} \|\,\boldsymbol{\theta} - \boldsymbol{\varphi}\,\|_1 \le ch^2\,\|\,\boldsymbol{\theta}\,\|_3, \tag{3.44}$$

$$t\|\boldsymbol{\gamma} - \Pi_h\boldsymbol{\gamma}\|_0 \le ch^2 t\|\boldsymbol{\gamma}\|_2, \tag{3.45}$$

$$\|\boldsymbol{\nabla} w - \Pi_h\boldsymbol{\nabla} w\|_0 \le ch^2\|w\|_3. \tag{3.46}$$

To treat A_1 (see (3.15)), we use the orthogonality of $(I - \Pi_h)\boldsymbol{\varphi}$ to the piecewise constants (given in (3.42)); taking $\bar{\boldsymbol{\gamma}}$ as the piecewise constant function representing the mean value of $\boldsymbol{\gamma}$ on every triangle, we have

$$A_1 = \sup_{\boldsymbol{\varphi}\in\boldsymbol{\Theta}_h} \frac{(\boldsymbol{\gamma} - \bar{\boldsymbol{\gamma}}, (I - \Pi_h)\boldsymbol{\varphi})}{\|(I - \Pi_h)\boldsymbol{\varphi}\|_0}. \tag{3.47}$$

Now, using the Cauchy–Schwarz inequality on (3.47) and classical polynomial interpolation results, we infer

$$A_1 \leq c\,h\,\|\boldsymbol{\gamma}\|_1. \tag{3.48}$$

Using instead (3.41), with similar reasoning we obtain for A_2

$$A_2 \leq c\,h^{3/2}\,\|M_{ns}\|_{3/2,\Sigma_f}, \tag{3.49}$$

which, recalling the definition of M_{ns} and classical trace operator results for Sobolev spaces, give

$$A_2 \leq c\,h^{3/2}\,\|\boldsymbol{\theta}\|_3. \tag{3.50}$$

The proof in the $s = 2$ case follows immediately combining the above statements, while the $s = 1$ case is done with similar arguments. Finally, the extension to a general $1 \leq s \leq 2$ is done by the usual space interpolation techniques. ∎

3.1.2. Some finite element families. In [11], a recipe for building finite elements that satisfy P1–P5 is given. To apply such methods to this new free plate model, we must check an additional set of conditions.

1. *The validity of* P6. To apply Proposition 3.2, it is essential to check P6. In [11, 12], the analyzed problem is a clamped plate; therefore, the shear stresses being null at the boundary, Π_h is built as an application from $H_0(\mathrm{rot};\Omega)$ to $\boldsymbol{\Gamma}_h \subset H_0(\mathrm{rot};\Omega)$. Consequently, it is easily seen that the natural extension of Π_h to $H(\mathrm{rot};\Omega)$ (i.e., treating boundary edges as internal edges) satisfies P6.

2. *Practical applicability of the free boundary condition.* We must check that the free boundary condition in (3.4) can be expressed as a direct relation between the degrees of freedom of $\boldsymbol{\Theta}_h$ and W_h. But this usually follows naturally from the good properties of the discretization spaces and the operator Π_h, which, roughly speaking, are already built to interact well. For example this holds true for all elements introduced in [11, 12].

3. *Estimates for A_1 and A_2 in Proposition* 3.2. We must check that A_1 and A_2 can be bounded with an order in h which is sufficiently high; we want to avoid deterioration of the global estimate (3.14) by the additional A_1, A_2 terms. This usually can be done using orthogonality properties of Π_h as already shown for the MITC7. These orthogonality properties are, for example, already part of the definition of Π_h in almost all the elements of [11, 12].

Using Proposition 3.2, applying classical polynomial interpolation results, and checking the above points (see the MITC7 example), the following proposition follows easily.

PROPOSITION 3.4. *For the triangular families* I *and* III *of* [12] *of general order k, and for all the quadrilateral elements of* [11] *(both MITC*9 *($k = 2$) and higher order elements ($k = 3$)), the following error estimate holds:*

$$\|\boldsymbol{\theta} - \boldsymbol{\theta}_h\|_1 + t\|\boldsymbol{\gamma} - \boldsymbol{\gamma}_h\|_0 + \|\boldsymbol{\nabla}(w - w_h)\|_0 \leq c\,h^s(\,\|\,\boldsymbol{\theta}\,\|_{s+1} + t\|\boldsymbol{\gamma}\|_s + \|\boldsymbol{\gamma}\|_{s-1}\,), \tag{3.51}$$

where $1 \leq s \leq k$.

Remark 1. The triangular elements of [11] are not mentioned here because they are already included in those of [12]. Note also that the quadrilateral elements of [11] can be easily extended to $k \geq 4$.

Remark 2. The finite element family II of [12] was not included because point 3 above does not follow immediately (by orthogonality) as in the other cases. Clearly, this does not imply that the estimate could not be obtained by other means.

Remark 3. Recalling (2.19), the above proposition gives an error estimate of up to order 3/2 on the full domain for our free plate problem. Estimates of up to order k can, however, be expected in parts of the domain where the solution is more regular, for example, in interior subdomains.

Remark 4. The elements above are all at least of order 2. A first order element following this philosophy was presented in [9] and another will be presented in what follows.

3.1.3. A first order nonconforming element. We present here a first order method which follows this philosophy. Given a regular triangulation $\mathcal{T}_h$ of Ω of maximum diameter h, let T_+ and T_- be any two triangles with an edge e in common, and let $\mathbf{n}^+, \mathbf{n}^-$ be their outward normal unit vectors. Furthemore, given a piecewise continuous function φ on Ω (either scalar or vectorial), call φ^+ (respectively, φ^-) the trace of $\varphi\,|_{T_+}$ (respectively, $\varphi\,|_{T_-}$) on e. Then, the jump of φ across e is given by

$$[\varphi] = \varphi^+\mathbf{n}^+ + \varphi^-\mathbf{n}^- \qquad \text{for } \varphi \text{ scalar}, \tag{3.52}$$

$$[\boldsymbol{\varphi}] = (\boldsymbol{\varphi}^+ \otimes \mathbf{n}^+)_{sym} + (\boldsymbol{\varphi}^- \otimes \mathbf{n}^-)_{sym} \qquad \text{for } \varphi \text{ vectorial}, \tag{3.53}$$

where the symbol $_{sym}$ denotes the symmetric part of the tensor. If instead e is a boundary edge, then the jump function is simply $[\varphi] = \varphi\mathbf{n}$ or $[\boldsymbol{\varphi}] = (\boldsymbol{\varphi} \otimes \mathbf{n})_{sym}$, where $\mathbf{n}$ is again the outward normal.

Let Σ_i be the set of all internal edges; we introduce the space $\boldsymbol{\Theta}_h$ as

$$\boldsymbol{\Theta}_h = \left\{ \boldsymbol{\varphi} \,:\, \boldsymbol{\varphi}|_T \in P_1(T)\ \forall\, T,\ \int_e [\boldsymbol{\varphi}] = 0\ \forall e \in \Sigma_c \cup \Sigma_i,\ \int_e [\boldsymbol{\varphi}_s] = 0\ \forall e \in \Sigma_s \right\}. \tag{3.54}$$

This space follows a classical nonconforming approximation of $[H^1(\Omega)]^2$; the basic degrees of freedom are simply the values on the midpoints of the triangle edges, adjusted according to the boundary conditions.

We also define (see also (3.37))

$$W_h = \{v \,:\, v \in W,\ v|_T \in P_1(T)\ \forall\, T\}, \tag{3.55}$$

$$\boldsymbol{\Gamma}_h = \{\boldsymbol{\delta} \,:\, \boldsymbol{\delta} \in H(\mathrm{rot};\Omega),\ \boldsymbol{\delta}|_T \in RT_0(T)\ \forall\, T\}, \tag{3.56}$$

and Π_h as the classical interpolant for RT_0 (see, for example, [20]) uniquely defined on each triangle T by

$$\int_e (\boldsymbol{\delta} - \Pi_h\boldsymbol{\delta})_s \,\mathrm{d}s = 0 \quad \forall e \text{ edge of } T \tag{3.57}$$

for all sufficiently regular $\boldsymbol{\delta}$. Finally, the space $\mathcal{V}_h$ is defined as in (3.4).

We have the following proposition.

PROPOSITION 3.5. *Let $((\boldsymbol{\theta}, w), \boldsymbol{\gamma})$ be the solution of the continuous problem (see section 2). Let $((\boldsymbol{\theta}_h, w_h), \boldsymbol{\gamma}_h)$ be the solution of the discrete problem*

$$\begin{cases} \text{Find } ((\boldsymbol{\theta}_h, w_h), \boldsymbol{\gamma}_h) \in \mathcal{V}_h \times \boldsymbol{\Gamma}_h \text{ such that} \\ a(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) + j(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) - (\boldsymbol{\gamma}_h, \Pi_h\boldsymbol{\eta}_h - \boldsymbol{\nabla} v_h) = (g, v_h), \qquad (\boldsymbol{\eta}_h, v_h) \in \mathcal{V}_h, \\ \lambda^{-1}t^2(\boldsymbol{\gamma}_h, \boldsymbol{\delta}_h) - (\boldsymbol{\nabla} w_h, \boldsymbol{\delta}_h) + (\Pi_h\boldsymbol{\theta}_h, \boldsymbol{\delta}_h) = 0, \qquad \boldsymbol{\delta}_h \in \boldsymbol{\Gamma}_h, \end{cases} \tag{3.58}$$

where the jump penalty

$$j(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) = \sum_{e \in \Sigma_i \cup \Sigma_c} \frac{1}{|\, e \,|} \int_e [\boldsymbol{\theta}_h] : [\boldsymbol{\eta}_h] \, ds + \sum_{e \in \Sigma_s} \frac{1}{|\, e \,|} \int_e [(\theta_h)_s] \cdot [(\eta_h)_s] \, ds. \tag{3.59}$$

Then, we have the error estimate

$$\|\boldsymbol{\theta} - \boldsymbol{\theta}_h\|_1 + t\|\boldsymbol{\gamma} - \boldsymbol{\gamma}_h\|_0 + \|\boldsymbol{\nabla}(w - w_h)\|_0 \le c\, h(\,\|\, \boldsymbol{\varphi} \,\|_2 + t\|\boldsymbol{\gamma}\|_1 + \|\boldsymbol{\gamma}\|_0 \,). \tag{3.60}$$

Proof. The proof will be presented rather briefly. This method is nonconforming because the space $\boldsymbol{\Theta}_h$ is not in $H^1(\Omega)$. We start defining the norm on $\boldsymbol{\Theta}_h$,

$$\|\boldsymbol{\eta}\|_\theta^2 := \|\boldsymbol{\eta}\|_1^2 + j(\boldsymbol{\eta}, \boldsymbol{\eta}), \tag{3.61}$$

which is also well defined for all θ in $[H^1(\Omega)]^2$. Then, it can be proved that the discrete Korn inequality

$$\alpha\|\boldsymbol{\eta}\|_\theta^2 \le a(\boldsymbol{\eta}, \boldsymbol{\eta}) + j(\boldsymbol{\eta}, \boldsymbol{\eta}) \qquad \forall \boldsymbol{\eta} \in \boldsymbol{\Theta}_h \tag{3.62}$$

holds (see, for example, [13, 3]) and that $a(\cdot, \cdot)$ is continuous with respect to the norm (3.61). For these finite elements, if we define w_I as the usual Lagrange interpolant of w and $\boldsymbol{\theta}_I$ as the unique element of $\boldsymbol{\Theta}_h$ satisfying

$$\int_e (\boldsymbol{\theta} - \boldsymbol{\theta}_I) \, \mathrm{d}s = \mathbf{0} \quad \forall e \text{ edge of } \mathcal{T}_h, \tag{3.63}$$

where the integral is to be intended component by component, we easily infer Lemma 3.1.

Consequently, and without referring to P1–P6, we can follow the same steps as in the proof of Proposition 3.2, starting from the ellipticity of $a(\cdot, \cdot)$ in the $\|\cdot\|_\theta$ norm. The main difference is that now, due to the nonconformity of $\boldsymbol{\Theta}_h$, when we test (2.1) and (2.3) on the discrete spaces, we get an additional addendum in the right-hand side of the error equation (3.20). Without showing the calculations, such a term is

$$\sum_{e \in \Sigma_i \cup \Sigma_c} \int_e \mathbf{M}_n \boldsymbol{\eta} \, \mathrm{d}s + \sum_{e \in \Sigma_s} \int_e M_{ns} \eta_s \, \mathrm{d}s, \tag{3.64}$$

where $\mathbf{n}$ is the outward normal to each triangle (see (2.4)). For simplicity, we will now assume $\Sigma_s = \emptyset$; the general case can be treated with the same arguments as below. When tested with $\boldsymbol{\eta} = \boldsymbol{\theta}_I - \boldsymbol{\theta}_h$ and $v = w_I - w_h$ (see (3.22)), the term (3.64) gives the additional addendum in (3.23):

$$T_5 = \sum_{e \in \Sigma_i \cup \Sigma_i} \int_e \mathbf{M}_n (\boldsymbol{\theta}_I - \boldsymbol{\theta}_h) \, \mathrm{d}s. \tag{3.65}$$

It can be checked that

$$T_5 = \sum_{e \in \Sigma_i \cup \Sigma_i} \int_e \mathbf{M} : [\boldsymbol{\theta}_I - \boldsymbol{\theta}_h] \, \mathrm{d}s, \tag{3.66}$$

where we also used that, due to the regularity of $\boldsymbol{\theta}$, $\mathbf{M}$ is continuous across the internal edges (see, for instance, [2, 13] for a similar computation); otherwise we should simply substitute $\mathbf{M}$ above with the average between the traces of $M\,|_{T_+}$ and $M\,|_{T_-}$ on e.

From the definition of $\boldsymbol{\Theta}_h$, the jumps $[\boldsymbol{\theta}_I - \boldsymbol{\theta}_h]$ are orthogonal to the constants. Therefore, for any family $\{\bar{\mathbf{M}}_e\}_{e\in\Sigma_i\cup\Sigma_c}$ of constant tensors

(3.67)
$$T_5 = \sum_{e\in\Sigma_i\cup\Sigma_c}\int_e (\mathbf{M}-\bar{\mathbf{M}}_e) : [\boldsymbol{\theta}_I - \boldsymbol{\theta}_h]\,\mathrm{d}s \le \sum_{e\in\Sigma_i\cup\Sigma_c} \|(\mathbf{M}-\bar{\mathbf{M}}_e)\|_{0,e}\|[\boldsymbol{\theta}_I - \boldsymbol{\theta}_h]\|_{0,e}.$$

Without showing the details, from the Cauchy–Schwarz inequality in l^2, the Agmon inequality (3.31), classical polynomial interpolation results, and the definition of M, we obtain

$$\begin{aligned} T_5 &\le c\left(h\sum_{T\in\mathcal{T}_h}\|\boldsymbol{\theta}\|^2_{2,T}\right)^{1/2}\left(h\sum_{e\in\Sigma_i\cup\Sigma_c}\frac{1}{|\,e\,|}\|[\boldsymbol{\theta}_I-\boldsymbol{\theta}_h]\|^2_{0,e}\right)^{1/2} \\ &\le ch\|\boldsymbol{\theta}\|_2\|\boldsymbol{\theta}_I-\boldsymbol{\theta}_h\|_\theta. \end{aligned} \tag{3.68}$$

All the other terms T_1–T_4 have the same identical form as in (3.24)–(3.27) and can be bounded by an $O(h)$ following the same arguments as in the proof of Propositions 3.2 and 3.3. Therefore, bounding the error for the deflections as already done in (3.35), the proposition is proved. □

4. Discretization following the linked interpolation philosophy. Another class of finite element methods for plates that give good results are the ones based on the kinematic linked interpolation philosophy. We will show how these methods can be adapted to our free plate model, but by following a path different from the previous section. The aim here mainly is to introduce this extension and to show another viable way to enforce our new free boundary condition in a finite element setting; therefore we will be rather brief on some more standard parts of the demonstrations.

We start with a quick introduction to the linked interpolation method, referring, for example, to [6, 7, 21, 22] and references therein for a deeper presentation. Let $\mathcal{T}_h$ be a (regular) grid on the domain Ω. Call h_K the diameter of each element K and h the maximum of all the diameters. With the usual notation, now let $\boldsymbol{\Theta}_h \subset \boldsymbol{\Theta}$, $W_h \subset W$, $\boldsymbol{\Gamma}_h \subset [L^2(\Omega)]^2$ be the finite element spaces adopted; then, the linked interpolation method is based on the introduction of a linear and uniformly bounded operator $L : \boldsymbol{\Theta}_h \to W$.

The final form of the discrete problem takes the form

(4.1)
$$\begin{cases} \text{Find } ((\boldsymbol{\theta}_h, w_h), \boldsymbol{\gamma}_h) \in \boldsymbol{\Theta}_h \times W_h \times \boldsymbol{\Gamma}_h \text{ such that} \\ a(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) - (\boldsymbol{\gamma}_h, \boldsymbol{\eta}_h - \boldsymbol{\nabla}(v_h + L\boldsymbol{\eta}_h)) = (g, v_h + L\boldsymbol{\eta}_h), & (\boldsymbol{\eta}_h, v_h) \in \boldsymbol{\Theta}_h \times W_h, \\ \lambda^{-1}t^2(\boldsymbol{\gamma}_h, \boldsymbol{\delta}_h) + (\boldsymbol{\theta}_h - \boldsymbol{\nabla}(w_h + L\boldsymbol{\theta}_h), \boldsymbol{\delta}_h) = 0, & \boldsymbol{\delta}_h \in \boldsymbol{\Gamma}_h. \end{cases}$$

Then, for all $(\boldsymbol{\theta}, w, \boldsymbol{\gamma}) \in [H^1(\Omega)]^2 \times H^1(\Omega) \times [L^2(\Omega)]^2$, we define the norms

$$\|\boldsymbol{\gamma}\|_h^2 := \sum_{K\in\mathcal{T}_h} h_K^2\|\boldsymbol{\gamma}\|_{0,K}, \tag{4.2}$$

$$|\!|\!|\boldsymbol{\theta}, w, \boldsymbol{\gamma}|\!|\!|^2 := \|\boldsymbol{\theta}\|_1^2 + \|w\|_1^2 + \|\boldsymbol{\gamma}\|_h^2 + t^2\|\boldsymbol{\gamma}\|_0^2. \tag{4.3}$$

Assume also that the following two properties hold for the discretization spaces:

$$\boldsymbol{\nabla} W_h \subset \boldsymbol{\Gamma}_h, \tag{4.4}$$

$$\sup_{(\boldsymbol{\eta}_h, v_h)\in\boldsymbol{\Theta}_h\times W_h} \frac{(\boldsymbol{\delta}_h, \boldsymbol{\eta}_h - \boldsymbol{\nabla}(\boldsymbol{\eta}_h + Lv_h))}{\|\boldsymbol{\eta}_h\|_1 + \|v_h\|_1} \ge \beta\|\boldsymbol{\delta}_h\|_h \quad \forall \boldsymbol{\delta}_h \in \boldsymbol{\Gamma}_h, \tag{4.5}$$

where β is a positive constant independent of h.

Under this hypothesis, optimal error estimates (with respect to the order of the polynomial spaces used) in the $|||\cdot|||$ norm are proved in [6]; the results are shown in the clamped plate case but can be immediately extended to hard simply supported and free plates. The extension to our new free plate model is instead to be handled with some care; the projection operator which is hidden in the linked formulation is not suitable to directly enforce $\theta_s = w_{/s}$ on Σ_f in a relaxed way as done in (3.4). On the other hand, the particular approximation properties of this finite element allow us to enforce the free boundary condition by penalization.

4.1. A new discrete formulation. We start introducing the symmetric bilinear form (see (2.4)–(2.5)),

$$\begin{aligned} C(\boldsymbol{\theta}, w; \boldsymbol{\eta}, v) = &\sum_{e\in\Sigma_f} \int_e M_{ns}[\boldsymbol{\theta}](\boldsymbol{\eta} - \boldsymbol{\nabla} v)_s \,\mathrm{d}s + \int_e (\boldsymbol{\theta} - \boldsymbol{\nabla} w)_s M_{ns}[\boldsymbol{\eta}] \,\mathrm{d}s \\ &+ \frac{1}{|\ e\ |} \int_e (\boldsymbol{\theta} - \boldsymbol{\nabla} w)_s (\boldsymbol{\eta} - \boldsymbol{\nabla} v)_s \,\mathrm{d}s, \end{aligned} \tag{4.6}$$

which in particular is well defined on the discrete space $\boldsymbol{\Theta}_h \times W_h$.

We now remark that L can be extended to all $\boldsymbol{\Theta}$ by composition with the L^2 projection on $\boldsymbol{\Theta}_h$. Then, starting from (4.3), we can define the norm

$$|||\boldsymbol{\eta}, v, \boldsymbol{\delta}|||_*^2 := |||\boldsymbol{\eta}, v, \boldsymbol{\delta}|||^2 + \sum_{e\in\Sigma_f} \frac{1}{|\ e\ |} \int_e (\boldsymbol{\eta} - \boldsymbol{\nabla}(v + L\boldsymbol{\eta}))_s^2 \,\mathrm{d}s, \tag{4.7}$$

defined for all $(\boldsymbol{\eta}, v, \boldsymbol{\delta})$ in the discrete space and, for instance, for all $(\boldsymbol{\eta}, v, \boldsymbol{\delta}) \in [H^1(\Omega)]^2 \times H^2(\Omega) \times [L^2(\Omega)]^2$.

The condition $\theta_s = w_{/s}$ on Σ_f will be enforced through the addition of the bilinear form (4.6) to the original discrete plate problem. In simple words, the first term is introduced to reach consistency with the continuous problem, the second to obtain a symmetric form, and the third to add stability.

Our discrete problem is therefore

(4.8)
$$\begin{cases} \text{Find } ((\boldsymbol{\theta}_h, w_h), \boldsymbol{\gamma}_h) \in \boldsymbol{\Theta}_h \times W_h \times \boldsymbol{\Gamma}_h \text{ such that} \\ a(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) + C(\boldsymbol{\theta}_h, w_h + L\boldsymbol{\theta}_h; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) - (\boldsymbol{\gamma}_h, \boldsymbol{\eta}_h - \boldsymbol{\nabla}(v_h + L\boldsymbol{\eta}_h)) \\ \qquad\qquad = (g, v_h + L\boldsymbol{\eta}_h) \qquad \forall (\boldsymbol{\eta}_h, v_h) \in \boldsymbol{\Theta}_h \times W_h, \\ \lambda^{-1} t^2 (\boldsymbol{\gamma}_h, \boldsymbol{\delta}_h) + (\boldsymbol{\theta}_h - \boldsymbol{\nabla}(w_h + L\boldsymbol{\theta}_h), \boldsymbol{\delta}_h) = 0 \qquad \forall \boldsymbol{\delta}_h \in \boldsymbol{\Gamma}_h. \end{cases}$$

Letting

$$\begin{aligned} &A(\boldsymbol{\theta}_h, w_h, \boldsymbol{\gamma}_h; v_h, \boldsymbol{\eta}_h, \boldsymbol{\delta}_h) \\ &\quad := a(\boldsymbol{\theta}_h, \boldsymbol{\eta}_h) - (\boldsymbol{\gamma}_h, \boldsymbol{\eta}_h - \boldsymbol{\nabla} v_h) + (\boldsymbol{\theta}_h - \boldsymbol{\nabla} w_h, \boldsymbol{\delta}_h) + \lambda^{-1} t^2 (\boldsymbol{\gamma}_h, \boldsymbol{\delta}_h), \end{aligned} \tag{4.9}$$

problem (4.8) is equivalent to

(4.10)
$$\begin{cases} \text{Find } (\boldsymbol{\theta}_h, w_h, \boldsymbol{\gamma}_h) \in \boldsymbol{\Theta}_h \times W_h \times \boldsymbol{\Gamma}_h \text{ such that} \\ A(\boldsymbol{\theta}_h, w_h + L\boldsymbol{\theta}_h, \boldsymbol{\gamma}_h; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h, \boldsymbol{\delta}_h) + C(\boldsymbol{\theta}_h, w_h + L\boldsymbol{\theta}_h; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) \\ \qquad\qquad = (g, v_h + L\boldsymbol{\eta}_h) \quad \forall (\boldsymbol{\eta}_h, v_h, \boldsymbol{\delta}_h) \in \boldsymbol{\Theta}_h \times W_h \times \boldsymbol{\Gamma}_h. \end{cases}$$

We have the following lemma.

LEMMA 4.1. *Let* $\boldsymbol{\theta}, w, \boldsymbol{\gamma}$ *be the solution of the continuous problem of section* 2 ((2.1)–(2.3) *plus boundary conditions* (2.7), (2.8), *and* (2.11)). *Then, it holds that*

$$A(\boldsymbol{\theta}, w, \boldsymbol{\gamma}; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h, \boldsymbol{\delta}_h) + C(\boldsymbol{\theta}, w; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) = (g, v_h + L\boldsymbol{\eta}_h) \tag{4.11}$$

for all $(\boldsymbol{\eta}_h, v_h, \boldsymbol{\delta}_h) \in \boldsymbol{\Theta}_h \times W_h \times \boldsymbol{\Gamma}_h$.

Proof. The proof follows by standard variational means, testing (2.1)–(2.3), respectively, on $\boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h, \boldsymbol{\delta}_h$, then integrating by parts and recalling the boundary conditions (2.7), (2.8), and (2.11). Because the finite element space used does not satisfy a priori the condition on Σ_f, a nonconforming term appears; but this is taken care of by the additional bilinear form C introduced. We note that the regularity of w and $\boldsymbol{\theta}$ (see (2.19)) is sufficient to ensure the well posedness of the form C in the variational equation (4.11). ∎

The following proposition, which states the uniform invertibility of the discrete problem, is fundamental for the following estimates. Its proof relies strongly on the inf-sup condition (4.5) and adopts the same technique of [6, 19, 15]; therefore we will not include it here.

PROPOSITION 4.2. *There exists a positive constant* k *independent of* h *such that for any* $(\boldsymbol{\theta}_h, w_h, \boldsymbol{\gamma}_h) \in \boldsymbol{\Theta}_h \times W_h \times \boldsymbol{\Gamma}_h$ *there exists* $(\boldsymbol{\eta}_h, v_h, \boldsymbol{\delta}_h) \in \boldsymbol{\Theta}_h \times W_h \times \boldsymbol{\Gamma}_h$, *giving*

$$\begin{aligned} &A(\boldsymbol{\theta}_h, w_h + L\boldsymbol{\theta}_h, \boldsymbol{\gamma}_h; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h, \boldsymbol{\delta}_h) + C(\boldsymbol{\theta}_h, w_h + L\boldsymbol{\theta}_h; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) \\ &\geq |||\boldsymbol{\theta}_h, w_h, \boldsymbol{\gamma}_h|||_*, \end{aligned} \tag{4.12}$$

$$|||\boldsymbol{\eta}_h, v_h, \boldsymbol{\delta}_h|||_* \leq k. \tag{4.13}$$

For any $\boldsymbol{\eta}$ sufficiently regular, we indicate (here and in what follows) by $\boldsymbol{\eta}_{II}$ the interpolant of $\boldsymbol{\eta}$ in $\boldsymbol{\Theta}_h$. Analogously, v_I will indicate the interpolant of v in W_h and $\boldsymbol{\delta}_*$ the interpolant of $\boldsymbol{\delta}$ in $\boldsymbol{\Gamma}_h$.

We will assume, in addition to (4.4) and (4.5), that the property

$$\boldsymbol{\gamma}_s = 0 \text{ on } e \Longrightarrow (L\boldsymbol{\gamma}_{II})_s = 0 \text{ on } e \tag{4.14}$$

holds for all boundary edges e. We remark that, being already implicit in the linking philosophy, this condition is not restrictive; for example, it holds for all the linked elements presented in [6, 7, 8], using the natural interpolant in $\boldsymbol{\Theta}_h$.

Now, following the mainstream of [6], we introduce the operator

$$\Pi v := v_I + L(\boldsymbol{\nabla} v)_{II} \qquad \forall v \text{ sufficiently regular.} \tag{4.15}$$

We can finally state the main result.

PROPOSITION 4.3. *Let* $(\boldsymbol{\theta}_h, w_h, \boldsymbol{\gamma}_h)$ *be the solution of problem* (4.8) *and let* $(\boldsymbol{\theta}, w, \boldsymbol{\gamma})$ *be the solution of the continuous problem of section* 2 *((2.1)–(2.3) plus boundary conditions* (2.7), (2.8), *and* (2.11)). *Then, we have the following estimate:*

$$\begin{aligned} &|||\boldsymbol{\theta} - \boldsymbol{\theta}_h, w - w_h, \boldsymbol{\gamma} - \boldsymbol{\gamma}_h|||_* \\ &\quad \leq c[h\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_2 + \|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_1 + h^{-1}\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_0 + \|w - \Pi w\|_2 \\ &\qquad + h^{-1}\|w - \Pi w\|_1 + \|\boldsymbol{\gamma} - \boldsymbol{\gamma}_*\|_{H^{-1}(\mathrm{div})} + t\|\boldsymbol{\gamma} - \boldsymbol{\gamma}_*\|_0 + t\|\boldsymbol{\nabla} L\gamma_{II}\|_0]. \end{aligned} \tag{4.16}$$

Proof. We start applying Proposition 4.2 to $(\boldsymbol{\theta}_h - \boldsymbol{\theta}_{II}, w_h - w_I, \boldsymbol{\gamma}_h - \boldsymbol{\gamma}_*)$ and find

$(\boldsymbol{\eta}_h, v_h, \boldsymbol{\delta}_h)$ in the discrete space such that

$$
\begin{aligned}
&A(\boldsymbol{\theta}_h - \boldsymbol{\theta}_{II}, w_h - w_I + L(\boldsymbol{\theta}_h - \boldsymbol{\theta}_{II}), \boldsymbol{\gamma}_h - \boldsymbol{\gamma}_*; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h, \boldsymbol{\delta}_h) \\
&\qquad + C(\boldsymbol{\theta}_h - \boldsymbol{\theta}_{II}, w_h - w_I + L(\boldsymbol{\theta}_h - \boldsymbol{\theta}_{II}); \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) \\
&\geq |\!|\!| \boldsymbol{\theta}_h - \boldsymbol{\theta}_{II}, w_h - w_I, \boldsymbol{\gamma}_h - \boldsymbol{\gamma}_* |\!|\!|_*, \qquad (4.17) \\
&|\!|\!| \boldsymbol{\eta}_h, v_h, \boldsymbol{\delta}_h |\!|\!|_* \leq k. \qquad (4.18)
\end{aligned}
$$

Adding and subtracting as usual

$$
A(\boldsymbol{\theta}, w, \boldsymbol{\gamma}; v_h + L\boldsymbol{\eta}_h, \boldsymbol{\eta}_h, \boldsymbol{\delta}_h) + C(\boldsymbol{\theta}, w; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) \qquad (4.19)
$$

in (4.17), and then using the error equation given by the difference of (4.10) and (4.11), we obtain in the end

$$
\begin{aligned}
&|\!|\!| \boldsymbol{\theta}_h - \boldsymbol{\theta}_{II}, w_h - w_I, \boldsymbol{\gamma}_h - \boldsymbol{\gamma}_* |\!|\!|_* \\
&\quad \leq A(\boldsymbol{\theta} - \boldsymbol{\theta}_{II}, w - w_I - L\boldsymbol{\theta}_{II}, \boldsymbol{\gamma} - \boldsymbol{\gamma}_*; v_h + L\boldsymbol{\eta}_h, \boldsymbol{\eta}_h, \boldsymbol{\delta}_h) \\
&\qquad + C(\boldsymbol{\theta} - \boldsymbol{\theta}_{II}, w - w_I - L\boldsymbol{\theta}_{II}; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h). \qquad (4.20)
\end{aligned}
$$

Recalling definition (4.9), and using the Cauchy–Schwarz inequality, the continuity of $a(\cdot,\cdot)$, and the bound (4.18), we can derive by standard means,

$$
\begin{aligned}
&A(\boldsymbol{\theta} - \boldsymbol{\theta}_{II}, w - w_I - L\boldsymbol{\theta}_{II}, \boldsymbol{\gamma} - \boldsymbol{\gamma}_*; v_h + L\boldsymbol{\eta}_h, \boldsymbol{\eta}_h, \boldsymbol{\delta}_h) \leq c[\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_1 \\
&+ \|\boldsymbol{\gamma} - \boldsymbol{\gamma}_*\|_{H^{-1}(\mathrm{div})} + t\|\boldsymbol{\gamma} - \boldsymbol{\gamma}_*\|_0 + (\boldsymbol{\delta}_h, \boldsymbol{\theta} - \boldsymbol{\theta}_{II} - \boldsymbol{\nabla}(w - w_I - L\boldsymbol{\theta}_{II}))]. \qquad (4.21)
\end{aligned}
$$

To bound the last term, we argue as in [6], and we refer there for the details. Starting from (2.3), it is immediate to see that

$$
\boldsymbol{\nabla} L\boldsymbol{\theta}_{II} = \boldsymbol{\nabla} L(\boldsymbol{\nabla} w)_{II} + \lambda^{-1} t^2 \boldsymbol{\nabla} L\gamma_{II}. \qquad (4.22)
$$

We now substitute (4.22) into the last member of (4.21) and use the Cauchy–Schwarz inequality in L^2. Observing that, due to (4.18), $\|\boldsymbol{\delta}_h\|_h + t\|\delta_h\|_0$ is bounded, and recalling (4.15), we obtain

$$
(\boldsymbol{\delta}_h, \boldsymbol{\theta} - \boldsymbol{\theta}_{II} - \boldsymbol{\nabla}(w - w_I - L\boldsymbol{\theta}_{II})) \leq c(h^{-1}\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_0 + h^{-1}\|w - \Pi w\|_1 + t\|\boldsymbol{\nabla} L\gamma_{II}\|_0). \qquad (4.23)
$$

To estimate the right-hand side of (4.20), we still need to bound the free boundary part (defined in (4.6)),

$$
\begin{aligned}
&C(\boldsymbol{\theta} - \boldsymbol{\theta}_{II}, w - w_I - L\boldsymbol{\theta}_{II}; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h) \\
&\quad = \sum_{e \in \Sigma_f} \int_e M_{ns}[\boldsymbol{\theta} - \boldsymbol{\theta}_{II}](\boldsymbol{\eta}_h - \boldsymbol{\nabla}(v_h + L\boldsymbol{\eta}_h))_s \, \mathrm{d}s \\
&\qquad + \int_e (\boldsymbol{\theta} - \boldsymbol{\theta}_{II} - \boldsymbol{\nabla}(w - w_I - L\boldsymbol{\theta}_{II}))_s M_{ns}[\boldsymbol{\eta}_h] \, \mathrm{d}s \\
&\qquad + \frac{1}{|\, e \,|} \int_e (\boldsymbol{\theta} - \boldsymbol{\theta}_{II} - \boldsymbol{\nabla}(w - w_I - L\boldsymbol{\theta}_{II}))_s (\boldsymbol{\eta}_h - \boldsymbol{\nabla}(v_h + L\boldsymbol{\eta}_h))_s \, \mathrm{d}s. \qquad (4.24)
\end{aligned}
$$

We start observing that, recalling the definition of M_{ns} in (2.5) and the Agmon inequality (3.31), we have

$$
\begin{aligned}
\sum_{e \in \Sigma_f} \|M_{ns}[\boldsymbol{\theta} - \boldsymbol{\theta}_{II}]\|^2_{0,e} &\leq c \sum_{K \in \mathcal{T}_h} h^{-1}\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|^2_{1,T} + h\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|^2_{2,T} \\
&\leq h^{-1}\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|^2_{1,\Omega} + h\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|^2_{2,\Omega}, \qquad (4.25)
\end{aligned}
$$

while, from the definition (4.7) and bound (4.18), it follows that

$$\sum_{e\in\Sigma_f} \|(\boldsymbol{\eta}_h - \boldsymbol{\nabla}(v_h + L\boldsymbol{\eta}_h))_s\|_{0,e}^2$$
$$\leq h \sum_{e\in\Sigma_f} \frac{1}{|\ e\ |}\|(\boldsymbol{\eta}_h - \boldsymbol{\nabla}(v_h + L\boldsymbol{\eta}_h))_s\|_{0,e}^2 \leq h\|\!|\boldsymbol{\eta}_h, v_h, \boldsymbol{\delta}_h|\!\|_*^2 \leq c\,h. \tag{4.26}$$

Applying the Cauchy–Schwarz inequality (first in $L^2(e)$, then in l^2), we can bound the first term in the right-hand side of (4.24) with the product of the square roots of (4.25) and (4.26). Summing over all $e \in \Sigma_f$, this easily gives

$$\sum_{e\in\Sigma_f} \int_e M_{ns}[\boldsymbol{\theta} - \boldsymbol{\theta}_{II}](\boldsymbol{\eta}_h - \boldsymbol{\nabla}(v_h + L\boldsymbol{\eta}_h))_s\,\mathrm{d}s \leq c[\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_1 + h\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_2]. \tag{4.27}$$

From (4.22) and the definition of Π in (4.15) it follows that

$$\|(\boldsymbol{\theta} - \boldsymbol{\theta}_{II} - \boldsymbol{\nabla}(w - w_I - L\boldsymbol{\theta}_{II}))_s\|_{0,e} \leq \|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_{0,e} + |\ w - \Pi w\ |_{1,e} + \lambda^{-1}t^2\|(L\boldsymbol{\gamma}_{II})_s\|_{1,e}, \tag{4.28}$$

where $e \in \Sigma_f$.

Due to the boundary condition (2.11) and property (4.14), the last term in (4.28) is null. Therefore, using the Agmon inequality on each $e \in \Sigma_f$ and then summing over all $K \in \mathcal{T}_h$, we have

$$\sum_{e\in\Sigma_f} \|(\boldsymbol{\theta} - \boldsymbol{\theta}_{II} - \boldsymbol{\nabla}(w - w_I - L\boldsymbol{\theta}_{II}))_s\|_{0,e}^2$$
$$\leq c[h^{-1}\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_{0,\Omega}^2 + h\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_{1,\Omega}^2 + h^{-1}\|w - \Pi w\|_{1,\Omega}^2 + h\|w - \Pi w\|_{2,\Omega}^2]. \tag{4.29}$$

Using again the Agmon inequality, classical inverse inequalities for piecewise polynomials and then bound (4.18), we easily get

$$\sum_{e\in\Sigma_f} \|M_{ns}[\boldsymbol{\eta}_h]\|_{0,e}^2 \leq ch^{-1} \sum_{K\in\mathcal{T}_h} \|\boldsymbol{\eta}_h\|_{1,K}^2$$
$$\leq ch^{-1}\|\boldsymbol{\eta}_h\|_{1,\Omega}^2 \leq ch^{-1}\|\!|\boldsymbol{\eta}_h, v_h, \boldsymbol{\delta}_h|\!\|_*^2 \leq ch^{-1}. \tag{4.30}$$

Using (4.29) and (4.30) and the Cauchy–Schwarz inequality (as done in (4.27)), we can then bound the second term in the right-hand side of (4.24):

$$\sum_{e\in\Sigma_f} \int_e (\boldsymbol{\theta} - \boldsymbol{\theta}_{II} - \boldsymbol{\nabla}(w - w_I - L\boldsymbol{\theta}_{II}))_s M_{ns}[\boldsymbol{\eta}_h]\,\mathrm{d}s$$
$$\leq c[h^{-1}\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_0 + \|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_1 + h^{-1}\|w - \Pi w\|_1 + \|w - \Pi w\|_2]. \tag{4.31}$$

The last member of (4.24) can be bounded in a similar way using (4.26) and (4.29); combining (4.27) and (4.31) with this last bound, we finally obtain from (4.24)

$$C(\boldsymbol{\theta} - \boldsymbol{\theta}_{II}, w - w_I - L\boldsymbol{\theta}_{II}; \boldsymbol{\eta}_h, v_h + L\boldsymbol{\eta}_h)$$
$$\leq c[\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_1 + h\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_2 + h^{-1}\|\boldsymbol{\theta} - \boldsymbol{\theta}_{II}\|_0 + h^{-1}\|w - \Pi w\|_1 + \|w - \Pi w\|_2]. \tag{4.32}$$

The proof follows by the triangle inequality and combining estimates (4.21), (4.23), and (4.32). □

Proposition 4.3 grants uniform and optimal error estimates for most of the linked elements in the literature applied to our new free boundary model.

Assume that properties (4.4), (4.5), and (4.14) are true, and that, for $k \leq 1$,

- the interpolant $\boldsymbol{\theta}_{II}$ is P_k invariant,
- the interpolant w_I is P_k invariant, and
- the interpolant $\boldsymbol{\gamma}_*$ is P_{k-1} invariant.

Assume also that, for the linear and uniformly bounded operator $L : \boldsymbol{\Theta}_h \to W$, it holds that

- the application Π (see (4.15)) is P_{k+1} invariant and
- $\mid L\boldsymbol{\delta} \mid_1 = O(h^k)$ for all sufficiently regular $\boldsymbol{\delta}$.

Then, it is easy to obtain from Proposition 4.3 and standard polynomial interpolation that, for all $1 \leq s \leq k$,

$$\begin{aligned} &\|\boldsymbol{\theta} - \boldsymbol{\theta}_h\|_1 + \|w - w_h\|_1 + \|\boldsymbol{\gamma} - \boldsymbol{\gamma}_h\|_h + t^2\|\boldsymbol{\gamma} - \boldsymbol{\gamma}_h\|_0 \\ &\qquad \leq ch^s(\,\|\,\boldsymbol{\varphi}\,\|_{s+1} + \|\,w\,\|_{s+2} + t\|\boldsymbol{\gamma}\|_s + \|\boldsymbol{\gamma}\|_{s-1} + \|\mathrm{div}\boldsymbol{\gamma}\|_{s-1}\,), \end{aligned} \tag{4.33}$$

which, remembering (2.19) and from Remark 6, gives an order of convergence of up to order $\min(3/2, k)$ on the full domain.

Remark 5. The last two conditions above may seem less natural, but they are fundamental requirements for any linked interpolation method and follow in each particular case from the form of the operator L. For example, all the above requirements are met by the triangular elements of [7] with $k = 1$, by the quadrilateral elements of [8] with $k = 1$, and by the higher order triangular elements of [6] with $k = 2$.

Remark 6. We note that for these elements, the higher order (but realistic) regularity (2.20) is required for w.

Remark 7. A similar method was applied and numerically tested in [16] for the PSRI plate elements.

A TIME-DOMAIN FINITE ELEMENT METHOD FOR MAXWELL'S EQUATIONS*

TRI VAN† AND AIHUA WOOD‡

Abstract. Presented here is a time-domain finite element method for approximating Maxwell's equations. The problem is to approximate the electromagnetic fields scattered by a bounded, inhomogeneous cavity embedded in an infinite ground plane. The time-dependent scattering problem is first discretized in time by Newmark's time-stepping scheme. The resulting semidiscrete problem is proved to be well posed. A nonlocal boundary condition on the cavity aperture is constructed to reduce the computational domain to the cavity itself. Stability analysis and error estimates of the fully discrete problem are provided.

Key words. Maxwell's equations, nonlocal boundary condition, time-domain finite element methods, Newmark scheme, stability, cavity

1. Introduction.

Time-harmonic (frequency-domain) Maxwell's equations for scattering problems are well studied and documented ([1, 19, 20, 21], to name a few) compared to their time-domain counterparts. This is due, to a large extent, to their obvious advantage of the absence of the time dependence and the limitations of computer power. The recent rapid advances in computing technology have prompted a growing popularity of numerical schemes for simulating electromagnetic transients (time-domain) for their potential to generate wide-band data and model nonlinear materials. Reports of new and faster numerical techniques for electromagnetic analysis have flourished in the engineering literature (see, for example, [18, 23, 12, 25]). However, very little analysis is known in the open literature. To the authors' knowledge, the first mathematical study of time-domain Maxwell's equations for scattering by a bounded perfectly electric conducting (PEC) body was reported in [22], in which a spatially discretized problem is analyzed. More recently, in [4, 5], fully discrete finite element methods for solving Maxwell's equations of bounded PEC scattering bodies are considered. In both cases, the problem is defined in a bounded domain. This paper serves as our first attempt to understand the various stability and convergence issues associated with the finite element method for modelling transient electromagnetic scattering from non-PEC bodies. The problem is defined in an infinite space.

As observed in [7], most numerical schemes for scattering problems are faced with the problem of truncating the infinite domain to a bounded computational domain

without introducing excessive error. This is usually achieved by introducing an artificial boundary with appropriately defined boundary conditions that reduce the reflection of waves incident on this artificial boundary. Among the more popular are the so-called absorbing boundary conditions (ABC), perfectly matched layer (PML), and exact nonreflecting boundary conditions (NRBC) (for a survey of nonreflecting boundary conditions see [14]). An NRBC is nonlocal in both time and space. The nonlocality of NRBC in time requires the storing of the entire history of the solution on the artificial boundary and can be very expensive for large problems. In [15], the numerical methods for solving three-dimensional acoustic and elastic wave problems are derived based on the Kirchhoff-type boundary condition which is nonlocal in both time and space. For electromagnetic scattering problems, exact NRBCs are developed in [16] by using vector spherical harmonic series expansions for the spherical artificial boundary. In this formulation the computational domain can be unnecessarily large when the scatterer geometry is highly irregular, such as a thin and long body. In this paper, we present a finite element/Fourier transform method for analyzing the transient electromagnetic scattering from three-dimensional cavities embedded in the infinite PEC ground plane. Contrary to the conventional approach, we first discretize the problem in time by the Newmark scheme. At each time step, a spatially nonlocal boundary condition is constructed right at the cavity aperture Γ so that the computational domain is reduced to a minimum: the cavity itself. The finite element matrix is precomputed outside of the time loop and is reused at each time step, significantly reducing storage and computational time. Since the memory requirement does not increase with time, one is able to numerically solve larger problems.

The next section describes the model problem. Section 3 demonstrates the time-discretization of the cavity problem by using the Newmark time-stepping scheme. This procedure yields the so-called semidiscrete problem, which is analytically solved in the exterior of the cavity by using Fourier transform. The exterior solution is used to construct a nonlocal boundary condition, which is then used to reduce the semidiscrete problem to a finite domain (the cavity itself). Section 4 establishes the existence and uniqueness of a weak solution of the semidiscrete problem. The semidiscrete problem is fully discretized in section 5 by the curl-conforming finite elements. Motivated by the work of Baker [2] and Cowsar, Dupont, and Wheeler [11] for second-order hyperbolic equations, stability of the time-marching scheme is analyzed. Convergence properties of the finite element method are also addressed. The paper is concluded in section 6.

2. Mathematical formulation. Let Ω denote a bounded Lipschitz domain (cavity) in $\mathbb{R}^3$ such that $\Omega \subset \{\boldsymbol{x} = (x_1, x_2, x_3) \in \mathbb{R}^3 : x_3 \leq 0\}$. The relative electric permittivity of Ω is characterized by the bounded positive function $\varepsilon_r = \varepsilon/\varepsilon_0$. It is assumed that the medium throughout is nonmagnetic, thus, $\mu_r = 1$. The cavity aperture is defined by the surface $\Gamma = \{\boldsymbol{x} \in \partial\Omega : x_3 = 0\}$. We are interested in the scattering properties of the cavity-backed aperture in an infinite ground plane. The infinite ground plane excluding the cavity is assumed to be PEC, hence, the tangential components of the total field and the scattered field vanish there. An incident electromagnetic field $(\boldsymbol{E}^i, \boldsymbol{H}^i)$ is assumed to be the classical solution of the time-domain Maxwell's equations in the free space

$$\begin{cases} \operatorname{curl} \boldsymbol{E}^i(\boldsymbol{x}, t) &= -\dfrac{\partial}{\partial t}\boldsymbol{H}^i(\boldsymbol{x}, t) \ \text{ in } \mathbb{R}^3 \times (0, T), \\ \operatorname{curl} \boldsymbol{H}^i(\boldsymbol{x}, t) &= \dfrac{\partial}{\partial t}\boldsymbol{E}^i(\boldsymbol{x}, t) \ \text{ in } \mathbb{R}^3 \times (0, T), \end{cases}$$

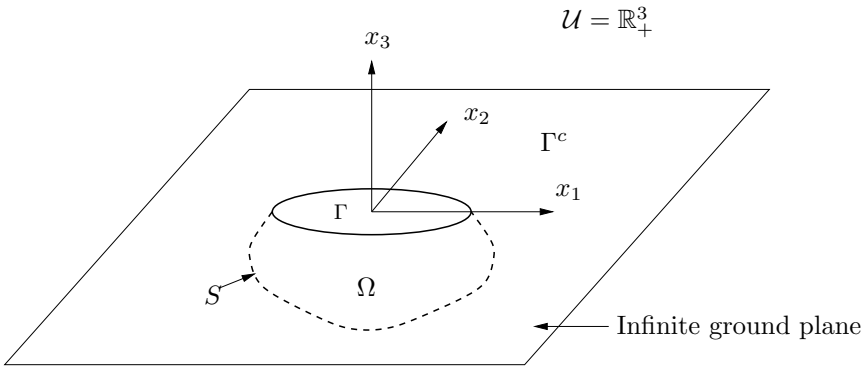

FIG. 2.1. *Cavity Ω in the infinite ground plane.*

where $0 < T < \infty$. The incident field interacts with the cavity to produce the total field $(\boldsymbol{E}, \boldsymbol{H})$ which satisfies the initial-value problem

$$\text{(2.1)} \qquad \begin{cases} \operatorname{curl} \boldsymbol{E}(\boldsymbol{x},t) &= -\dfrac{\partial}{\partial t}\boldsymbol{H}(\boldsymbol{x},t) \ \text{ in } \mathbb{R}^3 \times (0,T), \\ \operatorname{curl} \boldsymbol{H}(\boldsymbol{x},t) &= \varepsilon_r(\boldsymbol{x})\dfrac{\partial}{\partial t}\boldsymbol{E}(\boldsymbol{x},t) \ \text{ in } \mathbb{R}^3 \times (0,T), \\ \boldsymbol{E}(\boldsymbol{x},0) = \boldsymbol{E}_0 \quad &\text{and} \quad \boldsymbol{H}(\boldsymbol{x},0) = \boldsymbol{H}_0, \end{cases}$$

where $\boldsymbol{E}_0$ and $\boldsymbol{H}_0$ are initial conditions with compact support. Let $(\boldsymbol{E}^r, \boldsymbol{H}^r)$ denote the field reflected by the ground plane in the absence of the scatterer. The scattered field $(\boldsymbol{E}^s, \boldsymbol{H}^s)$ is defined by the differences

$$\boldsymbol{E}^s = \boldsymbol{E} - (\boldsymbol{E}^i + \boldsymbol{E}^r), \quad \boldsymbol{H}^s = \boldsymbol{H} - (\boldsymbol{H}^i + \boldsymbol{H}^r).$$

Let us denote S as the cavity walls, $\Gamma^c = \{x \in \mathbb{R}^3 : x_3 = 0\} \setminus \Gamma$, and $\mathcal{U}$ as the upper half space $\{\boldsymbol{x} \in \mathbb{R}^3 : x_3 > 0\}$. The domain of interest is $\mathcal{G} := \Omega \cup \mathcal{U}$. The surface $\partial\mathcal{G}$ is perfectly conducting, where $\partial\mathcal{G} = S \cup \Gamma^c$ (see Figure 2.1). Inside the cavity Ω we solve for the total field $\boldsymbol{E}$, while in the upper half space $\mathcal{U}$ we only need to solve for the scattered field $\boldsymbol{E}^s$ since both $\boldsymbol{E}^i$ and $\boldsymbol{E}^r$ are known in $\mathcal{U}$. We eliminate the magnetic field $\boldsymbol{H}$ in (2.1) to obtain a transmission-type problem,

$$\text{(2.2)} \qquad \begin{cases} \operatorname{curl}\operatorname{curl} \boldsymbol{E}(\boldsymbol{x},t) + \varepsilon_r \dfrac{\partial^2}{\partial t^2}\boldsymbol{E}(\boldsymbol{x},t) &= 0 \ \text{ in } \Omega \times (0,T), \\ \operatorname{curl}\operatorname{curl} \boldsymbol{E}^s(\boldsymbol{x},t) + \dfrac{\partial^2}{\partial t^2}\boldsymbol{E}^s(\boldsymbol{x},t) &= 0 \ \text{ in } \mathcal{U} \times (0,T), \end{cases}$$

with the transmission conditions

$$\begin{aligned} \hat{n} \times \boldsymbol{E} &= 0 \ \text{ on } S \times (0,T), \\ \hat{n} \times \boldsymbol{E}^s &= 0 \ \text{ on } \Gamma^c \times (0,T), \\ \hat{n} \times \boldsymbol{E} &= \hat{n} \times (\boldsymbol{E}^s + \boldsymbol{E}^i + \boldsymbol{E}^r) \ \text{ on } \Gamma \times (0,T), \\ \hat{n} \times \operatorname{curl} \boldsymbol{E} &= \hat{n} \times \operatorname{curl}(\boldsymbol{E}^s + \boldsymbol{E}^i + \boldsymbol{E}^r) \ \text{ on } \Gamma \times (0,T) \end{aligned}$$

and the initial conditions

$$\boldsymbol{E}(\boldsymbol{x},0) = \boldsymbol{E}_0(\boldsymbol{x}), \quad \partial_t \boldsymbol{E}(\boldsymbol{x},0) = \boldsymbol{E}_1(\boldsymbol{x}) = \operatorname{curl} \boldsymbol{H}_0(\boldsymbol{x})/\varepsilon_r(\boldsymbol{x}),$$

where $\boldsymbol{E}_0$ and $\boldsymbol{H}_0$ are the given electric and magnetic fields at time $t = 0$. In the rest of the paper, we wish to numerically solve the time-dependent problem (2.2).

3. Semidiscrete problem. In this section, we shall first discretize the model problem (2.2) in time using Newmark's time-marching scheme [26, 27]. At each time step, we solve the resulting semidiscrete problem exactly in the exterior of the cavity using Fourier transform method. The solution is then used to construct an exact nonlocal boundary condition over the cavity aperture. This boundary condition is key to reducing the infinite problem to a bounded (interior) computational domain.

3.1. Time-discretization. We begin by describing the Newmark time-stepping scheme. Let $\Delta t > 0$ be the (constant) time step

$$\Delta t = T/\mathcal{N},$$

where $\mathcal{N}$ is an arbitrary positive integer and T the total time. Let $t_n = n\Delta t$ be the nth time step. Newmark's scheme can be defined as follows. Consider the following expansion of a sufficiently regular function $y(t)$:

$$y(t_{n+1}) = y(t_n) + \Delta t y'(t_n) + (\Delta t)^2 \left[\beta y''(t_{n+1}) + \left(\frac{1}{2} - \beta\right) y''(t_n)\right] + \mathcal{O}(\Delta t^3),$$
$$y'(t_{n+1}) = y'(t_n) + \Delta t \left[\gamma y''(t_{n+1}) + (1-\gamma) y''(t_n)\right] + \mathcal{O}(\Delta t^2),$$

where β and γ are parameters. Define the approximations y^{n+1}, $\dot{y}^{n+1}$, and $\ddot{y}^{n+1}$ of $y(t_{n+1})$, $y'(t_{n+1})$, and $y''(t_{n+1})$, respectively, by

$$y^{n+1} = y^n + \Delta t \dot{y}^n + (\Delta t)^2 \left[\beta \ddot{y}^{n+1} + \left(\frac{1}{2} - \beta\right) \ddot{y}^n\right], \quad n = 0, 1, \ldots, \mathcal{N},$$
$$\dot{y}^{n+1} = \dot{y}^n + \Delta t \left[\gamma \ddot{y}^{n+1} + (1-\gamma)\ddot{y}^n\right], \quad n = 0, 1, \ldots, \mathcal{N}.$$

The above recurrence equations are called the Newmark time-stepping scheme. We note that the scheme is *explicit* if $\beta = 0$, i.e., y_{n+1} depends only on the terms at the nth time step, and *implicit* otherwise. The scheme accuracy is $\mathcal{O}(\Delta t^2)$ if $\gamma = 1/2$ and $\mathcal{O}(\Delta t)$ if $\gamma \neq 1/2$, which can be seen from the Taylor expansion

$$y'(t_{n+1}) = y'(t_n) + \frac{\Delta t}{2} y''(t_n) + \mathcal{O}(\Delta t^2).$$

Throughout the paper, we apply the Newmark scheme with $\gamma = 1/2$. By applying the scheme to (2.2) we have

$$\text{(3.1)} \qquad \begin{cases} \operatorname{curl}\operatorname{curl} \boldsymbol{E}^{n+1} + \varepsilon_r \ddot{\boldsymbol{E}}^{n+1} = 0\,, \\ \boldsymbol{E}^{n+1} = \boldsymbol{E}^n + \Delta t \dot{\boldsymbol{E}}^n + \dfrac{(\Delta t)^2}{2}[(1-2\beta)\ddot{\boldsymbol{E}}^n + 2\beta \ddot{\boldsymbol{E}}^{n+1}]\,, \\ \dot{\boldsymbol{E}}^{n+1} = \dot{\boldsymbol{E}}^n + \Delta t \left[\dfrac{\ddot{\boldsymbol{E}}^n}{2} + \dfrac{\ddot{\boldsymbol{E}}^{n+1}}{2}\right], \end{cases}$$

where $\boldsymbol{E}^n = \boldsymbol{E}^n(\boldsymbol{x})$, $\dot{\boldsymbol{E}}^n = \dot{\boldsymbol{E}}^n(\boldsymbol{x})$, and $\ddot{\boldsymbol{E}}^n$, are the *temporal approximations* of $\boldsymbol{E}(\boldsymbol{x}, t_n)$, $\frac{\partial \boldsymbol{E}}{\partial t}(\boldsymbol{x}, t_n)$, and $\frac{\partial^2 \boldsymbol{E}}{\partial t^2}(\boldsymbol{x}, t_n)$, respectively, for $n = 1, 2, \ldots, \mathcal{N}$. If $n = 0$,

we set

$$\boldsymbol{E}^0 = \boldsymbol{E}(0), \quad \dot{\boldsymbol{E}}^0 = \frac{\partial}{\partial t}\boldsymbol{E}(0).$$

From (3.1) we can derive the following *semidiscrete problem* (recursive relations):

$$(3.2)\quad \begin{cases} (\Delta t)^2\beta \operatorname{curl}\operatorname{curl}\boldsymbol{E}^{n+1} + \varepsilon_r \boldsymbol{E}^{n+1} = \varepsilon_r \left[\boldsymbol{E}^n + \Delta t v_n + \dfrac{(\Delta t)^2}{2}(1-2\beta)\ddot{\boldsymbol{E}}^n\right], \\ \ddot{\boldsymbol{E}}^{n+1} = \dfrac{1}{2\beta}\left[\dfrac{2}{(\Delta t)^2}(\boldsymbol{E}^{n+1} - \boldsymbol{E}^n - \Delta t\dot{\boldsymbol{E}}^n) - (1-2\beta)\ddot{\boldsymbol{E}}^n\right], \\ \dot{\boldsymbol{E}}^{n+1} = \dot{\boldsymbol{E}}^n + \Delta t\left[\dfrac{\ddot{\boldsymbol{E}}^n}{2} + \dfrac{\ddot{\boldsymbol{E}}^{n+1}}{2}\right]. \end{cases}$$

We note that the first equation in (3.2) is a partial differential equation in terms of the function $\boldsymbol{E}^{n+1}$, in which the right-hand side is known at the current time step. The discrete version of the boundary condition on $\partial\mathcal{G}$, as well as some radiation condition, must be added to (3.2) to complete the statement of the problem. From an implementation viewpoint, it is beneficial to write these equations in a predictor-corrector form as follows.

Prediction:

$$\tilde{\boldsymbol{E}}^{n+1} = \boldsymbol{E}^n + \Delta t\dot{\boldsymbol{E}}^n + \frac{(\Delta t)^2}{2}(1-2\beta)\ddot{\boldsymbol{E}}^n,$$

$$\tilde{\dot{\boldsymbol{E}}}^{n+1} = \dot{\boldsymbol{E}}^n + \frac{\Delta t}{2}\ddot{\boldsymbol{E}}^n.$$

Solution:

$$(P^{n+1})\begin{cases} (\Delta t)^2\beta \operatorname{curl}\operatorname{curl}\boldsymbol{E}^{n+1} + \varepsilon_r\boldsymbol{E}^{n+1} = \varepsilon_r\tilde{\boldsymbol{E}}^{n+1} & \text{in } \Omega, \\ \hat{n}\times\boldsymbol{E}^{n+1} = 0 & \text{on } S, \\ \hat{n}\times\boldsymbol{E}^{n+1} = \hat{n}\times(\boldsymbol{E}^{s,n+1} + \boldsymbol{E}^{i,n+1} + \boldsymbol{E}^{r,n+1}) & \text{on } \Gamma, \\ \hat{n}\times\operatorname{curl}\boldsymbol{E}^{n+1} = \hat{n}\times\operatorname{curl}(\boldsymbol{E}^{s,n+1} + \boldsymbol{E}^{i,n+1} + \boldsymbol{E}^{r,n+1}) & \text{on } \Gamma. \end{cases}$$

Correction:

$$\ddot{\boldsymbol{E}}^{n+1} = \frac{1}{\beta(\Delta t)^2}(\boldsymbol{E}^{n+1} - \tilde{\boldsymbol{E}}^{n+1}),$$

$$\dot{\boldsymbol{E}}^{n+1} = \tilde{\dot{\boldsymbol{E}}}^{n+1} + \frac{\Delta t}{2}\ddot{\boldsymbol{E}}^{n+1}.$$

Thus, in addition to the updating performed in the *prediction* and the *correction*, we have to solve in each time step the boundary value problem in the *solution*. We also note that the differential operator $(\operatorname{curl}\operatorname{curl} + \varepsilon_r I)$ in (P^{n+1}) is independent of time; hence it need be inverted only once. To solve the sequence of boundary value problems (P^{n+1}), $n = 0, 1, 2, \ldots, \mathcal{N}-1$, we use the standard finite element method with an appropriate nonlocal boundary condition. We now concentrate on the partial

differential equation in (P^{n+1}):

$$
\left\{
\begin{aligned}
\operatorname{curl}\operatorname{curl}\boldsymbol{E}^{n+1}+\alpha^2\varepsilon_r\boldsymbol{E}^{n+1} &= \boldsymbol{h}^{n+1} \quad \text{in } \Omega,\\
\operatorname{curl}\operatorname{curl}\boldsymbol{E}^{s,n+1}+\alpha^2\boldsymbol{E}^{s,n+1} &= \boldsymbol{h}^{s,n+1} \quad \text{in } \mathcal{U},\\
\hat{n}\times\boldsymbol{E}^{n+1} &= 0 \quad \text{on } S,\\
\hat{n}\times\boldsymbol{E}^{s,n+1} &= 0 \quad \text{on } \Gamma^c,\\
\hat{n}\times\operatorname{curl}\boldsymbol{E}^{n+1} &= \hat{n}\times\operatorname{curl}(\boldsymbol{E}^s+\boldsymbol{E}^i+\boldsymbol{E}^r)^{n+1} \quad \text{on } \Gamma,\\
\hat{n}\times\boldsymbol{E}^{n+1} &= \hat{n}\times(\boldsymbol{E}^s+\boldsymbol{E}^i+\boldsymbol{E}^r)^{n+1} \quad \text{on } \Gamma,
\end{aligned}
\right. \tag{3.3}
$$

where

$$\alpha^2=\frac{1}{(\Delta t)^2\beta}, \tag{3.4}$$

$$\boldsymbol{h}^{n+1}=\alpha^2\varepsilon_r(\boldsymbol{x})\tilde{\boldsymbol{E}}^{n+1} \quad \text{in } \Omega, \tag{3.5}$$

$$\boldsymbol{h}^{s,n+1}=\alpha^2\tilde{\boldsymbol{E}}^{s,n+1} \quad \text{in } \mathcal{U}. \tag{3.6}$$

In the next subsection, we wish to solve for the scattered field $\boldsymbol{E}^{s,n+1}$ in (3.3) exactly by using Fourier transformation. We can then construct a nonlocal boundary operator which relates the tangential components of $\operatorname{curl}\boldsymbol{E}$ and $\boldsymbol{E}$ for $\boldsymbol{E}\in H(\operatorname{curl},\Omega)$.

3.2. Exterior problem and nonlocal boundary condition. Let $\tilde{\Gamma}$ be a closed smooth surface such that $\bar{\Gamma}\subset\tilde{\Gamma}$. Let $\operatorname{div}_\Gamma$ and $\operatorname{curl}_\Gamma$ be the surface divergence and the scalar surface rotational, respectively. For the detailed definitions of these operators, the reader is referred to [3, 8]. We define the following Sobolev spaces:

$$
\begin{aligned}
H^{1/2}(\Gamma)&=\{\phi|_\Gamma:\phi\in H^{1/2}(\tilde{\Gamma})\},\\
\tilde{H}^{1/2}(\Gamma)&=\{\phi|_\Gamma:\phi\in H^{1/2}(\tilde{\Gamma}),\ \operatorname{supp}(\phi)\subset\bar{\Gamma}\},
\end{aligned}
$$

and

$$
\begin{aligned}
H^{-1/2}(\Gamma)&=(\tilde{H}^{1/2}(\Gamma))',\\
\tilde{H}^{-1/2}(\Gamma)&=(H^{1/2}(\Gamma))'.
\end{aligned}
$$

We also need

$$
\begin{aligned}
H^{-1/2}(\operatorname{div}_\Gamma,\Gamma)&=\{\Phi\in[H^{-1/2}(\Gamma)]^3:\Phi\cdot\hat{x}_3=0,\ \operatorname{div}_\Gamma\Phi\in H^{-1/2}(\Gamma),\ \text{and } \nu\cdot\Phi|_{\partial\Gamma}=0\},\\
H^{-1/2}(\operatorname{curl}_\Gamma,\Gamma)&:=\{\Phi\in[H^{-1/2}(\Gamma)]^3:\Phi\cdot\hat{x}_3=0,\ \operatorname{curl}_\Gamma\Phi\in H^{-1/2}(\Gamma),\ \text{and } \nu\cdot\Phi|_{\partial\Gamma}=0\},
\end{aligned}
$$

where ν is the norm to the boundary of Γ. Denote

$$\Phi^{n+1}(x_1,x_2)=(-\phi_2^{n+1},\phi_1^{n+1},0)=\hat{x}_3\times\boldsymbol{E}^{s,n+1} \quad \text{on } \{x_3=0\}.$$

Consider the semidiscrete problem (3.3) in the upper half space $\mathcal{U}$:

Given $\boldsymbol{h}^{s,n+1}\in[L^2(\mathcal{U})]^3$ and $\Phi\in H^{-1/2}(\operatorname{div}_\Gamma,\Gamma)$, find $\boldsymbol{E}^{s,n+1}\in H(\operatorname{curl},\mathcal{U})$, $n=0,1,\ldots,\mathcal{N}-1$, such that

$$
\left\{
\begin{aligned}
\operatorname{curl}\operatorname{curl}\boldsymbol{E}^{s,n+1}+\alpha^2\boldsymbol{E}^{s,n+1} &= \boldsymbol{h}^{s,n+1} \quad \text{in } \mathcal{U},\\
\hat{x}_3\times\boldsymbol{E}^{s,n+1} &= \Phi^{n+1} \quad \text{on } \Gamma,\\
\hat{x}_3\times\boldsymbol{E}^{s,n+1} &= 0 \quad \text{on } \Gamma^c.
\end{aligned}
\right. \tag{3.7}
$$

We shall omit the superscript $n+1$ in (3.7) for the rest of this section. We have the following well-posedness result for the exterior problem. The proof of the result is based on the construction of the solution to the Fourier transformed equation of (3.7).

THEOREM 1. *For each* $\boldsymbol{h}^s \in [L^2(\mathcal{U})]^3$ *and* $\Phi \in H^{-1/2}(\mathrm{div}_\Gamma, \Gamma)$, *there exists a unique solution* $\boldsymbol{E}^s \in H(\mathrm{curl}, \mathcal{U})$ *to* (3.7).

Proof. In the homogeneous upper half space $\mathcal{U}$, $\boldsymbol{E}^s$ is divergence-free ($\mathrm{div}\, \boldsymbol{E}^s = 0$). By the identity $\mathrm{curl}\,\mathrm{curl}\, u = -\Delta u + \mathrm{grad}(\mathrm{div}\, u)$, (3.7) becomes

$$\begin{cases} -\Delta \boldsymbol{E}^s + \alpha^2 \boldsymbol{E}^s &= \boldsymbol{h}^s \ \text{ in } \mathcal{U}, \\ \hat{x}_3 \times \boldsymbol{E}^s &= \Phi \ \text{ on } \Gamma, \\ \hat{n} \times \boldsymbol{E}^s &= 0 \ \text{ on } \Gamma^c. \end{cases}$$

Or, for $j = 1, 2$,

$$\begin{cases} -\Delta E_j^s + \alpha^2 E_j^s &= h_j^s \ \text{ in } \mathcal{U}, \\ E_j^s &= \phi_j \ \text{ on } \{x_3 = 0\}, \\ \lim\limits_{r\to\infty} r E_j^s &= 0, \end{cases} \tag{3.8}$$

where

$$E_j^s = \phi_j \text{ iff } \int_{x_3=0} E_j^s \psi = \int_{x_3=0} \phi_j \psi \quad \forall \psi \in \tilde{H}^{1/2}(\Gamma).$$

By the divergence-free property of $\boldsymbol{E}^s$, we only need to solve for the components E_1^s and E_2^s. Taking the two-dimensional Fourier transform of the distributions with respect to (x_1, x_2) of (3.8), we get, for $j = 1, 2$,

$$\begin{cases} \left[\dfrac{\partial^2}{\partial x_3^2} - (\alpha^2 + \xi_1^2 + \xi_2^2)\right] \hat{E}_j^s(\xi, x_3) &= -\hat{h}_j^s(\xi, x_3) \ \text{ in } \{x_3 > 0\}, \\ \hat{E}_j^s(\xi, 0) &= \hat{\phi}_j(\xi) \ \text{ on } \{x_3 = 0\}, \end{cases} \tag{3.9}$$

where $\xi = (\xi_1, \xi_2)$.

REMARK 2. *Since* $\boldsymbol{E}$ *is real, the Fourier transforms of* E_j^s, h_j^s, *and* ϕ_j *are of the form*

$$\begin{aligned} \hat{f}(\xi, x_3) &= \frac{1}{2\pi} \int_{\mathbb{R}^2} f(x_1, x_2, x_3) e^{-i(x_1\xi_1 + x_2\xi_2)} dx_1 dx_2 \\ &= 4\,\mathrm{Re} \left\{ \frac{1}{2\pi} \int_{\mathbb{R}^2_+} f(x_1, x_2, x_3) e^{-i(x_1\xi_1 + x_2\xi_2)} dx_1 dx_2 \right\}. \end{aligned}$$

The solution of the nonhomogeneous differential equation (3.9) is unique and can be expressed as the sum of the homogeneous solution and the particular solution

$$\hat{E}_j^s(\xi, x_3) = w_j(x_3) + \int_0^\infty G(x_3, x_3')(-\hat{h}_j^s(\xi, x_3'))dx_3', \tag{3.10}$$

where w_j is the solution of

$$\begin{cases} w_j'' - \eta^2 w_j &= 0 \quad \text{in } \{x_3 > 0\}, \\ w_j &= \hat{\phi}_j \quad \text{on } \{x_3 = 0\}, \\ \lim\limits_{x_3\to\infty} x_3 w_j &= 0, \end{cases}$$

where

$$\eta = \sqrt{\alpha^2 + \xi_1^2 + \xi_2^2},$$

and $G(x, x')$ is the associated Green function, corresponding to the homogeneous boundary conditions [17, p. 234]. We now derive w_j and $G(x, x')$. It is easy to see that the homogeneous solution w_j is

$$w_j(x_3) = \hat{\phi}_j e^{-\eta x_3}. \tag{3.11}$$

The Green's function is defined by

$$G(x, x') = \begin{cases} \phi(x')\psi(x)W(x')^{-1} & \text{if } x \le x', \\ \psi(x')\phi(x)W(x')^{-1} & \text{if } x \ge x', \end{cases}$$

where

$$\begin{aligned} \phi(x') &= e^{-\eta x'}, \\ \psi(x') &= e^{\eta x'} - e^{-\eta x'} = 2\sinh \eta x', \\ W(x') &= \psi(x')\phi'(x') - \phi(x')\psi'(x') = -2\eta. \end{aligned}$$

Hence,

$$G(x, x') = \begin{cases} -e^{-\eta x'} \sinh(\eta x)/\eta & \text{if } x \le x', \\ -\sinh(\eta x')e^{-\eta x}/\eta & \text{if } x \ge x'. \end{cases} \tag{3.12}$$

Taking the partial derivative of G with respect to $\boldsymbol{x}$ yields

$$\frac{\partial G(x, x')}{\partial x} = \begin{cases} -e^{-\eta x'} \cosh(\eta x) & \text{if } x \le x', \\ \sinh(\eta x')e^{-\eta x} & \text{if } x \ge x'. \end{cases}$$

Hence, $\partial_3 \hat{E}_j^s,\ j = 1, 2$, are

$$\partial_3 \hat{E}_j^s = -\eta \hat{\phi}_j e^{-\eta x_3} - \int_0^\infty \frac{\partial G(x_3, x_3')}{\partial x_3} \hat{h}_j^s(x_3') dx_3'.$$

By taking the inverse Fourier transform of (3.10), we obtain, for $j = 1, 2$,

$$\begin{aligned} E_j^s &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \hat{E}_j^s e^{i(x_1\xi_1 + x_2\xi_2)} d\xi_1 d\xi_2 \\ &= \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \hat{\phi}_j e^{-\eta x_3} e^{i(\xi_1 x_1 + \xi_2 x_2)} d\xi_1 d\xi_2 \\ &\quad - \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left\{ \int_0^\infty G(x_3, x_3') \hat{h}_j^s dx_3' \right\} e^{i(\xi_1 x_1 + \xi_2 x_2)} d\xi_1 d\xi_2. \end{aligned} \tag{3.13}$$

For the third component, we note that

$$\hat{E}_3^s = \eta^{-2} \left(\frac{\partial^2 \hat{E}_3^s}{\partial x_3^2} + \hat{h}_3 \right).$$

Since $\operatorname{div} \boldsymbol{E}^s = 0$ in $\mathcal{U}$, its Fourier transform also vanishes; thus,

$$\frac{\partial \hat{E}_3^s}{\partial x_3} = -i(\xi_1 \hat{E}_1^s + \xi_2 \hat{E}_2^s).$$

Hence, we get

$$\begin{aligned}\hat{E}_3^s &= \eta^{-2}\left[-i\frac{\partial}{\partial x_3}(\xi_1\hat{E}_1^s+\xi_2\hat{E}_2^s)+\hat{h}_3^s\right],\\ &= \frac{i}{\eta}(\xi_1\hat{\phi}_1+\xi_2\hat{\phi}_2)e^{-\eta x_3}+\frac{i}{\eta^2}\int_0^\infty \frac{\partial G(x_3,x_3')}{\partial x_3}(\xi_1\hat{h}_1^s+\xi_2\hat{h}_2^s)dx_3'+\frac{1}{\eta^2}\hat{h}_3^s.\end{aligned}$$

Taking the inverse Fourier transform gives

$$\begin{aligned}E_3^s &= \frac{i}{2\pi}\int_{-\infty}^\infty\int_{-\infty}^\infty \frac{1}{\eta}(\xi_1\hat{\phi}_1+\xi_2\hat{\phi}_2)e^{-\eta x_3}e^{i(\xi_1x_1+\xi_2x_2)}d\xi_1d\xi_2\\ &+\frac{i}{2\pi}\int_{-\infty}^\infty\int_{-\infty}^\infty \frac{1}{\eta^2}\left\{\int_0^\infty \frac{\partial G(x_3,x_3')}{\partial x_3}(\xi_1\hat{h}_1^s+\xi_2\hat{h}_2^s)dx_3'\right\}e^{i(\xi_1x_1+\xi_2x_2)}d\xi_1d\xi_2\\ &+\frac{1}{2\pi}\int_{-\infty}^\infty\int_{-\infty}^\infty \frac{1}{\eta^2}\hat{h}_3^s e^{i(\xi_1x_1+\xi_2x_2)}d\xi_1d\xi_2. \qquad (3.14)\end{aligned}$$

Therefore, (3.13) and (3.14) yield the solution $\boldsymbol{E}^s$ to (3.7). ∎

From the solution $\boldsymbol{E}^s$, we now construct the nonlocal boundary operator. The tangential components of curl $\boldsymbol{E}^s$ on Γ,

$$\hat{n}\times\operatorname{curl}\boldsymbol{E}^s = (-(\partial_3E_1^s-\partial_1E_3^s),\partial_2E_3^s-\partial_3E_2^s,0),$$

can be expressed in terms of Φ and $\boldsymbol{h}^s$ as follows. Denote $x=(x_1,x_2)$, for $x_3=0$,

$$\begin{aligned}-\partial_3E_1^s+\partial_1E_3^s &= \frac{1}{2\pi}\int_{\mathbb{R}^2}\left\{\eta\hat{\phi}_1-\frac{1}{\eta}(\xi_1\hat{\phi}_1+\xi_2\hat{\phi}_2)\xi_1\right\}e^{i\xi\cdot x}d\xi\\ -\frac{1}{2\pi}\int_{\mathbb{R}^2}e^{i\xi\cdot x}d\xi\int_0^\infty \frac{\partial G(x_3,x_3')}{\partial x_3}&\left[\hat{h}_1^s+\frac{1}{\eta^2}(\xi_1\hat{h}_1^s+\xi_2\hat{h}_2^s)\xi_1\right]_{x_3=0}dx_3' \qquad (3.15)\\ &+\frac{i}{2\pi}\int_{\mathbb{R}^2}\frac{\xi_1}{\eta^2}\hat{h}_3^s|_{x_3=0}\,e^{i\xi\cdot x}d\xi,\end{aligned}$$

and

$$\begin{aligned}-\partial_3E_2^s+\partial_2E_3^s &= \frac{1}{2\pi}\int_{\mathbb{R}^2}\left\{\eta\hat{\phi}_2-\frac{1}{\eta}(\xi_2\hat{\phi}_1+\xi_2\hat{\phi}_2)\xi_2\right\}e^{i\xi\cdot x}d\xi\\ -\frac{1}{2\pi}\int_{\mathbb{R}^2}e^{i\xi\cdot x}d\xi\int_0^\infty \frac{\partial G(x_3,x_3')}{\partial x_3}&\left[\hat{h}_2^s+\frac{1}{\eta^2}(\xi_1\hat{h}_1^s+\xi_2\hat{h}_2^s)\xi_2\right]_{x_3=0}dx_3' \qquad (3.16)\\ &+\frac{i}{2\pi}\int_{\mathbb{R}^2}\frac{\xi_2}{\eta^2}\hat{h}_3^s|_{x_3=0}\,e^{i\xi\cdot x}d\xi.\end{aligned}$$

We note that only the first term on the right-hand side of (3.15) and (3.16) contains the boundary function ϕ. So, we define the operator T by

$$T(\hat{x}_3\times u) = [T^{(1)}(\hat{x}_3\times u),T^{(2)}(\hat{x}_3\times u)] \quad \text{on } \Gamma, \qquad (3.17)$$

where

$$T^{(1)}(\hat{x}_3\times u)(x) = \frac{1}{2\pi}\int_{\mathbb{R}^2}\left\{\eta\hat{u}_1-\frac{1}{\eta}(\xi_1\hat{u}_1+\xi_2\hat{u}_2)\xi_1\right\}e^{i\xi\cdot x}d\xi, \qquad (3.18)$$

$$T^{(2)}(\hat{x}_3\times u)(x) = \frac{1}{2\pi}\int_{\mathbb{R}^2}\left\{\eta\hat{u}_2-\frac{1}{\eta}(\xi_1\hat{u}_1+\xi_2\hat{u}_2)\xi_2\right\}e^{i\xi\cdot x}d\xi. \qquad (3.19)$$

Thus, we have

$$\hat{x}_3 \times \operatorname{curl} \boldsymbol{E}^s = T(\hat{x}_3 \times \boldsymbol{E}^s) + Q\boldsymbol{h}^s, \tag{3.20}$$

where $Q\boldsymbol{h}^s = [Q^{(1)}\boldsymbol{h}^s, Q^{(2)}\boldsymbol{h}^s]$ with

$$Q^{(1)}\boldsymbol{h}^s = -\frac{1}{2\pi}\int_{\mathbb{R}^2} e^{i\xi\cdot x}d\xi \int_0^\infty \frac{\partial G(x_3,x_3')}{\partial x_3}\left[\hat{h}_1^s + \frac{1}{\eta^2}(\xi_1\hat{h}_1^s + \xi_2\hat{h}_2^s)\xi_1\right]dx_3'$$
$$+\frac{i}{2\pi}\int_{\mathbb{R}^2}\frac{1}{\eta^2}\xi_1\hat{h}_3^s e^{i\xi\cdot x}d\xi, \quad \text{for } x_3 = 0,$$

and

$$Q^{(2)}\boldsymbol{h}^s = -\frac{1}{2\pi}\int_{\mathbb{R}^2} e^{i\xi\cdot x}d\xi \int_0^\infty \frac{\partial G(x_3,x_3')}{\partial x_3}\left[\hat{h}_2^s + \frac{1}{\eta^2}(\xi_1\hat{h}_1^s + \xi_2\hat{h}_2^s)\xi_2\right]dx_3'$$
$$+\frac{i}{2\pi}\int_{\mathbb{R}^2}\frac{1}{\eta^2}\xi_2\hat{h}_3^s e^{i\xi\cdot x}d\xi, \quad \text{for } x_3 = 0.$$

LEMMA 3. *The operator $T : H^{-1/2}(\operatorname{div},\Gamma) \to [H^{-1/2}(\operatorname{curl},\Gamma)]^*$, the dual space of $H^{-1/2}(\operatorname{curl},\Gamma)$, is a linear bounded operator. Furthermore,*

$$\langle T(\hat{x}_3 \times u), \hat{x}_3 \times \hat{x}_3 \times u\rangle_\Gamma \le 0.$$

Proof. We shall prove that

$$|\langle T(\hat{x}_3 \times u), \phi\rangle| \le C\|\hat{x}_3 \times u\|_{H^{-1/2}(\operatorname{div},\Gamma)}\|\phi\|_{H^{-1/2}(\operatorname{curl},\Gamma)} \quad \forall \phi \in H^{-1/2}(\operatorname{curl},\Gamma).$$

Recall that

$$\|\hat{x}_3 \times u\|^2_{H^{-1/2}(\operatorname{div},\Gamma)} = \int_{\mathbb{R}^2}\frac{1}{\sqrt{1+|\xi|^2}}\Big[|\hat{u}_1|^2 + |\hat{u}_2|^2 + |-\xi_1\hat{u}_2 + \xi_2\hat{u}_1|^2\Big]d\xi$$

and

$$\|\phi\|^2_{H^{-1/2}(\operatorname{curl},\Gamma)} = \int_{\mathbb{R}^2}\frac{1}{\sqrt{1+|\xi|^2}}\Big[|\hat{\phi}_1|^2 + |\hat{\phi}_2|^2 + |\xi_1\hat{\phi}_2 - \xi_2\hat{\phi}_1|^2\Big]d\xi.$$

By the definition of T, we have

$$\begin{aligned}
&\langle T(\hat{x}_3 \times u), \phi\rangle = \int_\Gamma T(\hat{x}_3 \times u)\cdot\bar{\phi}dx\\
&= \int_{x_3=0} T^{(1)}(\hat{x}_3 \times u)\cdot\bar{\phi}_1 dx + \int_{x_3=0} T^{(2)}(\hat{x}_3 \times u)\cdot\bar{\phi}_2 dx\\
&= \int\left[\eta\hat{u}_1 - \frac{1}{\eta}(\xi_1\hat{u}_1 + \xi_2\hat{u}_2)\xi_1\right]\bar{\tilde{v}}_1 d\xi + \int\left[\eta\hat{u}_2 - \frac{1}{\eta}(\xi_1\hat{u}_1 + \xi_2\hat{u}_2)\xi_2\right]\bar{\tilde{v}}_2 d\xi\\
&= \int\frac{1}{\eta}\Big[\eta^2(\hat{u}_1\bar{\tilde{v}}_1 + \hat{u}_2\bar{\tilde{v}}_2) - (\xi_1\hat{u}_1 + \xi_2\hat{u}_2)(\xi_1\bar{\tilde{v}}_1 + \xi_2\bar{\tilde{v}}_2)\Big]d\xi\\
&= \int\frac{1}{\eta}\Big[\alpha^2(\hat{u}_1\bar{\tilde{v}}_1 + \hat{u}_2\bar{\tilde{v}}_2) + \xi_2^2\hat{u}_1\bar{\tilde{v}}_1 + \xi_1^2\hat{u}_2\bar{\tilde{v}}_2 - \xi_1\xi_2\hat{u}_2\bar{\tilde{v}}_1 - \xi_1\xi_2\hat{u}_1\bar{\tilde{v}}_2\Big]d\xi\\
&= \int\frac{1}{\eta}\Big[\alpha^2(\hat{u}_1\bar{\tilde{v}}_1 + \hat{u}_2\bar{\tilde{v}}_2) + (-\xi_1\hat{u}_2 + \xi_2\hat{u}_1)(\xi_2\bar{\tilde{v}}_1 - \xi_1\bar{\tilde{v}}_2)\Big]d\xi.
\end{aligned}$$

By the Cauchy–Schwarz inequality, we obtain

$$|\langle T(\hat{x}_3 \times u), \phi\rangle| \le C\|\hat{x}_3 \times u\|_{H^{-1/2}(\mathrm{div},\Gamma)}\|\phi\|_{H^{-1/2}(\mathrm{curl},\Gamma)}.$$

To show the operator T is nonpositive, we observe that

$$\begin{aligned}
&-(2\pi)^2\langle T(\hat{x}_3 \times u), \hat{x}_3 \times \hat{x}_3 \times u\rangle_\Gamma \\
&= \int_\Gamma T^{(1)}(\hat{x}_3 \times u)u_1 + \int_\Gamma T^{(2)}(\hat{x}_3 \times u)u_2 \\
&= \int_{\mathbb{R}^2}\left\{\eta\hat{u}_1 - \frac{1}{\eta}(\xi_1\hat{u}_1 + \xi_2\hat{u}_2)\xi_1\right\}\hat{u}_1 d\xi + \int_{\mathbb{R}^2}\left\{\eta\hat{u}_2 - \frac{1}{\eta}(\xi_1\hat{u}_1 + \xi_2\hat{u}_2)\xi_2\right\}\hat{u}_2 d\xi \\
&= \int_{\mathbb{R}^2}\left\{\eta(\hat{u}_1^2 + \hat{u}_2^2) - \frac{1}{\eta}\left(\xi_1\hat{u}_1 + \xi_2\hat{u}_2\right)^2\right\} d\xi \\
&= \int_{\mathbb{R}^2}\frac{1}{\eta}\left\{\eta^2(\hat{u}_1^2 + \hat{u}_2^2) - (\xi_1\hat{u}_1 + \xi_2\hat{u}_2)^2\right\} d\xi.
\end{aligned}$$

Recall that $\eta = (\alpha^2 + \xi_1^2 + \xi_2^2)^{1/2}$; the last integrand is clearly positive. Therefore, we have

$$\langle T(\hat{x}_3 \times u), \hat{x}_3 \times \hat{x}_3 \times u\rangle \le 0$$

as desired. ∎

This lemma will be used in the next section to obtain the existence and uniqueness of the weak solutions to the variational problem defined in the cavity Ω (Lax–Milgram theorem).

4. Interior problem and variational formulation. In this section, we consider the problem defined in the cavity Ω:

$$\left\{\begin{array}{rcl}
\operatorname{curl}\operatorname{curl}\boldsymbol{E}^{n+1} + \alpha^2\varepsilon_r\boldsymbol{E}^{n+1} &=& \boldsymbol{h}^{n+1} \ \text{ in } \Omega, \\
\hat{n} \times \boldsymbol{E}^{n+1} &=& 0 \ \text{ on } S, \\
\hat{x}_3 \times \boldsymbol{E}^{n+1} &=& \hat{x}_3 \times (\boldsymbol{E}^i + \boldsymbol{E}^r + \boldsymbol{E}^s)^{n+1} \ \text{ on } \Gamma,
\end{array}\right. \tag{4.1}$$

where $\boldsymbol{h}^{n+1} = \alpha^2\varepsilon_r\tilde{\boldsymbol{E}}^{n+1}$ as before. We formally multiply the first equation of (4.1) with a suitable test function $\boldsymbol{\phi}$ and integrate by parts over Ω to obtain

$$(\operatorname{curl}\boldsymbol{E}^{n+1}, \operatorname{curl}\boldsymbol{\phi}) + \alpha^2(\varepsilon_r E^{n+1}, \boldsymbol{\phi}) - \left\langle \hat{x}_3 \times \operatorname{curl}\boldsymbol{E}^{n+1}, \hat{x}_3 \times (\hat{x}_3 \times \boldsymbol{\phi})\right\rangle_\Gamma = (\boldsymbol{h}^{n+1}, \boldsymbol{\phi}).$$

We wish to couple the total field $\boldsymbol{E}^{n+1}$ in Ω to the total field in the upper half space through Γ. This can be accomplished by finding a relation between $\hat{x}_3 \times \operatorname{curl}\boldsymbol{E}^{n+1}$ and $\hat{x}_3 \times \boldsymbol{E}^{n+1}$. Since $\hat{x}_3 \times (\boldsymbol{E}^{i,n+1} + \boldsymbol{E}^{r,n+1}) = 0$ on Γ, we have

$$\begin{aligned}
\hat{x}_3 \times \operatorname{curl}\boldsymbol{E}^{s,n+1} &= T(\hat{x}_3 \times (\boldsymbol{E}^{n+1} - \boldsymbol{E}^{i,n+1} - \boldsymbol{E}^{r,n+1})) \\
&\quad + Q(\boldsymbol{h}^{n+1} - \boldsymbol{h}^{i,n+1} - \boldsymbol{h}^{r,n+1}) \\
&= T(\hat{x}_3 \times \boldsymbol{E}^{n+1}) + Q\boldsymbol{h}^{n+1} - Q(\boldsymbol{h}^{i,n+1} + \boldsymbol{h}^{r,n+1}).
\end{aligned}$$

Hence, we obtain the following relation on Γ:

$$\begin{aligned}
\hat{x}_3 \times \operatorname{curl}\boldsymbol{E}^{n+1} &= T(\hat{x}_3 \times \boldsymbol{E}^{n+1}) + \hat{x}_3 \times (\operatorname{curl}\boldsymbol{E}^{i,n+1} + \operatorname{curl}\boldsymbol{E}^{r,n+1}) \\
&\quad + Q\boldsymbol{h}^{n+1} - Q(\boldsymbol{h}^{i,n+1} + \boldsymbol{h}^{r,n+1}) \\
&= T(\hat{x}_3 \times \boldsymbol{E}^{n+1}) + \boldsymbol{M}^{n+1},
\end{aligned} \tag{4.2}$$

where

$$\boldsymbol{M}^{n+1} = \hat{x}_3 \times (\operatorname{curl} \boldsymbol{E}^{i,n+1} + \operatorname{curl} \boldsymbol{E}^{r,n+1}) + Q\boldsymbol{h}^{n+1} - Q(\boldsymbol{h}^{i,n+1} + \boldsymbol{h}^{r,n+1}).$$

The nonlocal boundary condition (4.2) on Γ is exact for each t_{n+1}. Now we can state the interior problem (4.1) as the following.

Given $\boldsymbol{h}^{n+1} \in [L^2(\Omega)]^3$, find $\boldsymbol{E}^{n+1} \in H(\operatorname{curl}, \Omega)$, $n = 0, 1, \ldots, \mathcal{N} - 1$, such that

$$\text{(4.3)} \qquad \begin{cases} \operatorname{curl}\operatorname{curl} \boldsymbol{E}^{n+1} + \alpha^2 \varepsilon_r \boldsymbol{E}^{n+1} &= \boldsymbol{h}^{n+1} \quad \text{in } \Omega, \\ \hat{n} \times \boldsymbol{E}^{n+1} &= 0 \quad \text{on } S, \\ \hat{x}_3 \times \operatorname{curl} \boldsymbol{E}^{n+1} &= T(\hat{x}_3 \times \boldsymbol{E}^{n+1}) + \boldsymbol{M}^{n+1} \quad \text{on } \Gamma. \end{cases}$$

The semidiscrete problem (4.3) is solved numerically by a variational method.

Define the variational space $V \subset H(\operatorname{curl}, \Omega)$ as

$$V = \{\boldsymbol{u} \in H(\operatorname{curl}, \Omega) : \hat{n} \times \boldsymbol{u}|_S = 0\}.$$

Then the corresponding variational form of the interior problem is

$$\text{(4.4)} \qquad a(\boldsymbol{E}^{n+1}, \boldsymbol{\phi}) = b^{n+1}(\boldsymbol{\phi}) \quad \forall \boldsymbol{\phi} \in V, \quad n = 0, 1, \ldots, \mathcal{N} - 1,$$

where

$$a(\boldsymbol{E}^{n+1}, \boldsymbol{\phi}) = (\operatorname{curl} \boldsymbol{E}^{n+1}, \operatorname{curl} \phi) + \alpha^2 (\varepsilon_r \boldsymbol{E}^{n+1}, \boldsymbol{\phi}) - \left\langle T(\hat{x}_3 \times \boldsymbol{E}^{n+1}), \hat{x}_3 \times (\hat{x}_3 \times \boldsymbol{\phi}) \right\rangle_\Gamma \quad \text{(4.5)}$$

and

$$\text{(4.6)} \qquad b^{n+1}(\boldsymbol{\phi}) = (\boldsymbol{h}^{n+1}, \boldsymbol{\phi}) + \left\langle \boldsymbol{M}^{n+1}, \hat{x}_3 \times (\hat{x}_3 \times \boldsymbol{\phi}) \right\rangle_\Gamma.$$

REMARK 4. *The time-stepping scheme can be described as the following.*

1. *Form the matrix A defined by the bilinear form $a(u, v)$ in* (4.5).
   Time-loop: for $n = 0, 1, 2 \ldots$
   2. *Compute the predicted values $\tilde{\boldsymbol{E}}^{n+1}$, $\tilde{\dot{\boldsymbol{E}}}^{n+1}$ in the interior Ω.*
   3. *Compute the predicted values $\tilde{\boldsymbol{E}}^{n+1}$, $\tilde{\dot{\boldsymbol{E}}}^{n+1}$ in the exterior $\mathcal{U}$.*
   4. *Form the right-hand side vector F^{n+1} defined by $b^{n+1}(\boldsymbol{\phi})$ in* (4.6).
   5. *Solve for the unknown expansion coefficients E^{n+1} in $AE^{n+1} = F^{n+1}$ in* (4.4).
   6. *Compute the solution $\boldsymbol{E}^{n+1}$ in the exterior $\mathcal{U}$ by* (3.6).
   7. *Correct $\ddot{\boldsymbol{E}}^{n+1}$ and $\dot{\boldsymbol{E}}^{n+1}$ in Ω.*
   8. *Correct $\ddot{\boldsymbol{E}}^{n+1}$ and $\dot{\boldsymbol{E}}^{n+1}$ in $\mathcal{U}$.*

Note that the matrix A is defined outside of the time loop; thus it can be precomputed and reused for each time step. This significantly reduces the storage and computational time.

We now show that the variational problem (4.4) has a unique solution in $H(\operatorname{curl}, \Omega)$ at each time step t_n.

THEOREM 5. *There exists a unique solution $\boldsymbol{u} \in V$ such that*

$$a(\boldsymbol{u}, \boldsymbol{v}) = b(\boldsymbol{v}) \quad \forall \boldsymbol{v} \in V.$$

Proof. Since $\varepsilon_r > 0$ and T is negative, it is easy to see that

$$\begin{aligned} a(\boldsymbol{u},\boldsymbol{u}) &= \|\operatorname{curl}\boldsymbol{u}\|_0^2 + \alpha^2(\varepsilon_r\boldsymbol{u},\boldsymbol{u}) - \langle T(\hat{x}_3\times\boldsymbol{u}),\hat{x}_3\times x_3\times\boldsymbol{u}\rangle_\Gamma \\ &\geq C\|\boldsymbol{u}\|^2_{H(\operatorname{curl},\Omega)}, \quad C>0. \end{aligned}$$

The bilinear form $a(\cdot,\cdot)$ is continuous in V, that is,

$$|a(\boldsymbol{u},\boldsymbol{v})| \leq C\|\boldsymbol{u}\|_{H(\operatorname{curl},\Omega)}\|\boldsymbol{v}\|_{H(\operatorname{curl},\Omega)}, \quad \forall \boldsymbol{u},\boldsymbol{v}\in V.$$

In fact, by the property of T and the trace theorem we have

$$\begin{aligned} |\langle T(\hat{x}_3\times\boldsymbol{u}),\hat{x}_3\times x_3\times\boldsymbol{v}\rangle_\Gamma| &\leq C\|\hat{x}_3\times\boldsymbol{u}\|_{H^{-1/2}(\operatorname{div}_\Gamma,\Gamma)}\|\hat{x}_3\times\hat{x}_3\times\boldsymbol{v}\|_{H^{-1/2}(\operatorname{curl}_\Gamma,\Gamma)} \\ &\leq C\|\boldsymbol{u}\|_{H(\operatorname{curl},\Omega)}\|\boldsymbol{v}\|_{H(\operatorname{curl},\Omega)}. \end{aligned}$$

Therefore, by the Lax–Milgram theorem the variational problem has a unique solution in V. ∎

In the next section, we use finite element methods to numerically solve the variational problem (4.4). We will also analyze the finite element error in $H(\operatorname{curl},\Omega)$-norm and the stability of the Newmark time-stepping scheme.

5. Fully discrete problem and finite element analysis. We assume that the cavity Ω can be decomposed into Lipschitz subregions Ω_i, $i = 1,2,\ldots,M$, so that $\epsilon_r|_{\Omega_i}$ is Lipschitz continuous and uniformly bounded. Let Ω be covered by a tetrahedral mesh $\mathcal{T}_h$ of regular, quasi-uniform finite elements with a maximum diameter $h > 0$. We will use linear edge elements as approximating functions which can be defined as follows. Let $\tilde{K}$ denote the reference tetrahedron

$$\tilde{K} = \{\tilde{\boldsymbol{x}}\in\mathbb{R}^3 : 1-\tilde{x}_1-\tilde{x}_2-\tilde{x}_3\geq 0,\ \tilde{x}_i\geq 0\}.$$

Let K be a tetrahedron in $\mathcal{T}_h$. Then there exists an affine map F_K such that $F_K(\tilde{K}) = K$. We define the set of "linear" functions on the reference tetrahedron

$$\mathcal{R}_1 = \{\tilde{\mathbf{u}} : \tilde{K}\to\mathbb{C}^3 : \tilde{\mathbf{u}} = \mathbf{a}+\mathbf{b}\times\tilde{\mathbf{x}},\ \mathbf{a},\mathbf{b}\in\mathbb{C}^3\},$$

and using this set we define for each $K\in\mathcal{T}_h$

$$\begin{aligned} \mathcal{R}_1(K) = \Big\{ &\mathbf{u}:\mathbf{K}\to\mathbb{C}^{\mathbf{3}} : \mathbf{u}(\mathbf{F_K}(\tilde{\mathbf{x}})) = [\mathbf{DF_K}^{\mathbf{T}}]^{-\mathbf{1}}(\tilde{\mathbf{x}})\tilde{\mathbf{u}}(\tilde{\mathbf{x}}) \\ &\text{for some } \tilde{\mathbf{u}}\in\mathcal{R}_1 \text{ and } \forall\tilde{\mathbf{x}}\in\tilde{K}\Big\}, \end{aligned}$$

where DF_K is the Jacobian of the transformation F_K. Thus, the linear edge element space V_h is defined as

$$V_h := \{\boldsymbol{v}_h\in V : \boldsymbol{v}_h|_K\in\mathcal{R}_1(K) \quad \forall K\in\mathcal{T}_h\}.$$

The degrees of freedom for this space are the moments of the tangential components of the field along the edges in the meshes and are defined by, for each tetrahedron K,

$$M_e(\boldsymbol{u}) = \left\{\int_e(\boldsymbol{u}\cdot\boldsymbol{\tau}_e)q\,ds : q\in P_1(e) \text{ on six edges of } K\right\},$$

where $\boldsymbol{\tau}_e$ is the unit tangential vector on e and $P_1(e)$ is the set of polynomial of degree one defined on e (for more details, see [13, 19]). In order for the integral in M_e to

make sense, it is required that $u \in W^{1,s}(\Omega)^3$ for $s > 2$ [13]. The discrete version of the variational problem (4.4) is the following. Find $\boldsymbol{E}_h \in V_h$ such that

$$a(\boldsymbol{E}_h^{n+1}, \boldsymbol{v}_h) = b(\boldsymbol{v}_h) \quad \forall \boldsymbol{v}_h \in V_h, \quad n = 0, 1, \ldots, \mathcal{N}. \tag{5.1}$$

Again by the Lax–Milgram theorem, we have the following theorem.

THEOREM 6. *The fully discrete problem* (5.1) *has a unique solution* $\boldsymbol{E}_h$ *in* V_h.

Approximation properties of V_h*:* The approximation properties of the finite element subspace V_h are well established (see, e.g., [13]) and are summarized as follows. Let $\boldsymbol{u} \in [W^{1,s}(\Omega)]^3$, $s > 2$ and $r_h : [W^{1,s}(\Omega)]^3 \to V_h$ be the interpolation operator defined by the moments M_e. If $\boldsymbol{u} \in [H^2(\Omega)]^3$,

$$\|\boldsymbol{u} - r_h\boldsymbol{u}\|_{L^2(\Omega)} + h\,\|\boldsymbol{u} - r_h\boldsymbol{u}\|_{H(\mathrm{curl},\Omega)} \le Ch\,\|\boldsymbol{u}\|_{H^2(\Omega)}\,.$$

Error estimate in $H(\mathrm{curl}, \Omega)$ for the finite element method is obtained by Céa's theorem [6].

THEOREM 7. *Let* $\boldsymbol{E}^n \in V$ *and* $\boldsymbol{E}_h^n \in V_h$ *be the semidiscrete solution and the fully discrete solution, respectively, to the variational equation. Then there exists* $C > 0$ *independent on* h *such that*

$$\|\boldsymbol{E} - \boldsymbol{E}_h\|_{H(\mathrm{curl},\Omega)} \le C \inf_{\boldsymbol{v}_h \in V_h} \|\boldsymbol{E} - \boldsymbol{v}_h\|_{H(\mathrm{curl},\Omega)}.$$

By using the approximation property of the linear edge elements we also have the following corollary.

COROLLARY 8. *Let* $\boldsymbol{E} \in V$ *be a solution of* (4.4) *and* $\boldsymbol{E} \in [H^2(\Omega_i)]^3$, $i = 1, 2, \ldots, M$. *Then*

$$\|\boldsymbol{E} - \boldsymbol{E}_h\|_{H(\mathrm{curl},\Omega_i)} \le C_i h\,\|\boldsymbol{E}\|_{H^2(\Omega_i)}\,, \quad i = 1, 2, \ldots, M.$$

We now analyze the stability of the Newmark scheme and the error estimate for the finite element approximation. With $\gamma = 1/2$, the Newmark scheme can also be expressed in terms of

$$\partial_\tau \boldsymbol{E}^n = \frac{\boldsymbol{E}^{n+1} - \boldsymbol{E}^n}{\Delta t}, \quad \partial_\tau^2 \boldsymbol{E}^n = \frac{\boldsymbol{E}^{n+1} - 2\boldsymbol{E}^n + \boldsymbol{E}^{n-1}}{(\Delta t)^2},$$
$$\boldsymbol{E}^{n,\beta} = \beta \boldsymbol{E}^{n+1} + (1 - 2\beta)\boldsymbol{E}^n + \beta \boldsymbol{E}^{n-1},$$

and (4.3) can be rewritten as

$$\begin{aligned}&(\partial_\tau^2 \boldsymbol{E}^n, \boldsymbol{v}) + (\mathrm{curl}\,\boldsymbol{E}^{n,\beta}, \mathrm{curl}\,\boldsymbol{v}) - \left\langle T(\hat{x}_3 \times \boldsymbol{E}^{n,\beta}), \hat{x}_3 \times \hat{x}_3 \times \boldsymbol{v} \right\rangle \\ &= (\boldsymbol{h}^{n,\beta}, \boldsymbol{v}) + \left\langle \boldsymbol{H}^{n,\beta}, \hat{x}_3 \times \hat{x}_3 \times \boldsymbol{v} \right\rangle, \quad n = 0, 1, \ldots, \mathcal{N},\end{aligned}$$

where

$$\boldsymbol{h}^{n,\beta} = \frac{\varepsilon_r}{\Delta t^2 \beta}\left[\boldsymbol{E}^{n-1,\beta} + \Delta t \dot{\boldsymbol{E}}^{n-1,\beta} + \frac{(1 - 2\beta)\Delta t^2}{2}\ddot{\boldsymbol{E}}^{n-1,\beta}\right].$$

To analyze the stability, we consider the homogeneous equation

$$(\partial_\tau^2 \boldsymbol{E}^n, \boldsymbol{v}) + (\mathrm{curl}\,\boldsymbol{E}^{n,\beta}, \mathrm{curl}\,\boldsymbol{v}) - \left\langle T(\hat{x}_3 \times \boldsymbol{E}^{n,\beta}), \hat{x}_3 \times \hat{x}_3 \times \boldsymbol{v} \right\rangle = 0\,. \tag{5.2}$$

We note that

$$\partial_\tau^2 \boldsymbol{E}^n = \frac{1}{\Delta t}(\partial_\tau \boldsymbol{E}^n - \partial_\tau \boldsymbol{E}^{n-1}), \tag{5.3}$$

and we define

$$\delta_\tau \boldsymbol{E}^n = \frac{1}{2}(\partial_\tau \boldsymbol{E}^n + \partial_\tau \boldsymbol{E}^{n-1}), \tag{5.4}$$

or equivalently,

$$\delta_\tau \boldsymbol{E}^n = \frac{1}{2\Delta t}(\boldsymbol{E}^{n+1} - \boldsymbol{E}^{n-1}). \tag{5.5}$$

By setting $\boldsymbol{v} = \delta_\tau \boldsymbol{E}^n$ in the homogeneous equation (5.2), we get

(5.6)

$$\begin{aligned} 0 &= (\partial_\tau^2 \boldsymbol{E}^n, \delta_\tau \boldsymbol{E}^n) + (\operatorname{curl} \boldsymbol{E}^{n,\beta}, \operatorname{curl} \delta_\tau \boldsymbol{E}^n) - \left\langle T(\hat{x}_3 \times \boldsymbol{E}^{n,\beta}), \hat{x}_3 \times \hat{x}_3 \times \delta_\tau \boldsymbol{E}^n \right\rangle \\ &\equiv I + II + III. \end{aligned}$$

We consider the first term I:

$$\begin{aligned} I = (\partial_\tau^2 \boldsymbol{E}^n, \delta_\tau \boldsymbol{E}^n) &= \frac{1}{2\Delta t}((\partial_\tau \boldsymbol{E}^n - \partial_\tau \boldsymbol{E}^{n-1}), (\partial_\tau \boldsymbol{E}^n + \partial_\tau \boldsymbol{E}^{n-1})) \\ &= \frac{1}{2\Delta t}\left(\|\partial_\tau \boldsymbol{E}^n\|_0^2 - \|\partial_\tau \boldsymbol{E}^{n-1}\|_0^2\right). \end{aligned}$$

For the second term II, we write

$$\begin{aligned} \boldsymbol{E}^{n,\beta} &= \beta(\boldsymbol{E}^{n+1} - 2\boldsymbol{E}^n + \boldsymbol{E}^{n-1}) + \boldsymbol{E}^n \\ &= \beta \Delta t^2 \partial_\tau^2 \boldsymbol{E}^n + \boldsymbol{E}^n, \end{aligned} \tag{5.7}$$

and denote

$$\boldsymbol{E}^{n+1/2} = \frac{1}{2}(\boldsymbol{E}^{n+1} + \boldsymbol{E}^n).$$

So, in terms of $\boldsymbol{E}^{n\pm 1/2}$ we have

$$\delta_\tau \boldsymbol{E}^n = \frac{1}{\Delta t}(\boldsymbol{E}^{n+1/2} - \boldsymbol{E}^{n-1/2}), \tag{5.8}$$

$$\boldsymbol{E}^n = \frac{\boldsymbol{E}^{n+1/2} + \boldsymbol{E}^{n-1/2}}{2} - \frac{\Delta t^2}{4}\partial_\tau^2 \boldsymbol{E}^n. \tag{5.9}$$

Substituting (5.9) into (5.7), we get

$$\begin{aligned} \boldsymbol{E}^{n,\beta} &= \beta \Delta t^2 \partial_\tau^2 \boldsymbol{E}^n + \frac{\boldsymbol{E}^{n+1/2} + \boldsymbol{E}^{n-1/2}}{2} - \frac{\Delta t^2}{4}\partial_\tau^2 \boldsymbol{E}^n \\ &= \left(\beta - \frac{1}{4}\right)\Delta t^2 \partial_\tau^2 \boldsymbol{E}^n + \frac{\boldsymbol{E}^{n+1/2} + \boldsymbol{E}^{n-1/2}}{2}. \end{aligned} \tag{5.10}$$

Hence, II becomes

$$\begin{aligned} II &= (\operatorname{curl} \boldsymbol{E}^{n,\beta}, \operatorname{curl} \delta_\tau \boldsymbol{E}^n) \\ &= \left(\beta - \frac{1}{4}\right)\Delta t^2 (\operatorname{curl} \partial_\tau^2 \boldsymbol{E}^n, \operatorname{curl} \delta_\tau \boldsymbol{E}^n) - \frac{1}{2}(\operatorname{curl} \boldsymbol{E}^{n+1/2} + \operatorname{curl} \boldsymbol{E}^{n-1/2}, \operatorname{curl} \delta_\tau \boldsymbol{E}^n) \\ &= \left(\beta - \frac{1}{4}\right)\frac{\Delta t}{2}\left(\|\operatorname{curl} \partial_\tau \boldsymbol{E}^n\|_0^2 - \|\operatorname{curl} \partial_\tau \boldsymbol{E}^{n-1}\|_0^2\right) \\ &\quad + \frac{1}{2\Delta t}\left(\|\operatorname{curl} \boldsymbol{E}^{n+1/2}\|_0^2 - \|\operatorname{curl} \boldsymbol{E}^{n-1/2}\|_0^2\right). \end{aligned}$$

Finally, we consider the boundary term *III*. From (5.3, 5.4, 5.8, 5.10) we have

$$\begin{aligned}
&\left\langle T(\hat{x}_3 \times \boldsymbol{E}^{n,\beta}), \hat{x}_3 \times \hat{x}_3 \times \delta_\tau \boldsymbol{E}^n \right\rangle \\
&= \left(\beta - \frac{1}{4}\right) \frac{\Delta t}{2} \left\langle T(\hat{x}_3 \times (\partial_\tau \boldsymbol{E}^n + \partial_\tau \boldsymbol{E}^{n-1})), \hat{x}_3 \times \hat{x}_3 \times (\partial_\tau \boldsymbol{E}^n - \partial_\tau \boldsymbol{E}^{n-1}) \right\rangle \\
&\quad + \frac{1}{2\Delta t} \left\langle T(\hat{x}_3 \times (\boldsymbol{E}^{n+1/2} + \boldsymbol{E}^{n-1/2})), \hat{x}_3 \times \hat{x}_3 \times (\boldsymbol{E}^{n+1/2} - \boldsymbol{E}^{n-1/2}) \right\rangle.
\end{aligned}$$

Summing (5.6) over n, $n = 0, 1, 2, 3, \ldots, \mathcal{N} - 1$, and by the property of the operator T we obtain

$$\begin{aligned}
&\frac{1}{2\Delta t} \|\partial_\tau \boldsymbol{E}^{\mathcal{N}}\|_0^2 + \left(\beta - \frac{1}{4}\right) \frac{\Delta t}{2} \|\operatorname{curl} \partial_\tau \boldsymbol{E}^{\mathcal{N}}\|_0^2 + \frac{1}{2\Delta t} \|\operatorname{curl} \boldsymbol{E}^{\mathcal{N}+1/2}\|_0^2 \\
&\qquad - \left(\beta - \frac{1}{4}\right) \frac{\Delta t}{2} \left\langle T(\hat{x}_3 \times \partial_\tau \boldsymbol{E}^{\mathcal{N}}), \hat{x}_3 \times \hat{x}_3 \times \partial_\tau \boldsymbol{E}^{\mathcal{N}} \right\rangle \\
&\qquad\quad - \frac{1}{2\Delta t} \left\langle T(\hat{x}_3 \times \boldsymbol{E}^{\mathcal{N}+1/2}), \hat{x}_3 \times \hat{x}_3 \times \boldsymbol{E}^{\mathcal{N}+1/2} \right\rangle \\
&= \frac{1}{2\Delta t} \|\partial_\tau \boldsymbol{E}^0\|_0^2 + \left(\beta - \frac{1}{4}\right) \frac{\Delta t}{2} \|\operatorname{curl} \partial_\tau \boldsymbol{E}^0\|_0^2 + \frac{1}{2\Delta t} \|\operatorname{curl} \boldsymbol{E}^{1/2}\|_0^2 \\
&\qquad - \left(\beta - \frac{1}{4}\right) \frac{\Delta t}{2} \left\langle T(\hat{x}_3 \times \partial_\tau \boldsymbol{E}^0), \hat{x}_3 \times \hat{x}_3 \times \partial_\tau \boldsymbol{E}^0 \right\rangle \\
&\qquad\quad - \frac{1}{2\Delta t} \left\langle T(\hat{x}_3 \times \boldsymbol{E}^{1/2}), \hat{x}_3 \times \hat{x}_3 \times \boldsymbol{E}^{1/2} \right\rangle,
\end{aligned}$$

which implies

$$\begin{aligned}
&\|\partial_\tau \boldsymbol{E}^{\mathcal{N}}\|_0^2 + \left(\beta - \frac{1}{4}\right) \Delta t^2 \|\operatorname{curl} \partial_\tau \boldsymbol{E}^{\mathcal{N}}\|_0^2 + \|\operatorname{curl} \boldsymbol{E}^{\mathcal{N}+1/2}\|_0^2 \\
&\le \|\partial_\tau \boldsymbol{E}^0\|_0^2 + \left(\beta - \frac{1}{4}\right) \Delta t^2 \|\operatorname{curl} \partial_\tau \boldsymbol{E}^0\|_0^2 + \|\operatorname{curl} \boldsymbol{E}^{1/2}\|_0^2 \\
&\quad - \left(\beta - \frac{1}{4}\right) \Delta t^2 \left\langle T(\hat{x}_3 \times \partial_\tau \boldsymbol{E}^0), \hat{x}_3 \times \hat{x}_3 \times \partial_\tau \boldsymbol{E}^0 \right\rangle \\
&\quad - \left\langle T(\hat{x}_3 \times \boldsymbol{E}^{1/2}), \hat{x}_3 \times \hat{x}_3 \times \boldsymbol{E}^{1/2} \right\rangle.
\end{aligned} \tag{5.11}$$

It is clear from the inequality (5.11) that if $1/4 \le \beta \le 1$, there exists a positive constant C_0 such that

$$\|\partial_\tau \boldsymbol{E}^{\mathcal{N}}\|_{H(\operatorname{curl},\Omega)}^2 + \|\operatorname{curl} \boldsymbol{E}^{\mathcal{N}+1/2}\|_0^2 \le C_0 \left(\|\partial_\tau \boldsymbol{E}^0\|_{H(\operatorname{curl},\Omega)}^2 + \|\boldsymbol{E}^{1/2}\|_{H(\operatorname{curl},\Omega)}^2 \right),$$

where C_0 depends only on $\beta, \Delta t$, and Ω. If $0 \le \beta < 1/4$, then we will not have an unconditionally stable scheme. For example, if we choose $\beta = 0$, then the scheme is explicit. Consequently, we need to find a condition imposed on Δt and h (mesh size) to guarantee the stability of the scheme. This can be accomplished by the "inverse assumption" for quasi-uniform triangulations [6],

$$\|\operatorname{curl} \boldsymbol{v}_h\|_0 \le C h^{-1} \|\boldsymbol{v}_h\|_0 \quad \forall \boldsymbol{v}_h \in V_h,\ C > 0.$$

When $\beta = 0$, we have

$$\left(1 - C^2\frac{\Delta t^2}{4h^2}\right)\|\partial_\tau \boldsymbol{E}^{\mathcal{N}}\|_0^2 + \|\operatorname{curl}\boldsymbol{E}^{\mathcal{N}+1/2}\|_0^2 \le C_1(\|\partial_\tau \boldsymbol{E}^0\|_{H(\operatorname{curl},\Omega)}^2 + \|\boldsymbol{E}^{1/2}\|_{H(\operatorname{curl},\Omega)}^2).$$

Hence, if $C\dfrac{\Delta t}{2h} < 1$, then the scheme is stable; that is,

$$\left(1 - C^2\frac{\Delta t^2}{4h^2}\right)\|\partial_\tau \boldsymbol{E}^{\mathcal{N}}\|_0^2 + \|\operatorname{curl}\boldsymbol{E}^{\mathcal{N}+1/2}\|_0^2$$

is bounded by the initial data. Therefore, we have shown that the following is true.

THEOREM 9. *If $1/4 \le \beta \le 1$, the Newmark scheme is unconditionally stable. If $0 \le \beta \le 1$, the Newmark scheme is conditionally stable. In particular, if $\beta = 0$, we impose the stability condition*

$$C\frac{\Delta t}{2h} < 1 \tag{5.12}$$

to have a stable scheme. Here, the constant $C > 0$ is determined by the inverse assumption.

Therefore, we conclude that if the solution $\boldsymbol{E}^n$ is assumed to be in $[H^2(\Omega_i)]^3$ for $i = 1, 2, \ldots, M$ and the stability of the Newmark scheme (with $\gamma = 1/2$) is achieved, then we obtain the optimal error estimate

$$\begin{aligned}\max_{1\le n\le \mathcal{N}}\|\boldsymbol{E}(t^n) - \boldsymbol{E}_h^n\|_{H(\operatorname{curl},\Omega)} &\le \max_{1\le n\le \mathcal{N}}\left\{\|\boldsymbol{E}(t^n) - \boldsymbol{E}^n\|_{H(\operatorname{curl},\Omega)} + \|\boldsymbol{E}^n - \boldsymbol{E}_h^n\|_{H(\operatorname{curl},\Omega)}\right\}\\ &= \mathcal{O}(\Delta t^2) + \mathcal{O}(h).\end{aligned}$$

REMARK 10. *Readers are referred to* [9, 10] *for further details on the regularity property of a solution to Maxwell's equations.*

6. Conclusion. We have presented a finite element/Fourier transform method for analyzing transient electromagnetic scattering from inhomogeneous cavities embedded in the infinite ground plane. Our method is shown to lead a well-posed semidiscrete problem in space. Stability conditions are given for the time-marching scheme. Convergence properties of the finite element scheme for the fully discrete problem are also discussed. Numerical experiments are performed for two-dimensional cavity problems that demonstrate the accuracy and stability of the method and are reported in [24].

We believe this is the first mathematical treatment of time-domain Maxwell's equations for scattering problems defined in an unbounded domain. Computationally, the exact nonlocal boundary condition introduced here has the potential to lead more accurate hybridization schemes (vs. those using ABC, PML, or the like) coupling the integral equation solution to the exterior infinite domain and the finite element treatment of the interior bounded domain.

COMPUTING BOUNDS FOR LINEAR FUNCTIONALS OF EXACT WEAK SOLUTIONS TO POISSON'S EQUATION*

A. M. SAUER-BUDGE†, J. BONET‡, A. HUERTA§, AND J. PERAIRE†

Abstract. We present a method for Poisson's equation that computes guaranteed upper and lower bounds for the values of piecewise-polynomial linear functional outputs of the exact weak solution of the infinite-dimensional continuum problem with piecewise-polynomial forcing. The method results from exploiting the Lagrangian saddle point property engendered by recasting the output problem as a constrained minimization problem. Localization is achieved by Lagrangian relaxation and the bounds are computed by appeal to a local dual problem. The proposed method computes approximate Lagrange multipliers using traditional finite element approximations to calculate a primal and an adjoint solution along with well-known hybridization techniques to calculate interelement continuity multipliers. The computed bounds hold uniformly for any level of refinement, and in the asymptotic convergence regime of the finite element method, the bound gap decreases at twice the rate of the energy norm measure of the error in the finite element solution. Given a finite element solution and its output adjoint solution, the method can be used to provide a certificate of precision for the output with an asymptotic complexity that is linear in the number of elements in the finite element discretization. The elemental contributions to the bound gap are always positive and hence lend themselves to be used as adaptive indicators, as we demonstrate with a numerical example.

Key words. bounds, PDEs, Poisson, exact solutions, certificates, functional outputs, error estimation

1. Introduction.

Uncertainty about the reliability of numerical approximations frequently undermines the utility of field simulations in the engineering design process: simulations are often not trusted because they lack reliable feedback on accuracy, or are more costly than necessary because they are performed with greater fidelity than necessary in an attempt to bolster trust. In addition to devitalized confidence, numerical uncertainty often causes ambiguity about the source of any discrepancies when using simulation results in concert with experimental measurements. Can the discretization error account for the discrepancies, or is the underlying continuum model inadequate?

While confidence in the precision of a field simulation can be buoyed by performing convergence studies, such studies are computationally very expensive and in practice are often not performed at more than a few conditions, if at all, due to cost and time constraints. For this reason, researchers and practitioners employ adaptive methods to converge the solution in a manner that costs less in time and resources than uniform refinement. Adaptive methods powered by current error estimation technology, however, provide only asymptotic guarantees of precision, at best, and no guarantees of precision, at worse, since the convergence of adaptive methods remains an open question [12].

Our observations of engineering practice inform us that integrated quantities such as forces and total fluxes are frequently queried quantitative outputs from field simulations and that design and analysis does not always require the full precision available. The primary objective of our method, therefore, is to certify the precision of integrated outputs for low-fidelity simulations as well as high-fidelity simulations. We call our bounds *uniform* to differentiate our goal of obtaining quantitative bounds for all levels of refinement from the lesser goal of obtaining quantitative bounds only asymptotically in the limit of refinement. In this regard, the complete procedure can be viewed as a polynomial time algorithm in the number of mesh elements that provides a certificate of precision for a predicted output. The certificate guarantees a minimum level of precision in the output from a particular *finite*-dimensional approximation with respect to the output from the *infinite*-dimensional model that it is approximating. Furthermore, the procedure provides local information that can be used in conjunction with adaptive meshing to efficiently drive a solution to an arbitrary and guaranteed precision.

Verification and a posteriori error analysis have a long history in the development of the finite element method with many different approaches forwarded and investigated. Ainsworth and Oden give a detailed overview of many of the approaches in [2]. Conceptually, our method descends from a long line of complementary energy methods beginning in the early 1970s when Fraeijs de Veubeke [7] proposed verifying the precision of a simulation by comparing the energy computed from a global primal approximation with the complementary energy computed from a global dual approximation. Global primal-dual methods offer a rich context for approximation, but suffer from the delicate nature of the global dual approximation, relatively high cost, and for verification, from a lack of relevant measure because the upper and lower bounding properties hold only for the total energy.

Much more closely related to our work are the works of Ladevèze and Rougeot [10], Ladeveze and Leguillon [9], Ainsworth and Oden [1], and of Destuynder and Métivet [6], all of which consider local complementary energy problems for developing estimates for the energy norm of the error. In contrast to the work of Ladevèze, we endeavor to compute uniformly guaranteed two-sided bounds on an output, not an estimate of the error in an abstract norm. While the work of Ainsworth and Oden as well as the related work of Cao, Kelly, and Sloan [5] require the exact solution of infinite-dimensional local problems in order to guarantee bounds, our method guarantees bounds uniformly with the solution of a finite-dimensional local problem. Our method differs from that of Destuynder and Métivet in that it is not burdened with the explicit construction of globally conforming approximations to dual admissible vector fields. The work we present here extends earlier work done by Paraschivoiu, Peraire, and Patera [14] and Paraschivoiu and Patera [13] on two-level residual based techniques for computing output bounds.

In this paper, we focus on the overarching structure of the method and do not consider the details of its implementation, nor extensions to non-piecewise-polynomial forcing or curved domains, nor more general equations such as nonsymmetric dissipative operators, which will be presented in a future publication [18]. Section 2 presents the core concepts in the simpler setting of energy bounds, where the method has a clear variational meaning and a direct relationship to hybrid methods. Section 3 recasts the energy bound method as a method for linear functional output bounds, simultaneously carrying out an explicit extension to more relevant error measures and an implicit extension to nonvariational problems. Finally, the last section demon-

strates the method with numerical results for three example problems. The last of the three examples shows how the method can be used to drive an adaptive refinement process.

1.1. Poisson's equation. We consider Poisson's equation posed on polygonal domains, Ω, in d spacial dimensions and, only for the sake of simplicity of presentation, homogeneous Dirichlet boundaries, $\Gamma = \partial\Omega$. The Poisson problem is formulated weakly as: find $u \in \mathcal{U}$ such that

$$\int_\Omega \nabla u \cdot \nabla v \, \mathrm{d}\Omega = \int_\Omega f \, v \, \mathrm{d}\Omega \quad \forall v \in \mathcal{U}, \tag{1.1}$$

where $\mathcal{U}(\Omega) \equiv \{ u \in \mathcal{H}^1(\Omega) \mid u|_\Gamma = 0 \}$ and the domain Ω is assumed when otherwise unspecified, that is, $\mathcal{U} \equiv \mathcal{U}(\Omega)$. As a consequence of all the Dirichlet boundaries being homogeneous, $\mathcal{U}$ serves as both the function set and test space in our presentation. While we present the method for homogeneous Dirichlet data, it can be easily extended to nonhomogeneous data and Neumann boundary conditions.

2. Computing energy bounds. We begin by developing a lower bound on the total energy of the system, $\frac{1}{2}\int_\Omega \nabla u \cdot \nabla u \, \mathrm{d}\Omega - \int_\Omega f \, u \, \mathrm{d}\Omega$, which in the context of heat conduction, combines the heat dissipation energy, $\frac{1}{2}\int_\Omega \nabla u \cdot \nabla u \, \mathrm{d}\Omega$, and the potential energy of the thermal loads, $-\int_\Omega f \, u \, \mathrm{d}\Omega$. There is a well-known physical principle at work in this problem, related to the symmetric positive definite nature of the diffusion operator, which states that the solution, u, is the function that minimizes the total energy with respect to all other candidates in $\mathcal{U}$,

$$u = \arg \inf_{w \in \mathcal{U}} \frac{1}{2} \int_\Omega \nabla w \cdot \nabla w \, \mathrm{d}\Omega - \int_\Omega f \, w \, \mathrm{d}\Omega, \tag{2.1}$$

as can easily be verified by comparing the Euler–Lagrange equation of this minimization statement to Poisson's equation (1.1). This minimization formulation makes it clear that if we look for a discrete approximation of (1.1) in a finite set of conforming functions, $\mathcal{U}_h$, for which $\mathcal{U}_h \subset \mathcal{U}$, then the resulting total energy predicted by the approximation will approach the exact value from above.

While insightful, this upper bound on the total energy has limited usefulness for two primary reasons. First, only rarely will the total energy be relevant to the purpose of solving the original problem. Second, even when it is relevant, the upper bound will most likely not be helpful for managing approximation uncertainty. In an engineering design task, the upper bound usually corresponds to the "best case scenario," as opposed to the "worst case scenario" which would be required to ensure feasibility of the design.

Our strategy for obtaining lower bounds on the energy in a cost efficient manner is to first decompose the global problem into independent local elemental subproblems by relaxing the continuity of the set $\mathcal{U}$ along edges of a triangular partitioning of Ω, using approximate Lagrange multipliers, then accumulate the lower bound from the objective values of approximate local dual subproblems.

2.1. Weak continuity reformulation. We begin by partitioning the domain into a mesh, $\mathcal{T}_h$, of nonoverlapping open subdomains, T, called elements, for which $\bigcup_{T \in \mathcal{T}_h} \overline{T} = \bar{\Omega}$. We denote by ∂T the edges, γ, constituting the boundary of a single element T, and by $\partial\mathcal{T}_h$ the network of all edges in the mesh. We have not yet evoked a

discretization of $\mathcal{U}$, but merely a domain decomposition represented by a mesh. With the broken space

$$\hat{\mathcal{U}} \equiv \left\{ v \in L^2(\Omega) \;\middle|\; v|_T \in \mathcal{H}^1(T)\ \forall T \in \mathcal{T}_h \right\}, \tag{2.2}$$

in which the continuity of $\mathcal{U}$ is broken across the mesh edges, $\partial\mathcal{T}_h$, we can reformulate the energy minimization statement (2.1) by explicitly enforcing continuity

$$\begin{aligned} u = \arg \inf_{\hat{w}\in\hat{\mathcal{U}}} \quad & \frac{1}{2}\int_\Omega \nabla\hat{w}\cdot\nabla\hat{w}\,\mathrm{d}\Omega - \int_\Omega f\,\hat{w}\,\mathrm{d}\Omega \\ \text{s.t.} \quad & \sum_{T\in\mathcal{T}_h}\int_{\partial T}\sigma_T\,\lambda\,\hat{w}\,\mathrm{d}\Gamma = 0 \quad \forall\lambda\in\Lambda, \end{aligned} \tag{2.3}$$

where, for $T, T_{\mathrm{N}} \in \mathcal{T}_h$ and an arbitrary ordering of the elements,

$$\sigma_T(x) = \begin{cases} -1, & x \in \overline{T}\cap\overline{T}_{\mathrm{N}}, T < T_{\mathrm{N}}, \\ +1, & \text{otherwise.} \end{cases} \tag{2.4}$$

Integrals over the broken domain, such as $\int_\Omega \nabla\hat{w}\cdot\nabla\hat{v}\,\mathrm{d}\Omega$, are understood as sums of integrals over the subdomains, such as $\sum_{T\in\mathcal{T}_h}\int_T \nabla\hat{w}|_T\cdot\nabla\hat{v}|_T\,\mathrm{d}\Omega$. As there is no ambiguity, we have suppressed the trace operators from our notation for the boundary integrals to simplify the appearance of the expressions.

To see how the constraint arises, consider a single edge, $\gamma \in \partial\mathcal{T}_h$, with neighboring elements T and T_{N}, for which a strong continuity constraint can be written roughly as $\hat{w}|_{T,\gamma} - \hat{w}|_{T_{\mathrm{N}},\gamma} = 0$ on γ. An integral weak representation is obtained by multiplying by an arbitrary test function, λ_γ, taken from an appropriate space, $\Lambda(\gamma)$, integrating along the edge, and ensuring the resulting integrated quantity is zero for all possible test functions: $\int_\gamma (\hat{w}|_{T,\gamma} - \hat{w}|_{T_{\mathrm{N}},\gamma})\,\lambda_\gamma\,\mathrm{d}\Gamma = 0 \quad \forall\lambda_\gamma\in\Lambda(\gamma)$. The constraint used above is obtained by rewriting the combination of all edge constraints as a combination of elemental contributions, using σ_T to track the sign of the contribution. Since $\hat{w}|_T$ is a member of $\mathcal{H}^1(T)$, the trace of $\hat{w}|_T$ on an edge γ is a member of $\mathcal{H}^{\frac{1}{2}}(\partial T)$. Therefore, λ on γ is a member of the dual of the trace space, $\mathcal{H}^{-\frac{1}{2}}(\gamma)$, and the continuity multiplier space Λ is the corresponding product space taken over all the edges of the mesh.

Notice that we have relaxed the Dirichlet boundary conditions as well as the interior continuity. The homogeneous Dirichlet conditions are weakly enforced implicitly by the continuity constraint. We shall not prove it here, but it is important to know that the minimizer of the constrained minimization problem (2.3) is indeed u, the exact solution of Poisson's equation (1.1) [2, 4].

2.2. Localization by continuity relaxation. Considering the Lagrangian of the constrained minimization (2.3),

$$\mathcal{L}(\hat{w};\lambda) \equiv \frac{1}{2}\int_\Omega \nabla\hat{w}\cdot\nabla\hat{w}\,\mathrm{d}\Omega - \int_\Omega f\,\hat{w}\,\mathrm{d}\Omega - \sum_{T\in\mathcal{T}_h}\int_{\partial T}\sigma_T\,\lambda\,\hat{w}\,\mathrm{d}\Gamma, \tag{2.5}$$

we recall from the saddle point property of Lagrange multipliers and the strong duality of convex minimizations that $\forall\tilde{\lambda}\in\Lambda$ there exists a lower energy bound, ε^-, satisfying

$$\varepsilon^- \le \inf_{\hat{w}\in\hat{\mathcal{U}}}\mathcal{L}(\hat{w};\tilde{\lambda}) \le \sup_{\lambda\in\Lambda}\inf_{\hat{w}\in\hat{\mathcal{U}}}\mathcal{L}(\hat{w};\lambda) = \inf_{\hat{w}\in\hat{\mathcal{U}}}\sup_{\lambda\in\Lambda}\mathcal{L}(\hat{w};\lambda) = \varepsilon,$$

where the value at optimality is the minimum total energy of the continuum system, $\varepsilon = \frac{1}{2}\int_\Omega \nabla u \cdot \nabla u \,\mathrm{d}\Omega - \int_\Omega f\, u \,\mathrm{d}\Omega$. The lower bounding minimization for a given $\tilde{\lambda}$ is separable, an important property allowing us to treat each element independently. In order to obtain a lower bound, $\tilde{\lambda}$ cannot be chosen arbitrarily. We obtain $\tilde{\lambda}$ by approximating the problem using finite elements in a manner that guarantees that the relaxed minimization is bounded from below.

2.2.1. Continuity multiplier approximation. We now introduce the finite element approximation of Poisson's equation (1.1) as means of obtaining an approximate Lagrange multiplier. We first solve the finite-dimensional Poisson problem: find $u_h \in \mathcal{U}_h$ such that

$$\int_\Omega \nabla u_h \cdot \nabla v \,\mathrm{d}\Omega = \int_\Omega f\, v \,\mathrm{d}\Omega \quad \forall v \in \mathcal{U}_h, \tag{2.6}$$

where $\mathcal{U}_h \equiv \{\, v \in \mathcal{U} \mid v|_T \in \mathbb{P}^p(T)\ \forall T \in \mathcal{T}_h \,\}$ for $\mathbb{P}^p(T)$ is the space of polynomials on element T (in d spacial dimensions) with degree less than or equal to p. Along with $\mathcal{U}_h$, we introduce the broken discrete space $\hat{\mathcal{U}}_h \equiv \{\, v \in \hat{\mathcal{U}} \mid v|_T \in \mathbb{P}^p(T)\ \forall T \in \mathcal{T}_h \,\}$ and the companion discrete Lagrange multiplier space $\Lambda_h \equiv \{\, \lambda \in \Lambda \mid \lambda|_\gamma \in \mathbb{P}^p(\gamma)\ \forall \gamma \in \partial\mathcal{T}_h \,\}$, where $\mathbb{P}^p(\gamma)$ is the space of polynomials on element edge γ (in $d-1$ spacial dimensions) with degree less than or equal to p.

Once we have obtained u_h, we solve the gradient condition of (2.5) to obtain λ_h: find $\lambda_h \in \Lambda_h$ such that

$$\sum_{T\in\mathcal{T}_h} \int_{\partial T} \sigma_T\, \lambda_h\, \hat{v} \,\mathrm{d}\Gamma = \int_\Omega \nabla u_h \cdot \nabla \hat{v} \,\mathrm{d}\Omega - \int_\Omega f\, \hat{v} \,\mathrm{d}\Omega \quad \forall \hat{v} \in \hat{\mathcal{U}}_h. \tag{2.7}$$

We call this the equilibration problem, and we call any compatible Lagrange multiplier "equilibrating," since the problem has a nonunique solution. In the context of hybrid methods [4], this continuity multiplier is often referred to as a hybrid flux. As mentioned previously, this particular choice for the Lagrange multiplier ensures a finite lower bound.

LEMMA 2.1. *If a Lagrange multiplier $\lambda_h \in \Lambda_h$ satisfies the equilibration condition* (2.7), *then* $\inf_{\hat{w}\in\hat{\mathcal{U}}} \mathcal{L}(\hat{w};\lambda_h)$ *is bounded from below.*

Proof. Recall that the null space for the Poisson operator is the one-dimensional space of constants, $\mathbb{P}^0$, and let $\hat{\mathbb{P}}^0 = \prod_{T\in\mathcal{T}_h} \mathbb{P}^0(T)$ denote the null space of the broken operator. Considering $\hat{c} \in \hat{\mathbb{P}}^0 \subset \hat{\mathcal{U}}_h$ in the equilibration problem (2.7) and that any $\hat{w} \in \hat{\mathcal{U}}$ can be represented as $\hat{w}' + \hat{c}$ for $\hat{w}' \in \hat{\mathcal{U}} \setminus \hat{\mathbb{P}}^0$, it is easily shown that $\mathcal{L}(\hat{w}' + \hat{c};\lambda_h) = \mathcal{L}(\hat{w}';\lambda_h)$. For the Poisson equation, equilibration ensures that null space of the operator does not cause the minimization to become unbounded below. The existence of a minimum now follows from the coercivity of the Poisson operator in $\hat{\mathcal{U}} \setminus \hat{\mathbb{P}}^0$. ∎

While not part of the classical finite element problem set, the equilibration problem has been addressed a number of times and in a number of contexts in the finite element community, not the least of which is in the context of error estimation. For our implementation, we use a method due to Ladeveze and Leguillon [9] and Ainsworth and Oden [2] which has an asymptotically linear computational cost in the number of mesh vertices.

2.3. Local dual subproblem. Now that we have successfully decomposed the global problem into local elemental subproblems and determined a suitable approxi-

mation λ_h for our continuity multiplier $\tilde{\lambda}$, we can write the lower bounding minimization induced by the Lagrange saddle point property as

$$\inf_{\hat{w}\in\hat{\mathcal{U}}} \mathcal{L}(\hat{w};\tilde{\lambda}) = \sum_{T\in\mathcal{T}_h} \inf_{w\in\mathcal{U}(T)} J_T(w)$$

for

$$J_T(w) \equiv \frac{1}{2}\int_T \nabla w\cdot\nabla w\,\mathrm{d}\Omega - \int_T f\,w\,\mathrm{d}\Omega - \int_{\partial T}\sigma_T\,\tilde{\lambda}\,w\,\mathrm{d}\Gamma, \tag{2.8}$$

and consider a representative minimization subproblem. The minimization subproblem simply corresponds to a Poisson problem of the type represented in equation (1.1) with Neumann boundary conditions posed on a single subdomain. We have done nothing to change the nature of the original problem, but have only acted to decompose the global problem into a sequence of independent local problems.

We do not require, and in general cannot compute, the exact minimum of the infinite-dimensional local subproblem, but we do require a lower bound for it and we proceed now to introduce the primary ingredient for obtaining this local lower bound.

PROPOSITION 2.2. *If we define the positive functional*

$$J_T^c(\mathbf{q}) \equiv \frac{1}{2}\int_T \mathbf{q}\cdot\mathbf{q}\,\mathrm{d}\Omega, \tag{2.9}$$

where $\mathbf{q}\in\mathcal{H}(\mathrm{div};T)$ *and* $\mathcal{H}(\mathrm{div};T)\equiv\left\{\mathbf{q}\,|\,\mathbf{q}\in(L^2(T))^d,\ \nabla\cdot\mathbf{q}\in L^2(T)\right\}$ *for a problem posed in d spacial dimensions, then we have*

$$J_T(w) \geq -J_T^c(\mathbf{q}) \quad \forall w\in\mathcal{H}^1(T),\ \forall\mathbf{q}\in\mathcal{Q}(T;\tilde{\lambda}), \tag{2.10}$$

for the set of functions

$$\mathcal{Q}(T;\tilde{\lambda}) \equiv \left\{\mathbf{q}\in\mathcal{H}(\mathrm{div};T)\;\middle|\; \int_T \nabla\cdot\mathbf{q}\,v\,\mathrm{d}\Omega - \int_{\partial T}\mathbf{q}\cdot\mathbf{n}\,v\,\mathrm{d}\Gamma = -\int_T f\,v\,\mathrm{d}\Omega - \int_{\partial T}\sigma_T\tilde{\lambda}\,v\,\mathrm{d}\Gamma \quad \forall v\in\mathcal{H}^1(T)\right\}. \tag{2.11}$$

Proof. We begin by appealing to the following positive expression:

$$\frac{1}{2}\int_T (\mathbf{q}-\nabla w)^2\,\mathrm{d}\Omega \geq 0$$

for any $w\in\mathcal{H}^1(T)$ and any $\mathbf{q}\in\mathcal{Q}(T;\tilde{\lambda})$. This expression expands to

$$\frac{1}{2}\int_T \mathbf{q}\cdot\mathbf{q}\,\mathrm{d}\Omega + \frac{1}{2}\int_T \nabla w\cdot\nabla w\,\mathrm{d}\Omega - \int_T \mathbf{q}\cdot\nabla w\,\mathrm{d}\Omega \geq 0,$$

in which we apply the Green's identity $-\int_T \mathbf{q}\cdot\nabla w\,\mathrm{d}\Omega = \int_T \nabla\cdot\mathbf{q}\,w\,\mathrm{d}\Omega - \int_{\partial T}\mathbf{q}\cdot\mathbf{n}\,w\,\mathrm{d}\Gamma$ to obtain

$$\frac{1}{2}\int_T \mathbf{q}\cdot\mathbf{q}\,\mathrm{d}\Omega + \frac{1}{2}\int_T \nabla w\cdot\nabla w\,\mathrm{d}\Omega + \int_T \nabla\cdot\mathbf{q}\,w\,\mathrm{d}\Omega - \int_{\partial T}\mathbf{q}\cdot\mathbf{n}\,w\,\mathrm{d}\Gamma \geq 0. \tag{2.12}$$

The constraint contained in $\mathcal{Q}(T;\tilde{\lambda})$ makes this expression equivalent to

$$\frac{1}{2}\int_T \mathbf{q}\cdot\mathbf{q}\,\mathrm{d}\Omega + \frac{1}{2}\int_T \nabla w\cdot\nabla w\,\mathrm{d}\Omega - \int_T f\,w\,\mathrm{d}\Omega - \int_{\partial T}\sigma_T\,\tilde{\lambda}\,w\,\mathrm{d}\Gamma \geq 0. \tag{2.13}$$

Identifying $J_T(w)$ and $J_T^c(\mathbf{q})$ we arrive at the desired expression for the local lower bound. ∎

The best possible local lower bound can be obtained with the following maximization problem:

$$\sup_{\mathbf{q}\in\mathcal{Q}(T;\tilde{\lambda})} -J_T^c(\mathbf{q}) \leq \inf_{w\in\mathcal{U}(T)} J_T(w),$$

for which we will obtain equality as a result of the convexity of J_T and J_T^c. It is clear that we have derived a classic dual formulation[1] for our local elemental minimization problem and essentially transformed a primal minimization problem into a dual feasibility problem. As we have alluded to earlier, the functional $J_T^c(\mathbf{q})$ is often called the *complementary energy* functional [16], when taken over the whole domain, Ω, with a globally admissible complementary field.

2.3.1. Subproblem approximation. Significantly, we can make these subproblems computable by choosing an appropriate finite-dimensional set in which to search for $\mathbf{q}$. At the very least the set must be chosen so that the divergence of its functions contain the forcing function, f, in T and the normal traces of its functions contain the approximate continuity multiplier, λ_h, on ∂T. In multiple dimensions, however, the polynomial approximation for the continuity multiplier will nullify any components of the set with nonpolynomial normal trace. Therefore, we choose the polynomial approximation subset

$$\begin{aligned}\mathcal{Q}_h(T) \equiv \Bigg\{ \mathbf{q}\in(\mathbb{P}^q(T))^d \;\Bigg|\; & \int_T \nabla\cdot\mathbf{q}\,v\,\mathrm{d}\Omega - \int_{\partial T}\mathbf{q}\cdot\mathbf{n}\,v\,\mathrm{d}\Gamma \\ & = -\int_T f\,v\,\mathrm{d}\Omega - \int_{\partial T}\sigma_T\lambda_h\,v\,\mathrm{d}\Gamma\ \forall v\in\mathcal{H}^1(T)\Bigg\}\end{aligned} \tag{2.14}$$

with $q\geq p$. As a consequence, the method as we have presented it is limited to forcing functions, $f|_T$, that are members of the polynomial space $\mathbb{P}^r(T)$ for $q>r$ on each elemental domain. While in one dimension we gain no advantage in taking q greater than $r+1$, in multiple dimensions we can do so in an attempt to sharpen the bounds. The interior constraint data, f, and the boundary constraint data, $\sigma_T\lambda_h$, cannot be chosen independently of each other, but must satisfy a compatibility condition in order to ensure solvability as manifest by the following lemma.

LEMMA 2.3. *Suppose the forcing function $f|_T$ is a member of $\mathbb{P}^r(T)$ and that λ_h satisfies* (2.7)*, then there exists at least one dual feasible function, $\mathbf{q}$, that is a member of $\mathcal{Q}_h(T)$ for $q\geq p$ and $q>r$.*

Proof. We begin by expressing $\mathbf{q}$, a member of $(\mathbb{P}^q(T))^d$, as the combination $\mathbf{q}=\mathbf{q}_D+\mathbf{q}_0$, with $\mathbf{q}_D$ a normal boundary condition satisfying component, $\mathbf{q}_D\cdot\mathbf{n}=$

[1] The classic derivation for the dual of the Poisson problem would begin by letting $\mathbf{q}=\nabla w$ (a statement of Fourier's law in the context of heat conduction) and proceed by eliminating w from the problem.

$\sigma_T \lambda_h$ on ∂T, and $\mathbf{q}_0$ a homogeneous normal boundary condition satisfying component, $\mathbf{q}_0 \cdot \mathbf{n} = 0$ on ∂T. With this lifting, we can write the feasibility constraint as

$$-\int_T \nabla \cdot \mathbf{q}_0 \, v \, \mathrm{d}\Omega = \int_T f \, v \, \mathrm{d}\Omega + \int_T \nabla \cdot \mathbf{q}_D \, v \, \mathrm{d}\Omega.$$

Recognizing the divergence operator on the left-hand side, which maps $(\mathbb{P}^q(T))^d$ into $\mathbb{P}^{q-1}(T)$, we note that we need only test against $v \in \mathbb{P}^{q-1}(T)$. Furthermore, finite-dimensional linear equations are solvable if and only if the right-hand side data lies in the range of the operator, which is orthogonal to the null space of the adjoint operator. The adjoint operator is easily found to be $\int_T \mathbf{q}_0 \cdot \nabla v \, \mathrm{d}\Omega$ which has the null space $v \in \mathbb{P}^0(T)$, and thus the right-hand side data must be in $\mathbb{P}^{q-1}(T) \setminus \mathbb{P}^0(T)$.

To prove solvability, we need only to verify that the right-hand side data is orthogonal to the constants, since the requirements that $q \geq p$ and $q > r$ ensure that the right-hand side data is in $\mathbb{P}^{q-1}$. Choosing $v = \text{const}$ in the right-hand side of the constraint, rewritten as

$$\int_T f \, v \, \mathrm{d}\Omega + \int_T \nabla \cdot \mathbf{q}_D \, v \, \mathrm{d}\Omega = \int_T f \, v \, \mathrm{d}\Omega - \int_T \mathbf{q}_D \cdot \nabla v \, \mathrm{d}\Omega + \int_{\partial T} \sigma_T \lambda_h \, v \, \mathrm{d}\Gamma,$$

reveals the compatibility condition

$$\int_{\partial T} \sigma_T \lambda_h \, \mathrm{d}\Gamma = -\int_T f \, \mathrm{d}\Omega, \tag{2.15}$$

which is satisfied by our choice for λ_h, as can be seen by choosing $\hat{v} = \text{const}$ on T in the equilibration condition (2.7). The equilibration condition thus ensures that the constraint data is compatible and that there exists at least one $\mathbf{q}$ satisfying the constraint. ∎

2.4. Energy bound procedure. In discussing the global procedure and its properties, we denote the global aggregate of independent elemental quantities by accenting them with a diacritical hat as we did for the global broken quantities, and we denote the aggregate of local functional forms by dropping the subscript T. In particular, $\hat{\mathcal{Q}}_h$ denotes the aggregate approximate dual function space, $\prod_{T \in \mathcal{T}_h} \mathcal{Q}_h(T)$, and $J^c(\hat{\mathbf{q}})$ the aggregate dual energy functional, $\sum_{T \in \mathcal{T}_h} J^c_T(\mathbf{q}|_T)$. The complete method for the energy bounds consists of three steps.

1. *Global approximation:* Find $u_h \in \mathcal{U}_h$ such that

$$\int_\Omega \nabla u_h \cdot \nabla v \, \mathrm{d}\Omega = \int_\Omega f \, v \, \mathrm{d}\Omega \quad \forall v \in \mathcal{U}_h, \tag{2.16}$$

   and calculate the upper bound $\varepsilon_h^+ = -\frac{1}{2} \int_\Omega \nabla u_h \cdot \nabla u_h \, \mathrm{d}\Omega$.
2. *Global equilibration:* Find $\lambda_h \in \Lambda_h$ such that

$$\sum_{T \in \mathcal{T}_h} \int_{\partial T} \sigma_T \, \lambda_h \, \hat{v} \, \mathrm{d}\Gamma = \int_\Omega \nabla u_h \cdot \nabla \hat{v} \, \mathrm{d}\Omega - \int_\Omega f \, \hat{v} \, \mathrm{d}\Omega \quad \forall \hat{v} \in \hat{\mathcal{U}}_h. \tag{2.17}$$

3. *Local dual approximations:* Find ε_h^- such that

$$\varepsilon_h^- = \sup_{\hat{\mathbf{q}}_h \in \hat{\mathcal{Q}}_h} -J^c(\hat{\mathbf{q}}_h). \tag{2.18}$$

The last step requires the solution of a series of finite-dimensional quadratic programming problems with convex objective functions and linear equality constraints. The per-element cost remains low due to the small size of the elemental subproblems, while the total cost of computing the lower bound is asymptotically linear in the number elements.

2.4.1. Properties of the energy bound. As previously discussed, the upper bound follows directly from the conforming nature of the finite element approximation and the lower bound follows directly from Proposition 2.2. We close our presentation of the energy bound method by showing that the lower bound converges at the same rate as the upper bound, and thus inherits the well-known a priori finite element convergence property for the energy norm of the error. We begin by proving an orthogonality result.

LEMMA 2.4. *Let $\hat{\mathbf{p}}$ be any dual feasibility correction to ∇u_h such that $\hat{\mathbf{q}} = \nabla u_h + \hat{\mathbf{p}}$ is a member of $\hat{\mathcal{Q}}(\lambda_h)$, then $\hat{\mathbf{p}}$ satisfies the orthogonality property*

$$\sum_{T\in\mathcal{T}_h} \int_T \hat{\mathbf{p}} \cdot \nabla \hat{v} \, \mathrm{d}\Omega = 0 \quad \forall \hat{v} \in \hat{\mathcal{U}}_h. \tag{2.19}$$

Proof. We begin by examining the condition that the feasibility correction $\hat{\mathbf{p}}$ must satisfy by substituting $\nabla u_h + \hat{\mathbf{p}}$ into the constraint contained in the definition of $\hat{\mathcal{Q}}(\lambda_h)$ to obtain

$$\begin{aligned} \int_\Omega \nabla \cdot \hat{\mathbf{p}} \, \hat{v} \, \mathrm{d}\Omega - \sum_{T\in\mathcal{T}_h} \int_{\partial T} \hat{\mathbf{p}} \cdot \mathbf{n} \, \hat{v} \, \mathrm{d}\Gamma = &- \int_\Omega f \, \hat{v} \, \mathrm{d}\Omega - \int_\Omega \nabla \cdot \nabla u_h \, \hat{v} \, \mathrm{d}\Omega \\ &- \sum_{T\in\mathcal{T}_h} \int_{\partial T} \sigma_T \lambda_h \, \hat{v} \, \mathrm{d}\Gamma + \sum_{T\in\mathcal{T}_h} \int_{\partial T} \nabla u_h \cdot \mathbf{n} \, \hat{v} \, \mathrm{d}\Gamma \quad \forall \hat{v} \in \hat{\mathcal{U}}_h. \end{aligned} \tag{2.20}$$

Applying Green's formula to both the $\hat{\mathbf{p}}$ and u_h terms yields the equivalent constraint

$$\int_\Omega \hat{\mathbf{p}} \cdot \nabla \hat{v} \, \mathrm{d}\Omega = \int_\Omega f \, \hat{v} \, \mathrm{d}\Omega - \int_\Omega \nabla u_h \cdot \nabla \hat{v} \, \mathrm{d}\Omega + \sum_{T\in\mathcal{T}_h} \int_{\partial T} \sigma_T \lambda_h \, \hat{v} \, \mathrm{d}\Gamma \quad \forall \hat{v} \in \hat{\mathcal{U}}_h. \tag{2.21}$$

Restricting $\hat{v}$ to $\hat{\mathcal{U}}_h$ produces the sought orthogonality property as a consequence of equilibration (2.17). ∎

LEMMA 2.5. *Let $\hat{\mathbf{p}}_h^*$ be the dual feasibility correction to ∇u_h that maximizes $-J^c(\hat{\mathbf{p}}_h)$ such that $\nabla u_h + \hat{\mathbf{p}}_h^*$ is a member of $\hat{\mathcal{Q}}_h$, then $J^c(\hat{\mathbf{p}}_h^*)$ is bounded from above by*

$$J^c(\hat{\mathbf{p}}_h^*) \leq C|u - u_h|_1^2, \tag{2.22}$$

for the seminorm $|v|_1^2 \equiv \int_\Omega \nabla v \cdot \nabla v \, \mathrm{d}\Omega$, if the approximate continuity multiplier λ_h computed in (2.17) *has the bound*

$$\sum_{T\in\mathcal{T}_h} h^{\frac{1}{2}} \|\lambda - \lambda_h\|_{\partial T} \leq C|u - u_h|_1, \tag{2.23}$$

where $\lambda|_{\partial T} \equiv \sigma_T \frac{\partial u}{\partial \mathbf{n}}$ is the exact continuity multiplier and $\|v\|_{\partial T}^2 \equiv \int_{\partial T} v^2 \, \mathrm{d}\Gamma$. Everywhere, C is a generic constant independent of $h = \mathrm{diam}(T)$.

Proof. Using (2.21), the constrained maximization for the continuous dual feasible correction $\hat{\mathbf{p}}^*$ can be written as $\sup_{\hat{\mathbf{p}}\in\hat{\mathcal{Q}}(\lambda_h)} -\frac{1}{2}\int_\Omega \hat{\mathbf{p}}\cdot\hat{\mathbf{p}}\,\mathrm{d}\Omega$. Explicitly, the constraint for this maximization problem is written as

$$-\int_\Omega \hat{\mathbf{p}}\cdot\nabla\hat{\phi}\,\mathrm{d}\Omega = \int_\Omega \nabla u_h\cdot\nabla\hat{\phi}\,\mathrm{d}\Omega - \int_\Omega f\,\hat{\phi}\,\mathrm{d}\Omega - \sum_{T\in\mathcal{T}_h}\int_{\partial T}\sigma_T\lambda_h\,\hat{\phi}\,\mathrm{d}\Gamma \quad \forall\hat{\phi}\in\hat{\mathcal{U}}. \tag{2.24}$$

The gradient condition then informs us that $\hat{\mathbf{p}}^* = \nabla\hat{\phi}^*$.

The approximate solution u_h has an associated approximate continuity multiplier λ_h satisfying (2.17), while the exact solution u also has an associated exact continuity multiplier λ satisfying

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T}\sigma_T\,\lambda\,\hat{v}\,\mathrm{d}\Gamma = \int_\Omega \nabla u\cdot\nabla\hat{v}\,\mathrm{d}\Omega - \int_\Omega f\,\hat{v}\,\mathrm{d}\Omega \quad \forall\hat{v}\in\hat{\mathcal{U}}, \tag{2.25}$$

as can be verified by integration by parts. Adding (2.25) to the constraint of (2.24) with $\hat{\mathbf{p}} = \hat{\mathbf{p}}^*$ and $\hat{v} = \hat{\phi}^*$ we find for $\|\hat{v}\|^2 = \sum_{T\in\mathcal{T}_h}\int_T v^2\,\mathrm{d}\Omega$ that

$$\begin{aligned}\int_\Omega \hat{\mathbf{p}}^*\cdot\nabla\hat{\phi}^*\,\mathrm{d}\Omega &= \int_\Omega \nabla(u-u_h)\cdot\nabla\hat{\phi}^*\,\mathrm{d}\Omega - \sum_{T\in\mathcal{T}_h}\int_{\partial T}\sigma_T(\lambda-\lambda_h)\hat{\phi}^*\,\mathrm{d}\Gamma\\ &\le C|u-u_h|_1\|\nabla\hat{\phi}^*\| + \sum_{T\in\mathcal{T}_h} C\|\lambda-\lambda_h\|_{\partial T}\|\hat{\phi}^*\|_{\partial T}\\ &\le C|u-u_h|_1\|\nabla\hat{\phi}^*\| + \sum_{T\in\mathcal{T}_h} Ch^{\frac{1}{2}}\|\lambda-\lambda_h\|_{\partial T}\|\nabla\hat{\phi}^*\|,\end{aligned}$$

in which we applied the inequality $\|w\|_{\partial T}\le Ch^{\frac{1}{2}}|w|_{1,T}$, valid for any $w\in\mathcal{H}^1(T)$ that has zero mean [11].

We then invoke the bound (2.23) and substitute $\nabla\hat{\phi}^* = \hat{\mathbf{p}}^*$ before dividing both sides by $\|\hat{\mathbf{p}}^*\|$ and recognizing that $\|\hat{\mathbf{p}}^*\|^2 = 2J^c(\hat{\mathbf{p}}^*)$ to obtain

$$J^c(\hat{\mathbf{p}}^*)\le C|u-u_h|_1^2.$$

The proof is completed by showing that $J^c(\hat{\mathbf{p}}_h^*)\le\tilde{C}J^c(\hat{\mathbf{p}}^*)$. This can be done by noting that $\hat{\mathbf{p}}_h^*$ can be obtained from $\hat{\mathbf{p}}^*$ by a bounded projection. A standard scaling argument can then be used to show that the constant $\tilde{C}$ is independent of h; see [4, 17]. ∎

Ainsworth and Oden prove in [1] that under certain assumptions the flux average of the finite element solution across the edges is bounded by (2.23) so that, by way of the triangle inequality, the burden rests in showing that the nonunique equilibrating corrections required to satisfy (2.17) decrease at the requisite rate. Maday and Patera give in [11] a basic method for computing approximate continuity multipliers that has been proven a priori to satisfy (2.23).

PROPOSITION 2.6. *Suppose that λ_h is the solution of the equilibration problem* (2.17) *for u_h the solution of the finite element approximation problem* (2.16)*, then*

$$\varepsilon-\varepsilon^-\le C|u-u_h|_1^2. \tag{2.26}$$

Proof. Let $\hat{\mathbf{p}}_h^*$ be chosen according to Lemma 2.5, then

$$-J^c(\nabla u_h + \hat{\mathbf{p}}_h^*) \leq \sup_{\hat{\mathbf{q}}_h \in \hat{\mathcal{Q}}_h} -J^c(\hat{\mathbf{q}}_h) = -J^c(\hat{\mathbf{q}}_h^*)$$

for $\hat{\mathbf{q}}_h^* = \arg\sup_{\hat{\mathbf{q}}_h \in \hat{\mathcal{Q}}_h} -J^c(\hat{\mathbf{q}}_h)$. From this relationship and from the definition of $\hat{\mathbf{p}}_h^*$ we know that $J^c(\hat{\mathbf{q}}_h^*) \leq J^c(\nabla u_h) + J^c(\hat{\mathbf{p}}_h^*)$, because $\sum_{T \in \mathcal{T}_h} \int_T \hat{\mathbf{p}}_h^* \cdot \nabla u_h \, \mathrm{d}\Omega = 0$ from Lemma 2.4 and the fact that u_h is a member of $\hat{\mathcal{U}}_h$. Adding the exact energy $\varepsilon = -J^c(\nabla u)$ to each side and recalling that $\varepsilon_h^+ = -J^c(\nabla u_h)$ and $\varepsilon_h^- = -J^c(\hat{\mathbf{q}}_h^*)$, we have our desired result

$$\varepsilon - \varepsilon_h^- \leq \varepsilon - \varepsilon_h^+ + J^c(\hat{\mathbf{p}}_h^*) \leq C|u - u_h|_1^2,$$

where we have again evoked Lemma 2.5 in addition to the well-known finite element energy error bound. ∎

3. Computing output bounds. We will continue to keep the presentation simple by considering only simple linear functional interior outputs. In particular, we will develop upper and lower bounds, $s^{\pm}$, on the output quantity

$$s \equiv \int_\Omega f^{\mathcal{O}} \, u \, \mathrm{d}\Omega, \tag{3.1}$$

where u is the exact solution of Poisson's equation (1.1) and $f^{\mathcal{O}}|_T$ is a member of $\mathbb{P}^r(T)$ for all elements T in $\mathcal{T}_h$. We stress, however, that more interesting outputs, such as boundary fluxes, can also be treated using techniques previously employed in the context of two-level methods (see, for example, the treatment of the normal force output for linear elasticity in [14]).

3.1. Weak continuity reformulation. To begin, we must formulate a generalized analogue to the minimization statement (2.3). There are two parts to this task. First, we must replace the intrinsic energy of the variational problem with an energy reformulation of the linear output functional. Second, now that the minimization of the objective functional no longer corresponds to the solution of our original equation, we must explicitly ensure that the minimizer is the solution to our problem by including it as a constraint. Furthermore, to obtain both upper and lower bounds, we consider two cases which vary by the sign of the original output. The resulting pair of constrained minimization statements for the homogeneous[2] Dirichlet boundary problem under consideration are

(3.2)

$$\begin{aligned} \mp s = \inf_{\hat{w}^{\pm} \in \hat{\mathcal{U}}} \; & \mp \int_\Omega f^{\mathcal{O}} \, \hat{w}^{\pm} \, \mathrm{d}\Omega + \frac{\kappa}{2} \left\{ \int_\Omega \nabla \hat{w}^{\pm} \cdot \nabla (\hat{w}^{\pm} - \bar{u}) \, \mathrm{d}\Omega - \int_\Omega f \, (\hat{w}^{\pm} - \bar{u}) \, \mathrm{d}\Omega \right\} \\ \text{s.t.} \quad & \int_\Omega \nabla \hat{w}^{\pm} \cdot \nabla \psi \, \mathrm{d}\Omega = \int_\Omega f \, \psi \, \mathrm{d}\Omega \quad \forall \psi \in \mathcal{U}, \\ & \sum_{T \in \mathcal{T}_h} \int_{\partial T} \sigma_T \, \lambda \, \hat{w}^{\pm} \, \mathrm{d}\Gamma = 0 \qquad\qquad \forall \lambda \in \Lambda, \end{aligned}$$

[2]The extension to nonhomogeneous Dirichlet boundaries requires choosing $\bar{u}$ from the set of admissible functions and weakly enforcing the Dirichlet boundary data, u_D, by replacing the continuity constraint with $\sum_{T \in \mathcal{T}_h} \int_{\partial T} \sigma_T \, \lambda \, \hat{w}^{\pm} \, \mathrm{d}\Gamma = \sum_{\gamma \in \partial \mathcal{T}_h} \int_\gamma \sigma_{T(\gamma)} \, \lambda \, u_D \, \mathrm{d}\Gamma \; \forall \lambda \in \Lambda$.

where $\bar{u}$ is any element of space $\mathcal{U}$, and κ is a positive real scaling parameter which serves both as a coefficient providing dimensional consistency in the engineering context and as an additional degree of freedom which we will use to tighten the bounds. The quadratic objective functional has been constructed so that all terms but the desired output functional vanish when $\hat{w}^{\pm}$ is the exact solution, u, while the constraints enforce equilibrium and interelement continuity.

Paraschivoiu, Peraire, and Patera [14] and Paraschivoiu and Patera [13] originally proposed this reformulation in the context of two-level output bounding methods which appeal to a second refined but localized finite element approximation, and therefore provided bounds only against a refined finite element approximation instead of the exact infinite-dimensional solution. With this constrained minimization reformulation, we can proceed more or less mechanically to apply the ideas from the energy bound to this more general context. The development of the output bound is very close to that for the energy bound, but with the extra burden of carrying an additional Lagrange multiplier for the equilibrium constraint and of managing the concurrent development of both upper and lower bounds on the output, as neither arise implicitly from the finite element discretization.

3.2. Localization by continuity relaxation. Considering the Lagrangian of problem (3.2),

$$
\begin{aligned}
(3.3)\quad & \mathcal{L}^{\pm}(\hat{w}^{\pm};\psi^{\pm},\lambda^{\pm}) \\
& \equiv \mp\int_{\Omega} f^{\mathcal{O}}\,\hat{w}^{\pm}\,\mathrm{d}\Omega + \frac{\kappa}{2}\left\{\int_{\Omega}\nabla\hat{w}^{\pm}\cdot\nabla(\hat{w}^{\pm}-\bar{u})\,\mathrm{d}\Omega - \int_{\Omega} f\,(\hat{w}^{\pm}-\bar{u})\,\mathrm{d}\Omega\right\} \\
& \quad + \int_{\Omega} f\,\psi^{\pm}\,\mathrm{d}\Omega - \int_{\Omega}\nabla\hat{w}^{\pm}\cdot\nabla\psi^{\pm}\,\mathrm{d}\Omega - \sum_{T\in\mathcal{T}_h}\int_{\partial T}\sigma_T\,\lambda^{\pm}\,\hat{w}^{\pm}\,\mathrm{d}\Gamma,
\end{aligned}
$$

we know, as we did for the energy bound, from the saddle point property of Lagrange multipliers and from the strong duality of convex minimizations that

$$
\inf_{\hat{w}^{\pm}\in\hat{\mathcal{U}}}\mathcal{L}^{\pm}(\hat{w}^{\pm};\tilde{\psi}^{\pm},\tilde{\lambda}^{\pm}) \le \sup_{\substack{\psi^{\pm}\in\mathcal{U}\\ \lambda\in\Lambda}}\inf_{\hat{w}^{\pm}\in\hat{\mathcal{U}}}\mathcal{L}^{\pm}(\hat{w}^{\pm};\psi^{\pm},\lambda^{\pm}) = \mp s
$$

$\forall(\tilde{\psi}^{\pm},\tilde{\lambda}^{\pm})\in\mathcal{U}\times\Lambda$. The lower bounding minimization for a given $\tilde{\lambda}^{\pm}$ and $\tilde{\psi}^{\pm}$ is separable and, for an appropriate choice for $\tilde{\lambda}^{\pm}$, provides nontrivial upper and lower bounds on the exact output s.

3.2.1. Lagrange multiplier approximation. We proceed, as we did for the energy bound, to obtain approximate Lagrange multipliers with a finite element discretization of the gradient condition of (3.3). Let $\psi_h^{\pm} = \pm\psi_h$, $\lambda_h^{\pm} = \frac{\kappa}{2}\lambda_h^u \pm \lambda_h^{\psi}$, and $\bar{u} = u_h$, all of which we find by solving the following discrete problems:

1. Find $u_h\in\mathcal{U}_h$ such that

$$
(3.4)\qquad \int_{\Omega}\nabla u_h\cdot\nabla v\,\mathrm{d}\Omega = \int_{\Omega} f\,v\,\mathrm{d}\Omega \quad \forall v\in\mathcal{U}_h.
$$

2. Find $\psi_h\in\mathcal{U}_h$ such that

$$
(3.5)\qquad \int_{\Omega}\nabla v\cdot\nabla\psi_h\,\mathrm{d}\Omega = -\int_{\Omega} f^{\mathcal{O}}\,v\,\mathrm{d}\Omega \quad \forall v\in\mathcal{U}_h.
$$

3. Find $\lambda_h^u \in \Lambda_h$ such that

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T}\sigma_T\,\lambda_h^u\,\hat{v}\,\mathrm{d}\Gamma=\int_\Omega\nabla u_h\cdot\nabla\hat{v}\,\mathrm{d}\Omega-\int_\Omega f\,\hat{v}\,\mathrm{d}\Omega\quad\forall\hat{v}\in\hat{\mathcal{U}}_h. \tag{3.6}$$

4. Find $\lambda_h^\psi \in \Lambda_h$ such that

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T}\sigma_T\,\lambda_h^\psi\,\hat{v}\,\mathrm{d}\Gamma=-\int_\Omega f^{\mathcal{O}}\,\hat{v}\,\mathrm{d}\Omega-\int_\Omega\nabla\hat{v}\cdot\nabla\psi_h\,\mathrm{d}\Omega\quad\forall\hat{v}\in\hat{\mathcal{U}}_h. \tag{3.7}$$

The first two problems comprise the well-known primal-adjoint pair which occur often in output oriented a posteriori error estimation techniques [3, 14, 13] as well as in computational approaches to design optimization [8], while the last two problems are their independent equilibrations. The first and third problems are identical to the global approximation problems required for the energy bound. These particular choices for the Lagrange multipliers ensure a finite lower bound in the saddle point property.

LEMMA 3.1. *If the Lagrange multipliers* $\psi_h^\pm=\pm\psi_h$ *and* $\lambda_h^\pm=\frac{\kappa}{2}\lambda_h^u\pm\lambda_h^\psi$ *satisfy the equilibration conditions* (3.6) *and* (3.7), *then the minimums* $\inf_{\hat{w}^\pm\in\hat{\mathcal{U}}}\mathcal{L}(\hat{w}^\pm;\psi_h^\pm,\lambda_h^\pm)$ *are bounded from below.*

Proof. This is true for essentially the same reason that it is true for Lemma 2.1. The only algebraic difference being that in the present output bounding case the property $\mathcal{L}^\pm(\hat{w}^{\pm'}+\hat{c};\psi_h^\pm,\lambda_h^\pm)=\mathcal{L}(\hat{w}^{\pm'};\psi_h^\pm,\lambda_h)$ results from the combined action of both equilibration conditions. ∎

3.3. Local dual subproblem. Restricting our attention to a single elemental subproblem, $T\in\mathcal{T}_h$, we first rewrite our local Lagrangian functional in a form suitable for applying the ideas developed for the energy bound. Every term other than the dissipative energy term, $\frac{\kappa}{2}\int_T\nabla w\cdot\nabla w\,\mathrm{d}\Omega$, must not involve derivatives of $\hat{w}^\pm$, which we can do in the present case by application of the Green's identity, $-\int_T\nabla u\cdot\nabla w\,\mathrm{d}\Omega=\int_T\Delta u\,w\,\mathrm{d}\Omega-\int_{\partial T}\nabla u\cdot\mathbf{n}\,w\,\mathrm{d}\Gamma$, to obtain the equivalent local Lagrangian functional

$$\begin{aligned}\mathcal{L}_T^\pm(w^\pm;\pm\tilde{\psi},\frac{\kappa}{2}\tilde{\lambda}^u\pm\tilde{\lambda}^\psi)&\equiv\frac{\kappa}{2}\int_T\nabla w^\pm\cdot\nabla w^\pm\,\mathrm{d}\Omega\\&-\frac{\kappa}{2}\left\{\int_T(f-\Delta\bar{u})\;w^\pm\,\mathrm{d}\Omega+\int_{\partial T}\left(\sigma_T\tilde{\lambda}^u+\nabla\bar{u}\cdot\mathbf{n}\right)\;w^\pm\,\mathrm{d}\Gamma+\int_T f\,\bar{u}\,\mathrm{d}\Omega\right\}\\&\mp\left\{\int_T\left(f^{\mathcal{O}}-\Delta\tilde{\psi}\right)\;w^\pm\,\mathrm{d}\Omega+\int_{\partial T}\left(\sigma_T\tilde{\lambda}^\psi+\nabla\tilde{\psi}\cdot\mathbf{n}\right)\;w^\pm\,\mathrm{d}\Gamma+\int_T f\,\tilde{\psi}\,\mathrm{d}\Omega\right\}.\end{aligned} \tag{3.8}$$

The functional we wish to minimize over $w^\pm$ can now be defined as

$$J_T^\pm(w^\pm)\equiv\frac{\kappa}{2}\int_T\nabla w^\pm\cdot\nabla w^\pm\,\mathrm{d}\Omega-\int_T f^\pm\,w^\pm\,\mathrm{d}\Omega-\int_{\partial T}g^\pm\,w^\pm\,\mathrm{d}\Gamma \tag{3.9}$$

for $f^\pm\equiv\frac{\kappa}{2}\{f-\Delta\bar{u}\}\pm\{f^{\mathcal{O}}-\Delta\tilde{\psi}\}$ and $g^\pm\equiv\frac{\kappa}{2}\{\sigma_T\tilde{\lambda}^u+\nabla\bar{u}\cdot\mathbf{n}\}\pm\{\sigma_T\tilde{\lambda}^\psi+\nabla\tilde{\psi}\cdot\mathbf{n}\}$. Thus, the local relaxed primal minimization once again corresponds to a Poisson problem of the type represented in (1.1) with Neumann boundary conditions posed on a single element.

As was the case for the energy bound, we do not require, and in general cannot compute, the exact minimum of this local infinite-dimensional primal subproblem,

but we can apply the same technique of dualizing this minimization problem in order to procure a computable lower bounding approximate to it.

PROPOSITION 3.2. *If we define the positive functional*

$$J_T^c(\mathbf{q}) \equiv \frac{1}{2}\int_T \mathbf{q}\cdot\mathbf{q}\,\mathrm{d}\Omega, \tag{3.10}$$

where $\mathbf{q}\in\mathcal{H}(\mathrm{div};T)$*, then we have*

$$J_T^{\pm}(w^{\pm}) \geq -\frac{1}{\kappa}J_T^c(\mathbf{q}^{\pm}) \quad \forall w^{\pm}\in\mathcal{H}^1(T),\ \forall \mathbf{q}^{\pm}\in\mathcal{Q}^{\pm}(T), \tag{3.11}$$

for the set of functions

$$\mathcal{Q}^{\pm}(T) \equiv \left\{ \mathbf{q}\in\mathcal{H}(\mathrm{div};T) \;\middle|\; \int_T \nabla\cdot\mathbf{q}\,v\,\mathrm{d}\Omega - \int_{\partial T}\mathbf{q}\cdot\mathbf{n}\,v\,\mathrm{d}\Gamma = -\int_T f^{\pm}\,v\,\mathrm{d}\Omega - \int_{\partial T} g^{\pm}\,v\,\mathrm{d}\Gamma,\ \forall v\in\mathcal{H}^1(T)\right\}. \tag{3.12}$$

Proof. The local dual problem is derived as it was for the energy bound, but with modified data and the addition of the scaling parameter, κ. After expanding the positive expression for $\mathbf{q}\in\mathcal{Q}^{\pm}(T)$,

$$\frac{1}{2\kappa}\int_T (\mathbf{q}^{\pm}-\kappa\nabla w)^2\,\mathrm{d}\Omega \geq 0, \tag{3.13}$$

applying Green's formula, and substituting the constraint from $\mathcal{Q}^{\pm}(T)$, we obtain the expression

$$\frac{1}{2\kappa}\int_T \mathbf{q}^{\pm}\cdot\mathbf{q}^{\pm}\,\mathrm{d}\Omega + \frac{\kappa}{2}\int_T \nabla w^{\pm}\cdot\nabla w^{\pm}\,\mathrm{d}\Omega - \int_T f^{\pm}\,w^{\pm}\,\mathrm{d}\Omega - \int_{\partial T} g^{\pm}\,w^{\pm}\,\mathrm{d}\Gamma \geq 0. \tag{3.14}$$

Identifying $J_T^{\pm}(w^{\pm})$ and $J_T^c(\mathbf{q}^{\pm})$ we arrive at the desired expression for the local lower bound. ∎

As the functional $J_T^{\pm}(w^{\pm})$ contains only the terms from the Lagrangian that depended on $w^{\pm}$, we must reintroduce the constant terms to secure the complete contributions from the local dual subproblems:

$$\mp s_T^{\pm} = \int_T f\left(\frac{\kappa}{2}u_h \pm \psi_h\right)\mathrm{d}\Omega + \sup_{\mathbf{q}^{\pm}\in\mathcal{Q}^{\pm}(T)} -\frac{1}{\kappa}J_T^c(\mathbf{q}^{\pm}). \tag{3.15}$$

3.3.1. Subproblem approximation. Consider the splitting implied by the definition $\mathbf{q}_h = \kappa\nabla\bar{u} + \frac{\kappa}{2}\mathbf{q}_h^u \pm \mathbf{q}_h^{\psi}$. Propagation of this definition into the elemental subproblem reveals through the linearity of the gradient condition that indeed $\mathbf{q}_h^u$ and $\mathbf{q}_h^{\psi}$ can be computed independently. The resulting subproblems are

$$\begin{aligned} \mathbf{q}_h^u &= \arg\inf_{\mathbf{q}_h\in\mathcal{Q}_h^u(T)} J^c(\mathbf{q}_h), \\ \mathbf{q}_h^{\psi} &= \arg\inf_{\mathbf{q}_h\in\mathcal{Q}_h^{\psi}(T)} J^c(\mathbf{q}_h), \end{aligned} \tag{3.16}$$

for the dual feasible approximation sets

(3.17)
$$\mathcal{Q}_h^u(T) \equiv \left\{ \mathbf{q} \in (\mathbb{P}^q(T))^d \;\middle|\; \int_T \nabla \cdot \mathbf{q}\, v \,\mathrm{d}\Omega - \int_{\partial T} \mathbf{q}\cdot\mathbf{n}\, v \,\mathrm{d}\Gamma = -\int_T (f + \Delta u_h)\, v \,\mathrm{d}\Omega \right.$$
$$\left. - \int_{\partial T} (\sigma_T \lambda_h^u - \nabla u_h \cdot \mathbf{n})\, v \,\mathrm{d}\Gamma \;\forall v \in \mathcal{H}^1(T) \right\},$$
$$\mathcal{Q}_h^\psi(T) \equiv \left\{ \mathbf{q} \in (\mathbb{P}^q(T))^d \;\middle|\; \int_T \nabla \cdot \mathbf{q}\, v \,\mathrm{d}\Omega - \int_{\partial T} \mathbf{q}\cdot\mathbf{n}\, v \,\mathrm{d}\Gamma = -\int_T (f^{\mathcal{O}} - \Delta \psi_h)\, v \,\mathrm{d}\Omega \right.$$
$$\left. - \int_{\partial T} (\sigma_T \lambda_h^\psi + \nabla \psi_h \cdot \mathbf{n})\, v \,\mathrm{d}\Gamma \;\forall v \in \mathcal{H}^1(T) \right\},$$

in which we have again chosen $\bar{u} = u_h$ commensurate with our choice for the approximate multipliers. As the additional terms in the data of the dual feasibility constraint are just polynomial functions in the local finite element basis, there are no difficulties in choosing our dual approximation sets in this manner. The solvability of these subproblems is addressed by the following result.

LEMMA 3.3. *Suppose the forcing function $f|_T$ and output function $f^{\mathcal{O}}|_T$ are members of $\mathbb{P}^r(T)$, that λ_h^u satisfies* (3.6)*, and that λ_h^ψ satisfies* (3.7)*, then there exists at least one dual feasible function $\mathbf{q}_h^u$ that is a member of $\mathcal{Q}_h^u(T)$ and one dual feasible function $\mathbf{q}_h^\psi$ that is a member of $\mathcal{Q}_h^\psi(T)$ for $q \geq p$ and $q > r$.*

Proof. Applying Green's formula to the u_h Laplacian term in the constraint data for $\mathcal{Q}_h^u(T)$ of (3.17) and duplicating the proof of Lemma 2.3 with the resulting constraint data reveals the compatibility condition

$$\int_{\partial T} \sigma_T \lambda_h^u \,\mathrm{d}\Gamma = -\int_T f \,\mathrm{d}\Omega, \tag{3.18}$$

which is satisfied by our choice for λ_h^u as can be seen by choosing $\hat{v} = \text{const}$ on T in the equilibration condition (3.6). The same argument holds for the adjoint dual subproblem, yielding the analogous compatibility condition

$$\int_{\partial T} \sigma_T \lambda_h^\psi \,\mathrm{d}\Gamma = -\int_T f^{\mathcal{O}} \,\mathrm{d}\Omega \tag{3.19}$$

for $f^{\mathcal{O}}$ and λ_h^ψ. ∎

With the subproblem splitting just defined, the aggregated contributions to the upper and lower bounds become

$$\begin{aligned} s_h^{\pm} &= \mp \int_\Omega f \left(\frac{\kappa}{2} u_h \pm \psi_h\right) \mathrm{d}\Omega \pm \frac{1}{\kappa} J^c(\kappa \nabla u_h + \frac{\kappa}{2}\hat{\mathbf{q}}_h^u \pm \hat{\mathbf{q}}_h^\psi) \\ &= \mp \int_\Omega f \left(\frac{\kappa}{2} u_h \pm \psi_h\right) \mathrm{d}\Omega \pm \frac{\kappa}{2}\int_\Omega \nabla u_h \cdot \nabla u_h \,\mathrm{d}\Omega + \int_\Omega (\frac{\kappa}{2}\hat{\mathbf{q}}_h^u \pm \hat{\mathbf{q}}_h^\psi)\cdot \nabla u_h \,\mathrm{d}\Omega \\ &\quad + \frac{1}{2}\int_\Omega \hat{\mathbf{q}}_h^u \cdot \hat{\mathbf{q}}_h^\psi \,\mathrm{d}\Omega \pm \frac{\kappa}{4} J^c(\hat{\mathbf{q}}_h^u) \pm \frac{1}{\kappa} J^c(\hat{\mathbf{q}}_h^\psi) \\ &= -\int_\Omega f\, \psi_h \,\mathrm{d}\Omega + \frac{1}{2}\int_\Omega \hat{\mathbf{q}}_h^u \cdot \hat{\mathbf{q}}_h^\psi \,\mathrm{d}\Omega \pm \frac{\kappa}{4} J^c(\hat{\mathbf{q}}_h^u) \pm \frac{1}{\kappa} J^c(\hat{\mathbf{q}}_h^\psi), \end{aligned}$$

in which we have invoked (3.4) with $v = u_h$ and we have used orthogonality relationships analogous to that proved in Lemma 2.4 as well.

3.4. Output bound procedure. The introduction of the scaling parameter κ allows us to optimize the sharpness of the computed bounds in addition to providing dimensional consistency. From the previous section we have the expression for the upper and lower output bounds

$$s_h^{\pm} = \bar{s}_h \pm \kappa z_h^u \pm \frac{1}{\kappa} z_h^{\psi},$$

where

$$\bar{s}_h = \frac{1}{2}\int_\Omega \hat{\mathbf{q}}_h^u \cdot \hat{\mathbf{q}}_h^{\psi}\,\mathrm{d}\Omega - \int_\Omega f\,\psi_h\,\mathrm{d}\Omega, \qquad z_h^u = \frac{1}{4} J^c(\hat{\mathbf{q}}_h^u), \qquad z_h^{\psi} = J^c(\hat{\mathbf{q}}_h^{\psi}). \tag{3.20}$$

Maximizing the lower bound and minimizing the upper bound with respect to κ yield the optimal value $\kappa^2 = z_h^{\psi}/z_h^u$.

The complete method with optimal scaling for upper and lower bounds on linear functional outputs can now be written as three steps.

1. *Global approximation:* Find $u_h \in \mathcal{U}_h$ such that

$$\int_\Omega \nabla u_h \cdot \nabla v\,\mathrm{d}\Omega = \int_\Omega f\,v\,\mathrm{d}\Omega \quad \forall v \in \mathcal{U}_h, \tag{3.21}$$

and find $\psi_h \in \mathcal{U}_h$ such that

$$\int_\Omega \nabla v \cdot \nabla \psi_h\,\mathrm{d}\Omega = -\int_\Omega f^{\mathcal{O}}\,v\,\mathrm{d}\Omega \quad \forall v \in \mathcal{U}_h. \tag{3.22}$$

2. *Global equilibration:* Find $\lambda_h^u \in \Lambda_h$ such that

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T} \sigma_T\,\lambda_h^u\,\hat{v}\,\mathrm{d}\Gamma = \int_\Omega \nabla u_h \cdot \nabla \hat{v}\,\mathrm{d}\Omega - \int_\Omega f\,\hat{v}\,\mathrm{d}\Omega \quad \forall \hat{v} \in \hat{\mathcal{U}}_h, \tag{3.23}$$

and find $\lambda_h^{\psi} \in \Lambda_h$ such that

$$\sum_{T\in\mathcal{T}_h}\int_{\partial T} \sigma_T\,\lambda_h^{\psi}\,\hat{v}\,\mathrm{d}\Gamma = -\int_\Omega f\,\hat{v}\,\mathrm{d}\Omega - \int_\Omega \nabla \hat{v} \cdot \nabla \psi_h\,\mathrm{d}\Omega \quad \forall \hat{v} \in \hat{\mathcal{U}}_h. \tag{3.24}$$

3. *Local dual subproblems:* Find $\hat{\mathbf{q}}_h^u$ such that

$$\hat{\mathbf{q}}_h^u = \arg \inf_{\hat{\mathbf{q}}_h \in \hat{\mathcal{Q}}_h^u} J^c(\hat{\mathbf{q}}_h), \tag{3.25}$$

find $\hat{\mathbf{q}}_h^{\psi}$ such that

$$\hat{\mathbf{q}}_h^{\psi} = \arg \inf_{\hat{\mathbf{q}}_h \in \hat{\mathcal{Q}}_h^{\psi}} J^c(\hat{\mathbf{q}}_h), \tag{3.26}$$

and, from (3.20) and the optimal κ, calculate

$$s_h^{\pm} = \bar{s}_h \pm 2\sqrt{z_h^u z_h^{\psi}}. \tag{3.27}$$

The local dual subproblems for the output bounds can be solved in the same manner as the local energy dual subproblems. The important point being that once the finite element approximations u_h and ψ_h have been computed, the solutions can be equilibrated and quantitative bounds computed on the exact output to the infinite-dimensional continuum equation with asymptotically linear cost in the size of the finite element discretization and in parallel. In addition, the elemental contribution to the bound gap, $\frac{\kappa}{4} J_T^c(\mathbf{q}_h^u) + \frac{1}{\kappa} J_T^c(\mathbf{q}_h^{\psi})$, can serve as an informative mesh adaptivity indicator for controlling the error in the *output*, as was done in [15] for a two-level error bound method and in [3] for an asymptotic error estimation method.

3.4.1. Properties of the output bounds. The upper and lower bounding properties are direct consequences of the saddle point property of the relaxed constrained minimization reformulation (3.2) and the local dual property of Proposition 3.2. The following proposition addresses the accuracy of the computed bounds by showing that the bounds will converge at the optimal rate when both the primal and adjoint finite element approximations are in the asymptotic convergence regime.

PROPOSITION 3.4. *Suppose that u_h, ψ_h, λ_h^u, and λ_h^ψ are solutions of the above finite element approximation problems and equilibration problems, then*

$$\begin{aligned} s - s_h^- &\le C|u - u_h|_1|\psi - \psi_h|_1, \\ s_h^+ - s &\le C|u - u_h|_1|\psi - \psi_h|_1. \end{aligned} \tag{3.28}$$

Proof. Applying the definitions from the procedure, we know that the lower a posteriori bound, for instance, itself has the bound $s - s_h^- \le s_h^+ - s_h^- = 2\sqrt{z_h^u z_h^\psi}$. The arguments of Lemma 2.5 can be applied to the z_h^u and z_h^ψ factors to show that they are bounded by $C|u - u_h|_1^2$ and $C|\psi - \psi_h|_1^2$, respectively. ∎

4. Numerical results. We verify the method numerically for three cases: constant forcing on the unit square, linear forcing on the unit square, and zero forcing on an L-shaped domain with a corner singularity. Linear finite elements, $p = 1$, and quadratic subproblems, $q = 2$, are employed with the domain average output $s = \int_\Omega f^{\mathcal{O}} u \, \mathrm{d}\Omega$, where $f^{\mathcal{O}} = \text{const}$, for all cases.

All three cases have analytically exact solutions with which we are able to verify the method and calculate the effectivities of the bounds,

$$\theta^\pm = \frac{|s - s_h^\pm|}{|s - s_h|}, \tag{4.1}$$

which indicate the sharpness by comparing the error in the bounds to the error in the finite element approximation.

4.1. Uniformly forced square domain. The first case is a uniformly forced unit square domain with $f = f^{\mathcal{O}} = \sqrt{10}$. The analytical solution is given by

$$u(x,y) = \frac{16\sqrt{10}}{\pi^4} \sum_{\text{odd } i,j=1}^{\infty} \frac{(-1)^{(i+j)/2-1}}{ij(i^2+j^2)} \cos\left(i\frac{\pi}{2}x\right)\cos\left(j\frac{\pi}{2}y\right).$$

This case is special in that the forcing and output are identical and the boundary data is homogeneous, leading to primal and adjoint problem data which differ by only a sign. It is well known that for this special case, called compliance, the finite element approximation for the output is a lower bound. The numerical results given in Table 4.1 and Figure 4.1 demonstrate that our method, while more expensive, does no worse than the inherent bound for this special case. The results for both the finite element approximation and the output bounds asymptotically approach the optimal finite element convergence rate of $O(h^2)$. This example also evinces that the bound average, $\bar{s}_h$, can sometimes be a more accurate output approximation than that from the finite element approximation.

4.2. Linearly forced square domain. The second case is a linearly forced square domain with $f^{\mathcal{O}} = 1$, and the forcing and nonhomogeneous boundary conditions chosen to produce the exact solution

$$u(x,y) = \frac{3}{2}y^2(1-y) + 4xy.$$

TABLE 4.1

$\frac{1}{16}$	0.347	0.347	0.353	0.358	1.0	1.5

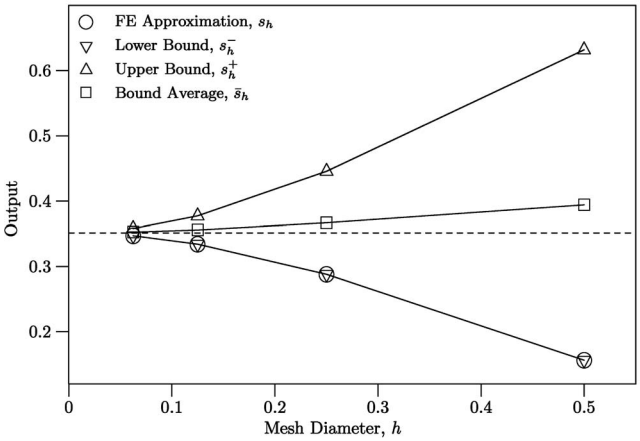

FIG. 4.1. *Uniformly forced square domain.*

As this test case is not a special case, the convergence histories of Table 4.2 and Figure 4.2 depict the more general situation in which none of the computed quantities coincide. Whereas in the first example we saw that the bound average can possibly be a more accurate output approximation than the finite element approximation, in this example we see that this is definitely not always true since the finite element approximation for the output is 0.5% better. As for the first example, the results for both the finite element approximation and the output bounds asymptotically approach the optimal finite element convergence rate of $O(h^2)$.

4.3. Unforced corner domain. Last, we consider the Laplace equation on a nonconvex domain with $f^{\mathcal{O}} = 1$. The domain is the standard L-shaped domain with a reentrant corner that results from removing the lower-right quadrant of the unit square. The Dirichlet boundary conditions were chosen to produce the solution

$$u(r, \phi) = r^{\frac{2}{3}} \sin \frac{2}{3}\phi,$$

where the distance from the corner point is $r(x, y) = \{(x - 1/2)^2 + (y - 1/2)^2\}^{\frac{1}{2}}$ and the angle from the upper surface of the corner is $\phi(x, y) = \arctan(\frac{y-1/2}{x-1/2})$.

In this example we demonstrate that the bounds are valid even for problems with singularities. As can be seen from Table 4.3 and Figure 4.3, the results for both the finite element approximation and the output bounds asymptotically approach the optimal finite element convergence rate of $O(h^{\frac{4}{3}})$ for elliptic problems posed on a domain with right-angled reentrant corner [19]. Once again we see that the bound average has the potential to be a better output approximation than the finite element method.

FIG. 4.4. *Unforced corner domain adaptive solutions, local indicators and meshes.*

We close by demonstrating the use of the previously introduced elemental contributions to the bound gap, $\Delta_T \equiv \frac{\kappa}{4} J_T^c(\mathbf{q}_h^u) + \frac{1}{\kappa} J_T^c(\mathbf{q}_h^\psi)$, as a mesh adaptivity indicator for controlling the error in the output. Figure 4.4 displays the solution field, adjoint field, intermediate local error indicators, and final adaptive mesh that results from preferentially refining elements with relatively high contributions to the bound gap. We initiated the adaptive process on a uniform mesh of 6 elements and adaptively refined until the output uncertainty was less than 0.005, that is, until we had a certificate of precision at least as good as $s = s_h \pm 0.005$. The adaptive refinement process met this target by producing the certificate of precision $s = 0.791 \pm 0.00456$ using 1167 elements. Achieving the same certainty with uniform refinement requires 6144 elements.

Acknowledgments. We would like to acknowledge our long-standing and fecund collaboration with Professor A. T. Patera at MIT. We would also like to thank Nuria Pares-Marine for her insightful comments on the convergence analysis provided while revising the manuscript.

A COMPARISON OF DEFLATION AND COARSE GRID CORRECTION APPLIED TO POROUS MEDIA FLOW*

R. NABBEN† AND C. VUIK‡

Abstract. In this paper we compare various preconditioners for the numerical solution of partial differential equations. We compare a coarse grid correction preconditioner used in domain decomposition methods with a so-called deflation preconditioner. We prove that the effective condition number of the deflated preconditioned system is always, for all deflation vectors and all restrictions and prolongations, below the condition number of the system preconditioned by the coarse grid correction. This implies that the conjugate gradient method applied to the deflated preconditioned system is expected always to converge faster than the conjugate gradient method applied to the system preconditioned by the coarse grid correction. Numerical results for porous media flows emphasize the theoretical results.

Key words. deflation, coarse grid correction, preconditioners, conjugate gradients, porous media flow, scalable parallel preconditioner

1. Introduction.

It is well known that the convergence rate of the conjugate gradient (CG) method is bounded as a function of the condition number of the system matrix to which it is applied. Let $A \in \mathbb{R}^{n\times n}$ be symmetric positive definite. We assume that the vector $b \in \mathbb{R}^n$ represents a discrete function on a grid Ω and that we are searching for the vector $x \in \mathbb{R}^n$ on Ω which solves the linear system

$$Ax = b.$$

Such systems are encountered, for example, when a finite volume/difference/element method is used to discretize an elliptic PDE defined on the continuous analogue of Ω.

Let us denote the ith eigenvalue in nondecreasing order by $\lambda_i(A)$ or simply by λ_i when it is clear to which matrix we are referring. After k iterations of the CG method, the error is bounded by (cf. [9, Thm. 10.2.6])

$$\|x - x_k\|_A \leq 2\,\|x - x_0\|_A \left(\frac{\sqrt{\kappa}-1}{\sqrt{\kappa}+1}\right)^k, \tag{1.1}$$

where $\kappa = \kappa(A) = \lambda_n/\lambda_1$ is the spectral condition number of A and the A-norm of x is given by $\|x\|_A = (x^T Ax)^{1/2}$. The convergence may be significantly faster if the eigenvalues of A are clustered (see [24]).

If the condition number of A is large it is advisable to solve, instead, a preconditioned system $M^{-1}Ax = M^{-1}b$, where the symmetric positive definite preconditioner M is chosen such that $M^{-1}A$ has a more clustered spectrum or a smaller condition number than that of A. Furthermore, M must be cheap to solve relative to the

improvement it provides in convergence rate. A final desirable property in a preconditioner is that it should parallelize well, especially on distributed memory computers. Probably one of the most effective preconditioning strategies in common use is to take $M = LL^T$ to be an incomplete Cholesky (IC) factorization of A (see [16]). We denote the preconditioned conjugate gradient method as PCG.

With respect to the known preconditioners, at least two problems remain:

- If there are large jumps in the coefficients of the discretized PDE, the convergence of PCG becomes very slow, and
- if a block preconditioner is used in a domain decomposition algorithm the condition number of the preconditioned matrix deteriorates if the number of blocks increases.

Both problems can be solved by a deflation technique or a suitable coarse grid correction. In this section we describe both methods, which are compared in the next sections. To describe the deflation method we define the projection P_D by

$$P_D = I - AZ(Z^T AZ)^{-1}Z^T, \quad Z \in \mathbb{R}^{n\times r}, \tag{1.2}$$

where the column space of Z is the deflation subspace, i.e., the space to be projected out of the residual, and I is the identity matrix of appropriate size. We assume that $r \ll n$ and that Z has rank r. Under this assumption $E \equiv Z^T AZ$ may be easily computed and factored and is symmetric positive definite. Since $x = (I - P_D^T)x + P_D^T x$ and because

$$(I - P_D^T)x = Z(Z^T AZ)^{-1}Z^T Ax = ZE^{-1}Z^T b \tag{1.3}$$

can be immediately computed, we only need to compute $P_D^T x$. In light of the identity $AP_D^T = P_D A$, we can solve the deflated system

$$P_D A\tilde{x} = P_D b \tag{1.4}$$

for $\tilde{x}$ using the CG method, premultiply this by P_D^T, and add it to (1.3).

Obviously (1.4) is singular. What consequences does the singularity of (1.4) imply for the CG method? Kaasschieter [12] notes that a positive semidefinite system can be solved as long as the right-hand side is consistent (i.e., as long as $b = Ax$ for some x). This is certainly true for (1.4), where the same projection is applied to both sides of the nonsingular system. Furthermore, he notes (with reference to [24]) that because the null space never enters the iteration, the corresponding zero eigenvalues do not influence the convergence. Motivated by this fact, we define the *effective condition number* of a positive semidefinite matrix $C \in \mathbb{R}^{n\times n}$ with r zero eigenvalues to be the ratio of its largest to smallest *positive* eigenvalues:

$$\kappa_{\text{eff}}(C) = \frac{\lambda_n}{\lambda_{r+1}}.$$

It is possible to combine both a standard preconditioning and preconditioning by deflation (for details, see [8]). The convergence is then described by the effective condition number of $M^{-1}P_D A$.

The deflation technique has been exploited by several authors. For nonsymmetric systems, approximate eigenvectors can be extracted from the Krylov subspace produced by GMRES. Morgan [17] uses this approach to improve the convergence after a restart. In this case, deflation is not applied as a preconditioner, but the deflation

vectors are augmented with the Krylov subspace and the minimization property of GMRES ensures that the deflation subspace is projected out of the residual (for related references, we refer the reader to [8] and [7]). A comparable approach for the CG method is described in [22]. Mansfield [14] shows how Schur complement-type domain decomposition methods can be seen as a series of deflations. Nicolaides [19] chooses Z to be a piecewise constant interpolation from a set of r subdomains and points out that deflation might be effectively used with a conventional preconditioner. Mansfield [15] uses the same "subdomain deflation" in combination with damped Jacobi smoothing, obtaining a preconditioner which is related to the two-grid method. In [13] Kolotilina uses a twofold deflation technique for simultaneously deflating the r largest and the r smallest eigenvalues using an appropriate deflating subspace of dimension r. Other authors have attempted to choose a subspace a priori that effectively represents the slowest modes. In [27] deflation is used to remove a few stubborn but *known* modes from the spectrum. This method is used in [3] to solve electromagnetic problems with large jumps in the coefficients. Thereafter this method has been generalized to other choices of the deflation vectors (see [26, 28]). Finally, an analysis of the effective condition number and a parallel implementation is given in [8, 25].

We compare the deflation preconditioner with a well-known coarse grid correction preconditioner of the form

$$P_C = I + ZE^{-1}Z^T \tag{1.5}$$

and in the preconditioned case

$$P_{CM^{-1}} = M^{-1} + ZE^{-1}Z^T. \tag{1.6}$$

In the multigrid or domain decomposition language the matrices Z and Z^T are known as restriction and prolongation or interpolation operator. Moreover, the matrix $E = Z^T AZ$ is the Galerkin operator.

The above coarse grid correction preconditioner belongs to the class of additive Schwarz preconditioner. It is called the two-level additive Schwarz preconditioner. If used in domain decomposition methods, typically M^{-1} is the sum of the local (exact or inexact) solves in each domain. To speed up convergence a coarse grid correction $ZE^{-1}Z^T$ is added.

These methods are introduced by Bramble, Pasciak, and Schatz [2], Dryja and Widlund [5, 6], and Dryja [4]. They show under mild conditions that the convergence rate of the PCG method is independent of the grid sizes.

For more details about this preconditioner we refer the reader to the books of Quarteroni and Valli [21] and Smith, Bjørstad, and Gropp [23]. A more abstract analysis of this preconditioner is given by Padiy, Axelsson, and Polman [20]. To make the condition number of $P_{CM^{-1}}A$ smaller, Padiy, Axelsson, and Polman used a parameter $\sigma > 0$ and considered

$$P_C = I + \sigma ZE^{-1}Z^T \tag{1.7}$$

and

$$P_{CM^{-1}} = M^{-1} + \sigma ZE^{-1}Z^T. \tag{1.8}$$

If $M = I$, Z consists of eigenvectors, and λ_{max} is known, then a good choice is $\sigma = \lambda_{max}$, which implies that $\kappa(P_C A) \leq \frac{2\lambda_{max}}{\lambda_{r+1}}$ (see [20]). If $M \neq I$ and/or Z consists of general vectors, and λ_{max} is not known, it is not clear how to choose σ.

More abstract results about Schwarz methods applied to nonsymmetric problems are given by Benzi et al. [1] and Nabben [18].

In this paper we prove that the effective condition number of the deflated preconditioned system $M^{-1}P_DA$ is always below the condition number of the system preconditioned by the coarse grid correction $P_{CM^{-1}}A$. This implies that for all matrices $Z \in \mathbb{R}^{n\times r}$ and all positive definite preconditioners M^{-1} the CG method applied to the deflated preconditioned system is expected always to converge faster than the CG method applied to the system preconditioned by the coarse grid correction. These results are stated in section 2. In section 3 we compare other properties of the deflation and coarse grid preconditioner. These properties are scaling, approximation of E^{-1}, and an estimate of the smallest eigenvalue. Section 4 contains our numerical results for porous media flows and parallel problems.

2. Spectral properties. In this section we compare the effective condition number for the deflation and coarse grid correction preconditioned matrices. In section 2.1 we give some definitions and preliminary results. Thereafter a comparison is made if the projection vectors are equal to eigenvectors in section 2.2 and for general projection vectors in section 2.3.

2.1. Notations and preliminary results. In the following we denote by $\lambda_i(M)$ the eigenvalues of a matrix M. If the eigenvalues are real, the $\lambda_i(M)$'s are ordered increasingly.

For two Hermitian $n \times n$ matrices A and B we write $A \succeq B$, if $A - B$ is positive semidefinite.

Next we mention well-known properties of the eigenvalues of Hermitian matrices.

LEMMA 2.1. *Let $A, B \in \mathbb{C}^{n\times n}$ be Hermitian. For each $k = 1, 2, \ldots, n$ we have*

$$\lambda_k(A) + \lambda_1(B) \leq \lambda_k(A + B) \leq \lambda_k(A) + \lambda_n(B).$$

From the above lemma we easily obtain the next lemma.

LEMMA 2.2. *If $A, B \in \mathbb{C}^{n\times n}$ are positive semidefinite with $A \succeq B$, then $\lambda_i(A) \geq \lambda_i(B)$.*

Moreover, we will use the following lemma.

LEMMA 2.3. *Let $A, B \in \mathbb{C}^{n\times n}$ be Hermitian, and suppose that B has rank at most r. Then*

- $\lambda_k(A + B) \leq \lambda_{k+r}(A), \quad k = 1, 2, \cdots n - r,$
- $\lambda_k(A) \leq \lambda_{k+r}(A + B), \quad k = 1, 2, \cdots n - r.$

Lemmas 2.1, 2.2, and 2.3 can be found, e.g., as Theorem 4.3.1, Corollary 7.7.4., and Theorem 4.3.6, respectively, in [10].

2.2. Projection vectors chosen as eigenvectors. In this section we compare the effective condition number of P_DA and P_CA if the projection vectors are equal to eigenvectors of A.

DEFINITION 2.4. *Choose the eigenvectors v_k of A such that $v_k^T v_j = \delta_{kj}$, and define $Z = [v_1 \ldots v_r]$.*

THEOREM 2.5. *Using Z as given in Definition 2.4, the spectra of P_DA and P_CA given in (1.2) and (1.7) are*

$$\text{spectrum}(P_DA) = \{0, \ldots, 0, \lambda_{r+1}, \ldots, \lambda_n\} \text{ and}$$

$$\text{spectrum}(P_CA) = \{\sigma + \lambda_1, \ldots, \sigma + \lambda_r, \lambda_{r+1}, \ldots, \lambda_n\}.$$

Proof. For this choice of Z we have that

$$E = Z^T AZ = \operatorname{diag}(\lambda_1, \ldots, \lambda_r). \tag{2.1}$$

To prove the first part we note that (2.1) implies $P_D = I - AZE^{-1}Z^T = I - ZZ^T$. Consider $P_D A v_k = (I - ZZ^T)\lambda_k v_k$ for $k = 1, \ldots, n$. Since $ZZ^T v_k = v_k$, for $k = 1, \ldots, r$ and $ZZ^T v_k = 0$ for $k = r+1, \ldots, n$ it is easy to show that

$$P_D A v_k = 0, \text{ for } k = 1, \ldots, r, \text{ and } P_D A v_k = \lambda_k v_k, \text{ for } k = r+1, \ldots, n,$$

which proves the first part.

Second, we consider $P_C A v_k$. For $k = 1, \ldots, r$ we obtain

$$P_C A v_k = \left(I + \sigma Z \operatorname{diag}\left(\frac{1}{\lambda_1}, \ldots, \frac{1}{\lambda_r} \right) Z^T \right) \lambda_k v_k = (\sigma + \lambda_k) v_k,$$

whereas for $k = r+1, \ldots, n$ it appears that

$$P_C A v_k = \left(I + \sigma Z \operatorname{diag}\left(\frac{1}{\lambda_1}, \ldots, \frac{1}{\lambda_r} \right) Z^T \right) \lambda_k v_k = \lambda_k v_k$$

since $Z^T v_k = 0$ for $k = r+1, \ldots, n$. This proves the second part (cf. Theorem 2.6 in [20]). ∎

In order to compare both approaches we note that

$$\kappa_{eff}(P_D A) = \frac{\lambda_n}{\lambda_{r+1}} \tag{2.2}$$

and

$$\kappa(P_C A) = \frac{\max\{\sigma + \lambda_r, \lambda_n\}}{\min\{\sigma + \lambda_1, \lambda_{r+1}\}}. \tag{2.3}$$

From (2.2) and (2.3) it follows that $\kappa(P_C A) \geq \kappa_{eff}(P_D A)$, so the convergence bound based on the effective condition number implies that deflated CG converges faster than CG combined with coarse grid correction if both methods use the eigenvectors corresponding to the r smallest eigenvalues as projection vectors.

2.3. Projection vectors chosen as general vectors. In the last section we showed that the deflation technique is better than a coarse grid correction, if eigenvectors are used. However, computing the r smallest eigenvalues is, in general, very expensive. Moreover, in multigrid methods and domain decomposition methods special interpolation and prolongation matrices are used to obtain grid independent convergence rates. So a comparison only for eigenvectors is not enough. But in this section we generalize the results of section 2.2. We prove that the effective condition number of the deflated preconditioned system is always, for all matrices $Z \in \mathbb{R}^{n \times r}$, below the condition number of the system preconditioned by the coarse grid correction.

THEOREM 2.6. *Let $A \in \mathbb{R}^{n \times n}$ be symmetric positive definite. Let $Z \in \mathbb{R}^{n \times r}$ with* rank $Z = r$. *Then the preconditioner defined in* (1.2) *and* (1.7) *satisfies*

$$\lambda_1(P_D A) = \cdots = \lambda_r(P_D A) = 0, \tag{2.4}$$

$$\lambda_n(P_D A) \leq \lambda_n(P_C A), \tag{2.5}$$

$$\lambda_{r+1}(P_D A) \geq \lambda_1(P_C A). \tag{2.6}$$

Proof. Obviously all eigenvalues of $P_C A$ are real and positive. By Lemma 2.1 of [8], $P_D A$ is positive semidefinite. Thus, all eigenvalues of $P_D A$ are real and nonnegative. Since $P_D AZ = 0$, statement (2.4) holds.

We obtain

$$A^{\frac{1}{2}} P_C A^{\frac{1}{2}} - P_D A = AZE^{-1}Z^T A + \sigma A^{\frac{1}{2}} ZE^{-1}Z^T A^{\frac{1}{2}}.$$

The right-hand side is positive semidefinite. Thus, we have with Lemma 2.2 that

$$\lambda_i(P_C A) = \lambda_i(A^{\frac{1}{2}} P_C A^{\frac{1}{2}}) \geq \lambda_i(P_D A).$$

Hence, (2.5) holds. Next consider

$$\begin{aligned} P_C A P_C - P_D A &= A + \sigma ZE^{-1}Z^T A + \sigma AZE^{-1}Z^T + \sigma^2 ZE^{-1}Z^T AZE^{-1}Z^T \\ &\quad -A + AZE^{-1}Z^T A \\ &= \sigma ZE^{-1}Z^T A + \sigma AZE^{-1}Z^T + \sigma^2 ZE^{-1}Z^T + AZE^{-1}Z^T A \\ &= (A + \sigma I)ZE^{-1}Z^T(A + \sigma I). \end{aligned}$$

Thus, $P_C A P_C - P_D A$ is symmetric and of rank r. Using Lemma 2.3 we obtain

$$\lambda_{r+1}(P_D A) \geq \lambda_1(P_C A P_C) = \lambda_1(P_C^2 A).$$

But since $P_C - I$ is positive semidefinite, $P_C^2 - P_C$ and $A^{\frac{1}{2}} P_C^2 A^{\frac{1}{2}} - A^{\frac{1}{2}} P_C A^{\frac{1}{2}}$ are positive semidefinite also. Hence,

$$\lambda_i(P_C^2 A) = \lambda_i(A^{\frac{1}{2}} P_C^2 A^{\frac{1}{2}}) \geq \lambda_i(A^{\frac{1}{2}} P_C A^{\frac{1}{2}}) = \lambda_i(P_C A).$$

Thus,

$$\lambda_{r+1}(P_D A) \geq \lambda_1(P_C^2 A) \geq \lambda_1(P_C A). \qquad \square$$

It follows from Theorem 2.6 that

$$\kappa(P_C A) \geq \kappa_{eff}(P_D A),$$

so the convergence bound based on the effective condition number implies that deflated CG converges faster than CG combined with coarse grid correction for arbitrary matrices $Z \in \mathbb{R}^{n \times r}$.

In Theorem 2.11 we will extend this result to the preconditioned versions of the deflation and coarse grid correction preconditioners.

Before that, we will show how the deflated preconditioner behaves if we increase the number of deflation vectors. In detail we will show that the effective condition number decreases if we use a matrix Z_2 in (1.2) satisfying $ImZ \subseteq ImZ_2$ rather than Z. To do so we need several lemmas.

The first lemma is probably well known, but for completeness we give the proof here.

LEMMA 2.7. *Let $A \in \mathbb{R}^{n \times n}$ be nonsingular and be partitioned as*

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix},$$

where $A_{11} \in M_r(R)$ and $A_{22} \in M_{n-r}(R)$. Assume that A_{11} is nonsingular. Define

$$\tilde{A}_{11}^{-1} := \begin{bmatrix} A_{11}^{-1} & 0 \\ 0 & 0 \end{bmatrix}.$$

Then, rank $(A^{-1} - \tilde{A}_{11}^{-1}) = n - r$.

Proof. The inverse of A is given by

$$A^{-1} = \begin{bmatrix} A_{11}^{-1} + A_{11}^{-1}A_{12}S^{-1}A_{21}A_{11}^{-1} & -A_{11}^{-1}A_{12}S^{-1} \\ -S^{-1}A_{21}A_{11}^{-1} & S^{-1} \end{bmatrix},$$

where $S = A_{22} - A_{21}A_{11}^{-1}A_{12}$. Hence

$$\begin{aligned} A^{-1} - \tilde{A}_{11}^{-1} &= \begin{bmatrix} A_{11}^{-1}A_{12}S^{-1}A_{21}A_{11}^{-1} & -A_{11}^{-1}A_{12}S^{-1} \\ -S^{-1}A_{21}A_{11}^{-1} & S^{-1} \end{bmatrix} \\ &= \begin{bmatrix} A_{11}^{-1}A_{12}S^{-1} \\ -S^{-1} \end{bmatrix} \left[A_{21}A_{11}^{-1}, -I\right]. \end{aligned}$$

Since S and the $n-r \times n-r$ identity matrix I have rank $n-r$, we get rank $(A^{-1} - \tilde{A}_{11}^{-1}) = n - r$. ∎

In the next lemma we compare the preconditioned matrices if a different number of deflation vectors is used.

LEMMA 2.8. *Let $A \in \mathbb{R}^{n\times n}$ be symmetric positive definite. Let $Z_1 \in \mathbb{R}^{n\times r}$ and $Z_2 \in \mathbb{R}^{n\times s}$ with* rank $Z_1 = r$ *and* rank $Z_2 = s$. *Define $E_1 := Z_1^T A Z_1$ and $E_2 := Z_2^T A Z_2$. If $ImZ_1 \subseteq ImZ_2$, then*

$$(I - AZ_1E_1^{-1}Z_1^T)A \succeq (I - AZ_2E_2^{-1}Z_2^T)A.$$

Proof. It suffices to prove that

$$Z_2E_2^{-1}Z_2^T \succeq Z_1E_1^{-1}Z_1^T.$$

Since $ImZ_1 \subseteq ImZ_2$, there exists a matrix $T \in M_{s\times r}(R)$ such that

$$Z_1 = Z_2T.$$

Therefore,

$$\begin{aligned} Z_2E_2^{-1}Z_2^T - Z_1E_1^{-1}Z_1^T &= Z_2(E_2^{-1} - TE_1^{-1}T^T)Z_2^T \\ &= Z_2E_2^{-\frac{1}{2}}(I - E_2^{\frac{1}{2}}TE_1^{-1}T^TE_2^{\frac{1}{2}})E_2^{-\frac{1}{2}}Z_2^T. \end{aligned}$$

Moreover, we have

$$\begin{aligned} (E_2^{\frac{1}{2}}TE_1^{-1}T^TE_2^{\frac{1}{2}})^2 &= E_2^{\frac{1}{2}}TE_1^{-1}T^TE_2TE_1^{-1}T^TE_2^{\frac{1}{2}} \\ &= E_2^{\frac{1}{2}}TE_1^{-1}T^TZ_2^TAZ_2TE_1^{-1}T^TE_2^{\frac{1}{2}} \\ &= E_2^{\frac{1}{2}}TE_1^{-1}Z_1^TAZ_1E_1^{-1}T^TE_2^{\frac{1}{2}} \\ &= E_2^{\frac{1}{2}}TE_1^{-1}E_1E_1^{-1}T^TE_2^{\frac{1}{2}} \\ &= E_2^{\frac{1}{2}}TE_1^{-1}T^TE_2^{\frac{1}{2}}. \end{aligned}$$

Hence, $E_2^{\frac{1}{2}}TE_1^{-1}T^TE_2^{\frac{1}{2}}$ is an orthogonal projection. Thus $E_2^{\frac{1}{2}}TE_1^{-1}T^TE_2^{\frac{1}{2}}$ has only the eigenvalues 0 and 1. Hence, $I - E_2^{\frac{1}{2}}TE_1^{-1}T^TE_2^{\frac{1}{2}}$ is positive semidefinite. Therefore,

$$Z_2E_2^{-1}Z_2^T \succeq Z_1E_1^{-1}Z_1^T.$$ ∎

In the next lemma we show that $P_{D_1}A = P_{D_2}A$, if $ImZ_1 = ImZ_2$.

LEMMA 2.9. *Let $A \in \mathbb{R}^{n\times n}$ be symmetric positive definite. Let $Z_1 \in \mathbb{R}^{n\times r}$ and $Z_2 \in \mathbb{R}^{n\times r}$ with* $\text{rank}Z_1 = \text{rank}Z_2 = r$. *Define $E_1 := Z_1^T AZ_1$ and $E_2 := Z_2^T AZ_2$. If $ImZ_1 = ImZ_2$, then*

$$(I - AZ_1E_1^{-1}Z_1^T)A = (I - AZ_2E_2^{-1}Z_2^T)A.$$

Proof. We can follow the proof of Lemma 2.8. Since $ImZ_1 = ImZ_2$, the matrix T is nonsingular. Hence,

$$\begin{aligned} Z_2E_2^{-1}Z_2^T - Z_1E_1^{-1}Z_1^T &= Z_2(E_2^{-1} - TE_1^{-1}T^T)Z_2^T \\ &= Z_2E_2^{-\frac{1}{2}}(I - E_2^{\frac{1}{2}}TE_1^{-1}T^TE_2^{\frac{1}{2}})E_2^{-\frac{1}{2}}Z_2^T. \\ &= Z_2E_2^{-\frac{1}{2}}(I - E_2^{\frac{1}{2}}T(T^TE_2T)^{-1}T^TE_2^{\frac{1}{2}})E_2^{-\frac{1}{2}}Z_2^T \\ &= Z_2E_2^{-\frac{1}{2}}(I - E_2^{\frac{1}{2}}TT^{-1}E_2^{-1}T^{-T}T^TE_2^{\frac{1}{2}})E_2^{-\frac{1}{2}}Z_2^T \\ &= 0. \qquad \square \end{aligned}$$

Using the above lemmas, we can prove the following theorem.

THEOREM 2.10. *Let $A \in \mathbb{R}^{n\times n}$ be symmetric positive definite. Let $Z_1 \in \mathbb{R}^{n\times r}$ and $Z_2 \in \mathbb{R}^{n\times s}$ with* $\text{rank}Z_1 = r$ *and* $\text{rank}Z_2 = s$. *Let $E_1 := Z_1^T AZ_1$ and $E_2 := Z_2^T AZ_2$. If $ImZ_1 \subseteq ImZ_2$, then*

$$\lambda_n((I - AZ_1E_1^{-1}Z_1^T)A) \geq \lambda_n((I - AZ_2E_2^{-1}Z_2^T)A), \tag{2.7}$$

$$\lambda_{r+1}((I - AZ_1E_1^{-1}Z_1^T)A) \leq \lambda_{s+1}((I - AZ_2E_2^{-1}Z_2^T)A). \tag{2.8}$$

Proof. With Lemmas 2.2 and 2.8 we obtain inequality (2.7).

Next, we will prove (2.8). Observe that $Z_1E_1^{-1}Z_1^T$ and $Z_2E_2^{-1}Z_2^T$ are invariant under permutations of the columns of Z_1 and Z_2, respectively.

Thus, using Lemma 2.9, we can assume without loss of generality that $Z_2 = [Z_1, D]$ with $D \in \mathbb{R}^{n\times s-r}$.

Moreover, define the $s \times s$ matrix

$$\tilde{E}_1^{-1} = \begin{bmatrix} E_1^{-1} & 0 \\ 0 & 0 \end{bmatrix}.$$

Obviously, we then obtain

$$Z_1E_1^{-1}Z_1^T = Z_2\tilde{E}_1^{-1}Z_2^T.$$

Thus,

$$\begin{aligned} (I - AZ_2E_2^{-1}Z_2^T)A - (I - AZ_1E_1^{-1}Z_1^T)A &= A(Z_1E_1^{-1}Z_1^T - Z_2E_2^{-1}Z_2^T)A \\ &= A(Z_2\tilde{E}_1^{-1}Z_2 - Z_2E_2^{-1}Z_2^T)A \\ &= AZ_2(\tilde{E}_1^{-1} - E_2^{-1})Z_2^TA. \end{aligned}$$

But since E_1 is the leading principal $r \times r$ submatrix of E_2, we can apply Lemma 2.7. Thus $(I - AZ_2E_2^{-1}Z_2^T)A - (I - AZ_1E_1^{-1}Z_1^T)A$ is of rank $s - r$. Hence, with Lemma 2.3,

$$\lambda_{r+1}((I - AZ_1E_1^{-1}Z_1^T)A) \leq \lambda_{s+1}((I - AZ_2E_2^{-1}Z_2^T)A). \qquad \square$$

Theorem 2.10 states that the effective condition number decreases if we increase the number of deflation vectors. However, the dimension of the system Z^TAZ which has to be solved increases also.

Next, we include an additional symmetric positive definite preconditioner M^{-1}. Then we consider the coarse grid preconditioner

$$P_{CM^{-1}} := M^{-1} + \sigma ZE^{-1}Z^T. \tag{2.9}$$

This type of preconditioner includes many well-known preconditioners. It belongs to the class of additive Schwarz preconditioners and is called the two-level additive Schwarz preconditioner. If used in domain decomposition methods, typically M^{-1} is the sum of the local (exact or inexact) solves in each domain. To speed up convergence a coarse grid correction $ZE^{-1}Z^T$ is added. Notice that the Bramble–Pasciak–Schatz (BPS) preconditioner introduced in [2] and by Dryja and Widlund [5, 6] and Dryja [4] are of the same type. They show under mild conditions that the convergence rate of the PCG method is independent of the grid sizes.

We compare the preconditioner (2.9) with the corresponding deflated preconditioner

$$M^{-1}P_D. \tag{2.10}$$

We obtain the following theorem.

THEOREM 2.11. *Let $A \in \mathbb{R}^{n\times n}$ and $M \in \mathbb{R}^{n\times n}$ be symmetric positive definite. Let $Z \in \mathbb{R}^{n\times r}$ with* $\mathrm{rank}Z = r$. *Then*

$$\lambda_n(M^{-1}P_DA) \le \lambda_n(P_{CM^{-1}}A), \tag{2.11}$$

$$\lambda_{r+1}(M^{-1}P_DA) \ge \lambda_1(P_{CM^{-1}}A). \tag{2.12}$$

Proof. First observe that Theorem 2.6 still holds if we replace A everywhere by $L^{-1}AL^{-T}$ with an arbitrary nonsingular matrix L. Here, we will consider $M^{-\frac{1}{2}}AM^{-\frac{1}{2}}$. The idea is to transform P_D and P_C to this form. We start with

$$M^{-1}P_DA = M^{-1}(A - AZE^{-1}Z^TA).$$

The eigenvalues of this matrix are the same as the eigenvalues of

$$M^{-\frac{1}{2}}P_DAM^{-\frac{1}{2}} = M^{-\frac{1}{2}}(A - AZE^{-1}Z^TA)M^{-\frac{1}{2}}.$$

Define the matrix G such that $G = M^{\frac{1}{2}}Z$ and thus $Z = M^{-\frac{1}{2}}G$. Substituting this in the previous matrix leads to $E = Z^TAZ = G^TM^{-\frac{1}{2}}AM^{-\frac{1}{2}}G$ and

$$\begin{aligned} M^{-\frac{1}{2}}P_DAM^{-\frac{1}{2}} &= M^{-\frac{1}{2}}(A - AM^{-\frac{1}{2}}GE^{-1}G^TM^{-\frac{1}{2}}A)M^{-\frac{1}{2}} \\ &= (I - M^{-\frac{1}{2}}AM^{-\frac{1}{2}}GE^{-1}G^T)M^{-\frac{1}{2}}AM^{-\frac{1}{2}}, \end{aligned}$$

which is in the required form.

In the same way we can transform $P_{CM^{-1}}A = (M^{-1} + \sigma ZE^{-1}Z^T)A$ to

$$P_{CM^{-1}}A = M^{-1}A + \sigma M^{-\frac{1}{2}}GE^{-1}G^TM^{-\frac{1}{2}}A,$$

which has the same eigenvalues as

$$M^{-\frac{1}{2}}AM^{-\frac{1}{2}} + \sigma GE^{-1}G^TM^{-\frac{1}{2}}AM^{-\frac{1}{2}} = (I + \sigma GE^{-1}G^T)M^{-\frac{1}{2}}AM^{-\frac{1}{2}},$$

which is also in the required form.

Thus, Theorem 2.6 gives the desired result. ∎

For the case $L^{-1}AL^{-T}$ the same result can be proved if one chooses $G = L^T Z$.

Theorem 2.11 describes the most general case. Arbitrary vectors or matrices $Z \in \mathbb{R}^{n\times r}$ combined with arbitrary preconditioners are considered. The effective condition number of the deflated CG method is always below the condition number of the CG method preconditioned by the coarse grid correction. Thus, the interpolation or prolongation matrices Z used, for example, in the BPS method give a better preconditioner if used in a deflation technique.

At the end of this section we generalize Theorem 2.10.

THEOREM 2.12. *Let $A, M \in \mathbb{R}^{n\times n}$ be symmetric positive definite. Let $Z_1 \in \mathbb{R}^{n\times r}$ and $Z_2 \in \mathbb{R}^{n\times s}$ with* $\text{rank}Z_1 = r$ *and* $\text{rank}Z_2 = s$. *Let $E_1 := Z_1^T A Z_1$ and $E_2 := Z_2^T A Z_2$. If $ImZ_1 \subseteq ImZ_2$, then*

$$\lambda_n(M^{-1}(I - AZ_1E_1^{-1}Z_1^T)A) \geq \lambda_n(M^{-1}(I - AZ_2E_2^{-1}Z_2^T)A), \tag{2.13}$$

$$\lambda_{r+1}(M^{-1}(I - AZ_1E_1^{-1}Z_1^T)A) \leq \lambda_{s+1}(M^{-1}(I - AZ_2E_2^{-1}Z_2^T)A). \tag{2.14}$$

Proof. The proof is almost the same as the proof of Theorem 2.10.

3. Other properties of deflation and coarse grid correction. In this section we compare other properties of deflation and coarse grid correction. These properties are scaling, inaccurate solution, and an estimate of the smallest eigenvalue.

Scaling. Note that $P_D A$ is scaling invariant, whereas $P_C A$ is not scaling invariant. This means that if deflation is applied to a system $\gamma Ax = \gamma b$, the effective condition number of $P_{D\gamma A}\gamma A = (I - \gamma AZ(Z^T\gamma AZ)^{-1}Z^T)\gamma A$ is independent of the scalar γ, i.e.,

$$\kappa_{eff}(P_{D\gamma A}\gamma A) = \frac{\gamma\lambda_n(P_{DA}A)}{\gamma\lambda_{r+1}(P_{DA}A)} = \kappa_{eff}(P_{DA}A).$$

Whereas the condition number of $P_C\gamma A$ depends on the choice of γ,

$$\kappa(P_{C\gamma A}\gamma A) \neq \kappa(P_{CA}A).$$

Inaccurate solution. If the dimension matrix E becomes large (i.e., many projection vectors are used), it seems to be good to compute E^{-1} approximately (by an iterative method or by doing the procedure recursively). It appears that the coarse grid correction operator is insensitive to the accuracy of the approximation of E^{-1}, while the deflation is sensitive to it. A proof of this property if the projection vectors are eigenvectors is given in the next lemma.

LEMMA 3.1. *Use Z as given in Definition* 2.4*, and assume that*

$$\tilde{E}^{-1} = \text{diag}\left(\frac{1}{\lambda_1}(1-\epsilon_1), \ldots, \frac{1}{\lambda_r}(1-\epsilon_r)\right)$$

is an approximation of E^{-1}, where $|\epsilon_i|$ is small. The spectra of $\tilde{P}_D A$ and $\tilde{P}_C A$ given in (1.2) *and* (1.5)*, where E^{-1} is replaced by $\tilde{E}^{-1}$, are*

$$\text{spectrum}(\tilde{P}_D A) = \{\lambda_1\epsilon_1, \ldots, \lambda_r\epsilon_r, \lambda_{r+1}, \ldots, \lambda_n\} \text{ and}$$

$$\text{spectrum}(\tilde{P}_C A) = \{\lambda_1 + \sigma(1-\epsilon_1), \ldots, \lambda_r + \sigma(1-\epsilon_r), \lambda_{r+1}, \ldots, \lambda_n\}.$$

Proof. The proof of this lemma is almost the same as the proof of Theorem 2.5. ∎

For general vectors a similar situation appears. Assume that $\tilde{E}^{-1} = (I-F)E^{-1}(I-F)$ is a symmetric approximation ($F = F^T$) of E^{-1}. Let $H := -FE^{-1} - E^{-1}F + FE^{-1}F$. Then we have

$$\tilde{P}_D A = P_D A + AZHZ^T A.$$

Hence, using Lemma 2.1 we obtain

$$\lambda_k(P_D A) + \lambda_1(AZHZ^T A) \leq \lambda_k(\tilde{P}_D A) \leq \lambda_k(P_D A) + \lambda_n(AZHZ^T A).$$

Since the first r eigenvalues of $\lambda_k(P_D A)$ are 0, we get for $i = 1, \ldots, r$,

$$\lambda_1(AZHZ^T A) \leq \lambda_i(\tilde{P}_D A) \leq \lambda_n(AZHZ^T A).$$

If all eigenvalues of $AZHZ^T A$ are small, the first r eigenvalues $\lambda_i(\tilde{P}_D A)$ also are very small. Observe that $\lambda_1(\tilde{P}_D A)$ can be negative if the perturbation H is negative definite.

For the coarse grid correction

$$\tilde{P}_C A = P_C A + ZHZ^T A,$$

we obtain

$$\lambda_k(P_C A) + \lambda_1(ZHZ^T A) \leq \lambda_k(\tilde{P}_C A) \leq \lambda_k(P_C A) + \lambda_n(ZHZ^T A).$$

Thus, if all eigenvalues of $ZHZ^T A$ are small, the perturbation does not have much effect.

Hence, the coarse grid correction operator is insensitive for the accuracy of the approximation, whereas deflation is sensitive.

To illustrate this we consider two problems. The first one is motivated by a porous media flow with large contrasts in the coefficients (ratio 10^{-6}; see the seven-layer problem in section 4), and the second one is a Poisson problem. In both examples $r = 7$ *algebraic* projection vectors are used (see [28, Def. 4]). We replace E^{-1} by $\tilde{E}^{-1} = (I + \epsilon R)E^{-1}(I + \epsilon R)$, where R is a symmetric $r \times r$ matrix with random elements chosen from the interval $[-\frac{1}{2}, \frac{1}{2}]$. From Figure 3.1 (porous media flow) it follows that the convergence of the error remains good for $|\epsilon| < 10^{-12}$. For larger values of $|\epsilon|$ we see that the convergence stagnates. For the Poisson problem it appears that the convergence is good as long as $|\epsilon| < 10^{-6}$ (see Figure 3.2). For the coarse grid correction operator, there is no difference in the convergence behavior. Using the coarse grid correction operator we need 75 iterations for the porous media flow problem and 70 iterations for the Poisson problem.

We also have investigated the convergence behavior of deflation if a perturbed Cholesky decomposition of E is used. For this experiment we compute the Cholesky factor L of E and use in the deflation method the matrix $\tilde{L}$ which is such that $\tilde{L}_{ij} = L_{ij}(1 + \epsilon_{ij})$ and $|\epsilon_{ij}| < \epsilon$. In Figure 3.3 the results are given. We observe again that the convergence stagnates if ϵ is too large.

Estimate of smallest eigenvalue. In this paragraph we restrict ourselves to the case that the deflation vectors approximate the eigenvectors corresponding to the smallest eigenvalues. In practice it is very important to have a reliable stopping criterion,

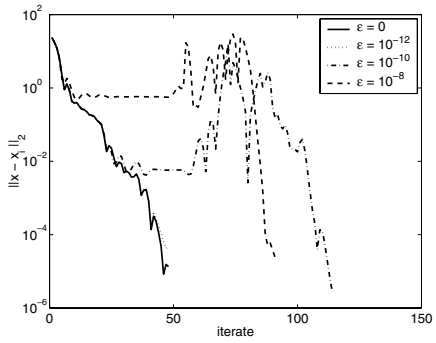

FIG. 3.1. *Convergence behavior of DICCG for the straight layers problem.*

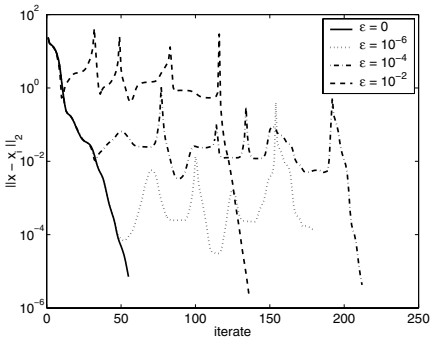

FIG. 3.2. *Convergence behavior of DICCG for the Poisson problem.*

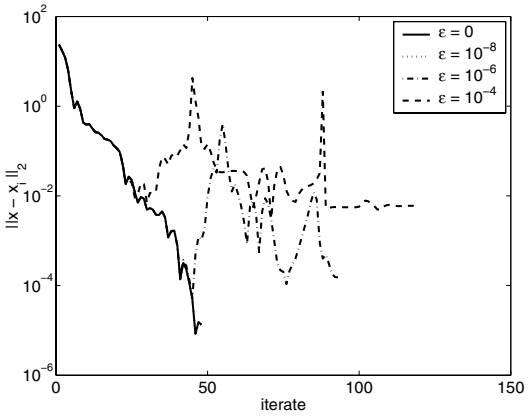

FIG. 3.3. *DICCG for the straight layers problem with a perturbed Cholesky decomposition.*

especially for a porous media flow problem, because for such a problem the linear system is ill conditioned. The following stopping criterion

$$\|r_k\|_2 \leq \lambda_1 \|x_k\|_2 \epsilon \tag{3.1}$$

gives that

$$\frac{\|x - x_k\|_2}{\|x_k\|_2} \leq \epsilon,$$

which implies that the relative error is small. To use this criterion, an estimate of the smallest eigenvalue should be available. From the CG method an approximation of the extreme eigenvalues can be obtained from the Ritz values (see [11]). However, for the deflated operator $P_D A$ this leads to an estimate of λ_{r+1} instead of λ_1. The same holds for the preconditioned system. In order to estimate λ_1 we note that

$$\lambda_1(M^{-\frac{1}{2}} A M^{-\frac{1}{2}}) \leq \min_{y \in \mathbb{R}^r} \frac{y^T G^T M^{-\frac{1}{2}} A M^{-\frac{1}{2}} G y}{y^T G^T G y} = \min_{y \in \mathbb{R}^r} \frac{y^T Z^T A Z y}{y^T Z^T M Z y}.$$

This means that the smallest eigenvalue μ_{min} of the generalized eigenvalue problem

$$Ey = \mu Z^T M Z y$$

is an upper bound for the smallest eigenvalue of $M^{-\frac{1}{2}}AM^{-\frac{1}{2}}$, whereas the smallest eigenvalue μ_{min} of the generalized eigenvalue problem

$$Ey = \mu Z^T Zy$$

is an upper bound for the smallest eigenvalue of A. From experiments for the porous media flow problem, it appears that the estimates are reasonably sharp (see Table 3.1), so they can be used in stopping criterion (3.1).

TABLE 3.1
The estimated smallest eigenvalue using matrix E.

Matrix	λ_1	$\lambda_1(estimated)$
$M^{-\frac{1}{2}}AM^{-\frac{1}{2}}$	$0.7 \cdot 10^{-8}$	$3.1 \cdot 10^{-8}$
A	$3.3 \cdot 10^{-9}$	$9.9 \cdot 10^{-9}$

4. Numerical experiments. All numerical experiments are done by using the SEPRAN FEM package developed at Delft University of Technology. The multiplication $y = E^{-1}b$ is always done by solving y from $Ey = b$, where E is decomposed in its Cholesky factor. The choice of the boundary conditions is such that all problems have as exact solution the vector with components equal to 1. In order to make the convergence behavior representative for general problems, we chose a random vector as starting solution, instead of the zero start vector.

4.1. Porous media flows. In this section we consider problems motivated by porous media flow (see [27]). Our first problem is a simple two-dimensional model problem, whereas our second problem mimics the flow of oil in a reservoir. In both problems *physical* projection vectors are used (see [28, Def. 2]), which approximate the eigenvectors corresponding to the small eigenvalues.

Seven-layer problem. We solve the equation

$$\text{div } (\sigma \nabla p) = 0$$

with p the fluid pressure and σ the permeability. At the earth's surface the fluid pressure is prescribed. At the other boundaries we use homogeneous Neumann conditions. In this two-dimensional problem we consider seven horizontal layers. We use linear triangular elements, and the number of grid points is equal to 22,680. The top layer is sandstone, then a shale layer, etc. We assume that σ in sandstone is equal to 1 and σ in shale is equal to 10^{-7}. From [26] it follows that the IC preconditioned matrix has three eigenvalues of order 10^{-7}, whereas the remaining eigenvalues are of order 1. Computing the solution with three projection vectors, we observe that in every iteration the norm of the residual using deflation or coarse grid correction is comparable. In Figure 4.1 the norm of the error for both methods is given. Note that the error using deflation stagnates at a lower level than that of coarse grid correction. This surprises us because the results presented in section 3 suggested that deflation can be more sensitive to rounding errors than coarse grid correction.

An oil flow problem. In this paragraph we simulate a porous media flow in a three-dimensional layered geometry, where the layers vary in thickness and orientation (see Figures 4.2 and 4.3 for a four-layer problem). Figure 4.2 shows a part of the earth's crust. The depth of this part varies between three and six kilometers, whereas horizontally its dimensions are 40 x 60 kilometers. The upper layer is a mixture of sandstone and shale and has a permeability of 10^{-4}. Below this layer, shale and

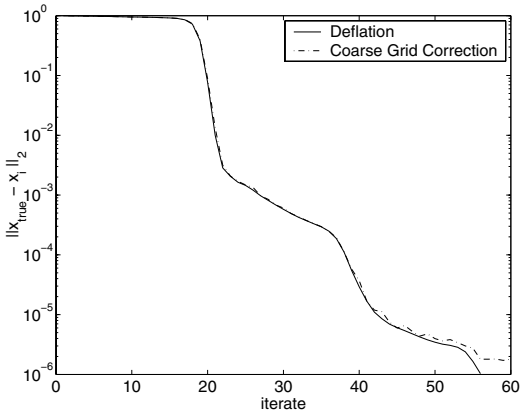

FIG. 4.1. *The norm of the error for projected ICCG for the seven-layer problem.*

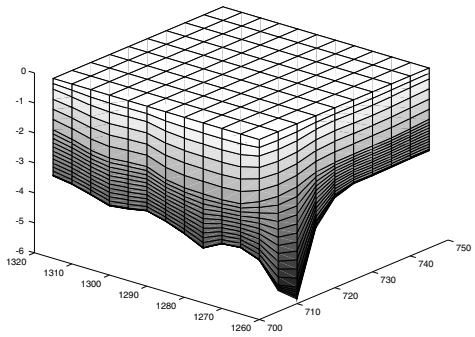

FIG. 4.2. *The geometry of an oil flow problem.*

sandstone layers are present with permeabilities of 10^{-7} and 10, respectively. We consider a problem with nine layers. Five sandstone layers are separated by four shale layers. At the top of the first sandstone/shale layer a Dirichlet boundary condition is posed, so the IC preconditioned matrix has four small eigenvalues. We use four *physical* projection vectors and stop if $\|r_k\|_2 \leq 10^{-5}$. Trilinear hexahedral elements are used, and the total number of gridpoints is equal to 148,185. The results are given in Table 4.1 and correspond well with our theoretical results.

4.2. Parallel problems. In this section we consider a Poisson equation on a two-dimensional rectangular domain. On top a Dirichlet boundary condition is posed, whereas at the other boundaries a homogeneous Neumann condition is used. We use linear triangular elements. We stop the iteration if $\|r_k\|_2 \leq 10^{-8}$.

As a first test we solve a problem, in which the grid is decomposed into seven layers with various gridsizes per layer. The results are given in Table 4.2. In this table the symbol "No" means that there is no projection method used. Note that in the parallel case we use a block IC preconditioner. Deflation again needs fewer iterations than coarse grid correction. However, both projection methods lead to a considerable gain in the number of iterations. Note that the number of iterations increases if the gridsize per layer increases.

Second, we consider the parallel performance for an increasing number of layers

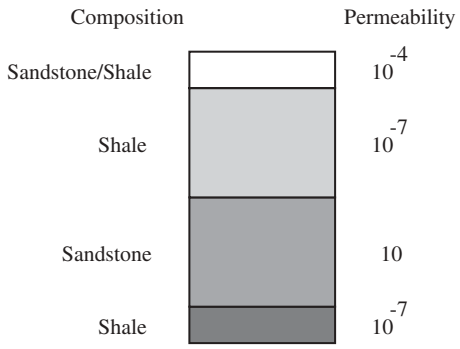

FIG. 4.3. *Permeabilities for each layer.*

TABLE 4.1
The results for the oil flow problem.

Method	Deflation	CGC
Iterations	36	47
CPU time	5.9	8.2

TABLE 4.2
The effect of the gridsize per layer.

	Sequential			Parallel		
Grid points	Deflation	CGC	No	Deflation	CGC	No
10×10	21	29	35	25	38	50
20×20	36	48	65	42	61	90
40×40	62	82	125	80	103	168
80×80	106	131	244	128	161	321

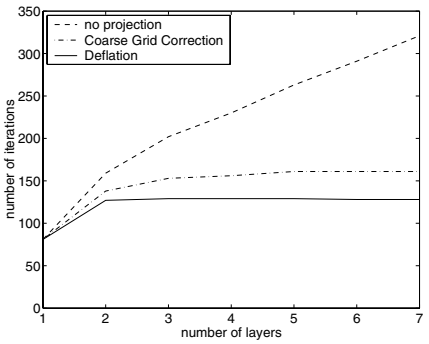

FIG. 4.4. *The number of iterations for a layered domain decomposition.*

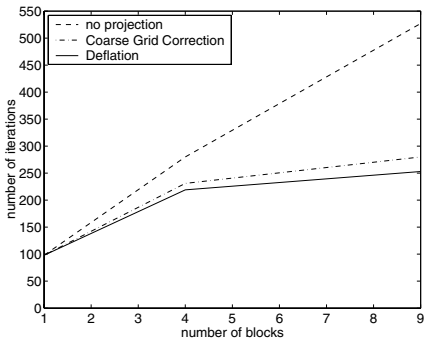

FIG. 4.5. *The number of iterations for a block domain decomposition.*

or blocks. The gridsize per layer is 80×80 and per block is 100×100. This implies that the total number of grid points increases proportionally to the number of layers/blocks. In Figures 4.4 and 4.5 the results are given. Note that initially both projection methods show a small increase in the number of iterations if the number of layers/blocks increases but thereafter the number of iterations is constant (scalable). If no projection method is used, the number of iterations keep increasing.

5. Conclusions. We have compared various preconditioners used in the numerical solution of partial differential equations. On one hand we considered a coarse grid correction preconditioner. On the other hand a so-called deflation preconditioner was studied. It turned out that the effective condition number of the deflated preconditioned system is always, for all deflation vectors and all restrictions and prolongations, below the condition number of the system preconditioned by the coarse grid correction. This implies that the CG method applied to the deflated preconditioned system converges always faster than the CG method applied to the system preconditioned by the coarse grid correction. Numerical results for porous media flows and parallel preconditioners emphasized the theoretical results.

UNIFORM CONVERGENCE OF AN EXPONENTIALLY FITTED SCHEME FOR THE QUANTUM DRIFT DIFFUSION MODEL*

RENÉ PINNAU†

Abstract. We analyze an exponentially fitted finite element scheme for the unipolar quantum drift diffusion model in one-dimensional space. The existence of discrete solutions is shown under very mild assumptions, and convergence of a subsequence is proved by compactness arguments. The scheme is constructed in such a way that it reduces in the semiclassical limit to the well-known Scharfetter–Gummel discretization for the classical drift diffusion model. We derive uniform error bounds which allow for the semiclassical limit on the discrete level. Numerical tests underlining the analytical results are presented.

Key words. quantum drift diffusion, generalized Scharfetter–Gummel discretization, mixed finite elements, exponential fitting, uniform convergence, semiclassical limit, semiconductor

1. Introduction.

From the earliest days of semiconductor industry there has been a never-ending drive towards increased miniaturization. The original aim was to produce more devices per unit area, but now scientists and engineers are exploiting quantum size effects to introduce new electronic properties into existing materials. Many devices, like MOSFETs or resonant tunneling structures, already reached the decanano length scale [19]. The Semiconductor Industry Association (SIA) projects that by 2009 the leading edge MOS device will employ a 0.05 μm length scale and an oxide thickness of 1.5 nm or less. But already today quantum mechanical effects, like confinement in barrier structures or inversion layers as well as direct tunneling through the oxide causing gate leakage in MOS structures are no longer negligible [18]. Hence, scientists are in charge to develop "correct" models which can be easily incorporated into existing modern simulation tools.

During the last years much effort has been spent on the derivation and analysis of *macroscopic* quantum models, which allow for an accurate description of the underlying physics of the devices by reasonable numerical costs. Nowadays, there exists a whole hierarchy of macroscopic models leading from the quantum hydrodynamic (QHD) models [25, 20] over the quantum energy transport (QET) model to the quantum drift diffusion (QDD) model, which can be derived from a moment expansion of the Wigner–Poisson system (see [26, 31] and the references therein for a comprehensive overview). Recently, extensions of these models were derived, which are better suited to deal with quantum tunneling and coherence effects [21, 22, 13, 17].

In this work we analyze a new numerical scheme for the QDD model. The mathematical analysis and numerical understanding of this model is in a rather mature state [31]. Essentially, this model is a dispersive regularization of the classical drift diffusion (DD) model of Van Roosbroeck [29], which accounted for the immense success of the macroscopic theory of charge transport in semiconductors and is commonly

used (with all its enhancements) in modern simulation tools. First, Ancona [8], Ancona and Tiersten [5], and Ancona and Iafrate [10] proposed a quantum correction of this well-understood system. This *density-gradient theory* is impressively capable of describing the correct device behavior in the vicinity of strong inversion layers in MOS structures when compared to one-electron quantum mechanic simulations [8]. But already the shrinking device size poses severe numerical problems, since the local field strength increases and interior layers in the solution become more abrupt [14]. The QDD model was employed for the simulation of many quantum semiconductor devices and has proved its numerical efficiency, especially in several space dimensions [7, 11, 37]. Due to its numerical robustness it is already programmed into the 2d/3d PROPHET simulation code from *Lucent Technologies* as well as into various commercial device simulators, e.g., those from *ISE* and *Silvaco*. Encouraging comparisons with Schrödinger–Poisson simulations can be found in [3, 37].

The unscaled QDD model equations stated on a bounded domain $\Omega \subset \mathbb{R}^d$, $d = 1, 2$, or 3, read as

$$\frac{\partial n}{\partial t} + \frac{1}{q} \operatorname{div} J = 0, \tag{1.1a}$$

$$\frac{q\, k_B\, T_0}{m} \nabla n + \frac{q^2}{m}\, n\, \nabla V - \frac{q\, \hbar^2}{2\, m^2}\, n\, \nabla \left(\frac{\Delta \sqrt{n}}{\sqrt{n}} \right) = -\frac{J}{\tau_0}, \tag{1.1b}$$

which are self-consistently coupled with the Poisson equation for the electrostatic potential

$$-\epsilon\, \Delta V = q\, (n - C_{dop})\,. \tag{1.1c}$$

The variables are the electron density $n = n(x,t)$, the current density $J = J(x,t)$, and the electrostatic potential $V = V(x,t)$. The physical constants are the elementary charge q, the Boltzmann constant k_B, the effective electron mass m, and the reduced Planck constant $\hbar$. For the values of these constants we refer the reader to [29]. Physical parameters are the permittivity ϵ, the relaxation time τ_0, and the lattice temperature T_0. The time-independent doping profile $C_{dop} = C_{dop}(x)$ represents the distribution of charged background ions.

In this paper we consider the stationary QDD model for unipolar devices in one-dimensional space. We introduce the diffusion scaling, where the new dimensionless quantities are marked by a tilde:

$$n \to C_m\, \tilde{n}, \qquad C_{dop} \to C_m\, \tilde{C}_{dop}, \qquad x \to L\, \tilde{x},$$
$$t \to \frac{m\, L^2}{k_B\, T_0\, \tau_0} \tilde{t}, \qquad V \to \frac{k_B\, T_0}{q} \tilde{V}, \qquad J \to \frac{q\, k_B\, T_0\, C_m\, \tau_0}{L\, m} \tilde{J}.$$

Here, C_m denotes the maximal absolute value of the doping profile C_{dop} and L is a characteristic device length, e.g., the diameter. Defining the scaled Planck constant ε and the scaled Debye length λ,

$$\varepsilon^2 = \frac{\hbar^2}{2\, m\, k_B\, T_0\, L^2}, \quad \lambda^2 = \frac{\epsilon\, k_B\, T_0}{q^2\, C_m\, L^2},$$

and introducing the quantum quasi-Fermi level F via $J = n\, \partial_x F$, we can divide equation (1.1b) by n and integrate once. This yields the scaled QDD model stated

on the bounded domain $\Omega = (0,1)$:

$$\partial_x (n\, \partial_x F) = 0, \tag{1.2a}$$

$$-\varepsilon^2 \frac{\partial_{xx}\sqrt{n}}{\sqrt{n}} + \log(n) + V = F, \tag{1.2b}$$

$$-\lambda^2 \partial_{xx} V = n - C_{dop}. \tag{1.2c}$$

Throughout the paper we assume that $C_{dop} \in L^\infty(\Omega)$. In (1.2) the electron density $n = n(x) \geq 0$, the quantum quasi-Fermi level $F = F(x)$, and the electrostatic potential $V = V(x)$ are unknown.

The model equations (1.2) are supplemented with Dirichlet boundary conditions modeling the Ohmic contacts of the device:

$$n = n_D > 0, \quad V = V_D \overset{\text{def}}{=} V_{eq} + V_{ext}, \quad F = F_D \overset{\text{def}}{=} F_{eq} + V_{ext} \quad \text{on } \partial\Omega, \tag{1.3}$$

where V_{ext} is the applied biasing voltage. This set of boundary conditions is motivated by its analogy to the classical DD model [30, 27, 28]. Nevertheless, the correct choice of the Dirichlet data is still an open problem. A recent discussion can be found in [6]. Clearly, the thermal equilibrium density n_{eq} is a possible candidate for n_D. The built-in potential is given by V_{eq}, and F_{eq} is chosen accordingly.

Remark 1. The restriction to the unipolar case is just to keep the notation simple. In fact, Ben Abdallah and Unterreiter [1] proved existence of solutions and considered the semiclassical limit for the bipolar case. The results of this paper are easily extendable to the bipolar setting.

So far, only standard discretization schemes were employed, which require very fine meshes to ensure an adequate resolution of the desired quantities. To account for this problems we want to generalize the classical Scharfetter–Gummel (SG) discretization for the DD equations [35] to this quantum model. A first step in this direction can be found in [9, 4] where a nonlinear discretization scheme is suggested. Here, we follow a different approach [33] since we are moreover interested in a scheme which is stable in the semiclassical limit $\varepsilon \to 0$ recovering the classical SG scheme. However, the SG method relies on the introduction of the so-called Slotboom variable which allows for the symmetrization of the continuity equation [29]. This is impossible in the formulation (1.2) of the QDD model, since we have the additional quantum Bohm potential. Nevertheless, we can deal with this problem by interpreting the Bohm potential as a correction of the classical electrostatic potential V and introducing the *corrected potential* G via

$$G = -\varepsilon^2 \frac{\partial_{xx}\sqrt{n}}{\sqrt{n}} + V$$

which yields for the current density $J = \partial_x n + n\partial_x G$; i.e., the drift is now given by G. Then, system (1.2) can be written as

$$\partial_x J = 0, \quad J = \partial_x n + n\partial_x G, \tag{1.4a}$$

$$-\varepsilon^2 \frac{\partial_{xx}\sqrt{n}}{\sqrt{n}} + V = G, \tag{1.4b}$$

$$-\lambda^2 \partial_{xx} V = n - C_{dop}. \tag{1.4c}$$

We introduce the generalized Slotboom variable $u = e^G n$, which yields for the current density $J = e^{-G}\partial_x u$. Assuming vanishing quantum effects and vanishing quantum

current at the boundary, we get

$$G = V_D, \quad u = e^{V_D} n_D \quad \text{on } \partial\Omega. \tag{1.5}$$

This nonlinear system is discretized using a mixed finite element discretization for the current density J and the Slotboom variable u, and standard linear elements for n and V. For an overview of stabilized discretization schemes for the classical DD model see [23] and the references therein.

We prove under very mild assumptions that the resulting nonlinear discrete system possesses a solution and that at least a subsequence of the sequence of discrete solutions converges to a continuous solution. Since we have no uniqueness for the QDD model in general, we cannot expect convergence of the full sequence. The proof is based on a variational argument similar to the one used in [1] and the derivation of appropriate a priori bounds. Especially, we can show that a discrete solution fulfills the same maximum principle as a continuous solution.

Our mixed finite element scheme is chosen in such a way that in the case of vanishing quantum effects ($\varepsilon = 0$) one recovers the classical SG discretization of the DD model. By deriving a priori bounds on the discrete solutions which are independent of ε, we can even perform the semiclassical limit $\varepsilon \to 0$ on the discrete level and derive estimates on the convergence rate, which are uniform in ε.

We present simulations of a ballistic diode and a resonant tunneling structure which exactly reproduce the predicted accuracy results underlining the feasibility of our approach. Moreover, these simulations show that the asymptotic constant in the error estimate for the current density seems to be almost independent of the size of the scaled Planck constant ε, which is essential from the engineering point of view, since it allows for an accurate computation of the current density also in the semiclassical limit.

The paper is organized as follows. In section 2 we introduce our nonlinear discrete scheme and section 3 is devoted to the proof of the existence and convergence of discrete solutions. The semiclassical limit is performed in section 4, where also uniform convergence rates are given. Finally, simulations of a ballistic diode and a resonant tunneling structure are presented in section 5. Concluding remarks are given in section 6.

2. A generalized SG discretization. In this section we present a discretization of system (1.4) in the spirit of the well-known SG discretization for the classical DD model [35]. Here the drift is given by the generalized potential G, such that we have to take additional care about (1.4b) which involves the quantum Bohm potential.

First, we write (1.4) in a weak form. For notational convenience we define the spaces

$$X = H_0^1(\Omega), \quad \Sigma = L^2(\Omega),$$

and testing appropriately we get the following:

Find $n \in n_D + X$, $V \in V_D + X$, $G \in G_D + X$, and $J \in \Sigma$ such that

$$\int_\Omega e^G J \cdot \tau \, dx - \int_\Omega \partial_x \left(e^G n\right) \cdot \tau \, dx = 0, \tag{2.1a}$$

$$\int_\Omega J \cdot \partial_x \phi \, dx = 0, \tag{2.1b}$$

$$\varepsilon^2 \int_\Omega \partial_x \sqrt{n} \partial_x \left(\frac{\phi}{\sqrt{n}} \right) \, dx = \int_\Omega (G - V)\phi \, dx, \tag{2.1c}$$

$$\lambda^2 \int_\Omega \partial_x V \partial_x \phi \, dx = \int_\Omega (n - C_{dop})\phi \, dx \tag{2.1d}$$

for all $\phi \in X$ *and* $\tau \in \Sigma$.

We discretize (2.1) on the possibly nonuniform grid $0 = x_0 < x_1 < \cdots < x_N = 1$ defining the subintervals and the grid spacing by

$$I_i = (x_{i-1}, x_i], \quad h_i = x_i - x_{i-1}, \quad h = \max_i h_i.$$

We employ finite-dimensional spaces of linear and constant finite elements:

$$X_h = \left\{ w \in H_0^1(\Omega) : w|_{I_i} \in P_1, i = 1, \ldots, N \right\},$$
$$\Sigma_h = \left\{ w \in L^2(\Omega) : w|_{I_i} \in P_0, i = 1, \ldots, N \right\}.$$

For every function $w \in C^0(\bar{\Omega})$ let w^I denote the linear interpolant verifying $w^I(x_i) = w(x_i)$ for $i = 0, \ldots, N$. We will make frequent use of the following interpolation result [23].

PROPOSITION 2.1. *There exists a constant* $c > 0$, *independent of* h, *such that*

$$\left| w - w^I \right|_{H^1(\Omega)} \le c\, h \left(\sum_i |w|^2_{H^2(I_i)} \right)^{1/2},$$
$$\left| w - w^I \right|_{L^2(\Omega)} \le c\, h^2 \left(\sum_i |w|^2_{H^2(I_i)} \right)^{1/2}$$

for all $w \in H^1(\Omega) \cap \left\{ H^2(I_i), \text{ for all } i = 1, \ldots, N \right\}$.

Let $(\cdot, \cdot)$ denote the standard inner product on $L^2(\Omega)$. We define its discrete analogue using the trapezoidal rule

$$(u, v)_h \stackrel{\text{def}}{=} \int_\Omega (uv)^I \, dx = \sum_{i=0}^N \omega_i \, u(x_i) v(x_i),$$

where $\omega_i > 0$ denotes the corresponding weights of the quadrature formula. We have the following consistency result for the discrete inner product.

LEMMA 2.2. *Let* $f, g \in X_h$. *Then there exists a constant* $c > 0$, *independent of* h, *such that*

$$|(f, g) - (f, g)_h| \le c h^2 \left\| \partial_x f \right\|_{L^2(\Omega)} \left\| \partial_x g \right\|_{L^2(\Omega)}.$$

The corresponding discretization of (2.1) reads as follows:

Find $n_h \in n_D + X_h$, $V_h \in V_D + X_h$, $G_h \in G_D + X_h$, *and* $J_h \in \Sigma_h$ *such that*

$$\left(e^{G_h} J_h, \tau_h \right) - \left(\partial_x \left(e^{G_h} n_h \right)^I, \tau_h \right) = 0, \tag{2.2a}$$

$$(J_h, \partial_x \phi_h) = 0, \tag{2.2b}$$

$$\varepsilon^2 \left(\partial_x (\sqrt{n_h})^I, \partial_x \left(\frac{\phi_h}{\sqrt{n_h}} \right)^I \right) = (G_h - V_h, \phi_h)_h, \tag{2.2c}$$

$$\lambda^2 \left(\partial_x V_h, \partial_x \phi_h \right) = \left(n_h - C_{dop}, \phi_h \right)_h \tag{2.2d}$$

for all $\phi_h \in X_h$ *and* $\tau_h \in \Sigma_h$.

The discretization of the generalized Slotboom variable u is given by $u_h = \left(e^{G_h}\, n_h\right)^I$.

We define the piecewise constant function $\bar{G}_h$ by

$$e^{\bar{G}_h}|_{I_i} = \frac{1}{h_i} \int_{I_i} e^{G_h}\, dx.$$

Using that the discrete current density J_h is constant on each element and the identity

$$G_h = \log\left(\frac{u_h}{n_h}\right)^I = \log(u_h)^I - \log(n_h)^I,$$

we can rewrite (2.2) equivalently as follows:

Find $n_h \in n_D + X_h$, $V_h \in V_D + X_h$, $u_h \in u_D + X_h$, *and* $G_h \in G_D + X_h$ *such that*

$$\left(e^{-\bar{G}_h} \partial_x u_h, \partial_x \phi_h\right) = 0, \tag{2.3a}$$

$$\varepsilon^2 \left(\partial_x (\sqrt{n_h})^I, \partial_x \left(\frac{\phi_h}{\sqrt{n_h}}\right)^I\right) + \left(\log(n_h)^I, \phi_h\right)_h = \left(\log(u_h)^I - V_h, \phi_h\right)_h, \tag{2.3b}$$

$$\lambda^2 \left(\partial_x V_h, \partial_x \phi_h\right) = \left(n_h - C_{dop}, \phi_h\right)_h. \tag{2.3c}$$

Remark 2. Formally, we deduce from (2.2c) that for $\varepsilon = 0$ it holds that $G_h \equiv V_h$ and the mixed finite element scheme reduces to the classical one. Note that in contrast to the classical SG scheme, (2.3a) determines the unknown corrected potential G_h, while (2.3b) is now the one for the electron density n_h.

Remark 3. The *nonlinear discretization scheme* developed in [9, 4] is based on finite differences and differs in the discretization of (2.3b). There, additionally some kind of exponential fitting is used for this equation; i.e., the electron density is approximated by an exponential function on each element. The scheme performs extremely well especially for large grid-spacings, but so far no numerical analysis is available. It is worth noting that an exponential transformation ($n = \exp(w)$) was also employed in the study of the transient problem [27, 28], but a numerical analysis for the fully discrete tranformed system is left for future research.

3. Existence and convergence of discrete solutions. We show that the nonlinear discrete system (2.3) possesses at least one solution and we derive a priori bounds on the sequence of discrete solution which ensure that there exists a subsequence converging to the continuous solution. The existence proof is based on a variational argument, which also allows to derive the desired a priori bounds.

We state the main theorem of this section establishing existence of a discrete solution and its convergence.

THEOREM 3.1. *For each* $h > 0$ *there exists a discrete solution* $(n_h, V_h, G_h, u_h) \in (n_D, V_D, G_D, u_D) + X_h^4$ *of* (2.3). *Further, there exists a subsequence, again denoted by* (n_h, V_h, G_h, u_h), *such that*

$$\left((\sqrt{n_h})^I, V_h, G_h, u_h\right) \to \left(\sqrt{n}, V, G, u\right) \quad \text{in } \left[H^1(\Omega)\right]^4,$$

for $h \to 0$, *where* $(n, V, G, u) \in (n_D, V_D, G_D, u_D) + X^4$ *solves the continuous problem* (2.1).

COROLLARY 3.2. *The sequence of discrete current densities* (J_h) *possesses a subsequence such that* $J_h \to J$ *in* $L^2(\Omega)$ *for* $h \to 0$.

Remark 4. Generally, we cannot expect convergence of the whole sequence, since the continuous as well as the discrete QDD model may admit for multiple solutions. Uniqueness can only be proven near to the thermal equilibrium state, i.e., for small applied biasing voltages V_{ext} [34].

For the existence proof we employ Brouwer's fixed point theorem. We define the closed, bounded, and convex set

$$\mathcal{U}_h \stackrel{\text{def}}{=} \{u_h \in u_D + X_h : \underline{u} \le u_h \le \overline{u}\},$$

where the lower and upper bound are given by

$$\underline{u} \stackrel{\text{def}}{=} \min_{\partial\Omega} e^{V_D} n_D, \quad \overline{u} \stackrel{\text{def}}{=} \max_{\partial\Omega} e^{V_D} n_D.$$

On this set we define the fixed point mapping $T_h : \mathcal{U}_h \to \mathcal{U}_h$, where $u_h = T_h(w_h)$ is calculated via the following iteration:

1. *Find* $(n_h, V_h) \in (n_D, V_D) + X_h^2$ *as the solution of*

(3.1a)
$$\varepsilon^2 \left(\partial_x (\sqrt{n_h})^I, \partial_x \left(\frac{\phi_h}{\sqrt{n_h}} \right)^I \right) + \left(\log(n_h)^I, \phi_h \right)_h = \left(\log(w_h)^I - V_h, \phi_h \right)_h,$$

(3.1b)
$$\lambda^2 \left(\partial_x V_h, \partial_x \phi_h \right) = \left(n_h - C_{dop}, \phi_h \right)_h$$

for all $\phi_h \in X_h$.

2. *Set* $G_h = \log(w_h)^I - \log(n_h)^I$.
3. *Find* $u_h \in u_D + X_h$ *as the solution of*

(3.2)
$$\left(e^{-\bar{G}_h} \partial_x u_h, \partial_x \phi_h \right) = 0$$

for all $\phi_h \in X_h$.

3.1. Well-posedness of the fixed point mapping. The well-posedness of the first step is the content of the following result, which also provides uniform bounds on the electron density n_h and the potential V_h.

LEMMA 3.3. *Let* $w_h \in \mathcal{U}_h$ *be given. Then there exists a unique solution* $(n_h, V_h) \in (n_D, V_D) + X_h^2$ *of the nonlinear system* (3.1). *Further, there exists a constant* $\theta \in (0,1)$, *independent of* h, *such that*

$$\theta \le n_h \le 1/\theta, \quad \left\| (\sqrt{n_h})^I \right\|_{H^1(\Omega)} \le 1/\theta, \quad \|V_h\|_{H^1(\Omega)} \le 1/\theta. \tag{3.3}$$

Proof. For the proof we employ a variational argument following the ideas in [36]. Let $H(s)$ be a primitive of $\log(s)^I$ with $H \ge 0$. We introduce the auxiliary variable $\rho_h \stackrel{\text{def}}{=} \sqrt{n_h}$. On the closed set

$$\mathcal{R}_h \stackrel{\text{def}}{=} \left\{ \rho_h : \rho_h^2 \in n_D + X_h, \rho_h \ge 0 \right\},$$

we define the functional

$$E(\rho) \stackrel{\text{def}}{=} \varepsilon^2 \int_\Omega \left| \partial_x \rho^I \right|^2 \, dx + \sum_{i=0}^N \omega_i H(\rho_i^2) + \frac{\lambda^2}{2} \int_\Omega \left| \partial_x V_h [\rho^2 - C_{dop}] \right|^2 \, dx - \sum_{i=0}^N \omega_i \log(w_i) \, \rho_i^2,$$

where $V_h \stackrel{\text{def}}{=} V_h[\rho^2 - C_{dop}] \in V_D + X_h$ is the unique discrete solution of Poisson's equation $\lambda^2(\partial_x V_h, \partial_x \phi_h) = (\rho^2 - C_{dop}, \phi_h)_h$ for all $\phi_h \in X_h$. Identifying ρ with its vector of nodal values in $\mathbb{R}^{N+1}$ one easily verifies that E possesses a unique minimizer $\rho_h \in \mathcal{R}_h$, since E is bounded from below, continuous, and convex with respect to ρ_h^2 [34]. The minimizer also satisfies the Euler–Lagrange equation

$$\varepsilon^2 \left(\partial_x \rho_h^I, \partial_x \phi_h\right) + \left(\rho_h \log(\rho_h^2)^I, \phi_h\right)_h = \left(\rho_h(\log(w_h)^I - V_h[\rho^2 - C_{dop}]), \phi_h\right)_h \tag{3.4}$$

for all $\phi_h \in X_h$.

Now we derive uniform estimates on the solution. In the following let $\theta \in (0,1)$ denote not necessarily identical constants, which are assumed to be independent of h. Choosing $\rho_D \stackrel{\text{def}}{=} \sqrt{n_D} \in \mathcal{R}_h$ as a comparison function we clearly have $E(\rho_h) \le E(\rho_D)$, from which we deduce

$$\varepsilon^2 \int_\Omega \left|\partial_x \rho_h^I\right|^2 \, dx + \frac{\lambda^2}{2} \int_\Omega \left|\partial_x V_h[\rho_h^2 - C_{dop}]\right|^2 \, dx + \sum_{i=0}^N \omega_i H(\rho_i^2) \le E(\rho_D) + |\log(\overline{u})| \, (\rho_h, \rho_h)_h \, .$$

This yields immediately the existence of a constant $\theta \in (0,1)$, independent of h, such that

$$\left\|\partial_x \rho_h^I\right\|_{L^2(\Omega)} \le 1/\theta \quad \text{and} \quad \|\partial_x V_h\|_{L^2(\Omega)} \le 1/\theta.$$

Employing Sobolev's embedding theorem in one-dimensional space [2], i.e., $H^1(\Omega) \hookrightarrow C^{0,\beta}(\bar{\Omega})$, $\beta \in [0, 1/2)$, we find a uniform constant $\theta \in (0,1)$ with

$$\left\|\rho_h^I\right\|_{C^{0,\beta}(\bar{\Omega})} \le 1/\theta \quad \text{and} \quad \|V_h\|_{C^{0,\beta}(\bar{\Omega})} \le 1/\theta.$$

A direct calculation finally yields $\|n_h\|_{L^\infty(\Omega)} \le 1/\theta$, for some uniform constant $\theta \in (0,1)$.

Next we prove the uniform positivity of ρ_h. Let $[\phi]^-$ denote the linear interpolant of $\phi^- \stackrel{\text{def}}{=} \min(0, \phi)$. Testing (3.4) with $\phi_h = [\rho_h - \underline{\rho}]^-$ for $\underline{\rho} > 0$ yields

$$\varepsilon^2 \left(\partial_x \rho_h^I, \partial_x [\rho_h - \underline{\rho}]^-\right) = \left(\left[-\log(\rho_h^2)^I + \log(w_h)^I - V_h[\rho_h^2 - C_{dop}]\right] \rho_h, [\rho_h - \underline{\rho}]^-\right)_h ,$$

which can be estimated as follows:

$$\varepsilon^2 \left(\partial_x \rho_h^I, \partial_x [\rho_h - \underline{\rho}]^-\right) \le \sum_{i=0}^N \left[\omega_i(-\log(\rho_i^2) + \log(\underline{u}) - 1/\theta)\rho_i(\rho_i - \underline{\rho})^-\right] \le 0$$

if we choose $\underline{\rho}^2 = e^{-1/\theta}\underline{u}$. Further we calculate

$$\left(\partial_x \rho_h^I, \partial_x [\rho_h - \underline{\rho}]^-\right) = \sum_{i=0}^N h_i(\rho_{i+1} - \rho_i)\left[(\rho_{i+1} - \underline{\rho})^- - (\rho_i - \underline{\rho})^-\right] \ge \sum_{i=0}^N h_i \left|(\rho_{i+1} - \underline{\rho})^- - (\rho_i - \underline{\rho})^-\right|^2 .$$

Hence,

$$\sum_{i=0}^{N} h_i \left|(\rho_{i+1}-\underline{\rho})^- - (\rho_i-\underline{\rho})^-\right|^2 \le 0,$$

which implies $(\rho_{i+1}-\underline{\rho})^- = (\rho_i-\underline{\rho})^-, i \in \{0,\dots,N-1\}$, and due to the positivity of ρ_D we have

$$(\rho_i-\underline{\rho})^- \equiv 0 \quad \text{for all } i \in \{0,\dots,N\}.$$

Thus, it holds that, $\rho_h \ge \underline{\rho}$ and $n_h \ge \underline{\rho}^2$, respectively. ∎

An easy consequence of Lemma 3.3 is the following result, which establishes uniform $L^\infty(\Omega)$-bounds on the discrete generalized potential G_h.

COROLLARY 3.4. *Let $w_h \in \mathcal{U}_h$ be given. Then there exist uniform bounds $\underline{G}, \overline{G} > 0$, independent of h, such that*

$$\underline{G} \le G_h \le \overline{G}. \tag{3.5}$$

Further, Corollary 3.4 and standard results from elliptic theory [16, 24] yield the unique solvability of (3.2).

LEMMA 3.5. *Let $G_h \in G_D + X_h$ be given with $G_h > \underline{G}$ uniformly in h. Then there exists a unique solution $u_h \in \mathcal{U}_h$ of (3.2). Further, there exists a constant $\theta \in (0,1)$, independent of h, such that*

$$\|u_h\|_{H^1(\Omega)} \le 1/\theta. \tag{3.6}$$

3.2. Proof of the existence theorem. The results derived so far ensure the well-posedness of the fixed point mapping and we are now in the position to prove the convergence theorem.

Proof of Theorem 3.1. First we note that the fixed point mapping T_h is well defined and continuous due to Lemma 3.3, Corollary 3.4, and Lemma 3.5.

Identifying u_h with its vector of nodal values in $\mathbb{R}^{N+1}$ we deduce the existence of a fixed point $u_h \in \mathcal{U}_h$ from Brouwer's fixed point theorem [38], since $\mathcal{U}_h$ is a closed, convex and compact subset of $\mathbb{R}^{N+1}$.

The uniform bounds given in Lemma 3.3, Corollary 3.4, and Lemma 3.5 imply the existence of a subsequence $(\rho_{h_k}, V_{h_k}, G_{h_k}, u_{h_k})$ such that

$$\left(\rho^I_{h_k}, V_{h_k}, G_{h_k}, u_{h_k}\right) \rightharpoonup (\rho, V, G, u) \quad \text{weakly in } \left[H^1(\Omega)\right]^4,$$

for $h_k \to 0$, where $(\rho^2, V, G, u) \in (n_D, V_D, G_D, u_D) + X_h^2$.

These convergences are by far sufficient to pass to the limit in (2.3): due to Sobolev's embedding theorem we have $\rho^I_{h_k} \to \rho$ and also $\rho_{h_k} \to \rho$ in $L^\infty(\Omega)$, such that we can deduce the strong $H^1(\Omega)$ convergence of $(\rho^I_{h_k})$ from (3.4). Standard results from elliptic theory [24] yield

$$\begin{aligned} V_{h_k} &\to V \quad \text{in } H^1(\Omega),\\ u_{h_k} &\to u \quad \text{in } H^1(\Omega), \end{aligned}$$

and finally $G_{h_k} \to G$ in $H^1(\Omega)$ for $h_k \to 0$.

Hence, (ρ^2, V, G, u) is in fact a solution of (2.3), which ends the proof. ∎

3.3. Convergence rates. For completeness we also state a result establishing convergence rates for the finite element discretization (2.2). Since we consider a fully nonlinear system of equations which may admit multiple solutions, we have to impose an additional assumption on the isolatedness of the continuous solution.

THEOREM 3.6. *Let $(n, V, G, u) \in \left[H^2(\Omega)\right]^4$ be a solution of the continuous problem and assume that the Fréchet derivative $(I-DT)(u) \in \mathcal{L}(H^1(\Omega), H^1(\Omega))$ of $I-T : H^1(\Omega) \to H^1(\Omega)$ at u is boundedly invertible. Then there exists a constant $h_0 > 0$ such that for $h < h_0$ there exists a solution (n_h, V_h, G_h, u_h) of the discrete problem (2.3). Further, there exists a constant $c > 0$, independent of h, such that*

$$\|n - n_h\|_{H^1(\Omega)} + \|V - V_h\|_{H^1(\Omega)} + \|u - u_h\|_{H^1(\Omega)} \leq c\, h. \tag{3.7}$$

The proof can be found in [32]. Note that here the constant c generally depends on ε, such that the performance of the semiclassical limit is not possible on this level. In the next section we will use different techniques to overcome this problem.

4. Semiclassical limit—Uniform convergence. In this section we provide estimates independent of the parameter ε, which allow to perform the semiclassical limit in the numerical scheme recovering the classical SG discretization.

We need estimates on the discrete solution, which are independent of ε and h, generalizing the estimates given in section 3. Examining carefully the proofs of that section, we conclude that they crucially depend on ε, since we exploited the monotonicity of the quantum Bohm potential. But in fact we can introduce a different fixed point mapping. The key idea is to reinterpret the equation for n as the one for G and vice versa. This yields the fixed point map $N : n_D + X \to n_D + X$ with $N(m) = n$, where given $m \in n_D + X$ the solution n is calculated via the following iteration:

1. *Find $V \in V_D + X$ such that*

$$\lambda^2 \int_\Omega \partial_x V\, \partial_x \phi\, dx = \int_\Omega (m - C_{dop})\phi\, dx \tag{4.1a}$$

for all $\phi \in X$.

2. *Find $(n, G) \in (n_D, G_D) + X^2$ such that*

$$-\int_\Omega n\, \partial_x G\, \partial_x \phi\, dx - \int_\Omega \partial_x n\, \partial_x \phi\, dx = 0, \tag{4.1b}$$

$$\varepsilon^2 \int_\Omega \partial_x \sqrt{n}\, \partial_x \left(\frac{\phi}{\sqrt{n}}\right) dx = \int_\Omega (G - V)\phi\, dx \tag{4.1c}$$

for all $\phi \in X$.

Remark 5. The reader easily verifies that the fixed point mapping N is well defined and possesses a fixed point exploiting the relation $G = F - \log(n)$. Hence, (4.1) is just a reformulation of (1.2).

Also the discrete system (2.2) can be reformulated in the former manner:

Find $n_h \in n_D + X_h$, $V_h \in V_D + X_h$, and $G_h \in G_D + X_h$ such that,

$$-\int_\Omega \partial_x n_h\, \partial_x \phi_h\, dx - \int_\Omega n_h\, \partial_x G_h \partial_x \phi_h\, dx = \langle f_h, \phi_h \rangle\,, \tag{4.2a}$$

$$\varepsilon^2 \int_\Omega \partial_x (\sqrt{n_h})^I\, \partial_x \left(\frac{\phi_h}{\sqrt{n_h}}\right)^I dx = (G_h - V_h, \phi_h)_h, \tag{4.2b}$$

$$\lambda^2 \int_\Omega \partial_x V_h\, \partial_x \phi_h\, dx = (n_h - C_{dop}, \phi_h)_h \tag{4.2c}$$

for all $\phi_h \in X_h$.

Here, the right-hand side f_h is given by

$$\langle f_h, \phi_h \rangle \stackrel{\text{def}}{=} \int_\Omega e^{-G_h} \partial_x \left(e^{G_h} n_h \right) \partial_x \phi_h \, dx - \int_\Omega e^{-\bar{G}_h} \partial_x \left(e^{G_h} n_h \right)^I \partial_x \phi_h \, dx.$$

The main result of this section reads as follows.

THEOREM 4.1. *Let* $(n, V, G, u) \in \left[H^2(\Omega)\right]^4$ *be a solution of the continuous problem* (1.2) *and assume that the Fréchet derivative* $(I - DN)(n) \in \mathcal{L}(H^1(\Omega), H^1(\Omega))$ *of the mapping* $I - N : H^1(\Omega) \to H^1(\Omega)$ *at a solution* n *is uniformly bounded invertible, i.e.,*

$$\left\| (I - DN)^{-1} \right\|_{\mathcal{L}(H^1(\Omega), H^1(\Omega))} \leq M,$$

where $M > 0$ *is independent of* ε.

Then there exists a constant $c > 0$ *such that for each* $0 < \varepsilon < \varepsilon_0$ *with* $\varepsilon_0 = \varepsilon_0(h) > 0$ *we have the uniform estimates*

$$\|n - n_h\|_{H^1(\Omega)} \leq c\, h, \tag{4.3a}$$

$$\|V - V_h\|_{H^1(\Omega)} \leq c\, h, \tag{4.3b}$$

$$\|G - G_h\|_{H^1(\Omega)} \leq c\, h, \tag{4.3c}$$

$$\|u - u_h\|_{H^1(\Omega)} \leq c\, h, \tag{4.3d}$$

$$\|J - J_h\|_{L^2(\Omega)} \leq c\, h. \tag{4.3e}$$

The proof of Theorem 4.1 is done in several steps.

4.1. Regularity of weak solutions. First, we show that a weak solution of system (2.1) is in fact in $\left[H^2(\Omega)\right]^4$ and that the stronger norm is also uniformly bounded in ε. This generalizes the results given in [1].

THEOREM 4.2. *Let* (n, V, G, J) *be a weak solution of* (2.1). *Then it holds that* $(n, V, G) \in \left[H^2(\Omega)\right]^3$ *and there exists a constant* $K > 0$, *independent of* ε, *such that*

$$\|n\|_{H^2(\Omega)} + \|V\|_{H^2(\Omega)} + \|G\|_{H^2(\Omega)} \leq K.$$

Proof. We eliminate G and J in (1.4) and introduce the auxiliary $\rho = \sqrt{n}$, which yields the fourth-order equation

$$\varepsilon^2 \rho_{xxxx} - \varepsilon^2 \frac{\rho_{xx}^2}{\rho} - 2\rho_{xx} - 2\frac{\rho_x^2}{\rho} - 2\rho_x V_x - \rho V_{xx} = 0$$

supplemented with boundary conditions

$$\rho = \rho_D, \quad \rho_{xx} = 0 \quad \text{ on } \partial\Omega.$$

This equation possesses a unique weak solution $\rho \in H^4(\Omega)$ (see [27]). Testing the fourth-order equation with $\phi = -\rho_{xx}$ we get

$$\varepsilon^2 \int_\Omega \rho_{xxx}^2 \, dx + \varepsilon^2 \int_\Omega \frac{\rho_{xx}^3}{\rho} \, dx + 2 \int_\Omega \rho_{xx}^2 \, dx + 2 \int_\Omega \frac{\rho_x^2}{\rho} \rho_{xx} \, dx + 2 \int_\Omega \rho_x V_x \rho_{xx} \, dx + \int_\Omega \rho V_{xx} \rho_{xx} \, dx = 0.$$

From the Gagliardo–Nierenberg inequality [24] we derive

$$\|\rho_x\|_{L^4(\Omega)} \le c_1 \|\rho\|^{1/4}_{H^2(\Omega)} \|\rho\|^{3/4}_{H^1(\Omega)},$$

with $c_1 = c_1(\Omega) > 0$, which yields, using Poincaré's inequality,

$$\begin{aligned} 2\int_\Omega \frac{\rho_x^2}{\rho}\rho_{xx} &\le \frac{2}{\underline{\rho}} \|\rho_x\|^2_{L^4(\Omega)} \|\rho_{xx}\|_{L^2(\Omega)} \\ &\le 2\frac{c_2(\Omega)}{\underline{\rho}} \|\rho\|^{3/2}_{H^2(\Omega)} \|\rho\|^{3/2}_{H^1(\Omega)} \\ &\le \frac{1}{2}\|\rho\|^2_{H^2(\Omega)} + 2\frac{c_2^2}{\underline{\rho}^2}\|\rho\|^6_{H^1(\Omega)}. \end{aligned}$$

Note that the upper and lower bounds $\underline{\rho} \le \rho \le \overline{\rho}$ are also uniform in ε (see [1]). Further, the Gagliardo–Nierenberg inequality gives

$$\|\rho_{xx}\|_{L^3(\Omega)} \le c_3(\Omega) \|\rho\|^{7/12}_{H^3(\Omega)} \|\rho\|^{5/12}_{H^1(\Omega)},$$

which yields

$$\begin{aligned} \varepsilon^2 \int_\Omega \frac{\rho_{xx}^3}{\rho} &\le \frac{\varepsilon^2}{\underline{\rho}} \|\rho_{xx}\|^3_{L^3(\Omega)} \\ &\le \frac{\varepsilon^2 c_3}{\underline{\rho}} \|\rho\|^{7/4}_{H^3(\Omega)} \|\rho\|^{5/4}_{H^1(\Omega)} \\ &\le \frac{\varepsilon^2}{2}\|\rho\|^2_{H^3(\Omega)} + \frac{\varepsilon^2 c_3^2}{2\underline{\rho}}\|\rho\|^{10}_{H^1(\Omega)}. \end{aligned}$$

Finally, we derive from Sobolev's embedding theorem and standard regularity results [24]

$$\begin{aligned} 2\int_\Omega \rho_x V_x \rho_{xx} &\le 2\|\rho_x\|_{L^2(\Omega)} \|\rho_{xx}\|_{L^2(\Omega)} \|V_x\|_{L^\infty(\Omega)} \\ &\le \frac{1}{4}\|\rho_{xx}\|^2_{L^2(\Omega)} + c_4 \|\rho\|^2_{H^1(\Omega)} \|V\|^2_{H^2(\Omega)} \\ &\le \frac{1}{4}\|\rho_{xx}\|^2_{L^2(\Omega)} + c_4 \|\rho\|^4_{H^1(\Omega)} \end{aligned}$$

and

$$\begin{aligned} \int_\Omega \rho V_{xx}\rho_{xx} &= -\frac{1}{\lambda^2}\int_\Omega \rho\rho_{xx}(\rho^2 - C_{dop}) \\ &\le \frac{1}{\lambda^2}\|\rho\|_{L^\infty(\Omega)} \left(\|\rho\|^2_{L^\infty(\Omega)} + \|C_{dop}\|_{L^\infty(\Omega)}\right) \|\rho_{xx}\|_{L^2(\Omega)} \\ &\le \frac{1}{8}\|\rho_{xx}\|^2_{L^2(\Omega)} + c_5(\lambda, \overline{\rho}, C_{dop}). \end{aligned}$$

Combining these estimates and using Poincaré's inequality we get

$$\frac{\varepsilon^2}{2}\int_\Omega \rho_{xxx}^2 + \frac{1}{4}\int_\Omega \rho_{xx}^2 \le c_6(\Omega, \lambda, \underline{\rho}, \|\rho\|_{H^1(\Omega)}),$$

where c_6 is independent of ε.

Hence, we established $\|\rho\|_{H^2(\Omega)} \leq \tilde{K}$ for some $\tilde{K} > 0$ uniformly in ε and due to the uniform upper and lower bounds, it even holds that $\|n\|_{H^2(\Omega)} \leq K$. The uniform boundedness of $\|V\|_{H^2(\Omega)}$ and $\|G\|_{H^2(\Omega)}$ follows now from the standard elliptic theory. ∎

4.2. Uniform bounds on the discrete solution. Secondly, we derive uniform bounds for the discrete solution of system (2.2).

LEMMA 4.3. *There exist constants $K > 0$ and $\theta \in (0,1)$, independent of ε and h, such that*

$$\left\|(\sqrt{n_h})^I\right\|_{H^1(\Omega)} + \|V_h\|_{H^1(\Omega)} + \|u_h\|_{H^1(\Omega)} + \|G_h\|_{H^1(\Omega)} \leq K,$$
$$\theta \leq n_h, u_h \leq 1/\theta.$$

Proof. By construction we have $\underline{u} \leq u_h \leq \overline{u}$. Further, $\inf_{\mathcal{R}_h} E$ is also uniformly bounded in ε, such that each term of $E(\rho_h)$ is uniformly bounded. This implies $\|V_h\|_{H^1(\Omega)} \leq K$, where the constant $K > 0$ is independent of ε and h. Mimicking the proof of Lemma 3.3 we get $\theta \leq n_h$, where $\theta \in (0,1)$ is independent of ε and h. This yields $G_h \leq 1/\theta$, which in turn implies $\|u_h\|_{H^1(\Omega)} \leq K$.

Now let $\xi_h \in \mathcal{R}_h$ be the unique minimizer of the classical energy functional

$$E_{class}(\xi) = \int_\Omega H(\xi^2)\, dx + \frac{\lambda^2}{2} \int_\Omega \left|\partial_x V_h[\xi^2 - C_{dop}]\right|^2\, dx - \int_\Omega \log(u_h)^I\, \xi^2\, dx.$$

For $\rho_h = \sqrt{n_h}$ it holds that $E(\rho_h) \leq E(\xi_h)$ and $E_{class}(\xi_h) \leq E_{class}(\rho_h)$, which implies

$$\int_\Omega \left|\partial_x \rho_h^I\right|^2\, dx \leq \int_\Omega \left|\partial_x \xi_h^I\right|^2\, dx.$$

In fact, we can calculate ξ_h explicitly from $\xi_h^2 = (u_h\, e^{-V_h})^I$. The bounds derived so far ensure the uniform boundedness of ξ_h in $H^1(\Omega)$ with respect to ε and h. Hence, we finally get $\left\|(\sqrt{n_h})^I\right\|_{H^1(\Omega)} \leq K$ and $n_h \leq 1/\theta$ as well as $-1/\theta \leq G_h$. From $G_h = \log(u_h)^I - \log(n_h)^I$ we deduce that $\|G_h\|_{H^1(\Omega)} \leq K$ by a direct calculation. ∎

4.3. Consistency of the discrete fixed point operator. Third, we introduce some auxiliary problems, which allow to derive the consistency of the two steps of the fixed point mapping N. Let $\hat{n} \overset{\text{def}}{=} N(n_h) \in n_D + X$ and define $\hat{n}_h \in n_D + X$ as the solution of

$$-\int_\Omega \partial_x \hat{n}_h\, \partial_x \phi\, dx - \int_\Omega \hat{n}_h\, \partial_x G_h\, \partial_x \phi\, dx = \langle f_h, \phi \rangle$$

for all $\phi \in X$. The functions $\hat{V}$ and $\hat{G}$ as well as $\hat{V}_h$ and $\hat{G}_h$ are defined in analogy.

Standard results for finite element approximations of linear elliptic equations directly yield the following result [16].

LEMMA 4.4. *Let $(\hat{n}_h, \hat{V}_h)$ be defined as above and (n_h, V_h) is a discrete solution of (4.2). Then there exists a constant $c > 0$, independent of ε and h, such that*

$$\|\hat{n}_h - n_h\|_{H^1(\Omega)} + \left\|\hat{V}_h - V_h\right\|_{H^1(\Omega)} \leq ch.$$

Further, we introduce the auxiliary variables $\hat{u} \stackrel{\text{def}}{=} e^{\hat{G}}\hat{n} \in u_D + X$ and $\hat{u}_h \stackrel{\text{def}}{=} e^{G_h}\hat{n}_h \in u_D + X$, which fulfill

$$-\int_\Omega e^{-\hat{G}}\partial_x\hat{u}\,\partial_x\phi\,dx = 0 \quad \text{and} \quad -\int_\Omega e^{-G_h}\partial_x\hat{u}_h\,\partial_x\phi\,dx = \langle f_h, \phi\rangle$$

for all $\phi \in X$.

Taking the difference of these two equations and testing with $\phi = \hat{u} - \hat{u}_h \in X$ yield

$$e^{-\hat{G}}\,\|\partial_x(\hat{u}-\hat{u}_h)\|_{L^2(\Omega)} \le \left\|e^{-\hat{G}} - e^{-G_h}\right\|_{L^\infty(\Omega)} \|\partial_x\hat{u}_h\|_{L^2(\Omega)} + \|f_h\|_{L^2(\Omega)}\,,$$

from which we deduce

$$\|\hat{u}-\hat{u}_h\|_{H^1(\Omega)} \le c\left\{\left\|\hat{G}-G_h\right\|_{H^1(\Omega)} + h\right\}. \tag{4.4}$$

Further, we have by a direct calculation

$$\|\partial_x(\hat{n}-\hat{n}_h)\|_{L^2(\Omega)} \le c\left(\|\partial_x(\hat{u}-\hat{u}_h)\|_{L^2(\Omega)} + \left\|\hat{G}-G_h\right\|_{H^1(\Omega)}\right) \tag{4.5}$$

for some constant $c > 0$.

We need the following consistency result, which can be easily derived by cumbersome calculations and thus are omitted here for the sake of a compact presentation.

LEMMA 4.5. *There exists a constant $c > 0$, independent of ε and h, such that*

$$\sup_{\|\phi\|_{H^1(\Omega)}=1} |\langle f_h, \phi\rangle| \le ch.$$

Next, we prove the key estimate, which will finally allow for the derivation of the uniform convergence rates.

LEMMA 4.6. *Let $\hat{G}$ be defined as above and G_h a solution of (4.2). Then there exists a constant $c = c(\hat{n}, \hat{V}, \hat{G}) > 0$, independent of ε and h, such that*

$$\left\|G_h - \hat{G}^I\right\|_{L^2(\Omega)} \le c\left(h^2 + h^{-1}\varepsilon^2\,\|\hat{n}-n_h\|_{H^1(\Omega)} + \varepsilon^2\right).$$

Proof. We define

$$\langle A(n),\phi\rangle \stackrel{\text{def}}{=} \varepsilon^2\int_\Omega \partial_x(\sqrt{n})\,\partial_x\left(\frac{\phi}{\sqrt{n}}\right)\,dx,$$
$$\langle A_h(n_h),\phi\rangle \stackrel{\text{def}}{=} \varepsilon^2\int_\Omega \partial_x(\sqrt{n_h})^I\,\partial_x\left(\frac{\phi}{\sqrt{n_h}}\right)^I\,dx.$$

First, we estimate the difference $G_h - \hat{G}^I$. Due to (4.1) it holds that

$$\langle A_h(n_h),\phi_h\rangle = (G_h - V_h, \phi_h)_h \quad \text{for all } \phi_h \in X_h,$$
$$\langle A(\hat{n}),\phi\rangle = \int_\Omega (\hat{G}-\hat{V})\phi\,dx \quad \text{for all } \phi \in X.$$

Testing the difference of these two equations with $\phi = G_h - \hat{G}^I \in X_h$ yields

$$\begin{aligned}
&\langle A_h(n_h) - A(\hat{n}), \phi\rangle \\
&= \left(G_h - \hat{G} - (V_h - \hat{V}), \phi\right) + (G_h - V_h, \phi) - (G_h - V_h, \phi)_h \\
&= \left(G_h - \hat{G}^I, \phi\right) + \left(\hat{G}^I - \hat{G}, \phi\right) - \left(V_h - \hat{V}, \phi\right) + (G_h - V_h, \phi) - (G_h - V_h, \phi)_h ,
\end{aligned}$$

which implies, due to Lemma 2.2,

$$\begin{aligned}
\left\|G_h - \hat{G}^I\right\|^2_{L^2(\Omega)} \le{}& \left\|\hat{G}^I - \hat{G}\right\|_{L^2(\Omega)} \|\phi\|_{L^2(\Omega)} + \left\|V_h - \hat{V}\right\|_{L^2(\Omega)} \|\phi\|_{L^2(\Omega)} \\
&+ c_1 h^2 \|\partial_x (G_h - V_h)\|_{L^2(\Omega)} \|\partial_x \phi\|_{L^2(\Omega)} + \langle A_h(n_h) - A_h(\hat{n}), \phi\rangle \\
&+ \langle A_h(\hat{n}) - A(\hat{n}), \phi\rangle .
\end{aligned}$$

We estimate termwise. First,

$$\begin{aligned}
|\langle A_h(n_h) - A_h(\hat{n}), \phi\rangle| &= \varepsilon^2 \int_\Omega \partial_x \left(\sqrt{n_h} - \sqrt{\hat{n}}\right)^I \partial_x \left(\frac{\phi}{\sqrt{\hat{n}}}\right)^I dx \\
&\quad + \varepsilon^2 \int_\Omega \partial_x \left(\sqrt{n_h}\right)^I \partial_x \left(\frac{\phi}{\sqrt{n_h}} - \frac{\phi}{\sqrt{\hat{n}}}\right)^I dx \\
&\le \varepsilon^2 \left\|\partial_x \left(\sqrt{n_h} - \sqrt{\hat{n}}\right)^I\right\|_{L^2(\Omega)} \left\|\partial_x \left(\frac{\phi}{\sqrt{\hat{n}}}\right)^I\right\|_{L^2(\Omega)} \\
&\quad + \varepsilon^2 \left\|\partial_x \left(\sqrt{n_h}\right)^I\right\|_{L^2(\Omega)} \left\|\partial_x \left(\frac{\phi}{\sqrt{n_h}} - \frac{\phi}{\sqrt{\hat{n}}}\right)^I\right\|_{L^2(\Omega)}
\end{aligned}$$

which can be estimated using Proposition 2.1 by

$$\begin{aligned}
|\langle A_h(n_h) - A_h(\hat{n}), \phi\rangle| &\le \varepsilon^2 c_2 \left\|\partial_x \left(\sqrt{n_h} - \sqrt{\hat{n}}\right)\right\|_{L^2(\Omega)} \left\|\partial_x \left(\frac{\phi}{\sqrt{\hat{n}}}\right)\right\|_{L^2(\Omega)} \\
&\quad + \varepsilon^2 c_3 \|\partial_x \left(\sqrt{n_h}\right)\|_{L^2(\Omega)} \left\|\partial_x \left(\frac{\phi}{\sqrt{n_h}} - \frac{\phi}{\sqrt{\hat{n}}}\right)\right\|_{L^2(\Omega)}
\end{aligned}$$

and employing the uniform bounds derived so far

$$\begin{aligned}
|\langle A_h(n_h) - A_h(\hat{n}), \phi\rangle| &\le \|n_h - \hat{n}\|_{H^1(\Omega)} \left\{\varepsilon^2 c_4 \|\phi\|_{H^1(\Omega)} + \varepsilon^2 c_5 \|\partial_x \phi\|_{L^2(\Omega)}\right\} \\
&\le \varepsilon^2 c_6 \|n_h - \hat{n}\|_{H^1(\Omega)} \|\phi\|_{H^1(\Omega)}
\end{aligned}$$

for some uniform constants $c_i > 0$, $i = 1, \ldots, 6$.

Second, employing successively Proposition 2.1 we get

$$\begin{aligned}
|\langle A_h(\hat{n}) - A(\hat{n}), \phi\rangle| &= \varepsilon^2 \int_\Omega \partial_x \left(\left(\sqrt{\hat{n}}\right)^I - \sqrt{\hat{n}} \right) \partial_x \left(\frac{\phi}{\sqrt{\hat{n}}} \right) \, dx \\
&\quad + \varepsilon^2 \int_\Omega \partial_x \left(\sqrt{\hat{n}}\right)^I \partial_x \left[\left(\frac{\phi}{\sqrt{\hat{n}}} \right)^I - \left(\frac{\phi}{\sqrt{\hat{n}}} \right) \right] \, dx \\
&\le \varepsilon^2 \left\| \partial_x \left(\left(\sqrt{\hat{n}}\right)^I - \sqrt{\hat{n}} \right) \right\|_{L^2(\Omega)} \left\| \partial_x \left(\frac{\phi}{\sqrt{\hat{n}}} \right) \right\|_{L^2(\Omega)} \\
&\quad + \varepsilon^2 \left\| \partial_x \left(\sqrt{\hat{n}}\right)^I \right\|_{L^2(\Omega)} \left\| \partial_x \left[\left(\frac{\phi}{\sqrt{\hat{n}}} \right)^I - \left(\frac{\phi}{\sqrt{\hat{n}}} \right) \right] \right\|_{L^2(\Omega)} \\
&\le \varepsilon^2 c_7 h \left\| \sqrt{\hat{n}} \right\|_{H^2(\Omega)} \|\phi\|_{H^1(\Omega)} + \varepsilon^2 c_8 h \left\| \frac{\phi}{\sqrt{\hat{n}}} \right\|_{H^2(\Omega)} \\
&\le c_9 \, \varepsilon^2 h \, \|\hat{n}\|_{H^2(\Omega)} \, \|\phi\|_{H^1(\Omega)}
\end{aligned}$$

for some uniform constants $c_i > 0$, $i = 7, 8, 9$.

Combining the estimates derived so far we have

$$\begin{aligned}
\left\| G_h - \hat{G}^I \right\|_{L^2(\Omega)} &\le \varepsilon^2 c_6 h^{-1} \|n_h - \hat{n}\|_{H^1(\Omega)} + c_9 \, \varepsilon^2 \\
&\quad + \left\| \hat{G}^I - \hat{G} \right\|_{L^2(\Omega)} + \left\| V_h - \hat{V} \right\|_{L^2(\Omega)} + c_1 h \, \|\partial_x (G_h - V_h)\|_{L^2(\Omega)} \,,
\end{aligned}$$

where we employed the inverse estimate $\|\phi_h\|_{H^1(\Omega)} \le c h^{-1} \|\phi_h\|_{L^2(\Omega)}$ for all $\phi_h \in X_h$. Finally, we use again Proposition 2.1 to end with

$$\left\| G_h - \hat{G}^I \right\|_{L^2(\Omega)} \le c_{10} \left\{ \varepsilon^2 h^{-1} \|n_h - \hat{n}\|_{H^1(\Omega)} + \varepsilon^2 + h^2 + h \right\}. \qquad \square$$

Next, we estimate the remaining difference $n_h - \hat{n}$.

LEMMA 4.7. *Let $\hat{n}$ be defined as above and n_h a solution of (4.2). Then there exist constants $c = c(\hat{n}, \hat{V}, \hat{G}, \hat{u}) > 0$, independent of ε and h, and $\varepsilon_0 = \varepsilon_0(h) > 0$ such that for $\varepsilon < \varepsilon_0$ it holds that*

$$\|n_h - \hat{n}\|_{H^1(\Omega)} \le ch.$$

Proof. We estimate

$$\|n_h - \hat{n}\|_{H^1(\Omega)} \le \|n_h - \hat{n}_h\|_{H^1(\Omega)} + \|\hat{n}_h - \hat{n}\|_{H^1(\Omega)}$$

and using Lemma 4.4 as well as (4.4) and (4.5)

$$\begin{aligned}
\|n_h - \hat{n}\|_{H^1(\Omega)} &\le c_1 \left\{ \|\hat{u} - \hat{u}_h\|_{H^1(\Omega)} + \left\| G_h - \hat{G} \right\|_{H^1(\Omega)} + h \right\} \\
&\le c_2 \left\{ \left\| G_h - \hat{G} \right\|_{H^1(\Omega)} + h \right\} \\
&\le c_2 \left\{ \left\| G_h - \hat{G}^I \right\|_{H^1(\Omega)} + \left\| \hat{G}^I - \hat{G} \right\|_{H^1(\Omega)} + h \right\}
\end{aligned}$$

and employing Proposition 2.1 and the inverse estimate $\|\phi_h\|_{H^1(\Omega)} \leq ch^{-1} \|\phi_h\|_{L^2(\Omega)}$ for all $\phi_h \in X_h$, we have using Lemma 4.6

$$\begin{aligned}\|n_h - \hat{n}\|_{H^1(\Omega)} &\leq c_3 \left\{ h \left\| \hat{G} \right\|_{H^2(\Omega)} + h^{-1} \left\| G_h - \hat{G}^I \right\|_{L^2(\Omega)} + h \right\} \\ &\leq c_4 \left\{ h + h^{-2}\varepsilon^2 \|n_h - \hat{n}\|_{H^1(\Omega)} + h^{-1}\varepsilon^2 \right\}\end{aligned}$$

for some uniform constants $c_i > 0$, $i = 1, \ldots, 4$. Now we assume

$$\varepsilon^2 \leq \varepsilon_0^2 \stackrel{\text{def}}{=} \frac{h^2}{2c_4},$$

which yields the desired estimate $\|n_h - \hat{n}\|_{H^1(\Omega)} \leq ch$, with $c = 2c_4 + 1$. ∎

4.4. Proof of the uniform convergence result. Now we are in the position to prove the main theorem of this section.

Proof of Theorem 4.1. We have the identity

$$n_h - n + N(n) - N(n_h) = (I - DN(\xi))(n_h - n) = n_h - \hat{n}_h + \hat{n}_h - \hat{n},$$

which yields

$$\|n - n_h\|_{H^1(\Omega)} \leq \left\| (I - DN)^{-1} \right\|_{\mathcal{L}(H^1(\Omega), H^1(\Omega))} \|n_h - \hat{n}\|_{H^1(\Omega)}.$$

Hence, we have due to Lemma 4.7

$$\|n - n_h\|_{H^1(\Omega)} \leq ch$$

for some constant $c > 0$, independent of ε and h. Finally, the other uniform estimates follow from standard results for the approximation of elliptic equations. ∎

5. Numerical results. In this section we present numerical simulations underlining the feasibility of the previously analyzed extended SG discretization. We study a ballistic n^+–n–n^+ diode fabricated of GaAs and a resonant tunneling structure. Both devices consist of a channel and source and drain contact regions, which are assumed to be equally long. The channel is moderately doped with a doping density of $5 \cdot 10^{21}\,\mathrm{m}^{-3}$, while the drain and source are highly doped with $10^{24}\,\mathrm{m}^{-3}$. The resonant tunneling diode has the same underlying structure, but the channel is replaced by a quantum well sandwiched between two barriers. This resonant barrier structure is itself sandwiched between two spacer layers (see Figure 5.1). The physical effect of the barriers is a shift in the Fermi level, which can be modeled by an additional step function B added to the electrostatic potential; i.e., V is replaced by $V + B$. Since, we need more smoothness of B for the numerical analysis, we used instead a smoothed function B, which is depicted together with the doping profile in Figure 5.2. We choose a scaled Debye length of $\lambda^2 = 10^{-2}$ and set the scaled biasing voltage to $V_{ext} = 5$. To emphasize the large gradients occurring in the electron density in the case of the resonant tunneling diode, we show in Figure 5.2 also the computed densities for the different values of the scaled Planck constant ε. These are in fact a consequence of the barrier function and can only be smoothed for large ε. Note that for $\varepsilon^2 = 10^{-5}$ there is already no visible difference to the classical solution.

Remark 6. There is numerical evidence that the QDD model shows negative differential resistance for some resonant tunneling diodes [34, 15], but one has to admit

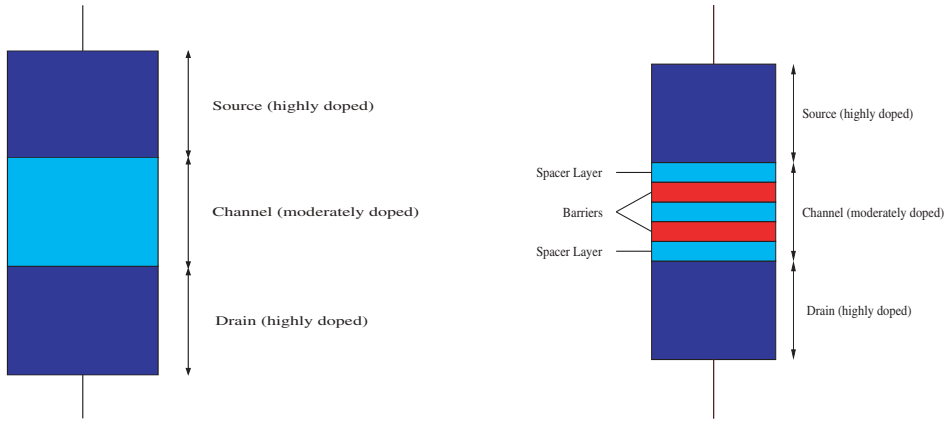

FIG. 5.1. *Diode structure (left: ballistic, right: RTD).*

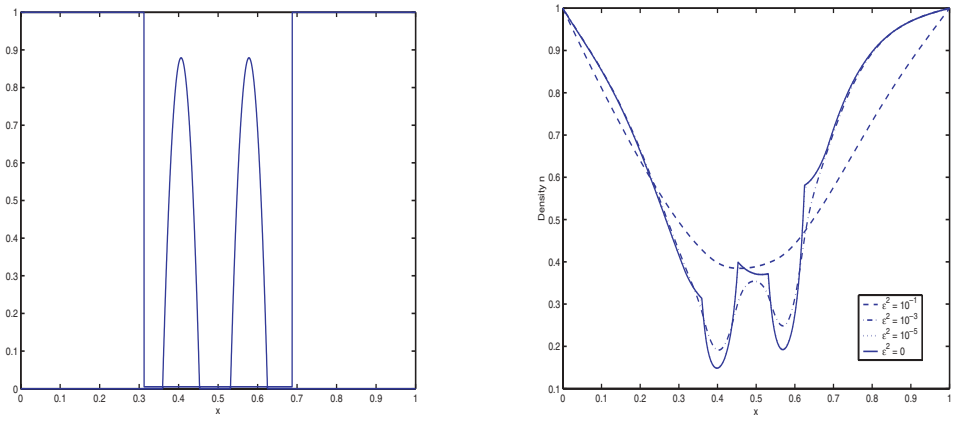

FIG. 5.2. *RTD (left: doping profile, barriers, right: electron densities).*

that the model is far from giving accurate quantitative results for this application. This stems from the fact that the model is mainly designed for scattering dominated transport and no quantum coherence is included. Nevertheless, this device is a good test example due to the large gradients in the electron density near to the barriers.

For the computations we used several uniform grids of variable size and the discretization (2.2). To investigate the semiclassical limit numerically we decreased the scaled squared Planck constant ε^2 from 10^{-1} to 0. The discrete nonlinear system is solved with a damped Newton iteration, which proved to be stable. In Figure 5.3 to Figure 5.5 we present the errors in the electron densities n, the electrostatic potentials V, and the generalized potentials G measured in the $H^1(\Omega)$-seminorm. Further, we depict in Figure 5.6 the error of the current densities J in the $L^2(\Omega)$-norm. The left picture always corresponds to the ballistic diode, while the right one shows the error for the resonant tunneling structure. Since in both cases an analytical solution is not available, we take the solution on the finest grid ($h = 1/4096$) as the "exact" solution.

The numerical results show in both cases that the error behaves like $\mathcal{O}(h)$ for all independent variables. Further, the scheme is stable in the semiclassical limit since the convergence rate is not affected by the size of ε. Note that the error in

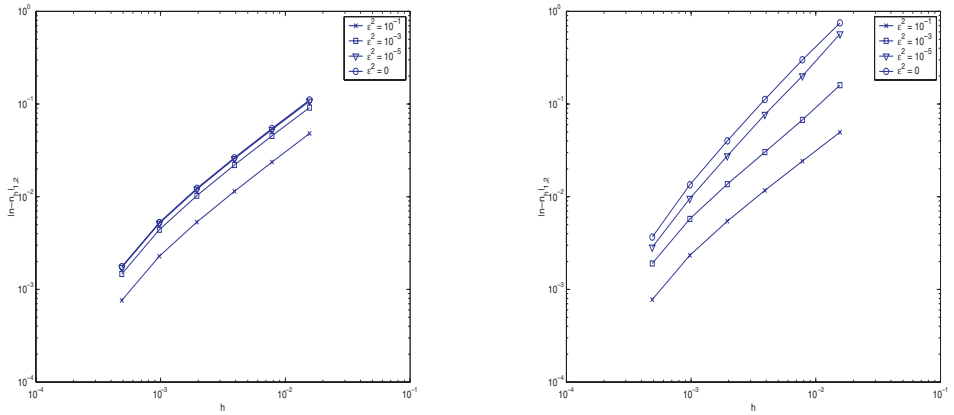

FIG. 5.3. *Error of the electron density (left: ballistic, right: RTD).*

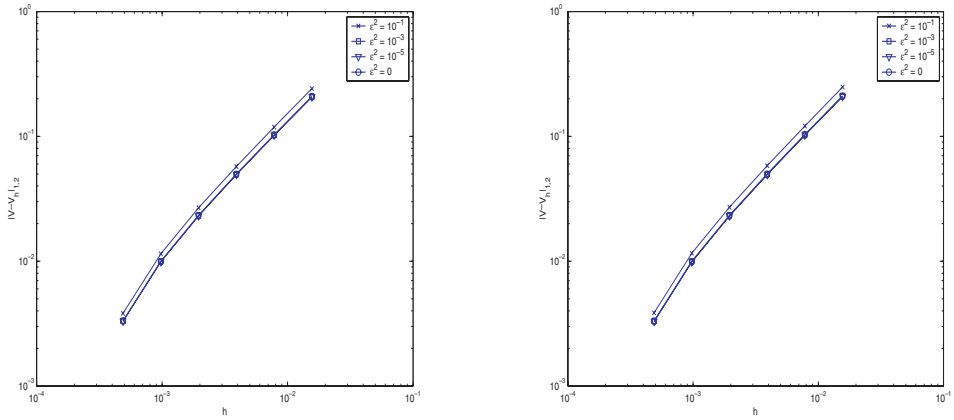

FIG. 5.4. *Error of the potential (left: ballistic, right: RTD).*

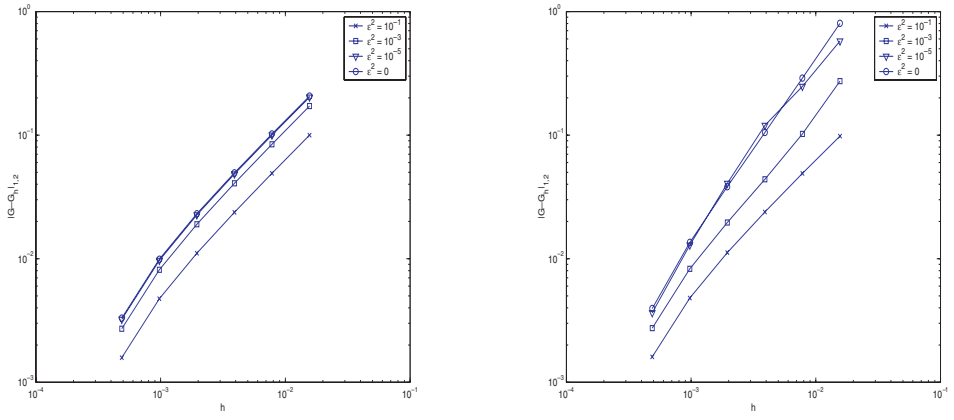

FIG. 5.5. *Error of the generalized potential (left: ballistic, right: RTD).*

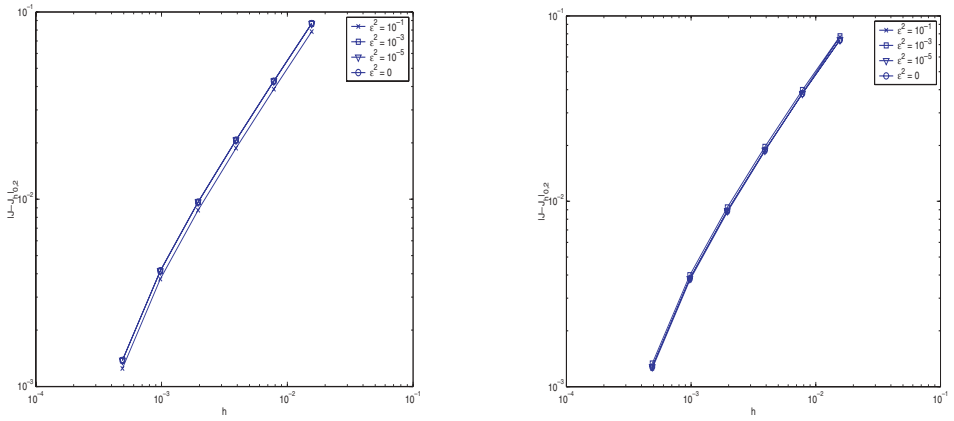

FIG. 5.6. *Error of the current density (left: ballistic, right: RTD).*

the electron density and the generalized potential of the RTD is much more affected by the size of ε, which is a consequence of the additional barrier function B. Most interestingly, in both cases the error in the current density even does not depend on ε. This observation is essential from the engineering point of view, since it allows for an accurate computation of current voltage characteristics also in the semiclassical limit.

6. Conclusions. We presented and analyzed a new stabilized finite element discretization for the quantum drift diffusion model, which is a generalization of the well-known Scharfetter–Gummel discretization for the classical drift diffusion model. The scheme yields the expected approximation errors and allows for the performance of the semiclassical limit on the discrete level, in such a way that the error estimates hold uniformly. The extension to bipolar devices is straightforward. Further, the numerical scheme can be easily extended to space dimensions larger than one using, e.g., the finite element spaces described in [12]. However, the proofs in this paper are not directly extendible, since we employed embedding theorems and inverse estimates, which crucially depend on the space dimension.

ON GENERALIZING THE ALGEBRAIC MULTIGRID FRAMEWORK*

ROBERT D. FALGOUT† AND PANAYOT S. VASSILEVSKI†

Abstract. We present a theory for algebraic multigrid (AMG) methods that allows for general smoothing processes and general coarsening approaches. The goal of the theory is to provide guidance in the development of new, more robust, AMG algorithms. In particular, we introduce several compatible relaxation methods and give theoretical justification for their use as tools for measuring the quality of coarse grids.

Key words. algebraic multigrid, compatible relaxation

AMS subject classifications. 65N30, 65F10

DOI. 10.1137/S0036142903429742

1. Introduction.

The algebraic multigrid (AMG) method was originally developed to solve general matrix equations using multigrid principles [6, 17, 3, 18]. The fact that it used only information in the underlying matrix made it attractive as a potential black box solver, a notion that has largely been abandoned. Instead, a wide variety of AMG algorithms have been developed that target different problem classes and have different robustness and efficiency properties.

In recent years, much work has been done to increase the robustness of AMG methods. The classical AMG method of Ruge and Stüben [18] was built upon heuristics based on properties of M-matrices. Although this algorithm works remarkably well for a wide variety of problems [10], the M-matrix assumption still limits its applicability. To address this, a new class of algorithms was developed based on multigrid theory: AMGe (element-based AMG) [7, 14], element-free AMGe [12], and spectral AMGe [9]. All of these algorithms (including Ruge–Stüben AMG) assume a basic framework in their construction: they assume that relaxation is a simple pointwise method, then they build the coarse-grid correction step to eliminate the so-called *algebraically smooth* error left over by the relaxation process. In the AMGe methods, this is done with the help of a *measure* and an associated approximation property that, if satisfied, implies uniform multigrid convergence. The approximation property induces a new heuristic that relates the accuracy of interpolation to the spectrum of the system matrix, namely, that eigenmodes with small associated eigenvalue must be interpolated well.

In this paper, we present a theory that generalizes the AMG framework to address even broader classes of problems. For example, the eddy current formulation of Maxwell's equations (when discretized using the common Nédélec finite elements) has a particularly large (near) null space. In the previous framework, it would be necessary to take all $O(N)$ of the null-space components to the coarse grid, yielding a nonoptimal method. This difficulty can be overcome by using non-pointwise

smoothers that damp some of the null space components on the fine grid, leaving a more manageable system to solve on the coarse grid. Examples include overlapping block relaxation [1] and a form of Brandt's distributive relaxation [5, 19] described by Hiptmair in [13].

The theory presented here allows for more general smoothing processes, and changes the above AMGe heuristic in a subtle but important way. It also allows for general coarsening approaches, including vertex-based, cell-based, and agglomeration-based approaches. Yet another aspect of the new theory and framework is *compatible relaxation*, an idea originally proposed by Brandt [4]. We introduce several variants of compatible relaxation and give theoretical justification for its use. The hope is that this work will provide guidance in the development of new AMG methods able to handle difficult problems such as Maxwell's equations.

We assume that the reader is somewhat familiar with AMG research, as numerous comparisons will be made to AMGe and other methods such as smoothed aggregation [20]. In section 2, we introduce two new measures and provide two-level convergence theory. In section 3, we analyze the min-max problem for the new measures. In section 4, we discuss the process of building interpolation, and provide additional theory to support this approach. In section 5, we show how to use compatible relaxation to evaluate the measure and select coarse grids. In section 6, we present two examples illustrating the application of the theory to real problems.

2. New measures and convergence theory. We begin with some notation. Capital italic Roman letters (A, M, P, R) denote matrices and bold lowercase Roman and Greek letters denote vectors $(\mathbf{u}, \mathbf{v}, \boldsymbol{\varepsilon})$. Other lowercase letters denote scalars, while capital calligraphic letters denote sets and spaces $(\mathcal{C}, \mathcal{F}, \mathcal{S})$. We represent the standard Euclidean inner product by $\langle \cdot, \cdot \rangle$ with associated norm $\| \cdot \| := \langle \cdot, \cdot \rangle^{1/2}$. The A-norm (also called the energy norm) is defined by $\| \cdot \|_A := \langle A\cdot, \cdot \rangle^{1/2}$.

Consider solving via AMG the linear system

$$A\mathbf{u} = \mathbf{f}, \tag{2.1}$$

where A is a real symmetric positive definite (SPD) matrix, with $\mathbf{u}, \mathbf{f} \in \mathbb{R}^n$. We consider smoothers (relaxation methods) of the form

$$\mathbf{u}_{k+1} = \mathbf{u}_k + M^{-1}\mathbf{r}_k, \tag{2.2}$$

where $\mathbf{r}_k = \mathbf{f} - A\mathbf{u}_k$ is the residual at the kth iteration. The error propagation for this iteration is given by

$$\mathbf{e}_{k+1} = (I - M^{-1}A)\mathbf{e}_k. \tag{2.3}$$

We also assume that $(M + M^T - A)$ is SPD. It is easy to see that this is a necessary and sufficient condition for convergence (e.g., see the first line in the proof of Theorem 2.2), and hence a reasonable assumption.

Let $P : \mathbb{R}^{n_c} \to \mathbb{R}^n$ be the *interpolation* (or *prolongation*) operator, where $\mathbb{R}^{n_c}$ is a lower-dimensional (*coarse*) vector space, and define $Q : \mathbb{R}^n \to \mathbb{R}^n$ to be a projection onto range (P),

$$Q = PR, \tag{2.4}$$

for some restriction operator $R : \mathbb{R}^n \to \mathbb{R}^{n_c}$ such that $RP = I_c$, the identity on $\mathbb{R}^{n_c}$. Note that R is not the multigrid restriction operator (we will use P^T and the Galerkin

procedure). Also note that the form of R will be important in the remaining sections of the paper.

Define the following measure (we will introduce a second, simpler measure later):

$$\mu(Q,\mathbf{e}) := \frac{\langle M(M+M^T-A)^{-1}M^T(I-Q)\mathbf{e},(I-Q)\mathbf{e}\rangle}{\langle A\mathbf{e},\mathbf{e}\rangle}. \tag{2.5}$$

This measure differs from the AMGe measure in [7] by the inclusion of the term $M(M+M^T-A)^{-1}M^T$ in the numerator. The additional term takes into account the general relaxation process in (2.2). It also provides a natural scaling that eliminates the need to pre-scale A to have diagonal equal one, as in the theory for AMGe.

We now prove that if the measure in (2.5) is bounded by a constant, then two-level multigrid converges uniformly. Furthermore, a smaller measure yields faster convergence. Denote the A-orthogonal projector onto range (P) by

$$Q_A := P(P^TAP)^{-1}P^TA, \tag{2.6}$$

so that $I-Q_A$ represents the error propagation matrix for the coarse-grid correction step. We first prove the following lemma.

LEMMA 2.1. *Let Q be any projection onto* range (P). *Assume that the following approximation property is satisfied for some constant K:*

$$\mu(Q,\mathbf{e}) \le K \quad \forall \mathbf{e}\in\mathbb{R}^n\setminus\{0\}. \tag{2.7}$$

If $\langle A\mathbf{e},\mathbf{v}\rangle = 0\ \forall \mathbf{v}\in$ range (P), then

$$\|(M+M^T-A)^{1/2}M^{-1}A\mathbf{e}\|^2 \ge \frac{1}{K}\langle A\mathbf{e},\mathbf{e}\rangle. \tag{2.8}$$

Proof. Note that range (Q) = range (P), hence

$$\langle A\mathbf{e},Q\mathbf{v}\rangle = 0 \quad \forall \mathbf{v}\in\mathbb{R}^n. \tag{2.9}$$

Assume that (2.7) holds. From (2.9) and the Cauchy–Schwartz inequality, we have

$$\begin{aligned}\langle A\mathbf{e},\mathbf{e}\rangle &= \langle A\mathbf{e},(I-Q)\mathbf{e}\rangle\\ &= \langle (M+M^T-A)^{1/2}M^{-1}A\mathbf{e},(M+M^T-A)^{-1/2}M^T(I-Q)\mathbf{e}\rangle\\ &\le \|(M+M^T-A)^{1/2}M^{-1}A\mathbf{e}\|\|(M+M^T-A)^{-1/2}M^T(I-Q)\mathbf{e}\|\\ &\le \|(M+M^T-A)^{1/2}M^{-1}A\mathbf{e}\|K^{1/2}\langle A\mathbf{e},\mathbf{e}\rangle^{1/2}.\end{aligned}$$

The result (2.8) now follows by dividing through by $\langle A\mathbf{e},\mathbf{e}\rangle K^{1/2}$ and squaring the result. ∎

THEOREM 2.2. *Assume that approximation property* (2.7) *is satisfied for some constant K. Then $K\ge 1$ and*

$$\|(I-M^{-1}A)(I-Q_A)\mathbf{e}\|_A \le \left(1-\frac{1}{K}\right)^{1/2}\|\mathbf{e}\|_A. \tag{2.10}$$

Proof. We have the following identity:

$$\begin{aligned}\|(I-M^{-1}A)\mathbf{e}\|_A^2 &= \langle A\mathbf{e},\mathbf{e}\rangle - \langle A\mathbf{e},M^{-1}A\mathbf{e}\rangle\\ &\quad - \langle M^{-1}A\mathbf{e},A\mathbf{e}\rangle + \langle AM^{-1}A\mathbf{e},M^{-1}A\mathbf{e}\rangle\\ &= \langle A\mathbf{e},\mathbf{e}\rangle - \langle (M+M^T-A)(M^{-1}A)\mathbf{e},(M^{-1}A)\mathbf{e}\rangle.\end{aligned}$$

Replacing $\mathbf{e}$ with $(I - Q_A)\mathbf{e}$ and applying the result in Lemma 2.1 yield

$$\begin{aligned}\|(I - M^{-1}A)(I - Q_A)\mathbf{e}\|_A^2 &\leq \left(1 - \frac{1}{K}\right)\|(I - Q_A)\mathbf{e}\|_A^2 \\ &\leq \left(1 - \frac{1}{K}\right)\|\mathbf{e}\|_A^2 .\end{aligned}$$

To show that $K \geq 1$, note that the identity at the beginning of the proof implies (since norms are nonnegative)

$$\|(M + M^T - A)^{1/2}M^{-1}A\mathbf{e}\|^2 \leq \langle A\mathbf{e}, \mathbf{e}\rangle .$$

The result follows by restricting $\mathbf{e} \neq 0$ to be A-orthogonal to range (P) and applying Lemma 2.1. ∎

The result in Theorem 2.2 is similar to the AMGe result in [7], but applies to more general relaxation methods (than Richardson relaxation). As in AMGe, the bound on the convergence factor approaches 1 as K becomes large, while a smaller K yields a smaller bound on the convergence factor. Note, however, that neither the new measure μ nor the corresponding convergence result reduces to the AMGe measure or convergence result in the case of Richardson relaxation. To complete the connection between the two theories, we now introduce a second, simpler measure,

$$\mu_\sigma(Q, \mathbf{e}) := \frac{\langle \sigma(M)(I - Q)\mathbf{e}, (I - Q)\mathbf{e}\rangle}{\langle A\mathbf{e}, \mathbf{e}\rangle}, \tag{2.11}$$

where $\sigma(M) := \frac{1}{2}(M + M^T)$ is the symmetric part of M. Note that the term $\sigma(M)$ can be replaced equivalently by M, but the symmetric form of this measure is more natural in the theory that follows. The relationship between the measures μ and μ_σ is given in the next lemma.

LEMMA 2.3. *Assume that $(M + M^T - A)$ is SPD. Then,*

$$\mu(Q, \mathbf{e}) \leq \frac{\Delta^2}{2 - \omega}\mu_\sigma(Q, \mathbf{e}), \tag{2.12}$$

where $\Delta \geq 1$ measures the deviation of M from its symmetric part in the sense that

$$\langle M\mathbf{v}, \mathbf{w}\rangle \leq \Delta\langle \sigma(M)\mathbf{v}, \mathbf{v}\rangle^{1/2}\langle \sigma(M)\mathbf{w}, \mathbf{w}\rangle^{1/2}, \tag{2.13}$$

and where

$$0 < \omega := \lambda_{\max}(\sigma(M)^{-1}A) < 2. \tag{2.14}$$

Proof. Note that since $(M + M^T - A)$ is SPD, then both $\sigma(M)$ and $\sigma(M^{-1})$ are also SPD. From (2.13), letting $\mathbf{v} = M^{-1}\mathbf{x}$ and $\mathbf{w} = \sigma(M)^{-1}\mathbf{x}$, we have that

$$\langle \sigma(M)^{-1}\mathbf{x}, \mathbf{x}\rangle^2 \leq \Delta^2\langle \sigma(M)M^{-1}\mathbf{x}, M^{-1}\mathbf{x}\rangle\langle \sigma(M)^{-1}\mathbf{x}, \mathbf{x}\rangle.$$

Dividing both sides by $\langle \sigma(M)^{-1}\mathbf{x}, \mathbf{x}\rangle$ yields

$$\begin{aligned}\langle \sigma(M)^{-1}\mathbf{x}, \mathbf{x}\rangle &\leq \Delta^2\langle MM^{-1}\mathbf{x}, M^{-1}\mathbf{x}\rangle \\ &= \Delta^2\langle M^{-T}\mathbf{x}, \mathbf{x}\rangle \\ &= \Delta^2\langle \sigma(M^{-1})\mathbf{x}, \mathbf{x}\rangle.\end{aligned}$$

From this and (2.14), we then have

$$\begin{aligned}
\mu(Q,\mathbf{e}) &= \frac{\langle M(M+M^T-A)^{-1}M^T(I-Q)\mathbf{e},(I-Q)\mathbf{e}\rangle}{\langle A\mathbf{e},\mathbf{e}\rangle} \\
&\le \max_{\mathbf{x}} \frac{\langle M(M+M^T-A)^{-1}M^T\mathbf{x},\mathbf{x}\rangle}{\langle \sigma(M)\mathbf{x},\mathbf{x}\rangle}\mu_\sigma(Q,\mathbf{e}) \\
&\le \left(\min_{\mathbf{x}} \frac{\langle (M(M+M^T-A)^{-1}M^T)^{-1}\mathbf{x},\mathbf{x}\rangle}{\langle \sigma(M^{-1})\mathbf{x},\mathbf{x}\rangle}\right)^{-1} \Delta^2\mu_\sigma(Q,\mathbf{e}) \\
&= \frac{\Delta^2}{\lambda_{\min}(\sigma(M^{-1})^{-1}(2\sigma(M^{-1})-M^{-T}AM^{-1}))}\mu_\sigma(Q,\mathbf{e}) \\
&= \frac{\Delta^2}{2-\omega}\mu_\sigma(Q,\mathbf{e}). \qquad \square
\end{aligned}$$

Lemma 2.3 provides an obvious corollary to Theorem 2.2 for measure μ_σ. This corollary is the analogue to the AMGe two-level convergence theory in [7]. To see this, note that for a weighted Richardson iteration with weight ω_r, we have that $M^{-1} = \omega_r\|A\|^{-1}I$. If we assume that the AMGe measure is bounded by some constant K_r, then the lemma implies that $\Delta = 1$ and $\omega = \omega_r$, and hence

$$\mu(Q,\mathbf{e}) \le \omega_r^{-1}(2-\omega_r)^{-1}\,\|A\|\,K_r.$$

Applying Theorem 2.2 then yields the AMGe convergence result.

In order for μ_σ to be a useful measure in practice, we need the constants ω and Δ to be "good" constants. In particular, we want both constants to be mesh independent, and we want ω to be bounded away from two. Bounding ω away from two is always possible by using appropriate weighting factors in the relaxation method. In the classical setting, this requirement is equivalent to satisfying a smoothing property; in general, it means that the smoother must damp large eigenmodes of A. Note that this does not preclude the smoother from also damping small eigenmodes (e.g., as required for Maxwell's equations).

To further elaborate on the constants ω and Δ, consider the discrete Laplacian on a uniform grid in one, two, or three dimensions, i.e., the standard 3-pt, 5-pt, and 7-pt operators that arise from finite difference discretizations. First, define $m := \lambda_{\max}(D^{-1}A)$, where D is the diagonal of A. For weighted Jacobi relaxation with weighting factor 2/3, we have that $\omega = (2/3)m$. Since $m \le 2$ for the Laplacian, then $\omega \le 4/3$. For Gauss–Seidel relaxation, let $A = D + L + L^T$, where L is the strictly lower-triangular part of A. Then, $M = D + L$ implies that $\sigma(M) = \frac{1}{2}(D + A)$, and hence

$$\omega = \lambda_{\max}[2(D+A)^{-1}A] = \frac{2}{1+m^{-1}}. \tag{2.15}$$

For the Laplacian, this again implies that $\omega \le 4/3$. We can also use (2.15) to estimate ω in more general settings. For example, in the case of finite elements, one can show that m is not larger than the maximum number of element degrees of freedom. Likewise for any sparse matrix A, one can show that m is not larger than the maximum number of nonzeros per row (column) of A.

The constant Δ is equal to 1 when M is symmetric. As an example of a nonsymmetric M, again, consider Gauss–Seidel. With m equal to the maximum number of

nonzeros in a row (column) of A, and letting $\mathbf{v} = (v_i)$, $\mathbf{w} = (w_i)$, and $A = (a_{ij})$, we have

$$\begin{aligned}
\langle M\mathbf{v}, \mathbf{w}\rangle &\leq \sum_{j\leq i: a_{ij}\neq 0} |a_{ij}|\,|v_j|\,|w_i| \\
&\leq \sum_{j\leq i: a_{ij}\neq 0} \sqrt{a_{jj}}\sqrt{a_{ii}}|v_j|\,|w_i| \\
&\leq \left[\sum_{j\leq i: a_{ij}\neq 0} a_{jj}(v_j)^2\right]^{1/2} \left[\sum_{j\leq i: a_{ij}\neq 0} a_{ii}(w_i)^2\right]^{1/2} \\
&\leq 1/2(m+1)\langle D\mathbf{v}, \mathbf{v}\rangle^{1/2}\langle D\mathbf{w}, \mathbf{w}\rangle^{1/2} \\
&\leq 1/2(m+1)\langle (D+A)\mathbf{v}, \mathbf{v}\rangle^{1/2}\langle (D+A)\mathbf{w}, \mathbf{w}\rangle^{1/2} \\
&= (m+1)\langle \sigma(M)\mathbf{v}, \mathbf{v}\rangle^{1/2}\langle \sigma(M)\mathbf{w}, \mathbf{w}\rangle^{1/2}.
\end{aligned}$$

3. The min-max problem. In this section, we analyze the optimal min-max solution of the measures (2.5) and (2.11), and use the results as a discussion point for relating and comparing the new theory to existing methods such as AMGe, spectral AMGe, and smoothed aggregation [20]. We also introduce generalized notions of the C-pt (coarse point) and F-pt (fine point) terminology used in the classical Ruge–Stüben AMG algorithm. The material in this section serves as a launching pad for the ideas and results in the remainder of the paper.

To analyze the min-max solution of (2.5) and (2.11), we analyze the following base measure:

$$\mu_{_X}(Q, \mathbf{e}) := \frac{\langle X(I-Q)\mathbf{e}, (I-Q)\mathbf{e}\rangle}{\langle A\mathbf{e}, \mathbf{e}\rangle}, \tag{3.1}$$

where, here again, Q has the form $Q = PR$ for some restriction operator $R : \mathbb{R}^n \to \mathbb{R}^{n_c}$ such that $RP = I_c$, and where X represents any given SPD matrix. In the remainder of the paper, it will be important that we fix R so that it does not depend on P (as in spectral AMGe). This operator defines the *coarse-grid variables* [4], $\mathbf{u}_c = R\mathbf{u}$, and specifies, for example, whether they are a subset of the fine-grid variables (vertex-centered), averages of fine-grid variables (cell-centered), or coefficients of fine-grid basis functions (agglomeration, e.g., as in spectral AMGe or smoothed aggregation). The coarse-grid variables, $R\mathbf{u}$, are analogous to C-pts in Ruge–Stüben AMG.

Now, define $S : \mathbb{R}^{n_s} \to \mathbb{R}^n$, where $n_s = n - n_c$, such that $RS = 0$. Think of range(S) as the "smoother space", i.e., the space on which the smoother must be effective. Note that S is not unique (but range(S) is). The variables $S^T\mathbf{u}$ are analogous to F-pts. Note also that S and R^T define an orthogonal decomposition of $\mathbb{R}^n$. That is, any vector $\mathbf{e}$ can be written as $\mathbf{e} = S\mathbf{e}_s + R^T\mathbf{e}_c$ for some $\mathbf{e}_s$ and $\mathbf{e}_c$. We will see in Theorem 3.1 below that the min-max problem of this section also induces an A-orthogonal decomposition of $\mathbb{R}^n$ involving the operator S.

THEOREM 3.1. *Assume we are given a coarse grid Ω_c, and define*

$$\mu_{_X}^\star := \min_P \max_{\mathbf{e}\neq 0} \mu_{_X}(PR, \mathbf{e}). \tag{3.2}$$

The arg min *of* (3.2)*, $P_\star$, satisfies*

$$P_\star^T AS = 0. \tag{3.3}$$

The minimum is given by

$$\mu_X^\star = \frac{1}{\lambda_{\min}((S^T X S)^{-1}(S^T A S))}. \tag{3.4}$$

Proof. Note that since $Q = PR$, $RP = I_c$, and $RS = 0$, we have

$$(I - Q)P = 0; \qquad (I - Q)S = S. \tag{3.5}$$

Also note that $\mathbf{e} - PR\mathbf{e} = (I - Q)\mathbf{e} \in \text{range}\,(S)$ since $R(I - Q) = 0$. Hence $\mathbf{e} = S\mathbf{e}_s + P\mathbf{e}_c$ for some $\mathbf{e}_s$ and $\mathbf{e}_c = R\mathbf{e}$. From (3.2), using (3.5), we then have that

$$\mu_X^\star = \min_P \max_{\mathbf{e}_c, \mathbf{e}_s} \frac{\langle XS\mathbf{e}_s, S\mathbf{e}_s\rangle}{\langle AS\mathbf{e}_s, S\mathbf{e}_s\rangle + 2\langle AS\mathbf{e}_s, P\mathbf{e}_c\rangle + \langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle} \tag{3.6}$$

$$= \min_P \max_{\mathbf{e}_s} \frac{\langle XS\mathbf{e}_s, S\mathbf{e}_s\rangle}{\min_{\mathbf{e}_c}\left(\langle S^T AS\mathbf{e}_s, \mathbf{e}_s\rangle + 2\langle P^T AS\mathbf{e}_s, \mathbf{e}_c\rangle + \langle P^T AP\mathbf{e}_c, \mathbf{e}_c\rangle\right)}. \tag{3.7}$$

The denominator in (3.7) is a quadratic form in the variable $\mathbf{e}_c$ with solution

$$\mathbf{e}_c = -(P^T AP)^{-1} P^T AS\mathbf{e}_s. \tag{3.8}$$

Plugging (3.8) back into (3.7) gives

$$\mu_X^\star = \min_P \max_{\mathbf{e}_s \neq 0} \frac{\langle XS\mathbf{e}_s, S\mathbf{e}_s\rangle}{\langle S^T AS\mathbf{e}_s, \mathbf{e}_s\rangle - \langle (P^T AP)^{-1} P^T AS\mathbf{e}_s, P^T AS\mathbf{e}_s\rangle}. \tag{3.9}$$

Since the second term in the denominator of (3.9) is nonnegative for any $\mathbf{e}_s$, the arg min must satisfy $P_\star^T AS = 0$. Hence,

$$\mu_X^\star = \max_{\mathbf{e}_s \neq 0} \frac{\langle S^T XS\mathbf{e}_s, \mathbf{e}_s\rangle}{\langle S^T AS\mathbf{e}_s, \mathbf{e}_s\rangle} = \frac{1}{\lambda_{\min}((S^T XS)^{-1}(S^T AS))}. \qquad \square$$

Theorem 3.1 is used to motivate the main result in section 4. It will also be used to prove many of the results in sections 4 and 5. Note that $P_\star$ is unique, even though S is not, since R is fixed and $RP = I_c$. An interesting corollary to the theorem is the following.

COROLLARY 3.2. *The optimal $P_\star$ in Theorem* 3.1 *is given by the formula*

$$P_\star = \begin{bmatrix} S & R^T \end{bmatrix} \begin{bmatrix} -(S^T AS)^{-1}(S^T AR^T) \\ I \end{bmatrix} = (I - S(S^T AS)^{-1} S^T A)R^T. \tag{3.10}$$

Proof. This is obtained by solving the equation $S^T AP_\star = 0$. For any $\mathbf{v}$ consider $\mathbf{w} = P_\star \mathbf{v}_c$ and use its decomposition $\mathbf{w} = S\mathbf{w}_s + R^T \mathbf{w}_c$. We have $\mathbf{v}_c = RP_* \mathbf{v}_c = R\mathbf{w} = RR^T \mathbf{w}_c = \mathbf{w}_c$. On the other hand, since $S^T A\mathbf{w} = 0$ one arrives at

$$S^T AS\mathbf{w}_s + S^T AR^T \mathbf{w}_c = 0.$$

That is, $\mathbf{w}_s = -(S^T AS)^{-1} S^T AR^T \mathbf{w}_c = -(S^T AS)^{-1} S^T AR^T \mathbf{v}_c$. Thus

$$P_\star \mathbf{v}_c = (-S(S^T AS)^{-1} S^T A + I)R^T \mathbf{v}_c,$$

which completes the proof. $\square$

Remark 3.3. The first expression in (3.10) can be viewed as a generalization of the optimal interpolation for the AMGe measure (see Corollary 3.4 below). Alternatively, the second expression in (3.10) can be viewed as a kind of smoothed aggregation method. That is, the operator R^T is a type of tentative prolongator, and the term $(I - S(S^TAS)^{-1}S^TA)$ is a type of smoother (because it removes error components in the "smoother space" spanned by S). The interpolation operator in the smoothed aggregation method is formed similarly by smoothing a tentative prolongation operator, except that a simpler, local smoother is used. Another similarity is that the smoothed aggregation smoother is designed to leave unchanged the kernel components in range (R^T) (those kernel components that are representable on the coarse grid). In (3.10), the fact that range (S) is A-orthogonal to range $(P_\star)$ also insures this.

The following two corollaries specialize the results in Theorem 3.1 and Corollary 3.2 to the particular cases of AMGe and spectral AMGe. These results are useful primarily because of the insight and guidance they provide for developing algorithms in these settings.

COROLLARY 3.4. *Assume that P and R are as in AMGe and have the specific forms*

$$P = \begin{bmatrix} W \\ I \end{bmatrix}, \qquad R = \begin{bmatrix} 0 & I \end{bmatrix}, \tag{3.11}$$

where we have reordered the equations so that

$$A = \begin{bmatrix} A_{ff} & A_{fc} \\ A_{cf} & A_{cc} \end{bmatrix}. \tag{3.12}$$

Let $X = \|A\|I$ in (3.1). *Then, the* arg min *and minimum of* (3.2) *are given by*

$$P_\star = \begin{bmatrix} -A_{ff}^{-1}A_{fc} \\ I \end{bmatrix}, \qquad \mu_X^\star = \frac{\|A\|}{\lambda_{\min}(A_{ff})}. \tag{3.13}$$

Proof. Let $S = [I\ 0]^T$. Then $RS = 0$ and $S^TAS = A_{ff}$. The result then follows trivially from (3.10) and (3.4). ∎

COROLLARY 3.5. *Assume that R has the form*

$$R^T = [\mathbf{p}_1, \ldots, \mathbf{p}_c], \tag{3.14}$$

where the $\mathbf{p}_i$, $1 \le i \le n$, are the orthonormal eigenvectors of A with corresponding eigenvalues $\lambda_1 \le \cdots \le \lambda_c \le \cdots \le \lambda_n$. Let $X = \|A\|I$ in (3.1). *Then, the* arg min *and minimum of* (3.2) *are given by*

$$P_\star = R^T, \qquad \mu_X^\star = \frac{\|A\|}{\lambda_{c+1}} = \frac{\lambda_n}{\lambda_{c+1}}. \tag{3.15}$$

Proof. Let $S = [\mathbf{p}_{c+1}, \ldots, \mathbf{p}_n]$. Then $RS = 0$ and $S^TAS = \operatorname{diag}(\lambda_{c+1}, \ldots, \lambda_n)$. The result then follows trivially from (3.10) and (3.4). ∎

Now, consider tailoring the base min-max problem (3.2) to the case of the new measures in (2.5) and (2.11). Assume again that Q has the form $Q = PR$ for some fixed restriction operator $R : \mathbb{R}^n \to \mathbb{R}^{n_c}$ such that $RP = I_c$. As before, define $S : \mathbb{R}^{n_s} \to \mathbb{R}^n$ such that $RS = 0$, and assume we are given a coarse grid Ω_c. Define, based on (2.5) and (2.11),

$$\mu^\star := \min_P \max_{\mathbf{e}\neq 0} \mu(PR, \mathbf{e}), \tag{3.16}$$

$$\mu_\sigma^\star := \min_P \max_{\mathbf{e}\neq 0} \mu_\sigma(PR, \mathbf{e}). \tag{3.17}$$

The quantities $\mu^\star$ and $\mu_\sigma^\star$ measure the ability of the coarse grid to represent algebraically smooth error, where algebraically smooth error is defined to be error components that are not being effectively damped by the more general relaxation process in (2.2). Strictly speaking, this interpretation of $\mu^\star$ and $\mu_\sigma^\star$ assumes that the interpolation operator is the optimal one; i.e., that $P = P_\star$. Hence, given a coarse grid, small quantities indicate that there exists *some* interpolation operator that can interpolate smooth error. Whether or not there exists a practical (e.g., local) interpolation operator is an important research question that is not addressed in this paper. However, empirical evidence so far indicates that $\mu^\star$ and $\mu_\sigma^\star$ are useful measures in practice, particularly for PDE problems.

4. Building interpolation. In the previous section, we defined the quantities $\mu^\star$ and $\mu_\sigma^\star$ as indicators of the ability of the coarse grid to represent smooth error. Assuming that either of these quantities is "small" (we will present an efficient approach for estimating $\mu^\star$ and $\mu_\sigma^\star$ in the next section), we then need to build an interpolation operator. In practice, this means that we must somehow localize the new measure. However, note that the result (3.3) in Theorem 3.1 does not depend on the X in (3.1). This suggests the possibility that, once an adequate coarse grid has been chosen, the procedure for building an interpolation operator can be done without knowledge of the relaxation process. This is quantified in the next lemma and theorem.

LEMMA 4.1. *The following statements are equivalent, where $Q = PR$, P, R, and S are as before, and where $\eta \geq 1$ is some constant:*

$$\langle AQ\mathbf{e}, Q\mathbf{e}\rangle \leq \eta \langle A\mathbf{e}, \mathbf{e}\rangle \quad \forall \mathbf{e}; \tag{4.1}$$

$$\langle A(I-Q)\mathbf{e}, (I-Q)\mathbf{e}\rangle \leq \eta \langle A\mathbf{e}, \mathbf{e}\rangle \quad \forall \mathbf{e}; \tag{4.2}$$

$$\langle AP\mathbf{e}_c, S\mathbf{e}_s\rangle^2 \leq \left(1 - \frac{1}{\eta}\right) \langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle \langle AS\mathbf{e}_s, S\mathbf{e}_s\rangle \quad \forall \mathbf{e}_c, \mathbf{e}_s. \tag{4.3}$$

Proof. We first show that the approximate harmonic property of P, (4.1), implies the strengthened Cauchy–Schwarz inequality (4.3). Letting $\mathbf{e} = tS\mathbf{e}_s + P\mathbf{e}_c$ for any $\mathbf{e}_c$, $\mathbf{e}_s$ and any real t, and noting that $Q\mathbf{e} = P\mathbf{e}_c$, then (4.1) leads to the following quadratic inequality for t:

$$t^2\langle AS\mathbf{e}_s, S\mathbf{e}_s\rangle + 2t\langle AP\mathbf{e}_c, S\mathbf{e}_s\rangle + \left(1 - \frac{1}{\eta}\right)\langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle \geq 0.$$

This implies that the discriminant of the above quadratic form is nonpositive, which is exactly the strengthened Cauchy–Schwarz inequality (4.3). In the same way, we can also show that (4.2) implies (4.3) by noting that $(I-Q)\mathbf{e} = tS\mathbf{e}_s$.

To show that the strengthened Cauchy–Schwarz inequality (4.3) implies the approximate harmonic property (4.1), let $\mathbf{e} = S\mathbf{e}_s + R^T\mathbf{e}_c$ and note that $R(I-Q)\mathbf{e} = 0$. Therefore, there is an $\hat{\mathbf{e}}_s$ such that $(I-Q)\mathbf{e} = S\hat{\mathbf{e}}_s$. That is, $\mathbf{e} = S\hat{\mathbf{e}}_s + P\mathbf{e}_c$, and one has

$$\langle A\mathbf{e}, \mathbf{e}\rangle = \langle AS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle + 2\langle AS\hat{\mathbf{e}}_s, P\mathbf{e}_c\rangle + \langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle.$$

Using (4.3) implies

$$\begin{aligned}
\langle A\mathbf{e}, \mathbf{e}\rangle &\geq \langle AS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle - 2\sqrt{1-\frac{1}{\eta}}\langle AS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle^{1/2}\langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle^{1/2} + \langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle \\
&= \frac{1}{\eta}\langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle + \left[\langle AS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle^{1/2} - \sqrt{1-\frac{1}{\eta}}\langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle^{1/2}\right]^2 \\
&\geq \frac{1}{\eta}\langle AQ\mathbf{e}, Q\mathbf{e}\rangle.
\end{aligned}$$

In the same way, we can also show that (4.3) implies (4.2). ∎

THEOREM 4.2. *Define μ_X and $\mu_X^\star$ as in* (3.1) *and* (3.2) *for any SPD matrix X. Assume that a coarse grid has been chosen such that the following condition holds:*

C1: *$\mu_X^\star \leq K$ for some constant K.*

Assume also that an interpolation operator P has been defined, and satisfies the following additional condition:

C2: (4.1), (4.2), *or* (4.3) *holds for some constant $\eta \geq 1$.*

Then, the following weak approximation property holds:

$$\mu_X(Q,\mathbf{e}) \leq \eta K \quad \forall \mathbf{e} \in \mathbb{R}^n \setminus \{0\}. \tag{4.4}$$

Proof. From Lemma 4.1, we can assume the strengthened Cauchy–Schwarz inequality (4.3). Now, consider the left-hand side of the desired inequality (4.4) and decompose $\mathbf{e} = S\mathbf{e}_s + R^T\mathbf{e}_c$. Note that $R(I-Q)\mathbf{e} = 0$, which implies there is an $\hat{\mathbf{e}}_s$ such that $(I-Q)\mathbf{e} = S\hat{\mathbf{e}}_s$. Hence, using (4.3) and Theorem 3.1, we have

$$\begin{aligned}
\max_{\mathbf{e}} \mu_X(Q,\mathbf{e}) &= \max_{\hat{\mathbf{e}}_s} \max_{\mathbf{e}_c} \frac{\langle XS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle}{\langle A(S\hat{\mathbf{e}}_s + P\mathbf{e}_c), (S\hat{\mathbf{e}}_s + P\mathbf{e}_c)\rangle} \\
&= \max_{\hat{\mathbf{e}}_s} \max_{\mathbf{e}_c} \max_{t\in\mathbb{R}} \frac{\langle XS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle}{\langle A(S\hat{\mathbf{e}}_s + tP\mathbf{e}_c), (S\hat{\mathbf{e}}_s + tP\mathbf{e}_c)\rangle} \\
&= \max_{\hat{\mathbf{e}}_s} \max_{\mathbf{e}_c} \frac{\langle XS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle}{\min_{t\in\mathbb{R}}\langle A(S\hat{\mathbf{e}}_s + tP\mathbf{e}_c), (S\hat{\mathbf{e}}_s + tP\mathbf{e}_c)\rangle} \\
&= \max_{\hat{\mathbf{e}}_s} \max_{\mathbf{e}_c} \frac{\langle XS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle}{\langle AS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle - \frac{\langle AP\mathbf{e}_c, S\hat{\mathbf{e}}_s\rangle^2}{\langle AP\mathbf{e}_c, P\mathbf{e}_c\rangle}} \\
&\leq \max_{\hat{\mathbf{e}}_s} \frac{\langle XS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle}{\langle AS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle - (1-\frac{1}{\eta})\langle AS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle} \\
&= \eta \max_{\hat{\mathbf{e}}_s} \frac{\langle XS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle}{\langle AS\hat{\mathbf{e}}_s, S\hat{\mathbf{e}}_s\rangle} \\
&= \eta\mu_X^\star \\
&\leq \eta K. \qquad \square
\end{aligned}$$

The corollaries to Theorem 4.2 for measures μ and μ_σ separate coarse-grid correction into two distinct parts: **C1** insures the quality of the coarse grid, i.e., its ability to represent algebraically smooth error components; and **C2** insures that these smooth components are adequately interpolated. Hence, once an adequate coarse grid is chosen, it is sufficient to build interpolation based on any one of the three statements in **C2**. In fact, the following result holds.

COROLLARY 4.3. *The statements in* **C2** *are necessary conditions for obtaining a uniformly convergent method.*

Proof. To see this in the case of measure μ_σ, note that our assumption that $(M + M^T - A)$ is SPD implies that $2\langle\sigma(M)\mathbf{e},\mathbf{e}\rangle \geq \langle A\mathbf{e},\mathbf{e}\rangle$. Hence, an approximation property that bounds the measure μ_σ (with constant K_σ) also implies (4.2) (with $\eta = 2K_\sigma$). $\square$

The significance of the above result is that the statements in **C2** nowhere involve the relaxation process. This implies that we can construct interpolation coefficients (again, assuming a coarse grid has already been chosen) using previously developed methods, even those methods that assumed a pointwise smoother. For example, in

AMGe, a local procedure is used for constructing interpolation that produces an approximation property of the form

$$\|A\|\|(I-Q)\mathbf{e}\|^2 \leq \eta \langle A\mathbf{e}, \mathbf{e}\rangle . \tag{4.5}$$

But, it is obvious that this also implies (4.2), which in turn implies the more general result in Theorem 4.2. Note that, even if the constant η is sharp in (4.5), this may be an extremely pessimistic constant for (4.2). See section 6.1 for an example.

5. Compatible relaxation. In this section, we introduce the idea of *compatible relaxation* and show how its convergence rate may be used to estimate the quantities $\mu^\star$ and $\mu^\star_\sigma$ in (3.16) and (3.17). That is, we will show how compatible relaxation may be used to insure **C1** of Theorem 4.2. We will present four variants of compatible relaxation, each having its own advantages and disadvantages, and suggest a simple algorithm for using these techniques to choose coarse grids in AMG methods.

Compatible relaxation, as defined by Brandt [4], is *a modified relaxation scheme that keeps the coarse-level variables invariant.* Consider the following compatible relaxation iteration (represented here by its corresponding error propagation):

$$\mathbf{e}_{k+1} = (I - S(S^TMS)^{-1}S^TA)\mathbf{e}_k, \tag{5.1}$$

where $S : \mathbb{R}^{n_s} \to \mathbb{R}^n$ is defined, as before, in terms of some restriction operator R. Recall that the coarse-grid variables are defined by $\mathbf{u}_c = R\mathbf{u}$. Since $RS = 0$, we see from (5.1) that $R\mathbf{e}_{k+1} = R\mathbf{e}_k$; that is, the coarse-grid variables are invariant under this iteration. Hence, we need only consider compatible relaxation in the complementary space via the following iteration:

$$\mathbf{e}_{k+1} = (I - (S^TMS)^{-1}(S^TAS))\mathbf{e}_k. \tag{5.2}$$

Brandt states that *a general measure for the quality of the set of coarse variables is the convergence rate of compatible relaxation.* In the next theorem, we will make this statement rigorous by relating the convergence of the compatible relaxation process in (5.2) to the measure $\mu^\star$ in (3.16) (equivalently, $\mu^\star_\sigma$ in (3.17)).

THEOREM 5.1. *Assume that* $(M + M^T - A)$ *is SPD. Then,*

$$\mu^\star \leq \frac{\Delta^2}{2-\omega} \cdot \frac{1}{1-\rho_s}, \tag{5.3}$$

where constants Δ *and* ω *are as in Lemma* 2.3*, and where*

$$\rho_s = \|(I - M_s^{-1}A_s)\|_{A_s} \tag{5.4}$$

with $M_s = (S^TMS)$ *and* $A_s = (S^TAS)$*. Note that, although we use* ρ *to represent the spectral radius of a matrix, the quantity* ρ_s *is in general only an upper bound for the spectral radius of compatible relaxation; it is equal to the spectral radius when* M *is symmetric.*

Proof. From (3.16), (3.17), and Lemma 2.3, we have that

$$\mu^\star \leq \frac{\Delta^2}{2-\omega}\mu^\star_\sigma.$$

But, from (2.11) and Theorem 3.1,

$$\begin{aligned}\mu_\sigma^\star &= \frac{1}{\lambda_{\min}(\sigma(M_s)^{-1}A_s)}\\ &= \max_{\mathbf{v}_s}\frac{\langle M_s\mathbf{v}_s,\mathbf{v}_s\rangle}{\langle A_s\mathbf{v}_s,\mathbf{v}_s\rangle}\\ &\le \|A_s^{-1/2}M_sA_s^{-1/2}\|.\end{aligned}$$

Hence, we have

$$\mu^\star \le \frac{\Delta^2}{2-\omega}\|A_s^{-1/2}M_sA_s^{-1/2}\|,$$

and it remains to show that

$$\|A_s^{-1/2}M_sA_s^{-1/2}\| \le (1-\rho_s)^{-1}. \tag{5.5}$$

Consider the following symmetric compatible relaxation matrix:

$$H_{ss} = (I - M_s^{-1}A_s)(I - M_s^{-T}A_s).$$

We have that

$$\begin{aligned}\rho(H_{ss}) &= \rho(A_s^{1/2}H_{ss}A_s^{-1/2})\\ &= \rho((I - A_s^{1/2}M_s^{-1}A_s^{1/2})^T(I - A_s^{1/2}M_s^{-1}A_s^{1/2}))\\ &= \|(I - A_s^{1/2}M_s^{-1}A_s^{1/2})\|^2\\ &= \|(I - M_s^{-1}A_s)\|_{A_s}^2\\ &= \rho_s^2.\end{aligned}$$

Noting that H_{ss} can also be written as $I - M_{ss}^{-1}A_s$, where

$$M_{ss}^{-1} = (M_s^{-1} + M_s^{-T} - M_s^{-1}A_sM_s^{-T}),$$

we have that

$$\rho_s^2 = \rho(H_{ss}) = \max_\lambda |1 - \lambda(M_{ss}^{-1}A_s)| \ge 1 - \lambda_{\min}(M_{ss}^{-1}A_s).$$

Letting $Y_s^{-1} = A_s^{1/2}M_s^{-1}A_s^{1/2}$, one arrives at the coercivity estimate

$$\begin{aligned}(1-\rho_s^2)\langle\mathbf{v}_s,\mathbf{v}_s\rangle &\le \langle M_{ss}^{-1}A_s^{1/2}\mathbf{v}_s, A_s^{1/2}\mathbf{v}_s\rangle\\ &= \langle(Y_s^{-T} + Y_s^{-1} - Y_s^{-1}Y_s^{-T})\mathbf{v}_s,\mathbf{v}_s\rangle\\ &= 2\langle Y_s^{-T}\mathbf{v}_s,\mathbf{v}_s\rangle - \langle Y_s^{-T}\mathbf{v}_s, Y_s^{-T}\mathbf{v}_s\rangle.\end{aligned} \tag{5.6}$$

Using the Cauchy–Schwarz inequality,

$$\langle Y_s^{-T}\mathbf{v}_s,\mathbf{v}_s\rangle \le \langle\mathbf{v}_s,\mathbf{v}_s\rangle^{1/2}\langle Y_s^{-T}\mathbf{v}_s, Y_s^{-T}\mathbf{v}_s\rangle^{1/2},$$

in (5.6), we arrive at

$$(\langle\mathbf{v}_s,\mathbf{v}_s\rangle^{1/2} - \langle Y_s^{-T}\mathbf{v}_s, Y_s^{-T}\mathbf{v}_s\rangle^{1/2})^2 \le \rho_s^2\langle\mathbf{v}_s,\mathbf{v}_s\rangle.$$

That is,

$$(1-\rho_s)^2\langle \mathbf{v}_s, \mathbf{v}_s\rangle \le \langle Y_s^{-T}\mathbf{v}_s, Y_s^{-T}\mathbf{v}_s\rangle.$$

Adding the left- and right-hand sides of the last estimate and estimate (5.6), one gets

$$(1-\rho_s)\langle \mathbf{v}_s, \mathbf{v}_s\rangle \le \langle Y_s^{-T}\mathbf{v}_s, \mathbf{v}_s\rangle.$$

This implies, letting $\mathbf{v}_s := Y_s\mathbf{v}_s$, that

$$\begin{aligned}\|Y_s\mathbf{v}_s\|^2 &= \langle Y_s\mathbf{v}_s, Y_s\mathbf{v}_s\rangle \\ &\le (1-\rho_s)^{-1}\langle \mathbf{v}_s, Y_s\mathbf{v}_s\rangle \\ &\le (1-\rho_s)^{-1}\|Y_s\mathbf{v}_s\|\|\mathbf{v}_s\|.\end{aligned}$$

Therefore, $\|Y_s\mathbf{v}_s\| \le (1-\rho_s)^{-1}\|\mathbf{v}_s\|$, which implies (5.5), and hence, the result. ∎

Theorem 5.1 shows that if compatible relaxation is fast to converge (i.e., ρ_s is small), then $\mu^\star$ is small (similarly for $\mu_\sigma^\star$). To use this result in practice as a means of measuring the quality of a given coarse grid, we must be able to efficiently estimate the value of ρ_s in (5.4). One obvious approach for doing this is to run the compatible relaxation iteration in (5.2) and monitor its convergence. In some cases, this may not be feasible. However, in the case where M is derived from a matrix splitting, $A = M - N$, such that M is explicitly available, the iteration in (5.2) is at least computable.

5.1. Compatible relaxation via subspace correction. Another practical form of compatible relaxation is based on the general subspace correction method framework [21], which encompasses both additive and multiplicative Schwarz. Of particular interest is the question of how to define a compatible relaxation variant of overlapping Schwarz. The iteration in (5.2) does not readily admit how to achieve this. In fact, the question of how to define compatible relaxation variants of general subspace correction methods requires some care.

Consider the following additive method:

$$I - M^{-1}A; \quad M^{-1} = \sum_i I_i(I_i^T A I_i)^{-1} I_i^T, \tag{5.7}$$

where $I_i : \mathbb{R}^{n_i} \to \mathbb{R}^n$ has full rank, $n_i < n$, and $\mathbb{R}^n = \bigcup_i \text{range}\,(I_i)$. Define full rank normalized operators S_i and R_i^T such that

$$\text{range}\,(S_i) = \text{range}\,(I_i^T S), \tag{5.8}$$

$$\text{range}\,(R_i^T) = \text{range}\,(I_i^T R^T). \tag{5.9}$$

In order to define a usable additive version of compatible relaxation, the I_i must be chosen so that the local spaces S_i and R_i^T are orthogonal, i.e., $R_i S_i = 0$. Compatible relaxation is then defined as follows:

$$I - M_{cr}^{-1}A_s; \quad M_{cr}^{-1} = \sum_i S^T I_{s,i}(I_{s,i}^T A I_{s,i})^{-1} I_{s,i}^T S; \quad I_{s,i} = I_i S_i. \tag{5.10}$$

One natural relaxation method that is represented by (5.10) is additive Schwarz. We will discuss this method in more detail below. First, we prove the following lemma and theorem.

LEMMA 5.2. *Assume that we are given the decomposition*

$$\mathbf{v} = S\mathbf{v}_s + R^T\mathbf{v}_c = \begin{bmatrix} S & R^T \end{bmatrix} \begin{bmatrix} \mathbf{v}_s \\ \mathbf{v}_c \end{bmatrix},$$

such that $RS = 0$ *and* $S^TS = I$. *For any matrix* M, *we have that*

$$(S^TM^{-1}S)^{-1} = \overline{M}_{\text{Schur}} := S^TMS - S^TMR^T(RMR^T)^{-1}RMS.$$

If M *is SPD, then the following also holds:*

$$\langle (S^TM^{-1}S)^{-1}\mathbf{v}_s, \mathbf{v}_s\rangle = \min_{\mathbf{v}_c} \langle M(S\mathbf{v}_s + R^T\mathbf{v}_c), (S\mathbf{v}_s + R^T\mathbf{v}_c)\rangle.$$

Proof. Define the hierarchical basis matrix

$$\overline{M} := \begin{bmatrix} S & R^T \end{bmatrix}^T M \begin{bmatrix} S & R^T \end{bmatrix} = \begin{bmatrix} \overline{M}_{ss} & \overline{M}_{sc} \\ \overline{M}_{cs} & \overline{M}_{cc} \end{bmatrix}. \tag{5.11}$$

One has $S^TMS = \overline{M}_{ss}$ by definition. Again, from the definition of $\overline{M}$,

$$\begin{bmatrix} S & R^T \end{bmatrix} \overline{M}^{-1} \begin{bmatrix} S & R^T \end{bmatrix}^T = M^{-1}.$$

Hence,

$$S^TM^{-1}S = S^T \begin{bmatrix} S & R^T \end{bmatrix} \overline{M}^{-1} \begin{bmatrix} S & R^T \end{bmatrix}^T S.$$

Now, using the fact that $RS = 0$ and $S^TS = I$, one gets

$$S^TM^{-1}S = \begin{bmatrix} I & 0 \end{bmatrix} \overline{M}^{-1} \begin{bmatrix} I & 0 \end{bmatrix}^T.$$

Finally, since

$$\overline{M}^{-1} = \begin{bmatrix} (\overline{M}_{\text{Schur}})^{-1} & \star \\ \star & \star \end{bmatrix},$$

one gets

$$S^TM^{-1}S = \begin{bmatrix} I & 0 \end{bmatrix} \overline{M}^{-1} \begin{bmatrix} I & 0 \end{bmatrix}^T = (\overline{M}_{\text{Schur}})^{-1},$$

which implies the first result. The second result follows trivially by noting that

$$\min_{\mathbf{v}_c} \langle M(S\mathbf{v}_s + R^T\mathbf{v}_c), (S\mathbf{v}_s + R^T\mathbf{v}_c)\rangle$$

is a quadratic form in the variable $\mathbf{v}_c$. The minimum is $\langle \overline{M}_{\text{Schur}}\mathbf{v}_s, \mathbf{v}_s\rangle$. ∎

THEOREM 5.3. *Let* M^{-1} *and* M_{cr}^{-1} *be as in* (5.7) *and* (5.10), *respectively. Define* ω *as in Theorem* 5.1, *and define*

$$\rho_{cr} = \|(I - M_{cr}^{-1}A_s)\|_{A_s} = \rho(I - M_{cr}^{-1}A_s). \tag{5.12}$$

Then,

$$\mu^\star \le \frac{1}{2-\omega} \cdot \frac{1}{1-\rho_{cr}}. \tag{5.13}$$

Proof. As before, we can write any vector $\mathbf{e}$ as $\mathbf{e} = S\mathbf{e}_s + R^T\mathbf{e}_c$ for some $\mathbf{e}_s$ and $\mathbf{e}_c$. From (5.8) and (5.9), there exist vectors $\mathbf{e}_{s,i}$ and $\mathbf{e}_{c,i}$ such that $S_i\mathbf{e}_{s,i} = I_i^T S\mathbf{e}_s$ and $R_i^T\mathbf{e}_{c,i} = I_i^T R^T\mathbf{e}_c$. Using this, together with the result in Lemma 5.2 (replacing M^{-1} by $(I_i^T A I_i)$, and R and S by R_i and S_i, respectively), we have

$$\begin{aligned}
\langle M_{cr}^{-1}\mathbf{e}_s, \mathbf{e}_s\rangle &= \sum_i \langle (S_i^T I_i^T A I_i S_i)^{-1} S_i^T I_i^T S\mathbf{e}_s, S_i^T I_i^T S\mathbf{e}_s\rangle \\
&= \sum_i \langle (S_i^T I_i^T A I_i S_i)^{-1}\mathbf{e}_{s,i}, \mathbf{e}_{s,i}\rangle \\
&\le \sum_i \left\langle (I_i^T A I_i)^{-1}\begin{bmatrix} S_i & R_i^T\end{bmatrix}\begin{bmatrix}\mathbf{e}_{s,i}\\ \mathbf{e}_{c,i}\end{bmatrix}, \begin{bmatrix} S_i & R_i^T\end{bmatrix}\begin{bmatrix}\mathbf{e}_{s,i}\\ \mathbf{e}_{c,i}\end{bmatrix}\right\rangle \\
&= \sum_i \left\langle (I_i^T A I_i)^{-1} I_i^T\begin{bmatrix} S & R^T\end{bmatrix}\begin{bmatrix}\mathbf{e}_{s}\\ \mathbf{e}_{c}\end{bmatrix}, I_i^T\begin{bmatrix} S & R^T\end{bmatrix}\begin{bmatrix}\mathbf{e}_{s}\\ \mathbf{e}_{c}\end{bmatrix}\right\rangle \\
&= \sum_i \langle I_i (I_i^T A I_i)^{-1} I_i^T\mathbf{e}, \mathbf{e}\rangle \\
&= \langle M^{-1}\mathbf{e}, \mathbf{e}\rangle.
\end{aligned}$$

Since $\mathbf{e}_c$ was arbitrary, this implies (again, using Lemma 5.2) that

$$\langle M_{cr}^{-1}\mathbf{e}_s, \mathbf{e}_s\rangle \le \min_{\mathbf{e}_c}\langle M^{-1}\mathbf{e}, \mathbf{e}\rangle = \langle (S^T M S)^{-1}\mathbf{e}_s, \mathbf{e}_s\rangle = \langle M_s^{-1}\mathbf{e}_s, \mathbf{e}_s\rangle.$$

Hence, from (3.16), (3.17), and Lemma 2.3, we have that

$$\begin{aligned}
\mu^\star &\le (2-\omega)^{-1}\mu_\sigma^\star \\
&= (2-\omega)^{-1}\frac{1}{\lambda_{\min}(M_s^{-1}A_s)} \\
&\le (2-\omega)^{-1}\frac{1}{\lambda_{\min}(M_{cr}^{-1}A_s)} \\
&\le (2-\omega)^{-1}(1-\rho_{cr})^{-1}. \qquad \square
\end{aligned}$$

When the coarse-grid variables are a subset of the fine-grid variables, then we have that $R = [0\ I]$ and $S = [I\ 0]^T$, and the additive Schwarz method satisfies the criteria for the compatible relaxation in (5.10). To see this, note that, for additive Schwarz, each I_i is a characteristic function over some local subdomain Ω_i. That is, $I_i\mathbf{w} = \mathbf{w}_i$ on Ω_i and zero outside of Ω_i. From the construction of S_i and R_i^T in (5.8) and (5.9), it is clear that they are also just characteristic functions: R_i^T over the C-pts in Ω_i; and S_i over the F-pts in Ω_i. Hence, $R_i S_i = 0\ \forall i$.

Multiplicative versions of compatible relaxation are also possible but more difficult to construct, and may not be necessary anyway. Standard Gauss–Seidel and block Gauss–Seidel methods have straightforward compatible relaxation variants, but a general form for multiplicative subspace correction or multiplicative Schwarz (with overlap) is not apparent.

Multiplicative methods are not as practical in the parallel setting, but have better smoothing properties in the sense that ω is usually bounded away from two without the need for additional damping factors. In practice, a good smoother to use is the natural generalization of F-C relaxation. That is, (post) smoothing should consist of the above additive compatible relaxation process followed by the analogous additive compatible relaxation process on the R^T space. Since $S^T A S$ and RAR^T are well-conditioned in some sense, the additive compatible relaxation methods should work well.

5.2. A more general form of compatible relaxation. Although the compatible relaxation methods presented so far cover many of the traditional relaxation methods, there are still some that may not be represented. In particular, the iteration in (5.2) requires that the matrix M is available *and* that the matrix S^TMS is easily inverted. This may not always be feasible. Additive Schwarz is one such example, albeit one that fortunately has a remedy as described in (5.10). In general, the action of M^{-1} is always available, and motivates us to consider the following compatible relaxation process:

$$\mathbf{e}_{k+1} = (I - (S^TM^{-1}S)(S^TAS))\mathbf{e}_k, \tag{5.14}$$

where, here, S must be normalized so that $S^TS = I_s$, the identity on $\mathbb{R}^{n_s}$. This method is always computable, but must be used with care, as we describe below. First, we state the following result.

THEOREM 5.4. *Assume that the smoother (SPD) M is stable w.r.t. the decomposition $\mathbf{v} = S\mathbf{v}_s + R^T\mathbf{v}_c$ in the sense that for some constant $\gamma \in [0,1)$ the following strengthened Cauchy–Schwarz inequality holds:*

$$\langle MS\mathbf{v}_s, R^T\mathbf{v}_c\rangle \le \gamma\langle MS\mathbf{v}_s, S\mathbf{v}_s\rangle^{1/2}\langle MR^T\mathbf{v}_c, R^T\mathbf{v}_c\rangle^{1/2} \quad \forall \mathbf{v}_s, \mathbf{v}_c. \tag{5.15}$$

Then, the following estimates hold for all $\mathbf{v}_s$:

$$\langle (S^TMS)^{-1}\mathbf{v}_s, \mathbf{v}_s\rangle \le \langle S^TM^{-1}S\mathbf{v}_s, \mathbf{v}_s\rangle \le \frac{1}{1-\gamma^2}\langle (S^TMS)^{-1}\mathbf{v}_s, \mathbf{v}_s\rangle.$$

In other words, the modified compatible relaxation matrix, $(S^TM^{-1}S)$, is spectrally equivalent to the true one, $(S^TMS)^{-1}$.

Proof. Define $\overline{M}$ as in (5.11) in the proof of Lemma 5.2. From the lemma, one trivially has

$$\langle (S^TM^{-1}S)^{-1}\mathbf{v}_s, \mathbf{v}_s\rangle = \langle \overline{M}_{\text{Schur}}\mathbf{v}_s, \mathbf{v}_s\rangle \le \langle S^TMS\mathbf{v}_s, \mathbf{v}_s\rangle.$$

Replacing M by M^{-1} yields the first inequality. The second inequality follows from the corollary to the strengthened Schwarz inequality,

$$\langle \overline{M}_{ss}\mathbf{v}_s, \mathbf{v}_s\rangle \le \frac{1}{1-\gamma^2}\min_{\mathbf{v}_c}\left\langle \overline{M}\begin{bmatrix}\mathbf{v}_s\\ \mathbf{v}_c\end{bmatrix}, \begin{bmatrix}\mathbf{v}_s\\ \mathbf{v}_c\end{bmatrix}\right\rangle = \frac{1}{1-\gamma^2}\langle \overline{M}_{\text{Schur}}\mathbf{v}_s, \mathbf{v}_s\rangle.$$

Here again, replace M by M^{-1} to get the result. ∎

The above theorem implies the following about the eigenvalues of the corresponding iteration matrix (5.14) and the original compatible relaxation matrix in (5.2):

$$\begin{aligned}\lambda(I - (S^TM^{-1}S)A_s) &\le \lambda(I - (S^TMS)^{-1}A_s)\\ &\le \gamma^2 + (1-\gamma^2)\lambda(I - (S^TM^{-1}S)A_s).\end{aligned}$$

Hence, if ρ_g is the spectral radius of $(I - (S^TM^{-1}S)A_s)$, we arrive at the following result, analogous to the results of Theorems 5.1 and 5.3:

$$\mu^\star \le \frac{1}{2-\omega}\cdot\frac{1}{1-\gamma^2}\cdot\frac{1}{1-\rho_g}. \tag{5.16}$$

From this, we see that in order to use the compatible relaxation method in (5.14), we must first have an estimate for the size of γ.

In practice, γ can often be estimated locally. This is the case, for example, when M is assembled from small matrices. That is, let $\langle M\mathbf{v},\mathbf{v}\rangle = \sum_e \langle M_e\mathbf{v}_e,\mathbf{v}_e\rangle = \sum_e \langle M_e(I_e)^T\mathbf{v},(I_e)^T\mathbf{v}\rangle$. Here, $\mathbf{v}_e := \mathbf{v}|_e$. Similarly, for a given $\mathbf{v}_e$ on e, $I_e\mathbf{v}_e$ is the extension of $\mathbf{v}_e$ as zero outside e. Let also $(I_e)^T S = S_e(I_{s,e})^T$ and $(I_e)^T R = R_e(I_{c,e})^T$ for S_e, $I_{s,e}$, R_e, and $I_{c,e}$ supported in e. Then,

$$\langle S^T MS\mathbf{v}_s,\mathbf{v}_s\rangle = \sum_e \langle (S_e)^T M_e S_e \mathbf{v}_{s,e},\mathbf{v}_{s,e}\rangle.$$

If one can say something about the local matrices $(S_e)^T M_e S_e$ and the local Schur complement $\overline{M}_{e,\mathrm{Schur}}$ of $\overline{M}_e = [S_e\ R_e^T]^T M_e [S_e\ R_e^T]$, the maximum of all local γ_e's gives an upper bound for the global γ. This technique is well known in the two-level hierarchical basis literature; cf., e.g., Bank [2].

A similar approach can be used to estimate γ in the case where M^{-1} is obtained by assembling local matrices. As an example, for additive Schwarz, we have that

$$M^{-1} = \sum_i I_i (I_i^T A I_i)^{-1} I_i^T,$$

where, as described near the end of the previous section, I_i is the characteristic function over some local subdomain Ω_i. If we have a local estimate of the form

$$\langle S_i^T (I_i^T A I_i)^{-1} S_i \mathbf{e}_{s,i},\mathbf{e}_{s,i}\rangle \le \frac{1}{1-\gamma_i^2}\langle (S_i^T I_i^T A I_i S_i)^{-1}\mathbf{e}_{s,i},\mathbf{e}_{s,i}\rangle,$$

then, using the proof of Theorem 5.3 for the last inequality below, we can show that

$$\begin{aligned}
\left\langle M^{-1}S\mathbf{e}_s, S\mathbf{e}_s\right\rangle &= \sum_i \langle I_i (I_i^T A I_i)^{-1} I_i^T S\mathbf{e}_s, S\mathbf{e}_s\rangle \\
&= \sum_i \langle S_i^T (I_i^T A I_i)^{-1} S_i \mathbf{e}_{s,i},\mathbf{e}_{s,i}\rangle \\
&\le \frac{1}{1-\max_i \gamma_i^2} \sum_i \langle (S_i^T I_i^T A I_i S_i)^{-1}\mathbf{e}_{s,i},\mathbf{e}_{s,i}\rangle \\
&\le \frac{1}{1-\max_i \gamma_i^2} \langle (S^T MS)^{-1}\mathbf{e}_s,\mathbf{e}_s\rangle.
\end{aligned}$$

The compatible relaxation method in (5.14) is similar to the habituated compatible relaxation scheme in [15]. The latter has the error propagation

$$\mathbf{e}_{k+1} = (I - S^T M^{-1} A S)\mathbf{e}_k. \tag{5.17}$$

The theoretical result is similar to (5.16). We have the following theorem.

THEOREM 5.5. *Assume that the smoother (SPD) M is stable w.r.t. the decomposition $\mathbf{v} = S\mathbf{v}_s + R^T\mathbf{v}_c$ in the sense that for some constant $\gamma \in [0,1)$ the strengthened Cauchy–Schwarz inequality in* (5.15) *holds. Assume that for some constant $\rho_h < 1$ the following convergence estimate holds:*

$$\langle A_s\mathbf{e}_{k+1},\mathbf{e}_{k+1}\rangle \le \rho_h^2 \langle A_s\mathbf{e}_k,\mathbf{e}_k\rangle.$$

Then, the following coercivity estimate holds:

$$\delta\langle M_g\mathbf{e}_s,\mathbf{e}_s\rangle \le \langle A_s\mathbf{e}_s,\mathbf{e}_s\rangle,$$

where $M_g = (S^T M^{-1} S)^{-1}$ *and* $\delta \geq \frac{1}{2}(1-\rho_h)^2$. *The latter coercivity estimate implies convergence of the compatible relaxation method in* (5.14) *with convergence factor* $\rho_g = (1-\delta)$.

Proof. Given $\mathbf{e}_s$, consider the solution $\mathbf{x}$ of the problem

$$M\mathbf{x} = AS\mathbf{e}_s.$$

The following inequality then follows:

$$\begin{aligned}\langle M\mathbf{x}, \mathbf{x}\rangle &= \langle M^{-1/2} AS\mathbf{e}_s, M^{1/2}\mathbf{x}\rangle \\ &\leq \langle M^{-1} AS\mathbf{e}_s, AS\mathbf{e}_s\rangle^{1/2} \langle M\mathbf{x}, \mathbf{x}\rangle^{1/2}.\end{aligned}$$

This implies that $\langle M\mathbf{x}, \mathbf{x}\rangle \leq \langle M^{-1} AS\mathbf{e}_s, AS\mathbf{e}_s\rangle$ which, from Lemma 5.2 and the fact that $2M - A$ is SPD, leads to

$$\begin{aligned}\langle M_g \mathbf{x}_s, \mathbf{x}_s\rangle &= \min_{\mathbf{x}_c} \langle M(S\mathbf{x}_s + R^T\mathbf{x}_c), (S\mathbf{x}_s + R^T\mathbf{x}_c)\rangle \\ &\leq \langle M\mathbf{x}, \mathbf{x}\rangle \leq \langle M^{-1} AS\mathbf{e}_s, AS\mathbf{e}_s\rangle \leq 2\langle A_s\mathbf{e}_s, \mathbf{e}_s\rangle.\end{aligned} \tag{5.18}$$

Now, using Cauchy–Schwarz and the fact that the habituated compatible relaxation is convergent, one has

$$\begin{aligned}\langle M_g\mathbf{e}_s, \mathbf{e}_s - \mathbf{x}_s\rangle &= \langle A_s^{-1/2} M_g\mathbf{e}_s, A_s^{1/2}(I - S^T M^{-1} AS)\mathbf{e}_s\rangle \\ &\leq \rho_h \langle A_s^{-1} M_g\mathbf{e}_s, M_g\mathbf{e}_s\rangle^{1/2} \langle A_s\mathbf{e}_s, \mathbf{e}_s\rangle^{1/2}.\end{aligned}$$

This inequality, using Cauchy–Schwarz and estimate (5.18), implies

$$\begin{aligned}\langle M_g\mathbf{e}_s, \mathbf{e}_s\rangle &\leq \langle \mathbf{x}_s, M_g\mathbf{e}_s\rangle + \rho_h \langle A_s^{-1} M_g\mathbf{e}_s, M_g\mathbf{e}_s\rangle^{1/2} \langle A_s\mathbf{e}_s, \mathbf{e}_s\rangle^{1/2} \\ &\leq \sqrt{2}\langle A_s\mathbf{e}_s, \mathbf{e}_s\rangle^{1/2} \langle M_g\mathbf{e}_s, \mathbf{e}_s\rangle^{1/2} \\ &\quad + \rho_h \langle A_s^{-1} M_g\mathbf{e}_s, M_g\mathbf{e}_s\rangle^{1/2} \langle A_s\mathbf{e}_s, \mathbf{e}_s\rangle^{1/2}.\end{aligned}$$

Dividing through by $\langle A_s\mathbf{e}_s, \mathbf{e}_s\rangle^{1/2} \langle M_g\mathbf{e}_s, \mathbf{e}_s\rangle^{1/2}$, one ends up with the inequality

$$\sqrt{\frac{\langle M_g\mathbf{e}_s, \mathbf{e}_s\rangle}{\langle A_s\mathbf{e}_s, \mathbf{e}_s\rangle}} \leq \sqrt{2} + \rho_h \sqrt{\frac{\langle A_s^{-1} M_g\mathbf{e}_s, M_g\mathbf{e}_s\rangle}{\langle M_g\mathbf{e}_s, \mathbf{e}_s\rangle}}.$$

Now, let

$$\frac{1}{\delta} = \sup_{\mathbf{e}_s} \frac{\langle M_g\mathbf{e}_s, \mathbf{e}_s\rangle}{\langle A_s\mathbf{e}_s, \mathbf{e}_s\rangle} = \sup_{\mathbf{e}_s} \frac{\langle A_s^{-1}\mathbf{e}_s, \mathbf{e}_s\rangle}{\langle M_g^{-1}\mathbf{e}_s, \mathbf{e}_s\rangle}.$$

Then, the following inequality is obtained:

$$\frac{1}{\sqrt{\delta}} \leq \sqrt{2} + \rho_h \frac{1}{\sqrt{\delta}}.$$

That is,

$$\frac{1}{\delta} \leq \frac{2}{(1-\rho_h)^2}. \qquad \square$$

From the theorem and (5.16), we have the following result for habituated compatible relaxation:

$$\mu^\star \le \frac{1}{2-\omega} \cdot \frac{1}{1-\gamma^2} \cdot \frac{2}{(1-\rho_h)^2}. \tag{5.19}$$

This result is weaker than the previous results for the other compatible relaxation methods. However, as with the method in (5.14), habituated compatible relaxation is always computable. In fact, it is the easiest to implement in practice because it directly involves the global smoother $I - M^{-1}A$. To see this, note that since S is normalized, the S^T and S in (5.17) can be pulled outside of the parentheses.

5.3. A coarsening algorithm. The above results suggest that compatible relaxation may serve as a useful tool for selecting coarse grids in AMG methods. We now present a prototype for such a coarsening algorithm in the case where the coarse grid is a subset of the fine grid. That is, consider the case where $R = [0\ I]$ and $S = [I\ 0]^T$. In the coarsening algorithm, one may apply any of the compatible relaxation methods above, i.e., either (5.2), (5.10), (5.14), or (5.17) to the homogeneous equations

$$(S^T A S)\mathbf{x} = 0 \tag{5.20}$$

with some initial guess, say $\mathbf{x}^0 = (x_i^0)$, where $x_i^0 = 1$ or random positive numbers.

(5.21a) Initialize $\mathcal{U} = \Omega$; $\quad \mathcal{C} = \emptyset$

(5.21b) While $\mathcal{U} \neq \emptyset$

(5.21c) Do ν compatible relaxation sweeps

(5.21d) $\mathcal{U} = \{i : (|x_i^\nu|/|x_i^{\nu-1}|) > \theta\}$

(5.21e) $\mathcal{C} = \mathcal{C} \cup \{\text{independent set of } \mathcal{U}\}$

This algorithm is similar to what Livne [15] and Brandt [4] use. Note that the pointwise convergence factor in step (5.21d) is not a meaningful measure when ν is large, and the question of how to choose the candidate set $\mathcal{C}$ is an active area of research.

6. Examples. In this section, we present two examples illustrating the theoretical results of the paper. The first example is a simple anisotropic diffusion problem that demonstrates the ability of the theory (and compatible relaxation) to account for a more general relaxation process; in this case, line relaxation. The example also demonstrates the use of previously developed methods (here, AMGe) for defining adequate interpolation operators in the sense of satisfying **C2** in Theorem 4.2. The second example illustrates how a nontrivial geometric multigrid method for $\mathbf{H}(\mathrm{div})$ fits into the new framework.

6.1. Compatible line relaxation for anisotropic diffusion. Consider the grid-aligned anisotropic problem

$$-\epsilon u_{xx} - u_{yy} = f, \quad (x, y) \in \Omega = (0, 1)^2,$$

with Dirichlet boundary conditions, discretized on a uniform rectangular grid with mesh size $h_x = h_y = h = 2^{-\ell}$ as in Figure 6.1. Using piecewise linear elements on

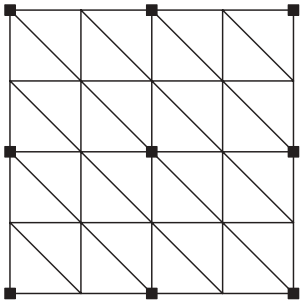

FIG. 6.1. *Uniform grid with triangular elements and standard coarse grid.*

triangles, the resulting macroelement matrix for each rectangle is given by

$$A_e = \epsilon \begin{bmatrix} 1 & -1 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ 0 & 0 & 1 & -1 \\ 0 & 0 & -1 & 1 \end{bmatrix} + \begin{bmatrix} 1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1 \\ -1 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{bmatrix}.$$

The vertices (nodes) of every rectangle are assumed to have the ordering (x_i, y_j), (x_{i+1}, y_j), (x_i, y_{j+1}), (x_{i+1}, y_{j+1}); where $x_i = ih_x$, $y_j = jh_y$, $i, j = 0, 1, \ldots, 2^\ell$.

Consider a block smoother, where the blocks are given by vertical lines of nodes in the grid. That is, consider a line smoother, where the lines are in the "strong" vertical direction. We note that M can be assembled from the same element matrices as A by zeroing some couplings in A_e (namely, the ones in the x-direction), yielding

$$M_e = \epsilon \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} + \begin{bmatrix} 1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1 \\ -1 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{bmatrix}.$$

Assume standard coarsening, so that $S = [I\ 0]^T$, where the zero block corresponds to the coarse nodes. We now analyze the convergence rate of the compatible relaxation process in (5.2). Note that $S^T M S$ and $S^T A S$ can also be assembled from local matrices $M_{s,e}$ and $A_{s,e}$; namely, those obtained from the above matrices in which a row and a column are deleted corresponding to the only coarse node in each rectangular element. Due to symmetry, we delete the last row and last column to get

$$A_{s,e} = \epsilon \begin{bmatrix} 1 & -1 & 0 \\ -1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} + \begin{bmatrix} 1 & 0 & -1 \\ 0 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix} \tag{6.1}$$

and

$$M_{s,e} = \epsilon \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} + \begin{bmatrix} 1 & 0 & -1 \\ 0 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix}.$$

It is sufficient to compute the eigenvalues of the generalized eigenvalue problem

$$A_{s,e}\mathbf{x} = \lambda M_{s,e}\mathbf{x}.$$

This leads to the following cubic equation for λ:

$$\begin{vmatrix} (1-\lambda)(1+\epsilon) & -\epsilon & -(1-\lambda) \\ -\epsilon & (1-\lambda)(1+\epsilon) & 0 \\ -(1-\lambda) & 0 & (1-\lambda)(1+\epsilon) \end{vmatrix} = 0.$$

The roots are

$$\lambda = 1, 1 \pm \sqrt{\frac{\epsilon}{2+\epsilon}}.$$

Hence, the spectrum of the compatible relaxation iteration matrix $(I - M_s^{-1}A_s)$ is contained in the interval

$$\left[-\sqrt{\frac{\epsilon}{2+\epsilon}}, \sqrt{\frac{\epsilon}{2+\epsilon}}\right].$$

For $\epsilon \in (0, 1]$, this implies that $\rho_s \leq 1/\sqrt{3}$. It is well known that linear interpolation is bounded in energy; i.e., it satisfies (4.1) for some constant η independent of ϵ. In fact, for right-angled triangles, one has $\eta = \frac{1}{1-\gamma^2}$ with $\gamma^2 = \frac{1}{2}$; cf. [16]. Hence, from Theorems 4.2 and 2.2, we can conclude that the two-grid method with the above line smoother converges with a rate bounded independent of ϵ (also a well-known fact).

Now, consider the AMGe measure η in (4.5). We know from Corollary 3.4 that

$$\eta \geq \|A\| \frac{1}{\lambda_{\min}(A_{ff})} \tag{6.2}$$

for any interpolation operator P. Again, because of symmetry, we can bound the minimum eigenvalue of A_{ff} by considering the eigenvalues of the local stiffness matrix with the first and last rows deleted. That is, we can look at the eigenvalues of $A_{s,e}$ in (6.1), which satisfy the following cubic equation for λ:

$$\begin{vmatrix} (1+\epsilon-\lambda) & -\epsilon & -1 \\ -\epsilon & (1+\epsilon-\lambda) & 0 \\ -1 & 0 & (1+\epsilon-\lambda) \end{vmatrix} = 0.$$

The roots are

$$\lambda = (1+\epsilon), (1+\epsilon) \pm \sqrt{1+\epsilon^2}. \tag{6.3}$$

Hence,

$$\lambda_{\min}(A_{ff}) = (1+\epsilon) - \sqrt{1+\epsilon^2} \leq \epsilon, \tag{6.4}$$

which implies that

$$\eta \geq \|A\| \frac{1}{\epsilon} \tag{6.5}$$

for any interpolation operator P. But, as mentioned earlier in this example, linear interpolation satisfies (4.1) for a constant η independent of ϵ. Hence, although the AMGe measure η in (4.5) also implies (4.1), it is clearly a poor estimate for the latter. Note, however, that we may still use (4.5) to construct good interpolation operators. In particular, the AMGe method can produce linear interpolation for this example; the method is just unable to judge the quality of this interpolation operator when the smoother is line relaxation.

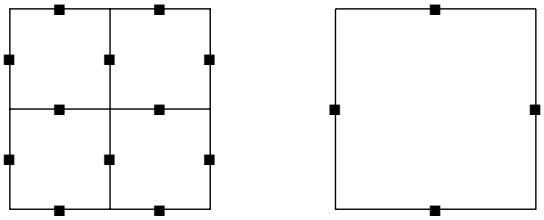

FIG. 6.2. *Coarse rectangle and its refinement. The DOFs of the respective Raviart–Thomas elements are associated with the midpoints of the edges of the elements.*

6.2. Geometric two-grid method for H(div). The space $\mathbf{H}(\mathrm{div})$ is spanned by vector functions $\underline{\chi}$ in $(L_2(\Omega))^d$ ($d = 2$ in the present example) whose divergence is also in $L_2(\Omega)$. Consider the Raviart–Thomas finite element discretization [11] of the $\mathbf{H}(\mathrm{div})$ bilinear form

$$(k^{-1}\underline{\chi}, \underline{\theta}) + (\nabla \cdot \underline{\chi}, \underline{\theta}). \tag{6.6}$$

Here, $k = k(x)$ is a given positive coefficient and $(\cdot, \cdot)$ stands for the $L_2(\Omega)$ inner product. The two-dimensional domain Ω is formed from rectangular fine-grid elements of mesh size h. The elements are obtained by successive steps of uniform refinement of an initial rectangular coarse mesh. The Raviart–Thomas finite element space of lowest order is spanned locally on every fine-grid rectangle by vector polynomials of the form

$$\begin{bmatrix} ax + b \\ cy + d \end{bmatrix}. \tag{6.7}$$

It is clear that by specifying $\underline{\chi} \cdot \mathbf{n}$ on every edge of the rectangles, then every rectangle has four degrees of freedom, and hence the four coefficients a, b, c, and d are uniquely determined. One also notices that $\underline{\chi} \cdot \mathbf{n}$ on every edge is constant. Hence, $\underline{\chi} \cdot \mathbf{n}$ is continuous across every edge of the fine-grid elements and the vector function $\underline{\chi}$ is globally contained in $\mathbf{H}(\mathrm{div})$.

Consider now two triangulations: fine-grid rectangles of mesh size h and coarse-grid rectangles of mesh size $H = 2h$. The degrees of freedom are shown in Figure 6.2. A standard "Lagrangian" basis of V_h is constructed by choosing, for every fine-grid edge, a function $\underline{\phi}$ which has normal component equal to 1 and zero normal components at the remaining edges. Let T be a coarse rectangle formed by four fine-grid ones. The degrees of freedom (DOFs) of a fine-grid vector $\mathbf{v}$ (w.r.t. the chosen Lagrangian basis) restricted to T can be partitioned into two groups: interior (to T) DOFs and boundary DOFs. The boundary DOFs on every edge of T are given by

$$\begin{bmatrix} \mathbf{v} \cdot \mathbf{n}_1 \\ \mathbf{v} \cdot \mathbf{n}_2 \end{bmatrix} \begin{matrix} \} \text{ first fine-grid edge} \\ \} \text{ second fine-grid edge,} \end{matrix}$$

and can be decomposed as follows:

$$\begin{bmatrix} \mathbf{v} \cdot \mathbf{n}_1 \\ \mathbf{v} \cdot \mathbf{n}_2 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} \mathbf{v} \cdot \mathbf{n}_1 - \mathbf{v} \cdot \mathbf{n}_2 \\ \mathbf{v} \cdot \mathbf{n}_2 - \mathbf{v} \cdot \mathbf{n}_1 \end{bmatrix} + \frac{1}{2} \begin{bmatrix} \mathbf{v} \cdot \mathbf{n}_1 + \mathbf{v} \cdot \mathbf{n}_2 \\ \mathbf{v} \cdot \mathbf{n}_1 + \mathbf{v} \cdot \mathbf{n}_2 \end{bmatrix}.$$

Introduce now the operators acting on vectors spanned by the boundary DOFs,

$$R_B = \frac{1}{\sqrt{2}} \begin{bmatrix} I & I \end{bmatrix} \quad \text{and} \quad S_B = \frac{1}{\sqrt{2}} \begin{bmatrix} I & -I \end{bmatrix}^T. \tag{6.8}$$

Next, partition the stiffness matrix A into a 2×2 block form with blocks corresponding to the interior and boundary DOFs. That is,

$$A = \begin{bmatrix} A_{II} & A_{IB} \\ A_{BI} & A_{BB} \end{bmatrix} \begin{matrix} \} \text{ interior fine-grid edges w.r.t. to coarse elements} \\ \} \text{ boundary fine-grid edges w.r.t. to coarse elements.} \end{matrix}$$

Note that A_{II} is block-diagonal with blocks of size 4×4. Denote the reduced matrix (obtained by "static condensation") $A_B = A_{BB} - A_{BI}(A_{II})^{-1}A_{IB}$. Note that A_B is sparse and explicitly available. For every coarse element edge, fix an ordering of the underlying fine-grid edges. This induces a natural partitioning of the boundary DOFs into two groups, corresponding to the above block structure (6.8) of R_B and S_B. Finally, introduce the global decomposition operators

$$S = \begin{bmatrix} I & -A_{II}^{-1}A_{IB}S_B \\ 0 & S_B \end{bmatrix} \tag{6.9}$$

and

$$R = \begin{bmatrix} 0 & R_B \end{bmatrix}. \tag{6.10}$$

Clearly, $RS = 0$ and $RR^T = R_B(R_B)^T = I$.

We now choose the following smoother:

$$\begin{aligned} M &= \begin{bmatrix} A_{II} & 0 \\ A_{BI} & \operatorname{diag}(A_B) \end{bmatrix} \begin{bmatrix} I & -A_{II}^{-1}A_{IB} \\ 0 & I \end{bmatrix} \\ &= \begin{bmatrix} A_{II} & A_{IB} \\ A_{BI} & \operatorname{diag}(A_B) + A_{BI}A_{II}^{-1}A_{IB} \end{bmatrix}. \end{aligned} \tag{6.11}$$

Since M is in a factored form, it is straightforward to implement its inverse action; it involves two actions of the block-diagonal matrix $(A_{II})^{-1}$ and one solves with the scalar diagonal matrix $\operatorname{diag}(A_B)$.

One can see that

$$S^T M S = \begin{bmatrix} A_{II} & 0 \\ 0 & S_B^T \operatorname{diag}(A_B) S_B \end{bmatrix}.$$

Similarly,

$$S^T A S = \begin{bmatrix} A_{II} & 0 \\ 0 & S_B^T A_B S_B \end{bmatrix}.$$

The compatible relaxation in (5.2) tells us to look at the matrix

$$(S^T M S)^{-1}(S^T A S) = \begin{bmatrix} I & 0 \\ 0 & (S_B^T \operatorname{diag}(A_B) S_B)^{-1} S_B^T A_B S_B \end{bmatrix}.$$

Based on a result by Cai, Goldstein, and Pasciak [8], one can show that $S_B^T A_B S_B$ is spectrally equivalent to a diagonal matrix. In particular, it is spectrally equivalent to the matrix $\text{const} \cdot I_B$, where const is piecewise constant w.r.t. the coarse element edges. This verifies that the respective compatible relaxation gives rise to a well-conditioned matrix $(S^T M S)^{-1}(S^T A S)$.

It remains to construct a bounded in energy ("approximate harmonic") interpolation operator P. We choose here the P which is naturally defined from the embedding

$V_H \subset V_h$. In operator form, P is the identity. However, in matrix form, its action is computed as follows. Given $\mathbf{v}_H$, consider its four DOFs of the form $\mathbf{v}_H \cdot \mathbf{n}$ for the four edges of every coarse element. These are four constants. Based on these DOFs, one finds the polynomial representation of $\mathbf{v}_H$ on every coarse element. It has the form (6.7). That is, one determines the four constants a, b, c, and d. Then one computes $\mathbf{v}_H \cdot \mathbf{n}$ for all interior fine-grid edges. These, as mentioned above, are also constants (four). Then on every fine-grid edge we have specified the fine-grid DOFs $\mathbf{v} \cdot \mathbf{n}$ which are used in the computation.

To prove the energy boundedness of P we proceed as follows. Given $\mathbf{v} \in V_h$. Compute $R\mathbf{v}$. This takes into account only the DOFs which correspond to the boundary (w.r.t. the coarse elements) fine-grid edges. Using function notation it means that we have computed the coarse edge integrals $\int_F \mathbf{v} \cdot \mathbf{n}\, d\varrho$ for every coarse edge F. Based on the four values for every coarse element we construct the unique coarse vector $\mathbf{v}_H = P(R\mathbf{v})$. It has the property that $\int_F \mathbf{v}_H \cdot \mathbf{n}\, d\varrho = \sqrt{2} \int_F \mathbf{v} \cdot \mathbf{n}\, d\varrho$. In other words, for any constant function w on a given coarse element T, we get

$$\int_{\partial T} w\mathbf{v}_H \cdot \mathbf{n}\, d\varrho = \sqrt{2} \int_{\partial T} w\mathbf{v} \cdot \mathbf{n}\, d\varrho.$$

Using the fact that $\nabla w = 0$ on T and the divergence theorem, we get

$$\int_T w \nabla \cdot \mathbf{v}_H\, dx\, dy = \sqrt{2} \int_T w \nabla \cdot \mathbf{v}\, dx\, dy.$$

If one introduces the elementwise L_2-projection Q_H onto the space of piecewise constant functions (w.r.t. the coarse elements), the above identity shows that $\nabla \cdot (PR\mathbf{v}) = \sqrt{2} Q_H \nabla \cdot \mathbf{v}$. This immediately implies the inequality

$$(\nabla \cdot (PR\mathbf{v}), \nabla \cdot (PR\mathbf{v})) = 2(Q_H \nabla \cdot \mathbf{v}, Q_H \nabla \cdot \mathbf{v}) \le 2(\nabla \cdot \mathbf{v}, \nabla \cdot \mathbf{v}).$$

It remains to bound the L_2-norm of $(PR\mathbf{v})$,

$$(PR\mathbf{v}, PR\mathbf{v}) \le \eta(\mathbf{v}, \mathbf{v}),$$

for a mesh-independent constant η. We note that

$$\int_T \mathbf{v} \cdot \mathbf{v}\, dxdy \simeq h^2 \sum_{f\text{: edge of fine-grid element } \tau \subset T} (\mathbf{v} \cdot \mathbf{n}_f)^2.$$

Similarly,

$$\int_T \mathbf{v}_H \cdot \mathbf{v}_H\, dxdy \simeq H^2 \sum_{F\text{: edge of } T} (\mathbf{v}_H \cdot \mathbf{n}_F)^2.$$

Let $F = f_1 \cup f_2$. Since $\mathbf{v}_H \cdot \mathbf{n}_F = \frac{1}{\sqrt{2}}(\mathbf{v} \cdot \mathbf{n}_{f_1} + \mathbf{v} \cdot \mathbf{n}_{f_2})$, hence

$$(\mathbf{v}_H \cdot \mathbf{n}_F)^2 = \frac{1}{2}(\mathbf{v} \cdot \mathbf{n}_{f_1} + \mathbf{v} \cdot \mathbf{n}_{f_2})^2 \le (\mathbf{v} \cdot \mathbf{n}_{f_1})^2 + (\mathbf{v} \cdot \mathbf{n}_{f_2})^2.$$

This shows that there exists a mesh-independent constant η such that

$$\int_T \mathbf{v}_H \cdot \mathbf{v}_H\, dxdy \le \eta \int_T \mathbf{v} \cdot \mathbf{v}\, dxdy,$$

which after summation over all coarse elements leads to the required L_2-boundedness of PR. Thus, we get the desired result that PR is bounded in $\mathbf{H}(\mathrm{div})$-norm.

CONSTRAINT-PRESERVING UPWIND METHODS FOR MULTIDIMENSIONAL ADVECTION EQUATIONS*

M. TORRILHON† AND M. FEY†

Abstract. A general framework for constructing constraint-preserving numerical methods is presented and applied to a multidimensional divergence-constrained advection equation. This equation is part of a set of hyperbolic equations that evolve a vector field while locally preserving either its divergence or its curl. We discuss the properties of these equations and their relation to ordinary advection. Due to the constraint, such equations form model equations for general evolution equations with intrinsic constraints which appear frequently in physics.

The general framework allows the construction of numerical methods that preserve *exactly* the discretized constraint by special flux distribution. Assuming a rectangular, two-dimensional grid as a first approach, application of this framework leads to a locally constraint-preserving multidimensional upwind method. We prove consistency and stability of the new method and present several numerical experiments. Finally, extensions of the method to the three-dimensional case are described.

1. Introduction.

Many evolution equations in physics and engineering come with intrinsic constraints, i.e., local differential constraints that follow directly from the evolution operator. Such evolutions will be called *constraint-preserving*. The most popular example is the evolution of the magnetic flux density $\mathbf{B}$ in electrodynamics: The divergence of $\mathbf{B}$ must be zero for the initial conditions; afterwards the analytic evolution will keep the divergence of the field untouched. The same property is present in the system of magnetohydrodynamics of plasma flows (e.g., [6]), and a similar operator arises in the vorticity equation of incompressible flow (e.g., [12]). Vorticity-preserving equations are used, e.g., in meteorological flows [19], while in [20] a vorticity-preserving system is investigated, which may be related to the linearized Euler equations. Furthermore, the evolution equations of general relativity possess constraints whose properties are lively discussed; see, e.g., [22].

Intrinsic constraints are also expected to hold in numerical calculations of the corresponding evolution, at least in a discrete manner. The discrete approximation of the evolution operator should mimic the analytic properties as far as possible in order to obtain a most physical discrete solution. Nevertheless, the construction of commonly available numerical methods ignores constraints and indeed those methods generally introduce disturbances to the constraints. These disturbances may be argued to be small due to consistency: Since the constraint is an analytic property of the evolution operator it will be respected in a converged solution (see [3] in the context of general relativity). But this argument holds only for smooth solutions, where the disturbances of the constraint are of the order of the truncation error. For discontinuous solutions the error of the constraint becomes so large that computations completely fail (see, e.g., [6] in the context of magnetohydrodynamics). In

general, relativity errors in the constraints can excite instabilities [22]. It becomes obvious that controlling intrinsic constraints in numerical methods is required in the construction of accurate and reliable schemes. Even if the constraint is not preserved by the complete evolution operator but only by a part of it, a corresponding partial constraint-preserving discretization is most desirable. This yields that the constraint is numerically only affected by those causes which arose from the discretization of the nonpreserving part in the equations. A similar statement may also be found in [27].

The literature provides many works which deal with the divergence-constraint in the equations of magnetohydrodynamics. Global approaches like in [2] solve elliptic equations each time step in order to correct the solution. A popular approach uses a local correction procedure with the help of a staggered grid (see [1], [5], and [8]) which is applied after a time step of a usual finite-volume method. A third approach modifies the evolution equation (see [21], [6]) so that the error in the constraint is advected or diffused away. The common idea of these approaches is to *correct an existing error* of the constraint. See also [26] for a collection and comparison of methods and [7] for an approach on unstructured grids.

The staggered approach is equivalent to the mimetic discretizations as presented in [13] and [14] if applied to a rectangular grid. These schemes store different variables at different locations in the grid, like edges and vertices. The starting point is to derive discrete vector-analytic identities using special div-, curl-, and grad-definitions. These identities are responsible for discrete constraint preservation. The results of [13] are used in computational electrodynamics; see [14]. The application in finite-volume schemes is complicated since the usage of cell averages for the variables is then mandatory. Examples for a staggered grid scheme in meteorological flows and in vorticity methods are given in [19] and [12], respectively.

This paper will present a general framework for constructing genuine locally constraint-preserving finite-volume methods. We aim at explicit methods that use only a primary finite-volume grid. All variables will be stored in the cell centers and considered as cell mean values. The constraints as well as the flux operator will be discretized with this single grid using the cell averaged values. As an example we will consider so-called constraint-preserving advection equations. These advection equations must be seen as model equations for general evolution equations with constraints. Besides this they also provide interesting aspects of the advection of vector fields. The application of the presented general framework to constraint-preserving advection leads to an upwind method which exactly preserves the local values of the discrete constraint. This is the discrete imitation of the analytic property. The main idea is the usage of a special discrete operator for the constraint. Since the constraint and its preservation are relevant only in more than one dimension the resulting scheme is necessarily multidimensional. We obtain a method that is second order in time and space and is stable for Courant numbers $|c| \leq 1$. Consistency and stability are proven. Several numerical experiments with smooth and discontinuous solutions demonstrate the performance of the scheme. Within the framework we could also re-derive two methods that are known in the literature but which are inappropriate for solving constraint-preserving advection due to instabilities. The main part of the paper considers a two-dimensional setting on a rectangular grid. The presented framework also applies to general grids at the cost of more involved calculations. Methods on unstructured grids are the subject of future work. In the last section we give a sketch of the method in three dimensions.

The paper is organized as follows: In the next section we introduce constrained advection equations for vector fields and discuss their properties and their relation to

ordinary advection as well as to real physical models. In section 3 the general framework is presented that describes how numerical constraint-preserving methods may be constructed. The application of this framework to constraint-preserving advection follows in section 4. In the beginning of that section we discuss discrete constraint operators and deduce some instructive methods, while the final upwind method and its properties are presented in section 4.3. Section 5 is devoted to the numerical experiments and considers smooth as well as discontinuous solutions. Finally, we give details of the three-dimensional case in section 6 and draw conclusions in the last section.

2. Constrained advection equations. We consider a given velocity field $\mathbf{v}$ in a domain Ω of the three-dimensional space

$$\mathbf{v} : \Omega \subseteq \mathbb{R}^3 \to \mathbb{R}^3 \tag{1}$$

which remains constant in time. A second vector field $\mathbf{u} : \Omega \to \mathbb{R}^3$ is said to be advected in the velocity field $\mathbf{v}$ if it obeys the evolution equation

$$\partial_t \mathbf{u} + \operatorname{div}(\mathbf{u} \otimes \mathbf{v}) = 0 \quad \text{in } \Omega, \tag{2}$$

where the divergence acts on the rows of the tensorial product $\mathbf{u} \otimes \mathbf{v}$, i.e., in the components of $\mathbf{v}$. Hence, (2) represents scalar advection equations for each component of $\mathbf{u}$. In components the vector field $\mathbf{u}$ and the advection velocity $\mathbf{v}$ are written as

$$\mathbf{u} = (u^{(x)}, u^{(y)}, u^{(z)})^T, \quad \mathbf{v} = (v^{(x)}, v^{(y)}, v^{(z)})^T. \tag{3}$$

An evolution like (2) represents a raw model for virtually any physical transport process. Correspondingly there exists a vast amount of work concerning analytical and numerical aspects of (2) in the literature. Note that advection of type (2) decouples the components of the vector field $\mathbf{u}$ and each component is advected separately. We will call this *ordinary advection*.

2.1. div / curl-preserving advection. There are two more evolution equations which we shall show to be closely related to ordinary advection. They follow formally from (2) by replacing the differential operator and the tensorial product. We write

$$\begin{aligned} \partial_t \mathbf{u} + \operatorname{grad}(\mathbf{u} \cdot \mathbf{v}) &= 0, \\ \partial_t \mathbf{u} + \operatorname{curl}(\mathbf{u} \times \mathbf{v}) &= 0, \end{aligned} \tag{4}$$

where $\mathbf{u} \cdot \mathbf{v}$ and $\mathbf{u} \times \mathbf{v}$ denote the scalar product and the cross product, respectively. Note that the components of $\mathbf{u}$ are now coupled in the equations (4).

Since for any function ψ we have $\operatorname{curl}\operatorname{grad}\psi \equiv 0$ and $\operatorname{div}\operatorname{curl}\psi \equiv 0$ we can deduce an accompanying equation for both types of evolutions in (4) which may be integrated. We obtain for the considered domain Ω

$$\begin{aligned} &\text{for } (4)_{\text{grad}} \to && \operatorname{curl}\mathbf{u} = \text{const in time}, \\ &\text{for } (4)_{\text{curl}} \to && \operatorname{div}\mathbf{u} = \text{const in time} \end{aligned} \tag{5}$$

as additional equations. These equations state that the curl of the vector field in the case of $(4)_{\text{grad}}$ or its divergence in the case of $(4)_{\text{curl}}$ stays locally (hence globally) unaffected from the evolution. The initial fields of curl or divergence in the particular cases are frozen and their values stay locally the same. We therefore denote the evolution equation $(4)_{\text{grad}}$ by *curl-preserving advection* and $(4)_{\text{curl}}$ by *div-preserving advection*.

The equations (5) may be viewed as *intrinsic or inherent constraints* to the evolution equations in (4). In the language of [4] these constraints form involutions of the equations (4). We stress that these constraints are intrinsic to the evolution equations since they must not be additionally imposed to the solution. They are an inherent property of the transport operator. Any analytic solution of (4) fulfills the constraints of (5) automatically. However, this might not be true in a numerical setting where the equations are discretized. Furthermore, the apparently elliptic character of the constraints do not influence the character of the evolution. We will show later that the equations in (4) are purely hyperbolic.

2.2. Physical examples. Though less frequently than ordinary advection, the constraint-preserving evolution equations in (4) may be found in physical models as well. Furthermore, both equations should be viewed as special cases of more general models where the differential evolution operators act on general functions of $\mathbf{u}$.

A well-known example is the Maxwell equations of electrodynamics

$$\begin{aligned} \partial_t \mathbf{B} + \operatorname{curl} \mathbf{E} &= 0, \\ \partial_t \mathbf{D} - \operatorname{curl} \mathbf{H} &= \mathbf{j}, \end{aligned} \tag{6}$$

where $\mathbf{B}$ is the magnetic flux density and $\mathbf{D}$ the electric displacement. Both evolutions have the structure of $(4)_{\mathrm{curl}}$. Since $\operatorname{div} \mathbf{B} = 0$ is stated in the third Maxwell equation, the intrinsic constraint of $(6)_1$ establishes the solenoidality of the $\mathbf{B}$-field during the entire evolution. The second equation $(6)_2$ together with the fourth Maxwell equation $\operatorname{div} \mathbf{D} = \rho$ yields the conservation law for the charge density ρ. This additional law must be viewed as a constraint to the evolution $(6)_2$.

In ideal magnetohydrodynamics of plasma flows only the first Maxwell equation $(6)_1$ plays a role and $\mathbf{E}$ is given by $\mathbf{E} = -\mathbf{v} \times \mathbf{B}$, where $\mathbf{v}$ is the plasma velocity. Thus we have

$$\partial_t \mathbf{B} + \operatorname{curl}(\mathbf{B} \times \mathbf{v}) = 0 \tag{7}$$

as evolution equation for the $\mathbf{B}$-field which is identical to $(4)_{\mathrm{curl}}$. Due to the intrinsic constraint of (7), the divergence of $\mathbf{B}$ remains zero if it is zero initially. Since this property is spoiled in an ordinary numerical calculation, the preservation of the divergence is a major issue in computational magnetohydrodynamics; see, e.g., [6].

The Navier–Stokes equations for incompressible flow read as

$$\begin{aligned} \partial_t \mathbf{v} + \mathbf{v} \cdot \operatorname{grad} \mathbf{v} + \operatorname{grad} p &= \Delta \mathbf{v}, \\ \operatorname{div} \mathbf{v} &= 0, \end{aligned} \tag{8}$$

where $\mathbf{v}$ is the flow velocity and p is the pressure. Note that the second equation *is not an intrinsic constraint*. It does not follow from the evolution equation for $\mathbf{v}$; instead it is an equation to determine the pressure. In some approaches (see, e.g., [12]) the system of Navier–Stokes is rewritten in terms of the vorticity $\Omega = \operatorname{curl} \mathbf{v}$. The evolution equation for the vorticity may then be found from $(8)_1$ using the identity $\mathbf{v} \cdot \operatorname{grad} \mathbf{v} = \operatorname{grad} \frac{1}{2}\mathbf{v}^2 - \mathbf{v} \times \operatorname{curl} \mathbf{v}$ and is given by

$$\partial_t \Omega + \operatorname{curl}(\Omega \times \mathbf{v}) = \Delta \Omega. \tag{9}$$

This represents again a div-preserving evolution like $(4)_{\mathrm{curl}}$.

An evolution like $(4)_{\mathrm{grad}}$ appears to be less frequent. It is encountered, for example, in meteorological models where it originates from the system for shallow water

flows, and the preservation of $\operatorname{curl}\mathbf{v}$ is a concern in numerical meteorology; see, e.g., [19]. The shallow water system is usually written in conservation laws

$$\begin{aligned} \partial_t h + \operatorname{div}(h\mathbf{v}) &= 0, \\ \partial_t h\mathbf{v} + \operatorname{div}\left(h\mathbf{v}\otimes\mathbf{v} + (\tfrac{1}{2}g\,h^2)\mathbf{I}\right) &= 0 \end{aligned} \tag{10}$$

for the water height h and the flow velocity $\mathbf{v}$. The gravitational constant is g. In meteorology the flow is assumed to be smooth and the momentum balance $(10)_2$ is reduced to an equation for $\mathbf{v}$. Using the first equation and again the identity $\mathbf{v}\cdot\operatorname{grad}\mathbf{v} = \operatorname{grad}\frac{1}{2}\mathbf{v}^2 - \mathbf{v}\times\operatorname{curl}\mathbf{v}$ we obtain

$$\partial_t\mathbf{v} + \operatorname{grad}(\tfrac{1}{2}\mathbf{v}^2 + g\,h) = \mathbf{v}\times\Omega, \tag{11}$$

where again $\Omega = \operatorname{curl}\mathbf{v}$ is introduced. In this equation the curl-preserving operator of $(4)_{\text{grad}}$ is present. Here, the vector field $\mathbf{u}$ coincides with the advection velocity $\mathbf{v}$. The shallow water system is a two-dimensional model ($\partial_z \equiv 0$) with vanishing z-component of $\mathbf{v}$. Hence, the vorticity Ω has only one nonvanishing component $\Omega = \partial_x v^{(y)} - \partial_y v^{(x)}$ and the right-hand side of (11) has the form $\left(\Omega\, v^{(y)}, -\Omega\, v^{(x)}\right)^T$.

2.3. Identification as degenerated advection. We return to the equations in (4) to discuss more of its properties. So far it is not obvious that these equations are related to a kind of advection. Clearly, they state processes different from ordinary advection. We proceed to uncover the relation. A first inspection leads to the fact that both equations in (4) may be transformed into the form of a conservation law $\partial_t\mathbf{u} + \operatorname{div}\mathbf{f}(\mathbf{u}) = 0$ with appropriate definition of the matrix $\mathbf{f}(\mathbf{u})$. We obtain

$$\begin{aligned} &\text{for } (4)_{\text{grad}} \rightarrow && \partial_t\mathbf{u} + \operatorname{div}\left((\mathbf{u}\cdot\mathbf{v})\,\mathbf{I}\right) = 0, \\ &\text{for } (4)_{\text{curl}} \rightarrow && \partial_t\mathbf{u} + \operatorname{div}(\mathbf{u}\otimes\mathbf{v} - \mathbf{v}\otimes\mathbf{u}) = 0, \end{aligned} \tag{12}$$

where $\mathbf{I}$ represents the identity matrix. Thus, in both processes each component of $\mathbf{u}$ is conserved and the evolution equations are conservation laws. Now, to investigate (12) the matrix $\mathbf{A}(\mathbf{n})$ of linear combinations of the directional Jacobians of the flux function $\mathbf{f}$ is formed. We have

$$\mathbf{A}(\mathbf{n}) = D\mathbf{f}(\mathbf{u})\,\mathbf{n}, \tag{13}$$

where $\mathbf{n}$ is a space direction to be chosen. This matrix is used to classify a conservation law; see, e.g., [23]. An equation is hyperbolic if $\mathbf{A}(\mathbf{n})$ has real eigenvalues and a complete set of eigenvectors for any direction of $\mathbf{n}$. The eigenvalues are then interpreted as characteristic velocities. The eigenvectors represent the part of the conserved vector $\mathbf{u}$ which is transported with the corresponding velocity.

We recall that in case of ordinary advection we have $\mathbf{f}(\mathbf{u}) = \mathbf{u}\otimes\mathbf{v}$ and

$$\mathbf{A}^{(\text{ordinary})}(\mathbf{n}) = (\mathbf{n}\cdot\mathbf{v})\,\mathbf{I} \quad\Rightarrow\quad \lambda_{1,2,3} = \mathbf{n}\cdot\mathbf{v}, \quad V_{1,2,3} = \mathbb{R}^3 \tag{14}$$

with eigenvalues λ_i and corresponding eigenspaces V_i. The eigenvalue $\mathbf{n}\cdot\mathbf{v}$ is real and threefold and the complete 3-space is the eigenspace for this eigenvalue. The process of advection may be defined by the presence of an eigenvalue $\mathbf{n}\cdot\mathbf{v}$. This follows from the Friedrichs diagram (see, e.g., [16]), which displays the propagation of a point disturbance associated to a certain characteristic velocity. In case of advection, the point disturbance remains a point and is simply propagated with the advection velocity $\mathbf{v}$. Due to the eigenspace in this case any vector from 3-space can be advected which corresponds to the decoupling of the advection equations in (2).

For the evolution equation of type $(4)_{\text{grad}}$ we obtain

$$\mathbf{A}^{(\text{grad})}(\mathbf{n}) = \mathbf{n} \otimes \mathbf{v} \quad \Rightarrow \quad \begin{cases} \lambda_1 = \mathbf{n} \cdot \mathbf{v}, & V_1 = [\mathbf{n}], \\ \lambda_{2,3} = 0, & V_{2,3} = [\mathbf{v}]^{\perp} \end{cases} \tag{15}$$

for the eigenvalues and eigenspaces. One eigenvalue is given by $\mathbf{n} \cdot \mathbf{v}$ which identifies the process as advection. However, there exists a second eigenvalue which is zero, and this leads to a splitting of the 3-space into two eigenspaces. That is, not all components of a vector $\mathbf{u}$ are advected in the Friedrichs diagram. Indeed, according to $V_{2,3}$ any vector *orthogonal* to the advection velocity will stay in place. Any other vector is simply advected. This behavior must be viewed against the background of the constraint-preserving property: The eigenvalue $\lambda_{2,3}$ represents the constraint mode (see also [22]) which keeps the curl of $\mathbf{u}$ locally untouched.

The evolution of type (4) shows the analogous behavior. Eigenvalues and eigenspaces are given by

$$\mathbf{A}^{(\text{curl})}(\mathbf{n}) = (\mathbf{n} \cdot \mathbf{v})\,\mathbf{I} - \mathbf{v} \otimes \mathbf{n} \quad \Rightarrow \quad \begin{cases} \lambda_1 = 0, & V_1 = [\mathbf{v}], \\ \lambda_{2,3} = \mathbf{n} \cdot \mathbf{v}, & V_{2,3} = [\mathbf{n}]^{\perp}. \end{cases} \tag{16}$$

Again we can identify the process as advection due to the eigenvalue $\lambda_{2,3}$. The first eigenvalue is zero and represents the constraint mode. In this case vectors *parallel* to $\mathbf{v}$ remain untouched due to the eigenspace V_1. This corresponds to the preservation of the divergence of $\mathbf{u}$.

Note that it is not possible to decouple the equations in (12) since the spatial derivatives do not diagonalize simultaneously. Furthermore, though only real eigenvalues exists, the hyperbolicity of the evolution equations in (12) degenerates due to the lack of eigenvectors in certain cases. Indeed, in both cases of the evolutions (4), directions $\mathbf{n}$ orthogonal to the advection velocity give only $V_1 \subset V_{2,3} \subset \mathbb{R}^3$.

2.4. Special cases. It is instructive to consider some special cases of curl-preserving and div-preserving advection. They will emphasize the advection character of the equations.

If the value of the curl or of the divergence of $\mathbf{u}$ is assumed to vanish initially in Ω, i.e.,

$$\begin{aligned} &\text{for } (4)_{\text{grad}} \rightarrow && \operatorname{curl} \mathbf{u} \equiv 0, \\ &\text{for } (4)_{\text{curl}} \rightarrow && \operatorname{div} \mathbf{u} \equiv 0, \end{aligned} \tag{17}$$

then their value will stay zero for all times. For div-preserving advection in case of $\mathbf{u}$ being a magnetic flux this is the physically relevant case. If we additionally assume a constant advection velocity

$$\operatorname{grad} \mathbf{v} = 0, \tag{18}$$

all evolution equations (2), $(4)_{\text{grad}}$, and $(4)_{\text{curl}}$ are reduced to the form

$$\partial_t \mathbf{u} + \mathbf{v} \cdot \operatorname{grad} \mathbf{u} = 0. \tag{19}$$

Hence, all types of advection become indistinguishable from constant advection.

If, still under the assumption of vanishing constraints, the velocity field is purely rotational, we have

$$\operatorname{grad} \mathbf{v} = -(\operatorname{grad} \mathbf{v})^T. \tag{20}$$

In such a case the advection given in (4) differs from ordinary advection. However, if we consider the 2-norm of $\mathbf{u}$, we obtain the ordinary advection equation

$$\partial_t \|\mathbf{u}\|^2 + \mathbf{v} \cdot \operatorname{grad} \|\mathbf{u}\|^2 = 0 \tag{21}$$

for both curl-preserving and div-preserving advection. Hence, $\|\mathbf{u}\|^2$ is rotated as scalar quantity. The components of $\mathbf{u}$, however, are not advected as scalar quantities. In fact, the vector $\mathbf{u}$ is advected as a whole preserving its position relative to the rotating velocity.

2.5. Two-dimensional equations. The numerical methods in the next sections are mainly developed for the two-dimensional case, that is, $\partial_z \to 0$. We proceed to display the two-dimensional equations.

For the div-preserving advection $(4)_{\text{curl}}$ the equation for the component $u^{(z)}$ decouples from the first two equations for $(u^{(x)}, u^{(y)})$. Furthermore, the constraint $\operatorname{div} \mathbf{u}$ is no longer influenced by $u^{(z)}$. Hence, we will discard the equation for $u^{(z)}$ in the following. The remaining equations are given by

$$\begin{aligned} &\partial_t u^{(x)} + \partial_y (u^{(x)} v^{(y)} - v^{(x)} u^{(y)}) = 0, \\ &\partial_t u^{(y)} - \partial_x (u^{(x)} v^{(y)} - v^{(x)} u^{(y)}) = 0 \end{aligned} \tag{22}$$

for the components $(u^{(x)}, u^{(y)})$. Note that $u^{(z)}$ is not zero, nor is its evolution trivial. The component $u^{(z)}$ and its evolution simply does not play a role in the following construction of div-preserving methods.

In the two-dimensional case of $(4)_{\text{grad}}$ it follows $u^{(z)} = \text{const}$ in time; however, the equations for $(u^{(x)}, u^{(y)})$ still depend on $u^{(z)}$. In the most important application of curl-preserving advection—the shallow water system—the additional condition $v^{(z)} = 0$ holds, which yields decoupled equations. Having in mind this kind of application, the remaining equations for the components $(u^{(x)}, u^{(y)})$ are written as

$$\begin{aligned} &\partial_t u^{(x)} + \partial_x (u^{(x)} v^{(x)} + v^{(y)} u^{(y)}) = 0, \\ &\partial_t u^{(y)} + \partial_y (u^{(x)} v^{(x)} + v^{(y)} u^{(y)}) = 0 \end{aligned} \tag{23}$$

for the two-dimensional version of $(4)_{\text{grad}}$. As in the case of (22) the component $u^{(z)}$ is not further considered.

Correspondingly the constraints are written

$$\begin{aligned} &\text{for } (4)_{\text{grad}} \to \quad && \partial_x u^{(y)} - \partial_y u^{(x)} = \text{const}, \\ &\text{for } (4)_{\text{curl}} \to \quad && \partial_x u^{(x)} + \partial_y u^{(y)} = \text{const} \end{aligned} \tag{24}$$

in two dimensions. Note that the constraint of type $(4)_{\text{grad}}$, which was a vectorial quantity in (5), became a scalar equation.

The dual behavior of curl-preserving and div-preserving advection already observable in the previous section becomes perfect in the two-dimensional case. By substituting the two-dimensional vector $\mathbf{u}$ by its orthogonal complement

$$\begin{pmatrix} u^{(x)} \\ u^{(y)} \end{pmatrix} \leftrightarrow \begin{pmatrix} u^{(y)} \\ -u^{(x)} \end{pmatrix} \quad \Longleftrightarrow \quad (23) \leftrightarrow (22), \tag{25}$$

we can transform curl-preserving and div-preserving advection into each other. Hence, in what follows, any statement or numerical method for the system (23) can be transformed into a statement or numerical method for (22) with the same properties and vice versa.

3. General framework. A numerical solution of equations like curl-preserving and div-preserving advection should respect the intrinsic constraints in a numerical way. That is, a discrete version of the constraint should follow directly from the numerical discretization of the evolutions. Ordinary numerical schemes, however, do not care about the constraints which leads to well-known problems, e.g., in calculating magnetohydrodynamical flows [6]. We propose that a numerical scheme has to be constructed on the basis given by a discretization of the constraints. Since the equations of interest are hyperbolic with local domain of dependency we expect that the constraint can be controlled locally as well. In this section we set up a general framework for locally constrained transport schemes.

We consider $\mathbf{u} \in \Omega \subseteq \mathbb{R}^D$ (D: space-dimension) and a generic evolution

$$\partial_t \mathbf{u} + \mathcal{F}(\mathbf{u}; \mathbf{x}) = 0 \tag{26}$$

with a transport operator $\mathcal{F}$ depending explicitly on the space variable $\mathbf{x}$. The generic constraint $\mathcal{C}$ is assumed to be linear and intrinsic for (26), that is, the relation

$$\mathcal{C}(\mathcal{F}(\mathbf{u}; \mathbf{x})) \equiv 0 \tag{27}$$

holds independently of $\mathbf{u}$ and $\mathbf{x}$, which directly implies

$$\mathcal{C}(\mathbf{u}) = \text{const in time} \tag{28}$$

for any solution of (26); see also [4]. The computational domain Ω is covered by a grid $\mathcal{T} = \{K_i\}_{i=1,2,\ldots}$ with nonoverlapping polygonal cells K_i whose inner diameter is bounded by h. Two cells are called neighbors if they have a common edge *or* if they only share a vertex. The set $\mathcal{N}(K)$ gives all neighbors of the cell K. A time discretization by Δt leads to a cell-wise constant grid function $\tilde{\mathbf{u}}^m : \mathcal{T} \to \mathbb{R}^D$ which approximates $\mathbf{u}$ after m time steps by cell mean values.

3.1. Flux distribution formulation. The central quantity of this paper is the so-called flux distribution. It will be the structure of the flux distribution that determines whether a certain scheme is *constraint-preserving*.

DEFINITION 3.1 (flux distribution). *Given the space of vector-valued grid functions denoted by* $V = \{g : \mathcal{T} \to \mathbb{R}^D\}$, *we define a "flux distribution"* $\Phi_K : V \to V$ *which is attached to a grid cell and maps the grid function* $\tilde{\mathbf{u}}$ *into another grid function, that is,*

$$\Phi_K(\tilde{\mathbf{u}}) : \mathcal{T} \to \mathbb{R}^D \tag{29}$$

with $\operatorname{supp}(\Phi_K(\tilde{\mathbf{u}})) = K \cup \bigcup_{\hat{K} \in \mathcal{N}(K)} \hat{K}$. *The evaluation* $\Phi_K(\tilde{\mathbf{u}})|_{\hat{K}}$ *gives the change of* $\tilde{\mathbf{u}}$ *at cell* $\hat{K}$ *caused by cell* K *during a time step, that is, the flux.*

A flux distribution is assigned to each cell of the grid and may depend on the value of $\tilde{\mathbf{u}}$ in this particular cell but also on that in other cells. The definition is more general than that of usual intercell fluxes, since it admits fluxes to any neighboring cell, especially across corners. This incorporates multidimensionality from the very beginning. Conservation of $\tilde{\mathbf{u}}$ may be expressed by the statement that the integral of $\Phi_K(\tilde{\mathbf{u}})$ vanishes.

A certain form of the flux distribution and its dependency on $\tilde{\mathbf{u}}$ is usually constructed from consistency with the transport equation. Once the flux distribution is defined, an explicit evolution scheme follows by simply collecting contributions of all

flux distributions. Written in complete grid functions we have

$$\tilde{\mathbf{u}}^{m+1} = \tilde{\mathbf{u}}^m + \sum\nolimits_{\hat{K}} \Phi_{\hat{K}}\left(\tilde{\mathbf{u}}^m\right) \tag{30}$$

as an update for the complete grid. The restriction to a certain cell yields a local formulation, viz.,

$$\tilde{\mathbf{u}}^{m+1}|_K = \tilde{\mathbf{u}}^m\big|_K + \sum_{\hat{K}\in\{K\}\cup\mathcal{N}(K)} \Phi_{\hat{K}}\left(\tilde{\mathbf{u}}^m\right)|_K. \tag{31}$$

Here the value of $\tilde{\mathbf{u}}$ in a cell K is updated by contributions of all neighboring cells which are given by evaluations of flux distributions. Note that virtually any finite-volume scheme can be written in the form (31), and the flux distribution may then be identified.

To approximate the transport equation given in (26) consistency is required in the form of cell mean values, viz.,

$$\mathcal{F}\left(\mathbf{u};\mathbf{x}\right)|_K = -\lim_{\Delta t,h\to 0} \frac{1}{\Delta t} \sum_{\hat{K}\in\{K\}\cup\mathcal{N}(K)} \Phi_{\hat{K}}\left(\tilde{\mathbf{u}}\right)|_K, \tag{32}$$

where $\tilde{\mathbf{u}}$ is the projection of $\mathbf{u}$ onto the grid.

In order to clarify the notion of a flux distribution, we briefly present a possible flux distribution for one-dimensional constant advection $u_t + a\,u_x = 0$ on a uniform mesh. The flux distribution given by

$$\Phi_i\left(\tilde{u}^m\right) = \begin{cases} \frac{\max(0,a)\Delta t}{h}\tilde{u}_i^m & \text{for cell } i+1, \\ -\left(\frac{\max(0,a)\Delta t}{h} + \frac{\min(0,a)\Delta t}{h}\right)\tilde{u}_i^m & \text{for cell } i, \\ \frac{\min(0,a)\Delta t}{h}\tilde{u}_i^m & \text{for cell } i-1 \end{cases} \tag{33}$$

has entries in cell i and its neighbors $i \pm 1$. The evolution (31) may then be written

$$\tilde{u}_i^{m+1} = \tilde{u}_i^m - \frac{\max\left(0,a\right)\Delta t}{h}(\tilde{u}_i^m - \tilde{u}_{i-1}^m) + \frac{\min\left(0,a\right)\Delta t}{h}(\tilde{u}_{i+1}^m - \tilde{u}_i^m), \tag{34}$$

which represents the donor cell scheme for constant advection.

3.2. Constraint preservation. Since the constraint is linear we expect a discretization which may be written as matrix operation

$$\mathcal{C}\left(\mathbf{u}\right)\big|_K = \tilde{C}_K\,\tilde{\mathbf{u}} + O\left(h^n\right) \tag{35}$$

on the grid function $\tilde{\mathbf{u}}$ which is obtained from the function $\mathbf{u}$ by cell-wise constant projection. If preservation of the constraint should be achieved for the scheme (30), the following quite obvious statement leads the way.

LEMMA 3.2 (constraint preservation). *If the condition*

$$\tilde{C}_K\,\Phi_{\hat{K}}(\tilde{\mathbf{u}}) = 0 \quad \forall K, \hat{K}, \tilde{\mathbf{u}} \tag{36}$$

holds for a specific discrete constraint and a flux distribution, it follows for the evolution scheme given in (30)

$$\tilde{C}_K\,\tilde{\mathbf{u}}^{m+1} = \tilde{C}_K\,\tilde{\mathbf{u}}^m, \tag{37}$$

i.e., the discrete operator is preserved locally by this scheme.

Note that condition (36) is sufficient only for constraint preservation, since the flux distribution is completely unspecified. Contributions of different flux distributions in (30) could interact in such a way that the discrete constraint is preserved even if (36) is not valid. However, we will not consider such schemes.

Since the condition is difficult to control for any grid function $\tilde{\mathbf{u}}$, we assume a decomposition

$$\Phi_K(\tilde{\mathbf{u}}) = \varphi_K(\tilde{\mathbf{u}})\ \hat{\Phi}_K \tag{38}$$

into a factor $\varphi_K(\tilde{\mathbf{u}}) \in \mathbb{R}$ and a skeleton or shape function $\hat{\Phi}_K$. As indicated, only the factor depends on the field $\tilde{\mathbf{u}}$. Due to the linearity of the constraint this factor drops out of the condition in (36) and we obtain

$$\tilde{\mathcal{C}}_K\, \hat{\Phi}_{\hat{K}} = 0 \quad \forall K, \hat{K} \tag{39}$$

as a purely geometric condition. To some extent this is the discrete analogon to (27) which states that the constraint is intrinsic. Indeed, for the case of div-preserving advection the curl in $(4)_{\text{curl}}$ must be discretized in an update $\hat{\Phi}_{\hat{K}}$ such that a discrete divergence $\tilde{\mathcal{C}}_K$ gives exactly zero. This is also the approach in [13], [14], where discrete analogons of vector-analytic relations are considered and used to discretize Maxwell's equations. The work of [13], [14], however, relies on using different locations, i.e., cell-center, face, edge, and vertex, to discretize vector functions and define the differential operators. The operators div and curl are then defined on different grids and for differently stored variables. For a finite-volume approach with exclusive use of cell mean values this is unsatisfactory. The condition in (39) aims at discrete operators and updates that use only cell centered variables. However, at least one of the resulting schemes may be translated in a "mimetic" scheme described in [14] by appropriate averaging. This will be demonstrated at the end of section 4.2.2.

If a generic cell $\hat{K}$ is fixed, (39) gives a homogeneous linear system of equations and the flux distributions are elements of its kernel. The system will be finite if the discrete constraint has a finite stencil since then evaluations of (39) for cells K far off the support of $\Phi_{\hat{K}}$ will vanish identically. The crucial task of designing constrained transport schemes is to find nontrivial solutions of (39) for a given discrete constraint operator. A nontrivial solution of (39) is expected to exist if functions with compact support exist for which the analytic constraint vanishes. The structure of the solutions depends strongly on the discretization used of the constraint operator.

The system (39) for a fixed cell $\hat{K}$ is homogeneous and possesses more equations than unknowns since the evaluation of $\tilde{\mathcal{C}}_K$ on cells neighboring the support of $\hat{\Phi}_{\hat{K}}$ will yield nontrivial expressions. Experience with concrete examples showed that due to symmetry most equations are linear dependent and the entire system has a rank less than the number of unknowns. However, a proof of the general statement that the system (39) always has a rank less than the number of equations is not yet available. We expect a solution space for (39) from which we only consider an appropriate basis set of flux distributions $\{\hat{\Phi}_K^{(g)}\}$ with $g = 1, 2, \ldots$ which are all constraint-preserving. The final flux distribution has to be assembled from these solutions,

$$\Phi_K(\tilde{\mathbf{u}}) = \sum\nolimits_g \varphi_K^{(g)}(\tilde{\mathbf{u}})\, \hat{\Phi}_K^{(g)} \tag{40}$$

with unknown coefficients $\varphi_K^{(g)}$. Note that the choice of $\varphi_K^{(g)}$ does not affect the preservation of the constraint which is already established by the skeletons of the

flux distributions. The expression for Φ_K enters the scheme (31), and the remaining coefficients $\varphi_K^{(g)}$ have to follow from consistency (32) and stability as well.

The local character of the constraint is crucial at this point. If the constraint has a global influence, like the divergence condition in the elliptic Stokes problem, it will not be possible to find a flux distribution which is consistent *and* locally constraint-preserving. In the case of the elliptic Stokes problem either the constraint condition (39) for a consistent flux distribution or the consistency condition (32) for a preserving one would result in a global problem accounting for the ellipticity.

4. Rectangular grid in two dimensions. We proceed with applying the general framework of the preceding section to the system (22), thus concentrating on div-preserving advection. Both equations in (22) are governed by a single flux function which we denote by

$$F(\mathbf{u}, \mathbf{v}) = u^{(x)} v^{(y)} - v^{(x)} u^{(y)}. \tag{41}$$

As indicated in section 2.3, a numerical scheme for (22) can be directly transformed into a scheme for (23) by duality. Further investigations will be presented in the case of a rectangular grid with cells $K = (i, j)$ at positions (x_i, y_j) and size $\Delta x \times \Delta y$. The geometry factor of the grid $\alpha = \frac{\Delta x}{\Delta y}$ shall be bounded from above and below. In cases of accuracy considerations we refer to $h = \max(\Delta x, \Delta y)$.

Note that the general framework is valid for any kind of polygonal grid. However, the construction and investigation of discrete constraint operators on triangular or quadrilateral grids become complicated. The extension to more general grids is subject to future work.

4.1. Discrete constraints. Since the discrete version of the constraint operator influences the structure of the flux distribution, we present a certain class of discrete divergence operators. Each operator is obtained from a discretization of the first derivative in a finite difference approach. We require a symmetric 3×3 stencil and an approximation of second order. The following lemma gives all possible approximations of this type.

LEMMA 4.1 (discrete first derivatives). *Any second order approximation of the first derivative of a smooth function ψ in the center cell (i, j) of a symmetric 3×3 Cartesian stencil has the form*

$$\left.\frac{\partial \psi}{\partial x}\right|_{i,j} = \tilde{\mathcal{D}}_{i,j}(\alpha, \beta, \gamma)\ \tilde{\psi} + O\left(h^2\right) \tag{42}$$

with arbitrary values for α, β, γ and

$$\begin{aligned}\tilde{\mathcal{D}}_{i,j}(\alpha, \beta, \gamma) =& \frac{1}{2\Delta x} \begin{array}{|c|c|c|}\hline 0 & 0 & 0 \\ \hline -1 & 0 & 1 \\ \hline 0 & 0 & 0 \\ \hline \end{array} + \frac{\alpha}{\Delta x} \begin{array}{|c|c|c|}\hline -1 & 0 & 1 \\ \hline 2 & 0 & -2 \\ \hline -1 & 0 & 1 \\ \hline \end{array} \\ &+ \frac{\beta}{\Delta x} \begin{array}{|c|c|c|}\hline 1 & -2 & 1 \\ \hline 0 & 0 & 0 \\ \hline -1 & 2 & -1 \\ \hline \end{array} + \frac{\gamma}{\Delta x} \begin{array}{|c|c|c|}\hline 1 & -2 & 1 \\ \hline -2 & 4 & -2 \\ \hline 1 & -2 & 1 \\ \hline \end{array}\end{aligned} \tag{43}$$

as weights in the grid. In the tables the middle cell corresponds to the cell (i, j).

Proof. In the case $\alpha = \beta = \gamma = 0$ the operator (43) reduces to the classical symmetric finite differences which are visible in the first block of (43). Assuming sufficient smoothness of ψ, this gives a second order approximation to the first derivative of ψ. We need only to show that the additional blocks in (43) do contribute only terms of $O\left(h^2\right)$. Indeed, since these blocks are discretizations of higher order cross derivatives, evaluation yields

$$\begin{aligned}\tilde{\mathcal{D}}\left(\alpha,\beta,\gamma\right)\,\psi &= \frac{\partial\psi}{\partial x} + O\left(\Delta x^2\right) + \frac{\alpha}{\Delta x}\left(2\Delta x\Delta y^2\frac{\partial^3\psi}{\partial x\partial y^2} + O\left(h^3\right)\right)\\ &\quad + \frac{\beta}{\Delta x}\left(2\Delta x^2\Delta y\frac{\partial^3\psi}{\partial x^2\partial y} + O\left(h^3\right)\right)\\ &\quad + \frac{\gamma}{\Delta x}\left(\Delta x^2\Delta y^2\frac{\partial^4\psi}{\partial x^2\partial y^2} + O\left(h^4\right)\right)\\ &= \frac{\partial\psi}{\partial x} + O\left(h^2\right).\end{aligned}$$

Finally, we observe that it is not possible to include more discrete cross derivatives. They would be built from at least third order derivatives with respect to x or y which have no representation with a 3×3 stencil. ∎

In the following, we will evaluate discrete derivatives via (43) by using cell mean values instead of point values, which introduces only an error of second order.

The constraint for $(4)_{\text{curl}}$ in (24) is now to be replaced with a discrete formulation. By the lemma on discrete first derivatives given above a discrete divergence operator $\tilde{\mathcal{C}}_{i,j}$ has the form

$$\begin{aligned}\operatorname{div}\mathbf{u}|_{i,j} &= \tilde{\mathcal{D}}_{i,j}\left(\alpha,\beta,\gamma\right)\,\tilde{u}^{(x)} - \tilde{\mathcal{D}}^T_{i,j}\left(\alpha,\beta,\gamma\right)\,\tilde{u}^{(y)} + O\left(h^2\right)\\ &\equiv \tilde{\mathcal{C}}_{i,j}\left(\alpha,\beta,\gamma\right)\,\tilde{\mathbf{u}} + O\left(h^2\right),\end{aligned} \tag{44}$$

which leads to a three parameter family of operators. We mention that if any operator taken from (44) by specifying α, β, γ vanishes, all other operators give a result of $O\left(h^2\right)$ for smooth functions. Hence, if a numerical scheme respects one operator exactly, all others will give only a discretization error. Even in the discontinuous case the control of a single operator is sufficient to avoid nonphysical solutions. See, e.g., [5], where a staggered operator is controlled.

4.2. Flux distributions. In order to derive divergence-preserving flux distributions we have to look for nontrivial solutions of (39) for a specific operator chosen from (44). The flux distribution skeleton $\hat{\Phi}_{i,j}$ in the two-dimensional rectangular case covers a region of 3×3 cells and gives a two-vector in each cell, thus consisting of $2\times 9 = 18$ unknown entries. If we fix $\hat{K}$ in (39) and evaluate the divergence operator around the flux distribution in the cells of a 5×5 area with center $\hat{K}$, we obtain a system of 25 equations which describes the skeleton entries. The divergence of more remote cells is not influenced by the flux distribution at cell $\hat{K}$ and need not to be considered. The resulting system, of course, depends on the chosen operator.

4.2.1. Classical operator. The classical discrete divergence operator $\tilde{\mathcal{C}}^{(0)}_{i,j}$ is obtained from (44) by setting $\alpha = \beta = \gamma = 0$, which leads to

$$\tilde{\mathcal{C}}^{(0)}_{i,j}\,\tilde{\mathbf{u}} = \tilde{\mathcal{C}}_{i,j}\left(0,0,0\right)\,\tilde{\mathbf{u}} = \frac{\tilde{u}^{(x)}_{i+1,j} - \tilde{u}^{(x)}_{i-1,j}}{2\Delta x} + \frac{\tilde{u}^{(y)}_{i,j+1} - \tilde{u}^{(y)}_{i,j-1}}{2\Delta y}. \tag{45}$$

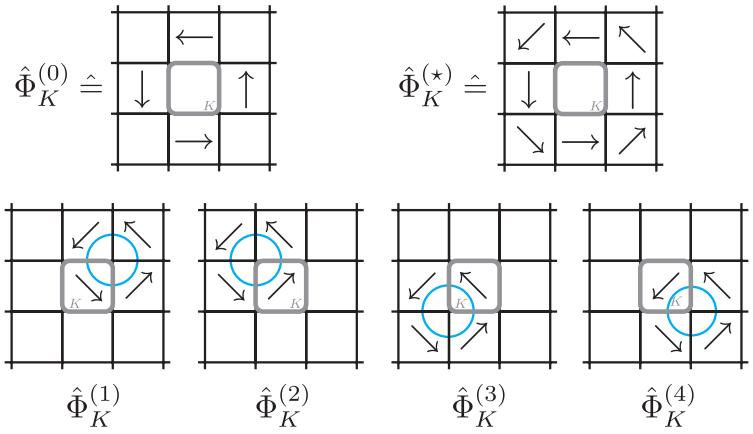

FIG. 1. *Several shape functions for flux distributions that are divergence-preserving. All of them share the same physical interpretation: They have to approximate closed curves in order to avoid introducing sources into the vector field* $\mathbf{u}$ *and thus they preserve the divergence. In terms of differential forms, these flux distributions are minimal co-cycles of the discrete outer derivative.*

In general, this operator represents the best second order approximation to $\operatorname{div} \mathbf{u}$ in the sense that the constant hidden in $O\left(h^2\right)$, i.e., the residual of the second order Taylor expansion, is minimal. The linear system (39) for this operator has rank 17, thus it has a one-dimensional null space. We choose a representative of this kernel and denote it by $\hat{\Phi}_{i,j}^{(0)}$. The nonvanishing entries are given by

$$\begin{aligned} \hat{\Phi}_{i,j}^{(0)}\Big|_{i+1,j} &= (0, \Delta y), \quad & \hat{\Phi}_{i,j}^{(0)}\Big|_{i,j+1} &= (-\Delta x, 0), \\ \hat{\Phi}_{i,j}^{(0)}\Big|_{i,j-1} &= (\Delta x, 0), \quad & \hat{\Phi}_{i,j}^{(0)}\Big|_{i-1,j} &= (0, -\Delta y), \end{aligned} \tag{46}$$

and all other elements of the kernel follow by multiplication with a constant factor. This flux distribution is sketched in the upper left corner of Figure 1. The picture has to be interpreted as follows: A flux originating in K may change the value of $\tilde{\mathbf{u}}$ in the right neighboring cell only in the y-direction. Furthermore, if this neighbor is changed in that way, all other neighboring cells have to be changed correspondingly as depicted in the figure in order to obey the constraint. Of course, the value $\tilde{u}^{(x)}$ in the right neighbor of K does not remain constant, since it may be changed by flux distributions originating from other cells. This kind of flux distribution results in a coupling of fluxes into neighboring cells, and it is this coupling that is responsible for the local preservation of the divergence.

The divergence-preserving flux distributions also have interpretations in the theory of differential forms. They represent minimal discrete co-cycles of the corresponding discrete outer derivatives; see [7], [15], [24].

In order to construct the final scheme we assemble the shape function $\hat{\Phi}_{i,j}$ of the flux distribution according to

$$\Phi_{i,j}^{(0)}\left(\tilde{\mathbf{u}}\right) = \varphi_{i,j}^{(0)}(\tilde{\mathbf{u}})\, \hat{\Phi}_{i,j}^{(0)} \tag{47}$$

with an unknown function φ. Note that $\hat{\Phi}_{i,j} = O(h)$ and, since $\Phi_{i,j}$ has to be $O(1)$, it follows that $\varphi_{i,j} = O(h^{-1})$. The final scheme is obtained by following (31) with (46)

and reads as

$$\begin{pmatrix} \tilde{u}^{(x)} \\ \tilde{u}^{(y)} \end{pmatrix}_{i,j}^{m+1} = \begin{pmatrix} \tilde{u}^{(x)} \\ \tilde{u}^{(y)} \end{pmatrix}_{i,j}^{m} + \begin{pmatrix} (\varphi_{i,j-1}^{(0)}(\tilde{\mathbf{u}}) - \varphi_{i,j+1}^{(0)}(\tilde{\mathbf{u}}))\Delta x \\ (\varphi_{i+1,j}^{(0)}(\tilde{\mathbf{u}}) - \varphi_{i-1,j}^{(0)}(\tilde{\mathbf{u}}))\Delta y \end{pmatrix}^{m}. \tag{48}$$

By Taylor expansion and comparison with the original equation (22), we deduce

$$\varphi_{i,j}^{(0)}(\tilde{\mathbf{u}}) = -\frac{\Delta t}{2\Delta x \Delta y} F\left(\tilde{\mathbf{u}}_{i,j}, \mathbf{v}_{i,j}\right), \tag{49}$$

which makes (48) consistent up to second order. This scheme solves for div-preserving advection while *exactly* preserving the value of the classical divergence operator (45). The scheme introduces central differences for the derivatives in (22) and was proposed ad hoc by Toth [26] in a magnetohydrodynamic setting. Since $\hat{\Phi}_{i,j}^{(0)}$ is the only flux distribution respecting condition (39) with the classical operator, we conclude that this scheme is the only second order scheme which preserves the divergence via the classical operator (45).

However, the scheme (48) is unconditionally unstable due to central differences. For the investigation of stability we have to look for the maximal spectral radius of the amplifier matrix

$$\rho_{\max} = \max_{\xi,\eta \in (-\pi.\pi)} \rho\left(\mathbf{T}_{\xi,\eta}\right) \tag{50}$$

(see section 4.3.2 for more details). Assuming a constant advection velocity and defining the Courant numbers

$$a = \frac{\Delta t\, v^{(x)}}{\Delta x}, \quad b = \frac{\Delta t\, v^{(y)}}{\Delta y} \tag{51}$$

we obtain the result

$$\rho_{\max}^{(0)} = \max_{\xi,\eta \in (-\pi,\pi)} |1 - \mathbf{i}\,(a \sin\xi + b \sin\eta)| > 1 \tag{52}$$

unless $a = b = 0$ for the case of (48). The imaginary unit is denoted by $\mathbf{i} = \sqrt{-1}$. In spite of this instability the scheme (48) could be used in [26] in the context of magnetohydrodynamics due to the use of predictor values for $\mathbf{u}$.

4.2.2. Extended operator. In order to design a more flexible scheme we look for a different divergence operator which leads to a larger null space of (39) and thus provides more nontrivial solutions. Empirical evaluations of the family given in (43) by computer algebra software suggest that the choice $\alpha = \frac{1}{8}$, $\gamma = 0$ admits a four-dimensional kernel for any value of β; i.e., the system (39) has rank 14. The best approximation is then given by $\beta = 0$, and the resulting operator is called *extended* operator $\tilde{\mathcal{C}}_{i,j}^{(\star)}$. Operators with larger kernels could not be found. The extended operator is defined by

$$\begin{aligned} \tilde{\mathcal{C}}_{i,j}^{(\star)}\,\tilde{\mathbf{u}} &= \tilde{\mathcal{C}}_{i,j}\left(\tfrac{1}{8}, 0, 0\right)\,\tilde{\mathbf{u}} \\ &= \frac{\{\tilde{u}_{i+1,j}^{(x)}\}_y - \{\tilde{u}_{i-1,j}^{(x)}\}_y}{2\Delta x} + \frac{\{\tilde{u}_{i,j+1}^{(y)}\}_x - \{\tilde{u}_{i,j-1}^{(y)}\}_x}{2\Delta y}, \end{aligned} \tag{53}$$

where curled brackets stand for

$$\begin{aligned} \{\psi_{i,j}\}_y &= \tfrac{1}{4}\left(\psi_{i,j+1} + 2\psi_{i,j} + \psi_{i,j-1}\right), \\ \{\psi_{i,j}\}_x &= \tfrac{1}{4}\left(\psi_{i+1,j} + 2\psi_{i,j} + \psi_{i-1,j}\right), \end{aligned} \tag{54}$$

i.e., averaging in x- and y-direction. The four admissible skeletons of flux distributions are displayed in the lower row of Figure 1. In detail, the nonvanishing entries of the first one are given by

$$\begin{aligned} \hat{\Phi}^{(1)}_{i,j}\Big|_{i+1,j+1} &= (-\Delta x, \Delta y), \qquad \hat{\Phi}^{(1)}_{i,j}\Big|_{i,j+1} = (-\Delta x, -\Delta y), \\ \hat{\Phi}^{(1)}_{i,j}\Big|_{i,j} &= (\Delta x, -\Delta y), \qquad\qquad \hat{\Phi}^{(1)}_{i,j}\Big|_{i+1,j} = (\Delta x, \Delta y) \end{aligned} \tag{55}$$

and the remaining three flux distributions follow by translation. Note that the classical operator applied to these flux distributions will not vanish. We remark further that any scheme built upon these flux distribution skeletons will be conservative, since the cell-wise sum of all flux distribution components, i.e., the integral, gives zero.

As first choice for a flux distribution, we choose the symmetric distribution $\hat{\Phi}^{(\star)}_{i,j}$ which is given by

$$\hat{\Phi}^{(\star)}_{i,j} = \hat{\Phi}^{(1)}_{i,j} + \hat{\Phi}^{(2)}_{i,j} + \hat{\Phi}^{(3)}_{i,j} + \hat{\Phi}^{(4)}_{i,j} \tag{56}$$

and shown in the upper right corner of Figure 1. Like in the preceding section this flux distribution is assembled with an unknown function φ to give

$$\Phi^{(\star)}_{i,j}\left(\tilde{\mathbf{u}}\right) = \varphi^{(\star)}_{i,j}(\tilde{\mathbf{u}})\,\hat{\Phi}^{(\star)}_{i,j}. \tag{57}$$

For the resulting scheme we obtain

$$\begin{pmatrix} \tilde{u}^{(x)} \\ \tilde{u}^{(y)} \end{pmatrix}^{m+1}_{i,j} = \begin{pmatrix} \tilde{u}^{(x)} \\ \tilde{u}^{(y)} \end{pmatrix}^{m}_{i,j} + \begin{pmatrix} (\{\varphi^{(\star)}_{i,j-1}(\tilde{\mathbf{u}})\}_x - \{\varphi^{(\star)}_{i,j+1}(\tilde{\mathbf{u}})\}_x)\Delta x \\ (\{\varphi^{(\star)}_{i+1,j}(\tilde{\mathbf{u}})\}_y - \{\varphi^{(\star)}_{i-1,j}(\tilde{\mathbf{u}})\}_y)\Delta y \end{pmatrix}^{m}, \tag{58}$$

where again the curled brackets denote the averaging of (54). The demand for second order consistency with (22) leads to

$$\varphi^{(\star)}_{i,j}(\tilde{\mathbf{u}}) = -\frac{\Delta t}{2\Delta x \Delta y} F\left(\tilde{\mathbf{u}}_{i,j}, \mathbf{v}_{i,j}\right). \tag{59}$$

This scheme *exactly* preserves the value of the extended divergence operator (53). However, as in the case of the $\Phi^{(0)}$-scheme, this scheme is unconditionally unstable. For the maximal spectral radius of the amplifier matrix we calculate with constant advection and Courant numbers from (51)

$$\rho^{(\star)}_{\max} = \max_{\xi,\eta\in(-\pi,\pi)} \left|1 - \mathbf{i}\left(a\sin\xi\tfrac{1+\cos\eta}{2} + b\sin\eta\tfrac{1+\cos\xi}{2}\right)\right| \geq 1, \tag{60}$$

where equality holds only if $a = b = 0$. The instability of schemes (58) as well as (48) could also be observed in our numerical experiments.

Equivalence with staggered approach. In the context of magnetohydrodynamics one approach of controlling the divergence is to store the components of $\mathbf{u}$ in the edges of the cells, the so-called staggered grid. This idea was proposed in [8] and

further developed by [5], [1]. We follow the presentation in [26]. In our notation the resulting staggered grid scheme reads

$$\begin{pmatrix} \tilde{u}^{(x)}_{i+\frac{1}{2},j} \\ \tilde{u}^{(y)}_{i,j+\frac{1}{2}} \end{pmatrix}^{m+1} = \begin{pmatrix} \tilde{u}^{(x)}_{i+\frac{1}{2},j} \\ \tilde{u}^{(y)}_{i,j+\frac{1}{2}} \end{pmatrix}^{m} + \begin{pmatrix} \frac{\Delta t}{\Delta y}(F_{i+\frac{1}{2},j+\frac{1}{2}} - F_{i+\frac{1}{2},j-\frac{1}{2}}) \\ \frac{\Delta t}{\Delta x}(F_{i+\frac{1}{2},j+\frac{1}{2}} - F_{i-\frac{1}{2},j+\frac{1}{2}}) \end{pmatrix}^{m} \tag{61}$$

for the normal components $\tilde{u}^{(x)}_{i+\frac{1}{2},j}$ and $\tilde{u}^{(y)}_{i,j+\frac{1}{2}}$ on each edge and the function $F_{i+\frac{1}{2},j+\frac{1}{2}}$ evaluated at the vertices. This scheme corresponds to the so-called mimetic discretization of [13], [14] for the equation $(4)_{\mathrm{curl}}$ if it is applied in the case of a rectangular grid.

In the context of computational magnetohydrodynamics and in this paper all variables are represented as mean values located in the cell centers. Hence, the staggered variables in (61) have to be substituted; see [26]. The flux function at the vertices is obtained by averaging

$$F_{i+\frac{1}{2},j+\frac{1}{2}} = \frac{1}{4}\left(F_{i,j} + F_{i+1,j} + F_{i,j+1} + F_{j+1,i+1}\right), \tag{62}$$

where the expression $F_{i,j}$ corresponds to the evaluation of the flux function (41) in the cell (i,j). Finally, the edge values of $u^{(x)}$ and $u^{(y)}$ are averaged via

$$\tilde{u}^{(x)}_{i,j} = \frac{1}{2}\left(\tilde{u}^{(x)}_{i+\frac{1}{2},j} + \tilde{u}^{(x)}_{i-\frac{1}{2},j}\right), \quad \tilde{u}^{(y)}_{i,j} = \frac{1}{2}\left(\tilde{u}^{(y)}_{i,j+\frac{1}{2}} + \tilde{u}^{(y)}_{i,j-\frac{1}{2}}\right) \tag{63}$$

after each time step (61). In [26] it was noted that this averaging procedure can be done explicitly with the scheme (61), which leads to a scheme where staggered values of $\mathbf{u}$ are eliminated. The resulting scheme (formerly staggered) is equivalent to the symmetric $\Phi^{(\star)}$-scheme in (58).

Furthermore, this shows that the extended operator $\tilde{\mathcal{C}}^{(\star)}_{i,j}$ is exactly preserved on the primary grid cells in a staggered grid calculation. This also suggests a close relation between the present extended divergence operator $\tilde{\mathcal{C}}^{(\star)}_{i,j}$ and the DIV-operator which is preserved in the mimetic schemes of [14]. The DIV-operator for the normal components on the edges is written

$$DIV\,\mathbf{u}|_{i,j} = \frac{\tilde{u}^{(x)}_{i+\frac{1}{2},j} - \tilde{u}^{(x)}_{i-\frac{1}{2},j}}{\Delta x} - \frac{\tilde{u}^{(y)}_{i,j+\frac{1}{2}} - \tilde{u}^{(y)}_{i,j-\frac{1}{2}}}{\Delta y} \tag{64}$$

in the rectangular case; see [13]. This is exactly the $\tilde{\mathcal{C}}^{(\star)}_{i,j}$-operator if the edge values are obtained from the cell centered variables by averaging

$$\tilde{u}^{(x)}_{i+\frac{1}{2},j} = \frac{\tilde{u}^{(x)}_{i+1,j+1} + 2\tilde{u}^{(x)}_{i+1,j} + \tilde{u}^{(x)}_{i+1,j-1} + \tilde{u}^{(x)}_{i,j+1} + 2\tilde{u}^{(x)}_{i,j} + \tilde{u}^{(x)}_{i,j-1}}{8}, \tag{65}$$

and analogously for $\tilde{u}^{(y)}_{i,j+\frac{1}{2}}$. This is also the same averaging formula which is used in [19] to switch from cell centered variables to normal edge components.

The symmetric scheme in (58) as well as the staggered approach is unstable, since these schemes do not take upwind directions into account. As in the case of (48) the staggered grid scheme is stabilized in magnetohydrodynamics calculations by use of predictors; see [1], [5], and [26].

4.3. Upwind scheme. The symmetric flux distribution (56) uses the same coefficient $\varphi^{(\star)}$ for all basis elements $\Phi^{(g)}$. This results in central differences and instability of the final scheme. To construct an upwind scheme we propose

$$\Phi^{(\mathrm{up})}_{i,j}\left(\tilde{\mathbf{u}}\right) = \sum_{g=1}^{4} \varphi^{(g)}_{i,j}(\tilde{\mathbf{u}})\, \hat{\Phi}^{(g)}_{i,j} \tag{66}$$

as flux distribution with four coefficients $\varphi^{(g)}$ yet to be specified. The final scheme reads as

(67)
$$\begin{aligned}\begin{pmatrix}\tilde{u}^{(x)}\\ \tilde{u}^{(y)}\end{pmatrix}^{m+1}_{i,j} &= \begin{pmatrix}\tilde{u}^{(x)}\\ \tilde{u}^{(y)}\end{pmatrix}^{m}_{i,j} + \begin{pmatrix}\delta^{(y)}_{i-\frac{1}{2},j-\frac{1}{2}}(\varphi^{(1)})\Delta x\\ -\delta^{(x)}_{i-\frac{1}{2},j-\frac{1}{2}}(\varphi^{(1)})\Delta y\end{pmatrix} + \begin{pmatrix}\delta^{(y)}_{i+\frac{1}{2},j-\frac{1}{2}}(\varphi^{(2)})\Delta x\\ -\delta^{(x)}_{i+\frac{1}{2},j-\frac{1}{2}}(\varphi^{(2)})\Delta y\end{pmatrix}\\ &\quad + \begin{pmatrix}\delta^{(y)}_{i+\frac{1}{2},j+\frac{1}{2}}(\varphi^{(3)})\Delta x\\ -\delta^{(x)}_{i+\frac{1}{2},j+\frac{1}{2}}(\varphi^{(3)})\Delta y\end{pmatrix} + \begin{pmatrix}\delta^{(y)}_{i-\frac{1}{2},j+\frac{1}{2}}(\varphi^{(4)})\Delta x\\ -\delta^{(x)}_{i-\frac{1}{2},j+\frac{1}{2}}(\varphi^{(4)})\Delta y\end{pmatrix},\end{aligned}$$

where we used the abbreviations

$$\begin{aligned}\delta^{(x)}_{i+\frac{1}{2},j+\frac{1}{2}}(\varphi) &= \varphi_{i+1,j+1} + \varphi_{i+1,j} - \varphi_{i,j+1} - \varphi_{i,j},\\ \delta^{(y)}_{i+\frac{1}{2},j+\frac{1}{2}}(\varphi) &= \varphi_{i+1,j+1} + \varphi_{i,j+1} - \varphi_{i+1,j} - \varphi_{i,j},\end{aligned} \tag{68}$$

which represent finite differences. The next two subsections specify the coefficients $\varphi^{(g)}$ by requiring consistency and stability of the scheme (67).

4.3.1. Consistency. The following lemma gives expressions for $\varphi^{(g)}$ such that a first or second order method is obtained. A weight function $\omega^{(g)}$ which controls the influence of the different basis flux distributions remains unspecified.

THEOREM 4.2 (consistency). *Let the values $\omega^{(g)}$ $(g = 1, 2, 3, 4)$ be weights such that $\sum_{g=1}^{4} \omega^{(g)} = 1$. In general these weights depend on $\tilde{\mathbf{u}}$ and $\mathbf{v}$. Furthermore let the expressions $\frac{\Delta t}{\Delta x}$ and $\frac{\Delta t}{\Delta y}$ be $O(1)$, the geometry factor $\alpha = \frac{\Delta x}{\Delta y}$ be bounded from above and below, and $h = \max(\Delta x, \Delta y)$. Then the scheme displayed in* (67) *is consistent with the constrained advection equation* (22) *in smooth regions of the solution up to*

(i) *first order in space and time, if the flux distribution factor in* (66) *is given by*

$$\varphi^{(g)}_{i,j}\left(\tilde{\mathbf{u}}\right) = -\frac{\Delta t}{2\Delta x \Delta y}\omega^{(g)}(\tilde{\mathbf{u}}_{i,j}, \mathbf{v}_{i,j}) F\left(\tilde{\mathbf{u}}_{i,j}, \mathbf{v}_{i,j}\right); \tag{69}$$

(ii) *second order in space and time, if the flux distribution factor in* (66) *is given by*

$$\varphi^{(g)}_{i,j}\left(\tilde{\mathbf{u}}\right) = -\frac{\Delta t}{2\Delta x \Delta y}\omega^{(g)}(\tilde{\mathbf{u}}_{i,j}, \mathbf{v}_{i,j}) \left(F - \frac{\Delta t}{2}(v^{(x)}\partial_x F + v^{(y)}\partial_y F) + \Lambda\right)_{i,j} \tag{70}$$

with $\Lambda = \sum_{g=1}^{4}(\frac{\Delta x}{2}\, r_g\, \partial_x(\omega^{(g)}F) + \frac{\Delta y}{2}\, l_g\, \partial_x(\omega^{(g)}F))$ and coefficients r_g and l_g as given in the table (71).

We remark that the second order result (70) uses derivatives of the weight function ω. Hence, ω considered as a function in the domain Ω needs to have at least one continuous derivative in order to obtain second order accuracy. We will present numerical experiments where second order is not recovered due to a nonsmooth weight function.

Proof. We consider the flux distribution factor $\varphi_{i,j}$ as function $\varphi_{i,j} \equiv \varphi(x_i, y_j)$ whose evaluations in different grid cells can be expanded in a Taylor series. Second order expansion of the scheme (67) gives

$$\begin{aligned}\begin{pmatrix}\tilde{u}^{(x)}\\ \tilde{u}^{(y)}\end{pmatrix}_{i,j}^{m+1} &= \begin{pmatrix}\tilde{u}^{(x)}\\ \tilde{u}^{(y)}\end{pmatrix}_{i,j}^{m}\\ &+ \begin{pmatrix} \frac{\partial}{\partial y}\sum_{g=1}^{4}\left(2\varphi^{(g)} - \Delta x\, r_g\, \partial_x\varphi^{(g)} - \Delta y\, l_g\, \partial_y\varphi^{(g)}\right)\Delta x\Delta y \\ -\frac{\partial}{\partial x}\sum_{g=1}^{4}\left(2\varphi^{(g)} - \Delta y\, l_g\, \partial_y\varphi^{(g)} - \Delta x\, r_g\, \partial_x\varphi^{(g)}\right)\Delta y\Delta x \end{pmatrix}_{i,j}\\ &+ O\left(h^3\right),\end{aligned}$$

where l_g and r_g are defined by the table

(71)

	$g=1$	$g=2$	$g=3$	$g=4$
l_g	1	1	–1	–1
r_g	1	–1	–1	1

and φ_x, φ_y are derivatives of φ. Note that we changed the interpretation of $\tilde{\mathbf{u}}_{i,j}$ from cell mean value to point value in the middle of the cell. This switch introduces only an error of $O(h^2)$ on both the left-hand and the right-hand sides of the equation. However, the leading expression within $O(h^2)$ cancels on both sides and the remaining error is $O(h^3)$.

By use of (22) with the definition of the flux function F in (41) we obtain the expansion of the exact solution

$$\begin{aligned}\mathbf{u}_{i,j}\left(t+\Delta t\right) &= \mathbf{u}_{i,j}\left(t\right) - \Delta t \begin{pmatrix}\partial_y F\\ -\partial_x F\end{pmatrix}_{i,j}\\ &+ \frac{\Delta t^2}{2}\begin{pmatrix}\partial_y\left(v^{(x)}\partial_x F + v^{(y)}\partial_y F\right)\\ -\partial_x\left(v^{(x)}\partial_x F + v^{(y)}\partial_y F\right)\end{pmatrix}_{i,j} + O\left(\Delta t^3\right).\end{aligned}$$

Since the Courant numbers are bounded we have $O(h^3) = O(\Delta t^3)$. Hence, the direct comparison of exact and numerical increments of $\mathbf{u}_{i,j}$ yields the *consistency condition*

$$\begin{aligned}&\sum_{g=1}^{4}\left(2\varphi^{(g)} - \Delta x\, r_g\, \partial_x\varphi^{(g)} - \Delta y\, l_g\, \partial_y\varphi^{(g)}\right)\Delta x\Delta y\\ &\quad = -\Delta t\, F + \frac{\Delta t^2}{2}\left(v^{(x)}\partial_x F + v^{(y)}\partial_y F\right).\end{aligned}$$

This relation can be solved for $\varphi^{(g)}$ by means of an ansatz with a first order and a second order contribution to $\varphi^{(g)}$, viz.,

$$\varphi^{(g)} = \frac{\Delta t}{\Delta x\Delta y}\varphi^{(g,1)} + \frac{\Delta t^2}{\Delta x\Delta y}\varphi^{(g,2)}.$$

Introducing this into the consistency condition and comparison of coefficients of Δt-expressions leads us to

$$\sum_{g=1}^{4}\varphi^{(g,1)} = -\frac{1}{2}F,$$

which, of course, can be satisfied in many ways. We propose weights $\omega^{(g)}$, yet unspecified, which sum up to unity and write

$$\varphi^{(g,1)} = -\omega^{(g)} \frac{1}{2} F$$

as first order flux distribution factor. By using this in our ansatz and further comparison of Δt^2-coefficients in the consistency condition, the second order factor

$$\varphi^{(g,2)} = \omega^{(g)} \frac{1}{4} \left(v^{(x)} \partial_x F + v^{(y)} \partial_y F - \sum_{g=1}^{4} \left(\frac{\Delta x}{\Delta t} r_g \, \partial_x (\omega^{(g)} F) + \frac{\Delta y}{\Delta t} l_g \, \partial_y (\omega^{(g)} F) \right) \right)$$

is obtained. □

In implementations we substitute the x- and y-derivatives in (70) by appropriate finite differences. Following the TVD analysis of one-dimensional methods, these finite differences need a limiting procedure in order to obtain nonoscillatory solutions. In the numerical experiments with discontinuous solutions we used the so-called WENO-limiter (see [17]), which is given by

$$WENO(d_1, d_2) = \frac{\frac{d_1}{\sqrt{d_1^2+\varepsilon}} + \frac{d_2}{\sqrt{d_2^2+\varepsilon}}}{\frac{1}{\sqrt{d_1^2+\varepsilon}} + \frac{1}{\sqrt{d_2^2+\varepsilon}}}, \tag{72}$$

where d_1 and d_2 are left- and right-hand side finite differences and ε is a small number ($\varepsilon \approx 10^{-8}$). With use of this limiter we have

$$\left. \frac{\partial \psi}{\partial x} \right|_i = \frac{WENO(\psi_i - \psi_{i-1}, \psi_{i+1} - \psi_i)}{\Delta x} \tag{73}$$

for the limited derivative of a grid function ψ.

4.3.2. Stability. The weights which have been introduced during the proof of consistency control the activation of the different basis flux distributions shown in Figure 1 (lower row). Their value should be chosen according to the direction of the advection. Clearly, one would not activate the first flux distribution $\hat{\Phi}^{(1)}$ which is oriented towards the upper right if the wind is pointing in opposite direction. This would yield an unstable scheme. Indeed, stability is the issue that will specify the right choice of weights.

To investigate the stability we consider the *one-sided* scheme which uses only the first and the fourth flux distribution. Hence, it follows for the weights

$$\omega^{(1)} \equiv \omega, \quad \omega^{(2,3)} = 0, \quad \omega^{(4)} = 1 - \omega \tag{74}$$

with unknown ω. An impression of how different choices of ω influences the stability of the scheme is given in Figure 2. It shows the contours of the maximal eigenvalue of the amplifier matrix $\rho_{\max}$ for different choices of ω and different directions of the flow. The contour values and their shape have been obtained numerically for the first order scheme. We can see that a flow pointing exactly in the direction of a flux distribution ($\theta_1 = 0$ or $\theta_4 = 0$) requires the activation of only the corresponding flux distribution ($\omega_1 = 1$ or $\omega_4 = 1$) to yield stability. Furthermore $\omega_1 = \omega_4 = 1/2$ gives a stable scheme only for flows in the x-direction. This corresponds to the intuitive choices in these cases. In between these extreme cases Figure 2 indicates the existence of a single stable choice $\bar{\omega}(\theta)$ for the weight.

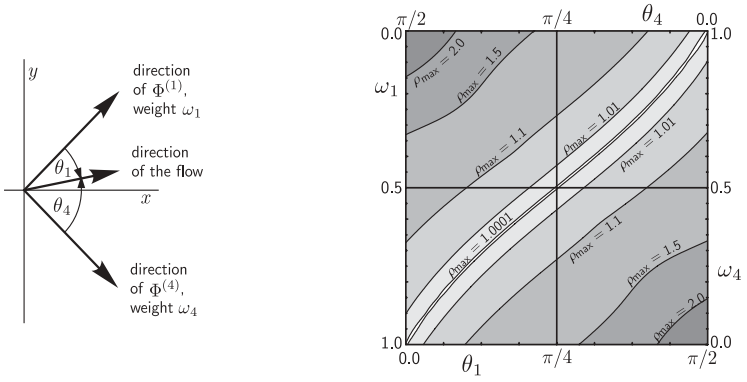

FIG. 2. *Left: A sketch of the elements of the one-sided scheme to clarify the notation used. Right: Numerical evaluations of the maximal spectral radius of the amplifier matrix in the* (θ_1, ω_1)*-plane for the first order one-sided scheme. The plot exhibits a distinct function* $\bar{\omega}(\theta)$ *which yields stability.*

The following lemma specifies this weight and the stability conditions of the one-sided scheme.

THEOREM 4.3 (stability). *Assume the advection velocity to be constant and* $\left|v^{(x)}\right| \neq 0$. *Then, the one-sided, first order scheme consisting of flux distribution* $\Phi^{(1)}$ *and* $\Phi^{(4)}$ *with single weight* ω, *time step* Δt, *and cells* $\Delta x \times \Delta y$ *is stable in the sense of a von Neumann analysis under the conditions*

$$\left(\frac{\Delta t\, v^{(y)}}{\Delta y}\right)^2 \leq \frac{\Delta t\, v^{(x)}}{\Delta x} \leq 1 \quad \textit{and} \quad \omega \equiv \bar{\omega} = \frac{1}{2}\left(1 + \frac{\Delta x}{\Delta y}\frac{v^{(y)}}{v^{(x)}}\right). \tag{75}$$

Under these stability conditions we have, furthermore, for the maximal spectral radius $\rho_{\max}$ *of the amplifier matrix*

$$\rho_{\max}(\bar{\omega} + \delta\omega) = 1 + c\,\delta\omega^2 + O(\delta\omega^3) \quad \textit{with } c > 0, \tag{76}$$

i.e., the weight $\bar{\omega}$ *is a local minimum of* $\rho_{\max}$.

Proof. We follow the stability analysis of von Neumann (see, e.g., [11]). The Fourier transform of the grid function $\mathbf{u}_{i,j}$ is denoted by

$$\hat{\mathbf{u}}_{i,j} = \hat{\mathbf{u}}_0\, e^{\mathbf{i}(i\,\xi + j\,\eta)}$$

and introduced into the scheme (67) with (69) and (74), which leads to

$$\hat{\mathbf{u}}_0^{m+1} = \mathbf{T}_{\xi,\eta}\,\hat{\mathbf{u}}_0^m.$$

Here, $\mathbf{T}_{\xi,\eta}$ is the amplifier matrix of the scheme. The imaginary unit is denoted by $\mathbf{i} = \sqrt{-1}$. Since the advection velocity is assumed to be constant the amplifier matrix has the form

$$\mathbf{T}_{\xi,\eta} = \begin{pmatrix} 1 - b\,t^{(x)}(\xi,\eta,\omega) & a\,\alpha\,t^{(x)}(\xi,\eta,\omega) \\ -b\,\frac{1}{\alpha}\,t^{(y)}(\xi,\eta,\omega) & 1 + a\,t^{(y)}(\xi,\eta,\omega) \end{pmatrix}$$

with the Courant numbers $a = \frac{\Delta t\, v^{(x)}}{\Delta x}$ and $b = \frac{\Delta t\, v^{(y)}}{\Delta y}$ as well as $\alpha = \frac{\Delta x}{\Delta y}$. The functions $t^{(x)}$ and $t^{(y)}$ depend on ξ, η, and ω and follow from the scheme. For stability

the maximal spectral radius

$$\rho_{\max}(a,b,\omega) = \max_{\xi,\eta\in(-\pi,\pi)} \rho\left(\mathbf{T}_{\xi,\eta}\right)$$

has to be smaller or equal to unity. The geometry factor α drops out during the calculation. Obviously, $\mathbf{T}_{\xi,\eta}$ has the eigenvector $(v^{(x)}, v^{(y)})^T$ with eigenvalue $\lambda_1 = 1$, which corresponds to the first eigenvalue and eigenvector of the Jacobian given in (16) if the identity matrix is added. The second eigenvalue of $\mathbf{T}_{\xi,\eta}$ varies with ξ and η. It has the form $\lambda_2 = \tau_1(\eta) + \tau_2(\eta)\, e^{\mathbf{i}\,\xi}$ with $\tau_{1,2}(\eta) \in \mathbb{R}$, thus its maximal absolute value $|\lambda_2| = |\tau_1(\eta)| + |\tau_2(\eta)|$ depends only on η. A straightforward calculation leads to

$$\rho_{\max}(a,\beta,\omega) = \max_{\eta\in(-\pi,\pi)} \left(\sqrt{\left(1 - a + a(1+\beta-2\,\omega\,\beta)\tfrac{1-\cos\eta}{2}\right)^2 + \tfrac{a^2}{4}\left(1+\beta-2\,\omega\right)^2 \sin^2\eta} + \sqrt{\left(a - a(1-\beta+2\,\omega\,\beta)\tfrac{1-\cos\eta}{2}\right)^2 + \tfrac{a^2}{4}\left(1-\beta-2\,\omega\right)^2 \sin^2\eta} \right),$$

where we assumed $|a| > 0$ and defined the ratio $\beta = \frac{b}{a}$.

The stable weight as defined in (75) can be written as

$$\bar{\omega} = \frac{a+b}{2a} = \frac{1+\beta}{2},$$

which may be introduced into $\rho_{\max}$, yielding

$$\rho_{\max}(a,\beta,\bar{\omega}) = \max_{\eta\in(-\pi,\pi)} \left(\left| 1 - a\left(1 - (1-\beta^2)\tfrac{1-\cos\eta}{2}\right)\right| + |a| \left(1 - (1-\beta^2)\tfrac{1-\cos\eta}{2}\right)\right)$$

after some calculation. The expression in large brackets is a positive quantity with the bounds

$$0 \le \min\left(1,\beta^2\right) \le 1 - (1-\beta^2)\tfrac{1-\cos\eta}{2} \le \max\left(1,\beta^2\right).$$

Especially, for a given value of β there exists an η such that this expression is non-vanishing. From this fact we conclude for $\rho_{\max}\left(a,\beta,\bar{\omega}\right)$

$$a < 0 \quad \Rightarrow \quad \rho_{\max} > 1;$$

hence $a \ge 0$ is necessary for stability. The conditions for $\rho_{\max} \le 1$ now follow from the condition that the modulus expression in $\rho_{\max}$ should be nonnegative. Thus we obtain

$$a\left(1 - (1-\beta^2)\tfrac{1-\cos\eta}{2}\right) \le 1 \quad \Rightarrow \quad a \max\left(1,\beta^2\right) \le 1,$$

which, since $\beta = b/a$, finally gives $b^2 \le a \le 1$ as stated in the lemma.

For the second part of the lemma we consider the Taylor expansion

$$\rho_{\max}(a,\beta,\bar{\omega}+\delta\omega) = \rho_{\max}|_{\omega=\bar{\omega}} + \left.\frac{\partial\rho_{\max}}{\partial\omega}\right|_{\omega=\bar{\omega}} \delta\omega + \left.\frac{\partial^2\rho_{\max}}{\partial\omega^2}\right|_{\omega=\bar{\omega}} \delta\omega^2 + \mathcal{O}(\delta\omega^3)$$

for the maximal spectral radius. Under the conditions $b^2 \le a \le 1$ we have shown $\rho_{\max}|_{\omega=\bar{\omega}} = 1$. Starting with the general formula for $\rho_{\max}(a,b,\omega)$ as given above, computer algebra software easily gives

$$\frac{\partial\rho_{\max}}{\partial\omega}(a,\beta,\bar{\omega}) = 0$$

and

$$\frac{\partial^2 \rho_{\max}}{\partial \omega^2}(a,\beta,\bar{\omega}) = \frac{2\,a\sin^2\eta}{|1+\beta^2+(1-\beta^2)\cos\eta|} + \frac{2\,a^2\sin^2\eta}{|2-a(1+\beta^2)-(1-\beta^2)\cos\eta|}$$

for the derivatives, which justifies the expansion with positive constant c. □

Note that stability of the one-sided scheme is given also for specific flows with $\theta_1 < 0$ or $\theta_4 < 0$ (according to Figure 2), which point outside the range given by the two flux distributions. Intuitively, we would expect $|b| \le a$ for the Courant numbers, but the lemma states only $|b| \le \sqrt{a}$. This condition becomes more and more restrictive if the angles $\theta_{1,4}$ approach $-\pi/4$. For the extreme cases $\theta_{1,4} = -\pi/4$ we would obtain a flow in a negative (respectively, positive) y-direction and the condition $|b| \le \sqrt{a} = 0$. Furthermore, one of the weights becomes negative if $\theta_1 < 0$ or $\theta_4 < 0$ holds.

Lemma 4.1 investigates the first order scheme. The analysis for the second order scheme becomes much more involved and hardly solvable by hand. But numerical experiments suggest that the second order scheme appears to remain stable under the same conditions. Furthermore the numerical exploration of the amplifier matrix results in a picture very similar to the right-hand side of Figure 2. A detailed investigation of the second order scheme remains for future work.

Finally, we generalize the result for the one-sided scheme to the full upwind scheme with four flux distributions. The one-sided scheme may easily be formulated for all four possible coordinate directions. For a general scheme, we propose a superposition of these four one-sided schemes in order to obtain a full upwind scheme. Hence, for any flow the weights are chosen such that two flux distributions are activated according to the appropriate one-sided case. The resulting weights may be constructed from the direction vector each skeleton is associated with. These vectors are given by

$$\mathbf{n}_1 = (1,1)\,, \quad \mathbf{n}_2 = (-1,1), \quad \mathbf{n}_3 = (-1,-1), \quad \mathbf{n}_4 = (1,-1), \tag{77}$$

following the numbering of the sketch in Figure 1. Based on these vectors the general local weights $\omega^{(1,2,3,4)}$ have the representation

$$\omega^{(g)}\left(\mathbf{v}_{i,j}\right) = \frac{\max(\mathbf{n}_g \cdot \mathbf{v}_{i,j}, 0)}{\sum_{\gamma=1}^{4} \max(\mathbf{n}_\gamma \cdot \mathbf{v}_{i,j}, 0)}, \tag{78}$$

which may be verified to coincide with the appropriate one-sided case depending on the direction of $\mathbf{v}$. In addition we define $\omega^{(g)}(\mathbf{0}) = 0$. By extrapolation of Lemma 4 we may draw the conclusion that the scheme (67) with the weights (78) will be stable provided we have

$$\max_{x,y\in\Omega}(|a_{i,j}|) \le 1 \quad \text{and} \quad \max_{x,y\in\Omega}(|b_{i,j}|) \le 1, \tag{79}$$

where $a_{i,j}$ and $b_{i,j}$ are local Courant numbers. One of the weights of (78) is displayed in Figure 3 as the dark curve. Note the correspondence of the shapes between the curve in this figure and the contour in Figure 2. Unfortunately, the weight given in (78) is not differentiable at points where $\mathbf{v}$ is orthogonal to any of the $\mathbf{n}_g$ due to the function $\max(\cdot,0)$. However, at least one continuous derivative is needed for second order accuracy as stated in the remark following Lemma 3.2. As regularization of $\max(\cdot,0)$, we propose

$$\max_\varepsilon(x,0) = \frac{1}{2}(x + \sqrt{x^2+4\varepsilon}) \tag{80}$$

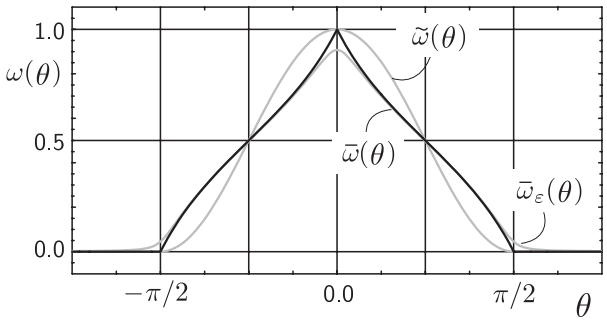

FIG. 3. *The nonsmooth weight function $\bar{\omega}$ obtained from Lemma 4 (dark curve) and two possible regularizations ω_ε and $\tilde{\omega}$. The angle θ is the angle between the flow and the direction of the flux distribution. Compare this plot with the stability contours in Figure 2.*

for use in (78) resulting in a regularized weight $\bar{\omega}_\varepsilon$. The curve of $\bar{\omega}_\varepsilon$ is also shown in Figure 3. Note that this weight gives a deviation from the weight $\bar{\omega}$ obtained in Lemma 4.1. However, if we choose $\varepsilon = h = \max(\Delta x, \Delta y)$ we have

$$\rho_{\max}(\bar{\omega}_\varepsilon) \approx \rho_{\max}(\bar{\omega} + \sqrt{h}) \approx 1 + c\,h \tag{81}$$

according to the second statement in Lemma 4.1. This increases the error constant of the scheme but still gives stability; see, e.g., [11].

Another possible regularization is given by

$$\tilde{\omega}^{(g)}(\mathbf{v}) = \frac{\max(\mathbf{n}_g \cdot \mathbf{v}, 0)^2}{2\,\|\mathbf{v}\|^2}, \tag{82}$$

which is also depicted in Figure 3. This weight deviates considerably from $\bar{\omega}$ and stability is not assured by Lemma 4.1. However, we want to remark that in our numerical calculations with this weight instabilities did not occur. This fact needs further investigation. It could be possible that error modes considered by the von Neumann analysis are not excited in the numerical evaluations due to the constraint-preserving property.

5. Numerical experiments. We proceed to present numerical experiments for two-dimensional div-preserving advection (22) calculated with the upwind scheme given in (67). This scheme exactly preserves the extended divergence operator $\tilde{\mathcal{C}}^{(\star)}$. The symmetric schemes (48), which preserves the classical operator and (58) are not considered due to their instability. For the scheme (67) we write FD, which is an abbreviation of "flux distribution." $FD^{(2)}$ stands for the second order scheme (70) with weight $\bar{\omega}$, while $FD^{(2)}_\varepsilon$ uses the regularized weight $\bar{\omega}_\varepsilon$. Analogously, $FD^{(1)}$ denotes the first order scheme (69) with weight $\bar{\omega}$. For the smooth test cases we used central finite differences to approximate the derivatives in the second order flux distribution coefficient given by (70).

5.1. Smooth test cases. In order to obtain empirical orders of convergence we considered smooth initial conditions

$$\mathbf{u}_0(x, y) = \begin{pmatrix} -1 + \frac{1}{2}\sin(\pi x) + \frac{1}{4}\cos(\pi y) \\ 1 + \frac{1}{2}\cos(\pi x) + \frac{1}{4}\sin(\pi y) \end{pmatrix} \tag{83}$$

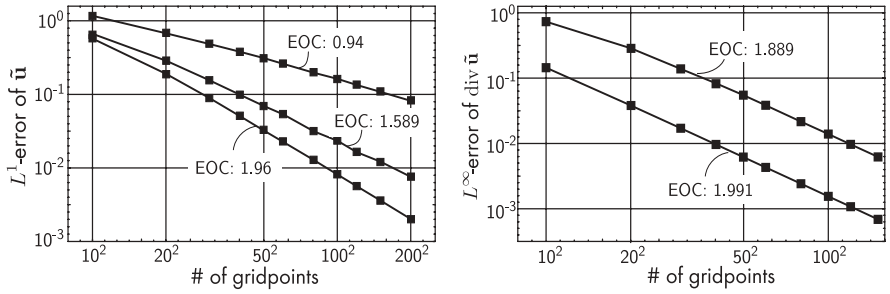

FIG. 4. *Empirical order of convergence for a smooth solution and the divergence of the solution; for problem specification see section* 5.1. *From above, the three curves in the left plot refer to the first order upwind scheme, the second order upwind scheme with nonregularized weight, and the second order upwind scheme with regularized weight. On the right, the upper (lower) curve shows evaluations of the classical (extended) discrete divergence operator. Beside the error curves, averaged empirical orders of convergence are displayed.*

in the computational domain $\Omega = [-1, 1]^2$. To eliminate the influence of boundary conditions periodic boundaries were furnished in both dimensions. The initial vector field $\mathbf{u}_0$ has a nonvanishing divergence which will be frozen under div-preserving advection. The vector field is advected by the velocity field

$$\mathbf{v}(x, y) = \begin{pmatrix} 1 + \frac{1}{4}\cos(\pi x) + \frac{1}{2}\sin(\pi y) \\ 1 + \frac{1}{4}\sin(\pi x) + \frac{1}{2}\cos(\pi y) \end{pmatrix}, \tag{84}$$

which is periodic as $\mathbf{u}_0$. As end time, $t = 0.5$ was chosen. Since an analytic solution is not available for this case, a reference solution has been calculated on a uniform grid with 1200×1200 points and 540 constant time steps. The maximal Courant number

$$c_{\max} = \max_{x,y\in\Omega} \left(\frac{v^{(x)}\Delta t}{\Delta x}, \frac{v^{(y)}\Delta t}{\Delta y} \right) \tag{85}$$

for this solution was approximately 0.97.

The reference solution is used to calculate empirical orders of convergence for calculations on $N \times N$ grids with $N = 10, 20, 30, 40, 50, 60, 80, 100, 120, 150, 200$. All these calculations were performed with constant time steps such that $c_{\max} \approx 0.875$. For the coarsest grid with 10×10 this results in five time steps. The left-hand side of Figure 4 shows the L^1-errors of second order schemes with regularized and nonregularized weight as well as the L^1-errors of the first order scheme. As predicted in the preceding section, the $FD^{(2)}$-scheme does not achieve full second order. Only due to the regularization (80) full second order is obtained with the $FD^{(2)}_\varepsilon$-scheme. The errors and the order of convergence depend slightly on the regularization parameter ε. In Figure 4, $\varepsilon = 5\Delta x$ was chosen. Higher values give a slightly improved order of convergence. $FD^{(1)}$ exhibits first order independently of the regularity of the weight.

The right-hand side of Figure 4 displays the L^∞-error of discrete divergences of the $FD^{(2)}_\varepsilon$-solution at $t = 0.5$. The curves refer to evaluations with the classical and the extended operator, $\tilde{\mathcal{C}}^{(0)}$ and $\tilde{\mathcal{C}}^{(\star)}$ as given in (45) and (53), respectively. Due to the constraint preservation of all FD-schemes, the evaluation of the extended operator $\tilde{\mathcal{C}}^{(\star)}$ yields the *same numerical value for the divergence during the entire calculation*. This value is given by the discrete initial conditions. Hence, the lower curve in Figure 4 (right) simply represents the increasing resolution of the initial

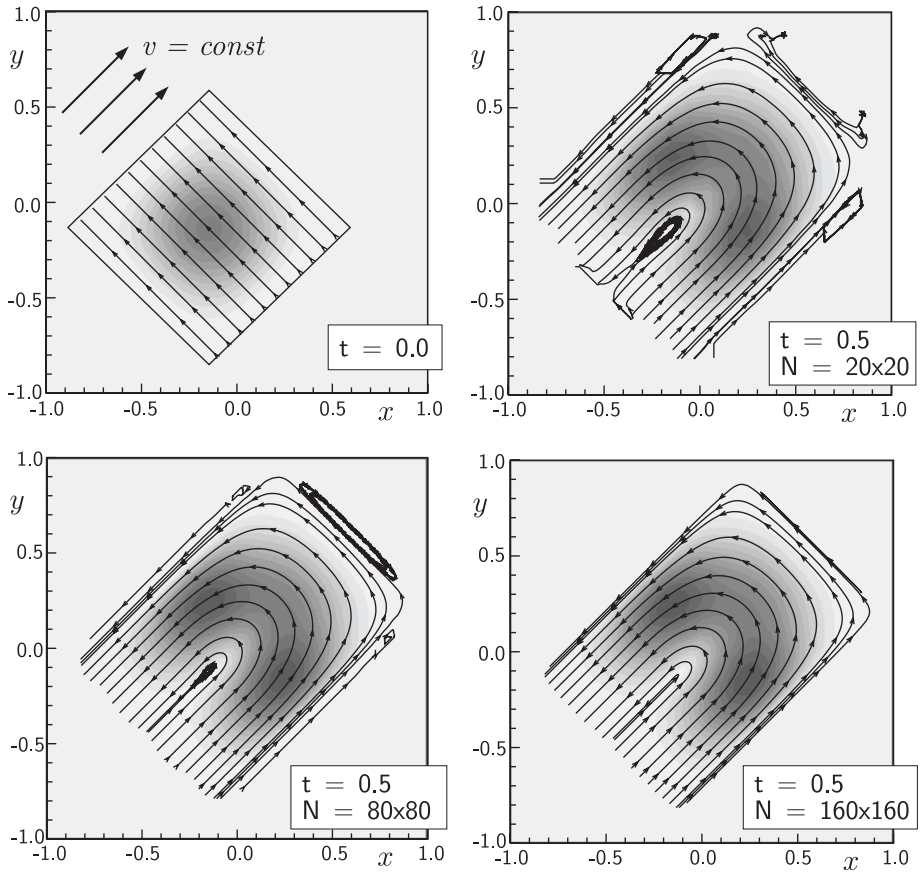

FIG. 5. *Numerical results for the box test case (see section* 5.1.1*) for three different grids. The initial conditions and the direction of the constant advection velocity are shown in the upper left corner.*

conditions and demonstrates second order for the extended operator. In contrast, the value of the classical operator is affected during the numerical calculation (not shown). However, since the solution is smooth the evaluation of $\tilde{\mathcal{C}}^{(0)}$ at $t = 0.5$ is converging, which is visible in the right plot (upper curve) of Figure 4.

5.1.1. Box test case. If initial conditions for the div-preserving advection (22) are given in the form

$$\mathbf{u}_0(x,y) = (0, g'(x)\, g'(y)) \tag{86}$$

with derivatives of a function g and the velocity field by $\mathbf{v}(x,y) = (1,0)$, i.e., pointing constantly in the x-direction, the exact solution has the form

$$\mathbf{u}(x,y,t) = (g''(y)\,(g(x) - g(x-t))\,, g'(x-t)\, g'(y))\,. \tag{87}$$

As an example we choose

$$g(x) = \begin{cases} \frac{16}{5}s^5 - \frac{8}{3}s^3 + s, & -\frac{1}{2} < s < \frac{1}{2}, \\ \pm\frac{4}{15} & \text{else}, \end{cases} \tag{88}$$

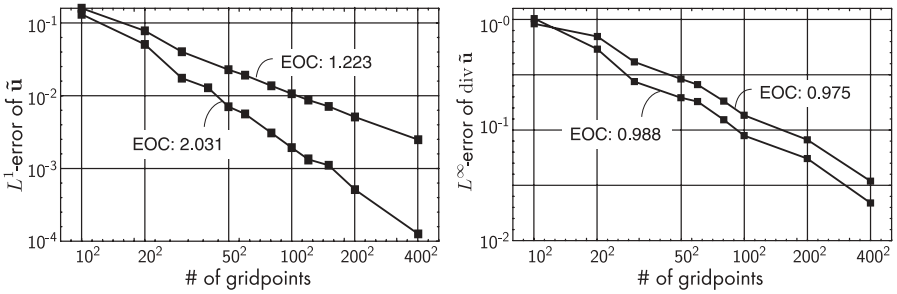

FIG. 6. *Numerical errors of the solution of the box test case at $t = 0.5$ with different grids. Left: L^1-error of $\mathbf{u}$. The upper curve is obtained with the first order scheme $FD^{(1)}$, the lower curve refers to $FD^{(2)}$. Note that regularity of the weight does not play a role in this example due to constant advection velocity. Right: L^∞-error for the extended (lower curve) and classical (upper curve) divergence operator. Beside the error curves averaged empirical orders of convergence are displayed.*

so that the initial field $\mathbf{u}_0$ is nonvanishing only inside the box $(-1/2, 1/2)^2$. The initial condition has a nonvanishing divergence; hence, the advection will differ from ordinary advection, though the advection velocity is constant.

In the numerical test the system given by these initial conditions is rotated by 45° such that advection takes place in a diagonal grid direction. The initial conditions are displayed in the upper left corner of Figure 5. The center of the box is moved to $(-0.1, -0.1)$. The contour shading represents values of $\|\tilde{\mathbf{u}}\|$, which ranges form zero to 1.36, while the lines in the plots represent field lines of $\tilde{\mathbf{u}}$ (the flow which is induced by $\tilde{\mathbf{u}}$). The calculation is conducted in the domain $[-1, 1]^2$ with constant extrapolation in the boundary cells. Besides the initial conditions, Figure 5 displays numerical results at $t = 0.5$ for three uniform meshes with different resolutions. All results were obtained with the $FD^{(2)}$ scheme with constant time steps such that the maximal courant number $c_{\max} \approx 0.884$. Note that the weight is constant in this example since the advection velocity is constant. In the exact solutions the field lines are bent outside the box due to the advection. Since the divergence of $\tilde{\mathbf{u}}$ does not vanish initially, the field lines fill up the way and their starting and ending points stay inside the initial box. In other words, the nonvanishing divergence inside the box acts as source and sink for the field lines.

On the coarse grid the solution is spoiled at the sides by artificial field lines. These field lines correspond to values of $\tilde{\mathbf{u}}$ in the magnitude of the truncation error which are introduced by the finite stencil of the scheme at the boundary of the box. Note that outside the initial box erroneous field lines appear as closed lines which indicates the solenoidal character of the scheme. On the fine mesh the solution is well resolved.

In Figure 6 we display the L^1-error of the variable $\mathbf{u}$ and the L^∞-error of the divergence for the box test case together with averaged empirical orders of convergence. Second order is well obtained, while the $FD^{(1)}$-scheme shows a slight superconvergence for this example. The irregularities in the second order error curve might be due to the nonsmooth gradient of the solution (87) with (88) along the lines $y = \pm\frac{1}{2}$. This is also the reason that the convergence of the divergence on the right-hand side of the figure is reduced to first order. Like in the smooth test case, the divergence error for the extended operator gives the same value during the entire simulation since this value is locally preserved by the scheme. The method freezes the discrete divergence of the initial conditions like the analytical system does.

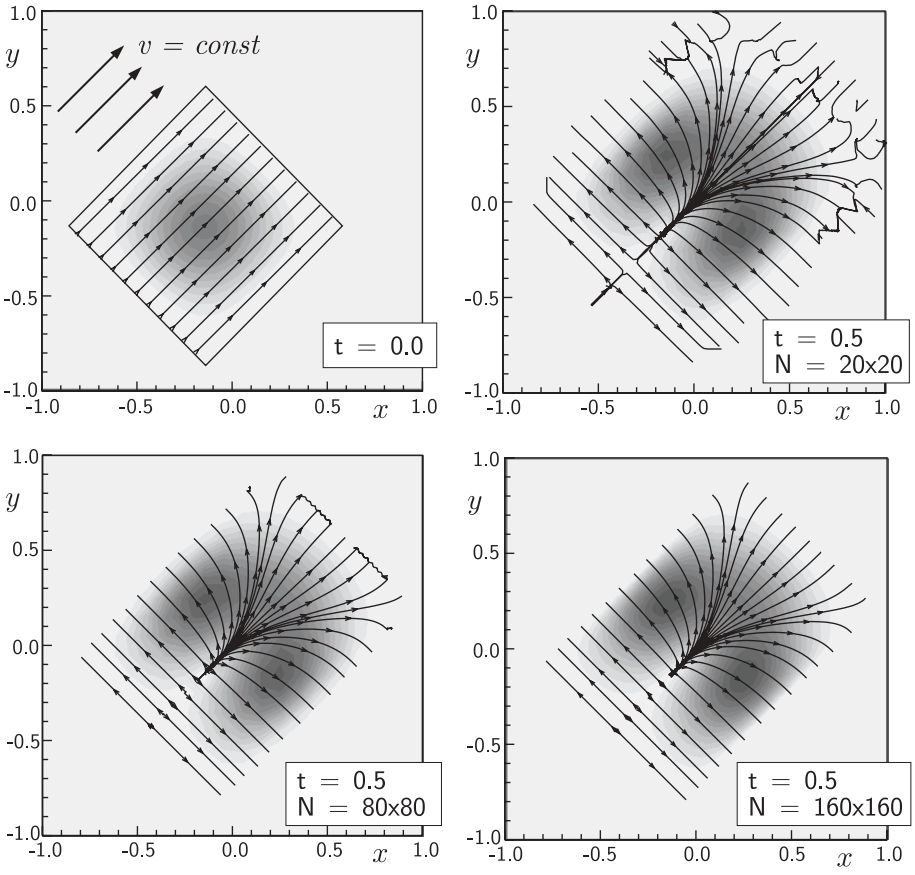

FIG. 7. *Initial conditions and grid convergence study for the box test case of* curl*-free advection. The initial conditions and the result are dual to that of* div*-free advection and should be compared to the corresponding results in Figure* 5.

Box test case for curl*-preserving advection.* It is interesting to ask for the dual solution of the box test case in the sense of the duality of curl-preserving and div-preserving advection as indicated in (25). The solution is depicted in Figure 7, which should be directly compared with Figure 5. The dual solution is obtained by taking the orthogonal complement of the initial conditions (86) as well as of the solution (87). The result is a solution of the curl-preserving advection (23). Accordingly, the field lines in Figures 5 and 7 are orthogonal.

The plots in Figure 7 can be obtained equivalently in two ways: either by taking the orthogonal vector in each cell of the result of the scheme for div-preserving advection or by constructing the corresponding flux distribution scheme for curl-preserving advection and applying it to the dual initial conditions. In fact, this scheme would differ from the div-preserving scheme only in the structure of the flux distribution shape functions in (55). These shape functions are substituted by their orthogonal complement, yielding outward pointing arrows instead of the approximate loops in Figure 1. The resulting scheme preserves perfectly the discrete value of the curl but has the same properties in consistency and stability as its dual counterpart, which was constructed in the preceding sections. Indeed the plot of errors and the empirical

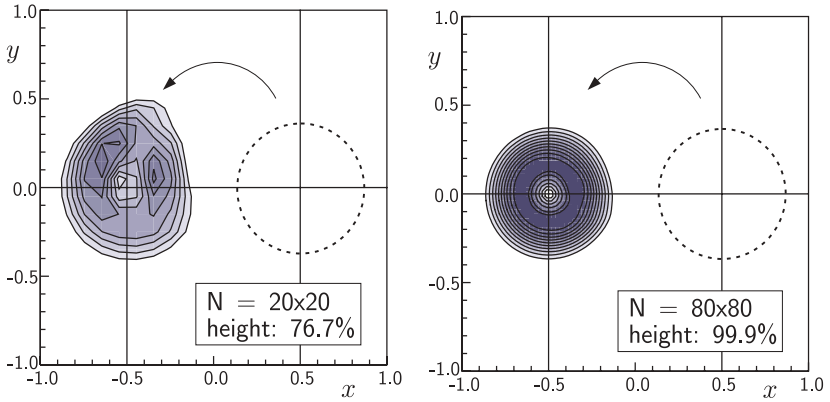

FIG. 8. *Calculation of a smooth hump rotating around the origin on two different grids. Both results were obtained with the second order method* $FD_\varepsilon^{(2)}$. *The plots show the calculation for* $t = \pi$. *The loss of height compared to the exact solution is also displayed.*

order of convergence in Figure 6 also hold identically for the curl-preserving scheme.

5.1.2. Rotating hump. The advection velocity $\mathbf{v}(x, y) = (-y, x)^T$ results in a rotational flow around the origin. As mentioned in section 2.4, the components of $\mathbf{u}$ are not ordinarily advected in such a flow if div-preserving advection is considered. Indeed, the exact solution for divergence-preserving advection given in (22) with a rotational flow is given by

$$\mathbf{u}(\mathbf{x}, t) = \mathbf{R}(t)^{-1}\, \mathbf{u}_0(\mathbf{R}(t)\,\mathbf{x}), \tag{89}$$

where $\mathbf{R}(t)$ is a orthogonal matrix which rotates a vector by the angle t and $\mathbf{u}_0$ is the initial condition. In the case of ordinary advection the inverse $\mathbf{R}^{-1}$ would be missing in the solution. However, if $\mathbf{u}$ has initially vanishing divergence, the 2-norm $\|\mathbf{u}\|$ satisfies an ordinary advection equation, which follows directly from (89).

We consider the initial condition

$$\mathbf{u}_0(x, y) = \frac{1}{5\varepsilon} \begin{pmatrix} -y \\ x - \frac{1}{2} \end{pmatrix} \exp\left(-\frac{(x - \frac{1}{2})^2 + y^2}{\varepsilon}\right) \tag{90}$$

with $\varepsilon = \frac{1}{20}$. This vector field is easily verified to be solenoidal. It produces field lines circling around $(\frac{1}{2}, 0)$ and a smooth but distinct hump in $\|\mathbf{u}\|$ with an essential radius of approximately $\frac{1}{2}$. Note that in the center of this hump, $\|\mathbf{u}\|$ is zero. The computations are conducted in the domain $[-1, 1]^2$, where the exact solution is prescribed in the ghost cells of the boundary.

Two numerical solutions of the problem calculated with $FD_\varepsilon^{(2)}$ are depicted in Figure 8 at time $t = \pi$. The Courant number in these calculations was 0.963. The figure shows contours and contour lines of the absolute value $\|\tilde{\mathbf{u}}\|$ for results obtained with two different grids, 20×20 and 80×80 cells. It also displays the loss of height of the hump compared to the exact solution. The fine grid calculation exhibits a good preservation of symmetry and height.

5.2. Calculating discontinuities. Finally, we present numerical experiments with discontinuous solutions. Discontinuities are most challenging for divergence-

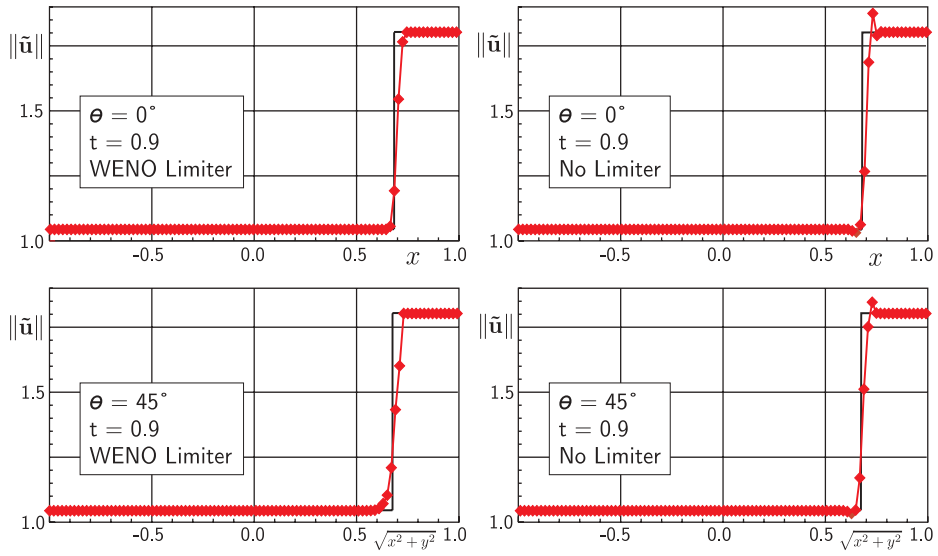

FIG. 9. *Cuts through two-dimensional calculations of advected discontinuities. The upper and lower rows show the results for horizontal and diagonal advection, respectively. Both problems have been computed with and without limited finite differences in the second order scheme.*

preserving methods in the context of magnetohydrodynamics where the magnetic field jumps across shock waves; see, e.g., [6], [26].

5.2.1. Horizontal and diagonal direction. We consider constant advection in the x-direction, i.e., $\mathbf{v}(x,y) = (\frac{3}{4}, 0)^T$. The initial vector field is given by

$$\mathbf{u}_0(x,y) = \begin{pmatrix} 1.0 \\ 0.3 + 1.2\,h(x) \end{pmatrix} \tag{91}$$

with the Heaviside function $h(x)$, which is zero for $x \leq 0$ and unity if x is positive. In both half spaces $x \lessgtr 0$ the vector field is smooth and its divergence is zero. Furthermore, across the discontinuity the normal component of $\mathbf{u}_0$ remains constant, which leads to zero divergence in the weak sense. The vector field $\mathbf{u}_0$ mimics the behavior of the magnetic field in a magnetohydrodynamic shock wave. As the divergence vanishes and the advection is constant, the discontinuity will be linearly advected. The setting will be varied by rotation with an angle θ. Horizontal advection corresponds to $\theta = 0$.

The problem at hand is calculated in $\Omega = [-1,1]^2$ with the second order scheme $FD^{(2)}$ on a grid with 100×100 cells up to time $t = 0.9$. Ghost cells at the boundary are filled by constant extrapolation and adjustment according to the angle θ. In Figure 9 we display the results for horizontal ($\theta = 0$) and diagonal ($\theta = 45^\circ$) advection. Both problems have been computed either with central finite difference or limited differences (73). The time step for both horizontal and diagonal advection was chosen after a Courant number of approximately 0.96; hence the horizontal advection took more time steps due to a more restrictive stability condition. The figure shows the absolute value $\|\tilde{\mathbf{u}}\|$ by following cuts of the solutions normal to the discontinuities. The solutions with central finite differences exhibit familiar oscillations which are eliminated by the use of the limiter. The discontinuities are well resolved. Note the slight asymmetry in the profiles of the discontinuities compared to the exact solution,

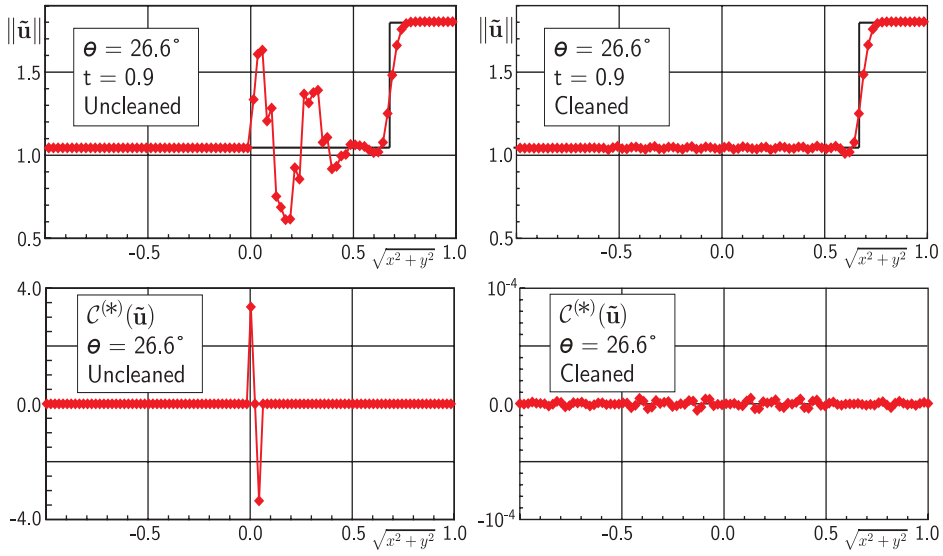

FIG. 10. *Divergence-cleaned and uncleaned solutions of the discontinuous test example in the case of a rotation with* $\theta = 26.6$ *(upper row). Below, the discrete initial divergence of both cases are displayed. The strong deviation from zero leads to a misfit of the computed solution. A divergence cleaning procedure applied to the* initial *conditions removes the disagreement. Both computations are conducted with use of WENO limitation.*

which is drawn as a thin line in Figure 9. This is due to displaying $\|\tilde{\mathbf{u}}\|$ instead of the components $\tilde{u}^{(x)}$ or $\tilde{u}^{(y)}$.

5.2.2. Oblique directions and initial divergence cleaning. The evaluations of both the extended and the classical divergence operator give exactly zero for the initial conditions of the horizontal or diagonal discontinuity. This comes due to symmetry. For discontinuities in all other noncoordinate and nondiagonal directions this is no longer true. Though the analytic initial condition is divergence-free, the discrete evaluation of the divergence in the vicinity of the discontinuity leads to significant deviations from zero.

The left-hand side of Figure 10 shows the result of the computation with $\theta \approx 26.6,^\circ$ which corresponds to $\tan\theta = \frac{1}{2}$. The upper right plot displays the run of $\|\tilde{\mathbf{u}}\|$ along a normal cut and exhibits a complete disagreement with the exact solution (thin line). The plot below shows the evaluation of the extended divergence operator $\tilde{\mathcal{C}}^{(\star)}$ along the same cut of the initial conditions. Due to the constraint preservation this curve stays the same for all time steps. The strong deviations of the divergence from zero are responsible for the disagreement of the computed with the exact solution. Hence, the upper right plot does not represent a failure of the method, but rather indicates the high quality of the constraint preservation. In fact, the computed result belongs to a solution for analytic initial conditions whose divergence is disturbed according to the curve in the lower right plot.

In order to get rid of the divergence in the initial conditions, the discrete field has to be corrected as proposed, e.g., in [2]. We stress that this cleaning procedure is *only* needed for *initial* conditions with nonvanishing divergence due to discontinuities. Hence, the procedure is only applied once in the beginning of the calculation. If the discrete initial divergence is zero, it stays zero due to the properties of our scheme.

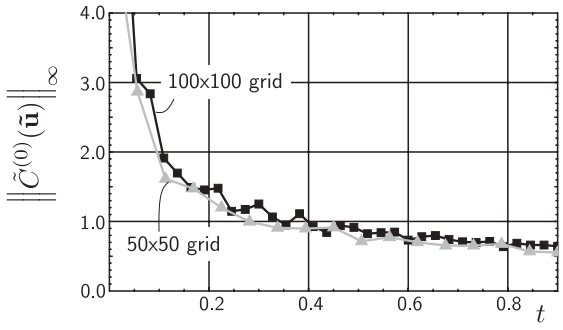

FIG. 11. *Maximal value of the discrete divergence obtained with the classical operator during the two calculations of the discontinuous test example. Independent of the grid size, the classical operator gives decreasing value due to the smoothing of the numerical method.*

The cleaning procedure solves the elliptic equations

$$\begin{aligned} \operatorname{div}\operatorname{grad}\psi &= \operatorname{div}\tilde{\mathbf{u}} \quad \text{in } \Omega, \\ \psi &= 0 \qquad \text{on } \partial\Omega \end{aligned} \tag{92}$$

for the auxiliary discrete field ψ. The discrete initial field $\tilde{\mathbf{u}}$ is afterwards corrected by $\tilde{\mathbf{u}} \to \tilde{\mathbf{u}} - \operatorname{grad}\psi$ which gives a discrete solenoidal field. This procedure represents the projection onto the divergence-free space (Hodge projection). The differential operator $divgrad \equiv \triangle$ has to be built from the extended divergence operator (53) since the result should give a divergence-free field according the extended operator. The use of the traditional discretization of Laplace operator will not lead to this property. The construction of the Laplace operator by applying an appropriate discrete gradient and afterwards $\tilde{\mathcal{C}}^{(\star)}$ to the field ψ results in a special discrete Laplace operator which assures that the evaluation of $\tilde{\mathcal{C}}^{(\star)}$ on the corrected solution will be zero. The discretized form of (92) may be solved by using iterative linear solvers.

The discrete divergence of the corrected initial condition (91) in the case of $\theta = 26.6°$ is shown in the lower right plot of Figure 10. Note the scale of the ordinate. Finally, the approximation ability of the scheme is fully revealed as can be seen in the upper right plot of Figure 10. The small fluctuations visible in the solution are introduced by the initial cleaning procedure, they vanish with grid refinement.

Note that during the cleaning procedure based on the extended operator $\tilde{\mathcal{C}}^{(\star)}$ we have no control over the value of the *classical* operator (45). Correspondingly, the value of the divergence obtained with this operator is not vanishing if evaluated for the initial conditions. It will also vary during the time steps of the flux distribution scheme. However, the maximal value remains finite during the calculation independent of the grid size as is visible in Figure 11. Moreover, the value of the classical operator decreases due to the numerical smoothing of the discontinuous solution.

6. Sketch of the method in 3 dimensions. We will shortly give a sketch how to extend the constraint-preserving method to the three-dimensional case. The presentation will not be exhaustive but will provide evidence that three-dimensional methods may be constructed from the presented framework as well.

We restrict ourself to div-preserving advection, given in $(4)_{\text{curl}}$. In three dimensions, methods for curl-preserving advection cannot be obtained by duality but need extra considerations. Furthermore, the most important application of curl-preserving advection is the shallow water system which is restricted to two dimensions.

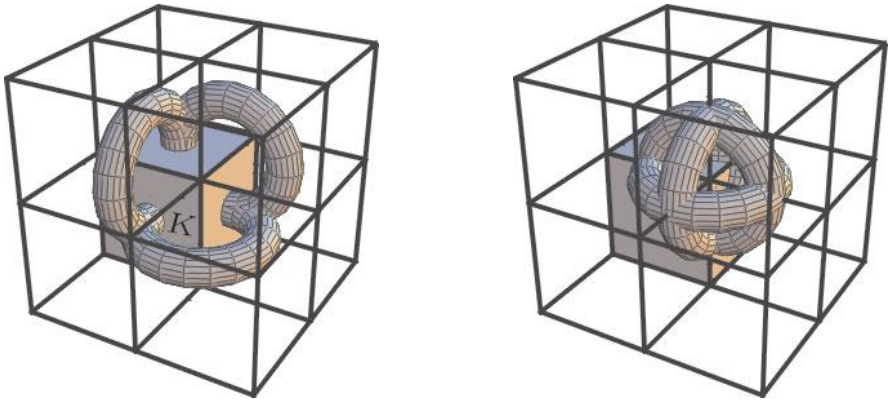

FIG. 12. *Possible sets of shape functions for flux distributions in three dimensions. This figure is to be compared with Figure* 1. *Again the flux distributions has to approximate closed lines which are overstated as tubes in the figure. The right-hand side shape functions result from appropriate averaging.*

6.1. Flux distributions. For discrete divergence operators in three dimensions a representation similar to that of Lemma 2 may be found. However, in this case there exists a family of operators with 17 parameters which is quite involved. Inspired by the two-dimensional results, we proceed by generalizing the extended operator (53) directly to three dimensions, obtaining

$$\begin{aligned}\tilde{\mathcal{C}}_K^{(\star)}\tilde{\mathbf{u}} = {} & \frac{\{\tilde{u}^{(x)}_{i+1,j,k}\}_{y,z} - \{\tilde{u}^{(x)}_{i-1,j,k}\}_{y,z}}{2\Delta x} \\ & + \frac{\{\tilde{u}^{(y)}_{i,j+1,k}\}_{x,z} - \{\tilde{u}^{(y)}_{i,j-1,k}\}_{x,z}}{2\Delta y} + \frac{\{\tilde{u}^{(z)}_{i,j,k+1}\}_{x,y} - \{\tilde{u}^{(z)}_{i,j,k-1}\}_{x,y}}{2\Delta z},\end{aligned} \tag{93}$$

where curled brackets this time stand for

$$\begin{aligned}\{\psi_{i,j,k}\}_{y,z} &= \tfrac{1}{16}(4\psi_{i,j,k} + 2\psi_{i,j+1,k} + 2\psi_{i,j-1,k} + 2\psi_{i,j,k-1} + 2\psi_{i,j,k+1} \\ &\quad +\psi_{i,j+1,k+1} + \psi_{i,j+1,k-1} + \psi_{i,j-1,k+1} + \psi_{i,j-1,k-1}), \\ \{\psi_{i,j,k}\}_{x,z} &= \tfrac{1}{16}(4\psi_{i,j,k} + 2\psi_{i+1,j,k} + 2\psi_{i-1,j,k} + 2\psi_{i,j,k-1} + 2\psi_{i,j,k+1} \\ &\quad +\psi_{i+1,j,k+1} + \psi_{i+1,j,k-1} + \psi_{i-1,j,k+1} + \psi_{i-1,j,k-1}), \\ \{\psi_{i,j,k}\}_{x,y} &= \tfrac{1}{16}(4\psi_{i,j,k} + 2\psi_{i+1,j,k} + 2\psi_{i-1,j,k} + 2\psi_{i,j-1,k} + 2\psi_{i,j+1,k} \\ &\quad +\psi_{i+1,j+1,k} + \psi_{i+1,j-1,k} + \psi_{i-1,j+1,k} + \psi_{i-1,j-1,k}),\end{aligned} \tag{94}$$

i.e., plane-wise averaging. Solving the linear system (39) now gives possible shape functions for flux distributions. All the resulting skeletons have essentially the two-dimensional shape given in (55) and depicted in Figure 1, except they now come with three possible orientations, approximating a circle either in the (x, y)-plane, the (x, z)-plane, or the (y, z)-plane. Hence, there are 36 possible flux distributions altogether, four circles in each cut of the $3 \times 3 \times 3$ grid box. Three of them are sketched on the left-hand side of Figure 12.

Note that it is necessary to take at least three flux distributions to construct a three-dimensional method, since the flux $\mathbf{F} = \mathbf{u} \times \mathbf{v}$ in $(4)_{\text{curl}}$ now has three independent components.

6.2. Possible methods. The dimensionally split character of the three-dimensional flux distributions leads to a method which uses directly the two-dimensional

results. Indeed, the evolution equation $(4)_{\text{curl}}$ may be split into three two-dimensional operators as well. We write

$$\frac{\partial}{\partial t}\begin{pmatrix} u^{(x)} \\ u^{(y)} \\ u^{(z)} \end{pmatrix} + \begin{pmatrix} \partial_y F^{(z)} \\ -\partial_x F^{(z)} \\ 0 \end{pmatrix} + \begin{pmatrix} -\partial_z F^{(y)} \\ 0 \\ \partial_x F^{(y)} \end{pmatrix} + \begin{pmatrix} 0 \\ \partial_z F^{(x)} \\ -\partial_y F^{(x)} \end{pmatrix} = 0, \tag{95}$$

where $\mathbf{F} = (F^{(x)}, F^{(y)}, F^{(z)})^T = \mathbf{u} \times \mathbf{v}$ represents the flux function. It becomes obvious that each bracket can be discretized by the two-dimensional method (67). The resulting flux across a corner is represented by the left picture in Figure 12. The procedure is similar to the operator splitting approach where each flux in a multidimensional conservation law is discretized in a one-dimensional manner (see e.g., [11]), except here we use two-dimensional methods for the single operators. Nevertheless, we expect loss of stability since the cell directly across the corner (see Figure 12, left) is not affected in a single time step. Possible and straightforward help would be to use a fractional time step method, e.g., with Strang splitting, which updates the brackets in (95) successively.

To circumvent the use of splitting it is possible to construct a fully three-dimensional flux distribution as sketched in Figure 12 (right). These flux distributions result from averaging each flux distribution on the left-hand side of the figure with its counterpart in the neighboring parallel grid plane (not shown). A scheme using this single set of flux distributions has the form

$$\begin{aligned} \begin{pmatrix} \tilde{u}^{(x)} \\ \tilde{u}^{(y)} \\ \tilde{u}^{(z)} \end{pmatrix}_{i,j}^{m+1} &= \begin{pmatrix} \tilde{u}^{(x)} \\ \tilde{u}^{(y)} \\ \tilde{u}^{(z)} \end{pmatrix}_{i,j}^{m} \\ &+ \begin{pmatrix} \delta^{(y)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi^{(z,1)})\Delta x - \delta^{(z)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi^{(y,1)})\Delta x \\ -\delta^{(x)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi^{(z,1)})\Delta y + \delta^{(z)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi^{(x,1)})\Delta y \\ \delta^{(x)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi^{(y,1)})\Delta z - \delta^{(y)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi^{(x,1)})\Delta z \end{pmatrix}, \end{aligned} \tag{96}$$

where we used the abbreviations

$$\begin{aligned} \delta^{(x)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi) &= \varphi_{i+1,j+1,k} + \varphi_{i+1,j,k} + \varphi_{i+1,j+1,k+1} + \varphi_{i+1,j,k+1} \\ &\quad -\varphi_{i,j+1,k} - \varphi_{i,j,k} - \varphi_{i,j+1,k+1} - \varphi_{i,j,k+1}, \\ \delta^{(y)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi) &= \varphi_{i+1,j+1,k} + \varphi_{i,j+1,k} + \varphi_{i+1,j+1,k+1} + \varphi_{i,j+1,k+1} \\ &\quad -\varphi_{i+1,j,k} - \varphi_{i,j,k} - \varphi_{i+1,j,k+1} - \varphi_{i,j,k+1}, \\ \delta^{(z)}_{i+\frac{1}{2},j+\frac{1}{2},k+\frac{1}{2}}(\varphi) &= \varphi_{i,j+1,k+1} + \varphi_{i+1,j,k+1} + \varphi_{i+1,j+1,k+1} + \varphi_{i,j,k+1} \\ &\quad -\varphi_{i,j+1,k} - \varphi_{i+1,j,k} - \varphi_{i+1,j+1,k} - \varphi_{i,j,k}\,. \end{aligned} \tag{97}$$

Analogously one has to incorporate the flux distributions for the rest of the corners of the grid cell. First order consistency for the single set of flux distributions in (96) leads to

$$\begin{pmatrix} \varphi^{(x,1)} \\ \varphi^{(y,1)} \\ \varphi^{(z,1)} \end{pmatrix} = -\frac{\Delta t}{4\Delta x \Delta y \Delta z}\begin{pmatrix} \Delta x\, F^{(x)} \\ \Delta y\, F^{(y)} \\ \Delta z\, F^{(z)} \end{pmatrix}, \tag{98}$$

which gives a method for div-free advection in three dimensions which exactly preserves the discrete value of the divergence evaluated by (93). The flux distributions

of the rest of the corners could be incorporated by weights as in the two-dimensional case. The elaboration of the details of the three-dimensional method remains for future work.

7. Conclusions. In this paper we drew attention to constraint-preserving advection equations. These equations are characterized by the existence of an intrinsic differential constraint which holds locally during the evolution. They form models for general evolution equations with constraints which can be found in various fields of physics and engineering.

Starting from the hypothesis that numerical methods should respect the constraints, we proposed a general framework for constructing constraint-preserving schemes. Based on this framework a multidimensional upwind method was developed. Consistency and stability were proven, and various numerical experiments demonstrated the ability and reliability of the new scheme. We also re-derived former numerical schemes within our framework. The new method relies on special flux distribution and does not require staggered grids, time-step-wise global correction procedures, or modified evolution equations as proposed in former approaches, e.g., [8], [2], [6].

In [18] a precursor of the present method was used in the context of the method of transport [9], [10] to solve the magnetic evolution part of a magnetohydrodynamic computation. In [25] the results of this paper are used to derive general divergence-preserving finite-volume schemes for magnetohydrodynamics. Future work will also include applications to electrodynamics, meteorological flows, and Einstein equations.

In this work we considered a rectangular mesh as a first approach. The treatment of more general grids, e.g., triangular or quadrilateral, is a major issue for future work. The framework given in this paper allows for constraint-preserving methods on such grids. The main problem is to find an appropriate discretization of the constraint on the given grid. In [25] divergence-preserving methods on triangular grids are derived using the framework of this paper. In [7] an approach to triangular grids is presented based on staggered grids.

The discrete constraint preservations also requires further investigations on discrete data treatment. Implementations of boundary conditions as well as restriction and prolongation in an adaptive grid (see [27]) should be revised from the angle of constraint preservation.

GLOBAL SUPERCONVERGENCE AND A POSTERIORI ERROR ESTIMATORS OF THE FINITE ELEMENT METHOD FOR A QUASI-LINEAR ELLIPTIC BOUNDARY VALUE PROBLEM OF NONMONOTONE TYPE*

LIPING LIU†, TANG LIU‡, MICHAL KŘÍŽEK§, TAO LIN¶, AND SHUHUA ZHANG‡

Abstract. In this paper we are concerned with finite element approximations to a nonlinear elliptic partial differential equation with homogeneous Dirichlet boundary conditions. This kind of problems arises for example from modeling a stationary heat conduction in nonlinear inhomogeneous and anisotropic media. For finite elements of degree $k \geq 1$ in each variable, by means of an interpolation postprocessing technique, we obtain the global superconvergence of $O(h^{k+1})$ in the H^1-norm and $O(h^{k+2})$ in the L^2-norm provided the weak solution is sufficiently smooth. As by-products, the global superconvergence results can be used to generate efficient a posteriori error estimators. Representative numerical examples are also given to illustrate our theoretical analysis.

1. Introduction.

Our purpose in this paper is to study the Galerkin finite element method for a quasi-linear elliptic problem whose classical formulation is as follows: Find $u \in C(\overline{\Omega})$ such that $u|_\Omega \in C^2(\Omega)$ and

$$\begin{aligned} -\nabla \cdot (A(x,u)\nabla u) &= f \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^d$, $d \in \{1,2,3\}$, is an open bounded polyhedral domain with a Lipschitz boundary, $f \in L^2(\Omega)$, and $A = (a_{ij})_{i,j=1}^d$ is a bounded uniformly positive definite matrix, i.e.,

$$\max_{x\in\Omega} \max_{\xi\in\mathbb{R}} |a_{ij}(x,\xi)| \leq C \quad \forall i,j \in \{1,\dots,d\}, \tag{1.2}$$

$$C_0 \eta^T \eta \leq \eta^T A(x,\xi)\eta \quad \forall \eta \in \mathbb{R}^d, \quad \forall x \in \Omega, \quad \forall \xi \in \mathbb{R}, \tag{1.3}$$

where C and C_0 are positive constants. In addition, we assume that the derivatives $\partial a_{ij}/\partial\xi$, $\partial^2 a_{ij}/\partial\xi^2$, and $\partial^2 a_{ij}/\partial\xi\partial x_\ell$ are bounded and continuous on $\overline{\Omega}\times\mathbb{R}$ for all $i,j,\ell\in\{1,\dots,d\}$. However, the matrix A is not necessarily symmetric.

Unlike nonlinear problems of other types, for $d>1$ problem (1.1) cannot be converted, in general, by the well-known Kirchhoff transformation (see [14]) to a linear problem even if A would be independent of x, since A is a matrix function. This makes its theoretical and numerical analysis much more difficult.

As mentioned in [19], since an analogue of the well-known Céa's lemma holds for those nonlinear elliptic problems whose associated operators are strongly monotone and Lipschitz continuous (see, for example, [4, 14]), it is easy for these problems to derive the rate of convergence $O(h^k)$ in the H^1-norm for the Lagrange elements of degree k. Thus, their finite element approximations have been extensively studied. See, for instance, [7, 8, 24]. In [10, 13] some one-dimensional examples are presented to illustrate that problem (1.1) is of a nonmonotone and nonpotential type.

There are some results available for problem (1.1). For example, the uniqueness of the classical and weak solutions was proven in [12, 13], respectively. In [13], the existence of the weak solution was derived as a weak limit of Galerkin approximations. Other existence results for various kinds of boundary conditions are presented in [9, 10, 13, 21]. As to numerical methods, Douglas and Dupont [6] proved an optimal rate of convergence of the finite element approximation for problem (1.1) in the case that

$$A(x,u)=\lambda(x,u)I, \tag{1.4}$$

where I is the identity matrix and λ is a smooth scalar function. Nitsche [22] derived an asymptotic error estimate of the finite element method in the L^∞-norm for the case (1.4). In [20], a mixed finite element method was studied which also has an optimal rate of convergence in the L^p-norm for the case (1.4). Similar results were also obtained in [1, 2].

In [19], the result from [6] was generalized to any smooth uniformly positive definite matrix $A(x,u)$ satisfying (1.2) and (1.3), which represents a practically interesting case, since problem (1.1) describes a steady-state heat conduction in nonlinear inhomogeneous anisotropic media (e.g., in magnetic cores of large transformers [14]), where the unknown function u stands for the temperature, A is the matrix of heat conductivities, and f is the density of volume heat sources (in that case A is symmetric). In fact, for finite elements of degree $k\geq 1$, [19] shows that optimal rates of convergence of $O(h^k)$ in the H^1-norm and $O(h^{k+1})$ in the L^2-norm, provided that the weak solution of (1.1) is sufficiently smooth.

There are several papers dealing with superconvergence of finite element methods for nonlinear elliptic boundary value problems, see survey paper [15, pp. 319–320]. They usually require that the operator associated with a given nonlinear elliptic problem be (strongly) monotone, which is not our case. Also, Wahlbin [23, Chapter 9] presents a linearization technique to examine superconvergence phenomena for nonlinear elliptic problems. However, our technique introduced in this paper is totally different from his. In [3], a superconvergence at the Gauss points of rectangular biquadratic elements is proved for a class of semilinear problems. This class contains nonlinearities only in the absolute term, whereas the nonlinearities of problem (1.1) stand at the second derivatives.

Our aim in this paper is to investigate the global superconvergence and a posteriori error estimators of finite element methods for problem (1.1). By means of an

optimal partition and an optimal interpolation technique, we first establish the superapproximation between the finite element solution and an interpolation function of the weak solution of problem (1.1). Then, we obtain global superconvergent approximations by virtue of a class of interpolation postprocessing methods. On the basis of global superconvergent approximations, efficient a posteriori error estimators are provided to assess the accuracy of finite element solutions in applications.

2. Weak formulation and finite element approximation. In this paper we employ the standard Sobolev space notation. The norm in the product Sobolev space $(W_p^k(\Omega))^n$, $k \in \{0, 1, \ldots\}$, $p \in [1, \infty]$, $n \in \{1, 2, \ldots\}$, is denoted by $\|\cdot\|_{k,p}$. In particular, if $p = 2$, then we set $H^k(\Omega) = W_2^k(\Omega)$ and $\|\cdot\|_k = \|\cdot\|_{k,2}$. By $H_0^1(\Omega)$ we mean the space of functions from $H^1(\Omega)$ whose traces vanish on $\partial\Omega$. The symbol $(\cdot, \cdot)$ stands for the usual scalar product in $L^2(\Omega)$.

The weak formulation of problem (1.1) consists of finding $u \in H_0^1(\Omega)$ such that

$$a(u; u, v) = (f, v) \quad \forall v \in H_0^1(\Omega), \tag{2.1}$$

where

$$a(z; v, w) = \int_\Omega (\nabla w)^T A(x, z) \nabla v \, dx, \quad v, w \in H^1(\Omega),\ z \in L^2(\Omega).$$

The variable x will be sometimes omitted from now on. It follows from (1.3), (1.2), and Friedrichs' inequality that there exist positive constants C_0 and C_1 such that

$$a(z; v, v) \geq C_0 \|v\|_1^2 \quad \forall z \in L^2(\Omega),\ \forall v \in H_0^1(\Omega),$$

and

$$|a(z; w, v)| \leq C_1 \|v\|_1 \|w\|_1 \quad \forall z \in L^2(\Omega),\ \forall w, v \in H^1(\Omega).$$

This means that $a(\cdot; \cdot, \cdot)$ is uniformly $H_0^1(\Omega)$-elliptic and continuous. In [13], it has been proven that the weak solution of (2.1) exists uniquely.

Let $\{\mathcal{T}_h\}$ be a regular family of finite element partitions of $\overline{\Omega}$ (see [4]) and let $V_h \subset H_0^1(\Omega)$ be associated finite element spaces. The finite element solution of (1.1) or (2.1) is then defined as the function $u_h \in V_h$ such that

$$a(u_h; u_h, v_h) = (f, v_h) \quad \forall v_h \in V_h. \tag{2.2}$$

The space V_h can consist of, for example, the Lagrange elements.

The existence of at least one solution u_h of (2.2) can be proven by the Brouwer fixed-point theorem (see [13]). Sufficient conditions guaranteeing the uniqueness of u_h have been presented in [11, 13]. However, the uniqueness of u_h, in general, remains an open problem.

3. Global superconvergence. From now on, all generic constants C will possibly depend on the weak solution u, but they will be independent of the discretization parameter h.

In [13], the convergence of finite element solutions u_h to the weak solution u of (1.1) in the H^1-norm is proven. However, no attempt to derive any rate of convergence is made there. Optimal convergence rates in the H^1-norm and in the L^2-norm are derived in [19]. They are based on the following adjoint problem: Find $\varphi \in H^2(\Omega) \cap H_0^1(\Omega)$ such that

$$L^*\varphi \equiv -\nabla \cdot (A^T(x, u)\nabla\varphi) + (\nabla u)^T A_u^T(x, u)\nabla\varphi = \theta \quad \text{in } \Omega, \tag{3.1}$$

where u is the unique solution of (2.1), $\theta \in L^2(\Omega)$, $A_u = ((a_{ij})_u)_{i,j=1}^d$, and the subscript u means the differentiation with respect to the last variable, i.e., $(a_{ij})_u = \partial a_{ij}(x,u)/\partial u$. In [19], a sufficient condition guaranteeing the existence and uniqueness of the weak (generalized) solution of linear problem (3.1) is given. Moreover, we assume the following elliptic regularity:

$$\|\varphi\|_2 \le C\|\theta\|_0. \tag{3.2}$$

Using this, we have the optimal error estimates [19] for problem (1.1).

THEOREM 3.1. *Let $u \in H^{k+1}(\Omega)$ for $k \ge 1$ be the weak solution of* (1.1)*, let the second derivatives $\partial^2 a_{ij}/\partial u^2$ be bounded and continuous on $\overline{\Omega} \times \mathbb{R}$, and let* (3.2) *hold. Let V_h contain polynomials up to degree k. If u_h is a solution of* (2.2)*, then there exist C, $h_0 > 0$ such that for any $h \in (0, h_0)$ we have*

$$\|u - u_h\|_0 + h\|u - u_h\|_1 \le Ch^{k+1},$$

where $C = \overline{C}\|u\|_{k+1}(1 + \|u\|_{k+1})$ and $\overline{C}$ is independent of u (see [18, p. 48]*).*

Throughout the paper generic constants C may depend on derivatives of u up to order $k+1$. In this section, we shall investigate the global superconvergence of the finite element approximation to problem (1.1). To this end, we employ a class of projection interpolation operators and integral identities proposed in [16, 17] to establish the supercloseness between the finite element solution and an interpolant of the exact solution of (1.1). On the basis of this supercloseness, we utilize an interpolation postprocessing technique to prove the global superconvergence.

For simplicity, we assume from now on that the domain Ω is an open rectangle and $\mathcal{T}_h$ is a rectangular partition over $\overline{\Omega}$. In fact, our analysis here is also true for $d = 1$ and $d = 3$. The finite element space V_h will be constructed by means of spaces $Q_k(e)$, $e \in \mathcal{T}_h$; i.e., for $k = 1, 2, 3, \ldots$ we shall use bilinear, biquadratic, bicubic, ... elements, respectively. For $k > 1$ we shall define a special type of projection interpolation operators i_h^k as we have mentioned above, rather than the usual nodal Lagrange interpolation operators, of degree not exceeding k (≥ 2) in x_1 and x_2. Let $e \in \mathcal{T}_h$ be any rectangular element, and let l_i and p_i ($i = 1, 2, 3, 4$) be its edges and vertices, respectively. Then, the bi-kth interpolation operator i_h^k is defined for $u \in H^2(\Omega)$ according to the following so-called vertex-edge-element conditions (see [16, p. 28]):

$$\begin{cases} i_h^k u \in Q_k(e), \\ i_h^k u(p_i) = u(p_i), \qquad i = 1, 2, 3, 4, \\ \displaystyle\int_{l_i} (i_h^k u - u)v\, ds = 0, \quad \forall v \in P_{k-2}(l_i),\ i = 1, 2, 3, 4, \\ \displaystyle\int_e (i_h^k u - u)v\, dx = 0, \quad \forall v \in Q_{k-2}(e), \end{cases} \tag{3.3}$$

where $P_{k-2}(l_i)$ are the polynomial spaces of degree no more than $k-2$ on l_i. In our further analysis, the notation i_h^1 stands for the usual nodal Lagrange bilinear interpolation operator.

By the standard interpolation theory (based on the Bramble–Hilbert lemma) we find that

$$\begin{aligned} \|u - i_h^k u\|_0 &\le Ch^{k+1}\|u\|_{k+1}, \\ \|u - i_h^k u\|_{0,\infty} &\le Ch^{k+1}\|u\|_{k+1,\infty}. \end{aligned} \tag{3.4}$$

Employing an integral identity technique, we obtain the following lemma [16] (for a special case see also [17]).

LEMMA 3.2. *In* (1.1), *assume that entries of the uniformly positive definite matrix* A *are in* $W^{1,\infty}(\Omega)$. *Then there exists a constant* $C > 0$ *such that for all* $v_h \in V_h$ *we have the following estimates:*

$$a(u; u - i_h^k u, v_h) \le \begin{cases} Ch^{k+1}\|u\|_{k+2}\|v_h\|_1, & k \ge 1, \\ Ch^{k+2}\|u\|_{k+2}|||v_h|||_{2,h}, & k \ge 2, \end{cases}$$

where $|||v_h|||_{2,h} := (\sum_e \|v_h\|_{2,e}^2)^{1/2}$.

Now we are in a position to get our main theorems on supercloseness of this section.

THEOREM 3.3. *Let* $u \in H^{k+2}(\Omega)$ *be the weak solution of* (1.1) *for* $k \ge 1$ *and let* u_h *be the corresponding finite element solution. Then we have under the assumptions of Theorem* 3.1 *and Lemma* 3.2 *that*

$$\|u_h - i_h^k u\|_1 \le Ch^{k+1}\|u\|_{k+2},$$

where C *depends on* $\|u\|_{k+1}$.

Proof. It follows from the uniform $H_0^1(\Omega)$-ellipticity of $a(\cdot;\cdot,\cdot)$, (2.1), and (2.2) that

$$\begin{aligned} C_0\|u_h - i_h^k u\|_1^2 &\le a(u_h; u_h - i_h^k u, u_h - i_h^k u) \\ &= a(u_h; u_h, u_h - i_h^k u) - a(u_h; i_h^k u, u_h - i_h^k u) \\ &= a(u; u, u_h - i_h^k u) - a(u_h; i_h^k u, u_h - i_h^k u) \\ &= a(u; u - i_h^k u, u_h - i_h^k u) \\ &\quad + [a(u; i_h^k u, u_h - i_h^k u) - a(u_h; i_h^k u, u_h - i_h^k u)] \\ &=: I_1 + I_2. \end{aligned} \tag{3.5}$$

From Lemma 3.2 we obtain that

$$\begin{aligned} |I_1| &= |a(u; u - i_h^k u, u_h - i_h^k u)| \\ &\le Ch^{k+1}\|u\|_{k+2}\|u_h - i_h^k u\|_1. \end{aligned} \tag{3.6}$$

For any $x \in \Omega$ we have by the mean value theorem that

$$\begin{aligned} A(x,u) - A(x,u_h) &= (u - u_h)\int_0^1 A_u(x, u + t(u_h - u))\,dt \\ &= (u - u_h)\overline{A}_u(x), \end{aligned} \tag{3.7}$$

where $\overline{A}_u = ((\overline{a}_{ij})_u)_{i,j=1}^2$ and $(\overline{a}_{ij})_u = (a_{ij})_u(u + \theta_{ij}(u_h - u))$ for some $\theta_{ij} = \theta_{ij}^h(x) \in [0,1]$. This, together with Theorem 3.1, leads to

$$\|A(x,u) - A(x,u_h)\|_0 \le C\|u - u_h\|_0 \le Ch^{k+1}. \tag{3.8}$$

By the interpolation theorem (see, for example, [4]) and the Sobolev imbedding theorem,

$$\|i_h^k u\|_{1,\infty} \le \|u - i_h^k u\|_{1,\infty} + \|u\|_{1,\infty} \le C\|u\|_{k+2}.$$

From this, by means of the Cauchy–Schwarz inequality and (3.8) we have

$$
\begin{aligned}
|I_2| &= |a(u; i_h^k u, u_h - i_h^k u) - a(u_h; i_h^k u, u_h - i_h^k u)| \\
&= \left| \int_\Omega (\nabla(u_h - i_h^k u))^T [A(x,u) - A(x,u_h)] \nabla i_h^k u \, dx \right| \\
&\le \|i_h^k u\|_{1,\infty} \|A(x,u) - A(x,u_h)\|_0 \|u_h - i_h^k u\|_1 \\
&\le C h^{k+1} \|u\|_{k+2} \|u_h - i_h^k u\|_1.
\end{aligned} \tag{3.9}
$$

Combining (3.6) and (3.9) with (3.5) yields

$$C_0 \|u_h - i_h^k u\|_1^2 \le C h^{k+1} \|u\|_{k+2} \|u_h - i_h^k u\|_1,$$

and hence

$$\|u_h - i_h^k u\|_1 \le C h^{k+1} \|u\|_{k+2}.$$

Thus, the proof of the theorem is complete. ∎

THEOREM 3.4. *Under the assumptions of Theorem* 3.3 *we have for* $k \ge 2$ *that*

$$\|u_h - i_h^k u\|_0 \le C h^{k+2} \|u\|_{k+2},$$

where C *depends on* $\|u\|_{k+1}$.

Proof. We use a duality argument based on the Aubin–Nitsche trick to prove the theorem. Let $\varphi \in H_0^1(\Omega) \cap H^2(\Omega)$ be the weak solution of the linear adjoint problem (3.1) with

$$\theta = u_h - i_h^k u.$$

Then, we have by the Green formula that

$$
\begin{aligned}
\|\theta\|_0^2 &= \int_\Omega \theta^2 \, dx = \int_\Omega \theta (L^* \varphi) \, dx \\
&= \int_\Omega [(\nabla\theta)^T A^T(u) \nabla\varphi + \theta (\nabla u)^T A_u^T(u) \nabla\varphi] \, dx \\
&= \int_\Omega [(\nabla\varphi)^T A(u) \nabla\theta + \theta (\nabla u)^T A_u^T(u) \nabla\varphi] \, dx \\
&= \int_\Omega [(\nabla(\varphi - v_h))^T A(u) \nabla\theta + (\nabla v_h)^T A(u) \nabla\theta + \theta (\nabla u)^T A_u^T(u) \nabla\varphi] \, dx
\end{aligned}
$$

for some $v_h \in V_h$. Therefore,

$$
\begin{aligned}
\|\theta\|_0^2 = & \int_\Omega (\nabla(\varphi - v_h))^T A(u) \nabla\theta \, dx + \int_\Omega (\nabla v_h)^T A(u) \nabla(u - i_h^k u) \, dx \\
& + \int_\Omega [(\nabla v_h)^T A(u) \nabla(u_h - u) + \theta (\nabla\varphi)^T A_u(u) \nabla u] \, dx \\
= & \int_\Omega (\nabla(\varphi - v_h))^T A(u) \nabla\theta \, dx + a(u; u - i_h^k u, v_h) \\
& + \int_\Omega [(\nabla v_h)^T A(u) \nabla(u_h - u) + \theta (\nabla\varphi)^T A_u(u) \nabla u] \, dx \\
=: & \, II_1 + II_2 + II_3,
\end{aligned} \tag{3.10}
$$

where $v_h \in \hat{V}_h = \{\psi \in H_0^1(\Omega) \cap H^2(\Omega) : \psi|_e \in Q_k(e),\ e \in \mathcal{T}_h\} \subset V_h$. The space $\hat{V}_h$ for a fixed k possesses the following approximation properties:

$$\min_{v_h \in \hat{V}_h} \{\|\varphi - v_h\|_0 + h\|\varphi - v_h\|_1 + h^2\|\varphi - v_h\|_2\} \le Ch^l\|\varphi\|_l, \quad \varphi \in H_0^1(\Omega) \cap H^l(\Omega), \quad 2 \le l \le k+1, \tag{3.11}$$

which leads to

$$\|v_h\|_2 \le \|v_h - \varphi\|_2 + \|\varphi\|_2 \le C\|\varphi\|_2 \tag{3.12}$$

for v_h being the best approximation to φ in $\hat{V}_h$ in the sense of (3.11). Therefore, from (3.11) and Theorem 3.3 we know that

$$|II_1| \le C\|\varphi - v_h\|_1\|\theta\|_1 \le Ch^{k+2}\|\varphi\|_2\|u\|_{k+2}. \tag{3.13}$$

From Lemma 3.2 and (3.12) we find that

$$|II_2| \le Ch^{k+2}\|v_h\|_2\|u\|_{k+2} \le Ch^{k+2}\|\varphi\|_2\|u\|_{k+2}. \tag{3.14}$$

Setting $A_u = A_u(u)$, it follows from (3.10), (2.1), (2.2), and (3.7) that

$$\begin{aligned}
II_3 &= \int_\Omega [(\nabla v_h)^T A(u)\nabla u_h - (\nabla v_h)^T A(u)\nabla u + \theta(\nabla\varphi)^T A_u \nabla u]\, dx \\
&= \int_\Omega [(\nabla v_h)^T (A(u) - A(u_h))\nabla u_h + \theta(\nabla\varphi)^T A_u \nabla u]\, dx \\
&= \int_\Omega [(\nabla v_h)^T (u - u_h)\overline{A}_u \nabla u_h + \theta(\nabla\varphi)^T A_u \nabla u]\, dx \\
&= \int_\Omega [(\nabla v_h)^T (u - i_h^k u)\overline{A}_u \nabla u_h - \theta(\nabla v_h)^T \overline{A}_u \nabla u_h + \theta(\nabla\varphi)^T A_u \nabla u]\, dx \\
&= \int_\Omega [(\nabla v_h)^T (u - i_h^k u)\overline{A}_u \nabla (u_h - u) + (\nabla v_h)^T (u - i_h^k u)\overline{A}_u \nabla u]\, dx \\
&\quad + \int_\Omega [-\theta(\nabla v_h)^T \overline{A}_u \nabla u_h + \theta(\nabla\varphi)^T A_u \nabla u]\, dx,
\end{aligned}$$

that is,

$$\begin{aligned}
II_3 &= \int_\Omega (\nabla v_h)^T (u - i_h^k u)\overline{A}_u \nabla (u_h - u)\, dx \\
&\quad + \int_\Omega (\nabla (v_h - \varphi))^T (u - i_h^k u)\overline{A}_u \nabla u\, dx \\
&\quad + \int_\Omega (\nabla\varphi)^T (u - i_h^k u)\overline{A}_u \nabla u\, dx + \int_\Omega \theta(\nabla v_h)^T \overline{A}_u \nabla (u - u_h)\, dx \\
&\quad + \int_\Omega \theta(\nabla(\varphi - v_h))^T \overline{A}_u \nabla u\, dx + \int_\Omega \theta(\nabla\varphi)^T (A_u - \overline{A}_u)\nabla u\, dx \\
&=: \sum_{i=1}^6 II_3^i.
\end{aligned} \tag{3.15}$$

According to (3.12), (3.4), Theorem 3.1, and the imbedding $H^2(\Omega) \hookrightarrow C(\overline{\Omega})$, we obtain

$$\begin{aligned} |II_3^1| &= \left| \int_\Omega (\nabla v_h)^T (u - i_h^k u) \overline{A}_u \nabla (u_h - u)\, dx \right| \\ &\le C \|u - i_h^k u\|_{0,\infty} \|v_h\|_1 \|u - u_h\|_1 \\ &\le C h^2 \|u\|_{2,\infty} \|\varphi\|_2 \|u - u_h\|_1 \\ &\le C h^2 \|u\|_4 \|\varphi\|_2\, h^k \|u\|_{k+1} \\ &\le C h^{k+2} \|\varphi\|_2 \|u\|_{k+2}. \end{aligned} \tag{3.16}$$

From (3.11) and the interpolation theorem again, we get

$$\begin{aligned} |II_3^2| &= \left| \int_\Omega (u - i_h^k u)(\nabla (v_h - \varphi))^T \overline{A}_u \nabla u\, dx \right| \\ &\le C \|u - i_h^k u\|_0 \|v_h - \varphi\|_1 \\ &\le C h^{k+2} \|\varphi\|_2 \|u\|_{k+2}. \end{aligned} \tag{3.17}$$

Let

$$\alpha(x) = (\nabla \varphi)^T \overline{A}_u \nabla u \qquad \text{and} \qquad \overline{\alpha}|_e = \frac{1}{|e|} \int_e \alpha(x)\, dx,$$

where $|e|$ is the area of the element e.

It is well known (see [5]) that

$$\|\alpha - \overline{\alpha}\|_0 \le C h \|\alpha\|_1. \tag{3.18}$$

Using the fact that the derivatives $\frac{\partial^2 a_{ij}}{\partial u \partial x_1}$, $\frac{\partial^2 a_{ij}}{\partial u \partial x_2}$, and $\frac{\partial^2 a_{ij}}{\partial u^2}$ are bounded, we shall prove now that

$$\|\alpha\|_1 \le C \|\varphi\|_2.$$

In fact, it follows from

$$\begin{aligned} \alpha(x) &= (\nabla \varphi)^T \overline{A}_u \nabla u = (\varphi_{x_1} \;\; \varphi_{x_2}) \int_0^1 A_u(x, u + t(u_h - u)) dt \begin{pmatrix} u_{x_1} \\ u_{x_2} \end{pmatrix} \\ &= \varphi_{x_1} u_{x_1} \int_0^1 (a_{11})_u (x, u + t(u_h - u)) dt + \varphi_{x_2} u_{x_1} \int_0^1 (a_{21})_u (x, u + t(u_h - u)) dt \\ &\quad + \varphi_{x_1} u_{x_2} \int_0^1 (a_{12})_u (x, u + t(u_h - u)) dt + \varphi_{x_2} u_{x_2} \int_0^1 (a_{22})_u (x, u + t(u_h - u)) dt \\ &= \sum_{i=1}^4 Y_i \end{aligned}$$

that

$$\alpha_{x_1}(x) = \sum_{i=1}^4 \frac{\partial Y_i}{\partial x_1}.$$

Moreover, we have

$$\begin{aligned}\frac{\partial Y_1}{\partial x_1} &= (\varphi_{x_1x_1}u_{x_1} + \varphi_{x_1}u_{x_1x_1})\int_0^1 (a_{11})_u(x, u + t(u_h - u))dt \\ &\quad + \varphi_{x_1}u_{x_1}\int_0^1 (a_{11})_{ux_1}(x, u + t(u_h - u))dt \\ &\quad + \varphi_{x_1}u_{x_1}\int_0^1 (a_{11})_{uu}(x, u + t(u_h - u)) \cdot (u_{x_1} + t(u_h - u)_{x_1})dt,\end{aligned}$$

which, together with the boundedness of $\frac{\partial^2 a_{11}}{\partial u \partial x_1}$ and $\frac{\partial^2 a_{11}}{\partial u^2}$ as well as the estimate $\|u - u_h\|_1 \le Ch\|u\|_2$ in Theorem 3.1, leads to

$$\int_\Omega \left(\frac{\partial Y_1}{\partial x_1}\right)^2 dx \le C\int_\Omega (\varphi^2_{x_1x_1} + \varphi^2_{x_1})dx.$$

By the same argument, we can obtain the similar estimates for $\frac{\partial Y_i}{\partial x_1}$ $(i = 2, 3, 4)$. Thus, we have

$$\int_\Omega \left(\frac{\partial \alpha}{\partial x_1}\right)^2 dx \le C\|\varphi\|_2^2,$$

and analogously we have

$$\int_\Omega \left(\frac{\partial \alpha}{\partial x_2}\right)^2 dx \le C\|\varphi\|_2^2,$$

which yields

$$\|\alpha\|_1 \le C\|\varphi\|_2.$$

From the definition of the interpolation operator i_h^k given by (3.3) we know that

$$\int_\Omega (u - i_h^k u)\overline{\alpha}\, dx = \sum_e \int_e (u - i_h^k u)\overline{\alpha}\, dx = 0,$$

which yields by (3.18) that

$$\begin{aligned}|II_3^3| &= \left|\int_\Omega (u - i_h^k u)\alpha(x)\, dx\right| \\ &= \left|\int_\Omega (u - i_h^k u)\overline{\alpha}\, dx + \int_\Omega (u - i_h^k u)(\alpha - \overline{\alpha})\, dx\right| \\ &\le \|u - i_h^k u\|_0 \|\alpha - \overline{\alpha}\|_0 \\ &\le Ch^{k+2}\|\alpha\|_1\|u\|_{k+2} \\ &\le Ch^{k+2}\|\varphi\|_2\|u\|_{k+2}.\end{aligned} \tag{3.19}$$

As to II_3^4 we have by means of the Hölder inequality that

$$\begin{aligned}|II_3^4| &= \left|\int_\Omega \theta(\nabla v_h)^T \overline{A}_u \nabla(u - u_h)\, dx\right| \\ &\le C\|\theta\|_{0,3}\|\nabla v_h\|_{0,6}\|\nabla(u - u_h)\|_0.\end{aligned}$$

Since

$$\|\theta\|_{0,3} \le C\|\theta\|_1 \qquad \text{and} \qquad H^2(\Omega) \hookrightarrow W_6^1(\Omega),$$

we further have according to (3.12) and Theorems 3.1 and 3.3 that

$$|II_3^4| \le Ch\|\theta\|_1\|v_h\|_2 \le Ch^{k+2}\|\varphi\|_2\|u\|_{k+2}. \tag{3.20}$$

It follows from the Hölder inequality again, the fact that $\nabla u \in (H^3(\Omega))^2 \hookrightarrow (C(\overline{\Omega}))^2$, and estimates (3.11) and (3.12) that

$$\begin{aligned} |II_3^5| &= \left| \int_\Omega \theta(\nabla(\varphi - v_h))^T \overline{A}_u \nabla u \, dx \right| \\ &\le C\|\theta\|_{0,3}\|\nabla(\varphi - v_h)\|_0\|\nabla u\|_{0,6} \\ &\le C\|\theta\|_1\|\varphi - v_h\|_1 \\ &\le Ch\|\theta\|_1\|\varphi\|_2 \le Ch^{k+2}\|\varphi\|_2\|u\|_{k+2}. \end{aligned} \tag{3.21}$$

Using similar arguments as before and the differentiability of A with respect to u up to order two and the substitution $z = st$, we find for any $x \in \Omega$ that

$$\begin{aligned} A_u(x,u) - \overline{A}_u(x) &= \int_0^1 [A_u(x,u) - A_u(x, u + t(u_h - u))]\, dt \\ &= \int_0^1 \left(\int_0^1 A_{uu}(x, u + st(u_h - u))t(u - u_h)\, ds \right) dt \\ &= (u_h - u)\int_0^1 \left(\int_0^t A_{uu}(x, u + z(u_h - u))\, dz \right) dt \\ &= (u_h - u)\int_0^1 \left(\int_z^1 A_{uu}(x, u + z(u_h - u))\, dt \right) dz \\ &= (u_h - u)\int_0^1 (1 - z) A_{uu}(x, u + z(u_h - u))\, dz \\ &=: (u_h - u)\overline{A}_{uu}(x). \end{aligned}$$

Therefore, we have by the Hölder inequality, the relation $\nabla u \in (H^3(\Omega))^2 \hookrightarrow (C(\overline{\Omega}))^2$, and Theorems 3.1 and 3.3 that

$$\begin{aligned} |II_3^6| &= \left| \int_\Omega \theta(\nabla\varphi)^T (A_u - \overline{A}_u)\nabla u \, dx \right| \\ &= \left| \int_\Omega \theta(u_h - u)(\nabla\varphi)^T \overline{A}_{uu} \nabla u \, dx \right| \\ &\le C\|\theta\|_{0,3}\|u_h - u\|_0\|\nabla\varphi\|_{0,6} \\ &\le Ch\|\theta\|_1\|\varphi\|_2 \le Ch^{k+2}\|\varphi\|_2\|u\|_{k+2} \end{aligned}$$

which, together with (3.15)–(3.21), leads to

$$|II_3| \le Ch^{k+2}\|\varphi\|_2\|u\|_{k+2}. \tag{3.22}$$

Combining (3.13), (3.14), and (3.22) with (3.10) implies

$$\|\theta\|_0^2 \le Ch^{k+2}\|\varphi\|_2\|u\|_{k+2}$$

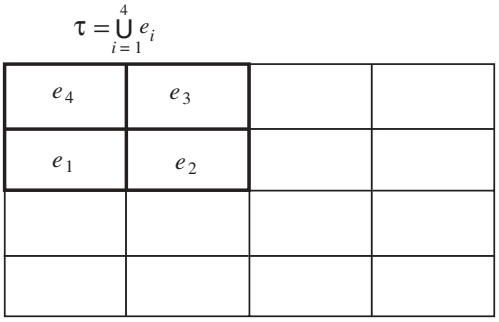

FIG. 3.1.

which, together with (3.2), leads to

$$\|\theta\|_0 \le Ch^{k+2}\|u\|_{k+2}.$$

Thus, the proof of the theorem is complete. □

In order to improve the accuracy of the finite element approximation in the whole domain, a simple postprocessing method is proposed [16, 17]. To this end, we need to define a postprocessing interpolation operator I_{2h}^{k+1} of degree at most $k+1$ in x_1- and x_2-direction. Thus, we assume that $\mathcal{T}_h$ has been obtained from $\mathcal{T}_{2h}$ with mesh size $2h$ by subdividing each element of $\mathcal{T}_{2h}$ into four congruent rectangles (see Figure 3.1). Let $\tau := \bigcup_{i=1}^{4} e_i \in \mathcal{T}_{2h}$ with $e_i \in \mathcal{T}_h$.

To express this idea clearly, we first consider the one-dimensional case, where I_{2h}^{k+1} $(k \ge 3)$ is determined by the following "vertex-interval" conditions [16]:

$$\begin{cases} I_{2h}^{k+1}u(p_i) = u(p_i), \quad i = 1,2,3, \\ \displaystyle\int_{l_i} I_{2h}^{k+1}u\,ds = \int_{l_i} u\,ds, \quad i = 1,2, \\ \displaystyle\int_{L} I_{2h}^{k+1}uv\,ds = \int_{L} uv\,ds \quad \forall v \in P_{k-3}(L)/P_0(L). \end{cases}$$

Here, $L := l_1 \cup l_2 \in \mathcal{T}_{2h}$, $l_i \in \mathcal{T}_h$, and p_i $(i = 1,2,3)$ are the vertices of l_1 and l_2. If $k < 3$, then I_{2h}^{2} is defined by $I_{2h}^{2}u(p_i) = u(p_i)$ $(i = 1,2,3)$, and I_{2h}^{3} by $I_{2h}^{3}u(p_i) = u(p_i)$ $(i = 1,2,3)$ and $\int_{l_1} I_{2h}^{3}u\,ds = \int_{l_1} u\,ds$ (or $\int_{l_2} I_{2h}^{3}u\,ds = \int_{l_2} u\,ds$). The operator I_{2h}^{k+1} in the two-dimensional case is now constructed by the tensor product of the two one-dimensional interpolation operators $I_{2h}^{k+1}(x_1)$ and $I_{2h}^{k+1}(x_2)$ of degree not exceeding $k+1$ in x_1- and x_2-direction, respectively, as follows:

$$I_{2h}^{k+1}(x_1,x_2) := I_{2h}^{k+1}(x_1) \otimes I_{2h}^{k+1}(x_2).$$

Moreover, the following properties can be checked [16, 17]:

$$\begin{cases} I_{2h}^{k+1}i_h^k = I_{2h}^{k+1}, \\ \|I_{2h}^{k+1}v_h\|_q \le C\|v_h\|_q \quad \forall v_h \in V_h,\ q = 0,1, \\ \|I_{2h}^{k+1}u - u\|_q \le Ch^{k+2-q}\|u\|_{k+2} \quad \forall u \in H^{k+2}(\Omega),\ q = 0,1. \end{cases} \tag{3.23}$$

Then, on the basis of Theorems 3.3 and 3.4 we obtain the following global superconvergence theorem.

THEOREM 3.5. *Let the assumptions of Theorem* 3.3 *hold. Then we have*

$$\|I_{2h}^{k+1}u_h - u\|_1 \le Ch^{k+1}\|u\|_{k+2}, \quad k \ge 1, \tag{3.24}$$

$$\|I_{2h}^{k+1}u_h - u\|_0 \le Ch^{k+2}\|u\|_{k+2}, \quad k \ge 2. \tag{3.25}$$

Proof. We find from the first property of the operator I_{2h}^{k+1} in (3.23) that

$$I_{2h}^{k+1}u_h - u = I_{2h}^{k+1}(u_h - i_h^k u) + (I_{2h}^{k+1}u - u).$$

Therefore, it follows from (3.23) and Theorem 3.3 that

$$\begin{aligned}\|I_{2h}^{k+1}u_h - u\|_1 &\le C\|u_h - i_h^k u\|_1 + Ch^{k+1}\|u\|_{k+2}\\ &\le Ch^{k+1}\|u\|_{k+2},\end{aligned}$$

and thus (3.24) is proven.

Estimate (3.25) can also be derived from Theorem 3.4 and the same arguments as those for deriving (3.24). ∎

4. A posteriori error estimators. It is of great importance for a finite element method to have a computable a posteriori error estimator by which we can assess the accuracy of the finite element solution in applications. One way to construct error estimators is to employ certain superconvergent approximations properties of finite element solutions. In fact, the following theorem holds.

THEOREM 4.1. *Under the assumptions of Theorem* 3.3 *we have*

$$\|u - u_h\|_1 = \|I_{2h}^{k+1}u_h - u_h\|_1 + O(h^{k+1}), \quad k \ge 1, \tag{4.1}$$

$$\|u - u_h\|_0 = \|I_{2h}^{k+1}u_h - u_h\|_0 + O(h^{k+2}), \quad k \ge 2. \tag{4.2}$$

In addition, if there exist positive constants C_1, C_2 *and* $\varepsilon_1, \varepsilon_2 \in (0,1)$ *such that*

$$\|u - u_h\|_1 \ge C_1 h^{k+1-\varepsilon_1}, \tag{4.3}$$

$$\|u - u_h\|_0 \ge C_2 h^{k+2-\varepsilon_2}, \tag{4.4}$$

then for the effectivity index we have

$$\lim_{h\to 0} \frac{\|I_{2h}^{k+1}u_h - u_h\|_1}{\|u - u_h\|_1} = 1, \tag{4.5}$$

$$\lim_{h\to 0} \frac{\|I_{2h}^{k+1}u_h - u_h\|_0}{\|u - u_h\|_0} = 1. \tag{4.6}$$

Proof. It follows from Theorem 3.5 and the equality

$$u - u_h = (I_{2h}^{k+1}u_h - u_h) + (u - I_{2h}^{k+1}u_h)$$

that

$$\|u - u_h\|_1 = \|I_{2h}^{k+1}u_h - u_h\|_1 + O(h^{k+1}).$$

Thus, by (4.3) we have

$$\frac{\|I_{2h}^{k+1}u_h - u_h\|_1}{\|u - u_h\|_1} + Ch^{\varepsilon_1} \ge 1$$

or

$$\lim_{h \to 0} \frac{\|I_{2h}^{k+1} u_h - u_h\|_1}{\|u - u_h\|_1} \geq 1. \tag{4.7}$$

Similarly, it follows from (4.3) and

$$\|I_{2h}^{k+1} u_h - u_h\|_1 = \|u - u_h\|_1 + O(h^{k+1})$$

that

$$\overline{\lim_{h \to 0}} \frac{\|I_{2h}^{k+1} u_h - u_h\|_1}{\|u - u_h\|_1} \leq 1,$$

which, together with (4.7), leads to (4.5).

Analogously, we can obtain (4.2) from Theorem 3.5 and (4.6) from condition (4.4). □

Remark 4.2. We know from (4.1) that the computable error estimate $\|I_{2h}^{k+1} u_h - u_h\|_1$ is the principal part of the finite element error $\|u - u_h\|_1$, and can be used as an a posteriori error estimator to assess the accuracy of the finite element solution. Estimate (4.3) seems to be a reasonable assumption, because $O(h^k)$ is the optimal convergence rate of the finite element solution in H^1-norm by Theorem 3.1, and from (4.5) we can further see that $\|I_{2h}^{k+1} u_h - u_h\|_1$ is a quite reliable a posteriori error estimator. The same comments are valid also for (4.2), (4.4), and (4.6).

5. Numerical experiments. In this section, we present some typical results obtained with numerical experiments carried out for the following boundary value problem:

$$\begin{aligned} -\nabla \cdot (A(x,u)\nabla u) &= f, \quad x = (x_1, x_2) \in \Omega, \\ u|_{\partial\Omega} &= 0, \end{aligned}$$

where $\Omega = (0,1) \times (0,1)$,

$$A(x_1, x_2, u) = \left(1 + x_1^2 + x_2^4 + \frac{1}{2}\sin u\right) I,$$

(cf. (1.4)) and f is chosen such that

$$u(x_1, x_2) = \sin(\pi x_1)\sin(2\pi x_2)$$

is the exact solution. The nonlinear problem is obtained with the aid of the standard Gauss quadrature formulae exact for all quintic polynomials and it is solved by Kačanov's method [14]. In the postprocessing we use again use the Gauss quadrature formulae. In the tables below listing the numerical results, we will use

$$E_0(u,v) = \sqrt{\int_\Omega (u-v)^2 \, dx},$$

$$E_1(u,v) = \sqrt{\int_\Omega (\nabla(u-v))^T \nabla(u-v) \, dx}$$

to denote the difference between two functions u and v. Obviously, $E_0(u,v)$ measures the difference in the usual L^2-norm, while $E_1(u,v)$ measures the difference in the usual H^1-seminorm.

TABLE 5.1

TABLE 5.3
H^1-errors of the biquadratic FE solutions and the corresponding postprocessed FE solutions.

h	$E_1(u_h, u)$	Reduction factor	$E_1(I_{2h}^3 u_h, u)$	Reduction factor
1/10	5.72e-2	None	1.60e-2	None
1/20	1.28e-2	4.4341	1.61e-3	9.9379
1/40	3.06e-3	4.2157	1.86e-4	8.6559
1/80	7.46e-4	4.1019	2.23e-5	8.3408
1/160	1.84e-4	4.0543	2.74e-6	8.1387

Table 5.1 lists the results for the approximations generated by the bilinear finite element (FE) solutions. We also calculated the problem for $h = 1/10$, $h = 1/20$, $h = 1/30$, ..., $h = 1/150$, $h = 1/160$. Using the linear regression, we find that the obtained data satisfy the following relations:

$$E_1(u_h, u) \approx 6.7634\ h^{1.0284},$$
$$E_1(I_{2h}^2 u_h, u) \approx 24.8825\ h^{2.0498}.$$

These approximations and the reduction factors in Table 5.1 confirm the theoretical results of Theorem 3.5 for the case in which $k = 1$.

Tables 5.2 and 5.3 list the results for the approximations generated by the biquadratic finite element basis functions ($k = 2$). Applying linear regression to the obtained data for $h = 1/10$, $h = 1/20$, $h = 1/30$, ... , $h = 1/150$, $h = 1/160$, we find that

$$E_0(u_h, u) \approx 1.1007\ h^{3.0858},$$
$$E_0(I_{2h}^3 u_h, u) \approx 6.8671\ h^{4.2865},$$
$$E_1(u_h, u) \approx 6.2018\ h^{2.0577},$$
$$E_1(I_{2h}^3 u_h, u) \approx 18.0236\ h^{3.1004},$$

These and the reduction factors in Tables 5.2 and 5.3 corroborate the predictions of Theorem 3.5 for the case in which $k = 2$.

TABLE 5.4
H^1-errors of the bilinear FE solutions and their estimates by the postprocessed FE solutions.

h	$E_1(u_h, u)$	$E_1(u_h, I_{2h}^2 u_h)$	Effectivity index
1/10	6.499e-1	6.704e-1	1.0315
1/20	3.089e-1	3.098e-1	1.0029
1/40	1.506e-1	1.506e-1	1.0000
1/80	7.434e-2	7.434e-2	1.0000
1/160	3.694e-2	3.694e-2	1.0000

TABLE 5.5
Errors of the biquadratic FE solutions and their estimates by the postprocessed FE solutions.

h	$E_0(u_h, u)$	$E_0(u_h, I_{2h}^3 u_h)$	Eff. index	$E_1(u_h, u)$	$E_1(u_h, I_{2h}^3 u_h)$	Eff. index
1/10	9.762e-4	1.043e-3	1.0684	5.724e-2	5.477e-2	0.95685
1/20	1.046e-4	1.039e-4	0.99331	1.289e-2	1.273e-2	0.98759
1/40	1.211e-5	1.208e-5	0.99752	3.062e-3	3.053e-3	0.99706
1/80	1.458e-6	1.456e-6	0.99863	7.463e-4	7.457e-4	0.99920
1/160	1.788e-7	1.788e-7	1.0000	1.842e-4	1.842e-4	1.0000

Table 5.4 compares the actual errors in the bilinear finite element solutions with their estimates by the postprocessed finite element solutions. Not only we can see that the computable quantity $E_1(u_h, I_{2h}^2 u_h)$ yields an accurate assessment of the actual error, but also, by applying linear regression to the data for $h = 1/10$, $h = 1/20$, $h = 1/30, \ldots, h = 1/150$, $h = 1/160$, we can see that the difference between the actual error and the estimated one satisfies the following relation:

$$|E_1(u_h, u) - E_1(u_h, I_{2h}^2 u_h)| \approx 6.3438\ h^{3.2954},$$

which is within the prediction of Theorem 4.1.

Table 5.5 compares the actual errors in the biquadratic finite element solutions and their estimates by the postprocessed finite element solutions. Again, we can see that both computable quantities $E_0(u_h, I_{2h}^3 u_h)$ and $E_1(u_h, I_{2h}^3 u_h)$ yield accurate assessments of the actual errors, and by applying linear regression to the data for $h = 1/10$, $h = 1/20$, $h = 1/30, \ldots, h = 1/150$, $h = 1/160$, we can see that the difference between the actual errors and those estimated satisfies the following relations:

$$|E_0(u_h, u) - E_0(u_h, I_{2h}^3 u_h)| \approx 3.0081\ h^{4.9526},$$
$$|E_1(u_h, u) - E_1(u_h, I_{2h}^3 u_h)| \approx 13.0755\ h^{3.8155},$$

which are again within the prediction of Theorem 4.1.

Acknowledgment. The authors would like to thank Professor Miloslav Feistauer, Karel Kolman, and Tomáš Vejchodský for their valuable suggestions.

A LOCAL MINIMAX-NEWTON METHOD FOR FINDING MULTIPLE SADDLE POINTS WITH SYMMETRIES*

ZHI-QIANG WANG† AND JIANXIN ZHOU‡

Abstract. In this paper, a local minimax-Newton method is developed to solve for multiple saddle points. The local minimax method [*SIAM J. Sci. Comput.*, 23 (2001), pp. 840–865]. is used to locate an initial guess and a version of the generalized Newton method is used to speed up convergence. When a problem possesses a symmetry, the local minimax method is invariant to the symmetry. Thus the symmetry can be used to greatly enhance the efficiency and stability of the local minimax method. But such an invariance is sensitive to numerical error and the Haar projection has been used to enforce the symmetry [*SIAM J. Numer. Anal.*, submitted]. In this paper, we prove that the Newton method is invariant to symmetries and that such an invariance is insensitive to numerical error. When a symmetric degeneracy takes place, it is proved that the Newton direction can be easily solved in an invariant subspace. Thus the Newton method can be used not only to speed up convergence but also to avoid using the Haar projection if the symmetric degeneracy is removable by a discretization. Finally, numerical examples are presented to illustrate the theory.

1. Introduction.

Let H be a Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and $J \in C^2(H, \mathbb{R})$, $J' : H \to H^*$ be its Frechet derivative and $\nabla J : H \to H$ be the gradient, and $J'' : H \to L(H, H^*)$ its second Fréchet derivative. Since there is a canonical identification between H^* and H, $\nabla J(u)$ is the identification of $J'(u)$. We may also use the identification of $J''(u)$ so $J''(u)$ is seen as in $L(H, H)$. A point $u \in H$ is a critical point of J if u solves the Euler–Lagrange equation $J'(u) = 0$. Many boundary value problems in nonlinear elliptic PDEs can be converted to solving its Euler–Lagrange equation for a critical point. A critical point u is nondegenerate if $J''(u)$ is invertible. The first candidates for a critical point are the local extrema which are well studied in the classical calculus of variation. Traditional numerical (variational) methods focus on finding such stable solutions. Critical points that are not local extrema are *unstable* and are called *saddle points*. In physical systems, saddle points appear as unstable equilibria or transient excited states. A huge number of papers exist in the literature on the existence of multiple saddle points in various nonlinear problems [1, 5, 6, 8, 9, 10, 17, 21, 24, 25, 26, 28].

To theoretical and computational physics and chemistry, saddle points between two stable states on the potential hypersurface are of great interests and lie in the theme of the so-called Transition State Theory or Activated Complex Theory, as they correspond to the transition states or the minimum energy paths between reactant molecules and product molecules [13]. A large literature can be found in this area.

Solitons arise in many fields, such as condensed matter physics, dynamics of biomolecules, nonlinear optics, etc. Among them, solutions which are not ground states, are the so-called excited states. In the study of self-guided light waves in nonlinear optics [11, 12, 19], excited states are of great interests. All those solitons are saddle points, thus unstable solutions.

On the other hand, symmetries exist in many natural phenomena, such as in crystals, elementary particle physics, symmetry of the Schrödinger equation for the atomic nucleus and the electron shell with respect to permutations and rotations, energy conservation law for systems which are invariant with respect to time translation, etc. Symmetries described by compact group actions in variational problems have been used in the literature to prove the existence of *multiple critical points*, typically, in the Ljusternik–Schnirelman theory (see, e.g., [14] and others). It is known that symmetries in a nonlinear variational problem can lead to the existence of many solutions of saddle type and can also cause (symmetric) degeneracy.

Due to the unstable nature, finding multiple saddle points numerically *in a stable way* is very challenging. There is virtually no theory in the literature to devise such a numerical algorithm until recently a local minimax method was developed in [15, 16] to find multiple saddle points in a sequential order of their Morse indices and its convergence was established in [16]. Techniques to enhance efficiency and stability of this method for computing saddle points with symmetries by using the Haar projection are developed in [27].

Since the local minimax method [15, 16] is a gradient type, first-order algorithm, to speed up convergence, it is quite natural to consider a Newton's method. Due to the instability and multiplicity nature of our problems, we consider a Newton's method of the form

$$u_{k+1} = u_k - s_k \nu_k \quad \text{with } \nu_k = (J''(u_k))^{-1} J'(u_k),$$

where ν_k is the Newton direction and $s_k > 0$ is a stepsize to enhance the stability of the algorithm; e.g., in Armijo's rule, $s_k > 0$ is chosen such that

$$\|\nabla J(u_{k+1})\| - \|\nabla J(u_k)\| < -\frac{1}{2} s_k \|\nabla J(u_k)\|. \tag{1.1}$$

For the algorithm to converge to a desirable critical point, two basic conditions are assumed:

(a) a good initial guess to start with, otherwise it can be extremely slow or divergent, or can lead to an unwanted trivial or known critical point;

(b) the problem has to be nondegenerate; i.e., $J''(u_k)$ is invertible along the trajectory of a Newton's method.

When $J''(u_k)$ is not invertible, a generalized Newton's method is suggested in the literature by using the generalized (Moore–Penrose) inverse $J''(u_k)^\dagger$, where the Newton direction $\nu_k = J''(u_k)^\dagger J'(u_k)$ is the least-norm solution to the minimization problem

$$\min_{\nu \in H} \|J''(u_k)\nu - J'(u_k)\|. \tag{1.2}$$

Under standard conditions and $s_k \equiv 1$, the generalized Newton method converges locally and quadratically [20]. This approach seems to be very general but also too complicated to apply to solve an infinite-dimensional problem. Therefore people tend to avoid using the generalized Newton method in solving variational problems. It is

also very difficult for us to examine its response to the effects of a symmetry in a problem.

Although attempts have been made by several researchers, e.g., [18, 22], to use a Newton's method to find multiple saddle points in various problems, the answer to how to deal with those two basic issues (a) and (b) remains largely unsatisfactory. Locating a good initial guess in an infinite-dimensional space is itself a challenging problem, in particular, when multiple solutions are involved. By using the local minimax method [15, 16], a good initial guess can be provided. However, degeneracy exists in every multiple saddle point problem due to a sign change of the eigenvalues of $J''(u)$. Either a solution to be found is degenerate or $J''(u)$ is not invertible at a point u along the Newton trajectory. How to handle such a case within the framework of a Newton's method remains a very interesting problem. On the other hand, when the problems possess some symmetries, they may create symmetric degeneracy; see Example 2.5. How a Newton's method responds to symmetries of the problems is, in general, still unknown. In this paper we shall try to address these questions. To do so, we use an approach somewhat between the standard and the generalized Newton method. When J is C^2 and $J''(u)$ has a closed range, for given $u \in H$, we consider a solution ν to

$$J''(u)\nu = J'(u). \tag{1.3}$$

In the following we assume that $J''(u)$ is a Fredholm operator with index zero. Since $J''(u)$ is self-adjoint, it has a finite-dimensional kernel, $\ker(J''(u))$, and a closed range. Then it is known that (1.3) may have none, unique, or infinitely many solutions, and (1.3) has a solution if and only if $\nabla J(u) \perp \ker(J''(u))$. In this case, *the Newton direction is just the least-norm solution* to the linear system (1.3). Note that in general, with the Armijo rule (1.1), the Newton method may approximate a critical point u^* of the function $g(u) = \|\nabla J(u)\|$, i.e.,

$$\langle g'(u^*), v\rangle = \frac{\langle J''(u^*)v, \nabla J(u^*)\rangle}{\|\nabla J(u^*)\|} = 0 \quad \forall v \in H.$$

If we choose $v = \nu$, a solution to (1.3), we have $J''(u^*)\nu = \nabla J(u^*)$ and $\langle g'(u^*), \nu\rangle = \|\nabla J(u^*)\| = 0$. Thus a critical point u^* of $g(u) = \|\nabla J(u)\|$ where (1.3) is solvable must be a critical point of J.

In this paper, we assume that a solution u^* to be found possesses certain symmetry and that the degeneracy of u^* is created *only* by the symmetry. Our method will be particularly useful in situations where there are multiple-saddle-point-type solutions due to symmetries. Our analysis uncovers the effects of symmetries in the problems on the Newton method. In summary, we shall undertake the following steps towards giving a theoretical strategy and implementing a numerical algorithm for computing multiple-saddle-point-type solutions when symmetries are present:

(1) prove the invariance of the Newton direction under symmetries;
(2) prove the solvability of (1.3) under symmetric degeneracies;
(3) show that the invariance of the Newton direction to symmetries is insensitive to numerical error, which contrasts to the fact that the invariance of the local minimax method to symmetries is sensitive to numerical error [27].

Due to the invariance of the local minimax method to symmetries, symmetries can be used to greatly enhance the efficiency and stability of the method [27]. However, such an invariance is sensitive to numerical error. Thus the Haar projection has to be used to enforce the symmetry. When a symmetry is associated with a continuous

group of actions, the corresponding Haar projection is an integral over the group. It becomes very difficult to compute. On the other hand, in many applications such as those examples in this paper, such a symmetric degeneracy is removable when a discretization of the problem is used. After the analysis in this paper we realize that with a least-norm solution linear solver, the Newton method can be used, following the local minimax method, to not only speed up convergence but also avoid using the Haar projection when the symmetric degeneracy is removable by a discretization. This is the *local minimax-Newton method* we shall describe in this paper. In the last section, we present several numerical examples to illustrate the theory.

2. The Newton method. We will need some preliminaries from transformation groups and invariant functionals [2]. Let H be a Hilbert space, $\mathcal{G}$ be a compact Lie group that acts isometrically on H, and $J \in C^2(H, \mathbb{R})$ be $\mathcal{G}$-invariant, i.e., $J(gu) = J(u)$, $\forall g \in \mathcal{G}$ and $u \in H$, and $J''(u)$ have a closed range for each $u \in H$. For a subgroup G of $\mathcal{G}$, let $H_G = \{u \in H \mid gu = u \ \forall g \in G\}$ be the invariant subspace of H under the group actions of G. For $u \in H$, the G-orbit of u is the set $Gu = \{gu : g \in G\}$ and the isotropy subgroup of u is $\mathcal{G}_u = \{g \in \mathcal{G} : gu = u\}$. When Gu is differentiable at u, we denote by $T_u(Gu)$ the tangent space of Gu at u.

2.1. Invariance and solvability of the Newton direction.

LEMMA 2.1.

(a) *∇J is $\mathcal{G}$-equivariant, i.e., $\nabla J(gu) = g^{-1}\nabla J(u)$ $\forall u \in H$, $g \in \mathcal{G}$;*

(b) *$\nabla J(u) \in H_G$ for any subgroup $G \subset \mathcal{G}$ and $u \in H_G$;*

(c) *$\langle J''(u)w, v\rangle = \langle J''(gu)gw, gv\rangle$ $\forall u, v, w \in H$, $g \in \mathcal{G}$, and in particular, we have $J''(u)(H_G) \subset H_G$ for any subgroup $G \subset \mathcal{G}$ and $u \in H_G$.*

Proof. By using the invariance of J, $\langle J'(gu), v\rangle = \langle J'(u), gv\rangle = \langle g^{-1}J'(u), v\rangle$. This shows $\nabla J(gu) = g^{-1}\nabla J(u)$, which implies (a) and (b). Let G be a subgroup of $\mathcal{G}$. To prove (c), differentiating again we have $\langle J''(u)w, v\rangle = \langle J''(gu)gw, gv\rangle$ $\forall u, v, w \in H$. For $u \in H_G$ and $w \in H_G$, we obtain $\langle J''(u)w, v\rangle = \langle g^{-1}J''(u)w, v\rangle$. Thus $J''(u)w = g^{-1}J''(u)w$ $\forall g \in G$, and we conclude $J''(u)w \in H_G$, i.e, $J''(u)(H_G) \subset H_G$. ∎

Lemma 2.1(a) states that if u^* is a critical point, i.e., $\nabla J(u^*) = 0$, then $\nabla J(gu^*) = 0$ $\forall g \in \mathcal{G}$. This implies that when $\mathcal{G}$ has a continuous subgroup G and $u^* \notin H_G$, the continuous orbit G_{u^*} is a critical point set continuous at u^*. Thus u^* is not isolated and therefore degenerate, i.e., $\ker(J''(u^*)) \neq \{0\}$. If G is differentiable subgroup of $\mathcal{G}$, we have the following lemma.

LEMMA 2.2. *Let G be a differentiable subgroup of $\mathcal{G}$ and $u \notin H_G$ be a critical point of J. Then $T_u(Gu) \subset \ker(J''(u))$. Here $T_u(Gu)$ is the tangent space of Gu at u.*

Proof. Let $v \in T_u(Gu)$ and consider a one-parameter curve $\gamma : (-\epsilon, \epsilon) \to Gu$ such that $\gamma(0) = u$ and $\gamma'(0) = v$. Then $J'(\gamma(t)) = 0$ $\forall t \in (-\epsilon, \epsilon)$. For any fixed w let $g : (-\epsilon, \epsilon) \to \mathbb{R}$ be defined by $g(t) = (J'(\gamma(t)), w)$. Then $g'(0) = 0$, but $g'(0) = (J''(u)v, w)$. Since w is arbitrary we have $J''(u)v = 0$. ∎

If u^* is a nondegenerate critical point of J, that is, $\ker(J''(u^*)) = \{0\}$, then $\ker(J''(u)) = \{0\}$ for u close to u^*. When the degeneracy of a critical point u^* is caused only by differentiable group actions of G, i.e., $\ker(J''(u^*)) = T_{u^*}(Gu^*)$, we must have $u^* \notin H_G$. Thus it is reasonable to assume that for u close to u^* and $u \in H \setminus H_G$, $\ker(J''(u)) \subset T_u(Gu)$ holds. Then we have the following lemma.

LEMMA 2.3. *Let G be a differentiable subgroup of $\mathcal{G}$ and $u \in H \setminus H_G$. If $\ker(J''(u)) \subset T_u(Gu)$, then (1.3) is always solvable.*

Proof. If $\nabla J(u) = 0$, the lemma is obvious. Let $v \in T_u(Gu)$ and consider a one-parameter curve $\gamma : (-\epsilon, \epsilon) \to Gu$ such that $\gamma(0) = u$ and $\gamma'(0) = v$. Let $g(t) = J(\gamma(t))$. Then $g'(0) = 0$ due to the invariance of the functional J. Since

$g'(0) = (\nabla J(u), v)$, we have $\nabla J(u) \perp T_u(Gu)$ and therefore $\nabla J(u) \perp \ker(J''(u))$ when $\ker(J''(u)) \subset T_u(Gu)$. So (1.3) is always solvable. ∎

The above result implies that the Newton direction ν of J at u can be solved from (1.3) instead of the much more complicated problem (1.2) when u is close to a critical point u^* whose degeneracy is caused only by differentiable subgroup actions of G. Can (1.3) be uniquely solved? Will the Newton direction ν of J at u have the same symmetry as that of u? These two uniqueness and invariance problems are actually closely related.

LEMMA 2.4. *Let G be a subgroup of $\mathcal{G}$ and $u \in H_G$. If $w \in H$ is a solution to* (1.3)*, then $w_G \in H_G$ is a solution of* (1.3) *where $w_G = \int_G g(w)dg$ is the Haar projection of w onto H_G. Thus the Newton direction is always in H_G. Furthermore, if* (1.3) *is uniquely solvable in H_G, then w_G is the Newton direction.*

Proof. Since $\nabla J(u) \in H_G$ by Lemma 2.1(b) and $w_G \in H_G$ by the Haar projection, we only have to prove that w_G is a solution to (1.3). By Lemma 2.1(c), we have

$$\langle \nabla J(u), v\rangle = \langle J''(u)w, v\rangle = \langle J''(gu)gw, gv\rangle \quad \forall v \in H,\ g \in \mathcal{G}.$$

Taking $v \in H_G$ and $g \in G$, we obtain $\langle J''(gu)gw, gv\rangle = \langle J''(u)gw, v\rangle$. Thus

$$\langle J''(u)gw - \nabla J(u), v\rangle = 0 \quad \text{or} \quad (J''(u)gw - \nabla J(u)) \perp H_G \quad \forall g \in G.$$

Since the Haar integral is linear and normalized, and $\nabla J(u) \in H_G$, it follows that

$$\int_G (J''(u)gw - \nabla J(u))\, dg = (J''(u)w_G - \nabla J(u)) \perp H_G$$

as well. Then by Lemma 2.1(c), $w_G \in H_G$ implies $J''(u)w_G - \nabla J(u) \in H_G$. We must have $J''(u)w_G - \nabla J(u) = 0$. When (1.3) is solvable, the Newton direction ν must be a solution to (1.3). It has been shown in [27] that the Haar projection ν_G of ν is the orthogonal projection of ν onto H_G and ν_G is also a solution to (1.3) by the previous part. We have $\|\nu_G\| \le \|\nu\|$ and the equality holds if and only if $\nu \in H_G$.

If (1.3) is uniquely solvable in H_G, which means for all solutions w of (1.3), their orthogonal projections w_G onto H_G are the same, then w_G is the Newton direction. ∎

We conclude here that finding w_G by the Haar projection is equivalent to solving the least-norm solution to the linear system (1.3).

2.2. Implementation of the Newton method. Let G be a differentiable subgroup of $\mathcal{G}$ and $u^* \in H \setminus H_G$ be a critical point to be found whose degeneracy is created only by the group actions of G. Thus $u^* \in H_{\mathcal{G}_{u^*}}$. Assume that each $u \in H_{\mathcal{G}_{u^*}}$ is an isolated point in $H_{\mathcal{G}_{u^*}} \cap Gu$.[1] Thus the degeneracy caused by the group actions of G does not take place in $H_{\mathcal{G}_{u^*}}$. It follows that the equation $J''(u)\nu = v$ has a unique solution ν in $H_{\mathcal{G}_{u^*}}$ $\forall u, v \in H_{\mathcal{G}_{u^*}}$. Therefore the uniqueness and invariance problems can be solved by confining our problem to the subspace $H_{\mathcal{G}_{u^*}}$. This implies that we have to enforce the symmetries defined by the isotropy subgroup $\mathcal{G}_{u^*}$. For numerical implementation, it can be easily done as follows.

Choose an initial guess $u_0 \in H_{\mathcal{G}_{u^*}}$ close to u^* (such that u_0 has the same symmetry as u^*). This can be done by the local minimax method due to its invariance to symmetries (see [27]). Then by Lemma 2.1, $J'(u_0) \in H_{\mathcal{G}_{u^*}}$ and (1.3) or $J''(u_0)\nu = J'(u_0)$ has a unique solution $\nu_0 \in H_{\mathcal{G}_{u^*}}$ which can be found through solving (1.3) for

[1] For most applications this assumption will be satisfied.

the least-norm solution. The updated solution $u_1 = u_0 - s_0 v_0 \in H_{\mathcal{G}_{u^*}}$ where $s_0 > 0$ is a stepsize determined by, e.g., Armijo's rule, has the same symmetry as that of u_0. Thus the symmetry of u_0 is preserved and passed to u_1 and we can continue this way to obtain the uniqueness and invariance of the Newton direction in $H_{\mathcal{G}_{u^*}}$. The local convergence of the generalized Newton method is then applied. When numerical error is considered, to overcome the symmetric degeneracy problem, in general, the Haar projection is needed to ensure the solvability of (1.3). The following example is instructional.

Example 2.5. Let $J(x,y) = \frac{1}{2}r^2 - \frac{1}{4}r^4$ where $r^2 = x^2 + y^2$. Then

$$J'(x,y) = \begin{bmatrix} x(1-r^2) \\ y(1-r^2) \end{bmatrix}, \qquad J''(x,y) = \begin{bmatrix} 1-2x^2-r^2 & -2xy \\ -2xy & 1-2y^2-r^2 \end{bmatrix},$$
$$\det(J''(x,y)) = (1-r^2)(1-3r^2).$$

Thus $(0,0)$ is the local minimum-type critical point and (x_s, y_s) with $x_s^2 + y_s^2 = 1$ are the saddle points. Let $\mathcal{G} = \mathbb{O}(2) = \mathbb{Z}_2 \times \mathbb{S}^1$ where $\mathbb{O}(2)$ is the group of all 2×2 orthogonal matrices, $\mathbb{Z}_2$ is generated by the matrix $\left[\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right]$ and $\mathbb{S}^1$ is the group of all matrices $\left[\begin{smallmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{smallmatrix}\right]$, $0 \le \theta < 2\pi$. Thus the subgroup $\mathbb{Z}_2$ represents the reflection about the line $x = y$ and the subgroup $\mathbb{S}^1$ represents all rotations. The subgroup $G = \mathbb{S}^1$ is differentiable and creates degeneracy of a critical point not in H_G. We have $(0,0) \in H_G$ and $(x_s, y_s) \notin H_G$. It is clear that $(0,0)$ is a nondegenerate critical point with $\det(J''(0,0)) = 1$ and all the saddle points (x_s, y_s) are degenerate. For each $u = (x_s, y_s)$, $Gu = \{(x,y) : x^2 + y^2 = 1\}$ and $T_u(Gu) = \{(x,y) : x_s x + y_s y = 0\} = \{(x, -\frac{x_s x}{y_s}) : x \in \mathbb{R}\}$. By Lemma 2.2, $T_u(Gu) \subset \ker(J''(x_s, y_s))$. Indeed we have $J''(x_s, y_s)(x, -\frac{x_s x}{y_s})^T = (0,0)^T$.

Although for all (x,y) with $x^2 + y^2 \neq 1, \frac{1}{3}$, $J''(x,y)$ is invertible, the condition number of the matrix $J''(x,y)$ gets worse as $(x,y) \to (x_s, y_s)$. The usual Newton method will fail to provide any reliable solution. If we consider the saddle point $u^* = (\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2})$, the isotropy subgroup at u^* is $\mathbb{Z}_2$. The corresponding invariant subspace is $H_{\mathbb{Z}_2} = \{(x,y)^T\}$ such that $\left[\begin{smallmatrix} x \\ y \end{smallmatrix}\right] = \left[\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right]\left[\begin{smallmatrix} x \\ y \end{smallmatrix}\right]$, i.e., $H_{\mathbb{Z}_2} = \{(x,x)^T\}$. By confining the problem in the subspace $H_{\mathbb{Z}_2}$, we have $J(x) = x^2 - x^4$, $J'(x) = 2x(1-2x^2)$, and $J''(x) = 2(1-6x^2)$. At the saddle point $x = \frac{\sqrt{2}}{2}$, $J''(\frac{\sqrt{2}}{2}) = -4$ is invertible. In implementation, for each $u = (z,z)^T \in H_{\mathbb{Z}_2}$, we have $H_{\mathbb{Z}_2} \cap Gu = \{u, -u\}$. Thus G will not cause any degeneracy in $H_{\mathbb{Z}_2}$. With $J'(z,z) = (z(1-2z^2), z(1-2z^2))^T \in H_{\mathbb{Z}_2}$, the equation $J''(z,z)(x,y)^T = J'(z,z)$ has a unique solution $(x,y) \in H_{\mathbb{Z}_2}$ where $x = y = \frac{z(1-2z^2)}{1-6z^2}$ and $-\frac{\sqrt{6}}{6} < z < \frac{\sqrt{6}}{6}$.

2.3. Insensitivity of invariance of Newton's method to numerical error. In [27], the invariance of the local minimax method to a symmetry is proved; i.e., if an initial guess u_0 is chosen in an invariant subspace H_G under a subgroup $G \subset \mathcal{G}$, then the sequence generated by the algorithm will remain in H_G. However, such an invariance is sensitive to numerical error in computing saddle points, because it searches a saddle point through a min-max method. The minimization process keeps J strictly descending along the sequence $\{u_k\}$ generated by the algorithm. To see the significant differences, let $u_k \in H_G$ be a point close to a saddle point $u^* \in H_G$. Thus $\nabla J(u_k)$ is small, the numerical errors in computing $\nabla J(u_k)$ dominate the symmetry of $\nabla J(u_k)$. This leads to $u_{k+1} \in H \setminus H_G$. For the minimax method, since u^* is a saddle point, the minimization search finds a slider (a descent direction) outside H_G away from u^*. Then $\|\nabla J(u_{k+1})\|$ increases and the asymmetric part of $\nabla J(u_{k+1})$

gets larger. Consequently the invariance of the sequence $\{u_k\}$ collapses and the search fails to reach u^*. The Haar projection has to be used (see [7, 27]) to preserve the symmetry of $\nabla J(u_k)$. In contrast to the local minimax method, the Newton method does not assume or use a variational structure. It finds a local minimum point u^*, not a saddle point, of $\|\nabla J(u)\|$. Once u_k is in a local basin of $\|\nabla J(u)\|$ around u^*, due to Armijo's rule, it keeps $\|\nabla J(u_k)\|$ strictly descending. Although $u_{k+1} \in H \setminus H_G$, $\|\nabla J(u_{k+1})\|$ is closer to 0. Thus u_{k+1} is still in the local basin around u^* and is a better approximation to $u^* \in H_G$. The asymmetric part of u_k will be kept within the norm of the numerical errors. In conclusion, the invariance of the Newton method is insensitive to numerical errors, therefore the Haar projection (an averaging formula) as suggested and used for the local minimax method in [27] is not necessary for the Newton method to preserve a symmetry.

The insensitivity of the invariance of the Newton method to numerical errors is double edged. If one knows the symmetry of a solution u^* to be found, then it is advantageous to use. One can choose an initial guess u_0 with the same symmetry of u^* to obtain an easy implementation for finding the Newton direction and preserve its invariance. Otherwise, it becomes a trap, when an initial guess u_0 has a symmetry different from that of u^*, the whole sequence generated by the Newton method will be trapped in the invariant subspace defined by the symmetry of u_0 and fails to reach u^*.

When a symmetry is associated with a continuous group G of actions, it causes degeneracy and the corresponding Haar projection is an integral over G and very difficult to compute. To overcome the symmetric degeneracy problem with numerical error, the Haar projection is needed in general. However, in many applications such as the examples in section 3, such a symmetric degeneracy is removable when a discretization is used, because after a discretization, G is approximated by a finite group. The truncation error is unpredictable, but it is in a much high order than the discretization error, which actually makes (1.3) more solvable. The above analysis suggests that in this case, the Haar projection is not needed to overcome the symmetric degeneracy problem with numerical error. Thus the Newton method can be used not only to speed up convergence but also to avoid using the Haar projection. This leads to the following *local minimax-Newton algorithm*.

2.4. A local minimax-Newton algorithm.

Step 1: Given $\varepsilon_M > \varepsilon_N > 0$ and $n-1$ previously found critical points $w_1, \dots, w_{n-1}$, of which w_{n-1} has the highest critical value. Set the support space $L = \text{span}\{w_1, \dots, w_{n-1}\}$. Let $v^1 \in L^\perp$ be an ascent direction at w_{n-1}. Let $t_0^0 = 1$, $v_L^0 = w_{n-1}$ and set $k = 0$;

Step 2: Using the initial guess $w = t_0^k v^k + v_L^k$, solve for $w^k = \arg\max_{u \in [L, v^k]} J(u)$ and denote $w^k = t_0^k v^k + v_L^k$ where t_0^k, v_L^k have been updated;

Step 3: Compute the negative gradient $d^k = -\nabla J(w^k)$;

Step 4: If $\|d^k\| \le \varepsilon_M$, then set $w^0 = w^k$, $k = 0$ and goto Step 7; else goto Step 5;

Step 5: Set $v^k(s^k) = \frac{v^k + s^k d^k}{\|v^k + s^k d^k\|}$ where s^k satisfies certain stepsize rule (see [15, 16]);

Step 6: Set $v^{k+1} = v^k(s^k)$ and update $k = k + 1$ then goto Step 2;

Step 7: Solve $J''(w^k)\nu = J'(w^k)$ for the least-norm solution ν^k;

Step 8: Set $w^{k+1} = w^k - s^k \nu^k$ where s^k satisfies, e.g., the Armijo's rule (1.1);

Step 9: Compute the gradient $\nabla J(w^{k+1})$;

Step 10: If $\|\nabla J(w^{k+1})\| < \varepsilon_N$, then output w^{k+1} and stop; else set $k = k + 1$, goto Step 7.

Steps 1–6 represent the local minimax method [15, 16] to locate an initial guess

that is sufficiently close to a desirable saddle point and Steps 7–10 represent the Newton method described in this paper to speed up the convergence.

When a symmetry is involved in a saddle point u^* to be found, we

(1) identify the symmetry of u^* by defining an invariant subspace H_G. Let $L_G = L \cap H_G$ and replace L by L_G in the algorithm; In many cases, such as those examples in section 3, we have $L_G = \{0\}$;

(2) choose an initial guess $v^1 \in H_G$;

(3) do iterations from Step 2 to Step 6.

Case 1. If we do not want to enforce the symmetry, we should choose $\varepsilon_M = 10\varepsilon$ where ε represents the order of the numerical error in computing $\nabla J(w^k)$, e.g., $\varepsilon = 10^{-2}$. Since the minimax method is invariant to a symmetry, when $\|\nabla J(w^k)\| > \varepsilon_M$, the symmetry of $\nabla J(w^k)$ still dominates the numerical error in $\nabla J(w^k)$. Usually the numerical error starts to dominate the symmetry of $\nabla J(w^k)$ when $\|\nabla J(w^k)\|$ is close to ε.

Case 2. If we want to enforce the symmetry, we only have to change Step 3 as $d^k = -\mathcal{H}(\nabla J(w^k))$ where $\mathcal{H}$ is the Haar projection defined in Lemma 2.4. In this case, we can choose $\varepsilon_M = 10\varepsilon$ or smaller.

(4) For Steps 7–10, if a degeneracy caused by a continuous group G of actions is removable by a discretization, then no Haar projection is needed, otherwise do the Haar projection.

3. Applications to semilinear elliptic equations.

3.1. Problems and setting up. The model equation we look at is the following semilinear elliptic equation:

$$\begin{cases} -\Delta u(x) = f(x, u(x)) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.1}$$

where $\Omega \subset \mathbb{R}^N$ is bounded, f is a C^1 function satisfying certain growth and regularity conditions [23] and we seek weak solutions in $H = W_0^{1,2}(\Omega)$. The energy functional is

$$J(u) = \int_\Omega \left\{ \frac{1}{2}|\nabla u(x)|^2 - F(x, u(x)) \right\} dx, \quad \text{where } F(x,t) = \int_0^t f(x,\tau)d\tau. \tag{3.2}$$

Then critical points of $J(u)$ correspond to weak solutions of (3.1). Problems of this type appear as models in many applied areas. Mathematically, people have been interested in understanding the solution structures in terms of existence and nonexistence, the number of solutions as well as in obtaining qualitative property of solutions such as the geometric, symmetric, and nodal properties. Though great progress has been made, still many important open questions remain unsettled. Here, we are mainly concerned in uncovering new phenomena by numerically examining the qualitative behavior of both positive solutions and nodal solutions of this type of elliptic boundary value problem. For $u, w \in H$, we have

$$\langle J'(u), w\rangle_{H^*\times H} = \frac{d}{dt}\bigg|_{t=0} J(u + tw) = \int_\Omega \nabla u \nabla w - f(x, u(x))w\, dx.$$

Thus $d = \nabla J(u) = u - (-\Delta)^{-1} f(x,u) \in H$. Taking the second derivative, we have

$$\langle J''(u)\nu, w\rangle = \frac{d}{dt}\bigg|_{t=0} \langle J'(u + t\nu), w\rangle = \int_\Omega \nabla\nu\nabla w - f'_u(x, u(x))\nu w\, dx \quad \forall \nu \in H,$$

which implies that $J''(u) = I - (-\Delta)^{-1} f'_u(\cdot, u)$. Under standard conditions [23] on f, $(-\Delta)^{-1} f'_u(\cdot, u)$ is a compact operator and $J''(u)$ is a Fredholm operator with index zero. By setting $\langle J'(u), w\rangle = \langle J''(u)\nu, w\rangle \ \forall w \in H$, the Newton direction ν as defined in (1.3) can be obtained from weakly solving

$$\begin{cases} -\Delta\nu(x) - f'_u(x, u(x))\nu(x) = -\Delta u(x) - f(x, u(x)), & x \in \Omega, \\ \nu(x) = 0, & x \in \partial\Omega. \end{cases} \tag{3.3}$$

Remark 3.1. (a) Newton's method has been applied to variational problems in the literature usually by solving a discretized Euler–Lagrange equation. This approach requires to solve for $J'(u)$ and $J''(u)$, then compute $\nu = (J''(u))^{-1} J'(u)$, or, $\nu = (J''(u))^{\dagger} J'(u)$ when $J''(u)$ is not invertible, and therefore is much more computationally expensive and difficult. While solving the Newton direction ν directly from (3.3) is much simpler and less expensive. In many cases when $J''(u)$ is not invertible, ν is still solvable from (3.3), such as the case where the singularity of $J''(u)$ is caused only by a continuous group of actions.

(b) When an initial guess u_0 and its Laplacian Δu_0 are given, the Newton direction ν_0 is solved from (3.3) and s_0 is determined by, e.g., the Armijo rule. Then $u_1 = u_0 - s_0\nu_0$ and $\Delta u_1 = \Delta u_0 - s_0\Delta\nu_0$ where $\Delta\nu_0(x) = \Delta u_0(x) + f(x, u_0(x)) - f'_u(x, u_0(x))\nu_0(x)$ is known. Thus no computation of the Laplacian of the updated numerical solution u_1 is required.

3.2. Numerical examples. In this section, we apply the local minimax method (MM), the Newton method (NM) and the local minimax-Newton method (MM+NM) to numerically solve the Henon equation

$$\begin{cases} -\Delta u(x) = |x|^q u^3(x) & \text{in } \Omega, \\ u(x) = 0 & \text{on } \partial\Omega \end{cases} \tag{3.4}$$

for multiple solutions in $H = H_0^1(\Omega)$ where Ω is either the unit disk or an annulus. We are interested in finding new phenomena in symmetry breaking and nodal property of solution structure. The symmetries of the problem can be described by the group actions $\mathcal{G} = \mathbb{O}(2) = \mathbb{Z}_2 \times \mathbb{S}^1$ where $\mathbb{O}(2)$ is the set of all 2×2 orthogonal matrices, $\mathbb{Z}_2$ and $\mathbb{S}^1$ represent, respectively, the reflection about the x-axis and all the rotations. For $u \in H$, $g \in \mathbb{S}^1$, and the generator $\bar{h} \in \mathbb{Z}_2$, we define $g(u)(x) = u(gx)$ and $h(u)(x) = \pm u(\bar{h}x)$, where $+1$ and -1 represent, respectively, the even and the odd reflections, and the odd reflection is applicable if an even n-rotationally symmetry is considered. Then $\mathcal{G}$ becomes a compact Lie group that acts isometrically on H and $G = \mathbb{S}^1$ is a differentiable subgroup that creates degeneracy for a critical point $u^* \notin H_G$, i.e., u^* is radially asymmetric (or nonradial).

For a radially asymmetric but n-rotationally symmetric solution u^*, the isotropy subgroup of $\mathcal{G}$ at u^* is $\mathcal{G}_{u^*} = \{h^i g_i,\ i = 0, 1, \dots, n-1\}$ where $g_i = \left[\begin{smallmatrix} \cos\theta_i & \sin\theta_i \\ -\sin\theta_i & \cos\theta_i \end{smallmatrix}\right]$ and $\theta_i = i\frac{2\pi}{n}$, $i = 0, 1, \dots, n-1$, and for each $u \in H_{\mathcal{G}_{u^*}}$, $H_{\mathcal{G}_{u^*}} \cap Gu = \{g_i u,\ i = 0, 1, \dots, n-1\}$. Thus the differentiable subgroup G causes no degeneracy in $H_{\mathcal{G}_{u^*}}$. By confining the problem in $H_{\mathcal{G}_{u^*}}$, the Newton direction can be uniquely solved from (3.3) in $H_{\mathcal{G}_{u^*}}$. For implementation, this means that we need only to take an initial guess u_0 in $H_{\mathcal{G}_{u^*}}$ and close to u^*. In the following numerical examples, $\varepsilon = \|\nabla J(u_k)\|$

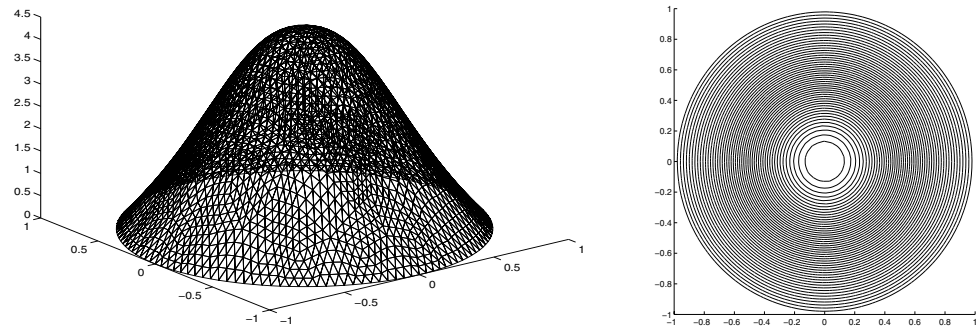

FIG. 1. $q = 0.5$. *The radially symmetric ground state with* $J = 21.5347$.

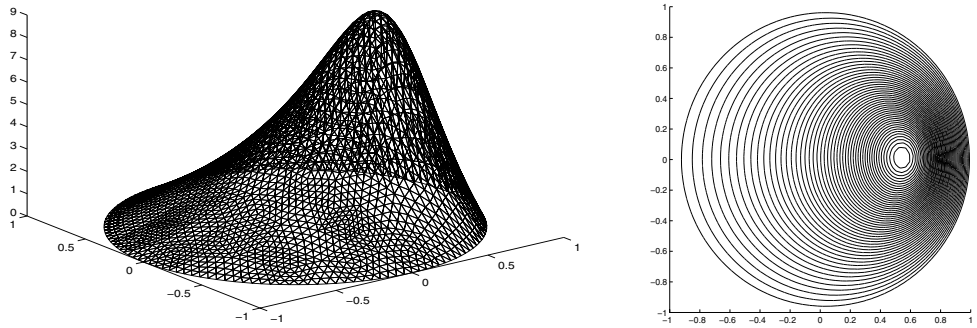

FIG. 2. $q = 2$. *A radially asymmetric ground state with* $J = 70.9280$.

and u_0 is computed from solving the linear equation

(3.5)

$$\begin{cases} -\Delta u_0(x) = c(x), & x \in \Omega, \\ u_0(x) = 0, & x \in \partial\Omega, \end{cases} \qquad \text{where } c(x) = \begin{cases} +1 & \text{if } u_0 \text{ is concave down at } x, \\ -1 & \text{if } u_0 \text{ is concave up a } x, \\ 0 & \text{otherwise.} \end{cases}$$

Case 1: $\Omega = \{(x_1, x_2) : x_1^2 + x_2^2 < 1\}$.

(1) Let $q = 0.5$ in (3.4). It is known that the equation has a unique positive solution which is radially symmetric as shown in Figure 1.

(a) Using an initial guess u_0 which is radially asymmetric but symmetric about the x-axis with $c(x_1, x_2) = -1$ if $|(x_1, x_2) - (0.5, 0)| \le 0.5$ and $c(x_1, x_2) = 0$ otherwise. Then NM failed to converge in 120 iterations and 35 MM iterations yield $\varepsilon < 10^{-4}$. While 6 MM iterations give $\varepsilon < 10^{-1}$ and then followed by 5 NM iterations, it yields $\varepsilon < 10^{-8}$.

(b) Using a radially symmetric initial guess u_0 from $c(x_1, x_2) = -1$. Then 5 NM iterations yield $\varepsilon < 10^{-12}$ and 8 MM iterations reach $\varepsilon < 10^{-4}$.

(2) Next let $q = 2$ in (3.4). Then the equation has a radially symmetric positive solution and other radially asymmetric positive solutions (see [3]). Rotating a radially

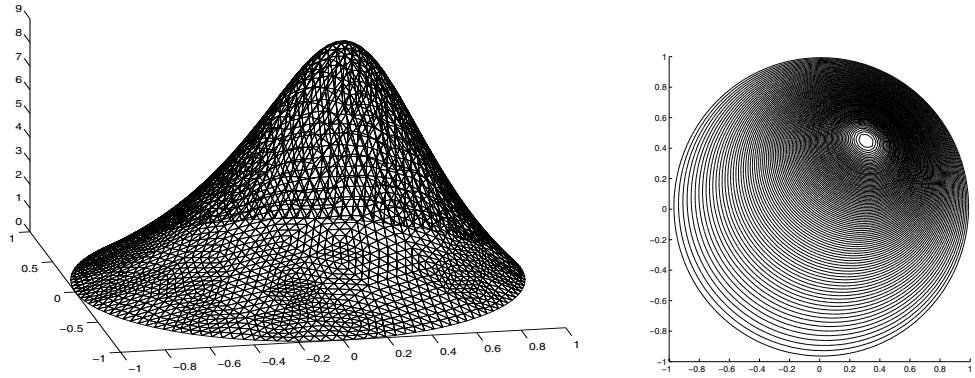

FIG. 3. $q = 2$. *Another radially asymmetric ground state with* $J = 70.8941$.

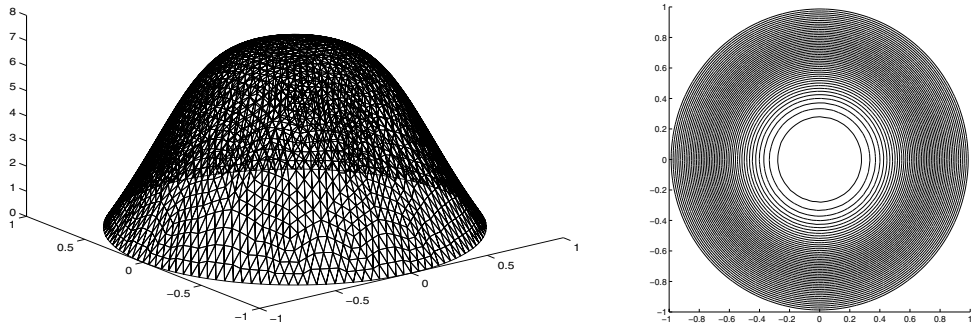

FIG. 4. $q = 2$. *The radially symmetric solution with* $J = 88.1740$.

asymmetric solution for any angle gives a radially asymmetric solution as well. Thus such a solution is degenerate. The radially symmetric positive solution has the highest energy among all the positive solutions. Without using the symmetry, such a solution is extremely elusive to capture.

(a) Using a radially asymmetric initial guess u_0 from $c(x_1, x_2) = -1$ if $|(x_1, x_2) - (0.5, 0)| \leq 0.5$ and $c(x_1, x_2) = 0$ otherwise. Then 11 MM iterations get the solution as in Figure 2 with $\varepsilon < 5 * 10^{-3}$ and 7 NM iterations find the same solution with $\varepsilon < 10^{-7}$.

(b) Using a radially symmetric initial guess u_0 from $c(x_1, x_2) = -1$. Then 21 MM iterations obtain the solution as in Figure 3 with $\varepsilon < 3 * 10^{-3}$, which is a rotation of the solution in Figure 2 and 4 NM iterations find the radially symmetric solution as in Figure 4 with $\varepsilon < 10^{-7}$. Such a solution cannot be captured by MM without enforcing the symmetry.

(c) Using an initial guess u_0 from $c(x_1, x_2) = -\text{sign}(x_1)$. u_0 is odd 2-rotation y-axis symmetric. NM failed to converge. Then first 2 MM iterations followed by 8 NM iterations yield a sign-changing solution as in Figure 5 with $\varepsilon < 10^{-7}$. Note that the solution in Figure 5 has the same symmetries as that of the initial guess u_0.

(d) To show that the invariance of NM is very insensitive to numerical error, using an initial guess u_0 from $c(x_1, x_2) = +1$ if $-\frac{1}{4}\pi < \tan^{-1}(\frac{x_2}{x_1}) < \frac{1}{4}\pi$ or $\frac{3}{4}\pi <$

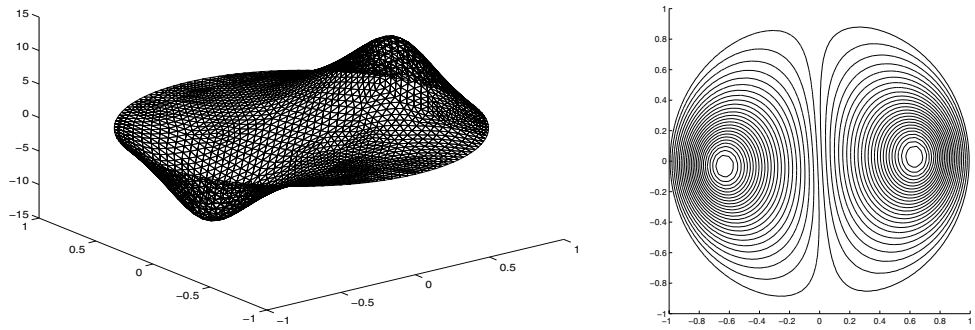

FIG. 5. $q = 2$. *An odd* 2*-rotationally symmetric sign-changing solution with* $J = 182.9987$.

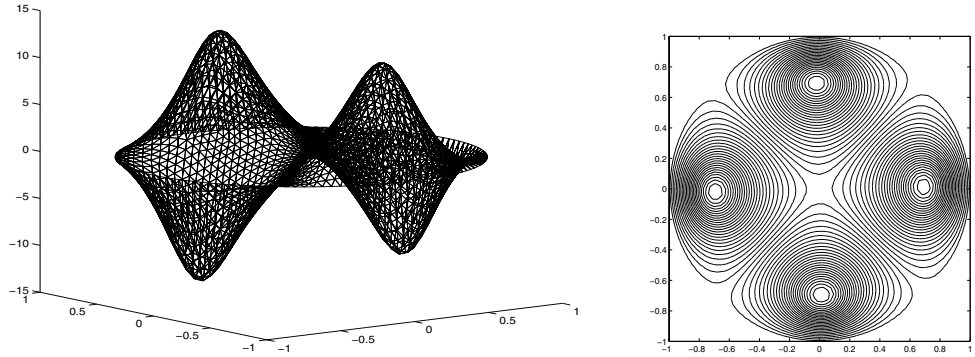

FIG. 6. $q = 2$. *An odd* 4*-rotationally symmetric sign-changing solution with* $J = 489.2240$.

$\tan^{-1}(\frac{x_2}{x_1}) < \frac{5}{4}\pi$ and $g(x_1, x_2) = -1$ otherwise. u_0 is odd 4-rotationally symmetric. The corresponding invariant subspace is much smaller. Again NM failed to converge. First 2 MM iterations followed by 9 NM iterations yield a solution as in Figure 6 with $\varepsilon < 10^{-11}$.

Case 2: $\Omega = \{(x_1, x_2) : 0.4 < x_1^2 + x_2^2 < 1\}$ and $q = 2$ in (3.4).

The equation has a radially symmetric and other radially asymmetric positive solutions (see [4]). Rotating a radially asymmetric solution for any angle is still a radially asymmetric solution. Thus such a solution is degenerate. The radially symmetric positive solution has the highest energy among all the positive solutions. Without using the symmetry, such a solution is extremely elusive to capture.

(a) Using a radially asymmetric initial guess u_0 from $c(x_1, x_2) = -1$ if $|(x_1, x_2) - (0.7, 0)| \le 0.3$ and $c(x_1, x_2) = 0$ otherwise. Then 17 MM iterations get the solution as in Figure 7 with $\varepsilon < 3 * 10^{-3}$ and 9 NM iterations yield the same solution with $\varepsilon < 10^{-9}$.

(b) Using an initial guess u_0 from $c(x_1, x_2) = -1$ if $-\frac{1}{4}\pi < \tan^{-1}(\frac{x_2}{x_1}) < \frac{1}{4}\pi$ or $\frac{3}{4}\pi < \tan^{-1}(\frac{x_2}{x_1}) < \frac{5}{4}\pi$ and $c(x_1, x_2) = 0$ otherwise. u_0 is even 2-rotationally symmetric. First 2 MM iterations followed by 6 NM iterations yield a solution as in Figure 8 with $\varepsilon < 10^{-11}$.

(c) Using an initial guess u_0 from $c(x_1, x_2) = -1$ if $-\frac{1}{6}\pi < \tan^{-1}(\frac{x_2}{x_1}) < \frac{1}{6}\pi$,

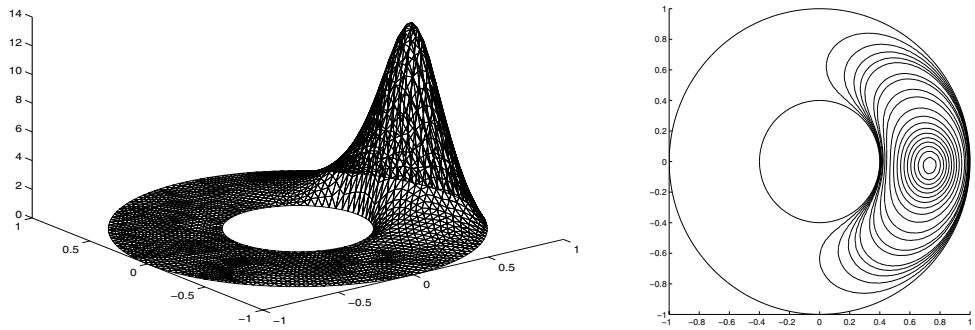

FIG. 7. $q = 2$. *A radially asymmetric ground state with* $J = 143.9674$.

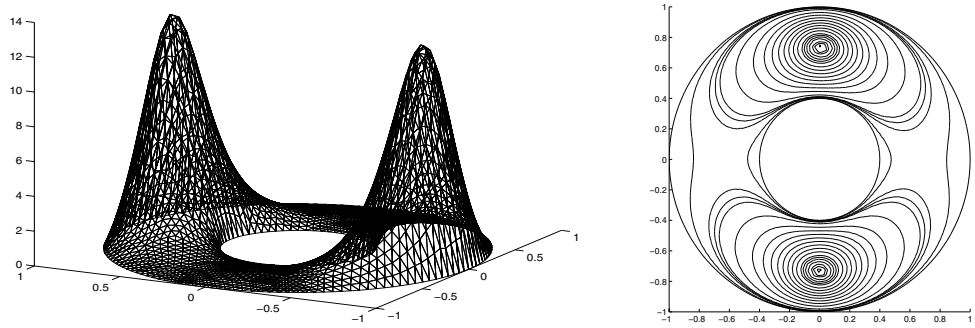

FIG. 8. $q = 2$. *An even* 2*-rotationally symmetric solution with* $J = 288.5556$.

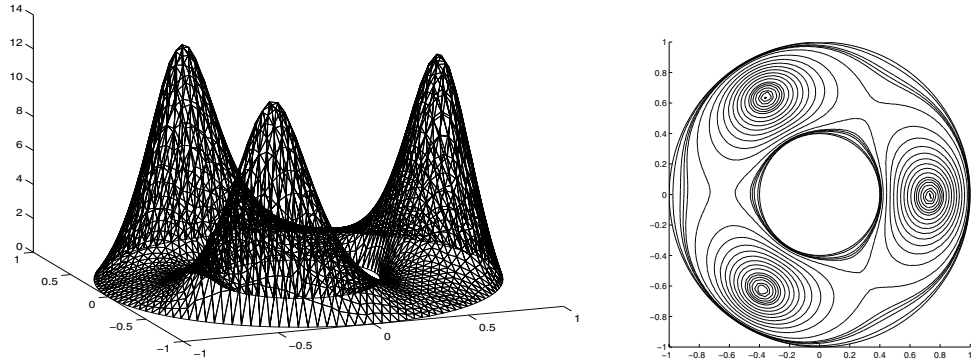

FIG. 9. $q = 2$. *A* 3*-rotationally symmetric solution with* $J = 429.9529$.

$\frac{1}{2}\pi < \tan^{-1}(\frac{x_2}{x_1}) < \frac{5}{6}\pi$ or $-\frac{5}{6}\pi < \tan^{-1}(\frac{x_2}{x_1}) < -\frac{1}{2}\pi$ and $c(x_1, x_2) = 0$ otherwise. u_0 is even 3-rotationally symmetric. First 2 MM iterations followed by 7 NM iterations yield a solution as in Figure 9 with $\varepsilon < 10^{-10}$.

(d) Using a radially symmetric initial guess u_0 by setting $c(x_1, x_2) \equiv -1$. Then

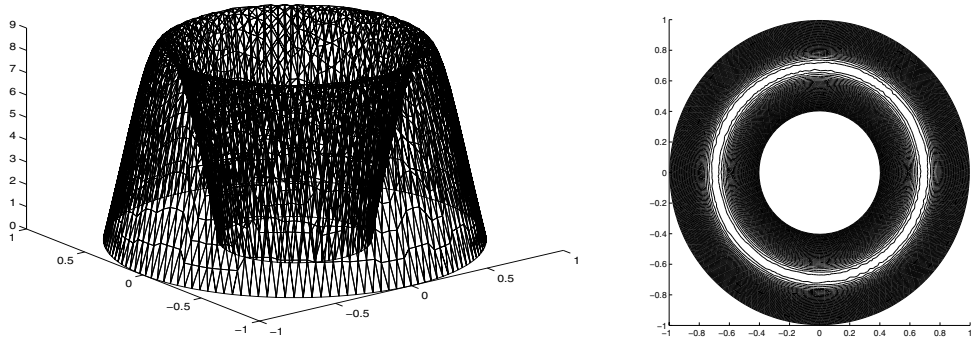

FIG. 10. $q = 2$. *The radially symmetric solution with* $J = 631.9575$.

4 NM iterations yield the radially symmetric solution as in Figure 10 with $\varepsilon < 10^{-7}$. But MM fails to find the solution without enforcing the symmetry.

For all numerical examples in this section, the Matlab PDE Toolbox is used to generate the domains and finite-element meshes and do computations. The Matlab function **assempde** is used to solve (3.3) for the Newton direction. Note that the degeneracy caused by symmetries in the examples is removable when a discretization is used. Since when the disk or annulus is discretized into finite-element grids, the continuous subgroup S^1 is approximated by a finite subgroup $S^1_n = \{g_i,\ i = 0, 1, \dots, n-1\}$ and the radial symmetry of the problem is approximated by the n-rotationally symmetry. With this approximation, the symmetric degeneracy of the problem is removed. Without a degeneracy, (3.3) is uniquely solvable and yields the Newton direction ν. By our analysis in section 2, (3.3) is solvable without numerical error and now it is also solvable with numerical error, therefore such an approximation or a refinement of discretization (finite-element grids) should be stable. Thus no Haar projection is needed.

With the local minimax-Newton algorithm, we are able to carry out many numerical investigations for examining the qualitative behavior and finding new phenomena of both positive and nodal solutions of nonlinear elliptic boundary value problems, e.g., the symmetry breaking and bifurcation phenomena, and the dependency of solutions on boundary approximation. We will address those new findings in subsequential papers.

Acknowledgment. The authors wish to thank two anonymous reviewers for their comments which stimulate us for this revision.

ON KOROBOV LATTICE RULES IN WEIGHTED SPACES*

XIAOQUN WANG†‡, IAN H. SLOAN‡, AND JOSEF DICK‡

Abstract. This paper studies the error bounds of multivariate integration in weighted function spaces using lattice rules of the Korobov form, in which the generating vector for an n-point rule with n prime has the form $(1, a, \ldots, a^{d-1}) (\mathrm{mod}\, n)$. With the parameter a chosen optimally, we establish new error bounds for Korobov lattice rules in weighted Korobov spaces. In particular, we prove that if the weights decay sufficiently fast, the optimal Korobov lattice rule has an error bound of order $O(n^{-\alpha/2+\delta})$ (for arbitrary $\delta > 0$), with the implied constant depending at worst polynomially on the dimension. Here $\alpha > 1$ is the smoothness parameter of the weighted Korobov spaces. We generalize the construction to the case where n is a product of arbitrary distinct prime numbers, with the purpose of reducing the construction cost without sacrificing much of the quality of the lattice rules. A corresponding result is deduced for weighted Sobolev spaces of nonperiodic functions, using randomly shifted optimal Korobov lattice rules. A comparison of the worst-case errors for Korobov lattice rules and the recent component-by-component constructions is presented. The investigation establishes the usefulness of (shifted) optimal Korobov lattice rules for integration, even in high dimensions, if the weights which characterize the weighted spaces are suitably chosen.

Key words. quasi-Monte Carlo methods, good lattice rules, multivariate integration

1. Introduction.

The computation of high-dimensional integrals plays a central role in many applications. Consider an integral over the d-dimensional unit cube

$$I_d(f) = \int_{[0,1)^d} f(\mathbf{x}) d\mathbf{x}.$$

We are mostly interested in cases where the dimension d is large. For large d, classical methods based on the Cartesian product of a one-dimensional integration rule (trapezoidal rule, Simpson's rule, Gaussian rule, etc.) are not practical because of the *curse of dimensionality*: the computational cost grows exponentially with the dimension. High-dimensional integrals are usually approximated by Monte Carlo or quasi-Monte Carlo (QMC) algorithms of the form

$$Q_{n,d}(f; \mathbf{P}_n) = \frac{1}{n} \sum_{k=0}^{n-1} f(\mathbf{x}_k),$$

where $\mathbf{P}_n = \{\mathbf{x}_0, \ldots, \mathbf{x}_{n-1}\} \subset [0,1)^d$ is a set of random points in Monte Carlo, or a set of points chosen in some deterministic way in QMC.

In the present work we consider only the special class of QMC algorithms known as rank-1 lattice rules (see [15, 19]) having the form

$$Q_{n,d}(f; \mathbf{P}_n) = \frac{1}{n} \sum_{k=0}^{n-1} f\left(\left\{ \frac{k\mathbf{z}}{n} \right\} \right), \tag{1}$$

where $\mathbf{z} = (z_1, \ldots, z_d)$, called the "generating vector," is an integer vector with no factor in common with n, and the notation $\{\mathbf{x}\}$ means that each component of $\mathbf{x}$ is replaced by its fractional part. The accuracy of a lattice rule depends on the generating vector $\mathbf{z}$ and on the functions f.

How should the vector $\mathbf{z}$ in (1) be chosen? In this paper we present new algorithms for choosing $\mathbf{z}$, in the setting of the "weighted" spaces of functions introduced by Sloan and Woźniakowski in [22, 23], and with the choice of $\mathbf{z}$ restricted to the very classical form introduced by Korobov [12, 13]: if n is prime,

$$\mathbf{z} := (1, a, \ldots, a^{d-1}) \,(\mathrm{mod}\, n), \tag{2}$$

where a is a suitable integer from the set $\{1, \ldots, n-1\}$. The role of the corresponding algorithm is then to make a "good" choice of a. The theory to be developed here guarantees that the worst-case error of the resulting algorithm in an appropriately weighted space grows only slowly with the dimension d.

The results to be obtained here will be compared to those for the recently proposed "component-by-component" (or CBC) constructions for the vector $\mathbf{z}$, investigated in [14, 21]. The present theoretical results are almost, but not quite, as good as those for the CBC constructions. (For the CBC construction the bound for the worst-case error in an appropriately weighted space does not grow at all with d, whereas for the present construction a polynomial growth with d is the best we can prove.)

On the other hand, the present algorithm is both simpler and faster if the algorithm is needed only for a single value of dimension d. (The cost of the present algorithm is $O(dn^2)$, whereas the cost of the CBC algorithm is $O(d^2n^2)$.) Moreover, the observed performance in the two cases (see section 6) turns out to be quite similar, in spite of the difference between the theoretical bounds.

It should be emphasized that the resulting vector $\mathbf{z}$, though of the classical Korobov form (2), will almost always be quite different from that produced by the classical algorithm. In the classical theory of lattice rules (see [15, 19]) the function f is assumed to be a periodic function in the Korobov class $E_{\alpha,d}(c)$, for $c > 0$ and $\alpha > 1$, which is the class of functions with Fourier coefficients $\widehat{f}(\mathbf{h})$ satisfying

$$|\widehat{f}(\mathbf{h})| \le \frac{c}{(\bar{h}_1 \cdots \bar{h}_d)^\alpha},$$

where $\mathbf{h} = (h_1, \ldots, h_d)$ with integers h_j,

$$\hat{f}(\mathbf{h}) = \int_{[0,1]^d} \exp(-2\pi i \mathbf{h} \cdot \mathbf{x}) f(\mathbf{x}) d\mathbf{x},$$

$\mathbf{h} \cdot \mathbf{x} = h_1 x_1 + \cdots + h_d x_d$, and $\bar{h}_j = \max(1, |h_j|)$. The classical quality measure for rank-1 lattice rules is the worst-case quadrature error P_α in the Korobov class $E_{\alpha,d}(1)$:

$$P_\alpha := \sup\{|I_d(f) - Q_{n,d}(f; \mathbf{P}_n)| : f \in E_{\alpha,d}(1)\} = \sum_{\mathbf{h}\cdot\mathbf{z} \equiv 0 \,(\mathrm{mod}\, n)}{}' \frac{1}{(\bar{h}_1 \cdots \bar{h}_d)^\alpha},$$

where the prime on the sum indicates that the term $\mathbf{h} = \mathbf{0}$ is omitted. For a function $f \in E_{\alpha,d}(c)$, a simple error bound for a rank-1 lattice rule is (see [15, 19])

$$\left| I_d(f) - \frac{1}{n} \sum_{k=0}^{n-1} f\left(\left\{ \frac{k\mathbf{z}}{n} \right\} \right) \right| \le c\, P_\alpha.$$

It has been known for many years [15, 19] that there exists a "good" generating vector $\mathbf{z}$ such that

$$P_\alpha = O(n^{-\alpha}(\log n)^\beta)$$

for some β of the order of d (this is nearly the best possible, since Sarygin [18] proved a general lower bound which shows that P_α is at least of the order of magnitude $O(n^{-\alpha}(\log n)^{d-1})$). For fixed dimension d, this convergence is asymptotically much faster than the Monte Carlo convergence $O(n^{-1/2})$. The problem for larger values of d is that the error bound for functions from the classical Korobov classes, even for the optimal lattice rules, is *exponentially* dependent on d. Integration problems where the dimension d is large occur commonly in practice, for example, in finance [1, 17]. For large d (say, $d > 10$), the advantage of the classical Korobov lattice rules disappears in this setting. In fact, in high dimensions the optimal Korobov lattice rules constructed in the classical way (using P_α as the measure) may lead to error bounds that are worse, or much worse, than those for the Monte Carlo algorithm. The possible poor quality of P_α as a criterion was already pointed out in [6]. Generalizations of P_α were studied in [8].

In many applications the importance of successive variables decreases (see [27] for examples in finance, where it was shown that the sensitivity indices of successive variables decrease). It is also common that the lower-order "interactions" among variables are more important than higher-order "interactions." Such properties of functions often lead to small *effective dimension* in truncation or in superposition sense (see [1, 16, 26]). The problem of why high-dimensional problems in finance are often of low effective dimension was investigated in [28]. Intuitively, functions of small effective dimension might be easier to integrate by QMC methods.

To quantify the different importance of variables, Sloan and Woźniakowski [22, 23] introduced *weighted* spaces, where a sequence of weights is introduced to characterize the relative importance of successive variables, with the products of the weights for a group of variables relating to the importance of that group. They proved nonconstructively that there exists a lattice rule for which the worst-case error is bounded in d, or grows only slowly with d, provided the weights decay sufficiently rapidly. In this setting the CBC constructions (see above) achieve the same bound, which is known (see [23]) to be optimal.

This paper is organized as follows. In the next section, we introduce weighted Korobov spaces. In section 3, we study the error bounds in those spaces of the QMC algorithms based on the optimal Korobov lattice rules when n is prime. In section 4, we generalize the results to the case of n being a product of several distinct primes. A brief investigation on weighted Sobolev spaces of nonperiodic functions is presented in section 5. A numerical comparison of the worst-case errors is given in section 6. Concluding remarks are presented in the last section.

2. Weighted Korobov spaces. Let H_d be a Hilbert space of functions defined on $[0,1)^d$ with norm $||\cdot||_{H_d}$. Define the worst-case error of the algorithm $Q_{n,d}(f;\mathbf{P}_n)$ as the worst-case error over the unit ball of H_d:

$$e(\mathbf{P}_n; H_d) = \sup\{|I_d(f) - Q_{n,d}(f;\mathbf{P}_n)| : f \in H_d, ||f||_{H_d} \le 1\}.$$

The worst-case error $e(\mathbf{P}_n; H_d)$ is a natural quality measure of an algorithm.

We now briefly describe the "weighted Korobov spaces" introduced in [23]. They are (weighted) L_2 versions of the classical Korobov spaces.

Let $\mathbf{Z} = \{\ldots, -1, 0, 1, \ldots\}$ be the set of integers and let $\mathbf{Z}^d$ be the Cartesian product of d copies of $\mathbf{Z}$. We define a *weighted* Korobov space $H(K_{d,\alpha,\gamma})$ with the following reproducing kernel:

$$K_{d,\alpha,\gamma}(\mathbf{x},\mathbf{y}) = \prod_{j=1}^{d}\left(1+\gamma_j \sum_{h\in\mathbf{Z}}{}' \frac{e^{2\pi i h(x_j-y_j)}}{|h|^\alpha}\right), \qquad \alpha>1,\ i=\sqrt{-1}, \tag{3}$$

where $\gamma := \{\gamma_j\}$ is a sequence of positive numbers, which quantify the relative importance of successive variables. These function spaces are spaces of periodic functions with absolutely convergent Fourier series. The smoothness parameter $\alpha > 1$ characterizes the rate of decay of the Fourier coefficients. If $\gamma_j = 1$ for all j, then the space $H(K_{d,\alpha,\gamma})$ is the L_2 version of the classical (unweighted) Korobov space. The space $H(K_{d,\alpha,\gamma})$ is equipped with the inner product

$$\langle f, g\rangle = \sum_{\mathbf{h}\in\mathbf{Z}^d}\left[\prod_{j=1}^{d} r_\alpha(\gamma_j,h_j)\right]\ \hat{f}(\mathbf{h})\,\overline{\hat{g}(\mathbf{h})},$$

where

$$r_\alpha(\gamma,h) = \begin{cases} 1 & \text{if } h=0,\\ \gamma^{-1}|h|^\alpha & \text{if } h\neq 0.\end{cases}$$

Note that if a weight γ_j is small, then a function $f(\mathbf{x})$ with a norm at most 1 can depend only weakly on the jth variable. In this sense, the weights characterize the relative importance of variables.

For the lattice points (1) with the generating vector $\mathbf{z}$, the corresponding squared worst-case error can be expressed as (see [23])

$$e^2_{n,d}(\mathbf{z}) := e^2(\mathbf{P}_n; H(K_{d,\alpha,\gamma})) = -1+\frac{1}{n}\sum_{k=0}^{n-1}\prod_{j=1}^{d}\left(1+\gamma_j\sum_{h\in\mathbf{Z}}{}'\frac{\exp(2\pi i h k z_j/n)}{|h|^\alpha}\right). \tag{4}$$

For the case where α is an even integer, it is known that

$$\sum_{h\in\mathbf{Z}}{}'\frac{e^{2\pi i h x}}{|h|^\alpha} = \frac{(2\pi)^\alpha}{(-1)^{\frac{\alpha}{2}+1}\alpha!}\,B_\alpha(x), \qquad x\in[0,1], \tag{5}$$

where $B_\alpha(x)$ is the Bernoulli polynomial of degree α. In particular, $B_2(x) = x^2 - x + 1/6$. Thus the infinite sum in the formula of the worst-case error (4) can be computed easily when α is even.

3. The error bounds for optimal Korobov lattice rules. Suppose initially that n is prime. Consider the generators of Korobov form:

$$\mathbf{z}_1(a) := (1, a, \ldots, a^{d-1}) \,(\mathrm{mod}\, n) \ \text{ with } \ a\in\{1,2,\ldots,n-1\}. \tag{6}$$

Such generators have been used in the classical unweighted Korobov spaces, as mentioned in the introduction. Here we use these generators in the weighted Korobov spaces. The quality measure used is the worst-case error instead of the classical quantity P_α. The algorithm to find the optimal Korobov lattice rules in the weighted Korobov spaces is as follows.

ALGORITHM 1 (for prime n). *For each fixed dimension d and given weights $\{\gamma_j\}$, the optimal Korobov generator is found by minimizing the squared worst-case error*

$$e^2_{n,d}(\mathbf{z}_1(a)) = -1 + \frac{1}{n}\sum_{k=0}^{n-1}\prod_{j=1}^{d}\left(1+\gamma_j \sum_{h\in\mathbf{Z}}{}' \frac{\exp\left(2\pi i k h a^{j-1}/n\right)}{|h|^\alpha}\right)$$

with respect to $a \in \{1,2,\dots,n-1\}$, where $\mathbf{z}_1(a)$ is a vector in Korobov form (6).

We emphasize that the optimal Korobov generator depends on the weights γ_j. The number of operations needed to find the optimal Korobov lattice rule for even α and a single dimension d is $O(dn^2)$.

Let a_* be a minimizer of $e^2_{n,d}(\mathbf{z}_1(a))$. To see how small $e_{n,d}(\mathbf{z}_1(a_*))$ might be, we define

$$M_{n,d}(\alpha) := \frac{1}{n-1}\sum_{a=1}^{n-1} e^2_{n,d}\left(\mathbf{z}_1(a)\right), \tag{7}$$

the average of the squared worst-case error over all lattice rules of the Korobov form (6). We have the following results.

THEOREM 1. *Suppose n is a prime number and $M_{n,d}(\alpha)$ is defined by* (7)*; then*

$$M_{n,d}(\alpha) \le \frac{d}{n-1}\exp\left(2\zeta(\alpha)\sum_{j=1}^{d}\gamma_j\right),$$

where ζ is the Riemann zeta function, $\zeta(\alpha) = \sum_{h=1}^{\infty} h^{-\alpha}$ (for $\alpha > 1$). Hence, the optimal Korobov generator $\mathbf{z}_1(a_*) = (1, a_*, \dots, a_*^{d-1}) \pmod n$ obtained from Algorithm 1 satisfies

$$e^2_{n,d}(\mathbf{z}_1(a_*)) \le \frac{d}{n-1}\exp\left(2\zeta(\alpha)\sum_{j=1}^{d}\gamma_j\right). \tag{8}$$

For the proof it is convenient to make use of the following two lemmas. The first lemma gives an equivalent expression for the worst-case error $e_{n,d}(\mathbf{z})$. Similar expressions appeared in [19, 23].

LEMMA 2. *For the rank-1 lattice points* (1)*, the squared worst-case error in the weighted Korobov spaces $H(K_{d,\alpha,\gamma})$ can be written as*

$$e^2_{n,d}(\mathbf{z}) = \sum_{\mathbf{h}\in\mathbf{Z}^d}{}' \frac{\delta_n(\mathbf{h}\cdot\mathbf{z})}{\prod_{j=1}^{d} r_\alpha(\gamma_j, h_j)},$$

where

$$\delta_n(m) = \begin{cases} 1 & \text{if } m \equiv 0 \pmod n, \\ 0 & \text{if } m \not\equiv 0 \pmod n. \end{cases}$$

It is clear that if $\gamma_j = 1$ for all j, then $e^2_{n,d}(\mathbf{z}) = P_\alpha$. Thus the worst-case error is a natural generalization of the classical quality measure P_α.

The next lemma is well known in number theory (see [5]). It is significant when n is much larger than d (which is usually true in numerical integration) and is important for establishing the error bounds.

LEMMA 3. *Suppose that n is prime. Let $g(x) := h_1 + h_2 x + \cdots + h_d x^{d-1} = \mathbf{h} \cdot (1, x, \ldots, x^{d-1})$ be a polynomial with integer coefficients $h_1, \ldots, h_d$. Let $A_n(\mathbf{h})$ be the number of integers x with $0 \le x \le n-1$ satisfying $g(x) \equiv 0 \pmod n$. Let D be the greatest common divisor of $h_1, \ldots, h_d$. Then*

$$A_n(\mathbf{h}) \begin{cases} = n & \text{if } D \equiv 0 \pmod n, \\ \le (d-1) & \text{if } D \not\equiv 0 \pmod n. \end{cases}$$

Proof of Theorem 1. From Lemma 2 and the definition of $M_{n,d}(\alpha)$, we have

$$\begin{aligned} M_{n,d}(\alpha) &= \frac{1}{n-1} \sum_{a=1}^{n-1} {\sum_{\mathbf{h} \in \mathbf{Z}^d}}' \frac{\delta_n(\mathbf{h} \cdot \mathbf{z}_1(a))}{\prod_{j=1}^d r_\alpha(\gamma_j, h_j)} \\ &= \frac{1}{n-1} {\sum_{\mathbf{h} \in \mathbf{Z}^d}}' \prod_{j=1}^d [r_\alpha(\gamma_j, h_j)]^{-1} \sum_{a=1}^{n-1} \delta_n\left(\mathbf{h} \cdot (1, a, \ldots, a^{d-1})\right) \\ &=: S_1 + S_2, \end{aligned}$$

where in the last step the sum over $\mathbf{h}$ is split into two sums S_1 and S_2, with S_1 being the sum over all those $\mathbf{h}$ such that at least one component of $\mathbf{h}$ is not a multiple of n, and S_2 being the sum over all those nonzero $\mathbf{h}$ such that each component is a multiple of n.

For the first sum S_1, since at least one of the components of $\mathbf{h}$ is not a multiple of n, and since n is prime, we have $\gcd(h_1, \ldots, h_d) \not\equiv 0 \pmod n$. From Lemma 3, it follows that

$$\sum_{a=1}^{n-1} \delta_n\left(\mathbf{h} \cdot (1, a, \ldots, a^{d-1})\right) \le \sum_{a=0}^{n-1} \delta_n\left(\mathbf{h} \cdot (1, a, \ldots, a^{d-1})\right) = A_n(\mathbf{h}) \le d-1,$$

where $A_n(\mathbf{h})$ is defined in Lemma 3. Thus we have

$$\begin{aligned} S_1 &\le \frac{d-1}{n-1} {\sum_{\mathbf{h} \in \mathbf{Z}^d}}' \prod_{j=1}^d [r_\alpha(\gamma_j, h_j)]^{-1} \\ &< \frac{d-1}{n-1} \prod_{j=1}^d \left(1 + \gamma_j {\sum_{h \in \mathbf{Z}}}' |h|^{-\alpha}\right) \\ &= \frac{d-1}{n-1} \prod_{j=1}^d (1 + 2\zeta(\alpha)\gamma_j) \\ &= \frac{d-1}{n-1} \exp\left(\sum_{j=1}^d \log(1 + 2\zeta(\alpha)\gamma_j)\right) \\ &\le \frac{d-1}{n-1} \exp\left(2\zeta(\alpha) \sum_{j=1}^d \gamma_j\right). \end{aligned}$$

For the second sum S_2, since each component of the corresponding $\mathbf{h}$ is a multiple of n, i.e., $\mathbf{h} = (nm_1, \ldots, nm_d)$ for some nonzero integer vector $\mathbf{m} = (m_1, \ldots, m_d) \in \mathbf{Z}^d$, we have for arbitrary $a = 1, \ldots, n-1$ that

$$\delta_n\left(\mathbf{h} \cdot (1, a, \ldots, a^{d-1})\right) = \delta_n\left(n\mathbf{m} \cdot (1, a, \ldots, a^{d-1})\right) = 1.$$

Therefore,

$$\begin{aligned}
S_2 &= \frac{1}{n-1} {\sum_{\mathbf{m}\in\mathbf{Z}^d}}' \prod_{j=1}^{d} [r_\alpha(\gamma_j, nm_j)]^{-1} \sum_{a=1}^{n-1} \delta_n\left(n\mathbf{m}\cdot(1,a,\dots,a^{d-1})\right) \\
&= {\sum_{\mathbf{m}\in\mathbf{Z}^d}}' \prod_{j=1}^{d} [r_\alpha(\gamma_j, nm_j)]^{-1} \\
&= \prod_{j=1}^{d} \left(1 + \gamma_j {\sum_{m\in\mathbf{Z}}}' n^{-\alpha}|m|^{-\alpha}\right) - 1 \\
&= \prod_{j=1}^{d} \left(1 + \frac{2\zeta(\alpha)\gamma_j}{n^\alpha}\right) - 1 \\
&\le \frac{1}{n^\alpha} \prod_{j=1}^{d} (1 + 2\zeta(\alpha)\gamma_j) \\
&\le \frac{1}{n^\alpha} \exp\left(2\zeta(\alpha) \sum_{j=1}^{d} \gamma_j\right) \\
&< \frac{1}{n-1} \exp\left(2\zeta(\alpha) \sum_{j=1}^{d} \gamma_j\right).
\end{aligned}$$

Finally, we obtain

$$M_{n,d}(\alpha) = S_1 + S_2 \le \frac{d}{n-1} \exp\left(2\zeta(\alpha) \sum_{j=1}^{d} \gamma_j\right).$$

This completes the proof of the first part.

The second assertion is obvious: the squared worst-case error corresponding to the optimal Korobov generator $\mathbf{z}_1(a_*)$ is no larger than the average $M_{n,d}(\alpha)$; thus the bound (8) is satisfied. □

Note that the bound (8) is significant only when n is much larger than d (which is usually the case in numerical integration). If $\gamma_j = 1$ for all j as in the classical case, the upper bound (8) depends on d *exponentially*, whereas if $\sum_{j=1}^{\infty} \gamma_j < \infty$, then it depends only *linearly* on d. The factor of d is not present in the error bound for the global *optimal* rank-1 lattice rule in weighted Korobov spaces (see [23]). The convergence order shown in Theorem 1 is only $O(n^{-1/2})$ for fixed d, the same as that of the Monte Carlo algorithm. A higher convergence order can be proved if the weights decay sufficiently fast. In the optimal case, the convergence order can be $O(n^{-\alpha/2+\delta})$ (for any $\delta > 0$), with the implied constant depending at worst polynomially on d.

Before we state and prove the next theorem, we recall Jensen's inequality:

$$\sum_k A_k \le \left(\sum A_k^\beta\right)^{1/\beta} \quad \text{for } 0 < \beta \le 1,$$

where A_k are nonnegative numbers.

THEOREM 4. *Let n be a prime and $\mathbf{z}_1(a_*)$ be the optimal Korobov generator found by Algorithm* 1.

(i) *For arbitrary* $\tau \in [1, \alpha)$, *we have*

$$e_{n,d}(\mathbf{z}_1(a_*)) \le C_d(\alpha,\tau)\left(\frac{d}{n-1}\right)^{\tau/2}, \tag{9}$$

where

$$C_d(\alpha,\tau) = \exp\left(\tau\zeta(\alpha/\tau)\sum_{j=1}^{d}\gamma_j^{1/\tau}\right). \tag{10}$$

(ii) *Suppose the weight sequence* $\{\gamma_j\}$ *satisfies* $\sum_{j=1}^{\infty}\gamma_j < \infty$. *Let* τ_0 *be defined by*

$$\tau_0 := \sup\left\{\tau : \sum_{j=1}^{\infty}\gamma_j^{1/\tau} < \infty\right\}.$$

Then for any $\tau \in [1, \min(\tau_0, \alpha))$ (*or if* $\tau_0 = 1$, *put* $\tau = 1$), *we have*

$$C_d(\alpha,\tau) \le C_\infty(\alpha,\tau) := \lim_{d\to\infty} C_d(\alpha,\tau) < \infty;$$

i.e., $C_d(\alpha,\tau)$ *is uniformly bounded in* d *and the bound* (9) *is polynomial in dimension* d.

(iii) *Suppose that*

$$B^* := \limsup_{d\to\infty}\frac{\sum_{j=1}^{d}\gamma_j}{\log d} < \infty.$$

Then for any $\delta > 0$, *there exists a constant* C_δ *independent of* d *and* n, *such that*

$$e_{n,d}(\mathbf{z}_1(a_*)) \le C_\delta\, d^{1/2+\zeta(\alpha)(B^*+\delta)}(n-1)^{-1/2}.$$

Proof. We introduce temporarily an alternative notation $e_{n,d}(\mathbf{z},\alpha,\gamma)$ for the worst-case error $e_{n,d}(\mathbf{z})$ to stress its dependence on the parameter α and the weight sequence $\{\gamma_j\}$. According to Lemma 2, we have

$$e^2_{n,d}(\mathbf{z},\alpha,\gamma) = \sum_{\mathbf{h}\in\mathbf{Z}^d}{}' \frac{\delta_n(\mathbf{h}\cdot\mathbf{z})}{\prod_{j=1}^{d} r_\alpha(\gamma_j,h_j)} = \sum_{\mathbf{h}\cdot\mathbf{z}\equiv 0 \,(\mathrm{mod}\, n)}{}' \prod_{j=1}^{d}[r_\alpha(\gamma_j,h_j)]^{-1}.$$

By applying the Jensen inequality to the sum on the right-hand side, we have

$$e^2_{n,d}(\mathbf{z},\alpha,\gamma) \le \left(\sum_{\mathbf{h}\cdot\mathbf{z}\equiv 0 \,(\mathrm{mod}\, n)}{}' \prod_{j=1}^{d}[r_\alpha(\gamma_j,h_j)]^{-\beta}\right)^{1/\beta} = \left(e^2_{n,d}(\mathbf{z},\alpha\beta,\gamma^\beta)\right)^{1/\beta} \tag{11}$$

for $\frac{1}{\alpha} < \beta \le 1$, where γ^β means the weight sequence with values γ_j^β, and we use the relation that $[r_\alpha(\gamma,h)]^\beta = r_{\alpha\beta}(\gamma^\beta,h)$.

We see from Theorem 1, with α replaced by $\alpha\beta$ and γ_j replaced by γ_j^β, that there exists a generator of Korobov form $\overline{\mathbf{z}}_\beta = (1,\overline{a},\ldots,\overline{a}^{d-1}) \,(\mathrm{mod}\, n)$ such that

$$e^2_{n,d}(\overline{\mathbf{z}}_\beta,\alpha\beta,\gamma^\beta) \le \frac{d}{n-1}\exp\left(2\zeta(\alpha\beta)\sum_{j=1}^{d}\gamma_j^\beta\right).$$

(Note that since $\frac{1}{\alpha} < \beta$, we have $\alpha\beta > 1$ and thus $\zeta(\alpha\beta)$ is finite.) Thus for this $\overline{\mathbf{z}}_\beta$, we have from (11)

$$e^2_{n,d}(\overline{\mathbf{z}}_\beta, \alpha, \gamma) \le \left(\frac{d}{n-1}\right)^{1/\beta} \exp\left(\frac{2}{\beta}\zeta(\alpha\beta)\sum_{j=1}^{d}\gamma_j^\beta\right).$$

Therefore, for the optimal Korobov form generator $\mathbf{z}_1(a_*)$ we have for any $\frac{1}{\alpha} < \beta \le 1$ that

$$e^2_{n,d}(\mathbf{z}_1(a_*), \alpha, \gamma) \le \left(\frac{d}{n-1}\right)^{1/\beta} \exp\left(\frac{2}{\beta}\zeta(\alpha\beta)\sum_{j=1}^{d}\gamma_j^\beta\right). \tag{12}$$

For any $\tau \in [1, \alpha)$, putting $\beta = 1/\tau$ in (12), the error bound (9) follows immediately.

Now we prove (ii). Since $\sum_{j=1}^{\infty}\gamma_j < \infty$, we have $\tau_0 \ge 1$. If $\tau_0 = 1$, the result is trivial. If $\tau_0 > 1$, then for any $\tau \in [1, \min(\tau_0, \alpha))$, we have

$$C_d(\alpha, \tau) \le \exp\left(\tau\zeta(\alpha/\tau)\sum_{j=1}^{\infty}\gamma_j^{1/\tau}\right) := C_\infty(\alpha, \tau).$$

Clearly, $C_\infty(\alpha, \tau)$ is a constant independent of d and n. It is well defined: $\zeta(\alpha/\tau)$ is finite since $\tau < \alpha$, and $\sum_{j=1}^{\infty}\gamma_j^{1/\tau}$ converges since $\tau < \tau_0$. Thus the constant $C_d(\alpha, \tau)$ is uniformly bounded in d, and the bound (9) is polynomial in d.

Now we prove (iii). Since B^* is finite, we have that for any $\delta > 0$ there exists d_δ such that

$$\sum_{j=1}^{d}\gamma_j \le (B^* + \delta)\log d \quad \forall d \ge d_\delta.$$

Hence, from Theorem 1 we have for $d \ge d_\delta$ that

$$M_{n,d}(\alpha) \le \frac{d}{n-1}\exp\left(2\zeta(\alpha)(B^* + \delta)\log d\right) = \frac{1}{n-1}\, d^{1+2\zeta(\alpha)(B^*+\delta)}.$$

Thus there exists a constant C_δ^2 such that for all $d \ge 1$

$$M_{n,d}(\alpha) \le C_\delta^2\, d^{1+2\zeta(\alpha)(B^*+\delta)}(n-1)^{-1}.$$

Therefore, the optimal Korobov lattice rule satisfies

$$e^2_{n,d}(\mathbf{z}_1(a_*)) \le C_\delta^2\, d^{1+2\zeta(\alpha)(B^*+\delta)}(n-1)^{-1}.$$

This concludes the proof. ∎

4. Korobov lattice rules with nonprime number of points. The number of operations to find an optimal Korobov lattice rule needed in Algorithm 1 is $O(dn^2)$. For large n, this is expensive. The search cost can be substantially reduced if we allow the number of points to be a nonprime number. In this section we study the cases where the number of points n is large and is the product of distinct primes. We first consider the case of two distinct prime numbers, then we generalize to the case of an arbitrary number of distinct primes.

4.1. The case of two distinct primes. Consider the case where $n = pq$, with p and q being two distinct primes. The Korobov construction [13] can also be generalized to the weighted Korobov spaces. The algorithm is as follows.

ALGORITHM 2 (for $n = pq$).

(i) *Find the optimal* $a_* \in \{1, 2, \ldots, p-1\}$ *by using Algorithm* 1 *in section* 3, *but with* n *replaced by* p.

(ii) *Let the generating vector* $\mathbf{z}_2(b)$ *be of the form*

(13)
$$\mathbf{z}_2(b) := \left(p\,(1, b, \ldots, b^{d-1}) + q\,(1, a_*, \ldots, a_*^{d-1})\right) (\mathrm{mod}\ pq), \quad b \in \{1, 2, \ldots, q-1\},$$

where $a_* \in \{1, 2, \ldots, p-1\}$ *is the number obtained in step* (i). *Find the optimal* $b_* \in \{1, \ldots, q-1\}$ *such that the squared worst-case error*

$$e^2_{pq,d}(\mathbf{z}_2(b)) = -1 + \frac{1}{pq} \sum_{k=0}^{pq-1} \prod_{j=1}^{d} \left(1 + \gamma_j \sum_{h \in \mathbf{Z}}{}' \frac{\exp[2\pi i h k (p b^{j-1} + q a_*^{j-1})/(pq)]}{|h|^\alpha}\right)$$

is minimized with respect to b. *We obtain the optimal Korobov generator* $\mathbf{z}_2(b_*)$.

In order to study the worst-case error corresponding to the optimal Korobov generator $\mathbf{z}_2(b_*)$, we define

$$\widetilde{M}_{n,d}(\alpha) := \frac{1}{q-1} \sum_{b=1}^{q-1} e^2_{n,d}\left(\mathbf{z}_2(b)\right), \tag{14}$$

which is the average (over all b) of the squared worst-case error of the lattice rules with the generators of the form (13). We have the following bound.

THEOREM 5. *Suppose* $n = pq$, *with* p *and* q *being two distinct primes. Let* $\widetilde{M}_{n,d}(\alpha)$ *be defined by* (14); *then*

$$\widetilde{M}_{n,d}(\alpha) \le \frac{d^2}{(p-1)(q-1)} \exp\left(2\zeta(\alpha) \sum_{j=1}^{d} \gamma_j\right).$$

The squared worst-case error $e^2_{n,d}(\mathbf{z}_2(b_*))$ *corresponding to the optimal Korobov generator* $\mathbf{z}_2(b_*)$ *satisfies the same upper bound.*

Proof. From Lemma 2 we have

$$e^2_{n,d}(\mathbf{z}_2(b)) = \sum_{\mathbf{h} \in \mathbf{Z}^d}{}' \frac{\delta_{pq}(\mathbf{h} \cdot \mathbf{z}_2(b))}{\prod_{j=1}^{d} r_\alpha(\gamma_j, h_j)}. \tag{15}$$

Note that for integers n_1 and n_2, if $\gcd(p, q) = 1$ (which is certainly satisfied if p and q are distinct prime numbers), then $n_1 p + n_2 q \equiv 0 \pmod{pq}$ is equivalent to $n_1 \equiv 0 \pmod{q}$ and $n_2 \equiv 0 \pmod{p}$. Thus

$$\begin{aligned}\delta_{pq}(\mathbf{h} \cdot \mathbf{z}_2(b)) &= \delta_{pq}\left(p\,\mathbf{h} \cdot (1, b, \ldots, b^{d-1}) + q\,\mathbf{h} \cdot (1, a_*, \ldots, a_*^{d-1})\right) \\ &= \delta_p\left(\mathbf{h} \cdot (1, a_*, \ldots, a_*^{d-1})\right)\ \delta_q\left(\mathbf{h} \cdot (1, b, \ldots, b^{d-1})\right).\end{aligned}$$

Based on this equality, from (14) and (15) we have

$$\widetilde{M}_{n,d}(\alpha) = \frac{1}{q-1} \sum_{b=1}^{q-1} \sum_{\mathbf{h} \in \mathbf{Z}^d}{}' \frac{\delta_n(\mathbf{h} \cdot \mathbf{z}_2(b))}{\prod_{j=1}^{d} r_\alpha(\gamma_j, h_j)}$$

$$= \frac{1}{q-1} \sum_{\mathbf{h}\in\mathbf{Z}^d}{}' \frac{\delta_p\left(\mathbf{h}\cdot(1,a_*,\ldots,a_*^{d-1})\right)}{\prod_{j=1}^d r_\alpha(\gamma_j,h_j)} \sum_{b=1}^{q-1} \delta_q\left(\mathbf{h}\cdot(1,b,\ldots,b^{d-1})\right)$$
$$=: R_1 + R_2,$$

where in the last step the sum over $\mathbf{h}$ is split into R_1 and R_2, with R_1 being the sum over all those $\mathbf{h}\in\mathbf{Z}^d$ such that at least one component of $\mathbf{h}$ is not a multiple of q, and R_2 being the sum over all those nonzero $\mathbf{h}\in\mathbf{Z}^d$ such that each component is a multiple of q.

Consider the first sum R_1. Since q is a prime number, according to Lemma 3 we have

$$\sum_{b=1}^{q-1} \delta_q\left(\mathbf{h}\cdot(1,b,\ldots,b^{d-1})\right) \le A_q(\mathbf{h}) \le d-1.$$

Thus

$$R_1 \le \frac{d-1}{q-1} \sum_{\mathbf{h}\in\mathbf{Z}^d}{}' \frac{\delta_p\left(\mathbf{h}\cdot(1,a_*,\ldots,a_*^{d-1})\right)}{\prod_{j=1}^d r_\alpha(\gamma_j,h_j)} = \frac{d-1}{q-1}\, e_{p,d}^2(\mathbf{z}_1(a_*)),$$

where $\mathbf{z}_1(a_*) = (1,a_*,\ldots,a_*^{d-1}) \pmod p$ is the optimal generator found in step (i) of Algorithm 2.

For the second sum R_2, each component of the corresponding $\mathbf{h}$ is a multiple of q; i.e., $\mathbf{h} = (qm_1,\ldots,qm_d)$ for some nonzero integer vector $\mathbf{m} = (m_1,\ldots,m_d)\in\mathbf{Z}^d$. So for arbitrary $b = 1,\ldots,q-1$, we have

$$\delta_q\left(\mathbf{h}\cdot(1,b,\ldots,b^{d-1})\right) = 1.$$

Thus

$$R_2 = \sum_{\mathbf{m}\in\mathbf{Z}^d}{}' \frac{\delta_p\left(\mathbf{m}\cdot(1,a_*,\ldots,a_*^{d-1})\right)}{\prod_{j=1}^d r_\alpha(\gamma_j,qm_j)} \le \frac{1}{q^\alpha} \sum_{\mathbf{m}\in\mathbf{Z}^d}{}' \frac{\delta_p\left(\mathbf{m}\cdot(1,a_*,\ldots,a_*^{d-1})\right)}{\prod_{j=1}^d r_\alpha(\gamma_j,m_j)} \le \frac{1}{q-1}\, e_{p,d}^2(\mathbf{z}_1(a_*)).$$

Finally, we have

$$\widetilde{M}_{n,d}(\alpha) = R_1 + R_2 \le \frac{d}{q-1}\, e_{p,d}^2(\mathbf{z}_1(a_*)), \tag{16}$$

and therefore,

$$e_{n,d}^2(\mathbf{z}_2(b_*)) \le \frac{d}{q-1}\, e_{p,d}^2(\mathbf{z}_1(a_*)). \tag{17}$$

Since $\mathbf{z}_1(a_*)$ is the optimal Korobov generator found in step (i) of Algorithm 2 with the number of points p (which is a prime), from Theorem 1 it follows that

$$e_{p,d}^2(\mathbf{z}_1(a_*)) \le \frac{d}{(p-1)} \exp\left(2\zeta(\alpha)\sum_{j=1}^d \gamma_j\right).$$

Combining this inequality with (16) and (17), the results follow immediately. ∎

From (17) one can see that there is a guarantee that $e_{pq,d}(\mathbf{z}_2(b_*))$ is less than $e_{p,d}(\mathbf{z}_1(a_*))$ only if $q > d+1$.

Remark 1. From the nature of the proof, the relations (16) and (17) can be generalized as follows: Let p be an integer and q be a prime. If $\gcd(p,q) = 1$, then for an arbitrary vector $\mathbf{z} = (z_1, \ldots, z_d)$ with $z_j \in \{1, \ldots, p-1\}$, there exists $\overline{b} \in \{1, \ldots, q-1\}$ such that

$$e^2_{pq,d}\left(\left(p\ \left(1, \overline{b}, \ldots, \overline{b}^{d-1}\right) + q\mathbf{z}\right)\ (\mathrm{mod}\ pq)\right) \le \frac{d}{q-1}\ e^2_{p,d}(\mathbf{z}).$$

This relation will be useful in the next subsection.

Based on Theorem 5, similar error bounds to those in Theorem 4 can be proved for the optimal Korobov lattice rules constructed by Algorithm 2.

THEOREM 6. *Let $n = pq$, with p and q being two distinct primes, and let $\mathbf{z}_2(b_*)$ be the optimal Korobov generator found by Algorithm* 2.

(i) *For arbitrary $\tau \in [1, \alpha)$, we have*

$$e_{n,d}(\mathbf{z}_2(b_*)) \le C_d(\alpha,\tau) d^{1+\tau/2}(p-1)^{-\tau/2}(q-1)^{-1/2}, \tag{18}$$

where $C_d(\alpha,\tau)$ is defined in (10). *The quantity $C_d(\alpha,\tau)$ is uniformly bounded in d under the same conditions as in Theorem* 4(ii).

(ii) *Let B^* be the same as in Theorem* 4(iii). *Then the optimal Korobov generator $\mathbf{z}_2(b_*)$ satisfies*

$$e_{n,d}(\mathbf{z}_2(b_*)) \le C_\delta\ d^{1+\zeta(\alpha)(B^*+\delta)}(p-1)^{-1/2}(q-1)^{-1/2} \quad \forall \delta > 0,$$

where C_δ is a constant independent of d and n.

Proof. From Theorem 4(i), for any $\tau \in [1, \alpha)$ we have (with n replaced by p in (9))

$$e_{p,d}(\mathbf{z}_1(a_*)) \le C_d(\alpha,\tau) d^{\tau/2}(p-1)^{-\tau/2}, \tag{19}$$

where the constant $C_d(\alpha,\tau)$ is given in (10). Combining this inequality with (17), the error bound (18) follows immediately. The conclusion (ii) can be proved by combining Theorem 4(iii) with the relation (17). ∎

Remark 2. From Theorem 6, for fast decaying weights the improved convergence (or even nearly the optimal convergence) for the case of $n = pq$ can only be achieved by the first factor p. For the other factor q, the low convergence order $O(q^{-1/2})$ remains the same as in Theorem 5. The same happens in the CBC construction of lattice rules [3].

4.2. The case of multiple distinct primes. Now we consider the case of $n = \prod_{j=1}^t p_j$, with $p_1, p_2, \ldots, p_t$ being distinct primes ($t \ge 2$). Algorithm 2 in the previous subsection can be generalized as follows.

ALGORITHM 3 (for $n = \prod_{j=1}^t p_j$).

(i) *Find the optimal $a_1 \in \{1, \ldots, p_1 - 1\}$ using Algorithm* 1 *in section* 3, *but with n replaced by p_1. We obtain a vector $\mathbf{z}_1(a_1) := (1, a_1, \ldots, a_1^{d-1})\ (\mathrm{mod}\, p_1)$.*

(ii) *For fixed $\ell = 2, \ldots, t$, let $p := \prod_{j=1}^{\ell-1} p_j$ and $q := p_\ell$. Let the generating vector $\mathbf{z}_\ell(a)$ be of the form*

$$\mathbf{z}_\ell(a) := \left(p\ (1, a, \ldots, a^{d-1}) + q\, \mathbf{z}_{\ell-1}(a_{\ell-1})\right)\ (\mathrm{mod}\, pq),$$

where $\mathbf{z}_{\ell-1}(a_{\ell-1})$ *is the vector found in the previous step. Find the optimal* $a_\ell \in \{1,\dots,p_\ell-1\}$*, such that the following squared worst-case error is minimized with respect to* a*:*

$$e^2_{pq,d}(\mathbf{z}_\ell(a)) = -1 + \frac{1}{pq}\sum_{k=0}^{pq-1}\prod_{j=1}^{d}\left(1+\gamma_j\sum_{h\in\mathbf{Z}}{}'\,\frac{\exp\left(2\pi i hk(pa^{j-1}+qa_{\ell-1}^{j-1})/(pq)\right)}{|h|^\alpha}\right).$$

At the last step, we obtain the optimal generator $\mathbf{z}_t(a_t)$. We shall still call the resulting lattice rule an optimal Korobov lattice rule (though it is not of the original Korobov form any more).

THEOREM 7. *Suppose* $n=\prod_{j=1}^t p_j$*, with* $p_1,\dots,p_t$ *being distinct primes* ($t\ge 2$)*. Let* $\mathbf{z}_t(a_t)$ *be the final optimal generator found by Algorithm* 3*. Then*

$$e^2_{n,d}(\mathbf{z}_t(a_t)) \le \frac{d^t}{\prod_{j=1}^t(p_j-1)}\exp\left(2\zeta(\alpha)\sum_{j=1}^{d}\gamma_j\right).$$

Proof. Let $a_1,a_2,\dots,a_t$ be the integers found in successive steps of Algorithm 3 and let $\mathbf{z}_1(a_1),\mathbf{z}_2(a_2),\dots,\mathbf{z}_t(a_t)$ be the corresponding vectors. For any fixed ℓ with $2\le\ell\le t$, let $p=\prod_{j=1}^{\ell-1}p_j$ and $q=p_\ell$. Since $p_1,\dots,p_\ell$ are distinct primes, we have $\gcd(p,q)=1$ and q is prime. Similar arguments as those presented in Theorem 5, which led to relation (17), are applicable here (see Remark 1 in the previous subsection). Thus we have a recursive relation

$$e^2_{pq,d}(\mathbf{z}_\ell(a_\ell)) \le \frac{d}{q-1}\,e^2_{p,d}(\mathbf{z}_{\ell-1}(a_{\ell-1})),\quad \ell=2,\dots,t.$$

Using this recursive relation, we have

$$\begin{aligned} e^2_{p_1\cdots p_t,d}(\mathbf{z}_t(a_t)) &\le \frac{d^{t-1}}{\prod_{j=2}^t(p_j-1)}\,e^2_{p_1,d}(\mathbf{z}_1(a_1)) \\ &\le \frac{d^t}{\prod_{j=1}^t(p_j-1)}\exp\left(2\zeta(\alpha)\sum_{j=1}^{d}\gamma_j\right). \end{aligned}$$

In the second step we used Theorem 1. ∎

Based on this theorem, similar error bounds to those in Theorems 4 and 6 can be established for the optimal Korobov lattice rules constructed by Algorithm 3. For example, for arbitrary $\tau\in[1,\alpha)$, we have

$$e_{n,d}(\mathbf{z}_t(a_t)) \le C_d(\alpha,\tau)\,d^{t-1+\tau/2}(p_1-1)^{-\tau/2}\prod_{j=2}^{t}(p_j-1)^{-1/2}, \tag{20}$$

where $C_d(\alpha,\tau)$ is given in (10), which is uniformly bounded in d under the same conditions as Theorem 4(ii).

The advantage of Algorithm 3 over Algorithm 1 is that the construction cost of Algorithm 3 is much cheaper (for approximately the same n). Indeed, in dimension d the total number of operations needed to find the final optimal generator $\mathbf{z}_t(a_t)$ for even α by Algorithm 3 is

$$O\left(d(p_1^2+p_1p_2^2+p_1\cdots p_{t-1}p_t^2)\right).$$

By choosing

$$p_{t-1} \approx p_t^2,\ p_{t-2} \approx p_{t-1}^2 \approx p_t^4, \ldots, p_1 \approx p_2^2 \approx p_t^{2^{t-1}},$$

the number of operations needed to find the final generator is $O(dn^{1+(2^t-1)^{-1}})$. For example, for $t = 2$ (corresponding to Algorithm 2) or $t = 3$, the number of operations needed is $O(dn^{4/3})$ or $O(dn^{8/7})$, respectively. Note that even one evaluation of the worst-case error $e_{n,d}(\mathbf{z})$ requires $O(dn)$ operations. Thus the number of operations needed in Algorithms 2 or 3 is much smaller than that in Algorithm 1 (for prime n), for which the number of operations is $O(dn^2)$.

In general, the larger the value of t, the cheaper the construction. However, there is a trade-off—for larger values of t the convergence order is worse, and the dependence on the dimension is stronger, which implies that the quality of the resulting lattice rules might be worse. For example, by choosing $p_1, \ldots, p_t$ as above, if $\alpha = 2$ and $\tau_0 \geq 2$, then from (20) the convergence order is approximately $O\left(n^{-(2^t+2^{t-1}-1)/(2^{t+1}-2)}\right)$, with the implied constant depending at worst polynomially on d. For a large value t, it is approximately $O(n^{-3/4})$. For $t = 2$ or $t = 3$, the convergence order is approximately $O(n^{-5/6})$ or $O(n^{-11/14})$, respectively. In general, if the required number of points n is relatively small, one may use Algorithm 1; if n is very large, then one may use Algorithm 2 or 3. It is not recommended to use Algorithm 2 or 3 if n is relatively small and d is large.

Remark 3. The theoretical bounds on the worst-case errors for Korobov lattice rules in sections 3 and 4 grow polynomially with the dimension d even for rapidly decaying weights, so the theoretical properties of such lattice rules are worse than those of the CBC lattice rules, for which the corresponding errors can be bounded uniformly in d for fast decaying weights [14]. However, the bounds are established by "averaging arguments" and are in general quite conservative. The numerical comparison of the worst-case errors in section 6 suggests that the true dependence of the worst-case error of the optimal Korobov lattice rules on the dimension is almost the same as that of the CBC lattice rules.

5. Weighted Sobolev spaces. In this section, we briefly study multivariate integration in weighted Sobolev spaces of nonperiodic functions using shifted Korobov lattice rules. We use a similar technique to that in [23]. However, we consider a more general class of weighted Sobolev spaces $H(K_{d,\gamma}^{\mathrm{sob}})$ with the following reproducing kernels (see [7, 24]):

$$K_{d,\gamma}^{\mathrm{sob}}(\mathbf{x}, \mathbf{y}) = \prod_{j=1}^{d} [1 + \gamma_j \eta(x_j, y_j)],$$

where

$$\eta(x, y) = \frac{1}{2} B_2(\{x - y\}) + (x - 1/2)(y - 1/2) + \mu(x) + \mu(y) + M.$$

Here $B_2(x)$ is the Bernoulli polynomial of degree 2, $\mu(x)$ is a function with bounded derivative in $[0, 1)$ such that $\int_0^1 \mu(x)dx = 0$, and the constant M is equal to $\int_0^1 (\mu'(x))^2 dx$. Several common choices of $\mu(x)$ are

$$(A)\ \ \mu(x) = \frac{1}{6} - \frac{x^2}{2};\ \ (B)\ \ \mu(x) = -\frac{1}{2} B_2(\{x - 1/2\});\ \ (C)\ \ \mu(x) = 0.$$

For example, for the first choice of $\mu(x)$ the kernel is

$$K_{d,\gamma}^{\rm sob}(\mathbf{x},\mathbf{y}) = \prod_{j=1}^{d}[1+\gamma_j \min(1-x_j, 1-y_j)].$$

The tractability of multivariate integration in the corresponding Hilbert space is studied in a nonconstructive way in [22], and in constructive ways in [10, 20, 25]. For the third choice of $\mu(x)$ the reproducing kernel is

$$K_{d,\gamma}^{\rm sob}(\mathbf{x},\mathbf{y}) = \prod_{j=1}^{d}\left[1+\gamma_j\left(\frac{1}{2}B_2(\{x-y\})+(x-1/2)(y-1/2)\right)\right],$$

which has been studied in [4, 24]. In this third case there is a good property for the functions in the corresponding Hilbert space: the Hilbert space decomposition of a function coincides with the ANOVA (analysis of variance) decomposition [4].

The shift-invariant kernel $K_{d,\gamma}^{\rm shift}(\mathbf{x},\mathbf{y})$ associated with the kernel $K_{d,\gamma}^{\rm sob}(\mathbf{x},\mathbf{y})$ is

$$\begin{aligned} K_{d,\gamma}^{\rm shift}(\mathbf{x},\mathbf{y}) &:= \int_{[0,1)^d} K_{d,\gamma}^{\rm sob}(\{\mathbf{x}+\Delta\},\{\mathbf{y}+\Delta\})d\Delta \\ &= \prod_{j=1}^{d}[1+\gamma_j(B_2(\{x-y\})+M)] \\ &= \prod_{j=1}^{d}(1+M\gamma_j)\prod_{j=1}^{d}[1+2\pi^2\widehat{\gamma}_j B_2(\{x-y\})] \end{aligned}$$

with

$$\widehat{\gamma}_j = \frac{\gamma_j}{2\pi^2(1+M\gamma_j)}. \tag{21}$$

Different choices of the function $\mu(x)$ correspond to similar shift-invariant kernels; only the constant M and the weights $\widehat{\gamma}_j$ are different. Note that the Bernoulli polynomial of degree 2 can be expressed as (see (5))

$$B_2(x) = \frac{1}{2\pi^2}\sum_{h\in\mathbf{Z}}{}' \frac{e^{2\pi i h x}}{h^2}, \quad x\in[0,1).$$

Therefore, apart from the factor $\prod_{j=1}^{d}(1+M\gamma_j)$, the kernel $K_{d,\gamma}^{\rm shift}(\mathbf{x},\mathbf{y})$ is just the Korobov reproducing kernel $K_{d,2,\widehat{\gamma}}(\mathbf{x},\mathbf{y})$ in (3) with $\alpha=2$ and the weight sequence $\widehat{\gamma} := \{\widehat{\gamma}_j\}$, i.e.,

$$K_{d,\gamma}^{\rm shift}(\mathbf{x},\mathbf{y}) = \prod_{j=1}^{d}(1+M\gamma_j)\, K_{d,2,\widehat{\gamma}}(\mathbf{x},\mathbf{y}).$$

It is shown in [8, 11] that for a point set $\mathbf{P}_n = \{\mathbf{x}_0,\mathbf{x}_1,\dots,\mathbf{x}_{n-1}\}\subset[0,1)^d$,

$$\begin{aligned} \int_{[0,1)^d} e^2(\mathbf{P}_n+\Delta; H(K_{d,\gamma}^{\rm sob}))d\Delta &= e^2(\mathbf{P}_n; H(K_{d,\gamma}^{\rm shift})) \\ &= \prod_{j=1}^{d}(1+M\gamma_j)\, e^2(\mathbf{P}_n; H(K_{d,2,\widehat{\gamma}})), \end{aligned}$$

where $\mathbf{P}_n + \Delta$ denotes the shifted point set $\{\{\mathbf{x}_0 + \Delta\}, \ldots, \{\mathbf{x}_{n-1} + \Delta\}\}$. Clearly, the square of the initial integration error in the space $H(K^{\rm sob}_{d,\gamma})$ is

$$e^2(0; H(K^{\rm sob}_{d,\gamma})) := \prod_{j=1}^{d}(1 + M\gamma_j).$$

Thus there exists a shift $\Delta \in [0,1)^d$ such that

$$e(\mathbf{P}_n + \Delta; H(K^{\rm sob}_{d,\gamma})) \le e(0; H(K^{\rm sob}_{d,\gamma}))\ \ e(\mathbf{P}_n; H(K_{d,2,\widehat{\gamma}})).$$

Therefore, in order to reduce the worst-case error in the weighted Sobolev space $H(K^{\rm sob}_{d,\gamma})$ by a factor of ε from its initial error, it is sufficient to reduce the worst-case error in the weighted Korobov space $H(K_{d,2,\widehat{\gamma}})$ to ε, where the weights $\widehat{\gamma}_j$ are given by (21). The error bounds in the space $H(K_{d,2,\widehat{\gamma}})$ have been studied in the previous sections (corresponding to $\alpha = 2$ and the weights $\widehat{\gamma}_j$). Thus similar error bounds for randomly shifted optimal Korobov lattice rules can be established in weighted Sobolev spaces. We only state the case for prime n and omit the proof.

THEOREM 8. *Suppose n is a prime. Let $\mathbf{P}_n$ be the lattice point set corresponding to the optimal Korobov lattice rule found by Algorithm 1 (with γ_j replaced by $\hat{\gamma}_j$).*

(i) *There exists a shift $\Delta \in [0,1)^d$ such that*

$$e^2(\mathbf{P}_n + \Delta; H(K^{\rm sob}_{d,\gamma})) \le \frac{d}{n-1}\ \exp\left(\frac{1}{6}\sum_{j=1}^{d}\gamma_j\right) e(0; H(K^{\rm sob}_{d,\gamma})).$$

(ii) *There exists a shift $\Delta \in [0,1)^d$ such that for arbitrary $\tau \in [1,2)$*

$$e(\mathbf{P}_n + \Delta; H(K^{\rm sob}_{d,\gamma})) \le C'_d(\tau)\left(\frac{d}{n-1}\right)^{\tau/2} e(0; H(K^{\rm sob}_{d,\gamma})),$$

where

$$C'_d(\tau) = \exp\left(\frac{\tau\zeta(2/\tau)}{\sqrt{2}\,\pi}\sum_{j=1}^{d}\gamma_j^{1/\tau}\right).$$

(iii) *Suppose that the weights γ_j satisfy $\sum_{j=1}^{\infty}\gamma_j < \infty$. Let τ_0 be the same as in Theorem 4. Then for any $\tau \in [1, \min(\tau_0, 2))$ (or if $\tau_0 = 1$, then put $\tau = 1$), we have*

$$C'_d(\tau) \le C'_\infty(\tau) := \lim_{d\to\infty} C'_d(\tau) < \infty;$$

i.e., $C'_d(\tau)$ is uniformly bounded in d.

(iv) *Let B^* be the same as in Theorem 4. Then there exists a shift $\Delta \in [0,1)^d$ such that the shifted optimal Korobov lattice point set $\mathbf{P}_n + \Delta$ satisfies*

$$e(\mathbf{P}_n + \Delta; H(K^{\rm sob}_{d,\gamma})) \le \frac{C_\delta}{(n-1)^{1/2}}\ d^{\frac{1}{2}+\frac{1}{12}(B^*+2\pi^2\delta)} e(0; H(K^{\rm sob}_{d,\gamma}))$$

for any $\delta > 0$, where C_δ is a constant independent of d and n.

Note that it is not necessary to determine the optimal "shift" for practical use. Instead, we may choose it randomly [2, 21], since for fixed $\mathbf{P}_n$, the family of QMC algorithms with points $\{\mathbf{P}_n + \Delta\}$ (where Δ is uniformly distributed on $\in [0,1]^d$) is an unbiased family. This approach allows a probabilistic error estimation.

6. Numerical comparisons of the worst-case errors. We perform a comparison of the worst-case errors in weighted Korobov spaces. Two kinds of lattice rules are considered: the optimal Korobov lattice rules and the CBC lattice rules. The root mean square worst-case errors over random points and the root mean square worst-case errors over all lattice rules are also included as benchmarks. We are mainly interested in the effect of the dimension and the convergence order. We focus our attention only on the case where $\alpha = 2$ and n is prime. The mean square worst-case error averaged over random points is defined and calculated as

$$(E^{\mathrm{av}}_{n,d})^2 := \int_{[0,1)^{nd}} e^2(\{\mathbf{x}_k\}; H(K_{d,\alpha,\gamma}))d\mathbf{x}_0 \cdots d\mathbf{x}_{n-1} = \frac{1}{n}\left(\prod_{j=1}^{d}(1+2\zeta(\alpha)\gamma_j) - 1\right).$$

For prime n, the mean square worst-case error over all rank-1 lattice rules is (see [23])

$$\begin{aligned} M^{(\mathrm{LR})}_{n,d}(\alpha) &:= \frac{1}{(n-1)^d}\sum_{z_1=1}^{n-1}\cdots\sum_{z_d=1}^{n-1} e^2_{n,d}((z_1,\ldots,z_d)) \\ &= -1 + \frac{1}{n}\prod_{j=1}^{d}(1+2\zeta(\alpha)\gamma_j) + (1-n^{-1})\prod_{j=1}^{d}\left(1 - \frac{2\gamma_j\zeta(\alpha)(1-n^{1-\alpha})}{n-1}\right). \end{aligned}$$

We consider weights of the form

$$\gamma_j = a\theta^j, \quad j = 1,\ldots,d,$$

where a and θ are parameters. We intend to use a to mainly characterize the relative importance of different orders of "interaction" and use θ to reflect the relative importance of successive variables. We consider the following three choices:

$$(A)\ a = 1, \quad \theta = 1; \qquad (B)\ a = 0.098, \quad \theta = 0.98; \qquad (C)\ a = 0.25, \quad \theta = 0.75.$$

The first case corresponds to the classical unweighted case. The latter two choices are found to be "suitable" for some problems in finance (see [27]).

Computational results are given in Tables 1–3 in the appendix. The rate of convergence of the worst-case error (i.e., the value r in an expression of the form $O(n^{-r})$ for convergence, estimated from linear regression on the empirical data) is also given. Note that the root mean square worst-case error over random points converges as $O(n^{-1/2})$. The root mean square worst-case error over all rank-1 lattice rules has convergence $O(n^{-1})$ for $d=1$ and $O(n^{-1/2})$ for $d>1$. These serve as benchmarks.

Table 1, for the unweighted case (A), draws attention to the importance of incorporating weights into our function spaces: in this unweighted case the worst-case errors for both the Korobov and CBC lattice rules grow exponentially in d. This is, of course, expected from the known intractability of the problem in this case (see [23]). For large d, neither method is significantly better than the two root mean square values (which are essentially the same). For all values of d, there is little difference between the two constructions. Tables 2 and 3 show a dramatic reduction in the worst-case errors produced by decaying weights. This is especially true for the latter case, where the rapid decay of the weights leads to essentially no change in the worst-case errors beyond $d = 32$, and a high convergence is achieved by the Korobov and CBC constructions even in high dimensions. The worst-case errors of the two kinds of lattice rules are here smaller or much smaller than the mean values.

7. Concluding remarks. The striking conclusion from all the numerical results in section 6 is that the worst-case errors for the Korobov construction are always comparable with those for CBC construction. In particular, the worst-case errors for the Korobov construction do not seem to show the faster growth with d predicted by the theoretical error bounds in Theorem 4. Thus there remains a gap between theory and observation. We mentioned that the theoretical bounds are established by averaging arguments and are in general conservative.

The Korobov construction has the advantage of speed and simplicity over the CBC construction, in that Algorithm 1 requires a time of order only $O(dn^2)$ if n is prime and only a single n-point lattice rule is needed. (And the time is further reduced if n is a product of primes as in Algorithms 2 and 3). On the other hand, the CBC algorithm is extensible in dimension, whereas the Korobov construction is not. The existence of good rank-1 lattice rules that are extensible both in d and n is proved in [9], but no construction is given.

The weighted Korobov spaces are characterized by the weights, which are supposed for our theoretical analysis to be given. The weights have a strong influence on the properties (e.g., effective dimensions) of the functions in the weighted spaces (see [26, 27]). An important problem for practical application is: *What weights should be used?* Some attempts have been made in [4, 27] to choose the weights to reflect the characteristics of the functions to be integrated. In [27] it is shown that the performance of lattice rules strongly depends on the weights, and that blind use of lattice rules based on classical weights may lead to estimates that are worse than Monte Carlo estimates, especially in high dimensions (it is shown in [27] that the classical weights $\gamma_j = 1$ are "too large" for some typical high-dimensional problems in finance). Thus the problem of choosing the weights must be considered hand-in-hand with the problem addressed here, that of choosing the algorithm.

Appendix. Comparisons of the worst-case errors.

TABLE 1

The comparison of the worst-case errors in weighted Korobov spaces and the apparent convergence order in dimensions up to 64 *for the case* $(A) : \gamma_j = 1$. *(The abbreviations "Mean" and "Mean LR" denote root mean square worst-case errors over all random points and root mean square worst-case errors over all rank-*1 *lattice rules, respectively.)*

A POSTERIORI ERROR ESTIMATES BASED ON THE POLYNOMIAL PRESERVING RECOVERY*

AHMED NAGA† AND ZHIMIN ZHANG‡

Abstract. Superconvergence of order $O(h^{1+\rho})$, for some $\rho > 0$, is established for the gradient recovered with the polynomial preserving recovery (PPR) when the mesh is mildly structured. Consequently, the PPR-recovered gradient can be used in building an asymptotically exact a posteriori error estimator.

Key words. finite element method, superconvergence patch recovery, polynomial preserving recovery, discrete least-squares best fitting, superconvergence, a posteriori error estimator

DOI. 10.1137/S0036142903413002

1. Introduction.

Adaptive control based on a posteriori error estimates have become standard in finite element methods since the pioneering work by Babuška and Rheinboldt [2]. The field of the a posteriori error estimators attracted many researchers and has become the focus of intensive investigations. For the literature, the reader is referred to recent books by Ainsworth and Oden [1] and Babuška and Strouboulis [3], a conference proceeding [8], a survey article by Bank [4], and an earlier book by Verfürth [10].

Generally speaking, error estimators can be classified under two categories. The residual type estimators (for example, see [5]) constitute the first category, while recovery based error estimators (for example, see [14]) constitute the second one. In recovery based estimators, the finite element solution (or its gradient) is postprocessed as a first step. For example, Zienkiewicz and Zhu [15] introduced the superconvergence patch recovery (SPR) that is used to recover a gradient from the gradient of the finite element solution. In another strategy, Wiberg and Li [11] and Li and Wiberg [9] used the finite element solution to build another solution. If the recovered quantity better approximates the exact one, then it can be used in building an asymptotically exact a posteriori error estimator (see [1] and [3] for some general discussion and literature).

In this work, we consider a posteriori error estimators that are based on gradient recovery. As is shown in [1], if the recovered gradient superconverges to the exact one, the corresponding a posteriori error estimator is asymptotically exact. A good example of such estimators is the Zienkiewicz–Zhu error estimator based on the SPR-recovered gradient (see [16]). The polynomial preserving recovery (PPR) is a new gradient recovery technique introduced in [13]. The PPR-recovered gradient, as we shall soon see, has superconvergence properties in mildly structured meshes. Consequently, it can be used in constructing an asymptotically exact a posteriori error estimator.

1.1. Model problem. To fix the ideas, consider the boundary value problem

$$\begin{cases} -\nabla(\mathcal{D}\nabla u + \boldsymbol{b}u) + cu = f & \text{in } \Omega, \\ \boldsymbol{n}\cdot(\mathcal{D}\nabla u + \boldsymbol{b}u) = g & \text{on } \Gamma_N, \\ u = 0 & \text{on } \Gamma_D, \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^2$ is a bounded domain with Lipschitz boundary $\partial\Omega = \overline{\Gamma_N} \cup \overline{\Gamma_D}$, the boundary segments Γ_N and Γ_D are disjoint, $\boldsymbol{n}$ is the unit outward normal vector to $\partial\Omega$, and $\mathcal{D}$ is a 2×2 symmetric positive definite matrix. If $\Gamma_N = \partial\Omega, \boldsymbol{b} = 0,$ and $c = 0$, the compatibility condition $\int_\Omega f + \int_{\partial\Omega} g = 0$ must be satisfied and the condition $\int_\Omega u = 0$ is used to ensure the uniqueness. For simplicity, Ω is assumed to be a polygonal domain.

As usual, $W_p^m(\Omega)$ and $H^m(\Omega)$ are the classical Sobolev spaces equipped with the norms $\| \quad \|_{m,p,\Omega}$, and $\| \quad \|_{m,\Omega}$, respectively.

The variational form of this problem is to find $u \in V$ such that

$$\mathcal{B}(u,v) = L(v) \text{ for all } v \in V, \tag{1.2}$$

where

$$V = \{v \in H^1(\Omega) : v|_{\Gamma_D} = 0\},$$

$$\mathcal{B}(u,v) = \int_\Omega [(\mathcal{D}\nabla u + \boldsymbol{b}u)\nabla v + cuv]dxdy,$$

and

$$L(v) = \int_\Omega fvdxdy + \int_{\Gamma_N} gvds.$$

If Γ_D is empty, we take $V = H^1(\Omega)$. We assume that the bilinear operator $\mathcal{B}$ is continuous and V-elliptic, and the linear operator L is bounded. (Of course, this requires the problem data to satisfy some conditions.) Under these assumptions, the variational problem in (1.2) has a unique weak solution $u \in V$.

Let $\mathcal{T}_h$ be a triangular partition of Ω, and let $\mathcal{N}_h$ denote the set of the mesh nodes. The area of a mesh triangle $T \in \mathcal{T}_h$ will be denoted by $|T|$. A mesh node z is called an *internal* (*boundary*) mesh node if $z \in \Omega$ ($z \in \partial\Omega$). Consider the C^0 linear finite element space $S_h \subset H^1(\Omega)$ associated with $\mathcal{T}_h$ and defined by

$$S_h = \{v \in H^1(\Omega) : v \in P_1(T) \text{ for every triangle } T, \in \mathcal{T}_h\},$$

where $P_r(\mathcal{A})$ denotes the set of all polynomials defined on $\mathcal{A} \subseteq \mathbb{R}^2$ of total degree $\leq r$. The basis functions for S_h are the standard Lagrange basis functions and I_h will denote the Lagrange interpolation operator associated with S_h. The finite element solution of (1.2) is $u_h \in S_h \cap V$ such that

$$\mathcal{B}(u_h,v) = L(v) \text{ for all } v \in S_h \cap V. \tag{1.3}$$

1.2. The SPR and PPR techniques. In general, ∇u_h is inherently discontinuous across elements boundaries, and a postprocessing operation is needed to correct this problem. Recovery techniques such as the SPR and the PPR can be used for this purpose. The recovered gradient definition in both the SPR and the PPR relies

on the following simple observation: The basis functions of S_h are the Lagrange basis functions. Hence, every function in S_h is uniquely defined by its values at the mesh nodes. Let $\{v_z : z \in \mathcal{N}_h\}$ be the Lagrange basis of S_h, and let R_h denote the gradient recovery operator associated with either the SPR or the PPR. Assuming that $R_h u_h$ is defined at every mesh node $z \in \mathcal{N}_h$, the recovered gradient $R_h u_h$ on $\overline{\Omega}$ is defined to be

$$R_h u_h = \sum_{z \in \mathcal{N}_h} R_h u_h(z) v_z.$$

According to this definition, $R_h u_h \in S_h \times S_h$, and it remains to define $R_h u_h$ at the mesh nodes. This is where the SPR and the PPR are different.

Remark 1.1. The definition of the SPR- and the PPR-recovered gradients at mesh nodes involves best fitting operations. In this paper, the best fitting is carried out in a discrete least-squares sense.

The definition of the SPR-recovered gradient at $z \in \mathcal{N}_h$ depends on the location of z.

If $z \in \Omega$, let $\mathcal{K}_z$ denote the patch consisting of the triangles attached to z as shown in Figure 1(a). Let $p_x \in P_1(\mathcal{K}_z)$ be the linear polynomial that best fits $\partial_x u_h$ at the triangle centroids in $\mathcal{K}_z$. The recovered x-derivative at z is defined to be $p_x(z)$. Similarly, we can define the recovered y-derivative at z.

If $z \in \partial\Omega$ is directly connected to no internal mesh nodes, the recovered gradient at z is defined to be $\nabla u_h(z)$.

If $z \in \partial\Omega$ is directly connected to the internal mesh nodes $z_1, z_2, \ldots, z_{N_z}$, let $\mathcal{K}_{z_i}$ be the patch associated with z_i. Again, $\mathcal{K}_{z_i}$ consists of the mesh triangles that are directly attached to z_i. Let $p_{x,z_i} \in P_1(\mathcal{K}_{z_i})$ be the linear polynomial that best fits $\partial_x u_h$ at the triangle centroids in $\mathcal{K}_{z_i}$. The recovered x-derivative at z is defined to be

$$\frac{1}{N_z} \sum_{i=1}^{N_z} p_{x,z_i}(z).$$

Similarly, we can define the recovered y-derivative at z.

Next, we turn our attention to the definition of the PPR-recovered gradient at $z \in \mathcal{N}_h$. Starting with a patch $\mathcal{K}_z$, let $p \in P_2(\mathcal{K}_z)$ be the quadratic polynomial that best fits u_h at the mesh nodes in $\mathcal{K}_z$. The PPR-recovered gradient at z is defined to be $\nabla p(z)$. The construction of $\mathcal{K}_z$ is not straightforward as in the SPR. As we will soon see, $\mathcal{K}_z$ must have at least six mesh nodes that are not on a conic section. This is to guarantee the existence and the uniqueness of p. Indeed, the construction of $\mathcal{K}_z$ starts by the patch $\mathcal{K}_{z,0}$ that consists of the mesh triangles directly attached with z. The next construction step depends on the location of z.

If $z \in \Omega$ and $\mathcal{K}_{z,0}$ has at least five mesh triangles, then $\mathcal{K}_z = \mathcal{K}_{z,0}$ as shown in Figure 1(a).

If $z \in \Omega$ and $\mathcal{K}_{z,0}$ has three or four mesh triangles, then

$$\mathcal{K}_z = \mathcal{K}_{z,0} \cup \{T \in \mathcal{T}_h : T \cap \mathcal{K}_{z,0} \text{ is an edge of } T\}$$

as shown in Figure 1(b).

If $z \in \partial\Omega$ and $\mathcal{K}_{z,0}$ has at least one internal mesh node, then

$$\mathcal{K}_z = \mathcal{K}_{z,0} \cup \{\mathcal{K}_{\hat{z}} : \hat{z} \in \mathcal{K}_{z,0} \text{ is an internal mesh node}\} \tag{1.4}$$

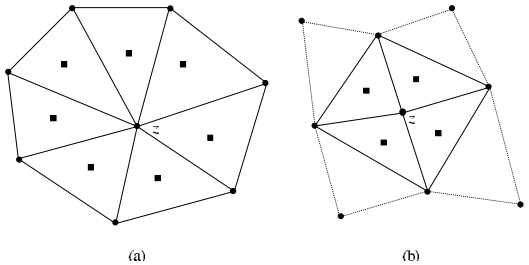

FIG. 1. *Patches used in gradient recovery at an internal mesh node z. Sampling points for the SPR are marked with ■, while those needed for the PPR are marked with ●.*

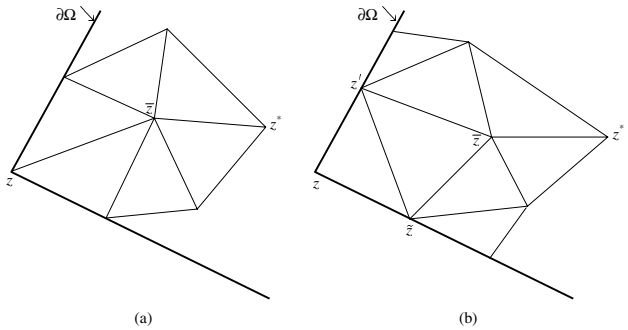

FIG. 2. *Examples for patches used in the PPR at a boundary mesh node z.*

as shown in Figure 2(a). If $\mathcal{K}_{z,0}$ has no internal mesh nodes, replace $\mathcal{K}_{z,0}$ in (1.4) by a bigger patch

$$\mathcal{K}_{z,1} = \bigcup \{\mathcal{K}_{\hat{z},0} : \hat{z} \in \mathcal{K}_{z,0} \text{ is a mesh node } \}. \tag{1.5}$$

An example of this situation is depicted in Figure 2(b). Practically, $\mathcal{K}_{z,1}$ must have at least one internal mesh node. If this is not the case, iterate the extension process in (1.5).

Having introduced the definitions of the SPR and the PPR, we have the following remarks.

1. The main difference between the SPR and the PPR is that the SPR works on ∇u_h while the PPR works on u_h.

2. The PPR has good approximation properties as it satisfies the *consistency condition*. A recovery operator R_h is said to satisfy the consistency condition if

$$R_h(I_h p) = \nabla p \quad \text{for all } p \in P_2(\Omega). \tag{1.6}$$

If R_h satisfies (1.6), the Bramble–Hilbert lemma can be used to show that

$$\|\nabla u - R_h I_h u\|_{L^\infty(\Omega)} \le C h^2 |u|_{3,\infty,\Omega} \quad \text{for all } u \in W^3_\infty(\Omega),$$

where $C > 0$ is some constant independent of u and h (see [13] for more details). The PPR satisfies (1.6) because the best fit polynomials over individual patches and the original polynomial are typically the same. On the other hand, the SPR does not satisfy the consistency condition unless $\mathcal{T}_h$ has some special structure.

3. Basically, the PPR can be viewed as a dynamic way to generate difference formulas for first order partial derivatives. The generated formulas can recover the

exact derivatives of quadratic polynomials. Babuška and Strouboulis [3] proposed a technique to generate this kind of difference formulas a priori (see Example 4.8*.4 in [3]), but this technique is not suitable for real time computations on real meshes.

4. The idea of best fitting the nodal values of u_h by a quadratic polynomial is well known in engineering applications. For example, Wiberg and Li [11] and Li and Wiberg [9] used this idea in constructing a recovered solution $\tilde{u}_h$ from u_h. According to their strategy, the true error $\|u-u_h\|_{L^2(T)}$ on $T \in \mathcal{T}_h$ is estimated using $\|\tilde{u}_h - u_h\|_{L^2(T)}$. Indeed, Wiberg and Li were mainly concerned about estimating the error and not recovering the gradient.

5. The PPR gradient recovery can be easily extended to higher order elements and to problems in $\mathbb{R}^3$. This will be the topic of a future work.

1.3. Gradient recovery and the superconvergence property. As mentioned previously, if the recovered gradient enjoys the superconvergence property, then it can be used in building an asymptotically exact a posteriori error estimator. Ainsworth and Oden [1] established a general framework that can be used in proving the superconvergence property, if it exists. Let R_h denote the recovery operator associated with a gradient recovery technique. According to this framework, there are three main requirements to show that $R_h u_h$ superconverges to ∇u:

1. R_h satisfies the consistency condition.
2. The recovery operator R_h is bounded in the following sense:

$$\|R_h v\|_{L^2(T)} \le C|v|_{1,\mathcal{K}_T} \qquad \text{for all } T \in \mathcal{T}_h \text{ and for all } v \in S_h, \tag{1.7}$$

where $\mathcal{K}_T$ is a patch of triangles containing T.

3. ∇u_h enjoys superconvergence in the following sense:

$$\|\nabla(I_h u - u_h)\|_{L^2(\Omega)} \le C h^{1+\rho} \tag{1.8}$$

for some $\rho \in (0,1]$ and some constant $C > 0$ that is independent of h.

If u_h and R_h satisfy the above requirements, then it is possible to prove that

$$\|\nabla u - R_h u_h\|_{L^2(\Omega)} \le C h^{1+\rho}. \tag{1.9}$$

With this result in hand, it is straightforward to prove that the a posteriori error estimator

$$\eta_h = \|R_h u_h - \nabla u_h\|_{L^2(\Omega)} \tag{1.10}$$

is asymptotically exact.

From this point on, we will concentrate on the PPR and its corresponding operator, which we will denote by $\mathrm{G^h}$. Our target in this paper is to show that $\mathrm{G^h}u_h$ superconverges to ∇u following the above framework. By construction, and as explained previously, $\mathrm{G^h}$ satisfies the first requirement. For the third requirement, Xu and Zhang [12] had recently established (1.8) for a wide range of meshes that are mildly structured in the sense of the following definition.

DEFINITION 1.2. *The triangulation $\mathcal{T}_h$ is said to satisfy the* condition (α, σ) *if there exist a partition $\mathcal{T}_{h,1} \cup \mathcal{T}_{h,2}$ of $\mathcal{T}_h$ and positive constants α and σ such that every two adjacent triangles in $\mathcal{T}_{h,1}$ form an $O(h^{1+\alpha})$ parallelogram and*

$$\sum_{T \in \mathcal{T}_{h,2}} |T| = O(h^{\sigma}).$$

An $O(h^{\alpha+1})$ parallelogram is a quadrilateral in which the difference between the lengths of any two opposite sides is $O(h^{\alpha+1})$. When $\alpha = \infty$, every pair of adjacent triangles in $\mathcal{T}_{h,1}$ form a parallelogram. When $\alpha = \sigma = \infty$, $\mathcal{T}_h$ is uniformly generated by lines parallel to three fixed directions. This case was handled in [7], where $u - u_h$ was expanded at mesh nodes, and the case in which $\alpha = 1$ was handled in [6]. For general α and σ, Xu and Zhang [12] proved the following theorem.

THEOREM 1.3. *Let u be the solution of* (1.2)*, let $u_h \in S_h$ be the finite element solution of* (1.3)*, and let $I_h u \in S_h$ be the linear interpolation of u. If the triangulation $\mathcal{T}_h$ satisfies the condition (α, σ) and $u \in H^3(\Omega) \cap W^2_\infty(\Omega)$, then*

$$\|u_h - I_h u\|_{1,\Omega} \le h^{1+\rho}(\|u\|_{3,\Omega} + |u|_{2,\infty,\Omega}),$$

where $\rho = \min(\alpha, \frac{1}{2}, \frac{\sigma}{2})$.

Remark 1.4. The condition(α, σ) is sufficient to guarantee the superconvergence result in (1.8), although it is not necessary, as we shall see in the numerical examples. Nevertheless, this condition is satisfied for meshes generated by many automatic mesh generators as described in [12].

The second requirement is somewhat easy to establish when the recovery technique works directly on the gradient as in weighted average recovery and the SPR. However, the situation is much harder for the PPR as it works on function values. It is not even clear how to relate $\mathrm{G^h}v$ to ∇v, where $v \in S_h$. Actually, the core of this paper is devoted to showing that $\mathrm{G^h}$ satisfies the third requirement. Having this result paves the way to show that $\mathrm{G^h}$ enjoys the superconvergence property in (1.9) and that the error estimator η_h is asymptotically exact. At the end of the paper, some numerical examples are provided to practically show that the PPR-recovered gradient superconverges to the exact gradient.

2. Definition and existence of $\mathbf{G^h}$. As mentioned previously, the construction of $\mathrm{G^h}v \in S_h \times S_h$ for a function $v \in S_h$ is complete if $(\mathrm{G^h}v)(z)$ is defined for every $z \in \mathcal{N}_h$. Therefore, it suffices to address the definition and existence questions at the level of mesh nodes.

Consider a mesh node z, and let $\mathcal{K}_z$ denote its corresponding patch. In the patch $\mathcal{K}_z$, let $T_1, T_2, \ldots, T_m$ denote the mesh triangles and let $z_0 = (x_0, y_0), z_1 = (x_1, y_1), \ldots, z_n = (x_n, y_n)$ denote the mesh nodes. Without loss of generality, let $z = z_0$. Let $h_z = \max\{\|z_i - z_0\| : 1 \le i \le n\}$. To avoid the computational instability associated with small h_z, the computations will be carried out on the patch

$$\omega_z = F_z(\mathcal{K}_z), \text{ where } F_z : (x, y) \to (\hat{x}, \hat{y}) = \frac{(x, y) - (x_0, y_0)}{h_z}. \tag{2.1}$$

The patch ω_z will be called *the reference patch associated with* z. For $0 \le i \le n$, let $\hat{z}_i = (\hat{x}_i, \hat{y}_i) = F(z_i)$ and set $v_i = (v \circ F_z^{-1})(\hat{z}_i) = v(z_i)$. Let $p_z \in P_2(\omega_z)$ be the quadratic polynomial that best fits the data points $\{(\hat{z}_i, v_i) : 0 \le i \le n\}$. For $(\hat{x}, \hat{y}) \in \omega_z$, $p_z(\hat{x}, \hat{y})$ can be written in the form

$$p_z(\hat{x}, \hat{y}) = \hat{\boldsymbol{x}}^T \boldsymbol{c_z},$$

where $\boldsymbol{c}_z$ is the coefficients vector $\begin{bmatrix} c_{z,1} & c_{z,2} & c_{z,3} & c_{z,4} & c_{z,5} & c_{z,6} \end{bmatrix}^T$ and $\hat{\boldsymbol{x}}$ is the monomials vector $\begin{bmatrix} 1 & \hat{x} & \hat{y} & \hat{x}^2 & \hat{x}\hat{y} & \hat{y}^2 \end{bmatrix}^T$. Since we are using discrete least-squares fitting, the coefficients vector $\boldsymbol{c}_z$ is determined by the linear system

$$A_z^T A_z \boldsymbol{c}_z = A_z^T \boldsymbol{v}_z,$$

where

$$A_z = \begin{bmatrix} \hat{\boldsymbol{x}}_0^T \\ \hat{\boldsymbol{x}}_1^T \\ \hat{\boldsymbol{x}}_2^T \\ \vdots \\ \hat{\boldsymbol{x}}_n^T \end{bmatrix}, \hat{\boldsymbol{x}}_i = \begin{bmatrix} 1 \\ \hat{x}_i \\ \hat{y}_i \\ \hat{x}_i^2 \\ \hat{x}_i\hat{y}_i \\ \hat{y}_i^2 \end{bmatrix} \text{ for } 0 \le i \le n, \text{ and } \boldsymbol{v}_z = \begin{bmatrix} v_0 \\ v_1 \\ v_2 \\ \vdots \\ v_n \end{bmatrix}. \tag{2.2}$$

Set

$$B_z = A_z^T A_z,$$

then, assuming the existence of B_z^{-1},

$$\boldsymbol{c}_z = B_z^{-1} A_z^T \boldsymbol{v}_z.$$

By definition,

$$\mathrm{G^h} v(z) = \frac{1}{h_z} \begin{bmatrix} \partial_{\hat{x}} p_z(0,0) & \partial_{\hat{y}} p_z(0,0) \end{bmatrix}^T.$$

Therefore,

$$\mathrm{G^h} v(z) = \frac{1}{h_z} \begin{bmatrix} c_{z,2} & c_{z,3} \end{bmatrix}^T = \frac{1}{h_z} \begin{bmatrix} \boldsymbol{v}_z^T A_z B_z^{-1} e_2 & \boldsymbol{v}_z^T A_z B_z^{-1} e_3 \end{bmatrix}^T, \tag{2.3}$$

where e_2 and e_3 are the second and third columns, respectively, of the identity matrix $I_{6\times 6}$.

To this end, it is important to address the following question: Are there any sufficient conditions that guarantee the existence of B_z^{-1}? The answer to this question relies on the following simple proposition.

PROPOSITION 2.1.

1. *If B_z is not invertible, then there is a conic section passing through the mesh nodes in $\mathcal{K}_z$.*
2. *Any tangent to a branch of a hyperbola cannot intersect with the other branch.*

Proof. If B_z is not invertible, then $\boldsymbol{c}_z$ has infinitely many solutions. Therefore, there are infinitely many polynomials in $P_2(\omega_z)$ that pass through the data points $\{(\hat{z}_i, v_i) : 0 \le i \le n\}$. Let $p_{z,1}$ and $p_{z,2}$ be two such polynomials, and let $q = p_{z,1} - p_{z,2}$. Then, $q(\hat{z}_i) = 0$ for $0 \le i \le n$, and the conic section $\{(\hat{x}, \hat{y}) : q_z(\hat{x}, \hat{y}) = 0\}$ passes through $\{\hat{z}_i : 0 \le i \le n\}$. Since conic sections are invariant under affine mappings, the proof of the first part is complete. The proof of the second part is elementary. ∎

DEFINITION 2.2. *The patch $\mathcal{K}_z$ (or ω_z) is said to satisfy the* angle condition *if the sum of any two adjacent angles inside $\mathcal{K}_z$ is at most π, and is said to satisfy the* line condition *if its mesh nodes are not lying on two lines.*

Let n_1 denote the number of mesh nodes that are directly connected to z, and set $n_2 = n - n_1$. If $z \in \Omega$, then $n_1 \ge 3$. Practically, a good mesh generator can detect any node z for which $n_1 = 3$ and remove it. So, we may assume that $n_1 \ge 4$. It is obvious that for an internal mesh node z with $n_1 > 4$, $\mathcal{K}_z$ automatically satisfies the line condition. If $n_1 = 4$, $\mathcal{K}_z$ may violate this condition as shown in Figure 4.

The following theorem plays the crucial part in proving the boundedness of $\mathrm{G^h}$.

THEOREM 2.3. *Let z be an internal mesh node with $n_1 \geq 4$, and let $\mathcal{K}_z$ be its corresponding patch that satisfies the angle condition. In addition, let $\mathcal{K}_z$ satisfy the line condition when $n_1 = 4$. Then, B_z is invertible.*

Proof. By the first part of Proposition 2.1, it suffices to show that $\mathcal{K}_z$ has six distinct nodes that are not on a conic section. Since $z \in \Omega$, the sum of the angles at z is 2π. Hence, the nodes in $\mathcal{K}_z$ cannot lie on a circle, on a parabola, on an ellipse, or on one branch of a hyperbola. Since $\mathcal{K}_z$ satisfies the line condition, the nodes cannot be on two lines. The remaining possibility is to have the nodes distributed on two branches of a hyperbola. Depending on n_1, we can have one of the following two cases.

Case 1: $n_1 = 4$. In this case the triangles attached to z_0 form a quadrilateral as shown in Figure 4. Since $\mathcal{K}_z$ satisfies the angle condition, z_0 must be the intersection point of the quadrilateral diagonals. Hence, the nodes in $\mathcal{K}_z$ cannot be distributed on two branches of a hyperbola as a line intersects with a hyperbola at no more than two points.

Case 2: $n_1 > 4$. Proceed by contradiction and assume that the nodes in $\mathcal{K}_z$ are distributed on two branches of a hyperbola. Without loss of generality, assume that the real axis of the hyperbola is horizontal and that z_0 is on the right branch of the hyperbola. The left branch cannot have more than two mesh nodes. If it has three nodes as in Figure 3(a), then the sum of the angles at z_2 is more than π.

If the left branch has two nodes, then $\mathcal{K}_z$ must have nodes z_3 and z_4 on the right branch as shown in Figure 3(b). We claim that $\mathcal{K}_z$ cannot have any more nodes on the right branch. If this claim is true, $\mathcal{K}_z$ will have $n_1 = 4$ and this is a contradiction as $n_1 > 4$ by assumption. To prove the previous claim, assume that $\mathcal{K}_z$ has another node z_5 as in Figure 3(b). Then, the sum of the angles at node z_3 is greater than π unless the nodes z_1, z_3, and z_5 lie on a line that is tangent to the right branch of the hyperbola, which is impossible by the second part of Proposition 2.1.

The only remaining possibility is to have exactly one node on the left branch of the hyperbola as in Figure 3(c). Again, by an argument similar to the one used in previous case, this leads to a contradiction. ∎

COROLLARY 2.4. *Consider a boundary mesh node z, and let $\mathcal{K}_z$ be its corresponding patch. Suppose that $\mathcal{K}_z$ contains another patch $\mathcal{K}_{\hat{z}}$ corresponding to an internal mesh node $\hat{z}$. If $\mathcal{K}_{\hat{z}}$ satisfies the angle and the line conditions, then B_z is invertible.*

3. Boundedness of $\mathbf{G^h}$. Let $v \in S_h$, let $\mathcal{K}_z$ be the patch associated with $z \in \mathcal{N}_h$, and consider the mesh triangle $T_k \subset \mathcal{K}_z$ for some $1 \leq k \leq m$. Let the vertices of T_k be $(x_{k,1}, y_{k,1})$, $(x_{k,2}, y_{k,2})$, and $(x_{k,3}, y_{k,3})$, where the numbering is in a counterclockwise direction. Since $v \in P_1(T_k)$, it is easy to verify that

$$\partial_x v(x,y) = \sum_{j=1}^{3} a_{k,j} v_{k,j} \text{ and } \partial_y v(x,y) = \sum_{j=1}^{3} b_{k,j} v_{k,j} \text{ for } (x,y) \in T_k, \tag{3.1}$$

where

$$a_{k,j} = \frac{1}{2|T_k|}(y_{k,j+1} - y_{k,j+2}), b_{k,j} = \frac{1}{2|T_k|}(x_{k,j+2} - x_{k,j+1}), v_{k,j} = v(x_{k,j}, y_{k,j}),$$

and the addition in indices is mod 3. Equivalently,

$$\partial_x v(x,y) = \boldsymbol{v}_k^T \boldsymbol{a}_k \text{ and } \partial_y v(x,y) = \boldsymbol{v}_k^T \boldsymbol{b}_k \text{ for } (x,y) \in T_k,$$

where $\boldsymbol{a}_k = \begin{bmatrix} a_{k,1} & a_{k,2} & a_{k,3} \end{bmatrix}^T$, $\boldsymbol{b}_k = \begin{bmatrix} b_{k,1} & b_{k,2} & b_{k,3} \end{bmatrix}^T$, and $\boldsymbol{v}_k = \begin{bmatrix} v_{k,1} & v_{k,2} & v_{k,3} \end{bmatrix}^T$.

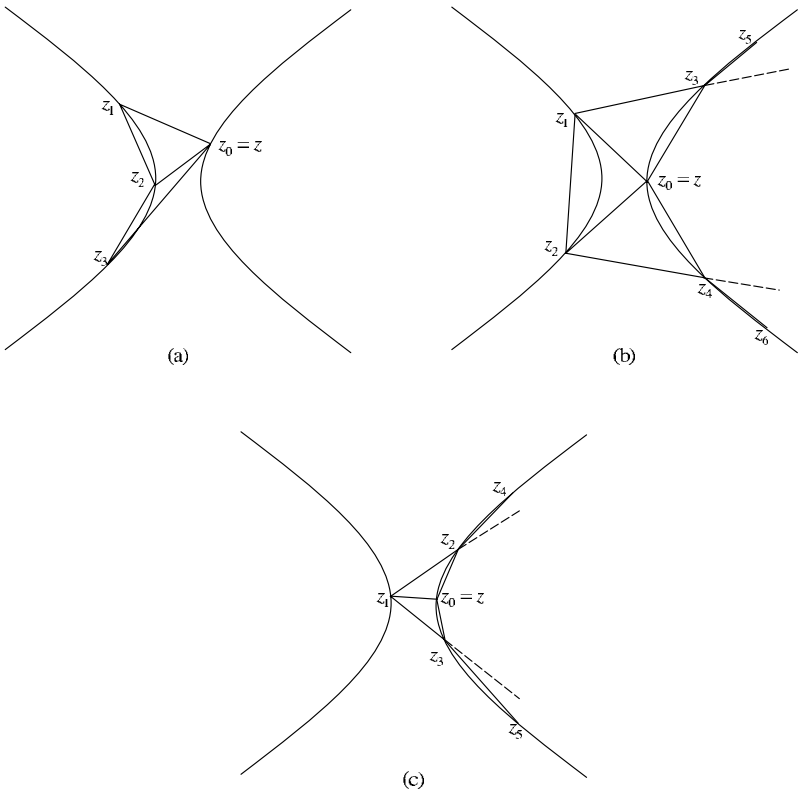

FIG. 3. *Nodes in ω_z cannot be distributed on two branches of a hyperbola when ω_z satisfies the angle condition.*

Let E_k be an $(n+1) \times 3$ Boolean matrix defined for T_k, where

$$E_k(i,j) = \begin{cases} 1 & \text{if the node } i \text{ in } \mathcal{K}_z \text{ is the vertex } j \text{ in } T_k, \\ 0 & \text{otherwise.} \end{cases}$$

Then,

$$\boldsymbol{v}_k = E_k^T \boldsymbol{v}_z$$

and (3.1) can be simplified to the form

$$\partial_x v(x,y) = \boldsymbol{v}_z^T E_k \boldsymbol{a}_k \text{ and } \partial_y v(x,y) = \boldsymbol{v}_z^T E_k \boldsymbol{b}_k \text{ for } (x,y) \in T_k. \tag{3.2}$$

Let ω_z be the reference patch associated with z, and let F_z be the affine mapping from $\mathcal{K}_z$ to ω_z. Let $\hat{T}_k = F_z(T_k)$, and let $(\hat{x}_{k,j}, \hat{y}_{k,j}) = F_z(x_{k,j}, y_{k,j})$ for $1 \le j \le 3$. It is easy to verify that

$$a_{k,j} = \frac{\hat{a}_{k,j}}{h_z} \text{ and } b_{k,j} = \frac{\hat{b}_{k,j}}{h_z},$$

where

$$\hat{a}_{k,j} = \frac{1}{2|\hat{T}_k|}(\hat{y}_{k,j+1} - \hat{y}_{k,j+2}) \text{ and } \hat{b}_{k,j} = \frac{1}{2|\hat{T}_k|}(\hat{x}_{k,j+2} - \hat{x}_{k,j+1}).$$

Let $\hat{\boldsymbol{a}}_k = \begin{bmatrix} \hat{a}_{k,1} & \hat{a}_{k,2} & \hat{a}_{k,3} \end{bmatrix}^T$ and $\hat{\boldsymbol{b}}_k = \begin{bmatrix} \hat{b}_{k,1} & \hat{b}_{k,2} & \hat{b}_{k,3} \end{bmatrix}^T$. Then (3.2) can be rewritten in the form

$$\partial_x v(x,y) = \frac{\boldsymbol{v}_z^T E_k \hat{\boldsymbol{a}}_k}{h_z} \text{ and } \partial_y v(x,y) = \frac{\boldsymbol{v}_z^T E_k \hat{\boldsymbol{b}}_k}{h_z} \text{ for } (x,y) \in T_k. \tag{3.3}$$

Let $\mathrm{G}^{\mathrm{h}}_1 v$ and $\mathrm{G}^{\mathrm{h}}_2 v$ stand for the recovered x- and y-derivatives, respectively. Establishing the boundedness of G^{h} in the sense of (1.7) would be easy if $\mathrm{G}^{\mathrm{h}}_l v(z)$ can be expressed as a linear combination of the first partial derivatives of v on the triangles of ω_z for $l = 1, 2$. So, we will try to find a set of *bounded values* $\alpha_{z,l,1}, \ldots, \alpha_{z,l,m}, \beta_{z,l,1}, \ldots, \beta_{z,l,m}$ such that

$$\mathrm{G}^{\mathrm{h}}_l v(z) = \sum_{k=1}^{m} [\alpha_{z,l,k} (\partial_x v)_k + \beta_{z,l,k} (\partial_y v)_k] \text{ for } l = 1, 2, \tag{3.4}$$

where $(\partial_x v)_k$ and $(\partial_y v)_k$ are the first partial derivatives of v in T_k. Using (2.3) and (3.3) in (3.4), we get

$$\boldsymbol{v}_z^T \sum_{k=1}^{m} [\alpha_{z,l,k} E_k \hat{\boldsymbol{a}}_k + \beta_{z,l,k} E_k \hat{\boldsymbol{b}}_k] = \boldsymbol{v}_z^T A_z B_z^{-1} e_{l+1} \text{ for } l = 1, 2.$$

Setting

$$M_z = \begin{bmatrix} E_1 \hat{\boldsymbol{a}}_1 & \cdots & E_m \hat{\boldsymbol{a}}_m & E_1 \hat{\boldsymbol{b}}_1 & \cdots & E_m \hat{\boldsymbol{b}}_m \end{bmatrix} \tag{3.5}$$

and

$$\boldsymbol{\gamma}_{z,l} = \begin{bmatrix} \alpha_{z,l,1} & \cdots & \alpha_{z,l,m} & \beta_{z,l,1} & \cdots & \beta_{z,l,m} \end{bmatrix}^T,$$

we get

$$\boldsymbol{v}_z^T M_z \boldsymbol{\gamma}_{z,l} = \boldsymbol{v}_z^T A_z B_z^{-1} e_{l+1} \text{ for } l = 1, 2.$$

Since this is true for all $v \in S_h$,

$$M_z \boldsymbol{\gamma}_{z,l} = A_z B_z^{-1} e_{l+1} \text{ for } l = 1, 2. \tag{3.6}$$

Note that the order of M_z is $(n+1) \times (2m)$.

LEMMA 3.1. *Consider $z \in \mathcal{N}_h$. If the patch $\mathcal{K}_z$ corresponding to z has no degenerate triangles and B_z is invertible, then* $\operatorname{Rank} M_z = n$ *and the system in* (3.6) *has infinitely many solutions.*

Proof. Since $\mathcal{K}_z$ is simply connected, then, using Euler's theorem, $(n+1) - e + m = 1$, where e is the number of edges in $\mathcal{K}_z$. Hence, $(n+1) - 2m = e - 3m + 1$. By a simple induction argument on m, we can show that $e - 3m + 1 < 0$ for $m \geq 3$. Hence, the system in (3.6) is underdetermined.

To prove that $\operatorname{Rank} M_z = n$, consider the homogeneous linear system

$$M_z^T \boldsymbol{w} = 0 \tag{3.7}$$

with $\boldsymbol{w} = \begin{bmatrix} w_0 & w_1 & \cdots & w_n \end{bmatrix}^T$. We can view $w_0, w_1, \ldots, w_n$ as the nodal values of some function $w \in S_h$ at the nodes $z_0, z_1, \ldots, z_n$ in $\mathcal{K}_z$. With this in mind, the homogeneous system in (3.7) implies that $\nabla w = 0$ in T_k for $k = 1, 2, \ldots, m$. Hence,

w is constant on $\mathcal{K}_z$, as $w \in S_h$, and $w_0 = w_1 = \cdots = w_n$ in any solution $\boldsymbol{w}$ of (3.7). Consequently, the dimension of the null space of M_z^T is 1 and $\operatorname{Rank} M_z^T = \operatorname{Rank} M_z = n$. Moreover, the only row operation on M_z that leads to a row of zeros is adding all the rows together. Since $\mathrm{G^h}$ recovers the exact gradient for any polynomial $p \in P_2(\omega_z)$, it is easy to verify that the row sum of $A_z B_z^{-1} e_{l+1}$ is 0 for $l = 1, 2$. Therefore, the homogeneous system in (3.6) is consistent for $l = 1, 2$. ∎

Among all the solutions of (3.6), we consider the one with the minimum length given by

$$\boldsymbol{\gamma}_{z,l}^* = M_z^\dagger A_z B_z^{-1} e_{l+1} \text{ for } l = 1, 2, \tag{3.8}$$

where $M_z^\dagger$ is the pseudoinverse of M_z. For every mesh triangle T, define the patch

$$\mathcal{K}_T = \bigcup \{\mathcal{K}_z : z \text{ is a vertex of } T\}.$$

For any matrix $K \in \mathbb{R}^{k_1 \times k_2}$, let $\sigma_1(K)$ and $\sigma_{\min(k1,k2)}(K)$ denote the largest and the smallest singular values of K, respectively. Recall that $\sigma_l^2(K) = \sigma_l(K^T K)$ for $l = 1, 2, \ldots, \min(k1, k2)$.

THEOREM 3.2. *Let $0 < C_1 \le \sigma_6(A_z) \le \sigma_1(A_z) \le C_2$ and $0 < C_3 \le \sigma_n(M_z)$ for every mesh node $z \in \mathcal{N}_h$ and for some constants C_1, C_2, and C_3 that are independent of h. Then, there exists a constant C, independent of h, such that*

$$\| \mathrm{G^h} v\|_{L^2(T)} \le C |v|_{1,\mathcal{K}_T} \tag{3.9}$$

for all $T \in \mathcal{T}_h$ and for all $v \in S_h$.

Proof. Consider a mesh triangle T, and let $\mathcal{K}_T$ be the patch corresponding to T. Let z be a vertex of T and consider any $v \in S_h$. Using (3.4) and (3.8) we get

$$\begin{aligned} |\, \mathrm{G^h}_l\, v(z)| &\le \|\boldsymbol{\gamma}_l^*\|_1 |v|_{1,\infty,\mathcal{K}_z} \le c_1 \|\boldsymbol{\gamma}_l^*\|_2 |v|_{1,\infty,\mathcal{K}_T} \\ &\le c_2 \|M^\dagger\|_2 \|A\|_2 \|B^{-1}\|_2 |v|_{1,\infty,\mathcal{K}_T} \\ &\le \frac{c_2 C_2}{C_3 C_1^2} |v|_{1,\infty,\mathcal{K}_T} \end{aligned}$$

for $l = 1, 2$. Since $\mathrm{G^h} v \in P_1(T) \times P_1(T)$,

$$\| \mathrm{G^h} v\|_{L^\infty(T)} \le C |v|_{1,\infty,\mathcal{K}_T}.$$

Hence,

$$\begin{aligned} \| \mathrm{G^h} v\|_{L^2(T)} &\le \sqrt{|T|}\, \| \mathrm{G^h} v\|_{L^\infty(T)} \le C \operatorname{diam}(T) |v|_{1,\infty,\mathcal{K}_T} \\ &\le C \frac{\operatorname{diam}(T)}{\operatorname{diam}(\mathcal{K}_T)} |v|_{1,\mathcal{K}_T} \le C |v|_{1,\mathcal{K}_T}. \end{aligned} \tag{3.10}$$

The inequality in (3.10) is obtained using an inverse estimate. ∎

It is obvious that the bounds assumed about the singular values of A_z and M_z in Theorem 3.2 depend on the mesh geometry as shown in the following theorem.

THEOREM 3.3. *Let $\mathcal{T}_h$ be a triangular partition of Ω that satisfies the following conditions.*

1. *There exists a finite positive integer N such that $n_1 \le N$ for all $z \in \mathcal{N}_h$, and $n_1 \ge 4$ if $z \in \Omega$.*
2. *The sum of any two adjacent angles at $z \in \mathcal{N}_h$ is π if $z \in \Omega$ with $n_1 = 4$, and is at most π if $z \in \partial\Omega$ or if $z \in \Omega$ with $n_1 > 4$.*

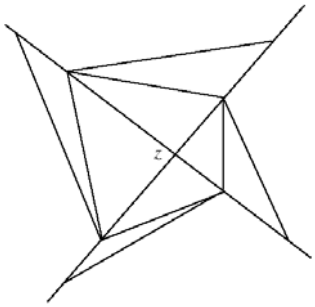

FIG. 4. *An example for patch $\mathcal{K}_z$, corresponding to an internal mesh node z, that does not satisfy the line condition.*

3. *If $z \in \Omega$ with $n_1 = 4$, then the sum of the two adjacent angles in $\mathcal{K}_z$ at one of the mesh nodes directly connected to z is at most $\pi - \phi$ for some $0 < \phi < \pi$.*
4. *If $\theta_{min,h}$ and $\theta_{max,h}$ are the smallest and the largest angles in $\mathcal{T}_h$, respectively, then there exist constants $\underline{\phi}$ and $\overline{\phi} < \pi$ such that*

$$0 < \underline{\phi} \le \theta_{min,h} \le \theta_{max,h} \le \overline{\phi} < \pi.$$

5. *Every boundary mesh node z is connected to an internal mesh node $\bar{z}$ either directly or indirectly through at most one boundary mesh node.*

Then, there exist constants C_1, C_2, and C_3, independent of h, such that

$$0 < C_1 \le \sigma_6(A_z) \le \sigma_1(A_z) \le C_2 \text{ and } 0 < C_3 \le \sigma_n(M_z) \quad \text{for all } z \in \mathcal{N}_h.$$

Remark 3.4. The third condition in Theorem 3.3 is imposed to avoid the singular situation shown in Figure 4. Also, the fifth condition can be relaxed.

Proof. Let $z \in \mathcal{N}_h$, and let D denote the closed unit disk centered at (0,0). Since the reference patch $\omega_z \subset D$, $|B_z(i,j)| \le (n+1)$ for $1 \le i, j \le 6$. Hence,

$$\sigma_1(A_z) = \sqrt{\sigma_1(B_z)} \le \sqrt{\sigma_1(|B_z|)} \le \sqrt{6(n+1)}.$$

By the first and the fifth conditions, it is easy to verify that $n \le N$ if $z \in \Omega$, $n \le N^2 - 5N + 10$ if $z \in \partial\Omega$ and z is directly attached to an internal node, and $n \le 3N - 2$ if $z \in \partial\Omega$ and z is indirectly attached to an internal node through a third boundary node. Hence, there exists $C_2 = C_2(N)$ such that $\sigma_1(A_z) \le C_2$.

To establish the existence of C_1, let us first consider the internal nodes. Let ω_z be a reference patch associated with an internal mesh node z. By definition, $\omega_z \subset D$, ω_z has a node at $(0,0)$, and ω_z has at least one node on ∂D. The first four conditions imply that ω_z has no degenerate triangles and that ω_z satisfies the line and the angle conditions. To show that $\inf\{\sigma_6(A_z) : z \in \mathcal{N}_h \cap \Omega\} \ge C_1 > 0$ for any $h > 0$, proceed by contradiction and assume that there exists a sequence of reference patches $\{\omega_i\}_{i=1}^{\infty}$ such that ω_i has all the properties of ω_z for all $i \ge 1$ and $\sigma_6(A_i) \to 0$, where A_i is the matrix defined for ω_i as in (2.2). Without loss of generality, and by the first condition, one may assume n and n_1 are the same for any patch ω_i; otherwise, we may pass to a subsequence. For $i \ge 1$, the nodes in ω_i are $\tilde{z}_{i,0} = (0,0), \tilde{z}_{i,1}, \tilde{z}_{i,2}, \ldots, \tilde{z}_{i,n}$. According to n_1, we have two cases.

Case 1: $n_1 > 4$. By compactness of D, one may assume that $\tilde{z}_{i,j} \to \tilde{z}_j \in D$ for $0 \le j \le n$; otherwise, one may pass to a subsequence. The nodes $\tilde{z}_0 = (0,0), \tilde{z}_1, \tilde{z}_2, \ldots, \tilde{z}_n$

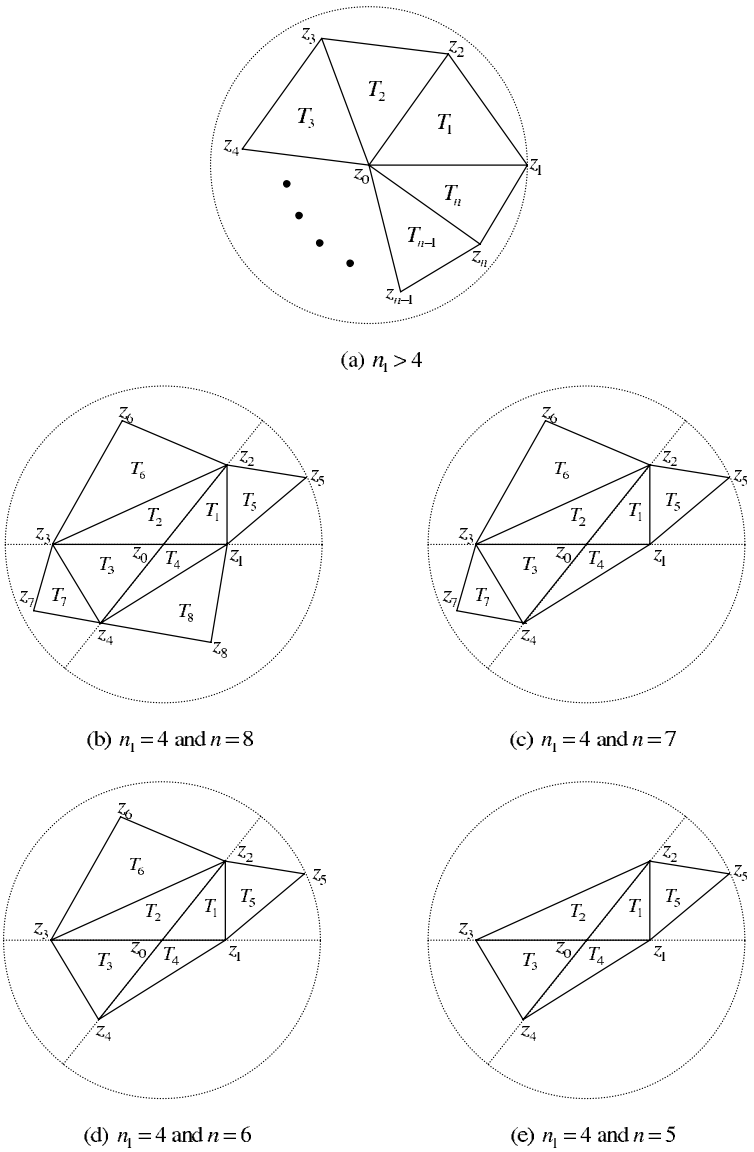

FIG. 5. *The possible patterns for a patch $\mathcal{K}_z$ corresponding to an internal mesh node z.*

can be viewed as the nodes of a patch ω whose pattern is similar to the one shown in Figure 5(a). Using the properties of ω_i, none of the triangles in ω is degenerate, ω has at least one node on ∂D, and the sum of any two adjacent angles in ω cannot exceed π. Hence, ω satisfies the angle and the line conditions. If A denotes the matrix defined for ω as in (2.2), then $\sigma_6(A) \neq 0$. Since $\tilde{z}_{i,j} \to \tilde{z}_j$ for all $0 \leq j \leq n$, $A_i \to A$ in any matrix norm. Hence, $0 \neq \sigma_6(A) = \lim_{i\to\infty} \sigma_6(A_i) = 0$, which is a contradiction.

Case 2: $n_1 = 4$. Since ω_i satisfies the angle condition, it contains four nodes that are corners of a convex quadrilateral whose diagonals intersect at $\tilde{z}_{i,0} = (0, 0)$. Denote the quadrilateral in ω_i by Q_i and denote the set of its diagonals by ℓ_i. Since one of the nodes in ω_i is on ∂D, it is easy to verify that Q_i inscribes a circle whose radius is

at least $\delta = \delta(\underline{\phi})$ for some $\delta > 0$ and for all $i \geq 1$. Consequently,

$$\max\{\text{dist}(\tilde{z}_{i,j}, \ell_i) : 0 \leq j \leq n\} \geq \delta \sin(\phi) > 0. \tag{3.11}$$

Since D is compact, assume that $\tilde{z}_{i,j} \to \tilde{z}_j$ for $0 \leq j \leq n$. The nodes $\tilde{z}_0 = (0,0), \tilde{z}_1, \tilde{z}_2, \ldots, \tilde{z}_n$ can be viewed as the nodes of a patch ω similar to one of the patterns shown in Figure 5(b)–(e). The patch ω has a quadrilateral denoted by Q, and the diagonals of Q are denoted by ℓ. The corners Q are the limits of the corners in Q_i. Hence, (3.11) leads to

$$\max\{\text{dist}(\tilde{z}_j, \ell) : 0 \leq j \leq n\} \geq \delta \sin(\phi),$$

and ω satisfies the line and the angle conditions. As in the previous case, this leads to a contradiction.

Let us turn our attention to the boundary mesh nodes, and let $\mathcal{K}_z$ be the patch corresponding to a boundary mesh node z. By construction, $\mathcal{K}_z$ contains, at least, one patch $\mathcal{K}_{\bar{z}}$ corresponding to an internal mesh node $\bar{z}$. By the fifth condition, $\bar{z}$ is either connected to z directly or indirectly through a third boundary mesh node $\tilde{z}$. As before, $\mathcal{K}_z$ is a subset of a disk centered at z and its radius is h_z. Hence, and without loss of generality, there exists a mesh node $z^* \in \mathcal{K}_{\bar{z}}$, as shown in Figure 2, such that

$$\|z - \bar{z}\| + \|\bar{z} - z^*\| \geq \|z - z^*\| = h_z.$$

This implies that $\max(\|z - \bar{z}\|, \|\bar{z} - z^*\|) \geq h_z/2$. If z is directly connected to $\bar{z}$ as in Figure 2(a), then $\text{diam}(\mathcal{K}_{\bar{z}}) \geq h_z$. If z is indirectly connected to $\bar{z}$ as in Figure 2(a), then we have two situations depending on whether $\|\bar{z} - z^*\| \geq h_z/2$ or $\|z - \bar{z}\| \geq h_z/2$. In the former situation $\text{diam}(\mathcal{K}_{\bar{z}}) \geq h_z$, and for the later situation consider the triangle $z\tilde{z}\bar{z}$. In this triangle the angle at z is at least $\underline{\phi}/2$ by the fourth condition, and hence $\|\bar{z} - \tilde{z}\| \geq h_z \sin(\underline{\phi}/2)/2$. If not, we can use the triangle $z\acute{z}\bar{z}$. Consequently, $\text{diam}(\mathcal{K}_{\bar{z}}) \geq h_z \sin(\underline{\phi}/2)$.

Hence, the reference patch ω_z contains a patch $\bar{\omega}$ that is a scaled translation of the reference patch $\omega_{\bar{z}}$ with $\text{diam}(\bar{\omega}) \geq \sin(\underline{\phi}/2)$. We may write $A_z = [A_{z,1}^T \, A_{z,2}^T]^T$, where $A_{1,z}$ corresponds to the nodes in $\bar{\omega}$ and $A_{z,2}$ corresponds to the rest of the nodes in ω_z. Hence, $B_z = A_{z,1}^T A_{z,1} + A_{z,2}^T A_{z,2}$. Set $B_{z,1} = A_{z,1}^T A_{z,1}$. Since $\bar{\omega}$ satisfies both the line and the angle conditions, both B_z and $B_{z,1}$ are positive definite. Moreover, $\sigma_6(B_z) \geq \sigma_6(B_{z,1})$. Hence,

$$\sigma_6(A_z) = \sqrt{\sigma_6(B_z)} \geq \sqrt{\sigma_6(B_{z,1})} = \sigma_6(A_{z,1}).$$

Using the results established for internal nodes, $\sigma_6(A_z) \geq \tilde{C}_1 > 0$ for all $z \in \partial\Omega$.

Next, we prove the second inequality about $\sigma_n(M_z)$. Again, let $z \in \mathcal{N}_h$, and let $\mathcal{K}_z$ be its corresponding patch. By the fourth condition, none of the mesh triangles in $\mathcal{K}_z$ is degenerate. Since $\sigma_6(A_z) \geq C_1 > 0$, B_z is invertible. Hence, and by Lemma 3.1, $\text{Rank}\, M_z = n$. Since the rank of a matrix can be viewed as the number of its nonzero singular values, $\sigma_n(M_z) > 0$. Using this fact and an argument similar to the one used to establish $\sigma_6(A_z) \geq C_1 > 0$, one can show that $\sigma_n(M_z) \geq C_3 > 0$. ∎

4. Superconvergence property of the PPR-recovered gradient. The following theorem establishes the superconvergence property for the PPR-recovered gradient.

THEOREM 4.1. *Let $\mathcal{T}_h$ be a triangulation of Ω that satisfies the condition (α, σ) and the assumptions in Theorem* 3.3. *If $u \in W^3_\infty(\Omega)$, then*

$$\|\nabla u - \mathrm{G^h} u_h\|_{L^2(\Omega)} \le C h^{1+\rho} \|u\|_{3,\infty,\Omega},$$

where $\rho = \min(\alpha, \frac{1}{2}, \frac{\sigma}{2})$.

Proof. Since

$$\nabla u - \mathrm{G^h} u_h = (\nabla u - \mathrm{G^h}(I_h u)) + (\mathrm{G^h}(I_h u - u_h)), \tag{4.1}$$

estimating $(\nabla u - \mathrm{G^h}(I_h u))$ and $\mathrm{G^h}(I_h u - u_h)$ establishes the proof. To estimate $(\nabla u - \mathrm{G^h}(I_h u))$, recall that $\mathrm{G^h}$ preserves polynomials in $P_2(\Omega)$. Hence, and as was shown in [13],

$$\|\nabla u - \mathrm{G^h}(I_h u)\|_{L^\infty(\Omega)} \le C h^2 |u|_{3,\infty,\Omega}. \tag{4.2}$$

Therefore,

$$\|\nabla u - \mathrm{G^h}(I_h u)\|_{L^2(\Omega)} \le C h^2 \sqrt{|\Omega|} \|u\|_{3,\infty,\Omega}. \tag{4.3}$$

To estimate $\mathrm{G^h}(I_h u - u_h)$, Theorems 3.2 and 3.3 imply the boundedness of $\mathrm{G^h}$. Thus,

$$\|\mathrm{G^h}(I_h u - u_h)\|_{L^2(T)} < C_1 \|\nabla(I_h u - u_h)\|_{L^2(\omega_T)} \text{ for all } T \in \mathcal{T}_h. \tag{4.4}$$

Consequently,

$$\begin{aligned} \|\mathrm{G^h}(I_h u - u_h)\|^2_{L^2(\Omega)} &= \sum_{T \in \mathcal{T}_h} \|\mathrm{G^h}(I_h u - u_h)\|^2_{L^2(T)} \\ &\le \sum_{T \in \mathcal{T}_h} C_1^2 \|\nabla(I_h u - u_h)\|^2_{L^2(\omega_T)} \\ &\le C \|\nabla(I_h u - u_h)\|^2_{L^2(\Omega)}. \end{aligned} \tag{4.5}$$

Since $\mathcal{T}_h$ satisfies the condition (α, σ),

$$\|\nabla(I_h u - u_h)\|_{L^2(\Omega)} \le C_2 h^{1+\rho} \|u\|_{3,\infty,\Omega}, \tag{4.6}$$

where $\rho = \min(\alpha, \frac{1}{2}, \frac{\sigma}{2})$. Using (4.6) in (4.5), we have

$$\|\mathrm{G^h}(I_h u - u_h)\|_{L^2(\Omega)} \le C h^{1+\rho} \|u\|_{3,\infty,\Omega}. \tag{4.7}$$

Using (4.3) and (4.7) in (4.1) completes the proof. ∎

Remark 4.2. The conclusion of Theorem 4.1 is true if the condition (α, σ) is replaced by any other condition that guarantees superconvergence in $\nabla(I_h u - u_h)$. But, the condition (α, σ) covers a wide range of meshes used in practice.

Consider the global a posteriori error estimator η_h defined by

$$\eta_h = \|\mathrm{G^h} u_h - \nabla u_h\|_{L^2(\Omega)}.$$

COROLLARY 4.3. *If, in addition to the assumptions in Theorem* 4.1,

$$\|\nabla(u - u_h)\|_{L^2(\Omega)} \ge c(u) h, \tag{4.8}$$

then

$$\left| \frac{\eta_h}{\|\nabla(u - u_h)\|_{L^2(\Omega)}} - 1 \right| \le C h^\rho.$$

Proof. By Theorem 4.1, and the assumption in (4.8), we have

$$\left| \frac{\eta_h}{\|\nabla(u - u_h)\|_{L^2(\Omega)}} - 1 \right| \le \frac{\|\mathrm{G^h} u_h - \nabla u_h\|_{L^2(\Omega)}}{\|\nabla(u - u_h)\|_{L^2(\Omega)}} \le \frac{C h^{1+\rho} \|u\|_{3,\infty,\Omega}}{c(u) h} = C h^\rho. \qquad ∎$$

5. Numerical results. In this section we will go over some numerical examples that demonstrate the superconvergence property of G^h and the asymptotic exactness of the G^h-based a posteriori error estimator. As it is known, the SPR is one of the best gradient recovery techniques. Moreover, the computer-based theory, developed by Babuška and Strouboulis [3], showed that the SPR-based a posteriori error estimator is the most robust one. Hence, quality of the PPR can be measured using the SPR as a reference.

As before, the gradient recovery operator associated with either the SPR or the PPR is denoted by R_h. The examples considered in this section are based on the model problem

$$-\triangle u = f \text{ in } \Omega \text{ and } u = g \text{ on } \partial\Omega.$$

In general, the quality of $R_h u_h$ deteriorates near $\partial\Omega$. Therefore, we should study separately the behavior of $R_h u_h$ inside Ω and near $\partial\Omega$. To distinguish between the regions inside Ω and the ones adjacent to $\partial\Omega$, $\mathcal{N}_h$ is partitioned into $\mathcal{N}_{h,1} \cup \mathcal{N}_{h,2}$, where

$$\mathcal{N}_{h,1} = \{z \in \mathcal{N}_h : \text{dist}(z, \partial\Omega) \geq H\}$$

for some $H > 0$. Next, $\overline{\Omega}$ is partitioned into $\Omega_1 \cup \Omega_2$, where

$$\Omega_1 = \bigcup \{T \in \mathcal{T}_h : T \text{ has all of its vertices in } \mathcal{N}_{h,1}\}.$$

Let $\mathcal{A} \subseteq \overline{\Omega}$ be the union of a set of mesh triangles in $\mathcal{T}_h$. The R_h-based a posteriori error estimator in $\mathcal{A}$ is

$$\eta_{h,\mathcal{A}} = \|R_h u_h - \nabla u_h\|_{L^2(\mathcal{A})}.$$

To measure the accuracy of $\eta_{h,\mathcal{A}}$, we use the effectivity index $\theta_{h,\mathcal{A}}$ defined by

$$\theta_{h,\mathcal{A}} = \frac{\eta_{h,\mathcal{A}}}{\|\nabla(u - u_h)\|_{L^2(\mathcal{A})}}.$$

It is customary to use colorful pictures to trace the accuracy of the a posteriori error estimator in each of the mesh triangles in $\mathcal{A}$. Instead, we will trace the mean, $\mu_{h,\mathcal{A}}$, and the standard deviation, $\sigma_{h,\mathcal{A}}$, of the effectivity indices in these triangles. If the estimator is asymptotically exact in each of the triangles in $\mathcal{A}$, then $\mu_{h,\mathcal{A}} \to 1$ and $\sigma_{h,\mathcal{A}} \to 0$ as $h \to 0$. Note that

$$\mu_{h,\mathcal{A}} = \frac{1}{N_{h,\mathcal{A}}} \sum_{T \subset \mathcal{A}} \theta_{h,T}$$

and

$$\sigma^2_{h,\mathcal{A}} = \frac{1}{N_{h,\mathcal{A}}} \sum_{T \subset \mathcal{A}} (\theta_{h,T} - \mu_{h,\mathcal{A}})^2,$$

where $N_{h,\mathcal{A}}$ is the number of mesh triangles in $\mathcal{A}$.

Example 1. In this example $\Omega = (0,1)^2$, the solution is $u = \sin(\pi x)\sin(\pi y)$, and H is $1/8$. For mesh generation we consider two cases.

In the first case, we start with an initial mesh generated by the Delaunay triangulation with $h = 0.1$ as shown in Figure 6(a). From this figure, it is clear that

(a) Initial Mesh

(b) Properties of $\mathrm{R}_h u_h$

(c) Properties of θ_h

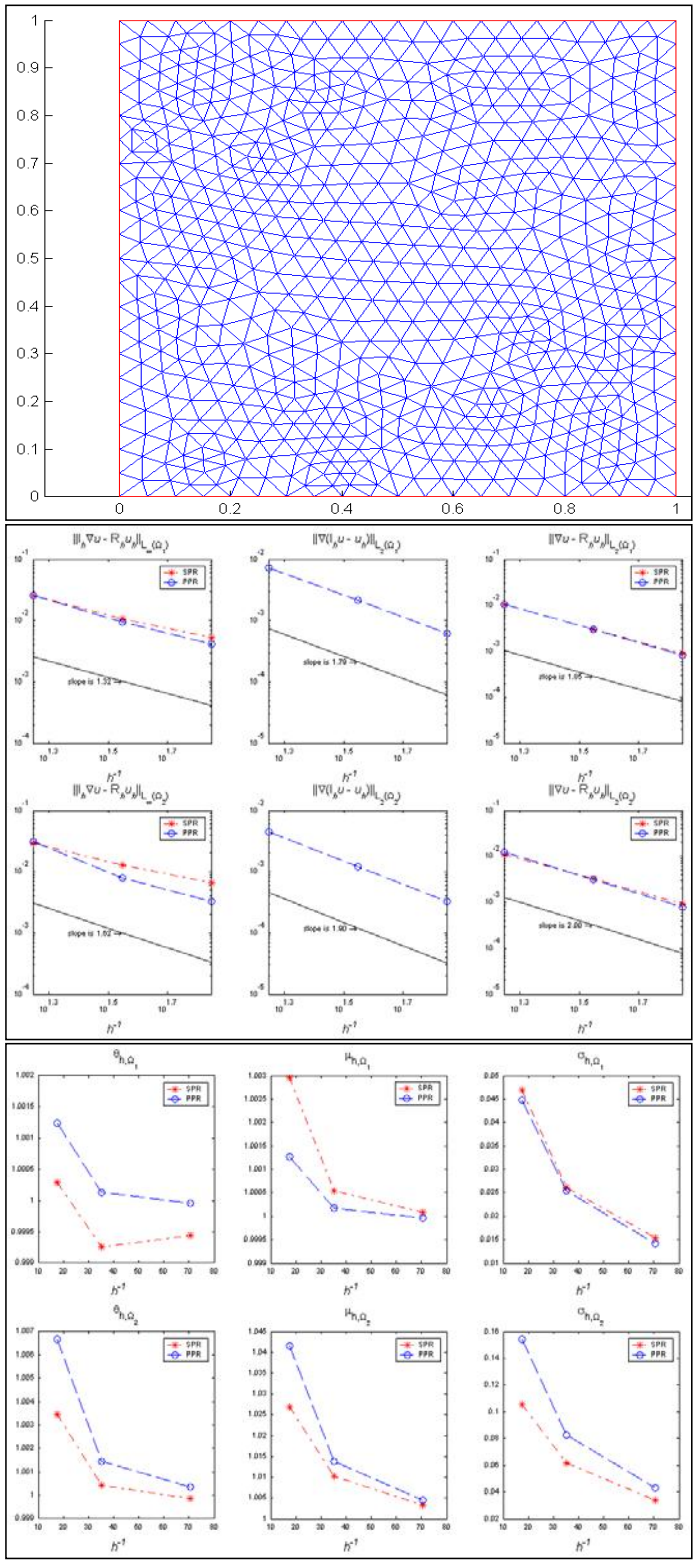

FIG. 6. *Example* 1 *(Delaunay triangulation).*

the Delaunay-generated mesh satisfies the condition (α, σ) with α close to 1 and σ relatively large.
Moreover, this mesh satisfies the conditions in Theorem 3.3. Hence, G^h is bounded, Theorem 1.3 is applicable, and the PPR-recovered gradient enjoys superconvergence. In successive iterations, the new mesh is obtained from the old one by regular refinement. The results are shown in Figure 6(b) and 6(c), where we can note two things. First, although the PPR and the SPR have almost the same global behavior in Ω_1, the statistics show that the PPR is slightly better when we consider the local behavior. Second, the global and local properties of the PPR are much better when it comes to Ω_2.

In the second case, the successive meshes are obtained by decomposing the unit square into $N \times N$ equal squares and then dividing every square into two triangles such that the mesh triangles are arranged in the Chevron pattern. This is done for $N = 16, 32$, and 64. The mesh for $N = 16$ is shown in Figure 7(a). Before we go over the results for this case, note that G^h is bounded and that Theorem 1.3 is not applicable as any pair of triangles sharing a vertical edge form a bigger triangle. As shown in Figure 7(b), we can see that $\nabla(I_h u - u_h)$ has superconvergence that enables G^h to produce superconvergent recovered gradient as mentioned in Remark 4.2. This is not the case with the SPR as it does not preserve polynomials of order 2. Consequently, the behavior of the a posteriori error estimator based on the SPR is inferior to that based on the PPR as shown in Figure 7(c). We can see that the error estimator based on the SPR is underestimating the actual error in Ω_1 and is overestimating it in Ω_2. However, the PPR error estimator is asymptotically exact in both Ω_1 and Ω_2. Moreover, the statistics in Figure 7(c) show that the PPR error estimator is asymptotically exact in each of the mesh triangles.

Example 2. In this example

$$\Omega = (-1, 1)^2 \setminus [1/2, 1)^2.$$

Using a polar coordinate system at (1/2,1/2), the solution is

$$u = r^{\frac{1}{3}} \sin\left(\frac{2\theta - \pi}{3}\right),$$

where

$$\pi/2 \leq \theta \leq 2\pi.$$

As before, H is 1/8, and we start with an initial mesh generated with the Delaunay triangulation at $h = 0.2$. Since we have singularity at the re-entrant corner (1/2,1/2), we have to refine the triangles near this point in the initial mesh so that the pollution effect is minimized. So, after getting the Delaunay triangulation we use regular refinement for the triangles that are within 0.1 from (1/2,1/2). This will serve as our initial mesh, which is shown in Figure 8(a). In the successive iterations, the mesh is regularly refined. The numerical results for this example are shown in Figure 8(b) and Figure 8(c). We should note that the mesh in this example, even after the refinement near the re-entrant corner, is not as good as the one in Figure 7(a). We can see many pairs of triangles that do not form "good" quadrilaterals, i.e., σ is relatively small. Also, because of the singularity at the re-entrant corner (1/2,1/2), we expect both the PPR and the SPR to behave badly near this point. Of course, this affects the convergence rates for the recovered gradients, especially in Ω_1, but still the PPR yields some what better results, even on individual mesh triangles.

(a) Initial Mesh

(b) Properties of $\mathrm{R}_h u_h$

(c) Properties of θ_h

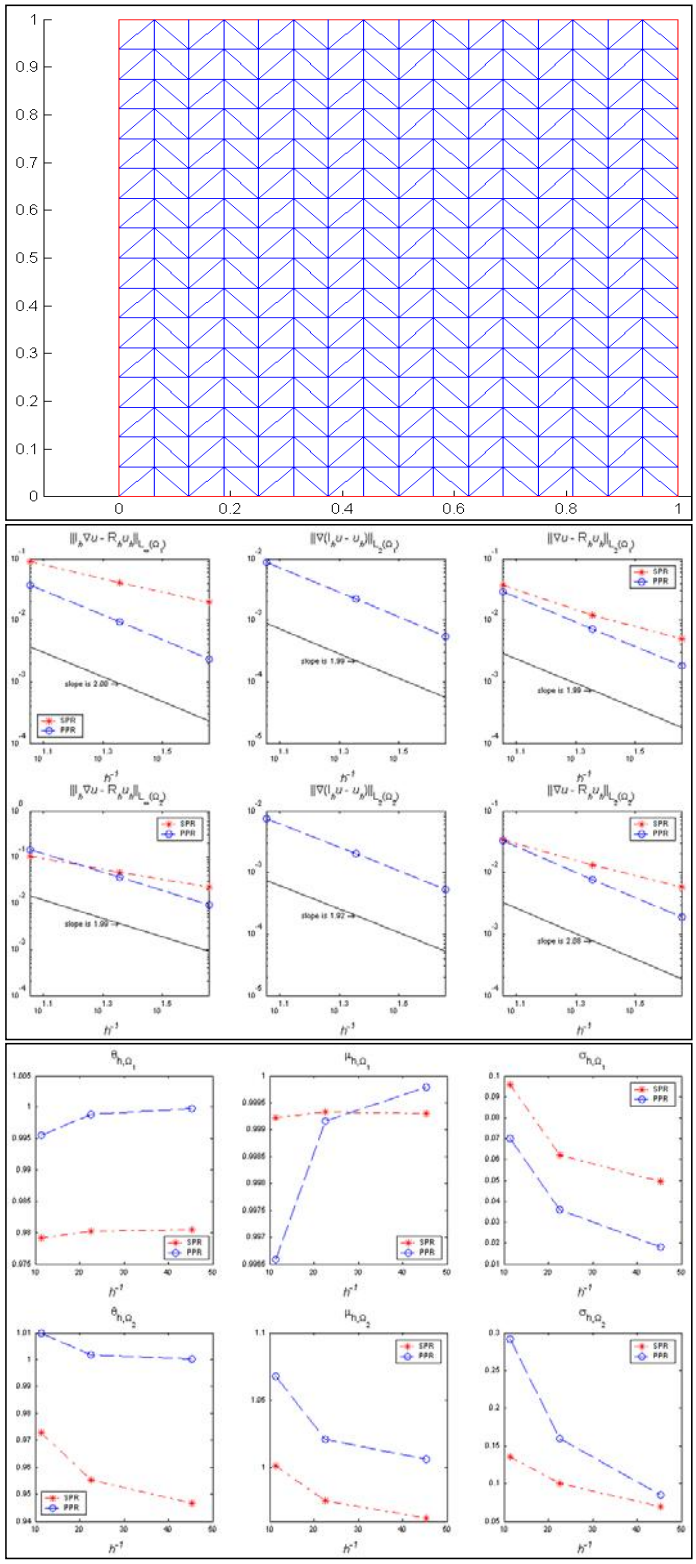

FIG. 7. *Example* 1 *(Chevron mesh).*

(a) Initial Mesh

(b) Properties of $\mathrm{R}_h u_h$

(c) Properties of θ_h

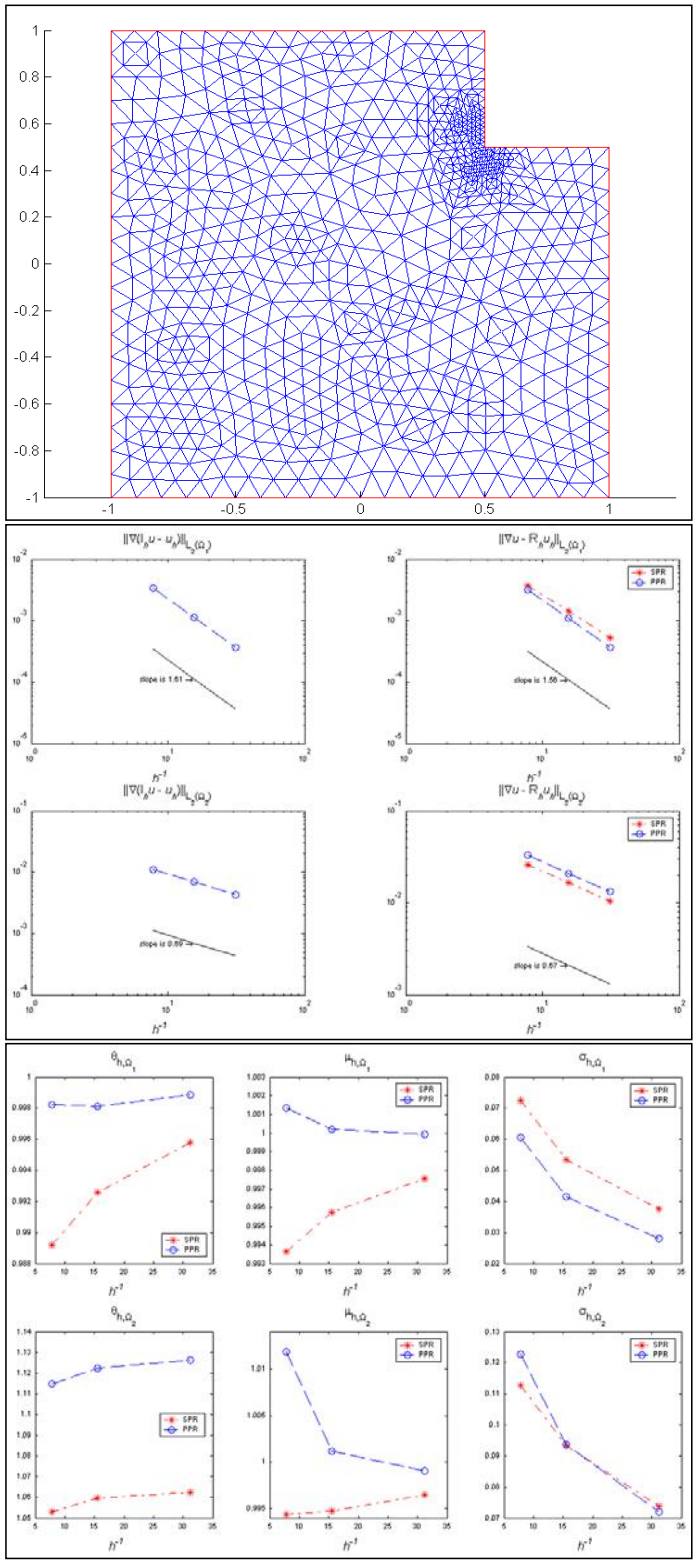

FIG. 8. *Example* 2.

In conclusion, under mild conditions, we have shown that G^h can detect any superconvergence in $\nabla(I_h u - u_h)$ and reflects it in the recovered gradient. Consequently, the PPR error estimator is asymptotically exact, at least globally. The numerical examples indicate that the PPR is, at least, as good as the SPR both inside Ω and near the $\partial\Omega$.

CONVERGENCE OF THE DISCONTINUOUS GALERKIN METHOD FOR DISCONTINUOUS SOLUTIONS*

NOEL J. WALKINGTON†

Abstract. We consider linear first order scalar equations of the form $\rho_t + \mathrm{div}(\rho v) + a\rho = f$ with appropriate initial and boundary conditions. It is shown that approximate solutions computed using the discontinuous Galerkin method will converge in $L^2[0,T;L^2(\Omega)]$ when the coefficients v and a and data f satisfy the minimal assumptions required to establish existence and uniqueness of solutions. In particular, v need not be Lipschitz, so characteristics of the equation may not be defined, and the solutions being approximated my not have bounded variation.

Key words. convergence, discontinuous Galerkin method, hyperbolic equations

DOI. 10.1137/S0036142902412233

1. Introduction.

1.1. Overview. In 1989 DiPerna and Lions [5] proved that weak solutions $\rho : [0,T) \times \Omega \to \mathbb{R}$ of the convection equation

$$\rho_t + \mathrm{div}(\rho v) + a\rho = f \ \text{ in } \Omega, \qquad \rho|_{t=0} = \rho_0, \tag{1.1}$$

are unique when the velocity field v is in certain Sobolev spaces; in particular, v need not be continuous. While weak solutions exist under much weaker hypotheses, the uniqueness result is subtle. They also proved the following remarkable stability result (specialized here to $L^2(\Omega)$).

THEOREM 1.1 (see DiPerna and Lions [5]). *Let $\{\rho_k\}_{k=0}^{\infty} \subset L^\infty[0,T;L^2(\Omega)]$ be weak solutions of*

$$\rho_{kt} + \mathrm{div}(\rho v_k) + a_k\rho_k = f_k \quad \text{in } \Omega$$

with initial data $\rho_k(0) = \rho_{k0}$. Assume that

- *$\{v_k\} \subset L^1[0,T;H_0^1(\Omega)]$, $v_k \to v$ in $L^1[0,T;L^2(\Omega)]$, and $\mathrm{div}(v_k) \to \mathrm{div}(v)$ in $L^1[0,T;L^\infty(\Omega)]$ with $v \in L^1[0,T;H_0^1(\Omega)]$, and*
- *$a_k \to a$ in $L^1[0,T;L^\infty(\Omega)]$, $f_k \to f$ in $L^1[0,T;L^2(\Omega)]$, and $\rho_{k0} \to \rho_0$ in $L^2(\Omega)$.*

Then $\rho_k \to \rho$ in $L^2[0,T;L^2(\Omega)]$, where ρ is the unique solution of (1.1).

In this paper we prove an analogue of this theorem for approximate solutions computed using the discontinuous method.

While the original motivation of DiPerna and Lions concerned the Bolzman equation, their results provided the tools needed to establish existence of solutions for the incompressible Navier–Stokes equations with variable density and viscosity. In modeling the flow of incompressible immiscible fluids the density is discontinuous, and both

the density and viscosity, $\mu = \mu(\rho)$, appear as coefficients multiplying the principle terms of the momentum equation. To obtain existence of the coupled system the strong convergence guaranteed by Theorem 1.1 is used in an essential fashion [14].

Similarly, to prove convergence of numerical approximations to the equations modeling incompressible, immiscible fluids, or flows containing particles, strong convergence of the approximate densities ρ_h will be required when the velocity fields are also computed approximately, and this is what is addressed here. Below we show that approximate solutions of the density equation converge strongly in $L^2[0,T;L^2(\Omega)]$ when the coefficients and data satisfy the minimal hypotheses required to obtain existence and uniqueness of the continuous problem.

While many numerical schemes have been proposed for the solution of first order hyperbolic equations, the discontinuous Galerkin method stands out as one of the best schemes in practice. In his introductory text [7] Johnson states "the discontinuous Galerkin method performs remarkably well and we know of no (linear) finite difference method that is better." Another advantage is that discontinuous Galerkin approximations of the density equation couple correctly with natural approximations of the momentum equation so that the discrete system inherits estimates on the kinetic energy $\rho(|v|^2/2)$. To recover such energy estimates it is natural to multiply the density equation by $|v|^2/2$. Since stable approximations of the momentum equation typically approximate v with piecewise quadratic functions, this suggests that piecewise quartic functions are a natural choice of discrete spaces for the discontinuous Galerkin approximation of the balance of mass. Our results below show that the discontinuous Galerkin scheme will converge when piecewise polynomial approximations of arbitrary degree in the spatial variables are used; however, for technical reasons the degree of the piecewise polynomial temporal variation is restricted to be zero or one.

1.2. Discontinuous Galerkin method. The discontinuous Galerkin method was introduced to simulate neutron transport, and in this context the coefficients v and a are constant. Most of the analysis of this method concerns rates of convergence [8, 11, 12] and requires the solution to be smooth, so is not applicable to problems involving discontinuous solutions. One exception is the work of Lin and Zhou [13], who consider equations in the form $V.\nabla\rho + a\rho = f$, which is slightly more general than the evolution equation considered here (put $V = (1, v)$ and $\nabla = (\partial_t, \nabla_x)$ to recover the evolution form). Lin and Zhou require $V \in W^{1,1}(\Omega)$ and show that if the solution is in $H^{1/2}(\Omega)$, then piecewise constant solutions of the discontinuous Galerkin method will converge to certain weak solutions (the definition of a weak solution in [13] is not standard). Below we exploit the evolution structure of the equation in an essential fashion. This allows us to avoid any smoothness assumptions on v with respect to the time variable, $v \in L^1[0,T;H_0^1(\Omega)]$. Under this assumption ρ will not be of bounded variation and typically will not belong to the fractional Sobolev space $H^{1/2}$.

Since (1.1) is a conservation law in divergence form, it is natural to consider the substantial literature concerning numerical schemes developed for nonlinear conservation laws of the form $\rho_t + \operatorname{div}(F(\rho)) = f$. Essentially all the methods (including the discontinuous Galerkin method) and theory developed in this context assume that F is independent of x and t, the exception being Kruzkov's original work [10], which allows F to depend on x and t in a C^1 fashion. In this context solutions of the conservation laws are regular in the sense that they have bounded variation and frequently stability of numerical schemes is ensured by flux limiters, which limit the variation [3, 4, 6, 9]. The best regularity one can expect for the velocity field of immiscible fluids is $v \in L^2[0,T;H_0^1(\Omega)]$ and the variation of the corresponding density will fail

to be bounded, so any scheme that limits the variation of the discrete solution could not converge strongly.

The level set method has also been used to solve certain hyperbolic equations [15]. If $a = f = \operatorname{div}(v) = 0$, then (1.1) can be written as $\rho_t/|\nabla\rho| = -v.(\nabla\rho/|\nabla\rho|)$, showing that the level sets of ρ move with normal velocity $-v$. Frequently it is possible to find a smooth function ϕ_0 having the same level sets as ρ_0 with $\rho_0 = \beta(\phi_0)$, where $\beta : \mathbb{R} \to \mathbb{R}$ is a discontinuous function. Since $\rho = \beta(\phi)$ for all subsequent times, this eliminates the need to deal with discontinuous functions. This approach has been applied to problems in fluid mechanics [2].

1.3. Notation. In this paper, $\Omega \subset \mathbb{R}^d$ is a bounded domain with unit outward normal n. We consider a regular family of finite element meshes $\{\mathcal{T}_h\}_{h>0}$ each of which we assume triangulates Ω exactly. It is assumed that the finite elements have uniformly bounded aspect ratio. The parameter $h > 0$ represents the diameter of the largest element in $\mathcal{T}_h$ and $|K|$ denotes the area (two dimensions) or volume (three dimensions) of an element $K \in \mathcal{T}_h$. Similarly, if $e \subset K$ is an edge or face, then $|e|$ denotes the length or area of e, respectively. The discontinuous Galerkin method is constructed using space-time elements of the form $K \times (t^{m-1}, t^m)$ with $K \in \mathcal{T}_h$, where $\{t^m\}_{n=0}^M$ is a partition of $[0, T]$. The space of polynomials of degree k on an element K is denoted $\mathcal{P}_k(K)$. For simplicity we assume that for each $h > 0$ a uniform partition of $[0, T]$ used with $t^m = m\tau$ where $\tau = T/M$ is assumed to converge to zero as h tends to zero. We denote the approximate solutions by ρ_h; in particular, the dependence on τ is implicit. If $a \in \mathbb{R}$, the positive and negative parts are denoted by $a^{\pm}$ with $a^+ = \max(a, 0)$ and $a^- = \min(a, 0)$.

The traces of functions ρ_h play an important role in the discontinuous Galerkin method and give rise to a lot of notation. In general, ρ_h denotes a discontinuous piecewise polynomial approximate solution of the convection equation, and annotations of the form ρ^m, ρ_-, etc., refer to various traces of ρ_h (i.e., the subscript h is omitted). We write $\rho^m = \rho_h(t^m_-) = \lim_{t \nearrow t^m} \rho_h(t)$, and the trace from above is denoted by $\rho^m_+ = \lim_{t \searrow t^m} \rho_h(t)$. The jump in ρ_h at t^m is denoted by $[\rho^m] = \rho^m_+ - \rho^m$. Integrals of the form $\int_{\partial K}(\rho_h \ldots)$ compute the trace of ρ_h from within K: $\rho_h|_{\partial K}(t, x) = \lim_{\epsilon \searrow 0} \rho_h(t, x - \epsilon n)$, where n is the unit outward normal to ∂K. An orientation of each edge, e, (face in three dimensions) between two finite elements is selected by arbitrarily selecting one of its normals, which is denoted by N (see Figure 2.1). We write $e = K_+ \cap K_-$, where N points from K_- to K_+, and write $[\rho_e] = \rho_+ - \rho_-$, where $\rho_\pm$ are the traces taken from within $K_\pm$.

Standard notation is adopted for the Lebesgue spaces, $L^p(\Omega)$, and the Sobolev spaces, $W^{m,p}(\Omega)$ or $H^m(\Omega)$. The dual exponent to p is denoted by p', $1/p + 1/p' = 1$. Solutions of the evolution equation will be functions from $[0, T]$ into these spaces, and we adopt the usual notion, $L^2[0, T; H^1(\Omega)]$, $C[0, T; H^1(\Omega)]$, etc., to indicate the temporal regularity of such functions. The space of C^∞ test functions having compact support in Ω is denoted by $\mathcal{D}(\Omega)$. For vector valued quantities, such as the velocity v, we write $v \in L^2(\Omega)$, to indicate that each component lies in the specified space. The space $H(\operatorname{div}; \Omega)$ is the set of vector valued functions in $L^2[0, T; L^2(\Omega)]$ with divergence in $L^2[0, T; L^2(\Omega)]$. Strong convergence of a sequence is indicated as $\rho_h \to \rho$ and weak convergence by $\rho_h \rightharpoonup \rho$.

2. Background. In this section we recall the essential results developed by DiPerna and Lions [5] for (1.1) and recall the discontinuous Galerkin method for approximating solutions of (1.1). Our proof of convergence is essentially a verification of the old adage "a stable consistent scheme is convergent." To make this rigorous

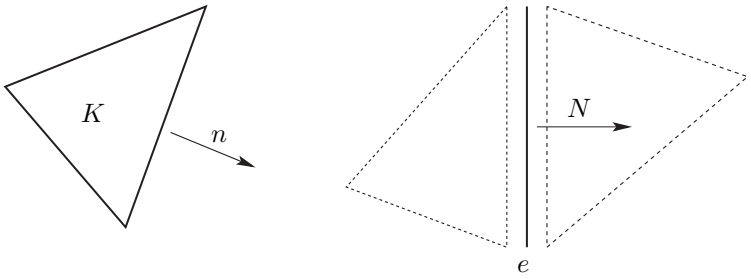

FIG. 2.1. (a) *The outward normal vector of a triangle (tetrahedra in three dimensions) is denoted by n.* (b) *A normal to each edge (face in three dimensions) is arbitrarily chosen and denoted by N.*

we use Theorem 2.2, taken from [14], in a crucial fashion. This theorem states that certain elementary relations that hold for classical solutions of (1.1) continue to hold for weak solutions. As stated above, our convergence results require the approximate solutions to be either piecewise constant or piecewise linear in time. This can be directly attributed to a lack of stability; in general, there are no estimates for the time derivative of the discrete solution. Lacking bounds on the time derivative we can't show that natural piecewise constant approximations converge weakly to the same limit as higher degree piecewise polynomial approximations; see Corollary 3.2.

2.1. DiPerna–Lions theory. For technical reasons DiPerna and Lions [5] considered velocity fields v which vanished on the boundary, and for this reason we always require $v(t) \in H_0^1(\Omega)$. In this situation no boundary conditions are required for ρ; otherwise, ρ would be specified on the inflow boundary, where $v.n < 0$. The following definition of a weak solution of (1.1) is standard and allows us to admit the possibility of discontinuous solutions.

DEFINITION 2.1. *Let $v|_{\partial\Omega} = 0$; then $\rho : [0,T) \times \Omega \to \mathbb{R}$ is a weak solution of* (1.1) *if*

$$-\int_0^T \int_\Omega \rho(\psi_t + v.\nabla\psi - a\psi) = \int_\Omega \rho_0\psi(0) + \int_0^T \int_\Omega f\psi \tag{2.1}$$

for all $\psi \in \mathcal{D}([0,T) \times \Omega)$.

If $\beta : \mathbb{R} \to \mathbb{R}$ is differentiable, then multiplying (1.1) by $\beta'(\rho)$ and formally rearranging the derivatives shows that $\beta(\rho)$ satisfies

$$\beta(\rho)_t + \operatorname{div}(\beta(\rho)v) + \big(\rho\beta'(\rho) - \beta(\rho)\big)\operatorname{div}(v) + a\rho\beta'(\rho) = f\beta'(\rho). \tag{2.2}$$

The following theorem by DiPerna and Lions [5] states that weak solutions of (1.1) will also be weak solutions of (2.2) provided each term is integrable.

THEOREM 2.2. *Let $1 \le p \le \infty$ and suppose that*

$$v \in L^1[0,T,W_0^{1,p'}(\Omega)], \qquad a, \operatorname{div}(v) \in L^1[0,T;L^\infty(\Omega)], \qquad f \in L^1[0,T;L^p(\Omega)].$$

Then for each $\rho_0 \in L^p(\Omega)$ there exists a unique weak solution $\rho \in L^\infty[0,T,L^p(\Omega)]$ of (1.1). *This solution satisfies as follows:*

- *$\rho \in C[0,T;L^p(\Omega)]$ if $p < \infty$.*

- *If $\beta \in C^1(\mathbb{R})$ satisfies $\beta'(t) \le C(1+|t|^r)$ for $C > 0$, and $r = p-1$ if $p < d/(d-1)$, $r < p-1$ if $p = d/(d-1)$, and $r = p/d$ if $p > d/(d-1)$ (r arbitrary if $p = \infty$), then (2.2) is satisfied weakly.*
- *If $\beta \in C^1(\mathbb{R})$ satisfies $\beta'(t) \le C(1+|t|^r)$ for $C > 0$ and $r \le p-1$ (β arbitrary if $p = \infty$), then*

$$\frac{d}{dt}\int_\Omega \beta(\rho) + \int_\Omega \operatorname{div}(v)(\rho\beta'(\rho) - \beta(\rho)) + a\rho\beta'(\rho) = \int_\Omega f\beta'(\rho). \tag{2.3}$$

Remark. The restrictions on r in the second statement of the theorem and the Sobolev embedding theorem guarantee that the term $\beta(\rho)v.\nabla\psi$ is integrable. Similarly, the restriction $r \le p-1$ in the third statement guarantees that each term is integrable.

2.2. Discontinuous Galerkin method. We allow for the possibility that the coefficients are computed only approximately on each mesh; $v \simeq v_h$ and $a \simeq a_h$. Since $\operatorname{div}(v_h)$ may not be bounded in $L^1[0,T;L^\infty(\Omega)]$, care is required to construct a stable approximation scheme. Let

$$\begin{aligned}\mathcal{R}_h = \{&\rho_h \in L^2[0,T;L^2(\Omega)] \mid \rho_h|_{K\times(t^{m-1},t^m)} \in \mathcal{P}_k(K)\otimes\mathcal{P}_\ell(t^{m-1},t^m),\\ &K \in \mathcal{T}_h,\ m = 1,2,\dots\}.\end{aligned}$$

The discontinuous Galerkin method requires $\rho_h \in \mathcal{R}_h$ to satisfy

$$\begin{aligned}&\int_K \left(\rho^m\psi(t_-^m) - \rho^{m-1}\psi(t_+^{m-1})\right)\\ &\quad - \int_{t^{m-1}}^{t^m}\int_K \rho_h\left(\psi_t + v_h.\nabla\psi + (1/2)(\operatorname{div}(v_h) - \operatorname{div}(v))\psi - a_h\psi\right)\\ &\quad + \int_{t^{m-1}}^{t^m}\int_{\partial K} \rho_{in}(v_h.n)\psi = \int_{t^{m-1}}^{t^m}\int_K f\psi\end{aligned} \tag{2.4}$$

for each $K \in \mathcal{T}_h$, $m = 1,2,\dots$, and $\psi \in \mathcal{R}_h$. Since functions in $\mathcal{R}_h$ are discontinuous at the boundary of each space-time element, $K\times(t^{m-1},t^m)$, we specify how the traces are to be evaluated. In all instances traces of ρ_h are taken from the upwind direction, and traces of ψ are taken from within $K\times(t^{m-1},t^m)$. That is, ρ^m and ρ^{m-1} are the traces taken from below, $\rho^m = \lim_{s\nearrow t^m}\rho_h(s)$, ρ_{in} is the inflow trace, $\rho_{in}(x) = \lim_{\epsilon\searrow 0}\rho_h(x-\epsilon v_h)$, and the subscripts $t_\pm$ are used to indicate the traces of ψ at each end of the time interval.

If $(v.n) = (v.n)^+ + (v.n)^-$ is the decomposition of $v.n|_{\partial K}$ into positive and negative parts and $e = K\cap K_-$ is an edge (face in three dimensions) common to K and K_-, then the upwind term can be written as

$$\rho_{in}(v.n) = \rho_h|_{\partial K_-}(v.n)^- + \rho_h|_{\partial K}(v.n)^+.$$

If a global orientation of e is determined by (arbitrarily) selecting one of its normals N (see Figure 2.1), then the weak statement on each element can be summed to give

$$\begin{aligned}&\int_\Omega \rho^m\psi(t_-^m) - \sum_{k=0}^{m-1}\int_\Omega \rho^k[\psi^k] - \int_0^{t^m}\int_\Omega \rho_h\left(\psi_t + v_h.\nabla\psi + (1/2)(\operatorname{div}(v_h) - \operatorname{div}(v))\psi - a_h\psi\right)\\ &\quad - \sum_e \int_0^{t^m}\int_e \left(\rho_-(v_h.N)^+ + \rho_+(v_h.N)^-\right)[\psi_e] = \int_\Omega \rho^0\psi(t_-^0) + \int_0^{t^m}\int_\Omega f\psi.\end{aligned} \tag{2.5}$$

The jump in ψ on the element boundaries is denoted by $[\psi_e] = \psi_+ - \psi_-$ with $\psi_\pm$ determined by the orientation N on an edge and the positive time direction at a temporal interface. We abused the notation by writing $\sum_K \int_K (.) = \int_\Omega (.)$ for integrands involving gradients and similarly for temporal integrals. When ψ is continuous the above expression reduces to a standard weak statement of (1.1).

Remarks. The variant of the discontinuous Galerkin scheme presented here is formulated to be convergent when the velocity field v was known only approximately but the divergence of the v was known precisely. The canonical example of this would be when v_h is an approximation of the velocity of an incompressible fluid for which $\operatorname{div}(v) = 0$. Typically $v_h \to v$ in $L^2[0,T;L^2(\Omega)]$, but $\operatorname{div}(v_h) \neq 0$ since it is difficult to construct divergence free subspaces of $H_0^1(\Omega)$; in particular, $\operatorname{div}(v_h) \not\to 0$ in $L^1[0,T;L^2(\Omega)]$.

The assumptions $v \in L^1[0,T;H_0^1(\Omega)]$ and $\operatorname{div}(v) \in L^1[0,T;L^\infty(\Omega)]$ are required for uniqueness of the solution of (1.1); however, the approximation v_h of v used in the computations need not converge to v in these spaces. For the scheme to be well defined, traces of $v_h.n$ must exist on element boundaries and the traces from each side must agree. For these reasons we require v_h to lie in the space

$$V_h = \{v_h \in L^1[0,T;H(\operatorname{div};\Omega)] \mid v_h(t)|_K \in \mathcal{P}_k(K)\}$$

for some fixed integer $k \geq 0$. Note that uniqueness of the continuous problem requires $v \in L^2[0,T;H_0^1(\Omega)]$, but we do not require $v_h \in L^2[0,T;H_0^1(\Omega)]$.

3. Stability. The following stability result is standard.

THEOREM 3.1 (stability). *Let $\rho_h \in \mathcal{R}_h$ be the approximate solution of* (1.1) *obtained with the discontinuous scheme* (2.4) *and suppose that $\rho^0 \in L^2(\Omega)$, $v_h \in V_h$,*

$$v \in L^1[0,T;H_0^1(\Omega)], \qquad a_h,\, \operatorname{div}(v) \in L^1[0,T;L^\infty(\Omega)], \qquad f \in L^1[0,T;L^2(\Omega)];$$

then

$$\begin{aligned}(1/2)\|\rho^m\|^2_{L^2(\Omega)} + (1/2)\sum_{k=0}^{m-1}\|[\rho^k]\|^2_{L^2(\Omega)} + (1/2)\sum_e \int_0^{t^m}\int_e |v_h.n|[\rho_h]^2 \\ + \int_0^{t^m}\int_\Omega (\operatorname{div}(v)/2 + a_h)\rho_h^2 = (1/2)\|\rho^0\|^2_{L^2(\Omega)} + \int_0^{t^m}\int_\Omega f\rho_h.\end{aligned} \tag{3.1}$$

(1) *If $(\operatorname{div}(v)/2 + a_h) \geq c > 0$ and $f \in L^2[0,T;L^2(\Omega)]$, then*

$$\begin{aligned}\|\rho^m\|^2_{L^2(\Omega)} + \sum_{k=0}^{m-1}\|[\rho^k]\|^2_{L^2(\Omega)} + \sum_e \int_0^{t^m}\int_e |v_h.n|[\rho_h]^2 + c\int_0^{t^m}\|\rho_h(s)\|^2_{L^2(\Omega)}\,ds \\ \leq \|\rho^0\|^2_{L^2(\Omega)} + (1/c)\int_0^{t^m}\|f(s)\|^2_{L^2(\Omega)}\,ds.\end{aligned}$$

(2) *If ρ_h is piecewise constant in time or piecewise linear in time ($\ell = 0$ or 1 in the definition of $\mathcal{R}_h$), and τ is sufficiently small, then*

$$\|\rho^m\|^2_{L^2(\Omega)} + \sum_{k=0}^{m-1}\|[\rho^k]\|^2_{L^2(\Omega)} + \sum_e \int_0^{t^m}\int_e |v_h.n|[\rho_h]^2 \leq C_1\|\rho^0\|^2_{L^2(\Omega)}\exp(C_2 t^m),$$

where C_1 and C_2 depend on the coefficients v and a_h and the data f.

Remark. When $\operatorname{div}(v)$ and a are bounded it is possible to introduce a change of variables to guarantee that $\operatorname{div}(v)/2 + a \geq c > 0$. Specifically, if $\rho = re^{\alpha t}$, then r satisfies

$$r_t + \operatorname{div}(rv) + (\alpha + a)r = e^{-\alpha t} f.$$

Proof. Selecting $\psi = \rho_h$ in (2.4) gives

$$(1/2)\int_K (\rho^m)^2 + [\rho^{m-1}]^2 - (\rho^{m-1})^2 + \int_{t^{m-1}}^{t^m}\int_K (\operatorname{div}(v)/2 + a_h)\rho_h^2 + (1/2)\int_{t^{m-1}}^{t^m}\int_{\partial K} \rho_h^2 (v_h.n)^+ + \rho_-^2 (v_h.n)^- - [\rho_h]^2 (v_h.n)^- = \int_{t^{m-1}}^{t^m}\int_K f\rho_h.$$

Summing this expression and collecting terms establishes (3.1), and if $(\operatorname{div}(v)/2 + a_h) \geq c > 0$, statement (1) follows immediately.

If ρ_h is piecewise constant in time, then

$$\int_0^{t^m}\int_\Omega f\rho_h - (\operatorname{div}(v)/2 + a_h)\rho_h^2 \leq F^m \max_{1\leq k\leq n} \|\rho^k\|_{L^2(\Omega)} + \sum_{k=1}^m \gamma_k \|\rho^k\|^2_{L^2(\Omega)},$$

where

$$\gamma_k = \int_{t^{k-1}}^{t^k} \left((1/2)\|\operatorname{div}(v(s))\|_{L^\infty(\Omega)} + \|a_h(s)\|_{L^\infty(\Omega)}\right) ds, \qquad F^m = \int_0^{t^m} \|f(s)\|_{L^2(\Omega)}\, ds.$$

If ρ_h is piecewise linear in time, then for $s \in (t^{m-1}, t^m)$

$$\begin{aligned}\|\rho_h(s)\|_{L^2(\Omega)} &= \|\rho^m(s - t^{m-1})/\tau + \rho_+^{m-1}(t^m - s)/\tau\|_{L^2(\Omega)} \\ &= \|\rho^m(s - t^{m-1})/\tau + ([\rho^{m-1}] - \rho^{m-1})(t^m - s)/\tau\|_{L^2(\Omega)} \\ &\leq \|\rho^m\|_{L^2(\Omega)}(s - t^{m-1})/\tau + \|[\rho^{m-1}] - \rho^{m-1}\|_{L^2(\Omega)}(t^m - s)/\tau.\end{aligned}$$

Then

$$\|\rho_h\|_{L^\infty[0,t^m;L^2(\Omega)]} \leq \max_{0\leq k\leq m} \|\rho^k\|_{L^2(\Omega)} + \max_{0\leq k\leq m-1} \|[\rho^k]\|_{L^2(\Omega)}$$

and

$$\|\rho_h(s)\|^2_{L^2(\Omega)} \leq \|\rho^m\|^2_{L^2(\Omega)} + 2\|\rho^{m-1}\|^2_{L^2(\Omega)} + 2\|[\rho^{m-1}]\|^2_{L^2(\Omega)}.$$

It follows that

$$\int_0^{t^m}\int_\Omega f\rho_h - (\operatorname{div}(v)/2 + a_h)\rho_h^2 \leq F^m \left(\max_{0\leq k\leq m} \|\rho^k\|_{L^2(\Omega)} + \max_{0\leq k\leq m-1} \|[\rho^k]\|_{L^2(\Omega)}\right)$$
$$+ \left(\gamma_m \|\rho^m\|^2_{L^2(\Omega)} + 2\gamma_1 \|\rho^0\|^2_{L^2(\Omega)}\right) + \sum_{k=1}^{m-1} \left((\gamma_k + 2\gamma_{k+1})\|\rho^k\|^2_{L^2(\Omega)} + 2\gamma_k \|[\rho^{k-1}]\|^2_{L^2(\Omega)}\right).$$

In each instance an estimate of the form

$$\begin{aligned}&\|\rho^m\|^2_{L^2(\Omega)} + (1 - \hat\gamma)\sum_{k=0}^{m-1} \|[\rho^k]\|^2_{L^2(\Omega)} + \sum_e \int_0^{t^m}\int_e |v_h.n|[\rho_e]^2 \\ &\quad\leq (1 + \hat\gamma_0)\|\rho^0\|^2_{L^2(\Omega)} + (C/c)(F^m)^2 + \sum_{k=1}^m \left(\hat\gamma_k \|\rho^k\|^2_{L^2(\Omega)}\right) \\ &\qquad + c\left(\max_{0\leq k\leq m} \|\rho^k\|^2_{L^2(\Omega)} + \max_{0\leq k\leq m-1} \|[\rho^k]\|^2_{L^2(\Omega)}\right)\end{aligned}$$

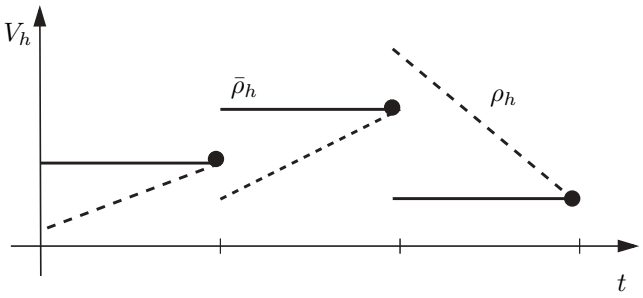

FIG. 3.1. *$\bar\rho_h$ is piecewise constant time and is equal to $\rho_h(t^m_-)$ on $(t^{m-1}, t^m]$.*

holds, where $c > 0$ is arbitrary and $\hat\gamma$ and $\hat\gamma_k$ are bounded by integrals of functions in $L^1[0,T]$ over intervals of length τ. If τ is sufficiently small, all these constants will be less than $1/2$, and statement (2) follows from the discrete Gronwall inequality. ∎

When $\operatorname{div}(v)/2 + a_h = 0$ the stability estimate only bounds ρ_h at the discrete times $\{t^m\}_{n=0}^M$. If $\bar\rho_h(t) = \rho^m$ on $(t^{m-1}, t^m]$ (see Figure 3.1), the lemma shows that $\bar\rho_h$ can be bounded in $L^\infty[0,T;L^2(\Omega)]$. Clearly $\bar\rho_h = \rho_h$ when ρ_h is piecewise constant in time ($\ell = 0$); however, when $\ell > 1$ it may happen that $\bar\rho_h$ and ρ_h have different weak limits. The following corollary shows that this will not happen when $\ell = 1$.

COROLLARY 3.2. *Let $\rho_h \in \mathcal{R}_h$ be piecewise linear in time ($\ell = 1$) and let $\bar\rho_h \in \mathcal{R}_h$ be the function piecewise constant in time equal to $\rho^m = \rho_h(t^m_-)$ on $(t^{m-1}, t^m]$.*

- *If $\psi \in L^2[0,T;L^2(\Omega)]$, then*

$$\left|\int_0^T\int_\Omega (\bar\rho_h - \rho_h)\psi\right| \le \|\bar\rho_h\|_{L^2[0,T;L^2(\Omega)]}\|\psi - \psi(.+\tau)\|_{L^2[0,T-\tau;L^2(\Omega)]}$$
$$+\sqrt{(\tau/2)}\left(\|\rho^M\|_{L^2(\Omega)} + \|\rho^0\|_{L^2(\Omega)} + \left(\sum_{m=0}^{M-1}\|[\rho^m]\|^2_{L^2(\Omega)}\right)^{1/2}\right)\|\psi\|_{L^2[0,T;L^2(\Omega)]}.$$

- $\|\rho_h\|_{L^\infty[0,T;L^2(\Omega)]} \le \|\bar\rho_h\|_{L^\infty[0,T;L^2(\Omega)]} + \max_{0\le m\le M-1}\|[\rho_h^m]\|_{L^2(\Omega)}$ *and*

$$\|\bar\rho_h - \rho_h\|^2_{L^2[0,T;L^2(\Omega)]}$$
$$\le (2/3)\left(\|\bar\rho_h - \bar\rho_h(.+\tau)\|_{L^2[0,T-\tau;L^2(\Omega)]} + \tau\sum_{m=0}^{M-1}\|[\rho^m]\|^2_{L^2(\Omega)}\right).$$

Proof. On the interval $(t^{m-1}, t^m]$ we have $\bar\rho_h - \rho_h = (\rho^m - \rho_+^{m-1})(t^m - t)/\tau$ (recall that $\rho^m = \rho^m_-$). Then

$$\int_0^T\int_\Omega(\bar\rho_h - \rho_h)\psi = \int_\Omega\sum_{m=1}^M\int_0^\tau(\rho^m - \rho_+^{m-1})(1 - s/\tau)\psi(t^{m-1}+s)\,ds$$
$$= \int_\Omega\int_0^\tau\Bigg(\rho^M\psi(t^{M-1}+s) - \rho_+^0\psi(s)$$
$$+\sum_{m=1}^{M-1}(\rho^m\psi(t^{m-1}+s) - \rho_+^m\psi(t^m+s))\Bigg)(1 - s/\tau)\,ds$$

$$= \int_\Omega \int_0^\tau \Bigg(\rho^M \psi(t^{M-1}+s) - \rho^0 \psi(s) + \sum_{m=1}^{M-1} \rho^m (\psi(t^{m-1}+s) - \psi(t^m+s)) + \sum_{m=0}^{M-1} (\rho^m - \rho_+^m)\psi(t^m+s) \Bigg) (1-s/\tau)\, ds.$$

The first statement then follows upon observing that the last term can be bounded by

$$\int_\Omega \int_0^\tau \sum_{m=0}^{M-1} (\rho^m - \rho_+^m)\psi(t^m+s)(1-s\tau) \le \sqrt{(\tau/2)} \left(\sum_{m=0}^{M-1} \|[\rho^m]\|_{L^2(\Omega)}^2 \right)^{1/2} \|\psi\|_{L^2[0,T;L^2(\Omega)]}.$$

To establish the second statement we compute

$$\begin{aligned} \|\bar\rho_h - \rho_h\|_{L^2[0,T;L^2(\Omega)]}^2 &= \sum_{m=1}^M \int_0^\tau \|\rho^m - \rho_+^{m-1}\|^2 (1-s/\tau)^2\, ds \\ &\le \sum_{m=1}^M (\tau/3) \|\rho^m - \rho^{m-1} + [\rho^{m-1}]\|^2 \\ &\le (2/3) \left(\|\bar\rho_h - \bar\rho_h(.+\tau)\|_{L^2[0,T-\tau;L^2(\Omega)]} + \tau \sum_{m=0}^{M-1} \|[\rho^m]\|_{L^2(\Omega)}^2 \right). \end{aligned}$$

∎

4. Consistency. The bounds established above show that subsequences of the approximate solutions converge weakly-star in $L^\infty[0,T;L^2(\Omega)]$. In this section we show that the limits of these sequences are weak solutions of (1.1). This is easy to show when the space $\mathcal{R}_h$ contains the continuous finite element spaces; however, when $k=0$ the only continuous functions are constants, which complicates the proof. We begin with a technical lemma.

LEMMA 4.1. *Let $K \subset \mathbb{R}^d$ be a simplex, $v \in H^1(K)^d$, and $\psi \in W^{1,p}(K)$ with $p \ge 4d/(d+4)$. Then there exists a constant C depending only on d and the aspect ratio of K such that*

$$\int_{\partial K} |v.n||\psi - \bar\psi|^2 \le C|K|^{(1/2-2/p)} h_K \|v\|_{H^1(K)} \|\psi\|_{W^{1,p}(K)}^2,$$

where $\bar\psi = (1/|K|)\int_K \psi$ is the average of ψ on K and h_K is the diameter of K.

If each component of v is a polynomial of degree k, then

$$\int_{\partial K} |v.n||\psi - \bar\psi|^2 \le C|K|^{(1/2-2/p)} h_K \|v\|_{L^2(K)} \|\psi\|_{W^{1,p}(K)}^2,$$

where C may now depend additionally on k.

Proof. Let $\hat K$ be the usual reference simplex and $\chi(\xi) = x_0 + B\xi$ be an affine mapping of $\hat K$ to K. We use a hat to denote the natural correspondence between functions defined on K and $\hat K$, $\hat\psi = \psi \circ \chi$. Writing the integral over the boundary as

the sum over the faces $e \subset \partial K$, the trace theorem with $p \geq 4d/(d+4)$ enables us to write

$$\begin{aligned}\int_{\partial K} |v.n||\psi - \bar{\psi}|^2 &= \sum_{e \subset \partial K} \int_e |v.n||\psi - \bar{\psi}|^2 \\ &= \sum_{\hat{e} \subset \partial \hat{K}} \frac{|e|}{|\hat{e}|} \int_{\hat{e}} |\hat{v}.n||\hat{\psi} - \bar{\psi}|^2 \\ &\leq C \sum_{\hat{e} \subset \partial \hat{K}} |e| \|\hat{v}\|_{H^1(\hat{K})} \|\hat{\psi} - \bar{\psi}\|^2_{W^{1,p}(\hat{K})} \\ &\leq C \sum_{\hat{e} \subset \partial \hat{K}} |e| \|\hat{v}\|_{H^1(\hat{K})} |\hat{\psi}|^2_{W^{1,p}(\hat{K})}.\end{aligned}$$

We used the fact that the average of ψ is the average of $\hat{\psi}$ and the Poincaré inequality to pass to the $W^{1,p}$ seminorm in the last line. Notice that if $v \in \mathcal{P}_k(K)^d$, then $\|\hat{v}\|_{H^1(\hat{K})}$ is equivalent to $\|\hat{v}\|_{L^2(\hat{K})}$ since $\mathcal{P}_k(\hat{K})$ is finite dimensional.

Recalling that $\|\hat{v}\|_{L^2(\hat{K})} = (|\hat{K}|/|K|)^{1/2} \|\hat{v}\|_{L^2(K))}$, $|B| \leq C h_K$,

$$|\hat{\psi}|_{W^{1,p}(\hat{K})} \leq (|\hat{K}|/|K|)^{1/p} |B| |\psi|_{W^{1,p}(K)} \leq C(|\hat{K}|/|K|)^{1/p} h_K |\psi|_{W^{1,p}(K)},$$

and $|\nabla \hat{v}|_{L^2(\hat{K})} \leq C(|\hat{K}|/|K|)^{1/2} h_K \|\nabla v\|_{L^2(K)}$, we deduce that

$$\int_{\partial K} |v.n||\psi - \bar{\psi}|^2 \leq C \sum_{e \subset \partial K} \frac{|e|}{|K|^{(1/2+2/p)}} h_K^2 \|v\|_{H^1(K)} |\psi|^2_{W^{1,p}(K)}$$

(with $\|v\|_{L^2(K)}$ replacing $\|v\|_{H^1(K)}$ if $v \in \mathcal{P}_k(K)^d$). Since

$$|K| = (1/d)|e| \times (\text{perpendicular height}) \geq c|e|h_K,$$

where c depends on the aspect ratio of K, it follows that $|e|h_K \leq C|K|$, and the proof follows. ∎

The following lemma provides sufficient conditions on the coefficients v_h and a_h that suffice to establish consistency of the discontinuous Galerkin method.

LEMMA 4.2. *Let $\{\rho_h\}$ be a (sub-) sequence of solutions of the discontinuous Galerkin scheme* (2.4) *computed on a sequence of quasi-regular meshes and suppose that $\rho_h \rightharpoonup^* \rho$ in $L^\infty[0,T;L^2(\Omega)]$. Assume that $f \in L^1[0,T;L^2(\Omega)]$, $v \in L^1[0,T;H^1_0(\Omega)]$, $v_h(t) \in V_h$, $\rho^0 \rightharpoonup \rho_0$ in $L^2(\Omega)$,*

$$v_h \to v, \quad \text{and} \quad a_h \to a, \ \text{in } L^1[0,T;L^2(\Omega)],$$

and either (1) $\operatorname{div}(v_h) \to \operatorname{div}(v)$ *in* $L^1[0,T;L^2(\Omega)]$ *or* (2) $(\operatorname{div}(v_h) - \operatorname{div}(v))|_K \perp \mathcal{P}_k(K)$ *in* $L^2(K)$ *for each* $K \in \mathcal{T}_h$. *Then ρ is a weak solution of* (1.1).

Proof. When $k, \ell > 0$ $\mathcal{R}_h$ contains the usual continuous finite element spaces, so if $\psi \in \mathcal{D}([0,T) \times \Omega)$, then the classical Lagrange interpolant $\psi_h \in \mathcal{R}_h \cap C([0,T] \times \bar{\Omega})$ converges to ψ in $W^{1,\infty}((0,T) \times \Omega)$. When ψ_h is substituted into (2.5) all the jump

terms vanish to give

$$-\int_0^T\int_\Omega \rho_h\big(\psi_{ht}+v_h.\nabla\psi_h+(1/2)(\operatorname{div}(v_h)-\operatorname{div}(v))\psi_h-a_h\psi_h\big)=\int_\Omega \rho^0\psi(0)+\int_0^T\int_\Omega f\psi_h.$$

If $\operatorname{div}(v_h)\to\operatorname{div}(v)$ in $L^1[0,T;L^2(\Omega)]$ the hypotheses suffice to pass to the limit term by term in the above equation to show that ρ is a weak solution of (1.1). If $(\operatorname{div}(v_h)-\operatorname{div}(v)|_K\perp\mathcal{P}_k(K)$ for $K\in\mathcal{T}_h$ the term involving $\operatorname{div}(v_h)-\operatorname{div}(v)$ still vanishes since

$$\begin{aligned}\int_0^T\int_\Omega \rho_h(\operatorname{div}(v_h)-\operatorname{div}(v))\psi_h &= \int_0^T\int_\Omega \rho_h(\operatorname{div}(v_h)-\operatorname{div}(v))(\psi_h-\bar\psi)\\ &\le \|\rho_h\|_{L^\infty[0,T;L^2(\Omega)]}\|\operatorname{div}(v_h)-\operatorname{div}(v)\|_{L^1[0,T;L^2(\Omega)]}Ch\\ &\to 0,\end{aligned}$$

where $\bar\psi(t,x)$ is the average of $\psi_h(t,.)$ over the element K containing x.

When $\ell=0$ or $k=0$, functions in $\mathcal{R}_h$ are piecewise constant in time or space, respectively. In this situation the terms involving ψ_{ht} or $\nabla\psi_h$ vanish and it is necessary to show that the corresponding jump terms in (2.5) approximate the missing terms: $-\sum_{k=0}^{M-1}\int_\Omega \rho^k[\psi^k]\sim-\int_0^T\int_\Omega\rho\psi_t$ and

$$-\sum_e\int_0^T\int_e\left(\rho_-(v_h.N)^+ +\rho_+(v_h.N)^-\right)[\psi_h]\sim\int_0^T\int_\Omega\rho v.\nabla\psi.$$

If $\ell=0$ and $\psi\in\mathcal{D}([0,T)\times\Omega)$, let ψ^k be a projection of $\psi(t^k)$ onto the (spatial) finite element space $\{\psi_h\in L^2(\Omega)\mid\psi_h|_K\in\mathcal{P}_k(K),\,K\in\mathcal{T}_h\}$, and let $\hat\psi_h$ denote the piecewise linear interpolant of $\{\psi^k\}$ in time. Then $\hat\psi_h$ converges to ψ in $W^{1,\infty}[0,T;L^\infty(\Omega)]$ and temporal jump terms become

$$-\sum_{k=0}^{M-1}\int_\Omega\rho^k[\psi^k]=-\sum_{k=0}^{M-1}\int_\Omega\rho^k(\psi^{k+1}-\psi^k)=-\int_0^T\int_\Omega\rho_h\hat\psi_{ht}\to-\int_0^T\int_\Omega\rho\psi_t$$

as required.

Finally consider the spatial jump terms when $k=0$. Let ψ be piecewise polynomial of degree ℓ in time with values in $\mathcal{D}(\Omega)$. Selecting $\psi_h(t)|_K$ to be the spatial average of $\psi(t)$ over each element the spatial jump terms in (2.5) become

$$\begin{aligned}&-\sum_e\int_0^T\int_e\left(\rho_-(v_h.N)^+ +\rho_+(v_h.N)^-\right)[\psi_h]\\ &=-\sum_e\int_0^T\int_e\left(\rho_-(v_h.N)^+ +\rho_+(v_h.N)^-\right)[\psi_h-\psi]\\ &=-\int_0^T\sum_K\int_{\partial K}\left(\rho_{K-}(v_h.n)^- +\rho_K(v_h.n)^+\right)(\psi_K-\psi),\end{aligned}$$

where ψ_K is the average value of ψ on K, ρ_K is the value of ρ_h on K, and ρ_{K-} is the

value of ρ_h on the upwind element K_-. Then

$$
\begin{aligned}
&-\sum_e \int_0^T \int_e \left(\rho_-(v_h.N)^+ + \rho_+(v_h.N)^-\right)[\psi_h] \\
&= -\int_0^T \sum_K \int_{\partial K} \left((\rho_{K_-} - \rho_K)(v_h.n)^- + \rho_K(v_h.n)\right)(\psi_K - \psi) \\
&= -\int_0^T \sum_K \int_K \operatorname{div}(\rho_K v_h(\psi_K - \psi)) + \int_{\partial K} [\rho_h](v_h.n)^-(\psi_K - \psi) \\
&= -\int_0^T \int_\Omega \left(\rho_h v_h.\nabla\psi + \rho_h \operatorname{div}(v_h)(\psi_h - \psi)\right) + \int_0^T \sum_K \int_{\partial K} [\rho_h](v_h.n)^-(\psi_K - \psi).
\end{aligned}
$$

Clearly the first term converges to $\int\int \rho v.\nabla\psi$; we need to show that the second term vanishes in the limit. Using Lemma 4.1, with $p = 4$, we obtain

$$
\begin{aligned}
&\int_0^T \sum_K \int_{\partial K} [\rho_h](v_h.n)^-(\psi_K - \psi) \\
&\le \left(\int_0^T \sum_K \int_{\partial K} |v_h.n|[\rho_h]^2\right)^{1/2} \left(\int_0^T \sum_K \int_{\partial K} |v_h.n|(\psi_K - \psi)^2\right)^{1/2} \\
&\le \left(\int_0^T 2\sum_e \int_e |v_h.N|[\rho_h]^2\right)^{1/2} \left(\sum_K Ch_K \int_0^T \|v_h\|_{L^2(K)} \|\psi\|^2_{W^{1,4}(K)}\right)^{1/2} \\
&\le \left(\int_0^T \sum_e \int_e |v_h.N|[\rho_h]^2\right)^{1/2} C\sqrt{h}\, \|v_h\|^{1/2}_{L^1[0,T;L^2(\Omega)]} \|\psi\|_{L^\infty[0,T;W^{1,4}(\Omega)]}.
\end{aligned}
$$

Theorem 3.1 shows that the first term is bounded so the expression above vanishes as $h \to 0$. □

Remark. The second hypotheses on the divergence in Lemma 4.2 is useful in the context of finite element approximations of incompressible fluids. If $\tilde{v}_h \in L^1[0,T; H_0^1(\Omega)]$ is a classical finite element approximation of v, then typically $\tilde{v}_h \to v$ in $L^1[0,T;L^2(\Omega)]$, but $\operatorname{div}(\tilde{v}_h)$ will only converge weakly to $\operatorname{div}(v)$ in $L^2[0,T;L^2(\Omega)]$. However, we can construct v_h satisfying the hypothesis of the Lemma as follows. At each time t let $v_h(t)$ be the $L^2(\Omega)$ projection of $\tilde{v}_h(t)$ onto the space

$$
\bar{V}_h(v) = \left\{ v_h \in RT_h^k(\Omega) \;\middle|\; \int_K \operatorname{div}(v_h)p(x) = \int_K \operatorname{div}(v)p(x),\ p \in \mathcal{P}_k(K),\ K \in \mathcal{T}_h \right\}.
$$

Here $RT_h^k(\Omega)$ is the Raviart–Thomas subspace of $H(\operatorname{div};\Omega)$ constructed using piecewise polynomials of degree k on $\mathcal{T}_h$ [1].

By construction $\operatorname{div}(v_h) - \operatorname{div}(v)$ is orthogonal to $\mathcal{P}_k(K)$ for each element K. To see that v_h also converges to v first observe that

$$
(\tilde{v}_h - v_h, w_h)_{L^2(\Omega)} = 0 \qquad \forall\ w_h \in \bar{V}_h \equiv \bar{V}_h(0).
$$

Then

$$
\begin{aligned}
\|\tilde{v}_h - v_h\|^2_{L^2(\Omega)} &= (\tilde{v}_h - v_h, \tilde{v}_h - I_h v + I_h v - v_h)_{L^2(\Omega)} \\
&= (\tilde{v}_h - v_h, \tilde{v}_h - I_h v)_{L^2(\Omega)},
\end{aligned}
$$

where $I_h v$ is the interpolant of v onto the Raviart–Thomas space [1]. The degrees of freedom of I_h are constructed to guarantee that $I_h v - v_h \in \bar{V}_h$. Then

$$\begin{aligned}\|\tilde{v}_h - v_h\|_{L^2(\Omega)} &\le \|\tilde{v}_h - v\|_{L^2(\Omega)} + \|v - I_h v\|_{L^2(\Omega)} \\ &\le \|\tilde{v}_h - v\|_{L^2(\Omega)} + Ch\|v\|_{H_0^1(\Omega)},\end{aligned}$$

so $v_h \to v$ if $\tilde{v}_h \to v$ and v is bounded in $L^1[0,T;H_0^1(\Omega)]$.

5. Convergence. When ρ_h is piecewise constant or linear in time ($\ell = 0$ or 1) the stability estimate guarantees that it is possible to pass to a subsequence for which

$$\bar{\rho}_h \rightharpoonup^* \bar{\rho} \ \text{ and } \ \rho_h \rightharpoonup^* \rho \qquad \text{in } L^\infty[0,T;L^2(\Omega)],$$

and Corollary 3.2 shows that the weak limits coincide, $\rho = \bar{\rho}$. (Recall that $\bar{\rho}_h$ is piecewise constant in time and assumes the values ρ^m in $(t^{m-1}, t^m]$ (see Figure 3.1).) If additionally $v \in L^1[0,T;H_0^1(\Omega)]$, then Theorem 2.2 shows that ρ is unique. In this situation the whole sequence $\{\rho_h\}$ converges weakly, and in the following theorem we establish strong convergence in $L^2[0,T;L^2(\Omega)]$.

THEOREM 5.1. *Let $\{\rho_h\}_{h>0}$ be the sequence of solutions of the discontinuous Galerkin scheme* (2.4) *with either $\ell = 0$ or $\ell = 1$ (ρ_h piecewise constant or linear in time) computed on a sequence of quasi-regular meshes. Assume $\rho_0 \in L^2(\Omega)$,*

$$v \in L^1[0,T;H_0^1(\Omega)], \qquad a,\ \operatorname{div}(v) \in L^1[0,T;L^\infty(\Omega)], \qquad f \in L^1[0,T;L^2(\Omega)],$$

and $\operatorname{div}(v)/2 + a \ge 0$. *If $\rho^0 \to \rho_0$ in $L^2(\Omega)$, $a_h \to a$ in $L^1[0,T;L^\infty(\Omega)]$, and $v_h \in V_h$ is an approximation of v for which $v_h \to v$ in $L^2[0,T;L^2(\Omega)]$ and either* (1) $\operatorname{div}(v_h) \to \operatorname{div}(v)$ *in $L^1[0,T;L^2(\Omega)]$ or* (2) $(\operatorname{div}(v_h) - \operatorname{div}(v))|_K \perp \mathcal{P}_k(K)$ *in $L^2(K)$ for each $K \in \mathcal{T}_h$, then ρ_h converges in $L^2[0,T;L^2(\Omega)]$ to ρ, the weak solution of* (1.1). *Moreover, the jump term*

$$J_h^M = (1/2)\sum_{k=0}^{M-1} \|[\rho^k]\|_{L^2(\Omega)}^2 + (1/2)\sum_e \int_0^T \int_e |v_h.n|[\rho_e]^2$$

converges to zero.

Proof. The idea of the proof is to show that

$$\liminf_h \|\bar{\rho}_h\|_{L^2[0,T;L^2(\Omega)]} \le \|\rho\|_{L^2[0,T;L^2(\Omega)]}. \tag{5.1}$$

If $\ell = 0$, then $\bar{\rho}_h = \rho_h$ and strong convergence of ρ_h follows. When $\ell = 1$, the first estimate in Corollary 3.2 shows that $\bar{\rho}_h$ and ρ_h have the same weak limit so $\bar{\rho}_h$ converges strongly to ρ. The second estimate in Corollary 3.2 shows that strong convergence of $\bar{\rho}_h$ implies strong convergence of ρ_h.

To establish (5.1), the key step is to observe that (2.3) in Theorem 2.2 is an *equation* instead of the usual *inequality*. The hypotheses on v allow us to select $\beta(s) = (1/2)s^2$ in Theorem 2.2 to obtain

$$\begin{aligned}(1/2)\|\rho(t)\|_{L^2(\Omega)}^2 + \int_0^t \int_\Omega ((1/2)\operatorname{div}(v) + a)\rho^2 &= (1/2)\|\rho_0\|_{L^2(\Omega)}^2 + \int_0^t \int_\Omega f\rho \\ &= \liminf_{h\to 0} \left((1/2)\|\rho^0\|_{L^2(\Omega)}^2 + \int_0^t \int_\Omega f\rho_h \right). \end{aligned} \tag{5.2}$$

Integrating both sides with respect to t and using the dominated convergence theorem to interchange the limit and integral gives

$$(1/2)\|\rho\|^2_{L^2[0,T;L^2(\Omega)]} + \int_0^T \gamma(t;\rho)\,dt = \liminf_{h\to 0} \int_0^T \left((1/2)\|\rho^0\|^2_{L^2(\Omega)} + \int_0^t \int_\Omega f\rho_h \right) dt,$$

where

$$\gamma(t;\rho) = \int_0^t \int_\Omega ((1/2)\mathrm{div}(v) + a)\rho^2.$$

Below we use (3.1) to show that

$$\begin{aligned} &\liminf_{h\to 0} \int_0^T \left((1/2)\|\rho^0\|^2_{L^2(\Omega)} + \int_0^t \int_\Omega f\rho_h \right) dt \\ &\geq \liminf_{h\to 0} \left((1/2)\|\bar\rho_h\|^2_{L^2[0,T;L^2(\Omega)]} + \int_0^T \gamma(t;\rho_h)\,dt \right), \end{aligned} \tag{5.3}$$

so that

$$(1/2)\|\rho\|^2_{L^2[0,T;L^2(\Omega)]} + \int_0^T \gamma(t;\rho)\,dt \geq \liminf_{h\to 0} \left((1/2)\|\bar\rho_h\|^2_{L^2[0,T;L^2(\Omega)]} + \int_0^T \gamma(t;\rho_h)\,dt \right).$$

Since $0 \leq (\mathrm{div}(v)/2 + a) \in L^1[0,T;L^\infty(\Omega)]$ it follows that $\gamma(t,.)$ is nonnegative and lower semicontinuous with respect to weak-star convergence in $L^\infty[0,T;L^2(\Omega)]$. Then applying Fatou's lemma to the right-hand side of the above expression shows that $\|\rho\|_{L^2[0,T;L^2(\Omega)]} \geq \liminf_h \|\bar\rho_h\|_{L^2[0,T;L^2(\Omega)]}$, which establishes (5.1).

To verify inequality (5.3), multiply (3.1) by τ and sum to obtain

$$\begin{aligned} \int_0^T \left((1/2)\|\rho^0\|^2_{L^2(\Omega)} + \int_0^t \int_\Omega f\rho_h \right) dt &= (1/2)\|\bar\rho_h\|^2_{L^2[0,T;L^2(\Omega)]} + \int_0^T \gamma(t,\rho_h) + \sum_{m=1}^M \tau J_h^m \\ &\quad + \int_0^T \int_0^t \int_\Omega f\rho_h - \sum_{m=1}^M \tau \int_0^{t^m} \int_\Omega f\rho_h \\ &\quad + \sum_{m=1}^M \tau\gamma(t^m;\rho_h) - \int_0^T \gamma(t,\rho_h)\,dt \\ &\quad + \sum_{m=1}^M \tau \int_0^{t^m} \int_\Omega (a - a_h)\rho_h^2. \end{aligned}$$

To complete the convergence proof we show that the terms in the last three lines vanish as $h \to 0$.

- The terms involving f can be combined as

$$\begin{aligned} \int_0^T \int_0^t \int_\Omega f\rho_h - \sum_{m=1}^M \tau \int_0^{t^m} \int_\Omega f\rho_h &= \sum_{m=1}^M \int_\Omega \left(\int_{t^{m-1}}^{t^m} \int_0^t f\rho_h - \tau \int_0^{t^m} f\rho_h \right) \\ &= \sum_{m=1}^M \int_\Omega \left(\int_{t^{m-1}}^{t^m} \int_{t^{m-1}}^t f\rho_h - \tau \int_{t^{m-1}}^{t^m} f\rho_h \right) \\ &= \sum_{m=1}^M \int_\Omega \int_{t^{m-1}}^{t^m} (t^m - s - \tau) f(s)\rho_h(s)\,ds, \end{aligned}$$

where the last line follows on interchanging the order of integration. It follows that

$$\left|\int_0^T\int_0^t\int_\Omega f\rho_h - \sum_{m=1}^M \tau\int_0^{t^m}\int_\Omega f\rho_h\right| \le 2\tau\|f\|_{L^1[0,T;L^2(\Omega)]}\|\rho_h\|_{L^\infty[0,T;L^2(\Omega)]}.$$

- A similar calculation is used to estimate the terms involving $\gamma(.;\rho_h)$,

$$\sum_{m=1}^M \tau\gamma(t^m;\rho_h) - \int_0^T \gamma(t,\rho_h)\,dt = \sum_{m=1}^M \int_\Omega\int_{t^{m-1}}^{t^m} (t^m - s - \tau)\left(\operatorname{div}(v)/2 + a\right)\rho_h^2\,ds,$$

so that

$$\left|\int_0^T\int_0^t \gamma(s;\rho_h)\,ds\,dt - \sum_{m=0}^M \tau\int_0^{t^m}\gamma(s;\rho_h)\,ds\right| \le 2\tau\|(1/2)\operatorname{div}(v) + a\|_{L^1[0,T;L^\infty(\Omega)]}\|\rho_h\|^2_{L^\infty[0,T;L^2(\Omega)]}.$$

- The last term is bounded by $T\|a - a_h\|_{L^1[0,T;L^\infty(\Omega)]}\|\rho_h\|^2_{L^\infty[0,T;L^2(\Omega)]}$.

To show that the jump terms converge to zero we combine (5.2) and (3.1) to get

$$\|\rho(t)\|^2_{L^2(\Omega)} + \gamma(t,\rho) = \lim_{h\to 0}\left(\|\rho^m\|_{L^2(\Omega)} + \gamma(t^m,\rho_h) + J_h^m\right),$$

where $m = m(h)$ is chosen so that $t \in (t^{m-1}, t^m]$. With this choice $\rho^m = \bar\rho_h(t)$, and since $\|\bar\rho_h(t)\|_{L^2(\Omega)}$ converges to $\|\rho(t)\|_{L^2(\Omega)}$ in $L^2[0,T]$, selecting t to be a Lebesgue point and noting that $\gamma(.,.)$ is continuous on $\mathbb{R}\times L^2[0,T;L^2(\Omega)]$ shows that $\lim_{h\to 0} J_h^m = 0$. Since $J_h^m \ge J_h^M$ for $m \ge M$, and observing that the final time can be chosen arbitrarily, we can choose a Lebesgue point $t \ge T$ to conclude that $J_h^M \to 0$. ∎

6. Monotonicity of the piecewise constant scheme. As stated above, the form of the discontinuous Galerkin method proposed in section 2 was chosen to guarantee convergence when the velocity field was known only approximately. In particular, the factor of 1/2 in the term $(1/2)(\operatorname{div}(v_h) - \operatorname{div}(v))$ guarantees stability in $L^2(\Omega)$; however, $L^p(\Omega)$ estimates would require a different weight. In particular, the piecewise constant scheme, $k = \ell = 0$, may fail to be monotone.

When $k = \ell = 0$, the discontinuous Galerkin scheme (2.4) can be written as

$$|K|(\rho_K^m - \rho_K^{m-1}) + \int_{t^{m-1}}^{t^m}\int_K \left(a_h + (1/2)(\operatorname{div}(v) + \operatorname{div}(v_h))\right)\rho_K^m + \int_{t^{m-1}}^{t^m}\int_{\partial K}(\rho_-^m - \rho^m)(v_h.n)^- = \int_{t^{m-1}}^{t^m}\int_K f.$$

Notice that if K is selected so that ρ_K^m is maximal/minimal, then the boundary term in nonnegative/positive so

$$\max(\rho^m) \le \frac{\max(\rho^{m-1}) + F^m}{1 - C^m} \qquad \text{and} \qquad \min(\rho^m) \ge \frac{\min(\rho^{m-1})}{1 + C^m} - \frac{F^m}{1 - C^m},$$

where

$$F^m = \int_{t^{m-1}}^{t^m}\|f\|_{L^\infty(\Omega)} \quad \text{and} \quad C^m = \int_{t^{m-1}}^{t^m}\|a_h + (1/2)(\operatorname{div}(v) + \operatorname{div}(v_h))\|_{L^\infty(\Omega)},$$

and we have assumed that $\min(\rho^{m-1}) \geq 0$ and τ is sufficiently small to guarantee that $C^m < 1$. Defining

$$\gamma(t) = \int_0^t \|a_h + (1/2)(\operatorname{div}(v) + \operatorname{div}(v_h))\|_{L^\infty(\Omega)}$$

then, assuming $\max(\rho^0) \geq 0$, we compute

$$(1 - o(\tau)) \max(\rho^m) \leq e^{\gamma(t^m)} \max(\rho^0) + \int_0^{t^m} e^{\gamma(t^m)-\gamma(s)} \|f(s)\|_{L^\infty(\Omega)}\, ds,$$

and if $\min(\rho^0) \geq 0$

$$(1 + o(\tau)) \min(\rho^m) \geq e^{-\gamma(t^m)} \min(\rho^0) - \int_0^{t^m} e^{\gamma(t^m)-\gamma(s)} \|f(s)\|_{L^\infty(\Omega)}\, ds,$$

whenever the right-hand side is nonnegative. The terms $1 \pm o(\tau)$ arise when products of the form $\prod_{i=1}^m 1/(1 - C^i)$ are approximated by exponentials of the form $\exp(\sum_{i=1}^m C^i) = \exp(\gamma(t^m))$. Specifically, if $0 \leq C^i \leq 1$, then

$$1 - \sum_{i=1}^m (C^i)^2 \leq \left(\prod_{i=1}^m (1 - C^i)\right) \exp\left(\sum_{i=1}^m C^i\right).$$

Since $\sum_{i=1}^m C^i = \gamma(t^m)$ is bounded and $C^i \to 0$ as $\tau \to 0$, it follows that

$$1 - \sum_{i=1}^m (C^i)^2 \geq 1 - \left(\max_{1\leq i\leq m} C^i\right) \sum_{i=1}^m C^i = 1 - o(\tau).$$

Since it is unlikely that $\operatorname{div}(v_h)$ is bounded in $L^1[0,T;L^\infty(\Omega)]$, this estimate is not particularly useful as it stands. For example, typically it will not be possible to choose τ sufficiently small to guarantee that $C^m < 1$. However, if the construction at the end of section 4 is used to guarantee that $\operatorname{div}(v_h)$ and $\operatorname{div}(v)$ have the same average on each element, then the piecewise constant discontinuous Galerkin scheme becomes

$$|K|(\rho_K^m - \rho_K^{m-1}) + \int_{t^{m-1}}^{t^m} \int_K (a_h + \operatorname{div}(v))\rho_K^m + \int_{t^{m-1}}^{t^m} \int_{\partial K} (\rho_-^m - \rho^m)(v_h.n)^- = \int_{t^{m-1}}^{t^m} \int_K f.$$

In this situation the scheme will be monotone and convergent. The following theorem summarizes these observations.

THEOREM 6.1. *Let $\{\rho_h\}_{h>0}$ be the sequence of solutions of the piecewise constant ($k = \ell = 0$) discontinuous Galerkin scheme* (2.4). *Assume that $v \in L^1[0,T;H_0^1(\Omega)]$, $v_h \in V_h$ and that the averages of* $\operatorname{div}(v_h)$ *and* $\operatorname{div}(v)$ *agree on each element $K \in \mathcal{T}_h$. If a_h,* $\operatorname{div}(v)$, *and f are bounded in $L^1[0,T;L^\infty(\Omega)]$, $0 \leq \alpha \leq \rho^0 \leq \beta$, and τ is sufficiently small, then*

$$(1 - o(\tau)) \max(\rho^m) \leq e^{\gamma(t^m)} \max(\rho^0) + \int_0^{t^m} e^{\gamma(t^m)-\gamma(s)} \|f(s)\|_{L^\infty(\Omega)}\, ds$$

and

$$(1 + o(\tau)) \min(\rho^m) \geq e^{-\gamma(t^m)} \min(\rho^0) - \int_0^{t^m} e^{\gamma(t^m)-\gamma(s)} \|f(s)\|_{L^\infty(\Omega)}\, ds,$$

provided the right-hand side is nonnegative. Here

$$\gamma(t) = \int_0^t \|a_h + \operatorname{div}(v)\|_{L^\infty(\Omega)},$$

and τ sufficiently small is interpreted to mean $\gamma(t^m+\tau)-\gamma(t^m) < 1$ for $m = 0, 1, \ldots$.

Remark. The monotonicity estimates above can be improved slightly if one-sided bounds are used instead of absolute values. For example, in the upper bound $\|a_h + \operatorname{div}(v))\|_{L^\infty(\Omega)}$ can be replaced by $\|(a_h + \operatorname{div}(v))^-\|_{L^\infty(\Omega)}$ and $\|f\|_{L^\infty(\Omega)}$ by $\|f^+\|_{L^\infty(\Omega)}$.

DISCRETE COMPACTNESS FOR EDGE ELEMENTS IN THE PRESENCE OF MIXED BOUNDARY CONDITIONS*

MIRCO RAFFETTO†

Abstract. It is shown—for the first time, to the best of the author's knowledge—that when the finite dimensional space sequence is generated by using Nedelec's edge elements of any order and of both families defined on tetrahedra, the so-called discrete compactness property holds true for Lipschitz polyhedra even in the presence of mixed boundary conditions. The family of meshes is not required to be quasi-uniform but just regular. A standard way to deal with general dielectric permittivities completes the picture.

Key words. discrete compactness property, edge elements, mixed boundary conditions, Galerkin finite element approximations, convergence, electromagnetic boundary value problems, electromagnetic eigenproblems

1. Introduction.

The importance of the discrete compactness property [1] has recently become evident in computational electromagnetics [2], [3], [4]. In particular, it plays a crucial role in proving the convergence of Galerkin finite element approximations for both eigenproblems [5], [2], [6], [7] and driven problems [8], [9], [4].

It is well known that the discrete compactness property was first proved for first-order Nedelec tetrahedral edge elements of the first family [10] by Kikuchi in 1989 [1]. This fundamental first proof was carried out under some regularity assumptions which are not always satisfied when material properties are discontinuous or when different boundary conditions are given on submanifolds having a common boundary [11], [12]. In other contributions [4], [2] the same property was proved for all Nedelec edge elements (of both families for tetrahedra [10], [13] and of the first family for hexahedra), but the indicated limitations of the original proof were retained. Some results in the presence of boundary conditions of different types are actually available but just for problems where the indicated lack of regularity does not arise. This is the case of [7], where eigenproblems with mixed boundary conditions are introduced to exploit the domain symmetry, or when different boundary conditions are given on different connected components of the boundary [9]. On the contrary, the technique introduced in [6] makes it possible to generalize quite easily all known proofs of discrete compactness to cover cases involving all materials of practical interest [7], [9]. Thus, thanks to this result, today "truly" mixed boundary conditions are one of the main obstacles to be overcome in order to obtain a general proof of the discrete compactness property for edge elements.

Unfortunately, in several models of practical interest different boundary conditions are given on submanifolds having a common boundary. This is the case, for example, for the classical model introduced in [14, pp. 299–301] to deal with aperture coupled rectangular waveguides. Another example is provided in [15, p. 593], where the problem of radiation by apertures is considered. In such cases $\mathbf{n} \times \mathbf{E} = \mathbf{0}$ on part

of a plane, and $\mathbf{n} \times \mathbf{H} \neq \mathbf{0}$ on the complementary part of the plane belonging to the boundary. For these and for many other simple and important models the regularity of solenoidal fields is not enough [11] for all known proofs of discrete compactness to hold true. Thus, at present, no convergence result is available for finite element approximations of these practically important problems.

The purpose of this paper is to prove that edge elements of any order and of both families defined on tetrahedra [10], [13] satisfy the discrete compactness property, provided that the family of triangulations is regular [16], independent of the presence of mixed boundary conditions (and, of course, of material inhomogeneities). Thus, as a by-product, a convergence result for edge-based finite element approximations of electromagnetic problems can be established independently of the presence of mixed boundary conditions.

This paper is organized as follows. In section 2 some assumptions on the domain, its boundary, material properties, and the family of triangulations are introduced. In section 3, a set of four conditions is proved to be sufficient for the discrete compactness property to hold true even in the presence of mixed boundary conditions. In carrying out the proof, vector fields are thought of as elements of $H(\mathrm{curl};\Omega)$ and just for the solenoidal fields of this space a standard regularity result is exploited. Then, in section 4, Nedelec's edge elements of any order and of both families defined on tetrahedra are proved to satisfy the sufficient conditions reported in section 3.

2. Assumptions and notations. Let $\Omega \subset \mathbb{R}^3$ be a simply connected Lipschitz polyhedral domain [17]. Let $\Gamma = \partial\Omega$ be its connected boundary and suppose that it splits into two disjoint open submanifolds Γ_τ and Γ_ν satisfying $\overline{\Gamma}_\tau \cup \overline{\Gamma}_\nu = \Gamma$ and $\overline{\Gamma}_\tau \cap \overline{\Gamma}_\nu \neq \emptyset$. Hence, $\overline{\Gamma}_\tau$ and $\overline{\Gamma}_\nu$ have a nonempty common boundary. Moreover, we assume that this common boundary is a piecewise straight simple closed curve. The outward unit vector normal to Γ will be denoted by $\mathbf{n}$. Notice that the limit cases where one of the above submanifolds is empty are not allowed since the result we are looking for is already known [1] in these cases. For the same reason [9], the case of an empty common boundary is also excluded. The above assumptions on Ω, Γ, Γ_τ, and Γ_ν are useful to simplify the following discussion, but not all of them are necessary; our result can be stated under very general topological assumptions [18] (see also [6] for an analogous approach).

It would be possible to introduce some notations to deal with material properties. However, as pointed out in the introduction, Proposition 2.27 of [6] provides a clear indication that material properties are no longer an obstacle. This proposition was exploited in [6] and [7] for proving the convergence of finite element approximations of electromagnetic eigenproblems and, for example, in [9] to deal with electromagnetic driven problems. Thus, we will consider only problems involving homogeneous media.

A consequence of the previous assumptions is that we can use many of the symbols introduced in [6]. For the sake of clarity, however, we report the most important spaces [18] for the next developments:

$$U = H(\mathrm{curl};\Omega), \tag{2.1}$$

$$U_0 = \{\mathbf{u} \in U \mid \mathrm{curl}\,\mathbf{u} = \mathbf{0}\}, \tag{2.2}$$

$$U_1 = \{\mathbf{u} \in U \mid (\mathbf{u},\mathbf{u}_0)_{0,\Omega} = 0 \ \forall \mathbf{u}_0 \in U_0\}, \tag{2.3}$$

$$V = \{\mathbf{v} \in U \mid \mathbf{v} \times \mathbf{n}_{|\Gamma_\tau} = \mathbf{0}\}, \tag{2.4}$$

$$V_0 = V \cap U_0, \tag{2.5}$$

$$V_1 = \{\mathbf{v} \in V \mid (\mathbf{v}, \mathbf{v}_0)_{0,\Omega} = 0 \ \forall \mathbf{v}_0 \in V_0\}, \tag{2.6}$$

where $(\mathbf{u}, \mathbf{v})_{0,\Omega} = \int_\Omega \mathbf{u} \cdot \mathbf{v}^*$ denotes the usual scalar product in $(L^2(\Omega))^3$ for complex valued vector functions. The scalar product in U is denoted by $(\ ,\ )_{curl,\Omega}$ ($(\mathbf{u}, \mathbf{v})_{curl,\Omega} = (\operatorname{curl} \mathbf{u}, \operatorname{curl} \mathbf{v})_{0,\Omega} + (\mathbf{u}, \mathbf{v})_{0,\Omega}$), and the norms in $(L^2(\Omega))^3$ and U are denoted by $\| \ \|_{0,\Omega}$ and $\| \ \|_{curl,\Omega}$, respectively.

Let us now introduce a sequence of finite dimensional subspaces of V. In order to do so, let us introduce a family of triangulations $\{\mathcal{T}_h\}_{h\in I}$ of $\overline{\Omega}$ and a specific finite element on the triangulation $\mathcal{T}_h$, thus defining a family $\{V_h\}_{h\in I}$ (or simply $\{V_h\}$) of finite dimensional subspaces of V [16]. We will assume, as usual, that h denotes the maximum diameter of all elements of the triangulation $\mathcal{T}_h$, that I is a denumerable and bounded set of strictly positive numbers having zero as the only limit point, that the family of triangulations is regular [16], that, for every h, $\mathcal{T}_h$ exactly covers $\overline{\Omega}$ (i.e., $\overline{\Omega} = \cup_{K\in\mathcal{T}_h} K$, where K denotes as usual a generic element of the triangulation $\mathcal{T}_h$), and, finally, that, for every h, $\overline{\Gamma}_\nu$ and $\overline{\Gamma}_\tau$ are the union of faces of elements of $\mathcal{T}_h$. Due to their practical importance, in this paper we will be particularly interested in the properties of Nedelec's tetrahedral edge elements. With this aim, let us consider the following spaces [10], [13], [7] ($l \in \mathbb{N}, l > 0$, $m \in \mathbb{N}, m > 0$):

$$R_{l,hV} = \{\mathbf{u}_h \in U : \mathbf{u}_h|_K \in R_l \ \forall K \in \mathcal{T}_h\} \cap V, \tag{2.7}$$

$$Q_{l,hV} = \{\mathbf{u}_h \in U : \mathbf{u}_h|_K \in Q_l \ \forall K \in \mathcal{T}_h\} \cap V, \tag{2.8}$$

$$F_{l,hV} = \{\mathbf{u}_h \in U : \mathbf{u}_h|_K \in F_l \ \forall K \in \mathcal{T}_h\} \cap V, \tag{2.9}$$

$$E_{l+1,hV} = \{\mathbf{u}_h \in U : \mathbf{u}_h|_K \in E_{l+1} \ \forall K \in \mathcal{T}_h\} \cap V, \tag{2.10}$$

$$\begin{aligned} P_{m,1,hV} &= \{\mathbf{u}_h \in U : \mathbf{u}_h|_K \in P_{m,1} \ \forall K \in \mathcal{T}_h\} \cap V \\ &= R_{1,hV} \oplus E_{2,hV} \oplus E_{3,hV} \oplus \cdots \oplus E_{m+1,hV}, \end{aligned} \tag{2.11}$$

where R_l and Q_l are defined in [10] and [13] and are usually referred to as the first and second family of Nedelec's elements, respectively. F_l, E_{l+1}, and $P_{m,1}$ are defined in definitions 1 and 2, p. 340, for F_l and E_{l+1}, respectively, and Remark 6, p. 345, for $P_{m,1}$, of [7] as

$$F_l = \{\mathbf{u} \in Q_l : \text{ all degrees of freedom defined for } R_l \text{ vanish}\}, \tag{2.12}$$

$$E_{l+1} = \{\mathbf{u} \in R_{l+1} : \text{ all degrees of freedom defined for } Q_l \text{ vanish}\}, \tag{2.13}$$

$$P_{m,1} = R_1 \oplus E_2 \oplus E_3 \oplus \cdots \oplus E_{m+1}, \tag{2.14}$$

being the indicated degrees of freedom defined, for example, in [10], [13], [9], and [7]. These spaces will be used, as already pointed out, to define V_h. We will also make use of the following spaces:

$$P_{1,h} = \left\{p_h \in H^1(\Omega) : p_h|_K \in P_1 \ \forall K \in \mathcal{T}_h\right\}, \tag{2.15}$$

$$P_{1,hV} = P_{1,h} \cap H^1_{0,\Gamma_\tau}(\Omega), \tag{2.16}$$

where P_n is the space of polynomials of degree at most n ($n \in \mathbb{N}, n \geq 0$) [16].

Finally, by using the notation

$$V_{0h} = V_h \cap V_0, \tag{2.17}$$

$$V_{1h} = \{\mathbf{v}_h \in V_h \mid (\mathbf{v}_h, \mathbf{v}_{0h})_{0,\Omega} = 0 \ \forall \mathbf{v}_{0h} \in V_{0h}\}, \tag{2.18}$$

let us recall the conditions on $\{V_h\}$ with which we will mainly work:

(DCP) "discrete compactness property"
Any sequence $\{\mathbf{v}_h\}$ such that $\mathbf{v}_h \in V_{1h}$, $\|\mathbf{v}_h\|_{curl,\Omega} \leq C \ \forall h \in I$ contains a subsequence (still denoted by $\{\mathbf{v}_h\}$) such that $\exists \mathbf{v} \in (L^2(\Omega))^3$ such that

$$\lim_{h\to 0} \|\mathbf{v}_h - \mathbf{v}\|_{0,\Omega} = 0;$$

(CDK) "completeness of the discrete kernel"

$$\lim_{h\to 0} \inf_{\mathbf{v}_h \in V_{0h}} \|\mathbf{v} - \mathbf{v}_h\|_{curl,\Omega} = 0 \quad \forall \mathbf{v} \in V_0.$$

In the next section we prove that a sequence $\{V_h\}$ satisfies (DCP) in the presence of mixed boundary conditions, provided that a set of sufficient conditions is satisfied. In order to simplify the notation we will use the same symbols for sequences and their subsequences.

3. Sufficient conditions on $\{V_h\}$ for discrete compactness. The following proposition provides a first abstract result. The main idea is to avoid the problems due to the lack of regularity of the solenoidal fields in V by thinking of an element of V as an element of U.

PROPOSITION 3.1. *Suppose that the hypotheses reported in section* 2 *concerning the domain, its boundary, the homogeneous material, and the triangulation of the domain are satisfied. Then (DCP) is satisfied for any sequence of subspaces* $\{V_h\}$ *satisfying*

H1. $V_h \subset V \ \forall h \in I$,
H2. $\mathbf{v}_h|_K \in (H^1(K))^3 \ \forall h \in I, \forall \mathbf{v}_h \in V_h,$ and $\forall K \in \mathcal{T}_h$,
H3. $\exists C \in \mathbb{R}, C > 0$, C *independent of* h, $\mathbf{v}_h$, *and* K *such that* $\|\mathbf{v}_h|_K\|_{1,K} \leq C\|\mathbf{v}_h|_K\|_{curl,K}$,
H4. $\operatorname{grad}(P_{1,hV}) \subset V_{0h} \ \forall h \in I$.

Proof. The proof is split into five steps.

Step 1. *Definition of a new sequence.* Let us consider a sequence $\{\mathbf{v}_h\}$ such that $\mathbf{v}_h \in V_{1h}$, $\|\mathbf{v}_h\|_{curl,\Omega} \leq C_0 \ \forall h \in I$, $C_0 \in \mathbb{R}$, $C_0 > 0$.

Since $V \subset U = U_0 \oplus U_1$, by using H1 we deduce

$$\mathbf{v}_h = \mathbf{u}_{0ch} + \mathbf{u}_{1ch}, \tag{3.1}$$

where $\mathbf{u}_{0ch} \in U_0$, $\mathbf{u}_{1ch} \in U_1$, and, by the orthogonality in U of the decomposition and the boundedness of the sequence $\{\mathbf{v}_h\}$, $\|\mathbf{u}_{0ch}\|_{curl,\Omega} \leq C_0 \ \forall h \in I$ and $\|\mathbf{u}_{1ch}\|_{curl,\Omega} \leq C_0 \ \forall h \in I$.

The sequence we will mainly work with is $\{\mathbf{u}_{0ch}\}$. Since we are considering a topologically trivial situation we have that

$$\exists! p_{ch} \in H^1(\Omega) : \ \operatorname{grad} p_{ch} = \mathbf{u}_{0ch}, \quad \int_\Omega p_{ch} = 0. \tag{3.2}$$

Step 2. *Approximation of the new sequence.* Since $\mathbf{u}_{1ch} \in U_1 \subset U \cap H_0(\mathrm{div}^0;\Omega) = U \cap \{\mathbf{v} \in H(\mathrm{div};\Omega) : \mathrm{div}\,\mathbf{v} = 0,\ \mathbf{v}\cdot\mathbf{n}|_\Gamma = 0\}$, we obtain $\mathbf{u}_{1ch} \in (H^s(\Omega))^3$, $s > 1/2$, $\|\mathbf{u}_{1ch}\|_{s,\Omega} \le C_1\|\mathbf{u}_{1ch}\|_{curl,\Omega}$ [19, Proposition 3.7], being $\|\ \|_{s,\Omega}$, the natural norm in $(H^s(\Omega))^3$, and C_1, a positive constant depending only on Ω. Moreover, by using H2 we have $\mathbf{v}_h|_K \in (H^1(K))^3\ \forall K \in \mathcal{T}_h$. Then we deduce $\mathbf{u}_{0ch}|_K \in (H^s(K))^3\ \forall K \in \mathcal{T}_h$, $s > 1/2$, which implies $p_{ch}|_K \in H^{1+s}(K) \quad \forall K \in \mathcal{T}_h, \quad s > 1/2$. Thus, by Lemma 4 of [1],

$$p_{ch} \in C^0(\overline{\Omega}) \ \ \forall h \in I, \tag{3.3}$$

and if π_h denotes the standard [16] global P_1 interpolation operator for scalar fields (on tetrahedra), $\exists p_h = \pi_h p_{ch} \in P_{1,h}, \exists C_2 \in \mathbb{R}, C_2 > 0$, C_2 independent of p_{ch} and h:

$$\begin{aligned}
\|\mathrm{grad}\,p_{ch} - \mathrm{grad}\,p_h\|_{0,\Omega} &\le C_2 h^s \left(\sum_{K\in\mathcal{T}_h} \|\mathrm{grad}\,p_{ch}|_K\|^2_{s,K}\right)^{1/2} \\
&= C_2 h^s \left(\sum_{K\in\mathcal{T}_h} \|\mathbf{v}_h|_K - \mathbf{u}_{1ch}|_K\|^2_{s,K}\right)^{1/2} \\
&\le C_2 h^s \left(\sum_{K\in\mathcal{T}_h} (2\|\mathbf{v}_h|_K\|^2_{s,K} + 2\|\mathbf{u}_{1ch}|_K\|^2_{s,K})\right)^{1/2} \\
&\le 2C_2 h^s \left(\|\mathbf{u}_{1ch}\|^2_{s,\Omega} + \sum_{K\in\mathcal{T}_h} \|\mathbf{v}_h|_K\|^2_{1,K}\right)^{1/2} \\
&\le 2C_2 h^s \left(C_1^2\|\mathbf{u}_{1ch}\|^2_{curl,\Omega} + \sum_{K\in\mathcal{T}_h} \|\mathbf{v}_h|_K\|^2_{1,K}\right)^{1/2} \\
&\le 2C_2 h^s \left(C_1^2 C_0^2 + \sum_{K\in\mathcal{T}_h} \|\mathbf{v}_h|_K\|^2_{1,K}\right)^{1/2}. \qquad (3.4)
\end{aligned}$$

Further, by using H3 we obtain

$$\begin{aligned}
\|\mathrm{grad}\,p_{ch} - \mathrm{grad}\,p_h\|_{0,\Omega} &\le 2C_2 h^s \left(C_1^2 C_0^2 + C^2 \sum_{K\in\mathcal{T}_h} \|\mathbf{v}_h|_K\|^2_{curl,K}\right)^{1/2} \\
&\le 2C_2 h^s (C_1^2 C_0^2 + C^2 C_0^2)^{1/2} \le C_4 h^s. \qquad (3.5)
\end{aligned}$$

Step 3. *Behavior of* $p_{ch}|_{\Gamma_\tau}$. By using (3.2), inequality $|p_{ch}|_{1,\Omega} = \|\mathbf{u}_{0ch}\|_{0,\Omega} \le C_0$, and Poincaré's inequality for functions with vanishing mean value, we deduce $\|p_{ch}\|^2_{0,\Omega} \le C_5^2 C_0^2$. Then we immediately obtain $\|p_{ch}\|^2_{1,\Omega} \le C_6^2$ and, consequently, $\|p_{ch}|_\Gamma\|_{1/2,\Gamma} \le C_7$, which in turn implies $\|p_{ch}|_{\Gamma_\tau}\|_{1/2,\Gamma_\tau} \le C_8$. Thus we can conclude that

$$\|p_{ch}|_{\Gamma_\tau}\|_{0,\Gamma_\tau} \le C_8. \tag{3.6}$$

Since by H1 $\mathbf{v}_h \in V$, we have that on Γ_τ

$$\mathbf{n}\times\mathbf{u}_{0ch}|_{\Gamma_\tau} = \mathbf{n}\times(\mathrm{grad}\,p_{ch})|_{\Gamma_\tau} = \mathbf{n}\times\mathbf{v}_h|_{\Gamma_\tau} - \mathbf{n}\times\mathbf{u}_{1ch}|_{\Gamma_\tau} = -\mathbf{n}\times\mathbf{u}_{1ch}|_{\Gamma_\tau}. \tag{3.7}$$

Let Γ_j, $j = 1,\dots,J$, denote the faces of the polyhedron Ω and let $\Gamma_{\tau_j} = \Gamma_j \cap \Gamma_\tau$. We assume that if $j \in M \subset \{1,\dots,J\}$, then Γ_{τ_j} is not empty. On each face Γ_j the

outward unit vector $\mathbf{n}$ normal to Γ is a constant vector. Thus, by using (3.7) and the regularity of $\mathbf{u}_{1ch}$, we deduce

$$\begin{aligned}\|(\mathbf{n}\times(\operatorname{grad} p_{ch})|_{\Gamma_{\tau_j}})\times\mathbf{n}\|_{s-1/2,\Gamma_{\tau_j}} &= \|(\mathbf{n}\times\mathbf{u}_{1ch}|_{\Gamma_{\tau_j}})\times\mathbf{n}\|_{s-1/2,\Gamma_{\tau_j}}\\ &= \|\mathbf{n}\times\mathbf{u}_{1ch}|_{\Gamma_{\tau_j}}\|_{s-1/2,\Gamma_{\tau_j}} \le \|\mathbf{n}\times\mathbf{u}_{1ch}|_{\Gamma_\tau}\|_{s-1/2,\Gamma_\tau}\\ &\le \|\mathbf{n}\times\mathbf{u}_{1ch}|_{\Gamma}\|_{s-1/2,\Gamma} \le C_9\|\mathbf{u}_{1ch}\|_{s,\Omega} \le C_{10},\ j\in M. \end{aligned} \tag{3.8}$$

Finally, by using the fact that $(\mathbf{n}\times(\operatorname{grad} p_{ch})|_{\Gamma_{\tau_j}})\times\mathbf{n}$ is equal to the surface gradient of $p_{ch}|_{\Gamma_{\tau_j}}$ on Γ_{τ_j} [9], [20], by definition 1.3.2.1 of [21], and by inequalities (3.6) and (3.8), we deduce

$$p_{ch}|_{\Gamma_{\tau_j}} \in H^{1/2+s}(\Gamma_{\tau_j}),\quad \|p_{ch}|_{\Gamma_{\tau_j}}\|_{1/2+s,\Gamma_{\tau_j}} \le C_{11},\quad j\in M. \tag{3.9}$$

Let us define $e_{j_1,j_2} = (\overline{\Gamma}_{\tau_{j_1}}\cap\overline{\Gamma}_{\tau_{j_2}})^\circ, j_1, j_2 \in M$, and denote by $\gamma_{2D,j}$ the trace operator from $H^{1/2+s}(\Gamma_{\tau_j})$ to $H^s(\partial\Gamma_{\tau_j})$. By (3.3) we deduce

$$p_{ch}|_{\Gamma_\tau} \in C^0(\overline{\Gamma}_\tau)\ \ \forall h\in I. \tag{3.10}$$

Then, by (3.9) and (3.10) we obtain

$$\gamma_{2D,j_1}(p_{ch}|_{\Gamma_{\tau_{j_1}}})|_{e_{j_1,j_2}} = \gamma_{2D,j_2}(p_{ch}|_{\Gamma_{\tau_{j_2}}})|_{e_{j_1,j_2}},\quad j_1,j_2\in M, \tag{3.11}$$

in the sense of $H^s(e_{j_1,j_2})$ when e_{j_1,j_2} is not empty (if this is not the case condition (3.11) is trivial). When (3.9) and (3.11) are satisfied, in order to simplify the notation we will say that

$$p_{ch}|_{\Gamma_\tau} \in H^{1/2+s}(\Gamma_\tau) \tag{3.12}$$

and

$$\|p_{ch}|_{\Gamma_\tau}\|^2_{1/2+s,\Gamma_\tau} = \sum_{j\in M}\|p_{ch}|_{\Gamma_{\tau_j}}\|^2_{1/2+s,\Gamma_{\tau_j}}, \tag{3.13}$$

and the same notation will be adopted for spaces of functions with domain Γ [22].

By using Sobolev's imbedding theorem [23] for each $p_{ch}|_{\Gamma_{\tau_j}}$, $j\in M$, we deduce that

$$\exists p_{tj}\in H^{1+\delta}(\Gamma_{\tau_j}),\ 0<\delta<s-1/2, \tag{3.14}$$

and for a subsequence of $\{p_{ch}|_{\Gamma_{\tau_j}}\}$

$$\lim_{h\to 0}\|p_{ch}|_{\Gamma_{\tau_j}} - p_{tj}\|_{1+\delta,\Gamma_{\tau_j}} = 0,\quad j\in M. \tag{3.15}$$

By using (3.15), the continuity and the linearity of each trace operator $\gamma_{2D,j}$ from $H^{1+\delta}(\Gamma_{\tau_j})$ to $H^{1/2+\delta}(\partial\Gamma_{\tau_j})$, $j\in M$, and (3.11), we deduce

$$\begin{aligned}&\exists p_t : p_t|_{\Gamma_{\tau_j}} = p_{tj}\in H^{1+\delta}(\Gamma_{\tau_j}),\ j\in M,\\ &\gamma_{2D,j_1}(p_t|_{\Gamma_{\tau_{j_1}}})|_{e_{j_1,j_2}} = \gamma_{2D,j_2}(p_t|_{\Gamma_{\tau_{j_2}}})|_{e_{j_1,j_2}},\quad j_1,j_2\in M\end{aligned} \tag{3.16}$$

(the last condition being trivial when $e_{j_1,j_2}=\emptyset$); that is, according to our notation

$$p_t\in H^{1+\delta}(\Gamma_\tau). \tag{3.17}$$

Moreover, by using (3.15), (3.16) and the norm indicated in (3.13), we obtain

$$\lim_{h\to 0} \|p_{ch}|_{\Gamma_\tau} - p_t\|_{1+\delta,\Gamma_\tau} = 0. \tag{3.18}$$

Step 4. *Some auxiliary scalar fields.* By using Poincaré's inequality and the Lax–Milgram lemma, we define $q_{ch} \in H^1_{0,\Gamma_\tau}(\Omega)$ by

$$\begin{aligned} &\text{find } q_{ch} \in H^1_{0,\Gamma_\tau}(\Omega): \ (\operatorname{grad} q_{ch}, \operatorname{grad} t)_{0,\Omega} \\ &\quad = -(\operatorname{grad} p_{ch}, \operatorname{grad} t)_{0,\Omega} \quad \forall t \in H^1_{0,\Gamma_\tau}(\Omega) \end{aligned} \tag{3.19}$$

and $r_{ch} = p_{ch} + q_{ch} \in H^1(\Omega)$. Note that, $\forall h \in I$, r_{ch} is the unique field in $H^1(\Omega)$ satisfying $r_{ch}|_{\Gamma_\tau} = p_{ch}|_{\Gamma_\tau}$ and $(\operatorname{grad} r_{ch}, \operatorname{grad} t)_{0,\Omega} = 0 \quad \forall t \in H^1_{0,\Gamma_\tau}(\Omega)$.

The same decomposition of p_h is possible. Thus we define $q_h \in P_{1,hV}$ by

$$\begin{aligned} &\text{find } q_h \in P_{1,hV}: \ (\operatorname{grad} q_h, \operatorname{grad} t_h)_{0,\Omega} \\ &\quad = -(\operatorname{grad} p_h, \operatorname{grad} t_h)_{0,\Omega} \quad \forall t_h \in P_{1,hV} \end{aligned} \tag{3.20}$$

and $r_h = p_h + q_h \in P_{1,h}$. For all $h \in I$, r_h is the unique field in $P_{1,h}$ satisfying $r_h|_{\Gamma_\tau} = p_h|_{\Gamma_\tau}$ and $(\operatorname{grad} r_h, \operatorname{grad} t_h)_{0,\Omega} = 0 \quad \forall t_h \in P_{1,hV}$.

Step 5. *A sufficient condition for (DCP) holds true.* The orthogonal decomposition $V = V_0 \oplus V_1$ and hypothesis H1 imply

$$\mathbf{v}_h = \mathbf{v}_{0ch} + \mathbf{v}_{1ch}, \tag{3.21}$$

$\mathbf{v}_{0ch} \in V_0$, $\mathbf{v}_{1ch} \in V_1$, $\|\mathbf{v}_{0ch}\|_{curl,\Omega} \le C_0 \ \forall h \in I$ and $\|\mathbf{v}_{1ch}\|_{curl,\Omega} \le C_0 \ \forall h \in I$. Since V_1 is compactly imbedded in $(L^2(\Omega))^3$ [18, Proposition 7.3], a sufficient condition for the convergence in $(L^2(\Omega))^3$ of $\mathbf{v}_h$ is the convergence in $(L^2(\Omega))^3$ of $\mathbf{v}_{0ch}$.

But note that $\operatorname{grad} q_{ch} = \mathbf{v}_{0ch}$. As a matter of fact, $\operatorname{grad} q_{ch}$ is the V_0 $(= \operatorname{grad}(H^1_{0,\Gamma_\tau}(\Omega)))$ component of $\operatorname{grad} p_{ch} = \mathbf{u}_{0ch} = \mathbf{v}_h - \mathbf{u}_{1ch}$, and $\mathbf{u}_{1ch} \in U_1$ is orthogonal to $U_0 \supset V_0$. Thus inequality (3.5) implies

$$\|\operatorname{grad} r_{ch} - \mathbf{v}_{0ch} - \operatorname{grad} r_h + \operatorname{grad} q_h\|_{0,\Omega} \le C_4 h^s. \tag{3.22}$$

The following sufficient condition for (DCP),

$$\lim_{h\to 0} \|\operatorname{grad} r_{ch} - \operatorname{grad} r_h\|_{0,\Omega} = 0, \tag{3.23}$$

would imply $\lim_{h\to 0} \|\mathbf{v}_{0ch} - \operatorname{grad} q_h\|_{0,\Omega} = 0$, which, in turn, implies $\lim_{h\to 0} \|\mathbf{v}_{0ch}\|_{0,\Omega} = 0$ since $\mathbf{v}_{0ch}$ is orthogonal (in $(L^2(\Omega))^3$) to $V_{0h} \ \forall h \in I$ and by H4 to $\operatorname{grad} q_h \in \operatorname{grad}(P_{1,hV}) \ \forall h \in I$ (as $\mathbf{v}_h \in V_{1h}$ and $\mathbf{v}_{1ch} \in V_1$).

The next two lemmas prove that condition (3.23) is satisfied. □

Remark 3.2. The sequences appearing in condition (3.23) have peculiar properties. As a matter of fact, one could note that on one hand, r_{ch} is the weak solution of a problem for the Laplace operator with mixed boundary conditions given by $r_{ch}|_{\Gamma_\tau} = p_{ch}|_{\Gamma_\tau}$ on Γ_τ and the homogeneous Neumann condition on Γ_ν, with $p_{ch}|_{\Gamma_\tau}$ satisfying (3.18). On the other hand, r_h is its standard finite element approximation (see, for example, [17, p. 147]) obtained by setting $r_h(b_{ih}) = p_{ch}(b_{ih})$, where b_{ih} are the nodes of the triangulation $\mathcal{T}_h$ belonging to $\overline{\Gamma}_\tau$ (the above conditions make sense since $r_{ch}|_{\Gamma_\tau} = p_{ch}|_{\Gamma_\tau} \in C^0(\overline{\Gamma}_\tau)$ (see (3.10)). As a matter of fact, $r_h|_{\Gamma_\tau} = p_h|_{\Gamma_\tau}$ and by definition $p_h = \pi_h p_{ch}$.

Remark 3.3. A result analogous to the one provided by the next lemma can be found, for example, in [24, exercise 5.x.10, p. 132]. However, for the sake of completeness we provide a proof.

LEMMA 3.4. *If* $p_{ch}|_{\Gamma_\tau} = p_t \ \forall h \in I$, *then condition* (3.23) *is satisfied.*

Proof. We use a continuous linear extension operator R_1 from $H^{1+\delta}(\Gamma_\tau)$ into $H^{1+\delta}(\Gamma)$ to define $ep_t = R_1(p_t)$ such that $ep_t|_{\Gamma_\tau} = p_t$ and $\|ep_t\|_{1+\delta,\Gamma} \leq C_1\|p_t\|_{1+\delta,\Gamma_\tau}$. This is possible [21] since Γ_τ is a Lipschitz submanifold of Γ which, in turn, is the Lipschitz continuous boundary of a polyhedron. The same notation as that used in Step 3 of the proof of Proposition 3.1 for spaces of functions with domain Γ_τ or Γ is here adopted.

Now, by using Theorem 2 of [22] there exists a continuous inverse R_2 of the first-order trace operator $\gamma^{(1)}$ [22] such that $r_{02} = R_2(ep_t) \in H^{3/2+\delta}(\Omega)$, $r_{02}|_\Gamma = ep_t$, $r_{02}|_{\Gamma_\tau} = p_t$, and $\|r_{02}\|_{3/2+\delta,\Omega} \leq C_2\|ep_t\|_{1+\delta,\Gamma} \leq C_2C_1\|p_t\|_{1+\delta,\Gamma_\tau}$.

By using Poincaré's inequality and the Lax–Milgram lemma, we define $\phi_2 \in H^1_{0,\Gamma_\tau}(\Omega)$ by

$$\text{find } \phi_2 \in H^1_{0,\Gamma_\tau}(\Omega): \ (\operatorname{grad}\phi_2, \operatorname{grad} t)_{0,\Omega} = -(\operatorname{grad} r_{02}, \operatorname{grad} t)_{0,\Omega} \quad \forall t \in H^1_{0,\Gamma_\tau}(\Omega) \tag{3.24}$$

and $r_2 = \phi_2 + r_{02} \in H^1(\Omega)$. Note that $|\phi_2|_{1,\Omega} \leq |r_{02}|_{1,\Omega} \leq \|r_{02}\|_{3/2+\delta,\Omega} \leq C_2C_1 \|p_t\|_{1+\delta,\Gamma_\tau}$ and that $|r_2|_{1,\Omega} \leq |r_{02}|_{1,\Omega} + |\phi_2|_{1,\Omega} \leq 2C_2C_1\|p_t\|_{1+\delta,\Gamma_\tau}$. Note, moreover, that r_2 is the unique field in $H^1(\Omega)$ satisfying $r_2|_{\Gamma_\tau} = r_{02}|_{\Gamma_\tau} = p_t$ and $(\operatorname{grad} r_2, \operatorname{grad} t)_{0,\Omega} = 0 \quad \forall t \in H^1_{0,\Gamma_\tau}(\Omega)$. The decomposition $r_2 = \phi_2 + r_{02}$ is useful since the irregular component ϕ_2 satisfies homogeneous boundary conditions on Γ_τ.

Since $r_{02} \in H^{3/2+\delta}(\Omega)$ with $\delta > 0$ we can define $r_{02h} = \pi_h r_{02}$. By Theorem 5.48 of [9] we deduce

$$\|r_{02h} - r_{02}\|_{1,\Omega} \leq C_4\|r_{02}\|_{3/2+\delta,\Omega}\, h^{1/2+\delta} \leq C_4C_2C_1\|p_t\|_{1+\delta,\Gamma_\tau}\, h^{1/2+\delta}. \tag{3.25}$$

By definition we have $r_{02h}(b_{ih}) = p_t(b_{ih})$, where b_{ih} are the nodes of the triangulation $\mathcal{T}_h$ belonging to $\overline{\Gamma}_\tau \ \forall h \in I$.

Now we define ϕ_{2h} as follows:

$$\text{find } \phi_{2h} \in P_{1,hV}: \ (\operatorname{grad}\phi_{2h}, \operatorname{grad} t_h)_{0,\Omega} = -(\operatorname{grad} r_{02h}, \operatorname{grad} t_h)_{0,\Omega} \quad \forall t_h \in P_{1,hV}. \tag{3.26}$$

We define also $\phi_{2h,1}$ and $\phi_{2h,2}$ by substituting r_{02h} with $r_{02h} - r_{02}$ and r_{02h} with r_{02} in the above problem, respectively. Thus $\phi_{2h} = \phi_{2h,1} + \phi_{2h,2}$ and we have that $|\phi_{2h,1}|_{1,\Omega} \leq |r_{02h} - r_{02}|_{1,\Omega} \leq C_4C_2C_1\|p_t\|_{1+\delta,\Gamma_\tau}\, h^{1/2+\delta}$. Moreover, it is well known [17, Theorem 18.2] that $\|\operatorname{grad}\phi_2 - \operatorname{grad}\phi_{2h,2}\|_{0,\Omega} = 0$.

Finally, let us define $r_{2h} = \phi_{2h} + r_{02h}$. We have $r_{2h}(b_{ih}) = p_t(b_{ih})$, $\forall b_{ih} \in \overline{\Gamma}_\tau$, $\forall h \in I$ and $(\operatorname{grad} r_{2h}, \operatorname{grad} t_h)_{0,\Omega} = 0 \quad \forall t_h \in P_{1,hV}$. Thus, on one hand, r_{2h} is the unique field in $P_{1,h}$ having these properties and, on the other hand,

$$\begin{aligned} |r_2 - r_{2h}|_{1,\Omega} &= |\phi_2 + r_{02} - \phi_{2h} - r_{02h}|_{1,\Omega} \\ &\leq |\phi_2 - \phi_{2h,1} - \phi_{2h,2}|_{1,\Omega} + |r_{02} - r_{02h}|_{1,\Omega} \\ &\leq |\phi_2 - \phi_{2h,2}|_{1,\Omega} + |\phi_{2h,1}|_{1,\Omega} + |r_{02} - r_{02h}|_{1,\Omega} \\ &\leq |\phi_2 - \phi_{2h,2}|_{1,\Omega} + 2C_4C_2C_1\|p_t\|_{1+\delta,\Gamma_\tau}\, h^{1/2+\delta}. \end{aligned} \tag{3.27}$$

We can conclude the proof by observing that r_2 and r_{2h} can be easily identified with r_{ch} and r_h of Proposition 3.1, respectively, subject to the boundary conditions stated in the present lemma. ∎

LEMMA 3.5. *Condition* (3.23) *is satisfied whenever condition* (3.18) *holds true.*

Proof. This is a trivial consequence of Lemma 3.4. Let us consider $p_{ch}|_{\Gamma_\tau} = p_{ch}|_{\Gamma_\tau} - p_t + p_t = p_{th1} + p_t \ \forall h \in I$.

Consider first just the part of the boundary condition given by p_{th1}. Let us denote by r_{1ch} ($\forall h \in I$) the unique field in $H^1(\Omega)$ corresponding to r_2 in the proof of Lemma 3.4. This means that r_{1ch} is defined by the same procedure we used to define r_2 in the proof of Lemma 3.4, but, in this case, the boundary conditions are given by p_{th1} instead of p_t. Then $|r_{1ch}|_{1,\Omega} \leq 2C_2C_1\|p_{th1}\|_{1+\delta,\Gamma_\tau}$. The components ϕ_{1ch} and r_{01ch} corresponding to ϕ_2 and r_{02} of Lemma 3.4, respectively, satisfy $|\phi_{1ch}|_{1,\Omega} \leq C_2C_1\|p_{th1}\|_{1+\delta,\Gamma_\tau}$ and $\|r_{01ch}\|_{3/2+\delta,\Omega} \leq C_2C_1\|p_{th1}\|_{1+\delta,\Gamma_\tau}$. Finally, the discrete field r_{01h} corresponding to r_{02h} satisfies $\|r_{01h} - r_{01ch}\|_{1,\Omega} \leq C_4C_2C_1\|p_{th1}\|_{1+\delta,\Gamma_\tau}h^{1/2+\delta}$. Condition (3.18) means that $\|p_{th1}\|_{1+\delta,\Gamma_\tau} \to 0$ as $h \to 0$. Thus $|r_{1ch}|_{1,\Omega} \to 0$ and $|r_{01ch}|_{1,\Omega} \to 0$ as $h \to 0$ and therefore $|r_{01h}|_{1,\Omega} \to 0$ as $h \to 0$. Finally, by (3.26) even ϕ_{1h} (corresponding to ϕ_{2h}) is such that $|\phi_{1h}|_{1,\Omega} \to 0$ as $h \to 0$ so that r_{1h} (corresponding to r_{2h}) is such that $|r_{1h}|_{1,\Omega} \to 0$ as $h \to 0$. We deduce that $|r_{1ch} - r_{1h}|_{1,\Omega} \to 0$ as $h \to 0$.

Now, we consider the part of the boundary condition given by $p_{ch}|_{\Gamma_\tau} = p_t$. By Lemma 3.4 we deduce $|r_2 - r_{2h}|_{1,\Omega} \to 0$ as $h \to 0$.

Since r_{ch} and r_h of Proposition 3.1 are such that $r_{ch} = r_{1ch} + r_2$ and $r_h = r_{1h} + r_{2h}$ we deduce condition (3.23). ∎

In the next section we prove that when the sequence of subspaces $\{V_h\}$ is defined by using Nedelec's tetrahedral edge elements (i.e., $V_h = R_{l,hV}\ \forall h \in I$ for any fixed $l \in \mathbb{N},\ l > 0$, or $V_h = Q_{l,hV}\ \forall h \in I$ for any fixed $l \in \mathbb{N},\ l > 0$), conditions H1, H2, H3, and H4 are satisfied.

4. Discrete compactness property for all elements of the two Nedelec families defined on tetrahedra. In this section we simply try to verify that conditions H1, H2, H3, and H4 hold true for the elements of interest.

First, let us point out that H4 is satisfied, provided that $V_h \supset R_{1,hV}$. This is trivially true for $V_h = R_{l,hV}$ and $V_h = Q_{l,hV}$, $l \in \mathbb{N},\ l > 0$, as is well known. However, the same is true by definition (2.11) when $V_h = P_{m,1,hV},\ m \in \mathbb{N}, m > 0$ [7, pp. 338–342 and p. 345].

Second, again by definitions (2.7), (2.8), and (2.11), condition H1 is satisfied for all the above spaces.

Moreover, condition H2 simply requires H^1 regularity on an element-by-element basis. Thus H2 is trivially satisfied by all standard elements and by the elements of interest in particular.

Thus we have to work just on H3. When first-order edge elements of the first Nedelec family are considered, this condition is satisfied by Lemma 5 of [1].

In order to obtain the same result for all other elements we work on the spaces $V_h = P_{m,1,hV},\ m \in \mathbb{N},\ m > 0$. Suppose, for a moment, that we know that the space sequence so generated satisfies (DCP), for any fixed $m > 0$. Since, as already pointed out, $P_{m,1,hV} \supset R_{1,hV}\ \forall m \in \mathbb{N},\ m > 0$ [7, p. 345], a standard result [17] implies that (CDK) is satisfied. Now observe that $\forall h \in I$

- $Q_{1,hV} = R_{1,hV} \oplus F_{1,hV}$ [7, Lemma 19],
- $R_{l,hV} = P_{l-1,1,hV} \oplus F_{1,hV} \oplus F_{2,hV} \oplus \cdots \oplus F_{l-1,hV},\ l > 1$, [7],
- $Q_{l,hV} = P_{l-1,1,hV} \oplus F_{1,hV} \oplus F_{2,hV} \oplus \cdots \oplus F_{l,hV},\ l > 1$, [7],

and $F_{l,hV} \subset V_0\ \forall l > 0$ [7, Lemma 20]. Then a direct application of Lemma 27 of [7] implies that the sequences generated by $V_h = R_{l,hV}\ \forall h \in I$ or by $V_h = Q_{l,hV}\ \forall h \in I$ satisfies (DCP) for any fixed $l \in \mathbb{N},\ l > 0$.

It just remains to prove (DCP) for the space sequence generated by $P_{m,1,hV}$ $\forall m \in \mathbb{N},\ m > 0$. This is done by exploiting the following slight modification of Lemma 30 of [7] ($\hat{\mathbf{z}} = 0$ in the original statement is replaced by $\operatorname{grad} \hat{\mathbf{z}} = 0$ in the following lemma).

LEMMA 4.1. *If Z is a finite dimensional subspace of $(H^1(\hat{K}))^3$ such that $\forall \hat{\mathbf{z}} \in Z$ $\operatorname{curl} \hat{\mathbf{z}} = 0$ implies $\operatorname{grad} \hat{\mathbf{z}} = 0$, then $\exists C > 0$, C independent of $\hat{\mathbf{z}}$, such that $|\hat{\mathbf{z}}|_{1,\hat{K}} \leq C \|\operatorname{curl} \hat{\mathbf{z}}\|_{0,\hat{K}}$.*

Proof. Let $Z_{0c} = \{\mathbf{z} \in Z \mid \operatorname{curl} \mathbf{z} = \mathbf{0}\}$ and $Z_{0g} = \{\mathbf{z} \in Z \mid \operatorname{grad} \mathbf{z} = \mathbf{0}\}$. One of the hypotheses easily implies $Z_{0c} = Z_{0g}$. In order to simplify the notation we denote this space by Z_0. The scalar products $(\ ,\ )_{0,\Omega}$, $(\ ,\ )_{1,\Omega}$, and $(\ ,\ )_{curl,\Omega}$ are all exactly the same when at least one of the two fields involved belongs to Z_0.

Let us now define $Z_0^{\perp} = \{\mathbf{z} \in Z \mid (\mathbf{z}, \mathbf{z}_0)_{0,\Omega} = (\mathbf{z}, \mathbf{z}_0)_{1,\Omega} = (\mathbf{z}, \mathbf{z}_0)_{curl,\Omega} = 0\ \forall \mathbf{z}_0 \in Z_0\}$. We have that in the finite dimensional space $Z_0^{\perp}$ (subspace of Z) the seminorms $|\ |_{1,\hat{K}}$ and $|\ |_{curl,\hat{K}}$ are actually norms, since $Z_0 \cap Z_0^{\perp} = \{0\}$. Thus they are equivalent; i.e., $\exists C > 0$, C independent of $\overline{\mathbf{z}}_1$, such that $|\overline{\mathbf{z}}_1|_{1,\hat{K}} \leq C \|\operatorname{curl} \overline{\mathbf{z}}_1\|_{0,\hat{K}}\ \forall \overline{\mathbf{z}}_1 \in Z_0^{\perp}$.

Since any component $\overline{\mathbf{z}}_0 \in Z_0$ of any $\overline{\mathbf{z}} \in Z$ ($\overline{\mathbf{z}} = \overline{\mathbf{z}}_0 + \overline{\mathbf{z}}_1$) is not able to affect the two seminorms appearing on the left- and right-hand sides of the last inequality, the lemma is proved. ∎

Then Lemma 33 and Corollary 2 of [7] hold true with the same modification. This modified version of Corollary 2 of [7] is the statement we needed since, provided its hypotheses are verified, it implies H3. To help the reader, we report below such a corollary with its original hypotheses.

COROLLARY. *Let us suppose $K \in \mathcal{T}_h$ is affine equivalent to $\hat{K}$. Moreover, let $\sigma > 0$ be such that $\frac{h_K}{\rho_K} \leq \sigma\ \forall K \in \mathcal{T}_h$, $\forall h \in I$. If $Z \subset H^1(K)^3$ is finite dimensional, $\hat{Z} = B_K^T(Z)$ and $\forall \underline{\hat{z}} \in \hat{Z}$, $\operatorname{curl} \underline{\hat{z}} = 0$ implies $\underline{\hat{z}} = 0$, then $\exists C > 0$, C independent of $\underline{z}$, K, and h such that $\|\underline{z}\|_{1,K} \leq C \|\underline{z}\|_{\operatorname{curl},K}\ \forall \underline{z} \in Z$.*

But we always consider a regular family of meshes, so that, by using the notation of the above corollary, there exists $\sigma > 0$ such that $\frac{h_K}{\rho_K} \leq \sigma\ \forall K \in \mathcal{T}_h$, $\forall h \in I$ [17]. Moreover, $\forall \mathbf{w}_h \in P_{m,1,hV}$ we have $\mathbf{w}_h|_K \in P_{m,1} = R_1 \oplus E_2 \oplus \cdots \oplus E_{m+1}\ \forall K \in \mathcal{T}_h, \forall h \in I$, and by Lemma 18 of [7] (see also [23]) the spaces R_l and E_{l+1} are invariant $\forall l > 0$ under the usual affine transformation [23] so that, with the notation of the corollary, $\hat{Z} = B_K^T(Z)\ \forall K \in \mathcal{T}_h$ affine equivalent to $\hat{K}$. Finally, if $\hat{\mathbf{z}} = \hat{\mathbf{y}}_1 + \hat{\mathbf{y}}_2 + \cdots + \hat{\mathbf{y}}_{m+1}$, $\hat{\mathbf{z}} \in P_{m,1} \subset R_{m+1}$, $\hat{\mathbf{y}}_1 \in R_1 \subset Q_1$, $\hat{\mathbf{y}}_i \in E_i \subset Q_i$, $i = 2, \ldots, m+1$, satisfies $\operatorname{curl} \hat{\mathbf{z}} = 0$, we have by Lemma 9 of [7] that $\hat{\mathbf{z}} \in Q_m$. But $\hat{\mathbf{y}}_i \in E_i \subset Q_i \subset Q_m$, $i = 2, \ldots, m$, and $\hat{\mathbf{y}}_1 \in R_1 \subset Q_1 \subset Q_m$. Then also $\hat{\mathbf{y}}_{m+1} \in Q_m$. Since by Lemma 16 of [7] $E_{m+1} \cap Q_m = \{0\}$, we obtain $\hat{\mathbf{y}}_{m+1} = 0$. In an analogous way we can prove $\hat{\mathbf{y}}_i = 0$, $2 \leq i \leq m$. Thus $\hat{\mathbf{z}} \in R_1$, which implies $\hat{\mathbf{z}} \in P_0^3$, i.e., $\operatorname{grad} \hat{\mathbf{z}} = 0$. Then all hypotheses of the modified version of Corollary 2 of [7] are satisfied and we thus have proved the following proposition.

PROPOSITION 4.2. *Suppose that the hypotheses reported in section 2 concerning the domain, its boundary, the homogeneous material, and the triangulation of the domain are satisfied. Then (DCP) is satisfied for the sequence of subspaces $\{V_h\}$ defined by $V_h = R_{l,hV}\ \forall h \in I$ for any fixed $l \in \mathbb{N},\ l > 0$ or by $V_h = Q_{l,hV}\ \forall h \in I$ for any fixed $l \in \mathbb{N},\ l > 0$.*

Remark 4.3. With the above procedure we have also proved (DCP) for many other sequences of spaces.

Remark 4.4. By using Proposition 2.27 of [6] we could remove the hypothesis concerning the homogeneous material from the statement of Propositions 3.1 and 4.2. As a matter of fact, a generalization of Proposition 2.27 of [6] can be proved when the

dielectric permittivity is a matrix-valued complex function which satisfies conditions H1 and H2 of [25, section 2] (see [9] for a result in this direction). Thus, for the first time, to the best of the author's knowledge, we have proved that (DCP) holds true for all Nedelec edge elements (of any order and of both families defined on tetrahedra) in most cases of interest in engineering applications.

Acknowledgment. The author would like to thank three anonymous reviewers for their very helpful comments.

ASYMPTOTIC MESH INDEPENDENCE OF NEWTON'S METHOD REVISITED*

MARTIN WEISER†, ANTON SCHIELA‡, AND PETER DEUFLHARD§

Abstract. The paper presents a new affine invariant theory on asymptotic mesh independence of Newton's method for discretized nonlinear operator equations. Compared to earlier attempts, the new approach is both much simpler and more intuitive from the algorithmic point of view. The theory is exemplified at finite element methods for elliptic PDE problems.

Key words. asymptotic mesh independence, Newton's method, affine invariance

DOI. 10.1137/S0036142903434047

Introduction. The term "mesh independence" characterizes the observation that finite dimensional Newton methods, when applied to a nonlinear PDE on successively finer discretizations with comparable initial guesses, show roughly the same convergence behavior on all sufficiently fine discretizations. The "mesh independence principle" has been stated and even exploited for mesh design in papers by Allgower and Böhmer [1] and McCormick [19]. Further theoretical investigations of the phenomenon have been given in [2] by Allgower, Böhmer, Potra, and Rheinboldt. Those papers, however, lacked certain important features in the theoretical characterization that made their application to discretized PDEs difficult. This drawback has been avoided in the affine invariant theoretical study by Deuflhard and Potra in [8]; from that analysis, the modified term "asymptotic mesh independence" naturally emerged. The present paper suggests a different approach, which is also affine invariant but much simpler and more natural from the algorithmic point of view.

In a number of papers subsequent to [2], mesh independence principles for different problem settings or different algorithms were established; we mention generalized equations [11, 3], SQP methods [20, 21], shape design [18], constrained Gauss–Newton methods [15], Newton-like methods [16], and gradient projection [17].

The paper is organized as follows. In section 1 we first revisit the theoretical approaches given up to now to treat mesh independence for operator equations. In section 2 we compare discrete versus continuous Newton methods, again in affine invariant terms; in contrast to the earlier treatment in [8], we use only terminology that naturally arises from the algorithmic point of view, such as Newton sequences and approximation errors. The new theory is then exemplified at finite element methods (FEM) for elliptic PDEs (section 3).

1. Preliminary considerations. Let a nonlinear operator equation be denoted by

$$F(x) = 0,$$

where $F : D \to Y$ is defined on a convex domain $D \subset X$ of a Banach space X with values in a Banach space Y. Throughout the paper we assume the existence of a unique solution x^* of this operator equation. The corresponding ordinary Newton method in Banach space may be written as

$$F'(x^k)\Delta x^k = -F(x^k), \quad x^{k+1} = x^k + \Delta x^k, \quad k = 0, 1, \ldots, \tag{1.1}$$

assuming, of course, that the derivatives are invertible. In each Newton step, the linearized operator equation must be solved, which is why this approach is often also called *quasilinearization*. For F, we assume that Theorem 1 from [7] holds, an affine invariant version of the classical Newton–Mysovskikh theorem, whose essence we recall here for the purpose of later reference.

THEOREM 1.1. *Let $F : D \to Y$ be a continuously differentiable mapping with $D \subset X$ convex. Let $\|\cdot\|$ denote the norm in the domain space X. Suppose that $F'(x)$ is invertible for each $x \in D$. Assume that, for collinear x, y, $z \in D$, the following affine invariant Lipschitz condition holds:*

$$\big\|F'(z)^{-1}\big(F'(y) - F'(x)\big)v\big\| \le \omega\|y - x\|\,\|v\|. \tag{1.2}$$

For the initial guess $x^0 \in D$ assume that

$$h_0 = \omega\|\Delta x^0\| < 2$$

and that $\bar{S}(x^0, \rho) \subset D$ for $\rho = \frac{\|\Delta x^0\|}{1 - h_0/2}$.

Then the sequence $\{x^k\}$ of ordinary Newton iterates remains in $S(x^0, \rho)$ and converges to a unique solution $x^* \in \bar{S}(x^0, \rho)$. Its convergence speed can be estimated as

$$\|x^{k+1} - x^k\| \le \tfrac{1}{2}\omega\|x^k - x^{k-1}\|^2.$$

In actual computation, we can solve only discretized nonlinear equations of finite dimension, at best on a sequence of successively finer mesh levels, say,

$$F_j(x_j) = 0, \quad j = 0, 1, \ldots, \tag{1.3}$$

where $F_j : D_j \to Y_j$ denotes a nonlinear mapping defined on a convex domain $D_j \subset X_j$ of a finite dimensional subspace $X_j \subset X$ with values in a finite dimensional space Y_j. We assume F_j results from a Petrov–Galerkin discretization, such that $F_j(x_j) = r_j F(x_j)$ with some linear restriction $r_j : Y \to Y_j$. The corresponding finite dimensional ordinary Newton method reads

$$F_j'(x_j^k)\Delta x_j^k = -F_j(x_j^k), \quad x_j^{k+1} = x_j^k + \Delta x_j^k, \quad k = 0, 1, \ldots.$$

In each Newton step, a system of linear equations must be solved. Since $(F_j)' = r_j F'$, this system can equally well be interpreted either as a discretization of the linearized operator equation (1.1) or as a linearization of the discrete nonlinear system (1.3). Again we assume that Theorem 1.1 holds, this time for the finite dimensional mapping F_j. Let ω_j denote the corresponding affine invariant Lipschitz constant. Then the quadratic convergence of this Newton method is governed by the relation

$$\|x_j^{k+1} - x_j^k\| \le \tfrac{1}{2}\omega_j\|x_j^k - x_j^{k-1}\|^2.$$

Under the assumptions of Theorem 1.1 there exist unique discrete solutions x_j^* on each level j. Of course, we want to choose appropriate discretization schemes such that

$$\lim_{j\to\infty} x_j^* = x^*. \tag{1.4}$$

From the synopsis of the discrete and the continuous Newton method, we immediately see that any comparison of the convergence behavior on different discretization levels j will direct us toward a comparison of the affine covariant Lipschitz constants ω_j. Of particular interest is the connection with the Lipschitz constant ω of the underlying operator equation.

In the earlier papers [1, 2] on mesh independence two assumptions of the kind

$$\|F_j'(x_j)^{-1}\| \le \beta_j, \quad \|F_j'(x_j + v_j) - F_j'(x_j)\| \le \gamma_j \|v_j\|$$

have been made in combination with the *uniformity* requirements

$$\beta_j \le \beta, \quad \gamma_j \le \gamma. \tag{1.5}$$

Obviously, these assumptions lack affine invariance. More important, however, and as a consequence of the noninvariance, these conditions are phrased in terms of *operator norms*, which, in turn, depend on the relation of norms in the domain and the image space of the mappings F_j and F, respectively. For typical PDEs and typical choices of norms we would obtain

$$\lim_{j\to\infty} \beta_j \to \infty,$$

which clearly contradicts the uniformity assumption (1.5). Consequently, an analysis in terms of β_j and γ_j would not be applicable to this important case.

The situation is different with the affine invariant Lipschitz constants ω_j: They depend only on the choice of *norms in the domain space*. It is easy to verify that

$$\omega_j \le \beta_j \gamma_j.$$

In section 2 below we will show that the ω_j remain bounded in the limit $j \to \infty$, as long as ω is bounded—even if either β_j or γ_j blow up. Moreover, even when the product $\beta_j\gamma_j$ remains bounded, the Lipschitz constant ω_j may be considerably lower, i.e.,

$$\omega_j \ll \beta_j \gamma_j.$$

A prerequisite for the asymptotic property (1.4) to hold is that the elements of the infinite dimensional space X can be well approximated by elements of the finite dimensional subspaces X_j. In general, however, the solution x^* has "better smoothness properties" than the generic elements of the space X. For this reason, the earlier papers [2, 8] had restricted their analysis to some smoother subset $W^* \subset X$ and explicitly assumed that

$$x^*, x^k, \Delta x^k, x^k - x^* \in W^*, \quad k = 0, 1, \ldots.$$

However, such an assumption is hard to confirm in the concrete case. That is why we will drop it for our analysis to be presented.

Next, we revisit the paper [8] in some necessary detail. In that paper a family of linear projections

$$\pi_j : X \to X_j, \quad j = 0, 1, \ldots,$$

was introduced, assumed to satisfy the *stability condition*

$$q_j = \sup_{x \in W^*, x \neq 0} \frac{\|\pi_j x\|}{\|x\|} \leq \overline{q} < \infty, \quad j = 0, 1, \ldots. \tag{1.6}$$

The projection property $\pi_j^2 = \pi_j$ immediately gives rise to the lower bound

$$q_j \geq 1. \tag{1.7}$$

As a measure of the *approximation quality* that paper defined

$$\delta_j = \sup_{x \in W^*, x \neq 0} \frac{\|x - \pi_j x\|}{\|x\|}, \quad j = 0, 1, \ldots. \tag{1.8}$$

The rather natural idea that a refinement of the discretization improves the approximation quality was expressed by the asymptotic assumption

$$\lim_{j \to \infty} \delta_j = 0. \tag{1.9}$$

The triangle inequality and (1.6) supplied the upper bound

$$q_j \leq 1 + \delta_j. \tag{1.10}$$

By combination of (1.7), (1.9), and (1.10), asymptotic stability arose as

$$\lim_{j \to \infty} q_j = 1. \tag{1.11}$$

However, as has been pointed out by Braess [6], the above theory has some weak points. In fact, from (1.6) we conclude that $x = 0$ implies $\pi_j x = 0$. The reverse, however, will not be true in general. Hence, one must be aware of pathological elements $x \neq 0$ with corresponding approximations $\pi_j x = 0$. On a uniform one-dimensional grid, such a pathological element might look just like $x(t)$ represented graphically in Figure 1.1. Insertion of such elements into (1.8) would yield

$$\delta_j \geq 1$$

on each level j, on which such pathological elements exist. If one were to accept such an occurrence on *all* levels, then this would be in clear contradiction to the desired asymptotic property (1.9) and its consequence (1.11).

In order to close this gap of that theory, one would have to relate the subset W^* and the projections π_j such that the occurrence of pathological elements would

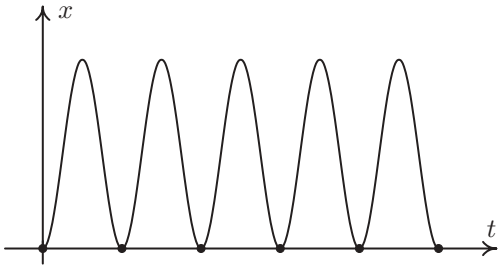

FIG. 1.1. *Pathological element $x \neq 0$ with $\pi_j x = 0$ (•: mesh nodes).*

be asymptotically excluded. As an example, assume we have *nested* subspaces X_j, e.g., constructed by uniform mesh refinement. Suppose we begin with a "sufficiently good" initial projection π_0 on a "sufficiently" fine mesh, which already captures the main qualitative behavior of the solution x^* correctly. Then "pathological" elements would no longer be expected to occur on finer meshes in actual computation. Thus, upon carefully choosing appropriate subsets of W^*, the theory from [8] could, in principle, be repaired. However, the technicalities of such a theory tend to obscure the underlying simple idea.

For this reason, here we abandon that approach and turn to a different one, which seems to us both simpler and more intuitive from the algorithmic point of view: We will avoid the (anyway computationally unavailable) projections π_j and define the approximation quality δ_j differently, just exploiting usual approximation results for discretization schemes.

2. Discrete versus continuous Newton sequences. In this section, we study the comparative behavior of discrete versus continuous Newton sequences. If not explicitly stated otherwise, the notation is taken from the previous section.

We will consider the phenomenon of mesh independence of Newton's method in two steps. First, we will show that the discrete Newton sequence tracks the continuous Newton sequence closely, with a maximal distance bounded in terms of the mesh size; both of the Newton sequences behave nearly identically until, eventually, a small neighborhood of the solution is reached. Second, we prove the existence of affine invariant Lipschitz constants ω_j for the discretized problems, which approach the Lipschitz constant ω of the continuous problem in the limit $j \to \infty$; again, the distance can be bounded in terms of the mesh size. Upon combining these two lines, we finally establish the existence of locally unique discrete solutions x_j^* in a vicinity of the continuous solution x^*.

To begin with, we prove the following nonlinear perturbation lemma.

LEMMA 2.1. *Consider two Newton sequences $\{x^k\}$, $\{y^k\}$ starting at initial guesses x^0, y^0 and continuing as*

$$x^{k+1} = x^k + \Delta x^k, \quad y^{k+1} = y^k + \Delta y^k,$$

where $\Delta x^k, \Delta y^k$ are the corresponding ordinary Newton corrections. Assume the affine invariant Lipschitz condition (1.2) *is satisfied. Then the following contraction result holds:*

$$\|x^{k+1} - y^{k+1}\| \leq \omega \left(\tfrac{1}{2}\|x^k - y^k\| + \|\Delta x^k\|\right) \|x^k - y^k\|. \tag{2.1}$$

Proof. Dropping the iteration index k, we start with

$$\begin{aligned}
x + \Delta x - y - \Delta y
&= x - F'(x)^{-1}F(x) - y + F'(y)^{-1}F(y) \\
&= x - F'(x)^{-1}F(x) + F'(x)^{-1}F(y) - F'(x)^{-1}F(y) - y + F'(y)^{-1}F(y) \\
&= x - y - F'(x)^{-1}\big(F(x) - F(y)\big) + F'(x)^{-1}\big(F'(y) - F'(x)\big)F'(y)^{-1}F(y) \\
&= F'(x)^{-1}\left(F'(x)(x-y) - \int_{t=0}^{1} F'(y + t(x-y))(x-y)\,dt\right) \\
&\quad + F'(x)^{-1}(F'(y) - F'(x))\Delta y.
\end{aligned}$$

Upon using assumption (1.2), we conclude that

$$\begin{aligned}
\|x^{k+1} - y^{k+1}\| &\le \int_{t=0}^{1} \|F'(x^k)^{-1}\big(F'(x^k) - F'(y^k + t(x^k - y^k))\big)(x^k - y^k)\|\,dt \\
&\quad + \|F'(x^k)^{-1}(F'(y^k) - F'(x^k))\Delta y^k\| \\
&\le \frac{\omega}{2}\|x^k - y^k\|^2 + \omega\|x^k - y^k\|\,\|\Delta y^k\|,
\end{aligned}$$

which confirms (2.1). ∎

With the above auxiliary result, we are now ready to study the relative behavior of discrete versus continuous Newton sequences.

THEOREM 2.2. *In addition to the notation as already introduced, let $x^0 = x_j^0 \in X_j$ denote a given starting value such that the assumptions of Theorem* 1.1 *hold for the continuous Newton iteration, including*

$$h_0 = \omega\|\Delta x^0\| < 2.$$

For the discrete mapping F_j and all arguments $x_j \in D_j = D \cap X_j$ define

$$F_j'(x_j)\Delta x_j = -F_j(x_j), \quad F'(x_j)\Delta x = -F(x_j). \tag{2.2}$$

Assume that the discretization is fine enough such that

$$\|\Delta x_j - \Delta x\| \le \delta_j \le \frac{\min\{1, 2 - h_0\}}{2\omega} \tag{2.3}$$

uniformly for $x_j \in D_j$. Assume furthermore $\bar{S}\left(x^0, \rho_j\right) \cap X_j \subset D_j$ for

$$\rho_j := \frac{\|\Delta x_0\|}{1 - h_0/2} + \frac{2\delta_j}{\min\{1, 2 - h_0\}}.$$

Then the sequence of the discrete Newton iterates x_j^k remains in $B(x_0, \rho_j) \cap X_j$ and the following error estimates hold:

$$\|x_j^k - x^k\| \le \frac{2\delta_j}{\min\{1, 2 - h_0\}} \le \frac{1}{\omega} \quad \textit{for all } k \in \mathbb{N}, \tag{2.4}$$

$$\limsup_{k\to\infty} \|x_j^k - x^k\| \le 2\delta_j. \tag{2.5}$$

Proof. In [14, pp. 99, 160], Hairer, Nørsett, and Wanner introduced "Lady Windermere's fan" as a tool to prove discretization error results for evolution problems

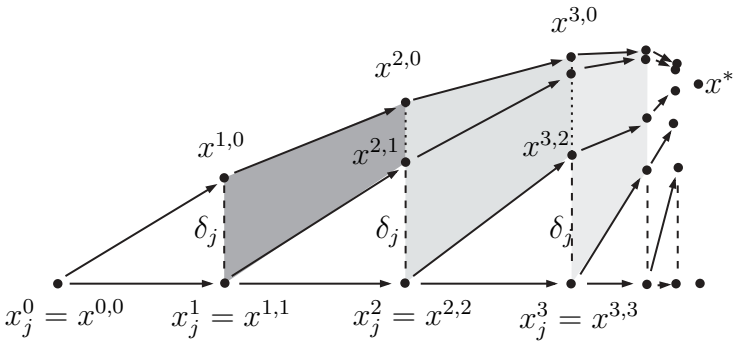

FIG. 2.1. *"Lady Windermere's fan" for the discrete and the continuous Newton method.*

based on some linear perturbation lemma. We may copy this idea and exploit our nonlinear perturbation Lemma 2.1 in the present case. The situation is represented graphically in Figure 2.1.

The discrete Newton sequence starting at the given initial point $x_j^0 = x^{0,0}$ is written as $\{x^{k,k}\}$. The continuous Newton sequence, written as $\{x^{k,0}\}$, starts at the same initial point $x^0 = x^{0,0}$ and runs toward the solution point x^*. In between we define further continuous Newton sequences, written as $\{x^{i,k}\}, k = i, i+1, \ldots$, which start at the discrete Newton iterates $x_j^i = x^{i,i}$ and also run toward x^*. Note that the existence or even uniqueness of a discrete solution point x_j^* is not implied by the assumptions of the theorem.

For the purpose of repeated induction, we assume that

$$\|x_j^{k-1} - x^0\| < \rho_j,$$

which certainly holds for $k = 1$. In order to characterize the deviation between discrete and continuous Newton sequences, we introduce the two majorants

$$\omega\|\Delta x^k\| \le h_k, \quad \|x_j^k - x^k\| \le \epsilon_k.$$

Recall from Theorem 1.1 that

$$h_{k+1} = \frac{1}{2}h_k^2. \tag{2.6}$$

For the derivation of a second majorant recursion, we apply the triangle inequality in the form

$$\|x^{k+1,k+1} - x^{k+1,0}\| \le \|x^{k+1,k+1} - x^{k+1,k}\| + \|x^{k+1,k} - x^{k+1,0}\|.$$

The first term can be treated using assumption (2.3) so that

$$\begin{aligned}\|x^{k+1,k+1} - x^{k+1,k}\| = \|x_j^k + \Delta x_j^k - \left(x^{k,k} + \Delta x^{k,k}\right)\| &= \|\Delta x_j^k - \Delta x^{k,k}\| \\ &\le \delta_j.\end{aligned} \tag{2.7}$$

For the second term, we may apply our nonlinear perturbation Lemma 2.1 (see the shaded regions in Figure 2.1) to obtain

$$\|x^{k+1,k} - x^{k+1,0}\| \le \omega\left(\frac{1}{2}\|x^{k,k} - x^{k,0}\| + \|\Delta x^{k,0}\|\right)\|x^{k,k} - x^{k,0}\|.$$

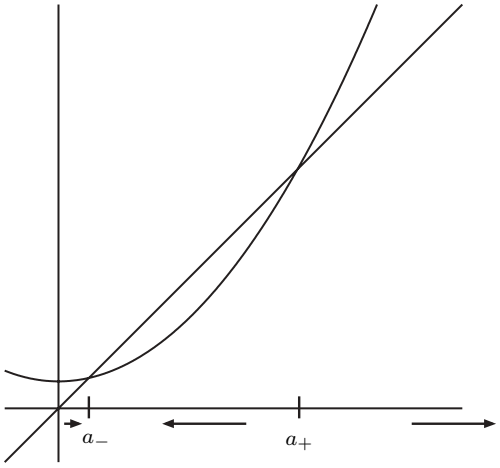

FIG. 2.2. *Fixed point recursion* a_k.

Combining these results then leads to

$$\|x^{k+1,k+1} - x^{k+1,0}\| \le \delta_j + \frac{\omega}{2}\epsilon_k^2 + h_k\epsilon_k.$$

The above right-hand side may be defined to be ϵ_{k+1}. Hence, together with (2.6), we arrive at the following set of majorant equations:

$$\begin{aligned} h_{k+1} &= \frac{1}{2}h_k^2, & h_0 &= \omega\|\Delta x_0\|, \\ \epsilon_{k+1} &= \delta_j + \frac{1}{2}\omega\epsilon_k^2 + h_k\epsilon_k, & \epsilon_0 &= 0. \end{aligned}$$

Now for $\beta \ge 1$ we multiply the second recursion by $\beta\omega$ and add both recursions. This yields the following recursion for $\beta\omega\epsilon_k + h_k$:

$$\beta\omega\epsilon_{k+1} + h_{k+1} = \beta\omega\delta_j + \frac{1}{2}(\beta\omega\epsilon_k + h_k)^2 - \left[\tfrac{1}{2}(\beta-1)\beta\omega^2\epsilon_k^2\right].$$

Since the term in squared brackets is positive, the sequence a_k defined by

$$a_{k+1} = \beta\omega\delta_j + \frac{1}{2}a_k^2, \qquad a_0 = h_0, \tag{2.8}$$

is a majorant to $\beta\omega\epsilon_k + h_k$. Solving (2.8) yields the equilibrium points

$$a_\pm = 1 \pm \sqrt{1 - 2\beta\omega\delta_j} \tag{2.9}$$

if $2\beta\omega\delta_j \le 1$, which is always possible to guarantee by choosing $1 \le \beta \le (2\omega\delta_j)^{-1}$ due to (2.3). The sequence converges monotonically toward the stable fixed point a_- in case $h_0 < a_+$ (see Figure 2.2). We consider the two cases $h_0 \le 1$ and $h_0 > 1$ separately. If $h_0 \le 1$, we choose

$$\beta = \frac{1}{2\omega\delta_j},$$

such that $h_0 \le a_- = 1$. Due to monotonicity the sequence a_k is bounded from above by $a_- = 1$. We then derive the upper bound

$$\epsilon_k \le \frac{a_-}{\beta\omega} \le 2\delta_j.$$

Both (2.4) and (2.5) are covered by this result. For $1 < h_0 < 2$, we choose $\sigma > 0$ sufficiently small and

$$\beta = \frac{h_0(2-h_0)}{(2+\sigma)\omega\delta_j},$$

such that both $\beta \ge 1$ and $h_0 < a_+$ are satisfied. Due to monotonicity, the sequence a_k is bounded from above by $a_0 = h_0$, and we obtain

$$\epsilon_k \le \frac{h_0}{\beta\omega} = \frac{(2+\sigma)\delta_j}{2-h_0}. \tag{2.10}$$

Since (2.10) holds for all sufficiently small $\sigma > 0$, we obtain

$$\epsilon_k \le \frac{2\delta_j}{2-h_0},$$

which proves (2.4). The asymptotic result (2.5) is now an immediate consequence of $a_k \to a_-$.

Finally, with application of the triangle inequality

$$\|x_j^{k+1} - x^0\| \le \|x^{k+1} - x^0\| + \epsilon_{k+1} < \frac{\|\Delta x_0\|}{1-h_0/2} + \frac{2\delta_j}{\min\{1, 2-h_0\}} = \rho_j,$$

the induction and therefore the whole proof are completed. ∎

We are interested in the question of whether a discrete solution point x_j^* exists. The above tracking theorem, however, states only that the discrete Newton sequence stays close to the continuous Newton sequence and therefore has an accumulation point close to the continuous solution.

COROLLARY 2.3. *Under the assumptions of Theorem* 2.2*, there exists at least one accumulation point*

$$\hat{x}_j \in \bar{S}\,(x^*, 2\delta_j) \cap X_j \;\subset\; S\left(x^*, \frac{1}{\omega}\right) \cap X_j,$$

which need not be a solution point of the discrete equations $F_j(x_j) = 0$.

In order to prove more, Theorem 1.1 directs us to study whether a Lipschitz condition of the kind (1.2) additionally holds.

LEMMA 2.4. *Assume Theorem* 1.1 *holds for the mapping* $F : X \to Y$. *For collinear* $x_j, y_j, z_j \in X_j$, *define* $u_j \in X_j$ *and* $u \in X$ *according to*

$$F'(x_j)u = (F'(z_j) - F'(y_j))\, v_j, \tag{2.11}$$

$$F_j'(x_j)u_j = \left(F_j'(z_j) - F_j'(y_j)\right) v_j \tag{2.12}$$

for arbitrary $v_j \in X_j$. *Assume that the discretization method satisfies*

$$\|u - u_j\| \le \sigma_j \|z_j - y_j\|\, \|v_j\|. \tag{2.13}$$

Then there exist constants

$$\omega_j \le \omega + \sigma_j\,, \tag{2.14}$$

such that the affine invariant Lipschitz condition

$$\|u_j\| \le \omega_j \|z_j - y_j\|\,\|v_j\|$$

holds.

Proof. The proof is a simple application of the triangle inequality:

$$\begin{aligned}\|u_j\| \le \|u\| + \|u_j - u\| &\le \omega\|z_j - y_j\|\,\|v_j\| + \sigma_j\|z_j - y_j\|\,\|v_j\| \\ &= (\omega + \sigma_j)\,\|z_j - y_j\|\,\|v_j\|. \qquad \square\end{aligned}$$

Finally, the existence of a unique discrete solution x_j^* close to the continuous solution x^* is a direct consequence.

COROLLARY 2.5. *Under the assumptions of Theorem* 2.2 *and Lemma* 2.4 *the discrete Newton sequence* $\{x_j^k\}, k = 0, 1, \ldots,$ *converges q-quadratically to a unique discrete solution point*

$$x_j^* \in \bar{S}\,(x^*, 2\delta_j) \cap X_j \;\subset\; S\left(x^*, \frac{1}{\omega}\right) \cap X_j.$$

Proof. We just need to apply Theorem 1.1 to the finite dimensional mapping F_j with the starting value $x_j^0 = x^0$, and the affine invariant Lipschitz constant ω_j from (2.14). $\square$

Summarizing, we come to the following conclusion, at least in terms of the analyzed upper bounds: If the asymptotic properties

$$\lim_{j\to\infty} \delta_j = 0, \quad \lim_{j\to\infty} \sigma_j = 0,$$

can be shown to hold, then the convergence speed of the discrete ordinary Newton method is asymptotically just the same as that of the continuous ordinary Newton method. Moreover, if related initial guesses x^0 and x_j^0 and a common termination criterion are chosen, then even the number of iterations will be nearly the same.

3. Application to discretization schemes. In order to apply the abstract mesh independence principles of section 2 to discretization schemes for differential equations, we have to show two features. First,

$$\|\Delta x - \Delta x_j\| \le \delta_j, \qquad \lim_{j\to\infty} \delta_j = 0, \tag{3.1}$$

where Δx is the exact and Δx_j is the approximate solution of the Newton equations (2.2), respectively.

Second,

$$\|u - u_j\| \le \sigma_j \|z_j - y_j\|\,\|v_j\|, \qquad \lim_{j\to\infty} \sigma_j = 0, \tag{3.2}$$

where u and u_j are the solutions of the Lipschitz equations (2.11) and (2.12), respectively.

The structure of the argumentation will be straightforward. The first step is to apply classical error estimates for the numerical method under consideration. These estimates usually depend on the regularity of the exact solution y of the linear correction problems. The second step is then to show appropriate regularity results for y.

We concentrate on FEM for elliptic PDEs. Collocation methods for ODEs are discussed in [22].

FEM for semilinear elliptic PDEs. Assume $f : \mathbb{R} \to \mathbb{R}$ is monotonically increasing and locally Lipschitz continuously differentiable with

$$|f'(x) - f'(y)| \le L(1 + \max(|x|, |y|))|x - y|. \tag{3.3}$$

This implies the growth condition $f = \mathcal{O}(|x|^3)$, which in turn implies that the nonlinear superposition (or Nemyckii) operator $\mathbf{f}$ generated by f maps $H_0^1(\Omega)$ continuously into $L_2(\Omega)$ on some convex polygonal domain $\Omega \subset \mathbb{R}^d$, $d \le 3$, via the embedding $H_0^1(\Omega) \hookrightarrow L_6(\Omega)$ (cf. [4, 12]). We define the continuous problem $F(x) = 0$ as the boundary value problem

$$F(x) = -\mathrm{div}(\kappa \nabla x) + \mathbf{f}(x) = 0, \quad x \in H_0^1(\Omega), \tag{3.4}$$

with $0 < \underline{\kappa} \le \kappa \le \overline{\kappa}$. The discretizations F_j are provided by finite element approximations on shape-regular triangulations $\mathcal{T}_j$ with mesh size $\tau_j = \max_{T \in \mathcal{T}_j} \mathrm{diam}\, T$. We consider piecewise linear finite element spaces $X_j \subset H_0^1(\Omega)$ on the triangulations $\mathcal{T}_j$.

THEOREM 3.1. *Let a bounded set $D \subset H_0^1(\Omega)$ be given. Then there exist constants $M_1, M_2 < \infty$ depending only on D and the problem setting $P = (\Omega, \kappa, f)$, such that the Newton-FEM discretizations F_j satisfy the Newton approximation condition* (3.1) *with $\delta_j = M_1 \tau_j$,*

$$\|\Delta x - \Delta x_j\|_{H^1} \le M_1 \tau_j \quad \textit{uniformly for } x_j \in D \cap X_j, \tag{3.5}$$

and the Lipschitz approximation condition (3.2) *with $\sigma_j = M_2 \tau_j$,*

$$\|u - u_j\|_{H^1} \le M_2 \tau_j \|z_j - y_j\|_{H^1} \|v_j\|_{H^1} \tag{3.6}$$

uniformly for all $y_j, z_j \in D \cap X_j$ and $v_j \in X_j$.

Proof. First we prove (3.5). Let Δx satisfy $F'(x_j)\Delta x = -F(x_j)$ and let Δx_j be its FEM approximation. Returning to (2.7) we notice that $x^{k+1,k}$ is more regular than $\Delta x^{k,k}$. Thus we introduce $w = x_j + \Delta x$, which satisfies

$$-\mathrm{div}(\kappa \nabla w) + \mathbf{f}'(x_j) w = -\mathbf{f}(x_j) + \mathbf{f}'(x_j) x_j. \tag{3.7}$$

The growth condition (3.3) implies $\mathbf{f}(x_j) \in L_2$ and $\mathbf{f}'(x_j) \in L_3$, such that the right-hand side of (3.7) is contained in L_2. We may estimate

$$\begin{aligned}
\|\mathbf{f}(x_j) - \mathbf{f}'(x_j) x_j\|_{L_2} &= \left\| \int_{t=0}^{1} (\mathbf{f}'(t x_j) - \mathbf{f}'(x_j)) x_j \, dt + \mathbf{f}(0) \right\|_{L_2} \\
&\le \int_{t=0}^{1} L(1-t) \|(1 + |x_j|) x_j^2\|_{L_2} \, dt + c \\
&\le \frac{L}{2} (\|x_j^2\|_{L_2} + \|x_j^3\|_{L_2}) + c \\
&= c(\|x_j\|_{L_4}^2 + \|x_j\|_{L_6}^3 + 1) \\
&\le c(\|x_j\|_{H^1}^2 + \|x_j\|_{H^1}^3 + 1) \\
&\le c,
\end{aligned}$$

where c denotes a generic constant independent of the discretization and x_j. Since the Helmholtz term in (3.7) is positive semidefinite due to the monotonicity of f, the inverse of the differential operator can be bounded in terms of the ellipticity constant of its main part only, which is independent of x_j. Thus we obtain

$$\|w\|_{H^1} \le c \|\mathbf{f}(x_j) - \mathbf{f}'(x_j) x_j\|_{L_2} \le c.$$

Using Hölder's inequality and the embedding $H_0^1(\Omega) \hookrightarrow L_6(\Omega)$, we estimate

$$\|\mathbf{f}'(x_j)w\|_{L_2} \le \|w\|_{L_6}\|\mathbf{f}'(x_j)\|_{L_3} \le \|w\|_{H^1} c(1 + \|x_j\|_{L_6}^2) \le c.$$

We now rewrite (3.7) as

$$-\mathrm{div}(\kappa\nabla w) = -\mathbf{f}(x_j) + \mathbf{f}'(x_j)x_j - \mathbf{f}'(x_j)w.$$

Since the right-hand side is contained in L_2, the solution w is H^2-regular (cf. [13]) with

$$\|w\|_{H^2} \le c\|\mathbf{f}(x_j) - \mathbf{f}'(x_j)x_j + \mathbf{f}'(x_j)w\|_{L_2} \le c.$$

We thus obtain an approximation error

$$\|w_j - w\|_{H^1} \le c\tau_j\|w\|_{H^2} \le c\tau_j$$

for its FEM approximation $w_j = x_j + \Delta x_j$ (cf. [5, p. 79]), uniformly for all x_j. For the approximation error $\Delta x_j - \Delta x$ we now obtain

$$\|\Delta x_j - \Delta x\|_{H^1} = \|w_j - w\|_{H^1} \le c\tau_j.$$

Second, we prove (3.6). u is defined by

$$F'(x_j)u = (F'(z_j) - F'(y_j))v_j = (\mathbf{f}'(z_j) - \mathbf{f}'(y_j))v_j.$$

As before, the right-hand side is contained in L_2 and the solution u is H^2-regular, such that we obtain

$$\|u_j - u\|_{H^1} \le c\tau_j\|(\mathbf{f}'(z_j) - \mathbf{f}'(y_j))v_j\|_{L_2}.$$

Upon using Hölder's inequality twice we conclude that

$$\begin{aligned}\|(\mathbf{f}'(z_j) - \mathbf{f}'(y_j))v_j\|_{L_2} &\le \|L^2(1 + \max(|y_j|, |z_j|))^2(z_j - y_j)^2 v_j^2\|_{L_1}^{1/2} \\ &\le \left(\|L^2(1 + \max(|y_j|, |z_j|))^2\|_{L_3}\|(z_j - y_j)^2\|_{L_3}\|v_j^2\|_{L_3}\right)^{1/2} \\ &= L\|1 + \max(|y_j|, |z_j|)\|_{L_6}\|z_j - y_j\|_{L_6}\|v_j\|_{L_6} \le c,\end{aligned}$$

which completes the proof. ∎

Combining Theorem 2.2 and Lemma 2.4 with Theorem 3.1 we obtain asymptotic mesh independence for FEM approximations of semilinear elliptic equations.

COROLLARY 3.2. *Assume that there exists a convex and bounded set $D \subset H^1$, such that on D the assumptions of Theorem* 1.1 *(in particular $\omega < \infty$) and Theorem* 3.1 *are satisfied for the nonlinear equation* (3.4).

Then there exists a constant M_1 and a mesh size $\tau_0 > 0$, such that for all discretizations X_j with corresponding mesh size $\tau_j < \tau_0$ and starting values $x^0 = x_j^0 \in X_j$ with

$$h_0 = \omega\|\Delta x^0\|_{H^1} < 2 \tag{3.8}$$

and

$$\bar{S}\left(x^0, \frac{\|\Delta x_0\| + 2M_1\tau_j}{1 - h_0/2}\right) \subset D, \tag{3.9}$$

the discrete Newton sequence remains in D, and its distance to the continuous Newton sequence is bounded by

$$\|x_j^k - x^k\|_{H^1} \le \frac{2M_1\tau_j}{1-h_0/2}. \tag{3.10}$$

Moreover, both sequences converge q-quadratically to solutions x_j^* and x^*, respectively, with

$$\|x_j^* - x^*\|_{H^1} \le 2M_1\tau_j. \tag{3.11}$$

Proof. Application of Theorem 3.1 on D yields constants $M_1, M_2 < \infty$ such that $\|\Delta x - \Delta x_j\|_{H^1} \le M_1\tau_j$ and $\|u-u_j\|_{H^1} \le M_2\tau_j\|z_j-y_j\|_{H^1}\|v_j\|_{H^1}$ hold for all $x_j \in D$ in terms of (3.1) and (3.2). We will verify Corollary 3.2 for

$$\tau_j < \tau_0 := \min\left\{\frac{1-h_0/2}{2\omega M_1}, \frac{1}{2M_2}\left(\sqrt{\omega^2 + \frac{M_2(1-h_0/2)}{M_1}} - \omega\right)\right\}.$$

Note that the continuous Newton sequence satisfying (3.8) and (3.9) remains in $S(x^0, \frac{\|\Delta x_0\|_{H^1}}{1-h_0/2}) \subset D$ due to Theorem 1.1. Because of

$$\tau_j < \tau_0 \le \frac{1-h_0/2}{2\omega M_1} \le \frac{\min\{1, 2-h_0\}}{2\omega M_1},$$

condition (2.3) is clearly satisfied, such that we can apply Theorem 2.2 and obtain (3.10), (3.11), and $x_j^k \in D$.

Now we turn to q-quadratic convergence of the discrete Newton sequence. A direct consequence of (3.10) is the estimate

$$\begin{aligned}\|\Delta x_j^k\|_{H^1} &\le \|x_j^{k+1} - x^{k+1}\|_{H^1} + \|\Delta x^k\|_{H^1} + \|x^k - x_j^k\|_{H^1} \\ &\le \frac{4M_1\tau_j}{1-h_0/2} + \|\Delta x^k\|_{H^1}.\end{aligned}$$

As $\lim_{k\to\infty}\|\Delta x^k\|_{H^1} = 0$ by Theorem 1.1 we can find an index k_0 such that

$$\|\Delta x_j^k\|_{H^1} \le \frac{8M_1\tau_j}{1-h_0/2} \qquad \text{for all } k \ge k_0.$$

Application of Lemma 2.4 yields $\omega_j \le \omega + \tau_j M_2$ and therefore

$$h_j^k := \omega_j\|\Delta x_j^k\|_{H^1} \le (\omega + \tau_j M_2)\frac{8M_1\tau_j}{1-h_0/2} \qquad \text{for all } k \ge k_0.$$

Now

$$\tau_j < \tau_0 \le \frac{1}{2M_2}\left(\sqrt{\omega^2 + \frac{M_2(1-h_0/2)}{M_1}} - \omega\right)$$

implies $h_j^{k_0} < 2$, such that Theorem 1.1 yields q-quadratic convergence of the discrete Newton iteration starting at $x_j^{k_0}$. ∎

FEM for strongly nonlinear elliptic PDEs. For strongly nonlinear PDEs with a second order differential operator depending on the solution, the analytic treatment of the approximation conditions (3.1) and (3.2) is considerably more difficult. The global regularity of the right-hand side is, in general, only H^{-1}, which results in sharp edges in the Newton correction. These bucklings, however, coincide geometrically with the edges of the triangulation, such that the finite element approximation quality does not deteriorate. This effect is indeed observed in actual computation.

The regularity theory necessary for addressing such problems is beyond the scope of the present paper. As a substitute, we give a numerical example from [10], where the phenomenon of asymptotic mesh independence may be studied.

Example: Parametric minimal surface. Consider the variational problem

$$\min \int_\Omega \sqrt{1+|\nabla u|^2}\, dx$$

subject to the boundary conditions

$$\begin{aligned} u &= \cos(x)\cos(y) && \text{on } \Gamma_D = \partial\Omega \backslash \Gamma_N, \\ \frac{\partial u}{\partial n} &= 0 && \text{on } \Gamma_N \end{aligned}$$

on $\Omega = [-\pi/2, 0]^2$. The functional gives rise to the first and second order expressions

$$\begin{aligned} \langle F(u), v\rangle &= \int_\Omega \left(1+|\nabla u|^2\right)^{-1/2} \nabla u^T \nabla v\, dx, \\ \langle F'(u)v, w\rangle &= \int_\Omega \Big(-\left(1+|\nabla u|^2\right)^{-3/2} \nabla w^T (\nabla u \nabla u^T) \nabla v \\ &\qquad + \left(1+|\nabla u|^2\right)^{-1/2} \nabla w^T \nabla v \Big)\, dx. \end{aligned}$$

We define two different problem settings by choosing

(a) $\Gamma_N = [-\pi/2, 0] \times \{0\}$,

(b) $\Gamma_N = [-\pi/2, 0] \times \{0\} \cup \{0\} \times [-\pi/4, 0]$.

Note that by symmetry, problem (a) represents a Dirichlet problem on a convex domain, whereas the deliberate choice of boundary conditions (b) leads to a Dirichlet problem on a highly nonconvex slit domain, on which no physically meaningful solution exists.

The adaptive Newton-multilevel code Newton-KASKADE [9, 10] has been run on both problems, providing affine invariant computational estimates $[\omega_j] \le \omega_j$ on each mesh refinement level j. On each level, a few Newton steps have been computed using the approximation from the level before, and the maximum estimate encountered in these steps has been selected as $[\omega_j]$. As can be seen from Table 3.1, the Lipschitz constants for the well-defined problem (a) remain bounded and rather independent of the refinement level, apart from some fluctuation due to the finite sampling of ω_j. In contrast to that, the estimates for the Lipschitz constant of problem (b) are dramatically increasing by five orders of magnitude. This indicates that the problem has finite dimensional solutions on each of the successive meshes, each unique within the corresponding finite dimensional Kantorovich ball with radius $\rho_j \sim 1/\omega_j$; however, these balls shrink from radius $\rho_0 \approx 1$ to $\rho_{12} \approx 10^{-5}$. Frank extrapolation of this effect insinuates the conjecture that there exists no continuous unique solution of the underlying minimization problem.

TABLE 3.1
Estimated Lipschitz constants $[\omega_j]$ on different refinement levels j.

	Problem (a)		Problem (b)	
j	♯nodes	$[\omega_j]$	♯nodes	$[\omega_j]$
0	4	1.32	5	7.5
1	7	1.17	10	4.2
2	18	4.55	17	7.3

ON COMPARING THE WRITHE OF A SMOOTH CURVE TO THE WRITHE OF AN INSCRIBED POLYGON*

JASON CANTARELLA†

Abstract. We find bounds on the difference between the writhing numbers of a smooth curve and a polygonal curve inscribed within. The proof is based on an extension of Fuller's difference of writhe formula to the case of polygonal curves. The results establish error bounds useful in the numerical computation of writhe in terms of bounds on the edge lengths of the polygon and the derivatives of the curve. The bounds are "adaptive" in the sense that they improve when regions of the smooth curve with larger derivatives are approximated by shorter edges of the polygon.

Key words. writhing number, numerical quadrature

AMS subject classifications. 53A04, 65D18, 65D30

DOI. 10.1137/S0036142902403164

1. Introduction.

The writhing number measures the wrapping and coiling of space curves. Writhe has proved useful in molecular biology, where it is used to study the geometry of tangled strands of DNA [19]; often with the famous Călugăreanu–White formula for a curve C in space with a normal field V [5, 6, 21, 15]:

$$\mathrm{Lk}(C, C + \epsilon V) = \mathrm{Tw}(C, V) + \mathrm{Wr}(C).$$

Writhe has proved important in the study of elastic rods in biology [20] and has even been used as the basis for a system for automatically classifying protein structures [16].

In these applications, and in numerical simulations performed by biologists and mathematicians, it is often required to compute writhing numbers using numerical methods.

For polygonal curves, there is a well-developed set of algorithms for computing writhe. These methods range from Banchoff's original exact sum formula for the writhe of a polygonal curve [3], to Agarwal, Edelsbrunner, and Wang's fast sweepline algorithm [1], which is based on deep results from computational geometry. Many other methods are surveyed by Klenin and Langowski in [13] (see also [9, 19]).

For smooth curves, the only existing methods are the standard tools for numerical integration, such as adaptive quadrature. It would be desirable to apply the sophisticated algorithms developed for the polygonal case in this setting, but there is a missing ingredient: We must be able to bound the error introduced in approximating a smooth curve by an inscribed polygonal curve. The purpose of this paper is to bridge this gap by proving the following theorem.

THEOREM 1. *Suppose $C(t)$ is a simple, closed curve of class $\mathcal{C}^4$. We assume $C(t)$ is parametrized so that $|C'(t)| \geq 1$, and that we have upper bounds $B_1, \ldots, B_4$ on $|C'(t)|, \ldots, |C^{(4)}(t)|$. Let $C_n(t)$ be any n-edge polygonal curve inscribed in C with maximum edge length x and $1/x > 5B_2$.*

If the ribbon formed by joining $C_n(t)$ to $C(t)$ for every t is embedded,

$$|\operatorname{Wr}(C) - \operatorname{Wr}(C_n)| < \alpha\, n x^3 + n O(x^4), \tag{1}$$

where α is a numerical constant less than $B_2(5B_2^2 + B_3)$.

That is, if the lengths of the edges of C_n are approximately constant, the error is bounded by a multiple of $1/n^2$. We also derive a "local" version of these bounds which is useful when the derivatives of the curve are large in some regions and small in others. In this case, we may split the curve and derive independent bounds on each region's contribution to the overall approximation error (see Corollary 17). This allows us to use more edges of C_n to approximate regions where C has large derivatives.

The proof is based on Fuller's ΔWr formula, which gives the difference in writhing number between two curves as the spherical area of the ribbon bounded by the curves on S^2 swept out by their unit tangent vectors [11]. (Following Solomon [18], we will refer to such curves as *tantrices*, though they are classically referred to as *tangent indicatrices*.)

We begin by defining the writhing number in section 2. Sections 3 and 4 then introduce the original form of Fuller's ΔWr formula. In sections 5 and 6 we extend Fuller's formula to the case where one curve is polygonal and the other is of class $\mathcal{C}^2$ using a natural geometric idea: The tantrix of a polygonal curve should be defined to be the chain of geodesic segments on S^2 joining the (isolated) tangent vectors of the curve (this was pointed out by Chern in [8]). In the process, we discover a surprising fact: The writhe of a polygonal curve is *equal* to the writhe of any smooth curve obtained by carefully rounding off its corners!

Section 8 contains the remainder of our work: estimating the terms in our improved version of the ΔWr formula to obtain Theorem 13. We test our error bounds in section 9 by computing the writhe of a collection of polygonal curves inscribed in a smooth curve of known writhe.

The last section contains a discussion of some open problems inspired by the present work. We state the most important of them now: Like most of the theory of writhing numbers, the proof of our main theorem depends essentially on the fact that C is closed. Can these methods be extended to open curves?

2. Definitions. The writhing number of a space curve is defined by the following definition.

Definition 2. *The* writhe *of a piecewise differentiable curve $C(s)$ is given by*

$$\operatorname{Wr}(C) = \frac{1}{4\pi} \int_{C\times C} \frac{C'(s) \times C'(t) \cdot (C(s) - C(t))}{|C(s) - C(t)|^3}\, \mathrm{d}s\, \mathrm{d}t. \tag{2}$$

Definition 2 is inspired by the Gauss formula for the linking number of two space curves, $A(s)$ and $B(s)$ (see Epple [10] for a fascinating discussion of the history of this formula):

$$\operatorname{Lk}(A, B) = \frac{1}{4\pi} \int_{A\times B} \frac{A'(s) \times B'(t) \cdot (A(s) - B(t))}{|A(s) - B(t)|^3}\, \mathrm{d}s\, \mathrm{d}t. \tag{3}$$

When the two curves A and B become a single curve, their linking number becomes the writhing number. This introduces a potential singularity on the diagonal of $C \times C$, but a careful calculation shows that the integral still converges. In fact, the integrand of (2) approaches 0 on the diagonal of $C \times C$, even when the curve C has a corner.

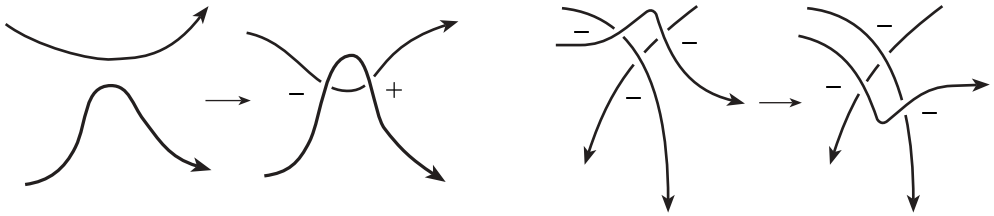

FIG. 1. *Changing the projection direction within a cell can only alter the diagram by one of these two moves. Neither changes the signed crossing number of the diagram, as we can see by counting the + and − markers at the crossings of C.*

From now on, we will assume that C is simple. With this assumption, another way to look at the integral of Definition 2 is to observe that the integrand is the pullback of the area form on S^2 under the Gauss map $C \times C \to S^2$ defined by

$$(C(s), C(t)) \mapsto \frac{C(s) - C(t)}{|C(s) - C(t)|}. \tag{4}$$

From this perspective, we can see that the (signed) multiplicity of the Gauss map at any point p on S^2 is just the number of self-crossings of the projection of C in direction p.

3. Fuller's ΔWr formula. Suppose we have a differentiable curve $C(t)$, with unit tangent vector $T(t)$. As we mentioned in section 1, the curve $T(t)$ on the unit sphere is known as the tantrix of C. This curve divides the unit sphere into a number of cells. Within each cell, the signed crossing number of the projection of C is constant: Changing projection directions within the cell amounts to altering the projection of the knot by a regular isotopy consisting of Reidemeister moves of types II and III (pictured in Figure 1). Neither of these moves changes the signed crossing number of the knot.

This observation motivates the idea that the writhe of a closed space curve is related to the fraction of the sphere's area enclosed by its tantrix. In 1978, Brock Fuller stated the following formula.

THEOREM 3 (Fuller's spherical area formula). *For any closed space curve $C(s)$ of class $\mathcal{C}^3$, let A be the spherical area enclosed by the tantrix of C. Then*

$$1 + \mathrm{Wr}(C) = \frac{A}{2\pi} \mod 2. \tag{5}$$

Fuller used this formula to conclude that the difference in writhe between two curves X_0 and X_1 whose tantrices T_0 and T_1 are sufficiently close is given by a certain formula, which represents the spherical area of the ribbon between T_0 and T_1.

To be more specific, suppose that X_0 and X_1 are simple closed space curves of class $\mathcal{C}^2$, with regular parametrization (that is, parametrized so that X_0' and X_1' never vanish), and unit tangent vectors T_0 and T_1. Let $F : S^1 \times [0,1] \to \mathbf{R}^3$ be a continuous deformation of X_0 into X_1, where $F(t,\lambda) = X_\lambda(t)$ and the X_λ are simple curves of class $\mathcal{C}^1$, with unit tangent vectors $T_\lambda(t)$ continuous in (t,λ).

THEOREM 4 (Fuller's ΔWr formula). *If $T_1(t)$ and $T_\lambda(t)$ are not antipodal for all (t,λ), then*

$$\mathrm{Wr}(X_1) - \mathrm{Wr}(X_0) = \frac{1}{2\pi} \int_C \frac{T_0(t) \times T_1(t)}{1 + T_0(t) \cdot T_1(t)} \cdot [T_0'(t) + T_1'(t)] \, \mathrm{d}t. \tag{6}$$

We observe that this formula does not require an arc-length parametrization of X_0 and X_1.

4. Justifying Fuller's interpretation of the ΔWr formula. While Fuller stated both of these theorems in 1978, he did not provide complete proofs for either. The first rigorous proofs of Theorems 3 and 4 were given by Aldinger, Klapper, and Tabor [2] in 1995. While these authors proved both theorems as stated, they did not show that the formula in Theorem 4 represents the spherical area of the ribbon between T_0 and T_1 (in [2], the right-hand side of (6) describes the difference between the twist of two frames on X_0 and X_1.)

In the spirit of their paper, we now justify Fuller's original intuition about (6).

PROPOSITION 5. *Given two curves $T_0(t), T_1(t) : [0,1] \to S^2$, where $T_0(t)$ and $T_1(t)$ are never antipodal, the area of the spherical region R bounded by T_0, T_1 and the great circle arcs joining their endpoints is given by*

$$\text{Area}(R) = \int \frac{T_0(t) \times T_1(t)}{1 + T_0(t) \cdot T_1(t)} \cdot (T_0' + T_1') \, \mathrm{d}t. \tag{7}$$

Proof. We let

$$u(\theta, t) = \cos\theta \; T_0(t) + \sin\theta \; T_1(t)$$

and parametrize the region R by

$$v(\theta, t) = \frac{u(\theta, t)}{|u(\theta, t)|},$$

where θ ranges from 0 to $\pi/2$. Plugging this parametrization into the area form on S^2 and using the properties of the triple product, we find

$$\mathrm{d}\,\text{Area} = \frac{1}{|u|^3} \left(\frac{\partial u}{\partial \theta} \times \frac{\partial u}{\partial s} \cdot u \right) \mathrm{d}\theta \wedge \mathrm{d}t.$$

Using the definition of $u(\theta, t)$, this simplifies to

$$\mathrm{d}\,\text{Area} = T_0 \times T_1 \cdot \left(\frac{\cos\theta}{(1 + 2\cos\theta \sin\theta \; T_0 \cdot T_1)^{\frac{3}{2}}} T_0' + \frac{\sin\theta}{(1 + 2\cos\theta \sin\theta \; T_0 \cdot T_1)^{\frac{3}{2}}} T_1' \right) \mathrm{d}\theta \wedge \mathrm{d}t.$$

Using the formula $\sin 2\theta = 2\cos\theta \sin\theta$ and the fact that the definite integrals of each of the trigonometric expressions above from 0 to $\pi/2$ are equal, we have

$$\text{Area}(R) = \int_0^1 T_0 \times T_1 \cdot \left[\int_0^{\pi/2} \frac{\cos\theta}{(1 + \sin 2\theta \; T_0 \cdot T_1)^{3/2}} \, \mathrm{d}\theta \right] (T_0' + T_1') \, \mathrm{d}t.$$

This can be solved by the general integration formula

$$\int \frac{\cos\theta}{(1 + a\sin 2\theta)^{3/2}} \, \mathrm{d}\theta = \frac{-a\cos\theta - \sin\theta}{(a^2 - 1)\sqrt{1 + a\sin 2\theta}}, \tag{8}$$

which yields the formula in the statement of the proposition. ∎

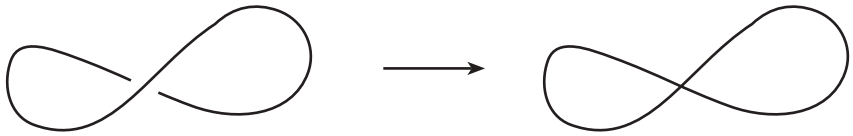

FIG. 2. *The family of almost-planar curves on the left converge in any C^k norm to the planar figure eight curve on the right. However, the writhe of the curves on the left approaches one, while the writhe of the planar figure eight is zero. This shows that writhe is not continuous in any C^k norm on curves.*

5. Extending Fuller's formulas to polygonal curves: I. To measure the difference in writhe between a smooth curve and a polygonal curve inscribed in the smooth curve, we must extend Theorem 4 to polygonal curves. This raises an immediate objection: Theorem 4 deals with the area enclosed by a curve's tantrix, while the set of tangent vectors of a polygon is a collection of isolated points!

To make sense of Fuller's theorem in this context, we recall the following definition from Chern [8].

DEFINITION 6. *The tantrix of a piecewise C^1 curve $C(s)$ with positive corner angles is the image of $T(s)$ on the unit sphere, together with the great circle arcs joining the pairs of tangent vectors at each corner of the curve.*

We will show that Theorem 4 holds for polygons under this definition. To do so, we intend to approximate each polygonal curve with a family of smooth curves so that the writhe of the smooth curves converges to the writhe of the polygonal curve.

Examining Definition 2, it might seem that this would be easy. For instance, one might conjecture that Wr was continuous in the C^1 norm on curves and hope to obtain an approximating family using standard techniques. Unfortunately, the situation is not so simple; as the example in Figure 2 shows, writhe is not continuous in any C^k norm on curves. Thus, our proof depends explicitly on the hypothesis that the limit curve is polygonal; it cannot be easily extended to the case where the limit curve is merely piecewise C^2.

To prepare for the proof, we establish some notation for polygonal curves. Let $C(t)$ be a polygonal curve with corners at cyclically ordered parameter values $t_0 < t_1 < \cdots < t_n = t_0$. We let $T(t)$ denote the unit tangent to C and set up the convention that $T(t_i)$ will be the tangent vector *leaving* $C(t_i)$.

We now construct a family of smooth curves approximating our polygonal curve.

PROPOSITION 7. *Given an embedded polygonal curve C with corners at $t_0, \ldots, t_{n-1}$, $t_n = t_0$, there exists a family of smooth curves C_i converging pointwise to C with*

1. *$C_i = C$ outside a neighborhood of each corner point $C(t_j)$ of radius $1/i$;*
2. *near each corner, the tangent vectors of C_i interpolate between $T(t_{j-1})$ and $T(t_j)$;*
3. *$\mathrm{Wr}(C_i) \to \mathrm{Wr}(C)$.*

Proof. It is easy to construct a family of $C_i \to C$ obeying conditions 1 and 2 by rounding off each corner of C. We claim that this can be done in such a way that the writhe integrand has a uniform upper bound on all the C_i. Since condition 1 implies that the $C_i \to C$ pointwise in the $\mathcal{C}^1$ norm, the bounded convergence theorem [17, p. 81] will then yield condition 3.

Since any pair of adjacent edges is planar, we can choose the C_i so that the region of each C_i approximating a pair of adjacent edges is also planar. This means that for some universal ϵ, the writhe integrand of each C_i vanishes in an ϵ-neighborhood of the diagonal of $C_i \times C_i$.

Since C has no self-intersections and the angle at each corner of C_i is positive, the distance between any pair of nonadjacent edges of C is bounded below by some constant. Since the C_i converge to C pointwise, we may assume the same for the portions of the C_i approximating any pair of disjoint edges. Throwing away finitely many of the C_i if necessary, this means that for any $\delta > 0$, there exists a universal lower bound (depending on δ) on the distance between any pair of points in $C_i \times C_i$ *outside* an δ-neighborhood of the diagonal.

But for any pair of points on C_i, the writhe integrand is bounded above by the inverse square of the distance between them. Thus, our lower bound on self-distances yields a universal upper bound on the writhe integrand for C and all the C_i outside a δ-neighborhood of the diagonal. Choosing $\delta < \epsilon$, this completes the proof of the proposition. □

6. Extending Fuller's formulas to polygonal curves: II. We now state our extension of Fuller's theorem. Our formula will apply to the following situation (cf. section 3): Suppose that X_0 and X_1 are simple closed space curves, with X_0 of class $\mathcal{C}^2$ and X_1 polygonal, with regular parametrization (that is, parametrized so that X_0' and X_1' never vanish where they are defined), and unit tangent vectors T_0 and T_1.

Let $F : S^1 \times [0,1] \to \mathbf{R}^3$ be a C^0 deformation of X_0 into X_1, where $F(t,\lambda) = X_\lambda(t)$, so that the X_λ are simple curves of class C^1 for $\lambda \in [0,1)$, with unit tangent vectors $T_\lambda(t)$ continuous in (t,λ). As above, we take the corners of X_1 to be at parameter values $t_0, t_1, \ldots, t_n = t_0$. We let T_1 denote the unit tangent vector to X_1, and let $T_1(t_i)$ be the tangent vector *leaving* $X_1(t_i)$.

THEOREM 8. *If each corner angle of X_1 is strictly greater than $\pi/2$ and each $T_1(t)$ and $T_\lambda(t)$ are at an angle less than $\pi/2$, then*

$$\mathrm{Wr}(X_1) - \mathrm{Wr}(X_0) = \frac{1}{2\pi} \operatorname{Area} R(T_0, T_1),$$

where $R(T_0, T_1)$ is the spherical region bounded by the tantrices of X_0 and X_1 (using Definition 6*) and great circle segments joining their endpoints, and* Area *represents oriented area on S^2.*

COROLLARY 9. *If each corner angle of X_1 is strictly greater than $\pi/2$ and each $T_1(t)$ and $T_\lambda(t)$ are at an angle less than $\pi/2$, then*

$$\begin{aligned}\mathrm{Wr}(X_1) - \mathrm{Wr}(X_0) = \frac{1}{2\pi} \sum_{i=1}^{n} &\operatorname{Area} R(T_0(t_i), T_0(t_{i+1}), T_1(t_i)) \\ &+ \operatorname{Area} \triangle T_0(t_i) T_1(t_{i-1}) T_1(t_i).\end{aligned}$$

Here $R(T_0(t_i), T_0(t_{i+1}), T_1(t_i))$ is the spherical region bounded by geodesics from $T_1(t_i)$ to $T_0(t_i)$ and $T_0(t_{i+1})$ and the portion of T_0 between t_i and t_{i+1}, $\triangle T_0(t_i) T_1(t_{i-1}) T_1(t_i)$ is the spherical triangle with these three vertices, and Area *represents oriented area on S^2.*

Proof. Construct a sequence of smooth curves $C_j \to X_1$ using Proposition 7. For large enough j, each of these curves can be homotoped to X_1 through a family of simple $\mathcal{C}^1$ curves with a continuous family of tangent vectors, as in the setup for the statement of Theorem 8.

Joining these homotopies to the homotopy from X_1 to X_0 assumed by our hypotheses generates a family of (nonsmooth) homotopies from the X_0 to each of the

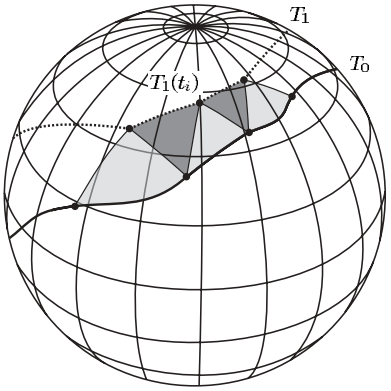

FIG. 3. *This figure shows the two types of regions in the sum in the statement of Theorem* 8. *The top (dotted) curve shows the great circle arcs joining the tangent vectors $T(t_i)$ of the polygonal curve X_1. The bottom curve shows the continuous curve of unit tangents T_0 to the smooth curve X_0. The light gray regions show the first terms in the sum, while the dark gray spherical triangles show the second terms.*

C_j. We wish to smooth each of these to obtain homotopies from X_0 to C_j which obey the conditions of Fuller's ΔWr formula (Theorem 4).

We first prove that the tangent vectors of each of the intermediate curves in each homotopy from X_0 to C_j are never antipodal to the corresponding tangent vectors T_j of C_j. By hypothesis, for each t and λ, $\angle T_\lambda(t), T_1(t) < \pi/2$. On the other hand, since the difference between the tangent vectors to X_1 at any corner is less than $\pi/2$, for large enough j, $\angle T_1(t), T_j(t) < \pi/2$. Putting these equations together, we see that $\angle T_\lambda(t), T_j(t) < \pi$, and so these vectors are never antipodal.

It is easy to smooth the combined homotopy from X_0 to C_j so that each of the intermediate curves is of class $\mathcal{C}^1$ while preserving this condition. Since the smoothed homotopy satisfies the hypotheses of Fuller's ΔWr formula (Theorem 4), Proposition 5 tells us that the difference between $\mathrm{Wr}(X_0)$ and $\mathrm{Wr}(C_j)$ is the spherical area of the ribbon joining T_0 and T_j.

For each i, the contribution to the spherical area from the straight part of C_j between t_i and t_{i+1} comes from the ribbon between $T_1(t_i)$ and the portion of T_0 with $t \in (t_i + 1/j, t_{i+1} - 1/j)$. As $j \to \infty$, this area converges to the area of the ribbon between the portion of T_0 with $t \in (t_i, t_{i+1})$ and $T_1(t_i)$. This is the first term in our sum above.

At each vertex t_i of X_1, the contribution to our spherical area from the curved part of C_j comes from the ribbon between the great circle arc connecting $T_1(t_{i-1})$ and $T_1(t_i)$ and a portion of T_0 of parameter length $2/j$. As $j \to \infty$, the area of this ribbon converges to the area of the spherical triangle with vertices $T_0(t_i)$, $T_1(t_i)$, $T_1(t_{i-1})$. This is the second term in our sum above. Figure 3 shows both of these terms on the unit sphere.

We have shown that the right-hand side of the statement of this theorem is equal to the limit $\lim_{j\to\infty}(\mathrm{Wr}(C_j) - \mathrm{Wr}(X_0))$. However, by Proposition 7, $\lim_{j\to\infty} \mathrm{Wr}(C_j) = \mathrm{Wr}(X_1)$. Thus

$$\lim_{j\to\infty} \mathrm{Wr}(C_j) - \mathrm{Wr}(X_0) = \mathrm{Wr}(X_1) - \mathrm{Wr}(X_0), \tag{9}$$

which is the left-hand side in the statement of this theorem. This completes the proof. □

We now make a surprising observation: Since the tantrices of the C_j differ as curves on S^2 only in parametrization, the area between each of these curves and the tantrix of X_0 is constant. Thus, by Fuller's formula, each C_j has the same writhe! And since (by Proposition 7) these writhing numbers converge to the writhe of X_1, each $\mathrm{Wr}(C_j)$ is equal to $\mathrm{Wr}(X_1)$ as well! So we have the following corollary.

COROLLARY 10. *If C_n is a polygonal curve, and C is a smooth curve obtained by rounding off the corners of C_n under the conditions of Proposition* 7, *then*

$$\mathrm{Wr}(C_n) = \mathrm{Wr}(C). \tag{10}$$

7. Extending Fuller's formulas to polygonal curves: III. Corollary 10 allows us to close this circle of ideas by observing that we have also extended Theorem 3 to polygons (cf. Proposition 3 in Cimasoni [9]).

THEOREM 11 (Fuller's spherical area formula for polygons). *For any closed space polygon P, let A be the spherical area enclosed by the tantrix of P, where we define this tantrix by Definition* 6. *Then*

$$1 + \mathrm{Wr}(P) = \frac{A}{2\pi} \mod 2. \tag{11}$$

Proof. Round off the corners of P under the conditions of Proposition 7 to obtain a C^3 curve C. The tantrices of C and of P have the same spherical image, and so enclose the same area, while C and P have the same writhe by Corollary 10. But the classical form of Fuller's spherical area formula applies to C. □

Our proof of Fuller's difference of writhe formula above also applies to a pair of polygons (one simply approximates each by smooth curves and constructs a three-stage homotopy between pairs of smooth curves), under somewhat stricter hypotheses, as seen in the following theorem.

THEOREM 12. *Suppose X_0 and X_1 are polygons, and let $F : S^1 \times [0,1] \to \mathbf{R}^3$ be a C^0 deformation of X_0 into X_1, where $F(t,\lambda) = X_\lambda(t)$, so that the X_λ are simple curves of class C^1 for $\lambda \in (0,1)$, with unit tangent vectors $T_\lambda(t)$ continuous in (t,λ).*

If each corner angle of X_i is strictly greater than $\pi/4$ and each $T_i(t)$ and $T_\lambda(t)$ are at an angle less than $\pi/2$, then

$$\mathrm{Wr}(X_1) - \mathrm{Wr}(X_0) = \frac{1}{2\pi} \operatorname{Area} R(T_0, T_1),$$

where $R(T_0, T_1)$ is the spherical region bounded by the tantrices of X_0 and X_1 (using Definition 6*) and great circle segments joining their endpoints, and* Area *represents oriented area on S^2.*

8. Bounding the ΔWr formula. We now prove our main theorem by finding asymptotic bounds for Fuller's ΔWr formula. Our theorem deals with the following situation: Assume that $C(t)$ is a simple closed curve of class $\mathcal{C}^4$, parametrized so that $|C'(t)| \geq 1$. (Given any initial parametrization, this can be accomplished by rescaling.) Further, assume we have upper bounds $B_1, \ldots, B_4$ on the norms of the first four derivatives of C. In particular, we do not require that C be parametrized by arclength and state our bounds in terms of curvature and torsion because in practice it is very difficult to obtain an arc-length parametrization of a given curve, while it is comparatively easy to obtain values for these derivative bounds.

Let $C_n(t)$ be any n-edge polygonal curve inscribed in C. We assume that the maximum edge length of C is bounded by x.

THEOREM 13. *If the ribbon formed by joining $C_n(t)$ to $C(t)$ for every t is embedded and $1/x > 5B_2$,*

$$|\operatorname{Wr}(C) - \operatorname{Wr}(C_n)| < \alpha\, n x^3 + nO(x^4), \tag{12}$$

where α is a numerical constant less than $B_2(5B_2^2 + B_3)$.

We make a few comments on this theorem before diving into the proof. First, we observe that if the lengths of the edges of C_n are all of the same order of magnitude, the difference between the writhe of C and the writhe of C_n is of order $1/n^2$.

Next, we discuss the role of the additional hypotheses in the statement above, that is, that the ribbon between C and C_n be embedded and that $1/x$ be greater than $5B_2$. Both are intended to exert enough control over the approximation to guarantee the existence of a homotopy from C to C_n obeying the requirements of Theorem 8.

We can guarantee that C_n satisfies the first hypothesis by proving that C_n lies in an embedded tubular neighborhood of C. Since C is of class $\mathcal{C}^4$, and has no self-intersections, such a neighborhood is guaranteed to exist: For a discussion of how to compute the radius of this tube (which is known as the *thickness* of C), see the literature on *ropelength* of knots (e.g., [12, 7, 14]).

Proof. We begin by reparametrizing our curve by arclength. This forces us to recompute our bounds for the derivatives of $C(t)$ (a standard computation), arriving at

$$|C'(s)| = 1, \qquad |C''(s)| < K := 2B_2, \qquad |C'''(s)| < T := 2B_3 + 10B_2^2, \tag{13}$$

while $C^{(4)}(s)$ is again bounded above. To remind ourselves of the connection between these bounds and the curvature and torsion of our curve, we will refer to the bound for the second derivative as K and the bound for the third derivative as T. Further, we note that the curvature $\kappa(s)$ of our curve is bounded above by K and that our hypotheses imply that $1/x > (5/2)K$.

We also establish the convention that the corners of C_n are at parameter values cyclically ordered as $s_0, \ldots, s_{n-1}, s_n = s_0$.

By smoothing the linear interpolation between C and C_n, we can construct a homotopy between C and C_n according to the conditions of Theorem 8 as long as the following hold:

1. the ribbon joining C to C_n is embedded,
2. the angle at each corner of C_n is at least $\pi/2$,
3. the angle between $T(s)$ and $T_n(s)$ is at most $\pi/2$ for any s.

Borrowing from Lemma 16 (below), we see that our assumption that $1/x > (5/2)K$ is enough to bound the angle in condition 3 by $0.20402 < \pi/4$. At any corner s_i, the same lemma implies that the corner angle is the supplement of at most twice 0.20402, so this is enough to ensure that condition 2 holds as well.

Theorem 8 now tells us that

$$\begin{aligned} |\operatorname{Wr}(C) - \operatorname{Wr}(C_n)| \leq \frac{1}{2\pi} \sum_{i=1}^{n} &|\operatorname{Area} R\left(T\left(s_i\right), T\left(s_{i+1}\right), T_n\left(s_i\right)\right)| \\ &+ \left|\operatorname{Area} \triangle T\left(s_i\right) T_n\left(s_{i-1}\right) T_n\left(s_i\right)\right|, \end{aligned} \tag{14}$$

where the first term is the area of the spherical region bounded by the geodesics from $T_n(s_i)$ to $T(s_i)$ and $T(s_{i+1})$ and the portion of T between s_i and s_{i+1}, and the second term is the area of the spherical triangle. Our job now is to estimate the areas of these regions. To do so, we first recall Taylor's theorem.

THEOREM 14 (Taylor's theorem). *Suppose $C(s)$ is a curve of class $\mathcal{C}^4$, with fourth derivative bounded by B_4'. Then (choosing coordinates so that $C(0)$ is at the origin),*

$$C(s) = sC'(0) + \frac{s^2}{2}C''(0) + \frac{s^3}{6}C'''(0) + R_4(s), \tag{15}$$

where $|R_4(s)| < s^4 B_4'$.

We will use this expression for $C(s)$ frequently in our work below.

LEMMA 15. *For any s, we have*

$$|s - |C(s)|| < \frac{K^2}{24}|s^3| + \frac{1}{120}|s^5| \qquad \text{and} \qquad |C(s)| \le |s|. \tag{16}$$

Further, for any edge of C_n, the difference $|s_{i+1} - s_i|$ is at most $1.01\,x$.

Proof. We assume without loss of generality that s is positive. By Schur's lemma [8], since the curvature of C is bounded above by K, $|C(x)|$ is at least the length of a chord across an arc of length s on a circle of radius $1/K$, or $(2/K)\sin(K/2)s$. This means that we have

$$\frac{2}{K}\sin\frac{K}{2}s = s - \frac{K^2}{24}s^3 + R_5(s),$$

where $R_5(s)$ is the term of order s^5 which comes from the usual Taylor expansion of $\sin s$. In particular,

$$\begin{aligned} |s - |C(s)|| &< s - \frac{2}{K}\sin\frac{K}{2}s \\ &< \frac{K^2}{24}s^3 - R_5(s), \end{aligned}$$

where $R_5(s) < \frac{1}{120}s^5$. The upper bound on $|C(s)|$ comes from the fact that C is unit-speed.

The second statement is another Schur's lemma calculation, this time invoking our hypothesis that $x > (5/2)K$ and observing that $1.01\sin y > y$ for y between 0 and $1/5$. □

We will also need an upper bound on the angle between $T(s)$ and $C_n(s)$.

LEMMA 16. *The angle between the tangent vector $T(s)$ and the corresponding tangent vector $T_n(s)$ to C_n is bounded above by*

$$\angle T(s)T_n(s) < 0.51005Kx. \tag{17}$$

Proof. Assume that s is between s_i and s_{i+1}. Then

$$\sin\angle T(s)T_n(s) = \frac{|[C(s_{i+1}) - C(s_i)] \times T(s)|}{|C(s_{i+1}) - C(s_i)|}. \tag{18}$$

But we have

$$C(s_{i+1}) - C(s_i) = \int_{s_i}^{s_{i+1}} T(t)\,dt,$$

and for any t, we have

$$T(t) = T(s) + \int_s^t T'(u)\,du.$$

This means that

$$[C(s_{i+1}) - C(s_i)] \times T(s) = \int_{s_i}^{s_{i+1}} T(t) \times T(s)\, dt \tag{19}$$

$$= \int_{s_i}^{s_{i+1}} \int_{s}^{t} T'(u) \times T(s)\, du\, dt. \tag{20}$$

Since $|T'(u) \times T(s)| \leq |T'(u)||T(s)| \leq \kappa(u) < K$, and s is between s_i and s_{i+1}, a small computation reveals that this integral is bounded by $\frac{K}{2}(s_{i+1} - s_i)^2$.

Since the length $|C(s_{i+1}) - C(s_i)|$ is bounded below by $(1/1.01)(s_{i+1} - s_i)$ by Lemma 15, we get

$$\sin \angle T(t)T_n(t) < \frac{1.01}{2} Kx. \tag{21}$$

Since $1/x > (5/2)K$, this is always bounded above by $1.01/5$, and so

$$\angle T(t)T_n(t) < \frac{1.01^2}{2} Kx. \qquad \square \tag{22}$$

We are now ready to embark on the main work of the proof: estimating the areas in (14). We begin with the first term: the area bounded by the portion of $T(s)$ between s_i and s_{i+1}, together with the great circle arcs joining $T(s_i)$ and $T(s_{i+1})$ to $T_n(s_i)$. Without loss of generality, we may assume that $i = 0$, that $s_0 = 0$, and that $C(0) = \mathbf{0}$, and apply the Taylor expansion of (15) to C at 0. Our strategy is to prove that this region is contained in a neighborhood of the great circle arc joining $T(0)$ and $T(s_1)$. Suppose s is between 0 and s_1. We want to bound the height of $T(s)$ above the $T(0)$, $T(s_1)$ plane, or

$$h(s) := \frac{C'(s) \cdot C'(0) \times C'(s_1)}{|C'(0) \times C'(s_1)|}. \tag{23}$$

First, we have

$$C'(s_1) = C'(0) + s_1 C''(0) + \frac{s_1^2}{2} C'''(0) + R_3(s_1),$$
$$C'(s) = C'(0) + sC''(0) + \frac{s^2}{2} C'''(0) + R_3(s).$$

Using the triple product identities, we can rewrite $h(s)$ in terms of the inner product of $C'(0)$ and the cross product of these vectors. For the triple product, we get

$$\left[\frac{s_1^2 s}{2} - \frac{s^2 s_1}{2}\right] C'(0) \cdot C''(0) \times C'''(0) + C'(0) \cdot [R_3(s_1) \times C'(s) + C'(s_1) \times R_3(s)]\,. \tag{24}$$

Expanding the last term, we see that it is the sum of a term of order $s_1 s^3$ and a term of order $s s_1^3$. Thus, to leading order, the norm of the entire triple product is bounded above by

$$|h(s)| < H := \frac{KT}{2|C'(0) \times C'(s_1)|} s_1^3 + O(s_1^4), \tag{25}$$

since $s \in [0, s_1]$. We now consider the height of $T_n(0)$ above the $T(0)$, $T(s_1)$ plane. Since $T_n(0)$ is the normalization of $C(s_1) - C(0) = C(s_1)$, this height is given by

$$\frac{C(s_1)}{|C(s_1)|} \cdot \frac{C'(0) \times C'(s_1)}{|C'(0) \times C'(s_1)|}. \tag{26}$$

As before, we get

$$C'(0) \times C'(s_1) = s_1 C'(0) \times C''(0) + \frac{s_1^2}{2} C'(0) \times C'''(0) + O(s_1^3). \tag{27}$$

Taking the dot product with the Taylor expansion of $C(s_1)$, we get only terms of order $O(s_1^4)$ and higher. Thus, to leading order, this region is contained in a rectangle based on the great circle arc joining $C'(0)$ and $C'(s_1)$ of height H. We now estimate the area of this rectangle.

First, we note that the length of the great circle joining $C'(0)$ and $C'(s_1)$ is given by the angle θ between $C'(0)$ and $C'(s_1)$. Since $s_1 < 1.01\,x$ by Lemma 15, this length is bounded above by $1.01\,Kx$, which is less than 0.404 by our hypotheses on x. Since H is small compared to s, we may assume that the entire rectangle is contained within a spherical disk of radius 0.5.

We project the rectangle to the plane by central projection: This map is increasing on lengths and areas, and increases length by at most a factor of 1.01. The area of the rectangle in the plane is overestimated by the product $1.01\,\theta H$. On the other hand, we have $|C'(0) \times C'(s_1)| = \sin\theta$. And for $\theta < 0.404$, $1.02 \sin\theta > \theta$. Keeping track of the various constants involved, and using the fact that $s_1 < 1.01\,x$ again, the area of this spherical region is overestimated by

$$\text{Area}\, R(T(s_i), T(s_{i+1}), T_n(s_i)) < KT\,x^3 + O(x^4). \tag{28}$$

We now turn to the second term in (14): the area of the spherical triangle bounded by $T(s_i)$, $T_n(s_{i-1})$, and $T_n(s_i)$. Without loss of generality we assume that $i = 1$, that $s_1 = 0$, and that $C(0) = \mathbf{0}$, and we expand C around 0 using (15). We wish to compute

$$\text{Area}\, \triangle \left(\frac{C(s_0)}{|C(s_0)|}, \frac{C(s_2)}{|C(s_2)|}, C'(0) \right) = \left| \left(\frac{C(s_0)}{|C(s_0)|} - C'(0) \right) \times \left(\frac{C(s_2)}{|C(s_2)|} - C'(0) \right) \right|. \tag{29}$$

If we factor out $1/|C(s_0)||C(s_2)|$, we are left with the norm of the cross product of two terms:

$$C(s_0) - |C(s_0)|C'(0) = (s_0 - |C(s_0)|)\, C'(0) + \frac{s_0^2}{2} C''(0) + \frac{s_0^3}{6} C'''(0) + R_4(s_0),$$
$$C(s_2) - |C(s_2)|C'(0) = (s_2 - |C(s_2)|)\, C'(0) + \frac{s_2^2}{2} C''(0) + \frac{s_2^3}{6} C'''(0) + R_4(s_2).$$

Using Lemma 15, we see that $|s - |C(s)|| < (K^2/24)s^3 + O(s^5)$, and we see that the leading term of this expression contains fifth powers of s_0 and s_2, and is bounded by

$$s_0^2 s_2^2 \left(\frac{K^3}{48} + \frac{KT}{12} \right) (s_0 + s_2). \tag{30}$$

However, we must still divide by $|C(s_0)||C(s_2)|$. By Lemma 15, we see that the ratios $s_0/|C(s_0)|$ and $s_2/|C(s_2)|$ are bounded above by 1.01. Thus, using the same lemma to

conclude that s_2 and s_0 are less than $1.01\,x$, and making a central projection argument as before, we are left with

$$\text{Area}\,\triangle(T_n(s_i), T_n(s_{i-1}), T(s_i)) < \frac{K^3 + KT}{3}x^3 + O(x^4). \tag{31}$$

Summing over i and dividing by 2π, then writing K and T in terms of B_2 and B_3, we obtain the statement of Theorem 13. Note that we have overestimated the numerical constants to simplify the resulting formula. □

If a curve has a small region of high curvature and larger regions of low curvature, it may be desirable to approximate the curve more carefully in the regions of high curvature in order to save time in the computation of writhe. Since our error bound is additive along the curve, these methods are well suited to this case. We have the following corollary.

COROLLARY 17. *Suppose C is a $\mathcal{C}^4$ curve and C_n is a curve inscribed in C so that C and C_n obey the hypotheses of Theorem* 13.

If C and C_n are divided into regions R_i, each containing n_i edges which are bounded above in length by x_i, and so that the derivatives of C are bounded by $B_{1i}, \ldots, B_{4i}$ and $1/x_i > 5B_{2i}$, then

$$|\,\mathrm{Wr}(C) - \mathrm{Wr}(C_p)| < \sum_i \alpha_i\, n_i x_i^3 + n_i O(x_i^4),$$

where each α_i is a numerical constant less than $B_{2i}(5B_{2i}^2 + B_{3i})$.

We make one more observation.

PROPOSITION 18. *Let C be a simple, closed space curve of class $\mathcal{C}^2$ and let C_p be a polygonal approximating curve as in Theorem* 13 *or Corollary* 17.

If the arc joining the endpoints of a sequence of n edges of C_p is planar, then the $n-2$ edges interior to this region contribute nothing to the error bound in the theorem.

In particular, this means that the derivative bounds in both statements can be taken to be bounds on the derivatives of the nonplanar *regions of the curve C.*

Proof. On these edges, the tantrix of the smooth curve and the polygonal curve parametrize the same great circle arc on S^2. Thus, the ribbon between these curves has zero area. □

9. Example computations. We are now prepared to test Theorem 1 by computing the writhing numbers of various polygonal approximations of a smooth curve and comparing the results to the exact writhe of the smooth curve. To control the numerical error introduced in these calculations, all of these computations were performed using an arbitrary-precision implementation of Banchoff's formula [3] for the writhing number of a polygonal curve. The initial runs were performed with 45 decimal digits of precision. They were checked against runs performed with 54 digits of precision. Since the results agreed, we feel confident that roundoff error does not affect the computations reported on below.

The curve whose writhe we computed is an example of Fuller [11] (see Figure 4).

Using Theorem 3 and the Călugăreanu–White formula, it is easy to see that the writhe of this curve is $3(1-\sin 0.33) \simeq 2.0278709$. After all, the area enclosed by the tantrix of this curve C is that of a hemisphere, plus three enclosures of a spherical cap of radius $\pi/2 - 0.33$. Thus the writhe of the curve is equal to $1 - \sin 0.33 \mod 2$. To complete the computation, one sets up a frame on the curve and computes its twist and linking number. (Details for this computation can be found in [11].)

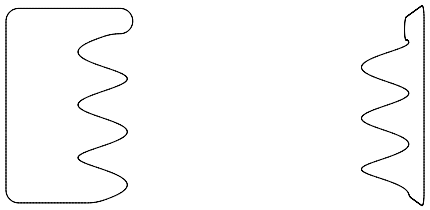

FIG. 4. *This example of Fuller's "closed helix" is composed of* 3 *turns of a helix of radius* 1 *with pitch angle* 0.33*, with ends joined by a planar curve.*

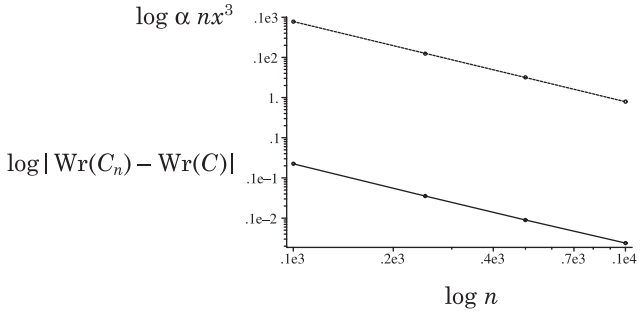

FIG. 5. *This graph shows a log-log plot of the actual error in computing the writhing number for one of Fuller's "closed helices" with various numbers of edges (lower solid line), together with our error bounds (upper dotted line). The fact that the lines are parallel shows that the convergence is of order* n^2*, as predicted by Theorem* 13*.*

We now take a series of polygonal approximations to C and compare the difference between their writhing numbers and the writhe of C to the bounds of Theorem 13.

We begin by finding bounds on the derivatives of C and the edge length of our approximations. By Proposition 18, it suffices to find derivative bounds for the helical region of C. Since the helix has unit radius, both B_2 and B_3 can be taken to be one. The curve is parametrized so that $|C'(s)| \geq 1$, and we can take $\alpha = 6$.

Here are the results of computing writhe with various numbers of edges:

n	$\mathrm{Wr}(C_n)$	$\lvert\mathrm{Wr}(C_n) - \mathrm{Wr}(C)\rvert$	x	$\alpha\, nx^3$
100	2.00541	0.02246	0.506	77.73
250	2.02434	0.00353	0.203	12.55
500	2.02697	0.0009	0.101	3.09
1000	2.02763	0.00024	0.051	0.786

It is worth examing a graph of these results (see Figure 5).

10. Discussion of results and further directions. In this paper, we have given a set of asymptotic error bounds that allow us to compute the writhe of a closed space curve with defined accuracy by computing the writhe of a polygonal approximation to this curve. The example we computed in section 9 shows that our bounds are of the right order of magnitude: Roughly speaking, the writhe converges quadratically in the number of edges of the approximation.

We have now built a new family of algorithms for computing the writhe integral with bounded error: Estimate the number of edges required using Theorem 1 and then compute the writhe of that inscribed polygon using any of the methods mentioned in the introduction.

To test one of these algorithms in practice, we implemented the most basic of the polygonal writhe computation algorithms (Banchoff's exact sum formula [3]) and tested it against the well-developed adaptive quadrature routine `CUHRE` [4]. Our tests reveal that our simple method does not yet outperform `CUHRE`, but the routines can be comparable. For instance, on a sample computation of Fuller's closed helix, `CUHRE` made 11895 evaluations of the writhe integrand for an actual error of 0.0014732694, while our algorithm computed 44850 terms in an exact sum for an actual error of 0.00150432 (the error estimates for each algorithm were 0.2052 and 0.5121, respectively). Since the more advanced algorithms for computing the writhe of polygonal curves are often orders of magnitude faster than Banchoff's algorithm, this holds out the hope that a better method based on our theorem may improve significantly on adaptive quadrature. Clearly, more work is required in this area.

We have proved versions of Fuller's spherical area formula (Theorem 11) and Fuller's difference of writhe formula (Theorem 12). But it is puzzling that our approximation theorem for curves with corners (Proposition 7) should depend on the hypothesis that the limit curve is polygonal.

We suspect that the following conjecture holds.

CONJECTURE 19. *Fuller's spherical area formula (Theorem* 3*) and Fuller's* $\Delta\mathrm{Wr}$ *formula (Theorem* 4*) hold for piecewise* C^2 *curves with the extended definition of tantrix given by Definition* 6.

The proofs of both of these theorems depend on the Călugăreanu–White formula, which applies only to closed curves. Thus all of our results are restricted to closed curves. This leaves open the following much more important problem.

PROBLEM 20. *Extend all these theorems (the Călugăreanu–White formula, Fuller's spherical area formula, and Fuller's* $\Delta\mathrm{Wr}$ *formula) to open curves.*

In particular, extending the results of this paper to open curves would be useful for applications in biology, where the curves of interest are not necessarily closed. We note that while Fuller's ΔWr formula makes sense for open curves, computational examples show that it does not give the correct answer: Boundary terms must be added to account for the ends of the curves.

Acknowledgments. I am grateful to Herbert Edelsbrunner, Herman Gluck, Issac Klapper, John Maddocks, Kathleen Rogers, and David Swigon, among many others, for fruitful conversations. I would also like to acknowledge Mark Peletier and Robert Planque, whose insightful questions and perceptive observations have helped me rethink the writhing number.

AN EXPLICIT FINITE DIFFERENCE METHOD AND A NEW VON NEUMANN-TYPE STABILITY ANALYSIS FOR FRACTIONAL DIFFUSION EQUATIONS*

S. B. YUSTE† AND L. ACEDO†

Abstract. A numerical method for solving the fractional diffusion equation, which could also be easily extended to other fractional partial differential equations, is considered. In this paper we combine the forward time centered space (FTCS) method, well known for the numerical integration of ordinary diffusion equations, with the Grünwald–Letnikov discretization of the Riemann–Liouville derivative to obtain an explicit FTCS scheme for solving the fractional diffusion equation. The stability analysis of this scheme is carried out by means of a powerful and simple new procedure close to the well-known von Neumann method for nonfractional partial differential equations. The analytical stability bounds are in excellent agreement with numerical test. A comparison between exact analytical solutions and numerical predictions is made.

Key words. fractional diffusion equation, von Neumann stability analysis, parabolic integro-differential equations, finite difference methods

1. Introduction.

The study of fractional differential equations has been a highly specialized and isolated field of mathematics for many years [1]. However, in the last decade there has been increasing interest in the description of physical and chemical processes by means of equations involving fractional derivatives and integrals. This mathematical technique has a broad potential range of application [2]: relaxation in polymer systems, dynamics of protein molecules, and the diffusion of contaminants in complex geological formations are some of the most recently suggested applications [3].

Fractional kinetic equations have proved particularly useful in the context of anomalous slow diffusion (subdiffusion) [4]. Anomalous diffusion is characterized by an asymptotic long-time behavior of the mean square displacement of the form

$$\left\langle x^2(t)\right\rangle \sim \frac{2K_\gamma}{\Gamma(1+\gamma)}t^\gamma, \quad t\to\infty, \tag{1.1}$$

where γ is the anomalous diffusion exponent. The process is usually referred to as subdiffusive when $0<\gamma<1$. Ordinary (or Brownian) diffusion corresponds to $\gamma=1$ with $K_1=D$ (the diffusion coefficient). From a continuous point of view, the diffusion process is described by the diffusion equation $u_t(x,t)=D\,u_{xx}(x,t)$, where $u(x,t)$ represents the probability density of finding a "particle" at x at time t, and where $u_{\eta\zeta\ldots}$ is the partial derivative with respect to the variables η,$\zeta\ldots$. It turns out that the probability density function $u(x,t)$ that describes anomalous (sub)diffusive particles follows the fractional diffusion equation [4, 5, 6, 7]:

$$\frac{\partial}{\partial t}u(x,t) = K_\gamma\, {}_0D_t^{1-\gamma}\frac{\partial^2}{\partial x^2}u(x,t), \quad t \geq 0, \tag{1.2}$$

where ${}_0D_t^{1-\gamma}$ is the fractional derivative defined through the Riemann–Liouville operator (see section 2). Fractional subdiffusion-advection equations, and fractional Fokker–Planck equations, have also been proposed [8, 9, 10, 11], and even subdiffusion-limited reactions have been discussed within this framework [12, 13]. These equations are also referred to as parabolic integrodifferential equations with weakly singular kernels [14].

These current applications of fractional differential equations, and many others that may well be devised in the near future, make it imperative to search for methods of solution. Some exact analytical solutions for a few cases, although important, are already known in terms of special functions such as the Wright function and Fox's H-function [6, 7, 15, 16]. Some of these results have been obtained by means of the Mellin transform [6, 7] and the method of images [16]. The powerful method of separation of variables can also be applied to fractional equations in the same way as for the usual diffusion equations (an example is given in section 4). Another route to solving fractional equations is through the integration of the product of the solution of the corresponding nonfractional equation (the Brownian counterpart obtained by setting $\gamma \to 1$) and a one-sided Lévy stable density [4, 17]. However, as also for the Brownian case, the availability of numerical methods for solving (1.2) would be most desirable, especially for those cases where no analytical solution is available. One possibility was discussed recently by Gorenflo and Mainardi [18], Gorenflo, De Fabritiis, and Mainardi [19], and Gorenflo et al. [20], who presented a scheme for building discrete models of random walks suitable for the Monte Carlo simulation of random variables with a probability density governed by fractional diffusion equations. Another, more standard, approach is to build difference schemes of the type used for solving Volterra-type integrodifferential equations [14]. Along this line, some implicit (*backward* Euler and Crank–Nicholson) methods have been proposed [14, 21, 22, 23, 24, 25].

In this paper we shall use the *forward* Euler difference formula for the time derivative $\partial u/\partial t$ in (1.2) to build an *explicit* method that we will call the fractional forward time centered space (FTCS) method. For Brownian ($\gamma = 1$) diffusion equations, this explicit procedure is the simplest numerical methods workhorse [26, 27]. However, for fractional diffusion equations, this explicit method has been overlooked, perhaps because of the difficulty in finding the conditions under which the procedure is stable. This problem is solved here by means of a new stability analysis procedure close to the usual Fourier–von Neumann method for nonfractional partial differential equations.

The plan of the paper is as follows. In section 2 we give a short introduction to some results and definitions in fractional calculus. The numerical procedure for solving the fractional diffusion equation (1.2) by means of the explicit FTCS method is given in section 3. In this section we also discuss the stability and the truncating errors of the FTCS scheme. In section 4 we compare exact analytical solutions with numerical ones and check the reliability of the analytical stability condition. Some concluding remarks are given in section 5.

2. Basic concepts of fractional calculus. The notion of fractional calculus was anticipated by Leibniz, one of the founders of standard calculus, in a letter written in 1695 [1, 4]. But it was in the next two centuries that this subject fully developed into a field of mathematics with the work of Laplace, Cayley, Riemann, Liouville, and many others.

There are two alternative definitions for the fractional derivative ${}_0D_t^{1-\gamma}$ of a function $f(t)$. On the one hand, there is the Riemann–Liouville operator definition

$$ {}_0D_t^{1-\gamma} f(t) = \frac{1}{\Gamma(\gamma)} \frac{\partial}{\partial t} \int_0^t d\tau \frac{f(\tau)}{(t-\tau)^{1-\gamma}} , \tag{2.1} $$

with $0 < \gamma < 1$. For $\gamma = 1$ one recovers the identity operator and for $\gamma = 0$ the ordinary first-order derivative. On the other hand, the fractional derivative of order $1-\gamma$ of a function $f(t)$ in the Grünwald–Letnikov form is

$$ {}_0D_t^{1-\gamma} f(t) = \lim_{h\to 0} \frac{1}{h^{(1-\gamma)}} \sum_{k=0}^{[t/h]} \omega_k^{(1-\gamma)} f(t-kh), \quad t \geq 0, \tag{2.2} $$

where $[t/h]$ means the integer part of t/h and $\omega_k^{(1-\gamma)} = (-1)^k \binom{1-\gamma}{k}$. The Grünwald–Letnikov definition is simply a generalization of the ordinary discretization formulas for integer order derivatives [1]. The Riemann–Liouville and the Grünwald–Letnikov approaches coincide under relatively weak conditions: if $f(t)$ is continuous and $f'(t)$ is integrable in the interval $[0,t]$, then for every order $0 < 1-\gamma < 1$ both the Riemann–Liouville and the Grünwald–Letnikov derivatives exist and coincide for any time inside the interval $[0,t]$ [1, sect. 2.3.7]. This theorem of fractional calculus ensures the consistency of both definitions for most physical applications, where the functions are expected to be sufficiently smooth.

The Grünwald–Letnikov definition is important for our purposes because it allows us to estimate ${}_0D_t^{1-\gamma} f(t)$ numerically in a simple and efficient way:

$$ {}_0D_t^{1-\gamma} f(t) = \frac{1}{h^{(1-\gamma)}} \sum_{k=0}^{[t/h]} \omega_k^{(1-\gamma)} f(t-kh) + O(h^p) . \tag{2.3} $$

This formula is not unique because there are many different valid choices for $\omega_k^{(\alpha)}$ that lead to approximations of different order p [28]. Let $\omega(z,\alpha)$ be the generating function of the coefficients $\omega_k^{(\alpha)}$, i.e.,

$$ \omega(z,\alpha) = \sum_{k=0}^{\infty} \omega_k^{(\alpha)} z^k. \tag{2.4} $$

If the generating function is

$$ \omega(z,\alpha) = (1-z)^\alpha, \tag{2.5} $$

then we get the backward difference formula of order $p = 1$ (BDF1) [1, 28]. This is also called the backward Euler formula of order 1 or, simply, the Grünwald–Letnikov formula. These coefficients are $\omega_k^{(\alpha)} = (-1)^k \binom{\alpha}{k}$ and can be evaluated recursively:

$$ \omega_0^{(\alpha)} = 1, \qquad \omega_k^{(\alpha)} = \left(1 - \frac{\alpha+1}{k}\right) \omega_{k-1}^{(\alpha)}. \tag{2.6} $$

The generating function for the backward difference formula of order $p = 2$ (BDF2) is [1, 28]

$$ \omega(z,\alpha) = \left(\frac{3}{2} - 2z + \frac{1}{2}z^2\right)^\alpha . \tag{2.7} $$

These coefficients can be easily calculated using fast Fourier transforms [1]. However, for the fractional FTCS method discussed in this paper, we will show in the next section that nothing is gained by using second-order approximations for the fractional derivative. Additionally, the stability bound is smaller if one uses the BDF2 formula. Finally, it is important to note that the error estimates given in (2.3) are valid only if either $t/h \gg 1$ [1] or $u(x,t)$ is sufficiently smooth at the time origin $t = 0$ [29].

3. Fractional FTCS method. We will use the customary notation $x_j = j\Delta x$, $t_m = m\Delta t$, and $u(x_j, t_m) \equiv u_j^{(m)} \simeq U_j^{(m)}$, where $U_j^{(m)}$ stands for the numerical estimate of the exact value of $u(x,t)$ at the point (x_j, t_m). In the usual FTCS method, the diffusion equation is replaced with a difference recurrence system for the quantities $u_j^{(m)}$:

$$\frac{u_j^{(m+1)} - u_j^{(m)}}{\Delta t} = D\,\frac{u_{j-1}^{(m)} - 2u_j^{(m)} + u_{j+1}^{(m)}}{(\Delta x)^2} + T(x,t), \tag{3.1}$$

with $T(x,t)$ being the truncation term [26]. In the same way, the fractional equation is replaced with

$$\frac{u_j^{(m+1)} - u_j^{(m)}}{\Delta t} = K_\gamma\ {}_0D_t^{1-\gamma}\frac{u_{j-1}^{(m)} - 2u_j^{(m)} + u_{j+1}^{(m)}}{(\Delta x)^2} + T(x,t). \tag{3.2}$$

The estimate of the truncation term will be given in section 3.2. Inserting the Grünwald–Letnikov definition of the fractional derivative given in (2.3) into (3.2), neglecting the truncation term, and rearranging the terms, we finally get the explicit FTCS difference scheme

$$U_j^{(m+1)} = U_j^{(m)} + S_\gamma \sum_{k=0}^{m} \omega_k^{(1-\gamma)} \left[U_{j-1}^{(m-k)} - 2U_j^{(m-k)} + U_{j+1}^{(m-k)}\right], \tag{3.3}$$

where $S_\gamma = K_\gamma \Delta t/[h^{1-\gamma}(\Delta x)^2]$. In this scheme, $U_j^{(m+1)}$, for every position j, is given *explicitly* in terms of all the previous states $U_j^{(n)}$, $n = 0, 1, \ldots, m$. Because the estimates $U_j^{(m)}$ of $u(x_j, t_m)$ are made at the times $m\Delta t$, $m = 1, 2, \ldots$, and because the evaluation of ${}_0D_t^{1-\gamma}u(x_j,t)$ by means of (2.3) requires knowing $u(x_j,t)$ at the times nh, $n = 0, 1, 2, \ldots$, it is natural to choose $h = \Delta t$. In this case,

$$S_\gamma = K_\gamma \frac{\Delta t^\gamma}{(\Delta x)^2}. \tag{3.4}$$

We assume that the system is prepared in an initial state $u_j^{(0)} = U_j^{(0)}$ with $u_j^{(n)} = 0$ if $n \le -1$. The iteration process described by (3.3) is easily implementable as a computer algorithm, but the resulting program is far more memory hungry than the elementary Markov diffusive analogue because, in evaluating $U_j^{(m+1)}$, one has to save all the previous estimates $U_{j-1}^{(n)}$, $U_j^{(n)}$, and $U_{j+1}^{(n)}$ for $n = 0, 1, \ldots, m$. However, the use of the short-memory principle [1] or the nested mesh procedure [30] could alleviate this burden. Regardless, before tackling (3.3) seriously we must first discuss two fundamental questions concerning any integration algorithm: its stability and the magnitude of the errors committed by the replacement of the continuous equation with the discrete algorithm.

3.1. Stability of the fractional FTCS method. Here we will show that the stability of the fractional numerical schemes can be analyzed very easily and efficiently with a method close to the well-known Von Neumann (or Fourier) method of nonfractional partial differential equations. In this section, we will apply it to the fractional FTCS difference scheme (3.3).

We start by assuming a solution (a subdiffusion mode or eigenfunction) with the form $u_j^{(m)} = \zeta_m e^{iqj\Delta x}$, where q is a real spatial wave number. Inserting this expression into (3.3) one gets

$$\zeta_{m+1} = \zeta_m - 4S \sin^2\left(\frac{q\Delta x}{2}\right) \sum_{k=0}^{m} \omega_k^{(1-\gamma)} \zeta_{m-k}. \tag{3.5}$$

It is interesting to note that this equation is the discretized version of

$$\frac{d\psi(t)}{dt} = -4C \sin^2\left(\frac{q\Delta x}{2}\right) \, {}_0D_t^{1-\gamma}\psi(t) \tag{3.6}$$

(with $C = S(\Delta t)^\gamma$) whose solution can be expressed in terms of the Mittag–Leffler function $E_\gamma(-\lambda t^\gamma)$ [2, 4]. This result is not unexpected because the subdiffusion modes of (1.2) decay as Mittag–Leffler functions [4] (e.g., see (4.4)).

The stability of the solution is determined by the behavior of ζ_m. Unfortunately, solving (3.5) is much more difficult than solving the corresponding equation for the diffusive case. However, let us write

$$\zeta_{m+1} = \xi \zeta_m, \tag{3.7}$$

and let us *assume* for the moment that $\xi \equiv \xi(q)$ is independent of time. Then (3.5) implies a closed equation for the amplification factor ξ of the subdiffusion mode:

$$\xi = 1 - 4S_\gamma \sin^2\left(\frac{q\Delta x}{2}\right) \sum_{k=0}^{m} \omega_k^{(1-\gamma)} \xi^{-k} \, . \tag{3.8}$$

If $|\xi| > 1$ for some q, the temporal factor of the solution grows to infinity according to (3.7) and the mode is unstable. Considering the extreme value $\xi = -1$, we obtain from (3.8) the following stability bound on S_γ:

$$S_\gamma \sin^2\left(\frac{q\Delta x}{2}\right) \le \frac{1/2}{\sum_{k=0}^{m} (-1)^k \omega_k^{(1-\gamma)}} \equiv S_{\gamma,m}^{\times} \, . \tag{3.9}$$

The bound expressed in (3.9) depends on the number of iterations m. Nevertheless, this dependence is weak: $S_{\gamma,m}^{\times}$ approaches $S_\gamma^{\times} \equiv \lim_{m\to\infty} S_{\gamma,m}^{\times}$ in the form of oscillations with small decaying amplitudes (see Figure 3.1). The value of $S_\gamma^{\times}$ can be deduced from (3.9) by taking into account that $\sum_{k=0}^{\infty} (-1)^k \omega_k^{(1-\gamma)} \equiv \omega(-1, 1-\gamma)$ (see (2.4)). Therefore, we find that the FTCS method is stable as long as

$$S_\gamma \sin^2\left(\frac{q\Delta x}{2}\right) \le S_\gamma^{\times} \tag{3.10}$$

with

$$S_\gamma^{\times} = \frac{1}{2\omega(-1, 1-\gamma)} \, . \tag{3.11}$$

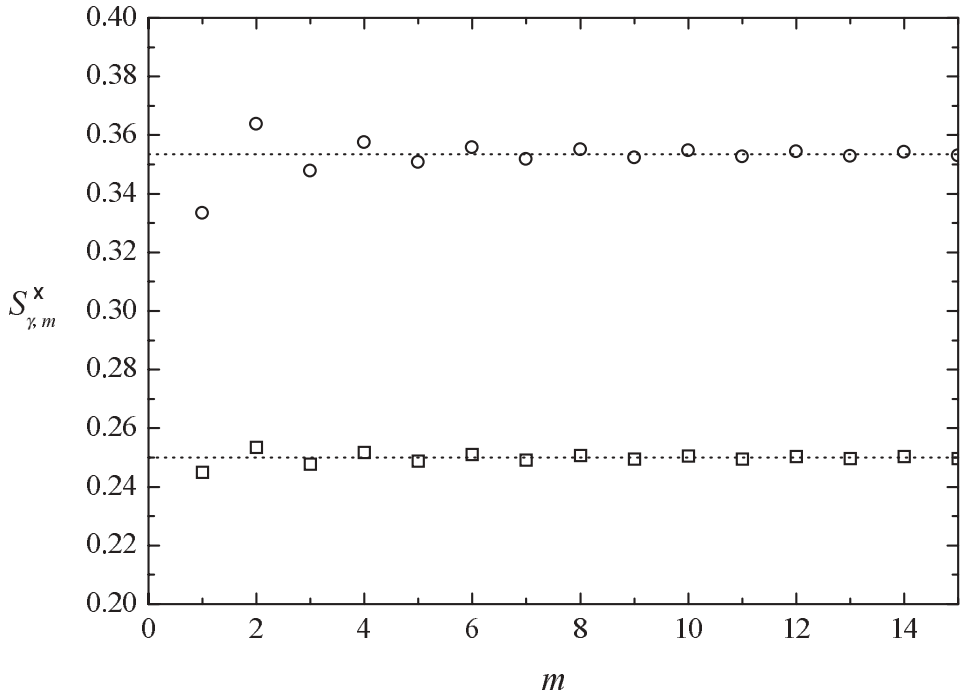

FIG. 3.1. *First values of $S_{\gamma,m}$ versus m for $\gamma = 1/2$ when the first-order coefficients (circles) and second-order coefficients (squares) are used. The lines mark the corresponding limit values $S^{\times}_{\gamma}$ given by* (3.12) *and* (3.13).

In particular, when the BDF1 coefficients given by (2.5) are used, one gets

$$S^{\times}_{\gamma} = \frac{1}{2(1-\xi)^{1-\gamma}\big|_{\xi\to -1}} = \frac{1}{2^{2-\gamma}}\ . \tag{3.12}$$

Similarly, when the BDF2 coefficients given by (2.7) are used, one gets

$$S^{\times}_{\gamma} = \frac{1}{2\left(\frac{3}{2} - 2\xi + \frac{1}{2}\xi^2\right)^{1-\gamma}\Big|_{\xi\to -1}} = \frac{1}{4^{3/2-\gamma}}. \tag{3.13}$$

We will verify numerically in section 4 that the explicit integration method as given by (3.3) is stable when

$$S_{\gamma} \le \frac{S^{\times}_{\gamma}}{\sin^2\left(\frac{q\Delta x}{2}\right)} \tag{3.14}$$

and unstable otherwise. As the maximum value of the square of the sine function is bounded by 1, we can give a more conservative but simpler bound: the fractional FTCS method will be stable when

$$S_{\gamma} = K_{\gamma}\frac{\Delta t^{\gamma}}{(\Delta x)^2} \le S^{\times}_{\gamma}. \tag{3.15}$$

The physical interpretation of this restriction is the same as for the diffusive case, namely, (3.15) means that the maximum allowed time step Δt is, up to a numerical factor, the (sub)diffusion time across a distance of length Δx (cf. (1.1)).

Notice that the value of $S_\gamma^\times = 1/4^{3/2-\gamma}$ given by (3.13) is smaller than $1/2^{2-\gamma}$ for any $\gamma < 1$ (if $\gamma = 1$, we recover the bound $S^\times = 1/2$ of the usual explicit FTCS method for the ordinary diffusion equation [26, 27]). Consequently, the fractional FTCS method that uses a second-order approximation in the fractional derivative is "less robust" than the fractional FTCS method that uses the first-order coefficients $\omega_k^{(1-\gamma)}$. Taking into account that the two methods (BDF1 and BDF2) have the same precision (see section 3.2) we note that nothing is gained by using the fractional derivative with higher precision. Therefore, in practical applications, here we will use only the first-order coefficients (2.6).

3.2. Truncating error of the fractional FTCS method. The truncating error $T(x,t)$ of the fractional FTCS difference scheme is (see (3.2))

$$T(x,t) = \frac{u_j^{(m+1)} - u_j^{(m)}}{\Delta t} - K_\gamma \, D_t^{1-\gamma} \left[\frac{u_{j-1}^{(m)} - 2u_j^{(m)} + u_{j+1}^{(m)}}{(\Delta x)^2} \right] . \tag{3.16}$$

But

$$\frac{u_j^{(m+1)} - u_j^{(m)}}{\Delta t} = u_t + \frac{1}{2} u_{tt} \Delta t + O(\Delta t)^2 \tag{3.17}$$

and

$$ {}_0D_t^{1-\gamma} \left[u_{j-1}^{(m)} - 2u_j^{(m)} + u_{j+1}^{(m)} \right] = \frac{1}{h^{1-\gamma}} \sum_{k=0}^{m} w_k^{1-\gamma} \left[u_{xx} + \frac{1}{12} u_{xxxx} \, (\Delta x)^2 + \cdots \right] + O\left(h^p\right) \tag{3.18}$$

so that, taking into account that $u(x,t)$ is the exact solution of (1.2), we finally get from (3.16), (3.17), and (3.18) the following result:

$$T(x,t) = O(h^p) + \frac{1}{2} u_{tt} \Delta t - \frac{K_\gamma (\Delta x)^2}{12} \, {}_0D_t^{1-\gamma} u_{xxxx} + \cdots \tag{3.19}$$

$$= O(h^p) + O(\Delta t) + O(\Delta x)^2 \, . \tag{3.20}$$

Therefore, (i) assuming that the initial boundary data for u are consistent (as assumed for the usual FTCS method [26]) and (ii) assuming that u is sufficiently smooth at the origin $t = 0$ (see the remark below (2.7)), we conclude that the method discussed in this paper is unconditionally consistent for any order p because $T(x,t) \to 0$ as h, Δt, $\Delta x \to 0$. As remarked above, in practical calculations it is convenient to use $h = \Delta t$ so that, due to the term $O(\Delta t)$ in (3.20), no improvements are achieved by considering higher orders than $p = 1$ in the fractional derivative. It is interesting to note that for the diffusion equation ($\gamma = 1$) it is possible to cancel out the last two terms in (3.19) with the choice $\Delta t = (\Delta x)^2/(6K_\gamma)$, thereby obtaining a scheme that is "second-order accurate" [26]. This is not possible for the fractional case because of the fractional operator.

4. Numerical solutions and the stability bound on S_γ. The objective of this section is twofold: first, we want to test the reliability of the numerical algorithm defined in (3.3) by applying it to two fractional problems with known exact solutions and, second, we want to check the stability bounds obtained in section 3.1.

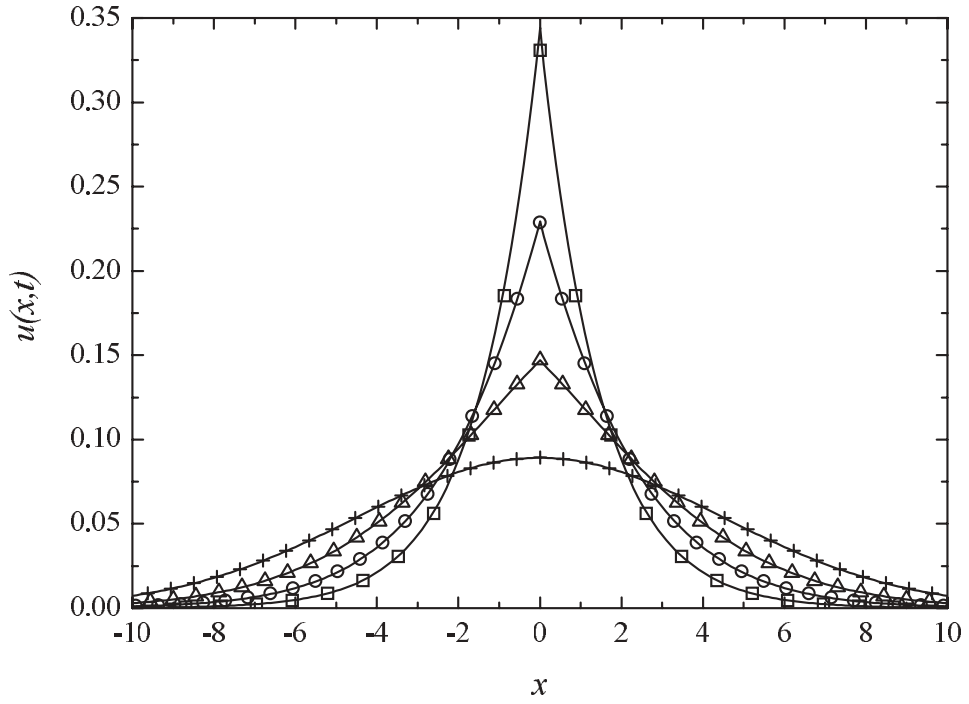

FIG. 4.1. *Numerical solution of the subdiffusion equation for the problem defined in the unbounded space,* $-\infty < x < \infty$ *with initial condition* $u(x, t = 0) = \delta(x)$ *for* $\gamma = 1/4$ *(squares),* $\gamma = 1/2$ *(circles),* $\gamma = 3/4$ *(triangles), and* $\gamma = 1$ *(crosses), and* $t = 10$. *The lines correspond to the exact analytical solution.*

4.1. Numerical solution versus exact solution: Two examples. The fundamental solution of the subdiffusion equation in (1.2) corresponds to the problem defined in the unbounded space, $-\infty < x < \infty$, where the initial condition is $u(x, t = 0) = \delta(x)$. This solution is called the propagator, or Green's function, and can be expressed in terms of Fox's H-function [4]:

$$u(x,t) = \frac{1}{\sqrt{4\pi K_\gamma t^\gamma}}\, H_{11}^{10}\left[\frac{|x|}{\sqrt{K_\gamma t^\gamma}}\,\middle|\,\begin{matrix}(1-\gamma/2,\gamma/2)\\(0,1)\end{matrix}\right]. \tag{4.1}$$

In our numerical solution we used the boundary conditions $u(-L, t) = u(L, t) = 0$ with a sufficiently large L in order to avoid finite size effects. In Figure 4.1 we compare the numerical integration results with the exact solution (4.1) for $\gamma = 1/4$, $1/2$, $3/4$, 1 at $t = 10$. The time step used was $\Delta t = 0.01$ and $\Delta x = \sqrt{K_\gamma (\Delta t)^\gamma / S_\gamma}$ with $K_\gamma = 1$ and $S_\gamma = 0.28$, 0.33, 0.4, and 0.5. All these values of S_γ are just below the stability bound $S_\gamma^\times$ (see (3.12)). The agreement is excellent except for $\gamma = 1/4$ and $x = 0$, but this minor discrepancy is surely due to the large spatial cell $\Delta x \simeq 1.06$ used in this case.

We have also considered a problem with absorbing boundaries, $u(0, t) = u(1, t) = 0$, and initial condition $u(x, t = 0) = x(1 - x)$, with $0 \le x \le 1$. The exact analytical solution of (1.2) is easily found by the method of separation of variables: $u(x, t) =$

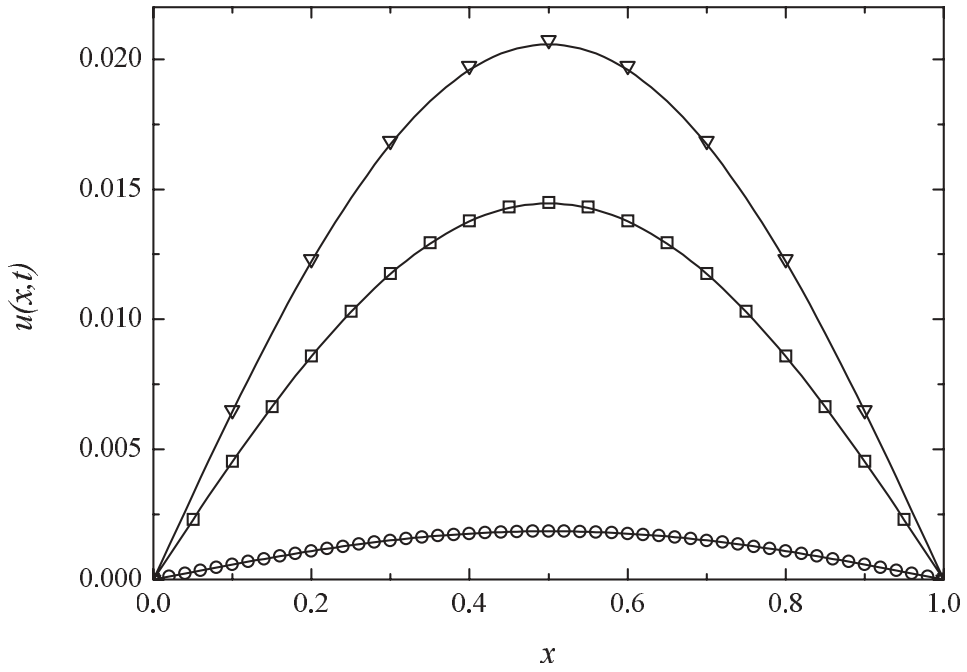

FIG. 4.2. *Numerical solution of the subdiffusion equation for the problem with absorbing boundary conditions* $u(0,t) = u(1,t) = 0$ *and initial condition* $u(x,0) = x(1-x)$, $0 \le x \le 1$, *for* $t = 0.5$. *The solution* $u(x,t)$ *is shown for* $\gamma = 0.5$ *(triangles),* $\gamma = 0.75$ *(squares), and* $\gamma = 1$ *(circles). The lines correspond to the exact analytical solution.*

$X(x)T(t)$. We thus find $X_n(x) = \sin(n\pi x)$ and

$$\frac{dT}{dt} = -K_\gamma \lambda_n^2 \, {}_0D_t^{1-\gamma} T \, , \tag{4.2}$$

where $\lambda_n = n\pi$, $n = 1, 2, \ldots$. The solution of (4.2) is found in terms of the Mittag–Leffler function [4]:

$$T_n(t) = E_\gamma(-K_\gamma n^2 \pi^2 t^\gamma) \, . \tag{4.3}$$

Imposing the initial condition we obtain

$$u(x,t) = \frac{8}{\pi^3} \sum_{n=0}^{\infty} \frac{1}{(2n+1)^3} \sin[(2n+1)\pi x] E_\gamma[-K(2n+1)^2 \pi^2 t^\gamma] \, . \tag{4.4}$$

In Figure 4.2 we compare this exact solution with the results of the numerical integration scheme for $\gamma = 0.5$, $\gamma = 0.75$, and $\gamma = 1$ for $t = 0.5$ and $K_\gamma = 1$. The values of S_γ used were $S_\gamma = 0.33$, 0.4, and 0.5 with $\Delta x = 1/10$, $1/20$, and $1/50$, respectively. The values of Δt for fixed S_γ and Δx stem from the definition of S_γ:

$$\Delta t = \left[\frac{S_\gamma (\Delta x)^2}{K_\gamma} \right]^{1/\gamma} \, . \tag{4.5}$$

Excellent agreement is observed for the three values of γ, it being slightly poorer for the smallest value, which is not surprising because in this case the mesh size $\Delta x = 1/10$ used is the largest.

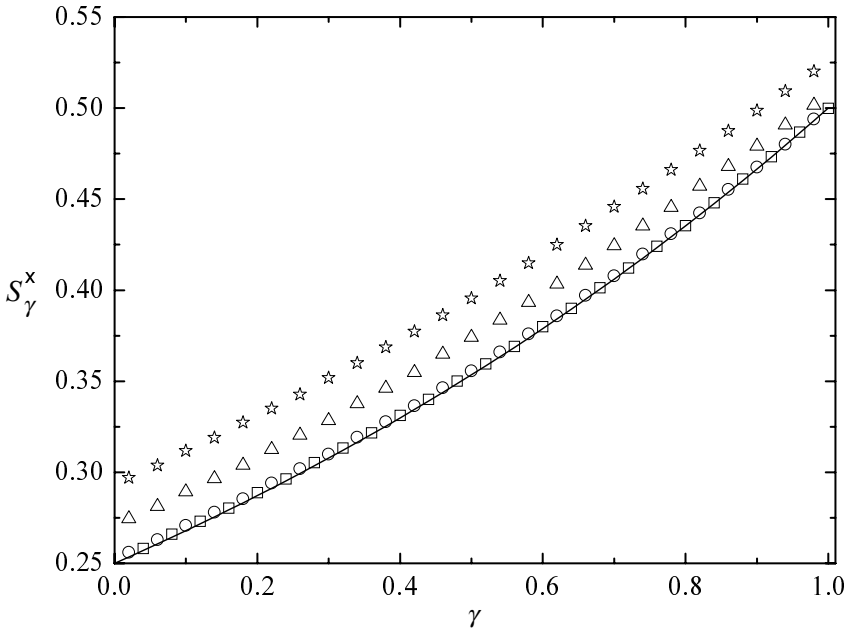

FIG. 4.3. *Values of $S_\gamma^\times$ corresponding to the onset of instability versus the subdiffusion exponent γ. The solid line is the prediction of the Fourier–von Neumann analysis and the symbols denote the results of the numerical tests with the criterion in* (4.6)*: stars, triangles, and squares for the absorbing boundary problem with $u(x,0) = x(1-x)$ with $M = 50$, 100 and 1000, respectively, and circles for the propagator with $M = 1000$.*

4.2. Numerical check of the stability analysis. We checked the stability bound on the value of the S_γ given in (3.12) in the following way. For a set of values of γ in the interval $[0,1]$, and for values of S_γ starting at $S_\gamma = 0.98 S_\gamma^\times$ (in particular, for $S_\gamma = 0.98/2^{2-\gamma} + 0.001\,n$, $n = 0, 1, 2, \dots$) we applied the fractional FTCS integration until step M. We say that the resulting integration for given values of γ and S_γ is unstable when the following condition is satisfied at any position j:

$$\left| \frac{u_j^{m-1}}{u_j^m} - \Xi \right| > \Xi \quad \text{for any} \quad m = M - \Delta M, M - \Delta M + 1, \dots, M, \tag{4.6}$$

where $\Xi = 5$ and $\Delta M = 10$. This means that the numerical solution is considered unstable if the quotient u_j^{m-1}/u_j^m becomes negative or larger than 2Ξ at any of the last ΔM steps. (Of course, this criterion is arbitrary; however, the results do not change substantially for any other reasonable choice of Ξ and ΔM.) Let $S_\gamma^{\min}$ be the smallest value of $S_\gamma = 0.98/2^{2-\gamma} + 0.001\,n$ that verifies the criterion (4.6). For the absorbing boundary problem we calculate these values using $\Delta x = 1/2N$ with $N = 5$, $M = 50$, $M = 100$, and $M = 1000$. For the propagator, we calculate $S_\gamma^{\min}$ using $M = 1000$ and $\Delta t = 5 \times 10^{-4}$ in a lattice with absorbing frontiers placed at $x = -N\Delta x$ and $x = N\Delta x$ with $N = 50$. It is well known that for a lattice with $2N + 1$ points (including the absorbing boundaries) the maximum value of $\sin(q\Delta x/2)$ in (3.10) occurs for $q\Delta x = (2N-1)\pi/(2N)$, so that in Figure 4.3 we plot $S_\gamma^{\min} \sin^2[(2N-1)\pi/(4N)]$. We observe that for large M the stability bound predicted by (3.12) agrees with the result of the numerical test. The larger values obtained for smaller M mean that the method must

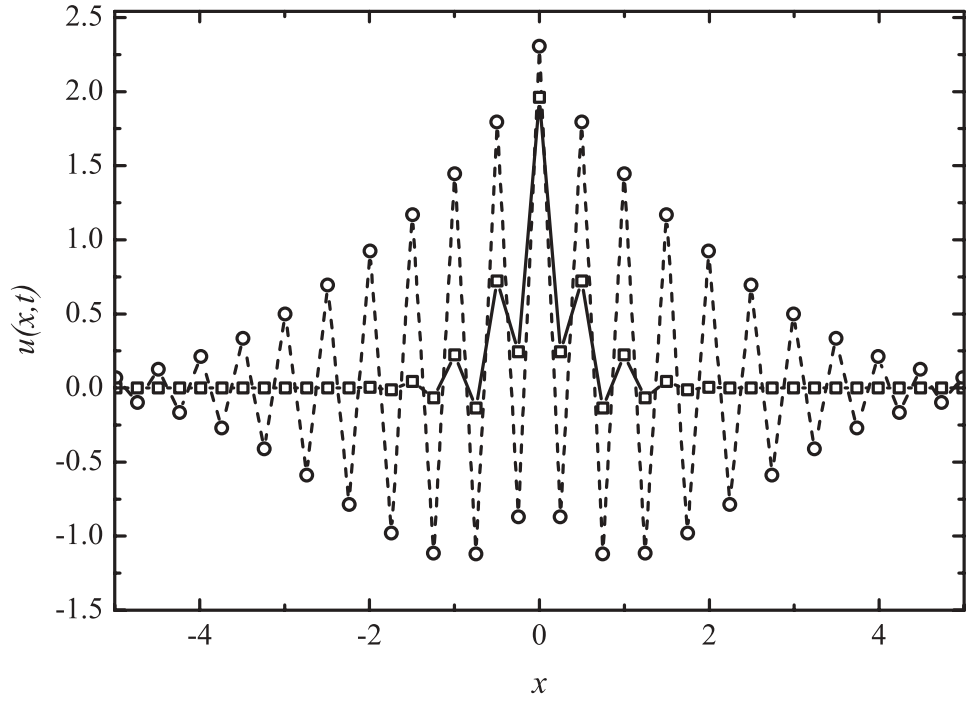

FIG. 4.4. *Unstable numerical solution of the subdiffusion equation for the problem defined in the unbounded space with initial condition* $u(x, t = 0) = \delta(x)$ *for* $\gamma = 1/2$, $K_\gamma = 1$, $S = 0.36$ *and* $t = 0.005$ *(squares), and* $t = 0.05$ *(circles). The time step is* $\Delta t = 0.0005$ *and the spatial mesh* Δx *is obtained according to* (4.5). *The lines are plotted as a visual guide.*

be "very unstable" to fulfill our instability criterion in so few steps. The success of the numerical test is truly remarkable and supports the application of our Fourier–von Neumann-type stability analysis to the fractional FTCS scheme made in section 3.1.

In Figure 4.4 we plot the numerical solution when $S_\gamma = 0.36 > S_\gamma^\times$ in the case of the propagator with $\gamma = 1/2$. This kind of awkward oscillatory behavior in the unstable domain is also typical for ordinary partial differential equations.

5. Concluding remarks. The availability of efficient numerical algorithms for the integration of fractional equations is important, as these equations are becoming essential tools for the description of a wide range of systems [3]. In this paper we have discussed a numerical algorithm for the solution of the fractional (sub)diffusion equation (1.2). Although we have dealt with this particular equation, our procedure could be extended to any fractional integrodifferential equation (for example, to fractional diffusion-wave equations) by means of an obvious combination of the Grünwald–Letnikov definition of the fractional derivative [1, 2, 4] with standard discretization algorithms used in the context of ordinary partial differential equations [26]. Furthermore, the method (given its explicit nature) can be trivially extended to d-dimensional problems, which is not such an easy task when implicit methods are considered.

In our numerical method the state of the system at a given time $t = m\Delta t$ is given explicitly in terms of the previous states at $t = (m-1)\Delta t, \ldots, \Delta t, 0$ by means of the FTCS scheme (3.3). We verified that for some standard initial conditions with exact analytical solution, namely, (a) the propagator in an unlimited

system with $u(x, t = 0) = \delta(x)$, and (b) a system with absorbing boundaries and $u(x, t = 0) = x(1 - x)$, the present algorithm leads to numerical solutions which are in excellent agreement with the exact solutions. Using a Fourier–von Neumann technique we have provided the conditions for which the fractional FTCS method is stable (cf. (3.10) and (3.11)). For $\gamma = 1$ the well-known bound $S = D\Delta t/(\Delta x)^2 \leq 1/2$ of the ordinary explicit method for the diffusion equation is recovered.

Concerning the implementation of the method, we must remark that the evaluation of the state of the system at a given time step $m\Delta t$ requires information about all previous states at $t = (m-1)\Delta t, (m-2)\Delta t, \ldots, \Delta t, 0$ and not merely the immediately preceding state as in ordinary diffusion. This is a consequence of the non-Markovian nature of subdiffusion and implies the need for massive computer memory in order to store the evolution of the system, which is especially cumbersome in computations of long-time asymptotic behaviors. This could be palliated by using the "short-memory" principle [1] or the nested mesh procedure [30]. Another feature of the explicit numerical scheme is the interdependence of the temporal and spatial discrete steps for a fixed S_γ. If, as usual, one intends to integrate an equation with a given mesh Δx, then the corresponding step size Δt for a given $S_\gamma < S_\gamma^\times$ is of the order $(\Delta x)^{2/\gamma}$. As a consequence, Δt could become extremely small even for no too small values of Δx, especially when the problem is far from the diffusion limit, i.e., for small values of γ, so that the number of steps needed to reach even moderate times would become prohibitively large. In this case, resorting to other methods (e.g., implicit methods [14, 21, 22, 23, 24, 25]) that are stable for larger values of Δt is compulsory.

A POSTERIORI ERROR ANALYSIS FOR THE MEAN CURVATURE FLOW OF GRAPHS*

OMAR LAKKIS† AND RICARDO H. NOCHETTO‡

Abstract. We study the equation describing the motion of a nonparametric surface according to its mean curvature flow. This is a nonlinear nonuniformly parabolic PDE that can be discretized in space via a finite element method. We conduct an a posteriori error analysis of the spatial discretization and derive upper bounds on the error in terms of computable estimators based on local residual indicators. The reliability of the estimators is illustrated with two numerical simulations, one of which treats the case of a singular solution.

Key words. finite element, mean curvature, error analysis, a posteriori, nonlinear PDE, parabolic equation, geometric motion, convergence, reliability, efficiency, sharp estimates, effectivity index

1. Introduction. The objective of this article is the derivation of reliable a posteriori error estimates for the *mean curvature flow (MCF)* of a d-dimensional time-dependent submanifold $\Gamma(t)$ of the Euclidean space $\mathbb{R}^{d+1}$. We pay special attention to the physically relevant cases ($d = 1, 2, 3$), and we refer to $\Gamma(t)$ simply as a *moving surface*. A geometric definition of the MCF, whose details can be found in Huisken [15] and the references therein, is given by

$$\boldsymbol{V}(\boldsymbol{x}, t) = -\boldsymbol{\kappa}(\boldsymbol{x}, t) \quad \text{for } \boldsymbol{x} \in \Gamma(t),\ t \in \mathbb{R}, \tag{1.1}$$

where $\boldsymbol{V}$ and $\boldsymbol{\kappa}$ are respectively the velocity and the vector mean curvature of Γ. More general definitions of MCF are found in the literature [5, 11, 4], but will not be used.

In this paper we are interested in the *graph* (also called *nonparametric*) *description* in which the moving surface is described as the graph of a function u defined on a space-time domain $\Omega \times [0, T] \subset \mathbb{R}^d \times \mathbb{R}$. This description leads to the following PDE, referred to as the *mean curvature flow of graphs (MCFG)*:

$$\frac{\partial_t u(\boldsymbol{x}, t)}{Qu(\boldsymbol{x}, t)} - \frac{1}{d} \operatorname{div} \frac{\nabla u(\boldsymbol{x}, t)}{Qu(\boldsymbol{x}, t)} = 0 \quad \text{for } \boldsymbol{x} \in \Omega,\ t \in [0, T], \tag{1.2}$$

where ∇ denotes the derivative with respect to $\boldsymbol{x}$ and Q the *elementary area* operator defined by

$$Qw := (1 + |\nabla w|^2)^{1/2}. \tag{1.3}$$

We drop the factor $1/d$, through a time rescaling by d, and we study the following initial-boundary value problem associated with (1.2).

PROBLEM 1.1 (Cauchy–Dirichlet problem for the MCFG). *Given functions* $f : \Omega \times (0,T] \to \mathbb{R}$ *and* $g : \partial_{\mathrm{p}}(\Omega \times (0,T)) \to \mathbb{R}$, *find* $u : \overline{\Omega} \times [0,T] \to \mathbb{R}$ *such that*

$$\frac{\partial_t u(\boldsymbol{x},t)}{Qu(\boldsymbol{x},t)} - \operatorname{div} \frac{\nabla u(\boldsymbol{x},t)}{Qu(\boldsymbol{x},t)} = f(\boldsymbol{x},t) \quad \text{for } (\boldsymbol{x},t) \in \Omega \times (0,T], \tag{1.4}$$

$$u(\boldsymbol{x},t) = g(\boldsymbol{x},t) \quad \text{for } (\boldsymbol{x},t) \in \partial_{\mathrm{p}}(\Omega \times (0,T)), \tag{1.5}$$

where $\partial_{\mathrm{p}}(\Omega \times (0,T))$ *is the* parabolic boundary *defined as* $\Omega \times \{0\} \cup \partial\Omega \times [0,T]$.

Arguably the MCF plays the role of model geometric motion, in the same way as the heat equation plays the role of model diffusion equation. For more than two decades the MCF has been the object of mathematical analysis [1, 4, 5, 11, 15, 16] as well as computer simulations [5, 8, 23, 20] and numerical analysis [6, 7, 8, 28]. It has also attracted the interest of practitioners, especially in the fields of materials science and phase transition where the MCF, or some closely related geometric motion, often models the motion of a free boundary [3, 13, 24].

A straightforward way to approximate numerically the solution of Problem 1.1 is first to discretize the spatial variable through a finite element method—which comes naturally, as (1.4) is written in "divergence form"—and secondly to discretize the time variable with a finite difference scheme known as *semi-implicit*, in which the nonlinearity is treated explicitly and the linear part implicitly [8]. The first stage of this process, discussed in sections 2.1–2.5, is referred to as the *spatial (semi-) discretization*. Deckelnick and Dziuk [7] and Dziuk [8] have derived a priori error estimates for both the spatially discrete and the semi-implicit fully discrete scheme.

The study of *a posteriori error estimates* for evolution equations, which has developed in the last 15 years, is mainly motivated by their successful use in deriving adaptive mesh refinement algorithms. The lack of such estimates in the case of the MCFG and the interest in adaptive methods for this problem are the driving motives behind this article. Our main results, discussed in section 3, are a posteriori upper bounds on the error for the spatially discrete approximation. A posteriori error estimates have been established for linear parabolic problems [9, 19] and used to derive adaptive mesh refinement algorithms. Analogous results have also been derived for certain nonlinear elliptic [12, 26] and parabolic [10, 17, 18] equations, but these cannot be applied to the MCFG.

As observed since the early days of adaptive finite element methods (FEM) [2], an adaptive mesh refinement algorithm must satisfy two fundamental properties: *reliability* and *efficiency*. These two algorithmic concepts are closely related to the nature of the error bounds. Indeed, an algorithm is called *reliable* if the error between its output and the exact solution is bounded from above by a given tolerance; in terms of estimators, reliability is achieved if the error/estimator ratio—known as the *effectivity index* in the literature—is bounded from above by a positive constant. On the other hand, an algorithm is called *efficient* if it produces a result with a prescribed error in the least amount of computational time; the efficiency of an algorithm translates, in the language of estimators, into the effectivity index being bounded from below. For an estimator to be both reliable and efficient, it is necessary for it to be *sharp*, meaning that the order of convergence of the error and that of the estimator must be equal, as the meshsize goes to zero. In particular, *sharpness* allows the estimators to be used in stopping criteria for adaptive algorithms. In this paper, besides proving reliable error estimates (upper error bounds), we will also conduct numerical experiments to

understand whether these estimates are also sharp. For this, the numerical examples we shall present in section 7 are mainly designed toward comparing the numerical asymptotic convergence rates of the error and of the estimators.

The MCFG is an example of an evolution equation that is not covered by any of the general techniques developed so far for the derivation of a posteriori error estimates for nonlinear equations [10, 17, 27]. This is mainly due to the nonuniformly parabolic nature of the equation and, more philosophically, to the fact that general nonlinear theories end up being less reliable and harder to apply. In this paper we employ an ad hoc energy technique to derive the estimates. To the best of our knowledge, the energy technique is the only practical way to achieve our aim. A distinctive feature of this paper is the use of special quantities to quantify the error. Like in most nonuniformly parabolic equations, the Sobolev norms are extremely hard to handle in the MCFG context, and we are naturally led to use the *geometric errors*, which are introduced next. These are not Sobolev norms of the error $u - u_h$, where u and u_h are respectively the exact and approximate solutions, but more specialized measures of the error (see section 2.5). The geometric errors are not even symmetric in u and u_h, yet they satisfactorily quantify the error and are easy to use.

DEFINITION 1.2 (geometric error). *Let u be the solution of Problem* 1.1 *and u_h be the finite element solution given by Problem* 2.5. *For each $t \in [0,T]$, define*

$$A(t) := \int_\Omega |\boldsymbol{N}u_h(\boldsymbol{x},t) - \boldsymbol{N}u(\boldsymbol{x},t)|^2 \, Qu(\boldsymbol{x},t)\,\mathrm{d}\boldsymbol{x}, \tag{1.6}$$

$$B(t) := \int_0^t \int_\Omega \left(Vu_h(\boldsymbol{x},s) - Vu(\boldsymbol{x},s)\right)^2 Qu(\boldsymbol{x},s)\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}s, \tag{1.7}$$

where

$$\begin{aligned} &\mathrm{W}^1(\Omega) \ni w \mapsto \boldsymbol{N}w := \frac{(\nabla w; -1)}{Qw} \in \mathrm{L}_\infty(\Omega)^{d+1} \\ \text{and} \quad &\mathrm{W}^1_1(\Omega\times(0,T)) \ni w \mapsto Vw := \frac{\partial_t w}{Qw} \in \mathrm{L}_1^{\mathrm{loc}}(\Omega\times(0,T)) \end{aligned} \tag{1.8}$$

are, respectively, the normal vector *and the* normal velocity *operators. We will denote by $\mathrm{C}^k(\Omega)$ (resp., $\mathrm{W}^k(\Omega)$) the space of k times continuously (resp., weakly) differentiable functions, by $\mathrm{W}^k_p(\Omega)$ the usual Sobolev space of functions in $\mathrm{W}^k(\Omega)$ with derivatives in $\mathrm{L}_p(\Omega)$, and by $\overset{\circ}{\mathrm{W}}{}^k_p(\Omega)$ the subspace of functions with vanishing trace. The functions of time A and B are the building blocks of the* total geometric error E *defined by*

$$E(t)^2 := B(t) + \sup_{[0,t]} A(s) = \int_0^t \int_\Omega (Vu_h - Vu)^2\, Qu + \sup_{(0,t)} \int_\Omega |\boldsymbol{N}u_h - \boldsymbol{N}u|^2\, Qu. \tag{1.9}$$

We refer to $\sup_{[0,t]} A^{1/2}$ *and* $B^{1/2}$ *as the* geometric energy error *and* normal velocity error*, respectively.*

The integrals of the form $\int_\Omega \cdot\, Qu(\boldsymbol{x},t)\,\mathrm{d}\boldsymbol{x}$ in (1.9) can be interpreted as integrals over the moving surface $\Gamma(t)$, which give us the $\mathrm{L}_2(\Gamma)$ norm of the *difference of normals* and the *difference of normal velocities*. A comparison with the integrals appearing on the left-hand side of (2.6) explains in part why they "fit" the problem.

We point out that, despite the natural relation between our notion of error and the MCFG, no related concept of error has yet been used in the context of a posteriori error control for parabolic equations. In fact, the geometric nature contrasts sharply with the pure analytic setting found, for instance, in Verfürth's monograph [26]. A related, symmetric, geometric error is employed by Fierro and Veeser for the stationary case [12].

It is important to observe that the sharpest estimate in this article, given by Theorem 3.6, is a *conditional estimate*. By conditional we mean that the estimate is valid only if a certain condition on how close the approximate solution is to the exact solution is satisfied. A relevant feature of our result in this respect is that the condition can be machine-checked since it entails computable quantities. This is of paramount importance for a result to be fully "a posteriori" (see Remark 3.7). In this sense, to the best of our knowledge, our result is the first conditional a posteriori estimate for nonlinear parabolic equations. Conditional results have also been derived for the prescribed mean curvature (elliptic) equation by Fierro and Veeser [12]. We notice that Verfürth has also established conditional results, but the conditions are not fully a posteriori and cannot be machine-checked [26]. In order to appreciate the sharpness of the conditional result of Theorem 3.6, an *unconditional estimate* is given in Theorem 3.4 for the sake of comparison. Our numerical results provide a practical comparison between the two theoretical bounds and show that the conditional estimate is sharp while the unconditional estimate is not.

Dziuk has shown an a priori error bound of rate $\mathrm{O}(h)$ on the geometric error in the spatially discrete case [8]. The geometric error introduced in Definition 1.2 is similar to the one used by Dziuk, but in his case the integrals are evaluated on the discrete surface, while we compute them on the exact surface. In this respect our a posteriori viewpoint can be seen, roughly speaking, as dual to the a priori approach. We notice, however, that our results are valid under weaker regularity assumptions on the exact solution u (see Example 7.5). Our analysis also includes *time-dependent boundary value* g and nonhomogeneous right-hand side f, while Dziuk's analysis is limited to the homogeneous and time-independent boundary value case.

The rest of this paper is organized as follows. In section 2 we discuss some properties of Problem 1.1 and introduce the associated spatial finite element method. In section 3 we state the main results and make some observations. Next, in sections 4–6 we prove these results. Finally, numerical tests are discussed in section 7.

2. The Cauchy–Dirichlet problem and its spatial discretization.

ASSUMPTION 2.1 (solvability and regularity). *Unless otherwise stated, the following conditions will be assumed to hold:*

(a) Classical solvability: *Problem* 1.1 *admits a unique classical solution* u *in* $\mathrm{C}^{2,1}(\Omega \times (0,T]) \cap \mathrm{C}^0(\overline{\Omega} \times [0,T])$ *for some* $T > 0$.

(b) Boundary regularity of contact angle:[1]

$$\frac{\nabla u(t)}{Qu(t)} \in \mathrm{W}^1_d(\Omega) \qquad \forall t \in [0,T]. \tag{2.1}$$

(c) Regularity of normal velocity:

$$Vu(t) = \frac{\partial_t u(t)}{Qu(t)} \in \mathrm{L}_d(\Omega) \qquad \forall t \in [0,T]. \tag{2.2}$$

[1] We use the following convention throughout this article: whenever a space-time function $w : \Omega \times [0,T] \to \mathbb{R}^N$ $(N = 1, d)$ is written with only one argument, it means that the argument is a time variable and that its value—e.g., $w(t)$ or $w(1/2)$—is a function with domain Ω.

(d) Regularity of vertical velocity:

$$\partial_t u(t) \in \mathrm{W}_1^1(\Omega) \cap \mathrm{L}_2(\Omega) \qquad \forall t \in [0,T]. \tag{2.3}$$

Remark 2.2 (about the regularity assumptions). Assumption 2.1(a) is backed up by the fact that Problem 1.1 admits classical solutions under certain sufficient conditions relating the mean-convexity of $\partial\Omega$ and the function $|f|$ [16, section 12.8]. Solutions, which are classical up to blow-up, can also exist in more general situations where the domain is non–mean-convex or compatibility conditions are violated [25]. There are two implicit assumptions that are immediate consequences of Assumption 2.1(a): we necessarily have $f \in \mathrm{C}^0(\Omega \times (0,T])$ and $g \in \mathrm{C}^0(\partial_{\mathrm{p}}(\Omega \times (0,T]))$. Although a "weak form" of Problem 1.1 will be derived in section 2.3, we do not know of any satisfactory concept of a "weak solution" for it.

The reason that we assume (2.3) is technical: this assumption will be needed to test (1.4) by $\partial_t u$ (see sections 2.3, 2.4, and 4.3). Notice that for $d \le 2$, in view of the Sobolev embedding, this assumption can be simplified to $\partial_t u \in \mathrm{W}_1^1(\Omega)$ and implies (2.2). Notice also that, for $d \ge 1$, the Sobolev embedding and (2.3) imply that $\partial_t u \in \mathrm{L}_{d'}(\Omega)$ for $d' = d/(d-1)$.

Proposition 2.3 (weak form). *Let $u \in \mathrm{C}^{2,1}(\Omega \times (0,T]) \cap \mathrm{C}^0(\overline{\Omega} \times [0,T])$ be a given function that satisfies* (2.1) *and* (2.2). *The function u is a classical solution of Problem* 1.1 *if and only if*

$$\left\langle \frac{\partial_t u(t)}{Qu(t)}, \phi \right\rangle + \left\langle \frac{\nabla u(t)}{Qu(t)}, \nabla\phi \right\rangle = \langle f(t), \phi\rangle \qquad \forall \phi \in \mathring{\mathrm{W}}_1^1(\Omega),\ t \in (0,T], \tag{2.4}$$

$$u(t) - \tilde{g}(t) \in \mathring{\mathrm{W}}_1^1(\Omega) \quad \forall t \in (0,T], \quad \textit{and} \quad u(0) = g(0), \tag{2.5}$$

where $\tilde{g}(t)$ is an extension of $g(t)$ to all of Ω.

We use the notation $\langle v, w\rangle_D := \int_D v(\boldsymbol{x}) w(\boldsymbol{x})\, \mathrm{d}\mu(\boldsymbol{x})$ for functions v and w such that $vw \in \mathrm{L}_1(D,\mu)$, $D \subset \mathbb{R}^d$, and $\mathrm{d}\mu$ is the Lebesgue measure "$\mathrm{d}\cdot$" or the $(d-1)$-dimensional Hausdorff measure, depending on the Hausdorff dimension of D. If $D = \Omega$, we omit the subscript in the brackets.

The proof of Proposition 2.3 follows basic PDE techniques and is omitted. We observe that the existence of $\tilde{g}$, for $g(t) \in \mathrm{L}_1(\partial\Omega)$, is guaranteed in view of [22, eq. (5.5)].

Lemma 2.4 (stability estimate). *If we have $f \in \mathrm{L}_2(0,T;\mathrm{L}_\infty(\Omega))$ and $g \in \mathrm{W}_1^1(\partial_{\mathrm{p}}(\Omega \times (0,T)))$, then*

$$\begin{aligned} &\frac{1}{2}\int_0^t \int_\Omega |Vu|^2\, Qu + \int_\Omega Qu(t) \\ &\qquad \le \exp\left(\frac{1}{2}\int_0^t \|f\|^2_{\mathrm{L}_\infty(\Omega)}\right)\left(\|Qg(0)\|_{\mathrm{L}_1(\Omega)} + \|\partial_t g\|_{\mathrm{L}_1(\partial\Omega\times(0,t))}\right). \end{aligned} \tag{2.6}$$

Proof. Test (1.4) by $\partial_t u \in \mathrm{L}_{d'}(\Omega)$ and, owing to (2.1) and (2.3), apply the integration by parts formula on Ω:

$$0 = \int_\Omega |Vu|^2\, Qu + \int_\Omega \frac{\nabla u}{Qu} \cdot \nabla \partial_t u - \int_{\partial\Omega} \frac{\nabla u \cdot \boldsymbol{\nu}}{Qu} \partial_t u - \int_\Omega f \partial_t u. \tag{2.7}$$

The first term, which is equal to $\int_\Omega Vu\, \partial_t u$, is well defined thanks to (2.3) and (2.2). The third and fourth terms are bounded as follows:

$$\int_{\partial\Omega} \frac{\nabla u \cdot \boldsymbol{\nu}}{Qu} \partial_t u = \int_{\partial\Omega} \left(\frac{\nabla u}{Qu} \cdot \boldsymbol{\nu}\right) \partial_t g \le \|\partial_t g\|_{\mathrm{L}_1(\partial\Omega)}, \tag{2.8}$$

$$\int_\Omega f\partial_t u = \int_\Omega f\sqrt{Qu}\frac{\partial_t u}{\sqrt{Qu}} \le \frac{1}{2}\int_\Omega |Vu|^2\, Qu + \frac{1}{2}\|f\|^2_{\mathrm{L}_\infty(\Omega)}\int_\Omega Qu. \tag{2.9}$$

Next we observe that the basic identity

$$\partial_t Qu(\boldsymbol{x},t) = \partial_t\sqrt{1+|\nabla u|^2} = \frac{\nabla u\cdot\partial_t\nabla u}{Qu} \tag{2.10}$$

implies

$$\frac{1}{2}\int_\Omega |Vu|^2\, Qu + \mathrm{d}_t\int_\Omega Qu \le \|\partial_t g\|_{\mathrm{L}_1(\partial\Omega)} + \frac{1}{2}\|f\|^2_{\mathrm{L}_\infty(\Omega)}\int_\Omega Qu. \tag{2.11}$$

The result is obtained by integrating on $[0,t]$ and applying the Gronwall lemma. ∎

Inequality (2.6) acquires a geometric meaning upon observing that $\int_\Omega Qu$ is the area of graph(u). This gives us a control on the growth of the area in time in terms of the data. In particular, if the forcing term $f=0$ and the boundary conditions are time-independent, then (2.6) quantifies the decrease in area of the graph that tends toward a nonparametric minimal surface as time grows. The MCF, with $f=0$, is thus interpreted as the gradient descent method for the area functional with respect to the $\mathrm{L}_2(\Gamma(t))$ norm.

2.1. Finite element discretization. We start by introducing $\{\mathscr{T}_h\}_h$, a shape-regular family of triangulations (simplicial partitions) of the domain Ω. This means that there exists a constant $\sigma_0\in\mathbb{R}^+$, independent of the particular triangulation $\mathscr{T}_h$, such that

$$\frac{\sup\{\rho\in\mathbb{R}^+:\ \mathrm{B}_\rho(\boldsymbol{x})\subset K\}}{\operatorname{diam}(K)} \ge \sigma_0 \qquad \forall K\in\mathscr{T}_h. \tag{2.12}$$

We will refer to σ_0 as the *shape-regularity* of the family $\{\mathscr{T}_h\}_h$. We assume that the *approximate domain* $\Omega_h = \operatorname{int}\left(\bigcup_{K\in\mathscr{T}_h}\overline{K}\right)$ coincides with Ω; this is a simplifying assumption that could be removed at the cost of seriously complicating the analysis, without adding much content to the results we intend to present. The symbol h stands for both the *local meshsize function* and the global meshsize of $\mathscr{T}_h$; this abuse of notation should not cause confusion.

Given a simplex $K\in\mathscr{T}_h$ and $\psi:\Omega\to\mathbb{R}$, we denote by ψ_K the restriction $\psi|_K$—e.g., if $\psi=h$, we have $h_K=\operatorname{diam}(K)$—and by $\mathscr{U}_K^h$, the $\mathscr{T}_h$*-neighborhood* of K,

$$\mathscr{U}_K^h := \operatorname{int}\Big(\bigcup\big\{\overline{K'}\in\mathscr{T}_h:\ \overline{K'}\cap\overline{K}\neq\emptyset\big\}\Big). \tag{2.13}$$

We also associate with $\mathscr{T}_h$ its *internal mesh* $\Sigma_h := \bigcup_{S\in\mathscr{S}_h^\circ} S$, where $\mathscr{S}_h^\circ$ is the set of internal edges (or faces) of the simplexes in $\mathscr{T}_h$. The *finite element spaces*, constructed on $\mathscr{T}_h$, that will be employed are

$$\mathbb{V}_h := \big\{\phi\in\mathrm{W}_1^1(\Omega):\ \phi_K\in\mathbb{P}^\ell\ \forall K\in\mathscr{T}_h\big\} \quad\text{and}\quad \mathring{\mathbb{V}}_h := \mathbb{V}_h\cap\mathring{\mathrm{W}}_1^1(\Omega), \tag{2.14}$$

where $\ell\in\mathbb{Z}^+$ and $\mathbb{P}^\ell$ is the space of polynomials of degree at most ℓ. A spatial finite element discretization of Problem 1.1 can be now derived from (2.4).

Problem 2.5 (spatially discrete scheme for the MCFG). *Let $\tilde g_h(t)\in\mathbb{V}_h$ be an interpolant of $\tilde g(t)$. Find $u_h\in\mathrm{C}^1([0,T];\mathbb{V}_h)$ such that, for each $t\in[0,T]$,*

$$u_h(t) - \tilde g_h(t) \in \mathring{\mathbb{V}}_h, \tag{2.15}$$

$$\left\langle \frac{\partial_t u_h(t)}{Qu_h(t)}, \phi_h \right\rangle + \left\langle \frac{\nabla u_h(t)}{Qu_h(t)}, \nabla \phi_h \right\rangle = \langle f(t), \phi_h \rangle \qquad \forall \phi_h \in \mathring{\mathbb{V}}_h. \tag{2.16}$$

Solvability of Problem 2.5 and a priori error estimates are studied by Dziuk [8, Thm. 1]. Throughout the paper, u_h will denote the solution of Problem 2.5.

3. A posteriori error estimates. In this section we state our main results. We start by introducing some definitions.

DEFINITION 3.1 (residual functions). *For each $t \in [0,T]$, let $r(t)$ be the* internal residual *and let $j(t)$ be the* jump residual *associated with u_h. These two functions are defined on $\Omega \setminus \Sigma_h$ and Σ_h, respectively, and are given by*

$$r(\boldsymbol{x},t) := \frac{\partial_t u_h(\boldsymbol{x},t)}{Qu_h(\boldsymbol{x},t)} - f(\boldsymbol{x},t) - \operatorname{div}\left(\frac{\nabla u_h(\boldsymbol{x},t)}{Qu_h(\boldsymbol{x},t)}\right) \qquad \text{for } \boldsymbol{x} \in \Omega \setminus \Sigma_h, \tag{3.1}$$

$$j(\boldsymbol{x},t) := \left[\frac{\nabla u_h(\boldsymbol{x},t)}{Qu_h(\boldsymbol{x},t)}\right]_S \qquad \text{for } \boldsymbol{x} \in S \in \mathscr{S}_h^\circ, \tag{3.2}$$

where the jump of a vector field $\boldsymbol{\psi}$ *across an edge S is defined as*

$$[\boldsymbol{\psi}]_S(\boldsymbol{x}) := \lim_{\varepsilon \to 0} \left(\boldsymbol{\psi}(\boldsymbol{x} + \varepsilon \boldsymbol{\nu}_S) - \boldsymbol{\psi}(\boldsymbol{x} - \varepsilon \boldsymbol{\nu}_S)\right) \cdot \boldsymbol{\nu}_S \tag{3.3}$$

with $\boldsymbol{x} \in S$ and $\boldsymbol{\nu}_S$ denoting one of the two normals to S (the choice is arbitrary and does not affect the definition).

DEFINITION 3.2 (local indicators and weights). *Denote by C_1 and C_2 the Scott–Zhang interpolation inequality constants, which depend only on the shape-regularity σ_0 of $\mathscr{T}_h$ and which we introduce later in inequalities* (6.2) *and* (6.3)*, respectively. With each $K \in \mathscr{T}_h$ we associate the* local

$$\text{elliptic indicator} \qquad \eta_0^K(t) := h_K^{d/2}\left(C_1 \|r(t)\|_{\mathrm{L}_d(K)} + C_2 \|j(t)\|_{\mathrm{L}_\infty(\partial K)}\right), \tag{3.4}$$

$$\text{parabolic indicator} \qquad \eta_1^K(t) := h_K^{d/2}\left(C_1 \|\partial_t r(t)\|_{\mathrm{L}_d(K)} + C_2 \|\partial_t j(t)\|_{\mathrm{L}_\infty(\partial K)}\right), \tag{3.5}$$

and the local weights

$$\omega^K(t) := \sup_{\boldsymbol{x} \in \mathscr{U}_K^h} Qu_h(\boldsymbol{x},t)^2, \qquad \alpha^K(t) := \omega^K(t)^2 \sup_{\boldsymbol{x} \in \mathscr{U}_K^h} \frac{1}{Qu(\boldsymbol{x},t)}. \tag{3.6}$$

DEFINITION 3.3 (a posteriori error estimators). *Denote by M and γ two positive constants, depending only on the shape-regularity σ_0, which we will introduce in detail in the proof of Lemma* 6.4*. We define the* elliptic part of the proper estimator

$$\mathscr{E}_{2,0}(t) := \sup_{s \in [0,t]} \hat{\mathscr{E}}_{2,0}(s), \qquad \text{where} \quad \hat{\mathscr{E}}_{2,0}(t)^2 := \gamma^2 \sum_{K \in \mathscr{T}_h} \alpha^K(t) \eta_0^K(t)^2, \tag{3.7}$$

the parabolic part of the proper estimator

$$\mathscr{E}_{2,1}(t) := \int_0^t \dot{\mathscr{E}}_{2,1}(s)\,\mathrm{d}s, \qquad \text{where} \quad \dot{\mathscr{E}}_{2,1}(t)^2 := \gamma^2 \sum_{K \in \mathscr{T}_h} \alpha^K(t) \eta_1^K(t)^2, \tag{3.8}$$

the elliptic part of the vicinity estimator

$$\mathscr{E}_{\infty,0}(t) := \sup_{s \in [0,t]} \hat{\mathscr{E}}_{\infty,0}(s), \quad \text{where} \quad \hat{\mathscr{E}}_{\infty,0}(t) := M \max_{K \in \mathscr{T}_h} \left(h_K^{-d/2} \omega^K(t) \eta_0^K(t)\right), \tag{3.9}$$

and the parabolic part of the vicinity estimator

$$\mathscr{E}_{\infty,1}(t) := \int_0^t \dot{\mathscr{E}}_{\infty,1}(s)\,\mathrm{d}s, \quad \textit{where} \quad \dot{\mathscr{E}}_{\infty,1}(t) := M \max_{K\in\mathscr{T}_h} \left(h_K^{-d/2} \omega^K(t) \eta_1^K(t) \right). \tag{3.10}$$

These definitions allow us to introduce the proper estimator *and the* vicinity estimator*, respectively, as*

$$\mathscr{E}_2(t) := \left(\mathscr{E}_{2,0}(t)^2 + \mathscr{E}_{2,1}(t)^2 \right)^{1/2} \quad \textit{and} \quad \mathscr{E}_\infty(t) := \mathscr{E}_{\infty,0}(t) + \mathscr{E}_{\infty,1}(t). \tag{3.11}$$

We finally introduce the initial estimator *and* total estimator*, respectively, as*

$$\mathscr{E}_0 := \left((1 + 2\mathscr{E}_{\infty,0}(0))\, A(0) + 2\mathscr{E}_{2,0}(0) \sqrt{A(0)} \right)^{1/2} \tag{3.12}$$

and

$$\mathscr{E}(t) := \left(\mathscr{E}_0^2 + \mathscr{E}_2(t)^2 + \mathscr{E}_\infty(t) \right)^{1/2}. \tag{3.13}$$

The motivation for our terminology will become clear in Theorem 3.6 *below: there the vicinity estimator $\mathscr{E}_\infty$ does not enter directly into the conditional estimate, but dictates a "closeness condition" that must be satisfied for the estimate to hold. This conditional estimate then involves the initial and proper estimators $\mathscr{E}_0$ and $\mathscr{E}_2$.*

We are now ready to state the main results, whose proofs are spread through sections 4–6.

THEOREM 3.4 (unconditional a posteriori estimate). *Let u be the solution of Problem* 1.1*, and u_h the finite element solution of Problem* 2.5*. For all $t \in [0,T]$ there exist $C = C[u_h, f, t]$ and $C' = C'[f, g, t]$ such that*

$$C \le \exp \int_0^t \left(2 \left\| \partial_t u_h(s) \right\|^2_{\mathrm{L}_\infty(\Omega)} + 4 \left\| \nabla \partial_t u_h(s) \right\|_{\mathrm{L}_\infty(\Omega)} \right) \mathrm{d}s, \tag{3.14}$$

$$C' \le \exp \left(\frac{1}{2} \left\| f(s) \right\|^2_{\mathrm{L}_\infty(\Omega)} \right) \left(\left\| Qg(0) \right\|_{\mathrm{L}_1(\Omega)} + \left\| \partial_t g \right\|_{\mathrm{L}_1(\partial\Omega\times(0,t))} \right), \tag{3.15}$$

$$\int_0^t \int_\Omega (Vu_h - Vu)^2 Qu + \frac{1}{2} \sup_{[0,t]} \int_\Omega \left| \boldsymbol{N} u_h - \boldsymbol{N} u \right|^2 Qu \le C \left({\mathscr{E}_0}^2 + 4\mathscr{E}_2(t)^2 + 8C'\mathscr{E}_\infty(t) \right). \tag{3.16}$$

Remark 3.5 (the sharpness of the unconditional estimate). The estimate (3.16) holds, regardless of whether the approximate solution u_h is close to or far from the exact solution u. The presence of the vicinity estimator $\mathscr{E}_\infty$ on the right-hand side is undesirable because, even under the most optimistic assumptions of regularity on u, there is no indication that this estimator will have the same order of convergence, as h goes to zero, as the square of the geometric error on the left-hand side. In fact, the numerical tests described in section 7 bear strong evidence that $\mathscr{E}_\infty$ does not decay with a sufficiently high power of h. This means that the above estimate is not sharp and that it cannot be relied upon as a stopping criterion in an adaptive scheme. A crucial point of this paper is that *this estimate can be improved, provided that u_h is sufficiently close to u,* as stated in the next theorem.

THEOREM 3.6 (conditional a posteriori estimate). *Let u be the solution of Problem* 1.1*, and u_h the finite element solution of Problem* 2.5*. For each $t \in [0,T]$, if*

$$\mathscr{E}_\infty(t) \leq \frac{1}{8}, \tag{3.17}$$

then there exists a constant $C = C[u_h, t]$ such that

$$C \leq \exp \int_0^t \left(2 \left\| \partial_t u_h(s) \right\|^2_{\mathrm{L}_\infty(\Omega)} + 4 \left\| \nabla \partial_t u_h(s) \right\|_{\mathrm{L}_\infty(\Omega)} \right) \mathrm{d}s, \tag{3.18}$$

$$\int_0^t \int_\Omega (Vu_h - Vu)^2 Qu + \frac{1}{2} \sup_{[0,t]} \int_\Omega \left| \boldsymbol{N} u_h - \boldsymbol{N} u \right|^2 Qu \leq C \left(\mathscr{E}_0{}^2 + 8 \mathscr{E}_2(t)^2 \right). \tag{3.19}$$

Remark 3.7 (a posteriori nature of condition (3.17)). Theorem 3.6 is a conditional result, typical in nonlinear analysis. The condition (3.17) can be interpreted as follows: the approximate solution u_h needs to be sufficiently close to the exact solution u for the estimate to hold. The technique we use can be thought of as a linearization of the equation about u_h, instead of a linearization about u, which would be natural in an a priori setting. This leads to the important fact that *condition* (3.17) *can be effectively verified* since it involves exclusively a posteriori, and therefore computable, quantities. Thus, in a practical adaptive method where a stopping criterion is needed, Theorem 3.4 would be used in the early preasymptotic stages in order to get close enough to the exact solution; the estimate of Theorem 3.6 would then provide a sharper criterion once the algorithm enters a second stage in which the condition (3.17) is satisfied.

4. The error equation. We divide the proof of Theorems 3.4 and 3.6 into several steps that will spread over the next two sections. Here we introduce the residual-based energy technique and we formulate the error equation.

4.1. The residual. The *residual* is defined as the difference between the exact operator acting on the approximate solution and the exact operator acting on the exact solution. In our setting, the result has to be understood in the following weak sense:

$$\langle \mathscr{R} \,|\, \phi \rangle := \left\langle \frac{\partial_t u_h}{Qu_h} - \frac{\partial_t u}{Qu}, \phi \right\rangle + \left\langle \frac{\nabla u_h}{Qu_h} - \frac{\nabla u}{Qu}, \nabla \phi \right\rangle \qquad \forall \phi \in \mathring{\mathrm{W}}{}^1_1(\Omega). \tag{4.1}$$

Here $\langle \cdot \,|\, \cdot \rangle$ stands for the duality pairing. The distribution $\mathscr{R}$ is time-dependent and, owing to Assumption 2.1, $\mathscr{R}(t)$ is a bounded linear functional on $\mathring{\mathrm{W}}{}^1_1(\Omega)$ for all $t \in [0,T]$. We will refer to $\mathscr{R}$ as the *residual functional*. The use of (2.4) and an integration by parts in the space variable lead to the residual functional *representation*

$$\begin{aligned} \langle \mathscr{R} \,|\, \phi \rangle &= \left\langle \frac{\partial_t u_h}{Qu_h} - f - \operatorname{div} \left(\frac{\nabla u_h}{Qu_h} \right), \phi \right\rangle + \left\langle \left[\frac{\nabla u_h}{Qu_h} \right], \phi \right\rangle_{\Sigma_h} \\ &= \langle r, \phi \rangle + \langle j, \phi \rangle_{\Sigma_h} \qquad \forall \phi \in \mathring{\mathrm{W}}{}^1_1(\Omega), \end{aligned} \tag{4.2}$$

where the residual functions r and j are those introduced in section 3.1.

4.2. Galerkin orthogonality and the error equation. The starting point of our residual-based a posteriori estimation is exploiting the property that $\mathscr{R}$ vanishes

on $\mathring{\mathbb{V}}_h$. This is the so-called *Galerkin orthogonality* property, which yields the following *error equation*:

$$\left\langle \frac{\partial_t u_h}{Qu_h} - \frac{\partial_t u}{Qu}, \phi \right\rangle + \left\langle \frac{\nabla u_h}{Qu_h} - \frac{\nabla u}{Qu}, \nabla\phi \right\rangle = \langle \mathscr{R} \,|\, \phi - \phi_h \rangle \tag{4.3}$$

for all $\phi \in \mathring{\mathrm{W}}^1_1(\Omega)$, $\phi_h \in \mathring{\mathbb{V}}_h$.

4.3. Choice of the test function. The energy technique relies on an appropriate choice of test functions ϕ and ϕ_h in (4.3). Let us denote by e the error

$$e(\boldsymbol{x}, t) := u_h(\boldsymbol{x}, t) - u(\boldsymbol{x}, t) \tag{4.4}$$

and make the following choices for the test functions:

$$\phi(\boldsymbol{x}, t) := \partial_t e(\boldsymbol{x}, t), \tag{4.5}$$

$$\phi_h(\boldsymbol{x}, t) := I_h \phi(\boldsymbol{x}, t), \tag{4.6}$$

where I_h is the Scott–Zhang interpolation operator which will be briefly discussed in section 6.2 and section 6.3. For $\partial_t e$ to be admissible as a test function ϕ in (4.3), it must vanish on $\partial\Omega$, which is not necessarily true. This motivates the following temporary assumption, which will be removed in section 6.3 where we deal with general boundary data.

ASSUMPTION 4.1 (exact boundary data resolution). *Until* section 6.3*, let either*
(a) *the boundary value g be approximated exactly by g_h, or*
(b) *g be time independent.*

5. Coercivity. Our objective in this section is to derive a lower bound on the left-hand side of (4.3) with the choice made in (4.5). To achieve this objective we exhibit as much coercivity as the nonlinearity allows; we will make a liberal use of the word "coercivity" in this sense. The geometric error functions of time A and B, introduced in section 1.2, will be used extensively in this section and in the next one. We begin by stating some simple yet fundamental geometric relations observed by Dziuk.

LEMMA 5.1 (basic geometry [8]). *Given $\boldsymbol{p}_1, \boldsymbol{p}_2 \in \mathbb{R}^d$, if $q_i := (1 + |\boldsymbol{p}_i|^2)^{1/2}$ and $\boldsymbol{n}_i := (\boldsymbol{p}_i; -1)/q_i \in \mathbb{R}^d$ for $i = 1, 2$, then the following geometric relations hold:*

$$1 - \frac{1 + \boldsymbol{p}_1 \cdot \boldsymbol{p}_2}{q_1 q_2} = \frac{1}{2} |\boldsymbol{n}_1 - \boldsymbol{n}_2|^2, \tag{5.1}$$

$$\left| \left(\frac{1}{q_1} - \frac{1}{q_2} \right) \left(\frac{\boldsymbol{p}_1}{q_1} - \frac{\boldsymbol{p}_2}{q_2} \right) \right| \le \frac{1}{2} |\boldsymbol{n}_1 - \boldsymbol{n}_2|^2, \tag{5.2}$$

$$\frac{|\boldsymbol{p}_1 - \boldsymbol{p}_2|}{q_1} \le (1 + |\boldsymbol{p}_2|) |\boldsymbol{n}_1 - \boldsymbol{n}_2|. \tag{5.3}$$

LEMMA 5.2 (Dziuk identity [8]). *If v and w are sufficiently differentiable functions on $\Omega \times [0, T]$, then*

$$\begin{aligned} \frac{1}{2}\partial_t \left(|\boldsymbol{N}v - \boldsymbol{N}w|^2 Qw \right) = {} & \left(\frac{\nabla v}{Qv} - \frac{\nabla w}{Qw} \right) \cdot \nabla \left(\partial_t v - \partial_t w \right) \\ & - \nabla \partial_t v \cdot \left(\frac{\nabla w}{Qv} - \frac{\nabla w}{Qw} + \frac{\nabla v}{Qv} - \frac{1 + \nabla w \cdot \nabla v}{(Qv)^2} \frac{\nabla v}{Qv} \right). \end{aligned} \tag{5.4}$$

The first term in the left-hand side of (4.3) is handled through the following inequality.

LEMMA 5.3 (coercivity of the velocity term). *With the notation*

$$\varrho_1(t) := \frac{1}{2}\left\|\partial_t u_h(t)\right\|^2_{\mathrm{L}_\infty(\Omega)}, \tag{5.5}$$

we have that, for all $t \in [0,T]$,

$$\left\langle \frac{\partial_t u_h}{Qu_h} - \frac{\partial_t u}{Qu}, \partial_t u_h - \partial_t u \right\rangle \geq \frac{1}{2}\,\mathrm{d}_t B(t) - \varrho_1 A(t). \tag{5.6}$$

Proof. Basic manipulations imply

$$\begin{aligned}
&\left\langle \frac{\partial_t u_h}{Qu_h} - \frac{\partial_t u}{Qu}, \partial_t u_h - \partial_t u \right\rangle \\
&\quad = \int_\Omega (Vu_h - Vu)^2 Qu + \int_\Omega \partial_t u_h \left(\frac{1}{Qu} - \frac{1}{Qu_h}\right)(Vu_h - Vu)Qu \\
&\quad \geq \mathrm{d}_t B(t) - \left\|\partial_t u_h\right\|_{\mathrm{L}_\infty(\Omega)} \int_\Omega \left|\frac{1}{Qu} - \frac{1}{Qu_h}\right| \sqrt{Qu}\,|Vu_h - Vu|\,\sqrt{Qu} \\
&\quad \geq \mathrm{d}_t B(t) - \left\|\partial_t u_h\right\|_{\mathrm{L}_\infty(\Omega)} \left(\int_\Omega \left|\boldsymbol{N}u_h - \boldsymbol{N}u\right|^2 Qu\right)^{1/2} \left(\int_\Omega (Vu_h - Vu)^2 Qu\right)^{1/2}.
\end{aligned}$$

Consequently

$$\left\langle \frac{\partial_t u_h}{Qu_h} - \frac{\partial_t u}{Qu}, \partial_t u_h - \partial_t u \right\rangle \geq \mathrm{d}_t B(t) - \frac{1}{2}\,\mathrm{d}_t B(t) - \varrho_1(t)A(t) = \frac{1}{2}\,\mathrm{d}_t B(t) - \varrho_1 A(t),$$

as asserted. ∎

LEMMA 5.4 (coercivity for normals and gradients). *With the notation*

$$\varrho_2(t) := \left\|\nabla \partial_t u_h(t)\right\|_{\mathrm{L}_\infty(\Omega)}, \tag{5.7}$$

we have that, for all $t \in [0,T]$,

$$\left\langle \frac{\nabla u_h}{Qu_h} - \frac{\nabla u}{Qu}, \nabla(\partial_t u_h - \partial_t u) \right\rangle \geq \frac{1}{2}\,\mathrm{d}_t A(t) - \varrho_2(t)A(t). \tag{5.8}$$

Proof. Integrating in space both sides of (5.4) and rearranging terms yields

$$\begin{aligned}
\left\langle \frac{\nabla u_h}{Qu_h} - \frac{\nabla u}{Qu}, \nabla(\partial_t u_h - \partial_t u) \right\rangle &= \frac{1}{2}\,\mathrm{d}_t A(t) \\
&\quad + \int_\Omega \nabla \partial_t u_h \cdot \left(\frac{\nabla u}{Qu_h} - \frac{\nabla u}{Qu} + \frac{\nabla u_h}{Qu_h} - \frac{1 + \nabla u \cdot \nabla u_h}{(Qu_h)^2}\frac{\nabla u_h}{Qu_h}\right).
\end{aligned}$$

To show the result it is sufficient to show that the last integral above is bounded from below by $-\varrho_2(t)A(t)$. To do this we add and subtract $-(Qu\nabla u_h)/(Qu_h)^2$ and rewrite this term as the sum of two integrals:

$$\begin{aligned}
I_1 + I_2 := &\int_\Omega \nabla \partial_t u_h \cdot \left(\frac{\nabla u}{Qu_h} - \frac{\nabla u}{Qu} + \frac{\nabla u_h}{Qu_h} - \frac{Qu\nabla u_h}{(Qu_h)^2}\right) \\
&+ \int_\Omega \nabla \partial_t u_h \cdot \left(\frac{Qu\nabla u_h}{(Qu_h)^2} - \frac{1 + \nabla u \cdot \nabla u_h}{(Qu_h)^2}\frac{\nabla u_h}{Qu_h}\right).
\end{aligned} \tag{5.9}$$

The integrals in (5.9) are bounded, by using (5.2) for the first one,

$$I_1 \geq -\left\|\nabla \partial_t u_h\right\|_{\mathrm{L}_\infty(\Omega)} \int_\Omega \left| \left(\frac{1}{Qu} - \frac{1}{Qu_h} \right) \left(\frac{\nabla u_h}{Qu_h} - \frac{\nabla u}{Qu} \right) Qu \right| \geq -\frac{\varrho_2(t)}{2} A(t),$$

and with the help of (5.1) for the second one,

$$I_2 \geq -\left\|\nabla \partial_t u_h\right\|_{\mathrm{L}_\infty(\Omega)} \int_\Omega \left| \left(1 - \frac{1 + \nabla u_h \cdot \nabla u}{Qu_h Qu} \right) Qu \frac{\nabla u_h}{(Qu_h)^2} \right| \geq -\frac{\varrho_2(t)}{2} A(t).$$

This proves the assertion. ∎

LEMMA 5.5 (estimate of the geometric terms). *With the notation*

$$\varrho(t) := \varrho_1(t) + \varrho_2(t), \tag{5.10}$$

we have that, for all $t \in [0,T]$,

$$A(t) + B(t) \leq A(0) + 2\int_0^t \varrho(s) A(s)\, \mathrm{d}s + 2\int_0^t \langle \mathscr{R}(s) \,|\, \partial_t \left(e(s) - I_h e(s) \right) \rangle \, \mathrm{d}s. \tag{5.11}$$

Proof. Using (4.5), (4.6), (5.6), and (5.8) in (4.3), we obtain

$$\frac{1}{2} \left(\mathrm{d}_t A(t) + \mathrm{d}_t B(t) \right) \leq \langle \mathscr{R} \,|\, \partial_t e(t) - I_h \partial_t e(t) \rangle + \varrho(t) A(t) \tag{5.12}$$

for all $t \in [0,T]$. An integration in time over the interval $[0,t]$ yields the result. ∎

6. Bounding the residual by the estimators. We prove in this section Theorems 3.4 and 3.6 by estimating $\int_0^t \langle \mathscr{R} \,|\, \partial_t \left(e - I_h e \right) \rangle$ appearing in (5.11). We will denote by $d' = d/(d-1)$ the conjugate exponent of d, the latter being the surface's dimension. We start by stating two lemmas bearing a fundamental geometric relationship and an interpolation theory result, respectively.

LEMMA 6.1 (Fierro–Veeser inequality [12]). *Adopting the same notation as in Lemma* 5.1*, the following inequality holds:*

$$\left| \boldsymbol{p}_1 - \boldsymbol{p}_2 \right| \frac{1}{q_1^2} \leq 2 \left| \boldsymbol{n}_1 - \boldsymbol{n}_2 \right| + \left| \boldsymbol{n}_1 - \boldsymbol{n}_2 \right|^2 q_2. \tag{6.1}$$

LEMMA 6.2 (Scott–Zhang interpolation [22]). *If* I_h *denotes the averaging interpolation operator that was introduced by Scott and Zhang—called the* Scott–Zhang interpolator *in what follows—then the following interpolation inequalities hold:*

$$\left\| \psi - I_h \psi \right\|_{\mathrm{L}_{d'}(K)} \leq C_1 \left| \psi \right|_{\mathrm{W}_1^1(\mathscr{U}_K^h)}, \tag{6.2}$$

$$\left\| \psi - I_h \psi \right\|_{\mathrm{L}_1(\partial K)} \leq 2 C_2 \left| \psi \right|_{\mathrm{W}_1^1(\mathscr{U}_K^h)}, \tag{6.3}$$

where $\mathscr{U}_K^h$ *is the* $\mathscr{T}_h$*-neighborhood of* K *defined in* (2.13).

Remark 6.3. The particular choice of the norms in Lemma 6.2 is motivated by our wish for $\sqrt{A(t)}$ to appear in an upper bound on the right-hand side of (5.11).

Indeed, estimating the residual $\mathscr{R}$ in energy norms would typically lead to dealing with $|\nabla u_h - \nabla u|$. In light of the geometric errors A and B in the left-hand side of (5.11), a straightforward idea would be to bound its L_2 norm, that is, $|\nabla u_h - \nabla u|^2$, from above by $C \left| \boldsymbol{N} u_h - \boldsymbol{N} u \right|^2 Qu$, with the constant $C = C[u_h]$ independent of u

(think of u_h being unrelated to u in this paragraph). The only practical way to derive such a bound would be a pointwise geometric relation like

$$\frac{|\boldsymbol{p}_1 - \boldsymbol{p}_2|^2}{\kappa(\boldsymbol{p}_1)\,|\boldsymbol{n}_1 - \boldsymbol{n}_2|^2\, q_2} \le 1, \tag{6.4}$$

where $\boldsymbol{p}_1 = \nabla u_h$, $\boldsymbol{n}_1 = N u_h$, $q_1 = Q u_h$, the quantities with subscript 2 refer to u, and κ is some function of $\boldsymbol{p}_1$ only. Unfortunately this is not possible because (6.4) is false. To see this, fix $\boldsymbol{p}_1$ and observe that $\boldsymbol{n}_1 - \boldsymbol{n}_2$ is bounded; by letting $|\boldsymbol{p}_2| \to \infty$, we obtain, in contrast with (6.4),

$$\frac{|\boldsymbol{p}_1 - \boldsymbol{p}_2|^2}{\kappa(\boldsymbol{p}_1)\,|\boldsymbol{n}_1 - \boldsymbol{n}_2|^2\, q_2} \ge C\frac{|\boldsymbol{p}_1 - \boldsymbol{p}_2|^2}{q_2} = \mathrm{O}(|\boldsymbol{p}_2|) \to \infty. \tag{6.5}$$

This difficulty can be circumvented by using the L_1 norm of $|\nabla u - \nabla u_h|$, instead of the L_2 norm, and the Fierro–Veeser inequality (6.1), which reads

$$\begin{aligned} |\nabla u_h - \nabla u| &= (Q u_h)^2 \frac{|\nabla u_h - \nabla u|}{(Q u_h)^2} \\ &\le (Q u_h)^2 (2\,|\boldsymbol{N} u_h - \boldsymbol{N} u| + |\boldsymbol{N} u_h - \boldsymbol{N} u|^2\, Q u). \end{aligned} \tag{6.6}$$

Notice that the last term is cumbersome because its power is too high—it is the "price to pay." This term will yield a term of the form $\varrho(t)A(t)$ on the right-hand side which has to be handled carefully in order to close the estimate.

Recalling first the notation in section 1.2 and section 3.3, we now state and prove the central result of this paper.

LEMMA 6.4 (residual estimate). *The following inequality holds for all* $t \in [0,T]$:

$$\begin{aligned} A(t) + B(t) &\le \mathscr{E}_0{}^2 + 2\hat{\mathscr{E}}_{2,0}(t) A(t)^{1/2} + 2\hat{\mathscr{E}}_{\infty,0}(t) A(t) \\ &\quad + 2\int_0^t \dot{\mathscr{E}}_{2,1}(s) A(s)^{1/2}\,\mathrm{d}s + 2\int_0^t \dot{\mathscr{E}}_{\infty,1}(s) A(s)\,\mathrm{d}s + 2\int_0^t \varrho(s) A(s)\,\mathrm{d}s. \end{aligned} \tag{6.7}$$

Proof. Apply the representation formula (4.2) with $\phi = \partial_t \delta_h e$, where $\delta_h e(t) := e(t) - I_h e(t)$, integrate by parts in time, and use the commutativity property $\partial_t I_h = I_h \partial_t$, to obtain

$$\begin{aligned} \int_0^t \langle \mathscr{R}(s) \,|\, \partial_t \delta_h e(s) \rangle\,\mathrm{d}s &= \int_0^t \langle r(s), \partial_t \delta_h e(s) \rangle + \langle j(s), \partial_t \delta_h e(s) \rangle_{\Sigma_h}\,\mathrm{d}s \\ &= \big[\langle r, \delta_h e \rangle + \langle j, \delta_h e \rangle_{\Sigma_h}\big]_0^t - \int_0^t \langle \partial_t r(s), \delta_h e(s) \rangle + \langle \partial_t j(s), \delta_h e(s) \rangle_{\Sigma_h}\,\mathrm{d}s. \end{aligned}$$

Hence

$$\begin{aligned} &\int_0^t \langle \mathscr{R}(s) \,|\, \partial_t \delta_h e(s) \rangle\,\mathrm{d}s \\ &\quad \le \sum_{K \in \mathscr{T}_h} \left(\sum_{s \in \{0,t\}} \left(\|r(s)\|_{\mathrm{L}_d(K)}\, \|\delta_h e(s)\|_{\mathrm{L}_{d'}(K)} + \frac{1}{2}\, \|j(s)\|_{\mathrm{L}_\infty(\partial K)}\, \|\delta_h e(s)\|_{\mathrm{L}_1(\partial K)} \right) \right. \\ &\qquad \left. + \int_0^t \|\partial_t r(s)\|_{\mathrm{L}_d(K)}\, \|\delta_h e(s)\|_{\mathrm{L}_{d'}(K)} + \frac{1}{2}\, \|\partial_t j(s)\|_{\mathrm{L}_\infty(\partial K)}\, \|\delta_h e(s)\|_{\mathrm{L}_1(\partial K)}\,\mathrm{d}s \right). \end{aligned}$$

Owing to the approximation properties of the Scott–Zhang interpolator in Lemma 6.2, and using the local indicators η_i^K introduced in Definition 3.2, we may write

$$\int_0^t \langle \mathscr{R}(s) \,|\, \partial_t \delta_h e(s) \rangle \,\mathrm{d}s \le \sum_{K\in\mathscr{T}_h} h_K^{-d/2} \Big(\eta_0^K(0) \,\|\nabla e(0)\|_{\mathrm{L}_1(\mathscr{U}_K^h)} + \eta_0^K(t) \,\|\nabla e(t)\|_{\mathrm{L}_1(\mathscr{U}_K^h)} + \int_0^t \eta_1^K(s) \,\|\nabla e(s)\|_{\mathrm{L}_1(\mathscr{U}_K^h)} \,\mathrm{d}s \Big). \tag{6.8}$$

We proceed by observing that inequality (6.6) implies

$$\|\nabla e(t)\|_{\mathrm{L}_1(\mathscr{U}_K^h)} \le \sup_{\mathscr{U}_K^h} (Qu_h)^2 \int_{\mathscr{U}_K^h} \left(\frac{2\mathscr{N}(t)}{\sqrt{Qu(t)}} + \mathscr{N}(t)^2 \right), \tag{6.9}$$

where, in order to simplify notation, we introduce the shorthand

$$\mathscr{N} := |\boldsymbol{N} u_h - \boldsymbol{N} u| \,\sqrt{Qu}. \tag{6.10}$$

We continue the bound in (6.8) by using (6.9) as follows:

$$\begin{aligned} &\int_0^t \langle \mathscr{R}(s) \,|\, \partial_t e(s) - I_h \partial_t e(s) \rangle \,\mathrm{d}s \\ &\quad \le \sum_{K\in\mathscr{T}_h} \eta_0^K(0) h_K^{-d/2} \omega^K(0) \int_{\mathscr{U}_K^h} \left(\frac{2\mathscr{N}(0)}{\sqrt{Qu(0)}} + \mathscr{N}(0)^2 \right) \\ &\quad + \sum_{K\in\mathscr{T}_h} \eta_0^K(t) h_K^{-d/2} \omega^K(t) \int_{\mathscr{U}_K^h} \left(\frac{2\mathscr{N}(t)}{\sqrt{Qu(t)}} + \mathscr{N}(t)^2 \right) \\ &\quad + \sum_{K\in\mathscr{T}_h} \int_0^t \eta_1^K(s) h_K^{-d/2} \omega^K(s) \int_{\mathscr{U}_K^h} \left(\frac{2\mathscr{N}(s)}{\sqrt{Qu(s)}} + \mathscr{N}(s)^2 \right) \mathrm{d}s. \end{aligned} \tag{6.11}$$

The first two terms in (6.11) can be bounded at once through the following inequality (where we simply take $t = 0$ for the first term):

$$\begin{aligned} &\sum_{K\in\mathscr{T}_h} \eta_0^K(t) h_K^{-d/2} \omega^K(t) \int_{\mathscr{U}_K^h} \left(\frac{2\mathscr{N}(t)}{\sqrt{Qu(t)}} + \mathscr{N}(t)^2 \right) \\ &\quad \le 2 \left(\sum_{K\in\mathscr{T}_h} \eta_0^K(t)^2 h_K^{-d} \omega^K(t)^2 \,|\mathscr{U}_K^h| \sup_{\mathscr{U}_K^h} \frac{1}{Qu(t)} \right)^{1/2} \left(\sum_{K\in\mathscr{T}_h} \int_{\mathscr{U}_K^h} \mathscr{N}(t)^2 \right)^{1/2} \\ &\qquad + \max_{K\in\mathscr{T}_h} \left(\eta_0^K(t) h_K^{-d/2} \omega^K(t) \right) \left(\sum_{K\in\mathscr{T}_h} \int_{\mathscr{U}_K^h} \mathscr{N}(t)^2 \right). \end{aligned}$$

Likewise, the last term in (6.11) is bounded by

$$\begin{aligned} &\int_0^t \left(2 \left(\sum_{K\in\mathscr{T}_h} \eta_1^K(s)^2 h_K^{-d} \omega^K(s)^2 \,|\mathscr{U}_K^h| \sup_{\mathscr{U}_K^h} \frac{1}{Qu(s)} \right)^{1/2} \left(\sum_{K\in\mathscr{T}_h} \int_{\mathscr{U}_K^h} \mathscr{N}(s)^2 \right)^{1/2} \right. \\ &\qquad \left. + \max_{K\in\mathscr{T}_h} \left(\eta_1^K(s) h_K^{-d/2} \omega^K(s) \right) \left(\sum_{K\in\mathscr{T}_h} \int_{\mathscr{U}_K^h} \mathscr{N}(s)^2 \right) \right) \mathrm{d}s. \end{aligned}$$

To conclude the proof, we observe that the shape-regularity of $\mathscr{T}_h$ (2.12) implies the existence of two constants $\gamma_0 \in \mathbb{R}^+$ and $M \in \mathbb{Z}^+$, depending only on σ_0 and the space dimension d, such that the number of simplexes of $\mathscr{T}_h$ contained in $\mathscr{U}_K^h$ does not exceed M and $\left|\mathscr{U}_K^h\right| \leq M\gamma_0^2 h_K^d$. Defining $\gamma := 2M\gamma_0$, it follows that

$$\begin{aligned}
&\int_0^t \langle \mathscr{R}(s) \,|\, \partial_t \delta_h e(s) \rangle \, \mathrm{d}s \\
&\quad \leq \gamma \left(\sum_{K \in \mathscr{T}_h} \alpha^K(0) \eta_0^K(0)^2 \right)^{1/2} A(0)^{1/2} + M \max_{K \in \mathscr{T}_h} \left(h_K^{-d/2} \omega^K(0) \eta_0^K(0) \right) A(0) \\
&\quad + \gamma \left(\sum_{K \in \mathscr{T}_h} \alpha^K(t) \eta_0^K(t)^2 \right)^{1/2} A(t)^{1/2} + M \max_{K \in \mathscr{T}_h} \left(h_K^{-d/2} \omega^K(t) \eta_0^K(t) \right) A(t) \\
&\quad + \gamma \int_0^t \left(\sum_{K \in \mathscr{T}_h} \alpha^K(s) \eta_1^K(s)^2 \right)^{1/2} A(s)^{1/2} \, \mathrm{d}s + M \int_0^t \max_{K \in \mathscr{T}_h} \left(h_K^{-d/2} \omega^K(s) \eta_1^K(s) \right) A(s) \, \mathrm{d}s.
\end{aligned}$$

Recalling Definition 3.3, we combine the last inequality with (5.11) and obtain (6.7), as asserted. ∎

Next we prove the theorems stated in section 3 with the aid of Lemma 6.4. For (6.7) to be useful we must control the terms containing $A(t)$ on the right-hand side by those on the left-hand side. We distinguish two main ways of doing this. The first way, which is direct and somewhat naive, uses the stability Lemma 2.4 and leads to the unconditional a posteriori estimate in Theorem 3.4. The second, more careful, way results in the conditional but sharper estimate in Theorem 3.6. To shorten the discussion, we first show the latter and then the former, which is simpler.

6.1. Proof of Theorem 3.6. Our starting point is inequality (6.7). Introduce the notation $A^*(t) := \sup_{[0,t]} A$, apply the Hölder inequality, and use the Young inequality with a parameter μ at our disposal, to obtain

$$\begin{aligned}
A(t) + B(t) \leq {\mathscr{E}_0}^2 + \mu A(t) + \frac{1}{\mu} \hat{\mathscr{E}}_{2,0}(t)^2 + \mu A^*(t) + \frac{1}{\mu} \mathscr{E}_{2,1}(t)^2 \\
+ 2\hat{\mathscr{E}}_{\infty,0}(t) A(t) + 2A^*(t) \mathscr{E}_{\infty,1}(t) + 2 \int_0^t \varrho(s) A(s) \, \mathrm{d}s.
\end{aligned} \tag{6.12}$$

Choosing $\mu = 1/8$; taking the supremum over $[0,t]$ on both sides; recalling that B, $\mathscr{E}_{2,1}$, and $\mathscr{E}_{\infty,1}$ are nondecreasing; and using Definition 3.3, we can write

$$A^*(t) + B(t) \leq \mathscr{E}_0^2 + \frac{1}{4} A^*(t) + 8\mathscr{E}_2(t)^2 + 2\mathscr{E}_\infty A^*(t) + 2 \int_0^t \varrho(s) A^*(s) \, \mathrm{d}s. \tag{6.13}$$

The condition (3.17), i.e., $\mathscr{E}_\infty \leq 1/8$, and the last inequality imply

$$\frac{1}{2} A^*(t) + B(t) \leq {\mathscr{E}_0}^2 + 8\mathscr{E}_2(t)^2 + 2 \int_0^t \varrho(s) A^*(s) \, \mathrm{d}s. \tag{6.14}$$

To conclude the proof, it suffices now to apply the Gronwall lemma in the above inequality, and to recall (5.10), (5.5), and (5.7), in order to derive (3.18) and (3.19). ∎

6.2. Proof of Theorem 3.4. The proof is a direct combination of Lemma 6.4 and the elementary fact that

$$A(t) = \int_\Omega |\boldsymbol{N}u_h(t) - \boldsymbol{N}u(t)|^2 \, Qu(t) \le 4 \int_\Omega Qu(t). \tag{6.15}$$

The stability Lemma 2.4 provides us with an upper bound on the last integral in terms of the data f and g. To conclude, it is enough to proceed along the lines of section 6.1 with $\mu = 1/4$ and apply the Gronwall lemma. ∎

Remark 6.5 (slowly varying solutions). Notice that if $\int_0^t \varrho$ is small enough (for which it is necessary for $\|\partial_t u_h\|_{\mathrm{L}_1(\mathrm{W}^1_\infty)}$ to be small), the Gronwall lemma argument is not needed and the exponential bound on C can be dropped. This is particularly true for solutions that are close to stationary points, i.e., if $\partial_t f$ and $\partial_t g$ are very small. We will not pursue this issue further in this paper, but we remark that this condition is also a posteriori and could be checked automatically if needed.

6.3. Time-dependent Dirichlet boundary data. As promised earlier, we now remove Assumption 4.1; that is, we allow

$$\partial_t (u_h - u)|_{\partial\Omega} = \partial_t (g_h - g) \neq 0. \tag{6.16}$$

We study the case where the boundary value g is discretized as follows:

$$\tilde{g}_h := I_h \tilde{g} \quad \text{and} \quad g_h := \tilde{g}_h|_{\partial\Omega}\,, \tag{6.17}$$

where I_h it the Scott–Zhang interpolator of Lemma 6.2 and $\tilde{g}$ denotes the extension of g to the whole domain Ω [22, eq. (5.5)]. The error $e = u_h - u$ can thus be decomposed as follows:

$$e = e_0 + \epsilon := (u_h - \tilde{g}_h - u + \tilde{g}) + (\tilde{g}_h - \tilde{g}). \tag{6.18}$$

The residual $\mathscr{R}$, as defined in (4.1), can be naturally extended to be a functional on $\mathrm{W}^1_1(\Omega)$. It follows that if we take $\phi = \partial_t e$ in (4.3), we have

$$\langle \mathscr{R} \,|\, \partial_t e \rangle = \langle \mathscr{R} \,|\, \partial_t e_0 \rangle + \langle \mathscr{R} \,|\, \partial_t \epsilon \rangle = \langle \mathscr{R} \,|\, \partial_t e_0 - I_h \partial_t e_0 \rangle + \langle \mathscr{R} \,|\, \partial_t \epsilon \rangle\,. \tag{6.19}$$

Notice that a Galerkin orthogonality argument can be applied directly to the part with the admissible error $e_0 \in \mathring{\mathrm{W}}^1_1$. As for the last term in (6.19), we use the $\mathbb{V}_h$-invariance property of the Scott–Zhang interpolator I_h, namely $I_h I_h \psi = I_h \psi$ for all $\psi \in \mathrm{W}^1_1(\Omega)$, and (6.17) to conclude that

$$I_h \epsilon = I_h \tilde{g}_h - I_h \tilde{g} = I_h I_h \tilde{g} - I_h \tilde{g} = 0.$$

This implies that $\partial_t I_h \epsilon = 0$, and thus $\langle \mathscr{R} \,|\, \partial_t \epsilon \rangle = \langle \mathscr{R} \,|\, \partial_t (\epsilon - I_h \epsilon) \rangle$, whence the following representation formula follows from (6.19) and elementwise integration by parts:

$$\langle \mathscr{R} \,|\, \partial_t e \rangle = \langle r, \partial_t e - I_h \partial_t e \rangle + \langle j, \partial_t e - I_h \partial_t e \rangle + \langle \beta - \beta_h, \partial_t \epsilon \rangle_{\partial\Omega}\,, \tag{6.20}$$

where $\beta := (\nabla u \cdot \boldsymbol{\nu})/Qu$ and $\beta_h = (\nabla u_h \cdot \boldsymbol{\nu})/Qu_h$.

In order to obtain a lower bound on the left-hand side of (6.20), which is equal to the left-hand side of (4.3) with $\phi = \partial_t e$, we proceed in the same fashion as in section 5 and thereby we again derive (5.11). The first two terms on the right-hand

side of (6.20) can be dealt with exactly as in section 6, while the fact that $\beta, \beta_h \leq 1$ implies the following bound for the last term:

$$\langle \beta - \beta_h, \partial_t \epsilon \rangle_{\partial\Omega} \leq 2 \left\| \partial_t \epsilon \right\|_{\mathrm{L}_1(\partial\Omega)} = 2 \left\| \partial_t g - \partial_t g_h \right\|_{\mathrm{L}_1(\partial\Omega)}. \tag{6.21}$$

This proves the following generalization of Lemma 6.4.

LEMMA 6.6 (residual estimate with boundary values). *With the notation* $\mathscr{E}_\partial(t) := \int_0^t \left\| \partial_t (g - g_h) \right\|_{\mathrm{L}_1(\partial\Omega)}$, *we have that, for all* $t \in [0,T]$,

$$\begin{aligned} A(t) + B(t) &\leq {\mathscr{E}_0}^2 + 2\mathscr{E}_\partial(t) + 2\hat{\mathscr{E}}_{2,0}(t) A(t)^{1/2} + 2\hat{\mathscr{E}}_{\infty,0} A(t) \\ &\quad + 2\int_0^t \dot{\mathscr{E}}_{2,1}(s) A(s)^{1/2} \, \mathrm{d}s + 2\int_0^t \dot{\mathscr{E}}_{\infty,1}(s) A(s) \, \mathrm{d}s + 2\int_0^t \varrho(s) A(s) \, \mathrm{d}s. \end{aligned} \tag{6.22}$$

This lemma enables us to obtain extended versions of Theorems 3.6 and 3.4 by just adding $\mathscr{E}_\partial$ to the estimators therein. We omit the statement of these results as they can be written in a straightforward manner.

7. Numerical experiments. We now present some numerical computations that we have performed in order to confirm the reliability and test the sharpness of the error estimates derived in Theorems 3.6 and 3.4. Many of the comments in this section are given as figure captions in order to make the reading easier.

DEFINITION 7.1 (fully discrete semi-implicit scheme [7, 8]). *Let* $N \in \mathbb{Z}^+$ *and* $0 = t_0 < t_1 < \cdots < t_N = T$ *be a partition of the time interval* $[0,T]$. *For each* $n \in [1:N]$, *denote by* $\tau_n := t_n - t_{n-1}$ *the* n*th step size. Given* U_h^0 *(an approximation of* $g(0)$*) and* $\tilde{g}_h^n$ *(the extension to* Ω *of an interpolant of* $g(t_n)$*), find a sequence of functions* $U_h^n \in \mathbb{V}_h$ *such that, for each* $n \in [1:N]$,

$$\left\langle \frac{\nabla U_h^n}{Q U_h^{n-1}}, \nabla \phi_h \right\rangle + \left\langle \frac{U_h^n}{\tau_n Q U_h^{n-1}}, \phi_h \right\rangle = \left\langle \frac{U_h^{n-1}}{\tau_n Q U_h^{n-1}} + f^n, \phi_h \right\rangle \quad \forall \phi_h \in \mathring{\mathbb{V}}_h, \tag{7.1}$$

$$U_h^n - \tilde{g}_h^n \in \mathring{\mathbb{V}}_h. \tag{7.2}$$

We implemented this scheme, which is due to Dziuk [8], with the help of the C finite element toolbox ALBERT of Schmidt and Siebert [21]. All the computations are based on piecewise linear ($\mathbb{P}^1$) finite elements.

7.1. Main goal of the numerical results. With reference to Definition 3.3, we introduce the *full proper estimator* defined as $\widetilde{\mathscr{E}} := ({\mathscr{E}_0}^2 + {\mathscr{E}_2}^2)^{1/2}$, and we recall that we denote by $\mathscr{E}_\infty$ the *vicinity estimator*, by $\mathscr{E}$ the *total estimator*, and by E the *geometric error*, introduced in (1.9). With this notation the *unconditional estimate* of Theorem 3.4 can be written as

$$E \leq C\mathscr{E} = C\left(\widetilde{\mathscr{E}}^2 + C' \mathscr{E}_\infty \right)^{1/2}, \tag{7.3}$$

while the *conditional estimate* provided by Theorem 3.6 can be summarized as follows:

$$\mathscr{E}_\infty \leq c \quad \Rightarrow \quad E \leq \widetilde{C} \widetilde{\mathscr{E}}. \tag{7.4}$$

The main goal of our numerical experiments is to see that the error bound (7.4) is sharp whereas (7.3) is not. This will be illustrated by comparing the *experimental order of convergence (EOC)* of E, $\widetilde{\mathscr{E}}$, and $\mathscr{E}_\infty^{1/2}$. The EOC is defined as follows: for a given finite sequence of uniform triangulations $\{\mathscr{T}_{h_i}\}_{i=1,\ldots,I}$ of meshsize h_i, the EOC

of a corresponding sequence of some triangulation-dependent quantity $e(i)$ (like an error or an estimator) is itself a sequence defined as

$$\operatorname{EOC} e(i) = \frac{\log(e(i+1)/e(i))}{\log(h_{i+1}/h_i)}. \tag{7.5}$$

Notice that for (7.4) to be sharp it is sufficient to have $\operatorname{EOC} E \approx \operatorname{EOC} \widetilde{\mathscr{E}}$ and $\mathscr{E}_\infty = \mathrm{o}(1)$, as i increases—this will be satisfied in our numerical tests—whereas for (7.3) to be sharp it is necessary to have the stronger requirement that $\operatorname{EOC} E \approx \operatorname{EOC} \widetilde{\mathscr{E}}$ and $\operatorname{EOC} E \approx \operatorname{EOC} \mathscr{E}_\infty^{1/2}$—this will fail in our numerical tests. We will focus also on understanding when $\mathscr{E}_\infty = \mathrm{o}(1)$ might fail and on computing the *effectivity index*, which is a practical bound on the constant $\widetilde{C}$, and is defined as $E/\widetilde{\mathscr{E}}$, at the finest level I. Since we view the errors and the estimators as functions of time, the EOC and the effectivity index are also presented as functions of time.

Remark 7.2 (practical version of the error estimators). To test the reliability and the sharpness of the upper bound given by the estimators, we compute a fully discrete version of the spatially discrete global estimators introduced in Definition 3.3. These estimators are sums of the local indicators

$$\eta_i^K(t) := h_K^{d/2}(C_1 \left\|(\partial_t)^i r(t)\right\|_{\mathrm{L}_d(K)} + C_2 \left\|(\partial_t)^i j(t)\right\|_{\mathrm{L}_\infty(\partial K)}), \quad i = 0, 1, \tag{7.6}$$

which involve the L_∞ norm that is not so practical. Since we use piecewise linear elements, the jump residuals are constant functions on each edge, and thus the L_∞ norm can be replaced by the L_2 norm using the inverse estimate

$$\|v\|_{\mathrm{L}_\infty(\partial K)} \le C h_K^{(1-d)/2} \|v\|_{\mathrm{L}_2(\partial K)} \tag{7.7}$$

for all v that are constants on each edge of ∂K. It is hence legitimate to use, instead of η_K^i, the handier local indicators

$$\bar{\eta}_i^K(t) := h_K^{d/2} C_1 \left\|(\partial_t)^i r(t)\right\|_{\mathrm{L}_d(K)} + h_K^{1/2} C_2 \left\|(\partial_t)^i j(t)\right\|_{\mathrm{L}_2(\partial K)}, \quad i = 0, 1. \tag{7.8}$$

All the integrals are in fact quadratures: while ALBERT's built-in Gaussian quadrature is used to approximate the space integrals, a simple midpoint rule is used for the time integrals. Time derivatives are replaced by backward finite differences.

Remark 7.3 (the discrete initial condition). In our computations, we take the *minimal surface projection* for the discrete initial values, i.e., $U_h^0 := u_h(0) = M_h g(0)$, where $M_h v$ is defined, for each $v \in \mathrm{W}_1^1(\Omega)$, as the unique function in $\mathbb{V}_h$ such that

$$\left\langle \frac{\nabla M_h v}{Q M_h v}, \nabla \phi_h \right\rangle = \left\langle \frac{\nabla v}{Qv}, \nabla \phi_h \right\rangle \qquad \forall \phi_h \in \mathring{\mathbb{V}}_h, \tag{7.9}$$

and that interpolates v on the boundary.

This choice of the discrete initial value reduces the initial transients that can occur with other choices for the discrete initial values such as Lagrange interpolation.

Example 7.4 (smooth exact solution on a square). Our first series of tests use the following exact solution as a benchmark:

$$u(x, y; t) = t(\sin(t) - \sin(t - x(1-x)y(1-y))), \quad (x, y, t) \in [0, 1]^2 \times [0, 8]. \tag{7.10}$$

The function u is smooth, it has zero initial and boundary values, which allows us to focus on the effect of the estimators only, and it is the solution of Problem 1.1

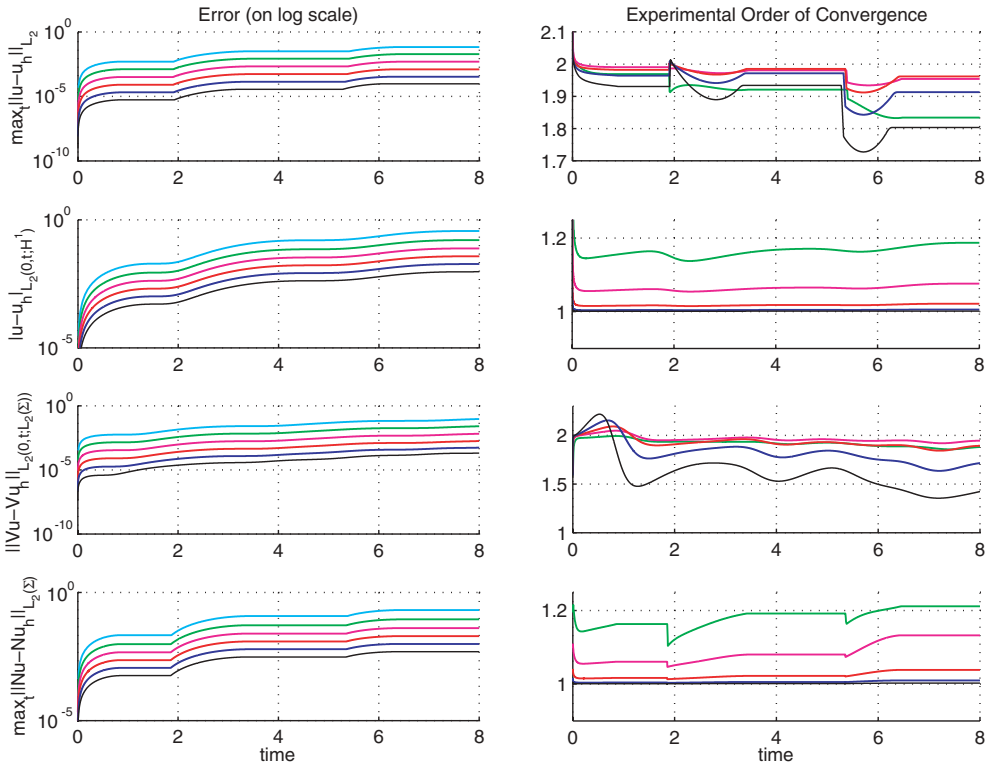

FIG. 7.1. *Errors and EOC vs. time for Example* 7.4. *In the left column, we plot the errors in the customary Sobolev norms, related to the heat equation, and the geometric energy error and normal velocity error introduced in Definition* 1.2. *In the right column, we plot the corresponding EOC. The different gray tones, from light to dark, correspond to the decreasing meshsizes* h. *Notice that the behavior of the Sobolev energy norm error* $|e|_{\mathrm{L}_2(\mathrm{H}^1_0)}$ *and the geometric energy error is similar and that both have EOC close to* 1.

where the right-hand side f is obtained by applying the differential operator of (1.2) on u. We performed a series of computations, on uniform meshes, with the meshsizes $h_i = (0.5)^i$ for $1 \leq i \leq 6$. We report the results in the form of graphs, where the abscissa always denotes the time variable; this allows us to track the behavior of the errors and estimators in time. Figure 7.1 shows the behavior of the exact spatial errors, namely, the geometric errors and those in the customary Sobolev norms for evolution equations. Figure 7.2 shows the behavior of the proper and vicinity estimators with respect to time.

As shown by the right-hand subfigure in Figure 7.1, the $\mathrm{EOC}\, E \approx 1$—this is to be expected from the a priori results, derived in the case of smooth solutions [8]. Although the normal velocity error tends to decrease faster, the geometric error decreases like the geometric energy error, which has order 1.

The sharpness of estimate (7.4) can be seen from the fact that $\mathrm{EOC}\, \widetilde{\mathscr{E}} \approx 1$ and that $\mathscr{E}_\infty \to 0$. On the other hand, we notice that $\mathrm{EOC}\, \mathscr{E}_\infty \leq 1$, which implies that $\mathrm{EOC}(\mathscr{E}_\infty^{1/2}) \prec \mathrm{EOC}\, E$, and thus indicates that the unconditional estimate (7.3) is not sharp.

The effectivity index $\widetilde{C}$, relative to the estimate (7.4), is plotted in Figure 7.3(a) as a function of time. In this example, the effectivity index is bounded in time, and

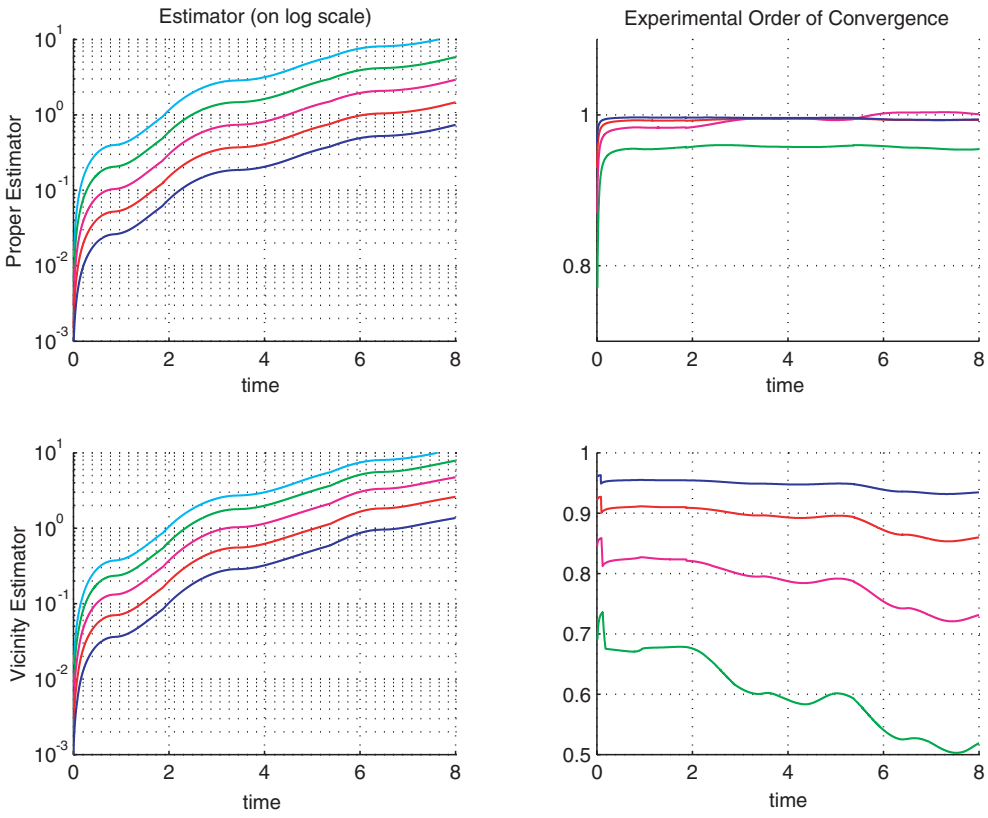

FIG. 7.2. *Estimators and EOC vs. time for Example* 7.4 *for* $i \geq 2$. *The upper panels show the proper estimator* $\widetilde{\mathscr{E}}$ *and the corresponding EOC (notice that in this particular figure we do not plot the proper estimator for the first meshsize* $h = 0.5$*, for reasons of clarity). The lower panels exhibit the vicinity estimator behavior which is seen to converge to zero. According to Figure* 7.1*, we have* $\mathrm{EOC}\, E \approx 1$ *and, according to the current figure, we have* $\mathrm{EOC}\, \widetilde{\mathscr{E}} \approx 1$ *which means that the proper estimator is sharp as expected. Notice also that, for the vicinity estimator, we have* $\mathrm{EOC}\, \mathscr{E}_\infty \approx 0.95 \leq 1$*, which implies that* $\mathrm{EOC}\, \mathscr{E} \leq 1/2$*: this is strong numerical evidence that the unconditional estimate* (7.3) *cannot be sharp, in that the estimators decay with a much lower order than the errors, and justifies the need for the sharper conditional result of Theorem* 3.6.

we do not detect the exponential behavior predicted by the worst-case-scenario bound in (3.19).

Example 7.5 (shrinking spherical segment). This second numerical example is inspired by a simple geometric situation. A sphere that moves by mean curvature flow shrinks to a point in finite time [14]. If we assume that the initial radius of the sphere equals 2 and that the center is fixed at $(0, 0, 0)$, then the segment of the surface that lies above the square $[0, 1] \times [0, 1] \times \{0\} \in \mathbb{R}^3$ is the graph of the function

$$u(\boldsymbol{x}, t) = \sqrt{4 - 4t - |\boldsymbol{x}|^2}, \quad (\boldsymbol{x}, t) \in [0, 1]^2 \times [0, 0.5]. \tag{7.11}$$

The function u thus constitutes a solution of Problem 1.1 with zero right-hand side f and time-dependent Dirichlet boundary value g. This is an interesting example because of a blow-up of the gradient which occurs at the space-time boundary point $(1, 1; 1/2)$.

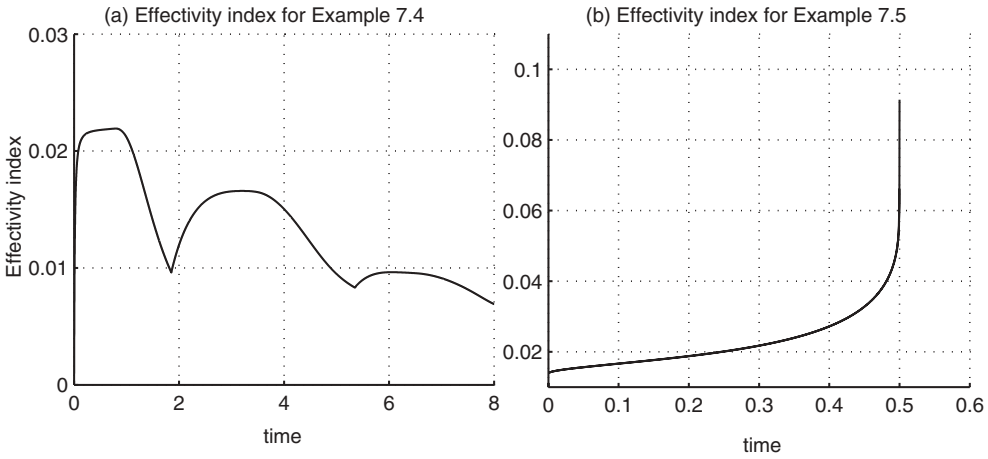

FIG. 7.3. *Effectivity indexes for Examples* 7.4 *and* 7.5. *These indexes, which are defined for the finest mesh, are numerical realizations of the constants on the right-hand side of* (3.16) *or* (3.18). *Panel* (a) *refers to the smooth exact solution of Example* 7.4*; the effectivity index behaves well in time. Panel* (b) *shows the effectivity index for the proper estimator* 7.5*, which has a blow-up at time* $t = 0.5$. *Consequently, the exponential behavior predicted for the factor* C *in Theorem* 3.6 *might be sharp. The behavior of the graph in* (b) *close to* $t = 0.5$ *is to be taken with care, though, as the vicinity estimator blows up there according to Figure* 7.5*, and thus the conditional estimate is not guaranteed to hold anymore.*

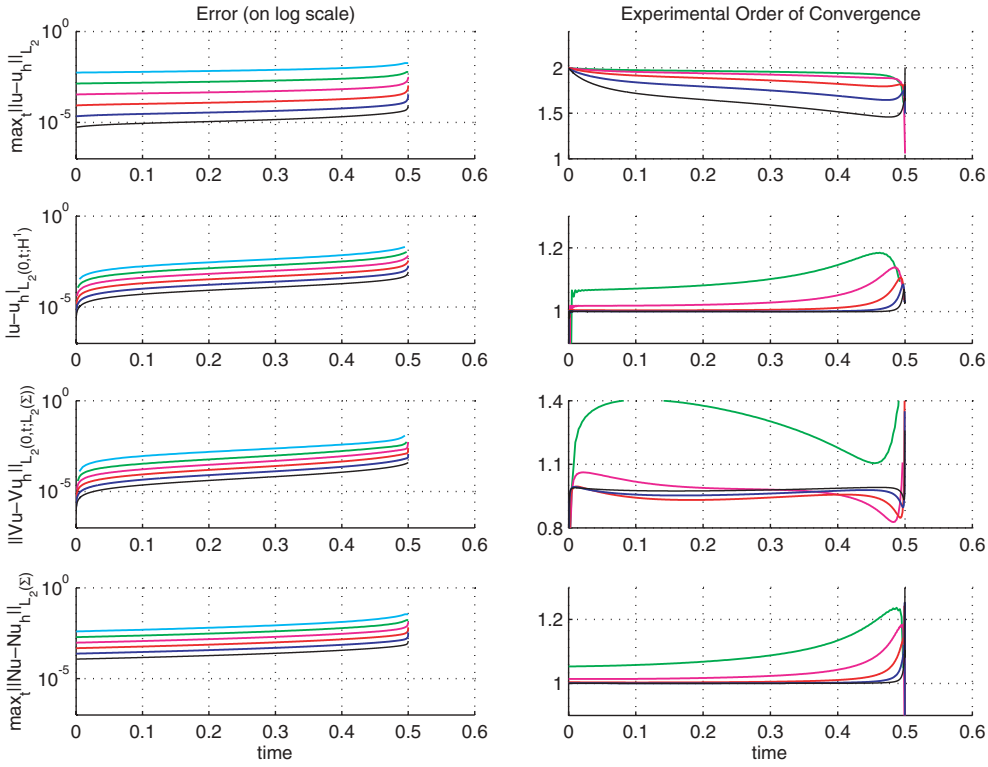

FIG. 7.4. *Sobolev norm errors and geometric errors for the shrinking sphere of Example* 7.5. *The different gray tones correspond to decreasing meshsize* h. *In this example a blow-up in the gradient occurs at the boundary at time* $t = 0.5$.

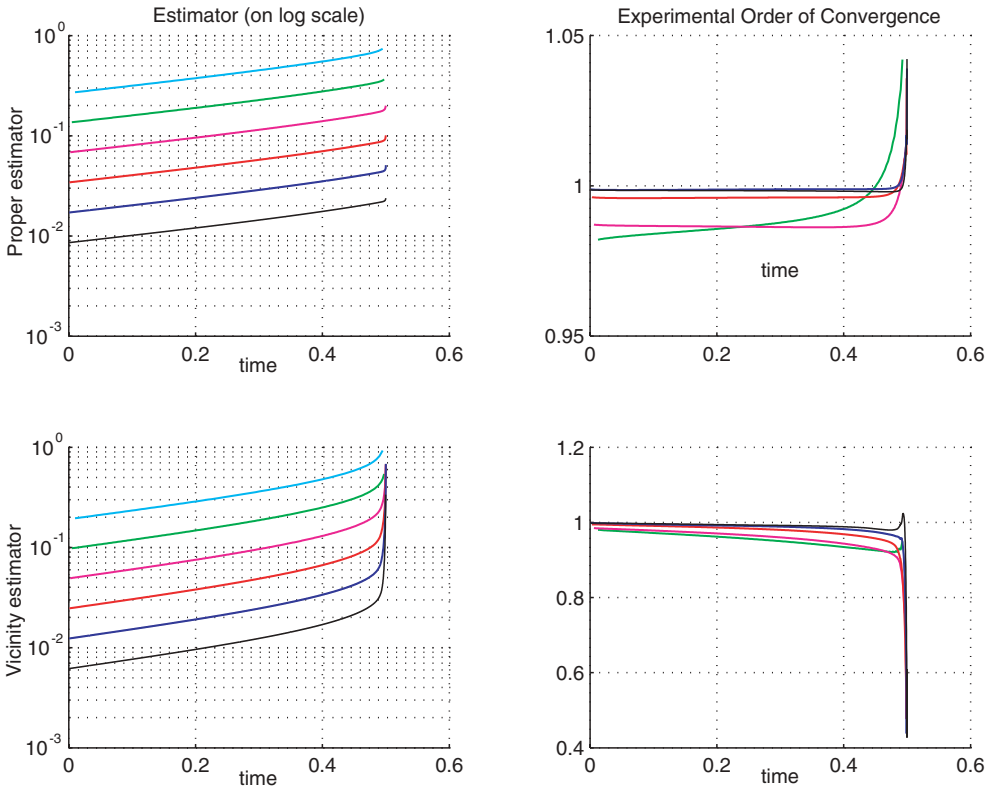

FIG. 7.5. *Estimators and EOC vs. time for the shrinking sphere segment of Example* 7.5. *We exhibit the behavior of the proper estimator in the upper row and that of the vicinity estimator in the lower row. Darker gray tones correspond to decreasing meshsizes* h. *We can observe two stages as time approaches the blow-up* $t = 0.5$. *In the first stage, the same observations made for Example* 7.4 *are valid in that* $\mathrm{EOC}\,\widetilde{\mathscr{E}} \approx \mathrm{EOC}\,E$ *and* $\mathscr{E}_\infty \to 0$ *(justifying once more the need for Theorem* 3.6*). In the second stage, the vicinity estimator* $\mathscr{E}_\infty$ *exhibits a blow-up, which means that the condition* (3.17) *of Theorem* 3.6 *is violated and that we can no longer rely on the proper estimator* $\widetilde{\mathscr{E}}$. *The vicinity estimator blow-up can be interpreted as numerical evidence of the boundary gradient blow-up occurring at* $t = 0.5$.

Despite this singular behavior, the function u still satisfies Assumption 2.1, and our a posteriori error analysis applies. Notice that the a priori error analysis of Deckelnick and Dziuk [7, Prop. 3] does not apply in this case because of the overly stringent regularity assumptions. This example allows us to appreciate the exponential worst-case-scenario bound on $\widetilde{C}$ (factor C in Theorem 3.6), as that bound is expected to behave like $\exp(1/\sqrt{0.5-t})$ as $t \to 0.5$. Numerical solutions have been computed on uniform triangulations with meshsizes $h_i = (0.5)^i$, $i = 2, \ldots, 7$. The type of data we report is similar to that in section 7.4: the errors and their asymptotic behavior are reported in Figure 7.4, while Figure 7.5 shows the behavior of the estimators. We refer to the caption for a comment on the blow-up at $t = 0.5$ and its effect on the estimators and estimate validity. In Figure 7.3(b) we report the effectivity index of the proper estimator, which justifies in part the exponential behavior predicted by the theory. Notice that because of the blow-up behavior, the effectivity index is not so meaningful in the last part of the graph, close to $t = 0.5$, where the vicinity estimator is too big.

Acknowledgments. We express our thanks to Gerhard Dziuk for fruitful discussions, Kunibert Siebert and Alfred Schmidt for introducing us to ALBERT [21], and Claudio Verdi for his advice and support during the stay of O. Lakkis at the Dipartimento di Matematica, Università di Milan, Italy. We are also grateful to the Isaac Newton Institute, Cambridge, UK, where this work was finished. The program *Computational Challenges in PDEs* 2003 at the Isaac Newton Institute provided excellent support as well as a stimulating and friendly scientific environment. Finally, we thank the referees for their careful reading and constructive criticism.

CONVERGENCE OF THE BINOMIAL TREE METHOD FOR AMERICAN OPTIONS IN A JUMP-DIFFUSION MODEL*

XIAO-SONG QIAN†, CHENG-LONG XU‡, LI-SHANG JIANG‡, AND BAO-JUN BIAN‡

Abstract. The paper studies the binomial tree method for American options in a jump-diffusion model. We employ the theory of viscosity solution to show uniform convergence of the binomial tree method for American options. We also prove existence and convergence of the optimal exercise boundary in the binomial tree approximation. In addition, the terminal value of the optimal exercise boundary is given for American options in jump-diffusion models.

Key words. binomial tree method, explicit difference method, American option, jump-diffusion model, integrodifferential equation, viscosity solution

1. Introduction.

Consider a financial market with two assets (B_t, S_t). The first is a risk-free asset whose price B_t is governed by the equation $dB_t = rB_t dt$, where r is the constant positive interest rate; the other is a risky stock. In a given probability space $(\Omega, \mathcal{F}, \mathrm{P})$, the stock price evolves according to the stochastic differential equation

$$\frac{dS_t}{S_t} = (\mu - q)dt + \sigma dW_t + d\left(\sum_{j=1}^{N_t} U_j\right), \tag{1.1}$$

where the coefficients μ, q, σ are positive constants, q is the dividend yield, $(W_t)_{t\geq 0}$ is a standard Brownian motion, $(N_t)_{t\geq 0}$ is a Poisson process with constant intensity λ, and the sequence $(U_j)_{j\geq 1}$ are square integrable independently and identically distributed (i.i.d.) random variables taking values in $(-1, +\infty)$ (since the price of a financial asset should be positive).

Let K be the striking price of option, let S be the price of stock and $z^+ = \max\{z, 0\}$. Then the payoff of an American option is $\varphi(S)$, where $\varphi(S) = (S-K)^+$ (call options) or $\varphi(S) = (K-S)^+$(put options). Because the market here is not complete, according to Harrison and Kreps [7], each equivalent martingale measure Q defines an admissible price of contingent claim. To simplify analysis and focus attention on early exercise considerations, we assume $Q = P$; then we must have $\mu = r - \lambda k$, where $k = E(U_1)$ and E is the expectation operator over the random variable U_1 (see [6]). Using an argument similar to that of Pham [6], it can be shown that an American option's price $V_t = V(S, t)$ solves the following parabolic variational

inequality:

$$\text{(1.2)}\qquad \begin{cases} \min\{-\hat{L}V(S,t), V(S,t)-\varphi(S)\}=0, & S>0,\ 0\le t<T,\\ V(S,T)=\varphi(S), & S>0, \end{cases}$$

where $\hat{L}$ is the parabolic integrodifferential operator

$$\hat{L}V=\frac{\partial V}{\partial t}+\frac{\sigma^2}{2}S^2\frac{\partial^2 V}{\partial S^2}+(r-q-\lambda k)S\frac{\partial V}{\partial S}-(r+\lambda)V+\lambda\int_{-1}^{\infty}V(S(1+y),t)dN(y)$$

and $N(y)$ is the distribution function of random variable U_1.

There is usually no explicit formula for the price of American options, so numerical methods for computing the price of American options are necessary and important. The binomial tree method, as a discrete time model first proposed by Cox, Ross, and Rubinstein [4] is the most popular numerical approach to pricing options in diffusion models. Amin [2] generalized their algorithm to jump-diffusion models. Xu, Qian, and Jiang [10] gave an optimal error estimation of European options in Amin's model. In essence, the binomial tree method belongs to the probabilistic one; however, it can be proved that the binomial tree method is consistent with a certain explicit difference scheme. By virtue of the notion of viscosity solution (see [5]), Barles, Daher, and Romano [3] and Jiang and Dai [8] presented a framework to prove the convergence of difference schemes for parabolic equations in diffusion models. However, in jump-diffusion models, the equations associated to option pricing are so-called integrodifferential equations. Fortunately, Alvarez and Tourin [1] developed the notion of viscosity solution for second order integrodifferential equations. The main purpose of this paper is to use numerical analysis and the theory of viscosity solution to prove the convergence of Amin's binomial tree method for American options in jump-diffusion models. We also show existence and convergence of optimal exercise boundary in the binomial tree approximation.

The rest of this paper is organized as follows. In the next section, the equivalence of the binomial tree method and an explicit difference scheme are discussed. Section 3 is devoted to the convergence proof of the binomial tree method. In section 4, we prove the existence and convergence of approximate optimal exercise boundary. Finally, we give a proof of comparison principle, which is used in section 3.

2. Binomial tree method. First, we recall the binomial tree method developed by Amin [2] when the underlying asset follows a jump-diffusion process. Let $\mathbf{Z}=\{l: l=0,\pm1,\pm2,\ldots\}$, let N be the number of discrete time points, $\Delta t=\frac{T}{N}$, $\rho=e^{r\Delta t}=1+r\Delta t+O(\Delta t^2)$, and let V_j^n be the option price at time point $n\Delta t$ with stock price $e^{j\sigma\sqrt{\Delta t}}$. Then we have (see Amin [2])

$$\text{(2.1)}\qquad \begin{cases} V_j^n=\max\Big\{\frac{1}{\rho}\big[(1-\lambda\Delta t)\left(pV_{j+1}^{n+1}+(1-p)V_{j-1}^{n+1}\right)+\lambda\Delta t\sum_{l\in\mathbf{Z}}V_{j+l}^{n+1}\hat{p}_l\big],\\ \qquad\qquad (e^{j\sigma\sqrt{\Delta t}}-K)^+\Big\}, \qquad j\in\mathbf{Z},\ 0\le n\le N-1,\\ V_j^N=(e^{j\sigma\sqrt{\Delta t}}-K)^+, \qquad j\in\mathbf{Z}, \end{cases}$$

where

$$p=\frac{\frac{e^{(r-q)\Delta t}-\lambda\Delta t\sum_{l\in\mathbf{Z}}e^{l\sigma\sqrt{\Delta t}}\hat{p}_l}{1-\lambda\Delta t}-e^{j\sigma\sqrt{\Delta t}}}{e^{\sigma\sqrt{\Delta t}}-e^{-\sigma\sqrt{\Delta t}}}$$

and

$$\begin{aligned}\hat{p}_l &= \text{Prob}\left(\ln(1+U_1) \in [(l-\tfrac{1}{2})\sigma\sqrt{\Delta t}, (l+\tfrac{1}{2})\sigma\sqrt{\Delta t})\right)\\ &= N(\mathrm{e}^{(l+\frac{1}{2})\sigma\sqrt{\Delta t}} - 1) - N(\mathrm{e}^{(l-\frac{1}{2})\sigma\sqrt{\Delta t}} - 1).\end{aligned}$$

In view of [2], we have

$$\begin{aligned}&\textstyle\sum_{l\in\mathbf{Z}} e^{l\sigma\sqrt{\Delta t}}\hat{p}_l = 1 + k + O(\Delta t),\\ &p = \frac{1}{2} + \left(r - q - \lambda k - \frac{\sigma^2}{2}\right)\frac{\sqrt{\Delta t}}{2\sigma} + O(\Delta t^{\frac{3}{2}}).\end{aligned} \tag{2.2}$$

Then we deduce from (2.1) and (2.2) that

$$\begin{aligned}V_j^n = \max\Bigg\{ &\frac{1-\lambda\Delta t}{1+r\Delta t + O(\Delta t^2)}\left[\left(\frac{1}{2} + \left(r - q - \lambda k - \frac{\sigma^2}{2}\right)\frac{\sqrt{\Delta t}}{2\sigma} + O(\Delta t^{\frac{3}{2}})\right)V_{j+1}^{n+1}\right.\\ &\left. + \left(\frac{1}{2} - \left(r - q - \lambda k - \frac{\sigma^2}{2}\right)\frac{\sqrt{\Delta t}}{2\sigma} + O(\Delta t^{\frac{3}{2}})\right)V_{j-1}^{n+1}\right]\\ &+ \frac{\lambda\Delta t}{1+r\Delta t + O(\Delta t^2)}\sum_{l\in\mathbf{Z}} V_{j+l}^{n+1}\hat{p}_l, \quad (e^{j\sigma\sqrt{\Delta t}} - K)^+\Bigg\}.\end{aligned} \tag{2.3}$$

Next, we discuss the equivalence of the binomial tree method and explicit difference scheme. Let $\mathbf{R}$ be the set of all real numbers, $Q_T = \{(x,t) : 0 \le t < T, x \in \mathbf{R}\}$. Using a simple transformation $S = \mathrm{e}^x$, $v(x,t) = V(S,t)$, (1.2) changes to the constant-coefficients problem

$$\begin{cases} \min\Big\{ - Lv(x,t), v(x,t) - \varphi(e^x)\Big\} = 0, & (x,t) \in Q_T,\\ v(x,T) = \varphi(e^x), & x \in \mathbf{R},\end{cases} \tag{2.4}$$

where L is the operator

$$Lv = \frac{\partial v}{\partial t} + \frac{\sigma^2}{2}\frac{\partial^2 v}{\partial x^2} + \left(r - q - \lambda k - \frac{\sigma^2}{2}\right)\frac{\partial v}{\partial x} - (r+\lambda)v + \lambda\int_{\mathbf{R}} v(x+y,t)d\tilde{N}(y),$$

and $\tilde{N}(y) = N(\mathrm{e}^y - 1)$.

We now present an explicit finite difference scheme for (2.4). Given mesh size $\Delta x, \Delta t, N\Delta t = T$, let $Q_h = \{(n\Delta t, j\Delta x) : 0 \le n \le N, j \in \mathbf{Z}\}$ stand for the set of lattice, v_j^n represent the value of numerical approximation of $v(x,t)$ at $(n\Delta t, j\Delta x) \in Q_h$, and $\varphi_i = \varphi(e^{j\Delta x}) = (e^{j\Delta x} - K)^+$. Then we have

$$\begin{cases} \min\left\{ -\dfrac{v_j^{n+1} - v_j^n}{\Delta t} - \dfrac{\sigma^2}{2}\dfrac{v_{j+1}^{n+1} - 2v_j^{n+1} + v_{j-1}^{n+1}}{\Delta x^2} - \left(r - q - \lambda k - \dfrac{\sigma^2}{2}\right)\dfrac{v_{j+1}^{n+1} - v_{j-1}^{n+1}}{2\Delta x}\right.\\ \qquad \left. + (r+\lambda)v_j^n - \lambda\displaystyle\sum_{l\in\mathbf{Z}} v_{j+l}^{n+1}p_l,\ v_j^n - \varphi_j\right\} = 0, \qquad j \in \mathbf{Z},\ 0 \le n \le N-1,\\ v_j^N = \varphi_j, \qquad j \in \mathbf{Z},\end{cases} \tag{2.5}$$

or

$$v_j^n = \max\left\{ \frac{1}{1+r\Delta t}\frac{1}{1+\frac{\lambda\Delta t}{1+r\Delta t}}\left((1-\frac{\sigma^2\Delta t}{\Delta x^2})v_j^{n+1} + (\frac{\sigma^2\Delta t}{2\Delta x^2} + \left(r-q-\lambda k-\frac{\sigma^2}{2}\right)\frac{\Delta t}{2\Delta x})v_{j+1}^{n+1} \right.\right.$$
$$\left.\left. + (\frac{\sigma^2\Delta t}{2\Delta x^2} - (r-q-\lambda k-\frac{\sigma^2}{2})\frac{\Delta t}{2\Delta x})v_{j-1}^{n+1}\right) + \frac{1}{1+r\Delta t}\cdot\frac{\lambda\Delta t}{1+\frac{\lambda\Delta t}{1+r\Delta t}}\sum_{l\in\mathbf{Z}} v_{j+l}^{n+1}p_l,\ \varphi_i \right\},$$

where

$$p_l = \int_{(l-\frac{1}{2})\Delta x}^{(l+\frac{1}{2})\Delta x} d\tilde{N}(y) = N(e^{(l+\frac{1}{2})\Delta x}-1) - N(e^{(l-\frac{1}{2})\Delta x}-1).$$

If $\sigma^2\Delta t/\Delta x^2 = 1$, then we have

$$p_l = \hat{p}_l \tag{2.6}$$

and

$$\begin{cases} v_j^n = \max\left\{ \frac{1-\lambda\Delta t+O(\Delta t^2)}{1+r\Delta t}\left[(\frac{1}{2}+(r-q-\lambda k-\frac{\sigma^2}{2})\frac{\sqrt{\Delta t}}{2\sigma})v_{j+1}^{n+1}\right.\right. \\ \qquad\left.\left. + (\frac{1}{2}-(r-q-\lambda k-\frac{\sigma^2}{2})\frac{\sqrt{\Delta t}}{2\sigma})v_{j-1}^{n+1}\right] + \frac{\lambda\Delta t+O(\Delta t^2)}{1+r\Delta t}\sum_{l\in\mathbf{Z}} v_{j+l}^{n+1}p_l,\ \varphi_j \right\}, \\ \qquad\qquad j\in\mathbf{Z},\ 0\le n\le \mathbf{N}-1, \\ v_j^N = \varphi_j = (e^{j\sigma\sqrt{\Delta t}}-K)^+, \qquad j\in\mathbf{Z}. \end{cases} \tag{2.7}$$

Comparing (2.3) and (2.7), we deduce the following result.

THEOREM 2.1. *The binomial tree method* (2.1) *is equivalent to the explicit difference scheme* (2.5) *with* $\frac{\sigma^2\Delta t}{\Delta x^2} = 1$ *in the sense of neglecting a higher order* $\Delta t^{\frac{3}{2}}$.

3. Convergence. This section is devoted to the convergence of the binomial tree method. From now on, we will concentrate on American call option. It is easy to generalize all main results to American put option.

Without loss of generality, we assume $\sigma^2\Delta t/\Delta x^2 = 1$ and

$$0 < p < 1, \tag{3.1}$$

which always holds for Δt small enough. In addition, we should assume $q > 0$, because when $q = 0$, an American call option is reduced to the European option.

Now we investigate the properties of the binomial tree method (2.1).

LEMMA 3.1. *The binomial tree method* (2.1) *has the following properties:*

(1) $V_j^n \le V_{j+1}^n$ *for all* j, n.

(2) $V_j^{n+1} \le V_j^n$ *for all* $n < N,\ j$.

(3) $V_j^n \le e^{j\Delta x}$ *for all* j, n.

(4) $V_j^n - V_i^n \le e^{j\Delta x} - e^{i\Delta x}$ *for all* $i \le j,\ n$.

Proof. We use the induction to prove the properties.

(1) Clearly, $V_j^N = \varphi_j \le \varphi_{j+1} = V_{j+1}^N$. If $V_j^{m+1} \le V_{j+1}^{m+1}$ for all j, then

$$\begin{aligned} V_j^m &= \max\left\{\frac{1}{\rho}\left[(1-\lambda\Delta t)(pV_{j+1}^{m+1}+(1-p)V_{j-1}^{m+1})+\lambda\Delta t\sum_{l\in\mathbf{Z}}V_{j+l}^{m+1}p_l\right],\ \varphi_j\right\} \\ &\le \max\left\{\frac{1}{\rho}\left[(1-\lambda\Delta t)(pV_{j+2}^{m+1}+(1-p)V_{j}^{m+1})+\lambda\Delta t\sum_{l\in\mathbf{Z}}V_{j+1+l}^{m+1}p_l\right],\ \varphi_{j+1}\right\} \\ &= V_{j+1}^m, \end{aligned}$$

which is the desired result.

(2) By (2.1), $V_j^{N-1} \ge \varphi_j = V_j^N$. If $V_j^{m+1} \ge V_j^{m+2}$ for all j, then

$$\begin{aligned} V_j^m &= \max\left\{\frac{1}{\rho}\left[(1-\lambda\Delta t)(pV_{j+1}^{m+1}+(1-p)V_{j-1}^{m+1})+\lambda\Delta t\sum_{l\in\mathbf{Z}}V_{j+l}^{m+1}p_l\right],\ \varphi_j\right\} \\ &\ge \max\left\{\frac{1}{\rho}\left[(1-\lambda\Delta t)(pV_{j+1}^{m+2}+(1-p)V_{j-1}^{m+2})+\lambda\Delta t\sum_{l\in\mathbf{Z}}V_{j+l}^{m+2}p_l\right],\ \varphi_j\right\} \\ &= V_j^{m+1}. \end{aligned}$$

Property (2) is proved.

(3) Let V^m denote $\{V_j^m\}_{j\in\mathbf{Z}}$. We introduce a weighted norm $\|\cdot\|$ as follows:

$$\|V^m\| = \sup_{j\in\mathbf{Z}} |e^{-j\Delta x}V_j^m|.$$

It suffices to show that $\|V^m\| \le 1$ for all m. Clearly, $\|V^N\| = \sup_{j\in\mathbf{Z}}|e^{-j\Delta x}\varphi_j| = 1$. If $\|V^{m+1}\| \le 1$, then

$$\begin{aligned} e^{-j\Delta x}V_j^m &= \max\left\{\tfrac{1}{\rho}\left[(1-\lambda\Delta t)(pe^{\Delta x}e^{-(j+1)\Delta x}V_{j+1}^{m+1}+e^{-\Delta x}e^{-(j-1)\Delta x}(1-p)V_{j-1}^{m+1})\right.\right. \\ &\qquad \left.\left. +\ \lambda\Delta t\sum_{l\in\mathbf{Z}}e^{l\Delta x}e^{-(j+l)\Delta x}V_{j+l}^{m+1}p_l\right],\ e^{-j\Delta x}\varphi_j\right\} \\ &\le \max\left\{\frac{\|V^{m+1}\|}{\rho}\left[(1-\lambda\Delta t)(pe^{\Delta x}+(1-p)e^{-\Delta x})+\lambda\Delta t\sum_{l\in\mathbf{Z}}e^{l\Delta x}p_l\right],\ 1\right\}. \end{aligned}$$

Due to

$$pe^{\Delta x}+(1-p)e^{-\Delta x} = \frac{e^{(r-q)\Delta t}-\lambda\Delta t\sum_{l\in\mathbf{Z}}e^{l\Delta x}p_l}{1-\lambda\Delta t}, \tag{3.2}$$

we have

$$\begin{aligned} \|V^m\| &\le \max\left\{\frac{\|V^{m+1}\|}{\rho}e^{(r-q)\Delta t},\ 1\right\} \\ &\le \max\{e^{-q\Delta t},\ 1\} \le 1, \end{aligned}$$

which yields the desired result.

(4) For $i \le j$,

$$V_j^N - V_i^N = (e^{j\Delta x} - K)^+ - (e^{i\Delta x} - K)^+ = \begin{cases} e^{j\Delta x} - e^{i\Delta x} & \text{if } e^{j\Delta x} \ge e^{i\Delta x} \ge K, \\ e^{j\Delta x} - K \le e^{j\Delta x} - e^{i\Delta x} & \text{if } e^{j\Delta x} \ge K \ge e^{i\Delta x}, \\ 0 \le e^{j\Delta x} - e^{i\Delta x} & \text{if } K \ge e^{j\Delta x} \ge e^{i\Delta x}. \end{cases}$$

So we deduce

$$V_j^N - V_i^N = \varphi_j - \varphi_i \le e^{j\Delta x} - e^{i\Delta x} \quad \text{for all } i \le j. \tag{3.3}$$

Suppose $V_j^{m+1} - V_i^{m+1} \le e^{j\Delta x} - e^{i\Delta x}$ for all $i \le j$. To simplify writing, we set

$$I_j^m = (1 - \lambda\Delta t)(pV_{j+1}^m + (1-p)V_{j-1}^m) + \lambda\Delta t \sum_{l\in\mathbf{Z}} V_{j+l}^m p_l.$$

Then

$$\begin{aligned} &\tfrac{1}{\rho} I_j^{m+1} - \tfrac{1}{\rho} I_i^{m+1} \\ &= \tfrac{1}{\rho}\left[[(1-\lambda\Delta t)\big(p(V_{j+1}^{m+1} - V_{i+1}^{m+1}) + (1-p)(V_{j-1}^{m+1} - V_{i-1}^{m+1})\big) \right. \\ &\qquad \left. + \lambda\Delta t \sum_{l\in\mathbf{Z}} (e^{(j+l)\Delta x} - e^{(i+l)\Delta x}) p_l \right] \\ &\le \tfrac{1}{\rho}(e^{j\Delta x} - e^{i\Delta x}) \left[(1-\lambda\Delta t)\big(pe^{j\Delta x} + (1-p)e^{-j\Delta x}\big) + \lambda\Delta t \sum_{l\in\mathbf{Z}} e^{l\Delta x} p_l \right] \\ &= e^{-q\Delta t}\big[e^{j\Delta x} - e^{i\Delta x}\big] \\ &\le e^{j\Delta x} - e^{i\Delta x} \qquad \text{for all } \ i \le j, \end{aligned} \tag{3.4}$$

where the third equality follows from (3.2). So we have

$$V_j^m - V_i^m = \begin{cases} \frac{1}{\rho} I_j^{m+1} - \frac{1}{\rho} I_i^{m+1} & \text{if } \frac{1}{\rho} I_j^{m+1} \ge \varphi_j \text{ and } \frac{1}{\rho} I_i^{m+1} \ge \varphi_i, \\ \varphi_j - \varphi_i & \text{if } \frac{1}{\rho} I_j^{m+1} \le \varphi_j \text{ and } \frac{1}{\rho} I_i^{m+1} \le \varphi_i, \\ \frac{1}{\rho} I_j^{m+1} - \varphi_i \le \frac{1}{\rho} I_j^{m+1} - \frac{1}{\rho} I_i^{m+1} & \text{if } \frac{1}{\rho} I_j^{m+1} \ge \varphi_j \text{ and } \frac{1}{\rho} I_i^{m+1} \le \varphi_i, \\ \varphi_j - \frac{1}{\rho} I_i^{m+1} \le \varphi_j - \varphi_i & \text{if } \frac{1}{\rho} I_j^{m+1} \le \varphi_j \text{ and } \frac{1}{\rho} I_i^{m+1} \ge \varphi_i. \end{cases}$$

In all cases we can deduce from (3.3) and (3.4) that

$$V_j^m - V_i^m \le e^{j\Delta x} - e^{i\Delta x} \qquad \text{for all } \ i \le j,$$

which is the desired result. The proof is completed. □

To simplify notation, (2.1) can be written as

$$V^n = F(\Delta t)(V^{n+1}),$$

where $V^m = \{V_j^m\}_{j\in\mathbf{Z}}$. It is easy to check that $F(\Delta t)$ has the following properties:

LEMMA 3.2. (1) $F(\Delta t)$ *is monotone, i.e.,*

$$F(\Delta t)U \le F(\Delta t)V \qquad \text{if } U \le V.$$

(2) $F(\Delta t)$ *can commute with nonnegative constants, i.e.,*

$$F(\Delta t)(V+K) \le F(\Delta t)V + K, \quad K \ge 0.$$

Let $u_{\Delta t}(x,t)$ be defined as the extension function of V_j^n as follows:

$$u_{\Delta t}(x,t) = \begin{cases} V_j^n \ \text{ for } \ x \in \big[(j-\frac{1}{2})\Delta x, (j+\frac{1}{2})\Delta x\big), t \in \big[(n-\frac{1}{2})\Delta t, (n+\frac{1}{2})\Delta t\big), \\ \qquad j \in \mathbf{Z}, 1 \le n \le N-1, \\ V_j^N \text{ for } \ x \in \big[(j-\frac{1}{2})\Delta x, (j+\frac{1}{2})\Delta x\big), t \in \big[(N-\frac{1}{2})\Delta t, T\big), \ j \in \mathbf{Z}, \\ V_j^0 \ \text{ for } \ x \in \big[(j-\frac{1}{2})\Delta x, (j+\frac{1}{2})\Delta x\big), t \in \big[0, \frac{1}{2}\Delta t\big), \ j \in \mathbf{Z}. \end{cases}$$

By definition and Lemma 3.1(3), we have

$$u_{\Delta t}(x,t) = \big(F(\Delta t)u_{\Delta t}(\,\cdot\,, t+\Delta t)\big)(x) \quad \text{for all } (x,t) \in \mathbf{R} \times [0, T-\Delta t]$$

and

$$0 \le u_{\Delta t}(x,t) \le e^{x+\frac{\Delta x}{2}} \quad \text{for small } \Delta t. \tag{3.5}$$

We will show the convergence of the binomial tree method for American options.

THEOREM 3.3. *As $\Delta t \to 0$, we have that $u_{\Delta t}(x,t)$ converges locally uniformly to $u(x,t)$ in $\mathbf{R} \times [0,T]$, where $u(x,t)$ is the unique solution to the problem* (2.4).

The proof of Theorem 3.3 relies on the notion of viscosity solution. It will be useful to have the notations

$$\mathrm{USC}\big(\mathbf{R} \times [0,T]\big) = \big\{\text{upper semicontinuous functions } u : \ \mathbf{R} \times [0,T] \to \mathbf{R}\big\},$$
$$\mathrm{LSC}\big(\mathbf{R} \times [0,T]\big) = \big\{\text{lower semicontinuous functions } u : \ \mathbf{R} \times [0,T] \to \mathbf{R}\big\}.$$

DEFINITION 3.4. (1) *Any $u \in \mathrm{USC}(\mathbf{R} \times [0,T])(\mathrm{LSC}(\mathbf{R} \times [0,T]))$ is a viscosity subsolution (supersolution) of* (2.4) *if*

$$\begin{cases} \min\Big\{-\dfrac{\partial \phi}{\partial t} - \dfrac{\sigma^2}{2}\dfrac{\partial^2 \phi}{\partial x^2} - \left(r - q - \lambda k - \dfrac{\sigma^2}{2}\right)\dfrac{\partial \phi}{\partial x} + (r+\lambda)u \\ \qquad\qquad - \lambda \displaystyle\int_{\mathbf{R}} \phi(x+y,t)d\tilde{N}(y), u - (e^x - K)^+\Big\} \le 0 \ (\ge 0), \quad (x,t) \in \mathbf{R} \times [0,T), \\ u(x,T) \le \ (\ge) \ (e^x - K)^+, \qquad x \in \mathbf{R}, \end{cases}$$

whenever $\phi \in C^2(\mathbf{R} \times [0,T])$ and $u - \phi$ has a global maximum (minimum) at $(x,t) \in \mathbf{R} \times [0,T)$.

(2) *u is a viscosity solution of* (2.4) *if it is simultaneously a subsolution and a supersolution.*

Now we establish the comparison principle for problem (2.4).

THEOREM 3.5. *Suppose u and v are viscosity subsolution and supersolution of* (2.4) *and*

$$|u(x,t)|, |v(x,t)| \le e^x.$$

Then

$$u \le v \qquad \text{on } \mathbf{R} \times (0,T].$$

The proof of this theorem will be given in the appendix of this paper.

Remark 3.6. By Theorem 3.5, we obtain the uniqueness of problem (2.4) immediately.

Proof of Theorem 3.3. Denote

$$u^*(x,t) = \limsup_{\Delta t \to 0,(y,s)\to(x,t)} u_{\Delta t}(y,s),$$

$$u_*(x,t) = \liminf_{\Delta t \to 0,(y,s)\to(x,t)} u_{\Delta t}(y,s).$$

Owing to (3.5), u^* and u_* are well defined and

$$0 \le u_*(x,t) \le u^*(x,t) \le e^x. \tag{3.6}$$

Obviously, $u^* \in \mathrm{USC}(\mathbf{R}\times[0,T])$ and $u_* \in \mathrm{LSC}(\mathbf{R}\times[0,T])$. If we can show u^* and u_* are subsolution and supersolution of (2.4), respectively, then in terms of Theorem 3.5, we deduce $u^* \le u_*$ and thus $u^* = u_* = u(x,t)$, which guarantees that the whole sequence converges to the unique viscosity solution $u(x,t)$.

We only need to show that u^* is a subsolution of (2.4). It can be shown that $u^*(x,T) = (e^x - K)^+$. Suppose that for $\phi \in C^2(\mathbf{R}\times[0,T))$, $u^* - \phi$ attains a global maximum at $(x_0,t_0) \in \mathbf{R}\times[0,T)$ and $(u^*-\phi)(x_0,t_0) = 0$. We then should assume that (x_0,t_0) is a strict global maximum. Set $\Phi = \phi - \varepsilon, \varepsilon > 0$; then $u^* - \Phi$ attains a strict global maximum at (x_0,t_0) and

$$(u^* - \Phi)(x_0,t_0) > 0. \tag{3.7}$$

By the definition of u^*, there exists a sequence $u_{\Delta t_m}(y_m,s_m)$ such that

$$\Delta t_m \to 0,\ (y_m,s_m)\to(x_0,t_0),\ u_{\Delta t_m}(y_m,s_m)\to u^*(x_0,t_0) \qquad \text{as } m\to+\infty.$$

Assuming that $(\hat y_m,\hat s_m)$ is a global maximum point of $u_{\Delta t_m} - \Phi$ on $\mathbf{R}\times[0,T)$, we can deduce that there is a subsequence $u_{\Delta t_{m_i}}(\hat y_{m_i},\hat s_{m_i})$ such that

$$\Delta t_{m_i} \to 0,\ (\hat y_{m_i},\hat s_{m_i}) \to (x_0,t_0),\ (u_{\Delta t_{m_i}} - \Phi)(\hat y_{m_i},\hat s_{m_i}) \to (u^*-\Phi)(x_0,t_0) \tag{3.8}$$

as $m_i \to +\infty$. Indeed, suppose $(\hat y_{m_i},\hat s_{m_i}) \to (\hat y,\hat s)$; then

$$\begin{aligned}(u^*-\Phi)(x_0,t_0) &= \lim_{m_i\to\infty}(u_{\Delta t_{m_i}} - \Phi)(y_{m_i},s_{m_i})\\ &\le \lim_{m_i\to\infty}(u_{\Delta t_{m_i}} - \Phi)(\hat y_{m_i},\hat s_{m_i}) \le (u^*-\Phi)(\hat y,\hat s),\end{aligned}$$

which forces $(\hat y,\hat s) = (x_0,t_0)$ since (x_0,t_0) is a strict global maximum point of $u^* - \Phi$. Therefore,

$$(u_{\Delta t_{m_i}} - \Phi)(\,\cdot\,,\hat s_{m_i} + \Delta t_{m_i}) \le (u_{\Delta t_{m_i}} - \Phi)(\hat y_{m_i},\hat s_{m_i}) \quad \text{in } \mathbf{R},$$

that is,

$$u_{\Delta t_{m_i}}(\,\cdot\,,\hat s_{m_i} + \Delta t_{m_i}) \le \Phi(\,\cdot\,,\hat s_{m_i} + \Delta t_{m_i}) + (u_{\Delta t_{m_i}} - \Phi)(\hat y_{m_i},\hat s_{m_i}) \quad \text{in } \mathbf{R}. \tag{3.9}$$

From (3.7) and (3.8), we also deduce the important fact

$$(u_{\Delta t_{m_i}} - \Phi)(\hat y_{m_i},\hat s_{m_i}) > 0 \tag{3.10}$$

when m_i is large enough.

Then by (3.7)–(3.10) and Lemma 3.2, we have

$$\begin{aligned} u_{\Delta t_{m_i}}(\hat{y}_{m_i},\hat{s}_{m_i}) &= \Big(F(\Delta t_{m_i})u_{\Delta t_{m_i}}(\,\cdot\,,\hat{s}_{m_i}+\Delta t_{m_i})\Big)(\hat{y}_{m_i}) \\ &\le \Big(F(\Delta t_{m_i})\big(\Phi(\,\cdot\,,\hat{s}_{m_i}+\Delta t_{m_i})+(u_{\Delta t_{m_i}}-\Phi)(\hat{y}_{m_i},\hat{s}_{m_i})\big)\Big)(\hat{y}_{m_i}) \\ &\le \Big(F(\Delta t_{m_i})\Phi(\,\cdot\,,\hat{s}_{m_i}+\Delta t_{m_i})\Big)(\hat{y}_{m_i})+(u_{\Delta t_{m_i}}-\Phi)(\hat{y}_{m_i},\hat{s}_{m_i}). \end{aligned}$$

Thus

$$\Phi(\hat{y}_{m_i},\hat{s}_{m_i})-(F(\Delta t_{m_i})\Phi(\,\cdot\,,\hat{s}_{m_i}+\Delta t_{m_i}))(\hat{y}_{m_i})\le 0. \tag{3.11}$$

Let m_i tend to infinity, and by Theorem 2.1, we get from (3.11) that

$$\begin{aligned} \min\Bigg\{ &-\frac{\partial\Phi}{\partial t}-\frac{\sigma^2}{2}\frac{\partial^2\Phi}{\partial x^2}-\left(r-q-\lambda k-\frac{\sigma^2}{2}\right)\frac{\partial\Phi}{\partial x}+(r+\lambda)\Phi \\ &-\lambda\int_{\mathbf{R}}\Phi(x+y,t)d\tilde{N}(y),\ \Phi-(e^x-K)^+\Bigg\}(x_0,t_0)\le 0. \end{aligned}$$

Letting ε tend to zero, we have

$$\begin{aligned} \min\Bigg\{ &-\frac{\partial\phi}{\partial t}-\frac{\sigma^2}{2}\frac{\partial^2\phi}{\partial x^2}-\left(r-q-\lambda k-\frac{\sigma^2}{2}\right)\frac{\partial\phi}{\partial x}+(r+\lambda)\phi \\ &-\lambda\int_{\mathbf{R}}\phi(x+y,t)d\tilde{N}(y),\ \phi-(e^x-K)^+\Bigg\}(x_0,t_0)\le 0. \end{aligned} \tag{3.12}$$

Recalling that $u^*(x_0,t_0)=\phi(x_0,t_0)$, we conclude from (3.12) that u^* is a subsolution of (2.4). Similarly, we can show that u_* is a supersolution of (2.4). Thus, we have proved $u_{\Delta t}(x,t)$ converges to $u(x,t)$ as $\Delta t\to 0$. Because $u(x,t)$ is continuous and monotone with respect to x and t (see [6]), and $u_{\Delta t}(x,t)$ is also a monotone function of x and t from Lemma 3.1, we know [8, Lemma 4.5] that this convergence is uniform on any semibounded domain $(-\infty,M)\times[0,T]$, which is the desired result. □

Remark 3.7. From Theorem 3.5, we can only deduce that $u^*\le u_*$ on $\mathbf{R}\times(0,T]$. However, we can make some extension of $u_{\Delta t}(x,t)$ by (2.1) for $n=-1,-2,\ldots,-N'$ to let u^* and u_* have definition in $\mathbf{R}\times[-\delta,T]$ for some $\delta=N'\Delta t>0$. It can still be shown that u^* and u_*, satisfying (3.6), are viscosity subsolution and supersolution of problem (2.4) on $\mathbf{R}\times[-\delta,T]$. Then we conclude by Theorem 3.5 that $u^*\le u_*$ on $\mathbf{R}\times(\delta,T]$, which implies $u^*=u_*$ on $\mathbf{R}\times[0,T]$.

4. Optimal exercise boundary. This section investigates properties of optimal exercise boundary (i.e., free boundary). We will show existence and convergence of optimal exercise boundary in the binomial tree method. We also achieve the terminal value $s(T)$ of the optimal exercise boundary $s(t)$ of problem (2.4).

To prove the existence of approximate optimal exercise boundary in the binomial tree method, it suffices to show the following.

LEMMA 4.1. *Let Δt be sufficiently small. For each $n<N$, there exists an integer j_n such that*

$$\begin{cases} V_j^n=\varphi_j>\dfrac{1}{\rho}\left[(1-\lambda\Delta t)\big(pV_{j+1}^{n+1}+(1-p)V_{j-1}^{n+1}\big)+\lambda\Delta t\displaystyle\sum_{l\in\mathbf{Z}}V_{j+l}^{n+1}p_l\right], & j\ge j_n, \\ V_j^n=\dfrac{1}{\rho}\left[(1-\lambda\Delta t)\big(pV_{j+1}^{n+1}+(1-p)V_{j-1}^{n+1}\big)+\lambda\Delta t\displaystyle\sum_{l\in\mathbf{Z}}V_{j+l}^{n+1}p_l\right]\ge\varphi_j, & j<j_n. \end{cases} \tag{4.1}$$

Furthermore, we have

$$j_n \le j_{n-1}.$$

Proof. We use induction to prove this lemma. Let $m_1 = \inf\{j :\ e^{j\Delta x} - K \ge 0\}$. If $j \ge m_1 + 1$, in terms of (3.2), we can get

$$\begin{aligned} I_j^N &= (1-\lambda\Delta t)\big[pV_{j+1}^N + (1-p)V_{j-1}^N\big] + \lambda\Delta t\sum_{l\in\mathbf{Z}} V_{j+l}^N p_l \\ &= (1-\lambda\Delta t)\big[p(e^{(j+1)\Delta x} - K) + (1-p)(e^{(j-1)\Delta x} - K)\big] + \lambda\Delta t\sum_{l\in\mathbf{Z}}(e^{(j+l)\Delta x} - K)^+ p_l \\ &= (1-\lambda\Delta t)e^{j\Delta x}\big[pe^{\Delta x} + (1-p)e^{-\Delta x}\big] - (1-\lambda\Delta t)K + \lambda\Delta t\sum_{l\ge m_1-j}(e^{(j+l)\Delta x} - K)p_l \\ &= e^{j\Delta x+(r-q)\Delta t} - K + \lambda\Delta t\sum_{l<m_1-j}(K - e^{(j+l)\Delta x})p_l, \qquad j \ge m_1+1. \end{aligned}$$

Then

$$\begin{aligned} I_j^N - \rho\varphi_j &= e^{j\Delta x}(e^{(r-q)\Delta t} - e^{r\Delta t}) + K(e^{r\Delta t} - 1) + \lambda\Delta t\sum_{l<m_1-j}(K - e^{(j+l)\Delta x})p_l \\ &= \left[rK - qe^{j\Delta x} + \lambda\sum_{l<m_1-j}(K - e^{(j+l)\Delta x})p_l\right]\frac{\Delta x^2}{\sigma^2} + O(\Delta x^4), \qquad j \ge m_1+1. \end{aligned}$$

Noting that

$$\begin{aligned} \sum_{l<m_1-j}(K - e^{(j+l)\Delta x})p_l &= \sum_{l<m_1-(j+1)}(K - e^{(j+l)\Delta x})p_l + (K - e^{(m_1-1)\Delta x})p_{k_1-j-1} \\ &\ge \sum_{l<m_1-(j+1)}(K - e^{(j+1+l)\Delta x})p_l \end{aligned}$$

and

$$0 \le \sum_{l<m_1-j}(K - e^{(j+l)\Delta x})p_l \le K,$$

it is easy to see that, for Δx small enough and $j \ge m_1 + 1$, $I_j^N - \rho\varphi_j$ is strictly monotonically decreasing with respect to $j\Delta x$ and when j is sufficiently large, we must have $I_j^N - \rho\varphi_j < 0$. So take

$$m_2 = \inf\left\{j \ge m_1 + 1 :\ rK - qe^{j\Delta x} + \lambda\sum_{l<m_1-j}(K - e^{(j+l)\Delta x})p_l \le 0\right\}. \tag{4.2}$$

When $j \ge m_2 + 1$, due to the strict monotonicity of $I_j^N - \rho\varphi_j$, we get $V_j^{N-1} = \varphi_j > \frac{1}{\rho}I_j^N$; when $j < m_1$, $V_j^{N-1} = \frac{1}{\rho}I_j^N \ge 0 = \varphi_j$. At the same time, we have

$$\begin{aligned} I_{m_1}^N - \rho\varphi_{m_1} &= (1-\lambda\Delta t)\big[p\varphi_{m_1+1} + (1-p)\varphi_{m_1-1}\big] + \lambda\Delta t\sum_{l\in\mathbf{Z}}\varphi_{m_1+l}p_l \\ &> \left[rK - qe^{m_1\Delta x} + \lambda\sum_{l<0}\big(K - e^{(m_1+l)\Delta x}\big)p_l\right]\frac{\Delta x^2}{\sigma^2} + O(\Delta x^4) \\ &> I_{m_1+1}^N - \rho\varphi_{m_1+1}, \end{aligned}$$

where the second inequality follows from $\varphi_{m_1-1} = 0 > e^{(m_1-1)\Delta x} - K$. Thus we know that $I_j^N - \rho\varphi_j$ is also strictly monotonically decreasing for $j \geq m_1$. So, when $m_2 = m_1 + 1$, if $\varphi_{m_1} > \frac{1}{\rho} I_{m_1}^N$ we choose $j_{N-1} = m_1 (= m_2 - 1)$; otherwise we choose $j_{N-1} = m_2$ or $m_2 + 1$. When $m_2 > m_1 + 1$, which implies $I_{m_1}^N - \rho\varphi_{m_1} \geq I_{m_1+j}^N - \rho\varphi_{m_1+j} \geq 0$ for $1 \leq j \leq m_2 - m_1 - 1$, we choose $j_{N-1} = m_2$ or $m_2 + 1$. Thus we have shown that there exists $j_{N-1} \in [m_2 - 1, m_2 + 1]$ such that (4.1) holds.

Suppose (4.1) is true when $n = m + 1$. When $j < j_{m+1}$, due to Lemma 3.1(2), we have $\frac{1}{\rho} I_j^{m+1} \geq \frac{1}{\rho} I_j^{m+2} \geq \varphi_j$ (which implies that $j_m \geq j_{m+1}$ if j_m exists); when $j \geq j_{m+1} + 1$,

$$\begin{aligned} I_j^{m+1} - \rho\varphi_j &= (1 - \lambda\Delta t)\big[pV_{j+1}^{m+1} + (1-p)V_{j-1}^{m+1}\big] + \lambda\Delta t \sum_{l\in\mathbf{Z}} V_{j+l}^{m+1} p_l - \rho\varphi_j \\ &= (1 - \lambda\Delta t)\Big[p\varphi_{j+1} + (1-p)\varphi_{j-1}\Big] + \lambda\Delta t \sum_{l\in\mathbf{Z}} V_{j+l}^{m+1} p_l - \rho\varphi_j \\ &= \left[rK - qe^{j\Delta x} + \lambda \sum_{l\in\mathbf{Z}} \big(V_{j+l}^{m+1} - (e^{(j+l)\Delta x} - K)\big) p_l\right] \frac{\Delta x^2}{\sigma^2} + O(\Delta x^4) \\ &= \left[rK - qe^{j\Delta x} + \lambda \sum_{l<j_{m+1}-j} \big(V_{j+l}^{m+1} - e^{(j+l)\Delta x} + K\big) p_l\right] \frac{\Delta x^2}{\sigma^2} + O(\Delta x^4). \end{aligned}$$

From Lemma 3.1(4), we can deduce that $I_j^{m+1} - \rho\varphi_j$ is strictly monotonically decreasing with respect to $j\Delta x$ for Δx small enough and $j \geq j_{m+1} + 1$. From Lemma 3.1(3) we know that $I_j^{m+1} - \rho\varphi_j < 0$ when j is sufficiently large. Take

$$m_3 = \inf\left\{ j \geq j_{m+1} + 1 :\ rK - qe^{j\Delta x} + \lambda \sum_{l<j_{m+1}-j} (V_{j+l}^{m+1} - e^{(j+l)\Delta x} + K) p_l \leq 0 \right\}.$$

Similar to the case of $n = N - 1$, we can show that there exists $j_m \in [m_3 - 1, m_3 + 1]$ such that (4.1) holds. Thus the proof is completed. ∎

By Lemma 4.1, we can define the approximate optimal exercise boundary.

DEFINITION 4.2. *For fixed Δt, define the approximate optimal exercise boundary $x = s_{\Delta t}(t)$ as follows: for $t \in [(n-1)t, n\Delta t]$, $1 \leq n < N$,*

$$s_{\Delta t}(t) = \frac{t - (n-1)\Delta t}{\Delta t} j_n \Delta x + \frac{n\Delta t - t}{\Delta t} j_{n-1} \Delta x.$$

By definition, $s_{\Delta t}(t)$ is monotonically decreasing.

Similar to the proof of Jiang [8, Theorem 4.1(2)] and Lamberton [9, Theorem 3.1], we have the following.

THEOREM 4.3. *If the genuine optimal exercise boundary $s(t)$ of problem (2.4) is continuous, then $s_{\Delta t}(t)$ converges uniformly to $s(t)$ as $\Delta t \to 0$.*

Now we can give the terminal value $s(T)$ of the genuine optimal exercise boundary $s(t)$.

THEOREM 4.4. *If $s(t)$ is continuous, we have*

$$s(T) = \max\{\ln K, x_0\}, \tag{4.3}$$

where x_0 is the unique solution of the equation

$$rK - qe^x + \lambda \int_{-\infty}^{\ln K - x} (K - e^{x+y}) d\tilde{N}(y) = 0. \tag{4.4}$$

Proof. From the proof of Lemma 4.1, we know that $s_{\Delta t}(T - \Delta t) = j_{N-1}\Delta x \in [(m_2 - 1)\Delta x, (m_2 + 1)\Delta x]$, where m_2 is defined by (4.2). Let $\Delta t \to 0$; then we can easily deduce (4.3) from Theorem 4.3 and (4.2) . We only have to verify that equation (4.4) has an unique solution. Let

$$f(x) = rK - qe^x + \lambda \int_{-\infty}^{\ln K - x} (K - e^{x+y}) d\tilde{N}(y);$$

then

$$f'(x) = -qe^x - \lambda \int_{-\infty}^{\ln K - x} e^{x+y} d\tilde{N}(y) < 0$$

and

$$\lim_{x \to +\infty} f(x) = -\infty, \quad \lim_{x \to -\infty} f(x) \geq rK > 0.$$

We conclude that the equation $f(x) = 0$ has a unique solution x_0. The proof is completed. □

Remark 4.5. From Theorem 4.4, we know that for American call options in jump-diffusion models, the terminal value of optimal exercise boundary is $\max\{K, e^{x_0}\}$. When there is no jump, i.e., $\lambda = 0$, the value is $\max\{K, \frac{r}{q}K\}$, which is a well-known result in diffusion models.

Remark 4.6. It's easy to see that the solution of (4.4) tends to infinity as q tends to zero. Then the optimal exercise boundary also tends to infinity. Indeed, when $q = 0$, American call options are equal to European ones. However, when dividends are considered, the valuation of American call options, just as puts, is a free-boundary problem.

Remark 4.7. In this paper American call options are considered because the approximate sequence to call options is not uniformly bounded in the L^∞-norm as opposed to puts. However, it is easy to generalize all main results to American put options. Similarly, for American puts, we can prove that the terminal value of optimal exercise boundary is $\min\{K, e^{y_0}\}$, where y_0 is the unique solution of the following equation:

$$-rK + qe^y + \lambda \int_{\ln K - y}^{+\infty} (e^{x+y} - K) d\tilde{N}(x) = 0.$$

Appendix. Proof of Theorem 3.5. For all $u \in \mathrm{USC}(\mathbf{R} \times [0, T])$ and $(x, t) \in \mathbf{R} \times [0, T)$, we define the parabolic superjet:

$$\begin{aligned} \mathcal{P}^{2,+}u(x,t) = \Big\{ & (a, p, X) \in \mathbf{R} \times \mathbf{R} \times \mathbf{R} / u(y, s) \leq u(x, t) + a(s - t) + p(y - x) \\ & + \frac{X}{2}(y - x)^2 + o(|s - t| + |y - x|^2) \quad \text{as} \quad (y, s) \to (x, t) \Big\} \end{aligned}$$

and its closure

$$\begin{aligned} \bar{\mathcal{P}}^{2,+}u(x,t) = \{ & (a, p, X) = \lim_{n \to \infty} (a_n, p_n, X_n) \text{ with } (a_n, p_n, X_n) \in \mathcal{P}^{2,+}u(x_n, t_n) \\ & \text{and } \lim_{n \to \infty} (x_n, t_n, u(x_n, t_n)) = (x, t, u(x, t)) \}. \end{aligned}$$

Similarly, if $v \in \mathrm{LSC}(\mathbf{R} \times [0,T])$, we consider the parabolic subject $\mathcal{P}^{2,-}v(x,t) = -\mathcal{P}^{2,-}(-v)(x,t)$ and its closure $\overline{\mathcal{P}}^{2,-}v(x,t) = -\overline{\mathcal{P}}^{2,-}(-v)(x,t)$.

Repeating the argument of Alvarez and Tourin, we can obtain another formulation for viscosity solution, as follows.

LEMMA A.1. *Let $u \in \mathrm{USC}(\mathbf{R} \times [0,T])(\mathrm{LSC}(\mathbf{R} \times [0,T])$ and $|u(x,t)| \le e^x$; then u is a viscosity subsolution (supersolution) of* (2.4) *if*

$$\begin{cases} \min\left\{-a - \dfrac{\sigma^2}{2}X - \left(r - q - \lambda k - \dfrac{\sigma^2}{2}\right)p + (r+\lambda)u - \lambda\displaystyle\int_{\mathbf{R}} u(x+y,t)d\tilde{N}(y),\right. \\ \qquad \left. u - (e^x - K)^+\right\} \le 0\ (\ge 0), \quad (x,t) \in \mathbf{R} \times (0,T), \\ \qquad\qquad (a,p,X) \in \ \mathcal{P}^{2,+}u(x,t)(\mathcal{P}^{2,-}u(x,t)), \\ u(x,T) \le\ (\ge)\ (e^x - K)^+, \qquad x \in \mathbf{R}. \end{cases}$$

Using the transformation $v(x,t) = e^x u(x,t)$, (2.4) is transformed into the following equation:

$$\text{(A.1)} \quad \begin{cases} \min\left\{ -\dfrac{\partial u}{\partial t} - \dfrac{\sigma^2}{2}\dfrac{\partial^2 u}{\partial x^2} - \left(r - q - \lambda k + \dfrac{\sigma^2}{2}\right)\dfrac{\partial v}{\partial x} + (q + \lambda + \lambda k)u \right. \\ \qquad \left. - \lambda\displaystyle\int_{\mathbf{R}} u(x+y,t)e^y d\tilde{N}(y), u - g(x)\right\} = 0, \qquad (x,t) \in \mathbf{R} \times [0,T), \\ u(x,T) = g(x), \qquad x \in \mathbf{R}, \end{cases}$$

where $g(x) = (1 - e^{-x}K)^+$.

So we only have to prove comparison for (A.1) with bounded solutions.

Let u and v be subsolution and supersolution of (A.1), respectively, and $|u|, |v| \le 1$. We argue by contradiction and thus assume that

$$\text{(A.2)} \qquad (z,s) \in \mathbf{R} \times (0,T) \quad \text{and} \quad u(z,s) - v(z,s) = \delta > 0.$$

For all $\varepsilon, \alpha, \beta > 0$, we define a function $\Phi(x,y,t)$ in $\mathbf{R} \times \mathbf{R} \times (0,T]$:

$$\Phi(x,y,t) = u(x,t) - v(y,t) - \frac{\varepsilon}{2}(x^2 + y^2) - \frac{\alpha}{2}|x-y|^2 - \frac{\beta}{t}.$$

Since $|u|, |v| \le 1$ and $\lim_{t \to 0} \Phi(x,y,t) = -\infty$, Φ admits a maximum at $(\hat{x}, \hat{y}, \hat{t}) \in \mathbf{R} \times \mathbf{R} \times (0,T]$ (we omit the dependence on ε and α to alleviate notations) and $\hat{x}^2 + \hat{y}^2 < +\infty$ (otherwise $\Phi(\hat{x}, \hat{y}, \hat{t}) \to -\infty$). By (A.2),

$$\text{(A.3)} \qquad \Phi(\hat{x}, \hat{y}, \hat{t}) \ge \delta - \varepsilon z^2 - \frac{\beta}{s} \ge \frac{\delta}{2} > 0 \quad \text{when } \varepsilon \text{ and } \beta \text{ is small enough.}$$

It is easy [5, Lemma 3.1] to check

$$\text{(A.4)} \qquad \lim_{\alpha \to \infty} \alpha|\hat{x} - \hat{y}|^2 = 0.$$

If $\hat{t} = T$, we have

$$0 < \frac{\delta}{2} \le \Phi(\hat{x}, \hat{y}, T) \le g(\hat{x}) - g(\hat{y}) - \frac{\alpha}{2}|\hat{x} - \hat{y}|^2;$$

however, the right-hand side above tends to zero as $\alpha \to \infty$ by (A.4). So $\hat{t} < T$ if α is large.

Applying Theorem 8.3 of [5] to the function $\Phi(x,y,t)$ at $(\hat{x},\hat{y},\hat{t}) \in \mathbf{R}\times\mathbf{R}\times(0,T)$, we can find $a,b,X,Y \in \mathbf{R}$ such that

$$(a, \alpha(\hat{x}-\hat{y})+\varepsilon\hat{x}, X) \in \bar{\mathcal{P}}^{2,+}u(\hat{x},\hat{t}),\ (b, \alpha(\hat{x}-\hat{y})-\varepsilon\hat{y}, Y) \in \bar{\mathcal{P}}^{2,-}v(\hat{y},\hat{t})$$

and

$$a-b=-\frac{\beta}{\hat{t}^2},\quad X-Y \le 2\varepsilon+\frac{2\varepsilon^2}{\alpha}. \tag{A.5}$$

The fact that u and v are, respectively, subsolution and supersolution of (A.1) and Lemma A.1 yields

$$\begin{aligned}\min\Big\{ &-a-\frac{\sigma^2}{2}X-\left(r-q-\lambda k+\frac{\sigma^2}{2}\right)[\alpha(\hat{x}-\hat{y})+\varepsilon\hat{x}]+(q+\lambda+\lambda k)u(\hat{x},\hat{t})\\ &-\lambda\int_{\mathbf{R}} u(\hat{x}+y,\hat{t})e^y d\tilde{N}(y),\ u(\hat{x},\hat{t})-g(\hat{x})\Big\}\le 0\end{aligned}$$

and

$$\begin{aligned}\min\Big\{ &-b-\frac{\sigma^2}{2}Y-\left(r-q-\lambda k+\frac{\sigma^2}{2}\right)[\alpha(\hat{x}-\hat{y})-\varepsilon\hat{y}]+(q+\lambda+\lambda k)v(\hat{y},\hat{t})\\ &-\lambda\int_{\mathbf{R}} v(\hat{y}+y,\hat{t})e^y d\tilde{N}(y),\ v(\hat{y},\hat{t})-g(\hat{y})\Big\}\ge 0.\end{aligned}$$

Subtracting these two inequalities and remarking that $\min(c,d)-\min(e,f)\le 0$ implies either $c-e\le 0$ or $d-f\le 0$; we divide our consideration into two cases:

(1) The first case is

$$\begin{aligned}&(q+\lambda+\lambda k)[u(\hat{x},\hat{t})-v(\hat{y},\hat{t})]-\lambda\int_{\mathbf{R}}[u(\hat{x}+y,\hat{t})-v(\hat{y}+y,\hat{t})]e^y d\tilde{N}(y)\\ &\le -\frac{\beta}{\hat{t}^2}+\frac{\sigma^2}{2}(X-Y)+(r-q-\lambda k+\tfrac{\sigma^2}{2})\varepsilon(\hat{x}+\hat{y}).\end{aligned} \tag{A.6}$$

Because

$$\Phi(\hat{x},\hat{y},\hat{t}) \ge \Phi(\hat{x}+y,\hat{y}+y,\hat{t}),$$

we have

$$u(\hat{x}+y,\hat{t})-v(\hat{y}+y,\hat{t}) \le u(\hat{x},\hat{t})-v(\hat{y},\hat{t})+\varepsilon[y(\hat{x}+\hat{y})+y^2]. \tag{A.7}$$

We conclude from (A.5), (A.6), and (A.7) that

$$\begin{aligned}&\left(q+\lambda+\lambda k-\lambda\int_{\mathbf{R}} e^y d\tilde{N}(y)\right)[u(\hat{x},\hat{t})-v(\hat{y},\hat{t})]\\ &\le -\frac{\beta}{\hat{t}^2}+\frac{\sigma^2}{2}(2\varepsilon+\frac{2\varepsilon^2}{\alpha})+\varepsilon(r-q-\lambda k+\frac{\sigma^2}{2})(\hat{x}+\hat{y})+\varepsilon\lambda\int_{\mathbf{R}} e^y[y(\hat{x}+\hat{y})+y^2]d\tilde{N}(y).\end{aligned} \tag{A.8}$$

We recall that

$$\begin{aligned}&\int_{\mathbf{R}} e^y d\tilde{N}(y)=\int_{-1}^{+\infty}(1+y)dN(y)=1+k,\\ &\int_{\mathbf{R}} e^y y^2 d\tilde{N}(y)=\int_{-1}^{+\infty}(1+y)\ln^2(1+y)dN(y)\le\int_{-1}^{+\infty} y^2 dN(y)<+\infty,\\ &\hat{x}^2+\hat{y}^2<+\infty.\end{aligned} \tag{A.9}$$

At the same time, by (A.3),

$$u(\hat{x},\hat{t}) - v(\hat{y},\hat{t}) \geq \Phi(\hat{x},\hat{y},\hat{t}) \geq \frac{\delta}{2} > 0 \quad \text{if } \varepsilon \text{ is small enough.} \tag{A.10}$$

So by choosing α sufficiently large and sending $\varepsilon \to 0, \beta \to 0$ in (A.8), we deduce from (A.8), (A.9), and (A.10) that

$$0 < \frac{q\delta}{2} \leq 0,$$

which is a contradiction.

(2) The second case occurs if

$$u(\hat{x},\hat{t}) - v(\hat{y},\hat{t}) \leq g(\hat{x}) - g(\hat{y}). \tag{A.11}$$

In view of (A.4), (A.10), and continuity of $g(x)$, we can easily deduce a contradiction from (A.11) when $\alpha \to \infty$. □

A FAMILY OF RECTANGULAR MIXED ELEMENTS WITH A CONTINUOUS FLUX FOR SECOND ORDER ELLIPTIC PROBLEMS*

TODD ARBOGAST† AND MARY F. WHEELER‡

Abstract. We present a family of mixed finite element spaces for second order elliptic equations in two and three space dimensions. Our spaces approximate the vector flux by a continuous function. Our spaces generalize certain spaces used for approximation of Stokes problems. The finite element method incorporates projections of the Dirichlet data and certain low order terms. The method is locally conservative on the average. Suboptimal convergence is proven and demonstrated numerically. The key result is to construct a flux π-projection operator that is bounded in the Sobolev space H^1, preserves a projection of the divergence, and approximates optimally. Moreover, the corresponding Raviart–Thomas flux preserving π-projection operator is an L^2-projection when restricted to this family of spaces.

Key words. mixed finite element method, continuous flux, elliptic equation, error estimates

1. Introduction.

Mixed finite element methods have been used effectively to solve many problems, including second order elliptic problems [10, 15, 31, 34]. Both the scalar variable and its vector flux are approximated directly. While it is necessary to approximate the flux in $H(\mathrm{div})$, the space of L^2 vectors whose divergence is also in L^2, it is not necessary that the flux be fully continuous. In the usual mixed spaces (see, e.g., [12, 13, 14, 17, 29, 31]), only the normal component of the approximate flux is continuous. The tangential components are discontinuous across element boundaries.

In some applications, it is desirable that the flux be continuous. The applications we have in mind come from simulating fluid flow in a porous medium [7, 30, 32]. Miscible displacement in a petroleum reservoir or groundwater transport problems require the solution to a system of equations in model form:

$$ap + \nabla \cdot \mathbf{u} = b, \quad \Omega, \tag{1.1}$$

$$d\mathbf{u} = -\nabla p + \mathbf{c}, \quad \Omega, \tag{1.2}$$

$$\phi \frac{\partial c}{\partial t} - \nabla \cdot \big(D(\mathbf{u})\nabla c - \mathbf{u}c\big) = \hat{c}f^+ - cf^-, \quad \Omega,\ t > 0, \tag{1.3}$$

where p is the pressure, $\mathbf{u}$ is the Darcy velocity (i.e., the flux), c is the concentration of a dissolved chemical that is transported by the flow, and a, b, $\mathbf{c}$, d, ϕ, D, and $\hat{c}$ are

various parameters. To these equations, we must add boundary and initial conditions. For the subsystem (1.1)–(1.2), let $\partial\Omega$ be decomposed into Γ_N and Γ_D, and set

$$\mathbf{u}\cdot\nu = g_N, \quad \Gamma_N, \tag{1.4}$$

$$p = p_D, \quad \Gamma_D, \tag{1.5}$$

where ν is the outer unit normal vector, g_N is the given boundary flux, and p_D is the given boundary pressure.

Since $D(\mathbf{u}) \approx 0$, equation (1.3) is nearly hyperbolic. Characteristic methods have been successful in treating this equation (see, e.g., [4, 20, 22, 23]); however, they rely heavily on the velocity $\mathbf{u}$. To obtain good characteristic trace-backs, $\mathbf{u}_h \approx \mathbf{u}$ should satisfy

(i) $\nabla\cdot\mathbf{u}_h = \mathcal{P}_W f$, where $\mathcal{P}_W$ is an appropriate projection;

(ii) $\mathbf{u}_h$ is continuous.

Property (i) gives a proper divergence to the flow so that mass is conserved, while (ii) is required for consistency in tracing regions through the flow field.

A second application involves the coupling of Stokes flow with Darcy flow in a region with open channel flow adjacent to a porous medium [8]. Usual approaches require that the Stokes equations be approximated by a continuous velocity, since it must remain in H^1. However, this is not properly matched on the open/porous interface to a discontinuous Darcy velocity. A continuous Darcy velocity would therefore be desirable. These spaces have been exploited in [1, 2, 3].

Current mixed methods achieve (i) at the expense of (ii). Our goal is to relax (i), so that it holds only "on the average", but maintain (ii). Brezzi, Fortin, and Marini [16] presented a stabilization technique that allows the use of continuous finite element spaces. Their technique involves a modification of the usual mixed equations. Herein, we provide a family of mixed methods that is stable for the original set of mixed equations. These methods are defined on rectangular grids, and they generalize the Stokes elements of Fortin [24] (cf. Bernardi and Raugel [9]). We present the full development for two dimensions, and discuss the three dimensional case in the last section.

2. Some general notation. Throughout the paper, for domain ω, we denote by $L^p(\omega)$ the usual Lebesgue space of index p, $1 \le p \le \infty$, and by $W^{k,p}(\omega)$ the usual Sobolev space of k weak derivatives in $L^p(\omega)$. We denote by $(\cdot,\cdot)_\omega$ the $L^2(\omega)$ inner product (i.e., Lebesgue integration over ω). Moreover, $\|\cdot\|_{k,\omega}$ is the norm of $H^k(\omega) \equiv W^{k,2}(\omega)$, and $|\cdot|_{r,\omega}$ denotes the $H^r(\omega)$ seminorm. In the notation we may suppress ω when it is Ω. On a domain boundary e, we use the notation $\langle\cdot,\cdot\rangle_e$ for the $L^2(e)$ inner product. For d-dimensional set S, $|S|$ is its d-dimensional Lebesgue measure.

Let $P_k(\omega)$ denote the space of polynomials of degree at most k over the set ω. Moreover, in $\mathbb{R}^2$, let $Q_{i,j}(\omega)$ be the set of polynomials of degree at most i in x and j in y over ω, and similarly define $Q_{i,j,k}(\omega)$ in $\mathbb{R}^3$. We will make use of scaling arguments, so let us define $\hat{R} = [-1,1]^2$ as our reference rectangle. Moreover, let $\hat{\lambda}_j$ denote the Legendre polynomial of degree j on $[-1,1]$. Recall that they are $L^2([-1,1])$-orthogonal polynomials, and that by convention, they are normalized so that $\hat{\lambda}_j(1) = 1$; then also $\hat{\lambda}_j(-1) = (-1)^j$.

Finally, if X is a closed subspace of $L^2(\omega)$, we denote by $\mathcal{P}_X : L^2(\omega) \to X$ the $L^2(\omega)$-projection operator onto X defined for $\psi \in L^2(\omega)$ as the unique $\mathcal{P}_X\psi \in X$ such that

$$(\psi - \mathcal{P}_X\psi, \varphi)_\omega = 0 \quad \forall\varphi \in X.$$

3. An illustrative example. To illustrate our finite element spaces, consider (1.1)–(1.2) in mixed form for $\Omega \subset \mathbb{R}^2$ a bounded domain, with the natural boundary conditions $\Gamma_N = \partial\Omega$ and $g_N = 0$, and a and $\mathbf{c}$ set to 0:

$$(\nabla \cdot \mathbf{u}, w) = (b, w) \qquad \forall w \in L^2(\Omega)/\mathbb{R}, \tag{3.1}$$

$$(d\mathbf{u}, \mathbf{v}) - (p, \nabla \cdot \mathbf{v}) = 0 \quad \forall \mathbf{v} \in H_0(\mathrm{div}; \Omega), \tag{3.2}$$

where $H_0(\mathrm{div}; \Omega)$ is the subset of $H(\mathrm{div}; \Omega)$ with vanishing normal trace on $\partial\Omega$. Let $\mathbf{V}_h \times W_h$ denote some mixed finite element space, and solve (3.1)–(3.2) for $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times W_h$ with the restrictions that $w \in W_h$ and $\mathbf{v} \in \mathbf{V}_h$.

If $\mathbf{V}_h \times W_h$ is the lowest order Raviart–Thomas space [29, 31, 34], the solution $\mathbf{u}_h$ is discontinuous. On a rectangular element R, the x-coordinate of $\mathbf{u}_h$, $u_{h,1}$, is in

$$V_{h,1}^{RT_0}(R) = Q_{1,0}(R).$$

This space has one degree of freedom for each edge normal to the x-direction. If we add four degrees of freedom by defining

$$V_{h,1}(R) = Q_{1,2}(R),$$

the extra corner degrees of freedom allow us to enforce continuity, while the two edge degrees of freedom allow us to maintain the *average* flux across each normal edge, i.e., the proper average divergence of the flow. A similar modification in y, $V_{h,2}(R) = Q_{2,1}(R)$, gives a new element with the required properties on all edges of R. This is a Stokes element due to Fortin [24].

4. The spaces in two dimensions on rectangles. Assume $\Omega \subset \mathbb{R}^2$. Let $\mathcal{T}_h$ denote a quasi-regular, conforming finite element partition of Ω into rectangles of diameter bounded by h. By quasi-regular, we mean that the aspect ratio of the rectangles is bounded by a fixed constant. We now define our family of mixed spaces; it contains the element of the previous section as its lowest order member.

DEFINITION 4.1. *For each integer $k \geq 1$, the linear space $\mathbf{V}_h^k \times W_h^{k-1}$ is defined so that, for any rectangle $R \in \mathcal{T}_h$,*

$$\begin{aligned} \mathbf{V}_h^k(R) &= Q_{k,k+1}(R) \times Q_{k+1,k}(R), \\ W_h^{k-1}(R) &= Q_{k-1,k-1}(R), \end{aligned}$$

and

$$\begin{aligned} \mathbf{V}_h^k &= \{\mathbf{v} \in (C^0(\Omega))^2 : \mathbf{v}|_R \in \mathbf{V}_h^k(R) \quad \forall R \in \mathcal{T}_h\}, \\ W_h^{k-1} &= \{w \in L^2(\Omega) : w|_R \in W_h^{k-1}(R) \quad \forall R \in \mathcal{T}_h\}. \end{aligned}$$

A local basis for $W_h^{k-1}(R)$ is trivial to construct; moreover, since W_h^{k-1} is discontinuous across element boundaries, a global basis can be constructed immediately.

A local nodal basis can be defined for $\mathbf{V}_h^k(R)$ by the degrees of freedom given in the next lemma. Moreover, because these degrees of freedom uniquely determine the function on each edge, they can be pieced together across edges and vertices to form a global basis for the continuous function space $\mathbf{V}_h^k$.

LEMMA 4.2. *For R a rectangle, $\mathbf{u}_h \in \mathbf{V}_h^k(R)$ is uniquely defined by the following degrees of freedom:*

(i) *for each corner point $P \in \partial R$ and Cartesian direction $j = 1, 2$,*

$$DOF^{(\mathrm{i})}_{P,j}(\mathbf{u}_h) = u_{h,j}(P) = \mathbf{u}_h(P) \cdot \mathbf{e}_j;$$

(ii) *on each edge $e \subset \partial R$,*

$$DOF^{(\mathrm{ii})}_{e,\lambda}(\mathbf{u}_h) = \langle \mathbf{u}_h \cdot \tau_e, \lambda \rangle_e \quad \forall \lambda \in P_{k-2}(e),$$

where τ_e is a unit tangential direction;

(iii) *on each edge $e \subset \partial R$,*

$$DOF^{(\mathrm{iii})}_{e,\lambda}(\mathbf{u}_h) = \langle \mathbf{u}_h \cdot \nu_e, \lambda \rangle_e \quad \forall \lambda \in P_{k-1}(e),$$

where ν_e is the outer unit normal direction;

(iv) *over R,*

$$DOF^{(\mathrm{iv})}_{\mathbf{v}}(\mathbf{u}_h) = (\mathbf{u}_h, \mathbf{v})_R \quad \forall \mathbf{v} \in Q_{k-2,k-1}(R) \times Q_{k-1,k-2}(R).$$

Moreover, on each edge $e \subset \partial R$, $\mathbf{u}_h|_e$ is uniquely defined by the degrees of freedom (i)–(iii) *restricted to e.*

Proof. We restrict our analysis to the case where $R = \hat{R} = [-1, 1]^2$; an affine map can be used to show the result for a general rectangle R. As usual, since our function spaces are finite-dimensional vector spaces, the degrees of freedom uniquely determine the function if and only if both the dimension of the function space and the number of independent degrees of freedom agree; whenever the degrees of freedom vanish, the function also vanishes.

We begin by considering $\mathbf{u}_h$ on an edge e. Now $\mathbf{u}_h \cdot \tau_e \in P_k(e)$ and $\mathbf{u}_h \cdot \nu_e \in P_{k+1}(e)$, so the total dimension of this space is $2k + 3$. The number of degrees of freedom that act on e are 4 for (i), $k - 1$ for (ii), k for (iii), and 0 for (iv), leading to the same number $2k + 3$ degrees of freedom on e. Suppose that the degrees of freedom (i)–(iii) restricted to e vanish. We conclude from (i) that

$$\mathbf{u}_h \cdot \tau_e(\xi) = (1 - \xi^2)\, q(\xi),$$

where $q \in P_{k-2}$ (and $\mathbf{u}_h \cdot \tau_e \equiv 0$ if $k = 1$). Then (ii) implies that $q = 0$, and we conclude that $\mathbf{u}_h \cdot \tau_e \equiv 0$ on e. Similarly, we conclude from (i) and (iii) that $\mathbf{u}_h \cdot \nu_e \equiv 0$ on e. We have thereby demonstrated the last statement of the lemma.

Note that the total number of degrees of freedom is 8 for (i), $4(k - 1)$ for (ii), $4k$ for (iii), and $2(k - 1)k$ for (iv), so that the total is $2k^2 + 6k + 4$. This is the same as

$$\dim \mathbf{V}^k_h(R) = 2(k + 1)(k + 2) = 2k^2 + 6k + 4.$$

So suppose that all degrees of freedom of $\mathbf{u}_h$ vanish. We have already shown that then $\mathbf{u}_h|_{\partial R}$ vanishes, so

$$\mathbf{u}_h(x, y) = (1 - x^2)(1 - y^2)\, \mathbf{v}(x, y)$$

for some $\mathbf{v}(x, y) \in Q_{k-2,k-1}(R) \times Q_{k-1,k-2}(R)$. By degree of freedom (iv), we conclude that $\mathbf{v} \equiv 0$, and so also $\mathbf{u}_h \equiv 0$, completing the proof. ∎

For completeness and future reference, we show how to construct an explicit nodal basis on the reference rectangle $\hat{R} = [-1, 1]^2$. A nodal basis has the property that each member has one degree of freedom evaluate to 1 and the rest to 0. Recall that $\hat{\lambda}_j$

is the Legendre polynomial of degree j on $\hat{R}$, that $\langle \hat{\lambda}_i, \hat{\lambda}_j \rangle_{[-1,1]} = 0$ if $i \neq j$, and that $\hat{\lambda}_j(1) = 1$ and $\hat{\lambda}_j(-1) = (-1)^j$. For degrees of freedom (ii)–(iv), we need to select a basis for the test spaces. Since $\{\hat{\lambda}_j\}_{j \leq k}$ forms a basis for $P_k(-1,1)$, we can restrict the polynomials in the degrees of freedom (ii) and (iii) to Legendre polynomials, and to tensor products of such in (iv).

For degree of freedom (i), we define for corner point $P = (-1,-1)$ and direction 1 the basis function

$$\hat{\mathbf{v}}^{(\mathrm{i})}_{P,1} = -\frac{1}{4}(\hat{\lambda}_k(\hat{x}) - \hat{\lambda}_{k-1}(\hat{x}))(\hat{\lambda}_{k+1}(\hat{y}) - \hat{\lambda}_k(\hat{y}))\mathbf{e}_1.$$

This function has the property that it is $\mathbf{e}_1$ at P and vanishes at the three other corner points, and the degrees of freedom (ii)–(iv) vanish. We similarly define a basis function for the other three corner points, and for direction 2. For degree of freedom (ii), with edge $e = (-1,1) \times \{-1\}$ and $\lambda = \hat{\lambda}_j(\hat{x})$, $0 \leq j \leq k-2$, we define

$$\hat{\mathbf{v}}^{(\mathrm{ii})}_{e,j} = \alpha^{(\mathrm{ii})}_{e,j}(\hat{\lambda}_j(\hat{x}) - \hat{\lambda}_{k_j}(\hat{x}))(\hat{\lambda}_{k+1}(\hat{y}) - \hat{\lambda}_k(\hat{y}))\mathbf{e}_1,$$

where k_j is either $k-1$ or k so that k_j and j have the same even/odd parity (i.e., so that $\hat{\lambda}_{k_j}(-1) = \hat{\lambda}_j(-1)$), and $\alpha^{(\mathrm{ii})}_{e,j}$ is chosen to fix the normalization

$$\mathrm{DOF}^{(\mathrm{ii})}_{e,\lambda_j}(\hat{\mathbf{v}}^{(\mathrm{ii})}_{e,j}) = \langle \hat{\mathbf{v}}^{(\mathrm{ii})}_{e,j} \cdot \tau_e, \hat{\lambda}_j \rangle_e = 1.$$

The other basis functions of type (ii) are defined similarly. For degree of freedom (iii), with edge $e = \{-1\} \times (-1,1)$ and $\lambda = \hat{\lambda}_j(\hat{y})$, $0 \leq j \leq k-1$, we define

$$\hat{\mathbf{v}}^{(\mathrm{iii})}_{e,j} = \alpha^{(\mathrm{iii})}_{e,j}(\hat{\lambda}_k(\hat{x}) - \hat{\lambda}_{k-1}(\hat{x}))(\hat{\lambda}_j(\hat{y}) - \hat{\lambda}_{k_j}(\hat{y}))\mathbf{e}_1,$$

where k_j is either k or $k+1$ so that k_j and j have the same parity and $\alpha^{(\mathrm{iii})}_{e,j}$ is chosen to make

$$\mathrm{DOF}^{(\mathrm{iii})}_{e,\lambda_j}(\hat{\mathbf{v}}^{(\mathrm{iii})}_{e,j}) = \langle \hat{\mathbf{v}}^{(\mathrm{iii})}_{e,j} \cdot \nu_e, \hat{\lambda}_j \rangle_e = 1.$$

The other basis functions of type (iii) are defined similarly. Finally, for degree of freedom (iv), with $\mathbf{v} = \hat{\lambda}_j(\hat{x})\hat{\lambda}_\ell(\hat{y})\mathbf{e}_1$, $0 \leq j \leq k-2$, $0 \leq \ell \leq k-1$, we define

$$\hat{\mathbf{v}}^{(\mathrm{iv})}_{j,\ell} = \alpha^{(\mathrm{iv})}_{j,\ell}(\hat{\lambda}_j(\hat{x}) - \hat{\lambda}_{k_j}(\hat{x}))(\hat{\lambda}_\ell(\hat{y}) - \hat{\lambda}_{k_\ell}(\hat{y}))\mathbf{e}_1,$$

where k_j is either $k-1$ or k so that $\hat{\lambda}_{k_j}(-1) = \hat{\lambda}_j(-1)$, and k_ℓ is either k or $k+1$ so that $\hat{\lambda}_{k_\ell}(-1) = \hat{\lambda}_\ell(-1)$, and $\alpha^{(\mathrm{iv})}_{j,\ell}$ is defined so that

$$\mathrm{DOF}^{(\mathrm{iv})}_{\hat{\lambda}_j\hat{\lambda}_\ell}(\hat{\mathbf{v}}^{(\mathrm{iv})}_{j,\ell}) = (\hat{\mathbf{v}}^{(\mathrm{ii})}_{j,\ell}, \hat{\lambda}_j\hat{\lambda}_\ell)_{\hat{R}} = 1.$$

The other type (iv) nodal basis functions are defined similarly.

The nodal basis on $\mathcal{T}_h$ is constructed from these local basis functions via local affine mappings. On $R \in \mathcal{T}_h$, we would map R to $\hat{R}$ by $x \mapsto \hat{x} \equiv (x - x_0)/h_1$ and $y \mapsto \hat{y} \equiv (y - y_0)/h_2$, where R has side lengths h_1 and h_2 and lower left corner (x_0, y_0). The important part of the construction is that the reference basis functions $\hat{\mathbf{v}}^{(\mathrm{i})}, \ldots, \hat{\mathbf{v}}^{(\mathrm{iv})}$ are independent of h.

We close this section with a remark about the finite element basis. We chose degrees of freedom and a local basis that are useful for the numerical analysis that

follows. This is primarily due to degree of freedom (iii), which says that moments of the normal flux are controlled. However, an equivalent set of degrees of freedom would be to replace (ii) and (iii) by evaluation at an appropriate number of points along the boundary. This would be a better basis for implementation, since it is simpler to construct.

5. A π operator. For simplicity, let $\mathcal{P}_W^{k-1} : L^2(\Omega) \to W_h^{k-1}$ denote the $L^2(\Omega)$-projection $\mathcal{P}_{W_h^{k-1}}$. As is usual for mixed spaces, we will define a π operator [15, 21, 31] for our spaces. Our π operator should map $(H^1(\Omega))^2$ onto $\mathbf{V}_h^k$. When $\mathbf{u} \in (H^1(\Omega))^2$, the normal or tangential trace of $\mathbf{u}$ on an edge e is in $H^{1/2}(e)$, and so degrees of freedom (ii) and (iii), and also (iv), are defined. However, degree of freedom (i) causes some problems.

We can resolve the difficulty by using the Clément [19] (or the Scott–Zhang [33]) interpolant $\mathcal{I}^k : H^1(\Omega) \to Q_h^k$, where Q_h^k is the space of continuous functions with $Q_h^k|_R = Q_{k,k}(R)$ for any $R \in \mathcal{T}_h$. For completeness, we define $\mathcal{I}^k$ as in [19]. The interpolant of $\psi \in L^2(\Omega)$ is defined at the nodal points of Q_h^k by setting the value to a local L^2-projection of ψ. Let N denote the set of nodal points of Q_h^k; these are, for example, the union over $R \in \mathcal{T}_h$ of the $(k+1)^2$ grid points of a $k \times k$ uniform grid over R. For each $P \in N$, let

$$\Delta_P = \bigcup_{R \in \mathcal{T}_h \text{ with } P \in R} R$$

be the union of the rectangles containing P. Then define $\psi_P \in Q_{k,k}(\Delta_P)$ by

$$(\psi - \psi_P, \varphi)_{\Delta_P} = 0 \quad \forall \varphi \in Q_{k,k}(\Delta_P),$$

and set $\mathcal{I}^k\psi(P) = \psi_P(P)$. This uniquely defines $\mathcal{I}^k\psi \in Q_h^k$; moreover, we have the estimate

$$\|\psi - \mathcal{I}^k\psi\|_j \le C\|\psi\|_r h^{r-j}, \quad j \le r \le k+1,\ j = 0, 1. \tag{5.1}$$

DEFINITION 5.1. *For $\mathbf{u} \in (H^1(\Omega))^2$, let $\pi^k\mathbf{u} \in \mathbf{V}_h^k$ be defined as the interpolant of the degrees of freedom from Lemma 4.2, modified by the Clément operator $\mathcal{I}^k$. That is, for each $R \in \mathcal{T}_h$, we require the following:*

(1) *For each corner point $P \in \partial R$ and direction $j = 1, 2$,*

$$\pi^k\mathbf{u}(P) \cdot \mathbf{e}_j = \mathcal{I}^k\mathbf{u}(P) \cdot \mathbf{e}_j.$$

(2) *On each edge $e \subset \partial R$,*

$$\langle \pi^k\mathbf{u} \cdot \tau_e, \lambda \rangle_e = \langle \mathbf{u} \cdot \tau_e, \lambda \rangle_e \quad \forall \lambda \in P_{k-2}(e).$$

(3) *On each edge $e \subset \partial R$,*

$$\langle \pi^k\mathbf{u} \cdot \nu_e, \lambda \rangle_e = \langle \mathbf{u} \cdot \nu_e, \lambda \rangle_e \quad \forall \lambda \in P_{k-1}(e).$$

(4) *Over R,*

$$(\pi^k\mathbf{u}, \mathbf{v})_R = (\mathbf{u}, \mathbf{v})_R \quad \forall \mathbf{v} \in Q_{k-2,k-1}(R) \times Q_{k-1,k-2}(R).$$

The operator π^k is linear, and it is well defined by Lemma 4.2. Before deriving properties of this operator, we consider its explicit construction using the global nodal basis given in section 4. Let us denote this basis as $\{\mathbf{v}_{j_1}^{(\mathrm{i})}, \mathbf{v}_{j_2}^{(\mathrm{ii})}, \mathbf{v}_{j_3}^{(\mathrm{iii})}, \mathbf{v}_{j_4}^{(\mathrm{iv})}\}_{j_1,j_2,j_3,j_4}$, where the superscript designates the degree of freedom type, and for consistency of notation below, the index ranges do not overlap. Basis function $\mathbf{v}_{j_2}^{(\mathrm{ii})}$, of degree of freedom type (ii), is defined with respect to some grid edge e_{j_2} and Legendre polynomial λ^{j_2} on e_{j_2}, and similarly for $\mathbf{v}_{j_3}^{(\mathrm{iii})}$. For $\mathbf{v}_{j_4}^{(\mathrm{iv})}$, it is defined with respect to rectangle R_{j_4} and a tensor product of Legendre polynomials $\mathbf{v}^{j_4}$.

We claim that we can represent, for $\mathbf{u} \in (H^1(\Omega))^2$,

$$\begin{aligned}\pi^k\mathbf{u} = \mathcal{I}^k\mathbf{u} &+ \sum_{j_2} \frac{1}{|e_{j_2}|}\langle(\mathbf{u}-\mathcal{I}^k\mathbf{u})\cdot\tau_{e_{j_2}}, \lambda^{j_2}\rangle_{e_{j_2}}\,\mathbf{v}_{j_2}^{(\mathrm{ii})} \\ &+ \sum_{j_3} \frac{1}{|e_{j_3}|}\langle(\mathbf{u}-\mathcal{I}^k\mathbf{u})\cdot\nu_{e_{j_3}}, \lambda^{j_3}\rangle_{e_{j_3}}\,\mathbf{v}_{j_3}^{(\mathrm{iii})} \\ &+ \sum_{j_4} \frac{1}{|R_{j_4}|}(\mathbf{u}-\mathcal{I}^k\mathbf{u}, \mathbf{v}^{j_4})\,\mathbf{v}_{j_4}^{(\mathrm{iv})},\end{aligned} \tag{5.2}$$

which is indeed in $\mathbf{V}_h^k$. We note that, after a local change of variables,

$$\langle\mathbf{v}\cdot\xi,\lambda\rangle_e = |e|\langle\hat{\mathbf{v}}\cdot\hat{\xi},\hat{\lambda}\rangle_{\hat{e}} \quad\text{and}\quad (\mathbf{v},\psi)_R = |R|(\hat{\mathbf{v}},\hat{\psi})_{\hat{R}},$$

and thus by our normalization of the reference basis functions, the degrees of freedom (ii)–(iv) of $\pi^k\mathbf{u}$ match $\mathbf{u}$, and $\pi^k\mathbf{u}$ has the correct values at the grid points.

LEMMA 5.2. *Assume that $u \in (H^1(\Omega))^2$.*

(a) *The linear operator π^k is bounded on $(H^1(\Omega))^2$ independently of h.*

(b) *There exists some constant C independent of h such that for $R \in \mathcal{T}_h$ and $\mathbf{u} \in (H^r(\Delta_R))^2$,*

$$|\pi^k\mathbf{u}-\mathbf{u}|_{j,R} \le C|\mathbf{u}|_{r,\Delta_R}h_R^{r-j}, \quad 1 \le r \le k+1,\ j = 0,1,$$

where $h_R = \operatorname{diam}(R)$ and Δ_R is the union of R and its nearest neighboring elements in $\mathcal{T}_h$.

(c) *For $\mathbf{u} \in (H^r(\Omega))^2$,*

$$|\pi^k\mathbf{u}-\mathbf{u}|_j \le C|\mathbf{u}|_r h^{r-j}, \quad 1 \le r \le k+1,\ j = 0,1.$$

(d) $\mathcal{P}_W^{k-1}\nabla\cdot\mathbf{u} = \mathcal{P}_W^{k-1}\nabla\cdot\pi^k\mathbf{u}$.

Proof. To show (a), we use the representation (5.2) derived above, which when squared implies

$$\begin{aligned}|\pi^k\mathbf{u}|^2 \le |\mathcal{I}^k\mathbf{u}|^2 &+ \sum_{j_2} \frac{1}{|e_{j_2}|^2}|\langle(\mathbf{u}-\mathcal{I}^k\mathbf{u})\cdot\tau_{e_{j_2}}, \lambda^{j_2}\rangle_{e_{j_2}}\,\mathbf{v}_{j_2}^{(\mathrm{ii})}|^2 \\ &+ \sum_{j_3} \frac{1}{|e_{j_3}|^2}|\langle(\mathbf{u}-\mathcal{I}^k\mathbf{u})\cdot\nu_{e_{j_3}}, \lambda^{j_3}\rangle_{e_{j_3}}\mathbf{v}_{j_3}^{(\mathrm{iii})}|^2 \\ &+ \sum_{j_4} \frac{1}{|R_{j_4}|^2}|(\mathbf{u}-\mathcal{I}^k\mathbf{u}, \mathbf{v}^{j_4})\,\mathbf{v}_{j_4}^{(\mathrm{iv})}|^2,\end{aligned}$$

since at each point $x \in \Omega$ the sums are finite with the number depending on k but not on h. A similar expression holds for the gradient, and so, after integrating,

$$\begin{aligned}\|\pi^k \mathbf{u}\|_1^2 \le \|\mathcal{I}^k \mathbf{u}\|_1^2 &+ \sum_{j_2} \frac{1}{|e_{j_2}|^2} \|\langle (\mathbf{u} - \mathcal{I}^k \mathbf{u}) \cdot \tau_{e_{j_2}}, \lambda^{j_2} \rangle_{e_{j_2}}^2 \, \mathbf{v}_{j_2}^{(\mathrm{ii})}\|_1^2 \\ &+ \sum_{j_3} \frac{1}{|e_{j_3}|^2} \|\langle (\mathbf{u} - \mathcal{I}^k \mathbf{u}) \cdot \nu_{e_{j_3}}, \lambda^{j_3} \rangle_{e_{j_3}}^2 \, \mathbf{v}_{j_3}^{(\mathrm{iii})}\|_1^2 \\ &+ \sum_{j_4} \frac{1}{|R_{j_4}|^2} \|(\mathbf{u} - \mathcal{I}^k \mathbf{u}, \mathbf{v}^{j_4})^2 \, \mathbf{v}_{j_4}^{(\mathrm{iv})}\|_1^2. \end{aligned} \tag{5.3}$$

We begin with the second term on the right-hand side above. By the standard affine change of variables $R \mapsto \hat{R}$ and the quasi regularity of the grid, we deduce that for any ψ

$$\|\psi\|_{0,R} = |R|^{1/2} \, \|\hat{\psi}\|_{0,\hat{R}}, \tag{5.4}$$

$$|\psi|_{1,R} \le C|R|^{1/2} h^{-1} \, |\hat{\psi}|_{1,\hat{R}} \le C \, |\hat{\psi}|_{1,\hat{R}} \le C \, |\psi|_{1,R}, \tag{5.5}$$

since in two dimensions $|R|^{1/2} = O(h)$. Now

$$\|\mathbf{v}_{j_2}^{(\mathrm{ii})}\|_1 = \left\{ \sum_R \|\mathbf{v}_{j_2}^{(\mathrm{ii})}\|_{1,R}^2 \right\}^{1/2} \le C \left\{ \sum_R \|\hat{\mathbf{v}}_{j_2}^{(\mathrm{ii})}\|_{1,\hat{R}}^2 \right\}^{1/2} \le C,$$

since $\hat{\mathbf{v}}_{j_2}^{(\mathrm{ii})}$ is supported in at most four rectangles and is independent of h. Moreover, if $e_{j_2} \subset R' \in \mathcal{T}_h$, then by the trace theorem (see, e.g., [26]),

$$\begin{aligned}\frac{1}{|e_{j_2}|} |\langle \mathbf{v} \cdot \tau_{e_{j_2}}, \lambda^{j_2} \rangle_{e_{j_2}}| &= |\langle \hat{\mathbf{v}} \cdot \hat{\tau}_{\hat{e}_{j_2}}, \hat{\lambda}^{j_2} \rangle_{\hat{e}_{j_2}}| \\ &\le C \|\hat{\mathbf{v}}\|_{1,\hat{R}'} \|\hat{\lambda}^{j_2}\|_{0,\hat{e}_{j_2}} \le C\big\{ h^{-1} \|\mathbf{v}\|_{0,R'} + |\mathbf{v}|_{1,R'} \big\}, \end{aligned}$$

and so

$$\begin{aligned}\sum_{j_2} \frac{1}{|e_{j_2}|^2} \|\langle \mathbf{v} \cdot \tau_{e_{j_2}}, \lambda^{j_2} \rangle_{e_{j_2}} \mathbf{v}_{j_2}^{(\mathrm{ii})}\|_1^2 &\le C \sum_{j_2} \big\{ h^{-1} \|\mathbf{v}\|_{0,R'} + |\mathbf{v}|_{1,R'} \big\}^2 \\ &\le C\big\{ h^{-2} \|\mathbf{v}\|_0^2 + |\mathbf{v}|_1^2 \big\}, \end{aligned} \tag{5.6}$$

since a given rectangle $R' \supset e_{j_2}$ appears at most four times in the sum. Similarly,

$$\sum_{j_3} \frac{1}{|e_{j_3}|^2} \|\langle \mathbf{v} \cdot \nu_{e_{j_3}}, \lambda^{j_3} \rangle_{e_{j_3}} \mathbf{v}_{j_3}^{(\mathrm{iii})}\|_1^2 \le C\big\{ h^{-2} \|\mathbf{v}\|_0^2 + |\mathbf{v}|_1^2 \big\} \tag{5.7}$$

and

$$\sum_{j_4} \frac{1}{|R_{j_4}|^2} \|(\mathbf{v}, \mathbf{v}^{j_4}) \, \mathbf{v}_{j_4}^{(\mathrm{iv})}\|_1^2 \le C h^{-2} \|\mathbf{v}\|_0^2 \, . \tag{5.8}$$

Thus from (5.3) we deduce that

$$\|\pi^k \mathbf{u}\|_1 \le C\big\{ \|\mathcal{I}^k \mathbf{u}\|_1 + h^{-1} \|\mathbf{u} - \mathcal{I}^k \mathbf{u}\|_0 + |\mathbf{u} - \mathcal{I}^k \mathbf{u}|_1 \big\} \le C \|\mathbf{u}\|_1. \tag{5.9}$$

Now (b), with $j = 1$, follows from the Bramble–Hilbert lemma [10], since locally π^k is a kth degree polynomial preserving operator. To prove the $j = 0$ case when $k > 1$, we need only compute

$$\|\mathbf{u} - \pi^k \mathbf{u}\|_{0,R}^2 = \|\mathbf{u} - \bar{\mathbf{u}} - (\pi^k \mathbf{u} - \overline{\pi^k \mathbf{u}})\|_{0,R}^2 \le C \|\mathbf{u} - \pi^k \mathbf{u}\|_{1,R}^2 h^2,$$

where the over-line denotes the local average and we use the fact that $\bar{\mathbf{u}} = \overline{\pi^k \mathbf{u}}$ by degree of freedom (iv). The case of $k = 1$ follows directly from a careful scaling analysis of (5.2) as above and (5.1). The argument appears in [26]: noting (5.4) and modifying (5.6)–(5.8), we see as in (5.9) that

$$\begin{aligned}
\|\mathbf{u} - \pi^k \mathbf{u}\|_0 &\le \|\mathbf{u} - \mathcal{I}^k \mathbf{u}\|_0 + \sum_{j_2} \frac{1}{|e_{j_2}|} \|\langle (\mathbf{u} - \mathcal{I}^k \mathbf{u}) \cdot \tau_{e_{j_2}}, \lambda^{j_2} \rangle_{e_{j_2}} \mathbf{v}_{j_2}^{(\mathrm{ii})}\|_0 \\
&\quad + \sum_{j_3} \frac{1}{|e_{j_3}|} \|\langle (\mathbf{u} - \mathcal{I}^k \mathbf{u}) \cdot \nu_{e_{j_3}}, \lambda^{j_3} \rangle_{e_{j_3}} \mathbf{v}_{j_3}^{(\mathrm{iii})}\|_0 \\
&\quad + \sum_{j_4} \frac{1}{|R_{j_4}|} \|(\mathbf{u} - \mathcal{I}^k \mathbf{u}, \mathbf{v}^{j_4}) \mathbf{v}_{j_4}^{(\mathrm{iv})}\|_0 \\
&\le C \big\{ \|\mathbf{u} - \mathcal{I}^k \mathbf{u}\|_0 + h |\mathbf{u} - \mathcal{I}^k \mathbf{u}|_1 \big\} \le C h^r \|\mathbf{u}\|_r,
\end{aligned}$$

where $r = 1$ or 2.

Result (c) follows from (b). For (d), let $w \in W_h^{k-1}$ and compute

$$\begin{aligned}
(\nabla \cdot \mathbf{u}, w)_R &= \langle \mathbf{u} \cdot \nu, w \rangle_{\partial R} - (\mathbf{u}, \nabla w)_R \\
&= \langle \pi^k \mathbf{u} \cdot \nu, w \rangle_{\partial R} - (\pi^k \mathbf{u}, \nabla w)_R = (\nabla \cdot \pi^k \mathbf{u}, w)_R,
\end{aligned}$$

since $w|_e \in P_{k-1}(e)$ and $\nabla w|_R \in Q_{k-2,k-1}(R) \times Q_{k-1,k-2}(R)$. ∎

Remark 5.1. The usual mixed spaces satisfy

$$\mathcal{P}_{W_{h,usual}} \nabla \cdot \mathbf{u} = \nabla \cdot \pi_{usual} u, \tag{5.10}$$

since $\nabla \cdot \mathbf{V}_{h,usual} \subset W_{h,usual}$. This is *not* true for the spaces of Definition 4.1.

Our spaces can be viewed as generalizations of the Raviart–Thomas spaces RT_{k-1} [29, 31]. Our analysis will make strong use of the RT_{k-1}-projection operator $\tilde{\pi}^{k-1}$. We briefly review RT_{k-1}. By definition,

$$RT_{k-1} = \tilde{\mathbf{V}}_h^{k-1} \times W_h^{k-1},$$

where

$$\begin{aligned}
&\tilde{\mathbf{V}}_h^{k-1}(R) = Q_{k,k-1}(R) \times Q_{k-1,k}(R), \\
&\tilde{\mathbf{V}}_h^{k-1} = \{ \mathbf{v} \in H(\mathrm{div}; \Omega) : \mathbf{v}|_R \in \tilde{\mathbf{V}}_h^{k-1}(R) \quad \forall R \in \mathcal{T}_h \}.
\end{aligned}$$

The operator

$$\tilde{\pi}^{k-1} : (H^1(\Omega))^2 \to \tilde{\mathbf{V}}_h^{k-1}$$

is defined on a rectangle R by the degrees of freedom

(i) $\langle \tilde{\pi}^{k-1} \mathbf{u} \cdot \nu, \lambda \rangle_e = \langle \mathbf{u} \cdot \nu, \lambda \rangle_e$ for all $\lambda \in P_{k-1}(e)$ and edges $e \subset \partial R$,

(ii) $(\tilde{\pi}^{k-1} \mathbf{u}, \mathbf{v})_R = (\mathbf{u}, \mathbf{v})_R$ for all $\mathbf{v} \in Q_{k-2,k-1}(R) \times Q_{k-1,k-2}(R)$.

We recall that

$$\nabla \cdot \tilde{\pi}^{k-1}\mathbf{u} = \mathcal{P}_W^{k-1}\nabla \cdot \mathbf{u}, \tag{5.11}$$

$$\|\mathbf{u} - \tilde{\pi}^{k-1}\mathbf{u}\|_0 \le C\|\mathbf{u}\|_r h^r, \quad 1 \le r \le k. \tag{5.12}$$

Let $\mathcal{P}_{\tilde{V}}^{k-1} : (L^2(\Omega))^2 \to \tilde{\mathbf{V}}_h^{k-1}$ denote projection $\mathcal{P}_{\tilde{V}_h^{k-1}}$. Relations between π^k and $\tilde{\pi}^{k-1}$ are given as follows.

LEMMA 5.3. *Assume that* $\mathbf{u} \in (H^1(\Omega))^2$.

(a) $\tilde{\pi}^{k-1}\pi^k\mathbf{u} = \tilde{\pi}^{k-1}\mathbf{u}$.

(b) $\tilde{\pi}^{k-1}\mathbf{u} = \mathcal{P}_{\tilde{V}}^{k-1}\pi^k\mathbf{u}$.

(c) $\tilde{\pi}^{k-1}\mathbf{u} = \mathcal{P}_{\tilde{V}}^{k-1}\mathbf{u}$, *provided* $\mathbf{u} \in \mathbf{V}_h^k$.

Proof. For (a), π^k preserves the degrees of freedom of $\tilde{\pi}^{k-1}$. Result (b) is a corollary of (a) and (c).

For (c), since $\tilde{\pi}^{k-1}$ is constructed locally on each element, we restrict our analysis to a rectangle R. Assume without loss of generality that $R = \hat{R}$. Since x and y components are independent, we consider only x-components. Then

$$\tilde{V}_{h,1}^{k-1} = \text{span}\{\lambda_i(x)\lambda_j(y) : i \le k\ ,\ j \le k-1\},$$
$$V_{h,1}^{k} = \text{span}\{\lambda_i(x)\lambda_j(y) : i \le k\ ,\ j \le k+1\}.$$

We wish to show that for $\mathbf{u} \in \mathbf{V}_h^k(R)$,

$$((\tilde{\pi}^{k-1}\mathbf{u})_1 - u_1, v_1)_R = 0 \quad \forall\ v_1 \in \tilde{V}_{h,1}^{k-1}(R).$$

If $\mathbf{u} \in \tilde{\mathbf{V}}_h^{k-1}(R)$, the result is trivial, so assume

$$u_1 \in \text{span}\{\lambda_i(x)\lambda_j(y) : i \le k, \quad j = k, k+1\}.$$

Then $(u_1, v_1)_R = 0$ for all $v_1 \in \tilde{V}_{h,1}^{k-1}(R)$. Moreover, if e is an edge of ∂R with x constant (i.e., with $\nu = \mathbf{e}_1$), then by the orthogonality of the Legendre polynomials,

(i) $\langle u_1(x,\cdot), q\rangle_e = 0$ for all $q(y) \in P_{k-1}(e)$,

(ii) $(u_1, v_1)_R = 0$ for all $v_1 \in Q_{k-2,k-1}(R)$.

These are the degrees of freedom that define the x-component of $\tilde{\pi}^{k-1}$, and so $(\tilde{\pi}^{k-1}\mathbf{u})_1 = 0 = (\mathcal{P}_{\tilde{V}}^{k-1}\mathbf{u})_1$. ∎

6. A mixed finite element method. To approximate (1.1)–(1.2), (1.4)–(1.5), we first rewrite the equations in mixed variational form. Let

$$\mathbf{V}_0 = \{\mathbf{v} \in H(\text{div};\Omega) : \mathbf{v} \cdot \nu = 0 \text{ on } \Gamma_N\},$$

and $W = L^2(\Omega)$, unless $a \equiv 0$ and $\Gamma_N = \partial\Omega$ (the pure Neumann problem), in which case $W = \{w \in L^2(\Omega) : \int_\Omega w = 0\}$. In the latter case, we also assume the usual compatibility condition between b and g_N.

We find $(\mathbf{u}, p) \in H(\text{div};\Omega) \times W$ such that $\mathbf{u} \cdot \nu = g_N$ on Γ_N and

$$(ap, w) + (\nabla \cdot \mathbf{u}, w) = (b, w) \qquad \forall w \in W, \tag{6.1}$$

$$(d\mathbf{u}, \mathbf{v}) - (p, \nabla \cdot \mathbf{v}) = -\langle p_D, \mathbf{v} \cdot \nu\rangle_{\Gamma_D} + (\mathbf{c}, \mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{V}_0. \tag{6.2}$$

Normally one merely restricts to the finite element spaces to define the mixed method. For our spaces, however, this is not the proper definition of the method

when nonhomogeneous boundary terms appear. We assume that the grid is such that for any edge $e \subset R \in \mathcal{T}_h$, either $e \subset \Gamma_N$ or $e \subset \Gamma_D$.

We begin with Dirichlet conditions. Let us define for edge $e \subset \Gamma_N \cap \partial R$, $R \in \mathcal{T}_h$,

$$\Lambda_h^k(e) = \mathbf{V}_h^k(R) \cdot \nu = P_{k+1}(e),$$
$$\tilde{\Lambda}_h^{k-1}(e) = \tilde{\mathbf{V}}_h^{k-1}(R) \cdot \nu = P_{k-1}(e),$$

and the full spaces Λ_h^k of continuous functions and $\tilde{\Lambda}_h^{k-1}$ of discontinuous functions over Γ_N. With the definition $\mathcal{P}_{\tilde{\Lambda}}^{k-1} = \mathcal{P}_{\tilde{\Lambda}_h^{k-1}}$, we replace p_D by $\mathcal{P}_{\tilde{\Lambda}}^{k-1} p_D$ in the equations.

For Neumann conditions, we need to set $\mathbf{u}_h \cdot \nu$ on Γ_N. This can be done in any reasonable way, but for the error analysis to follow it is convenient to set $\mathbf{u}_h \cdot \nu$ to $\pi^k \mathbf{u}$. Since $\mathbf{u}$ is unknown, we need to define it using only g_N. Near the boundary only, we use the Scott–Zhang [33] modification of the Clément operator $\mathcal{I}^k$ [19] considered in section 5, which has similar properties, except that in (5.1) we must have $r \geq 1$. We set the corner values to a local L^2-projection defined entirely on the boundary of the domain, instead of over rectangles in the domain, so that $\mathcal{I}^k \mathbf{u} \cdot \nu|_{\Gamma_N}$ is defined entirely by $\mathbf{u} \cdot \nu|_{\Gamma_N} = g_N$. Further, we can define an operator $\mathcal{I}_\Lambda^k : L^2(\Gamma_N) \to \Lambda_h^k$ by

$$\mathcal{I}_\Lambda^k g(P) = \mathcal{I}^k g(P)$$

for each corner point P of the grid restricted to Γ_N, and, on each grid edge $e \subset \Gamma_N$,

$$\langle \mathcal{I}_\Lambda^k g, \lambda \rangle_e = \langle g, \lambda \rangle_e \quad \forall \lambda \in P_k(e).$$

Then it is easy to check that

$$\pi^k \mathbf{u} \cdot \nu|_{\Gamma_N} = \mathcal{I}_\Lambda^k g_N.$$

Finally, to set the Neumann boundary condition, we set $\mathbf{u}_h \cdot \nu = \mathcal{I}_\Lambda^k g_N$ on Γ_N.

Let

$$\mathbf{V}_{h,0}^k = \{\mathbf{v} \in \mathbf{V}_h^k : \mathbf{v} \cdot \nu = 0 \text{ on } \Gamma_N\}.$$

We now define our mixed finite element method for (6.1)–(6.2). Find $(\mathbf{u}_h, p_h) \in \mathbf{V}_h^k \times W_h^{k-1}$ such that $\mathbf{u}_h \cdot \nu = \mathcal{I}_\Lambda^k g_N$ on Γ_N and

$$(ap_h, w_h) + (\nabla \cdot \mathbf{u}_h, w_h) = (b, w_h) \qquad \forall w_h \in W_h, \tag{6.3}$$
$$(d\mathbf{u}_h, \mathbf{v}_h) - (p_h, \nabla \cdot \mathbf{v}_h) = -\langle \mathcal{P}_{\tilde{\Lambda}}^{k-1} p_D, \mathbf{v}_h \cdot \nu \rangle_{\Gamma_D} + (\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} \mathbf{c}, \mathbf{v}_h) \quad \forall \mathbf{v}_h \in \mathbf{V}_{h,0}^k. \tag{6.4}$$

7. Mixed method error analysis. We now analyze the error in approximating (6.1)–(6.2) by (6.3)–(6.4). In (6.2) let $\mathbf{v}$ be replaced by $\tilde{\pi}^{k-1} \mathbf{v}_h$ for $\mathbf{v}_h \in \mathbf{V}_{h,0}^k$. By Lemma 5.3, $\tilde{\pi}^{k-1} \mathbf{v}_h = \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} \mathbf{v}_h$, and with (5.11) we obtain

$$\begin{aligned}(\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u}, \mathbf{v}_h) - (\mathcal{P}_W^{k-1} p, \nabla \cdot \mathbf{v}_h) &= -\langle \mathcal{P}_{\tilde{\Lambda}}^{k-1} p_D, \mathbf{v}_h \cdot \nu \rangle_{\Gamma_D} \\ &\quad + (\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} \mathbf{c}, \mathbf{v}_h), \quad \mathbf{v}_h \in \mathbf{V}_{h,0}^k. \end{aligned} \tag{7.1}$$

Note that in (6.1), if $w \in W_h^{k-1}$, we can replace $\mathbf{u}$ by $\pi^k \mathbf{u}$. Thus the difference of (6.1), (7.1) and (6.3)–(6.4) is

$$(a(p - p_h), w_h) + (\nabla \cdot (\pi^k \mathbf{u} - \mathbf{u}_h), w_h) = 0, \qquad w_h \in W_h^{k-1}, \tag{7.2}$$
$$(\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u} - d\mathbf{u}_h, \mathbf{v}_h) - (\mathcal{P}_W^{k-1} p - p_h, \nabla \cdot \mathbf{v}_h) = 0, \quad \mathbf{v}_h \in \mathbf{V}_{h,0}^k. \tag{7.3}$$

Select the standard test functions

$$\mathbf{v}_h = \pi^k \mathbf{u} - \mathbf{u}_h \in \mathbf{V}_{h,0}^k \quad \text{and} \quad w_h = \mathcal{P}_W^{k-1} p - p_h \in W_h^{k-1} \ .$$

Then the sum of (7.2)–(7.3) is

$$\begin{aligned}(a(p-p_h), p-p_h) &+ (d(\mathbf{u}-\mathbf{u}_h), \mathbf{u}-\mathbf{u}_h) \\ &= (a(p-p_h), p-\mathcal{P}_W^{k-1}p) + (d(\mathbf{u}-\mathbf{u}_h), \mathbf{u}-\pi^k\mathbf{u}) + (d\mathbf{u} - \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u}, \pi^k\mathbf{u} - \mathbf{u}_h),\end{aligned}$$

from which we conclude, using standard approximation theory [10, 18] and Lemma 5.2, that

$$\begin{aligned}&\|\sqrt{a}(p-p_h)\|_0 + \|d^{1/2}(\mathbf{u}-\mathbf{u}_h)\|_0 \\ &\quad \le C\big\{\|p - \mathcal{P}_W^{k-1}p\|_0 + \|\mathbf{u}-\pi^k\mathbf{u}\|_0 + \|d\mathbf{u} - \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u}\|_0\big\} \\ &\quad \le C\big\{\|p\|_r + \|\mathbf{u}\|_r\big\}h^r \qquad (7.4)\end{aligned}$$

for any $1 \le r \le k$.

THEOREM 7.1. *If $\mathbf{u} \in (H^1(\Omega))^2$, the coefficients $a \ge 0$ and d are sufficiently smooth, and d is uniformly elliptic, then there is some constant C, independent of h, such that*

$$\begin{aligned}&\text{(a) } \|\sqrt{a}(p-p_h)\|_0 + \|\mathbf{u}-\mathbf{u}_h\|_0 \le C\big\{\|p\|_r + \|\mathbf{u}\|_r\big\}h^r, && 1 \le r \le k, \\ &\text{(b) } \|\mathcal{P}_W^{k-1}p - p_h\|_0 \le C\big\{\|p\|_r + \|\mathbf{u}\|_{r+1}\big\}h^{r+1}, && 0 \le r \le k, \\ &\text{(c) } \|p-p_h\|_0 \le C\big\{\|p\|_r + \|\mathbf{u}\|_r\big\}h^r, && 1 \le r \le k, \\ &\text{(d) } \|\mathcal{P}_W^{k-1}\nabla\cdot(\mathbf{u}-\mathbf{u}_h)\|_0 \le C\big\{\|p\|_r + \|\mathbf{u}\|_r\big\}h^r, && 1 \le r \le k, \\ &\text{(e) } \|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)\|_0 \le C\big\{\|p\|_r + \|\mathbf{u}\|_r\big\}h^{r-1}, && 1 \le r \le k,\end{aligned}$$

where for (b) *and* (c) *we have assumed that problem* (7.5)–(7.7) *below is* 2*-regular, i.e., its solution satisfies* (7.8)*, and for* (e) *we assume that the finite element partition is quasi-uniform.*

While results (c) and (d) are optimal in the rate of convergence, results (a) and (e) are only suboptimal. Result (b) exhibits a superconvergence phenomenon typical of mixed methods. If $k = 1$, we do not control the full divergence error; however, we at least have stability. See, e.g., [25, 27] for conditions that imply 2-regularity.

Proof. We have shown (a) above. For (b) and (c), let $\psi \in L^2(\Omega)$ be such that $\|\psi\|_0 \le 1$ and consider the solution $\varphi \in H^2(\Omega)$ to

$$a\varphi - \nabla\cdot d^{-1}\nabla\varphi = \psi, \quad \Omega, \qquad (7.5)$$

$$d^{-1}\nabla\varphi\cdot\nu = 0, \quad \Gamma_N, \qquad (7.6)$$

$$\varphi = 0\ , \quad \Gamma_D. \qquad (7.7)$$

By hypothesis the problem is 2-regular, so by definition there is some constant $C > 0$ such that

$$\|\varphi\|_2 \le C\|\psi\|_0 \le C. \qquad (7.8)$$

Then, using Lemma 5.2(d),

$$\begin{aligned}(\mathcal{P}_W^{k-1}p - p_h, \psi) &= (a(\mathcal{P}_W^{k-1}p - p_h), \varphi) - (\mathcal{P}_W^{k-1}p - p_h, \nabla\cdot d^{-1}\nabla\varphi) \\ &= (a(\mathcal{P}_W^{k-1}p - p_h), \varphi) - (\mathcal{P}_W^{k-1}p - p_h, \nabla\cdot \pi^k d^{-1}\nabla\varphi) \\ &= (a(\mathcal{P}_W^{k-1}p - p_h), \varphi) - (\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u} - d\mathbf{u}_h, \pi^k d^{-1}\nabla\varphi),\end{aligned}$$

by (7.3), since $\pi^k d^{-1}\nabla\varphi \in \mathbf{V}_{h,0}^k$. Our immediate goal is to cancel the coefficients d and d^{-1} in the last term, so we compute

$$\begin{aligned}(\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u} - d\mathbf{u}_h, \pi^k d^{-1}\nabla\varphi) &= (\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u} - d\mathbf{u}_h, \pi^k d^{-1}\nabla\varphi - \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d^{-1}\nabla\varphi)\\ &\quad + (\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u} - d\mathbf{u}_h, \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d^{-1}\nabla\varphi)\\ &= (\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u} - d\mathbf{u}_h, \pi^k d^{-1}\nabla\varphi - \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d^{-1}\nabla\varphi)\\ &\quad + (d(\mathbf{u} - \mathbf{u}_h), \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d^{-1}\nabla\varphi - d^{-1}\nabla\varphi) + (\mathbf{u} - \mathbf{u}_h, \nabla\varphi).\end{aligned}$$

We now wish to integrate the last term above by parts and use the other error equation (7.2). However, we must do this carefully, so as to obtain the superconvergence claimed in the theorem. We compute

$$\begin{aligned}(\mathbf{u} - \mathbf{u}_h, \nabla\varphi) &= (\mathbf{u} - \pi^k\mathbf{u}, \nabla\varphi) + (\pi^k\mathbf{u} - \mathbf{u}_h, \nabla\varphi - \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1}\nabla\varphi)\\ &\quad + (\pi^k\mathbf{u} - \mathbf{u}_h, \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1}\nabla\varphi).\end{aligned}$$

Now, using Lemma 5.3, (5.11), and (7.2),

$$\begin{aligned}(\pi^k\mathbf{u} - \mathbf{u}_h, \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1}\nabla\varphi) &= (\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1}(\pi^k\mathbf{u} - \mathbf{u}_h), \nabla\varphi)\\ &= (\tilde{\pi}^{k-1}(\pi^k\mathbf{u} - \mathbf{u}_h), \nabla\varphi)\\ &= -(\nabla\cdot\tilde{\pi}^{k-1}(\pi^k\mathbf{u} - \mathbf{u}_h), \varphi)\\ &= -(\nabla\cdot(\pi^k\mathbf{u} - \mathbf{u}_h), \mathcal{P}_W^{k-1}\varphi)\\ &= (a(p - p_h), \mathcal{P}_W^{k-1}\varphi)\\ &= (a(\mathcal{P}_W^{k-1}p - p_h), \mathcal{P}_W^{k-1}\varphi) + ((a - \mathcal{P}_W^0 a)(p - \mathcal{P}_W^{k-1}p), \mathcal{P}_W^{k-1}\varphi),\end{aligned}$$

since $\mathcal{P}_W^{k-1}(\mathcal{P}_W^0 a(p - \mathcal{P}_W^{k-1}p)) = 0$. Combining and using the approximation properties of the various projections and (7.4), we obtain that

$$\begin{aligned}(\mathcal{P}_W^{k-1}p - p_h, \psi) &= (a(\mathcal{P}_W^{k-1}p - p_h), \varphi - \mathcal{P}_W^{k-1}\varphi)\\ &\quad - (\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u} - d\mathbf{u}_h, \pi^k d^{-1}\nabla\varphi - \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d^{-1}\nabla\varphi)\\ &\quad - (d(\mathbf{u} - \mathbf{u}_h), \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d^{-1}\nabla\varphi - d^{-1}\nabla\varphi) - (\mathbf{u} - \pi^k\mathbf{u}, \nabla\varphi)\\ &\quad - (\pi^k\mathbf{u} - \mathbf{u}_h, \nabla\varphi - \mathcal{P}_{\tilde{\mathbf{V}}}^{k-1}\nabla\varphi) - ((a - \mathcal{P}_W^0 a)(p - \mathcal{P}_W^{k-1}p), \mathcal{P}_W^{k-1}\varphi)\\ &\le C\big\{\big(\|\sqrt{a}(\mathcal{P}_W^{k-1}p - p_h)\|_0 + \|\mathbf{u} - \mathbf{u}_h\|_0 + \|\mathcal{P}_{\tilde{\mathbf{V}}}^{k-1} d\mathbf{u} - d\mathbf{u}\|_0\\ &\qquad + \|\pi^k\mathbf{u} - \mathbf{u}\|_0 + \|a\|_{W^{1,\infty}}\|p - \mathcal{P}_W^{k-1}p\|_0\big)\, h + \|\mathbf{u} - \pi^k\mathbf{u}\|_0\big\}\|\varphi\|_2\\ &\le C\big\{\|p\|_r + \|\mathbf{u}\|_{r+1}\big\}h^{r+1},\end{aligned}$$

where $0 \le r \le k$. Thus (b) and (c) follow.

Substituting $w_h = \mathcal{P}_W^{k-1}\nabla\cdot(\mathbf{u} - \mathbf{u}_h) \in W_h^{k-1}$ into (7.2) and using (7.4) leads to (d). For (e), we have a standard inverse inequality argument [10]. On a quasi-uniform partition (i.e., one that is quasi-regular and has the size of the largest to smallest rectangle bounded independently of h), we compute

$$\begin{aligned}\|\nabla\cdot(\mathbf{u} - \mathbf{u}_h)\|_0 &\le \|\nabla\cdot(\mathbf{u} - \pi^k\mathbf{u})\|_0 + \|\nabla\cdot(\pi^k\mathbf{u} - \mathbf{u}_h)\|_0\\ &\le \|\mathbf{u} - \pi^k\mathbf{u}\|_1 + Ch^{-1}\|\pi^k\mathbf{u} - \mathbf{u}_h\|_0,\end{aligned}$$

and the result follows easily. □

8. The inf-sup condition. Our spaces satisfy the celebrated LBB or inf-sup condition of Ladyzhenskaya [28], Babuška [6], Brezzi [11], and Brezzi and Fortin [15].

THEOREM 8.1. *If Ω is a polygonal domain, then there exists a constant $\gamma > 0$ such that*

$$\inf_{w \in W_h^{k-1}} \sup_{\mathbf{v} \in \mathbf{V}_{h,0}^k} \frac{(\nabla \cdot \mathbf{v}, w)}{\|\mathbf{v}\| \|w\|_0} \geq \gamma > 0,$$

wherein functions of W_h^{k-1} have mean zero if $\Gamma_N = \partial\Omega$ and we take the norm on $\mathbf{V}_h^k$ to be any one of

$$\|\mathbf{v}\| = \left\{ \|\mathbf{v}\|_0^2 + \|\nabla \cdot \mathbf{v}\|_0^2 \right\}^{1/2} \equiv \|\mathbf{v}\|_{H(\mathrm{div})},$$
$$\|\mathbf{v}\| = \left\{ \|\mathbf{v}\|_0^2 + \|\mathcal{P}_W^{k-1} \nabla \cdot \mathbf{v}\|_0^2 \right\}^{1/2} \equiv |||v|||,$$

or $\|\mathbf{v}\| = \|\mathbf{v}\|_1$.

Proof. It suffices to show the result for the $(H^1(\Omega))^2$-norm on V_h^k, since

$$|||\mathbf{v}||| \leq \|\mathbf{v}\|_{H(\mathrm{div})} \leq \|\mathbf{v}\|_1.$$

There exists a $\beta > 0$ such that, given $w \in L^2(\Omega)$ (or $w \in L^2(\Omega)/\mathbb{R}$ if $\Gamma_N = \partial\Omega$), there is some $\psi \in (H^1(\Omega))^2$ such that both $\nabla \cdot \psi = w$ and $\|\psi\|_1 \leq \beta \|w\|_0$ (see [5]). Then for $w \in W_h^{k-1}$,

$$\sup_{\mathbf{v} \in \mathbf{V}_{h,0}^k} \frac{(\nabla \cdot \mathbf{v}, w)}{\|\mathbf{v}\|_1 \|w\|_0} \geq \frac{(\nabla \cdot \pi^k \psi, w)}{\|\pi^k \psi\|_1 \|w\|_0} \geq \frac{\|w\|_0}{C \|\psi\|_1} \geq \frac{1}{\beta C} > 0,$$

since π^k is bounded on $(H^1(\Omega))^2$. ∎

We analyzed our finite element method in a direct way in section 7 above, rather than use the inf-sup theory of saddle point problems [6, 10, 11, 15]. This is because it is not straightforward to apply the theory. To do so would require both that the form $(\nabla \cdot \mathbf{v}, w)$ be continuous and that $(d\mathbf{v}, \mathbf{v})$ be coercive on the set $Z = \{\mathbf{v} \in \mathbf{V}_{h,0}^k : (\nabla \cdot \mathbf{v}, w) = 0 \ \forall w \in W_h^{k-1}\}$. For the former, we would need to take the norm on $\mathbf{V}_h^k$ to be at least $\|\cdot\|_{H(\mathrm{div})}$, while for the latter we would need the norm to be no stronger than $|||\cdot|||$. The problem is that testing $(\nabla \cdot \mathbf{v}, w)$ by $w \in W_h^{k-1}$ does not control the full divergence of $\mathbf{v}$, but only its projection $\mathcal{P}_W^{k-1} \nabla \cdot \mathbf{v}$.

9. Numerical examples. In this section we present some numerical results on the problem (1.1)–(1.2), (1.5) with $\Omega = (0,1)^2$, $\Gamma_D = \partial\Omega$, $a = 0$, and $\mathbf{c} = 0$. We fix the true solution and then define p_D and b so that the equations are satisfied. The test cases are summarized in Table 9.1, wherein d and p are defined, as well as a statement as to whether the grid is uniform or not. The observed convergence errors are shown in Table 9.2, and in Table 9.3 we show the observed convergence rates. The norms of the errors were computed using a tensor product 3-point Gauss rule, and the convergence rates were obtained by fitting the norms of the errors to $\exp(m \log h + b)$, with m being the convergence rate.

As can be seen from Table 9.3, p converges to p_h as $O(h)$, and $\mathcal{P}_W^0 p$ as $O(h^2)$, both as expected from Theorem 7.1. We also see that $\mathbf{u}$ converges to $\mathbf{u}_h$ somewhat better than expected. It appears that on the uniform grid we attain $O(h^{3/2})$ superconvergence in the L^2-norm, and $O(h^{1/2})$ in the H^1-seminorm. On the random grid, the superconvergence appears to be lost, at least mostly so. For these test cases,

TABLE 9.1
Numerical test cases.

$\mathcal{P}_W^0 \nabla\cdot\mathbf{u}_h = \mathcal{P}_W^0 \nabla\cdot\mathbf{u}$. However, it appears that $\nabla\cdot\mathbf{u}$ approaches $\nabla\cdot\mathbf{u}_h$ with rate $O(h)$. We have not been able to demonstrate that this is true in general.

If the projection of the Dirichlet data is *not* used in (6.4), then the results degrade significantly. Thus, it is important to include this projection in the method. In our tests, it amounts to simplifying the computation by replacing the Dirichlet value on each boundary element edge by its average value.

10. The spaces in three dimensions. There are several ways to define our mixed finite element spaces in three dimensions. We present the version with as few degrees of freedom as seems possible.

Let

$$\tilde{Q}_{j,j} = \{p \in Q_{j,j} : p \text{ has exact degree } j\}.$$

Then $\dim Q_{j,j} = 2j+1$. Moreover, let

$$\tilde{Q}^x_{i,j,j} = \{p \in Q_{i,j,j} : p \text{ has exact degree } j \text{ in } y \text{ and } z\},$$

and define similarly $\tilde{Q}^y_{j,i,j}$ and $\tilde{Q}^z_{j,j,i}$, each with dimension $(i+1)(2j+1)$.

We next define some spaces of "bubble" functions. For each integer $k \geq 1$, let $R = (a_0, a_1) \times (b_0, b_1) \times (c_0, c_1)$ and

$$\begin{aligned} B^k_x(R) = \big\{ & p : p(x,y,z) \\ & = (y-b_0)(b_1-y)(z-c_0)(c_1-z)\big[(a_1-x)\, q_0(y,z) + (x-a_0)\, q_1(y,z)\big] \\ & \text{for some } q_0, q_1 \in \tilde{Q}_{k-1,k-1}((b_0,b_1)\times(c_0,c_1))\big\} \\ \subset\ & Q_{1,k+1,k+1}(R), \end{aligned}$$

with a similar definition for $B^k_y(R)$ and $B^k_z(R)$. Also let

$$\begin{aligned} \mathbf{B}^k(R) = \big\{ & \mathbf{v} : \mathbf{v}(x,y,z) = (x-a_0)(a_1-x)(y-b_0)(b_1-y)(z-c_0)(c_1-z)\,\psi(x,y,z) \\ & \text{for some } \psi \in \tilde{Q}^x_{k-2,k-1,k-1}(R) \times \tilde{Q}^y_{k-1,k-2,k-1}(R) \times \tilde{Q}^z_{k-1,k-1,k-2}(R)\big\} \\ \subset\ & Q_{k,k+1,k+1}(R) \times Q_{k+1,k,k+1}(R) \times Q_{k+1,k+1,k}(R). \end{aligned}$$

DEFINITION 10.1. *For each integer $k \geq 1$, for any $R \in \mathcal{T}_h$, let*

$$\begin{aligned} \mathbf{V}^k_h(R) &= \big(Q_{k,k,k}(R)\big)^3 + B^k_x(R) \times B^k_y(R) \times B^k_z(R) + \mathbf{B}^k(R) \\ &\subset Q_{k,k+1,k+1}(R) \times Q_{k+1,k,k+1}(R) \times Q_{k+1,k+1,k}(R), \\ W^{k-1}_h(R) &= Q_{k-1,k-1,k-1}(R), \end{aligned}$$

and define $\mathbf{V}^k_h \times W^{k-1}_h$ as in Definition 4.1.

LEMMA 10.2. *Let R be a rectangular parallelepiped in three dimensions. For each edge $e \in \partial R$, fix a set $\mathcal{S}_e$ of $k+1$ distinct points, including the endpoints. Then $\mathbf{u}_h \in \mathbf{V}^k_h(R)$ is uniquely defined by the following degrees of freedom:*

(i) *For each edge $e \in \partial R$, point $P \in \mathcal{S}_e$, and Cartesian direction $j = 1, 2, 3$,*

$$DOF^{(\mathrm{i})}_{P,j}(\mathbf{u}_h) = u_{h,j}(P) = \mathbf{u}_h(P) \cdot \mathbf{e}_j.$$

(ii) *On each face $f \subset \partial R$,*

$$DOF^{(\mathrm{ii})}_{f,\tau_f,\lambda}(\mathbf{u}_h) = \langle \mathbf{u}_h \cdot \tau_f, \lambda \rangle_f \quad \forall \lambda \in Q_{k-2,k-2}(f),$$

where τ_f is one of the two linearly independent Cartesian unit tangential directions.

(iii) *On each face $f \subset \partial R$,*

$$DOF^{(\mathrm{iii})}_{f,\lambda}(\mathbf{u}_h) = \langle \mathbf{u}_h \cdot \nu_f, \lambda \rangle_f \quad \forall \lambda \in Q_{k-1,k-1}(f),$$

where ν_f is the outer unit normal direction.

(iv) *Over R,*

$$DOF^{(\mathrm{iv})}_{\mathbf{v}}(\mathbf{u}_h) = (\mathbf{u}_h, \mathbf{v})_R \quad \forall \mathbf{v} \in Q_{k-2,k-1,k-1}(R) \times Q_{k-1,k-2,k-1}(R) \times Q_{k-1,k-1,k-2}(R).$$

Moreover, on each edge $e \subset \partial R$, $\mathbf{u}_h|_e$ is uniquely defined by the degrees of freedom (i) *restricted to e, and on each face $f \subset \partial R$, $\mathbf{u}_h|_f$ is uniquely defined by the degrees of freedom* (i)–(iii) *restricted to f.*

The dimension of $\mathbf{V}_h^k(R)$ is

$$\begin{aligned}\dim \mathbf{V}_h^k(R) &= 3(k+1)^3 + 6(2k-1) + 3(k-1)(2k-1) = 3(k^3+5k^2+4k)\\ &= 3k(k+1)(k+4).\end{aligned}$$

The number of independent degrees of freedom for (i) is $3(12(k-1)+8) = 36k-12$, for (ii) is $12(k-1)^2 = 12k^2-24k+12$, for (iii) is $6k^2$, and for (iv) is $3k^2(k-1)$, for a total matching the dimension of the space. Therefore the proof of the lemma is similar to that for Lemma 4.2, and we omit it.

The theoretical results of the previous sections can be developed for these spaces in a relatively straightforward way. In particular, we have analogues of the definition of π^k, Lemmas 5.2 and 5.3, the development of the mixed finite element method, and Theorems 7.1 and 8.1.

ERROR ESTIMATES FOR A FINITE VOLUME ELEMENT METHOD FOR ELLIPTIC PDEs IN NONCONVEX POLYGONAL DOMAINS*

P. CHATZIPANTELIDIS† AND R. D. LAZAROV†

Abstract. We consider standard finite volume piecewise linear approximations for second order elliptic boundary value problems on a nonconvex polygonal domain. Based on sharp shift estimates, we derive error estimations in H^1-, L_2- and L_∞-norms, taking into consideration the regularity of the data. Numerical experiments and counterexamples illustrate the theoretical results.

Key words. finite volume element method, nonconvex polygons, error estimations

1. Introduction.

We analyze the standard finite volume element method for the discretization of second order linear elliptic PDEs on a nonconvex polygonal domain $\Omega \subset \mathbb{R}^2$. Namely, for a given function f, we seek u such that

$$Lu \equiv -\operatorname{div}(A\nabla u) = f \quad \text{in } \Omega, \quad \text{and} \quad u = 0 \quad \text{on } \partial\Omega \tag{1.1}$$

with $A = (a_{ij})_{i,j=1}^2$ a given symmetric matrix function with real-value entries $a_{ij} \in W_\infty^1$, $1 \le i, j \le 2$. We assume that the matrix A is uniformly positive definite in Ω, i.e., there exists a positive constant α_0 such that

$$\xi^T A(x)\xi \ge \alpha_0 \xi^T \xi \quad \forall \xi \in \mathbb{R}^2, \forall x \in \bar{\Omega}. \tag{1.2}$$

The class of finite volume methods is based on some approximation of the balance relation

$$-\int_{\partial b} A\nabla u \cdot n \, ds = \int_b f \, dx, \tag{1.3}$$

which is valid for any subdomain $b \subset \Omega$. Here n denotes the outer unit normal vector to the boundary of b.

There are various approaches to the finite volume method. One, the finite volume element method, uses a finite element partition of Ω, where the solution space consists of continuous piecewise linear functions, a collection of vertex-centered control volumes, and a test space of piecewise constant functions over the control volumes (cf., e.g., [6, 10, 25, 28]). A second approach, usually called the finite volume difference method, uses cell-centered grids and approximates the derivatives in the balance equation by finite differences (cf., e.g., [22, 29, 33]). Another approach uses mixed reformulation of the problem [12, 16]. The first approach is quite close to the finite element method but nevertheless has some new properties that make it attractive for the applications [1, 20]. The second approach is closer to the classical finite difference method and extends it to more general than rectangular meshes. It is used mostly on perpendicular bisection or Voronoi type meshes. Approximations on such rectangular

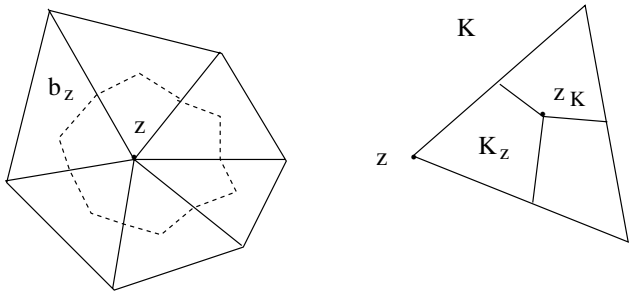

FIG. 1.1. *Left-hand side: A sample region with dotted lines indicating the corresponding box b_z. Right-hand side: A triangle K partitioned into three subregions K_z.*

and triangular meshes were studied, for example, in [34] and [26], respectively. The third approach is close to mixed and hybrid finite element methods and can deal, for example, with irregular quadrilateral and hexahedral cells [12, 30]. Finite volume discretizations for more general convection-diffusion-reaction problems were studied by many authors. For a comprehensive presentation and more references of existing results we refer to the monographs on the finite volume difference method [22] and on the finite volume element method [28], and for various applications on the special issue [21].

We shall consider a finite volume element discretization of (1.1), in the standard conforming space of piecewise linear functions,

$$X_h = \{\chi \in C(\Omega) : \ \chi|_K \text{ is linear } \forall K \in T_h \text{ and } \chi|_{\partial\Omega} = 0\}$$

with $\{T_h\}_{0<h<1}$ a given family of triangulations of Ω with h denoting the maximum diameter of the triangles of T_h. For simplicity we shall assume that T_h is a quasi-uniform triangulation. However, this assumption is only required to show L_∞-norm error estimates. For L_2- and H^1-norm error estimations, *nondegenerate* triangulations [9, equation (4.4.16)] are sufficient.

The finite volume problem will satisfy a relation similar to (1.3) for b in a finite collection of subregions of Ω called control volumes, the number of which will be equal to the dimension of the finite element space X_h. These control volumes are constructed in the following way: Let z_K be the barycenter of $K \in T_h$. We connect z_K with line segments to the midpoints of the edges of K, thus partitioning K into three quadrilaterals K_z, $z \in Z_h(K)$, where $Z_h(K)$ are the vertices of K. Then with each vertex $z \in Z_h = \cup_{K\in T_h} Z_h(K)$ we associate a control volume (also called a box) b_z, which consists of the union of the subregions K_z, sharing the vertex z (see Figure 1.1). We denote the set of interior vertices of Z_h by Z_h^0.

The finite volume element method is then to find $u_h \in X_h$ such that

$$-\int_{\partial b_z} (A\nabla u_h)\cdot n\, ds = \int_{b_z} f\, dx, \quad \forall z \in Z_h^0. \tag{1.4}$$

Before we start our description of this work we introduce some notation. We will use the standard notation for the Sobolev spaces W_p^s and $H^s = W_2^s$ (cf. [2]). Namely, $L_p(V)$, $1 \le p < \infty$, denotes the space of p-integrable real functions over $V \subset \mathbb{R}^2$, $(\cdot,\cdot)_V$ the inner product in $L_2(V)$, $|\cdot|_{H^s(V)}$ and $\|\cdot\|_{H^s(V)}$ the seminorm and norm, respectively, in $H^s(V)$, $|\cdot|_{W_p^s(V)}$ and $\|\cdot\|_{W_p^s(V)}$ the seminorm and norm, respectively,

in $W_p^s(V)$, $p \geq 1$, and $s \in \mathbb{R}$. In addition, if $V = \Omega$ we suppress the index V, and if $p = 2$ and $s = 0$ we also suppress these indexes and denote $\|\cdot\|_{W_2^0} = \|\cdot\|$. Further, we shall denote with p' the adjoint of p, i.e., $\frac{1}{p} + \frac{1}{p'} = 1$, $p > 1$.

We begin with some comments. It is well known that in the case of a polygonal Ω, if $f \in L_p$, $1 < p < \infty$, then the solution u of (1.1) is not always in W_p^2 (cf., e.g., [24] and section 2). However, it is always in $W_{\bar{p}}^2$ or in a fractional order space H^{1+s} for some $0 < s < 1$, where s and $\bar{p}$, given in section 2, depend on both the maximal interior angle of Ω and p. In short, for p large, s and $\bar{p}$ depend on the maximal interior angle, while for p close to 1, they depend on p.

In this paper we study the influence of the corner singularities imposed by the nonconvex polygonal domain Ω and the possible insufficient regularity of the right-hand side f, say, $f \in L_p(\Omega)$, $p < 2$, or $f \in H^{-\ell}(\Omega)$, $0 \leq \ell < 1/2$, on the convergence rate of the finite volume element method. For domains with smooth boundary and convex polygonal domains, H^1- and L_2-norm error estimates were derived in [15] and [23], respectively, taking into account the regularity of f.

Note that we use the conservative version of the method, namely the right-hand side of the scheme is computed by the L_2–inner product of f with the characteristic functions of the finite volumes (or equivalently by the duality between H^ℓ and $H^{-\ell}$ for $0 \leq \ell < 1/2$). The reason for $\ell < 1/2$ is that (1.4) makes sense for at least $f \in L_1$. For results concerning finite volume schemes for problems with more singular f, i.e., $f \in H^{-1}$, we refer to [19], where an approximation of $\int_b f$ is considered.

As a model for our analysis we shall consider the corresponding Galerkin finite element method, which is to find $\underline{u}_h \in X_h$ such that

$$a(\underline{u}_h, \chi) = (f, \chi), \quad \forall \chi \in X_h, \tag{1.5}$$

with $a(\cdot,\cdot)$ the bilinear form defined by

$$a(v, w) = \int_\Omega A\nabla v \cdot \nabla w \, dx.$$

It is known that $\underline{u}_h$ satisfies (cf., e.g., [3, 8] and [9, Chapter 12])

$$\|u - \underline{u}_h\| + h^\delta \|u - \underline{u}_h\|_{H^1} \leq Ch^{s+\delta} \begin{cases} \|u\|_{H^{1+s}}, \\ \|u\|_{W_{\bar{p}}^2}, \end{cases} \quad \text{any } \delta < \pi/\omega, \tag{1.6}$$

where s is given by (2.4) or (2.6), $\bar{p}$ by (2.3), and ω denotes the biggest interior angle of Ω (cf. section 2). Note that the convergence rate of the finite element method (1.5) is optimal in the H^1-norm and suboptimal in the L_2-norm, since X_h has the following approximation properties (cf., e.g., [9, p. 285]):

$$\inf_{\chi \in X_h} (\|v - \chi\| + h\|v - \chi\|_{H^1}) \leq \begin{cases} Ch^{1+s}\|v\|_{H^{1+s}}, & \forall v \in H^{1+s} \cap H_0^1, \ 0 < s < 1, \\ Ch^{3-2/p}\|v\|_{W_p^2}, & \forall v \in W_p^2 \cap H_0^1, \ 1 \leq p \leq 2. \end{cases} \tag{1.7}$$

In the literature there are various techniques for improving the convergence rate of a finite element method in nonconvex domains, e.g., mesh refinement, augmenting the basis functions with appropriate singular functions (cf., e.g., [8, 11]). Also, recently in [18] such a method was analyzed for some finite volume element methods. Here, we are interested in the analysis of (1.4) in a mesh T_h, which does not have any prior knowledge of the singularity imposed by the domain.

TABLE 1.1

Theoretical convergence rate of the finite volume element method versus the finite element method in a nonconvex polygonal domain, when the exact solution u of problem (1.1) is in H^{1+s}, where s is defined by (2.4) or (2.6), and any $\delta < \pi/\omega$.

$p_\omega = 2/(2-\pi/\omega)$, $s_0 = 1-\pi/\omega$		H^1-norm		L_2-norm		L_∞-norm	
$\tilde{p}_\omega = 2p_\omega/(3p_\omega - 2)$		FVE	FE	FVE	FE	FVE	FE
$p_\omega < 2$	$1 < p < \tilde{p}_\omega$	s		$s+\delta$	$s+\delta$	$\approx s$	
$\tilde{p}_\omega < p_\omega$	$\tilde{p}_\omega < p < p_\omega$			$\min(1, s+\delta)$			
$f \in L_p$	$p_\omega \le p$			1			
$f \in W^t_\alpha$	$1 < \alpha < \tilde{p}_\omega$			$s+\delta$			
	$\tilde{p}_\omega \le \alpha \le 2$			$\min(s+\delta, 1+t)$			
$s_0 < 1/2$	$\ell < s_0$			$1-\ell$			
$f \in H^{-\ell}$	$s_0 < \ell < 1/2$			$1-\ell$			

In Theorems 4.3 and 5.2, we show optimal order H^1-norm error estimates for the finite volume element method (1.4), if $f \in L_p$, $p > 1$, and $f \in H^{-\ell}$, $\ell \in (0, 1/2)$. Thus, the finite element (1.5) and finite volume element method (1.4) converge with the same rate in the H^1-norm.

However, as in the convex case (cf., e.g., [13, 27]), the situation in the L_2-norm error estimate is quite different. The convergence rate in the L_2-norm of the finite volume element method (1.4) is suboptimal and lower than the corresponding finite element method. In Theorem 4.3, for $f \in L_p$, $p > 1$, we show L_2-norm error estimations where the order cannot be higher than 1. However, assuming additional regularity for f, namely, $f \in W^t_\alpha$, $t \in (0, 1]$, $\alpha \in (1, 2]$, we are able to show, in Theorem 4.6, L_2-norm error estimations that, depending on α and t, could be of the same order as the finite element method. For example, this is true for α or t sufficiently close to 1. Also, in Theorem 4.8 we derive almost optimal order L_∞-norm error estimates.

In section 5, we consider the case where $f \in H^{-\ell}$, $\ell \in (0, 1/2)$ with $A = I$ and show optimal order H^1-norm, suboptimal L_2-norm, and almost optimal L_∞-norm error estimates. In Theorem 5.2, we show again that the convergence rate of the finite volume element method (1.4) in the L_2-norm is suboptimal and lower than the corresponding suboptimal rate of the finite element method.

In Table 1.1, we summarize the theoretical results concerning the convergence rate of the finite volume element method in the H^1-, L_2-, and L_∞-norms obtained in sections 4 and 5 and compare them with the corresponding known results for the finite element method. According to (1.6) the rate of the finite element method in the H^1-norm and L_2-norm is s and $s+\delta$, respectively, for any $\delta < \pi/\omega$ and s given by either (2.4) or (2.6), depending on whether $f \in L_p$ or $f \in H^{-\ell}$. Note that if we assume that $f \in W^t_\alpha$, with $t \in (0, 1]$ and $\alpha \in (1, 2]$, both methods give the same convergence rate, if $\alpha < \tilde{p}_\omega = 2p_\omega/(3p_\omega - 2)$ with $p_\omega = 2/(2-\pi/\omega)$. Otherwise, this is determined by $\min(s+\pi/\omega, 1+t)$.

Also, in section 7 we present some numerical results for Poisson's equation on a Γ-shaped domain. The particular examples we consider justify the theoretical results of Theorems 4.3, 4.6, and 4.8. However, these do not show the lower convergence rate in the L_2-norm of Theorem 4.3, which occurs if $f \in L_p$, $p > 1$, and $f \notin W^t_\alpha$, for any $\alpha \in (1, 2]$ and $t \in (0, 1)$. To show that the L_2-norm estimates of Theorems 4.3 and 5.2 are sharp, following [27], we consider two counterexamples.

A short presentation of parts of this work can be found in [14]. For simplicity we choose not to include convection terms in the differential equation (1.1). But they

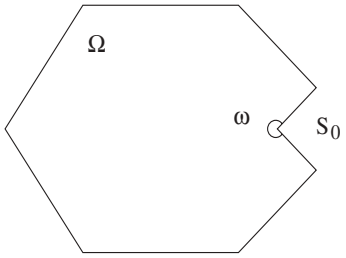

FIG. 2.1. *A nonconvex domain* Ω.

can be included provided they are bounded and the diffusion term is dominating. A brief description of this paper is the following: In section 2 we give, in short, known sharp regularity estimates for the exact solution of problems (1.1) and (2.1), based on [24, 4]. In section 3 we present the finite volume element method. In sections 4 and 5, we analyze the finite volume element method (1.4) and derive error estimates in the H^1-, L_2- and L_∞-norms. The approach follows the one developed in [13] and uses known sharp regularity results for the solutions of elliptic boundary value problems (cf. [24]). In section 6, we derive some auxiliary results, needed in proving Theorems 4.3, 4.6, 4.8, 5.2, 5.4, and 5.5. Finally in section 7, we present numerical examples that illustrate the theoretical results of section 4.

2. Preliminaries. Let us first consider the Dirichlet problem for Poisson's equation: Given $f \in L_p$, $p > 1$, find a function $u : \Omega \to \mathbb{R}^2$ such that

$$-\Delta u = f, \quad \text{in } \Omega, \quad \text{and} \quad u = 0 \quad \text{on } \partial\Omega \tag{2.1}$$

with Ω a bounded, nonconvex, polygonal domain in $\mathbb{R}^2$. For simplicity we assume that Ω has only one interior angle greater than π, namely $\omega \in (\pi, 2\pi)$ (cf. Figure 2.1). It is well known that for such domains there exists a unique solution $u \in H_0^1$ of (2.1).

The solution u could be represented in the form $u = u_S + u_R$, where $u_R \in W_p^2 \cap H_0^1$, and $u_S = cr^{\lambda_m} \frac{1}{\sqrt{\omega}\lambda_m} \sin(\lambda_m\theta)\eta(re^{i\theta})$, expressed in polar coordinates (r, θ) with respect to the vertex S_0 with angle ω (cf. [24]). Here c is a constant, $\lambda_m = \frac{m\pi}{\omega}$, $m \in \mathbb{N}$, and η is a cutoff function which is one near S_0 and zero away from S_0. A crucial role in determining the regularity of the solution u of (1.1) is played by the constant $p_\omega \equiv \frac{2}{2-\pi/\omega}$. According to [24, p. 233],

$$\text{if } f \in L_p, \ p > 1, \quad \text{then } u \in W_{\bar{p}}^2, \tag{2.2}$$

where

$$\bar{p} = \begin{cases} p, & p < p_\omega, \\ \gamma, \quad \text{any } \gamma < p_\omega, & p \geq p_\omega, \end{cases} \qquad p_\omega \equiv \frac{2}{2-\pi/\omega}. \tag{2.3}$$

Using also the imbedding $W_{\bar{p}}^2 \subset H^{1+s}$, for $s = 2 - 2/\bar{p}$ (cf., e.g., [24, p. 34]), we obtain the following:

$$\text{if } f \in L_p, \ p > 1, \quad \text{then } u \in H^{1+s}, \text{ for } s = 2 - \frac{2}{\bar{p}}. \tag{2.4}$$

Also, for problem (2.1) we have (cf., e.g., [4]),

$$\text{if } f \in H^{-\ell}, \ 0 \leq \ell \leq 1, \quad \text{then } u \in H^{1+s}, \tag{2.5}$$

where

$$s = \begin{cases} 1-\ell, & s_0 < \ell \le 1, \\ \delta, \quad \text{any } \delta < \pi/\omega, & 0 \le \ell \le s_0, \end{cases} \qquad s_0 = \frac{2}{p_0} - 1 = 1 - \frac{\pi}{\omega}. \tag{2.6}$$
