REMARKS ON THE DISCRETIZATION OF SOME NONCOERCIVE OPERATOR WITH APPLICATIONS TO HETEROGENEOUS MAXWELL EQUATIONS*

ANNALISA BUFFA†

Abstract. We aim to provide a framework for the analysis of convergence for the Galerkin approximation for a class of noncoercive problems. We provide a sufficient condition on the finite element space for the convergence and optimality of the Galerkin scheme. This theory is then applied to the study of the well-posedness and approximability of two problems in electromagnetism.

Key words. finite elements, boundary elements, Maxwell equations

1. Introduction.

The aim of this paper is to provide a general framework for the analysis of convergence of Galerkin schemes for a class of linear continuous operators which are not definite (neither positive nor negative) and has, in general, no compact inverse. More precisely, letting X be a separable Hilbert space, we consider the class of operators verifying the following assumption.

Assumption 1. We assume that

(a) $A : X \to X'$ is a linear, continuous, and injective operator. We denote by M the continuity constant;

(b) there exists a stable splitting of the space X in $V \oplus W$ and denote by Θ the operator associated to the mapping: $u = v + w \mapsto v - w$;

(c) there exists a *compact* operator $T : X \to X'$ and a positive $\alpha \in \mathbb{R}_+$ such that

$$\mathrm{Re}\langle (A+T)u, \Theta\overline{u}\rangle_X \geq \alpha \, \|u\|_X^2. \tag{1.1}$$

Although the present theory could in principle be generalized to a more general expression of the operator Θ, we prefer to base the development of our main concepts on the above framework. This makes our exposition easier and, on the other hand, more general assumptions would be artificially complicated by the fact that we don't have a precise application in mind. Assumption 1 can be written in a different way, which might make it more clear. We rephrase it in section 2.

At the continuous level the invertibility of the operator A is an immediate consequence of Assumption 1. On the contrary, when we consider its Galerkin approximation, some care has to be devoted to the analysis of stability and convergence of the associated Galerkin scheme. The standard requirement [18] on the family of finite dimensional spaces $\{X_h\}_{h>0}$ is that $\overline{\bigcup_h X_h} = X$, but this turns out to be insufficient for ensuring the well-posedness of the associated Galerkin projection. Several papers exist on this subject and the most recent ones are devoted to the discretization of Maxwell equations; see, e.g., [20], [21], [5], [4], [17]. On the other hand, when concentrating on the edge elements approximation for the Maxwell problem with constant coefficients in a bounded domain (see section 4.1 for the definition of the Maxwell

†MATI-CNR, Sede di Pavia, Via Ferrata 1, 27100 Pavia, Italy (annalisa@imati.cnr.it).

problem), the precise structure of the operators is used to write exhaustive, but dedicated, results which cannot be used for similar problems. For example, when trying to tackle the integral formulation of electromagnetic wave propagation, we find that the problem under consideration is mathematically more intricate (being of nonlocal, integrodifferential type) but reveals "almost" the same structure. This will be one of the applications we treat in this paper.

It is then natural to try to extend the known results to a general class of operators in order to fit all of them into the same framework. This is partially possible, and the aim of this paper is to collect some results in this direction. Thus, in section 3 we consider a condition on the finite element discretization (that we call the (GAP) property) and try to extract some consequences. The idea behind this condition goes back to Kato [28] and is the basis of the theory developed recently in the context of integral equations; see [14], [17], [8], [26]. We analyze further the consequences of this condition and attempt to give a comprehensive theory. We also approach the problem of deducing from (GAP) "spectral correctness" of the approximation in the sense of [20], but the results in this direction are incomplete. Finally, the question of whether, and/or when, (GAP) is a necessary condition for well-posedness is discussed but not answered.

Section 4 is devoted to applications. More precisely, in section 4.1, we show that the present theory easily permits the extension of the known results about the approximation of the Maxwell operator to the case of general bounded coefficients. In section 4.2, we consider a similar physical phenomenon, but one which has a more intricate mathematical formulation: the boundary integral formulation for electromagnetic wave propagation for piecewise homogeneous dielectric scatterers. Here, the effort to set up the problem is quite major, and it is a nontrivial application of the theory developed in this paper. We try our best to emphasize the structure of the problem. We dedicate a lot of room to this application because it shows the generality of the approach and, moreover, it is relevant in itself. Boundary integral discretization of electromagnetic problems is widely used in the engineering community, but mathematics had failed until now to prove the well-posedness of some related boundary element schemes.

Finally, in section 4 we inform the reader that we do not pretend that the section is self-contained; if it were, this would make the section far too long. Instead, we give detailed references for all results we use.

2. Setting of the problem. Let H , X be two complex separable Hilbert spaces such that $X \subset H$ with dense injection. We denote by X' the dual space of X when H plays the role of pivot space. We denote by $\|\cdot\|_H$ and $\|\cdot\|_X$ the associated norms and by $(\cdot,\cdot)_H$ and $(\cdot,\cdot)_X$ the inner product of H and X, respectively. Finally, $\langle\cdot,\cdot\rangle_X$ denotes the duality pairing in X.

First of all, we rephrase Assumption 1 in order to make more clear in which class of operators we are interested. Suppose that $A : X \to X'$ verifies Assumption 1. Since the splitting $X = V \oplus W$ is stable, there exists a projection $\Pi_V : X \to V$ such that Π is onto and $\ker\{\Pi_V\} = W$. We denote by Π_V' its adjoint with respect to the duality product $\langle\cdot,\cdot\rangle_X$. The operator A has a natural matrix representation associated with the splitting:

$$A \ \leftrightarrow \ \begin{pmatrix} A_{VV} & A_{VW} \\ A_{WV} & A_{WW} \end{pmatrix} \text{ with } \begin{array}{rl} A_{VV} = \Pi_V' A \Pi_V\,, & A_{WW} = (I-\Pi_V)'A(I-\Pi_V), \\ A_{VW} = \Pi_V' A(I-\Pi_V)\,, & A_{WV} = (I-\Pi_V)'A\Pi_V. \end{array}$$

Equation (1.1) can be expressed now by the following statement: The operator $A_{VV} -$

$A_{WW} + (A_{VW} - A_{WV})$ verifies the Gårding inequality. In the applications we have in mind, it will happen that $(A_{VW} - A_{WV})$ is either equal to zero (the self-adjoint case) or compact. In this case, Assumption 1 is equivalent to the requirement that $A_{VV} : V \to V'$ and $-A_{WW} : W \to W'$ verify a Gårding inequality.

Let $a : X \times X \to \mathbb{C}$ be the bilinear form associated with A, i.e., $a(u, u^t) = \langle Au, u^t \rangle_X$. We then solve the following.

PROBLEM 1 (continuous problem). *Given $f \in X'$, find*

$$u \in X \ : \ a(u, u^t) = \langle f, u^t \rangle_X \quad \forall\, u^t \in X.$$

It is easy to see by the following that Problem 1 is well-posed.

THEOREM 2.1. *For every $f \in X'$, there exists a unique solution $u \in X$ of the problem $Au = f$. Finally, there exists an isomorphism $\tilde{\Theta} : X \to X$ such that $\tilde{\Theta} - \Theta$ is compact and*

$$\mathrm{Re}\langle Au, \tilde{\Theta}\overline{u} \rangle \geq \alpha \|u\|_X^2.$$

Proof. The fact that A is injective and $A + T$ is invertible implies that A as well as its adjoint is invertible (see, e.g., [23]). It is immediate to construct $\tilde{\Theta}$ as $\tilde{\Theta} = (I + (A')^{-1}T')\Theta$, where A', T' are the adjoints of A, T. □

Finally, we are interested in operators enjoying some further properties and show how these have discrete counterparts for the associated Galerkin scheme.

To this aim we introduce two assumptions.

Assumption 2. Let $X = V \oplus W$ be the decomposition in Assumption 1; then $V \hookrightarrow H$ is compact.

Assumption 3. Let $X = V \oplus W$ be the decomposition in Assumption 1; then

$$\mathrm{Re}\, a(v, \overline{v}) \geq \beta \|v\|_X^2 \quad \forall\, v \in V.$$

3. Discretization. In this section we analyze the Galerkin discretization of Problem 1. Our aim is to provide sufficient conditions for the stability of the discrete problem and for the quasi optimality of the discretization scheme (in the sense of Ciarlet [18]).

The structure of this section is similar to the one chosen by Caorsi, Fernandes, and Raffetto in [16], while some of the results are a revision of the approach chosen in [17] and [8].

Let $\{X_h\}_{h \geq 0} \subset X$ be a family of finite dimensional subspace verifying the following.

Complete approximation space (CAS). $\lim_{h \downarrow 0} \inf_{u_h \in X_h} \|u - u_h\|_X = 0$.

When (CAS) is verified, we say that X_h is *approximating* in X. We denote by $I_h : X \to X_h$ the projection operator defined as $((u - I_h u, v))_X = 0 \ \forall\, v \in X_h$. The family $\{I_h\}_{h>0}$ is uniformly bounded with respect to h, and, if (CAS) holds, $I_h \to I$ pointwise in X.

The discrete variational problem reads as follows.

PROBLEM 2 (Galerkin projection). *Find $u_h \in X_h$ such that*

$$a(u_h, u_h^t) = \langle f, u_h^t \rangle_X \qquad \forall\, u_h^t \in X_h. \tag{3.1}$$

Gap property (GAP). We say that X_h verifies a gap property associated with Assumption 1 when there exist two subsets V_h, W_h of X_h such that

$$\delta_h = \max\{\delta(V_h, V), \delta(W_h, W)\} \to 0 \text{ when } h \to 0,$$

where

$$\delta(V_h, V) = \sup_{v_h \in V_h} \inf_{v \in V} \frac{\|v - v_h\|_X}{\|v_h\|_X}.$$

The (GAP) property has several consequences which are here written as theorems and lemmas. First of all, due to (GAP), there exists a continuous operator $\Pi : V_h \to V$ such that $\|v_h - \Pi v_h\| \leq 2\delta_h \|v_h\|_X$ (the same for W). This implies the following.

LEMMA 3.1. *The fact that $\delta(V_h, V) \leq \delta_h$, $\delta_h \to 0$ when $h \to 0$ implies that every continuous projector $P_0 : X \to V$, which is onto in V, verifies*

$$\|v_h - P_0 v_h\|_X \lesssim \delta_h \|v_h\|_X, \qquad v_h \in V_h.$$

Proof. It is enough to compute

$$\begin{aligned} \|v_h - P_0 v_h\|_X &= \|v_h - \Pi v_h + \Pi v_h - P_0 v_h\|_X \\ &= \|(I - P_0)(v_h - \Pi v_h)\|_X \leq 2\|I - P_0\|\delta_h \|v_h\|_X. \qquad \square \end{aligned}$$

We then can prove the following theorem.

THEOREM 3.2. *(GAP) implies that the splitting $X_h = V_h \oplus W_h$ is uniformly stable $\forall\ h < h_1$ for some $h_1 \in \mathbb{R}_+$.*

Proof (cf. [8]). We denote by P the projection with range V and kernel W. It commutes with conjugation. For any $(v_h, w_h) \in V_h \times W_h$ we have, with $u_h = v_h + w_h$,

$$\|v_h - Pv_h\|_X \leq 2\|I - P\|\delta_h \|v_h\|_X \lesssim \delta_h \|v_h\|_X, \tag{3.2}$$

and similarly,

$$\|Pw_h\|_X = \|w_h - (I - P)w_h\|_X \lesssim \delta_h \|w_h\|_X. \tag{3.3}$$

We use the identity

$$v_h = P(u_h) + ((I - P)w_h - w_h) + (v_h - Pv_h)$$

and, by triangle inequality, we obtain

$$\begin{aligned} \|v_h\|_X &\leq \|P(v_h + w_h)\|_X + \|(I - P)w_h - w_h\|_X + \|Pv_h - v_h\|_X \\ &\leq \|P\|\|u_h\|_X + 2\|P\|\delta_h \|w_h\|_X + 2\|I - P\|\delta_h \|v_h\|_X. \end{aligned}$$

Similarly,

$$\|w_h\|_X \leq \|I - P\|\|u_h\|_X + 2\|I - P\|\delta_h \|v_h\|_X + 2\|P\|\delta_h \|w_h\|_X.$$

Adding and rearranging we obtain for h small enough

$$\|v_h\|_X + \|w_h\|_X \leq 2(1 - \delta_h \max\{\|P\|, \|I - P\|\})^{-1} \max\{\|P\|, \|I - P\|\}\|u_h\|_X. \qquad \square \tag{3.4}$$

Since the splitting is stable for h sufficiently small, we denote by $P_h : X_h \to X_h$ the associated projection operator having V_h as range and W_h as kernel.

THEOREM 3.3. *(GAP) and (CAS) imply that V_h is approximating in V and that W_h is approximating in W, i.e.,*

$$\lim_{h \downarrow 0} \inf_{v_h \in V_h} \|v - v_h\|_X = 0,\ \lim_{h \downarrow 0} \inf_{w_h \in W_h} \|w - w_h\|_X = 0 \quad \forall\, v \in V,\ w \in W. \tag{3.5}$$

Proof. We estimate the best approximation error as follows:

$$\inf_{v_h \in V_h} \|v - v_h\|_X \leq \|v - P_h I_h v\|_X. \tag{3.6}$$

It is easy to see that $v - P_h I_h v = P(v - I_h v) + (P - P_h)(I_h v)$ and that, if we set $I_h v = v_h + w_h$ with $v_h \in V_h$, $w_h \in W_h$, we obtain

$$\|(P - P_h) I_h v\|_X \leq \|P v_h - v_h\|_X + \|P w_h\|_X \lesssim \delta_h \|I_h v\|_X.$$

As a consequence,

$$\begin{aligned} \inf_{v_h \in V_h} \|v - v_h\|_X &\lesssim \|v - P_h I_h v\|_X \\ &\lesssim \|P(v - v_h)\|_X + \delta_h \|I_h(v)\|_X \lesssim \|v - I_h v\|_X + \delta_h \|v\|_X. \end{aligned}$$

The statement is then proved since I_h is a linear and continuous operator, and (CAS) implies that $(I - I_h)$ is pointwise converging to 0. □

Remark 3.4. In the particular case in which $W_h \subset W$, we have of course that $\delta(W_h, W) = 0$. This means that the condition $\delta(V_h, V) \to 0$ for $h \to 0$ implies that W_h is approximating in W.

THEOREM 3.5. *(GAP) implies the following:*

(i) *If Assumption* 3 *holds, then there exists an* h_2 *such that* $\forall\ h < h_2$*, it holds that*

$$\operatorname{Re} a(v_h, v_h) \geq \frac{\beta}{2} \|v_h\|_X^2.$$

(ii) *If Assumption* 2 *holds, then we have the following: Let* $\{v_h\}_{h>0}$ *be a sequence such that* $v_h \in V_h\ \forall\ h > 0$*, and it verifies* $\|v_h\|_X \leq 1\ \forall\ h$*; there exists a subsequence* (*denoted again by* $\{v_h\}_{h>0}$) *and a* $v \in V$ *such that* $v_h \to v$ *strongly in* H.

Proof. (i) Let $v_h \in V_h$. Then

$$\begin{aligned} \operatorname{Re} a(v_h, \overline{v}_h) &= \operatorname{Re} a(\Pi v_h, \overline{\Pi v_h}) + \operatorname{Re}\{a(\Pi v_h - v_h, \overline{\Pi v_h}) - a(v_h, \overline{\Pi v_h - v_h})\} \\ &\geq \|\Pi v_h\|_X^2 - 2M \|v_h\|_X 2\delta_h \|v_h\|_X. \end{aligned}$$

We conclude by recalling the definition of Π and fixing h_2 such that $\beta(1 - 2\delta_h) - 4M\delta_h(1 + \delta_h) \geq \beta/2$.

(ii) Consider a sequence $\{v_{h_j}\}_{j \in \mathbb{N}}$, $h_j \to 0$, for $j \to \infty$ such that $\|v_{h_j}\|_X \leq 1$. We define $v_j = \Pi v_{h_j}$; by continuity of Π, we have $\|v_j\|_X \leq C$. This implies that there exists an increasing sequence j_k such that $v_{j_k} \to v$ strongly in H due to Assumption 3. On the other hand, (GAP) implies that $\|v_{h_{j_k}} - v_{j_k}\|_X \leq C\delta_{h_{j_k}}$, where $\delta_{h_{j_k}} \to 0$, when $k \to \infty$. Hence,

$$\|v_{h_{j_k}} - v\|_H \leq \|v_{j_k} - v\|_H + \|v_{h_{j_k}} - v_{j_k}\|_X \to 0, \quad k \to \infty, \tag{3.7}$$

which means $v_{h_{j_k}} \to v$ strongly in H. □

Remark 3.6. Property (ii) in Theorem 3.5 is commonly called the *discrete compactness property* for V_h and has been the object of several papers concerning edge elements approximation for Maxwell equations. See the very recent book [32] or papers [29], [30], [2], [3], [33]. Further comments are due, and we postpone them to section 4 (Remark 4.5).

We come now to the well-posedness of the discrete problem. Such a result has basically been proved in [14] (see also [8]). We report it here in its most general form.

THEOREM 3.7. *Let (CAS) and (GAP) hold. There exists an h_3 such that $\forall\, h < h_3$, Problem 2 is well-posed. Moreover, let $u \in X$, $u_h \in X_h$ be the solution of Problems 1 and 2. We have*

$$\|u - u_h\|_X \lesssim \inf_{\xi_h \in X_h} \|u - \xi_h\|_X. \tag{3.8}$$

Proof. As in the proof of Theorem 2.1, we have with $\tilde{\Theta} := (I + (A')^{-1}T')\Theta$ that

$$\forall u \in X : \quad \mathrm{Re}\langle Au, \tilde{\Theta}\overline{u}\rangle_X \geq \alpha \|u\|_X^2.$$

Moreover, $\tilde{\Theta} - \Theta = (A')^{-1}T'\Theta$ is compact.

Then

$$\left\|(I - I_h)\tilde{\Theta}u_h\right\|_X \leq \left\|(I - I_h)(\tilde{\Theta} - \Theta)u_h\right\|_X + \|(I - I_h)\Theta u_h\|_X\,.$$

Using (CAS) we have $\forall\ U \in X$ that $\|(I - I_h)U\|_X \to 0$ as $h \to 0$. Since $\tilde{\Theta} - \Theta$ is compact we obtain that

$$\epsilon_h := \left\|(I - I_h)(\tilde{\Theta} - \Theta)\right\|_{X \to X} \to 0 \quad \text{as } h \to 0.$$

Now let $u_h \in X_h$ be arbitrary. Then u_h has the decomposition $u_h = v + w$ with $v \in V$, $w \in W$, and we have $\Theta u_h = v - w$. There is also the decomposition $u_h = v_h + w_h$ with $v_h \in V_h$, $w_h \in W_h$. We have for $\Theta u_h = v - w$

$$\begin{aligned} \|(I - I_h)\Theta u_h\|_X &= \left\|(I - I_h)\Big(\Theta u_h - (v_h - w_h)\Big)\right\|_X \\ &\lesssim \|(v - w) - (v_h - w_h)\|_X \\ &\lesssim (\|v - v_h\|_X + \|w - w_h\|_X). \end{aligned} \tag{3.9}$$

Now, using the same argument as in the proof of Theorem 3.3, we have

$$\|v - v_h\|_X \lesssim (\|Pv_h - v_h\|_X + \|Pw_h\|_X) \lesssim \delta_h \|u_h\|_X.$$

As $w - w_h = -(v - v_h)$ we obtain

$$\|v - v_h\|_X + \|w - w_h\|_X \lesssim \delta_h\, \|u_h\|_X \tag{3.10}$$

and we obtain $\forall\ u_h \in X_h$

$$\left\|(I - I_h)\tilde{\Theta}u_h\right\|_X \leq (\epsilon_h + C\delta_h)\, \|u_h\|_X\,,$$

which implies that for sufficiently small h and $\forall\ u_h \in X_h$

$$\mathrm{Re}\langle Au_h, I_h\tilde{\Theta}u_h\rangle \geq \mathrm{Re}\langle Au_h, \tilde{\Theta}u_h\rangle - C(\varepsilon_h + C\delta_h)\, \|u_h\|_X^2 \geq \alpha/2\, \|u_h\|_X^2\,.$$

Since $I_h\tilde{\Theta} : X_h \to X_h$ is bounded independently of h, we have proved that there exist $\alpha > 0$ and $h_\star > 0$ such that $\forall h < h_\star$

$$\inf_{0 \neq u_h \in X_h} \sup_{0 \neq u_h^t \in X_h} \frac{\mathrm{Re}\langle Au_h, u_h^t\rangle}{\|u_h\|_X\, \|u_h^t\|_X} \geq \frac{\alpha}{2}. \tag{3.11}$$

It is well known that this discrete inf-sup condition implies that Problem 2 has a unique solution and that (3.8) holds. □

We end this section with a result concerning the correctness of the spectral approximation, i.e., we want to know if the Galerkin operator $A_h : X_h \to X'$ is a *correct spectral approximation* of A. To this aim, we need to recall some definitions and introduce some nomenclature.

First of all, we consider the solution operators $S : H \to X$, $S_h : X_h \to X_h$ defined as

$$a(Su, u^t) = (u, u^t)_H \;\; \forall\, u^t \in X \,, \quad a(S_h u_h, u_h^t) = (u_h, u_h^t)_H \;\; \forall\, u_h^t \in X_h. \tag{3.12}$$

By Theorems 2.1 and 3.7, we know that $S\,,\ S_h$ exist and are continuous, at least for h sufficiently small.

Let $\sigma(S)$ denote the spectrum of the operator S, and $\sigma(S_h)$ the one for the operator S_h.

Finally, following [21] (see also [20]), we define

$$\|S - S_h\|_h = \inf_{u_h \in X_h\,, \|u_h\|_X \le 1} \|(S - S)u_h\|_X.$$

It is known that if (CAS) holds and we also have that $\|S - S_h\|_h \to 0$ when $h \to 0$, then S_h provides a correct approximation of the spectrum in the sense expressed in [20]. We report the details of this definition only in the self-adjoint case and refer to [20] for the general case; when S and S_h are self-adjoint, we say that S_h is asymptotically spectrally correct if the following hold:

1. $\lim_{h \downarrow 0} \delta(\lambda, \sigma(S_h)) = 0 \,\forall\, \lambda \in \sigma(S_h)$.
2. If λ has multiplicity m, there are exactly m discrete eigenvalues converging to λ.
3. Let $\lambda \in \sigma(S)$ with multiplicity m and $E_\lambda(S)$ the associated eigenspace, and $\lambda_{h,i} \in \sigma(S_h)$, $i = 1, \dots, m$, the discrete approximation of λ with $E_{\lambda_{h,i}}(S_h)$ the corresponding eigenspace. Then
$$\delta(E_\lambda(S), \oplus_i E_{\lambda_{h,i}}(S_h))\,,\ \delta(\oplus_i E_{\lambda_{h,i}}(S_h), E_\lambda(S)) \to 0\,, \quad h \to 0.$$

THEOREM 3.8. *Let Assumption* 2 *hold and suppose, moreover, that*

$$\sup_{w_h \in W_h\,, \|w_h\|_X \le 1} \inf_{\lambda_h \in X_h} \|S w_h - \lambda_h\|_X \to 0 \textit{ when } h \to 0.$$

Then (CAS) and (GAP) imply that $\|S_h - S\|_h \to 0$ when $h \to 0$.

Proof. Let us fix $x_h \in X_h$, $\|x_h\|_X \le 1$. We estimate

$$\begin{aligned}
\|(S - S_h)x_h\|_X^2 &\lesssim a((S - S_h)x_h, \tilde{\Theta}(S - S_h)x_h) \\
&\lesssim a((S - S_h)x_h, \Theta(S - S_h)x_h) + \epsilon_h \|(S - S_h)x_h\|_X^2 \\
&\lesssim \inf_{\lambda_h \in X_h} a((S - S_h)x_h, \Theta(S - S_h)x_h - \Theta_h \lambda_h) \\
&\qquad + \epsilon_h \|(S - S_h)x_h\|_X^2 \\
&\lesssim \inf_{\lambda_h \in X_h} a((S - S_h)x_h, \Theta(Sx_h - \lambda_h)) + \epsilon_h \|(S - S_h)x_h\|_X^2 \\
&\qquad + \delta_h \|\lambda_h\|_X \|(S - S_h)x_h\|_X,
\end{aligned} \tag{3.13}$$

where we have used that $\tilde{\Theta} - \Theta$ is compact, the Galerkin orthogonality and, finally, that $\|(\Theta - \Theta_h)\lambda_h\|_X \lesssim \delta_h \|\lambda_h\|_X$, which is an immediate consequence of (GAP). From

(3.13), for h small enough, and using the continuity of the bilinear form a, we can deduce that

$$\|(S-S_h)x_h\|_X \lesssim \inf_{\lambda_h\in X_h} \|Sx_h-\lambda_h\|_X + \delta_h\|\lambda_h\|_X, \tag{3.14}$$

which is "almost" a pure approximation property. Since $\|Sx_h\| \lesssim 1$,

$$\inf_{\lambda_h\in X_h} \|Sx_h-\lambda_h\|_X = \|Sx_h - I_hSx_h\|_X = \inf_{\lambda_h\in X_h \|\lambda_h\|_X\lesssim 1} \|Sx_h-\lambda_h\|_X.$$

It is easy to see that, $\forall\ x_h$ such that $\|x_h\|_X \leq 1$, (3.14) implies

$$\|(S-S_h)x_h\|_X \lesssim \delta_h + \inf_{\lambda_h\in X_h} \|Sx_h-\lambda_h\|_X. \tag{3.15}$$

Now, select $x_h \in V_h$. Assumption 2 ensures that there exists a $\tilde{v}\in V$ such that, up to extractions, $\|x_h-\tilde{v}\|_H \to 0$ when $h\to 0$. Thus

$$\|(S-S_h)x_h\|_X \lesssim \delta_h + \|x_h-\tilde{v}\|_H + \inf_{\lambda_h\in X_h} \|S\tilde{v}-\lambda_h\|_X.$$

Hence, (CAS) allows us to conclude that

$$\sup_{x_h\in V_h\ ,\|V_h\|_X\leq 1} \|(S-S_h)x_h\| \to 0 \text{ when } h\to 0.$$

The statement is proved since

$$\begin{aligned}\sup_{u_h\in X_h\ ,\ \|u_h\|_X\leq 1} \|(S-S_h)u_h\|_X^2 \leq & \sup_{v_h\in V_h\ ,\ \|v_h\|_X\lesssim 1} \|(S-S_h)v_h\|_X^2 \\ & + \sup_{w_h\in w_h\ ,\ \|w_h\|_X\lesssim 1} \|(S-S_h)w_h\|_X^2,\end{aligned} \tag{3.16}$$

and the second term in the right-hand side is converging to 0 by assumption. □

Corollary 3.9. *If $S_{|W} : W \to X$ is either compact or a multipication by a sufficiently regular function, then S_h is asymptotically spectrally correct.*

Proof. It is a consequence of (3.15) and (3.16). □

Remark 3.10. This theorem is not completely satisfactory. We expect the statement to hold under much weaker conditions on $S_{|W}$. In the case of Maxwell equations in bounded domains, the discrete compactness property, which is a consequence of (GAP), turns out to be a sufficient condition for the associated Galerkin approximation to be spectrally correct [2] and also spurious free in the sense given in [16]. Finally, the following reasonable question remains open: "Letting (GAP) hold, under Assumptions 1, 2, can we prove that at least a part of the spectrum is well approximated for h sufficiently small?"

4. Applications. We will present here two applications of this theory. They concern two different problems in electromagnetism: (i) Compute solutions of Maxwell equations in a cavity characterized by variable magnetic and electric properties. (ii) Compute the electromagnetic diffraction due to a heterogeneous/piecewise homogeneous dielectric material.

Note that this section will not be self-contained in the sense that we will not recall (with precise statements) all the known properties about the finite elements we use; we provide instead a list of references and we try, when possible, to refer to the recent book [32] or to the review paper [24].

Let D (∂D, $\mathbf{n}_D$, resp.) denote a bounded connected Lipschitz domain (its boundary and the unit outer normal to D on ∂D, resp.) and D^c denote its complement. We set ϵ to be the electric permittivity and μ to be the magnetic permeability.

$\mathbf{E}$ and $\mathbf{H}$ denote the electric and magnetic fields, respectively, and we assume they satisfy the linear time-harmonic Maxwell equations

$$\mathbf{curl}\,\mathbf{E} - i\omega\mu\mathbf{H} = 0\,, \quad \mathbf{curl}\,\mathbf{H} + i\omega\epsilon\mathbf{E} = \mathbf{J} \quad \text{in} \quad D, \tag{4.1}$$

where $\omega \in \mathbb{R}_+$ is a fixed frequency and $\mathbf{J}$ is an imposed current density.

Let us introduce some Sobolev spaces and some operators which will be used throughout this section. We define

$$\begin{aligned}\mathbf{H}(\mathbf{curl}, D) &= \{\mathbf{u} \in L^2(D)^3 \ : \ \mathbf{curl}\,\mathbf{u} \in L^2(D)^3\};\\ \mathbf{H}_{\mathrm{loc}}(\mathbf{curl}, D^c) &= \{\mathbf{u} \in L^2_{\mathrm{loc}}(D^c)^3 \ : \ \mathbf{curl}\,\mathbf{u} \in L^2_{\mathrm{loc}}(D^c)^3\};\\ \mathbf{H}(\mathbf{curl}^2, D) &= \{\,\mathbf{u} \in \mathbf{H}(\mathbf{curl}, D) \mid \mathbf{curl}\,\mu^{-1}\,\mathbf{curl}\,\mathbf{u} \in L^2(D)^3\,\}.\end{aligned}$$

We denote by γ_D the tangential trace operator mapping $\mathbf{u}$ in $\mathbf{n}_D \times \mathbf{u}_{|\partial D}$, $\mathbf{u} \in C^\infty(\overline{D})$. Let $\mathbf{H}^{1/2}_\times(\partial D) = \gamma_D\{H^1(D)^3\}$ and $\mathbf{H}^{-1/2}_\times(\partial D)$ be its dual with respect to the natural duality pairing $b(\boldsymbol{\lambda}, \boldsymbol{\xi}) = \int_{\partial D} \boldsymbol{\lambda} \cdot (\boldsymbol{\xi} \times \mathbf{n})$. Note that the injection $\mathbf{H}^{1/2}_\times(\partial D) \hookrightarrow \mathbf{L}^2_t(\partial D) := \{\mathbf{u} \in L^2(\Gamma)^3 \ : \ \mathbf{u} \cdot \mathbf{n}_D = 0\}$ is compact.

We set $\mathbf{X}(\partial D) := \{\boldsymbol{\lambda} \in \mathbf{H}^{-1/2}_\times(\partial D) \ : \ \mathrm{div}_\Gamma\, \boldsymbol{\lambda} \in H^{-1/2}(\partial D)\}$. See [7], [9], [10], and also [14] for definitions and details. The idea to keep in mind is that vectors in $\mathbf{X}(\partial D)$ are tangential vector fields of Sobolev regularity $-1/2$, with surface divergence of Sobolev regularity $-1/2$, and that the related definitions for nonsmooth boundaries can be given as extensions of the same well-known definitions for regular manifolds.

It is known that $\gamma_D : \mathbf{H}(\mathbf{curl}, D) \to \mathbf{X}(\partial D)$ and $\gamma^c_D : \mathbf{H}_{\mathrm{loc}}(\mathbf{curl}, D^c) \to \mathbf{X}(\partial D)$ are linear continuous and admit a right inverse [12], [7]. Finally, we denote by γ_N the Neumann trace operator associated with the mapping $\mathbf{u} \mapsto \gamma_D(\mu^{-1}\,\mathbf{curl}\,\mathbf{u})$. It turns out [11], [14] that $\gamma_N : \mathbf{H}(\mathbf{curl}^2, D) \to \mathbf{X}(\partial D)$ is linear, continuous, and admits a right inverse. Finally, we set

$$\mathbf{H}_0(\mathbf{curl}, D) = \{\mathbf{u} \in L^2(D)^3 \ : \ \mathbf{curl}\,\mathbf{u} \in L^2(D)^3\,,\ \gamma_D(\mathbf{u}) = 0\}.$$

4.1. Maxwell interior problem.

Let Ω be a Lipschitz bounded polyhedron in $\mathbb{R}^3$.

In this section we consider (4.1) on Ω together with a perfect conductor boundary condition, i.e., $\gamma_D\mathbf{E} = 0$ on $\partial\Omega$. We suppose that $\epsilon\,, \mu \in L^\infty(\Omega)$, $0 < c_0 \leq \epsilon(\mathbf{x})\,, \mu(\mathbf{x}) \leq C_0$, for almost all $\mathbf{x} \in \Omega$.

Eliminating the field $\mathbf{H}$, defining $\mathbf{f} := i\omega\mathbf{J}$, and integrating by parts, we obtain the following (well-known) variational formulation.

PROBLEM 3. *Given* $\mathbf{f} \in L^2(\Omega)^3$, *find* $\mathbf{u} \in \mathbf{H}_0(\mathbf{curl}, \Omega)$ *such that* $\forall\, \mathbf{v} \in \mathbf{H}_0(\mathbf{curl}, \Omega)$

$$\int_\Omega \mu^{-1}\,\mathbf{curl}\,\mathbf{u}\,\mathbf{curl}\,\mathbf{v} - \omega^2 \int_\Omega \epsilon\,\mathbf{u} \cdot \mathbf{v} = \int_\Omega \mathbf{f} \cdot \mathbf{v}. \tag{4.2}$$

The following theorem is well known and has been proved, e.g., in [40] (see also [39] for the fundamental compactness result which is the basis of this theorem).

THEOREM 4.1. *Problem* 3 *admits a unique solution* $\mathbf{u} \in \mathbf{H}_0(\mathbf{curl}, \Omega)$ *except for* $\omega \subset \{0\} \cup \{\omega_j\}_{j>0}$, *where* $\{\omega_j\}$ *is a positive increasing sequence diverging to* $+\infty$. *If* $\mathrm{div}\,\mathbf{J} = 0$, *then* $\mathrm{div}(\epsilon\mathbf{u}) = 0$.

Now we decompose the space $\mathbf{X} := \mathbf{H}_0(\mathbf{curl}, \Omega)$ as $\mathbf{X} = \mathbf{V} \oplus \mathbf{W}$:

$$\mathbf{V} = \{\mathbf{u} \in \mathbf{H}_0(\mathbf{curl}, \Omega) \ : \ \operatorname{div} \mathbf{u} = 0\}\,, \ \mathbf{W} = \nabla H^1_0. \tag{4.3}$$

It is known (see, e.g., [1]) that there exists a positive σ such that $\mathbf{V} \hookrightarrow H^{1/2+\sigma}(\Omega)^3$. This means in particular that $\int_\Omega \epsilon \mathbf{v} \cdot \mathbf{w}$ is a compact bilinear form ($\mathbf{V} \hookrightarrow \mathbf{L}^2(\Omega)$ is compact). Calling Θ the mapping $\mathbf{u} = \mathbf{v} + \mathbf{w} \mapsto \mathbf{v} - \mathbf{w}$ associated with the decomposition (4.3), and $a(\cdot, \cdot)$ the bilinear form of the left-hand side of (4.2), we have

$$a(\mathbf{u}, \Theta\overline{\mathbf{u}}) \geq \alpha \|\mathbf{u}\|^2_{\mathbf{H}(\mathbf{curl},\Omega)} - c(\mathbf{u}, \Theta\overline{\mathbf{u}}),$$

where $c(\cdot, \cdot) : \mathbf{X} \times \mathbf{X} \to \mathbb{C}$ is a compact bilinear form. Thus, when ω is not an eigenvalue of Problem 3, i.e., $\omega \notin \{0\} \cup \{\omega_j\}_{j>0}$, Problem 3 fits exactly into Assumption 1 and also Assumption 2.

Now we pass to the discretization, and we consider the family of conforming finite dimensional spaces $\{\mathbf{X}_h\}_{h>0}$ generated by Nédélec finite elements of the first family of degree k fixed. The family $\{\mathbf{X}_h\}_{h>0}$ corresponds to a family of triangulations $\{\mathcal{T}_h(\Omega)\}_{h>0}$ of the domain Ω which, we assume for simplicity, to be made of tetrahedra. We defer the reader to [35], [22] (see also [31]), or again [24] for a precise definition. Here we list only the properties we need:

1. The space $\mathbf{X}_h$ constructed by Nédélec elements of degree k is approximating in $\mathbf{H}(\mathbf{curl}, \Omega)$, i.e., (CAS) is verified.
2. Let $\mathcal{P}_h$ be the H^1_0-conforming finite element space generated by piecewise polynomials of degree k on $\mathcal{T}_h(\Omega)$. Then, $\nabla \mathcal{P}_h = \{\mathbf{u}_h \in \mathbf{X}_h \ : \ \mathbf{curl}\, \mathbf{u}_h = 0\}$.
3. Denote by Π_k the Nédélec interpolant, we have that
   (a) Π_k is well defined on the space $\mathbf{V}^h = \{\mathbf{v} \in \mathbf{V} \ : \ \mathbf{curl}\, \mathbf{v} \subset \mathbf{curl}\, \mathbf{X}_h\}$ and continuous as an operator from $\mathbf{V}^h$ to $\mathbf{X}_h$;
   (b) $\forall\, \mathbf{v} \in \mathbf{V}^h$, $\mathbf{curl}\, \mathbf{v} = \mathbf{curl}\, \Pi_k \mathbf{v}$, and $\|\mathbf{v}\|_{\mathbf{H}(\mathbf{curl},\Omega)} \approx \|\Pi_k \mathbf{v}\|_{\mathbf{H}(\mathbf{curl},\Omega)}$.

Property 3 is a nontrivial property of Nédélec finite elements, which is basically due to V. Girault, and was first used in [19]. We refer to [24] for its proof and some comments. We set $\mathbf{V}_h = \Pi_k \mathbf{V}^h$ and $\mathbf{W}_h = \nabla \mathcal{P}_h$. We need to prove that $\mathbf{X}_h = \mathbf{V}_h + \mathbf{W}_h$. Letting $\mathbf{u}_h \in \mathbf{X}_h \subset \mathbf{X}$, it can be decomposed as $\mathbf{u}_h = \mathbf{v} + \nabla p$, $\mathbf{v} \in \mathbf{V}\,,\ \nabla p \in \mathbf{W}$. Since $\mathbf{curl}\, \mathbf{u}_h = \mathbf{curl}\, \mathbf{v}$, we deduce $\mathbf{v} \in \mathbf{V}^h$. On the other hand, $\mathbf{u}_h = \Pi_k \mathbf{u}_h = \Pi_k \mathbf{v} + \Pi_k \nabla p = \Pi_k \mathbf{v} + \nabla p_h$, $p_h \in \mathcal{P}_h$. Thus, $\nabla p_h \in \mathbf{W}_h$, $\Pi_k \mathbf{v} \in \mathbf{V}_h$.

It is immediate to see that $\mathbf{W}_h \subset \mathbf{W}$ and also $\mathbf{X}_h = \mathbf{V}_h \oplus \mathbf{W}_h$. We need only prove the following.

Theorem 4.2. *$\delta(\mathbf{V}_h, \mathbf{V})\,,\ \delta(\mathbf{W}_h, \mathbf{W}) \to 0$ when $h \to 0$, i.e., (GAP) holds.*

Proof. The building block of this proof basically exists in several papers; see, e.g., [24]. First of all, $\delta(\mathbf{W}_h, \mathbf{W}) = 0$.

Let $\mathbf{v}_h \in \mathbf{V}_h$. We know that $\mathbf{v}_h = \Pi_k \mathbf{v}$ for some $\mathbf{v} \in \mathbf{V}^h$. Moreover, $\mathbf{curl}\, \mathbf{v} = \mathbf{curl}\, \mathbf{v}_h$ and the regularity results proved in [1] ensure that there exists $\sigma > 0$ such that $\mathbf{v} \in H^{1/2+\sigma}(\Omega)$ with the continuity estimate

$$\|\mathbf{v}\|_{H^{1/2+\sigma}(\Omega)^3} \lesssim \|\,\mathbf{curl}\, \mathbf{v}_h\|_{L^2(\Omega)^3}.$$

Using the approximation properties of Π_k on $\mathbf{V}^h$, we have that $\forall\, \mathbf{v} \in \mathbf{V}^h$,

$$\begin{aligned} \|\mathbf{v} - \Pi_k \mathbf{v}\|_{L^2(\Omega)^3} &\lesssim h^{1/2+\sigma}(\|\mathbf{v}\|_{H^{1/2+\sigma}(\Omega)^3} + \|\,\mathbf{curl}\, \mathbf{v}_h\|_{L^2(\Omega)^3}) \\ &\lesssim h^{1/2+\sigma} \|\mathbf{v}_h\|_{\mathbf{H}(\mathbf{curl},\Omega)}. \qquad \square \end{aligned}$$

We are now ready to define the Galerkin approximation of Problem 3.

PROBLEM 4 (Galerkin). *Given $\mathbf{f} \in L^2(\Omega)^3$, let $\omega \in \mathbb{R}_+$ be such that Problem* 3 *is well-posed.*

Find $\mathbf{u}_h \in \mathbf{X}_h$ such that $\forall\, \mathbf{v} \in \mathbf{X}_h$,

$$\int_\Omega \mu^{-1}\, \mathbf{curl}\, \mathbf{u}_h \cdot \mathbf{curl}\, \mathbf{v}_h - \omega^2 \int_\Omega \epsilon\, \mathbf{u}_h \cdot \mathbf{v}_h = \int_\Omega \mathbf{f} \cdot \mathbf{v}_h. \tag{4.4}$$

The general setting developed in section 3 (and Theorem 3.7) provides the following statement as a corollary of Theorem 4.2.

COROLLARY 4.3. *There exists an $h_\star$ such that $\forall\, h < h_\star$ Problem* 4 *is wellposed. Moreover,*

$$\|\mathbf{u} - \mathbf{u}_h\|_{\mathbf{X}} \leq C \inf_{\mathbf{v}_h \in \mathbf{X}_h} \|\mathbf{u} - \mathbf{v}_h\|_{\mathbf{X}}.$$

Remark 4.4. Thanks to our general setting, the proof of well-posedness for Problem 4 is completely independent of the fact that we treat general coefficients (note that the numerical method is proved convergent under the most general assumption of $\epsilon\,,\ \mu \in L^\infty(\Omega)$, $0 < c_0 \leq \epsilon(\mathbf{x})\,,\ \mu(\mathbf{x}) < C_0$).

Remark 4.5 (spectral correctness). The relevant eigenvalue problem associated with Problem 3 is, of course, the one of computing the frequency ω for which the problem is not well-posed. This fits into the theory developed in section 3 when choosing as space H the space $L^2(\Omega)^3$ endowed with the inner product $(\mathbf{u}, \mathbf{u}^t)_H = \int_\Omega \epsilon\, \mathbf{u} \cdot \mathbf{u}^t$, $\mathbf{u}\,,\ \mathbf{u}^t \in L^2(\Omega)^3$. In this case, it is immediate to see that the associated solution operator S (see (3.12)) coincides with $-\frac{1}{\omega^2} I$ on $\mathbf{W}$, i.e., Theorem 3.8 and Corollary 3.9 can be applied and ensure asymptotic spectral correctness. This statement is not new for Maxwell equations and has been proved in [16]. Actually, there it was proved that the *discrete compactness property* (see Remark 3.6) together with the fact that $\mathbf{W}_h$ is approximating in $\mathbf{W}$ is a necessary and sufficient condition for the spurious free asymptotic spectral correctness (see [16] for definitions). Nonetheless, as before, the result expressed in our framework is completely independent of the fact that we treat general coefficients. Finally, it is easy to see that for this particular application, the *discrete compactness property* is equivalent to (GAP) and $\delta(\mathbf{W}_h, \mathbf{W}) = 0$.

4.2. Maxwell transmission problem. We suppose that the space is filled with different magnetic materials; i.e., the electric permittivity and the magnetic permeability ϵ and μ are piecewise positive constants on a fixed nonoverlapping polyhedral partition $\mathcal{P}$ of $\mathbb{R}^3$, $\mathbb{R}^3 = \bigcup_{j=1}^J \overline{\Omega}_j$. Moreover, we suppose that Ω_J is the only unbounded element of the partition and call $\Omega = \mathbb{R}^3 \setminus \overline{\Omega_J}$.

We define the piecewise constant function $k := k(\mathbf{x}) := \omega\sqrt{\epsilon\mu}$ and denote by Σ the set of interfaces, i.e., $\Sigma = \bigcup_{j=1}^J \partial\Omega_i$. Note that according to the notation introduced, $\mathbb{R}^3 = \bigcup_{j=1}^J \Omega_j \cup \Sigma$. The problem we want to solve is the following: Find $\mathbf{u} \in \mathbf{H}_{\mathrm{loc}}(\mathbf{curl}, \mathbb{R}^3 \setminus \Sigma)$ verifying (i)

$$\mathbf{curl}\, \mathbf{curl}\, \mathbf{u} - k^2 \mathbf{u} = 0 \quad \text{in } \mathbb{R}^3 \setminus \Sigma; \tag{4.5a}$$

(ii) Silver–Müller condition at infinity:

$$\left| \mathbf{curl}\, \mathbf{u}(\mathbf{r}) \times \frac{\mathbf{r}}{|\mathbf{r}|} - ik\mathbf{u} \right| = o\left(\frac{1}{|\mathbf{r}|}\right), \quad |\mathbf{r}| \to \infty; \tag{4.5b}$$

(iii) suitable transmission conditions on the set of interfaces Σ. In order to make precise the transmission conditions, we need to introduce suitable notation. First of all, for any vector $\mathbf{v}$ defined almost everywhere in $\mathbb{R}^3$, $\mathbf{v}_j$ always denotes its restriction to Ω_j.

Let $\Gamma_j = \partial\Omega_j$ and $\mathbf{n}_j$ be the unit outer normal to Ω_j, $j = 1, \dots, J$; we have at our disposal the space $\mathbf{X}(\Gamma_j)$ defined at the beginning of the section. We can then construct

$$\mathcal{X} := \mathbf{X}(\Gamma_1) \times \mathbf{X}(\Gamma_2) \times \cdots \times \mathbf{X}(\Gamma_J), \quad \underline{\boldsymbol{\xi}} = (\boldsymbol{\xi}_1, \dots, \boldsymbol{\xi}_J), \tag{4.6}$$

endowed with the product norm $\|\underline{\boldsymbol{\xi}}\|_{\mathcal{X}} = \sum_j \|\boldsymbol{\xi}_j\|_{\mathbf{X}(\Gamma_j)}$. On such a space, we define the *jump operator* $[\cdot]$ as the mapping

$$[\underline{\boldsymbol{\xi}}] \;:\; [\underline{\boldsymbol{\xi}}]_{|\Gamma_{ij}} = \boldsymbol{\xi}_i + \boldsymbol{\xi}_j \qquad \forall\, i, j = 1, \dots, J \text{ s.t. } \Gamma_j \cap \Gamma_i \neq \emptyset. \tag{4.7}$$

Now, if $\mathbf{u}$ solves (4.5a), we can construct the set of its Cauchy data as follows: Let $\boldsymbol{\xi}_j = \binom{\gamma_D \mathbf{u}_j}{\gamma_N \mathbf{u}_j}$ and $\underline{\boldsymbol{\xi}} = (\boldsymbol{\xi}_1, \dots, \boldsymbol{\xi}_J)$.[1] Then, $\underline{\boldsymbol{\xi}} \in \mathcal{X} \times \mathcal{X}$. Applying the jump operator to each of the two lines of $\underline{\boldsymbol{\xi}}$, we impose the transmission condition as

$$[\underline{\boldsymbol{\xi}}] = \underline{\mathbf{f}} \qquad \text{for some fixed } \underline{\mathbf{f}},\ \underline{\mathbf{f}} \in [\mathcal{X}]^2. \tag{4.8}$$

Remark 4.6. We have to be careful in the definition of transmission conditions because the tangential trace operators depend on the orientation. Hence, the transmission condition cannot be defined directly on Σ, because Σ is never orientable.

A uniqueness result is available as follows.

THEOREM 4.7. *The problem* (4.5)–(4.8) *admits at most one solution.*

Proof. This is a direct consequence of Rellich's theorem (see Müller [34] for a proof). □

4.3. Statement of the problem. In order to show existence and to discretize the problem (4.5)–(4.8), we need to formulate it in terms of boundary integral equations on the interfaces Σ. We adopt a construction of the system of integral equations inspired by [14]. Other derivations are possible; see, e.g., [27].

We first introduce the 1-*dielectric* problem: Find $\mathbf{E} \in \mathbf{H}_{\text{loc}}(\mathbf{curl}, \Omega_j \cup \Omega_j^c)$ such that:

$$\begin{aligned} &\mathbf{curl}\,\mathbf{curl}\,\mathbf{E} - k_j^2 \mathbf{E} = 0 \qquad \text{in} \quad \Omega_j \cup \Omega_j^c, \\ &[\gamma_D]\mathbf{E} = \mathbf{m}; \qquad [\gamma_N]\mathbf{E} = \mathbf{j} \qquad \text{on} \quad \Gamma_j, \\ &\text{Silver–Müller radiation condition at } \infty, \end{aligned} \tag{4.9}$$

where $k_j \in \mathbb{R}_+$, $k_j = k(\mathbf{x})|_{\Omega_j}$, and $\mathbf{m}\,, \mathbf{j}$ are imposed transmission conditions. There exists an explicit representation for the solution $\mathbf{E}$ of (4.9), which reads for almost all $\mathbf{x} \in \Omega_j \cup \Omega_j^c$ as

$$\mathbf{E} = -\Psi_{\text{SL}}^j(\mathbf{j}) - \Psi_{\text{DL}}^j(\mathbf{m}),$$

[1] Note that the operators γ_D and γ_N are not indexed to keep the notation shorter. If applied to a field defined on Ω_j for some j, they represent the tangential trace operators on the boundary of Ω_j, i.e., Γ_j. Moreover, if they are applied to a field $\mathbf{u} \in \mathbf{H}_{\text{loc}}(\mathbf{curl}, \mathbb{R}^3)$, $\gamma_D \mathbf{u}$ stands for the vector $(\gamma_D \mathbf{u}_1, \dots, \gamma_D \mathbf{u}_J)$, γ_N stands for $(\gamma_N \mathbf{u}_1, \gamma_N \mathbf{u}_2, \dots, \gamma_N \mathbf{u}_J)$.

where Ψ^j_{SL} and Ψ^j_{DL} denote the single and double layer operators for the Maxwell problems as defined in [13]. More precisely, let $G(\mathbf{x},\mathbf{y}) = \frac{e^{ik|\mathbf{x}-\mathbf{y}|}}{4\pi|\mathbf{x}-\mathbf{y}|}$ be the standard Helmholtz kernel; then for $\mathbf{x} \in \Omega_j \cup \Omega_j^c$, Ψ^j_{SL} and Ψ^j_{DL} are given by

$$\Psi^j_{\mathrm{SL}}\mathbf{j}(\mathbf{x}) := \int_{\Gamma_j} G(\mathbf{x},\mathbf{y})\mathbf{j}(\mathbf{y})\,ds(y) + k^{-2}\nabla \int_{\Gamma_j} G(\mathbf{x},\mathbf{y})\,\mathrm{div}_\Gamma\,\mathbf{j}(\mathbf{y})\,ds(y),$$

$$\Psi_{\mathrm{DL}}\mathbf{m}(\mathbf{x}) := \mathbf{curl}\int_{\Gamma_j} G(\mathbf{x},\mathbf{y})\mathbf{m}(\mathbf{y})\,ds(y).$$

Let $\{\gamma_D\} := \frac{1}{2}(\gamma_D + \gamma_D^c)$, $\{\gamma_N\} := \frac{1}{2}(\gamma_N + \gamma_N^c)$. We construct the operator A_j associated with the domain Ω_j as

$$A_j \begin{pmatrix}\mathbf{m}\\ \mathbf{j}\end{pmatrix} := \begin{pmatrix}\{\gamma_D\}\\ \{\gamma_N\}\end{pmatrix}(-\Psi^j_{\mathrm{SL}}\mathbf{j} - \Psi^j_{\mathrm{DL}}\mathbf{m}). \tag{4.10}$$

Finally, for each Ω_j, we define the *antisymmetric* bilinear form $B_j \colon \mathbf{X}(\Gamma_j)^2 \times \mathbf{X}(\Gamma_j)^2 \to \mathbb{C}$ acting on sets of Cauchy data as

$$B_j\left(\begin{pmatrix}\mathbf{m}\\ \mathbf{j}\end{pmatrix}, \begin{pmatrix}\tilde{\mathbf{m}}\\ \tilde{\jmath}\end{pmatrix}\right) := -b_j(\mathbf{m},\tilde{\jmath}) + b_j(\tilde{\mathbf{m}},\mathbf{j}) \quad \forall \begin{pmatrix}\mathbf{m}\\ \mathbf{j}\end{pmatrix}, \begin{pmatrix}\tilde{\mathbf{m}}\\ \tilde{\jmath}\end{pmatrix} \in \mathbf{X}(\Gamma_j)^2, \tag{4.11}$$

where $b(\cdot,\cdot)$ is the duality pairing defined, as at the beginning of this section, as $b_j(\boldsymbol{\mu},\boldsymbol{\lambda}) = \int_{\Gamma_j} \boldsymbol{\mu}\cdot(\boldsymbol{\lambda}\times\mathbf{n}_j)$.

The following theorem has been proved in [14].

Theorem 4.8. *Let* $\mathbf{W}(\Gamma_j) = \{\boldsymbol{\lambda} \in \mathbf{X}(\Gamma_j) \ :\ \mathrm{div}_\Gamma\,\boldsymbol{\lambda} = 0\}$ *and let* $\mathbf{V}(\Gamma_j)$ *be any supplement of* $\mathbf{W}(\Gamma_j)$ *in* $\mathbf{X}(\Gamma_j)$ *such that* (i) $\mathbf{V}(\Gamma_j) \hookrightarrow \mathbf{L}^2_t(\Gamma_j)$ *is compact;* (ii) *the decomposition* $\mathbf{X}(\Gamma_j) = \mathbf{V}(\Gamma_j) \oplus \mathbf{W}(\Gamma_j)$ *is stable in* $\mathbf{X}(\Gamma_j)$. *Then call* $\Theta : \mathbf{X}(\Gamma_j)^2 \to \mathbf{X}(\Gamma_j)^2$ *the operator associated with the mapping* $\mathbf{u} = \mathbf{v}+\mathbf{w} \mapsto \mathbf{v}-\mathbf{w}$ *componentwise. The operator* A_j *is injective and verifies*

$$\mathrm{Re}\,B((A+T)\boldsymbol{\xi}, \Theta(\overline{\boldsymbol{\xi}})) \geq \|\boldsymbol{\xi}\|^2_X, \qquad T : \mathbf{X}(\Gamma_j)^2 \to \mathbf{X}(\Gamma_j)^2 \quad \textit{compact.}$$

In other words, we are within Assumptions 1 and 2. Note that the supplement $\mathbf{V}(\Gamma_j)$ fulfilling the assumptions of Theorem 4.8 can be constructed in several ways [14], [25].

We are now ready to give the integral formulation associated with (4.5)–(4.8).

Proposition 4.9. *Let* $\mathbb{A} = \mathrm{diag}\{A_1,\ldots,A_J\}$, *and*

$$\underline{B}(\underline{\boldsymbol{\xi}},\underline{\boldsymbol{\lambda}}) = \sum_{j=1}^{J} B_j(\boldsymbol{\xi}_j,\boldsymbol{\lambda}_j), \qquad \underline{\boldsymbol{\xi}},\ \underline{\boldsymbol{\lambda}} \in \mathcal{X}^2. \tag{4.12}$$

The vector field $\mathbf{u}$ *is a solution of* (4.5)–(4.8) if and only if *its Cauchy data verifies* $\underline{\boldsymbol{\xi}} = \underline{\boldsymbol{\xi}}^0 + \underline{\boldsymbol{\xi}}_{\boldsymbol{hom}}$, $[\underline{\boldsymbol{\xi}}^0] = \underline{\boldsymbol{f}}$, *and*

$$\underline{\boldsymbol{\xi}}_{\boldsymbol{hom}} \in \mathcal{X}^2_{\boldsymbol{hom}} \quad : \quad \underline{B}(\mathbb{A}\underline{\boldsymbol{\xi}}_{\boldsymbol{hom}}, \underline{\boldsymbol{\lambda}}_{\boldsymbol{hom}}) = \underline{B}((\tfrac{1}{2}\mathbb{I} - \mathbb{A})\underline{\boldsymbol{\xi}}^0, \underline{\boldsymbol{\lambda}}_{\boldsymbol{hom}}) \qquad \forall\, \underline{\boldsymbol{\lambda}}_{\boldsymbol{hom}} \in \mathcal{X}^2_{\boldsymbol{hom}}. \tag{4.13}$$

The proof of this result is completely equivalent to the one for the corresponding Helmholtz problem and can be found in [37] (see also [38] and [15]). The next section is devoted to showing that this problem fits into our framework.

4.3.1. Verification of Assumption 1. We want to prove that the operator $\mathbb{A} : \mathcal{X}^2_{\mathbf{hom}} \to (\mathcal{X}^2_{\mathbf{hom}})'$, $(\mathcal{X}^2_{\mathbf{hom}})'$ being the dual of $\mathcal{X}^2_{\mathbf{hom}}$ with respect to the duality product $\underline{B}(\cdot,\cdot)$ fits Assumption 1. We have the following theorem.

Theorem 4.10. *Define*

$$\mathbf{W}_{hom} = \{\underline{\boldsymbol{\xi}} \in \mathcal{X}_{hom}\,, \quad \mathrm{div}_\Gamma\, \boldsymbol{\xi}_j = 0 \ \forall\, j\}.$$

Then there exists a supplement $\mathbf{V}_{hom}$ of $\mathbf{W}_{hom}$ in $\mathcal{X}_{hom}$ such that

$$\mathcal{X}_{hom} = \mathbf{V}_{hom} \oplus \mathbf{W}_{hom} \qquad \textit{with} \quad \mathbf{V}_{hom} \hookrightarrow \underline{\mathbf{L}}^2_t(\Sigma) \ \textit{compact}, \tag{4.14}$$

where $\underline{\mathbf{L}}^2_t(\Sigma) = \otimes_{j=1}^J \mathbf{L}^2_t(\Gamma_j)$. Moreover, the splitting is stable, i.e., the following stability estimate holds: $\underline{\boldsymbol{\lambda}} \in \mathcal{X}$, $\underline{\boldsymbol{\lambda}} = \underline{\mathbf{v}} + \underline{\mathbf{w}}$, $\underline{\mathbf{v}} \in \underline{\mathbf{V}}$, $\underline{\mathbf{w}} \in \underline{\mathbf{W}}$, and

$$\|\underline{\mathbf{v}}\|_{\mathcal{X}} + \|\underline{\mathbf{w}}\|_{\mathcal{X}} \lesssim \|\underline{\boldsymbol{\lambda}}\|_{\mathcal{X}} \lesssim \|\underline{\mathbf{v}}\|_{\mathcal{X}} + \|\underline{\mathbf{w}}\|_{\mathcal{X}}. \tag{4.15}$$

Proof. We assume for simplicity that each Ω_j is connected and simply connected, we construct the space $\mathbf{V}_{\mathbf{hom}}$ by the definition of a projector $\Pi_{\mathbf{V}_{\mathbf{hom}}} : \mathcal{X}_{\mathbf{hom}} \to \mathcal{X}_{\mathbf{hom}}$ such that $\ker\{\Pi_{\mathbf{V}_{\mathbf{hom}}}\} = \mathbf{W}_{\mathbf{hom}}$, and choose $\mathbf{V}_{\mathbf{hom}} = \Pi_{\mathbf{V}_{\mathbf{hom}}}(\mathcal{X}_{\mathbf{hom}})$. Let $\underline{\boldsymbol{\xi}} \in \mathcal{X}_{\mathbf{hom}}$ and B_R be a ball of radius R sufficiently large to ensure that $\Sigma \subset B_R$. Solve the following problems in each Ω_j:

$$\begin{array}{ll} -\Delta p_j = 0 & \text{in } \Omega_j \cap B_R, \\ \nabla p_j \cdot \mathbf{n}_j = \mathrm{div}_\Gamma\, \boldsymbol{\xi}_j & \text{on } \Gamma_j \text{ (and, for } j = J\,, \nabla p_J \cdot \mathbf{n}_R = 0 \text{ on } \partial B_R). \end{array} \tag{4.16}$$

We denote by $\underline{\boldsymbol{\varphi}}$ the function defined as $\boldsymbol{\varphi}_j = \nabla p_j$. We deduce then that $\mathrm{div}\, \underline{\boldsymbol{\varphi}} = 0$ on B_R since $\mathrm{div}\, \boldsymbol{\varphi}_j = 0$ in Ω_j and $\boldsymbol{\varphi}_j \cdot \mathbf{n}_j + \boldsymbol{\varphi}_i \cdot \mathbf{n}_i = 0$ on Γ_{ij} $\forall\, i, j$, since $\underline{\boldsymbol{\xi}} \in \mathcal{X}_{\mathbf{hom}}$.

Using, e.g., [1], $\underline{\boldsymbol{\varphi}}$ admits a vector potential in B_R, $\underline{\mathbf{V}} \in \mathbf{H}^1(B_R) \cap \mathbf{H}_0(\mathbf{curl}, B_R)$ verifying

$$\mathbf{curl}\, \underline{\mathbf{V}} = \underline{\boldsymbol{\varphi}}, \quad \mathrm{div}\, \underline{\mathbf{V}} = 0.$$

By continuity we have

$$\|\underline{\mathbf{V}}\|_{\mathbf{H}^1(B_R)} \lesssim \|\underline{\boldsymbol{\varphi}}\|_{\mathbf{L}^2(B_R)} \lesssim \|\,\mathrm{div}_\Gamma\, \underline{\boldsymbol{\xi}}\|_{-1/2,\Sigma}.$$

Set $\Pi_{\mathbf{V}_{\mathbf{hom}}} \underline{\boldsymbol{\xi}} = \gamma_D \underline{\mathbf{V}}$. By construction $\Pi_{\mathbf{V}_{\mathbf{hom}}} : \mathcal{X} \to \mathbf{H}^{1/2}_\times(\Sigma)$ and $\ker\{\Pi_{\mathbf{V}_{\mathbf{hom}}}\} = \mathbf{W}_{\mathbf{hom}}$, and for $\mathbf{v}_j = (\gamma_D \underline{\mathbf{V}})_j$, $\mathrm{div}_\Gamma\, \mathbf{v}_j = (\mathbf{curl}\, \underline{\mathbf{V}})_{|\Omega_j} \cdot \mathbf{n}_j = \boldsymbol{\varphi}_j \cdot \mathbf{n}_j = \mathrm{div}_\Gamma\, \boldsymbol{\xi}_j$. Thus, $\Pi_{\mathbf{V}_{\mathbf{hom}}}$ is a projection and we conclude by observing that $\mathbf{H}^{1/2}_\times(\Sigma)$ is compactly embedded in $\underline{\mathbf{L}}^2_t(\Sigma)$. ◻

We consider an operator $\Theta : \mathcal{X}^2_{\mathbf{hom}} \to \mathcal{X}^2_{\mathbf{hom}}$ which maps $\underline{\boldsymbol{\xi}} \in \mathcal{X}^2_{\mathbf{hom}}$ with Hodge decomposition (Theorem 4.10 applied twice) $\underline{\boldsymbol{\xi}} = \underline{\mathbf{v}} + \underline{\mathbf{w}}$ into $\Theta(\underline{\boldsymbol{\xi}}) = \underline{\mathbf{v}} - \underline{\mathbf{w}}$. The next theorem follows then as an immediate consequence of Theorems 4.8 and 4.10.

Theorem 4.11. *There exists a compact operator $T : \mathcal{X}^2_{hom} \to \mathcal{X}^2_{hom}$ and a constant $\alpha > 0$ such that*

$$\mathrm{Re}\, \underline{B}((\mathbb{A} + T)\underline{\boldsymbol{\xi}}, \Theta(\overline{\underline{\boldsymbol{\xi}}})) \geq \alpha \left\|\underline{\boldsymbol{\xi}}\right\|^2_{\mathcal{X}^2}. \tag{4.17}$$

Proof. We use the definitions of $\underline{B}$ and $\mathbb{A}$:

$$\underline{B}(\mathbb{A}\underline{\boldsymbol{\xi}}, \Theta(\underline{\boldsymbol{\xi}})) = \sum_j B_j(A_j(\mathbf{v}_j + \mathbf{w}_j), \overline{\mathbf{v}}_j - \overline{\mathbf{w}}_j)$$

with $\underline{\boldsymbol{\xi}} = \underline{\mathbf{v}} + \underline{\mathbf{w}}$, $\underline{\mathbf{v}} = (\mathbf{v}_1, \dots, \mathbf{v}_J)$ and $\underline{\mathbf{w}} = (\mathbf{w}_1, \dots, \mathbf{w}_J)$. Applying Theorem 4.8, we know that, for each j, there exists a compact operator $T_j : \mathbf{X}(\Gamma_j)^2 \to \mathbf{X}(\Gamma_j)^2$ such that

$$\operatorname{Re} B_j(A_j + T_j(\mathbf{v}_j + \mathbf{w}_j), \overline{\mathbf{v}}_j - \overline{\mathbf{w}}_j) \geq \|\boldsymbol{\xi}_j\|_{\mathbf{X}(\Gamma_j)^2}. \tag{4.18}$$

Summing (4.18) over j, the statement is proved. □

Since we know that (4.13) admits at most one solution (as a consequence of Theorem 4.7 and Proposition 4.9), this theorem says that (4.13) is in our framework, i.e., it verifies Assumption 1. As a matter of fact, it verifies also Assumption 2.

4.3.2. Discretization and verification of the (GAP) property.

We concentrate now on the discretization of the problem (4.13). First we construct a compatible mesh on the interfaces Σ in the following way: Consider that there exists a triangulation $\mathcal{T}_h(B_R)$ of a ball B_R containing Σ and such that Σ is composed only of faces of the underlying triangulation $\mathcal{T}_h(B_R)$, i.e., Σ does not cut elements of the mesh. This automatically generates a compatible triangulation of Σ, $\mathcal{T}_h(\Sigma)$ and of course also triangulations of Γ_j's, that we denote by $\mathcal{T}_h(\Gamma_j)$.

Each single space $\mathbf{X}(\Gamma_j)$ is discretized by means of Raviart–Thomas finite elements of degree k defined on $\mathcal{T}_h(\Gamma_j)$, [36], [22]. We denote the discrete spaces by $\mathbf{X}_h(\Gamma_j)$.

Now, the discrete counterpart of $\mathcal{X}$ is $\mathcal{X}_h = \mathbf{X}_h(\Gamma_1) \times \cdots \times \mathbf{X}_h(\Gamma_J)$, and the discrete counterpart of $\mathcal{X}_{\mathbf{hom}}$ is

$$(\mathcal{X}_h)_{\mathbf{hom}} = \mathcal{X}_h \cap \mathcal{X}_{\mathbf{hom}}. \tag{4.19}$$

Note that, thanks to the fact that the nonempty intersections $\Gamma_{ij} = \Gamma_i \cap \Gamma_j$ are discretized by means of only one triangulation, namely, $\mathcal{T}_h(\Sigma)_{|\Gamma_{ij}}$, the space $(\mathcal{X}_h)_{\mathbf{hom}}$ is well defined as a constrained subspace of $\mathcal{X}_h$. We are then ready to state the theorem.

Theorem 4.12. *There exists a splitting $(\mathcal{X}_h)_{\boldsymbol{hom}} = (\mathbf{V}_h)_{\boldsymbol{hom}} \oplus (\mathbf{W}_h)_{\boldsymbol{hom}}$ such that*

$$\delta((\mathbf{V}_h)_{\boldsymbol{hom}}, \mathbf{V}_{\boldsymbol{hom}}) \to 0 \textit{ when } h \to 0 \qquad \textit{and} \qquad \delta((\mathbf{W}_h)_{\boldsymbol{hom}}, \mathbf{W}_{\boldsymbol{hom}}) = 0.$$

Proof. We assume for the sake of simplicity that each Ω_j is connected and simply connected.

We set $(\mathbf{W}_h)_{\mathbf{hom}} = \mathbf{W}_{\mathbf{hom}} \cap \mathcal{X}_h$. An alternate definition is the following: Set $\mathbf{W}_h(\Gamma_j) = \{\boldsymbol{\lambda}_h \in \mathbf{X}_h(\Gamma_j) \ : \ \operatorname{div}_\Gamma \boldsymbol{\lambda}_h = 0\}$. $\mathbf{W}_h(\Gamma_j)$ is the finite elements space of $\mathbf{curl}_\Gamma\, \mathcal{P}_h$, where $\mathcal{P}_h$ is the space of continuous piecewise polynomials of degree k [22], [11], i.e., characterized by degrees of freedom attached to vertices, edges, and triangles on Γ_j. Then we set $\mathbf{W}_h = \mathbf{W}_h(\Gamma_1) \times \cdots \times \mathbf{W}_h(\Gamma_J)$; this space has for each vertex (or edge, or triangle) belonging to an intersection Γ_{ij} two sets of independent degrees of freedom, one defining $\mathbf{W}_h(\Gamma_i)$ and the other $\mathbf{W}_h(\Gamma_j)$. Now, in $(\mathbf{W}_h)_{\mathbf{hom}} = \mathbf{W}_h \cap \mathcal{X}_{\mathbf{hom}}$, the degrees of freedom belonging to these two sets are constrained to be equal for each vertex, edge, or triangle.

Now we construct the supplement $(\mathbf{V}_h)_{\mathbf{hom}}$. We use two intermediate finite elements spaces: the Nédélec edge elements of degree k, $\mathbf{X}_h(B_R)$, as introduced in section 4.1, but on B_R (with vanishing tangential component on ∂B_R), and the Raviart–Thomas finite elements of degree k, $\mathbf{Y}_h(B_R)$, with vanishing normal component on ∂B_R. We construct local Nédélec and Raviart–Thomas elements as $\mathbf{X}_h(\Omega_j) =$

$\mathbf{X}_h(B_R)_{|\Omega_j}$ and $\mathbf{Y}_h(\Omega_j) := \mathbf{Y}_h(B_R)_{|\Omega_j}$ (and $\mathbf{X}_h(\Omega_J) = \mathbf{X}_h(B_R)_{\Omega_J \cap B_R}$, $\mathbf{Y}_h(\Omega_J) := \mathbf{Y}_h(B_R)_{|\Omega_J \cap B_R}$). We refer to [36], [6], [22] for suitable definitions and properties. We construct the space $(\mathbf{V}_h)_{\mathbf{hom}}$ as we did for $\mathbf{V}_{\mathbf{hom}}$ in the proof of Theorem 4.10, i.e., by constructing a projection operator $\Pi : (\mathcal{X}_h)_{\mathbf{hom}} \to (\mathcal{X}_h)_{\mathbf{hom}}$ with $\ker\{\Pi\} = (\mathbf{W}_h)_{\mathbf{hom}}$.

Then let $\underline{\boldsymbol{\lambda}}_h \in (\mathcal{X}_h)_{\mathbf{hom}}$, $\underline{\boldsymbol{\lambda}}_h = (\boldsymbol{\lambda}_{1,h}, \ldots, \boldsymbol{\lambda}_{J,h})$, $\boldsymbol{\lambda}_{j,h} \in \mathbf{X}_h(\Gamma_j)$. We solve the following:

$$\text{Find } \boldsymbol{\Xi}_{j,h} \in \mathbf{Y}_h(\Omega_j) \ : \begin{cases} \operatorname{div} \boldsymbol{\Xi}_{j,h} = 0 & \text{on } \Omega_j, \\ \int_{\Omega_j} \boldsymbol{\Xi}_{j,h} \, \mathbf{curl}\, \boldsymbol{\chi}_h = 0 & \forall\, \boldsymbol{\chi}_h \in \mathbf{X}_h(\Omega_j), \\ \boldsymbol{\Xi}_{j,h} \cdot \mathbf{n}_j = \operatorname{div}_\Gamma \boldsymbol{\lambda}_{j,h} & \text{on } \Gamma_j \,. \end{cases}$$

This problem is solvable since $\int_{\Gamma_j} \operatorname{div}_\Gamma \boldsymbol{\lambda}_{j,h} = 0$; moreover, it is uniquely solvable [6]. Now, since $\underline{\boldsymbol{\lambda}}_h \in (\mathcal{X}_h)_{\mathbf{hom}}$, by construction the vector $\boldsymbol{\Xi}_h$, $\boldsymbol{\Xi}_{h|\Omega_j} := \boldsymbol{\Xi}_{j,h}$, belongs to $\mathbf{Y}_h(B_R)$. Now we solve the discrete and continuous vector potential problem:

$$\text{Find } \boldsymbol{\Psi}_h \in \mathbf{X}_h(B_R) \ : \quad \begin{cases} \mathbf{curl}\, \boldsymbol{\Psi}_h = \boldsymbol{\Xi}_h & \text{on } B_R, \\ \int_{B_R} \boldsymbol{\Psi}_h \cdot \mathbf{w}_h = 0 & \forall\, \mathbf{w}_h \in \mathbf{X}_h(B_R)\,,\ \mathbf{curl}\, \mathbf{w}_h = 0, \end{cases}$$

$$\text{Find } \boldsymbol{\Psi} \in \mathbf{H}_0(\mathbf{curl}, B_R) \ : \ \begin{cases} \mathbf{curl}\, \boldsymbol{\Psi} = \boldsymbol{\Xi}_h & \text{on } B_R, \\ \operatorname{div} \boldsymbol{\Psi} = 0 & \text{on } B_R. \end{cases}$$

These problems are uniquely solvable [1]; moreover, the continuity estimate

$$\|\boldsymbol{\Psi}\|_{\mathbf{H}^1(B_R)} + \|\boldsymbol{\Psi}_h\|_{\mathbf{H}(\mathbf{curl}, B_R)} \lesssim \|\boldsymbol{\Xi}_h\|_{L^2(B_R)} \lesssim \sum_{j=1}^{J} \| \operatorname{div}_\Gamma \boldsymbol{\lambda}_j\|_{H^{-1/2}(\Gamma_j)} \tag{4.20}$$

holds.

Now the proof is basically finished. Denote by $\boldsymbol{\Psi}_{j,h}$ ($\boldsymbol{\Psi}_j$, resp.) the restriction of $\boldsymbol{\Psi}_h$ ($\boldsymbol{\Psi}$, resp.) to Ω_j (for $j = J$ to $\Omega_J \cap B_R$) $\forall\, j$.

It is enough to set $\Pi \underline{\boldsymbol{\lambda}}_h = \underline{\boldsymbol{\lambda}}_h^{\mathbf{V}} := (\gamma_D(\boldsymbol{\Psi}_{1,h}), \ldots, (\boldsymbol{\Psi}_{J,h}))$; by construction,

$$\operatorname{div}_\Gamma \boldsymbol{\lambda}_{j,h}^{\mathbf{V}} = \mathbf{curl}\, \boldsymbol{\Psi}_{j,h|\Gamma_j} \cdot \mathbf{n}_j = \boldsymbol{\Xi}_{j,h} \cdot \mathbf{n}_j = \operatorname{div}_\Gamma \boldsymbol{\lambda}_{j,h}.$$

Thus, $\ker\{\Pi\} = (\mathbf{W}_h)_{\mathbf{hom}}$. Set $\underline{\boldsymbol{\lambda}}^{\mathbf{V}} = (\gamma_D(\boldsymbol{\Psi}_1), \ldots, \gamma_D(\boldsymbol{\Psi}_J))$; by construction, $\underline{\boldsymbol{\lambda}}^{\mathbf{V}} \in \mathbf{V}_{\mathbf{hom}}$. It is the candidate in $\mathbf{V}_{\mathbf{hom}}$ that is needed to verify the (GAP) property:

$$\begin{aligned} \|\underline{\boldsymbol{\lambda}}^{\mathbf{V}} - \underline{\boldsymbol{\lambda}}_h^{\mathbf{V}}\|_{\mathcal{X}} &\lesssim \|\boldsymbol{\Psi} - \boldsymbol{\Psi}_h\|_{\mathbf{H}(\mathbf{curl}, B_R)} \lesssim \|\boldsymbol{\Psi} - \boldsymbol{\Psi}_h\|_{L^2(B_R)} \\ &\lesssim h \|\boldsymbol{\Psi}\|_{\mathbf{H}^1(B_R)} \lesssim h \|\boldsymbol{\Xi}_h\|_{L^2(B_R)} \\ &\lesssim h \sum_{j=1}^{J} \| \operatorname{div}_\Gamma \boldsymbol{\lambda}_{j,h}\|_{H^{-1/2}(\Gamma_j)} \lesssim h \|\underline{\boldsymbol{\lambda}}_h^{\mathbf{V}}\|_{\mathcal{X}}, \end{aligned} \tag{4.21}$$

which proves that $\delta((\mathbf{V}_h)_{\mathbf{hom}}, \mathbf{V}_{\mathbf{hom}}) \lesssim h$. Note that the forth estimate in (4.21) comes from the (GAP) property for Nédélec finite elements, which has been proved in section 4.1. □

COROLLARY 4.13. *The following Galerkin problem admits a unique solution when h is sufficiently small: Find* $\underline{\boldsymbol{\xi}}_h \in (\mathcal{X}_h)^2_{\mathit{hom}}$ *such that*

$$\underline{B}(\mathbb{A} \underline{\boldsymbol{\xi}}_h, \underline{\boldsymbol{\lambda}}_h) = \underline{B}((\tfrac{1}{2}\mathbb{I} - \mathbb{A})\underline{\boldsymbol{\xi}}^0, \underline{\boldsymbol{\lambda}}_h) \qquad \forall\, \underline{\boldsymbol{\lambda}}_h \in (\mathcal{X}_h)^2_{\mathit{hom}}, \tag{4.22}$$

Moreover, let $\underline{\boldsymbol{\xi}}_{hom} \in \mathcal{X}^2_{hom}$ be the solution of (4.13). *Then it holds that*

$$\|\underline{\boldsymbol{\xi}}_{hom} - \underline{\boldsymbol{\xi}}_h\|_{\mathcal{X}^2} \lesssim \inf_{\underline{\boldsymbol{\lambda}}_h \in (\mathcal{X}_h)^2_{hom}} \|\underline{\boldsymbol{\xi}}_{hom} - \underline{\boldsymbol{\lambda}}_h\|_{\mathcal{X}^2}.$$

ON THE ERROR OF LINEAR INTERPOLATION AND THE ORIENTATION, ASPECT RATIO, AND INTERNAL ANGLES OF A TRIANGLE*

WEIMING CAO†

Abstract. In this paper, we attempt to reveal the precise relation between the error of linear interpolation on a general triangle and the geometric characters of the triangle. Taking the model problem of interpolating quadratic functions, we derive two exact formulas for the H^1-seminorm and L^2-norm of the interpolation error in terms of the area, aspect ratio, orientation, and internal angles of the triangle. These formulas indicate that (1) for highly anisotropic triangular meshes the H^1-seminorm of the interpolation error is almost a monotonically decreasing function of the angle between the orientations of the triangle and the function; (2) maximum angle condition is not essential if the mesh is aligned with the function and the aspect ratio is of magnitude $\sqrt{|\lambda_1/\lambda_2|}$ or less, where λ_1 and λ_2 are the eigenvalues of the Hessian matrix of the function. With these formulas we identify the optimal triangles, which produce the smallest H^1-seminorm of the interpolation error, to be the acute isosceles aligned with the solution and of an aspect ratio about $0.8|\frac{\lambda_1}{\lambda_2}|$. The L^2-norm of the interpolation error depends on the orientation and the aspect ratio of the triangle, but not directly on its maximum or minimum angles. The optimal triangles for the L^2-norm are those aligned with the solution and of an aspect ratio $\sqrt{|\lambda_1/\lambda_2|}$. These formulas can be used to formulate more accurate mesh quality measures and to derive tighter error bounds for interpolations.

Key words. anisotropic mesh, linear interpolation, aspect ratio, mesh alignment, maximum angle condition

1. Introduction.

It is well known that on quasi-uniform meshes the accuracy of piecewise linear interpolation is first order in the H^1-norm. More precisely, denote by $H^m(\Omega)$ the usual Sobolev spaces of order m on a bounded domain $\Omega \in \mathcal{R}^2$. For any $u \in H^2(\Omega)$, the H^1-norm of the error between u and its piecewise linear interpolation u_I can be bounded by

$$\|u - u_I\|_{H^1(\Omega)} \leq ch|u|_{H^2(\Omega)},$$

where h is the diameter of the triangles in the mesh, and c is a constant independent of h and u.

If the mesh is not quasi-uniform, then the error contributed from each triangle K can be bounded by

$$\|u - u_I\|_{H^1(K)} \leq c\frac{h^2}{\rho}|u|_{H^2(K)},$$

where ρ is the diameter of the largest inscribed circle in K. This error bound guarantees the H^1-norm of the error converge to 0 as $h \to 0$, as long as $\frac{h}{\rho}$ remains bounded. This is equivalent to requiring that the minimum angle of K is bounded from 0 [5].

http://www.siam.org/journals/sinum/43-1/43349.html

†Department of Applied Mathematics, University of Texas at San Antonio, San Antonio, TX 78249 (wcao@math.utsa.edu).

However, this error estimate is not tight when the triangle has only one small angle. Babuška and Aziz [2] showed that the minimum angle condition is actually not essential for the convergence of linear interpolation. They improved the error bound as

$$\|u - u_I\|_{H^1(K)} \le \Gamma(\alpha) h |u|_{H^2(K)},$$

where $\Gamma(\alpha)$ is an increasing function of the maximum angle α of K. Therefore, in order to guarantee the convergence it is only required that the maximum angle be bounded from π. This is the well-known maximum angle condition. This condition is necessary and sufficient for the convergence of the linear interpolation process over the class of functions of $H^2(K)$.

In adaptive computation, one often knows a priori or a posteriori some information of the functions to be approximated. This information can be used to restrict the set of functions considered and to avoid the divergence case although the triangle has a maximum angle close to π. Indeed, long and thin triangles violating the maximum angle condition have been used successfully in engineering, particularly in computational fluid dynamics [1, 15]. For problems with very different length scales in different spatial directions, long and thin triangles turn out to be better choices than shape regular ones if they are properly used. This motivated an intensive study on the error analysis for anisotropic meshes in the finite element method (FEM). For instance, Apel [1] described an error estimate in terms of the length scales h_1 and h_2 along the x and y directions, respectively,

$$|u - u_I|_{W^{m,p}(K)} \le c \sum_{\alpha_1+\alpha_2=\ell-m} h_1^{\alpha_1} h_2^{\alpha_2} |\frac{\partial^{\ell-m} u}{\partial x^{\alpha_1} \partial y^{\alpha_2}}|_{W^{m,p}(K)}, \qquad m = 0, 1,$$

where $W^{m,p}(K)$ is the Sobolev space of functions whose up to mth order derivatives are L^p-integratable. If u and K are aligned and the maximum angle condition is satisfied, this estimate is asymptotically accurate, i.e., both sides of the above inequality have the same h_i order. But when the maximum angle of K approaches π, the ratio of the error bound over the actual error norm goes to infinity [7]. Formaggia and Perotto [7] presented another type of estimate of the H^1-norm for the interpolation error based on the eigendecomposition of the affine mapping from a standard element to K. Their estimate is accurate when u and K are aligned and the maximum angle of K is close to π. However, the ratio of their estimate over the actual error norm goes to infinity when two angles of K approach $\frac{\pi}{2}$.

More recent error analyses have been based on the overall mesh properties and the behavior of the approximation functions. For instance, Berzins [4] developed a mesh quality indicator measuring the correlation between the anisotropic features of the mesh and those of the solutions. Kunert [11] proposed a so-called matching function to quantify how good overall a mesh is for a specific solution. Huang [8] introduced measures for three aspects of the mesh qualities—aspect ratio, alignment, and adaptation—and an overall quality mesh measure based on them. He formulated the error bounds in terms of these measures and proposed a variational formulation to optimize the overall mesh quality measure to control the interpolation error. A similar idea was used by Huang and Sun [9] in formulating the monitor function in variational mesh adaptation.

Needless to say, the interpolation error depends on the solution and the size and shape of the elements in the mesh. Understanding this relation is crucial for the generation of efficient and effective meshes for the FEM. However, in all the error estimates for anisotropic meshes, the relation between the error and the geometric characters of a triangle, such as the alignment, aspect ratio, and internal angles, has not been revealed explicitly. In the mesh generation community, this relation is studied more closely for the model problem of interpolating quadratic functions. This model is a reasonable simplification of the cases involving general functions, since quadratic functions are the leading terms in the local expansion of the linear interpolation errors. For instance, Nadler [12] derived an exact expression for the L^2-norm of the linear interpolation error in terms of the three sides $\boldsymbol{\ell}_1, \boldsymbol{\ell}_2$, and $\boldsymbol{\ell}_3$ of the triangle K,

$$\|u - u_I\|^2_{L^2(K)} = \frac{|K|}{180}[(d_1 + d_2 + d_3)^2 + d_1 d_2 + d_2 d_3 + d_1 d_3],$$

where $|K|$ is the area of the triangle, $d_i = \boldsymbol{\ell}_i \cdot H \boldsymbol{\ell}_i$ with H being the Hessian matrix of u. Bank and Smith [3] gave a similar formula for the H^1-seminorm of the linear interpolation error; see (8) in section 3. Assuming $u = \lambda_1 x^2 + \lambda_2 y^2$, D'Azevedo and Simpson [6] derived the exact formula for the maximum norm of the interpolation error

$$\|u - u_I\|^2_{L^\infty(K)} = \frac{D_{12} D_{23} D_{31}}{16 \lambda_1 \lambda_2 |K|^2},$$

where $D_{ij} = \boldsymbol{\ell}_i \cdot \mathrm{diag}(\lambda_1, \lambda_2) \boldsymbol{\ell}_i$. Based on the geometric interpretation of this formula, they proved that for a fixed area the optimal triangle, which produces the smallest maximum interpolation error, is the one obtained by compressing an equilateral triangle by factors $\sqrt{\lambda_1}$ and $\sqrt{\lambda_2}$ along the two eigenvectors of the Hessian matrix of u. Furthermore, the optimal incidence for a given set of interpolation points is the Delaunay triangulation based on the stretching map (by factors $\sqrt{\lambda_1}$ and $\sqrt{\lambda_2}$ along the two eigenvector directions) of the grid points. Rippa [13] showed that the mesh obtained this way is also optimal for the L^p-norm of the error for any $1 \le p \le \infty$.

Thought these formulas are exact, they do not describe explicitly the relation between the error and the geometric characters of the triangle. In this paper, we attempt to reveal this relation explicitly and precisely. Taking the model problem of linear interpolation of quadratic functions, we derive two exact expressions for the H^1-seminorm and L^2-norm of the interpolation error in terms of the area, aspect ratio, alignment direction, and internal angles of the triangle. From these formulas the effects of the geometric characters of a triangle can be clearly identified. They indicate that (1) for highly anisotropic triangular meshes the H^1-seminorm of the interpolation error is almost a monotonically decreasing function of the angle between the orientation of the triangle and the orientation of the function; (2) maximum angle condition is critical if the mesh is not aligned with the function or if the aspect ratio is larger than $\sqrt{|\lambda_1/\lambda_2|}$; (3) if the triangles are aligned with the function and the aspect ratio is about $\sqrt{|\lambda_1/\lambda_2|}$ or less, then the error is not sensitive to the maximum angle of the triangle. Also, we can easily identify the best triangles which produce the smallest H^1- or L^2-norm of the interpolation error. It turns out that in the sense of the H^1-seminorm, the optimal triangle with a given area is the acute isosceles aligned with the function and of the aspect ratio about $0.8|\frac{\lambda_1}{\lambda_2}|$. The L^2-norm of the interpolation error depends on the alignment and the aspect ratio of the triangle, but not directly on its maximum or minimum angles. The optimal triangles for the L^2-norm are those aligned with the solution and of an aspect ratio $\sqrt{|\lambda_1/\lambda_2|}$.

The organization of this paper is as follows. In section 2 we give a precise definition of the orientation and the aspect ratio of a triangle by using the singular value decomposition (SVD) of the affine mapping from a standard element to the triangle. In section 3 we derive the exact formulas for the H^1-seminorm and L^2-norm of the interpolation error for the quadratic functions. Then we identify in section 4 a number of special cases that are of interests to the optimal design of meshes. Optimal choices of the aspect ratio and the alignment direction are discussed here. In section 5 we elaborate in more detail the effects of various geometric characters of a triangle on the interpolation error. Finally we demonstrate by an example the accuracy of the linear interpolation errors on different meshes.

2. Mapping and the geometric characters of a triangle. Let K be a triangle in the xy-plane, and let $\boldsymbol{x}_1, \boldsymbol{x}_2$, and $\boldsymbol{x}_3$ be the vertices of K. Denote by $\boldsymbol{\ell}_i$ the vector of the side opposite to $\boldsymbol{x}_i$ (in counterclockwise direction). Let $\hat{K}$ be the equilateral triangle with the vertices

$$\boldsymbol{\xi}_1 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad \boldsymbol{\xi}_2 = \begin{bmatrix} -\frac{\sqrt{3}}{2} \\ -\frac{1}{2} \end{bmatrix}, \quad \boldsymbol{\xi}_3 = \begin{bmatrix} \frac{\sqrt{3}}{2} \\ -\frac{1}{2} \end{bmatrix}.$$

The three sides of $\hat{K}$ are $\boldsymbol{e}_i = \sqrt{3}[\cos(2(i-1)\pi/3), \sin(2(i-1)\pi/3)]^T, i = 1, 2, 3$. See Figure 1.

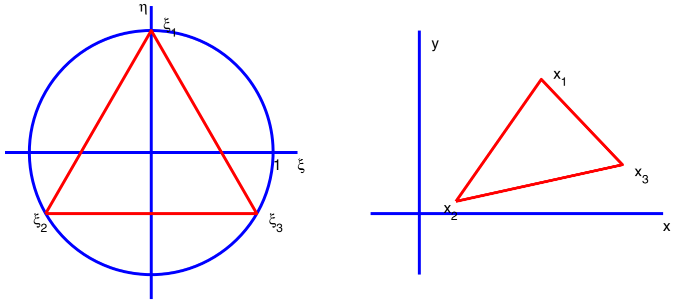

Fig. 1. *Standard element $\hat{K}$ and physical element K.*

Let $\boldsymbol{x}_c = \frac{1}{3}(\boldsymbol{x}_1 + \boldsymbol{x}_2 + \boldsymbol{x}_3)$ be the center of K. The affine mapping (which maps $\boldsymbol{\xi}_i$ to $\boldsymbol{x}_i$) from $\hat{K}$ to K can be expressed as $\boldsymbol{x} = M\boldsymbol{\xi} + \boldsymbol{x}_c$ with

$$M = \left(\frac{1}{\sqrt{3}}(\boldsymbol{x}_1 - \boldsymbol{x}_3), \boldsymbol{x}_2 - \boldsymbol{x}_c \right).$$

Denote by $M = U\Sigma V^*$ the SVD of the 2×2 matrix M. Without loss of generality, we assume $\Sigma = \text{diag}(\sigma_1, \sigma_2)$ with $\sigma_1 \geq \sigma_2 > 0$, and

$$U = R_{\phi_u} = \begin{bmatrix} \cos\phi_u & -\sin\phi_u \\ \sin\phi_u & \cos\phi_u \end{bmatrix}, \quad V = R_{\phi_v} = \begin{bmatrix} \cos\phi_v & -\sin\phi_v \\ \sin\phi_v & \cos\phi_v \end{bmatrix}.$$

R_{ϕ_u} and R_{ϕ_v} represent the linear transform of rotation (counterclockwise) by angles ϕ_u and ϕ_v, respectively.

The mapping $\boldsymbol{x} = M\boldsymbol{\xi}$ maps $\hat{K}$ into a triangle centered at the origin. Its effect can be understood as the composition of three operations (see, e.g., [16]): (1) rotation clockwise by angle ϕ_v; then (2) stretching by factors σ_1 and σ_2 in ξ and η directions, respectively; and finally (3) rotation counterclockwise by angle ϕ_u. A circle (centered at (0,0)) in the $\xi\eta$-plane will be mapped into an ellipse in the xy-plane with two axes σ_1 and σ_2, and the longer axis forms an angle ϕ_u with the x-axis. See Figure 2.

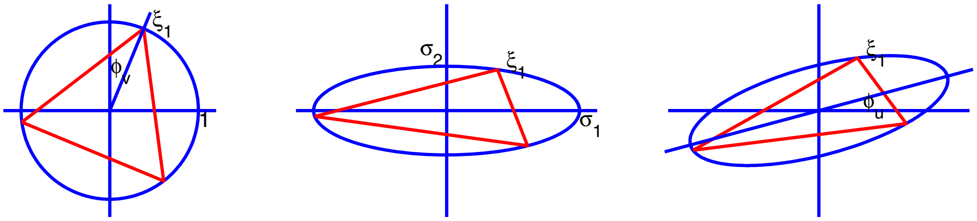

FIG. 2. *From $\hat{K}$ to K under the mapping M: $R^*_{\phi_v}\hat{K}$, $\Sigma R^*_{\phi_v}\hat{K}$, $R_{\phi_u}\Sigma R^*_{\phi_v}\hat{K}$.*

We define the aspect ratio of the triangle K as

$$r_{12} = \frac{\sigma_1}{\sigma_2} \tag{1}$$

and define the orientation of K as the direction of angle ϕ_u with the x-axis.

It can be seen that K is equilateral if and only if $\sigma_1 = \sigma_2$ and that K is isosceles if and only if $\phi_v = \frac{m\pi}{6}$ with integer m or $\sigma_1 = \sigma_2$. Together with the aspect ratio, ϕ_v determines the three internal angles of the triangle. For a fixed aspect ratio, the maximum internal angle of K is a periodic even function of ϕ_v with period $\frac{\pi}{3}$, and it is decreasing in $(0, \frac{\pi}{6})$. K is an obtuse isosceles triangle when $\phi_v = \frac{m\pi}{3}$ and an acute isosceles triangle when $\phi_v = \frac{(2m+1)\pi}{6}$. If K is an obtuse/acute isosceles, then its orientation is in parallel/perpendicular to its base. Furthermore, let b and h be the length of the base and the height over the base of an isosceles triangle; then

$$\left\{\begin{array}{lllll} \sigma_1 = \frac{\sqrt{3}}{3}b, & \sigma_2 = \frac{2}{3}h, & r_{12} = \frac{\sqrt{3}}{2}\frac{b}{h}, & \phi_v = 0 & \text{when } h \le \frac{\sqrt{3}}{2}b, \\ \sigma_1 = \frac{2}{3}h, & \sigma_2 = \frac{\sqrt{3}}{3}b, & r_{12} = \frac{2}{\sqrt{3}}\frac{h}{b}, & \phi_v = \frac{\pi}{6} & \text{when } h > \frac{\sqrt{3}}{2}b. \end{array}\right.$$

For general triangles, the aspect ratio r_{12} can be found as follows. Let

$$q(K) = \frac{1}{2}\left(\frac{\sigma_1}{\sigma_2} + \frac{\sigma_2}{\sigma_1}\right) \in [1, \infty).$$

This quantity can be calculated from the three sides and the area of K as (see formula (10) below)

$$q(K) = \frac{\sigma_1^2 + \sigma_2^2}{2\sigma_1\sigma_2} = \frac{|\boldsymbol{\ell}_1|^2 + |\boldsymbol{\ell}_2|^2 + |\boldsymbol{\ell}_3|^2}{4\sqrt{3}|K|}. \tag{2}$$

Therefore,

$$r_{12} = q + \sqrt{q^2 - 1}.$$

Clearly, the closer r_{12} is to 1, the closer K is to being equilateral. The same is true for the quantity $q(K)$. Therefore, both r_{12} and $q(K)$ can be used to measure the closeness of a triangle to being equilateral. Indeed, the reciprocal of the right-hand-side expression in (2) was used by Bank and Smith [3] as the "shape regularity quantity" of a triangle. $q(K)$ can also be expressed in terms of the matrix M directly. Note that σ_1 and σ_2 are eigenvalues of $(M^T M)^{1/2}$; it is easy to see that

$$q(K) = \frac{\|M\|_F^2}{2\ \det(M)},$$

where $\|\cdot\|_F$ stands for the Frobenius norm of a matrix. This formula was used by Knupp, Margolin, and Shashkov [10] in certain functionals characterizing the smoothness of the mesh.

There are several other ways to define the aspect ratio and the orientation of a triangular element in the finite element analysis. For instance, the aspect ratio is usually defined as the ratio of the length of the longest side over the perpendicular distance from it to the opposite vertex, or as the ratio of the diameter of the triangle over the diameter of the largest inscribed circle in the triangle. The orientation can be defined as the direction of the longest side. It is easy to see that these definitions are equivalent to (1) up to some bounded constants. However, they are not precise enough for describing accurately the behavior of the interpolation errors.

3. Formulas for H^1- and L^2- norms of the interpolation error. Without loss of generality, assume K is a triangle with its center at the origin and its orientation being the x-axis, i.e., $\boldsymbol{x}_c = \boldsymbol{0}, \phi_u = 0$. We study the H^1- and L^2-norms of the error for the linear interpolation of a quadratic function u over K. Since the first order terms of u have no contribution to the error of linear interpolation, we assume in particular that $u = \frac{1}{2}\boldsymbol{x} \cdot H\boldsymbol{x}$, where H is the Hessian of u. Since H is a 2×2 symmetric matrix, we may decompose it into

$$H = R_{\phi_h} \begin{bmatrix} \lambda_1 & \\ & \lambda_2 \end{bmatrix} R_{\phi_h}^T, \tag{3}$$

where R_{ϕ_h} is the matrix of rotation by an angle ϕ_h. We also assume that $\lambda_1 \geq |\lambda_2|$. Other cases can be covered by simply considering the function $-u$. It is easy to see that the contour lines of u are concentrical ellipses (when $\lambda_1\lambda_2 > 0$) or hyperbolas (when $\lambda_1\lambda_2 < 0$). Their axes are multiples of $1/\sqrt{\lambda_1}$ and $1/\sqrt{\lambda_2}$, and the longer axis (with λ_2) is of angle ϕ_h with the y-axis. We define this direction as the orientation of function u. When $\phi_h = \frac{\pi}{2}$, u is oriented along the x-axis, i.e., in the same direction as triangle K. In this case, we say K and u are aligned. When $\phi_h = 0$, u is oriented along the y-axis, i.e., perpendicular to the orientation of K. See Figure 3.

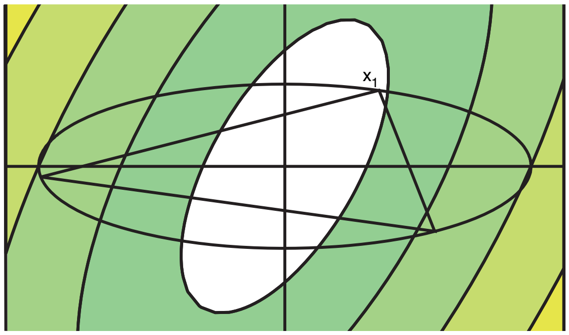

FIG. 3. *Triangle K and the contour lines of a function u. ϕ_h is about $-\frac{\pi}{6}$ in this graph.*

Denote by u_I the linear interpolation of u at the three vertices of K. Clearly the norm of the error $u - u_I$ depends on the size and the shape of triangle K, as well as the magnitude and the orientation of function u. We derive in this section the exact formulas for the H^1- and L^2-norms of the interpolation error in terms of these factors.

THEOREM 3.1. *Let K be a triangle oriented along the x-axis. r_{12} is the aspect ratio of K, $r_{21} = 1/r_{12}$. Let u be a quadratic function. λ_1 and λ_2 are the eigenvalues of the Hessian matrix of u, and the orientation of u is of angle ϕ_h with the y-axis; then*

$$\begin{aligned}\|\nabla(u-u_I)\|^2_{L^2(K)} = \frac{\sqrt{3}}{36}|K|^2\Big\{&[(r_{12}+r_{21})(\lambda_1^2+\lambda_2^2)+(r_{12}-r_{21})(\lambda_1^2-\lambda_2^2)\cos(2\phi_h)]\\ &+\frac{1}{2}\Big[-4\lambda_1\lambda_2+\frac{1}{4}(\ (\lambda_1+\lambda_2)(r_{12}+r_{21})+(\lambda_1-\lambda_2)(r_{12}-r_{21})\\ &\cdot\cos(2\phi_h)\ )^2\Big][(r_{12}+r_{21}+(r_{12}-r_{21})\cos(6\phi_v+4\theta)]\Big\},\end{aligned}\tag{4}$$

where ϕ_v is the rotation angle in the mapping from $\hat{K}$ to K, and

$$\theta = \frac{1}{2}\ \mathrm{atan}\left(\frac{2(\lambda_1-\lambda_2)\sin(2\phi_h)}{(\lambda_1+\lambda_2)(r_{12}-r_{21})+(\lambda_1-\lambda_2)(r_{12}+r_{21})\cos(2\phi_h)}\right).\tag{5}$$

Proof.

Step 1. We start with a result established by Bank and Smith in [3]. Let $c_i(x,y), i = 1,2,3$, be the barycentrical coordinates of a point (x,y) in K. The side basis functions (taking value $\frac{1}{4}$ at a midpoint) are

$$\begin{aligned}b_1(x,y) &= c_2(x,y)\ c_3(x,y),\\ b_2(x,y) &= c_3(x,y)\ c_1(x,y),\\ b_3(x,y) &= c_1(x,y)\ c_2(x,y).\end{aligned}$$

It is easy to see that

$$u - u_I = -\frac{1}{2}(v_1\ b_1(x,y) + v_2\ b_2(x,y) + v_3\ b_3(x,y)),\tag{6}$$

where

$$v_i = \boldsymbol{\ell}_i \cdot H\boldsymbol{\ell}_i, \qquad i = 1,2,3.\tag{7}$$

Let $\boldsymbol{v} = [v_1, v_2, v_3]^T$. It is further established in [3] that

$$\int_K |\nabla(u-u_I)|^2\ dxdy = \frac{1}{4}\boldsymbol{v}\cdot B\boldsymbol{v},\tag{8}$$

where

$$\begin{aligned}B &= \left(\int_K \nabla b_i \cdot \nabla b_j dxdy\right)\\ &= \frac{1}{48|K|}\begin{bmatrix} |\boldsymbol{\ell}_1|^2+|\boldsymbol{\ell}_2|^2+|\boldsymbol{\ell}_3|^2 & 2\boldsymbol{\ell}_1\cdot\boldsymbol{\ell}_2 & 2\boldsymbol{\ell}_1\cdot\boldsymbol{\ell}_3\\ & |\boldsymbol{\ell}_1|^2+|\boldsymbol{\ell}_2|^2+|\boldsymbol{\ell}_3|^2 & 2\boldsymbol{\ell}_2\cdot\boldsymbol{\ell}_3\\ \text{symm.} & & |\boldsymbol{\ell}_1|^2+|\boldsymbol{\ell}_2|^2+|\boldsymbol{\ell}_3|^2\end{bmatrix}.\end{aligned}$$

We first derive a formula for the matrix B in terms of the singular values and the rotation angle ϕ_v of the mapping M. Note that we assume $\phi_u = 0$; therefore

$$\boldsymbol{\ell}_i = M\boldsymbol{e}_i = \Sigma R^*_{\phi_v}\boldsymbol{e}_i = \sqrt{3}\begin{bmatrix} \sigma_1\cos\alpha_i \\ \sigma_2\sin\alpha_i \end{bmatrix},$$

where

$$\alpha_i = 2(i-1)\pi/3 - \phi_v, \qquad i = 1,2,3. \tag{9}$$

With formula (A.1) in the appendix it is easy to verify that

$$|\boldsymbol{\ell}_1|^2 + |\boldsymbol{\ell}_2|^2 + |\boldsymbol{\ell}_3|^2 = 3\sigma_1^2\sum_{i=1}^{3}\cos^2\alpha_i + 3\sigma_2^2\sum_{i=1}^{3}\sin^2\alpha_i = \frac{9}{2}(\sigma_1^2+\sigma_2^2). \tag{10}$$

Let

$$f_{ij} = \frac{\sigma_1^2}{\sigma_1^2+\sigma_2^2}\cos\alpha_i\cos\alpha_j + \frac{\sigma_2^2}{\sigma_1^2+\sigma_2^2}\sin\alpha_i\sin\alpha_j. \tag{11}$$

Then

$$\boldsymbol{\ell}_i\cdot\boldsymbol{\ell}_j = 3(\sigma_1^2\cos\alpha_i\cos\alpha_j + \sigma_2^2\sin\alpha_i\sin\alpha_j) = 3(\sigma_1^2+\sigma_2^2)f_{ij}, \qquad 1 \le i,j \le 3.$$

Note that $|K| = \frac{3\sqrt{3}}{4}\sigma_1\sigma_2$. We may express B as

$$B = \frac{\sqrt{3}}{24}\frac{\sigma_1^2+\sigma_2^2}{\sigma_1\sigma_2}\begin{bmatrix} 1 & \frac{4}{3}f_{12} & \frac{4}{3}f_{13} \\ & 1 & \frac{4}{3}f_{23} \\ & \text{symm.} & 1 \end{bmatrix},$$

and rewrite the norm of the error as

$$\|\nabla(u-u_I)\|^2_{L^2(K)} = \frac{\sqrt{3}}{96}\frac{\sigma_1^2+\sigma_2^2}{\sigma_1\sigma_2} \cdot \left[\sum_{i=1}^{3}(v_i)^2 + \frac{8}{3}(f_{12}\ v_1v_2 + f_{13}\ v_1v_3 + f_{23}\ v_2v_3)\right]. \tag{12}$$

Step 2. We next simplify the terms involving v_i. Assume the Hessian matrix $H = (h_{ij})$, and denote by

$$\tilde{H} = \begin{bmatrix} \frac{\sigma_1}{\sigma_2}h_{11} & h_{12} \\ h_{12} & \frac{\sigma_2}{\sigma_1}h_{22} \end{bmatrix}. \tag{13}$$

Since $\tilde{H}$ is a 2×2 symmetric matrix, we may decompose it into

$$\tilde{H} = R_\theta\begin{bmatrix} \mu_1 & \\ & \mu_2 \end{bmatrix}R_\theta^T, \tag{14}$$

where R_θ is the matrix for the counterclockwise rotation by an angle θ, and μ_1 and μ_2 are the eigenvalues of $\tilde{H}$. By the facts that

$$\begin{aligned} v_i &= \boldsymbol{\ell}_i\cdot H\boldsymbol{\ell}_i = (R^*_{\phi_v}\boldsymbol{e}_i)\cdot(\Sigma^T H\Sigma)\ (R^*_{\phi_v}\boldsymbol{e}_i) = \sigma_1\sigma_2(R^*_{\phi_v}\boldsymbol{e}_i)\cdot\tilde{H}\ (R^*_{\phi_v}\boldsymbol{e}_i) \\ &= \sigma_1\sigma_2(R^*_\theta R^*_{\phi_v}\boldsymbol{e}_i)\cdot\operatorname{diag}(\mu_1,\mu_2)\ (R^*_\theta R^*_{\phi_v}\boldsymbol{e}_i) \end{aligned}$$

and that

$$R_\theta^* R_{\phi_v}^* \boldsymbol{e}_i = \sqrt{3}[\cos(\alpha_i - \theta), \sin(\alpha_i - \theta)]^T,$$

we have

$$\begin{aligned} v_i &= 3\sigma_1\sigma_2[\mu_1 \cos^2(\alpha_i - \theta) + \mu_2 \sin^2(\alpha_i - \theta)] \\ &= \tfrac{3}{2}\sigma_1\sigma_2[(\mu_1 + \mu_2) + (\mu_1 - \mu_2)\cos 2(\alpha_i - \theta)]. \end{aligned}$$

Therefore it follows from formulas (A.2) and (A.3) that

$$\begin{aligned} \sum_{i=1}^{3}(v_i)^2 &= \frac{9}{4}(\sigma_1\sigma_2)^2 \left[3(\mu_1 + \mu_2)^2 + \frac{3}{2}(\mu_1 - \mu_2)^2\right] \\ &= \frac{81}{8}(\sigma_1\sigma_2)^2 \left[\mu_1^2 + \mu_2^2 + \frac{2}{3}\mu_1\mu_2\right]. \end{aligned} \tag{15}$$

Expand $v_i v_j$ as follows:

$$\begin{aligned} v_i v_j = \frac{9}{4}(\sigma_1\sigma_2)^2[(\mu_1 + \mu_2)^2 &+ (\mu_1^2 - \mu_2^2)(\cos 2(\alpha_i - \theta) + \cos 2(\alpha_j - \theta)) \\ &+ (\mu_1 - \mu_2)^2 \cos 2(\alpha_i - \theta)\cos 2(\alpha_j - \theta)]. \end{aligned} \tag{16}$$

Let $\beta = \phi_v + \theta$. Then $\alpha_i - \theta = 2(i-1)\pi/3 - \beta$, and

$$\cos 2(\alpha_i - \theta) + \cos 2(\alpha_j - \theta) = \begin{cases} \cos(2\beta + \frac{\pi}{3}) & \text{for } (i,j) = (1,2), \\ \cos(2\beta - \frac{\pi}{3}) & \text{for } (i,j) = (1,3), \\ \cos(2\beta + \pi) & \text{for } (i,j) = (2,3) \end{cases}$$

and

$$\cos 2(\alpha_i - \theta) \cdot \cos 2(\alpha_j - \theta) = \begin{cases} -\frac{1}{4} - \frac{1}{2}\cos(4\beta - \frac{\pi}{3}) & \text{for } (i,j) = (1,2), \\ -\frac{1}{4} - \frac{1}{2}\cos(4\beta + \frac{\pi}{3}) & \text{for } (i,j) = (1,3), \\ -\frac{1}{4} - \frac{1}{2}\cos(4\beta + \pi) & \text{for } (i,j) = (2,3). \end{cases}$$

Substituting the above formulas into (17), we have

$$\begin{aligned} & f_{12}\ v_1v_2 + f_{13}\ v_1v_3 + f_{23}\ v_2v_3 \\ & = \tfrac{9}{4}(\sigma_1\sigma_2)^2\ \{[(\mu_1 + \mu_2)^2 - \tfrac{1}{4}(\mu_1 - \mu_2)^2]\ (f_{12} + f_{13} + f_{23}) \\ & \quad + (\mu_1^2 - \mu_2^2)\ [f_{12}\cos(2\beta + \tfrac{\pi}{3}) + f_{13}\cos(2\beta - \tfrac{\pi}{3}) + f_{23}\cos(2\beta + \pi)] \\ & \quad - \tfrac{1}{2}(\mu_1 - \mu_2)^2\ [f_{12}\cos(4\beta - \tfrac{\pi}{3}) + f_{13}\cos(4\beta + \tfrac{\pi}{3}) + f_{23}\cos(4\beta + \pi)]\ \}. \end{aligned} \tag{17}$$

By using the definition (11) for f_{ij}, we have from formula (A.4) that

$$f_{12} + f_{13} + f_{23} = -\frac{3}{4}; \tag{18}$$

from formulas (A.5) and (A.6) that

$$\begin{aligned} & f_{12}\cos(2\beta + \tfrac{\pi}{3}) + f_{13}\cos(2\beta - \tfrac{\pi}{3}) + f_{23}\cos(2\beta + \pi) \\ & = -\tfrac{3}{4}\ \frac{\sigma_1^2 - \sigma_2^2}{\sigma_1^2 + \sigma_2^2}\cos(2\theta); \end{aligned} \tag{19}$$

and from formulas (A.7) and (A.8) that

$$\begin{aligned} &f_{12}\cos(4\beta-\tfrac{\pi}{3})+f_{13}\cos(4\beta+\tfrac{\pi}{3})+f_{23}\cos(4\beta+\pi)\\ &=-\tfrac{3}{4}\ \frac{\sigma_1^2-\sigma_2^2}{\sigma_1^2+\sigma_2^2}\cos(6\phi_v+4\theta). \end{aligned} \tag{20}$$

Put (17)–(20) into (13); we may express the norm of the error as

$$\begin{aligned} \|\nabla(u-u_I)\|^2_{L^2(K)}=\frac{3\sqrt{3}}{64}(\sigma_1^2+\sigma_2^2)\sigma_1\sigma_2\Bigg\{&\left[\mu_1^2+\mu_2^2-\frac{\sigma_1^2-\sigma_2^2}{\sigma_1^2+\sigma_2^2}(\mu_1^2-\mu_2^2)\cos(2\theta)\right]\\ &+\ \frac{1}{2}(\mu_1-\mu_2)^2\left[1+\frac{\sigma_1^2-\sigma_2^2}{\sigma_1^2+\sigma_2^2}\cos(6\phi_v+4\theta)\right]\Bigg\}. \end{aligned} \tag{21}$$

Step 3. Finally we express μ_1,μ_2, and θ in terms of the eigenvalues of the Hessian H and the aspect ratio r_{12} of K. According to the eigendecomposition (3) of H,

$$H=\begin{bmatrix} \lambda_1\cos^2\phi_h+\lambda_2\sin^2\phi_h & (\lambda_1-\lambda_2)\sin\phi_h\cos\phi_h\\ (\lambda_1-\lambda_2)\sin\phi_h\cos\phi_h & \lambda_1\sin^2\phi_h+\lambda_2\cos^2\phi_h \end{bmatrix}.$$

Therefore

$$\tilde{H}=(\tilde{h}_{ij})=\begin{bmatrix} r_{12}(A+D\cos2\phi_h) & D\sin2\phi_h\\ D\sin2\phi_h & r_{21}(A-D\cos2\phi_h) \end{bmatrix}$$

with

$$A=\frac{1}{2}(\lambda_1+\lambda_2),\qquad D=\frac{1}{2}(\lambda_1-\lambda_2).$$

Recall the eigendecomposition (14), it is not difficult to establish for the eigenvalues μ_1 and μ_2 of $\tilde{H}$ that

$$\begin{aligned} \mu_1^2+\mu_2^2 &=(\tilde{h}_{11})^2+(\tilde{h}_{22})^2+2(\tilde{h}_{12})^2\\ &=(A^2+D^2\cos^2(2\phi_h))(r_{12}^2+r_{21}^2)+2AD(r_{12}^2-r_{21}^2)\cos(2\phi_h)\\ &\quad+\ 2D^2\sin^2(2\phi_h),\\ (\mu_1^2-\mu_2^2)\cos2\theta &=(\tilde{h}_{11})^2-(\tilde{h}_{22})^2\\ &=(A^2+D^2\cos^2(2\phi_h))(r_{12}^2-r_{21}^2)+2AD(r_{12}^2+r_{21}^2)\cos(2\phi_h),\\ (\mu_1-\mu_2)^2 &=(\tilde{h}_{11}-\tilde{h}_{22})^2+4(\tilde{h}_{12})^2\\ &=4D^2+A^2(r_{12}-r_{21})^2+\ 2AD(r_{12}^2-r_{21}^2)\cos(2\phi_h)\\ &\quad+D^2(r_{12}-r_{21})^2\cos^2(2\phi_h)\\ &=4(D^2-A^2)+A^2(r_{12}+r_{21})^2+\ 2AD(r_{12}^2-r_{21}^2)\cos(2\phi_h)\\ &\quad+D^2(r_{12}-r_{21})^2\cos^2(2\phi_h)\\ &=-\ 4\lambda_1\lambda_2+[A(r_{12}+r_{21})+D(r_{12}-r_{21})\cos(2\phi_h)]^2 \end{aligned}$$

and that

$$\tan(2\theta)=\frac{2\tilde{h}_{12}}{\tilde{h}_{11}-\tilde{h}_{22}}=\frac{2D\sin2\phi_h}{A(r_{12}-r_{21})+D(r_{12}+r_{21})\cos2\phi_h}.$$

Substitute the above formulas into the right-hand side of (21) and simplify, and we obtain the formula (5). $\square$

We next derive the formula for the L^2-norm of the linear interpolation error.

THEOREM 3.2. *Let K be a triangle oriented along the x-axis. r_{12} is the aspect ratio of K, $r_{21} = 1/r_{12}$. Let u be a quadratic function. λ_1 and λ_2 are the eigenvalues of its Hessian, and the orientation of u is of angle ϕ_h with the y-axis. Then*

$$\|u - u_I\|^2_{L^2(K)} = \frac{|K|^3}{160}\left\{ -\frac{16}{9}\lambda_1\lambda_2 + [(\lambda_1+\lambda_2)(r_{12}+r_{21}) + (\lambda_1-\lambda_2)(r_{12}-r_{21})\cos(2\phi_h)]^2 \right\}. \tag{22}$$

Proof. It follows from (6) that

$$\int_K |u-u_I|^2 \; dxdy = \frac{1}{4}\boldsymbol{v}\cdot B_0\boldsymbol{v}, \tag{23}$$

where

$$B_0 = \left(\int_K b_i \cdot b_j dxdy\right).$$

An elementary calculation of the integrals leads to

$$B_0 = \frac{|K|}{180}\begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 1 & 1 & 2 \end{bmatrix}.$$

Therefore

$$\int_K |u-u_I|^2 \; dxdy = \frac{|K|}{360}\left(\sum_{i=1}^{3}(v_i)^2 + v_1v_2 + v_1v_3 + v_2v_3\right), \tag{24}$$

where v_1, v_2, and v_3 are defined as in (7). We have similar to (17) that

$$v_1v_2 + v_1v_3 + v_2v_3 = \frac{81}{16}(\sigma_1\sigma_2)^2\left(\mu_1^2 + \mu_2^2 + \frac{10}{3}\mu_1\mu_2\right),$$

which, together with (15), yields

$$\int_K |u-u_I|^2 \; dxdy = \frac{|K|^3}{40}\left((\mu_1+\mu_2)^2 - \frac{4}{9}\mu_1\mu_2\right). \tag{25}$$

Finally, by $\mu_1\mu_2 = \det(\tilde{H}) = \det(H) = \lambda_1\lambda_2$ and

$$\mu_1 + \mu_2 = \tilde{h}_{11} + \tilde{h}_{22} = A(r_{12}+r_{21}) + D(r_{12}-r_{21})\cos(2\phi_h),$$

we prove the conclusion of this theorem. □

4. Discussion about some special cases. Denote by T_1, T_2, and T_3 the terms in the square brackets on the right-hand side of (5), i.e.,

$$T_1 = (r_{12}+r_{21})(\lambda_1^2+\lambda_2^2) + (r_{12}-r_{21})(\lambda_1^2-\lambda_2^2)\cos(2\phi_h), \tag{26}$$

$$T_2 = -4\lambda_1\lambda_2 + \frac{1}{4}\left((\lambda_1+\lambda_2)(r_{12}+r_{21}) + (\lambda_1-\lambda_2)(r_{12}-r_{21})\cos(2\phi_h)\right)^2, \tag{27}$$

$$T_3 = r_{12} + r_{21} + (r_{12}-r_{21})\cos(6\phi_v + 4\theta). \tag{28}$$

Recall that we assume $r_{12} = \sigma_1/\sigma_2 \geq 1$ and $\lambda_1 \geq |\lambda_2|$; therefore all the three terms above are nonnegative, and we may write

$$\|\nabla(u - u_I)\|^2_{L^2(K)} = \frac{\sqrt{3}}{36}|K|^2 \left(T_1 + \frac{1}{2}\,T_2 \cdot T_3\right). \tag{29}$$

We may also restrict $0 \leq \phi_v < \frac{\pi}{3}$ and $0 \leq \phi_h < \pi$. Other cases are covered by the symmetry and periodicity of the error norms. For a fixed aspect ratio, the extremum values of T_1, T_2, and T_3 are

$$T_1 = \begin{cases} \min\,(T_1) = 2(r_{21}\lambda_1^2 + r_{12}\lambda_2^2) & \text{when } \phi_h = \frac{\pi}{2}, \\ \max\,(T_1) = 2(r_{12}\lambda_1^2 + r_{21}\lambda_2^2) & \text{when } \phi_h = 0, \end{cases} \tag{30}$$

$$T_2 = \begin{cases} \min\,(T_2) = (r_{21}\lambda_1 - r_{12}\lambda_2)^2 & \text{when } \phi_h = \frac{\pi}{2}, \\ \max\,(T_2) = (r_{12}\lambda_1 - r_{21}\lambda_2)^2 & \text{when } \phi_h = 0, \end{cases} \tag{31}$$

$$T_3 = \begin{cases} \min\,(T_3) = 2r_{21} & \text{when } 6\phi_v + 4\theta = (2m+1)\pi, \\ \max\,(T_3) = 2r_{12} & \text{when } 6\phi_v + 4\theta = 2m\pi. \end{cases} \tag{32}$$

We give more details about these cases.

Case 1. $\phi_h = \frac{\pi}{2}$ and $\phi_v = \frac{\pi}{6}$, i.e., K is an acute isosceles triangle aligned with u. In this case, $\theta = 0$ by (5). Therefore, T_1, T_2, and T_3 all take their minimum values, which yields

$$\|\nabla(u - u_I)\|^2_{L^2(K)} = \frac{\sqrt{3}}{36}|K|^2\ [\ 2(r_{21}\lambda_1^2 + r_{12}\lambda_2^2) + r_{21}(r_{21}\lambda_1 - r_{12}\lambda_2)^2\ ]. \tag{33}$$

This is the smallest H^1-seminorm of the interpolation error for all the triangles with a fixed aspect ratio and a fixed area.

We may consider the optimal choice of the aspect ratio in this case. Let

$$\begin{aligned} f(r) &= 2\Big(\tfrac{1}{r}\lambda_1^2 + r\lambda_2^2\Big) + \tfrac{1}{r}\Big(\tfrac{1}{r}\lambda_1 - r\lambda_2\Big)^2 \\ &= 3\lambda_2^2 r + 2(2\lambda_1^2 - 4\lambda_1\lambda_2)\tfrac{1}{r} + \lambda_1^2\frac{1}{r^3}. \end{aligned}$$

It can be seen that f is decreasing in $[1, r_*^{(1)})$ and increasing in $(r_*^{(1)}, \infty)$, where

$$r_*^{(1)} = \sqrt{\frac{\lambda_1(\lambda_1 - \lambda_2) + \lambda_1\sqrt{(\lambda_1 - \lambda_2)^2 + 9\lambda_2^2}}{3\lambda_2^2}}. \tag{34}$$

Therefore $r_{12} = r_*^{(1)}$ is the best aspect ratio. Moreover, since T_1, T_2, and T_3 all take minimum values in this case, we conclude that the acute isosceles triangle, which is aligned with u and of the aspect ratio $r_*^{(1)}$, is the best one that produces the smallest H^1-seminorm of the interpolation error among all the triangles with the same area!

It is noted that for u with $\lambda_1 = \lambda_2$ (isotropic u), the best aspect ratio is $r_*^{(1)} = 1$ (with isotropic K). For u with $\lambda_2 = -\lambda_1$, the best aspect ratio is $r_*^{(1)} = \sqrt{(2 + \sqrt{13})/3}$ ≈ 1.367. When $\lambda_1 >> |\lambda_2|$, we have

$$r_*^{(1)} \approx \sqrt{\frac{2}{3}\left|\frac{\lambda_1}{\lambda_2}\right|} \approx 0.816\left|\frac{\lambda_1}{\lambda_2}\right|,$$

with which the interpolation error is of the smallest possible magnitude

$$\|\nabla(u-u_I)\|^2_{L^2(K)} \approx \frac{\sqrt{2}}{6}|K|^2|\lambda_1\lambda_2| \approx 0.235|K|^2|\lambda_1\lambda_2|. \tag{35}$$

We may also compare the above optimal choice of the aspect ratio with some intuitive choices. For instance, if we choose $r_{12}=1$, then

$$\|\nabla(u-u_I)\|^2_{L^2(K)} \approx \frac{\sqrt{3}}{36}|K|^2(3(\lambda_1^2+\lambda_2^2)-2\lambda_1\lambda_2), \tag{36}$$

which is between $0.128|K|^2\lambda_1^2$ and $0.193|K|^2\lambda_1^2$. If we choose $r_{12}=|\frac{\lambda_1}{\lambda_2}|$, then in the case $\lambda_1 >> |\lambda_2|$,

$$\|\nabla(u-u_I)\|^2_{L^2(K)} \approx \frac{5\sqrt{3}}{36}|K|^2|\lambda_1\lambda_2| \approx 0.240|K|^2|\lambda_1\lambda_2|; \tag{37}$$

if we choose $r_{12}=\sqrt{|\lambda_1/\lambda_2|}$, then we have

$$\|\nabla(u-u_I)\|^2_{L^2(K)} = \frac{\sqrt{3}}{18}|K|^2\sqrt{|\lambda_1^3\lambda_2|} \approx 0.0962|K|^2\sqrt{|\lambda_1^3\lambda_2|}. \tag{38}$$

Note that when u and K are aligned, the inverse mapping $\boldsymbol{\xi} = M^{-1}\boldsymbol{x}$ with $r_{12} = \sqrt{|\lambda_1/\lambda_2|}$ transforms $u(x,y)$ into const.$(\xi^2 \pm \eta^2)$ and K into an equilateral triangle. It was shown by D'Azevedo and Simpson [6] and Rippa [13] that triangles with such an aspect ratio lead to the smallest maximum-norm and L^p-norm of the interpolation error among all triangles of the same area. However, this aspect ratio is not the optimal for the interpolation error in the sense of H^1-seminorm.

Case 2. $\phi_h = \frac{\pi}{2}$ and $\phi_v = 0$, i.e., K is an obtuse isosceles triangle aligned with u. We have in this case

$$\|\nabla(u-u_I)\|^2_{L^2(K)} = \frac{\sqrt{3}}{36}|K|^2\ [\ 2(r_{21}\lambda_1^2+r_{12}\lambda_2^2)+r_{12}(r_{21}\lambda_1-r_{12}\lambda_2)^2\ ]. \tag{39}$$

This error formula differs from that of Case 1 only in the coefficient of the second term.

To study the optimal choice of the aspect ratio in this case, let

$$\begin{aligned} g(r) &= 2\Big(\frac{1}{r}\lambda_1^2 + r\lambda_2^2\Big) + r\Big(\frac{1}{r}\lambda_1 - r\lambda_2\Big)^2 \\ &= 3\lambda_1^2\frac{1}{r} + 2(\lambda_2^2-\lambda_1\lambda_2)r + \lambda_2^2 r^3. \end{aligned}$$

It can be shown that the minimum of g is attained at

$$r_*^{(2)} = \sqrt{\frac{\lambda_2(\lambda_1-\lambda_2)+|\lambda_2|\sqrt{(\lambda_1-\lambda_2)^2+9\lambda_2^2}}{3\lambda_2^2}}. \tag{40}$$

When $\lambda_1=\lambda_2$, the best aspect ratio is $r_*^{(2)}=1$. When $\lambda_2=-\lambda_2$, the best aspect ratio is $r_*^{(1)}=\sqrt{(2+\sqrt{13})/3}\approx 1.367$. When $|\lambda_1| >> |\lambda_2|$, we have

$$r_*^{(2)} \approx \begin{cases} \sqrt{\frac{\sqrt{10}+1}{3}|\frac{\lambda_1}{\lambda_2}|} \approx 1.178\sqrt{|\frac{\lambda_1}{\lambda_2}|} & \text{when } \lambda_1\lambda_2>0, \\ \sqrt{\frac{\sqrt{10}-1}{3}|\frac{\lambda_1}{\lambda_2}|} \approx 0.849\sqrt{|\frac{\lambda_1}{\lambda_2}|} & \text{when } \lambda_1\lambda_2<0. \end{cases}$$

With this choice of aspect ratio, the interpolation error is of the magnitude

$$\|\nabla(u-u_I)\|^2_{L^2(K)} \approx \begin{cases} 0.0878|K|^2\sqrt{|\lambda_1^3\lambda_2|} & \text{when } \lambda_1\lambda_2 > 0, \\ 0.281|K|^2\sqrt{|\lambda_1^3\lambda_2|} & \text{when } \lambda_1\lambda_2 < 0. \end{cases} \tag{41}$$

We may compare this case (obtuse isosceles) with the previous one (acute isosceles). When the triangle is aligned with u and the aspect ratio $r_{12} \approx \sqrt{|\lambda_1/\lambda_2|}$, the interpolation error is nearly the same for both acute and obtuse triangles if $\lambda_1\lambda_2 > 0$. For u with $\lambda_1\lambda_2 < 0$, $\|\nabla(u-u_I)\|_{L^2(K)}$ is about 1.7 times smaller with the acute isosceles triangle than that with the obtuse one. Furthermore, because for general triangles with arbitrary ϕ_v, the error norm $\|\nabla(u-u_I)\|_{L^2(K)}$ is between those of Case 1 and Case 2, we may conclude that the H^1-seminorm of the interpolation error is not sensitive to the maximum angle of the triangle, as long as the triangle is aligned with the function u and the aspect ratio $r_{12} \approx \sqrt{|\lambda_1/\lambda_2|}$ is used.

Case 3. $\phi_h = 0$. In this case the orientation of u is perpendicular to the triangle. We have

$$\begin{aligned} \|\nabla(u-u_I)\|^2_{L^2(K)} = \frac{\sqrt{3}}{18}|K|^2\ [2(r_{12}\lambda_1^2 + r_{21}\lambda_2^2) + (r_{12}\lambda_1 - r_{21}\lambda_2)^2 \\ \cdot (r_{12} + r_{21} + (r_{12} - r_{21})\cos(6\phi_v))] \end{aligned} \tag{42}$$

For given $|K|$ and ϕ_v, it can be shown the error norm is an increasing function of r_{12}. Therefore, the best aspect ratio is $r_{12} = 1$. This is not surprising, since when the triangle is perpendicular to the orientation of u, increasing the aspect ratio leads to lower resolution in the needy direction and larger interpolation error, no matter what value ϕ_v takes.

We should emphasize that in the above discussion on the optimal aspect ratios the area and the orientation of the triangle are assumed fixed. In adaptive mesh generation there may be some other constraints on the triangles in a mesh, e.g., one side of a triangle or the vertices of the triangles are fixed. Optimal choices of the aspect ratio subject to those constraints can be quite different from the above values.

5. General discussion about orientation, aspect ratio, and angle condition.

In this section we present a general discussion about the effects of the orientation, aspect ratio, and the angle ϕ_v. We first study the H^1-seminorm of the interpolation error.

Mesh alignment. Given a triangle K (fixed $|K|$, r_{12}, and ϕ_v), it is commonly believed that the interpolation error is the smallest when the triangle is aligned with the function, i.e., when $\phi_h = \frac{\pi}{2}$. We present a justification of this viewpoint. We consider the case where both the solutions and the triangles are highly anisotropic, i.e., we assume $\lambda_1 >> |\lambda_2|$ and $r_{12} >> 1$. In this case we have for the three terms (26)–(28) in the error norm $\|\nabla(u-u_I)\|^2_{L^2(K)}$ that

$$\begin{aligned} T_1 &= r_{12}\lambda_1^2(1+\cos 2\phi_h) + \text{LOT}, \\ T_2 &= \tfrac{1}{4}(r_{12}\lambda_1)^2(1+\cos 2\phi_h)^2 + \text{LOT}, \\ T_3 &= r_{12}(1+\cos(6\phi_v + 4\theta)) + \text{LOT} \end{aligned}$$

and for the angle θ in (5) that

$$\tan(2\theta) \approx \frac{2\lambda_1 \sin 2\phi_h}{\lambda_1 r_{12}(1+\cos 2\phi_h)} = 2r_{21}\tan\phi_h,$$

where the lower order terms LOT include $r_{12}\lambda_2^2, r_{12}\lambda_1^2, r_{21}\lambda_2^2$, etc. In this case the error norm is dominated by

$$\|\nabla(u-u_I)\|^2_{L^2(K)} \approx \frac{\sqrt{3}}{36}|K|^2 \quad \begin{aligned}&[r_{12}\lambda_1^2 + \tfrac{1}{4}r_{12}^3\lambda_1^2(1+\cos 2\phi_h)(1+\cos(6\phi_v+4\theta))]\\ &\cdot\ (1+\cos 2\phi_h) + \text{LOT}.\end{aligned}$$

Note that by (5) θ is an increasing function of ϕ_h, and $\cos(2\phi_h)$ is a decreasing function of ϕ_h in $(0, \frac{\pi}{2})$. Therefore, we may conclude that the H^1-seminorm of the error is almost a monotonically decreasing function of the angle ϕ_h in $(0, \frac{\pi}{2})$.

We plot in Figure 4 the graph of $\|\nabla(u-u_I)\|^2_{L^2(K)}$ versus ϕ_h for various λ_1, λ_2, ϕ_v and r_{12}. It is observed that for all aspect ratios and ϕ_v, the error is smallest when ϕ_h is near $\frac{\pi}{2}$. Also seen in Figure 4 is a small peak of the error norm around $\phi_h = \frac{\pi}{2}$. This is because when ϕ_h is very close to $\frac{\pi}{2}$, the leading terms in T_1 and T_2 go to 0 and the lower order terms become the major components in the error.

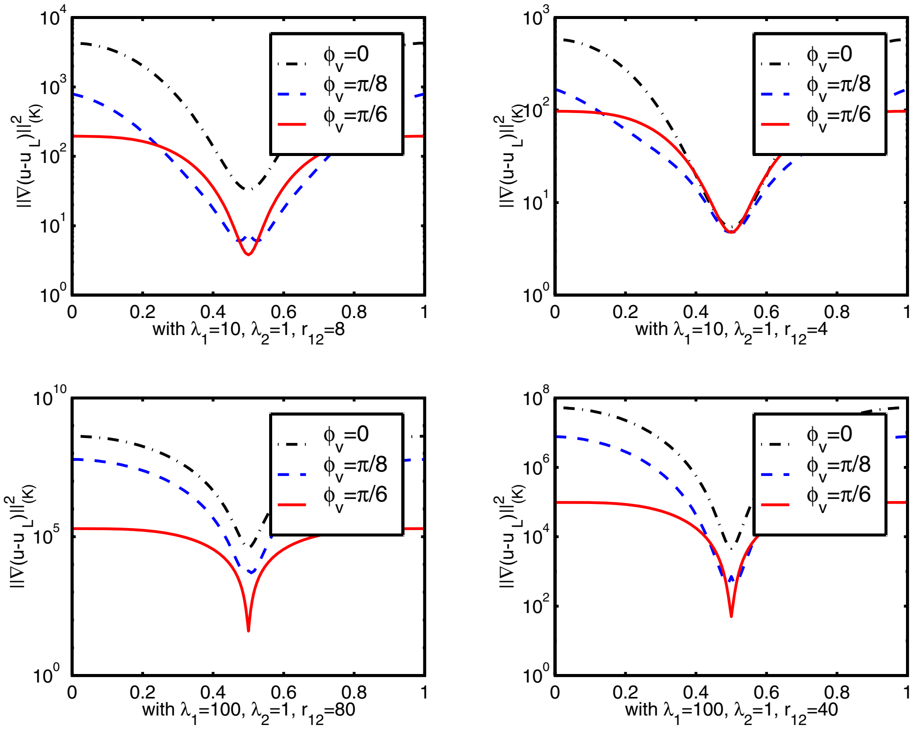

FIG. 4. $\|u-u_I\|^2_{L^2(K)}$ *versus the alignment angle* ϕ_h/π *with* $|K| = \frac{3\sqrt{3}}{4}$ *fixed.*

Aspect ratio. We are interested here in the question of, given a function u and a fixed triangle orientation ϕ_h, how one chooses the aspect ratio of the triangle. We plot in Figure 5 the graph of $\|\nabla(u-u_I)\|_{L^2(K)}$ versus r_{12} with various ϕ_h. It is observed that when $\phi_h = \frac{\pi}{2}$ (K aligned with u), the best aspect ratio r_{12} is in between $r_*^{(2)} = \sqrt{|\lambda_1/\lambda_2|}$ and $r_*^{(1)} \approx 0.8|\lambda_1/\lambda_2|$, while when $\phi_h \approx 0$ (K perpendicular to u), the best aspect ratio is 1. For other ϕ_v and ϕ_h, the optimal choice of r_{12} lies between 1 and $|\lambda_1/\lambda_2|$. Therefore, in practice, when a good mesh alignment is ensured, the proper aspect ratio should be between the magnitude of $\sqrt{|\lambda_1/\lambda_2|}$ and $0.8|\lambda_1/\lambda_2|$, with the lower end taken for the mesh with mostly obtuse triangles and the upper

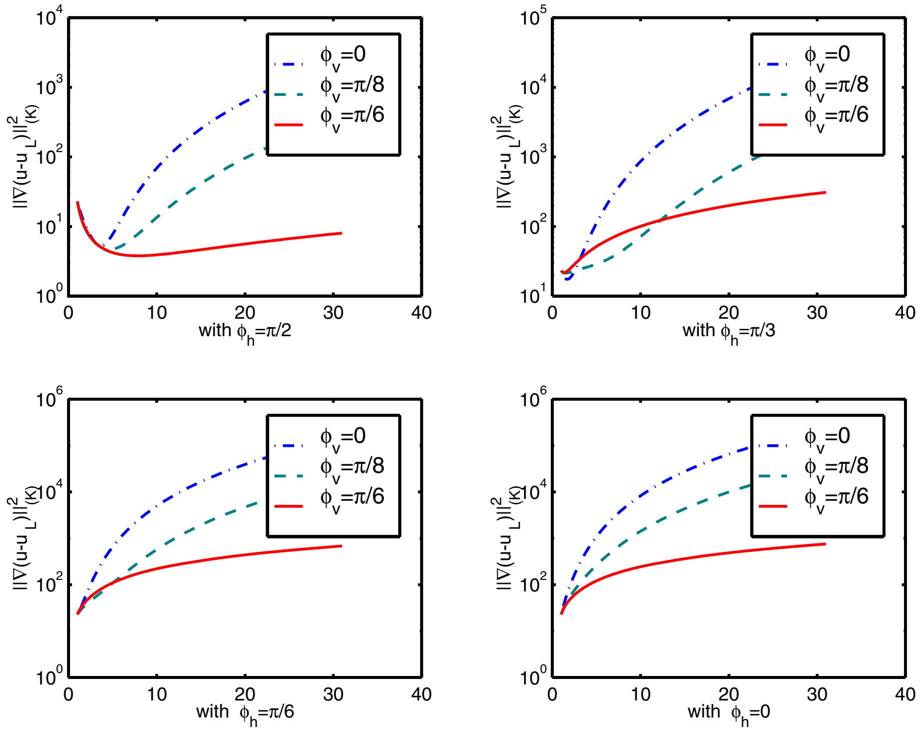

FIG. 5. $\|\nabla(u-u_I)\|^2_{L^2(K)}$ *versus the aspect ratio* r_{12} *with* $\lambda_1 = 10, \lambda_2 = 1$, *and* $|K| = \frac{3\sqrt{3}}{4}$.

end taken for the mesh with mostly acute triangles. The less the mesh alignment, the smaller r_{12} should be.

Maximum angle condition. It is well known that a good mesh for finite element approximation should respect the so-called maximum angle condition, i.e., the maximum angles of the triangular elements should be bounded from π. In [2], Babuška and Aziz gave an example showing that when the maximum angle condition is violated, the H^1-seminorm of the error of linear interpolation can go to infinity, although the element area approaches 0. Their example is in our notation the case with $\lambda_1 = 1, \lambda_2 = 0, |K| = \frac{\epsilon}{2}, r_{12} = \frac{\sqrt{3}}{2\epsilon}, \phi_h = 0, \phi_v = 0$, and thus $\|\nabla(u-u_I)\|^2_{L^2(K)} = \frac{9}{256}(\epsilon + \frac{3}{8\epsilon})$. We discuss here the impact of the maximum angle condition on the accuracy of linear interpolation. Taking as an example with $\lambda_1 = 100$ and $\lambda_2 = 1$, we plot in Figure 6 the graph of $\|\nabla(u-u_I)\|^2_{L^2(K)}$ versus ϕ_v with given aspect ratios and alignment directions. It is easy to see the following:

(a) When λ_1/λ_2 and r_{12} are high, triangles with $\phi_v \approx \frac{\pi}{6}$ or $\frac{\pi}{2}$ produce the smallest error, and triangles with $\phi_v \approx 0$ or $\frac{\pi}{3}$ produce the largest error, whether they are aligned with u or not. This can be justified by looking into formula (5) for the error norm. When $\lambda_1 >> |\lambda_2|$ and $r_{12} >> 1$, we have $\theta \approx 0$. Hence, the term T_3, and therefore $\|\nabla(u-u_I)\|_{L^2(K)}$, attains its minimum when $\phi_v \approx \frac{\pi}{6}$ or $\frac{\pi}{2}$.

Note that the maximum internal angle of K is an even periodic function of ϕ_v with the period $\pi/3$. It is decreasing in $(0, \pi/6)$. Hence $\phi_v = 0, \pi/3$ corresponds to the case where the maximum internal angle of K is the largest among all the triangles of the same aspect ratio, and $\phi_v = \pi/6, \pi/2$ corresponds to the case where the maximum internal angle is the smallest among all triangles. Therefore, in this case it is important to use triangles with smaller maximum internal angles, regardless of whether or not the mesh alignment is satisfied.

(b) When the triangle is aligned with u and the aspect ratio $r_{12} \approx \sqrt{|\lambda_1/\lambda_2|}$, the error is insensitive to ϕ_v and is therefore insensitive to the maximum internal angle of the triangle. In particular, if $\phi_h = \frac{\pi}{2}$, $\lambda_1\lambda_2 > 0$, and $r_{12} = \sqrt{\lambda_1/\lambda_2}$, then $T_2 = 0$, and by (29) $\|\nabla(u - u_I)\|_{L^2(K)}$ is independent of ϕ_v. See the lower left graph of Figure 6 and the analysis in Cases 1 and 2 in section 4.

(c) When $r_{12} \approx 1$, the best ϕ_v may be different from $\frac{\pi}{6}$ and $\frac{\pi}{2}$. However, in this case the difference between the maximum and the minimum of the error is not significant.

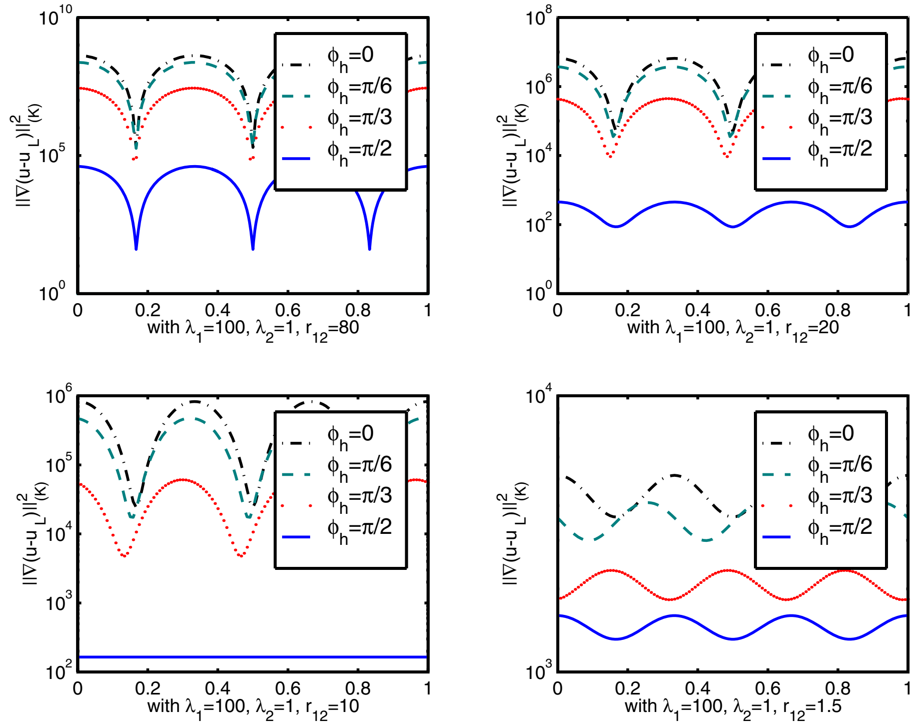

Fig. 6. $\|\nabla(u - u_I)\|^2_{L^2(K)}$ *versus the angle* ϕ_v/π *with* $|K| = \frac{3\sqrt{3}}{4}$ *fixed.*

In summary, we conclude that if the triangle is aligned with the function and the aspect ratio is of an magnitude $\sqrt{|\lambda_1/\lambda_2|}$ or smaller, then the maximum angle condition is not essential to the H^1-seminorm of the interpolation error. Otherwise, the maximum angle is critical to the magnitude of the error.

L^2-norm. From (23) we can conclude the following for the L^2-norm of the linear interpolation error:

(1) $\|u - u_I\|_{L^2(K)}$ does not depend on the angle ϕ_v. Therefore, for a given function, the L^2-norm of its linear interpolation error depends only on the area, aspect ratio, and orientation of the triangle. Maximum/minimum angle conditions are irrelevant to the L^2-norm of the interpolation error.

(2) $\|u - u_I\|_{L^2(K)}$ is a π-periodic even function of ϕ_h. It is decreasing in ϕ_h in

$(0, \frac{\pi}{2})$. When $\phi_h = \frac{\pi}{2}$ (K aligned with u),

$$\|u - u_I\|^2_{L^2(K)} = \frac{|K|^3}{40} \left[(\lambda_1 r_{21} + \lambda_2 r_{12})^2 - \frac{4}{9}\lambda_1\lambda_2 \right]$$

is the smallest, and when $\phi_h = 0$ (K perpendicular to u)

$$\|u - u_I\|^2_{L^2(K)} = \frac{|K|^3}{40} \left[(\lambda_1 r_{12} + \lambda_2 r_{21})^2 - \frac{4}{9}\lambda_1\lambda_2 \right]$$

is the largest.

(3) With the same orientation, it can be shown that when ϕ_h is in $(0, \frac{\pi}{4}) \cup (\frac{3\pi}{4}, \pi)$ (i.e., K is aligned more to the perpendicular direction of u), the best aspect ratio is $r_{12} = 1$; when $\frac{\pi}{4} \le \phi_h \le \frac{3\pi}{4}$ (i.e., K is aligned more to the orientation of u), the best aspect ratio is

$$r_{12} = \sqrt{\left| \frac{\lambda_1 + \lambda_2 - (\lambda_1 - \lambda_2)\cos(2\phi_h)}{\lambda_1 + \lambda_2 + (\lambda_1 - \lambda_2)\cos(2\phi_h)} \right|}. \tag{43}$$

We plot in Figure 7 the L^2-norm of the error versus the aspect ratio for the case of $\lambda_1 = 400, \lambda_2 = 1$, and $|K| = \frac{3\sqrt{3}}{4}$.

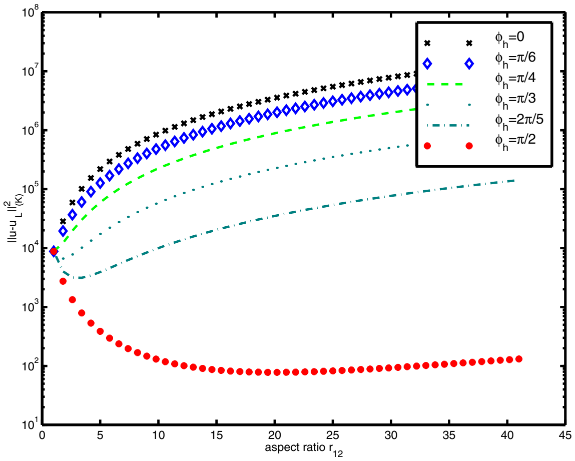

FIG. 7. $\|u - u_I\|^2_{L^2(K)}$ *versus the aspect ratio* r_{12} *with* $\lambda_1 = 400, \lambda_2 = 1$ *and* $|K| = \frac{3\sqrt{3}}{4}$.

(4) For a fixed triangle area, the minimum L^2-norm of the linear interpolation error is attained at $\phi_h = \frac{\pi}{2}$ and $r_{12} = \sqrt{|\lambda_1/\lambda_2|}$. The minimum value is

$$\|u - u_I\|^2_{L^2(K)} = \begin{cases} \frac{8}{90}|K|^3|\lambda_1\lambda_2| & \text{when } \lambda_1\lambda_2 > 0, \\ \frac{1}{90}|K|^3|\lambda_1\lambda_2| & \text{when } \lambda_1\lambda_2 < 0. \end{cases}$$

6. An example of linear interpolation on different meshes. In this section, we present the results of piecewise linear interpolation of a quadratic function on different types of mesh. We choose

$$u(x, y) = x^2 + 100y^2,$$

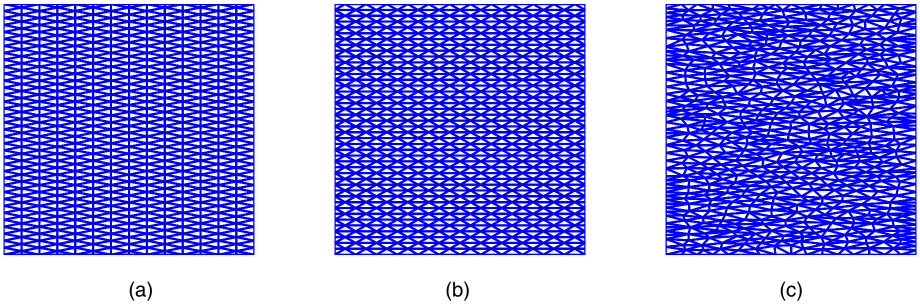

FIG. 8. *Three types of mesh used for piecewise linear interpolation.*

which corresponds to $\lambda_1 = 100, \lambda_2 = 1$, and the orientation along the x-axis. We consider the following three types of mesh on $[0,1] \times [0,1]$:

(a) The first type of mesh is as shown in Figure 8(a). There are M and N equal partitions in x and y directions, respectively. When $M/N < 2/\sqrt{3}$, all the triangles in this mesh, except those on the top and the bottom boundaries, are aligned exactly with the x-axis. Their aspect ratio is

$$r_{12} = \frac{2N}{\sqrt{3}M}$$

and their angle ϕ_v is $\frac{\pi}{6}$.

(b) The second type of mesh is as shown in Figure 8(b) with M and N equal partitions in x and y directions, respectively. When $M/N < \sqrt{3}/2$, all the triangles, except those on the left and the right boundaries, are aligned with the x-axis. Their aspect ratio is

$$r_{12} = \frac{\sqrt{3}N}{2M}$$

and their angle ϕ_v is 0.

(c) The third type is the unstructured meshes generated in the following way. First we create a Delaunay triangulation by using the package Triangle [14] on a rectangle $[0,1] \times [0, r_s]$, where $r_s \geq 1$ is a real number. Then we compress the rectangle in y direction by a factor r_s. The desired mesh on the unit square is the image of the Delaunay triangulation under the compression. See Figure 8(c) for a typical mesh of this type. By Delaunay triangulation the minimum internal angle of the triangles in the mesh is maximized, and all the triangles in the mesh over $[0,1] \times [0, r_s]$ are approximately of the same size and close to unilateral. Therefore, most triangles in the mesh over the unit square are roughly aligned with the x-axis (when $r_s > 1$) and are of the aspect ratio

$$r_{12} \approx r_s.$$

However, in this type of mesh the angle ϕ_v varies for different triangles (approximately uniformly distributed between 0 and $\pi/3$).

We are interested in the accuracy of the linear interpolation of u on different types of mesh and with various aspect ratios, in particular with the following three ratios: (1) $r_*^{(1)} = 81.6$, which is the best aspect ratio (for H^1-seminorm) calculated according to (34) for the case of acute isosceles triangles; (2) $r_*^{(2)} = 11.79$, which is the best aspect ratio (in H^1-seminorm) calculated according to (40) for the case of obtuse isosceles triangles; and (3) $r_*^{(\infty)} = \sqrt{|\frac{\lambda_1}{\lambda_2}|} = 10$, which is the best aspect ratio for the L^p-norm, $1 \leq p \leq \infty$. We also report the results with the aspect ratios $r_{12} = \lambda_1/\lambda_2 = 10$ and $r_{12} = 1$.

We list in Table 1 the various norms of the interpolation error with different choices of M, N, and r_s. Note that for all the meshes, the total number of elements is around 4000 and the total number of nodes is around 2200. The smallest H^1-seminorm for type (a) meshes is with $r_{12} = 92.37$; the smallest H^1-seminorm for type (b) meshes is with $r_{12} = 11.54$. For type (c) meshes, the smallest H^1-seminorm is achieved at $r_s = 11.78 \approx r_*^{(2)}$. This is because for this type of mesh, the error from the obtuse triangles (with $\phi_v \approx 0$) dominates in the global error. Therefore, the aspect ratio close to $r_*^{(2)}$ is the best choice for the global error norm.

For the L^2-, L^1-, and maximum norms, the smallest interpolation error is obtained with $r_{12} \approx r_*^{(\infty)}$ for all the three meshes.

In summary, we conclude that when the mesh is in good alignment with the solution and most of the triangles are acute isosceles, the aspect ratio should be chosen around $r_*^{(1)} \approx 0.8|\frac{\lambda_1}{\lambda_2}|$. If the mesh is in good alignment but with mostly obtuse triangles, or with varied maximum internal angles, then the aspect ratio should be chosen around $r_*^{(2)}$, which is approximately $1.178\sqrt{|\lambda_1/\lambda_2|}$ for the case $\lambda_1\lambda_1 > 0$, and $0.849\sqrt{|\lambda_1/\lambda_2|}$ for the case $\lambda_1\lambda_1 < 0$.

Table 1

The L^1- and L^2-norms, H^1-seminorm, and maximum norm of the interpolation error over the entire domain. (∗1) and (∗2) indicate the aspect ratio close to the best values for the H^1 seminorm in each case.

INTERPOLATION AND APPROXIMATION OF PIECEWISE SMOOTH FUNCTIONS[*]

FRANCESC ARANDIGA[†], ALBERT COHEN[‡], ROSA DONAT[†], AND NIRA DYN[§]

Abstract. This paper provides approximation orders for a class of nonlinear interpolation procedures for uniformly sampled univariate data. The interpolation is based on essentially nonoscillatory (ENO) and subcell resolution (SR) reconstruction techniques. These nonlinear techniques aim at reducing significantly the approximation error for functions with isolated singularities and are therefore attractive for applications such as shock computations or image compression. We prove that in the presence of isolated singularities, the approximation order provided by the interpolation procedure is improved by a factor of h relative to the linear methods, where h is the sampling rate. Moreover, for h below a critical value, we recover the optimal approximation order as for uniformly smooth functions.

Key words. piecewise smooth functions, interpolation, ENO, subcell resolution, critical sampling rate

1. Introduction.

This paper is concerned with the analysis of a class of univariate high order interpolation and approximation techniques for piecewise smooth functions, introduced by Harten [10], namely, *essentially nonoscillatory* (ENO) and *subcell resolution* (SR) reconstructions. These methods automatically adapt near the singularities of the approximated function, and they are by essence data dependent and nonlinear.

While their initial motivation was in the context of finite volume methods for shock computations, ENO-SR methods have found natural applications in data compression algorithms, in particular through the development of multiscale decompositions, similar to wavelet expansions, which incorporate nonlinear reconstructions [11, 12, 4]. In such decompositions, the wavelet coefficients are interpreted as the errors between the sampled data and its reconstruction from a sampling at a twice coarser scale. When dealing with data sampled from a piecewise smooth function, the adaptive treatment of singularities results in more accurate reconstructions and therefore in sparser decompositions than when using standard wavelet basis. In recent years, ENO-SR techniques have been extended to two-dimensional (2D) image data, either by tensor product [1, 2, 6] or by intrinsically 2D reconstructions [14, 3]. Other related nonlinear multiscale representations have been introduced in [5] in the context of the lifting scheme.

From a theoretical point of view, the adaptive treatment of singularities allows

us to expect strictly better approximation rates than with linear methods in the case of piecewise smooth functions and images. A rigorous analysis of this improvement in the one-dimensional (1D) case is the main objective of this paper. Our next perspective, which is the object of an ongoing work, is to study in a similar way the approximation properties of edge-adapted techniques for 2D functions and images such as those introduced in [14, 3]. It should well be understood that the 2D case is not a trivial generalization of the 1D case by tensor product technique: point discontinuities are then replaced by edges, which are not only characterized by their spatial locations but also by some geometrical features such as orientation and curvature. In turn, the development and analysis of 2D edge-adapted reconstruction strategies are significantly more involved, and the present paper can be viewed as an elementary yet instructive "starter" to this research program.

Consider at first the following situation: from a set of uniformly sampled data $(f(kh))_{k\in\mathbb{Z}}$, we are interested in building an interpolant $\mathcal{I}_h f$, i.e., a function such that $\mathcal{I}_h(kh) = f(kh)$ for all $k \in \mathbb{Z}$. There are many ways to build an interpolant $\mathcal{I}_h f$ of a prescribed order $m > 0$, i.e., such that if $f \in C^m$, one has

$$|\mathcal{I}_h f - f| \le C h^m \sup |f^{(m)}|. \tag{1}$$

Basically, one can do it with a linear operator $\mathcal{I}_h$ which is (i) local, (ii) exact for polynomials of degree $m-1$, and (iii) stable. We are interested in the interpolation of continuous functions f which are smooth everywhere except at isolated points. For such functions, we can only expect an error bound of order $\mathcal{O}(h)$ with a linear method, independently of its order.

In order to explain in a nutshell the principles of the ENO and SR techniques, first consider the following piecewise polynomial interpolation of the data $(f(kh))_{k\in\mathbb{Z}}$: to each interval

$$I_k := [kh, (k+1)h], \quad k \in \mathbb{Z}, \tag{2}$$

we attach the stencil S_k of size m around I_k, i.e.,

$$S_k := \{(k-m_1)h, \dots, (k+m_2)h\}, \tag{3}$$

where $m_1 \ge 0$ and $m_2 > 0$ are fixed integers such that $m_1 + m_2 = m - 1$. We define a unique polynomial $p_k \in \Pi_{m-1}$ which agrees with f on S_k. A linear interpolation operator is then defined by

$$\mathcal{I}_h f(x) = p_k(x), \quad x \in I_k. \tag{4}$$

This interpolant has accuracy of order m: if f is C^m on $[(k-m_1)h, (k+m_2)h]$, we have the estimate

$$\|f - \mathcal{I}_h f\|_{L^\infty(I_k)} \le C h^m \|f^{(m)}\|_{L^\infty([(k-m_1)h,(k+m_2)h])}. \tag{5}$$

Clearly, for a smooth function f with an isolated singularity of f' situated in the interval I_k, the order of accuracy is reduced to $\mathcal{O}(h)$ on all the intervals I_{k+l} for $l = -m_2+1, \dots, m_1$, due to the systematic use of a fixed stencil.

The principle of ENO interpolation is to allow for data-dependent stencils in order to reduce the influence of the singularity on the approximation. For this purpose, one typically introduces a measure of the oscillation of f on the stencil S_k. Since we are interested in detecting jump discontinuities in the first derivative, this measure is typically based on the evaluation of the second order differences,

$$\Delta_h^2 f(x) := f(x) - 2f(x+h) + f(x+2h) \tag{6}$$

for $x = (k-m_1)h, \dots, (k+m_2-2)h$. For each k, we select among all the stencils $\{S_{k-m_2+1}, \dots, S_{k+m_1}\}$ which contain I_k, the stencil $\tilde{S}_k$ which minimizes a chosen measure. The ENO interpolant is then given by

$$\mathcal{I}_h f(x) = \tilde{p}_k(x), \quad x \in I_k, \tag{7}$$

where $\tilde{p}_k$ is the polynomial which agrees with f on the stencil $\tilde{S}_k$. In comparison with the linear interpolation based on a fixed stencil, ENO interpolation has the same order of accuracy m and reduces the effect of an isolated singularity, since the selected stencil will tend to avoid it. We therefore expect that the precision only deteriorates on the interval which contains the singularity.

The goal of the SR technique is to improve the approximation properties of the interpolant even on this interval. It is based on a detection mechanism which labels as B (bad) an interval I_k which is suspected to contain a singularity, in the sense that the selected stencils for its immediate neighbors tend to avoid it. Thus I_k is B if $\tilde{S}_{k-1} = S_{k-m_2}$ and $\tilde{S}_{k+1} = S_{k+m_1+1}$. Other intervals are labeled as G (good). On a G interval I_k, we use the above-described ENO interpolation to define $\mathcal{I}_h f$. On a B interval I_k, we use the polynomials $\tilde{p}_{k-1}$ and $\tilde{p}_{k+1}$ to predict the location of the singularity: if these polynomials intersect at a single point a_k of I_k, we define for $x \in I_k$ the interpolant by

$$\mathcal{I}_h f(x) = \tilde{p}_{k-1}(x) \text{ if } x \le a_k, \;\; \tilde{p}_{k+1}(x) \text{ if } x \ge a_k. \tag{8}$$

In the case that these polynomials do not intersect at a single point of I_k, the interval is relabeled as G and the ENO interpolation is used.

An intuitive statement is that ENO-SR interpolation has accuracy of order $\mathcal{O}(h^m)$ for piecewise smooth functions. Some initial results suggesting the validity of this statement were given in [13] and in [10, 9]—for ENO and ENO-SR, respectively—in the context of building and analyzing high order schemes for conservation laws, and in [6] in the context of signal and image approximation and compression.

Our goal here is to investigate this statement in a rigorous way. For simplicity we consider functions which are smooth except at one unknown point a but are globally continuous. We also assume that $f \in C^m(\mathbb{R} \setminus \{a\})$ in the sense that its derivatives up to order m are uniformly bounded on $\mathbb{R} \setminus \{a\}$. Thus the derivatives of f have jumps $([f'], [f''], \dots)$ at the point a. Ideally we could hope for an estimate of the form

$$\|f - \mathcal{I}_h f\|_{L^\infty} \le C h^m \sup_{\mathbb{R}\setminus\{a\}} |f^{(m)}| \tag{9}$$

for all $h > 0$. Unfortunately, we shall see with a simple example that we cannot hope for such a result for $m > 2$. In fact (9) holds for h smaller than a fixed fraction of a critical scale h_c depending itself on the function f according to

$$h_c := \frac{[f']}{4 \sup_{x \in \mathbb{R}\setminus\{a\}} |f''(x)|}. \tag{10}$$

This critical scale h_c corresponds to the minimal level of resolution which ensures the detection of the singularity. To our knowledge, this notion was not used in previous works dealing with ENO and ENO-SR interpolation, particularly in the abovementioned references.

Therefore we can only achieve

$$\|f - \mathcal{I}_h f\|_{L^\infty} \le C h^m \sup_{\mathbb{R}\backslash\{a\}} |f^{(m)}|, \quad h \le K h_c(f). \tag{11}$$

We shall yet prove that we have for all $h > 0$ an estimate of the form

$$\|f - \mathcal{I}_h f\|_{L^\infty} \le C h^2 \sup_{\mathbb{R}\backslash\{a\}} |f''|, \tag{12}$$

i.e., at least a gain of one order of accuracy relative to any linear method. Note that since the interpolation process is local, our analysis applies also to the case of several isolated singularities which are sufficiently separated relative to the sampling scale (typically by mh).

When dealing with functions f which are piecewise smooth with an isolated jump discontinuity in the function itself, there is no more hope that a nonlinear reconstruction of f from its samples $f(kh)$ brings any improvement on the interval that contains the jump point, since the location of this point cannot be resolved at a finer resolution from these samples. Moreover these samples are not well defined a priori if f is not a continuous function. We should therefore replace the point value sampling by local averaging, in the sense that we are now given the cell averages $f_k^h := \frac{1}{h}\int_{kh}^{(k+1)h} f(t)dt$ for $k \in \mathbb{Z}$. We can build ENO-SR reconstruction procedures from such data in a way similar to that for point value data. In fact, reconstruction from cell averages can be derived by differentiating the point value interpolant obtained from the discrete primitive values $\sum_{l=0}^{k-1} f_l^h$. In turn, the results that we establish for piecewise smooth continuous functions in the point value setting can be used to establish similar results for piecewise smooth discontinuous functions in the cell average setting.

Note that most nonlinear approximation methods that deal with local singularities are based on either adaptive mesh refinement or wavelet thresholding (see, e.g., [8, 7] for surveys on such nonlinear approximation). A specific feature of the present approach is that it does not rely on any local refinement of the sampled data: the function is accurately reconstructed from a given uniform sampling, by a locally defined data dependent operator. A similar approach, yet based on different tools (in particular Fourier analysis), was developed in [15].

Our paper is organized as follows. We first show by an example in section 2 that one cannot hope for more than second order accuracy when a singularity occurs (still better than first order with linear methods). We introduce in section 3 a specific singularity detection mechanism together with an ENO-SR interpolation process, which slightly differs from the original ENO-SR, yet with the same basic principles, and we discuss the organization of the intervals which are detected by this mechanism. We prove in section 4 that detection always occurs for $h < h_c$ and that the position of the singularity is accurately estimated. We then use these results in section 5 to prove that our version of the ENO-SR interpolation technique has accuracy of order $\mathcal{O}(h^m)$ for h smaller than Kh_c, where $0 < K < 1$ is a fixed constant, and that it is second order accurate for all $h > 0$, which is the best that we can hope for according to the example of section 2. These findings are demonstrated in section 6 by numerical examples. Finally in section 7, we derive similar approximation results for piecewise smooth discontinuous functions in the cell average setting, measuring the error in the L^p norm as well as in the Hausdorff distance between graphs as a substitute to the L^∞ norm.

2. An instructive example. The following elementary example is meant to show that one cannot expect more than second order accuracy for a general class of continuous functions with jump discontinuities, as well as to illustrate the notion of critical scale.

Consider the functions f_+ and f_- which depend on $h_0 > 0$:

$$f_+(x) = 0 \text{ if } x < 0, \quad f_+(x) = x(x - h_0) \text{ if } x \geq 0, \tag{13}$$

and

$$f_-(x) = 0 \text{ if } x < h_0, \quad f_-(x) = x(x - h_0) \text{ if } x \geq h_0. \tag{14}$$

We notice that both functions agree on $h_0\mathbb{Z}$ so that if $\mathcal{I}_h$ is *any* interpolation operator on the grid $\mathbb{Z}h$, we have the following when $h = h_0$:

$$\mathcal{I}_h f_+ = \mathcal{I}_h f_-. \tag{15}$$

Since $\|f_+ - f_-\|_{L^\infty} = h^2/4$, by the triangle inequality we have either

$$\|f_+ - \mathcal{I}_h f_+\|_{L^\infty} \geq h^2/8 \geq \frac{h^2}{16} \sup_{x \in \mathbb{R} \setminus \{0\}} |f_+''| \tag{16}$$

or

$$\|f_- - \mathcal{I}_h f_-\|_{L^\infty} \geq h^2/8 \geq \frac{h^2}{16} \sup_{x \in \mathbb{R} \setminus \{h\}} |f_-''|. \tag{17}$$

Since we also have

$$\sup_{x \in \mathbb{R} \setminus \{h\}} |f_-^{(m)}| = \sup_{x \in \mathbb{R} \setminus \{0\}} |f_+^{(m)}| = 0, \quad m > 2, \tag{18}$$

this simple example shows us that (9) cannot be achieved with $m > 2$. Here h_0 plays the role of a *critical scale* above which singularities cannot be precisely detected. For $h \ll h_0$, our nonlinear interpolation method gives an exact reconstruction of f_+ and f_-. However, we certainly cannot ensure more than second order accuracy over all piecewise smooth functions and all $h > 0$.

3. A modified ENO-SR detection and interpolation mechanism. For a given approximation order m, our detection mechanism defines a set of intervals labeled B, which potentially contain the singularity, according to the following rules:

1. If

   $$|\Delta_h^2 f((k-1)h)| > |\Delta_h^2 f((k-1 \pm n)h)|, \quad n = 1, \dots, m. \tag{19}$$

   both I_{k-1} and I_k are labeled B. Notice that (19) indicates that the point kh lies at the center of the largest second divided difference (among those being compared). Hence either I_{k-1} or I_k could potentially contain the singularity.
2. If

   $$|\Delta_h^2 f(kh)| > |\Delta_h^2 f((k+n)h)|, \quad n = 1, \dots, m-1, \tag{20}$$

   and

   $$|\Delta_h^2 f((k-1)h)| > |\Delta_h^2 f((k-1-n)h)|, \quad n = 1, \dots, m-1, \tag{21}$$

   then I_k is labeled B. In this case the two largest divided differences involved in the comparison process include I_k, which is then a candidate to contain the singularity.

All other intervals are labeled G.

This detection mechanism is designed in such a way that for h sufficiently small, the interval I_k containing the singularity a is labeled B, while all intervals labeled G are in smooth regions of f. On the other hand it is also possible that an interval I_k might be labeled B in a smooth region at an arbitrarily small scale. In case of such false alarms, it is crucial that the polynomials which are used to construct the interpolation are built from stencils which only contain G intervals, i.e., from smooth regions. This is ensured by the following lemma, which describes the organization of the B and G intervals.

LEMMA 1. *The groups of adjacent B intervals are at most of size 2. They are separated by groups of adjacent G intervals which are at least of size $m-1$.*

Proof. Assume that I_0 and I_k are B with $1 < k < m$. We have three cases:

1. I_0 and I_k have been labeled B by the second rule. Then it follows that both $|\Delta_h^2 f(0)| > |\Delta_h^2 f((k-1)h)|$ and $|\Delta_h^2 f(0)| < |\Delta_h^2 f((k-1)h)|$, which is a contradiction.
2. I_0 has been labeled B by the second rule and I_k has been labeled B by the first rule. Then either I_{k-1} or I_{k+1} is also a B interval. Hence we obtain that both $|\Delta_h^2 f(0)| > |\Delta_h^2 f(qh)|$ and $|\Delta_h^2 f(0)| < |\Delta_h^2 f(qh)|$ for some $q \in \{k-1, k\}$, which is a contradiction. The case where I_0 has been labeled B by the first rule and I_k has been labeled B by the second rule is treated in a similar way.
3. I_0 and I_k have been labeled B by the first rule; hence each one is a member of a B-pair (two adjacent B intervals). Hence we obtain that both $|\Delta_h^2 f(ph)| > |\Delta_h^2 f(qh)|$ and $|\Delta_h^2 f(ph)| < |\Delta_h^2 f(qh)|$ for some $p \in \{-1, 0\}$ and $q \in \{k-1, k\}$, which is a contradiction.

We therefore obtain that no two B intervals can have a difference of indices strictly between 1 and m, which concludes the proof. □

Remark. Our detection mechanism is based only on comparing second order divided differences and is therefore different from the hierarchical mechanism originally proposed by Harten in [10]. The main motivation is that the final goal of our procedure is really to detect singularities and isolate them sufficiently from false alarms in order to derive our approximation results in an elementary way. Harten's detection mechanism needs to be modified to ensure Lemma 1; we need to compare a larger number of divided differences than that necessary for the stencil selection mechanism. The validity of Lemma 1 is crucial in order to obtain the desired approximation result, presented in Theorem 1. In fact, one can prove that this result does not hold when using the detection mechanism of [10], although the counterexamples seem to be of a pathological nature and are seldom observed numerically.

Based on the above-described detection mechanism, we propose the following interpolation procedure:

1. If I_k is a G interval, define $\mathcal{I}_h f$ on I_k as a polynomial p_k of degree $m-1$ obtained by interpolation of f on a stencil $\{ph, \dots, (p+m-1)h\}$ such that $p \le k < k+1 \le p+m-1$ and such that this stencil contains only G intervals. Such a stencil always exists, according to Lemma 1, yet is not unique. In practice, we may choose the stencil which is the most centered around the interval I_k or we may use the standard ENO procedure.
2. If I_k is an isolated B interval, we obtain polynomials p_k^- and p_k^+ of degree $m-1$ by interpolation of f on the stencils $\{(k-m+1)h, \dots, kh\}$ and $\{(k+1)h, \dots, (k+m)h\}$ and use them to predict the location of the singularity: if these polynomials intersect at a single point y of I_k, then for $x \in I_k$ we define

the interpolant by

$$\mathcal{I}_h f(x) = p_k^-(x) \text{ if } x \le y, \;\; p_k^+(x) \text{ if } x \ge y. \tag{22}$$

In the case where these polynomials do not intersect at a single point of I_k, the interval is relabeled G and we return to the previous case.

3. If (I_k, I_{k+1}) is a B-pair, we treat $I_k \cup I_{k+1}$ as I_k in the previous case; i.e., we obtain polynomials p_k^- and p_{k+1}^+ of degree $m-1$ by interpolation of f at stencils $\{(k-m+1)h, \ldots, kh\}$ and $\{(k+2)h, \ldots, (k+m+1)h\}$ and use them to predict the location of the singularity: if these polynomials intersect at a single point y of $I_k \cup I_{k+1}$, then for $x \in I_k \cup I_{k+1}$ we define the interpolant by

$$\mathcal{I}_h f(x) = p_k^-(x) \text{ if } x \le y, \;\; p_{k+1}^+(x) \text{ if } x \ge y. \tag{23}$$

In the case where these polynomials do not intersect at a single point of $I_k \cup I_{k+1}$, both intervals are relabeled G and we return to the first case.

Note that the interpolation operator $\mathcal{I}_h f$ described above does not make use of the data at midpoints of B-pairs. Hence $\mathcal{I}_h f$ does not interpolate f at these points. This is a specific feature of our modified ENO-SR interpolation which greatly facilitates the proof of our main approximation result in section 5.

4. Properties of the detection mechanism.

The goal of this section is to establish some properties of the detection mechanism which will be used in section 5 for proving the improved approximation order of $\mathcal{I}_h f$ announced in the introduction.

The properties are expressed by two lemmas. The first one ensures that the singularity is always detected under some critical scale.

LEMMA 2. *Let f be a globally continuous function with a bounded second derivative on $\mathbb{R} \setminus \{a\}$ and a discontinuity in the first derivative at a point a. Define the critical scale*

$$h_c := \frac{|[f']|}{4 \sup_{x \in \mathbb{R}\setminus\{a\}} |f''(x)|}, \tag{24}$$

where $[f']$ is the jump of the first derivative f' at the point a. Then for $h < h_c$, the interval I_k which contains a is labeled B. Moreover, if a is close to one endpoint of the interval I_k by at most a quarter of its size, then the interval adjacent to this endpoint is also labeled B.

Proof. Without loss of generality, we can assume that a is located on the first half of the interval I_0, i.e., $0 \le a \le h/2$. For $k > 0$ and $k < -1$, we find that

$$|\Delta_h^2 f(kh)| \le h^2 \sup_{x \in \mathbb{R}\setminus\{a\}} |f''(x)|. \tag{25}$$

For $k = -1$ and $k = 0$, the second order finite differences can be estimated by decomposing f into

$$f(x) = f_1(x) + f_2(x), \tag{26}$$

with $f_1(x) = [f'](x-a)_+$ and $f_2(x)$ a C^1 function with a bounded second derivative on $\mathbb{R} \setminus \{a\}$, such that

$$\sup_{x \in \mathbb{R}\setminus\{a\}} |f_2''(x)| = \sup_{x \in \mathbb{R}\setminus\{a\}} |f''(x)|. \tag{27}$$

We therefore have for all $k \in \mathbb{Z}$

$$|\Delta_h^2 f_2(kh)| \le h^2 \sup_{x \in \mathbb{R} \setminus \{a\}} |f''(x)|. \tag{28}$$

On the other hand, we have

$$|\Delta_h^2 f_1(-h)| = |(h-a)[f']|. \tag{29}$$

It follows that

$$|\Delta_h^2 f(-h)| \ge |(h-a)[f']| - h^2 \sup_{x \in \mathbb{R} \setminus \{a\}} |f''(x)|, \tag{30}$$

and therefore

$$|\Delta_h^2 f(-h)| \ge \frac{h}{2}|[f']| - h^2 \sup_{x \in \mathbb{R} \setminus \{a\}} |f''(x)|. \tag{31}$$

So if $h < h_c$, we get by (24)

$$|\Delta_h^2 f(-h)| > h^2 \sup_{x \in \mathbb{R} \setminus \{a\}} |f''(x)| \tag{32}$$

Combining this with (25), we find that if $h < h_c$

$$|\Delta_h^2 f(-h)| > |\Delta_h^2 f(kh)| \tag{33}$$

for $k < -1$ and $k > 0$. In the case where $|\Delta_h^2 f(-h)| > |\Delta_h^2 f(0)|$, we find that I_{-1} and I_0 are a B-pair according to the first detection rule. Otherwise, if $|\Delta_h^2 f(-h)| \le |\Delta_h^2 f(0)|$, we find that I_0 must be labeled B according to the second detection rule.

Finally, we notice that

$$|\Delta_h^2 f_1(0)| = |a[f']|, \tag{34}$$

so that

$$|\Delta_h^2 f(0)| \le |a[f']| + h^2 \sup_{x \in \mathbb{R} \setminus \{a\}} |f''(x)|. \tag{35}$$

Therefore, combining (35) and (30), we are always in the case of I_{-1} and I_0 constituting a B-pair whenever

$$2h^2 \sup_{x \in \mathbb{R} \setminus \{a\}} |f''(x)| < (h-2a)|[f']|, \tag{36}$$

which holds whenever $h < h_c$ and $a < h/4$. □

The next lemma expresses the fact that the location of the singularity is accurately estimated when h is less than a fixed fraction of the critical scale.

LEMMA 3. *There exist constants $C > 0$ and $0 < K < 1$ such that for all continuous f with uniformly bounded mth derivative on $\mathbb{R} \setminus \{a\}$ and for $h < Kh_c$ with h_c defined by* (24)*, the following holds:*

1. *The singularity a is contained in an isolated B interval I_k (Case 1) or in a B-pair (I_k, I_{k+1}) (Case 2).*

2. *The two polynomials* (p_k^-, p_k^+) *(Case* 1*) or* (p_k^-, p_{k+1}^+) *(Case* 2*) which are used in the definition of* $\mathcal{I}_h f$ *have only one intersection point* y *inside* I_k *(Case* 1*) or inside* $I_k \cup I_{k+1}$ *(Case* 2*).*
3. *The distance between* a *and* y *is bounded by*

$$|a-y| \leq C \frac{h^m \sup_{\mathbb{R}\setminus\{a\}} |f^{(m)}|}{|[f']|}. \tag{37}$$

Proof. Since $K < 1$, the first statement has already been proved in Lemma 2. Without loss of generality, we assume that $0 \leq a \leq h/2$. In this case we know by Lemma 2 that I_0 is B for $h < h_c$. For the sake of notational simplicity we denote by $I = [b, c]$ the interval where we perform the subcell resolution process, which is either I_0 (Case 1) or $I_{-1} \cup I_0$ (Case 2) or $I_0 \cup I_1$ (Case 2). By Lemma 2, we are ensured that $I = I_{-1} \cup I_0$ when $a < h/4$, and therefore

$$\min\{|a-b|, |a-c|\} \geq h/4. \tag{38}$$

We also denote by (p_-, p_+) the polynomials which are used in the subcell resolution of I. Finally we note that for any $2 \leq k \leq m$ we can write

$$f = f_- \chi_{]-\infty,a]} + f_+ \chi_{[a,+\infty[}, \tag{39}$$

where f^- and f^+ are functions which are globally C^k over $\mathbb{R}$ and such that

$$\sup_{x\in\mathbb{R}} |f_\pm^{(k)}(x)| \leq \sup_{x\in\mathbb{R}\setminus\{a\}} |f^{(k)}(x)|. \tag{40}$$

For example, we can define these functions by extension of f using its left or right Taylor expansion of order k at the point a. In order to prove the second statement of the lemma, we choose $k = 2$. We note that p_- and p_+ can also be viewed as Lagrange interpolation of f_- and f_+. It then follows from classical results on Lagrange interpolation that there exists a constant D independent of f such that for all $t \in I$,

$$|f_\pm(t) - p_\pm(t)| \leq Dh^2 \sup_{x\in\mathbb{R}} |f_\pm''(x)| = Dh^2 \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|, \tag{41}$$

and

$$|f_\pm'(t) - p_\pm'(t)| \leq Dh \sup_{x\in\mathbb{R}} |f_\pm''(x)| = Dh \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|. \tag{42}$$

Since $|t-a| \leq 2h$ when $t \in I$, we also have

$$|f_\pm'(t) - f_\pm'(a)| \leq 2h \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|, \tag{43}$$

and therefore we get from (42)

$$|f_\pm'(a) - p_\pm'(t)| \leq (D+2)h \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|, \quad t \in I. \tag{44}$$

It follows that for all $t \in I$,

$$|p_+'(t) - p_-'(t)| \geq |[f']| - 2(D+2)h \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|. \tag{45}$$

Thus, for $h < \frac{2}{D+2}h_c$ the function $p_+ - p_-$ is strictly monotone on I and has at most one root. Therefore, we are ensured that p_+ and p_- intersect at most at a single point inside I. In order to prove that this point y exists, we need to show that $p_+ - p_-$ has a sign change inside I. Without loss of generality, assume here that $[f'] > 0$. By second order Taylor expansion at the point a, we find that

$$(f_+ - f_-)(b) \leq -(a-b)[f'] + (a-b)^2 \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|, \tag{46}$$

and

$$(f_+ - f_-)(c) \geq (c-a)[f'] - (c-a)^2 \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|. \tag{47}$$

Combining with (41), we thus obtain

$$(p_+ - p_-)(b) \leq -(a-b)[f'] + ((a-b)^2 + 2Dh^2) \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|, \tag{48}$$

and

$$(p_+ - p_-)(c) \geq (c-a)[f'] - ((c-a)^2 + 2Dh^2) \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|. \tag{49}$$

Using (38), we therefore obtain

$$(p_+ - p_-)(b) \leq -\frac{h}{4}[f'] + (2D+4)h^2 \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|, \tag{50}$$

and

$$(p_+ - p_-)(c) \geq \frac{h}{4}[f'] - (2D+4)h^2 \sup_{x\in\mathbb{R}\setminus\{a\}} |f''(x)|. \tag{51}$$

It follows that for $h < \frac{1}{4D+8}h_c$, we have

$$(p_+ - p_-)(b) \leq -\frac{h}{8}[f'] < 0, \tag{52}$$

and

$$(p_+ - p_-)(c) \geq \frac{h}{8}[f'] > 0, \tag{53}$$

so that there exists a single intersection point $y \in I$. So defining $K := \frac{1}{4D+8}$, we have proved the two first statements of the lemma.

In order to prove the third statement (37), we now choose $k = m$ in the definition of the extensions f_+ and f_-. It again follows from classical results on Lagrange interpolation that there exists a constant $\tilde{D}$ such that for all $t \in I$,

$$|f_\pm(t) - p_\pm(t)| \leq \tilde{D}h^m \sup_{x\in\mathbb{R}\setminus\{a\}} |f^{(m)}(x)|, \tag{54}$$

and therefore, if we define $g = f_+ - f_-$ and $q = p_+ - p_-$, we obtain, for all $t \in I$,

$$|g(t) - q(t)| \leq 2\tilde{D}h^m \sup_{x\in\mathbb{R}\setminus\{a\}} |f^{(m)}(x)|, \tag{55}$$

so that for $t = a$,

$$|q(a)| \leq 2\tilde{D}h^m \sup_{x\in\mathbb{R}\setminus\{a\}} |f^{(m)}(x)|. \tag{56}$$

Now note that for $t \in I$ and $h < Kh_c$, by (45)

$$|q'(t)| = \frac{|[f']|}{2}, \tag{57}$$

and therefore

$$|q(a)| = |q(y) - q(a)| \geq |y - a|\frac{|[f']|}{2}. \tag{58}$$

Combining this with (56), we therefore obtain (37) with $C = 4\tilde{D}$. □

5. Approximation properties of $\mathcal{I}_h$. We are now ready to derive our main approximation result.

THEOREM 1. *For all continuous f with derivatives up to degree m uniformly bounded on $\mathbb{R} \setminus \{a\}$, the nonlinear interpolant $\mathcal{I}_h f$ satisfies*

$$\|f - \mathcal{I}_h f\|_{L^\infty} \leq Ch^2 \sup_{\mathbb{R}\setminus\{a\}} |f''| \tag{59}$$

for all $h > 0$, with $C > 0$ independent of f. Moreover there exists $0 < K < 1$ independent of f such that, for $h < Kh_c$ with h_c defined by (24), we have

$$\|f - \mathcal{I}_h f\|_{L^\infty} \leq Ch^m \sup_{\mathbb{R}\setminus\{a\}} |f^{(m)}|. \tag{60}$$

Proof. We choose for K the constant in Lemma 3. Note first that for $h < Kh_c$, according to Lemmas 1 and 2, all the polynomials which are used in the construction of $\mathcal{I}_h$ are built from stencils over which the function is smooth. It follows from classical results on Lagrange interpolation that the estimate

$$|f(x) - \mathcal{I}_h f(x)| \leq Ch^m \sup_{\mathbb{R}\setminus\{a\}} |f^{(m)}| \tag{61}$$

holds whenever x belongs to a G interval or to an isolated B interval or B-pair which does not contain a (i.e., false alarms do not deteriorate the convergence rate). Let us now assume that x belongs to the group of adjacent B intervals which contains a. Here, we shall assume, again without loss of generality, that $0 \leq a \leq h/2$ and use the notation $I = [b, c]$, p_+, p_-, f_+, f_- that were introduced in the proof of Lemma 3. We also assume that $a \leq y$, the case $y \leq a$ being treated in a similar way. For $x \in [b, a]$, we have the estimate

$$|f(x) - \mathcal{I}_h f(x)| = |f_-(x) - p_-(x)| \leq Ch^m \sup_{\mathbb{R}\setminus\{a\}} |f^{(m)}|, \tag{62}$$

and for $x \in [y, c]$, we have the estimate

$$|f(x) - \mathcal{I}_h f(x)| = |f_+(x) - p_+(x)| \leq Ch^m \sup_{\mathbb{R}\setminus\{a\}} |f^{(m)}|. \tag{63}$$

It remains to consider the case $a < x < y$. In this case, we have

$$|f(x) - \mathcal{I}_h f(x)| = |f_+(x) - p_-(x)| \leq |f_+(x) - f_-(x)| + |f_-(x) - p_-(x)|. \tag{64}$$

The second term is again bounded by $Ch^m \sup_{\mathbb{R}\backslash\{a\}} |f^{(m)}|$. For the first term, we use second order Taylor expansion to derive

$$\begin{aligned}|f_+(x) - f_-(x)| &\le |[f']|(y-a) + (y-a)^2 \sup_{\mathbb{R}\backslash\{a\}} |f''| \\ &\le (y-a)(|[f']| + h \sup_{\mathbb{R}\backslash\{a\}} |f''|).\end{aligned}$$

Since $h < h_c$, this gives

$$|f_+(x) - f_-(x)| \le \frac{5}{4}|[f']|](y-a). \tag{65}$$

Combining this with (37) of Lemma 3, we also obtain the bound $Ch^m \sup_{\mathbb{R}\backslash\{a\}} |f^{(m)}|$ for $|f_+(x) - f_-(x)|$, which concludes the proof in the case $h < Kh_c$.

In the case $h \ge Kh_c$, the estimate

$$|f(x) - \mathcal{I}_h f(x)| \le Ch^m \sup_{\mathbb{R}\backslash\{a\}} |f^{(m)}| \tag{66}$$

is guaranteed to hold only when x is at distance not less than $(m+1)h$ from a. We also have the lower order estimate

$$|f(x) - \mathcal{I}_h f(x)| \le Ch^2 \sup_{\mathbb{R}\backslash\{a\}} |f''|. \tag{67}$$

Let us now prove that this estimate remains valid if $|x-a| \le (m+1)h$. For this purpose we consider the decomposition $f = f_1 + f_2$ used in the proof of Lemma 2. The errors of polynomial interpolation of f_1 and f_2 are, respectively, bounded by $Ch|[f'|]$ and $Ch^2 \sup_{\mathbb{R}\backslash\{a\}} |f''|$. Since $h \ge Kh_c$ the second bound dominates the first one so that the above estimate is valid. The proof of the theorem is now complete. □

6. Numerical examples. We consider the functions

$$f_\varepsilon(x) = \begin{cases} (x - \pi/6)(x - \pi/6 - \varepsilon) + \sin(\pi x/8)/8, & x < \pi/6, \\ \sin(\pi x/8)/8 & \text{otherwise} \end{cases} \tag{68}$$

for four values of ε $(2^{-6}, 2^{-8}, 2^{-10}, 2^{-12})$. Each of these functions is globally continuous with a jump of ε in its first derivative at the point $\pi/6$, while its higher derivatives are uniformly bounded independently of ε. The f_ε are piecewise polynomial functions similar to the example in section 2, to which we add the smooth function $\sin(\pi x/8)/8$ in order to avoid a 0 approximation error for h less than a critical scale.

We apply our technique with $m = 4$. For different values of h we compute $\mathcal{I}_h f_\varepsilon$ for the four values of ε and plot log $\| f_\varepsilon - \mathcal{I}_h f_\varepsilon \|_\infty$ versus $-\log(h)$ in Figure 1. In Table 1 we give the corresponding values of $\| f_\varepsilon - \mathcal{I}_h f_\varepsilon \|_\infty$.

We observe that we always have accuracy of order $\mathcal{O}(h^2)$ and that for h smaller than some h_ε, we recover the optimal accuracy of order $\mathcal{O}(h^4)$. This is ensured by Theorem 1 for $h < Kh_c$, where

$$h_c := \frac{|[f'_\varepsilon]|}{4 \sup_{x\in\mathbb{R}-\{\pi/6\}} |f''_\varepsilon(x)|} = \varepsilon/8$$

and $0 < K < 1$. However, we observe that $h_\varepsilon > \varepsilon/8$, which means that the order of accuracy $\mathcal{O}(h^4)$ is attained even for some $h > Kh_c$.

Remark. We have performed the same test for the original SR technique of Harten [10], modified in order to ensure that Lemma 1 is satisfied. The behavior in terms of approximation errors and orders is absolutely similar to that shown in Figure 1 and Table 1.

7. Approximation of discontinuous functions. In this last section, we derive similar approximation results for piecewise smooth functions with jump discontinuities, sampled by their cell averages

$$f_k^h := \frac{1}{h}\int_{kh}^{(k+1)h} f(t)dt. \tag{69}$$

For such data, the reconstruction $\mathcal{A}_h f$ is defined on each interval I_k by a polynomial or piecewise polynomial function such that its cell average on I_k coincides with f_k^h. In the case of a linear method, a polynomial q_k of degree $m-2$ is uniquely determined by the $f_{k-m_1}^h, \dots, f_{k+m_2-1}^h$, where $m_1 \geq 0$ and $m_2 > 0$ are fixed integers such that $m_1 + m_2 = m - 1$.

A simple connection can be established between cell average and point value reconstructions: the polynomial p_k of degree m which interpolates the point values of the primitive $F(x) = \int_0^x f(t)dt$ at the points $(k-m_1)h, \dots, (k+m_2)h$ satisfies

$$p_k' = q_k. \tag{70}$$

Since these point values are given by the discrete primitive

$$F(kh) = h\sum_{l=0}^{k-1} f_l^h,\ k>0,\ \ F(kh) = h\sum_{l=k}^{-1} f_l^h,\ k<0 \ \text{ and } \ F(0)=0, \tag{71}$$

the cell average–based reconstruction operator $\mathcal{A}_h$ by polynomials of degree $m-2$ can thus be interpreted as

$$\mathcal{A}_h = \mathcal{D}\mathcal{I}_h\mathcal{P}_d, \tag{72}$$

where $\mathcal{P}_d$ is the discrete primitive operator $\mathcal{P}_d(\{f_k^h\}) = \{F(kh)\}$, $\mathcal{I}_h$ is the point value interpolation operator of degree $m-1$, and $\mathcal{D}$ is the continuous differentiation $\mathcal{D}f = f'$ (see [4]). The choice of our ENO-SR point value interpolation of degree $m-1$ as $\mathcal{I}_h$ in the above formula leads to a natural definition of an ENO-SR cell average–based reconstruction operator $\mathcal{A}_h$.

We can use (72) in order to derive approximation results for $\mathcal{A}_h$ applied to piecewise smooth discontinuous functions from the approximation result of section 5. Here we shall analyze the error in L^p for $1 \le p < \infty$ on a fixed bounded interval I, since we necessarily have an $\mathcal{O}(1)$ error in the L^∞ norm near the discontinuity. We assume here that f is C^{m-1} on $\mathbb{R}\setminus\{a\}$ in the sense that its derivatives up to degree $m-1$ are uniformly bounded on $\mathbb{R}\setminus\{a\}$, with a jump $[f]$ at the point a. Therefore, its approximation $\mathcal{A}_h f$ by a linear cell average–based reconstruction will have $\mathcal{O}(1)$ accuracy on the intervals I_k which are such that a is contained in $[(k-m_1)h,(k+m_2)h]$, and $\mathcal{O}(h^{m-1})$ elsewhere, resulting in a global L^p error behaving like

$$\|f-\mathcal{A}_h f\|_{L^p(I)} \le C\max\{h^{m-1}, h^{1/p}\}. \tag{73}$$

If we now consider the nonlinear approximation $\mathcal{A}_h f$ obtained by our ENO-SR reconstruction, we know that

$$\mathcal{A}_h f = (\mathcal{I}_h F)', \tag{74}$$

where F is the primitive of f. Since F is C^m on $\mathbb{R}\setminus\{a\}$, defining the critical scale as

$$h_c := \frac{|[F']|}{4\sup_{x\in\mathbb{R}\setminus\{a\}}|F''(x)|} = \frac{|[f]|}{4\sup_{x\in\mathbb{R}\setminus\{a\}}|f'(x)|}, \tag{75}$$

we obtain the same conclusions as in Lemma 3 for $h < Kh_c$. We can then revisit the proof of Theorem 1 as follows.

For $h < Kh_c$, classical results on Lagrange interpolation show that the estimate

$$|F'(x) - (\mathcal{I}_h F)'(x)| \le Ch^{m-1}\sup_{\mathbb{R}\setminus\{a\}}|F^{(m)}|, \tag{76}$$

or, equivalently,

$$|f(x) - \mathcal{A}_h f(x)| \le Ch^{m-1}\sup_{\mathbb{R}\setminus\{a\}}|f^{(m-1)}|, \tag{77}$$

holds whenever x belongs to a G interval or to a group of adjacent B intervals which do not contain a (i.e., false alarms do not deteriorate the convergence rate). When x belongs to the group of adjacent B intervals which contains a, the same analysis as in the proof of Theorem 1 shows that this estimate remains valid when x is not located on the interval $[a, y]$ (or $[y, a]$) on which we cannot avoid an $\mathcal{O}(1)$ error. However, since this interval has its size estimated by

$$|a - y| \leq C \frac{h^m \sup_{\mathbb{R}\setminus\{a\}} |F^{(m)}|}{|[F']|} = C \frac{h^m \sup_{\mathbb{R}\setminus\{a\}} |f^{(m-1)}|}{|[f]|}, \tag{78}$$

we obtain a global L^p error behaving like

$$\|f - \mathcal{A}_h f\|_{L^p(I)} \leq C \max\{h^{m-1}, h^{m/p}\}. \tag{79}$$

For $h \geq K h_c$, the estimate

$$|f(x) - \mathcal{A}_h f(x)| \leq C h^{m-1} \sup_{\mathbb{R}\setminus\{a\}} |f^{(m-1)}| \tag{80}$$

is valid only when x is at distance at least $(m+1)h$ from a. For $|x - a| \leq (m+1)h$, we consider the decomposition $F = F_1 + F_2$ used in the proof of Lemma 2, for which we have

$$|F_1'(x) - (\mathcal{I}_h F_1)'(x)| \leq C|[F']| = C|[f]|, \tag{81}$$

and

$$|F_2'(x) - (\mathcal{I}_h F_2)'(x)| \leq C h \sup_{\mathbb{R}\setminus\{a\}} |F''| = C h \sup_{\mathbb{R}\setminus\{a\}} |f'|. \tag{82}$$

Since $h \geq K h_c$ the second bound dominates the first one. It follows that we obtain a global L^p error behaving like

$$\|f - \mathcal{A}_h f\|_{L^p(I)} \leq C \max\{h^{m-1}, h^{1+1/p}\}. \tag{83}$$

Note that both estimates (83) and (79) constitute an improvement of (73). Combining these estimates, we find that for all $h > 0$

$$\|f - \mathcal{A}_h f\|_{L^p(I)} \leq C \max\{h^{m-1}, h^{m/p}, h^{1+1/p}\}. \tag{84}$$

In the case $p = 1$ and $m > 1$, we find a statement very similar to that obtained in the point value setting: while approximation by a linear method behaves like $\mathcal{O}(h)$, our ENO-SR approximation behaves like $\mathcal{O}(h^{m-1})$ for $h < K h_c$ and like $\mathcal{O}(h^2)$ for all h.

The estimate (84) degenerates, however, to $\mathcal{O}(1)$ for $p = \infty$, which reflects the fact that we cannot hope to approximate a function with a jump in the L^∞ norm. For such discontinuous functions, a natural substitute to the L^∞ norm is given by the Hausdorff distance between graph, namely,

$$d(f, g) := d_{\mathcal{H}}(G_f, G_g), \tag{85}$$

where G_f and G_g are the completed graph of f and g and

$$d_{\mathcal{H}}(A, B) := \sup_{x \in A} \inf_{y \in B} |x - y| + \sup_{x \in B} \inf_{y \in A} |x - y| \tag{86}$$

is the Hausdorff distance between sets A and B of $\mathbb{R}^2$ (here $|x - y|$ is the Euclidean distance between x and y in $\mathbb{R}^2$). Recall that the completed graph of a discontinuous function f which admits left and right limits at its jumps consists of the points

$(x, f(x))$ when f is continuous at x and of the vertical segments $[f(x-0), f(x+0)]$ at the jump points x.

The approximation accuracy in the Hausdorff distance therefore measures the closeness in the L^∞ norm away from the jumps and the accuracy in resolving the exact location of the discontinuity. Note that this distance also penalizes the Gibbs phenomenon, which is the persistence of oscillations at fixed amplitude in the approximation near the discontinuity. In turn when applying a linear cell average–based reconstruction of degree $m-2>0$ to a piecewise smooth function with a jump discontinuity, we cannot expect any convergence in this distance and we thus have only $d(f, \mathcal{A}_h f) = \mathcal{O}(1)$.

Consider now the nonlinear approximation $\mathcal{A}_h f$ obtained by our ENO-SR reconstruction. For $h < Kh_c$, we have already seen that f is approximated from both sides with precision (77) and the jump point is approximated with accuracy (78). In this case, the Gibbs phenomenon is avoided and we obtain the asymptotical behavior

$$d(f, \mathcal{A}_h f) \leq Ch^{m-1}. \tag{87}$$

For $h \geq Kh_c$, the detection of the jump discontinuity is not ensured. In this case, we crudely estimate the Hausdorff distance by the L^∞ norm and obtain

$$d(f, \mathcal{A}_h f) \leq \|f - \mathcal{A}_h\|_{L^\infty} \leq Ch \sup_{x \in \mathbb{R} \setminus \{a\}} |f'(x)| + C|[f]|, \tag{88}$$

where the second term accounts for the Gibbs phenomenon generated by the singularity. Since $h \geq Kh_c$, the first term is dominant, and we therefore obtain for all $h > 0$ the estimate

$$d(f, \mathcal{A}_h f) \leq Ch. \tag{89}$$

The fact that we can obtain convergence rates in the Hausdorff distance is a very nice specific feature of ENO-SR nonlinear reconstruction, which reflects in particular its nonoscillatory nature.

We can summarize our findings on the cell average reconstruction of piecewise smooth functions with jump discontinuities in the following statement.

Theorem 2. *For all f with derivatives up to degree $m-1$ uniformly bounded on $\mathbb{R} \setminus \{a\}$, the nonlinear reconstruction $\mathcal{A}_h f$ satisfies*

$$\|f - \mathcal{A}_h f\|_{L^p(I)} \leq C \max\{h^{m-1}, h^{m/p}, h^{1+1/p}\}, \tag{90}$$

and

$$d(f, \mathcal{A}_h f) \leq Ch \tag{91}$$

for all $h > 0$. Moreover there exists $0 < K < 1$ independent of f such that for $h < Kh_c$ with h_c defined by (75)*, we have*

$$\|f - \mathcal{A}_h f\|_{L^p(I)} \leq C \max\{h^{m-1}, h^{m/p}\}, \tag{92}$$

and

$$d(f, \mathcal{A}_h f) \leq Ch^{m-1}. \tag{93}$$

HERMITE SPECTRAL METHODS WITH A TIME-DEPENDENT SCALING FOR PARABOLIC EQUATIONS IN UNBOUNDED DOMAINS[*]

HEPING MA[†], WEIWEI SUN[‡], AND TAO TANG[§]

Abstract. Hermite spectral methods are investigated for linear diffusion equations and nonlinear convection-diffusion equations in unbounded domains. When the solution domain is unbounded, the diffusion operator no longer has a compact resolvent, which makes the Hermite spectral methods unstable. To overcome this difficulty, a time-dependent scaling factor is employed in the Hermite expansions, which yields a positive bilinear form. As a consequence, stability and spectral convergence can be established for this approach. The present method plays a similar role in the stability of the similarity transformation technique proposed by Funaro and Kavian [*Math. Comp.*, 57 (1991), pp. 597–619]. However, since coordinate transformations are not required, the present approach is more efficient and is easier to implement. In fact, with the time-dependent scaling the resulting discretization system is of the same form as that associated with the classical (straightforward but unstable) Hermite spectral method. Numerical experiments are carried out to support the theoretical stability and convergence results.

Key words. Hermite spectral method, time-dependent scaling, stability, convergence

1. Introduction.

Spectral methods for approximating solutions of differential equations in unbounded domains have received considerable attention, mainly due to their high accuracy and being free from using artificial boundary conditions. The spectral approaches employ orthogonal systems in unbounded domains, e.g., using the Laguerre spectral methods for problems in semibounded or exterior domains [2, 4, 8, 12, 17, 18, 21] and the Hermite spectral methods for the problems in unbounded domains [1, 5, 6, 7, 10, 20]. An alternative approximation for such problems is the rational spectral method which has also been studied by several authors [3, 9, 11, 13, 25].

When the Hermite method is applied to second-order differential equations directly, it is found in [7] that the nonsymmetric bilinear form is not of the desired coercity property. To see this, let us consider the following simple parabolic problem:

The research of this author was supported by the Hong Kong Research Grants Council (projects HKBU 2044/00P and HKBU2083/01P) and the International Research Team on Complex System of Chinese Academy of Sciences.

$$\begin{cases} \partial_t U - \nu \partial_x^2 U = f(x,t), & x \in \mathbb{R}, \quad t > 0, \\ U(x,0) = U_0(x), & x \in \mathbb{R}, \end{cases} \tag{1.1}$$

where the diffusion constant $\nu > 0$, and $\mathbb{R} = (-\infty, \infty)$. The solution U and its partial derivative $\partial_x U$ have to satisfy certain decay conditions as $|x| \to \infty$. Let $\mathbb{P}_N(\mathbb{R})$ be the space of polynomials of degree at most N and let

$$V_N = \{ v_N(x) = \omega_\beta \phi_N(x) \mid \phi_N(x) \in \mathbb{P}_N(\mathbb{R}) \}, \tag{1.2}$$

where $\omega_\beta = \mathrm{e}^{-(\beta x)^2}$ with β being a constant. The semidiscrete Hermite function method for (1.1) is to find $u_N(t) \in V_N$ such that for any $\varphi_N \in \mathbb{P}_N(\mathbb{R})$,

$$\begin{cases} (\partial_t u_N(t), \varphi_N) + \nu(\partial_x u_N(t), \partial_x \varphi_N) = (f(t), \varphi_N), & t > 0, \\ (u_N(0), \varphi_N) = (U_0, \varphi_N), \end{cases} \tag{1.3}$$

where $(\cdot,\cdot)$ is the conventional inner product in the $L^2(\mathbb{R})$ space.

We demonstrate that neither is the nonsymmetric bilinear form in (1.3) coercive nor can a corresponding Gårding's type inequality be established. To show this, we denote by $H_l(x)$ the Hermite polynomial of degree l orthogonal on $\mathbb{R}$ with respect to the weight $\omega_1(x) = e^{-x^2}$. Let $\beta > 0$ and let

$$\underline{H}_l(x) := (2^l l! \sqrt{\pi})^{-1/2} H_l(x), \qquad H_l^{(\beta)}(x) := \sqrt{\beta}\, \underline{H}_l(\beta x).$$

Note that $\|\underline{H}_l\|_{\omega_1} = 1$ and $\|H_l^{(\beta)}\|_{\omega_\beta} = 1$. Then, for $u_N = \omega_\beta \phi_N$ with $\phi_N := \sum_{l=0}^N \hat{u}_l H_l^{(\beta)}$, we have

$$\begin{aligned} (\partial_x u_N, \partial_x \phi_N) &= |\phi_N|^2_{1,\omega_\beta} + \beta^2 \|\phi_N\|^2_{\omega_\beta} - 2\beta^4 \|x\phi_N\|^2_{\omega_\beta} \\ &= -2\beta^2 \sum_{l=2}^N \sqrt{l(l-2)}\, \hat{u}_l \hat{u}_{l-2}, \end{aligned} \tag{1.4}$$

which cannot be controlled by $\|u_N\|^2_{\omega_\beta^{-1}} = \sum_{l=0}^N |\hat{u}_l|^2$. In other words, the stability for (1.3) cannot be established by using the classical energy method. On the other hand, the instability is observed numerically, as seen in section 6. To overcome this difficulty, a *similarity transformation* was introduced by Funaro and Kavian [6], which is defined by

$$s = \ln(1+t), \qquad y = x(1+t)^{-\frac{1}{2}}. \tag{1.5}$$

With this transformation, they were able to obtain the optimal error estimate of the Hermite function approximation for the linear problem (1.1). This similarity transformation technique has been extended recently to study the nonlinear convection-diffusion equations; see, e.g., [7, 10]. By using this transformation, the diffusion operator in (1.1) is changed into an operator whose eigenfunctions are the Hermite functions. This property can lead to a desired stability result. However, the transformation may make the underlying equations more complicated, which leads to difficulties in theoretical analysis and practical implementation. It is desirable to develop some simpler and more efficient Hermite spectral methods.

In this paper, we present a Petrov–Galerkin Hermite spectral method which uses a time-dependent weight function. On the one hand, the method keeps the advantage of the similarity transformation method, namely, it gives a positive definite bilinear form. On the other hand, the scheme can be easily formulated in the classical form of (1.3), without introducing any extra new terms. As a result, a priori explicit transformation is not needed. Moreover, the time-dependent weight function behaves like a spatial scaling. The importance of the scaling factor has been demonstrated by Tang [22] and Schumer and Holloway [20]. We will apply the proposed method to the analysis of the nonlinear convection-diffusion equations. Stability and optimal error estimates for the Hermite spectral methods, in both semidiscrete and fully discrete forms, are obtained for the nonlinear equation. It will be shown by numerical experiments that the time-dependent weight works well for solutions with time-dependent and time-independent decays.

An outline of the paper is as follows. In section 2 we briefly discuss the Hermite spectral methods with a time-dependent scaling. Section 3 presents some basic properties of the Hermite functions in weighted spaces, which will be useful in the stability and convergence analysis. In sections 4 and 5, stability and convergence analysis is carried out for the semidiscrete and fully discrete schemes, respectively. The analysis is devoted not only to the linear parabolic equation (1.1), but also to the nonlinear convection-diffusion problems. In section 6, numerical results will be presented.

2. Hermite method with time-dependent scaling. We present a Petrov–Galerkin Hermite spectral method with a time-dependent scaling for the simple model problem (1.1). Let $\alpha = \alpha(t) > 0$. We take

$$\alpha(t) = \frac{1}{2\sqrt{\nu\delta_0(\delta t + 1)}}, \tag{2.1}$$

where δ_0 and δ are some positive parameters. It can be verified that

$$\alpha'(t) = -2\nu\delta_0\delta\alpha^{3(t)}.$$

The motivation for this choice of α can be found in Remark 4.1 in section 4. The semidiscrete Hermite spectral method for (1.1) is to find $u_N(t) \in V_N(t)$ such that for any $\varphi_N \in \mathbb{P}_N(\mathbb{R})$,

$$\begin{cases} (\partial_t u_N(t), \varphi_N) + \nu(\partial_x u_N(t), \partial_x \varphi_N) = (f(t), \varphi_N), & t > 0, \\ (u_N(0), \varphi_N) = (U_0, \varphi_N), \end{cases} \tag{2.2}$$

where the trial space $V_N(t)$ is defined by

$$V_N(t) = \left\{ v_N(x) = \omega_{\alpha(t)}\phi_N(x) \mid \phi_N(x) \in \mathbb{P}_N(\mathbb{R}) \right\}. \tag{2.3}$$

The scheme (2.2) is almost the same as (1.3): the only difference is that here the weight function ω_α in the trial function space V_N varies with time. The scheme (2.2) can be rewritten as

$$\frac{d}{dt}(u_N(t), \varphi_N(t)) + (u_N(t), L^*\varphi_N(t)) = (f(t), \varphi_N(t)), \tag{2.4}$$

where $L^* := -\partial_t - \nu\partial_x^2$. To simplify the computation, let

(2.5)

$$u_N(x,t) = \frac{\omega_\alpha}{\sqrt{\pi}} \sum_{l=0}^{N} \hat{u}_l(t) H_l(\alpha x), \qquad \varphi_N(x,t) = \frac{\alpha(t)}{(2^m m!)} H_m(\alpha(t)x) \quad (0 \le m \le N).$$

In other words, we expand the unknown solution using the scaled Hermite functions with a time-dependent scaling factor. The test function φ_N is now also dependent on t. It can be verified that

$$\begin{aligned}
&(\omega_\alpha H_l(\alpha x), L^*(\alpha H_m(\alpha x)))\\
&\quad= -\alpha'\alpha^{-1}(\|H_m\|^2_{\omega_1}\delta_{lm} + (yH_l, H'_m)_{\omega_1}) - 2\nu\alpha^2(yH_l, H'_m)_{\omega_1} + \nu\alpha^2\|H'_m\|^2_{\omega_1}\delta_{lm}\\
&\quad= \delta_0\delta\nu\alpha^2\|H_m\|^2_{\omega_1}\delta_{lm} + (\delta_0\delta-1)\nu\alpha^2(H_{l+1}+2lH_{l-1}, 2mH_{m-1})_{\omega_1} + \nu\alpha^2|H_m|^2_{1,\omega_1}\delta_{lm}\\
&\quad= \nu\alpha^2 2^m m!\sqrt{\pi}(2\delta_0\delta\delta_{lm} + (\delta_0\delta-1)(\delta_{(l+2)m}+2m\delta_{lm}) + 2m\delta_{lm}).
\end{aligned}$$

Applying the above result to (2.2) gives

$$\tag{2.6}\begin{cases} \dfrac{d\mathbf{u}(t)}{dt} + \nu\alpha(t)^2\mathbf{A}\mathbf{u}(t) = \mathbf{f}(t), \quad t>0,\\ (\mathbf{u}(0))_m = \alpha(0)(2^m m!)^{-1}(U_0, H_m(\alpha(0)x)), \quad 0\le m\le N, \end{cases}$$

where $\alpha(0) = 1/2\sqrt{\nu\delta_0}$, $\mathbf{u} = (\hat{u}_0, \hat{u}_1, \dots, \hat{u}_N)^T$. The elements of the matrix $\mathbf{A}$ are given by

$$(\mathbf{A})_{ml} = \begin{cases} 2(m+1)\delta_0\delta, & l=m,\\ \delta_0\delta-1, & l=m-2,\\ 0 & \text{otherwise},\ 0\le l,m\le N, \end{cases}$$

and the entries f_m of $\mathbf{f}$ are given by

$$\begin{aligned}\hat{f}_m := (\mathbf{f})_m &= \alpha(2^m m!)^{-1}(f, H_m(\alpha x))\\ &= (2^m m!)^{-1}(\mathrm{e}^{y^2}f(\alpha^{-1}y), H_m(y))_{\omega_1}.\end{aligned}$$

Fully discrete methods can be designed by using (2.6) based on the method-of-lines approach. Here we consider the Crank–Nicolson scheme. Let τ be the time-step $t_k = k\tau$ $(k=0,1,\dots,n_T;\ T=n_T\tau)$, and let $\mathbf{v}^k = \mathbf{v}(t_k)$. The fully discrete Petrov–Galerkin method for (1.1) is to find

$$u_N^k = \frac{\omega_{\alpha(t_k)}}{\sqrt{\pi}}\sum_{l=0}^N \hat{u}_l^k H_l(\alpha(t_k)x)$$

such that

$$\tag{2.7}\begin{cases} \dfrac{\mathbf{u}^{k+1}-\mathbf{u}^k}{\tau} + \nu\alpha^2(t_k+\tau/2)\mathbf{A}\dfrac{\mathbf{u}^{k+1}+\mathbf{u}^k}{2} = \dfrac{\mathbf{f}^{k+1}+\mathbf{f}^k}{2}, & 0\le k\le n_T-1,\\ (\mathbf{u}^0)_m = (2^m m!)^{-1}(\mathrm{e}^{y^2}U_0(y/\alpha(0)), H_m(y))_{\omega_1}, & 0\le m\le N. \end{cases}$$

Since the matrix $\mathbf{A}$ is independent of time, the above scheme can be solved easily.

Remark 2.1. Note that the matrix $\mathbf{A}$ is an upper triangular matrix whose diagonal entries are $2(m+1)\delta_0\delta$. By the classical stability theory, both the semidiscrete scheme (2.6) and fully discrete scheme (2.7) are stable and convergent provided that $\delta_0\delta>0$. However, $\delta_0=0$ in the classical approach (1.3) yields numerical instability.

3. Approximation properties of Hermite functions. In this section, we present some basic approximation properties for the Hermite functions and the Hermite polynomials. Some of them are similar to those obtained in [5, 6, 7, 19, 23, 24] and we will only briefly outline the proofs.

Let $H^\sigma(\mathbb{R}) := W^{\sigma,2}(\mathbb{R})$ be the Sobolev spaces with the norm $\|\cdot\|_\sigma$ and seminorm $|\cdot|_\sigma$. For a nonnegative weight $\omega(x)$ on $\mathbb{R}$, the inner product and norm of $L^2_\omega(\mathbb{R})$ are denoted by $(\cdot,\cdot)_\omega$ and $\|\cdot\|_\omega$, respectively. The subscript ω will be dropped whenever $\omega(x) \equiv 1$. For a positive integer σ, the weighted Sobolev space $H^\sigma_\omega(\mathbb{R})$ is defined by

$$H^\sigma_\omega(\mathbb{R}) = \left\{ v \mid \partial^r_x v \in L^2_\omega(\mathbb{R}), \quad 0 \le r \le \sigma \right\}$$

with the seminorm and norm

$$|v|_{\sigma,\omega} = \|\partial^\sigma_x v\|_\omega, \qquad \|v\|_{\sigma,\omega} = \left(\sum_{r=0}^{\sigma} |v|^2_{r,\omega} \right)^{1/2}.$$

Denote by $H_l(x)$ the Hermite polynomial of degree l:

$$H_l(x) = (-1)^l \omega_1^{-1}(x) \partial^l_x(\omega_1(x)).$$

In theoretical analysis, it seems more convenient to use the normalized Hermite polynomials

$$\underline{H}_l(x) := (2^l l! \sqrt{\pi})^{-1/2} H_l(x).$$

We will work with the scaled Hermite polynomial $H^{(\beta)}_l(x) := \sqrt{\beta}\underline{H}_l(\beta x)$, where $\beta > 0$ is a constant. For nonnegative integers r and l, let

$$A^r_l = \begin{cases} l!/(l-r)!, & l \ge r \ge 1, \\ 1, & l \ge 0, r = 0, \\ 0, & l < r. \end{cases}$$

We have

$$(3.1) \qquad (\partial^r_x H^{(\beta)}_l, \partial^r_x H^{(\beta)}_m)_{\omega_\beta} = \beta^{2r}(\partial^r_x \underline{H}_l, \partial^r_x \underline{H}_m)_{\omega_1} = (2\beta^2)^r \sqrt{A^r_l A^r_m}\, \delta_{lm}$$

so that $\{\partial^r_x H^{(\beta)}_l\}$ are orthogonal on $\mathbb{R}$ with respect to the weight $\omega_\beta = e^{-(\beta x)^2}$. Let $P^\beta_N : L^2_{\omega_\beta}(\mathbb{R}) \to \mathbb{P}_N(\mathbb{R})$ be the $L^2_{\omega_\beta}$-orthogonal projection operator defined by

$$(3.2) \qquad (P^\beta_N v - v, \varphi_N)_{\omega_\beta} = 0 \qquad \forall\, \varphi_N \in \mathbb{P}_N(\mathbb{R}).$$

For $v \in H^r_{\omega_\beta}(\mathbb{R})$ $(r < N)$, we have $\partial^r_x P^\beta_N v = P^\beta_{N-r} \partial^r_x v$ and

$$(3.3) \qquad (\partial^r_x(P^\beta_N v - v), \varphi_{N-r})_{\omega_\beta} = 0 \qquad \forall\, \varphi_{N-r} \in \mathbb{P}_{N-r}(\mathbb{R}).$$

We consider the approximation by the Hermite functions; i.e., we approximate $v\omega_\beta^{-1}$ by using the Hermite polynomials. Let $\mathcal{P}^\beta_N : L^2_{\omega_\beta^{-1}}(\mathbb{R}) \to V_N$ be the $L^2_{\omega_\beta^{-1}}$-orthogonal projection operator defined by

$$(3.4) \qquad (\mathcal{P}^\beta_N v - v, \varphi_N)_{\omega_\beta^{-1}} = 0 \qquad \forall\, \varphi_N \in V_N.$$

It is easy to verify that $\mathcal{P}_N^\beta v = \omega_\beta P_N^\beta(v\omega_\beta^{-1})$. For $v \in H^r_{\omega_\beta^{-1}}(\mathbb{R})$ $(r < N)$, we have $\partial_x^r \mathcal{P}_N^\beta v = \mathcal{P}_{N+r}^\beta \partial_x^r v$ and

$$(\partial_x^r(\mathcal{P}_N^\beta v - v), \varphi_{N+r}) = 0 \qquad \forall\, \varphi_{N+r} \in \mathbb{P}_{N+r}(\mathbb{R}). \tag{3.5}$$

Lemma 3.1. *If r is a nonnegative integer, then $v \in H^r_{\omega_\beta^{-1}}(\mathbb{R})$ is equivalent to $v\omega_\beta^{-1} \in H^r_{\omega_\beta}(\mathbb{R})$. Moreover,*

$$\sum_{j=0}^{r}(2\beta^2)^{r-j}\|\partial_x^j[(I-P_m^\beta)(v\omega_\beta^{-1})]\|^2_{\omega_\beta} \le \|\partial_x^r[(I-\mathcal{P}_m^\beta)v]\|^2_{\omega_\beta^{-1}} \quad \forall m \ge 0, \tag{3.6}$$

$$\|\partial_x^r[(I-\mathcal{P}_N^\beta)v]\|_{\omega_\beta^{-1}} \le C(r)\|\partial_x^r[(I-P_N^\beta)(v\omega_\beta^{-1})]\|_{\omega_\beta} \quad \forall N > r, \tag{3.7}$$

where $P_0^\beta = \mathcal{P}_0^\beta = \mathbf{0}$ and $C(r)$ is a constant depending only on r.

Proof. By a direct calculation,

$$\partial_x^r(\omega_\beta H_l^{(\beta)}(x)) = (-\beta)^r 2^{r/2}\sqrt{A^r_{l+r}}\,\omega_\beta H^{(\beta)}_{l+r}(x). \tag{3.8}$$

Using this result we can verify that $\{\partial_x^r(\omega_\beta H_l^{(\beta)})\}$ are orthogonal with respect to the weight ω_β^{-1} on $\mathbb{R}$:

$$\begin{aligned}(\partial_x^r(\omega_\beta H_l^{(\beta)}), \partial_x^r(\omega_\beta H_m^{(\beta)}))_{\omega_\beta^{-1}} &= (2\beta^2)^r\sqrt{A^r_{l+r}A^r_{m+r}}(H^{(\beta)}_{l+r}, H^{(\beta)}_{m+r})_{\omega_\beta}\\ &= (2\beta^2)^r\sqrt{A^r_{l+r}A^r_{m+r}}\,\delta_{lm} \quad \forall l,\ m \ge r \ge 0.\end{aligned} \tag{3.9}$$

Let $v = \omega_\beta\sum_{l=0}^\infty \hat{v}_l H_l^{(\beta)}$. Then we have

$$(I-\mathcal{P}_m^\beta)v = \omega_\beta(I-P_m^\beta)(v\omega_\beta^{-1}) = \omega_\beta\sum_{l\ge m}\hat{v}_l H_l^{(\beta)}\,.$$

The above result, together with (3.9), gives

$$\begin{aligned}&\|\partial_x^r[(I-\mathcal{P}_m^\beta)v]\|^2_{\omega_\beta^{-1}} = (2\beta^2)^r\sum_{l\ge m}A^r_{l+r}|\hat{v}_l|^2\\ &\ge (2\beta^2)^r\sum_{l\ge m}\sum_{j=0}^{r}A_l^j|\hat{v}_l|^2 \ge (2\beta^2)^r\sum_{j=0}^{r}\sum_{l\ge\max\{m,j\}}A_l^j|\hat{v}_l|^2\\ &= \sum_{j=0}^{r}(2\beta^2)^{r-j}\|\partial_x^j[(I-P_m^\beta)(v\omega_\beta^{-1})]\|^2_{\omega_\beta}.\end{aligned}$$

This proves the result (3.6). The inequality (3.7) can be established similarly. □

Lemma 3.2. *If $0 \le r \le \sigma < N$, then*

$$\|\partial_x^r(v-P_N^\beta v)\|_{\omega_\beta} \le C(r,\sigma)(2\beta^2N)^{(r-\sigma)/2}\|\partial_x^\sigma v\|_{\omega_\beta} \qquad \forall\, v \in H^\sigma_{\omega_\beta}(\mathbb{R}), \tag{3.10}$$

$$\|\partial_x^r(v-\mathcal{P}_N^\beta v)\|_{\omega_\beta^{-1}} \le C(r,\sigma)(2\beta^2N)^{(r-\sigma)/2}\|\partial_x^\sigma v\|_{\omega_\beta^{-1}} \qquad \forall\, v \in H^\sigma_{\omega_\beta^{-1}}(\mathbb{R}), \tag{3.11}$$

where $C(r,\sigma)$ is a constant depending only on r and σ.

Proof. Let $v = \sum\limits_{l=0}^{\infty} \hat{v}_l H_l^{(\beta)}$. Then, it follows from (3.1) that

$$\begin{aligned}
\|\partial_x^r(v - P_N^\beta v)\|_{\omega_\beta}^2 &= \sum_{l>N} (2\beta^2)^r A_l^r |\hat{v}_l|^2 \\
&= (2\beta^2)^{r-\sigma} \sum_{l>N} (A_{l-r}^{\sigma-r})^{-1} (2\beta^2)^\sigma A_l^\sigma |\hat{v}_l|^2 \le (2\beta^2)^{r-\sigma} (A_{N+1-r}^{\sigma-r})^{-1} \|\partial_x^\sigma(v - P_N^\beta v)\|_{\omega_\beta}^2 \\
&= (2\beta^2)^{r-\sigma} \prod_{m=r-1}^{\sigma-2} \left(1 - \frac{m}{N}\right)^{-1} N^{r-\sigma} \|\partial_x^\sigma (v - P_N^\beta v)\|_{\omega_\beta}^2,
\end{aligned}$$

which gives (3.10). Using (3.7), (3.10), and (3.6) gives

$$\begin{aligned}
\|\partial_x^r(v - \mathcal{P}_N^\beta v)\|_{\omega_\beta^{-1}}^2 &\le C(r) \|\partial_x^r[(I - P_N^\beta)(v\omega_\beta^{-1})]\|_{\omega_\beta} \\
&\le C(r,\sigma)(2\beta^2 N)^{(r-\sigma)/2} \|\partial_x^\sigma[(I - P_N^\beta)(v\omega_\beta^{-1})]\|_{\omega_\beta} \\
&\le C(r,\sigma)(2\beta^2 N)^{(r-\sigma)/2} \|\partial_x^\sigma[(I - \mathcal{P}_N^\beta)v]\|_{\omega_\beta^{-1}},
\end{aligned}$$

which gives (3.11). □

LEMMA 3.3. *Let r, σ be nonnegative integers. We have*

$$\lim_{|x|\to\infty} x(\partial_x^r v)^2(x)\omega_\beta^{-1}(x) \to 0 \qquad \forall\, v \in H^\sigma_{\omega_\beta^{-1}}(\mathbb{R}),\ r \le \sigma - 1, \tag{3.12}$$

$$\|v^2\omega_\beta^{-1}\|_{L^\infty(\mathbb{R})} \le 2|v|_{1,\omega_\beta^{-1}} \|v\|_{\omega_\alpha^{-1}} \qquad \forall\, v \in H^1_{\omega_\beta^{-1}}(\mathbb{R}), \tag{3.13}$$

$$|\varphi_N|_{\sigma,\omega_\beta^{-1}} \le (4\beta^2 N)^{(\sigma-r)/2} |\varphi_N|_{r,\omega_\beta^{-1}} \qquad \forall\, \varphi_N \in V_N,\ r \le \sigma \le N, \tag{3.14}$$

$$\left\| \sqrt{\omega_\beta^{-1}}\varphi_N \right\|_{L^\infty(\mathbb{R})} \le 2(\beta^2 N)^{1/4} \|\varphi_N\|_{\omega_\beta^{-1}} \qquad \forall\, \varphi_N \in V_N,\ r \le \sigma \le N. \tag{3.15}$$

Proof. The first two results, (3.12) and (3.13), can be obtained by the arguments similar to those given in [5, 7]. Let $\varphi_N = \omega_\beta \sum_{l=0}^N \hat{\varphi}_l H_l^{(\beta)} \in V_N$. It follows from (3.9) that

$$\begin{aligned}
|\varphi_N|_{\sigma,\omega_\beta^{-1}}^2 &= (2\beta^2)^{\sigma-r} (2\beta^2)^r \sum_{l=0}^N A_{l+\sigma}^{\sigma-r} A_{l+r}^r |\hat{\varphi}_l|^2 \\
&\le (2\beta^2 N)^{\sigma-r} \prod_{j=r+1}^{\sigma} \left(1 + \frac{j}{N}\right) |\varphi_N|_{r,\omega_\beta^{-1}}^2,
\end{aligned}$$

which gives (3.14). Moreover, using (3.13) and (3.14) gives

$$\|\omega_\beta^{-1}\varphi_N^2\|_{L^\infty(\mathbb{R})} \le 2(4\beta^2 N)^{1/2} \|\varphi_N\|_{\omega_\beta^{-1}}^2 \le 4\beta N^{1/2} \|\varphi_N\|_{\omega_\beta^{-1}}^2.$$

This completes the proof of this lemma. □

4. Stability and convergence: Semidiscretization. To demonstrate the stability and convergence analysis for the proposed spectral method, we take the time-dependent weight

$$\omega_{\alpha(t)} = \mathrm{e}^{-(\alpha(t)x)^2}, \tag{4.1}$$

where $\alpha(t)$ is defined by (2.1). We expand

$$u_N(x,t) = \omega_{\alpha(t)} \sum_{l=0}^{N} \hat{u}_l(t) H_l^{(\alpha(t))}(x). \tag{4.2}$$

It can be verified that $\|u_N\|_{\omega_\alpha^{-1}} = \|\mathbf{u}\|$. The solution expansion (4.2) is slightly different from the one in (2.5) but is more suitable for theoretical analysis. With this expansion, the matrix form for the scheme (2.2) becomes

$$\frac{d\mathbf{u}}{dt} + \nu\alpha(t)^2 \mathbf{B}\mathbf{u} = \mathbf{f}, \tag{4.3}$$

where the elements of the matrices $\mathbf{B}$ and the vector $\mathbf{f}$ are given by

$$\begin{aligned} (\mathbf{B})_{ml} &= \begin{cases} \delta_0\delta(2m+1), & l = m, \\ (\delta_0\delta - 1)2\sqrt{m(m-1)}, & l = m-2, \\ 0 & \text{otherwise,} \end{cases} \\ \hat{f}_m &:= (\mathbf{f})_m = (f, H_m^{(\alpha)}), \qquad\qquad 0 \le l, m \le N. \end{aligned} \tag{4.4}$$

The stability and convergence properties can be established following the discussions in section 2. To be more precise, let

$$\underline{\delta} = \min\{1, 2\delta_0\delta - 1\} > 0, \quad \mathbf{D} = 2\mathrm{diag}(0, 1, \dots, N) \tag{4.5}$$

and let $\mathbf{I}$ be the identity matrix. Since

$$\mathbf{u}^T\mathbf{B}\mathbf{u} \ge \underline{\delta}\mathbf{u}^T(\mathbf{D}+\mathbf{I})\mathbf{u},$$

we obtain

$$\begin{aligned} &\|\mathbf{u}(t)\|^2 + \underline{\delta}\nu \int_0^t \alpha^2 \|(\mathbf{D}+\mathbf{I})^{1/2}\mathbf{u}(s)\|^2\, ds \\ &\quad\le \|\mathbf{u}(0)\|^2 + 4\delta_0\underline{\delta}^{-1} \int_0^t (\delta s + 1)\|(\mathbf{D}+\mathbf{I})^{-1/2}\mathbf{f}(s)\|^2\, ds, \quad t > 0, \end{aligned} \tag{4.6}$$

or, equivalently,

$$\begin{aligned} &\|u_N(t)\|^2_{\omega_\alpha^{-1}} + \underline{\delta}\nu \int_0^t |u_N(t)|^2_{1,\omega_\alpha^{-1}}\, ds \\ &\qquad \le \|u_N(0)\|^2_{\omega_\alpha^{-1}} + (\underline{\delta}\nu)^{-1} \int_0^t \|\partial_x^{-1} f(s)\|^2_{\omega_\alpha^{-1}}\, ds, \end{aligned} \tag{4.7}$$

where $\partial_x^{-1} v(x) = \int_{-\infty}^x v(y)\, dy$.

Remark 4.1. In the classical approach (1.3), we fail to obtain the stability due to the term $\|x\phi_N\|_{\omega_\beta}$ in (1.4). However, when α depends on time, an extra term is gained in the $\|xu_N\|_{\omega_\alpha}$ term:

$$\begin{aligned} &\frac{d}{dt}\|u_N(t)\|^2_{\omega_\alpha^{-1}} + 2\nu(|u_N|^2_{1,\omega_\alpha^{-1}} - \alpha^2\|u_N(t)\|^2_{\omega_\alpha^{-1}}) \\ &\qquad - 2\alpha(\alpha' + 2\nu\alpha^3)\|xu_N(t)\|^2_{\omega_\alpha^{-1}} = 2(f(t), u_N(t))_{\omega_\alpha^{-1}}. \end{aligned} \tag{4.8}$$

Stability can be obtained if α is chosen to satisfy $\alpha' + 2\nu\alpha^3 \le 0$.

We now briefly outline the convergence of the approximation (2.2). Our rigorous analysis will be carried out for the nonlinear convection-diffusion equations, which take (2.2) as a special case. It is interesting to note that the solutions of (1.3) and (2.2) are both of the same form: $u_N = \mathcal{P}_N^\alpha U$. In fact, assuming $U \in C(0,T; H^1_{\omega_\alpha}(\mathbb{R}))$, we have from (3.5) that for any $\varphi_N \in \mathbb{P}_N(\mathbb{R})$,

$$\tag{4.9} \begin{cases} (\partial_t \mathcal{P}_N^\alpha U(t), \varphi_N) + \nu(\partial_x \mathcal{P}_N^\alpha U(t), \partial_x \varphi_N) = (\partial_t U(t), \varphi_N) + \nu(\partial_x U(t), \partial_x \varphi_N) = (f(t), \varphi_N), \\ (\mathcal{P}_N^\alpha U(0), \varphi_N) = (U_0, \varphi_N). \end{cases}$$

However, the scheme (1.3) may not work since the bilinear form is not coercive. Since $u_N = \mathcal{P}_N^\alpha U$, it follows from (3.11) that if $U \in C(0,T; H^\sigma_{\omega_\alpha^{-1}}(\mathbb{R}))$ $(\sigma \geq 1)$, then

$$\tag{4.10} \|u_N(t) - U(t)\|_{r,\omega_\alpha^{-1}} \leq C N^{(r-\sigma)/2} \|U(t)\|_{\sigma,\omega_\alpha^{-1}} \quad \forall\, 0 \leq r \leq \sigma, \quad t \in (0,T),$$

which is analogous to the result obtained in [6] by using the similarity transformation.

The above method can be easily applied to some nonlinear equations. Consider the nonlinear convection-diffusion equation

$$\tag{4.11} \begin{cases} \partial_t U + \partial_x F(U) - \nu \partial_x^2 U = f(x,t), & (x,t) \in \mathbb{R} \times (0,T), \\ U(x,0) = U_0(x), & x \in \mathbb{R}, \end{cases}$$

where F is a smooth function, the constant $\nu > 0$, and U and $\partial_x U$ satisfy certain decay conditions at infinity. The semidiscrete Hermite function method for (4.11) is to find $u_N \in V_N$ such that for any $\varphi_N \in \mathbb{P}_N(\mathbb{R})$,

$$\tag{4.12} \begin{cases} (\partial_t u_N(t), \varphi_N) + (\partial_x F(u_N(t)), \varphi_N) + \nu(\partial_x u_N(t), \partial_x \varphi_N) = (f(t), \varphi_N), \quad t \in (0,T), \\ (u_N(0), \varphi_N) = (U_0, \varphi_N). \end{cases}$$

We investigate the stability property of the scheme (4.12). Suppose that u_N and the term on the right-hand side of (4.12) have the errors $\tilde{u}_N$ and $\tilde{f}$, respectively. Then, we have

$$\tag{4.13} (\partial_t \tilde{u}_N, \varphi_N) + (\partial_x \tilde{F}, \varphi_N) - \nu(\partial_x^2 \tilde{u}_N, \varphi_N) = (\tilde{f}, \varphi_N) \quad \forall \varphi_N \in \mathbb{P}_N(\mathbb{R}),\ t \in (0,T),$$

where $\tilde{F} := F(u_N + \tilde{u}_N) - F(u_N)$. Taking $\varphi_N = \omega_\alpha^{-1} \tilde{u}_N$ in (4.13), we obtain, similarly to (4.8),

$$\tag{4.14} \begin{aligned} &\frac{d}{dt}\|u_N(t)\|^2_{\omega_\alpha^{-1}} + \underline{\delta}\nu(|u_N(t)|^2_{1,\omega_\alpha^{-1}} + |\omega_\alpha^{-1} u_N(t)|^2_{1,\omega_\alpha}) \\ &\quad = 2(\tilde{f}(t) - \partial_x \tilde{F}(t), \tilde{u}_N(t))_{\omega_\alpha^{-1}} \\ &\quad \leq 2(\underline{\delta}\nu)^{-1}(\|\partial_x^{-1} \tilde{f}(t)\|^2_{\omega_\alpha^{-1}} + \|\tilde{F}\|^2_{\omega_\alpha^{-1}}) + \underline{\delta}\nu |\omega_\alpha^{-1} \tilde{u}_N(t)|^2_{1,\omega_\alpha}. \end{aligned}$$

Let $\tilde{M}$ be a positive constant and let

$$\tag{4.15} M(u) = \max_{0 \leq s \leq T} \|u_N(s)\|_{L^\infty(I)}, \qquad C_F = \max_{|z| \leq M(u) + \tilde{M}} |F'(z)|.$$

For any given $t \in (0,T)$, if

$$2(\alpha^2 N)^{1/4}\|\tilde{u}_N(s)\|_{\omega_\alpha^{-1}} \le \tilde{M} \qquad \forall\, s \in (0,t),$$

then by (3.15),

$$\begin{aligned}&\|\tilde{u}_N(s)\|_{L^\infty(I)} \le \tilde{M}\,,\\ &\|\tilde{F}(s)\|_{\omega_\alpha^{-1}} = \left\|\int_0^1 F'(u_N(s)+\theta\tilde{u}_N(s))\tilde{u}_N(s)\,d\theta\right\|_{\omega_\alpha^{-1}} \le C_F\|\tilde{u}_N(s)\|_{\omega_\alpha^{-1}} \quad \forall s \in (0,t).\end{aligned}$$

Substituting the above estimates into (4.14) gives

$$\frac{d}{dt}\|\tilde{u}_N(t)\|^2_{\omega_\alpha^{-1}} + \underline{\delta}\nu|\tilde{u}_N(t)|^2_{1,\omega_\alpha^{-1}} \le 2(\underline{\delta}\nu)^{-1}(C_F\|\tilde{u}_N(t)\|^2_{\omega_\alpha^{-1}} + \|\partial_x^{-1}\tilde{f}(t)\|^2_{\omega_\alpha^{-1}}). \tag{4.16}$$

Define

$$E(\tilde{u}_N,t) = \|\tilde{u}_N(t)\|^2_{\omega^{-1}_{\alpha(t)}} + \underline{\delta}\nu\int_0^t |\tilde{u}_N(s)|^2_{1,\omega^{-1}_{\alpha(s)}}\,ds, \tag{4.17}$$

$$\rho(\tilde{u}_N,\tilde{f},t) = \|\tilde{u}_N(0)\|^2_{\omega^{-1}_{\alpha(0)}} + 2(\underline{\delta}\nu)^{-1}\int_0^t \|\partial_x^{-1}\tilde{f}(s)\|^2_{\omega^{-1}_{\alpha(s)}}\,ds. \tag{4.18}$$

Integrating (4.16) with respect to t yields

$$E(\tilde{u}_N,t) \le \rho(\tilde{u}_N,\tilde{f},t) + C\int_0^t E(\tilde{u}_N,s)\,ds, \tag{4.19}$$

where C is a positive constant depending on $(\underline{\delta}\nu)^{-1}$ and C_F. Then, by a nonlinear Gronwall-like inequality [14],

$$E(\tilde{u}_N,t) \le \mathrm{e}^{Ct}\rho(\tilde{u}_N,\tilde{f},t) \qquad \forall\, 0 < t \le T, \tag{4.20}$$

provided that

$$4\alpha(t)N^{1/2}\mathrm{e}^{Ct}\rho(\tilde{u}_N,\tilde{f},t) \le \tilde{M}^2. \tag{4.21}$$

We now consider the convergence for the semidiscrete scheme (4.12). As we have shown for the linear problem (1.1), the projection $\mathcal{P}_N^\alpha U$ is a good comparison function. Let $u_* = \mathcal{P}_N^\alpha U$. Then, for any $\varphi_N \in \mathbb{P}_N(\mathbb{R})$,

(4.22)
$$\begin{cases}(\partial_t u_*(t),\varphi_N) + (\partial_x F(u_*(t)),\varphi_N) + \nu(\partial_x u_*(t),\partial_x\varphi_N) = (f(t),\varphi_N) - (\partial_x g(t),\varphi_N),\\ (u_*(0),\varphi_N) = (U_0,\varphi_N),\end{cases}$$

where $g(t) = F(U(t)) - F(u_*(t))$. Let $e_N = u_N - u_*$. We have

(4.23)
$$\begin{cases}(\partial_t e_N(t),\varphi_N) + (\partial_x G(t),\varphi_N) + \nu(\partial_x e_N(t),\partial_x\varphi_N) = (\partial_x g(t),\varphi_N), \quad t \in (0,T),\\ (e_N(0),\varphi_N) = 0,\end{cases}$$

where $G(t) = F(u_*(t) + e_N(t)) - F(u_*(t))$. Using the same argument as used in deriving the stability result (4.20), we can obtain

$$\begin{aligned}\|e_N(t)\|^2_{\omega^{-1}_{\alpha(t)}} &\le C\int_0^t \|g(s)\|^2_{\omega^{-1}_{\alpha(s)}}\,ds \le CC'_F\int_0^t \|(I-\mathcal{P}^\alpha_N)U(s)\|^2_{\omega^{-1}_{\alpha(s)}}\,ds\\ &\le CN^{-\sigma}\int_0^t \|\partial_x^\sigma U(s)\|^2_{\omega^{-1}_{\alpha(s)}}\,ds \le CN^{-\sigma}\|U\|^2_{L^2(0,T;H^\sigma_{\omega^{-1}_\alpha}(\mathbb{R}))}.\end{aligned}$$

THEOREM 4.1. *Let U and u_N be the solutions of* (4.11) *and* (4.12), *respectively. Assume that $U \in C(0,T;H^\sigma_{\omega^{-1}_\alpha}(\mathbb{R}))$ $(\sigma \ge 1)$, $F(z) \in C^1(\mathbb{R})$, the function $\alpha(t)$ is defined by* (2.1), *and $\underline{\delta}$ defined by* (4.5) *is positive. Then*

$$\|u_N(t) - U(t)\|_{\omega^{-1}_\alpha} \le CN^{-\sigma/2} \qquad \forall\, 0 < t < T,$$

where C is a constant depending on $(\underline{\delta}\nu)^{-1}, \delta_0, \delta, T$, and the regularity of $U$and F.

5. Stability and convergence: Fully discrete scheme. In this section, we further discretize the scheme (4.12) by using the method-of-lines approach. Without loss of generality, the analysis will be carried out for the nonlinear convection-diffusion equations. Noting that

$$(\partial_x F(u_N), H_m^{(\alpha)}) = -\sqrt{2m}\,\alpha(F(u_N), H_{m-1}^{(\alpha)}),$$

we can rewrite the scheme (4.12) in a matrix form as in (4.3):

$$\frac{d\mathbf{u}}{dt} - \alpha(t)\mathbf{D}^{1/2}\mathbf{F}(u_N) + \nu\alpha(t)^2\mathbf{B}\mathbf{u} = \mathbf{f}, \tag{5.1}$$

where $\mathbf{D}, \mathbf{B}, \mathbf{f}$ are the same as in (4.4) and (4.5), and the elements of the vector $\mathbf{F}$ are defined by

$$(\mathbf{F})_0 = 0\,, \quad (\mathbf{F})_m = (F(u_N), H_{m-1}^{(\alpha)}) \quad (1 \le m \le N).$$

For the time discretization, we use a second-order Crank–Nicolson/leapfrog scheme, which is implicit for the linear term and explicit for the nonlinear term [14, 15]. For the similarity transformation method (1.5), if the step size Δs for the transformed variable s is fixed, then the corresponding time-step in t is nonuniform. In our present approach, a uniform time-step is employed.

Let τ be the time-step size and let $t_k = k\tau$ $(k = 0, 1, \ldots, n_T;\ T = n_T\tau)$. We denote $v(x, t_k)$ by $v^k(x)$ or simply by v^k and $\mathbf{v}(t_k)$ by $\mathbf{v}^k$. Let

$$\mathbf{v}^k_{\hat{t}} = \frac{1}{2\tau}(\mathbf{v}^{k+1} - \mathbf{v}^{k-1}), \quad \mathbf{v}^{\hat{k}} = \frac{1}{2}(\mathbf{v}^{k+1} + \mathbf{v}^{k-1}).$$

For $v = \omega_{\alpha(t)}\sum_{l=0}^\infty \hat{v}_l(t)H_l^{(\alpha(t))}$, we define

$$D_t v = \omega_\alpha \sum_{l=0}^\infty \frac{d\hat{v}_l}{dt}H_l^{(\alpha)}.$$

The fully discrete Hermite spectral method to the nonlinear convection-diffusion equation (4.11) is to find

$$u_N^k = \omega_{\alpha(t)}\sum_{l=0}^N \hat{u}_l^k(t)H_l^{(\alpha(t))} \in V_N$$

satisfying

$$(5.2)\qquad \begin{cases} \mathbf{u}^k_{\hat t} - \alpha^k \mathbf{D}^{1/2}\mathbf{F}(u^k_N) + \nu(\alpha^k)^2 \mathbf{B}\mathbf{u}^{\hat k} = \mathbf{f}^k, & 1 \le k \le n_T - 1,\\ (\mathbf{u}^1)_m = (\mathbf{u}^0)_m + \tau(D_t U(0), H_m^{(\alpha(0))}), & 0 \le m \le N,\\ (\mathbf{u}^0)_m = (U_0, H_m^{(\alpha(0))}), & 0 \le m \le N, \end{cases}$$

where $(D_t U(0), H_m^{(\alpha(0))})$ can be computed from $\frac{d\mathbf{u}}{dt}(0)$ using the initial condition and (5.1).

We now present a stability analysis for the scheme (5.2). Assume that the solution and the term on the right-hand side of (5.2) have errors $\tilde{\mathbf{u}}^k := (\tilde{\hat{u}}^k_0, \tilde{\hat{u}}^k_1, \ldots, \tilde{\hat{u}}^k_N)^T$ and $\tilde{\mathbf{f}}^k$, respectively, with $\tilde u^k_N = \omega_\alpha \sum_{l=0}^N \tilde{\hat{u}}^k_l H_l^{(\alpha)}$. Then the errors satisfy

$$(5.3)\qquad \tilde{\mathbf{u}}^k_{\hat t} - \alpha^k \mathbf{D}^{1/2}\tilde{\mathbf{F}}^k + \nu(\alpha^k)^2 \mathbf{B}\tilde{\mathbf{u}}^{\hat k} = \tilde{\mathbf{f}}^k, \qquad 1 \le k \le n_T - 1,$$

where $\tilde{\mathbf{F}}^k = \mathbf{F}(u^k_N + \tilde u^k_N) - \mathbf{F}(u^k_N)$. Multiplying both sides of (5.3) with $2\tilde{\mathbf{u}}^{\hat k}$ and assuming that $\underline{\delta} = \min\{1, 2\delta_0\delta - 1\} > 0$, we obtain

$$(5.4)\qquad \begin{aligned} &(\|\tilde{\mathbf{u}}^k\|^2)_{\hat t} + 2\underline{\delta}\nu(\alpha^k)^2 \|(\mathbf{D}+\mathbf{I})^{1/2}\tilde{\mathbf{u}}^{\hat k}\|^2 \le 2(\tilde{\mathbf{f}}^{\hat k} + \alpha^k \mathbf{D}^{1/2}\tilde{\mathbf{F}}^k, \tilde{\mathbf{u}}^{\hat k})\\ &\quad \le 2(\underline{\delta}\nu)^{-1}((\alpha^k)^{-2}\|(\mathbf{D}+\mathbf{I})^{-1/2}\tilde{\mathbf{f}}^k\|^2 + \|\tilde{\mathbf{F}}^k\|^2) + \underline{\delta}\nu(\alpha^k)^2\|(\mathbf{D}+\mathbf{I})^{1/2}\tilde{\mathbf{u}}^{\hat k}\|^2. \end{aligned}$$

Let $\tilde M$ be a positive constant and let

$$(5.5)\qquad M(u) = \max_{0 \le k \le n_T} \|u^k_N\|_{L^\infty(I)}, \qquad C_F = \max_{|z| \le M(u) + \tilde M} |F'(z)|.$$

For a fixed $n \le n_T$, if

$$\|\tilde{\mathbf{u}}^k\| = \|\tilde u^k_N\|_{\omega_\alpha^{-1}} \le (4\alpha^k N^{1/2})^{-1/2}\tilde M \qquad \forall\, 1 \le k \le n-1,$$

then, by (3.15), we have $\|\tilde u^k_N\|_{L^\infty(I)} \le \tilde M$ and

$$\begin{aligned} \|\tilde{\mathbf{F}}^k\| &= \|\mathcal{P}^\alpha_{N-1}(F(u^k_N + \tilde u^k_N) - F(u^k_N))\|_{\omega_\alpha^{-1}}\\ &\le \|F(u^k_N + \tilde u^k_N) - F(u^k_N)\|_{\omega_\alpha^{-1}} \le C_F\|\tilde u^k_N\|^2_{\omega_\alpha^{-1}} = C_F\|\tilde{\mathbf{u}}^k\|. \end{aligned}$$

Define

$$(5.6)\qquad E^n(\mathbf{v}) = \|\mathbf{v}^n\|^2 + 2\underline{\delta}\nu\tau\sum_{k=1}^{n-1}(\alpha^k)^2\|(\mathbf{D}+\mathbf{I})^{1/2}\mathbf{v}^{\hat k}\|^2,$$

$$(5.7)\qquad \rho^n(\mathbf{v},\mathbf{g}) = \|\mathbf{v}^0\|^2 + \|\mathbf{v}^1\|^2 + 4(\underline{\delta}\nu)^{-1}\tau\sum_{k=0}^{n-1}(\alpha^k)^{-2}\|(\mathbf{D}+\mathbf{I})^{-1/2}\mathbf{g}^k\|^2.$$

Summing (5.4) for $1 \le k \le n-1$ gives

$$E^n(\tilde{\mathbf{u}}) \le \rho^n(\tilde{\mathbf{u}},\tilde{\mathbf{f}}) + 2(\underline{\delta}\nu)^{-1}C_F\tau\sum_{k=1}^{n-1}E^k(\tilde{\mathbf{u}}).$$

It follows from a discrete nonlinear Gronwall-like inequality [14] that

$$E^n(\tilde{\mathbf{u}}) \le \mathrm{e}^{Cn\tau}\rho^n(\tilde{\mathbf{u}},\tilde{\mathbf{f}}) \qquad \forall\, 0 < n \le n_T,$$

provided that $4\max_{0\le k\le n}\alpha^k N^{1/2}\mathrm{e}^{Ck\tau}\rho^k(\tilde{\mathbf{u}},\tilde{\mathbf{f}}) \le \tilde M^2$.

THEOREM 5.1. *Let u_N be the solution of* (4.12) *and let $\tilde M$ be a positive number. Assume that the function $\alpha(t)$ is defined by* (2.1) *and that $\underline{\delta}$ defined by* (4.5) *is positive. For $0 < n \le n_T$, if*

$$4\max_{0\le k\le n}\alpha^k N^{1/2}\mathrm{e}^{Ck\tau}\rho^k(\tilde{\mathbf{u}},\tilde{\mathbf{f}})\le \tilde{M}^2\,, \tag{5.8}$$

then

$$E^k(\tilde{\mathbf{u}})\le \mathrm{e}^{Ck\tau}\rho^k(\tilde{\mathbf{u}},\tilde{\mathbf{f}})\qquad \forall\, 0<k\le n,$$

where E^k and ρ^k are defined by (5.6) *and* (5.7)*, respectively, and C is a constant linearly proportional to $(\underline{\delta}\nu)^{-1}$ and C_F.*

We now analyze the convergence of the fully discrete scheme (5.2). Let $u_* = \mathcal{P}^{\alpha}_{N}U$ with the following Hermite expansion:

$$u_* = \omega_\alpha\sum_{l=0}^{N}\hat{u}_{*l}H^{(\alpha)}_l\,.$$

Denote the coefficients of the above expansion by $\mathbf{u}_* := (\hat{u}_{*0},\hat{u}_{*1},\dots,\hat{u}_{*N})^T$. It follows from (4.22) that

$$\mathbf{u}^k_{*\hat{t}} - \alpha^k\mathbf{D}^{1/2}\mathbf{F}(u^k_*) + \nu(\alpha^k)^2\mathbf{B}\mathbf{u}^{\hat{k}}_* = \mathbf{f}^k - \mathbf{g}^k, \tag{5.9}$$

where we split $\mathbf{g}^k$ into $\mathbf{g}^k_1$, $\mathbf{g}^k_2$, $\mathbf{g}^k_3$ as follows:

$$\begin{aligned}\mathbf{g}^k &= \left[\left(\frac{d\mathbf{u}_*}{dt}\right)^k - \mathbf{u}^k_{*\hat{t}}\right] + [\alpha^k\mathbf{D}^{1/2}(\mathbf{F}(u^k_*) - \mathbf{F}(U^k))] + [\nu(\alpha^k)^2\mathbf{B}(\mathbf{u}^k_* - \mathbf{u}^{\hat{k}}_*)]\\ &=: \mathbf{g}^k_1 + \mathbf{g}^k_2 + \mathbf{g}^k_3.\end{aligned} \tag{5.10}$$

Let $e^k_{N} = u^k_{N} - u^k_*$ and $\mathbf{e}^k = \mathbf{u}^k - \mathbf{u}^k_*$. Then it can be verified that

$$\begin{cases}\mathbf{e}^k_{\hat{t}} - \alpha^k\mathbf{D}^{1/2}\mathbf{G}^k + \nu(\alpha^k)^2\mathbf{B}\mathbf{e}^{\hat{k}} = \mathbf{g}^k, & 1\le k\le n_{T}-1,\\ \mathbf{e}^0 = 0, \qquad \mathbf{e}^1 = \mathbf{u}_*(0) + \tau\dfrac{d\mathbf{u}_*}{dt}(0) - \mathbf{u}_*(\tau), & \end{cases} \tag{5.11}$$

where $\mathbf{G}^k = \mathbf{F}(u^k_* + e^k_{N}) - \mathbf{F}(u^k_*)$. By the same arguments as in the stability analysis above, we can obtain

$$\|e^n_{N}\|^2_{\omega_\alpha^{-1}} = \|\mathbf{e}^n\|^2 \le C\left(\|\mathbf{e}^0\|^2 + \|\mathbf{e}^1\|^2 + (\underline{\delta}\nu)^{-1}\tau\sum_{k=0}^{n-1}(\alpha^k)^{-2}\|(\mathbf{D}+\mathbf{I})^{-1/2}\mathbf{g}^k\|^2\right).$$

The last term on the right-hand side can be bounded by using the facts below:

$$\tau\sum_{k=0}^{n-1}\|(\mathbf{D}+\mathbf{I})^{-1/2}\mathbf{g}^k_1\|^2 \le C\tau^4\|D^3_tU\|^2_{L^2(0,T;H^{-1}_{\omega_\alpha^{-1}}(\mathbb{R}))}, \tag{5.12}$$

$$\begin{aligned}\tau\sum_{k=0}^{n-1}\|(\mathbf{D}+\mathbf{I})^{-1/2}\mathbf{g}^k_2\|^2 &\le C\tau\sum_{k=0}^{n-1}\|F(u^k_*) - F(U^k)\|^2_{\omega_\alpha^{-1}}\\ &\le CC'_FN^{-\sigma}\|U\|^2_{C(0,T;H^{\sigma}_{\omega_\alpha^{-1}}(\mathbb{R}))},\end{aligned} \tag{5.13}$$

$$\tau\sum_{k=0}^{n-1}\|(\mathbf{D}+\mathbf{I})^{-1/2}\mathbf{g}^k_3\|^2 \le C\tau^4\|D^2_tU\|^2_{L^2(0,T;H^{1}_{\omega_\alpha^{-1}}(\mathbb{R}))}. \tag{5.14}$$

The initial errors can be bounded by using the Taylor expansion:

$$\begin{aligned} \|\mathbf{e}^1\| &= \left\| \int_0^\tau (\tau - s) \frac{d^2 \mathbf{u}_*}{dt^2}(s)\, ds \right\| \le \tau^2 \max_{0\le s\le\tau} \left\| \frac{d^2\mathbf{u}_*}{dt^2}(s) \right\| \\ &\le \tau^2 \|D_t^2 U(s)\|_{C(0,\tau;L^2_{\omega_\alpha^{-1}}(\mathbb{R}))}. \end{aligned} \tag{5.15}$$

Combining the above results, we arrive at the following optimal error estimate.

THEOREM 5.2. *Let U and u_{N} be the solutions of* (4.11) *and* (4.12)*, respectively. Assume that $U \in C(0,T;H^\sigma_{\omega_\alpha^{-1}}(\mathbb{R}))$ $(\sigma \ge 1)$, $D_t^2 U \in L^2(0,T;H^1_{\omega_\alpha^{-1}}(\mathbb{R})) \cap C(0,\tau;L^2_{\omega_\alpha^{-1}}(\mathbb{R}))$, $D_t^3 U \in L^2(0,T;H^{-1}_{\omega_\alpha^{-1}}(\mathbb{R}))$, and $F(z) \in C^1(\mathbb{R})$. Moreover, assume that the function $\alpha(t)$ is defined by* (2.1)*, $\underline{\delta}$ defined by* (4.5) *is positive, and $\tau N^{1/8} \le c_0$ is sufficiently small. Then, for $0 \le n \le n_{T}$,*

$$\|u_{N}^n - U^n\|_{\omega^{-1}_{\alpha(t_n)}} \le C(\tau^2 + N^{-\sigma/2}),$$

where C is a constant depending on $(\underline{\delta}\nu)^{-1}, \delta_0, \delta, T$, and the regularity of U and F.

Remark 5.1. If the underlying PDE solution does not satisfy the exponential decay property required by the Hermite function approximation, one may use the Hermite polynomial approximation directly. In this case, the Hermite polynomial approximation should be used together with a time-dependent scaling,

$$\alpha(t) = \frac{1}{2\sqrt{\nu\delta_0(\delta(T-t)+1)}}. \tag{5.16}$$

For the linear parabolic equation (1.1) and the nonlinear convection-diffusion equation (4.11), it can be verified that with the choice (5.16), the desired stability and convergence results can be established in some appropriate function space.

6. Numerical results. In this section, we present some numerical examples using the proposed method for both linear and nonlinear equations. The numerical results will be compared with those obtained by using the classical method (1.3) and by using the similarity transformation technique. In the following computations, the integrals involved are computed by the Hermite–Gauss quadrature rules with $N+1$ quadrature points. Let

$$E_{N}(t) = \|u_{N}(t) - U^{N}(t)\|_{\omega_\alpha^{-1}}, \qquad E_{N,\infty}(t) = \frac{\max_{0\le j\le N} |u_{N}(y_j,t) - U(y_j,t)|}{\max_{0\le j\le N} |U(y_j,t)|},$$

where $U^{N} \in V_{N}$ is the interpolation of U at the Hermite–Gauss points $\{y_j\}_{j=0}^N$. The examples used below are taken from [6] and [10], where the diffusion coefficient ν in (1.1) is chosen as 1. In the linear case our approach is appropriate for the general choice of $\nu > 0$ due to the use of the scaling factor (2.1). However, for nonlinear problems (such as Example 6.3 below) with sufficiently small values of ν, steep layers may be developed, and in this case some special techniques such as the spectral viscosity method [16] should be applied.

Example 6.1 (linear problem). Consider the parabolic problem (1.1) with $\nu = 1$ and the following source term:

$$f(x,t) = (x\cos x + (t+1)\sin x)(t+1)^{-3/2} e^{-x^2/4(t+1)}. \tag{6.1}$$

TABLE 6.1

1E-3		1.696E-07	9.769E-08	$\tau^{2.00}$
1E-4		1.696E-09	9.798E-10	$\tau^{2.00}$
1E-4	10	5.161E-03	1.192E-03	
	20	1.177E-06	1.246E-07	$N^{-12.10}$
	30	1.696E-09	9.798E-10	$N^{-16.14}$

This example was used by Funaro and Kavian [6]. Its exact solution is of the form

$$U(x,t) = \frac{\sin x}{\sqrt{t+1}} e^{-x^2/4(t+1)}. \tag{6.2}$$

We solve the above problem with $(\delta_0, \delta) = (1.5, 0)$, which corresponds to the classical approach (1.3), and with $(\delta_0, \delta) = (1, 1)$, which corresponds to the method proposed in this work. For ease of comparison, we use the same mesh size as used in [6]. Table 6.1 shows the error $E_{20}(t)$ at $t = 1$ with different time-steps. Note that the result in [6] is obtained by using (explicit) first-order forward difference in time.

Table 6.2 shows the order of accuracy for the scheme (2.7) with $\delta_0 = \delta = 1$. The numerical results are in good agreement with the theoretical prediction that the numerical scheme (2.7) is of second-order accuracy in time and spectral accuracy in space.

Example 6.2 (linear problem). Consider the parabolic problem (1.1) with $\nu = 1$ and the following source term:

$$f(x,t) = \left(k(1+4c^2x)\cos k(x+t) - (k^2 + 2c^2(1-2(cx)^2))\sin k(x+t)\right) \mathrm{e}^{-(cx)^2}, \tag{6.3}$$

where c is a constant. The exact solution of this example has a time-independent decay:

$$U(x,t) = \sin k(x+t)\mathrm{e}^{-c^2x^2}. \tag{6.4}$$

Table 6.3
Example 6.2: *Comparison of the classical approach and the present method.*

		Classical method (1.3)		Proposed method (2.7)	
τ	Steps	$E_{160}(1)$	$E_{160,\infty}(1)$	$E_{160}(1)$	$E_{160,\infty}(1)$
1E-3	250	5.66E-07	3.93E-07	4.30E-06	1.87E-06
	500	1.52E-04	8.50E-06	2.73E-06	2.03E-06
	750	3.72E+01	2.67E+00	2.08E-06	1.44E-06
	1000	8.20E+06	2.02E+05	1.75E-06	1.34E-06
1E-4	2500	5.66E-09	3.94E-09	4.30E-08	1.87E-08
	5000	1.45E-04	8.01E-06	2.73E-08	2.03E-08
	7500	4.30E+01	2.41E+00	2.08E-08	1.44E-08
	10000	8.95E+06	4.97E+04	1.73E-08	1.36E-08

The purpose for choosing this example is to demonstrate that the Hermite spectral method with a time-dependent scaling also works well for the solutions with time-independent decays. In our computations, the parameters k and c are taken as 5 and 0.5, respectively. We solve this problem by using a constant weight $\alpha(t) \equiv 0.5$, which not only corresponds to the classical method (1.3) but also matches the exponential solution-decay exactly. We also solve the problem by using the scheme (2.7) with $(\delta_0, \delta) = (0.6, 1)$. This choice of the parameters satisfies $\underline{\delta} = 0.2 > 0$, and therefore stability and convergence are expected. It is seen from Table 6.3 that although the classical method (1.3) matches the exponential decay exactly, the error is accumulated due to numerical instability. On the other hand, the Hermite spectral method with a time-dependent scaling produces highly accurate and stable numerical approximations.

Example 6.3 (nonlinear viscous Burgers equation). Consider the viscous Burgers equation

$$\partial_t U + U\partial_x U - \nu\partial_x^2 U = f(x,t), \quad x \in \mathbb{R}, \quad t > 0. \tag{6.5}$$

It was computed in [10] via the transformation

$$y = \frac{x}{2\sqrt{\nu(t+1)}}, \qquad s = \ln(t+1) \tag{6.6}$$

for a soliton-like solution

$$U(x,t) = \mathrm{e}^{-y^2}\operatorname{sech}^2(ay - bs - c). \tag{6.7}$$

We will recompute this problem with parameters $a = 0.3$, $b = 0.5$, $c = -3$, and $\nu = 1$.

We use the fully discrete scheme (5.2) to solve the problem with $(\delta_0, \delta) = (1, 1)$. The numerical errors at $t = \mathrm{e} - 1$ are presented in Table 6.4, where the comparison is made with those given in [10]. It is seen that the present method is more accurate than the similarity transformation solution.

To show the rate of convergence for (5.2), we list in Table 6.5 the numerical errors at $t = 1$ with various τ and N. The fully discrete scheme (5.2) is applied to the viscous Burgers problem with $(\delta_0, \delta) = (1, 1)$. It again confirms the theoretical prediction that the present method is of second-order accuracy in time and spectral accuracy in space.

CONSTRUCTION ALGORITHMS FOR DIGITAL NETS WITH LOW WEIGHTED STAR DISCREPANCY[*]

JOSEF DICK[†], GUNTHER LEOBACHER[‡], AND FRIEDRICH PILLICHSHAMMER[‡]

Abstract. We introduce a new construction method for digital nets which yield point sets in the s-dimensional unit cube with low star discrepancy. The digital nets are constructed using polynomials over finite fields. It has long been known that there exist polynomials which yield point sets with low (unweighted) star discrepancy. This result was obtained by Niederreiter by the means of averaging over all polynomials. Hence concrete examples of good polynomials were not known in many cases. Here we show that good polynomials can be found by computer search. The search algorithm introduced in this paper is based on minimizing a quantity closely related to the star discrepancy.

It has been pointed out that many integration problems can be modeled by weighted function spaces and it has been shown that in this case point sets with low weighted discrepancy are required. Hence it is particularly useful to be able to adjust a point set to some given weights. We are able to extend our results from the unweighted case to show that this can be done using our construction algorithms. This way we can find point sets with low weighted star discrepancy, making such point sets especially useful for many applications.

Key words. digital net, weighted star discrepancy, component-by-component algorithm

1. Introduction.

In many applications one wants to approximate an s-dimensional integral over the unit cube,

$$I_s(F) := \int_{[0,1)^s} F(\boldsymbol{x}) d\boldsymbol{x},$$

by an N point quasi-Monte Carlo (QMC) rule,

$$Q_{N,s}(F) := \frac{1}{N} \sum_{n=0}^{N-1} F(\boldsymbol{x}_n).$$

For QMC rules the points $\boldsymbol{x}_0, \dots, \boldsymbol{x}_{N-1}$ are chosen deterministically, with the aim to obtain a small integration error. It has been shown that uniformly distributed point sets yield a small integration error for functions from certain function classes. Several quality measures of point sets in the unit cube are known. One popular way of measuring the distribution quality is based on the discrepancy function Δ. For a point set $\boldsymbol{x}_0, \dots, \boldsymbol{x}_{N-1}$ in the s-dimensional unit cube $[0,1)^s$ the discrepancy function Δ is defined as

$$\Delta(\alpha_1, \dots, \alpha_s) := \frac{A_N\left(\prod_{i=1}^s [0, \alpha_i)\right)}{N} - \alpha_1 \dots \alpha_s,$$

where $0 \le \alpha_1, \ldots, \alpha_s \le 1$. Here $A_N(E)$ denotes the number of indices n, $0 \le n \le N-1$, such that $\boldsymbol{x}_n$ is contained in the set E. By taking a norm of the discrepancy function we obtain a measure for the irregularity of distribution of the point set. We have the following definition (see, for example, Drmota and Tichy [4] or Kuipers and Niederreiter [10]).

Definition 1.1. *For a point set $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}$ in $[0,1)^s$ the star discrepancy D_N^* is defined as the supremums norm of the discrepancy function, i.e.,*

$$D_N^* = D_N^*(\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}) := \sup_{\substack{0 \le \alpha_i \le 1 \\ 1 \le i \le s}} |\Delta(\alpha_1, \ldots, \alpha_s)|.$$

Informally we will say a point set has "low" or "small" star discrepancy if the star discrepancy is of order $O((\log N)^s/N)$; see [4, Chapter 3].

The star discrepancy of a finite point set is intimately related to the worst-case error of multivariate integration of functions with bounded variation in the sense of Hardy and Krause. Here the basic error estimate for the integration error is given by the Koksma–Hlawka inequality (see, for example, [10, Theorem 5.5] or [13, Theorem 2.11]), which states that

$$|I_s(F) - Q_{N,s}(F)| \le V(F) D_N^*,$$

where $V(F)$ is the variation of F in the sense of Hardy and Krause and D_N^* is the star discrepancy of the point set $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}$.

Having observed that different coordinates may have different influence on the quality of the approximation, Sloan and Woźniakowski [20] introduced a generalized ("weighted") version of the Koksma–Hlawka inequality. The star discrepancy for this case is then called weighted star discrepancy. We will give the definition subsequently, but first we introduce some notation used throughout the paper. Let $\boldsymbol{\gamma} = (\gamma_i)_{i \ge 1}$ denote a sequence of positive real numbers, the "weights," and let $E = \{1, 2, \ldots, s\}$ denote the set of coordinate indices. For $u \subseteq E$ let $\gamma_u = \prod_{i \in u} \gamma_i$, $\gamma_\emptyset = 1$, $|u|$ be the cardinality of u, and for a vector $\boldsymbol{z} \in [0,1)^s$ let $\boldsymbol{z}_u$ denote the vector $[0,1)^{|u|}$ containing only the components of $\boldsymbol{z}$ whose indices are in u. Moreover we write $(\boldsymbol{z}_u, \mathbf{1})$ for the vector that we obtain by replacing all the components of $\boldsymbol{z}$ not in u by 1. We have the following definition (see also [20]).

Definition 1.2. *For a point set $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}$ in $[0,1)^s$ and a sequence $\boldsymbol{\gamma} = (\gamma_i)_{i \ge 1}$ of weights the weighted star discrepancy $D_{N,\boldsymbol{\gamma}}^*$ is given by*

$$D_{N,\boldsymbol{\gamma}}^* = D_{N,\boldsymbol{\gamma}}^*(\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1}) := \sup_{\boldsymbol{z} \in [0,1)^s} \max_{\substack{u \subseteq E \\ u \neq \emptyset}} \gamma_u |\Delta(\boldsymbol{z}_u, \mathbf{1})|,$$

where $\gamma_u = \prod_{i \in u} \gamma_i$.

Note that for the choice $\boldsymbol{\gamma} = \mathbf{1}$, that is, $\gamma_i = 1$ for all $i \ge 1$, we have $D_{N,\mathbf{1}}^* = D_N^*$ from Definition 1.1. Henceforth we will refer to the unweighted star discrepancy as classical star discrepancy or simply star discrepancy.

Sloan and Woźniakowski [20] continued by showing that for all functions in the Sobolev space $W_2^{(1,\ldots,1)}([0,1)^s)$ we have

$$|I_s(F) - Q_{N,s}(F)| \le D_{N,\boldsymbol{\gamma}}^* \|F\|_{s,\boldsymbol{\gamma}},$$

where the norm is defined as

$$\|F\|_{s,\boldsymbol{\gamma}} := \sum_{u \subseteq E} \gamma_u^{-1} \int_{[0,1)^{|u|}} \left| \frac{\partial^{|u|}}{\partial \boldsymbol{x}_u} F(\boldsymbol{x}_u, \mathbf{1}) \right| d\boldsymbol{x}_u.$$

(Sloan and Woźniakowski [20] concentrated mainly on the Hilbertian case. See also [11] for a more specialized treatment of the L^q case for $q \neq 2$.) Therefore point sets with low weighted star discrepancy guarantee a small worst-case error for numerical integration and hence the need for point sets with low weighted star discrepancy.

Note that the best upper bounds on the classical star discrepancy are of the form $C_s(\log N)^s/N$ for some constant C_s independent of N. Because of the factor $(\log N)^s$ such bounds are useful only if N is exponentially large in the dimension s. Using a weighted star discrepancy that focuses mainly on lower dimensional projections, the effect of $(\log N)^s$ can be much reduced, yielding useful upper bounds on the star discrepancy even for large dimensions s.

Currently the most effective constructions of point sets with low star discrepancy are based on the concept of (t, m, s)-nets in a base b. For a definition of such nets see [13, Definition 4.1]. In [14] (see also [13, Chapter 4.4]) Niederreiter introduced a special construction of such nets. This construction is based on rational functions over finite fields.

Henceforth let p be a prime. Further let $\mathbb{F}_p((x^{-1}))$ be the field of formal Laurent series over the finite field $\mathbb{F}_p$ consisting of p elements. Thus elements of $\mathbb{F}_p((x^{-1}))$ are of the form

$$L = \sum_{l=w}^{\infty} t_l x^{-l},$$

where w is an arbitrary integer and all $t_l \in \mathbb{F}_p$. Note that $\mathbb{F}_p((x^{-1}))$ contains the field of rational functions over $\mathbb{F}_p$ as a subfield. Further let $\mathbb{F}_p[x]$ be the set of all polynomials over $\mathbb{F}_p$ and let $m \geq 1$ be an integer. For a given dimension $s \geq 2$, choose $f \in \mathbb{F}_p[x]$, with $\deg(f) = m$, and let $g_1, \dots, g_s \in \mathbb{F}_p[x]$. Let φ_m be the map from $\mathbb{F}_p((x^{-1}))$ to the interval $[0, 1)$ defined by

$$\varphi_m\left(\sum_{l=w}^{\infty} t_l x^{-l}\right) = \sum_{l=\max(1,w)}^{m} t_l p^{-l}.$$

For $0 \leq n < p^m$ let $n = n_0 + n_1 p + \cdots + n_{m-1}p^{m-1}$ be the p-adic expansion of n. With each such n we associate the polynomial

$$n(x) = \sum_{r=0}^{m-1} n_r x^r \in \mathbb{F}_p[x].$$

Then $P(\boldsymbol{g}, f)$ is the point set consisting of the p^m points

$$\boldsymbol{x}_n = \left(\varphi_m\left(\frac{n(x)g_1(x)}{f(x)}\right), \dots, \varphi_m\left(\frac{n(x)g_s(x)}{f(x)}\right)\right) \in [0, 1)^s$$

for $0 \leq n \leq p^m - 1$. Due to the construction principle, a QMC rule using the point set $P(\boldsymbol{g}, f)$ is often called a *polynomial lattice rule*. The vector $\boldsymbol{g}$ is called the generating vector of $P(\boldsymbol{g}, f)$ or the generating vector of the polynomial lattice rule, depending on the context.

It has been shown (see [13, Theorem 4.43]) that for a given polynomial f there always exists a vector of polynomials $\boldsymbol{g}$ such that $P(\boldsymbol{g}, f)$ has low star discrepancy. This result was obtained by averaging over all possible choices of $\boldsymbol{g}$. Hence good examples of generating vectors $\boldsymbol{g}$ were not known. Here we show that such vectors of polynomials $\boldsymbol{g}$ can be found using computers. First we consider the classical unweighted case. This is done in the following section, where we introduce a component-by-component and a Korobov construction algorithm for polynomial lattice rules based on the quantity $R(\boldsymbol{g}, f)$, which is intimately related to the star discrepancy. We show that the resulting point set $P(\boldsymbol{g}, f)$ has low star discrepancy. In section 3 we extend those results to the weighted case where we obtain similar results. (A similar approach was taken by Joe [8] for ordinary lattice rules.) Note that our algorithms allow us to adjust the digital net to given weights, thereby paying more attention to important projections. Construction algorithms which allow such an adjustment were first introduced for lattice rules; see [8]. Further note that our approach is different from the classical approach for (t, m, s)-nets or (t, s)-sequences where one aims at minimizing the quality parameter t. It has been shown that certain (t, s)-sequences have lower dimensional projections of poor quality (see [12]), hence the need for more flexible construction algorithms. Furthermore we note that in the weighted case we are able to obtain useful upper bounds on the star discrepancy even for large dimensions s and a relatively small number of points N (see Table 5.2 and Table 5.3). For the unweighted case useful upper bounds for such cases are known only from [5], but those results are only existence results, leaving no clue on how to construct such point sets in practice.

Our construction algorithms allow us to extend polynomial lattice rules in the dimension. In [15] Niederreiter showed the existence of polynomial lattice rules extensible in both the number of points N and the dimension. How to extend polynomial lattice rules in N remains an interesting open question.

Section 4 deals with the efficient calculation of $R(\boldsymbol{g}, f)$ and its weighted counterpart $\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g}, f)$. Concretely, we show that for a given $\boldsymbol{g}$ and f the quantities $R(\boldsymbol{g}, f)$ and $\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g}, f)$ can be computed in $O(p^m s)$ operations. In section 5 we present some numerical results and we explain how the construction cost can be further reduced by computing $R(\boldsymbol{g}, f)$ and $\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g}, f)$ recursively with an additional storage cost of $O(p^m)$.

We introduce some notation. For an arbitrary $\boldsymbol{k} = (k_1, \dots, k_s) \in \mathbb{F}_p[x]^s$, we define the "inner product"

$$\boldsymbol{k} \cdot \boldsymbol{g} = \sum_{i=1}^{s} k_i g_i$$

and we write $g \equiv 0 \,(\mathrm{mod}\, f)$ if f divides g in $\mathbb{F}_p[x]$. Further, as above, we often associate a nonnegative integer $k = \kappa_0 + \kappa_1 p + \cdots + \kappa_r p^r$ with the polynomial $k(x) = \kappa_0 + \kappa_1 x + \cdots + \kappa_r x^r \in \mathbb{F}_p[x]$ and vice versa.

Further let $G_{p,m} := \{h \in \mathbb{F}_p[x] : \deg(h) < m\}$ and let $|G_{p,m}|$ denote the number of elements of $G_{p,m}$.

2. The classical star discrepancy. In this section we deal with the classical star discrepancy of the digital net $P(\boldsymbol{g}, f)$, where the base p is restricted to prime numbers. We show that good polynomials $g_1, \dots, g_s$ (by good polynomials we mean polynomials such that $P(\boldsymbol{g}, f)$ has low star discrepancy) may be obtained by using a component-by-component or Korobov construction algorithm. Our algorithm depends on the quantity $R(\boldsymbol{g}, f)$, which we will introduce below.

For $h \in G_{p,m}$ we define

$$r_p(h) := \begin{cases} 1 & \text{if } h = 0, \\ \frac{1}{p^{g+1} \sin^2\left(\frac{\pi}{p}\kappa_g\right)} & \text{if } h = \kappa_0 + \kappa_1 x + \cdots + \kappa_g x^g,\ \kappa_g \neq 0. \end{cases}$$

For $f \in \mathbb{F}_p[x]$, with $\deg(f) = m$, and $\boldsymbol{g} = (g_1, \dots, g_s) \in G_{p,m}^s$ we define the quantity

$$R(\boldsymbol{g}, f) := \sum_{\substack{\boldsymbol{h} \in G_{p,m}^s \setminus \{\boldsymbol{0}\} \\ \boldsymbol{h} \cdot \boldsymbol{g} \equiv 0 \pmod{f}}} \prod_{i=1}^{s} r_p(h_i),$$

where for $\boldsymbol{h} \in G_{p,m}^s$ we write $\boldsymbol{h} = (h_1, \dots, h_s)$. With this definitions we obtain the following proposition.

PROPOSITION 2.1. *For the star discrepancy $D_N^*(\boldsymbol{g}, f)$ of the point set $P(\boldsymbol{g}, f)$ we have*

$$D_N^*(\boldsymbol{g}, f) \leq 1 - \left(1 - \frac{1}{N}\right)^s + R(\boldsymbol{g}, f) \leq \frac{s}{N} + R(\boldsymbol{g}, f), \tag{2.1}$$

where $N = p^m$.

Proof. From [6, Theorem 1(ii)] together with equality (2.2) in section 2.3 it follows that

$$D_N^*(\boldsymbol{g}, f) \leq 1 - \left(1 - \frac{1}{N}\right)^s + \sum_{\substack{\boldsymbol{h} \in G_{p,m}^s \setminus \{\boldsymbol{0}\} \\ \boldsymbol{h} \cdot \boldsymbol{g} \equiv 0 \pmod{f}}} \prod_{i=1}^{s} \rho_{\text{Walsh}}^*(h_i),$$

where

$$\rho_{\text{Walsh}}^*(h) := \begin{cases} 1 & \text{if } h = 0, \\ \frac{1}{p^{g+1} \sin\left(\frac{\pi}{p}\kappa_g\right)} & \text{if } h = \kappa_0 + \kappa_1 x + \cdots + \kappa_g x^g,\ \kappa_g \neq 0. \end{cases}$$

Now the result follows by observing that $\sin^{-1}(x) \leq \sin^{-2}(x)$ for $0 < x < \pi$. □

Observe that an analogue's result exists for lattice rules, which was used by Joe in [8] to obtain lattice rules with small (weighted) star discrepancy. Indeed, we use an analogues approach to [8].

We remark that a result similar to Proposition 2.1 holds for the so-called extreme discrepancy, which is an unanchored version of the star discrepancy; see [6]. This can be obtained by using [6, Theorem 1(i)] together with equality (2.2) in section 2.3 and hence the subsequent results can be modified to obtain construction algorithms yielding point sets with small extreme discrepancy.

As it is much easier to analyze $R(\boldsymbol{g}, f)$ than $D_N^*(\boldsymbol{g}, f)$, we will subsequently mainly deal with $R(\boldsymbol{g}, f)$ rather than the star discrepancy directly. The results on the star discrepancy are then obtained via inequality (2.1).

Note that our definition of $r_p(h)$ yields a slightly weaker bound on the star discrepancy than by using the original definition of ρ_{Walsh}^* from [6]. But this change makes it possible to compute $R(\boldsymbol{g}, f)$ at a cost of $O(p^m s)$ as shown in section 4. We will exploit this fact in our construction algorithms.

The following lemma will be useful for our subsequent investigations.

LEMMA 2.2. *For $p \in \mathbb{N}$, $p \geq 2$, we have*

$$\sum_{\boldsymbol{h} \in G_{p,m}^s} \prod_{i=1}^{s} r_p(h_i) = \left(1 + m\frac{p^2 - 1}{3p}\right)^s.$$

Proof. For $p = 2$ the result is proved in [13, Lemma 3.13]. We have

$$\sum_{\boldsymbol{h} \in G_{p,m}^s} \prod_{i=1}^{s} r_p(h_i) = \prod_{i=1}^{s} \sum_{h_i \in G_{p,m}} r_p(h_i) = \left(\sum_{h \in G_{p,m}} r_p(h)\right)^s.$$

Now for $h \in G_{p,m}$, with $\deg(h) = a-1$, we write $h = h_0 + h_1 x + \cdots + h_{a-1}x^{a-1}$, where $h_{a-1} \neq 0$. Then

$$\begin{aligned}\sum_{h \in G_{p,m}} r_p(h) &= 1 + \sum_{a=1}^{m} \sum_{\substack{h \in G_{p,m} \\ \deg(h)=a-1}} r_p(h) \\ &= 1 + \sum_{a=1}^{m} \frac{1}{p^a} \sum_{\substack{h \in G_{p,m} \\ \deg(h)=a-1}} \frac{1}{\sin^2\left(\frac{h_{a-1}\pi}{p}\right)} \\ &= 1 + \sum_{a=1}^{m} \frac{1}{p^a} \sum_{h_{a-1}=1}^{p-1} p^{a-1} \frac{1}{\sin^2\left(\frac{h_{a-1}\pi}{p}\right)} \\ &= 1 + \frac{1}{p} \sum_{a=1}^{m} \sum_{h_{a-1}=1}^{p-1} \frac{1}{\sin^2\left(\frac{h_{a-1}\pi}{p}\right)}.\end{aligned}$$

In [3, Appendix C] it was shown that $\sum_{h=1}^{p-1} \frac{1}{\sin^2\left(\frac{h\pi}{p}\right)} = \frac{p^2-1}{3}$. The result follows. □

As a benchmark we calculate the average of $R(\boldsymbol{g}, f)$ over all vectors $\boldsymbol{g} \in (G_{p,m} \setminus \{0\})^s$. A similar result was proved by Niederreiter [13, Remark 4.44]. We have the following theorem.

THEOREM 2.3. *Let $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$. *We have*

$$\frac{1}{|G_{p,m} \setminus \{0\}|^s} \sum_{\boldsymbol{g} \in (G_{p,m}\setminus\{0\})^s} R(\boldsymbol{g}, f) = \frac{1}{p^m - 1}\left(\left(1 + m\frac{p^2-1}{3p}\right)^s - 1 - sm\frac{p^2-1}{3p}\right).$$

Proof. First observe that $|G_{p,m} \setminus \{0\}| = p^m - 1$. We have

$$\begin{aligned}\frac{1}{|G_{p,m} \setminus \{0\}|^s} \sum_{\boldsymbol{g} \in (G_{p,m}\setminus\{0\})^s} R(\boldsymbol{g}, f) &= \frac{1}{(p^m-1)^s} \sum_{\boldsymbol{g} \in (G_{p,m}\setminus\{0\})^s} \sum_{\substack{\boldsymbol{h} \in G_{p,m}^s \setminus\{\boldsymbol{0}\} \\ \boldsymbol{h}\cdot\boldsymbol{g} \equiv 0 \,(\mathrm{mod}\, f)}} \prod_{i=1}^{s} r_p(h_i) \\ &= \frac{1}{(p^m-1)^s} \sum_{\boldsymbol{h} \in G_{p,m}^s \setminus\{\boldsymbol{0}\}} \prod_{i=1}^{s} r_p(h_i) \sum_{\substack{\boldsymbol{g} \in (G_{p,m}\setminus\{0\})^s \\ \boldsymbol{h}\cdot\boldsymbol{g} \equiv 0 \,(\mathrm{mod}\, f)}} 1.\end{aligned}$$

For a fixed $\boldsymbol{h} \in G_{p,m}^s \setminus \{\boldsymbol{0}\}$ we have

$$\sum_{\substack{\boldsymbol{g} \in (G_{p,m}\setminus\{0\})^s \\ \boldsymbol{h}\cdot\boldsymbol{g} \equiv 0 \,(\mathrm{mod}\, f)}} 1 = |\{\boldsymbol{g} \in (G_{p,m} \setminus \{0\})^s : \boldsymbol{h}\cdot\boldsymbol{g} \equiv 0 \,(\mathrm{mod}\, f)\}|.$$

If $\boldsymbol{h} = (0, \dots, 0, h_i, 0, \dots, 0)$, with $h_i \neq 0$, then there is no polynomial $\boldsymbol{g} \in (G_{p,m} \setminus \{0\})^s$ such that $\boldsymbol{h}\cdot\boldsymbol{g} = h_i g_i \equiv 0 \,(\mathrm{mod}\, f)$, as $g_i \neq 0$ and f is irreducible. Otherwise the number of polynomials $\boldsymbol{g} \in (G_{p,m} \setminus \{0\})^s$ is $(p^m-1)^{s-1}$. Therefore we have

$$\begin{aligned}&\frac{1}{|G_{p,m} \setminus \{0\}|^s} \sum_{\boldsymbol{g} \in (G_{p,m}\setminus\{0\})^s} R(\boldsymbol{g}, f) \\ &\quad= \frac{1}{p^m-1} \sum_{\boldsymbol{h} \in G_{p,m}^s \setminus\{\boldsymbol{0}\}} \prod_{i=1}^{s} r_p(h_i) - \frac{1}{p^m-1} \sum_{i=1}^{s} \sum_{h_i \in G_{p,m}\setminus\{0\}} r_p(h_i) \prod_{\substack{j=1 \\ j\neq i}}^{s} r_p(0).\end{aligned}$$

The result now follows from Lemma 2.2. □

Remark 2.4. Niederreiter [13, Theorem 4.43] also proved a similar result for arbitrary (not necessarily irreducible) polynomials $f \in \mathbb{F}_p[x]$.

2.1. A component-by-component construction of $P(g, f)$ based on $R(g, f)$. So far we know from Theorem 2.3 and Proposition 2.1 that there exist polynomials which yield point sets with low star discrepancy. In the following we show how good polynomials can be found by computer search.

Algorithm 2.5. *Given a prime p, $m \geq 1$ and a polynomial $f \in \mathbb{F}_p[x]$, with* $\deg(f) = m$,

```
1. set $g_1^* = 1$;
2. for $d = 2, 3, \ldots, s$ find $g_d^* \in G_{p,m} \setminus \{0\}$ by minimizing $R((g_1^*, \ldots, g_{d-1}^*, g_d), f)$.
```

Remark 2.6. In section 4 it is shown how the quantity $R(\boldsymbol{g}, f)$ can be calculated in $O(p^m s)$ operations. Hence the cost for Algorithm 2.5 is of $O(p^{2m} s^2)$ operations. This order is the same as for other component-by-component construction algorithms; see [2, 8, 19]. Further, in section 5 we explain how the construction cost can be reduced to $O(p^{2m} s)$ operations with an additional storage cost of $O(p^m)$ (see also [19]).

Theorem 2.7. *Let p be prime, $m \geq 1$, and $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$. *Suppose $\boldsymbol{g}^* = (g_1^*, \ldots, g_s^*) \in (G_{p,m} \setminus \{0\})^s$ is constructed according to Algorithm* 2.5. *Then for all $d = 1, 2, \ldots, s$ we have*

$$R((g_1^*, \ldots, g_d^*), f) \leq \frac{1}{p^m - 1} \left(1 + m\frac{p^2 - 1}{3p}\right)^d.$$

Proof. Since f is irreducible it follows that $R(1, f) = 0$ and the result follows for $d = 1$. Suppose now that for some $2 \leq d < s$ we have already constructed $\boldsymbol{g}^* \in (G_{p,m} \setminus \{0\})^d$ and

$$R(\boldsymbol{g}^*, f) \leq \frac{1}{p^m - 1} \left(1 + m\frac{p^2 - 1}{3p}\right)^d.$$

Now we consider $R((\boldsymbol{g}^*, g_{d+1}), f)$. We have

$$\begin{aligned} R((\boldsymbol{g}^*, g_{d+1}), f) &= \sum_{\substack{(\boldsymbol{h}, h_{d+1}) \in G_{p,m}^{d+1} \setminus \{\boldsymbol{0}\} \\ \boldsymbol{h} \cdot \boldsymbol{g}^* + h_{d+1} g_{d+1} \equiv 0 \pmod{f}}} \prod_{i=1}^{d+1} r_p(h_i) \\ &= \sum_{\substack{\boldsymbol{h} \in G_{p,m}^d \setminus \{\boldsymbol{0}\} \\ \boldsymbol{h} \cdot \boldsymbol{g}^* \equiv 0 \pmod{f}}} \prod_{i=1}^{d} r_p(h_i) + \theta(g_{d+1}) \\ &= R(\boldsymbol{g}^*, f) + \theta(g_{d+1}), \end{aligned}$$

where

$$\theta(g_{d+1}) = \sum_{h_{d+1} \in G_{p,m} \setminus \{0\}} \left(r_p(h_{d+1}) \sum_{\substack{\boldsymbol{h} \in G_{p,m}^d \\ \boldsymbol{h} \cdot \boldsymbol{g}^* \equiv -h_{d+1} g_{d+1} \pmod{f}}} \prod_{i=1}^{d} r_p(h_i) \right).$$

Since g_{d+1}^* is a minimizer of $R((\boldsymbol{g}^*, g_{d+1}), f)$ it follows that g_{d+1}^* is also a minimizer of $\theta(g_{d+1})$ and hence we obtain

$$\theta(g_{d+1}^*) \leq \frac{1}{p^m - 1} \sum_{g_{d+1} \in G_{p,m} \setminus \{0\}} \theta(g_{d+1}).$$

Now we have

$$\begin{aligned}
&\theta(g_{d+1}^*) \\
&\leq \frac{1}{p^m-1} \sum_{g_{d+1} \in G_{p,m} \setminus \{0\}} \sum_{h_{d+1} \in G_{p,m} \setminus \{0\}} \left(r_p(h_{d+1}) \sum_{\substack{\boldsymbol{h} \in G_{p,m}^d \\ \boldsymbol{h} \cdot \boldsymbol{g}^* \equiv -h_{d+1} g_{d+1} \pmod{f}}} \prod_{i=1}^{d} r_p(h_i) \right) \\
&= \frac{1}{p^m-1} \sum_{h_{d+1} \in G_{p,m} \setminus \{0\}} r_p(h_{d+1}) \sum_{\boldsymbol{h} \in G_{p,m}^d} \prod_{i=1}^{d} r_p(h_i) \sum_{\substack{g_{d+1} \in G_{p,m} \setminus \{0\} \\ g_{d+1} h_{d+1} \equiv -\boldsymbol{h} \cdot \boldsymbol{g}^* \pmod{f}}} 1.
\end{aligned}$$

Since $\gcd(h_{d+1}, f) = 1$ it follows that the congruence

$$g_{d+1} h_{d+1} \equiv -\boldsymbol{h} \cdot \boldsymbol{g}^* \pmod{f}$$

has exactly one solution $g_{d+1} \in G_{p,m} \setminus \{0\}$ if $-\boldsymbol{h} \cdot \boldsymbol{g}^* \not\equiv 0 \pmod{f}$ and no solution if $-\boldsymbol{h} \cdot \boldsymbol{g}^* \equiv 0 \pmod{f}$. Therefore we obtain

$$\begin{aligned}
\theta(g_{d+1}^*) &\leq \frac{1}{p^m-1} \sum_{h_{d+1} \in G_{p,m} \setminus \{0\}} r_p(h_{d+1}) \sum_{\boldsymbol{h} \in G_{p,m}^d} \prod_{i=1}^{d} r_p(h_i) \\
&= \frac{1}{p^m-1} \left(1 + m\frac{p^2-1}{3p}\right)^d \sum_{h_{d+1} \in G_{p,m} \setminus \{0\}} r_p(h_{d+1}).
\end{aligned}$$

Now we obtain

$$\begin{aligned}
R((\boldsymbol{g}^*, g_{d+1}^*), f) &\leq R(\boldsymbol{g}^*, f) + \frac{1}{p^m-1} \left(1 + m\frac{p^2-1}{3p}\right)^d \sum_{h_{d+1} \in G_{p,m} \setminus \{0\}} r_p(h_{d+1}) \\
&\leq \frac{1}{p^m-1} \left(1 + m\frac{p^2-1}{3p}\right)^d \sum_{h_{d+1} \in G_{p,m}} r_p(h_{d+1}) \\
&= \frac{1}{p^m-1} \left(1 + m\frac{p^2-1}{3p}\right)^{d+1}.
\end{aligned}$$

The result follows by induction. □

From inequality (2.1) and Theorem 2.7 we obtain the following corollary.

COROLLARY 2.8. *Let p be prime, $m \geq 1$, and $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$. *Suppose $\boldsymbol{g}^* = (g_1^*, \dots, g_s^*) \in G_{p,m}^s$ is constructed according to Algorithm* 2.5. *Then for all $d = 1, \dots, s$ we have*

$$D_{p^m}^*((g_1^*, \dots, g_d^*), f) \leq \frac{d}{p^m} + \frac{1}{p^m-1} \left(1 + m\frac{p^2-1}{3p}\right)^d.$$

2.2. A Korobov construction of $\boldsymbol{P(g, f)}$ based on $\boldsymbol{R(g, f)}$. In the method of good lattice points one often restricts the attention to lattice points whose coordinates are successive powers of a single integer. Such a choice was first proposed by Korobov (see [9]) and therefore such lattice points are often called *Korobov lattice points.* Here we consider now s-tuples $\boldsymbol{g} = (g_1, \dots, g_s)$ of polynomials that are obtained by taking a polynomial $g \in G_{p,m}$ and putting $g_i \equiv g^{i-1} \pmod{f}$ with $\deg g_i < m$ for $1 \leq i \leq s$. For such s-tuples we use the notation $\boldsymbol{v}_s(g) \equiv (1, g, g^2, \dots, g^{s-1}) \pmod{f}$.

Algorithm 2.9. *Given a prime p, a dimension $s \geq 2$, $m \geq 1$, and a polynomial $f \in \mathbb{F}_p[x]$, with* $\deg(f) = m$, *find $g^* \in G_{p,m} \setminus \{0\}$ by minimizing $R(\boldsymbol{v}_s(g), f)$.*

Remark 2.10. In section 4 it is shown how the quantity $R(\boldsymbol{g}, f)$ can be calculated in $O(p^m s)$ operations. Hence the cost for Algorithm 2.9 is of $O(p^{2m} s)$ operations. This order is the same as for other Korobov construction algorithms; see [22]. Note that compared to Algorithm 2.5 the search cost is reduced, or, if one uses the method explained in section 5, there is no additional storage cost.

Theorem 2.11. *Let p be prime, $s \geq 2$, $m \geq 1$, and $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$. *Suppose $g^* \in G_{p,m} \setminus \{0\}$ is constructed according to Algorithm* 2.9. *Then we have*

$$R(\boldsymbol{v}_s(g^*), f) \leq \frac{s-1}{p^m - 1} \left(1 + m\frac{p^2-1}{3p}\right)^s.$$

Proof. Define

$$M_s(f) := \frac{1}{p^m - 1} \sum_{g \in G_{p,m} \setminus \{0\}} R(\boldsymbol{v}_s(g), f).$$

It follows from Algorithm 2.9 that $R(\boldsymbol{v}_s(g^*), f) \leq M_s(f)$. Hence it suffices to show that $M_s(f)$ satisfies the bound. We have

$$\begin{aligned} M_s(f) &= \frac{1}{p^m - 1} \sum_{g \in G_{p,m} \setminus \{0\}} \sum_{\substack{\boldsymbol{h} \in G_{p,m}^s \setminus \{\boldsymbol{0}\} \\ \boldsymbol{v}_s(g) \cdot \boldsymbol{h} \equiv 0 \pmod{f}}} \prod_{i=1}^{s} r_p(h_i) \\ &= \frac{1}{p^m - 1} \sum_{\boldsymbol{h} \in G_{p,m}^s \setminus \{\boldsymbol{0}\}} \prod_{i=1}^{s} r_p(h_i) \sum_{\substack{g \in G_{p,m} \setminus \{0\} \\ \boldsymbol{v}_s(g) \cdot \boldsymbol{h} \equiv 0 \pmod{f}}} 1. \end{aligned}$$

Now we recall that for an irreducible polynomial $f \in \mathbb{F}_p[x]$, with $\deg(f) = m \geq 1$, and a nonzero $(h_1, \dots, h_s) \in \mathbb{F}_p[x]^s$ with $\deg(h_i) < m$, $i = 1, \dots, s$, the congruence

$$h_1 + h_2 g + \cdots + h_s g^{s-1} \equiv 0 \pmod{f}$$

has at most $s - 1$ solutions $g \in G_{p,m} \setminus \{0\}$. Thus we have

$$M_s(f) \leq \frac{s-1}{p^m - 1} \sum_{\boldsymbol{h} \in G_{p,m}^s} \prod_{i=1}^{s} r_p(h_i).$$

The result now follows from Lemma 2.2. □

From inequality (2.1) and Theorem 2.11 we obtain the following corollary.

Corollary 2.12. *Let p be prime, $s \geq 2$, $m \geq 1$, and $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$. *Suppose $g^* \in G_{p,m} \setminus \{0\}$ is constructed according to Algorithm* 2.9. *Then we have*

$$D_{p^m}^*(\boldsymbol{v}_s(g^*), f) \leq \frac{s}{p^m} + \frac{s-1}{p^m - 1} \left(1 + m\frac{p^2-1}{3p}\right)^s.$$

2.3. Walsh functions and a formula for $R(\boldsymbol{g}, f)$. Before we close this section we show that the quantity $R(\boldsymbol{g}, f)$ can be represented in terms of Walsh functions. For an integer $b \geq 2$ let $\omega_b = e^{2\pi \mathrm{i}/b}$. For a nonnegative integer h with base b representation $h = h_0 + h_1 b + \cdots + h_r b^r$ the function ${}_b\mathrm{wal}_h : \mathbb{R} \longrightarrow \mathbb{C}$, periodic with period one, is defined by

$$ {}_b\mathrm{wal}_h(x) = \omega_b^{h_0 x_1 + \cdots + h_r x_{r+1}}, $$

where $x \in [0, 1)$ has base b representation $x = x_1/b + x_2/b^2 + \cdots$ (unique in the sense that infinitely many of the x_i must be different from $b - 1$).

It is clear from the definition that Walsh functions are piecewise constant. Further it can be shown that for any $b \geq 2$ the system $\{{}_b\mathrm{wal}_h : h = 0, 1, \dots\}$ is a complete orthonormal system in $L_2([0, 1))$. More information on Walsh functions can be found, for example, in [1, 3, 16, 17, 21].

Subsequently we will make use of the following equality, which follows from [13, Lemma 2.20] and [3, Lemma 2]. For the point set $P(\boldsymbol{g}, f) = \{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{p^m-1}\}$ with $\boldsymbol{x}_n = (x_n^{(1)}, \dots, x_n^{(s)})$ we have

$$ \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i=1}^{s} {}_p\mathrm{wal}_{h_i}(x_n^{(i)}) = \begin{cases} 1 & \text{if } \boldsymbol{g} \cdot \boldsymbol{h} \equiv 0 \,(\mathrm{mod}\, f), \\ 0 & \text{otherwise.} \end{cases} \tag{2.2} $$

As we always consider Walsh functions in base p we will often write wal_h instead of ${}_p\mathrm{wal}_h$.

Lemma 2.13. *Let $\boldsymbol{x}_0, \dots, \boldsymbol{x}_{p^m-1}$ be the point set $P(\boldsymbol{g}, f)$, $\boldsymbol{x}_n = (x_n^{(1)}, \dots, x_n^{(s)})$, $0 \leq n \leq p^m - 1$. Then we have*

$$ R(\boldsymbol{g}, f) = -1 + \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i=1}^{s} \left(1 + \sum_{h=1}^{p^m-1} r_p(h) \mathrm{wal}_h(x_n^{(i)}) \right). $$

Proof. Note that here we use the identification of a polynomial $h_0 + h_1 x + \cdots + h_{m-1} x^{m-1} \in G_{p,m}$ with the integer with base p representation $h_0 + h_1 p + \cdots + h_{m-1} p^{m-1}$. We have

$$ \begin{aligned} -1 + \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i=1}^{s} \left(1 + \sum_{h=1}^{p^m-1} r_p(h) \mathrm{wal}_h(x_n^{(i)}) \right) & \\ &= -1 + \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i=1}^{s} \sum_{h=0}^{p^m-1} r_p(h) \mathrm{wal}_h(x_n^{(i)}) \\ &= -1 + \frac{1}{p^m} \sum_{n=0}^{p^m-1} \sum_{h_1, \dots, h_s = 0}^{p^m-1} \prod_{i=1}^{s} r_p(h_i) \mathrm{wal}_{h_i}(x_n^{(i)}) \\ &= -1 + \sum_{h_1, \dots, h_s = 0}^{p^m-1} \prod_{i=1}^{s} r_p(h_i) \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i=1}^{s} \mathrm{wal}_{h_i}(x_n^{(i)}). \end{aligned} $$

By using (2.2) it follows that the last sum equals

$$ -1 + \sum_{\substack{\boldsymbol{h} \in G_{p,m}^s \\ \boldsymbol{g} \cdot \boldsymbol{h} \equiv 0 \,(\mathrm{mod}\, f)}} \prod_{i=1}^{s} r_p(h_i) = \sum_{\substack{\boldsymbol{h} \in G_{p,m}^s \setminus \{\boldsymbol{0}\} \\ \boldsymbol{g} \cdot \boldsymbol{h} \equiv 0 \,(\mathrm{mod}\, f)}} \prod_{i=1}^{s} r_p(h_i) = R(\boldsymbol{g}, f) $$

and the result follows. □

3. The weighted star discrepancy. In this section we extend the results from the previous section to the weighted case. First we find an analogue to inequality (2.1) for the weighted star discrepancy.

For the weighted star discrepancy $D^*_{N,\boldsymbol{\gamma}}$ of a point set $\boldsymbol{x}_0,\dots,\boldsymbol{x}_{N-1}$ in $[0,1)^s$ we have

$$D^*_{N,\boldsymbol{\gamma}} = \sup_{\boldsymbol{z}\in[0,1)^s} \max_{\substack{u\subseteq E\\ u\neq\emptyset}} \gamma_u |\Delta(\boldsymbol{z}_u,\mathbf{1})| \leq \max_{\substack{u\subseteq E\\ u\neq\emptyset}} \gamma_u \sup_{\boldsymbol{z}_u\in[0,1)^{|u|}} |\Delta(\boldsymbol{z}_u)| \leq \sum_{\substack{u\subseteq E\\ u\neq\emptyset}} \gamma_u D^*_N(u),$$

where $D^*_N(u)$ denotes the star discrepancy of the projection of the point set $\boldsymbol{x}_0,\dots,\boldsymbol{x}_{N-1}$ to the coordinates given by u. If we consider the point set $P(\boldsymbol{g},f)$, then (2.1) yields

$$D^*_N(u) \leq 1-\left(1-\frac{1}{N}\right)^{|u|} + R(\boldsymbol{g}_u,f)$$

for $u\neq\emptyset$, where $\boldsymbol{g}_u=(g_j)_{j\in u}$ and $R(\boldsymbol{g}_u,f)$ is given by

$$R(\boldsymbol{g}_u,f) = \sum_{\substack{\boldsymbol{h}\in G^{|u|}_{p,m}\setminus\{\boldsymbol{0}\}\\ \boldsymbol{h}\cdot\boldsymbol{g}_u\equiv 0 \pmod f}} \prod_{i=1}^{|u|} r_p(h_i).$$

Hence for the weighted star discrepancy $D^*_{N,\boldsymbol{\gamma}}$ of the point set $P(\boldsymbol{g},f)$ we get

$$D^*_{N,\boldsymbol{\gamma}}(\boldsymbol{g},f) \leq \sum_{\substack{u\subseteq E\\ u\neq\emptyset}} \gamma_u \left(1-\left(1-\frac{1}{N}\right)^{|u|}\right) + \widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g},f), \tag{3.1}$$

where

$$\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g},f) := \sum_{\substack{u\subseteq E\\ u\neq\emptyset}} \gamma_u R(\boldsymbol{g}_u,f).$$

Remark 3.1. It was proved by Joe [8] that if the sequence of weights $(\gamma_i)_{i\geq 1}$ satisfies $\sum_{i=1}^\infty \gamma_i<\infty$, then we have

$$\sum_{\substack{u\subseteq E\\ u\neq\emptyset}} \gamma_u \left(1-\left(1-\frac{1}{N}\right)^{|u|}\right) \leq \frac{\max(1,\Gamma)e^{\sum_{i=1}^\infty \gamma_i}}{N} \quad \text{for all } s\geq 1,$$

where $\Gamma := \sum_{i=1}^\infty \frac{\gamma_i}{1+\gamma_i}$.

In the following proposition we obtain a formula for $\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g},f)$.

PROPOSITION 3.2. *We have*

$$\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g},f) = \sum_{\substack{\boldsymbol{h}\in G^{s}_{p,m}\setminus\{\boldsymbol{0}\}\\ \boldsymbol{g}\cdot\boldsymbol{h}\equiv 0 \pmod f}} \prod_{i=1}^{s} \widetilde{r}_p(h_i,\gamma_i),$$

where

$$\widetilde{r}_p(h,\gamma) := \begin{cases} 1+\gamma & \text{if } h=0,\\ \gamma r_p(h) & \text{if } h\neq 0.\end{cases} \tag{3.2}$$

Proof. Let $\boldsymbol{x}_0, \dots, \boldsymbol{x}_{p^m-1}$ be the point set $P(\boldsymbol{g}, f)$, $\boldsymbol{x}_n = (x_n^{(1)}, \dots, x_n^{(s)})$, $0 \le n \le p^m - 1$. From Lemma 2.13 it follows that for $u \neq \emptyset$ we have

$$R(\boldsymbol{g}_u, f) = -1 + \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i \in u} \left(1 + \sum_{h=1}^{p^m-1} r_p(h) \mathrm{wal}_h(x_n^{(i)})\right).$$

Now we have

$$\begin{aligned}
&\sum_{\substack{u \subseteq E \\ u \neq \emptyset}} \gamma_u R(\boldsymbol{g}_u, f) \\
&= -\sum_{\substack{u \subseteq E \\ u \neq \emptyset}} \gamma_u + \sum_{\substack{u \subseteq E \\ u \neq \emptyset}} \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i \in u} \gamma_i \left(1 + \sum_{h=1}^{p^m-1} r_p(h) \mathrm{wal}_h(x_n^{(i)})\right) \\
&= -\left(-1 + \prod_{i=1}^{s} (1+\gamma_i)\right) + \frac{1}{p^m} \sum_{n=0}^{p^m-1} \left(-1 + \prod_{i=1}^{s} \left(1 + \gamma_i + \gamma_i \sum_{h=1}^{p^m-1} r_p(h) \mathrm{wal}_h(x_n^{(i)})\right)\right) \\
&= -\prod_{i=1}^{s} (1+\gamma_i) + \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i=1}^{s} \left(\sum_{h=0}^{p^m-1} \widetilde{r}_p(h, \gamma_i) \mathrm{wal}_h(x_n^{(i)})\right) \\
&= -\prod_{i=1}^{s} (1+\gamma_i) + \sum_{\boldsymbol{h} \in G_{p,m}^s} \prod_{i=1}^{s} \widetilde{r}_p(h_i, \gamma_i) \frac{1}{p^m} \sum_{n=0}^{p^m-1} \prod_{i=1}^{s} \mathrm{wal}_{h_i}(x_n^{(i)}) \\
&= -\prod_{i=1}^{s} (1+\gamma_i) + \sum_{\substack{\boldsymbol{h} \in G_{p,m}^s \\ \boldsymbol{g} \cdot \boldsymbol{h} \equiv 0 \ (\mathrm{mod}\ f)}} \prod_{i=1}^{s} \widetilde{r}_p(h_i, \gamma_i) \\
&= \sum_{\substack{\boldsymbol{h} \in G_{p,m}^s \setminus \{\boldsymbol{0}\} \\ \boldsymbol{g} \cdot \boldsymbol{h} \equiv 0 \ (\mathrm{mod}\ f)}} \prod_{i=1}^{s} \widetilde{r}_p(h_i, \gamma_i),
\end{aligned}$$

where we used (2.2). □

Proposition 3.2 shows that R and $\widetilde{R}_{\boldsymbol{\gamma}}$ differ only by the definitions of r_p and $\widetilde{r}_p$. Hence the main part of the proofs of the theorems in section 2 apply also for the weighted case. Only Lemma 2.2 needs to be established using $\widetilde{r}_p$. This is done subsequently.

LEMMA 3.3. *Let $\widetilde{r}_p(h, \gamma)$ be given by (3.2). Then we have*

$$\sum_{\boldsymbol{h} \in G_{p,m}^s} \prod_{i=1}^{s} \widetilde{r}_p(h_i, \gamma_i) = \prod_{i=1}^{s} \left(1 + \gamma_i \left(1 + m \frac{p^2-1}{3p}\right)\right).$$

Proof. We have

$$\begin{aligned}
\sum_{\boldsymbol{h} \in G_{p,m}^s} \prod_{i=1}^{s} \widetilde{r}_p(h_i, \gamma_i) &= \prod_{i=1}^{s} \sum_{h \in G_{p,m}} \widetilde{r}_p(h, \gamma_i) = \prod_{i=1}^{s} \left(\widetilde{r}_p(0, \gamma_i) + \sum_{h \in G_{p,m} \setminus \{0\}} \widetilde{r}_p(h, \gamma_i)\right) \\
&= \prod_{i=1}^{s} \left(1 + \gamma_i + \sum_{h \in G_{p,m} \setminus \{0\}} \gamma_i r_p(h)\right) = \prod_{i=1}^{s} \left(1 + \gamma_i \sum_{h \in G_{p,m}} r_p(h)\right)
\end{aligned}$$

and hence the result follows from Lemma 2.2. □

Using Proposition 3.2 and Lemma 3.3 the proofs of the following results can be obtained from section 2.

As for the classical star discrepancy (Theorem 2.3), we can now, for a given irreducible polynomial $f \in \mathbb{F}_p[x]$ with $\deg(f) = m$, compute the average of $\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g}, f)$ over all vectors $\boldsymbol{g} \in (G_{p,m} \setminus \{0\})^s$.

Theorem 3.4. *Let $f \in \mathbb{F}_p[x]$ be irreducible with* $\deg(f) = m$. *We have*

$$\frac{1}{|G_{p,m} \setminus \{0\}|^s} \sum_{\boldsymbol{g} \in (G_{p,m} \setminus \{0\})^s} \widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g}, f) = \frac{1}{p^m - 1} \sum_{\substack{u \subseteq E \\ |u| \geq 2}} \prod_{i \in u} \left(\gamma_i \left(m \frac{p^2 - 1}{3p} \right) \right) \prod_{i \notin u} (1 + \gamma_i) \, .$$

Let $c_p > 0$ be some constant depending only on p and let $\sum_{i=1}^{\infty} \gamma_i < \infty$. Then it was shown in [7] that for every $\delta > 0$ there is some constant $C'_{\boldsymbol{\gamma},\delta} > 0$ such that

$$\text{(3.3)} \quad \frac{1}{p^m - 1} \sum_{\substack{u \subseteq E \\ |u| \geq 2}} \prod_{i \in u} (\gamma_i m c_p) \prod_{i \notin u} (1 + \gamma_i) \leq \frac{1}{p^m - 1} \prod_{i=1}^{s} (1 + \gamma_i (1 + m c_p)) \leq \frac{C'_{\boldsymbol{\gamma},\delta}}{p^{m(1-\delta)}}$$

for all $m > 0$.

Hence it follows from (3.1), Remark 3.1, and (3.3) that if $\sum_{i=1}^{\infty} \gamma_i < \infty$, then for every irreducible polynomial $f \in \mathbb{F}_p[x]$ there exists a constant $C_{\boldsymbol{\gamma},\delta}$, independent of s and m, and a sequence of polynomials $(g_i)_{i \geq 1}$, with $g_i \in G_{p,m} \setminus \{0\}$, such that the star discrepancy of $P((g_1, \ldots, g_s), f)$ satisfies

$$\text{(3.4)} \qquad D^*_{p^m,\boldsymbol{\gamma}}((g_1, \ldots, g_s), f) \leq \frac{C_{\boldsymbol{\gamma},\delta}}{p^{m(1-\delta)}} \quad \text{for all } m, s \geq 1, \text{ and } \delta > 0.$$

We emphasize that in this case the weighted star discrepancy is bounded independently of the dimension. (See [20] for a thorough discussion on (strong) tractability.)

In the following subsection we introduce an algorithm which shows how the polynomials $g_i \in G_{p,m} \setminus \{0\}$, which satisfy a bound of the form (3.4), can be found by computer search.

3.1. A component-by-component construction of $\boldsymbol{P(g, f)}$ based on $\boldsymbol{\widetilde{R}(g, f)}$.

We are now ready to formulate the weighted analogue to Algorithm 2.5 and Theorem 2.7.

Algorithm 3.5. *Given a prime p, $m \geq 1$, a polynomial $f \in \mathbb{F}_p[x]$, with* $\deg(f) = m$, *and a sequence of weights $\boldsymbol{\gamma} = (\gamma_i)_{i \geq 1}$,*

1. *set $g_1^* = 1$;*
2. *for $d = 2, 3, \ldots, s$ find $g_d^* \in G_{p,m} \setminus \{0\}$ by minimizing $\widetilde{R}_{\boldsymbol{\gamma}}((g_1^*, \ldots, g_{d-1}^*, g_d), f)$.*

Remark 3.6. In section 4 it is shown how the quantity $\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g}, f)$ can be calculated in $O(p^m s)$ operations. Hence the cost for Algorithm 3.5 is of $O(p^{2m} s^2)$ operations. This order is the same as for other component-by-component construction algorithms; see Algorithm 2.5 and [2, 8, 19]. Further, in section 5 we explain how the construction cost can be reduced to $O(p^{2m} s)$ operations with an additional storage cost of $O(p^m)$ (see also [19]).

Theorem 3.7. *Let p be prime, $m \geq 1$, and $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$. *Suppose $\boldsymbol{g}^* = (g_1^*, \ldots, g_s^*) \in G_{p,m}^s$ is constructed according to Algorithm* 3.5. *Then for all $d = 1, 2, \ldots, s$ we have*

$$\widetilde{R}_{\boldsymbol{\gamma}}((g_1^*, \ldots, g_d^*), f) \leq \frac{1}{p^m - 1} \prod_{i=1}^{s} \left(1 + \gamma_i \left(1 + m \frac{p^2 - 1}{3p} \right) \right) .$$

From inequality (3.1), Remark 3.1, and Theorem 3.7 we obtain the following corollary.

COROLLARY 3.8. *Let p be prime, $m \geq 1$, $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$, *and* $\gamma_u = \prod_{i \in u} \gamma_i$. *Suppose $\boldsymbol{g}^* \in G_{p,m}^s$ is constructed according to Algorithm* 3.5. *Then we have*

$$D^*_{p^m,\boldsymbol{\gamma}}(\boldsymbol{g}^*, f) \leq \sum_{\substack{u \subseteq E \\ u \neq \emptyset}} \gamma_u \left(1 - \left(1 - \frac{1}{p^m}\right)^{|u|}\right) + \frac{1}{p^m - 1} \prod_{i=1}^{s} \left(1 + \gamma_i \left(1 + m\frac{p^2 - 1}{3p}\right)\right).$$

Hence it follows from Remark 3.1 and (3.3) that if $\sum_{i=1}^{\infty} \gamma_i < \infty$, then there is a constant $\bar{C}_{\boldsymbol{\gamma},\delta}$, independent of s and m, such that

$$D^*_{p^m,\boldsymbol{\gamma}}(\boldsymbol{g}^*, f) \leq \frac{\bar{C}_{\boldsymbol{\gamma},\delta}}{p^{m(1-\delta)}} \quad \text{for all } \delta > 0.$$

Again we emphasize that this bound is independent of the dimension.

3.2. A Korobov construction of $P(g, f)$ based on $\widetilde{R}_\gamma(g, f)$.

As in subsection 2.2, we also have a Korobov construction algorithm for the weighted case.

ALGORITHM 3.9. *Given a prime p, a dimension $s \geq 2$, $m \geq 1$, and an irreducible polynomial $f \in \mathbb{F}_p[x]$, with* $\deg(f) = m$, *and a sequence of weights $\boldsymbol{\gamma} = (\gamma_i)_{i \geq 1}$, find $g^* \in G_{p,m} \setminus \{0\}$ by minimizing $\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{v}_s(g), f)$.*

We have the following result.

THEOREM 3.10. *Let p be a prime, $s \geq 2$, $m \geq 1$, and $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$. *A minimizer g^* obtained from Algorithm* 3.9 *satisfies*

$$\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{v}_s(g^*), f) \leq \frac{s-1}{p^m - 1} \prod_{i=1}^{s} \left(1 + \gamma_i \left(1 + m\frac{p^2 - 1}{3p}\right)\right).$$

We also obtain the following corollary.

COROLLARY 3.11. *Let p be prime, $s \geq 2$, $m \geq 1$, $f \in \mathbb{F}_p[x]$ be irreducible, with* $\deg(f) = m$, *and* $\gamma_u = \prod_{i \in u} \gamma_i$. *Suppose $g^* \in G_{p,m}$ is constructed according to Algorithm* 3.9. *Then we have*

$$D^*_{p^m,\boldsymbol{\gamma}}(\boldsymbol{v}_s(g^*), f) \leq \sum_{\substack{u \subseteq E \\ u \neq \emptyset}} \gamma_u \left(1 - \left(1 - \frac{1}{p^m}\right)^{|u|}\right) + \frac{s-1}{p^m - 1} \prod_{i=1}^{s} \left(1 + \gamma_i \left(1 + m\frac{p^2 - 1}{3p}\right)\right).$$

As in other Korobov-type construction algorithms (see [2, 22]), we obtain an upper bound which depends polynomially on the dimension. Whether an upper bound independent of the dimension can be obtained for Korobov type constructions is an open problem. (Note that this question is open not only for the star discrepancy of polynomial lattices but also for the L_2 discrepancy (see [2]) and for the L_2 discrepancy and the star discrepancy of lattices (see [8, 22]).)

4. Calculation of $R(g, f)$ and $\widetilde{R}_\gamma(g, f)$.

In this section we show how the quantities $R(\boldsymbol{g}, f)$ and $\widetilde{R}(\boldsymbol{g}, f)$ can be computed efficiently. We define

$$\phi_{p,m}(x) := \sum_{h=0}^{p^m - 1} r_p(h) \, {}_p\mathrm{wal}_h(x).$$

Let $\boldsymbol{x} = (x_1, \ldots, x_s)$, $f \in \mathbb{F}_p[x]$, with $\deg(f) = m$, and $\boldsymbol{g} \in G_{p,m}^s$. It follows from Lemma 2.13 that

$$R(\boldsymbol{g}, f) = -1 + \frac{1}{|P(\boldsymbol{g}, f)|} \sum_{\boldsymbol{x} \in P(\boldsymbol{g}, f)} \prod_{i=1}^{s} \phi_{p,m}(x_i). \tag{4.1}$$

In the following we show that the function $\phi_{p,m}$ can be simplified. Let $h = h_0 + h_1 p + \cdots + h_d p^d$ with $h_d \neq 0$. For $0 \leq d < m$ and $1 \leq h_d < p$ let

$$D_{d,h_d,p,m}(x) := \sum_{h=h_d p^d}^{h_d p^d + p^d - 1} {}_p\mathrm{wal}_h(x);$$

then it follows that

$$\phi_{p,m}(x) = 1 + \sum_{d=0}^{m-1} \sum_{h_d=1}^{p-1} r_p(h_d p^d) D_{d,h_d,p,m}(x).$$

Let $\omega_p = e^{2\pi \mathtt{i}/p}$ and $x = \frac{x_1}{p} + \frac{x_2}{p^2} + \cdots$. We have

$$D_{d,h_d,p,m}(x) = \sum_{h=h_d p^d}^{h_d p^d + p^d - 1} {}_p\mathrm{wal}_h(x) = \omega_p^{h_d x_{d+1}} \sum_{h_{d-1}=0}^{p-1} \omega_p^{h_{d-1} x_d} \cdots \sum_{h_0=0}^{p-1} \omega_p^{h_0 x_1}.$$

As $\sum_{h_i=0}^{p-1} \omega_p^{h_i x_{i+1}} = 0$ if $x_{i+1} \neq 0$ and $\sum_{h_i=0}^{p-1} \omega_p^{h_i x_{i+1}} = p$ if $x_{i+1} = 0$ we have

$$D_{d,h_d,p,m}(x) = \begin{cases} \omega_p^{h_d x_{d+1}} p^d & \text{if } x_1 = \cdots = x_d = 0 \text{ or if } d = 0, \\ 0 & \text{otherwise.} \end{cases}$$

We have $r_p(0) = 1$ and for $h > 0$ with $h = h_0 + h_1 p + \cdots + h_d p^d$ and $h_d \neq 0$ we have $r_p(h) = p^{-d-1} \sin^{-2}\left(\frac{h_d \pi}{p}\right)$.

We restate a result from [3, Appendix C] which will be used subsequently. For any $l \in \{0, \ldots, p-1\}$ we have

$$\sum_{h=1}^{p-1} \frac{\omega_p^{hl}}{\sin^2(h\pi/p)} = 2l(l-p) + \frac{p^2-1}{3}. \tag{4.2}$$

First let $x_1 = \cdots = x_m = 0$; then we have

$$\begin{aligned} \phi_{p,m}(x) &= 1 + \sum_{d=0}^{m-1} \sum_{h_d=1}^{p-1} r_p(h_d p^d) p^d = 1 + \sum_{d=0}^{m-1} p^d \sum_{h_d=1}^{p-1} \frac{1}{p^{d+1}} \frac{1}{\sin^2\left(\frac{h_d \pi}{p}\right)} \\ &= 1 + \frac{1}{p} \sum_{d=0}^{m-1} \frac{p^2-1}{3} = 1 + m\frac{p^2-1}{3p}, \end{aligned}$$

where we used (4.2) with $l = 0$.

Let $i_0 = i_0(x)$ be such that $x_1 = \cdots = x_{i_0-1} = 0$ and $x_{i_0} \neq 0$ with $1 \leq i_0 \leq m$. Then we have

$$\begin{aligned}\phi_{p,m}(x) &= 1 + \sum_{d=0}^{m-1} \sum_{h_d=1}^{p-1} r_p(h_d p^d) D_{d,h_d,p,m}(x)\\ &= 1 + \sum_{d=0}^{i_0-2} \sum_{h_d=1}^{p-1} r_p(h_d p^d) p^d + \sum_{h_{i_0-1}=1}^{p-1} r_p(h_{i_0-1} p^{i_0-1}) p^{i_0-1} \omega_p^{h_{i_0-1} x_{i_0}}.\end{aligned}$$

Now

$$\begin{aligned}\sum_{d=0}^{i_0-2} \sum_{h_d=1}^{p-1} r_p(h_d p^d) p^d &= \sum_{d=0}^{i_0-2} \sum_{h_d=1}^{p-1} p^d \frac{1}{p^{d+1}} \frac{1}{\sin^2\left(\frac{h_d \pi}{p}\right)} = \frac{1}{p} \sum_{d=0}^{i_0-2} \sum_{h_d=1}^{p-1} \frac{1}{\sin^2\left(\frac{h_d \pi}{p}\right)}\\ &= \frac{1}{p} \sum_{d=0}^{i_0-2} \frac{p^2-1}{3} = \frac{p^2-1}{3p}(i_0 - 1),\end{aligned}$$

where we used (4.2) with $l = 0$ again. Further we have

$$\begin{aligned}\sum_{h_{i_0-1}=1}^{p-1} r_p(h_{i_0-1} p^{i_0-1}) p^{i_0-1} \omega_p^{h_{i_0-1} x_{i_0}} &= \sum_{k=1}^{p-1} p^{i_0-1} \omega_p^{k x_{i_0}} \frac{1}{p^{i_0}} \frac{1}{\sin^2\left(\frac{k\pi}{p}\right)}\\ &= \frac{1}{p} \sum_{k=1}^{p-1} \frac{\omega_p^{k x_{i_0}}}{\sin^2\left(\frac{k\pi}{p}\right)}\\ &= \frac{1}{p}\left(2 x_{i_0}(x_{i_0} - p) + \frac{p^2-1}{3}\right),\end{aligned}$$

where we used (4.2) with $l = x_{i_0}$. It follows that

$$\phi_{p,m}(x) = 1 + i_0 \frac{p^2-1}{3p} + \frac{2}{p} x_{i_0}(x_{i_0} - p)\,.$$

Thus we have

$$\phi_{p,m}(x) = \begin{cases} 1 + i_0 \frac{p^2-1}{3p} + \frac{2}{p} x_{i_0}(x_{i_0} - p) & \text{if } x_1 = \cdots = x_{i_0-1} = 0 \text{ and } x_{i_0} \neq 0, \\ & \text{with } 1 \leq i_0 \leq m, \\ 1 + m \frac{p^2-1}{3p} & \text{otherwise.} \end{cases} \tag{4.3}$$

Thus using (4.1) and (4.3) we can compute $R(\boldsymbol{g}, f)$ in $O(p^m s)$ operations.

Now we turn to the weighted case. We have

$$\begin{aligned}\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g}, f) &= \sum_{\substack{u \subseteq E\\ u \neq \emptyset}} \gamma_u R(\boldsymbol{g}_u, f) = -\sum_{\substack{u \subseteq E\\ u \neq \emptyset}} \gamma_u + \frac{1}{|P(\boldsymbol{g}, f)|} \sum_{\boldsymbol{x} \in P(\boldsymbol{g}, f)} \sum_{\substack{u \subseteq E\\ u \neq \emptyset}} \gamma_u \prod_{i \in u} \phi_{p,m}(x_i)\\ &= -\prod_{i=1}^{s}(1 + \gamma_i) + \frac{1}{|P(\boldsymbol{g}, f)|} \sum_{\boldsymbol{x} \in P(\boldsymbol{g}, f)} \prod_{i=1}^{s}(1 + \gamma_i \phi_{p,m}(x_i)).\end{aligned}$$

Again this quantity can be computed in $O(p^m s)$ operations using (4.3).

5. Numerical results and discussion. In this section we show how the construction cost can be reduced to $O(p^{2m}s)$ with an additional cost of $O(p^m)$ storage (see also [19]). Further, we point out problems concerning the accuracy of the computation and how those problems can be avoided. Finally we present tables of numerical results, showing the values of $R(\boldsymbol{g}, f)$ and $\widetilde{R}_{\boldsymbol{\gamma}}(\boldsymbol{g}, f)$ of our construction algorithms, and compare them with the choices of $\boldsymbol{g}$ from the so-called Salzburg tables [18].

First we compute $\phi_{p,m}(\varphi_m(\frac{n(x)g(x)}{f(x)}))$ for all possible choices of polynomials n and g and store the results in some array. The computation of the values $\phi_{p,m}(x_{n,k})$ in the expression for R and $\widetilde{R}$ then reduces to picking the corresponding values from the array, performing some multiplication, and adding up the results. It is advantageous to save these tables because they do not depend on the weights and the dimension but only on m, and so they can be reused.

Next we compute R recursively with respect to the dimension in the component-by-component construction. Recall that for given polynomials $g_1, \ldots, g_d$ we compute N points where the kth coordinate depends on g_k. We want to minimize

$$R((g_1, \ldots, g_d, g_{d+1}), f) = -1 + \frac{1}{|P(g_{d+1}))|} \sum_{\boldsymbol{x} \in P(g_{d+1})} \prod_{i=1}^{d+1} \phi_{p,m}(x_i),$$

where we suppressed the dependence of the point set $P(g_{d+1})$ on $g_1, \ldots, g_d$. Disregarding constants this amounts to minimizing the inner product $\sum_{n=0}^{N-1} \Phi_{n,d}\phi_{p,m}(x_{n,d+1})$ where $\Phi_{n,d} = \prod_{i=1}^{d} \phi_{p,m}(x_{n,i})$. Obviously, the numbers $\Phi_{n,d}$ can be computed recursively by

$$\Phi_{n,1} = \phi_{p,m}(x_{n,1}),$$

where the $x_{n,1}$ are generated using the polynomial 1 and

$$\Phi_{n,d+1} = \Phi_{n,d}\phi_{p,m}(x_{n,d+1}),$$

where the $x_{n,d+1}$ are generated by the polynomial g_{d+1} which minimizes the inner product $\sum_{n=0}^{N-1} \Phi_{n,d}\phi_{p,m}(x_{n,d+1})$. In fact we can ignore the first addend since $x_{0,i} = 0$ for all i and therefore $\Phi_{0,d} = (1 + m\frac{p^2-1}{3p})^d$.

The weighted case is a bit more complicated. Recall that in each step we want to minimize

$$\begin{aligned}
&\widetilde{R}((g_1, \ldots, g_d, g_{d+1}), f) \\
&= -\prod_{i=1}^{d+1}(1 + \gamma_i) + \frac{1}{|P(g_{d+1}))|} \sum_{\boldsymbol{x} \in P(g_{d+1})} \prod_{i=1}^{d+1}(1 + \gamma_i \phi_{p,m}(x_i)).
\end{aligned}$$

In principle we could deal with this in the same way as before. But for small weights a computer does not distinguish between $(1 + \gamma_i \phi_{p,m}(x_i))$ and 1. So if we compute the product $\prod_{i=1}^{d+1}(1 + \gamma_i \phi_{p,m}(x_i))$ for small weights we simply get 1. This leads to the well-known effect in component-by-component construction algorithms that from some dimension onward one always gets the same optimizing polynomial.

So this is how we proceed: first disregard the additive constant $-\prod_{i=1}^{d+1}(1 + \gamma_i)$ and the multiplicative constant $\frac{1}{|P(g_{d+1}))|}$. Note that the first addend in the sum is again constant, so we may disregard it for minimization. Then write

$$\begin{aligned}\sum_{n=1}^{N-1}\prod_{i=1}^{d+1}(1+\gamma_i\phi_{p,m}(x_{n,i})) &= \sum_{n=1}^{N-1}\prod_{i=1}^{d}(1+\gamma_i\phi_{p,m}(x_{n,i})) \\ &\quad + \gamma_{d+1}\sum_{n=1}^{N-1}\left(\prod_{i=1}^{d}(1+\gamma_i\phi_{p,m}(x_{n,i}))-1\right)\phi_{p,m}(x_{n,d+1}) \\ &\quad + \gamma_{d+1}\sum_{n=1}^{N-1}\phi_{p,m}(x_{n,d+1})\,.\end{aligned}$$

Obviously the first term does not depend on g_{d+1} and is therefore irrelevant for our minimization problem. But the last term is independent of g_{d+1}, since for an arbitrary g_{d+1} the $x_{n,d+1}$ run through all nonzero m-bit numbers if n runs from 1 to $N-1$ and therefore always give the same sum.

It is therefore sufficient to minimize the inner product

$$\sum_{n=1}^{N-1}\Psi_{n,d}\,\phi_{p,m}(x_{n,d+1}),$$

where $\Psi_{n,d}=(\prod_{i=1}^{d}(1+\gamma_i\phi_{p,m}(x_{n,i}))-1)$. Note that the order of magnitude of $\Psi_{n,d}$ is not 1 (for small weights). We can compute the number $\Psi_{n,d}$ recursively by

$$\Psi_{n,1}=\gamma_1\phi_{p,m}(x_{n,1}),$$

where the $x_{n,1}$ are generated using the polynomial 1 and

$$\Psi_{n,d+1}=\Psi_{n,d}+(\Psi_{n,d}+1)\gamma_{d+1}\phi_{p,m}(x_{n,d+1}),$$

where the $x_{n,d+1}$ are generated by the polynomial g_{d+1} which minimizes the inner product $\sum_{n=1}^{N-1}\Psi_{n,d}\phi_{p,m}(x_{n,d+1})$. Finally, we start with the smallest weight first, i.e., we arrange the weights in increasing order. This seems to have the effect that we do not always get the same polynomial for small weights. Since our proof did not take into account the order of the weights we still get a point set with an $\widetilde{R}$ less than the average. However, as can be seen from Table 5.2, the resulting $\widetilde{R}$ is consistently bigger than for descending order.

In our tables we computed the best R's and $\widetilde{R}$'s for different values of $N=p^m$ and different weights, where we restrict ourselves to the case $p=2$. We write CBC for the component-by-component construction and RCBC (reversed) for the component-by-component construction with weights in ascending order. "Korobov Salztab" means using a Korobov rule with the defining polynomial taken from the Salzburg tables [18]. Since the latter were chosen to minimize the t-parameter of the net instead of R it is not a surprise that it gives a slightly inferior value for R. However, it can be seen that there are differences in the weighted cases, confirming the view that point sets which are good for the unweighted case need not be good for the weighted case. Hence there is a necessity to adjust a point set to some given weights (the weights are determined by the task at hand), and, as we have shown in this paper, this can be achieved using a component-by-component or a Korobov construction algorithm.

In our numerical examples we use point sets consisting of up to 2^{13} points. The same programs can also be used for 2^{15} points, unfortunately requiring a rather long

computation time, although more careful programming might reduce the computation time considerably. For an even greater number of points computing time and storage requirements become too high for a personal computer.

INEXACT SEMIMONOTONIC AUGMENTED LAGRANGIANS WITH OPTIMAL FEASIBILITY CONVERGENCE FOR CONVEX BOUND AND EQUALITY CONSTRAINED QUADRATIC PROGRAMMING[*]

Z. DOSTÁL[†]

Abstract. A variant of the augmented Lagrangian-type algorithm for strictly convex quadratic programming problems with bounds and equality constraints is considered. The algorithm exploits the adaptive precision control in the solution of auxiliary bound constraint problems in the inner loop while the Lagrange multipliers for the equality constraints are updated in the outer loop. The update rule for the penalty parameter is introduced that depends on the increase of the augmented Lagrangian. Global convergence is proved and an explicit bound on the penalty parameter is given. A qualitatively new feature of our algorithm is a bound on the feasibility error that is independent of conditioning of the constraints. When applied to the class of problems with the spectrum of the Hessian matrix in a given interval, the algorithm returns the solution in $O(1)$ matrix-vector multiplications. The results are valid even for linearly dependent constraints. Theoretical results are illustrated by numerical experiments including the solution of an elliptic variational inequality.

1. Introduction.

We shall be concerned with the problem of finding a minimizer of a strictly convex quadratic function subject to simple bounds and linear equality constraints, that is

$$\text{minimize} \quad q(x) \quad \text{subject to (s.t.)} \quad x \in \Omega \tag{1.1}$$

with $\Omega = \{x \in \mathbb{R}^n : x \geq \ell \text{ and } Cx = 0\}$, $q(x) = \frac{1}{2}x^T Ax - b^T x$, $b \in \mathbb{R}^n$, $\ell \in \mathbb{R}^n$, $A \in \mathbb{R}^{n\times n}$ symmetric positive definite, and $C \in \mathbb{R}^{m\times n}$. We do not require that C is a full row rank matrix, as for some large problems it may be not trivial to verify such assumption, but we shall assume that Ω is not empty. Let us point out that confining ourselves to the homogeneous equality constraints does not mean any loss of generality, as we can use a simple transform to reduce any nonhomogeneous equality constraints to our case. Moreover, our results may be useful also in the more general case when A is positive definite only on the kernel of C, i.e., when only $R^T AR$ is positive definite with the matrix R formed by the basis of the kernel of C. The modification of our algorithm can be based on observation that in the latter case there is $\widehat{\rho} > 0$ such that $A + \widehat{\rho} C^T C$ is positive definite and that the problem (1.1) has the same solution as the problem

$$\text{minimize} \quad \widehat{q}(x) \quad \text{s.t.} \quad x \in \Omega, \quad \widehat{q}(x) = \frac{1}{2}x^T(A + \widehat{\rho} C^T C)x - b^T x.$$

We shall be especially interested in problems with the matrix A reasonably conditioned and either large and sparse or defined as a product of large and sparse matrices, so that the conjugate gradient–based methods are more efficient for the unconstrained minimization of q than the direct solvers. We shall also assume that the matrix C is sparse. Such problems arise, for example, from the discretization of semicoercive elliptic variational inequalities (e.g., Dostál [7]) or from application of the duality-based domain decomposition to the contact problems of elasticity (e.g., Dostál, Friedlander, and Santos [12], Dostál, Gomes Neto, and Santos [16] or Avery et al. [1]).

We restrict our attention to the algorithms that reduce problem (1.1) to a sequence of bound constrained quadratic programming problems. Our approach has been motivated by an effort to exploit recent progress in the solution of the latter problems, namely, effective application of projections and adaptive precision control of the solution of auxiliary problems (e.g., [23, 4, 8]). Most recently, these results were combined with the results on the gradient projections [29] to get algorithms with the R-linear rate of convergence in terms of the bounds on the spectrum of A [10, 21]. It simply follows that such algorithms can solve any class of problems with the spectrum of the Hessian matrix in a given interval $[a, b]$, $a > 0$, at the cost of $O(1)$ matrix-vector multiplications. These results were applied to the development of some optimal (i.e., with linear complexity) algorithms for the solution of elliptic boundary variational inequalities [18, 19, 20].

Our development is based on the algorithm proposed by Conn, Gould and Toint [5], who adapted the augmented Lagrangian method [2, 24] of Powell [28] and Hestenes [26] to the solution of problems with a general cost function subject to general equality constraints and simple bounds. When applied to (1.1), their algorithm reduces the solution to a sequence of simple bound constrained problems of the form

$$\text{minimize} \quad L(x, \mu^k, \rho_k) \quad \text{s.t.} \quad x \geq \ell, \tag{1.2}$$

where

$$L(x, \mu^k, \rho_k) = q(x) + (\mu^k)^T Cx + \frac{\rho_k}{2}\|Cx\|^2 \tag{1.3}$$

is known as the augmented Lagrangian function, $\mu^k = (\mu_1^k, \dots, \mu_m^k)^T$ is the vector of Lagrange multipliers for the equality constraints, ρ_k is the penalty parameter, and $\|\cdot\|$ denotes the Euclidean norm. In [5] the authors developed basic methods of analysis, proved the convergence results that cover also the possibility of solving inexactly the auxiliary problems (1.2), and established that a potentially troublesome penalty parameter is bounded. They implemented successfully their algorithm using the well-known package LANCELOT [6]. Later, Friedlander and Santos with the present author [15] proposed an adaptive precision control of the solution of the auxiliary problems (1.2) based on simple observation that the precision of the solution x^k of the auxiliary problems (1.2) should be related to the feasibility of x^k, i.e., $\|Cx^k\|$, since it does not seem reasonable to solve (1.2) to the high precision when μ^k is still far from the Lagrange multiplier corresponding to the solution of (1.1). Due to the choice introduced for the precision control, we obtained an estimate of the rate of convergence that does not have any term accounting for the inexact minimization. Moreover, it was proved that the penalty parameter generated by our algorithm remains bounded even with the inexact minimization of the auxiliary problems. It was also demonstrated that large penalty parameters need not slow down the rate of convergence in the inner loop [9]. The latter algorithm was then extensively used in development of parallel algorithms for the solution of variational inequalities [12, 16, 17]. For example, in combination with duality-based domain decomposition methods, the algorithm required as few as 65 conjugate gradient iterations and 3 outer iterations to solve an elliptic variational inequality discretized by 8,454,272 nodes with 2049 nodes on the contact interface [18], much cheaper then one direct solve of the related linear problem. Let us point out that the precision control that we use was proposed by Hager [25] for the solution of equality constrained problems by the augmented Lagrangian method with the least squares update of Lagrange multipliers.

Despite the improved results on the rate of convergence, the analysis in [15] indicates fast deterioration of the rate of convergence of the Lagrange multipliers with the diminishing smallest eigenvalue of $\widehat{C}\widehat{A}^{-1}\widehat{C}^T$, where $\widehat{C}$ is formed by the columns of C with indices of the constraints that are not active at the solution and $\widehat{A}$ is the corresponding diagonal block of A. This is not surprising, because when the matrix $\widehat{C}$ is not a full row rank matrix, then the multipliers of the solution are not uniquely determined and there is no reason to expect fast convergence when the rows of $\widehat{C}$ are nearly dependent. In fact, the analysis of [6, 15] requires that the solution is regular, i.e., that $\widehat{C}$ is a full column rank matrix. Moreover, the estimate assumes large values of the penalty parameter that are also related to the conditioning of $\widehat{C}\widehat{A}^{-1}\widehat{C}^T$. The results turned out to be insufficient to prove numerical scalability of our algorithms for solution of variational inequalities, despite the experimental evidence [17].

In this paper we show that it is possible to get results on convergence of the feasibility error that are independent of the conditioning of the equality constraints. Our main tool is a simple explicit bound on the penalty parameter [11] which guarantees an increase of the augmented Lagrangian provided the precision of the solution x^k of the auxiliary bound constrained problems is proportional to the feasibility error $\|Cx^k\|$. We exploit this observation to propose a new, less aggressive update rule for the penalty parameter which enables one to get an upper bound on the rate of convergence of $\|Cx^k\|$ that is independent of the eigenvalues of $\widehat{C}\widehat{A}^{-1}\widehat{C}^T$ as well as an explicit bound on the penalty parameter that is fully independent of the constraints data. When implemented with one of the algorithms mentioned above in the inner loop and applied to the class of problems with the spectrum of the Hessian matrix in a given interval of positive numbers, our new algorithm returns the solution of (1.1) in $O(1)$ matrix-vector multiplications. Our results on the rate of convergence of the algorithm remain valid even for the constraint matrix with dependent rows.

In section 2 we present the algorithm and prove that it is well defined. In section 3 we prove simple inequalities that will be exploited in the analysis of the algorithm in section 4. In section 5 we give new results on the convergence of the feasibility error that are independent of the form of the constraints and give a result on the "optimality" of the feasibility error estimate. The convergence results are presented in section 6. The results are illustrated on numerical solution of model problems in section 7. Finally, some conclusions are discussed in section 8.

2. Notation and preliminaries. Given nonempty sets of indices $\mathcal{I}, \mathcal{J} \subseteq \mathcal{N} \equiv \{1, \dots, n\}$, a matrix B, and a vector x, we define the submatrix $B_{\mathcal{I}\mathcal{J}}$ and the subvector $x_{\mathcal{I}}$ that comprise rows and columns determined by the sets $\mathcal{I}, \mathcal{J}$. For the matrix C of problem (1.1), we shall denote by $C_{\mathcal{J}}$ the submatrix of C formed by the same rows as C and columns in $\mathcal{J}$.

The first order update of the vector of Lagrange multipliers of the problem (1.1) and the gradients of the augmented Lagrangians (1.3) will be denoted, respectively, by

$$\widetilde{\mu} = \mu + \rho C x \tag{2.1}$$

and

$$g(x, \mu, \rho) = \nabla_x L(x, \mu, \rho) = \nabla q(x) + C^T \mu + \rho C^T C x. \tag{2.2}$$

For each vector $v = (v_1, \ldots, v_p) \in \mathbb{R}^p$, we shall denote by

$$\|v\| = (v_1^2 + v_2^2 + \cdots + v_p^2)^{1/2} \quad \text{and} \quad \|\mathrm{v}\|_1 = |\mathrm{v}_1| + |\mathrm{v}_2| + \cdots + |\mathrm{v}_\mathrm{p}|$$

its Euclidean and ℓ_1-norms, respectively.

Since problem (1.1) comprises minimization of a strictly convex cost function on a convex set, it is well known (e.g., [3]) that its solution x^* exists and is necessarily unique. It satisfies the Karush–Kuhn–Tucker (KKT) conditions for problems that may be conveniently described by the *projected gradient* g^P that is defined by

$$\begin{array}{lcllll} g_i^P(x, \mu, \rho) & = & g_i(x, \mu, \rho) & \text{if} \;\; x_i > \ell_i \;\; \text{or} & x_i = \ell_i & \text{and} \;\; g_i(x, \mu, \rho) < 0, \\ g_i^P(x, \mu, \rho) & = & 0 & \text{otherwise, i.e.,} & x_i = \ell_i & \text{and} \;\; g_i(x, \mu, \rho) \geq 0, \end{array} \tag{2.3}$$

where $g(x, \mu, \rho) = (g_1, \ldots, g_n)^T$. Thus the solution x^* is the only feasible (for problem (1.1)) vector for which there is μ such that $g^P(x, \mu, 0) = 0$, and the KKT conditions for problem (1.2) are satisfied at $x \geq \ell$ if and only if there is μ such that $g^P(x, \mu, \rho) = 0$.

For each vector $x \in \mathbb{R}^n$, we shall denote by $\mathcal{A}(x)$ and $\mathcal{F}(x)$ the *active* and *free* set of x, respectively, so that

$$\mathcal{A}(x) = \{i \in \mathcal{N} : x_i = \ell_i\} \;\; \text{and} \;\; \mathcal{F}(\mathrm{x}) = \{\mathrm{i} \in \mathcal{N} : \mathrm{x}_\mathrm{i} \neq \ell_\mathrm{i}\}.$$

We shall also define the *binding* set

$$\mathcal{B}(x, \mu, \rho) = \{i \in \mathcal{A}(x) : g_i(x, \mu, \rho) \geq 0\}.$$

Thus $\mathcal{B}(x, \mu, \rho)$ comprises the indices of the active constraints that satisfy the KKT conditions for problem (1.2).

As mentioned, the earlier papers required that the solution $x^* \in \Omega$ of problem (1.1) is *regular*, i.e., that the gradients of all the active constraints (equalities and inequalities) at x^* are linearly independent. We will not need this assumption here, although we will be able to prove some stronger results if the solution is regular.

3. Semimonotonic algorithm for bound and equality constraints.

The following algorithm is a modification of the classical augmented Lagrangian method for the solution of strictly convex quadratic programming problems with equality constraints that enables adaptive precision control of the solution of auxiliary problems.

ALGORITHM 3.1. Given $\eta > 0,\; \beta > 1,\; M > 0,\; \rho_0 > 0,$ and $\mu^0 \in \mathbb{R}^m$, set $k = 0$.

Step 1. {Inner iteration with adaptive precision control.}

Find x^k such that

$$\|g^P(x^k, \mu^k, \rho_k)\| \leq \min\{M\|Cx^k\|, \eta\}. \tag{3.1}$$

Step 2. {Update μ.}

$$\mu^{k+1} = \mu^k + \rho_k C x^k. \tag{3.2}$$

Step 3. {Update ρ provided the increase of the Lagrangian is not sufficient.}
If $k > 0$ and

$$L(x^k, \mu^k, \rho^k) < L(x^{k-1}, \mu^{k-1}, \rho_{k-1}) + \frac{\rho_k}{2}\|Cx^k\|^2, \tag{3.3}$$

then

$$\rho_{k+1} = \beta\rho_k; \tag{3.4}$$

else

$$\rho_{k+1} = \rho_k. \tag{3.5}$$

Step 4. Set $k = k + 1$ and return to Step 1.

In Step 1 we can use any convergent algorithm for minimizing the strictly convex quadratic function subject to the bound constraints, such as [23, 4, 10, 21, 8]. Let us point out that Algorithm 3.1 differs from those considered by Conn, Gould, and Toint [5] or Dostál, Friedlander, and Santos [15] by the condition on the update of the penalization parameter in Step 3.

The next lemma shows that Algorithm 3.1 is well defined, that is, any convergent algorithm for the solution of the auxiliary problem required in Step 1 will generate either x^k that satisfies (3.1) in a finite number of steps or a sequence of approximations that converges to the solution of (1.1). It is also clear that there is no hidden enforcement of exact solution in (3.1) and consequently typically inexact solutions of the auxiliary unconstrained problems are obtained in Step 1.

Lemma 3.1. *Let $M > 0, \mu \in \mathbb{R}^m$, and $\rho \geq 0$ be given and let $\{y^k\}$ denote any sequence that converges to the unique solution $\overline{y}$ of the problem*

$$\textit{minimize} \quad L(y, \mu, \rho) \quad \textit{s.t.} \quad y \geq \ell. \tag{3.6}$$

Then either $\{y^k\}$ converges to the solution $\widehat{x}$ of problem (1.1) *or there is an index k such that*

$$\|g^P(y^k, \mu, \rho)\| \leq \min\{M\|Cy^k\|, \eta\}. \tag{3.7}$$

Proof. See [15]. □

4. Inequalities involving the augmented Lagrangian. In this section we shall establish basic inequalities that relate the bound on the norm of the gradient g of the augmented Lagrangian L to the values of the augmented Lagrangian L. These inequalities will be the key ingredients in the proof of convergence of Algorithm 3.1.

Lemma 4.1. *Let $x, y, \ell \in \mathbb{R}^n,\ x \geq \ell,\ y \geq \ell,\ \mu \in \mathbb{R}^m,\ \rho > 0,\ \eta > 0,$ and $M > 0$. Let α denote the least eigenvalue of A and $\widetilde{\mu} = \mu + \rho Cx$.*

(i) *If*

$$\|g^P(x, \mu, \rho)\| \leq M\|Cx\|, \tag{4.1}$$

then

$$L(y, \widetilde{\mu}, \rho) \geq L(x, \mu, \rho) + \frac{1}{2}\left(\rho - \frac{M^2}{\alpha}\right)\|Cx\|^2 + \frac{\rho}{2}\|Cy\|^2. \tag{4.2}$$

(ii) *If*

$$\|g^P(x, \mu, \rho)\| \leq \eta, \tag{4.3}$$

then

$$L(y,\widetilde{\mu},\rho) \geq L(x,\mu,\rho) + \frac{\rho}{2}\|Cx\|^2 + \frac{\rho}{2}\|Cy\|^2 - \frac{\eta^2}{2\alpha}. \tag{4.4}$$

(iii) *If* (4.3) *holds and* $z_0 \in \Omega$, *then*

$$L(x,\mu,\rho) \leq q(z_0) + \frac{\eta^2}{2\alpha}. \tag{4.5}$$

Proof. Let us denote $\delta = y - x$, $H = A + \rho C^T C$ and recall that we assume $x \geq \ell$ and $y \geq \ell$, so that it may be easily verified that

$$\delta^T g^P(x,\mu,\rho) \leq \delta^T g(x,\mu,\rho).$$

Using the latter inequality with

$$L(x,\widetilde{\mu},\rho) = L(x,\mu,\rho) + \rho\|Cx\|^2 \quad \text{and} \quad g(x,\widetilde{\mu},\rho) = g(x,\mu,\rho) + \rho C^T Cx,$$

we get

$$\begin{aligned}
L(y,\widetilde{\mu},\rho) &= L(x,\widetilde{\mu},\rho) + \delta^T g(x,\widetilde{\mu},\rho) + \frac{1}{2}\delta^T H\delta \\
&= L(x,\mu,\rho) + \delta^T g(x,\mu,\rho) + \rho\delta^T C^T Cx + \frac{1}{2}\delta^T H\delta + \rho\|Cx\|^2 \\
&\geq L(x,\mu,\rho) + \delta^T g^P(x,\mu,\rho) + \rho\delta^T C^T Cx + \frac{1}{2}\delta^T H\delta + \rho\|Cx\|^2 \\
&\geq L(x,\mu,\rho) + \delta^T g^P(x,\mu,\rho) + \rho\delta^T C^T Cx + \frac{\alpha}{2}\|\delta\|^2 + \frac{\rho}{2}\|C\delta\|^2 + \rho\|Cx\|^2.
\end{aligned}$$

Noticing that

$$\frac{\rho}{2}\|Cy\|^2 = \frac{\rho}{2}\|C(\delta + x)\|^2 = \rho\delta^T C^T Cx + \frac{\rho}{2}\|C\delta\|^2 + \frac{\rho}{2}\|Cx\|^2,$$

we obtain

$$L(y,\widetilde{\mu},\rho) \geq L(x,\mu,\rho) + \delta^T g^P(x,\mu,\rho) + \frac{\alpha}{2}\|\delta\|^2 + \frac{\rho}{2}\|Cx\|^2 + \frac{\rho}{2}\|Cy\|^2. \tag{4.6}$$

Using (4.1) and simple manipulations we obtain

$$\begin{aligned}
L(y,\widetilde{\mu},\rho) &\geq L(x,\mu,\rho) - M\|\delta\|\|Cx\| + \frac{\alpha}{2}\|\delta\|^2 + \frac{\rho}{2}\|Cx\|^2 + \frac{\rho}{2}\|Cy\|^2 \\
&= L(x,\mu,\rho) + \left(\frac{\alpha}{2}\|\delta\|^2 - M\|\delta\|\|Cx\| + \frac{M^2\|Cx\|^2}{2\alpha}\right) \\
&\quad - \frac{M^2\|Cx\|^2}{2\alpha} + \frac{\rho}{2}\|Cx\|^2 + \frac{\rho}{2}\|Cy\|^2 \\
&\geq L(x,\mu,\rho) + \frac{1}{2}\left(\rho - \frac{M^2}{\alpha}\right)\|Cx\|^2 + \frac{\rho}{2}\|Cy\|^2,
\end{aligned}$$

which proves (i).

If we assume that (4.3) holds, then by (4.6)

$$\begin{aligned}
L(y,\widetilde{\mu},\rho) &\geq L(x,\mu,\rho) - \|\delta\|\eta + \frac{\alpha}{2}\|\delta\|^2 + \frac{\rho}{2}\|Cx\|^2 + \frac{\rho}{2}\|Cy\|^2 \\
&\geq L(x,\mu,\rho) + \frac{\rho}{2}\|Cx\|^2 + \frac{\rho}{2}\|Cy\|^2 - \frac{\eta^2}{2\alpha},
\end{aligned}$$

which proves (ii).

Finally, let $\overline{x}$ denote the solution of the auxiliary problem

$$\text{minimize } \ L(z,\mu,\rho) \ \text{ s.t. } \ z \geq \ell, \tag{4.7}$$

let $z_0 \in \Omega$ so that $Cz_0 = 0$, and let $\overline{\delta} = \overline{x} - x$. If (4.3) holds, then

$$0 \geq L(\overline{x},\mu,\rho) - L(x,\mu,\rho) = \overline{\delta}^T g(x,\mu,\rho) + \frac{1}{2}\overline{\delta}^T H\overline{\delta} \geq \overline{\delta}^T g^P(x,\mu,\rho) + \frac{1}{2}\overline{\delta}^T H\overline{\delta}$$
$$\geq -\|\overline{\delta}\|\eta + \frac{1}{2}\alpha\|\overline{\delta}\|^2 \geq -\frac{\eta^2}{2\alpha}.$$

Since $L(\overline{x},\mu,\rho) \leq L(z_0,\mu,\rho) = q(z_0)$, we conclude that

$$L(x,\mu,\rho) \leq L(x,\mu,\rho) - L(\overline{x},\mu,\rho) + q(z_0) \leq q(z_0) + \frac{\eta^2}{2\alpha}. \qquad \square$$

5. Monotonicity and feasibility.

LEMMA 5.1. *Let $\{x^k\}, \{\mu^k\}$, and $\{\rho_k\}$ be generated by Algorithm* 3.1 *with $\eta > 0$, $\beta > 1$, $M > 0$, $\rho_0 > 0$, and $\mu^0 \in \mathbb{R}^m$. Let α denote the least eigenvalue of the Hessian A of the quadratic q.*

(i) *If $k \geq 0$ and*

$$\rho_k \geq M^2/\alpha, \tag{5.1}$$

then

$$L(x^{k+1},\mu^{k+1},\rho_{k+1}) \geq L(x^k,\mu^k,\rho_k) + \frac{\rho_{k+1}}{2}\|Cx^{k+1}\|^2. \tag{5.2}$$

(ii) *For any $k \geq 0$*

$$L(x^{k+1},\mu^{k+1},\rho_{k+1}) \geq L(x^k,\mu^k,\rho_k) + \frac{\rho_k}{2}\|Cx^k\|^2 + \frac{\rho_{k+1}}{2}\|Cx^{k+1}\|^2 - \frac{\eta^2}{2\alpha}. \tag{5.3}$$

(iii) *For any $k \geq 0$ and $z_0 \in \Omega$*

$$L(x^k,\mu^k,\rho_k) \leq q(z_0) + \frac{\eta^2}{2\alpha}. \tag{5.4}$$

Proof. Let us substitute in Lemma 4.1 $x = x^k, \mu = \mu^k, \rho = \rho_k, y = x^{k+1}$, so that by (3.1) the inequality (4.1) holds and by (3.2) $\widetilde{\mu} = \mu^{k+1}$.

If (5.1) holds, we shall get by (4.2)

$$L(x^{k+1},\mu^{k+1},\rho_k) \geq L(x^k,\mu^k,\rho_k) + \frac{\rho_k}{2}\|Cx^{k+1}\|^2. \tag{5.5}$$

To prove (5.2), it is enough to add

$$\frac{\rho_{k+1}-\rho_k}{2}\|Cx^{k+1}\|^2 \tag{5.6}$$

to both sides of (5.5) and to use that

$$L(x^{k+1},\mu^{k+1},\rho_{k+1}) = L(x^{k+1},\mu^{k+1},\rho_k) + \frac{\rho_{k+1}-\rho_k}{2}\|Cx^{k+1}\|^2. \tag{5.7}$$

If we notice that, by the definition of Step 1 of Algorithm 3.1,

$$\|g(x^k, \mu^k, \rho_k)\| \leq \eta$$

and apply the same substitution as above to Lemma 3.1(ii), we shall get

$$L(x^{k+1}, \mu^{k+1}, \rho_k) \geq L(x^k, \mu^k, \rho_k) + \frac{\rho_k}{2}\|Cx^k\|^2 + \frac{\rho_k}{2}\|Cx^{k+1}\|^2 - \frac{\eta^2}{2\alpha}, \tag{5.8}$$

so that, after adding the nonnegative expression (5.6) to both sides of (5.8) and using (5.7), we get (5.3). Similarly, the definition of Algorithm 2.1 and application of the substitution to Lemma 4.1(iii) implies the inequality (5.4). □

THEOREM 5.2. *Let $\{x^k\}, \{\mu^k\}$, and $\{\rho_k\}$ be generated by Algorithm* 3.1 *with $\eta > 0,\ \beta > 1,\ M > 0,\ \rho_0 > 0,\ \ \mu^0 \in \mathbb{R}^m$. Let α denote the least eigenvalue of the Hessian A of the quadratic q and let $s \geq 0$ denote the smallest integer such that $\beta^s \rho_0 \geq M^2/\alpha$.*

(i) *The sequence $\{\rho_k\}$ is bounded and*

$$\rho_k \leq \beta^s \rho_0. \tag{5.9}$$

(ii) *If $z_0 \in \Omega$, then*

$$\sum_{k=1}^{\infty} \frac{\rho_k}{2}\|Cx^k\|^2 \leq q(z_0) - L(x^0, \mu^0, \rho_0) + (1+s)\frac{\eta^2}{2\alpha}. \tag{5.10}$$

(iii) *$\|Cx^k\|$ converges to* 0.

Proof. Let $s \geq 0$ denote the smallest integer such that $\beta^s \rho_0 \geq M^2/\alpha$ and let $\mathcal{I}$ denote the set of all indices k_i such that $\{\rho_{k_i}\}$ are generated in Step 3 of Algorithm 3.1 by (3.4). Using Lemma 5.1(i), $\rho_{k_i} = \beta\rho_{k_{i-1}} = \beta^i \rho_0$ for $k_i \in \mathcal{I}$, and $\beta^s \rho_0 \geq M^2/\alpha$, we conclude that there is no k such that $\rho_k > \beta^s \rho_0$. Thus $\mathcal{I}$ has at most s elements and (5.9) holds.

By the definition of Step 3, for $k > 0$ either $k+1 \notin \mathcal{I}$ and

$$\frac{\rho_k}{2}\|Cx^k\|^2 \leq L(x^k, \mu^k, \rho_k) - L(x^{k-1}, \mu^{k-1}, \rho_{k-1})$$

or $k+1 \in \mathcal{I}$ and by (5.3)

$$\begin{aligned}\frac{\rho_k}{2}\|Cx^k\|^2 &\leq \frac{\rho_{k-1}}{2}\|Cx^{k-1}\|^2 + \frac{\rho_k}{2}\|Cx^k\|^2 \\ &\leq L(x^k, \mu^k, \rho_k) - L(x^{k-1}, \mu^{k-1}, \rho_{k-1}) + \frac{\eta^2}{2\alpha}.\end{aligned}$$

Summing up appropriate cases of the last two inequalities for $k = 1, \ldots, n$ and taking into account that $\mathcal{I}$ has at most s elements, we get

$$\sum_{k=1}^{n} \frac{\rho_k}{2}\|Cx^k\|^2 \leq L(x^n, \mu^n, \rho_n) - L(x^0, \mu^0, \rho_0) + s\frac{\eta^2}{2\alpha}. \tag{5.11}$$

To get (5.10), it is enough to replace $L(x^n, \mu^n, \rho_n)$ by the upper bound (5.4).

Statement (iii) is an immediate consequence of (ii). □

Theorem 5.2 suggests that it is possible to give a uniform upper bound on the number of the outer iterations of Algorithm 3.1 that is necessary to achieve a prescribed feasibility error for any problem of (5.12). To present explicitly this qualitatively new feature of Algorithm 3.1, at least as compared to the related algorithms [15], let $\mathcal{T}$ denote any set of indices and let for any $t \in \mathcal{T}$ be defined a problem

$$\text{minimize } \; q_t(x) \;\text{ s.t. }\; x \in \Omega_t \tag{5.12}$$

with $\Omega_t = \{x \in \mathbb{R}^{n_t} : C_t x = 0 \;\text{ and }\; x \geq \ell_t\}$, $q_t(x) = \frac{1}{2}x^T A_t x - b_t^T x$, $A_t \in \mathbb{R}^{n_t \times n_t}$ symmetric positive definite, $C_t \in \mathbb{R}^{m_t \times n_t}$, and $b_t, \ell_t \in \mathbb{R}^{n_t}$. To simplify our exposition, we shall assume that the bound constraints ℓ_t are not positive so that $0 \in \Omega_t$. Our optimality result reads as follows.

Theorem 5.3. *Let $\{x_t^k\}, \{\mu_t^k\}$, and $\{\rho_{t,k}\}$ be generated by Algorithm 3.1 for (5.12) with $\|b_t\| \geq \eta_t > 0$, $\beta > 1$, $M > 0$, $\rho_{t,0} = \rho_0 > 0$, $\mu_t^0 = 0$. Let there be an $\alpha > 0$ such that the least eigenvalue α_t of the Hessian A_t of the quadratics q_t satisfies $\alpha_t \geq \alpha$, and let $s \geq 0$ denote the smallest integer such that $\beta^s \rho_0 \geq M^2/\alpha$. Then for each $\epsilon > 0$ and*

$$j \geq \frac{2+s}{\epsilon^2 \alpha \rho_0} \tag{5.13}$$

there are indices k_t such that

$$k_t \leq j \;\; \text{and} \;\; M^{-1}\|g^P(x_t^{k_t}, \mu_t^{k_t}, \rho_{t,k_t})\| \leq \|C_t x_t^{k_t}\| \leq \epsilon \|b_t\|. \tag{5.14}$$

Proof. First notice that for any index k

$$\frac{\rho_0 k}{2} \min\{\|C_t x_t^i\|^2 : i = 1, \dots, k\} \leq \sum_{i=1}^{k} \frac{\rho_{t,i}}{2}\|C_t x_t^i\|^2 \leq \sum_{i=1}^{\infty} \frac{\rho_{t,i}}{2}\|C_t x_t^i\|^2. \tag{5.15}$$

Denoting by $L_t(x, \mu, \rho)$ the augmented Lagrangian for the problem (5.12), we get for any $x \in \mathbb{R}^p$ and $\rho \geq 0$

$$L_t(x, 0, \rho) = \frac{1}{2}x^T(A_t + \rho C_t^T C_t)x - b_t^T x \geq \frac{1}{2}\alpha\|x\|^2 - \|b_t\|\|x\| \geq -\frac{\|b_t\|^2}{2\alpha}.$$

If we substitute this inequality and $z_0 = 0$ to (5.10) and use the assumption $\|b_t\| \geq \eta_t$, we get

$$\sum_{i=1}^{\infty} \frac{\rho_i}{2}\|C_t x_t^i\|^2 \leq \frac{\|b_t\|^2}{2\alpha} + (1+s)\frac{\eta^2}{2\alpha} \leq \frac{(2+s)\|b_t\|^2}{2\alpha}. \tag{5.16}$$

Taking for j any integer that satisfies (5.13) and denoting for any $t \in \mathcal{T}$ by $k_t \in \{1, \dots, j\}$ the index which minimizes $\{\|C_t x_t^i\| : i = 1, \dots, j\}$, we can use (5.15) and (5.16) with simple manipulations to obtain

$$\|C_t x_t^{k_t}\|^2 = \min\{\|C_t x_t^i\|^2 : i = 1, \dots, k\} \leq \frac{(2+s)\|b_t\|^2}{j\alpha\rho_0} \leq \epsilon^2\|b_t\|^2.$$

The inequality

$$M^{-1}\|g^P(x_t^{k_t}, \mu_t^{k_t}, \rho_{t,k_t})\| \leq \|C_t x_t^{k_t}\|$$

results easily from the definition of Step 1 of Algorithm 3.1. □

6. Convergence.

Lemma 6.1. *Let $\{x^k\}, \{\mu^k\}$, and $\{\rho_k\}$ be generated by Algorithm* 3.1 *with $\eta > 0,\ \beta > 1,\ M > 0,\ \rho_0 > 0,\ \ \mu^0 \in \mathbb{R}^m$. Then the sequence $\{x^k\}$ is bounded.*

Proof. Since there is only a finite number of different subsets $\mathcal{F}$ of $\mathcal{N}$ and $\{x^k\}$ is bounded if and only if $\{x^k_{\mathcal{F}(x^k)}\}$ is bounded, we can restrict our attention to analysis of infinite subsequences $\{x^k_{\mathcal{F}} : \mathcal{F}(x^k) = \mathcal{F}\}$ that are defined by nonempty subsets $\mathcal{F}$ of $\mathcal{N}$.

Let $\mathcal{F} \subseteq \mathcal{N},\ \mathcal{F} \neq \emptyset$ be such that $\{x^k : \mathcal{F}(x^k) = \mathcal{F}\}$ is infinite and denote $\mathcal{A} = \mathcal{N} \setminus \mathcal{F}$. Using Theorem 5.2(i), we get that there is an integer k_0 such that $\rho_k = \rho_{k_0}$ for $k \geq k_0$. Thus, for $k \geq k_0$, we can denote $H = A + \rho_k C^T C$ and

$$g^k = g(x^k, \mu^k, \rho_k) = Hx^k + C^T\mu^k - b,$$

so that

$$\begin{pmatrix} H_{\mathcal{F}\mathcal{F}} & C_{\mathcal{F}}^T \\ C_{\mathcal{F}} & 0 \end{pmatrix} \begin{pmatrix} x^k_{\mathcal{F}} \\ \mu^k \end{pmatrix} = \begin{pmatrix} g^k_{\mathcal{F}} + b_{\mathcal{F}} - H_{\mathcal{F}\mathcal{A}}\ell_{\mathcal{A}} \\ C_{\mathcal{F}}x^k_{\mathcal{F}} \end{pmatrix}. \tag{6.1}$$

Since $C_{\mathcal{F}}x^k_{\mathcal{F}} = Cx^k - C_{\mathcal{A}}\ell_{\mathcal{A}},\ \|g^k_{\mathcal{F}}\| = \|g_{\mathcal{F}}(x^k, \mu^k, \rho_k)\| \leq \|g^P(x^k\mu^k, \rho_k)\|$, and both $\|g^P(x^k, \mu^k, \rho_k)\|$ and $\|Cx^k\|$ converge to zero, the right-hand side of (6.1) is bounded. Thus both x^k and μ^k are bounded provided the matrix of the system (6.1) is regular. This happens when $C_{\mathcal{F}}$ is a full row rank matrix (e.g., [13]).

If $C_{\mathcal{F}} \in \mathbb{R}^{ps}$ is not a full row rank matrix, then its rank r satisfies $r < p$ and by the singular value decomposition theorem (see Theorem 7.3.5 in [27]) there are orthogonal matrices $U = (u_1, \dots, u_p)^T$, $V = (v_1, \dots, v_s)^T$ and a matrix $\Sigma \in \mathbb{R}^{ps}$ defined by a diagonal matrix $D = \operatorname{diag}(\sigma_1, \dots, \sigma_r, 0, \dots, 0) \in \mathbb{R}^{t \times t},\ t = \min\{p, s\}$ padded with zeros so that $C_{\mathcal{F}} = U^T\Sigma V$. Thus, taking $\widehat{U} = (u_1, \dots, u_r)^T$, $\widehat{D} = \operatorname{diag}(\sigma_1, \dots, \sigma_r)$ and $\widehat{V} = (v_1, \dots, v_r)^T$, we have $C_{\mathcal{F}} = \widehat{U}^T\widehat{D}\widehat{V}$ and we can define a full row rank matrix

$$\widehat{C}_{\mathcal{F}} = \ \widehat{D}\widehat{V} = \widehat{U}C_{\mathcal{F}}$$

that satisfies $\widehat{C}_{\mathcal{F}}^T\widehat{C}_{\mathcal{F}} = C_{\mathcal{F}}^TC_{\mathcal{F}}$ and $\|\widehat{C}_{\mathcal{F}}x_{\mathcal{F}}\| = \|C_{\mathcal{F}}x_{\mathcal{F}}\|$ for any vector x. We shall assign to any $\mu \in \mathbb{R}^m$ the vector

$$\widehat{\mu} = \widehat{U}\mu$$

so that $\widehat{C}_{\mathcal{F}}^T\widehat{\mu} = C_{\mathcal{F}}^T\mu$. Substituting the latter identity to (6.1), we get

$$\begin{pmatrix} H_{\mathcal{F}\mathcal{F}} & \widehat{C}_{\mathcal{F}}^T \\ C_{\mathcal{F}} & 0 \end{pmatrix} \begin{pmatrix} x^k_{\mathcal{F}} \\ \widehat{\mu}^k \end{pmatrix} = \begin{pmatrix} g^k_{\mathcal{F}} + b_{\mathcal{F}} - H_{\mathcal{F}\mathcal{A}}\ell_{\mathcal{A}} \\ C_{\mathcal{F}}x^k_{\mathcal{F}} \end{pmatrix}. \tag{6.2}$$

Since $C_{\mathcal{F}} = \widehat{U}^T\widehat{D}\widehat{V} = \widehat{U}^T\widehat{C}_{\mathcal{F}}$ and $\widehat{U}^T$ is a full column rank matrix, the latter system is equivalent to the system

$$\begin{pmatrix} H_{\mathcal{F}\mathcal{F}} & \widehat{C}_{\mathcal{F}}^T \\ \widehat{C}_{\mathcal{F}} & 0 \end{pmatrix} \begin{pmatrix} x^k_{\mathcal{F}} \\ \widehat{\mu}^k \end{pmatrix} = \begin{pmatrix} g^k_{\mathcal{F}} + b_{\mathcal{F}} - H_{\mathcal{F}\mathcal{A}}\ell_{\mathcal{A}} \\ \widehat{C}_{\mathcal{F}}x^k_{\mathcal{F}} \end{pmatrix} \tag{6.3}$$

with a regular matrix. The right-hand side of (6.3) being bounded due to $\|\widehat{C}_{\mathcal{F}}x^k_{\mathcal{F}}\| = \|C_{\mathcal{F}}x^k_{\mathcal{F}}\|$, we conclude that $\{x^k_{\mathcal{F}} : \mathcal{F}(x^k) = \mathcal{F}\}$ is bounded. □

Lemma 6.2. *Let $\{z^k\}$ denote a bounded sequence, let B denote a full column rank matrix, and let there be a sequence $\{\tau^k\}$ such that $B\tau^k \geq z^k$. Then there is a bounded sequence $\{\widehat{\tau}^k\}$ such that $B\widehat{\tau}^k \geq z^k$.*

Proof. Let us denote $e = (1, 1, \dots, 1)^T$ and consider for a given integer k a linear programming problem of the form

$$\min\{e^T B\xi : B\xi \geq z^k\} \tag{6.4}$$

with B and z_k of the lemma. Since τ^k satisfies $B\tau^k \geq z^k$, it follows that the problem (6.4) is feasible. Moreover, observing that for any feasible ξ

$$e^T B\xi = e^T(B\xi - z^k) + e^T z^k \geq e^T z^k,$$

we conclude that the problem (6.4) is also bounded from below, so that it has a solution ξ^k. Using the well known duality theory of linear programming (e.g., [3]), it follows that the dual problem

$$\max\{\eta^T z^k : \eta \geq 0 \ \text{ and } \ \mathrm{B^T}\eta = \mathrm{e}\} \tag{6.5}$$

is feasible and bounded from above, so that it attains its solution η^k at a vertex of the convex boundary of the feasible set of the dual problem (6.5) and

$$(\eta^k)^T z^k = e^T B\xi^k.$$

Since the number of the vertices is finite, it follows that there is only a finite number of different η^k, so that, as $\{z^k\}$ is bounded, there is a constant c such that $e^T B\xi^k = (\eta^k)^T z^k \leq c$ for any integer k. Thus

$$\begin{aligned}\|B\xi^k\|_1 &\leq \|B\xi^k - z^k\|_1 + \|z^k\|_1 = e^T(B\xi^k - z^k) + \|z^k\|_1\\ &\leq e^T B\xi^k + 2\|z^k\|_1 \leq c + 2\|z^k\|_1.\end{aligned}$$

Since $\{z^k\}$ is bounded and B is a full column rank matrix, also the vectors ξ^k are bounded and $\widehat{\tau}^k = \xi^k$ satisfies the statement of the lemma. □

LEMMA 6.3. *Let $\{x^k\}, \{\mu^k\}$, and $\{\rho_k\}$ be generated by Algorithm* 3.1 *with $\eta > 0,\ \beta > 1,\ M > 0,\ \rho_0 > 0,\ \ \mu^0 \in \mathbb{R}^m$. Then there is a bounded sequence $\widehat{\mu}^k$ such that*

$$g^P(x^k, \widehat{\mu}^k, \rho_k) = g^P(x^k, \mu^k, \rho_k). \tag{6.6}$$

Proof. Let $\mathcal{B} \subset \mathcal{N},\ \mathcal{B} \neq \emptyset,\ \mathcal{B} \neq \mathcal{N}$ be such that $\{x^k : \mathcal{B}(x^k, \mu^k, \rho^k) = \mathcal{B}\}$ is infinite and denote $\mathcal{C} = \mathcal{N} \setminus \mathcal{B}$. Using a variant of the Gramm–Schmidt orthogonalization process, we can find a regular matrices R such that

$$\begin{pmatrix} C_{\mathcal{C}}^T \\ C_{\mathcal{B}}^T \end{pmatrix} R = \begin{pmatrix} P & 0 & 0 \\ Q & T & 0 \end{pmatrix},$$

where P and T are full column rank matrices. Thus decomposing properly $R^{-1}\mu^k$ into the blocks $R^{-1}\mu^k = (\xi^k, \tau^k, \nu^k)^T$, we get

$$\begin{pmatrix} C_{\mathcal{C}}^T \\ C_{\mathcal{B}}^T \end{pmatrix} \mu^k = \begin{pmatrix} P & 0 & 0 \\ Q & T & 0 \end{pmatrix} \begin{pmatrix} \xi^k \\ \tau^k \\ \nu^k \end{pmatrix} = \begin{pmatrix} P & 0 & 0 \\ Q & T & 0 \end{pmatrix} \begin{pmatrix} \xi^k \\ \tau^k \\ 0 \end{pmatrix}. \tag{6.7}$$

Using Theorem 5.2(i), we get that there is an integer k_0 such that $\rho_k = \rho_{k_0}$ for $k \geq k_0$. Let us denote $H = A + \rho_{k_0} C^T C$ and $g^k = g(x^k, \mu^k, \rho_k)$, so that for $k \geq k_0$

$$C^T \mu^k = b + g^k - Hx^k. \tag{6.8}$$

Substituting into (6.7), we get for $k \geq k_0$

$$C_{\mathcal{C}}^T \mu^k = P\xi^k = b_{\mathcal{C}} + g_{\mathcal{C}}^k - H_{\mathcal{C}\mathcal{N}} x^k.$$

Since P is full column rank matrix, $\|g_{\mathcal{C}}^k\| = \|g^P(x^k, \mu^k, \rho_k)\|$ and both x^k and $g^P(x^k, \mu^k, \rho_k)$ are bounded, it follows that ξ^k is bounded. Similarly, for $k \geq k_0$ and $\mathcal{B} = \mathcal{B}(x^k, \mu^k, \rho^k)$

$$C_{\mathcal{B}}^T \mu^k = Q\xi^k + T\tau^k = b_{\mathcal{B}} + g_{\mathcal{B}}^k - H_{\mathcal{B}\mathcal{N}} x^k \geq b_{\mathcal{B}} - H_{\mathcal{B}\mathcal{N}} x^k.$$

The vectors x^k being bounded due to Lemma 6.1, we can apply Lemma 6.2 to get bounded sequence $\widehat{\tau}^k$ such that

$$T\widehat{\tau}^k \geq b_{\mathcal{B}} - H_{\mathcal{B}\mathcal{N}} x^k - Q\xi^k. \tag{6.9}$$

Let us now define for $k \geq k_0$ a bounded sequence

$$\widehat{\mu}^k = R \begin{pmatrix} \xi^k \\ \widehat{\tau}^k \\ 0 \end{pmatrix}$$

so that by (6.7)

$$C_{\mathcal{C}}^T \widehat{\mu}^k = C_{\mathcal{C}}^T R \begin{pmatrix} \xi^k \\ \widehat{\tau}^k \\ 0 \end{pmatrix} = P\xi^k = C_{\mathcal{C}}^T \mu^k$$

and

$$g_{\mathcal{C}}^k = g_{\mathcal{C}}(x^k, \mu^k, \rho_k) = g_{\mathcal{C}}^P(x^k, \mu^k, \rho_k). \tag{6.10}$$

Similarly,

$$C_{\mathcal{B}}^T \widehat{\mu}^k = C_{\mathcal{B}}^T R \begin{pmatrix} \xi^k \\ \widehat{\tau}^k \\ 0 \end{pmatrix} = Q\xi^k + T\widehat{\tau}^k \tag{6.11}$$

and by (6.9)

$$g_{\mathcal{B}}(x^k, \widehat{\mu}^k, \rho_k) = H_{\mathcal{B}\mathcal{N}} x^k - b_{\mathcal{B}} + C_{\mathcal{B}}^T \widehat{\mu}^k = H_{\mathcal{B}\mathcal{N}} x^k - b_{\mathcal{B}} + Q\xi^k + T\widehat{\tau}^k \geq 0.$$

Recalling that we assume that $\mathcal{B}(x^k, \mu^k, \rho^k) = \mathcal{B}$, the last equation together with (6.10) yields

$$g^P(x^k, \mu^k, \rho_k) = g^P(x^k, \widehat{\mu}^k, \rho_k).$$

If $\mathcal{B} = \emptyset$ or $\mathcal{B} = \mathcal{N}$ are such that $\{x^k : \mathcal{B}(x^k, \mu^k, \rho^k) = \mathcal{B}\}$ is infinite, we can find the multipliers $\widehat{\mu}^k$ that satisfy the statement of our lemma by specializing the above arguments. Since there is only a finite number of different subsets $\mathcal{B}$ of $\mathcal{N}$, we have shown that there are the multipliers $\widehat{\mu}^k$ that satisfy the statement of our lemma for all k except possibly finite number of indices for which we shall define $\widehat{\mu}^k = \mu^k$. This completes the proof. □

THEOREM 6.4. *Let* $\{x^k\}, \{\mu^k\}$, *and* $\{\rho_k\}$ *be generated by Algorithm* 3.1 *with* $\eta > 0,\ \beta > 1,\ M > 0,\ \rho_0 > 0,\ \ \mu^0 \in \mathbb{R}^m$.

(i) *The sequence* $\{x^k\}$ *converges to the solution* x^* *of* (1.1).

(ii) *If the solution* x^* *of* (1.1) *is regular, then* $\{x^k\}$ *and* $\{\mu^k\}$ *converge to the solution* x^* *and the vector* μ^* *of the Lagrange multipliers of* (1.1), *respectively.*

Proof. Let $\widehat{\mu}^k$ denote the sequence of Lemma 6.3 so that it satisfies $g^P(x^k, \mu^k, \rho_k) = g^P(x^k, \widehat{\mu}^k, \rho_k)$. Since both x^k and $\widehat{\mu}^k$ are bounded, it follows that there is a cluster point $(\bar{x}, \bar{\mu})$ of the sequence $(x^k, \widehat{\mu}^k)$. Using Theorem 5.2(i), we get that there is k_0 such that $\rho_k = \rho_{k_0}$ for $k \geq k_0$. Moreover, by Theorem 5.2(iii) and the definition of Step 1 of Algorithm 3.1, $C\bar{x} = 0$ and $g^P(\bar{x}, \bar{\mu}, \rho_{k_0}) = g^P(\bar{x}, \bar{\mu}, 0) = 0$. Since $\bar{x} \geq 0$, $\bar{x}$ is the solution of (1.1). The solution x^* of (1.1) being unique, it follows that x^k converges to $\bar{x} = x^*$.

Let k_0 be as above and assume that the solution x^* of (1.1) is regular. Since we have just proved that $\{x^k\}$ converges to x^*, it follows that there is $k_1 \geq k_0$ such that $\{x^k\}$ is regular for $k \geq k_1$. Denoting $\mathcal{F} = \mathcal{F}(x^*)$ and $H = A + \rho_{k_0} C_{\mathcal{F}}^T C_{\mathcal{F}}$, it follows that

$$g_{\mathcal{F}}^P(x^k, \mu^k, \rho_k) = H_{\mathcal{F}\mathcal{N}} x^k - b_{\mathcal{F}} + C_{\mathcal{F}}^T \mu^k$$

converges to zero, so that the sequence

$$C_{\mathcal{F}}^T \mu^k = b_{\mathcal{F}} - H_{\mathcal{F}\mathcal{N}} x^k + g_{\mathcal{F}}^P(x^k, \mu^k, \rho_k)$$

is bounded. Using that x^* is the regular solution of (1.1) so that $C_{\mathcal{F}}^T$ is a full column rank matrix, we conclude that μ^k is bounded and there is a cluster point $(x^*, \bar{\mu})$ of the sequence (x^k, μ^k) that satisfies $g^P(x^*, \bar{\mu}, 0) = 0$. Thus $(x^*, \bar{\mu})$ is the KKT couple for (1.1). Since the KKT couple (x^*, μ^*) of (1.1) is unique when the solution x^* of (1.1) is regular, it follows that μ^k converges to $\bar{\mu} = \mu^*$. □

7. Numerical experiments.

We have implemented Algorithm 3.1 in Matlab and solved two benchmarks with an aim to illustrate both its efficiency and the main theoretical results. The inner loop (Step 1) was realized by the reduced gradient projection algorithm with proportioning [21].

Problem 7.1. The first problem was designed to demonstrate the efficiency of our algorithm on the solution of a class of well conditioned sparse problems. The Hesssian matrix $A = A_P, P > 2$, of the quadratic function $q = q_P$ is the symmetric Toeplitz matrix of the order $2 * P^2$ that is fully determined by the entries $a_{11} = 12, a_{12} = -1$ and $a_{1,P-1} = -1$. The other vectors $b = b_P$ and $l = l_P$ are defined by the entries $b_i = -1,\ i = 1, \ldots, 2 * P^2$, and $l_i = -0.125 + 0.1 * \cos(2 * \pi * i/P^2),\ i = 1, \ldots, P^2$. The remaining entries of the vector l are set to $-\infty$. Finally the matrix $C = C_P$ has P rows with $2 * P^2$ entries which are zeros except that $c_{i,P^2-i+1} = 1$ and $c_{i,P^2+i} = -1,\ i = 1, \ldots, P$. The matrix C is designed to enforce the relations $x_{P^2-i+1} = x_{P^2+i},\ i = 1, \ldots, P$. Using the Gersghorin theorem [27], it is easy to see that the eigenvalues λ_i of any A_P satisfy $8 \leq \lambda_i \leq 16$. The initial approximation for x in the first run of the inner loop is zero, so that no bound constraints are active.

We solved the problem with $\eta = \|b_P\|,\ \beta = 10$ and $\mu^0 = 0$ using the stopping criteria $\left\|g_P^P(x, \mu, 0)\right\| \leq 10^{-5} \|b_P\|$ and $\|C_P x\| \leq 10^{-5} \|b_P\|$, where we denoted by g_P the gradient of the augmented Lagrangian

$$L_P(x, \mu, \rho) = q_P + \frac{1}{2}\rho \|C_P x\|^2 + \mu^T C_P x.$$

We have not observed any update of the penalty parameter, which confirms that our update rule is less aggressive than that introduced in [5] and used in our previous papers.

Table 7.1
Optimality of the semimonotonic algorithm with $M = 1$ and $\rho = 20$.

P	Dimension	Active bounds	Equality constraints	Outer iterations	cg iterations
10	200	47	10	9	38
50	5000	1239	50	9	41
100	20000	4997	100	8	39
250	125000	31193	250	8	44
500	500000	124887	500	8	44

Table 7.2
Effect of the penalty parameter ρ for $P = 100$ and $M = 1$.

ρ	Dimension	Outer iterations	cg iterations
1	20000	89	108
10	20000	13	42
100	20000	4	82
1000	20000	2	397

The results of numerical experiments with $M = 1$, $P \in \{10, 50, 100, 250, 500\}$, and $\rho = 20$ are in Table 7.1. For each value of P, the table includes also the number of the bound constraints that are active at the solution and the number of the inequality constraints in the columns labeled "Active bounds" and "Equality constraints," respectively. Observe that the value of ρ is an upper bound on the spectrum of A_P. This choice may be easily implemented in a more realistic situation and seems to work for well conditioned constraints. We can see that the number of outer iterations does not increase with the dimension of the problem which confirms a kind of optimality predicted by Theorem 5.3.

We examined also the effect of the choice of the penalty parameter ρ. In Table 7.2 there are the results of computations for $\rho \in \{1, 10, 100, 1000\}$ with $P = 100$ and $M = 1$, so that the dimension of the problem and the number of constraints was 20,000 and 100, respectively. We can observe the large number of iterations for $\rho = 1000$. This is caused by the short gradient projection step (in the algorithm for Step 1) which is inversely proportional to the penalty parameter and by the large number of active constraints of the solution that are not active at the initial approximation. Notice that the algorithm had to identify 4997 active bound constraints starting from the empty active set. The number of outer iterations decreases with the increasing penalty parameter.

To see the effect of the conditioning of the constraints, we modified the matrix C by adding to each row the sum of the rows of the original matrix that are above the modified row, normalized the modified rows with respect to the ℓ_2-norm, and then normalized the whole constraint matrix with respect to the ℓ_∞-norm. We used the penalty parameter $\rho = 200$. The results are in Table 7.3, which includes the conditioning of the constraints. We can see that the number of the outer iterations decreases although there is deteriorating conditioning of the constraints. The number of the inner iterations also surprisingly decreases with the increasing condition number of the constraint matrix.

To see what happens when the constraints are dependent, we first formed an auxiliary matrix $\widehat{C}$ by appending the first $P/2$ rows of C to C so that $\widehat{C}$ had $1.5 * P$ rows, and then we modified the matrix $\widehat{C}$ by summing and normalizing as above.

TABLE 7.3
Effect of conditioning of the equality constraints for $\rho = 200$ and $M = 1$.

P	Dimension	Equality constraints	Outer iterations	cg iterations	Conditioning
10	200	10	123	263	15.0816
50	5000	50	68	171	79.5278
100	20000	100	43	143	161.4914
250	125000	2500	22	118	408.9432

TABLE 7.4
Experiments with dependent rows with $\rho = 200$ and $M = 1$.

P	Dimension	Equality constraints	Outer iterations	cg iterations	Conditioning
10	200	15	95	233	19.5937
50	5000	75	26	135	87.1887
100	20000	150	16	139	170.7854
250	125000	375	10	145	539.1429

Thus the resulting constraint matrix corresponding to P has the same first P rows as the constraint matrix of the previous experiments and $P/2$ additional rows that are linear combinations of the first ones. We can observe that the results in Table 7.4 are even better that those in Table 7.3. By "Conditioning" we understand here the ratio of the largest singular value of the constraint matrix to the smallest nonzero one. The constraint matrix corresponding to P has in these experiments P nonzero singular values of $1.5 * P$.

Problem 7.2. The second problem illustrates the performance of the algorithm on the solution of a model elliptic boundary variational inequality introduced in [14] modifying the experimental code produced by Horák [17]. We shall describe it here only briefly, referring the interested reader to [14] or [17].

Let us start from the following continuous problem:

$$\text{(7.1)} \qquad \begin{aligned} &\text{Minimize } q(u_1, u_2) = \sum_{i=1}^{2} \left(\int_{\Omega^i} |\nabla u_i|^2 d\Omega - \int_{\Omega^i} f u_i d\Omega \right) \\ &\text{s.t. } u_1(0, y) \equiv 0 \text{ and } u_1(1, y) \leq u_2(1, y) \text{ for } y \in [0, 1], \end{aligned}$$

where $\Omega^1 = (0,1)\times(0,1)$, $\Omega^2 = (1,2)\times(0,1)$, $f(x,y) = -5$ for $(x,y) \in (0,1)\times[0.75,1)$, $f(x,y) = 0$ for $(x,y) \in (0,1) \times (0,0.75)$, $f(x,y) = -1$ for $(x,y) \in (1,2) \times (0,0.25)$, and $f(x,y) = 0$ for $(x,y) \in (1,2) \times (0.25,1)$. This problem is semicoercive due to the lack of Dirichlet data on the boundary of Ω^2.

The solution of the model problem may be interpreted as the displacement of two membranes under the traction f. The left membrane is fixed on the left and the left edge of the right membrane is not allowed to penetrate below the right edge of the left membrane. The solution is unique because the right membrane is pressed down. More details about this model problem, including some other results, may be found in [14].

To solve the problem (7.1), we used the well established FETI domain decomposition method with the natural coarse grid preconditioning that was introduced for linear problems by Farhat, Mandel, and Roux (e.g., [22]) and adapted to variational inequalities by Friedlander, Gomes, Santos, and the present author [12, 14]. Each domain Ω^i, $i = 1, 2$, was first decomposed into identical squares Ω^{ij} with sides of the length H. The squares were discretized by regular grids defined by the stepsize h. We fixed the ratio $H/h = 4$ and considered $H = 1/2, 1/4$, and $1/8$. After having introduced the equality constraints and the inequalities to enforce continuity across the artificial interfaces between the squares and nonpenetration of the edges of the membranes, respectively, indexing contiguously the nodes and entries of corresponding vectors in the subdomains, and using the finite element discretization, we get the discretized version of problem (7.1) with the auxiliary domain decomposition that reads

$$\min \frac{1}{2} u^T K u - f^T u \quad \text{s.t.} \quad B^I u \leq 0 \quad \text{and} \quad B^E u = 0. \tag{7.2}$$

In (7.2), $K = \operatorname{diag}(K_1, \ldots, K_s),\ s = 1, \ldots, 2/H^2$ denotes a positive semidefinite block-diagonal stiffness matrix, the full rank matrices B^I and B^E describe the discretized nonpenetration and gluing conditions, respectively, and f represents the discrete analogue of the linear term.

Introducing the notation

$$\lambda = \begin{bmatrix} \lambda^I \\ \lambda^E \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} B^I \\ B^E \end{bmatrix},$$

we can write the Lagrangian associated with problem (7.2) briefly as

$$L(u, \lambda) = \frac{1}{2} u^T K u - f^T u + \lambda^T B u.$$

It is well known [3] that (7.2) is equivalent to the saddle point problem

$$\text{Find} \quad (\overline{u}, \overline{\lambda}) \quad \text{s.t.} \quad L(\overline{u}, \overline{\lambda}) = \sup_{\lambda_I \geq 0} \inf_{u} L(u, \lambda). \tag{7.3}$$

After eliminating the primal variables u from (7.3), we shall obtain the minimization problem

$$\min \Theta(\lambda) \quad \text{s.t.} \quad \lambda_I \geq 0 \quad \text{and} \quad R^T(f - B^T \lambda) = 0, \tag{7.4}$$

where

$$\Theta(\lambda) = \frac{1}{2} \lambda^T B A^\dagger B^T \lambda - \lambda^T B A^\dagger f, \tag{7.5}$$

$A^\dagger$ denotes a generalized inverse that satisfies $AA^\dagger A = A$, and R denotes the full rank matrix whose columns span the kernel of A. Let us recall that the multiplication by $A^\dagger$ may be efficiently evaluated by means of the triangular decomposition $A = LL^T$ [14]. We shall choose R so that its entries belong to $\{0, 1\}$ and each column corresponds to some floating auxiliary subdomain Ω^{ij} with the nonzero entries in the positions corresponding to the indices of nodes belonging to Ω^{ij}.

Although problem (7.4) is much more suitable for computations than (7.2), further improvement may be achieved by adapting some simple observations and the results of Farhat, Mandel, and Roux [22]. Let us denote

$$F = BA^\dagger B^T, \quad G = R^T B^T, \quad \widetilde{e} = R^T f, \quad \widetilde{d} = BA^\dagger f,$$

and let $\widetilde{\lambda}$ solve $G\widetilde{\lambda} = \widetilde{e}$. We can now transform the problem (7.4) to minimization on the subset of the vector space by looking for the solution in the form $\lambda = \mu + \widetilde{\lambda}$. Since

$$\frac{1}{2} \lambda^\top F \lambda - \lambda^\top \widetilde{d} = \frac{1}{2} \mu^\top F \mu - \mu^\top (\widetilde{d} - F\widetilde{\lambda}) + \frac{1}{2} \widetilde{\lambda}^\top F \widetilde{\lambda} - \widetilde{\lambda}^\top \widetilde{d},$$

problem (7.4) is, after returning to the old notation, equivalent to

$$\min \quad \frac{1}{2}\lambda^\top F\lambda - \lambda^\top d \quad \text{s.t} \quad G\lambda = 0 \quad \text{and} \quad \lambda^I \geq -\widetilde{\lambda}^I \tag{7.6}$$

with $d = \widetilde{d} - F\widetilde{\lambda}$. It is possible [19] to find $\widetilde{\lambda}$ such that $\widetilde{\lambda}^I \geq 0$.

Our final step is based on observation that the problem (7.6) is equivalent to

$$\min q(\lambda) \qquad \text{s.t} \quad G\lambda = 0 \quad \text{and} \quad \lambda^I \geq -\widetilde{\lambda}^I \tag{7.7}$$

where

$$q(\lambda) \ = \ \frac{1}{2}\lambda^T(PFP + \widehat{\rho}Q)\lambda - \lambda^T Pd$$

and

$$Q = G^T(GG^T)^{-1}G, \qquad\qquad P = I - Q,$$

denote the orthogonal projectors on the image space of $G^\top$ and on the kernel of G, respectively, and $\widehat{\rho}$ is a (small) positive number. Let us point out that $\widehat{\rho}$ is important rather from the point of view of analysis than in computations. In what follows we shall denote by ρ_i the sum of $\widehat{\rho}$ and of the penalty parameter in the augmented Lagrangian. Since we implemented Step 1 of Algorithm 3.1 with the conjugate gradient method, it is important to note that image spaces of the projectors P and Q are the invariant subspaces of the Hessian $PFP + \rho Q$ of the augmented Lagrangian for the problem (7.7), so that the convergence of the conjugate gradients may be fast even for large penalty parameters [9].

Each discretization of the model problem (7.1) is determined by a couple $D = (H, h)$ of the decomposition and the discretization parameter H and h, respectively. Thus using the domain decomposition and the discretization of the model problem (7.1), we get the set of quadratic programming problems

$$\min\ q_D(\lambda) \ \text{ s.t. } \ C_D\lambda = 0 \ \text{ and } \ \lambda \geq e_D, \qquad q_D = \lambda^T A_D\lambda - b_D^T\lambda, \tag{7.8}$$

that are defined for each

$$D \in \mathcal{T} = \{D = (H, h) : 0 < h < H \leq 1, h^{-1} \in \mathbb{N}, H^{-1} \in \mathbb{N}, H/h \in \mathbb{N}\}.$$

Let us recall that the Hessian A_D is in this case the product of eight large and sparse matrices. More details concerning the application of FETI may be found in [14, 17].

We first solved the problems by Algorithm 3.1 with $\rho_0 = 100, \eta = \|b_D\|, \beta = 10$, and $\mu^0 = 0$ using the stopping criteria $\left\|g_D^P(\lambda, \mu, 0)\right\| \leq 10^{-4}\|b_D\|$ and $\|C_D\lambda\| \leq 10^{-4}\|b_D\|$, where we denoted by g_D the gradient of the augmented Lagrangian for the problem (7.7) with the discretization D. We kept H/h fixed so that the assumptions of Theorem 5.3 were satisfied [19]. The results are given in Table 7.5. We can see that the number of the outer iterations is only 3 regardless the value of the parameter H, the dimension of the problem, and even the number of constraints. An interesting feature of the experiments is also the small number of the conjugate gradient iterations due to efficiency of both FETI and our algorithms. We shall discuss this point elsewhere.

Theorem 5.2 indicates that the rate of convergence of the feasibility error depends on the initial penalty parameter. To illustrate this feature, we used varying initial penalty parameter to solve our model problem with $H/h = 8$ and $H = 1/4$. The

1000	24	1	$4.16e-6$			

dimension of the dual and the primal problem was 447 and 2592, respectively, with 28 equality constraints. The record of the development of the feasibility error is given in Table 7.6. We observed that the penalty parameter was updated only once, after the first iteration with $\rho_0 = 1$, which was the only case when we recorded the decrease of the augmented Lagrangian.

The values of the augmented Lagrangian are given in Table 7.7. Observe that the algorithm can generate for the small penalty parameters values of the augmented Lagrangian that are greater than its value at the solution. We conclude that the results are in agreement with the theory.

8. Comments and conclusions. We have introduced a new update rule for the penalty parameter that enforces at a certain stage monotonic increase of the augmented Lagrangian. We implemented this rule using our earlier algorithm and proved global convergence results for the augmented Lagrangian method. This method uses adaptive precision control in the solution of the auxiliary problems for quadratic programming problems with equality constraints. The precision is controlled by the feasibility of the current iteration. The new feature of the algorithm is that it does not take any special measures to treat the iterations that are not regular and the theory supports convergence even in the case when the equality constraints are dependent.

The algorithm is a variant of the well established algorithm [15] which has already proved to be useful in the development of scalable algorithms for the numerical solution of elliptic variational inequalities [17] and for the solution of contact problems of elasticity [12]. In fact, if ρ_0 is chosen in the algorithm [15] to be sufficiently large so that it is not updated, and if all the iterations are regular, then the performance of both algorithms is identical. This paper may be considered a complement of [15] in the sense that it explains what happens when the penalty parameter in this type of algorithm is relatively small without any reference to convergence of the Lagrange multipliers.

The main results of the paper are the *bounds on the feasibility error and the penalty parameters that do not depend on the form of constraints*. When applied to a class of problems with the spectrum of the Hessian matrix in a given interval, the algorithm returns the solution in $O(1)$ matrix-vector multiplications. In combination with the recent results on the solution of the bound constrained quadratic programming problems [10, 21], it follows that if the cost of the matrix-vector multiplication

by the Hessian matrix is proportional to its dimension, *the algorithm finds the approximate solution to the prescribed relative precision at the optimal (i.e., asymptotically proportional to the dimension of the problem) cost.* The results were also confirmed numerically on the solution of two model problems and were shown to be valid even for linearly dependent constraints. The result of the paper is an important ingredient in the development of scalable algorithms for variational inequalities. We shall describe this application in more detail elsewhere.

Let us recall that there are algorithms with even superlinear convergence (e.g., variants of the primal-dual interior point methods [30]), but their typical step requires the solution of an auxiliary ill conditioned linear problem which may be, for sufficiently large and sparse problems, much more expensive than the solution of the whole problem by the algorithm presented here.

Acknowledgments. I wish to express here my thanks to D. Horák, who assisted with the numerical experiments and reading the paper. My special thanks go to A. R. Conn and the anonymous referee for their valuable comments that resulted in considerable improvement of the paper.

A DIV-CURL LEMMA FOR EDGE ELEMENTS[*]

SNORRE H. CHRISTIANSEN[†]

Abstract. A variant of Murat and Tartar's div-curl lemma is stated and proved for Nédélec's edge elements. Given two sequences of vector fields of this type, converging weakly in L^2 as the mesh width tends to 0, we prove that their scalar product converges in the sense of distributions when one of the sequences consists of so-called discrete divergence-free fields whereas the other has relatively compact curl in H^{-1}. The proof uses a uniform norm equivalence related to discrete compactness properties of vector finite element spaces and a super-approximation property of scalar finite element spaces.

Key words. div-curl lemma, compensated compactness, edge elements, discrete compactness

DOI. 10.1137/S0036142903433807

1. Introduction.

Given two sequences of vector fields converging weakly in L^2, the div-curl lemma of Murat [29] and Tartar [37], recalled in Theorem 1.1 below, gives sufficient conditions under which their scalar product converges to the right scalar field in the weak-star sense of distributions. Following Schwartz, the space of compactly supported smooth functions is denoted $\mathcal{D}$, and the space of distributions, which contains L^1 and is dual to $\mathcal{D}$ for a certain topology, is denoted $\mathcal{D}'$.

THEOREM 1.1. *Suppose (u_h) and (u'_h) are sequences of vector fields converging weakly in L^2 to u and u'. Suppose, furthermore, that $(\operatorname{div} u_h)$ is relatively compact in H^{-1} and that $(\operatorname{curl} u'_h)$ is relatively compact in H^{-1}. Then for each $\phi \in \mathcal{D}$ we have*

$$\lim_h \int (u_h \cdot u'_h)\phi = \int (u \cdot u')\phi. \tag{1.1}$$

Following Folland [20] we shall refer to weak-star as vague convergence, since this leads to adjectives more easily. Thus (1.1) expresses that the sequence $(u_h \cdot u'_h)$ converges vaguely to $u \cdot u'$ in $\mathcal{D}'$.

Over the years the curl conforming finite element (FE) spaces constructed by Nédélec [31, 32], also referred to as edge elements since the principal degrees of freedom are attached to the edges, have emerged as the spaces of choice for discretizing Maxwell's equations (Cessenat [12], Jackson [24], Nédélec [33]). This success is based on numerous numerical and theoretical studies; for surveys and references, see Monk [28], Hiptmair [23], and Joly [25]. For the purposes of this paper we notice in particular that a discrete compactness property of Kikuchi [27] has been used to show that edge element spaces do not yield spurious eigenvalues when used to compute eigenvalues of the curl curl operator, contrary to some tempting so-called nodal FE spaces (see Boffi, Brezzi, and Gastaldi [4], Boffi, Fernandes, and Gastaldi [5], and Boffi [6]).

In this paper we prove another good property of edge elements, this time related to nonlinear convergence theory. Most numerical schemes of electromagnetics do not offer direct control of the divergence of the discrete vector fields. However, it is widely acknowledged that the success of edge elements is related to weak divergence control.

[†] CMA, Universitet i Oslo, PB 1053 Blindern, NO-0316 Oslo, Norway (snorrec@math.uio.no).

In the simplest case the mechanism is as follows: Let X_h denote the space of lowest order Nédélec edge elements on a simplicial triangulation with mesh width h, and let Y_h denote the continuous piecewise affine functions on the same triangulation. The first (by now standard) remark is that the cohomology group of the sequence

$$Y_h \xrightarrow{\text{grad}} X_h \xrightarrow{\text{curl}} \mathrm{L}^2, \tag{1.2}$$

has the dimension of its continuous counterpart, essentially because simplicial cohomology is equivalent to De Rham cohomology. This accounts for the naturality of considering Y_h and X_h together and has attracted much interest in the numerical analysis community; see Arnold [2]. We denote by $\widetilde{Y}_h$ the intersection $Y_h \cap \mathrm{H}^1_0$. In the Galerkin formulation of electromagnetic problems the only information available a priori on the divergence of an electric field $u_h \in X_h$ is through the graph

$$\left\{ \left(p_h, \int u_h \cdot \operatorname{grad} p_h \right) : \; p_h \in \widetilde{Y}_h \right\}. \tag{1.3}$$

How does this discrete divergence information translate into H^{-1} estimates on $\operatorname{div} u_h$? For instance a basic question is, suppose that we have a sequence $(\mathcal{T}_h)$ of meshes with mesh width $h \to 0$, yielding sequences of spaces (X_h) and (Y_h) and suppose that (u_h) is a sequence of vector fields $u_h \in X_h$, bounded in L^2 and discrete divergence-free in the sense that

$$\forall p_h \in \widetilde{Y}_h, \qquad \int u_h \cdot \operatorname{grad} p_h = 0; \tag{1.4}$$

is $(\operatorname{div} u_h)$ relatively compact in H^{-1}?

I do not know the answer to this question but if affirmative, then a direct consequence of Theorem 1.1 would be Corollary 4.2. One of the main goals of this paper is nevertheless to prove this corollary. It is a special case of Theorem 4.1, which is a div-curl lemma for edge elements paralleling Theorem 1.1. Thus, loosely speaking, we prove that with respect to the convergence of edge element vector fields under div-curl control, everything happens as if the answer to the above question were affirmative.

The paper is organized as follows. In section 2 we introduce the general setting we shall use in this paper and check that the edge element spaces fit into it. In section 3 we introduce some tools used to prove the proposed div-curl lemma. This proof is provided in section 4. Finally in section 5 we establish some links between the estimates proved in this paper, other estimates on discrete Helmholtz decompositions, and the previously mentioned discrete compactness property of Kikuchi.

2. Setting.

2.1. Generalities.

Let Ω be a connected bounded domain in $\mathbb{R}^3$ with a smooth boundary. For simplicity we suppose that Ω has the topological property that the kernel of the curl operator on $\mathrm{L}^2 = \mathrm{L}^2(\Omega)$ is exactly the range of the gradient on $\mathrm{H}^1 = \mathrm{H}^1(\Omega)$. The extension of the following results to general topology is straightforward using the fact that the edge elements approximate the L^2 realizations of cohomology groups (harmonic vector fields) extremely well (see, e.g., section 2.3 in [15]). The standard norms and seminorms on H^k are denoted $\| \cdot \|_k$ and $| \cdot |_k$, respectively.

Let X denote the space L^2, W the kernel of the curl : $X \to \mathrm{H}^{-1}$, and V its L^2 orthogonal in X. Thus we have

$$W = \{\operatorname{grad} p\colon \; p \in \mathrm{H}^1\}, \tag{2.1}$$

and, denoting by n the exterior normal on $\partial\Omega$,

$$V = \{v \in \mathrm{L}^2\colon\ \operatorname{div} v = 0 \text{ and } v \cdot n|_{\partial\Omega} = 0\}. \tag{2.2}$$

Let P_V denote the projection with range V and kernel W. It is nothing but the L^2 projection onto V and it preserves the curl; i.e., for all vector fields $u \in \mathrm{L}^2$,

$$\operatorname{curl} P_V u = \operatorname{curl} u. \tag{2.3}$$

A less straightforward property of V is the following.

Proposition 2.1. *On V, $\|\operatorname{curl}(\cdot)\|_{-1}$ is a norm equivalent to the* L^2 *norm.*

Proof. The map curl : $V \to \mathrm{H}^{-1}$ is continuous and injective, so it remains to prove that it has closed range. By the closed range theorems it suffices to prove that the range of curl : $\mathrm{H}^1_0 \to \mathrm{L}^2$ is closed. However, this latter space is a subspace of V, and Theorem 3.20 (which requires $C^{1,1}$ regularity of the boundary) in [1] provides a closed subspace U of H^1_0 such that curl : $U \to V$ is an isomorphism. In particular the range of curl : $\mathrm{H}^1_0 \to \mathrm{L}^2$ must be V, which is closed. This completes the proof. □

Remark. M. Costabel has indicated to me that by slightly adapting techniques from Girault–Raviart [22] one can show that the above result remains true for domains whose boundary is locally the graph of Lipschitz functions.

We will use the following setting. In accordance with widespread notational conventions for FE discretizations, we consider families indexed by a given countable set of positive reals accumulating only at 0. The dummy variable is denoted h and we are interested in the limit $h \to 0$. Let (X_h) and (Y_h) denote two sequences of finite-dimensional spaces such that

$$Y_h \subset \mathrm{H}^1 \quad \text{and} \quad X_h \subset \{u \in \mathrm{L}^2\colon\ \operatorname{curl} u \in \mathrm{L}^2\}. \tag{2.4}$$

We suppose that Y_h contains the constant scalar fields and that the operator grad maps Y_h *onto* the kernel W_h of the curl operator restricted to X_h. We denote by V_h the L^2-orthogonal of W_h in X_h. Thus we have an exact sequence

$$\mathbb{R} \to Y_h \to X_h \to \mathrm{L}^2, \tag{2.5}$$

and L^2-orthogonal splittings

$$X_h = V_h \oplus W_h. \tag{2.6}$$

We also put $\widetilde{Y}_h = Y_h \cap \mathrm{H}^1_0$, define $\widetilde{W}_h = \operatorname{grad} \widetilde{Y}_h$, and denote by $\widetilde{V}_h$ the L^2-orthogonal of $\widetilde{W}_h$ in X_h.

Some approximation properties are also assumed for (X_h) and (Y_h) throughout the rest of this paper without further notice:

$$\forall u \in \mathrm{L}^2, \quad \lim_{h\to 0} \inf_{u_h \in X_h} \|u - u_h\|_0 = 0, \tag{2.7}$$

$$\forall p \in \mathrm{H}^1, \quad \lim_{h\to 0} \inf_{p_h \in Y_h} \|p - p_h\|_1 = 0, \tag{2.8}$$

$$\forall p \in \mathrm{H}^1_0, \quad \lim_{h\to 0} \inf_{p_h \in \tilde{Y}_h} \|p - p_h\|_1 = 0. \tag{2.9}$$

Of course all FE spaces satisfy them, and they can be interpreted as the pointwise convergence of the corresponding L^2 and H^1 projectors.

Unless specified otherwise, the above hypotheses are the only ones we assume in the next sections of the paper. However, for most of our results one or two of the following assumptions will play a crucial role.

UNE (uniform norm equivalence). There is $C > 0$ such that

$$\forall h \; \forall v_h \in V_h, \quad \|v_h\|_0 \leq C \| \operatorname{curl} v_h \|_{-1}. \tag{2.10}$$

SA (super-approximation). For any function $\phi \in \mathcal{D}$ (smooth and compactly supported) we have

$$\lim_{h \to 0} \sup_{p_h \in Y_h} \inf_{\widetilde{p}_h \in \widetilde{Y}_h} \|\phi p_h - \widetilde{p}_h\|_1 / \|p_h\|_1 = 0. \tag{2.11}$$

When they are needed, we will specify them as part of the hypotheses of the statements.

Remark. Since Y_h is assumed to contain the constant functions and $\mathcal{D}$ is dense in H^1_0, (SA) implies (2.9).

2.2. Edge elements. Let $(\mathcal{T}_h)$ be a family of simplicial meshes on Ω such that (in accordance with widespread notational practice) the mesh width of $\mathcal{T}_h$ is h. We suppose furthermore that $(\mathcal{T}_h)$ is shape-regular and uniform in the standard senses (see, e.g., Braess [8, p. 61]), so that in particular inverse inequalities can be used.

Given an integer $k \geq 1$ we consider (for each h) on $\mathcal{T}_h$ the edge element space X_h of Nédélec of the first or second family and constructed with (incomplete vector) polynomials of maximum degree k, as well as the associated space Y_h of continuous piecewise polynomial functions. We suppose that these spaces have been adequately fitted near the curved boundary as in Dubois [19]. These spaces fit into the above setting, and in the next two propositions we check that they also satisfy (UNE) and (SA).

PROPOSITION 2.2. *The family* (X_h) *satisfies* (UNE).

As we shall see this is a very strong statement. For instance it is a considerable strengthening of Proposition 4.6 in [1], but has a more restrictive boundary regularity hypothesis. It is unknown to me if the present proposition remains true for Lipschitz domains or without the uniformity hypothesis on the meshes.

Proof. Let Π_h denote the standard edge element interpolator. It maps curl-free fields to curl-free fields, due to the commuting diagram property of standard interpolation operators. For any v_h in V_h, $P_V v_h$ is in H^1, due to our regularity assumptions on the boundary, and has a piecewise smooth curl. Therefore Π_h is well defined on $P_V v_h$ and we may write

$$\operatorname{curl}(\Pi_h P_V v_h - v_h) = \operatorname{curl} \Pi_h (P_V v_h - v_h) = 0. \tag{2.12}$$

Hence v_h, $P_V v_h$, and $\Pi_h P_V v_h$ have the same curl. Next we use a trick due to V. Girault for which I refer to the proof of Lemma 4.1 in Ciarlet–Zou [16]. A Bramble–Hilbert type error estimate for Π_h, using the additional information available on $\operatorname{curl} v_h$ (when transported from the cells of $\mathcal{T}_h$ to the reference cell, it lies in a fixed finite-dimensional space), yields

$$\|\Pi_h P_V v_h - P_V v_h\|_0 \leq Ch |P_V v_h|_1. \tag{2.13}$$

Then Lemma 2.11 in [1] gives

$$\|\Pi_h P_V v_h - P_V v_h\|_0 \leq Ch \| \operatorname{curl} v_h \|_0, \tag{2.14}$$

and we proceed as in the proof of Theorem 3.5 in [13].

Putting $w_h = \Pi_h P_V v_h - v_h \in W_h$ we remark that w_h is L^2-orthogonal to $v_h \in V_h$ and (being a gradient) also to $P_V v_h \in V$. Hence we have

$$\|w_h\|_0^2 = \int w_h \cdot (\Pi_h P_V v_h - P_V v_h) \leq \|w_h\|_0 \|\Pi_h P_V v_h - P_V v_h\|_0. \tag{2.15}$$

It follows that

$$\|w_h\|_0 \leq Ch \|\operatorname{curl} v_h\|_0. \tag{2.16}$$

Now, using an inverse inequality, we obtain

$$\begin{aligned} \|P_V v_h - v_h\|_0 &\leq \|\Pi_h P_V v_h - P_V v_h\|_0 + \|\Pi_h P_V v_h - v_h\|_0 && (2.17)\\ &\leq Ch \|\operatorname{curl} v_h\|_0 && (2.18)\\ &\leq C \|\operatorname{curl} v_h\|_{-1}. && (2.19) \end{aligned}$$

Using Proposition 2.1 we deduce

$$\begin{aligned} \|v_h\|_0 &\leq \|P_V v_h\|_0 + \|P_V v_h - v_h\|_0 && (2.20)\\ &\leq C \|\operatorname{curl} v_h\|_{-1}, && (2.21) \end{aligned}$$

which is the desired result. □

PROPOSITION 2.3. *The family* (Y_h) *satisfies* (SA).

Remark. In fact much more elaborate estimates are known and used in proofs of super-convergence properties; see Wahlbin [39, pp. 36–37] for a discussion of the techniques involved.

Remark. I thank one of the referees for showing me how to get rid of the uniformity hypothesis on the meshes in the proof of this proposition.

Proof. Denote by k the maximum degree of the polynomials used to construct the spaces Y_h. Let Π_h be the standard nodal interpolator. For any tetrahedron T we denote by h_T its diameter, and by $\|\cdot\|_{T,i}$ and $|\cdot|_{T,i}$ the standard $\mathrm{H}^i(T)$ norms and seminorms, respectively.

Pick $\phi \in \mathcal{D}$. For each h, each $p_h \in Y_h$, and each tetrahedron T of $\mathcal{T}_h$, we may write

$$\begin{aligned} \|\phi p_h - \Pi_h(\phi p_h)\|_{T,1} &\leq C h_T^k |\phi p_h|_{T,k+1} && (2.22)\\ &\leq C h_T^k \sum_{i=0}^{k} |p_h|_{T,i}, && (2.23) \end{aligned}$$

where we used first the standard Bramble–Hilbert lemma and second the Leibniz rule together with the fact that the derivatives of p_h of order $k+1$ vanish. Next, for $2 \leq i \leq k$, we use an inverse estimate (local to each T) to obtain

$$|p_h|_{T,i} \leq C h_T^{1-i} \|p_h\|_{T,1}. \tag{2.24}$$

Combining the above estimates and adding over all tetrahedra of $\mathcal{T}_h$ yields

$$\|\phi p_h - \Pi_h(\phi p_h)\|_1 \leq Ch \|p_h\|_1. \tag{2.25}$$

This completes the proof. □

3. Three tools. The proof of the proposed div-curl lemma is based on the following three results.

Lemma 3.1. *Suppose (u_h) is a sequence of vector fields $u_h \in X_h$ converging weakly in* L^2 *to $u = v + w$ with $v \in V$ and $w \in W$. Then with the decomposition $u_h = v_h + w_h$, with $v_h \in V_h$ and $w_h \in W_h$, the sequences (v_h) and (w_h) converge weakly to v and w in* L^2. *A similar result holds for the splitting $X_h = \widetilde{V}_h \oplus \widetilde{W}_h$.*

Proof. Put $w_h = \operatorname{grad} p_h$ with $p_h \in Y_h$ with vanishing integral. Let P_h denote the Galerkin projection onto the subspace of elements of Y_h with vanishing integral, with respect to the bilinear form

$$(p, p') \to \int \operatorname{grad} p \cdot \operatorname{grad} p'. \tag{3.1}$$

Then we have, for all $p' \in \mathrm{H}^1(\Omega)$ with vanishing integral,

$$\int \operatorname{grad} p_h \cdot \operatorname{grad} p' = \int \operatorname{grad} p_h \cdot \operatorname{grad} P_h p' = \int u_h \cdot \operatorname{grad} P_h p'. \tag{3.2}$$

Since $(P_h p')$ converges strongly to p' in H^1 by the approximation property of (2.8), the above quantity converges to

$$\int u \cdot \operatorname{grad} p' = \int w \cdot \operatorname{grad} p'. \tag{3.3}$$

It follows that (w_h) converges weakly in L^2 to w. Therefore (v_h) also converges weakly to v.

To prove the similar result for the splitting $X_h = \widetilde{V}_h \oplus \widetilde{W}_h$ one can use a similar technique, relying on estimate (2.9) instead of estimate (2.8). □

Proposition 3.2. *Suppose* (UNE) *holds. Let (v_h) be a sequence of vector fields such that $v_h \in V_h$. If* $(\operatorname{curl} v_h)$ *converges to* $\operatorname{curl} v$ *in* H^{-1} *for some $v \in V$, then (v_h) converges to v in* L^2.

Proof. By Proposition 2.1, $(P_V v_h)$ converges to v in L^2. Also, if we let P_h denote the L^2 projection onto X_h, $(P_h v)$ converges to v in L^2 by the approximation property of (2.7). Moreover P_h maps V into V_h. We can now write

$$\|P_h v - v_h\|_0 \leq C\|\operatorname{curl} P_h v - \operatorname{curl} v_h\|_{-1} \tag{3.4}$$

$$\leq C\|\operatorname{curl} P_h v - \operatorname{curl} P_V v_h\|_{-1} \tag{3.5}$$

$$\leq C\|P_h v - P_V v_h\|_0. \tag{3.6}$$

It follows that (v_h) converges to v. □

Corollary 3.3. *Suppose* (UNE) *holds. Let (v_h) be a sequence of vector fields such that $v_h \in V_h$. If* $(\operatorname{curl} v_h)$ *is relatively compact in* H^{-1}, *then (v_h) is relatively compact in* L^2.

Proposition 3.4. *Suppose* (SA) *holds. Suppose (v_h) is a sequence of vector fields $v_h \in \widetilde{V}_h$ converging weakly in* L^2 *to v, and (p_h) is a sequence of scalar fields $p_h \in Y_h$ converging weakly in* H^1 *to p. Then $(v_h \cdot \operatorname{grad} p_h)$ converges vaguely to $v \cdot \operatorname{grad} p$ in $\mathcal{D}'$.*

Proof. Pick $\phi \in \mathcal{D}$. We have

$$\int (v_h \cdot \operatorname{grad} p_h)\phi = \int v_h \cdot \operatorname{grad}(\phi p_h) - \int (v_h \cdot \operatorname{grad} \phi) p_h. \tag{3.7}$$

Since $v_h \in \widetilde{V}_h$, the first term can be replaced by

$$\int v_h \cdot \operatorname{grad}(\phi p_h - \widetilde{p}_h) \tag{3.8}$$

for any $\widetilde{p}_h \in \widetilde{Y}_h$. It converges to 0 by (SA).

In the second term we remark that $(v_h \cdot \operatorname{grad} \phi)$ converges weakly to $v \cdot \operatorname{grad} \phi$ in L^2, whereas (p_h) converges strongly in L^2 by the compactness of the injection $\mathrm{H}^1 \to \mathrm{L}^2$.

Therefore,

$$\int (v_h \cdot \operatorname{grad} p_h)\phi \;\to\; -\int (v \cdot \operatorname{grad} \phi) p = \int (v \cdot \operatorname{grad} p)\phi. \tag{3.9}$$

This completes the proof. □

4. Div-curl lemma for edge elements. We are now ready to prove our main result.

THEOREM 4.1. *Suppose both* (UNE) *and* (SA) *hold. Suppose* (u_h) *and* (u'_h) *are sequences of vector fields* $u_h, u'_h \in X_h$ *converging weakly in* L^2 *to* u *and* u'. *Suppose, furthermore, that with the decomposition* $u_h = v_h + \operatorname{grad} p_h$ *for* $v_h \in \widetilde{V}_h$ *and* $p_h \in \widetilde{Y}_h$, (p_h) *is relatively compact in* H^1_0, *and* $(\operatorname{curl} u'_h)$ *is relatively compact in* H^{-1}.

Then $(u_h \cdot u'_h)$ *converges vaguely to* $u \cdot u'$ *in* $\mathcal{D}'$.

Proof. Decompose also $u'_h = v'_h + \operatorname{grad} p'_h$ with $v'_h \in V_h$ and $p'_h \in Y_h$. Recall that by Lemma 3.1, all terms of the decompositions converge weakly. The limits will be denoted by skipping the subscript h.

Pick $\phi \in \mathcal{D}$. Each $\int (u_h \cdot u'_h)\phi$ can be decomposed into several terms studied separately.

First, we remark that $(\operatorname{grad} p_h)$ converges strongly in L^2 by the hypothesis. Therefore we have

$$\int (\operatorname{grad} p_h \cdot u'_h)\ \phi \;\to \int (\operatorname{grad} p \cdot u')\phi. \tag{4.1}$$

Next, we remark that by Proposition 3.2, (v'_h) converges strongly in L^2 to v. Hence we have

$$\int (v_h \cdot v'_h)\phi \;\to\; \int (v \cdot v')\phi. \tag{4.2}$$

Finally, we remark that by Proposition 3.4 we have

$$\int (v_h \cdot \operatorname{grad} p'_h)\ \phi \;\to \int (v \cdot \operatorname{grad} p')\phi. \tag{4.3}$$

This completes the proof. □

A useful special case of Theorem 4.1 is the following.

COROLLARY 4.2. *Suppose both* (UNE) *and* (SA) *hold. Suppose* (u_h) *and* (u'_h) *are sequences of vector fields* $u_h, u'_h \in X_h$ *converging weakly in* L^2 *to* u *and* u'. *Suppose furthermore that* u_h *is discrete divergence-free (i.e., is in* $\widetilde{V}_h$*) and that* $(\operatorname{curl} u'_h)$ *is bounded in* L^2.

Then $(u_h \cdot u'_h)$ *converges vaguely to* $u \cdot u'$ *in* $\mathcal{D}'$.

The next remark shows that on one point the hypothesis of Theorem 4.1 is not strictly stronger than that of Theorem 1.1.

Remark. Suppose (u_h) is a sequence of vector fields $u_h \in X_h$ such that $(\operatorname{div} u_h)$ is relatively compact in H^{-1}. Then with the decomposition $u_h = v_h + \operatorname{grad} p_h$, for $v_h \in \widetilde{V}_h$ and $p_h \in \widetilde{Y}_h$, (p_h) is relatively compact in H^1_0.

Proof. This follows from the uniform continuity and pointwise convergence in H^1_0 of the Galerkin projectors onto $\widetilde{Y}_h$ with respect to the bilinear form with expression (3.1). □

5. On discrete compactness. In this section we provide results on the relationship between the estimates of this paper and some more well-known ones.

First we show that (UNE) implies a *gap property* of discrete Helmholtz or Hodge decompositions, which in turn implies a *discrete compactness property* of edge elements in the sense of Kikuchi [27] (with natural rather than essential boundary conditions for the curl operator). The gap property proved useful in analyzing some integral equations describing electromagnetic phenomena (Christiansen [13] and Buffa and Christiansen [11]) whereas the discrete compactness property is crucial in the analysis of discrete eigenvalue problems of electromagnetics (see in particular Boffi, Brezzi, and Gastaldi [4] and Boffi, Fernandes, and Gastaldi [5]).

Then we show that a weakened (local) version of discrete compactness can be deduced from the proposed discrete div-curl lemma (without reference to (UNE) or (SA)).

Suppose G is a Hilbert space such that $\mathrm{L}^2 \subset G \subset \mathrm{H}^{-1}$ with continuous inclusions. Suppose furthermore that the injection $G \to \mathrm{H}^{-1}$ is compact.

PROPOSITION 5.1. *Suppose* (X_h) *satisfies* (UNE). *Then we have*

$$\lim_{h \to 0} \sup_{v_h \in V_h} \|v_h - P_V v_h\|_0 / \|\operatorname{curl} v_h\|_G = 0. \tag{5.1}$$

Proof. Indeed if this were not true we would have a subsequence (v_h) with $v_h \in V_h$ such that $(\|\operatorname{curl} v_h\|_G)$ is bounded and $(\|v_h - P_V v_h\|_0)$ does not converge to 0. From it we can extract a subsequence such that $(\operatorname{curl} v_h)$ converges weakly in G. But then $(\operatorname{curl} v_h)$ converges strongly in H^{-1}. One obtains a contradiction with Proposition 3.2. □

Consider the Hilbert space X^G of vector fields in L^2 with curl in G equipped with its natural norm $\|\cdot\|_{0G}$. In X^G let V^G be the L^2-orthogonal of (the closed subspace) $W = \operatorname{grad} \mathrm{H}^1$ and let $\delta_G(\cdot,\cdot)$ denote the gap between subspaces in the sense of Kato [26]. Thus for nonzero subspaces U, U' we have

$$\delta_G(U, U') = \sup_{u \in U, \|u\|=1} \inf_{u' \in U'} \|u - u'\|_{0G}. \tag{5.2}$$

COROLLARY 5.2. *Suppose* (X_h) *satisfies estimate* (5.1). *Then we have*

$$\lim_{h \to 0} \delta_G(V_h, V^G) = 0. \tag{5.3}$$

Proof. Just remark that

$$\|v_h - P_V v_h\|_{0G} = \|v_h - P_V v_h\|_0 \quad \text{and} \quad \|\operatorname{curl} v_h\|_G \le \|v_h\|_{0G}, \tag{5.4}$$

and conclude using estimate (5.1). □

From this gap property in the case $G = \mathrm{H}^0 = \mathrm{L}^2$ one easily deduces the following discrete compactness property. Let X^0 denote the space of vector fields u in L^2 such that $\operatorname{curl} u$ is in L^2. Let V^0 denote the L^2-orthogonal of the closed subspace

$W = \operatorname{grad} \mathrm{H}^1$ of X^0. The elements of V^0 thus have vanishing divergence and vanishing normal component on $\partial\Omega$. By a result of Weber, for which we refer to Theorem 2.8 in [1], the space V^0, when equipped with the norm inherited from X^0, is compactly embedded in L^2. This result has the following discrete analogue.

Corollary 5.3. *Suppose* (X_h) *satisfies the gap property* (5.3) *and that* (v_h) *is a sequence of vector fields* $v_h \in V_h$*, which is bounded in* X^0*. Then there is a subsequence which converges in* L^2*.*

Proof. If (v_h) is such a sequence, then $(P_V v_h)$ is bounded in V^0 and $(\|v_h - P_V v_h\|_0)$ tends to 0. □

Concerning directly the relationship between Theorem 4.1 and the discrete compactness, we make the following remark.

Proposition 5.4. *Suppose that* (X_h) *is a family of subspaces (not necessarily satisfying* (UNE) *or* (SA) *a priori) for which the conclusions of Theorem* 4.1 *(resp., Corollary* 4.2*) are true. Then for each sequence* (u_h) *of vector fields* $u_h \in \tilde{V}_h$ *which is bounded in* L^2 *and such that* $(\operatorname{curl} u_h)$ *is relatively compact in* H^{-1} *(resp., bounded in* L^2*), there is a subsequence converging in* L^2_{loc}*.*

Proof. Indeed we can extract a subsequence converging weakly in L^2 to some u. Then we have, for all $\phi \in \mathcal{D}$,

$$\int |u_h|^2 \phi \to \int |u|^2 \phi. \tag{5.5}$$

Following standard procedure we deduce

$$\int |u_h - u|^2 \phi = \int |u_h|^2 \phi - 2 \int (u_h \cdot u)\phi + \int |u|^2 \phi \to 0, \tag{5.6}$$

which is a characterization of L^2_{loc} convergence. □

In other words, the above local discrete compactness property can be viewed as the special case of the discrete div-curl lemma where the sequences (u_h) and (u'_h) are equal. Furthermore, we remark that in the absence of boundary conditions on u_h one should not expect to be able to strengthen convergence from L^2_{loc} to L^2 in this result; see Proposition 2.7 in [1].

6. Discussion.

We close this paper with some remarks.

Of course, if an entire physical field is to be approximated numerically, a scheme which is only vaguely converging is of little practical use. Indeed the consensus seems to be to aim for rapid convergence in the energy norm. However, a method which satisfies a given property (vague convergence, for instance) under *the weakest of assumptions* shows a sign of *robustness*, in the sense that under extreme conditions it performs as well as one can reasonably hope for. Therefore the above result can be interpreted as a robustness property of edge elements with respect to a class of nonlinearities.

It is sometimes useful to state properties of discretized electromagnetic fields in terms of (nonsmooth) differentiable forms, a point of view developed by Bossavit [7] (see Hiptmair [23] for more on this). Likewise the div-curl lemma of Murat and Tartar can be stated in terms of differential forms (see, e.g., Taylor [38, pp. 358–359]). The translation of the results of this paper into this framework is unproblematic. A case of particular interest is when considering div conforming face elements [34, 10]. One obtains a similar div-curl lemma for face elements based this time on the discrete information on the curl (obtained by integrating against the curl of the naturally associated edge element space).

The question whether L^2-bounded sequences in $\widetilde{V}_h$ (discrete vector fields which are discrete divergence-free) have relatively compact divergence in H^{-1} is as of today unsettled for the standard FE spaces and, as mentioned in the introduction, the present paper can be seen as a circumvention of this question. The affirmative would imply a slightly stronger version of Theorem 4.1 (the condition $u'_h \in X_h$ can then be dropped).

The div-curl lemma is closely related to Hardy space estimates (see, e.g., Coifman et al. [17]) and a translation of the above results into uniform Hardy space estimates for edge elements could be an important step forward. More generally, this lemma is the prototype for so-called bilinear estimates which play a prominent role in the analysis of many nonlinear PDE. The original motivation for the present work was to develop some tools for the numerical analysis of the discretization of Yang–Mills equations [14], where consequences of weak divergence control are investigated.

hp-INTERPOLATION OF NONSMOOTH FUNCTIONS AND AN APPLICATION TO *hp*-A POSTERIORI ERROR ESTIMATION[*]

J. M. MELENK[†]

Abstract. The quasi-interpolation operators of Clément and Scott–Zhang type are generalized to the setting of the *hp*-FEM (finite element method). New polynomial lifting and inverse estimates are presented. The classical residual based a posteriori error estimator is generalized to the *hp*-FEM.

Key words. Clément interpolant, quasi interpolation, *hp*-FEM, polynomial inverse estimates, a posteriori error estimation

AMS subject classifications. 65N30, 65N35, 65N50

DOI. 10.1137/S0036142903432930

1. Introduction.

Quasi-interpolation operators, that is, operators achieving optimal rates of convergence also for classes of functions of low regularity have a long history, for example, in spline theory (see, e.g., [24] for an overview). In connection with the finite element method (FEM) such an operator was constructed by Clément in [22], where he showed how H^1-functions can be approximated by piecewise linear functions. Subsequent refinements and variations include [5,13,16,20,21,27,36,38] to account for higher order polynomials of fixed degree p, preservation of piecewise polynomial boundary conditions, curvilinear elements, Hermite elements, and anisotropic elements. Several of these refinements were done with a view to an application in residual-based finite element error estimation as discussed in the monographs [4,7,40].

While quasi interpolation in the context of the h-version FEM is well documented in the literature, the situation is less favorable for the p-version and particularly the hp-version of the FEM, where the approximation properties of spaces of piecewise polynomials are quantified in terms of both the local mesh size and the local polynomial degree. The one-dimensional situation of polynomial approximation on an interval has been thoroughly studied, and we refer the reader to [24] for an excellent exposition of pertinent results. In higher dimensions, the situation is somewhat less developed: Approximation results suitable for the application to the p-version FEM/spectral method in higher dimensions can be found in the survey article [17] (for L^2-based weighted and unweighted Sobolev spaces on tensor product domains) and [8,37] (likewise for L^2-based Sobolev spaces), where, however, extra regularity of the function to be approximated is assumed, namely, that it be in the Sobolev spaces H^s for some $s > d/2$, where $d \in \mathbb{N}$ is the spatial dimension. Quasi-interpolation operators making minimal regularity assumption have been constructed in [2,3] (for the Sobolev spaces $W^{k,q}$); their approximation results include, however, logarithmic factors if $q \neq 2$.

In the present paper, we develop optimal quasi-interpolation operators suitable for an application in the framework of the hp-version of the FEM. We exhibit two kinds of closely related operators: Clément-type operators (see Theorem 3.1) defined on the

space L^1 and Scott/Zhang-type operators (see Theorems 3.3, 3.4) defined on $W^{1,q}$ (so that traces on the boundary are defined) that preserve piecewise polynomial boundary conditions. Both operators achieve optimal rates of convergence. The paper restricts itself to problems in $\mathbb{R}^2$. This restriction is largely due to the way the operators that preserve piecewise polynomial boundary conditions are constructed, that is, to the method of the proof of Theorems 3.3 and 3.4. Theorem 3.1 can readily be extended to higher dimensions.

A particular application of the operators developed in the present paper is that they permit the extension of the h-FEM residual-based error estimation to the hp-FEM [34]. We illustrate the salient features in section 4.

This paper is organized as follows: In section 2, we introduce the necessary notation, in particular γ-shape regular triangulations of two-dimensional domains and the hp-FEM spaces of piecewise mapped polynomials. We emphasize that the element maps need not be affine, which is an important aspect in hp-FEM, and that variable approximation order is considered. Section 3, which is the heart of our paper, presents the quasi-interpolation operators. Section 4 illustrates how the quasi-interpolation operators of section 3 can be employed for reliable a posteriori error estimation. Finally, section 5 is devoted to the proof of the approximation properties of our quasi-interpolation operators. Since polynomial approximation of $W^{k,q}$-functions on reference configurations and polynomial liftings rely on fairly technical constructions, several of these constructions are relegated to the appendix.

2. Notation and assumptions.

We will denote by $\mathbb{N} = \{1, 2, \dots\}$ the positive integers; $\mathbb{N}_0 = \mathbb{N} \cup \{0\}$ denotes the nonnegative integers.

2.1. Triangulations.

We start with the standard definitions of meshes and triangulations for two-dimensional domains.

A triangulation $\mathcal{T}$ of a set $\Omega \subset \mathbb{R}^2$ is a collection of elements $K \in \mathcal{T}$; associated with each element K is an element map $F_K : \widehat{K} \to K$, where the reference element $\widehat{K}$ corresponding to K is either the reference square $S = (0,1)^2$ or the reference triangle

$$T = \{(x,y) \in \mathbb{R}^2 \,|\, 0 < x < 1,\ 0 < y < \min(x, 1-x)\}. \tag{2.1}$$

We consider triangulations that satisfy the following standard conditions:

(M1) The element maps $F_K : \widehat{K} \to K = F_K(\widehat{K})$ are C^1-diffeomorphisms between $\overline{\widehat{K}}$ and $\overline{K}$; i.e., there exist domains $\widehat{K}'$ and K' with $\overline{\widehat{K}} \subset \widehat{K}'$, $\overline{K} \subset K'$ such that F_K is in fact a C^1-diffeomorphism between $\widehat{K}'$ and K'.

(M2) For two elements K, K' the intersection $\Gamma := \overline{K} \cap \overline{K'}$ falls into exactly one of the following categories: Γ is empty, or a vertex, or a whole edge, or K and K' coincide (i.e., $F_K^{-1}(\Gamma)$ and $F_{K'}^{-1}(\Gamma)$ are edges, or vertices of the corresponding reference elements $\widehat{K}$, $\widehat{K}'$). Additionally, we require the map

$$Q : F_K^{-1}(\Gamma) \to F_{K'}^{-1}(\Gamma) : \quad x \mapsto (F_{K'}^{-1} \circ F_K)(x)$$

to be an affine homeomorphism.

(M3) $\Omega \setminus \cup_{K \in \mathcal{T}}$ is a set of Lebesgue measure zero.

A triangulation $\mathcal{T}$ is called γ-shape regular if additionally

$$h_K^{-1} \|F_K'\|_{L^\infty(\widehat{K})} + h_K \| \left(F_K'\right)^{-1} \|_{L^\infty(\widehat{K})} \le \gamma, \tag{2.2}$$

where $h_K = \operatorname{diam} K$. We say that the triangulation is *affine* if all element maps F_K are affine maps. The restriction $\mathcal{T}|_\omega$ denotes the subset of $\mathcal{T}$ that represents the triangulation of $\omega \subset \Omega$ satisfying (M1)–(M3).

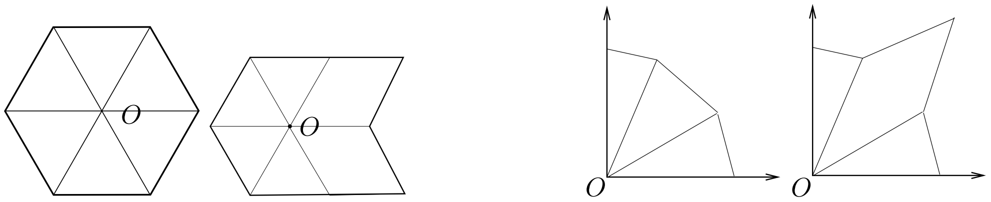

FIG. 2.1. *Left: interior reference patches $\omega_{int,6,1}$ and $\omega_{int,6,j}$ for some $j \in \{2,\dots,2^6\}$. Right: boundary reference patches $\omega_{bdy,3,1}$ and $\omega_{bdy,3,j}$ for some $j \in \{2,\dots,2^3\}$.*

For each element $K \in \mathcal{T}$ we denote by $\mathcal{E}(K)$ the set of edges of K and by $\mathcal{N}(K)$ the set of vertices of K. Similarly, $\mathcal{N}(\mathcal{T})$ denotes the set of all vertices of $\mathcal{T}$ and $\mathcal{E}(\mathcal{T})$ the set of all edges. Setting

$$\hat{I} = (0,1)$$

the assumption (M2) implies that we can define *edge maps* $F_e : \hat{I} \to e$ for each $e \in \mathcal{E}(\mathcal{T})$ by taking an element K such that e is an edge of K, then identifying the edge $F_K^{-1}(e)$ of $\hat{K}$ with $\hat{I}$ via an affine map, and finally taking F_e as the restriction of F_K to $F_K^{-1}(e)$; the assumption (M2) guarantees that the map F_e obtained in this way is independent of the choice of K. Additionally, we introduce the notion of the *patch* ω_V associated with a node $V \in \mathcal{N}(\mathcal{T})$ by

$$\omega_V := \{x \in \Omega \,|\, x \in \overline{K} \quad \text{for some } K \text{ with } V \in \overline{K}\}^\circ, \tag{2.3}$$

where A° denotes the interior of the set A. We note that the patches ω_V are open subsets of Ω. Of importance will be the connectivity of the patches. Our tool for classifying patches according to their connectivity will be the notion of *reference patches* that we make precise in the following definition.

DEFINITION 2.1 (reference patch). *Reference patches are Lipschitz domains that are either labeled* interior *or* boundary *patches. They are characterized as follows:*

1. Interior patches: *For each $M \in \mathbb{N}$, $M \geq 3$, we define 2^M* interior reference patches *$\omega_{int,M,j}$, $j = 1,\dots,2^M$, as follows: $\omega_{int,M,1}$ is defined to be the regular polygon with M edges of length 1 that is centered at the origin $0 \in \mathbb{R}^2$ and is triangulated with M triangles all sharing the vertex 0. The remaining $2^M - 1$ reference patches are obtained from this one by replacing one or several of these isosceles triangles by parallelograms (see Figure 2.1).*
2. Boundary patches: *For each $M \in \mathbb{N}$ we define 2^M* boundary reference patches *$\omega_{bdy,M,j}$, $j = 1,\dots,2^M$, in the following way: $\omega_{bdy,M,1} \subset \{(x,y) \,|\, x > 0, y > 0\}$ is the polygon that consists of M isosceles triangles all sharing the vertex $0 \in \mathbb{R}^2$ and having angle $\pi/(2M)$ at 0. The remaining $2^M - 1$ patches are obtained from this one by replacing one or several of these isosceles triangles by parallelograms (see Figure 2.1).*

We will only consider triangulations whose patches can be related to these reference patches:

(M4) For each vertex $V \in \mathcal{N}(\mathcal{T})$ there exists a reference patch $\widehat{\omega}_V$ of the form given in Definition 2.1 together with a homeomorphism $F_V : \widehat{\omega}_V \to \omega_V$ with $F_V(0) = V$, which has the form

$$F_V^{-1}|_K = A_{K,V} \circ F_K^{-1} \qquad \forall K \in \mathcal{T}|_{\omega_V},$$

where the maps $A_{K,V} : \mathbb{R}^2 \to \mathbb{R}^2$ are *affine.*

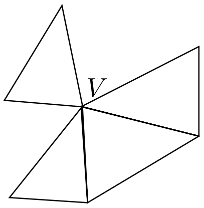

FIG. 2.2. *Example of a mesh excluded by* (M4).

Remark 2.2. It is worth pointing out that slit domains are not excluded by (M4). However, other kinds of domains that fail to be Lipschitz domain are not covered by the present results: For example, domains such as the one depicted in Figure 2.2 are not admitted since the vertex cannot be mapped to a boundary reference patch in the way condition (M4) requires.

We finish this subsection by noting that the γ-shape regularity of the element maps implies that only a finite number of elements can meet at a vertex.

LEMMA 2.3. *Let $\mathcal{T}$ be a γ-shape regular triangulation satisfying* (M1)–(M3). *Then there exists a constant $M \in \mathbb{N}$, which depends only on γ, such that*

1. *no more than M elements share a common vertex;*
2. *for any two elements K, K' with $\overline{K} \cap \overline{K'} \neq \emptyset$ there holds $M^{-1}h_K \leq h_{K'} \leq Mh_K$.*

If the triangulation satisfies additionally (M4), *then the maps $A_{K,V}$ appearing in condition* (M4) *satisfy*

$$\|A'_{K,V}\|_{L^\infty(\hat{K})} + \|A'^{-1}_{K,V}\|_{L^\infty(\hat{K})} \leq C$$

for some $C > 0$ that depends only on γ. Additionally, $F_V \in W^{1,\infty}(\widehat{\omega}_V)$ and $F_V^{-1} \in W^{1,\infty}(\omega_V)$, and we have the bound

$$h_V^{-1}\|F_V'\|_{L^\infty(\widehat{\omega}_V)} + h_V\left\|\left(F_V'\right)^{-1}\right\|_{L^\infty(\widehat{\omega}_V)} \leq C, \qquad h_V = \min_{K:V\in\mathcal{N}(K)} h_K$$

for some $C > 0$ depending solely on γ.

Proof.

Step 1. The element maps F_K are C^1 up to the boundary of the reference elements. The fact that the interior angles of the reference elements are nondegenerate and the γ-shape regularity assumption (2.2) then imply that the interior angles of elements $K \in \mathcal{T}$ are within $(\varepsilon, \pi - \varepsilon)$ for an $\varepsilon > 0$, which depends solely on γ. The first claim of the lemma then follows if we choose $M \in \mathbb{N}$ such that $M \geq 2\pi/\varepsilon$.

Step 2. The γ-shape regularity assumption (2.2) also implies the existence of $C > 0$ depending solely on γ such that

$$C^{-1}h_K \leq |e| \leq Ch_K \qquad \forall e \in \mathcal{E}(K) \qquad \forall K \in \mathcal{T}.$$

This fact together with the observation of the first step easily implies the second claim after appropriately adjusting the constant M.

Step 3. We will only show that $F_V^{-1} \in W^{1,\infty}(\omega_V)$ with the corresponding bound for the derivative. By assumption $F_V^{-1}|_K \in C^1(\overline{K})$ for each element $K \in \mathcal{T}|_{\omega_V}$. Then an elementwise integration by parts together with the observation $F_V^{-1} \in C(\omega_V)$ implies that the weak derivative is elementwise given by $(F_V^{-1})'|_K = A_{K,V} \cdot (F_K^{-1})'$. From this representation, we readily infer $F_V^{-1} \in W^{1,\infty}(\omega_V)$ and the desired bound. □

2.2. Polynomial spaces. The finite element spaces that we consider are the variable order piecewise mapped polynomials, an early implementation of which is discussed in [23]: For each element $K \in \mathcal{T}$, we choose a polynomial degree $p_K \in \mathbb{N}$ and collect these numbers in the polynomial degree vector $\mathbf{p} = (p_K)_{K\in\mathcal{T}}$. We then define the space $S^{\mathbf{p}}(\mathcal{T}) \subset W^{1,\infty}(\Omega)$ by

$$S^{\mathbf{p}}(\mathcal{T}) = \{u \in C(\Omega) \,|\, u|_K \circ F_K \in \Pi_{p_K}(\widehat{K})\}, \tag{2.4}$$

where we set

$$\Pi_p(\widehat{K}) = \begin{cases} \mathcal{P}_p := \operatorname{span}\{x^i y^j \,|\, 0 \le i+j \le p\} & \text{if } \widehat{K} = T, \\ \mathcal{Q}_p := \operatorname{span}\{x^i y^j \,|\, 0 \le i,j \le p\} & \text{if } \widehat{K} = S. \end{cases} \tag{2.5}$$

We will write $S^p(\mathcal{T})$ if the degree vector $\mathbf{p}$ satisfies $p_K = p$ for all $K \in \mathcal{T}$. In this case, we will also permit the choice $p = 0$, where $S^0(\mathcal{T})$ reduces to a one-dimensional space.

A key property of the spaces $S^{\mathbf{p}}(\mathcal{T})$ is that we can identify "nodal shape functions" that form a partition of unity; i.e., for each vertex $V \in \mathcal{N}(\mathcal{T})$, we can find a function $\varphi_V \in S^1(\mathcal{T})$ such that

$$\varphi_V|_{\Omega\setminus\omega_V} \equiv 0 \qquad \text{and} \qquad \sum_{V\in\mathcal{N}(\mathcal{T})} \varphi_V \equiv 1 \quad \text{on } \Omega. \tag{2.6}$$

A well-known consequence of the γ-shape regularity of the triangulation is that these nodal shape functions satisfy for some constant $C > 0$, which depends solely on γ,

$$\|\varphi_V\|_{L^\infty(\Omega)} \le 1, \qquad \|\nabla\varphi_V\|_{L^\infty(\Omega)} \le C h_K^{-1} \qquad \forall K \in \mathcal{T}|_{\omega_V}. \tag{2.7}$$

In the present paper we consider only γ-shape regular triangulations. Such triangulations have the property that neighboring elements are comparable in size (cf. Lemma 2.3). We impose a similar condition on the polynomial degree distribution:

$$\gamma^{-1} p_K \le p_{K'} \le \gamma p_K \qquad \forall K, K' \in \mathcal{T} \quad \text{such that (s.t.) } \overline{K} \cap \overline{K'} \ne \emptyset. \tag{2.8}$$

We will also employ the notation

$$p_V := \min\{p_K \,|\; V \in \mathcal{N}(K)\}, \qquad p_e := \min\{p_K \,|\; e \in \mathcal{E}(K)\}. \tag{2.9}$$

2.3. Notation for Sobolev spaces. For domains $\Omega \subset \mathbb{R}^2$ and $k \in \mathbb{N}_0$, $q \in [1,\infty]$ we employ standard Sobolev spaces $W^{k,q}(\Omega)$ as described in, e.g., [1]. For the reference interval $\hat{I} = (0,1)$, $\kappa \in (0,1)$, and $q \in [1,\infty)$, we equip the space $W^{\kappa,q}(\hat{I})$ with the Slobodeckij norm

$$\|u\|^q_{W^{\kappa,q}(\hat{I})} = \|u\|^q_{L^q(\hat{I})} + \int_{\hat{I}}\int_{\hat{I}} \frac{|u(x) - y(y)|^q}{|x-y|^{1+q\kappa}}\,dx\,dy. \tag{2.10}$$

We will also require the spaces $\widetilde{W}^{\kappa,q}(\hat{I})$, which consist of the functions $u \in W^{\kappa,q}(\hat{I})$ such that their trivial extension (i.e., by zero) to $\mathbb{R}$ is an element of $W^{\kappa,q}(\mathbb{R})$. This space is equipped with the norm

$$\|u\|^q_{\widetilde{W}^{\kappa,q}(\hat{I})} = \|u\|^q_{W^{\kappa,q}(\hat{I})} + \int_0^1 \frac{|u(x)|^q}{x^{\kappa q}}\,dx + \int_0^1 \frac{|u(x)|^q}{(1-x)^{\kappa q}}\,dx. \tag{2.11}$$

In analogy with the spaces $\widetilde{W}^{\kappa,q}(\hat{I})$ we can define the spaces $\widetilde{W}_l^{\kappa,q}(\hat{I})$ if the trivial extension to $I' = \{x \in \mathbb{R} \,|\, x < 1\}$ is in $W^{\kappa,q}(I')$. This space is equipped with the norm

$$\|u\|^q_{\widetilde{W}_l^{\kappa,q}(\hat{I})} = \|u\|^q_{W^{\kappa,q}(\hat{I})} + \int_0^1 \frac{|u(x)|^q}{x^{\kappa q}}\,dx. \tag{2.12}$$

We also note how functions transform under concatenation with the patch maps F_V.

Lemma 2.4. *Let $\mathcal{T}$ be a γ-shape regular triangulation satisfying* (M1)–(M4). *Let $q \in [1,\infty]$. Then for every patch ω_V, $V \in \mathcal{N}(\mathcal{T})$, and every $u \in W^{1,q}(\omega_V)$ we have that $\widehat{u} := u \circ F_V \in W^{1,q}(\widehat{\omega}_V)$ and*

$$\|\widehat{u}\|_{L^q(\widehat{\omega}_V)} \sim h_V^{-2/q}\|u\|_{L^q(\omega_V)}, \qquad \|\nabla\widehat{u}\|_{L^q(\widehat{\omega}_V)} \sim h_V^{1-2/q}\|\nabla u\|_{L^q(\omega_V)}, \tag{2.13}$$

where $h_V = \min_{K:K\subset\omega_V} h_K$. The constants hidden in the $\sim$-notation depend solely on γ and q.

Proof. We claim that the pull-back $\widehat{u}$ is in $W^{1,q}(\widehat{\omega}_V)$. To see this, we first consider the case $q < \infty$. For each element K of the patch ω_V and its corresponding element $K' := F_V^{-1}(K) \subset \widehat{\omega}_V$, the assumption (M1) guarantees that $F_V|_{K'} \in C^1(\overline{K'})$ and likewise $F_V^{-1} \in C^1(\overline{K})$. Hence by standard properties of Sobolev space (see, e.g., [1, Chap. III, Thm. 3.35]) we have for each element K that $u\circ F_V|_{K'} \in W^{1,q}(K')$ and the derivative satisfies $(\nabla(u\circ F_V))|_{K'} = (\nabla u \circ F_V)F_V'$. In order to see that $u\circ F_V$ is in $W^{1,q}(\widehat{\omega}_V)$ we have to check that the traces on the edges shared by two elements K_1, K_2 of $\widehat{\omega}_V$ coincide. This follows easily from the assumption (M3). The case $q = \infty$ is obtained by inspection: Since the weak derivative has been identified as $(\nabla u \circ F_V)F_V'$, one merely has to check that it is in $L^\infty(\widehat{\omega}_V)$, which is indeed the case. The bounds (2.13) now follow from (2.2). □

3. Quasi interpolation of nonsmooth functions.

We present two types of quasi-interpolation results for $W^{1,q}$-functions: In Theorem 3.1 we exhibit a quasi-interpolation operator of Clément type; in Theorem 3.3 we present an operator that additionally preserves homogeneous boundary conditions that may be imposed on parts of the boundary. This latter operator is generalized in Theorem 3.4 to an operator that preserves arbitrary piecewise polynomial Dirichlet boundary conditions.

In order to formulate these results, we introduce the following additional notation: For $e \in \mathcal{E}(\mathcal{T})$ we denote by $\mathcal{N}(e)$ the two endpoints of e, i.e., $\mathcal{N}(e) = \{V \in \mathcal{N}(\mathcal{T}) \,|\, V \in \overline{e}\}$. Patches of order $j \in \mathbb{N}$ associated with an element $K \in \mathcal{T}$ or an edge $e \in \mathcal{E}(\mathcal{T})$ are defined thus:

$$\omega_e^1 := \bigcup_{V\in\mathcal{N}(e)} \omega_V, \qquad \omega_e^{j+1} := \bigcup_{V\in\mathcal{N}(\mathcal{T}):V\in\overline{\omega_e^j}} \omega_V, \quad j = 1,2,\ldots, \tag{3.1}$$

$$\omega_K^1 := \bigcup_{V\in\mathcal{N}(K)} \omega_V, \qquad \omega_K^{j+1} := \bigcup_{V\in\mathcal{N}(\mathcal{T}):V\in\overline{\omega_K^j}} \omega_V, \quad j = 1,2,\ldots. \tag{3.2}$$

3.1. Clément-type approximation.

Quasi interpolation of Clément type takes the following form.

Theorem 3.1 (Clément-type quasi interpolation). *Let $\mathcal{T}$ be a γ-shape regular triangulation of a domain $\Omega \subset \mathbb{R}^2$ satisfying* (M1)–(M4) *and let $\mathbf{p}$ be a polynomial degree distribution satisfying* (2.8). *Then there exists a bounded linear operator I^{hp} : $L^1(\Omega) \to S^{\mathbf{p}}(\mathcal{T}) \subset L^1(\Omega)$, and there exists a constant $C > 0$, which depends solely on*

$q \in [1, \infty]$ and γ, such that for every $u \in W^{1,q}(\Omega)$ and all elements $K \in \mathcal{T}$ and all edges $e \in \mathcal{E}(\mathcal{T})$

$$\|u - I^{hp}u\|_{L^q(K)} + \frac{h_K}{p_K}\|\nabla(u - I^{hp}u)\|_{L^q(K)} \le C\frac{h_K}{p_K}\|\nabla u\|_{L^q(\omega_K^1)}, \tag{3.3}$$

$$\|u - I^{hp}u\|_{L^q(e)} \le C\left(\frac{h_e}{p_e}\right)^{1-1/q}\|\nabla u\|_{L^q(\omega_e^1)}. \tag{3.4}$$

Proof. The proof can be found in section 5.2. □

3.2. Scott–Zhang-type approximation. The operator I^{hp} of Theorem 3.1 does not preserve piecewise polynomial boundary conditions if applied to functions of $W^{1,q}(\Omega)$. The operators of Theorem 3.1 can, however, be modified to have this property.

Let a set $\mathcal{B} \subset \mathcal{E}(\mathcal{T})$ of boundary edges of the triangulation $\mathcal{T}$ be given, i.e.,

$$\mathcal{B} \subset \mathcal{E}(\mathcal{T}) \quad \text{and} \quad b \subset \partial\Omega \qquad \forall b \in \mathcal{B}. \tag{3.5}$$

Next, we define for $q \in (1, \infty)$ the spaces

$$W^{1,q}_{\mathcal{B},0} := \{u \in W^{1,q}(\Omega) \,|\, u|_b = 0 \text{ for all } b \in \mathcal{B}\}, \tag{3.6}$$

$$W^{1,q}_{\mathcal{B},\mathbf{p}} := \{u \in W^{1,q}(\Omega) \,|\, u|_b \circ F_b \in \mathcal{P}_{p_b} \text{ for all } b \in \mathcal{B} \text{ and (3.8) holds}\}, \tag{3.7}$$

where the continuity condition (3.8) is

$$\text{for all } b, b' \in \mathcal{B} \text{ and } V \in \mathcal{N}(b) \cap \mathcal{N}(b') \text{ there holds } \lim_{\substack{x\to V\\ x\in b}} u(x) = \lim_{\substack{x\to V\\ x\in b'}} u(x). \tag{3.8}$$

Remark 3.2. Since the edges of $\mathcal{B}$ are part of the boundary of $\partial\Omega$, the function values are understood in the sense of traces. In the case of slit domains appropriate limits have to be taken.

We then have the following approximation results.

THEOREM 3.3 (homogeneous boundary conditions). *Let $\mathcal{T}$ be a γ-shape regular triangulation of a domain $\Omega \subset \mathbb{R}^2$ satisfying* (M1)–(M4)*. Let $\mathbf{p}$ be a polynomial degree distribution satisfying* (2.8)*. Let $q \in (1, \infty)$ and a set $\mathcal{B} \subset \mathcal{E}(\mathcal{T})$ of boundary edges be given. Then there exists a linear operator $I^{hp}_{hom} : W^{1,q}_{\mathcal{B},0}(\Omega) \to S^{\mathbf{p}}(\mathcal{T}) \cap W^{1,q}_{\mathcal{B},0}(\Omega)$, and there exists a constant $C > 0$ depending solely on γ and q such that*

$$\|u - I^{hp}_{hom}u\|_{L^q(K)} + \frac{h_K}{p_K}\|\nabla(u - I^{hp}_{hom}u)\|_{L^q(K)} \le C\frac{h_K}{p_K}\|\nabla u\|_{L^q(\omega_K^1)}, \tag{3.9}$$

$$\|u - I^{hp}_{hom}u\|_{L^q(e)} \le C\left(\frac{h_e}{p_e}\right)^{1-1/q}\|\nabla u\|_{L^q(\omega_e^1)}. \tag{3.10}$$

Proof. The proof can be found in section 5.3. □

A slightly different situation arises if nonhomogeneous piecewise polynomial boundary conditions are to be preserved: The domain of influence in the local bounds is enlarged, and we impose a restriction on the variation in polynomial degree distribution for elements near the Dirichlet part of the boundary.

THEOREM 3.4 (Scott–Zhang-type quasi interpolation). *Let $q \in (1, \infty)$ and let $\mathcal{T}$ be a γ-shape regular triangulation of a domain $\Omega \subset \mathbb{R}^2$ satisfying* (M1)–(M4)*. Let $\mathbf{p}$*

be a polynomial degree distribution satisfying (2.8)*. Let* $\mathcal{B} \subset \mathcal{E}(\mathcal{T})$ *be a collection of boundary edges. If* $q \neq 2$*, assume additionally that*

$$|p_K - p_{K'}| \leq \gamma \qquad \forall K, K' \text{ s.t. } \overline{K} \cap \overline{K'} \cap \bar{b} \neq \emptyset \text{ for some } b \in \mathcal{B}. \tag{3.11}$$

Then there exists a linear operator $I^{hp}_{inhom} : W^{1,q}_{\mathcal{B},\mathbf{p}}(\Omega) \to S^{\mathbf{p}}(\mathcal{T})$ *such that*

$$(I^{hp}_{inhom} u)|_b = u|_b \qquad \forall b \in \mathcal{B}.$$

Furthermore, there exists a constant $C > 0$ *depending only on* γ *and* q *such that for all elements* $K \in \mathcal{T}$ *and all edges* $e \in \mathcal{E}(\mathcal{T})$

$$\|u - I^{hp}_{inhom} u\|_{L^q(K)} + \frac{h_K}{p_K} \|\nabla(u - I^{hp}_{inhom} u)\|_{L^q(K)} \leq C \frac{h_K}{p_K} \|\nabla u\|_{L^q(\omega^4_K)},$$

$$\|u - I^{hp}_{inhom} u\|_{L^q(e)} \leq C \left(\frac{h_K}{p_K}\right)^{1-1/q} \|\nabla u\|_{L^q(\omega^4_e)}.$$

Proof. The proof can be found in section 5.4. □

Remark 3.5. The dependence on the domains ω^4_K, ω^4_e is not optimal. A careful inspection of the proof allows slightly sharper bounds. For example, for elements K such that $\omega^4_K \subset\subset \Omega$ we can replace ω^4_K with ω^1_K.

4. Residual-based a posteriori error estimation.

The Clément-type interpolation operators can be utilized for a posteriori error estimation as discussed in [34]. The following proposition illustrates the type of results that can be obtained for a simple model problem.

PROPOSITION 4.1. *Let* $\mathcal{T}$ *be a triangulation of a domain* $\Omega \subset \mathbb{R}^2$ *that satisfies* (M1)–(M4)*. Assume that a polynomial degree distribution* $\mathbf{p}$ *satisfies* (2.8)*. For* $f \in L^2(\Omega)$ *let* $u \in H^1_0(\Omega)$ *be the weak solution of*

$$-\Delta u = f \qquad \text{on } \Omega, \qquad u|_{\partial\Omega} = 0. \tag{4.1}$$

Let $u_{FE} \in S^{\mathbf{p}}(\mathcal{T}) \cap H^1_0(\Omega)$ *be the finite element approximation to* u*. Then*

$$\|\nabla(u - u_{FE})\|^2_{L^2(\Omega)} \leq C \sum_{K \in \mathcal{T}} \eta^2_K, \tag{4.2}$$

where the local error indicators η_K *are defined by*

$$\eta^2_K := \left(\frac{h_K}{p_K}\right)^2 \|f + \Delta u_{FE}\|^2_{L^2(K)} + \sum_{\substack{e \in \mathcal{E}(K) \\ e \not\subset \partial\Omega}} \frac{h_e}{p_e} \|[\partial_n u_{FE}]\|^2_{L^2(e)}, \tag{4.3}$$

and $[\partial_n u_{FE}]$ *denotes the jump of the normal derivative of* u_{FE} *across the edge* e*. The constant* $C > 0$ *in* (4.2) *depends solely on* γ*.*

Proof. The proof follows along standard lines of residual-based a posteriori error estimation as outlined, for example, in [40]. We have the characterization

$$\|\nabla(u - u_{FE})\|_{L^2(\Omega)} = \sup_{v \in H^1_0(\Omega)} \frac{R(v)}{\|\nabla v\|_{L^2(\Omega)}}, \qquad R(v) := \int_\Omega \nabla(u - u_{FE}) \cdot \nabla v \, dx. \tag{4.4}$$

From the standard Galerkin orthogonality satisfied by the finite element solution u_{FE}, we have $R(v) = 0$ for all $v \in S^{\mathbf{p}}(\mathcal{T}) \cap H_0^1(\Omega)$. In particular, therefore $R(v) = R(v - I_{hom}^{hp} v)$ for all $v \in H_0^1(\Omega)$. Breaking up the integral over Ω into a sum of integrals over elements and an elementwise integration by parts yields for arbitrary $v \in H_0^1(\Omega)$

$$R(v) = R(v - I_{hom}^{hp} v) = \sum_{K \in \mathcal{T}} \int_K (f + \Delta u_{FE})(v - I_{hom}^{hp} v) + \int_{\partial K} \partial_n u_{FE}\, (v - I_{hom}^{hp} v)\, ds.$$

Hence using the abbreviations $r_K := f + \Delta u_{FE}$ and $r_e := [\partial_n u_{FE}]$ for the element residuals and edge residuals, the Cauchy–Schwarz inequality and Theorem 3.3 yield

$$\begin{aligned} |R(v)| &\leq \sum_{K \in \mathcal{T}} \|r_K\|_{L^2(K)} \|v - I_{hom}^{hp} v\|_{L^2(K)} + \sum_{\substack{e \in \mathcal{E}(\mathcal{T}) \\ e \not\subset \partial\Omega}} \|r_e\|_{L^2(e)} \|v - I_{hom}^{hp} v\|_{L^2(e)} \\ &\leq C \left\{ \sum_{K \in \mathcal{T}} \eta_K^2 \right\}^{1/2} \left\{ \sum_{K \in \mathcal{T}} \|\nabla v\|^2_{L^2(\omega_K^1)} \right\}^{1/2} \leq C \left\{ \sum_{K \in \mathcal{T}} \eta_K^2 \right\}^{1/2} \|\nabla v\|_{L^2(\Omega)}, \end{aligned}$$

where, in the last step, we employed a variation of Lemma 2.3 to conclude the existence of a constant $M > 0$ depending solely on γ such that each element $K \in \mathcal{T}$ is contained in not more than M sets of the form $\omega_{K'}^1$, $K' \in \mathcal{T}$. This concludes the argument. $\square$

Proposition 4.1 shows that the error estimator defined as the sum of the error indicators (4.1) is reliable. A corresponding lower bound, also known as efficiency estimate, is well known in the *h*-FEM. The difficulty in the present case of the *hp*-version is that polynomial inverse estimates have to be employed. The resulting lower bound then turns out to be independent of the local mesh size but dependent on the local polynomial degree. We refer to [34] for more details.

5. Proofs of the approximation results of section 3. We prove Theorems 3.1, 3.3, and 3.4 in turn, since Theorem 3.3 depends on Theorem 3.1, and Theorem 3.4 depends on both Theorem 3.1 and Theorem 3.3. For the proof of Theorem 3.1, we require polynomial approximation results on a reference configuration, which we choose to be a hyper cube, in section 5.1.1. For the proof of Theorems 3.3 and 3.4, we additionally require polynomial lifting results that are provided in section 5.1.2.

5.1. Polynomial approximation and lifting.

5.1.1. Polynomial approximation. For polynomial approximation on hyper cubes we have the following result.

THEOREM 5.1. *Let $d \in \mathbb{N}$ and I_i, $i = 1, \ldots, d$, be bounded intervals. Set $I = I_1 \times \cdots \times I_d$. Let $R \in \mathbb{N}$. Then for each $N \in \mathbb{N}_0$ there exists a bounded linear operator $J_{R,N} : L^1(I) \to \mathcal{Q}_N(I)$ with the following properties: For each $q \in [1, \infty]$ there exists a constant $C > 0$, which depends only on R, q, and I, such that for all $N \geq R - 1$ and all $0 \leq r \leq R$*

$$J_{R,N} u = u \qquad \forall u \in \mathcal{Q}_{R-1}, \tag{5.1}$$

$$\|u - J_{R,N} u\|_{W^{l,q}(I)} \leq C (N+1)^{-(r-l)} |u|_{W^{r,q}(I)}, \qquad l = 0, \ldots, r. \tag{5.2}$$

Proof. The operator $J_{R,N}$ is constructed as the tensor product of one-dimensional operators that are often employed in approximation theory. The detailed arguments can be found in Appendix A. $\square$

5.1.2. Polynomial liftings and extensions. In order to enforce polynomial boundary conditions, polynomial lifting results are required.

THEOREM 5.2. *Let K be the reference triangle or the reference square. Let $\Gamma = \overline{\Gamma} \subset \partial K$ be the union of closed edges of K. Let $q \in (1,\infty)$. Then there exists a constant $C > 0$ with the following property: For each $f \in C(\Gamma)$ such that f is a polynomial of degree p on each edge contained in Γ, there exists a polynomial $F \in \mathcal{P}_p$ if K is the triangle or $F \in \mathcal{Q}_p$ if K is the square such that $F|_\Gamma = f$ and*

$$\|F\|_{L^q(T)} \leq C\|f\|_{L^q(\Gamma)},$$
$$\|F\|_{W^{1,q}(T)} \leq C\|f\|_{W^{1-1/q,q}(\Gamma)}.$$

Moreover, the mapping $f \mapsto F$ is linear, and it reproduces constant functions.

Proof. The proof can be found in Appendix B.2.1. □

The lifting result Theorem 5.2 allows us to construct $W^{1,q}$-stable liftings from the boundary of the reference element. Our constructions will require an additional lifting where the L^q-norm of the lifting is smaller than that of Theorem 5.2. This is the merit of the next proposition.

PROPOSITION 5.3. *Let K be the reference triangle or the reference square. Let $\Gamma = \overline{\Gamma} \subset \partial K$ be a union of edges of K. Let $q \in (1,\infty)$. Then there exists $C > 0$ such that for every $f \in C(\Gamma)$, which is a polynomial of degree $p \in \mathbb{N}$ on each edge of K, there exists a polynomial F (if K is the reference triangle, then $F \in \mathcal{P}_{3p}$; otherwise $F \in \mathcal{Q}_{4p}$) such that $F|_{\partial\Gamma} = f$ and*

$$p\|F\|_{L^q(K)} + \|F\|_{W^{1,q}(K)} \leq C\|f\|_{W^{1-1/q,q}(\Gamma)} + Cp^{1-1/q}\|f\|_{L^q(\Gamma)}.$$

Furthermore, the mapping $f \mapsto F$ is linear.

Proof. The proof can be found in Appendix B.2.2. We mention that the proof of Proposition 5.3 can be modified so that $F \in \mathcal{P}_{\lceil \lambda p \rceil}$ or $F \in \mathcal{Q}_{\lceil \lambda p \rceil}$ for arbitrarily chosen $\lambda > 1$. The constant $C > 0$ does depends on λ, however. □

We will also employ the following one-dimensional extension result.

LEMMA 5.4. *Let $\hat{I} = (0,1)$, $q \in (1,\infty)$. Let $k \in \mathbb{N}_0$. Then there exists $C > 0$ such that for every $p \in \mathbb{N}_0$ with $p \geq k$ there exists a linear operator $Z_{p,p-k} : \mathcal{P}_p \to \mathcal{P}_{p-k}$ with the following properties:*

$$Z_{p,p-k}1 = 1, \qquad (Z_{p,p-k}u)(0) = u(0),$$
$$\|Z_{p,p-k}u\|_{L^q(\hat{I})} \leq C\|u\|_{L^q(\hat{I})}, \qquad \|Z_{p,p-k}u\|_{W^{1-1/q,q}(\hat{I})} \leq C\|u\|_{W^{1-1/q,q}(\hat{I})},$$
$$\|Z_{p,p-k}u - u\|_{\widetilde{W}_l^{1-1/q,q}(\hat{I})} \leq C\|u\|_{W^{1-1/q,q}(\hat{I})}.$$

Proof. The proof can be found in Appendix C. □

For $q = 2$ a sharper construction is possible, namely, to take the Gauß–Lobatto interpolant.

LEMMA 5.5. *Let $q = 2$ and $\lambda \in (0,1)$. Denote by $\mathcal{I}_{\lfloor \lambda p \rfloor} : \mathcal{P}_p \to \mathcal{P}_{\lfloor \lambda p \rfloor}$, the Gauß–Lobatto interpolation operator scaled to the interval $\hat{I}$. Then $i_{\lfloor \lambda p \rfloor}1 = 1$, $(\mathcal{I}_{\lfloor \lambda p \rfloor}u)(0) = u(0)$ for all $u \in \mathcal{P}_p$, and there exists $C > 0$ depending only on λ such that*

$$\|\mathcal{I}_{\lfloor \lambda p \rfloor}u\|_{L^2(\hat{I})} \leq C\|u\|_{L^2(\hat{I})}, \quad \|\mathcal{I}_{\lfloor \lambda p \rfloor}u\|_{W^{1/2,2}(\hat{I})} \leq C\|u\|_{W^{1/2,2}(\hat{I})}, \tag{5.3}$$

$$\|u - \mathcal{I}_{\lfloor \lambda p \rfloor}u\|_{\widetilde{W}^{1/2,2}(\hat{I})} \leq C\|u\|_{W^{1/2,2}(\hat{I})}. \tag{5.4}$$

Proof. The key step of the proof consists in stability estimates for the Gauß–Lobatto interpolation and can be obtained by combining the results of [17, Rem. 13.5]

(L^2-stability of the Gauß–Lobatto interpolation when applied to polynomials), [17, eq. (13.27)] (stability of the Gauß–Lobatto interpolation operator in H^1), and a bound in a weighted L^2-space [17, Thm. 13.4]. For a detailed version of the proof, we refer to [25, Lem. 4.1]. □

5.2. Proof of Theorem 3.1. The Clément-type interpolation operator I^{hp} is constructed in two steps: For each patch ω_V a local approximation I_V operator is constructed; in a second step, these local approximations are combined into a global one using the ideas of the partition of unity method [33]. The local approximation operator I_V is defined on the corresponding reference patch $\widehat{\omega}_V$ by extending to a suitable square containing $\widehat{\omega}_V$ and then employing the polynomial approximation result (Theorem 5.1).

We start by recalling a result from [33].

Lemma 5.6. *Let $\mathcal{T}$ be a γ-shape regular triangulation triangulation of a domain $\Omega \subset \mathbb{R}^2$ satisfying* (M1)–(M3). *Let $q \in [1, \infty]$, and let $\mathbf{p}$ be an arbitrary polynomial degree distribution. Let $u \in W^{1,q}(\Omega)$ and let, for each $V \in \mathcal{N}(\mathcal{T})$, a function $u_V \in S^{p_V - 1}(\mathcal{T}|_{\omega_V})$ be given, where p_V is defined in* (2.9). *Then there exists $C > 0$ depending solely on γ such that the function $\widetilde{u} := \sum_{V \in \mathcal{N}(\mathcal{T})} \varphi_V u_V \in S^{\mathbf{p}}(\mathcal{T})$ and*

$$\|u - \tilde{u}\|_{L^q(K)} \leq C \sum_{V \in \mathcal{N}(K)} \|u - u_V\|_{L^q(K)},$$

$$\|\nabla(u - \tilde{u})\|_{L^q(K)} \leq C \sum_{V \in \mathcal{N}(K)} \left[\|\nabla(u - u_V)\|_{L^q(K)} + \frac{1}{h_K} \|u - u_V\|_{L^q(K)} \right],$$

$$\|u - \tilde{u}\|_{L^q(e)} \leq C \sum_{V \in \mathcal{N}(e)} \|u - u_V\|_{L^q(e)}.$$

Proof. We start by ascertaining $\tilde{u} \in C(\Omega)$. This follows easily from the support properties of the functions $\varphi_V \in C(\Omega)$, namely, $\varphi|_{\Omega \setminus \omega_V} \equiv 0$, together with $u_V \in C(\omega_V) \cap L^\infty(\omega_V)$. In order to see $\tilde{u} \in S^{\mathbf{p}}(\mathcal{T})$ we have to make sure that $(\varphi_V u_V) \circ F_K \in \Pi_{p_K}(\hat{K})$ for all $K \in \mathcal{T}|_{\omega_V}$ for all $V \in \mathcal{N}(\mathcal{T})$. This follows easily from $\varphi_V \in S^1(\mathcal{T})$ and $u_V \in S^{p_V - 1}(\mathcal{T}|_{\omega_V})$. The essential ingredient for proving the estimates is the observation that $\sum_{V \in \mathcal{N}(K)} \varphi_V \equiv 1$ on K for every $K \in \mathcal{T}$ and $\sum_{V \in \mathcal{N}(e)} \varphi_V \equiv 1$ on e for every $e \in \mathcal{E}(\mathcal{T})$. The bounds on $(u - \tilde{u})|_K$ then follow from the observation that $(u - \tilde{u})|_K = \sum_{V \in \mathcal{N}(K)} \varphi_V (u - u_V)$, where the sum extends over at most four terms, and from the bounds (2.6) on the functions φ_V. □

Lemma 5.7. *Let $\mathcal{T}$ a γ-shape regular triangulation of a domain $\Omega \subset \mathbb{R}^2$ satisfying* (M1)–(M4). *Assume that the polynomial degree distribution $\mathbf{p}$ satisfies* (2.8). *Then for each vertex V there exists a bounded linear operator $I_V : L^1(\omega_V) \to S^{p_V - 1}(\mathcal{T}|_{\omega_V})$, and there exists a constant $C > 0$, which depends solely on γ, such that for each $u \in W^{1,q}(\omega_V)$, each $K \in \mathcal{T}|_{\omega_V}$, and each edge $e \in \mathcal{E}(\mathcal{T}|_{\omega_V})$*

$$\|u - I_V u\|_{L^q(K)} + \frac{h_K}{p_K} \|\nabla(u - I_V u)\|_{L^q(K)} \leq C \frac{h_V}{p_V} \|\nabla u\|_{L^q(\omega_V)},$$

$$\|u - I_V u\|_{L^q(e)} \leq C \left(\frac{h_V}{p_V} \right)^{1 - 1/q} \|\nabla u\|_{L^q(\omega_V)}.$$

Proof. Consider a patch ω_V. Condition (M4) provides the patch map $F_V : \widehat{\omega}_V \to \omega_V$ and Lemma 2.4 gives $\widehat{u}_V = u|_K \circ F_V \in W^{1,q}(\widehat{\omega}_V)$ together with

$$\|\widehat{u}_V\|_{L^q(\widehat{\omega}_V)} \leq C h_V^{2/q} \|u\|_{L^q(\omega_V)}, \qquad \|\nabla \widehat{u}_V\|_{L^q(\widehat{\omega}_V)} \leq C h_V^{1 - 2/q} \|\nabla u\|_{L^q(\omega_V)}.$$

Let $\widehat{S}$ be a square such that $\widehat{\omega}_V \subset\subset \widehat{S}$ and denote by $E : L^1(\widehat{\omega}_V) \to L^1(\widehat{S})$ the universal linear extension operator of [39]. We then have the existence of a constant $C_q > 0$, which depends solely on $q \in [1,\infty]$ and $\widehat{\omega}_V$, such that

$$\|E\widehat{u}_V\|_{L^q(\widehat{S})} \le C_q \|\widehat{u}_V\|_{L^q(\widehat{\omega}_V)}, \qquad \|E\widehat{u}_V\|_{W^{1,q}(\widehat{S})} \le C\|\widehat{u}_V\|_{W^{1,q}(\widehat{\omega}_V)}.$$

Choosing $N = \lfloor (p_V - 1)/2 \rfloor$ in the approximation result (Theorem 5.1), we obtain a bounded linear operator $J_{1,N} : L^1(\widehat{S}) \to \mathcal{Q}_N \subset \mathcal{P}_{p_V-1}$ that reproduces constant functions and satisfies

$$(p_V+1)\|v - J_{1,N}v\|_{L^q(\widehat{S})} + \|\nabla(v - J_{1,N}v)\|_{L^q(\widehat{S})} \le C\|v\|_{W^{1,q}(\widehat{S})} \qquad \forall v \in W^{1,q}(\widehat{S}).$$

We next define the operator $J_{p_V} : L^1(\widehat{\omega}_V) \to \mathcal{P}_{p_V-1}$ by

$$J_{p_V} v := \overline{v} + J_{1,N} \circ E(v - \overline{v}), \qquad \overline{v} := \frac{1}{|\widehat{\omega}_V|}\int_{\widehat{\omega}_V} v(x)\,dx.$$

J_{p_V} is a bounded linear operator on $L^1(\widehat{\omega}_V)$, and we obtain for $W^{1,q}$-functions

$$(p_V+1)\|v - J_{p_V}v\|_{L^q(\widehat{\omega}_V)} + \|\nabla(v - J_{p_V}v)\|_{L^q(\widehat{\omega}_V)} \le C\|v - \overline{v}\|_{W^{1,q}(\widehat{\omega}_V)} \le C\|\nabla v\|_{L^q(\widehat{\omega}_V)},$$

where in the last estimate we employed the second Poincaré inequality. Applying this operator to the pull-back $\widehat{u}_V$, we obtain

$$\begin{aligned}(p_V+1)\|\widehat{u}_V - J_{p_V}\widehat{u}_V\|_{L^q(\widehat{\omega}_V)} + \|\nabla(\widehat{u}_V - J_{p_V}\widehat{u}_V)\|_{L^q(\widehat{\omega}_V)} &\le C\|\nabla \widehat{u}_V\|_{L^q(\widehat{\omega}_V)}\\ &\le Ch_V^{1-2/q}\|u_V\|_{L^q(\omega_V)}.\end{aligned}$$

Returning to the patch ω_V, we observe that the function u_{p_V} defined on ω_V by $u_{p_V} = (J_{p_V}\widehat{u}_V) \circ F_V^{-1}$ is an element of $S^{p_V-1}(\mathcal{T}|_{\omega_V})$ (this is due to the fact that elementwise F_V is the composition of an *affine* map and the element map) and

$$(p_V+1)h_V^{-2/q}\|u_V - u_{p_V}\|_{L^q(\omega_V)} + h_V^{1-2/q}\|\nabla(u_V - u_{p_V})\|_{L^q(\omega_V)} \le Ch_V^{1-2/q}\|\widehat{u}_V\|_{L^q(\omega_V)}.$$

This leads to the desired bound on elements $K \in \mathcal{T}|_{\omega_V}$. For the bound on an edge $e \in \mathcal{E}(\mathcal{T}|_{\omega_V})$, we employ a trace theorem on $\widehat{\omega}_V$ before transforming back to ω_V.

Checking the steps of the construction, we see that the map $u_V \mapsto u_{p_V}$ is linear and that it is at the same time a bounded linear map $L^1(\omega_V) \to \mathcal{P}_{p_V-1}$.

The constant in the last estimate does depend on the reference patch $\widehat{\omega}_V$. We observe, however, that for a given (upper bound on) γ, only finitely many reference patches have to be considered since only finitely many elements can abut on a vertex (cf. Lemma 2.3). This concludes the argument. □

Proof of Theorem 3.1. Theorem 3.1 now follows from combining Lemmata 5.6 and 5.7. For each vertex V, we construct the local approximation $I_V u \in S^{p_V-1}(\mathcal{T}|_{\omega_V})$ with the aid of Lemma 5.7. The operator $I^{hp} : L^1(\Omega) \to S^{\mathbf{p}}(\mathcal{T})$ is then defined as

$$I^{hp}u = \sum_{V \in \mathcal{N}(\mathcal{T})} \varphi_V I_V u,$$

where the vertex shape functions $\varphi_V \in S^1(\mathcal{T})$ have the support properties of (2.6). The operator I^{hp} maps indeed into $S^{\mathbf{p}}(\mathcal{T})$ since $I_V u \in s^{p_V-1}(\mathcal{T}|_{\omega_V})$. By inspection, we observe that $I^{hp} : L^1(\Omega) \to S^{\mathbf{p}}(\mathcal{T})$ is a bounded linear operator. Its approximation properties, when applied to $W^{1,q}$-functions, follow from Lemmata 5.6 and 5.7. □

5.3. Proof of Theorem 3.3. We modify the approximation operator of Theorem 3.1 so as to enforce homogeneous Dirichlet boundary conditions. Since we need the trace theorem to hold, the operator is now defined on $W^{1,q}(\Omega)$ instead of $L^1(\Omega)$. The construction of this operator is again patch oriented. The difference is that we will change the definition of the linear maps I_V for $V \in \mathcal{N}(\mathcal{B})$. Here, we defined

$$\mathcal{N}(\mathcal{B}) := \bigcup_{b\in\mathcal{B}} \mathcal{N}(b). \tag{5.5}$$

We first analyze the prototypical situation on a boundary reference patch.

LEMMA 5.8. *Let $q \in (1,\infty)$. Let $\widehat{\omega} = \omega_{bdy,M,j}$ for some $M \in \mathbb{N}$ and $j \in \{1,\dots,2^M\}$ and denote by $\widehat{\mathcal{T}}$ the triangulation of $\widehat{\omega}$. Denote by Γ_0 the edge of $\widehat{\omega}$ lying on the x-axis and by Γ_M the edge lying on the y-axis (cf. Figure* 5.1*). Let Γ_D be either Γ_0, Γ_M, or $\Gamma_0 \cup \Gamma_M \cup \{0\}$. Denote $W^{1,q}_{\Gamma_D,0}(\widehat{\omega}) = \{u \in W^{1,q}(\widehat{\omega}) \,|\, u|_{\Gamma_D} = 0\}$. Then for every $p \in \mathbb{N}_0$ there exists a bounded linear map $I_p : W^{1,q}_{\Gamma_D,0}(\widehat{\omega}) \to S^p(\widehat{\mathcal{T}}) \cap W^{1,q}_{\Gamma_D,0}(\widehat{\omega})$ such that*

$$(p+1)\|u - I_p u\|_{L^q(\widehat{\omega})} + \|\nabla(u - I_p u)\|_{L^q(\widehat{\omega})} \le C\|\nabla u\|_{L^q(\widehat{\omega})}, \tag{5.6}$$

where the constant $C > 0$ is independent of p and $u \in W^{1,q}_{\Gamma_D,0}(\widehat{\omega})$.

Proof. We will demonstrate the result for the case $\Gamma_D = \Gamma_0 \cup \Gamma_M \cup \{0\}$, the other two cases being handled similarly. The construction of I_p is done in two steps: First, we let $J_p : L^1(\widehat{\omega}) \to \mathcal{P}_p$ be the linear operator of the proof of Lemma 5.7. It satisfies for $u \in W^{1,q}(\widehat{\omega})$

$$(p+1)\|u - J_p u\|_{L^q(\widehat{\omega})} + \|\nabla(u - J_p u)\|_{L^q(\widehat{\omega})} \le C\|\nabla u\|_{L^q(\widehat{\omega})}.$$

In particular, from the multiplicative trace inequality (see, e.g., [19, Thm. 1.6.6]) and the fact that $u|_{\Gamma_D} = 0$, we get

$$\begin{aligned}\|J_p u\|_{L^q(\Gamma_D)} &= \|u - J_p u\|_{L^q(\Gamma_D)} \le C(p+1)^{-(1-1/q)}\|\nabla u\|_{L^q(\widehat{\omega})},\\ \|J_p u\|_{W^{1-1/q,q}(\Gamma_D)} &= \|u - J_p u\|_{W^{1-1/q,q}(\Gamma_D)} \le C\|\nabla u\|_{L^q(\widehat{\omega})}.\end{aligned}$$

The function $J_p u$ does not, however, satisfy homogeneous boundary conditions on Γ_D. This is corrected in a second step by an element-by-element construction using appropriate polynomial liftings. To that end, we enumerate the edges of $\widehat{\mathcal{T}}$ emanating from the origin in a counterclockwise fashion as depicted in Figure 5.1. Likewise, the elements are labeled K_i, $i = 0,\dots,M-1$. Next, we observe that the functions $u_0 := (u - J_p u)|_{\Gamma_0} = (J_p u)|_{\Gamma_0}$ and $u_M := (u - J_p u)|_{\Gamma_M} = (J_p u)|_{\Gamma_M}$ are polynomials of degree p. Additionally, we note that each edge Γ_i, $i = 0,\dots,M$, is homeomorphic to the reference interval $\hat{I} = (0,1)$ by means of an affine map $\gamma_i : \hat{I} \to \Gamma_i$, which we may choose to satisfy $\gamma_i(0) = 0$ for $i \in \{0,\dots,M\}$. We then define a function $z \in C(\cup_{i=0}^M \overline{\Gamma_i})$ by

$$\begin{aligned} z \circ \gamma_i(x) &:= u_0 \circ \gamma_0(x), \qquad x \in \overline{\hat{I}}, \quad i = 0,\dots,M-1,\\ z \circ \gamma_M(x) &:= u_M \circ \gamma_M(x).\end{aligned}$$

Clearly, for $i \in \{0,\dots,M\}$ we have

$$\|z\|_{L^q(\Gamma_i)} \le C\left[\|u_0\|_{L^q(\Gamma_0)} + \|u_M\|_{L^q(\Gamma_M)}\right] \le C(p+1)^{-1+1/q}\|\nabla u\|_{L^q(\widehat{\omega})}.$$

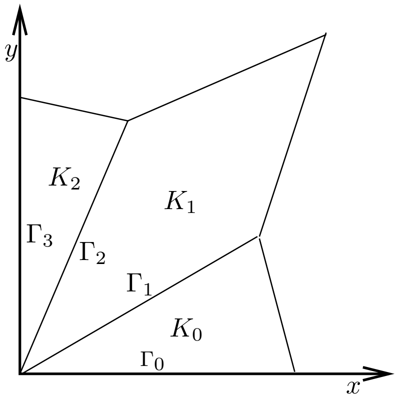

FIG. 5.1. *Numbering of elements and edges of a boundary reference patch for $M = 3$.*

We next define for each element K_i the set

$$\Gamma_{i,i+1} := \Gamma_i \cup \Gamma_{i+1} \cup \{0\} \subset \partial K_i, \qquad i = 0, \dots, M-1. \tag{5.7}$$

We then ascertain

$$\|z\|_{W^{1-1/q,q}(\Gamma_{i,i+1})} \leq C\|J_p u\|_{W^{1-1/q,q}(\Gamma_D)} \leq C\|u\|_{W^{1,q}(\widehat{\omega})}.$$

This follows easily from the fact that for two edges Γ_i, Γ_j with $i \neq j$ we have the characterization (see, e.g., [28, Thm. 1.5.2.3])

$$\|z\|^q_{W^{1-1/q,q}(\Gamma_i \cup \Gamma_j \cup \{0\})} \sim \|\hat{z}_i\|^q_{W^{1-1/q,q}(\hat{I})} + \|\hat{z}_j\|^q_{W^{1-1/q,q}(\hat{I})} + \int_0^1 \frac{|\hat{z}_i(x) - \hat{z}_j(x)|^q}{x^{q-1}}\,dx,$$

where we wrote $\hat{z}_i = z \circ \gamma_i$, $\hat{z}_j = z \circ \gamma_j$. Here, the constants hidden in the $\sim$-notation depend solely on Γ_i, Γ_j, and q. We finally construct with the aid of Proposition 5.3 a function $Z \in S^{4p}(\widehat{\mathcal{T}})$ such that $Z|_{\Gamma_i} = z|_{\Gamma_i}$ for all $i \in \{0, \dots, M\}$ and

$$\begin{aligned}(p+1)\|Z\|_{L^q(K_i)} + \|\nabla Z\|_{L^q(K_i)} &\leq C\left[\|z\|_{W^{1-1/q,q}(\Gamma_{i,i+1})} + (p+1)^{1-1/q}\|z\|_{L^q(\Gamma_{i,i+1})}\right] \\ &\leq C\|\nabla u\|_{L^q(\widehat{\omega})}, \qquad i = 0, \dots, M-1.\end{aligned}$$

We conclude the argument by noting that the map $u \mapsto J_p u + Z$ is linear and bounded. Since $J_p u + Z \in S^{4p}(\widehat{\mathcal{T}})$, replacing p with $\lfloor p/4 \rfloor$ gives the desired result. ∎

Proof of Theorem 3.3. The proof of Theorem 3.3 now follows by the same arguments as that of Theorem 3.1. Merely for the patches ω_V with $V \in \mathcal{N}(\mathcal{B})$ we replace the local approximation $I_V u$ of Lemma 5.7 with the pushforward $(I_{p_V} \widehat{u}_V) \circ F_V^{-1}$ of $I_{p_V} \widehat{u}_V$, where $I_{p_V} \widehat{u}_V$ with $\widehat{u}_V = u|_{\omega_V} \circ F_V$ is defined in Lemma 5.8. ∎

5.4. Proof of Theorem 3.4.

5.4.1. Lifting from $\mathcal{B}$. The proof of Theorem 3.4 follows along the same lines as that of Theorem 3.3. The key difference is that additionally appropriate (polynomial) liftings are required. Providing these is the purpose of the present subsection.

We start with a "vertex lifting" result on boundary reference patches that yields the correct value at a boundary vertex. Given a collection of boundary edges $\widehat{\mathcal{B}}$ of the reference patch $\widehat{\omega}$, the spaces $W^{1,q}_{\widehat{\mathcal{B}},\mathbf{p}}(\widehat{\omega})$ on $\widehat{\omega}$ are defined analogously to the way the spaces $W^{1,q}_{\mathcal{B},\mathbf{p}}(\Omega)$ are defined in (3.6). We then have the following lemma.

LEMMA 5.9. *Let $\widehat{\omega} = \widehat{\omega}_{bdy,M,j}$ for some $M \in \mathbb{N}$, $j \in \{1,\ldots,2^M\}$, and denote by $\widehat{\mathcal{T}}$ the triangulation of $\widehat{\omega}$. Let $\mathbf{p}$ be a polynomial degree distribution on $\widehat{\mathcal{T}}$ that satisfies* (2.8)*. If $q \neq 2$, assume additionally*

$$|p_K - p_{K'}| \le k \qquad \forall K, K' \in \widehat{\mathcal{T}}.$$

Define $p' := \min\{p_K - 1 \,|\, K \in \widehat{\mathcal{T}}\} \in \mathbb{N}_0$.

Let $\widehat{\mathcal{B}} = \{\Gamma_0\}$ or $\widehat{\mathcal{B}} = \{\Gamma_M\}$ or $\widehat{\mathcal{B}} = \{\Gamma_0, \Gamma_M\}$ (cf. Figure 5.1*). Then there exists a constant $C > 0$ that depends solely on $\widehat{\omega}$ (i.e., on M, j) and γ of* (2.8)*, k (if $q \neq 2$), q, and there exists a bounded linear operator $L : W^{1,q}_{\widehat{\mathcal{B}},\mathbf{p}}(\widehat{\omega}) \to S^{p'}(\widehat{\mathcal{T}})$ such that*

$$(Lu - u)(0) = 0, \tag{5.8}$$

$$\|Lu - u\|_{W^{1,q}(\widehat{\omega})} \le C\|\nabla u\|_{L^q(\widehat{\omega})}, \tag{5.9}$$

$$\|(Lu - u)\circ\gamma_b\|_{\widetilde{W}_l^{1-1/q,q}(\hat{I})} \le C\|\nabla u\|_{L^q(\widehat{\omega})} \qquad \forall b \in \widehat{\mathcal{B}}, \tag{5.10}$$

where $\gamma_b : \hat{I} \to b$ is the affine parametrization of $b \in \widehat{\mathcal{B}}$ satisfying $\gamma_b(0) = 0$.

Proof. We employ ideas similar to those of the proof of Theorem 3.3. For simplicity of notation, we consider the case $\widehat{\mathcal{B}} = \{\Gamma_0, \Gamma_M\}$; the other two cases are treated in a similar fashion. We denote by $\gamma_i : \hat{I} \to \Gamma_i$, $i = 0,\ldots,M$, the affine parametrizations of the edges Γ_i, which are assumed without loss of generality to satisfy $\gamma_i(0) = 0$. We will construct Lu first on the edges Γ_i and in a second step define Lu on the elements via appropriate liftings. We will only consider the case $q \neq 2$—the reader may check that in the case $q = 2$, the operator $Z_{p,p'}$ of Lemma 5.4 can be replaced with the Gauß–Lobatto interpolation operator $\mathcal{I}_{p'}$ discussed in Lemma 5.5.

We write $p = \max\{p_K \,|\, K \in \widehat{\mathcal{T}}\} \in \mathbb{N}$. Choose $b \in \widehat{\mathcal{B}}$. Without loss of generality, we assume that $b = \Gamma_0$. By assumption $u \circ \gamma_0 \in \mathcal{P}_p$, so that we may define $l_0 := Z_{p,p'}(u\circ\gamma_0)$, where the linear operator $Z_{p,p'} : \mathcal{P}_p \to \mathcal{P}_{p'}$ is the polynomial extension operator of Lemma 5.4. We then have $l_0(0) = u(0)$ and additionally by properties of $Z_{p,p'}$ and the trace theorem

$$\|l_0 - u|_{\Gamma_0}\circ\gamma_0\|_{\widetilde{W}_l^{1-1/q,q}(\hat{I})} \le C\|u\|_{W^{1-1/q,q}(\Gamma_0)} \le C\|u\|_{W^{1,q}(\widehat{\omega})}, \tag{5.11}$$

$$\|l_0 - u|_{\Gamma_M}\circ\gamma_M\|_{\widetilde{W}_l^{1-1/q,q}(\hat{I})} \le C\|u\|_{W^{1,q}(\widehat{\omega})}. \tag{5.12}$$

Next, we define

$$(Lu)|_{\Gamma_i} = l_0 \circ \gamma_i^{-1}, \qquad i = 0,\ldots,M.$$

This gives $(Lu)(0) = u(0)$. Furthermore, this definition of $(Lu)|_{\Gamma_i}$ in conjunction with the bounds (5.11), (5.12) implies

$$\|Lu\|_{W^{1-1/q,q}(\Gamma_{i,i+1})} \le C\|u\|_{W^{1,q}(\widehat{\omega})}, \qquad i = 0,\ldots,M-1,$$

where we abbreviate $\Gamma_{i,i+1} = \Gamma_i \cup \Gamma_{i+1} \cup \{0\}$ as in (5.7). From the lifting result (Theorem 5.2), there exists then a function $Lu \in S^{p'}(\widehat{\mathcal{T}})$ with

$$\|Lu\|_{W^{1,q}(\widehat{\omega})} \le C\|u\|_{W^{1,q}(\widehat{\omega})}. \tag{5.13}$$

Furthermore, inspection of the construction of Lu reveals that $u \mapsto Lu$ is linear. Since the operator $Z_{p,p'}$ of Lemma 5.4 satisfies $Z_{p,p'}1 = 1$ and the lifting of Theorem 5.2 likewise ensures that constant functions are reproduced, we conclude $L1 = 1$. By a standard argument, we can therefore strengthen (5.13) to yield (5.9). The estimates (5.10) are ensured by the way we defined $(Lu)|_{\Gamma_i}$ for $i \in \{0, \ldots, M\}$. □

Lemma 5.7 allows us to construct a lifting operator as follows.

PROPOSITION 5.10. *Let $\mathcal{T}$ be a γ-shape regular triangulation of a domain $\Omega \subset \mathbb{R}^2$ satisfying* (M1)–(M4). *Let $\mathcal{B} \subset \mathcal{E}(\mathcal{T})$ be a collection of boundary edges. Let $q \in (1, \infty)$ be given. Assume that the polynomial degree distribution $\mathbf{p}$ satisfies* (2.8) *and additionally* (3.11) *if $q \neq 2$. Then there exists a constant $C > 0$, which depends solely on γ and q, and there exists a bounded linear operator $I^{hp}_{lift} : W^{1,q}_{\mathcal{B},\mathbf{p}}(\Omega) \to S^{\mathbf{p}}(\mathcal{T})$ such that*

$$
\begin{aligned}
(I^{hp}_{lift}u)|_b &= u|_b \qquad \forall b \in \mathcal{B},\\
(I^{hp}_{lift}u)|_K &= 0 \qquad \textit{if } \omega_{K,\mathcal{B}} = \emptyset,
\end{aligned}
$$

$$\|I^{hp}_{lift}u\|_{L^q(K)} + h_K\|\nabla I^{hp}_{lift}u\|_{L^q(K)} \le C\big[\|u\|_{L^q(\omega_{K,\mathcal{B}})} + h_K\|\nabla u\|_{L^q(\omega_{K,\mathcal{B}})}\big] \quad \textit{if } \omega_{K,\mathcal{B}} \neq \emptyset,$$

where for an element $K \in \mathcal{T}$ we define

$$\omega_{K,\mathcal{B}} := \bigcup_{V \in \mathcal{N}(K) \cap \mathcal{N}(\mathcal{B})} \omega_V. \tag{5.14}$$

Proof. The lifting $I^{hp}_{lift}u$ is constructed as the sum of u_1 and u_2. The term u_1 is constructed such that the correct behavior at the vertices of the triangulation is ensured. In this way, the construction of the lifting is then reduced to an edgewise construction, which defines u_2.

Given $u \in W^{1,q}_{\mathcal{B},\mathbf{p}}(\Omega)$, we construct $u_1 \in S^{\mathbf{p}}(\mathcal{T})$ patchwise as

$$u_1 = \sum_{V \in \mathcal{N}(\mathcal{T})} \varphi_V L_V u,$$

where the patch operators L_V are defined with the aid of Lemma 5.9 according to the following rules:

(a) if $V \notin \mathcal{N}(\mathcal{B})$, then $L_V u = 0$;

(b) if $V \in \mathcal{N}(\mathcal{B})$, then $L_V u$ is defined on the corresponding reference patch $\widehat{\omega}_V$ as $(L_V u) \circ F_V = L\widehat{u}$, where L is the operator of Lemma 5.9. Here, $\widehat{u} = u \circ F_V$ and the polynomial degrees p and p' are defined as $p = \max\{p_K \mid K \in \mathcal{T}|_{\omega_V}\}$ and $p' = \min\{p_K \mid K \in \mathcal{T}|_{\omega_V}\} - 1$.

By the choice of the polynomial degrees p', we get $u_1 \in S^{\mathbf{p}}(\mathcal{T})$. Additionally, the function $L_V u$ satisfies for $V \in \mathcal{N}(\mathcal{B})$

$$
\begin{aligned}
(L_V u)(V) &= u(V),\\
\|L_V u\|_{L^q(\omega_V)} &\le C\left[\|u\|_{L^q(\omega_V)} + h_V\|\nabla u\|_{L^q(\omega_V)}\right],\\
\|\nabla L_V u\|_{L^q(\omega_V)} &\le C\|\nabla u\|_{L^q(\omega_V)}.
\end{aligned}
$$

Moreover, for edges $b \in \mathcal{B}$ and vertices $V \in \mathcal{N}(b)$ we have upon denoting by $\gamma_{b,V}$ the map $\gamma_{b,V} : \hat{I} \to b$ that is determined by the element maps and the condition $\gamma_{b,V}(0) = V$, the following bound:

$$\|(u - L_V u) \circ \gamma_{b,V}\|_{\widetilde{W}^{1-1/q,q}_l(\hat{I})} \le C h_V^{1-2/q}\|\nabla u\|_{L^q(\omega_V)} \qquad \forall b \in \mathcal{B}, \quad V \in \mathcal{N}(b).$$

For elements K with $\omega_{K,\mathcal{B}} = \emptyset$, our construction implies $(u_1)|_K = 0$. For elements K with $\omega_{K,\mathcal{B}} \neq \emptyset$ we get

$$\begin{aligned} u_1(V) &= u(V) \qquad \forall V \in \mathcal{N}(\mathcal{B}), \\ \|u_1\|_{L^q(K)} + h_K\|\nabla u_1\|_{L^q(K)} &\leq C\left[\|u\|_{L^q(\omega_{K,\mathcal{B}})} + h_K\|\nabla u\|_{L^q(\omega_{K,\mathcal{B}})}\right], \\ \|(u-u_1)\circ\gamma_b\|_{\widetilde{W}^{1-1/q,q}(\hat{I})} &\leq C h_b^{1-2/q}\|\nabla u\|_{L^q(\omega_b^1)} \qquad \forall b \in \mathcal{B}. \end{aligned}$$

For the last estimate, we employed additionally Lemma C.2.

We now turn to the construction of u_2. Since u_1 and u coincide in the vertices that lie on the Dirichlet boundary, we can proceed in an element-by-element fashion. For elements K with $\mathcal{E}(K)\cap\mathcal{B} = \emptyset$, we set $u_2|_K = 0$. For elements K with $\mathcal{E}(K)\cap\mathcal{B} \neq \emptyset$, we construct $u_2|_K$ using the following considerations: We set $\mathcal{B}_K = \mathcal{E}(K)\cap\mathcal{B}$, denote by $\widehat{b} := F_K^{-1}(b)$ the pull-back of an edge $b \in \mathcal{B}_K$, and construct with the aid of the lifting result (Theorem 5.2) on the reference element $\hat{K}$ the polynomial $\widehat{u}_{2,K} \in \mathcal{P}_{p_K}$ such that

$$\begin{aligned} \widehat{u}_{2,K}|_{\widehat{b}} &= ((u-u_1)\circ F_K)|_{\widehat{b}} \qquad \forall b \in \mathcal{B}_K, \\ \widehat{u}_{2,K}|_{F_K^{-1}(e)} &= 0 \qquad \forall e \in \mathcal{E}(K)\setminus\mathcal{B}_K, \\ \|\widehat{u}_2\|_{W^{1,q}(\widehat{K})} &\leq C\sum_{b\in\mathcal{B}_K}\|(u-u_1)\circ F_b\|_{\widetilde{W}^{1-1/q,q}(\hat{I})} \leq C h_K^{1-2/q}\|\nabla u\|_{L^q(\omega_{K,\mathcal{B}})}, \end{aligned}$$

where $F_b : \hat{I} \to b$ denotes the parametrization of b determined by the element maps. Pushing forward these estimates to the element K, the function $u_2|_K := \widehat{u}_{2,K}\circ F_K^{-1}$ then satisfies

$$\begin{aligned} u_2|_b &= (u-u_1)|_b \qquad \forall b \in \mathcal{B}_K, \\ u_2|_e &= 0 \qquad \forall e \in \mathcal{E}(K)\setminus\mathcal{B}_K, \\ \|u_2\|_{L^q(K)} &\leq C h_K^{2/q}\|\widehat{u}_2\|_{L^q(\widehat{K})} \leq C h_K\|\nabla u\|_{L^q(\omega_{K,\mathcal{B}})}, \\ \|\nabla u_2\|_{L^q(K)} &\leq C h_K^{2/q-1}\|\nabla\widehat{u}_2\|_{L^q(\widehat{K})} \leq C\|\nabla u\|_{L^q(\omega_{K,\mathcal{B}})}. \end{aligned}$$

The sum $u_1 + u_2$ is an element of $S^{\mathbf{p}}(\mathcal{T})$; it satisfies $(u_1+u_2)|_b = u|_b$ for all $b \in \mathcal{B}$, and we have the estimates

$$\|u_1+u_2\|_{L^q(K)} + h_K\|\nabla(u_1+u_2)\|_{L^q(K)} \leq C\left[\|u\|_{L^q(\omega_{K,\mathcal{B}})} + h_K\|\nabla u\|_{L^q(\omega_{K,\mathcal{B}})}\right].$$

Inspection of the construction shows that the map $u \mapsto u_1 + u_2$ is linear. □

5.4.2. Proof of Theorem 3.4. We are now in a position to prove Theorem 3.4.

Proof of Theorem 3.4. We employ the lifting operator I^{hp}_{lift} of Proposition 5.10 and the approximation operators I^{hp}_{hom}, I^{hp} of Theorems 3.3 and 3.1. We define

$$\begin{aligned} L &:= I^{hp}_{lift}\circ(\mathrm{Id} - I^{hp}) + I^{hp}, \\ I^{hp}_{inhom} &:= L + I^{hp}_{hom}\circ(\mathrm{Id} - L). \end{aligned}$$

I^{hp}_{inhom} is a linear operator mapping into $S^{\mathbf{p}}(\mathcal{T})$. We easily check that for $u \in W^{1,q}_{\mathcal{B},\mathbf{p}}(\Omega)$

$$(I^{hp}_{inhom}u)|_b = u|_b \qquad \forall b \in \mathcal{B}.$$

It remains to check the approximation properties. Upon writing

$$(\operatorname{Id} - I^{hp}_{inhom}) = (\operatorname{Id} - I^{hp}_{hom}) \circ (\operatorname{Id} - L),$$

we see that the desired approximation follow from the approximation properties of I^{hp}_{hom} together with stability properties of $\operatorname{Id} - L$. These stability properties can be inferred by writing

$$\operatorname{Id} - L = (\operatorname{Id} - I^{hp}_{lift}) \circ (\operatorname{Id} - I^{hp})$$

and then observing that Proposition 5.10 implies

$$\|\nabla(u - Lu)\|_{L^q(K)} \leq C \left[\frac{1}{h_K} \|u - I^{hp} u\|_{L^q(\omega^2_K)} + \|\nabla(u - I^{hp} u)\|_{L^q(\omega^2_K)} \right] \leq C \|\nabla u\|_{L^q(\omega^3_K)}.$$

Theorem 3.3 then implies

$$\|u - I^{hp}_{inhom} u\|_{L^q(K)} + \frac{h_K}{p_K} \|\nabla(u - I^{hp}_{inhom} u)\|_{L^q(K)} \leq C \frac{h_K}{p_K} \|\nabla u\|_{L^q(\omega^4_K)}.$$

From this, the desired estimate for the edges follows. □

Appendix A. Approximation results.

A.1. Polynomial approximation results on hyper cubes. We establish polynomial approximation results for the approximation of functions of Sobolev spaces $W^{r,q}(I)$, where I is a hyper cube. Similar results have been obtained in [2,3]. Our exposition here ignores effects related to the behavior of polynomials near the endpoints of an interval. While in the one-dimensional situation a characterization of the functions that can be approximated at a certain rate can be done using weighted spaces, these results do not easily extend to higher dimensions. We refer to [24] for an exposition of the one-dimensional results (so-called direct and inverse estimates) and mention also [9,10] where related results for the two-dimensional case are proved.

We recall a one-dimensional result on simultaneous trigonometric approximation.

LEMMA A.1. *Let $\mathbb{T}$ be the one-dimensional torus and denote for $r \in \mathbb{N}_0$, $q \in [1, \infty]$ by $W^{r,q}(\mathbb{T})$ the set of functions with r weak derivatives whose derivatives are in $L^q(\mathbb{T})$. Denote by T_N the set of trigonometric polynomials of degree $N \in \mathbb{N}$. Then for each $R \in \mathbb{N}$ and each N there exists a linear operator $J_{R,N} : L^1(\mathbb{T}) \to T_N$ and a constant $C_R > 0$ (which depends solely on R) such that for all $r \in \mathbb{N}_0$ with $0 \leq r \leq R$, all $q \in [1, \infty]$, and all $u \in W^{r,q}(\mathbb{T})$*

$$\|\,(u - J_{R,N}\, u)^{(j)}\,\|_{L^q(\mathbb{T})} \leq C_r (N+1)^{-(r-j)} \|u^{(r)}\|_{L^q(\mathbb{T})}, \qquad j = 0, \ldots, r. \tag{A.1}$$

Proof. Jackson-type results of this form are well known in approximation theory. The linear operators $J_{R,N}$, whose existence is ascertained in Lemma A.1, can be chosen as in [24, Chap. 7, eq. (2.8)]. The results concerning simultaneous approximation then follow from combining Theorems 2.3, 2.7, and 2.8 of [24, Chap. 7] and a check that the case $q = \infty$ is included in the form stated in Lemma A.1. The details can be found in [32, Prop. E.1]. □

As is well known, trigonometric approximation result implies polynomial approximation results by means of the transformation $x = \cos\theta$. For future reference, we formulate this in the following proposition.

PROPOSITION A.2. *Let $I \subset \mathbb{R}$ be a bounded interval. Let $R \in \mathbb{N}$ and $q \in [1, \infty]$. Then for each $N \in \mathbb{N}_0$ there exists a linear operator $J_{R,N} : L^1(I) \to \mathcal{P}_N$ and a constant $C > 0$, which depends only on R, q, I, such that for each $0 \leq r \leq R$*

$$\|u - J_{R,N} u\|_{W^{j,q}(I)} \leq C(N+1)^{-(r-j)} \|u\|_{W^{r,q}(I)}, \qquad j = 0, \ldots, r. \tag{A.2}$$

Furthermore, the linear operator $J_{R,N}$ may be constructed such that for $0 \leq r \leq R$ and $N \geq R - 1$

$$J_{R,N} u = u \qquad \forall u \in \mathcal{P}_{R-1} \tag{A.3}$$

$$\|u - J_{R,N} u\|_{W^{j,q}(I)} \leq C(N+1)^{-(r-j)} |u|_{W^{r,q}(I)}, \qquad j = 0, \ldots, r. \tag{A.4}$$

Proof. The proof for $N = 0$ is trivial; we will therefore assume $N \in \mathbb{N}$. We will obtain the results for polynomial approximation from those for trigonometric approximation. We construct for given $u \in W^{r,q}(I)$ the approximant $J_N u \in \mathcal{P}_N$; tracing the steps of the construction then reveals that $u \mapsto J_N u$ is in fact a linear operator. Without loss of generality, we may assume that I is such that the closed interval $\overline{I}$ satisfies $\overline{I} = [-\cos\varepsilon, \cos\varepsilon]$ for some chosen $\varepsilon \in (0, \pi/2)$.

Step 1. Define the interval $\Theta = (\varepsilon, \pi - \varepsilon)$. For every function v (defined on I) we define a function v_θ on Θ by $v_\theta(\theta) = v(\cos\theta)$. Then for every $j \in \mathbb{N}_0$, $q \in [1, \infty]$ there exists a constant $C > 0$, which depends only on j, q, and ε, such that

$$C^{-1} \|v\|_{W^{j,q}(I)} \leq \|v_\theta\|_{W^{j,q}(\Theta)} \leq C \|v\|_{W^{j,q}(I)}. \tag{A.5}$$

Step 2. We construct a function $\widetilde{u}_\theta$ on the torus $\mathbb{T}$ with the properties that (a) $\widetilde{u}_\theta = u_\theta$ on Θ, (b) $\widetilde{u}_\theta$ is symmetric with respect to $\theta = 0$, and (c) $\|\widetilde{u}_\theta\|_{W^{r,q}(\mathbb{T})} \leq C\|u\|_{W^{r,q}(I)}$. To that end, we extend u_θ to a function in $W^{r,q}(\mathbb{R})$ such that the extended function (again denoted by u_θ) satisfies

$$\|u_\theta\|_{W^{r,q}(\mathbb{R})} \leq C \|u_\theta\|_{W^{r,q}(\Theta)};$$

such an extension is constructed, for example, in [39]. Furthermore, using smooth cut-off functions, we may assume that this extension satisfies $\operatorname{supp} u_\theta \subset [\varepsilon/2, \pi - \varepsilon/2]$. We then define on the interval $(-\pi, \pi)$ the symmetric extension of u_θ by

$$\widetilde{u}_\theta(x) := \begin{cases} u_\theta(x) & \text{if } x \in (0, \pi), \\ u_\theta(-x) & \text{if } x \in (-\pi, 0). \end{cases}$$

By the support properties of u_θ we then conclude

$$\|\widetilde{u}_\theta\|_{W^{r,q}(\mathbb{T})} \leq C \|u\|_{W^{r,q}(I)}.$$

Step 3. From Lemma A.1, we get for the trigonometric polynomial $J_N := J_{R,N}\, \widetilde{u}_\theta$

$$\|\widetilde{u}_\theta - J_N\|_{W^{j,q}(\mathbb{T})} \leq C N^{-(r-j)} \|u\|_{W^{r,q}(I)}. \tag{A.6}$$

We wish to approximate $\widetilde{u}_\theta$ by a symmetric trigonometric polynomial. Since $\widetilde{u}_\theta$ is symmetric with respect to $\theta = 0$, we get that the trigonometric polynomial $\widetilde{J}_N$ defined by $\widetilde{J}_N(x) = J_N(-x)$ also satisfies

$$\|\widetilde{u}_\theta - \widetilde{J}_N\|_{W^{j,q}(\mathbb{T})} \leq C N^{-(r-j)} \|u\|_{W^{r,q}(I)}. \tag{A.7}$$

Combining (A.6), (A.7), we conclude that the symmetric trigonometric polynomial

$$\widehat{J}_N := \frac{1}{2}\left(J_N + \widetilde{J}_N\right)$$

satisfies

$$\|\widetilde{u}_\theta - \widehat{J}_N\|_{W^{j,q}(\mathbb{T})} \leq CN^{-(r-j)}\|u\|_{W^{r,q}(I)}. \tag{A.8}$$

Step 4. Since the symmetric trigonometric polynomial $\widehat{J}_N$ can be written in the form $\widehat{J}_N(\theta) = P_N(\cos(\theta))$ for a polynomial $P_N \in \mathcal{P}_N$, we get the desired operator $J_{R,N}$ and the bound (A.2) from (A.8) and (A.5).

Step 5. As a preparation to the final step, we recall the Bramble–Hilbert lemma [19, Lem. 4.3.8]: For $r \geq 1$, we have

$$\inf_{v \in \mathcal{P}_{r-1}} \|u - v\|_{W^{r,q}(I)} \leq C\|u^{(r)}\|_{L^q(I)}. \tag{A.9}$$

Next, we choose a bounded linear operator $Q : L^1(I) \to \mathcal{P}_{R-1}$ such that $Qv = v$ for all $v \in \mathcal{P}_{R-1}$. Such a projector is constructed, for example, in [19, sect. 4.1], where it is shown in [19, Prop. 4.3.8] that

$$\|u - Qu\|_{W^{r,q}(I)} \leq \|u^{(r)}\|_{L^q(I)}, \qquad 0 \leq r \leq R.$$

We claim that the operator $u \mapsto J_{R,N}(u - Qu) + Qu$ has all the desired properties. By exploiting the stability properties (A.2) of $J_{R,N}$ constructed so far we get

$$\begin{aligned}\|u - (J_{R,N}(u - Qu) + Qu)\|_{W^{j,q}(I)} &\leq C(N+1)^{-(r-j)}\|u - Qu\|_{W^{r,q}(I)}\\ &\leq C(N+1)^{-(r-j)}\|u^{(r)}\|_{L^q(I)}.\end{aligned}$$

This concludes the argument, since $J_{R,N}(u - Qu) + Qu = u$ for $u \in \mathcal{P}_{R-1}$. □

The one-dimensional operator $J_{R,N}$ of Proposition A.2 can be tensorized to yield the polynomial approximation result (Theorem 5.1) for functions defined on hyper cubes. This result is proved as follows.

Proof of Theorem 5.1. The operator $J_{R,N}$ is taken as the tensor product of the one-dimensional ones given by Proposition A.2. To simplify the notation, we will drop the indices R, N and write $J_1, \ldots, J_d$ to denote these one-dimensional operators and J to denote the tensor product. From Proposition A.2 we obtain the following stability and approximation results.

$$|J_i u|_{W^{l,q}(I_i)} \leq C|u|_{W^{l,q}(I_i)}, \qquad l = 0, \ldots, r, \tag{A.10}$$

$$|u - J_i u|_{W^{l,q}(I_i)} \leq C(N+1)^{-(r-l)}|u|_{W^{l,q}(I_i)}, \qquad 0 \leq l \leq r, \tag{A.11}$$

where $i = 1, \ldots, d$. These stability estimates then allow us to obtain approximation results in the standard way. We illustrate the procedure for the case $d = 2$. Let α, $\beta \geq 0$ with $\alpha + \beta = l \leq r$. Since the operators ∂_i and J_j commute if $i \neq j$, we get

$$\begin{aligned}\|\partial_1^\alpha \partial_2^\beta (u - J_1 \otimes J_2 u)\|_{L^q(I)} &\leq \|\partial_1^\alpha \partial_2^\beta (u - J_1 u)\|_{L^q(I)} + \|\partial_1^\alpha \partial_2^\beta J_1(u - J_2 u)\|_{L^q(I)}\\ &\leq \|\partial_1^\alpha \left((\partial_2^\beta u) - J_1(\partial_2^\beta u)\right)\|_{L^q(I)} + \|\partial_1^\alpha J_1 \partial_2^\beta (u - J_2 u)\|_{L^q(I)}.\end{aligned}$$

We consider the first term. The function $v(\cdot, x_2) = \partial_2^\beta u(\cdot, x_2)$ is defined for a.e. $x_2 \in I_2$ and $v(\cdot, x_2) \in W^{r-\beta,q}(I_1)$. Hence, we obtain from (A.11) for a.e. $x_2 \in I_2$

$$\|\partial_1^\alpha (v(\cdot, x_2) - J_1 v(\cdot, x_2))\|_{L^q(I_1)} \leq C(N+1)^{-(r-\beta-\alpha)}|v(\cdot, x_2)|_{W^{r-\beta,q}(I_1)}.$$

Substituting again the definition of v and integrating over I_2 yields

$$\|\partial_1^\alpha \left((\partial_2^\beta u) - J_1(\partial_2^\beta u)\right) \|_{L^q(I)} \leq C(N+1)^{-(r-\beta-\alpha)}|u|_{W^{r,q}(I)}.$$

By similar arguments (here, we additionally employ the stability result (A.10)) we can bound

$$\|\partial_1^\alpha J_1 \partial_2^\beta (u - J_2 u)\|_{L^q(I)} \leq C(N+1)^{-(r-\alpha-\beta)}|u|_{W^{r,q}(I)}.$$

Combining these last two estimates and summing over all combinations of α, β with $\alpha + \beta = l$ yields the desired bound. The fact (5.1) follows readily from the property (A.3) of the one-dimensional operators. □

Appendix B. Polynomial liftings. A general trace lifting operator of the form (B.1) was studied, for example, in [26, 30]. The subsequent observation that it also maps polynomials to polynomials (cf. Proposition B.1) was the basis for polynomial liftings from $H^{1/2}(\partial\hat{K})$ to $H^1(\hat{K})$, where $\hat{K}$ is the reference square or triangle [6, 14, 31]. We generalize these results to the L^q-setting. In principle, the techniques employed here are applicable to three-dimensional problems as well, although they are technically more involved. Polynomial lifting results for hexahedra, prisms, and tetrahedra are available (in Hilbert space settings) in [11, 12, 15, 35].

B.1. The operator $F^{[f]}$. We recall the definition of the reference triangle T in (2.1) and denote its bottom side by

$$\Gamma = \{(x, 0) \mid 0 < x < 1\}.$$

We will view Γ as embedded in $\mathbb{R}$ in the natural way. We choose $\alpha \in (0, 1)$ and define for a function $f \in L^q(\mathbb{R})$ the extension operator by

$$f \mapsto F^{[f]}(x, y) = \frac{1}{2\alpha y} \int_{x-\alpha y}^{x+\alpha y} f(t)\, dt. \tag{B.1}$$

Proposition B.1. *Let the extension operator be given by* (B.1). *Then $f \mapsto F^{[f]}$ is linear and $F^{[f]} \in \mathcal{P}_p$ if $f \in \mathcal{P}_p$. Furthermore, $F^{[f]}|_T$ depends only on the values of f on Γ, and for each $q \in (1, \infty)$ there exists a constant $C > 0$ such that for functions f defined on Γ the following bounds hold (provided that the right-hand side is finite):*

$$\|F^{[f]}\|_{L^q(T)} \leq C\|(x(1-x))^{1/q} f\|_{L^q(\Gamma)}, \tag{B.2}$$

$$\|F^{[f]}\|_{W^{1,q}(T)} \leq C\|f\|_{W^{1-1/q,q}(\Gamma)}, \tag{B.3}$$

$$\|(x-y)F^{[f/t]}\|_{L^q(T)} \leq C\|f\|_{L^q(\Gamma)}, \tag{B.4}$$

$$\|(x-y)(1-x-y)F^{[f/(t(1-t))]}\|_{L^q(T)} \leq C\|f\|_{L^q(\Gamma)}, \tag{B.5}$$

$$\|(x-y)F^{[f/t]}\|_{W^{1,q}(T)} \leq C\Bigg[\|f\|_{W^{1-1/q,q}(\Gamma)} + \left\|\frac{f(x)}{x^{1-1/q}}\right\|_{L^q(\Gamma)}\Bigg], \tag{B.6}$$

$$\|(x-y)(1-x-y)F^{[f/(t(1-t))]}\|_{W^{1,q}(T)} \leq C\|f\|_{\widetilde{W}^{1-1/q,q}(\Gamma)}. \tag{B.7}$$

Here, we employed the shorthand f/t to indicate the function $t \mapsto f(t)/t$ and $(x - y)F^{[f/t]}$ to denote the function $(x, y) \mapsto (x-y)F^{[f/t]}(x, y)$. Additionally, we have

$$\|F^{[f]}\|_{L^q(\partial T)} \leq C\|f\|_{L^q(\Gamma)}.$$

Proof. We first show (B.2). From (B.11) below we bound for each fixed $x \in (0,1)$

$$\int_{y=0}^{\min(x,1-x)} |F^{[f]}(x,y)|^q \, dy \le C \int_{x-\alpha\min(x,1-x)}^{x+\alpha\min(x,1-x)} |f(y)|^q \, dy.$$

Integrating over $x \in (0,1)$ we get from Lemma B.3

$$\|F^{[f]}\|^q_{L^q(T)} \le C \int_{y=0}^{1} y(1-y)|f(y)|^q \, dy = C\|(x(1-x))^{1/q} f\|^q_{L^q(\Gamma)}.$$

The estimate (B.4) follows immediately from (B.13) of Lemma B.2. The symmetry of T with respect to the line $x = 1/2$ together with (B.4) implies

$$\|(1-x-y)F^{[f/(1-t)]}\|_{L^q(T)} \le C\|f\|_{L^q(\Gamma)}.$$

From this and (B.4) we can easily obtain (B.5) if we observe

$$\frac{f(t)}{t(1-t)} = \frac{f(t)}{t} + \frac{f(t)}{1-t}.$$

It remains to obtain the bounds (B.3), (B.6), and (B.7). We compute

$$\begin{aligned}
\partial_x F^{[f]}(x,y) &= \frac{1}{2\alpha y}\left[f(x-\alpha y) - f(x+\alpha y)\right],\\
\partial_y F^{[f]}(x,y) &= \frac{1}{2\alpha}\left[-\frac{1}{y^2}\int_{x-\alpha y}^{x+\alpha y} f(t)\,dt + \frac{\alpha}{y}\left(f(x+\alpha y) + f(x-\alpha y)\right)\right]\\
&= -\frac{1}{2\alpha y^2}\int_{x-\alpha y}^{x+\alpha y} f(t) - f(x)\,dt - \frac{f(x) - f(x-\alpha y)}{2y} - \frac{f(x) - f(x+\alpha y)}{2y}.
\end{aligned}$$

From the definition of the $W^{1-1/q,q}$-norm and the bound (B.10) of Lemma B.2 we get

$$\|\nabla F^{[f]}\|_{W^{1,q}(T)} \le C\|f\|_{W^{1-1/q,q}(\Gamma)},$$

which shows (B.3). For the bound (B.6), we compute

$$\begin{aligned}
\partial_x\left((x-y)F^{[f/t]}\right) &= F^{[f/t]} + (x-y)\partial_x F^{[f/t]},\\
\partial_y\left((x-y)F^{[f/t]}\right) &= -F^{[f/t]} + (x-y)\partial_y F^{[f/t]},
\end{aligned}$$

and

$$\begin{aligned}
\partial_x F^{[f/t]} &= \frac{1}{2\alpha y}\left[\frac{f(x+\alpha y)}{x+\alpha y} - \frac{f(x-\alpha y)}{x-\alpha y}\right],\\
\partial_y F^{[f/t]} &= -\frac{1}{2\alpha y^2}\int_{x-\alpha y}^{x+\alpha y}\frac{f(t)}{t}\,dt + \frac{1}{2y}\left[\frac{f(x+\alpha y)}{x+\alpha y} + \frac{f(x-\alpha y)}{x-\alpha y}\right]\\
&= \frac{-1}{2\alpha y^2}\int_{x-\alpha y}^{x+\alpha y}\frac{f(t)}{t} - \frac{f(x)}{x}\,dt + \frac{1}{2y}\left[\frac{f(x+\alpha y)}{x+\alpha y} - \frac{f(x)}{x} + \frac{f(x-\alpha y)}{x-\alpha y} - \frac{f(x)}{x}\right].
\end{aligned}$$

With (B.9) and Lemma B.3 we can bound

$$\begin{aligned}
\|F^{[f/t]}\|^q_{L^q(T)} &\le C\int_{x=0}^{1}\int_{x-\alpha\min(x,1-x)}^{x+\alpha\min(x,1-x)}\left|\frac{f(t)}{t}\right|^q dt\,dx \le C\int_{x=0}^{1} x(1-x)\left|\frac{f(x)}{x}\right|^q dx\\
&\le C\int_{x=0}^{1}\left|\frac{f(x)}{x^{1-1/q}}\right|^q dx. \qquad \text{(B.8)}
\end{aligned}$$

The estimate (B.15) of Lemma B.2 implies

$$\int_T \left| \frac{(x-y)}{y^2} \int_{x-\alpha y}^{x+\alpha y} \frac{f(t)}{t} - \frac{f(x)}{x}\, dt \right|^q dx\, dy \le C \left[\|f\|^q_{W^{1-1/q,q}(\Gamma)} + \|f(x)/x\|_{L^q(\Gamma)} \right].$$

It remains to bound terms of the form

$$\left\| \frac{x-y}{y} \left(\frac{f(x \pm \alpha y)}{x \pm \alpha y} - \frac{f(x)}{x} \right) \right\|_{L^q(T)}.$$

Rearranging terms, we arrive at

$$\left\| \frac{x-y}{y} \left(\frac{f(x \pm \alpha y)}{x \pm \alpha y} - \frac{f(x)}{x} \right) \right\|_{L^q(T)} =$$
$$\left\| \frac{x-y}{x \pm \alpha y} \frac{f(x \pm \alpha y) - f(x)}{y} - \frac{\pm\alpha(x-y)}{x \pm \alpha y} \frac{f(x)}{x} \right\|_{L^q(T)} \le |f|_{W^{1-1/q,q}(\Gamma)} + \left\| \frac{f(x)}{x} \right\|_{L^q(T)},$$

where we employed the observation $|\frac{x-y}{x \pm \alpha y}| \le 1$ for $0 < y < x$. The term $\|\frac{f(x)}{x}\|_{L^q(T)}$ is now controlled in the desired fashion as in (B.8).

It remains to show (B.7). By symmetry considerations we obtain, analogous to (B.6),

$$\|(1-x-y)F^{[f/(1-t)]}\|_{W^{1,q}(T)} \le C \left[\|f\|_{W^{1-1/q,q}(\Gamma)} + \left\| \frac{f(x)}{(1-x)^{1-1/q}} \right\|_{L^q(\Gamma)} \right].$$

Since $\frac{f(t)}{t(1-t)} = \frac{f(t)}{t} + \frac{f(t)}{1-t}$, the desired bound (B.7) now follows easily. □

The following lemma contains estimates of Hardy type.

LEMMA B.2. *Let $a \le b$, $\alpha \in (0,1)$, T be the reference triangle. Then for $q \in (1,\infty)$*

$$\int_a^b \left| \frac{1}{x-a} \int_a^x |g(\xi)|\, d\xi \right|^q \le \left(\frac{q}{q-1} \right)^q \int_a^b |g(\xi)|^q\, d\xi, \tag{B.9}$$

$$\int_a^b \left| \frac{1}{(x-a)^2} \int_a^x g(\xi) - g(a)\, d\xi \right|^q dx \le \left(\frac{q}{q-1} \right)^q \int_a^b \left| \frac{g(\xi) - g(a)}{\xi - a} \right|^q d\xi. \tag{B.10}$$

Furthermore, for each $x \in (0,1)$ we have upon setting $m := \min(x, 1-x)$

$$\int_{y=0}^m \left| \frac{1}{y} \int_{x-\alpha y}^{x+\alpha y} g(t)\, dt \right|^q \le \left(\frac{q}{q-1} \right)^q \alpha^{q-1} \int_{x-\alpha m}^{x+\alpha m} |g(y)|^q\, dy, \tag{B.11}$$

$$\int_{y=0}^m \frac{1}{y^2} \int_{x-\alpha y}^{x+\alpha y} |g(t) - g(x)|\, dt\, dy \le \alpha^{2q-1} \left(\frac{q}{q-1} \right)^q \times \int_{x-\alpha m}^{x+\alpha m} \left| \frac{g(t) - g(x)}{t-x} \right|^q dt. \tag{B.12}$$

Finally, we have for some constant $C > 0$ that depends only on q and α,

$$\int_T \left| (x-y) \frac{1}{y} \int_{x-\alpha y}^{x+\alpha y} \frac{g(t)}{t}\, dt \right|^q dx\, dy \le C \|g\|^q_{L^q(\Gamma)}, \tag{B.13}$$

(B.14)

$$\int_T \left| \frac{x-y}{y^2} \int_{x-\alpha y}^{x+\alpha y} \frac{g(t)}{t} - \frac{g(x)}{x}\,dt \right|^q dxdy \le C \Big[\|g\|^q_{W^{1-1/q,q}(\Gamma)} + \left\| \frac{g(x)}{x} \right\|_{L^q(\Gamma)} \Big].$$

In all the above estimates, it is implicitly assumed that the right-hand side is finite.

Proof. The first estimate is the well-known Hardy inequality [29, Thm. 327]. For the second estimate, we note

$$\begin{aligned} \int_a^b \left| \frac{1}{|x-a|^2} \int_a^x |g(\xi)-g(a)| \right|^q dx &= \int_a^b \left| \frac{1}{|x-a|^2} \int_a^x \frac{|g(\xi)-g(a)|}{|\xi-a|} |\xi - a|\,d\xi\,dx \right|^q \\ &\le \int_a^b \left| \frac{1}{|x-a|} \int_a^x \frac{|g(\xi)-g(a)|}{|\xi-a|}\,d\xi \right|^q dx. \end{aligned}$$

The result (B.10) now follows from (B.9). The bounds (B.11), (B.12) follow from (B.9) and (B.10), respectively. To proceed further, we note that for $x \in (0,1)$ we have

(B.15) $$(1-\alpha)\,x \le x - \alpha y \le x + \alpha y \le (1+\alpha)x, \qquad 0 \le y \le \min(x, 1-x).$$

We are now in a position to prove (B.13). From (B.15) and (B.11) we get (again with the abbreviation $m = \min(x, 1-x)$)

$$\int_T \left| \frac{(x-y)}{y} \int_{x-\alpha y}^{x+\alpha y} \frac{g(t)}{t}\,dt \right|^q dx \le C \int_T \left| \frac{1}{y} \int_{x-\alpha y}^{x+\alpha y} g(t)\,dt \right|^q \le C \|g\|^q_{L^q(\Gamma)}.$$

We now turn to the proof of the last inequality, (B.15). We employ (B.12) and obtain

$$\int_T \left| \frac{x-y}{y^2} \int_{x-\alpha y}^{x+\alpha y} \frac{g(t)}{t} - \frac{g(x)}{x}\,dt \right|^q dy\,dx \le C \int_{x=0}^1 x^q \int_{t=x-\alpha m}^{x+\alpha m} \left| \frac{\frac{g(t)}{t} - \frac{g(x)}{x}}{t-x} \right|^q dt\,dx.$$

We next rewrite the integrand as

$$\frac{g(t)}{t} - \frac{g(x)}{x} = \frac{g(t)-g(x)}{t} - \frac{t-x}{tx} g(x)$$

and arrive at

$$\begin{aligned} &\int_T \left| \frac{x-y}{y^2} \int_{x-\alpha y}^{x+\alpha y} \frac{g(t)}{t} - \frac{g(x)}{x}\,dt \right|^q dy\,dx \\ &\le C \int_{x=0}^1 x^q \int_{t=x-\alpha m}^{x+\alpha m} t^{-q} \left| \frac{g(t)-g(x)}{t-x} \right|^q + C \int_{x=0}^1 x^q \int_{t=x-\alpha m}^{x+\alpha m} |g(x)|^q \frac{1}{|tx|^q}\,dt\,dx \\ &\le C \int_{\Gamma\times\Gamma} \left| \frac{g(t)-g(x)}{t-x} \right|^q dt\,dx + C \int_\Gamma \left| \frac{g(x)}{x^{1-1/q}} \right|^q dx. \end{aligned}$$

This concludes the proof of the lemma. □

LEMMA B.3. *Let $\alpha \in (0,1)$. Then for some $C > 0$ depending solely on α,*

$$\int_{x=0}^1 \int_{y=x-\alpha\min(x,1-x)}^{x+\alpha\min(x,1-x)} |g(y)|\,dy\,dx \le C \int_{y=0}^1 y(1-y)|g(y)|\,dy.$$

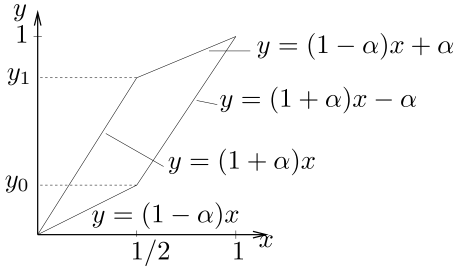

FIG. B.1. *Integration domain in Lemma* B.3.

Proof. The integration domain is sketched in Figure B.1. Interchanging the order of integration, we get

$$\int_{x=0}^{1} \int_{y=x-\alpha \min(x,1-x)}^{x+\alpha \min(x,1-x)} |g(y)|\, dy\, dx = \int_{y=0}^{y_0} \int_{x=y/(1+\alpha)}^{y/(1-\alpha)} |g(y)|\, dx\, dy$$
$$+ \int_{y=y_0}^{y_1} \int_{x=y/(1+\alpha)}^{(y+\alpha)/(1+\alpha)} |g(y)|\, dx\, dy + \int_{y=y_1}^{1} \int_{x=(y-\alpha)/(1-\alpha)}^{(y+\alpha)/(1+\alpha)} |g(y)|\, dx\, dy,$$

where $y_0 = \frac{1-\alpha}{2}$ and $y_1 = \frac{1+\alpha}{2}$. The result follows by elementary calculations. □

B.2. Polynomial lifting from the boundary.

B.2.1. $W^{1,q}$-stable liftings. The operator $f \mapsto F^{[f]}$ is the basic building block for the polynomial trace liftings of Theorem 5.2, which we now prove.

Proof of Theorem 5.2. We consider the case $\hat{K} = T$. Three cases may occur:

Γ *is a single edge:* We may assume $\Gamma = \{(x,0)\,|\, 0 < x < 1\}$ and choose F as $F^{[f]}$.

Γ *consists of two edges* Γ_1, Γ_2*:* The function F is defined in two steps. First, the lifting operator F of section B.1 is employed to construct a function $F_1 \in \mathcal{P}_p$ with $F_1|_{\Gamma_1} = f|_{\Gamma_1}$ and

$$\|F_1\|_{W^{1,q}(T)} \leq C\|f\|_{W^{1-1/q,q}(\Gamma_1)}, \quad \|F_1\|_{L^q(\Gamma_2)} + \|F_1\|_{L^q(T)} \leq C\|f\|_{L^q(\Gamma_1)}.$$

We have thus reduced the problem to one where f vanishes on one of the sides Γ_1, Γ_2. Without loss of generality, we assume that $\Gamma_1 = \{(x,0)\,|\, 0 < x < 1\}$ and $f|_{\Gamma_2} = 0$ with $\Gamma_2 = \{(x,x)\,|\, 0 < x < 1/2\}$. The mapping $f \mapsto (x-y)F^{[f/t]}(x,y)$ of section B.1 then has the desired properties.

$\Gamma = \partial K$*:* After having constructed a lifting from two adjacent edges as in the above construction, we may assume that f vanishes on two sides of T. Without loss of generality, we may therefore assume that $f|_{\Gamma_i} = 0$ for $i \in \{2,3\}$, where Γ_1 is the third side of ∂T given by $\Gamma_1 = \{(x,0)\,|\, 0 < x < 1\}$. The construction of a polynomial F with the property $F|_{\Gamma_1} = f$ and $F|_{\Gamma_i} = 0$ for $i \in \{2,3\}$ is then achieved with the operator $f \mapsto (x-y)(1-x-y)F^{[f/(t(1-t))]}(x,y)$ of section B.1.

The case of a square is proved similarly using the ideas of [6]. Note that in the case of a square, the set Γ may be disconnected, i.e., it consists of two parallel edges of $\hat{K}$. In this event, we easily reduce the construction to the case where f vanishes on one of the two edges and construct $F \in \mathcal{Q}_p$ in the same way as the function U in the proof of Lemma C.1.

We finally turn to the statement that constant functions are reproduced. This follows from the observation that the lifting operator constructed above is independent of the polynomial degree p. Since for $p = 0$ the constant function is reproduced, this operator reproduces constants for any $p \in \mathbb{N}_0$. □

B.2.2. Polynomial liftings with improved L^q-bounds. The basis of the results of section B.2.1 is the operator $f \mapsto F^{[f]}$ of section B.1. We introduce a new operator $\widetilde{F}^{[f]}$ by

$$\widetilde{F}^{[f]}(x,y) = (1-y)^p F^{[f]}(x,y). \tag{B.16}$$

We note that, if $f \in \mathcal{P}_p$, then $\widetilde{F} \in \mathcal{P}_{2p}$. Furthermore, $\widetilde{F}^{[f]}|_\Gamma = f$, where $\Gamma = \{(x,0)\,|\,0<x<1\}$. We also have the following lemma.

Lemma B.4. *Let T be the reference triangle. Then there exists $C>0$ such that for every $p \in \mathbb{N}$ the functions $\widetilde{F}^{[f]}$, $F_1 := (x-y)\widetilde{F}^{[f/t]}$, $F_2 := (x-y)(1-x-y)\widetilde{F}^{[f/(t(1-t))]}$ satisfy*

$$\begin{aligned}
p\|\widetilde{F}^{[f]}\|_{L^q(T)} + \|\widetilde{F}^{[f]}\|_{W^{1,q}(T)} &\le C\|f\|_{W^{1-1/q,q}(\Gamma)} + Cp^{1-1/q}\|f\|_{L^q(\Gamma)},\\
p\|F_1\|_{L^q(T)} + \|F_1\|_{W^{1,q}(T)} &\le C\|f\|_{W^{1-1/q,q}(\Gamma)} + C\|\frac{f(x)}{x^{1-1/q}}\|_{L^q(\Gamma)} + Cp^{1-1/q}\|f\|_{L^q(\Gamma)},\\
p\|F_2\|_{L^q(T)} + \|F_2\|_{W^{1,q}(T)} &\le C\|f\|_{\widetilde{W}^{1-1/q,q}(\Gamma)} + Cp^{1-1/q}\|f\|_{L^q(\Gamma)}.
\end{aligned}$$

Furthermore,

$$\|\widetilde{F}^{[f]}\|_{L^q(\partial T)} \le C\|f\|_{L^q(\Gamma)}.$$

Proof. The lemma follows from Lemma B.5 below and the properties of the operator $F^{[f]}$ of section B.1. □

This lemma allows us now to prove Proposition 5.3.

Proof of Proposition 5.3. The proof is similar to that of Theorem 5.2. The appeals to Proposition B.1 are replaced with those to Lemma B.4. □

Lemma B.5. *K be the reference triangle or the reference square. Set $\Gamma = \{(x,0)\,|\,0<x<1\}$ and let $q \in (1,\infty)$. Then there exists $C>0$ such that for every $p \in \mathbb{N}$ and every function $g \in W^{1,q}(K)$*

$$p\|(1-y)^p g\|_{L^q(K)} + \|(1-y)^p g\|_{W^{1,q}(K)} \le C|g|_{W^{1,q}(K)} + p^{1-1/q}\|g\|_{L^q(\Gamma)}.$$

Proof. We express the function g for $y>0$ as $g(x,y) = g(x,0) + \int_{t=0}^y g_y(x,t)\,dt$. Then

$$(1-y)^p g(x,y) = [(1-y)^p y]\,\frac{1}{y}\int_0^y g_y(x,t)\,dt + (1-y)^p g(x,0).$$

Since $\sup_{y\in(0,1)}(1-y)^p y \le \frac{C}{p}$, we conclude with the Hardy inequality (B.9)

$$\|(1-y)^p g\|_{L^q(K)} \le \frac{C}{p}|g|_{W^{1,q}(K)} + p^{-1/q}\|g\|_{L^q(\Gamma)}.$$

For the bound on the derivative of $(1-y)^p g$, we write

$$\nabla((1-y)^p g) = p(1-y)^{p-1}g + (1-y)^p\nabla g;$$

we treat the first term as above and for the second term we use

$$|1-y| \le 1 \text{ on } K. \qquad \square$$

Appendix C. One-dimensional extension operators.

Proof of Lemma 5.4. The key to this result is the following approximation result of [18, Cor. 3.7]:

$$\inf_{v \in \mathcal{P}_{p-k}} \|u - v\|_{L^\infty(J)} \leq 12(4p)^{k-1} |J|^{p-k+1} \|u\|_{L^\infty(\hat{I})} \qquad \forall u \in \mathcal{P}_p, \tag{C.1}$$

where $J \subset \hat{I}$ is an arbitrary subinterval of $\hat{I}$ and $|J|$ denotes the length of J. We (arbitrarily) choose $J = (0, 1/2)$, denote by $\mathcal{I}_{p-k} : C(\overline{J}) \to \mathcal{P}_{p-k}$ the Gauß–Lobatto interpolation operator and set

$$(Z_{p,p-k} u)(x) = (\mathcal{I}_{p-k} u)(2x).$$

By construction $(Z_{p,p-k} u) \in \mathcal{P}_{p-k}$. Additionally, the fact that the endpoint 0 of J is an interpolation point implies $(Z_{p,p-k} u)(0) = u(0)$. In order to see the remaining estimates, we see that (C.1) together with standard inverse estimates (see, e.g., [24, Chap. 4, Thms. 1.4 and 2.6]) implies

$$\|u - \mathcal{I}_{p-k} u\|_{W^{1,\infty}(J)} \leq C p^2 \|u - \mathcal{I}_{p-k} u\|_{L^\infty(J)} \leq C \rho^{p-k} \|u\|_{L^\infty(\hat{I})} \leq C \tilde{\rho}^{p-k} \|u\|_{L^q(\hat{I})}$$

for some suitable $C > 0$ and $\tilde{\rho} \in (0, 1)$ that are both independent of p and u. In particular, since $u(0) = (\mathcal{I}_{p-k} u)(0)$, we get

$$\max_{x \in J} \frac{|u(x) - (\mathcal{I}_{p-k} u)(x)|}{|x|} \leq \|u' - (\mathcal{I}_{p-k} u)'\|_{L^\infty(J)} \leq C \tilde{\rho}^{p-k} \|u\|_{L^q(\hat{I})}.$$

From this and the triangle inequality, we can easily infer the estimates

$$\|\mathcal{I}_{p-k} u\|_{L^q(J)} \leq C \|u\|_{L^q(\hat{I})},$$
$$\|\mathcal{I}_{p-k} u\|_{W^{1-1/q,q}(J)} \leq C \|u\|_{W^{1-1/q,q}(\hat{I})},$$
$$\int_0^{1/2} \frac{|u(x) - \mathcal{I}_{p-k} u(x)|^q}{x^{q-1}} \, dx \leq C \|u\|^q_{L^q(\hat{I})}.$$

This and the change of variables $x \mapsto 2x$ imply the desired bounds for $Z_{p,p-k}$. □

A closely related extension result is the following.

Lemma C.1. *Let $\hat{I} = (0, 1)$ and $q \in (1, \infty)$. Then there exists a bounded linear operator $Z : W^{1-1/q,q}(\hat{I}) \to W^{1-1/q,q}(\hat{I})$ with the following properties:*

1. $\int_{x=0}^1 \frac{|u(x) - Zu(x)|^q}{x^{q-1}} \, dx \leq C \|u\|^q_{W^{1-1/q,q}(\hat{I})}$;
2. *if $u \in \mathcal{P}_p$, then $Zu \in \mathcal{P}_p$;*
3. $Zu(1) = 0$ *and* $\int_{-1}^0 \frac{|Zu(x)|^q}{(1-x)^{q-1}} \, dx \leq C \|u\|^q_{W^{1-1/q,q}(\hat{I})}$;
4. $\|Zu\|_{L^q(I)} \leq C \|u\|_{L^q(\hat{I})}$.

Proof. Let T be the reference triangle and identify $\hat{I}$ with the edge of $\hat{K}$ lying on the x-axis. Consider the trapezoid $\tilde{T} := \{(x, y) \in T \,|\, 0 < y < 1/4\}$ and define $\Gamma = \{(x, x) \,|\, 0 < x < 1/4\}$. An elementary calculation reveals

$$\|F^{[u]}(\cdot, 1/4)\|_{W^{1,\infty}((1/4,3/4))} \leq C \|u\|_{L^q(\hat{I})}$$

for some appropriate $C > 0$. Hence, the function

$$U(x, y) = F^{[u]}(x, y) - 4y F^{[u]}(x, 1/4)$$

satisfies

$$\|U\|_{W^{1,q}(\tilde{T})} \leq C\|u\|_{W^{1-1/q,q}(\hat{I})}, \quad \|U\|_{L^q(\Gamma)} \leq C\|u\|_{L^q(\hat{I})}, \quad U|_{y=1/4} = 0.$$

Additionally, if $u \in \mathcal{P}_p$, then $U \in \mathcal{Q}_p$. Defining $Zu(x)$ for $x \in (0,1)$ by $(Zu)(x) = U(x/4, x/4)$ and appealing to the trace theorem concludes the proof. □

Lemma C.2. *Let $\hat{I} = (0,1)$ and $q \in (1,\infty)$. Then $u \in W^{1-1/q,q}(\hat{I})$ implies that the function $\tilde{u} : x \mapsto xu(x)$ is in $W^{1-1/q,q}(\hat{I})$ and satisfies*

$$\int_0^1 \frac{|\tilde{u}(x)|^q}{x^{q-1}}\, dx + \|\tilde{u}\|^q_{W^{1-1/q,q}(\hat{I})} \leq C\|u\|^q_{W^{1-1/q,q}(\hat{I})}$$

for some $C > 0$ that is independent of u.

Proof. The estimate $\|\tilde{u}\|_{W^{1-1/q,q}(\hat{I})} \leq C\|u\|_{W^{1-1/q,q}(\hat{I})}$ follows from the smoothness of the function $x \mapsto x$. The remaining estimate follows by inspection. □

AN OPTIMAL A PRIORI ERROR ESTIMATE FOR NONLINEAR MULTIBODY CONTACT PROBLEMS*

S. HÜEBER[†] AND B. I. WOHLMUTH[†]

Abstract. Nonconforming domain decomposition methods provide a powerful tool for the numerical approximation of partial differential equations. For the discretization of a nonlinear multibody contact problem, we use linear mortar finite elements based on dual Lagrange multipliers. Under some regularity assumptions on the solution, an optimal convergence order of $h^{0.5+\nu}$, $0 < \nu \leq 0.5$, can be established in two dimensions (2D) and three dimensions (3D). Compared with a standard linear saddle point formulation, two additional terms which provide a measure for the nonconformity and the nonlinearity of the approach have to be taken in account. Numerical examples illustrating the performance of the nonconforming method and confirming our theoretical result are presented.

Key words. multibody contact problems, a priori error estimates, mortar finite element methods, dual Lagrange multipliers, linear elasticity

1. Introduction.

The numerical approximation of nonlinear multibody contact problems is a challenging task. Modern discretization techniques are very often based on flexible nonconforming approaches. Here, we provide a new optimal a priori bound for the discretization error of the mortar method. We focus on piecewise linear dual Lagrange multipliers which have been introduced for the lowest-order case in [Woh00]. Dual Lagrange multiplier spaces are based on a biorthogonal basis resulting in a diagonal mass matrix. Thus we obtain for each node on the slave side a local nonpenetration condition. The main advantage of dual Lagrange multipliers is that fast and efficient monotone multigrid methods [KK01] can be generalized to multibody contact problems [WK03]. In case of standard Lagrange multipliers, local monotone multigrid methods cannot be applied.

In this paper, we give a new optimal a priori error estimate for the discretization error in the H^1-norm for the displacements and in the $H^{-1/2}$-norm for the Lagrange multiplier. The interest in contact problems and variational inequalities has led to an increased research activity in this field. Abstract error estimates for variational inequalities can be found, e.g., in [Fal74, BHR77, Glo84] and a priori bounds for the discretization error of unilateral contact problems are given, e.g., in [Hc81, Hcc96]. Recently a lot of work has been done to analyze mortar formulations based on standard Lagrange multipliers. A priori error estimates for the displacements in the H^1-norm and for the Lagrange multiplier in the $H^{-1/2}$-norm of order $h^{0.75}$ have been established; see, e.g., [BR03, LS99, BHL99, CHLS01], under H^2-regularity assumption. Using additional regularity assumptions on the Lagrange multiplier, order h has been shown; see, e.g., [Hil00, CHLS01]. Although the order h is optimal, the regularity assumptions are quite strong and restrictive. These first a priori results have been considerably improved during the last couple of years. In [Ben00], order

$h^{0.5+\nu}$, $0 < \nu < 0.5$, and order $h\sqrt{|\log h|}$ a priori results are given for the H^1-norm if the solution is $H^{3/2+\nu}$- and H^2-regular, respectively. A new and stronger result is given in [BR03], where order $h\sqrt[4]{|\log h|}$ can be found. In [HL02], quadratic finite elements are discussed and a priori estimates for the discretization error are given. Most of the theoretical results are obtained for standard Lagrange multipliers and in the two-dimensional setting.

In this paper, we consider the case of linear mortar finite elements based on dual Lagrange multipliers in two dimensions (2D) and three dimensions (3D). Moreover, we show order $h^{0.5+\nu}$ a priori estimates for the displacements and the Lagrange multiplier if the solution is $H^{3/2+\nu}$-regular, $0 < \nu \leq 0.5$. The techniques are based on introducing locally defined truncation operators measuring the nonconformity of the discretization and on Sobolev–Slobodeckij norms.

The rest of this paper is organized as follows. In section 2, we present the mathematical formulation of the nonlinear multibody contact problem. In section 3, we then consider the mortar discretization technique and establish the optimal a priori estimate. Finally in section 4, we provide several numerical examples illustrating the performance of the approach and confirming our theoretical results.

2. Unilateral Signorini contact problem. In this section, we give the formulation of a unilateral contact problem in linear elasticity. Let Ω_k, $k = m, s$, denote two elastic bodies, where $\Omega_k \subset \mathbb{R}^d$, $d = 2, 3$, are two bounded polyhedral domains. The nonmortar side is associated with the subdomain Ω_s and the mortar side with the subdomain Ω_m. We recall that in the mortar setting, the Lagrange multiplier is defined on the nonmortar side and that the displacements on the nonmortar side depend on the ones on the mortar side. Mortar and nonmortar sides are also called master and slave sides, respectively. This motivates the subscript s for the nonmortar side and the subscript m for the mortar side. Let $\Gamma_k := \partial\Omega_k$ be $\Gamma_k = \overline{\Gamma_{k,D}} \cup \overline{\Gamma_{k,N}} \cup \overline{\Gamma_{k,C}}$ with disjoint open subsets $\Gamma_{k,i}$, $i = D, N, C$. We assume homogeneous Dirichlet data on $\Gamma_D := \Gamma_{s,D} \cup \Gamma_{m,D}$ and we assume that $\Gamma_{k,D}$, $k = m, s$, has a nonzero measure. On $\Gamma_N := \Gamma_{s,N} \cup \Gamma_{m,N}$ Neumann data are given, and $\Gamma_{k,C}$ denotes the possible contact zone between the two bodies. Furthermore, we assume that the two bodies in the initial configuration are in contact on their common boundary part, i.e., $\Gamma_C := \Gamma_{m,C} = \Gamma_{s,C}$ and that $\overline{\Gamma_C}$ is a compact subset of $\partial\Omega_s \backslash \overline{\Gamma_{s,D}}$. The normal vector $\mathbf{n} := \mathbf{n}_s = -\mathbf{n}_m$ is assumed to be constant on Γ_C. Let $\mathbf{f}_k \in [L^2(\Omega_k)]^d$ be the volume forces on Ω_k. On each domain Ω_k, $k = m, s$, we have to consider the boundary value problem

$$
\begin{aligned}
-\operatorname{div} \boldsymbol{\sigma}_k(\mathbf{u}_k) &= \mathbf{f}_k \quad \text{in} \quad \Omega_k,\\
\mathbf{u}_k &= \mathbf{0} \quad \text{on} \quad \Gamma_{k,D},\\
\boldsymbol{\sigma}_k(\mathbf{u}_k)\,\mathbf{n}_k &= \mathbf{p}_k \quad \text{on} \quad \Gamma_{k,N}
\end{aligned}
\tag{2.1}
$$

with given boundary stresses $\mathbf{p}_k$ on $\Gamma_{k,N}$. The stress tensor $\boldsymbol{\sigma}_k$ on Ω_k is given by Hooke's law

$$\boldsymbol{\sigma}_{k,ij} := \mathbf{C}_{k,ijml}\boldsymbol{\epsilon}_{k,ml},$$

where the components of the symmetric and positive definite tensor $\mathbf{C}_k$ are

$$\mathbf{C}_{k,ijml} := \lambda_k\,\delta_{ij}\delta_{ml} + \mu_k\,(\delta_{im}\delta_{jl} + \delta_{il}\delta_{jm})$$

with the constant Lamé parameters λ_k and μ_k on Ω_k. Here $\boldsymbol{\epsilon}_k$ denotes the linearized strain tensor

$$\boldsymbol{\epsilon}_k(\mathbf{u}_k) := \frac{1}{2}\Big(\nabla\mathbf{u}_k + \big(\nabla\mathbf{u}_k\big)^\top\Big).$$

We refer the reader to [KO88, Wri01, Lau02] for an introduction to linear elasticity and contact problems. To specify the conditions modeling unilateral contact on the possible contact part Γ_C, we define for $k = m, s$ the normal stress $\sigma_{k,n}(\mathbf{u}_k)$ and the tangential stress $\boldsymbol{\sigma}_{k,T}$ on Γ_C by

$$\sigma_{k,n}(\mathbf{u}_k) := \big(\boldsymbol{\sigma}_k\left(\mathbf{u}_k\right)\mathbf{n}_k\big)\cdot\mathbf{n}_k \quad \text{and} \quad \boldsymbol{\sigma}_{k,T}\left(\mathbf{u}\right) := \boldsymbol{\sigma}_k\left(\mathbf{u}_k\right)\mathbf{n}_k - \sigma_{k,n}(\mathbf{u}_k)\,\mathbf{n}_k,$$

respectively. We consider frictionless unilateral contact problems, thus the contact conditions on the possible contact boundary Γ_C for $k = m, s$ are given by

$$\begin{aligned} -\boldsymbol{\sigma}_{s,T}\left(\mathbf{u}_s\right) = \boldsymbol{\sigma}_{m,T}\left(\mathbf{u}_m\right) &= 0, \\ \sigma_{m,n}(\mathbf{u}_m) = \sigma_{s,n}(\mathbf{u}_s) &\leq 0, \\ [\mathbf{u}\cdot\mathbf{n}] &\leq 0, \\ \sigma_n(\mathbf{u})[\mathbf{u}\cdot\mathbf{n}] &= 0, \end{aligned} \tag{2.2}$$

where $[\mathbf{u}\cdot\mathbf{n}]$ stands for the jump of the normal displacements $\mathbf{u}$ on the possible contact boundary Γ_C. It is defined as $[\mathbf{u}\cdot\mathbf{n}] := \mathbf{u}_m\cdot\mathbf{n}_m + \mathbf{u}_s\cdot\mathbf{n}_s$, and the normal part of the stresses on Γ_C is given by $\sigma_n(\mathbf{u}) := \sigma_{m,n}(\mathbf{u}_m) = \sigma_{s,n}(\mathbf{u}_s)$. The third condition is called the nonpenetration condition of the two bodies. Together with (2.1), the contact condition (2.2) formulate the problem of frictionless unilateral contact. The last condition in (2.2) implies that at the possible contact area Γ_C, we have either zero boundary stresses, i.e., $\sigma_n(\mathbf{u}) = 0$, or contact between the two bodies, i.e., $[\mathbf{u}\cdot\mathbf{n}] = 0$. We remark that we do not need any function modeling the distance between the two bodies, since we assume that they are in contact in the reference configuration. In the more general case, we have to replace the third condition in (2.2) by $[\mathbf{u}\cdot\mathbf{n}] \leq g$, where the gap function $g : \Gamma_{s,C} \to \mathbb{R}$ models the distance between the two bodies, and the jump has to be defined in terms of a suitable parametrization. To give the weak formulation of problem (2.1) with the contact conditions (2.2), we introduce the product space $\mathbf{V} := [H^1_*(\Omega_m)]^d \times [H^1_*(\Omega_s)]^d$, equipped with the broken H^1-norm $\|\mathbf{v}\|^2_{1,\Omega} := \sum_{k=m,s}\|\mathbf{v}\|^2_{1,\Omega_k}$, where the spaces $[H^1_*(\Omega_k)]^d$ are defined by

$$[H^1_*(\Omega_k)]^d := \left\{\mathbf{v}_k \in \left[H^1\left(\Omega_k\right)\right]^d \,:\, \mathbf{v}_{k|_{\Gamma_{k,D}}} = \mathbf{0}\right\}.$$

For $\mathbf{u} := (\mathbf{u}_m, \mathbf{u}_s) \in \mathbf{V}$ and $\mathbf{v} := (\mathbf{v}_m, \mathbf{v}_s) \in \mathbf{V}$, we define the bilinear form $a(\mathbf{u},\mathbf{v})$ and the linear form $f(\mathbf{v})$ by

$$a(\mathbf{u},\mathbf{v}) := \sum_{k=m,s}\int_{\Omega_k}\boldsymbol{\sigma}_k\left(\mathbf{u}_k\right) : \nabla\mathbf{v}_k\,dx,$$

$$f(\mathbf{v}) := \sum_{k=m,s}\left(\int_{\Omega_k}\mathbf{f}_k\cdot\mathbf{v}_k\,dx + \int_{\Gamma_{k,N}}\mathbf{p}_k\cdot\mathbf{v}_k\,ds\right).$$

Then the weak solution of our nonlinear contact problem (2.1) and (2.2) can be obtained as a solution of a minimization problem on the convex subset $\mathbf{K} := \{\mathbf{v} \in \mathbf{V} \,:\, [\mathbf{v}\cdot\mathbf{n}] \leq 0 \text{ on } \Gamma_C\}$

$$J(\mathbf{u}) = \min_{\mathbf{v}\in\mathbf{K}} J(\mathbf{v}) := \frac{1}{2}a(\mathbf{v},\mathbf{v}) - f(\mathbf{v}); \tag{2.3}$$

see, e.g., [Hc80, BGK87]. Furthermore, the minimization problem (2.3) is equivalent to a variational inequality on the convex subset $\mathbf{K} \subset \mathbf{V}$: find $\mathbf{u} \in \mathbf{K}$ such that

$$a(\mathbf{u}, \mathbf{v} - \mathbf{u}) \geq f(\mathbf{v} - \mathbf{u}), \qquad \mathbf{v} \in \mathbf{K}. \tag{2.4}$$

To give the saddle point formulation, we introduce a Lagrange multiplier space $\mathbf{M}$, being the dual space of the trace space $\mathbf{W}$ of $[H^1_*(\Omega_s)]^d$ restricted to Γ_C. By assumption $\overline{\Gamma_C}$ is a compact subset of $\partial\Omega_s \backslash \overline{\Gamma_{s,D}}$, and thus we have $\mathbf{W} = [H^{1/2}(\Gamma_C)]^d$. In the case $\overline{\Gamma_C} = \partial\Omega_s \backslash \Gamma_{s,D}$, we have to work with $[H^{1/2}_{00}(\Gamma_C)]^d$ instead of $[H^{1/2}(\Gamma_C)]^d$. We now define the following convex cone of Lagrange multipliers:

$$\mathbf{M}^+ := \left\{ \boldsymbol{\mu} \in \mathbf{M} \, : \, \langle \boldsymbol{\mu}, \mathbf{v} \rangle_{\Gamma_C} \geq 0, \quad \mathbf{v} \in \mathbf{W}^+ \right\}, \tag{2.5}$$

where $\langle \cdot, \cdot \rangle_{\Gamma_C}$ denotes the duality pairing between $\mathbf{M}$ and $\mathbf{W}$, and $\mathbf{W}^+ := \{\mathbf{v} \in \mathbf{W} : \mathbf{v} \cdot \mathbf{n} \geq 0\}$. Defining the bilinear form $b(\cdot, \cdot)$ on the product space $\mathbf{V} \times \mathbf{M}$ by

$$b(\mathbf{v}, \boldsymbol{\mu}) := \langle \boldsymbol{\mu} \cdot \mathbf{n}, [\mathbf{v} \cdot \mathbf{n}] \rangle_{\Gamma_C}, \qquad \boldsymbol{\mu} \in \mathbf{M}, \quad \mathbf{v} \in \mathbf{V},$$

we get the saddle point formulation of the unilateral contact problem without friction; see, e.g., [Hcc96, Chapter 1.3]: find $\mathbf{u} \in \mathbf{V}$ and $\boldsymbol{\lambda} \in \mathbf{M}^+$ such that

$$\begin{aligned} a(\mathbf{u}, \mathbf{v}) + b(\mathbf{v}, \boldsymbol{\lambda}) &= f(\mathbf{v}), & \mathbf{v} &\in \mathbf{V}, \\ b(\mathbf{u}, \boldsymbol{\mu} - \boldsymbol{\lambda}) &\leq 0, & \boldsymbol{\mu} &\in \mathbf{M}^+. \end{aligned} \tag{2.6}$$

The existence and uniqueness of $(\mathbf{u}, \boldsymbol{\lambda}) \in \mathbf{V} \times \mathbf{M}^+$ of (2.6) has been stated, e.g., in [Hcc96, Theorem 3.11 and Remark 3.10]. Moreover, $\mathbf{u}$ is also the unique solution of the minimization problem (2.3) and the variational inequality (2.4), and we find that $\boldsymbol{\lambda} = -\sigma_s(\mathbf{u}_s)\mathbf{n}$ and thus $\boldsymbol{\lambda} \cdot \mathbf{n} = -\sigma_n(\mathbf{u})$ and $\boldsymbol{\lambda} \times \mathbf{n} = 0$.

In the following, we denote by $\gamma_a \subset \Gamma_C$ the actual contact set, i.e., $[\mathbf{u} \cdot \mathbf{n}] = 0$ on γ_a and $[\mathbf{u} \cdot \mathbf{n}] < 0$ on $\gamma_c := \Gamma_C \backslash \gamma_a$. If the displacement $\mathbf{u}$ is a continuous function, then the actual contact zone γ_a is a well-defined and closed subset of Γ_C.

3. Discretization techniques and a priori error estimates. In this section, we consider a discrete formulation of the saddle point formulation (2.6). Mortar techniques with standard Lagrange multiplier spaces for contact problems have been considered and analyzed, e.g., in [BHL99, Hil00, CHLS01, HL02, BR03]. Here, we apply these techniques to dual Lagrange multiplier spaces; see, e.g., [Woh00]. New optimal a priori error estimates for the discretization error in the H^1-norm and for the Lagrange multiplier in the $H^{-1/2}$-norm will be given. To approximate $\mathbf{V}$, we use standard conforming finite elements of lowest order on quasi-uniform simplicial, quadrilateral, or hexahedral triangulations. The finite element space associated with the shape regular triangulation $\mathcal{T}_{h,\Omega_k}$ is denoted by $S_1(\Omega_k, \mathcal{T}_{h,\Omega_k})$. The meshsize h is defined by the maximal diameter of the elements in $\mathcal{T}_{h,\Omega_m}$ and $\mathcal{T}_{h,\Omega_s}$. We define the discrete product space $\mathbf{V}_h$ by

$$\mathbf{V}_h := \left\{ \mathbf{v}_h \in \prod_{k \in \{s,m\}} \left[S_1\left(\Omega_k, \, \mathcal{T}_{h,\Omega_k}\right)\right]^d \, : \, \mathbf{v}_{h|_{\Gamma_D}} = \mathbf{0} \right\} \subset \mathbf{V}.$$

As it is standard in the mortar context, the Lagrange multiplier space inherits its $(d-1)$-dimensional mesh from the d-dimensional triangulation on the slave side. We assume that Γ_C can be written as union of edges in 2D and faces in 3D on the slave side. Here, we use discontinuous piecewise linear or bilinear nodal basis functions for the dual Lagrange multiplier. The discrete Lagrange multiplier space is denoted by $\mathbf{M}_h$ and can be spanned by $\{\psi_i \mathbf{e}_l,\ i = 1, \ldots, N_{\mathbf{M}_h},\ l = 1, \ldots, d\}$, where $\mathbf{e}_l$ denotes the lth unit vector, ψ_i the ith scalar dual basis function, and $N_{\mathbf{M}_h}$ is the number of vertices on the slave side of $\overline{\Gamma_C}$. In contrast to the general mortar setting, we do not have to remove the degrees of freedom of $\mathbf{M}_h$ on $\partial\Gamma_C$. We note that this has to be done if $\overline{\Gamma_{s,D}} \cap \overline{\Gamma_{s,C}} \neq \emptyset$ but not in our case. We now define the discrete space of $\mathbf{M}^+$ (see (2.5)) by

$$\mathbf{M}_h^+ := \Big\{\boldsymbol{\mu}_h \in \mathbf{M}_h \,:\, \langle \boldsymbol{\mu}_h, \mathbf{v}_h \rangle_{\Gamma_C} \geq 0,\, \mathbf{v}_h \in \mathbf{W}_h^+ \Big\}, \tag{3.1}$$

where $\mathbf{W}_h^+ := \{\mathbf{v}_h \in \mathbf{W}_h \,:\, \mathbf{v}_h \cdot \mathbf{n} \geq 0\}$ and $\mathbf{W}_h$ is the vector-valued trace space of $[S_1(\Omega_s, \mathcal{T}_{h,\Omega_s})]^d$ restricted to Γ_C. The following lemma shows that the space $\mathbf{M}_h^+$ can be equivalently defined by

$$\widehat{\mathbf{M}}_h^+ := \left\{ \boldsymbol{\mu}_h = \sum_{i=1}^{N_{\mathbf{M}_h}} \boldsymbol{\alpha}_i \psi_i \,:\, \boldsymbol{\alpha}_i \in \mathbb{R}^d,\, \boldsymbol{\alpha}_i = \alpha_i^n \mathbf{n},\, \alpha_i^n \in \mathbb{R},\, \alpha_i^n \geq 0,\, i = 1, \ldots, N_{\mathbf{M}_h} \right\}.$$

LEMMA 3.1. $\mathbf{M}_h^+ = \widehat{\mathbf{M}}_h^+$.

Proof. To show the equivalence, we write $\mathbf{v}_h \in \mathbf{W}_h^+$ as $\mathbf{v}_h = \sum_{i=1}^{N_{\mathbf{M}_h}} (\beta_i^n \mathbf{n} + \boldsymbol{\beta}_i^t)\varphi_i$ with $\beta_i^n \in \mathbb{R}$, $\beta_i^n \geq 0$, and $\boldsymbol{\beta}_i^t \in \mathbb{R}^d$, $\boldsymbol{\beta}_i^t \cdot \mathbf{n} = 0$, where φ_j are the scalar nodal basis function of $S_1(\Omega_s, \mathcal{T}_{h,\Omega_s})$ restricted to Γ_C. Each $\boldsymbol{\mu}_h \in \mathbf{M}_h$ can be written in terms of the basis functions ψ_i as $\boldsymbol{\mu}_h = \sum_{i=1}^{N_{\mathbf{M}_h}} (\alpha_i^n \mathbf{n} + \boldsymbol{\alpha}_i^t)\psi_i$ with $\alpha_i^n \in \mathbb{R}$ and $\boldsymbol{\alpha}_i^t \in \mathbb{R}^d$, $\boldsymbol{\alpha}_i^t \cdot \mathbf{n} = 0$. Due to the biorthogonality of the basis functions

$$\int_{\Gamma_C} \psi_i \varphi_j \, ds = \delta_{ij} c_j, \qquad c_j := \int_{\Gamma_C} \varphi_j \, ds > 0,$$

we have

$$\langle \boldsymbol{\mu}_h, \mathbf{v}_h \rangle_{\Gamma_C} = \sum_{i=1}^{N_{\mathbf{M}_h}} \left(\alpha_i^n \beta_i^n + \boldsymbol{\alpha}_i^t \cdot \boldsymbol{\beta}_i^t \right) c_i. \tag{3.2}$$

Letting $\boldsymbol{\mu}_h \in \mathbf{M}_h^+$ and using the definition (3.1), the choice $\boldsymbol{\beta}_i^t = \mathbf{0}$ and $\beta_i^n = \delta_{ij}$ yields $\alpha_j^n \geq 0$ and the choice $\beta_i^n = 0$ and $\boldsymbol{\beta}_i^t = \pm\delta_{ij}\boldsymbol{\alpha}_j^t$ yields $\boldsymbol{\alpha}_j^t = \mathbf{0}$ and thus $\boldsymbol{\mu}_h \in \widehat{\mathbf{M}}_h^+$. Letting $\boldsymbol{\mu}_h \in \widehat{\mathbf{M}}_h^+$ and using (3.2) and $\beta_i^n \geq 0$, we find that $\boldsymbol{\mu}_h \in \mathbf{M}_h^+$. □

We remark that this is not a conforming approach for the Lagrange multiplier space, i.e., $\mathbf{M}_h^+ \not\subset \mathbf{M}^+$.

Remark 3.2. Using standard Lagrange multipliers, the spaces $\mathbf{M}_h^+$ and $\widehat{\mathbf{M}}_h^+$ are not the same. In that case, the convex cone $\widehat{\mathbf{M}}_h^+$ is a subset of the convex cone $\mathbf{M}_h^+$.

The discrete mortar formulation of the saddle point problem (2.6) is now given by the following: find $\mathbf{u}_h \in \mathbf{V}_h$ and $\boldsymbol{\lambda}_h \in \mathbf{M}_h^+$ such that

$$\begin{aligned} a(\mathbf{u}_h, \mathbf{v}_h) + b(\mathbf{v}_h, \boldsymbol{\lambda}_h) &= f(\mathbf{v}_h), & \mathbf{v}_h &\in \mathbf{V}_h, \\ b(\mathbf{u}_h, \boldsymbol{\mu}_h - \boldsymbol{\lambda}_h) &\leq 0, & \boldsymbol{\mu}_h &\in \mathbf{M}_h^+. \end{aligned} \tag{3.3}$$

Existence and uniqueness of a solution follows from a discrete inf-sup condition (see, e.g., [Woh01, Chapter 1.2.3]) for the spaces $\mathbf{M}_h^n$ and $\mathbf{V}_h$ with $\mathbf{M}_h^+ \subset \mathbf{M}_h^n := \{\boldsymbol{\mu}_h \in \mathbf{M}_h : \boldsymbol{\mu}_h \times \mathbf{n} = 0\}$ (see, e.g., [Hcc96, Chapter 2.4.2] or [HL02]).

In the rest of this section, we consider optimal a priori estimates for the discretization errors in the primal and dual variables. The starting point is the following abstract lemma; see, e.g., [HL02].

LEMMA 3.3. *Let* $(\mathbf{u}, \boldsymbol{\lambda}) \in \mathbf{V} \times \mathbf{M}^+$ *be the solution of* (2.6) *and let* $(\mathbf{u}_h, \boldsymbol{\lambda}_h) \in \mathbf{V}_h \times \mathbf{M}_h^+$ *be the solution of the discrete formulation* (3.3). *Then there exists a constant* $0 < C < \infty$ *independent of the meshsize* h, *such that*

$$\|\mathbf{u}-\mathbf{u}_h\|_{1,\Omega} + \|\boldsymbol{\lambda}-\boldsymbol{\lambda}_h\|_{-\frac{1}{2},\Gamma_C} \le C\Big\{ \inf_{\mathbf{v}_h\in\mathbf{V}_h} \|\mathbf{u}-\mathbf{v}_h\|_{1,\Omega} + \inf_{\boldsymbol{\mu}_h\in\mathbf{M}_h^n} \|\boldsymbol{\lambda}-\boldsymbol{\mu}_h\|_{-\frac{1}{2},\Gamma_C} \\ + \max\big(b(\mathbf{u},\boldsymbol{\lambda}_h),\, 0\big)^{\frac{1}{2}} + \max(b(\mathbf{u}_h,\boldsymbol{\lambda}),\, 0)^{\frac{1}{2}} \Big\}.$$

Proof. The proof can be found in [HL02] for scalar-valued standard Lagrange multipliers and quadratic finite elements. It applies also to our situation. For convenience of the reader, we briefly recall the basic steps. Starting with $a(\mathbf{u}-\mathbf{u}_h, \mathbf{u}-\mathbf{u}_h)$, we find for $\mathbf{v}_h \in \mathbf{V}_h$, using (2.6) and (3.3),

$$\begin{aligned} a(\mathbf{u}-\mathbf{u}_h, \mathbf{u}-\mathbf{u}_h) &= a(\mathbf{u}-\mathbf{u}_h, \mathbf{u}-\mathbf{v}_h) + a(\mathbf{u}-\mathbf{u}_h, \mathbf{v}_h-\mathbf{u}_h) \\ &= a(\mathbf{u}-\mathbf{u}_h, \mathbf{u}-\mathbf{v}_h) - b(\mathbf{v}_h-\mathbf{u}_h, \boldsymbol{\lambda}) + b(\mathbf{v}_h-\mathbf{u}_h, \boldsymbol{\lambda}_h) \\ &= a(\mathbf{u}-\mathbf{u}_h, \mathbf{u}-\mathbf{v}_h) - b(\mathbf{v}_h-\mathbf{u}, \boldsymbol{\lambda}-\boldsymbol{\lambda}_h) - b(\mathbf{u}-\mathbf{u}_h, \boldsymbol{\lambda}-\boldsymbol{\lambda}_h). \end{aligned}$$

Using the continuity of the bilinear forms $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$, the trace theorem, and Korn's inequality, we obtain the upper bound

$$\|\mathbf{u}-\mathbf{u}_h\|^2_{1,\Omega} \le C(\|\mathbf{u}-\mathbf{u}_h\|_{1,\Omega} + \|\boldsymbol{\lambda}-\boldsymbol{\lambda}_h\|_{-\frac{1}{2},\Gamma_C})\|\mathbf{u}-\mathbf{v}_h\|_{1,\Omega} - b(\mathbf{u}-\mathbf{u}_h, \boldsymbol{\lambda}-\boldsymbol{\lambda}_h). \tag{3.4}$$

In terms of the discrete inf-sup condition (see, e.g., [Woh01, Chapter 1.2.3]) and observing that $\|\boldsymbol{\mu}_h\|_{-\frac{1}{2},\Gamma_C} = \|\boldsymbol{\mu}_h \cdot \mathbf{n}\|_{-\frac{1}{2},\Gamma_C}$, $\boldsymbol{\mu}_h \in \mathbf{M}_h^n$, we find the upper bound

$$\begin{aligned} \|\boldsymbol{\mu}_h - \boldsymbol{\lambda}_h\|_{-\frac{1}{2},\Gamma_C} &\le C \sup_{\mathbf{w}_h\in\mathbf{v}_h} \frac{b(\mathbf{w}_h, \boldsymbol{\mu}_h-\boldsymbol{\lambda}_h)}{\|\mathbf{w}_h\|_{1,\Omega}} \\ &= C \sup_{\mathbf{w}_h\in\mathbf{v}_h} \frac{b(\mathbf{w}_h, \boldsymbol{\mu}_h-\boldsymbol{\lambda}) + a(\mathbf{u}_h-\mathbf{u}, \mathbf{w}_h)}{\|\mathbf{w}_h\|_{1,\Omega}} \\ &\le C(\|\boldsymbol{\mu}_h-\boldsymbol{\lambda}\|_{-\frac{1}{2},\Gamma_C} + \|\mathbf{u}_h-\mathbf{u}\|_{1,\Omega}). \end{aligned}$$

Setting $\boldsymbol{\mu} = \mathbf{0}$ in (2.6) and $\boldsymbol{\mu}_h = \mathbf{0}$ in (3.3), we find that $b(\mathbf{u}, \boldsymbol{\lambda}) \ge 0$ and $b(\mathbf{u}_h, \boldsymbol{\lambda}_h) \ge 0$. We note that $\mathbf{M}^+$ and $\mathbf{M}_h^+$ are convex cones. Using $\boldsymbol{\mu} = 2\boldsymbol{\lambda}$ and $\boldsymbol{\mu}_h = 2\boldsymbol{\lambda}_h$, we get $b(\mathbf{u}, \boldsymbol{\lambda}) \le 0$ and $b(\mathbf{u}_h, \boldsymbol{\lambda}_h) \le 0$, respectively. In terms of $b(\mathbf{u}, \boldsymbol{\lambda}) = b(\mathbf{u}_h, \boldsymbol{\lambda}_h) = 0$, the third term on the right side of (3.4) can be written as

$$-b(\mathbf{u}-\mathbf{u}_h, \boldsymbol{\lambda}-\boldsymbol{\lambda}_h) = b(\mathbf{u}, \boldsymbol{\lambda}_h) + b(\mathbf{u}_h, \boldsymbol{\lambda}) \le \max(b(\mathbf{u}, \boldsymbol{\lambda}_h),\, 0) + \max(b(\mathbf{u}_h, \boldsymbol{\lambda}),\, 0). \qquad \square$$

We remark that the term $\max(b(\mathbf{u}_h, \boldsymbol{\lambda}), 0)$ takes into account the discrete penetration of the two bodies on the actual contact set γ_a. The term $\max\big(b(\mathbf{u}, \boldsymbol{\lambda}_h), 0\big)$ can be greater than zero if the discrete Lagrange multiplier $\boldsymbol{\lambda}_h \cdot \mathbf{n}$ is negative on a part of γ_c. We recall that $\mathbf{M}_h^+$ is not a subspace of $\mathbf{M}^+$, and thus $\boldsymbol{\lambda}_h \cdot \mathbf{n}$, $\boldsymbol{\lambda}_h \in \mathbf{M}_h^+$, can be smaller than zero. The first two terms in the upper bound of Lemma 3.3 are the best approximation errors. They reflect the quality of the approximation of the spaces $\mathbf{v}_h$ and $\mathbf{M}_h^n$. The third and the fourth terms measure the nonconformity of the approach.

To prove optimal a priori error estimates under the H^s-regularity assumption for the displacements u with $\frac{3}{2} < s \leq 2$, we have to consider the two last terms for the bilinear form $b(\cdot,\cdot)$ in the upper bound of Lemma 3.3. In a first step, we briefly recall the definition of the mortar projection $\mathbf{\Pi}_h : [L^2(\Gamma_C)]^d \to \mathbf{w}_h$ and its dual operator $\mathbf{\Pi}_h^* : [L^2(\Gamma_C)]^d \to \mathbf{M}_h$:

$$\begin{aligned}\int_{\Gamma_C} (\mathbf{\Pi}_h \mathbf{w}) \cdot \boldsymbol{\mu}_h \, ds &:= \int_{\Gamma_C} \mathbf{w} \cdot \boldsymbol{\mu}_h \, ds, \qquad \boldsymbol{\mu}_h \in \mathbf{M}_h,\\ \int_{\Gamma_C} \mathbf{v}_h \cdot (\mathbf{\Pi}_h^* \boldsymbol{\mu}) \, ds &:= \int_{\Gamma_C} \mathbf{v}_h \cdot \boldsymbol{\mu} \, ds, \qquad \mathbf{v}_h \in \mathbf{w}_h.\end{aligned}$$

In terms of the stability of $\mathbf{\Pi}_h$ and $\mathbf{\Pi}_h^*$ (see the general mortar setting with dual Lagrange multipliers in [Woh01, Chapters 1.2.1 and 1.2.2]), both operators satisfy an approximation property

$$\|\mathbf{w} - \mathbf{\Pi}_h \mathbf{w}\|_{0,\Gamma_C} \leq C h^\tau |\mathbf{w}|_{\tau,\Gamma_C}, \qquad \|\boldsymbol{\mu} - \mathbf{\Pi}_h^* \boldsymbol{\mu}\|_{0,\Gamma_C} \leq C h^\nu |\boldsymbol{\mu}|_{\nu,\Gamma_C} \tag{3.5}$$

for $\mathbf{w} \in [H^\tau(\Gamma_C)]^d$, $0 \leq \tau \leq 2$, and $\boldsymbol{\mu} \in [H^\nu(\Gamma_C)]^d$, $0 \leq \nu \leq 1$.

The proof of the upper bound of $b(\mathbf{u}, \boldsymbol{\lambda}_h)$ is based on a regularity assumption for the actual contact zone.

Assumption 3.1. Regularity assumption on γ_a.

- In 2D, we assume that the number of points in $\overline{\mathring{\gamma}_a} \cap \overline{\gamma_c}$ is finite.
- In 3D, the regularity assumption will be specified in the proof of Lemma 3.5.

We now give two lemmas providing upper bounds for the consistency errors.

LEMMA 3.4. *Let* $(\mathbf{u}, \boldsymbol{\lambda}) \in \mathbf{v} \times \mathbf{M}^+$ *be the solution of* (2.6) *and let* $(\mathbf{u}_h, \boldsymbol{\lambda}_h) \in \mathbf{v}_h \times \mathbf{M}_h^+$ *be the solution of the discrete formulation* (3.3). *Under the regularity assumption* $\mathbf{u} \in \left[H^{\frac{3}{2}+\nu}(\Omega)\right]^d$, $0 < \nu \leq \frac{1}{2}$, *we then have the a priori error estimate*

$$b(\mathbf{u}_h, \boldsymbol{\lambda}) \leq C \left(h^{1+2\nu} |\mathbf{u}|^2_{\frac{3}{2}+\nu,\Omega} + h^{\frac{1}{2}+\nu} |\mathbf{u}|_{\frac{3}{2}+\nu,\Omega} \|\mathbf{u} - \mathbf{u}_h\|_{1,\Omega} \right)$$

for a positive constant $C < \infty$ *independent of* h.

Proof. For standard Lagrange multipliers, we refer the reader to [HL02]. Although our dual basis functions of $\mathbf{M}_h$ are not positive, we can apply the same techniques. Using the discrete saddle point formulation (3.3) and the definition of the mortar projection, we find that

$$b(\mathbf{u}_h, \boldsymbol{\mu}_h - \boldsymbol{\lambda}_h) = \int_{\Gamma_C} ((\boldsymbol{\mu}_h - \boldsymbol{\lambda}_h) \cdot \mathbf{n}) \, (\mathbf{\Pi}_h [\mathbf{u}_h] \cdot \mathbf{n}) \, ds \leq 0, \qquad \boldsymbol{\mu}_h \in \mathbf{M}_h^+.$$

The normal component of the mortar projection of $[\mathbf{u}_h]$ can be written as $\mathbf{\Pi}_h[\mathbf{u}_h] \cdot \mathbf{n} = \sum_{i=1}^{N_{\mathbf{M}_h}} \alpha_i^n \varphi_i$. Writing the normal components of $\boldsymbol{\mu}_h, \boldsymbol{\lambda}_h \in \mathbf{M}_h^+$ as linear combination of the dual basis functions yields $\boldsymbol{\mu}_h \cdot \mathbf{n} = \sum_{i=1}^{N_{\mathbf{M}_h}} \beta_i^n \psi_i$ and $\boldsymbol{\lambda}_h \cdot \mathbf{n} = \sum_{i=1}^{N_{\mathbf{M}_h}} \gamma_i^n \psi_i$, $\beta_i^n, \gamma_i^n \geq 0$. Setting $\beta_i^n := \gamma_i^n + \delta_{ij}$, we obtain

$$0 \geq b(\mathbf{u}_h, \boldsymbol{\mu}_h - \boldsymbol{\lambda}_h) = \int_{\Gamma_C} \psi_j \, (\mathbf{\Pi}_h [\mathbf{u}_h] \cdot \mathbf{n}) \, ds = \alpha_j^n \int_{\Gamma_C} \varphi_j \, ds.$$

We recall that $\varphi_j \geq 0$ and thus $\alpha_j^n \leq 0$, $1 \leq j \leq N_{\mathbf{M}_h}$. This results, in combination with $\boldsymbol{\lambda} \in \mathbf{M}^+$, in $\int_{\Gamma_C} (\boldsymbol{\lambda} \cdot \mathbf{n}) \, (\mathbf{\Pi}_h [\mathbf{u}_h] \cdot \mathbf{n}) \, ds \leq 0$. In contrast to the general mortar setting with crosspoints, $\mathbf{\Pi}_h$ restricted to the finite element trace space on the slave side is the identity. The approximation properties (3.5) yield the upper bound

$$\begin{aligned}
&b(\mathbf{u}_h, \boldsymbol{\lambda})\\
&= \int_{\Gamma_C} (\boldsymbol{\lambda} \cdot \mathbf{n})\big([\mathbf{u}_h \cdot \mathbf{n}] - \mathbf{\Pi}_h[\mathbf{u}_h] \cdot \mathbf{n} + \mathbf{\Pi}_h[\mathbf{u}_h] \cdot \mathbf{n}\big)\, ds\\
&\le \int_{\Gamma_C} \left(\boldsymbol{\lambda} - \mathbf{\Pi}_h^* \boldsymbol{\lambda}\right) \cdot \mathbf{n} \left([\mathbf{u}_h] - \mathbf{\Pi}_h[\mathbf{u}_h]\right) \cdot \mathbf{n}\, ds\\
&= \int_{\Gamma_C} \left(\boldsymbol{\lambda} - \mathbf{\Pi}_h^* \boldsymbol{\lambda}\right) \cdot \mathbf{n} \left(\mathbf{\Pi}_h \mathbf{u}_h^m - \mathbf{u}_h^m\right) \cdot \mathbf{n}\, ds\\
&\le \|\boldsymbol{\lambda} - \mathbf{\Pi}_h^* \boldsymbol{\lambda}\|_{0,\Gamma_C} \big(\|(\mathbf{u}_m - \mathbf{u}_h^m) - \mathbf{\Pi}_h(\mathbf{u}_m - \mathbf{u}_h^m)\|_{0,\Gamma_C} + \|\mathbf{u}_m - \mathbf{\Pi}_h \mathbf{u}_m\|_{0,\Gamma_C}\big)\\
&\le h^\nu |\boldsymbol{\lambda}|_{\nu,\Gamma_C} \big(h^{\frac{1}{2}} |\mathbf{u}_m - \mathbf{u}_h^m|_{\frac{1}{2},\Gamma_C} + h^{1+\nu} |\mathbf{u}_m|_{1+\nu,\Gamma_C}\big)\\
&\le C\big(h^{\frac{1}{2}+\nu} |\mathbf{u}|_{\frac{3}{2}+\nu,\Omega} \|\mathbf{u} - \mathbf{u}_h\|_{1,\Omega} + h^{1+2\nu} |\mathbf{u}|^2_{\frac{3}{2}+\nu,\Omega}\big). \qquad \square
\end{aligned}$$

A similar bound for the term $b(\mathbf{u}, \boldsymbol{\lambda}_h)$ can be established.

LEMMA 3.5. *Let* $(\mathbf{u}, \boldsymbol{\lambda}) \in \mathbf{v} \times \mathbf{M}^+$ *be the solution of* (2.6) *and let* $(\mathbf{u}_h, \boldsymbol{\lambda}_h) \in \mathbf{v}_h \times \mathbf{M}_h^+$ *be the solution of the discrete formulation* (3.3)*. Under Assumption* 3.1 *and the regularity assumption* $\mathbf{u} \in \left[H^{\frac{3}{2}+\nu}(\Omega)\right]^d$, $0 < \nu \le \frac{1}{2}$, *we then have the a priori error estimate*

$$b(\mathbf{u}, \boldsymbol{\lambda}_h) \le C h^{\frac{1}{2}+\nu} |\mathbf{u}|_{\frac{3}{2}+\nu,\Omega} \|\boldsymbol{\lambda} - \boldsymbol{\lambda}_h\|_{-\frac{1}{2},\Gamma_C}$$

for a positive constant $C < \infty$ *independent of* $h < h_0$*.*

Proof. The regularity assumptions guarantee that $[\mathbf{u} \cdot \mathbf{n}]$ restricted to Γ_C is continuous. In a first step, we consider the two-dimensional case. We denote by I_h the Lagrange interpolation operator with respect to the mesh on the slave side. Based on I_h, we consider a modified interpolation operator $\tilde{I}_h$. Let $\mathcal{P}_C := \{p_i \,:\, 1 \le i \le N_{\mathbf{M}_h}\}$ be the set of vertices on the slave side of $\overline{\Gamma_C}$ and $\mathcal{W}_C := \{w_j \,:\, 1 \le j \le N_w\}$ be the set of points in $\overline{\mathring{\gamma}_a} \cap \overline{\gamma_c}$. The minimum distance between the elements in $\mathcal{W}_C$ is denoted by a, i.e., $a = \inf\{|w_j - w_k| \,:\, 1 \le j \ne k \le N_w\}$, where $|\cdot|$ denotes the Euclidean norm. By Assumption 3.1, $N_w < \infty$ and thus $a > 0$. For $h < \frac{a}{2} =: h_0$, we find between two neighbor points in $\mathcal{W}_C$ at least two vertices in $\mathcal{P}_C$.

We now define the modified Lagrange interpolation operator $\tilde{I}_h$ as

$$(\tilde{I}_h\, [\mathbf{u} \cdot \mathbf{n}])(p_i) := \begin{cases} [\mathbf{u} \cdot \mathbf{n}](p_i) & \text{if supp } \varphi_i \subset \overline{\gamma_c}, \\ \mathbf{0} & \text{else}, \end{cases} \tag{3.6}$$

where φ_i is the standard nodal basis function associated with the vertex $p_i \in \mathcal{P}_C$; see Figure 3.1. Using $b(\mathbf{u}, \boldsymbol{\lambda}) = 0$, we find

$$b\,(\mathbf{u}, \boldsymbol{\lambda}_h) = \int_{\Gamma_C} ([\mathbf{u} \cdot \mathbf{n}] - \tilde{I}_h[\mathbf{u} \cdot \mathbf{n}])\big((\boldsymbol{\lambda}_h - \boldsymbol{\lambda}) \cdot \mathbf{n}\big)\, ds + \int_{\Gamma_C} \tilde{I}_h[\mathbf{u} \cdot \mathbf{n}]\big((\boldsymbol{\lambda}_h - \boldsymbol{\lambda}) \cdot \mathbf{n}\big)\, ds. \tag{3.7}$$

By construction $\tilde{I}_h[\mathbf{u} \cdot \mathbf{n}] \le 0$ and supp $\tilde{I}_h[\mathbf{u} \cdot \mathbf{n}] \subset$ supp $[\mathbf{u} \cdot \mathbf{n}] = \overline{\gamma_c}$, we then find in terms of (2.2) and (3.1) that

$$\int_{\Gamma_C} \tilde{I}_h[\mathbf{u} \cdot \mathbf{n}]\, (\boldsymbol{\lambda}_h \cdot \mathbf{n})\, ds \le 0, \qquad \int_{\Gamma_C} \tilde{I}_h[\mathbf{u} \cdot \mathbf{n}]\, (\boldsymbol{\lambda} \cdot \mathbf{n})\, ds = 0. \tag{3.8}$$

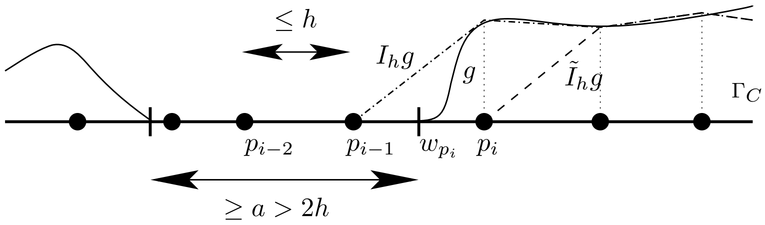

FIG. 3.1. *Functions g, $I_h g$, and $\tilde{I}_h g$.*

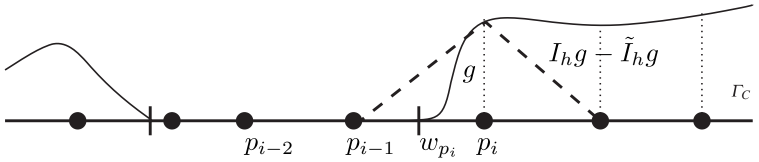

FIG. 3.2. *Difference of the interpolated functions $I_h g - \tilde{I}_h g$.*

Now we get from (3.7) the estimate

$$b\left(\mathbf{u}, \boldsymbol{\lambda}_h\right) \leq \|[\mathbf{u}\cdot\mathbf{n}] - \tilde{I}_h[\mathbf{u}\cdot\mathbf{n}]\|_{\frac{1}{2},\Gamma_C} \|\boldsymbol{\lambda}_h - \boldsymbol{\lambda}\|_{-\frac{1}{2},\Gamma_C}. \tag{3.9}$$

To estimate the term $\|[\mathbf{u}\cdot\mathbf{n}] - \tilde{I}_h[\mathbf{u}\cdot\mathbf{n}]\|_{\frac{1}{2},\Gamma_C}$, we define $g := -[\mathbf{u}\cdot\mathbf{n}]$ and consider the difference $I_h g - \tilde{I}_h g$ of the interpolated functions; see Figures 3.1 and 3.2.

In terms of the inverse inequality (see, e.g., [Bra97, Chapter 6]), we get

$$\|I_h g - \tilde{I}_h g\|^2_{\frac{1}{2},\Gamma_C} \leq \frac{C}{h}\|I_h g - \tilde{I}_h g\|^2_{0,\Gamma_C} \leq C \sum_{p_i \in \mathcal{M}_C} \left(g(p_i)\right)^2, \tag{3.10}$$

where the set of points $\mathcal{M}_C$ on the contact boundary Γ_C is defined by $\mathcal{M}_C := \{p_i \in \mathcal{P}_C \,:\, \tilde{I}_h g(p_i) \neq I_h g(p_i)\}$. Let $w_{p_i} \in \mathcal{W}_C$ be the unique closest point to $p_i \in \mathcal{M}_C$. Without loss of generality, we consider a lexicographically ordering of the indices and the case that $g = 0$ in the left neighborhood of w_{p_i} and $g > 0$ in the right neighborhood of w_{p_i}.

For $h < \frac{a}{2}$, we have $I_h g - \tilde{I}_h g = 0$ on $[p_{i-2}, p_{i-1}]$; see Figure 3.2. The regularity assumption on $\mathbf{u}$ yields $g \in H^{1+\nu}(\Gamma_C)$ and moreover $g = 0$ on $[p_{i-2}, w_{p_i}]$. Now the Cauchy–Schwarz inequality gives for each point $p_i \in \mathcal{M}_C$ the estimate

$$\begin{aligned}
\left(g(p_i)\right)^2 &= \left(\int_{w_{p_i}}^{p_i} g'(s)\,ds\right)^2 \\
&= \frac{1}{|w_{p_i} - p_{i-2}|^2}\left(\int_{w_{p_i}}^{p_i}\int_{p_{i-2}}^{w_{p_i}} \frac{g'(s) - g'(t)}{|s-t|^{\frac{1+2\nu}{2}}} |s-t|^{\frac{1+2\nu}{2}}\,dt\,ds\right)^2 \\
&\leq \frac{1}{|w_{p_i} - p_{i-2}|^2} \int_{p_{i-2}}^{p_i}\int_{p_{i-2}}^{p_i} \frac{\left(g'(s) - g'(t)\right)^2}{|s-t|^{1+2\nu}}\,dt\,ds \int_{w_{p_i}}^{p_i}\int_{p_{i-2}}^{w_{p_i}} |s-t|^{1+2\nu}\,dt\,ds \\
&\leq C\frac{1}{|w_{p_i} - p_{i-2}|^2} |g'|^2_{\nu,[p_{i-2},\,p_i]}\, h^{1+2\nu}\, |p_i - w_{p_i}|\, |w_{p_i} - p_{i-2}| \\
&= C|g'|^2_{\nu,[p_{i-2},\,p_i]}\, h^{1+2\nu}\, \frac{|p_i - w_{p_i}|}{|w_{p_i} - p_{i-2}|} \leq C|g'|^2_{\nu,[p_{i-2},\,p_i]}\, h^{1+2\nu},
\end{aligned}$$

where we used the shape regularity of the triangulation. To obtain an upper bound for $\|I_h g - \tilde{I}_h g\|_{\frac{1}{2},\Gamma_C}$, we have to sum over all $p_i \in \mathcal{M}_C$. We observe that by Assumption 3.1, the number of elements in $\mathcal{M}_C$ is finite. In terms of (3.9) and (3.10), we find now the bound

$$\begin{aligned} b(\mathbf{u}, \boldsymbol{\lambda}_h) &\leq \|\boldsymbol{\lambda} - \boldsymbol{\lambda}_h\|_{-\frac{1}{2},\Gamma_C} (\|g - I_h g\|_{\frac{1}{2},\Gamma_C} + \|I_h g - \tilde{I}_h g\|_{\frac{1}{2},\Gamma_C}) \\ &\leq C h^{\frac{1}{2}+\nu} |g|_{1+\nu,\Gamma_C} \|\boldsymbol{\lambda} - \boldsymbol{\lambda}_h\|_{-\frac{1}{2},\Gamma_C} \leq C h^{\frac{1}{2}+\nu} |\mathbf{u}|_{\frac{3}{2}+\nu,\Omega} \|\boldsymbol{\lambda} - \boldsymbol{\lambda}_h\|_{-\frac{1}{2},\Gamma_C}. \end{aligned}$$

If not stated otherwise, we use the same definitions and symbols in the three-dimensional setting as for the two-dimensional situation. The regularity assumption on $\mathbf{u}$ guarantees that g is continuous. In the three-dimensional case, we replace the Lagrange interpolation operator by a quasi-interpolation operator which is defined locally by its values at the nodes $p \in \mathcal{P}_C$

$$I_h g(p) := \frac{1}{2c_o h} \int_{S_p} g(s)\ ds,$$

where S_p is a one-dimensional interval of length $2c_0 h$, direction z, and p is the midpoint of S_p. The direction z is arbitrary but has to be fixed for each node $p \in \mathcal{P}_C$. The constant $c_0 > 0$ depends on the shape regularity of the mesh, but not on h. It is taken such that $B_p(c_0 h) \subset \operatorname{supp}(\varphi_p)$, where $B_p(c_0 h)$ is the circle with radius $c_0 h$ and center p. We note that I_h restricted to $\mathbf{n} \cdot \mathbf{w}_h$ is not the identity, but it reproduces a linear function. This operator is similar to the ones of Clément and Scott–Zhang, and thus it is easy to verify the estimate

$$\|g - I_h g\|_{\frac{1}{2},\Gamma_C} \leq C h^{\frac{1}{2}+\nu} |g|_{1+\nu,\Gamma_C}.$$

We also define analogously to (3.6) the modified operator $\tilde{I}_h$

$$(\tilde{I}_h g)(p_i) := \begin{cases} I_h g(p_i) & \text{if } \operatorname{supp} \varphi_i \subset \overline{\gamma_c}, \\ 0 & \text{else.} \end{cases}$$

We note that we cannot use the standard Scott–Zhang operator because it does not necessarily preserves the sign. The same reasoning as in the two-dimensional case yields (3.8) and thus (3.9). Furthermore in the three-dimensional case, the estimate (3.10) has the form

$$\|I_h g - \tilde{I}_h g\|^2_{\frac{1}{2},\Gamma_C} \leq \frac{C}{h} \|I_h g - \tilde{I}_h g\|^2_{0,\Gamma_C} \leq C h \sum_{p_i \in \mathcal{M}_C} (I_h g(p_i))^2\,, \tag{3.11}$$

and we have to estimate the terms $I_h g(p_i)$ for all $p_i \in \mathcal{M}_C$. The vertices $p_i \in \mathcal{M}_C$ are marked with empty circles and γ_c is the shaded domain, in the left picture of Figure 3.3.

We assume that for h small enough, there exists for each $p \in \mathcal{M}_C$ a shape regular quadrilateral R_p, such that S_p is one edge, and $R_p \cap \gamma_a$ contains a shape regular quadrilateral including the opposite edge of S_p, where all regularity constants depend only on the regularity of the triangulation and of $\overline{\gamma_c}$ but neither on the node p nor on h. This quadrilateral R_p can now be mapped by F_p to the reference square $\hat{R} := [0,h]^2$ of length h such that $\hat{g}(\hat{s}) := g(F_p^{-1}(\hat{s}))$, restricted to the lower half $\hat{R}_2 := [0,h] \times [0, 1/2h]$ of the square, is zero, and such that the Jacobian of F_p and its

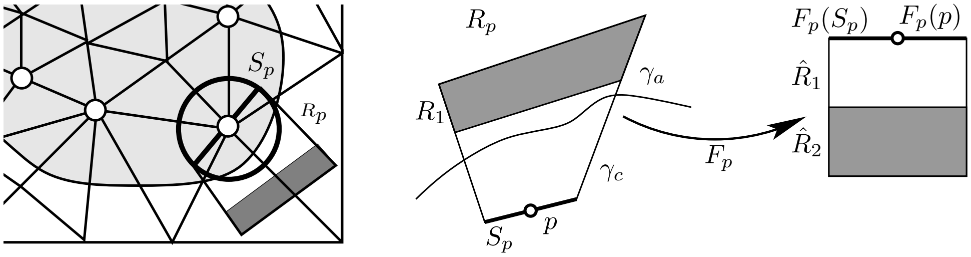

FIG. 3.3. *Vertices in $\mathcal{M}_C$ (left) and edge S_p; quadrilateral R_p and reference square $\hat{R}$ (right).*

inverse are bounded independently of h. We further assume that F_p restricted to S_p is affine and $F_p(S_p) = [0,h] \times \{1\}$. The upper half of the square is denoted by $\hat{R}_1$; see the right picture of Figure 3.3. Now we can proceed as in the two-dimensional case and find an upper bound for $I_h g(p)$

$$\begin{aligned}(I_h g(p))^2 &= \frac{1}{h^2}\left(\int_0^h \hat{g}(s_1,h)ds_1\right)^2 = \frac{1}{h^2}\left(\int_{\hat{R}_1} \hat{g}_{s_2}(s)ds\right)^2 \\ &= \frac{4}{h^6}\left(\int_{\hat{R}_2}\left(\int_{\hat{R}_1} \frac{\hat{g}_{s_2}(s)-\hat{g}_{s_2}(\tilde{s})}{|s-\tilde{s}|^{1+\nu}}|s-\tilde{s}|^{1+\nu}ds\right)d\tilde{s}\right)^2 \\ &\le \frac{4}{h^6}\int_{\hat{R}_2}\int_{\hat{R}_1}\frac{\left(\hat{g}_{s_2}(s)-\hat{g}_{s_2}(\tilde{s})\right)^2}{|s-\tilde{s}|^{2+2\nu}}dsd\tilde{s}\int_{\hat{R}_2}\int_{\hat{R}_1}|s-\tilde{s}|^{2+2\nu}ds\,d\tilde{s} \\ &\le \frac{C}{h^6}h^{2+2\nu}h^4\int_{\hat{R}}\int_{\hat{R}}\frac{\left(\hat{g}_{s_2}(s)-\hat{g}_{s_2}(\tilde{s})\right)^2}{|s-\tilde{s}|^{2+2\nu}}ds\,d\tilde{s} \\ &\le Ch^{2\nu}|\hat{g}_{s_2}|^2_{\nu,\hat{R}} \le Ch^{2\nu}|g|^2_{1+\nu,R_p}.\end{aligned}$$

In the last step, we have used the properties of the Jacobian of F_p. Summing over all $p \in \mathcal{M}_C$ and using a coloring argument, (3.11) yields finally as in the two-dimensional case the upper bound

$$\|I_h g - \tilde{I}_h g\|_{\frac{1}{2},\Gamma_C} \le Ch^{\frac{1}{2}+\nu}|g|_{1+\nu,\Gamma_C},$$

where the constant does not depend on the meshsize. □

Now we combine the previous results and formulate the optimal a priori error estimate for multibody contact problems.

THEOREM 3.6. *Let $(\mathbf{u},\boldsymbol{\lambda}) \in \mathbf{v} \times \mathbf{M}^+$ be the solution of* (2.6) *and let $(\mathbf{u}_h,\boldsymbol{\lambda}_h) \in \mathbf{v}_h \times \mathbf{M}_h^+$ be the solution of the discrete formulation* (3.3)*. Under Assumption* 3.1 *and the regularity assumption $\mathbf{u} \in \left[H^{\frac{3}{2}+\nu}(\Omega)\right]^d$, $0 < \nu \le \frac{1}{2}$, we then have the a priori error estimate*

$$\|\mathbf{u}-\mathbf{u}_h\|_{1,\Omega} + \|\boldsymbol{\lambda}-\boldsymbol{\lambda}_h\|_{-\frac{1}{2},\Gamma_C} \le Ch^{\frac{1}{2}+\nu}|\mathbf{u}|_{\frac{3}{2}+\nu,\Omega}$$

for a positive constant C.

Proof. Using the well-known approximation property for the spaces $\mathbf{v}_h$ and $\mathbf{M}_h$, the proof is a direct consequence of Lemmas 3.3, 3.4, and 3.5 and the application of Young's inequality. □

Remark 3.7. It is possible to establish an optimal a priori estimate for the Lagrange multiplier in a weighted L^2-norm, i.e., $\sqrt{h}\|\boldsymbol{\lambda}-\boldsymbol{\lambda}_h\|_{0,\Gamma_C}$. The proof follows the same lines as for the $H^{-1/2}$-norm and uses an inverse estimate.

Remark 3.8. Replacing $\mathbf{v}_h$ by quadratic finite elements, we obtain a higher-order a priori estimate. Quadratic finite elements and linear Lagrange multipliers yield an order $h^{\frac{1}{2}+\nu}$, $0 < \nu < 1$, upper bound for the discretization error if the solution is $H^{\frac{3}{2}+\nu}$-regular. Replacing the linear Lagrange multiplier space by quadratic Lagrange multipliers does not give a higher order; see, e.g., [HL02]. For a proof and numerical results comparing quadratic finite elements with linear Lagrange multipliers and with quadratic Lagrange multipliers, we refer the reader to [HMW04]; see also Table 4.4.

Remark 3.9. The same theoretical results can be obtained if a different dual Lagrange multiplier space is used, e.g., piecewise constant dual Lagrange multipliers or continuous piecewise cubic dual Lagrange multipliers as proposed in [Woh02]

4. Numerical results. In this section, we consider different examples for multibody contact problems. We focus on the discretization errors of the displacement in the L^2- and the H^1-norm and of the Lagrange multiplier in a weighted L^2-norm on the contact boundary. In general, multibody contact problems do not admit an analytical solution. To evaluate the discretization errors, we compute a reference solution denoted by $\mathbf{u}_{\text{ref}}$ for the displacements and a reference solution $\boldsymbol{\lambda}_{\text{ref}}$ for the Lagrange multiplier corresponding to a finer mesh. We note that in all our examples, the meshsize h_{ref} for the reference solution satisfies $h_{\text{ref}} \leq 1/4h$. A reference meshsize of $h_{\text{ref}} = 1/2h$ does not guarantee reliable numbers for the discretization errors. For the iterative solution of the nonlinear system, we use an inexact primal dual active set strategy; see [HW03]. In each outer iteration step, we apply one linear multigrid cycle. Alternatively, nonlinear Dirichlet–Neumann solvers [KW02, BSS02, EW03], monotone multigrid methods [KK01, Kra01, WK03], or finite element tearing and interconnecting (FETI) approaches [DFS98, DGS00, DH03] can be applied. The implementation is based on the finite element toolbox UG; see [BBJ$^+$97]. We start with a coarse triangulation and use uniform refinement techniques. Each element is decomposed into four subelements within the next refinement step.

Example 1. In our first example, we consider the problem depicted in Figure 4.1. The two bodies in their reference configuration are scaled squares, $\Omega_m := (0, 0.01) \times (0, 0.01)$ and $\Omega_s := (0.0, 0.01) \times (0.01, 0.02)$. On Ω_m, we set $E = 15 \times 10^9$ and $\nu = 0.2$ and on Ω_s, we use a different material with $E = 20 \times 10^9$ and $\nu = 0.4$. The lower boundary of Ω_m is clamped. The applied load $\mathbf{p}$ is given by $(10^5, -10^6)^\top$ on the left side and by $(-10^5, -10^6)^\top$ on the right side of Ω_m. Homogeneous Neumann boundary conditions are applied to both sides of Ω_s, and inhomogeneous Dirichlet data are given on the top of Ω_s. The displacements are set to be $(0.0, -5 \times 10^{-7})^\top$.

The initial triangulation on level 0 is shown in the left picture of Figure 4.1. We recall that the Lagrange multiplier $-\boldsymbol{\lambda}_h \cdot n$ of the mortar discretization approximates the contact pressure. In the right picture of Figure 4.1, we give the normal and tangential component of $\boldsymbol{\lambda}_h$ on level 6. The normal component is nonzero only in the part of Γ_C where the two bodies are actually in contact. As expected, the tangential component is equal to zero because no friction is taken into account. The distorted domains and stress components $\boldsymbol{\sigma}_{11}$ and $\boldsymbol{\sigma}_{22}$ are shown in the middle picture of Figure 4.1.

We use the finite element solution on level 8 as reference solution $(\mathbf{u}_{\text{ref}}, \boldsymbol{\lambda}_{\text{ref}})$. On level 8, we have 262,144 elements on Ω_s and 589,824 elements on Ω_m. In Table 4.1, we give the discretization errors of the displacements in the relative $L^2(\Omega)$-norm and in the relative $H^1(\Omega)$-norm. The error in the Lagrange multiplier is measured in a weighted $L^2(\Gamma_C)$-norm. The convergence rates in the L^2-norm for the displacements are approximately 1.8. Asymptotically, the convergence rates tend to 1 in the

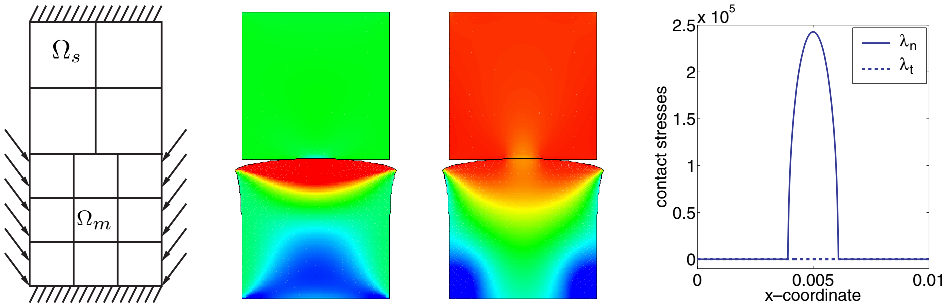

FIG. 4.1. *Example* 1: *Problem definition and initial triangulation (left), stress components $\boldsymbol{\sigma}_{11}$ and $\boldsymbol{\sigma}_{22}$ on distorted domains (distortion scaled by factor* 1000*) (middle), and contact stresses in normal and tangential direction (right).*

Level	$\Vert\mathbf{u}_h - \mathbf{u}_{\mathrm{ref}}\Vert_{0,\Omega}/\Vert\mathbf{u}_{\mathrm{ref}}\Vert_{0,\Omega}$		$\vert\mathbf{u}_h - \mathbf{u}_{\mathrm{ref}}\vert_{1,\Omega}/\vert\mathbf{u}_{\mathrm{ref}}\vert_{1,\Omega}$		$\Vert\boldsymbol{\lambda}_h - \boldsymbol{\lambda}_{\mathrm{ref}}\Vert_{-\frac{1}{2},h,\Gamma_C}$	
0	$6.447659e-02$	–	$4.447386e-01$	–	$9.507368e+02$	–
1	$1.947047e-02$	1.73	$2.422984e-01$	0.87	$3.709632e+02$	1.36
2	$5.719462e-03$	1.77	$1.323250e-01$	0.87	$1.937997e+02$	0.94
3	$1.798368e-03$	1.67	$7.137496e-02$	0.89	$8.890783e+01$	1.12
4	$5.181605e-04$	1.80	$3.815553e-02$	0.90	$3.743692e+01$	1.25
5	$1.551852e-04$	1.74	$2.012575e-02$	0.92	$1.503053e+01$	1.32
6	$4.544415e-05$	1.77	$1.027931e-02$	0.97	$5.607133e+00$	1.42

$H^1(\Omega)$-norm. As in the linear case, we observe better convergence rates for the Lagrange multiplier. The best approximation error of the Lagrange multiplier in the weighted $L^2(\Gamma_C)$-norm is of order $h^{1.5}$.

Example 2. In our second example, we use the same geometry and the same material parameters as in Example 1; see [HL02]. The upper part of Ω_s and the lower part of Ω_m are clamped. Inhomogeneous Neumann data are applied to the left part of Ω_s and to the right part of Ω_m. The scaled boundary forces are given by $\mathbf{p} = (10^5, -10^6)^\top$ and $\mathbf{p} = (-10^5, -10^6)^\top$; see Figure 4.2.

In the middle picture of Figure 4.2, the stress component $\boldsymbol{\sigma}_{11}$ is shown on the distorted domains. The normal component of the Lagrange multiplier is given in the right picture. In contrast to Example 1, we observe a singularity at the left endpoint of the contact zone. Here, we use bilinear finite elements and a conforming triangulation on the possible contact boundary Γ_C. The finite element solution on level 8 is taken as reference solution. Due to the lower regularity of the solution, we cannot expect a convergence rate of order h. The discretization errors for the relative $L^2(\Omega)$- and $H^1(\Omega)$-norm of the displacement are given in columns three and four of Table 4.2, respectively. The error of the Lagrange multiplier in the weighted $L^2(\Gamma_C)$-norm can be found in the last column. Asymptotically, the convergence rates tend to 0.9 in the $H^1(\Omega)$-norm. As in Example 1, we observe a higher convergence rate for the Lagrange multiplier. The convergence rate for the L^2-norm is approximately 1.5. The low regularity of the problem is reflected in smaller numerical convergence rates.

Example 3. Our third example is the Hertzian contact problem of a linear elastic circle with a plane. In this example, the contact stresses can be computed analytically; see [Her82, KO88]. So we are able to compare the numerically computed boundary stresses to the analytical ones. If an elastic circle with radius r and material parameters E and ν is pressed by a single point load $f = (0, -f)^\top$ on the top to a rigid plane, the analytical contact pressure is given by (see, e.g., [KO88, Chapter 6.6])

$$p(x) = \frac{2f}{\pi b^2}\sqrt{\left(b^2 - x^2\right)}, \qquad x \le b, \qquad b := 2\sqrt{\frac{fr(1-\nu^2)}{E\pi}}, \tag{4.1}$$

where b is the half-width of the contact surface and x is the distance to the center of the contact surface. In our setting, we replace the rigid plane by a linear elastic rectangle. Young's modulus of the rectangle is set to be larger than the one of the circle. We apply homogeneous Dirichlet boundary conditions at the bottom and at the two sides of the rectangle. On the circle with radius $r = 1$, we set the material parameters to be $E = 7000$ and $\nu = 0.3$. For the rectangle with height $w = 1$, we use $E = 10^6$ and $\nu = 0.45$. The circle, assumed to be the slave side, is pressed by a point load $f = (0, -100)^\top$ at the top of the rectangle. The problem definition and the geometry are shown in Figure 4.3. As done in [CSW99, KW02], we replace the point load by a surface load to avoid a strong singularity on the upper part of the circle.

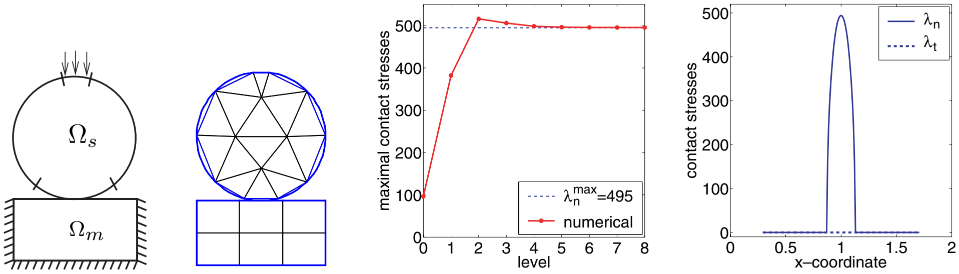

FIG. 4.3. *Example* 3: *Problem definition and initial triangulation (left), maximal contact stresses (middle), and contact stresses (right).*

TABLE 4.3
Example 3: *Relative* $L^2(\Omega)$*-error and relative* $H^1(\Omega)$*-error of* $\mathbf{u}_h$ *with respect to* $\mathbf{u}_{ref}$*, weighted* $L^2(\Gamma_C)$*-error of* $\boldsymbol{\lambda}_h$ *with respect to* $\boldsymbol{\lambda}_{ref}$*, and the numerical convergence orders.*

Level	$\Vert\mathbf{u}_h - \mathbf{u}_{\mathrm{ref}}\Vert_{0,\Omega}/\Vert\mathbf{u}_{\mathrm{ref}}\Vert_{0,\Omega}$		$\vert\mathbf{u}_h - \mathbf{u}_{\mathrm{ref}}\vert_{1,\Omega}/\vert\mathbf{u}_{\mathrm{ref}}\vert_{1,\Omega}$		$\Vert\boldsymbol{\lambda}_h - \boldsymbol{\lambda}_{\mathrm{ref}}\Vert_{-\frac{1}{2},h,\Gamma_C}$	
1	$5.227370e-02$	–	$4.663629e-01$	–	$5.845408+01$	–
2	$1.381026e-02$	1.92	$3.214708e-01$	0.54	$4.998951+01$	0.23
3	$4.844067e-03$	1.51	$1.807113e-01$	0.83	$2.120954+01$	1.24
4	$1.350194e-03$	1.84	$9.735769e-02$	0.89	$8.377665+00$	1.34
5	$4.175901e-04$	1.69	$5.111927e-02$	0.93	$3.269378+00$	1.36
6	$1.102450e-04$	1.92	$2.584385e-02$	0.98	$1.168388+00$	1.48

In order to obtain a unique discrete solution, we eliminate the horizontal degrees of freedom of the two inner nodes on the vertical symmetry axis; see Figure 4.3.

Using (4.1), the maximal normal contact stresses of the Hertzian contact problem is then given by $\boldsymbol{\lambda}_n^{\max} = 494.8$, and for the half-width of the contact zone we find $b = 0.129$. The pictures on the right of Figure 4.3 illustrate the numerical approximation of the contact stress. From level 4 on, the discrete maximal normal stress is a very good approximation of the analytical one. In the right picture, the normal and tangential contribution of the Lagrange multiplier are given.

To compute the discretization errors, we use the mortar finite element solution on level 8 as reference solution. The errors are given in Table 4.3. Asymptotically, we observe optimal convergence rates. In the L^2-norm, the convergence rate tends to 2 with increasing number of refinement steps, whereas the convergence rate in the $H^1(\Omega)$-norm tends to 1. We observe asymptotically a convergence rate of 1.5 for the Lagrange multiplier in the weighted L^2-norm on the contact zone. This results from the fact that the error in the energy norm restricted to a strip of width h can be bounded by $C\sqrt{h}\Vert\mathbf{u}\Vert_{1,\Omega}$.

In a last test, we consider the influence of the choice of the dual Lagrange multiplier on the displacement and the maximal contact stress. To do so, we compare three different dual Lagrange multipliers. In addition to the linear Lagrange multiplier, we use discontinuous piecewise constant and continuous piecewise cubic Lagrange multipliers; see [Woh02]. Table 4.4 shows in the first two columns the relative H^1-error for the dual constant and the dual cubic Lagrange multipliers. If we compare the results of Table 4.4 with those of Table 4.3, we find that all three of our dual Lagrange multipliers yield almost the same results. The differences in the H^1-norm of the error is negligible. This is also true for the maximal contact stress. The last three columns of

TABLE 4.4

Table 4.4 show $(\boldsymbol{\lambda}_h \cdot n)_{\max}$ for the three different discretizations.

Example 4. Finally, we consider an example with more than two subdomains. We use three circles and a rigid obstacle (see Figure 4.4) and two different sets of boundary data. The possible contact zone can be decomposed into two different types: the contact between two elastic circles and the contact between one elastic circle and the rigid obstacle. For this example, one circle has to have a master and a slave interface. The contact between the rigid obstacle and the elastic body is also discretized in terms of dual Lagrange multipliers defined on the elastic body which is the slave side. The two pictures in the left of Figure 4.4 show the stress components $\boldsymbol{\sigma}_{11}$ and $\boldsymbol{\sigma}_{12}$ of a symmetric boundary data. In the two pictures on the right, the rigid obstacle forms an L-shape, and the solution is nonsymmetric.

PRESSURE CORRECTION ALGEBRAIC SPLITTING METHODS FOR THE INCOMPRESSIBLE NAVIER–STOKES EQUATIONS*

F. SALERI† AND A. VENEZIANI†

Abstract. In this paper we present a new family of methods for the effective numerical solution of the incompressible unsteady Navier–Stokes equations. These methods resort to an algebraic splitting of the discretized problem based on inexact LU block factorizations of the corresponding matrix (following [A. Quarteroni, F. Saleri, and A. Veneziani, *Comput. Methods Appl. Mech. Engrg.*, 188 (2000), pp. 505–526]. In particular, we will start from inexact algebraic factorizations of *algebraic Chorin–Temam* and *Yosida* type and introduce a *pressure correction step* aimed at improving the time accuracy. One of the schemes obtained in this way (the algebraic Chorin–Temam pressure correction method) resembles a method previously introduced in the framework of differential projection schemes (see [L. Timmermans, P. Minev, and F. V. de Vosse, *Internat. J. Numer. Methods Fluids*, 22 (1996), pp. 673–688], [A. Prohl, *Projection and Quasi-Compressibility Methods for Solving the Incompressible Navier–Stokes Equations*, Teubner, Stuttgart, 1997]. The stability and the dependence of splitting error on the time step of the new methods is investigated and tested on several numerical cases.

Key words. incompressible Navier–Stokes equations, fractional steps schemes

1. Introduction.

The numerical computation of the unsteady Navier–Stokes equations for incompressible flows in real applications requires the solution of linear systems of large dimensions. These systems are typically not definite nor well conditioned, and therefore the setup of efficient methods is mandatory. Perhaps one of the most successful approaches is provided by the class of the projection methods at the differential (see, e.g., [3] and, more recently, [14]) and the algebraic level (see [20] and [22], [23]). These methods typically compute the velocity and pressure fields separately, (i) by computing an *auxiliary* (or *intermediate*) velocity; (ii) by solving a suitable problem for the pressure; (iii) by correcting the velocity (*end-of-step velocity*), to enforce the incompressibility constraint. In [23] we have introduced a general class of algebraic splitting methods that can be regarded in this framework. We recall, in particular, the *algebraic Chorin–Temam* scheme (see [20]) and the *Yosida* scheme (see [22]). These methods are based on a splitting that reduces the computational effort, without affecting the time accuracy of the solution driven by the time discretization. This is true for first order time discretizations, while for higher order accuracy the setup of suitable splittings is still an open problem (see, e.g., in the framework of differential schemes, [10]).

In the present paper, we aim at investigating splitting methods that arise whenever, in addition to the velocity, the pressure is obtained after a suitable *correction*

step. This step is set up in order to reduce the error associated with the splitting and obtain definitively a higher order of accuracy in time.

After a brief introduction to algebraic splitting methods (section 2), we will provide a general approach for setting up such *pressure correction* schemes (section 3). Then we will analyze, in particular, the schemes arising from the pressure correction of both the algebraic Chorin–Temam and the Yosida methods. The former is investigated in section 4. We analyze the splitting error reduction induced by the pressure correction step and prove that in the Stokes (linear) case the scheme features unconditional stability when starting from a backward difference (implicit) time discretization. Then (section 4.2) we establish some formal analogies between our scheme and other pressure correction schemes proposed at a differential level (see [26]).

The pressure correction formulation of the Yosida method is investigated in section 5. In particular, it is possible to prove that the consistency error induced by the splitting on the matrix to be solved at each time step depends on the cube of the time step, which is an improvement of the original Yosida scheme introduced by the pressure correction. On the other hand, we prove that the stability of this scheme is in general conditional, even if applied to the Stokes problem discretized with a backward difference (implicit) scheme.

In section 6 we provide several numerical results, testing the properties of pressure correction schemes. We analyze, in particular, the improvements induced by the pressure correction when applied to high order time discretization schemes. Some conclusions are drawn in section 7.

2. Inexact algebraic factorizations for the Navier–Stokes equations. Consider an open and bounded domain $\Omega \subset \mathbb{R}^d$ for $d = 2, 3$ with boundary $\partial\Omega$ for a time $t \geq 0$. The Navier–Stokes equations for incompressible flows in terms of the velocity, $\mathbf{u} = \mathbf{u}(\mathbf{x}, t)$, and the pressure, $p = p(\mathbf{x}, t)$, read as

$$\left\{ \begin{array}{l} \dfrac{\partial \mathbf{u}}{\partial t} + (\mathbf{u} \cdot \nabla)\mathbf{u} - \nu \triangle \mathbf{u} + \nabla p = \mathbf{f}, \\ \nabla \cdot \mathbf{u} = 0 \end{array} \right. \tag{2.1}$$

for any $(\mathbf{x}, t) \in \Omega \times (0, T]$, with $T > 0$. This system must be completed with the initial condition $\mathbf{u}(\mathbf{x}, 0) = \mathbf{u}^0(\mathbf{x})$ (where $\mathbf{u}^0(\mathbf{x})$ is a given function) and suitable boundary conditions on $\partial\Omega$. Since in the framework of algebraic splitting methods there is a complete independence of the numerical methods of the boundary conditions, we do not specify a specific boundary set. It is, however, understood that some (reasonable) boundary conditions are prescribed on $\partial\Omega$.

In order to have a quantitative evaluation of the flow field in real applications, a numerical approximation has to be carried out. To this aim, the problem has to be discretized with respect to time and space variables. Concerning the *space discretization* issue, we will basically refer to the *Galerkin method* and, in particular, to the *finite element method* (FEM). The most part of what follows can, however, be applied to other space discretization methods as well. For any details concerning the FEM discretization of the Navier–Stokes problem, we refer the reader, e.g., to [24]. In fact, we choose functional spaces for the approximate velocity and pressure fields which satisfy the *inf-sup* or *LBB condition* (see, e.g., [1]). We will denote by $N_{\mathbf{u}}$ the number of velocity degrees of freedom and by N_p the number of pressure degrees of freedom.

For what concerns the *time discretization*, we will refer to classic backward differences methods. Namely, we consider a decomposition of the time interval into

N subintervals (t^n, t^{n+1}) with $t^n = n\Delta t$, where $\Delta t = T/N$ is the uniform positive time step, and collocate the equation in the instants $t^n = n\Delta t$. For the treatment of the nonlinear convective term, we resort to the usual (semi-implicit) linearization $(\mathbf{u}(t^{n+1}) \cdot \nabla)\mathbf{u}(t^{n+1}) \simeq (\mathbf{u}(t^n) \cdot \nabla)\mathbf{u}(t^{n+1})$ or similar ones featuring higher order of time accuracy (see, e.g., [10]). We point out, however, that the most part of the methods investigated here relies on the pattern of the matrix associated with the discrete Navier–Stokes problem. Since the pattern is also the same for the inner iteration of a Newton method (solution of the Jacobian), the methods introduced here can also be applied to a fully implicit treatment of the nonlinear term.

The fully discretized and linearized incompressible Navier–Stokes equations at the time t^{n+1} therefore read

$$\mathcal{A}\mathbf{w}^{n+1} = \mathbf{b}^{n+1}, \tag{2.2}$$

where the vector $\mathbf{b}^k = \left[b_1^k, b_2^k\right]^T$ contains forcing terms and contributions of the boundary conditions, $\mathbf{w}^{n+1} = (\mathbf{u}^{n+1}, \mathbf{p}^{n+1})^T$ denotes the vector of the nodal values of the discrete velocity and pressure, and

$$\mathcal{A} = \begin{bmatrix} \mathrm{C} & \mathrm{D}^T \\ \mathrm{D} & 0 \end{bmatrix}. \tag{2.3}$$

Here D is the discrete divergence operator (i.e., $d_{ij} = -\int_\Omega \nabla \cdot \mathbf{v}_j q_i$, where $\{\mathbf{v}_k\}$ band $\{q_k\}$ are the basis functions for the velocity and the pressure, respectively). D^T denotes the discrete gradient operator, and C collects contributions from the time derivative and the advection and diffusion operators. More specifically, we denote

$$\mathrm{C} = \frac{\alpha}{\Delta t}\mathrm{M} + \mathrm{K},$$

where M is the velocity mass matrix, α is the coefficient of the backward difference formula (BDF) scheme at hand for the velocity field at time t^{n+1}, and K corresponds to the discretization of the diffusive and of the convective terms. In the case of the Stokes problem, K corresponds just to the Laplacian of the velocity, and it is therefore symmetric and positive definite (s.p.d.).

System (2.2) typically features large dimensions and bad conditioning properties. The splitting between the computation of the velocity field from that of the pressure is almost mandatory when large three-dimensional problems are faced. This can be obtained through inexact block LU decompositions. These strategies stem from the following "exact" LU-block factorization of $\mathcal{A}$:

$$\mathcal{A} = \begin{bmatrix} \mathrm{C} & 0 \\ \mathrm{D} & -\mathrm{D}\mathrm{C}^{-1}\mathrm{D}^T \end{bmatrix} \begin{bmatrix} \mathrm{I} & \mathrm{C}^{-1}\mathrm{D}^T \\ 0 & \mathrm{I} \end{bmatrix}.$$

Since the inverse C^{-1} is seldom available, we can set up different schemes, achieving a reduction in the computational cost by suitably approximating C^{-1} with a matrix H_1 in the L-block and H_2 in the U-block. This leads to the following *inexact block LU factorization* (see [23] and also [5] and [6]):

$$\widehat{\mathcal{A}} = \begin{bmatrix} \mathrm{C} & 0 \\ \mathrm{D} & -\mathrm{D}\mathrm{H}_1\mathrm{D}^T \end{bmatrix} \begin{bmatrix} \mathrm{I} & \mathrm{H}_2\mathrm{D}^T \\ 0 & \mathrm{I} \end{bmatrix} = \begin{bmatrix} \mathrm{C} & \mathrm{C}\mathrm{H}_2\mathrm{D}^T \\ \mathrm{D} & \mathrm{D}(\mathrm{H}_2 - \mathrm{H}_1)\mathrm{D}^T \end{bmatrix}. \tag{2.4}$$

The corresponding algebraic fractional-step methods require at the generic time level t^{n+1} the solution of the following systems:

$$\text{L-step}\quad \begin{cases} \mathrm{C}\widetilde{\mathbf{u}}^{n+1} = \mathbf{b}_1^{n+1}, \\ \mathrm{D}\widetilde{\mathbf{u}}^{n+1} - \mathrm{D}\mathrm{H}_1\mathrm{D}^T\tilde{\mathbf{p}}^{n+1} = \mathbf{b}_2^{n+1}, \end{cases} \tag{2.5}$$

$$\text{U-step}\quad \begin{cases} \mathbf{p}^{n+1} = \widetilde{\mathbf{p}}^{n+1}, \\ \mathbf{u}^{n+1} + \mathrm{H}_2\mathrm{D}^T\mathbf{p}^{n+1} = \widetilde{\mathbf{u}}^{n+1}. \end{cases} \tag{2.6}$$

Different choices can be pursued for the approximating matrices H_1 and H_2. In particular, we could take

$$\mathrm{H}_1 = \mathrm{H}_2 = \frac{\Delta t}{\alpha}\mathrm{M}^{-1}$$

or

$$\mathrm{H}_1 = \frac{\Delta t}{\alpha}\mathrm{M}^{-1}, \quad \mathrm{H}_2 = \mathrm{C}^{-1}.$$

The former choice yields a scheme (see [20]) that can be considered the *algebraic* counterpart of the *Chorin–Temam scheme* (briefly, ACT), because of the formal analogy with the original differential splitting method. The latter choice yields the so-called *Yosida method*, introduced in [23] and analyzed in [22]. See also [5] and [6].

The main difference between the two possibilities is that in the Chorin–Temam scheme only the discretized momentum equation is perturbed, while in the Yosida scheme only the mass conservation equation is perturbed (see [27]). In what follows, we will say that an algebraic fractional-step method is of *Yosida type* if $\mathrm{H}_1 = \mathrm{H}$ and $\mathrm{H}_2 = \mathrm{C}^{-1}$, and of *Chorin–Temam* type if $\mathrm{H}_1 = \mathrm{H}_2 = \mathrm{H}$, with H being any convenient approximation of C^{-1}. Note that the approximation of C^{-1} with $\Delta t/\alpha\mathrm{M}^{-1}$ stems from a truncation to the first term of the following well-known Neumann expansion:

$$\mathrm{C}^{-1} = \frac{\Delta t}{\alpha}\left(\mathrm{I}_{N_{\mathbf{u}}} + \frac{\Delta t}{\alpha}\mathrm{M}^{-1}K\right)^{-1}, \quad \mathrm{M}^{-1} = \frac{\Delta t}{\alpha}\sum_{i=0}^{\infty}\left(-\Delta t\mathrm{M}^{-1}K\right)^{i}\mathrm{M}^{-1}.$$

Here $\mathrm{I}_{N_{\mathbf{u}}}$ (I_{N_p}) denotes the identity matrix of dimension $N_{\mathbf{u}}$ (N_p). α is the coefficient of the term evaluated at t^{n+1} in the time discretization scheme adopted. For the implicit Euler scheme, $\alpha = 1$; for a BDF scheme of order two, $\alpha = 3/2$; and for a BDF scheme of order three, $\alpha = 11/6$. In order to improve the accuracy of the inexact factorization, one could choose H by taking more terms in the Neumann expansion. This strategy has been analyzed in [27], and it can lead to some relevant instabilities, even for the Stokes problem. In what follows, we will set

$$\mathrm{H} = \frac{\Delta t}{\alpha}\mathrm{M}^{-1}, \tag{2.7}$$

so that $\mathrm{C}^{-1} = \mathrm{H} + \mathcal{O}(\Delta t)$.

As previously pointed out, note that for both approaches the pressure is only predicted (in the L-step), while the velocity is first predicted in the L-step (with the so-called *intermediate velocity*, $\widetilde{\mathbf{u}}^{n+1}$) and next corrected in the U-step, computing the *end-step velocity.* One could expect some improvements in the accuracy of computation by resorting to a correction also for the pressure field, leading to an *end-step pressure.* In the next section we investigate such schemes.

Remark. A popular modification of the schemes presented above is the so-called *incremental approach.* This approach can be applied to differential projection methods and to algebraic splittings as well. It basically consists of a reformulation of the time-discrete Navier–Stokes problem in such a way that the pressure field p^{n+1} is computed as the sum of an *extrapolation* $\sigma_{n+1}p$ (which is a linear combination of the pressure at the previous time steps) and an *increment* $\delta_{n+1}p$. This reformulation for the algebraic (fully discretized) problem reads

$$\mathcal{A}\begin{bmatrix}\mathbf{U}^{n+1}\\ \mathbf{P}^{n+1}\end{bmatrix}=\begin{bmatrix}\mathbf{b}_1\\ \mathbf{b}_2\end{bmatrix}\Rightarrow\mathcal{A}\begin{bmatrix}\mathbf{U}^{n+1}\\ \delta_{n+1}\mathbf{P}\end{bmatrix}=\begin{bmatrix}\mathbf{b}_1-\sigma_{n+1}\mathbf{P}\\ \mathbf{b}_2\end{bmatrix}, \tag{2.8}$$

having set $\mathbf{P}^{n+1}=\sigma_{n+1}\mathbf{P}+\delta_{n+1}\mathbf{P}$. In this way, possible errors introduced by the splitting affect the pressure increment rather than the pressure itself. This modification improves the accuracy of the solution. For instance, in the van Kan scheme (see [16], [25]), we have

$$\sigma_{n+1}p=p^n,\quad \delta_{n+1}p=p^{n+1}-\sigma_{n+1}=p^{n+1}-p^n, \tag{2.9}$$

which coupled with a Crank–Nicolson time discretization yields a second order scheme (see also [10]). Recent results (see [15]) show that the incremental approach can improve the accuracy of the solution also for higher order time discretizations, e.g., coupling a BDF of order three with an incremental approach by setting

$$\sigma_{n+1}p=2p^n-p^{n-1},\quad \delta_{n+1}p=p^{n+1}-\sigma_{n+1}=p^{n+1}-2p^n+p^{n-1}. \tag{2.10}$$

In our analysis we do not consider the incremental approach, in order to put in evidence the role of the pressure corrections proposed in the next sections. However, in the numerical results section, we will present and comment on the impact of the incremental modification on pressure corrected schemes.

Remark. In the literature, there is an open discussion about the pros and cons of algebraic or differential approaches in the splitting (see [11]). Here, we investigate essentially an algebraic approach, even if we do not claim that this necessarily leads to more accurate results. In fact, as previously pointed out, the algebraic approach has, for sure, the advantage of including all the possible boundary conditions (not only Dirichlet conditions) without taking care of the setup of special (approximate) pressure conditions, which is conversely needed in differential splitting schemes. This makes the algebraic approach appealing in many real problems.

3. Pressure correction algebraic schemes. Let us consider the following *modified* inexact LU factorization of the matrix $\mathcal{A}$, defined in (2.3),

$$\widehat{\mathcal{A}}=\begin{bmatrix}\mathrm{C} & 0\\ \mathrm{D} & -\mathrm{DH}_1\mathrm{D}^T\end{bmatrix}\begin{bmatrix}\mathrm{I} & \mathrm{H}_2\mathrm{D}^T\mathrm{R}\\ 0 & \mathrm{Q}\end{bmatrix}=\begin{bmatrix}\mathrm{C} & \mathrm{CH}_2\mathrm{D}^T\mathrm{R}\\ \mathrm{D} & \mathrm{D}(\mathrm{H}_2\mathrm{D}^T\mathrm{R}-\mathrm{H}_1\mathrm{D}^T\mathrm{Q})\end{bmatrix}, \tag{3.1}$$

where R and Q are square $N_p\times N_p$ matrices that we choose in order to minimize the difference $\mathcal{A}-\widehat{\mathcal{A}}$ in some sense. This (generic) factorization leads to new algebraic fractional step methods, where the L-step is still given by (2.5), while the U-step becomes

$$\text{U-step}\quad \left\{ \begin{array}{l} \mathrm{Q}\mathbf{p}^{n+1} = \widetilde{\mathbf{p}}^{n+1}, \\ \mathbf{u}^{n+1} + \mathrm{H}_2\mathrm{D}^T\mathrm{R}\mathbf{p}^{n+1} = \widetilde{\mathbf{u}}^{n+1}. \end{array} \right. \tag{3.2}$$

Since we have now a pressure correction $(3.2)_1$, we give to schemes in the form (2.5), (3.2) the name *pressure correction methods.*

We still distinguish two approaches: the Chorin–Temam approach, in which we set $\mathrm{H}_1 = \mathrm{H}_2 = \mathrm{H}$, and the Yosida one, where $\mathrm{H}_2 = \mathrm{C}^{-1}$. In the first case, we obtain

$$\widehat{\mathcal{A}} = \left[\begin{array}{cc} \mathrm{C} & \mathrm{CHD}^T\mathrm{R} \\ \mathrm{D} & \mathrm{D}(\mathrm{HD}^T\mathrm{R} - \mathrm{HD}^T\mathrm{Q}) \end{array} \right]. \tag{3.3}$$

If we select $\mathrm{R} = \mathrm{Q}$, the (discrete) mass conservation equation is satisfied without any approximation. This choice will be investigated in the next section.

In the second case, we have

$$\widehat{\mathcal{A}} = \left[\begin{array}{cc} \mathrm{C} & \mathrm{D}^T\mathrm{R} \\ \mathrm{D} & \Sigma\mathrm{R} - \mathrm{SQ} \end{array} \right], \tag{3.4}$$

where

$$\Sigma = \mathrm{DC}^{-1}\mathrm{D}^T, \quad \mathrm{S} = \mathrm{DHD}^T. \tag{3.5}$$

Matrix $-\Sigma$ is the so-called pressure *Schur complement* of $\mathcal{A}$. Observe that thanks to (2.7), S is $\mathcal{O}(\Delta t)$. In this case, if $\mathrm{R} = \mathrm{I}_{N_p}$, the (discrete) momentum equation is fulfilled exactly. We investigate this choice in section 5.

4. The algebraic Chorin–Temam pressure correction scheme. Let us investigate the choice $\mathrm{H}_1 = \mathrm{H}_2$, with $\mathrm{R} = \mathrm{Q}$. Since we are introducing a pressure correction in the ACT method, we will call this choice the *algebraic Chorin–Temam pressure correction* (CTPC) scheme.

The splitting error matrix is

$$\widehat{\mathcal{E}} = \mathcal{A} - \widehat{\mathcal{A}} = \left[\begin{array}{cc} 0 & \mathrm{D}^T - \widehat{\mathrm{D}}^T \\ 0 & 0 \end{array} \right], \qquad \widehat{\mathrm{D}}^T = \mathrm{CHD}^T\mathrm{Q}; \tag{4.1}$$

thus the splitting error vanishes if

$$\mathrm{CHD}^T\mathrm{Q} = \mathrm{D}^T. \tag{4.2}$$

Matrix equation (4.2) is an overdetermined problem. In order to obtain a solution, multiply both the sides of (4.2) by the matrix DH, yielding $\mathrm{BQ} = \mathrm{S}$, where

$$\mathrm{B} = \mathrm{DHCHD}^T. \tag{4.3}$$

This implies that the matrix equation (4.2) is solved up to a nonzero matrix Z such that $\mathrm{DHZ} = 0$. Observe that if the inf-sup condition is fulfilled, matrix B is nonsingular, and then we can compute

$$\mathrm{Q} = \mathrm{B}^{-1}\mathrm{S}. \tag{4.4}$$

Remark. In the case of the Stokes problem, C is s.p.d., and the matrix Q corresponds to solving (4.2) in the least square sense, where the solution yields the minimal error in the norm $\| \cdot \|_{\mathrm{C}}$.

At each time step, the CTPC scheme reads (we neglect the time index $n+1$ for the sake of simplicity) as follows:

1. *Intermediate velocity computation*: $\mathrm{C}\widetilde{\mathbf{U}} = \mathbf{b}_1$.
2. *Intermediate pressure computation.* $\mathrm{S}\widetilde{\mathbf{P}} = \mathrm{D}\widetilde{\mathbf{U}} - \mathbf{b}_2$.
3. *End-of-step pressure computation*: $\mathrm{S}\mathbf{P} = \mathrm{B}\widetilde{\mathbf{P}}$.
4. *End-of-step velocity computation*: $\mathbf{U} = \widetilde{\mathbf{U}} - \mathrm{HD}^T\widetilde{\mathbf{P}}$.

Observe that the two systems for the pressure computation share the same matrix S. This is useful if S can be factorized all at once, allowing an effective direct strategy for the solution of the related systems (see section 6).

Remark. In order to solve (4.2), another possibility resorts to manipulate it in the form $\mathrm{HD}^T\mathrm{Q} = \mathrm{C}^{-1}\mathrm{D}^T$ and then solve it in the least square sense with respect to the matrix norm $\| \cdot \|_{\mathrm{H}^{1/2}}$. This strategy yields $\mathrm{Q} = \mathrm{S}^{-1}\Sigma$. This means that the pressure correction step reads $\mathrm{Q}\mathbf{P} = \widetilde{\mathbf{P}} \Rightarrow \Sigma\mathbf{P} = \mathrm{S}\widetilde{\mathbf{P}}$. This step involves the pressure Schur complement Σ, and it is, in fact, an (ineffective) reformulation of the pressure matrix method (see [24]), corresponding to exploiting the exact factorization (2.3). Therefore it is not feasible.

4.1. Stability and splitting error analysis of CTPC.

4.1.1. Preliminary results. We start with some preliminary notation and lemmas. Starting from the identity

$$\mathrm{CH} = \mathrm{I}_{N_{\mathbf{u}}} + \mathrm{E}_1, \qquad \mathrm{E}_1 = \mathrm{KH}, \tag{4.5}$$

we have

$$\mathrm{B} = \mathrm{DH}\left(\mathrm{I}_{N_{\mathbf{u}}} + \mathrm{E}_1\right)\mathrm{D}^T = \mathrm{S} + \mathrm{W} = \mathrm{S}\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right), \tag{4.6}$$

where

$$\mathrm{W} = \mathrm{DHKHD}^T, \qquad \mathrm{E}_2 = \mathrm{S}^{-1}\mathrm{W}. \tag{4.7}$$

Observe that W is $\mathcal{O}(\Delta t^2)$, thanks to (2.7). Consequently, E_2 is $\mathcal{O}(\Delta t)$. From (4.6) we have

$$\mathrm{B}^{-1} = \left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1}\mathrm{S}^{-1} \Rightarrow \mathrm{B}^{-1}\mathrm{S} = \left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1}. \tag{4.8}$$

Therefore, matrix $\widehat{\mathrm{D}}^T$ introduced in (4.1) admits the following factorization:

$$\hat{\mathrm{D}}^T = \mathrm{CHD}^T\mathrm{B}^{-1}\mathrm{S} = \left(\mathrm{I}_{N_{\mathbf{u}}} + \mathrm{E}_1\right)\mathrm{D}^T\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1}. \tag{4.9}$$

Observe that if H is proportional to $\mathrm{I}_{N_{\mathbf{u}}}$, as it happens in a finite difference discretization, it is possible to verify that the matrix DH is the Moore–Penrose pseudoinverse of $\mathrm{D}^T\mathrm{S}^{-1}$. In general (for a finite element or a spectral discretization) this is not true. In fact, it is possible to verify that $\mathrm{H}^{1/2}\mathrm{D}^T\mathrm{S}^{-1}$ is the Moore–Penrose pseudoinverse of $\mathrm{DH}^{1/2}$. However, for the purpose of the present work, it is useful in the following lemma.

Lemma 4.1. *Matrix* $\mathrm{I}_{N_{\mathbf{u}}} - \mathrm{D}^T\mathrm{S}^{-1}\mathrm{DH}$ *is similar to the matrix*

$$\begin{bmatrix} 0 & 0 \\ 0 & \mathrm{I}_{N_{\mathbf{u}}-N_p} \end{bmatrix}.$$

Proof. The singular value decomposition of the matrix $\mathrm{H}^{1/2}\mathrm{D}^T$ reads

$$\mathrm{H}^{1/2}\mathrm{D}^T = \mathrm{U}^T\Pi\mathrm{V}, \tag{4.10}$$

where U is an orthogonal $N_{\mathbf{u}} \times N_{\mathbf{u}}$ matrix, V is an orthogonal $N_p \times N_p$ matrix, and Π is the $N_{\mathbf{u}} \times N_p$ matrix such that $\Pi_{ij} = \sigma_i\delta_{ij}$, where $\{\sigma_i\}$ are the singular values and δ_{ij} is the Kronecker symbol. Observe that, thanks to the inf-sup condition, $\sigma_i \neq 0$ for any $i = 1, \dots, N_p$. Now, we have

$$\mathrm{I}_{N_{\mathbf{u}}} - \mathrm{D}^T\mathrm{S}^{-1}\mathrm{DH} = \mathrm{H}^{-1/2}\left(\mathrm{I}_{N_{\mathbf{u}}} - \mathrm{H}^{1/2}\mathrm{D}^T\left(\mathrm{DH}^{1/2}\mathrm{H}^{1/2}\mathrm{D}^T\right)^{-1}\mathrm{DH}^{1/2}\right)\mathrm{H}^{1/2}$$

and, thanks to (4.10),

$$\mathrm{I}_{N_{\mathbf{u}}} - \mathrm{H}^{1/2}\mathrm{D}^T\left(\mathrm{DH}^{1/2}\mathrm{H}^{1/2}\mathrm{D}^T\right)^{-1}\mathrm{DH}^{1/2} = \mathrm{I}_{N_{\mathbf{u}}} - \mathrm{U}^T\Pi\mathrm{V}\left(\mathrm{V}^T\Pi^T\mathrm{U}^T\mathrm{U}\Pi\mathrm{V}\right)^{-1}\mathrm{V}^T\Pi^T\mathrm{U}.$$

Observe that $\Pi^T\Pi$ is the $N_p \times N_p$ diagonal matrix with the square of the singular values on the diagonal. In what follows we will set $\Pi_0^2 = \Pi^T\Pi$. The thesis is a consequence of the fact that U and V are orthogonal and that

$$\Pi\Pi_0^{-2}\Pi^T = \begin{bmatrix} \mathrm{I}_{N_p} & 0 \\ 0 & 0 \end{bmatrix}. \qquad \square$$

4.1.2. Splitting error analysis. We are now in position to investigate the splitting error matrix $\mathcal{A} - \hat{\mathcal{A}}$ associated with the CTPC scheme, that is,

$$\widehat{\mathcal{E}}_{CTPC} = \begin{bmatrix} 0 & \mathrm{D}^T - \widehat{\mathrm{D}}^T \\ 0 & 0 \end{bmatrix}.$$

Setting

$$\mathrm{E} = \mathrm{D}^T - \widehat{\mathrm{D}}^T, \tag{4.11}$$

from the definition of $\widehat{\mathrm{D}}^T$ we can straightforwardly verify that

$$\mathrm{DHE} = 0. \tag{4.12}$$

This was to be expected, since we have solved the overdetermined problem (4.2), by projecting it into the subspace image of DH. From (4.9), it follows that

$$\mathrm{E} = \mathrm{D}^T - \left(\mathrm{I}_{N_{\mathbf{u}}} + \mathrm{E}_1\right)\mathrm{D}^T\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1}. \tag{4.13}$$

Assuming that Δt is small enough to exploit the Neumann expansion, which makes sense since E_2 is $\mathcal{O}(\Delta t)$,

$$\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1} = \sum_{k=0}^{\infty}(-\mathrm{E}_2)^k,$$

from (4.6), (4.7), (4.8), and (4.5) we have

$$\begin{aligned} &\mathrm{D}^T - \left(\mathrm{I}_{N_{\mathbf{u}}} + \mathrm{E}_1\right)\mathrm{D}^T\left(\mathrm{I}_{N_p} - \mathrm{E}_2 + \mathrm{E}_2^2 - \dots\right) \\ &= \mathrm{D}^T - \left(\mathrm{I}_{N_{\mathbf{u}}} + \mathrm{E}_1\right)\mathrm{D}^T\left(\mathrm{I}_{N_p} - \mathrm{E}_2 + \mathcal{O}(\Delta t^2)\right), \end{aligned} \tag{4.14}$$

yielding

$$\mathrm{E} = -\mathrm{E}_1\mathrm{D}^T \boxed{+\mathrm{D}^T\mathrm{E}_2} + \mathcal{O}(\Delta t^2).$$

In the boxed term we put in evidence the specific contribution on the error given by the pressure correction. Since both the matrices KHD^T and $\mathrm{D}^T\mathrm{S}^{-1}\mathrm{W}$ are $\mathcal{O}(\Delta t)$, we conclude that the splitting error is at least first order in time. Unfortunately, this conclusion does not give significant improvements in terms of order of accuracy with respect to the original ACT scheme. The main difference is that in the latter scheme the splitting error is dominated by the term KHD^T, while in the CTPC scheme the matrix error is dominated by

$$-\left(\mathrm{I}_{N_{\mathbf{u}}} - \mathrm{D}^T\mathrm{S}^{-1}\mathrm{DH}\right)\mathrm{E}_1\mathrm{D}^T. \tag{4.15}$$

Thanks to Lemma 4.1, it is to be expected that the matrix in brackets, having N_p null eigenvalues, will reduce the error associated with the scheme, in comparison with the ACT scheme, even if it is not possible to prove that the order of accuracy of the scheme is improved. Numerical results confirm that the scheme is in general only first order accurate in time (see section 6).

However, for some special space discretization, it is interesting to point out the following circumstance.

PROPOSITION 4.2. *If* $\mathrm{KHD}^T = \nu\mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{DHD}^T$*, the splitting error matrix* E *vanishes.*

Proof. From (4.13) it follows that

$$\mathrm{E}\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right) = \mathrm{D}^T + \mathrm{D}^T\mathrm{E}_2 - \mathrm{D}^T - \mathrm{E}_1\mathrm{D}^T = \mathrm{D}^T\mathrm{E}_2 - \mathrm{E}_2\mathrm{D}^T. \tag{4.16}$$

If $\mathrm{E}_1\mathrm{D}^T = \mathrm{KHD}^T = \nu\mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{DHD}^T$, then we have $\mathrm{E}_2 = \nu\mathrm{S}^{-1}\mathrm{DHD}^T\mathrm{M}_p^{-1}\mathrm{DHD}^T = \nu\mathrm{M}_p^{-1}\mathrm{S}$. Recalling that $\mathrm{S} = \mathrm{DHD}^T$, from (4.16) it follows that $\mathrm{E}\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right) = \nu\mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{S} - \nu\mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{DHD}^T = 0$. Thus, since $\mathrm{I}_{N_p} + \mathrm{E}_2$ is invertible, the thesis follows. □

Observe that the hypothesis in Proposition 4.2 reinterpreted at the continuous level yields the following identity:

$$-\nu\triangle\nabla = -\nu\nabla\cdot(\nabla)\nabla.$$

Moreover, in the context of finite difference space discretization the same hypothesis has been advocated in [18] as a *compatibility condition* holding for a special set of velocity boundary conditions in rectangular domains.

4.1.3. Stability analysis. The main result is the following proposition.

PROPOSITION 4.3. *Consider the Stokes problem discretized with an implicit Euler time discretization scheme ($\alpha = 1$). Then the CTPC scheme is* unconditionally stable.

Proof. We consider a problem where the forcing term and the boundary conditions are null as well, since they do not influence the stability properties of the scheme.

The CTPC scheme actually amounts to solving the following problem:

$$\begin{bmatrix} \mathrm{C} & \hat{\mathrm{D}}^T \\ \mathrm{D} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \mathbf{U}^{n+1} \\ \mathbf{P}^{n+1} \end{bmatrix} = \begin{bmatrix} \dfrac{1}{\Delta t}\mathrm{M}\mathbf{U}^n \\ \mathbf{0} \end{bmatrix}, \tag{4.17}$$

where $\mathrm{C} = \frac{1}{\Delta t}\mathrm{M}+\mathrm{K}$ (with K s.p.d.) and $\hat{\mathrm{D}}^T$ has been introduced in (4.1). Eliminating the pressure unknowns in (4.17), we obtain

$$\mathbf{U}^{n+1} = \frac{1}{\Delta t}\mathrm{C}^{-1}\mathrm{M}\mathbf{U}^n - \frac{1}{\Delta t}\mathrm{C}^{-1}\hat{\mathrm{D}}^T\left(\mathrm{D}\mathrm{C}^{-1}\hat{\mathrm{D}}^T\right)^{-1}\mathrm{D}\mathrm{C}^{-1}\mathrm{M}\mathbf{U}^n. \tag{4.18}$$

Observe that

$$\begin{aligned}\hat{\mathrm{D}}^T \quad & \left(\mathrm{D}\mathrm{C}^{-1}\hat{\mathrm{D}}^T\right)^{-1}\\ &= \left(\mathrm{I}_{N_\mathbf{u}}+\mathrm{E}_1\right)\mathrm{D}^T\left(\mathrm{I}_{N_p}+\mathrm{E}_2\right)^{-1}\left(\mathrm{D}\mathrm{C}^{-1}\left(\mathrm{I}_{N_\mathbf{u}}+\mathrm{E}_1\right)\mathrm{D}^T\left(\mathrm{I}_{N_p}+\mathrm{E}_2\right)^{-1}\right)^{-1}\\ &= \left(\mathrm{I}_{N_\mathbf{u}}+\mathrm{E}_1\right)\mathrm{D}^T\left(\mathrm{D}\mathrm{C}^{-1}\left(\mathrm{I}_{N_\mathbf{u}}+\mathrm{E}_1\right)\mathrm{D}^T\right)^{-1}.\end{aligned}$$

Moreover, from the definition of E_1 and C, we have

$$\mathrm{C}^{-1}\left(\mathrm{I}_{N_\mathbf{u}}+\mathrm{E}_1\right) = \Delta t\mathrm{M}^{-1}\left(\mathrm{I}_{N_\mathbf{u}}+\Delta t\mathrm{K}\mathrm{M}^{-1}\right)^{-1}\left(\mathrm{I}_{N_\mathbf{u}}+\mathrm{E}_1\right) = \Delta t\mathrm{M}^{-1},$$

so that $\hat{\mathrm{D}}^T(\mathrm{D}\mathrm{C}^{-1}\hat{\mathrm{D}}^T)^{-1}$ reduces to $\left(\mathrm{I}_{N_\mathbf{u}}+\Delta t\mathrm{K}\mathrm{M}^{-1}\right)\mathrm{D}^T\mathrm{S}^{-1}$. We have therefore that the second matrix on the right-hand side of (4.18) becomes

$$\frac{1}{\Delta t}\mathrm{C}^{-1}\hat{\mathrm{D}}^T\left(\mathrm{D}\mathrm{C}^{-1}\hat{\mathrm{D}}^T\right)^{-1}\mathrm{D}\mathrm{C}^{-1}\mathrm{M} = \mathrm{M}^{-1}\mathrm{D}^T\mathrm{S}^{-1}\mathrm{D}\mathrm{C}^{-1}\mathrm{M},$$

yielding

$$\mathbf{U}^{n+1} = \frac{1}{\Delta t}\left(\mathrm{M}^{-1}-\mathrm{M}^{-1}\mathrm{D}^T\left(\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T\right)^{-1}\mathrm{D}\mathrm{M}^{-1}\right)\mathrm{M}\mathrm{C}^{-1}\mathrm{M}\mathbf{U}^n, \tag{4.19}$$

or, equivalently,

$$\mathbf{U}^{n+1} = \mathrm{M}^{-1}\left(\mathrm{I}_{N_\mathbf{u}}-\mathrm{D}^T\left(\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T\right)^{-1}\mathrm{D}\mathrm{M}^{-1}\right)\mathrm{M}\left(\mathrm{I}_{N_\mathbf{u}}+\Delta t\mathrm{M}^{-1}\mathrm{K}\right)\mathbf{U}^n. \tag{4.20}$$

We prove that for any $\Delta t > 0$

$$\left\|\mathrm{M}^{-1}\left(\mathrm{I}_{N_\mathbf{u}}-\mathrm{D}^T\left(\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T\right)^{-1}\mathrm{D}\mathrm{M}^{-1}\right)\mathrm{M}\left(\mathrm{I}_{N_\mathbf{u}}+\Delta t\mathrm{M}^{-1}\mathrm{K}\right)^{-1}\right\|_2 < 1. \tag{4.21}$$

For a generic matrix X, we will denote by ρ_X its spectral radius. First of all, observe that

$$||\mathrm{I}_{N_\mathbf{u}}-\mathrm{D}^T\left(\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T\right)^{-1}\mathrm{D}\mathrm{M}^{-1}||_2 = 1. \tag{4.22}$$

This is, in fact, a consequence of Lemma 4.1, since the matrix in (4.22) corresponds exactly to the matrix $\mathrm{I}_{N_\mathbf{u}} - \mathrm{D}^T\mathrm{S}^{-1}\mathrm{D}\mathrm{H}$ considered in the lemma. If follows that the matrix $\mathrm{M}^{-1}(\mathrm{I}_{N_\mathbf{u}} - \mathrm{D}^T\left(\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T\right)^{-1}\mathrm{D}\mathrm{M}^{-1})\mathrm{M}$ still has a unit spectral radius, being similar to the one in (4.22). Now, due to the positiveness of $\Delta t\mathrm{M}^{-1}\mathrm{K}$ with respect to the scalar product weighted by the s.p.d. mass matrix M, we have that $\rho_{(\mathrm{I}_{N_\mathbf{u}}+\Delta t\mathrm{M}^{-1}\mathrm{K})^{-1}} < 1$. Therefore, we have

$$\begin{aligned}&\left\|\mathrm{M}^{-1}\left(\mathrm{I}_{N_\mathbf{u}}-\mathrm{D}^T\left(\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T\right)^{-1}\mathrm{D}\mathrm{M}^{-1}\right)\mathrm{M}\left(\mathrm{I}_{N_\mathbf{u}}+\Delta t\mathrm{M}^{-1}\mathrm{K}\right)^{-1}\right\|_2\\ &\le \left\|\mathrm{M}^{-1}\left(\mathrm{I}_{N_\mathbf{u}}-\mathrm{D}^T\left(\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T\right)^{-1}\mathrm{D}\mathrm{M}^{-1}\right)\right\|_2\left\|\left(\mathrm{I}_{N_\mathbf{u}}+\Delta t\mathrm{M}^{-1}\mathrm{K}\right)^{-1}\right\|_2 < 1.\end{aligned} \tag{4.23}$$

The first inequality is due to (4.22) and the fact that each matrix of the product is s.p.d., so its norm corresponds to its spectral radius. Equations (4.18) and (4.23) yield

$$||\mathbf{U}^{n+1}||_2 < ||\mathbf{U}^n||_2$$

for any $\Delta t > 0$, giving the unconditional stability result. □

Remark. With a similar approach, it can be proved that the unconditional stability holds also for any implicit (unconditionally stable) BDF time discretization.

Remark. It is worthwhile to point out the fact that on the stability of the scheme the error matrix E_2 does not play any role. Actually, since the error matrix E_1 of the present scheme is the same of the original ACT scheme, the unconditional stability of CTPC could be directly inferred from the unconditional stability of ACT. E_2 is therefore set up in such a way that it should reduce the splitting error without affecting the stability of the scheme. Other schemes featuring a high order splitting error do not share the same stability properties. As we will see, also the pressure correction of the Yosida scheme is affected by instabilities.

4.2. CTPC and differential pressure correction schemes. The introduction of a pressure correction for improving the numerical solution is not new in the field of projection methods for the Navier–Stokes equations. In Timmermans, Minev, and de Vosse [26] a variant of the second order van Kan scheme (see [16]) is proposed for improving the pressure computation in the framework of splitting (differential) schemes. Following Prohl [21], who has extensively analyzed this scheme, we present the corresponding formulation starting from the Chorin–Temam method. Suppose we have homogeneous Dirichlet conditions on the whole boundary of the computational domain Ω. First, compute the intermediate velocity $\widetilde{\mathbf{u}}^{n+1}$ as the solution of the following advection-diffusion semidiscrete problem:

$$\frac{1}{\Delta t}\left(\widetilde{\mathbf{u}}^{n+1} - \mathbf{u}^n\right) - \nu\triangle\widetilde{\mathbf{u}}^{n+1} + \left(\mathbf{u}^n \cdot \nabla\right)\widetilde{\mathbf{u}}^{n+1} = \mathbf{f}, \tag{4.24}$$

with $\widetilde{\mathbf{u}}^{n+1} = \mathbf{0}$ on $\partial\Omega$. Then compute an "intermediate" pressure as the solution of the following Poisson problem:

$$\Delta t\triangle\widetilde{p}^{n+1} = \nabla \cdot \widetilde{\mathbf{u}}^{n+1}, \tag{4.25}$$

with $\partial_{\mathbf{n}}\widetilde{p}^{n+1} = 0$ on $\partial\Omega$, where $\mathbf{n}$ is the outward normal unit vector to $\partial\Omega$. The end-of-step velocity is now given by

$$\mathbf{u}^{n+1} = \widetilde{\mathbf{u}}^{n+1} - \Delta t\nabla\widetilde{p}^{n+1}. \tag{4.26}$$

If we take $\widetilde{p}^{n+1}$ as the end-of-step pressure, we have actually the classical Chorin–Temam scheme. In the Timmermans proposal, we take

$$p^{n+1} = \widetilde{p}^{n+1} - \nu\nabla \cdot \widetilde{\mathbf{u}}^{n+1}. \tag{4.27}$$

At the semidiscrete level (time-discrete and space-continuous) it is possible to verify that this scheme is *strongly consistent* with the Stokes problem, i.e., that solving the Chorin–Temam method with the correction (4.27) amounts exactly to solve the Stokes equations, without any splitting error. This strong consistency, however, fails to be verified in the case of the Navier–Stokes problem. Actually, in this case, a Lagrangian treatment of the time derivative needs to be pursued [26]. Prohl has, moreover, proved that this pressure correction introduces a "smoothing effect" only on the pressure error in the interior domain, and, however, the pressure correction step does not improve the order of accuracy of the method.

Here we want to establish some relations between the Timmermans method and our CTPC scheme. Indeed, exploiting (4.25) we can eliminate $\widetilde{\mathbf{u}}^{n+1}$ in (4.27), yielding

$$p^{n+1} = \widetilde{p}^{n+1} - \nu\Delta t\Delta\widetilde{p}^{n+1} = (\mathcal{I} - \nu\Delta t\Delta)\,\widetilde{p}^{n+1}, \tag{4.28}$$

where $\mathcal{I}$ denotes the identity operator.

On the other hand, concerning the CTPC scheme applied to the Stokes problem, we assume that matrix $\Delta t\mathrm{K}\mathrm{M}^{-1}\mathrm{D}^T$ can be factorized as $\nu\Delta t\mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T$ (as we have assumed in Proposition 4.2). The end-of-step pressure of the CTPC schemes becomes

$$\begin{aligned}\mathbf{P}^{n+1} &= \mathrm{S}^{-1}\mathrm{B}\widetilde{\mathbf{P}}^{n+1} = \left(\mathrm{I}_{N_p} + \mathrm{S}^{-1}\mathrm{W}\right)\widetilde{\mathbf{P}}^{n+1}\\ &= \left(\mathrm{I}_{N_p} + \Delta t^2\mathrm{S}^{-1}\mathrm{D}\mathrm{M}^{-1}\mathrm{K}\mathrm{M}^{-1}\mathrm{D}^T\right)\widetilde{\mathbf{P}}^{n+1} = \left(\mathrm{I}_{N_p} + \nu\Delta t\mathrm{M}_p^{-1}\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T\right)\widetilde{\mathbf{P}}^{n+1}.\end{aligned}$$

A formal analogy with (4.28) can be drawn if we read matrix $\nu\mathrm{D}\mathrm{M}^{-1}\mathrm{D}^T$ as a discrete counterpart of the pressure operator $-\nu\Delta$.

The algebraic reformulation, actually, has some advantages. As already pointed out (also in [26]), in the differential framework there is the problem of determining boundary conditions for the pressure problem, which in the algebraic approach are not required. Moreover, we point out that the CTPC scheme naturally embodies the presence of a convective term, and it does not necessarily need a Lagrangian treatment of the time derivative or to an explicit treatment of the convective term, as required in the Timmermans work.

Finally, we point out that the CTPC scheme provides *discrete-divergence* solutions, which is not true for the Timmermans method (whose divergence is null at the continuous level).

5. The algebraic Yosida pressure correction scheme. Let us consider now the pressure correction approach applied following the Yosida strategy, i.e., $\mathrm{H}_2 = \mathrm{C}^{-1}$ and $\mathrm{R} = \mathrm{I}_{N_p}$. The splitting error matrix in this case is

$$\widehat{\mathcal{E}}_{YPC} = \mathcal{A} - \widehat{\mathcal{A}}_{YPC} = \begin{bmatrix} 0 & 0 \\ 0 & \mathrm{SQ} - \Sigma \end{bmatrix}. \tag{5.1}$$

The problem of finding out a matrix such that the splitting error vanishes this time is clearly well posed, and the solution is

$$\Sigma - \mathrm{SQ} = \mathbf{0} \Rightarrow \mathrm{Q} = \mathrm{S}^{-1}\Sigma, \tag{5.2}$$

corresponding to the pressure correction step $\Sigma\mathbf{P}^{n+1} = \mathrm{S}\widetilde{\mathbf{P}}^{n+1}$. This is another formulation of the pressure matrix method (see [24]) and therefore is not interesting in the perspective of the present work.

However, we would like to introduce an approximate computation of Q which is computationally affordable. It corresponds to solve again an overdetermined problem related to (5.2). Multiply the two sides of the first equation in (5.2) by $\mathrm{D}^T\mathrm{M}_p^{-1}$, yielding $\mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{D}\mathrm{C}^{-1}\mathrm{D}^T = \mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{D}\mathrm{H}\mathrm{D}^T\mathrm{Q}$. Since $\mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{D}$ is nonsingular if the inf-sup condition is fulfilled, we can write

$$\mathrm{C}^{-1}\mathrm{D}^T = \mathrm{H}\mathrm{D}^T\mathrm{Q} \Rightarrow \mathrm{D}\mathrm{H}\mathrm{D}^T = \mathrm{D}\mathrm{H}\mathrm{C}\mathrm{H}\mathrm{D}^T\mathrm{Q},$$

corresponding to the choice $\mathrm{Q} = \mathrm{B}^{-1}\mathrm{S}$, which is exactly the same matrix setup for the CTPC scheme (see (4.4), (4.3)). Dropping again the time index $n+1$, the Yosida pressure correction scheme therefore reads as follows:

1. *Intermediate velocity computation*: $\mathrm{C}\widetilde{\mathbf{U}} = \mathbf{b}_1$.
2. *Intermediate pressure computation*: $\mathrm{S}\widetilde{\mathbf{P}} = \mathrm{D}\widetilde{\mathbf{U}} - \mathbf{b}_2$.
3. *End-of-step pressure computation*: $\mathrm{S}\mathbf{P} = \mathrm{B}\widetilde{\mathbf{P}}$.
4. *End-of-step velocity computation*: $\mathrm{C}\mathbf{U} = \mathbf{b}_1 - \mathrm{D}^T\mathbf{P}$.

Observe that the two problems for both the intermediate and end-of-step pressures are still solved by solving the same matrix S.

5.1. Stability and splitting error analysis.

5.1.1. Splitting error analysis. Starting from (5.1), the splitting error is given by the block (2,2) of $\mathcal{E}_{YPC}$, where,

$$\mathrm{E}_{YPC} = \mathrm{S}\mathrm{B}^{-1}\mathrm{S} - \mathrm{D}\mathrm{C}^{-1}\mathrm{D}^T.$$

Exploiting (4.6), (4.7), (4.8), and (4.11), the previous matrix can be reduced to

$$\begin{aligned}
\mathrm{E}_{YPC} &= \mathrm{S}\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1} - \mathrm{DH}\left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)^{-1}\mathrm{D}^T \\
&= \mathrm{DHD}^T\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1} - \mathrm{DH}\left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)^{-1}\mathrm{D}^T \\
&= \mathrm{DH}\left(\mathrm{D}^T\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1} - \left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)^{-1}\mathrm{D}^T\right) \\
&= \mathrm{DH}\left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)^{-1}\left(\left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)\mathrm{D}^T\left(\mathrm{I}_{N_p} + \mathrm{S}^{-1}\mathrm{W}\right)^{-1} - \mathrm{D}^T\right) \\
&= -\mathrm{DH}\left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)^{-1}\mathrm{E}.
\end{aligned} \tag{5.3}$$

The splitting error associated with the Yosida pressure correction (YPC) scheme can now be estimated, by assuming that Δt is small enough to exploit the following Neumann expansion:

$$\left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)^{-1} = \sum_{i=0}^{\infty}(-\mathrm{E}_1)^i. \tag{5.4}$$

This makes sense, since, as we have pointed out, $\mathrm{E}_1 = \mathcal{O}(\Delta t)$.

PROPOSITION 5.1. *The splitting error matrix associated with the YPC scheme is* $\mathcal{O}(\Delta t^3)$

Proof. By exploiting the Neumann expansion (5.4), we have from (5.3) and (4.12)

$$\mathrm{DH}\left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)^{-1}\mathrm{E} = \mathrm{DHE} - \mathrm{DHE}_1\mathrm{E} + \mathrm{DHE}_1^2\mathrm{E} - \cdots = -\mathrm{DHE}_1\mathrm{E} + \text{high order terms.} \tag{5.5}$$

On the other hand, we have that $\mathrm{H} = \mathcal{O}(\Delta t)$, $\mathrm{E}_1 = \mathcal{O}(\Delta t)$, and (from the analysis carried out in section 4.1) $\mathrm{E} = \mathcal{O}(\Delta t)$, so that the thesis is proven. □

In order to have better insight to the benefits introduced by the pressure correction, let us suppose that, besides the Neumann expansion (5.4), it is possible to also expand $(\mathrm{I}_{N_p} + \mathrm{E}_2)^{-1}$, where $\mathrm{E}_2 = \mathrm{S}^{-1}\mathrm{W}$: $(\mathrm{I}_{N_p} + \mathrm{E}_2)^{-1} = \sum_{i=0}^{\infty}(-\mathrm{E}_2)^i$. This still makes sense since also E_2 is $\mathcal{O}(\Delta t)$. Exploiting the Neumann expansions and recalling (4.8), we have

$$\begin{aligned}
&\mathrm{E}_{YPC} = \mathrm{S}\left(\mathrm{I}_{N_p} + \mathrm{E}_2\right)^{-1} - \mathrm{DH}\left(\mathrm{I}_{N_\mathbf{u}} + \mathrm{E}_1\right)^{-1}\mathrm{D}^T \\
&= \mathrm{S}\left(\mathrm{I}_{N_p} - \boxed{\mathrm{E}_2 - \mathrm{E}_2^2 + \mathcal{O}(\Delta t^3)}\right) - \mathrm{DH}\left(\mathrm{I}_{N_\mathbf{u}} - \mathrm{E}_1 - E_1^2 + \mathcal{O}(\Delta t^3)\right)\mathrm{D}^T.
\end{aligned}$$

The boxed terms are the contribution of the error due to the pressure correction; i.e., they were absent in the original Yosida scheme. This is to outline how the pressure correction acts. Indeed, by recalling the definition of E_1 and E_2 in (3.5) and (4.7), the first two terms of the two Neumann expansions cancel themselves (in the original Yosida scheme only the first ones were canceled), yielding

$$\mathrm{E}_{YPC} = -\mathrm{DHKH}\left(\mathrm{I}_{N_{\mathbf{u}}} - \mathrm{D}^T\mathrm{S}^{-1}\mathrm{DH}\right)\mathrm{KHD}^T + \mathcal{O}(\Delta t^4),$$

the first term being $\mathcal{O}(\Delta t^3)$, as already proved. Observe that the matrix in brackets in this term is the same one investigated in Lemma 4.1, and its spectral radius is therefore 1.

Remark. From the expression of the splitting error (5.3) and Proposition 4.2 it follows that also for the YPC scheme *the splitting error vanishes* whenever $\mathrm{KHD}^T = \nu\mathrm{D}^T\mathrm{M}_p^{-1}\mathrm{DHD}^T$.

5.1.2. Stability analysis. A different formulation of the matrix E_{YPC} is needed in order to carry out a stability analysis. Let us introduce the QR factorization (remember that H is s.p.d.) $\mathrm{H}^{1/2}\mathrm{D}^T = \mathrm{UR}$, where U is an orthogonal square ($N_{\mathbf{u}}\times N_{\mathbf{u}}$) matrix, and, if the inf-sup condition holds, R is a triangular full-rank $N_{\mathbf{u}} \times N_p$ matrix such that $\mathrm{R} = \left[\begin{smallmatrix}\mathrm{R}_0\\ \mathbf{0}\end{smallmatrix}\right]$, where R_0 is nonsingular and square ($N_p \times N_p$). In this way, we have the Cholesky factorization $\mathrm{S} = \mathrm{R}_0^T\mathrm{R}_0$. Matrix $\mathrm{SB}^{-1}\mathrm{S}$ therefore reads

$$\begin{aligned}\mathrm{SB}^{-1}\mathrm{S} &= \mathrm{S}\left(\mathrm{DHCHD}^T\right)^{-1}\mathrm{S}\\ &= \mathrm{R}_0^T\mathrm{R}_0\left(\mathrm{R}^T\mathrm{U}^T\mathrm{H}^{1/2}\left(\mathrm{H}^{-1}+\mathrm{K}\right)\mathrm{H}^{1/2}\mathrm{UR}\right)^{-1}\mathrm{R}_0^T\mathrm{R}_0\\ &= \mathrm{R}_0^T\left(\mathrm{R}_0^{-T}\mathrm{R}^T\mathrm{U}^T\mathrm{H}^{1/2}\left(\mathrm{H}^{-1}+\mathrm{K}\right)\mathrm{H}^{1/2}\mathrm{URR}_0^{-1}\right)^{-1}\mathrm{R}_0\\ &= \mathrm{R}_0^T\left(\begin{bmatrix}\mathrm{I}_{N_p} & \mathbf{0}\end{bmatrix}\left(\mathrm{I}_{N_{\mathbf{u}}}+\mathrm{U}^T\mathrm{H}^{1/2}\mathrm{KH}^{1/2}\mathrm{U}\right)\begin{bmatrix}\mathrm{I}_{N_p} & \mathbf{0}\end{bmatrix}^T\right)^{-1}\mathrm{R}_0.\end{aligned} \tag{5.6}$$

Matrix Σ, on the other hand, can be resorted as follows:

$$\begin{aligned}&\Sigma = \mathrm{D}\left(\mathrm{H}^{-1}+\mathrm{K}\right)^{-1}\mathrm{D}^T = \mathrm{DH}^{1/2}\left(\mathrm{I}_{N_{\mathbf{u}}}+\mathrm{H}^{1/2}\mathrm{KH}^{1/2}\right)^{-1}\mathrm{H}^{1/2}\mathrm{D}^T\\ &= \mathrm{R}^T\mathrm{U}^T\left(\mathrm{I}_{N_{\mathbf{u}}}+\mathrm{H}^{1/2}\mathrm{KH}^{1/2}\right)^{-1}\mathrm{UR} = \begin{bmatrix}\mathrm{R}_0^T & \mathbf{0}\end{bmatrix}\left(\mathrm{I}_{N_{\mathbf{u}}}+\mathrm{U}^T\mathrm{H}^{1/2}\mathrm{KH}^{1/2}\mathrm{U}\right)^{-1}\begin{bmatrix}\mathrm{R}_0^T & \mathbf{0}\end{bmatrix}^T.\end{aligned} \tag{5.7}$$

Now set $\mathrm{N} = \mathrm{I}_{N_{\mathbf{u}}} + \mathrm{U}^T\mathrm{H}^{1/2}\mathrm{KH}^{1/2}\mathrm{U}$, and since N is s.p.d., we denote

$$\mathrm{N} = \begin{bmatrix}\mathrm{N}_{11} & \mathrm{N}_{12}\\ \mathrm{N}_{12}^T & \mathrm{N}_{22}\end{bmatrix},$$

where N_{11} is $N_p \times N_p$ and N_{22} is $(N_{\mathbf{u}} - N_p) \times (N_{\mathbf{u}} - N_p)$. Observe that, in the case of the Stokes problem (i.e., K is s.p.d.), from the Sylvester criterion both the diagonal blocks are s.p.d. With these positions, we have that

$$\mathrm{SQ} - \Sigma = \mathrm{R}_0^T\left(\mathrm{N}_{11}^{-1} - \left(\mathrm{N}_{11} - \mathrm{N}_{12}\mathrm{N}_{22}^{-1}\mathrm{N}_{12}^T\right)^{-1}\right)\mathrm{R}_0. \tag{5.8}$$

Observe that also matrix $\mathrm{N}_{11} - \mathrm{N}_{12}\mathrm{N}_{22}^{-1}\mathrm{N}_{12}^T$ is s.p.d., being the first $N_p \times N_p$ block component of the inverse of N.

Since N_{11} is s.p.d., we can rearrange the previous matrix in the following way:

$$\mathrm{SQ} - \Sigma = \mathrm{R}_0^T\mathrm{N}_{11}^{-1/2}\left(\mathrm{I}_{N_p} - \left(\mathrm{I}_{N_p} - \mathrm{N}_{11}^{-1/2}\mathrm{N}_{12}\mathrm{N}_{22}^{-1}\mathrm{N}_{12}^T\mathrm{N}_{11}^{-1/2}\right)^{-1}\right)\mathrm{N}_{11}^{-1/2}\mathrm{R}_0. \tag{5.9}$$

Starting from this reformulation of the error matrix, unfortunately we are not able to prove an unconditional stability result, even for the Stokes problem with an implicit Euler time discretization. Indeed, we have the following results.

Proposition 5.2. *In the Stokes case, discretized with the implicit Euler scheme, error matrix* $\mathrm{SQ} - \Sigma$ *is symmetric and negative semidefinite.*

Proof. Resorting to (5.9), consider the following scalar product:

$$s = \mathbf{x}^T \mathrm{R}_0^T \mathrm{N}_{11}^{-1/2} \left(\mathrm{I}_{N_p} - \left(\mathrm{I}_{N_p} - \mathrm{N}_{11}^{-1/2} \mathrm{N}_{12} \mathrm{N}_{22}^{-1} \mathrm{N}_{12}^T \mathrm{N}_{11}^{-1/2} \right)^{-1} \right) \mathrm{N}_{11}^{-1/2} \mathrm{R}_0 \mathbf{x}.$$

We prove that $s \leq 0$ for each $\mathbf{x} \in \mathbb{R}^{N_p}$. Set $\mathrm{V} = \mathrm{N}_{11}^{-1/2} \mathrm{N}_{12} \mathrm{N}_{22}^{-1} \mathrm{N}_{12}^T \mathrm{N}_{11}^{-1/2}$ and $\mathrm{J} = \left(\mathrm{I}_{N_p} - \mathrm{V} \right)^{-1}$. As previously pointed out, J is s.d.p. The thesis amounts therefore to prove that $\mathrm{I}_{N_p} - \mathrm{J}$ is negative semidefinite. First of all, observe that if we set $\mathbf{v} = \mathrm{J}\mathbf{y}$, we obtain by definition $\mathbf{v} - \mathrm{V}\mathbf{v} = \mathbf{y} \Rightarrow \mathrm{J}\mathbf{y} - \mathrm{VJ}\mathbf{y} = \mathbf{y} \Rightarrow \left(\mathrm{I}_{N_p} - \mathrm{J} \right) \mathbf{y} = -\mathrm{VJ}\mathbf{y}$. Therefore, since J is s.d.p. we get, with obvious notation, $s = -\mathbf{y}^T \mathrm{VJ} \mathbf{y} = -\mathbf{y}^T \mathrm{J}^{1/2} \mathrm{J}^{-1/2} \mathrm{V} \mathrm{J}^{1/2} \mathrm{J}^{1/2} \mathbf{y} = -\mathbf{z}^T \mathrm{J}^{-1/2} \mathrm{V} \mathrm{J}^{1/2} \mathbf{z}$, where $\mathbf{y} = \mathrm{N}_{11}^{-1/2} \mathrm{R}_0 \mathbf{x}$ and $\mathbf{z} = \mathrm{J}^{1/2} \mathbf{y}$. Since V and J are both symmetric and, by construction, share the same set of orthogonal eigenvectors, it is possible to verify that $\mathbf{z}^T \mathrm{J}^{-1/2} \mathrm{V} \mathrm{J}^{1/2} \mathbf{z} \geq 0$, yielding the thesis. □

The previous result is negative in view of the stability analysis of the scheme. Actually, it implies that the scheme introduces a mass source in the fluid. This clearly reflects negatively on the stability of the scheme.

Proposition 5.3. *In the case of the Stokes problem discretized in time with the implicit Euler method, the YPC scheme is conditionally stable.*

Proof. The YPC scheme associated with a backward Euler time discretization, in a homogeneous Dirichlet case with null forcing terms, resorts to solve at each time step the following system:

$$\left[\begin{array}{cc} \mathrm{C} & \mathrm{D}^T \\ -\mathrm{D} & \mathrm{SQ} - \Sigma \end{array} \right] \left[\begin{array}{c} \mathbf{U}^{n+1} \\ \mathbf{P}^{n+1} \end{array} \right] = \left[\begin{array}{c} \dfrac{1}{\Delta t} \mathrm{M} \mathbf{U}^n \\ \mathbf{0} \end{array} \right].$$

The conditional stability is proved by multiplying the two sides by $\left[\mathbf{U}^{n+1} \mathbf{P}^{n+1} \right]^T$ and applying the Young inequality. We obtain, indeed,

$$\frac{1}{2\Delta t} \mathbf{U}^{n+1} \mathrm{M} \mathbf{U}^{n+1} + \mathbf{U}^{n+1} \mathrm{K} \mathbf{U}^{n+1} - \left| \mathbf{P}^{n+1} \left(\mathrm{SQ} - \Sigma \right) \mathbf{P}^{n+1} \right| \leq \frac{1}{2\Delta t} \mathbf{U}^n \mathrm{M} \mathbf{U}^n.$$

Since $\mathrm{SQ} - \Sigma$ vanishes when Δt tends to zero, it is possible to select a time step Δt_{max} such that for each $\Delta t \leq \Delta t_{max}$ we have $\mathbf{U}^{n+1} \mathrm{K} \mathbf{U}^{n+1} - \left| \mathbf{P}^{n+1} \left(\mathrm{SQ} - \Sigma \right) \mathbf{P}^{n+1} \right| \geq 0$, yielding the (conditional) stability of the scheme. □

The actual impact of this conditional stability on numerical results will be discussed in section 6.

Remark. In [27] the use of inexact algebraic factorizations (Yosida and ACT without pressure corrections) as preconditioners for the Navier–Stokes problem has been extensively investigated. Following the same idea, the inexact factorizations with pressure corrections can be used in the same fashion. The outcome is a fast preconditioner which seems to be an effective generalization of the well-known Cahouet–Chabard preconditioner for the Stokes problem. Preliminary numerical results about this preconditioner can be found in [9].

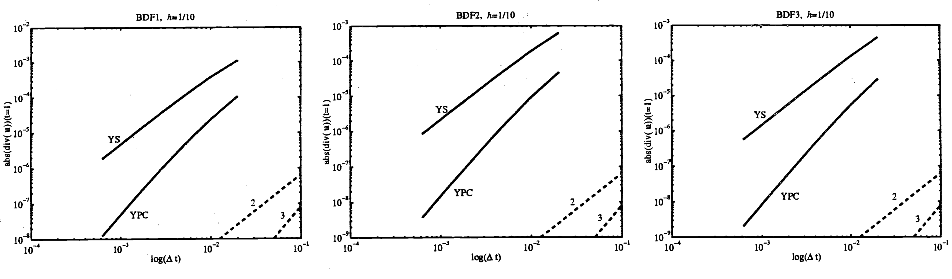

FIG. 6.1. *Divergence of the computed velocity field at $T_f = 1$ for different values of Δt. Comparison between the YS and YPC schemes with a BDF1 (left), a BDF2 (center), and a BDF3 (right) time discretization scheme.*

6. Numerical results. In this section we present some numerical results[1] that confirm the analysis carried out above and give a deeper insight into the real accuracy and stability properties of the methods presented. In particular, we consider BDF schemes of order 1, 2, and 3, both in the *nonincremental* and *incremental* formulations. In particular, in the incremental case, we refer to the approach proposed in [15], with a pressure increment as in (2.9) for a BDF of order 2 and as in (2.10) for a BDF of order 3 (see the remark above (2.8)).

We refer to the two-dimensional nonlinear Navier–Stokes problem on the unit domain $(0,1)^2$ in the time interval $(0,1)$ where (time-dependent) Dirichlet boundary conditions for the velocity, initial conditions, and the forcing term are prescribed in such a way that the analytical solution is (see [11])

$$\mathbf{u}(x,y,t) = (\sin(x)\sin(y+t), \cos(x)\cos(y+t))^T, \ p(x,y,t) = \cos(x)\sin(y+t).$$

Similar results have been obtained also for other test cases, such as the Kim and Moin (see [17]) and the Timmermans (see [26]) cases.

For what concerns the space-discretization, we have adopted an *inf-sup* compatible couple of finite element spaces. In particular, for the numerical results of the present section, we resorted to a piecewise linear functions space $\mathbf{P}^1$ for the pressure fields, and we have used $\tilde{\mathbf{P}}^2 = \mathbf{P}^2 \oplus b$ finite elements for each component of the velocity, where b is a cubic bubble function. Following [4], the role of the bubble function is to give nonsingular (velocity) mass lumped matrices, which is useful in solving systems for matrix S.

Mass conservation and pressure errors (Yosida and YPC schemes). We start focusing our attention on the Yosida (denoted by YS) and YPC schemes. In particular, we consider the divergence of the velocity field computed by the two schemes at the final time ($T_f = 1$). From the analysis of section 5.1, the first effect of the pressure correction is to modify the dependence on Δt of the residual of the mass equation, which changes from $\mathcal{O}(\Delta t^2)$ to $\mathcal{O}(\Delta t^3)$, independently of the time discretization adopted. This is clearly confirmed by Figure 6.1, where for the three different orders of BDF schemes the divergence of the velocity field is computed for several time step sizes. The effect of the pressure correction is evident. The circumstance that the divergence of the computed velocity (independently of the time discretization scheme) is $\mathcal{O}(\Delta t^3)$

[1] Numerical results of the present section have been obtained with a MATLAB code developed by the authors.

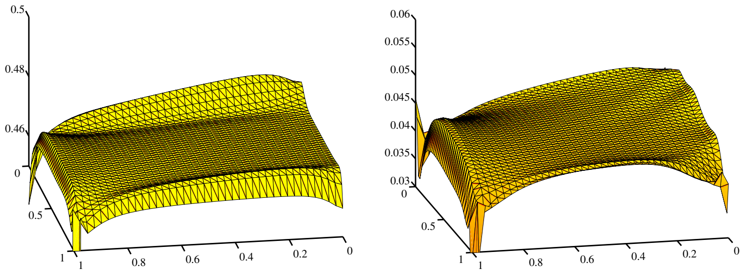

Fig. 6.2. *Space distribution of the pressure error for the YS (left) and the YPC (right) schemes.*

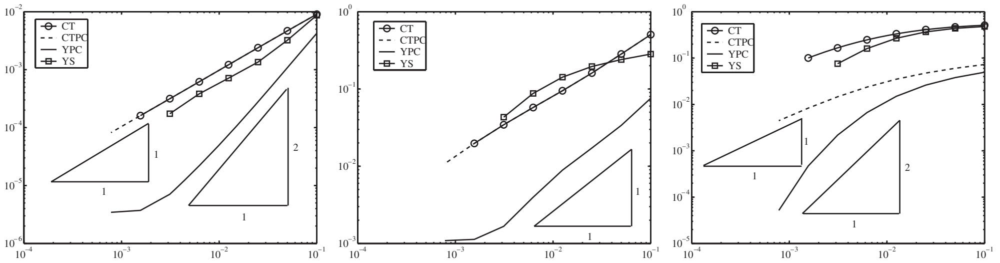

Fig. 6.3. *Errors in the* $L^\infty(\mathbf{L}^2)$*(left) and* $L^2(\mathbf{H}^1)$*(center) norms for the velocity and in the* $L^2(L^2)$*norm for the pressure (right) in the case of* BDF2 nonincremental *time discretization. Note that in all the figures presented in this section the error reduction with the time step stops whenever the error is completely due to the space discretization.*

is shared also by other schemes proposed in the differential splitting framework, which are an evolution of the Timmermans scheme (see [13] and also [12]).

Another way of investigating the effect of the pressure correction is to check the space distribution of the pressure error (see Figure 6.2). From this picture we infer that in the algebraic approach we actually do not have significant boundary layers for the pressure error (which is the case of "standard" differential splitting techniques), and this is particularly true for the pressure corrected scheme, whose associated error is significantly smaller than in the uncorrected case.

*Accuracy tests (BDF*2 *and BDF*3*).* We compare the numerical results obtained for $h = 1/40$ for different sizes of the time step. We consider, in particular, BDF time discretization schemes of order 2 and 3. The errors have been computed with respect to the norms $L^\infty(0,T,L^2(\Omega)\times L^2(\Omega)$ and $L^2(0,T,H^1(\Omega)\times H^1(\Omega))$ for the velocity and $L^2(0,T,L^2(\Omega))$ for the pressure. (In what follows, these norms will be denoted $L^\infty(\mathbf{L}^2)$, $L^2(\mathbf{H}^1)$, and $L^2(L^2)$, respectively.)

In Figure 6.3 we illustrate the results for the BDF2 *nonincremental* schemes. Results suggest that the pressure correction has a relevant effect for the YS, both for the velocity and the pressure. For the (algebraic) Chorin–Temam scheme (denoted by CT in the figures), the pressure correction gives a significant improvement only on the pressure. In particular, in the $L^\infty(\mathbf{L}^2)$norm, YPC exhibits a second order of accuracy which is not shared by the other schemes (in particular CTPC). In the $L^2(\mathbf{H}^1)$norm all the schemes are first order accurate, even if YPC features an error significantly lower than the others. For the pressure, results suggest that YPC is asymptotically second order accurate, while CTPC seems to be first order, even if there is an evident

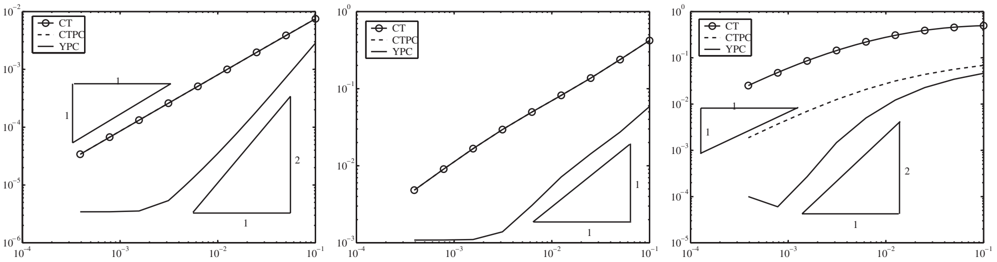

FIG. 6.4. *Errors in the* $L^\infty(\mathbf{L}^2)$*(left) and* $L^2(\mathbf{H}^1)$*(center) norms for the velocity and in the* $L^2(L^2)$*(right) norm for the pressure in the case of* BDF3 nonincremental *time discretization.*

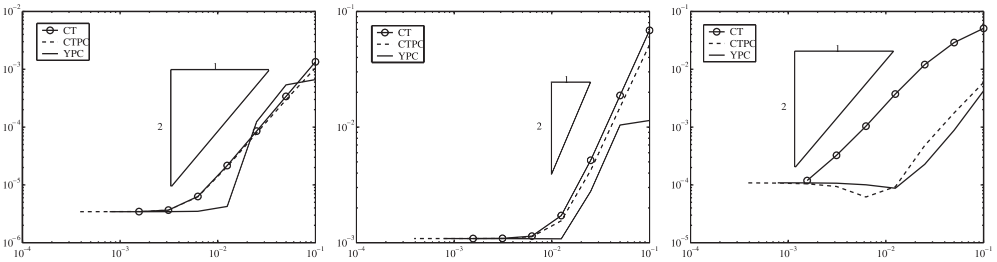

FIG. 6.5. *Errors in the* $L^\infty(\mathbf{L}^2)$*(left) and* $L^2(\mathbf{H}^1)$*(center) norms for the velocity and in the* $L^2(L^2)$*norm for the pressure (right) in the case of* BDF2 incremental *time discretization.*

error reduction with respect to the uncorrected CT scheme.

In Figure 6.4 numerical results for the BDF3 *nonincremental* schemes are reported. For what concerns the convergence order, we observe that it is substantially unchanged with respect to the case of a BDF2 time discretization. In particular, CTPC is first order accurate with respect to all the monitored norms (even if the pressure is by far more accurate with respect to the CT scheme), while YPC is second order accurate in the $L^\infty(\mathbf{L}^2)$(velocity) and $L^2(L^2)$(pressure) norms. It is first order accurate in the $L^2(\mathbf{H}^1)$norm of the velocity error. This means that the pressure correction by itself yields a splitting error $\mathcal{O}(\Delta t^2)$ which therefore does not affect the accuracy of a BDF2 time discretization, while it reduces the accuracy of the BDF3 one. It is, however, worthwhile to point out that the errors in the BDF3 case are slightly lower than the corresponding ones of the BDF2 case.

Now, let us consider the *incremental* case (see the remark above (2.8)). In Figure 6.5 we present the results of an BDF2 incremental scheme with a first order pressure extrapolation. Numerical results suggest that the method is second order accurate with respect to all the norms considered here. Actually, the improvements given by the pressure correction are minimal on the velocity for the CTPC scheme and more significant, if Δt is sufficiently small, for the YPC scheme. Pressure correction yields a relevant improvement of the solution on the pressure solution for both CTPC and YPC. For large values of Δt, YPC exhibits some strange behavior which is probably due to the poor stability properties of the method.

Specific considerations have to be deserved to the case of BDF3 incremental version. From the numerical results presented in Figure 6.6 we observe the following:

1. The uncorrected YS method in fact is second order accurate for the velocity and third order accurate for the pressure.

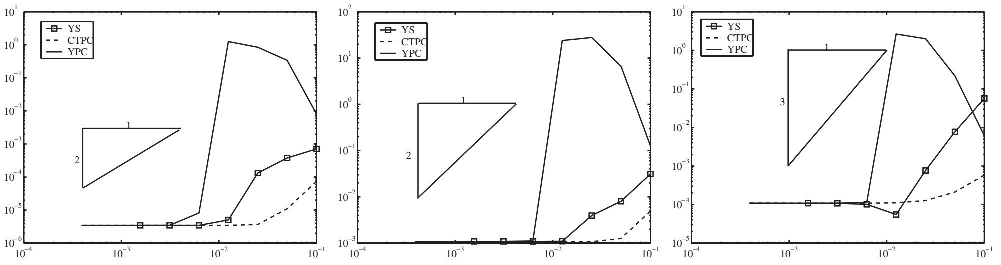

FIG. 6.6. *Errors in the* $L^\infty(\mathbf{L}^2)$*(left) and* $L^2(\mathbf{H}^1)$*(center) norms for the velocity and in the* $L^2(L^2)$*norm for the pressure (right) in the case of* BDF3 incremental *time discretization.*

2. The CTPC scheme features very good results also for large values of the time step, in such a way that it is difficult to draw an order of accuracy.
3. The YPC method has a strange behavior when Δt is large, which is probably induced by numerical instability. Surprisingly enough, under a threshold on the time step (which in our simulations is about 10^{-2}) the scheme is extremely accurate, reducing immediately the error to the contribution of the space discretization solely. We guess that in this case YPC is affected by some instabilities possibly due to the combination of the conditional stability of the BDF3 and of the YPC scheme. Further numerical investigations will be carried out for a deeper analysis of this circumstance.

Remark. The pressure correction yields improvements in the accuracy of the solution in particular on the pressure field. However, the computational cost is clearly increasing, since we need to solve two linear systems for S, rather than one. This increment can be reduced (at least in two-dimensional problems) by resorting to a direct method of solution. Since H is a s.p.d. matrix, we exploit the QR factorization $\mathrm{H}^{1/2}\mathrm{D}^T = \mathrm{QR}$, where Q is an orthogonal square ($N_{\mathbf{u}} \times N_{\mathbf{u}}$) matrix and, if the inf-sup condition holds, R is a triangular full-rank $N_{\mathbf{u}} \times N_p$ matrix such that $\mathrm{R} = \left[\mathrm{R}_0^T \; \mathbf{0}\right]^T$, where R_0 is a nonsingular $N_p \times N_p$ triangular matrix. In this way, $\mathrm{S} = \mathrm{R}_0^T\mathrm{R}_0$, yielding the Cholesky factorization of S. In this way, the solution for the system in S reduces to the solution of two triangular systems, whose computational cost is significantly lower. (For more details, see [27] and [19].) Another possibility for three-dimensional computations (see [2], [8]) is based on the idea of extracting at a given time step relevant information on the solution from the previous systems solved that share the same matrix S.

7. Conclusions and future developments. In this paper we introduce a new family of methods for the Navier–Stokes equations, based on a pressure correction step. The idea of pressure correction has already been introduced in the framework of differential schemes (Timmermans scheme), but it is new in the field of algebraic splitting. We give a mathematical basis to this approach and numerically verify that it actually improves solutions, yielding a reduction of the errors or even, in some cases, an increment of the accuracy order. The latter conclusion holds true in particular for the YPC scheme. The accuracy improvement, however, seems limited to the second order, at least in the nonincremental approach.

The pressure correction with a BDF3 incremental time advancing gives interesting results in the case of the CTPC scheme. While in all the other cases this method was usually worse than the YPC, in this case it exhibits good results that need to be investigated further. YPC features very good results in the nonincremental approach. On the other hand, whenever it is coupled with the incremental approach it can be unstable. In fact, we proved that YPC is only conditional stable, but with the nonincremental formulation we actually never observed numerical instabilities in a reasonable range for the time step sizes. Actually, it seems that the incremental approach can be somehow less stable. Moreover, it is worthwhile to mention that from preliminary numerical results the stability bound on Δt in the BDF3 incremental time advancing is proportional to the inverse of the viscosity. For low values of the viscosity (which means for high Reynolds numbers) our conjecture is that the stability bound becomes less restrictive. This observation is in agreement with the circumstance that the use of YPC as a preconditioner of the Navier–Stokes solver is well suited in particular for low viscosity problems (see [9] and also [7]). A more specific stability analysis for this scheme and, in particular, the role of the incremental formulation will be, however, the subject of a future development of this work.

SYMMETRIC AND NONSYMMETRIC DISCONTINUOUS GALERKIN METHODS FOR REACTIVE TRANSPORT IN POROUS MEDIA[*]

SHUYU SUN[†] AND MARY F. WHEELER[‡]

Abstract. For solving reactive transport problems in porous media, we analyze three primal discontinuous Galerkin (DG) methods with penalty, namely, symmetric interior penalty Galerkin (SIPG), nonsymmetric interior penalty Galerkin (NIPG), and incomplete interior penalty Galerkin (IIPG). A cut-off operator is introduced in DG to treat general kinetic chemistry. Error estimates in $L^2(H^1)$ are established, which are optimal in h and nearly optimal in p. We develop a parabolic lift technique for SIPG, which leads to h-optimal and nearly p-optimal error estimates in the $L^2(L^2)$ and negative norms. Numerical results validate these estimates. We also discuss implementation issues including penalty parameters and the choice of physical versus reference polynomial spaces.

1. Introduction.

Discontinuous Galerkin (DG) methods employ discontinuous piecewise polynomials to approximate the solutions of differential equations, with boundary conditions and interelement continuity weakly imposed through bilinear forms. Even though they often have larger numbers of degrees of freedom than conforming approaches, DG methods have recently gained popularity for a number of attractive features [19, 3, 4, 23, 27, 11, 25, 26, 9, 18, 15]: (1) they are element-wise conservative; (2) they support general nonconforming spaces including unstructured meshes, nonmatching grids and variable degrees of local approximations, thus allowing efficient h-, p-, and hp-adaptivities; (3) they tend to have localized errors, allowing sharp *a posteriori* error indicators and effective adaptivities; (4) they have less numerical diffusion; (5) they treat rough coefficient problems and effectively capture discontinuities in solutions; (6) they are robust and nonoscillatory in the presence of high gradients; (7) with appropriate meshing, they are capable of delivering exponential rates of convergences; (8) they have excellent parallel efficiency since data communications are relatively local; (9) for time-dependent problems in particular, their mass matrices are block diagonal, providing substantial computational advantages if explicit time integrations are used. In addition, by a simple extension from the average of the fluxes on element faces, DG can provide a continuous flux field defined over the entire domain, allowing efficient coupling with conforming methods.

Numerical modeling of reactive transport in porous media has important applications in hydrology, earth sciences, environmental protection, oil recovery, chemical

industry, and biomedical engineering. Realistic simulations for simultaneous advection, diffusion, and chemical reactions present significant computational challenges [2, 40, 10, 14, 24, 37, 41, 28, 7, 16, 8]. Recently, it has been shown that adaptive DG can effectively capture moving concentration fronts in reactive transport [31, 33, 36, 32, 29]. A posteriori error estimates of DG for reactive transport problems have been derived in the $L^2(L^2)$ [32] and $L^2(H^1)$ norms [35]. In addition, DG has been applied to coupled flow and transport problems in porous media [34, 39, 30]. However, to the best of our knowledge, optimal a priori *hp*-estimates in the $L^2(L^2)$ and negative norms have not been established.

The primal DG methods include four members: Oden–Babuška–Baumann DG (OBB-DG) formulation [19], symmetric interior penalty Galerkin (SIPG) [38], nonsymmetric interior penalty Galerkin (NIPG) [23, 21], and incomplete interior penalty Galerkin (IIPG) [12, 29]. In this paper, we analyze the three primal DG methods with penalty, i.e., SIPG, NIPG, and IIPG, for solving reactive transport problems in porous media. The primal DG method without penalty, i.e., the OBB-DG scheme, has been analyzed for reactive transport problems elsewhere [22]. In the following section, we describe the modeling equations. The DG schemes are introduced in section 3. Section 4 contains the $L^2(H^1)$ error analysis for SIPG, NIPG, and IIPG. In section 5, a parabolic lift technique is developed, and an $L^2(L^2)$ error analysis for SIPG is conducted. Optimal negative norm estimates are derived in section 6. In section 7, we present numerical studies of *h*- and *p*-convergences for the four primal DG schemes. In section 8, we discuss choices of penalty parameters as well as DG implementations using reference versus physical polynomial spaces. Conclusions are given in the last section.

2. Governing equations. For convenience of presentation, we consider reactive transport problems of only one species in a single flowing phase in porous media. Results for systems of multiple species with kinetic reactions can be derived by similar arguments. We assume that a Darcy velocity field $\mathbf{u}$ is given and time-independent, and satisfies $\nabla \cdot \mathbf{u} = q$, where q is the imposed external total flow rate. In addition, we assume that Ω is a polygonal and bounded domain in $\mathbb{R}^d$ ($d = 1$, 2, or 3) with boundary $\partial\Omega = \overline{\Gamma}_{\text{in}} \cup \overline{\Gamma}_{\text{out}}$. Here we denote by Γ_{in} the inflow boundary and by Γ_{out} the outflow/no-flow boundary, i.e.,

$$\Gamma_{\text{in}} := \{x \in \partial\Omega : \ \mathbf{u} \cdot \mathbf{n} < 0\},$$
$$\Gamma_{\text{out}} := \{x \in \partial\Omega : \ \mathbf{u} \cdot \mathbf{n} \geq 0\},$$

where $\mathbf{n}$ denotes the unit outward normal vector to $\partial\Omega$. Let T be the final simulation time. The classical advection-diffusion-reaction equation in porous media is given by

$$(2.1) \qquad \frac{\partial \phi c}{\partial t} + \nabla \cdot (\mathbf{u}c - \mathbf{D}(\mathbf{u})\nabla c) = qc^* + r(c), \quad (x,t) \in \Omega \times (0,T],$$

where the unknown variable c is the concentration of a species (amount per volume). Here ϕ is the effective porosity and is assumed to be time-independent, uniformly bounded above and below by positive numbers; $\mathbf{D}(\mathbf{u})$ is the dispersion-diffusion tensor and is assumed to be uniformly symmetric positive definite and bounded from above; $r(c)$ is the reaction term; qc^* is the source term, where the imposed external total flow rate q is a sum of sources (injection) and sinks (extraction); c^* is the injected concentration c_w if $q \geq 0$ and is the resident concentration c if $q < 0$.

We consider the following boundary conditions for this problem:

$$(\mathbf{u}c - \mathbf{D}(\mathbf{u})\nabla c)\cdot \mathbf{n} = c_B \mathbf{u}\cdot\mathbf{n}, \qquad (x,t) \in \Gamma_{\text{in}} \times (0,T], \tag{2.2}$$

$$(-\mathbf{D}(\mathbf{u})\nabla c)\cdot \mathbf{n} = 0, \qquad (x,t) \in \Gamma_{\text{out}} \times (0,T], \tag{2.3}$$

where c_B is the inflow concentration. The initial concentration is specified by

$$c(x,0) = c_0(x), \qquad x \in \Omega. \tag{2.4}$$

3. Discontinuous Galerkin schemes.

3.1. Notation. Let $\mathcal{E}_h$ be a family of nondegenerate, quasi-uniform and possibly nonconforming partitions of Ω composed of triangles or quadrilaterals if $d = 2$, or tetrahedra, prisms, or hexahedra if $d = 3$. The nondegeneracy requirement (also called regularity) is that the element is convex, and that there exists $\rho > 0$ such that if h_j is the diameter of $E_j \in \mathcal{E}_h$, then each of the subtriangles (for $d = 2$) or subtetrahedra (for $d = 3$) of element E_j contains a ball of radius ρh_j in its interior. The quasi-uniformity requirement is that there is $\tau > 0$ such that $(h/h_j) \le \tau$ for all $E_j \in \mathcal{E}_h$, where h is the maximum diameter of all elements. We assume that no element crosses the boundaries of Γ_{in} or Γ_{out}. The set of all interior edges (for $d = 2$) or faces (for $d = 3$) for $\mathcal{E}_h$ is denoted by Γ_h. On each edge or face $\gamma \in \Gamma_h$, a unit normal vector $\mathbf{n}_\gamma$ is chosen. The sets of all edges or faces on Γ_{out} and on Γ_{in} for $\mathcal{E}_h$ are denoted by $\Gamma_{h,\text{out}}$ and $\Gamma_{h,\text{in}}$, respectively, for which the normal vector $\mathbf{n}_\gamma$ coincides with the outward unit normal vector.

We now define the average and jump for $\phi \in H^s(\mathcal{E}_h)$, $s > 1/2$. Let $E_i, E_j \in \mathcal{E}_h$ and $\gamma = \partial E_i \cap \partial E_j \in \Gamma_h$ with $\mathbf{n}_\gamma$ exterior to E_i. We denote

$$\{\phi\} := \frac{1}{2}((\phi|_{E_i})|_\gamma + (\phi|_{E_j})|_\gamma), \qquad [\phi] := (\phi|_{E_i})|_\gamma - (\phi|_{E_j})|_\gamma.$$

The upwind value of a concentration $c^*|_\gamma$ is defined as

$$c^*|_\gamma := \begin{cases} c|_{E_i} & \text{if } \mathbf{u}\cdot\mathbf{n}_\gamma \ge 0, \\ c|_{E_j} & \text{if } \mathbf{u}\cdot\mathbf{n}_\gamma < 0. \end{cases}$$

We denote by $\|\cdot\|_{m,R}$ the usual Sobolev norm over a domain R [1]. The Sobolev norm $\|\cdot\|_{m,\Omega}$ over the entire domain Ω is also denoted simply by $\|\cdot\|_m$. For $s \ge 0$, we define the broken Sobolev space

$$H^s(\mathcal{E}_h) := \{\phi \in L^2(\Omega) : \ \phi|_E \in H^s(E), \ E \in \mathcal{E}_h\}.$$

One can show that $H^s(\mathcal{E}_h)$ is a normed linear space with its norm defined by

$$\|\phi\|_{H^s(\mathcal{E}_h)} := \left(\sum_{E\in\mathcal{E}_h} \|\phi\|^2_{s,E} \right)^{1/2}.$$

Following the tradition, we also use the notation $|\!|\!| \cdot |\!|\!|_s$ to denote the broken norm $\|\cdot\|_{H^s(\mathcal{E}_h)}$. For a given normed space X and a number $p \ge 1$, we define

$$L^p(0,T;X) := \{\phi : \ \phi(t) \in X, \|\phi\|_X \in L^p(0,T)\}.$$

The space $L^p(0,T;X)$ is also a normed linear space with its norm given by

$$\|\phi\|_{L^p(0,T;X)} := \|(\|\phi\|_X)\|_{L^p(0,T)}.$$

The broken norm $\|\cdot\|_{L^p(0,T;H^s(\mathcal{E}_h))}$ is also written as $|\!|\!|\cdot|\!|\!|_{L^p(0,T;H^s)}$ in the triple bar notation. We denote by $(\cdot,\cdot)_R$ the inner product in $(L^2(R))^d$ or $L^2(R)$ over a domain R. The inner product $(\cdot,\cdot)_\Omega$ over the entire domain Ω is also denoted simply by $(\cdot,\cdot)$. We also need the space $W_\infty^{r,s}$ and its norm:

$$W_\infty^{r,s}((0,T)\times\Omega) := \{f \in L^2((0,T)\times\Omega) : \ \|f\|_{W_\infty^{r,s}} < \infty\},$$
$$\|f\|_{W_\infty^{r,s}} := \sum_{|\alpha|\le r,\, \beta\le s} \operatorname{ess\,sup}_{(0,T)\times\Omega}(|D_x^\alpha f| + |D_t^\beta f|).$$

The discontinuous finite element space is taken to be

$$\mathcal{D}_r(\mathcal{E}_h) := \{\phi \in L^2(\Omega) : \ \phi|_E \in \mathbb{P}_r(E), \ E \in \mathcal{E}_h\}, \tag{3.1}$$

where $\mathbb{P}_r(E)$ denotes the space of polynomials of (total) degree less than or equal to r on E. Note that we present *hp*-results in this paper for the local space $\mathbb{P}_r$, but the results also apply to the local space $\mathbb{Q}_r$ because $\mathbb{P}_r(E) \subset \mathbb{Q}_r(E)$.

We define a cut-off operator as

$$\mathcal{M}(c)(x) := \min(c(x), M), \tag{3.2}$$

where M is a large positive constant. By a straightforward algebraic argument, we can show that the cut-off operator $\mathcal{M}$ is uniformly Lipschitz continuous.

Lemma 1 (property of operator $\mathcal{M}$). *The cut-off operator $\mathcal{M}$ defined in* (3.2) *is uniformly Lipschitz continuous with a Lipschitz constant of one; that is,*

$$\|\mathcal{M}(c) - \mathcal{M}(w)\|_{L^\infty(\Omega)} \le \|c - w\|_{L^\infty(\Omega)}. \tag{3.3}$$

We use the following *hp*-approximation results, which can be proved using the techniques in [6, 5]. Let $E \in \mathcal{E}_h$ and $\phi \in H^s(E)$. Then there exists a constant K, independent of ϕ, r, and h_E, and a sequence of $z_r^h \in \mathbb{P}_r(E)$, $r = 1, 2, \ldots$, such that

$$\begin{cases} \left\|\phi - z_r^h\right\|_{q,E} \le K \dfrac{h_E^{\mu-q}}{r^{s-q}} \|\phi\|_{s,E}, & 0 \le q < \mu, \\ \left\|\phi - z_r^h\right\|_{q,\partial E} \le K \dfrac{h_E^{\mu-q-\frac{1}{2}}}{r^{s-q-\frac{1}{2}}} \|\phi\|_{s,E}, & 0 \le q < \mu - \frac{1}{2}, \end{cases} \tag{3.4}$$

where $\mu = \min(r+1, s)$ and h_E denotes the diameter of E.

We shall also use the following inverse inequalities, which can be derived using the method in [27]. Let $E \in \mathcal{E}_h$ and $v \in \mathbb{P}_r(E)$. Then there exists a constant K, independent of v, r, and h_E, such that

$$\begin{cases} \|D^q v\|_{0,\partial E} \le K \dfrac{r}{h_E^{1/2}} \|D^q v\|_E, & q \ge 0, \\ \|D^{q+1} v\|_{0,E} \le K \dfrac{r^2}{h_E} \|D^q v\|_{0,E}, & q \ge 0. \end{cases} \tag{3.5}$$

3.2. Continuous-in-time DG schemes. We introduce a bilinear form:

$$\begin{aligned} B(c, w; \mathbf{u}) := {} & \sum_{E\in\mathcal{E}_h} \int_E (\mathbf{D}(\mathbf{u})\nabla c - c\mathbf{u}) \cdot \nabla w - \int_\Omega c q^- w \\ & - \sum_{\gamma\in\Gamma_h} \int_\gamma \{\mathbf{D}(\mathbf{u})\nabla c \cdot \mathbf{n}_\gamma\}[w] - s_{\text{form}} \sum_{\gamma\in\Gamma_h} \int_\gamma \{\mathbf{D}(\mathbf{u})\nabla w \cdot \mathbf{n}_\gamma\}[c] \\ & + \sum_{\gamma\in\Gamma_h} \int_\gamma c^* \mathbf{u} \cdot \mathbf{n}_\gamma [w] + \sum_{\gamma\in\Gamma_{h,\text{out}}} \int_\gamma c\mathbf{u} \cdot \mathbf{n}_\gamma w + J_0^\sigma(c, w). \end{aligned}$$

Here $s_{\text{form}} = 1$ for SIPG; $s_{\text{form}} = -1$ for OBB-DG or NIPG; and $s_{\text{form}} = 0$ for IIPG. For convenience of presentation, we denote the bilinear form as $B_S(c, w; \mathbf{u})$ when it is symmetric, i.e., $s_{\text{form}} = 1$. We denote by q^+ the injection source term and by q^- the extraction source term, i.e., $q^+ = \max(q, 0)$ and $q^- = \min(q, 0)$. By definition, we have $q = q^+ + q^-$. To impose interelement continuity weakly, an interior penalty term $J_0^\sigma(c, w)$ is formulated:

$$J_0^\sigma(c, w) := \sum_{\gamma \in \Gamma_h} \frac{r^2 \sigma_\gamma}{h_\gamma} \int_\gamma [c][w], \tag{3.6}$$

where σ is a discrete positive function that takes the constant value σ_γ on the edge or face γ. There is no penalty term, i.e., $\sigma = 0$, for OBB-DG. In the analysis of SIPG, NIPG, and IIPG in this paper, we assume $0 < \sigma_0 \leq \sigma_\gamma \leq \sigma_m$. In addition we define a linear functional:

$$L(w; \mathbf{u}, c) := \int_\Omega r(\mathcal{M}(c)) w + \int_\Omega c_w q^+ w - \sum_{\gamma \in \Gamma_{h,\text{in}}} \int_\gamma c_B \mathbf{u} \cdot \mathbf{n}_\gamma w. \tag{3.7}$$

The reactive transport problem can be stated in the following equivalent weak formulation.

Lemma 2 (weak formulation). *If c is a solution of* (2.1)–(2.3) *and c is essentially bounded, then c satisfies*

$$\left(\frac{\partial \phi c}{\partial t}, w \right) + B(c, w; \mathbf{u}) = L(w; \mathbf{u}, c) \qquad \forall w \in H^s(\mathcal{E}_h),\ s > \frac{3}{2} \quad \forall t \in (0, T], \tag{3.8}$$

provided that the constant M for the cut-off operator is sufficiently large.

Proof. Let $w \in H^s(\mathcal{E}_h)$, $s > 3/2$ and $E \in \mathcal{E}_h$. Multiplying (2.1) by w, integrating over E, and then integrating by parts, we observe

$$\left(\frac{\partial \phi c}{\partial t}, w \right)_E - \int_E (\mathbf{u}c - \mathbf{D}(\mathbf{u}) \nabla c) \cdot \nabla w + \int_{\partial E} (\mathbf{u}c - \mathbf{D}(\mathbf{u}) \nabla c) \cdot \mathbf{n}_{\partial E} w = \int_E q c^* w + r(c) w.$$

Summing it over all elements in $\mathcal{E}_h$, noting the fact that the traces of the concentration and its normal flux are continuous across element faces, and applying the boundary conditions, we obtain the desired result. □

The continuous-in-time DG approximation $C^{DG}(\cdot, t) \in \mathcal{D}_r(\mathcal{E}_h)$ to the solution of (2.1)–(2.4) is defined by

$$\left(\frac{\partial \phi C^{DG}}{\partial t}, w \right) + B(C^{DG}, w; \mathbf{u}) = L(w; \mathbf{u}, C^{DG}) \qquad \forall w \in \mathcal{D}_r(\mathcal{E}_h) \quad \forall t \in (0, T], \tag{3.9}$$

$$(\phi C^{DG}, w) = (\phi c_0, w) \qquad \forall w \in \mathcal{D}_r(\mathcal{E}_h), \quad t = 0. \tag{3.10}$$

As a valuable property, DG schemes possess element-wise mass conservation. OBB-DG satisfies local conservation strictly, whereas SIPG, NIPG, and IIPG are locally conservative if the concentration jump term is considered as part of the computed diffusive flux:

Lemma 3 (local mass balance). *The approximation of the concentration satisfies on each element E the following local mass balance equation:*

$$\begin{aligned}(3.11)\qquad &\int_E \frac{\partial \phi C^{DG}}{\partial t} - \int_{\partial E\setminus\partial\Omega} \{\mathbf{D}(\mathbf{u})\nabla C^{DG}\cdot \mathbf{n}_{\partial E}\} + \int_{\partial E} C^{DG*}\mathbf{u}\cdot\mathbf{n}_{\partial E}\\ &+ \sum_{\gamma\subset\partial E\setminus\partial\Omega} \frac{r^2\sigma_\gamma}{h_\gamma}\int_\gamma (C^{DG}|_E - C^{DG}|_{\Omega\setminus\overline{E}})\\ &= \int_E C^{DG*}q + \int_E r(\mathcal{M}(C^{DG})).\end{aligned}$$

Proof. The relationship (3.11) follows immediately from the DG schemes by fixing an element E and letting $w \in \mathcal{D}_r(\mathcal{E}_h)$ with $w|_E = 1$, $w|_{\Omega\setminus E} = 0$. □

It is also important to know that a DG scheme has a solution.

Lemma 4 (existence of a solution). *Assume that the reaction rate is a locally Lipschitz continuous function of the concentration. Then the discontinuous Galerkin scheme* (3.9) *and* (3.10) *has a unique solution for $t > 0$.*

Proof. We let $\{v_i\}_{i=1}^M$ be a basis of $\mathcal{D}_r(\mathcal{E}_h)$ and write $C^{DG} = \sum_{i=1}^M \zeta_i(t)v_i(x)$. Then (3.9) and (3.10) reduce to the following initial value problem:

$$\begin{cases} A\dfrac{d\zeta}{dt} = -B\zeta + R(\zeta),\\ A\zeta(0) = b,\end{cases}$$

where the mass matrix A is block-diagonal, symmetric, and positive definite. From the properties of the cut-off operator $\mathcal{M}$ and the reaction function, we observe that $R(\zeta)$ is (globally) Lipschitz continuous. It follows from the theory of ordinary differential equations that $\zeta(t)$ exists and is unique for $t > 0$. □

4. $L^2(H^1)$ and $L^\infty(L^2)$ error estimates.

Throughout the paper, we denote by K a generic positive constant independent of h and r, and by ϵ a fixed positive constant that may be chosen arbitrarily small.

Theorem 1 ($L^2(H^1)$ and $L^\infty(L^2)$ error estimates). *Let c be the solution to* (2.1)–(2.4), *and assume $c \in L^2(0,T;H^s(\mathcal{E}_h))$, $\partial c/\partial t \in L^2(0,T;H^{s-1}(\mathcal{E}_h))$, and $c_0 \in H^{s-1}(\mathcal{E}_h)$. We further assume that c, $\mathbf{u}$ and q are essentially bounded, that the reaction rate is a locally Lipschitz continuous function of c, and that the cut-off constant M and the penalty parameter σ_0 are sufficiently large. Then there exists a constant K, independent of h and r, such that*

$$\begin{aligned}&\|C^{DG} - c\|_{L^\infty(0,T;L^2)} + \|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla(C^{DG} - c)\|_{L^2(0,T;L^2)}\\ &+\left(\int_0^T J_0^\sigma(C^{DG}-c, C^{DG}-c)\right)^{\frac{1}{2}}\\ &\le K\frac{h^{\mu-1}}{r^{s-1-\delta}}\|c\|_{L^2(0,T;H^s)} + K\frac{h^{\mu-1}}{r^{s-1}}(\|\partial c/\partial t\|_{L^2(0,T;H^{s-1})} + \|c_0\|_{s-1}),\end{aligned}$$

where $\mu = \min(r+1, s)$, $r \ge 1$, $s \ge 2$, $\delta = 0$ for conforming meshes with triangles or tetrahedra, and $\delta = 1/2$ in general.

Proof. We let $\widehat{c} \in \mathcal{D}_r(\mathcal{E}_h)$ be an interpolant of concentration c such that the *hp*-results (3.4) hold, and define

$$(4.1)\qquad \xi = C^{DG} - c,$$

$$\xi^I = c - \widehat{c}, \tag{4.2}$$

$$\xi^A = C^{DG} - \widehat{c} = \xi + \xi^I. \tag{4.3}$$

Subtracting the weak formulation (3.8) from the DG scheme (3.9), choosing $w = \xi^A$, we obtain

$$\begin{aligned}(4.4)\qquad &\left(\frac{\partial \phi \xi^A}{\partial t}, \xi^A\right) + B(\xi^A, \xi^A; \mathbf{u}) \\ &\quad = L(\xi^A; \mathbf{u}, C^{DG}) - L(\xi^A; \mathbf{u}, c) + \left(\frac{\partial \phi \xi^I}{\partial t}, \xi^A\right) + B(\xi^I, \xi^A; \mathbf{u}).\end{aligned}$$

The first term of the error equation (4.4) may be written in a time derivative of an L^2 norm:

$$\left(\frac{\partial \phi \xi^A}{\partial t}, \xi^A\right) = \frac{1}{2}\frac{d}{dt}\left\|\sqrt{\phi}\xi^A\right\|_{0,\Omega}^2.$$

We expand the second term of (4.4) as

$$\begin{aligned} B(\xi^A, \xi^A; \mathbf{u}) = &\sum_{E\in\mathcal{E}_h}\int_E (\mathbf{D}(\mathbf{u})\nabla\xi^A - \xi^A\mathbf{u})\cdot\nabla\xi^A - \int_\Omega q^-(\xi^A)^2 \\ &-(1+s_{\text{form}})\sum_{\gamma\in\Gamma_h}\int_\gamma \{\mathbf{D}(\mathbf{u})\nabla\xi^A\cdot\mathbf{n}_\gamma\}[\xi^A] \\ &+\sum_{\gamma\in\Gamma_h}\int_\gamma \xi^{A*}\mathbf{u}\cdot\mathbf{n}_\gamma[\xi^A] + \sum_{\gamma\in\Gamma_{h,\text{out}}}\int_\gamma \mathbf{u}\cdot\mathbf{n}_\gamma(\xi^A)^2 + J_0^\sigma(\xi^A,\xi^A).\end{aligned}$$

Integrating the advection term by parts, we observe

$$\begin{aligned} &-\sum_{E\in\mathcal{E}_h}\int_E \xi^A\mathbf{u}\cdot\nabla\xi^A \\ &= -\frac{1}{2}\sum_{E\in\mathcal{E}_h}\int_E \mathbf{u}\cdot\nabla(\xi^A)^2 = -\frac{1}{2}\sum_{E\in\mathcal{E}_h}\int_{\partial E}\mathbf{u}\cdot\mathbf{n}_{\partial E}(\xi^A)^2 + \frac{1}{2}\sum_{E\in\mathcal{E}_h}\int_E q(\xi^A)^2 \\ &= -\frac{1}{2}\sum_{\gamma\in\Gamma_h}\int_\gamma \mathbf{u}\cdot\mathbf{n}_\gamma[(\xi^A)^2] - \frac{1}{2}\sum_{\gamma\in\Gamma_{h,\text{in}}\cup\Gamma_{h,\text{out}}}\int_\gamma \mathbf{u}\cdot\mathbf{n}_\gamma(\xi^A)^2 + \frac{1}{2}\sum_{E\in\mathcal{E}_h}\int_E q(\xi^A)^2.\end{aligned}$$

In addition, noting that $[c^2] = 2\{c\}[c]$ and $(c^* - \{c\})\text{sign}(\mathbf{u}\cdot\mathbf{n}) = [c]/2$, we have

$$\begin{aligned} B(\xi^A, \xi^A; \mathbf{u}) = &\|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A\|_0^2 + \frac{1}{2}\int_\Omega |q|(\xi^A)^2 - T_0 + J_0^\sigma(\xi^A,\xi^A) \\ &+\frac{1}{2}\sum_{\gamma\in\Gamma_h}\int_\gamma |\mathbf{u}\cdot\mathbf{n}_\gamma|[\xi^A]^2 + \frac{1}{2}\sum_{\gamma\in\Gamma_{h,\text{in}}\cup\Gamma_{h,\text{out}}}\int_\gamma |\mathbf{u}\cdot\mathbf{n}_\gamma|(\xi^A)^2,\end{aligned}$$

where T_0 is defined by

$$T_0 := (1+s_{\text{form}})\sum_{\gamma\in\Gamma_h}\int_\gamma \{\mathbf{D}(\mathbf{u})\nabla\xi^A\cdot\mathbf{n}_\gamma\}[\xi^A].$$

If the penalty parameter σ_0 is chosen to be sufficiently large, we may bound T_0 by applying the Cauchy–Schwarz and inverse inequalities:

$$\begin{aligned}(4.5)\qquad T_0 &\le \frac{h}{Kr^2}\sum_{E\in\mathcal{E}_h}\left\|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A\cdot\mathbf{n}_{\partial E}\right\|^2_{0,\partial E} + \frac{Kr^2}{h}\sum_{\gamma\in\Gamma_h}\|[\xi^A]\|^2_{0,\gamma}\\ &\le \frac{1}{2}|\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|\!|\!|^2_0 + \frac{1}{2}J_0^\sigma(\xi^A,\xi^A).\end{aligned}$$

The first two terms on the right-hand side of (4.4) may be estimated, by using Lemma 1, as

$$\begin{aligned}L(\xi^A;\mathbf{u},C^{DG}) - L(\xi^A;\mathbf{u},c) &= \int_\Omega (r(\mathcal{M}(C^{DG})) - r(\mathcal{M}(c)))\xi^A\\ \le K\|\sqrt{\phi}\xi^A\|^2_0 + K\|\xi^I\|^2_0 &\le K\|\sqrt{\phi}\xi^A\|^2_0 + K\frac{h^{2\mu}}{r^{2s}}|\!|\!|c|\!|\!|^2_s.\end{aligned}$$

We have a similar result for the third term:

$$\begin{aligned}&\left(\frac{\partial\phi\xi^I}{\partial t},\xi^A\right) \le K\left\|\frac{\partial\xi^I}{\partial t}\right\|_0\left\|\sqrt{\phi}\xi^A\right\|_0\\ &\le K\left\|\sqrt{\phi}\xi^A\right\|^2_0 + K\left\|\frac{\partial\xi^I}{\partial t}\right\|^2_0 \le K\left\|\sqrt{\phi}\xi^A\right\|^2_0 + K\frac{h^{2\mu-2}}{r^{2s-2}}|\!|\!|c_t|\!|\!|^2_{s-1}.\end{aligned}$$

The fourth term on the right-hand side of (4.4) consists of eight pieces:

$$\begin{aligned}&B(\xi^I,\xi^A;\mathbf{u})\\ &= \sum_{E\in\mathcal{E}_h}\int_E \mathbf{D}(\mathbf{u})\nabla\xi^I\cdot\nabla\xi^A - \sum_{E\in\mathcal{E}_h}\int_E \xi^I\mathbf{u}\cdot\nabla\xi^A - \int_\Omega q^-\xi^I\xi^A\\ &\quad - \sum_{\gamma\in\Gamma_h}\int_\gamma\{\mathbf{D}(\mathbf{u})\nabla\xi^I\cdot\mathbf{n}_\gamma\}[\xi^A] - s_{\mathrm{form}}\sum_{\gamma\in\Gamma_h}\int_\gamma\{\mathbf{D}(\mathbf{u})\nabla\xi^A\cdot\mathbf{n}_\gamma\}[\xi^I]\\ &\quad + \sum_{\gamma\in\Gamma_h}\int_\gamma \xi^{I*}\mathbf{u}\cdot\mathbf{n}_\gamma[\xi^A] + \sum_{\gamma\in\Gamma_{h,\mathrm{out}}}\int_\gamma \mathbf{u}\cdot\mathbf{n}_\gamma\xi^I\xi^A + J_0^\sigma(\xi^I,\xi^A)\\ &=: \sum_{i=1}^{8} T_i.\end{aligned}$$

The Cauchy–Schwarz inequality and approximation results yield

$$\begin{aligned}T_1 &\le \epsilon|\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|\!|\!|^2_0 + K\frac{h^{2\mu-2}}{r^{2s-2}}|\!|\!|c|\!|\!|^2_s,\\ T_2 &\le \epsilon|\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|\!|\!|^2_0 + K\frac{h^{2\mu}}{r^{2s}}|\!|\!|c|\!|\!|^2_s,\\ T_3 &\le \epsilon\int_\Omega |q^-|(\xi^A)^2 + K\frac{h^{2\mu}}{r^{2s}}|\!|\!|c|\!|\!|^2_s.\end{aligned}$$

We bound the terms T_4 and T_5 by hiding a large constant in the penalty term and by using the inverse inequality, respectively,

$$\begin{aligned}T_4 &\leq \epsilon\frac{\sigma_0 r^2}{h}\sum_{\gamma\in\Gamma_h}\|[\xi^A]\|_{0,\gamma}^2 + \frac{Kh}{r^2}\sum_{E\in\mathcal{E}_h}\|\nabla\xi^I\cdot\mathbf{n}_{\partial E}\|_{0,\partial E}^2\\ &\leq \epsilon J_0^\sigma(\xi^A,\xi^A) + K\frac{h^{2\mu-2}}{r^{2s-1}}|||c|||_s^2,\\ T_5 &\leq \frac{\epsilon h}{Kr^2}\sum_{E\in\mathcal{E}_h}\|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A\cdot\mathbf{n}_{\partial E}\|_{0,\partial E}^2 + \frac{Kr^2}{h}\sum_{E\in\mathcal{E}_h}\|\xi^I\|_{0,\partial E}^2\\ &\leq \epsilon|||\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|||_0^2 + K\frac{h^{2\mu-2}}{r^{2s-3}}|||c|||_s^2.\end{aligned}$$

Similar applications of the Cauchy–Schwarz inequality and approximation results give

$$\begin{aligned}T_6 &\leq \epsilon\sum_{\gamma\in\Gamma_h}\int_\gamma|\mathbf{u}\cdot\mathbf{n}_\gamma|[\xi^A]^2 + K\frac{h^{2\mu-1}}{r^{2s-1}}|||c|||_s^2,\\ T_7 &\leq \epsilon\sum_{\gamma\in\Gamma_{h,\mathrm{out}}}\int_\gamma|\mathbf{u}\cdot\mathbf{n}_\gamma|(\xi^A)^2 + K\frac{h^{2\mu-1}}{r^{2s-1}}|||c|||_s^2,\\ T_8 &\leq \epsilon J_0^\sigma(\xi^A,\xi^A) + K\frac{h^{2\mu-2}}{r^{2s-3}}|||c|||_s^2.\end{aligned}$$

For conforming meshes with triangles or tetrahedra, we can choose a continuous approximation $\widehat{c}$ to make the two terms T_5 and T_8 vanish. Substituting all the estimates into (4.4), we see that

$$\begin{aligned}&\frac{d}{dt}\|\sqrt{\phi}\xi^A\|_0^2 + |||\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|||_0^2 + J_0^\sigma(\xi^A,\xi^A)\\ &\quad\leq K\|\sqrt{\phi}\xi^A\|_0^2 + K\frac{h^{2\mu-2}}{r^{2s-2-2\delta}}|||c|||_s^2 + K\frac{h^{2\mu-2}}{r^{2s-2}}|||c_t|||_{s-1}^2,\end{aligned}\tag{4.6}$$

where $\delta = 0$ for conforming meshes with triangles or tetrahedra, and $\delta = 1/2$ in general. Integrating (4.6) with respect to the time t, noting that

$$\|\sqrt{\phi}E^A\|_0(0) \leq K\frac{h^{\mu-1}}{r^{s-1}}|||c_0|||_{s-1},$$

and applying Gronwall's inequality, we conclude that

$$\begin{aligned}&\|\sqrt{\phi}\xi^A\|_{L^\infty(0,T;L^2)} + |||\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|||_{L^2(0,T;L^2)} + (\int_0^T J_0^\sigma(\xi^A,\xi^A))^{\frac{1}{2}}\\ &\quad\leq K\frac{h^{\mu-1}}{r^{s-1-\delta}}|||c|||_{L^2(0,T;H^s)} + K\frac{h^{\mu-1}}{r^{s-1}}(|||\partial c/\partial t|||_{L^2(0,T;H^{s-1})} + |||c_0|||_{s-1}).\end{aligned}$$

The theorem follows by applying the triangle inequality, the approximation results and the fact that

$$|||c|||_{L^\infty(0,T;H^{s-1})} \leq K|||c_t|||_{L^2(0,T;H^{s-1})} + |||c_0|||_{s-1}. \qquad \square \tag{4.7}$$

We remark that, in [22], $L^\infty(L^2) + L^2(H^1)$ error estimates for the OBB-DG diffusion scheme applied to the transport problem established optimality in h and suboptimality in p by $3/2$. Here for SIPG, NIPG, and IIPG, we obtain optimality in h and p for conforming meshes with triangles and tetrahedra and a loss of $1/2$ in p for general grids. Obviously, penalty terms improve the provable p-optimality of DGs.

5. Optimal $\boldsymbol{L^2(L^2)}$ error estimates for the symmetric scheme. In this and following sections, we restrict our attention to SIPG. The derivation in this section is motivated by the h-optimal L^2 result for SIPG applied to an elliptic problem by Wheeler [38] and the h-optimal $L^2(L^2)$ result for continuous Galerkin methods applied to a parabolic problem by Palmer [20]. See also the h-optimal $L^2(L^2)$ result for continuous finite element modified methods of characteristics applied to a coupled system of partial differential equations (PDEs) by Dawson, Russell, and Wheeler [13] and the h-optimal $L^\infty(L^2)$ result for SIPG applied to a parabolic equation with diffusion term by Arnold [4, 3]. We first recall a theorem proved in [20, 17].

Theorem 2. *Consider the parabolic equation:*

$$\begin{aligned} \frac{\partial \phi \Phi}{\partial t} + \nabla \cdot (\mathbf{u}\Phi - \mathbf{D}\nabla\Phi) + a\Phi = f, &\qquad x \in \Omega,\ t \in (0,T], \\ \mathbf{D}\nabla\Phi \cdot \mathbf{n} = 0, &\qquad x \in \partial\Omega,\ t \in (0,T], \\ \Phi = 0, &\qquad x \in \Omega,\ t = 0. \end{aligned}$$

Assume that $0 < \phi_0 \le \phi(t,x) \le \phi_m$, $\mathbf{D}$ is uniformly symmetric positive definite and bounded from above, $\phi \in W^{2;1}_\infty((0,T)\times\Omega)$, $\mathbf{D}_{ij} \in W^{1;0}_\infty((0,T)\times\Omega)$, $\mathbf{u}_i \in L^\infty(\Omega)$ ($\mathbf{u}$ being independent of time), $a \in L^2(0,T;L^\infty(\Omega))$ and $f \in L^2(0,T;L^2(\Omega))$. Then there exists a unique solution Φ satisfying the above equation and the regularity bounds given by

$$\|\Phi\|_{L^\infty(0,T;H^1)} + \|\Phi\|_{L^2(0,T;H^2)} \le K\|f\|_{L^2(0,T;L^2)},$$

where K is a constant independent of the input data f.

For simplicity of presentation, we consider problems with no-flow boundary conditions, though the result can be generalized. We make additional assumptions: $\phi \in W^{2;1}_\infty((0,T)\times\Omega)$, $\mathbf{D}_{ij} \in W^{1;0}_\infty((0,T)\times\Omega)$, and $q^+ \in L^2(0,T;L^\infty(\Omega))$.

5.1. Parabolic lift for SIPG.

Lemma 5 (parabolic lift). *Let $a \in L^2(0,T;L^\infty(\Omega))$ and $e \in L^2(0,T;H^1(\mathcal{E}_h))$ satisfy*

$$\left(\frac{\partial \phi e}{\partial t}, w\right) + B_S(e,w;\mathbf{u}) + (ae,w) = 0 \qquad \forall w \in \mathcal{D}_r(\mathcal{E}_h) \quad \forall t \in (0,T], \tag{5.1}$$

$$(\phi e, w) = 0 \qquad \forall w \in \mathcal{D}_r(\mathcal{E}_h), \quad t = 0. \tag{5.2}$$

In addition we let the assumptions in Theorem 1 hold. Then there exists a constant K, independent of h, r, and e, such that

$$\begin{aligned} &\|e\|_{L^2(0,T;L^2)} \\ &\quad \le K\frac{h}{r}\|e\|_{L^\infty(0,T;L^2)} + K\frac{h^2}{r^2}\|e_t\|_{L^2(0,T;L^2)} \\ &\quad +K\frac{h}{r}\|\mathbf{D}^{\frac12}(\mathbf{u})\nabla e\|_{L^2(0,T;L^2)} + K\frac{h}{r^{\frac32-2\delta}}\left(\int_0^T J_0^\sigma(e,e)\right)^{\frac12} \\ &\quad +K\delta\frac{h^{\frac32}}{r^{\frac32}}\left(\sum_{E\in\mathcal{E}_h}\left(\|e\|^2_{L^2(0,T;L^2(\partial E))} + \|\nabla e \cdot \mathbf{n}_{\partial E}\|^2_{L^2(0,T;L^2(\partial E))}\right)\right)^{\frac12}, \end{aligned}$$

where $\delta = 0$ for conforming meshes with triangles or tetrahedra, and $\delta = 1/2$ in general.

Proof. Consider the backward or adjoint parabolic equation:

$$-\frac{\partial \phi\Phi}{\partial t} + \nabla\cdot(-\mathbf{u}\Phi - \mathbf{D}(\mathbf{u})\nabla\Phi) + (a+q^+)\Phi = e, \quad x\in\Omega,\, t\in[0,T), \tag{5.3}$$

$$\mathbf{D}(\mathbf{u})\nabla\Phi\cdot\mathbf{n}_{\partial\Omega} = 0, \quad x\in\partial\Omega,\, t\in[0,T), \tag{5.4}$$

$$\Phi = 0, \quad x\in\Omega,\, t=T. \tag{5.5}$$

Theorem 2 suggests a unique solution Φ for (5.3)–(5.5) satisfying

$$\|\Phi\|_{L^\infty(0,T;H^1)} + \|\Phi\|_{L^2(0,T;H^2)} \le K\|e\|_{L^2(0,T;L^2)}. \tag{5.6}$$

Observing that $\mathbf{D}(\mathbf{u})\nabla\Phi\cdot\mathbf{n}_{\partial\Omega}=0$ on $\partial\Omega$, $\nabla\cdot\mathbf{u}=q$, and $[\mathbf{D}(\mathbf{u})\nabla\Phi\cdot\mathbf{n}_\gamma]=[\Phi]=0$, we multiply both sides of the adjoint equation (5.3) by e, integrate it over the domain Ω, and then apply integration by parts to conclude that

$$\begin{aligned}\|e\|_0^2 &= -\frac{d}{dt}\sum_{E\in\mathcal{E}_h}(e,\phi\Phi)_E + \sum_{E\in\mathcal{E}_h}\left(\phi\frac{\partial e}{\partial t},\Phi\right)_E + \sum_{E\in\mathcal{E}_h}((a-q^-)e,\Phi)_E \\ &\quad + \sum_{E\in\mathcal{E}_h}(\nabla e,\mathbf{D}(\mathbf{u})\nabla\Phi)_E - \sum_{\gamma\in\Gamma_h}\int_\gamma\{\mathbf{D}(\mathbf{u})\nabla\Phi\cdot\mathbf{n}_\gamma\}[e] - \sum_{E\in\mathcal{E}_h}(e,\mathbf{u}\nabla\cdot\Phi)_E \\ &= -\frac{d}{dt}(e,\phi\Phi) + \left(\phi\frac{\partial e}{\partial t},\Phi\right) + (ae,\Phi) + B_S(e,\Phi;\mathbf{u}).\end{aligned}$$

Applying the orthogonality condition (5.1), we obtain

$$\|e\|_0^2 = -\frac{d}{dt}(e,\phi\Phi) + \left(\phi\frac{\partial e}{\partial t},\Phi-\hat\Phi\right) + (ae,\Phi-\hat\Phi) + B_S(e,\Phi-\hat\Phi;\mathbf{u}), \tag{5.7}$$

where $\hat\Phi\in\mathcal{D}_r(\mathcal{E}_h)$ is an interpolant satisfying (3.4) element-wise. The second and third terms on the right-hand side of (5.7) are bounded, by using the Cauchy–Schwarz inequality and approximation results, as

$$\begin{aligned}\left(\phi\frac{\partial e}{\partial t},\Phi-\hat\Phi\right) &\le K\|e_t\|_0\|\Phi-\hat\Phi\|_0 \le K\frac{h^2}{r^2}\|e_t\|_0\|\Phi\|_2,\\ (ae,\Phi-\hat\Phi) &\le K\|a\|_{L^\infty}\|e\|_0\|\Phi-\hat\Phi\|_0 \le K\frac{h^2}{r^2}\|a\|_{L^\infty}\|e\|_0\|\Phi\|_2.\end{aligned}$$

The last term in (5.7) is composed of eight parts:

$$\begin{aligned}&B_S(e,\Phi-\hat\Phi;\mathbf{u})\\ &\quad= \sum_{E\in\mathcal{E}_h}\int_E\mathbf{D}(\mathbf{u})\nabla e\cdot\nabla(\Phi-\hat\Phi) - \sum_{E\in\mathcal{E}_h}\int_E e\mathbf{u}\cdot\nabla(\Phi-\hat\Phi) - \int_\Omega q^- e(\Phi-\hat\Phi)\\ &\qquad - \sum_{\gamma\in\Gamma_h}\int_\gamma\{\mathbf{D}(\mathbf{u})\nabla e\cdot\mathbf{n}_\gamma\}[\Phi-\hat\Phi] - \sum_{\gamma\in\Gamma_h}\int_\gamma\{\mathbf{D}(\mathbf{u})\nabla(\Phi-\hat\Phi)\cdot\mathbf{n}_\gamma\}[e]\\ &\qquad + \sum_{\gamma\in\Gamma_h}\int_\gamma e^*\mathbf{u}\cdot\mathbf{n}_\gamma[\Phi-\hat\Phi] + \sum_{\gamma\in\Gamma_{h,\mathrm{out}}}\int_\gamma e\mathbf{u}\cdot\mathbf{n}_\gamma(\Phi-\hat\Phi) + J_0^\sigma(e,\Phi-\hat\Phi)\\ &\quad =: \sum_{i=1}^{8}T_i.\end{aligned}$$

Once again, the approximation results and Cauchy–Schwarz inequality yield the estimates for the terms T_1, T_2, and T_3:

$$\begin{aligned}
&T_1 \le K \|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla e\|_0 \|\nabla(\Phi - \hat{\Phi})\|_0 \le K\frac{h}{r}\|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla e\|_0 \|\Phi\|_2,\\
&T_2 \le K\frac{h}{r}\|e\|_0\|\Phi\|_2,\\
&T_3 \le K\frac{h^2}{r^2}\|e\|_0\|\Phi\|_2.
\end{aligned}$$

The term T_7 vanishes because of the assumed no-flow boundary condition. The remaining terms in the bilinear form can be bounded by applying the Cauchy–Schwarz inequality on element faces:

$$\begin{aligned}
&T_4 \le K \sum_{E\in\mathcal{E}_h} \|\nabla e\cdot \mathbf{n}_{\partial E}\|_{0,\partial E}\|\Phi - \hat{\Phi}\|_{0,\partial E} \le K\frac{h^{\frac{3}{2}}}{r^{\frac{3}{2}}}\left(\sum_{E\in\mathcal{E}_h}\|\nabla e\cdot \mathbf{n}_{\partial E}\|^2_{0,\partial E}\right)^{\frac{1}{2}}\|\Phi\|_2,\\
&T_5 \le \sum_{\gamma\in\Gamma_h}\|\{\mathbf{D}(\mathbf{u})\nabla(\Phi - \hat{\Phi})\cdot \mathbf{n}_\gamma\}\|_{0,\gamma}\|[e]\|_{0,\gamma} \le K\frac{h}{r^{\frac{3}{2}}}(J_0^\sigma(e,e))^{\frac{1}{2}}\|\Phi\|_2,\\
&T_6 \le K\frac{h^{\frac{3}{2}}}{r^{\frac{3}{2}}}\left(\sum_{E\in\mathcal{E}_h}\|e\|^2_{0,\partial E}\right)^{\frac{1}{2}}\|\Phi\|_2,\\
&T_8 \le (J_0^\sigma(e,e))^{\frac{1}{2}}(J_0^\sigma(\Phi - \hat{\Phi}, \Phi - \hat{\Phi}))^{\frac{1}{2}} \le K\frac{h}{r^{\frac{1}{2}}}(J_0^\sigma(e,e))^{\frac{1}{2}}\|\Phi\|_2.
\end{aligned}$$

We note that, for conforming meshes with triangles or tetrahedra, terms T_4, T_6, and T_8 vanish if we choose a continuous interpolant $\hat{\Phi}$. Substituting all the estimates back into (5.7), we find that

$$\begin{aligned}
\|e\|^2_{0,\Omega} \le& -\frac{d}{dt}(e,\phi\Phi) + K\frac{h^2}{r^2}\|e_t\|_0\|\Phi\|_2 + K\frac{h^2}{r^2}\|a\|_{L^\infty}\|e\|_0\|\Phi\|_2\\
&+K\frac{h}{r}\|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla e\|_0\|\Phi\|_2 + K\frac{h}{r}\|e\|_0\|\Phi\|_2 + K\frac{h}{r^{\frac{3}{2}-2\delta}}(J_0^\sigma(e,e))^{\frac{1}{2}}\|\Phi\|_2\\
&+K\delta\frac{h^{\frac{3}{2}}}{r^{\frac{3}{2}}}\left(\sum_{E\in\mathcal{E}_h}(\|e\|^2_{0,\partial E} + \|\nabla e\cdot\mathbf{n}\|^2_{0,\partial E})\right)^{\frac{1}{2}}\|\Phi\|_2,
\end{aligned}$$

where $\delta = 0$ for conforming meshes with triangles or tetrahedra, and $\delta = 1/2$ in general.

We complete the proof by integrating (5.8) over the time interval $[0,T]$, applying the Cauchy–Schwarz inequality in $L^2(0,T)$, recalling the regularity bound (5.6), and observing the fact that

$$\begin{aligned}
&(e,\phi\Phi)(0) = (\phi e, \Phi - \hat{\Phi})(0)\\
&\le K\frac{h}{r}\|e\|_0(0)\|\Phi\|_1(0) \le K\frac{h}{r}\|e\|_{L^\infty(0,T;L^2)}\|\Phi\|_{L^\infty(0,T;H^1)}. \qquad \square
\end{aligned}$$

5.2. An $L^2(L^2)$ error estimate for the time derivative of the concentration. To obtain an optimal $L^2(L^2)$ error estimate for the concentration, we need an estimate for its time derivative.

THEOREM 3 ($L^2(L^2)$ error estimate for $\mathbf{c}_t$). *Let the assumptions in Theorem* 1 *hold. Then there exists a constant K, independent of h and r, such that*

$$\left\|\frac{\partial}{\partial t}(C^{DG}-c)\right\|_{L^2(0,T;L^2)} + \|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla(C^{DG}-c)\|_{L^\infty(0,T;L^2)}$$
$$\leq K\frac{h^{\mu-2}}{r^{s-3-\delta}}\|c\|_{L^2(0,T;H^s)} + K\frac{h^{\mu-2}}{r^{s-2}}\|\partial c/\partial t\|_{L^2(0,T;H^{s-1})} + K\frac{h^{\mu-2}}{r^{s-5/2}}\|c_0\|_{s-1},$$

where $\mu = \min(r+1,s)$, $r \geq 1$, $s \geq 2$, $\delta = 0$ for conforming meshes with triangles or tetrahedra, and $\delta = 1/2$ in general.

Proof. Let ξ, ξ^I, and ξ^A be defined by (4.1)–(4.3), respectively. Subtracting (3.8) from (3.9), choosing $w = \partial\xi^A/\partial t$, and integrating the resultant equation over the time interval $[0,t]$, $0 < t \leq T$, we obtain

$$\begin{aligned}\int_0^t \left(\frac{\partial\phi\xi^A}{\partial t}, \frac{\partial\xi^A}{\partial t}\right) + \int_0^t B_S\left(\xi^A, \frac{\partial\xi^A}{\partial t}; \mathbf{u}\right) &= \int_0^t \left(L\left(\frac{\partial\xi^A}{\partial t}; \mathbf{u}, C^{DG}\right) - L\left(\frac{\partial\xi^A}{\partial t}; \mathbf{u}, c\right)\right)\\ &\quad + \int_0^t \left(\frac{\partial\phi\xi^I}{\partial t}, \frac{\partial\xi^A}{\partial t}\right) + \int_0^t B_S\left(\xi^I, \frac{\partial\xi^A}{\partial t}; \mathbf{u}\right).\end{aligned} \tag{5.8}$$

A simple manipulation breaks the bilinear form on the left-hide side of (5.8) into nine components:

$$B_S\left(\xi^A, \frac{\partial\xi^A}{\partial t}; \mathbf{u}\right) = \left(\frac{d}{dt}\sum_{i=1}^7 T_i\right) + T_8 + T_9,$$

where

$$\begin{aligned}\sum_{i=1}^7 T_i &:= \frac{1}{2}\sum_{E\in\mathcal{E}_h}\int_E \mathbf{D}(\mathbf{u})\nabla\xi^A\cdot\nabla\xi^A - \sum_{E\in\mathcal{E}_h}\int_E \xi^A\mathbf{u}\cdot\nabla\xi^A - \frac{1}{2}\int_\Omega q^-\left(\xi^A\right)^2\\ &\quad - \sum_{\gamma\in\Gamma_h}\int_\gamma \left\{\mathbf{D}(\mathbf{u})\nabla\xi^A\cdot\mathbf{n}_\gamma\right\}\left[\xi^A\right] + \sum_{\gamma\in\Gamma_h}\int_\gamma \xi^{A*}\mathbf{u}\cdot\mathbf{n}_\gamma\left[\xi^A\right]\\ &\quad + \frac{1}{2}\sum_{\gamma\in\Gamma_{h,\text{out}}}\int_\gamma \mathbf{u}\cdot\mathbf{n}_\gamma\left(\xi^A\right)^2 + \frac{1}{2}J_0^\sigma\left(\xi^A,\xi^A\right),\\ T_8 &:= \sum_{E\in\mathcal{E}_h}\int_E \frac{\partial\xi^A}{\partial t}\mathbf{u}\cdot\nabla\xi^A,\\ T_9 &:= -\sum_{\gamma\in\Gamma_h}\int_\gamma \frac{\partial\xi^{A*}}{\partial t}\mathbf{u}\cdot\mathbf{n}_\gamma\left[\xi^A\right].\end{aligned}$$

Consequently, the left-hand side of (5.8) may be written as

$$\begin{aligned}&\int_0^t \left(\frac{\partial\phi\xi^A}{\partial t}, \frac{\partial\xi^A}{\partial t}\right) + \int_0^t B_S\left(\xi^A, \frac{\partial\xi^A}{\partial t}; \mathbf{u}\right)\\ &\quad = \int_0^t \left\|\frac{\partial}{\partial t}\sqrt{\phi}\xi^A\right\|_0^2 + \sum_{i=1}^7 T_i(t) - \sum_{i=1}^7 T_i(0) + \int_0^t T_8 + \int_0^t T_9.\end{aligned}$$

It is easy to see that the terms $\int_0^t \|\frac{\partial}{\partial t}\sqrt{\phi}\xi^A\|_0^2$, $T_1(t)$, $T_3(t)$, $T_6(t)$, and $T_7(t)$ are nonnegative. By applying the Cauchy–Schwarz inequality and Theorem 1, the term $T_2(t)$ can be bounded as

$$\begin{aligned}
|T_2(t)| &\le \epsilon |\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|\!|\!|_0^2 + K\|\xi^A\|_0^2 \\
&\le \epsilon |\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|\!|\!|_0^2 + K\|\xi^A\|_{L^\infty(0,T;L^2)}^2 \\
&\le \epsilon |\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|\!|\!|_0^2 + KR_s^2,
\end{aligned}$$

where

$$R_s := \frac{h^{\mu-1}}{r^{s-1-\delta}}|\!|\!|c|\!|\!|_{L^2(0,T;H^s)} + \frac{h^{\mu-1}}{r^{s-1}}(|\!|\!|\partial c/\partial t|\!|\!|_{L^2(0,T;H^{s-1})} + |\!|\!|c_0|\!|\!|_{s-1}).$$

Recalling the definition of the penalty term and applying the Cauchy–Schwarz and inverse inequalities, we may bound the terms T_4 and T_5:

$$\begin{aligned}
|T_4(t)| &\le \frac{\epsilon}{K}\sum_{E\in\mathcal{E}_h}\frac{h}{r^2}\|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A\|_{0,\partial E}^2 + \epsilon J_0^\sigma(\xi^A,\xi^A) \\
&\le \epsilon |\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|\!|\!|_0^2 + \epsilon J_0^\sigma(\xi^A,\xi^A), \\
|T_5(t)| &\le K\sum_{E\in\mathcal{E}_h}\frac{h}{r^2}\|\xi^A\|_{0,\partial E}^2 + \epsilon J_0^\sigma(\xi^A,\xi^A) \le K\|\xi^A\|_0^2 + \epsilon J_0^\sigma(\xi^A,\xi^A) \\
&\le KR_s^2 + \epsilon J_0^\sigma(\xi^A,\xi^A).
\end{aligned}$$

Applications of the approximation results and the continuity of the L_2 projection give

$$\sum_{i=1}^7 |T_i(0)| \le K\frac{h^{2\mu-4}}{r^{2s-5}}|\!|\!|c_0|\!|\!|_{s-1}^2.$$

The Cauchy–Schwarz inequality and Theorem 1 imply

$$\begin{aligned}
\left|\int_0^t T_8\right| &\le \epsilon\left\|\sqrt{\phi}\frac{\partial\xi^A}{\partial t}\right\|_{L^2(0,T;L^2)}^2 + |\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla\xi^A|\!|\!|_{L^2(0,T;L^2)}^2 \\
&\le \epsilon\left\|\sqrt{\phi}\frac{\partial\xi^A}{\partial t}\right\|_{L^2(0,T;L^2)}^2 + KR_s^2.
\end{aligned}$$

An application of the Cauchy–Schwarz and inverse inequalities yields

$$\begin{aligned}
\left|\int_0^t T_9\right| &\le \epsilon\left\|\sqrt{\phi}\frac{\partial\xi^A}{\partial t}\right\|_{L^2(0,T;L^2)}^2 + K\int_0^t J_0^\sigma\left(\xi^A,\xi^A\right) \\
&\le \epsilon\left\|\sqrt{\phi}\frac{\partial\xi^A}{\partial t}\right\|_{L^2(0,T;L^2)}^2 + KR_s^2.
\end{aligned}$$

Collecting the above estimates, we conclude that the left-hide side of (5.8) has the following lower bound:

$$\begin{aligned}
&\int_0^t \left(\frac{\partial \phi \xi^A}{\partial t}, \frac{\partial \xi^A}{\partial t}\right) + \int_0^t B_S\left(\xi^A, \frac{\partial \xi^A}{\partial t}; \mathbf{u}\right) \\
&\quad \geq \frac{1}{2}\int_0^t \left\| \frac{\partial}{\partial t}\sqrt{\phi}\xi^A \right\|_0^2 + \frac{1}{3}|\!|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla \xi^A|\!|\!|_0^2 + \frac{1}{2}\int_\Omega \left|q^-\right| \left(\xi^A\right)^2 \\
&\qquad + \frac{1}{2}\sum_{\gamma\in\Gamma_{h,\mathrm{out}}} \int_\gamma \mathbf{u}\cdot\mathbf{n}_\gamma \left(\xi^A\right)^2 + \frac{1}{3}J_0^\sigma\left(\xi^A, \xi^A\right) \\
&\qquad - KR_s^2 - K\frac{h^{2\mu-4}}{r^{2s-5}}|\!|\!|c_0|\!|\!|_{s-1}^2.
\end{aligned}$$

The first integrand on the right-hand side of (5.8) may be bounded, by using the Cauchy–Schwarz inequality and the Lipschitz continuity of the cut-off operator, as

$$\begin{aligned}
&L\left(\frac{\partial \xi^A}{\partial t}; \mathbf{u}, C^{DG}\right) - L\left(\frac{\partial \xi^A}{\partial t}; \mathbf{u}, c\right) = \int_\Omega \left(r\left(\mathcal{M}(C^{DG})\right) - r\left(\mathcal{M}(c)\right)\right)\frac{\partial \xi^A}{\partial t} \\
&\leq \epsilon \left\| \frac{\partial}{\partial t}\sqrt{\phi}\xi^A \right\|_0^2 + K\left\|\xi\right\|_0^2 \leq \epsilon \left\| \frac{\partial}{\partial t}\sqrt{\phi}\xi^A \right\|_0^2 + KR_s^2.
\end{aligned}$$

An easy application of the Cauchy–Schwarz inequality and approximation results yields the following estimate for the second integrand:

$$\begin{aligned}
&\left(\frac{\partial \phi \xi^I}{\partial t}, \frac{\partial \xi^A}{\partial t}\right) \\
&\leq \epsilon \left\| \frac{\partial}{\partial t}\sqrt{\phi}\xi^A \right\|_0^2 + K\left\| \frac{\partial \xi^I}{\partial t} \right\|_0^2 \leq \epsilon \left\| \frac{\partial}{\partial t}\sqrt{\phi}\xi^A \right\|_0^2 + K\frac{h^{2\mu-2}}{r^{2s-2}}|\!|\!|c_t|\!|\!|_{s-1}^2.
\end{aligned}$$

The third integrand may be decomposed into eight parts:

$$\begin{aligned}
&B_S\left(\xi^I, \frac{\partial \xi^A}{\partial t}; \mathbf{u}\right) \\
&\quad = \sum_{E\in\mathcal{E}_h}\int_E \mathbf{D}(\mathbf{u})\nabla\xi^I\cdot\nabla\frac{\partial \xi^A}{\partial t} - \sum_{E\in\mathcal{E}_h}\int_E \xi^I\mathbf{u}\cdot\nabla\frac{\partial \xi^A}{\partial t} - \int_\Omega q^-\xi^I\frac{\partial \xi^A}{\partial t} \\
&\qquad - \sum_{\gamma\in\Gamma_h}\int_\gamma \left\{\mathbf{D}(\mathbf{u})\nabla\xi^I\cdot\mathbf{n}_\gamma\right\}\left[\frac{\partial \xi^A}{\partial t}\right] - \sum_{\gamma\in\Gamma_h}\int_\gamma \left\{\mathbf{D}(\mathbf{u})\nabla\frac{\partial \xi^A}{\partial t}\cdot\mathbf{n}_\gamma\right\}\left[\xi^I\right] \\
&\qquad + \sum_{\gamma\in\Gamma_h}\int_\gamma \xi^{I*}\mathbf{u}\cdot\mathbf{n}_\gamma\left[\frac{\partial \xi^A}{\partial t}\right] + \sum_{\gamma\in\Gamma_{h,\mathrm{out}}}\int_\gamma \mathbf{u}\cdot\mathbf{n}_\gamma\xi^I\frac{\partial \xi^A}{\partial t} + J_0^\sigma\left(\xi^I, \frac{\partial \xi^A}{\partial t}\right) \\
&\quad =: \sum_{i=1}^{8} S_i.
\end{aligned}$$

The terms S_3 and S_8 are bounded by applying the Cauchy–Schwarz inequality and approximation results:

$$\begin{aligned}
|S_3| &\leq \epsilon \left\| \frac{\partial}{\partial t}\sqrt{\phi}\xi^A \right\|_0^2 + K\frac{h^{2\mu}}{r^{2s}}|\!|\!|c|\!|\!|_s^2, \\
|S_8| &\leq \epsilon J_0^\sigma\left(\xi^A, \xi^A\right) + KJ_0^\sigma\left(\xi^I, \xi^I\right) \\
&\leq \epsilon J_0^\sigma\left(\xi^A, \xi^A\right) + K\frac{h^{2\mu-2}}{r^{2s-3}}|\!|\!|c|\!|\!|_s^2.
\end{aligned}$$

Applications of the Cauchy–Schwarz and inverse inequalities yield the following estimates for the remaining terms:

$$|S_1| + |S_2| + |S_4| + |S_6| + |S_7| \le \epsilon \left\| \frac{\partial}{\partial t} \sqrt{\phi} \xi^A \right\|_0^2 + K \frac{h^{2\mu-4}}{r^{2s-6}} \|\!|c|\!\|_s^2,$$

$$|S_5| \le \epsilon \left\| \frac{\partial}{\partial t} \sqrt{\phi} \xi^A \right\|_0^2 + K \frac{h^{2\mu-4}}{r^{2s-7}} \|\!|c|\!\|_s^2.$$

For conforming meshes with triangles or tetrahedra, we can choose a continuous $\widehat{c}$ to force $S_5 = S_8 = 0$. Combining the bounds for the terms S_i, we obtain

$$\begin{aligned} &\int_0^t B_S\left(\xi^I, \frac{\partial \xi^A}{\partial t}; \mathbf{u}\right) \\ &\quad \le \epsilon \int_0^t \left\| \frac{\partial}{\partial t} \sqrt{\phi} \xi^A \right\|_0^2 + \epsilon R_S^2 + K \frac{h^{2\mu-4}}{r^{2s-6-2\delta}} \|\!|c|\!\|_{L^2(0,T;H^s)}^2. \end{aligned}$$

By back-substituting the estimates into (5.8), we conclude that

$$\begin{aligned} &\int_0^t \left\| \frac{\partial}{\partial t} \sqrt{\phi} \xi^A \right\|_0^2 + \|\!|\mathbf{D}^{\frac{1}{2}}(\mathbf{u}) \nabla \xi^A|\!\|_0^2 + \int_\Omega |q^-| \left(\xi^A\right)^2 \\ &\quad + \sum_{\gamma \in \Gamma_{h,\text{out}}} \int_\gamma \mathbf{u} \cdot \mathbf{n}_\gamma \left(\xi^A\right)^2 + J_0^\sigma\left(\xi^A, \xi^A\right) \\ &\quad \le K \frac{h^{2\mu-4}}{r^{2s-6-2\delta}} \|\!|c|\!\|_{L^2(0,T;H^s)}^2 + K \frac{h^{2\mu-4}}{r^{2s-5}} \|\!|c_0|\!\|_{s-1}^2 + K R_s^2 \\ &\quad \le K \frac{h^{2\mu-4}}{r^{2s-6-2\delta}} \|\!|c|\!\|_{L^2(0,T;H^s)}^2 + K \frac{h^{2\mu-4}}{r^{2s-5}} \|\!|c_0|\!\|_{s-1}^2 + K \frac{h^{2\mu-2}}{r^{2s-2}} \|\!|c_t|\!\|_{L^2(0,T;H^{s-1})}^2. \end{aligned}$$

The theorem follows from the triangle inequality, approximation results, and (4.7). □

5.3. Face error estimates. We also need an error estimate on element faces in order to apply the parabolic lift lemma.

Theorem 4 (face error estimates). *Let the assumptions in Theorem* 1 *hold. Then there exists a constant* K, *independent of* h *and* r, *such that*

$$\begin{aligned} &\left(\sum_{E \in \mathcal{E}_h} \left\| C^{DG} - c \right\|_{L^2(0,T;L^2(\partial E))}^2 \right)^{\frac{1}{2}} + \left(\sum_{E \in \mathcal{E}_h} \left\| \nabla \left(C^{DG} - c\right) \cdot \mathbf{n}_{\partial E} \right\|_{L^2(0,T;L^2(\partial E))}^2 \right)^{\frac{1}{2}} \\ &\quad \le K \frac{h^{\mu - \frac{3}{2}}}{r^{s-2-\delta}} \|\!|c|\!\|_{L^2(0,T;H^s)} + K \frac{h^{\mu-\frac{3}{2}}}{r^{s-2}} \left(\|\!|\partial c/\partial t|\!\|_{L^2(0,T;H^{s-1})} + \|\!|c_0|\!\|_{s-1} \right), \end{aligned}$$

where $\mu = \min(r+1, s)$, $r \ge 1$, $s \ge 2$, $\delta = 0$ *for conforming meshes with triangles or tetrahedra, and* $\delta = 1/2$ *in general.*

Proof. As the first term can be bounded similarly with even sharper estimates, we only present the estimation of the second term, which can be obtained by applying the triangle and inverse inequalities, recalling Theorem 1 and using the approximation results:

$$
\begin{aligned}
&\left(\sum_{E\in\mathcal{E}_h} \left\|\nabla\left(C^{DG}-c\right)\cdot\mathbf{n}_{\partial E}\right\|^2_{L^2(0,T;L^2(\partial E))}\right)^{\frac{1}{2}}\\
&\quad\le \left(\sum_{E\in\mathcal{E}_h} \left\|\nabla\left(C^{DG}-\hat{c}\right)\right\|^2_{L^2(0,T;L^2(\partial E))}\right)^{\frac{1}{2}} + \left(\sum_{E\in\mathcal{E}_h} \left\|\nabla\left(\hat{c}-c\right)\right\|^2_{L^2(0,T;L^2(\partial E))}\right)^{\frac{1}{2}}\\
&\quad\le \frac{r}{h^{\frac{1}{2}}}\left(\sum_{E\in\mathcal{E}_h} \left\|\nabla\left(C^{DG}-\hat{c}\right)\right\|^2_{L^2(0,T;L^2(E))}\right)^{\frac{1}{2}} + K\frac{h^{\mu-\frac{3}{2}}}{r^{s-\frac{3}{2}}}|||c|||_{L^2(0,T;H^s)}\\
&\quad\le \frac{r}{h^{\frac{1}{2}}}\left(\sum_{E\in\mathcal{E}_h} \left\|\nabla\left(C^{DG}-c\right)\right\|^2_{L^2(0,T;L^2(E))}\right)^{\frac{1}{2}} + K\frac{r}{h^{\frac{1}{2}}}\frac{h^{\mu-1}}{r^{s-1}}|||c|||_{L^2(0,T;H^s)}\\
&\quad\le K\frac{h^{\mu-\frac{3}{2}}}{r^{s-2-\delta}}|||c|||_{L^2(0,T;H^s)} + K\frac{h^{\mu-\frac{3}{2}}}{r^{s-2}}\left(|||\partial c/\partial t|||_{L^2(0,T;H^{s-1})} + |||c_0|||_{s-1}\right). \qquad \square
\end{aligned}
$$

5.4. An $L^2(L^2)$ error estimate for the concentration.

THEOREM 5 ($L^2(L^2)$ error estimate for c). *Let the assumptions in Theorem* 1 *hold. Then there exists a constant K, independent of h and r, such that*

$$
\begin{aligned}
(5.9)\qquad &\left\|C^{DG}-c\right\|_{L^2(0,T;L^2)}\\
&\le K\frac{h^{\mu}}{r^{s-1-\delta}}|||c|||_{L^2(0,T;H^s)} + K\frac{h^{\mu}}{r^{s-\delta}}|||\partial c/\partial t|||_{L^2(0,T;H^{s-1})} + K\frac{h^{\mu}}{r^{s-1/2}}|||c_0|||_{s-1},
\end{aligned}
$$

where $\mu=\min(r+1,s)$, $r\ge 1$, $s\ge 2$, $\delta=0$ for conforming meshes with triangles or tetrahedra, and $\delta=1/2$ in general.

Proof. We recall the concentration error ξ in (4.1), and the error equation:

$$
\left(\frac{\partial\phi\xi}{\partial t}, w\right) + B(\xi, w;\mathbf{u}) = L\left(w;\mathbf{u}, C^{DG}\right) - L\left(w;\mathbf{u}, c\right) \qquad \forall w\in\mathcal{D}_r\left(\mathcal{E}_h\right).
$$

We define

$$
a(x,t) = \begin{cases} -\frac{r\left(\mathcal{M}(C^{DG}(x,t))\right)-r(\mathcal{M}(c(x,t)))}{C^{DG}(x,t)-c(x,t)} & \text{if } C^{DG}(x,t)-c(x,t)\neq 0,\\[2ex] 0 & \text{if } C^{DG}(x,t)-c(x,t)=0. \end{cases}
$$

Consequently, we have $L(w;\mathbf{u},C^{DG})-L(w;\mathbf{u},c) = -(a\xi,\,\omega)$. Noting the fact that $a\in L^\infty(0,T;L^\infty)\subset L^2(0,T;L^\infty)$ and recalling Theorems 1, 3, and 4, we obtain (5.9) by applying the parabolic lift argument of Lemma 5. $\square$

6. Optimal estimates in negative norms for the symmetric scheme.

6.1. Error estimates in terms of linear functionals.

We again assume no-flow boundary conditions. Given a function $f\in L^2(0,T;L^2(\Omega))$, we consider a linear functional $F(\cdot)$ of the following form:

$$
F(c) = \int_0^T\int_\Omega c(x,t)f(x,t)dx\,dt.
$$

LEMMA 6 (parabolic lift). *Let $e\in L^2(0,T;H^1(\mathcal{E}_h))$ satisfy* (5.1)–(5.2) *and let the assumptions in Theorem* 1 *hold. We further assume $\phi\in W^{s_1+2,1}_\infty((0,T)\times\Omega)$, $\mathbf{D}_{ij}\in$*

$W_\infty^{s_1+1,0}((0,T)\times\Omega)$, $\mathbf{u}_i \in W_\infty^{s_1}(\Omega)$, $a \in W_\infty^{s_1,0}((0,T)\times\Omega)$, and $q^+ \in W_\infty^{s_1,0}((0,T)\times\Omega)$. Then there exists a constant K, independent of h, r, e, and f, such that

$$
\begin{aligned}
|F(e)| \le K \|f\|_{L^2(0,T;H^{s_1})} \Bigg(& \frac{h^{\mu_1+1}}{r^{s_1+1}} \|e\|_{L^\infty(0,T;L^2)} + \frac{h^{\mu_1+2}}{r^{s_1+2}} \|e_t\|_{L^2(0,T;L^2)} \\
& + \frac{h^{\mu_1+1}}{r^{s_1+1}} \|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla e\|_{L^2(0,T;L^2)} + \frac{h^{\mu_1+1}}{r^{s_1+\frac{3}{2}-2\delta}} \left(\int_0^T J_0^\sigma(e,e) \right)^{\frac{1}{2}} \\
& + \frac{h^{\mu_1+\frac{3}{2}}}{r^{s_1+\frac{3}{2}}} \delta \left(\sum_{E\in\mathcal{E}_h} \left(\|e\|^2_{L^2(0,T;L^2(\partial E))} + \|\nabla e \cdot \mathbf{n}_{\partial E}\|^2_{L^2(0,T;L^2(\partial E))} \right) \right)^{\frac{1}{2}} \Bigg),
\end{aligned}
$$

where $\mu_1 = \min(r-1, s_1)$, $r \ge 1$, $s_1 \ge 0$, $\delta = 0$ for conforming meshes with triangles or tetrahedra, and $\delta = 1/2$ in general.

Proof. We revisit the adjoint parabolic equation (5.3)–(5.5) with e replaced by f. By applying Theorem 2 repeatedly, we obtain a unique solution Φ for (5.3)–(5.5) satisfying

$$
\|\Phi\|_{L^\infty(0,T;H^{s_1+1})} + \|\Phi\|_{L^2(0,T;H^{s_1+2})} \le K \|f\|_{L^2(0,T;H^{s_1})} . \tag{6.1}
$$

We now consider the $L^2(\Omega)$ inner product $(e,\, f)$ at $t \in (0,T]$:

$$
\begin{aligned}
(e,\, f) &= \sum_{E\in\mathcal{E}_h} (e,\, f)_E \\
&= \sum_{E\in\mathcal{E}_h} \left(e, -\frac{\partial \phi\Phi}{\partial t} \right)_E + \sum_{E\in\mathcal{E}_h} (e, \nabla\cdot(-\mathbf{u}\Phi - \mathbf{D}(\mathbf{u})\nabla\Phi))_E + \sum_{E\in\mathcal{E}_h} \left(e, (a+q^+)\Phi \right)_E .
\end{aligned}
$$

Integrating by parts, applying the orthogonality condition (5.1) and observing that $\mathbf{D}(\mathbf{u})\nabla\Phi\cdot\mathbf{n}_{\partial\Omega} = 0$ on $\partial\Omega$, $\nabla\cdot\mathbf{u} = q$, and $[\mathbf{D}(\mathbf{u})\nabla\Phi\cdot\mathbf{n}_\gamma] = [\Phi] = 0$, we conclude that

$$
(e,\, f) = -\frac{d}{dt}(e, \phi\Phi) + \left(\phi\frac{\partial e}{\partial t}, \Phi - \hat{\Phi} \right) + \left(ae, \Phi - \hat{\Phi} \right) + B_S\left(e, \Phi - \hat{\Phi}; \mathbf{u} \right), \tag{6.2}
$$

where we choose an interpolant $\hat{\Phi} \in \mathcal{D}_r(\mathcal{E}_h)$ with element-wise optimal approximation properties (3.4). Applying the Cauchy–Schwarz inequality and approximation results, we obtain estimates for the second and third terms on the right-hand side of (6.2):

$$
\begin{aligned}
\left(\phi\frac{\partial e}{\partial t}, \Phi - \hat{\Phi} \right) &\le K \|e_t\|_0 \|\Phi - \hat{\Phi}\|_0 \le K \frac{h^{\mu_1+2}}{r^{s_1+2}} \|e_t\|_0 \|\Phi\|_{s_1+2} , \\
\left(ae, \Phi - \hat{\Phi} \right) &\le K \|a\|_{L^\infty} \|e\|_0 \|\Phi - \hat{\Phi}\|_0 \le K \frac{h^{\mu_1+2}}{r^{s_1+2}} \|a\|_{L^\infty} \|e\|_0 \|\Phi\|_{s_1+2} .
\end{aligned}
$$

Similar but tedious arguments, together with the inverse inequality and the existence of continuous interpolants for conforming meshes with triangles or tetrahedra, yield a bound for the fourth term:

$$
\begin{aligned}
\left| B_S\left(e, \Phi - \hat{\Phi}; \mathbf{u} \right) \right| \le\; & K \frac{h^{\mu_1+1}}{r^{s_1+1}} \|\mathbf{D}^{\frac{1}{2}}(\mathbf{u})\nabla e\|_0 \|\Phi\|_{s_1+2} + K \frac{h^{\mu_1+1}}{r^{s_1+1}} \|e\|_0 \|\Phi\|_{s_1+2} \\
& + K \frac{h^{\mu_1+1}}{r^{s_1+\frac{3}{2}-2\delta}} \left(J_0^\sigma(e,e) \right)^{\frac{1}{2}} \|\Phi\|_{s_1+2} \\
& + K\delta \frac{h^{\mu_1+\frac{3}{2}}}{r^{s_1+\frac{3}{2}}} \left(\sum_{E\in\mathcal{E}_h} \left(\|e\|^2_{0,\partial E} + \|\nabla e\cdot\mathbf{n}_{\partial E}\|^2_{0,\partial E} \right) \right)^{\frac{1}{2}} \|\Phi\|_{s_1+2} .
\end{aligned}
$$

Observing the fact that

$$\begin{aligned}|F(e) - (e, \phi\Phi)(0)| &= \left| \int_0^T \left((e,\, f) + \frac{d}{dt}(e, \phi\Phi) \right) \right| \\ &\leq \int_0^T \left| (e,\, f) + \frac{d}{dt}(e, \phi\Phi) \right|\end{aligned}$$

and integrating (6.2) over the time interval $[0, T]$, we have

$$\begin{aligned}&|F(e) - (e, \phi\Phi)(0)| \\ &\leq K \left\| \Phi \right\|_{L^2(0,T;H^{s_1+2})} \left(\frac{h^{\mu_1+2}}{r^{s_1+2}} \left\| e_t \right\|_{L^2(0,T;L^2)} \right. \\ &+ \frac{h^{\mu_1+2}}{r^{s_1+2}} \left\| a \right\|_{L^2(0,T;L^\infty)} \left\| e \right\|_{L^\infty(0,T;L^2)} + \frac{h^{\mu_1+1}}{r^{s_1+1}} \left\| \mathbf{D}^{\frac{1}{2}}(\mathbf{u}) \nabla e \right\|_{L^2(0,T;L^2)} \\ &+ \frac{h^{\mu_1+1}}{r^{s_1+1}} \left\| e \right\|_{L^\infty(0,T;L^2)} + \frac{h^{\mu_1+1}}{r^{s_1+\frac{3}{2}-2\delta}} \left(\int_0^T J_0^\sigma(e,e) \right)^{\frac{1}{2}} \\ &\left. + \frac{h^{\mu_1+\frac{3}{2}}}{r^{s_1+\frac{3}{2}}} \delta \left(\sum_{E \in \mathcal{E}_h} \left(\left\| e \right\|^2_{L^2(0,T;L^2(\partial E))} + \left\| \nabla e \cdot \mathbf{n}_{\partial E} \right\|^2_{L^2(0,T;L^2(\partial E))} \right) \right)^{\frac{1}{2}} \right).\end{aligned}$$

The theorem follows from the regularity estimate (6.1) and the fact that

$$\begin{aligned}|(e, \phi\Phi)(0)| &= \left| \left(\phi e, \Phi - \hat{\Phi} \right)(0) \right| \\ &\leq K \frac{h^{\min(r+1, s_1+1)}}{r^{s_1+1}} \left\| e(\cdot, 0) \right\|_0 \left\| \Phi(\cdot, 0) \right\|_{s_1+1} \\ &\leq K \frac{h^{\mu_1+1}}{r^{s_1+1}} \left\| e \right\|_{L^\infty(0,T;L^2)} \left\| \Phi \right\|_{L^\infty(0,T;H^{s_1+1})}. \qquad \square\end{aligned}$$

Theorem 6 (linear functional estimates). *Let the assumptions in Theorem* 1 *hold. In addition, we assume* $\phi \in W_\infty^{s_1+2,1}((0,T) \times \Omega)$, $\mathbf{D}_{ij} \in W_\infty^{s_1+1,0}((0,T) \times \Omega)$, $\mathbf{u}_i \in W_\infty^{s_1}(\Omega)$, $q^+ \in W_\infty^{s_1,0}((0,T) \times \Omega)$, *and that the chemical reaction term has a linear form* $r(c) = k_0 + k_1 c$, *where* $k_0 = k_0(x,t)$ *and* $k_1 = k_1(x,t)$ *are reaction parameters with* $k_1 \in W_\infty^{s_1,0}((0,T) \times \Omega)$. *Then there exists a constant* K, *independent of* h, r, *and* f, *such that*

$$\begin{aligned}\left| F(C^{DG}) - F(c) \right| \leq K &\frac{h^{\mu_1+\mu}}{r^{s_1+s-1-\delta}} \left\| f \right\|_{L^2(0,T;H^{s_1})} \left\| c \right\|_{L^2(0,T;H^s)} \\ &+ K \frac{h^{\mu_1+\mu}}{r^{s_1+s-\delta}} \left\| f \right\|_{L^2(0,T;H^{s_1})} \left\| \partial c / \partial t \right\|_{L^2(0,T;H^{s-1})} \\ &+ K \frac{h^{\mu_1+\mu}}{r^{s_1+s-1/2}} \left\| f \right\|_{L^2(0,T;H^{s_1})} \left\| c_0 \right\|_{s-1},\end{aligned}$$

where $\mu = \min(r+1, s)$, $\mu_1 = \min(r-1, s_1)$, $r \geq 1$, $s \geq 2$, $s_1 \geq 0$, *and* $\delta = 0$ *for conforming meshes with triangles or tetrahedra, and* $\delta = 1/2$ *in general.*

Proof. Recalling the concentration error ξ in (4.1) and defining $a(x,t) = -k_1(x,t)$, we obtain the error equation in the following form, provided that the cut-off constant

M is chosen to be sufficiently large:

$$\left(\frac{\partial \phi \xi}{\partial t}, w\right) + B_S(\xi, w; \mathbf{u}) + (a\xi, w) = 0 \quad \forall w \in \mathcal{D}_r\left(\mathcal{E}_h\right) \quad \forall t \in (0, T].$$

We obtain the desired estimate by applying the parabolic lift of Lemma 6 together with estimates in Theorems 1, 3, and 4. ∎

6.2. Error estimates in negative norms. Assuming m is a positive integer, we define the negative Sobolev norm $\|\cdot\|_{H^{-m}(\Omega)}$ in the usual way:

$$\|c\|_{H^{-m}(\Omega)} = \sup_{v \in C_0^\infty(\Omega) \backslash \{0\}} \frac{|(c, v)|}{\|v\|_{H^m(\Omega)}}.$$

THEOREM 7 (estimates in negative norms). *Let the assumptions in Theorem* 1 *hold. In addition, we assume* $\phi \in W_\infty^{m+2,1}((0,T) \times \Omega)$, $\mathbf{D}_{ij} \in W_\infty^{m+1,0}((0,T) \times \Omega)$, $\mathbf{u}_i \in W_\infty^m(\Omega)$, $q^+ \in W_\infty^{m,0}((0,T) \times \Omega)$, *and that the chemical reaction term has a linear form* $r(c) = k_0 + k_1 c$, *where* $k_0 = k_0(x,t)$ *and* $k_1 = k_1(x,t)$ *are reaction parameters with* $k_1 \in W_\infty^{m,0}((0,T) \times \Omega)$. *Then there exists a constant* K, *independent of* h *and* r, *such that*

$$\begin{aligned} \left\|C^{DG} - c\right\|_{L^2(0,T;H^{-m}(\Omega))} \leq{}& K \frac{h^{\min(r-1,m)+\min(r+1,s)}}{r^{m+s-1-\delta}} \|c\|_{L^2(0,T;H^s)} \\ &+ K \frac{h^{\min(r-1,m)+\min(r+1,s)}}{r^{m+s-\delta}} \|\partial c/\partial t\|_{L^2(0,T;H^{s-1})} \\ &+ K \frac{h^{\min(r-1,m)+\min(r+1,s)}}{r^{m+s-1/2}} \|c_0\|_{s-1}, \end{aligned}$$

where $r \geq 1$, $s \geq 2$, $m \geq 0$, *and* $\delta = 0$ *for conforming meshes with triangles or tetrahedra, and* $\delta = 1/2$ *in general.*

Proof. The theorem follows directly from Theorem 6 and the definition of negative norms. ∎

7. Numerical examples. We consider the problem of (2.1)–(2.4) on a domain $\Omega = (0, 10)^2$ without injection or extraction, i.e., $q = 0$, and with a reaction term $r = r(x,t)$ independent of the concentration c. The domain is divided into two disjoint parts: $\overline{\Omega} = \overline{\Omega}_1 \cup \overline{\Omega}_2$ with $\Omega_1 = \{(x,y) \in \Omega : y < 3 + 0.4x\}$. The porosity ϕ has a constant value of 0.1, and the tensor $\mathbf{D}$ is a constant diagonal tensor with $\mathbf{D}_{ii} = 1.0$. We impose the velocities $\mathbf{u} = (-1, -0.4)$ in Ω_1 and $\mathbf{u} = (0,0)$ in Ω_2. We choose $r(x,t)$, c_B, and c_0 such that the equation has an analytical solution of $c = (1 + \cos(\frac{\pi}{5}x)\cos(\frac{\pi}{5}y))2^{-t/10}$. The penalty parameter is chosen according to the method presented in the next section. The coarsest mesh we take simply consists of the two quadrilateral elements Ω_1 and Ω_2. The simulation time interval is (0, 10], and we use the backward Euler method for time integration with a uniform time step $\Delta t = 0.1$.

7.1. Convergence of h-refinement. We solve the test case using OBB-DG, NIPG, IIPG, and SIPG. We use polynomials of degree $r = 2$ and vary h by uniform refinements starting from the coarsest mesh. The convergence behaviors of h-refinement in the norms of $L^2(L^2)$, $L^\infty(L^2)$, and $L^2(H^1)$ for NIPG are shown in Figure 7.1. It is observed that the errors in all norms are $O(1/n)$, where n is the number of degrees of freedom. As $n \propto 1/h^2$ for two-dimensional spaces, the experimental convergences

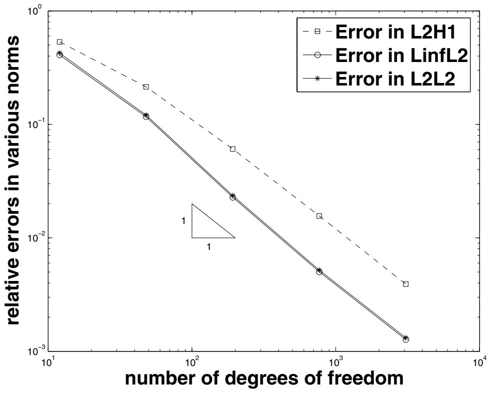

FIG. 7.1. *Convergence of h-refinement for NIPG.*

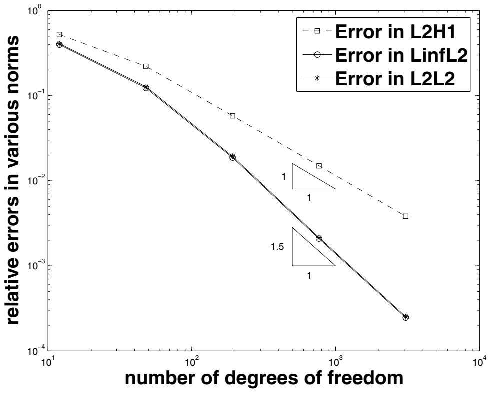

FIG. 7.2. *Convergence of h-refinement for SIPG.*

confirm our theoretical estimates in $L^2(H^1)$. In addition, the numerical results indicate that the errors in NIPG do not converge optimally in $L^\infty(L^2)$ or $L^2(L^2)$. The convergence behaviors of OBB-DG and IIPG (not shown) are nearly identical to those of NIPG. However, unlike NIPG, OBB-DG, and IIPG, the symmetric scheme (SIPG) possesses optimal convergence in all norms of $L^2(L^2)$, $L^\infty(L^2)$, and $L^2(H^1)$, as shown evidently in Figure 7.2, which also validates the predictions from our parabolic lift arguments.

7.2. Convergence of p-refinement. The test case is solved using the four primal DGs on the coarsest mesh with polynomials of degrees r=1, 2, 3, . . . , 10. Figure 7.3 illustrates the convergence behaviors of SIPG in the norms of $L^2(L^2)$, $L^\infty(L^2)$, and $L^2(H^1)$, where the expected exponential convergence rates are achieved. The exponential convergence patterns of OBB-DG, NIPG, and IIPG (not shown) are very similar to those of SIPG. An interesting experimental observation, which is not covered in previous theoretical sections, is that the DG methods with polynomials of odd orders have better performance than those of even orders; this is especially pronounced for OBB-DG.

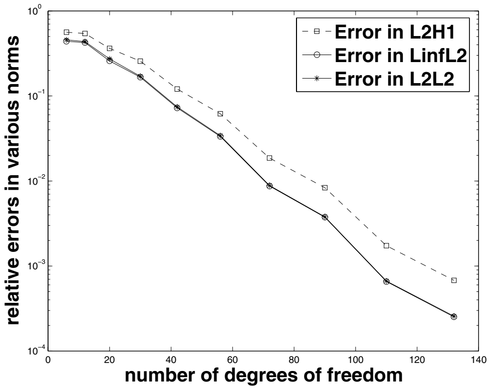

FIG. 7.3. *Convergence of p-refinement for SIPG.*

8. Discussion.

8.1. Penalty parameters for SIPG. Numerical experiments indicate that careful implementations of the penalty terms are crucial to SIPG: not only are the penalty terms necessary for the convergence of SIPG, but also choices of penalty parameters significantly influence the performance of SIPG. Small penalty parameters might result in divergences of the schemes. On the other hand, very large parameters, though ensuring the convergence theoretically, lead to a poor condition number for the resultant linear system, causing numerical difficulties in practice.

Reinvestigating (4.5), we see that it is sufficient to choose $\sigma_\gamma = O(|\mathbf{D}|^{1/2})$, where $|\cdot|$ is a matrix norm. Letting $\sigma_\gamma = \widehat{\sigma}|\mathbf{D}|^{1/2}$ and $\widehat{\sigma} = O(1)$, we have

$$J_0^\sigma(c,w) = \sum_{\gamma\in\Gamma_h} \widehat{\sigma}\sqrt{|\mathbf{D}|}\frac{r^2}{h_\gamma}\int_\gamma [c][w].$$

For most cases, we recommend $\widehat{\sigma} = 1$. It is found that $\widehat{\sigma}$ chosen from (0.1, 10) works well for many test cases. For cases where aspect ratios are very high and/or dispersion-diffusion is highly anisotropic, it is found that the following choice generally gives better results:

$$J_0^\sigma(c,w) = \sum_{\gamma\in\Gamma_h} \widehat{\sigma}\sqrt{|\mathbf{D}\mathbf{n}_\gamma|}\frac{r^2}{h_{m,\gamma}}\int_\gamma [c][w],$$

where $h_{m,\gamma} = \min_{E:\gamma\in E}(\mathrm{meas}(E)/\mathrm{meas}(\gamma))$.

8.2. Reference versus physical polynomial spaces. In the definition (3.1) of the DG space $\mathcal{D}_r(\mathcal{E}_h)$, the local space $\mathbb{P}_r(E)$ is the set of polynomials defined over a physical element E, rather than a reference element $\widehat{E}$. This distinction is unnecessary when E is a triangle or tetrahedron because the transformation from $\widehat{E}$ to E is affine. But for a general quadrilateral or hexahedron, these two spaces are different. We apply DG methods to the test case in section 7 using the uniform p-refinement in the coarsest mesh. Figure 8.1 provides the error ratio $\eta = \|e_r\|_{L^2(0,T;L^2(\Omega))}/\|e_f\|_{L^2(0,T;L^2(\Omega))}$ during the p-refinement, where e_r and e_f denote the DG errors based on the reference and physical spaces, respectively. Clearly, DG solutions based on physical spaces are more accurate than those of reference spaces for high order approximations; this is more significant for OBB-DG than for other primal DGs. This observation suggests

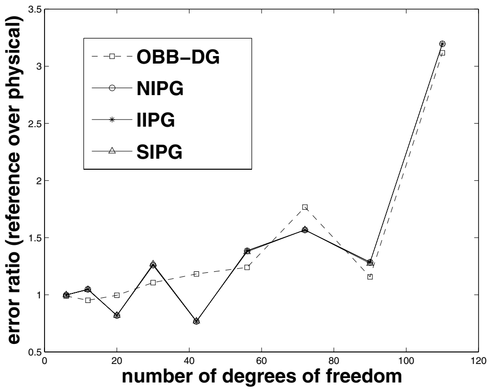

FIG. 8.1. *Comparison of reference versus physical polynomial spaces for DG methods (data of NIPG, SIPG, and IIPG are nearly identical).*

that physical polynomial spaces are preferred in p- and hp-implementations of DGs. It is also noted (not shown) that the improvement of physical over reference spaces is less pronounced on more refined meshes, because the transformation from $\widehat{E}$ to E becomes closer to an affine mapping. Consequently, a choice of physical versus reference spaces does not significantly impact h-versions of DGs.

9. Conclusions. Three primal DG methods with penalty have been analyzed for solving reactive transport problems in porous media. The cut-off operator was introduced in the DG formulations to ensure convergence for general nonlinear kinetic reactions. Error estimates in $L^2(H^1)$ for the concentration were derived for SIPG, NIPG, and IIPG, which are optimal in h and nearly optimal in p. In addition, we established $L^2(H^1)$ concentration error estimates on the element faces as well as $L^2(L^2)$ estimates for time derivatives. A parabolic lift technique for SIPG has been developed, which yields an h-optimal and nearly p-optimal error estimate in $L^2(L^2)$. The same lift technique applied to general linear functionals gives optimal estimates in negative norms. We have also numerically investigated the h- and p-convergence behaviors of OBB-DG, NIPG, IIPG, and SIPG. It was demonstrated that OBB-DG, IIPG, and NIPG possess h-optimal convergence rates in $L^2(H^1)$, but lack the optimality in $L^2(L^2)$ and $L^\infty(L^2)$, whereas SIPG performs h-optimally in the three norms. For smooth problems, exponential convergence rates in p are achieved by the four primal DG methods. In addition, it was observed that DGs with polynomials of odd orders perform better than those of even orders. Implementations of penalty terms are crucial to SIPG and a proper choice of the penalty parameter was proposed. Another important issue in implementations is the selection of physical versus reference spaces, for which we recommended the physical polynomial spaces for p- and hp-versions of DGs. As a future extension, we propose to study error estimates of primal DG methods for transport coupled with kinetic and local-equilibrium reactions and for multiphase flow in porous media.

STABILITY AND CONVERGENCE OF FINITE-ELEMENT APPROXIMATION SCHEMES FOR HARMONIC MAPS[*]

SÖREN BARTELS[†]

Abstract. This article discusses stability and convergence of approximation schemes for harmonic maps. A finite-element discretization of an iterative algorithm due to F. Alouges is introduced and shown to be stable and convergent in general only on acute-type triangulations. An a posteriori criterion is proposed which allows us to monitor sufficient conditions for weak convergence to a harmonic map on general triangulations and for adaptive mesh refinement. Numerical experiments show that an adaptive strategy automatically refines triangulations in neighborhoods of typical point singularities and thereby underline its efficiency.

Key words. harmonic maps, iterative algorithm, finite element method, weak convergence, liquid crystals, adaptive refinement

1. Introduction.

A variational model in the theory of nematic liquid crystals due to Oseen and Frank [29, 22, 13] leads to a minimization of the energy functional

$$I(v) := \frac{1}{2}\int_\Omega k_1|\operatorname{div} v|^2 + k_2|v\cdot\operatorname{curl} v|^2 + k_3|v\times\operatorname{curl} v|^2 + (k_2+k_4)\big(\operatorname{tr}\big[(Dv)^2\big] - (\operatorname{div} v)^2\big)\,\mathrm{d}x$$

over a space of admissible configurations

$$v \in \mathcal{A}(u_{\mathrm{D}}) := \big\{v \in H^1\big(\Omega;\mathbb{R}^3\big) : v|_{\partial\Omega} = u_{\mathrm{D}},\ |v| = 1 \text{ a.e. in } \Omega\big\}.$$

Here, $\Omega \subseteq \mathbb{R}^3$ is a bounded Lipschitz domain and represents the physical domain in which the liquid crystal is embedded, $u_{\mathrm{D}} \in H^{1/2}(\partial\Omega;\mathbb{R}^3)$ with $|u_{\mathrm{D}}| = 1$ almost everywhere on $\partial\Omega$ are given boundary data, and $k_1, k_2, k_3, k_4 \geq 0$ are material- and temperature-dependent constants. A vector field $v \in \mathcal{A}(u_{\mathrm{D}})$ locally represents the mean direction of the molecules that constitute the liquid crystal and a local minimizer of I in $\mathcal{A}(u_{\mathrm{D}})$ defines a stable configuration of the liquid crystal. The pointwise constraint $|v| = 1$ models the physically motivated assumption that in the liquid crystal phase the molecules are rod like with a fixed length.

Existence of (global) minimizers of I in $\mathcal{A}(u_{\mathrm{D}})$ can be established if $\mathcal{A}(u_{\mathrm{D}}) \neq \emptyset$ [14]. Sufficient for $\mathcal{A}(u_{\mathrm{D}}) \neq \emptyset$ is that u_{D} is Lipschitz continuous on $\partial\Omega$ [14]. Owing to the nonconvex constraint $|v| = 1$ uniqueness and higher regularity of solutions cannot be expected [7, 14, 15, 25, 26, 27, 28, 29]. Typically, stable points of I in $\mathcal{A}(u_{\mathrm{D}})$ are not continuous and have point singularities, which correspond to defects in the nematic material. In addition to nonuniqueness and existence of singularities, the nonconvex nature of the problem makes it extremely difficult to numerically approximate stationary points. The crux in the design of numerical schemes lies in a stable realization of the constraint $|v| = 1$. In order to make the main ideas for the approximation of

the constraint more clear we will only investigate the physically relevant one-constant approximation of I, which assumes $k_1 = k_2 = k_3 = 1$ and $k_4 = 0$ and reduces the minimization problem to the problem of finding harmonic maps

$$\text{(P)} \qquad \begin{cases} \text{Find } u \in \mathcal{A}(u_{\mathrm{D}}) \text{ which is a local minimizer for} \\ E : \mathcal{A}(u_{\mathrm{D}}) \to \mathbb{R},\ v \mapsto \dfrac{1}{2}\displaystyle\int_\Omega |Dv|^2 \, \mathrm{d}x. \end{cases}$$

Solutions of (P) will be called *harmonic maps.* They satisfy the Euler–Lagrange equations

$$-\Delta u = |Du|^2 u, \quad |u| = 1 \qquad \text{in } \Omega.$$

Iterative algorithms for the approximation of harmonic maps have been proposed in [10, 19, 9] and successfully been tested numerically. Convergence of an iterative scheme on a continuous level and stability of a related finite difference discretization have been proved in [1]. The goal of this work is to analyze finite-element discretizations of that algorithm which allows for local mesh refinement and thereby a more efficient resolution of point singularities of solutions. We prove that, in general, finite-element discretizations cannot be expected to be stable and are convergent only on structured triangulations. Sufficient for stability and convergence is that the underlying triangulation is of acute type (cf. Lemma 3.2 for details). We provide an a posteriori criterion that allows us to monitor reliability of the algorithm on general triangulations and gives rise to automatic local mesh refinement. Numerical experiments indicate that adaptive strategies are more efficient when compared to schemes on uniform triangulations. While we restrict the analysis to the one-constant approximation of I we stress that the ideas can be carried over to the full model and refer the reader to [2] for related ideas.

An alternative approach to approximating local minimizers of I consists in regularizing the problem by introducing a penalty term $\varepsilon^{-2}\||v|^2 - 1\|^2_{L^2(\Omega)}$ in I with $0 < \varepsilon \ll 1$ in order to approximate the constraint $|v| = 1$. Difficulties in analyzing such an approach stem from the lack of regularity of minimizers of I and a reliable discretization of the gradient flow of the penalized formulation generally requires very small time step sizes, which limit the practical use. For related approaches and the numerical analysis of more sophisticated models we refer the reader to [3, 4, 20, 21, 23, 12].

The rest of this article is organized as follows. We briefly recall the definition and the main properties of the iterative algorithm of [1] in Section 2. Section 3 discusses finite-element discretizations of that algorithm and gives sufficient a priori conditions for its convergence. A few numerical experiments show the efficiency of the discrete algorithm and are presented in Section 4. Section 5 is devoted to an a posteriori analysis and introduces local refinement indicators. The efficient performance of the resulting adaptive strategy is illustrated by some numerical experiments in Section 6.

2. Alouges' algorithm.

For an initial $u^{(0)} \in \mathcal{A}(u_{\mathrm{D}})$ Alouges' algorithm computes a sequence $\big(u^{(j)} : j \in \mathbb{N}\big) \subseteq H^1(\Omega; \mathbb{R}^3)$ by iterating the following two steps:

(A_1) Let $w^{(j)} \in K_{u^{(j)}}$ satisfy $E\big(u^{(j)} - w^{(j)}\big) \le E\big(u^{(j)} - v\big)$ for all $v \in K_{u^{(j)}}$, where $K_{u^{(j)}} := \big\{v \in H^1\big(\Omega; \mathbb{R}^3\big) : v|_{\partial\Omega} = 0,\ v \cdot u^{(j)} = 0 \text{ a.e. in } \Omega\big\}$.

(A_2) Set $u^{(j+1)} := \dfrac{u^{(j)} - w^{(j)}}{|u^{(j)} - w^{(j)}|}$.

Given any $u^{(j)} \in H^1(\Omega;\mathbb{R}^3)$ step (A$_1$) consists in minimizing an elliptic functional on a subspace of $H^1(\Omega;\mathbb{R}^3)$ and admits a unique solution $w^{(j)} \in K_{u^{(j)}}$. Supposing that $|u^{(j)}| = 1$ almost everywhere in Ω, the definition of $K_{u^{(j)}}$ yields

$$|u^{(j)} - w^{(j)}|^2 = |u^{(j)}|^2 + |w^{(j)}|^2 \geq 1$$

almost everywhere in Ω. Hence, $u^{(j+1)}$ in step (A$_2$) is well defined and satisfies $|u^{(j+1)}| = 1$ almost everywhere in Ω. It is not difficult to verify that for a function $v \in H^1(\Omega;\mathbb{R}^3)$ satisfying $|v| \geq 1$ almost everywhere in Ω there holds

$$E\biggl(\frac{v}{|v|}\biggr) \leq E(v), \tag{2.1}$$

in particular $v/|v| \in H^1(\Omega;\mathbb{R}^3)$ and thus $u^{(j+1)} \in \mathcal{A}(u_{\mathrm{D}})$. Noting that $v \equiv 0 \in K_{u^{(j)}}$ it thus follows that

$$E\bigl(u^{(j+1)}\bigr) = E\biggl(\frac{u^{(j)} - w^{(j)}}{|u^{(j)} - w^{(j)}|}\biggr) \leq E\bigl(u^{(j)} - w^{(j)}\bigr) \leq E\bigl(u^{(j)}\bigr).$$

This is the energy decreasing property of Alouges' algorithm. The main features of the iteration are summarized in the following theorem.

Theorem 2.1 (see [1]). *Let $u^{(0)} \in \mathcal{A}(u_{\mathrm{D}})$. Suppose that the sequences $\bigl(u^{(j)} : j \in \mathbb{N}\bigr)$ and $\bigl(w^{(j)} : j \in \mathbb{N}\bigr)$ are generated by iterating* (A$_1$) *and* (A$_2$)*. Then, for all $j \in \mathbb{N}$ there holds*

$$u^{(j)} \in \mathcal{A}(u_{\mathrm{D}}) \quad \textit{and} \quad E\bigl(u^{(j+1)}\bigr) \leq E\bigl(u^{(j)}\bigr).$$

There holds $w^{(j)} \to 0$ (strongly) in H^1 and there exists a subsequence $(u^{(k)} : k \in \mathbb{N})$ and a harmonic map $u^* \in \mathcal{A}(u_{\mathrm{D}})$ such that $u^{(k)} \rightharpoonup u^*$ (weakly) in H^1.

3. Finite-element discretization and numerical analysis of (A$_1$) and (A$_2$).

In order to make difficulties in a finite-element discretization of (A$_1$) and (A$_2$) more clear we will occasionally consider a two-dimensional situation in this section. Therefore, we assume that $n = 2$ or $n = 3$ and that Ω is a bounded, polygonal or polyhedral, respectively, Lipschitz domain in $\mathbb{R}^n$. Given a regular triangulation $\mathcal{T}$ of Ω into triangles ($n = 2$) or tetrahedra ($n = 3$), let $\mathcal{N}$ denote the set of nodes in $\mathcal{T}$. The lowest order finite-element space related to $\mathcal{T}$ is denoted by $\mathcal{S}^1(\mathcal{T}) \subseteq H^1(\Omega)$. The nodal basis functions $(\varphi_z : z \in \mathcal{N}) \subseteq \mathcal{S}^1(\mathcal{T})$ satisfy $\varphi_z(z) = 1$ and $\varphi_z(z') = 0$ for $z \in \mathcal{N}$ and $z' \in \mathcal{N}\backslash\{z\}$. We define $\mathcal{S}^1_0(\mathcal{T}) := \{v_h \in \mathcal{S}^1(\mathcal{T}) : v_h|_{\partial\Omega} = 0\}$. Throughout this section, m is a positive integer.

The pointwise constraint $|v_h| = 1$ is satisfied solely by functions $v_h \in \mathcal{S}^1(\mathcal{T})^m$, which are constant in Ω. Therefore, assuming $u_{\mathrm{D}} \in C(\partial\Omega;\mathbb{R}^m)$, a reasonable finite-element discretization of (P) replaces $\mathcal{A}(u_{\mathrm{D}})$ by the set

$$\mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}}) := \bigl\{v_h \in \mathcal{S}^1(\mathcal{T})^m : \forall z \in \mathcal{N} \cap \partial\Omega\, v_h(z) = u_{\mathrm{D}}(z), \forall z \in \mathcal{N}\, |v_h(z)| = 1\bigr\}$$

and seeks a local minimizer of E in $\mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$

$$(\mathrm{P}_h) \qquad \begin{cases} \text{Find } u_h \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}}), \text{ which is a local} \\ \text{minimizer for } E \text{ in } \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}}). \end{cases}$$

Existence of solutions for the finite dimensional problem (P$_h$) follows from compactness arguments. The computation of a solution, however, is not obvious.

We propose a discrete version of Alouges' algorithm and state sufficient conditions for its stability and convergence.

Algorithm (A_h). Input: $(\mathcal{T}, u_h^{(0)}, \delta)$, where $\mathcal{T}$ is a regular triangulation of Ω, $u_h^{(0)} \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$ is a starting value, and $\delta > 0$ is a termination parameter.

(a) Set $j := 0$.

(b) Solve the optimization problem

$$\begin{cases} \text{Minimize} & E\big(u_h^{(j)} - v_h\big) \\ \text{subject to} & v_h \in \mathcal{S}_0^1(\mathcal{T})^m \;\text{ and }\; v_h(z) \cdot u_h^{(j)}(z) = 0 \text{ for all } z \in \mathcal{N}. \end{cases}$$

Denote the solution by $w_h^{(j)}$.

(c) If $\|Dw_h^{(j)}\|_{L^2(\Omega)} \le \delta$ set $(u_h, w_h) := (u_h^{(j)}, w_h^{(j)})$ and stop.

(d) Define

$$u_h^{(j+1)} := \sum_{z \in \mathcal{N}} \frac{u_h^{(j)}(z) - w_h^{(j)}(z)}{|u_h^{(j)}(z) - w_h^{(j)}(z)|} \varphi_z.$$

(e) Set $j := j + 1$ and go to (b).

Output: $(u_h, w_h) \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}}) \times \mathcal{S}_0^1(\mathcal{T})^m$.

A discrete version of (2.1) is necessary for stability of step (d) in the algorithm. It will turn out that such an estimate in general only holds on acute-type triangulations.

3.1. Validity and possible failure of an energy decreasing property of $(\mathbf{A}_h)$.

The following definition gives a sufficient criterion for stability of step (d) in Algorithm (A_h).

Definition 3.1. *A regular triangulation $\mathcal{T}$ of Ω is said to satisfy* an energy decreasing condition (ED) *if for all $v_h \in \mathcal{S}^1(\mathcal{T})^m$ satisfying $|v_h(z)| \ge 1$ for all $z \in \mathcal{N}$, $|v_h(z)| = 1$ for all $z \in \mathcal{N} \cap \partial\Omega$, and $w_h \in \mathcal{S}^1(\mathcal{T})^m$ defined by*

$$w_h := \sum_{z \in \mathcal{N}} \frac{v_h(z)}{|v_h(z)|} \varphi_z$$

there holds

$$E(w_h) \le E(v_h).$$

The next lemma implies that acute-type triangulations [17] allow for condition (ED).

Lemma 3.2. *Let $\mathcal{T}$ be a regular triangulation of Ω and suppose that $\int_\Omega \nabla\varphi_z \cdot \nabla\varphi_y \,\mathrm{d}x \le 0$ for all $z \in \mathcal{N} \backslash \partial\Omega$ and $y \in \mathcal{N} \backslash \{z\}$. Then $\mathcal{T}$ satisfies condition* (ED).

Proof. For $z, y \in \mathcal{N}$ set $k_{zy} := \int_\Omega \nabla\varphi_z \cdot \nabla\varphi_y \,\mathrm{d}x$. Let $\phi_h \in \mathcal{S}^1(\mathcal{T})^m$ and define $\phi_z := \phi_h(z)$ for all $z \in \mathcal{N}$. Since $\sum_{y \in \mathcal{N}} k_{zy} = 0$ for all $z \in \mathcal{N}$ and since $k_{zy} = k_{yz}$ for all $z, y \in \mathcal{N}$ we have

$$\begin{aligned} \|\nabla\phi_h\|_{L^2(\Omega)}^2 &= \sum_{z,y \in \mathcal{N}} k_{zy} \phi_z \cdot \phi_y = \sum_{z,y \in \mathcal{N}} k_{zy} \phi_z \cdot (\phi_y - \phi_z) \\ &= \frac{1}{2} \sum_{z,y \in \mathcal{N}} k_{zy} \phi_z \cdot (\phi_y - \phi_z) + \frac{1}{2} \sum_{z,y \in \mathcal{N}} k_{zy} \phi_y \cdot (\phi_z - \phi_y) = -\frac{1}{2} \sum_{z,y \in \mathcal{N}} k_{zy} |\phi_z - \phi_y|^2. \end{aligned}$$

Suppose that v_h and w_h are as in Definition 3.1 and let $v_z := v_h(z)$ and $w_z := w_h(z)$ for $z \in \mathcal{N}$. Let $z, y \in \mathcal{N}$ be such that $z \neq y$. If $z \in \mathcal{N}\backslash\partial\Omega$ or $y \in \mathcal{N}\backslash\partial\Omega$ we have $k_{zy} \leq 0$ and hence by Lipschitz continuity of the mapping $\{s \in \mathbb{R}^m : |s| \geq 1\} \to \mathbb{R}^m$, $s \mapsto s/|s|$, with Lipschitz constant 1 that

$$-\frac{1}{2}k_{zy}|w_z - w_y|^2 = -\frac{1}{2}k_{zy}\left|\frac{w_z}{|w_z|} - \frac{w_y}{|w_y|}\right|^2 \leq -\frac{1}{2}k_{zy}|v_z - v_y|^2.$$

If $z, y \in \mathcal{N} \cap \partial\Omega$ we have $w_z = v_z$ and $w_y = v_y$ and hence

$$\|\nabla w_h\|^2_{L^2(\Omega)} = -\frac{1}{2}\sum_{z,y\in\mathcal{N}} k_{zy}|w_z - w_y|^2 \leq -\frac{1}{2}\sum_{z,y\in\mathcal{N}} k_{zy}|v_z - v_y|^2 = \|\nabla v_h\|^2_{L^2(\Omega)},$$

which proves the lemma. □

Remarks 3.3. (i) *Suppose $n = 2$. Given neighboring nodes $z \in \mathcal{N}\backslash\partial\Omega$ and $y \in \mathcal{N}\backslash\{z\}$ let $T_1, T_2 \in \mathcal{T}$ be such that $T_1 \cap T_2$ equals the interior edge connecting z and y. Let $\alpha^{(1)}_{zy}$ and $\alpha^{(2)}_{zy}$ be the angles of T_1 and T_2, respectively, opposite to the edge connecting z and y. There holds* [11]

$$\int_\Omega \nabla\varphi_z \cdot \nabla\varphi_y \,\mathrm{d}x = -\mathrm{cot}\alpha^{(1)}_{zy} - \mathrm{cot}\alpha^{(2)}_{zy}.$$

Sufficient for $\int_\Omega \nabla\varphi_z \cdot \nabla\varphi_y \,\mathrm{d}x \leq 0$ is that $\alpha^{(1)}_{zy} + \alpha^{(2)}_{zy} \leq \pi$.

(ii) *Suppose $n = 3$ and let $z \in \mathcal{N}\backslash\partial\Omega$ and $y \in \mathcal{N}\backslash\{z\}$ be such that $z, y \in T$ for some $T \in \mathcal{T}$. Given any $T \in \mathcal{T}$ such that $z, y \in \mathcal{N} \cap T$ let α_{zyT} be the angle between the two faces $F^{(1)}_{zyT}, F^{(2)}_{zyT} \subseteq \partial T$, which do not contain both z and y. There holds* [17]

$$t\int_\Omega \nabla\varphi_z \cdot \nabla\varphi_y \,\mathrm{d}x = -\sum_{T\in\mathcal{T},\, z,y\in\mathcal{N}\cap T} \frac{|F^{(1)}_{zyT}|\,|F^{(2)}_{zyT}|}{9|T|}\cos\alpha_{zyT},$$

where $|F^{(\ell)}_{zyT}|$ is the surface measure of $F^{(\ell)}_{zyT}$ for $\ell = 1, 2$ and $|T|$ denotes the volume of T. Sufficient for $\int_\Omega \nabla\varphi_z \cdot \nabla\varphi_y \,\mathrm{d}x \leq 0$ is that $\alpha_{zyT} \leq \pi/2$ for all $T \in \mathcal{T}$ such that $z, y \in \mathcal{N} \cap T$.

The conditions of Remark 3.3 are sharp in the sense of the following example.

Example 3.4. *Let $0 < \beta < 1/2$ and $\Omega := (0,1) \times (0,\beta)$. Let*

$$\begin{aligned}
&z_1 := (0,0), && z_2 := (1/2,0), && z_3 := (1,0), && z_4 := (0,\beta),\\
&z_5 := (1/2,\beta), && z_6 := (1,\beta), && z_7 := (1/4,\beta/2), && z_8 := (3/4,\beta/2)
\end{aligned}$$

and $\mathcal{T} := \{T_1, T_2, \ldots, T_8\}$ be defined through

$$\begin{aligned}
&T_1 := \mathrm{conv}\{z_1, z_2, z_7\}, && T_2 := \mathrm{conv}\{z_2, z_8, z_7\}, && T_3 := \mathrm{conv}\{z_2, z_3, z_8\},\\
&T_4 := \mathrm{conv}\{z_3, z_6, z_8\}, && T_5 := \mathrm{conv}\{z_8, z_6, z_5\}, && T_6 := \mathrm{conv}\{z_7, z_8, z_5\},\\
&T_7 := \mathrm{conv}\{z_7, z_5, z_4\}, && T_8 := \mathrm{conv}\{z_1, z_7, z_4\};
\end{aligned}$$

cf. Figure 3.1. Define $s := 1/2 - \beta$ and set $v_j := (1,0)$ for $j = 1, 2, \ldots, 6$, $v_7 := (-1,0)$, and $v_8 := (1,-s)$. Let $v_h, w_h \in \mathcal{S}^1(\mathcal{T})^2$ be such that $v_h(z_j) = v_j$ and $w_h(z_j) = w_j := v_j/|v_j|$ for $j = 1, 2, \ldots, 8$. There holds

$$E(w_h) > E(v_h).$$

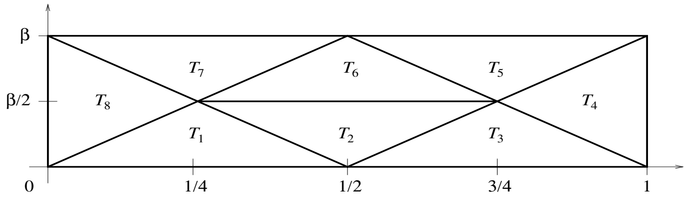

FIG. 3.1. *Triangulation $\mathcal{T}$ in Example* 3.4 *that does not satisfy condition* (ED) *for* $0 < \beta < 1/2$.

Proof. For $j, \ell = 1, 2, \dots, 8$ set $k_{j\ell} := \int_\Omega \nabla\varphi_{z_j} \cdot \nabla\varphi_{z_\ell}\,\mathrm{d}x$. Since $w_j = v_j$ for $j = 1, 2, \dots, 7$ we have (cf. the proof of Lemma 3.2)

$$\delta := \|\nabla v_h\|^2_{L^2(\Omega)} - \|\nabla w_h\|^2_{L^2(\Omega)} = -\frac{1}{2}\sum_{j,\ell=1}^{8} k_{j\ell}\big(|v_j - v_\ell|^2 - |w_j - w_\ell|^2\big)$$
$$= -\sum_{j=1}^{6} k_{j8}\big(|(1,0) - v_8|^2 - |(1,0) - w_8|^2\big) - k_{78}\big(|(-1,0) - v_8|^2 - |(-1,0) - w_8|^2\big).$$

We use $|(1,0) - v_8|^2 = s^2$, $|(-1,0) - v_8|^2 = 4 + s^2$ and abbreviate

$$\kappa_1^2 := |(1,0) - w_8|^2 = 2 - 2/\sqrt{1+s^2}, \quad \kappa_2^2 := |(-1,0) - w_8|^2 = 2 + 2/\sqrt{1+s^2}.$$

Using that $\sum_{j=1}^{8} k_{j8} = 0$ we verify $\sum_{j=1}^{6} k_{j8} = -k_{78} - k_{88}$ and obtain

$$\delta = \big(s^2 - \kappa_1^2\big)(k_{78} + k_{88}) - k_{78}\big(4 + s^2 - \kappa_2^2\big) = k_{88}\big(s^2 - \kappa_1^2\big) - k_{78}\big(4 + \kappa_1^2 - \kappa_2^2\big).$$

Elementary calculations show that

$$k_{88} = \big(12\beta^2 + 5\big)/(4\beta) \quad \text{and} \quad k_{78} = \big(1 - 4\beta^2\big)/(4\beta).$$

With a function ϕ such that $\sqrt{1+s^2} = 1 + \frac{1}{2}s^2 + \phi(s^2)$ we deduce

$$4\beta\sqrt{1+s^2}\delta = (12\beta^2 + 5)\left(\frac{1}{2}s^4 + s^2\phi(s^2) - 2\phi(s^2)\right) - (1 - 4\beta^2)(2s^2 + 4\phi(s^2)).$$

Using that $\beta^2 = \frac{1}{4} - s + s^2$ we verify

$$4\beta\sqrt{1+s^2}\delta = \big(8 - 12s + 12s^2\big)\left(\frac{1}{2}s^4 + s^2\phi(s^2) - 2\phi(s^2)\right) - 16(s - s^2)\left(\frac{1}{2}s^2 + \phi(s^2)\right)$$
$$= -8s^3 + 12s^4 - 6s^5 + 6s^6 + \phi(s^2)(-16 + 8s - 12s^3 + 12s^4)$$
$$= -6s^3(1 - 2s) - 6s^5(1 - s) + 4s\phi(s^2)(2 - 3s^2 + 3s^3) - 2(s^3 + 8\phi(s^2)).$$

Since $0 < s < 1/2$ and $\phi(s^2) < 0$, the first three terms on the right-hand side are negative. A Taylor expansion proves $-s^4/8 \le \phi(s^2)$ and implies that the last term on the right-hand side is nonpositive. This shows $\delta < 0$ and proves the lemma. ∎

We include another sufficient criterion for validity of condition (ED) that allows to construct triangulations of a large class of three-dimensional domains.

LEMMA 3.5. *Suppose $n = 3$ and assume that each $T \in \mathcal{T}$ has three mutually perpendicular edges. Then $\mathcal{T}$ satisfies condition* (ED).

Proof. Let $v_h, w_h \in \mathcal{S}^1(\mathcal{T})^m$ be as in Definition 3.1 and let $T \in \mathcal{T}$. Let $b_1, b_2, b_3 \in \mathbb{R}^3 \backslash \{0\}$ be mutually perpendicular and such that $b_j = z_j - y_j$, $j = 1, 2, 3$, where $z_j, y_j \in \mathcal{N} \cap T$ for $j = 1, 2, 3$. After an appropriate rotation we may assume $b_j = |b_j| e_j$ for $j = 1, 2, 3$, where e_j is the jth canonical basis vector in $\mathbb{R}^3$. Since $s \mapsto s/|s|$ for $s \in \mathbb{R}^m$ with $|s| \geq 1$ is Lipschitz continuous with Lipschitz constant 1 we deduce for $j = 1, 2, 3$ that

$$\left| \frac{\partial w_h|_T}{\partial x_j} \right| = \frac{1}{|z_j - y_j|} \left| \frac{v_h(z_j)}{|v_h(z_j)|} - \frac{v_h(y_j)}{|v_h(y_j)|} \right| \leq \frac{1}{|z_j - y_j|} |v_h(z_j) - v_h(y_j)| = \left| \frac{\partial v_h|_T}{\partial x_j} \right|,$$

which implies the lemma. □

REMARK 3.6. *It can be shown* [16] *that if $n = 3$ and each $T \in \mathcal{T}$ has* 3 *mutually perpendicular edges, which do not pass through the same vertex, then $\mathcal{T}$ is of acute type, i.e., satisfies the conditions of Remark* 3.3 (ii).

The following example defines a triangulation of the unit cube, which satisfies the conditions of Lemma 3.5. It allows to construct triangulations that satisfy condition (ED) of unions of finitely many quadrilaterals. Other constructions and acute-type refinement strategies of tetrahedra can be found in [17, 16].

EXAMPLE 3.7 (see [5]). *Set* $\mathcal{N} := \{z_1, z_2, \ldots, z_8\}$ *for*

$$z_1 := (0,0,0), \quad z_2 := (1,0,0), \quad z_3 := (0,0,1), \quad z_4 := (1,0,1),$$
$$z_5 := (0,1,0), \quad z_6 := (1,1,0), \quad z_7 := (0,1,1), \quad z_8 := (1,1,1).$$

Define $\mathcal{T} := \{T_1, T_2, \ldots, T_6\}$ *with*

$$T_1 := \mathrm{conv}\{z_1, z_2, z_3, z_6\}, \quad T_2 := \mathrm{conv}\{z_2, z_4, z_3, z_6\}, \quad T_3 := \mathrm{conv}\{z_3, z_4, z_8, z_6\},$$
$$T_4 := \mathrm{conv}\{z_3, z_8, z_7, z_6\}, \quad T_5 := \mathrm{conv}\{z_7, z_5, z_3, z_6\}, \quad T_6 := \mathrm{conv}\{z_3, z_5, z_1, z_6\}.$$

Then $\mathcal{T}$ is a regular triangulation of $(0,1)^3$ *and satisfies the assumptions of Lemma* 3.5*; cf. Figure* 3.2.

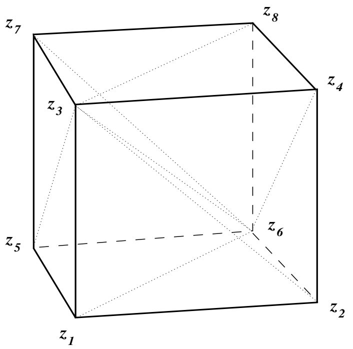

FIG. 3.2. *Triangulation $\mathcal{T}$ of the unit cube defined in Example* 3.7 *such that each element in $\mathcal{T}$ has three mutually perpendicular edges.*

3.2. Well posedness and termination of algorithm (A$_h$)**.** The following lemma shows that all steps in (A$_h$) are well defined and that the algorithm terminates within a finite number of iterations, provided that $\mathcal{T}$ satisfies condition (ED).

LEMMA 3.8. *Suppose $\mathcal{T}$ satisfies condition* (ED). *Given $\delta > 0$ and $u_h^{(0)} \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$, Algorithm* (A$_h$) *with input* $(\mathcal{T}, u_h^{(0)}, \delta)$ *terminates within a finite number*

M of iterations with output $(u_h, w_h) \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}}) \times \mathcal{S}^1_0(\mathcal{T})^m$ such that $\|Dw_h\|_{L^2(\Omega)} \leq \delta$ and

$$E(u_h) \leq E\big(u_h^{(0)}\big).$$

Proof. We proceed by induction to show $u_h^{(j)} \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$ and $E(u_h^{(j+1)}) \leq E(u_h^{(j)})$. Suppose that for some $j \geq 0$ we are given $u_h^{(j)} \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$. The set

$$L^{(j)} := \big\{ v_h \in \mathcal{S}^1_0(\mathcal{T})^m : \forall z \in \mathcal{N}\; v_h(z) \cdot u_h^{(j)}(z) = 0 \big\}$$

is a subspace of $\mathcal{S}^1_0(\mathcal{T})^m$. Hence, there exists $w_h \in L^{(j)}$ such that

$$\int_\Omega Dw_h : Dv_h \,\mathrm{d}x = \int_\Omega Du_h^{(j)} : Dv_h \,\mathrm{d}x \tag{3.1}$$

for all $v_h \in L^{(j)}$. This is equivalent to

$$E\big(u_h^{(j)} - w_h\big) \leq E\big(u_h^{(j)} - v_h\big)$$

for all $v_h \in L^{(j)}$. Thus, $w_h = w_h^{(j)}$ is the unique solution in step (b) of Algorithm (A$_h$). Since $w_h^{(j)}(z) \cdot u_h^{(j)}(z) = 0$ and $|u_h^{(j)}(z)| = 1$ there holds $|u_h^{(j)}(z) - w_h^{(j)}(z)| \geq 1$ for all $z \in \mathcal{N}$. Hence, $u_h^{(j+1)}$ is well defined and $u_h^{(j+1)} \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$. Since $0 \in L^{(j)}$ and $\mathcal{T}$ satisfies condition (ED) there holds $E(u_h^{(j+1)}) \leq E(u_h^{(j)} - w_h^{(j)}) \leq E(u_h^{(j)})$. Equation (3.1) with $v_h = w_h = w_h^{(j)}$ proves $E(u_h^{(j)} - w_h^{(j)}) = E(u_h^{(j)}) - E(w_h^{(j)})$ and a combination with the previous assertion shows

$$0 \leq E\big(w_h^{(j)}\big) \leq E\big(u_h^{(j)}\big) - E\big(u_h^{(j+1)}\big).$$

Since $\big(E(u_h^{(j)}) : j \in \mathbb{N}\big)$ is monotonically decreasing and bounded from below we conclude that it is a Cauchy sequence and hence $\|Dw_h^{(M)}\|_{L^2(\Omega)} \leq \delta$ for M sufficiently large. □

3.3. Convergence for $h \to 0$. The following theorem shows that for a sequence of triangulations with maximal mesh size tending to 0 the sequence of outputs of Algorithm (A$_h$) provides a weakly convergent subsequence whose weak limit is a harmonic map. The important questions whether this weak limit is (globally) energy minimizing in (P) or whether weak convergence can be improved to strong convergence are left for future research.

THEOREM 3.9. *Suppose $u_{\mathrm{D}} \in H^1(\partial\Omega; \mathbb{R}^3)$. Let $(\mathcal{T}_k : k \in \mathbb{N})$ be a sequence of regular triangulations of Ω satisfying condition* (ED) *with maximal mesh sizes $(h_k : k \in \mathbb{N})$ satisfying $h_k \to 0$ for $k \to \infty$ and let $(\delta_k : k \in \mathbb{N})$ be a sequence of positive numbers such that $\delta_k \to 0$ for $k \to \infty$. Suppose that $u_k^{(0)} \in \mathcal{A}_h(\mathcal{T}_k, u_{\mathrm{D}})$ and there exists $C_0 > 0$ such that*

$$\big\|Du_k^{(0)}\big\|_{L^2(\Omega)} \leq C_0$$

for all $k \in \mathbb{N}$. For each $k \in \mathbb{N}$, let (u_k, w_k) be the output of Algorithm (A$_h$) *applied to the input $(\mathcal{T}_k, u_k^{(0)}, \delta_k)$. Then there exists a subsequence $(u_\ell : \ell \in \mathbb{N})$ and a harmonic map $u^* \in \mathcal{A}(u_{\mathrm{D}})$ such that $u_\ell \rightharpoonup u^*$ (weakly) in H^1 and*

$$E(u^*) \leq \liminf_{\ell \to \infty} E(u_\ell).$$

The following lemma is essential in the proof of the theorem. For $c \in \mathbb{R}^3$ and a matrix $A \in \mathbb{R}^{3\times 3}$ with columns $a_1, a_2, a_3 \in \mathbb{R}^3$ we let $c \times A \in \mathbb{R}^{3\times 3}$ be the matrix whose columns equal $c \times a_j$ for $j = 1, 2, 3$.

LEMMA 3.10 (see [8]). *A function $u \in \mathcal{A}(u_{\rm D})$ is a harmonic map if and only if*

$$\int_\Omega \big(u \times Du\big) : D\phi \,\mathrm{d}x = 0 \tag{3.2}$$

for all $\phi \in H^1_0(\Omega;\mathbb{R}^3) \cap L^\infty(\Omega;\mathbb{R}^3)$.

Proof. Suppose that u is a harmonic map, i.e., for all $w \in H^1_0(\Omega;\mathbb{R}^3) \cap L^\infty(\Omega;\mathbb{R}^3)$ there holds

$$\int_\Omega Du : Dw \,\mathrm{d}x = \int_\Omega |Du|^2 u \cdot w \,\mathrm{d}x.$$

Let $\phi \in H^1_0(\Omega;\mathbb{R}^3) \cap L^\infty(\Omega;\mathbb{R}^3)$ and set $w := u \times \phi$. Using $(a \times b) \cdot c = -(a \times c) \cdot b$ for any $a, b, c \in \mathbb{R}^3$ we verify

$$Du : Dw = Du : \big(Du \times \phi + u \times D\phi\big) = Du : \big(u \times D\phi\big) = -\big(u \times Du\big) : D\phi$$

almost everywhere in Ω and since $u \cdot w = 0$ we find that u satisfies (3.2). Suppose now that u satisfies (3.2) and set $\phi := u \times w$. The identity $(a \times b) \cdot (c \times d) = (a \cdot c)(b \cdot d) - (b \cdot c)(a \cdot d)$ yields

$$\begin{aligned} D(u \times w) : \big(u \times Du\big) &= \big(Du \times w\big) : \big(u \times Du\big) + \big(u \times Dw\big) : \big(u \times Du\big) \\ &= \big(u^T Du\big) \cdot \big(w^T Du\big) - |Du|^2 u \cdot w + |u|^2 Dw : Du - \big(u^T Dw\big) \cdot \big(u^T Du\big) \end{aligned}$$

almost everywhere in Ω. The identity $|u|^2 = 1$ implies $u^T Du = 0$ almost everywhere in Ω. An integration over Ω finishes the proof of the lemma. □

Proof of Theorem 3.9. By Lemma 3.8 and the boundedness of $(u_k^{(0)})$ in H^1 there holds $\|Du_k\|_{L^2(\Omega)} \le \|Du_k^{(0)}\|_{L^2(\Omega)} \le C_0$ for all $k \in \mathbb{N}$. Hence, there exists a subsequence $(u_\ell : \ell \in \mathbb{N})$ and $u^* \in H^1(\Omega;\mathbb{R}^3)$ such that $u_\ell \rightharpoonup u^*$ (weakly) in H^1. Weak lower semicontinuity of E implies $E(u^*) \le \liminf_{\ell\to\infty} E(u_\ell)$. Since $|u_\ell(z)| = 1$ for all $z \in \mathcal{N}_\ell$ we have, by a $\mathcal{T}$ elementwise application of Poincaré's inequality and $|u_\ell| \le 1$ almost everywhere in Ω,

$$\|\, |u_\ell|^2 - 1 \,\|_{L^2(\Omega)} \le C_P h_\ell \big\| 2u_\ell^T Du_\ell \big\|_{L^2(\Omega)} \le 2 C_P C_0 h_\ell.$$

Since $u_\ell \to u^*$ almost everywhere in Ω we deduce $|u^*| = 1$ almost everywhere in Ω. Moreover, we have

$$\big\| u_\ell|_{\partial\Omega} - u_{\rm D} \big\|_{L^2(\partial\Omega)} \le C h_\ell \big\| \partial u_{\rm D}/\partial s \|_{L^2(\partial\Omega)}$$

(here, $\partial u_{\rm D}/\partial s$ denotes the surface gradient of $u_{\rm D}$ along $\partial\Omega$) and compactness of the trace operator as a mapping from $H^1(\Omega;\mathbb{R}^3)$ into $L^2(\partial\Omega;\mathbb{R}^3)$ (cf. [24] for details) implies $u^*|_{\partial\Omega} = u_{\rm D}$. It remains to show that u^* is a harmonic map. For all $\Psi_\ell \in \mathcal{S}^1_0(\mathcal{T}_\ell)^3$ with $\Psi_\ell(z) \cdot u_\ell(z) = 0$ for all $z \in \mathcal{N}_\ell$ there holds by definition of w_ℓ

$$\int_\Omega D(u_\ell - w_\ell) : D\Psi_\ell \,\mathrm{d}x = 0.$$

Given $\phi \in C_0^\infty(\Omega;\mathbb{R}^3)$ let $\Phi_\ell := \phi \times u_\ell$ and choose $\Psi_\ell := \mathcal{I}_\ell(\phi \times u_\ell)$, where $\mathcal{I}_\ell$ denotes the nodal interpolation operator on $\mathcal{T}_\ell$. We then have

$$\int_\Omega Du_\ell : D(\phi \times u_\ell)\,\mathrm{d}x = \int_\Omega D(u_\ell - w_\ell) : D(\Phi_\ell - \Psi_\ell)\,\mathrm{d}x + \int_\Omega Dw_\ell : D\Phi_\ell\,\mathrm{d}x. \tag{3.3}$$

Using

$$Du_\ell : D(\phi \times u_\ell) = Du_\ell : (D\phi \times u_\ell + \phi \times Du_\ell) = Du_\ell : (D\phi \times u_\ell) = D\phi : (u_\ell \times Du_\ell)$$

and $u_\ell \to u^*$ (strongly) in L^2, $Du_\ell \rightharpoonup Du^*$ (weakly) in H^1 we deduce

$$\int_\Omega Du_\ell : D(\phi \times u_\ell)\,\mathrm{d}x = \int_\Omega D\phi : (u_\ell \times Du_\ell)\,\mathrm{d}x \to \int_\Omega D\phi : (u^* \times Du^*)\,\mathrm{d}x. \tag{3.4}$$

Since u_ℓ is $\mathcal{T}$ elementwise affine there holds for each $T \in \mathcal{T}$

$$\begin{aligned}\|D(\Phi_\ell - \Psi_\ell)\|_{L^2(T)} &= \|D\big(\phi \times u_\ell - \mathcal{I}_\ell(\phi \times u_\ell)\big)\|_{L^2(T)} \le Ch_\ell \|D^2(\phi \times u_\ell)\|_{L^2(T)}\\ &\le Ch_\ell\big(\|D^2\phi\|_{L^2(T)} + \|D\phi\|_{L^\infty(\Omega)}\|Du_\ell\|_{L^2(T)}\big),\end{aligned}$$

and hence $\Phi_\ell - \Psi_\ell \to 0$ (strongly) in H^1. Notice that $u_\ell - w_\ell$ is uniformly bounded in H^1 so that

$$\int_\Omega D(u_\ell - w_\ell) : D(\Phi_\ell - \Psi_\ell)\,\mathrm{d}x \to 0. \tag{3.5}$$

Since Φ_ℓ is bounded in H^1 and $w_\ell \to 0$ (strongly) in H^1 we have

$$\int_\Omega Dw_\ell : D\Phi_\ell\,\mathrm{d}x \to 0. \tag{3.6}$$

A combination of (3.3)–(3.6) yields

$$\int_\Omega D\phi : (u^* \times Du^*)\,\mathrm{d}x = 0,$$

which, according to Lemma 3.10, shows that u^* is a harmonic map. □

4. Numerical experiments I.

In this section we report on some numerical experiments. We first discuss the implementation of Algorithm (A_h).

4.1. Uzawa iteration for the efficient solution of step (b).

Step (b) of Algorithm (A_h) requires the solution of a quadratic optimization problem with linear constraints. This can be solved directly, but may be inefficient. We thus propose the use of an Uzawa iteration. The optimization problem may be rewritten as a saddle point problem and the related optimality conditions read

$$(\mathrm{SP}_h) \qquad \begin{cases}\text{Find } w_h \in \mathcal{S}_0^1(\mathcal{T})^3 \text{ and } \lambda \in \mathbb{R}^{\mathcal{K}} \text{ such that, for all } v_h \in \mathcal{S}_0^1(\mathcal{T})^3,\\ \displaystyle\int_\Omega Dw_h : Dv_h\,\mathrm{d}x + \sum_{z\in\mathcal{K}} \lambda_z u_h^{(j)}(z)\cdot v_h(z) = \int_\Omega Du_h^{(j)} : Dv_h\,\mathrm{d}x,\\ w_h(z)\cdot u_h^{(j)}(z) = 0 \quad \text{for all } z \in \mathcal{K}.\end{cases}$$

Here, $\mathcal{K} := \mathcal{N} \cap \Omega$ denotes the set of free nodes in $\mathcal{N}$. The problem can be recast as

$$(\mathrm{SP}'_h) \qquad \begin{cases}\text{Find } x \in \mathbb{R}^{3N'} \text{ and } \lambda \in \mathbb{R}^{N'} \text{ such that}\\ A'x + B^T\lambda = b,\\ Bx = 0.\end{cases}$$

In this formulation, $x \in \mathbb{R}^{3N'}$ contains the values of w_h in the free nodes and we set $N' := \operatorname{card}(\mathcal{K})$. The constraint $u_h(z) \cdot w_h(z) = 0$, $z \in \mathcal{K}$, is realized by the matrix $B \in \mathbb{R}^{3N' \times N'}$. The positive definite matrix $A' \in \mathbb{R}^{3N' \times 3N'}$ is the restriction of A to $\mathcal{S}^1_0(\mathcal{T})^3$, where A is the stiffness matrix defined through the nodal basis in $\mathcal{S}^1(\mathcal{T})^3$. Finally, b is given by the restriction of $A\underline{u}$ to the free nodes, assuming that $\underline{u}$ contains the nodal values of $u_h^{(j)}$ in $\mathcal{N}$. The efficient iterative solution of (SP'_h) is realized by an Uzawa algorithm with conjugate directions and an LU decomposition of A' (cf., e.g., [6]).

4.2. Numerical examples. For the first numerical experiments we specify (P) in the following example.

EXAMPLE 4.1. *Set* $\Omega := (-1/2, 1/2)^3$ *and* $u_{\mathrm{D}}(x) := x/|x|$, $x \in \partial\Omega$. *Then,* $u(x) = x/|x|$, $x \in \Omega$, *is the unique solution of* (P) [18].

In order to satisfy the conditions that guarantee convergence in Theorem 3.9 we construct triangulations of Ω that satisfy condition (ED) by scaling, translating, and assembling copies of the triangulation $\mathcal{T}$ from Example 3.7.

EXAMPLE 4.2. *Given an integer* $k \geq 1$ *set* $h_k := 1/k$,

$$C_k := \big\{h_k(\ell, m, n) : 0 \leq \ell, m, n \leq k-1\big\} - (1,1,1)/2,$$

and define, with $\tilde{\mathcal{T}}$ *from Example* 3.7,

$$\mathcal{T}_k := \big\{c + h_k T : c \in C_k,\, T \in \mathcal{T}\big\}.$$

Then, $\mathcal{T}_k$ *is a regular triangulation of* $\Omega = (-1/2, 1/2)^3$ *with maximal mesh size* $\sqrt{3}/k$ *and satisfies condition* (ED).

We used four triangulations $\mathcal{T}_k$, specified through $k = 4, 8, 16, 32$ in Example 4.1, with $3N'_k = 375, 2187, 14739, 107811$ degrees of freedom (i.e., N'_k free nodes in $\mathcal{T}_k$). We set $\delta_k := 10^{-4}/\log_2(k)$ and define initial functions $u_k^{(0)} \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$ by

$$u_k^{(0)}(z) := \begin{cases} z/|z| & \text{for } z \in \mathcal{N}_k \cap \partial\Omega, \\ (0,1,0) & \text{for } z \in \mathcal{N}_k \cap \Omega. \end{cases}$$

In all experiments the Uzawa iteration was stopped when the ℓ^2 norm of the residual Bx in (SP'_h) was less than 10^{-6}. In most of the experiments this stopping criterion was satisfied after at most 20 iterations.

Figure 4.1 displays the decay of the energy $E(u_k^{(j)})$, $j = 1, 2, \ldots$, in the iteration of Algorithm (A_h) with input $(\mathcal{T}_k, u_k^{(0)}, \delta_k)$ for $k = 4, 8, 16, 32$. The plot shows that the decrease in the energy is largest for the first few iterations. This yields the conjecture that the choice of the termination criteria $\delta_k = 10^{-4}/\log_2 k$ is inefficient in this example if one is only interested in an asymptotic behavior for $h \to 0$.

Figure 4.2 shows the projection of the vector fields $u_{32}^{(j)}(0, \cdot, \cdot)$ obtained from Algorithm (A_h) onto $\{(x, y, z) \in \mathbb{R}^3 : x = 0\}$ in $(-1/2, 1/2)^2$ for $j = 0, 10, 50, 315$. We observe that only a few iterations are needed to rotate vectors in such a way that only one degree-1 singularity is present. The subsequent iterations move this singularity to the origin. After 317 iterations Algorithm (A_h) with input $(\mathcal{T}_{32}, u_{32}^{(0)}, \delta_{32})$ terminates and the nodal values of the output u_{32} appear to be very close to the exact solution away from 0. The value of the numerical solution at 0, where the exact solution has a singularity, has no particular meaning and seems to depend on the triangulation and the initial value.

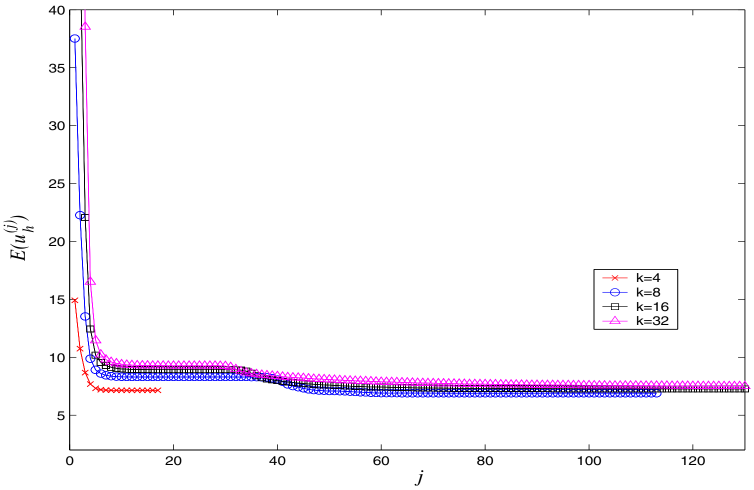

FIG. 4.1. *Decay of the energy in the iteration of Algorithm* (A_h) *on* $\mathcal{T}_k$ *with* $k = 4, 8, 16, 32$ *in Example* 4.1 *and initial* $u_k^{(0)} \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$.

We assume that our definition of $u_k^{(0)}$ is suboptimal as it admits large gradients in a neighborhood of $\partial\Omega$. In particular, this choice does not satisfy $\|Du_k^{(0)}\|_{L^2(\Omega)} \le C_0$ for $h_k \to 0$. However, even if for all $z \in \mathcal{K}$, $\xi(z)$ is a random unit vector in $\mathbb{R}^3$ and the starting value $\tilde{u}_k^{(0)} \in \mathcal{A}_h(\mathcal{T}, u_{\mathrm{D}})$ is defined by

$$\tilde{u}_k^{(0)}(z) := \begin{cases} z/|z| & \text{for } z \in \mathcal{N}_k \cap \partial\Omega, \\ \xi(z) & \text{for } z \in \mathcal{N}_k \cap \Omega, \end{cases}$$

then we observe in Figure 4.3 that the energy still decreases rapidly in the first iterations and becomes stationary almost as fast as for the previous choice. We assume that the number of iterations depends on the initial energy and can be reduced with an optimal choice of $u_k^{(0)}$. Indeed, the proof of Lemma 3.8 shows that the sequence of corrections $w_k^{(j)}$ satisfies for all $\ell \ge 0$

$$\sum_{j=0}^{\ell} \|Dw_k^{(j)}\|_{L^2(\Omega)}^2 \le \|Du_k^{(0)}\|_{L^2(\Omega)}^2,$$

and assuming that $\|Du_k^{(0)}\|_{L^2(\Omega)} \le C_0$ (for a k-independent constant $C_0 > 0$) then the number of iterations can be expected to grow less fast than in the presented experiments.

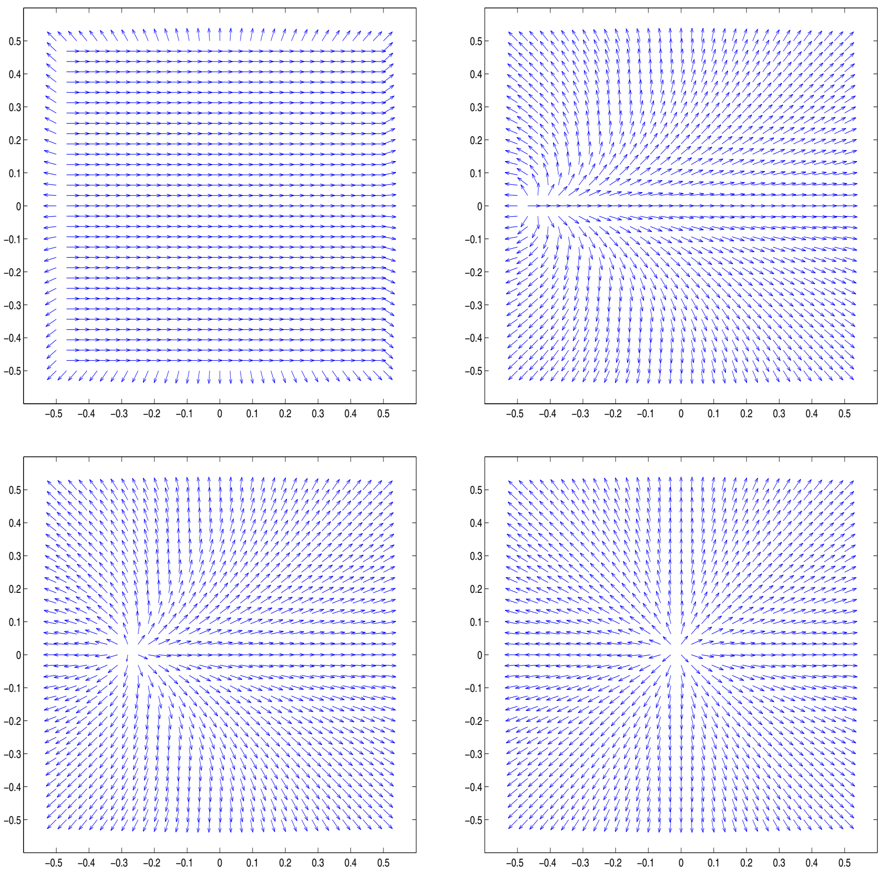

FIG. 4.2. *Projection of the vector fields* $u_{32}^{(j)}(0,\cdot,\cdot)$ *onto* $\{(x,y,z)\in\mathbb{R}^3 : x=0\}$ *in* $(-1/2,1/2)^2$ *for* $j=0,10,50,315$ *in Example* 4.1 *and initial* $u_k^{(0)}\in\mathcal{A}_h(\mathcal{T},u_{\mathrm{D}})$.

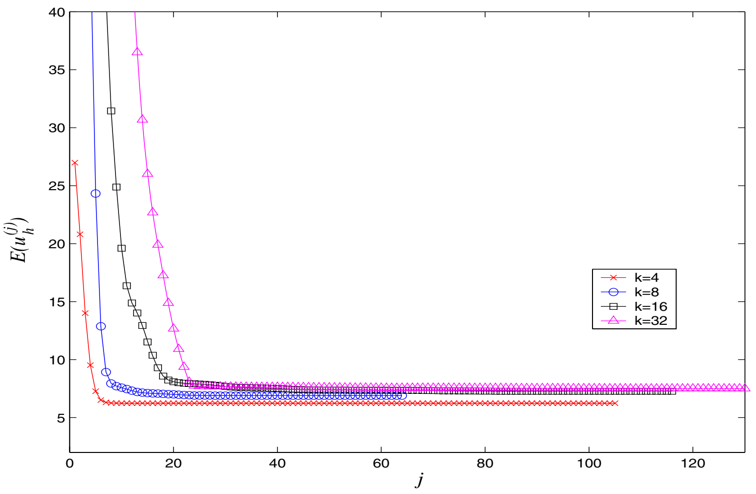

FIG. 4.3. *Decay of the energy in the iteration of Algorithm* (A_h) *on* $\mathcal{T}_k$ *with* $k=4,8,16,32$ *in Example* 4.1 *with random initial data* $\tilde{u}_k^{(0)}\in\mathcal{A}_h(\mathcal{T},u_{\mathrm{D}})$.

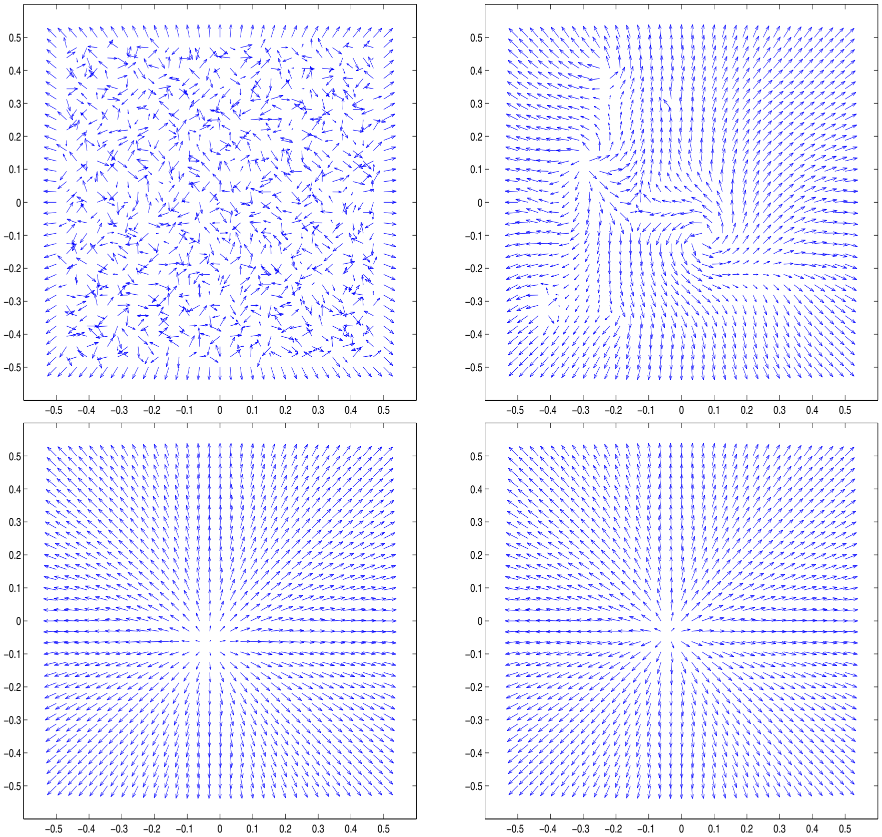

FIG. 4.4. *Projection of the vector fields* $u_{32}^{(j)}(0,\cdot,\cdot)$ *onto* $\{(x,y,z)\in\mathbb{R}^3 : x=0\}$ *in* $(-1/2,1/2)^2$ *for* $j=0,10,50,165$ *in Example* 4.1 *with initial data* $\tilde{u}_{32}^{(0)}\in\mathcal{A}_h(\mathcal{T},u_{\mathrm{D}})$.

Figure 4.4 shows the projection of the vector fields $u_{32}^{(j)}(0,\cdot,\cdot)$ onto $\{(x,y,z)\in\mathbb{R}^3 : x=0\}$ in $(-1/2,1/2)^2$ for $j=0,10,50,165$ produced by Algorithm (A_h) with initial data $\tilde{u}_{32}^{(0)}$. We observe that the algorithm immediately changes the highly unordered initial configuration into a more stable one; after 10 iterations only one degree-1 singularity with high symmetry can be seen. The subsequent iterations move the singularity to the origin.

5. Local refinement criteria. The main assertion of this section is a modification of the assumptions of Theorem 3.9. It replaces the assumption that the maximal mesh size tends to 0 and that the employed triangulations are of acute type by the weaker assumption that certain computable quantities tend to 0. Moreover, the assertion is independent of a particular scheme since the computable quantities are entirely determined by an approximation u_h.

Given a regular triangulation $\mathcal{T}$ of Ω let $h_{\mathcal{T}}\in L^\infty(\Omega)$ be the $\mathcal{T}$-elementwise constant function satisfying $h_{\mathcal{T}}|_T=\operatorname{diam}(T)$ for all $T\in\mathcal{T}$. $\mathcal{F}$ denotes the set of all faces in $\mathcal{T}$ and $h_{\mathcal{F}}$ is defined on $\cup\mathcal{F}$ through $h_{\mathcal{F}}|_F:=\operatorname{diam}(F)$ for all $F\in\mathcal{F}$. For a $\mathcal{T}$-elementwise smooth (e.g., $\mathcal{T}$-elementwise constant) function $\Sigma\in L^\infty(\Omega;\mathbb{R}^{3\times 3})$ we set

$$\big[\Sigma\cdot n_{\mathcal{F}}\big]|_F := \big((\Sigma|_{T_2})|_F-(\Sigma|_{T_1})|_F\big)\cdot n_F,$$

where $F \in \mathcal{F} \cap \Omega$, $T_1, T_2 \in \mathcal{T}$ such that $T_1 \cap T_2 = F$, and $n_F \in \mathbb{R}^3$ is the unit normal vector to F pointing from T_1 into T_2.

Definition 5.1. *Given any $u_h \in \mathcal{S}^1(\mathcal{T})^3$ let $w_h \in \mathcal{S}^1_0(\mathcal{T})^3$ satisfy $w_h(z) \cdot u_h(z) = 0$ for all $z \in \mathcal{N}$ and*

$$\int_\Omega Dw_h : Dv_h \, \mathrm{d}x = \int_\Omega Du_h : Dv_h \, \mathrm{d}x$$

for all $v_h \in \mathcal{S}^1_0(\mathcal{T})^3$ with $v_h(z) \cdot u_h(z) = 0$ for all $z \in \mathcal{N}$. For each $T \in \mathcal{T}$ set

$$\begin{aligned} \eta_1(T, u_h)^2 &:= \big\| |u_h|^2 - 1 \big\|^2_{L^2(T)} + \big\| u_h|_{\partial\Omega} - u_{\mathrm{D}} \big\|^2_{L^2(\partial T \cap \partial\Omega)}, \\ \eta_2(T, u_h)^2 &:= \big\| h_{\mathcal{F}}^{1/2} [D(u_h - w_h) \cdot n_{\mathcal{F}}] \big\|^2_{L^2(\partial T \cap \Omega)} + \| Dw_h \|^2_{L^2(T)}. \end{aligned}$$

Note that the following assertion does not assume that u_h is obtained by Algorithm (A_h), that the maximal mesh sizes tend to 0, or that the triangulations satisfy condition (ED).

Proposition 5.2. *Suppose that $(\mathcal{T}_k : k \in \mathbb{N})$ is a sequence of regular triangulations of Ω, and let $(u_k : k \in \mathbb{N}) \subseteq \mathcal{S}^1(\mathcal{T}_k)^3$ be such that $\|Du_k\|_{L^2(\Omega)} \le C_1$ for some $C_1 > 0$ and all $k \ge 0$. Suppose that*

$$\sum_{T \in \mathcal{T}_k} \eta_1(T, u_k)^2 + \eta_2(T, u_k)^2 \to 0 \quad \textit{for } k \to \infty.$$

Then there exists a subsequence $(u_\ell : \ell \in \mathbb{N})$ and a harmonic map $u^* \in \mathcal{A}(u_{\mathrm{D}})$ such that $u_\ell \rightharpoonup u^*$ (weakly) in H^1 and

$$E(u^*) \le \liminf_{\ell \to \infty} E(u_\ell). \tag{5.1}$$

Proof. The boundedness of $\|Du_k\|^2_{L^2(\Omega)} + \|u_k\|^2_{L^2(\Omega)}$ implies the existence of a weakly convergent subsequence $(u_\ell : \ell \in \mathcal{N})$ and a weak limit $u^* \in H^1(\Omega; \mathbb{R}^3)$. Since $\sum_{T \in \mathcal{T}} \eta_1(T, u_\ell)^2 \to 0$ one verifies that $u^* \in \mathcal{A}(u_{\mathrm{D}})$. The weak lower semicontinuity of E proves (5.1). It remains to show that u^* is a harmonic map. Given any $\phi \in C_0^\infty(\Omega; \mathbb{R}^3)$ we set $\Phi_\ell := \phi \times u_\ell$ and let $\Psi_\ell := \mathcal{I}_\ell \Phi_\ell$ be the nodal interpolant of Φ_ℓ on $\mathcal{T}_\ell$. As in the proof of Theorem 3.9 we have to show that

$$\int_\Omega Du_\ell : D(\phi \times u_\ell) \, \mathrm{d}x = \int_\Omega D(u_\ell - w_\ell) : D(\Phi_\ell - \Psi_\ell) \, \mathrm{d}x + \int_\Omega Dw_\ell : D\Phi_\ell \, \mathrm{d}x \to 0.$$

A $\mathcal{T}_\ell$-elementwise integration by parts and standard interpolation estimates yield

$$\begin{aligned} \int_\Omega D(u_\ell - w_\ell) : D(\Phi_\ell - \Psi_\ell) \, \mathrm{d}x &= \sum_{F \in \mathcal{F}_\ell,\, F \subseteq \Omega} \int_F [D(u_h - w_h) \cdot n_{\mathcal{F}_\ell}] \cdot (\Phi_\ell - \Psi_\ell) \, \mathrm{d}s \\ &\le C \Big(\sum_{T \in \mathcal{T}} \eta_2(T, u_\ell)^2 \Big)^{1/2} \|D\Phi_\ell\|_{L^2(\Omega)}. \end{aligned}$$

Hölder's inequality implies

$$\int_\Omega Dw_\ell : D\Phi_\ell \, \mathrm{d}x \le \Big(\sum_{T \in \mathcal{T}_k} \eta_2(T, u_k)^2 \Big)^{1/2} \|D\Phi_\ell\|_{L^2(\Omega)}.$$

The proof of Theorem 3.9 shows

$$\int_\Omega Du_\ell : D(\phi \times u_\ell)\,\mathrm{d}x \to \int_\Omega D\phi : (u^* \times Du^*)\,\mathrm{d}x.$$

A combination of the assertions with Lemma 3.10 and $\|D\Phi_\ell\|_{L^2(\Omega)} \le C$ shows that u^* is a harmonic map. □

6. Numerical experiments II.

6.1. Adaptive algorithm. Proposition 5.2 motivates the following adaptive mesh refinement algorithm. It realizes uniform mesh refinement for $\Theta = 0$ and adaptive mesh refinement for $\Theta = 1/2$. The idea is to iterate steps (b) and (d) of Algorithm (A_h) as long as the energy is significantly decreasing. A termination criterion that may be based on smallness of the local refinement indicators $\eta_j(T, u_h)$ can easily be included.

Algorithm (A_h^Θ). Input: $(\mathcal{T}, u_h^{(0)}, \kappa)$, where $\mathcal{T}$ is a regular triangulation of Ω, $u_h^{(0)} \in \mathcal{A}_h(\mathcal{T}, u_\mathrm{D})$, and $\kappa > 0$.

(a) Set $j := 0$.

  (a1) Solve the optimization problem

$$\begin{cases} \text{Minimize} & E\Big(u_h^{(j)} - v_h\Big) \\ \text{subject to} & v_h \in \mathcal{S}_0^1(\mathcal{T})^3 \ \text{ and } \ v_h(z) \cdot u_h^{(j)}(z) = 0 \text{ for all } z \in \mathcal{N}. \end{cases}$$

  Denote the solution by $w_h^{(j)}$.

  (a2) Define

$$u_h^{(j+1)} := \sum_{z \in \mathcal{N}} \frac{u_h^{(j)}(z) - w_h^{(j)}(z)}{|u_h^{(j)}(z) - w_h^{(j)}(z)|}\varphi_z.$$

  (a3) If $E(u_h^{(j+1)}) \le E(u_h^{(j)}) - \kappa$ set $j := j+1$ and go to (a1).

(b) Set $u_h := u_h^{(j)}$.

(c) For each $T \in \mathcal{T}$ compute $\eta(T)^2 := \sum_{j=1}^2 \eta_j(T, u_h)^2$.

(d) Mark all $T \in \mathcal{T}$ which satisfy $\eta(T) \ge \Theta \max_{S \in \mathcal{T}} \eta(S)$ for refinement and generate a new regular triangulation $\mathcal{T}'$ such that all marked elements are refined.

(e) Set $\mathcal{T} := \mathcal{T}'$, construct $u_h^{(0)} \in \mathcal{A}_h(\mathcal{T}, u_\mathrm{D})$ by interpolating nodal values of u_h, and go to (a).

6.2. Numerical example. We ran Algorithm (A_h^Θ) with $\Theta = 0$ and $\Theta = 1/2$ in Example 4.1 and an initial triangulation of Ω into five tetrahedra. We chose the termination criterion $\kappa := 10^{-4}$ for the iteration in step (a) of Algorithm (A_h^Θ). The mesh refinement was realized by a bisection strategy for $\Theta = 1/2$ and by uniform (red) refinement for $\Theta = 0$.

The left plot in Figure 6.1 displays the L^2 error $\|u - u_h\|_{L^2(\Omega)}$ for uniform and adaptive mesh refinement with the iterates u_h of Algorithm (A_h^Θ). We used a logarithmic scaling on both axes to identify a relation between the number of degrees of freedom and the L^2 error.

We observe that the L^2 error is significantly smaller at comparable numbers of degrees of freedom when the refinement indicators of Proposition 5.2 are used to refine

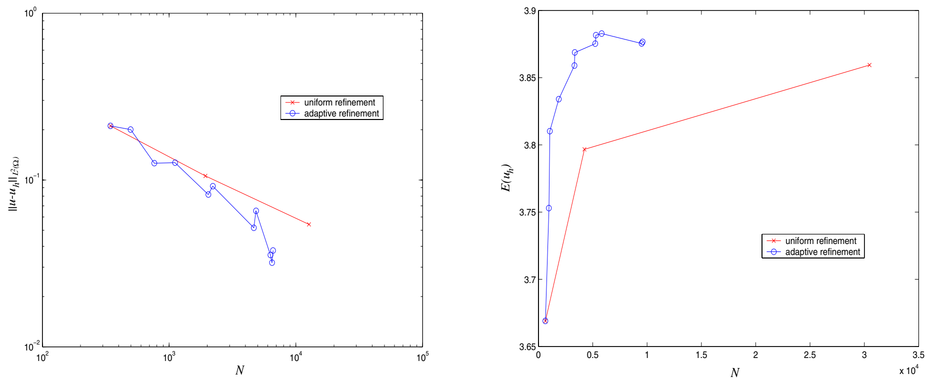

FIG. 6.1. *L^2 error for uniform and adaptive mesh refinement in Example* 4.1 *(left). Discrete energies $E(u_h)$ for uniform and adaptive mesh refinement (right).*

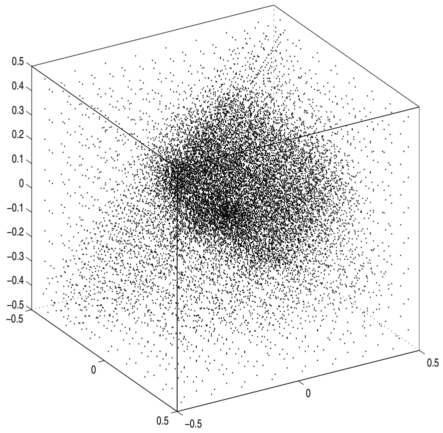

FIG. 6.2. *Midpoints of tetrahedra (indicated by dots) in the adaptively generated triangulation $\mathcal{T}$ after four iterations of Algorithm* $(\mathrm{A}_h^{1/2})$ *in Example* 4.1.

the mesh locally. Moreover, the experimental convergence rate for uniform meshes is only $\mathcal{O}(h)$ (owing to $h = N^{-1/3}$ for uniform meshes) instead of the optimal convergence rate $\mathcal{O}(h^2)$. The adaptive refinement strategy leads to an improved experimental convergence rate. The right plot in Figure 6.1 displays the discrete energies $E(u_h)$ for uniform and adaptive mesh refinement and we observe that the adaptive strategy reaches a stable value for a smaller number of degrees of freedom than the uniform refinement strategy.

Figure 6.2 displays the adapted triangulation generated by four iterations of Algorithm $(\mathrm{A}_h^{1/2})$. The dots in the plot indicate the location of a midpoint of a tetrahedron and we observe a refinement toward the origin, where the exact solution has a point singularity.

6.3. Instability of a degree-2 singularity. The final numerical example discusses a situation that leads to more than one degree-1 singularity.

EXAMPLE 6.1 (see [1, 14]). *Let $\pi_s : S^2 \to \mathbb{C}$ denote the stereographic projection of the unit sphere $S^2 \subseteq \mathbb{R}^3$ into the complex numbers $\mathbb{C}$ and let $\omega(z) := z^2$. Set*

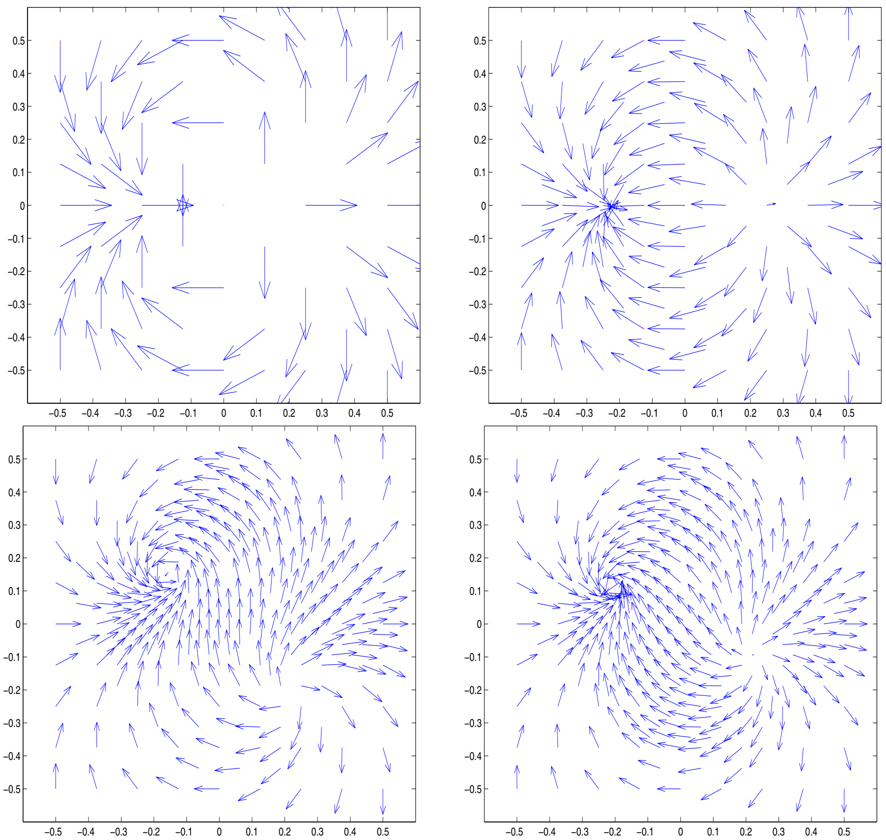

Fig. 6.3. *Intermediate solutions* $u_h(\cdot,\cdot,0)$ *in* $(-1/2,1/2)^2$ *after* $0,4,8,$ *and* 12 *iterations of Algorithm* $(\mathrm{A}_h^{1/2})$ *in Example* 6.1.

$\Omega := (-1/2,1/2)^3$ *and* $u_{\mathrm{D}}(x) := \pi_s^{-1} \circ \omega \circ \pi_s(x/|x|)$ *for* $x \in \partial\Omega$*.*

We employed Algorithm (A_h^{Θ}) with $\Theta = 1/2$ in Example 6.1 with an initial triangulation of Ω into five tetrahedra. We defined an initial function $u_h^{(0)}$ by nodal interpolation of the initial data. Figure 6.3 displays projections of intermediate solutions restricted to $\{(x,y,0) : -1/2 \le x,y \le 1/2\}$ on the adapted meshes after 0, 4, 8, and 12 iterations of the algorithm. We observe that the initial degree-2 singularity splits into two degree-1 singularities and the mesh is refined mostly between the two singularities in which the discrete vector field has a large gradient.

Acknowledgments. The author is grateful to one anonymous referee for pointing out the proof of Lemma 3.2. The author is also thankful to G.K. Dolzmann and R.H. Nochetto for stimulating discussions. The author wishes to thank J. Bolte for sharing his knowledge on three-dimensional mesh refinement.

ERROR ANALYSIS OF PRESSURE-CORRECTION SCHEMES FOR THE TIME-DEPENDENT STOKES EQUATIONS WITH OPEN BOUNDARY CONDITIONS[*]

J. L. GUERMOND[†], P. MINEV[‡], AND J. SHEN[§]

Abstract. The incompressible Stokes equations with prescribed normal stress (open) boundary conditions on part of the boundary are considered. It is shown that the standard pressure-correction method is not suitable for approximating the Stokes equations with open boundary conditions, whereas the rotational pressure-correction method yields reasonably good error estimates. These results appear to be the first ever published for splitting schemes with open boundary conditions. Numerical results in agreement with the error estimates are presented.

Key words. Navier–Stokes and Stokes equations, incompressibility, pressure-correction methods, open boundary conditions, finite elements, spectral approximations

1. Introduction.

In this paper we consider the time-dependent Navier–Stokes equations with normal stress boundary conditions prescribed on parts of the boundary. These conditions are usually imposed to model outflow boundaries or free surfaces. For Newtonian flows, the boundary conditions in question take the form

$$\left[\mathsf{p}n - \nu(\nabla \mathsf{u} + (\nabla \mathsf{u})^T)n\right]|_\Gamma = b,$$

where u is the velocity vector field, p is the pressure, Γ is the boundary of the domain Ω, n is the unit outward normal, and b is the prescribed data.

There are numerous ways to discretize the time-dependent incompressible Navier–Stokes equations in time. Undoubtedly, the most popular one consists of using projection methods. Most of these techniques are based on the original ideas of Chorin [2] and Temam [22]. They are usually fractional step methods composed of two substeps such that either the Laplacian of the velocity or the pressure gradient is made explicit in one substep and (implicitly) corrected in the other substep. In both cases, one substep always consists of the projection of some vector field onto a divergence-free space. Following the terminology introduced in [11], a scheme is classified as a pressure-correction (resp., velocity-correction) method if the pressure gradient (resp., Laplacian of the velocity) is treated explicitly in one substep and (implicitly) corrected in the other substep. In the present paper we restrict ourselves to pressure-correction methods. Each of the above two classes of methods has a standard form and a rotational form (see [9, 10]), and each of them can be implemented either in algebraic

form (cf. [4, 5, 15]) or in differential form. However, to the best of our knowledge, no rigorous error analysis of any of these schemes with open boundary conditions is available in the literature. Moreover, there is some confusion in the literature over the performance of these methods with this type of boundary condition. The aim of this paper is to discuss some of these issues and to derive error estimates.

We show that the standard pressure-correction schemes, implemented either in algebraic form or in differential form (in fact, they can be shown to be equivalent), are not suitable for approximating the Navier–Stokes equations supplemented with open boundary conditions. However, we show that the rotational pressure-correction schemes yield reasonable error estimates. More precisely, assuming full regularity of the Stokes problem, the second-order rotational pressure-correction method yields $\mathcal{O}(\Delta t^{3/2})$ convergence rate for the velocity in the L^2-norm and $\mathcal{O}(\Delta t)$ convergence rate for both the velocity in the H^1-norm and the pressure in the L^2-norm. These estimates deteriorate if the Stokes problem does not possesses full regularity, as is probably the case in three dimensions.

2. Preliminaries.

We shall consider the time-dependent Navier–Stokes equations on a finite time interval $[0,T]$ and in an open, connected, bounded domain $\Omega \subset \mathbb{R}^d$ ($d = 2$, or 3) with a boundary Γ sufficiently smooth. We assume that the following nontrivial partition holds: $\Gamma = \Gamma_1 \cup \Gamma_2$, $\Gamma_1 \cap \Gamma_2 = \emptyset$, $\text{meas}(\Gamma_1) \neq \emptyset$, $\text{meas}(\Gamma_2) \neq \emptyset$.

2.1. Notation.

We denote by $H^m(\Omega)$ and $\|\cdot\|_m$ ($m = 0, \pm 1, \ldots$) the standard Sobolev spaces and norms. In particular, the norm and inner product of $L^2(\Omega) = H^0(\Omega)$ are denoted by $\|\cdot\|_0$ and $(\cdot,\cdot)$, respectively. We shall also make use of fractional Sobolev spaces $H^s(\Omega)$ which are defined by interpolation. To account for homogeneous Dirichlet boundary conditions on Γ_1, we define

$$X = \{v \in H^1(\Omega) : v|_{\Gamma_1} = 0\}. \tag{2.1}$$

Owing to the Poincaré inequality, $\|\nabla v\|_0$ is a norm equivalent to $\|v\|_1$ for all $v \in X$. Henceforth, we redefine the norm $\|\cdot\|_1$ in X such that $\|v\|_1 := \|\nabla v\|_0$.

We introduce two spaces of incompressible vector fields,

$$H = \{v \in L^2(\Omega)^d;\ \nabla\cdot v = 0;\ v \cdot n|_{\Gamma_1} = 0\}, \tag{2.2}$$

$$V = \{v \in H^1(\Omega)^d;\ \nabla\cdot v = 0;\ v|_{\Gamma_1} = 0\}, \tag{2.3}$$

and we define P_H to be the L^2-orthogonal projection onto H, i.e.,

$$(u - P_H u, v) = 0 \quad \forall u \in L^2(\Omega)^d,\ \forall v \in H. \tag{2.4}$$

We also denote

$$N = \{q \in H^1(\Omega);\ q|_{\Gamma_2} = 0\}. \tag{2.5}$$

The following well-known lemma plays a key role in the analysis of projection methods.

LEMMA 2.1. *The following orthogonal decomposition of $L^2(\Omega)^d$ holds:*

$$L^2(\Omega)^d = H \oplus \nabla N. \tag{2.6}$$

Since the nonlinear term in the Navier–Stokes equations has a marginal influence on the splitting error, we shall hereafter consider only the time-dependent Stokes equations written in terms of velocity, u, and pressure, p:

$$\begin{cases} \partial_t \mathsf{u} + A\mathsf{u} + \nabla \mathsf{p} = f \quad \text{in } \Omega \times [0,T], \\ \nabla \cdot \mathsf{u} = 0 \quad \text{in } \Omega \times [0,T], \\ \mathsf{u}|_{\Gamma_1} = 0, \quad \text{and} \quad (\mathsf{p}n - \nu(D\mathsf{u})n)|_{\Gamma_2} = 0 \quad \text{in } [0,T], \\ \mathsf{u}|_{t=0} = u_0 \quad \text{in } \Omega. \end{cases} \tag{2.7}$$

Henceforth, the operators A and D may assume one of the two following forms:

$$Av = -2\nu \nabla \cdot Dv, \tag{2.8}$$

$$Dv = \begin{cases} \frac{1}{2}\nabla v, & \text{case 1}, \\ \frac{1}{2}(\nabla v + (\nabla v)^T), & \text{case 2}. \end{cases} \tag{2.9}$$

We recall that the symmetric positive definite bilinear form

$$a(u,v) = \nu(Du, Dv) \tag{2.10}$$

induces a norm on X that is equivalent to the H^1-norm. We denote by α the coercivity constant of a:

$$a(v,v) \geq \alpha \|\nabla v\|_0^2 \quad \forall v \in X. \tag{2.11}$$

In case 1, $\alpha = \nu$, whereas in case 2, $\alpha = c\nu$, where c is a constant that can be derived by using a Korn inequality; see, e.g., [1].

To simplify our presentation, we assume that the unique solution (u, p) to the above system is as smooth as needed.

To perform the temporal discretization of the problem, we define $\Delta t > 0$ to be a time step and we set $t^k = k\Delta t$ for $0 \leq k \leq K = [T/\Delta t]$. Let $\phi^0, \phi^1, \ldots, \phi^K$ be a sequence of functions in some Hilbert space E. We denote by $\phi_{\Delta t}$ this sequence, and we use the following discrete norms:

$$\|\phi_{\Delta t}\|_{\ell^2(E)} := \left(\Delta t \sum_{k=0}^{K} \|\phi^k\|_E^2 \right)^{1/2}, \qquad \|\phi_{\Delta t}\|_{\ell^\infty(E)} := \max_{0 \leq k \leq K} \left(\|\phi^k\|_E \right). \tag{2.12}$$

We denote by c a generic constant that is independent of small parameters like ϵ, Δt, and h but possibly depends on the data and the solution. We shall use the expression $A \lesssim B$ to say that there exists a generic constant c such that $A \leq cB$.

Let μ be a positive real number. We shall repeatedly make use of the following interpolation result, whose proof is fairly standard and so we omit it due to the space limitation.

Lemma 2.2. *For all $0 \leq s \leq 1$, there exists an operator $\mathcal{I}_{\mu,s} : H^s(\Omega) \longrightarrow H_0^1(\Omega)$ such that for all r in $H^s(\Omega)$ we have*

$$\|r - \mathcal{I}_{\mu,s} r\|_0 \lesssim \mu^{\frac{s}{2}} \|r\|_{H^s(\Omega)}, \tag{2.13}$$

$$\|\mathcal{I}_{\mu,s} r\|_1 \lesssim \mu^{-1+\frac{s}{2}} \|r\|_{H^s(\Omega)}. \tag{2.14}$$

2.1.1. The inverse of the Stokes operator and its regularity index. In this section we recall properties of the inverse of the Stokes operator. Let X' be the dual space of X. We denote by $\langle \cdot, \cdot \rangle$ the duality pairing between X' and X. The inverse of the Stokes operator, which we shall denote by $S : X' \longrightarrow X$, is defined as follows. For all v in X', $S(v) \in X$ is the solution to the dual problem

$$\begin{cases} a(w, S(v)) - (r, \nabla \cdot w) = \langle v, w \rangle & \forall w \in X, \\ (q, \nabla \cdot S(v)) = 0 \qquad \forall q \in L^2(\Omega). \end{cases} \tag{2.15}$$

Obviously, we have

$$\forall v \in X', \qquad \|S(v)\|_1 + \|r\|_0 \leq c\|v\|_{X'}. \tag{2.16}$$

It is well known that when Dirichlet boundary conditions on the velocity are enforced on the entire boundary and Ω is smooth or convex, we have $\|r\|_1 \lesssim \|v\|_0$ (see, for instance, [23]). In the present case, where boundary conditions are mixed, it is a nontrivial task to determine the regularity of r. It is generally expected that the H^1-regularity does not hold in the three-dimensional case. However, it is possible that regularity in some fractional Sobolev space holds. To account for this, we make the following definition.

Definition 2.1 (regularity index of the Stokes operator). *The regularity index of the Stokes operator is the largest number, s, such that for all $v \in L^2(\Omega)^d$, the solution $r \in L^2(\Omega)$ to the dual Stokes problem* (2.15) *satisfies* $\|r\|_{H^s(\Omega)} \lesssim \|v\|_0$.

We observe from (2.16) that $s \geq 0$, and it is clear that $s \leq 1$. Hence, the case $s = 0$ is referred to as *no regularity* while the case $s = 1$ is referred to as *full regularity.* We refer to [14] for techniques to evaluate this index in two dimensions.

The operator S has interesting properties, as listed below.

Lemma 2.3. *For all v in X, all $0 < \gamma < 1$, and all $0 < \mu < 1$, we have*

$$a(v, S(v)) \geq (1 - \gamma)\|v\|_0^2 - c(\gamma)\left(\mu^{2\alpha_1}\|\nabla \cdot v\|_0^2 + \mu^{-2\alpha_2}\|v - P_H v\|_0^2\right),$$

with $\alpha_1 = \frac{s}{2}$ and $\alpha_2 = 1 - \frac{s}{2}$ and s being the regularity index of the Stokes operator. In particular, for all $v \in V$, $(\nabla S(v), \nabla v) = \|v\|_0^2$.

Proof. Owing to the definition of $S(v)$ and to the fact $\mathcal{I}_{\varepsilon,s} r$ is zero on Γ_2, we have

$$\begin{aligned} a(v, S(v)) &= \|v\|_0^2 + (r, \nabla \cdot v) \\ &= \|v\|_0^2 + (r - \mathcal{I}_{\mu,s} r, \nabla \cdot v) + (\nabla \mathcal{I}_{\mu,s} r, v) \\ &= \|v\|_0^2 + (r - \mathcal{I}_{\mu,s} r, \nabla \cdot v) + (\nabla \mathcal{I}_{\mu,s} r, v - P_H v) \\ &\geq \|v\|_0^2 - \left(\mu^{\alpha_1}\|\nabla \cdot v\|_0 + \mu^{-\alpha_2}\|v - P_H v\|_0\right)\|r\|_{H^s(\Omega)}. \end{aligned}$$

Then using the fact that s is the regularity index of the Stokes operator (see Definition 2.1), we derive the desired bound. ◻

Lemma 2.4. *The bilinear form $X' \times X' \ni (v, w) \longmapsto \langle S(v), w \rangle := a(S(v), S(w)) \in \mathbb{R}$ induces a seminorm on X' that we denote by $|\cdot|_\star$, and*

$$\forall v \in X', \qquad |v|_\star = a(S(v), S(v))^{1/2} \lesssim \|v\|_{X'}.$$

Proof. It is clear that the bilinear form is symmetric, $\langle S(v), w \rangle = a(S(v), S(w)) = \langle S(w), v \rangle$, and positive, $\langle S(v), v \rangle = a(S(v), S(v))$; hence, $\langle S(v), w \rangle$ induces a seminorm on X'. Furthermore, $|v|_\star^2 = \langle S(v), v \rangle = a(S(v), S(v)) \lesssim \|v\|_{X'}^2$. The proof is complete. ◻

3. Standard pressure-correction methods. For purely Dirichlet boundary conditions, the second-order pressure-correction scheme is known to be one-order more accurate than the original projection scheme of Chorin–Temam (cf. [25, 3, 21, 7]). Using the second-order backward difference formula (BDF2) to discretize the time derivative, the second-order pressure-correction scheme takes the following form:

Set $u^0 = u_0$, $p^0 = \mathsf{p}|_{t=0}$, which can be computed from the data, and compute $(\tilde{u}^1, u^1, p^1)$ by using the scheme below with BDF2 replaced by the backward Euler formula. Then, for $k \geq 1$, compute $(\tilde{u}^{k+1}, u^{k+1}, p^{k+1})$ such that

$$\text{(3.1)} \qquad \begin{cases} \dfrac{3\tilde{u}^{k+1} - 4u^k + u^{k-1}}{2\Delta t} + A\tilde{u}^{k+1} + \nabla p^k = f(t^{k+1}), \\ \tilde{u}^{k+1}|_{\Gamma_1} = 0 \quad \text{and} \quad (p^k n - \nu(D\tilde{u}^{k+1})n)|_{\Gamma_2} = 0 \end{cases}$$

and

$$\text{(3.2)} \qquad \begin{cases} \dfrac{3u^{k+1} - 3\tilde{u}^{k+1}}{2\Delta t} + \nabla(p^{k+1} - p^k) = 0, \\ \nabla \cdot u^{k+1} = 0, \\ u^{k+1} \cdot n|_{\Gamma_1} = 0 \quad \text{and} \quad (p^{k+1} - p^k)|_{\Gamma_2} = 0. \end{cases}$$

The first substep accounts for viscous effects, whereas the second one accounts for incompressibility. The second substep is usually referred to as the projection step, for it is a realization of the identity $u^{k+1} = P_H \tilde{u}^{k+1}$. We emphasize that it is essential, for stability considerations, that $(p^{k+1} - p^k)|_{\Gamma_2} = 0$ is enforced. Otherwise, (3.2) can not be interpreted as a projection step. Note that the boundary conditions in (3.2) lead to the series of equalities

$$\text{(3.3)} \qquad \begin{aligned} &\frac{\partial}{\partial n} p^{k+1}|_{\Gamma_1} = \frac{\partial}{\partial n} p^k|_{\Gamma_1} = \cdots = \frac{\partial}{\partial n} p^1|_{\Gamma_1}, \\ &p^{k+1}|_{\Gamma_2} = p^k|_{\Gamma_2} = \cdots = p^1|_{\Gamma_2}, \end{aligned}$$

which are certainly inaccurate since they are almost never satisfied by the exact solution. In the purely Dirichlet case, i.e., $\Gamma_2 = \emptyset$, it is possible to deduce a reasonably good approximation result for the pressure in the L^2-norm. But when $\Gamma_2 \neq \emptyset$ the pressure approximation is severely degraded.

Not being aware of any published convergence result for the scheme (3.1)–(3.2), we shall prove the following result.

THEOREM 3.1. *If* (u, p)*, the solution to* (2.7)*, is smooth enough in space and time, the solution to* (3.1)–(3.2) *satisfies the following error estimates:*

$$\begin{aligned} \|\mathsf{p}_{\Delta t} - p_{\Delta t}\|_{\ell^\infty(L^2(\Omega))} + \|\mathsf{u}_{\Delta t} - \tilde{u}_{\Delta t}\|_{\ell^\infty(H^1(\Omega)^d)} &\lesssim \Delta t^{\frac{1}{2}}, \\ \|\mathsf{u}_{\Delta t} - u_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)} + \|\mathsf{u}_{\Delta t} - \tilde{u}_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)} &\lesssim \Delta t^{\frac{s+1}{2}}, \end{aligned}$$

where s is the regularity index of the Stokes operator.

Proof. As will become clear in the course of the proof, using BDF2 instead of the backward Euler formula does not improve the accuracy in the presence of open boundary conditions. So to simplify the presentation, we consider the backward Euler formula for the time derivative:

$$\text{(3.4)} \qquad \begin{cases} \dfrac{\tilde{u}^{k+1} - u^k}{\Delta t} + A\tilde{u}^{k+1} + \nabla p^k = f(t^{k+1}), \\ \tilde{u}^{k+1}|_{\Gamma_1} = 0 \quad \text{and} \quad (p^k n - \nu(D\tilde{u}^{k+1})n)|_{\Gamma_2} = 0 \end{cases}$$

and

$$\begin{cases} \dfrac{u^{k+1} - \tilde{u}^{k+1}}{\Delta t} + \nabla(p^{k+1} - p^k) = 0, \\ \nabla \cdot u^{k+1} = 0, \\ u^{k+1} \cdot n|_{\Gamma_1} = 0 \quad \text{and} \quad (p^{k+1} - p^k)|_{\Gamma_2} = 0. \end{cases} \tag{3.5}$$

Technically, the proof is very similar to those in Shen [21] and Guermond [6]; hence we show only those steps where the consistency error is degraded.

Let us introduce the interpolation operator $\mathcal{I}_{\Delta t,1} : H^1(\Omega) \longmapsto H^1_0(\Omega)$ defined in Lemma 2.2. This operator is such that for all r in $H^1(\Omega)$,

$$\|\mathcal{I}_{\Delta t,1} r - r\|_0 \lesssim \Delta t^{\frac{1}{2}} \|r\|_1, \tag{3.6}$$

$$\|\nabla \mathcal{I}_{\Delta t,1} r\|_0 \lesssim \Delta t^{-\frac{1}{2}} \|r\|_1. \tag{3.7}$$

Without introducing any essential extra error, we can take $p^0 = \mathcal{I}_{\Delta t,1} \mathsf{p}|_{t=0}$, which implies $p^k|_{\Gamma_2} = 0$ for all k.

Now we introduce the following notation:

$$\begin{cases} e^k = \mathsf{u}(t^k) - u^k, & \tilde{e}^k = \mathsf{u}(t^k) - \tilde{u}^k, \\ \psi^k = \mathcal{I}_{\Delta t,1} \mathsf{p}(t^{k+1}) - p^k, & q^k = \mathcal{I}_{\Delta t,1} \mathsf{p}(t^k) - p^k. \end{cases}$$

The weak form of the error equation that corresponds to the viscous step (3.4) is given by

$$\begin{aligned} \frac{1}{\Delta t}(\tilde{e}^{k+1} - e^k, v) + a(\tilde{e}^{k+1}, v) - (\psi^k, \nabla \cdot v) = (R(t^{k+1}), v) \\ + (\mathsf{p}(t^{k+1}) - \mathcal{I}_{\Delta t,1} \mathsf{p}(t^{k+1}), \nabla \cdot v) \quad \forall v \in X, \end{aligned}$$

where $R(t^{k+1}) = \frac{1}{\Delta t}(u(t^{k+1}) - u(t^k)) - u_t(t^{k+1}) = \mathcal{O}(\Delta t)$. Note that the surface integrals resulting from the integration by parts cancel on both Γ_1 and Γ_2 due to the boundary conditions in (3.4).

Taking $v = 2\Delta t \tilde{e}^{k+1}$ in the above equation and using (3.6), we can derive

$$2\Delta t(\mathsf{p}(t^{k+1}) - \mathcal{I}_{\Delta t,1} \mathsf{p}(t^{k+1}), \nabla \cdot \tilde{e}^{k+1}) \lesssim \Delta t^2 + \alpha \Delta t \|\tilde{e}^{k+1}\|_1^2,$$

$$\|\tilde{e}^{k+1}\|_0^2 + \|\tilde{e}^{k+1} - e^k\|_0^2 + \alpha \Delta t \|\tilde{e}^{k+1}\|_1^2 - 2\Delta t(\psi^k, \nabla \cdot \tilde{e}^{k+1}) \le \|e^k\|_0^2 + c\Delta t^2. \tag{3.8}$$

Note that the consistency error is degraded at this step; more precisely, a Δt factor is already missing in the above estimate.

The error equation corresponding to the projection step (3.5) can be written as

$$\begin{cases} \dfrac{1}{\Delta t} e^{k+1} + \nabla q^{k+1} = \dfrac{1}{\Delta t} \tilde{e}^{k+1} + \nabla \psi^k, \\ \nabla \cdot e^{k+1} = 0, \\ e^{k+1} \cdot n|_{\Gamma_1} = 0 \quad \text{and} \quad q^{k+1}|_{\Gamma_2} = 0. \end{cases}$$

Taking the square of the first relation above and multiplying the result by Δt^2, we infer

$$\|e^{k+1}\|_0^2 + \Delta t^2 \|\nabla q^{k+1}\|_0^2 = \|\tilde{e}^{k+1}\|_0^2 + \Delta t^2 \|\nabla \psi^k\|_0^2 - 2\Delta t(\psi^k, \nabla \cdot \tilde{e}^{k+1}). \tag{3.9}$$

Note that integration by parts can be performed on both sides owing to the fact that $q^{k+1}|_{\Gamma_2} = 0 = \psi^k|_{\Gamma_2}$. Now we have

$$\begin{aligned}\Delta t^2 \|\nabla \psi^k\|_0^2 &= \Delta t^2 \|\nabla q^k + \nabla(\mathcal{I}_{\Delta t}(\mathsf{p}(t^{k+1}) - \mathsf{p}(t^k)))\|_0^2,\\ &\le \Delta t^2 (\|\nabla q^k\|_0^2 + c\Delta t^{1-\frac{1}{2}} \|\nabla q^k\|_0 + c'\Delta t^{2(1-\frac{1}{2})})\\ &\le \Delta t^2 (1+\Delta t)\|\nabla q^k\|_0^2 + c\Delta t^2,\end{aligned}$$

where the consistency error is also degraded by a factor of $\mathcal{O}(\Delta t)$. Combining this result and the previous one, we have

$$\begin{aligned}\|e^{k+1}\|_0^2 + \Delta t^2 \|\nabla q^{k+1}\|_0^2 \le \|\tilde{e}^{k+1}\|_0^2 + \Delta t^2(1+\Delta t)\|\nabla q^k\|_0^2\\ - 2\Delta t(\psi^{k+1}, \nabla\cdot \tilde{e}^{k+1}) + c\Delta t^2.\end{aligned} \tag{3.10}$$

The first error estimate of the theorem is obtained by combining (3.8) and (3.10), using the discrete Gronwall lemma, and repeating the whole argument for time increments. The second estimate can be derived by a duality argument similar to that used in the proof of Lemma 4.4. □

REMARK 3.1. *Note that the error on the pressure in the L^2-norm is $\mathcal{O}(\Delta t^{\frac{1}{2}})$, whereas it is $\mathcal{O}(\Delta t)$ when Dirichlet boundary conditions are enforced on the whole boundary. It is clear that the artificial Dirichlet boundary condition* (3.3) *is responsible for this poor convergence property. Since using an inexact factorization (cf.* [4, 5, 15, 16, 17, 13]*) of the discrete Stokes operator does not enforce the Dirichlet boundary condition on* Γ_2 explicitly*, some authors have argued that the inexact factorization scheme does not suffer from the error due to the artificial Dirichlet boundary condition. However, it can be shown (see* [12] *for details) that the inexact factorization scheme actually enforces the artificial Dirichlet boundary condition* weakly *and hence suffers from the same accuracy loss as its PDE counterpart. In other words, mere algebraic manipulations cannot overcome essential difficulties encountered in functional analysis.*

REMARK 3.2. *Note that the need to integrate by parts the term* $2\Delta t(\nabla\psi^{k+1}, \tilde{e}^{k+1})$ *in* (3.9) *is critical, and it is made possible by enforcing the homogeneous Dirichlet boundary condition on the pressure at* Γ_2 *in the projection step* (3.2)*.*

We finish this section by recalling that to simulate outflow boundary conditions, an alternative set of conditions is $p|_{\Gamma_2} = 0$, $u \times n|_{\Gamma_2} = 0$. This set of conditions is not equivalent to the zero normal stress conditions studied above. Nevertheless, an interesting property of these boundary conditions is that they are compatible with the pressure-correction algorithm (3.1)–(3.2); i.e., they yield near optimal convergence rates. We refer to [8] for other technical details on this matter.

4. Rotational pressure-correction methods.

In this section, we show that the rotational pressure-correction scheme introduced in [24] improves, by a factor of $\Delta t^{1/2}$, the error estimates of the standard pressure-correction scheme. It is proved in [11, 10] that when Dirichlet boundary conditions are enforced on the entire boundary, the same improvement holds. The main result is stated in Theorem 4.1.

4.1. Rotational form.

When applied to problems with open boundary conditions on Γ_2, the rotational pressure-correction scheme takes the following form:

Set $u^0 = u_0$, $p^0 = \mathsf{p}|_{t=0}$, which can be computed from the data, and compute $(\tilde{u}^1, u^1, p^1)$ by using the scheme shown below with BDF2 replaced by the backward

Euler formula. Then, for $k \geq 1$, compute $(\tilde{u}^{k+1}, u^{k+1}, p^{k+1})$ such that

$$\left\{\begin{array}{l}\dfrac{3\tilde{u}^{k+1} - 4u^k + u^{k-1}}{2\Delta t} + A\tilde{u}^{k+1} + \nabla p^k = f(t^{k+1}), \\ \tilde{u}^{k+1}|_{\Gamma_1} = 0, \quad (p^k n - \nu(D\tilde{u}^{k+1})n)|_{\Gamma_2} = 0,\end{array}\right. \tag{4.1}$$

$$\left\{\begin{array}{l}\dfrac{3u^{k+1} - 3\tilde{u}^{k+1}}{2\Delta t} + \nabla\phi^{k+1} = 0, \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n|_{\Gamma_1} = 0, \quad \phi^{k+1}|_{\Gamma_2} = 0.\end{array}\right. \tag{4.2}$$

$$\phi^{k+1} = p^{k+1} - p^k + \chi\nabla\cdot\tilde{u}^{k+1}, \tag{4.3}$$

where χ is a tunable positive coefficient.

Remark 4.1. *As originally introduced in* [24]*, the coefficient χ was taken to be equal to α, defined in* (2.11)*, which is simply ν in the Newtonian case. The analysis performed in* [11, 10] *shows that this choice is sufficient to guarantee stability and convergence when Dirichlet boundary conditions are enforced. However, when natural boundary conditions are enforced on parts of the boundary, the analysis (see below) shows that χ should be chosen such that*

$$0 < \chi < 2\alpha \inf_{v\in X} \frac{\|\nabla v\|^2}{\|\nabla\cdot v\|^2}. \tag{4.4}$$

Owing to the inequality $\|\nabla\cdot v\|^2 \leq d\|\nabla v\|^2$, where d is the space dimension, it is sufficient to choose

$$0 < \chi < \frac{2}{d}\alpha. \tag{4.5}$$

4.2. A corresponding singularly perturbed system. To better understand the behavior of the scheme (4.1)–(4.3), we examine first a singularly perturbed system corresponding to the limiting case as $\Delta t \to 0$ (with $\varepsilon \sim \Delta t$). This system of PDEs is obtained by eliminating u^k from (4.1)–(4.2) and dropping some higher-order terms in ε:

$$\left\{\begin{array}{l}\partial_t u^\varepsilon + Au^\varepsilon + \nabla p^\varepsilon = f, \quad u^\varepsilon|_{\Gamma_1} = 0, \quad (p^\varepsilon n - \nu(Du^\varepsilon)n)|_{\Gamma_2} = 0, \\ \nabla\cdot u^\varepsilon - \varepsilon\nabla^2\phi^\varepsilon = 0, \quad \dfrac{\partial\phi^\varepsilon}{\partial n}|_{\Gamma_1} = 0, \quad \phi^\varepsilon|_{\Gamma_2} = 0, \\ \varepsilon\partial_t p^\varepsilon = \phi^\varepsilon - \chi\nabla\cdot u^\varepsilon,\end{array}\right. \tag{4.6}$$

with $u^\varepsilon|_{t=0} = u(0)$ and $p^\varepsilon(0) = p(0)$.

4.2.1. An estimate on $\nabla\cdot u^\varepsilon$. The following lemma is the key to obtaining improved error estimates.

Lemma 4.1. *Provided* u *and* p *are smooth enough in time and space, we have*

$$\|\nabla\cdot u^\varepsilon\|_{L^\infty(L^2(\Omega)^d)} + \sqrt{\varepsilon}\|\nabla\phi^\varepsilon\|_{L^\infty(L^2(\Omega))} \lesssim \varepsilon^{\frac{5}{4}}.$$

Proof. We set $e = u^\varepsilon - \mathsf{u}$ and $q = p^\varepsilon - \mathsf{p}$. Subtracting (4.6) from (2.7), we find

$$e_t + Ae + \nabla q = 0; \quad e|_{\Gamma_1} = 0, \quad (qn - \nu(De)n)|_{\Gamma_2} = 0, \tag{4.7}$$

$$\nabla\cdot e - \varepsilon\nabla^2\phi^\varepsilon = 0, \quad \frac{\partial\phi^\varepsilon}{\partial n}|_{\Gamma_1} = 0, \quad \phi^\varepsilon|_{\Gamma_2} = 0, \tag{4.8}$$

$$\varepsilon q_t = \phi^\varepsilon - \chi\nabla\cdot e - \varepsilon\mathsf{p}_t, \tag{4.9}$$

with $e(0) = 0$ and $q(0) = 0$.

Taking the inner product of the time derivative of (4.7) with e_t, we find

$$\frac{1}{2}\partial_t\|e_t\|_0^2 + \alpha\|\nabla e_t\|_0^2 - (q_t, \nabla\cdot e_t) \leq 0. \tag{4.10}$$

The inner product of (4.9) with $\nabla\cdot e_t$ yields

$$(q_t, \nabla\cdot e_t) = \frac{1}{\varepsilon}(\phi^\varepsilon, \nabla\cdot e_t) - (\mathsf{p}_t, \nabla\cdot e_t) - \frac{\chi}{2\varepsilon}\partial_t\|\nabla\cdot e\|^2, \tag{4.11}$$

and the inner product of the time derivative of (4.8) with ϕ^ε yields

$$\frac{1}{\varepsilon}(\phi^\varepsilon, \nabla\cdot e_t) = -(\nabla\phi^\varepsilon_t, \nabla\phi^\varepsilon). \tag{4.12}$$

The above two relations lead to

$$(q_t, \nabla\cdot e_t) = -\frac{1}{2}\partial_t\|\nabla\phi^\varepsilon\|_0^2 - (\mathsf{p}_t, \nabla\cdot e_t) - \frac{\chi}{2\varepsilon}\partial_t\|\nabla\cdot e\|^2. \tag{4.13}$$

Substituting this expression into (4.10) we obtain

$$\frac{1}{2}\partial_t\|e_t\|_0^2 + \alpha\|\nabla e_t\|_0^2 + \frac{1}{2}\partial_t\|\nabla\phi^\varepsilon\|_0^2 + \frac{\chi}{2\varepsilon}\partial_t\|\nabla\cdot e\|_0^2 \leq -(\mathsf{p}_t, \nabla\cdot e_t). \tag{4.14}$$

At this point, one would like to replace $\nabla\cdot e_t$ by $\varepsilon\nabla^2\phi^\varepsilon_t$ in $(\mathsf{p}_t, \nabla\cdot e_t)$ and integrate by parts. The integration by parts is not possible since neither p_t nor $\partial_n\phi^\varepsilon_t$ is zero at the boundary Γ_2. To account for this fact, we introduce the interpolation operator $\mathcal{J}_\varepsilon : H^1(\Omega) \longmapsto H^1_0(\Omega) \subset N$ such that $\mathcal{J}_\varepsilon = \mathcal{I}_{\sqrt{\varepsilon},1}$, where $\mathcal{I}_{\mu,s}$ has been defined in Lemma 2.2. Recall that for all r in $H^1(\Omega)$, Lemma 2.2 (with $\mu = \sqrt{\varepsilon}$, $s = 1$) yields

$$\|\mathcal{J}_\varepsilon r - r\|_0 \lesssim \varepsilon^{\frac{1}{4}}\|r\|_1, \qquad \|\nabla\mathcal{J}_\varepsilon r\|_0 \lesssim \varepsilon^{-\frac{1}{4}}\|r\|_1. \tag{4.15}$$

We rewrite (4.14) as

$$\frac{1}{2}\partial_t\left(\|e_t\|_0^2 + \|\nabla\phi^\varepsilon\|^2 + \frac{\chi}{\varepsilon}\|\nabla\cdot e\|_0^2\right) + \alpha\|\nabla e_t\|_0^2 = -(\mathsf{p}_t - \mathcal{J}_\varepsilon\mathsf{p}_t, \nabla\cdot e_t) + \varepsilon(\nabla\mathcal{J}_\varepsilon\mathsf{p}_t, \nabla\phi^\varepsilon_t).$$

Note that we used the fact that $\mathcal{J}_\varepsilon\mathsf{p}_t$ is zero at Γ_2 to integrate by parts. This is the key argument in this proof. Since $e(0) = 0$ and $q(0) = 0$, we infer $e_t(0) = 0$. Since $\nabla\cdot u^\varepsilon(0) = \nabla\cdot u(0) = 0$, we derive from (4.8) that $\phi^\varepsilon(0) = 0$. By integrating in time between 0 and t, we obtain

$$\begin{aligned}
\frac{1}{2}&\left(\|e_t\|_0^2 + \|\nabla\phi^\varepsilon\|_0^2 + \frac{\chi}{\varepsilon}\|\nabla\cdot e\|_0^2\right) + \alpha\int_0^t \|\nabla e_t\|_0^2 d\tau \\
&\leq -(\mathsf{p}_t - \mathcal{J}_\varepsilon\mathsf{p}_t, \nabla\cdot e) + \int_0^t (\mathsf{p}_{\tau\tau} - \mathcal{J}_\varepsilon\mathsf{p}_{\tau\tau}, \nabla\cdot e)d\tau \\
&\quad + \varepsilon(\nabla\mathcal{J}_\varepsilon\mathsf{p}_t, \nabla\phi^\varepsilon) - \int_0^t \varepsilon(\nabla\mathcal{J}_\varepsilon\mathsf{p}_{\tau\tau}, \nabla\phi^\varepsilon)d\tau \\
&\leq \frac{1}{4}\left(\frac{\chi}{\varepsilon}\|\nabla\cdot e\|_0^2 + \|\nabla\phi^\varepsilon\|_0^2\right) + \int_0^t \left(\frac{\chi}{\varepsilon}\|\nabla\cdot e\|_0^2 + \|\nabla\phi^\varepsilon\|_0^2\right)d\tau \\
&\quad + c\,\varepsilon\|\mathsf{p}_t - \mathcal{J}_\varepsilon\mathsf{p}_t\|^2_{L^\infty(0,t;L^2(\Omega))} + c'\,\varepsilon^2\|\mathcal{J}_\varepsilon\mathsf{p}_t\|^2_{L^\infty(0,t;H^1(\Omega))} \\
&\quad + c\,\varepsilon\|\mathsf{p}_{tt} - \mathcal{J}_\varepsilon\mathsf{p}_{tt}\|^2_{L^2(0,t;L^2(\Omega))} + c'\,\varepsilon^2\|\mathcal{J}_\varepsilon\mathsf{p}_{tt}\|^2_{L^2(0,t;H^1(\Omega))}.
\end{aligned}$$

Using the estimates (4.15), we infer

$$\frac{1}{4}\left(\|e_t\|_0^2+\|\nabla\phi^\varepsilon\|_0^2+\frac{\chi}{\varepsilon}\|\nabla\cdot e\|_0^2\right)+\alpha\int_0^t\|\nabla e_t\|_0^2d\tau\le\int_0^t\left(\frac{\chi}{\varepsilon}\|\nabla\cdot e\|_0^2+\|\nabla\phi^\varepsilon\|_0^2\right)d\tau+c\,\varepsilon^{\frac{3}{2}}.$$

An application of the Gronwall lemma leads to

$$\|e_t\|_0^2+\|\nabla\phi^\varepsilon\|_0^2+\frac{\chi}{\varepsilon}\|\nabla\cdot e\|_0^2+\int_0^t\|\nabla e_\tau\|_0^2d\tau\lesssim\varepsilon^{\frac{3}{2}}. \tag{4.16}$$

The proof is complete. □

4.2.2. L^2-estimate on the velocity. An estimation of the error on the velocity in the L^2-norm is given by the following lemma.

LEMMA 4.2. *Provided* u *and* p *are smooth enough in time and space, then*

$$\|\mathsf{u}-u^\varepsilon\|_{L^2(L^2(\Omega)^d)}\lesssim\varepsilon^{\frac{5+s}{4}}, \tag{4.17}$$

where s is the regularity index of the Stokes operator.

Proof. We multiply (4.7) by $S(e)$. Owing to Lemma 2.4 we infer

$$\frac{1}{2}\partial_t|e|_\star^2+a(e,S(e))=0.$$

Using Lemma 2.3 with $\mu=\sqrt{\varepsilon}$, we obtain

$$\frac{1}{2}\partial_t|e|_\star^2+\frac{1}{2}\|e\|_0^2\lesssim\varepsilon^{\alpha_1}\|\nabla\cdot e\|_0^2+\varepsilon^{-\alpha_2}\|e-P_He\|_0^2.$$

From the definition of ϕ^ε, it is clear that $\varepsilon\nabla\phi^\varepsilon=e-P_He$; we then derive from the estimates in Lemma 4.1 that

$$\frac{1}{2}\partial_t|e|_\star^2+\frac{1}{2}\|e\|_0^2\lesssim\varepsilon^{\alpha_1}\|\nabla\cdot e\|_0^2+\varepsilon^{1-\alpha_2}\varepsilon\|\nabla\phi^\varepsilon\|_0^2\lesssim\varepsilon^{\frac{5}{2}}(\varepsilon^{\alpha_1}+\varepsilon^{1-\alpha_2}).$$

Since $\alpha_1=1-\alpha_2$, we find

$$\frac{1}{2}\partial_t|e|_\star^2+\frac{1}{2}\|e\|_0^2\lesssim\varepsilon^{\frac{5}{2}+\alpha_1}=\varepsilon^{\frac{5+s}{2}}.$$

The proof is completed using an integration in time. □

4.3. Error estimates for the time discrete case. The main result in this paper is the following.

THEOREM 4.1. *Let $0<\chi<\frac{2\alpha}{d}$. Assuming that the solution to (2.7) is smooth enough in time and space, the solution $(u^k,\tilde{u}^k,p^k)$ to (4.1)–(4.3) satisfies the estimates*

$$\|\mathsf{u}_{\Delta t}-u_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)}+\|\mathsf{u}_{\Delta t}-\tilde{u}_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)}\lesssim\Delta t^{\frac{5+s}{4}},$$
$$\|\mathsf{u}_{\Delta t}-\tilde{u}_{\Delta t}\|_{\ell^2(H^1(\Omega)^d)}+\|\mathsf{p}_{\Delta t}-p_{\Delta t}\|_{\ell^2(L^2(\Omega))}\lesssim\Delta t^{\frac{3+s}{4}},$$

where s is the regularity index of the Stokes operator.

REMARK 4.2. *With full Stokes regularity, i.e., $s=1$, the L^2-norm of the error on the velocity is $\mathcal{O}(\Delta t^{\frac{3}{2}})$, and the H^1-norm of the error on the velocity and the L^2-norm of the error on the pressure are $\mathcal{O}(\Delta t)$. In view of Lemma 4.1 and of the first estimate in Lemma 4.3, we believe that the H^1-estimates can be improved up to $\mathcal{O}(\Delta t^{\frac{5}{4}})$ by a* *sophisticated argument using weighted seminorms in time as in* [18, 20]*. However, the details of this proof are beyond the scope of this paper. Numerical results reported in section* 5 *seem to confirm this conjecture, at least in two dimensions.*

The proof of Theorem 4.1 is carried out in a way similar to that of Theorem 4.1 in [10], but since there are several important differences in the proofs of the underlying lemmas, we give all the details. In particular the error analysis reveals why a homogeneous Dirichlet boundary condition must be enforced on ϕ^{k+1} on Γ_2; it explains also the origin of the factor χ in (4.3).

Let us first introduce some notation. For any sequence $\varphi^0, \varphi^1, \dots$, we set

$$\delta_t\varphi^k = \varphi^k - \varphi^{k-1}, \quad \delta_{tt}\varphi^k = \delta_t(\delta_t\varphi^k), \quad \delta_{ttt}\varphi^k = \delta_t(\delta_{tt}\varphi^k),$$

and

$$\begin{cases} e^k = \mathsf{u}(t^k) - u^k, & \tilde{e}^k = \mathsf{u}(t^k) - \tilde{u}^k, \\ \psi^k = \mathsf{p}(t^{k+1}) - p^k, & q^k = \mathsf{p}(t^k) - p^k. \end{cases} \tag{4.18}$$

It is straightforward to show that $(\tilde{u}^1, u^1, p^1)$ obtained by using the scheme (4.1)–(4.3), with BDF2 replaced by backward Euler, satisfies the following estimates:

$$\begin{aligned} \|e^1\|_0 + \|\tilde{e}^1\|_0 + \Delta t^{\frac{1}{2}}(\|\nabla e^1\|_0 + \|\nabla \tilde{e}^1\|_0) &\lesssim \Delta t^2, \\ \|q^1\|_0 &\lesssim \Delta t. \end{aligned} \tag{4.19}$$

Note that for any bilinear form $(\cdot,\cdot)$ and any sequences $a^0, a^1, \dots$, and $b^0, b^1, \dots$, the following holds:

$$\delta_t(a^{k+1}, b^{k+1}) = (\delta_t a^{k+1}, b^{k+1}) + (a^k, \delta_t b^{k+1}). \tag{4.20}$$

The error estimates of Theorem 4.1 are proved through a succession of lemmas. The following result is the discrete counterpart of Lemma 4.1.

Lemma 4.3. *Under the hypotheses of Theorem* 4.1*, we have*

$$\begin{aligned} \|\nabla\cdot\tilde{u}_{\Delta t}\|_{\ell^\infty(L^2(\Omega))} + \sqrt{\Delta t}\|\nabla\phi_{\Delta t}\|_{\ell^\infty(L^2(\Omega))} &\lesssim \Delta t^{\frac{5}{4}}, \\ \|\delta_t\tilde{e}_{\Delta t}\|_{\ell^2(H^1(\Omega)^d)} &\lesssim \Delta t^{\frac{7}{4}}, \\ \|\delta_t\tilde{e}_{\Delta t} - \delta_t e_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)} &\lesssim \Delta t^{\frac{9}{4}}. \end{aligned}$$

Proof. Upon defining

$$R^k = \partial_t\mathsf{u}(t^k) - \frac{3\mathsf{u}(t^k) - 4\mathsf{u}(t^{k-1}) + \mathsf{u}(t^{k-2})}{2\Delta t}, \tag{4.21}$$

then, for $k \geq 2$, the equations that control the time increments of the errors are

$$\begin{cases} \dfrac{3\delta_t\tilde{e}^{k+1} - 4\delta_t e^k + \delta_t e^{k-1}}{2\Delta t} + A\delta_t\tilde{e}^{k+1} + \nabla\delta_t\psi^k = \delta_t R^{k+1}, \\ \delta_t\tilde{e}^{k+1}|_{\Gamma_1} = 0, \quad (\delta_t\psi^k n - \nu(D\delta_t\tilde{e}^{k+1})n)|_{\Gamma_2} = 0 \end{cases} \tag{4.22}$$

and

$$\begin{cases} \dfrac{3}{2\Delta t}\delta_t e^{k+1} - \nabla\phi^{k+1} = \dfrac{3}{2\Delta t}\delta_t\tilde{e}^{k+1} - \nabla\phi^k, \\ \nabla\cdot\delta_t e^{k+1} = 0, \\ \delta_t e^{k+1}\cdot n|_{\Gamma_1} = 0, \quad \phi^{k+1}|_{\Gamma_2} = \phi^k|_{\Gamma_2} = 0. \end{cases} \tag{4.23}$$

We take the inner product of (4.22) with $4\Delta t\,\delta_t\tilde{e}^{k+1}$ and obtain

$$\begin{aligned}2(\delta_t\tilde{e}^{k+1}, 3\delta_t\tilde{e}^{k+1} - 4\delta_t e^k + \delta_t e^{k-1}) &+ 4\alpha\Delta t\|\nabla\delta_t\tilde{e}^{k+1}\|_0^2 \\ &- 4\Delta t(\nabla\cdot\delta_t\tilde{e}^{k+1}, \delta_t\psi^k) = 4\Delta t(\delta_t\tilde{e}^{k+1}, \delta_t R^{k+1}) \\ &\leq \gamma\alpha\Delta t\|\nabla\delta_t\tilde{e}^{k+1}\|_0^2 + c\Delta t^7,\end{aligned}\tag{4.24}$$

where γ will be chosen later, and we have used the coercivity of the bilinear form a together with the fact that $\|\delta_t R^{k+1}\|_0 \lesssim \Delta t^3$. Note also that we have used the inequality $2ab \leq \gamma a^2 + b^2/\gamma$, which holds for all $\gamma > 0$. We shall repeatedly use this standard trick hereafter without mentioning it anymore.

Let us denote $I = 2(\delta_t\tilde{e}^{k+1}, 3\delta_t\tilde{e}^{k+1} - 4\delta_t e^k + \delta_t e^{k-1})$; then we have

$$\begin{aligned}I = 6(\delta_t\tilde{e}^{k+1}, \delta_t\tilde{e}^{k+1} - \delta_t e^{k+1}) &+ 2(\delta_t\tilde{e}^{k+1} - \delta_t e^{k+1}, 3\delta_t e^{k+1} - 4\delta_t e^k + \delta_t e^{k-1}) \\ + 2(\delta_t e^{k+1}, 3\delta_t e^{k+1} &- 4\delta_t e^k + \delta_t e^{k-1}).\end{aligned}$$

Let I_1, I_2, and I_3 be the three terms in the right-hand side. Using the algebraic identities

$$2(a^{k+1}, a^{k+1} - a^k) = |a^{k+1}|^2 + |a^{k+1} - a^k|^2 - |a^k|^2,\tag{4.25}$$

$$\begin{aligned}2(a^{k+1}, 3a^{k+1} - 4a^k + a^{k-1}) = |a^{k+1}|^2 &+ |2a^{k+1} - a^k|^2 + |\delta_{tt}a^{k+1}|^2 \\ &- |a^k|^2 - |2a^k - a^{k-1}|^2,\end{aligned}\tag{4.26}$$

we derive

$$\begin{aligned}I_1 &= 3\|\delta_t\tilde{e}^{k+1}\|_0^2 + 3\|\delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}\|_0^2 - 3\|\delta_t e^{k+1}\|_0^2, \\ I_3 &= \|\delta_t e^{k+1}\|_0^2 + \|2\delta_t e^{k+1} - \delta_t e^k\|_0^2 + \|\delta_{ttt}e^{k+1}\|_0^2 - \|\delta_t e^k\|_0^2 - \|2\delta_t e^k - \delta_t e^{k-1}\|_0^2.\end{aligned}$$

Owing to (4.23) and using the fact that $e^k \in H$, we derive the following equality:

$$\frac{3}{2\Delta t}I_2 = -2(\nabla\delta_t\phi^{k+1}, 3\delta_t e^{k+1} - 4\delta_t e^k + \delta_t e^{k-1}) = 0.$$

Collecting all the above results, we obtain

$$\begin{aligned}3\|\delta_t\tilde{e}^{k+1}\|_0^2 - 3\|\delta_t e^{k+1}\|_0^2 &+ \|\delta_t e^{k+1}\|_0^2 + \|2\delta_t e^{k+1} - \delta_t e^k\|_0^2 \\ &+ 3\|\delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}\|_0^2 + \|\delta_{ttt}e^{k+1}\|_0^2 \\ &+ (4-\gamma)\alpha\Delta t\|\nabla\delta_t\tilde{e}^{k+1}\|_0^2 - 4\Delta t(\nabla\cdot\delta_t\tilde{e}^{k+1}, \delta_t\psi^k) \\ &\leq c\,\Delta t^7 + \|\delta_t e^k\|_0^2 + \|2\delta_t e^k - \delta_t e^{k-1}\|_0^2.\end{aligned}\tag{4.27}$$

Taking the square of (4.23) and integrating over the domain, we obtain

$$\begin{aligned}3\|\delta_t e^{k+1}\|_0^2 + \frac{4}{3}\Delta t^2\|\nabla\phi^{k+1}\|_0^2 = 3\|\delta_t\tilde{e}^{k+1}\|_0^2 &+ \frac{4}{3}\Delta t^2\|\nabla\phi^k\|_0^2 \\ &+ 4\Delta t(\nabla\cdot\delta_t\tilde{e}^{k+1}, \phi^k).\end{aligned}\tag{4.28}$$

Note that integration by parts on $(\delta_t e^{k+1}, \nabla\phi^{k+1})$ and $(\delta_t\tilde{e}^{k+1}, \nabla\phi^k)$ is legitimate because both $\phi^{k+1}|_{\Gamma_2}$ and $\phi^k|_{\Gamma_2}$ are zero. Since $\phi^k = p^k - p^{k-1} - \chi\nabla\cdot\tilde{e}^k$, we can bound the inner product in the right-hand side of (4.28) as follows:

$$\begin{aligned}4\Delta t(\nabla\cdot\delta_t\tilde{e}^{k+1}, \phi^k) &= 4\Delta t(\nabla\cdot\delta_t\tilde{e}^{k+1}, p^k - p^{k-1} - \chi\nabla\cdot\tilde{e}^k) \\ &= 2\chi\Delta t(-\|\nabla\cdot\tilde{e}^{k+1}\|_0^2 + \|\nabla\cdot\tilde{e}^k\|_0^2 + \|\nabla\cdot\delta_t\tilde{e}^{k+1}\|_0^2) \\ &\quad - 4\Delta t(\nabla\cdot\delta_t\tilde{e}^{k+1}, \delta_t\psi^k) + 4\Delta t(\nabla\cdot\delta_t\tilde{e}^{k+1}, \delta_t\mathsf{p}(t^{k+1})).\end{aligned}\tag{4.29}$$

To control the troublesome term $\Delta t\|\nabla\cdot\delta_t\tilde{e}^{k+1}\|_0^2$ we use

$$\chi\|\nabla\cdot v\|_0^2 \le 2\gamma'\alpha\|\nabla v\|_0^2 \quad \forall v \in X. \tag{4.30}$$

Due to the condition χ, (4.4), we know that the constant γ' is such that $0 < \gamma' < 1$. Summing (4.27), (4.28), and (4.29), and using (4.30), we finally obtain

$$\begin{aligned}&\|\delta_t e^{k+1}\|_0^2 + \|2\delta_t e^{k+1} - \delta_t e^k\|_0^2 + \frac{4}{3}\Delta t^2\|\nabla\phi^{k+1}\|_0^2 + 2\chi\Delta t\|\nabla\cdot\tilde{e}^{k+1}\|_0^2\\ &\qquad + (4-4\gamma'-\gamma)\alpha\Delta t\|\nabla\delta_t\tilde{e}^{k+1}\|_0^2 + 3\|\delta_t(e^{k+1}-\tilde{e}^{k+1})\|_0^2 + \|\delta_{ttt}e^{k+1}\|_0^2\\ &\quad \le \|\delta_t e^k\|_0^2 + \|2\delta_t e^k - \delta_t e^{k-1}\|_0^2 + \frac{4}{3}\Delta t^2\|\nabla\phi^k\|_0^2 + 2\chi\Delta t\|\nabla\cdot\tilde{e}^k\|_0^2\\ &\qquad + 4\Delta t(\nabla\cdot\delta_t\tilde{e}^{k+1}, \delta_t\mathsf{p}(t^{k+1})) + c\Delta t^7.\end{aligned} \tag{4.31}$$

At this point, we are formally at the same stage as (4.14). To integrate by parts in time the term $(\nabla\cdot\delta_t\tilde{e}^{k+1}, \delta_t\mathsf{p}(t^{k+1}))$, we use (4.20) as follows:

$$(\nabla\cdot\delta_t\tilde{e}^{k+1}, \delta_t\mathsf{p}(t^{k+1})) = \delta_t(\nabla\cdot\tilde{e}^{k+1}, \delta_t\mathsf{p}(t^{k+1})) - (\nabla\cdot\tilde{e}^k, \delta_{tt}\mathsf{p}(t^{k+1})).$$

Next, we use the interpolation operator defined in (4.15). Let us denote $\mathcal{R}^{k+1} = \mathsf{p}(t^{k+1}) - \mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1}))$ (where $\mathcal{J}_{\Delta t} = \mathcal{I}_{\sqrt{\Delta t},1}$). Then we have

$$\frac{1}{\Delta t}\|\delta_{tt}\mathcal{R}^{k+1}\|_0^2 + \|\nabla\delta_{tt}\mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1}))\|_0^2 \lesssim \Delta t^{\frac{7}{2}}.$$

Since $\mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1}))$ is zero on Γ_2, we have

$$\begin{aligned}(\nabla\cdot\delta_t\tilde{e}^{k+1}, \delta_t\mathsf{p}(t^{k+1})) &= \delta_t(\nabla\cdot\tilde{e}^{k+1}, \delta_t\mathcal{R}^{k+1}) + \delta_t(\nabla\cdot\tilde{e}^{k+1}, \delta_t\mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1})))\\ &\quad - (\nabla\cdot\tilde{e}^k, \delta_{tt}\mathcal{R}^{k+1}) - (\nabla\cdot\tilde{e}^k, \delta_{tt}\mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1})))\\ &= \delta_t(\nabla\cdot\tilde{e}^{k+1}, \delta_t\mathcal{R}^{k+1}) + \frac{2\Delta t}{3}\delta_t(\nabla\phi^{k+1}, \nabla\delta_t\mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1})))\\ &\quad - (\nabla\cdot\tilde{e}^k, \delta_{tt}\mathcal{R}^{k+1}) - \frac{2\Delta t}{3}(\nabla\phi^k, \nabla\delta_{tt}\mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1})))\\ &\le \delta_t(\nabla\cdot\tilde{e}^{k+1}, \delta_t\mathcal{R}^{k+1}) + \frac{2\Delta t}{3}\delta_t(\nabla\phi^{k+1}, \nabla\delta_t\mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1})))\\ &\quad + \frac{\chi\Delta t}{2}\|\nabla\cdot\tilde{e}^k\|_0^2 + \frac{\Delta t^2}{3}\|\nabla\phi^k\|_0^2 + c\Delta t^{\frac{7}{2}}.\end{aligned}$$

By inserting this bound into (4.31), we obtain

$$\begin{aligned}&\|\delta_t e^{k+1}\|_0^2 + \|2\delta_t e^{k+1} - \delta_t e^k\|_0^2 + \frac{4}{3}\Delta t^2\|\nabla\phi^{k+1}\|_0^2 + 2\chi\Delta t\|\nabla\cdot\tilde{e}^{k+1}\|_0^2\\ &\qquad + (4-4\gamma'-\gamma)\alpha\Delta t\|\nabla\delta_t\tilde{e}^{k+1}\|_0^2 + 3\|\delta_t(e^{k+1}-\tilde{e}^{k+1})\|_0^2 + \|\delta_{ttt}e^{k+1}\|_0^2\\ &\quad \le \|\delta_t e^k\|_0^2 + \|2\delta_t e^k - \delta_t e^{k-1}\|_0^2\\ &\qquad + \frac{4}{3}\Delta t^2(1+\Delta t)\|\nabla\phi^k\|_0^2 + 2\chi\Delta t(1+\Delta t)\|\nabla\cdot\tilde{e}^k\|_0^2\\ &\qquad + 4\Delta t\delta_t(\nabla\cdot\tilde{e}^{k+1}, \delta_t\mathcal{R}^{k+1}) + \frac{8\Delta t^2}{3}\delta_t(\nabla\phi^{k+1}, \nabla\delta_t\mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1}))) + c\,\Delta t^{\frac{9}{2}}.\end{aligned}$$

Summing up the relation above for $l = 2, \dots, k$ and taking into account (4.19), we obtain

$$\begin{aligned}
&\|\delta_t e^{k+1}\|_0^2 + \|2\delta_t e^{k+1} - \delta_t e^k\|_0^2 + \frac{4}{3}\Delta t^2 \|\nabla \phi^{k+1}\|_0^2 + 2\chi \Delta t \|\nabla\cdot \tilde{e}^{k+1}\|_0^2 \\
&\qquad + (4 - 4\gamma' - \gamma)\alpha \Delta t \sum_{l=2}^{k} \|\nabla \delta_t \tilde{e}^{l+1}\|_0^2 + 3\sum_{l=2}^{k} \|\delta_t e^{l+1} - \delta_t \tilde{e}^{l+1}\|_0^2 \\
&\quad \le c\left(\|\delta_t e^2\|_0^2 + \|2\delta_t e^2 - \delta_t e^1\|_0^2 + \Delta t^2 \|\nabla\phi^2\|_0^2 + \Delta t \|\nabla\cdot \tilde{e}^2\|_0^2 + \Delta t^{\frac{7}{2}}\right) \\
&\qquad + \Delta t \sum_{l=2}^{k} \left(\frac{4}{3}\Delta t^2 \|\nabla\phi^l\|_0^2 + 2\chi\Delta t \|\nabla\cdot \tilde{e}^l\|_0^2\right) \\
&\qquad - 4\Delta t(\nabla\cdot \tilde{e}^{k+1}, \delta_t \mathcal{R}^{k+1}) - \frac{8\Delta t^2}{3}(\nabla\phi^{k+1}, \nabla \delta_t \mathcal{J}_{\Delta t}(\mathsf{p}(t^{k+1}))) \\
&\qquad + 4\Delta t(\nabla\cdot \tilde{e}^2, \delta_t \mathcal{R}^2) + \frac{8\Delta t^2}{3}(\nabla\phi^2, \nabla\delta_t \mathcal{J}_{\Delta t}(\mathsf{p}(t^2))) \\
&\quad \le c\Delta t^{\frac{7}{2}} + \frac{2}{3}\Delta t^2 \|\nabla\phi^{k+1}\|_0^2 + \chi\Delta t \|\nabla\cdot \tilde{e}^{k+1}\|_0^2 \\
&\qquad + \Delta t \sum_{l=2}^{k} \left(\frac{4}{3}\Delta t^2 \|\nabla\phi^l\|_0^2 + 2\chi\Delta t\|\nabla\cdot\tilde{e}^l\|_0^2\right).
\end{aligned}$$

Since $0 < \gamma' < 1$, we can choose γ such that $4 - 4\gamma' - \gamma \ge 0$. Then an application of the discrete Gronwall lemma yields the desired result. □

REMARK 4.3. *Note that to balance the term* $-(\nabla\cdot\delta_t \tilde{e}^{k+1}, \psi^k)$ *in* (4.27) *it is necessary to integrate by parts the term* $(\delta_t \tilde{e}^{k+1}, \nabla\phi^k)$ *in* (4.28). *This is possible only because the Dirichlet boundary condition* $\phi^k|_{\Gamma_2} = 0$ *is enforced. This fact is the main reason why we enforce a homogeneous Dirichlet boundary condition on* ϕ^{k+1} *in* (4.2). *This argument shows the importance of the error analysis (or stability analysis) performed in the proof of Lemma* 4.3. *The necessity of the Dirichlet boundary condition also becomes clear when one understands that* (4.2) *is a realization of* $u^{k+1} = P_H \tilde{u}^{k+1}$, *since the orthogonal complement of* H *is* ∇N *according to Lemma* 2.1.

REMARK 4.4. *The introduction of the parameter* χ *together with the bound* (4.4) *is justified by step* (4.30). *Whether the bound* (4.4) *is sharp is not yet clear.*

LEMMA 4.4. *Under the hypotheses of Theorem* 4.1, *we have*

$$\|\mathsf{u}_{\Delta t} - \tilde{u}_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)} + \|\mathsf{u}_{\Delta t} - u_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)} \lesssim \Delta t^{\frac{5+s}{4}}.$$

Proof. By using the relation $e^l = \tilde{e}^l + \frac{2\Delta t}{3}\nabla\phi^l$, for all $l \ge 2$, one obtains

$$(4.32)\qquad \begin{cases} \dfrac{3\tilde{e}^{k+1} - 4\tilde{e}^k + \tilde{e}^{k-1}}{2\Delta t} + A\tilde{e}^{k+1} + \nabla\gamma^k = R^{k+1}, \\ \tilde{e}^{k+1}|_{\Gamma_1} = 0, \quad (\gamma^k n - \nu(D\tilde{e}^{k+1})n)|_{\Gamma_2} = 0, \end{cases}$$

where $\nabla\gamma^k$ stands for the collection of all the gradient terms.

As in the time continuous case, we make use of the inverse Stokes operator. By taking the inner product of (4.32) with $4\Delta t S(\tilde{e}^{k+1})$ and using the identity (4.26), we obtain

$$\begin{aligned}
&|\tilde{e}^{k+1}|_\star^2 + |2\tilde{e}^{k+1} - \tilde{e}^k|_\star^2 + |\delta_{tt}\tilde{e}^{k+1}|_\star^2 + 4\Delta t\, a(\tilde{e}^{k+1}, S(\tilde{e}^{k+1})) \\
&\qquad\qquad = 4\Delta t\,(R^{k+1}, S(\tilde{e}^{k+1})) + |\tilde{e}^k|_\star^2 + |2\tilde{e}^k - \tilde{e}^{k-1}|_\star^2.
\end{aligned}$$

Using Lemma 2.3 with $\mu = \sqrt{\Delta t}$ and Lemma 4.3, we infer

$$\begin{aligned}4a(\tilde{e}^{k+1}, S(\tilde{e}^{k+1})) &\geq 2\|\tilde{e}^{k+1}\|_0^2 - c(\Delta t^{\alpha_1}\,\|\nabla\cdot\tilde{e}^{k+1}\|_0^2 + \Delta t^{-\alpha_2}\,\|\tilde{e}^{k+1} - e^{k+1}\|^2)\\ &\geq 2\|\tilde{e}^{k+1}\|_0^2 - c(\Delta t^{\alpha_1}\,\|\nabla\cdot\tilde{e}^{k+1}\|_0^2 + \Delta t^{1-\alpha_2}\,\Delta t\|\nabla\phi^{k+1}\|^2\\ &\geq 2\|\tilde{e}^{k+1}\|_0^2 - c\Delta t^{\alpha_1+\frac{5}{2}} \geq 2\|\tilde{e}^{k+1}\|_0^2 - c\Delta t^{\frac{5+s}{2}}.\end{aligned}$$

We also derive from the Cauchy–Schwarz inequality and (2.16) that

$$4\Delta t(R^{k+1}, S(\tilde{e}^{k+1})) \leq c\Delta t\|R^{k+1}\|_{X'}^2 + \Delta t\|\tilde{e}^{k+1}\|_0^2 \leq c'\Delta t^5 + \Delta t\|\tilde{e}^{k+1}\|_0^2.$$

Combining these two estimates, we obtain

$$|\tilde{e}^{k+1}|_\star^2 + |2\tilde{e}^{k+1} - \tilde{e}^k|_\star^2 + \Delta t\|\tilde{e}^{k+1}\|_0^2 \leq |\tilde{e}^k|_\star^2 + |2\tilde{e}^k - \tilde{e}^{k-1}|_\star^2 + c\Delta t^{1+\frac{5+s}{2}}.$$

The desired result is now an easy consequence of the discrete Gronwall lemma. The estimate on $\|\mathsf{u}_{\Delta t} - u_{\Delta t}\|_0$ is obtained by using the triangular inequality $\|\mathsf{u}_{\Delta t} - u_{\Delta t}\|_0 \leq \|\mathsf{u}_{\Delta t} - \tilde{u}_{\Delta t}\|_0 + \frac{2\Delta t}{3}\|\nabla\phi_{\Delta t}\|_0$ (derived from (4.2)) and Lemma 4.3. □

The key for obtaining improved estimates on $\|\tilde{e}_{\Delta t}\|_{\ell^2(H^1(\Omega)^d)}$ and $\|q_{\Delta t}\|_{\ell^2(L^2(\Omega))}$ is to derive an improved estimate on $\frac{1}{2\Delta t}(3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1})$. To this end, for any sequence of functions $\phi^0, \phi^1, \ldots$, we define

$$D_t\phi^{k+1} := \frac{1}{2}(3\phi^{k+1} - 4\phi^k + \phi^{k-1}).$$

Lemma 4.5. *Under the hypotheses of Theorem* 4.1, *we have*

$$\Delta t^{-1}\|(D_t\tilde{e})_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)} \lesssim \Delta t^{\frac{3+s}{4}}.$$

Proof. We use the same argument as in the proof of the L^2-estimate, but we use it on the time increment $\delta_t\tilde{e}^{k+1}$. For $k \geq 2$ we have

$$\frac{3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1}}{2\Delta t} + A\delta_t\tilde{e}^{k+1} + \nabla\delta_t\gamma^{k+1} = \delta_t R^{k+1}.$$

Taking the inner product of the above relation with $4\Delta t S(\delta_t\tilde{e}^{k+1})$, using Lemma 2.3 with $\mu = \sqrt{\Delta t}$, and repeating the same arguments as in the previous lemma, we obtain

$$\begin{aligned}&|\delta_t\tilde{e}^{k+1}|_\star^2 + |2\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^k|_\star^2 + |\delta_{ttt}\tilde{e}^{k+1}|_\star^2 + \Delta t\|\delta_t\tilde{e}^{k+1}\|_0^2\\ &\quad\leq c\Delta t\|\delta_t R^{k+1}\|_0^2 + c\Delta t(\Delta t^{\alpha_1}\|\nabla\cdot\delta_t\tilde{e}^{k+1}\|_0^2 + \Delta t^{-\alpha_2}\|\delta_t\tilde{e}^{k+1} - \delta_t e^{k+1}\|_0^2)\\ &\qquad + |\delta_t\tilde{e}^k|_\star^2 + |2\delta_t\tilde{e}^k - \delta_t\tilde{e}^{k-1}|_\star^2.\end{aligned}$$

Applying the discrete Gronwall lemma, and using the initial estimates and Lemma 4.3, we obtain

$$\|\delta_t\tilde{e}_{\Delta t}\|_{l^2(L^2(\Omega)^d)}^2 \lesssim \Delta t^{\frac{7+s}{2}}.$$

We conclude by using the fact that $2D_t\tilde{e}^{k+1} = 3\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^k$. □

We are now in position to prove the remaining claims in Theorem 4.1.

Lemma 4.6. *Under the hypotheses of Theorem* 4.1, *we have*

$$\|\mathsf{u}_{\Delta t} - \tilde{u}_{\Delta t}\|_{\ell^2(H^1(\Omega)^d)} + \|\mathsf{p}_{\Delta t} - p_{\Delta t}\|_{\ell^2(L^2(\Omega))} \lesssim \Delta t^{\frac{3+s}{4}}.$$

Proof. By adding the viscous step and the projection step, it is clear that we have

$$\begin{cases} A\tilde{e}^{k+1} + \nabla(q^{k+1} + \chi\nabla\cdot\tilde{e}^{k+1}) = h^{k+1}, \\ \nabla\cdot\tilde{e}^{k+1} = g^{k+1}, \quad \tilde{e}^{k+1}|_{\Gamma_1} = 0, \quad ((q^{k+1} + \chi\nabla\cdot\tilde{e}^{k+1})n - (D\tilde{e}^{k+1})n)|_{\Gamma_2} = 0, \end{cases} \tag{4.33}$$

where

$$h^{k+1} = R^{k+1} - \frac{D_t e^{k+1}}{\Delta t}, \qquad g^{k+1} = -\frac{2\Delta t}{3}\nabla^2\phi^{k+1}. \tag{4.34}$$

Owing to Lemma 4.3, we have

$$\|g^{k+1}\|_0 = \|\nabla\cdot\tilde{e}^{k+1}\|_0 \lesssim \Delta t^{\frac{5}{4}} \qquad \forall k. \tag{4.35}$$

Since $e^k = P_H\tilde{e}^k$, owing to Lemma 4.5, we infer

$$\Delta t^{-1}\|\delta_t e_{\Delta t}\|_{l^2(L^2(\Omega)^d)} \leq \Delta t^{-1}\|\delta_t\tilde{e}_{\Delta t}\|_{l^2(L^2(\Omega)^d)} \lesssim \Delta t^{\frac{3+s}{4}}.$$

Hence, we have

$$\|h_{\Delta t}\|_{\ell^2(X')} \lesssim \|R_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)} + \Delta t^{-1}\|D_t\tilde{e}_{\Delta t}\|_{\ell^2(L^2(\Omega)^d)} \lesssim \Delta t^{\frac{3+s}{4}}. \tag{4.36}$$

Now, we apply the following standard stability result for nonhomogeneous Stokes systems to (4.33) (cf. [23]):

$$\|\tilde{e}^{k+1}\|_1 + \|(q^{k+1} + \chi\nabla\cdot\tilde{e}^{k+1})\|_0 \lesssim \|h^{k+1}\|_{X'} + \|g^{k+1}\|_0. \tag{4.37}$$

Owing to (4.35) and (4.36), we derive

$$\|\tilde{e}_{\Delta t}\|_{\ell^2(H^1(\Omega)^d)} + \|(q + \chi\nabla\cdot\tilde{e})\|_{\ell^2(L^2(\Omega))} \lesssim \Delta t^{\frac{3+s}{4}}.$$

Then, from

$$\|q^{k+1}\|_0 \leq \|q^{k+1} + \chi\nabla\cdot\tilde{e}^{k+1}\|_0 + \chi\|\nabla\cdot\tilde{e}^{k+1}\|_0,$$

we derive $\|q_{\Delta t}\|_{l^2(L^2(\Omega))} \lesssim \Delta t^{\frac{3+s}{4}}$. □

Thus, all the results in Theorem 4.1 have been proved.

5. Numerical results and discussions.

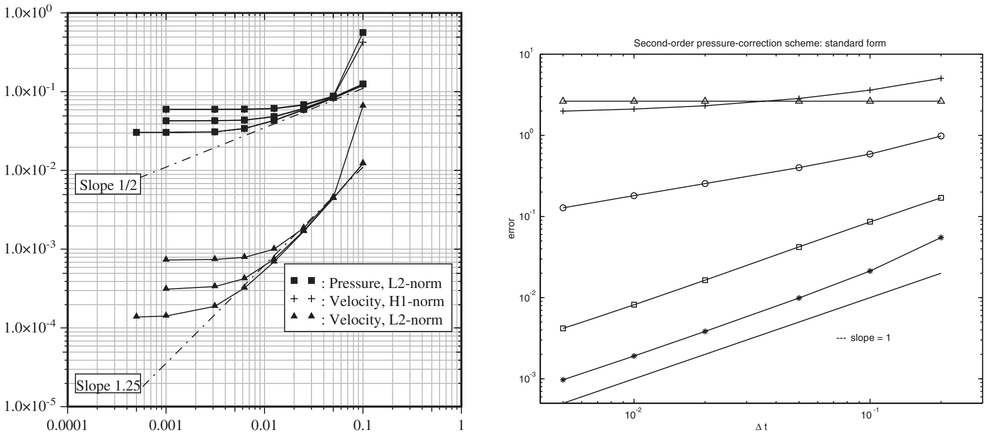
5.1. Standard pressure-correction scheme. We take the exact solution $(\mathsf{u}_1, \mathsf{u}_2, \mathsf{p})$ of the linearized Navier–Stokes equations to be

$$\mathsf{u}_1(x,y,t) = \sin x\sin(y+t), \ \mathsf{u}_2(x,y,t) = \cos x\cos(y+t), \ \mathsf{p}(x,y,t) = \cos x\sin(y+t).$$

We set $\Omega =]0,1[^2$, $\Gamma_2 = \{(x,y) \in \Gamma, \, x = 0\}$. This solution satisfies the following open boundary conditions:

$$-\partial_x\mathsf{u}_2|_{\Gamma_2} = 0, \qquad \mathsf{p} - \partial_x\mathsf{u}_1|_{\Gamma_2} = 0.$$

To confirm the results in Theorem 3.1, we have carried out convergence tests in time using $\mathbb{P}_2/\mathbb{P}_1$ finite elements as well as the $\mathbb{P}_N^2 \times \mathbb{P}_{N-2}$ Legendre–Galerkin method [19] (where $\mathbb{P}_k$ denotes the space of polynomials of degree less than or equal



Finite elements with $h = 1/20$, $1/40$, and $1/80$. Legendre–Galerkin with $N = 40$.

FIG. 5.1. *Errors vs.* Δt, *standard pressure-correction scheme: Note that the curves corresponding to the error on the velocity in* H^1*-norm and the pressure in* L^2*-norm almost coincide.*

to k). We use the standard BDF2 pressure-correction scheme, which enforces a homogeneous Dirichlet boundary condition on the pressure increment at the open boundary in the projection step.

For the finite elements, the errors at $t = 1$ for three meshes ($h = 1/20$, $1/40$, $1/80$) and $5.10^{-4} \leq \Delta t \leq 10^{-1}$ are reported in the left panel of Figure 5.1. Note that the error for small time steps is dominated by the spatial discretization error. The reference slope represents the asymptotic convergence rate as $h \to 0$.

For the Legendre–Galerkin method, the results with $N = 40$ are reported in the right panel of Figure 5.1. For the range of time steps explored, the spatial discretization error is negligible compared to the time discretization error.

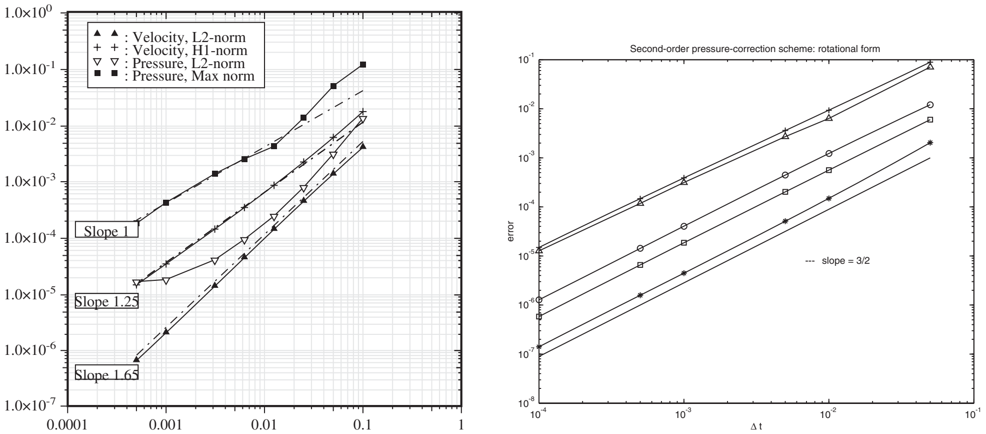
These tests clearly indicate that the L^2-error of the velocity (resp., the pressure) is of order Δt (resp., $\Delta t^{\frac{1}{2}}$), which are consistent with Theorem 3.1.

5.2. Rotational pressure-correction scheme. We again use the analytical solution described above to test the time accuracy of the rotational pressure-correction scheme (4.1)–(4.3).

We first report the results with $\mathbb{P}_2/\mathbb{P}_1$ finite elements. We use $h = 1/80$ to guarantee that the error in space is significantly smaller than the splitting error. The results are reported in the left panel of Figure 5.2. The convergence rate of the error on the velocity in the L^2-norm is close to $\mathcal{O}(\Delta t^{3/2})$, and that of the H^1-norm behaves like $\mathcal{O}(\Delta t^{5/4})$, which is higher than the $\mathcal{O}(\Delta t)$ rate predicted by Theorem 4.1 (see Remark 4.2 and Lemma 4.3). The convergence rate of the error on the pressure in the L^∞-norm is $\mathcal{O}(\Delta t)$, and that of the L^2-norm is between $\mathcal{O}(\Delta t)$ and $\mathcal{O}(\Delta t^{\frac{3}{2}})$. These rates are mostly consistent with the error estimates in Theorem 4.1. The accuracy saturation observed for small time steps comes from the spatial discretization error.

The results using the Legendre–Galerkin method are reported in the right panel of Figure 5.2. We note that the convergence rate for the error on the velocity in the L^2-norm is of order $O(\Delta t^{\frac{3}{2}})$, as predicted by Theorem 4.1. The convergence rates on all the other quantities are also close to $O(\Delta t^{\frac{3}{2}})$, which is higher than what Theorem 4.1 predicts (see Remark 4.2).

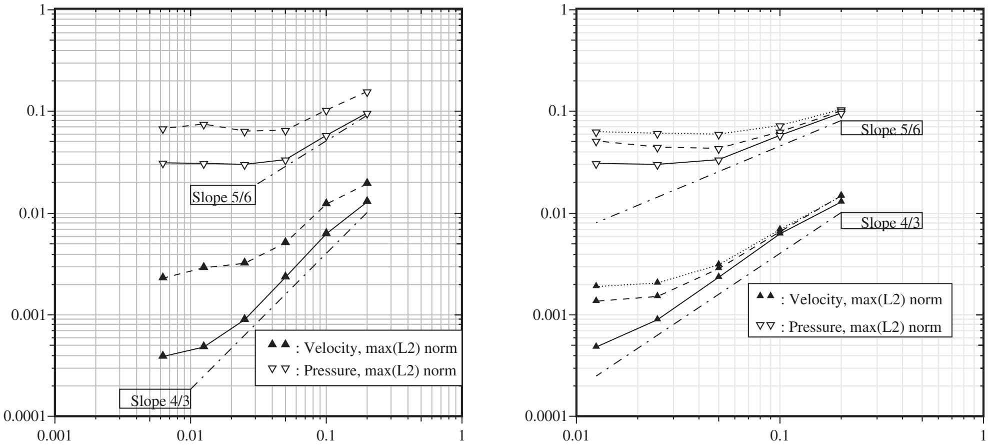
To complete this series of tests, we have performed convergence tests in three



Velocity: (▲) L^2-norm; (+) H^1-norm.
Pressure: (▽) L^2-norm; (■) L^∞-norm.

Velocity: (*) L^2-norm; (□) H^1-norm.
Pressure: (○) L^2; (+) H^1; (△) L^∞.

FIG. 5.2. *Rotational pressure-correction scheme: Left, finite elements; errors at $t = 1$ vs. Δt (using $h = 1/80$). Right, spectral method; error vs. Δt with $N = 40$ fixed.*



$h = 1/40$. Standard form (dashes) vs. rotational form (solid line)

$h = 1/10$, $1/20$, $1/40$. Rotational form, $\chi = 2/3$.

FIG. 5.3. *Pressure-correction scheme with $\mathbb{P}_2/\mathbb{P}_1$ finite elements in three dimensions. Errors vs. Δt. Velocity: (▲) L^2-norm. Pressure: (▽) L^2-norm.*

dimensions using $\mathbb{P}_2/\mathbb{P}_1$ finite elements. The boundary conditions and the source term in the Stokes equations are set so that the solution is given by

$$\mathsf{u}_1(x,y,z,t) = \sin x \sin(y+z+t),\ \mathsf{u}_2(x,y,z,t) = \cos x \cos(y+z+t),$$
$$\mathsf{u}_3(x,y,z,t) = \cos(x)\sin(y+t),\ \mathsf{p}(x,y,t) = \cos x \sin(y+z+t).$$

Both the standard and the rotational forms of the BDF2 pressure-correction scheme were tested. We show in Figure 5.3 the maximum in time of the L^2-norm of the errors on the velocity and the pressure for both schemes. On the left panel we compare the standard and rotational forms of the scheme using $h = 1/40$. Unfortunately, using a higher uniform resolution in space was not possible due to the high cost of the computations. The grid with a stepsize $h = 1/40$ already contains close to

500,000 $\mathbb{P}_2$ nodes. On the right panel we show the errors for the rotational form of the scheme using three different meshes: $h = 1/10$, $1/20$, $1/40$. The convergence rates of the standard version of the scheme are clearly lower than those of the rotational form. The slopes for both the velocity and the pressure errors obtained with the rotational form of the scheme are slightly lower than the best possible estimate following from the claim of Theorem 4.1. The rates $\mathcal{O}(\Delta t^{\frac{4}{3}})$ and $\mathcal{O}(\Delta t^{\frac{5}{6}})$ seem to correspond to a regularity index $s < 1$.

6. Concluding remarks. In this paper, we have analyzed pressure-correction schemes for approximating the incompressible Navier–Stokes equations with prescribed normal stress boundary conditions enforced on parts of the boundary. Our conclusions are twofold.

First, we have shown that the convergence rates of standard pressure-correction methods are too poor to be recommendable for approximating the Navier–Stokes equations in these circumstances. The main reason for the poor accuracy is that an *artificial* homogeneous Dirichlet boundary condition on the pressure has to be imposed to ensure stability.

Second, we have shown that the rotational pressure-correction method leads to reasonably good error estimates. More precisely, assuming full regularity of the Stokes problem, we have shown that the second-order rotational pressure-correction method yields $\mathcal{O}(\Delta t^{3/2})$ accuracy for the velocity in the L^2-norm and $\mathcal{O}(\Delta t)$ accuracy for the velocity in the H^1-norm and the pressure in the L^2-norm. To the best of our knowledge, the results presented in this paper are the first published convergence estimates for a splitting method solving the time-dependent Stokes equations with open boundary conditions.

Finally, it is clear that even though the second-order rotational pressure-correction method yields the best error estimates to date, these are still suboptimal and more research is needed to find a splitting scheme with better properties.

POLYNOMIAL FITTING FOR EDGE DETECTION IN IRREGULARLY SAMPLED SIGNALS AND IMAGES*

RICK ARCHIBALD[†], ANNE GELB[‡], AND JUNGHO YOON[§]

Abstract. We propose a new edge detection method that is effective on multivariate irregular data in any domain. The method is based on a local polynomial annihilation technique and can be characterized by its convergence to zero for any value away from discontinuities. The method is numerically cost efficient and entirely independent of any specific shape or complexity of boundaries. Application of the *minmod* function to the edge detection method of various orders ensures a high rate of convergence away from the discontinuities while reducing the inherent oscillations near the discontinuities. It further enables distinction of jump discontinuities from steep gradients, even in instances where only sparse nonuniform data is available. These results are successfully demonstrated in both one and two dimensions.

Key words. *minmod* function, multivariate edge detection, Newton divided differencing, nonuniform grids

1. Introduction.

Edge detection is of fundamental importance in image analysis. In particular, a reliable and efficient edge detection method can both provide the possibility of processing an image with high accuracy as well as serve to simplify the analysis of images by drastically reducing the amount of data to be processed. Among the many common criteria relevant to edge detector performance, there are two very important issues. The first and most obvious issue is the possibility of failing to find real edge points and/or falsely identifying nonedge points. Regardless of specific types of data (regular or irregular) and domains, it is imperative that the edges occurring in the image should not be missed, and that there be no spurious responses. This is critical since the edges of the image constitute piecewise smooth regions. Hence errors in edge identification could also have drastic consequences on image reconstruction. The second issue is the necessity for simple implementation and cost efficiency.

To address these issues, this study constructs an edge detection method based on local Taylor expansions. Indeed, several well-known methods exist in the univariate case (see, e.g., [2], [3], [4], [5], [11], and the references therein). However, for the bivariate case, particularly with irregular points, no successful method has thus far been developed. Recent developments (see [1] and [15]) in essentially nonoscillatory (ENO) and weighted essentially nonoscillatory (WENO) methods for hyperbolic conservation laws and Hamilton–Jacobi equations on multidimensional unstructured meshes also utilize Taylor expansions to determine regions of analyticity. For uniform sampling,

we note that while ENO and WENO methods identify stencils yielding the "most" smooth polynomial interpolations, they do not distinguish between, say, steep gradients and edges. In our method, Taylor expansions are used for the exclusive purpose of determining the true edges of an image by incorporating various orders and stencil sizes.

In this paper we present an edge detection method for multivariate irregular data that has the following desirable properties: (I) It can be applied to any irregular data in any domain. (II) It is independent of any specific shape of discontinuities in both the univariate and bivariate cases. (III) The method depends only on locally sampled signals, making it easy to implement numerically, since for each point our scheme needs only to solve a simple matrix and no global system of equations needs to be solved. (IV) It has a fast rate of convergence to zero away from the discontinuities. The benefit of the last property is that the edge detection method will be able to distinguish jumps from steep gradients more readily than methods of slower convergence. There will be additional considerations, as it will become apparent that high order edge detection methods produce more oscillations in the neighborhoods of the jump discontinuities. To distinguish true jump locations from neighborhood oscillations, we find from [13] that the *minmod* function (see Definition 3.1), typically used for reducing oscillations in the presence of shocks in numerical solutions for conservation laws (see, e.g., [7]), may help to reduce oscillations in the presence of jump discontinuities. We extend this idea to our edge detection method for the case of multivariate irregular data and moreover provide a proof for its convergence rate to zero away from the discontinuities, which has previously not been accomplished.

This study is primarily concerned with the detection of jump discontinuities (or fault detection). While it is important to consider the effects of a noisy environment on an edge detection method, it is beyond the scope of this introductory paper. Hence we leave the study of noise for future investigations.

This paper is organized as follows: In section 2 we present the formulation of the edge detection method. In section 3 we use this formulation to construct an edge detection method for the one-dimensional case and employ the *minmod* function to the edge detection method. Section 4 is devoted to analyzing the behavior of the edge detection method in two dimensions. Finally, some numerical algorithms are provided in Appendices A and B.

2. General formulation for edge detection.

Let us first introduce the following notation, which will be used throughout this paper:

For $x = (x_1, \dots, x_d)$ in $\mathbb{R}^d$, $|x| := (x_1^2 + x_2^2 + \cdots + x_d^2)^{1/2}$ stands for its Euclidean norm. For any finite set of points $\mathcal{S}$ in $\mathbb{R}^d$ we use the notation $K_{\mathcal{S}}$ for the convex hull of the set $\mathcal{S}$. We denote by $\mathbb{N} := \{1, 2, \dots, \}$ the set of natural numbers and by $\mathbb{Z}_+ := \{0, 1, 2, \dots, \}$ the set of nonnegative integers. For any $\alpha \in \{(\alpha_1, \dots, \alpha_d) : \alpha_1, \dots, \alpha_d \in \mathbb{Z}_+\} := \mathbb{Z}_+^d$, we set $|\alpha|_1 := \sum_{k=1}^d \alpha_k$, and $\alpha! := \alpha_1! \cdots \alpha_d!$. Throughout α is a multivariate nonnegative integer that will change dimension based upon the dimension under discussion. We denote a uniform grid of density h as $h\mathbb{Z}^d := \{h\alpha | \alpha \in \mathbb{Z}^d\}$. We use the usual notation $\lceil s \rceil$ to indicate the smallest integer greater than or equal to s. For any $m \in \mathbb{Z}_+$, Π_m denotes the space of all polynomials of degree $\le m$ in $d \in \mathbb{N}$ variables where the dimension of Π_m is denoted by

$$m_d := \binom{m+d}{d}. \tag{2.1}$$

We recall the Dirac delta function

$$\delta_{i,j} = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{if } i \neq j. \end{cases} \tag{2.2}$$

Finally, throughout this paper we use A to represent an arbitrary constant that may change value.

We introduce an edge detection method on the set of irregularly distributed points in a bounded domain Ω in $\mathbb{R}^d$. Let $\mathcal{S}$ be a set of discrete points in Ω and let f be a piecewise smooth function known only on $\mathcal{S}$. In order to identify the jump discontinuities of f, we construct a function $L_m f$, $m \in \mathbb{N}$, which can be characterized by the asymptotical convergence property,

$$L_m f(x) \longrightarrow 0,$$

for any x away from discontinuities, with the convergence rate depending in part on the given positive integer m. The choice of m is user dependent, but a higher number m provides a faster rate of convergence in smooth regions of f.

The edge detection method presented here is based on a local polynomial annihilation property. The general form of $L_m f$ is given by the following two step method. In the first step, for any $x \in \Omega$, we choose a set

$$\mathcal{S}_x := \mathcal{S}_{m_d,x} := \{x_1, \ldots, x_{m_d}\}, \tag{2.3}$$

which is a local set of m_d (2.1) points around x. In practice, though the dimension d can be arbitrary, we consider only the case $d \leq 2$ and note that for $d > 2$ the method is the same although the numerical algorithms are more complicated.

In order to annihilate polynomials up to degree $m-1$, we solve a linear system for the coefficients $c_j(x)$, $j = 1, \ldots, m_d$, given by

$$\sum_{x_j \in \mathcal{S}_x} c_j(x) p_i(x_j) = \sum_{|\alpha|_1 = m} p_i^{(\alpha)}(x), \quad \alpha \in \mathbb{Z}_+^d, \tag{2.4}$$

where p_i, $i = 1, \ldots, m_d$, is a basis of Π_m. Note that the solution (2.4) exists and is unique. Our edge detector $L_m f$ is defined, using the solution of (2.4), as

$$L_m f(x) = \frac{1}{q_{m,d}(x)} \sum_{x_j \in \mathcal{S}_x} c_j(x) f(x_j). \tag{2.5}$$

Here $q_{m,d}(x)$ is a suitable normalization factor depending on m, the dimension d, and the local set $\mathcal{S}_x$ (2.3). In the following sections, we will determine $q_{m,d}(x)$ specifically for $d = 1, 2$. Indeed, for the univariate case the normalization factor $q_{m,d}(x)$ is important in detecting the jump amount at a discontinuity. However, in the multivariate case, it is no longer meaningful since the jump amount varies depending on the directions at a discontinuity. In this case $q_{m,d}(x)$ can be used to estimate the magnitude of the jump in its normal direction, as will be explained later.

It is evident from (2.5) that $L_m f$ is *local* in the sense that it employs data only in a small neighborhood of x. It is also apparent that (2.5) detects edges regardless of the geometrical aspects of the discontinuities. Furthermore, we will show that $L_m f(x)$ converges to zero away from the discontinuities with a certain rate depending on m and the local smoothness of the function f.

3. Edge detection in one dimension.

3.1. Formulation.

3.1. Formulation. Throughout section 3, let f be a piecewise smooth function on an interval $[a, b]$, known only at the finite discrete points

$$\mathcal{S} \subset [a, b], \quad \#\mathcal{S} =: N < \infty,$$

which we will call "nodes." Suppose that f has jump discontinuities with well-defined one-sided limits, and let

$$J = \{\xi : a \le \xi \le b\}$$

denote the set of jump discontinuities of f in $[a, b]$. We define the local jump function corresponding to f as

$$[f](x) := f(x+) - f(x-),$$

where $f(x+)$ and $f(x-)$ are the right- and left-hand limits of the function f at x. Clearly, if f is continuous at x, then $[f](x) = 0$ and for any $\xi \in J$, $[f](\xi) = f(\xi+) - f(\xi-) \neq 0$.

The ability to find the locations and corresponding amplitudes of the jump discontinuities depends on the accuracy of the approximation to the jump function $[f](x)$. Hence we construct $L_m f(x)$ in (2.5) to be an approximation to $[f](x)$ such that

$$L_m f(x) \longrightarrow \begin{cases} [f](\xi) & \text{if } x_{j-1} \le \xi, x \le x_j \text{ for } \xi \in J, \\ 0 & \text{if } I_x \cap J = \emptyset, \end{cases} \tag{3.1}$$

where I_x is the smallest closed interval such that $\mathcal{S}_x \subset I_x$, with $\mathcal{S}_x$ defined in (2.3). In this way, a jump discontinuity $\xi \in J$ is identified by its enclosed cell, $x_{j-1} \le \xi \le x_j$, and the convergence rate of the approximation $L_m f(x)$ to the jump function $[f](x)$ is given in terms of

$$h(x) := \max\{|x_i - x_{i-1}| \ : \ x_{i-1}, x_i \in \mathcal{S}_x\}. \tag{3.2}$$

Clearly $h(x)$ is dependent upon the density of $\mathcal{S}_x$.

The function $L_m f$ for the univariate case is defined as follows: For the given positive integer m, we choose a local set $\mathcal{S}_x$ of m_1 points around x. Here m_1 is the dimension of Π_m in $\mathbb{R}$ as given by (2.1), i.e., $m_1 = m + 1$. The coefficients utilized in the edge detection method are determined by the solution of the linear system

$$\sum_{x_j \in \mathcal{S}_x} c_j(x) p_i(x_j) = p_i^{(m)}(x), \quad i = 1, \ldots, m_1, \tag{3.3}$$

where p_i, $i = 1, \ldots, m_1$, is a basis of Π_m. Clearly, the coefficients $c_j(x)$ are uniquely determined by the local set $\mathcal{S}_x$, and are of order $\mathcal{O}(h(x)^{-m})$ as $h(x) \to 0$. Fortunately, an explicit formula exists for $c_j(x)$ that will be described later in Theorem 3.2.

Next, by defining

$$\mathcal{S}_x^+ := \{x_j \in \mathcal{S}_x | x_j \ge x\} \quad \text{and} \quad \mathcal{S}_x^- := \mathcal{S}_x \setminus \mathcal{S}_x^+, \tag{3.4}$$

we set the normalization factor in (2.5) as

$$q_m(x) := q_{m,1}(x) := \sum_{x_j \in \mathcal{S}_x^+} c_j(x), \tag{3.5}$$

such that $q_m(x) \neq 0$. Note from (3.3) that it is clear that $q_m(x)$ is of order $\mathcal{O}(h(x)^{-m})$ as well.

Finally, the edge detection method (2.5) in the one-dimensional case is

$$L_m f(x) = \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x} c_j(x) f(x_j). \tag{3.6}$$

There is no restriction in choosing the sets $\mathcal{S}_x^+$ and $\mathcal{S}_x^-$ in (3.4), but from a practical point of view, a good choice is to put almost the same numbers of nodes on each side of x. For instance, if m is odd, one may choose $\mathcal{S}_x^+$ and $\mathcal{S}_x^-$ such that $\#\mathcal{S}_x^+ = \#\mathcal{S}_x^-$. These sets will have to be adjusted near the boundary of the domain, and naturally will become more one-sided.

In order for $L_m f$ in (3.6) to be successful, it should approximate the jump function $[f](x)$ with high accuracy. Theorem 3.1 shows that $L_m f(x)$ converges to zero away from the jump discontinuities of f with a certain rate depending on m and the local smoothness of f.

THEOREM 3.1. *Let $m \in \mathbb{N}$ and $L_m f(x)$ be defined as in* (3.6) *using a local set $\mathcal{S}_x$ with $\#\mathcal{S}_x = m_1 = m + 1$. Then we have*

$$L_m f(x) = \begin{cases} [f](\xi) + \mathcal{O}(h(x)) & \text{if } x_{j-1} \le \xi, x \le x_j, \\ \mathcal{O}(h^{\min(m,k)}(x)) & \text{if } f \in C^k(I_x) \text{ for } k > 0, \end{cases}$$

where $h(x)$ is given in (3.2) *and I_x is the smallest closed interval such that $\mathcal{S}_x \subset I_x$.*

Proof. Assume first that $f \in C^k(I_x)$ for some $k > 0$. Denote $k_m := \min(k, m) > 0$ and let $T_{k_m-1}f$ be the Taylor expansion of f of degree $k_m - 1$ around x, namely,

$$T_{k_m-1}f(\cdot) = \sum_{\alpha=0}^{k_m-1} (\cdot - x)^\alpha f^{(\alpha)}(x)/\alpha!.$$

Since $T_{k_m-1}f$ is a polynomial of degree less than m, the definition of $c_j(x)$ in (3.3) implies that

$$\sum_{x_j \in \mathcal{S}_x} c_j(x) T_{k_m-1} f(x_j) = 0. \tag{3.7}$$

By rewriting $f = T_{k_m-1}f + R_{k_m-1}f$, where $R_{k_m-1}f$ is the remainder of Taylor expansion, it follows from (3.7) that

$$\begin{aligned} |L_m f(x)| &= \left| \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x} c_j(x) R_{k_m-1} f(x_j) \right| \\ &= \left| \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x} c_j(x) (x_j - x)^{k_m} f^{(k_m)}(\zeta_j)/k_m! \right| \\ &\le A h^{k_m}(x) \frac{1}{|q_m(x)|} \sum_{x_j \in \mathcal{S}_x} |c_j(x)| \end{aligned}$$

for some ζ_j between x and x_j, where the last inequality is implied since $|x - x_j| \le mh(x)$ for any $x_j \in \mathcal{S}_x$ and $|f^{(k_m)}(x)/k_m!|$ is bounded for $x \in I_x$. Since both $c_j(x)$ and $q_m(x)$ are $\mathcal{O}(h^{-m}(x))$, it is clear that $|L_m f(x)| \le A h^{k_m}(x)$.

Next, consider the case that $x_{j-1} \le \xi, x \le x_j$ for $\xi \in J$ and $x_{j-1}, x_j \in \mathcal{S}_x$. Without loss of generality, assume that ξ is the only discontinuity of f in a neighborhood I_ξ and $\mathcal{S}_x \subset I_\xi$. Invoking the notation $\mathcal{S}_x^+$ and $\mathcal{S}_x^-$ in (3.4), we have

$$\begin{aligned} L_m f(x) &= \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x^+} c_j(x) f(x_j) + \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x^-} c_j(x) f(x_j) \\ &= \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x^+} c_j(x) \left[f(\xi^+) + (x_j - \xi) f'(\zeta_j^+) \right] \\ &\quad + \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x^-} c_j(x) \left[f(\xi^-) + (x_j - \xi) f'(\zeta_j^-) \right] \end{aligned}$$

for some ζ_j^+ and ζ_j^-. Since (2.4) implies that $\sum_{x_j \in \mathcal{S}_x} c_j(x) = 0$, it follows that

$$\sum_{x_j \in \mathcal{S}_x^+} c_j(x) = - \sum_{x_j \in \mathcal{S}_x^-} c_j(x).$$

Utilization of (3.5) yields

$$L_m f(x) = (f(\xi^+) - f(\xi^-)) + \mathcal{O}(h(x))$$

to complete the proof. □

Next, Theorem 3.2 establishes the relationship between the edge detection method (3.6) and Newton divide differences, which are frequently employed to determine smooth regions in finite difference schemes (see, for example, [6], [9], and [12]). This beneficial relationship provides an explicit formula for the coefficients $c_j(x)$ without solving the linear system (3.3). Denoting $\mathcal{S}_x =: \{x_1, \ldots, x_{m_1}\}$ with $m_1 = m+1$, recall the definition of the m_1th degree Newton divided difference for a smooth function $f(x)$ on $\mathcal{S}_x$:

$$\begin{aligned} f[\mathcal{S}_x] := f[x_1, x_2, \ldots, x_{m_1}] &= \frac{f[x_1, x_2, \ldots, x_{m_1 - 1}] - f[x_2, x_3, \ldots, x_{m_1}]}{x_1 - x_{m_1}} \\ &= \sum_{j=1}^{m_1} \frac{f(x_j)}{\omega_j(\mathcal{S}_x)} = \frac{f^{(m)}(\xi)}{m!}, \end{aligned} \tag{3.8}$$

where $\xi \in (x_1, x_{m_1})$ and

$$\omega_j(\mathcal{S}_x) := \prod_{\substack{i=1 \\ i \ne j}}^{m_1} (x_j - x_i). \tag{3.9}$$

THEOREM 3.2. *Under the same conditions and notation as Theorem* 3.1, *the coefficients $c_j(x)$ can be directly solved as*

$$c_j(x) = \frac{m!}{\omega_j(\mathcal{S}_x)}, \quad j = 1, \ldots, m_1, \tag{3.10}$$

with $\omega_j(\mathcal{S}_x)$ in (3.9). *Furthermore, the $L_m f(x)$ in* (3.6) *can be expressed as*

$$L_m f(x) = \frac{m!}{q_m(x)} f[\mathcal{S}_x].$$

Proof. Since the coefficients $c_j(x)$ that solve (3.3) are independent of the basis of Π_m, it is enough to consider the basis $p_i(x) = x^{i-1}$ for $i = 1, \dots, m_1$. The mth derivative of these basis functions satisfies

$$p_i^{(m)}(x) = m!\delta_{i,m_1} \quad \text{for all } x \in \mathbb{R}. \tag{3.11}$$

By (3.8), it is possible to conclude that $p_i[\mathcal{S}_x] = \delta_{i,m_1}$, yielding $m!p_i[\mathcal{S}_x] = p_i^{(m)}(x)$, $i = 1, \dots, m_1$. Hence by (3.8) we have

$$m! \sum_{j=1}^{m_1} \frac{p_i(x_j)}{\omega_j(\mathcal{S}_x)} = p_i^{(m)}(x), \quad i = 1, \dots, m_1,$$

indicating that the coefficients $c_j(x)$ can also be formulated by (3.10).

Given the direct representation (3.10) of the coefficients $c_j(x)$ as the solution of the linear system (3.3), the edge detection method (3.6) can be expressed as

$$\begin{aligned} L_m f(x) &= \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x} c_j(x) f(x_j), \\ &= \frac{m!}{q_m(x)} \sum_{x_j \in \mathcal{S}_x} \frac{f(x_j)}{\omega_j(\mathcal{S}_x)} = \frac{m!}{q_m(x)} f[\mathcal{S}_x], \end{aligned}$$

finishing the proof. □

Remark 3.1. Let $x \in (a, b)$ be fixed and let I_x^+ be the smallest closed interval such that $\mathcal{S}_x^+ \subset I_x^+$. Choosing $f = \chi_{I_x^+}$ with $\chi_{I_x^+}$ the characteristic function on I_x^+, Theorem 3.2 implies that the normalization factor $q_m(x)$ in (3.5) can be written as

$$\begin{aligned} q_m(x) &= \sum_{x_j \in \mathcal{S}_x^+} c_j(x) \\ &= \sum_{x_j \in \mathcal{S}_x} c_j(x) \chi_{I_x^+}(x_j) = m! \chi_{I_x^+}[\mathcal{S}_x]. \end{aligned}$$

Thus, the assumption $q_m(x) \neq 0$ is reasonable.

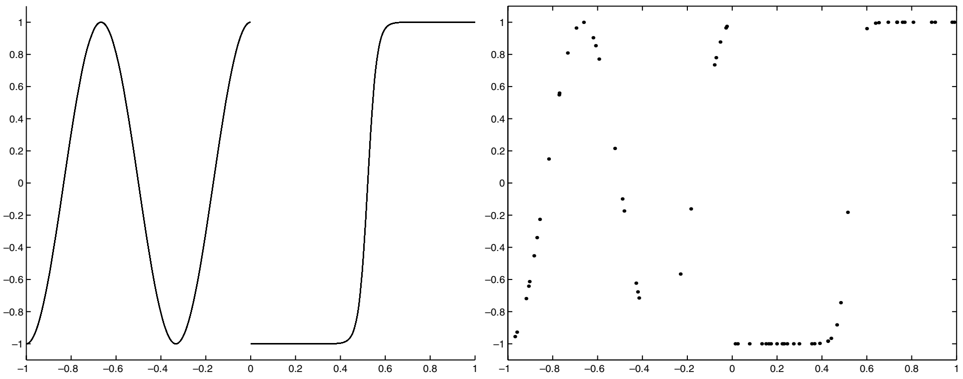
Remark 3.2. As discussed above, for any given data $(\mathcal{S}, f|_{\mathcal{S}})$, the evaluation of $L_m f(x)$ involves only finite local data $(\mathcal{S}_x, f|_{\mathcal{S}_x})$ around x. Accordingly, if $\mathcal{S}$ is a set of irregular points, the coefficients $c_j(x)$ may vary depending on the location x. However, if the given set $\mathcal{S}$ is uniform, say,

$$\mathcal{S} := \{a + nh \mid n = 0, \dots, N\}, \quad h = \frac{b-a}{N} > 0, \tag{3.12}$$

then there exists only one set of coefficients $c_j(x) = c_j$, $j = 1, \dots, m_1$, which are independent of the position x inside $[a, b]$ (but away from the boundary). Specifically, (3.10) can be directly applied to obtain the coefficients

$$c_j = \frac{m!}{\omega_j(\mathcal{S}_x)} = \frac{m!}{h \prod_{i=1, i \neq j}^{m_1} (j - i)}, \quad j = 1, \dots, m_1,$$

which in turn yields the normalization factor $q_m = q_m(x)$ in (3.5). Hence $\frac{c_j}{q_m}$ in (3.6) is bounded and independent of both h and x, and consequently the numerical computation of (3.6) is further simplified, while keeping the same convergence properties in Theorem 3.1.



(a) **(b)**

FIG. 3.1. (a) *Graph of* $f_1(x)$. (b) *Random sampling of* $f_1(x)$ *on* $N = 64$ *points.*

To demonstrate the efficacy of the edge detection method $L_m f(x)$, let us consider the following example.

Example 3.1.

$$f(x) := \begin{cases} \cos(3\pi x), & -1 \le x < 0, \\ \frac{2}{1+3e^{-50x+25}} - 1, & 0 < x \le 1. \end{cases} \tag{3.13}$$

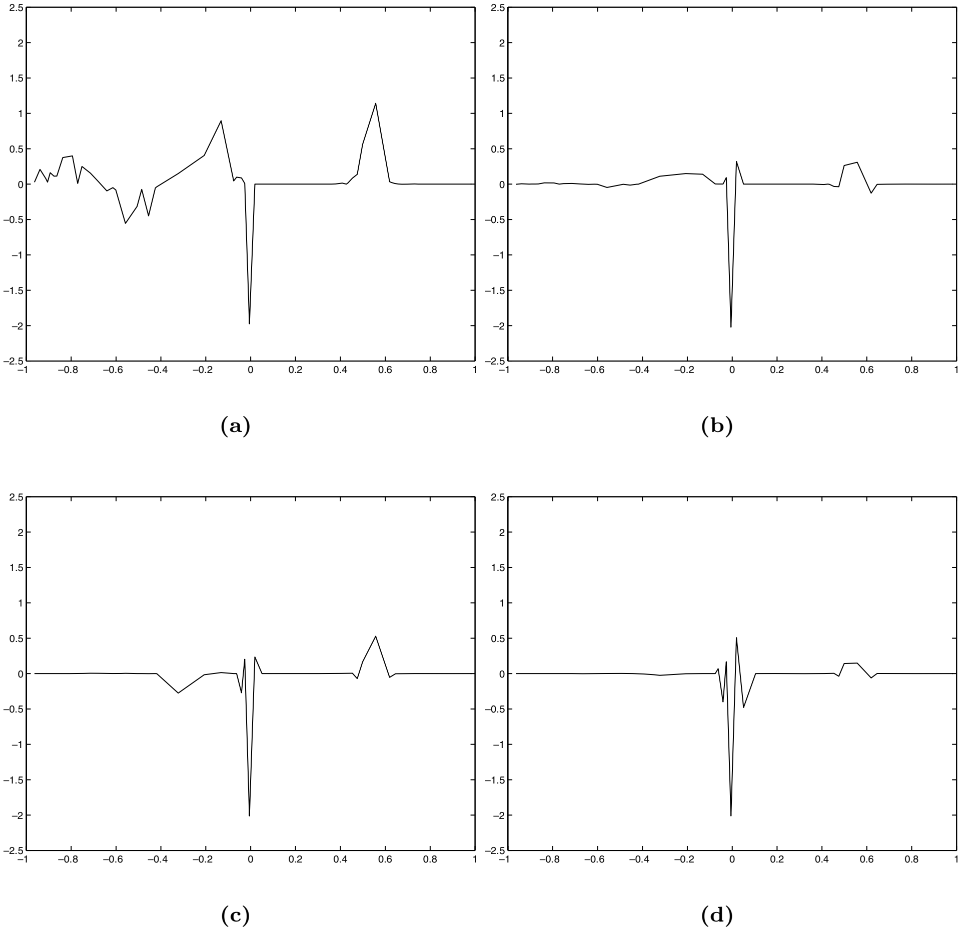
The function $f(x)$ has an edge at $x = 0$ and the corresponding jump function

$$[f](x) = \begin{cases} -2 & \text{if } x = 0, \\ 0 & \text{else.} \end{cases} \tag{3.14}$$

We wish to approximate $[f](x)$, based on the scattered grid point values generated randomly by MATLAB and depicted in Figure 3.1(b). Figure 3.2 demonstrates the application of $L_m f(x)$ for $m = 1, 3, 4$, and 6.

Observe in Figure 3.2 that the application of (3.6) encounters some problems in the approximation of jump functions. Specifically, as m increases, oscillations that occur in the neighborhood of a jump discontinuity can be misidentified as true edges. On the other hand, for smaller m, there is a risk of identifying a steep gradient as an edge, especially in regions where the scattered grid points are far apart. We wish to avoid the possibility of misidentification due either to the low resolution problems associated with the low order edge detection or to the oscillations inherent in the high order case. Presented in the following section is the *minmod* edge detection method that helps to prevent the edge detection method (3.6) from misidentifying edges.

3.2. ***Minmod*** **edge detection in one dimension.** It was observed in [13] that the *minmod* function, typically used in numerical conservation laws to reduce oscillations (see, e.g., [7]), could also be applied to distinguish true jump discontinuities from neighborhood oscillations. In what follows we describe the oscillating behavior near the jump discontinuities that results from using our local edge detector (3.6). Thus motivated, we extend the use of the *minmod* function and incorporate various orders of m for nonuniform grids. Moreover, we provide the proof of its convergence rate to zero away from the discontinuities. We will refer to this technique as the *minmod* edge detection method.



(a) **(b)**

(c) **(d)**

FIG. 3.2. *The edge detection method* $L_m f(x)$ *given by* (3.6) *for* (a) $m = 1$, (b) $m = 3$, (c) $m = 4$, *and* (d) $m = 6$.

The next theorem describes the behavior of the edge detection method (3.6) in the neighborhoods of discontinuities and motivates the need for further refinement by the *minmod* function.

THEOREM 3.3. *Let* $m \in \mathbb{N}$ *and* $L_m f(x)$ *be defined as in* (3.6) *using* $\mathcal{S}_x$ *with* $\#\mathcal{S}_x = m_1$, *and let*

$$Q_m(\xi, x) := \sum_{x_j \in \mathcal{S}_\xi^+} c_j(x) \tag{3.15}$$

with $\mathcal{S}_\xi^+ := \{x_j \in \mathcal{S}_x | x_j \geq \xi\}$ *as given in* (3.4). *Then*

$$L_m f(x) = \begin{cases} \frac{Q_m(\xi,x)}{q_m(x)}[f](\xi) + \mathcal{O}(h(x)) & \text{if } I_x \cap \xi \neq \emptyset \text{ for } \xi \in J, \\ \mathcal{O}(h^{\min(m,k)}(x)) & \text{if } f \in C^k(I_x) \text{ for } k > 0. \end{cases}$$

Here, I_x *is the smallest closed interval such that the local set* $\mathcal{S}_x \subset I_x$.

Proof. Assume first that $I_x \cap J = \emptyset$ and therefore $f \in C^k(I_x)$ for some $k > 0$. It is therefore possible to conclude by Theorem 3.1 that $L_m f(x) = \mathcal{O}(h^{\min(m,k)}(x))$.

Next, let us consider the case that $I_x \cap J \neq \emptyset$. Without loss of generality, assume that ξ is the only discontinuity of f in a neighborhood I_x. Invoking the notation $\mathcal{S}_\xi^+$ and $\mathcal{S}_\xi^-$ in (3.4), we see that

$$\begin{aligned} L_m f(x) &= \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_\xi^+} c_j(x) f(x_j) + \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_\xi^-} c_j(x) f(x_j) \\ &= \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_\xi^+} c_j(x) \left[f(\xi^+) + (x_j - \xi) f'(\zeta_j) \right] \\ &\quad + \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_\xi^-} c_j(x) \left[f(\xi^-) + (x_j - \xi) f'(\zeta_j) \right] \end{aligned}$$

with ζ_j between x_j and ξ. Here, from the condition $\sum_{x_j \in \mathcal{S}_x} c_j(x) = 0$ in (3.3), it is clear that

$$Q_m(\xi, x) := \sum_{j \in \mathcal{S}_\xi^+} c_j(x) = - \sum_{j \in \mathcal{S}_\xi^-} c_j(x).$$

Hence

$$L_m f(x) = \frac{Q_m(\xi, x)}{q_m(x)} (f(\xi^+) - f(\xi^-)) + \mathcal{O}(h(x)),$$

which completes the proof. □

The behavior characterized in Theorem 3.3 is visible in Figure 3.2 as m increases in (3.6). Specifically, the edge detection method approximates the jump function with high order outside the neighborhoods of the discontinuities. Unfortunately, inside the neighborhoods of the discontinuities the edge detection method oscillates according to the fraction $\frac{Q_m(\xi,x)}{q_m(x)}[f](\xi)$.

The *minmod* edge detection method, as defined below, uses the *minmod* function to exploit the characteristics of the edge detection method of various orders both inside and outside the neighborhoods of the discontinuities to ensure the highest order of convergence possible away from the discontinuity, as well as to reduce the oscillations inside the neighborhoods of discontinuities.

DEFINITION 3.1. *For a given finite set $\mathcal{M} \subset \mathbb{N}$ of positive integers, consider the set $L_\mathcal{M} f = \{L_m f : \mathbb{R} \to \mathbb{R} \,|\, m \in \mathcal{M}\}$. The minmod function is defined by*

$$(3.16)\quad MM\Big(L_\mathcal{M} f(x)\Big) = \begin{cases} \min\limits_{m \in \mathcal{M}} L_m f(x) & \text{if } L_m f(x) > 0 \text{ for all } m \in \mathcal{M}, \\ \max\limits_{m \in \mathcal{M}} L_m f(x) & \text{if } L_m f(x) < 0 \text{ for all } m \in \mathcal{M}, \\ 0 & \text{otherwise}. \end{cases}$$

Theorem 3.4 characterizes the convergence of the *minmod* function applied to the set of edge detectors $L_m f$ of various order m and demonstrates its ability to distinguish jump discontinuities from neighborhood oscillations.

THEOREM 3.4. *If $\mathcal{M} = \{1, 2, \ldots, \mu\}$, we have*

$$MM\Big(L_\mathcal{M} f(x)\Big) = \begin{cases} [f](\xi) + \mathcal{O}(h(x)) & \text{if } x_{j-1} \leq \xi, x \leq x_j, \\ \mathcal{O}(h^{\min(\mathcal{M}_x, k)}(x)) & \text{if } f \in C^k(I_x), \end{cases}$$

where I_x is the smallest closed interval such that $\mathcal{S}_x \subset I_x$ with $\#\mathcal{S}_x \leq \binom{\mathcal{M}_x+1}{1}$, and $\mathcal{M}_x$ is defined by

$$\mathcal{M}_x := \max\big\{m \in \mathcal{M} \,|\, \#\mathcal{S}_x = m_1,\ I_x \cap J = \emptyset\big\}. \tag{3.17}$$

Proof. For $x \in [a,b]$, assume without loss of generality that $x_{j-1} \leq x \leq x_j$ for some $x_{j-1}, x_j \in \mathcal{S}$. If there exists $\xi \in J$ such that $x_{j-1} \leq \xi \leq x_j$, then by Theorem 3.1 we have

$$L_m f(x) = [f](\xi) + \mathcal{O}(h(x))$$

for any $m \in \mathcal{M}$. Therefore, it is possible to conclude that

$$MM\big(L_{\mathcal{M}} f(x)\big) = [f](\xi) + \mathcal{O}(h(x)).$$

If $J \cap [x_{j-1}, x_j] = \emptyset$, then by definition we have $\mathcal{M}_x \geq 1$. Also from the definition of $\mathcal{M}_x$, for any $m \in \mathcal{M}$ such that $m \leq \mathcal{M}_x$ and $\#\mathcal{S}_x = m_1$ we have $I_x \cap J = \emptyset$. Therefore, Theorem 3.1 implies that $L_m f(x) = \mathcal{O}(h^{\min(m,k)}(x))$, yielding

$$MM\big(L_{\mathcal{M}} f(x)\big) = \mathcal{O}(h^{\min(\mathcal{M}_x,k)}(x))$$

to complete the proof. ∎

By including $1 \in \mathcal{M}$ in Theorem 3.4, first order convergence is ensured at edges, even in the case where edges are in neighboring centers. Large values are also included in the set $\mathcal{M}$ so that there will be a high order of convergence away from the discontinuity.

The *minmod* edge detection method relaxes the assumption for edge resolution in Theorem 3.1, specifically that edge detection is possible only if a maximum of one edge is contained in each local set, or equivalently

$$\#\big([x_j, x_{j+m_1}] \cap J\big) \leq 1 \quad \text{for } j = 1, \ldots, N - m_1, \tag{3.18}$$

where J is the set of discontinuities of f on $[a,b]$. In this case, only a certain density of edges can be resolved, i.e., only one discontinuity can be resolved for each m_1 points. Furthermore, the order of the method is restricted to the "closeness" of the edges in terms of their grid point location. Theorem 3.4 relaxes this assumption so that edge resolution is possible if J, the set of discontinuities of f on $[a,b]$, satisfies

$$\#\big([x_j, x_{j+1}] \cap J\big) \leq 1 \quad \text{for } j = 1, \ldots, N - 1, \tag{3.19}$$

i.e., the edges can occur at neighboring grid point values. If this requirement is not satisfied, the problem is clearly underresolved.

The superior convergence properties of the *minmod* edge detection method for Example 3.1 with $\mathcal{M} = \{1, 2, \ldots, 6\}$ are evident in Figure 3.3. Of particular interest is the ability of the *minmod* edge detection method to resolve the local jump function even when the first order approximation, as displayed in Figure 3.2(a), detects edges in smooth regions that are artifacts of the variability of the function and sparse sampling. Residual small oscillations that are still evident can be removed by a thresholding process.

The algorithm in Appendix A details the one-dimensional edge detection computation of Examples 3.1, where the particular choice of local sets, reconstruction grid points, and basis functions are specified.

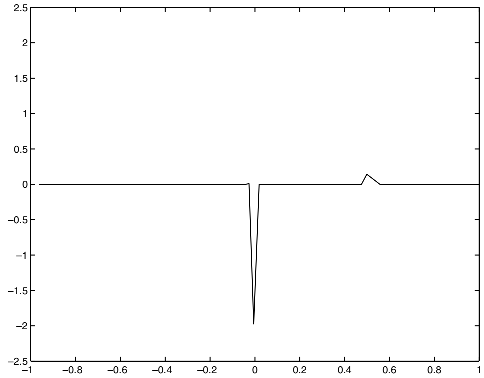


FIG. 3.3. *The minmod edge detection method, $MM(L_{\mathcal{M}}f(x))$, for Example* 3.1. *Here* $\mathcal{M} = \{1, 2, \ldots, 6\}$.

4. Edge detection in two dimensions.

4.1. Formulation. Throughout section 4, let f be a piecewise smooth function on a domain $\Omega \subset \mathbb{R}^2$ known only on the set of discrete nodes

$$\mathcal{S} \subset \Omega, \quad \#\mathcal{S} =: N < \infty.$$

Though d indicates an arbitrary dimension, here we consider only the bivariate case. The higher-dimensional case can be similarly constructed with more complicated numerical algorithms.

In two dimensions a jump discontinuity at $x = \xi$ is identified by its enclosed points (i.e., triangular points) and is characterized by the convergence property away from the discontinuities. Specifically, the enclosed points can be defined by the Delaunay triangulation for $\mathcal{S}$ that consists of the set of lines connecting each point to its natural neighbors [10]. These sets of lines form elementary triangles whose vertices consist of points in $\mathcal{S}$. A triangle is considered elementary if every combination of vertex pairs are natural neighbors. Let the number of elementary triangles of the set $\mathcal{S}$ be defined as N_T. We denote the set of vertices of all elementary triangles in the Delaunay triangulation of $\mathcal{S}$ as

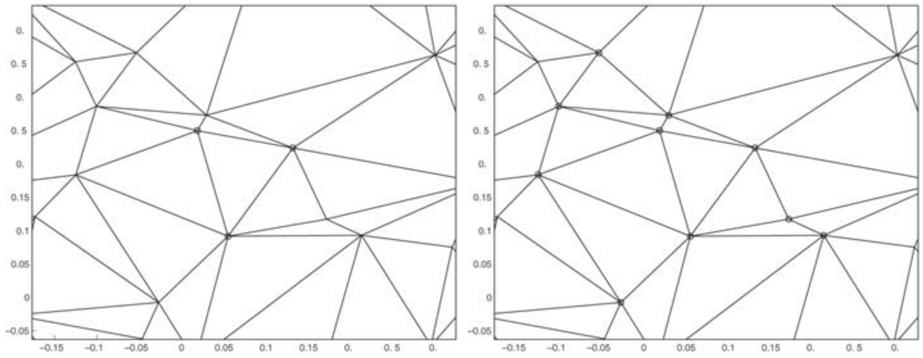
$$\mathcal{T}_{\mathcal{S}} = \left\{ T_j \middle| T_j := \{x_1^j, x_2^j, x_3^j\} \subset \mathcal{S} \text{ for } j = 1, \ldots, N_T \right\}, \tag{4.1}$$

where T_j is the set of vertices for an elementary triangle.

Since discontinuities are identified at specific points by their enclosed cells, the local sets $\mathcal{S}_x$ are chosen to include points that characterize these cells. For arbitrary $x \in \Omega$, we can assume without loss of generality that $x \in K_{T_j} \subset \Omega$. Recall that K_{T_j} is the convex hull of the set of vertices $T_j \in \mathcal{T}_{\mathcal{S}}$. Therefore the local set $\mathcal{S}_x$ for arbitrary $x \in \Omega$ can now be defined specifically to include the set that characterizes its enclosed points as

$$\mathcal{S}_x := T_j \cup \mathcal{S}_{T_j}, \tag{4.2}$$

where $T_j \in \mathcal{T}_{\mathcal{S}}$, $x \in K_{T_j}$, and $\mathcal{S}_{T_j}$ is the set of the $m_2 - 3$ closest points to x in the set $\mathcal{S} \setminus T_j$. To illustrate how $\mathcal{S}_x$ is chosen, Figure 4.1 depicts a region of the Delaunay



(a) **(b)**

FIG. 4.1. *A region of the Delaunay triangulation of* 256 *randomly sampled points on* $[-1,1]\times[-1,1]$. *(The region is enlarged for visibility purposes.)* (a) *The elementary triangle* T_j *that satisfies* $x \in K_{T_j}$*, represented by circles.* (b) *Pictorial representation of the local set* $\mathcal{S}_x := T_j \cup \mathcal{S}_{T_j}$*, where* $\#\mathcal{S}_x = 10$*.*

triangulation of 256 randomly sampled points on $[-1,1]\times[-1,1]$. Figure 4.1(a) displays a point x and the elementary triangle T_j that satisfies $x \in K_{T_j}$. Figure 4.1(b) exhibits a local set $\mathcal{S}_x$ as defined in (4.2), where $\#\mathcal{S}_x = 10$.

In order to quantify the convergence rate of the edge detection method, we define

$$h(x) := \max_{x \in K_{\mathcal{S}_x}} \min_{x_j \in \mathcal{S}_x} |x - x_j|, \tag{4.3}$$

which is dependent upon the density of the local set $\mathcal{S}_x$.

Recall that for a given positive integer m, the dimension of Π_m in $\mathbb{R}^2$ is denoted by m_2 (2.1). If $\mathcal{S}_x$ is a local set of m_2 points around x, the function $L_m f$ is given by

$$L_m f(x) = \frac{1}{q_{m,2}(x)} \sum_{x_j \in \mathcal{S}_x} c_j(x) f(x_j), \tag{4.4}$$

where the coefficients $c_j(x)$, $j = 1, \ldots, m_2$, are dependent upon the local set $\mathcal{S}_x$ and satisfy the linear system

$$\sum_{x_j \in S_x} c_j(x) p_i(x_j) = \sum_{|\alpha|_1 = m} p_i^{(\alpha)}(x), \quad i = 1, \ldots, m_2, \quad \alpha \in \mathbb{Z}_+^2. \tag{4.5}$$

Here p_i, $i = 1, \ldots, m_2$, form a basis of Π_m. Further illustration of the application of (4.5) for a particular basis of Π_m is detailed in Appendix B. It is easy to check that $c_j(x) = \mathcal{O}(h(x)^{-m})$, implying that $q_{m,2}(x) = \mathcal{O}(h(x)^{-m})$ as well. Recall that in the one-dimensional case, the constant $q_{m,1}$ is used to determine the jump amplitude at a discontinuity. In the bivariate case, the jump amplitude may vary depending on the paths through a given discontinuity, so quantifying the jump amount at such discontinuity points is not meaningful. However, in the case where jump discontinuities arise locally along a simple curve, we can estimate the jump magnitude in the normal direction with a suitable $q_{m,2}(x)$ and then apply the *minmod* edge detection method from (3.16) to pinpoint the edges. This will be discussed further in section 4.2. For now we limit our discussion to detecting edges without consideration of their jump amounts.

Since $c_j(x) = \mathcal{O}(h(x)^{-m})$, it is possible to bound $L_m f$ uniformly by defining

$$q_m(x) = q_{m,2}(x) := \sum_{x_j \in \mathcal{P}_x} c_j(x), \tag{4.6}$$

where $\mathcal{P}_x$ can be a suitable subset of $\mathcal{S}_x$ such that $q_m(x) \neq 0$. This will be discussed later following Definition 4.1, where we will see that the versatility of $\mathcal{P}_x$ can be utilized to provide a good approximation to the jump magnitudes in the normal directions of the edges in the multivariate case.

Theorem 4.1 establishes the convergence rate of $L_m f(x)$, defined in (4.4), away from the discontinuities of f.

THEOREM 4.1. *Suppose f is a piecewise smooth function on a domain Ω in $\mathbb{R}^2$ known only on discrete nodes $\mathcal{S}$. Let J denote the set of jump discontinuities of f in Ω, and let $L_m f$ be defined as in* (4.4) *with $m \in \mathbb{N}$. Then if $f \in C^k(K_{\mathcal{S}_x})$ for some $k > 0$, we have*

$$L_m f(x) = \mathcal{O}(h^{\min(k,m)}(x)).$$

Proof. The technique of proving Theorem 3.1 is adapted in a straightforward fashion to prove this theorem. Assuming that $f \in C^k(K_{\mathcal{S}_x})$ for some $k > 0$, we define $k_m := \min(k, m)$ and then separate f into two parts:

$$f = T_{k_m-1} f + R_{k_m-1} f,$$

where $T_{k_m-1} f$ is the Taylor polynomial of f of degree $(k_m - 1)$ around x, namely,

$$T_{k_m-1} f(y) = \sum_{|\alpha|_1 \leq k_m - 1} (y - x)^\alpha D^{(\alpha)} f(x)/\alpha!, \tag{4.7}$$

and $R_{k_m-1} f$ is its remainder. Then from the definition of $c_j(x)$ in (4.5) we see that

$$\sum_{x_j \in \mathcal{S}_x} c_j(x) T_{k_m-1}(x_j) = 0,$$

leading to the relation

$$\begin{aligned} L_m f(x) &= \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x} c_j(x) R_{k_m-1} f(x_j) \\ &= \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{S}_x} c_j(x) \sum_{|\alpha|_1 = k_m} (x_j - x)^\alpha D^{(\alpha)} f(\zeta_j)/\alpha! \end{aligned}$$

for some ζ_j between x_j and x. Since $c_j(x)$ and $q_m(x)$ are both $\mathcal{O}(h(x)^{-m})$, we obtain the relation $L_m f(x) = \mathcal{O}(h^{k_m}(x))$, which completes the proof. □

Remark 4.1. As in the univariate case, if the data are given on a uniform grid $\mathcal{S}$, we can find a unique set of coefficients $c_j(x) = c_j$, $j = 1, \ldots, m_2$, with m_2 given in (2.1), and apply it to construct $L_m f(x)$, regardless of the position x (away from the boundary of Ω) and the density $h(x)$ of points. Let $\mathbf{U}$ be a set of integers around the origin with $\#\mathbf{U} = m_2$, and assume that for any x, the shape of the stencil of S_x is the same as $\mathbf{U}$; i.e., there exists $\nu(x) \in h\mathbb{Z}^2 \cap \Omega$ such that

$$S_x = \nu(x) + h\mathbf{U}, \quad h > 0. \tag{4.8}$$

Solving the linear system

$$\sum_{j\in\mathbf{U}} c_j \frac{j^\alpha}{\alpha!} = \delta_{m_2,|\alpha|_1}, \quad \alpha \in \mathbb{Z}_+^2, \quad |\alpha|_1 \le m_2, \tag{4.9}$$

we define $L_m f$ as follows:

$$L_m f(x) = \frac{1}{q_m} \sum_{j\in\mathbf{U}} c_j f(\nu(x) + jh), \tag{4.10}$$

where q_m is also independent of x. Note that c_j and q_m are bounded by a constant, while if $\mathcal{S}_x$ is a scattered data set, they are $\mathcal{O}(h^{-m}(x))$. A straightforward application of the proof in Theorem 4.1 shows that for the uniform case with $h = h(x)$, we have

$$L_m f(x) = \mathcal{O}(h^{\min(k,m)}).$$

4.2. *Minmod* edge detection in two dimensions. As in the one-dimensional case, the utilization of the *minmod* edge detection method increases the area of convergence away from the discontinuities of f. Theorem 4.1 establishes that for a certain order m, the edge detection method $L_m f(x)$ defined in (4.4) converges to zero away from the discontinuities if $K_{\mathcal{S}_x} \cap J = \emptyset$. Here J denotes the set of jump discontinuities of f in Ω. Theorem 4.2 demonstrates that the *minmod* edge detection method converges to zero away from the discontinuities if $K_{T_j} \cap J = \emptyset$, where $T_j \in \mathcal{T}_{\mathcal{S}}$ is defined in (4.1). Clearly this is an improvement since $K_{T_j} \subset K_{\mathcal{S}_x}$.

THEOREM 4.2. *If $x \in K_{T_j}$ and $K_{T_j} \cap J = \emptyset$ for some $T_j \in \mathcal{T}_{\mathcal{S}}$* (4.1), *then the minmod edge detection method* (3.16) *for the set $\mathcal{M} = \{1, 2, \dots, \mu\}$ has the property*

$$MM\big(L_{\mathcal{M}} f(x)\big) = \mathcal{O}(h^{\min(\mathcal{M}_x,k)}(x)),$$

where $\mathcal{M}_x$ is defined as

$$\mathcal{M}_x := \max\big\{m \in \mathcal{M} \,:\, K_{\mathcal{S}_x} \cap J = \emptyset,\ \#\mathcal{S}_x = m_2\big\}, \tag{4.11}$$

and $f \in C^k(K_{\mathcal{S}_x})$ for some $k > 0$ with $\#\mathcal{S}_x \le \binom{\mathcal{M}_x+2}{2}$.

Proof. Assume that $x \in K_{T_j}$ and $K_{T_j} \cap J = \emptyset$ for some $T_j \in \mathcal{T}_{\mathcal{S}}$. Since $K_{T_j} \cap J = \emptyset$ we have $\mathcal{M}_x \ge 1$. Then for any $m \in \mathcal{M}$ such that $m \le \mathcal{M}_x$, the corresponding local set $\mathcal{S}_x$ such that $\#\mathcal{S}_x = m_2$ will satisfy $\mathcal{S}_x \cap J = \emptyset$. Theorem 4.1 then gives $L_m f(x) = \mathcal{O}(h^{\min(m,k)}(x))$. Therefore

$$MM\big(L_{\mathcal{M}} f(x)\big) = \mathcal{O}(h^{\min(\mathcal{M}_x,k)}(x)),$$

which finishes the proof. □

As in the case of one dimension, the choice of $\mathcal{M}$ in Theorem 4.2, an arbitrary set of positive integers, is purposeful. By including $1 \in \mathcal{M}$, first order convergence is ensured at the neighboring cells of discontinuities. Large values are also included in the set $\mathcal{M}$ so that there will be a high order of convergence away from the discontinuities.

Recall that for any particular point $x \in \Omega$, the normalization factor $q_m(x)$ in (4.6) is defined for a subset $\mathcal{P}_x \subset \mathcal{S}_x$ such that $q_m(x) \ne 0$. Theorem 4.3 demonstrates that for a particular $\mathcal{P}_x$ the *minmod* edge detection method will provide a good approximation to the jump magnitudes in the normal directions of the edges. To accomplish this approximation, we provide the following definition.

Definition 4.1. *For an arbitrary point $x \in \Omega$ of a piecewise smooth function f, define the subset $\mathcal{P}_x$ of the local set $\mathcal{S}_x \subset \mathcal{S}$ as*

$$\mathcal{P}_x = \arg\max_{\mathcal{P}}\{\#\mathcal{P}|\mathcal{P} \subset \mathcal{S}_x, \textit{ and } f \in C^k(K_{\mathcal{P}}) \textit{ for some } k > 0\}. \tag{4.12}$$

Therefore $\mathcal{P}_x$ is the largest subset of the local set $\mathcal{S}_x$ such that $f \in C^k(K_{\mathcal{P}_x})$ for some $k > 0$. (A technique for approximating this particular $\mathcal{P}_x$ is provided in Appendix B.*)*

As in the one-dimensional case, $q_m(x)$ can be considered as a generalized version of divided difference for the characteristic function $\chi_{\mathcal{P}_x}$ on $\mathcal{S}_x$ (see the "Remark" following Theorem 3.2). Hence, the condition $q_m(x) \neq 0$ is reasonable. Further, it is assumed without loss of generality in the following analysis that for a small enough local set, if $\mathcal{P}_x \neq \mathcal{S}_x$, then $f \in C^k(K_{\mathcal{P}_x^c \cap \mathcal{S}_x})$ for some $k > 0$. Here $\mathcal{P}_x^c$ indicates the complement of the set $\mathcal{P}_x$. This assumption is similar to the one-dimensional case, where it is assumed that each local set contains at most one discontinuity. If this assumption is not true, the problem is clearly underresolved.

Theorem 4.3 characterizes the *minmod* edge detection method for the two-dimensional edge detection function $|L_m f|$ in (4.4). In this case, we use the absolute value of (4.4) since the jump amplitude may vary depending on paths through a given discontinuity.

Theorem 4.3. *For each $m \in \mathbb{N}$, define $L_m f$ as in* (4.4) *with $q_m(x)$ given in* (4.6)*. If $x \in K_{T_j}$ for some $T_j \in \mathcal{T}_{\mathcal{S}}$, then the minmod edge detection method* (3.16) *for the set $\mathcal{M} = \{1, 2, \ldots, \mu\}$ has the property*

$$MM\big(|L_{\mathcal{M}} f(x)|\big) = \begin{cases} [F](x) + \mathcal{O}(h(x)) & \textit{if } K_{T_j} \cap J \neq \emptyset, \\ \mathcal{O}(h^{\min(\mathcal{M}_x, k)}(x)) & \textit{if } K_{T_j} \cap J = \emptyset, \end{cases}$$

where $\mathcal{M}_x$ is defined in (4.11)*, $f \in C^k(K_{\mathcal{S}_x})$ for some $k > 0$ with $\#\mathcal{S}_x \leq \binom{\mathcal{M}_x+2}{2}$, and*

$$[F](x) := \max\big\{|f(u) - f(v)| \,:\, u \in K_{\mathcal{P}_x} \cap K_{T_j},\ v \in K_{\mathcal{P}_x^c \cap \mathcal{S}_x} \cap K_{T_j}\big\}. \tag{4.13}$$

Proof. For any given integer $m \in \mathcal{M}$, choose the local set $\mathcal{S}_x$ such that $\#\mathcal{S}_x = m_2$. Assume first $K_{T_j} \cap J \neq \emptyset$. Then clearly $\mathcal{P}_x, \mathcal{P}_x^c \cap \mathcal{S}_x \neq \emptyset$. Now, for some $\beta_j, \gamma_j \in (0, 1)$, we have

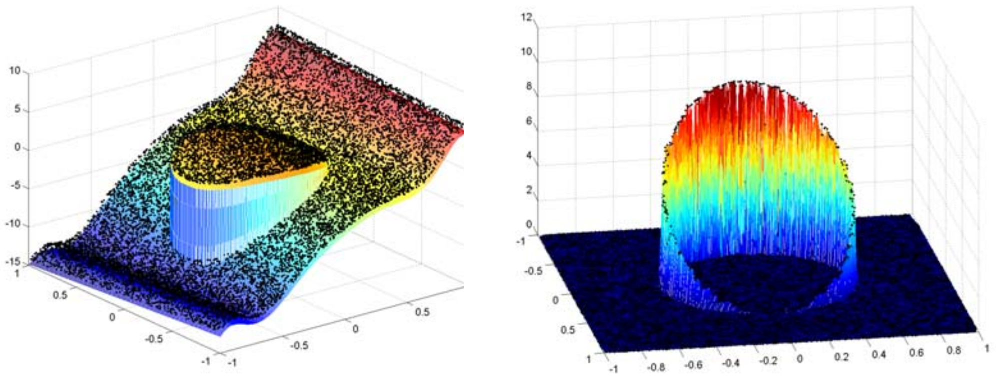
$$\begin{aligned} |L_m f(x)| &= \left| \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{P}_x} c_j(x) f(x_j) + \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{P}_x^c \cap \mathcal{S}_x} c_j(x) f(x_j) \right| \\ &= \Bigg| \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{P}_x} c_j(x) \Bigg[f(u) + \sum_{|\alpha|_1 = 1} (x_j - u)^\alpha D^\alpha f(u + \beta_j(x_j - u)) \Bigg] \\ &\quad + \frac{1}{q_m(x)} \sum_{x_j \in \mathcal{P}_x^c \cap \mathcal{S}_x} c_j(x) \Bigg[f(v) + \sum_{|\alpha|_1 = 1} (x_j - v)^\alpha D^\alpha f(v + \beta_j(x_j - u)) \Bigg] \Bigg| \end{aligned}$$

for any $u \in K_{\mathcal{P}_x} \cap K_{T_j}$ and $v \in K_{\mathcal{P}_x^c \cap \mathcal{S}_x} \cap K_{T_j}$. From the condition $\sum_{j \in \mathcal{S}_x} c_j(x) = 0$, we see from (4.6) that

$$q_m(x) = \sum_{x_j \in \mathcal{P}_x} c_j(x) = - \sum_{x_j \in \mathcal{P}_x^c \cap \mathcal{S}_x} c_j(x),$$

and therefore

$$|L_m f(x)| = |f(u) - f(v)| + \mathcal{O}(h(x)).$$



(a) **(b)**

FIG. 4.2. (a) $f_1(x)$ *from Example* 4.1 *sampled on random points with* $\#\mathcal{S} = 128^2$. (b) *The minmod edge detection method of* $MM(L_{\mathcal{M}} f_1(x))$ *for* $\mathcal{M} = \{1, 2, 3, 4\}$.

Since u and v are arbitrary points in the sets $K_{\mathcal{P}_x} \cap K_{T_j}$ and $K_{\mathcal{P}_x^c \cap \mathcal{S}_x} \cap K_{T_j}$, respectively, we obtain that $|L_m f(x)| = [F](x) + \mathcal{O}(h(x))$, where $[F](x)$ is defined in (4.13), yielding

$$MM\big(|L_{\mathcal{M}} f(x)|\big) = [F](x) + \mathcal{O}(h(x)).$$

Next, assume that $K_{T_j} \cap J = \emptyset$. By definition, $\mathcal{M}_x \geq 1$. Then for any $m \in \mathcal{M}$ such that $m \leq \mathcal{M}_x$, the corresponding local set $\mathcal{S}_x$ such that $\#\mathcal{S}_x = m_2$ will satisfy $\mathcal{S}_x \cap J = \emptyset$. Theorem 4.1 then gives $L_m f(x) = \mathcal{O}(h^{\min(m,k)}(x))$. Clearly it can be concluded that

$$MM\big(|L_{\mathcal{M}} f(x)|\big) = \mathcal{O}(h^{\min(\mathcal{M}_x,k)}(x)),$$

which finishes the proof. □

To demonstrate the efficacy of the *minmod* edge detection method in two dimensions we consider the following example.

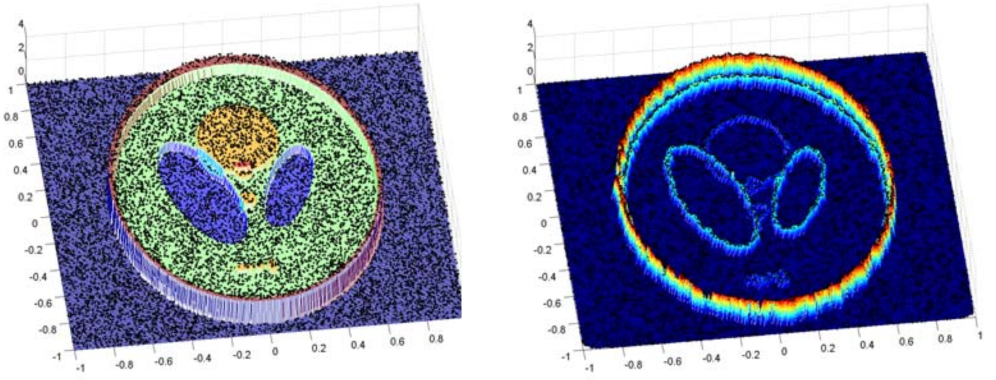
Example 4.1.

$$f_1(x) := f_1(u,v) := \begin{cases} uv + \cos(2\pi u^2) - \sin(2\pi u^2) & \text{if } u^2 + v^2 \leq \frac{1}{4}, \\ 10u - 5 + uv + \cos(2\pi u^2) - \sin(2\pi u^2) & \text{if } u^2 + v^2 > \frac{1}{4} \end{cases}$$

for $-1 \leq u, v \leq 1$.

Note that the edges comprise the circle $u^2 + v^2 = \frac{1}{4}$ with the exception of $u = \frac{1}{2}$, where the function is smooth. Figure 4.2(a) shows $f_1(x)$ sampled on a MATLAB randomly generated data set $\mathcal{S}$ with $\#\mathcal{S} = 128^2$. Figure 4.2(b) displays the results of applying the *minmod* edge detection method to $L_m f_1$ with $m \in \mathcal{M} = \{1, 2, 3, 4\}$. Of particular interest is the ability of the *minmod* edge detection method to resolve the positions and magnitudes in the normal direction of the edges even in areas of sparse sampling and steep gradients.

Let us now turn our attention to a practical example often used as a benchmark test for edge detection in magnetic resonance imaging (MRI).



(a) **(b)**

FIG. 4.3. (a) $f_2(x)$ *from Example* 4.2 *sampled on random points with* $\#\mathcal{S} = 128^2$. (b) *The minmod edge detection method of* $MM(L_{\mathcal{M}} f_2(x))$ *for* $\mathcal{M} = \{1, 2, 3, 4\}$.

Example 4.2. The so-called Shepp–Logan phantom, $f_2(x)$, defined in Appendix C.

Note that the edges of the Shepp–Logan phantom comprise various ellipses of different sizes and orientations, some of which overlap. Figure 4.3(a) shows the Shepp–Logan phantom (denoted as $f_2(x)$), sampled on a MATLAB randomly generated data set $\mathcal{S}$ with $\#\mathcal{S} = 128^2$. Figure 4.3(b) displays the results of applying the *minmod* edge detection method on $L_m f_2(x)$ with $m \in \mathcal{M} = \{1, 2, 3, 4\}$. Of particular interest is the ability of the *minmod* edge detection method to resolve edges that reside in neighboring centers.

The algorithm in Appendix B details the two-dimensional edge detection computation for Examples 4.1 and 4.2, where the particular choice of local sets, reconstruction points, and basis functions are specified. Although no formal computational cost studies were conducted, our experiments indicate that the two-dimensional algorithm experiences minimal increase in computational effort.

5. Concluding remarks. In this paper we have introduced an edge detection method (2.5) based on a local polynomial annihilation property on a set of irregularly distributed points in a bounded domain $\Omega \subset \mathbb{R}^d$. The method successfully captures discontinuities that are identified by their enclosed cells by characterizing the convergence away from the discontinuities. Although the convergence of the edge detection method can be of high order away from discontinuities, there are problematic oscillations in the neighborhoods of discontinuities. The *minmod* function (3.6) for one-dimensional global edge detection methods enables the distinction of jump discontinuities from neighborhood oscillations by the effective use of the information intrinsic to the edge detection approximation. The resulting *minmod* edge detection method ensures the highest rate of convergence *up to* the enclosed points of discontinuities.

The edge detection method described in our study is local, numerically cost efficient, and entirely independent of any specific shape or complexity of boundaries. Furthermore, it demonstrates the ability to detect edges of piecewise smooth functions with steep gradients as well as in low resolution environments with sparse, nonuniform sampling. For uniformly distributed points, the cost of computation is significantly reduced since the coefficients in the edge detection method are constant for every type of local stencil.

This study is concerned with the detection of jump discontinuities. Our future work will focus on integrating this method to real signals and images in various scientific disciplines, where noise, poor resolution, and numerical efficiency all become critical issues. We also are currently generalizing our method to determine jump discontinuities in the derivatives, critical for resolving texture in images.

Appendix A. One-dimensional edge detection algorithm. For any $x \in [a,b]$, let $\mathcal{S}_x$ be the closest $m_1 = m+1$ points to x in $\mathcal{S}$. As a basis of Π_m, choose $p_i(x) = x^{i-1}$ for $i = 1, \ldots, m_1$. The *minmod* function for $\mathcal{M} = \{1, 2, \ldots, \mu\}$ will be reconstructed on the points $x_{j+\frac{1}{2}} = \frac{1}{2}(x_{j+1} + x_j)$ with $j = 1, \ldots, N-1$.

```
for $m = 1$ to $\mu$ and $j = 1$ to $N-1$
    step 1. For each $x_{j+\frac{1}{2}}$, define $\mathcal{S}^+_{x_{j+\frac{1}{2}}} = \{x_n | x_n > x_{j+\frac{1}{2}}\}$ and set $r = \#\mathcal{S}^+_{x_{j+\frac{1}{2}}}$.
    step 2. Calculate the coefficients
            $c_i(x_{j+\frac{1}{2}}) = \frac{m!}{\omega_i(\mathcal{S}_{x_{j+\frac{1}{2}}})}, \quad i = 1, \ldots, m_1,$
        where $\omega_i(\mathcal{S}_{x_{j+\frac{1}{2}}})$ is defined as in (3.9).
    step 3. Calculate the normalization factor
            $q_m(x_{j+\frac{1}{2}}) = \sum_{i=m_1-r+1}^{m_1} c_i(x_{j+\frac{1}{2}}).$
    step 4. Compute the jump function
            $L_m f(x_{j+\frac{1}{2}}) = \frac{1}{q_m(x_{j+\frac{1}{2}})} \sum_{i=1}^{m_1} c_i(x_{j+\frac{1}{2}}) f(x_{i+j+r-m_1}).$
end ($m$, $j$)
step 5. Apply minmod edge detection method $MM\big(L_{\mathcal{M}} f(x_{j+\frac{1}{2}})\big)$.
```

Appendix B. Two-dimensional edge detection algorithm. Let $\mathcal{S} := \{x_j := (u_j, v_j) \,|\, j = 1, \ldots, N\} \subset \Omega$ and choose $p_\alpha(x) = u^{\alpha_1} v^{\alpha_2}$ for $x = (u,v)$ and $\alpha = (\alpha_1, \alpha_2) \in \mathbb{Z}^2_+$ such that $|\alpha|_1 \leq m$ as a basis of Π_m. The *minmod* function for $\mathcal{M} = \{1, 2, \ldots, \mu\}$ will be reconstructed on the set

$$\mathcal{D}_{\mathcal{T}_\mathcal{S}} = \left\{ \bar{x}_j \,\middle|\, \bar{x}_j = \frac{\sum_{i=1}^{3} x_i^j}{3}, \text{ where } T_j = \{x_1^j, x_2^j, x_3^j\} \in \mathcal{T}_\mathcal{S} \text{ for } j = 1, \ldots, N_T \right\}. \tag{B.1}$$

```
for $m = 1$ to $\mu$ and $j = 1$ to $N_T$
    step 1. For $\bar{x}_j$ in (B.1), determine $\mathcal{S}_{\bar{x}_j}$ as in (4.2) with $\#\mathcal{S}_{\bar{x}_j} = m_2 = \binom{m+2}{2}$.
            Set $\mathcal{S}_{\bar{x}_j} = \{x_1, \ldots, x_{m_2}\}$ such that $f(x_1) \leq f(x_2) \leq \cdots \leq f(x_{m_2})$.
    step 2. Solve the linear system
            $\sum_{x_i \in S_{\bar{x}_j}} c_i(\bar{x}_j) p_\alpha(x_i) = \begin{cases} 0 & \text{if } \alpha_1 + \alpha_2 < m, \\ \alpha_1! \alpha_2! & \text{if } \alpha_1 + \alpha_2 = m \end{cases}$
        for $\alpha_1, \alpha_2 = 0, \ldots, m$, such that $\alpha_1 + \alpha_2 \leq m$.
    step 3. Calculate $q_m(\bar{x}_j)$ as in (4.6). Here the subset $\mathcal{P}_x$ (4.12) of $\mathcal{S}_{\bar{x}_j}$ is computed as
                $\mathcal{P}_x = \{x_1, \ldots, x_r\}$,
            where
                $|f(x_{r+1}) - f(x_r)| = \max_{i=1,\ldots,m_2-1} |f(x_{i+1}) - f(x_i)|$.
            If such $r$ is not unique, choose the smallest one.
    step 4. Calculate $L_m f(\bar{x}_j) = \frac{1}{q_m(\bar{x}_j)} \sum_{x_i \in \mathcal{S}_{\bar{x}_j}} c_i(\bar{x}_j) f(x_i)$.
end $(m, j)$
step 5. Apply minmod edge detection method $MM\big(L_{\mathcal{M}} f(\bar{x}_j)\big)$.
```

Appendix C. Shepp–Logan phantom algorithm. The Shepp–Logan phantom is a piecewise smooth function on the domain $\Omega = [-1,1] \times [-1,1]$ in $\mathbb{R}^2$. For any arbitrary point $(u,v) \in \Omega$ the value of the Shepp–Logan phantom $z = f(u,v)$ is calculated as follows:

```
for each point $(u,v)$
    let $z = 0$, $\xi_1 = (u - .22)\cos(.4\pi) + v\sin(.4\pi)$, $\eta_1 = -(u - .22)\sin(.4\pi) + v\cos(.4\pi)$, $\xi_2 = (u+.22)\cos(.6\pi) + v\sin(.6\pi)$, and $\eta_2 = -(u+.22)\sin(.6\pi) + v\cos(.6\pi)$.
    if $(\frac{u}{.69})^2 + (\frac{v}{.92})^2 \leq 1$,
        then $z = 2$.
    if $(\frac{u}{.06624})^2 + (\frac{v+.0184}{.874})^2 \leq 1$,
        then $z = z - .98$.
    if $(\frac{\xi_1}{.31})^2 + (\frac{\eta_1}{.11})^2 \leq 1$ or $(\frac{\xi_2}{.41})^2 + (\frac{\eta_2}{.16})^2 \leq 1$,
        then $z = z - .02$.
    if $(\frac{u-.35}{.3})^2 + (\frac{v}{.6})^2 \leq 1$, or $(\frac{u}{.21})^2 + (\frac{v-.35}{.25})^2 \leq 1$, or $(\frac{u}{.046})^2 + (\frac{v-.1}{.046})^2 \leq 1$, or $(\frac{u}{.046})^2 + (\frac{v+.1}{.046})^2 \leq 1$, or $(\frac{u+.08}{.046})^2 + (\frac{v+.605}{.023})^2 \leq 1$, or $(\frac{u}{.023})^2 + (\frac{v+.605}{.023})^2 \leq 1$, or $(\frac{u-.06}{.023})^2 + (\frac{v+.605}{.023})^2 \leq 1$,
        then $z = z + .01$.
end.

A DISCONTINUOUS PETROV–GALERKIN METHOD WITH LAGRANGIAN MULTIPLIERS FOR SECOND ORDER ELLIPTIC PROBLEMS*

PAOLA CAUSIN[†] AND RICCARDO SACCO[‡]

Abstract. We present a discontinuous Petrov–Galerkin (DPG) method for the finite element discretization of second order elliptic boundary value problems. The novel approach emanates from a one-element weak formulation of the differential problem. This procedure, which is typical of discontinuous Galerkin (DG) methods, is based on introducing variables defined in the interior and on the boundary of the element. The interface variables are suitable Lagrangian multipliers that enforce interelement continuity of the solution and of its normal derivative, thus providing the proper connection between neighboring elements. The internal variables can be eliminated in favor of the interface variables using static condensation to end up with a system of reduced size in the sole Lagrangian multipliers. A stability and convergence analysis of the novel formulation is carried out and its connection with mixed-hybrid and DG methods is explored. Numerical tests on several benchmark problems are included to validate the convergence performance and the flux-conservation properties of the DPG method.

Key words. Petrov–Galerkin formulations, mixed and hybrid finite element methods, discontinuous Galerkin methods, elliptic problems

1. Introduction and motivation.

Recent years have seen an ever increasing use, development, and analysis of *discontinuous methods* in the approximation of boundary value problems. Within this active research area, discontinuous Galerkin (DG) formulations certainly occupy a prominent position (we refer to [19] for a survey on the state-of-the-art of the literature on DG methods) and their success in the approximation of hyperbolic problems has extended their use to cover the case of parabolic and elliptic equations.

A considerable impulse in the direction of extending the use of DG methods to parabolic and elliptic equations is due to the contributions given in [6, 7], where discontinuous finite elements of high order are used in the numerical solution of the compressible Navier–Stokes equations. Two methodological aspects in [6, 7] are of particular importance for their influence on later research activity.

The first aspect is the technique used to accommodate the viscous terms arising in the momentum and energy balance equations within the structure of the DG formulations traditionally devoted to hyperbolic problems. The technique consists of introducing a new unknown, related to the gradient of the conservative variables, and then providing a consistent approximation for the new unknown. This strategy is closely related to classical *mixed methods* and is one of the starting motivations of the work conducted, although in different directions, in [2, 3, 16] and in the present article.

The second aspect is the extension of the concept and use of *numerical fluxes* in the treatment of boundary terms arising from integration by parts of the equations at the element level. Numerical fluxes are a key ingredient of any performing DG formulation and must be properly designed to impart stability and accuracy to the approximation. This is usually done by borrowing their expression from finite volume techniques, as discussed in [3] in the case of DG methods applied to the numerical solution of elliptic boundary value problems. The choice of numerical fluxes in DG methods is not trivial since it must be tailored to the problem at hand, leading in some cases to an involved implementation of the resulting scheme, a drawback that is quite common to many high-order finite volume formulations.

The motivation of the discontinuous Petrov–Galerkin (DPG) method proposed in the present article strongly arises from this latter observation. It is indeed a fact that the *values of the variables on the element boundaries* (or an appropriate representation of them) are the ingredients to be used to provide the necessary coupling between neighboring elements. Having this clearly in mind, an alternative approach to numerical flux definition may be pursued by introducing *independent interface variables* that are single-valued functions solely defined on element boundaries (*hybrid interface variables*). The hybrid interface variables are suitable Lagrangian multipliers that enforce the continuity of the displacement (the scalar variable of the problem) and of the normal stress (the vector variable of the problem) across the interfaces of the finite element triangulation. By doing so, proper interelement connection can be enforced without needing to exhibit any specific upfront recipe for the numerical flux. Therefore, the DPG method establishes a connection between DG and hybrid methods, a connection that is presently the object of analogous research activity by many authors in different areas (see, for example, [21, 22, 20]).

The DPG method was proposed in [10], where a stability and convergence analysis of the formulation was carried out in one spatial dimension. Then, the method was applied to the numerical solution of scalar advective-diffusive models [12, 11] and of fluid-mechanical problems in both compressible and incompressible regimes [17].

In the present article we carry out the theoretical analysis of the stability and convergence properties of the novel formulation applied to the solution of an elliptic boundary value model problem in two spatial dimensions, an aspect that was still lacking. We also discuss the efficient computer implementation of the scheme, thus strengthening the connection between the DPG methodology and classical DG and mixed-hybrid approaches. Numerical results are then shown to demonstrate the convergence and conservation properties of the novel formulation.

The paper is organized as follows: in section 2 we introduce the one-element weak formulation that is the starting point of the DPG approach. In section 3 we set up the formulation at the continuous level and we carry out its stability analysis. In section 4 we introduce the corresponding approximation and in section 5 we discuss the construction of appropriate finite element spaces, addressing in particular the case of the element of lowest degree (DPG_0) for which we carry out a stability and error analysis in section 6. We address the issue of an efficient implementation of the DPG_0 formulation in section 7. In section 8 we present some numerical results to validate the convergence performance, while in section 9 we assess the conservation properties of the DPG method. Finally, in section 10 we end with some concluding remarks.

2. One-element formulation of the elliptic model problem.

We consider the following elliptic model problem:

$$-\mathrm{div}\,\nabla\, u = f \quad \text{in } \Omega, \qquad u = g_D \quad \text{on } \Gamma_D, \qquad \nabla\, u \cdot \boldsymbol{n} = g_N \quad \text{on } \Gamma_N, \tag{2.1}$$

where Ω is an open bounded set of $\mathbb{R}^2$ with Lipschitz continuous boundary $\Gamma = \partial\Omega$ such that $\Gamma = \Gamma_D \cup \Gamma_N$, $\Gamma_D \neq \emptyset$, and where f, g_D, and g_N are given functions. Problem (2.1) will be referred to as the *primal formulation* and u as the *primal unknown*. Upon introducing the auxiliary unknown $\boldsymbol{\sigma} = \nabla u$, problem (2.1) may be rewritten as the first order system

$$\left\{ \begin{array}{llll} -\mathrm{div}\,\boldsymbol{\sigma} = f & \text{in}\,\Omega, & \boldsymbol{\sigma} = \nabla u & \text{in}\,\Omega, \\ u = g_D & \text{on}\,\Gamma_D, & \boldsymbol{\sigma}\cdot\boldsymbol{n} = g_N & \text{on}\,\Gamma_N. \end{array} \right. \tag{2.2}$$

Problem (2.2) will be referred to as the *mixed formulation* of (2.1). In this latter context we shall refer in a generalized sense to the mixed unknowns u and $\boldsymbol{\sigma}$ as *displacements* and *stresses*, respectively.

Given a triangulation $\mathcal{T}_h$ of Ω made of triangles, we consider the following *one-element* weak form of problem (2.2) (see section 3.1 for the notation):

$\forall\, K \in \mathcal{T}_h$, find $(\boldsymbol{\sigma}^K, u^K)$ such that

(2.3)
$$\left\{ \begin{array}{ll} \displaystyle\int_K \boldsymbol{\sigma}^K \cdot \boldsymbol{q}^K\,dx + \int_K u^K\,\mathrm{div}\,\boldsymbol{q}^K\,dx - \int_{\partial K} u_{\partial K}\,\boldsymbol{q}_{\partial K}\cdot\boldsymbol{n}_K\,ds = 0 & \forall\,\boldsymbol{q}^K, \\ \displaystyle\int_K \boldsymbol{\sigma}^K \cdot \nabla v^K\,dx - \int_{\partial K} \boldsymbol{\sigma}_{\partial K}\cdot\boldsymbol{n}_K\,v_{\partial K}\,ds = \int_K f^K\,v^K\,dx & \forall v^K, \end{array} \right.$$

where $\boldsymbol{\sigma}^K, u^K, \boldsymbol{q}^K$, and v^K belong to spaces of smooth vector and scalar functions defined on K and where the symbols $\boldsymbol{\sigma}_{\partial K}$ and $u_{\partial K}$ represent the traces on ∂K of $\boldsymbol{\sigma}^K$ and u^K, respectively, properly accounting for the boundary conditions. Notice that a formal integration by parts has been performed on both equations in (2.2).

System (2.3) is a general setting from which both discontinuous Galerkin and hybrid formulations can be derived, the latter after a suitable use of integration by parts in $(2.3)_1$ or $(2.3)_2$. The common factor shared by DG and hybrid formulations relies on the role played by the variables traced on the element interfaces that are the connectors demanded to preserve the proper coupling between K and its neighbors.

In DG methods the interelement constraints are enforced by defining on ∂K specific expressions for $\boldsymbol{\sigma}_{\partial K}$ and $u_{\partial K}$ as functions of the internal variables, the so-called *numerical fluxes* (see [2, 3, 16]).

In hybrid formulations the variables traced on the element interfaces are instead suitable Lagrange multipliers and are *additional* unknowns of the problem. In particular, primal mixed-hybrid methods [35, 37] are obtained by integrating by parts $(2.3)_1$, while dual mixed-hybrid methods [14] are obtained by integrating by parts $(2.3)_2$. System (2.3) is thus in dual-primal mixed-hybrid form. In both cases a symmetric Galerkin formulation is obtained from the nonsymmetric formulation (2.3) and only *one* Lagrangian multiplier is introduced, with the conclusion that in hybrid formulations a different numerical treatment is applied to the displacement and stress fields.

The choice of introducing independent interface unknowns as interelement connectors, thus avoiding the need of ad hoc definition of the numerical fluxes, while preserving at the same time a completely parithetic (and discontinuous) approximation of u and $\boldsymbol{\sigma}$ on $\mathcal{T}_h$, as in DG formulations, is the main idea underlying the DPG method discussed in the forthcoming sections.

3. The DPG formulation.

In what follows we introduce the DPG formulation and carry out a stability and convergence analysis of the method.

3.1. Notation and functional setting. We let $\overline{\Omega} = \cup \overline{K}$ be a regular partition $\mathcal{T}_h$ of the domain Ω into triangular elements K (see [18]); i.e., we suppose that there exists a constant $\sigma \geq 1$ such that $(h_K/\rho_K) \leq \sigma$ for all $K \in \mathcal{T}_h$, h_K being the diameter of K and $\rho_K = \sup\{\mathrm{diam}(S) \,|\, S \,\text{is a ball contained in}\, K\}$. We let $\mathcal{E}_h$ be the set of the edges of $\mathcal{T}_h$, and the edge shared by the elements K and K' will be referred to as $e_{K-K'}$. For each element $K \in \mathcal{T}_h$, we denote by ∂K the Lipschitz continuous boundary of K and by $\boldsymbol{n}_K$ the unit outward normal vector along the boundary ∂K. We also let $\partial K_D = \partial K \cap \Gamma_D$, $\partial K_N = \partial K \cap \Gamma_N$. Moreover, if v is any function defined in Ω, we denote by v^K its restriction to the element K and by $v_{\partial K}$ its restriction to the element boundary ∂K. Similarly, if η is any function defined on $\mathcal{E}_h$, we denote by $\eta_{\partial K}$ its restriction on $\mathcal{E}_h \cap \partial K$.

Given an integer $m \geq 0$ and the real numbers $p, q \in [1, \infty)$, we define the following local space:

$$W^{m,p}(K) = \{v \in L^p(K) \,|\, D^\alpha v \in L^p(K) \,\forall \alpha, |\alpha| \leq m\} \qquad \forall K \in \mathcal{T}_h,$$

endowed with the usual norm and seminorm $||v||_{m,p,K}$ and $|v|_{m,p,K}$. When $p = 2$, $W^{m,2}(K)$ is the usual $H^m(K)$ Sobolev space (see [27, 28]), and the simplified notation $||.||_{m,K}$ and $|.|_{m,K}$ will be used. We also introduce the local space

$$W_q(\mathrm{div}; K) = \left\{\boldsymbol{\tau} \in (L^q(K))^2 \,|\, \mathrm{div}\, \boldsymbol{\tau} \in L^q(K)\right\},$$

endowed with the usual graph norm $||\boldsymbol{\tau}||_{q,\mathrm{div},K}$. When $q = 2$, the space $W_2(\mathrm{div}; K)$ is the Sobolev space $H(\mathrm{div}; K)$ (see [14]).

From now on, p and q will be chosen to be conjugate numbers, i.e., $1/p + 1/q = 1$. It will be useful in what follows to consider the space of the traces on ∂K of functions $v \in W^{1,p}(K)$ and $\boldsymbol{\tau} \in W_q(\mathrm{div}; K)$. Notice that the trace $v_{\partial K}$ belongs to the space $W^{1/q,p}(\partial K)$, while the normal trace $\boldsymbol{\tau} \cdot \boldsymbol{n}|_{\partial K}$ belongs to the space $W^{-1/q,q}(\partial K)$; the spaces $W^{1/q,p}(\partial K)$ and $W^{-1/q,q}(\partial K)$ are endowed with the following norms:

$$(3.1) \qquad ||\boldsymbol{\tau} \cdot \boldsymbol{n}||_{-1/q,q,\partial K} = \sup_{v \in W^{1,p}(K)} \frac{\langle \boldsymbol{\tau} \cdot \boldsymbol{n}, v\rangle_{\partial K}}{||v||_{1,p,K}} \quad \forall \boldsymbol{\tau} \in W_q(\mathrm{div}; K)$$

and

$$(3.2) \qquad ||v||_{1/q,p,\partial K} = \sup_{\boldsymbol{\tau} \in W_q(\mathrm{div};K)} \frac{\langle \boldsymbol{\tau} \cdot \boldsymbol{n}, v\rangle_{\partial K}}{||\boldsymbol{\tau}||_{W_q(\mathrm{div};K)}} \qquad \forall v \in W^{1,p}(K).$$

Note that for $p = q = 2$ the quantity in (3.1) is the standard norm $||\boldsymbol{\tau} \cdot \boldsymbol{n}||_{-1/2,\partial K}$.

3.2. DPG weak formulation. Proceeding along the same lines as in [23, 24], we assume henceforth that $\frac{4}{3} < p < 2$, and thus $2 < q < 4$.

We introduce the trial function spaces

$$\Sigma = (L^q(\Omega))^2, \qquad U = L^q(\Omega),$$

$$\Lambda = \Bigg\{\lambda \in \prod_{K \in \mathcal{T}_h} W^{1/q,p}(\partial K), \lambda^K = \lambda^{K'} \text{ on } e_{K-K'} \;\forall K, K' \in \mathcal{T}_h,$$
$$\lambda^K = g_D \text{ on } \partial K_D \;\forall K \in \mathcal{T}_h\Bigg\},$$

$$M = \Bigg\{\mu \in \prod_{K \in \mathcal{T}_h} H^{-1/2}(\partial K),\; \mu^K + \mu^{K'} = 0 \text{ on } e_{K-K'} \;\forall K, K' \in \mathcal{T}_h,$$
$$\mu^K = g_N \text{ on } \partial K_N \;\forall K \in \mathcal{T}_h\Bigg\}$$

and the test function spaces $W = \prod_{K\in\mathcal{T}_h} W_q(\mathrm{div}; K)$ and $V = \prod_{K\in\mathcal{T}_h} H^1(K)$. We set $X = (U \times \Lambda)$, $Y = (\Sigma \times M)$ and we introduce the compact notation $\widetilde{u} = (u; \lambda)$ and $\widetilde{\boldsymbol{\sigma}} = (\boldsymbol{\sigma}; \mu)$. The DPG weak formulation of problem (2.1) is obtained from (2.3) by introducing the hybrid variables λ and μ to represent the values $u_{\partial K}$ and $\sigma_{\partial K}$, respectively, and by summing up on the triangles and reads:

find $(\widetilde{u}, \widetilde{\boldsymbol{\sigma}}) \in \big(X \times Y\big)$ such that

$$\left\{\begin{array}{lclcll} a(\widetilde{\boldsymbol{\sigma}}, \boldsymbol{q}) & + & b_1(\widetilde{u}, \boldsymbol{q}) & = & 0 & \forall \boldsymbol{q} \in W, \\ b_2(\widetilde{\boldsymbol{\sigma}}, v) & & & = & (f, v) & \forall v \in V, \end{array}\right. \tag{3.3}$$

where $(\cdot,\cdot)$ is the usual L^2 product and where we have set

$$a(\widetilde{\boldsymbol{\sigma}}, \boldsymbol{q}) = \sum_{K\in\mathcal{T}_h} \int_K \boldsymbol{\sigma} \cdot \boldsymbol{q}\, dx, \qquad b_1(\widetilde{u}, \boldsymbol{q}) = \sum_{K\in\mathcal{T}_h} \left(\int_K u \,\mathrm{div}\boldsymbol{q}\, dx - \int_{\partial K} \lambda \boldsymbol{q} \cdot \boldsymbol{n}\, ds \right),$$

$$b_2(\widetilde{\boldsymbol{\sigma}}, v) = \sum_{K\in\mathcal{T}_h} \left(\int_K \boldsymbol{\sigma} \cdot \nabla v\, dx - \int_{\partial K} \mu\, v\, ds \right).$$

Due to the *simultaneous* presence of the two Lagrangian multipliers λ and μ, the resulting scheme lacks the formal symmetry of a standard Galerkin mixed-hybrid formulation and becomes a DPG method for the numerical approximation of second order boundary value problems. It is characterized by a completely equal treatment of the mixed variables u and $\boldsymbol{\sigma}$. Indeed, since the integration by parts has relaxed all the regularity requirements on u and $\boldsymbol{\sigma}$ at the expense of more regular test functions $\boldsymbol{q}$ and v, an equal-order interpolation for these internal fields is allowed in the finite element approximation of (3.3).

Remark 3.1. The choice of the unknowns and of the corresponding functional setting in (3.3) allows one to interpret the DPG formulation as a (suitable) hybridization of the dual-mixed problem (2.2), the hybridization procedure being carried out here "on the continuous level" rather than "on the discrete level" as done in the classical reference work [1]. The advantage of dual-mixed formulations with hybridization on standard dual-hybrid formulations is that the former yield an approximation of the normal stresses that is *continuous* on each edge of $\mathcal{T}_h$, while the latter ensure flux conservation only in an average sense over the patch of elements surrounding each node of the triangulation. In [1], this goal is achieved by introducing a hybrid variable that appears only as a discrete function (the so-called λ-trick), while with the present functional setting, functions in $W^{1/q,p}(\partial K)$ need not be continuous at the vertices of ∂K, which allows for a *fully discontinuous* approximation of the hybrid variable over $\mathcal{E}_h$. Notice that the extra amount of regularity ($q > 2$) required to achieve the desired conservation properties has no practical limiting consequences on the choice of the finite element spaces for the approximation of functions in $W_q(\mathrm{div}; K)$.

Remark 3.2. Given the above functional spaces, it will be possible to prove the (weak) coerciveness of $a(\cdot,\cdot)$, $b_1(\cdot,\cdot)$, and $b_2(\cdot,\cdot)$ in norms weaker than the natural ones (cf. Propositions 3.3, 3.4, and 3.5, Corollary 3.7, and the corresponding discrete ones in section 6.1). This, however, will be enough [23, 24] to establish uniqueness of the weak solution of (3.3) and of its corresponding finite element discretization (see section 6.1), as well as superconvergence error estimates for the approximation λ_h of the hybrid variable λ in a natural boundary norm (see section 6.3).

Remark 3.3. Whenever continuous test functions $\boldsymbol{q}$ and v are used in (3.3), we recover the dual-primal method proposed and analyzed in [30]. Therefore, the DPG method can be fully regarded as a hybridization of the above-mentioned scheme. Moreover, the mixed system obtained by taking continuous test functions on Ω for $\boldsymbol{\sigma}$ and u in $(3.4)_1$ and $(3.6)_1$ yields, upon summing over $\mathcal{T}_h$, the primal-dual formulation proposed and analyzed in [39].

Remark 3.4. Equation $(3.3)_1$ may be thought of as derived from the following integral form:

$$\int_K (\boldsymbol{\sigma}^K - \nabla u^K) \cdot \boldsymbol{q}^K \, dx + \int_{\partial K} (u_{\partial K} - \lambda_{\partial K}) \eta_{\partial K} \, ds = 0 \quad \forall \, \boldsymbol{q}, \eta, \tag{3.4}$$

where $\boldsymbol{q}$ and η are smooth enough test functions. Choosing $\eta_{\partial K} = \boldsymbol{q}^K \cdot \boldsymbol{n}_K|_{\partial K}$ and integrating by parts yields

$$\int_K (\boldsymbol{\sigma}^K \cdot \boldsymbol{q}^K + u^K \operatorname{div} \boldsymbol{q}^K) \, dx - \int_{\partial K} \lambda_{\partial K} \, \boldsymbol{q}_{\partial K} \cdot \boldsymbol{n}_K \, ds = 0 \qquad \forall \boldsymbol{q}. \tag{3.5}$$

Similarly, $(3.3)_2$ may be thought of as derived from the following integral form:

$$\int_K (\operatorname{div} \boldsymbol{\sigma}^K + f^K) v^K \, dx + \int_{\partial K} (\boldsymbol{\sigma}_{\partial K} \cdot \boldsymbol{n}_K - \mu_{\partial K}) \, \xi_{\partial K} \, ds = 0 \quad \forall \, v, \xi, \tag{3.6}$$

where v and ξ are smooth enough test functions. Choosing $\xi_{\partial K} = v_{\partial K}$ and integrating by parts yields

$$\int_K \boldsymbol{\sigma}^K \cdot \nabla \, v^K \, dx - \int_{\partial K} \mu_{\partial K} \, v_{\partial K} \, ds = 0 \qquad \forall v. \tag{3.7}$$

The DPG weak formulation can then be formally interpreted as a mixed-hybrid virtual work principle where *nonvanishing* virtual variations $\delta u = v$ and $\delta(\boldsymbol{\sigma} \cdot \boldsymbol{n}) = \boldsymbol{q} \cdot \boldsymbol{n}$ are allowed on ∂K_D and ∂K_N, respectively (see, e.g., [4] for an extensive discussion of this topic).

3.3. Existence and uniqueness of the DPG solution. In this section we prove the existence and uniqueness of the solution of problem (3.3). To do so, we make use of the generalized saddle point problem theory introduced in [33] and further developed in [8]. For ease of presentation, we assume henceforth that $\Gamma \equiv \Gamma_D$ with $g_D = 0$.

Lemma 3.1 (existence). *Assume that the solution* $\overline{u}$ *of problem* (2.1) *is such that* $\overline{\boldsymbol{\sigma}} \in (L^q(\Omega))^2 \cap H(\mathrm{div};\Omega)$, *where* $\overline{\boldsymbol{\sigma}} = \nabla \overline{u}$. *Then, we have that* $\widetilde{u} = (\overline{u}, \overline{u}|_{\mathcal{E}_h})$ *and* $\widetilde{\boldsymbol{\sigma}} = (\overline{\boldsymbol{\sigma}}, (\overline{\boldsymbol{\sigma}} \cdot \boldsymbol{n})|_{\mathcal{E}_h})$ *is a solution of problem* (3.3).

Proof. Taking $v \in H_0^1(\Omega)$ in $(3.3)_2$ yields (see [14, Chap. 3, Prop. 1.1])

$$\sum_{K \in \mathcal{T}_h} \int_{\partial K} \mu v \, ds = 0 \qquad \forall v \in H_0^1(\Omega).$$

Then $(3.3)_2$ becomes

$$\int_\Omega \boldsymbol{\sigma} \cdot \nabla v \, dx = \int_\Omega f \, v \, dx \qquad \forall v \in H_0^1(\Omega),$$

from which it follows that $\overline{\boldsymbol{\sigma}} = \nabla \overline{u}$ is a solution. Similarly, taking $\boldsymbol{q} \in W_q(\mathrm{div};\Omega)$ in $(3.3)_1$ yields

$$\sum_{K \in \mathcal{T}_h} \int_{\partial K} \lambda \, \boldsymbol{q} \cdot \boldsymbol{n} \, ds = 0 \qquad \forall \boldsymbol{q} \in W_q(\mathrm{div};\Omega).$$

Then $(3.3)_1$ becomes

$$\int_\Omega \nabla\overline{u}\cdot\boldsymbol{q}\,dx + \int_\Omega u\,\mathrm{div}\,\boldsymbol{q}\;dx\; = 0 \qquad \forall\boldsymbol{q}\in W_q(\mathrm{div};\Omega),$$

for which $\overline{u}$ is a solution.

Let us now go back to the hybrid fields; integrating by parts the first term in the bilinear form $b_2(\cdot,\cdot)$, we obtain

$$\sum_{K\in\mathcal{T}_h}\left(\int_{\partial K} v\,\overline{\boldsymbol{\sigma}}\cdot\boldsymbol{n}\,ds - \int_{\partial K}\mu\,v\,ds\right) = 0 \qquad \forall v\in V,$$

which shows that $\mu|_{\partial K} = \overline{\boldsymbol{\sigma}}\cdot\boldsymbol{n}|_{\partial K}$ is a solution (recall indeed that $\overline{\boldsymbol{\sigma}}\in H(\mathrm{div};\Omega)$ implies $\overline{\boldsymbol{\sigma}}^K\cdot\boldsymbol{n}_K + \overline{\boldsymbol{\sigma}}^{K'}\cdot\boldsymbol{n}_{K'} = 0 \quad \forall e_{K-K'}$). Proceeding similarly with the bilinear form $b_1(\cdot,\cdot)$, we obtain

$$\sum_{K\in\mathcal{T}_h}\int_{\partial K}(\overline{u}-\lambda)\boldsymbol{q}\cdot\boldsymbol{n}\,ds = 0 \qquad \forall\boldsymbol{q}\in W,$$

which shows that $\lambda|_{\partial K} = \overline{u}|_{\partial K}$ is a solution. The consistency of the continuous DPG formulation with the original problem is thus proved. □

Before dealing with the issue of the uniqueness of the solution of problem (3.3), we state the following useful property that is an extension of the Helmholtz decomposition principle to the present functional setting (cf. [14, Chap. VII, Prop. 3.4 and Remark 3.3] and [25]).

PROPOSITION 3.2. *Every function $\boldsymbol{w}\in(L^q(\Omega))^2$ admits the orthogonal decomposition*

$$\boldsymbol{w} = \nabla\xi\oplus\mathrm{curl}\,\phi,$$

where $\xi\in W_0^{1,q}(\Omega), \phi\in W^{1,q}(\Omega)\setminus\mathbb{R}$, and $\mathrm{curl}\,\phi = (\frac{\partial\phi}{\partial x_1}, -\frac{\partial\phi}{\partial x_2})^T$.

Using the above proposition, we can characterize the null spaces $\mathcal{K}_1$ and $\mathcal{K}_2$ associated with the bilinear forms $b_1(\cdot,\cdot)$ and $b_2(\cdot,\cdot)$ as follows:

$$\mathcal{K}_1 = \{\boldsymbol{q}\in W\,|\,b_1(\widetilde{u},\boldsymbol{q}) = 0\,\forall\widetilde{u}\in X\} = \{\boldsymbol{q}\in W_q(\mathrm{div};\Omega)\,|\,\mathrm{div}\,\boldsymbol{q} = 0 \text{ in }\Omega\},$$

$$\mathcal{K}_2 = \{\widetilde{\boldsymbol{\sigma}}\in Y\,|\,b_2(\widetilde{\boldsymbol{\sigma}},v) = 0\,\forall v\in V\} = \{\boldsymbol{\sigma}\in\mathcal{K}_1;\,\mu = \boldsymbol{\sigma}\cdot\boldsymbol{n}\text{ on }\partial K\;\forall K\in\mathcal{T}_h\}.$$

The continuous bilinear forms $b_1(\cdot,\cdot)$ and $b_2(\cdot,\cdot)$ induce the following orthogonal decompositions in terms of the closed subspaces $\mathcal{K}_1$ and $\mathcal{K}_2$, respectively:

$$W = \mathcal{K}_1\oplus\mathcal{W}_1 \quad\text{and}\quad Y = \mathcal{K}_2\oplus\mathcal{W}_2,$$

where $\mathcal{W}_1 = \mathcal{K}_1^\perp$ and $\mathcal{W}_2 = \mathcal{K}_2^\perp$.

In order to prove the uniqueness of the solution of the DPG weak formulation, let us check the weak coerciveness of $a(\cdot,\cdot)$ and the inf-sup condition for $b_1(\cdot,\cdot)$ and $b_2(\cdot,\cdot)$.

PROPOSITION 3.3. *There exists a constant $\delta > 0$ such that*

$$\sup_{\boldsymbol{q}\in\mathcal{K}_1} a(\widetilde{\boldsymbol{\sigma}},\boldsymbol{q}) \geq \delta||\boldsymbol{\sigma}||_{0,\Omega}\,||\boldsymbol{q}||_{0,\Omega} \quad \forall\widetilde{\boldsymbol{\sigma}}\in\mathcal{K}_2, \tag{3.8}$$

$$\sup_{\widetilde{\boldsymbol{\sigma}}\in\mathcal{K}_2} a(\widetilde{\boldsymbol{\sigma}},\boldsymbol{q}) > 0 \quad \forall \boldsymbol{q}\in\mathcal{K}_1, \boldsymbol{q}\neq 0. \tag{3.9}$$

Proof. Let $\widetilde{\boldsymbol{\sigma}} \in \mathcal{K}_2$ and take $\boldsymbol{q}^* \in \mathcal{K}_1$. Condition (3.8) is immediately verified with $\delta = 1$ by taking $\boldsymbol{q}^\star = \widetilde{\boldsymbol{\sigma}}$ since $a(\widetilde{\boldsymbol{\sigma}},\boldsymbol{q}^*) = ||\boldsymbol{\sigma}||_{0,\Omega}\,||\boldsymbol{q}^*||_{0,\Omega}\ \forall\,\widetilde{\boldsymbol{\sigma}} \in \mathcal{K}_2$. Now let $\boldsymbol{q} \in \mathcal{K}_1$, $\boldsymbol{q} \neq 0$, and $\widetilde{\boldsymbol{\sigma}}^* \in \mathcal{K}_2$. Taking $\widetilde{\boldsymbol{\sigma}}^* = \boldsymbol{q}$, condition (3.9) is immediately verified. □

Proposition 3.4. *There exists a constant* $\gamma_1 > 0$ *such that*

$$\sup_{\boldsymbol{q}\in W} b_1(\widetilde{u},\boldsymbol{q}) \geq \gamma_1||u||_{0,\Omega}||\boldsymbol{q}||_{0,\Omega} \quad \forall \widetilde{u}\in X. \tag{3.10}$$

Proof. Let $\widetilde{u} \in X$ and $\boldsymbol{q}^* = \nabla w$, where w is the solution of the Dirichlet problem

$$\triangle w = u \quad \text{in } \Omega, \qquad w = 0 \quad \text{on } \Gamma.$$

Since $u \in L^q(\Omega)$, we have $\boldsymbol{q}^* \in W_q(\mathrm{div};\Omega)$, and there exists a constant C such that $||\boldsymbol{q}^*||_{0,\Omega} \leq C||u||_{0,\Omega}$. Moreover, it is easy to verify that $b_1(\widetilde{u},\boldsymbol{q}^*) = ||u||^2_{0,\Omega}$ from which (3.10) immediately follows. □

Proposition 3.5. *There exists a constant* $\gamma_2 > 0$ *such that*

$$\sup_{\widetilde{\boldsymbol{\sigma}}\in X} b_2(\widetilde{\boldsymbol{\sigma}},v) \geq \gamma_2||\boldsymbol{\sigma}||_{0,\Omega}||v||_{0,\Omega} \quad \forall v\in V. \tag{3.11}$$

Proof. Let $v \in V$ and $\boldsymbol{\sigma}^* \in W_q(\mathrm{div};\Omega)$, $\mathrm{div}\boldsymbol{\sigma}^* \neq 0$ and $\mu^* = \boldsymbol{\sigma}^*\cdot\boldsymbol{n}$ on ∂K, $\forall K \in \mathcal{T}_h$. Then, after integrating by parts over each element $K \in \mathcal{T}_h$, we have

$$b_2((\boldsymbol{\sigma}^*;\mu^*),v) = -\sum_{K\in\mathcal{T}_h}\int_K v\,\mathrm{div}\boldsymbol{\sigma}^*\,dx,$$

from which we prove (3.11) following the same proof as in Proposition 3.4. □

The following theorem is an immediate consequence of the previous results.

Theorem 3.6. *Under the regularity assumptions stated in Lemma* 3.1*, problem* (3.3) *admits a unique solution* $(\widetilde{u},\widetilde{\boldsymbol{\sigma}}) \in (X \times Y)$.

Having proved Propositions 3.3, 3.4, and 3.5, we can state the following stability result.

Corollary 3.7. *The solution* $(\widetilde{\boldsymbol{\sigma}},\widetilde{u})$ *of the DPG problem* (3.3) *satisfies the estimate*

$$|||\widetilde{u}|||_X \leq K_1||f||_{0,\Omega}, \qquad |||\widetilde{\boldsymbol{\sigma}}|||_Y \leq K_2||f||_{0,\Omega},$$

where $|||\widetilde{u}|||^2_X = ||u||^2_{0,\Omega} + ||\lambda||^2_\Lambda$, $|||\widetilde{\boldsymbol{\sigma}}|||^2_Y = ||\sigma||^2_{0,\Omega} + ||\mu||^2_M$, *and where* $K_1 = (c_1^2 + c_2^2)^{1/2}$, $K_2 = (c_3^2 + c_4^2)^{1/2}$, *with*

$$c_1 = \frac{\delta(2+\gamma_2)+2}{\gamma_2\delta}, \quad c_2 = \frac{2}{\delta}, \quad c_3 = \frac{\delta(2+\gamma_2)+2}{\gamma_2\delta}, \quad c_4 = \frac{2}{\delta}.$$

4. The DPG finite element approximation. Given the finite-dimensional spaces

$$X_h \subset X, \quad Y_h \subset Y, \qquad \text{and} \qquad W_h \subset W, \quad V_h \subset V,$$

the DPG finite element approximation of problem (2.1) reads:

find $(\widetilde{u}_h, \widetilde{\boldsymbol{\sigma}}_h) \in \big(X_h \times Y_h\big)$ such that

$$\left\{ \begin{array}{llll} a(\widetilde{\boldsymbol{\sigma}}_h, \boldsymbol{q}_h) \quad + \quad b_1(\widetilde{u}_h, \boldsymbol{q}_h) & = & 0 & \forall \boldsymbol{q}_h \in W_h, \\ b_2(\widetilde{\boldsymbol{\sigma}}_h, v_h) & = & (f, v_h) & \forall v_h \in V_h. \end{array} \right. \tag{4.1}$$

We have to define the spaces X_h, V_h, W_h, V_h and specify their degrees of freedom.

The choice of the finite element spaces is absolutely nontrivial in mixed Petrov–Galerkin formulations. The idea is first to lay down the properties we want the trial finite element spaces to satisfy and then to select accordingly the discrete test finite element spaces in order to end up with a stable and convergent approximate scheme.

4.1. Trial finite element spaces. The objectives we want the discrete approximation to achieve are the highest possible level of discontinuity and an equal-order interpolation for u_h and $\boldsymbol{\sigma}_h$ and for λ_h and μ_h, respectively. The motivation for adopting equal-order interpolation for both mixed and hybrid variables is that by doing so the numerical performance of a scheme may be significantly enhanced. As a matter of fact, mixed formulations can be interpreted as a *phase-space* approach. Established approaches in dynamics problems applications suggest that an equal-order treatment of the two fields is the right key to achieving correct energy conservation (see [9]).

A natural choice for both internal and interface unknown fields is to consider on each triangle K polynomial finite elements of equal order, respectively, in K and on each edge of ∂K. Henceforth we let k be a nonnegative integer and we denote by $\mathbb{P}_k(K)$ the space of all polynomials of degree $\leq k$ on K and by $R_k(\partial K)$ the space of all functions defined over the boundary ∂K of K whose restrictions to any side $e \in \partial K$ are polynomials of degree $\leq k$. Notice that functions in $R_k(\partial K)$ need not be continuous at the vertices of K.

We take on each triangle $K \in \mathcal{T}_h$

$$X_h^k(K) = \mathbb{P}_k(K) \times R_k(\partial K), \qquad Y_h^k(K) = (\mathbb{P}_k(K))^2 \times R_k(\partial K), \tag{4.2}$$

and we set

$$X_h^k = \prod_{K \in \mathcal{T}_h} X_h^k(K), \qquad Y_h^k = \prod_{K \in \mathcal{T}_h} Y_h^k(K), \tag{4.3}$$

where functions belonging to $R_k(\partial K)$ are single-valued on each internal edge and satisfy the appropriate boundary conditions on Γ_D and Γ_N, respectively. For brevity of notation we also set $\mathcal{X}_h^k(K) = X_h^k(K) \times Y_h^k(K)$ and $\mathcal{X}_h^k = X_h^k \times Y_h^k$.

4.2. Test finite element spaces. Let us now address the issue of properly choosing the finite element test spaces for the DPG approximation. We will start by setting up necessary conditions for the dimension of the test finite element spaces in order for the linear system arising from (4.1) to be a square one. The stability of the approximation will provide a sufficient criterion for explicitly selecting the discrete test functions.

We start with performing a count of the total degrees of freedom corresponding to the choice (4.2) as a function of the polynomial degree k. Subtracting the total number of constraints enforced by the definition of the hybrid field finite element spaces from the previously obtained amount provides the total number of equations that must be written to end up with a *square* algebraic linear system for each value of k. Denoting by NE, Ned, Ni, and Nb the number of triangles, edges, internal edges, and boundary edges, respectively, we have

$$\dim(\mathcal{X}_h^k) = \frac{3}{2}(k+1)(k+6)\texttt{NE}, \tag{4.4}$$

while the total number of constraints is $\texttt{Nc} = (\text{k+1})(2\ \texttt{Ni} + \texttt{Nb})$.

Applying Euler's theorem ($\texttt{Ned} = (3\ \texttt{NE} + \texttt{Nb})/2$), we can express the total number of constraints as a function of NE as $\texttt{Nc} = 3(\text{k+1})\texttt{NE}$, from which it follows that the dimension of the global finite element test space

$$\mathcal{V}_h^k(K) = W_h^k(K) \times V_h^k(K), \qquad \mathcal{V}_h^k = W_h^k \times V_h^k$$

that is needed to end up with a square linear system for each value of k is

$$\dim(\mathcal{V}_h^k) = \dim(\mathcal{X}_h^k) - \texttt{Nc} = \frac{3}{2}(k+1)(k+4)\texttt{NE}. \tag{4.5}$$

Looking at (4.4) and (4.5) it clearly appears that for each k, the degrees of freedom for both trial and test spaces as well as the total number of constraints can all be expressed as a function of the sole number of mesh triangles NE. Therefore, the proper design of the finite element test function spaces can be carried out at the single element level. Precisely, denoting by $\texttt{Nc}(K)$ the number of constraints on triangle K, relation (4.5) can be written at the element level as

$$\dim(\mathcal{V}_h^k(K)) = \dim(\mathcal{X}_h^k(K)) - \texttt{Nc}(K) = \frac{3}{2}(k+1)(k+4) \quad \forall K \in \mathcal{T}_h. \tag{4.6}$$

This equation expresses the balance between degrees of freedom, constraints, and number of equations that must be fulfilled independently on each single element K. Based on these constraints, we start in the next section with the construction of the finite element test space $\mathcal{X}_h^k(K)$ in the lowest degree case $k = 0$. The resulting local finite element space will be denoted as $\text{DPG}_0(K) = \mathcal{X}_h^0(K) \times \mathcal{V}_h^0(K)\ \forall K \in \mathcal{T}_h$.

5. Choice of the finite element spaces.

In this section we discuss in detail the lowest order finite element approximation DPG_0 and then we use this procedure as a guideline for the generation of higher order elements.

5.1. DPG_0 finite element approximation.

Setting $k = 0$, relation (4.6) gives

$$\dim(\mathcal{V}_h^k(K)) = \dim(W_h^0(K)) + \dim(V_h^0(K)) = 6 \qquad \forall K \in \mathcal{T}_h.$$

The minimal choice for the scalar finite element test space is $V_h^0(K) = \mathbb{P}_1(K)$. By doing so, 3 degrees of freedom are left for the vector finite element test space, which can be conveniently saturated by setting $W_h^0(K) = \mathbb{RT}_0(K)$, where $\mathbb{RT}_k(K) = (\mathbb{P}_k(K))^2 \oplus \boldsymbol{x}\mathbb{P}_k(K)\ \forall K \in \mathcal{T}_h$ is the Raviart–Thomas finite element space of degree k [36]. The DPG_0 local finite element space is then defined on each element as

$$\text{DPG}_0(K) = \underbrace{\left(\mathbb{P}_0(K) \times R_0(\partial K) \times (\mathbb{P}_0(K))^2 \times R_0(\partial K)\right)}_{\mathcal{X}_h^0(K)} \times \underbrace{\left(\mathbb{RT}_0(K) \times \mathbb{P}_1(K)\right)}_{\mathcal{V}_h^0(K)}. \tag{5.1}$$

5.2. Higher order DPG methods. Higher order finite elements will be consistently denoted as $\mathrm{DPG}_k(K) = \mathcal{X}_h^k(K) \times \mathcal{V}_h^k(K)\ \forall K \in \mathcal{T}_h$. Under the assumption that the local finite element trial space is defined as in (4.2)–(4.3), the question is how to construct a suitable test finite element space such that the following conditions are satisfied:

1. the dimension of the test finite element space is

$$\dim(\mathcal{V}_h^k(K)) = \dim(W_h^k(K)) + \dim(V_h^k(K)) = \frac{3}{2}(k+1)(k+4) \quad \forall K \in \mathcal{T}_h; \tag{5.2}$$

2. the following inf-sup condition is verified:

$$\mu_h \in R_k(\partial K), \quad \int_{\partial K} \mu_h\, v_h\, ds = 0 \qquad \forall v \in V_h^k(K) \quad \text{implies} \quad \mu_h = 0. \tag{5.3}$$

The first condition ensures that we end up with a square system. The second condition forces a restriction on the minimum order of the polynomial space for v_h. There is no need of such a condition for the term $\int_{\partial K} \lambda_h\, \boldsymbol{q}_h \cdot \boldsymbol{n}\, ds$ since both λ_h and the normal traces of functions in $W_h^k(K)$ are *discontinuous* on ∂K.

In the construction procedure, we must distinguish between the case when k is an even or an odd integer. Indeed, using the results stated by Lemmas 4 and 6 in [35] (where the same compatibility problem occurs), we have that condition (5.3) holds if

$$\begin{cases} v_h \in \mathbb{P}_{k+1}(K) & \text{for } k \text{ even, } k \geq 0, \\ v_h \in \widehat{\mathbb{P}}(K),\ \mathbb{P}_{k+1}(K) \subset \widehat{\mathbb{P}}(K) \subset \mathbb{P}_{k+2}(K) & \text{for } k \text{ odd, } k \geq 1. \end{cases} \tag{5.4}$$

In the first case (k even), the family of finite element spaces is immediately built by setting $V_h^k(K) = \mathbb{P}_{k+1}(K)$ and then suitably saturating the degrees of freedom implied by (5.2)

$$\dim(W_h^k(K)) = \dim(\mathcal{V}_h^k(K)) - \dim(V_h^k(K)) = k^2 + 5k + 3 \qquad \forall K \in \mathcal{T}_h \tag{5.5}$$

by choosing $W_h^k(K) = \mathbb{BDFM}_{k+1}(K)$, $k \geq 0$ (for the definition of this space and its properties, see [13, 14]).

The situation is more complicated when k is odd. In this case the choice $v_h \in \mathbb{P}_{k+1}(K)$ is not allowed by (5.4), while the choice $v_h \in \mathbb{P}_{k+2}(K)$ is acceptable but unnecessarily expensive. In [35] it has been shown that in order to satisfy condition (5.4) it is sufficient to enrich the space $\mathbb{P}_{k+1}(K)$ with a single additional degree of freedom suitably excerpted from the space $\mathbb{P}_{k+2}(K)$. Setting thus $V_h^k(K) = \widehat{\mathbb{P}}(K)$, relation (5.2) becomes for each $K \in \mathcal{T}_h$

$$\dim(W_h^k(K)) = \dim(\mathcal{V}_h^k(K)) - \dim(V_h^k(K)) = k^2 + 5k + 2. \tag{5.6}$$

A possible choice is then

$$W_h^k(K) = \mathbb{RT}_k(K) \oplus B_{k-1}(K) \oplus B_k(K) \oplus \cdots \oplus B_{2k-3}(K), \qquad k \geq 1,$$

where $(k+1)(k+3)$ degrees of freedom are saturated by the $\mathbb{RT}_k$ space and the remaining $(k-1)$ degrees of freedom are saturated by adding $(k-1)$ bubble functions B_l defined as (see [38]) $B_l(K) = \{\boldsymbol{q} \mid \boldsymbol{q} = \mathrm{curl}\,(b_K w)\}$, with $w \in \mathbb{P}_l(K)$, $b_K = \prod_{i=1}^{3} z_i(\boldsymbol{x})$, z_i, $i = 1, 2, 3$, being the barycentric coordinates in K.

To summarize, the family of DPG$_k$ finite element spaces is defined as

$$X_h^k(K) = \mathbb{P}_k(K) \times R_k(\partial K), \qquad Y_h^k(K) = (\mathbb{P}_k(K))^2 \times R_k(\partial K), \quad k = 0, 1, 2, \dots,$$

and letting $m = 0, 1, 2, \dots,$ we have

$$\begin{cases} W_h^{2m}(K) = \mathbb{BDFM}_{2m+1}(K), \quad V_h^{2m}(K) = \mathbb{P}_{2m+1}(K), \qquad k = 2m, \\ W_h^{2m+1}(K) = \mathbb{RT}_{2m+1}(K) \oplus B_{2m}(K) \cdots \oplus B_{4m-1}(K),\ V_h^{2m+1}(K) = \widehat{\mathbb{P}}(K), \\ \qquad k = 2m+1. \end{cases}$$

Notice that with the above choices the matrix arising from the term $\int_{\partial K} \lambda_h \boldsymbol{q}_h \cdot \boldsymbol{n}\, ds$ is always square and nonsingular since both $\lambda_h|_{\partial K}$ and $\boldsymbol{q}_h \cdot \boldsymbol{n}|_{\partial K}$ belong to the same finite element space due to the properties of the $\mathbb{RT}_k$ and $\mathbb{BDFM}_{k+1}$ spaces (see [14, Chap. 3]).

6. Stability and convergence analysis of the approximate DPG$_0$ solution.

In this section and in the remainder of the article, we focus our attention on the member of the DPG$_k$ family of lowest degree, the DPG$_0$ finite element. Numerical results on the convergence performance of higher order elements of the family can be found in [10].

6.1. Existence and uniqueness of the DPG$_0$ solution.

We start proving the uniqueness (and thus the existence) of the solution of problem (4.1). To do so, we characterize the discrete null spaces $\mathcal{K}_1^h$ and $\mathcal{K}_2^h$ as

$$\begin{aligned} \mathcal{K}_1^h &= \{\boldsymbol{q}_h \in W_h \,|\, b_1(\widetilde{u}_h, \boldsymbol{q}_h) = 0 \,\forall \widetilde{u}_h \in X_h\} \\ &= \{\boldsymbol{q}_h \in W_h \,|\, \boldsymbol{q}_K \cdot \boldsymbol{n}_K + \boldsymbol{q}_{K'} \cdot \boldsymbol{n}_{K'} = 0 \ \forall e_{K-K'},\ \operatorname{div} \boldsymbol{q}_h = 0 \text{ in } \Omega\}, \\ \mathcal{K}_2^h &= \{\widetilde{\boldsymbol{\sigma}}_h \in Y_h \,|\, b_2(\widetilde{\boldsymbol{\sigma}}_h, v_h) = 0 \,\forall v \in V_h\} \\ &= \{\boldsymbol{\sigma}_h \in \Sigma \,|\, \boldsymbol{\sigma}_K \cdot \boldsymbol{n}_K + \boldsymbol{\sigma}_{K'} \cdot \boldsymbol{n}_{K'} = 0 \ \forall e_{K-K'};\ \mu_h = \boldsymbol{\sigma}_h \cdot \boldsymbol{n} \text{ on } \partial K \ \forall K \in \mathcal{T}_h\}. \end{aligned}$$

The continuous bilinear forms $b_1(\cdot, \cdot)$ and $b_2(\cdot, \cdot)$ induce the following orthogonal decompositions in terms of the closed subspaces $\mathcal{K}_1^h$ and $\mathcal{K}_2^h$, respectively:

$$W_h = \mathcal{K}_1^h \oplus \mathcal{W}_1^h \quad \text{and} \quad Y_h = \mathcal{K}_2^h \oplus \mathcal{W}_2^h, \quad \text{where } \mathcal{W}_1^h = \mathcal{K}_1^{h,\perp},\ \mathcal{W}_2^h = \mathcal{K}_2^{h,\perp}.$$

Moreover, the following properties hold.

PROPOSITION 6.1. *There exists a constant $\delta' > 0$ independent of h such that*

$$\begin{aligned} &\sup\nolimits_{\boldsymbol{q}_h \in \mathcal{K}_1^h} a(\widetilde{\boldsymbol{\sigma}}_h, \boldsymbol{q}_h) \geq \delta' ||\boldsymbol{\sigma}_h||_{0,\Omega}\, ||\boldsymbol{q}_h||_{0,\Omega} \quad \forall \widetilde{\boldsymbol{\sigma}}_h \in \mathcal{K}_2^h, \\ &\sup\nolimits_{\boldsymbol{\sigma}_h \in \mathcal{K}_2^h} a(\widetilde{\boldsymbol{\sigma}}_h, \boldsymbol{q}_h) > 0 \quad \forall \boldsymbol{q}_h \in \mathcal{K}_1^h, \boldsymbol{q}_h \neq 0. \end{aligned} \tag{6.1}$$

Proof. Let $\widetilde{\boldsymbol{\sigma}}_h \in \mathcal{K}_2^h$ and take $\boldsymbol{q}_h^* \in \mathcal{K}_1^h$. Condition $(6.1)_1$ is immediately verified with $\delta' = 1$ by taking $\boldsymbol{q}_h^* = \widetilde{\boldsymbol{\sigma}}_h$ since $a(\widetilde{\boldsymbol{\sigma}}_h, \boldsymbol{q}_h^*) = ||\boldsymbol{\sigma}_h||_{0,\Omega}\, ||\boldsymbol{q}_h^*||_{0,\Omega}\ \forall\, \widetilde{\boldsymbol{\sigma}}_h \in \mathcal{K}_2^h$. Now let $\boldsymbol{q}_h \in \mathcal{K}_1^h$, $\boldsymbol{q}_h \neq 0$ and $\widetilde{\boldsymbol{\sigma}}_h^* \in \mathcal{K}_2^h$. Taking $\widetilde{\boldsymbol{\sigma}}_h^* = \boldsymbol{q}_h$, condition $(6.1)_2$ is immediately verified. □

PROPOSITION 6.2. *There exists a constant $\gamma_1' > 0$ independent of h such that*

$$\sup_{\boldsymbol{q}_h \in W_h} b_1(\widetilde{u}_h, \boldsymbol{q}_h) \geq \gamma_1' ||u_h||_{0,\Omega} ||\boldsymbol{q}_h||_{0,\Omega} \quad \forall \widetilde{u}_h \in X_h. \tag{6.2}$$

Proof. Let $\widetilde{u}_h \in X_h$ and take $\boldsymbol{q}^* \in W_h$ such that $\boldsymbol{q}^*_K \cdot \boldsymbol{n}_K + \boldsymbol{q}^*_{K'} \cdot \boldsymbol{n}_{K'} = 0$ on $e_{K-K'}$ $\forall K, K' \in \mathcal{T}_h$. Then using Lemma 7.2.1 of [34] and noting that $||\boldsymbol{q}_h||_{H(\text{div};\Omega)} \geq ||\boldsymbol{q}_h||_{0,\Omega}$, condition (6.2) immediately follows. □

To prove the discrete inf-sup condition for the bilinear form $b_2(\cdot,\cdot)$, we need to introduce the space $\widetilde{V} = \prod_{K\in\mathcal{T}_h}(H^1(K) \setminus \mathbb{R})$, equipped with the norm $|||v|||_{\widetilde{V}} = (\sum_{K\in\mathcal{T}_h} |v|^2_{1,K})^{1/2}$. Notice that this norm is indeed a norm on the space $\widetilde{V}$ and is equivalent to the norm $||\cdot||_V$ for functions $v \in \widetilde{V}$. We also consider a finite-dimensional approximation of $\widetilde{V}$, i.e., the space $\widetilde{V}_h \subset \widetilde{V}$ defined as $\widetilde{V}_h = \prod_{K\in\mathcal{T}_h} \mathbb{P}_1(K) \setminus \mathbb{R}$.

PROPOSITION 6.3. *There exists a constant $\gamma'_2 > 0$ independent of h such that*

$$\sup_{\widetilde{\boldsymbol{\sigma}}_h \in Y_h} b_2(\widetilde{\boldsymbol{\sigma}}_h, v_h) \geq \gamma'_2 ||\boldsymbol{\sigma}_h||_{0,\Omega} |||v_h|||_{\widetilde{V}} \quad \forall v_h \in \widetilde{V}_h. \tag{6.3}$$

Proof. Let $v_h \in \widetilde{V}_h$. Take $\boldsymbol{\sigma}^*_h \in \Sigma_h$ such that $\boldsymbol{\sigma}^*_h = \nabla v_h$ on K $\forall v_h \in \widetilde{V}_h$, $\forall K \in \mathcal{T}_h$ and set $\mu^*_h \equiv 0$. Then we have $b_2(\widetilde{\boldsymbol{\sigma}}^*_h, v_h) = ||\boldsymbol{\sigma}^*_h||_{0,\Omega} |||v_h|||_{\widetilde{V}}$, and (6.3) immediately follows with $\gamma'_2 = 1$. □

Remark 6.1. The above proof reveals that the choice $v_h =$ constant on each $K \in \mathcal{T}_h$ by itself does not allow us to state condition (6.3). However, taking $v_h = 1$ on K and equal to zero elsewhere is a possible and significant choice since it provides the local conservation property of the DPG formulation $-\int_{\partial K} \mu_h \, ds = \int_K f \, dx$. Moreover, a global conservation property can be shown to hold as well by taking $v_h \equiv 1$ on Ω, yielding the relation $-\int_\Gamma \mu_h \, ds = \int_\Omega f \, dx$. A detailed discussion of this subject will be carried out in section 9.

Remark 6.2. Choosing $\boldsymbol{\sigma}^*_h = 0$, the bilinear form $b_2(\cdot,\cdot)$ yields the familiar relation of primal hybrid formulations $\sum_{K\in\mathcal{T}_h} \int_K \mu_h v_h = 0$ $\forall v_h \in V_h$, which admits the unique solution $\mu_h \equiv 0$.

The following theorem is an immediate consequence of the previous results.

THEOREM 6.4. *The DPG$_0$ approximation of problem* (2.2) *admits a unique solution* $(\widetilde{u}_h, \widetilde{\boldsymbol{\sigma}}_h) \in (X_h \times Y_h)$.

6.2. Error estimates.

In the following sections we establish optimal error estimates for the mixed variables u_h and $\boldsymbol{\sigma}_h$ and for the hybrid variables λ_h and μ_h.

6.2.1. Projection operators.

In view of the error analysis of the DPG formulation, it is useful to introduce some approximation operators. We denote by P_K the projection operator from $L^2(K)$ onto $\mathbb{P}_0(K)$ satisfying the approximation property

$$||v - P_K v||_{0,K} \leq Ch|v|_{1,K} \qquad \forall v \in H^1(K). \tag{6.4}$$

From the operator P_K, for all $v \in L^2(\Omega)$, we construct the global operator P_h as

$$P_h v|_K = P_K v \qquad \forall K \in \mathcal{T}_h. \tag{6.5}$$

We also need to introduce the projection operator ρ^0_h from $\prod_{K\in\mathcal{T}_h} L^2(\partial K)$ onto $R_0(\partial K)$ such that, for all $\lambda \in \prod_{K\in\mathcal{T}_h} L^2(\partial K)$, we have

$$\int_{\partial K} (\rho^0_h \lambda - \lambda) r_0 \, ds = 0 \qquad \forall r_0 \in R_0(\partial K), \qquad \forall K \in \mathcal{T}_h. \tag{6.6}$$

Remark 6.3. The operator ρ^0_h is well defined since, by Sobolev's embedding theorem [27, 28], we have that $W^{1/q,p}(\partial K) \hookrightarrow L^2(\partial K)$.

6.2.2. Error estimates for the mixed variables. The following optimal error estimates hold.

THEOREM 6.5. *Let $(u, \boldsymbol{\sigma})$ be the solution of* (3.3) *and let $(u_h, \boldsymbol{\sigma}_h)$ be the solution of* (4.1). *If $\boldsymbol{\sigma} \in (H^1(\Omega))^2$, then there exists a positive constant C independent of h such that*

$$\begin{aligned} ||u - u_h||_{0,\Omega} &\leq Ch(|u|_{1,\Omega} + |\boldsymbol{\sigma}|_{1,\Omega}), \\ ||\boldsymbol{\sigma} - \boldsymbol{\sigma}_h||_{0,\Omega} &\leq Ch|\boldsymbol{\sigma}|_{1,\Omega}. \end{aligned} \tag{6.7}$$

Proof. From (3.3) and (4.1) we have

$$\left\{ \begin{array}{lclcll} a(\widetilde{\boldsymbol{\sigma}} - \widetilde{\boldsymbol{\sigma}}_h, \boldsymbol{q}_h) & + & b_1(\widetilde{u} - \widetilde{u}_h, \boldsymbol{q}_h) & = & 0 & \forall \boldsymbol{q}_h \in W_h, \\ b_2(\widetilde{\boldsymbol{\sigma}} - \widetilde{\boldsymbol{\sigma}}_h, v_h) & & & = & 0 & \forall v_h \in V_h. \end{array} \right. \tag{6.8}$$

Taking $\boldsymbol{q}_h \in \mathcal{K}_1^h$, the first relation in (6.8) becomes

$$a(\widetilde{\boldsymbol{\sigma}} - \widetilde{\boldsymbol{\sigma}}_h, \boldsymbol{q}_h) = 0 \qquad \forall \boldsymbol{q}_h \in \mathcal{K}_1^h. \tag{6.9}$$

Let us introduce the decomposition $\widetilde{\boldsymbol{\sigma}}_h = (\boldsymbol{\sigma}_h, \mu_h) = \widetilde{\boldsymbol{\sigma}}_h^0 + \widetilde{\boldsymbol{\sigma}}_h^\perp$, where $\widetilde{\boldsymbol{\sigma}}_h^0 = (\boldsymbol{\sigma}_h^0, \mu_h^0) \in \mathcal{K}_2^h$ and $\widetilde{\boldsymbol{\sigma}}_h^\perp = (\boldsymbol{\sigma}_h^\perp, \mu_h^\perp) \in \mathcal{W}_2^h$. Introducing the projection operator $\widetilde{\Pi}_h = ((P_h)^2, \rho_h^0)$, where P_h and ρ_h^0 have been defined in (6.5) and (6.6), respectively, and using the decomposition $\sigma_h = (\boldsymbol{\sigma}_h^0 + \boldsymbol{\sigma}_h^\perp)$, equation (6.9) reads

$$a((\widetilde{\Pi}_h \boldsymbol{\sigma})^0 - \boldsymbol{\sigma}_h^0, \boldsymbol{q}_h) = a(\widetilde{\Pi}_h \boldsymbol{\sigma} - \boldsymbol{\sigma}, \boldsymbol{q}_h) + a(\boldsymbol{\sigma}_h^\perp - (\widetilde{\Pi}_h \boldsymbol{\sigma})^\perp, \boldsymbol{q}_h) \qquad \forall \boldsymbol{q}_h \in \mathcal{K}_1^h,$$

which, using the coercivity and continuity of the bilinear form $a(\cdot,\cdot)$, yields

$$||(\widetilde{\Pi}_h \boldsymbol{\sigma})^0 - \boldsymbol{\sigma}_h^0||_{0,\Omega} \leq (||\widetilde{\Pi}_h \boldsymbol{\sigma} - \boldsymbol{\sigma}||_{0,\Omega} + ||(\widetilde{\Pi}_h \boldsymbol{\sigma})^\perp - \boldsymbol{\sigma}_h^\perp||_{0,\Omega}). \tag{6.10}$$

Now we need to bound the quantity $||(\widetilde{\Pi}_h \boldsymbol{\sigma})^\perp - \boldsymbol{\sigma}_h^\perp||_{0,\Omega}$. Using (6.5) into $(6.8)_2$, we get

(6.11)
$$b_2(\widetilde{\Pi}_h \widetilde{\boldsymbol{\sigma}} - \widetilde{\boldsymbol{\sigma}}_h, v_h) = b_2(\widetilde{\Pi}_h \widetilde{\boldsymbol{\sigma}} - \widetilde{\boldsymbol{\sigma}}, v_h) = -\sum_{K \in \mathcal{T}_h} \int_{\partial K} (\rho_h^0 \mu - \mu) v_h \, ds \qquad \forall v_h \in V_h.$$

Recalling Lemma 9 in [35], we have that

$$\int_{\partial K} (\boldsymbol{\sigma} \cdot \boldsymbol{n} - \rho_h^0 \mu) v \, ds \leq C \frac{h_K}{\rho_K} |\boldsymbol{\sigma}|_{1,K} |v|_{1,K} \qquad \forall v \in H^1(K).$$

Using this latter relation in (6.11) and the discrete inf-sup condition for $b_2(\cdot,\cdot)$, we get the estimate

$$||(\widetilde{\Pi}_h \boldsymbol{\sigma})^\perp - \boldsymbol{\sigma}_h^\perp||_{0,\Omega} \leq Ch|\boldsymbol{\sigma}|_{1,\Omega}. \tag{6.12}$$

Now, gathering (6.10) and (6.12) and using the triangle inequality, we get $(6.7)_2$.

Let us now prove $(6.7)_1$. Taking $\boldsymbol{q}_h \in \mathcal{W}_1^h$ in the first equation of (6.8) we get

$$b_1(\widetilde{u} - \widetilde{u}_h, \boldsymbol{q}_h) = a(\boldsymbol{\sigma}_h - \boldsymbol{\sigma}, \boldsymbol{q}_h) \qquad \forall \boldsymbol{q}_h \in \mathcal{W}_1^h.$$

Introducing the projection operator $\widetilde{P}_h = (P_h, \rho_h^0)$, we write the latter relation as

$$b_1(\widetilde{P}_h \widetilde{u} - \widetilde{u}_h, \boldsymbol{q}_h) = a(\boldsymbol{\sigma}_h - \boldsymbol{\sigma}, \boldsymbol{q}_h) \qquad \forall \boldsymbol{q}_h \in \mathcal{W}_1^h.$$

Then using the discrete inf-sup condition for $b_1(\cdot,\cdot)$, we get

$$||P_h u - u_h||_{0,\Omega} \leq C||\boldsymbol{\sigma} - \boldsymbol{\sigma}_h||_{0,\Omega} \leq Ch|\boldsymbol{\sigma}|_{1,\Omega}. \tag{6.13}$$

Eventually, using $(6.7)_2$, (6.4), and the triangle inequality, we get $(6.7)_1$. □

6.3. Error estimates for the hybrid variables. In this section, we derive a priori error estimates for the discretization errors associated with the hybrid variables λ_h and μ_h. In doing this, we shall prove some equivalence results between the DPG_0 method and hybrid formulations, both of primal and dual type.

To start with, we let $W_{h,0}^{NC}$ denote the set of nonconforming functions in V_h that are affine on each $K \in \mathcal{T}_h$ and are continuous at the midpoint of each edge and vanish at the midpoint of each edge of Γ. Then, we define $u_h^* \in W_{h,0}^{NC}$ as the piecewise linear nonconforming function such that

$$\int_{\partial K} u_h^* \, \eta_h \, ds = \int_{\partial K} \lambda_h \, \eta_h \, ds \qquad \forall \eta_h \in R_0(\partial K), \qquad \forall K \in \mathcal{T}_h, \tag{6.14}$$

which implies in particular that $u_h^*(x_{MP,i}) = \lambda_{h,e_i}$ for each edge $e_i \in \partial K$, $x_{MP,i}$ being the coordinate vector of the midpoint of e_i. Using the fact that $\boldsymbol{q}_h \cdot \boldsymbol{n}_K \in R_0(\partial K)$ and (6.14), we get

$$\int_{\partial K} \lambda_h \boldsymbol{q}_h \cdot \boldsymbol{n}_K \, ds = \int_{\partial K} u_h^* \boldsymbol{q}_h \cdot \boldsymbol{n}_K \, ds = \int_K u_h^* \mathrm{div} \boldsymbol{q}_h \, dx + \int_K \boldsymbol{q}_h \cdot \nabla u_h^* \, dx \ \ \forall \boldsymbol{q}_h \in W_h(K).$$

Substituting this latter expression in $(4.1)_1$, we obtain

$$\int_K (\boldsymbol{\sigma}_h - \nabla u_h^*) \cdot \boldsymbol{q}_h \, dx + \int_K (u_h - u_h^*) \mathrm{div} \boldsymbol{q}_h \, dx = 0 \qquad \forall \boldsymbol{q}_h \in W_h(K). \tag{6.15}$$

Taking $q_h \in (\mathbb{P}_0(K))^2$ in (6.15) yields

$$\boldsymbol{\sigma}_h^K = \nabla u_h^* \qquad \forall K \in \mathcal{T}_h, \tag{6.16}$$

while taking $q_h = (x, y)^T$ in (6.15) and using (6.14) yields

$$u_h^K = \frac{\int_K u_h^* \, dx}{|K|} = P_K u_h^* = \frac{1}{3} \sum_{i=1}^{3} \lambda_{h,e_i} \qquad \forall K \in \mathcal{T}_h. \tag{6.17}$$

Relation (6.17) shows that u_h^K is the *average value* of u_h^* on K and thus the average value of the hybrid variables λ_h on the edges of the element. Let us now consider $(4.1)_2$ and take $v_h \in W_{h,0}^{NC}$. Equation $(4.1)_2$ becomes

$$\sum_{K \in \mathcal{T}_h} \int_K \nabla u_h^* \cdot \nabla v_h \, dx = \sum_{K \in \mathcal{T}_h} \int_K f v_h \, dx \qquad \forall v_h \in W_{h,0}^{NC}. \tag{6.18}$$

Relation (6.18) shows that u_h^* actually *coincides* with the solution $u_h^{NC} \in W_{h,0}^{NC}$ of problem (2.1), which is obtained with the nonconforming finite element approximation (see [35]).

Then, the following error estimate can be proved.

THEOREM 6.6. *Let u be the solution of problem* (2.1) *such that $u \in H^2(\Omega) \cap H_0^1(\Omega)$, and let u_h^* be the solution of problem* (6.18) *such that* (6.14) *holds. Then, under the assumption that the polygonal domain Ω is convex, we have (see* [35]*)*

$$||u - u_h^*||_{0,\Omega} \leq C h^2 |u|_{2,\Omega}. \tag{6.19}$$

The above theorem is a superconvergence result for the piecewise linear nonconforming extension over Ω of the hybrid variable λ_h computed by the DPG_0 formulation. Moreover, the estimate (6.19) can be regarded as the counterpart for the DPG formulation of Theorem 2.2 in [1] valid for the dual-mixed method with hybridization.

Considering again $(4.1)_2$ and taking this time $v_h \in V_h$, we obtain

$$\int_{\partial K} \mu_h \, v_h \, ds = \int_K \nabla u_h^* \cdot \nabla v_h \, dx - \int_K f v_h \, dx \qquad \forall v_h \in V_h(K), \quad \forall K \in \mathcal{T}_h, \tag{6.20}$$

which coincides with the postprocessing procedure discussed in [37, section 19] for the primal-hybrid formulation. This result actually demonstrates that the hybrid field μ_h computed by the DPG$_0$ approximation coincides with the field $\mathbf{p}_h \cdot \boldsymbol{n}$ computed by the primal-hybrid formulation. We then have the following result.

Theorem 6.7. *Under the assumptions of Theorem* 6.6 *and the condition stated in Remark* 6.2*, we have*

$$||\boldsymbol{\sigma} \cdot \boldsymbol{n} - \mu_h||_{-1/2,h} \leq Ch|\boldsymbol{\sigma}|_{1,\Omega},$$

where $\forall \xi \in R_0(\partial K)$ *we define the norm* $||\xi||_{-1/2,h} = (\sum_{e\in\mathcal{E}_h} |e|||\xi||_{0,e}^2)^{1/2}$ *(see* [1]*).*

Proceeding along the above guideline, it is possible to further explore the connection existing between the DPG$_0$ formulation and the dual-mixed method. In view of establishing this connection, we assume henceforth f to be piecewise constant over $\mathcal{T}_h$. Under this hypothesis, we can use the following result proved in [29]:

$$\begin{aligned} u_h^{DM} - P_K u_h^* &= u_h^{DM} - u_h^K = -\frac{f^K}{4}\left(|x_{CG,K}^2| - \frac{1}{|K|}\int_K |x|^2 \, dx\right) \\ &= \frac{1}{144} f^K \sum_{i=1}^{3} |e_i|^2 = \mathcal{O}(h_K^2) \qquad \forall K \in \mathcal{T}_h, \end{aligned} \tag{6.21}$$

where $x_{CG,K}$ is the coordinate vector of the center of gravity of K and $u_h^{DM} \in \mathbb{P}_0(K)$ is the solution computed by the dual-mixed method. Using the result (6.21) and recalling the standard estimates for the dual-mixed approximation (see [23, 14]) gives by the triangle inequality the following result.

Theorem 6.8. *Let* $(u, \boldsymbol{\sigma})$ *be the solution of* (2.1) *and* $(u_h, \boldsymbol{\sigma}_h)$ *be the solution of* (4.1)*. If the triangulation* $\mathcal{T}_h$ *is uniformly regular and* $\boldsymbol{\sigma} \in (H^1(\Omega))^2$, $\mathrm{div}\boldsymbol{\sigma} \in H^1(\Omega)$, *then*

$$||P_h u - u_h||_{0,\Omega} \leq Ch^2(|\boldsymbol{\sigma}|_{1,\Omega}| + |\mathrm{div}\boldsymbol{\sigma}|_{1,\Omega}). \tag{6.22}$$

Relation (6.22) can be interpreted as a superconvergence result for u_h at the center of gravity of each triangle K. This latter result also allows us to derive an optimal estimate for the quantity $||\rho_h^0 \lambda - \lambda_h||_{1/q,p,\partial K}$. To proceed, we first need to recall the following result [23].

Lemma 6.9. *For all* $T \in W^{-1/q,q}(\partial K)$ *there exists a unique* $\boldsymbol{q}_h \in \mathbb{RT}_0(K)$ *such that* $\forall K \in \mathcal{T}_h$ *we have*

$$\int_{\partial K} (\boldsymbol{q}_h \cdot \boldsymbol{n} - T) \, r_0 \, ds = 0 \qquad \forall r_0 \in R_0(\partial K). \tag{6.23}$$

Furthermore, if $\mathcal{T}_h$ *is uniformly regular, then there is a constant* C *independent of* K *such that*

$$||\boldsymbol{q}_h||_{0,K} \leq Ch^{2/p-1}||T||_{-1/q,q,\partial K}, \quad ||\mathrm{div}\boldsymbol{q}_h||_{0,K} \leq Ch^{2/p-2}||T||_{-1/q,q,\partial K}, \tag{6.24}$$

where the norm $||.||_{-1/q,q,\partial K}$ *has been defined in* (3.1)*.*

For the definition of a uniformly regular triangulation, see [18].

We are now in a position to state the following result.

THEOREM 6.10. *Under the assumptions of Theorem* 6.8*, we have*

$$||\rho_h^0\lambda - \lambda_h||_{1/q,p,\partial K} \le Ch^{2/p}\,(|\boldsymbol{\sigma}|_{1,\Omega} + |\mathrm{div}\boldsymbol{\sigma}|_{1,\Omega}) \qquad \forall K \in \mathcal{T}_h. \tag{6.25}$$

Proof. Let $\boldsymbol{q}$ be any element of $W_q(\mathrm{div};K)$ and let $\overline{\boldsymbol{q}}_h \in \mathbb{RT}_0(K)$ be defined by (6.23) with $T = \boldsymbol{q}\cdot\boldsymbol{n}|_{\partial K}$ and such that $\boldsymbol{q}_h|_K = \overline{\boldsymbol{q}}_h$, $\boldsymbol{q}_h|_{K'} = 0\ \forall K' \neq K$, $\forall K \in \mathcal{T}_h$. Subtracting the first equation of (4.1) from the first equation of (3.3), we get

$$\int_{\partial K} \overline{\boldsymbol{q}}_h \cdot \boldsymbol{n}(\lambda - \lambda_h)\,ds = \int_K (\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)\cdot\overline{\boldsymbol{q}}_h\,dx + \int_K (u - u_h)\,\mathrm{div}\overline{\boldsymbol{q}}_h\,dx,$$

which can be written as

$$\int_{\partial K} \overline{\boldsymbol{q}}_h \cdot \boldsymbol{n}(\rho_h^0\lambda - \lambda_h)\,ds = \int_K (\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)\cdot\overline{\boldsymbol{q}}_h\,dx + \int_K (P_K u - u_h)\,\mathrm{div}\overline{\boldsymbol{q}}_h\,dx.$$

Owing to the definition of $\overline{\boldsymbol{q}}_h$, using (6.24), (6.22), and the definition (3.2), we eventually get the estimate (6.25). □

Since $p < 2$, estimate (6.25) can be regarded as a superconvergence property for λ_h.

To conclude our equivalence analysis, we show that

$$\mu_h^K = \boldsymbol{\sigma}_h^{DM}\cdot\boldsymbol{n}_K \qquad \forall K \in \mathcal{T}_h, \tag{6.26}$$

where $\boldsymbol{\sigma}_h^{DM} \in \mathbb{RT}_0(K)$ is the solution computed by the dual-mixed method. We recall the following result proved in [29]:

$$\boldsymbol{\sigma}_h \equiv \nabla u_h^* = \boldsymbol{\sigma}_h^{DM} + (x - x_{CG})\frac{f^K}{2} \qquad \forall K \in \mathcal{T}_h.$$

Substituting the above relation into $(4.1)_2$, integrating by parts, and observing that $\mathrm{div}\boldsymbol{\sigma}_h^{DM} + f^K = 0$, we obtain

$$\int_{\partial K} (\mu_h^K - \boldsymbol{\sigma}_h^{DM}\cdot\boldsymbol{n}_K)v_h\,dx = 0 \qquad \forall v_h \in \mathbb{P}_1(K),$$

which clearly implies $\mu_h = \boldsymbol{\sigma}_h^{DM}\cdot\boldsymbol{n}_K$ on ∂K. This result shows that the values μ_h are actually the degrees of freedom of the variable $\boldsymbol{\sigma}_h^{DM}$ and as such provide a simple procedure to recover a self-equilibrated stress field within each element satisfying interelement traction reciprocity.

6.4. Elliptic problem with variable coefficients.

We come now to briefly addressing the extension of the DPG$_0$ method to the case of an elliptic model problem with variable coefficients. With this aim, we consider the Poisson problem

$$-\mathrm{div}(a(x)\nabla u) = f \quad \text{in} \quad \Omega, \qquad u = 0 \quad \text{on} \quad \Gamma, \tag{6.27}$$

where $a = a(x)$ is a symmetric positive definite matrix-valued function. The mixed form of (6.27) reads

$$-\mathrm{div}\,\boldsymbol{\sigma} = f \quad \text{in} \quad \Omega, \qquad \boldsymbol{\sigma} = a(x)\nabla u \quad \text{in} \quad \Omega, \qquad u = 0 \quad \text{on} \quad \Gamma. \tag{6.28}$$

In this case, the discrete formulation (4.1) becomes find $(u_h, \lambda_h; \boldsymbol{\sigma}_h, \mu_h) \in (X_h \times Y_h)$ such that

(6.29)
$$\begin{cases} \displaystyle\sum_{K\in\mathcal{T}_h} \left(\int_K a^{-1}\boldsymbol{\sigma}_h \cdot \boldsymbol{q}_h \, dx + \int_K u_h \mathrm{div}\boldsymbol{q}_h \, dx - \int_{\partial K} \lambda_h \, \boldsymbol{q}_h \cdot \boldsymbol{n} \, ds \right) = 0 & \forall \boldsymbol{q}_h \in W_h, \\ \displaystyle\sum_{K\in\mathcal{T}_h} \left(\int_K \boldsymbol{\sigma}_h \cdot \nabla v_h \, dx - \int_{\partial K} \mu_h \, v_h \, ds \right) = \int_\Omega f v_h \, dx & \forall v_h \in V_h. \end{cases}$$

We again let u_h^* be a nonconforming approximation of the solution u of problem (6.27) satisfying (6.14). Taking $\boldsymbol{q}_h \in (\mathbb{P}_0(K))^2$ in $(6.29)_1$ and integrating by parts as done in the case $a(x) \equiv 1$, we obtain

$$\int_K \left(a^{-1}\boldsymbol{\sigma}_h \cdot \boldsymbol{q}_h - \nabla u_h^* \cdot \boldsymbol{q}_h \right) dx = 0 \qquad \forall K \in \mathcal{T}_h.$$

Upon introducing the *harmonic average* of $a(x)$ defined as $\widetilde{\alpha}_K := (\frac{1}{|K|}\int_K (a(x))^{-1}\, dx)^{-1}$, we immediately get the equivalence

$$\boldsymbol{\sigma}_h = \widetilde{\alpha}^{-1}\nabla u_h^* \qquad \forall K \in \mathcal{T}_h.$$

Taking $v_h \in W_{h,0}^{NC}$ in $(6.29)_2$ and using the previous relation yields

$$\sum_{K\in\mathcal{T}_h} \int_K \widetilde{\alpha}_K^{-1} \nabla u_h^* \cdot \nabla v_h \, dx = \sum_{K\in\mathcal{T}_h} \int_K f v_h \, dx \qquad \forall v_h \in W_{h,0}^{NC}, \tag{6.30}$$

demonstrating that u_h^* turns out to be the nonconforming approximation of problem (6.28) *with harmonic averaging of the coefficient* $a(x)$. It is relevant to observe that u_h^* actually differs from the solution u_h^{NC} of the standard nonconforming approximation of problem (6.28), which would simply read

$$\sum_{K\in\mathcal{T}_h} \int_K \overline{a}_K \, \nabla u_h^{NC} \cdot \nabla v_h \, dx = \sum_{K\in\mathcal{T}_h} \int_K f v_h \, dx \qquad \forall v_h \in W_{h,0}^{NC},$$

where $\overline{a}_K := \frac{1}{|K|}\int_K a(x)\, dx$ is the usual average of $a(x)$ on K. In the presence of strong variations of the coefficient a, the harmonic average is well known to provide superior accuracy and stability compared to the standard average (see [5, 1, 15, 31]).

7. Computer implementation of the DPG method. The object of the present section is to discuss an efficient computer implementation of the DPG$_0$ method. The main issue is to reduce the dimension of the algebraic linear system arising from (4.1). To start with, we consider the following system of 6 equations in 9 unknowns that arises from the contribution of each triangle in (4.1):

$$\begin{bmatrix} A & B & C & \emptyset \\ D & \emptyset & \emptyset & E \end{bmatrix} \begin{pmatrix} \boldsymbol{\sigma} \\ \mathbf{u} \\ \boldsymbol{\lambda} \\ \boldsymbol{\mu} \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ \mathbf{f} \end{pmatrix}, \tag{7.1}$$

where the bold symbols represent the vectors of unknowns and given data, and $\mathbf{f}$ is the right-hand side integral in $(4.1)_2$.

On the one hand, one can exploit the nature of hybrid formulations of the DPG method performing a static condensation of the internal variables in favor of the hybrid variables. Defining the new variable $\widehat{\boldsymbol{\sigma}} = [\boldsymbol{\sigma}, \mathbf{u}]^T$, system (7.1) can be rewritten as

$$\begin{bmatrix} \mathcal{A} & C & \emptyset \\ \mathcal{D} & \emptyset & E \end{bmatrix} \begin{pmatrix} \widehat{\boldsymbol{\sigma}} \\ \boldsymbol{\lambda} \\ \boldsymbol{\mu} \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ \mathbf{f} \end{pmatrix}, \qquad \text{with} \quad \mathcal{A} = [A,\, B]\,, \qquad \mathcal{D} = [D,\, \emptyset]\,. \tag{7.2}$$

The (3×3) matrix $\mathcal{A}$ is nonsingular, so that $\widehat{\boldsymbol{\sigma}}$ can be eliminated in favor of the sole edge variable $\boldsymbol{\lambda}$, obtaining the following reduced system of 3 equations in 6 interface unknowns:

$$-\mathcal{D}\mathcal{A}^{-1}C\boldsymbol{\lambda} + E\boldsymbol{\mu} = \mathbf{f} \qquad \forall K \in \mathcal{T}_h, \tag{7.3}$$

which is the algebraic form of (6.20). The matrix E is square and nonsingular because it emanates from the bilinear form $\int_{\partial K} \mu_h \, v_h \, ds$, $\mu_h \in R_0(\partial K)$, $v_h \in \mathbb{P}_1(K)$, which satisfies the discrete inf-sup condition. Therefore, we can eliminate $\boldsymbol{\mu}$ in favor of the sole unknown $\boldsymbol{\lambda}$:

$$\boldsymbol{\mu} = E^{-1}\mathcal{D}\mathcal{A}^{-1}C\boldsymbol{\lambda} + E^{-1}\mathbf{f} \qquad \forall K \in \mathcal{T}_h. \tag{7.4}$$

Enforcing the condition that the hybrid variable μ_h is single-valued on each internal edge yields a square symmetric and positive definite linear system for the sole unknown $\boldsymbol{\lambda}$ of dimension `Ni`.

On the other hand, one can instead exploit the DG nature of the DPG method, eliminating the hybrid variables (counterpart of the numerical fluxes) in favor of the internal variables. Since both E and C are square nonsingular matrices, $\boldsymbol{\lambda}$ and $\boldsymbol{\mu}$ can be eliminated in favor of $\widehat{\boldsymbol{\sigma}}$, obtaining on each element $K \in \mathcal{T}_h$

$$\boldsymbol{\lambda} = \mathcal{A}\widehat{\boldsymbol{\sigma}}, \qquad \boldsymbol{\mu} = E^{-1}(\mathbf{f} - \mathcal{D}\widehat{\boldsymbol{\sigma}}). \tag{7.5}$$

After some algebra, one sees that the first relation in (7.5) expresses λ_h on each element as a discrete Taylor expansion of u about the center of gravity of the element, while the second relation in (7.5) represents a *conservative finite volume-like* discretization of the equilibrium equation. Enforcing now the hybrid variables to be single-valued on each internal edge of the triangulation, we end up with a square nonsingular linear algebraic system of dimension 3`NE` in the sole internal (and fully discontinuous over $\mathcal{T}_h$) unknown vector $\widehat{\boldsymbol{\sigma}}$.

It is interesting to compare the computational effort associated with the two implementation approaches discussed above. Using Euler's theorem (2 `Ni` + `Nb` = 3`NE`) shows that the cost of the solution of the system in the discontinuous unknown $\widehat{\boldsymbol{\sigma}}$ *is (asymptotically) twice* the cost associated with the solution of the system in the sole hybrid unknown $\boldsymbol{\lambda}$. The superior efficiency of this latter formulation makes it preferable in computations, and it is the reason why it has been used in all of the numerical examples shown in the next sections.

8. Numerical results.

In this section we present the results obtained by applying the DPG$_0$ formulation to the numerical solution of two elliptic model problems.

8.1. Elliptic model problem 1.

We consider problem (2.1) on the unit square with $\Gamma \equiv \Gamma_D$, such that the exact solution is the "bubble function" $u = x(1-x)y(1-y)$, with the right-hand side f computed accordingly. In Figure 8.1 (left) we show the computed convergence rates using four different unstructured meshes for the quantities $||u - u_h||_{0,\Omega}$, ($\circ$); $||P_h u - u_h||_{0,\Omega}$, ($\nabla$); $||u - u_h^*||_{0,\Omega}$, ($\square$); and $||\rho_h^0 \lambda - \lambda_h||_{-1/2,h}$, ($*$), while in Figure 8.1 (right) we show the computed convergence rates for the quantities $||\boldsymbol{\sigma} - \boldsymbol{\sigma}_h||_{0,\Omega}$, ($\square$), and $||\rho_h^0 \mu - \mu_h||_{-1/2,h}$, ($\circ$). The computed errors are in agreement with the theoretical estimates of section 6.2.

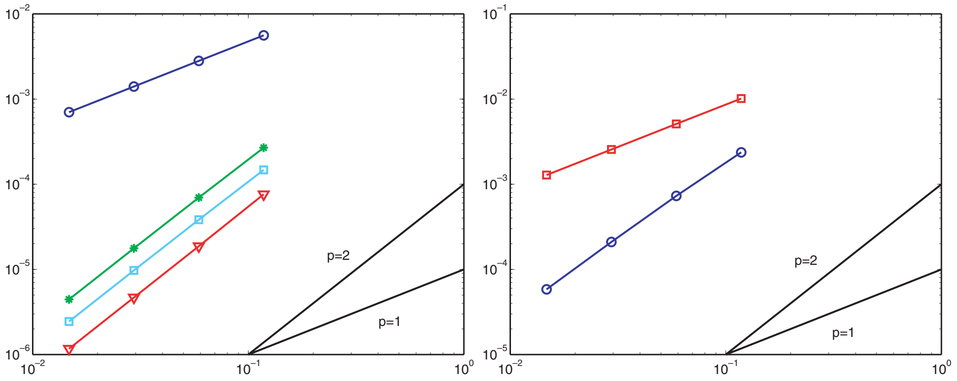

FIG. 8.1. *Error norms for the elliptic model problem* 1.

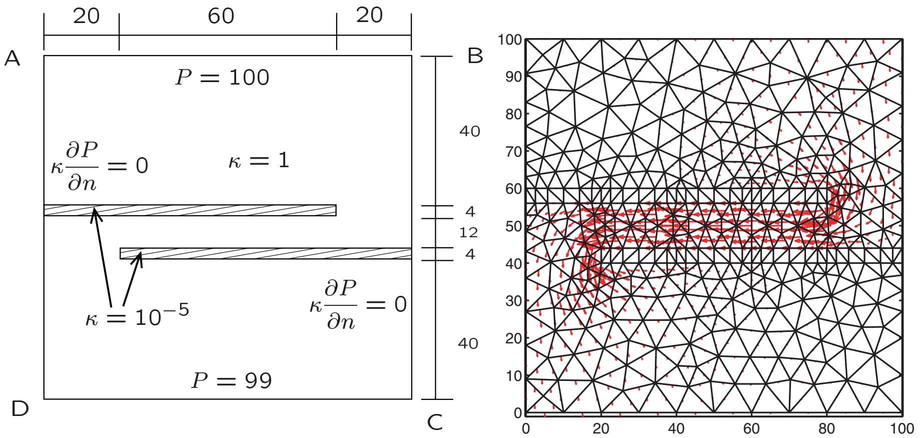

FIG. 8.2. *Problem setting for the flow in a porous medium (left) and associated velocity field (right).*

8.2. Elliptic model problem 2. We study the problem of a two-dimensional steady flow system in a porous medium modeled by Darcy's law [32]: find the hydraulic potential P and the associated velocity field $q = \kappa \nabla P$, where κ is the hydraulic conductivity tensor such that

$$\left\{ \begin{array}{llll} -\operatorname{div} q = 0 & \text{in} \quad \Omega, & q = \kappa \nabla P & \text{in} \quad \Omega, \\ P = P_D & \text{on} \quad \Gamma_D, & q \cdot n = q_N & \text{on} \quad \Gamma_N. \end{array} \right. \tag{8.1}$$

In Figure 8.2 (left) we show the computational domain, the boundary conditions, and the piecewise constant values of κ which are seen to attain strong variations on Ω. In Figure 8.2 (right), we show the velocity field represented as an $\mathbb{RT}_0$ finite element function reconstructed over $\overline{\Omega}$ from the computed values μ_h as in (6.20). The continuity of the normal component of the velocity field across interelement edges is a crucial property when computing the flow streamlines (see [32] for a discussion of this issue).

9. Conservation properties of the DPG method. The present section is aimed at enlightening through a numerical example the conservation properties of the DPG method. We observe that

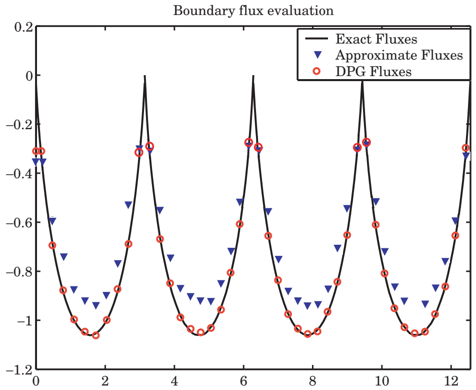

FIG. 9.1. *Exact fluxes on* Γ *compared with the fluxes computed by the* CG *method with no postprocessing and with the interface field* μ_h *computed by the* DPG$_0$ *method.*

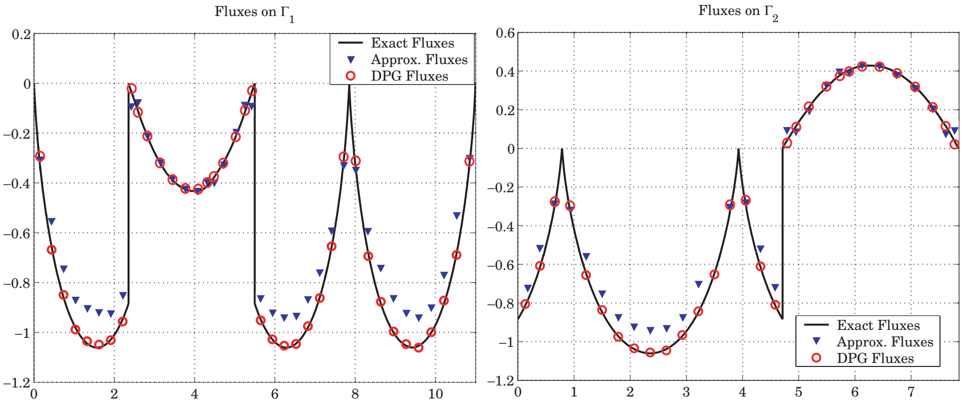

FIG. 9.2. *Exact fluxes on the boundaries* Γ_1 *(left) and* Γ_2 *(right) compared with the fluxes computed by the* CG *method with no postprocessing and interface fields computed by the* DPG$_0$ *method.*

1. integral global conservation is achieved by taking in (4.1) $\boldsymbol{q}_h \equiv [1,1]^T$ and $v_h \equiv 1$ in Ω, respectively;
2. integral local conservation is achieved by taking in (4.1) $\boldsymbol{q}_h = [1,1]^T$ and $v_h = 1$, in any subdomain $\mathcal{S} \subseteq \Omega$ and zero elsewhere, respectively.

In the standard continuous Galerkin (CG) method neither the first nor the second choice for the test function is admissible [26]. Recovering fluxes that enjoy the desired conservation properties requires a postprocessing procedure, thus adding additional computational cost to the basic CG discretization. Moreover, if, for example, a nodal flux approach is used as in [26], overshoots and undershoots appear when a node coincides with an endpoint of the interface, since there the flux is artificially enforced to be continuous.

To numerically assess these concepts, we solve the Poisson equation on the domain $\Omega = [0,\pi] \times [0,\pi]$ with $u = 0$ on $\Gamma = \partial\Omega$ and $f = 1$. To test local conservation properties, we split Ω into the subdomains $\Omega_1 = [0, \frac{3}{4}\pi] \times [0,\pi]$, $\Omega_2 = [\frac{3}{4}\pi, \pi] \times [0,\pi]$ such that $\Omega = \Omega_1 \cup \Omega_2$ and with boundaries Γ_1 and Γ_2, respectively. From the exact solution of the problem (see [40]), we compute the fluxes $\boldsymbol{\sigma} \cdot \boldsymbol{n} = \nabla u \cdot \boldsymbol{n}$ on Γ (Figure 9.1), Γ_1 (Figure 9.2, left), and Γ_2 (Figure 9.2, right) and we compare them with the numerical fluxes obtained from the displacement field u_{CG} of a piecewise linear CG approximation and with the field μ_h obtained from the DPG_0 (using the same grid). The DPG fluxes are accurate and do not exhibit spurious oscillations at the endpoints of the boundaries. Moreover, the global equilibrium $\int_\Omega f\,dx + \int_\Gamma \boldsymbol{\sigma}\cdot\boldsymbol{n}\,ds = 0$ is verified to machine precision by the DPG approximation.

10. Conclusions. In this article we have presented the DPG method for the finite element discretization scheme of second order elliptic boundary value problems. A stability and convergence analysis of the novel formulation has been carried out, and numerical results have been shown to validate the computational performance of the novel formulation. Introducing the DPG formulation has established a clear connection between mixed-hybrid and DG methods. This result is the motivation and starting point for future investigations and applications of the novel scheme to deal with more general problems.

Acknowledgments. The authors wish to thank Professor F. Brezzi and Professor L. D. Marini for their time in fruitful discussions and their suggestions. Moreover, the observations, remarks, and suggestions of the referees are also gratefully acknowledged.

CONVERGENCE ANALYSIS OF FULLY DISCRETE FINITE VOLUME METHODS FOR MAXWELL'S EQUATIONS IN NONHOMOGENEOUS MEDIA[*]

ERIC T. CHUNG[†] AND BJORN ENGQUIST[‡]

Abstract. We will consider both explicit and implicit fully discrete finite volume schemes for solving three-dimensional Maxwell's equations with discontinuous physical coefficients on general polyhedral domains. Stability and convergence for both schemes are analyzed. We prove that the schemes are second order accurate in time. Both schemes are proved to be first order accurate in space for the Voronoi–Delaunay grids and second order accurate for nonuniform rectangular grids. We also derive explicit expressions for the dependence on the physical parameters in all estimates.

Key words. convergence, stability, finite volume, fully discrete, Maxwell equations

1. Introduction.

The finite volume method (FVM) has been developed as a practical compromise between the finite difference method (FDM) and the finite element method (FEM) in the numerical solutions of electromagnetic problems [1, 2, 3, 4, 6, 9, 10, 11, 15, 16]. It allows for unstructured grids, as the FEM does, but it is typically explicit and as computationally efficient as the FDM.

Even though FEMs provide excellent tools for solving electromagnetic problems on geometrically complex domains, marching techniques applied to FEMs produce implicit schemes. In order to obtain an explicit scheme to solve Maxwell's equations on domains which are geometrically complicated, FVMs are considered. There has been serious stability problems with some FVM approximations of the Maxwell's equations. In this paper we will present a class of FVMs for which we prove stability and convergence. We will in particular consider inhomogeneous media with discontinuous coefficients. The methods presented here are based on the semidiscrete techniques introduced by Chung, Du, and Zou [4, 6]. Rigorous analysis of fully discrete FVMs for electromagnetics is rarely seen in the literature. It is the purpose of this paper to provide stability and convergence analysis of two fully discrete FVMs. The first one is the leapfrog scheme. We will analyze this scheme by using the approach suggested in Nicolaides and Wang [13], where an FVM for Maxwell's equations with constant coefficients is considered. The second one is the Crank–Nicolson scheme. This scheme is unconditionally stable, so that larger time steps can be used. In addition to stability and convergence, we also prove existence and uniqueness of solution of the discrete problem resulting from the implicit Crank–Nicolson discretization.

Let us first introduce notation and formulate the differential equations to be approximated. Let Ω be a polyhedral domain in $\mathbb{R}^3$ and $T > 0$. Then the electric

field $\mathbf{E}(\mathbf{x},t)$ and the magnetic field $\mathbf{H}(\mathbf{x},t)$ satisfy the Maxwell's equations

$$\varepsilon\frac{\partial\mathbf{E}}{\partial t} - \mathbf{curl}\,\mathbf{H} = \mathbf{J} \quad \text{in} \quad \Omega\times(0,T), \tag{1.1}$$

$$\mu\frac{\partial\mathbf{H}}{\partial t} + \mathbf{curl}\,\mathbf{E} = 0 \quad \text{in} \quad \Omega\times(0,T), \tag{1.2}$$

$$\operatorname{div}(\varepsilon\mathbf{E}) = \rho \quad \text{in} \quad \Omega\times(0,T), \tag{1.3}$$

$$\operatorname{div}(\mu\mathbf{H}) = 0 \quad \text{in} \quad \Omega\times(0,T), \tag{1.4}$$

where $\mathbf{J}(\mathbf{x},t)$ and $\rho(\mathbf{x},t)$ are the applied current density and the charge density, respectively. We also have the constitutive relations $\mathbf{D}=\varepsilon\mathbf{E}$ and $\mathbf{B}=\mu\mathbf{H}$, where $\mathbf{D}$ and $\mathbf{B}$ are the electric flux density and the magnetic flux density, respectively. The paper is concerned with the case where the domain Ω is composed of two distinct dielectric materials. Let $\Omega_1\subset\Omega$ be a polyhedral subdomain and $\Omega_2=\Omega\backslash\bar{\Omega}_1$. We assume the electric permittivity ε and the magnetic permeability μ are piecewise constant functions such that $\varepsilon=\varepsilon_i$ and $\mu=\mu_i$ in Ω_i, where ε_i and μ_i are positive constants for $i=1,2$. We supplement the system (1.1)–(1.4) with the perfect conductor boundary condition $\mathbf{E}\times\mathbf{n}=0$ and initial condition. On the interface $\Gamma := \partial\Omega_1$, $\mathbf{E}$ and $\mathbf{H}$ satisfy

$$[\mathbf{E}\times\mathbf{m}]=0, \quad [\varepsilon\mathbf{E}\cdot\mathbf{m}]=\rho_\Gamma, \tag{1.5}$$

$$[\mathbf{H}\times\mathbf{m}]=0, \quad [\mu\mathbf{H}\cdot\mathbf{m}]=0, \tag{1.6}$$

where $\rho_\Gamma(\mathbf{x})$ is the surface charge density, $\mathbf{m}$ is the unit normal of $\partial\Omega_1$, and $[f] := f_2|_\Gamma - f_1|_\Gamma$ is the jump of the function f across the interface with $f_i=f|_{\Omega_i}$ for $i=1,2$.

The rest of the paper is organized as follows. In section 2, we will describe the triangulation of the domain as well as some discrete vector spaces and operators defined on it. In section 3, we will briefly summarize the finite volume spatial discretization of Maxwell's equations. In section 4, we will derive both explicit and implicit fully discrete finite volume schemes. They are based on leapfrog and Crank–Nicolson time discretization, respectively. Convergence and stability will be analyzed in case of general tetrahedral grids. In section 5, we extend the schemes to nonuniform rectangular grids. It can be shown that the spatial convergence is one order higher. We will also provide an example in one space dimension to show the optimality of our estimates in this section.

2. Discrete vector spaces. In this section, we will briefly summarize the triangulation of the domain as well as discrete vector spaces and operators defined on it. The domain Ω is triangulated by the standard Voronoi–Delaunay triangulation (cf. [8]). We will refer to the Delaunay triangulation, which contains tetrahedral cells, as the primal grid and the Voronoi triangulation, which contains polyhedral cells and are formed by connecting the circumcenters of adjacent primal cells, as the dual grid. The primal grid is chosen so that the faces of the primal cells align with the interface Γ. For a more detailed description and assumption of the triangulation, see Chung, Du, and Zou [6]. Throughout this paper, we use K to represent a generic constant which is independent of the mesh size and the physical coefficients ε and μ.

Now, we will discuss the discrete vector spaces and operators. Let F_1 and M_1 be the number of interior primal faces and interior primal edges, respectively. Then F_1 is also the number of dual edges and M_1 is also the number of dual faces. The individual primal face and edge will be denoted by κ_j and σ_k with $s_j=|\kappa_j|$ and $h_k=|\sigma_k|$. The corresponding quantities related to the dual grid are denoted by primed form such as κ_j', σ_k', s_j', and h_k'. Let $(\cdot,\cdot)$ be the standard Euclidean inner product. For any u and

v in $\mathbb{R}^{F_1}$, we define the inner product $(u, v)_W := (Su, D'v)$, where $S := \mathrm{diag}(s_j)$ and $D' := \mathrm{diag}(\bar{h}'_j)$ with $\bar{h}'_j := (\mu_1^{-1} a_j + \mu_2^{-1}(1 - a_j))h'_j$. Here a_j, $0 \leq a_j \leq 1$, is the ratio of the length of the portion of σ'_j that belongs to Ω_1 over the length of σ'_j. We also define an inner product in $\mathbb{R}^{M_1}$ by $(u, v)_{W'} = (S'u, Dv)$, where $S' := \mathrm{diag}(\bar{s}'_j)$ and $D := \mathrm{diag}(h_j)$ with $\bar{s}'_j := (\varepsilon_1 b_j + \varepsilon_2(1 - b_j))s'_j$ and b_j, $0 \leq b_j \leq 1$, is the ratio of the area of the portion of κ'_j that belongs to Ω_1 over the area of κ'_j.

Each primal and dual edge is assigned a direction. Direction is also assigned to each primal and dual face such that it is the same as the corresponding dual and primal edge, respectively. We say $\sigma'_j \in \partial\kappa'_i$ is oriented positively along $\partial\kappa'_i$ if the direction of σ'_j agrees with the one of $\partial\kappa'_i$ formed by the right-hand rule with the thumb pointing in the direction of σ_i. Otherwise, we say σ'_j is oriented negatively along $\partial\kappa'_i$. We define an $F_1 \times M_1$ matrix G as

$$(G)_{ji} := \begin{cases} 1 & \text{if } \sigma'_j \text{ is oriented positively along } \partial\kappa'_i, \\ -1 & \text{if } \sigma'_j \text{ is oriented negatively along } \partial\kappa'_i, \\ 0 & \text{if } \sigma'_j \text{ does not meet } \partial\kappa'_i. \end{cases}$$

Then, for $w \in \mathbb{R}^{M_1}$ and $v \in \mathbb{R}^{F_1}$, we define $Cw := GDw$ and $C'v := G^T D'v$, which also satisfy the following discrete Green's formula:

$$(Cw, D'v) = (C'v, Dw). \tag{2.1}$$

See [5, 6, 12, 13, 14] for more details about these operators and related topics.

3. FVM. The FVM proposed in Chung and Zou [4] can be stated as follows:

Find $E \in \mathbb{R}^{M_1}$ and $B \in \mathbb{R}^{F_1}$ such that

$$S' \frac{dE}{dt} - C'B = \tilde{J}, \tag{3.1}$$

$$S \frac{dB}{dt} + CE = 0, \tag{3.2}$$

where $\tilde{J} \in \mathbb{R}^{M_1}$ is defined by $(\tilde{J})_j := \int_{\kappa'_j} \mathbf{J} \cdot \mathbf{n} \, d\sigma$. Convergence and stability analysis of the semidiscrete scheme (3.1)–(3.2) was given in Chung, Du, and Zou [6]. In the following sections, we will give our main results in this paper, which are the full discretizations of the semidiscrete scheme (3.1)–(3.2).

For subsequent analysis, derived in [4], we have

$$s_j \frac{d}{dt}(B_f)_j + (CE_e)_{\kappa_j} = 0, \tag{3.3}$$

$$\bar{s}'_j \frac{d}{dt}(E'_f)_j - (C'B'_e)_{\kappa'_j} = \tilde{J}_j, \tag{3.4}$$

where B_f, B'_e, E'_f, and E_e are average quantities defined in Chung, Du, and Zou [4, 6].

4. Fully discrete schemes. In this section, we will give two different time discretizations for (3.1)–(3.2). First, we will consider an explicit scheme, which is a standard leapfrog scheme. With a stability condition, this scheme can be shown to be first order convergent in space and second order convergent in time. Second, we will consider an implicit scheme, which is a Crank–Nicolson time discretization of

(3.1)–(3.2). It can be shown that this method is unconditionally stable with the same rate of convergence as the explicit counterpart.

Consider a uniform partition of $[0,T]$ with N_T subintervals. Let $\Delta t := T/N_T$. For $n = 0, 1, \dots, N_T - 1$, we define $t_n := n\Delta t$ and $t_{n+\frac{1}{2}} := (n + \frac{1}{2})\Delta t$. For subsequent analysis, we define

$$c_m := (\min(\varepsilon_1, \varepsilon_2)\min(\mu_1, \mu_2))^{-\frac{1}{2}}.$$

We also denoted by M_2 the maximum of the ratios of maximum to minimum side lengths over adjacent tetrahedra and by M_3 the maximum number of sides over all dual faces. Furthermore, by $\min(h)$ we mean the minimum side length over all primal and dual edges.

4.1. Explicit scheme. We will apply a leapfrog scheme to (3.1)–(3.2). We approximate $\mathbf{E}(t)$ at t_n and $\mathbf{B}(t)$ at $t_{n+\frac{1}{2}}$ with approximations denoted by E^n and $B^{n+\frac{1}{2}}$, respectively. Given $(E^n, B^{n+\frac{1}{2}})$, the next approximation $(E^{n+1}, B^{n+\frac{3}{2}})$ will be obtained by solving

$$S'(E^{n+1} - E^n) - \Delta t C' B^{n+\frac{1}{2}} = \tilde{J}^{n+\frac{1}{2}}, \tag{4.1}$$

$$S(B^{n+\frac{3}{2}} - B^{n+\frac{1}{2}}) + \Delta t C E^{n+1} = 0, \tag{4.2}$$

where $\tilde{J}^{n+\frac{1}{2}} := \int_{n\Delta t}^{(n+1)\Delta t} \tilde{J}(s)\, ds$. The initial conditions are given by $E^0 := E_e(t_0)$ and $B^{\frac{1}{2}} := B_e'(t_{\frac{1}{2}})$. The value of $B_e'(t_{\frac{1}{2}})$ can be calculated by using (1.2) and the Taylor series method. Now, we have the following stability estimate.

THEOREM 4.1. *Under the stability condition*

$$\delta := \Delta t c_m \frac{M_2 M_3^{\frac{1}{2}}}{\min(h)} < 1, \tag{4.3}$$

the fully discrete scheme (4.1)–(4.2) *is stable. Moreover, the following stability estimate holds for* $1 \le k \le N_T - 1$*:*

$$\begin{aligned} &\|E^k\|_{W'}^2 + \|B^{k+\frac{1}{2}}\|_W^2 \\ &\quad\le \frac{2(1+\delta)}{1-\delta}(\|E^0\|_{W'}^2 + \|B^{\frac{1}{2}}\|_W^2) + \frac{4T}{(1-\delta)^2}\int_0^T \|S'^{-1}\tilde{J}(t)\|_{W'}^2\, dt. \end{aligned} \tag{4.4}$$

Proof. Multiplying (4.1) by $D(E^{n+1} + E^n)$ and (4.2) by $D'(B^{n+\frac{3}{2}} + B^{n+\frac{1}{2}})$ yields

$$(E^{n+1} - E^n, E^{n+1} + E^n)_{W'} - \Delta t(C'B^{n+\frac{1}{2}}, D(E^{n+1} + E^n)) = R^{n+\frac{1}{2}},$$

$$(B^{n+\frac{3}{2}} - B^{n+\frac{1}{2}}, B^{n+\frac{3}{2}} + B^{n+\frac{1}{2}})_W + \Delta t(CE^{n+1}, D'(B^{n+\frac{3}{2}} + B^{n+\frac{1}{2}})) = 0,$$

where $R^{n+\frac{1}{2}} := (\tilde{J}^{n+\frac{1}{2}}, D(E^{n+1} + E^n))$. Let k be an integer satisfying $1 \le k \le N_T - 1$. Adding all equations from $n = 0$ to $n = k - 1$ and using (2.1), we have

$$\begin{aligned} &\|E^k\|_{W'}^2 + \|B^{k+\frac{1}{2}}\|_W^2 \\ &= \|E^0\|_{W'}^2 + \|B^{\frac{1}{2}}\|_W^2 + \Delta t(C'B^{\frac{1}{2}}, DE^0) - \Delta t(DE^k, C'B^{k+\frac{1}{2}}) + \sum_{n=0}^{k-1} R^{n+\frac{1}{2}}. \end{aligned} \tag{4.5}$$

Notice that

$$\Delta t(C'B^{\frac{1}{2}}, DE^0) \leq \Delta t\|(DS^{'-1})^{\frac{1}{2}}C'(SD')^{-\frac{1}{2}}\|_2\|B^{\frac{1}{2}}\|_W\|E^0\|_{W'}.$$

By the definition of the matrix 2-norm, $\|(DS^{'-1})^{\frac{1}{2}}C'(SD')^{-\frac{1}{2}}\|_2$ is bounded above by the square root of the largest eigenvalue of $(SD')^{-\frac{1}{2}}D'GDS^{'-1}G^TD'(SD')^{-\frac{1}{2}}$. By Gershgorin's theorem, the largest eigenvalue of GG^T is bounded above by $3M_3$, as every primal face has 3 sides and every dual face has at most M_3 sides. So,

$$\|(DS^{'-1})^{\frac{1}{2}}C'(SD')^{-\frac{1}{2}}\|_2 \leq c_m \max_{1\leq j\leq F_1}\left(\frac{\max_j(h)}{\min_j(h)^2}\right)(3M_3)^{\frac{1}{2}},$$

where $\max_j(h)$ and $\min_j(h)$ are the local maximum and local minimum of side lengths around a primal face κ_j, respectively. So, we have

$$\Delta t(C'B^{\frac{1}{2}}, DE^0) \leq \Delta t c_m \frac{M_2M_3^{\frac{1}{2}}}{\min(h)}(\|B^{\frac{1}{2}}\|_W^2 + \|E^0\|_{W'}^2).$$

A similar inequality holds for $\Delta t(C'B^{k+\frac{1}{2}}, DE^k)$. Hence, (4.5) can be written as

$$\|E^k\|_{W'}^2 + \|B^{k+\frac{1}{2}}\|_W^2 \leq \frac{1+\delta}{1-\delta}(\|E^0\|_{W'}^2 + \|B^{\frac{1}{2}}\|_W^2) + \frac{1}{1-\delta}\sum_{n=0}^{k-1}R^{n+\frac{1}{2}}.$$

Now, (4.4) follows from the Cauchy–Schwarz inequality. □

We are now in a position to study the convergence theory of the method (4.1)–(4.2). To do so, for brevity, we define

$$\mathbf{e}(E)^n := E^n - E_e(t_n), \quad \mathbf{e}(B)^n := B^n - B'_e(t_n), \tag{4.6}$$

$$\mathbf{f}(E)^n := E^n - E'_f(t_n), \quad \mathbf{f}(B)^n := B^n - B_f(t_n). \tag{4.7}$$

Then we subtract (4.1) by (3.4) and (4.2) by (3.3) to obtain

$$S'(\mathbf{f}(E)^{n+1} - \mathbf{f}(E)^n) - \Delta t C'\mathbf{e}(B)^{n+\frac{1}{2}} = P_1^{n+\frac{1}{2}}, \tag{4.8}$$

$$S(\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}) + \Delta t C\mathbf{e}(E)^{n+1} = P_2^{n+1}, \tag{4.9}$$

where

$$P_1^{n+\frac{1}{2}} := \tilde{J}^{n+\frac{1}{2}} - S'(E'_f(t_{n+1}) - E'_f(t_n)) + \Delta t C'B'_e(t_{n+\frac{1}{2}}), \tag{4.10}$$

$$P_2^{n+1} := -S(B_f(t_{n+\frac{3}{2}}) - B_f(t_{n+\frac{1}{2}})) - \Delta t C E_e(t_{n+1}). \tag{4.11}$$

Multiplying (4.8) by $D\mathbf{e}(E)^n + D\mathbf{e}(E)^{n+1}$ and (4.9) by $D'\mathbf{e}(B)^{n+\frac{3}{2}} + D'\mathbf{e}(B)^{n+\frac{1}{2}}$, adding the two resulting equations, and using (2.1), (4.6), and (4.7), we have

$$\begin{aligned}
&(\mathbf{e}(E)^{n+1} - \mathbf{e}(E)^n, \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'} \\
&\quad + (\mathbf{e}(B)^{n+\frac{3}{2}} - \mathbf{e}(B)^{n+\frac{1}{2}}, \mathbf{e}(B)^{n+\frac{3}{2}} + \mathbf{e}(B)^{n+\frac{1}{2}})_W \\
&= ((E'_f(t_{n+1}) - E_e(t_{n+1})) - (E'_f(t_n) - E_e(t_n)), \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'} \\
&\quad + ((B_f(t_{n+\frac{3}{2}}) - B'_e(t_{n+\frac{3}{2}})) - (B_f(t_{n+\frac{1}{2}}) - B'_e(t_{n+\frac{1}{2}})), \mathbf{e}(B)^{n+\frac{3}{2}} + \mathbf{e}(B)^{n+\frac{1}{2}})_W \\
&\quad + (P_1^{n+\frac{1}{2}}, D(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})) + (P_2^{n+1}, D'(\mathbf{e}(B)^{n+\frac{3}{2}} + \mathbf{e}(B)^{n+\frac{1}{2}})) \\
&\quad + \Delta t(C'\mathbf{e}(B)^{n+\frac{1}{2}}, D\mathbf{e}(E)^n) - \Delta t(D\mathbf{e}(E)^{n+1}, C'\mathbf{e}(B)^{n+\frac{3}{2}}).
\end{aligned}$$

Adding from $n = 0$ to $n = k - 1$, we have

$$\begin{aligned}
&\|\mathbf{e}(E)^k\|_{W'}^2 + \|\mathbf{e}(B)^{k+\frac{1}{2}}\|_W^2 \\
&= -\Delta t(D\mathbf{e}(E)^k, C'\mathbf{e}(B)^{k+\frac{1}{2}}) \\
&\quad + \sum_{n=0}^{k-1}\Big\{((E_f'(t_{n+1}) - E_e(t_{n+1})) - (E_f'(t_n) - E_e(t_n)), \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'} \\
&\quad + ((B_f(t_{n+\frac{3}{2}}) - B_e'(t_{n+\frac{3}{2}})) - (B_f(t_{n+\frac{1}{2}}) - B_e'(t_{n+\frac{1}{2}})), \mathbf{e}(B)^{n+\frac{1}{2}} + \mathbf{e}(B)^{n+\frac{3}{2}})_W \\
&\quad + (P_1^{n+\frac{1}{2}}, D(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})) + (P_2^{n+1}, D'(\mathbf{e}(B)^{n+\frac{1}{2}} + \mathbf{e}(B)^{n+\frac{3}{2}}))\Big\}.
\end{aligned} \tag{4.12}$$

Next, we will prove the following truncation error for the discretization of the semidiscrete scheme (3.1)–(3.2) by leapfrog time stepping. We will use a dot to represent the time derivative.

LEMMA 4.2. *Assume* $(\mathbf{B}, \mathbf{E}) \in H^2(0, T; W^{1,p}(\Omega_r)^3)^2$ *for* $2 < p \leq 3$ *and* $r = 1, 2$. *Then for general unstructured grids,*

$$\sum_{n=0}^{k-1} \|S'^{-1}P_1^{n+\frac{1}{2}}\|_{W'} \leq c_m K(\Delta t)^2 \sum_{r=1}^{2} \|\mu_r^{-\frac{1}{2}}\mathbf{B}\|_{H^2(0,T;W^{1,p}(\Omega_r)^3)}, \tag{4.13}$$

$$\sum_{n=0}^{k-1} \|S^{-1}P_2^{n+1}\|_W \leq c_m K(\Delta t)^2 \sum_{r=1}^{2} \|\varepsilon_r^{\frac{1}{2}}\mathbf{E}\|_{H^2(0,T;W^{1,p}(\Omega_r)^3)}. \tag{4.14}$$

Proof. We will give a proof for (4.13). The proof for (4.14) can be done in a similar way. For the jth dual face, using (3.4) and (4.10), we have

$$(P_1^{n+\frac{1}{2}})_j = -\int_{n\Delta t}^{(n+1)\Delta t} (C'B_e')_j(s)\, ds + \Delta t (C'B_e')_j(t_{n+\frac{1}{2}}).$$

By the Sobolev embedding theorem, $(P_1^{n+\frac{1}{2}})_j$ defines a bounded linear functional on $W^{2,1}(n\Delta t, (n+1)\Delta t)$ and vanishes for any linear functions in time. So by the Bramble–Hilbert lemma [7] and the standard scale change technique, we have

$$|(P_1^{n+\frac{1}{2}})_j| \leq K(\Delta t)^2 \int_{n\Delta t}^{(n+1)\Delta t} |(C'\ddot{B}_e')_j(s)|\, ds.$$

Using the tangential continuity of $\mathbf{H}$ across the interface Γ, we conclude that $(C'\ddot{B}_e)_j$ vanishes for constant functions in space. By the Bramble–Hilbert lemma and scale change argument,

$$|(C'\ddot{B}_e')_j| \leq Kh^{2-\frac{3}{p}} |\ddot{\mathbf{H}}|_{W^{1,p}(\tau_k' \cup \tau_l')^3},$$

where τ_k' and τ_l' are the two dual cells sharing the same dual face κ_j'. So, we have

$$|(P_1^{n+\frac{1}{2}})_j| \leq Kh^{2-\frac{3}{p}} (\Delta t)^2 \int_{n\Delta t}^{(n+1)\Delta t} |\ddot{\mathbf{H}}|_{W^{1,p}(\tau_k' \cup \tau_l')^3}\, ds.$$

Hence, the result (4.13) follows from the definitions of c_m and the W'-norm. □

The following theorem gives the main result of this section. It states that the explicit scheme (4.1)–(4.2) is first order convergent in space and second order convergent in time under an assumption on the regularity of the true solution and a CFL stability condition.

THEOREM 4.3. *Assume that* $(\mathbf{E},\mathbf{B}) \in H^2(0,T;W^{1,p}(\Omega_r)^3)^2$, $2 < p \le 3$, $r = 1,2$, *is the solution to* (1.1)–(1.2) *and* $(E^n, B^{n+\frac{1}{2}})$ *is the solution to the explicit fully discrete scheme* (4.1)–(4.2). *Then, under the stability condition* (4.3),

$$\begin{aligned}&\max_{0\le n\le N_T-1}(\|E^n - E_e(t_n)\|_{W'} + \|B^{n+\frac{1}{2}} - B'_e(t_{n+\frac{1}{2}})\|_W)\\ &\le \frac{K}{1-\delta}(h + c_m(\Delta t)^2)\sum_{r=1}^{2}\|(\varepsilon_r^{\frac{1}{2}}\mathbf{E}, \mu_r^{-\frac{1}{2}}\mathbf{B})\|_{H^2(0,T;W^{1,p}(\Omega_r)^3)^2}.\end{aligned} \tag{4.15}$$

Proof. The proof is based on (4.12). First, by resembling the techniques used in the proof of Theorem 4.1, we have

$$\Delta t(D\mathbf{e}(E)^k, C'\mathbf{e}(B)^{k+\frac{1}{2}}) \le \Delta t c_m \frac{M_2 M_3^{\frac{1}{2}}}{\min(h)}(\|\mathbf{e}(B)^{k+\frac{1}{2}}\|_W^2 + \|\mathbf{e}(E)^k\|_{W'}^2).$$

Second, by integrating in time and the definition of the W'-norm, we have

$$\|(E'_f(t_{n+1}) - E_e(t_{n+1})) - (E'_f(t_n) - E_e(t_n))\|_{W'}^2 \le \Delta t \int_{n\Delta t}^{(n+1)\Delta t} \|\dot{E}'_f - \dot{E}_e\|_{W'}^2\, ds.$$

Using Theorem 5.1 of [6],

$$\begin{aligned}&((E'_f(t_{n+1}) - E_e(t_{n+1})) - (E'_f(t_n) - E_e(t_n)), \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'}\\ &\le Kh\sqrt{\Delta t}\max_{0\le n\le k}\|\mathbf{e}(E)^n\|_{W'}\sum_{r=1}^{2}\|\varepsilon_r^{\frac{1}{2}}\dot{\mathbf{E}}\|_{L^2(n\Delta t,(n+1)\Delta t;W^{1,p}(\Omega_r)^3)}.\end{aligned}$$

Similarly, we have

$$\begin{aligned}&((B_f(t_{n+\frac{3}{2}}) - B'_e(t_{n+\frac{3}{2}}) - (B_f(t_{n+\frac{1}{2}}) - B'_e(t_{n+\frac{1}{2}})), \mathbf{e}(B)^{n+\frac{1}{2}} + \mathbf{e}(B)^{n+\frac{3}{2}})_W\\ &\le Kh\sqrt{\Delta t}\max_{0\le n\le k}\|\mathbf{e}(B)^{n+\frac{1}{2}}\|_W\sum_{r=1}^{2}\|\mu_r^{-\frac{1}{2}}\dot{\mathbf{B}}\|_{L^2((n+\frac{1}{2})\Delta t,(n+\frac{3}{2})\Delta t;W^{1,p}(\Omega_r)^3)}.\end{aligned}$$

Third, by the Cauchy–Schwarz inequality,

$$\begin{aligned}(P_1^{n+\frac{1}{2}}, D(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})) &\le \|S^{'-1}P_1^{n+\frac{1}{2}}\|_{W'}\|\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1}\|_{W'},\\ (P_2^{n+1}, D'(\mathbf{e}(B)^{n+\frac{1}{2}} + \mathbf{e}(B)^{n+\frac{3}{2}})) &\le \|S^{-1}P_2^{n+1}\|_W\|\mathbf{e}(B)^{n+\frac{1}{2}} + \mathbf{e}(B)^{n+\frac{3}{2}}\|_W.\end{aligned}$$

Now, by using (4.13)–(4.14) and collecting all of the above results, we have shown the desired convergence estimate. □

4.2. Implicit scheme. In this section, we will consider an implicit scheme for (3.1)–(3.2). We will apply a standard Crank–Nicolson time discretization. The approximate solutions of $\mathbf{E}(t)$ and $\mathbf{B}(t)$ will be obtained at t_n and denoted by E^n and

B^n, respectively. Given (E^n, B^n), the next approximation (E^{n+1}, B^{n+1}) will be obtained by solving

$$S'(E^{n+1} - E^n) - \frac{\Delta t}{2}(C'B^n + C'B^{n+1}) = \tilde{J}^{n+\frac{1}{2}}, \tag{4.16}$$

$$S(B^{n+1} - B^n) + \frac{\Delta t}{2}(CE^n + CE^{n+1}) = 0. \tag{4.17}$$

That is, in each time step, we need to solve a linear system $Ax = b$ for x with

$$A := \begin{pmatrix} S' & -\frac{\Delta t}{2}C' \\ \frac{\Delta t}{2}C & S \end{pmatrix} \quad \text{and} \quad b := \begin{pmatrix} \tilde{J}^{n+\frac{1}{2}} + S'E^n + \frac{\Delta t}{2}C'B^n \\ SB^n - \frac{\Delta t}{2}CE^n \end{pmatrix}. \tag{4.18}$$

The question of well-posedness of problem (4.16)–(4.17) will be given by the following theorem. We emphasize here that the scheme is unconditionally stable with respect to the time step Δt.

THEOREM 4.4. *The implicit fully discrete scheme* (4.16)–(4.17) *is well-posed. Moreover, the following stability inequality holds for* $1 \leq n \leq N_T$*:*

$$\|E^n\|^2_{W'} + \|B^n\|^2_W \leq 2\|E^0\|^2_{W'} + 2\|B^0\|^2_W + 4T\int_0^T \|S^{'-1}\tilde{J}(t)\|^2_{W'}\, dt. \tag{4.19}$$

Proof. We first show that the system (4.16)–(4.17) has a unique solution. To do this, we prove that all eigenvalues of the matrix A in (4.18) are nonzero. We rewrite A as

$$A = \begin{pmatrix} S' & 0 \\ 0 & S \end{pmatrix} + \frac{\Delta t}{2}\begin{pmatrix} 0 & -C' \\ C & 0 \end{pmatrix}.$$

By the definitions of C and C', it suffices to consider the matrix

$$A_1 := \begin{pmatrix} S'D^{-1} & -\frac{\Delta t}{2}G^T \\ \frac{\Delta t}{2}G & SD^{'-1} \end{pmatrix}.$$

Let $x = (x_1 \; x_2)$, where $x_1 \in \mathbb{C}^{M_1}$ and $x_2 \in \mathbb{C}^{F_1}$, be an eigenvector of A_1 of unit length. Then

$$x^* A_1 x = (x_1)^* S'D^{-1}x_1 + (x_2)^* SD^{'-1}x_2 + \Delta t\, \mathrm{Im}((x_2)^* G x_1) i,$$

where $*$ denotes the conjugate transpose and $i = \sqrt{-1}$. Hence, all eigenvalues of A_1 have positive real part, which shows that the matrix A_1 is invertible.

To prove the stability estimate, we multiply (4.16) by $D(E^{n+1} + E^n)$ and (4.17) by $D'(B^{n+1} + B^n)$ and add up the two resulting equations using (2.1) to get

$$\|E^{n+1}\|^2_{W'} + \|B^{n+1}\|^2_W = \|E^n\|^2_{W'} + \|B^n\|^2_W + (\tilde{J}^{n+\frac{1}{2}}, D(E^{n+1} + E^n)). \tag{4.20}$$

By induction, we have, for any $0 \leq n \leq N_T$,

$$\|E^n\|^2_{W'} + \|B^n\|^2_W = \|E^0\|^2_{W'} + \|B^0\|^2_W + \sum_{k=1}^{n}(\tilde{J}^{k-\frac{1}{2}}, D(E^k + E^{k-1})).$$

Now, (4.19) follows from a standard application of Cauchy–Schwarz inequality. □

If we compare (4.5) and (4.20), we see that the appearance of terms of the form $\Delta t(DE^k, C'B^{k+\frac{1}{2}})$ makes the explicit scheme (4.1)–(4.2) conditionally stable, while the absence of these terms makes the implicit scheme (4.16)–(4.17) unconditionally stable.

We are now in a position to study the convergence theory of the method (4.16)–(4.17). Applying the same technique used to prove (4.12), we have

$$\begin{aligned}
&\|\mathbf{e}(E)^k\|_{W'}^2 + \|\mathbf{e}(B)^k\|_W^2 \\
&= \sum_{n=0}^{k-1} \Big\{((E'_f(t_{n+1}) - E_e(t_{n+1})) - (E'_f(t_n) - E_e(t_n)), \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'} \\
&\quad + ((B'_f(t_{n+1}) - B_e(t_{n+1})) - (B'_f(t_n) - B_e(t_n)), \mathbf{e}(B)^n + \mathbf{e}(B)^{n+1})_W \\
&\quad + (Q_1^{n+\frac{1}{2}}, D(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})) + (Q_2^{n+\frac{1}{2}}, D'(\mathbf{e}(B)^n + \mathbf{e}(B)^{n+1}))\Big\},
\end{aligned} \tag{4.21}$$

where

$$Q_1^{n+\frac{1}{2}} := \tilde{J}^{n+\frac{1}{2}} - S'(E'_f(t_{n+1}) - E'_f(t_n)) + \frac{\Delta t}{2}(C'B'_e(t_n) + C'B'_e(t_{n+1})), \tag{4.22}$$

$$Q_2^{n+\frac{1}{2}} := -S(B_f(t_{n+1}) - B_f(t_n)) - \frac{\Delta t}{2}(CE_e(t_n) + CE_e(t_{n+1})). \tag{4.23}$$

Similar to Lemma 4.2, we have the following consistency error estimate of the Crank–Nicolson time discretization of (4.16)–(4.17). The proof is similar to that of Lemma 4.2.

LEMMA 4.5. *Assume that* $(\mathbf{B}, \mathbf{E}) \in H^2(0,T; W^{1,p}(\Omega_r)^3)^2$ *for* $2 < p \leq 3$ *and* $r = 1, 2$. *Then on general unstructured grids,*

$$\sum_{n=0}^{k-1} \|S^{'-1} Q_1^{n+\frac{1}{2}}\|_{W'} \leq c_m K (\Delta t)^2 \sum_{r=1}^{2} \|\varepsilon_r^{\frac{1}{2}} \mathbf{E}\|_{H^2(0,T;W^{1,p}(\Omega_r)^3)}, \tag{4.24}$$

$$\sum_{n=0}^{k-1} \|S^{-1} Q_2^{n+\frac{1}{2}}\|_{W} \leq c_m K (\Delta t)^2 \sum_{r=1}^{2} \|\mu_r^{-\frac{1}{2}} \mathbf{B}\|_{H^2(0,T;W^{1,p}(\Omega_r)^3)}. \tag{4.25}$$

The following theorem gives the main result in this section. It can be proved by using a technique similar to that used to prove Theorem 4.3.

THEOREM 4.6. *Assume that* $(\mathbf{E}, \mathbf{B}) \in H^2(0,T; W^{1,p}(\Omega_r)^3)^2$, $2 < p \leq 3$, $r = 1, 2$, *is the solution to* (1.1)–(1.2) *and* (E^n, B^n) *is the solution to the implicit fully discrete scheme* (4.16)–(4.17). *Then*

$$\begin{aligned}
&\max_{0 \leq n \leq N_T} (\|E^n - E_e(t_n)\|_{W'} + \|B^n - B'_e(t_n)\|_W) \\
&\leq K(h + c_m(\Delta t)^2) \sum_{r=1}^{2} \|(\varepsilon_r^{\frac{1}{2}} \mathbf{E}, \mu_r^{-\frac{1}{2}} \mathbf{B})\|_{H^2(0,T;W^{1,p}(\Omega_r)^3)^2}.
\end{aligned} \tag{4.26}$$

5. Analysis on rectangular grids. In this section, we will consider the explicit finite volume scheme (4.1)–(4.2) and the implicit finite volume scheme (4.16)–(4.17) on rectangular grids. It is clear that all primal and dual elements are cuboids and all faces are rectangles. All definitions that we made in previous sections can be made in exactly the same way on nonuniform rectangular grids. For instance, $M_3 = 4$ for rectangular grids. It can be shown that the two schemes (4.1)–(4.2) and (4.16)–(4.17) are second order convergent in space. The second order convergence comes from the fact that the circumcenter of a cuboid is also its barycenter. In section 5.2, we give a one-dimensional counterexample to show that without taking the barycenter as dual node the scheme may reduce to first order.

5.1. Convergence analysis. We will first consider convergence analysis on the explicit fully discrete scheme (4.1)–(4.2) for nonuniform rectangular grids. It is easy to show that

$$\begin{aligned}
&\|\mathbf{e}(E)^k\|_{W'}^2 + \|\mathbf{f}(B)^{k+\frac{1}{2}}\|_W^2 \\
= &-\Delta t(D\mathbf{e}(E)^k, C'\mathbf{e}(B)^{k+\frac{1}{2}}) \\
&+ \sum_{n=0}^{k-1}\Big\{((E'_f(t_{n+1}) - E_e(t_{n+1})) - (E'_f(t_n) - E_e(t_n)), \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'} \\
&- (\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}, (B_f(t_{n+\frac{3}{2}}) - B'_e(t_{n+\frac{3}{2}})) + (B_f(t_{n+\frac{1}{2}}) - B'_e(t_{n+\frac{1}{2}})))_W \\
&+ (P_1^{n+\frac{1}{2}}, D(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})) + (P_2^{n+1}, D'(\mathbf{e}(B)^{n+\frac{1}{2}} + \mathbf{e}(B)^{n+\frac{3}{2}}))\Big\}.
\end{aligned} \tag{5.1}$$

The following theorem gives the convergence result for the explicit finite volume scheme (4.1)–(4.2) on nonuniform rectangular grids.

Theorem 5.1. *Assume that*

$$\begin{aligned}
&\mathbf{B}(\mathbf{x}, t) \in H^1(0, T; H^3(\Omega_r)^3), \\
&\mathbf{E}(\mathbf{x}, t) \in H^1(0, T; H^3(\Omega_r)^3) \cap H^2(0, T; W^{2,p}(\Omega_r)^3),
\end{aligned}$$

for $p > 3$ *and* $r = 1, 2$, *is the solution to* (1.1)–(1.2) *and* $(E^n, B^{n+\frac{1}{2}})$ *is the solution to the explicit fully discrete scheme* (4.1)–(4.2) *on nonuniform rectangular grids. Then, under the stability condition* $\delta < \frac{1}{2}$,

$$\begin{aligned}
&\max_{0\le n\le N_T-1}(\|E^n - E_e(t_n)\|_{W'} + \|B^{n+\frac{1}{2}} - B_f(t_{n+\frac{1}{2}})\|_W) \\
&\le \frac{K}{1-\delta}(h^2 + c_m(\Delta t)^2) \\
&\times \sum_{r=1}^{2}\Big\{\|(\varepsilon_r^{\frac{1}{2}}\mathbf{E}, \mu_r^{-\frac{1}{2}}\mathbf{B})\|_{H^1(0,T;H^3(\Omega_r)^3)} + \|\varepsilon_r^{\frac{1}{2}}\mathbf{E}\|_{H^2(0,T;W^{2,p}(\Omega_r)^3)}\Big\}.
\end{aligned} \tag{5.2}$$

Proof. The proof is based on (5.1).

(i) To begin, notice that the first term on the right-hand side of (5.1) can be estimated as follows:

$$\begin{aligned}
&\Delta t(D\mathbf{e}(E)^k, C'\mathbf{e}(B)^{k+\frac{1}{2}}) \\
&= \Delta t(D\mathbf{e}(E)^k, C'\mathbf{f}(B)^{k+\frac{1}{2}}) + \Delta t(D\mathbf{e}(E)^k, C'(B_f(t_{k+\frac{1}{2}}) - B'_e(t_{k+\frac{1}{2}}))).
\end{aligned}$$

Applying the technique used in proving Theorem 4.1, we have

$$\Delta t(D\mathbf{e}(E)^k, C'\mathbf{f}(B)^{k+\frac{1}{2}}) \le \Delta t c_m \frac{M_2 M_3^{\frac{1}{2}}}{\min(h)}(\|\mathbf{e}(E)^k\|_{W'}^2 + \|\mathbf{f}(B)^{k+\frac{1}{2}}\|_W^2).$$

Applying (2.1) and [6, Lemma 5.2], we have

$$\begin{aligned}&\Delta t(D\mathbf{e}(E)^k, C'(B_f(t_{k+\frac{1}{2}}) - B'_e(t_{k+\frac{1}{2}})))\\ &= \Delta t(C\mathbf{e}(E)^k, D'(B_f(t_{k+\frac{1}{2}}) - B'_e(t_{k+\frac{1}{2}})))\\ &= \Delta t(C\mathbf{e}(E)^k, D'u^{k+\frac{1}{2}}) + \Delta t(C\mathbf{e}(E)^k, \xi^{k+\frac{1}{2}})\\ &= \Delta t(D\mathbf{e}(E)^k, C'u^{k+\frac{1}{2}}) + \Delta t(D\mathbf{e}(E)^k, C'D^{'-1}\xi^{k+\frac{1}{2}}),\end{aligned}$$

where $\|u^{k+\frac{1}{2}}\|_W$ and $\|D^{'-1}\xi^{k+\frac{1}{2}}\|_W$ are $O(h^2)$. So, we obtain

$$\begin{aligned}&\Delta t(D\mathbf{e}(E)^k, C'(B_f(t_{k+\frac{1}{2}}) - B'_e(t_{k+\frac{1}{2}})))\\ &\le \Delta t c_m \frac{M_2 M_3^{\frac{1}{2}}}{\min(h)}(2\|\mathbf{e}(E)^k\|^2_{W'} + \|u^{k+\frac{1}{2}}\|^2_W + \|D^{'-1}\xi^{k+\frac{1}{2}}\|^2_W).\end{aligned}$$

(ii) By Lemma 5.3 in [6] with $\phi = \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1}$, we have

$$\begin{aligned}&(\dot{E}'_f(t_n) - \dot{E}_e(t_n), \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'}\\ &= (\dot{v}, \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'} + (D'\dot{w}, C(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1}))\\ &\quad + (S^{'-1}\dot{\lambda}, \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'}.\end{aligned}$$

So, we have

$$\begin{aligned}&((E'_f(t_{n+1}) - E_e(t_{n+1})) - (E'_f(t_n) - E_e(t_n)), \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'}\\ &= \int_{n\Delta t}^{(n+1)\Delta t} \Big\{(\dot{v}, \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'} + (D'\dot{w}, C(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1}))\\ &\quad + (S^{'-1}\dot{\lambda}, \mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})_{W'}\Big\}\, ds\\ &\le 2(\max_{0\le n\le k}\|\mathbf{e}(E)^n\|_{W'}) \times \int_{n\Delta t}^{(n+1)\Delta t} \|\dot{v} + S^{'-1}\dot{\lambda}\, ds\|_{W'}\\ &\quad + \int_{n\Delta t}^{(n+1)\Delta t} (D'\dot{w}, C(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1}))\, ds.\end{aligned}$$

By the definition of the W'-norm and the estimate of $\|\dot{v}\|_{W'}$ from [6],

$$\begin{aligned}\int_{n\Delta t}^{(n+1)\Delta t} \|\dot{v}\, ds\|^2_{W'} &\le \Delta t \int_{n\Delta t}^{(n+1)\Delta t} \|\dot{v}\|^2_{W'}\, ds\\ &\le K h^4 \Delta t \sum_{r=1}^{2} \|\varepsilon_r^{\frac{1}{2}}\dot{\mathbf{E}}\|^2_{L^2(n\Delta t,(n+1)\Delta t;H^3(\Omega_r)^3)}.\end{aligned}$$

Similarly, by the definition of the W'-norm and the estimate of $\|S^{'-1}\dot{\lambda}\|_{W'}$ from [6], we have

$$\int_{n\Delta t}^{(n+1)\Delta t} \|S^{'-1}\dot{\lambda}\, ds\|^2_{W'} \le K h^4 \Delta t \sum_{r=1}^{2} \|\varepsilon_r^{\frac{1}{2}}\dot{\mathbf{E}}\|^2_{L^2(n\Delta t,(n+1)\Delta t;H^3(\Omega_r)^3)}.$$

Using (4.9) and the mean value theorem for integral, we have

$$\begin{aligned}
&\int_{n\Delta t}^{(n+1)\Delta t} (D'\dot{w}, C(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1}))\, ds \\
&= -\frac{1}{\Delta t}\int_{n\Delta t}^{(n+1)\Delta t} \Big\{(D'\dot{w}, S(\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n-\frac{1}{2}})) - (D'\dot{w}, P_2^n + P_2^{n+1})\Big\}\, ds \\
&= -(D'\dot{w}(\eta^{n+\frac{1}{2}}), S(\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n-\frac{1}{2}})) + \frac{1}{\Delta t}\int_{n\Delta t}^{(n+1)\Delta t} (D'\dot{w}, P_2^n + P_2^{n+1})\, ds,
\end{aligned}$$

where $t_n < \eta^{n+\frac{1}{2}} < t_{n+1}$. Applying summation by parts,

$$\begin{aligned}
&\sum_{n=0}^{k-1}(D'\dot{w}(\eta^{n+\frac{1}{2}}), S(\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n-\frac{1}{2}})) \\
&= (D'\dot{w}(\eta^{k-\frac{3}{2}}), S\mathbf{f}(B)^{k-\frac{1}{2}}) + (D'\dot{w}(\eta^{k-\frac{1}{2}}), S\mathbf{f}(B)^{k+\frac{1}{2}}) \\
&\quad - \sum_{n=1}^{k-2}(D'(\dot{w}(\eta^{n+\frac{3}{2}}) - \dot{w}(\eta^{n-\frac{1}{2}})), S\mathbf{f}(B)^{n+\frac{1}{2}}).
\end{aligned}$$

The first two terms on the right-hand side of the previous equation can be bounded by using the estimate of $\|\dot{w}\|_W$ from [6]. For the third term, we notice that

$$|\dot{w}(\eta^{n+\frac{3}{2}}) - \dot{w}(\eta^{n-\frac{1}{2}})|^2 \leq 3\Delta t \int_{(n-1)\Delta t}^{(n+2)\Delta t} |\ddot{w}|^2\, ds.$$

By the definition of the W-norm and the estimate of $\|\dot{w}\|_W$ from [6],

$$\|\dot{w}(\eta^{n+\frac{3}{2}}) - \dot{w}(\eta^{n-\frac{1}{2}})\|_W^2 \leq Kh^4\Delta t \sum_{r=1}^{2} \|\varepsilon_r^{\frac{1}{2}}\ddot{\mathbf{E}}\|^2_{L^2((n-1)\Delta t,(n+2)\Delta t;W^{2,p}(\Omega_r)^3)}.$$

By the Sobolev embedding theorem and the estimate of $\|\dot{w}\|_W$ from [6], we get

$$\begin{aligned}
&\frac{1}{\Delta t}\int_{n\Delta t}^{(n+1)\Delta t} (D'\dot{w}, P_2^n + P_2^{n+1})\, ds \\
&\leq \max_{0\leq s\leq T} \|\dot{w}(s)\|_W \|S^{-1}(P_2^n + P_2^{n+1})\|_W \\
&\leq Kh^2 \|S^{-1}(P_2^n + P_2^{n+1})\|_W \sum_{r=1}^{2} \|\varepsilon_r^{\frac{1}{2}}\mathbf{E}\|_{H^2(0,T;W^{2,p}(\Omega_r)^3)},
\end{aligned}$$

where the last term can be estimated by (4.14).

(iii) Using (4.9) and (4.11), we have

$$\begin{aligned}
&S(\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}) \\
&= -\Delta t C\mathbf{e}(E)^{n+1} + P_2^{n+1} \\
&= -\Delta t C\mathbf{e}(E)^{n+1} - \int_{(n+\frac{1}{2})\Delta t}^{(n+\frac{3}{2})\Delta t} S\dot{B}_f\, ds - \Delta t CE_e(t_{n+1}).
\end{aligned}$$

By (3.3), we have $S(\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}) = C\phi$ with

$$\phi = -\Delta t\mathbf{e}(E)^{n+1} + \int_{(n+\frac{1}{2})\Delta t}^{(n+\frac{3}{2})\Delta t} E_e(s)\, ds - \Delta t E_e(t_{n+1}).$$

Hence, by Lemma 5.2 from [6], we have

$$\begin{aligned}&(\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}, B_f(t_{n+\frac{3}{2}}) - B'_e(t_{n+\frac{3}{2}}))_W \\ &= (\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}, u^{n+\frac{3}{2}})_W + (\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}, D^{'-1}\xi^{n+\frac{3}{2}})_W.\end{aligned}$$

Applying summation by parts, we obtain

$$\begin{aligned}&\sum_{n=0}^{k-1} (\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}, u^{n+\frac{3}{2}})_W \\ &\quad = (\mathbf{f}(B)^{k+\frac{1}{2}}, u^{k+\frac{1}{2}})_W - \sum_{n=1}^{k-1} (\mathbf{f}(B)^{n+\frac{1}{2}}, u^{n+\frac{3}{2}} - u^{n+\frac{1}{2}})_W.\end{aligned}$$

We remark that a similar result holds for $(\mathbf{f}(B)^{n+\frac{3}{2}} - \mathbf{f}(B)^{n+\frac{1}{2}}, D^{'-1}\xi^{n+\frac{3}{2}})_W$.

(iv) We have

$$(P_1^{n+\frac{1}{2}}, D(\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1})) \leq \|S^{'-1}P_1^{n+\frac{1}{2}}\|_{W'}\|\mathbf{e}(E)^n + \mathbf{e}(E)^{n+1}\|_{W'},$$

which can be estimated by using (4.13).

(v) Notice that

$$\begin{aligned}&(P_2^{n+1}, D'(\mathbf{e}(B)^{n+\frac{1}{2}} + \mathbf{e}(B)^{n+\frac{3}{2}})) \\ &= (P_2^{n+1}, D'(\mathbf{f}(B)^{n+\frac{1}{2}} + \mathbf{f}(B)^{n+\frac{3}{2}})) \\ &\quad + (P_2^{n+1}, D'((B_f(t_{n+\frac{3}{2}}) - B'_e(t_{n+\frac{3}{2}})) + (B_f(t_{n+\frac{1}{2}}) - B'_e(t_{n+\frac{1}{2}})))).\end{aligned}$$

The first term on the right-hand side can be estimated by using (4.14). Notice that P_2^{n+1} can be written as $C\tilde{\phi}$ for some $\tilde{\phi}$. So, by Lemma 5.2 from [6], we have

$$(P_2^{n+1}, D'(B_f(t_{n+\frac{3}{2}}) - B'_e(t_{n+\frac{3}{2}}))) = (P_2^{n+1}, D'u^{n+\frac{3}{2}}) + (P_2^{n+1}, \xi^{n+\frac{3}{2}}),$$

which can be estimated by using (4.14) and the estimates of $\|u\|_W$ and $\|D^{'-1}\xi\|_W$ from [6]. □

Finally, we will state, without proof, the convergence estimate for the implicit fully discrete scheme (4.16)–(4.17) for nonuniform rectangular grids.

THEOREM 5.2. *Assume that*

$$\begin{aligned}&\mathbf{B}(\mathbf{x}, t) \in H^1(0, T; H^3(\Omega_r)^3), \\ &\mathbf{E}(\mathbf{x}, t) \in H^1(0, T; H^3(\Omega_r)^3) \cap H^2(0, T; W^{2,p}(\Omega_r)^3),\end{aligned}$$

for $p > 3$ *and* $r = 1, 2$, *is the solution to* (1.1)–(1.2) *and* (E^n, B^n) *is the solution to the implicit fully discrete scheme* (4.16)–(4.17) *on nonuniform rectangular grids. Then*

$$\begin{aligned}&\max_{0\leq n\leq N_T} (\|E^n - E_e(t_n)\|_{W'} + \|B^n - B_f(t_n)\|_W) \\ &\leq K(h^2 + c_m(\Delta t)^2) \\ &\quad \times \sum_{r=1}^{2} \Big\{ \|(\varepsilon_r^{\frac{1}{2}}\mathbf{E}, \mu_r^{-\frac{1}{2}}\mathbf{B})\|_{H^1(0,T;H^3(\Omega_r)^3)} + \|\varepsilon_r^{\frac{1}{2}}\mathbf{E}\|_{H^2(0,T;W^{2,p}(\Omega_r)^3)} \Big\}.\end{aligned} \tag{5.3}$$

5.2. A counterexample. We see from the previous sections that the spatial convergence of the FVM on rectangular grids is one order higher than that on general unstructured mesh. One main difference between these two grids is that the circumcenter of a rectangle coincides with its barycenter. Without choosing the barycenter as dual node, the scheme remains first order accurate. We will show this by considering the following one-dimensional example. Consider the system

$$\begin{aligned} u_t &= v_x, \\ v_t &= u_x, \end{aligned}$$

with initial conditions

$$u(x,0) = 0, \quad v(x,0) = \frac{1}{2}x^2.$$

The exact solution to this problem is given by

$$u(x,t) = xt, \quad v(x,t) = \frac{1}{2}(x^2 + t^2).$$

Now, we consider a uniform grid with mesh size h. A dual node within each primal interval is chosen such that the distance between the left end point and the dual node is αh for fixed $0 < \alpha < 1$. Therefore, the distance between the right end point and the dual node is $(1-\alpha)h$. Also, the distance between two consecutive dual nodes is h. We consider the semidiscrete scheme

$$\begin{aligned} \frac{d}{dt}u_j &= \frac{v'_{j+1} - v'_j}{h}, \\ \frac{d}{dt}v'_j &= \frac{u_j - u_{j-1}}{h}, \end{aligned}$$

where u_j is defined corresponding to the primal node x_j, while v'_j is defined corresponding to the dual node x'_j. By a direct computation, it can be shown that the following is a solution to the semidiscrete scheme:

$$\begin{aligned} u_j &= x_j t + (\alpha^2 - (1-\alpha)^2)ht, \\ v'_j &= \frac{1}{2}((x'_j)^2 + t^2), \end{aligned}$$

resulting in an $O(h)$ error.

A LEAST-SQUARES MIXED FINITE ELEMENT METHOD FOR BIOT'S CONSOLIDATION PROBLEM IN POROUS MEDIA[*]

JOHANNES KORSAWE[†] AND GERHARD STARKE[†]

Abstract. A least-squares mixed finite element method for the coupled problem of flow and deformation is presented and analyzed in this paper. For the analysis, we restrict ourselves to fully saturated conditions for the flow process and to a linearly elastic material law for the deformation process. This is known in the literature as Biot's consolidation problem. For simplicity, the analysis is presented for the problem in two space dimensions. Our least-squares approach is motivated by the fact that all process variables, i.e., fluid pressure and flux as well as displacement field and stress tensor, are approximated directly by suitable finite element spaces. Ellipticity of the corresponding variational formulation is proven for the stationary case as well as for the subproblems arising at each step of an implicit time discretization in the general time-dependent case. Standard H^1-conforming piecewise linear and quadratic finite elements are used for the fluid pressure and for (each component of) the displacement, respectively. For the flux and stress components, the $H(\text{div})$-conforming Raviart–Thomas spaces (of lowest order) are used. Computational results are presented for some two-dimensional test problems.

1. Introduction.

In recent years, a lot of effort has been dedicated to the theoretical and numerical treatment of models for fluid flow and deformation in porous media. Our model will be based on the classical phenomenological approach by Biot [2] using the concept of effective stresses. Modern formulations based on multiphase mixture theories were developed in the last 30 years; see the monograph by de Boer [12] for an overview. Much of current research concerned with the numerical treatment of such coupled problems is devoted to the extension to two-phase flow and elastoplastic deformation models. The classical Biot consolidation problem assumes a fully saturated porous medium and a linearly elastic material law leading to a linear parabolic system. We restrict our attention to this linear problem since our aim is to analyze a least-squares mixed finite element method in the simplest possible situation. The novelty of our least-squares approach is the introduction of approximation spaces for the fluid flux and the stress tensor in addition to the primary variables fluid pressure and displacement field.

The numerical treatment of Biot's consolidation problem by the Taylor–Hood finite element spaces was studied by Murad and Loula in [16] and [17]. This work was continued with a detailed analytical investigation in the contribution by Murad, Thomée, and Loula [18]. A general reference for the use of the finite element method for the numerical simulation of fluid flow and deformation processes in porous media is the monograph by Lewis and Schrefler [15]. A nonlinearly elastic material law for fluid-saturated porous solids is considered in Ehlers and Eipper [13]. Wang and Kolditz [21] investigate the numerical treatment of elastoplastic material behavior

using a Drucker–Prager model for some two-dimensional plane strain problems under fully saturated conditions. Wieners et al. [22] consider saturated porous medium flow in three spatial dimensions where the material behavior of the porous skeleton is assumed to be elastoviscoplastic. Taylor–Hood elements are used in [22] for the approximation of the displacement field and fluid pressure.

Our purpose in this paper is the derivation and study of a least-squares finite element approach to the coupled mechanical and flow problem. The least-squares approach introduces finite element spaces for the approximation of all the process variables involved in our model. In the case of fluid flow in deformable porous media these consist of fluid pressure and flux as well as displacement field and stress tensor. At first sight this appears to increase the computational work by introducing more variables compared to standard approaches involving only pressure and displacements. However, the introduction of these variables does, in general, lead to significant simplifications at various stages of the solution algorithm. First, the variables coupling the flow and deformation processes are used directly to describe the problem, which makes it straightforward to derive the underlying variational formulation. In this way, all the variables of interest can be approximated directly and, for fluid flux and for the stress tensor, more accurately than by postprocessing from the results of the standard formulation. Moreover, the finite element spaces used for approximating the different process variables can be chosen independently since no inf-sup compatibility conditions are required in the least-squares finite element approach. Finally, the local evaluation of the least-squares functional provides an a posteriori error estimator at no additional cost.

The equivalence of the least-squares functional to the displacement components and fluid pressure measured in the H^1 norm and to the stress components and fluid flux measured in the $H(\mathrm{div})$ norm is the main analytical contribution of this paper. This ellipticity result ensures that the boundary value problem under consideration is well-posed and leads to finite element approximation estimates in a straightforward way. In the stationary case, the proof rests upon the results in [7] for the flow part and [9, 6] for the deformation part. For the time-dependent case a more careful analysis is carried out to establish ellipticity of the corresponding least-squares formulation. Standard H^1-conforming linear and quadratic finite elements are then used for the fluid pressure and the displacement components, respectively. The fluid flux and the stress components are approximated by the $H(\mathrm{div})$-conforming Raviart–Thomas spaces of lowest order.

For the mechanical part of the model we restrict ourselves to linear elastic material behavior. For linear elasticity a least-squares mixed finite element approach using displacement and stress as process variables has been proposed recently in [9, 10, 6]. This approach was extended to incompressible Newtonian flow in [8]. The first-order system studied in [8] has some similarities to the deformation part of the consolidation problem under investigation here. For the fluid flow part of the model we assume fully saturated conditions for our analysis. However, variably saturated porous media can also be treated using a least-squares mixed finite element approach for variably saturated subsurface flow, which was studied in [20] and [19]. The combination of these two methods for the treatment of the coupled problem of variably saturated fluid flow and mechanical deformation has been tested numerically in [14].

The remainder of this paper is organized as follows. In section 2 we present the least-squares mixed formulation of Biot's consolidation problem. The ellipticity of the bilinear form associated with the least-squares functional for the stationary case is proved in section 3. Ellipticity for the least-squares formulation resulting from an implicit Euler time discretization of the time-dependent problem is established in section 4. Section 5 provides the appropriate finite element spaces with the corresponding approximation properties and discusses the issue of error estimation. Finally, the results of computational experiments are presented in section 6.

2. Least-squares formulation of Biot's consolidation problem.

We start this section with a review of the least-squares formulation of linear elasticity due to [9] and [6]. We consider the equations of linear elasticity in the form

$$\begin{aligned} \operatorname{div} \boldsymbol{\sigma} &= \mathbf{0} \text{ in } \Omega, \\ \boldsymbol{\sigma} - \mathcal{C}\boldsymbol{\varepsilon}(\mathbf{u}) &= \mathbf{0} \text{ in } \Omega, \\ \mathbf{u} &= \mathbf{0} \text{ on } \Gamma_D^{\text{elas}}, \\ \boldsymbol{\sigma} \cdot \mathbf{n} &= \mathbf{g} \text{ on } \Gamma_N^{\text{elas}}, \end{aligned} \tag{2.1}$$

where $\Omega \subset \mathbb{R}^2$ is a bounded domain with the boundary divided into two disjoint parts Γ_D^{elas} and Γ_N^{elas} such that $\overline{\Gamma}_D^{\text{elas}} \cup \overline{\Gamma}_N^{\text{elas}} = \partial\Omega$. For simplicity we assume that Γ_D^{elas} and Γ_N^{elas} are both of positive length. The operator $\mathcal{C}$ is the linear mapping from strains to stresses given by

$$\mathcal{C}\boldsymbol{\varepsilon} = 2\mu\, \boldsymbol{\varepsilon} + \lambda\, (\operatorname{tr} \boldsymbol{\varepsilon})\, \mathbf{I}\,,\ \boldsymbol{\varepsilon} \in \mathbb{R}^{2\times 2}, \tag{2.2}$$

with the Lamé constants λ, μ. We allow $\lambda > 0$ to be arbitrarily large; i.e., the treatment of nearly incompressible materials is possible, but we assume that μ is on the order of one. Note that this can be achieved by a suitable rescaling of the displacements $\mathbf{u}$. The strain tensor in linear elasticity is given by

$$\boldsymbol{\varepsilon}(\mathbf{u}) = \begin{bmatrix} \partial_1 u_1 & \frac{1}{2}(\partial_2 u_1 + \partial_1 u_2) \\ \frac{1}{2}(\partial_2 u_1 + \partial_1 u_2) & \partial_2 u_2 \end{bmatrix}, \tag{2.3}$$

the symmetric gradient of $\mathbf{u}$. The traction boundary conditions in (2.1) are treated by extending the boundary values $\mathbf{g}$ on Γ_N^{elas} to a function $\boldsymbol{\sigma}^N \in H(\text{div}, \Omega)^2$. Such an extension exists if we assume $\mathbf{g} \in H^{-1/2}(\Gamma_N)$ and can be constructed as follows: Denote by $\mathbf{G} \in H^{1/2}(\Gamma_N)$ the antiderivative (componentwise) of $\mathbf{g}$ along Γ_N parametrized with respect to arc length (which implies that the tangential derivative $\mathbf{n} \times \nabla \mathbf{G} = \mathbf{g}$). Using well-known lifting theorems (see, e.g., [11, section IV.4]) an extension $\boldsymbol{\Psi} \in H^1(\Omega)$ with $\boldsymbol{\Psi} = \mathbf{G}$ on Γ_N is obtained. It can easily be verified that $\boldsymbol{\sigma}^N = \nabla^\perp \mathbf{G}$ has the desired properties (note that even $\operatorname{div} \boldsymbol{\sigma}^N = 0$ holds). This leads to the problem of finding

$$\begin{aligned} \hat{\boldsymbol{\sigma}} \in H_{\Gamma_N^{\text{elas}}}(\text{div}, \Omega)^2 &= \{\boldsymbol{\tau} \in H(\text{div}, \Omega)^2 : \boldsymbol{\tau} \cdot \mathbf{n} = \mathbf{0} \text{ on } \Gamma_N^{\text{elas}}\}, \\ \mathbf{u} \in H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2 &= \{\mathbf{v} \in H^1(\Omega)^2 : \mathbf{v} = \mathbf{0} \text{ on } \Gamma_D^{\text{elas}}\} \end{aligned}$$

with $\boldsymbol{\sigma} = \boldsymbol{\sigma}^N + \hat{\boldsymbol{\sigma}}$ and $\mathbf{u}$ satisfying the system (2.1).

From now on, the standard norm on $L^2(\Omega)$ (or $L^2(\Omega)^2$, $L^2(\Omega)^{2\times 2}$, respectively) is abbreviated by $\|\cdot\|$. Introducing the least-squares functional

$$\mathcal{F}_{\text{elas}}(\boldsymbol{\sigma}, \mathbf{u}) = \|\operatorname{div} \boldsymbol{\sigma}\|^2 + \|\mathcal{C}^{-1/2}\boldsymbol{\sigma} - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u})\|^2\,, \tag{2.4}$$

our aim is then to minimize $\mathcal{F}_{\text{elas}}(\boldsymbol{\sigma}, \mathbf{u})$ among all $\boldsymbol{\sigma} = \boldsymbol{\sigma}^N + \hat{\boldsymbol{\sigma}}$ with $\hat{\boldsymbol{\sigma}} \in H_{\Gamma_N^{\text{elas}}}(\text{div}, \Omega)^2$ and $\mathbf{u} \in H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2$. The scaling by $\mathcal{C}^{1/2}$ is necessary for the proper balance between both terms of the functional in the nearly incompressible case. The theoretical foundation of this choice of scaling is given in [9] and [6].

The fully saturated flow problem in the absence of deformation reads

$$\begin{aligned} \operatorname{div}\mathbf{w} &= 0 \text{ in } \Omega, \\ \mathbf{w} + \kappa\,\nabla p &= \mathbf{0} \text{ in } \Omega, \\ p &= p^D \text{ on } \Gamma_D^{\text{flow}}, \\ \mathbf{w}\cdot\mathbf{n} &= 0 \text{ on } \Gamma_N^{\text{flow}}. \end{aligned} \tag{2.5}$$

The splitting of the boundary $\partial\Omega = \overline{\Gamma}_D^{\text{flow}} \cup \overline{\Gamma}_N^{\text{flow}}$ into a Dirichlet and Neumann part will, in general, not be the same as for the elasticity problem. We assume, however, that Γ_D^{flow} has positive length. In (2.5), $\mathbf{w}$ denotes the volumetric flux of the fluid and p the pressure potential in Ω. Note that, in this definition, the true pressure in the porous medium may be recovered from p by adding the effect of the fluid weight due to gravity. Moreover, the diffusion parameter κ denotes the quotient of permeability and fluid viscosity. Assuming $p^D \in H^{1/2}(\Gamma_D)$, we may extend these boundary values to a function in $H^1(\Omega)$ also denoted by p^D (see again [11, section IV.4]). Our aim is to find $\mathbf{w} \in H_{\Gamma_N^{\text{flow}}}(\text{div}, \Omega)$ and $p = p^D + \hat{p}$ with $\hat{p} \in H^1_{\Gamma_D^{\text{flow}}}(\Omega)$ such that the least-squares functional

$$\mathcal{F}_{\text{flow}}(\mathbf{w}, p) = \|\text{div}\,\mathbf{w}\|^2 + \|\mathbf{w} + \kappa\nabla p\|^2 \tag{2.6}$$

is minimized. Here we assume that the percolation parameter κ is on the order of one, which can be achieved by a suitable rescaling of the pressure p. κ may vary in the domain Ω as long as $\underline{\kappa} \le \kappa \le \overline{\kappa}$ holds with positive constants $\underline{\kappa}, \overline{\kappa}$.

The consolidation process is described by a model which couples flow and deformation. The system (2.1), modeling the elastic deformation, needs to be modified in such away that it includes the stress field caused by the fluid pressure. To this end, the stress part $\boldsymbol{\sigma}$ associated with the material deformation, called effective stress, is introduced as a process variable, and the momentum balance equation is modified such that it incorporates stresses and forces connected to the fluid pressure. This leads to

$$\begin{aligned} \text{div}\,(\boldsymbol{\sigma} - p\mathbf{I}) &= \mathbf{0} \text{ in } \Omega\,, \\ \boldsymbol{\sigma} - \mathcal{C}\varepsilon(\mathbf{u}) &= \mathbf{0} \text{ in } \Omega\,, \\ \mathbf{u} &= \mathbf{0} \text{ on } \Gamma_D^{\text{elas}}\,, \\ \boldsymbol{\sigma}\cdot\mathbf{n} &= \mathbf{g} \text{ on } \Gamma_N^{\text{elas}}\,. \end{aligned} \tag{2.7}$$

Note that the displacement field $\mathbf{u}$ of this model is defined with respect to the equilibrium under gravity. The true effective stress in the porous medium may be computed from $\boldsymbol{\sigma}$ by adding the effect of its own weight due to gravity. The mass balance equation in the fluid flow model (2.5) needs to take care of the change in pore space due to the displacement, which leads to

$$\begin{aligned} \text{div}\,\mathbf{w} + \partial_t \text{div}\,\mathbf{u} &= 0 \text{ in } \Omega, \\ \mathbf{w} + \kappa\,\nabla p &= \mathbf{0} \text{ in } \Omega, \\ p &= p^D \text{ on } \Gamma_D^{\text{flow}}, \\ \mathbf{w}\cdot\mathbf{n} &= 0 \text{ on } \Gamma_N^{\text{flow}}\,. \end{aligned} \tag{2.8}$$

Note again that in this model p has the character of a hydraulic potential and does not represent the true pressure in the porous medium. The pressure includes an additional term due to the effect of the weight of the fluid under gravity. Using an implicit time discretization, one obtains from this system

$$\begin{aligned} \operatorname{div} \mathbf{w} + \frac{1}{k}(\operatorname{div} \mathbf{u} - \operatorname{div} \mathbf{u}^{\text{old}}) &= 0 \text{ in } \Omega, \\ \mathbf{w} + \kappa \nabla p &= \mathbf{0} \text{ in } \Omega, \\ p &= p^D \text{ on } \Gamma_D^{\text{flow}}, \\ \mathbf{w} \cdot \mathbf{n} &= 0 \text{ on } \Gamma_N^{\text{flow}}, \end{aligned} \tag{2.9}$$

where k is the time-step length and $\mathbf{u}^{\text{old}}$ denotes the displacement field at the previous time-step. The least-squares functional associated with the coupled problem (2.7), (2.9) is given by

$$\begin{aligned} \mathcal{F}(\boldsymbol{\sigma}, \mathbf{u}, \mathbf{w}, p; \mathbf{u}^{\text{old}}) = {} & \|\operatorname{div} (\boldsymbol{\sigma} - p\mathbf{I})\|^2 + \|\mathcal{C}^{-1/2}\boldsymbol{\sigma} - \mathcal{C}^{1/2}\varepsilon(\mathbf{u})\|^2 \\ & + \left\|\operatorname{div} \mathbf{w} + \frac{1}{k}(\operatorname{div} \mathbf{u} - \operatorname{div} \mathbf{u}^{\text{old}})\right\|^2 + \|\mathbf{w} + \kappa \nabla p\|^2 . \end{aligned} \tag{2.10}$$

The least-squares variational formulation consists in finding $\boldsymbol{\sigma} = \boldsymbol{\sigma}^N + \hat{\boldsymbol{\sigma}}$ with $\hat{\boldsymbol{\sigma}} \in H_{\Gamma_N^{\text{elas}}}(\operatorname{div}, \Omega)^2$, $\mathbf{u} \in H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2$, $\mathbf{w} \in H_{\Gamma_N^{\text{flow}}}(\operatorname{div}, \Omega)$, and $p = p^D + \hat{p}$ with $\hat{p} \in H^1_{\Gamma_D^{\text{flow}}}(\Omega)$ such that $\mathcal{F}(\boldsymbol{\sigma}, \mathbf{u}, \mathbf{w}, p; \mathbf{u}^{\text{old}})$ is minimized.

We abbreviate the standard inner product on $L^2(\Omega)$ (or $L^2(\Omega)^2$, $L^2(\Omega)^{2\times 2}$, respectively) by $(\,\cdot\,,\,\cdot\,)$. Associated with the quadratic least-squares functional (2.10) is then the bilinear form

$$\begin{aligned} \mathcal{B}(\boldsymbol{\sigma}, \mathbf{u}, \mathbf{w}, p; \boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q) = {} & (\operatorname{div} (\boldsymbol{\sigma} - p\mathbf{I}), \operatorname{div} (\boldsymbol{\tau} - q\mathbf{I})) \\ & + (\mathcal{C}^{-1/2}\boldsymbol{\sigma} - \mathcal{C}^{1/2}\varepsilon(\mathbf{u}), \mathcal{C}^{-1/2}\boldsymbol{\tau} - \mathcal{C}^{1/2}\varepsilon(\mathbf{v})) \\ & + \left(\operatorname{div} \mathbf{w} + \frac{1}{k}\operatorname{div} \mathbf{u}, \operatorname{div} \mathbf{z} + \frac{1}{k}\operatorname{div} \mathbf{v}\right) \\ & + (\mathbf{w} + \kappa \nabla p, \mathbf{z} + \kappa \nabla q) . \end{aligned} \tag{2.11}$$

The quadratic minimization problem above is then equivalent to the following variational problem: Find $\hat{\boldsymbol{\sigma}} \in H_{\Gamma_N^{\text{elas}}}(\operatorname{div}, \Omega)^2$, $\mathbf{u} \in H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2$, $\mathbf{w} \in H_{\Gamma_N^{\text{flow}}}(\operatorname{div}, \Omega)$, and $\hat{p} \in H^1_{\Gamma_D^{\text{flow}}}(\Omega)$ such that

$$\begin{aligned} & \mathcal{B}(\hat{\boldsymbol{\sigma}}, \mathbf{u}, \mathbf{w}, \hat{p}; \boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q) \\ & = - (\operatorname{div}\boldsymbol{\sigma}^N, \operatorname{div} (\boldsymbol{\tau} - q\mathbf{I})) - (\mathcal{C}^{-1/2}\boldsymbol{\sigma}^N, \mathcal{C}^{-1/2}\boldsymbol{\tau} - \mathcal{C}^{1/2}\varepsilon(\mathbf{v})) \\ & \quad + \left(\frac{1}{k}\operatorname{div} \mathbf{u}^{\text{old}}, \operatorname{div} \mathbf{z} + \frac{1}{k}\operatorname{div} \mathbf{v}\right) - (\kappa \nabla p^D, \mathbf{z} + \kappa \nabla q) \end{aligned} \tag{2.12}$$

for all $\boldsymbol{\tau} \in H_{\Gamma_N^{\text{elas}}}(\operatorname{div}, \Omega)^2$, $\mathbf{v} \in H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2$, $\mathbf{z} \in H_{\Gamma_N^{\text{flow}}}(\operatorname{div}, \Omega)$, and $q \in H^1_{\Gamma_D^{\text{flow}}}(\Omega)$.

3. Ellipticity of the least-squares formulation: Stationary case. In this section, we prove that the bilinear form (2.11) is coercive and continuous on the product space $H_{\Gamma_N^{\text{elas}}}(\operatorname{div}, \Omega)^2 \times H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2 \times H_{\Gamma_N^{\text{flow}}}(\operatorname{div}, \Omega) \times H^1_{\Gamma_D^{\text{flow}}}(\Omega)$. More precisely, in order to get approximation results which are uniform with respect to the Lamé parameters μ and λ, our aim is to show coercivity and continuity with constants which are independent of these parameters. To this end, we introduce the norm

$$
\begin{aligned}
|||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q)||| = \Big(&\|\mathrm{div}\,\boldsymbol{\tau}\|^2 + \|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 + \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&+ \|\mathrm{div}\,\mathbf{z}\|^2 + \|\mathbf{z}\|^2 + \|\nabla q\|^2\Big)^{1/2} .
\end{aligned}
\tag{3.1}
$$

Under our assumption on the boundary conditions, Korn's inequality, i.e.,

$$
\|\mathbf{v}\|^2 + \|\nabla \mathbf{v}\|^2 \le C_K \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 , \tag{3.2}
$$

for all $\mathbf{v} \in H^1_{\Gamma_D^{\mathrm{elas}}}(\Omega)^2$ holds (cf. [3, section VI.3]). Moreover, the Poincaré–Friedrichs inequality

$$
\|q\|^2 \le C_F \|\nabla q\|^2 \tag{3.3}
$$

is satisfied for all $q \in H^1_{\Gamma_D^{\mathrm{flow}}}(\Omega)$ (cf. [3, section II.1]). Therefore, $|||(\cdot,\cdot,\cdot,\cdot)|||$ defined in (3.1) is a norm on the product space $H_{\Gamma_N^{\mathrm{elas}}}(\mathrm{div},\Omega)^2 \times H^1_{\Gamma_D^{\mathrm{elas}}}(\Omega)^2 \times H_{\Gamma_N^{\mathrm{flow}}}(\mathrm{div},\Omega) \times H^1_{\Gamma_D^{\mathrm{flow}}}(\Omega)$.

Since the bilinear form $\mathcal{B}(\cdot,\cdot,\cdot,\cdot;\cdot,\cdot,\cdot,\cdot)$ is symmetric, the Cauchy–Schwarz inequality gives us

$$
\mathcal{B}(\boldsymbol{\sigma}, \mathbf{u}, \mathbf{w}, p; \boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q) \le \mathcal{F}(\boldsymbol{\sigma}, \mathbf{u}, \mathbf{w}, p; \mathbf{0})^{1/2} \mathcal{F}(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0})^{1/2} . \tag{3.4}
$$

It is therefore sufficient to show that

$$
\alpha\, |||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q)|||^2 \le \mathcal{F}(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0}) \le \beta\, |||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q)|||^2 \tag{3.5}
$$

holds for all $(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q) \in H_{\Gamma_N^{\mathrm{elas}}}(\mathrm{div},\Omega)^2 \times H^1_{\Gamma_D^{\mathrm{elas}}}(\Omega)^2 \times H_{\Gamma_N^{\mathrm{flow}}}(\mathrm{div},\Omega) \times H^1_{\Gamma_D^{\mathrm{flow}}}(\Omega)$ with positive constants α, β which are independent of the Lamé parameter λ.

The following lemma states these equivalence results for the least-squares functionals (2.4) and (2.6) associated with the deformation and flow subproblems, respectively. Our analysis of the coupled problem will be based on these results.

LEMMA 3.1. *There are positive constants* α_{elas} *and* β_{elas} *such that*

$$
\alpha_{\mathrm{elas}} |||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{0}, 0)|||^2 \le \mathcal{F}_{\mathrm{elas}}(\boldsymbol{\tau}, \mathbf{v}) \le \beta_{\mathrm{elas}} |||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{0}, 0)|||^2 \tag{3.6}
$$

holds for all $(\boldsymbol{\tau}, \mathbf{v}) \in H_{\Gamma_N^{\mathrm{elas}}}(\mathrm{div},\Omega)^2 \times H^1_{\Gamma_D^{\mathrm{elas}}}(\Omega)^2$ *uniformly as* $\lambda \to \infty$.

Furthermore, there are positive constants α_{flow} *and* β_{flow} *such that*

$$
\alpha_{\mathrm{flow}} |||(\mathbf{0}, \mathbf{0}, \mathbf{z}, q)|||^2 \le \mathcal{F}_{\mathrm{flow}}(\mathbf{z}, q) \le \beta_{\mathrm{flow}} |||(\mathbf{0}, \mathbf{0}, \mathbf{z}, q)|||^2 \tag{3.7}
$$

holds for all $(\mathbf{z}, q) \in H_{\Gamma_N^{\mathrm{flow}}}(\mathrm{div},\Omega) \times H^1_{\Gamma_D^{\mathrm{flow}}}(\Omega)$.

The equivalence (3.6) for the linear elasticity problem has been established in [9] and [6]. The stationary flow problem has been studied in [7], where (3.7) has been proven.

The least-squares functional associated with the stationary problem is given by

$$
\begin{aligned}
\mathcal{F}_{\mathrm{stat}}(\boldsymbol{\sigma}, \mathbf{u}, \mathbf{w}, p) = &\|\mathrm{div}\,(\boldsymbol{\sigma} - p\mathbf{I})\|^2 + \|\mathcal{C}^{-1/2}\boldsymbol{\sigma} - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u})\|^2 \\
&+ \|\mathrm{div}\,\mathbf{w}\|^2 + \|\mathbf{w} + \kappa\nabla p\|^2 .
\end{aligned}
\tag{3.8}
$$

Our aim is to prove that this functional is equivalent to $|||(\cdot,\cdot,\cdot,\cdot)|||^2$ uniformly in the Lamé parameters, which is the statement of the following theorem.

Theorem 3.2. *There are positive constants α_{stat} and β_{stat} such that*

$$\alpha_{\text{stat}}|||(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q)|||^2 \le \mathcal{F}_{\text{stat}}(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q) \le \beta_{\text{stat}}|||(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q)|||^2 \tag{3.9}$$

holds for all $(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q) \in H_{\Gamma_N^{\text{elas}}}(\text{div},\Omega)^2 \times H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2 \times H_{\Gamma_N^{\text{flow}}}(\text{div},\Omega) \times H^1_{\Gamma_D^{\text{flow}}}(\Omega)$ *uniformly as* $\lambda \to \infty$.

Proof. Since div $(q\mathbf{I}) = \nabla q$, we have

$$\mathcal{F}_{\text{stat}}(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q) = \mathcal{F}_{\text{elas}}(\boldsymbol{\tau},\mathbf{v}) + \mathcal{F}_{\text{flow}}(\mathbf{z},q) + \|\nabla q\|^2 - 2(\text{div}\,\boldsymbol{\tau},\nabla q)\,. \tag{3.10}$$

The proof of the lower bound in (3.9) is based on

$$\begin{aligned}\mathcal{F}_{\text{stat}}(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q) &\ge \mathcal{F}_{\text{elas}}(\boldsymbol{\tau},\mathbf{v}) + \mathcal{F}_{\text{flow}}(\mathbf{z},q) + \left(1-\frac{1}{\eta}\right)\|\nabla q\|^2 - \eta\|\text{div}\,\boldsymbol{\tau}\|^2\\ &\ge (1-\eta)\|\text{div}\,\boldsymbol{\tau}\|^2 + \|\mathcal{C}^{-1/2}\boldsymbol{\tau} - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2\\ &\quad + \alpha_{\text{flow}}\left(\|\text{div}\,\mathbf{z}\|^2 + \|\mathbf{z}\|^2\right) + \left(\alpha_{\text{flow}} + 1 - \frac{1}{\eta}\right)\|\nabla q\|^2\,,\end{aligned}$$

where we are still free to choose $\eta \in (0,1)$. Choosing η in such a way that

$$\frac{1}{\eta} - 1 = \frac{1}{2}\alpha_{\text{flow}}\ ,\ \text{i.e.,}\ \eta = \frac{2}{2+\alpha_{\text{flow}}},$$

leads to

$$\begin{aligned}\mathcal{F}_{\text{stat}}(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q) &\ge (1-\eta)\mathcal{F}_{\text{elas}}(\boldsymbol{\tau},\mathbf{v}) + \frac{1}{2}\alpha_{\text{flow}}|||(\mathbf{0},\mathbf{0},\mathbf{z},q)|||^2\\ &\ge \frac{\alpha_{\text{flow}}}{2+\alpha_{\text{flow}}}\alpha_{\text{elas}}|||(\boldsymbol{\tau},\mathbf{v},\mathbf{0},0)|||^2 + \frac{1}{2}\alpha_{\text{flow}}|||(\mathbf{0},\mathbf{0},\mathbf{z},q)|||^2\\ &\ge \min\left\{\frac{\alpha_{\text{flow}}}{2+\alpha_{\text{flow}}}\alpha_{\text{elas}}, \frac{1}{2}\alpha_{\text{flow}}\right\}|||(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q)|||^2\,.\end{aligned}$$

For the upper bound in (3.9), we use (3.6), (3.7), and Cauchy–Schwarz inequality to obtain from (3.10)

$$\begin{aligned}\mathcal{F}_{\text{stat}}(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q) &\le \beta_{\text{elas}}|||(\boldsymbol{\tau},\mathbf{v},\mathbf{0},0)|||^2 + \beta_{\text{flow}}|||(\mathbf{0},\mathbf{0},\mathbf{z},q)|||^2 + 2\|\nabla q\|^2 + \|\text{div}\,\boldsymbol{\tau}\|^2\\ &\le (\beta_{\text{elas}}+1)|||(\boldsymbol{\tau},\mathbf{v},\mathbf{0},0)|||^2 + (\beta_{\text{flow}}+2)|||(\mathbf{0},\mathbf{0},\mathbf{z},q)|||^2\\ &\le \max\{\beta_{\text{elas}}+1,\beta_{\text{flow}}+2\}|||(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q)|||^2\,. \qquad \square\end{aligned}$$

4. Ellipticity of the least-squares formulation: Time-dependent case. For the analysis of the time-dependent least-squares functional (2.10) we make the assumption that

$$\Gamma_N^{\text{elas}} = \Gamma_D^{\text{flow}} =: \Gamma_1 \quad \text{and} \quad \Gamma_D^{\text{elas}} = \Gamma_N^{\text{flow}} =: \Gamma_2\,.$$

This has the physical meaning that the normal stress is prescribed on the same part of the boundary as the fluid pressure. Similarly, the displacements and the normal flux are set to zero on the same boundary segments. This is not unrealistic from a physical point of view even though more general situations may occur in practice (see the examples in section 6). We introduce as new variables

$$\tilde{\boldsymbol{\sigma}} = \boldsymbol{\sigma} - p\mathbf{I} \quad \text{and} \quad \tilde{\mathbf{w}} = \mathbf{w} + \frac{1}{k}\mathbf{u} \tag{4.1}$$

and observe that

$$\begin{aligned} \boldsymbol{\sigma} \in H_{\Gamma_1}(\mathrm{div},\Omega)^2 \, , \; p \in H^1_{\Gamma_1}(\Omega) \quad &\Longrightarrow \quad \tilde{\boldsymbol{\sigma}} \in H_{\Gamma_1}(\mathrm{div},\Omega)^2 \, , \\ \mathbf{w} \in H_{\Gamma_2}(\mathrm{div},\Omega) \, , \; \mathbf{u} \in H^1_{\Gamma_2}(\Omega)^2 \quad &\Longrightarrow \quad \tilde{\mathbf{w}} \in H_{\Gamma_2}(\mathrm{div},\Omega) \, . \end{aligned}$$

For the time-dependent case, the behavior of the least-squares formulation for different time-step sizes is of interest. In order to eliminate the dependence of the equivalence constants on the time-step length as much as possible, we scale the least-squares functional (2.10) with k as

$$\begin{aligned} \mathcal{F}_k(\boldsymbol{\sigma}, \mathbf{u}, \mathbf{w}, p; \mathbf{u}^{\mathrm{old}}) = \|\mathrm{div}\,(\boldsymbol{\sigma} - p\mathbf{I})\|^2 + \|\mathcal{C}^{-1/2}\boldsymbol{\sigma} - \mathcal{C}^{1/2}\varepsilon(\mathbf{u})\|^2 \\ + k\left\|\mathrm{div}\,\mathbf{w} + \frac{1}{k}(\mathrm{div}\,\mathbf{u} - \mathrm{div}\,\mathbf{u}^{\mathrm{old}})\right\|^2 + k\|\mathbf{w} + \kappa\nabla p\|^2 \, . \end{aligned} \tag{4.2}$$

Note that it is sufficient to consider the case $\kappa \equiv 1$ in the analysis since

$$\begin{aligned} \|\mathbf{w} + \kappa\nabla p\|^2 &\geq \underline{\kappa}\|\kappa^{-1/2}\mathbf{w} + \kappa^{1/2}\nabla p\|^2 = \underline{\kappa}\left(\kappa^{-1}\|\mathbf{w}\|^2 + 2(\mathbf{w}, \nabla p) + \kappa\|\nabla p\|^2\right) \\ &\geq \underline{\kappa}\min\{\overline{\kappa}^{-1}, \underline{\kappa}\}\left(\|\mathbf{w}\|^2 + 2(\mathbf{w}, \nabla p) + \|\nabla p\|^2\right) \\ &= \min\{\underline{\kappa}\overline{\kappa}^{-1}, \underline{\kappa}^2\}\|\mathbf{w} + \nabla p\|^2 \, , \end{aligned}$$

$$\begin{aligned} \|\mathbf{w} + \kappa\nabla p\|^2 &\leq \overline{\kappa}\|\kappa^{-1/2}\mathbf{w} + \kappa^{1/2}\nabla p\|^2 = \overline{\kappa}\left(\kappa^{-1}\|\mathbf{w}\|^2 + 2(\mathbf{w}, \nabla p) + \kappa\|\nabla p\|^2\right) \\ &\leq \overline{\kappa}\max\{\underline{\kappa}^{-1}, \overline{\kappa}\}\left(\|\mathbf{w}\|^2 + 2(\mathbf{w}, \nabla p) + \|\nabla p\|^2\right) \\ &= \min\{\overline{\kappa}\underline{\kappa}^{-1}, \overline{\kappa}^2\}\|\mathbf{w} + \nabla p\|^2 \, . \end{aligned}$$

Our analysis is then carried out with respect to the scaled norm

$$\begin{aligned} |||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q)|||_k = \Big(\|\mathrm{div}\,\boldsymbol{\tau}\|^2 + \|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 + \|\mathcal{C}^{1/2}\varepsilon(\mathbf{v})\|^2 \\ + k\left(\|\mathrm{div}\,\mathbf{z}\|^2 + \|\mathbf{z}\|^2 + \|\nabla q\|^2\right)\Big)^{1/2} \, . \end{aligned} \tag{4.3}$$

The following lemma states that it is sufficient to prove ellipticity with respect to the transformed variables.

LEMMA 4.1. *For the norm* $|||(\,\cdot\,,\,\cdot\,,\,\cdot\,,\,\cdot\,)|||_k$ *defined in* (4.3) *and under the transformation* (4.1)*, the equivalence*

$$\frac{1}{\gamma}|||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q)|||_k^2 \leq |||(\tilde{\boldsymbol{\tau}}, \mathbf{v}, \tilde{\mathbf{z}}, q)|||_k^2 \leq \gamma|||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q)|||_k^2 \tag{4.4}$$

for all $(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q), (\tilde{\boldsymbol{\tau}}, \mathbf{v}, \tilde{\mathbf{z}}, q) \in H_{\Gamma_1}(\mathrm{div},\Omega)^2 \times H^1_{\Gamma_2}(\Omega)^2 \times H_{\Gamma_2}(\mathrm{div},\Omega) \times H^1_{\Gamma_1}(\Omega)$ *holds* *with*

$$\gamma = \max\left\{2\,,\ 1+\frac{4C_K}{k}, 1+\frac{2}{k}+\frac{2C_F}{k(\lambda+\mu)}\right\}\ .$$

Here, C_K and C_F denote the constants from Korn's inequality (3.2) *and the Poincaré–Friedrichs inequality* (3.3), *respectively.*

Proof. The left inequality in (4.4) follows from

$$\begin{aligned}
|||(\boldsymbol{\tau},\mathbf{v},\mathbf{z},q)|||_k^2 &= \left|\left|\left|\left(\tilde{\boldsymbol{\tau}}+q\mathbf{I},\mathbf{v},\tilde{\mathbf{z}}-\frac{1}{k}\mathbf{v},q\right)\right|\right|\right|_k^2 \\
&= \|\mathrm{div}\,(\tilde{\boldsymbol{\tau}}+q\mathbf{I})\|^2+\|\mathcal{C}^{-1/2}(\tilde{\boldsymbol{\tau}}+q\mathbf{I})\|^2+\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&+ k\left(\|\mathrm{div}\,(\tilde{\mathbf{z}}-\frac{1}{k}\mathbf{v})\|^2+\|\tilde{\mathbf{z}}-\frac{1}{k}\mathbf{v}\|^2+\|\nabla q\|^2\right) \\
&\le 2\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2+2\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2+\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2+\frac{2}{k}\|\mathrm{div}\,\mathbf{v}\|^2+\frac{2}{k}\|\mathbf{v}\|^2 \\
&+ 2k\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2+2k\|\tilde{\mathbf{z}}\|^2+(k+2)\|\nabla q\|^2+2\|\mathcal{C}^{-1/2}(q\mathbf{I})\|^2 \\
&\le 2\left(\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2+\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2\right)+\left(1+\frac{4C_K}{k}\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&+ 2k\left(\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2+\|\tilde{\mathbf{z}}\|^2\right)+\left(1+\frac{2}{k}+\frac{2C_F}{k(\lambda+\mu)}\right)k\|\nabla q\|^2\ .
\end{aligned}$$

For the last inequality, we have used

$$\begin{aligned}
\|\mathrm{div}\,\mathbf{v}\|^2+\|\mathbf{v}\|^2 &\le 2\|\nabla\mathbf{v}\|^2+\|\mathbf{v}\|^2\le 2C_K\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2\ , \\
\|\mathcal{C}^{-1/2}(q\,\mathbf{I})\|^2 &= (q\,\mathbf{I},\mathcal{C}^{-1}(q\,\mathbf{I}))=\frac{1}{\lambda+\mu}\|q\|^2\le\frac{C_F}{\lambda+\mu}\|\nabla q\|^2
\end{aligned}$$

(recall from (2.2) that $\mathcal{C}\,\mathbf{I}=2(\lambda+\mu)\,\mathbf{I}$). The right inequality in (4.4) follows along the same lines from

$$|||(\tilde{\boldsymbol{\tau}},\mathbf{v},\tilde{\mathbf{z}},q)|||_k^2 = \left|\left|\left|\left(\boldsymbol{\tau}-q\mathbf{I},\mathbf{v},\mathbf{z}+\frac{1}{k}\mathbf{v},q\right)\right|\right|\right|_k^2\ . \qquad \square$$

We prove the equivalence of the functional with respect to the transformed variables under (4.1). The following lemma will be useful in the analysis.

Lemma 4.2. *The antisymmetric part of the stress tensor,*

$$\mathrm{as}\,\tilde{\boldsymbol{\tau}}=\frac{1}{2}(\tilde{\boldsymbol{\tau}}-\tilde{\boldsymbol{\tau}}^T),$$

satisfies

$$\|\mathrm{as}\,\tilde{\boldsymbol{\tau}}\|^2\le 2\mu\|\mathcal{C}^{-1/2}(\tilde{\boldsymbol{\tau}}+q\,\mathbf{I})-\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2\ . \tag{4.5}$$

Proof. Using the special structure of $\mathcal{C}$ in (2.2), we are led to

$$\begin{aligned}
&\|\mathcal{C}^{-1/2}(\tilde{\boldsymbol{\tau}} + q\,\mathbf{I}) - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&= (\mathcal{C}^{-1}(\tilde{\boldsymbol{\tau}} + q\,\mathbf{I}), \tilde{\boldsymbol{\tau}} + q\,\mathbf{I}) - 2(\tilde{\boldsymbol{\tau}} + q\,\mathbf{I}, \boldsymbol{\varepsilon}(\mathbf{v})) + (\mathcal{C}\boldsymbol{\varepsilon}(\mathbf{v}), \boldsymbol{\varepsilon}(\mathbf{v})) \\
&= \left(\mathcal{C}^{-1}\begin{pmatrix} \tilde{\tau}_{11} + q & \tilde{\tau}_{12} \\ \tilde{\tau}_{21} & \tilde{\tau}_{22} + q \end{pmatrix}, \begin{pmatrix} \tilde{\tau}_{11} + q & \tilde{\tau}_{12} \\ \tilde{\tau}_{21} & \tilde{\tau}_{22} + q \end{pmatrix}\right) \\
&- 2\left(\begin{pmatrix} \tilde{\tau}_{11} + q & \tilde{\tau}_{12} \\ \tilde{\tau}_{21} & \tilde{\tau}_{22} + q \end{pmatrix}, \begin{pmatrix} \varepsilon_{11} & \varepsilon_{12} \\ \varepsilon_{21} & \varepsilon_{22} \end{pmatrix}\right) + \left(\mathcal{C}\begin{pmatrix} \varepsilon_{11} & \varepsilon_{12} \\ \varepsilon_{21} & \varepsilon_{22} \end{pmatrix}, \begin{pmatrix} \varepsilon_{11} & \varepsilon_{12} \\ \varepsilon_{21} & \varepsilon_{22} \end{pmatrix}\right) \\
&= \frac{1}{2\mu}\left(\begin{pmatrix} * & \tilde{\tau}_{12} \\ \tilde{\tau}_{21} & * \end{pmatrix}, \begin{pmatrix} * & \tilde{\tau}_{12} \\ \tilde{\tau}_{21} & * \end{pmatrix}\right) \\
&- 2\left(\begin{pmatrix} * & \tilde{\tau}_{12} \\ \tilde{\tau}_{21} & * \end{pmatrix}, \begin{pmatrix} * & \varepsilon_{12} \\ \varepsilon_{21} & * \end{pmatrix}\right) + 2\mu\left(\begin{pmatrix} * & \varepsilon_{12} \\ \varepsilon_{21} & * \end{pmatrix}, \begin{pmatrix} * & \varepsilon_{12} \\ \varepsilon_{21} & * \end{pmatrix}\right) .
\end{aligned}$$

This leads to

$$\begin{aligned}
\|\mathcal{C}^{-1/2}\boldsymbol{\tau} - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 &= \left\|\begin{pmatrix} * & \frac{1}{\sqrt{2\mu}}\tau_{12} - \sqrt{2\mu}\varepsilon_{12} \\ \frac{1}{\sqrt{2\mu}}\tau_{21} - \sqrt{2\mu}\varepsilon_{21} & * \end{pmatrix}\right\|^2 \\
&\geq \left\|\frac{1}{\sqrt{2\mu}}\tau_{12} - \sqrt{2\mu}\varepsilon_{12}\right\|^2 + \left\|\frac{1}{\sqrt{2\mu}}\tau_{21} - \sqrt{2\mu}\varepsilon_{21}\right\|^2 \\
&\geq \frac{1}{2}\left\|\frac{1}{\sqrt{2\mu}}(\tau_{12} - \tau_{21}) - \sqrt{2\mu}(\varepsilon_{12} - \varepsilon_{21})\right\|^2 \\
&= \frac{1}{2}\left\|\frac{1}{\sqrt{2\mu}}(\tau_{12} - \tau_{21})\right\|^2 = \frac{1}{4\mu}\|\tau_{12} - \tau_{21}\|^2 = \frac{1}{2\mu}\|\text{as}\,\boldsymbol{\tau}\|^2 . \qquad \square
\end{aligned}$$

THEOREM 4.3. *There are positive constants $\tilde{\alpha}$ and $\tilde{\beta}$ such that*

$$\tilde{\alpha}|||(\tilde{\boldsymbol{\tau}}, \mathbf{v}, \tilde{\mathbf{z}}, q)|||_k^2 \leq \mathcal{F}_k(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0}) \leq \tilde{\beta}|||(\tilde{\boldsymbol{\tau}}, \mathbf{v}, \tilde{\mathbf{z}}, q)|||_k^2 \tag{4.6}$$

holds for all $(\tilde{\boldsymbol{\tau}}, \mathbf{v}, \tilde{\mathbf{z}}, q) \in H_{\Gamma_1}(\text{div}, \Omega)^2 \times H^1_{\Gamma_2}(\Omega)^2 \times H_{\Gamma_2}(\text{div}, \Omega) \times H^1_{\Gamma_1}(\Omega)$ uniformly as $\lambda \to \infty$.

Proof. Writing the functional with respect to the transformed variables gives

$$\begin{aligned}
&\mathcal{F}_k(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0}) \\
&= \|\text{div}\,\tilde{\boldsymbol{\tau}}\|^2 + \|\mathcal{C}^{-1/2}(\tilde{\boldsymbol{\tau}} + q\mathbf{I}) - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 + k\|\text{div}\,\tilde{\mathbf{z}}\|^2 + k\left\|\tilde{\mathbf{z}} + \nabla q - \frac{1}{k}\mathbf{v}\right\|^2 .
\end{aligned}$$

The right inequality in (4.6) follows from straightforward application of the Cauchy–Schwarz inequality, and we may therefore restrict our attention to the lower bound.

Integration by parts, the elementary estimates

$$2(\text{tr}\,\tilde{\boldsymbol{\tau}}, q) \leq \frac{\xi}{2}\|\text{tr}\,\tilde{\boldsymbol{\tau}}\|^2 + \frac{2}{\xi}\|q\|^2 \quad \text{and} \quad 2(\tilde{\mathbf{z}}, \mathbf{v}) \leq k\eta\|\tilde{\mathbf{z}}\|^2 + \frac{1}{k\eta}\|\mathbf{v}\|^2$$

with constants $\xi, \eta \in (0, 1)$ to be selected appropriately, and the inequality

$$\|\mathrm{as}\,\tilde{\boldsymbol{\tau}}\|^2 \le 2\mu\|\mathcal{C}^{-1/2}(\tilde{\boldsymbol{\tau}} + q\,\mathbf{I}) - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2$$

shown in Lemma 4.2 will be the basis of the following chain of inequalities. With suitable positive constants A, B, and D to be chosen later, we have

$$\begin{aligned}
&\max\{A, 1+B, D\}\, \mathcal{F}_k(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0}) \\
&\ge A\,\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + (1+B)\|\mathcal{C}^{-1/2}(\tilde{\boldsymbol{\tau}} + q\,\mathbf{I}) - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&+ Dk\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2 + k\left\|\tilde{\mathbf{z}} + \nabla q - \frac{1}{k}\mathbf{v}\right\|^2 \\
&= A\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + B\|\mathcal{C}^{-1/2}(\tilde{\boldsymbol{\tau}} + q\,\mathbf{I}) - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 + \|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}} - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&+ \|\mathcal{C}^{-1/2}(q\,\mathbf{I})\|^2 + Dk\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2 + k\|\tilde{\mathbf{z}} + \nabla q\|^2 + \frac{1}{k}\|\mathbf{v}\|^2 \\
&+ 2(\mathrm{tr}\,(\mathcal{C}^{-1}\tilde{\boldsymbol{\tau}}) - \mathrm{div}\,\mathbf{v}, q) - 2(\tilde{\mathbf{z}} + \nabla q, \mathbf{v}) \\
&\ge A\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + \frac{B}{2\mu}\|\mathrm{as}\,\tilde{\boldsymbol{\tau}}\|^2 + \|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}} - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 + \frac{1}{k}\|\mathbf{v}\|^2 \\
&+ Dk\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2 + k\|\tilde{\mathbf{z}} + \nabla q\|^2 + \frac{1}{\lambda+\mu}\|q\|^2 + 2\left(\frac{1}{2(\lambda+\mu)}\mathrm{tr}\,\tilde{\boldsymbol{\tau}}, q\right) - 2(\tilde{\mathbf{z}}, \mathbf{v}) \\
&\ge A\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + \frac{B}{2\mu}\|\mathrm{as}\,\tilde{\boldsymbol{\tau}}\|^2 + \|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}} - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 - \frac{\xi}{4(\lambda+\mu)}\|\mathrm{tr}\,\tilde{\boldsymbol{\tau}}\|^2 \\
&- \frac{1}{k}\left(\frac{1}{\eta} - 1\right)\|\mathbf{v}\|^2 + Dk\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2 + k\left(\|\tilde{\mathbf{z}} + \nabla q\|^2 - \eta\|\tilde{\mathbf{z}}\|^2\right) \\
&- \left(\frac{1}{\xi} - 1\right)\frac{1}{\lambda+\mu}\|q\|^2 =: \mathcal{G}_1(\tilde{\boldsymbol{\tau}}, \mathbf{v}) + \mathcal{G}_2(\tilde{\mathbf{z}}, q)\,.
\end{aligned}$$

This implies

$$\mathcal{F}_k(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0}) \ge \min\left\{\frac{1}{A}, \frac{1}{1+B}, \frac{1}{D}\right\}\left(\mathcal{G}_1(\tilde{\boldsymbol{\tau}}, \mathbf{v}) + \mathcal{G}_2(\tilde{\mathbf{z}}, q)\right), \tag{4.7}$$

and we are left with estimating $\mathcal{G}_1$ and $\mathcal{G}_2$ separately.

For the first term, we use

$$\begin{aligned}
\|\mathrm{tr}\,\tilde{\boldsymbol{\tau}}\|^2 &= 2(\lambda+\mu)(\mathrm{tr}\,(\mathcal{C}^{-1}\tilde{\boldsymbol{\tau}}), \mathrm{tr}\,\tilde{\boldsymbol{\tau}}) \\
&= 4(\lambda+\mu)\left(\frac{1}{2}(\mathrm{tr}\,(\mathcal{C}^{-1}\tilde{\boldsymbol{\tau}}))\,\mathbf{I}, \frac{1}{2}(\mathrm{tr}\,\tilde{\boldsymbol{\tau}})\,\mathbf{I}\right) \\
&\le 4(\lambda+\mu)(\mathcal{C}^{-1}\tilde{\boldsymbol{\tau}}, \tilde{\boldsymbol{\tau}}) = 4(\lambda+\mu)\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2\,,
\end{aligned}$$

$$\begin{aligned}
(\tilde{\boldsymbol{\tau}}, \boldsymbol{\varepsilon}(\mathbf{v})) &= (\tilde{\boldsymbol{\tau}} - \mathrm{as}\,\tilde{\boldsymbol{\tau}}, \boldsymbol{\varepsilon}(\mathbf{v})) = (\tilde{\boldsymbol{\tau}} - \mathrm{as}\,\tilde{\boldsymbol{\tau}}, \nabla\mathbf{v}) \\
&= -(\mathrm{div}\,\tilde{\boldsymbol{\tau}}, \mathbf{v}) - (\mathrm{as}\,\tilde{\boldsymbol{\tau}}, \nabla\mathbf{v}),
\end{aligned}$$

and Korn's inequality (3.2) to obtain

$$\begin{aligned}
\mathcal{G}_1(\tilde{\boldsymbol{\tau}},\mathbf{v}) &\geq A\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + \frac{B}{2\mu}\|\mathrm{as}\,\tilde{\boldsymbol{\tau}}\|^2 + \|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}} - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 - \xi\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2 \\
&\quad - \frac{C_K}{k}\left(\frac{1}{\eta}-1\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&= A\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + \frac{B}{2\mu}\|\mathrm{as}\,\tilde{\boldsymbol{\tau}}\|^2 + (1-\xi)\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2 - 2(\tilde{\boldsymbol{\tau}},\boldsymbol{\varepsilon}(\mathbf{v})) \\
&\quad + \left(1 - \frac{C_K}{k}\left(\frac{1}{\eta}-1\right)\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&= A\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + \frac{B}{2\mu}\|\mathrm{as}\,\tilde{\boldsymbol{\tau}}\|^2 + (1-\xi)\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2 + 2(\mathrm{div}\,\tilde{\boldsymbol{\tau}},\mathbf{v}) \\
&\quad + 2(\mathrm{as}\,\tilde{\boldsymbol{\tau}},\nabla\mathbf{v}) + \left(1 - \frac{C_K}{k}\left(\frac{1}{\eta}-1\right)\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&= \left(A - \frac{1}{\rho}\right)\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + (1-\xi)\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2 + \left(1 - \frac{C_K}{k}\left(\frac{1}{\eta}-1\right)\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\
&\quad + \left\|\frac{1}{\rho^{1/2}}\mathrm{div}\,\tilde{\boldsymbol{\tau}} + \rho^{1/2}\mathbf{v}\right\|^2 - \rho\|\mathbf{v}\|^2 \\
&\quad + \left\|\left(\frac{B}{2\mu}\right)^{1/2}\mathrm{as}\,\tilde{\boldsymbol{\tau}} + \left(\frac{2\mu}{B}\right)^{1/2}\nabla\mathbf{v}\right\|^2 - \frac{2\mu}{B}\|\nabla\mathbf{v}\|^2 \\
&\geq \left(A - \frac{1}{\rho}\right)\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + (1-\xi)\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2 \\
&\quad + \left(1 - \frac{C_K}{k}\left(\frac{1}{\eta}-1\right) - C_K\max\left\{\rho,\frac{2\mu}{B}\right\}\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \,.
\end{aligned}$$

Choosing

$$\eta = \frac{1}{1+\frac{k}{4C_K}}\ ,\ \rho = \frac{1}{4C_K}\ ,\ A = 8C_K\ ,\ B = \frac{2\mu}{\rho} = 8\mu C_K$$

leads to

$$\mathcal{G}_1(\tilde{\boldsymbol{\tau}},\mathbf{v}) \geq 4C_K\|\mathrm{div}\,\tilde{\boldsymbol{\tau}}\|^2 + (1-\xi)\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2 + \frac{1}{2}\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \,. \tag{4.8}$$

Note that $\xi \in (0,1)$ is still free to be chosen appropriately for the estimation of $\mathcal{G}_2$ below.

For the second term, the Poincaré–Friedrichs inequality (3.3) leads to

$$\begin{aligned}
\mathcal{G}_2(\tilde{\mathbf{z}},q) &\geq Dk\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2 + k\left(\|\tilde{\mathbf{z}}+\nabla q\|^2 - \eta\|\tilde{\mathbf{z}}\|^2\right) - \left(\frac{1}{\xi}-1\right)\frac{C_F}{\lambda+\mu}\|\nabla q\|^2 \\
&= Dk\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2 + k(1-\eta)\|\tilde{\mathbf{z}}\|^2 + 2k(\tilde{\mathbf{z}},\nabla q) + \left(k - \left(\frac{1}{\xi}-1\right)\frac{C_F}{\lambda+\mu}\right)\|\nabla q\|^2 \\
&= Dk\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2 + k(1-\eta)\|\tilde{\mathbf{z}}\|^2 - 2k(\mathrm{div}\,\tilde{\mathbf{z}},q) + \left(k - \left(\frac{1}{\xi}-1\right)\frac{C_F}{\lambda+\mu}\right)\|\nabla q\|^2 \\
&\geq \frac{Dk}{2}\|\mathrm{div}\,\tilde{\mathbf{z}}\|^2 + k(1-\eta)\|\tilde{\mathbf{z}}\|^2 + \left(k - \left(\frac{1}{\xi}-1\right)\frac{C_F}{\lambda+\mu} - k\frac{2C_F}{D}\right)\|\nabla q\|^2 \,.
\end{aligned}$$

Here, we may choose

$$\xi = \frac{1}{1 + \frac{k(\lambda+\mu)}{3C_F}} \ , \ D = 6C_F,$$

which implies

$$\mathcal{G}_2(\tilde{\mathbf{z}}, q) \geq k \left(\frac{D}{2} \|\operatorname{div} \tilde{\mathbf{z}}\|^2 + (1-\eta)\|\tilde{\mathbf{z}}\|^2 + \frac{1}{3}\|\nabla q\|^2 \right) . \tag{4.9}$$

Therefore,

$$\mathcal{G}_1(\tilde{\boldsymbol{\tau}}, \mathbf{v}) + \mathcal{G}_2(\tilde{\mathbf{z}}, q) \geq \min \left\{ \frac{A}{2}, 1-\xi, \frac{1}{4}, \frac{D}{2}, 1-\eta, \frac{1}{3} \right\} \ |||(\tilde{\boldsymbol{\tau}}, \mathbf{v}, \tilde{\mathbf{z}}, q)|||_k^2,$$

which, together with (4.7), completes our proof. □

Finally, our main result follows easily from Theorems 4.3 and 4.1.

THEOREM 4.4. *There are positive constants* α *and* β *such that*

$$\alpha |||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q)|||_k^2 \leq \mathcal{F}_k(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0}) \leq \beta |||(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q)|||_k^2 \tag{4.10}$$

holds for all $(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q) \in H_{\Gamma_1}(\operatorname{div}, \Omega)^2 \times H^1_{\Gamma_2}(\Omega)^2 \times H_{\Gamma_2}(\operatorname{div}, \Omega) \times H^1_{\Gamma_1}(\Omega)$ *uniformly as* $\lambda \to \infty$.

Remark. The equivalence constants in (4.10) and (4.6) still depend on the time-step length k. The behavior of the finite element approximation obtained with the least-squares method for small k is of particular interest in connection with the reduced regularity of Biot's consolidation problem for $t \to 0$ analyzed in detail in [18]. A closer inspection of the proof of Theorem 4.3 shows that (4.6) can be sharpened to the following inequalities with constants α^*, β^* now independent of k:

$$\begin{aligned} \mathcal{F}_k(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0}) \geq \alpha^* (&\|\operatorname{div} \tilde{\boldsymbol{\tau}}\|^2 + k\|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2 + \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \\ &+ k\|\operatorname{div} \tilde{\mathbf{z}}\|^2 + k^2\|\tilde{\mathbf{z}}\|^2 + k\|\nabla q\|^2) , \end{aligned} \tag{4.11}$$

$$\begin{aligned} \mathcal{F}_k(\boldsymbol{\tau}, \mathbf{v}, \mathbf{z}, q; \mathbf{0}) \leq \beta^* \Big(&\|\operatorname{div} \tilde{\boldsymbol{\tau}}\|^2 + \|\mathcal{C}^{-1/2}\tilde{\boldsymbol{\tau}}\|^2 + \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 + \frac{1}{k}\|\mathbf{v}\|^2 \\ &+ k\|\operatorname{div} \tilde{\mathbf{z}}\|^2 + k\|\tilde{\mathbf{z}}\|^2 + k\|\nabla q\|^2 + \|q\|^2 \Big) . \end{aligned} \tag{4.12}$$

5. Finite element approximation. The finite element approximation of the least-squares formulation consists in minimizing the least-squares functional in (2.10) with respect to suitable finite-dimensional subspaces of $H_{\Gamma_N^{\text{elas}}}(\operatorname{div}, \Omega)^2 \times H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2 \times H_{\Gamma_N^{\text{flow}}}(\operatorname{div}, \Omega) \times H^1_{\Gamma_D^{\text{flow}}}(\Omega)$. In analogy to the derivation in section 2, the minimization with respect to these finite-dimensional spaces leads to a linear variational problem of the form (2.12) with respect to these finite-dimensional spaces. This leaves us with the question of choosing appropriate finite element spaces for

$$\hat{\boldsymbol{\sigma}} \in H_{\Gamma_N^{\text{elas}}}(\operatorname{div}, \Omega)^2 \ , \ \mathbf{u} \in H^1_{\Gamma_D^{\text{elas}}}(\Omega)^2 \ , \ \mathbf{w} \in H_{\Gamma_N^{\text{flow}}}(\operatorname{div}, \Omega) \ , \ \hat{p} \in H^1_{\Gamma_D^{\text{flow}}}(\Omega) \ .$$

In contrast to the situation for mixed finite element approaches based on a saddle point formulation, the finite element spaces do not have to satisfy the compatibility condition by Ladyshenskaja–Babuška–Brezzi. Instead the spaces can be chosen completely independently of each other in the least-squares approach. The convergence of the least-squares mixed finite element method is only governed by the ellipticity of the least-squares functional, i.e., its equivalence to a meaningful norm of the error, and by the approximation properties of the finite element spaces.

Our finite element spaces are based on a sequence of triangulations $\{\mathcal{T}_h\}$ of the domain Ω. Suitable finite element spaces for $H(\mathrm{div},\Omega)$ are the Raviart–Thomas spaces given by piecewise polynomials of the form

$$\mathbf{s}_h|_T = \begin{pmatrix} p_{m-1}^{(I)} \\ p_{m-1}^{(II)} \end{pmatrix} + \mathbf{x} p_{m-1}^{(III)}$$

on each triangle $T \in \mathcal{T}_h$, where $p_{m-1}^{(I)}$, $p_{m-1}^{(II)}$, and $p_{m-1}^{(III)}$ denote polynomials of degree $m-1$. For $m=1$, the case we use in our numerical computations presented in section 6, this implies

$$\mathbf{s}_h|_T = \begin{pmatrix} \alpha_T \\ \beta_T \end{pmatrix} + \gamma_T \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} .$$

The Raviart–Thomas space of degree m is also characterized as those polynomials of degree m (componentwise) with the property that the trace of $\mathbf{s}_h \cdot \mathbf{n}$ on each edge is a polynomial of degree $m-1$. Raviart–Thomas spaces are used in our computations for the approximation of each component of the stress tensor and for the fluid flux. Note that the boundary values for $\boldsymbol{\sigma} \cdot \mathbf{n}$ and $\mathbf{w} \cdot \mathbf{n}$ can easily be prescribed for these spaces since the degrees of freedom in the above basis representation are associated with these quantities. For the approximation of each component of the displacement and for the hydraulic potential, standard conforming piecewise polynomial spaces are used.

We investigate the theoretical approximation properties of our least-squares approach on a sequence of triangulations under sufficient regularity assumptions if we use the finite element spaces mentioned above. For the Raviart–Thomas elements, we have

$$\begin{aligned} \|\boldsymbol{\sigma} - \mathbf{P}_h\boldsymbol{\sigma}\| \le Ch^m|\boldsymbol{\sigma}|_{m,\Omega} \, , \quad & \|\mathrm{div}\,(\boldsymbol{\sigma} - \mathbf{P}_h\boldsymbol{\sigma})\| \le Ch^m|\mathrm{div}\,\boldsymbol{\sigma}|_{m,\Omega} \, , \\ \|\mathbf{w} - \mathbf{P}_h\mathbf{w}\| \le Ch^m|\mathbf{w}|_{m,\Omega} \, , \quad & \|\mathrm{div}\,(\mathbf{w} - \mathbf{P}_h\mathbf{w})\| \le Ch^m|\mathrm{div}\,\mathbf{w}|_{m,\Omega} \, , \end{aligned}$$

with a suitable interpolation operator $\mathbf{P}_h$ (cf. [5, Proposition III.3.9]). The standard finite element interpolation estimates (see, for example, [3, section II.6]) imply

$$\begin{aligned} \|\mathbf{u} - \mathbf{Q}_h\mathbf{u}\| \le Ch^m|\mathbf{u}|_{m,\Omega} \, , \quad & \|\nabla\,(\mathbf{u} - \mathbf{Q}_h\mathbf{u})\| \le Ch^m|\mathbf{u}|_{m+1,\Omega} \, , \\ \|p - Q_hp\| \le Ch^m|p|_{m,\Omega} \, , \quad & \|\nabla\,(p - Q_hp)\| \le Ch^m|p|_{m+1,\Omega} \, , \end{aligned}$$

where Q_h denotes the standard interpolation operator.

With (4.12) the above interpolation estimates lead to

$$\begin{aligned} \mathcal{F}_k(\boldsymbol{\sigma}_h, \mathbf{u}_h, \mathbf{w}_h, p_h; \mathbf{u}^{\mathrm{old}}) &= \mathcal{F}_k(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h, \mathbf{u} - \mathbf{u}_h, \mathbf{w} - \mathbf{w}_h, p - p_h; \mathbf{0}) \\ &\le \beta^* C^2 h^{2m} \Bigg(|\mathrm{div}\,\tilde{\boldsymbol{\sigma}}|_{m,\Omega}^2 + k|\tilde{\boldsymbol{\sigma}}|_{m,\Omega}^2 + |\mathbf{u}|_{m+1,\Omega}^2 + \frac{1}{k}|\mathbf{u}|_{m,\Omega}^2 \\ &\qquad + k|\mathrm{div}\,\tilde{\mathbf{w}}|_{m,\Omega}^2 + k|\tilde{\mathbf{w}}|_{m,\Omega}^2 + k|p|_{m+1,\Omega}^2 + |p|_{m,\Omega}^2 \Bigg) \\ &\le \beta^* C^2 h^{2m} \left(|\mathbf{u}|_{m+1,\Omega}^2 + \frac{1}{k}|\mathbf{u}|_{m,\Omega}^2 + k|\mathrm{div}\,\mathbf{w}|_{m,\Omega}^2 + k|p|_{m+1,\Omega}^2 + |p|_{m,\Omega}^2 \right) . \end{aligned} \tag{5.1}$$

If we combine this with (4.11), we obtain

$$\begin{aligned}&\|\mathrm{div}\ (\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}_h)\| + k^{1/2}\|\mathcal{C}^{-1/2}(\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}_h)\| + \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u} - \mathbf{u}_h)\| \\ &\quad + k^{1/2}\|\mathrm{div}\ (\tilde{\mathbf{w}} - \tilde{\mathbf{w}}_h)\| + k\|\tilde{\mathbf{w}} - \tilde{\mathbf{w}}_h\| + k^{1/2}\|\nabla(p - p_h)\| \\ &\le \sqrt{\frac{\beta^*}{\alpha^*}} C h^m \left(|\mathbf{u}|_{m+1,\Omega} + \frac{|\mathbf{u}|_{m,\Omega}}{k^{1/2}} + k^{1/2}|\mathrm{div}\ \mathbf{w}|_{m,\Omega} + k^{1/2}|p|_{m+1,\Omega} + |p|_{m,\Omega} \right) .\end{aligned}$$

In particular, for the approximation of the primal variables,

$$\begin{aligned}&\|\nabla(\mathbf{u} - \mathbf{u}_h)\| + k^{1/2}\|\nabla(p - p_h)\| \\ &\le \sqrt{\frac{\beta^*}{\alpha^*}} C h^m \left(|\mathbf{u}|_{m+1,\Omega} + \frac{|\mathbf{u}|_{m,\Omega}}{k^{1/2}} + k^{1/2}|\mathrm{div}\ \mathbf{w}|_{m,\Omega} + k^{1/2}|p|_{m+1,\Omega} + |p|_{m,\Omega} \right)\end{aligned} \tag{5.2}$$

holds.

In comparison, the standard mixed approach is based on the variational formulation of finding $\mathbf{u} \in H^1_{\Gamma_2}(\Omega)^2$ and $p \in p^D + H^1_{\Gamma_1}(\Omega)$ such that

$$\begin{aligned}(\mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}), \boldsymbol{\varepsilon}(\mathbf{v})) - (p, \mathrm{div}\ \mathbf{v}) &= (\mathbf{g}, \mathbf{v})_{\Gamma_1} - (p^D, \mathbf{n} \cdot \mathbf{v})_{\Gamma_1} \\ -(\mathrm{div}\ \mathbf{u}, q) - k(\kappa\, \nabla p, \nabla q) &= -(\mathrm{div}\ \mathbf{u}^{\mathrm{old}}, q)\end{aligned} \tag{5.3}$$

holds for all $\mathbf{v} \in H^1_{\Gamma_2}(\Omega)^2$ and $q \in H^1_{\Gamma_1}(\Omega)$. By $(\,\cdot\,,\,\cdot\,)_{\Gamma_1}$, the inner product in $L^2(\Gamma_1)$ is meant. If a compatible pair of finite element spaces satisfying the inf-sup condition is used, then approximation bounds are obtained which are uniform as $k \to 0$. In particular, for the Taylor–Hood elements combining piecewise polynomials of degree m for $\mathbf{u}$ with piecewise polynomials of degree $m-1$ for p, the estimates

$$\begin{aligned}\|\nabla(\mathbf{u} - \mathbf{u}_h)\| &\le C h^m |\mathbf{u}|_{m+1,\Omega}\ , \\ \|p - p_h\| + k^{1/2}\|\nabla(p - p_h)\| &\le C \left(h^m + k^{1/2} h^{m-1} \right) |p|_{m,\Omega}\end{aligned} \tag{5.4}$$

for $m \ge 2$ can be deduced from the results (for the case $k = 0$) in [4, section 12.6]. The regularity results in [18, Lemma 2.2] imply for the solution of the initial-boundary value problem (2.7), (2.8)

$$|\mathbf{u}(t)|_{m+1,\Omega} + |p(t)|_{m,\Omega} \le C_R t^{-m/2}\ , \tag{5.5}$$

where the constant C_R depends on the boundary data $\mathbf{g}$ and p^D. Of course, (5.5) only holds under suitable assumptions on the boundary conditions and on the smoothness of $\partial\Omega$. Based on these regularity estimates, the a priori estimates (5.4) for the mixed method lead to

$$\|\nabla(\mathbf{u} - \mathbf{u}_h)\| + \|p - p_h\| + k^{1/2}\|\nabla(p - p_h)\| \le C \left(\left(\frac{h}{k^{1/2}} \right)^m + \left(\frac{h}{k^{1/2}} \right)^{m-1} \right) . \tag{5.6}$$

In comparison, for our least-squares approach we obtain

$$\|\nabla(\mathbf{u} - \mathbf{u}_h)\| + k^{1/2}\|\nabla(p - p_h)\| \le C \left(\frac{h}{k^{1/2}} \right)^m \tag{5.7}$$

using (5.2). Note, however, that our motivation for the least-squares approach in this paper is the simultaneous approximation for the stress and flux variables as well as the availability of the least-squares functional as an a posteriori estimator for adaptive refinement of the finite element triangulation.

Table 6.1
Material parameters for numerical experiments.

Parameter	Value
Young's modulus E	$30 \ \frac{kN}{m^2}$
Poisson ratio ν	0.2
percolation coefficient κ	$10^{-4} \ \frac{m^4}{kNs}$
boundary condition σ_0	$1 \ \frac{kN}{m^2}$

6. Computational experiments. In this section, we study the behavior of the approximate solution of Biot's consolidation problem by the least-squares formulation (2.12). To this end, we consider two test examples with different properties in a two-dimensional domain. Both examples are taken from [17].

Example 1. The first example is a two-dimensional simulation of a one-dimensional consolidation problem in a column of porous soil of depth 1 with rigid and impermeable walls. This column shall be loaded on the top by a pressure σ_0 and is free to drain. This one-dimensional problem has an analytic solution which is given in terms of an infinite sum (see [17]). It is therefore perfectly suited for an illustration of the effects at the beginning of the simulation for different time-step sizes k.

For the two-dimensional simulation of the one-dimensional consolidation problem, a box of 0.1 m width and 1 m depth with the origin located on the upper left corner is used as simulation domain Ω with the following boundary conditions:

$$\begin{array}{llll} p = 0, & \sigma_{xy} = 0, & \sigma_{yy} = -\sigma_0 & \text{on } \{(x,y) \in \partial\Omega : y = 0\}, \\ w = 0, & u_x = 0, & \sigma_{yx} = 0 & \text{on } \{(x,y) \in \partial\Omega : x = 0\}, \\ w = 0, & u_x = 0, & \sigma_{yx} = 0 & \text{on } \{(x,y) \in \partial\Omega : x = 0.1\}, \\ w = 0, & \sigma_{xy} = 0, & u_y = 0 & \text{on } \{(x,y) \in \partial\Omega : y = -1\}. \end{array}$$

As initial conditions, $u = 0$ is prescribed in Ω for $t = 0$. The material parameters are given in Table 6.1.

The computations are based on the lowest-order case of finite element spaces ($m = 1$ in the notation of section 5) except for the displacement, which is approximated by piecewise quadratic functions. Our observations indicate that the overall finite element approximation is not satisfactory if only piecewise linear functions are used for the displacement. Note, however, that the choice of quadratic finite elements does not lead to uniform convergence for nearly incompressible materials. Uniform approximation in the incompressible limit could be achieved by the use of nonconforming finite elements. A detailed study of this topic for the elasticity subproblem using the least-squares functional (2.4), including computational results, is given in [6].

For $t \to 0$, the pressure front involves large gradients, as shown in Figure 6.1. This is caused by the Dirichlet boundary condition $p = 0$ at $y = 0$, which contradicts the asymptotic behavior $p \to \sigma_0$ for $t \to 0$ for all $x \in (0, 1)$. Due to this behavior, the length of the time-step influences the choice of an initial grid, which is fine enough to resolve this front. For this purpose, a nonuniform initial coarse triangulation is used in our computations which is refined near the top of the domain. Six steps of adaptive refinement are then performed starting from this initial triangulation of 1725 degrees of freedom for the time-step lengths $k = 100, 1$, and 0.001. The local evaluation of the least-squares functional is used as an a posteriori error estimator for the adaptive refinement process (cf. [1]). Tables 6.2, 6.3 and 6.4 demonstrate the effect of adaptive refinement by means of reduction of the least-squares functional. We give the total number of degrees of freedom (DOF) and the value of the least-squares

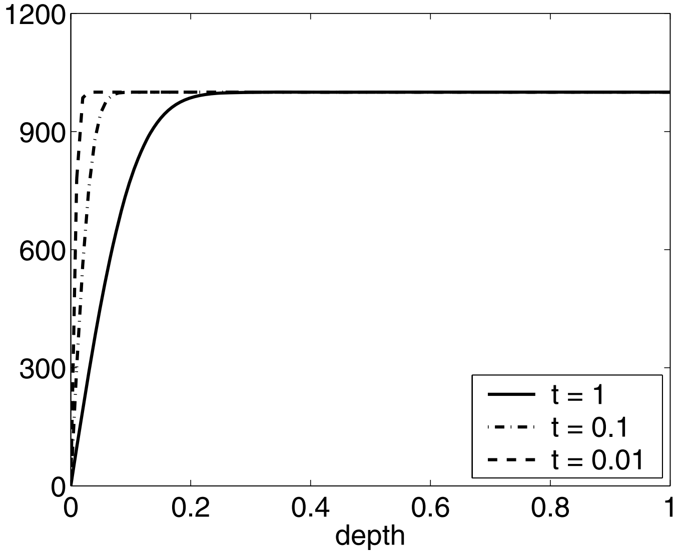

FIG. 6.1. *Pressure front for times* $t = 1, 0.1,$ *and* 0.01.

functional (LSF). Moreover, the ratio

$$\rho = \frac{\mathrm{LSF}|_{\text{current level}}}{\mathrm{LSF}|_{\text{previous level}}} \cdot \frac{\mathrm{DOF}|_{\text{current level}}}{\mathrm{DOF}|_{\text{previous level}}}$$

is listed in these tables. Ideally, for piecewise linear finite elements in two dimensions, the reduction rate of the least-squares functional

$$\frac{\mathrm{LSF}|_{\text{current level}}}{\mathrm{LSF}|_{\text{previous level}}} ,$$

which represents the square of the approximation error, should be inversely proportional to the increase in the number of unknowns

$$\frac{\mathrm{DOF}|_{\text{current level}}}{\mathrm{DOF}|_{\text{previous level}}} .$$

In other words, ρ should be roughly 1 for an optimal order of convergence in the adaptive process. In each of the tables, these numbers are given for times $t = k$ and $t = 10\,k$ to account for the time dependence of the problem.

The numbers show a nearly optimal convergence of the computed approximation according to a reduction of the least-squares functional proportional to the inverse of the increase in number of degrees of freedom (i.e., $\rho \approx 1$ in Tables 6.2–6.4). The estimates (5.1) and (5.5) from the previous section imply

$$\mathcal{F}_k(\boldsymbol{\sigma}_h, \mathbf{u}_h, \mathbf{w}_h, p_h; \mathbf{u}^{\text{old}}) \le \frac{C}{k} h^2 .$$

Fortunately, Tables 6.2, 6.3, and 6.4 show that the dependence of the functional minimum is by far not as dramatic as suggested by this formula in the actual computations.

Example 2. The second example is a true two-dimensional footing problem as given also in [17]. The simulation domain is a 8×5 m block of porous soil as given in

Figure 6.2. At the base of this domain the soil is assumed to be fixed and impervious, while at the upper left part of the domain a uniform load of intensity σ_0 is applied in a strip of length 1 m. The simulated domain then constitutes the right half of a model which is cut in the middle along its symmetry axis.

For the material parameters and the applied load the same values as in the previous example are used. As the initial condition we use $u = 0$ in Ω for $t = 0$, and the boundary data is given as follows:

$$\begin{array}{llll}
p = 0, & \sigma_{xy} = 0, & \sigma_{yy} = -\sigma_0 & \text{on } \{(x,y) \in \partial\Omega : y = 0, x \le 1\}, \\
p = 0, & \sigma_{xy} = 0, & \sigma_{yy} = 0 & \text{on } \{(x,y) \in \partial\Omega : y = 0, x > 1\}, \\
w = 0, & u_x = 0, & \sigma_{yx} = 0 & \text{on } \{(x,y) \in \partial\Omega : x = 0\}, \\
w = 0, & u_x = 0, & \sigma_{yx} = 0 & \text{on } \{(x,y) \in \partial\Omega : x = 8\}, \\
w = 0, & \sigma_{xy} = 0, & u_y = 0 & \text{on } \{(x,y) \in \partial\Omega : y = -5\}.
\end{array}$$

The finite element approximation spaces are also identical to those for Example 1.

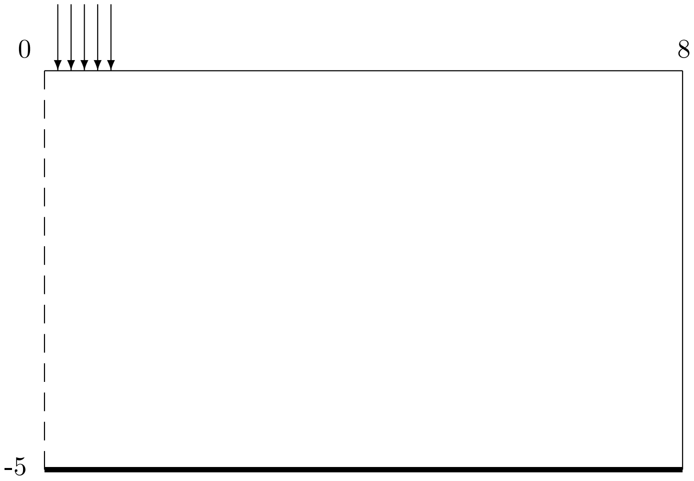

FIG. 6.2. *Example* 2: *Simulated domain with applied loads.*

8	18775	1.3011e-03	1.002

For the consolidation of the material, the following three different stages have been considered in [17]. For $t = 0$, an incompressible Stokes system needs to be solved, and then the consolidation process starts. The stationary state of the system can finally be obtained by the solution of decoupled deformation and flow problems.

Table 6.5 shows the results for the approximation of the stationary problem using eight steps of adaptive refinement. In this example, the stationary solution is actually $p \equiv 0$ for the fluid flow problem and reduces to an elastic deformation problem. The nearly optimal behavior of the adaptive algorithm can be seen from the numbers in Table 6.5.

The solution of the time-dependent problem is shown for various t in Figure 6.3. The graphs show the increasingly steeper gradients with a singular behavior for $t \to 0$.

That the time-dependent problems become more difficult for decreasing k due to this singular nature of the problem can be observed in Tables 6.6, 6.7, and 6.8 where the numerical results are listed for time-step lengths $k = 10000$, 100, and 1 and for two different times $t = k$ and $t = 10\,k$. Six steps of adaptive refinement with an initial grid of 1348 degrees of freedom are used. The notation is the same as in Example 1.

The triangulation after four steps of adaptive refinement for $k = 1$ and $t = 3$ is shown in Figure 6.4.

If we compare our results with those of Murad and Loula [17], we see a qualita-

tively similar behavior. The oscillations for small t which are present in the numerical results in [17], however, are avoided in our least-squares formulation. Adaptive refinement near the load boundary is crucial for the good performance of our least-squares approach as is the proper scaling of the individual terms in the least-squares functional.

Acknowledgments. The numerous discussions with Olaf Kolditz and Wenqing Wang at the Center for Applied Geosciences, University of Tübingen, have been of great importance for the work reported in this paper.

ON LEAST-SQUARES FINITE ELEMENT METHODS FOR THE POISSON EQUATION AND THEIR CONNECTION TO THE DIRICHLET AND KELVIN PRINCIPLES[*]

PAVEL BOCHEV[†] AND MAX GUNZBURGER[‡]

Abstract. Least-squares finite element methods for first-order formulations of the Poisson equation are not subject to the inf-sup condition and lead to stable solutions even when all variables are approximated by equal-order continuous finite element spaces. For such elements, one can also prove optimal convergence in the "energy" norm (equivalent to a norm on $H^1(\Omega) \times H(\Omega, \text{div})$) for all variables and optimal L^2 convergence for the scalar variable. However, showing optimal L^2 convergence for the flux has proven to be impossible without adding the redundant curl equation to the first-order system of partial differential equations. In fact, numerical evidence strongly suggests that nodal continuous flux approximations do not posses optimal L^2 accuracy. In this paper, we show that optimal L^2 error rates for the flux can be achieved without the curl constraint, provided that one uses the div-conforming family of Brezzi–Douglas–Marini or Brezzi–Douglas–Duran–Fortin elements. Then, we proceed to reveal an interesting connection between a least-squares finite element method involving $H(\Omega, \text{div})$-conforming flux approximations and mixed finite element methods based on the classical Dirichlet and Kelvin principles. We show that such least-squares finite element methods can be obtained by approximating, through an L^2 projection, the Hodge operator that connects the Kelvin and Dirichlet principles. Our principal conclusion is that when implemented in this way, a least-squares finite element method combines the best computational properties of finite element methods based on each of the classical principles.

1. Introduction.

Stable mixed finite element methods for the Poisson equation[1] (written in a first-order form in terms of a scalar variable and a flux) require the use of finite element spaces that satisfy an appropriate inf-sup condition. For methods based on the Dirichlet principle, the inf-sup condition can be easily satisfied but for the dual Kelvin principle, it imposes complicated restrictions on the choice of spaces; see [11]. In either case, it is well known that pairs of standard nodal-based, continuous finite element spaces fail the inf-sup condition and lead to unstable mixed methods. It is also well known that the inf-sup condition is circumvented if one uses such simple element pairs in finite element methods based on L^2 least-squares variational principles. Ever since such least-squares finite element methods for first-order formulations of the Poisson equation were first considered in [24], this fact

[1] Although we consider only the Poisson problem, much of what we discuss can be easily extended to more general second-order elliptic partial differential equations.

has been deemed as an important advantage of those methods over mixed Galerkin methods.

Already in [24], optimal L^2 error estimates for least-square finite element methods were established for the scalar variable; however, there, no optimal L^2 convergence results were obtained for nodal approximations of the flux. This situation persisted in all subsequent analyses: optimal L^2 error estimates for the flux could not be obtained[2] without the addition of a "redundant" curl equation; see, e.g., [13, 14, 15, 25, 27]. Moreover, computational studies in [16] strongly suggested that optimal L^2 convergence may in fact be nearly impossible if one uses pairs of standard nodal-based continuous finite element spaces. A notable exception was a case studied in [16] for which optimal L^2 error estimates for both the scalar variable and the flux were obtained when these variables were approximated by continuous nodal spaces built on a criss-cross grid. The key to their proof was the validity of the grid decomposition property (GDP) which was established for the criss-cross grid in [17]. So far, the criss-cross grid remains the only known case of a continuous nodal-based finite element space for which the GDP can be verified. More importantly, it was shown in [17] (see also [7]) that the GDP is necessary and sufficient for the stability of the mixed finite element method based on the Kelvin principle.

The correlation between the stability of mixed finite element methods and the optimal accuracy of least-squares finite element methods, established in [16], opens up the intriguing possibility that optimal L^2 accuracy for the flux may be obtainable for a least-squares finite element method, provided that this variable is approximated by $H(\Omega, \mathrm{div})$-conforming elements that are stable for mixed finite element methods based on the Kelvin principle. Today, the stability of mixed finite element methods based on the Kelvin principle is well understood, and many examples of stable finite element pairs are known. The first goal of our study is to show that the use of some of these spaces in a least-squares finite element method will indeed help to improve the L^2 accuracy of the flux approximation. Our second goal is to offer a new perspective on least-squares principles as resulting from a choice for the approximation of the Hodge $*$-operator that connects two mutually dual "energy" principles. Among other things, such an interpretation shows, in our context, why the use of $H(\Omega, \mathrm{div})$-conforming elements is in fact more natural than the use of equal-order C^0 spaces.

While our conclusions may disappoint the adherents of equal-order implementations, our results do not void least-squares finite element methods as a viable computational alternative. To the contrary, they demonstrate that when implemented correctly, a *least-squares finite element method combines the best computational properties of finite element methods based on both the Dirichlet and Kelvin principles,* and at the same time manages to avoid the indefinite linear systems that make the latter more difficult to solve. Although we reach this conclusion in the specific context of mixed and least-squares finite element methods for the Poisson problem, the idea of defining the latter type of method so that it inherits the best characteristics of a pair of mixed methods that are related through duality may have considerably wider application.

In the rest of this section, we briefly review the notation used throughout the paper. Then, in section 2.1, we recall the Dirichlet and Kelvin principles and the

[2] A somewhat different situation exists for negative-norm-based least-squares finite element methods, for which it is known that the L^2 accuracy of the flux is optimal with respect to the spaces used; however, for such methods, no error bound for the divergence of the flux could be established; see [10].

associated first-order div-grad formulation of the boundary value problem for the Poisson equation. There, in the context of the Kelvin principle, we also review basic definitions and properties of stable $H(\Omega, \mathrm{div})$-conforming mixed finite elements spaces for the flux and show that they satisfy the GDP. For the sake of brevity, we restrict attention to the well-known Raviart–Thomas (RT), Brezzi–Douglas–Marini (BDM), and Brezzi–Douglas–Duran–Fortin (BDDF) classes of affine families of finite elements. Section 3 deals with least-squares finite element methods for first-order formulations of the Poisson problem. After a brief review of known error estimates in $H^1(\Omega) \times H(\Omega, \mathrm{div})$, we turn our attention to the L^2 accuracy and the rarely discussed case of least-squares finite element methods using RT, BDM, or BDDF approximations of the flux. We show that BDM and BDDF spaces lead to optimal convergence of the flux in L^2. In section 4, we offer an interpretation of such least-squares finite element methods which is derived with the help of some notions from exterior calculus and differential forms.

1.1. Notation. Throughout, Ω denotes a bounded region in $\mathbb{R}^n$, $n = 2, 3$, with a Lipschitz continuous boundary $\Gamma = \partial\Omega$. We assume that Γ consists of two disjoint parts denoted by Γ_D and Γ_N. For $p > 0$, $H^p(\Omega)$ denotes the Sobolev space of order p with norm and inner product denoted by $\|\cdot\|_p$ and $(\cdot,\cdot)_p$, respectively. When $p = 0$, we use the standard notation $L^2(\Omega)$. The symbol $|\cdot|_k$, $0 \le k \le p$, denotes the kth seminorm on $H^p(\Omega)$. Vector-valued functions and vector analogues of the Sobolev spaces are denoted by lower- and upper case bold-face font, respectively, e.g., $\mathbf{u}$, $\mathbf{H}^1(\Omega)$, $\mathbf{L}^2(\Omega)$, etc. We recall the space

$$H(\Omega, \mathrm{div}) = \{\mathbf{u} \in \mathbf{L}^2(\Omega) \mid \nabla\cdot\mathbf{u} \in L^2(\Omega)\},$$

which is a Hilbert space when equipped with the norm

$$\|\mathbf{u}\|_{H(\Omega,\mathrm{div})} = (\|\mathbf{u}\|_0^2 + \|\nabla\cdot\mathbf{u}\|_0^2)^{1/2}.$$

To deal with the boundary conditions, we introduce the spaces

$$H^1_D(\Omega) = \{\phi \in H^1(\Omega) \mid \phi = 0 \quad \text{on } \Gamma_D\}$$

and

$$H_N(\Omega, \mathrm{div}\,) = \{\mathbf{v} \in H(\Omega, \mathrm{div}) \mid \mathbf{v}\cdot\mathbf{n} = 0 \quad \text{on } \Gamma_N\}.$$

Details about all the notation just introduced may be found, e.g., in [11, 18].

Throughout, we will refer to the problem

$$-\Delta\phi + \gamma\phi = f \quad \text{in } \Omega, \qquad \phi = 0 \quad \text{on } \Gamma_D, \quad \text{and} \quad \partial\phi/\partial n = 0 \quad \text{on } \Gamma_N \tag{1.1}$$

as the *Poisson problem*, even though that terminology is usually reserved for the case $\gamma = 0$.

2. Mixed finite element methods for the Poisson problem.

So as to provide a background for some of the discussions of sections 3 and 4 concerning least-squares finite element methods, we consider, in this section, primal and dual mixed finite element methods for the Poisson problem.

2.1. The generalized Dirichlet and Kelvin principles. The Dirichlet and Kelvin principles arise in a variety of applications. Mathematically, they provide two variational formulations for the Poisson problem and also form the basis for defining mixed finite element methods for approximations of the solution of that problem.

2.1.1. The generalized Dirichlet principle. Consider the functional

$$D(\phi, \mathbf{w}; f) = \frac{1}{2}\int_\Omega \left(|\mathbf{w}|^2 + \gamma|\phi|^2\right) d\Omega - \int_\Omega f\phi \, d\Omega$$

and the minimization problem

$$\min_{(\phi,\mathbf{w})\in H^1_D(\Omega)\times\nabla H^1_D(\Omega)} D(\phi, \mathbf{w}; f) \qquad \text{subject to} \qquad \mathbf{w} + \nabla\phi = 0, \tag{2.1}$$

where $\gamma \geq 0$ is a given function that is assumed to satisfy $\|\gamma\|_{L^\infty(\Omega)} \leq C$ for some constant $C \geq 0$. The minimization principle (2.1) is known as the (generalized) *Dirichlet principle*.[3] Although the constraint $\mathbf{w} + \nabla\phi = 0$ can be directly substituted into the functional to eliminate the flux $\mathbf{w}$,[4] it will be more profitable for our discussions to continue to consider the form (2.1).

With the help of a Lagrange multiplier $\mathbf{u}$ to enforce the constraint $\mathbf{w} + \nabla\phi = 0$ and the Lagrangian functional

$$L_D(\phi, \mathbf{w}, \mathbf{u}; f) = \frac{1}{2}\int_\Omega \left(|\mathbf{w}|^2 + \gamma|\phi|^2\right) d\Omega - \int_\Omega f\phi \, d\Omega - \int_\Omega \mathbf{u}\cdot(\mathbf{w} + \nabla\phi)\, d\Omega,$$

the constrained minimization problem (2.1) can be transformed into the unconstrained optimization problem of determining saddle-points $(\phi, \mathbf{w}, \mathbf{u}) \in H^1_D(\Omega) \times \nabla H^1_D(\Omega) \times \nabla H^1_D(\Omega)$ of $L_D(\phi, \mathbf{w}, \mathbf{u}; f)$. It is not difficult to see that the optimality system obtained by setting the first variations of $L_D(\phi, \mathbf{w}, \mathbf{u}; f)$ to zero is given by the following: seek $(\phi, \mathbf{w}, \mathbf{u}) \in H^1_D(\Omega) \times \nabla H^1_D(\Omega) \times \nabla H^1_D(\Omega)$ such that

$$\begin{cases} \displaystyle\int_\Omega \mathbf{w}\cdot\mathbf{v}\, d\Omega + \int_\Omega \nabla\phi\cdot\mathbf{v}\, d\Omega = 0 & \forall\, \mathbf{v} \in \nabla H^1_D(\Omega), \\ \displaystyle\int_\Omega (\mathbf{w} - \mathbf{u})\cdot\mathbf{q}\, d\Omega = 0 & \forall\, \mathbf{q} \in \nabla H^1_D(\Omega), \\ \displaystyle -\int_\Omega \mathbf{u}\cdot\nabla\psi\, d\Omega + \int_\Omega \gamma\phi\psi\, d\Omega = \int_\Omega f\psi\, d\Omega & \forall\, \psi \in H^1_D(\Omega). \end{cases} \tag{2.3}$$

The first and second equations may be easily combined to yield the simplified system

$$\begin{cases} \displaystyle\int_\Omega \mathbf{u}\cdot\mathbf{v}\, d\Omega + \int_\Omega \nabla\phi\cdot\mathbf{v}\, d\Omega = 0 & \forall\, \mathbf{v} \in \nabla H^1_D(\Omega), \\ \displaystyle\int_\Omega \nabla\psi\cdot\mathbf{u}\, d\Omega - \int_\Omega \gamma\psi\phi\, d\Omega = -\int_\Omega f\psi\, d\Omega & \forall\, \psi \in H^1_D(\Omega), \end{cases} \tag{2.4}$$

involving only $\phi \in H^1_D(\Omega)$ and $\mathbf{u} \in \nabla H^1_D(\Omega)$.

If solutions to the constrained minimization problem (2.1) or, equivalently, of (2.4), are sufficiently smooth, then without much difficulty one obtains that

[3] For $f = 0$, $\gamma = 0$, and appropriate boundary conditions, the Dirichlet principle in the inviscid fluid mechanics setting states that among all irrotational velocity fields, the one that minimizes the kinetic energy is the solenoidal one. In the solid mechanics setting, $\mathbf{w}$ is a tensor, and a simplified version of (2.1) is the *energy minimization principle.*

[4] This results in the certainly more familiar form for the (generalized) Dirichlet principle:

$$\min_{\phi\in H^1_D(\Omega)} \widetilde{D}(\phi; f), \quad \text{where} \quad \widetilde{D}(\phi; f) = \frac{1}{2}\int_\Omega (|\nabla\phi|^2 + \gamma|\phi|^2)\, d\Omega - \int_\Omega f\psi\, d\Omega. \tag{2.2}$$

$$\begin{cases} \nabla\cdot\mathbf{u}+\gamma\phi = f \quad \text{and} \quad \mathbf{u}+\nabla\phi=\mathbf{0} \quad \text{in } \Omega, \\ \phi = 0 \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{u}\cdot\mathbf{n}=0 \quad \text{on } \Gamma_N. \end{cases} \tag{2.5}$$

Note that from the second equation of (2.3) we also have that $\mathbf{w}=\mathbf{u}$. Eliminating the flux $\mathbf{u}$ from (2.5) (again assuming that sufficient smoothness is available), one obtains the Poisson problem[5] (1.1) for the scalar variable ϕ.

2.1.2. The generalized Kelvin principle. Now consider the functional

$$K(\lambda,\mathbf{u}) = \frac{1}{2}\int_\Omega \left(|\mathbf{u}|^2+\gamma|\lambda|^2\right) d\Omega$$

and the minimization problem

$$\min_{\lambda\in L^2(\Omega),\ \mathbf{u}\in H_N(\Omega,\mathrm{div})} K(\lambda,\mathbf{v}) \quad \text{subject to } \nabla\cdot\mathbf{u}+\gamma\lambda=f. \tag{2.7}$$

The minimization principle (2.7) is known as the (generalized) *Kelvin principle*;[6] it is dual to the (generalized) Dirichlet principle.[7]

With the help of a Lagrange multiplier ϕ to enforce the constraint and the Lagrangian functional

$$L_K(\lambda,\mathbf{u},\phi;f) = \frac{1}{2}\int_\Omega \left(|\mathbf{u}|^2+\gamma|\lambda|^2\right) d\Omega - \int_\Omega \phi(\nabla\cdot\mathbf{u}+\gamma\lambda-f)\, d\Omega,$$

the constrained minimization problem (2.7) can be transformed into the unconstrained problem of determining saddle-points $(\lambda,\mathbf{u},\phi)\in L^2(\Omega)\times H_N(\Omega,\mathrm{div})\times L^2(\Omega)$ of $L_K(\lambda,\mathbf{u},\phi;f)$. It is not difficult to see that the optimality system obtained by setting

[5] Note that since $\nabla\psi\in\mathbf{L}^2(\Omega)$, one can easily combine the two equations in (2.4) to yield the more familiar weak formulation

$$\int_\Omega \nabla\phi\cdot\nabla\psi\, d\Omega + \int_\Omega \gamma\psi\phi\, d\Omega = \int_\Omega f\psi\, d\Omega \qquad \forall\,\psi\in H^1_D(\Omega) \tag{2.6}$$

for the Poisson problem (1.1). Again, it will be more profitable for our discussion to continue to use (2.4) instead of the more familiar form (2.6).

[6] Setting $f=0$ and $\gamma=0$ and allowing for an inhomogeneous boundary condition for $\mathbf{u}\cdot\mathbf{n}$, the Kelvin principle for inviscid flows states that, among all incompressible velocity fields, the one that minimizes the kinetic energy is irrotational. In structural mechanics (where $\mathbf{u}$ is a tensor), a simplified version of (2.7) is known as the *complimentary energy principle*.

[7] Unlike the case of the Dirichlet principle, if $\gamma=0$, one cannot directly use the constraint $\nabla\cdot\mathbf{u}+\gamma\lambda=f$ to eliminate one of the variables. If $\gamma>0$, then it is possible to use the constraint to eliminate the scalar variable λ. In fact, in the latter case we are led to the problem

$$\min_{\mathbf{u}\in H_N(\Omega,\mathrm{div})} \widetilde{K}(\mathbf{u};f), \quad \text{where} \quad \widetilde{K}(\mathbf{u};f)=\frac{1}{2}\int_\Omega \left(|\mathbf{u}|^2+\frac{1}{\gamma}|\nabla\cdot\mathbf{u}-f|^2\right) d\Omega. \tag{2.8}$$

Comparing (2.2) and (2.8), we already see a big difference between the Kelvin and Dirichlet principles, in addition to the obvious difficulty seen in (2.8) for the case $\gamma=0$. The functional $\widetilde{D}(\cdot;f)$ in (2.2) involves all first derivatives of the scalar variable ϕ, which is why we can minimize it over the space $H^1_D(\Omega)$. On the other hand, the functional $\widetilde{K}(\cdot;f)$ in (2.8) only involves the combination $\nabla\cdot\mathbf{u}$ of first derivatives of the flux $\mathbf{u}$, which is why we can minimize it only with respect to a subspace of $H(\Omega,\mathrm{div})$, and not with respect to $\mathbf{H}^1(\Omega)$.

the first variations of $L(\lambda, \mathbf{u}, \phi; f)$ to zero is given by the following: seek $(\lambda, \mathbf{u}, \phi) \in L^2(\Omega) \times H_N(\Omega, \mathrm{div}\,) \times L^2(\Omega)$ such that

$$\text{(2.9)} \quad \begin{cases} \displaystyle\int_\Omega \mathbf{u} \cdot \mathbf{v}\, d\Omega - \int_\Omega \phi \nabla \cdot \mathbf{v}\, d\Omega = 0 & \forall\, \mathbf{v} \in H_N(\Omega, \mathrm{div}\,), \\ \displaystyle\int_\Omega \gamma(\lambda - \phi)\mu\, d\Omega = 0 & \forall\, \mu \in L^2(\Omega), \\ \displaystyle -\int_\Omega \psi \nabla \cdot \mathbf{u}\, d\Omega - \int_\Omega \gamma\psi\lambda\, d\Omega = -\int_\Omega f\psi\, d\Omega & \forall\, \psi \in L^2(\Omega). \end{cases}$$

For $\gamma \neq 0$, the second and third equations may be easily combined to yield the simplified system

$$\text{(2.10)} \quad \begin{cases} \displaystyle\int_\Omega \mathbf{u} \cdot \mathbf{v}\, d\Omega - \int_\Omega \phi \nabla \cdot \mathbf{v}\, d\Omega = 0 & \forall\, \mathbf{v} \in H_N(\Omega, \mathrm{div}\,), \\ \displaystyle -\int_\Omega \psi \nabla \cdot \mathbf{u}\, d\Omega - \int_\Omega \gamma\psi\phi\, d\Omega = -\int_\Omega f\psi\, d\Omega & \forall\, \psi \in L^2(\Omega), \end{cases}$$

involving only $\phi \in L^2(\Omega)$ and $\mathbf{u} \in H_N(\Omega, \mathrm{div}\,)$. If $\gamma = 0$, then (2.9) directly reduces to (2.10) so that the latter holds for any $\gamma \geq 0$.

The duality of the Dirichlet and Kelvin principles extends to the optimality systems (2.4) and (2.10). For example, they are respectively described using the dual operators ∇ and $-\nabla\cdot$. The domain of ∇ is all of $H^1_D(\Omega)$, while its range is a constrained subspace of $\mathbf{L}^2(\Omega)$ consisting of irrotational functions. In contrast, the domain of $\nabla\cdot$ is a constrained subspace of $\mathbf{L}^2(\Omega)$ and its range is all of $L^2(\Omega)$. We note again the difference between the domain spaces of the two operators: $H^1_D(\Omega)$ involves all first derivatives of the scalar variable, while $H_N(\Omega, \mathrm{div})$ only involves a combination of first derivatives of the flux.

2.2. Stable mixed finite element spaces. Finite element approximations of the mixed problems (2.4) and (2.10) are not stable unless the spaces chosen to approximate ϕ and $\mathbf{u}$ satisfy the inf-sup condition. To keep our presentation reasonably short and devoid of unnecessary technical details, we focus on affine families of stable spaces defined on simplicial triangulations $\mathcal{T}_h$ of the domain Ω into elements $\mathcal{K}$. In two dimensions, $\mathcal{K}$ are triangles, and in three dimensions, they are tetrahedra. The symbol $P_k(\mathcal{K})$ denotes the space of all polynomials of degree less than or equal to k defined on $\mathcal{K}$.

Nodal C^0 finite element spaces built from mth degree polynomials, $m \geq 1$, are denoted by[8] $\mathcal{W}^0_m(\Omega)$. We recall that there exists an interpolation operator $\mathcal{I}_0$ into $\mathcal{W}^0_m(\Omega)$ such that for any $\phi \in H^{m+1}(\Omega)$,

$$\text{(2.11)} \qquad \|\phi - \mathcal{I}_0\phi\|_0 + h\|\nabla(\phi - \mathcal{I}_0\phi)\|_0 \leq Ch^{m+1}|\phi|_{m+1}.$$

[8] The reasoning leading to the choice of notation $\mathcal{W}^i_k$ for the finite element spaces we employ will become clear later.

We denote by $\mathcal{W}_m^1(\Omega)$ the space $\nabla(\mathcal{W}_m^0(\Omega))$.[9] We will use the pair of finite element spaces $\mathcal{W}_m^0(\Omega)$ and $\mathcal{W}_m^1(\Omega)$ to discretize the Dirichlet principle.

For the Kelvin principle, we will use the[10] BDM_k and RT_k spaces on Ω that are built from the individual element spaces

$$\mathrm{BDM}_k(\mathcal{K}) = (P_k(\mathcal{K}))^n \quad \text{and} \quad \mathrm{RT}_k(\mathcal{K}) = (P_k(\mathcal{K}))^n + \mathbf{x}P_k(\mathcal{K})$$

in a manner that ensures the continuity of the normal component across element boundaries; see [11, pp. 113–116] for details and definitions of the corresponding element degrees of freedom. Since BDM_k and RT_k both contain complete polynomials of degree k, their approximation properties in L^2 are the same. In particular, one can show that for either the BDM_k or RT_k spaces there exists an interpolation operator $\mathcal{I}_2$ such that

$$\|\mathbf{u} - \mathcal{I}_2\mathbf{u}\|_0 \leq Ch^r|\mathbf{u}|_r \quad \forall\, \mathbf{u} \in \mathbf{H}^r(\Omega) \text{ and } 1 \leq r \leq k+1. \tag{2.12}$$

Since RT_k also contains the higher-degree polynomial component $\mathbf{x}P_k(\mathcal{K})$, it has better accuracy in $H(\Omega, \mathrm{div})$ than does BDM_k. Note, however, that this additional component does not help to improve the L^2 accuracy of RT_k spaces because it does not increase the order of complete polynomials contained in RT_k to $k+1$. In summary, we have the following estimates for the error in the divergence of the interpolant (see [11, p. 132]):

$$\|\nabla \cdot (\mathbf{u} - \mathcal{I}_2\mathbf{u})\|_0 \leq Ch^k\|\nabla \cdot \mathbf{u}\|_k \qquad \text{for } \mathrm{BDM}_k \text{ spaces} \tag{2.13}$$

and

$$\|\nabla \cdot (\mathbf{u} - \mathcal{I}_2\mathbf{u})\|_0 \leq Ch^{k+1}\|\nabla \cdot \mathbf{u}\|_{k+1} \qquad \text{for } \mathrm{RT}_k \text{ spaces.} \tag{2.14}$$

In what follows, we will denote by $\mathcal{W}_k^2(\Omega)$ the RT and BDM spaces having *equal approximation orders with respect to the divergence operator*, i.e.,

$$\mathcal{W}_k^2(\Omega) = \{\mathbf{v} \in H(\Omega, \mathrm{div}) | \mathbf{v}|_{\mathcal{K}} \in \mathcal{W}_k^2(\mathcal{K})\},$$

where $\mathcal{W}_k^2(\mathcal{K})$ is one of the finite element spaces $\mathrm{RT}_{k-1}(\mathcal{K})$ or $\mathrm{BDM}_k(\mathcal{K})$. We can now combine (2.13) and (2.14) into a single statement: there exists an interpolation operator $\mathcal{I}_2$ into $\mathcal{W}_k^2(\Omega)$ such that

$$\|\nabla \cdot (\mathbf{u} - \mathcal{I}_2\mathbf{u})\|_0 \leq Ch^k\|\nabla \cdot \mathbf{u}\|_k. \tag{2.15}$$

Note, however, that from (2.12) we have that the interpolation operator $\mathcal{I}_2$ into $\mathcal{W}_k^2(\Omega)$ satisfies

$$\|\mathbf{u} - \mathcal{I}_2\mathbf{u}\|_0 \leq Ch^r|\mathbf{u}|_r \qquad \begin{cases} \text{for } 1 < r \leq k & \text{if } \mathcal{W}_k^2(\mathcal{K}) = \mathrm{RT}_{k-1}, \\ \text{for } 1 < r \leq k+1 & \text{if } \mathcal{W}_k^2(\mathcal{K}) = \mathrm{BDM}_k. \end{cases} \tag{2.16}$$

[9] In our setting, $\mathcal{W}_m^1(\Omega)$ is a space of vector-valued functions that are discontinuous with respect to the simplicial triangulation $\mathcal{T}_h$ and whose components belong to a subspace $P_{m-1}(\mathcal{K})$ in each $\mathcal{K}$. Functions belonging to $\mathcal{W}_m^1(\Omega)$ must be curl-free within each element $\mathcal{K}$ (since they are gradients of function belonging to $\mathcal{W}_m^0(\Omega)$), so that, except for $m = 1$, they are not complete $(m-1)$st degree polynomials. However, the precise, explicit characterization of $\mathcal{W}_m^1(\Omega)$, e.g., the construction of a basis, is not difficult (using their irrotational property), and moreover, as we shall see, it turns out not to be necessary in practice. For future reference, we note that functions belonging to the approximating space $\mathcal{W}_m^0(\Omega)$ for the scalar variable are continuous across element boundaries, so that the tangential components of functions belonging to the approximating space $\mathcal{W}_m^1(\Omega) = \nabla(\mathcal{W}_m^0(\Omega))$ for the flux are *automatically* also continuous across element boundaries.

[10] To simplify notation, from now on we will denote both the BDM and BDDF spaces simply by BDM.

We denote by $\mathcal{W}_k^3(\Omega)$ the space $\nabla\cdot(\mathcal{W}_k^2(\Omega))$. For mixed finite element methods based on the Kelvin principle, we will use the finite element spaces RT_{k-1} or BDM_k to approximate the flux. For characterizations of these spaces and the associated spaces $\mathcal{W}_k^3(\Omega) = \nabla\cdot(\mathcal{W}_k^2(\Omega))$ for the scalar variable, see [11].

2.2.1. Stable mixed finite element spaces for the Dirichlet principle. A mixed finite element method based on the Dirichlet principle may be defined by discretizing (2.4), i.e.,

$$\text{(2.17)}\qquad \begin{cases} \displaystyle\int_\Omega \mathbf{u}_h\cdot\mathbf{v}_h\,d\Omega + \int_\Omega \nabla\phi_h\cdot\mathbf{v}_h\,d\Omega = 0 & \forall\,\mathbf{v}_h\in\mathcal{W}_m^1(\Omega),\\ \displaystyle\int_\Omega \nabla\psi_h\cdot\mathbf{u}_h\,d\Omega - \int_\Omega \gamma\psi_h\phi_h\,d\Omega = -\int_\Omega f\psi_h\,d\Omega & \forall\,\psi\in\mathcal{W}_m^0(\Omega). \end{cases}$$

Since $\mathcal{W}_m^1(\Omega)\equiv\nabla(\mathcal{W}_m^0(\Omega))$, note that, even at the discrete level, we may again eliminate the flux approximation to obtain the equivalent discrete problem

$$\text{(2.18)}\qquad \int_\Omega \nabla\phi_h\cdot\nabla\psi_h\,d\Omega + \int_\Omega \gamma\psi_h\phi_h\,d\Omega = \int_\Omega f\psi_h\,d\Omega \qquad \forall\,\psi\in\mathcal{W}_m^0(\Omega),$$

which we recognize as the standard Galerkin discretization of (2.2) or (2.6). In fact, using the pair of spaces $\mathcal{W}_m^0(\Omega)$ and $\mathcal{W}_m^1(\Omega)$ for approximating the scalar variable and the flux, respectively, in the discretization (2.17) of (2.4) is equivalent[11] to using the scalar space $\mathcal{W}_m^0(\Omega)$ in the standard Galerkin discretization (2.18) of (2.2) and then letting the approximation of the flux be the gradient of the resulting approximation of the scalar variable.

In this way we see that for discretizations of (2.4), i.e., the Dirichlet principle, the required inf-sup condition is completely benign in the sense that it can be avoided by eliminating the flux approximation $\mathbf{u}_h$ from (2.17), then solving (2.18) for the approximation ϕ_h of the scalar variable using a standard continuous nodal finite element space $\mathcal{W}_m^0(\Omega)$, and, at the end, determining the approximation to the flux from the exact relation $\mathbf{u}_h = -\nabla\phi_h$. The required inf-sup condition is implicitly satisfied by the pair of spaces $\mathcal{W}_m^0(\Omega)$ and $\mathcal{W}_m^1(\Omega) = \nabla(\mathcal{W}_m^0(\Omega))$. If one insists on solving (2.4), then one needs to explicitly produce a basis for $\mathcal{W}_m^1(\Omega)$; this is easily accomplished.

From either (2.17) or (2.18) one obtains, for the Dirichlet principle, that if $\phi\in H^{m+1}(\Omega)\cap H_D^1(\Omega)$, then

$$\text{(2.19)}\qquad \|\phi-\phi_h\|_0 \le h^{m+1}\|\phi\|_{m+1},$$

while the flux approximation is less accurate:

$$\text{(2.20)}\qquad \|\mathbf{u}-\mathbf{u}_h\|_0 = \|\nabla(\phi-\phi_h)\|_0 \le h^m\|\phi\|_{m+1}.$$

2.2.2. Stable mixed finite element spaces for the Kelvin principle. For discretizations of (2.10), i.e., the Kelvin principle, the inf-sup condition is much more onerous in the sense that defining a pair of stable finite element spaces for the scalar variable and the flux is not so straightforward a matter.

[11] Here, by *equivalent* we mean that they yield exactly the same approximate solutions.

The mixed finite element method associated with (2.10), i.e., the Kelvin principle, is given by the following: seek $(\phi_h, \mathbf{u}_h) \in \mathcal{W}_k^3(\Omega) \times \mathcal{W}_k^2(\Omega)$ such that

$$\text{(2.21)} \qquad \begin{cases} \displaystyle\int_\Omega \mathbf{u}_h \cdot \mathbf{v}_h \, d\Omega - \int_\Omega \phi_h \nabla \cdot \mathbf{v}_h \, d\Omega = 0 & \forall\, \mathbf{v}_h \in \mathcal{W}_k^2(\Omega), \\ \displaystyle\int_\Omega \psi_h \nabla \cdot \mathbf{u}_h \, d\Omega + \int_\Omega \gamma \psi_h \psi_h \, d\Omega = \int_\Omega f \psi_h \, d\Omega & \forall\, \psi_h \in \mathcal{W}_k^3(\Omega). \end{cases}$$

For the $\gamma = 0$ case, we refer to [11] for a proof that $(\mathcal{W}_k^3(\Omega), \mathcal{W}_k^2(\Omega))$ is a stable pair for the mixed finite element problem (2.21). Moreover, one can show [11, Proposition 1.2, p. 139] that for any sufficiently regular exact solution of (2.10) one has the error estimate

$$\text{(2.22)} \qquad \|\mathbf{u} - \mathbf{u}_h\|_0 \le Ch^r \|\mathbf{u}\|_r \qquad \begin{cases} \text{for } 1 < r \le k & \text{if } \mathcal{W}_k^2(\mathcal{K}) = \mathrm{RT}_{k-1}, \\ \text{for } 1 < r \le k+1 & \text{if } \mathcal{W}_k^2(\mathcal{K}) = \mathrm{BDM}_k, \end{cases}$$

while the error in the divergence is of the same order in both cases,

$$\text{(2.23)} \qquad \|\nabla \cdot (\mathbf{u} - \mathbf{u}_h)\|_0 \le Ch^r \|\nabla \cdot \mathbf{u}\|_r \qquad \text{for } 1 < r \le k,$$

as is the error in the scalar variable:

$$\text{(2.24)} \qquad \|\phi - \phi_h\|_0 \le Ch^r (\|\phi\|_r + \|\mathbf{u}\|_r) \qquad \text{for } 1 < r \le k.$$

These results also hold for the $\gamma > 0$ case, since the mixed finite element problem (2.21) is identical to what one obtains for penalty methods for the $\gamma = 0$ case; see, e.g., [11, 18], for details.

We have thus seen that the duality between the Dirichlet and Kelvin principles propagates to their numerical approximations by mixed finite element methods that themselves have, in a sense, complementary computational properties. For example, for the Dirichlet principle, one directly approximates the scalar variable in the H^1-conforming finite element space $W_m^0(\Omega)$, and the flux is approximated in the finite element space $W_m^1(\Omega) = \nabla(W_m^0(\Omega))$. With respect to $L^2(\Omega)$ norms, the mixed approximation ϕ_h to ϕ satisfies the optimal bound (2.19), while the approximation $\mathbf{u}_h$ of the flux $\mathbf{u}$ is less accurate; see (2.20). For the Kelvin principle, the situation is reversed in the sense that now one directly approximates the flux in the $H_N(\Omega, \mathrm{div}\,)$-conforming finite element space $\mathcal{W}_k^2(\Omega)$ and the scalar variable in $\mathcal{W}_k^3(\Omega) = \nabla \cdot (\mathcal{W}_k^2(\Omega))$. The approximation $\mathbf{u}_h$ to $\mathbf{u}$ now satisfies the optimal bound (2.22), while the scalar approximation is less accurate when $\mathcal{W}_k^2(\Omega) = \mathrm{BDM}_k$.

We have also seen the differences in how easily one can satisfy the inf-sup condition for mixed methods based on the two principles. From (2.18), one sees that for the Dirichlet principle one can essentially avoid the inf-sup condition, or, if one insists on using the mixed formulation (2.17), one can easily construct a stable pair of spaces. This is closely related to the fact that the null space of the gradient consists of the constant function and is trivial to approximate. On the other hand, for the Kelvin principle, one has to construct a pair of finite element spaces such that the space for approximating the scalar variable is the divergence of the space for approximating the flux and the latter is a subspace of $H(\Omega, \mathrm{div})$. This is a much more difficult construction since the divergence operator has a decidedly nontrivial null space that is much harder to approximate than the (trivial) null space of the gradient. Compared to the finite element subspaces that can be used for approximations of the Dirichlet principle, for the Kelvin principle this leads to the need to define more complicated finite element subspaces for the flux such as the RT and BDM spaces or continuous piecewise linear subspaces based on the criss-cross grid.

It is important to note that if one uses C^0 finite element spaces for both the scalar variable and the flux, then (2.17) and (2.21) are identical discrete systems. It is well known that this leads to unstable approximations, so that one cannot use such pairs of finite element spaces in mixed methods derived from either the Dirichlet or Kelvin principles.

2.3. The grid decomposition property. We continue our study of mixed methods based on the Kelvin principle by showing that the spaces $\mathcal{W}_k^2(\Omega)$ satisfy the GDP.[12]

THEOREM 2.1. *For every $\mathbf{u}_h \in \mathcal{W}_k^2(\Omega)$, there exist $\mathbf{w}_h, \mathbf{z}_h$ in $\mathcal{W}_k^2(\Omega)$ such that*[13]

$$\mathbf{u}_h = \mathbf{w}_h + \mathbf{z}_h, \tag{2.25}$$

$$\nabla \cdot \mathbf{z}_h = 0, \tag{2.26}$$

$$\int_\Omega \mathbf{w}_h \cdot \mathbf{z}_h \, d\Omega = 0, \tag{2.27}$$

$$\|\mathbf{w}_h\|_0 \le C(\|\nabla \cdot \mathbf{u}_h\|_{-1} + h\|\nabla \cdot \mathbf{u}_h\|_0). \tag{2.28}$$

Proof. Given a $\mathbf{u}_h \in \mathcal{W}_k^2(\Omega)$, define $\mathbf{w}_h$ to be a solution of the following mixed problem: seek $(\phi_h, \mathbf{w}_h) \in \mathcal{W}_k^3(\Omega) \times \mathcal{W}_k^2(\Omega)$ such that

$$\begin{aligned} \int_\Omega \mathbf{w}_h \cdot \mathbf{v}_h \, d\Omega - \int_\Omega \phi_h \nabla \cdot \mathbf{v}_h \, d\Omega = 0 \quad \forall\, \mathbf{v}_h \in \mathcal{W}_k^2(\Omega), \\ \int_\Omega \psi_h \nabla \cdot \mathbf{w}_h \, d\Omega = \int_\Omega \psi_h \nabla \cdot \mathbf{u}_h \, d\Omega \quad \forall\, \psi_h \in \mathcal{W}_k^3(\Omega). \end{aligned} \tag{2.29}$$

The second component is then defined as the algebraic complement

$$\mathbf{z}_h = \mathbf{u}_h - \mathbf{w}_h \tag{2.30}$$

of $\mathbf{u}_h$. Therefore, the first GDP property (2.25) is trivially satisfied.

To prove (2.26), we use the second equation in (2.29) to conclude that

$$\int_\Omega \psi_h \nabla \cdot \mathbf{z}_h \, d\Omega = \int_\Omega \psi_h (\nabla \cdot \mathbf{u}_h - \nabla \cdot \mathbf{w}_h) \, d\Omega = 0 \quad \forall\, \psi_h \in \mathcal{W}_k^3(\Omega).$$

Assume now that $\nabla \cdot \mathbf{z}_h \neq 0$. From the definition of $\mathcal{W}_k^3(\Omega)$, it follows that the divergence operator is a surjective mapping $\mathcal{W}_k^2(\Omega) \mapsto \mathcal{W}_k^3(\Omega)$. Therefore, there exists

[12] An analogous "GDP" can be defined in the context of the Dirichlet principle; it requires that for every $\phi_h \in \mathcal{W}_k^0(\Omega)$ there exist $\lambda_h, \chi_h \in \mathcal{W}_k^0(\Omega)$ such that $\phi_h = \lambda_h + \chi_h$, $\nabla \chi_h = 0$, $\int_\Omega \lambda_h \chi_h d\Omega = 0$, and $\|\lambda_h\|_0 \le C(\|\nabla \phi_h\|_{-1} + h\|\nabla \phi_h\|_0)$. Of course, these conditions are trivially satisfied since $\nabla \chi_h = 0$ and $\chi_h \in \mathcal{W}_k^0(\Omega)$ imply that $\chi_h = 0$ and therefore $\lambda_h = \phi_h$. Again, the fact that the null space of the gradient operator with respect to $H_D^1(\Omega)$ is trivial plays a crucial role in the triviality of the GDP for the Dirichlet principle. On the other hand, for the Kelvin principle, the fact that the null space of the divergence operator with respect to $H_N(\Omega, \mathrm{div}\,)$ is decidedly not trivial also plays a crucial role in the GDP for that principle. All this, of course, is related to the observations made above about the inf-sup conditions for the two principles.

[13] In its original form (see [17]), the GDP was formulated without the term $h\|\nabla \cdot \mathbf{u}_h\|_0$ in (2.28). However, thanks to the multiplicative h factor, this term will not affect the L^2 error rates.

a nonzero element $\widehat{\psi}_h \in \mathcal{W}_k^3(\Omega)$ such that $\widehat{\psi}_h = \nabla \cdot \mathbf{z}_h$. Then,

$$0 = \int_\Omega \widehat{\psi}_h \nabla \cdot \mathbf{z}_h \, d\Omega = \int_\Omega \widehat{\psi}_h \widehat{\psi}_h \, d\Omega \neq 0,$$

a contradiction.

To show that $\mathbf{w}_h$ and $\mathbf{z}_h$ are orthogonal, we use the first equation in (2.29) with $\mathbf{v}_h = \mathbf{z}_h$:

$$\int_\Omega \mathbf{w}_h \cdot \mathbf{z}_h \, d\Omega = \int_\Omega \phi_h \nabla \cdot \mathbf{z}_h \, d\Omega = 0.$$

To prove the last GDP property (2.28), we will need the solution $(\phi, \mathbf{w})$ of the first-order problem

$$\begin{cases} \nabla \cdot \mathbf{w} = \nabla \cdot \mathbf{u}_h \quad \text{and} \quad \mathbf{w} + \nabla \phi = \mathbf{0} \quad \text{in } \Omega, \\ \phi = 0 \quad \text{on } \Gamma_D \quad \text{and} \quad \mathbf{w} \cdot \mathbf{n} = 0 \quad \text{on } \Gamma_N. \end{cases}$$

It will be also necessary to assume that this problem has full elliptic regularity, i.e., $\mathbf{w} \in \mathbf{H}^1(\Omega)$ and $\phi \in H^2(\Omega)$. Lastly, we recall the a priori bounds

$$\|\mathbf{w}\|_0 \leq \|\nabla \cdot \mathbf{u}_h\|_{-1} \quad \text{and} \quad \|\mathbf{w}\|_1 \leq \|\nabla \cdot \mathbf{u}_h\|_0.$$

Then, from (2.22)

$$\|\mathbf{w} - \mathbf{w}_h\|_0 \leq Ch\|\mathbf{w}\|_1.$$

Using this error estimate, the a priori bounds, and the triangle inequality yields that

$$\begin{aligned} \|\mathbf{w}_h\|_0 &\leq \|\mathbf{w}_h - \mathbf{w}\|_0 + \|\mathbf{w}\|_0 \\ &\leq Ch\|\mathbf{w}\|_1 + \|\nabla \cdot \mathbf{u}_h\|_{-1} \leq Ch\|\nabla \cdot \mathbf{u}_h\|_0 + \|\nabla \cdot \mathbf{u}_h\|_{-1}. \qquad \square \end{aligned}$$

It was shown in [17] that the GDP, i.e., (2.25)–(2.28), along with the relation $\mathcal{W}_k^3(\Omega) = \nabla \cdot (\mathcal{W}_k^2(\Omega))$, are necessary and sufficient for the stability of a mixed finite element method based on the Kelvin principle.

3. Least-squares finite element methods. A least-squares finite element method for the Poisson equation replaces the search for saddle-points of the Lagrangian functional, either $L_D(\phi, \mathbf{w}, \mathbf{u}, f)$ or $L_K(\lambda, \mathbf{u}, \phi, f)$, by a search for the unconstrained global minimizer of the quadratic functional

$$J(\phi, \mathbf{u}; f) = \frac{1}{2}\big(\|\nabla \cdot \mathbf{u} + \gamma\phi - f\|_0^2 + \|\nabla\phi + \mathbf{u}\|_0^2\big). \tag{3.1}$$

The least-squares variational principle

$$\min_{(\phi,\mathbf{u}) \in H_D^1(\Omega) \times H_N(\Omega,\mathrm{div})} J(\phi, \mathbf{u}; f) \tag{3.2}$$

then has a solution that minimizes the L^2 residuals of the first-order system (2.5). It is clear that this solution coincides with the solution of (2.5) or, equivalently, (1.1), and that it can be determined from the following first-order optimality system for (3.2): seek $(\phi, \mathbf{u}) \in H_D^1(\Omega) \times H_N(\Omega, \mathrm{div}\,)$ such that

$$Q((\phi, \mathbf{u}); (\psi, \mathbf{v})) = \mathcal{F}(\psi, \mathbf{v}) \quad \forall\, (\psi, \mathbf{v}) \in H_D^1(\Omega) \times H_N(\Omega, \mathrm{div}), \tag{3.3}$$

where

$$Q((\phi,\mathbf{u});(\psi,\mathbf{v})) = \int_\Omega (\nabla\cdot\mathbf{u}+\gamma\phi)(\nabla\cdot\mathbf{v}+\gamma\psi)\,d\Omega + \int_\Omega (\nabla\phi+\mathbf{u})\cdot(\nabla\psi+\mathbf{v})\;d\Omega \tag{3.4}$$

and

$$\mathcal{F}(\psi,\mathbf{v}) = \int_\Omega f(\nabla\cdot\mathbf{v}+\gamma\psi)\,d\Omega. \tag{3.5}$$

To define a least-squares finite element method, we restrict (3.2) to the conforming subspace $\mathcal{W}_m^0(\Omega)\times\mathcal{W}_k^2(\Omega)\subset H_D^1(\Omega)\times H_N(\Omega,\mathrm{div}\,)$. The least-squares finite element approximation is then obtained from the following discrete optimality system: seek $(\phi_h,\mathbf{u}_h)\in\mathcal{W}_m^0(\Omega)\times\mathcal{W}_k^2(\Omega)$ such that

$$Q((\phi_h,\mathbf{u}_h);(\psi_h,\mathbf{v}_h)) = \mathcal{F}(\psi_h,\mathbf{v}_h) \quad \forall\,(\psi_h,\mathbf{v}_h)\in\mathcal{W}_m^0(\Omega)\times\mathcal{W}_k^2(\Omega). \tag{3.6}$$

The next theorem states that

$$|||\psi,\mathbf{v}||| = (Q((\psi,\mathbf{v});(\psi,\mathbf{v})))^{1/2}$$

is an equivalent norm on $H_D^1(\Omega)\times H_N(\Omega,\mathrm{div}\,)$. We call it the *energy norm* corresponding to the least-squares principle.

THEOREM 3.1. *There exist positive constants C_1 and C_2 such that for any $(\psi,\mathbf{v})\in H_D^1(\Omega)\times H_N(\Omega,\mathrm{div})$,*

$$C_1\big(\|\psi\|_1^2+\|\mathbf{v}\|_{H(\Omega,\mathrm{div})}^2\big) \le |||\psi,\mathbf{v}|||^2 \le C_2\big(\|\psi\|_1^2+\|\mathbf{v}\|_{H(\Omega,\mathrm{div})}^2\big). \tag{3.7}$$

For a proof, see any of [12, 13, 14, 27]. Theorem 3.1 implies that both the continuous variational problem (3.3) and its finite element restriction (3.6) are uniquely solvable and that their solutions are bounded by the norm of the data.

Note for later use that (3.3) and (3.6) imply the standard finite element orthogonality relation

$$Q((\phi-\phi_h,\mathbf{u}-\mathbf{u}_h);(\psi_h,\mathbf{v}_h)) = 0 \quad \forall\,(\psi_h,\mathbf{v}_h)\in\mathcal{W}_m^0(\Omega)\times\mathcal{W}_k^2(\Omega). \tag{3.8}$$

3.1. Error estimates in $H^1(\Omega)\times H(\Omega,\mathrm{div})$.

In this section, we review the convergence properties of least-squares finite element methods for the Poisson equation with respect to the $H^1(\Omega)\times H(\Omega,\mathrm{div})$ norm. Most of the details are omitted, as the proofs follow by standard elliptic finite element arguments.

THEOREM 3.2. *Assume that the solution $(\phi,\mathbf{u})$ of (3.3) satisfies $(\phi,\mathbf{u})\in H_D^1(\Omega)\cap H^{m+1}(\Omega)\times H_N(\Omega,\mathrm{div}\,)\cap\mathbf{H}^{k+1}(\Omega)$ for some integers $k,m\ge 1$. Let $(\phi_h,\mathbf{u}_h)\in\mathcal{W}_m^0(\Omega)\times\mathcal{W}_k^2(\Omega)$ be the solution of the least-squares finite element problem (3.6). Then, there exists a constant $C>0$ such that*

$$\|\phi-\phi_h\|_1+\|\mathbf{u}-\mathbf{u}_h\|_{H(\Omega,\mathrm{div})} \le C\left(h^k\|\mathbf{u}\|_{k+1}+h^m\|\phi\|_{m+1}\right). \tag{3.9}$$

The error estimate (3.9) remains valid when $\mathbf{u}_h$ is approximated by the C^0 space $(P_k(\Omega))^n$.

Proof. Since $(\phi_h, \mathbf{u}_h)$ is a projection with respect to the energy norm $|||\cdot|||$,

$$|||\phi - \phi_h; \mathbf{u} - \mathbf{u}_h||| \leq |||\phi - \psi_h; \mathbf{u} - \mathbf{v}_h||| \quad \forall\, \psi_h \in \mathcal{W}_m^0(\Omega), \;\; \mathbf{v}_h \in \mathcal{W}_k^2(\Omega).$$

Then, (3.9) easily follows from the norm equivalence relation (3.7) and the approximation theoretic estimates (2.11)–(2.15). □

Theorem 3.2 shows that the errors in $\mathbf{u}_h$ and ϕ_h will be equilibrated whenever $k = m$. For example, if any of the pairs (RT_0, P_1), (BDM_1, P_1), or $((P_1)^n, P_1)$ are used in the least-squares finite element method, the a priori bound (3.9) specializes to

$$\|\phi - \phi_h\|_1 + \|\mathbf{u} - \mathbf{u}_h\|_{H(\Omega,\mathrm{div})} \leq Ch\left(\|\mathbf{u}\|_2 + \|\phi\|_2\right).$$

Therefore, the asymptotic accuracy of all three pairs in the norm of $H^1(\Omega)\times H(\Omega,\mathrm{div})$ is the same. For this reason, in the implementation of the least-squares finite element method, one usually chooses the C^0 pair $((P_1)^n, P_1)$ because it is the easiest to implement. Indeed, the ability to use equal-order interpolation has been often cited as a primary reason for choosing to use least-squares finite element methods. Nevertheless, the C^0 pair is not flawless because optimal L^2 norm errors for the flux approximation have proven impossible to obtain without augmenting (2.5) with an additional redundant curl constraint equation. Also, as we have already mentioned, numerical studies in [16] indicate that the L^2 convergence of the flux is indeed suboptimal with C^0 finite element spaces.

The curl constraint, first introduced in the least-squares finite element setting in [15] and subsequently utilized by many others (see, e.g., [12, 13, 14, 25]), makes the least-squares functional norm-equivalent on $H^1(\Omega) \times \mathbf{H}^1(\Omega)$. However, in some situations the curl equation may unduly restrict the range of the differential operator and should be avoided. In the next section, we will see that if the nodal approximation of the flux is replaced by an approximation in $\mathcal{W}_k^2(\Omega)$, it may be possible to recover optimal L^2 convergence rates without adding the curl constraint. As in [16], the key to this is the GDP.

3.2. Error estimates in L^2.

Throughout this section, we let $(\phi, \mathbf{u})$ and $(\phi_h, \mathbf{u}_h) \in \mathcal{W}_m^0(\Omega) \times \mathcal{W}_k^2(\Omega)$ denote the solutions of (3.3) and (3.6), respectively. We assume that the solution of the problem

$$-\Delta\psi + \gamma\psi = \eta \quad \text{in } \Omega, \qquad \psi = 0 \quad \text{on } \Gamma_D, \qquad \frac{\partial\psi}{\partial n} = 0 \quad \text{on } \Gamma_D \tag{3.10}$$

satisfies the regularity estimate

$$\|\psi\|_{s+2} \leq C\|\eta\|_s \quad \text{for } s = 0, 1 \text{ and } \forall\, \eta \in H^s(\Omega). \tag{3.11}$$

This additional regularity is necessary since our L^2 error estimates are based on a duality argument.

3.2.1. L^2 error estimates for the scalar variable.

Our first lemma bounds the negative norm of the error in the first equation in (2.5) in terms of the energy norm of the total error. Note that (3.11) of course implies that $\|\nabla\psi\|_{s+1} \leq C\|\eta\|_s$ for $s = 0, 1$.

LEMMA 3.3. *Let $(\phi_h, \mathbf{u}_h)$ be a least-squares finite element approximation of $(\phi, \mathbf{u})$. Then,*

$$\|\nabla \cdot (\mathbf{u} - \mathbf{u}_h) + \gamma(\phi - \phi_h)\|_{-1} \leq Ch|||\phi - \phi_h, \mathbf{u} - \mathbf{u}_h|||. \tag{3.12}$$

Proof. Let $\eta \in H_0^1(\Omega)$ be an arbitrary function, let ψ solve the boundary value problem (3.10), and let $\mathbf{v} = -\nabla\psi$. One then obtains

$$\begin{aligned}
&\int_\Omega (\nabla\cdot(\mathbf{u}-\mathbf{u}_h) + \gamma(\phi-\phi_h))\,\eta\, d\Omega \\
&\qquad = \int_\Omega (\nabla\cdot(\mathbf{u}-\mathbf{u}_h) + \gamma(\phi-\phi_h))(\nabla\cdot\mathbf{v} + \gamma\psi)\, d\Omega \\
&\qquad = Q(\phi-\phi_h, \mathbf{u}-\mathbf{u}_h; \psi, \mathbf{v}) = Q(\phi-\phi_h, \mathbf{u}-\mathbf{u}_h; \psi - \mathcal{I}_0\psi, \mathbf{v}-\mathcal{I}_2\mathbf{v}) \\
&\qquad = \int_\Omega (\nabla\cdot(\mathbf{u}-\mathbf{u}_h) + \gamma(\phi-\phi_h))(\nabla\cdot(\mathbf{v}-\mathcal{I}_2\mathbf{v}) + \gamma(\psi-\mathcal{I}_0\psi)\, d\Omega \\
&\qquad\quad + \int_\Omega (\nabla(\phi-\phi_h) + (\mathbf{u}-\mathbf{u}_h))\cdot(\nabla(\psi-\mathcal{I}_0\psi) + (\mathbf{v}-\mathcal{I}_2\mathbf{v}))\, d\Omega \\
&\qquad \le C((\|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)\|_0 + \|\phi-\phi_h\|_0)(\|\nabla\cdot(\mathbf{v}-\mathcal{I}_2\mathbf{v})\|_0 + \|\psi-\mathcal{I}_0\psi\|_0) \\
&\qquad\qquad + (\|\nabla(\phi-\phi_h)\|_0 + \|\mathbf{u}-\mathbf{u}_h\|_0)(\|\nabla(\psi-\mathcal{I}_0\psi)\|_0 + \|\mathbf{v}-\mathcal{I}_2\mathbf{v}\|_0)),
\end{aligned}$$

where we have successively used $\nabla\psi + \mathbf{v} = 0$, the error orthogonality (3.8), the definition of $Q(\cdot,\cdot;\cdot,\cdot)$, and the Cauchy–Schwarz inequality. Using the interpolation error estimates (2.11)–(2.15) and the regularity assumption (3.11), we have that

$$\left.\begin{aligned}
\|\nabla\cdot(\mathbf{v}-\mathcal{I}_2\mathbf{v})\|_0 \le Ch\|\mathbf{v}\|_2 \le Ch\|\eta\|_1 \\
\|\mathbf{v}-\mathcal{I}_2\mathbf{v}\|_0 \le Ch\|\mathbf{v}\|_2 \le Ch\|\eta\|_1 \\
\|\nabla(\psi-\mathcal{I}_0\psi)\|_0 \le Ch\|\psi\|_2 \le Ch\|\eta\|_1 \\
\|\psi-\mathcal{I}_0\psi\|_0 \le Ch^2\|\psi\|_2 \le Ch^2\|\eta\|_1
\end{aligned}\right\}\qquad \forall\,\eta \in H_0^1(\Omega).$$

Combining the last two sets of results, we easily obtain that, for all $\eta \in H_0^1(\Omega)$,

$$\int_\Omega (\nabla\cdot(\mathbf{u}-\mathbf{u}_h) + \gamma(\phi-\phi_h))\,\eta\, d\Omega \le Ch(\|\phi-\phi_h\|_1 + \|\mathbf{u}-\mathbf{u}_h\|_{H(\Omega,\mathrm{div})})\|\eta\|_1,$$

while the left inequality in (3.7) gives

$$\int_\Omega (\nabla\cdot(\mathbf{u}-\mathbf{u}_h) + \gamma(\phi-\phi_h))\,\eta\, d\Omega \le Ch|||\phi-\phi_h, \mathbf{u}-\mathbf{u}_h|||\ \|\eta\|_1 \quad \forall\,\eta \in H_0^1(\Omega).$$

The lemma follows by taking a supremum over $\eta \in H_0^1(\Omega)$. □

Next, we bound the L^2 error in ϕ_h by the energy norm.

LEMMA 3.4. *Let $(\phi_h, \mathbf{u}_h)$ be a least-squares finite element approximation of $(\phi, \mathbf{u})$. Then,*

$$\|\phi-\phi_h\|_0 \le Ch|||\phi-\phi_h, \mathbf{u}-\mathbf{u}_h|||. \tag{3.13}$$

Proof. Let ψ solve the boundary value problem

$$\begin{cases} -\triangle\psi + \gamma\psi = \phi - \phi_h & \text{in } \Omega, \\ \psi = 0 \text{ on } \Gamma_D \quad \text{and} \quad \partial\psi/\partial n = 0 \text{ on } \Gamma_N. \end{cases} \tag{3.14}$$

The regularity assumption (3.11) implies that

$$\|\psi\|_2 \le C\|\phi-\phi_h\|_0. \tag{3.15}$$

Using the definition of ψ, integration by parts, and the definition of the least-squares form (3.4) yields

$$\begin{aligned}\|\phi-\phi_h\|_0^2 &= \int_\Omega (\phi-\phi_h)(-\triangle\psi+\gamma\psi)\,d\Omega = \int_\Omega (\nabla(\phi-\phi_h)\cdot\nabla\psi+\gamma(\phi-\phi_h)\psi)\,d\Omega\\ &= \int_\Omega (\nabla(\phi-\phi_h)+(\mathbf{u}-\mathbf{u}_h))\cdot\nabla\psi\,d\Omega\\ &\quad -\int_\Omega (\mathbf{u}-\mathbf{u}_h)\cdot\nabla\psi\,d\Omega+\int_\Omega \gamma(\phi-\phi_h)\psi\,d\Omega\\ &= Q(\phi-\phi_h,\mathbf{u}-\mathbf{u}_h;\psi,0)+\int_\Omega (1-\gamma)(\nabla\cdot(\mathbf{u}-\mathbf{u}_h)+\gamma(\phi-\phi_h))\,\psi\,d\Omega.\end{aligned}$$

Using the error orthogonality (3.8), the definition (3.14) for ψ, and the regularity assumption (3.15) yields

$$\begin{aligned}&Q(\phi-\phi_h,\mathbf{u}-\mathbf{u}_h;\psi,0) = Q(\phi-\phi_h,\mathbf{u}-\mathbf{u}_h;\psi-\mathcal{I}_0\psi,0)\\ &\quad\le |||\phi-\phi_h,\mathbf{u}-\mathbf{u}_h|||\,\|\psi-\mathcal{I}_0\psi\|_1 \le Ch|||\phi-\phi_h,\mathbf{u}-\mathbf{u}_h|||\,\|\psi\|_2\\ &\quad\le Ch|||\phi-\phi_h,\mathbf{u}-\mathbf{u}_h|||\,\|\phi-\phi_h\|_0.\end{aligned}$$

In addition, the definition (3.14) for ψ, (3.15), and (3.12) imply that

$$\begin{aligned}&\int_\Omega (1-\gamma)(\nabla\cdot(\mathbf{u}-\mathbf{u}_h)+\gamma(\phi-\phi_h))\,\psi\,d\Omega \le \|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)+\gamma(\phi-\phi_h)\|_{-1}\|\psi\|_1\\ &\quad\le C\|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)+\gamma(\phi-\phi_h)\|_{-1}\|\phi-\phi_h\|_0\\ &\quad\le Ch|||\phi-\phi_h,\mathbf{u}-\mathbf{u}_h|||\,\|\phi-\phi_h\|_0.\end{aligned}$$

The lemma easily follows by combining the last three results. □

COROLLARY 3.5. *Assume that the regularity assumption* (3.11) *is satisfied, and assume that the solution* $(\phi,\mathbf{u})$ *of* (3.3) *satisfies* $(\phi,\mathbf{u})\in H^1_D(\Omega)\cap H^{m+1}(\Omega)\times H_N(\Omega,\mathrm{div}\,)\cap\mathbf{H}^{k+1}(\Omega)$ *for some integers* $k,m\ge 1$. *Let* $(\phi_h,\mathbf{u}_h)\in\mathcal{W}^0_m(\Omega)\times\mathcal{W}^2_k(\Omega)$ *be the solution of the least-squares finite element problem* (3.6). *Then, there exists a constant* $C>0$ *such that*

$$\|\phi-\phi_h\|_0\le C(h^{k+1}\|\mathbf{u}\|_{k+1}+h^{m+1}\|\phi\|_{m+1}). \tag{3.16}$$

Proof. The corollary follows simply by a direct application of (3.7) and (3.9) to (3.13). □

The optimal L^2 error bound (3.16) for the scalar variable does not depend on whether or not the finite element space for the flux satisfies (2.25)–(2.28), i.e., the GDP. Thus, it remains valid even when equal-order C^0 finite element functions are used for the flux approximations, a result first shown in [24]. On the other hand, we will see that the GDP is needed if one wants to improve the L^2 accuracy of the flux.

3.2.2. L^2 error estimate for the flux.

Ultimately, the final L^2 error estimates for approximations to the flux depend on whether $\mathcal{W}^2_k(\Omega)$ represents the RT_{k-1} or the BDM_k family. To this end, we need the following result.

LEMMA 3.6. *Let* $(\phi_h,\mathbf{u}_h)\in\mathcal{W}^0_m(\Omega)\times\mathcal{W}^2_k(\Omega)$ *be the least-squares finite element approximation defined by* (3.6). *Then,*[14]

$$\|\mathbf{u}-\mathbf{u}_h\|_0\le C\big(h|||\phi-\phi_h,\mathbf{u}-\mathbf{u}_h|||+h\|\nabla\cdot(\mathbf{u}-\mathbf{v}_h)\|_0+\|\mathbf{u}-\mathbf{v}_h\|_0\big) \tag{3.17}$$

[14] It is clear from the proof of this lemma that it holds for any flux approximation that satisfies the GDP.

for any $\mathbf{v}_h \in \mathcal{W}_k^2(\Omega)$.

Proof. Let $\mathbf{v}_h$ be an arbitrary element of $\mathcal{W}_k^2(\Omega)$. From Theorem 2.1, we know that there exist $\mathbf{z}_h$ and $\mathbf{w}_h$, also in $\mathcal{W}_k^2(\Omega)$, such that

$$\mathbf{u}_h - \mathbf{v}_h = \mathbf{w}_h + \mathbf{z}_h$$

and the properties (2.26)–(2.28) hold. We recall for later use that

$$\|\nabla \cdot \mathbf{v}\|_{-1} \leq \|\mathbf{v}\|_0 \quad \forall\, \mathbf{v} \in H_N(\Omega, \mathrm{div}). \tag{3.18}$$

We now bound the two GDP components of $\mathbf{u}_h - \mathbf{v}_h$ in L^2. To estimate $\|\mathbf{w}_h\|_0$, we successively use (2.28), (3.18), (3.12), (3.7), and (3.13) to obtain

$$\begin{aligned}
\|\mathbf{w}_h\|_0 &\leq C(\|\nabla \cdot (\mathbf{u}_h - \mathbf{v}_h)\|_{-1} + h\|\nabla \cdot (\mathbf{u}_h - \mathbf{v}_h)\|_0) \\
&\leq C(\|\nabla \cdot (\mathbf{u} - \mathbf{u}_h)\|_{-1} + h\|\nabla \cdot (\mathbf{u} - \mathbf{u}_h)\|_0 \\
&\qquad + \|\nabla \cdot (\mathbf{u} - \mathbf{v}_h)\|_{-1} + h\|\nabla \cdot (\mathbf{u} - \mathbf{v}_h)\|_0) \\
&\leq C(\|\nabla \cdot (\mathbf{u} - \mathbf{u}_h) + \gamma(\phi - \phi_h)\|_{-1} + h\|\nabla \cdot (\mathbf{u} - \mathbf{u}_h)\|_0 \\
&\qquad + \|\gamma(\phi - \phi_h)\|_{-1} + \|\mathbf{u} - \mathbf{v}_h\|_0 + h\|\nabla \cdot (\mathbf{u} - \mathbf{v}_h)\|_0) \\
&\leq C(h|||\phi - \phi_h, \mathbf{u} - \mathbf{u}_h||| + \|\phi - \phi_h\|_0 + ||\mathbf{u} - \mathbf{v}_h\|_0 + h\|\nabla \cdot (\mathbf{u} - \mathbf{v}_h)\|_0) \\
&\leq C(h|||\phi - \phi_h, \mathbf{u} - \mathbf{u}_h||| + ||\mathbf{u} - \mathbf{v}_h\|_0 + h\|\nabla \cdot (\mathbf{u} - \mathbf{v}_h)\|_0).
\end{aligned}$$

To estimate $\|\mathbf{z}_h\|_0$, we use the error orthogonality (3.8) with $\psi_h = 0$ and $\mathbf{v}_h = \mathbf{z}_h$. Since from (2.26) we have that $\nabla \cdot \mathbf{z}_h = 0$, this identity reduces to

$$\int_\Omega (\nabla(\phi - \phi_h) + (\mathbf{u} - \mathbf{u}_h)) \cdot \mathbf{z}_h \, d\Omega = 0,$$

from which integrating by parts and again using $\nabla \cdot \mathbf{z}_h = 0$ yields

$$\int_\Omega (\mathbf{u} - \mathbf{u}_h) \cdot \mathbf{z}_h \, d\Omega = 0.$$

Using this result and the orthogonality of $\mathbf{z}_h$ and $\mathbf{w}_h$ (see (2.27)), we obtain

$$\begin{aligned}
\|\mathbf{z}_h\|_0^2 = \int_\Omega \mathbf{z}_h \cdot \mathbf{z}_h \, d\Omega &= \int_\Omega (\mathbf{z}_h + \mathbf{w}_h) \cdot \mathbf{z}_h \, d\Omega \\
= \int_\Omega (\mathbf{u}_h - \mathbf{v}_h) \cdot \mathbf{z}_h \, d\Omega &= \int_\Omega (\mathbf{u} - \mathbf{v}_h) \cdot \mathbf{z}_h \, d\Omega,
\end{aligned}$$

so that

$$\|\mathbf{z}_h\|_0 \leq \|\mathbf{u} - \mathbf{v}_h\|_0.$$

To complete the proof, we note that

$$\|\mathbf{u} - \mathbf{u}_h\|_0 \leq \|\mathbf{u} - \mathbf{v}_h\|_0 + \|\mathbf{u}_h - \mathbf{v}_h\|_0 \leq \|\mathbf{u} - \mathbf{v}_h\|_0 + \|\mathbf{w}_h\|_0 + \|\mathbf{z}_h\|_0$$

and then use the bounds on $\mathbf{z}_h$ and $\mathbf{w}_h$. ▯

Let us now inspect (3.17). The first term on the right-hand side is exactly the same one as in the L^2 bound (3.13) for the scalar variable. Let us further assume that the approximation orders of the spaces used for the scalar variable and the flux are equilibrated, i.e., $\phi_h \in \mathcal{W}_r^0(\Omega)$ and $\mathbf{u}_h \in \mathcal{W}_r^2(\Omega)$ for some $r \geq 1$. Then,

$$|||\phi - \phi_h, \mathbf{u} - \mathbf{u}_h||| \leq Ch^r(\|\phi\|_{r+1} + \|\mathbf{u}\|_{r+1}).$$

The additional factor h multiplying this term in (3.17) will increase the order of that term to $r+1$, just as in (3.16). However, (3.17) contains the two additional terms $h\|\nabla \cdot (\mathbf{u} - \mathbf{v}_h)\|_0$ and $\|\mathbf{u} - \mathbf{v}_h\|_0$. Recall that $\mathcal{W}_r^2(\Omega)$ represents RT and BDM spaces that are equilibrated with respect to the divergence error. Therefore, after setting $\mathbf{v}_h = \mathcal{I}_2\mathbf{u}$, from (2.15) it follows that

$$\|\nabla \cdot (\mathbf{u} - \mathbf{v}_h)\|_0 \leq Ch^r\|\mathbf{u}\|_{r+1}.$$

After multiplication by h, the order of this term also increases to $r+1$. However, the order of the last term will depend on whether $\mathcal{W}_r^2(\Omega)$ represents a BDM or RT space. Indeed, from (2.16),

$$\|\mathbf{u} - \mathbf{v}_h\|_0 \leq C\begin{cases} h^r\|\mathbf{u}\|_r & \text{if } \mathcal{W}_r^2(\Omega) = \mathrm{RT}_{r-1}, \\ h^{r+1}\|\mathbf{u}\|_{r+1} & \text{if } \mathcal{W}_r^2(\Omega) = \mathrm{BDM}_r. \end{cases}$$

The next corollary summarizes these observations.

Corollary 3.7. *Assume that the regularity assumption* (3.11) *is satisfied, and assume that the solution* $(\phi, \mathbf{u})$ *of* (3.3) *satisfies* $(\phi, \mathbf{u}) \in H_D^1(\Omega) \cap H^{r+1}(\Omega) \times H_N(\Omega, \mathrm{div}\,) \cap \mathbf{H}^{r+1}(\Omega)$ *for some integer* $r \geq 1$. *Let* $(\phi_h, \mathbf{u}_h) \in \mathcal{W}_r^0(\Omega) \times \mathcal{W}_r^2(\Omega)$ *be the solution of the least-squares finite element problem* (3.6). *Then, there exists a constant* $C > 0$ *such that*

$$\|\mathbf{u} - \mathbf{u}_h\|_0 \leq C\begin{cases} h^r(\|\mathbf{u}\|_{r+1} + \|\phi\|_{r+1}) & \textit{if } \mathcal{W}_r^2(\Omega) = \mathrm{RT}_{r-1}, \\ h^{r+1}(\|\mathbf{u}\|_{r+1} + \|\phi\|_{r+1}) & \textit{if } \mathcal{W}_r^2(\Omega) = \mathrm{BDM}_r. \end{cases} \tag{3.19}$$

Consider, for example, the lowest-order case for which $r = 1$, $\mathcal{W}_1^0(\Omega) = P_1$, and $\mathcal{W}_1^2(\Omega)$ is either RT_0 or BDM_1. If the least-squares finite element method is implemented with RT_0 elements, (3.19) specializes to

$$\|\mathbf{u} - \mathbf{u}_h\|_0 \leq h(\|\mathbf{u}\|_2 + \|\phi\|_2).$$

If instead we use BDM_1 elements, we then obtain the improved error bound

$$\|\mathbf{u} - \mathbf{u}_h\|_0 \leq h^2(\|\mathbf{u}\|_2 + \|\phi\|_2).$$

It is worth repeating that the reason for this difference in the L^2 errors is the structure of the RT spaces. Since $\mathrm{RT}_0 = (P_0)^n + \mathbf{x}P_0$, the approximation properties of RT_0 in L^2 are the same as those of P_0. However, it is easy to see that, thanks to the extra term $\mathbf{x}P_0$, $\nabla \cdot (\mathrm{RT}_0) = P_0$; i.e., the divergence of $\mathbf{u}$ is approximated to the same order as the field itself. For numerical examples with least-squares methods that illustrate this feature of RT spaces, we refer to [2].

4. Least-squares finite element methods and duality. We already saw that a least-squares finite element method implemented using equal-order C^0 finite element spaces approximates the scalar variable with the same accuracy as a Galerkin (or, equivalently, a mixed) method for the Dirichlet principle. However, the approximation properties of the Kelvin principle are only partially inherited in the sense that the accuracy in the approximation to the divergence of the flux is recovered, but the accuracy in the flux approximation itself may be of one order less. This should not be too much of a surprise because C^0 elements provide stable discretization only for the Dirichlet principle (with the exception of the criss-cross grid; see [16]). While least-squares minimization is stable enough to allow for the approximation of scalar variables and the flux by equal-order C^0 finite element spaces, it cannot completely recover from the fact that such spaces are unstable for the Kelvin principle.

The key observation from section 3.2 is that a least-squares finite element method can inherit the computational properties of *both the Dirichlet and the Kelvin* principles, provided the scalar variable and the flux are approximated by finite element spaces that are stable with respect to these two principles. Then, as our analysis showed, least-squares finite element solutions recover the accuracy of the Dirichlet principle for the scalar variable and the accuracy of the Kelvin principle for the flux.

In a way, we see that, implemented in this particular manner, the least-squares finite element method represents a balanced mixture of the two principles. Below, we provide an explanation of this observation using the apparatus of differential form calculus, albeit in a simplified form and without an explicit reference to differential forms on manifolds. For consistency, in what follows, $H(\Omega, \mathrm{grad})$, $H(\Omega, \mathbf{curl})$, and $H(\Omega, \mathrm{div})$ denote spaces of square integrable functions whose gradients, curls, and divergences, respectively, are also square integrable.[15]

The De Rham differential complex

$$\mathbb{R} \hookrightarrow H(\Omega, \mathrm{grad}) \overset{\nabla}{\longmapsto} H(\Omega, \mathbf{curl}) \overset{\nabla\times}{\longmapsto} H(\Omega, \mathrm{div}) \overset{\nabla\cdot}{\longmapsto} L^2(\Omega) \longmapsto 0 \tag{4.1}$$

is an exact sequence of spaces in the sense that each operator maps the space on its left to the kernel of the next operator in the sequence, and the last mapping is a surjection. We will now start to use the identifications

$$\mathcal{W}^0(\Omega) = H(\Omega, \mathrm{grad}),\ \mathcal{W}^1(\Omega) = H(\Omega, \mathbf{curl}),\ \mathcal{W}^2(\Omega) = H(\Omega, \mathrm{div}),\ \mathcal{W}^3(\Omega) = L^2(\Omega)$$

to indicate that these function spaces are comprised of *proxies* for differential forms of orders 0, 1, 2, and 3, respectively.[16] Exact sequences of finite element spaces provide piecewise polynomial approximations of the proxies. Commonly used terminologies for the finite element subspaces of $\mathcal{W}^0$, $\mathcal{W}^1$, $\mathcal{W}^2$, and $\mathcal{W}^3$ are nodal, edge, face, and volume (or discontinuous) elements, respectively.

Differential forms have always played a fundamental role in classical mechanics and numerical methods for Hamiltonian systems; see, e.g., [3, 6]. Their place as an abstraction tool for discretization of elliptic boundary value problems was perhaps first recognized in [21], while [8, 9] further affirmed their importance in computational electromagnetism.

Subsequently, the idea that a stable partial differential equation discretization can be developed using a discrete equivalent of the De Rham complex has been exploited by many researchers in finite element, finite volume, and finite difference methods

[15] Here we treat the case of $n = 3$; similar developments can be carried out for the two-dimensional case.

[16] This should explain the seemingly peculiar choice of notation introduced earlier in the paper.

[1, 5, 19, 20, 22, 23, 26]; see [4] for a more extensive bibliography. In particular, for second-order elliptic problems, a key tool for encoding their structure is provided by the *factorization* or *Tonti diagrams*; see [19, 20]. Essentially, these diagrams break the problem into topological relations between different spaces in a De Rham complex connected by metric relations expressed by the Hodge $*$-operator, a linear map $\mathcal{W}^k(\Omega) \mapsto \mathcal{W}^{n-k}(\Omega)$. The factorization diagram for the Poisson problem (see, e.g., [20, 26]) is

$$\begin{tikzcd}
\mathcal{W}^0(\Omega) & \phi \arrow[r, "\nabla"] \arrow[d, leftrightarrow, "\xi = *\phi"'] & -\mathbf{u} \arrow[d, leftrightarrow, "\mathbf{q} = *\mathbf{u}"] & \mathcal{W}^1(\Omega) \\
\mathcal{W}^3(\Omega) & \boxed{\mathrm{f}} - \gamma\xi & \mathbf{q} \arrow[l, "\nabla\cdot"'] & \mathcal{W}^2(\Omega)
\end{tikzcd} \tag{4.2}$$

We will refer to the relation and the variables on the top of the diagram as the *primal* variables and equilibrium equation. The dual variables and their "equilibrium" equation are represented by the bottom part of the diagram. The dual and primal variables serve as proxies for 0, 1 and 2, 3 differential forms, respectively.

The horizontal links in (4.2) correspond to the differential equations

$$\nabla\phi = -\mathbf{u} \quad \text{and} \quad \nabla\cdot\mathbf{q} = -\gamma\xi + f,$$

while the vertical links provide the "constitutive" relations

$$\xi = *\phi \quad \text{and} \quad \mathbf{q} = *\mathbf{u}.$$

The importance of structures such as (4.2) stems from the fact that they encode fundamental relationships between spaces and operators that are required for the stability of discretizations; see, e.g., [1, 4, 9, 20, 22].

Let us now show that the Dirichlet and Kelvin principles are obtained from (4.2) by the approximation of the Hodge operator by an identity operator and subsequent elimination of the dual or the primal variables, respectively.

If the dual variables are substituted by the primal ones according to

$$\xi = \phi \quad \text{and} \quad \mathbf{q} = \mathbf{u},$$

then the dual equation in (4.2) must be modified to account for the fact that $\mathbf{u}$ is a proxy of a 1-form, rather than of a 2-form. As such, $\mathbf{u}$ is in the domain of the curl operator but not in the domain of the divergence operator. Thus, in the dual equilibrium equation, we replace the divergence operator by a weak divergence operator defined through the following variational statement:

$$\widetilde{\nabla}\cdot\, : \mathcal{W}^1(\Omega) \mapsto \mathcal{W}^0(\Omega), \quad \widetilde{\nabla}\cdot\mathbf{u} = \phi,$$

if and only if

$$\int_\Omega \phi\psi\, d\Omega = -\int_\Omega \mathbf{u}\cdot\nabla\psi\, d\Omega \quad \forall\, \psi \in \mathcal{W}^0(\Omega).$$

This changes the original factorization diagram to one in terms of only the primal variables:

$$\begin{tikzcd}
\mathcal{W}^0(\Omega) & \phi \arrow[r, "\nabla"] \arrow[d, "\eta = \phi"'] & -\mathbf{u} \arrow[d, "\mathbf{v} = \mathbf{u}"] & \mathcal{W}^1(\Omega) \\
\mathcal{W}^0(\Omega) & \boxed{\mathrm{f}} - \gamma\phi & \mathbf{u} \arrow[l, "\widetilde{\nabla}\cdot"'] & \mathcal{W}^1(\Omega)
\end{tikzcd} \tag{4.3}$$

The partial differential equation system represented by this diagram is[17]

$$
\begin{aligned}
\nabla\phi + \mathbf{u} = 0 \qquad & \text{in } \mathcal{W}^1(\Omega),\\
-\int_\Omega \mathbf{u}\cdot\nabla\psi - \gamma\phi\psi\, d\Omega = \int_\Omega f\psi\, d\Omega \quad & \forall\,\psi \in \mathcal{W}^0(\Omega).
\end{aligned}
$$

One recognizes (4.3) as the optimality system (2.4) for the Dirichlet principle. The diagram (4.3) can be viewed as a representation of this principle.

If instead the primal variables are eliminated according to

$$\phi = \xi \quad \text{and} \quad \mathbf{u} = \mathbf{q},$$

then the primal equilibrium equation in (4.2) must be modified to account for the fact that ξ is a proxy of a 3-form, rather than for a 0-form. As such, ξ is not in the domain of the gradient operator, which therefore must be replaced by a weak one:

$$\widetilde{\nabla} : \mathcal{W}^3(\Omega), \mapsto \mathcal{W}^2(\Omega), \quad \widetilde{\nabla}\xi = \mathbf{q},$$

if and only if

$$\int_\Omega \mathbf{q}\cdot\mathbf{v}\, d\Omega = -\int_\Omega \xi\nabla\cdot\mathbf{v}\, d\Omega \quad \forall\,\mathbf{v} \in \mathcal{W}^2(\Omega).$$

The factorization diagram in terms of the dual variables is then given by

$$
\begin{tikzcd}
\mathcal{W}^3(\Omega) & & \xi \arrow[r, "\widetilde{\nabla}"] & -\mathbf{q} & & \mathcal{W}^2(\Omega) \\
(4.4) & \phi = \xi & \arrow[u] & \arrow[u] & \mathbf{u} = \mathbf{q} & \\
\mathcal{W}^3(\Omega) & & \boxed{\mathrm{f}} - \gamma\xi & \mathbf{q} \arrow[l, "\nabla\cdot"'] & & \mathcal{W}^2(\Omega)
\end{tikzcd}
$$

The problem represented by this diagram is

$$
\begin{aligned}
\int_\Omega \mathbf{q}\cdot\mathbf{v}\, d\Omega - \int_\Omega \xi\nabla\cdot\mathbf{v}\, d\Omega = 0 \quad & \forall\,\mathbf{v} \in \mathcal{W}^2(\Omega),\\
\nabla\cdot\mathbf{v} + \gamma\xi = f \qquad & \text{in } \mathcal{W}^3(\Omega).
\end{aligned}
$$

Now the second equation is an exact relation, and we see that, by elimination of the primal variables, we recover the optimality system (2.10) for the Kelvin principle.

It is now clear that each of the classical variational principles for the system (1.1) can be derived from (4.2) by elimination of one of the sets of variables (primal or dual) and relaxation of the complementary equilibrium equation. Elimination of variables, on the other hand, can be interpreted as approximation of the Hodge $*$-operator by an identity. This, of course, immediately leads to the following question: what kinds of variational principles can be obtained by using other ways of approximating the Hodge operator? Here, we will focus on one particular method wherein this operator is replaced by an L^2 projection. Not surprisingly, we will see that this approximation leads eventually to a least-squares principle for the first-order formulation of (1.1), but one that is necessarily implemented with spaces for the scalar inherited from the

[17] The first equation can also be stated in variational form; see (2.4). However, we write it in algebraic form to stress the fact that it represents an exact relationship.

Dirichlet principle, and, for the flux, from the Kelvin principle. Thus, in a sense, the least-squares method, when implemented in this manner, is indeed a mixture of the two classical principles that combines their best properties.

The idea is to keep both the primal and dual sets of variables, but to replace the Hodge operator by an optimization problem that penalizes the discrepancy between these sets. Then, the primal and dual equations become linear constraints that must be satisfied by the minimizers of this functional. Therefore, we are led to the following constrained optimization problem: seek $(\phi, \mathbf{u}, \xi, \mathbf{q})$ in $W^0(\Omega) \times \mathcal{W}^1(\Omega) \times \mathcal{W}^2(\Omega) \times \mathcal{W}^3(\Omega)$ such that

$$\mathcal{J}(\phi, \mathbf{u}, \xi, \mathbf{q}) = \frac{1}{2}(\|\xi - \phi\|_0^2 + \|\mathbf{q} - \mathbf{u}\|_0^2) \quad \mapsto \quad \min \tag{4.5}$$

subject to

$$\nabla \phi + \mathbf{u} = 0 \quad \text{and} \quad \nabla \cdot \mathbf{q} + \gamma \xi = f. \tag{4.6}$$

In this problem, the Hodge operator is approximated by the L^2 projections

$$(*_0) : \mathcal{W}^0(\Omega) \mapsto \mathcal{W}^3(\Omega) \quad \text{and} \quad (*_1) : \mathcal{W}^1(\Omega) \mapsto \mathcal{W}^2(\Omega)$$

defined implicitly via the optimization process.

It is possible to solve (4.5)–(4.6) by using Lagrange multipliers to enforce the constraints. However, a better strategy (that also reduces the number of variables) is to note that the constraint equations can be satisfied exactly if the spaces chosen for ϕ_h, $\mathbf{u}_h$, ξ_h, and $\mathbf{q}_h$ are from a discrete exact sequence. It is also important to note that primal and dual variables can be approximated by discrete exact sequences that are not necessarily defined on the same mesh. Thus, assume that for the primal side we have chosen $\mathcal{W}^0_m(\Omega)$ and $\mathcal{W}^1_m(\Omega)$ to approximate ϕ and $\mathbf{u}$, respectively, while for the dual side we work with the spaces $\mathcal{W}^2_k(\Omega)$ and $\mathcal{W}^3_k(\Omega)$ to approximate $\mathbf{q}$ and ξ, respectively. In this manner, each set of variables is represented in the discrete problem by an internal approximation, and we can use the equilibrium equations (rather than the constitutive relations) to eliminate ξ_h and $\mathbf{u}_h$. This leads to the following discrete minimization problem in terms of ϕ_h and $\mathbf{q}_h$ only:

$$\min_{\mathcal{W}^0_m(\Omega) \times \mathcal{W}^2_k(\Omega)} \frac{1}{2}(\|\nabla \cdot \mathbf{q}_h + \gamma \phi_h - f\|_0^2 + \|\mathbf{q}_h + \nabla \phi_h\|_0^2). \tag{4.7}$$

While this problem appears identical to a least-squares formulation derived directly from (2.5), the manner in which it was obtained retains the information about the origins of the different variables. In particular, we see that in (4.7), the scalar variable is inherited from the primal Dirichlet principle, while the flux is inherited from the dual Kelvin principle. As was shown in section 3.2, when this is taken into account in the choice of approximating finite element spaces, the computational properties of both principles are recovered by (4.7). This is perhaps the most important point of our discussion. Another important distinction between (4.7) and a nodal-based implementation of a least-squares principle is that (4.7) leads to a conservative approximation in the following sense. Once ϕ_h and $\mathbf{q}_h$ are found, we can recover the eliminated dual and primal variables so as to obtain four fields ϕ_h, $\mathbf{u}_h$, ξ_h, and $\mathbf{q}_h$ that exactly satisfy the relations

$$\nabla \phi_h + \mathbf{u}_h = 0 \quad \text{and} \quad \nabla \cdot \mathbf{q}_h + \gamma \xi_h = \Pi_3 f.$$

The operator Π_3 that appears above is the L^2 projection into the subspace $\mathcal{W}^3_k$ of $L^2(\Omega)$, while the discrete Hodge operators can be identified with L^2 projections from nodal to discontinuous elements and from edge to face elements, respectively.

5. Conclusions. We have demonstrated that least-squares finite element methods for the first-order Poisson equation can combine the best properties of the classical Dirichlet and Kelvin principles if their implementation uses spaces consistent with the origins of the scalar variable and the flux. In particular, we have shown that a least-squares formulation can be viewed as resulting from a particular choice in the approximation of the Hodge operator. From this point of view, the scalar variable is inherited from the Dirichlet principle and requires approximation by nodal elements. The flux is inherited from the Kelvin principle and must be approximated by $H(\Omega, \text{div})$ conforming families to enable recovery of optimal L^2 rates *without* the addition of curl constraints.

When implemented in this manner, the least-squares finite element method can be deemed superior to both the classical Galerkin and mixed methods because, on the one hand, it provides optimal approximation of all fields with the possibility of recovering an approximation that is conservative in the sense explained earlier, while, on the other hand, it leads to symmetric and positive definite algebraic systems of equations.

Acknowledgment. The authors wish to acknowledge their debt to George Fix, from whom they learned much about mixed and least-squares finite element methods and about science and mathematics in general. Without his guidance and contributions, much of this paper might not have been possible.

RELIABLE AND EFFICIENT APPROXIMATION OF POLYCONVEX ENVELOPES*

SÖREN BARTELS†

Abstract. An iterative algorithm that approximates the polyconvex envelope f^{pc} of a given function $f : \mathbb{R}^{n\times m} \to \mathbb{R}$, i.e., the largest function below f which is convex in all minors, is established. Also presented are a rigorous error analysis with a focus on reliability and optimal orders of convergence, an efficient strategy that reduces the large number of unknowns, as well as numerical experiments.

Key words. nonconvex variational problem, calculus of variations, quasi convexity, relaxed variational problems, microstructure, adaptive algorithm

1. Introduction.

A nonconvex variational problem due to [BJ] modeling phase transitions in crystalline solids and allowing for microstructure reads

$$\text{(M)} \qquad \text{Minimize} \quad I(u) := \int_\Omega f(x, u, \nabla u)\, dx \quad \text{among } u \in \mathcal{A}$$

for a bounded Lipschitz domain $\Omega \subseteq \mathbb{R}^n$, $p \geq 1$, a (nonconvex) continuous energy density $f : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^{n\times m} \to \mathbb{R}$ satisfying p-growth conditions, and a space of admissible deformations $\mathcal{A} \subseteq W^{1,p}(\Omega; \mathbb{R}^m)$ containing boundary conditions. Since I may not be weakly lower semicontinuous, minimizing sequences develop oscillations in the gradient variable, and their weak limits do not in general minimize I (see, e.g., [Da2, M, R2]). Together with a Young measure generated by a minimizing sequence in the sense of [B2], weak limits contain the most relevant information about microscopic and macroscopic effects. Moreover, each weak limit of a minimizing sequence is a solution of a relaxed problem in which f is replaced by its quasi-convex envelope f^{qc} (see, e.g., [Da2, M, R2]). In general, it is not possible to compute f^{qc} explicitly or even approximately in order to define the relaxed problem. Therefore, it is desirable to know upper and lower bounds for f^{qc}, and it is the aim of this paper to establish a reliable and efficient algorithm that computes a lower bound. Numerical schemes for the approximation of upper bounds can be found in [Do, DW, Ba2].

Error estimates for the approximation of (M) are available for the case either that $\mathcal{A}$ contains affine boundary conditions on $\partial\Omega$ defined through certain $F \in \mathbb{R}^{n\times m}$ (see, e.g., [L, CM, BP]) or that f^{qc} is convex (see, e.g., [NW2, CP1, CP2, CR, Ba1]). In the first case theoretical convergence rates for the approximation of (M) and thereby of $f^{qc}(\cdot, \cdot, F)$ are stated, but, owing to mesh-dependent oscillations, those approaches cannot be expected to lead to efficient numerical algorithms. In the second case efficient algorithms are available, but the proposed numerical schemes are restricted

to scalar problems. An algorithm that checks for different notions of convexity for a class of functions can be found in [DH].

By computing a (polyconvex) Young measure solution for (M) with affine boundary conditions, our iterative algorithm approximates the polyconvex envelope [B1, Da1] f^{pc} of f as a lower bound for f^{qc}. A straightforward discretization linearizes nonlinear constraints and results in a large but linear optimization problem. We show that for a large class of functions f the approximation is very accurate. The efficient iterative strategy for the solution of the linear optimization problem is based on results in [R1] that state sharp estimates on the support of a (polyconvex) Young measure solution for (M). Moreover, the strategy employs and generalizes a multilevel scheme of [CR] for the approximation of scalar nonconvex variational problems.

The proposed algorithm can be employed for the simultaneous (polyconvex) relaxation and approximation of nonconvex variational problems. This approach results in discrete problems with two numerical scales that reflect microscopic and macroscopic effects. We refer to [NW1, HH, ML, Kr, Ba1, Do, DW] for related numerical experiments. Moreover, in combination with the algorithms of [Do, DW, Ba2] for the approximation of an upper bound, the results of this paper allow are to numerically check for equality of polyconvex and rank-1 convex envelopes.

The rest of the paper is organized as follows. We present the approximation scheme with an error estimate in section 2. Some preliminaries in section 3 lead to the proof of the main result, which is given in section 4. Section 5 is devoted to a reliable and efficient algorithm that realizes the approximation scheme. Numerical experiments that illustrate the high efficiency and accuracy of the proposed algorithm are reported in section 6. Section 7 discusses the effective numerical solution of (M) based on the approximation of polyconvex envelopes.

2. Approximation scheme and main results. Throughout this article we suppose that f in (M) is independent of x and u; i.e., $f : \mathbb{R}^{n\times m} \to \mathbb{R}$, is continuous, and satisfies, for certain $c_f > 0$, $c_f' \geq 0$, $p > 0$, and all $F \in \mathbb{R}^{n\times m}$,

$$f(F) \geq c_f |F|^p - c_f'. \tag{2.1}$$

The polyconvex envelope f^{pc} of f is for $F \in \mathbb{R}^{n\times m}$ given by (see [B1, Da1])

$$f^{pc}(F) = \inf\left\{ \sum_{\ell=1}^{\tau+1} \varrho_\ell f(A_\ell) : A_\ell \in \mathbb{R}^{n\times m},\ \varrho_\ell \geq 0,\ \sum_{\ell=1}^{\tau+1} \varrho_\ell = 1,\ \sum_{\ell=1}^{\tau+1} \varrho_\ell T(A_\ell) = T(F) \right\}.$$

Here, $T(A) \in \mathbb{R}^\tau$ is a vector containing all minors of the matrix $A \in \mathbb{R}^{n\times m}$ in a fixed order and τ denotes its length; there holds $|T(A)| \leq c_T |A|_\infty^{\min\{n,m\}}$ if $|\cdot|_\infty$ denotes the maximum norm and $|A|_\infty \geq 1$. Choosing a set of points $\mathcal{N}_{d,r} := d\mathbb{Z}^{n\times m} \cap \overline{B_r(0)}$ for $r \geq d > 0$ and $B_r(0) := \{A \in \mathbb{R}^{n\times m} : |A|_\infty < r\}$ such that $F \in \operatorname{conv}\mathcal{N}_{d,r}$, an approximation of $f^{pc}(F)$ reads

$$\begin{aligned} f^{pc}_{d,r}(F) := \inf\Bigg\{ &\sum_{A\in\mathcal{N}_{d,r}} \theta_A f(A) : \forall A \in \mathcal{N}_{d,r},\ \theta_A \geq 0, \\ &\sum_{A\in\mathcal{N}_{d,r}} \theta_A = 1,\ \sum_{A\in\mathcal{N}_{d,r}} \theta_A T(A) = T(F) \Bigg\}. \end{aligned}$$

The latter infimum defines a finite-dimensional *linear* optimization problem and admits a solution and a Lagrange multiplier $\lambda^F_{d,r} \in \mathbb{R}^\tau$ associated with the constraint

$\sum_{A\in\mathcal{N}_{d,r}}\theta_A T(A)=T(F)$. Our main results concerning the approximation of polyconvex envelopes are summarized in Theorem A. We refer to section 4 for more general assertions and to [BKK] for conditions that ensure $f^{pc}\in C^{1,\alpha}_{loc}(\mathbb{R}^{n\times m})$ together with explicit bounds on $|f^{pc}|_{C^{1,\alpha}(B_d(F))}$.

THEOREM A. *Suppose that $F\in\operatorname{conv}\mathcal{N}_{d,r}$, $p\ge\min\{n,m\}=:n\wedge m$, $r\ge 1$, the computable a posteriori condition*

$$c_T(n\wedge m)|\lambda^F_{d,r}|\le pc_f r^{p-n\wedge m}\quad\text{and}\quad c_T|\lambda^F_{d,r}|r^{n\wedge m}-c_f r^p+c_f'\le\lambda^F_{d,r}\cdot T(F)-f^{pc}_{d,r}(F)$$

is satisfied, and $f\in C^{1,\alpha}_{loc}(\mathbb{R}^{n\times m})$ for some $\alpha\in[0,1]$. Then $f^{pc}_{d,r}(F)=\tilde f^{pc}_d(F)$ for a polyconvex function $\tilde f^{pc}_d:\mathbb{R}^{n\times m}\to\mathbb{R}$, $f^{pc}_{d,r}(F)=f^{pc}_{d,s}(F)$ for all $s\ge r$, and there exists $r'\ge r$ such that

$$|f^{pc}_{d,r}(F)-f^{pc}(F)|\le c_1\,d^{1+\alpha}|f|_{C^{1,\alpha}(B_{r'}(0))}.$$

If, additionally, $\alpha>0$ and $f^{pc}\in C^{1,\alpha}_{loc}(\mathbb{R}^{n\times m})$, then

$$|\lambda^F_{d,r}\cdot DT(F)-Df^{pc}(F)|\le c_2\,d^{\alpha}\big(|f|_{C^{1,\alpha}(B_{r'}(0))}+|f^{pc}|_{C^{1,\alpha}(B_d(F))}\big).$$

The constants $c_1,c_2>0$ depend only on n and m.

It can be shown that $\lambda^F_{d,r}$ and $f^{pc}_{d,r}(F)$ remain bounded for $r\to\infty$, so that the a posteriori condition of the theorem is satisfied if $p>n\wedge m$ and if r is large enough. The direct computation of $f^{pc}_{d,r}(F)$ requires the solution of a linear optimization problem with $(r/d)^{nm}$ unknowns and would therefore be very expensive. The combination of an active set strategy (due to [CR] for $\min\{n,m\}=1$) with local grid refinement and coarsening to avoid checking a maximum principle in all nodes of $\mathcal{N}_{d,r}$ leads to a very efficient but still reliable iterative algorithm that computes $f^{pc}_{d,r}(F)$.

3. Preliminaries. Throughout this article, $|\cdot|$ denotes the Frobenius norm of a vector or a matrix in $\mathbb{R}^n$, $\mathbb{R}^m$, $\mathbb{R}^\tau$, or $\mathbb{R}^{n\times m}$; e.g., for $A\in\mathbb{R}^{n\times m}$ with entries $(A)_{j,k}\in\mathbb{R}$ for $j=1,\dots,n$ and $k=1,\dots,m$

$$|A|^2=\sum_{j=1}^n\sum_{k=1}^m(A)^2_{j,k}.$$

The maximum norm of a vector or a matrix is denoted by $|\cdot|_\infty$, e.g., $|A|_\infty=\max_{j,k}|(A)_{j,k}|$; there holds $|v|_\infty\le|v|\le\sqrt{\ell}|v|_\infty$ for all $v\in\mathbb{R}^\ell$.

Given $r>0$ and $G\in\mathbb{R}^\ell$, we set $B_r(G):=\{A\in\mathbb{R}^\ell:|A-G|_\infty<r\}$ and, for a positive parameter $d>0$ with $d\le r$, define (cf. the left plot in Figure 1)

$$\mathcal{N}_{d,r}:=d\mathbb{Z}^{n\times m}\cap\overline{B_r(0)}\subseteq\mathbb{R}^{n\times m};$$

$\mathbb{Z}$ denotes the set of all integers. We let $\omega_{d,r}$ be the interior of the union of all closed (nm)-dimensional cubes $Q\subseteq\overline{B_r(0)}$ with vertices in $\mathcal{N}_{d,r}$, and define a uniform triangulation $\mathcal{T}_{d,r}$ of $\omega_{d,r}$ by setting (cf. the left plot in Figure 1)

$$\mathcal{T}_{d,r}:=\big\{Q\subseteq\overline{\omega}_{d,r}:Q\text{ is a closed cube with vertices in }\mathcal{N}_{d,r}\text{ and edges of length }d\big\}.$$

Note that each $Q\in\mathcal{T}_{d,r}$ is the convex hull of 2^{nm} nodes $M_1,\dots,M_{2^{nm}}\in\mathcal{N}_{d,r}$; i.e., $Q=\operatorname{conv}\{M_1,\dots,M_{2^{nm}}\}$. To $\mathcal{T}_{d,r}$ we associate the set of continuous $\mathcal{T}_{d,r}$-elementwise (nm)-linear functions

$$\mathcal{S}^1(\mathcal{T}_{d,r}):=\big\{v_h\in C(\overline{\omega}_{d,r}):\forall Q\in\mathcal{T}_{d,r},\ v_h|_Q\text{ is a polynomial of partial degree}\le 1\big\}.$$

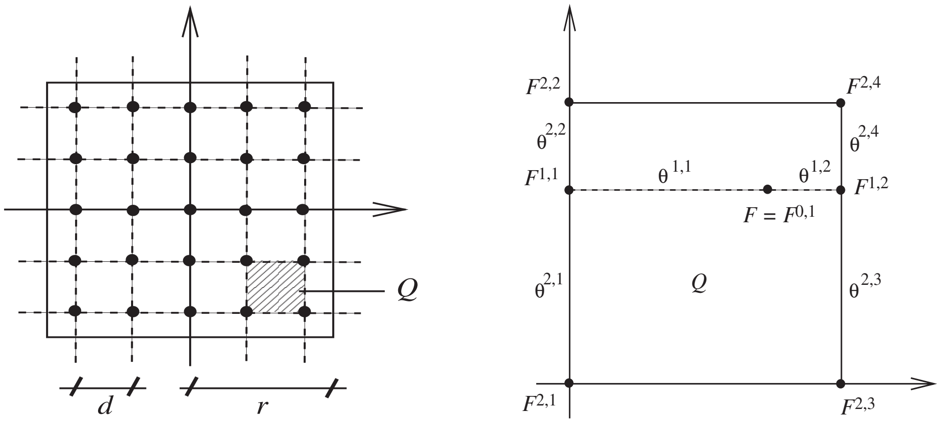

FIG. 1. *Left: set of nodes $\mathcal{N}_{d,r}$ (filled circles) and $Q \in \mathcal{T}_{d,r}$ (shaded small box). Right: decomposition of the matrix F in the proof of Lemma* 3.1 *for $n = 2$ and $m = 1$.*

The nodal interpolation operator $\mathcal{I}_{d,r}$ on $\mathcal{T}_{d,r}$ is for $v \in C(\overline{\omega}_{d,r})$ defined by

$$\mathcal{I}_{d,r} v := \sum_{A \in \mathcal{N}_{d,r}} v(A) \varphi_A.$$

Here, for each $A \in \mathcal{N}_{d,r}$ the function $\varphi_A \in \mathcal{S}^1(\mathcal{T}_{d,r})$ satisfies $\varphi_A(A) = 1$ and $\varphi_A(B) = 0$ for all $B \in \mathcal{N}_{d,r} \setminus \{A\}$. There exists $c_{\mathcal{I}} > 0$ such that

$$\|\mathcal{I}_{d,r} g - g\|_{L^\infty(\omega_{d,r})} \le c_{\mathcal{I}} d^{1+\alpha} |g|_{C^{1,\alpha}(B_r(0))} \tag{3.1}$$

for $\alpha \in (0, 1]$ and $g \in C^{1,\alpha}_{loc}(\mathbb{R}^{n\times m})$ or for $\alpha = 0$ and a locally Lipschitz continuous function $g : \mathbb{R}^{n\times m} \to \mathbb{R}$; $|g|_{C^{1,\alpha}(B_r(0))}$ denotes the α-Hölder constant of Dg on $B_r(0)$ if $\alpha > 0$, i.e.,

$$|g|_{C^{1,\alpha}(B_r(0))} := \sup_{G,H \in B_r(0)} \frac{|Dg(G) - Dg(H)|}{|G - H|^\alpha},$$

and the Lipschitz constant $|g|_{C^{1,0}(B_r(0))} := |g|_{Lip,r} = |g|_{Lip(B_r(0))}$ of g on $B_r(0)$ if $\alpha = 0$.

The operator $T : \mathbb{R}^{n\times m} \to \mathbb{R}^\tau$ for $A \in \mathbb{R}^{n\times m}$ is defined by

$$\begin{aligned} T(A) = \big((A)_{1,1}, \dots, (A)_{1,m}, (A)_{2,1}, \dots, (A)_{2,m}, \dots,& \\ (A)_{n,1}, \dots, (A)_{n,m}, \operatorname{adj}_2 A, \dots, \operatorname{adj}_{n\wedge m} A\big),& \end{aligned}$$

where for $2 \le \ell \le n \wedge m = \min\{n, m\}$, $\operatorname{adj}_\ell A$ is a vector containing all $\ell \times \ell$ minors of A and

$$\tau := \tau(n, m) = \sum_{\ell=1}^{n\wedge m} \sigma(\ell) \quad \text{for} \quad \sigma(\ell) = \frac{m!\, n!}{(\ell!)^2 (m-\ell)!(n-\ell)!}.$$

There exists $c_T > 0$ (which depends on n and m) such that $|T(A)| \le c_T |A|_\infty^{n\wedge m}$ for all $A \in \mathbb{R}^{n\times m}$ with $|A|_\infty \ge 1$; for $n = m = 2$ we have $\operatorname{adj}_2 A = \det A$ and we can choose $c_T = 2\sqrt{2}$.

The following observation is of central importance in our analysis. It shows that the values of the nodal basis functions in $\mathcal{S}^1(\mathcal{T}_{d,r})$ define a rank-1 decomposition of a matrix $F \in \overline{\omega}_{d,r}$.

LEMMA 3.1. *Let $Q \in \mathcal{T}_{d,r}$ and $M_1, \dots, M_{2^{nm}} \in \mathcal{N}_{d,r}$ be such that $Q = \operatorname{conv}\{M_1, \dots, M_{2^{nm}}\}$. Let $F \in Q$ and define $\theta_\iota := \varphi_{M_\iota}(F) \geq 0$, $\iota = 1, \dots, 2^{nm}$. There holds*

$$\sum_{\iota=1}^{2^{nm}} \theta_\iota = 1 \quad \textit{and} \quad \sum_{\iota=1}^{2^{nm}} \theta_\iota T(M_\iota) = T(F). \tag{3.2}$$

Proof. We construct convex coefficients that satisfy (3.2) and then show that they equal $\varphi_{M_\iota}(F)$. Suppose first that $d = 1$ and $Q = [0,1]^{n\times m}$ is the unit cube in $\mathbb{R}^{n\times m}$ so that $\{M_1, \dots, M_{2^{nm}}\} = \{0,1\}^{n\times m}$ are the vertices of Q. Set $F^{0,1} := F$ and $\varrho^{0,1} := 1$. Then, for $j = 1, \dots, n$ and $k = 1, \dots, m$ set $\ell := (j-1)m + k$ and define $F^{\ell,2\iota-1}, F^{\ell,2\iota} \in \mathbb{R}^{n\times m}$, $\iota = 1, \dots, 2^{\ell-1}$, by setting, for $j' = 1, \dots, n$ and $k' = 1, \dots, m$,

$$\begin{aligned} \big(F^{\ell,2\iota-1}\big)_{j',k'} &:= \begin{cases} \big(F^{\ell-1,\iota}\big)_{j',k'} & \text{for } (j',k') \neq (j,k), \\ 0 & \text{for } (j',k') = (j,k), \end{cases} \\ \big(F^{\ell,2\iota}\big)_{j',k'} &:= \begin{cases} \big(F^{\ell-1,\iota}\big)_{j',k'} & \text{for } (j',k') \neq (j,k), \\ 1 & \text{for } (j',k') = (j,k). \end{cases} \end{aligned}$$

Moreover, set $\theta^{\ell,2\iota-1} := 1 - (F^{\ell-1,\iota})_{j,k}$ and $\theta^{\ell,2\iota} := (F^{\ell-1,\iota})_{j,k}$ and

$$\varrho^{\ell,2\iota-1} := \varrho^{\ell-1,\iota}\big(1 - \big(F^{\ell-1,\iota}\big)_{j,k}\big), \qquad \varrho^{\ell,2\iota} := \varrho^{\ell-1,\iota}\big(F^{\ell-1,\iota}\big)_{j,k}. \tag{3.3}$$

(The right plot in Figure 1 schematically displays the decomposition for $n = 2$ and $m = 1$.) The decomposition of F has the following properties:

(i) $\big\{F^{nm,\iota} : \iota = 1, \dots, 2^{nm}\big\} = \{0,1\}^{n\times m}$;

(ii) $\theta^{\ell,2\iota-1}, \theta^{\ell,2\iota} \geq 0$, $\theta^{\ell,2\iota-1} + \theta^{\ell,2\iota} = 1$, and $F^{\ell-1,\iota} = \theta^{\ell,2\iota-1}F^{\ell,2\iota-1} + \theta^{\ell,2\iota}F^{\ell,2\iota}$ for $\ell = 1, \dots, nm$ and $\iota = 1, \dots, 2^{\ell-1}$;

(iii) $\operatorname{rank}(F^{\ell,2\iota-1} - F^{\ell,2\iota}) = 1$ for $\ell = 1, \dots, nm$ and $\iota = 1, \dots, 2^{\ell-1}$;

(iv) $\varphi_{F^{nm,\iota}}(F) = \varrho^{nm,\iota}$ for $\iota = 1, \dots, 2^{nm}$.

The proofs of (i)–(iii) follow directly from the decomposition. To verify (iv) we note that, according to (3.3), each $\varrho^{nm,\iota}$, $\iota = 1, \dots, 2^{nm}$, defines a polynomial in F of partial degree ≤ 1. Moreover, if $F \in \{0,1\}^{n\times m}$, then $F = F^{nm,\iota}$ for some $\iota \in \{1, \dots, 2^{nm}\}$, and by construction we then have $\varrho^{nm,\iota} = 1$ and $\varrho^{nm,\iota'} = 0$ for $\iota' \in \{1, \dots, 2^{nm}\} \setminus \{\iota\}$. This proves (iv).

Set $\theta_\iota := \varrho^{nm,\iota}$ for $\iota = 1, \dots, 2^{nm}$. The assertion of the lemma (for $Q = \operatorname{conv}\{0,1\}^{n\times m}$) follows from an induction over $\ell = 1, \dots, 2^{nm}$ with (i)–(iv) and the fact that T is affine along rank-1 connections. The case $Q \neq [0,1]^{n\times m}$ follows with a dilation and a translation from the special case. ∎

4. Proof of Theorem A. This section is devoted to the proof of Theorem A, which follows from several propositions that state more general results. The first proposition is a partial version of Theorem A but does not state sufficient conditions for an efficient choice of r. Throughout this section we consider a fixed $F \in \mathbb{R}^{n\times m}$ and assume that either $\alpha = 0$ and f is locally Lipschitz continuous or $\alpha \in (0,1]$ and $f \in C^{1,\alpha}_{loc}(\mathbb{R}^{n\times m})$.

PROPOSITION 4.1. *There exists $r' = r'(F) > 0$ such that*

$$|f^{pc}(F) - f^{pc}_{d,r'}(F)| \leq 2c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))}.$$

Proof. Let $t>0$ be such that $|f|_{C^{1,\alpha}(B_t(0))}>0$. By definition of $f^{pc}(F)$ there exist $\varrho_\ell \geq 0$ and $A_\ell \in \mathbb{R}^{n\times m}$, $\ell=1,\dots,\tau+1$, such that $\sum_{\ell=1}^{\tau+1}\varrho_\ell=1$, $\sum_{\ell=1}^{\tau+1}\varrho_\ell T(A_\ell)=T(F)$, and

$$f^{pc}(F)\leq \sum_{\ell=1}^{\tau+1}\varrho_\ell f(A_\ell)\leq f^{pc}(F)+c_{\mathcal{I}}d^{1+\alpha}|f|_{C^{1,\alpha}(B_t(0))}. \tag{4.1}$$

Choose $r'\geq t$ such that $A_1,\dots,A_{\tau+1}\in\omega_{d,r'}$. For each $\ell=1,\dots,\tau+1$, Lemma 3.1 guarantees the existence of $M_\iota^{(\ell)}\in\mathcal{N}_{d,r'}$ and $\theta_{M_\iota^{(\ell)}}=\varphi_{M_\iota^{(\ell)}}(A_\ell)\geq 0$, $\iota=1,\dots,2^{nm}$, such that $\sum_{\iota=1}^{2^{nm}}\theta_{M_\iota^{(\ell)}}=1$, $\sum_{\iota=1}^{2^{nm}}\theta_{M_\iota^{(\ell)}}T(M_\iota^{(\ell)})=T(A_\ell)$, and $A_\ell\in Q_\ell=\operatorname{conv}\{M_1^{(\ell)},\dots,M_{2^{nm}}^{(\ell)}\}\in\mathcal{T}_{d,r'}$. For $A\in\mathcal{N}_{d,r'}$ and $B\in\mathbb{R}^{n\times m}$ let $\chi_A(B)=1$ if $A=B$ and $\chi_A(B)=0$ otherwise. Setting for each $A\in\mathcal{N}_{d,r'}$

$$\tilde\theta_A=\sum_{\ell=1}^{\tau+1}\sum_{\iota=1}^{2^{nm}}\varrho_\ell\,\theta_{M_\iota^{(\ell)}}\chi_A(M_\iota^{(\ell)}) \tag{4.2}$$

defines a feasible $(\tilde\theta_A : A\in\mathcal{N}_{d,r'})$ to compute $f^{pc}_{d,r'}(F)$ so that

$$f^{pc}(F)\leq f^{pc}_{d,r'}(F)=\sum_{A\in\mathcal{N}_{d,r'}}\theta_A f(A)\leq\sum_{A\in\mathcal{N}_{d,r'}}\tilde\theta_A f(A), \tag{4.3}$$

where $(\theta_A : A\in\mathcal{N}_{d,r'})$ is optimal in $f^{pc}_{d,r'}(F)$. Since $|f|_{C^{1,\alpha}(B_t(0))}\leq|f|_{C^{1,\alpha}(B_{r'}(0))}$ and $\theta_{M_\iota^{(\ell)}}=\varphi_{M_\iota^{(\ell)}}(A_\ell)$, estimates (3.1) and (4.1)–(4.3) imply

$$\begin{aligned}0&\leq f^{pc}_{d,r'}(F)-f^{pc}(F)\\&\leq\sum_{A\in\mathcal{N}_{d,r'}}\tilde\theta_A f(A)-\sum_{\ell=1}^{\tau+1}\varrho_\ell f(A_\ell)+c_{\mathcal{I}}d^{1+\alpha}|f|_{C^{1,\alpha}(B_{r'}(0))}\\&=\sum_{\ell=1}^{\tau+1}\varrho_\ell\left(\sum_{\iota=1}^{2^{nm}}\theta_{M_\iota^{(\ell)}}f(M_\iota^{(\ell)})-f(A_\ell)\right)+c_{\mathcal{I}}d^{1+\alpha}|f|_{C^{1,\alpha}(B_{r'}(0))}\\&=\sum_{\ell=1}^{\tau+1}\varrho_\ell\big(\mathcal{I}_{d,r'}f(A_\ell)-f(A_\ell)\big)+c_{\mathcal{I}}d^{1+\alpha}|f|_{C^{1,\alpha}(B_{r'}(0))}\\&\leq 2c_{\mathcal{I}}d^{1+\alpha}|f|_{C^{1,\alpha}(B_{r'}(0))},\end{aligned} \tag{4.4}$$

which proves the proposition. □

Remark 4.1. The assumption $f\in C^{1,\alpha}_{loc}(\mathbb{R}^{n\times m})$ can be replaced by $f\in C^{1,\alpha}_{loc}(U_d)$, where $U_d=\{G\in\mathbb{R}^{n\times m}:\inf_{H\in U}|G-H|_\infty<d\}$ for $U=\{H\in\mathbb{R}^{n\times m}:f^{pc}(H)=f(H)\}$.

The subsequent lemma states the Kuhn–Tucker optimality conditions for the linear optimization problem that defines $f^{pc}_{d,r}(F)$ and which we will refer to through $f^{pc}_{d,r}(F)$. In particular, the lemma characterizes the Lagrange multiplier $\lambda^F_{d,r}$ mentioned in section 2. The equations have first been employed in the context of relaxation in the calculus of variations in [R1, R2] and have further been exploited in the numerical approximation of scalar nonconvex variational problems in [CR, Ba1].

LEMMA 4.1. *There exists* $\lambda^F_{d,r}\in\mathbb{R}^\tau$ *such that*

$$\max_{A\in\mathcal{N}_{d,r}}\big(\lambda^F_{d,r}\cdot T(A)-f(A)\big)\leq\lambda^F_{d,r}\cdot T(F)-f^{pc}_{d,r}(F). \tag{4.5}$$

Conversely, any $(\theta_A : A \in \mathcal{N}_{d,r})$ *that is feasible in* $f^{pc}_{d,r}(F)$ *is optimal if there exists* $\lambda^F_{d,r} \in \mathbb{R}^\tau$ *such that* (4.5) *holds with* $f^{pc}_{d,r}(F)$ *replaced by* $\sum_{A\in\mathcal{N}_{d,r}} \theta_A f(A)$. □

Employing the optimality conditions of Lemma 4.1, we can state sufficient conditions that ensure that $r \le r'$ is large enough so that $f^{pc}_{d,r}(F) = f^{pc}_{d,r'}(F)$, where r' is as in Proposition 4.1. If $p > n \wedge m$, condition (4.6) below can be employed as an a posteriori criterion to iteratively enlarge r.

PROPOSITION 4.2. *Let* $\lambda^F_{d,r} \in \mathbb{R}^\tau$ *be as in Lemma* 4.1, *suppose* $p \ge n \wedge m$, $r \ge 1$, *and*

$$\begin{aligned} c_T(n\wedge m)|\lambda^F_{d,r}| &\le p c_f r^{p-n\wedge m} \quad \textit{and} \\ c_T|\lambda^F_{d,r}| r^{n\wedge m} - c_f r^p + c'_f &\le \lambda^F_{d,r}\cdot T(F) - f^{pc}_{d,r}(F). \end{aligned} \tag{4.6}$$

Then, there holds

$$\max_{A\in d\mathbb{Z}^{n\times m}} \big(\lambda^F_{d,r}\cdot T(A) - f(A)\big) \le \lambda^F_{d,r}\cdot T(F) - f^{pc}_{d,r}(F) \tag{4.7}$$

and $f^{pc}_{d,r'}(F) = f^{pc}_{d,r}(F)$ *for all* $r' \ge r$.

Proof. Since $c_T(n\wedge m)|\lambda^F_{d,r}| \le p c_f r^{p-n\wedge m}$ and $p \ge n\wedge m$, the mapping

$$\{t \in \mathbb{R} : t \ge r\} \to \mathbb{R}, \quad t \mapsto c_f t^p - c'_f - c_T|\lambda^F_{d,r}| t^{n\wedge m}$$

is monotonically increasing. Since $|T(G)| \le c_T |G|^{n\wedge m}_\infty$ for all $G \in \mathbb{R}^{n\times m}$ with $|G|_\infty \ge 1$, we have, for all $A \in d\mathbb{Z}^{n\times m} \setminus \mathcal{N}_{d,r}$, i.e., for all $A \in d\mathbb{Z}^{n\times m}$ with $|A|_\infty > r \ge 1$,

$$\lambda^F_{d,r}\cdot T(A) - f(A) \le c_T|\lambda^F_{d,r}||A|^{n\wedge m}_\infty - c_f|A|^p_\infty + c'_f \le c_T|\lambda^F_{d,r}| r^{n\wedge m} - c_f r^p + c'_f.$$

Then, the second inequality in (4.6) implies, for all $A \in d\mathbb{Z}^{n\times m} \setminus \mathcal{N}_{d,r}$,

$$f(A) \ge \lambda^F_{d,r}\cdot T(A) - \lambda^F_{d,r}\cdot T(F) + f^{pc}_{d,r}(F),$$

while the optimality conditions (4.5) guarantee, for all $A \in \mathcal{N}_{d,r}$,

$$f(A) \ge \lambda^F_{d,r}\cdot T(A) - \lambda^F_{d,r}\cdot T(F) + f^{pc}_{d,r}(F).$$

The last two estimates prove (4.7). Let $r' \ge r$, and let $(\tilde\theta_A : A \in \mathcal{N}_{d,r'})$ be a solution to $f^{pc}_{d,r'}(F)$. Employing (4.7) and $\sum_{A\in\mathcal{N}_{d,r'}} \tilde\theta_A T(A) = T(F)$, we infer

$$f^{pc}_{d,r'}(F) = \sum_{A\in\mathcal{N}_{d,r'}} \tilde\theta_A f(A) \ge \sum_{A\in\mathcal{N}_{d,r'}} \tilde\theta_A\big(\lambda^F_{d,r}\cdot T(A) - \lambda^F_{d,r}T(F) + f^{pc}_{d,r}(F)\big) = f^{pc}_{d,r}(F).$$

The obvious estimate $f^{pc}_{d,r'}(F) \le f^{pc}_{d,r}(F)$ concludes the proof. □

We now turn to estimates for $\lambda^F_{d,r}$, for which we need to construct a polyconvex extension of $f^{pc}_{d,r}(F)$ to $\mathbb{R}^{n\times m}$. Note that the subsequent definition of this extension does not depend on F; i.e., it depends only on d.

DEFINITION 4.1. *Let* $\tilde f_d$ *be the nodal interpolant of* f *on* $\mathbb{R}^{n\times m}$ *with respect to nodes in* $d\mathbb{Z}^{n\times m}$; *i.e.,* $\tilde f_d(A) = f(A)$ *for all* $A \in d\mathbb{Z}^{n\times m}$, $\tilde f_d$ *is continuous, and* $\tilde f_d|_{\tilde Q}$ *is* (nm)*-linear for each cube* $\tilde Q \subseteq \mathbb{R}^{n\times m}$ *with vertices in* $d\mathbb{Z}^{n\times m}$ *and edges of length* d. *Then let* $\tilde f^{pc}_d$ *be the polyconvex envelope of* $\tilde f_d$; *i.e., for* $A \in \mathbb{R}^{n\times m}$,

$$\tilde f^{pc}_d(A) = \inf\left\{\sum_{\ell=1}^{\tau+1} \varrho_\ell \tilde f_d(A_\ell) : A_\ell \in \mathbb{R}^{n\times m},\ \varrho_\ell \ge 0,\ \sum_{\ell=1}^{\tau+1}\varrho_\ell = 1,\ \sum_{\ell=1}^{\tau+1}\varrho_\ell T(A_\ell) = T(A)\right\}.$$

The following lemma shows that $\tilde{f}_d^{pc}$ can be approximated arbitrarily well by convex combinations of nodal values of f.

LEMMA 4.2. *For all $\varepsilon > 0$ and all $A \in \mathbb{R}^{n\times m}$ there exist $B_\kappa \in d\mathbb{Z}^{n\times m}$, $\gamma_\kappa \geq 0$, $\kappa = 1, \dots, 2^{nm}(\tau+1)$, such that $\sum_{\kappa=1}^{2^{nm}(\tau+1)} \gamma_\kappa = 1$, $\sum_{\kappa=1}^{2^{nm}(\tau+1)} \gamma_\kappa T(B_\kappa) = T(A)$, and*

$$\tilde{f}_d^{pc}(A) \leq \sum_{\kappa=1}^{2^{nm}(\tau+1)} \gamma_\kappa f(B_\kappa) \leq \tilde{f}_d^{pc}(A) + \varepsilon. \tag{4.8}$$

Remark 4.2. Employing optimality conditions for the minimization problem $\tilde{f}_d^{pc}(A)$ in Definition 4.1, one can show that the infimum is attained if $p > n \wedge m$. In this case one may choose $\varepsilon = 0$ in Lemma 4.2.

Proof of Lemma 4.2. By definition of $\tilde{f}_d^{pc}(A)$ there exist $A_\ell \in \mathbb{R}^{n\times m}$ and $\varrho_\ell \geq 0$, $\ell = 1, \dots, \tau+1$, such that $\sum_{\ell=1}^{\tau+1} \varrho_\ell = 1$, $\sum_{\ell=1}^{\tau+1} \varrho_\ell T(A_\ell) = T(A)$, and

$$\sum_{\ell=1}^{\tau+1} \varrho_\ell \tilde{f}_d(A_\ell) \leq \tilde{f}_d^{pc}(A) + \varepsilon.$$

For each $\ell = 1, \dots, \tau+1$ let $\tilde{Q}_\ell = \operatorname{conv}\{M_1^{(\ell)}, \dots, M_{2^{nm}}^{(\ell)}\}$ be a cube in $\mathbb{R}^{n\times m}$ with vertices $M_1^{(\ell)}, \dots, M_{2^{nm}}^{(\ell)} \in d\mathbb{Z}^{n\times m}$, edges of length d, and such that $A_\ell \in \tilde{Q}_\ell$. By Lemma 3.1 (with $r = \tilde{r}$ for some $\tilde{r}$ large enough so that $A_\ell \in \tilde{Q}_\ell \subseteq \omega_{d,\tilde{r}}$), there exist $\theta_{M_\iota^{(\ell)}} \geq 0$, $\iota = 1, \dots, 2^{nm}$, such that $\sum_{\iota=1}^{2^{nm}} \theta_{M_\iota^{(\ell)}} = 1$, $\sum_{\iota=1}^{2^{nm}} \theta_{M_\iota^{(\ell)}} T(M_\iota^{(\ell)}) = T(A_\ell)$, and

$$\tilde{f}_d(A_\ell) = \sum_{\iota=1}^{2^{nm}} \varphi_{M_\iota^{(\ell)}}(A_\ell) f(M_\iota^{(\ell)}) = \sum_{\iota=1}^{2^{nm}} \theta_{M_\iota^{(\ell)}} f(M_\iota^{(\ell)}).$$

This implies

$$\sum_{\ell=1}^{\tau+1} \sum_{\iota=1}^{2^{nm}} \varrho_\ell \theta_{M_\iota^{(\ell)}} f(M_\iota^{(\ell)}) \leq \tilde{f}_d^{pc}(A) + \varepsilon,$$

which, after appropriate relabeling, is (4.8). □

The following assertion is due to Ball [B1].

LEMMA 4.3. *There exist convex functions $\hat{f}, \hat{f}_d : \mathbb{R}^\tau \to \mathbb{R}$ such that*

$$f^{pc} = \hat{f} \circ T \qquad \text{and} \qquad \tilde{f}_d^{pc} = \hat{f}_d \circ T.$$

For $g = f$ or $g = \tilde{f}_d$ the function $\hat{g} = \hat{f}$ or $\hat{g} = \hat{f}_d$, respectively, can be defined by

$$\hat{g}(X) = \inf\left\{ \sum_{\ell=1}^{\tau+1} \varrho_\ell g(A_\ell) : A_\ell \in \mathbb{R}^{n\times m},\ \varrho_\ell \geq 0,\ \sum_{\ell=1}^{\tau+1} \varrho_\ell = 1,\ \sum_{\ell=1}^{\tau+1} \varrho_\ell T(A_\ell) = X \right\}. \qquad \square$$

Remark 4.3. The function $\hat{g}$ is not unique, and the presented formula can be found in [Da2].

An estimate for the difference between $\hat{f}$ and $\hat{f}_d$ follows immediately.

LEMMA 4.4. (i) *Let $B^\tau = \{E_1, \dots, E_\tau\}$ be the canonical basis in $\mathbb{R}^\tau$. There exists $r' > 0$ such that, for all $E \in \pm B^\tau$, there holds*

$$|\hat{f}_d(T(F) + dE) - \hat{f}(T(F) + dE)| \leq 2c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))}.$$

(ii) *Let $B^{n\times m} = \{E_1, \dots, E_{nm}\}$ be the canonical basis in $\mathbb{R}^{n\times m}$. There exists $r' > 0$ such that, for all $E \in \pm B^{n\times m}$, there holds*

$$|\hat{f}_d(T(F+dE)) - f^{pc}(F+dE)| \le 2c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))}.$$

Proof. (i) Let $E \in \pm B^\tau$, and let $t > 0$ be such that $|f|_{C^{1,\alpha}(B_t(0))} > 0$. By definition of $\hat{f}$ and $\hat{f}_d$ there exist A_ℓ, $A_\ell^{(d)} \in \mathbb{R}^{n\times m}$ and ϱ_ℓ, $\varrho_\ell^{(d)} \ge 0$, $\ell = 1, \dots, \tau+1$, such that $\sum_{\ell=1}^{\tau+1} \varrho_\ell = \sum_{\ell=1}^{\tau+1} \varrho_\ell^{(d)} = 1$, $\sum_{\ell=1}^{\tau+1} \varrho_\ell A_\ell = \sum_{\ell=1}^{\tau+1} \varrho_\ell^{(d)} A_\ell^{(d)} = T(F) + dE$, and

$$\hat{f}(T(F)+dE) \le \sum_{\ell=1}^{\tau+1} \varrho_\ell f(A_\ell) \le \hat{f}(T(F)+dE) + c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_t(0))}$$

as well as

$$\hat{f}_d(T(F)+dE) \le \sum_{\ell=1}^{\tau+1} \varrho_\ell^{(d)} f(A_\ell^{(d)}) \le \hat{f}_d(T(F)+dE) + c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_t(0))}.$$

Let $r' \ge t$ be such that $A_\ell, A_\ell^{(d)} \in \omega_{d,r'}$ for all $\ell = 1, \dots, \tau+1$. If $\hat{f}(T(F)+dE) \ge \hat{f}_d(T(F)+dE)$, then

$$\begin{aligned} 0 &\le \hat{f}(T(F)+dE) - \hat{f}_d(T(F)+dE) \\ &\le \sum_{\ell=1}^{\tau+1} \varrho_\ell^{(d)} \big(f(A_\ell^{(d)}) - f_d(A_\ell^{(d)}) \big) + c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))} \\ &\le 2c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))}. \end{aligned}$$

Otherwise, if $\hat{f}(T(F)+dE) \le \hat{f}_d(T(F)+dE)$, then

$$\begin{aligned} 0 &\le \hat{f}_d(T(F)+dE) - \hat{f}(T(F)+dE) \\ &\le \sum_{\ell=1}^{\tau+1} \varrho_\ell \big(f_d(A_\ell) - f(A_\ell) \big) + c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))} \\ &\le 2c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))}. \end{aligned}$$

Choosing r' maximal so that for each $E \in \pm B^\tau$ one of the last two estimates holds proves the first part of the lemma.

(ii) The proof of the second assertion is similar to the proof of (i) and uses the fact that $\hat{f} \circ T = f^{pc}$. □

The next lemma is the key observation for the estimates for $\lambda_{d,r}^F$ for which we employ the concept of subgradients. Some elementary facts about the subgradient are cited in the following remark.

Remark 4.4 (see [C]). Let $h : \mathbb{R}^\ell \to \mathbb{R}$ be a continuous convex function. For $v_0 \in \mathbb{R}^\ell$ define

$$\partial h(v_0) := \{ s \in \mathbb{R}^\ell : \forall v \in \mathbb{R}^\ell, s \cdot (v - v_0) \le h(v) - h(v_0) \}.$$

The following hold: (i) If $g : \mathbb{R} \to \mathbb{R}^\ell$ is affine and $g(0) = v_0$, then $\partial(h \circ g)(0) = \partial h(v_0) \cdot Dg(0)$. (ii) If $\ell = 1$, then $\partial h(v_0) \subseteq \big[(h(v_0) - h(v_0 - s))/s, (h(v_0+s) - h(v_0))/s \big]$ for all $s > 0$. (iii) If $h(v_0) \le h(v)$ for all $v \in \mathbb{R}^\ell$, then $0 \in \partial h(v_0)$.

Lemma 4.5. *Suppose that*

$$\max_{A \in d\mathbb{Z}^{n\times m}} \big(\lambda_{d,r}^F \cdot T(A) - f(A) \big) \le \lambda_{d,r}^F \cdot T(F) - f_{d,r}^{pc}(F).$$

Then it holds that $\tilde{f}_d^{pc}(F) = f_{d,r}^{pc}(F)$ *and* $\lambda_{d,r}^F \in \partial \hat{f}_d(T(F))$.

Proof. We show that $\tilde{f}_d^{pc}(F) = f_{d,r}^{pc}(F)$ and

$$\max_{A\in\mathbb{R}^{n\times m}} \big(\lambda_{d,r}^F \cdot T(A) - \tilde{f}_d^{pc}(A)\big) \le \lambda_{d,r}^F \cdot T(F) - \tilde{f}_d^{pc}(F). \tag{4.9}$$

Then the asserted inclusion is deduced from these observations as follows. Let $\varepsilon > 0$. For $X \in \mathbb{R}^\tau$ there exist $A_\ell \in \mathbb{R}^{n\times m}$, $\varrho_\ell \ge 0$, $\ell = 1,\dots,\tau+1$, such that $\sum_{\ell=1}^{\tau+1} \varrho_\ell = 1$, $\sum_{\ell=1}^{\tau+1} \varrho_\ell T(A_\ell) = X$, and

$$\hat{f}_d(X) \ge \sum_{\ell=1}^{\tau+1} \varrho_\ell \tilde{f}_d(A_\ell) - \varepsilon.$$

Using $\tilde{f}_d^{pc} \le \tilde{f}_d$, $\tilde{f}_d^{pc}(F) = \hat{f}_d(T(F))$, and (4.9), we deduce

$$\begin{aligned}
\hat{f}_d(X) - \lambda_{d,r}^F \cdot X &\ge \sum_{\ell=1}^{\tau+1} \varrho_\ell \big(\tilde{f}_d(A_\ell) - \lambda_{d,r}^F \cdot T(A_\ell)\big) - \varepsilon \\
&\ge \sum_{\ell=1}^{\tau+1} \varrho_\ell \big(\tilde{f}_d^{pc}(A_\ell) - \lambda_{d,r}^F \cdot T(A_\ell)\big) - \varepsilon \\
&\ge \tilde{f}_d^{pc}(F) - \lambda_{d,r}^F \cdot T(F) - \varepsilon \\
&= \hat{f}_d(T(F)) - \lambda_{d,r}^F \cdot T(F) - \varepsilon.
\end{aligned}$$

By arbitrariness of $\varepsilon > 0$, the convex function $X \mapsto \hat{f}_d(X) - \lambda_{d,r}^F \cdot X$, $X \in \mathbb{R}^\tau$, has a minimum in $T(F)$ so that (iii) in Remark 4.4 implies the asserted inclusion.

To verify $\tilde{f}_d^{pc}(F) = f_{d,r}^{pc}(F)$ we note that $\tilde{f}_d^{pc}(F) \le f_{d,r}^{pc}(F)$ and let $\varepsilon > 0$. By Lemma 4.2 there exist $B_\kappa \in d\mathbb{Z}^{n\times m}$, $\gamma_\kappa \ge 0$, $\kappa = 1,\dots,2^{nm}(\tau+1)$, such that $\sum_{\kappa=1}^{2^{nm}(\tau+1)} \gamma_\kappa = 1$, $\sum_{\kappa=1}^{2^{nm}(\tau+1)} \gamma_\kappa T(B_\kappa) = T(F)$, and

$$\sum_{\kappa=1}^{2^{nm}(\tau+1)} \gamma_\kappa f(B_\kappa) \le \tilde{f}_d^{pc}(F) + \varepsilon.$$

The hypothesis of the lemma implies, for $\kappa = 1,\dots,2^{nm}(\tau+1)$,

$$f(B_\kappa) \ge \lambda_{d,r}^F \cdot T(B_\kappa) - \lambda_{d,r}^F \cdot T(F) + f_{d,r}^{pc}(F),$$

and this estimate yields

$$\tilde{f}_d^{pc}(F) \ge \sum_{\kappa=1}^{2^{nm}(\tau+1)} \gamma_\kappa f(B_\kappa) - \varepsilon \ge f_{d,r}^{pc}(F) - \varepsilon,$$

which, by arbitrariness of $\varepsilon > 0$, shows $\tilde{f}_d^{pc}(F) \ge f_{d,r}^{pc}(F)$ and hence yields $\tilde{f}_d^{pc}(F) = f_{d,r}^{pc}(F)$.

To prove (4.9), let $A^* \in \mathbb{R}^{n\times m}$ be maximal in the left-hand side of (4.9). For $\varepsilon > 0$ Lemma 4.2 guarantees the existence of $C_\kappa \in d\mathbb{Z}^{n\times m}$ and $\delta_\kappa \ge 0$, $\kappa = 1,\dots,2^{nm}(\tau+1)$, such that $\sum_{\kappa=1}^{2^{nm}(\tau+1)} \delta_\kappa = 1$, $\sum_{\kappa=1}^{2^{nm}(\tau+1)} \delta_\kappa T(C_\kappa) = T(A^*)$, and

$$\sum_{\kappa=1}^{2^{nm}(\tau+1)} \delta_\kappa f(C_\kappa) \le \tilde{f}_d^{pc}(A^*) + \varepsilon.$$

Then the hypothesis of the lemma and $\tilde{f}_d^{pc}(F) = f_{d,r}^{pc}(F)$ imply

$$\begin{aligned}\max_{A\in\mathbb{R}^{n\times m}}\big(\lambda_{d,r}^F\cdot T(A)-\tilde{f}_d^{pc}(A)\big) &\le \lambda_{d,r}^F\cdot T(A^*)-\tilde{f}_d^{pc}(A^*)\\ &\le \sum_{\kappa=1}^{2^{nm}(\tau+1)}\delta_\kappa\big(\lambda_{d,r}^F\cdot T(C_\kappa)-f(C_\kappa)\big)+\varepsilon\\ &\le \sum_{\kappa=1}^{2^{nm}(\tau+1)}\delta_\kappa\max_{A\in d\mathbb{Z}^{n\times m}}\big(\lambda_{d,r}^F\cdot T(A)-f(A)\big)+\varepsilon\\ &\le \lambda_{d,r}^F\cdot T(F)-f_{d,r}^{pc}(F)+\varepsilon\\ &= \lambda_{d,r}^F\cdot T(F)-\tilde{f}_d^{pc}(F)+\varepsilon,\end{aligned}$$

which, by arbitrariness of $\varepsilon > 0$, is (4.9) and therefore concludes the proof. ◻

Provided that $\hat{f}$ is of class $C_{loc}^{1,\alpha}$, we have an estimate for $|\lambda_{d,r}^F - D\hat{f}(T(F))|$.

PROPOSITION 4.3. *Assume that the hypothesis of Lemma* 4.5 *is satisfied, suppose that* $\alpha > 0$, *and let* $\hat{f} \in C_{loc}^{1,\alpha}(\mathbb{R}^\tau)$. *There exists* $r' > 0$ *such that*

$$|\lambda_{d,r}^F - D\hat{f}(T(F))| \le 4\sqrt{\tau}c_{\mathcal{I}}d^\alpha|f|_{C^{1,\alpha}(B_{r'}(0))} + \sqrt{\tau}d^\alpha|\hat{f}|_{C^{1,\alpha}(B_d(T(F)))}.$$

Proof. Let $B^\tau = \{E_1,\dots,E_\tau\}$ be the canonical basis in $\mathbb{R}^\tau$. Lemma 4.5 proves

$$\begin{aligned}|\lambda_{d,r}^F - D\hat{f}(T(F))| &\le \sup_{S\in\partial\hat{f}_d(T(F))}|S-D\hat{f}(T(F))|\\ &\le \sqrt{\tau}\sup_{S\in\partial\hat{f}_d(T(F))}|S-D\hat{f}(T(F))|_\infty\\ &= \sqrt{\tau}\sup_{S\in\partial\hat{f}_d(T(F))}\max_{E\in\pm B^\tau}|(S-D\hat{f}(T(F)))\cdot E|.\end{aligned}$$

Let $S \in \partial\hat{f}_d(T(F))$ and $E \in \pm B^\tau$. Since $\hat{f}_d$ is convex, (i) and (ii) in Remark 4.4 show $S\cdot E \in \partial\hat{f}_d(T(F))\cdot E \subseteq [S_-(E), S_+(E)]$ for

$$S_\pm(E) = \pm\frac{\hat{f}_d(T(F)\pm dE)-\hat{f}_d(T(F))}{d}.$$

Assume without loss of generality $S_-(E) \le S_+(E)$. Lemma 4.4 and Proposition 4.1 (note that $\hat{f}(T(F)) = f^{pc}(F)$ and $\hat{f}_d(T(F)) = f_{d,r}^{pc}(F)$) prove

$$S_+(E) \le \frac{\hat{f}(T(F)+dE)-\hat{f}(T(F))+4c_{\mathcal{I}}d^{1+\alpha}|f|_{C^{1,\alpha}(B_{r'}(0))}}{d}$$

and

$$S_-(E) \ge \frac{\hat{f}(T(F))-\hat{f}(T(F)-dE)-4c_{\mathcal{I}}d^{1+\alpha}|f|_{C^{1,\alpha}(B_{r'}(0))}}{d}.$$

From these estimates, the mean value theorem, and Hölder continuity of $D\hat{f}$ we infer

$$|(S-D\hat{f}(T(F)))\cdot E| \le 4c_{\mathcal{I}}d^\alpha|f|_{C^{1,\alpha}(B_{r'}(0))} + d^\alpha|\hat{f}|_{C^{1,\alpha}(B_d(T(F)))},$$

which concludes the proof. ◻

It is not known under which conditions there holds $\hat{f} \in C^{1,\alpha}_{loc}(\mathbb{R}^\tau)$ or under which conditions there exists a convex function $\tilde{f} \in C^{1,\alpha}_{loc}(\mathbb{R}^\tau)$ such that $\tilde{f} = f^{pc} \circ T$. A result in [BKK] shows that if

$$\liminf_{G\to\infty} \frac{f(G)}{|G|^p} > 0 \quad \text{and} \quad \limsup_{G\to\infty} \frac{f(G)}{|G|^{p+1}} = 0$$

or

$$\frac{f(G)}{|G|^p} \to \infty \text{ as } G \to \infty \quad \text{and} \quad \limsup_{G\to\infty} \frac{f(G)}{|G|^{p+1}} < \infty$$

and if there exists $c > 0$ such that, for all $G \in \mathbb{R}^{n\times m}$, there exists $S \in \partial f(G)$ such that

$$f(G+H) - f(H) - S \cdot H \le c \max\{f(G), 1\} |H|^{1+\alpha}$$

for all $H \in B_1(0)$, then $f^{pc} \in C^{1,\alpha}_{loc}(\mathbb{R}^{n\times m})$. Observing that $D\hat{f}(T(F)) \cdot DT(F) = Df^{pc}(F)$, a small modification (that does not use *any* regularity of $\hat{f}$) of the proof of Proposition 4.3 yields the following result.

Proposition 4.4. *Assume that the hypothesis of Lemma* 4.5 *is satisfied, suppose that* $\alpha > 0$, *and let* $f^{pc} \in C^{1,\alpha}_{loc}(\mathbb{R}^{n\times m})$. *Then, there exists* $r' > 0$ *such that*

$$|\lambda^F_{d,r} \cdot DT(F) - Df^{pc}(F)| \le 4\sqrt{nm} c_{\mathcal{I}} d^\alpha |f|_{C^{1,\alpha}(B_{r'}(0))} + \sqrt{nm} d^\alpha |f^{pc}|_{C^{1,\alpha}(B_d(F))}.$$

Proof. Let $B^{n\times m} = \{E_1, \dots, E_{n\times m}\}$ be the canonical basis in $\mathbb{R}^{n\times m}$. Lemma 4.5 proves

$$|\lambda^F_{d,r} \cdot DT(F) - Df^{pc}(F)| \le \sqrt{nm} \sup_{S\in\partial\hat{f}_d(T(F))} \max_{E\in\pm B^{n\times m}} |(S \cdot DT(F) - Df^{pc}(F)) \cdot E|.$$

Let $S \in \partial\hat{f}_d(T(F))$ and $E \in \pm B^{n\times m}$. Convexity of $t \mapsto \hat{f}_d(T(F+tE))$ shows $(S \cdot DT(F)) \cdot E \in [S_-(E), S_+(E)]$ (cf. Remark 4.4) for

$$S_\pm(E) = \pm \frac{\hat{f}_d(T(F \pm dE)) - \hat{f}_d(T(F))}{d}.$$

Assuming $S_-(E) \le S_+(E)$, Lemma 4.4, $\hat{f}(T(F)) = f^{pc}_{d,r}(F)$, and Proposition 4.1 show

$$S_+(E) \le \frac{f^{pc}(F+dE) - f^{pc}(F) + 4c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))}}{d}$$

and

$$S_-(E) \ge \frac{f^{pc}(F) - f^{pc}(F-dE) - 4c_{\mathcal{I}} d^{1+\alpha} |f|_{C^{1,\alpha}(B_{r'}(0))}}{d}.$$

These estimates, the mean value theorem, and the Hölder continuity of Df^{pc} imply

$$|(S \cdot DT(F) - Df^{pc}(F)) \cdot E| \le 4c_{\mathcal{I}} d^\alpha |f|_{C^{1,\alpha}(B_{r'}(0))} + d^\alpha |f^{pc}|_{C^{1,\alpha}(B_d(F))}$$

and thereby prove the proposition. ∎

Proof of Theorem A. This is a combination of Propositions 4.1, 4.2, and 4.4 and Lemma 4.5. ∎

5. Efficient computation of $f_{d,r}^{pc}(F)$. As mentioned in the introduction, the direct computation of $f_{d,r}^{pc}(F)$ is very expensive. To reduce the number of unknowns we use a multilevel scheme with local mesh refinement and coarsening.

5.1. Grid coarsening and local refinement. The following propositions define criteria that allow us to add nodes to and remove nodes from $\mathcal{N}_{d,r}$ to obtain a set of nodes that leads to a good approximation of $f_{d/2,r}^{pc}(F)$, provided that we computed (an approximation of) $f_{d,r}^{pc}(F)$. The first assertion allows us to remove nodes $A \in \mathcal{N}_{d/2,r}$ that cannot lead to volume fractions θ_A larger than a given threshold $\delta = c/M$ for a known constant c and a (large) parameter M.

PROPOSITION 5.1. *Let $(\theta_A : A \in \mathcal{N}_{d,r})$ be feasible and optimal for $f_{d,r}^{pc}(F)$ with corresponding multiplier $\lambda_{d,r}^F \in \mathbb{R}^\tau$. For each $A \in \mathcal{N}_{d,r}$ let $M(A) \geq M > 0$ and set*

$$Z = \{A \in \mathcal{N}_{d,r} : \lambda_{d,r}^F \cdot T(A) - f(A) \leq \lambda_{d,r}^F \cdot T(F) - f_{d,r}^{pc}(F) - d\,M(A)\}.$$

Let

$$Z' = \{A' \in \mathcal{N}_{d/2,r} : \exists A \in Z,\, |A - A'| \leq d\}.$$

Then for any $(\theta'_{A'} : A' \in \mathcal{N}_{d/2,r})$ that is feasible and optimal for $f_{d/2,r}^{pc}(F)$ there holds

$$\sum_{A' \in Z'} \theta'_{A'} \leq \frac{(|f|_{Lip,r} + |\lambda_{d,r}^F||T|_{Lip,r})}{M}.$$

Proof. For $A' \in Z'$ and $A \in Z$ such that $|A - A'| \leq d$, there holds

$$\begin{aligned} f(A') &\geq f(A) - d|f|_{Lip,r} \\ &\geq f_{d,r}^{pc}(F) + \lambda_{d,r}^F \cdot T(A) - \lambda_{d,r}^F \cdot T(F) + dM(A) - d|f|_{Lip,r} \\ &\geq f_{d,r}^{pc}(F) + \lambda_{d,r}^F \cdot T(A') - \lambda_{d,r}^F \cdot T(F) + dM(A) - d|f|_{Lip,r} - d|\lambda_{d,r}^F||T|_{Lip,r}. \end{aligned}$$

Let $B' \in \mathcal{N}_{d/2,r} \setminus Z'$ and $B \in \mathcal{N}_{d,r}$ be such that $|B' - B| \leq d$. Employing (4.5) and arguing similarly as in the previous estimate, we infer

$$f(B') \geq f_{d,r}^{pc}(F) + \lambda_{d,r}^F \cdot T(B') - \lambda_{d,r}^F \cdot T(F) - d|f|_{Lip,r} - d|\lambda_{d,r}^F||T|_{Lip,r}.$$

Let $(\theta'_{A'} : A' \in \mathcal{N}_{d/2,r})$ be feasible and optimal for $f_{d/2,r}^{pc}(F)$. The previous two estimates imply

$$\begin{aligned} f_{d/2,r}^{pc}(F) = \sum_{A' \in \mathcal{N}_{d/2,r}} \theta_{A'} f(A') &= \sum_{A' \in Z'} \theta_{A'} f(A') + \sum_{B' \in \mathcal{N}_{d/2,r} \setminus Z'} \theta_{B'} f(B') \\ &\geq f_{d,r}^{pc}(F) - (|f|_{Lip,r} + |\lambda_{d,r}^F||T|_{Lip,r})d + \sum_{A' \in Z'} \theta_{A'} Md. \end{aligned}$$

Using $f_{d/2,r}^{pc}(F) \leq f_{d,r}^{pc}(F)$, we are then able to deduce $\sum_{A' \in Z'} \theta_{A'} \leq (|f|_{Lip,r} + |\lambda_{d,r}^F||T|_{Lip,r})/M$. □

A more efficient and even more reliable assertion can be formulated if we have explicit estimates for $|f_{d,r}^{pc}(F) - f_{d/2,r}^{pc}(F)|$ and $|\lambda_{d,r}^F - \lambda_{d/2,r}^F|$. Sufficient for this is the knowledge of r' in Theorem A and $\hat{f} \in C_{loc}^{1,1}(\mathbb{R}^\tau)$ with $\hat{f}$ as in Lemma 4.3.

PROPOSITION 5.2. *For each $A \in \mathcal{N}_{d,r}$ let $M(A) > 0$, suppose that $|\lambda^F_{d,r} - \lambda^F_{d/2,r}| \leq c_{LM} d$, and let Z and Z' be as in Proposition* 5.1. *Assume that for all $A \in \mathcal{N}_{d,r}$ there holds*

$$c_{LM}|T|_{Lip,r'} + |\lambda^F_{d,r}|\,|T|_{Lip,r'} + 4c_{\mathcal{I}}|f|_{Lip,r'} + c_{LM}|T(A)| + c_{LM}|T(F)| < M(A). \tag{5.1}$$

Then for any $(\theta_A : A \in \mathcal{N}_{d/2,r})$ that is feasible and optimal for $f^{pc}_{d/2,r}(F)$ there holds $\theta_{A'} = 0$ for all $A' \in Z'$.

Proof. Let $A' \in Z'$ and $A \in Z$ such that $|A - A'| \leq d$. By the hypotheses and by Lipschitz continuity of f and T there holds

$$\begin{aligned}
&\lambda^F_{d/2,r} \cdot T(A') - f(A') \\
&= \lambda^F_{d,r} \cdot T(A) - f(A) + (\lambda^F_{d/2,r} - \lambda^F_{d,r}) \cdot T(A') + \lambda^F_{d,r} \cdot (T(A') - T(A)) + (f(A) - f(A')) \\
&\leq \lambda^F_{d,r} \cdot T(A) - f(A) + c_{LM} d|T(A')| + d|\lambda^F_{d,r}||T|_{Lip,r'} + d|f|_{Lip,r'} \\
&\leq \lambda^F_{d,r} \cdot T(F) - f^{pc}_{d,r}(F) - dM(A) + c_{LM} d|T(A')| + d|\lambda^F_{d,r}||T|_{Lip,r'} + d|f|_{Lip,r'}.
\end{aligned}$$

The definitions of Z and Z', Proposition 4.1, and again the assumed estimate for $|\lambda^F_{d,r} - \lambda^F_{d/2,r}|$ show

$$\begin{aligned}
&\lambda^F_{d,r} \cdot T(F) - f^{pc}_{d,r}(F) - dM(A) + c_{LM} d|T(A')| + d|\lambda^F_{d,r}||T|_{Lip,r'} + d|f|_{Lip,r'} \\
&= \lambda^F_{d/2,r} \cdot T(F) - f^{pc}_{d/2,r}(F) + \big(\lambda^F_{d,r} - \lambda^F_{d/2,r}\big) \cdot T(F) + \big(f^{pc}_{d/2,r}(F) - f^{pc}_{d,r}(F)\big) \\
&\quad - dM(A) + c_{LM} d|T(A')| + d|\lambda^F_{d,r}||T|_{Lip,r'} + 2c_{\mathcal{I}} d|f|_{Lip,r'} \\
&\leq \lambda^F_{d/2,r} \cdot T(F) - f^{pc}_{d/2,r}(F) + c_{LM} d|T(F)| + d|\lambda^F_{d,r}||T|_{Lip,r'} - dM(A) \\
&\quad + 2c_{\mathcal{I}} d|f|_{Lip,r'} + c_{LM} d|T(F)| + 2c_{\mathcal{I}} d|f|_{Lip,r'}.
\end{aligned}$$

Employing the Lipschitz continuity of T once more proves

$$\begin{aligned}
&\lambda^F_{d/2,r} \cdot T(F) - f^{pc}_{d/2,r}(F) \\
&\qquad + d\big(c_{LM}|T(A')| + |\lambda^F_{d,r}||T|_{Lip,r'} + 2c_{\mathcal{I}} d|f|_{Lip,r'} + c_{LM}|T(F)| - M(A)\big) \\
&\quad \leq \lambda^F_{d/2,r} \cdot T(F) - f^{pc}_{d/2,r}(F) + d\big(c_{LM}|T|_{Lip,r'} + c_{LM}|T(A)| + |\lambda^F_{d,r}||T|_{Lip,r'} \\
&\qquad\qquad + 4c_{\mathcal{I}}|f|_{Lip,r'} + c_{LM}|T(F)| - M(A)\big).
\end{aligned}$$

In view of (5.1), the last three estimates imply, for all $A' \in Z'$,

$$\lambda^F_{d/2,r} \cdot T(A') - f(A') < \lambda^F_{d/2,r} \cdot T(F) - f^{pc}_{d/2,r}(F). \tag{5.2}$$

The optimality conditions ensure, for all $A \in \mathcal{N}_{d/2,r}$,

$$\lambda^F_{d/2,r} \cdot T(A) - f(A) \leq \lambda^F_{d/2,r} \cdot T(F) - f^{pc}_{d/2,r}(F). \tag{5.3}$$

Let $(\theta_A : A \in \mathcal{N}_{d/2,r})$ be feasible and optimal for $f^{pc}_{d/2,r}(F)$, and suppose that there is $A \in Z'$ such that $\theta_A > 0$. Then, (5.2) and (5.3) imply

$$\begin{aligned}
f^{pc}_{d/2,r}(F) &= \sum_{A \in \mathcal{N}_{d/2,r}} \theta_A f(A) \\
&> \sum_{A \in \mathcal{N}_{d/2,r}} \theta_A \big(\lambda^F_{d/2,r} \cdot T(A') - \lambda^F_{d/2,r} \cdot T(F) + f^{pc}_{d/2,r}(F)\big) = f^{pc}_{d/2,r}(F).
\end{aligned} \tag{5.4}$$

This is a contradiction and proves $\theta_A = 0$ for all $A \in Z'$. □

5.2. Prediction of the active set. Following an idea in [CR] for the approximation of scalar nonconvex variational problems, we can further remove nodes temporarily from a mesh with nodes $\mathcal{N}$; e.g., $\mathcal{N} \subseteq \mathcal{N}_{d,r}$ is a refinement of $\mathcal{N}_{2d,r}$, using an iterative method that we establish in the following lemma. The method consists of defining an appropriate subset $X \subseteq \mathcal{N}$ and seeking for a solution of a lower-dimensional subproblem. For a discrete set $\mathcal{N} \subseteq \mathbb{R}^{n\times m}$ we define

$$f^{pc}_{\mathcal{N}}(F) := \min\left\{\sum_{A\in\mathcal{N}} \theta_A f(A) : \forall A \in \mathcal{N},\, \theta_A \geq 0,\, \sum_{A\in\mathcal{N}} \theta_A = 1,\, \sum_{A\in\mathcal{N}} \theta_A T(A) = T(F)\right\}.$$

Optimality conditions for $f^{pc}_{\mathcal{N}}(F)$ guarantee the existence of some $\lambda^F_{\mathcal{N}} \in \mathbb{R}^\tau$ such that

$$\max_{A\in\mathcal{N}} \big(\lambda^F_{\mathcal{N}} \cdot T(A) - f(A)\big) \leq \lambda^F_{\mathcal{N}} \cdot T(F) - f^{pc}_{\mathcal{N}}(F). \tag{5.5}$$

Conversely, any $(\theta_A : A \in \mathcal{N})$ that is feasible in $f^{pc}_{\mathcal{N}}(F)$ is optimal if there exists $\lambda^F_{\mathcal{N}} \in \mathbb{R}^\tau$ such that (5.5) holds with $f^{pc}_{\mathcal{N}}(F)$ replaced by $\sum_{A\in\mathcal{N}} \theta_A f(A)$.

Given $X \subseteq \mathcal{N}$, we consider the following lower-dimensional subproblem of $f^{pc}_{\mathcal{N}}(F)$:

$$f^{pc}_{\mathcal{N},X}(F) := \min\left\{\sum_{A\in X} \theta_A f(A) : \forall A \in X,\, \theta_A \geq 0,\, \sum_{A\in X} \theta_A = 1,\, \sum_{A\in X} \theta_A T(A) = T(F)\right\}.$$

The next lemma states sufficient conditions on X such that $f^{pc}_{\mathcal{N},X}(F) = f^{pc}_{\mathcal{N}}(F)$ and directly leads to an iterative algorithm.

LEMMA 5.1. *Let $(\theta_A : A \in \mathcal{N})$ be feasible and optimal for $f^{pc}_{\mathcal{N}}(F)$ with multiplier $\lambda^F_{\mathcal{N}} \in \mathbb{R}^\tau$. Assume that $\varepsilon_{AS} > 0$ and $\tilde\lambda^F \in \mathbb{R}^\tau$ satisfy $\sup_{A\in\mathcal{N}} |(\tilde\lambda^F - \lambda^F_{\mathcal{N}}) \cdot T(A)| \leq \varepsilon_{AS}/2$. If*

$$X = \left\{A \in \mathcal{N} : \tilde\lambda^F \cdot T(A) - f(A) \geq \max_{A'\in\mathcal{N}} \big(\tilde\lambda^F \cdot T(A') - f(A')\big) - \varepsilon_{AS}\right\}$$

and if the optimization problem $f^{pc}_{\mathcal{N},X}(F)$ is feasible, then $f^{pc}_{\mathcal{N},X}(F) = f^{pc}_{\mathcal{N}}(F)$.

Proof. The optimality conditions (5.5) show (cf. (5.4) in the proof of Proposition 5.2), for all $A \in \mathcal{N}$,

$$\theta_A > 0 \implies A \in Y := \{A' \in \mathcal{N} : \lambda^F_{\mathcal{N}} \cdot T(A') - f(A') = \lambda^F_{\mathcal{N}} \cdot T(F) - f^{pc}_{\mathcal{N}}(F)\}.$$

Hence it suffices to show that $Y \subseteq X$. Let $A \in Y$. By assumption on ε_{AS}, the definitions of X and Y, and (5.5), there holds

$$\begin{aligned}
\tilde\lambda^F \cdot T(A) - f(A) &\geq \lambda^F_{\mathcal{N}} \cdot T(A) - f(A) - \frac{\varepsilon_{AS}}{2} \\
&= \lambda^F_{\mathcal{N}} \cdot T(F) - f^{pc}_{\mathcal{N}}(F) - \frac{\varepsilon_{AS}}{2} \\
&= \max_{A'\in\mathcal{N}} \big(\lambda^F_{\mathcal{N}} \cdot T(A') - f(A')\big) - \frac{\varepsilon_{AS}}{2} \\
&\geq \max_{A'\in\mathcal{N}} \big(\tilde\lambda^F \cdot T(A') - f(A')\big) - \varepsilon_{AS},
\end{aligned}$$

i.e., $A \in X$. □

Given some $\tilde\lambda^F$, we do in general not know ε_{AS} to define X as in the lemma. We may, however, enlarge ε_{AS} successively until the optimality conditions (5.5) are satisfied. Having computed a solution for some parameter d, we may then use the corresponding multiplier to define X on a finer mesh.

5.3. An iterative, adaptive algorithm. The ideas of the preceding propositions lead to the following algorithm that iteratively computes, for prescribed $d_0 > 0$, $r_0 > 0$, $M > 0$, and $J > 0$, a solution to $f^{pc}_{d_0/2^J,2^\ell r_0}(F)$, where for some $\ell \geq 0$, $r = 2^\ell r_0$ satisfies the conditions of Theorem A for $d = d_0/2^J$ if $p > n \wedge m$. If $p = n \wedge m$, we suppose that r_0 is large enough, i.e., $r_0 \geq r'$ for r' as in Theorem A. We assume that $F \in \omega_{d_0,r_0}$.

Algorithm $(A^{pc,\,adapt}_{r_0,d_0,J,F,M})$.

(a) Set $j := 0$, $d := d_0$, $r := r_0$, $\tilde{\lambda}^F := 0$, $\mathcal{N} := \mathcal{N}_{d,r}$, and $\varepsilon_{AS} := \infty$.

(b) Define

$$X := \Big\{A \in \mathcal{N} : \tilde{\lambda}^F \cdot T(A) - f(A) \geq \max_{A' \in \mathcal{N}} \big(\tilde{\lambda}^F \cdot T(A') - f(A')\big) - \varepsilon_{AS}\Big\} \\ \cup \big\{A \in \mathcal{N}_{d,r} : |F - A| \leq d\big\}.$$

(c) Compute $f^{pc}_{\mathcal{N},X}(F)$ and obtain a multiplier $\lambda^F_{\mathcal{N}} \in \mathbb{R}^\tau$.

(d) If for all $A \in \mathcal{N}$ there holds

$$\lambda^F_{\mathcal{N}} \cdot T(A) - f(A) \leq \lambda^F_{\mathcal{N}} \cdot T(F) - f^{pc}_{\mathcal{N}}(F),$$

go to (f).

(e) Set $\tilde{\lambda}^F := \lambda^F_{\mathcal{N}}$, $\varepsilon_{AS} := 2\varepsilon_{AS}$, and go to (b).

(f) If $p = n \wedge m$ or

$$c_T(n \wedge m)|\lambda^F_{\mathcal{N}}| \leq p c_f r^{p - n\wedge m} \quad \text{and} \\ c_T|\lambda^F_{\mathcal{N}}| r^{n \wedge m} - c_f r^p + c'_f \leq \lambda^F_{\mathcal{N}} \cdot T(F) - f^{pc}_{\mathcal{N}}(F),$$

go to (h).

(g) Set $r := 2r$, $\tilde{\lambda}^F := \lambda^F_{\mathcal{N}}$, and go to (b).

(h) If $j < J$, define

$$\mathcal{N} = \big\{A' \in \mathcal{N}_{d/2,r} : \exists A \in \mathcal{N},\ |A - A'| \leq d, \\ \lambda^F_{\mathcal{N}} \cdot T(A) - f(A) > \lambda^F_{\mathcal{N}} \cdot T(F) - f^{pc}_{\mathcal{N}}(F) - Md\big\},$$

set $\tilde{\lambda}^F := \lambda^F_{\mathcal{N}}$, $\varepsilon_{AS} := d$, $d := d/2$, $j := j + 1$, and go to (b).

(j) Stop.

Remark 5.1. (i) We set $\varepsilon_{AS} = d$ in step (h), since in the optimal case (if $\hat{f} \in C^{1,1}_{loc}(\mathbb{R}^\tau)$) Proposition 4.3 guarantees $|\lambda^F_{d,r} - \lambda^F_{d/2,r}| \leq \mathcal{O}(d)$ so that the conditions of Lemma 5.1 are satisfied up to some constant of order $\mathcal{O}(1)$.

(ii) Note that $\mathcal{N}_{d/2,r}$ need not be computed explicitly, since we can add nodes to and remove nodes from $\mathcal{N}$ locally.

(iii) Adding $\big\{A \in \mathcal{N}_{d,r} : |F - A| \leq d\big\}$ to X in step (b) guarantees the feasibility of $f^{pc}_{\mathcal{N},X}(F)$.

6. Numerical experiments I. In this section we report on the practical performance of Algorithm $(A^{pc,\,adapt}_{r_0,d_0,J,F,M})$ when applied to three choices of f for which explicit formulae for f^{pc} and f^{rc} are known.

Example 6.1 (see [Da2]). For $n = m = 2$ and $F \in \mathbb{R}^{2\times 2}$ let

$$f(F) := (|F|^2 - 1)^2.$$

Then (2.1) holds for $p = 4$ and $c_f = (c-2)/c$, $c'_f = 2c-1$ for all $c > 2$, and we choose $c = 3$. In this example $f^{pc} = f^{qc} = f^{**}$, where f^{**} is the convex envelope of f and for $F \in \mathbb{R}^{2\times 2}$ given by

$$f^{**}(F) = \begin{cases} (|F|^2-1)^2 & \text{for } |F| \geq 1, \\ 0 & \text{for } |F| \leq 1. \end{cases}$$

Example 6.2 (see [Ko, DW]). For $n = m = 2$,

$$A_1 := \begin{pmatrix} 5/4 & 0 \\ 0 & 3/4 \end{pmatrix} \quad \text{and} \quad A_2 := \begin{pmatrix} 3\sqrt{8}/8 & 3/8 \\ -5/8 & 5\sqrt{3}/8 \end{pmatrix},$$

and $F \in \mathbb{R}^{2\times 2}$ let

$$f(F) := \frac{1}{2}\min\bigl\{|F-A_1|^2, |F-A_2|^2\bigr\}.$$

Then (2.1) holds for $p = 2$, $c_f = 1/2^3$, and $c'_f = \max\{|A_1|^2, |A_2|^2\}/2 = 17/16$. Here, $f^{**} \neq f^{pc} = f^{qc}$ and f^{pc} is for $F \in \mathbb{R}^{2\times 2}$ given by

$$f^{pc}(F) = \begin{cases} f_1(F) & \text{for } f_1(F) - f_2(F) \leq -\lambda/2, \\ f_2(F) - \bigl(f_2(F) - f_1(F) + \lambda/2\bigr)/(2\lambda) & \text{for } |f_1(F) - f_2(F)| \leq \lambda/2, \\ f_2(F), & \text{for } f_1(F) - f_2(F) \geq \lambda/2, \end{cases}$$

where $f_j(F) = |F-A_j|^2/2$, $j = 1, 2$, and $\lambda = |A_1 - A_2|$.

Example 6.3 (see [KS, Do]). For $n = m = 2$ and $F \in \mathbb{R}^{2\times 2}$ a modification proposed in [Do] (to ensure continuity of f) of an energy density occurring in an optimal design problem in [KS] reads

$$f(F) := \begin{cases} 1 + |F|^2 & \text{for } |F| \geq \sqrt{2}-1, \\ 2\sqrt{2}|F| & \text{for } |F| \leq \sqrt{2}-1. \end{cases}$$

Then (2.1) holds for $p = 2$, $c_f = 1$, and $c'_f = 0$. Letting $\varrho(F) := \sqrt{|F|^2 + 2|\det F|}$ for $F \in \mathbb{R}^{2\times 2}$, there holds

$$f^{pc}(F) = f^{qc}(F) = \begin{cases} 1 + |F|^2 & \text{for } \varrho(F) \geq 1, \\ 2(\varrho(F) - |\det F|) & \text{for } \varrho(F) \leq 1. \end{cases}$$

Note that $f^{**} \neq f^{pc}$ in this example.

We tested Algorithm ($A^{pc,\,adapt}_{r_0,d_0,J,F,M}$) in Examples 6.1–6.3. The implementation of the algorithm was performed in Matlab with a generation of the adaptively refined grids in C. The experiments were performed on a node of a Compaq SC-Cluster with four Alpha-EV68 processors (1 GHz, 8 MB Cache/CPU) and 32 GB RAM.

We set $r_0 = 1$, $d_0 = 1$, $M = 1$, $J = 5$, and

$$F = \frac{1}{5}\begin{pmatrix} \pi & 1 \\ -1 & \pi \end{pmatrix}$$

to run Algorithm ($A^{pc,\,adapt}_{r_0,d_0,J,F,M}$) in Example 6.1. The a posteriori criterion of Proposition 4.2 enforced the algorithm to enlarge r_0 from 1 to 4 on the first level, i.e., for the largest d. Table 1 presents the errors

$$e = |f^{pc}_{d,r}(F) - f^{pc}(F)| \quad \text{and} \quad e' = |\lambda^F_{d,r} \cdot DT(F) - Df^{pc}(F)|,$$

Table 1

Discretization parameter d; errors $e = |f^{pc}_{d,r}(F) - f^{pc}(F)|$ and $e' = |\lambda^F_{d,r} \cdot DT(F) - Df^{pc}(F)|$; number of active, possible, and theoretical nodes; and CPU-time needed to compute $f^{pc}_{d,r}(F)$ in Example 6.1.

Discretization parameter d; errors $e = |f^{pc}_{d,r}(F) - f^{pc}(F)|$ and $e' = |\lambda^F_{d,r} \cdot DT(F) - Df^{pc}(F)|$; number of active, possible, and theoretical nodes; and CPU-time needed to compute $f^{pc}_{d,r}(F)$ in Example 6.2.

d	e	e'	$\#X$	$\#\mathcal{N}$	$\#\mathcal{N}_{d,r}$	CPU-time
1	0.165 961	0.454 711	6,561	6,561	6,561	0.9 s
1/2	0.072 351	0.115 344	794	43,568	83,521	1.1 s
1/4	0.014 273	0.042 726	1,311	167,136	1,185,921	1.4 s
1/8	0.004 031	0.063 871	1,766	715,504	17,850,625	2.4 s
1/16	0.001 139	0.017 684	4,889	3,082,192	276,922,881	6.5 s
1/32	0.000 204	0.011 032	12,140	13,694,256	4,362,470,401	21.8 s

the number of nodes in the set $\mathcal{N}$, the number of activated nodes in X, the theoretical number of nodes (i.e., the number of nodes in $\mathcal{N}_{d,r}$), and the CPU-time in seconds needed to compute $f^{pc}_{\mathcal{N}}(F)$.

We observe that e converges to 0 with experimental rate 4, and the experimental convergence rate for e' is better than linear. Due to the grid coarsening strategy and the active set strategy, the number of activated nodes in X, i.e., the size of each linear optimization problem, is remarkably small when compared to the possible and theoretical numbers of nodes, and the CPU-time needed to obtain an absolute error of about 10^{-5} is only 3.7 seconds. We obtained similar numbers e and e' for the more reliable choice $M = 100$, but the number of activated nodes and the CPU-time was significantly larger; e.g., 9.4 seconds were needed to achieve $e \leq 10^{-3}$.

To test Algorithm $(A^{pc,\,adapt}_{r_0,d_0,J,F,M})$ in Example 6.2 we set $J = 6$, $r_0 = 4$, $d_0 = 1$, $M = 10$, and

$$F = \frac{1}{10}\begin{pmatrix} \sqrt{2}/3 & 1/3 \\ \sqrt{5}/5 & \sqrt{2}/3 \end{pmatrix}.$$

Table 2 presents the errors and the numbers of nodes as in the previous example. The error e converges with an experimental convergence rate 1.8, i.e, $e \approx d^{1.8}$, and there seems to be approximately linear decay in e', but convergence cannot be deduced. The choice $M = 10$ is very optimistic in this example and leads to very small sets $\mathcal{N}$.

We ran Algorithm $(A^{pc,\,adapt}_{r_0,d_0,J,F,M})$ in Example 6.3 with $M = 100$, $J = 6$, $r_0 = 4$, $d_0 = 1$, and

$$F = \frac{1}{5}\begin{pmatrix} \pi & 0 \\ 0 & \pi \end{pmatrix}.$$

TABLE 3

1/8	0.000 806	0.167 216	1,276	83,521	83,521	0.6 s
1/16	0.000 389	0.079 923	1,618	513,280	1,185,921	1.2 s
1/32	0.000 180	0.032 843	2,213	2,128,048	17,850,625	3.6 s

Table 3 presents the errors e and e'; the numbers of activated, possible, and theoretical nodes; and the CPU time as in the previous examples. We observe that e converges at least linearly to 0, while e' seems to converge linearly, at least for $d \leq 1/8$.

7. Numerical experiments II.

In this section we outline how our Algorithm $(A^{pc,\,adapt}_{r_0,d_0,J,F,M})$ may be used for the effective numerical simulation of nonconvex vectorial variational problems, and we report on two numerical experiments. The proposed algorithm aims to numerically relax and minimize variational problems of the form (M′), i.e.,

$$(\mathrm{M}') \quad \text{Minimize} \quad I(u) := \int_\Omega f(\nabla u)\,dx$$
$$\text{among } u \in \mathcal{A} := \{v \in W^{1,p}(\Omega;\mathbb{R}^m) : v|_{\Gamma_D} = u_D\},$$

where f is continuous and satisfies p-growth conditions, $\Omega \subseteq \mathbb{R}^n$ is a bounded Lipschitz domain, $\Gamma_D \subseteq \partial\Omega$ is closed and of positive surface measure, and $u_D = \tilde{u}|_{\Gamma_D}$ for some $\tilde{u}_D \in C(\overline{\Omega};\mathbb{R}^m)$. We further suppose that Ω is polyhedral and let $\mathcal{T}$ be a regular triangulation of Ω such that Γ_D is matched exactly by edges (respectively, faces) of elements in $\mathcal{T}$. We let $\mathcal{S}^1(\mathcal{T})^m$ denote the lowest order finite element space on $\mathcal{T}$ which consists of all globally continuous $\mathcal{T}$-elementwise affine functions in $W^{1,p}(\Omega;\mathbb{R}^m)$. Finally, we let $\tilde{u}_{D,h}$ be the nodal interpolant of $\tilde{u}_D$ on $\mathcal{T}$. The following algorithm is capable of finding an approximation of a weak limit of an infimizing sequence for the nonconvex vectorial variational problem (M′). The approximation scheme realizes a steepest descent approach and exploits the fact that Algorithm $(A^{pc,\,adapt}_{r_0,d_0,J,F,M})$ provides an approximation of $Df^{pc}(F)$.

ALGORITHM (A^{nvvp}). Input: $u_h^{(0)} \in \mathcal{S}^1(\mathcal{T})^m$ with $u_h^{(0)}|_{\Gamma_D} = \tilde{u}_{D,h}|_{\Gamma_D}$, parameters r_0, d_0, J, M for Algorithm $(A^{pc,\,adapt}_{r_0,d_0,J,\cdot,M})$, and a termination criterion $\delta > 0$.

(a) Set $j := 0$.

(b) Let $r_h \in \mathcal{S}^1(\mathcal{T})^m$ satisfy $r_h|_{\Gamma_D} = 0$ and

$$\int_\Omega \nabla r_h \cdot \nabla v_h\,dx = -\int_\Omega \big(\lambda^{\nabla u_h^{(j)}}_{d/4,r} \cdot DT(\nabla u_h^{(j)})\big) \cdot \nabla v_h\,dx$$

for all $v_h \in \mathcal{S}^1(\mathcal{T})^m$ with $v_h|_{\Gamma_D} = 0$.

(c) Compute $t^* \in [0,1]$, which is a local minimizer in $[0,1]$ for

$$t \mapsto \int_\Omega f^{pc}_{d,r}\big(\nabla(u_h^{(j)} + tr_h)\big)\,dx.$$

TABLE 4
Minimal energies for various approaches to the numerical solution of (M′) *in Example* 7.1.

h	f	f^{pc}	$f^{pc}_{d,r}$	f^{rc}_d
1/8	0.244 128	0.199 761	0.252 177 (0.313 327)	0.202 507
1/16	0.234 894	0.199 761	0.216 076 (0.274 192)	0.208 264
1/32	0.233 769	0.199 761	0.202 994 (0.261 244)	0.245 633

(d) Stop and set $u_h := u_h^{(j)}$ if $t^* < \delta$.

(e) Set $u_h^{(j+1)} := u_h^{(j)} + t^* r_h$, $j := j+1$, and go to (b).

Output: $u_h \in \mathcal{S}^1(\mathcal{T})^m$.

We specify f, Ω, $\tilde{u}_D$, and $\mathcal{T}$ in two examples. The first example involves affine boundary data on $\partial\Omega$.

Example 7.1 (see [DW]). Set $n = m := 2$, $\Omega := (0,1)^2$, $\tilde{u}_D(x) := Bx + c$ for

$$B = \begin{pmatrix} 1/2 & 1/4 \\ -1/4 & 15/32 \end{pmatrix}$$

and $c := (0, 1/4)$, and let f be as in Example 6.2. Given an integer $k > 0$, let $h_k := 1/k$ and $\mathcal{T}_k$ be the triangulation of Ω that consists of $2k^2$ triangles which are halved squares of side length h and with diagonals parallel to $(1,1)$.

For $\ell = 1, 2, 3$ we ran Algorithm (A^{nvvp}) with $r_0 = 2$, $M = 10$, $J_\ell = 2 + \ell$, and $k_\ell = 2^{2+\ell}$ in Example 7.1. The initial $u_h^{(0)}$ was chosen as $u_h^{(0)} = \tilde{u}_{D,h} + \xi_h$, where $\xi_h \in \mathcal{S}^1(\mathcal{T})^2$ with $\xi_h|_{\Gamma_D} = 0$ is obtained from a linear interpolation of random values $\xi_h(z) \in [-h_\ell, h_\ell]^2$ in the free nodes z of $\mathcal{T}$. The termination criterion δ was set to $\delta = 0.03$, and Algorithm (A^{nvvp}) terminated after 175, 86, and 8 iterations for $\ell = 1$, 2, and 3, respectively. Table 4 displays the numerically relaxed energies for the output u_{h_ℓ} in Example 7.1 and compares them to values that we obtained when $f^{pc}_{d,r}(F)$ and $\lambda^F_{d,r} \cdot DT(F)$ are replaced by f and Df, f^{pc} and Df^{pc}, and a numerical approximation f^{rc}_d of f^{rc} in steps (b) and (c) of Algorithm (A^{nvvp}). (The numbers for f^{rc}_d are taken from [DW].) We observe that Algorithm (A^{nvvp}) significantly reduces the initial (numerically relaxed) energies shown in brackets in the fourth column of Table 4. Moreover, we may deduce from the numerical results that the (numerically relaxed) energies of the outputs of Algorithm (A^{nvvp}) converge to the optimal value $f^{pc}(B) = 0.199761$ for $(d, h) \to 0$. No experimental convergence can be deduced when the original function f or the numerically obtained approximation of the rank-1 convex envelope f^{rc}_d were employed.

Figure 2 displays the initial $u_h^{(0)}$, the numerical solution obtained from direct numerical minimization of (M′), and the numerical solution obtained from the numerical relaxation realized by Algorithm (A^{nvvp}) in Example 7.1. We observe mesh-dependent oscillations in the stress field defined by the numerical solution when no relaxation is used, while we observe a rather smooth stress field when the nonconvex vectorial variational problem is numerically polyconvexified.

The second example incorporates nonaffine boundary conditions on Γ_D.

Example 7.2 (see [DW]). Let n, m, Ω, Γ_D, f, and $\mathcal{T}$ be as in Example 7.1, and define for $x \in \overline{\Omega}$

$$\tilde{u}_D(x) := \frac{x - (1/2, 1/2)}{\sqrt{\left|x - (1/2,1/2)\right|^2 + 1/4}}.$$

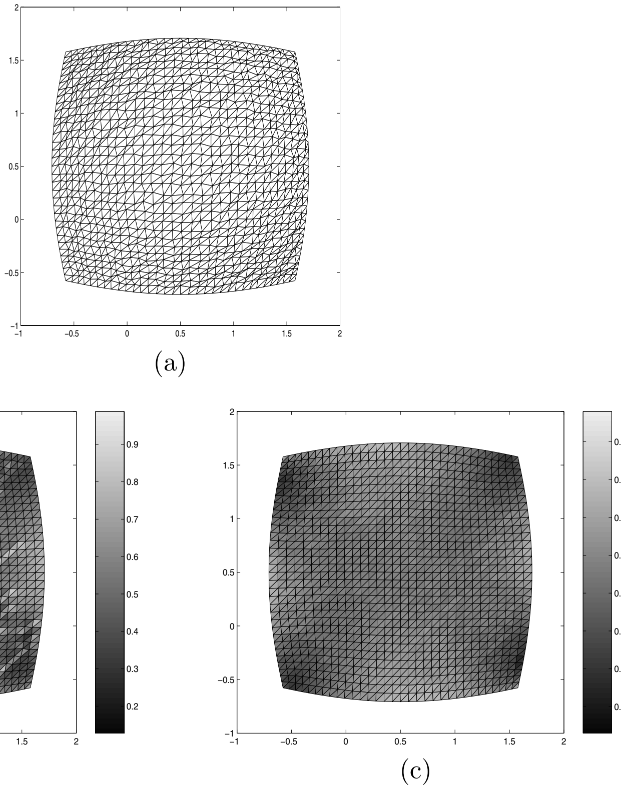
Minimal energies for various approaches to the numerical solution of (M′) *in Example* 7.2.

h	f	f^{pc}	$f_{d,r}^{pc}$	f_d^{rc}
1/8	0.186 939	0.170 023	0.231 421 (0.244 203)	0.175 216
1/16	0.189 875	0.168 945	0.186 094 (0.198 793)	0.173 716
1/32	0.188 556	0.168 583	0.173 779 (0.186 396)	0.183 599

Table 5 displays the minimal energies for various approaches to the numerical simulation of (M′) in Example 7.2. As in the previous example, we observe that the results obtained by Algorithm (A^{nvvp}) (with the same parameters as in the previous experiment) with the approximated polyconvex envelope of f approach the value that we obtained with the exact polyconvex envelope f^{pc}. The minimal energies obtained with the nonrelaxed functional and with the discrete approximation of the rank-1 convex envelope of f (numbers for f_d^{rc} are taken from [DW]) do not show a convergent behavior. As in the previous experiment, we observe in Figure 3 mesh-dependent oscillations in the numerical solution obtained from a direct minimization scheme. No significant oscillations can be found in the numerical solution computed with Algorithm (A^{nvvp}) and displayed in Figure 3(c).



(a)

(b)

(c)

FIG. 3. (a) *Initial deformation* $u_h^{(0)}$, (b) *numerical solution for direct minimization employing* f *with modulus of the related stress field* $|Df(\nabla u_h)|$, (c) *and numerical solution* u_h *obtained from numerical relaxation with Algorithm* (A^{nvvp}) *with stress field* $|\lambda_{d/4,r}^{\nabla u_h} \cdot DT(\nabla u_h)|$ *in Example* 7.2.

Remark 7.1. (i) A good initial $u_h^{(0)}$ may be obtained from solving (M′) with f replaced by a convex function, e.g., $F \mapsto |F|^2/2$, as a preprocessing step in Algorithm (A^{nvvp}).

(ii) A postprocessing procedure based on the algorithms in [Do, DW, Ba2] may be included in Algorithm (A^{nvvp}), which approximates the rank-1 convex envelope applied to ∇u_h almost everywhere in Ω. Then, if (up to numerical tolerances) there holds $f^{pc}(\nabla u_h) = f^{rc}(\nabla u_h)$ almost everywhere in Ω, one has that $f^{qc}(\nabla u_h) = f^{pc}(\nabla u_h)$ and (provided that $f^{pc} \le f^{qc} \le f^{rc}$ are smooth enough) that $Df^{qc}(\nabla u_h) = Df^{pc}(\nabla u_h)$ almost everywhere in Ω. In this case, u_h serves as an approximation of a stationary point of the quasi-convex relaxation of (M).

(iii) The computation of $f_{d,r}^{pc}(\nabla u_h^{(j)})$ and $\lambda_{d,r}^{\nabla u_h^{(j)}}$ in steps (b) and (c) of Algorithm (A^{nvvp}) has to be done on each element of the triangulation $\mathcal{T}$ (since ∇u_h is $\mathcal{T}$-elementwise constant). This may be time-consuming but can be parallelized without communication costs.

ANALYSIS OF FIRST-ORDER SYSTEM LEAST SQUARES (FOSLS) FOR ELLIPTIC PROBLEMS WITH DISCONTINUOUS COEFFICIENTS: PART I[*]

MARKUS BERNDT[†], THOMAS A. MANTEUFFEL[‡], STEPHEN F. MCCORMICK[‡], AND GERHARD STARKE[§]

Abstract. First-order system least squares (FOSLS) is a recently developed methodology for solving partial differential equations. Among its advantages are that the finite element spaces are not restricted by the inf-sup condition imposed, for example, on mixed methods and that the least-squares functional itself serves as an appropriate error measure. This paper studies the FOSLS approach for scalar second-order elliptic boundary value problems with discontinuous coefficients, irregular boundaries, and mixed boundary conditions. A least-squares functional is defined, and ellipticity is established in a natural norm of an appropriately scaled least-squares bilinear form. For some geometries, this ellipticity is independent of the size of the jumps in the coefficients. The occurrence of singularities at interface corners, cross points, reentrant corners, and irregular boundary points is discussed, and a basis of singular functions with local support around singular points is established. A companion paper shows that the singular basis functions can be added at little extra cost and lead to optimal performance of standard finite element discretization and multilevel solver techniques, also independent of the size of coefficient jumps for some geometries.

Key words. least-squares discretization, second-order elliptic problems, finite elements, multilevel methods

1. Introduction.

The purpose of this paper is to apply first-order system least squares (FOSLS; cf. [11] and [12]) to scalar second-order elliptic boundary value problems in two dimensions with discontinuous coefficients, irregular boundaries, and mixed boundary conditions. Such problems arise in various applications, including flow in heterogeneous porous media [29], neutron transport [1], and biophysics [20]. In many physical applications, one is interested not only in accurate approximation of the physical quantity that satisfies the scalar equation, but also in certain of its derivatives. For example, fluid flow in a porous medium can be modeled by the equation

$$-\nabla \cdot (a\nabla p) = f \tag{1.1}$$

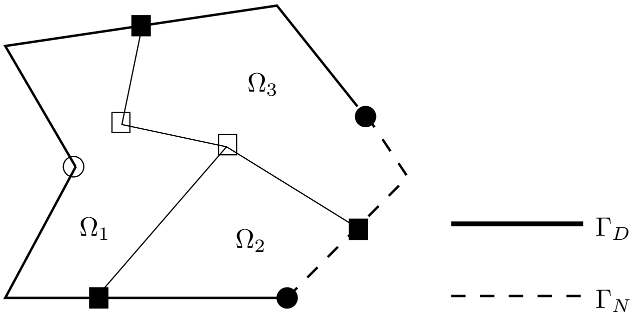

FIG. 1.1. *Polygonal domain Ω with subdomains Ω_i, $i = 1, 2, 3$, and two cross points.*

for the pressure p, where the scalar function a may have large jump discontinuities across interfaces. Of particular interest here is accurate approximation of the flux,

$$\mathbf{u} = a\nabla p. \tag{1.2}$$

For the purposes of discussion, consider problem (1.1) posed on a domain, Ω, composed of a union of polygonal subdomains, Ω_i, in which the coefficient a is constant on each subdomain (see Figure 1.1). In general, the flux, $\mathbf{u}$, will be infinite at certain points, which we will call singular points (see, for example, Strang and Fix [30, Chapter 8]). Singular points can be of several types:

Cross points: corner points of the boundary of Ω_i that lie in the interior of Ω (□ in Figure 1.1);

Boundary cross points: corner points of Ω_i on the boundary of Ω that touch another subdomain, Ω_j (■ in Figure 1.1);

Reentrant corners: reentrant corners of Ω (○ in Figure 1.1);

Irregular boundary points: points on the boundary of Ω that separate the Dirichlet boundary, Γ_D, from the Neumann boundary, Γ_N, for which the interior angle is greater than $\pi/2$ (● in Figure 1.1).

The solution, p, can be expressed as the sum of a finite number of singular functions plus a function that is locally smooth, that is, in $H^2(\Omega_i)$ for each i. Each singular function is associated with a singular point and, near the singular point, has the form $r^\alpha\Phi(\theta)$, where (r, θ) are polar coordinates about the singular point and $0 < \alpha < 1$. The character of a singular function depends only on local information near the singular point and is not difficult to compute (see section 5 and [3] for details).

There are many finite element methods for approximating the solution of (1.1). Some yield an approximate solution without specific knowledge of the singular functions, while others use the singular functions either implicitly or explicitly. Below we describe the major approaches.

Standard Galerkin method. The standard Galerkin method (cf. Strang and Fix [30]) establishes a weak form and seeks the approximation of p in $H^1(\Omega)$. Convergence deteriorates near the singular points. Early work using H^1 singular basis functions can be found in the monograph by Strang and Fix [30, section 8.2]. There, H^1 singular basis functions for p were introduced to eliminate the deteriorating finite element approximation near singular points. (See also Cox and Fix [16] and Grisvard [19, section 8.4.2].) A multilevel approach for simultaneously finding the approximate solution and determining the coefficients of the singular basis functions is developed by Brenner and Sung [9]. In [10], Cai and Kim describe a method that is equivalent to a Petrov/Galerkin method in which the singular basis functions are added to the trial space and the dual singular basis functions are added to the test space.

Mixed methods. In mixed finite element methods (see, e.g., [8, Chapter 10]), p and $\mathbf{u}$ are usually approximated by different finite element spaces, and, roughly speaking, a Galerkin condition is imposed on the first-order system resulting from (1.1) and (1.2). Normally, the pressure, p, is approximated in L^2 and the flux, $\mathbf{u}$, is approximated in $H(\mathrm{div})$. Only the integral of the flux is computed along edges of elements, and the pointwise resolution of singularities in the flux is poor.

The least squares methodology for systems of first order is by now several decades old and had its first application in continuum mechanics (see, for example, [21, 31, 22, 26, 15, 23]). Only fairly recently has it produced H^1 equivalent forms to which optimal multigrid solvers have been applied (see, for example, [12]). For a thorough review of the least-squares methodology, see [5] and the references therein. The following is an overview of specific least-squares methods and their applicability to the problem at hand.

Least-squares in $H(\mathrm{div})$. A similar approach is based on the FOSLS approach developed and analyzed, e.g., in [11, 12, 27, 28]. This methodology replaces the Galerkin condition by the minimization of a least-squares functional associated with a first-order system derived from (1.1) and (1.2). Assuming that $f \in L^2(\Omega)$, the least-squares functional can be defined using the $L^2(\Omega)$-norm. Even in the presence of discontinuities, this translates to ellipticity with respect to the H^1-norm for the pressure, p, and the $H(\mathrm{div})$-norm in the flux variable, $\mathbf{u}$. This approach, like the mixed method approach, computes only the integral flux and again does not resolve the singularity in the flux variable.

Weighted least-squares in $H(\mathrm{div})\cap H(\mathrm{curl})$. Augmenting the basic system with the curl-condition, $\nabla\times(\mathbf{u}/a) = 0$ (see [12, 27]), leads to ellipticity with respect to a scaled version of the $H(\mathrm{div}) \cap H(\mathrm{curl})$ norm in the flux variable. Standard finite element spaces, for example piecewise polynomials with the appropriate jump conditions across interfaces, are not dense in the scaled $H(\mathrm{div}) \cap H(\mathrm{curl})$ norm, and thus convergence cannot be obtained. However, the use of an appropriate weight function near each singular point yields ellipticity in a weighted (and scaled) $H(\mathrm{div})\cap H(\mathrm{curl})$ norm. The piecewise polynomial spaces are dense in this new space. The weighting effectively ignores the singularity while insulating the rest of the region from the presence of the singularity. For the case of reentrant corners, weighted least-squares approaches are presented and analyzed in [17, 16]. Specifically, the method presented in [17] for corner singularities does not rely on the explicit knowledge of the flux singularity at the corner. Its analytic part is computed implicitly. For a weighted least-squares approach in a more general setting, see [25].

Inverse norm functionals. Another potentially more general form of the least-squares approach is based on the $H^{-1}(\Omega)$-norm (see [6, 7, 13, 4]). Such schemes based on "inverse" norms can, in principle, be applied when $f \in H^{-1}(\Omega)$, although the theory has so far restricted f to $L^2(\Omega)$. Thus, both the $H^{-1}(\Omega)$ and $L^2(\Omega)$ versions of FOSLS have been developed under the same general assumptions that are usually in force for mixed methods. Standard finite element spaces are dense in L^2, and thus convergence is obtained, although only in an L^2 sense. This approach uses norms that do not generally take the coefficients of the equation into account and thus have performance that deteriorates for problems with large jumps in the coefficients.

FOSLL functionals.* A more recently developed approach, called FOSLL* [14], can be viewed as a least-squares method based on an inverse norm that involves the operator and thus has superior properties in the presence of large jumps in the coefficients. In addition, it handles the more general case, $f \in H^{-1}(\Omega)$.

Least-squares in $H(\mathrm{div}) \cap H(\mathrm{curl})$. The current paper is concerned with least-squares functionals using finite element spaces in $H(\mathrm{div}) \cap H(\mathrm{curl})$. This paper builds on the theory developed in [2]. Here, and in the companion paper [3], we describe a least-squares approach that includes a curl-condition, $\nabla \times (\mathbf{u}/a) = 0$. While the theory developed in [11] and [12] already allows for discontinuous coefficients, special care must be taken to prove ellipticity, in an appropriate norm, with constants that grow as slowly as possible with respect to the size of the jumps. For this purpose, an appropriate scaling of the least-squares functional that depends on the size of a in different parts of the domain is introduced.

The flux components will, in general, not be in $H^1(\Omega)$, nor will they be in $H^1(\Omega_i)$. Here, we construct singular basis functions for the flux, $\mathbf{u}$, that are in the scaled $H(\mathrm{div}) \cap H(\mathrm{curl})$ but not in $H^1(\Omega_i)$ and have support only near singular points. These are included in our finite element space. As a result, the flux can be computed very accurately near cross points. For standard mixed methods, it would be necessary to make sure that the Ladyzhenskaya–Babuška–Brezzi condition (cf. [8, section 10.5]) is satisfied for the finite element spaces that include the singular function. This is not the case for our first-order system least-squares approach.

In this paper and the companion paper [3], we show that one can add singular basis functions at little additional cost. A singular basis function is composed of a singular function multiplied by a cut-off function that takes the value one in a region around the singularity (the platform) and drops from one to zero in a narrow region around the platform (the fringe). The key is that the singular basis functions satisfy a homogeneous equation of type (1.1) in the platform. Thus, these singular basis functions are orthogonal to any standard basis function that is either supported completely inside the platform or supported completely outside the platform and fringe. Nonzero inner products arise only between singular basis functions and standard basis functions whose support intersects the fringe. As a result, the cost of adding a singular basis function is proportional to the number of grid points in the fringe. In our approach, the fringe has a width of one element, so this additional cost is $O(\sqrt{N})$, where N is the number of grid points.

In this paper, we introduce the problem in section 2; then, in section 3, we construct a scaled FOSLS functional for p and $\mathbf{u}$ and show that this functional is continuous and coercive in a scaled $H^1 \times H(\mathrm{div}) \cap H(\mathrm{curl})$-norm. The coercivity and continuity constants are shown to depend on the coefficient a in a complicated way that involves the geometry of the partition of Ω. We then introduce a *flux-only* functional for $\mathbf{u}$ alone and show that it is continuous and coercive in the scaled version of $H(\mathrm{div}) \cap H(\mathrm{curl})$. In section 4, we introduce the div-curl operator associated with the flux-only functional and discuss its properties. Then, in section 5, we show that the solution, $\mathbf{u}$, can be decomposed as

$$\mathbf{u} = \mathbf{u}_0 + \sum_{m=1}^{M} \sum_{n=1}^{N_m} b_{m,n} \mathbf{s}_{m,n},$$

where $\mathbf{s}_{m,n}$ are a finite number of singular basis functions associated with singular points $\mathbf{x}_m$, $m = 1, \ldots, M$, and $\mathbf{u}_0 \in H^1(\Omega_i)$ for every i. Thus, $\mathbf{u}_0$ can be approximated by standard finite elements within each domain, provided that they posses the proper jumps across domain interfaces.

In the companion paper [3], we show how to compute approximate singular basis functions, and then we construct a finite element basis using them. We develop error estimates by way of new results for nonconforming spaces in the FOSLS context. We prove that the accuracy of singular basis functions need only be $O(h^p)$, $p > 1/2$. Finally, we develop a multilevel algorithm that includes singular basis functions on all coarser levels and provide numerical results that illustrate its performance.

Our restriction to two-dimensional problems is mainly for the purpose of exposition. However, technical complications arise in higher dimensions. For example, two different types of singularities, associated with edges and with corners or cross points, arise in three dimensions. We do not consider these additional complications in the present paper.

2. Problem statement and preliminaries. Consider the following prototype problem on a bounded domain $\Omega \subset \Re^2$:

$$\begin{array}{rcll} -\nabla \cdot (a \nabla p) & = & f & \text{in } \Omega, \\ p & = & 0 & \text{on } \Gamma_D, \\ \mathbf{n} \cdot a \nabla p & = & 0 & \text{on } \Gamma_N, \end{array} \tag{2.1}$$

where $\mathbf{n}$ denotes the outward unit vector normal to the boundary, $f \in L^2(\Omega)$, and $a(x_1, x_2)$ is a scalar function that is uniformly positive and bounded in Ω a.e. but may have large jumps across interfaces. Suppose that Γ_D has positive measure, so that the Poincaré–Friedrichs inequality

$$\|p\|_{0,\Omega} \leq \gamma \|\nabla p\|_{0,\Omega} \tag{2.2}$$

holds for all functions satisfying the boundary conditions in (2.1). Then (2.1) has a unique solution in $H^1(\Omega)$.

Following [12], we rewrite (2.1) as a first-order system by introducing the flux variable, $\mathbf{u} = \sqrt{a} \nabla p$:

$$\begin{array}{rcll} \mathbf{u} - \sqrt{a} \nabla p & = & \mathbf{0} & \text{in } \Omega, \\ -\nabla \cdot \sqrt{a} \mathbf{u} & = & f & \text{in } \Omega, \\ p & = & 0 & \text{on } \Gamma_D, \\ \mathbf{n} \cdot \sqrt{a} \mathbf{u} & = & 0 & \text{on } \Gamma_N. \end{array} \tag{2.3}$$

Since $\mathbf{u}/\sqrt{a} = \nabla p$ with $p \in H^1(\Omega)$, we then have (cf. [18, Theorem 2.9])

$$\nabla \times \left(\frac{\mathbf{u}}{\sqrt{a}} \right) := \partial_1 \left(\frac{u_2}{\sqrt{a}} \right) - \partial_2 \left(\frac{u_1}{\sqrt{a}} \right) = 0 \quad \text{in } \Omega \, .$$

(By the term ∂_k, we mean $\partial / \partial x_k, k = 1, 2$.) Moreover, the homogeneous Dirichlet boundary condition on Γ_D implies the tangential flux condition

$$\boldsymbol{\tau} \cdot \left(\frac{\mathbf{u}}{\sqrt{a}} \right) := \frac{n_1 u_2 - n_2 u_1}{\sqrt{a}} = 0 \quad \text{on } \Gamma_D.$$

(Here, $\boldsymbol{\tau}$ is the counterclockwise unit tangent vector.)

Adding these equations to first-order system (2.3) yields the augmented, but consistent, system

$$
\begin{array}{rcll}
\mathbf{u} - \sqrt{a}\nabla p & = & \mathbf{0} & \text{in } \Omega, \\
-\nabla \cdot \sqrt{a}\mathbf{u} & = & f & \text{in } \Omega, \\
\nabla \times \left(\dfrac{\mathbf{u}}{\sqrt{a}} \right) & = & 0 & \text{in } \Omega, \\
p & = & 0 & \text{on } \Gamma_D, \\
\mathbf{n} \cdot \sqrt{a}\mathbf{u} & = & 0 & \text{on } \Gamma_N, \\
\boldsymbol{\tau} \cdot \left(\dfrac{\mathbf{u}}{\sqrt{a}} \right) & = & 0 & \text{on } \Gamma_D.
\end{array}
\tag{2.4}
$$

Problems (2.1) and (2.4) are equivalent in that their unique solutions are in correspondence (p solves (2.1) if and only if p and $\mathbf{u} = \sqrt{a}\nabla p$ solve (2.4)). If Γ_N is not connected, then we add the constraint

$$
\int_{\Gamma_{N_i}} \boldsymbol{\tau} \cdot \left(\frac{\mathbf{u}}{\sqrt{a}} \right) = 0 \tag{2.5}
$$

for every disjoint piece, Γ_{N_i}, of Γ_N. This constraint is necessary to ensure that the *flux-only* functional described below (see (3.17)) has a unique solution.

For both scalar and vector quantities, denote the standard Sobolev spaces as $L^2(\Omega)$ and $H^k(\Omega)$, with respective norms $\|\cdot\|_{0,\Omega}$ and $\|\cdot\|_{k,\Omega}$. We also define the spaces

$$
\begin{aligned}
H(\operatorname{div} a; \Omega) &:= \left\{ \mathbf{v} \in L^2(\Omega)^2 : \nabla \cdot \sqrt{a}\mathbf{v} \in L^2(\Omega) \right\}, \\
H(\operatorname{curl} a; \Omega) &:= \left\{ \mathbf{v} \in L^2(\Omega)^2 : \nabla \times \left(\frac{\mathbf{v}}{\sqrt{a}} \right) \in L^2(\Omega) \right\}, \\
V &:= \left\{ q \in H^1(\Omega) : q = 0 \text{ on } \Gamma_D \right\}, \\
\mathbf{W} &:= \Bigg\{ \mathbf{v} \in H(\operatorname{div} a; \Omega) \cap H(\operatorname{curl} a; \Omega) : \mathbf{n} \cdot \sqrt{a}\mathbf{v} = 0 \text{ on } \Gamma_N, \\
&\qquad\qquad \boldsymbol{\tau} \cdot \left(\frac{\mathbf{v}}{\sqrt{a}} \right) = 0 \text{ on } \Gamma_D, \int_{\Gamma_{N_i}} \boldsymbol{\tau} \cdot \left(\frac{\mathbf{u}}{\sqrt{a}} \right) = 0 \Bigg\}.
\end{aligned}
$$

Denote the respective seminorm and norm on $\mathbf{W}$ by

$$
\begin{aligned}
|\mathbf{v}|_{\mathbf{W}}^2 &:= \left\| \frac{1}{\sqrt{a}} \nabla \cdot \sqrt{a}\mathbf{v} \right\|_{0,\Omega}^2 + \left\| \sqrt{a}\nabla \times \frac{1}{\sqrt{a}}\mathbf{v} \right\|_{0,\Omega}^2, \\
\|\mathbf{v}\|_{\mathbf{W}}^2 &:= |\mathbf{v}|_{\mathbf{W}}^2 + \|\mathbf{v}\|_{0,\Omega}^2.
\end{aligned}
\tag{2.6}
$$

We show in Lemma 3.3 below that this seminorm is in fact a norm on $\mathbf{W}$ by establishing a Poincaré–Friedrichs-type inequality.

Note that $\mathbf{v} \in \mathbf{W}$ is characterized by the fact that, across any curve in Ω with normal $\mathbf{n}$ and tangent $\boldsymbol{\tau}$, both $\mathbf{n} \cdot \sqrt{a}\mathbf{v}$ and $\boldsymbol{\tau} \cdot \frac{1}{\sqrt{a}}\mathbf{v}$ are continuous (a.e.). (For the first condition see, for example, [32, Chapter 6.2]. The second condition can be derived analogously.) We refer to the continuity of these two terms at lines of discontinuity of a as *interface conditions* for $\mathbf{u} \in \mathbf{W}$. Clearly, for the solution of (2.1), we have $p \in V$ and $\mathbf{u} \in \mathbf{W}$, so it is appropriate to pose (2.4) on these spaces.

As mentioned above, our main interest is in the solution of (2.1) when $a(x_1, x_2)$ has large jumps. For this purpose, we assume that

$$\overline{\Omega} = \bigcup_{i=1}^{J} \overline{\Omega}_i, \tag{2.7}$$

where Ω_i are mutually disjoint, open, simply connected, polygonal regions (see Figure 1.1). Assume also that the restriction of $a(x_1, x_2)$ to Ω_i is in $C^{1,1}(\Omega_i)$ and that

$$c_1\omega_i \leq a(x_1, x_2) \leq c_2\omega_i \quad \text{for all } (x_1, x_2) \in \Omega_i, \tag{2.8}$$

with order one constants c_1, c_2 and arbitrary positive constants ω_i. In other words, $a(x_1, x_2)$ is assumed to be of approximate size ω_i throughout Ω_i for each i, but ω_i is allowed to have large variations over i. In the bounds derived below, we separate the dependence on the variation in $\{\omega_i\}$ from the variation within each Ω_i, that is, on c_1, c_2, and

$$c_3 := \max_{1\leq i\leq J} \|\nabla a\|_{0,\Omega_i} < \infty. \tag{2.9}$$

Given this decomposition of Ω, define the *split* seminorms and norms, respectively, as follows:

$$|\mathbf{v}|^2_{k,S} := \sum_{i=1}^{J} |\mathbf{v}|^2_{k,\Omega_i} \tag{2.10}$$

and

$$\|\mathbf{v}\|^2_{k,S} := \|\mathbf{v}\|^2_{0,\Omega} + \sum_{j=1}^{k} |\mathbf{v}|^2_{j,S}. \tag{2.11}$$

Let $H^k_S(\Omega)$ denote the closure of $C^\infty(\overline{\Omega})$ in the split norm, and define

$$\mathbf{W}^1_S := H^1_S(\Omega) \cap \mathbf{W}. \tag{2.12}$$

We now show that if a is piecewise constant ($c_1 = c_2$ in (2.8)) with respect to the decomposition, then

$$\|\mathbf{v}\|_{1,S} = \|\mathbf{v}\|_{\mathbf{W}} \quad \text{for every } \ \mathbf{v} \in H^1_S(\Omega). \tag{2.13}$$

We first need to establish two lemmas. For the first lemma, consider one polygonal, simply connected subdomain, Ω_i, of Ω, with vertices labeled $\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_K$ in counterclockwise order. Letting $\mathbf{x}_{K+1} = \mathbf{x}_1$, denote by Γ_j the side connecting $\mathbf{x}_j$ and $\mathbf{x}_{j+1}$. If Γ_j makes angle θ_j with the positive x_1-axis, then $\mathbf{n}_j = (\sin(\theta_j), -\cos(\theta_j))^t$ and $\boldsymbol{\tau}_j = (\cos(\theta_j), \sin(\theta_j))^t$ are the outward unit normal and counterclockwise unit tangent to Γ_j, respectively.

Lemma 2.1. *Assume that Ω_i is a polygonal domain and that $\mathbf{u} = (u_1, u_2)^t \in (H^2(\Omega_i))^2$; then*

$$\begin{aligned} \int\int_{\Omega_i} \partial_1 u_1 \partial_2 u_2 dz \quad &= \int\int_{\Omega_i} \partial_2 u_1 \partial_1 u_2 dz - \int_{\partial\Omega_i} (\boldsymbol{\tau}\cdot\mathbf{u}) d(\mathbf{n}\cdot\mathbf{u}) \\ &+ \frac{1}{2}\sum_{j=1}^{K} \left((\boldsymbol{\tau}_j\cdot\mathbf{u})(\mathbf{n}_j\cdot\mathbf{u})|_{\mathbf{x}_j} - (\boldsymbol{\tau}_{j-1}\cdot\mathbf{u})(\mathbf{n}_{j-1}\cdot\mathbf{u})|_{\mathbf{x}_j}\right). \end{aligned} \tag{2.14}$$

Proof. First, assume that Ω is simply connected. For $\mathbf{u} \in H^2(\Omega_i)$, Green's identity yields

$$\int\int_{\Omega_i} \partial_1 u_1 \partial_2 u_2 dz = \int\int_{\Omega_i} \partial_2 u_1 \partial_1 u_2 dz + \int_{\partial\Omega_i} u_1 du_2.$$

The definition of $\mathbf{n}_i$ and $\boldsymbol{\tau}_i$ and a bit of algebra yield

$$\int_{\Gamma_j} (\boldsymbol{\tau}_j \cdot \mathbf{u}) d(\mathbf{n}_j \cdot \mathbf{u}) = \frac{1}{2} \, (\boldsymbol{\tau}_j \cdot \mathbf{u})(\mathbf{n}_j \cdot \mathbf{u})|_{\mathbf{x}_j}^{\mathbf{x}_{j+1}} + \frac{1}{2} \, u_1 u_2|_{\mathbf{x}_j}^{\mathbf{x}_{j+1}} - \int_{\Gamma_j} u_1 du_2.$$

Summing over the edges yields the result. The result for a general connected polygonal domain is established by cutting Ω_i into simply connected polygonal subdomains and adding the result. □

Lemma 2.2. *For every* $\mathbf{u} \in \mathbf{W}_S^1$, *we have*

$$\int\int_{\Omega} \partial_1 u_1 \partial_2 u_2 dz = \int\int_{\Omega} \partial_2 u_1 \partial_1 u_2 dz. \tag{2.15}$$

Proof. First, let $\mathbf{u} \in H_S^2(\Omega) \cap \mathbf{W}$. The space $\mathbf{W}$ is characterized by the property that, for $\mathbf{u} \in \mathbf{W}$, both $\sqrt{a}\mathbf{n} \cdot \mathbf{u}$ and $\frac{1}{\sqrt{a}}\boldsymbol{\tau} \cdot \mathbf{u}$ are continuous (a.e.) across any curve in Ω. Thus, $(\mathbf{n} \cdot \mathbf{u})(\boldsymbol{\tau} \cdot \mathbf{u})$ is continuous (a.e.). In particular, this holds for the polygonal boundaries between the regions Ω_i. Let Γ_{ij} denote the edge joining Ω_i and Ω_j. Summing the boundary integrals in (2.14) over each Ω_i shows that Γ_{ij} is traversed once in each direction. Thus, only integrals on the boundary of Ω survive. This yields

$$\int\int_{\Omega} \partial_1 u_1 \partial_2 u_2 = \int\int_{\Omega} \partial_2 u_1 \partial_1 u_2 \tag{2.16}$$

$$+ \frac{1}{2} \sum_{j=1}^{\tilde{K}} \left((\tilde{\boldsymbol{\tau}}_j \cdot \mathbf{u})(\tilde{\mathbf{n}}_j \cdot \mathbf{u}) - (\tilde{\boldsymbol{\tau}}_{j-1} \cdot \mathbf{u})(\tilde{\mathbf{n}}_{j-1} \cdot \mathbf{u}) \right) |_{\tilde{\mathbf{x}}_j}, \tag{2.17}$$

where the $\tilde{\mathbf{x}}_j$ now denote the $\tilde{K}$ vertices $\tilde{\mathbf{x}}_j$ on the boundary of Ω, and the $\tilde{\mathbf{n}}_j$ and $\tilde{\boldsymbol{\tau}}_j$ are the corresponding standard normal and tangent vectors. The boundary conditions imposed on $\mathbf{W}$ now imply (2.15) for $\mathbf{u} \in H_S^2(\Omega) \cap \mathbf{W}$. The proof is completed by noting that Lemma 4.3.1.3 in [19] implies that $H_S^2(\Omega) \cap \mathbf{W}$ is dense in $\mathbf{W}_S^1 = H_S^1(\Omega) \cap \mathbf{W}$. □

The next result has important implications for the decomposition of $\mathbf{W}$.

Theorem 2.3. *Suppose* $a = \omega_i$ *(constant) on* Ω_i. *Then*

$$|\mathbf{u}|_{1,S} = |\mathbf{u}|_{\mathbf{W}} \quad \textit{for every} \;\; \mathbf{u} \in \mathbf{W}_S^1. \tag{2.18}$$

Proof. By definition,

$$\begin{aligned} |\mathbf{u}|_{\mathbf{W}}^2 &= \left\| \frac{1}{\sqrt{a}} \nabla \cdot \sqrt{a}\mathbf{u} \right\|_{0,\Omega}^2 + \left\| \sqrt{a} \nabla \times \frac{1}{\sqrt{a}} \mathbf{u} \right\|_{0,\Omega}^2 \\ &= \sum_{i=1}^{J} \left(\left\| \frac{1}{\sqrt{a}} \nabla \cdot \sqrt{a}\mathbf{u} \right\|_{0,\Omega_i}^2 + \left\| \sqrt{a} \nabla \times \frac{1}{\sqrt{a}} \mathbf{u} \right\|_{0,\Omega_i}^2 \right) \\ &= \sum_{i=1}^{J} (\|\nabla \cdot \mathbf{u}\|_{0,\Omega_i}^2 + \|\nabla \times \mathbf{u}\|_{0,\Omega_i}^2). \end{aligned}$$

The theorem now follows from Lemma 2.2 and the easily verified relation

$$\|\nabla\cdot\mathbf{u}\|_{0,\Omega_i}^2+\|\nabla\times\mathbf{u}\|_{0,\Omega_i}^2=|\mathbf{u}|_{1,\Omega_i}+2\langle\partial_1u_1,\,\partial_2u_2\rangle_{0,\Omega_i}-2\langle\partial_2u_1,\,\partial_1u_2\rangle_{0,\Omega_i}.\qquad\square$$

COROLLARY 2.4. *Suppose that $a(x,\,y)$ is now allowed to vary according to* (2.8) *and* (2.9). *Then,*

$$\frac{1}{\delta}\|\mathbf{u}\|_{\mathbf{W}}\le\|\mathbf{u}\|_{1,S}\le\delta\|\mathbf{u}\|_{\mathbf{W}}\quad\textit{for}\;\;\mathbf{u}\in\mathbf{W}_S^1,$$

where

$$\delta=\sqrt{1+c_3\left(\frac{c_3+\sqrt{c_3^2+8}}{4}\right)}$$

and c_3 is defined in (2.9).

Proof. Observe that

$$\left\|\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}\right\|_{0,\Omega_i}\le\|\nabla\cdot\mathbf{u}\|_{0,\Omega_i}+\left\|\frac{1}{2}(\nabla a)\cdot\mathbf{u}\right\|_{0,\Omega_i},$$
$$\left\|\sqrt{a}\nabla\times\frac{1}{\sqrt{a}}\mathbf{u}\right\|_{0,\Omega_i}\le\|\nabla\times\mathbf{u}\|_{0,\Omega_i}+\left\|\frac{1}{2}(\nabla^\perp a)\cdot\mathbf{u}\right\|_{0,\Omega_i}.$$

(Here, we use the notation $\nabla^\perp a:=(-\partial_2a,\,\partial_1a)^t$.) Using the ϵ-inequality twice now yields

$$\begin{aligned}|\mathbf{u}|_{\mathbf{W},\Omega_i}^2&\le\left(\|\nabla\cdot\mathbf{u}\|_{0,\Omega_i}+\frac{c_3}{2}\|\mathbf{u}\|_{0,\Omega_i}\right)^2+\left(\|\nabla\times\mathbf{u}\|_{0,\Omega_i}+\frac{c_3}{2}\|\mathbf{u}\|_{0,\Omega_i}\right)^2\\&\le(1+\epsilon)(\|\nabla\cdot\mathbf{u}\|_{0,\Omega_i}^2+\|\nabla\times\mathbf{u}\|_{0,\Omega_i}^2)+\left(1+\frac{1}{\epsilon}\right)\frac{c_3^2}{2}\|\mathbf{u}\|_{0,\Omega_i}^2\end{aligned}$$

for any $\epsilon>0$. Choosing $\epsilon=c_3\big(\frac{c_3+\sqrt{c_3^2+8}}{4}\big)$, summing over i, and appealing to Theorem 2.3 yields the lower bound. The upper bound is proved in a similar fashion. $\square$

Remark 1. Following the development in section 4.3 in [19], the above results can be extended to problem (2.1) with boundary conditions that involve both the conormal and tangential derivatives, as long as the coefficients remain constant on each edge. We believe that Theorem 2.3 also holds for regions Ω for which $\partial\Omega_i$ are piecewise $C^{1,1}$, but this remains an open question.

3. The least-squares functional. We now turn to the construction of the least-squares functional. An appropriate scaling of the equations in (2.4) leads to

$$G_\alpha(\mathbf{u},p;f):=\alpha\|\mathbf{u}-\sqrt{a}\nabla p\|_{0,\Omega}^2+\left\|\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}+\frac{1}{\sqrt{a}}f\right\|_{0,\Omega}^2+\left\|\sqrt{a}\,\nabla\times\frac{1}{\sqrt{a}}\mathbf{u}\right\|_{0,\Omega}^2\tag{3.1}$$

and associated bilinear form

$$\begin{aligned}\mathcal{F}_\alpha((\mathbf{u},p);(\mathbf{v},q))&=\alpha\langle\mathbf{u}-\sqrt{a}\nabla p,\mathbf{v}-\sqrt{a}\nabla q\rangle_{0,\Omega}\\&\quad+\left\langle\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u},\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{v}\right\rangle_{0,\Omega}+\left\langle\sqrt{a}\,\nabla\times\frac{1}{\sqrt{a}}\mathbf{u},\sqrt{a}\,\nabla\times\frac{1}{\sqrt{a}}\mathbf{v}\right\rangle_{0,\Omega},\end{aligned}\tag{3.2}$$

where $\alpha \geq 0$ will be determined later. Here, for the sake of notational simplicity, we agree that $\langle \cdot, \cdot \rangle_{0,\Omega}$ is meant componentwise for vector functions, e.g., if $\mathbf{w} = (w_1, w_2)$ and $\mathbf{z} = (z_1, z_2)$, then

$$\langle \mathbf{w}, \mathbf{z} \rangle_{0,\Omega} = \langle w_1, z_1 \rangle_{0,\Omega} + \langle w_2, z_2 \rangle_{0,\Omega} \,.$$

The solution of (2.4) also solves the minimization problem

$$G_\alpha(\mathbf{u}, p; f) = \min_{(\mathbf{v},q)\in \mathbf{W}\times V} G_\alpha(\mathbf{v}, q; f) \tag{3.3}$$

and, therefore, the variational problem

$$\mathcal{F}_\alpha((\mathbf{u}, p); (\mathbf{v}, q)) = -\left\langle \frac{1}{\sqrt{a}} f, \frac{1}{\sqrt{a}} \nabla \cdot \sqrt{a}\mathbf{v} \right\rangle_{0,\Omega} \quad \text{for all } (\mathbf{v}, q) \in \mathbf{W} \times V\,. \tag{3.4}$$

In Theorem 3.2, we will show that $(\mathcal{F}_\alpha((\mathbf{v}, q); (\mathbf{v}, q)))^{1/2}$ is uniformly equivalent to the scaled norm defined for $(\mathbf{v}, q) \in \mathbf{W} \times V$ by

$$\begin{aligned} &|||(\mathbf{v}, q)|||_\alpha \\ &:= \left(\left\| \frac{1}{\sqrt{a}} \nabla \cdot \sqrt{a}\mathbf{v} \right\|_{0,\Omega}^2 + \left\| \sqrt{a} \nabla \times \frac{1}{\sqrt{a}} \mathbf{v} \right\|_{0,\Omega}^2 + \alpha \|\mathbf{v}\|_{0,\Omega}^2 + \alpha \|\sqrt{a} \nabla q\|_{0,\Omega}^2 \right)^{1/2} . \end{aligned} \tag{3.5}$$

Note that, for sufficiently smooth a, we get

$$|||(\mathbf{v}, q)|||_\alpha \sim \left(\|\nabla \cdot \mathbf{v}\|_{0,\Omega}^2 + \|\nabla \times \mathbf{v}\|_{0,\Omega}^2 + \alpha \|\mathbf{v}\|_{0,\Omega}^2 + \alpha \|\sqrt{a} \nabla q\|_{0,\Omega}^2 \right)^{1/2} , \tag{3.6}$$

although our assumptions on a do not admit this equivalence in general.

Before we prove the main result, we must establish a scaled Poincaré–Friedrichs inequality. By assumption, Γ_D in (2.1) is a set of positive measures on $\partial\Omega$. Thus, a standard proof can be used to establish

$$\|p\|_{0,\Omega} \leq \gamma_0 \|\nabla p\|_{0,\Omega}, \tag{3.7}$$

for $p \in V$, where γ_0 depends only on Ω. In fact, we may choose γ_0 so that (3.7) holds on any subdomain composed of a union of the Ω_i whose closure is connected and intersects Γ_D in a set of positive measure. In this sense, γ_0 depends also on the partitioning (2.7).

Instead of (3.7), we seek scaled inequalities of the form

$$\|\sqrt{a} p\|_{0,\Omega} \leq c_4 \gamma_0 \|\sqrt{a} \nabla p\|_{0,\Omega} \quad \text{and} \quad \left\| \frac{1}{\sqrt{a}} p \right\|_{0,\Omega} \leq c_5 \gamma_0 \left\| \frac{1}{\sqrt{a}} \nabla^\perp p \right\|_{0,\Omega},$$

for $p \in V$. Of course, if each subdomain is such that $\Gamma_D \cap \overline{\Omega}_i$ is of positive measure, then we may choose, for example, $c_4 = \sqrt{c_2/c_1}$ (see (2.8)). In general, c_4 and c_5 depend on $a(x_1, x_2)$ in a more complicated way that we now characterize.

For each Ω_i, there is a connected path λ_i in Ω from Γ_D to Ω_i that passes through, say, $\overline{\Omega}_{j_1}, \overline{\Omega}_{j_2}, \ldots, \overline{\Omega}_{j_k} = \overline{\Omega}_i$ $(k \leq J)$ in turn, where $\Gamma_D \cap \overline{\Omega}_{j_1}$ and $\overline{\Omega}_{j_\ell} \cap \overline{\Omega}_{j_{\ell-1}}, \ell = 2, \ldots, k$, all have positive measure. We call such a path admissible. Now, let c_1, c_2, and ω_i be as in (2.8) and define

$$C_i = \min_{\lambda_i} \max_{\ell=1,\ldots,k} \frac{\omega_i}{\omega_{j_\ell}}, \quad D_i = \min_{\lambda_i} \max_{\ell=1,\ldots,k} \frac{\omega_{j_\ell}}{\omega_i}, \tag{3.8}$$

and

$$c_4 = \sqrt{\frac{c_2}{c_1}} \max_{i=1,\ldots,J} \sqrt{C_i}, \quad c_5 = \sqrt{\frac{c_2}{c_1}} \max_{i=1,\ldots,J} \sqrt{D_i}. \tag{3.9}$$

Note that, for certain geometries, c_4 or c_5 might depend on the maximum global variation in $a(x_1, x_2)$. However, for other geometries, c_4 or c_5 may be small even for arbitrary large global a-variations. We refer to this property by saying that c_4 and c_5 are P-uniform, meaning that c_4 and c_5 depend on a-variations along the best path to Γ_D, but are otherwise independent of the jumps in a.

LEMMA 3.1. *There exists a P-uniform constant, $\gamma \in (0, \sqrt{J}\gamma_0]$, such that*

$$\|\sqrt{a}p\|_{0,\Omega} \le c_4\gamma \|\sqrt{a}\nabla p\|_{0,\Omega} \quad \textit{for all} \;\; p \in V, \tag{3.10}$$

$$\left\|\frac{1}{\sqrt{a}}p\right\|_{0,\Omega} \le c_5\gamma \left\|\frac{1}{\sqrt{a}}\nabla^{\perp} p\right\|_{0,\Omega} \quad \textit{for all} \;\; p \in V, \tag{3.11}$$

where c_4 and c_5 are the P-uniform constants defined in (3.9).

Proof. Choose Ω_i and any of its admissible paths. By (3.7), we have

$$\sum_{\ell=1}^{k} \|p\|^2_{0,\Omega_{j_\ell}} \le \gamma_0^2 \sum_{\ell=1}^{k} \|\nabla p\|^2_{0,\Omega_{j_\ell}}.$$

In particular,

$$\|p\|^2_{0,\Omega_i} \le \gamma_0^2 \sum_{\ell=1}^{k} \|\nabla p\|^2_{0,\Omega_{j_\ell}}.$$

From (2.8), we have

$$\begin{aligned} \|\sqrt{a}p\|^2_{0,\Omega_i} &\le c_2\omega_i \|p\|^2_{0,\Omega_i} \le c_2\omega_i\gamma_0^2 \sum_{\ell=1}^{k} \|\nabla p\|^2_{0,\Omega_{j_\ell}} \\ &= c_2\gamma_0^2 \sum_{\ell=1}^{k} \frac{\omega_i}{\omega_{j_\ell}} \omega_{j_\ell} \|\nabla p\|^2_{0,\Omega_{j_\ell}} \le \frac{c_2}{c_1}\gamma_0^2 C_i \sum_{\ell=1}^{k} \|\sqrt{a}\nabla p\|^2_{0,\Omega_{j_\ell}}. \end{aligned}$$

Summation over i now yields (3.10) with $\gamma \le \sqrt{J}\gamma_0$. The proof of (3.11) is analogous. □

THEOREM 3.2. *If we choose $\alpha \le 1/c_4^2$, where c_4 is defined in* (3.9), *then there exist P-uniform constants γ_1 and γ_2 such that*

$$\mathcal{F}_\alpha((\mathbf{u}, p); (\mathbf{u}, p)) \ge \gamma_1 |||(\mathbf{u}, p)|||^2_\alpha \quad \textit{for all } (\mathbf{u}, p) \in \mathbf{W} \times V, \tag{3.12}$$

and

$$\mathcal{F}_\alpha((\mathbf{u}, p); (\mathbf{v}, q)) \le \gamma_2 |||(\mathbf{u}, p)|||_\alpha \; |||(\mathbf{v}, q)|||_\alpha \quad \textit{for all } (\mathbf{u}, p)\,, \, (\mathbf{v}, q) \in \mathbf{W} \times V. \tag{3.13}$$

Proof. The proof is similar to the proof of [11, Theorem 3.1] (see also [27, Theorems 2.1 and 2.2]). We include it here because we must confirm that the constants γ_1 and γ_2 are P-uniform. The main part of the proof consists of showing that the functionals

$$\hat{\mathcal{F}}_\alpha((\mathbf{u}, p); (\mathbf{v}, q)) := \alpha\langle \mathbf{u} - \sqrt{a}\nabla p, \mathbf{v} - \sqrt{a}\nabla q\rangle_{0,\Omega} + \left\langle \frac{1}{\sqrt{a}}\nabla \cdot \sqrt{a}\mathbf{u}, \frac{1}{\sqrt{a}}\nabla \cdot \sqrt{a}\mathbf{v} \right\rangle_{0,\Omega}$$

and

$$\hat{\mathcal{S}}_\alpha(\mathbf{u},p;\mathbf{v},q) := \alpha\langle \mathbf{u},\mathbf{v}\rangle_{0,\Omega} + \alpha\langle \sqrt{a}\nabla p, \sqrt{a}\nabla q\rangle_{0,\Omega} + \left\langle \frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}, \frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{v}\right\rangle_{0,\Omega}$$

satisfy

$$C_1\hat{\mathcal{S}}_\alpha(\mathbf{u},p;\mathbf{u},p) \le \hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{u},p)) \tag{3.14}$$

and

$$\hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{v},q)) \le C_2(\hat{\mathcal{S}}_\alpha(\mathbf{u},p;\mathbf{u},p))^{1/2}(\hat{\mathcal{S}}_\alpha(\mathbf{v},q;\mathbf{v},q))^{1/2}, \tag{3.15}$$

with constants C_1 and C_2 that are P-uniform. Since on $\partial\Omega$ we either have $p = 0$ or $\mathbf{n}\cdot\sqrt{a}\mathbf{u} = 0$, then integration by parts confirms that

$$\langle \mathbf{u}, \sqrt{a}\nabla p\rangle_{0,\Omega} + \langle \nabla\cdot\sqrt{a}\mathbf{u}, p\rangle_{0,\Omega} = 0.$$

For any $\beta > 0$, which we specify later, we have

$$\begin{aligned}
\hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{u},p)) &= \alpha\langle \mathbf{u},\mathbf{u}\rangle_{0,\Omega} + \alpha\langle \sqrt{a}\nabla p, \sqrt{a}\nabla p\rangle_{0,\Omega} - 2\alpha\langle \mathbf{u}, \sqrt{a}\nabla p\rangle_{0,\Omega}\\
&\quad + \left\langle \frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}, \frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}\right\rangle_{0,\Omega} + 2\alpha\beta\langle \nabla\cdot\sqrt{a}\mathbf{u}, p\rangle_{0,\Omega}\\
&\quad + 2\alpha\beta\langle \mathbf{u}, \sqrt{a}\nabla p\rangle_{0,\Omega} + \alpha^2\beta^2\langle \sqrt{a}p, \sqrt{a}p\rangle_{0,\Omega} - \alpha^2\beta^2\langle \sqrt{a}p, \sqrt{a}p\rangle_{0,\Omega}\\
&= \alpha\langle \mathbf{u} + (\beta-1)\sqrt{a}\nabla p, \mathbf{u} + (\beta-1)\sqrt{a}\nabla p\rangle_{0,\Omega}\\
&\quad + \left\langle \frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u} + \alpha\beta\sqrt{a}p, \frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u} + \alpha\beta\sqrt{a}p\right\rangle_{0,\Omega}\\
&\quad + \alpha(2\beta-\beta^2)\langle \sqrt{a}\nabla p, \sqrt{a}\nabla p\rangle_{0,\Omega} - \alpha^2\beta^2\langle \sqrt{a}p, \sqrt{a}p\rangle_{0,\Omega}\\
&\ge \alpha(2\beta-\beta^2)\langle \sqrt{a}\nabla p, \sqrt{a}\nabla p\rangle_{0,\Omega} - \alpha^2\beta^2\langle \sqrt{a}p, \sqrt{a}p\rangle_{0,\Omega}\\
&\ge \alpha(2\beta - (1+\gamma^2)\beta^2)\|\sqrt{a}\nabla p\|^2_{0,\Omega}\,,
\end{aligned}$$

where we used the assumption that $\alpha \le 1/c_4^2$ and where γ is from Lemma 3.1. Choosing $\beta = 1/(1+\gamma^2)$ leads to

$$\hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{u},p)) \ge \beta\alpha\|\sqrt{a}\nabla p\|^2_{0,\Omega}\,.$$

We then also have

$$\alpha\|\mathbf{u}\|^2_{0,\Omega} \le 2\alpha(\|\mathbf{u} - \sqrt{a}\nabla p\|^2_{0,\Omega} + \|\sqrt{a}\nabla p\|^2_{0,\Omega}) \le 2\left(1 + \frac{1}{\beta}\right)\hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{u},p))$$

and, clearly,

$$\left\|\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}\right\|^2_{0,\Omega} \le \hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{u},p)),$$

which completes the proof of (3.14). □

Upper bound (3.15) follows from

$$\hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{v},q)) \le 2(\hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{u},p)))^{1/2}(\hat{\mathcal{F}}_\alpha((\mathbf{v},q);(\mathbf{v},q)))^{1/2}$$

and

$$
\begin{aligned}
\hat{\mathcal{F}}_\alpha((\mathbf{u},p);(\mathbf{u},p)) &= \alpha\|\mathbf{u}-\sqrt{a}\nabla p\|_{0,\Omega}^2 + \left\|\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}\right\|_{0,\Omega}^2 \\
&\le 2\left(\alpha\|\mathbf{u}\|_{0,\Omega}^2 + \alpha\left\|\sqrt{a}\nabla p\right\|_{0,\Omega}^2 + \left\|\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}\right\|_{0,\Omega}^2\right) \qquad (3.16)\\
&= 2\hat{\mathcal{S}}_\alpha(\mathbf{u},p;\mathbf{u},p).
\end{aligned}
$$

The proof of Theorem 3.2 is completed by adding the term $\|\sqrt{a}\nabla\times(\mathbf{u}/\sqrt{a})\|_{0,\Omega}^2$ to both sides of inequalities (3.14) and (3.16). □

Theorem 3.2 establishes coercivity and continuity of the least-squares bilinear form $\mathcal{F}_\alpha((\cdot,\cdot);(\cdot,\cdot))$ in terms of the norm $|||(\cdot,\cdot)|||_\alpha$. This norm equivalence depends on the jumps in a along the best path to the Dirichlet boundary, but is otherwise independent of the jumps in a.

The scaling of the norm $|||(\cdot,\cdot)|||_\alpha$ has the following physical interpretation. Focusing first on p, imagine that the error q as measured by the term $\|\sqrt{a}\nabla q\|_{0,\Omega}^2$ is balanced over the domain; that is, $\sqrt{a}\nabla q$ is roughly constant. Then, in areas where $\sqrt{a}$ is relatively small, ∇q is correspondingly relatively large, and one has to expect a less accurate approximation (in the L^2 sense) there compared to areas where $\sqrt{a}$ is large and ∇q is therefore small. In contrast, approximation of the velocity $\mathbf{u}=\sqrt{a}\nabla p$ (assuming the error $\mathbf{v}$ is balanced in the sense of the term $|\mathbf{v}|_{1,\Omega}^2+\alpha\|\mathbf{v}\|_{0,\Omega}^2$; see (3.6)) can be expected to have balanced accuracy (in the L^2 sense) over Ω. Ellipticity with constants that are independent of the global jumps in a asserts that the scaling in $\mathcal{F}_\alpha((\cdot,\cdot);(\cdot,\cdot))$ correctly reflects these attributes.

Uniform coercivity and continuity of $\mathcal{F}$ in the norm $|||(\cdot,\cdot)|||_\alpha$ allows for effective computation of $\mathbf{u}$ and p together by finite element and multigrid techniques. Notice that the result is valid for all $\alpha\in[0,1/c_4^2]$. Proof of Theorem 3.2 for the case $\alpha=0$ is trivial, with $\gamma_1=\gamma_2=1$. Moreover, this choice reveals a perhaps simpler alternative: we can use a two-stage approach (cf. [13]) that first minimizes the flux-only functional,

$$
G_0(\mathbf{u};f) = \left\|\frac{1}{\sqrt{a}}(\nabla\cdot\sqrt{a}\mathbf{u}+f)\right\|_{0,\Omega}^2 + \left\|\sqrt{a}\,\nabla\times\left(\frac{\mathbf{u}}{\sqrt{a}}\right)\right\|_{0,\Omega}^2, \qquad (3.17)
$$

over $\mathbf{u}\in\mathbf{W}$, then fixes $\mathbf{u}/\sqrt{\mathbf{a}}$ and minimizes the Poisson functional,

$$
G_P\left(p;\frac{\mathbf{u}}{\sqrt{a}}\right) = \left\|\nabla p - \frac{\mathbf{u}}{\sqrt{a}}\right\|_{0,\Omega}^2,
$$

over $p\in V$. The efficacy of this two-stage approach is confirmed by the uniform coercivity and continuity of $G_P(p;0)$ in the $H^1(\Omega)$ seminorm $\|\nabla p\|_{0,\Omega}^2$, which by (3.7) is itself a norm on V, and of $G_1(\mathbf{u};0)$ in the $\mathbf{W}$ seminorm as defined in (2.6), which we now demonstrate is a norm on $\mathbf{W}$ by establishing a Poincaré–Friedrichs inequality.

LEMMA 3.3. *We have*

$$
\|\mathbf{u}\|_{0,\Omega} \le c_6\gamma|\mathbf{u}|_{\mathbf{W}} \quad \textit{for all} \quad \mathbf{u}\in\mathbf{W}, \qquad (3.18)
$$

where $c_6=\max\{c_4,c_5\}$ *(see* 3.9*) and* γ *is from Lemma* 3.1.

Proof. Consider a Helmholtz decomposition on $\mathbf{W}$: for $\mathbf{u}\in\mathbf{W}$, there exist p, $\psi\in H^1(\Omega)$ such that

$$
\mathbf{u} = \sqrt{a}\nabla p + \frac{1}{\sqrt{a}}\nabla^\perp\psi, \qquad (3.19)
$$

where p is unique the solution of (2.1) with $f = -\nabla \cdot \sqrt{a}\mathbf{u}$ and ψ is the unique (up to a constant) solution of

$$\begin{aligned} -\nabla \cdot \left(\frac{1}{a}\nabla\psi\right) &= -\nabla \times \frac{1}{\sqrt{a}}\mathbf{u} && \text{in } \Omega, \\ \psi &= C_i && \text{on } \Gamma_{N_i}, \\ \mathbf{n} \cdot \frac{1}{a}\nabla\psi &= 0 && \text{on } \Gamma_D, \end{aligned} \tag{3.20}$$

where C_i are arbitrary constants, one of which may be set to zero. Since $\mathbf{u} \in \mathbf{W}$, it satisfies the integral constraints

$$\int_{\Gamma_{N_i}} \boldsymbol{\tau} \cdot \frac{1}{\sqrt{a}}\mathbf{u} = 0$$

for each disjoint piece of Γ_N. Thus, we may set the constants $C_i = 0$, and (3.20) will have a unique solution.

Note that the decomposition is orthogonal in the L^2 sense:

$$\left\langle \sqrt{a}\nabla p,\, \frac{1}{\sqrt{a}}\nabla^\perp\psi \right\rangle_{0,\Omega} = 0. \tag{3.21}$$

We thus have

$$\|\mathbf{u}\|_{0,\Omega}^2 = \|\sqrt{a}\nabla p\|_{0,\Omega}^2 + \left\|\frac{1}{\sqrt{a}}\nabla^\perp\psi\right\|_{0,\Omega}^2. \tag{3.22}$$

Now,

$$-\nabla \cdot a\nabla p = -\nabla \cdot \sqrt{a}\mathbf{u},$$

so that, using (3.10),

$$\begin{aligned} \|\sqrt{a}\nabla p\|_{0,\Omega}^2 &= \langle -\nabla \cdot a\nabla p,\, p\rangle_{0,\Omega} \\ &= \langle -\nabla \cdot \sqrt{a}\mathbf{u},\, p\rangle_{0,\Omega} \\ &= \left\langle -\frac{1}{\sqrt{a}}\nabla \cdot \sqrt{a}\mathbf{u},\, \sqrt{a}p \right\rangle_{0,\Omega} \\ &\le \left\|\frac{1}{\sqrt{a}}\nabla \cdot \sqrt{a}\mathbf{u}\right\|_{0,\Omega} \|\sqrt{a}p\|_{0,\Omega} \\ &\le c_4\gamma \left\|\frac{1}{\sqrt{a}}\nabla \cdot \sqrt{a}\mathbf{u}\right\|_{0,\Omega} \|\sqrt{a}\nabla p\|_{0,\Omega}, \end{aligned}$$

which yields

$$\|\sqrt{a}\nabla p\|_{0,\Omega} \le c_4\gamma \left\|\frac{1}{\sqrt{a}}\nabla \cdot \sqrt{a}\mathbf{u}\right\|_{0,\Omega}. \tag{3.23}$$

Similarly, using (3.11),

$$\begin{aligned}\left\|\frac{1}{\sqrt{a}}\nabla^{\perp}\psi\right\|^2_{0,\Omega} &= \left\langle -\nabla\times\frac{1}{a}\nabla^{\perp}\psi,\, \psi\right\rangle_{0,\Omega}\\ &= \left\langle -\nabla\times\frac{1}{\sqrt{a}}\mathbf{u},\, \psi\right\rangle_{0,\Omega}\\ &= \left\langle -\sqrt{a}\nabla\times\frac{1}{\sqrt{a}}\mathbf{u},\, \frac{1}{\sqrt{a}}\psi\right\rangle_{0,\Omega}\\ &\le \left\|\sqrt{a}\nabla\times\frac{1}{\sqrt{a}}\mathbf{u}\right\|_{0,\Omega}\left\|\frac{1}{\sqrt{a}}\psi\right\|_{0,\Omega}\\ &\le c_5\gamma\left\|\sqrt{a}\nabla\times\frac{1}{\sqrt{a}}\mathbf{u}\right\|_{0,\Omega}\left\|\frac{1}{\sqrt{a}}\nabla^{\perp}\psi\right\|_{0,\Omega},\end{aligned}$$

which yields

$$\left\|\frac{1}{\sqrt{a}}\nabla^{\perp}\psi\right\|_{0,\Omega} \le c_5\gamma\left\|\sqrt{a}\nabla\times\frac{1}{\sqrt{a}}\mathbf{u}\right\|_{0,\Omega}. \tag{3.24}$$

The result now follows from (3.22)–(3.24), where $c_6 = \max\{c_4, c_5\}$. □

For simplicity of discussion, the following sections focus on the two-stage approach described above.

4. Scaled div-curl operator. We are now in a position to define the scaled div-curl operator and develop some tools that will aid in the proof of the decomposition of $\mathbf{W}$ in the next section. Define $\mathcal{L} : \mathbf{W} \to (L^2(\Omega))^2$ as follows:

$$\mathcal{L} := \begin{bmatrix} \frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a} \\ \\ \sqrt{a}\nabla\times\frac{1}{\sqrt{a}} \end{bmatrix}, \tag{4.1}$$

with domain $\mathcal{D}(\mathcal{L}) = \mathbf{W}$. It is straightforward to verify that the adjoint of $\mathcal{L}$ is given by

$$\mathcal{L}^* := -\left[\sqrt{a}\nabla\frac{1}{\sqrt{a}},\ \frac{1}{\sqrt{a}}\nabla^{\perp}\sqrt{a}\right], \tag{4.2}$$

with domain

(4.3)

$$\mathcal{D}(\mathcal{L}^*) := \left\{\mathbf{q}\ :\ \left(\frac{1}{\sqrt{a}}q_1,\, \sqrt{a}q_2\right)^t \in (H^1(\Omega))^2,\, q_1 = 0\ \text{ on }\ \Gamma_D,\, q_2 = C_i \text{ on } \Gamma_{N_i}\right\},$$

where C_i are arbitrary constants, one of which may be set to zero. We summarize properties of $\mathcal{L}$ and $\mathcal{L}^*$ in the following lemma.

LEMMA 4.1. *The operator $\mathcal{L}$ is continuous and coercive on $\mathbf{W}$, the range $\mathcal{R}(\mathcal{L})$ is closed in $(L^2(\Omega))^2$, and*

$$\mathcal{R}(\mathcal{L})^{\perp} = \mathcal{N}(\mathcal{L}^*) = \left\{\begin{pmatrix} 0 \\ \frac{1}{\sqrt{a}}\end{pmatrix}\right\}.$$

Proof. The first result follows directly from Lemma 3.3. For the second result, note for $\mathbf{u} \in \mathbf{W}$ we have

$$\|\mathbf{u}\|_{\mathbf{W}} \le (c_6\gamma + 1)|\mathbf{u}|_{\mathbf{W}} = \|\mathcal{L}\mathbf{u}\| \le \|\mathbf{u}\|_{\mathbf{W}}, \tag{4.4}$$

which implies that $\mathcal{R}(\mathcal{L})$ is closed in $(L^2(\Omega))^2$. For the last result, note for $\mathbf{u} \in \mathbf{W}$ that

$$\left\langle \frac{1}{\sqrt{a}}\nabla \cdot \sqrt{a}\mathbf{u},\, 0 \right\rangle + \left\langle \sqrt{a}\nabla \times \frac{1}{\sqrt{a}}\mathbf{u},\, \frac{1}{\sqrt{a}} \right\rangle = \int\int_{\Omega} \nabla \times \frac{1}{\sqrt{a}}\mathbf{u} = \oint \boldsymbol{\tau} \cdot \frac{1}{\sqrt{a}}\mathbf{u} = 0.$$

The last equality follows from the boundary conditions imposed on $\mathbf{u}$. Thus, $(0,\, \frac{1}{\sqrt{a}})^t \in \mathcal{R}(\mathcal{L})^{\perp} = \mathcal{N}(\mathcal{L}^*)$.

To show that this function spans $\mathcal{N}(\mathcal{L}^*)$, suppose that $\mathbf{q} \in \mathcal{D}(\mathcal{L}^*)$ satisfies

$$-\mathcal{L}^*\mathbf{q} = \sqrt{a}\nabla \frac{1}{\sqrt{a}} q_1 + \frac{1}{\sqrt{a}}\nabla^{\perp}\sqrt{a} q_2 = \mathbf{0}. \tag{4.5}$$

Let $p_1 = q_1/\sqrt{a}$, $p_2 = \sqrt{a}q_2$. From the boundary conditions on $\mathbf{q}$ and (4.5), we see that

$$\mathbf{n} \cdot \sqrt{a}\nabla p_1 = \mathbf{n} \cdot \left(\sqrt{a}\nabla p_1 + \frac{1}{\sqrt{a}}\nabla^{\perp} p_2 \right) = 0 \qquad \text{on } \Gamma_N. \tag{4.6}$$

Since $\frac{1}{\sqrt{a}}\nabla^{\perp} p_2 \in H(\operatorname{div} a; \Omega)$, then $\sqrt{a}\nabla p_1 \in H(\operatorname{div} a; \Omega)$. Thus, p_1 satisfies (2.1) with homogeneous data, which implies that $p_1 = 0$. This leaves $\nabla^{\perp} p_2 = 0$, which implies $p_2 = C$ and finally $q_2 = \frac{C}{\sqrt{a}}$ for some arbitrary constant C. Since this is the only solution of (4.5), the result is proved. □

Next, we define the restriction of $\mathcal{L}$ to $\mathbf{W}^1_S$:

$$\widehat{\mathcal{L}} := \mathcal{L}|_{\mathbf{W}^1_S}. \tag{4.7}$$

Since $\widehat{\mathcal{L}} \subseteq \mathcal{L}$, we know that $\mathcal{L}^* \subseteq \widehat{\mathcal{L}}^*$; that is,

$$\mathcal{D}(\widehat{\mathcal{L}}^*) = \left\{ \mathbf{q} \in (L^2(\Omega))^2 \ : \ \mathcal{L}^*\mathbf{q} \in (L^2(\Omega))^2,\, q_1 = 0 \text{ on } \Gamma_D,\, q_2 = C_i \text{ on } \Gamma_{N_i} \right\}. \tag{4.8}$$

This larger definition of $\mathcal{D}(\widehat{\mathcal{L}}^*)$ will be important in proving the decomposition in the next section. Finally, we have the following result.

LEMMA 4.2. *Subspace* $\mathbf{W}^1_S$ *is closed in* $\mathbf{W}$ *and* $\mathcal{R}(\widehat{\mathcal{L}}) \subseteq \mathcal{R}(\mathcal{L})$ *are both closed in* $(L^2(\Omega))^2$.

Proof. The result is an immediate consequence of Theorem 2.3, Corollary 2.4, and Lemma 4.1. □

5. Solution decomposition. Here, we introduce a splitting of the flux space $\mathbf{W}$ into a finite-dimensional space spanned by singular functions and locally smooth functions, that is, functions that are $H^1_S(\Omega)$. As a result, the flux $\mathbf{u}$ can be discretized as the sum of singular basis functions and standard basis functions that satisfy the interface conditions. This splitting provides the foundation for the finite element method that we present in [3]. For a detailed description of the finite element spaces, see also [2].

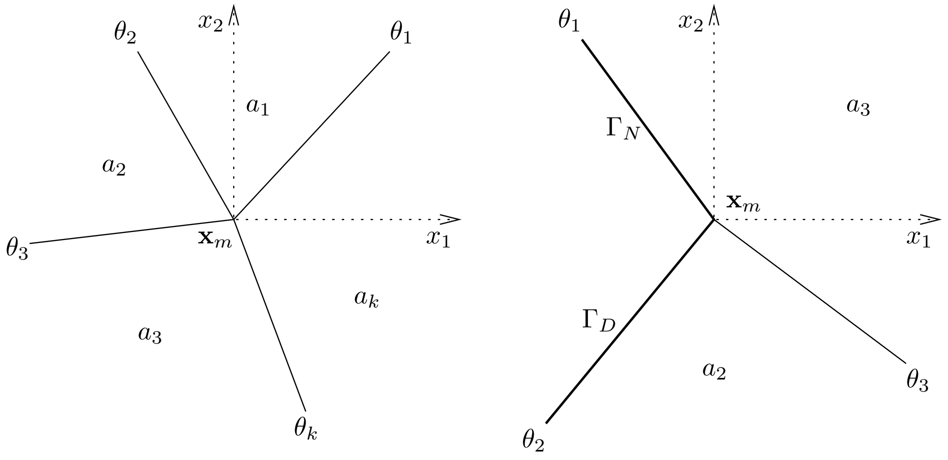

FIG. 5.1. *Cross point (on the left, $K = 4$), and boundary cross point (on the right, $K = 3$).*

In this context, a singular function is any function $\mathbf{u} \in \mathbf{W}$ such that $\mathbf{u} \notin \mathbf{W}^1_S(\Omega)$. This leads to a decomposition of any $\mathbf{u} \in \mathbf{W}$ as

$$\mathbf{u} = \mathbf{u}_0 + \sum_{m=1}^{M} \sum_{n=1}^{N_m} b_{m,n}\mathbf{s}_{m,n}, \tag{5.1}$$

where $\mathbf{u}_0 \in \mathbf{W}^1_S$, and $\mathbf{s}_{m,n}$, $n = 1, \ldots, N_m$, are singular functions associated with singular points $\mathbf{x}_m$, $m = 1, \ldots, M$.

This decomposition will be established, following the development in Kellogg [24] and Grisvard [19], by demonstrating a linearly independent set of functions $\mathbf{s}_{m,n} \in \mathbf{W}\backslash\mathbf{W}^1_S$ and then using a counting argument to show that they span all of $\mathbf{W}\backslash\mathbf{W}^1_S$. In fact, we will demonstrate two sets of functions, one associated with singular solutions of (2.1) and the other associated with singular solutions of (3.20), and show that they span the same space. The fact that they span the same space will be essential to the counting argument.

We first examine singular functions of the original equation (2.1). A singular function of (2.1) is a function $p \in H^1(\Omega) \setminus H^2_S(\Omega)$ for which $\nabla \cdot a\nabla p \in L^2(\Omega)$. As described in the introduction, singular points are associated with cross points, boundary cross points, reentrant corners, and irregular boundary points.

We begin with interior singular points. Boundary singular points are handled in a similar manner. First, we restrict our attention to the ball of radius R, call it $B_m(R)$, centered at the singular point $\mathbf{x}_m$ that contains no other singular points, and we establish a polar coordinate system (r, θ) centered at $\mathbf{x}_m$. For example, consider Figure 5.1. Denote the angle of the boundaries between segments to the positive x_1-axis by θ_i for $i = 1, \ldots, K$. In the following, we use the convention that $\theta_{-1} = \theta_K$ and $\theta_{K+1} = \theta_1$.

We seek solutions of the homogeneous equation

$$\nabla \cdot a\nabla p = \partial_r a\partial_r p + \frac{1}{r}a\partial_r p + \frac{1}{r^2}\partial_\theta a\partial_\theta p = 0 \tag{5.2}$$

in $B_m(R)$. Substituting $p = r^\alpha T(\theta)$ and dividing by $r^{\alpha-2}$ yields the problem

$$-(aT_\theta(\theta))_\theta = (a\alpha^2 + ra_r\alpha)T(\theta). \tag{5.3}$$

Here, we make the additional assumption on a that, within each segment, $\lim_{r\to 0} a_\theta = 0$. Since it was assumed above that $a \in C^{1,1}(\Omega_i)$ for each subdomain Ω_i, we also know that $\lim_{r\to 0} r a_r = 0$. Thus, we may substitute the value

$$\tilde{a}_i = \lim_{r\to 0} a(r,\theta) \qquad \text{in} \quad \Omega_i. \tag{5.4}$$

With this replacement, (5.3) now becomes the the Sturm–Liouville eigenvalue problem

$$-(\tilde{a}T')' = \tilde{a}\alpha^2 T \quad \text{on } [0, 2\pi). \tag{5.5}$$

Solutions of this equation are of the form

$$T_n(\theta) = A_{n,i}\cos(\alpha_n(\theta-\theta_i)) + B_{n,i}\sin(\alpha_n(\theta-\theta_i)), \tag{5.6}$$

for $\theta \in (\theta_i, \theta_{i+1})$, with corresponding eigenvalue

$$\lambda_n = \alpha_n^2. \tag{5.7}$$

The singular functions we seek are constructed by choosing only those $\alpha_n \in (0,1)$ for, say, $n = 1, \ldots, N_m$. Note that for any solution with $\alpha = \alpha_n \in (0,1)$, there is a solution with $\alpha = -\alpha_n \in (-1,0)$. These solutions will be important in the counting argument.

Now, let $\tilde{\delta}_m(r) \in H^2(0,R)$ be a smooth cut-off function that is equal to 1 for $r \in (0, R/2)$ and drops to 0 for $r \in (R/2, R)$. It is easy to see that

$$s_{m,n} := \tilde{\delta}_m(r) r^{\alpha_n} T_n(\theta) \tag{5.8}$$

is in the domain of boundary value problem (2.1). Moreover, for any cut-off function $\delta_m \in H^1(0,R)$, we see that

$$\mathbf{s}_{m,n} := \delta_m(r)\sqrt{a}\nabla r^{\alpha_n} T_n(\theta) \in \mathbf{W} \setminus \mathbf{W}_S^1. \tag{5.9}$$

The exponent α and the coefficients (A_i, B_i) can be determined by enforcing continuity of both $T(\theta)$ and $aT'(\theta)$ across interfaces. (We have dropped the first subscript for convenience.) This may be expressed as

$$\begin{bmatrix} 1 & 0 \\ 0 & -\tilde{a}_i \end{bmatrix} \begin{pmatrix} A_i \\ B_i \end{pmatrix} = \begin{bmatrix} \cos(\alpha(\theta_i-\theta_{i-1})) & \sin(\alpha(\theta_i-\theta_{i-1})) \\ \tilde{a}_{i-1}\sin(\alpha(\theta_i-\theta_{i-1})) & -\tilde{a}_{i-1}\cos(\alpha(\theta_i-\theta_{i-1})) \end{bmatrix} \begin{pmatrix} A_{i-1} \\ B_{i-1} \end{pmatrix}, \tag{5.10}$$

for $i = 1, \ldots, K$. Divide the second equation by $\tilde{a}_{i-1}$, define $\delta_i := \tilde{a}_i/\tilde{a}_{i-1}$ and

$$D_i := \begin{bmatrix} 1 & 0 \\ 0 & -\delta_i \end{bmatrix}, \qquad C_i := \begin{bmatrix} \cos(\alpha(\theta_i-\theta_{i-1})) & \sin(\alpha(\theta_i-\theta_{i-1})) \\ \sin(\alpha(\theta_i-\theta_{i-1})) & -\cos(\alpha(\theta_i-\theta_{i-1})) \end{bmatrix}, \tag{5.11}$$

and finally define $\underline{\beta}_i := (A_i, B_i)^t$. Then, the above constraints may be expressed by the homogeneous system

$$M\underline{b} = \begin{bmatrix} D_1 & 0 & \cdots & C_K \\ -C_1 & D_2 & \cdots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & \cdots & -C_{K-1} & D_K \end{bmatrix} \begin{pmatrix} \underline{\beta}_1 \\ \underline{\beta}_2 \\ \vdots \\ \underline{\beta}_K \end{pmatrix} = \begin{pmatrix} \underline{0} \\ \underline{0} \\ \vdots \\ \underline{0} \end{pmatrix}. \tag{5.12}$$

A nontrivial solution exists only when the determinant of M is zero. The corresponding null vector yields the coefficients.

We now turn our attention to singular solutions of the boundary value problem (3.20). In $B_m(R)$ we seek solutions to the homogeneous problem

$$\nabla \cdot \frac{1}{a} \nabla p = 0. \tag{5.13}$$

Following the same arguments, we are led to the Sturm–Liouville eigenvalue problem

$$-\left(\frac{1}{\tilde{a}}\hat{T}'\right)' = \frac{1}{\tilde{a}}\alpha^2 \hat{T} \quad \text{on } [0, 2\pi) \tag{5.14}$$

and solutions of the form

$$\hat{T}_n(\theta) = \hat{A}_{n,i}\cos(\alpha_n(\theta - \theta_i)) + \hat{B}_{n,i}\sin(\alpha_n(\theta - \theta_i)), \tag{5.15}$$

for $\theta \in (\theta_i, \theta i + 1)$.

Again, we choose only those $\alpha_n \in (0, 1)$. With $\tilde{\delta}(r) \in H^2(0, R)$, solutions of this Sturm–Liouville problem yield

$$\hat{s}_{m,n} = \tilde{\delta}_m(r) r^{\alpha_n} \hat{T}_n(\theta) \tag{5.16}$$

in the domain of boundary value problem (3.20) and, with $\delta_m \in H^1(0, R)$,

$$\hat{\mathbf{s}}_{m,n} = \delta_m(r)\frac{1}{\sqrt{a}}\nabla^{\perp} r^{\alpha_n}\hat{T}_n(\theta) \in \mathbf{W} \setminus \mathbf{W}^1_S. \tag{5.17}$$

It would appear that there are at least two families of singular function in $\mathbf{W}\backslash\mathbf{W}^1_S$. We now show that they are in fact the same family. To see this, first notice that the only change to the continuity constraints (5.10) is that $\tilde{a}_i$, $\tilde{a}_{i-1}$ are replaced by $1/\tilde{a}_i$ and $1/\tilde{a}_{i-1}$ respectively, which results in replacing D_i by D_i^{-1}. Thus, with the definition $\underline{\hat{\beta}}_i := (\hat{A}_i, \hat{B}_i)$ and similar notation for the other variables, the homogeneous system (5.12) becomes

$$\hat{M}\underline{\hat{b}} := \begin{bmatrix} D_1^{-1} & 0 & \cdots & C_K \\ -C_1 & D_2^{-1} & \cdots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & \cdots & -C_{K-1} & D_K^{-1} \end{bmatrix} \begin{pmatrix} \underline{\hat{\beta}}_1 \\ \underline{\hat{\beta}}_2 \\ \vdots \\ \underline{\hat{\beta}}_K \end{pmatrix} = \begin{pmatrix} \underline{0} \\ \underline{0} \\ \vdots \\ \underline{0} \end{pmatrix}. \tag{5.18}$$

We now show that $\det M = \det(\hat{M})$. Define the 2×2 rotation

$$Q_2 = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \tag{5.19}$$

and notice that $Q_2^t Q_2 = I_2, Q_2 C_i Q_2 = C_i$, and

$$Q_2 D_i Q_2 = \begin{bmatrix} \delta_i & 0 \\ 0 & -1 \end{bmatrix} = \delta_i D_i^{-1}. \tag{5.20}$$

Note that $\det(Q_2) = -1$ and define the $2K \times 2K$ block diagonal matrix $Q = \operatorname{diag}(Q_2, Q_2, \ldots, Q_2)$. This yields

$$QMQ = \begin{bmatrix} \delta_1 D_1^{-1} & 0 & \cdots & C_K \\ -C_1 & \delta_2 D_2^{-1} & \cdots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & \cdots & -C_{K-1} & \delta_K D_K^{-1} \end{bmatrix}. \tag{5.21}$$

Next, define the $2K \times 2K$ block matrices

$$\begin{aligned} \Delta_1 &:= \operatorname{diag}(\tilde{a}_1 I_2, \tilde{a}_2 I_2, \ldots, \tilde{a}_K I_2), \\ \Delta_2 &:= \operatorname{diag}(\tilde{a}_K I_2, \tilde{a}_1 I_2, \ldots, \tilde{a}_{K-1} I_2). \end{aligned}$$

We can now establish

$$\Delta_2 QMQ \Delta_1^{-1} = \hat{M}, \tag{5.22}$$

which yields

$$\det(\hat{M}) = \det(\Delta_1)\det(\Delta_2^{-1})\det(Q)^2\det(M) = \det(M). \tag{5.23}$$

Let $\alpha_n \in (0,1)$ be a root of $\det(M) = 0$, and consider the associated null vector $M\underline{b}_n = 0$. Using the above relationships, we have

$$0 = (\Delta_2 QM)\underline{b}_n = (\Delta_2 QMQ\Delta_1^{-1})(\Delta_1 Q^t \underline{b}_n) = \hat{M}(\Delta_1 Q^t \underline{b}_n). \tag{5.24}$$

Thus, $\hat{b}_n = (\Delta_1 Q^t \underline{b}_n)$ is the corresponding null vector of $\hat{M}$, which yields

$$\begin{pmatrix} \hat{A}_{n,i} \\ \hat{B}_{n,i} \end{pmatrix} = \tilde{a}_i \begin{pmatrix} -B_{n,i} \\ A_{n,i} \end{pmatrix}. \tag{5.25}$$

For convenience, define

$$\phi_n(r,\theta) = r^{\alpha_n}\left(A_{n,i}\cos(\alpha_n(\theta-\theta_i)) + B_{n,i}\sin(\alpha_n(\theta-\theta_i))\right), \tag{5.26}$$

$$\psi_n(r,\theta) = r^{\alpha_n}(\hat{A}_{n,i}\cos(\alpha_n(\theta-\theta_i)) + \hat{B}_{n,i}\sin(\alpha_n(\theta-\theta_i))), \tag{5.27}$$

for $\theta \in (\theta_i, \theta_{i+1})$. Recall that

$$\nabla = \begin{pmatrix} \partial_1 \\ \partial_2 \end{pmatrix} = \begin{bmatrix} \cos(\theta) & -\frac{1}{r}\sin(\theta) \\ \sin(\theta) & \frac{1}{r}\cos(\theta) \end{bmatrix} \begin{pmatrix} \partial_r \\ \partial_\theta \end{pmatrix} \tag{5.28}$$

and that $\nabla^\perp = Q_2^t \nabla$. Using (5.25), (5.26), and (5.28), it is a simple matter to confirm that

$$\sqrt{a}\nabla\phi_n = \frac{1}{\sqrt{a}}\nabla^\perp\psi_n. \tag{5.29}$$

Boundary singular points are handled in a similar fashion. Now, instead of periodic boundary conditions, the Sturm–Liouville problem (5.5) would require $T(\theta) = 0$ for θ corresponding to a boundary segment in Γ_D, and $T'(\theta) = 0$ for θ corresponding to Γ_N, while problem (5.14) would reverse the roles. It is straightforward to verify that the relationship (5.29) holds for these singular functions as well.

We summarize the above discussion and complete the proof of the decomposition (5.1) in the following theorem.

THEOREM 5.1. *Every* $\mathbf{u} \in \mathbf{W}$ *has a unique decomposition*

$$\mathbf{u} = \mathbf{u}_0 + \sum_{m=1}^{M} \sum_{n=1}^{N_m} b_{m,n} \mathbf{s}_{m,n},$$

where $\mathbf{u}_0 \in \mathbf{W}_S^1$ *and* $\mathbf{s}_{m,n}$, $n = 1, \ldots, N_m$, *are singular functions associated with singular points* $\mathbf{x}_m$, $m = 1, \ldots, M$.

Proof. From Lemma 4.1, we know that $\mathbf{W}_S^1$ is closed in $\mathbf{W}$, that $\mathcal{R}(\widehat{\mathcal{L}}) \subseteq \mathcal{R}(\mathcal{L})$ are both closed in $(L^2(\Omega))^2$, and that both $\mathcal{L}$ and $\widehat{\mathcal{L}}$ are injective. Thus, the codimension of $\mathbf{W}_S^1$ in $\mathbf{W}$ is the same as the codimension of $\mathcal{R}(\widehat{\mathcal{L}})$ in $\mathcal{R}(\mathcal{L})$. By Lemma 4.1, we know that the dimension of $\mathcal{R}(\mathcal{L})^\perp$ is one. We now seek $\mathcal{R}(\widehat{\mathcal{L}})^\perp = \mathcal{N}(\widehat{\mathcal{L}}^*)$. At each singular point $\mathbf{x}_m$, let $\hat{\delta} \in H^2(0, R)$ be a smooth cut-off function and, for each $\alpha_{m,n} \in (0, 1)$, construct functions similar to (5.8) and (5.16) as follows:

$$s_{m,n}^- := \delta_m(r) r^{-\alpha_{m,n}} T_{m,n}(\theta),$$
$$\hat{s}_{m,n}^- := \delta_m(r) r^{-\alpha_{m,n}} \hat{T}_{m,n}(\theta),$$

and define

$$\mathbf{s}_{m,n}^- := (s_{m,n}^-, -\hat{s}_{m,n}^-)^t. \tag{5.30}$$

From (5.29) we see that $\mathbf{s}_{m,n}^- \in \mathcal{D}(\widehat{\mathcal{L}}^*) \setminus \mathcal{D}(\mathcal{L}^*)$ and $\widehat{\mathcal{L}} \mathbf{s}_{m,n}^- \in (L^2(\Omega))^2$. Since $\mathcal{L}^*$ is surjective, we can find $\mathbf{q}_{m,n} \in \mathcal{D}(\mathcal{L}^*)$ such that

$$\mathcal{L}^* \mathbf{q}_{m,n} = -\widehat{\mathcal{L}}^* \mathbf{s}_{m,n}^- \tag{5.31}$$

and set

$$\mathbf{f}_{m,n} = \mathbf{q}_{m,n} + \mathbf{s}_{m,n}^-. \tag{5.32}$$

Clearly, $\mathbf{f}_{m,n} \in \mathcal{N}(\widehat{\mathcal{L}}^*)$.

It is straightforward to show that every element of $\mathcal{N}(\widehat{\mathcal{L}}^*)$ must be of this form, that is, must involve singular functions of both (2.1) and (3.20). Thus, the dimension of $\mathcal{N}(\widehat{\mathcal{L}}^*)$ is exactly equal to the number of such functions plus the one function in $\mathcal{N}(\mathcal{L}^*)$. We complete the proof by noting that the codimension of $\mathcal{N}(\mathcal{L}^*)$ in $\mathcal{N}(\widehat{\mathcal{L}}^*)$ is equal to the codimension of $\mathcal{R}(\widehat{\mathcal{L}})$ in $\mathcal{R}(\mathcal{L})$. □

This decomposition is the basis for the finite element discretization that is developed in the companion paper [3]. We only summarize the basic ideas here. Exponents and coefficients of singular basis functions $\mathbf{s}_{m,n}$ can be computed from the geometry of interfaces adjoining a singular point and the jumps in the coefficient a across these interfaces. Although our theoretical development employed cut-off functions independent of θ, any H^1 cut-off function may be used. We choose cut-off functions that equal one in a fixed region around the singular point and fall off to zero linearly in a small fringe region of width one grid cell.

The singular basis functions are included in the finite element space, together with standard elements, such as linear elements on triangles, that satisfy the interface conditions. Using functional G_0 to solve for the flux, inner products of standard elements with singular basis functions need only be calculated in the fringe region, thus saving a significant amount of work.

6. Conclusions. In this paper we have developed a FOSLS L^2 formulation for diffusion equations with discontinuous coefficients, irregular boundaries, and mixed boundary conditions. In Theorem 3.2, we showed the functional G_α in (3.1) to be coercive and continuous in $\mathbf{W} \times V$ with constants that are P-uniform. We then explored the flux-only functional, G_0 in (3.17), and in Lemma 3.3 and Lemma 4.1 showed that it is coercive and continuous in $\mathbf{W}$ with constants that are also P-uniform. Properties of the scaled div-curl operator (4.1) helped us to prove in Theorem 5.1 that $\mathbf{W}$ can be split into functions that are H^1 in each subdomain plus a finite number of singular basis functions with support in the neighborhood of the singular points.

These results form the theoretical basis for the finite element discretization of $\mathbf{W}$, a rigorous discretization error analysis, and a multilevel method, all of which are presented in the companion paper [3]. Our approach is different from others (see, for example, [9]) in that a rigorous discretization error analysis in the presence of approximate singular basis functions is possible, and a multilevel method can be devised that incorporates singular basis functions on all levels.

ANALYSIS OF FIRST-ORDER SYSTEM LEAST SQUARES (FOSLS) FOR ELLIPTIC PROBLEMS WITH DISCONTINUOUS COEFFICIENTS: PART II[*]

MARKUS BERNDT[†], THOMAS A. MANTEUFFEL[‡], AND STEPHEN F. MCCORMICK[‡]

Abstract. First-order system least squares (FOSLS) is a methodology that offers an alternative to standard methods for solving partial differential equations. This paper studies the first-order system least-squares approach for scalar second-order elliptic boundary value problems with discontinuous coefficients. In a companion paper [M. Berndt, T. A. Manteuffel, S. F. McCormick, and G. Starke, *Analysis of first-order system least squares (FOSLS) for elliptic problems with discontinuous coefficients: Part I*, SIAM J. Numer. Anal., 43 (2005), pp. 386–408], ellipticity of an appropriately scaled least-squares bilinear form is established in a natural norm. For some geometries this ellipticity is independent of the size of the jumps in the coefficients. The occurrence of singularities at interface corners, cross-points, reentrant corners, and irregular boundary points is discussed, and a basis of singular functions with local support around singular points is established. This paper describes a method for including discrete versions of the singular basis functions together with standard finite element spaces in a least-squares format at little additional computational cost. The singular basis functions are constructed to match the jump conditions that arise at interfaces between regions of continuity of the diffusion coefficient. Because these basis functions must be approximated in practice, the resulting discretization is by nature nonconforming. This necessitates the establishment here of a general error estimate for FOSLS L^2 minimization problems discretized by nonconforming finite elements. An advantage of the FOSLS formulation is that this estimate does not involve the consistency error term usually present in bounds for other methods. Based on this general estimate, error bounds are derived for the finite element space that includes singular basis functions. Numerical tests are included that confirm these discretization error bounds. Finally, a multilevel method is developed for solving the discrete system that uses singular basis functions on all levels, and its efficiency is demonstrated by the numerical results.

1. Introduction.

In this paper we consider the application of first-order system least squares (FOSLS [11, 12]) to diffusion equations in the plane with jump-discontinuous coefficients:

$$\begin{aligned} -\nabla \cdot (a \nabla p) &= f && \text{in } \Omega, \\ p &= g_{D} && \text{on } \Gamma_D, \\ \mathbf{n} \cdot (a \nabla p) &= g_{N} && \text{on } \Gamma_N. \end{aligned} \tag{1.1}$$

Here, $a > 0$ is a piecewise smooth function corresponding to some partition of domain $\Omega \subset \Re^2$, with boundary $\partial\Omega = \Gamma_D \cup \Gamma_N$ and outward unit normal $\mathbf{n}$, and the data $f, g_{_D}$, and $g_{_N}$ are appropriately smooth functions. Our focus is on a two-stage FOSLS scheme whose primary aim is to approximate the flux $a\nabla p$.

Studies of the problem of accurate approximation of p by inclusion of special basis functions (cf. [30, 23]) and adaptive refinement (cf. [28]) has been extensive, but the development of efficient multilevel algorithms for the calculation of stress intensity factors is lagging. The only example we are aware of is the full multigrid algorithm for interface problems stemming from cracks, introduced in [7, 9].

The least-squares methodology for systems of first order is by now several decades old and had its first applications in continuum mechanics (see, for example, [20, 32, 21, 25, 15, 22]). Only fairly recently has it produced H^1-equivalent forms to which optimal multigrid solvers have been applied (see, for example, [12]). For a thorough review of the least-squares methodology, see [4] and the references therein.

In the FOSLS formulations developed in [11, 12], the aim was to rewrite the original scalar equation as a first-order system in such a way that its associated least-squares functional has an H^1-equivalent homogeneous part. This equivalence enables simpler finite element discretization methods and ensures that the resulting discrete problem can be solved efficiently by a standard multigrid method. However, because we allow discontinuities in a here, the flux is discontinuous across interfaces and may be singular at some points in the domain. We are therefore led to the development of a special FOSLS L^2 approach for solving (1.1).

In this paper we develop a flux-only FOSLS functional that is continuous and coercive in a scaled space, $H(\operatorname{div} a, \Omega) \cap H(\operatorname{curl} a, \Omega)$, which we denote as $\mathbf{W}$ (see section 2). We denote the space of piecewise H^1 vector valued functions as $H^1_S(\Omega)$ (see section 4). In [2] it was shown that $H^1_S(\Omega) \cap \mathbf{W}$ has finite codimension in $\mathbf{W}$. The singular basis functions, together with $H^1_S(\Omega)\mathbf{W}$, span $\mathbf{W}$ (cf. [2]).

The basic idea behind our special FOSLS scheme is to include singular basis functions in the finite element space and thus accurately model the singular behavior of the flux. These basis functions are constructed so that their action in the weak form involves integration only inside a small fringe region around the singularity. Thus, the additional cost is minimal, yet optimal accuracy is retained.

Alternatives to the approach we develop here are described in detail in [2] and include adding H^1 singular basis functions in standard Galerkin methods to enhance the rate of convergence (cf. [30, 17, 7, 10]) and the use of $H(\operatorname{div})$ conforming finite element spaces with mixed formulations (see [8]) or with FOSLS functionals that are based on $H(\operatorname{div})$ (see [11, 26, 27]). Standard finite element spaces can be used with FOSLS functionals that are weighted to eliminate the overall impact on accuracy of the singular behavior of the flux [18, 17, 24]. Unfortunately, this weighting approach does not provide accurate resolution of the solution close to singularities of the flux, which is the main objective of the approach developed here.

Other alternatives use FOSLS based on inverse norms [6, 5, 13, 3] and FOSLS* [14]. The FOSLS L^2 approach developed here achieves accuracy in the stronger H^1-like norm, which may be preferred in many practical cases.

To estimate discretization accuracy for our special FOSLS scheme, we derive a general error bound for L^2-type FOSLS discretized by nonconforming finite elements. Similar nonconforming estimates for other methods typically involve consistency error terms (cf. [1]), but they are not needed in the FOSLS context. This special property of FOSLS is important because it means that error estimates for nonconforming finite elements may be derived solely from relatively simple interpolation error bounds.

The FOSLS reformulation of (1.1) is derived in section 2. In section 3, the calculation of exponents of singular basis functions is described, and, in section 4, we describe the finite element discretization scheme, complete with singular basis functions. In section 5, the general nonconforming error bound is derived and applied to estimating the accuracy of our augmented basis approach. These estimates are confirmed by the numerical results at the end of section 5. We introduce a multilevel solver in section 6 that is based on coarsening with singular basis functions on all levels. The W-cycle form of this algorithm exhibits typical multigrid convergence behavior, as the numerical results of section 7 also confirm.

2. Problem statement and FOSLS formulation. Assume that $\Omega \subset \Re^2$ is a simply connected polygonal region and that

$$\overline{\Omega} = \bigcup_{j=1}^{J} \overline{\Omega}_j, \tag{2.1}$$

where Ω_j are mutually disjoint open simply connected polygonal regions. Assume also that $\partial\Omega = \Gamma_D \cup \Gamma_N$, Γ_D has positive measure, and Γ_D and Γ_N both consist of a finite number of connected pieces. The case in which $\Gamma_D = \emptyset$ is a simple extension.

Consider the following div-curl first-order system for the scaled flux $\mathbf{u} := \sqrt{a}\nabla p$:

$$\begin{aligned} -\nabla \cdot (\sqrt{a}\mathbf{u}) &= f \quad \text{in } \Omega, \\ \nabla \times (\mathbf{u}/\sqrt{a}) &= 0 \quad \text{in } \Omega, \\ \mathbf{n} \cdot (\sqrt{a}\mathbf{u}) &= 0 \quad \text{on } \Gamma_N, \\ \mathbf{n} \times (\mathbf{u}/\sqrt{a}) &= 0 \quad \text{on } \Gamma_D. \end{aligned} \tag{2.2}$$

(We treat the homogeneous boundary condition case for simplicity. The general case of nonzero g_N and $g_D := \mathbf{n} \times \nabla p$ could be treated by standard lifting or superposition techniques.)

Under the additional smoothness assumptions $a \in C^{1,1}(\Omega)$, $f \in L^2(\Omega)$, and in the absence of reentrant corners and boundary points in which Γ_D and Γ_N meet with interior angle greater than $\pi/2$, we can assert the following [12]: scalar equation (1.1) has a unique solution $p \in H^2(\Omega)$; system (2.2) has a unique solution $\mathbf{u} \in H^1(\Omega)^2$; and the two problems are equivalent in the sense that their solutions correspond according to the relation $\mathbf{u} := \sqrt{a}\nabla p$.

We are interested here in the discontinuous coefficient case, where a is assumed only to be piecewise continuous. Theoretical properties of the first-order system and the corresponding FOSLS functional for this case are studied in the companion paper [2]. In the present paper, we focus on the discretization and multilevel solver for the discrete problem. Problems with reentrant corners and irregular boundary points can be handled in an analogous manner and are omitted for simplicity of presentation.

System (2.2) gives rise to the scaled least-squares functional

$$\mathcal{G}(\mathbf{u}; f) = \left\| (1/\sqrt{a})\nabla \cdot (\sqrt{a}\mathbf{u} + f) \right\|_0^2 + \left\| \sqrt{a}\nabla \times (\mathbf{u}/\sqrt{a}) \right\|_0^2 \tag{2.3}$$

and the associated FOSLS L^2 minimization problem

$$\mathbf{u} = \arg \min_{\mathbf{v} \in \mathbf{W}} \mathcal{G}(\mathbf{v}; f), \tag{2.4}$$

which is well posed on the space

$$\mathbf{W} = \{\mathbf{v} \in H(\operatorname{div} a, \Omega) \cap H(\operatorname{curl} a, \Omega) : \\ \mathbf{n} \cdot (\sqrt{a}\mathbf{v}) = 0 \,\text{on}\, \Gamma_N, \mathbf{n} \times (\mathbf{v}/\sqrt{a}) = 0 \text{ on}\, \Gamma_D\big\}, \tag{2.5}$$

where

$$H(\operatorname{div} a, \Omega) = \left\{\mathbf{v} \in L^2(\Omega)^2 : \nabla \cdot (\sqrt{a}\mathbf{v}) \in L^2(\Omega)\right\},$$
$$H(\operatorname{curl} a, \Omega) = \left\{\mathbf{v} \in L^2(\Omega)^2 : \nabla \times (\mathbf{v}/\sqrt{a}) \in L^2(\Omega)\right\}.$$

We equip $\mathbf{W}$ with the seminorm

$$|\mathbf{u}|_{\mathbf{W}} = \left\|(1/\sqrt{a})\nabla \cdot (\sqrt{a}\mathbf{u})\right\|_0^2 + \left\|\sqrt{a}\nabla \times (\mathbf{u}/\sqrt{a})\right\|_0^2.$$

Note that this is actually a norm because of the assumption that Γ_D has positive measure (see [2, Lemma 3.3]). Note also that $\mathcal{G}$ is trivially $\mathbf{W}$ elliptic in the sense that

$$\mathcal{G}(\mathbf{u}; 0) = |\mathbf{u}|_{\mathbf{W}}^2. \tag{2.6}$$

Minimization problem (2.4) leads to the following variational problem: find $\mathbf{u} \in \mathbf{W}$ such that

$$\mathcal{F}(\mathbf{u}, \mathbf{v}) = \left\langle f/a, \nabla \cdot (\sqrt{a}\mathbf{v})\right\rangle_{0,\Omega} \tag{2.7}$$

for all $\mathbf{v} \in \mathbf{W}$, with

$$\mathcal{F}(\mathbf{u}, \mathbf{v}) = \left\langle (1/a)\nabla \cdot (\sqrt{a}\mathbf{u}), \nabla \cdot (\sqrt{a}\mathbf{v})\right\rangle_{0,\Omega} + \left\langle a\nabla \times (\mathbf{u}/\sqrt{a}), \nabla \times (\mathbf{v}/\sqrt{a})\right\rangle_{0,\Omega}.$$

Suppose that a is piecewise continuous with respect to the partitioning (2.1) of Ω in the maximal sense; that is, a is continuous on Ω_j and no open set $\mathcal{O}_j \supset \Omega_j$ exists for which $a|_{\mathcal{O}_j}$ is continuous, $1 \leq j \leq J$. Under these assumptions, variational problem (2.7) has a unique solution in $\mathbf{W}$ that is also the unique solution of FOSLS minimization problem (2.4) (see [2]).

An edge that lies in the intersection of the closure of two subdomains is called an interface. Points where two interfaces meet are called cross-points. Cross-points, reentrant corners, and irregular boundary points are all potential singular points. Now, the solution $\mathbf{u} \in \mathbf{W}$ of problem (2.2) satisfies certain conditions across the interfaces. Denote by $\mathbf{n}_{\mathcal{I}}$ a unit vector normal to interface $\mathcal{I}$. Then

$$\mathbf{n}_{\mathcal{I}} \cdot (\sqrt{a}\mathbf{u}) \;\text{ and }\; \boldsymbol{\tau}_{\mathcal{I}} \cdot (\mathbf{u}/\sqrt{a}) \;\text{ are continuous a.e. across interfaces.} \tag{2.8}$$

These interface conditions must be true in order for the first two equations in (2.2) to make sense. For the first condition in (2.8) see, for example, [33, Chapter 6.2]. The second condition can be derived analogously.

3. Approximation of singularities.

In [2, section 5], a splitting of $\mathbf{W}$ into a finite-dimensional space spanned by singular functions and locally smooth functions is introduced. This leads to a decomposition of any $\mathbf{u} \in \mathbf{W}$ as

$$\mathbf{u} = \mathbf{u}_0 + \sum_{m=1}^{M} \sum_{n=1}^{N_m} \omega_m \delta_m \mathbf{s}_{m,n}, \tag{3.1}$$

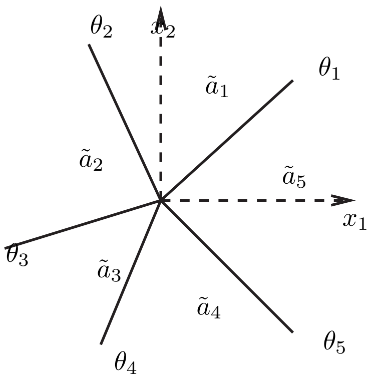

FIG. 3.1. *Cross-point,* $I = 5$.

where $\mathbf{u}_0|_{\Omega_i} \in H^1(\Omega_i)$, δ_m is a cut-off function at a singular point (see Figure 4.2 for an example), and $\mathbf{s}_{m,n}$, $n = 1, \ldots, N_m$, are the singular functions associated with singular point $\mathbf{x}_m$, $m = 1, \ldots, M$. In this paper, our focus is on singular points that are cross-points (see Figure 3.1 for an example). The other types of singular points, described in [2, section 5], can be treated in an analogous fashion.

The exact nature of a singularity at a cross-point can be calculated using a and the geometry of interfaces in the neighborhood of the cross-point. To obtain a simple representation of such singularities (see [23] and [30]), additional constraints on the behavior of a within Ω_i are necessary. We first summarize the results of [2, section 5] and then proceed to describe the numerical method that is used to calculate singular basis functions.

Given a polar coordinate system (r, θ), centered at a cross-point, we recall that $a \in C^{1,1}(\Omega_i)$, for each subdomain Ω_i, and assume that a satisfies

$$\lim_{r \to 0} a_\theta = 0, \qquad \lim_{r \to 0} r a_r = 0. \tag{3.2}$$

The task of finding a representation for the singularity at a cross-point reduces to finding solutions of the Sturm–Liouville eigenvalue problem (see [2, section 5] for a detailed derivation)

$$-(\tilde{a}T')' = \tilde{a}\alpha^2 T \ \text{ on } \ [0, 2\pi), \tag{3.3}$$

where $\tilde{a}_i = \lim_{r \to 0} a(r, \theta)$ in Ω_i.

Each interface that adjoins the cross-point is characterized by the angle of its tangent at the cross-point with the x_1-axis. Denote by I the number of interfaces adjoining at a given cross-point, and by θ_i, $i = 1, \ldots, I$, the angles their tangents make with the x_1-axis (see Figure 3.1 for an example with $I = 5$). Assume that these interface angles are ordered such that $\theta_i < \theta_{i+1}$, $i = 1, \ldots, I - 1$. Let $\theta_{I+1} = \theta_1$.

Eigenfunctions of (3.3) have the form

$$T_n(\theta) = \lambda_{n,i} \cos(\alpha_n \theta) + \mu_{n,i} \sin(\alpha_n \theta), \tag{3.4}$$

for $\theta \in (\theta_i, \theta_{i+1})$, where α_n^2 is the associated eigenvalue. According to [2, Theorem 5.1], we must calculate all eigenvalues $0 < \alpha_n^2 < 1$ and associated eigenfunctions of (3.3), to obtain all singular functions

$$\mathbf{s}_{m,n} = \sqrt{a}\nabla r^{\alpha_n} T_n(\theta) = \sqrt{a}\alpha_n r^{\alpha_n - 1} \begin{pmatrix} \lambda_{ni}\sin((\alpha_n-1)\theta) + \mu_{ni}\cos((\alpha_n-1)\theta) \\ \lambda_{ni}\cos((\alpha_n-1)\theta) - \mu_{ni}\sin((\alpha_n-1)\theta) \end{pmatrix}, \tag{3.5}$$

for $\theta \in (\theta_i,\, \theta_{i+1})$, where λ_{ni} and μ_{ni} are constant inside each Ω_i. Note also that $\mathbf{s}_{m,n} = \sqrt{a}\nabla\sigma_n$ with

$$\sigma_n(r,\theta) = r^{\alpha_n}(\lambda_{ni}\sin\alpha_n\theta + \mu_{ni}\cos\alpha_n\theta) \quad \text{for} \quad \theta \in (\theta_i,\, \theta_{i+1}). \tag{3.6}$$

Remark 1. In [2], a representation of the singular functions is used that differs slightly from (3.5). It is easy to show that the two representations are equivalent.

For convenience we will now drop the subscript n where the meaning is apparent. The exponent α and the coefficients (λ_i, μ_i) can be determined by enforcing continuity of both $T(\theta)$ and $\tilde{a}T'(\theta)$ across interfaces. To obtain first approximations to the eigenvalues α^2, we discretize eigenvalue problem (3.3) and solve the resulting algebraic generalized eigenvalue problem. Note that we are primarily interested in the smallest values of α^2, that is, $0 \leq \alpha^2 \leq 1$. The eigenvectors associated with these small eigenvalues are well approximated using a fairly coarse discretization. Values of α that are obtained in this way are used as starting values of a secant iteration that is based on the following idea.

Interface conditions (2.8) give rise to a $2I \times 2I$ nonlinear system of equations for α, λ_i, and μ_i, $i = 1, \ldots, I$, which can be written in the compact form

$$M(\alpha)(\lambda_1, \mu_1, \ldots, \lambda_I, \mu_I)^t = \underline{0}. \tag{3.7}$$

A nontrivial solution exists only when $M(\alpha)$ is singular, that is, when $\det M(\alpha) = 0$. To find roots of $\det M(\alpha)$, we use a secant iteration with starting values obtained from the solution of the discretized Sturm–Liouville eigenvalue discussed in above.

Suppose we compute an approximation $\tilde{\alpha} = \alpha + \eta$. To estimate η, we find $\underline{x}$ that has norm one and minimizes $\|M(\tilde{\alpha})\underline{x}\|$. Thus, $\underline{x}$ is a right singular vector of $M(\tilde{\alpha})$ and $\|M(\tilde{\alpha})\underline{x}\| = \sigma_n$, the smallest singular value of $M(\tilde{\alpha})$, which is easily computed because $M(\tilde{\alpha})$ is of small dimension. Moreover,

$$M(\tilde{\alpha})\underline{x} = \sigma_n \underline{r}, \tag{3.8}$$

where $\underline{r}$ is the left singular vector of $M(\tilde{\alpha})$ and $\|\underline{r}\| = 1$.

Let α be the exact value, and let the inexact $\tilde{\alpha} = \alpha + \eta$. Then we have the matrix expansion

$$M(\alpha + \eta) = M(\alpha) + \eta M'(\alpha + \hat{\eta}) \simeq M(\alpha) + \eta M'(\alpha + \eta),$$

where $\hat{\eta} \in (0, \eta)$. We can easily compute $M'(\alpha + \eta)$. Since $M(\alpha)$ is singular, we know that the distance from $M(\alpha + \eta)$ to $M(\alpha)$ in the Frobenius norm is larger than the smallest singular value of $M(\alpha + \eta)$; that is,

$$\sigma_n \leq \|M(\alpha + \eta) - M(\alpha)||_F \simeq \eta\|M'(\alpha + \eta)\|_F.$$

Thus, we get a lower bound on η. Conversely, we see that as $\eta \to 0$, we can get a bound on $\sigma_n \to 0$.

In conclusion, the coefficients become accurate at the same rate as alpha becomes accurate. Also, we can determine an approximate lower bound on the accuracy of alpha by computing the singular values of $M(\tilde{\alpha})$. If the error in alpha is too big, we do more computational work. (In [2, (5.12)], $M(\alpha)$ is scaled such that the dependence on a is lumped into 2×2 block diagonal terms D_i that have no dependence on α but depend on the ratio a_i/a_{i-1}. In this paper, we use a slightly different scaling, where $D_i = \text{diag}(a_{i-1}, -a_i)$.)

The calculations that are described in this section are not very costly, since typically, the number of interfaces adjoining a cross-point is very small, and the number of eigenvalues of the Sturm–Liouville problem (3.3) in which we are interested is of order $O(1)$ (see [23]).

4. Finite element discretization. For simplicity, we have assumed that domain Ω and its subdomains Ω_j are polygonal, which allows the geometry of the discontinuities of a to be resolved exactly using a triangular mesh. Let $\mathcal{T}_h$ be a quasiuniform triangulation (see, for example, [8, Definition 4.4.13]) constructed so that no element cuts across any interface (i.e., each element is contained in just one subdomain). Our discretization method is based on the decomposition introduced in [2] that isolates the singular functions from the piecewise H^1 functions. To this end, let $\delta_m \in H^1(\Omega)$ denote any given"cut-off" function that has value one in a small area about cross-point m and values that taper to 0 in a small outer "fringe," $1 \le m \le M$. (See Figure 4.2.) Let $\mathbf{s}_{m,n}$ be the nth singular basis function at cross-point m, $1 \le n \le N_m, 1 \le m \le M$. Then $\delta_m \mathbf{s}_{m,n} \in W$, provided that δ_m has support inside Ω and all interfaces inside the fringe and platform of δ_m are straight lines. We will be more specific about $\mathbf{s}_{m,n}$ below. Defining the "split" space of piecewise H^1 functions by

$$H^1_S(\Omega) := \left\{ \mathbf{u} \in (L^2(\Omega))^2 \ : \ \mathbf{u}|_{\Omega_j} \in (H^1(\Omega_j))^2, \ j = 1, \dots, J \right\} \tag{4.1}$$

and letting $\mathbf{W}^1_S := \mathbf{W} \cap H^1_S(\Omega)$, then our decomposition is given by

$$\mathbf{W} = \mathbf{W}^1_S \ \oplus \ \text{span}\left\{ \delta_m \mathbf{s}_{m,n} : 1 \le m \le M, 1 \le n \le N_m \right\}, \tag{4.2}$$

(cf. [2], Theorem 5.1). At interior nodes of the subdomains Ω_j, we use standard piecewise linear nodal basis functions, whose coefficients at the nodal values are the unknowns. (We will add certain quadratic basis functions shortly.) For vertices that lie on interfaces, we use piecewise linear basis functions that satisfy interface conditions (2.8) exactly and are scaled to have a maximum of one (see also Figure 4.1).

Singular components $\delta_m \mathbf{s}_{m,n}$ are discretized by choosing a discrete cut-off function $\delta_m = \delta^h_m$ and replacing $\mathbf{s}_{m,n}$ by a discrete approximation $\tilde{\mathbf{s}}_{m,n}$, as described in section 3. Each cross-point m is surrounded by the support of its cut-off function,

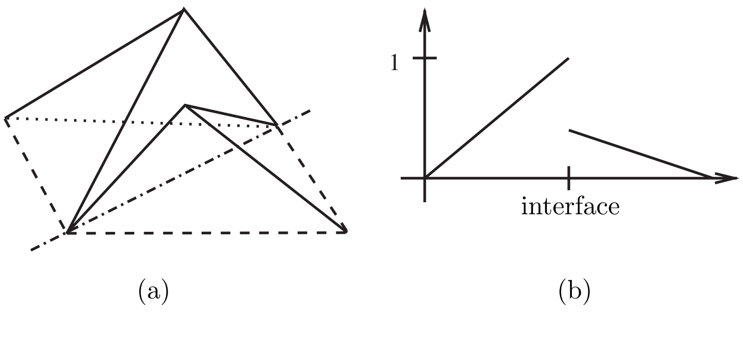

FIG. 4.1. *A discontinuous linear basis function in* 3D *view* (a) *and in side view* (b).

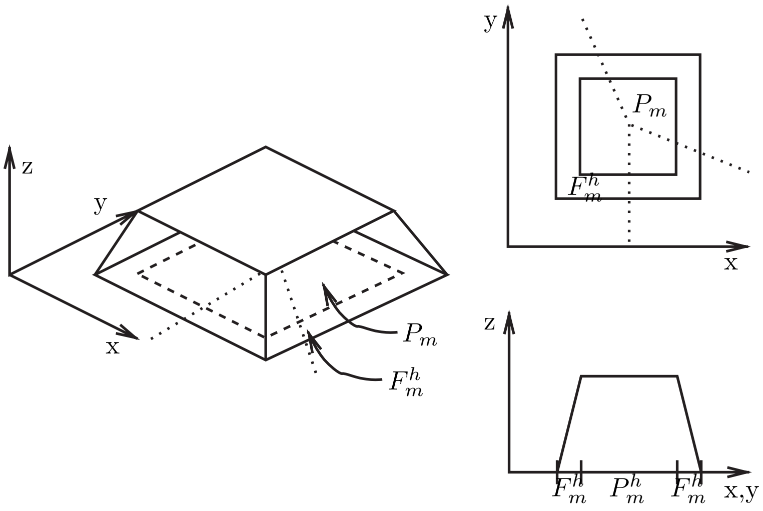

FIG. 4.2. *The cut-off function δ_m^h centered at a cross-point (P_m = platform, F_m^h = fringe, dotted lines are interfaces).*

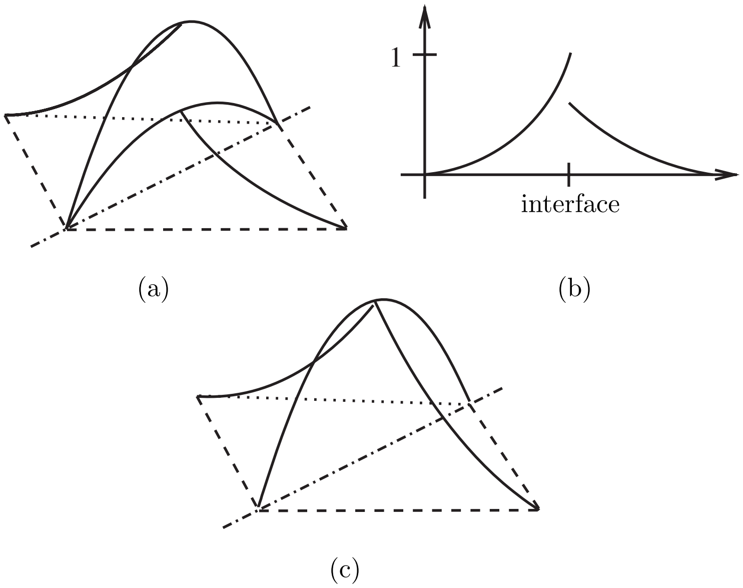
which consists of a platform P_m and outer fringe F_m^h consisting of one outer ring of level h triangles. The platform also consists of level h triangles, but it is otherwise fixed in size. The supports $P_m \cup F_m^h$ are constructed at each cross-point to be large enough to obtain a reasonable approximation to the singular functions but small enough to ensure that they do not intersect with each other. Cut-off function δ_m^h is then defined so that $\delta_m^h|_\tau$ is linear for all $\tau \subset F_m^h$ and has value 1 inside its platform. See Figure 4.2.

Denoting by $\mathcal{F}_\tau(\cdot,\cdot)$ the $\mathcal{F}$ inner product evaluated on the element τ, we have

$$\mathcal{F}_\tau(\delta_m^h \mathbf{s}_{m,n}, \mathbf{v}) = 0 \quad \text{for all} \;\; \tau \in P_m,$$

since $\delta_m^h = 1$ inside P_m. This implies that, for elements inside the platforms, entries in element stiffness matrices that involve singular basis functions are zero. Only elements in the fringes have element stiffness matrices that have contributions from integration of singular basis functions. To evaluate these fringe integral terms, we use two-dimensional Gaussian quadrature of order high enough to ensure that it does not corrupt the discretization error estimates we obtain in the following sections. (Recall that the singular functions are smooth in the fringe.) Outside platforms and fringes, there are no contributions from singular basis functions. In conclusion, each singular basis function need only be numerically integrated on the small number of elements that comprise the fringe of its cut-off function.

To control the computational work of integrating the singular basis functions, we have limited the fringes to width h, which reduces discretization accuracy. To avoid this loss, we introduce quadratic "bubble-like" basis functions in the fringes, with supports consisting of two triangles that share an edge within the fringe. Within each triangle, the quadratic function is defined to be the product of a linear function that is zero on one of the nonshared edges and another that is zero on the other nonshared edge. When the triangle pair is in a single Ω_j, the basis function is scaled to be 1 at the midpoint of the shared edge (see Figure 4.3(c)). If, instead, the edge coincides with an interface, the discontinuous basis function is such that it satisfies the interface



(a) (b)

(c)

Fig. 4.3. *A discontinuous quadratic basis function in* 3*D view* (a) *and in side view* (b); *a continuous quadratic basis function* (c).

conditions (2.8) exactly and has a maximum of one. See Figure 4.3(a) and (b) for a schematic.

In the next section, we derive an error estimate that illustrates the necessity for such an increase in discretization order inside the fringes (see the proof of Theorem 5.1).

Our discretization is, thus, defined by the space $\mathbf{W}^h$ of elements of the form

$$\mathbf{u}^h = \mathbf{u}_L^h + \mathbf{u}_Q^h + \sum_{m=1}^{M} \sum_{n=1}^{N_m} \omega_{m,n} \delta_m^h \tilde{\mathbf{s}}_{m,n}, \tag{4.3}$$

where is $\mathbf{u}_L^h$ is piecewise linear (with respect to $\mathcal{T}^h$) and continuous in Ω_j, $\mathbf{u}_Q^h$ is piecewise quadratic and continuous in Ω_j but with support contained in the fringe, and $\tilde{\mathbf{s}}_{m,n}$ is an approximation to $\mathbf{s}_{m,n}$. The discrete problem corresponding to (2.7) is then as follows: Find $\mathbf{v}^h \in \mathbf{W}^h$ such that

$$\mathcal{F}(\mathbf{u}^h, \mathbf{v}^h) = \left\langle f/a, \nabla \cdot (\sqrt{a}\mathbf{v}^h) \right\rangle_{0,\Omega} \tag{4.4}$$

for all $\mathbf{v}^h \in \mathbf{W}^h$.

Both $\mathbf{u}_L^h$ and $\mathbf{u}_Q^h$ satisfy the interface conditions exactly, but the singular function approximations $\tilde{\mathbf{s}}_{m,n}$ do not, because $\tilde{\alpha}$ is not exact. This means that the discrete space is generally nonconforming: $\mathbf{W}^h \not\subset \mathbf{W}$. Thus, standard theory for discretization accuracy does not apply, and we are left to develop our own estimates.

5. Error estimates. We begin by establishing an error estimate for the case of a conforming subspace, where the singular basis functions are assumed to be known exactly. To cover the practical case, where approximate singular basis functions are used, we then derive a general error estimate for FOSLS L^2 formulations with nonconforming finite elements and apply it to the case of nonconforming singular basis functions.

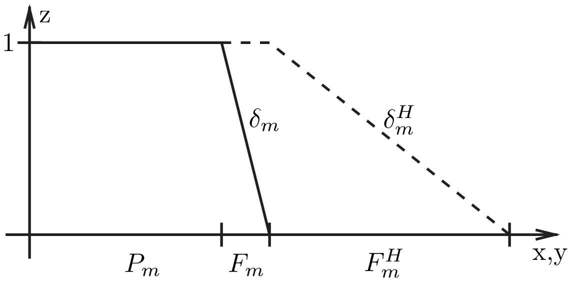


FIG. 5.1. *Side view of cut-off functions δ_m^h and δ_m^H.*

5.1. The conforming case: $\mathbf{W}^h \subset \mathbf{W}$. Let $2H_m$ be less than the shortest distance from P_m to the nearest other platform or boundary. Let F_m^H be a fringe of width H_m, and let δ_m^H be the associated cut-off function (see Figure 5.1). Using the decomposition of $\mathbf{W}$ given in (4.2), write the solution of variational problem (4.4) as

$$\mathbf{u} = \mathbf{u}_0 + \sum_{m=1}^{M}\sum_{n=1}^{N} \omega_{m,n}\delta_m^H \mathbf{s}_{m,n}, \tag{5.1}$$

where $\mathbf{u}_0 \in \mathbf{W}_S^1$. Now we state the error estimate for the conforming case.

THEOREM 5.1 (estimate for conforming $\mathbf{W}^h$). *Assume that $\mathbf{W}^h \subset \mathbf{W}$. Let $\mathbf{u} \in \mathbf{W}$ denote the solution of variational problem* (2.7) *and $\mathbf{u}^h \in \mathbf{W}^h$ the solution of discrete variational problem* (4.4). *Let $2H_m$ be less than the distance between P_m and the closest other platform or boundary, and assume that $0 < h < H_m$, for $m = 1, \ldots, M$. Then*

$$\left|\mathbf{u} - \mathbf{u}^h\right|_{\mathbf{W}} \le C_1 h^{\sigma-1} \left|\mathbf{u}_0\right|_{\sigma,S} + C_2 h \sup_{m,n} \left|\omega_{m,n}\right|, \tag{5.2}$$

where $\sigma \in (1, 2]$ depends on the smoothness of $\mathbf{u}_0$, $\omega_{m,n}$ are the coefficients in (5.1), *and the constants $C_1, C_2 > 0$ are independent of h.*

Proof. Since $\mathbf{W}^h \subset \mathbf{W}$, then by (4.4), $\mathbf{u}^h$ satisfies

$$\left|\mathbf{u} - \mathbf{u}^h\right|_{\mathbf{W}} = \inf_{\mathbf{v}^h \in \mathbf{W}^h} \left|\mathbf{u} - \mathbf{v}^h\right|_{\mathbf{W}} \le \left|\mathbf{u} - \mathbf{w}^h\right|_{\mathbf{W}}, \tag{5.3}$$

for any particular $\mathbf{w}^h \in \mathbf{W}^h$. As in (5.1), denote by δ_m^H the cut-off function that is one in $P_m \cup F_m$ and drops to zero linearly in the extended fringe F_m^H around $P_m \cup F_m^h$ of width H_m. See Figure 5.1 for a side view of this function. Note that all F_m^H, $m = 1, \ldots, M$, are mutually disjoint. Let $I^h : C(\Omega) \to \mathbf{W}$ denote a linear nodal interpolant operator outside $\bigcup_{m=1}^M F_m^h$ and a quadratic nodal interpolant operator in $\bigcup_{m=1}^M F_m^h$. Coefficients of linear basis functions are obtained by function evaluation at their vertex, whereas coefficients of quadratic basis functions are obtained by evaluating the difference of the function itself and the linear interpolant. We now write

$$\mathbf{u} = \mathbf{u}_0 + \sum_{m=1}^{M}\sum_{n=1}^{N_m} \omega_{m,n}(\delta_m^H - \delta_m^h)\mathbf{s}_{m,n} + \sum_{m=1}^{M}\sum_{n=1}^{N_m} \omega_{m,n}\delta_m^h \mathbf{s}_{m,n}, \tag{5.4}$$

where $\mathbf{u}_0 \in \mathbf{W}_S^1$ does not depend on h. Define

$$\mathbf{w}^h := I^h \left(\mathbf{u}_0 + \sum_{m=1}^{M} \sum_{n=1}^{N_m} \omega_{m,n} \psi_m \mathbf{s}_{m,n} \right) + \sum_{m=1}^{M} \sum_{n=1}^{N_m} \omega_{m,n} \delta_m^h \mathbf{s}_{m,n}, \tag{5.5}$$

where $\psi_m := \delta_m^H - \delta_m^h$. Substituting (5.4) and (5.5) into (5.3) and using the triangle inequality, we obtain

$$\left| \mathbf{u} - \mathbf{w}^h \right|_{\mathbf{W}} \leq \left| \mathbf{u}_0 - I^h \mathbf{u}_0 \right|_{\mathbf{W}} + \sum_{m=1}^{M} \sum_{n=1}^{N_m} |\omega_{m,n}| \left| \psi_m \mathbf{s}_{m,n} - I^h \psi_m \mathbf{s}_{m,n} \right|_{\mathbf{W}}. \tag{5.6}$$

Since $\mathbf{u}_0 \in \mathbf{W}_S^1$ does not depend on h, we can use [19, Theorem 4.4.20] to estimate the first term in (5.6):

$$\left| \mathbf{u}_0 - I^h \mathbf{u}_0 \right|_{\mathbf{W}} = \left| \mathbf{u}_0 - I^h \mathbf{u}_0 \right|_{1,S} \leq \tilde{C}_1 h^{\sigma - 1} \left| \mathbf{u}_0 \right|_{\sigma,S}. \tag{5.7}$$

Here, $1 < \sigma \leq 2$ depends on the smoothness of $\mathbf{u}_0$.

Since $\psi_m s_{m,n} \in \mathbf{W}_S^1$, we have

$$\left| (I - I^h) \psi_m s_{m,n} \right|_{\mathbf{W}}^2 \leq \sum_{\tau \in F_m^h} \left| (I - I^h) \psi_m s_{m,n} \right|_{1,\tau}^2 + \sum_{\tau \in F_m^H \backslash F_m^h} \left| (I - I^h) \psi_m s_{m,n} \right|_{1,\tau}^2.$$

Since the finite element space includes quadratics on F_m^h, the two terms on the right-hand side satisfy

$$\left| (I - I^h) \psi_m s_{m,n} \right|_{1,\tau} \leq \begin{cases} ch^2 \| \psi_m s_{m,n} \|_{3,\tau} & \text{for } \tau \in F_m^h, \\ ch \| \psi_m s_{m,n} \|_{2,\tau} & \text{for } \tau \in F_m^H \backslash F_m^h. \end{cases}$$

Using the inverse inequality and noting that ψ is linear, we have

$$\| \psi_m s_{m,n} \|_{3,\tau} \leq \frac{c}{h} \| s_{m,n} \|_{3,\tau} \qquad \text{for } \tau \in F_m^h$$

and

$$\| \psi_m s_{m,n} \|_{2,\tau} \leq \frac{c}{H_m} \| s_{m,n} \|_{2,\tau} \qquad \text{for } \tau \in F_m^H \backslash F_m^h.$$

Putting this all together, we have

$$\left| (I - I^h) \psi_m s_{m,n} \right|_{\mathbf{W}}^2 \leq ch^2 \| s_{m,n} \|_{3,F_m^h}^2 + \frac{c}{H_m} h^2 \| s_{m,n} \|_{2,F_m^H}^2. \tag{5.8}$$

Now, using (5.8) and (5.7) in (5.6), we obtain the estimate

$$\left| \mathbf{u} - \mathbf{w}^h \right|_{\mathbf{W}} \leq \tilde{C}_1 h^{\sigma-1} \left| \mathbf{u}_0 \right|_{\sigma,S} + h \sum_{m=1}^{M} C_m \sum_{n=1}^{N_m} |\omega_{m,n}| \, \| \mathbf{s}_{m,n} \|_{3,S,F_m^H} \tag{5.9}$$

$$\leq C_1 h^{\sigma-1} \left| \mathbf{u}_0 \right|_{\sigma,S} + C_2 h \sup_{m,n} |\omega_{m,n}|. \tag{5.10}$$

This completes the proof. □

Remark 2. If the right-hand side of (2.2) is sufficiently smooth, then adding all singular functions of the form (3.5) to the finite element space for which $\alpha_n \in (0, 2]$ yields a bound of $O(h)$ in (5.2) (see [7]).

In practice, subspace $\mathbf{W}^h$ contains only approximate singular basis functions, which implies $\mathbf{W}^h \not\subset \mathbf{W}$. In the next section, we derive an error estimate for a general nonconforming finite element space that is used in section 5.3.

5.2. A general error estimate for FOSLS L^2 formulations with nonconforming finite elements. In this section, we depart from the framework and notation that were introduced in the previous section. We introduce a general methodology for derivation of error estimates for FOSLS L^2 formulations that use nonconforming finite element spaces. First consider a general FOSLS L^2 functional

$$\mathcal{G}(\mathbf{u};\mathbf{f}) := \|\mathcal{L}\mathbf{u}-\mathbf{f}\|^2_{0,\Omega}\,, \tag{5.11}$$

where Ω is a bounded open domain, $\mathbf{u}$ an element of a Hilbert space $\boldsymbol{\mathcal{W}}$, $\mathbf{f} \in (L^2(\Omega))^k$, and $\mathcal{L}$ a first-order differential operator. This gives rise to the FOSLS L^2 minimization problem

$$\mathbf{u} = \arg\min_{\mathbf{v}\in\boldsymbol{\mathcal{W}}} \mathcal{G}(\mathbf{v};\mathbf{f}) \tag{5.12}$$

and its variational form: Find $\mathbf{u} \in \boldsymbol{\mathcal{W}}$ such that

$$\mathcal{F}(\mathbf{u},\mathbf{v}) = \ell(\mathbf{v}), \tag{5.13}$$

for all $\mathbf{v} \in \boldsymbol{\mathcal{W}}$, with

$$\begin{aligned}\mathcal{F}(\mathbf{u},\mathbf{v}) &= \langle\mathcal{L}\mathbf{u},\mathcal{L}\mathbf{v}\rangle_{0,\Omega}\,,\\ \ell(\mathbf{v}) &= \langle\mathbf{f},\mathcal{L}\mathbf{v}\rangle_{0,\Omega}\,.\end{aligned}$$

We assume that bilinear functional $\mathcal{F}$ is $\boldsymbol{\mathcal{W}}$-elliptic with respect to a norm $\|\cdot\|_{\boldsymbol{\mathcal{W}}}$ in the sense that respective continuity and coercivity constants C_{cont} and C_{coer} exist, for which

$$\begin{aligned}\mathcal{F}(\mathbf{u},\mathbf{v}) &\le C_{cont}\,\|\mathbf{u}\|_{\boldsymbol{\mathcal{W}}}\,\|\mathbf{v}\|_{\boldsymbol{\mathcal{W}}}\,,\\ C_{coer}\,\|\mathbf{u}\|^2_{\boldsymbol{\mathcal{W}}} &\le \mathcal{F}(\mathbf{u},\mathbf{u}),\end{aligned}$$

for all $\mathbf{u},\mathbf{v} \in \boldsymbol{\mathcal{W}}$.

Let $\{\Omega_j\}_{j=1,\dots,J}$ be an open partitioning of Ω such that all Ω_j are mutually disjoint and $\bigcup_{j=1}^J \overline{\Omega}_j = \overline{\Omega}$. Let $\boldsymbol{\mathcal{W}}^h$ be a finite element space for which the restriction of the operator $\mathcal{L}$ to the subdomain Ω_j is well defined. Define approximate bilinear form $\mathcal{F}^{nc}$ by

$$\mathcal{F}^{nc}(\mathbf{u}^h,\mathbf{v}^h) := \sum_{j=1}^J \left\langle\mathcal{L}\mathbf{u}^h,\mathcal{L}\mathbf{v}^h\right\rangle_{0,\Omega_j} \tag{5.14}$$

and approximate linear functional ℓ^{nc} by

$$\ell^{nc}(\mathbf{v}^h) := \sum_{j=1}^J \left\langle\mathbf{f},\mathcal{L}\mathbf{v}^h\right\rangle_{0,\Omega_j}\,, \tag{5.15}$$

for $\mathbf{u}^h,\mathbf{v}^h \in \boldsymbol{\mathcal{W}}^h$. Assume that $\mathcal{F}^{nc}$ is uniformly $\boldsymbol{\mathcal{W}}^h$-elliptic with respect to a norm $\|\cdot\|_{\boldsymbol{\mathcal{W}}^h}$, with respective continuity and coercivity constants $\tilde{C}_{cont}$ and $\tilde{C}_{coer}$. This ensures that the following approximate variational problem has a unique solution: Find $\mathbf{u}^h \in \boldsymbol{\mathcal{W}}^h$ such that

$$\mathcal{F}^{nc}(\mathbf{u}^h,\mathbf{v}^h) = \ell^{nc}(\mathbf{v}^h) \tag{5.16}$$

for all $\mathbf{v}^h \in \boldsymbol{\mathcal{W}}^h$.

THEOREM 5.2. *Consider a family of discrete problems that stem from a FOSLS L^2 minimization problem, whose associated approximate bilinear forms are uniformly $\boldsymbol{\mathcal{W}}^h$-elliptic. Then there exists a constant C, independent of the subspace $\boldsymbol{\mathcal{W}}^h$, such that*

$$\left\|\mathbf{u}-\mathbf{u}^h\right\|_{\boldsymbol{\mathcal{W}}^h} \leq C \inf_{\mathbf{v}^h \in \boldsymbol{\mathcal{W}}^h} \left\|\mathbf{u}-\mathbf{v}^h\right\|_{\boldsymbol{\mathcal{W}}^h} . \tag{5.17}$$

Proof. Let $\mathbf{v}^h \in \boldsymbol{\mathcal{W}}^h$ be arbitrary. Using $\boldsymbol{\mathcal{W}}^h$-ellipticity of $\mathcal{F}^{nc}$ and the definition of the approximate variational problem (5.16), we have

$$\begin{aligned} \tilde{C}_{coer} \left\|\mathbf{u}^h-\mathbf{v}^h\right\|^2_{\boldsymbol{\mathcal{W}}^h} &\leq \mathcal{F}^{nc}(\mathbf{u}^h-\mathbf{v}^h, \mathbf{u}^h-\mathbf{v}^h) \\ &= \mathcal{F}^{nc}(\mathbf{u}-\mathbf{v}^h, \mathbf{u}^h-\mathbf{v}^h) + \mathcal{F}^{nc}(\mathbf{u}^h-\mathbf{u}, \mathbf{u}^h-\mathbf{v}^h) \\ &= \mathcal{F}^{nc}(\mathbf{u}-\mathbf{v}^h, \mathbf{u}^h-\mathbf{v}^h) + \ell^{nc}(\mathbf{u}^h-\mathbf{v}^h) - \mathcal{F}^{nc}(\mathbf{u}, \mathbf{u}^h-\mathbf{v}^h). \end{aligned} \tag{5.18}$$

Using (5.14), (5.15), and the Cauchy–Schwarz inequality for any $\mathbf{w}^h \in \boldsymbol{\mathcal{W}}^h$, we have

$$\left|\ell^{nc}(\mathbf{w}^h) - \mathcal{F}^{nc}(\mathbf{u}, \mathbf{w}^h)\right| \leq \sum_{j=1}^{J} \left|\left\langle \mathbf{f}-\mathcal{L}\mathbf{u}, \mathcal{L}\mathbf{w}^h \right\rangle_{0,\Omega_j}\right| \leq \sum_{j=1}^{J} \|\mathbf{f}-\mathcal{L}\mathbf{u}\|_{0,\Omega_j} \left\|\mathcal{L}\mathbf{w}^h\right\|_{0,\Omega_j} .$$

Since $\mathbf{u} \in \boldsymbol{\mathcal{W}}$ is the solution of minimization problem (5.12), we deduce

$$\|\mathcal{L}\mathbf{u}-\mathbf{f}\|^2_{0,\Omega_j} \leq \mathcal{G}(\mathbf{u};\mathbf{f}) = 0$$

for all $j = 1, \ldots, J$, which implies

$$\ell^{nc}(\mathbf{w}^h) - \mathcal{F}^{nc}(\mathbf{u}, \mathbf{w}^h) = 0. \tag{5.19}$$

Choosing $\mathbf{w}^h = \mathbf{u}^h - \mathbf{v}^h$ in (5.18) and appealing to the continuity of $\mathcal{F}^{nc}$, we thus have

$$\tilde{C}_{coer} \left\|\mathbf{u}^h-\mathbf{v}^h\right\|_{\boldsymbol{\mathcal{W}}^h} \leq \tilde{C}_{cont} \left\|\mathbf{u}-\mathbf{v}^h\right\|_{\boldsymbol{\mathcal{W}}^h} . \tag{5.20}$$

The triangle inequality and (5.20) imply

$$\left\|\mathbf{u}-\mathbf{u}^h\right\|_{\boldsymbol{\mathcal{W}}^h} \leq \left(\frac{C_{cont}}{C_{coer}} + 1\right) \left\|\mathbf{u}-\mathbf{v}^h\right\|_{\boldsymbol{\mathcal{W}}^h} ,$$

which completes the proof. □

Remark 3. Uniform $\boldsymbol{\mathcal{W}}^h$ coercivity must be established before Theorem 5.2 can be applied.

Theorem 5.2 implies that, for a FOSLS L^2 formulation that is discretized using a nonconforming finite element space, an estimate analogous to Cea's lemma (cf. [16, Theorem 13.1]) holds. Inequality (5.17) does not involve a consistency error term, as in the fundamental estimate for nonconforming finite elements (see [1], commonly referred to as Strang's second lemma). In common use is a patch test (cf. [16, p. 221]), which determines whether this consistency error term approaches zero as $h \to 0$. The corollary shows that, in the FOSLS L^2 context, elements that do not satisfy such conditions can be used, provided that uniform $\boldsymbol{\mathcal{W}}^h$-ellipticity can be established for $\mathcal{F}^{nc}$ and an error estimate based solely on interpolation theory can be derived.

5.3. An error estimate in the nonconforming space $\mathbf{W}^h \not\subseteq \mathbf{W}$. The finite element space $\mathbf{W}^h$ contains singular functions that would ideally model the singular behavior of the solution at cross-points exactly. However, the exponents and coefficients of these singular functions can be calculated only approximately, which means generally that $\mathbf{W}^h \not\subseteq \mathbf{W}$.

We will use Theorem 5.2 to derive an error estimate for the nonconforming case. However, as noted in Remark 3, we first must establish uniform coercivity of the approximate bilinear form. Define the nonconforming functional by

$$G^{nc}(\mathbf{u}; f) = \sum_{i=1}^{J} \left\| \frac{1}{\sqrt{a}} (\nabla \cdot \sqrt{a}\mathbf{u} + f) \right\|_{0,\Omega_i}^2 + \left\| \frac{1}{\sqrt{a}} \nabla \times \left(\frac{\mathbf{u}}{\sqrt{a}} \right) \right\|_{0,\Omega_i}^2 , \tag{5.21}$$

the associated bilinear form

$$\mathcal{F}^{nc}(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^{K} \left\langle \frac{1}{\sqrt{a}} \nabla \cdot \sqrt{a}\mathbf{u}, \frac{1}{\sqrt{a}} \nabla \cdot \sqrt{a}\mathbf{v} \right\rangle_{\Omega_i}^2 + \left\langle \sqrt{a}\nabla \times \frac{1}{\sqrt{a}\mathbf{u}}, \sqrt{a}\nabla \times \frac{1}{\sqrt{a}}\mathbf{v} \right\rangle_{\Omega_i}^2 , \tag{5.22}$$

and the seminorm

$$\mathcal{F}^{nc}(\mathbf{u}, \mathbf{u}) := |\mathbf{u}|_{\mathbf{W}^h}^2 . \tag{5.23}$$

We show in Appendix A.2 that $\mathcal{F}^{nc}$ is uniformly coercive in the norm $\|\mathbf{u}\|_{\mathbf{W}^h}^2 := \|\mathbf{u}\|_0^2 + |\mathbf{u}|_{\mathbf{W}^h}^2$. Thus, in what follows we use the seminorm. Now Theorem 5.2 implies that

$$\mathcal{F}^{nc}(\mathbf{u} - \mathbf{u}^h, \mathbf{u} - \mathbf{u}^h)^{1/2} = \left|\mathbf{u} - \mathbf{u}^h\right|_{\mathbf{W}^h} \leq C \inf_{\mathbf{v}^h \in \mathbf{W}^h} \left|\mathbf{u} - \mathbf{v}^h\right|_{\mathbf{W}^h} . \tag{5.24}$$

Denote by $\delta_m^h \tilde{\mathbf{s}}_{m,n}$ an approximation of the singular basis function $\delta_m^h \mathbf{s}_{m,n}$ such that $\tilde{\mathbf{s}}_{m,n}$ can be written in the general form (3.5) with approximate exponent $\tilde{\alpha}_{m,n}$ and approximate coefficient vectors $\tilde{\lambda}_{m,n}$ and $\tilde{\mu}_{m,n}$. The exact solution $\mathbf{u} \in \mathbf{W}$ of the FOSLS minimization problem (2.4) has the form

$$\mathbf{u} = \mathbf{u}_0 + \sum_{m=1}^{M} \sum_{n=1}^{N_m} \omega_{m,n} \delta_m^h \mathbf{s}_{m,n} + \sum_{m=1}^{M} \sum_{n=1}^{N_m} \omega_{m,n} \left(\delta_m^H - \delta_m^h \right) \mathbf{s}_{m,n}, \tag{5.25}$$

with $\mathbf{u}_0 \in \mathbf{W}_S^1$ independent of h. We choose

$$\mathbf{v}^h := I^h \mathbf{u}_0 + \sum_{m=1}^{M} \sum_{n=1}^{N_m} \omega_{m,n} \delta_m^h \tilde{\mathbf{s}}_{m,n} + \sum_{m=1}^{M} \sum_{n=1}^{N_m} \omega_{m,n} \left(\delta_M^H - \delta_m^h \right) \tilde{\mathbf{s}}_{m,n},$$

where I^h is the interpolant operator that was introduced in (5.5). Using (5.24) and the triangle inequality, we have

$$\begin{aligned} \left|\mathbf{u} - \mathbf{u}^h\right|_{\mathbf{W}^h,\Omega_j} \leq C \left|\mathbf{u}_0 - \mathbf{v}^h\right|_{\mathbf{W}^h,\Omega_j} &+ \sum_{m=1}^{M} \sum_{n=1}^{N_m} |\omega_{m,n}| \left|\delta_m^h \left(\mathbf{s}_{m,n} - \tilde{\mathbf{s}}_{m,n}\right)\right|_{\mathbf{W}^h,\Omega_j} \\ &+ \sum_{m=1}^{M} \sum_{n=1}^{N_m} |\omega_{m,n}| \left|\left(\delta_m^H - \delta_m^h\right) \left(\mathbf{s}_{m,n} - \tilde{\mathbf{s}}_{m,n}\right)\right|_{\mathbf{W}^h,\Omega_j}, \end{aligned} \tag{5.26}$$

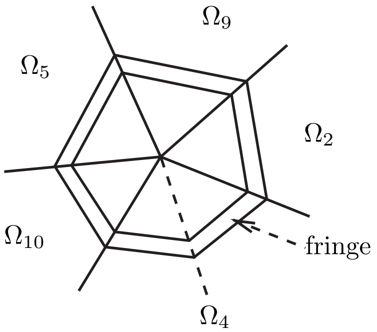

Fig. 5.2. *Geometry of interfaces meeting at a cross-point. Here, $I_m = 5$, $\{j_i\} = \{2, 9, 5, 10, 4\}$.*

for $j = 1, \ldots, J$. Standard interpolation error estimates can be used to estimate $|\mathbf{u}_0 - I^h\mathbf{u}_0|_{\mathbf{W}^h,\Omega_j}$, analogously to the proof of Theorem 5.1. We now derive estimates for the remaining terms, which involve the singular basis functions and their approximations.

Let $\Omega_{j_i} \subset \Omega$, $i = 1, \ldots, I_m$, be the set of subdomains that meet at cross-point m, ordered so that they appear consecutively with increasing i. (See Figure 5.2.) Let $\{\vartheta_{j_i}\}_{i=1,\ldots,I_m}$ be the set of angles at cross-point m. If the difference of two subsequent angles is greater than $\pi/2$, then we introduce artificial interfaces, equally spaced in the interval $(\vartheta_{j_i}, \vartheta_{j_{i+1}})$, such that the angles between subsequent interfaces are now smaller than $\pi/2$. (See the dashed interface line in Figure 5.2.) The platform and fringe are such that, for subdomains that do not require an artificial interface, $\Omega_{j_i} \cap (P_m \cup F_m)$ is an isosceles triangle. In the presence of artificial interfaces, platform and fringe are such that their intersection with Ω_{j_i} is the union of isosceles triangles whose sides are aligned with the artificial interfaces.

In the following calculations, we denote by $\tilde{I}_m$ the total number of actual and artificial interfaces, and by $\{\theta_{m,i}\}_{i=1,\ldots,\tilde{I}_m}$ the angles of these interfaces, ordered such that $\theta_{m,i} < \theta_{m,i+1}$, $i = 1, \ldots, \tilde{I}_m$ (define $\theta_{m,\tilde{I}_m+1} = 2\pi + \theta_{m,1}$). $P_{m,i}$ and $F_{m,i}$ are the parts of platform and fringe, respectively, that are enclosed by angles $\theta_{m,i}$ and $\theta_{m,i+1}$, $i = 1, \ldots, \tilde{I}_m$. Denote by $R_{m,i}$ the distance from $F_{m,i}$ to the cross-point, and by $h_{m,i}$ the radial width of $F_{m,i}$. We omit the subscript ${}_{m,n}$ for singular functions, when it is obvious to which singular functions we refer.

The cut-off function on $F_{m,i}$, for $\theta \in (\theta_{m,i}, \theta_{m,i+1})$, is

$$\delta^h(r,\theta) = \frac{\cos(\theta_{m,i+1/2} - \theta)}{h}\left(\frac{R_{m,i} + h_{m,i}}{\cos(\theta_{m,i+1/2} - \theta)} - r\right), \tag{5.27}$$

where $\theta_{m,i+1/2} = (\theta_{m,i+1} - \theta_{m,i})/2$, with partial derivatives

$$\delta^h_x(r,\theta) = -\frac{\cos\theta_{m,i+1/2}}{h}, \qquad \delta^h_y(r,\theta) = -\frac{\sin\theta_{m,i+1/2}}{h}. \tag{5.28}$$

In what follows, we assume the approximate singular basis functions, $\tilde{\mathbf{s}}_{m,n}$, are of the form (3.5), with known but inexact coefficients $\tilde{\alpha}_{m,n} = \alpha_{m,n} + \eta_m$, $\tilde{\lambda}_{m,n} = \lambda_{m,n} + O(\eta_m)$, and $\tilde{\mu}_{m,n} = \mu_{m,n} + O(\eta_m)$. We will drop subscripts where the meaning is clear.

Lemma 5.3. *Let $\eta_{m,n} = |\alpha_{m,n} - \tilde{\alpha}_{m,n}|$. The estimate*

$$\left|\delta^h_m \mathbf{s}_{m,n} - \delta^h_m \tilde{\mathbf{s}}_{m,n}\right|^2_{\mathbf{W}^h} \le \frac{C(a)\eta^2_{m,n}}{h} \tag{5.29}$$

holds for all cross-points and singular basis functions and some constant $C(a)$ independent of h and η.

Proof. Omitting the subscripts $_{m,n}$ for convenience, note that

$$\mathcal{F}^{nc}_{P_m}(\delta^h_m\mathbf{s}, \delta^h_m\mathbf{s}) = \mathcal{F}^{nc}_{P_m}(\delta^h_m\tilde{\mathbf{s}}, \delta^h_m\mathbf{s}) = \mathcal{F}^{nc}_{P_m}(\delta^h_m\tilde{\mathbf{s}}, \delta^h_m\tilde{\mathbf{s}}) = 0,$$

where P_m is the platform associated with singular function $\mathbf{s}$. Letting $\mathbf{s} = (s_1, s_2)^t$ and $\tilde{\mathbf{s}} = (\tilde{s}_1, \tilde{s}_2)^t$, (5.28) and some vector calculus implies

$$\begin{aligned}\left|\delta^h\mathbf{s} - \delta^h\tilde{\mathbf{s}}\right|_{\mathbf{W}^h,F_{m,i}} &= \left\|\nabla\cdot\left(\delta^h\mathbf{s} - \delta^h\tilde{\mathbf{s}}\right)\right\|^2_{0,F_{m,i}} + \left\|\nabla\times\left(\delta^h\mathbf{s} - \delta^h\tilde{\mathbf{s}}\right)\right\|^2_{0,F_{m,i}} \\ &= \left\|\nabla\delta^h\cdot(\mathbf{s} - \tilde{\mathbf{s}})\right\|^2_{0,F_{m,i}} + \left\|\nabla^\perp\delta^h\cdot(\mathbf{s} - \tilde{\mathbf{s}})\right\|^2_{0,F_{m,i}} \\ &= \frac{1}{h^2_{m,i}}\left(\|s_1 - \tilde{s}_1\|^2_{0,F_{m,i}} + \|s_2 - \tilde{s}_2\|^2_{0,F_{m,i}}\right).\end{aligned} \tag{5.30}$$

We now estimate only the last term in (5.30), since a similar estimate can be derived analogously for the other term. Let $\eta_\lambda = \lambda - \tilde{\lambda}$ and $\eta_\mu = \mu - \tilde{\mu}$, and note that η_λ and η_μ are of order $O(\eta)$. Then we get

$$\begin{aligned}\|s_2 - \tilde{s}_2\|^2_{0,F_{m,i}} &= a_i\left\|\alpha r^{\alpha-1}\left(\lambda\cos(\alpha-1)\theta - \mu\sin(\alpha-1)\theta\right)\right. \\ &\qquad \left.-\tilde{\alpha}r^{\tilde{\alpha}-1}(\tilde{\lambda}\cos(\alpha_h-1)\theta - \tilde{\mu}\sin(\tilde{\alpha}-1)\theta)\right\|^2_{0,F_{m,i}} \\ &= a_i\left\|(\alpha r^{\alpha-1} - \tilde{\alpha}r^{\tilde{\alpha}-1})(\lambda\cos(\alpha-1)\theta - \mu\sin(\alpha-1)\theta)\right. \\ &\qquad \left.-\tilde{\alpha}r^{\tilde{\alpha}-1}(\eta_\lambda\cos(\tilde{\alpha}-1)\theta - \eta_\mu\sin(\tilde{\alpha}-1)\theta)\right\|^2_{0,F_{m,i}} \\ &\le 2a_i\left\|(\alpha r^{\alpha-1} - \tilde{\alpha}r^{\tilde{\alpha}-1})(\lambda\cos(\alpha-1)\theta - \mu\sin(\alpha-1)\theta)\right\|^2_{0,F_{m,i}} \\ &\quad + 2a_i\left\|\tilde{\alpha}r^{\tilde{\alpha}-1}(\eta_\lambda\cos(\tilde{\alpha}-1)\theta - \eta_\mu\sin(\tilde{\alpha}-1)\theta)\right\|^2_{F_{m,i}} \\ &\le 4a_i(\lambda^2+\mu^2)\left\|\alpha r^{\alpha-1} - \tilde{\alpha}r^{\tilde{\alpha}-1}\right\|^2_{F_{m,i}} + 4a_i(\eta^2_\lambda + \eta^2_\mu)\left\|\tilde{\alpha}r^{\tilde{\alpha}-1}\right\|^2_{F_{m,i}}.\end{aligned} \tag{5.31}$$

Let $0 < r < R + h$, $0 < h < 1$, and $0 < \eta < 1$. Then we have

$$|1 - r^\eta| \le C_1\eta, \qquad \left\|\tilde{\alpha}r^{\tilde{\alpha}-1}\right\|^2_{0,F_{m,i}} \le C_2 h_{m,i}, \tag{5.32}$$

which, with $0 < \alpha, \tilde{\alpha} \le 1$, implies that

$$\begin{aligned}\left\|\alpha r^{\alpha-1} - \tilde{\alpha}r^{\tilde{\alpha}-1}\right\|^2_{0,F_{m,i}} &\le \left\|\alpha(r^{\alpha-1} - r^{\tilde{\alpha}-1}) - \eta r^{\tilde{\alpha}-1}\right\|^2_{0,F_{m,i}} \\ &\le 2\left\|r^{\alpha-1} - r^{\tilde{\alpha}-1}\right\|^2_{0,F_{m,i}} + 2\eta^2\left\|r^{\tilde{\alpha}-1}\right\|^2_{0,F_{m,i}} \\ &\le 2\left\|r^{\alpha-1}(1 - r^\eta)\right\|^2_{0,F_{m,i}} + 2\eta^2 C_2 h_{m,i} \\ &\le 2C_1^2\eta^2 C_2 h_{m,i} + 2\eta^2 C_2 h_{m,i} \\ &= C\eta^2 h_{m,i}.\end{aligned} \tag{5.33}$$

Combining estimates (5.31)–(5.33) with (5.30), we get

$$\left|\delta^h\mathbf{s} - \delta^h\tilde{\mathbf{s}}\right|_{\mathbf{W}^h,F_{m,i}} \le \frac{C(a_i)\eta^2}{h_{m,i}}. \tag{5.34}$$

TABLE 5.1

Summing over interfaces and artificial interfaces, and noting that $h_{m,i} = O(h)$, completes the proof. □

Using estimates (5.7) and (5.29) in (5.26) implies the main result of this section.

THEOREM 5.4. *Denote by* $\mathbf{u} \in \mathbf{W}$ *the solution of minimization problem* (2.4) *and by* $\mathbf{u}^h \in \mathbf{W}^h$ *the solution of the discretized variational problem* (2.7). *Also, let* $\eta > 0$ *be the maximum error in the exponent of the approximate singular basis function,* h *be the mesh size of triangulation* $\mathcal{T}^h$ *and the fringe width, and*

(5.35)
$$\kappa := \min_{\mathbf{s}}\{\alpha : \alpha \textit{ is the exponent of } \mathbf{s}, \alpha > 1, \nabla \cdot (\sqrt{a}\mathbf{s}) = 0, \textit{ and } \nabla \times (\mathbf{s}/\sqrt{a}) = 0\}.$$

Then

$$\left|\mathbf{u} - \mathbf{u}^h\right|_{\mathbf{W}^h} \le C(a)\left(h^{\kappa-1} + \eta/\sqrt{h}\right), \tag{5.36}$$

where the constant $C(a)$ *does not depend on* η, κ, *and* h.

To achieve a discretization error of order $O(h)$ in the nonconforming finite element space $\mathbf{W}^h$, we must ensure that $\kappa \ge 2$ and that the approximation error in the exponent η is of order $O(h^{3/2})$. The constraint on κ can be met by adding basis functions of the general form (3.5) that have exponents $1 < \alpha < 2$ and satisfy the first two equations in (2.2) with $f = 0$.

5.4. An example. Here, we present a numerical example to illustrate the theoretical results of the previous sections. We consider problem (2.2) on the unit square, with $f = 0$ and the Dirichlet boundary condition

$$\tau \cdot \mathbf{u} = \tau \cdot \mathbf{s} \quad \text{on } \partial(0,1)^2, \tag{5.37}$$

where $\mathbf{s}$ is the singular function associated with the coefficient

$$a(x,y) = \begin{cases} 1 & \text{for } 0 < x,y < 1/2 \text{ and } 1/2 < x,y < 1, \\ 100 & \text{elsewhere in } (0,1)^2. \end{cases} \tag{5.38}$$

For this checkerboard pattern, the exponent is approximately $\alpha \approx 0.126902069$.

Table 5.1 shows the value of the FOSLS functional at the solution for various values of h. The left two columns show results for the finite element space $\mathbf{W}^h$ consisting of linear, quadratic, and singular elements as described in section 4. The right two columns show results for a finite element space that contains only the linear and singular elements. The ratio refers to the quotient of two subsequent functional values: ratio $= \mathcal{G}(\mathbf{u}^h; f)/\mathcal{G}(\mathbf{u}^{h/2}; f)$. For the space $\mathbf{W}^h$, this ratio approaches 4 as h is decreased. In the space that does not contain quadratic elements in the fringe, the ratio approaches 2 for decreasing h. These results signal a lower approximation order when quadratic elements are not included in the finite element space.

6. A multilevel solver.

We now describe a multilevel solver for the linear system that arises from the finite element discretization using $\mathbf{W}^h$. Our goal is to use standard coarsening for linear elements and to include singular basis functions on every level. This results in a hierarchy of spaces $\mathbf{W}^{2^K h} \nsubseteq \mathbf{W}^{2^{K-1}h} \nsubseteq \cdots \nsubseteq \mathbf{W}^{2h} \nsubseteq \mathbf{W}^h$. The spaces are nested except for the singular basis functions, which are nonnested, since the fringes on different levels have different widths.

We coarsen such that the platform associated with a given cross-point has equal size on all levels. The choice of interpolation and restriction for linear and quadratic elements in fringes is driven by the interpolation for singular basis functions.

Consider interpolation of $\delta_m^{2h}\tilde{\mathbf{s}}_{m,n} \in \mathbf{W}^{2h}$ to $\mathbf{W}^h$. The coefficient $\omega_{m,n}^{2h}$ of $\delta_m^{2h}\tilde{\mathbf{s}}_{m,n}$ is transferred by injection: $\omega_{m,n}^h \leftarrow \omega_{m,n}^{2h}$. What is left is the difference $(\delta_m^{2h} - \delta_m^h)\tilde{\mathbf{s}}_{m,n}$ that is interpolated using standard linear and quadratic interpolation. Denote by N_L^h and N_Q^h the respective numbers of linear and quadratic basis functions in $\mathbf{W}^h$, and by $\boldsymbol{\psi}_l$, $l = 1, \ldots, N_L^h$, and $\boldsymbol{\phi}_k$, $k = 1, \ldots, N_Q^h$, the respective linear and quadratic basis functions in $\mathbf{W}^h$, such that

$$\begin{aligned}(6.1)\quad \mathbf{W}^h = \operatorname{span}\left\{\boldsymbol{\psi}_l \;:\; l = 1, \ldots, N_L^h\right\} \;\cup\; \operatorname{span}\left\{\boldsymbol{\phi}_k \;:\; k = 1, \ldots, N_Q^h\right\} \\ \cup\; \operatorname{span}\left\{\delta_m^h \tilde{\mathbf{s}}_{m,n} \;:\; m = 1, \ldots, M;\; n = 1, \ldots, N_m\right\}.\end{aligned}$$

Define the vectors $\boldsymbol{\beta}_{m,n}^h = \{\beta_{m,n}^{h,l}\}_{l=1,\ldots,N_L^h}$ and $\boldsymbol{\gamma}_{m,n}^h = \{\gamma_{m,n}^{h,k}\}_{k=1,\ldots,N_Q^h}$ so that their elements are the respective coefficients of linear and quadratic basis functions of the pointwise linear and quadratic interpolant of $(\delta_m^{2h} - \delta_m^h)\tilde{\mathbf{s}}_{m,n}$. We now have

$$(6.2)\qquad I^h(\delta_m^{2h} - \delta_m^h)\tilde{\mathbf{s}}_{m,n} := \sum_{l=1}^{N_L^h} \beta_l^h \boldsymbol{\psi}_{m,n}^{h,l} + \sum_{k=1}^{N_Q^h} \gamma_k^h \boldsymbol{\phi}_{m,n}^{h,k}.$$

Note that most of the $\beta_{m,n}^{h,l}$ and $\gamma_{m,n}^{h,k}$ are zero, since $\delta_m^{2h} - \delta_m^h$ is nonzero only in the fringe of level $2h$ associated with cross-point m.

Assume that the basis functions are ordered so that the first N_L^h are linear, the next N_Q^h are quadratic, and the last $N_S := \sum_{m=1}^M N_m$ are singular basis functions. Then the column in interpolation matrix $\mathcal{I}_{2h}^h$ corresponding to the singular basis function with index (m,n) is $(\beta_{m,n}^{h,1}, \ldots, \beta_{m,n}^{h,N_L^h}, \gamma_{m,n}^{h,1}, \ldots, \gamma_{m,n}^{h,N_Q^h}, 0, \ldots, 0, 1, 0, \ldots, 0)$. Fine-level linear basis functions centered at vertices inside the coarse-level fringe are interpolated using standard linear interpolation.

Figure 6.1 shows a section of the fringe in a triangular mesh of mesh size h (thick and thin lines), and a section of the fringe in the coarsened triangular mesh of mesh size $2h$ (thick lines). It illustrates the location of the quadratic nodes on both levels.

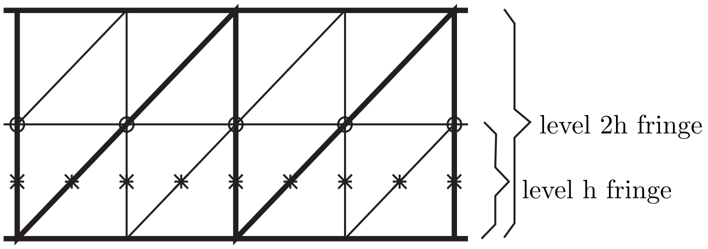

FIG. 6.1. *Location of quadratic points (level h: stars; level $2h$: circles).*

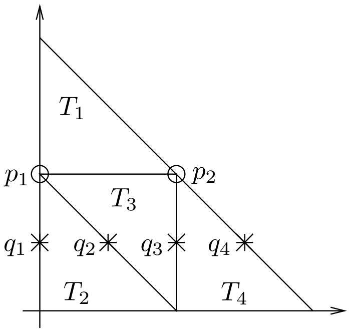

FIG. 6.2. *Coarse fringe triangle subdivided into four subtriangles.*

Note that quadratic nodes on level $2h$ coincide with vertices of triangles on level h. We now describe the interpolation formulas that are used for quadratic nodes on level h and linear nodes on level h that coincide with quadratic nodes on level $2h$. For the latter, we use linear interpolation from the two neighboring coarse points and add to that the value of the quadratic at that point.

Figure 6.2 shows a coarse fringe unit triangle in general (ξ, η) coordinates that is subdivided into four subtriangles $T_1, \ldots, T_4$. Triangles T_2, T_3, T_4 are in the fine fringe. Coarse-level quadratic basis functions are centered at points q_1^c and q_2^c, and fine-level quadratic basis functions are centered at points $q_1^f, \ldots, q_4^f$. (We denote by $q_1^c, q_2^c, q_1^f, \ldots, q_4^f$ the respective points, as well as the coefficients of quadratic basis functions at these points.) Assume that the linear part of the coarse-level function is zero. The quadratic part is

$$Q(\xi, \eta) = q_1^c Q_1^c(\xi, \eta) + q_2^c Q_2^c(\xi, \eta),$$

with

$$\begin{aligned} Q_1^c(\xi, \eta) &= 4\eta(1 - \xi - \eta), \\ Q_2^c(\xi, \eta) &= 4\xi\eta. \end{aligned}$$

First we interpolate the linear fine-level points that coincide with quadratic coarse-level points. We obtain the following linear functions:

$$\begin{aligned} L_2(\xi, \eta) &= 2\eta q_1^c && \text{in } T_2, \\ L_3(\xi, \eta) &= 2\eta(2(q_1^c - q_2^c)\xi - q_1^c) && \text{in } T_3, \\ L_4(\xi, \eta) &= 2\eta q_2^c && \text{in } T_4. \end{aligned}$$

We want the interpolant to be pointwise exact at fine-level quadratic points, so interpolation of fine-level quadratic points is determined by

$$\begin{array}{lcl cl} q_1^f &=& Q(0, 1/4) - L_2(0, 1/4) &=& 1/4\ q_1^c, \\ q_2^f &=& Q(1/4, 1/4) - L_2(1/4, 1/4) &=& 1/4\ q_2^c, \\ q_3^f &=& Q(1/2, 1/4) - L_4(1/2, 1/4) &=& 1/4\ q_1^c, \\ q_4^f &=& Q(3/4, 1/4) - L_4(3/4, 1/4) &=& 1/4\ q_2^c. \end{array} \tag{6.3}$$

Interpolation weights in (6.3) do not depend on ξ or η, so they are the same in (x, y) coordinates.

Denote by $\hat{I}_{2h}^{h} \in \Re^{(N_L+N_Q)\times(N_L+N_Q)}$ the matrix that interpolates linear and quadratic basis functions on level h from level $2h$, as defined above. Let $B^h := \{\boldsymbol{\beta}_{m,n}^h\}_{n=1,\ldots,N_m;m=1,\ldots,M}$ and $\Gamma^h := \{\boldsymbol{\gamma}_{m,n}^h\}_{n=1,\ldots,N_m;m=1,\ldots,M}$. Then we can write the interpolant operator $\mathcal{I}_{2h}^h : \mathbf{W}^{2h} \to \mathbf{W}^h$ in matrix form as

$$\mathcal{I}_{2h}^{h} = \left(\begin{array}{ccc} \multicolumn{2}{c}{\hat{I}_{2h}^{h}} & \begin{array}{c} B^h \\ \Gamma^h \end{array} \\ 0 & 0 & I \end{array} \right), \tag{6.4}$$

where I is the identity matrix in $\Re^{N_S \times N_S}$.

We extend this idea to all levels to obtain interpolation matrices $\mathcal{I}_{2^K h}^{2^{K-1}h}, \ldots, \mathcal{I}_{2h}^{h}$. The restriction operators are defined as the transpose of interpolation $\mathcal{I}_{2^k h}^{2^{k+1}h} = (\mathcal{I}_{2^{k+1}h}^{2^k h})^t$ for $k = 0, \ldots, K-1$. The coarse-grid stiffness matrix is determined from the Galerkin principle by fine-grid stiffness matrix S^h and interpolation matrix $\mathcal{I}_{2h}^h$:

$$S^{2h} = (\mathcal{I}_{2h}^{h})^t \; S^h \; \mathcal{I}_{2h}^{h}. \tag{6.5}$$

This definition is extended recursively to all levels.

We use Gauss–Seidel relaxation for pre- and postrelaxation in the multigrid iteration and solve the coarse grid problem approximately using algebraic multigrid (AMG) (see [29]). Numerical tests have shown that the standard AMG algorithm is not well suited to solving the resulting linear system. Therefore, we instead use a Schur complement approach that exploits the structure of the coarse-grid problem, with the subproblems treated by AMG.

To explain this Schur-AMG approach, note that the coarse-grid linear system has the general form

$$\begin{pmatrix} A & V \\ V^t & D \end{pmatrix} \begin{pmatrix} \mathbf{u} \\ \mathbf{w} \end{pmatrix} = \begin{pmatrix} \mathbf{f} \\ \mathbf{g} \end{pmatrix}, \tag{6.6}$$

where submatrix A represents connections between linear and quadratic basis functions and D represents connections between singular basis functions. A is sparse and D is block diagonal. The off-diagonal submatrix V represents connections between the linear and quadratic basis functions and the singular basis functions. Linear system (6.6) can be reduced to

$$\mathbf{u} = A^{-1}\mathbf{f} - A^{-1}V\mathbf{w}, \tag{6.7}$$

$$\mathbf{w} = (D - V^t A^{-1} V)^{-1}(\mathbf{g} - V^t A^{-1}\mathbf{f}). \tag{6.8}$$

We calculate $A^{-1}\mathbf{f}$ and $A^{-1}V$ approximately using AMG. The inverse of $D - V^t A^{-1} V$ is then calculated directly, using Gaussian elimination, since the number of singular basis functions is assumed to be small.

Denote by N_C the number of coarse-grid linear and quadratic basis functions and by N_S the number of singular basis functions. Thus, $A \in \Re^{N_C \times N_C}$, $V \in \Re^{N_C \times N_S}$, and $D \in \Re^{N_S \times N_S}$. AMG has complexity of order $O(N_C)$, and the inverse of $D - V^t A^{-1} V$ can be calculated in $O(N_S^3)$ operations. Hence, the complexity of the coarse-grid solver is of order $O(N_S^3 + N_S N_C)$. Since N_S is assumed to be small in comparison to N_C, we can deduce that standard multilevel complexity analysis applies (see, for example, [31]).

7. Numerical results. To study the convergence properties of the multigrid algorithm described above let the domain Ω be a square partitioned in a checkerboard fashion into square subdomains of equal size, where the coefficient a is constant. In our examples, a takes on two values that are distributed over the square subdomains in a checkerboard fashion. We report asymptotic convergence factors of the functional value $(\mathcal{G}(\mathbf{u}^h; f))^{1/2}$ that were obtained by setting $f = 0$ and imposing homogeneous Dirichlet boundary conditions $\mathbf{n} \times \sqrt{a}\mathbf{u}^h = 0$ on $\partial\Omega$. Thus, the exact solution of the problem is $\mathbf{u}^h = 0$, which allows us to perform many iterations without encountering serious machine representation effects. To properly test convergence, we initialize all variables randomly.

Table 7.1 shows asymptotic convergence factors for the $W(2,2)$ cycle for two examples of a. Four checkerboard patterns are investigated, ranging from one singular basis function to 16. Each column shows asymptotic convergence factors for fixed mesh-size h. Hence, the domain Ω changes for varying numbers of singular basis functions. However, the width of fringes does not change.

We observe that, for a larger number of levels, typical multigrid convergence factors that are h-independent are attained. For a smaller number of levels, the convergence factors appear to grow with the number of singular basis functions. However, this dependency appears to weaken as more levels are added; it appears to be stronger for larger jumps in the coefficient a.

In Table 7.2, the influence of the number of pre- and postrelaxation steps in the W-cycle is shown. We display effective convergence factors relative to the $W(1,1)$ cycle. Since for integer $k > 1$ one $W(k,k)$ cycle is k times more costly than one $W(1,1)$ cycle, we have $\rho_{W(k,k),\text{effective}} = \rho_{W(k,k)}^{1/k}$. Increasing the number of pre- and postrelaxation steps increases effective convergence factors. It is, hence, most efficient to use $W(1,1)$ cycles.

Table 7.3 shows results for two convergence tolerances for the AMG iteration that is used to invert A approximately. For the larger tolerance of $1e-1$ convergence of the multilevel iteration is somewhat slower than for the smaller tolerance of $1e-9$. This difference is less pronounced when more levels are added.

Table 7.3
Influence of the coarse grid solver on the overall convergence ($W(2,2)$ cycles, $a(x,y) \in \{1,100\}$).

8. Conclusions.

We introduced a finite element method for FOSLS L^2 formulation of the diffusion equation with discontinuous coefficients. Our approach uses singular basis functions to yield accurate approximation of the flux variable close to singular points in the domain at minimal additional computational cost. Stress intensity factors are also calculated. We developed a special discretization error analysis, since standard theory is not applicable. This led to a general error estimate for FOSLS L^2 discretizations with nonconforming finite elements. We also proposed a multilevel algorithm for the solution of the resulting linear system that uses nonstandard coarse spaces including coarse representations of singular basis functions. The performance of the algorithm is illustrated by numerical examples.

Appendix A. Uniform coercivity of $\mathcal{F}^{nc}$.

The purpose of this appendix is to establish the uniform coercivity of $\mathcal{F}^{nc}$. In [2] such a bound was established for the conforming functional. Here, we show that the coercivity constant will be independent of h and η, the error in the exponents of the singular basis function, only if η goes to zero at least as fast as the cosine of the angle between the mesh-dependent singular function $\delta_m^h \mathbf{s}_{m,n}^\eta$ and the subspace, $\mathbf{W}_S^1$, of piecewise H^1 functions. Unfortunately, a proof that the angle between the singular basis functions and $\mathbf{W}_S^1$ is $O(h)$ has not been found. In this next section we provide numerical proof.

A.1. Angle between $\delta_m^h \mathbf{s}_{m,n}$ and W_S^1.

In the example we present in Figure A.1, the domain Ω is divided into subdomains in a 2×2 checkerboard fashion, with $a = 1$ in the upper left and lower right subdomains, and $a = 100$ in the upper right and lower left subdomains. This configuration results in a singularity in the center of the domain with exponent $\alpha \approx 0.126902$. Figure A.1 depicts $1 - \cos\theta$ as a function of h, where θ is the angle between the singular basis function and the rest of

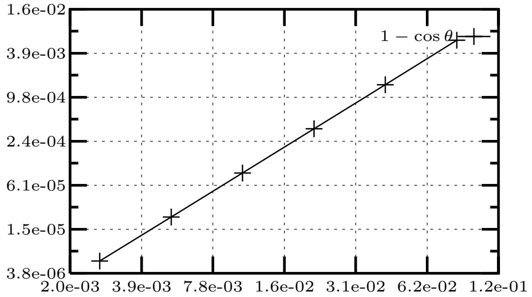

Fig. A.1. *A* $\log_2$*-*$\log_2$ *plot of* $1 - \cos\theta$ *(see* (A.1)*), where* h *is on the* x*-axis.* θ *is the angle between a singular basis function and the rest of the space.*

the space,

$$\cos\theta = \frac{\mathcal{F}^{nc}(\delta^h \mathbf{s}^h, I^h(\delta^h \mathbf{s}^h))}{\mathcal{F}^{nc}(\delta^h \mathbf{s}^h, \delta^h \mathbf{s}^h)^{1/2}\mathcal{F}^{nc}(I^h(\delta^h \mathbf{s}^h), I^h(\delta^h \mathbf{s}^h))^{1/2}}, \tag{A.1}$$

and I^h is the standard pointwise linear interpolation operator.

Both axes in the figure are on a $\log_2$ scale. All data points lie on a straight line, so we conjecture $1 - \cos\theta = O(h^2)$, and hence $\theta = O(h)$.

A.2. Uniform coercivity. We assume that the discrete space consists of the conforming linears and quadratics, with proper jumps across the interfaces, plus a finite number of singular basis functions. Here, as in section 5, we make the assumption that the approximate singular basis functions $\tilde{\mathbf{s}}_{m,n}$ are of the form (3.5), with known but inexact coefficients $\tilde{\alpha}_{m,n} = \alpha_{m,n} + \eta_{m,n}$, $\tilde{\lambda}_{m,n} = \lambda_{m,n} + O(\eta_{m,n})$, and $\tilde{\mu}_{m,n} = \mu_{m,n} + O(\eta_{m,n})$. We will drop subscripts where the meaning is clear.

We further assume that $\eta_{m,n}$ is sufficiently small to resolve the differences between exponents at a given singular point $\mathbf{x}_m$. That is, we assume that $\eta_{m,n} \leq \eta_{m,0}$ for $n = 1, \ldots, N_m$.

To emphasize the dependence on η, we denote the discrete subspace as

$$\mathbf{W}^{h,\eta} := \mathbf{W}_S^{1,h} + \operatorname{span}\left\{\delta_m^h \tilde{\mathbf{s}}_{m,n}\right\}_{n=1,m=1}^{N_m,M}. \tag{A.2}$$

Next we define a bound on the angle between the subspace spanned by the approximate singular basis functions at a given singular point $\mathbf{x}_m$ and the subspace $\mathbf{W}_S^1$. Let

$$\mathcal{S}_m(\eta, h) := \operatorname{span}\{\delta_m^h \tilde{\mathbf{s}}_{m,n}\}_{n=1}^{N_m}, \tag{A.3}$$

and let

$$\gamma_m(h) := \sup_{\eta \leq \eta_{m,0}} \sup_{\mathbf{s}\in\mathcal{S}_m, \mathbf{u}\in\mathbf{W}_S^1} \frac{\mathcal{F}^{nc}\langle \mathbf{s}, \mathbf{u}\rangle}{|\mathbf{s}|_{\mathbf{W}^h}|\mathbf{u}|_{\mathbf{W}^h}}. \tag{A.4}$$

This yields the following result.

LEMMA A.1 (strengthened Cauchy–Schwarz inequality). *For every singular point $\mathbf{x}_m$ there is a constant $\gamma_m(h) < 1.0$ such that*

$$\mathcal{F}^{nc}(\mathbf{s}, \mathbf{w}) \leq \gamma_m |\mathbf{s}|_{\mathbf{W}^h} |\mathbf{w}|_{\mathbf{W}^h} \tag{A.5}$$

for every $\mathbf{s} \in \mathcal{S}_m$ and $\mathbf{w} \in \mathbf{W}_S^1$.

Proof. For any fixed $h > 0, \eta > 0$, there is a positive angle between $\mathcal{S}_m$ and $\mathbf{W}_S^1$. Thus, $\gamma_m < 1.0$ □

This leads to the following bound.

LEMMA A.2. *Let $\mathbf{w} \in \mathbf{W}^{h,\eta}$ have the form*

$$\mathbf{w} = \sum_{m=1}^{M} \sum_{n=1}^{N_m} \beta_{m,n} \delta^m \tilde{\mathbf{s}}_{m,n} + \mathbf{w}_0^h, \tag{A.6}$$

where $\mathbf{w}_0^h \in \mathbf{W}_S^{1,h}$. Then

$$\sum_{m=1}^{M} \sum_{n=1}^{N_m} \beta_{m,n}^2 |\delta_m^h \tilde{\mathbf{s}}_{m,n}|_{\mathbf{W}^h}^2 \leq \frac{C}{1-\gamma^2} |\mathbf{w}|_{\mathbf{W}^h}^2, \tag{A.7}$$

where $\gamma = \max_m \gamma_m$.

Proof. The result follows from the fact that the singular basis functions associated with different singular points are mutually orthogonal and from the strengthened Cauchy–Schwarz inequality. For this proof only, let $\mathcal{P}_m$ represent the platform and fringe around singular point m.

$$\begin{aligned}
|\mathbf{w}|^2_{\mathbf{W}^h} &\geq \left| \sum_{i=1}^{M} \sum_{n=1}^{N-m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right|^2_{\mathbf{W}^h} - 2\mathcal{F} \left\langle \sum_{i=1}^{M} \sum_{n=1}^{N_m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n},\, \mathbf{w}_0 \right\rangle + |\mathbf{w}_0|^2_{\mathbf{W}^h} \\
&\geq \sum_{i=1}^{M} \left| \sum_{n=1}^{N_m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right|^2_{\mathbf{W}^h} \\
&\quad - 2 \sum_{i=1}^{M} \gamma_m \left| \sum_{n=1}^{N_m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right|_{\mathbf{W}^h} |\mathbf{w}_0|_{\mathbf{W}^h, \mathcal{P}_m} + |\mathbf{w}_0|^2_{\mathbf{W}^h} \\
&\geq (1-\gamma^2) \sum_{i=1}^{M} \left| \sum_{n=1}^{N_m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right|^2_{\mathbf{W}^h} + |\mathbf{w}_0|^2_{\mathbf{W}^h} - \sum_{m=1}^{M} |\mathbf{w}_0|^2_{\mathbf{W}^h, \mathcal{P}_m} \\
&\geq (1-\gamma^2) \sum_{i=1}^{M} \left| \sum_{n=1}^{N_m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right|^2_{\mathbf{W}^h} .
\end{aligned}$$

Since the singular functions associated with any give singular point are linearly independent, there exists a constant C_m independent of h such that

$$\left| \sum_{n=1}^{N_m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right|_{\mathbf{W}^h} \geq C_m \sum_{n=1}^{N_m} |\beta_{m,n}|^2 \left\| \delta^h_m \tilde{\mathbf{s}}_{m,n} \right\|^2_{\mathbf{W}^h}. \tag{A.8}$$

This completes the proof. □

We now show a Poincaré–Friedrichs inequality for the bilinear form. The nonconformity is rooted in the fact that the singular basis functions, $\delta^h_m \tilde{\mathbf{s}}_{m,n}$, do not satisfy the jump conditions exactly. Suppose that Γ_{ij} is the interface between Ω_I and Ω_J. Let $[g]_{\Gamma_{ij}}$ denote the jump in g across Γ_{ij} . Let $\mathbf{w} \in \mathbf{W}^{h,\eta}$ be defined as in (A.6). We have

$$\begin{aligned}
\left[\mathbf{n} \cdot \sqrt{a}\mathbf{w}\right]_{\Gamma_{ij}} &= \left[\mathbf{n} \cdot \sqrt{a} \sum_{m=1}^{M} \sum_{n=1}^{N_m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right]_{\Gamma_{ij}} \\
&= \sum_{m\ :\ \Gamma_{ij} \cap \mathcal{P}_k \neq \emptyset} \sum_{n=1}^{N_m} \beta_{m,n} \left[\mathbf{n} \cdot \sqrt{a} \delta^h_m \tilde{\mathbf{s}}_{m,n}\right]_{\Gamma_{ij}} , \\
\left[\boldsymbol{\tau} \cdot \frac{1}{\sqrt{a}} \mathbf{w} \right]_{\Gamma_{ij}} &= \left[\boldsymbol{\tau} \cdot \frac{1}{\sqrt{a}} \sum_{m=1}^{M} \sum_{n=1}^{N_m} \beta_{m,n} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right]_{\Gamma_{ij}} \\
&= \sum_{m\ :\ \Gamma_{ij} \cap \mathcal{P}_k \neq \emptyset} \sum_{n=1}^{N_m} \beta_{m,n} \left[\boldsymbol{\tau} \cdot \frac{1}{\sqrt{a}} \delta^h_m \tilde{\mathbf{s}}_{m,n} \right]_{\Gamma_{ij}} .
\end{aligned}$$

THEOREM A.3. *Let γ be defined as in Lemma* A.2. *Let η bound the maximum error in $\tilde{\alpha}_{m,n}$, $\tilde{\lambda}_{m,n}$, and $\tilde{\mu}_{m,n}$. Then, there exist constants C_1 and C_2 independent* *of h, η such that*

$$\|\mathbf{u}\|_{0,\Omega} \le C\frac{\eta^2}{1-\gamma^2}\,|\mathbf{u}|_{\mathbf{W}^h} \tag{A.9}$$

for all $\mathbf{w} \in \mathbf{W}^{h,\eta}$.

Proof. Consider a Helmholtz decomposition on $\mathbf{W}^h$: for $\mathbf{u} \in \mathbf{W}^h$, there exist p, $\psi \in H^1(\Omega)$ such that

$$\mathbf{u} = \sqrt{a}\nabla p + \frac{1}{\sqrt{a}}\nabla^\perp \psi \tag{A.10}$$

where p is the unique solution of the weak equation

$$\begin{array}{rcll} \langle a\nabla p,\, \nabla q\rangle & = & \langle \sqrt{a}\mathbf{u},\, \nabla q\rangle\,, & \\ p = q & = & 0 & \text{on } \Gamma_D, \\ \mathbf{n}\cdot a\nabla p & = & 0 & \text{on } \Gamma_N, \end{array} \tag{A.11}$$

and ψ is the unique (up to a constant) solution of

$$\begin{array}{ll} \left\langle \dfrac{1}{a}\nabla^\perp\psi,\, \nabla^\perp\phi\right\rangle = \left\langle \dfrac{1}{\sqrt{a}}\mathbf{u},\, \nabla^\perp\phi\right\rangle, & \\ \psi = C_i,\, \phi = 0 & \text{on } \Gamma_{N_i}, \\ \mathbf{n}\cdot\dfrac{1}{a}\nabla\psi = 0 & \text{on } \Gamma_D, \end{array} \tag{A.12}$$

where C_i are arbitrary constants, one of which may be set to zero.

Note that the decomposition is orthogonal in the L^2 sense:

$$\left\langle \sqrt{a}\nabla p,\, \frac{1}{\sqrt{a}}\nabla^\perp\psi\right\rangle_{0,\Omega} = 0. \tag{A.13}$$

We thus have

$$\|\mathbf{u}\|^2_{0,\Omega} = \left\|\sqrt{a}\nabla p\right\|^2_{0,\Omega} + \left\|\frac{1}{\sqrt{a}}\nabla^\perp\psi\right\|^2_{0,\Omega}. \tag{A.14}$$

This next step uses the fact that the jump conditions across boundaries are satisfied exactly except for the singular basis functions, which have support only on $\mathcal{P}_m$ for $m = 1, \dots, M$.

We assume that a is a constant on $\mathcal{P}_m \cap \Omega_i$ and that $\Gamma_{ij} \cap \mathcal{P}_k$ is a straight line starting from the singular point, $\mathbf{x}_m$. We have

$$\begin{aligned} \left\|\sqrt{a}\nabla p\right\|^2_{0,\Omega} &= \left\langle\sqrt{a}\nabla p,\, \sqrt{a}\nabla p\right\rangle_{0,\Omega} = \sum_{i=1}^{J}\langle a\nabla p,\, \nabla p\rangle_{0,\Omega_i} \\ &= \sum_{i=1}^{J}\left\langle -\nabla\cdot\sqrt{a}\mathbf{u},\, p\right\rangle_{0,\Omega_i} + \oint_{\partial\Omega_i}\left(\mathbf{n}\cdot\sqrt{a}\mathbf{u}\right)p \\ &= \sum_{i=1}^{J}\left\langle -\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u},\, \sqrt{a}p\right\rangle_{0,\Omega_i} + \sum_{ij}\int_{\Gamma_{ij}}\left[\mathbf{n}\cdot\sqrt{a}\mathbf{u}\right]p \\ &\le \sum_{i=1}^{J}\left\|\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\mathbf{u}\right\|_{0,\Omega_i}\left\|\sqrt{a}p\right\|_{0,\Omega_i} \\ &\quad + \left|\sum_{ij}\sum_{m:\Gamma_{ij}\cap\mathcal{P}_m\neq\emptyset}\int_{\Gamma_{ij}\cap\mathcal{P}_m}\sum_{n=1}^{N_m}\beta_{m,n}\left[\mathbf{n}\cdot\sqrt{a}\delta^h_m\tilde{\mathbf{s}}_{m,n}\right]p\right|. \end{aligned}$$

With our assumptions, we have

$$\begin{aligned}
&\int_{\Gamma_{ij}\cap\mathcal{P}_m} \sum_{n=1}^{N_m} \beta_{m,n} \left[\mathbf{n}\cdot\sqrt{a}\delta_m^h \tilde{\mathbf{s}}_{m,n}\right] p \\
&\leq C_m \eta \sum_{n=1}^{N_m} |\beta_{m,n}| \left| \int_0^{R_m} \delta_m^h(r) r^{(\tilde{\alpha}_n - 1)} p(r)dr \right| \\
&\leq C_m \eta \sum_{n=1}^{N_m} |\beta_{m,n}| \left(\left\|\sqrt{a}_i p\right\|_{1/2,\Gamma_{ij}\cap\mathcal{P}_k} + \left\|\sqrt{a}_j p\right\|_{1/2,\Gamma_{ij}\cap\mathcal{P}_m} \right),
\end{aligned}$$

where R_m is the radius of $\mathcal{P}_m$. Here C_m involves $\min_\Omega |a|$.

Plugging this into the expression above, after first using the ϵ-inequality twice, and using a trace inequality $\|\sqrt{a}p\|_{1/2,\partial(\Omega_i\cap\mathcal{P}_k)} \leq C\|\sqrt{a}\nabla p\|_{0,\Omega_i\cap\mathcal{P}_k}$, the fact that $\|\frac{1}{\sqrt{a}}\nabla\cdot\sqrt{a}\delta_k^h\tilde{\mathbf{s}}_k^\eta\|_{0,\mathcal{P}_k} \leq C$, where C is independent of h and η, and the Poincaré–Friedrichs inequality on p in [2, Lemma 3.1], we get

$$\begin{aligned}
&\left\|\sqrt{a}\nabla p\right\|_{0,\Omega}^2 \\
&\leq \sum_{i=1}^{J} \left\| \frac{1}{\sqrt{a}} \nabla\cdot\sqrt{a}\mathbf{u} \right\|_{0,\Omega_i} \left\|\sqrt{a}p\right\|_{0,\Omega_i} \\
&\quad + \sum_{ij} \sum_{m:\Gamma_{ij}\cap\mathcal{P}_m\neq\emptyset} C_m\eta \sum_{n=1}^{N_m} |\beta_{M,n}| \left(\left\|\sqrt{a}_i p\right\|_{1/2,\Gamma_{ij}\cap\mathcal{P}_m} + \left\|\sqrt{a}_j p\right\|_{1/2,\Gamma_{ij}\cap\mathcal{P}_m} \right) \\
&\leq \frac{1}{\epsilon_1} \sum_{i=1}^{J} \left\| \frac{1}{\sqrt{a}} \nabla\cdot\sqrt{a}\mathbf{u} \right\|_{0,\Omega_i}^2 + \epsilon_1 \left\|\sqrt{a}p\right\|_{0,\Omega_i}^2 + \frac{1}{\epsilon_2} \sum_m C_m^2 \eta^2 \sum_{n=1}^{N_m} |\beta_{m,n}|^2 \\
&\quad + 2\epsilon_2 \sum_{ij} \sum_{m:\Gamma_{ij}\cap\mathcal{P}_m\neq\emptyset} \left(\left\|\sqrt{a}_i p\right\|_{1/2,\Gamma_{ij}\cap\mathcal{P}_m}^2 + \left\|\sqrt{a}_j p\right\|_{1/2,\Gamma_{ij}\cap\mathcal{P}_m}^2 \right) \\
&\leq \frac{1}{\epsilon_1} \sum_{i=1}^{J} \left\| \frac{1}{\sqrt{a}} \nabla\cdot\sqrt{a}\mathbf{u} \right\|_{0,\Omega_i}^2 + \epsilon_1 c_4 \left\|\sqrt{a}\nabla p\right\|_{0,\Omega_i}^2 \\
&\quad + \frac{C\eta^2}{\epsilon_2} \sum_{i=1}^{J} \sum_{k:\Omega_i\cap\mathcal{P}_k\neq\emptyset} \sum_{n=1}^{N_m} |\beta_{m,n}|^2 \left\| \frac{1}{\sqrt{a}} \nabla\cdot\sqrt{a}\delta_m^h \tilde{\mathbf{s}}_{m,n} \right\|_{0,\Omega_i\cap\mathcal{P}_m}^2 + 2C_1\epsilon_2 \left\|\sqrt{a}\nabla p\right\|_{0,\Omega_i}^2 .
\end{aligned}$$

Choosing appropriate ϵ_1 and ϵ_2 yields

$$\begin{aligned}
\text{(A.15)}\quad \left\|\sqrt{a}\nabla p\right\|_{0,\Omega}^2 \leq C \Bigg(&\sum_{i=1}^{J} \left\| \frac{1}{\sqrt{a}} \nabla\cdot\sqrt{a}\mathbf{u} \right\|_{0,\Omega_i}^2 \\
&+ \eta^2 \sum_i \sum_{m:\Omega_i\cap\mathcal{P}_m\neq\emptyset} \sum_{n=1}^{N_m} |\beta_{m,n}|^2 \left\| \frac{1}{\sqrt{a}} \nabla\cdot\sqrt{a}\delta_m^h \tilde{\mathbf{s}}_{m,n} \right\|_{0,\Omega_i\cap\mathcal{P}_m}^2 \Bigg).
\end{aligned}$$

A similar result follows for the other term in the decomposition,

$$\text{(A.16)}\quad \left\|\frac{1}{\sqrt{a}}\nabla^{\perp}\psi\right\|_{0,\Omega}^2 \le C\left(\sum_{i=1}^{J}\left\|\sqrt{a}\nabla\times\frac{1}{\sqrt{a}}\mathbf{u}\right\|_{0,\Omega_i}^2 + \eta^2\sum_i\sum_{m:\Omega_i\cap\mathcal{P}_m\neq\emptyset}\sum_{n=1}^{N_m}|\beta_{m,n}|^2\left\|\sqrt{a}\nabla\times\frac{1}{\sqrt{a}}\delta_m^h\tilde{\mathbf{s}}_{m,n}\right\|_{0,\Omega_i\cap\mathcal{P}_m}^2\right).$$

Putting (A.15) and (A.16) together and applying Lemma A.2 yields

$$\text{(A.17)}\quad \begin{aligned}\|\mathbf{u}\|_{0,\Omega}^2 &= \left\|\sqrt{a}\nabla p\right\|_{0,\Omega}^2 + \left\|\frac{1}{\sqrt{a}}\nabla^{\perp}\psi\right\|_{0,\Omega}^2\\ &\le C|\mathbf{u}|_{\mathbf{W}^h}^2 + C\eta^2\sum_m\sum_{n=1}^{N_m}|\beta_{m,n}|^2|\delta_m^h\tilde{\mathbf{s}}_{m,n}|_{\mathbf{W}^h}^2\\ &\le\left(C_1+\frac{C_2\eta^2}{(1-\gamma^2)}\right)|\mathbf{u}|_{\mathbf{W}^h}^2.\end{aligned}$$

This completes the proof. □

COROLLARY A.4. *Under the assumption $\gamma = 1 - O(h^2)$, there are constant $C1$ and C_2, independent of h, such that*

$$\text{(A.18)}\quad \|\mathbf{u}\|_{0,\Omega}^2 \le \left(C_1 + C_2\frac{\eta^2}{h^2}\right)|\mathbf{u}|_{\mathbf{W}^h}.$$

Proof. The proof follows immediately from Theorem A.3. □

To eliminate h-dependence, we must ensure that $\eta = O(h)$. Recall that η is the error in the exponent of the singular basis function. In our numerical scheme for the calculation of the exponents, we have full control over their accuracy.

ANALYSIS OF SOME PADÉ–CHEBYSHEV APPROXIMANTS*

SIDI MAHMOUD KABER† AND YVON MADAY†

Abstract. We present some rational approximations of the sign function and analyze their convergence. The rate of convergence is shown to increase with the degree of the denominator of the rational approximation. Several numerical tests are presented.

Key words. Padé approximation, approximation by rational functions

AMS subject classifications. 41A21, 41A20

DOI. 10.1137/S0036142903436708

1. Introduction.

The motivation of this work comes primarily from the spectral discretization of partial differential equations (consult the monographs [1] and [12]). For regular solutions, the numerical spectral approximation is highly accurate. On the opposite, for discontinuous solutions the Gibbs phenomenon prevents the high convergence of the numerical approximations. However, the numerical solution u_N is close to the projection of the solution u on $\mathbb{P}_N$, the space of algebraic polynomials of degree $\leq N$. In other terms, the coefficients of u_N are close to those of the solution u. The way to design an accurate solution from the knowledge of the Fourier (or general orthogonal expansions) coefficients of the solution is called filtering in the numerical analysis literature. We refer to [11] for the state-of-the-art on the spectral approximation of discontinuous solutions and the filtering problem.

What we present here is a filtering procedure (or acceleration of convergence) based on rational approximation. The problem can be stated as follows: given the first K Chebyshev coefficients $\hat{u}_k$ of a function u, design a polynomial $\mathcal{P}$ of degree N and a polynomial $\mathcal{Q}$ of degree M in such a way that the rational function $\mathcal{P}/\mathcal{Q}$ is a better approximation of u (in a sense to be made more precise) than the best approximation of u by K-degree polynomials, namely, the finite expansion $\sum_{k=0}^{K} \hat{u}_k T_k$.

The idea of approximating by rational functions comes from the theory of Padé approximants [18], [2]. There exist linear and nonlinear Padé approximants of a function u with power series

$$u(x) = \sum_{k\geq 0} u_k x^k.$$

- The linear Padé approximant of u of order (n, m) is a rational function $r = p/q$, with polynomials p (of degree n) and q (of degree m) defined by

  $$q(x)u(x) - p(x) = \mathcal{O}(x^{n+m+1}) \tag{1.1}$$

  as $x \to 0$. Plugging $p = \sum_{i=1}^{n} p_i x^i$ and $q = \sum_{j=1}^{m} q_j x^j$ into (1.1) and equating the coefficients of the powers x^k, we get the linear system to be solved (with unknowns p_i and q_j) in order to compute q and p.

†Laboratoire Jacques-Louis Lions, Université Pierre et Marie Curie, Boite Courrier 187, 75252 Paris, Cedex 05, France (maday@ann.jussieu.fr). Part of this work was done while the first author was visiting the Department of Applied Mathematics, Brown University, Providence, RI.

- The nonlinear Padé approximants of u of order (n, m) are solutions $r = p/q$ of the following nonlinear problem:

$$\frac{p(x)}{q(x)} - u(x) = \mathcal{O}(x^{n+m+1}). \tag{1.2}$$

  Problem (1.1) always has a nontrivial solution, while problem (1.2) may have no solution. If a solution q of the linear Padé problem satisfies $q(0) \neq 0$, then $r = p/q$ is a solution of the nonlinear Padé problem.

Padé approximations can be generalized to polynomial expansions other than the powers x^k, namely, expansions in terms of orthogonal polynomials. For Fourier and Chebyshev expansions, consult [3], [13], [20] and the more recent reference [4].

In order to improve (by reducing the Gibbs phenomenon) the Fourier spectral method, some Padé–Fourier approximants were used in [10]. One can use the transformation $x = \cos\theta$ (then $T_k(x) = \cos(k\theta)$) to refer to the framework of [10]. The present work does not exploit this specific transformation and thus could be generalized to other orthogonal polynomial expansions. Let us specify that instead of the analyticity of the function u (required in the Padé approximations), we require here only that u belong to an L^2 space. General Padé–Jacobi expansions are presented in [6], where the case of quadratic denominators is analyzed. Numerical tests for the Legendre case are also presented in this reference. Recursive algorithms to compute some Padé–Legendre approximants are given in [14]. The first references on the Padé–Legendre approximants we are aware of are [8] and [9]. Several properties of the Padé–Legendre approximants can be found in [5], as well as various numerical tests showing that the rate of convergence of these approximations increases with the degree of their denominators. This is precisely what we prove in this work for Padé–Chebyshev approximants.

The paper is organized as follows: The remainder of this section is devoted to some notation and properties of some special functions. In section 2, we recall the limits of the polynomial approximation of discontinuous functions. Section 3 introduces the rational approximations, which are analyzed in section 4. Some numerical tests that confirm the analysis are also given. The paper ends with a list of some directions of work.

Notation.

- $\mathbb{P}_n$ is the set of algebraic polynomials of degree $\leq n$.
- $\mathbb{R}_{n,m}$ is the set of rational functions $r = p/q$, with $p \in \mathbb{P}_n$ and $q \in \mathbb{P}_m$.
- Γ denotes Euler's gamma function

$$\Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt.$$

  Note that $\Gamma(z+1) = z\Gamma(z) = z!$. We will make use of the formula (see [7, p. 3, eq. (6)])[1]

$$\Gamma(1+z)\Gamma(1-z) = \frac{\pi z}{\sin \pi z},$$

  with $z = n + 1/2$, $n \in \mathbb{N}$:

$$\Gamma\left(\frac{3}{2}+n\right)\Gamma\left(\frac{1}{2}-n\right) = (-1)^n\left(n+\frac{1}{2}\right)\pi \quad \forall n \in \mathbb{N}. \tag{1.3}$$

[1] We refer to [7] for all the properties of the special functions used in this work.

- For $z \in \mathbb{C}$ and $n \in \mathbb{N}$, $(z)_n$ is the Pochhammer symbol defined by

  $$(z)_n = \frac{\Gamma(z+n)}{\Gamma(z)} = \begin{cases} 1 & \text{if } n = 0, \\ z(z+1)\dots(z+n-1) & \text{if } n \geq 1. \end{cases} \tag{1.4}$$

  Note that $(1)_n = n!$ and for all $z \in \mathbb{N}$

  $$(-z)_n = 0 \quad \forall n \geq z+1.$$

- ${}_pF_q(x_1, \dots, x_p; y_1, \dots, y_q; .)$ is the hypergeometric function defined for $z \in \mathbb{C}$ by

  $${}_pF_q(x_1, \dots, x_p; y_1, \dots, y_q; z) = \sum_{k \geq 0} \frac{(x_1)_k \dots (x_p)_k}{(y_1)_k \dots (y_q)_k} \frac{z^k}{k!}. \tag{1.5}$$

  The sum in (1.5) is finite if one of the argument $x_i \in -\mathbb{N}$. In that case ${}_pF_q$ is an element of $\mathbb{P}_{-x_i}$. The particular case ($n \in \mathbb{N}$)

  $${}_3F_2(a, b, -n; d, e; z) = \sum_{k=0}^{n} \frac{(a)_k (b)_k (-n)_k}{(d)_k (e)_k} \frac{z^k}{k!} \quad (\in \mathbb{P}_n)$$

  with $e + d + n = 1 + a + b$ leads to the Saalchütz formula (see [7, p. 66, eq. (30)]),

  $${}_3F_2(a, b, -n; d, e; 1) = \frac{(d-a)_n (d-b)_n}{(d)_n (d-a-b)_n}. \tag{1.6}$$

2. Polynomial approximation of a discontinuous function. Let $\omega(x) = 1/\sqrt{1-x^2}$ be the standard Chebyshev weight. On the space L^2_ω of the functions $u : I =]-1, 1[\to \mathbb{R}$ such that $\int_I u^2(x)\omega(x)dx$ is finite, we define the scalar product

$$\langle u, v \rangle_\omega = \int_I u(x)v(x)\omega(x)dx \qquad \forall (u, v) \in L^2_\omega \times L^2_\omega \tag{2.1}$$

and the norm

$$\|u\|_\omega = \sqrt{\langle u, u \rangle_\omega} = \left(\int_I u(x)^2 \omega(x) \right)^{1/2} \qquad \forall u \in L^2_\omega.$$

The Chebyshev expansion of a function $u \in L^2_\omega$ is

$$u = \sum_{k=0}^{\infty} \hat{u}_k T_k, \quad \hat{u}_k = \frac{1}{\|T_k\|^2_\omega} \langle u, T_k \rangle_\omega,$$

with T_k the Chebyshev polynomial of degree k and

$$\|T_k\|_\omega = \begin{cases} \sqrt{\pi} & \text{if } k = 0, \\ \sqrt{\pi/2} & \text{if } k \geq 1. \end{cases}$$

The truncated series $\pi^n_\omega(u) = \sum_{k=0}^n \hat{u}_k T_k$ is the best approximation of u in $\mathbb{P}_n$ in the sense that

$$\|\pi^n_\omega(u) - u\|_\omega \ \leq \ \|q - u\|_\omega \quad \forall q \in \mathbb{P}_n.$$

It is also the projection of u onto $\mathbb{P}_n$:

$$\langle \pi_\omega^n(u), \varphi \rangle_\omega = \langle u, \varphi \rangle_\omega \quad \forall \varphi \in \mathbb{P}_n. \tag{2.2}$$

The approximation error is

$$e_{\omega,n}(u) = \|\pi_\omega^n(u) - u\|_\omega = \left(\frac{2}{\pi} \sum_{k>n} |\hat{u}_k|^2 \right)^{1/2} .$$

If not only u belongs to L^2_ω but also all the derivatives of u up to s, then the following decrease of the error holds:

$$e_{\omega,n}(u) \leq \mathrm{Const}(s) n^{-s} \left(\sum_{k=0}^{s} \|u^{(k)}\|_\omega^2 \right)^{1/2} .$$

This shows the rapid decay of the error if the function u is regular enough. On the contrary, let us consider the sign function

$$S(x) = \begin{cases} -1 & \text{for } x \in [-1, 0[, \\ \;\;1 & \text{for } x \in]0, 1], \end{cases}$$

with Chebyshev expansion $S = \sum_{k=0}^{\infty} \hat{s}_k T_k$. Straightforward computations give

$$\hat{s}_{2k} = 0, \quad \hat{s}_{2k+1} = \frac{4}{\pi} \frac{(-1)^k}{2k+1}. \tag{2.3}$$

Hence

$$S = \sum_{k=0}^{\infty} \hat{s}_{2k+1} T_{2k+1}, \tag{2.4}$$

and the approximation error is

$$e_{\omega,2n+1}(S) = \sqrt{\frac{8}{\pi}} \left(\sum_{k>n} \frac{1}{(2k+1)^2} \right)^{1/2} ,$$

which gives rise to the Gibbs phenomenon.

Gibbs phenomenon. There exists a constant C such that the equivalence

$$e_{\omega,2n+1}(S) \simeq \frac{C}{\sqrt{n}} \quad \text{as } n \to +\infty \tag{2.5}$$

holds. This shows the slow convergence of $\pi_\omega^n(S)$ toward S. On Figure 2.1 several approximations $\pi_\omega^n(S)$ are displayed. In particular, one can notice oscillations of order $\mathcal{O}(1)$ near the singularity $x = 0$. This is the Gibbs phenomenon. More precisely there exists a sequence $(x_n)_n \to 0^+$ such that [12]

$$\pi_\omega^n(S)(x_n) \to \gamma > S(0) = 0.$$

Filtering. The filtering procedures try to cancel the oscillations. Such oscillations (inherent to the Gibbs phenomenon) appear when discontinuous functions are approximated by polynomials (or other globally defined smooth functions, e.g., wavelets). This is the typical situation when using spectral methods to compute solutions of hyperbolic equations. We refer again to [11] for this problem.

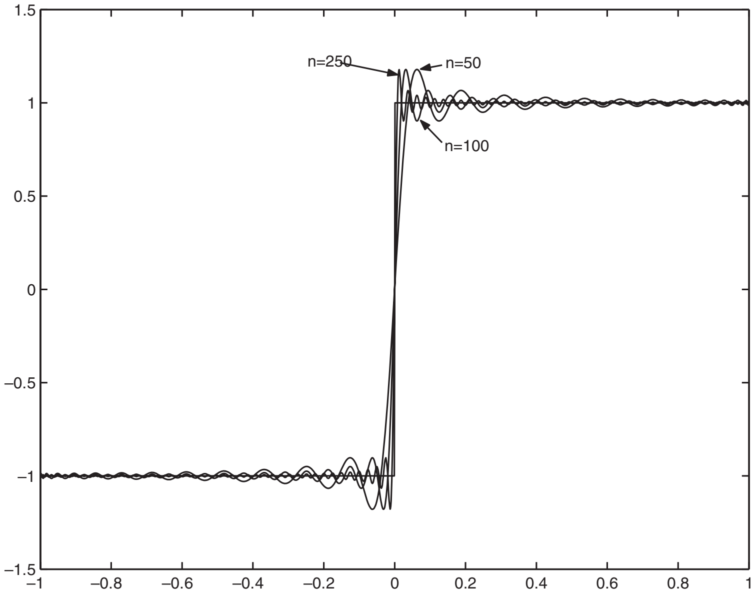

FIG. 2.1. *The sign function S and $\pi_\omega^n(S)$ for $n = 50, 100, 250$.*

Rational versus polynomial approximation. Let us recall the following result proved by Newman in [16]: there exists a rational approximation $r \in \mathbb{P}_{n,n}$ such that

$$\max_{-1\le x\le 1} |\, r(x) - |x|\, | \le 3e^{-\sqrt{n}}.$$

What is remarkable in this result is that polynomial approximation of $|x|$ is only of first order. Namely there exists $p \in \mathbb{P}_n$ such that

$$\forall q \in \mathbb{P}_n, \qquad \max_{-1\le x\le 1} |\, q(x) - |x|\, | \ge \max_{-1\le x\le 1} |\, p(x) - |x|\, | \simeq \frac{\text{Const}}{n}.$$

Newman's result motivates the use of rational approximations, especially when polynomial approximation fails to provide highly accurate approximation.

The main problem is related to the fact that $\mathbb{R}_{n,m}$ is not a linear space, unlike $\mathbb{P}_n$.

3. A rational approximation.

We explain how to define a suitable rational approximation $\mathcal{R}_{N,M}(u)$ of a function u having in mind the special case of the sign function.

$$\mathcal{R}_{N,M}(u) = \frac{\mathcal{P}_{N,M}}{\mathcal{Q}_{N,M}} \in \mathbb{R}_{N,M}.$$

Since $\mathbb{P}_N = \mathbb{R}_{N,0}$, rational approximation obviously contains polynomial approximation. The goal here is to improve the convergence rate, i.e.,

$$\|\mathcal{R}_{N,M}(u) - u\|_\omega \ll \|\pi_\omega^{N+M}(u) - u\|_\omega. \tag{3.1}$$

For the sake of simplicity and when this does not cause any confusion, we will drop the subscripts ${}_{N,M}$. Just like in the classical Padé setting, there are two ways to define the rational approximation $\mathcal{P}/\mathcal{Q}$.

3.1. Definition of the Padé–Chebyshev approximants.

Nonlinear Padé–Chebyshev approximation. The rational approximation $\mathcal{R}(u) = \mathcal{P}/\mathcal{Q}$ is defined by the orthogonality conditions

$$\left\langle \frac{\mathcal{P}}{\mathcal{Q}} - u, \varphi \right\rangle_{\omega} = 0 \qquad \forall \varphi \in \mathbb{P}_K, \tag{3.2}$$

with K as large as possible. That is to say, $\mathcal{R}(u) - u$ is orthogonal to $\mathbb{P}_K$ with respect to the scalar product (2.1). Equations (3.2) form a nonlinear system of $K+1$ nonlinear equations and $N+M+2$ unknowns. This system could have no solution, but if it admits a solution and if $\mathcal{Q}$ never vanishes on I, then this solution is unique [19]. The nonlinear system is hard to handle, especially for general orthogonal series (Legendre, for instance). Actually, this problem was solved in [10] for trigonometric polynomials. Using the transformation $x = \cos\theta$ a Chebyshev expansion becomes a trigonometric expansion, and the tools in [10] can be used. But such a transformation does not exist for other orthogonal polynomials. The present work does not exploit this specific transformation in order to be generalized to other orthogonal polynomial expansions.

Note that, for the sign function, explicit expression for the coefficients of the Padé–Chebyshev is given in [17], but the method cannot be generalized to other functions.

Note that from (3.2), the first Chebyshev coefficients of $\mathcal{R}(u)$ and that of the function u coincide. Note also that only a finite portion of the spectrum of u is required to define $\mathcal{R}(u)$. The complete knowledge of u (i.e., of $\hat{u}_k$ for all $k \in \mathbb{Z}$) is not necessary.

Linear Padé–Chebyshev approximation. Here one imposes the orthogonality relations

$$\langle \mathcal{Q}u - \mathcal{P}, \varphi \rangle_{\omega} = 0 \qquad \forall \varphi \in \mathbb{P}_K. \tag{3.3}$$

This means that $\mathcal{Q}u - \mathcal{P}$ is orthogonal to $\mathbb{P}_K$, or, in other terms, the function $\mathcal{Q}u - \mathcal{P}$ has only high frequencies,

$$\mathcal{Q}u - \mathcal{P} = \sum_{k>K} \gamma'_k T_k. \tag{3.4}$$

Writing (3.3) for $k = N+1, \dots, K$ gives the linear system to be solved by $\mathcal{Q}$:

$$\widehat{(\mathcal{Q}u)}_k = 0 \quad \forall k = N+1, \dots, K. \tag{3.5}$$

This homogeneous linear system has $M+1$ unknowns and $K-N$ equations. For $K \leq N+M$ the system admits a nonpotentially trivial solution. Note that the highest mode of u involved in system (3.5) is $\hat{u}_{K+M}$. Here also the complete knowledge of u is not required.

From now on, we consider only linear Padé approximation. Some properties of this rational approximation follow. A basic one is the reproduction of polynomials and rational functions if K is large enough.

3.2. Some general properties. The problem of existence and uniqueness of the rational approximation $\mathcal{R}$ is that of the existence and uniqueness of the denominator $\mathcal{Q}$. In the general case, uniqueness is not guaranteed. Let us consider the example $n \geq 1$, $K = N = n+1$, and $M = 1$ in (3.3). From the recurrence formula

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x),$$

we deduce that $2xT_n(x) - T_{n-1}(x)$ is orthogonal to $\mathbb{P}_n$ with respect to the weight ω. Hence $\frac{T_{n-1}}{2x} \in \mathbb{P}_{n,1}$ is a linear Padé approximant of T_n which is of course its own Padé approximant in $\mathbb{P}_{n,1}$.

One can insure uniqueness using the appropriate parameters N, M, and K.

Proposition 3.1 (uniqueness). *If $(\mathcal{Q}_1, \mathcal{P}_1)$ and $(\mathcal{Q}_2, \mathcal{P}_2)$ are two solutions of* (3.3)*, then for K large enough ($K \geq M + 2N$), they determine the same Padé–Chebyshev solution:*

$$\frac{\mathcal{P}_1}{\mathcal{Q}_1} = \frac{\mathcal{P}_2}{\mathcal{Q}_2}.$$

Proof. We first suppose $u > 0$ and prove that the polynomial $\mathcal{P}_1\mathcal{Q}_2 - \mathcal{P}_2\mathcal{Q}_1 \in \mathbb{P}_{M+N}$ is orthogonal to $\mathbb{P}_{K-N}$ with respect to the weight function $u(x)\omega(x)$. Hence, for $K - N \geq N + M$, $\mathcal{P}_1\mathcal{Q}_2 - \mathcal{P}_2\mathcal{Q}_1$ is the null polynomial. Indeed

$$\begin{aligned}\langle(\mathcal{P}_1\mathcal{Q}_2 - \mathcal{P}_2\mathcal{Q}_1)u, \varphi\rangle_\omega &= \langle u\mathcal{Q}_2, \mathcal{P}_1\varphi\rangle_\omega - \langle u\mathcal{Q}_1, \mathcal{P}_2\varphi\rangle_\omega,\\ &= \langle \mathcal{P}_2, \mathcal{P}_1\varphi\rangle_\omega - \langle \mathcal{P}_1, \mathcal{P}_2\varphi\rangle_\omega = 0 \qquad \forall\varphi \in \mathbb{P}_{K-N}.\end{aligned}$$

In the general case, consider the strictly positive function $v = u + M$ with $M > \|u\|_\infty$. □

Proposition 3.2. *If $u \in \mathbb{P}_N$ or $u \in \mathbb{R}_{N,M}$ with nonvanishing denominator, then $\mathcal{R}_{N,M}(u) = u$, provided $K \geq M + N$ in* (3.3).

Proof. If $u \in \mathbb{P}_N$, then the function $\mathcal{Q}u$ belongs to $\mathbb{P}_K$ and relations (3.4) imply $\mathcal{P} = \mathcal{Q}u$, that is, $\mathcal{R}_{N,M}(u) = u$. Now let $u = p/q$ with $p \in \mathbb{P}_N$, $q \in \mathbb{P}_M$, $q(x) \neq 0$, hence assumed $\mathcal{Q} > 0$ on I. The orthogonality relations (3.3) read, for all $\varphi \in \mathbb{P}_K$,

$$0 = \left\langle \mathcal{P} - \mathcal{Q}\frac{p}{q}, \varphi \right\rangle_\omega = \int_I (q\mathcal{P} - p\mathcal{Q})\,\frac{\varphi}{q}\omega(x)dx.$$

In other terms, the polynomial $q\mathcal{P} - p\mathcal{Q}$ is orthogonal to $\mathbb{P}_K$ with respect to the inner product defined by the function ω/q. But this polynomial has degree less than K, and hence it is the null polynomial and $\mathcal{R}_{N,M}(u) = u$. □

Proposition 3.3 (parity). *For $K \geq M + 2N$, and assuming $\mathcal{Q}(0) \neq 0$,*

$$\begin{cases} u \text{ is odd} & \Longrightarrow \quad \mathcal{Q} \text{ is even and } \mathcal{P} \text{ is odd},\\ u \text{ is even} & \Longrightarrow \quad \mathcal{Q} \text{ is even and } \mathcal{P} \text{ is even.}\end{cases}$$

Proof. Consider an odd function u. For all $\varphi \in \mathbb{P}_K$ the orthogonality relations give

$$\int_{-1}^{1} [\mathcal{Q}(-x)u(-x) - \mathcal{P}(-x)]\,\varphi(-x)\omega(-x)dx = 0,$$

or, equivalently, for all $\psi \in \mathbb{P}_K$,

$$\int_{-1}^{1} [\mathcal{Q}(-x)u(x) + \mathcal{P}(-x)]\,\psi(x)\omega(x)dx.$$

Hence $(-\mathcal{P}(-x), \mathcal{Q}(-x))$ is a couple of Padé approximants of u of order (N, M). Assuming $K \geq M+2N$, we know from Proposition 3.1 that $\mathcal{P}(x)\mathcal{Q}(-x) = -\mathcal{Q}(x)\mathcal{P}(-x)$. Hence the polynomial $\mathcal{P}(x)$ is a divisor of the polynomial $\mathcal{P}(-x)\mathcal{Q}(x)$. If $\mathcal{P}(x)/\mathcal{Q}(x)$ is irreducible, then $\mathcal{P}(x)$ is a divisor of $\mathcal{P}(-x)$, which means that $\mathcal{P}$ is an odd or an even polynomial, in which case $\mathcal{Q}$ is an even or an odd polynomial, respectively. Assuming that $\mathcal{Q}(0) \neq 0$, then $\mathcal{P}$ is even. The conclusion holds true if $\mathcal{P}(x)/\mathcal{Q}(x)$ is not irreducible by considering a common polynomial factor S such that $\mathcal{P} = S\mathcal{P}_1$ and $\mathcal{Q} = S\mathcal{Q}_1$ with $\mathcal{P}_1/\mathcal{Q}_1$ irreducible. □

Proposition 3.4. *Let $\mathcal{Q}$ be a solution of the system* (3.5) *with $K \geq N + M$. Then the numerator of the (linear) Padé approximation is*

$$\mathcal{P} = \pi_\omega^N\left(\mathcal{Q}u\right) = \pi_\omega^K\left(\mathcal{Q}u\right) = \pi_\omega^N\left(\mathcal{Q}\pi_\omega^K(u)\right). \tag{3.6}$$

Proof. The orthogonality relations (3.3) directly imply the first two equalities. For the last one, write, for all $k \leq N$,

$$\begin{aligned}\langle \pi_\omega^N\left(\mathcal{Q}\pi_\omega^K(u)\right), T_k\rangle_\omega &= \langle \mathcal{Q}\pi_\omega^K(u), T_k\rangle_\omega = \langle \pi_\omega^K(u), \mathcal{Q}T_k\rangle_\omega \\ &= \langle u, \mathcal{Q}T_k\rangle_\omega = \langle \mathcal{Q}u, T_k\rangle_\omega \\ &= \langle \pi_\omega^N\left(\mathcal{Q}(u)\right), T_k\rangle_\omega = \langle \mathcal{P}, T_k\rangle_\omega,\end{aligned}$$

which yields the statement. □

Before concentrating on the special case of the sign function, we list the different steps of our goal.

- First of all, compute the denominator $\mathcal{Q}$. This is the main problem.
- Define the numerator $\mathcal{P}$ by relations (3.6):

$$\mathcal{P} = \pi_\omega^N\left(\mathcal{Q}\pi_\omega^K u\right). \tag{3.7}$$

- Define the rational approximation $\mathcal{R}$ by

$$\mathcal{R}(u) = \frac{\mathcal{P}}{\mathcal{Q}}. \tag{3.8}$$

Once the rational approximation is defined, we have to

- prove the convergence

$$\lim_{N\to+\infty} \mathcal{R}(u) = u, \tag{3.9}$$

  in a sense to be specified later;
- evaluate the error $\|\mathcal{R}(u) - u\|_\omega$ and show that $\mathcal{R}$ behaves like a Chebyshev series whose coefficients decrease faster than the coefficients $\hat{u}_k$ of u.

From now on we consider only the sign function.

4. The special case of the sign function. Taking into account the parity of the sign function (see Proposition 3.3), we search for even $\mathcal{Q}$ and odd $\mathcal{P}$. We expand $\mathcal{P}$ in the Chebyshev basis,

$$\mathcal{P} = \sum_{n=0}^{\mathcal{N}} \hat{p}_{2n+1}T_{2n+1},$$

and $\mathcal{Q}$ in either the Chebyshev basis or the usual canonical basis:

$$\mathcal{Q} = \sum_{m=0}^{\mathcal{M}} q_{2m}T_{2m} \quad \text{or} \quad \mathcal{Q}(x) = \sum_{m=0}^{\mathcal{M}} q_{2m}x^{2m}.$$

4.1. How to compute the denominator. Let us develop the denominator $\mathcal{Q}$ in a basis $(\varphi_{_{2m}})_{m=0}^{\mathcal{M}}$ of even polynomials of $\mathbb{P}_{2\mathcal{M}}$:

$$\mathcal{Q} = \sum_{m=0}^{\mathcal{M}} q_{2m}\varphi_{_{2m}}.$$

The expansion of $\varphi_{_{2m}} S$ in the Chebyshev basis is

$$\varphi_{_{2m}} S = \sum_{k\geq 0} c_{2k+1}^{m} T_{2k+1},$$

with

$$c_{2k+1}^{m} = \frac{4}{\pi}\int_0^1 \varphi_{_{2m}}(x) T_{2k+1}(x)\omega(x)dx. \tag{4.1}$$

Hence the expansion of $\mathcal{Q}S$ in the Chebyshev basis is

$$\mathcal{Q}S = \sum_{k\geq 0} \Lambda_{2k+1}^{(\mathcal{M})} T_{2k+1},$$

with

$$\Lambda_{2k+1}^{(\mathcal{M})} = \sum_{m=0}^{\mathcal{M}} c_{2k+1}^{m} q_{2m}. \tag{4.2}$$

In order to satisfy (3.3), the idea is to split $\mathcal{Q}S$ into three terms,

$$\mathcal{Q}S = \sum_{k=0}^{\mathcal{N}} \Lambda_{2k+1}^{(\mathcal{M})} T_{2k+1} + \sum_{k=\mathcal{N}+1}^{K} \Lambda_{2k+1}^{(\mathcal{M})} T_{2k+1} + \sum_{k>K} \Lambda_{2k+1}^{(\mathcal{M})} T_{2k+1}. \tag{4.3}$$

The first term in the right-hand side will be the numerator of the rational approximation, the second term must vanish, and the last one is the remainder.

Determining the denominator is equivalent to finding $(q_{2m})_{m=0}^{\mathcal{M}}$ such that

$$\Lambda_{2k+1}^{(\mathcal{M})} = 0 \quad \forall k = \mathcal{N}+1, \ldots, K. \tag{4.4}$$

Remark 4.1. Problem (4.4) is a linear system of $K - \mathcal{N}$ equations and $\mathcal{M}+1$ unknowns. For $K \leq \mathcal{N} + \mathcal{M}$, the system always has a nontrivial solution. In what follows we fix

$$K = \mathcal{N} + \mathcal{M} \tag{4.5}$$

in order to ensure the existence of a nonzero solution. But we don't know if such a solution is unique since uniqueness is guaranteed only for $K \geq \mathcal{M} + 2\mathcal{N}$ (see Proposition 3.1).

4.1.1. First method. Let us first expand $\mathcal{Q}$ in the Chebyshev basis:

$$\mathcal{Q} = \sum_{m=0}^{\mathcal{M}} q_{2m} T_{2m}. \tag{4.6}$$

In this case

$$\begin{aligned} c_{2k+1}^m &= \frac{4}{\pi}\int_0^1 T_{2m}(x)T_{2k+1}(x)\omega(x)dx \\ &= \frac{4}{\pi}\int_0^{\pi/2} \cos(2m\theta)\cos[(2k+1)\theta]d\theta \\ &= (-1)^{m+k+1}\frac{4}{\pi}\frac{2k+1}{(2m+2k+1)(2m-2k-1)} \end{aligned}$$

and

$$\Lambda_{2k+1}^{(\mathcal{M})} = (-1)^{k+1}\frac{4}{\pi}(2k+1)\sum_{m=0}^{\mathcal{M}} \frac{(-1)^m}{(2m+2k+1)(2m-2k-1)}q_{2m}. \tag{4.7}$$

The next Proposition gives a solution of (4.4) expressed in the Chebyshev basis.

PROPOSITION 4.2. *The coefficients* q_{2m} *defined by*

$$q_{2m} = \frac{(-1)^m}{m!}\frac{(\mathcal{N}+\mathcal{M}+3/2)_m(-\mathcal{M})_m}{(\mathcal{N}+1/2)_m} \tag{4.8}$$

are solutions of the linear system (4.4)–(4.2)–(4.5).

Proof. We want to prove that for $k = \mathcal{N}+1, \dots, \mathcal{N}+\mathcal{M}$,

$$\sum_{m=0}^{\mathcal{M}} (-1)^m \frac{1}{(2m+2k+1)(2m-2k-1)}q_{2m} = 0, \tag{4.9}$$

or, equivalently,

$$\sum_{m=0}^{\mathcal{M}} (-1)^m \frac{(k-1/2)_m}{(k+3/2)_m}q_{2m} = 0,$$

by using the identities

$$2m+2k+1 = 2\left(k+\frac{1}{2}\right)\frac{(k+3/2)_m}{(k+1/2)_m}, \quad 2m-2k-1 = 2\left(k-\frac{1}{2}\right)\frac{(k+1/2)_m}{(k-1/2)_m}.$$

With the given values of q_{2m}, we have

$$\begin{aligned} \sum_{m=0}^{\mathcal{M}}(-1)^m\frac{(k-1/2)_m}{(k+3/2)_m}q_{2m} &= \sum_{m=0}^{\mathcal{M}}\frac{1}{m!}\frac{(k-1/2)_m(\mathcal{N}+\mathcal{M}+3/2)_m(-\mathcal{M})_m}{(k+3/2)_m(\mathcal{N}+1/2)_m} \\ &= {}_3F_2\left(k-\frac{1}{2}, \mathcal{N}+\mathcal{M}+\frac{3}{2}, -\mathcal{M}; k+\frac{3}{2}, \mathcal{N}+\frac{1}{2}; 1\right) \\ &= \frac{(2)_{\mathcal{M}}(k-\mathcal{N}-\mathcal{M})_{\mathcal{M}}}{(k+3/2)_{\mathcal{M}}(1/2-\mathcal{N}-\mathcal{M})_{\mathcal{M}}}. \end{aligned}$$

The last equality uses the Saalchütz formula (1.6). The factor $(k-\mathcal{N}-\mathcal{M})_{\mathcal{M}}$ vanishes for $k = \mathcal{N}+1, \dots, \mathcal{N}+\mathcal{M}$, and hence (4.9) holds. $\square$

Let us prove that asymptotically (i.e., when $\mathcal{N} \to \infty$) the denominators with degrees $\mathcal{M} = 2(2\mathcal{M}' + 1)$ vanish at $x = \pm 1/\sqrt{2}$. For fixed $\mathcal{M}$ and x, we define

$$\begin{aligned}\mathcal{Q}_{\infty,\mathcal{M}}(x) &= \lim_{\mathcal{N}\to+\infty} \mathcal{Q}_{\mathcal{N},\mathcal{M}}(x) = \sum_{m=0}^{\mathcal{M}} \left[\lim_{\mathcal{N}\to+\infty} q_{2m}\right] T_{2m}(x)\\ &= \sum_{m=0}^{\mathcal{M}} \frac{\mathcal{M}!}{m!(\mathcal{M}-m)!} T_{2m}(x) = \sum_{m=0}^{\mathcal{M}} \left(\begin{array}{c}\mathcal{M}\\ m\end{array}\right) T_{2m}(x).\end{aligned}$$

Hence

$$\begin{aligned}\mathcal{Q}_{\infty,\mathcal{M}}(\pm 1/\sqrt{2}) &= \sum_{m=0}^{\mathcal{M}} \left(\begin{array}{c}\mathcal{M}\\ m\end{array}\right) T_{2m}(1/\sqrt{2}) = \sum_{m=0}^{\mathcal{M}} \left(\begin{array}{c}\mathcal{M}\\ m\end{array}\right) \cos\left(m\frac{\pi}{2}\right)\\ &= \text{Real}\left[\sum_{m=0}^{\mathcal{M}} \left(\begin{array}{c}\mathcal{M}\\ m\end{array}\right) e^{im\frac{\pi}{2}}\right] = \text{Real}\left[(1+e^{i\frac{\pi}{2}})^{\mathcal{M}}\right]\\ &= \text{Real}\left[(1+i)^{\mathcal{M}}\right] = \text{Real}\left[\left((1+i)^2\right)^{2\mathcal{M}'+1}\right] = 0.\end{aligned}$$

Remark 4.3. The denominator computed by the first method may have zeros inside I. On the other hand $\mathcal{Q}(x)$ is the sum of term with different signs. These two properties are unsafe for numerical purposes.

4.1.2. Second method. We now expand $\mathcal{Q}$ in the canonical basis:

$$\mathcal{Q}(x) = \sum_{m=0}^{\mathcal{M}} q_{2m} x^{2m}. \tag{4.10}$$

In that case, using equation (30) of [7, p. 12], we get

$$\begin{aligned}c_{2k+1}^{m} &= \frac{4}{\pi}\int_0^1 x^{2m} T_{2k+1}(x)\omega(x)dx\\ &= \frac{4}{\pi}\int_0^{\pi/2} (\cos\theta)^{2m} \cos[(2k+1)\theta]d\theta\\ &= \frac{\Gamma(2m+1)}{2^{2m-1}} \frac{1}{\Gamma(m+k+3/2)\Gamma(m-k+1/2)}.\end{aligned}$$

Straightforward computations give

$$\left(\frac{1}{2}\right)_m = \prod_{j=1}^{m} \frac{2j-1}{2} = \frac{(2m)!}{m!\,2^{2m}} = \frac{\Gamma(2m+1)}{m!\,2^{2m}}.$$

From this, we deduce

$$c_{2k+1}^{m} = 2\frac{m!\left(\frac{1}{2}\right)_m}{\Gamma(m+k+3/2)\Gamma(m-k+1/2)}$$

and

$$\Lambda_{2k+1}^{(\mathcal{M})} = 2\sum_{m=0}^{\mathcal{M}} \frac{m!\;\left(\frac{1}{2}\right)_m}{\Gamma(m+k+3/2)\Gamma(m-k+1/2)} q_{2m}. \tag{4.11}$$

Remark 4.4. Using (1.3), we get

$$\Gamma(m+k+3/2)\Gamma(m-k+1/2) = (3/2+k)_m(1/2-k)_m(-1)^k(k+1/2)\pi$$

and an expression of $\Lambda_{2k+1}^{(\mathcal{M})}$ in terms of the coefficients of the sign function given in (2.3),

$$\Lambda_{2k+1}^{(\mathcal{M})} = \hat{s}_{2k+1} \underbrace{\sum_{m=0}^{\mathcal{M}} \frac{m!\,\left(\frac{1}{2}\right)_m}{(3/2+k)_m(1/2-k)_m} q_{2m}}_{=\sigma_k^{(\mathcal{M})}}. \tag{4.12}$$

The next proposition (taken from [15]) gives a solution of (4.4) expressed in the canonical basis.

Proposition 4.5. *The coefficients* q_{2m} *defined by*

$$q_{2m} = \frac{(-\mathcal{M})_m(-\mathcal{N}-1/2)_m(\mathcal{N}+\mathcal{M}+3/2)_m}{(m!)^2(1/2)_m}, \qquad m = 0,\dots,\mathcal{M}, \tag{4.13}$$

are solutions of the linear system (4.4)–(4.2)–(4.5).

Proof. Using (4.12) it is sufficient to compute $\sigma_k^{(\mathcal{M})}$ for $k = \mathcal{N}+1,\dots,\mathcal{N}+\mathcal{M}$:

$$\begin{aligned}
\sigma_k^{(\mathcal{M})} &= \sum_{m=0}^{\mathcal{M}} \frac{m!\,\left(\frac{1}{2}\right)_m}{(3/2+k)_m(1/2-k)_m} q_{2m} \\
&= \sum_{m=0}^{\mathcal{M}} \frac{(-\mathcal{M})_m(-\mathcal{N}-1/2)_m(\mathcal{N}+\mathcal{M}+3/2)_m}{(3/2+k)_m(1/2-k)_m} \frac{1}{m!} \\
&= {}_3F_2(-\mathcal{M}, -\mathcal{N}-1/2, \mathcal{N}+\mathcal{M}+3/2; 3/2+k, 1/2-k; 1).
\end{aligned}$$

Using the Saalchütz formula (1.6), we obtain

$$\sigma_k^{(\mathcal{M})} = \frac{(k+\mathcal{N}+2)_{\mathcal{M}}(k-\mathcal{N}-\mathcal{M})_{\mathcal{M}}}{(3/2+k)_{\mathcal{M}}(k-\mathcal{M}+1/2)_{\mathcal{M}}}. \tag{4.14}$$

For $k = \mathcal{N}+1,\dots,\mathcal{N}+\mathcal{M}$, the three factors $(k+\mathcal{N}+2)_{\mathcal{M}}$, $(3/2+k)_{\mathcal{M}}$, and $(k-\mathcal{M}+1/2)_{\mathcal{M}}$ never vanish while $(k-\mathcal{N}-\mathcal{M})_{\mathcal{M}} = 0$. □

We get an explicit representation of $\mathcal{Q}$:

$$\mathcal{Q}(x) = \sum_{m=0}^{\mathcal{M}} \frac{(-\mathcal{M})_m(-\mathcal{N}-1/2)_m(\mathcal{N}+\mathcal{M}+3/2)_m}{(m!)^2(1/2)_m} x^{2m}.$$

Let us now give some properties of $\mathcal{Q}$.

Remark 4.6 (sign of the denominator). For $\mathcal{N} \geq \mathcal{M}-1$ and $m \in [0,\mathcal{M}]$, $(-\mathcal{M})_m(-\mathcal{N}-1/2)_m > 0$. Hence $\mathcal{Q}(x)$ is the sum of positive terms, which is nice for the stability of the numerical computations. This was not the case in the previous method to compute the denominator, as mentioned in Remark 4.3. For $x > 0$, $\mathcal{Q}$ is a monotone increasing function, as it is a positive linear combination of monotone functions. Hence

$$\mathcal{Q}(x) > \mathcal{Q}(0) = 1.$$

For $\mathcal{M} = 1$, the roots of $\mathcal{Q}_{\mathcal{N},1}(x) = 1 + (2\mathcal{N} + 1)(\mathcal{N} + 5/2)x^2$ are imaginary $\simeq \pm\frac{i}{\sqrt{2\mathcal{N}}}$ and approach zero as $\mathcal{N} \to +\infty$. In the general case $\mathcal{M} > 1$, the zeros of $\mathcal{Q}_{\mathcal{N},\mathcal{M}}$ are closer and closer to 0 as $\mathcal{N} \to +\infty$. In order to prove this we first establish a bound of the form

$$\frac{q_{2m}}{q_{2(m+1)}} \leq s^2 \qquad \forall m = 0, \dots, \mathcal{M} - 1, \tag{4.15}$$

with s positive real number depending only on $\mathcal{M}$ and $\mathcal{N}$. It is easy to see that

$$s = \left(\frac{\mathcal{M}^3}{\mathcal{N}^2 - \mathcal{M}^2}\right)^{1/2} \tag{4.16}$$

satisfy (4.15).

PROPOSITION 4.7. *Let $z \in \mathbb{C}$ be a root of $\mathcal{Q}_{\mathcal{N},\mathcal{M}}$ defined by Proposition* 4.5 *with $\mathcal{N} > \mathcal{M}$; then*

$$|z|^2 \leq \frac{\mathcal{M}^3}{\mathcal{N}^2 - \mathcal{M}^2}. \tag{4.17}$$

Proof. For s given by (4.16), we define the scalars $s_{2m} = s^{2m}q_{2m}$ and the polynomial $\mathcal{Q}_s$:

$$\mathcal{Q}_s(x) = (1 - x^2)x^{2\mathcal{M}}\mathcal{Q}(s/x) = s_{2\mathcal{M}} - s_0 x^{2(\mathcal{M}+1)} + \sum_{m=0}^{\mathcal{M}-1}(s_{2m} - s_{2(m+1)})x^{2(\mathcal{M}-m)}.$$

Using the fact that (4.16) implies $0 < s_0 \leq s_2 \leq \cdots \leq s_{2\mathcal{M}}$, we lower bound $\mathcal{Q}_s(z)$ for all $z \in \mathbb{C}$,

$$|\mathcal{Q}_s(z)| \geq |s_{2\mathcal{M}}| - \left|s_0 z^{2(\mathcal{M}+1)}\right| - \sum_{m=0}^{\mathcal{M}-1}\left|(s_{2m} - s_{2(m+1)})z^{2(\mathcal{M}-m)}\right|.$$

For a z such that $|z| < 1$, we get

$$|\mathcal{Q}_s(z)| > |s_{2\mathcal{M}}| - |s_0| - \sum_{m=0}^{\mathcal{M}-1}\left|s_{2m} - s_{2(m+1)}\right| = 0.$$

Hence all the roots of $\mathcal{Q}_s$ have modulus larger than 1. Noticing that $\mathcal{Q}(z) = 0 \Longrightarrow \mathcal{Q}_s(s/z) = 0$, we get (4.17). □

Proposition 4.7 gives a rate of convergence of the poles of the rational approximation $\mathcal{R}_{\mathcal{N},\mathcal{M}}(\mathcal{S})$ toward the singularity of $\mathcal{S}$:

$$\forall z \in \mathbb{C}, \quad \mathcal{Q}_{\mathcal{N},\mathcal{M}}(z) = 0 \Longrightarrow \forall \varepsilon > 0, \lim_{\mathcal{N}\to+\infty} |\mathcal{N}^{1-\varepsilon}z| = 0.$$

From now on we consider only the second method to compute the denominator, namely, the one given by Proposition 4.5. Note that the expansion of the denominator in terms of x^k instead of the orthogonal polynomials T_k was already suggested in [5] for other purposes, not related to the locations of the poles of the rational approximation.

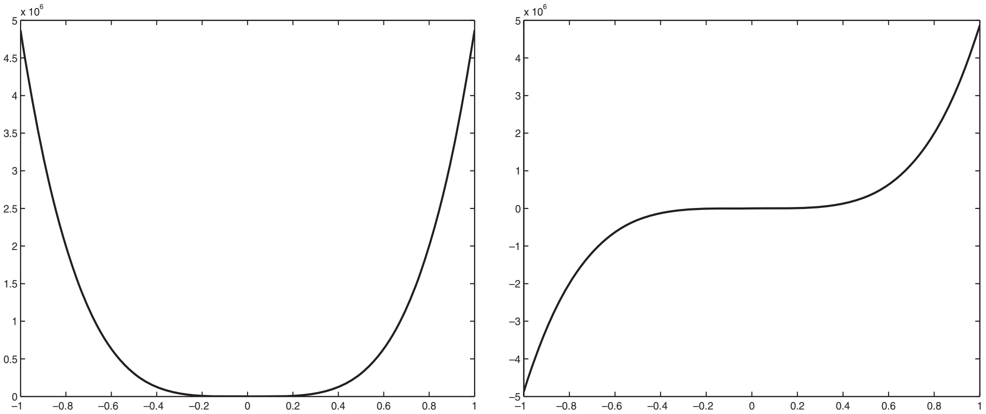

FIG. 4.1. *Typical shapes of $\mathcal{Q}$ and $\mathcal{P}$, $\mathcal{N} = 50$, $\mathcal{M} = 2$.*

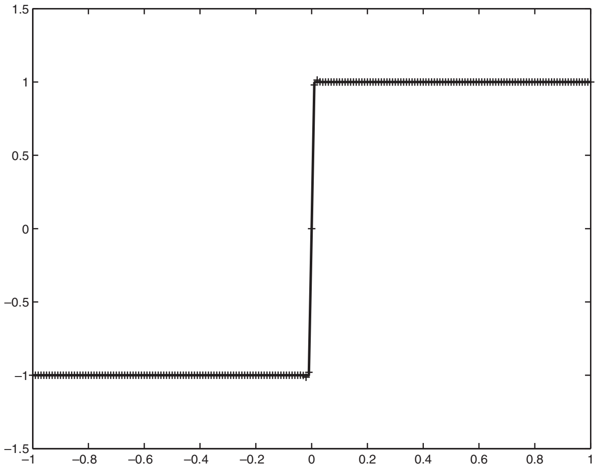

FIG. 4.2. *Rational approximation* (+) *of the sign function (solid line),* $\mathcal{N} = 50$, $\mathcal{M} = 2$.

4.2. Determination of the numerator. With the $q_{2\mathcal{M}}$ defined by Proposition 4.5 and the $\Lambda_{2k+1}^{(\mathcal{M})}$ given by (4.12)–(4.13), the expansion (4.3) leads to defining the numerator $\mathcal{P}$ by

$$\mathcal{P} = \sum_{n=0}^{\mathcal{N}} \hat{p}_{2n+1} T_{2n+1}, \quad \hat{p}_{2n+1} = \Lambda_{2n+1}^{(\mathcal{M})} \quad \forall n = 0, \dots, \mathcal{N}. \tag{4.18}$$

The typical shape of $\mathcal{P}$ is displayed on Figure 4.1.

4.3. Analysis of the rational approximation. We consider here the rational approximation defined by the second method. The approximation $\mathcal{R} = \mathcal{P}/\mathcal{Q}$ ($\mathcal{N} = 50$, $\mathcal{M} = 2$) plotted in Figure 4.2 is very accurate: the Gibbs phenomenon has almost been eliminated. The reader should consult [15] for a comparison of several methods aimed at eliminating this Gibbs phenomenon, in terms of reducing the Gibbs constant (the overshoot near the discontinuity) and increasing the steepness (the value of the derivative of the approximation at the discontinuity). In Figure 4.3 we displayed

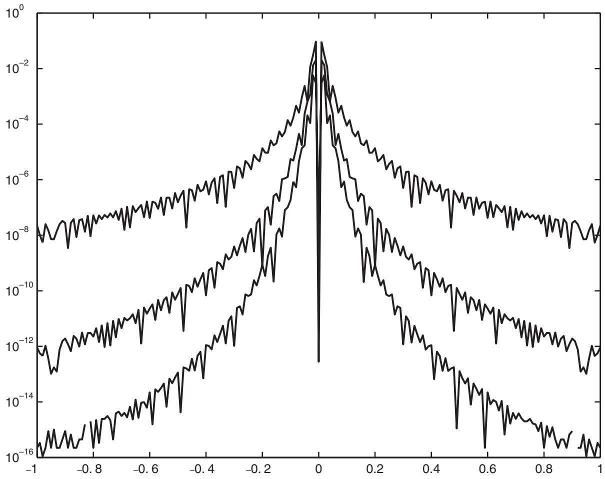

FIG. 4.3. *Rational approximation: log (decimal) of the error* $|\mathcal{R}(S)(x) - Sign(x)|$*,* $\mathcal{N} = 50$*,* $\mathcal{M} = 1, 2, 3$*.*

the pointwise error, $|\mathcal{R}(S)(x) - S(x)|$ for $\mathcal{M} = 1$, 2, and 3. This representation shows the efficiency of the method used as a filter for the spectral approximations of discontinuous solutions.

In this section, we analyze these spectacular results. Let the parameter $\mathcal{M}$ be fixed and the parameter $\mathcal{N} = K - \mathcal{M}$ go to infinity. We know from Proposition 4.5 that $\sigma_k^{(\mathcal{M},\mathcal{N})} = 0$ for $k = \mathcal{N}+1, \dots, K = \mathcal{N}+\mathcal{M}$. The next lemma makes precise the behavior of $\sigma_k^{(\mathcal{M},\mathcal{N})}$ for large values of k.

LEMMA 4.8. *The factors* $\sigma_k^{(\mathcal{M})}$ *introduced in* (4.12) *with* q_{2m} *defined by Proposition* 4.5 *satisfy, for fixed* $\mathcal{M}$*,*

$$\sigma_k^{(\mathcal{M})} \simeq \left(1 - \frac{\mathcal{N}^2}{k^2}\right)^{\mathcal{M}} \qquad \text{as } k \to +\infty. \tag{4.19}$$

Proof. We fix $\mathcal{M}$, and let the q_{2m}'s be as defined by Proposition 4.5. Using (1.4) in (4.14), we get

$$\begin{aligned}\sigma_k^{(\mathcal{M})} &= \frac{\Gamma(k+\mathcal{N}+\mathcal{M}+2)\Gamma(k-\mathcal{N})\Gamma(3/2+k)\Gamma(k+1/2-\mathcal{M})}{\Gamma(k+\mathcal{N}+2)\Gamma(k-\mathcal{N}-\mathcal{M})\Gamma(3/2+k+\mathcal{M})\Gamma(k+1/2)}\\ &= \gamma_1\gamma_2\gamma_3\gamma_4,\end{aligned}$$

with

$$\gamma_1 = \frac{\Gamma(k+\mathcal{N}+2+\mathcal{M})}{\Gamma(k+\mathcal{N}+2)} \simeq (k+\mathcal{N})^{\mathcal{M}} \qquad \text{for large values of } k,$$

$$\gamma_2 = \frac{\Gamma(k-\mathcal{N})}{\Gamma(k-\mathcal{N}-\mathcal{M})} \simeq (k-\mathcal{N})^{\mathcal{M}},$$

$$\gamma_3 = \frac{\Gamma(k+1/2-\mathcal{M})}{\Gamma(k+3/2+\mathcal{M})} = \frac{1}{(k+1/2-\mathcal{M})\cdots(k+1/2+\mathcal{M})} \simeq \frac{1}{k^{2\mathcal{M}+1}},$$

$$\gamma_4 = \frac{\Gamma(3/2+k)}{\Gamma(k+1/2)} = k+1/2.$$

For $k \to +\infty$, we get (4.19). □

THEOREM 4.9 (convergence). *The rational approximation $\mathcal{R}(S)$ with denominator's coefficients given by Proposition 4.5 and fixed $\mathcal{M}$ converges to S as $\mathcal{N} \to +\infty$:*

$$\lim_{\mathcal{N}\to+\infty} \mathcal{R}(S) = S \qquad \text{in } L^2_\omega. \tag{4.20}$$

Proof. The denominator $\mathcal{Q}$ never vanishes on I and is always ≥ 1; it follows that

$$\begin{aligned}
\|\mathcal{R}(S) - S\|^2_\omega &= \int_I \frac{(\mathcal{Q}S - \mathcal{P})^2}{\mathcal{Q}^2}\omega(x)dx \\
&\leq \int_I (\mathcal{Q}S - \mathcal{P})^2\omega(x)dx \qquad (\mathcal{Q}(x) \geq 1) \\
&\leq \frac{2}{\pi}\sum_{k>K} \left|(\widehat{\mathcal{Q}S - \mathcal{P}})_{2k+1}\right|^2 \\
&\leq \frac{2}{\pi}\sum_{k>K} |\Lambda^{(\mathcal{M})}_{2k+1}|^2 \qquad \text{(see (4.3))} \\
&\leq \frac{2}{\pi}\sum_{k>K} |\hat{s}_{2k+1}|^2|\sigma^{(\mathcal{M})}_k|^2 \qquad \text{(see (4.12))}.
\end{aligned}$$

The boundedness of $\sigma^{(\mathcal{M})}_k$ and $S \in L^2_\omega$ end the proof. □

The next theorem makes precise the rate of convergence of the rational approximation. If we consider the norm of the error $\mathcal{R}(S) - S$ in a region excluding a small vicinity of the singularity, we get an acceleration of the convergence. For $\varepsilon > 0$, let us define $\eta = 1/\mathcal{N}^\varepsilon$, $I_\eta =]-1, -\eta[\cup]\eta, 1[$ and $\|\mathcal{R}(S) - S\|_{L^2_\omega(I_\eta)} := (\int_{I_\eta} |\frac{\mathcal{P}}{\mathcal{Q}} - S|^2\omega(x)dx)^{1/2}$.

THEOREM 4.10 (acceleration). *There exists a constant $C_\mathcal{M} \in \mathbb{R}$ depending solely on $\mathcal{M}$ such that*

$$\|\mathcal{R}(S) - S\|_{L^2_\omega(I_\eta)} \leq \frac{C_\mathcal{M}}{\mathcal{N}^{(1-\varepsilon)2\mathcal{M}}}\|\pi^{2K+1}_\omega(S) - S\|_{L^2_\omega(I)}. \tag{4.21}$$

Proof. We derive from the monotonicity of $\mathcal{Q}$ and the asymptotic formula $q_{2\mathcal{M}} \simeq \text{Const}_\mathcal{M}\, \mathcal{N}^{2\mathcal{M}}$ a lower bound of $\mathcal{Q}(x)$:

$$|x| > \eta \Longrightarrow \mathcal{Q}(x) > \mathcal{Q}(\eta) > q_{2\mathcal{M}}\eta^{2\mathcal{M}} > \text{Const}_\mathcal{M}\, (\eta\mathcal{N})^{2\mathcal{M}}.$$

Using this bound, we write

$$\begin{aligned}
\|\mathcal{R}(S) - S\|^2_{L^2_\omega(I_\eta)} &= \int_{I_\eta} \frac{(\mathcal{Q}S - \mathcal{P})^2}{\mathcal{Q}^2}\omega(x)dx \\
&\leq \frac{\text{Const}}{(\eta\mathcal{N})^{4\mathcal{M}}}\int_{I_\eta} (\mathcal{Q}S - \mathcal{P})^2\omega(x)dx \\
&\leq \frac{\text{Const}}{(\eta\mathcal{N})^{4\mathcal{M}}}\int_{I} (\mathcal{Q}S - \mathcal{P})^2\omega(x)dx \\
&\leq \frac{\text{Const}'}{(\eta\mathcal{N})^{4\mathcal{M}}}\sum_{k>\mathcal{K}} |\hat{s}_{2k+1}\sigma^{(\mathcal{M})}_k|^2.
\end{aligned}$$

The boundedness of $\sigma^{(\mathcal{M})}_k$ stated in Lemma 4.8 ends the proof. □

For all $x \in I$, we have

$$\mathcal{R}(S)(x) = \sum_{n=0}^{\mathcal{N}} \frac{\hat{p}_{2n+1}}{\mathcal{Q}(x)} T_{2n+1}(x) = \sum_{n=0}^{\mathcal{N}} \frac{\hat{s}_{2n+1}\sigma_n^{(\mathcal{M})}}{\mathcal{Q}(x)} T_{2n+1}(x).$$

Hence the rational approximation is like a Chebyshev series with variable coefficients

$$\hat{r}_{2n+1}(x) = \frac{\hat{s}_{2n+1}\sigma_n^{(\mathcal{M})}}{\mathcal{Q}(x)}$$

decreasing faster than the coefficients of the original function. Taking $\eta = \frac{1}{\mathcal{N}^{\varepsilon}}$ $(\varepsilon > 0)$, we get

$$|x| > \frac{1}{\mathcal{N}^{\varepsilon}} \Longrightarrow |\hat{r}_{2n+1}(x)| < \frac{\text{Const}}{\mathcal{N}^{2\mathcal{M}-2\varepsilon\mathcal{M}}} |\hat{s}_{2n+1}|.$$

This indicates a local acceleration factor of up to $1/\mathcal{N}^{2\mathcal{M}}$.

5. Conclusions. The analysis of some rational approximations of the sign function have been performed. These approximations are built from a finite Chebyshev expansion of the solution. The rate of convergence of these approximations increases with the degree of the denominators. Numerical tests support the theoretical results. Several generalizations of this work should be done.

- Analysis of the Padé–Chebyshev approximations for general discontinuous functions
- Analysis of the Padé–Legendre approximations of the sign function. As far as we know, this has never been done. Quadratic denominators ($\mathcal{M} = 1$) are considered in [6], but the remarkable numerical results of [5] (obtained with $\mathcal{M} \geq 1$) have not yet been fully analyzed.

These two problems are currently under investigation.

Acknowledgment. The authors would like to thank the anonymous referees for valuable suggestions about the bibliography.

FOURTH-ORDER NONOSCILLATORY UPWIND AND CENTRAL SCHEMES FOR HYPERBOLIC CONSERVATION LAWS*

ÁNGEL BALAGUER† AND CARLOS CONDE‡

Abstract. The aim of this work is to solve hyperbolic conservation laws by means of a finite volume method for both spatial and time discretization. We extend the ideas developed in [X.-D. Liu and S. Osher, *SIAM J. Numer. Anal.,* 33 (1996), pp. 760–779; X.-D. Liu and E. Tadmor, *Numer. Math.,* 79 (1998), pp. 397–425] to fourth-order upwind and central schemes. In order to do this, once we know the cell-averages of the solution, $\overline{u}_j^n$, in cells I_j at time $T = t^n$, we define a new three-degree reconstruction polynomial that in each cell, I_j, presents the same shape as the cell-averages $\{\overline{u}_{j-1}^n, \overline{u}_j^n, \overline{u}_{j+1}^n\}$. By combining this reconstruction with the nonoscillatory property and the maximum principle requirement described in [X.-D. Liu and S. Osher, *SIAM J. Numer. Anal.,* 33 (1996), pp. 760–779] we obtain a fourth-order scheme that satisfies the total variation bounded (TVB) property. Extension to systems is carried out by componentwise application of the scalar framework. Numerical experiments confirm the order of the schemes presented in this paper and their nonoscillatory behavior in different test problems.

Key words. central schemes, upwind schemes, high order, nonoscillatory, hyperbolic conservation laws

AMS subject classification. 65M06

DOI. 10.1137/S0036142903437106

1. Introduction.

In this paper we present three fourth-order numerical schemes in order to solve one-dimensional hyperbolic conservation laws

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = 0, \quad u(x,0) = u_0(x), \tag{1.1}$$

where $u_0(x)$ is a known bounded function.

Many of the high-order methods used to solve this problem employ an interpolating polynomial that reconstructs the pointvalues of the solution in terms of the cell-averages. There are two main types of schemes: upwind schemes and central schemes. Godunov-type schemes [7] are the forerunner for upwind schemes, which compute the cell-averages of the solution in the same spatial cells at all time steps. Similarly, Van Leer [25] presented a scheme with second-order accuracy in space and time. Later, Colella and Woodward [5] used two-degree polynomials, although their scheme satisfies the total variation diminishing (TVD) property, and, hence, it is limited to second order of accuracy in the L^1 norm. Harten et al. [8] introduced the essentially nonoscillatory (ENO) schemes, with an order of accuracy higher than two and able to capture sharp shocks without introducing oscillations. Similarly, different high-order numerical schemes have been developed, such as the weighted ENO (WENO) schemes (see Liu, Osher, and Chan [18], Jiang and Shu [10], or Balsara and Shu [2]). Extensions to multidimensional systems can also be found in Casper

and Atkins [4] or Balaguer et al. [1]. The schemes found in the latter references use the high-order Runge–Kutta schemes developed in Shu and Osher [23] for time integration, which maintain the spatial operator stability properties.

Although the first-order Lax–Friedrich scheme (see [6]) is probably the forerunner for central schemes, the central scheme of Nessyahu and Tadmor [21] has generated a significant number of works on high-resolution schemes that maintain the simplicity of the Riemann solver-free approach. The scheme developed in Nessyahu and Tadmor [21] has been extended to accuracy orders higher than 2 (see Liu and Tadmor [20], Jiang et al. [11], or Qiu and Shu [22]) and to several spatial dimensions (see Levy and Tadmor [15] and Jiang and Tadmor [12]). High-order central WENO schemes are described in Levy, Puppo, and Russo [16], [17].

We have focused our attention on the upwind scheme developed in Liu and Osher [19] and the central scheme described in Liu and Tadmor [20], which are third-order schemes, in the sense of local truncation error in regions without discontinuities. The algorithm developed in Liu and Osher [19] leads to a conservative scheme that satisfies the local maximum principle and guarantees that the number of extrema in the solution does not exceed the number of extrema of the initial condition $u_0(x)$. These properties allow achieving the total variation bounded (TVB) property. The approach used in that reference uses a simple centered stencil with quadratic reconstruction.

Liu and Tadmor [20] apply the procedure described in Liu and Osher [19] to central schemes and show the results obtained when solving differential equation systems. The resulting scheme is third-order accurate in space and time. In both references ([19] and [20]), time integration is performed using a finite volume method, approximating the resulting integrals with respect to time by a Gauss [19] or a Simpson [20] quadrature rule. The values of the solution at half time steps are approximated using a Taylor expansion. Jiang et al. [11] present a procedure to convert schemes which are based on staggered spatial grids into nonstaggered schemes, which are simpler to implement in frameworks which involve complex geometries and boundary conditions. However, it has been in some cases superseded by the semidiscrete central schemes (see Kurganov and Tadmor [13]) and their high-order extensions.

This paper presents an extension of the schemes developed in Liu and Osher [19] and Liu and Tadmor [20]. In contrast to them, our scheme is a fourth-order scheme in the sense of local truncation error. To this end, we will use a finite volume method with a conservative degree-three polynomial reconstruction that calculates the pointvalues of the solution from the cell-averages, by avoiding the increase in the number of solution extrema at the interior of each cell. This condition, together with the nonoscillatory property and the maximum principle requirement described in Liu and Osher [19], avoids spurious numerical oscillations in the computed solution.

The integrals respecting the two variables, space and time, are evaluated by means of a two-point Gauss quadrature. The values of the solution at half-time steps are calculated using a Taylor expansion with a fourth-order error, using the local Cauchy–Kowalewski procedure (see [8]) to approximate the time derivatives of the solution as a function of the derivatives with respect to x. We also present an extension to systems of equations, where the computed solution at quadrature nodes is obtained by the so called natural continuous extension of Runge–Kutta schemes (see Zennaro [26], Bianco, Puppo, and Russo [3], or Levy, Puppo, and Russo [16]).

In this paper, first, we present the equations that define the upwind and central schemes for solving the problem (1.1). Next, the fourth-order nonoscillatory reconstruction procedure is described. It guarantees that the resulting numerical scheme satisfies the properties that generate its nonoscillatory behavior. Finally, some problems with known analytical solution are solved to verify the order of the schemes presented here and to compare their behavior with the schemes developed in Liu and Osher [19] and Liu and Tadmor [20].

2. Upwind and central schemes. Let us suppose that the time interval is discretized uniformly into the values $t^n = n \cdot \Delta t,\ n = 0, 1, 2, \ldots, NT$. We assume that the grid points $\{x_j\}$ are distributed uniformly at the spatial domain at which (1.1) will be defined, verifying that $x_j = x_{j-1} + \Delta x\, \forall j = 1, \ldots, NX$, where Δx is a known constant. Given a point (x_j, t^n), we consider the control volume defined by $[x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}}] \times \left[t^n, t^{n+1}\right]$, where $x_{j\pm\frac{1}{2}} = x_j \pm \Delta x/2$. By integrating (1.1) over this control volume, we obtain

$$\text{(2.1)}\ \overline{u}_j^{n+1} = \overline{u}_j^n - \frac{1}{\Delta x}\left[\int_{t^n}^{t^{n+1}} f\left(u\left(x_{j+\frac{1}{2}}, \tau\right)\right) d\tau - \int_{t^n}^{t^{n+1}} f\left(u\left(x_{j-\frac{1}{2}}, \tau\right)\right) d\tau\right],$$

where the cell average $\overline{u}_j^n$ is defined as

$$\text{(2.2)}\qquad \overline{u}_j^n = \frac{1}{\Delta x}\int_{I_j} u\left(\varphi, t^n\right) d\varphi, \quad I_j = \left\{\varphi, |\varphi - x| \le \frac{\Delta x}{2}\right\}.$$

In (2.1) there is a relationship between the average values of the solution at the limit of the time interval, $\overline{u}_j^n$, $\overline{u}_j^{n+1}$, and its pointvalues at the boundary of the space interval, $u(x_{j\pm\frac{1}{2}}, \tau)$. The steps to follow in the implementation of numerical schemes can be described as follows.

(1) For each time value $t^n,\ n \in \{0, 1, \ldots, NT - 1\}$, we have an approximation of the cell-averages of the solution $\overline{w}_j^n \cong \overline{u}_j^n\, \forall j \in \{0, 1, \ldots, NX\}$, at the nodes x_j. The approximation will be of order $O((\Delta x)^4)$.

(2) The pointvalues of $w(x, t^n)\, \forall x \in \{x_0 - \Delta x/2, \ldots, x_{NX} + \Delta x/2\}$ are reconstructed using a piecewise polynomial interpolation,

$$\text{(2.3)}\qquad w(x, t^n) \equiv \sum_{j=0}^{NX} R_j(x; \overline{w}^n)\chi_j(x), \quad \chi_j(x) = \begin{cases} 1 & \text{if} \quad x \in I_j, \\ 0 & \text{if} \quad x \notin I_j, \end{cases}$$

where $R_j(x; \overline{w}^n)$ is a polynomial that reconstructs the pointvalues of the solution using the discrete values $\overline{w}_i^n$, $i \in \{0, 1, \ldots, NX\}$, verifying

$$\text{(2.4)}\quad \frac{1}{\Delta x}\int_{x_{j-\frac{1}{2}}}^{x_{j+\frac{1}{2}}} R_j(x; \overline{w}^n) = \overline{w}_j^n, \quad R_j(x; \overline{w}^n) = w(x, t^n) + O((\Delta x)^4)\ \ \forall x \in I_j.$$

(3) In the case of the central schemes, the average values $\overline{w}_{j+\frac{1}{2}}^n$ are calculated using the approximation given in (2.3):

$$\text{(2.5)}\qquad \overline{w}_{j+\frac{1}{2}}^n \equiv \frac{1}{\Delta x}\left[\int_{x_j}^{x_j + \Delta x/2} R_j(x; \overline{w}^n)\, dx + \int_{x_j + \Delta x/2}^{x_{j+1}} R_{j+1}(x; \overline{w}^n)\, dx\right].$$

The integrals in (2.1) are evaluated in an exact way taking into account that $R_j(x; \overline{w}^n)$ and $R_{j+1}(x; \overline{w}^n)$ are degree-three polynomials.

(4) The integrals with respect to the time variable are approximated using a two-point Gauss quadrature. Thus,

$$\int_{t^n}^{t^{n+1}} f(w(x_{j\pm\frac{1}{2}},\tau))d\tau \approx \frac{\Delta t}{2}\Big(f(w(x_{j\pm\frac{1}{2}},t^n+\beta_0))+f(w(x_{j\pm\frac{1}{2}},t^n+\beta_1))\Big) \tag{2.6}$$

$$\beta_0=\Delta t\left(\frac{1-1/\sqrt{3}}{2}\right),\quad \beta_1=\Delta t\left(\frac{1+1/\sqrt{3}}{2}\right). \tag{2.7}$$

In order to approximate the pointvalues of w at the time steps that appear in (2.6), we may use a Taylor expansion with an error $O((\Delta x^4))$. This technique is used, for example, in Liu and Osher [19] and Liu and Tadmor [20]. Another efficient method would be the natural continuous extension of Runge–Kutta methods advocated by Bianco, Puppo, and Russo [3] and Levy, Puppo, and Russo [16]. We will use this method in the resolution of systems of equations which achieve the same accuracy with much lower computational effort.

(5) In order to calculate the cell-averages of w at t^{n+1}, we distinguish two cases.

(5a) *Upwind schemes.* The cells are intervals centered at each x_j (equation (2.1), after replacing the function u—in that equation—for the function w). In order to calculate the value of $f(w(x_{j\pm\frac{1}{2}},t^n+\beta_k))$ in expression (2.6), we will use the Roe flux with entropy fix, although other fluxes can also be used, as those described in Liu and Osher [19].

(5b) *Central schemes.* The cells are intervals centered at each $x_{j+\frac{1}{2}}$.

$$\overline{w}^{n+1}_{j+\frac{1}{2}}=\overline{w}^{n}_{j+\frac{1}{2}}-\frac{1}{\Delta x}\left[\int_{t^n}^{t^{n+1}} f\left(w\left(x_{j+1},\tau\right)\right)d\tau-\int_{t^n}^{t^{n+1}} f\left(w\left(x_{j},\tau\right)\right)d\tau\right]. \tag{2.8}$$

The terms on the right-hand side in (2.1) and (2.8) are calculated using the approximations (2.5)–(2.7).

(6) We go back to step (1) and restart the procedure until calculating $\overline{w}_i^{NT}\cong\overline{u}(x_i,t^{NT})$, $i\in\{0,1,\dots,NX\}$. Then, we use formula (2.3) to obtain the pointvalues with $O((\Delta x)^4)$.

3. Fourth-order nonoscillatory reconstruction.

This section presents the reconstruction procedure used to obtain each $R_j(x;\overline{w}^n)$ from the cell averages $\overline{w}^n_k$, $k\in\{j-2,j-1,j,j+1,j+2\}$.

3.1. Fourth order and conservation.

Initially, we will consider the degree-three polynomial that verifies these conditions:

$$p_j(x_j;\overline{w}^n)=\overline{w}^n_j,\quad p_j(x_{j-1};\overline{w}^n)=\overline{w}^n_{j-1},\quad p_j(x_{j+1};\overline{w}^n)=\overline{w}^n_{j+1}, \tag{3.1}$$

$$\Delta x\frac{dp_j}{dx}(x_j;\overline{w}^n)=\Delta x\frac{\partial\overline{w}}{\partial x}(x_j,t^n)\equiv d^n_j,\quad\text{where }\overline{w}(x,t^n)=\frac{1}{\Delta x}\int_{x-\Delta x/2}^{x+\Delta x/2} w(\varphi,t^n)\,d\varphi.$$

This polynomial can be expressed as

$$\begin{aligned}p_j\left(x;\overline{w}^n\right)=\overline{w}^n_j+d^n_j\cdot\left(\frac{x-x_j}{\Delta x}\right)+\left(\frac{\overline{w}^n_{j-1}-2\overline{w}^n_j+\overline{w}^n_{j+1}}{2}\right)\cdot\left(\frac{x-x_j}{\Delta x}\right)^2\\ +\left(\frac{-\overline{w}^n_{j-1}+\overline{w}^n_{j+1}-2d^n_j}{2}\right)\cdot\left(\frac{x-x_j}{\Delta x}\right)^3.\end{aligned} \tag{3.2}$$

Since

$$w(x,t^n)=\overline{w}(x,t^n)-\frac{1}{24}\left(\Delta x\right)^2\frac{\partial^2\overline{w}(x,t^n)}{\partial x^2}+O\left(\Delta x\right)^4, \tag{3.3}$$

the conservative polynomial, $q_j(x;\overline{w}^n)$ that verifies the conditions in (2.4) can be defined as

$$q_j(x;\overline{w}^n)=p_j(x;\overline{w}^n)-\frac{1}{24}\left(\Delta x\right)^2\frac{d^2p_j(x;\overline{w}^n)}{dx^2}. \tag{3.4}$$

Therefore,

$$\begin{aligned} q_j(x;\overline{w}^n)&=\overline{w}^n_j-\frac{1}{24}\left(\overline{w}^n_{j-1}-2\overline{w}^n_j+\overline{w}^n_{j+1}\right)+\left(\frac{\overline{w}^n_{j-1}-\overline{w}^n_{j+1}+10d^n_j}{8}\right)\left(\frac{x-x_j}{\Delta x}\right)\\ &+\left(\frac{\overline{w}^n_{j-1}-2\overline{w}^n_j+\overline{w}^n_{j+1}}{2}\right)\left(\frac{x-x_j}{\Delta x}\right)^2+\left(\frac{-\overline{w}^n_{j-1}+\overline{w}^n_{j+1}-2d^n_j}{2}\right)\left(\frac{x-x_j}{\Delta x}\right)^3. \end{aligned} \tag{3.5}$$

In case that

$$d^n_j=ds^n_j\equiv\frac{2}{3}\overline{w}^n_{j+1}-\frac{2}{3}\overline{w}^n_{j-1}-\frac{1}{12}\overline{w}^n_{j+2}+\frac{1}{12}\overline{w}^n_{j-2}, \tag{3.6}$$

$q_j(x;\overline{w}^n)$ coincides with the centered polynomial, defined as the average value between two conservative piecewise polynomials: the conservative polynomial which uses $\left\{\overline{w}^n_{j-1},\overline{w}^n_j,\overline{w}^n_{j+1},\overline{w}^n_{j+2}\right\}$ and the polynomial based on $\left\{\overline{w}^n_{j-2},\overline{w}^n_{j-1},\overline{w}^n_j,\overline{w}^n_{j+1}\right\}$. Then, by replacing the value of d^n_j given in (3.6) in expression (3.5), we obtain the following conservative polynomial that verifies conditions (2.4):

$$q^*_j(x;\overline{w}^n)=C^n_{o,j}+C^n_{1,j}\left(\frac{x-x_j}{\Delta x}\right)+C^n_{2,j}\left(\frac{x-x_j}{\Delta x}\right)^2+C^n_{3,j}\left(\frac{x-x_j}{\Delta x}\right)^3, \tag{3.7}$$

$$C^n_{o,j}=\overline{w}^n_j-\frac{1}{24}\left(\overline{w}^n_{j+1}-2\overline{w}^n_j+\overline{w}^n_{j-1}\right), C^n_{1,j}=\frac{-5\overline{w}^n_{j+2}+34\overline{w}^n_{j+1}-34\overline{w}^n_{j-1}+5\overline{w}^n_{j-2}}{48},$$

$$C^n_{2,j}=\frac{1}{2}\left(\overline{w}^n_{j+1}-2\overline{w}^n_j+\overline{w}^n_{j-1}\right),\ C^n_{3,j}=\frac{1}{12}\left(\overline{w}^n_{j+2}-2\overline{w}^n_{j+1}+2\overline{w}^n_{j-1}-\overline{w}^n_{j-2}\right).$$

3.2. Shape-preserving when the cell-averages form a monotone sequence. We will define d^n_j in (3.5) so that if the cell-averages $\{\overline{w}^n_{j-1},\overline{w}^n_j,\overline{w}^n_{j+1}\}$ form a monotone sequence, then $q_j(x;\overline{w}^n)$ is monotone on I_j. We will denote as shape-preserving properties the following:

(I) $q_j(x;\overline{w}^n)$ is monotonically increasing in I_j if $\overline{w}^n_{j-1}\le\overline{w}^n_j\le\overline{w}^n_{j+1}$.

(II) $q_j(x;\overline{w}^n)$ is monotonically decreasing in I_j if $\overline{w}^n_{j-1}\ge\overline{w}^n_j\ge\overline{w}^n_{j+1}$.

To simplify the notation, first we define

$$\overline{W}C^n_j=\overline{w}^n_{j+1}-\overline{w}^n_{j-1},\ \overline{W}R^n_j=\overline{w}^n_{j+1}-\overline{w}^n_j,\ \overline{W}C2^n_j=\overline{w}^n_{j+2}-\overline{w}^n_{j-2}. \tag{3.8}$$

Observation 1. If $d^n_j=\frac{\overline{W}C^n_j}{2}$, then according to (3.5) $q_j(x;\overline{w}^n)$ coincides with a quadratic polynomial. In this case, $\frac{dq_j(x_j\pm\Delta x/2;\overline{w}^n)}{dx}=\pm\frac{\overline{w}^n_{j\pm1}-\overline{w}^n_j}{\Delta x}$, and therefore the shape-preserving properties are verified.

Observation 2. In the case at which $d^n_j=ds^n_j$ (defined in (3.6)), the following hold.

1. If $\left(2\cdot\overline{W}C^n_j=\overline{W}C2^n_j\right)$, then $d^n_j=\frac{\overline{W}C^n_j}{2}$ (see Observation 1).

2. If $\left(2\cdot\overline{W}C_j^n > \overline{W}C2_j^n\right)$ and $\overline{w}_{j-1}^n \le \overline{w}_j^n \le \overline{w}_{j+1}^n$, then, according to (3.7),

$$\frac{d^3 q_j^*(x;\overline{w}^n)}{dx^3} = \frac{1}{(\Delta x)^3}\left(6\cdot C_{3,j}^n\right) = \frac{1}{2\cdot(\Delta x)^3}\left(\overline{W}C2_j^n - 2\cdot\overline{W}C_j^n\right) < 0,$$

and thus $\frac{d(q_j^*(x;\overline{w}^n))}{dx}$ achieves the minimum value at the endpoints of the interval under consideration. Since

$$\begin{aligned}\frac{dq_j^*(x_j+\Delta x/2;\overline{w}^n)}{dx} &= \frac{1}{24\Delta x}\left(-\overline{W}C2_j^n + 2\cdot\overline{W}C_j^n + 24\cdot\overline{W}R_j^n\right) > 0,\\ \frac{dq_j^*(x_j-\Delta x/2;\overline{w}^n)}{dx} &= \frac{1}{24\Delta x}\left(-\overline{W}C2_j^n + 26\cdot\overline{W}C_j^n - 24\cdot\overline{W}R_j^n\right) > 0,\end{aligned} \tag{3.9}$$

$\mathrm{Min}\{\frac{d(q_j^*(x;\overline{w}^n))}{dx}\ \forall x\in I_j\} > 0$ and $q_j^*(x;\overline{w}^n)$ is monotonically increasing in I_j.

3. If $\left(2\cdot\overline{W}C_j^n < \overline{W}C2_j^n\right)$ and $\overline{w}_{j-1}^n \le \overline{w}_j^n \le \overline{w}_{j+1}^n$, then the derivative of $q_j^*(x;\overline{w}^n)$, defined in (3.7), has a minimum at point

$$x_{MI} = x_j + \frac{\Delta x}{3}\left(\frac{2\cdot\overline{W}R_j^n - \overline{W}C_j^n}{(1/6)\left(2\cdot\overline{W}C_j^n - \overline{W}C2_j^n\right)}\right) = x_j - 4\cdot\Delta x\left(\frac{\overline{W}R_j^n - (1/2)\overline{W}C_j^n}{\left(\overline{W}C2_j^n - 2\cdot\overline{W}C_j^n\right)}\right).$$

In this way, if $\left|\overline{W}R_j^n - \frac{1}{2}\overline{W}C_j^n\right| \ge \frac{1}{8}\left|\overline{W}C2_j^n - 2\cdot\overline{W}C_j^n\right|$, then

$$\left(\overline{W}R_j^n > \frac{1}{2}\overline{W}C_j^n \Rightarrow x_{MI} \le x_j - \frac{\Delta x}{2}\right) \text{ and } \left(\overline{W}R_j^n < \frac{1}{2}\overline{W}C_j^n \Rightarrow x_{MI} \ge x_j + \frac{\Delta x}{2}\right).$$

Thus, the minimum $\mathrm{Min}\{\frac{d(q_j^*(x;\overline{w}^n))}{dx}\ \forall x\in I_j\}$ is achieved at one of these boundary points, $x = x_j \pm \frac{\Delta x}{2}$. However, in this case we cannot ensure that the inequalities given in (3.9) are always verified.

4. If $\left(2\cdot\overline{W}C_j^n < \overline{W}C2_j^n\right)$ and $\overline{w}_{j-1}^n \ge \overline{w}_j^n \ge \overline{w}_{j+1}^n$, then we can prove that $q_j^*(x;\overline{w}^n)$ is monotonically decreasing in I_j.

5. If $\left(2\cdot\overline{W}C_j^n > \overline{W}C2_j^n\right)$ and $\overline{w}_{j-1}^n \ge \overline{w}_j^n \ge \overline{w}_{j+1}^n$, then we can prove that $|x_{MI} - x_j| \ge \Delta x/2$ when $\left|\overline{W}R_j^n - \frac{1}{2}\overline{W}C_j^n\right| \ge \frac{1}{8}\left|\overline{W}C2_j^n - 2\cdot\overline{W}C_j^n\right|$, but we cannot ensure that $q_j^*(x;\overline{w}^n)$ is always monotonically decreasing in I_j.

Observation 3. Supposing that $2\cdot d_j^n < \overline{W}C_j^n$, then the derivative of $q_j(x;\overline{w}^n)$, defined in (3.5), has a minimum at point

$$x_{MI} = x_j + \frac{\Delta x}{3}\left(\frac{2\cdot\overline{W}R_j^n - \overline{W}C_j^n}{2\cdot d_j^n - \overline{W}C_j^n}\right).$$

In addition,

$$\frac{dq_j(x_{MI};\overline{w}^n)}{dx} = q_{xj}^n(d_j^n) \equiv \frac{1}{8\Delta x}\left(10\cdot d_j^n - \overline{W}C_j^n\right) + \frac{1}{6\Delta x}\left(\frac{\left(2\cdot\overline{W}R_j^n - \overline{W}C_j^n\right)^2}{\left(2\cdot d_j^n - \overline{W}C_j^n\right)}\right).$$

This is a function that depends on d_j^n and coincides with a hyperbola. In it, the value of $d_j^n = \frac{\overline{W}C_j^n}{2} - S_j^n\frac{\sqrt{15}}{15}\left|2\cdot\overline{W}R_j^n - \overline{W}C_j^n\right|$ is a local maximum of $q_{xj}^n(d_j^n)$ when $S_j^n > 0$ and a local minimum of $q_{xj}^n(d_j^n)$ when $S_j^n < 0$ being $S_j^n = \mathrm{Sign}(\overline{W}C_j^n)$.

3.2.1. Definition of d_j^n. The polynomial $q_j^*(x;\overline{w}^n)$ defined in (3.7) does not fulfill the shape-preserving properties defined in this subsection for any sequence of values $\left\{\overline{w}_{j-2}^n, \overline{w}_{j-1}^n, \overline{w}_j^n, \overline{w}_{j+1}^n, \overline{w}_{j+2}^n\right\}$. Therefore, we have to define a procedure that adequately defines the slopes d_j^n.

We will consider the value of $d_j^n = ds_j^n$ (given in (3.6)) except when this shape-preserving property is not fulfilled. For this, we use the notation

$$ds1_j^n = \frac{\overline{W}C_j^n}{10},\ ds2_j^n = \frac{1}{2}\left(\overline{W}C_j^n - 4\cdot \overline{W}R_j^n\right),\ ds3_j^n = \frac{1}{2}\left(4\cdot \overline{W}R_j^n - 3\cdot \overline{W}C_j^n\right),$$

$$(3.10)\quad S_j^n = \text{Sign}(\overline{W}C_j^n),\ C1 = \frac{\sqrt{15}}{15},\ C2 = \frac{15-\sqrt{15}}{28}$$

and define d_j^n in the following way:

(A1) If $S_j^n = 0$, then $d_j^n = 0$.

(A2) If $S_j^n \neq 0$ and $\left(2\cdot S_j^n \cdot \overline{W}C_j^n \geq S_j^n \cdot \overline{W}C2_j^n\right)$, then $d_j^n = ds_j^n$.

(A3) If $S_j^n \neq 0$ and $\left(2\cdot S_j^n \cdot \overline{W}C_j^n < S_j^n \cdot \overline{W}C2_j^n\right)$, then the following hold:

(A3.1) If $\overline{w}_j^n = \frac{\overline{w}_{j+1}^n + \overline{w}_{j-1}^n}{2}$, we define

$$d_j^n = \begin{cases} \text{Max}\left\{ds1_j^n, ds_j^n\right\} & \text{if } S_j^n > 0, \\ \text{Min}\left\{ds1_j^n, ds_j^n\right\} & \text{if } S_j^n < 0. \end{cases}$$

(A3.2) If $\overline{w}_j^n \neq \frac{\overline{w}_{j+1}^n + \overline{w}_{j-1}^n}{2}$, then the following hold:

(A3.2.1) If $\left|\overline{W}R_j^n - \frac{1}{2}\overline{W}C_j^n\right| \geq \frac{1}{8}\left|\overline{W}C2_j^n - 2\cdot \overline{W}C_j^n\right|$, then

$$d_j^n = \begin{cases} \text{Max}\left\{ds2_j^n,\ ds3_j^n,\ ds_j^n\right\} & \text{if } S_j^n > 0, \\ \text{Min}\left\{ds2_j^n,\ ds3_j^n,\ ds_j^n\right\} & \text{if } S_j^n < 0. \end{cases}$$

(A3.2.2) If $\left|\overline{W}R_j^n - \frac{1}{2}\overline{W}C_j^n\right| < \frac{1}{8}\left|\overline{W}C2_j^n - 2\cdot \overline{W}C_j^n\right|$, then

$$d_j^n = \begin{cases} \frac{\overline{W}C_j^n}{2} - S_j^n \cdot C1 \cdot \left|2\cdot \overline{W}R_j^n - \overline{W}C_j^n\right| & \text{if } \left|\frac{\overline{W}R_j^n}{\overline{W}C_j^n} - \frac{1}{2}\right| \leq C2, \\ \frac{\overline{W}C_j^n}{2} & \text{if } \left|\frac{\overline{W}R_j^n}{\overline{W}C_j^n} - \frac{1}{2}\right| > C2. \end{cases}$$

THEOREM 3.1. *With this definition of d_j^n the polynomial $q_j(x;\overline{w}^n)$ defined by means of* (3.5) *verifies the following shape-preserving properties:*

(I) *$q_j(x;\overline{w}^n)$ is monotonically increasing in I_j if $\overline{w}_{j-1}^n \leq \overline{w}_j^n \leq \overline{w}_{j+1}^n$.*

(II) *$q_j(x;\overline{w}^n)$ is monotonically decreasing in I_j if $\overline{w}_{j-1}^n \geq \overline{w}_j^n \geq \overline{w}_{j+1}^n$.*

Proof. Let us suppose that $\overline{w}_{j-1}^n \leq \overline{w}_j^n \leq \overline{w}_{j+1}^n$. We have to prove that $q_j(x;\overline{w}^n)$ is monotonically increasing in $I_j = \left[x_j - \frac{\Delta x}{2}, x_j + \frac{\Delta x}{2}\right]$. A similar argument allows us to prove that $q_j(x;\overline{w}^n)$ is monotonically decreasing in I_j when $\overline{w}_{j-1}^n \geq \overline{w}_j^n \geq \overline{w}_{j+1}^n$. We will consider all the possible cases.

Case (A1). $S_j^n = 0$, that is, $\overline{w}_{j-1}^n = \overline{w}_j^n = \overline{w}_{j+1}^n$. Then $d_j^n = 0$ and $q_j(x;\overline{w}^n) = \overline{w}_j^n$. This polynomial has the same degree of monotonicity as the cell averages $\left\{\overline{w}_{j-1}^n, \overline{w}_j^n, \overline{w}_{j+1}^n\right\}$.

Case (A2). $S_j^n = 1$ and $\left(2\cdot \overline{W}C_j^n \geq \overline{W}C2_j^n\right)$. In this case, $d_j^n = ds_j^n$ and, after observation 2, $q_j(x;\overline{w}^n)$ is monotonically increasing in I_j.

Case (A3.1). $S_j^n = 1$, $\left(2 \cdot \overline{W}C_j^n < \overline{W}C2_j^n\right)$, and $\overline{w}_j^n = \frac{\overline{w}_{j+1}^n + \overline{w}_{j-1}^n}{2}$. Then $(2 \cdot \overline{W}R_j^n = \overline{W}C_j^n)$ and according to Observation 3,

$$x_{MI} = x_j, \;\; \frac{dq_j(x_{MI}; \overline{w}^n)}{dx} = \frac{1}{8\Delta x}\left(10 \cdot d_j^n - \overline{W}C_j^n\right).$$

Since in this case $d_j^n = \text{Max}\{\frac{\overline{W}C_j^n}{10}, ds_j^n\}$, then $\frac{dq_j(x_{MI};\overline{w}^n)}{dx} \geq 0$ and $q_j(x;\overline{w}^n)$ is monotonically increasing in I_j.

Case (A3.2.1). $S_j^n = 1$, $\left(2 \cdot \overline{W}C_j^n < \overline{W}C2_j^n\right)$, $\overline{w}_j^n \neq \frac{\overline{w}_{j+1}^n + \overline{w}_{j-1}^n}{2}$, and $\left|\overline{W}R_j^n - \frac{1}{2}\overline{W}C_j^n\right| \geq \frac{1}{8}\left|\overline{W}C2_j^n - 2 \cdot \overline{W}C_j^n\right|$. In this case, $d_j^n = \text{Max}\{\frac{1}{2}(\overline{W}C_j^n - 4 \cdot \overline{W}R_j^n), \frac{1}{2}(4 \cdot \overline{W}R_j^n - 3 \cdot \overline{W}C_j^n),\, ds_j^n\}$. Since $\left(2 \cdot \overline{W}C_j^n < \overline{W}C2_j^n\right)$, then $2 \cdot ds_j^n < \overline{W}C_j^n$. In addition,

$$\overline{W}R_j^n = 0 \Rightarrow d_j^n = \frac{\overline{W}C_j^n}{2}, \;\; \overline{W}R_j^n = \overline{W}C_j^n \Rightarrow d_j^n = \frac{\overline{W}C_j^n}{2}.$$

If $d_j^n = \frac{\overline{W}C_j^n}{2}$, it follows that $q_j(x;\overline{w}^n)$ coincides with a quadratic polynomial, which is monotonically increasing in I_j, as we have seen in Observation 1. Therefore, we can suppose that $0 < \overline{W}R_j^n < \overline{W}C_j^n$. Hence

$$\left(\overline{W}C_j^n - 4 \cdot \overline{W}R_j^n\right) < \overline{W}C_j^n, \;\; \overline{W}C_j^n - \left(4 \cdot \overline{W}R_j^n - 3 \cdot \overline{W}C_j^n\right) = 4 \cdot \left(\overline{W}C_j^n - \overline{W}R_j^n\right) > 0$$

so that it follows that $(2 \cdot d_j^n < \overline{W}C_j^n)$. On the other hand, applying Observations 2 and 3,

$$\left.\begin{array}{l} d_j^n \geq ds_j^n \\ \overline{W}R_j^n > \frac{1}{2}\overline{W}C_j^n \end{array}\right\} \Rightarrow x_{MI} = x_j + \tfrac{\Delta x}{3}\left(\tfrac{2 \cdot \overline{W}R_j^n - \overline{W}C_j^n}{2 \cdot d_j^n - \overline{W}C_j^n}\right) \leq x_j + \tfrac{\Delta x}{3}\left(\tfrac{2 \cdot \overline{W}R_j^n - \overline{W}C_j^n}{2 \cdot ds_j^n - \overline{W}C_j^n}\right)$$
$$\leq x_j - \tfrac{\Delta x}{2},$$
$$\left.\begin{array}{l} d_j^n \geq ds_j^n \\ \overline{W}R_j^n < \frac{1}{2}\overline{W}C_j^n \end{array}\right\} \Rightarrow x_{MI} = x_j - \tfrac{\Delta x}{3}\left(\tfrac{\overline{W}C_j^n - 2 \cdot \overline{W}R_j^n}{2 \cdot d_j^n - \overline{W}C_j^n}\right) \geq x_j - \tfrac{\Delta x}{3}\left(\tfrac{\overline{W}C_j^n - 2 \cdot \overline{W}R_j^n}{2 \cdot ds_j^n - \overline{W}C_j^n}\right)$$
$$\geq x_j + \tfrac{\Delta x}{2}.$$

In this way, because of $d_j^n \geq ds_j^n$ we deduce the following:

$$x_{MI} \notin \left]x_j - \frac{\Delta x}{2}, x_j + \frac{\Delta x}{2}\right[.$$

Thus, the minimum, $\text{Min}\{\frac{d(q_j(x;\overline{w}^n))}{dx}\, \forall x \in I_j\}$, is achieved at one of the boundary points $x = x_j \pm \frac{\Delta x}{2}$. By derivating in formula (3.5), we get that

$$\frac{dq_j(x_j + \Delta x/2; \overline{w}^n)}{dx} \geq 0 \Longleftrightarrow d_j^n \geq \frac{1}{2}\left(\overline{W}C_j^n - 4 \cdot \overline{W}R_j^n\right),$$
$$\frac{dq_j(x_j - \Delta x/2; \overline{w}^n)}{dx} \geq 0 \Longleftrightarrow d_j^n \geq \frac{1}{2}\left(4 \cdot \overline{W}R_j^n - 3 \cdot \overline{W}C_j^n\right).$$

The definition of d_j^n allows us to state that $\text{Min}\{\frac{d(q_j(x;\overline{w}^n))}{dx}\, \forall x \in I_j\} \geq 0$, and thus we conclude that $q_j(x;\overline{w}^n)$ is monotonically increasing in I_j.

Case (A3.2.2). $S_j^n = 1$, $\left(2 \cdot \overline{W}C_j^n < \overline{W}C2_j^n\right)$, $\overline{w}_j^n \neq \frac{\overline{w}_{j+1}^n + \overline{w}_{j-1}^n}{2}$, and $\left|\,\overline{W}R_j^n - \frac{1}{2}\overline{W}C_j^n\,\right| < \frac{1}{8}\left|\,\overline{W}C2_j^n - 2 \cdot \overline{W}C_j^n\,\right|$. In this case,

$$d_j^n = \begin{cases} \frac{\overline{W}C_j^n}{2} - \frac{\sqrt{15}}{15}\left|\,2 \cdot \overline{W}R_j^n - \overline{W}C_j^n\,\right| & \text{if } \left|\frac{\overline{W}R_j^n}{\overline{W}C_j^n} - \frac{1}{2}\right| \leq \frac{15-\sqrt{15}}{28}, \\ \frac{\overline{W}C_j^n}{2} & \text{if } \left|\frac{\overline{W}R_j^n}{\overline{W}C_j^n} - \frac{1}{2}\right| > \frac{15-\sqrt{15}}{28} \end{cases}$$

so that it follows that $2\cdot d^n_j \leq \overline{W}C^n_j$. In the case in which $2\cdot d^n_j = \overline{W}C^n_j$ it follows that $q_j(x;\overline{w}^n)$ coincides with a two-degree polynomial, which is monotonically increasing in I_j, as we have seen in Observation 1. Therefore, we can suppose that $2\cdot d^n_j < \overline{W}C^n_j$ and $|\frac{\overline{W}R^n_j}{\overline{W}C^n_j} - \frac{1}{2}| \leq \frac{15-\sqrt{15}}{28}$. In this situation, $\frac{dq_j(x;\overline{w}^n)}{dx}$ reaches a minimum at point $x_{MI} = x_j + \frac{\Delta x}{3}(\frac{2\cdot\overline{W}R^n_j - \overline{W}C^n_j}{2\cdot d^n_j - \overline{W}C^n_j})$ (see Observation 3). Given that

$$\overline{W}R^n_j > \frac{1}{2}\overline{W}C^n_j \Rightarrow \left\{\left(\frac{5}{6}\,\overline{W}C^n_j - \frac{2}{3}\overline{W}R^n_j\right) < \frac{\overline{W}C^n_j}{2} - \frac{\sqrt{15}}{15}\left(2\cdot\overline{W}R^n_j - \overline{W}C^n_j\right) = d^n_j\right\},$$

$$\overline{W}R^n_j < \frac{1}{2}\overline{W}C^n_j \Rightarrow \left\{\left(\frac{1}{6}\,\overline{W}C^n_j + \frac{2}{3}\overline{W}R^n_j\right) < \frac{\overline{W}C^n_j}{2} - \frac{\sqrt{15}}{15}\left(\overline{W}C^n_j - 2\cdot\overline{W}R^n_j\right) = d^n_j\right\},$$

then

$$\overline{W}R^n_j > \tfrac{1}{2}\overline{W}C^n_j \Rightarrow \left\{x_{MI} = x_j + \tfrac{\Delta x}{3}\left(\tfrac{2\cdot\overline{W}R^n_j - \overline{W}C^n_j}{2\cdot d^n_j - \overline{W}C^n_j}\right) < x_j - \tfrac{\Delta x}{2}\right\},$$

$$\overline{W}R^n_j < \tfrac{1}{2}\overline{W}C^n_j \Rightarrow \left\{x_{MI} = x_j + \tfrac{\Delta x}{3}\left(\tfrac{2\cdot\overline{W}R^n_j - \overline{W}C^n_j}{2\cdot d^n_j - \overline{W}C^n_j}\right) > x_j + \tfrac{\Delta x}{2}\right\}.$$

On the other hand,

$$\overline{W}R^n_j > \tfrac{1}{2}\overline{W}C^n_j \Rightarrow \left\{\tfrac{dq_j(x_j \pm \Delta x/2;\overline{w}^n)}{dx} \geq 0 \Longleftrightarrow d^n_j \geq \tfrac{1}{2}\left(4\cdot\overline{W}R^n_j - 3\cdot\overline{W}C^n_j\right)\right\},$$

$$\overline{W}R^n_j < \tfrac{1}{2}\overline{W}C^n_j \Rightarrow \left\{\tfrac{dq_j(x_j \pm \Delta x/2;\overline{w}^n)}{dx} \geq 0 \Longleftrightarrow d^n_j \geq \tfrac{1}{2}\left(\overline{W}C^n_j - 4\cdot\overline{W}R^n_j\right)\right\}.$$

Given that we have supposed that $|\frac{\overline{W}R^n_j}{\overline{W}C^n_j} - \frac{1}{2}| \leq \frac{15-\sqrt{15}}{28}$, then d^n_j verifies the latter inequalities, and thus $q_j(x;\overline{w}^n)$ is monotonically increasing in I_j. □

3.3. Conditions in cells with extrema points. In order to guarantee that $q_j(x;\overline{w}^n)$ has the same shape as the cell-averages $\overline{w}^n_j$ in the domain I_j, we add these requirements to those used in the previous section:

1. $q_j(x;\overline{w}^n)$ has a maximum in I_j if and only if $\overline{w}^n_{j-1} < \overline{w}^n_j > \overline{w}^n_{j+1}$.
2. $q_j(x;\overline{w}^n)$ has a minimum in I_j if and only if $\overline{w}^n_{j-1} > \overline{w}^n_j < \overline{w}^n_{j+1}$.

On the other hand, the definition of θ^n_j that we will use later in (3.13) requires that the following properties are satisfied:

1. If $\overline{w}^n_{j-1} < \overline{w}^n_j > \overline{w}^n_{j+1}$, then $q_j\left(x_j - \frac{\Delta x}{2};\overline{w}^n\right) \geq \frac{1}{2}\left(\overline{w}^n_{j-1} + \overline{w}^n_j\right)$ and $q_j(x_j + \frac{\Delta x}{2};\overline{w}^n) \geq \frac{1}{2}\left(\overline{w}^n_j + \overline{w}^n_{j+1}\right)$.
2. If $\overline{w}^n_{j-1} > \overline{w}^n_j < \overline{w}^n_{j+1}$, then $q_j\left(x_j - \frac{\Delta x}{2};\overline{w}^n\right) \leq \frac{1}{2}\left(\overline{w}^n_{j-1} + \overline{w}^n_j\right)$ and $q_j(x_j + \frac{\Delta x}{2};\overline{w}^n) \leq \frac{1}{2}\left(\overline{w}^n_j + \overline{w}^n_{j+1}\right)$.

According to the notation given in (3.8) and (3.10), supposing that

$$ds4^n_j = \frac{1}{6}\left(5\cdot\overline{W}C^n_j - 4\cdot\overline{W}R^n_j\right),\ ds5^n_j = \frac{1}{6}\left(4\cdot\overline{W}R^n_j + \overline{W}C^n_j\right), \tag{3.11}$$

we define d^n_j in cells with extrema points in the following way:

(B) If $\overline{w}^n_{j-1} < \overline{w}^n_j > \overline{w}^n_{j+1}$ (the cell averages have a maximum), then the following hold:

(B1) If $\overline{W}C2^n_j = 2\cdot\overline{W}C^n_j$, then $d^n_j = ds^n_j \equiv \frac{2}{3}\overline{W}C^n_j - \frac{1}{12}\overline{W}C2^n_j = \frac{1}{2}\overline{W}C^n_j$.

(B2) If $\overline{W}C2_j^n < 2 \cdot \overline{W}C_j^n$, then $d_j^n = \mathrm{Min}\left\{ds2_j^n,\ ds4_j^n,\ ds_j^n\right\}$.

(B3) If $\overline{W}C2_j^n > 2 \cdot \overline{W}C_j^n$, then $d_j^n = \mathrm{Max}\left\{ds3_j^n,\ ds5_j^n,\ ds_j^n\right\}$.

(C) If $\overline{w}_{j-1}^n > \overline{w}_j^n < \overline{w}_{j+1}^n$ (the cell averages have a minimum), then the following hold:

(C1) If $\overline{W}C2_j^n = 2 \cdot \overline{W}C_j^n$, then $d_j^n = ds_j^n = \frac{2}{3}\overline{W}C_j^n - \frac{1}{12}\overline{W}C2_j^n = \frac{1}{2}\overline{W}C_j^n$.

(C2) If $\overline{W}C2_j^n < 2 \cdot \overline{W}C_j^n$, then $d_j^n = \mathrm{Min}\left\{ds3_j^n,\ ds5_j^n,\ ds_j^n\right\}$.

(C3) If $\overline{W}C2_j^n > 2 \cdot \overline{W}C_j^n$, then $d_j^n = \mathrm{Max}\left\{ds2_j^n,\ ds4_j^n,\ ds_j^n\right\}$.

Observation 4. Similar reasoning to that used in the proof of Theorem 3.1 allows us to prove that with this definition of d_j^n, if $\overline{w}_{j-1}^n < \overline{w}_j^n > \overline{w}_{j+1}^n$, then $q_j(x;\overline{w}^n)$ has a maximum at $\left[x_j - \frac{\Delta x}{2}, x_j + \frac{\Delta x}{2}\right]$, verifying these two relations:

$$q_j\left(x_j - \frac{\Delta x}{2};\overline{w}^n\right) \geq \frac{1}{2}\left(\overline{w}_{j-1}^n + \overline{w}_j^n\right), \quad q_j\left(x_j + \frac{\Delta x}{2};\overline{w}^n\right) \geq \frac{1}{2}\left(\overline{w}_j^n + \overline{w}_{j+1}^n\right).$$

Similarly, if we suppose that $\overline{w}_{j-1}^n > \overline{w}_j^n < \overline{w}_{j+1}^n$, then we can verify that $q_j(x;\overline{w}^n)$ has a minimum at $\left[x_j - \frac{\Delta x}{2}, x_j + \frac{\Delta x}{2}\right]$, verifying the following conditions:

$$q_j\left(x_j - \frac{\Delta x}{2};\overline{w}^n\right) \leq \frac{1}{2}\left(\overline{w}_{j-1}^n + \overline{w}_j^n\right), \quad q_j\left(x_j + \frac{\Delta x}{2};\overline{w}^n\right) \leq \frac{1}{2}\left(\overline{w}_j^n + \overline{w}_{j+1}^n\right).$$

3.4. Removing the spurious extrema of $w(x, t^n)$ at points $x_j + \Delta x/2$.

To obtain a nonoscillatory reconstruction we will add some additional requirements for the calculation of $R_j(x, \overline{w}^n)$:

$$\begin{aligned}
&\text{(a)}\, \overline{w}(x_j, t^n) > \overline{w}(x_{j+1}, t^n) \Rightarrow \left(R_j(x_j + \Delta x/2;\overline{w}^n) \geq R_{j+1}(x_j + \Delta x/2;\overline{w}^n)\right),\\
&\text{(b)}\, \overline{w}(x_j, t^n) < \overline{w}(x_{j+1}, t^n) \Rightarrow \left(R_j(x_j + \Delta x/2;\overline{w}^n) \leq R_{j+1}(x_j + \Delta x/2;\overline{w}^n)\right),\\
&\text{(c)}\, \overline{w}(x_j, t^n) = \overline{w}(x_{j+1}, t^n) \Rightarrow \left(R_j(x_j + \Delta x/2;\overline{w}^n) = R_{j+1}(x_j + \Delta x/2;\overline{w}^n)\right).
\end{aligned} \tag{3.12}$$

These properties together to those viewed in sections 3.2 and 3.3 have been defined so that the resulting reconstruction polynomial $w(x, t^n)$, defined in (2.3), presents a nonoscillatory nature in the sense that the number of extrema of $w(x, t^n)$ does not exceed the number shown in the function $\sum_{j=1}^{NX} \overline{w}_j^n \chi_j(x)$. The nonincreasing number of extrema implies convergence along the lines of Liu and Tadmor [20].

To verify (3.12), Liu and Osher [19] consider the modification of the form

$$R_j(x;\overline{w}^n) \equiv \theta_j^n q_j(x;\overline{w}^n) + (1 - \theta_j^n)\overline{w}_j^n, \tag{3.13}$$

where $\theta_j^n \in [0, 1]$. The algorithm that allows us to obtain θ_j^n is described in detail in Liu and Osher [19], although in that reference it is only used when $q_j(x;\overline{w}^n)$ is a conservative parabola. Notice that the value of θ_j^n that appears in formula (3.13) takes a value equal to 1 in all the cells with extrema points (see Liu and Osher [19]). Conditions given in section 3.3 avoid the development of spurious extrema of $R_j(x;\overline{w}^n)$ in the endpoints of an interval with a local maximum or a local minimum.

Remark 1. Parameter θ_j^n used in (3.13) is defined in Liu and Osher [19] so that $(1 - \theta_j^n)$ is proportional to the interface jump $q_{j+1}\left(x_j + \frac{\Delta x}{2};\overline{w}^n\right) - q_j\left(x_j + \frac{\Delta x}{2};\overline{w}^n\right)$. If $d_j^n = ds_j^n$ (given by (3.6)), then the reconstruction is fourth-order accurate. As a consequence of the fourth-order accuracy in polynomials $q_j(x;\overline{w}^n)$ and $q_{j+1}(x;\overline{w}^n)$, the size of the interface jump, and consequently of $(1 - \theta_j^n)$, is of order $O((\Delta x)^4)$. In this way, the definition of $R_j(x;\overline{w}^n)$ given in (3.13) still verifies the properties in (2.4).

However, the definition of d_j^n introduced in cases (A3.1), (A3.2.1), (A3.2.2), (B2), (B3), (C2), and (C3) may cause the value of $(1-\theta_j^n)$ to not be of order $O((\Delta x)^4)$ in a small number of cells, especially near a local maximum, a local minimum, or a discontinuity. For example, if $\overline{W}R_j^n \approx \overline{W}C_j^n$ or $\overline{W}R_j^n \approx 0$ and $S_j^n > 0$, then d_j^n can be closer to $\overline{W}C_j^n/2$ (which is the slope of the parabola) than to ds_j^n. Moreover, in case (A3.2.2) d_j^n can be equal to $\overline{W}C_j^n/2$. In order to achieve the experimental fourth-order of accuracy in some experiments with smooth solutions we will give a special treatment of the cells that are near extrema (see conditions (4.2)). In fact, one should require that $d_j^n/ds_j^n = 1 + O((\Delta x)^3)$ on smooth solutions.

Remark 2. $R_j(x;\overline{w}^n)$ defined in (3.13), with $q_j(x:\overline{w}^n)$ described in subsections 3.1, 3.2, and 3.3, has the same shape as the cell-averages $\{\overline{w}_{j-1}^n, \overline{w}_j^n, \overline{w}_{j+1}^n\}$.

3.5. Definition of slopes d_j^n in (3.2) so that $p_j(x;f^n)$ fulfills conditions given in sections 3.2 and 3.3. A few modifications are needed to compute the nonoscillatory reconstruction from pointvalues for the flux $f_j^n = f(w_j^n)$ which is needed in the Runge–Kutta method with natural continuous extension described in Levy, Puppo, and Russo [16]. According to (3.2) the degree-three polynomial from the pointvalues $f_k^n,\ k \in \{j-2, j-1, j, j+1, j+2\}$, is given by

$$\begin{aligned} p_j\left(x;f^n\right) = f_j^n + d_j^n \cdot \left(\frac{x-x_j}{\Delta x}\right) + \left(\frac{f_{j-1}^n - 2f_j^n + f_{j+1}^n}{2}\right) \cdot \left(\frac{x-x_j}{\Delta x}\right)^2 \\ + \left(\frac{-f_{j-1}^n + f_{j+1}^n - 2d_j^n}{2}\right) \cdot \left(\frac{x-x_j}{\Delta x}\right)^3 . \end{aligned} \tag{3.14}$$

To ensure that $p_j(x;f^n)$ fulfills the requirements of sections 3.2 and 3.3, we define d_j^n in the same way as in those sections with the exceptions that

$$ds1_j^n = 0,\ ds2_j^n = \frac{1}{2}\left(WC_j^n - 8 \cdot WR_j^n\right),\ ds3_j^n = \frac{1}{2}\left(8 \cdot WR_j^n - 7 \cdot WC_j^n\right), \tag{3.15}$$

$$C1 = \frac{\sqrt{3}}{6},\ C2 = \frac{6}{12+\sqrt{3}},\ WC_j^n = f_{j+1}^n - f_{j-1}^n,\ WR_j^n = f_{j+1}^n - f_j^n, \tag{3.16}$$

and cell-averages $\overline{w}_j^n$ are substituted by pointvalues f_j^n. The evaluation of $\partial f/\partial x$ in the Runge–Kutta step is performed by $\theta_j^n \frac{dp_j(x;f^n)}{dx}$, where θ_j^n is defined as in Liu and Osher [19]. Thus, we maintain high accuracy and control over oscillations.

4. Numerical experiments. In order to verify the behavior and accuracy of the numerical schemes that are presented in this paper, several test-type problems with known analytical solution are solved next. Time integrals are performed by a Taylor expansion (Taylor-upwind and Taylor-central schemes) or by the fourth-order Runge–Kutta method with natural continuous extensions developed in Levy, Puppo, and Russo [16] (RK-NCE-central scheme). In this last case the reconstruction defined in section 3.5 will also be used.

Problem 1. We solve the linear transport equation

$$\frac{\partial u(x,t)}{\partial t} + \frac{\partial u(x,t)}{\partial x} = 0,\ \ -1 \le x \le 1, \tag{4.1}$$

subject to 2-periodic initial data, $u(x,0) = u_0(x)$. To verify the accuracy of the numerical schemes, different $u_0(x)$ functions have been used.

Table 4.1

40	$1.531422\ 10^{-4}$	4.18	$1.689413\ 10^{-4}$	4.35
80	$8.423959\ 10^{-6}$	4.06	$8.305782\ 10^{-6}$	4.02
160	$5.053152\ 10^{-7}$	4.06	$5.130312\ 10^{-7}$	3.97
320	$3.034160\ 10^{-8}$		$3.280898\ 10^{-8}$	

The first function is $u_0(x) = \sin(\pi\, x)$. Table 4.1 shows the errors and the experimental order of accuracy in L^1 and L^∞ norms at time $T = 10$. NX indicates the total number of cells so that the step size $\Delta x = 2/NX$. Using a Taylor expansion for the time evolution, we have selected a time step so that $\Delta t = 0.8\Delta x$ in the upwind scheme, whereas in the central scheme $\Delta t = 0.4\Delta x$. When we use a RK-NCE-central scheme, $\Delta t = 0.25\Delta x$ as in Levy, Puppo, and Russo [16]. Table 4.1 shows that numerical schemes described in this paper are about fourth-order accuracy in L^1 and L^∞ norms, which is an improvement over the schemes described in Liu and Osher [19] and Liu and Tadmor [20], which are third-order schemes.

The second initial condition chosen is $u_0(x) = \sin^4(\pi\, x)$. Table 4.2 shows the errors in L^1 and L^∞ norms at time $T = 10$. The schemes presented here maintain the fourth-order accuracy, even with finer grids, without the need of satisfying the local maximum principle described in Liu and Osher [19]. The nonconsideration of that local maximum principle implies that the θ_j that appear in formula (3.13) take a value equal to 1 in all the cells with extrema points (see Liu and Osher [19]). To improve the accuracy of the numerical schemes presented in this paper, in the results shown in Table 4.2 we have added two additional requirements (see Remark 1):

$$\begin{aligned} &\text{If } \overline{w}^n_{j-1} < \overline{w}^n_j > \overline{w}^n_{j+1} \Rightarrow d^n_{j-1} = ds^n_{j-1},\ d^n_{j+1} = ds^n_{j+1}.\\ &\text{If } \overline{w}^n_{j-1} > \overline{w}^n_j < \overline{w}^n_{j+1} \Rightarrow d^n_{j-1} = ds^n_{j-1},\ d^n_{j+1} = ds^n_{j+1}. \end{aligned} \tag{4.2}$$

Thus, we avoid the slope d^n_j taking a value close to $\overline{W}C^n_j/2$ in the neighboring cells to those containing the extrema points of the solution. Remember that with such a slope, $q_j(x; \overline{w}^n)$ coincides with a conservative quadratic polynomial. As mentioned in Remark 1, parameter θ^n_j is defined in such a way that $(1 - \theta^n_j)$ is proportional to the interface jump of the cell centered in x_j. Conditions (4.2) cause the interface jump to be lower at the boundary of cells with extrema points.

The third initial condition is a discontinuous 2-periodic function that was used in Balsara and Shu [2]. This is a severe problem since it consists of a combination of functions that are not smooth, with other ones, which are smooth, but with a high

TABLE 4.2

640	2.237979 10^{-7}		2.539025 10^{-7}	

gradient in zones close to the peaks. The initial condition is given by

$$u_0(x) = \begin{cases} \frac{1}{6}\left(G(x,\beta,z-\delta) + G(x,\beta,z+\delta) + 4G(x,\beta,z)\right), & -0.8 \le x \le -0.6, \\ 1, & -0.4 \le x \le -0.2, \\ 1 - |10\,(x-0.1)|, & 0 \le x \le 0.2, \\ \frac{1}{6}\left(F(x,\alpha,a-\delta) + F(x,\alpha,a+\delta) + 4F(x,\alpha,a)\right), & 0.4 \le x \le 0.6, \\ 0 & \text{otherwise} \end{cases} \tag{4.3}$$

defined as

$$G(x,\beta,z) = e^{-\beta(x-z)^2}, \quad F(x,\alpha,a) = \sqrt{\operatorname{Max}\left(1-\alpha^2(x-a)^2, 0\right)}. \tag{4.4}$$

The constants that appear in (4.3) and (4.4) are given by

$$a = 0.5; \;\; z = -0.7; \;\; \delta = 0.005; \;\; \alpha = 10; \;\; \beta = \frac{\log(2)}{36\delta^2}. \tag{4.5}$$

Figure 4.1 shows the numerical results obtained at time $T = 20$, with the Taylor-central scheme developed in this paper, comparing the numerical solution with the analytical solution which is represented by a continuous line. Unlike the solutions presented in Balsara and Shu [2], here we have considered a coarser grid with $NX = 500$. This shows the greater accuracy of our scheme, in comparison with the conservative quadratic polynomial developed in Liu and Osher [19], in particular at the peaks of the Gaussian curve and in the triangle. In addition, the profiles are more symmetrical than those computed in Levy, Puppo, and Russo [16], and the values of the numerical solution are bounded by the maximum and minimum of the initial condition despite not using the maximum principle property given in Liu and Osher [19]. This is a condition that is not fulfilled when $q_j(x;\overline{w}^n)$ is replaced by the two-degree polynomial used in this reference. Previous remarks for the Taylor-central scheme are also valid for the Taylor-upwind and RK-NCE-central schemes.

The last initial condition is given by

$$u_0(x+0.5) = \begin{cases} -x\sin\left(\frac{3}{2}\pi\,x^2\right) & \text{if } -1 < x < -\frac{1}{3}, \\ |\sin(2\pi\,x)| & \text{if } |x| \le \frac{1}{3}, \\ 2x - 1 - \sin(3\pi\,x)/6, & \text{if } \frac{1}{3} < x \le 1, \end{cases} \tag{4.6}$$

supposing that it extends to the entire 2-period domain.

Condition (4.6) consists of a function highly discontinuous, used in the numerical experiments developed in Harten [9]. Figure 4.2 shows the results obtained at $T = 2$, with $NX = 120$, comparing the results obtained with our Taylor-central scheme and those in which $q_j(x; \overline{w}^n)$ is the conservative two-degree polynomial used in Liu and Osher [19] and Liu and Tadmor [20]. It can be observed that the greater accuracy of our schemes is especially noted around the discontinuities. On the other hand, the

numerical solution is delimited by the maximum and minimum of the initial condition without the need of satisfying the local maximum principle of Liu and Osher [19].

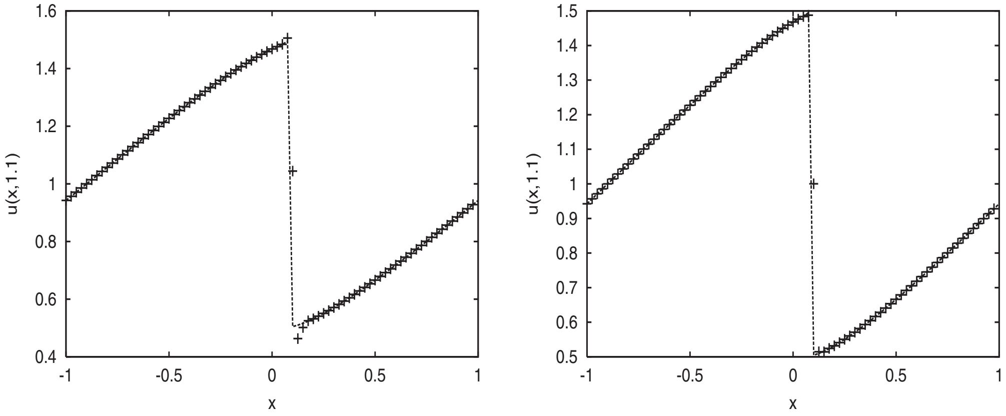
Problem 2. Burgers' equation is solved with 2-periodic initial data:

$$\frac{\partial u(x,t)}{\partial t} + \frac{\partial\left(\frac{1}{2}u^2(x,t)\right)}{\partial x} = 0, \quad -1 \le x \le 1, \quad u\left(x,0\right) = 1 + \frac{1}{2}\sin(\pi x). \tag{4.7}$$

Recall that the analytical solution of this problem is smooth up to the critical time $T = 2/\pi$. Liu and Osher [19] and Liu and Tadmor [20] show the results obtained using a parabolic reconstruction at $T = 0.3$. Table 4.3 presents the numerical errors obtained with our schemes, together with the experimental order of accuracy at $T = 0.3$. Our schemes (upwind and central) have an order of accuracy which is about 4 in both L^1 and L^∞ norms. However, the maximum order obtained with the schemes described by Liu and Osher [19] (Taylor-upwind scheme, $\Delta t = 0.6\Delta x$) and Liu and Tadmor [20] (Taylor-central scheme, $\Delta t = 0.33\Delta x$) is lower than 2.3 in the L^∞ norm and lower than 2.87 in the L^1 norm. In the RK-NCE-central scheme we have chosen $\Delta t = 0.18\Delta x$ as in Levy, Puppo, and Russo [16].

At $T = 1.1$ the analytical solution of problem (4.7) develops a discontinuity. Our numerical scheme maintains an order of accuracy of about 4 when the errors are calculated at a distance equal to 0.1 away from the discontinuity. Figure 4.3(a) shows the result obtained with our Taylor-central scheme. Like in the scheme developed in Liu and Tadmor [20], the numerical solution is not bounded by the maximum and minimum of the analytical solution. In order to obtain this property it is necessary to add the maximum principle requirement described in Liu and Osher [19], as we can see in Figure 4.3(b). However, without the condition of maximum principle, the numerical solution retains results of the same quality as the analytical solution. Previous remarks are also valid for the Taylor-upwind and RK-NCE-central schemes.

Problem 3. Here we apply the schemes developed in this paper to Buckley–



(a) (b)

FIG. 4.3. *Numerical and analytical solutions of Problem* 2 *at* $T = 1.1$*, with our Taylor-central scheme, considering a grid with* $NX = 80$ *and* $\Delta t = 0.33\Delta x$*.* (a) *Not using the local maximum principle.* (b) *Using the local maximum principle.*

Leverett's problem, whose flux is nonconvex:

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = 0, \quad -1 \leq x \leq 1, \quad f(u) = \frac{4u^2}{4u^2 + (1-u)^2} \tag{4.8}$$

subject to the initial condition

$$u_0(x) = \begin{cases} 1 & x \in [-0.5, 0], \\ 0 & \text{otherwise.} \end{cases} \tag{4.9}$$

Similarly to Liu and Osher [19] and Jiang et al. [11], we have computed the solution at $T = 0.4$ with our Taylor-upwind and central schemes. Figure 4.4 shows the results obtained with $NX = 80$. In contrast to the scheme described in Liu and Osher [19], our Taylor-upwind scheme presents instabilities in the solution of the problem (4.8)–(4.9) for $\Delta t = 0.3\Delta x$. However, it presents very accurate solutions when $\Delta t = 0.25\Delta x$. Moreover, the condition of the local maximum principle described in Liu and Osher [19] has not been necessary, as shown in Figure 4.4(a). The central schemes described in this paper provide smoother solutions than the upwind scheme for the resolution of the problem under study (Figures 4.4(a)–4.4(b)), although the three schemes present a similar behavior.

Euler equations of gas dynamics. We test our schemes on the system of Euler equations of gas dynamics for a gas with $\gamma = 1.4$. We consider a problem with smooth analytical solution and the two Riemann problems studied in Liu and Tadmor [20]. The variables ρ, m, E denote the density, momentum, and total energy per unit volume, respectively. Moreover, p denotes the pressure and v denotes the velocity.

Problem 4. The initial condition is set to be $\rho(x,0) = 1 + 0.2\sin(\pi x)$, $v(x,0) = 1$, $p(x,0) = 1$, with 2-periodic boundary conditions, $-1 \leq x \leq 1$. The exact solution is $\rho(x,t) = 1 + 0.2\sin(\pi(x-t))$, $v = 1$, $p = 1$. We compute the solution at $T = 2$ as in Qiu and Shu [22], using our RK-NCE-central scheme with the componentwise reconstruction described in this paper. Table 4.4 shows the results obtained considering $\Delta t = 0.1\Delta x$. We can see that our scheme achieves its designed order of accuracy.

640	$7.181752\ 10^{-11}$		$5.656586\ 10^{-11}$	

Problem 5. Shock tube problem with Sod's initial data [24]:

$$\begin{cases} (\rho_l, m_l, E_l) = (1, 0, 2.5), & x < 0.5, \\ (\rho_r, m_r, E_r) = (0.125, 0, 0.25), & x > 0.5. \end{cases}$$

Problem 6. Shock tube problem with the Lax's initial data [14]:

$$\begin{cases} (\rho_l, m_l, E_l) = (0.445, 0.311, 8.928), & x < 0.5, \\ (\rho_r, m_r, E_r) = (0.5, 0, 1.4275), & x > 0.5. \end{cases}$$

In Problems 5 and 6 the computational domain is $[0, 1]$. We integrate the equations to $T = 0.16$, i.e., before the perturbations reach the boundary of the computational region (free flow boundary conditions). We compute the numerical solution with our RK-NCE-central scheme, using the componentwise reconstruction described in this paper. In Figure 4.5 we plot the computed solution with $NX = 200$ grid points as in Liu and Tadmor [20]. We observe the improved resolution in comparison to the corresponding third-order central results of that reference. However, our solutions present more oscillations, which is in agreement with what is commented on in [22]. Qiu and Shu [22] conclude that the componentwise central WENO scheme will become more oscillatory when the order of accuracy increases. Qiu and Shu [22] also observe that the oscillations disappear when the reconstruction is performed on characteristic variables. It is conceivable to expect that the same thing will happen with the new reconstruction proposed in this paper. This will be explored in some future work.

We have considered that* $\Delta t = 0.1\Delta x$ *in the Sod problem and* $\Delta t = 0.09\Delta x$ *in the Lax problem.*

5. Conclusions. This paper presents a new fourth-order nonoscillatory reconstruction procedure for upwind and central schemes that solves hyperbolic conservation laws in one spatial dimension, improving the accuracy of the schemes developed in Liu and Osher [19] and Liu and Tadmor [20]. We have proved that our schemes are *number of extrema decreasing* and this implies convergence along the lines of Liu and Tadmor [20]. Numerical experiments have shown that our schemes are fourth-order accurate, conservative, and nonoscillatory, presenting good behavior without the need of satisfying the local maximum principle described in Liu and Osher [19]. Future research will extend these schemes to several spatial variables. We also may study the linear stability of these schemes by a procedure similar to that developed in Bianco, Puppo, and Russo [3].

Acknowledgments. We express our gratitude to the four anonymous reviewers for their helpful comments. We thank Dr. Arturo Hidalgo López for his suggestions. We would like to thank the Foreign Language Coordination Office at the Polytechnic University of Valencia for their help in translating this paper.

CONVERGENCE OF A NUMERICAL SCHEME FOR STRATIGRAPHIC MODELING*

R. EYMARD†, T. GALLOUËT‡, V. GERVAIS§, AND R. MASSON§

Abstract. In this paper, we consider a multilithology diffusion model used in the field of stratigraphic basin simulations to simulate large scale depositional transport processes of sediments described as a mixture of L lithologies. This model is a simplified one for which the surficial fluxes are proportional to the slope of the topography and to a lithology fraction with unitary diffusion coefficients.

The main variables of the system are the sediment thickness h, the L surface concentrations c_i^s in lithology i of the sediments at the top of the basin, and the L concentrations c_i in lithology i of the sediments inside the basin. For this simplified model, the sediment thickness decouples from the other unknowns and satisfies a linear parabolic equation. The remaining equations account for the mass conservation of the lithologies, and couple, for each lithology, a first order linear equation for c_i^s with a linear advection equation for c_i for which c_i^s appears as an input boundary condition. For this coupled system, a weak formulation is introduced.

The system is discretized by an implicit time integration and a cell centered finite volume method. This numerical scheme is shown to satisfy stability estimates and to converge, up to a subsequence, to a weak solution of the problem.

Key words. finite volume method, stratigraphic modeling, linear first order equations, convergence analysis, weak formulation

1. Introduction.

Recent progress in geosciences, and more especially in seismic- and sequence-stratigraphy, have improved the understanding of sedimentary basins infill. Indeed, the sediment's architecture is the response to complex interactions between the available space created in the basin by sea level variations, tectonic, compaction, the sediment supply (boundary fluxes, sediment production), and the transport of the sediments at the surface of the basin. In order to have a quantified view of this response and to determine the relative influence of each involved process, stratigraphic models have been developed.

Among basin infill models considering the dynamics of sediment transport, authors usually distinguish between fluid-flow and dynamic-slope models (see [14], [15]). The first ones use fluid-flow equations and empirical algorithms to simulate the transport of sediments in the hydrodynamic flow field (see, e.g., [16]). They provide an accurate description of depositional processes for small scales in time and space, but, at larger scale's such as basin scales, they are computationally too expensive.

Dynamic-slope models use mass conservation equations of sediments combined with diffusive transport laws. These laws do not describe each geological process in detail but average over these processes (river transport, creep, slumps, and small

slides). One can refer to [1], [7], [8], [10], [14], and [17] for a detailed description of these models. The dynamic-slope models have been shown to offer a good description of sedimentation and erosion processes for large time scales (greater than 10^4 y) and basin space scales (greater than 1 km).

We consider here a dynamic-slope model simulating the evolution of a sedimentary basin in which sediments are modeled as a mixture of several lithologies $i = 1, \dots, L$ characterized by different grain size populations. The surficial transport process is a multilithology diffusive model introduced in [14], for which the fluxes are proportional to the slope of the topography and to a lithology fraction c_i^s of the sediments at the surface of the basin (see also [9] and [5]). In what follows, a simplified model is considered for which the diffusion coefficients are taken equal to one. It results that the sediment thickness variable h is decoupled from the other unknowns of the system (i.e., for each lithology, the surface concentration c_i^s and the concentration c_i in lithology i of the sediments in the basin) and satisfies a linear parabolic equation.

The remaining equations accounting for the mass conservation of the lithologies couple, for all $i = 1, \dots, L$, a first order linear equation for the surface concentration variable c_i^s and a linear advection equation for the basin concentration variable c_i for which c_i^s appears as an input boundary condition at the top of the basin. In order to cope with the difficulty of defining the trace of the basin concentration c_i at the top of the basin, an original weak formulation is introduced for this coupled problem.

The system is discretized by an implicit integration in time and a cell centered finite volume scheme in space. The objective of this article is to prove, under Hypothesis 1, the convergence of the approximate solutions for the sediment thickness variable h and for the concentration variables c_i^s, c_i, $i = 1, \dots, L$, up to a subsequence, to a weak solution of problem (2.7) in the sense of Definition 2.1 as the mesh size and time step tend to 0. We state this result in Theorem 3.3 in section 3, after presenting the mathematical model, the weak formulation, and the finite volume scheme.

Regarding the coupling between the parabolic equation for h and the first order linear equations for the variables c_i^s, $i = 1, \dots, L$, our model shares some common features with two phase Darcy flows for which such coupling between an elliptic or parabolic equation and a hyperbolic equation also comes in. The convergence of various numerical schemes for such models have been the subject of several studies. For example, one can refer to [12] for finite differences, to [2] and [3] for mixed and hybrid finite element methods, to [4] for the control volume finite element discretization, and to [19], [18], and [6] for the cell centered finite volume scheme.

The main originality of this work is rather concerned with the coupling between the surface and the basin concentration variables.

The remaining of the paper outlines as follows. The mathematical model and its weak formulation are defined in section 2, and the fully implicit finite volume discretization is derived in section 3. In section 4, stability and error estimates on the discrete solution for the sediment thickness and its time derivative are obtained. Finally, the convergence of the approximate solutions to a weak solution of the problem is proved in section 5.

2. Mathematical model and weak formulation.

A basin model specifies the geometry defined by the basin horizontal extension, the position of its base due to vertical tectonics displacements, and the sea level variations. It provides a description of the sediments considered as a mixture of different lithologies such as sand or shale. Finally, it specifies the sediment transport laws and their coupling, as well as the sediment fluxes at the boundary of the basin (boundary conditions).

In this paper, the multilithology diffusion model described in [14], [9], and [5] is studied in a simplified case for which the diffusion coefficients of the lithologies are equal (to one to fix ideas). Also, for the sake of simplicity, the tectonics displacements as well as the sea level variations are not considered in what follows.

The projection of the basin on a reference horizontal plane is considered as a fixed domain $\Omega \subset \mathbb{R}^d$, defining the horizontal extension of the basin, with $d = 1$ for two dimensional basin models and $d = 2$ for three dimensional models.

We denote by h the sediment thickness variable defined on the domain $\mathcal{D} = \Omega \times \mathbb{R}_+^*$ and by $\mathcal{B}$ the domain $\{(x, z, t)$ such that $(x, t) \in \mathcal{D}, z < h(x, t)\}$.

The sediments are modeled as a mixture of L lithologies characterized by their grain size population. Each lithology, $i = 1, \ldots, L$, is considered as an uncompressible material of constant grain density and null porosity. On each point of the basin, the mixture is described by its composition given by the concentrations c_i, defined on $\mathcal{B}$, and such that $c_i \geq 0$ for $i = 1, \ldots, L$, and $\sum_{i=1}^{L} c_i = 1$.

The model assumes that the sediment fluxes are nonzero only at the surface of the basin (i.e., for $z = h$). The sediments transported by these surficial fluxes, i.e., which are deposited at the surface of the basin in case of sedimentation, or which pass through the surface in case of erosion, are characterized by their concentrations denoted by c_i^s, defined on $\mathcal{D}$, and such that $c_i^s \geq 0$ for $i = 1, \ldots, L$, and $\sum_{i=1}^{L} c_i^s = 1$.

Since the compaction is not considered, no change in time of the concentration c_i can occur inside the basin. It results that $\partial_t c_i = 0$ on $\mathcal{B}$. The evolution of c_i is governed by the boundary condition at the top of the basin stating that $c_i|_{z=h} = c_i^s$ in the case of sedimentation $\partial_t h > 0$. Let $\mathcal{D}^+$ denote the domain $\{(x, t) \in \mathcal{D}$ such that $\partial_t h(x, t) > 0\}$; then c_i satisfies the conservation equation;

$$(2.1) \qquad \begin{cases} \partial_t c_i = 0 & \text{on } \mathcal{B}, \\ c_i|_{z=h} = c_i^s & \text{on } \mathcal{D}^+. \end{cases}$$

The conservation of the thickness fraction in lithology i

$$(2.2) \qquad \mathcal{M}_i(x, t) = \int_0^{h(x,t)} c_i(x, z, t) dz, \ (x, t) \in \mathcal{D},$$

with $\sum_{i=1}^{L} \mathcal{M}_i = h$, states that for all $i = 1, \ldots, L$

$$(2.3) \qquad \begin{cases} \partial_t \mathcal{M}_i + \operatorname{div} \mathbf{f}_i = 0 & \text{on } \mathcal{D}, \\ \sum_{i=1}^{L} c_i^s = 1 & \text{on } \mathcal{D}. \end{cases}$$

In the multilithology diffusive model described in [14], the flux $\mathbf{f}_i$ is proportional to the gradient of the topography h and to the concentration c_i^s, with a diffusion coefficient k_i. In what follows, we shall restrict ourselves to the simplified case $k_i = 1$ for all $i = 1, \ldots, L$, i.e., $\mathbf{f}_i := -c_i^s \nabla h$, so that the sediment thickness variable h decouples from the concentrations and satisfies a linear parabolic equation (see (2.6)).

Neumann boundary conditions are imposed to h on $\partial\Omega \times \mathbb{R}_+^*$,

$$\nabla h \cdot \vec{n} = g \text{ on } \partial\Omega \times \mathbb{R}_+^*,$$

with $\vec{n}$ the unit normal vector to $\partial\Omega$, outward to Ω, and Dirichlet boundary conditions are prescribed to the surface concentrations

$$c_i^s = \tilde{c}_i \text{ on } \Sigma^+,$$

with $\Sigma^+ = \{(x, t) \in \partial\Omega \times \mathbb{R}_+^*, g(x, t) > 0\}$, $\tilde{c}_i \geq 0$ for all $i = 1, \ldots, L$, and $\sum_{i=1}^{L} \tilde{c}_i = 1$.

Initial conditions are prescribed to the sediment thickness such that $h|_{t=0} = h^0$ on Ω, and to the basin concentrations such that $c_i|_{t=0} = c_i^0$ on the domain $\{(x,z), x \in \Omega, z < h^0(x)\}$, with $c_i^0 \geq 0$ for all $i = 1,\dots,L$, and $\sum_{i=1}^L c_i^0 = 1$.

In the following, we shall consider the new coordinate system for which the vertical position of a point in the basin is measured downward from the top of the basin, i.e., given by the change of variable $(x,\xi,t) = (x', h(x',t') - z, t')$. In this coordinate system, let $u_i(x,\xi,t) = c_i(x, h(x,t) - \xi, t)$ on $\Omega \times \mathbb{R}_+^* \times \mathbb{R}_+^*$ and $u_i^0(x,\xi) = c_i^0(x, h^0(x) - \xi, t)$ on $\Omega \times \mathbb{R}_+^*$. Gathering all the equations, we obtain the following multilithology diffusive model:

$$\text{(2.4)} \qquad \text{surface conservations: } \begin{cases} u_i|_{\xi=0}\,\partial_t h + \operatorname{div}(-c_i^s \nabla h) = 0 & \text{on } \mathcal{D}, \\ \sum_{i=1}^L c_i^s = 1 & \text{on } \mathcal{D}, \\ \nabla h \cdot \vec{n}|_{\partial\Omega\times\mathbb{R}_+^*} = g & \text{on } \partial\Omega \times \mathbb{R}_+^*, \\ c_i^s|_{\Sigma^+} = \tilde{c}_i & \text{on } \Sigma^+, \\ h|_{t=0} = h^0 & \text{on } \Omega, \end{cases}$$

$$\text{(2.5)} \qquad \text{column conservations: } \begin{cases} \partial_t u_i + \partial_t h\, \partial_\xi u_i = 0 & \text{on } \Omega \times \mathbb{R}_+^* \times \mathbb{R}_+^*, \\ u_i|_{\xi=0} = c_i^s & \text{on } \mathcal{D}^+, \\ u_i^0|_{t=0} = u_i^0 & \text{on } \Omega \times \mathbb{R}_+^*, \end{cases}$$

where we have taken into account the equality $\partial_t \mathcal{M}_i = u_i|_{\xi=0}\,\partial_t h$ on $\mathcal{D}$ which derives formally from the definition (2.2) and the equation $\partial_t c_i = 0$ on $\mathcal{B}$.

For this simplified model, summing (2.4) over $i = 1,\dots,L$, it appears that the variable h satisfies the parabolic equation

$$\text{(2.6)} \qquad \begin{cases} \partial_t h - \Delta h = 0 & \text{on } \Omega \times \mathbb{R}_+^*, \\ \nabla h \cdot \vec{n}|_{\partial\Omega\times\mathbb{R}_+^*} = g & \text{on } \partial\Omega \times \mathbb{R}_+^*, \\ h_{|t=0} = h^0 & \text{on } \Omega, \end{cases}$$

while the remaining concentration variables (c_i^s, u_i) verify, for each $i = 1,\dots,L$, the system of equations

$$\text{(2.7)} \qquad \begin{cases} u_i|_{\xi=0}\,\partial_t h + \operatorname{div}(-c_i^s \nabla h) = 0 & \text{on } \mathcal{D}, \\ c_i^s|_{\Sigma_+} = \tilde{c}_i & \text{on } \Sigma^+, \\ \partial_t u_i + \partial_t h\, \partial_\xi u_i = 0 & \text{on } \Omega \times \mathbb{R}_+^* \times \mathbb{R}_+^*, \\ u_i|_{\xi=0} = c_i^s & \text{on } \mathcal{D}^+, \\ u_i|_{t=0} = u_i^0 & \text{on } \Omega \times \mathbb{R}_+^*. \end{cases}$$

The sediment thickness variable is decoupled from the concentrations variables and satisfies the linear system (2.6). The solution of this system is then used in problem (2.7), which is linear with respect to the variables c_i^s and u_i.

In what follows, the following assumptions are made on the data.

HYPOTHESIS 1.

(i) *Ω is an open bounded subset of $\mathbb{R}^d$, of class $\mathcal{C}^\infty$,*

(ii) *$h^0 \in \mathcal{C}^2(\bar{\Omega})$,*

(iii) *$g \in \mathcal{C}^1(\partial\Omega \times \mathbb{R}_+) \cap L^2(\partial\Omega \times \mathbb{R}_+)$,*

(iv) *g and h^0 are chosen according to the assumptions of Theorem* 5.3 *of* [11, p. 320] *so that the unique solution h of* (2.6) *is in $C^2(\bar{\Omega} \times [0,T])$ for all $T > 0$,*

(v) *$\tilde{c}_i \in L^\infty(\Sigma^+)$ with $\tilde{c}_i \geq 0$ for $i = 1,\dots,L$, and $\sum_{i=1}^L \tilde{c}_i = 1$,*

(vi) *$u_i^0 \in L^\infty(\Omega \times \mathbb{R}_+^*)$, $u_i^0 \geq 0$ for $i = 1,\dots,L$, and $\sum_{i=1}^L u_i^0 = 1$.*

In the following, we shall denote by $\mathcal{C}_c^\infty(\mathbb{R}^n)$ the space of real valued functions

$$\{\varphi \in \mathcal{C}^\infty(\mathbb{R}^n) \,|\, \mathrm{supp}(\varphi) \text{ bounded in } \mathbb{R}^n\}.$$

To obtain a rigorous mathematical formulation of (2.7), we are looking for weak solutions defined as follows for all $i = 1, \dots, L$.

DEFINITION 2.1. *Let us assume that Hypothesis* 1 *holds and let h denote the solution of problem* (2.6)*. Then $(c_i^s, u_i) \in L^\infty(\Omega \times \mathbb{R}_+^*) \times L^\infty(\Omega \times \mathbb{R}_+^* \times \mathbb{R}_+^*)$ is said to be a weak solution of* (2.7) *if it satisfies* (i) *for all $\varphi \in \mathcal{A} = \{v \in \mathcal{C}_c^\infty(\mathbb{R}^{d+2}) \,|\, v(.,0,.) = 0$ on $\mathcal{D} \setminus S^+\}$*

$$\begin{aligned}(2.8)\qquad &\int_\Omega \int_{\mathbb{R}_+} \int_{\mathbb{R}_+} \left[\partial_t \varphi(x,\xi,t) + \partial_t h(x,t)\, \partial_\xi \varphi(x,\xi,t)\right] u_i(x,\xi,t)\, dt\, d\xi\, dx \\ &+ \int_\Omega \int_{\mathbb{R}_+} u_i^0(x,\xi)\varphi(x,\xi,0)\, d\xi\, dx + \int_\Omega \int_{\mathbb{R}_+} \partial_t h(x,t) c_i^s(x,t)\varphi(x,0,t)\, dt\, dx = 0,\end{aligned}$$

(ii) *for all $\psi \in \mathcal{A}_0 = \{v \in \mathcal{C}_c^\infty(\mathbb{R}^{d+2}) \,|\, v(.,0,.) = 0$ on $\partial\Omega \times \mathbb{R}_+^* \setminus \Sigma^+\}$*

$$\begin{aligned}(2.9)\qquad &-\int_\Omega \int_{\mathbb{R}_+} \int_{\mathbb{R}_+} \left[\partial_t \psi(x,\xi,t) + \partial_t h(x,t)\, \partial_\xi \psi(x,\xi,t)\right] u_i(x,\xi,t)\, dt\, d\xi\, dx \\ &- \int_\Omega \int_{\mathbb{R}_+} u_i^0(x,\xi)\psi(x,\xi,0)\, d\xi\, dx + \int_{\mathbb{R}_+} \left(\int_\Omega c_i^s(x,t)\, \nabla h(x,t) \cdot \nabla \psi(x,0,t)\, dx \right. \\ &\left. - \int_{\partial\Omega} \tilde{c}_i(x,t) g(x,t) \psi(x,0,t) d\gamma(x) \right) dt = 0.\end{aligned}$$

3. Finite volume scheme. The system (2.4)–(2.5) is discretized by a fully implicit time integration and a finite volume method with cell centered variables. We shall consider in what follows admissible meshes according to the following definition.

DEFINITION 3.1 (admissible meshes). *Let Ω be a bounded domain of $\mathbb{R}^d$, $d = 1$ or* 2*. In the following, $m(.)$ will be used to denote a measure on R^d equal to the Lebesgue measure if $d \geq 1$, and, if $d = 0$, the measure of a point is set to one and the measure of the empty set to zero. An admissible finite volume mesh of Ω for the discretization of problem* (2.4)–(2.5) *is given by a family of "control volumes," denoted by $\mathcal{K}$, which are open disjoint subsets of Ω, and a family of points of Ω, denoted by $\mathcal{P}$, satisfying the following properties:*

(i) *The closure of the union of all the control volumes of $\mathcal{K}$ is $\bar{\Omega}$.*

(ii) *For any κ, $\kappa' \in \mathcal{K}$ with $\kappa \neq \kappa'$, either the $(d-1)$-dimensional measure $m(\bar{\kappa} \cap \bar{\kappa}')$ is null, or it is strictly positive and $\bar{\kappa} \cap \bar{\kappa}'$ is included in a hyperplane of $\mathbb{R}^d$. In the following, we will denote by Σ_{int} the family of subsets σ of Ω contained in hyperplanes of $\mathbb{R}^d$ with strictly positive measures, and such that there exist $\kappa, \kappa' \in \mathcal{K}$ with $m(\bar{\kappa} \cap \bar{\kappa}') > 0$ and $\bar{\sigma} = \bar{\kappa} \cap \bar{\kappa}'$. We shall also denote by $\kappa|\kappa' \in \Sigma_{int}$ the edge between the cells κ and κ'.*

(iii) *The family $\mathcal{P} = (x_\kappa)_{\kappa \in \mathcal{K}}$ is such that $x_\kappa \in \bar{\kappa}$ (for any $\kappa \in \mathcal{K}$), and, if $\sigma = \kappa|\kappa'$, it is assumed that $x_\kappa \neq x_{\kappa'}$ and that the straight line going through x_κ and $x_{\kappa'}$ is orthogonal to the edge $\kappa|\kappa'$.*

(iv) *For any $\kappa \in \mathcal{K}$, there exists a subset Σ_κ of Σ_{int} such that $\partial\kappa \setminus \partial\Omega = \bar{\kappa} \setminus (\kappa \cup \partial\Omega) = \cup_{\sigma \in \Sigma_\kappa} \bar{\sigma}$.*

We shall denote by $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ this admissible mesh.

Let $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ be an admissible mesh of Ω in the sense of Definition 3.1. In what follows, $\delta\mathcal{K} = \sup\{\mathrm{diam}(\kappa), \kappa \in \mathcal{K}\}$ will denote the mesh size of $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$, $|\kappa|$ (resp., $|\sigma|$, $|\partial\kappa \cap \partial\Omega|$) is the d-dimensional measure of the cell $m(\kappa)$ (resp., the $(d-1)$-dimensional measure $m(\sigma)$, $m(\partial\kappa \cap \partial\Omega)$), $\mathcal{K}_\kappa$ the set of neighboring cells of κ (excluding κ), $T_{\kappa\kappa'} = T_\sigma$ the transmissibility of the edge $\sigma = \kappa|\kappa'$, defined by $T_{\kappa\kappa'} := \frac{|\sigma|}{d(\kappa,\kappa')}$ with $d(\kappa,\kappa')$ the distance between the points x_κ and $x_{\kappa'}$, $\mathrm{reg}(\mathcal{K})$ the geometrical factor defined by $\mathrm{reg}(\mathcal{K}) = \max_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} \frac{\delta\mathcal{K}}{d(\kappa,\kappa')}$, and $\vec{n}_{\kappa\kappa'}$ the unit normal vector to $\sigma = \kappa|\kappa'$ outward to κ.

We shall also denote by $X(\mathcal{K})$ the set of real valued functions on Ω which are constant over each control volume of the mesh and, for any subset $\mathcal{O}$ of $\mathbb{R}^d$, by $\chi_{\mathcal{O}}$ the function on $\mathbb{R}^d$ equal to one on $\mathcal{O}$ and null elsewhere. Finally, for any function f, let us define $f^+ = \max(f,0) \geq 0$, $f^- = -\min(f,0) \geq 0$, such that $f = f^+ - f^-$, and $|f| = f^+ + f^-$.

Following [6], we shall use the discrete seminorm defined as follows.

Definition 3.2 (discrete $\mathcal{H}^1$ seminorm). *Let Ω be an open bounded subset of $\mathbb{R}^d$, $d=1$ or 2, and $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ be an admissible finite volume mesh of Ω in the sense of Definition* 3.1. *For $u \in X(\mathcal{K})$, the discrete $\mathcal{H}^1$ seminorm of u is defined by*

$$|u|_{1,\mathcal{K}} = \left(\sum_{\sigma\in\Sigma_{int}} T_\sigma (D_\sigma u)^2 \right)^{\frac{1}{2}},$$

where u_κ is the value of u in the control volume κ and $D_\sigma u = |u_\kappa - u_{\kappa'}|$ with $\sigma = \kappa|\kappa'$.

Remark 1. Let $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ be an admissible mesh of Ω in the sense of Definition 3.1 and $|\Omega|$ denote the d-dimensional measure of the domain Ω. Considering the d-dimensional measure of the set of cones of vertex x_κ and base $\sigma \in \Sigma_{int} \cap \partial\kappa$ for all $\kappa \in \mathcal{K}$ and $\sigma \in \Sigma_{int}$, one can prove that

$$\sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} |\sigma|\, d(\kappa,\kappa') \leq d\,|\Omega|. \tag{3.1}$$

The time discretization is denoted by $t^n, n \in \mathbb{N}$, such that $t^0 = 0$ and $\Delta t^{n+1} = t^{n+1} - t^n > 0$. In the following, the superscript n, $n \in \mathbb{N}$, will be used to denote that the variables are considered at time t^n. Assuming that the set $\{\Delta t^n \,|\, n \in \mathbb{N}\}$ is bounded, let Δt denote $\sup\{\Delta t^n \,|\, n \in \mathbb{N}\}$, and, for a given $T > 0$, let $N_{\Delta t}$ be the integer such that $t^{N_{\Delta t}} < T \leq t^{N_{\Delta t}+1}$.

Let us now recall the discretization of (2.4)–(2.5) already introduced in [5]. For all control volumes $\kappa \in \mathcal{K}$, the following initial values are defined:

1. h^0_κ is the initial approximation of h in κ defined by $h^0_\kappa = h^0(x_\kappa)$.
2. $u^0_{i,\kappa}$, for all species i, is the approximation of u^0_i on the cell κ, defined by $u^0_{i,\kappa}(\xi) = \frac{1}{|\kappa|}\int_\kappa u^0_i(x,\xi)\,dx$ for $\xi \in \mathbb{R}^*_+$, and let $c^0_{i,\kappa}$ be defined on $(-\infty, h^0_\kappa)$ by $c^0_{i,\kappa}(z) = u^0_{i,\kappa}(h^0_\kappa - z)$.

We now give a discretization of (2.4)–(2.5) within a given control volume $\kappa \in \mathcal{K}$ between times t^n and t^{n+1}.

Conservation of surface sediments:

$$\begin{aligned} &\frac{\Delta\mathcal{M}^{n+1}_{i,\kappa}}{\Delta t^{n+1}}\, |\kappa| \;+ \sum_{\kappa'\in\mathcal{K}_\kappa} c^{s,n+1}_{i,\kappa\kappa'}\, T_{\kappa\kappa'}(h^{n+1}_\kappa - h^{n+1}_{\kappa'}) \\ &\quad -|\partial\kappa\cap\partial\Omega|\,\tilde{c}^{n+1}_{i,\kappa}\, g^{(+),n+1}_\kappa + |\partial\kappa\cap\partial\Omega|\, c^{s,n+1}_{i,\kappa}\, g^{(-),n+1}_\kappa = 0, \end{aligned} \tag{3.2}$$

$$\sum_{i=1}^{L} c_{i,\kappa}^{s,n+1} = 1. \tag{3.3}$$

Conservation of column sediments:

$$\text{if } h_\kappa^{n+1} \geq h_\kappa^n \begin{cases} \Delta\mathcal{M}_{i,\kappa}^{n+1} = c_{i,\kappa}^{s,n+1}(h_\kappa^{n+1} - h_\kappa^n), \\ c_{i,\kappa}^{n+1}(z) = c_{i,\kappa}^n(z),\ z < h_\kappa^n, \\ c_{i,\kappa}^{n+1}(z) = c_{i,\kappa}^{s,n+1},\ z \in (h_\kappa^n, h_\kappa^{n+1}), \end{cases} \tag{3.4}$$

$$\text{else} \quad \begin{cases} \Delta\mathcal{M}_{i,\kappa}^{n+1} = \int_{h_\kappa^n}^{h_\kappa^{n+1}} c_{i,\kappa}^n(z)dz, \\ c_{i,\kappa}^{n+1}(z) = c_{i,\kappa}^n(z),\ z < h_\kappa^{n+1}. \end{cases} \tag{3.5}$$

In (3.2)–(3.5), the following notation is used.

1. h_κ^n is the approximation of the sediment thickness h at time t^n in κ.

2. $c_{i,\kappa}^{s,n+1}$ is the approximation of the surface sediment concentration i at time t^{n+1} in κ.

3. The function $c_{i,\kappa}^n$, defined on the column $(-\infty, h_\kappa^n)$. is the approximation of the sediment concentration in lithology i in the column $\{(x,z), x \in \kappa, z < h(x,t^n)\}$ at time t^n.

4. $c_{i,\kappa\kappa'}^{s,n+1}$ is the upstream weighted evaluation of the surface sediment concentration in lithology i at the edge σ between the cells κ and κ' with respect to the sign of $h_\kappa^{n+1} - h_{\kappa'}^{n+1}$:

$$c_{i,\kappa\kappa'}^{s,n+1} = \begin{cases} c_{i,\kappa}^{s,n+1} \text{ if } h_\kappa^{n+1} > h_{\kappa'}^{n+1}, \\ c_{i,\kappa'}^{s,n+1} \text{ otherwise.} \end{cases}$$

5. $g_\kappa^{(+),n+1}$ and $g_\kappa^{(-),n+1}$ are the following approximations of the boundary fluxes g^+ and g^-:

$$g_\kappa^{(+),n+1} = \begin{cases} \frac{1}{\Delta t^{n+1}} \frac{1}{|\partial\kappa\cap\partial\Omega|} \int_{t^n}^{t^{n+1}} \int_{\partial\kappa\cap\partial\Omega} g^+(x,t)\, d\gamma(x)dt & \text{if } |\partial\kappa \cap \partial\Omega| \neq 0, \\ 0 & \text{else,} \end{cases}$$

$$g_\kappa^{(-),n+1} = \begin{cases} \frac{1}{\Delta t^{n+1}} \frac{1}{|\partial\kappa\cap\partial\Omega|} \int_{t^n}^{t^{n+1}} \int_{\partial\kappa\cap\partial\Omega} g^-(x,t)\, d\gamma(x)dt & \text{if } |\partial\kappa \cap \partial\Omega| \neq 0, \\ 0 & \text{else,} \end{cases}$$

and consequently for all $\kappa \in \mathcal{K}$,

$$g_\kappa^{n+1} = \frac{1}{\Delta t^{n+1}} \frac{1}{|\partial\kappa \cap \partial\Omega|} \int_{t^n}^{t^{n+1}} \int_{\partial\kappa\cap\partial\Omega} g(x,t)\, d\gamma(x)dt = g_\kappa^{(+),n+1} - g_\kappa^{(-),n+1}.$$

6. $\tilde{c}_{i,\kappa}^{n+1}$ is the approximation of $\tilde{c}_i$ extended by 0 on $(\partial\Omega \times \mathbb{R}_+^*) \setminus \Sigma^+$:

$$\tilde{c}_{i,\kappa}^{n+1} = \begin{cases} \frac{1}{\Delta t^{n+1}} \frac{1}{|\partial\kappa\cap\partial\Omega|} \int_{t^n}^{t^{n+1}} \int_{\partial\kappa\cap\partial\Omega} \tilde{c}_i(x,t) d\gamma(x)dt & \text{if } |\partial\kappa \cap \partial\Omega| \neq 0, \\ 0 & \text{else,} \end{cases}$$

and it results that $\tilde{c}_{i,\kappa}^{n+1} \in [0,1]$.

Considering the coordinate system $\xi = h_\kappa^n - z$, the function $u_{i,\kappa}^n$ is defined for all $\kappa \in \mathcal{K}$, $n \geq 0$, and $i = 1, \ldots, L$ by

$$u_{i,\kappa}^n(\xi) = c_{i,\kappa}^n(h_\kappa^n - \xi) \text{ for all } \xi \in \mathbb{R}_+^*. \tag{3.6}$$

Let us note that, to obtain a fully discrete scheme, the initial condition $u^0_{i,\kappa}(\xi)$ is projected for each κ on a piecewise constant finite element subspace of $L^\infty(\mathbb{R}^*_+)$. Then, the scheme (3.4)–(3.5) generates a piecewise constant approximation of $u^n_{i,\kappa}(\xi)$ on each cell κ for all $i = 1, \dots, L$, with time-dependent mesh sizes in the direction ξ.

For the sake of simplicity, it is assumed in the remainder of this article that $\Delta t = \Delta t^n$ for all $n \geq 1$, although all the results presented in what follows readily extend to variable time steps.

In sections 4 and 5, we shall prove, for all $n \geq 0$, the existence of solutions $(h^n_\kappa)_{\kappa\in\mathcal{K}}$, $(c^{s,n+1}_{i,\kappa})_{\kappa\in\mathcal{K}}$, $(c^n_{i,\kappa})_{\kappa\in\mathcal{K}}$, and $(u^n_{i,\kappa})_{\kappa\in\mathcal{K}}$, $i = 1, \dots, L$, to problem (3.2)–(3.6). These solutions are unique except for the surface concentration $c^{s,n+1}_{i,\kappa}$ which is arbitrary (such that $\sum_{j=1}^L c^{s,n+1}_{j,\kappa} = 1$) at some degenerate points $(\kappa, n+1)$ for which it is chosen according to Lemma 5.1.

For any admissible mesh $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ of Ω in the sense of Definition 3.1, any time step $\Delta t > 0$, and $i = 1, \dots, L$, let $h_{\mathcal{K},\Delta t}$, $c^s_{i,\mathcal{K},\Delta t}$ defined on $\Omega \times \mathbb{R}^*_+$ and $u_{i,\mathcal{K},\Delta t}$ defined on $\Omega \times \mathbb{R}^*_+ \times \mathbb{R}^*_+$ denote the functions such that

$$\left\{ \begin{aligned} h_{\mathcal{K},\Delta t}(x,t) &= h^{n+1}_\kappa, \\ u_{i,\mathcal{K},\Delta t}(x,\xi,t) &= u^{n+1}_{i,\kappa}(\xi), \\ c^s_{i,\mathcal{K},\Delta t}(x,t) &= c^{s,n+1}_{i,\kappa} \end{aligned} \right. \tag{3.7}$$

for all $x \in \kappa$, $\kappa \in \mathcal{K}$, $t \in (t^n, t^{n+1}]$, $\xi \in \mathbb{R}^*_+$, $n \geq 0$, where h^n_κ, $c^{s,n+1}_{i,\kappa}$, $c^n_{i,\kappa}$ are any given solution of (3.2)–(3.6) chosen according to Lemma 5.1. From Lemma 5.1, the functions $h_{\mathcal{K},\Delta t}$ and $u_{i,\mathcal{K},\Delta t}$ do not depend on the choice of the solution of (3.2)–(3.6).

The aim of this article is then to prove the following theorem.

THEOREM 3.3. *Hypothesis* 1 *is assumed to hold. For all* $m \in \mathbb{N}$, *let* $(\mathcal{K}_m, \Sigma^m_{int}, \mathcal{P}_m)$ *be an admissible mesh of* Ω *in the sense of Definition* 3.1 *and* $\Delta t_m > 0$. *Let us assume that there exists* $\alpha > 0$ *such that* $reg(\mathcal{K}_m) \leq \alpha$ *for all* $m \in \mathbb{N}$, *and that* $\Delta t_m \to 0$, $\frac{\delta \mathcal{K}_m}{\sqrt{\Delta t_m}} \to 0$ *as* $m \to \infty$.

For all $m \in \mathbb{N}$ *and* $i = 1, \dots, L$, *let* $h_{\mathcal{K}_m,\Delta t_m}$, $u_{i,\mathcal{K}_m,\Delta t_m}$ *denote the unique functions defined by* (3.7) *and* $c^s_{i,\mathcal{K}_m,\Delta t_m}$ *be a function defined by* (3.7), *from any solution of* (3.2)–(3.6) *chosen according to Lemma* 5.1 *with* $\mathcal{K} = \mathcal{K}_m$, $\Delta t = \Delta t_m$.

Then, the sequence $(h_{\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ *converges to the solution* h *of problem* (2.6) *in* $L^\infty(0,T;L^2(\Omega))$ *for all* $T > 0$, *and there exists a subsequence of* $(\mathcal{K}_m, \Delta t_m)_{m\in\mathbb{N}}$, *still denoted by* $(\mathcal{K}_m, \Delta t_m)_{m\in\mathbb{N}}$, *such that, for all* $i \in \{1, \dots, L\}$, *the subsequence* $(c^s_{i,\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ (*resp.*, $(u_{i,\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$) *converges to a function* c^s_i *in* $L^\infty(\Omega \times \mathbb{R}^*_+)$ (*resp.*, u_i *in* $L^\infty(\Omega \times \mathbb{R}^*_+ \times \mathbb{R}^*_+)$) *for the weak-$\star$ topology. Furthermore, for all* $i \in \{1, \dots, L\}$, *the limit* (c^s_i, u_i) *is a weak solution of problem* (2.7) *in the sense of Definition* 2.1.

This convergence result will be obtained in section 4 for the approximate solution for the sediment thickness and in section 5 for the approximate concentrations.

4. Stability and convergence for the approximate sediment thickness and its time derivative. Summing (3.2) over $i = 1, \dots, L$ yields that for all $n \in \mathbb{N}$, the solution $(h^{n+1}_\kappa)_{\kappa\in\mathcal{K}}$ satisfies the following implicit finite volume discretization of (2.6):

$$|\kappa| \frac{h^{n+1}_\kappa - h^n_\kappa}{\Delta t} + \sum_{\kappa' \in \mathcal{K}_\kappa} T_{\kappa\kappa'}(h^{n+1}_\kappa - h^{n+1}_{\kappa'}) - |\partial\kappa \cap \partial\Omega|\, g^{n+1}_\kappa = 0, \tag{4.1}$$

with $h^0_\kappa = h^0(x_\kappa)$. The proof of existence and uniqueness of the solution $(h^n_\kappa)_{\kappa\in\mathcal{K}}$ for all $n \geq 0$ is classical and can be found, e.g., in [6] for any admissible mesh $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ of Ω.

The following proposition provides estimates of the error on h and its time derivative. The error estimates on h have already been proved in [6].

PROPOSITION 4.1. *Let us assume that Hypothesis* 1 *holds and let h denote the solution of problem* (2.6). *Let $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ be an admissible mesh of Ω in the sense of Definition* 3.1, *$T > 0$, and $\Delta t \in (0, T)$. For all $n \in \{0, \dots, N_{\Delta t} + 1\}$, let $(h^n_\kappa)_{\kappa\in\mathcal{K}}$ be the solution of* (4.1) *and $e^n_{\mathcal{K}} \in X(\mathcal{K})$ be defined by $e^n_{\mathcal{K}}(x) = e^n_\kappa = h(x_\kappa, t^n) - h^n_\kappa$ for all $x \in \kappa$, $\kappa \in \mathcal{K}$. Then, there exist D_1, D_2, D_3, and $D_4 > 0$ depending only on $\|\nabla\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, T, and Ω such that*

$$\|e^n_{\mathcal{K}}\|^2_{L^2(\Omega)} \leq D_1(\Delta t + \delta\mathcal{K})^2 \quad \textit{for all } n \in \{1, \dots, N_{\Delta t} + 1\}, \tag{4.2}$$

$$\sum_{n=0}^{N_{\Delta t}} \Delta t\, |e^{n+1}_{\mathcal{K}}|^2_{1,\mathcal{K}} \leq D_2\, (\Delta t + \delta\mathcal{K})^2, \tag{4.3}$$

$$\sum_{n=0}^{N_{\Delta t}} \Delta t \left\| \frac{e^{n+1}_{\mathcal{K}} - e^n_{\mathcal{K}}}{\Delta t} \right\|^2_{L^2(\Omega)} \leq D_3 \frac{(\delta\mathcal{K} + \Delta t)^2}{\Delta t}, \tag{4.4}$$

$$\begin{aligned} &\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int} \\ \sigma=\kappa|\kappa'}} |\sigma|\, d(\kappa,\kappa') \bigg(\frac{h^{n+1}_{\kappa'} - h^{n+1}_\kappa}{d(\kappa,\kappa')} \\ &- \frac{1}{\Delta t}\frac{1}{|\sigma|} \int_{t^n}^{t^{n+1}} \int_\sigma \nabla h(x,t)\cdot \vec{n}_{\kappa\kappa'} d\gamma(x)\, dt \bigg)^2 \leq D_4(\Delta t + \delta\mathcal{K})^2. \end{aligned} \tag{4.5}$$

Proof. Integrating (2.6) over the control volume $\kappa \in \mathcal{K}$ and time interval (t^n, t^{n+1}) for all $n \in \{0, \dots, N_{\Delta t}\}$, one obtains

$$\int_{t^n}^{t^{n+1}} \int_\kappa \partial_t h(x,t) dx dt - \int_{t^n}^{t^{n+1}} \int_{\partial\kappa} \nabla h(x,t)\cdot \vec{n}_\kappa d\gamma(x) dt = 0, \tag{4.6}$$

where $\vec{n}_\kappa$ is the normal unit vector to $\partial\kappa$ outward to κ. Subtracting (4.1) from (4.6)/Δt and using the definition of g^{n+1}_κ yield the following equation for the error e^{n+1}_k:

$$|\kappa| \frac{e^{n+1}_\kappa - e^n_\kappa}{\Delta t} + \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}(e^{n+1}_\kappa - e^{n+1}_{\kappa'}) = -|\kappa| P^n_\kappa - \sum_{\sigma\in\Sigma_\kappa} |\sigma| R^n_{\kappa,\sigma} \tag{4.7}$$

with the consistency residuals

$$R^n_{\kappa,\sigma} = \frac{1}{\Delta t}\frac{1}{|\sigma|} \int_{t^n}^{t^{n+1}} \int_\sigma \left[\frac{h(x_{\kappa'}, t^{n+1}) - h(x_\kappa, t^{n+1})}{d(\kappa,\kappa')} - \nabla h(x,t)\cdot\vec{n}_{\kappa\kappa'} \right] d\gamma(x) dt$$

for all $\kappa \in \mathcal{K}$ and $\sigma \in \Sigma_\kappa \cap \Sigma_{\kappa'}$, and

$$P^n_\kappa = \frac{1}{\Delta t}\frac{1}{|\kappa|} \int_{t^n}^{t^{n+1}} \int_\kappa (\partial_t h(x,t) - \partial_t h(x_\kappa, t))\, dx dt \qquad \text{for all } \kappa \in \mathcal{K}.$$

Thanks to the regularity of h, there exists $C_1 > 0$ depending on $\|\nabla\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$ only such that

$$|P^n_\kappa| \leq C_1\, \delta\mathcal{K}, \tag{4.8}$$

and $C_2 > 0$ depending only on $\|\partial_t \nabla h\|_{L^\infty(\Omega\times(0,2T))}$, and $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$ such that

$$|R^n_{\kappa,\sigma}| \le C_2\,(\delta\mathcal{K} + \Delta t). \tag{4.9}$$

Then, multiplying (4.7) by e^{n+1}_κ and summing over the cells $\kappa \in \mathcal{K}$ yield the estimate

$$\begin{aligned}\sum_{\kappa\in\mathcal{K}} |\kappa|(e^{n+1}_\kappa - e^n_\kappa)e^{n+1}_\kappa + \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}(e^{n+1}_\kappa - e^{n+1}_{\kappa'})^2 \\ = -\Delta t \sum_{\kappa\in\mathcal{K}} |\kappa| P^n_\kappa\, e^{n+1}_\kappa - \Delta t \sum_{\kappa\in\mathcal{K}}\sum_{\sigma\in\Sigma_\kappa} |\sigma| R^n_{\kappa,\sigma}\, e^{n+1}_\kappa.\end{aligned} \tag{4.10}$$

Let us note that $R_{\kappa,\sigma} = -R_{\kappa',\sigma}$ for all $\sigma = \kappa|\kappa' \in \Sigma_{int}$ so that $R_\sigma = |R_{\kappa,\sigma}|$ for $\sigma \in \Sigma_\kappa$ can be defined for all $\sigma \in \Sigma_{int}$. Then, using in (4.10) the equality $(e^{n+1}_\kappa - e^n_\kappa)\, e^{n+1}_\kappa = \frac{1}{2}\big[(e^{n+1}_\kappa)^2 - (e^n_\kappa)^2 + (e^{n+1}_\kappa - e^n_\kappa)^2\big]$, Young's inequality, (3.1), (4.8), and (4.9), we obtain

$$\begin{aligned}\|e^{n+1}_{\mathcal{K}}\|^2_{L^2(\Omega)} + \Delta t\, |e^{n+1}_{\mathcal{K}}|^2_{1,\mathcal{K}} \le \|e^n_{\mathcal{K}}\|^2_{L^2(\Omega)} \\ +\Delta t\, C_3\,(\Delta t + \delta\mathcal{K})\, \|e^{n+1}_{\mathcal{K}}\|^2_{L^2(\Omega)} + \Delta t\, C_4\,(\delta\mathcal{K} + \Delta t)^2,\end{aligned} \tag{4.11}$$

with C_3 and C_4 depending only on $\|\nabla\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, and Ω. Using the same arguments as in [6], the estimate (4.2) derives from (4.11). Summing (4.11) over $n \in \{0,\dots,N_{\Delta t}\}$ and using inequality (4.2) and the property $e^0_\kappa = 0$ for all $\kappa \in \mathcal{K}$, we obtain inequality (4.3).

Then, (4.3) is equivalent to

$$\begin{aligned}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} |\sigma|\, d(\kappa,\kappa')\left(\frac{h^{n+1}_{\kappa'} - h^{n+1}_\kappa}{d(\kappa,\kappa')} - \frac{h(x_{\kappa'},t^{n+1}) - h(x_\kappa,t^{n+1})}{d(\kappa,\kappa')}\right)^2 \\ \le D_2\,(\Delta t + \delta\mathcal{K})^2.\end{aligned} \tag{4.12}$$

Furthermore,

$$\begin{aligned}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} |\sigma|\, d(\kappa,\kappa')\bigg(\frac{h(x_{\kappa'},t^{n+1}) - h(x_\kappa,t^{n+1})}{d(\kappa,\kappa')} \\ -\frac{1}{\Delta t}\frac{1}{|\sigma|}\int_{t^n}^{t^{n+1}}\int_\sigma \nabla h(x,t)\cdot\vec{n}_{\kappa\kappa'}\,d\gamma(x)dt\bigg)^2 \\ = \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} |\sigma|\, d(\kappa,\kappa')(R^n_\sigma)^2 \;\le\; C_5\,(\delta\mathcal{K} + \Delta t)^2,\end{aligned} \tag{4.13}$$

with C_5 depending on $\|\nabla\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, T, and Ω. The estimate (4.5) derives from (4.12) and (4.13).

To prove (4.4), let us multiply (4.7) by $(e^{n+1}_\kappa - e^n_\kappa)/\Delta t$ and sum over $\kappa \in \mathcal{K}$:

$$\begin{aligned}\Delta t \sum_{\kappa\in\mathcal{K}} |\kappa| \left(\frac{e^{n+1}_\kappa - e^n_\kappa}{\Delta t}\right)^2 + \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}(e^{n+1}_\kappa - e^{n+1}_{\kappa'})(e^{n+1}_\kappa - e^{n+1}_{\kappa'} - e^n_\kappa + e^n_{\kappa'}) \\ = -\Delta t \sum_{\kappa\in\mathcal{K}} |\kappa|\, P^n_\kappa\, \frac{e^{n+1}_\kappa - e^n_\kappa}{\Delta t} - \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} |\sigma| R^n_{\kappa,\sigma}(e^{n+1}_\kappa - e^{n+1}_{\kappa'} - e^n_\kappa + e^n_{\kappa'}).\end{aligned}$$

From $(e_\kappa^{n+1}-e_{\kappa'}^{n+1})(e_\kappa^{n+1}-e_{\kappa'}^{n+1}-e_\kappa^n+e_{\kappa'}^n) = \frac{1}{2}\big[\,(e_\kappa^{n+1}-e_{\kappa'}^{n+1})^2-(e_\kappa^n-e_{\kappa'}^n)^2+(e_\kappa^{n+1}-e_{\kappa'}^{n+1}-e_\kappa^n+e_{\kappa'}^n)^2\,\big]$ and Young's inequality, it results that

$$\begin{aligned}
&2\Delta t\sum_{\kappa\in\mathcal{K}}|\kappa|\left(\frac{e_\kappa^{n+1}-e_\kappa^n}{\Delta t}\right)^2+\sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}}T_{\kappa\kappa'}(e_\kappa^{n+1}-e_{\kappa'}^{n+1}-e_\kappa^n+e_{\kappa'}^n)^2\\
&+\sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}}T_{\kappa\kappa'}(e_\kappa^{n+1}-e_{\kappa'}^{n+1})^2\le\sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}}T_{\kappa\kappa'}(e_\kappa^n-e_{\kappa'}^n)^2\\
&+\Delta t\sum_{\kappa\in\mathcal{K}}|\kappa|\,(P_\kappa^n)^2+\Delta t\sum_{\kappa\in\mathcal{K}}|\kappa|\left(\frac{e_\kappa^{n+1}-e_\kappa^n}{\Delta t}\right)^2\\
&+\sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}}d(\kappa,\kappa')\,|\sigma|\,(R_\sigma^n)^2+\sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}}T_{\kappa\kappa'}(e_\kappa^{n+1}-e_{\kappa'}^{n+1}-e_\kappa^n+e_{\kappa'}^n)^2.
\end{aligned}\tag{4.14}$$

Summing (4.14) for all $n\in\{0,\dots,N_{\Delta t}\}$ and using (4.8), (4.9), (3.1), and the property $e_\kappa^0=0$ for all $\kappa\in\mathcal{K}$, we get

$$\sum_{n=0}^{N_{\Delta t}}\Delta t\sum_{\kappa\in\mathcal{K}}|\kappa|\left(\frac{e_\kappa^{n+1}-e_\kappa^n}{\Delta t}\right)^2\le C_6\,(\delta\mathcal{K})^2+C_7\,\frac{(\Delta t+\delta\mathcal{K})^2}{\Delta t}$$

with C_6 and $C_7>0$ depending only on $\|\nabla\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, Ω, and T, which proves (4.4). ☐

Remark 2. According to (4.4) given in Proposition 4.1, the discrete time derivative of the error tends to zero with the mesh size and time step under an inverse CFL condition. This condition is due to the fact that the finite volume scheme is implicit in time and that few assumptions have been made on the regularity of h. However, it is possible to get rid of this inverse CFL condition by assuming h much more regular. Such a result can be found in [13].

COROLLARY 1. *Let us assume that Hypothesis* 1 *holds, and let h denote the solution of problem* (2.6). *Let $(\mathcal{K},\Sigma_{int},\mathcal{P})$ be an admissible mesh of Ω in the sense of Definition* 3.1, *$T>0$, $\Delta t\in(0,T)$, and let $\beta>0$ be such that $\delta\mathcal{K}\le\beta\sqrt{\Delta t}$. For all $n\in\{0,\dots,N_{\Delta t}+1\}$, let $(h_\kappa^n)_{\kappa\in\mathcal{K}}$ be the solution of* (4.1), *and let us define $h_\mathcal{K}^n\in X(\mathcal{K})$ (resp., $\delta_t h_\mathcal{K}^n\in X(\mathcal{K})$) by $h_\mathcal{K}^n(x)=h_\kappa^n$ (resp., $\delta_t h_\mathcal{K}^n(x)=\frac{h_\kappa^{n+1}-h_\kappa^n}{\Delta t}$) for $x\in\kappa$, $\kappa\in\mathcal{K}$. Then, there exist $D_5>0$ depending only on $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, $\|\nabla\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, Ω, and T and D_6, D_6', $D_6''>0$ depending on $\|\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, $\|\nabla\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, Ω, and T, with D_6 also depending on β, such that*

$$\sum_{n=0}^{N_{\Delta t}}\Delta t\,|h_\mathcal{K}^{n+1}|_{1,\mathcal{K}}^2\le D_5,\tag{4.15}$$

and

$$\sum_{n=0}^{N_{\Delta t}}\Delta t\,\|\delta_t h_\mathcal{K}^n\|_{L^2(\Omega)}^2\le D_6'+D_6''\,\frac{(\delta\mathcal{K}+\Delta t)^2}{\Delta t}\le D_6.\tag{4.16}$$

Proof. The proof is straightforward, using the error estimates (4.3) and (4.4), the regularity of h, and the estimate (3.1). ☐

For any admissible mesh $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ of Ω in the sense of Definition 3.1 and any time step $\Delta t > 0$, let $(h_\kappa^n)_{\kappa\in\mathcal{K}}$ for all $n \geq 0$ be the solution of (4.1), and let $\delta_t h_{\mathcal{K},\Delta t}$ denote the function defined on $\Omega \times \mathbb{R}_+^*$, such that for all $x \in \kappa$, $\kappa \in \mathcal{K}$, $t \in (t^n, t^{n+1}]$, $n \geq 0$,

$$\delta_t h_{\mathcal{K},\Delta t}(x,t) = \frac{h_\kappa^{n+1} - h_\kappa^n}{\Delta t}. \tag{4.17}$$

PROPOSITION 4.2. *Let us assume that Hypothesis* 1 *holds, and let h denote the solution of problem* (2.6)*. Let us consider a family of admissible discretizations $(\mathcal{K}, \Sigma_{int}, \mathcal{P}, \Delta t)$ of $\Omega \times \mathbb{R}_+^*$, with $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ an admissible mesh of Ω in the sense of Definition* 3.1 *and $\Delta t > 0$ a time step. For a given discretization $(\mathcal{K}, \Sigma_{int}, \mathcal{P}, \Delta t)$ of this family, let $h_{\mathcal{K},\Delta t}$ (resp., $\delta_t h_{\mathcal{K},\Delta t}$) be the function defined by* (3.7) *(resp., by* (4.17)*) from the solution of* (4.1)*. Then, for all $T > 0$, $h_{\mathcal{K},\Delta t}$ converges to h in $L^\infty(0,T;L^2(\Omega))$ as Δt and $\delta\mathcal{K}$ tend to* 0*, and $\delta_t h_{\mathcal{K},\Delta t}$ converges to $\partial_t h$ in $L^2(\Omega \times (0,T))$ as Δt, $\delta\mathcal{K}$ and $\frac{\delta\mathcal{K}}{\sqrt{\Delta t}}$ tend to* 0*.*

Proof. Let $T > 0$, and let $(\mathcal{K}, \Sigma_{int}, \mathcal{P}, \Delta t)$ be an admissible discretization of $\Omega \times \mathbb{R}_+^*$ with $\Delta t < T$. For all $x \in \kappa$, $\kappa \in \mathcal{K}$, and $t \in (t^n, t^{n+1}]$, $n \in \{0, \ldots, N_{\Delta t}\}$, one has

$$\begin{aligned} h(x,t) - h_{\mathcal{K},\Delta t}(x,t) &= (h(x,t) - h(x_\kappa, t^{n+1})) + (h(x_\kappa, t^{n+1}) - h_\kappa^{n+1}) \\ &= (h(x,t) - h(x_\kappa, t^{n+1})) + e_\kappa^{n+1}. \end{aligned}$$

Thus, for all $t \in (t^n, t^{n+1}]$, $n \in \{0, \ldots, N_{\Delta t}\}$,

$$\begin{aligned} &\int_\Omega |h(x,t) - h_{\mathcal{K},\Delta t}(x,t)|^2 dx \\ &\quad \leq 2 \sum_{\kappa\in\mathcal{K}} \left[\int_\kappa |h(x,t) - h(x_\kappa, t^{n+1})|^2 dx + |\kappa| (e_\kappa^{n+1})^2 \right]. \end{aligned} \tag{4.18}$$

Thanks to Proposition 4.1, there exists $C_1 > 0$ depending only on $\|\nabla \partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, and Ω such that

$$\sum_{\kappa\in\mathcal{K}} |\kappa| (e_\kappa^{n+1})^2 \leq C_1 \big(\Delta t + \delta\mathcal{K}\big)^2 \quad \text{for all } n \in \{0, \ldots, N_{\Delta t}\}. \tag{4.19}$$

Furthermore, thanks to the regularity of h, there exists $C_2 > 0$ depending only on $\|\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$ and $\|\nabla h\|_{L^\infty(\Omega\times(0,2T))}$ such that, for all $x \in \kappa$ and $t \in (t^n, t^{n+1}]$,

$$|h(x,t) - h(x_\kappa, t^{n+1})| \leq C_2 \big(\delta\mathcal{K} + \Delta t\big). \tag{4.20}$$

Then, using (4.19) and (4.20) in (4.18) yields, for all $t \in (0,T)$,

$$\|h(.,t) - h_{\mathcal{K},\Delta t}(.,t)\|_{L^2(\Omega)}^2 \leq C_3 \big(\delta\mathcal{K} + \Delta t\big)^2,$$

and consequently, $\|h - h_{\mathcal{K},\Delta t}\|_{L^\infty(0,T;L^2(\Omega))} \leq C_3' \big(\delta\mathcal{K} + \Delta t\big)$, where C_3, C_3' depend on $\|\nabla \partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, $\|\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, and Ω, so that the convergence holds.

Furthermore, for all $x \in \kappa$, $\kappa \in \mathcal{K}$, and $t \in (t^n, t^{n+1}]$, $n \in \{0, \ldots, N_{\Delta t}\}$, one has

$$\partial_t h(x,t) - \delta_t h_{\mathcal{K},\Delta t}(x,t) = \left(\partial_t h(x,t) - \frac{h(x_\kappa, t^{n+1}) - h(x_\kappa, t^n)}{\Delta t} \right) + \frac{e_\kappa^{n+1} - e_\kappa^n}{\Delta t}.$$

Thanks to the regularity of h, there exists a constant $C_4 > 0$ depending only on $\|\partial_t^2 h\|_{L^\infty(\Omega\times(0,2T))}$ and $\|\nabla\partial_t h\|_{L^\infty(\Omega\times(0,2T))}$, such that

$$\left|\frac{h(x_\kappa, t^{n+1}) - h(x_\kappa, t^n)}{\Delta t} - \partial_t h(x,t)\right| \le C_4\big(\delta\mathcal{K} + \Delta t\big),$$

from which, together with (4.4), results

$$\|\partial_t h - \delta_t h_{\mathcal{K},\Delta t}\|^2_{L^2(\Omega\times(0,T))} \le C_5\big(\delta\mathcal{K} + \Delta t\big)^2 + C_6\frac{\big(\delta\mathcal{K} + \Delta t\big)^2}{\Delta t},$$

with C_5 and C_6 depending only on Ω, T, $\|h\|_{W^{2,\infty}(\Omega\times(0,2T))}$. Thus, the convergence of $\delta_t h_{\mathcal{K},\Delta t}$ to $\partial_t h$ in $L^2(\Omega\times(0,T))$ as Δt, $\delta\mathcal{K}$, and $\frac{\delta\mathcal{K}}{\sqrt{\Delta t}} \to 0$ is proved. □

5. Convergence of sequences of approximate concentrations toward a weak solution. We shall first prove the existence of a solution for the concentrations satisfying stability estimates from which the weak-$\star$ convergence, up to a subsequence, of the concentrations in L^∞ is deduced.

Existence, stability, and weak-$\star$ convergence.

LEMMA 5.1. *Let $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ be an admissible mesh of Ω in the sense of Definition 3.1, $\Delta t > 0$, and, for all $n \in \mathbb{N}$, let $(h_\kappa^n)_{\kappa\in\mathcal{K}}$ be the solution of* (4.1)*. For $i \in \{1, \dots, L\}$ and $n \in \mathbb{N}$, there exists a unique solution $(c_{i,\kappa}^n)_{\kappa\in\mathcal{K}}$, and there exists at least one solution $(c_{i,\kappa}^{s,n+1})_{\kappa\in\mathcal{K}}$ to the set of equations* (3.2)*–*(3.5) *such that*

$$c_{i,\kappa}^{s,n+1} \in [0,1] \text{ for all } \kappa \in \mathcal{K} \text{ and } n \in \mathbb{N}. \tag{5.1}$$

Furthermore, one has

$$c_{i,\kappa}^n(z) \in [0,1] \text{ for all } \kappa \in \mathcal{K},\ z < h_\kappa^n, \text{ and } n \in \mathbb{N}.$$

Proof. The complete proof can be found in [5]. It is done by induction over $n \in \mathbb{N}^*$ and over the cells $\kappa \in \mathcal{K}$ sorted by decreasing topographical order. For the highest topographical point(s) κ, the fluxes at the edges of the cell κ are either input boundary fluxes or ouput fluxes. Let us consider a control volume $\kappa \in \mathcal{K}$ and a time $n \in \mathbb{N}^*$, and let us assume that the proposition holds for all the previous times t^{l+1}, $0 \le l < n$, and all the lower cells at time t^{n+1}. It results from the induction hypothesis and the upwinding of c_i^s that $c_{i,\kappa}^{s,n+1}$ can be computed explicitly from the lower cell concentrations c_i^s using (3.2), and that the inequality

$$\sum_{\kappa'\in\mathcal{K}_\kappa,\, h_\kappa^{n+1} < h_{\kappa'}^{n+1}} T_{\kappa\kappa'}\, c_{i,\kappa\kappa'}^{s,n+1}\,(h_\kappa^{n+1} - h_{\kappa'}^{n+1}) \le 0 \tag{5.2}$$

holds for all $i = 1, \dots, L$. Let us first assume that $h_\kappa^{n+1} - h_\kappa^n \le 0$ (erosion). It results from the induction hypothesis that

$$c_{i,\kappa}^{s,n+1}\left(\sum_{\kappa'\in\mathcal{K}_\kappa,\, h_\kappa^{n+1} \ge h_{\kappa'}^{n+1}} T_{\kappa\kappa'}\,(h_\kappa^{n+1} - h_{\kappa'}^{n+1}) + |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(-),n+1}\right) \ge 0$$

for all i. In this equation, either the term into brackets is strictly positive for all $i = 1, \dots, L$ and then $c_{i,\kappa}^{s,n+1} \ge 0$, or it vanishes for all i and the point $(\kappa, n+1)$ is a degenerate point in the sense that all the fluxes at the edges of the control volume κ vanish and $h_\kappa^{n+1} = h_\kappa^n$. The concentrations can in that case be chosen arbitrarily such that $\sum_{i=1}^L c_{i,\kappa}^{s,n+1} = 1$. Let us now consider the sedimentation case for which $h_\kappa^{n+1} - h_\kappa^n > 0$. It results from (3.2) and the induction hypothesis that

$$c_{i,\kappa}^{s,n+1}\left(\frac{h_\kappa^{n+1}-h_\kappa^n}{\Delta t^{n+1}}\,|\kappa| + \sum_{\kappa'\in\mathcal{K}_\kappa,\, h_\kappa^{n+1}\geq h_{\kappa'}^{n+1}} T_{\kappa\kappa'}\,(h_\kappa^{n+1}-h_{\kappa'}^{n+1}) + |\partial\kappa\cap\partial\Omega|\, g_\kappa^{(-),n+1}\right) \geq 0,$$

and hence $c_{i,\kappa}^{s,n+1} \geq 0$ for all $i = 1,\dots,L$. Since $h_\kappa^{n+1} = h_\kappa^n$ for any degenerate point $(\kappa, n+1)$, there exists a unique column concentration $c_{i,\kappa}^{n+1}$ solution of the set of equations (3.2)–(3.5) for each lithology. □

Let us define for all $\kappa \in \mathcal{K}$, $n \in \mathbb{N}$, and $t \in (t^n, t^{n+1}]$ the following interpolation of the discrete sediment thickness:

$$h_\kappa(t) = h_\kappa^n + (t - t^n)\,\frac{h_\kappa^{n+1} - h_\kappa^n}{\Delta t}. \tag{5.3}$$

Then, the discrete solutions $(c_{i,\kappa}^n)_{n\in\mathbb{N}}$, $(u_{i,\kappa}^n)_{n\in\mathbb{N}}$, and $(c_{i,\kappa}^{s,n+1})_{n\in\mathbb{N}}$, given by Lemma 5.1, are extended to $t \in \mathbb{R}_+$ for all $\kappa \in \mathcal{K}$ as follows:

$$\begin{cases} c_{i,\kappa}(z,t) = \begin{cases} c_{i,\kappa}^n(z)\,\chi_{(-\infty,h_\kappa^n]} + c_{i,\kappa}^{s,n+1}\,\chi_{(h_\kappa^n,h_\kappa(t))} & \text{if } h_\kappa^{n+1} \geq h_\kappa^n, \\ c_{i,\kappa}^n(z)\,\chi_{(-\infty,h_\kappa(t))} & \text{otherwise} \end{cases} \\ \qquad\qquad \text{for all } t \in (t^n, t^{n+1}] \text{ and } z < h_\kappa(t), \\ c_{i,\kappa}(z,0) = c_{i,\kappa}^0(z) \text{ for all } z < h_\kappa^0, \end{cases} \tag{5.4}$$

$$u_{i,\kappa}(\xi,t) = c_{i,\kappa}(h_\kappa(t)-\xi,t) \text{ for all } t \geq 0 \text{ and } \xi \in \mathbb{R}_+^*, \tag{5.5}$$

$$c_{i,\kappa}^s(t) = c_{i,\kappa}^{s,n+1} \text{ for all } t \in (t^n, t^{n+1}]. \tag{5.6}$$

For any admissible mesh $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ of Ω in the sense of Definition 3.1 and any time step $\Delta t > 0$, let $\bar{u}_{i,\mathcal{K},\Delta t}$ be defined on $\Omega \times \mathbb{R}_+^* \times \mathbb{R}_+$, and let $c_{i,\mathcal{K},\Delta t}$ be defined on $\{(z,t),\, t \geq 0,\, z < h_\kappa(t)\}$, such that

$$\begin{cases} \bar{u}_{i,\mathcal{K},\Delta t}(x,\xi,t) = u_{i,\kappa}(\xi,t), \\ c_{i,\mathcal{K},\Delta t}(x,z,t) = c_{i,\kappa}(z,t) \end{cases} \tag{5.7}$$

for all $x \in \kappa$, $\kappa \in \mathcal{K}$, $t \geq 0$, $\xi \in \mathbb{R}_+^*$, $z < h_\kappa(t)$.

From Lemma 5.1, the unique functions $c_{i,\mathcal{K},\Delta t}$, $\bar{u}_{i,\mathcal{K},\Delta t}$, $u_{i,\mathcal{K},\Delta t}$ defined by (5.7) and (3.7) and any function $c_{i,\mathcal{K},\Delta t}^s$ defined by (3.7) from any solution of (3.2)–(3.6) chosen according to Lemma 5.1 take their values into the interval $[0,1]$. We deduce the following result.

Proposition 5.2. *For all $m \in \mathbb{N}$, let $(\mathcal{K}_m, \Sigma_{int}^m, \mathcal{P}_m)$ be an admissible mesh of Ω in the sense of Definition* 3.1*, and let $\Delta t_m > 0$. Let us assume that $\Delta t_m \to 0$ and $\delta\mathcal{K}_m \to 0$ as $m \to \infty$.*

For all $m \in \mathbb{N}$ and $i = 1,\dots,L$, let $u_{i,\mathcal{K}_m,\Delta t_m}$ (resp., $\bar{u}_{i,\mathcal{K}_m,\Delta t_m}$) denote the unique function defined by (3.7) *(resp., by* (5.7)*) and $c_{i,\mathcal{K}_m,\Delta t_m}^s$ be a function defined by* (3.7)*, from any solution of* (3.2)*–*(3.6) *chosen according to Lemma* 5.1 *with $\mathcal{K} = \mathcal{K}_m$, $\Delta t = \Delta t_m$.*

Then, under Hypothesis 1*, there exists a subsequence of $(\mathcal{K}_m, \Delta t_m)_{m\in\mathbb{N}}$, still denoted by $(\mathcal{K}_m, \Delta t_m)_{m\in\mathbb{N}}$, such that for all $i \in \{1,\dots,L\}$*

(i) *the subsequence* $(c^s_{i,\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ *converges to a function* c^s_i *in* $L^\infty(\Omega\times\mathbb{R}^*_+)$ *for the weak-*$\star$ *topology, and*

(ii) *the subsequences* $(u_{i,\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ *and* $(\bar{u}_{i,\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ *converge to a function* u_i *in* $L^\infty(\Omega\times\mathbb{R}^*_+\times\mathbb{R}^*_+)$ *for the weak-*$\star$ *topology.*

Proof. For the sake of simplicity, the subscript i is dropped. Thanks to Lemma 5.1, the sequence $(c^s_{\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ (resp., $(u_{\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ and $(\bar{u}_{\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$) is bounded in $L^\infty(\Omega\times\mathbb{R}^*_+)$ (resp., in $L^\infty(\Omega\times\mathbb{R}^*_+\times\mathbb{R}^*_+)$). Then, there exists a subsequence of $(\mathcal{K}_m,\Delta t_m)_{m\in\mathbb{N}}$, still denoted by $(\mathcal{K}_m,\Delta t_m)_{m\in\mathbb{N}}$, such that $(c^s_{\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ (resp., $(u_{\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ and $(\bar{u}_{\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$) converges to c^s (resp., u and u') in $L^\infty(\Omega\times\mathbb{R}^*_+)$ (resp., in $L^\infty(\Omega\times\mathbb{R}^*_+\times\mathbb{R}^*_+)$) for the weak-$\star$ topology. It remains to prove that $u=u'$ in $L^\infty(\Omega\times\mathbb{R}^*_+\times\mathbb{R}^*_+)$.

Using definitions (3.6) and (5.5), for $x\in\kappa$, $\kappa\in\mathcal{K}_m$, and $t\in(t^n,t^{n+1}]$, the functions $\bar{u}_{\mathcal{K}_m,\Delta t_m}$ and $u_{\mathcal{K}_m,\Delta t_m}$ are related as follows:

$$u^{n+1}_\kappa(\xi)=\begin{cases}u_\kappa(\xi-(h_\kappa(t)-h^n_\kappa),t) & \text{for all } \xi\geq h_\kappa(t)-h^n_\kappa \quad \text{if } h^{n+1}_\kappa\geq h^n_\kappa,\\ u_\kappa(\xi+(h_\kappa(t)-h^{n+1}_\kappa),t) & \text{for all } \xi\geq 0 \quad \text{if } h^{n+1}_\kappa< h^n_\kappa.\end{cases}$$

Let $\varphi\in\mathcal{C}^\infty_c(\Omega\times\mathbb{R}^*_+\times\mathbb{R}^*_+)$ and $T>0$ be such that $\varphi(.,.,t)=0$ for all $t\geq T$. Since the concentrations are bounded in $[0,1]$, it can be shown that

$$\left|\int_\Omega\int_{\mathbb{R}^*_+}\int_{\mathbb{R}^*_+}(\bar{u}_{\mathcal{K}_m,\Delta t_m}-u_{\mathcal{K}_m,\Delta t_m})\,\varphi(x,\xi,t)\,dx\,d\xi\,dt\right|$$
$$\leq C_1\sum_{n=0}^{N_{\Delta t_m}}\Delta t_m\sum_{\kappa\in\mathcal{K}_m}|\kappa||h^{n+1}_\kappa-h^n_\kappa|,$$

with C_1 depending only on φ, Ω, and T. From the estimate (4.16) it results that

$$\left|\int_\Omega\int_{\mathbb{R}^*_+}\int_{\mathbb{R}^*_+}(\bar{u}_{\mathcal{K}_m,\Delta t_m}-u_{\mathcal{K}_m,\Delta t_m})\,\varphi(x,\xi,t)\,dx\,d\xi\,dt\right|\to 0 \text{ as } m\to\infty,$$

and $u=u'$ in the space of distributions on $\Omega\times\mathbb{R}^*_+\times\mathbb{R}^*_+$, and hence in $L^\infty(\Omega\times\mathbb{R}^*_+\times\mathbb{R}^*_+)$. □

Flux term. The following proposition provides a result of convergence for the flux term appearing in the discretization of the surface conservation equation. It will be used to show that (c^s_i,u_i) satisfies the second equation (2.9) of the weak formulation. The proof of this proposition is an adaptation to the coupling of a parabolic and a hyperbolic equation of the result proved in [6] for the coupling of an elliptic and a hyperbolic equation in the case of a two phase Darcy flow.

Proposition 5.3. *Let us assume that Hypothesis* 1 *holds and let* h *denote the solution of problem* (2.6). *Let us consider a family of admissible discretizations* $(\mathcal{K},\Sigma_{int},\mathcal{P},\Delta t)$ *of* $\Omega\times\mathbb{R}^*_+$, *with* $(\mathcal{K},\Sigma_{int},\mathcal{P})$ *an admissible mesh of* Ω *in the sense of Definition* 3.1 *and* $\Delta t>0$ *a time step. Let us also assume that there exist* α *and* $\beta>0$ *such that, for all discretizations* $(\mathcal{K},\Sigma_{int},\mathcal{P},\Delta t)$ *of this family,* $\delta\mathcal{K}\leq\beta\sqrt{\Delta t}$ *and* $reg(\mathcal{K})\leq\alpha$. *For any admissible discretization* $(\mathcal{K},\Sigma_{int},\mathcal{P},\Delta t)$, *let* $h_{\mathcal{K},\Delta t}$ *denote the function defined by* (3.7) *from the solution of* (4.1), *and let* $(c^{s,n+1}_{i,\kappa})_{\kappa\in\mathcal{K}_m,n\geq 0}$ *be any solution of* (3.2)–(3.5) *chosen according to Lemma* 5.1. *Let* $T>0$, *then, for all* $\varphi\in\mathcal{A}^s_0=\{v\in\mathcal{C}^\infty_c(\mathbb{R}^{d+1})\,|\,v(x,t)=0$ *on* $\partial\Omega\times\mathbb{R}^*_+\setminus\Sigma^+\}$, *and for all* $i=1,\ldots,L$,

$$T_{i,\mathcal{K},\Delta t}\to\int_0^T\left(\int_\Omega c^s_i(x,t)\,\nabla h(x,t)\cdot\nabla\varphi(x,t)\,dx-\int_{\partial\Omega}\tilde{c}_i(x,t)\,g(x,t)\,\varphi(x,t)\,d\gamma(x)\right)dt$$

as $\Delta t \to 0$, *with*

$$
\begin{aligned}
T_{i,\mathcal{K},\Delta t} = &\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c^{s,n+1}_{i,\kappa\kappa'} \left(h^{n+1}_\kappa - h^{n+1}_{\kappa'}\right) \varphi(x_\kappa, t^{n+1})\\
&- \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega| \left(g^{(+),n+1}_\kappa \tilde{c}^{n+1}_{i,\kappa} - g^{(-),n+1}_\kappa c^{s,n+1}_{i,\kappa}\right) \varphi(x_\kappa, t^{n+1}).
\end{aligned}
$$

Columns property. The following proposition states that the column concentrations interpolated in time $\bar{u}_{i,\mathcal{K},\Delta t}$, $i = 1, \ldots, L$, satisfy in the weak sense a linear advection equation. This property is used in the proof of Theorem 3.3 to show the convergence, up to a subsequence, of the approximate solutions to a solution of the weak formulation (2.7).

PROPOSITION 5.4. *Let us assume that Hypothesis* 1 *holds and let* h *denote the solution of problem* (2.6). *Let* $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ *be an admissible mesh of* Ω *in the sense of Definition* 3.1, $T > 0$, *and* $\Delta t \in (0, T)$.

Let $h_{\mathcal{K},\Delta t}$, $u_{i,\mathcal{K},\Delta t}$, $i = 1, \ldots, L$ *(resp.,* $\delta_t h_{\mathcal{K},\Delta t}$ *and* $\bar{u}_{i,\mathcal{K},\Delta t}$, $i = 1, \ldots, L$*), denote the unique functions defined by* (3.7) *(resp., by* (4.17) *and* (5.7)*) and* $c^s_{i,\mathcal{K},\Delta t}$, $i = 1, \ldots, L$, *be a function defined by* (3.7), *from any solution of* (3.2)–(3.6) *chosen according to Lemma* 5.1.

Then, for any $\kappa \in \mathcal{K}$ *and* $i \in \{1, \ldots, L\}$, *the following hold.*

(i) *For all* $\varphi \in W_T = \{v \in \mathcal{C}^\infty_c(\mathbb{R}^2) \,|\, v(.,T) = 0$ *on* $\mathbb{R}\}$,

$$
\begin{aligned}
&\int_0^T \int_{\mathbb{R}_+} \left[\partial_t\varphi(\xi,t) + \partial_t h_\kappa(t)\, \partial_\xi\varphi(\xi,t)\right] u_{i,\kappa}(\xi,t)\, d\xi\, dt\\
&\quad + \int_{\mathbb{R}_+} u^0_{i,\kappa}(\xi)\varphi(\xi,0)\, d\xi + \int_0^T \partial_t h_\kappa(t) u_{i,\kappa}(0,t)\varphi(0,t)\, dt = 0.
\end{aligned}
\tag{5.8}
$$

(ii) *For all* $\varphi \in \mathcal{A}^s_{T,\kappa} = \{v \in \mathcal{C}^\infty_c(\mathbb{R}^2) \,|\, v(.,T) = 0$ *on* $\mathbb{R}$ *and* $v(0,t) = 0$ *for all* $t \geq 0$ *such that* $\partial_t h_\kappa(t) \leq 0\}$,

$$
\begin{aligned}
&\int_0^T \int_{\mathbb{R}_+} \left[\partial_t\varphi(\xi,t) + \partial_t h_\kappa(t)\, \partial_\xi\varphi(\xi,t)\right] u_{i,\kappa}(\xi,t)\, d\xi\, dt\\
&\quad + \int_{\mathbb{R}_+} u^0_{i,\kappa}(\xi)\varphi(\xi,0)\, d\xi + \int_0^T \partial_t h_\kappa(t) c^s_{i,\kappa}(t)\varphi(0,t)\, dt = 0.
\end{aligned}
\tag{5.9}
$$

Proof. Thanks to definition (5.4), $\partial_t c_{i,\kappa}(z,t) = 0$ for all $z \in (-\infty, h_\kappa(t))$ and $t \in (0,T)$. It results that for all $\psi \in W^{1,\infty}(\mathbb{R} \times \mathbb{R}_+)$, compactly supported, one has

$$
\begin{aligned}
0 = &\int_0^T \int_{-\infty}^{h_\kappa(t)} \partial_t c_{i,\kappa}(z,t)\psi(z,t) dz\, dt = \int_0^T \partial_t \left(\int_{-\infty}^{h_\kappa(t)} c_{i,\kappa}(z,t)\psi(z,t) dz \right) dt\\
&- \int_0^T \int_{-\infty}^{h_\kappa(t)} c_{i,\kappa}(z,t)\partial_t\psi(z,t) dz\, dt - \int_0^T \partial_t h_\kappa(t) c_{i,\kappa}(h_\kappa(t),t)\psi(h_\kappa(t),t)\, dt,
\end{aligned}
$$

and consequently

$$
\begin{aligned}
&\int_0^T \int_{-\infty}^{h_\kappa(t)} c_{i,\kappa}(z,t)\partial_t\psi(z,t) dz\, dt + \int_0^T \partial_t h_\kappa(t) c_{i,\kappa}(h_\kappa(t),t)\psi(h_\kappa(t),t)\, dt\\
&\quad - \int_{-\infty}^{h_\kappa(T)} c_{i,\kappa}(z,T)\psi(z,T)\, dz + \int_{-\infty}^{h_\kappa(0)} c^0_{i,\kappa}(z)\psi(z,0)\, dz = 0.
\end{aligned}
\tag{5.10}
$$

Let φ be in W_T, and let $\psi \in W^{1,\infty}(\mathbb{R}\times\mathbb{R}_+)$ be such that

$$\psi(z,t) = \varphi(h_\kappa(t) - z, t) \quad \forall\,(z,t) \in \mathbb{R}\times\mathbb{R}_+.$$

Considering (5.10) in the new coordinate system $\xi = h_\kappa(t) - z$ and using the property $\varphi(.,T) = 0$, (5.8) is derived. Finally, thanks to the definition of $\mathcal{A}^s_{T,\kappa}$ and since $u_{i,\kappa}(0,t) = c^s_{i,\kappa}(t)$ if $\partial_t h_\kappa(t) > 0$, we obtain (5.9). □

Convergence. We will now prove that the limits $(c^s_i, u_i)_{i=1,\dots,L}$ are solutions of the weak formulation given in Definition 2.1.

Lemma 5.5. *Let $\mathcal{O}$ be an open bounded subset of $\mathbb{R}^d$, and let $(f_n)_{n\in\mathbb{N}}$ be a sequence of $L^1(\mathcal{O})$ which converges to f in $L^1(\mathcal{O})$. Let us define, for any $g \in L^1(\mathcal{O})$, $\mathcal{S}^+_g = \{x \in \mathcal{O}\,|\,g(x) > 0\}$ and $\mathcal{S}^-_g = \{x \in \mathcal{O}\,|\,g(x) \le 0\}$; then*

$$I_n = \int_{\mathcal{O}} f_n \chi_{\mathcal{S}^+_{f_n}\cap\mathcal{S}^-_f} \to 0 \text{ as } n\to\infty, \text{ and } J_n = \int_{\mathcal{O}} f_n \chi_{\mathcal{S}^-_{f_n}\cap\mathcal{S}^+_f} \to 0 \text{ as } n\to\infty.$$

Proof. Note that if $f \in L^1(\mathcal{O})$, then f^+ and f^- belong to $L^1(\mathcal{O})$; thus

$$I_n = \int_{\mathcal{O}} f_n \chi_{\mathcal{S}^+_{f_n}} \chi_{\mathcal{S}^-_f} = \int_{\mathcal{O}} f^+_n \chi_{\mathcal{S}^-_f} = \int_{\mathcal{O}} (f^+_n - f^+)\chi_{\mathcal{S}^-_f} + \int_{\mathcal{O}} f^+ \chi_{\mathcal{S}^-_f}.$$

Since $\int_{\mathcal{O}} f^+\chi_{\mathcal{S}^-_f} = 0$ and $|f^+_n - f^+| \le |f_n - f|$ on $\mathcal{O}$, we deduce that $I_n \to 0$ as $n\to\infty$. The proof is similar for J_n. □

Let us now prove the convergence result given by Theorem 3.3.

Proof of Theorem 3.3. The convergence of the approximate solutions for the sediment thickness toward the solution of problem (2.6) has already been proved in Proposition 4.2. Let us now show that the limits $(c^s_i, u_i)_{i=1,\dots,L}$ given by Proposition 5.2 satisfy the weak formulation of problem (2.7) in the sense of Definition 2.1.

Let i belong to $\{1,\dots,L\}$ and $\varphi \in \mathcal{A}$. Since $\varphi \in \mathcal{C}^\infty_c(\mathbb{R}^{d+2})$, there exists $T > 0$ such that, for all $t \ge T$, $\varphi(.,.,t) = 0$. Let $m_0 \in \mathbb{N}$ be such that $\Delta t_{m_0} < T$. For the sake of simplicity, we shall drop the subscript i.

For all $\kappa \in \mathcal{K}_m$, $m \in \mathbb{N}$, note that $\varphi(x_\kappa,.,.) \in W_T$. Applying (5.8) to the test function $\varphi(x_\kappa,.,.)$ and summing this equation over $\kappa \in \mathcal{K}_m$, we get, for any $m \ge m_0$,

$$\begin{aligned}
&\underbrace{\sum_{\kappa\in\mathcal{K}_m} |\kappa| \int_{\mathbb{R}_+}\int_0^T \left[\partial_t\varphi(x_\kappa,\xi,t) + \partial_t h_\kappa(t)\,\partial_\xi\varphi(x_\kappa,\xi,t)\right] u_\kappa(\xi,t)\,dt\,d\xi}_{(A_m)}\\
&\qquad + \underbrace{\sum_{\kappa\in\mathcal{K}_m} |\kappa| \int_{\mathbb{R}_+} u^0_\kappa(\xi)\varphi(x_\kappa,\xi,0)\,d\xi}_{(B_m)}\\
&\qquad + \underbrace{\sum_{\kappa\in\mathcal{K}_m} |\kappa| \int_0^T \partial_t h_\kappa(t) u_\kappa(0,t)\varphi(x_\kappa,0,t)\,dt}_{(C_m)} = 0.
\end{aligned}\tag{5.11}$$

In this equation, (A_m) is equal to

$$\int_\Omega\int_{\mathbb{R}_+}\int_0^T \left[\partial_t\varphi_{\mathcal{K}_m}(x,\xi,t) + \delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\,\partial_\xi\varphi_{\mathcal{K}_m}(x,\xi,t)\right] \bar{u}_{\mathcal{K}_m,\Delta t_m}(x,\xi,t)\,dt\,d\xi\,dx,$$

where $\varphi_{\mathcal{K}_m}(x,\xi,t) = \varphi(x_\kappa,\xi,t)$ for all $x \in \kappa$. Thanks to Proposition 4.2, the sequence of functions $(\delta_t h_{\mathcal{K}_m,\Delta t_m})$ converges strongly to $\partial_t h$ in $L^2(\Omega\times(0,T))$ as $m\to\infty$. Since $\varphi\in\mathcal{A}$, we deduce that the sequence $(\partial_\xi\varphi_{\mathcal{K}_m}\cdot\delta_t h_{\mathcal{K}_m,\Delta t_m})$ converges to $\partial_\xi\varphi\cdot\partial_t h$ in $L^1(\Omega\times\mathbb{R}_+^*\times\mathbb{R}_+^*)$. Since the sequence $(\bar{u}_{\mathcal{K}_m,\Delta t_m})$ converges to u in $L^\infty(\Omega\times\mathbb{R}_+^*\times\mathbb{R}_+^*)$ for the weak-$\star$ topology, we conclude that

$$(5.12)\quad (A_m)\to\int_\Omega\int_{\mathbb{R}_+}\int_{\mathbb{R}_+}\big[\partial_t\varphi(x,\xi,t)+\partial_t h(x,t)\,\partial_\xi\varphi(x,\xi,t)\big]u(x,\xi,t)\,dt\,d\xi\,dx$$
$$\text{as } m\to\infty.$$

Let us define $u^0_{\mathcal{K}_m}$ by $u^0_{\mathcal{K}_m}(x,\xi)=u^0_\kappa(\xi)$ for all $x\in\kappa$, $\kappa\in\mathcal{K}_m$, and $\xi\in\mathbb{R}_+^*$. From Hypothesis 1 on u^0, it results that $u^0_{\mathcal{K}_m}$ converges to u^0 in $L^1(\Omega\times(0,T))$ for all $T>0$, and consequently

$$(5.13)\qquad (B_m)\to\int_\Omega\int_{\mathbb{R}_+}u^0(x,\xi)\varphi(x,\xi,0)\,d\xi\,dx \text{ as } m\to\infty.$$

In (5.11), (C_m) is equal to

$$(C_m)=\int_\Omega\int_0^T\delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\bar{u}_{\mathcal{K}_m,\Delta t_m}(x,0,t)\varphi_{\mathcal{K}_m}(x,0,t)\,dt\,dx.$$

Let us introduce the following notation:

$$\begin{aligned}
\mathcal{P}^+_{\mathcal{K}_m} &= \{(x,t)\in\Omega\times(0,T)\,|\,\delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)>0\},\\
\mathcal{P}^-_{\mathcal{K}_m} &= \{(x,t)\in\Omega\times(0,T)\,|\,\delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\le 0\},\\
\mathcal{P}^+ &= \{(x,t)\in\Omega\times(0,T)\,|\,\partial_t h(x,t)>0\},\\
\mathcal{P}^- &= \{(x,t)\in\Omega\times(0,T)\,|\,\partial_t h(x,t)\le 0\}.
\end{aligned}$$

Noticing that $\mathcal{P}^+_{\mathcal{K}_m}=(\mathcal{P}^+\setminus(\mathcal{P}^+\cap\mathcal{P}^-_{\mathcal{K}_m}))\cup(\mathcal{P}^+_{\mathcal{K}_m}\cap\mathcal{P}^-)$ and $\mathcal{P}^-_{\mathcal{K}_m}=(\mathcal{P}^-\setminus(\mathcal{P}^-\cap\mathcal{P}^+_{\mathcal{K}_m}))\cup(\mathcal{P}^-_{\mathcal{K}_m}\cap\mathcal{P}^+)$, one has

$$\begin{aligned}
(C_m)=&\int_\Omega\int_0^T\delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\,c^s_{\mathcal{K}_m,\Delta t_m}(x,t)\,\varphi_{\mathcal{K}_m}(x,0,t)\\
&\qquad\cdot[\chi_{\mathcal{P}^+}-\chi_{\mathcal{P}^+\cap\mathcal{P}^-_{\mathcal{K}_m}}+\chi_{\mathcal{P}^+_{\mathcal{K}_m}\cap\mathcal{P}^-}]\,dt\,dx\\
&+\int_\Omega\int_0^T\delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\,\bar{u}_{\mathcal{K}_m,\Delta t_m}(x,0,t)\,\varphi_{\mathcal{K}_m}(x,0,t)\\
&\qquad\cdot[\chi_{\mathcal{P}^-}-\chi_{\mathcal{P}^-\cap\mathcal{P}^+_{\mathcal{K}_m}}+\chi_{\mathcal{P}^-_{\mathcal{K}_m}\cap\mathcal{P}^+}]\,dt\,dx.
\end{aligned}$$

Since the functions $c^s_{\mathcal{K}_m,\Delta t_m}(x,t)$, $\bar{u}_{\mathcal{K}_m,\Delta t_m}(x,0,t)$, and $\varphi_{\mathcal{K}_m}(x,0,t)$ are bounded on $\Omega\times(0,T)$ and $(\delta_t h_{\mathcal{K}_m,\Delta t_m})$ converges to $\partial_t h$ in $L^2(\Omega\times(0,T))$, Lemma 5.5 applied to the sequence $(\delta_t h_{\mathcal{K}_m,\Delta t_m})_{m\in\mathbb{N}}$ yields

$$\int_\Omega\int_0^T\delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\,c^s_{\mathcal{K}_m,\Delta t_m}(x,t)\,\varphi_{\mathcal{K}_m}(x,0,t)[-\chi_{\mathcal{P}^+\cap\mathcal{P}^-_{\mathcal{K}_m}}+\chi_{\mathcal{P}^+_{\mathcal{K}_m}\cap\mathcal{P}^-}]\,dt\,dx\to 0,$$

$$\int_\Omega\int_0^T\delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\,\bar{u}_{\mathcal{K}_m,\Delta t_m}(x,0,t)\varphi_{\mathcal{K}_m}(x,0,t)[-\chi_{\mathcal{P}^-\cap\mathcal{P}^+_{\mathcal{K}_m}}+\chi_{\mathcal{P}^-_{\mathcal{K}_m}\cap\mathcal{P}^+}]\,dt\,dx\to 0$$

as $m\to\infty$. Furthermore, $\varphi\in\mathcal{A}$, so that the sequence $(\varphi_{\mathcal{K}_m}(.,0,.)\,\delta_t h_{\mathcal{K}_m,\Delta t_m})$ converges to $\varphi(.,0,.)\,\partial_t h$ in $L^1(\Omega\times(0,T))$. As the sequence $(c^s_{\mathcal{K}_m,\Delta t_m})$ converges to

c^s in $L^\infty(\Omega \times \mathbb{R}_+^*)$ for the weak-$\star$ topology, we conclude that

$$\int_\Omega \int_0^T \delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t) c^s_{\mathcal{K}_m,\Delta t_m}(x,t) \varphi_{\mathcal{K}_m}(x,0,t)\, \chi_{\mathcal{P}_+}\, dt\, dx \to \int_\Omega \int_0^T \partial_t h(x,t) c^s(x,t) \varphi(x,0,t)\, \chi_{\mathcal{P}_+}\, dt\, dx \text{ as } m \to \infty.$$

On $\chi_{\mathcal{P}_-}$, by definition, one has $\varphi(x,0,t) = 0$. Since $\bar{u}_{\mathcal{K}_m,\Delta t_m}(x,0,t)$ is bounded and the sequence $(\varphi_{\mathcal{K}_m}(.,0,.)\, \delta_t h_{\mathcal{K}_m,\Delta t_m})$ converges to $\varphi(.,0,.)\, \partial_t h$ in $L^1(\Omega \times (0,T))$, we obtain

$$\int_\Omega \int_0^T \delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\, \bar{u}_{\mathcal{K}_m,\Delta t_m}(x,0,t)\, \varphi_{\mathcal{K}_m}(x,0,t)\, \chi_{\mathcal{P}_-}\, dt\, dx \to 0 \text{ as } m \to \infty,$$

and finally

$$(C_m) \to \int_\Omega \int_0^T \partial_t h(x,t) c^s(x,t) \varphi(x,0,t) dt\, dx = \int_\Omega \int_{\mathbb{R}_+} \partial_t h(x,t) c^s(x,t) \varphi(x,0,t)\, dt\, dx$$

as $m \to \infty$. Then (c_i^s, u_i) satisfy the first part (2.8) of the weak formulation.

Let $\varphi \in \mathcal{A}_0$. Since $\varphi \in \mathcal{C}_c^\infty(\mathbb{R}^{d+2})$, there exists $T > 0$ such that $\varphi(.,.,t) = 0$ for all $t \geq T$. Let $m_0 \in \mathbb{N}$ be such that $\Delta t_{m_0} < T$.

Multiplying the scheme (3.2) by $\varphi(x_\kappa, 0, t^{n+1})$ and summing over $\kappa \in \mathcal{K}_m$ and $n \in \{0, \dots, N_{\Delta t_m}\}$, one obtains, for any $m \geq m_0$,

$$\underbrace{\sum_{n=0}^{N_{\Delta t_m}} \sum_{\kappa \in \mathcal{K}_m} |\kappa| \Delta \mathcal{M}_\kappa^{n+1} \varphi(x_\kappa, 0, t^{n+1})}_{(1_m)}$$
$$+ \underbrace{\sum_{n=0}^{N_{\Delta t_m}} \Delta t_m \sum_{\kappa \in \mathcal{K}_m} \sum_{\kappa' \in \mathcal{K}_\kappa} c^{s,n+1}_{\kappa\kappa'} T_{\kappa\kappa'} (h_\kappa^{n+1} - h_{\kappa'}^{n+1}) \varphi(x_\kappa, 0, t^{n+1})}_{(2_m)}$$
$$\underbrace{- \sum_{n=0}^{N_{\Delta t_m}} \Delta t_m \sum_{\kappa \in \mathcal{K}_m} |\partial\kappa \cap \partial\Omega| \left(\tilde{c}_\kappa^{n+1} g_\kappa^{(+),n+1} - c_\kappa^{s,n+1} g_\kappa^{(-),n+1} \right) \varphi(x_\kappa, 0, t^{n+1})}_{(3_m)} = 0.$$

Since $\varphi(.,0,.) \in \mathcal{A}_0^s$, Proposition 5.3 with $\mathcal{K} = \mathcal{K}_m$ and $\Delta t = \Delta t_m$ states that (2_m)+(3_m) converges to

$$\begin{aligned} A &= \int_0^T \left(\int_\Omega c^s(x,t)\, \nabla h(x,t) \cdot \nabla \varphi(x,0,t)\, dx - \int_{\partial\Omega} \tilde{c}(x,t) g(x,t) \varphi(x,0,t) d\gamma(x) \right) dt \\ &= \int_{\mathbb{R}_+} \left(\int_\Omega c^s(x,t)\, \nabla h(x,t) \cdot \nabla \varphi(x,0,t)\, dx - \int_{\partial\Omega} \tilde{c}(x,t) g(x,t) \varphi(x,0,t) d\gamma(x) \right) dt, \end{aligned}$$

as $m \to \infty$. Let us now prove the convergence of

$$A'_m = -(1_m) = -\sum_{n=0}^{N_{\Delta t_m}} \sum_{\kappa \in \mathcal{K}_m} |\kappa| \Delta \mathcal{M}_\kappa^{n+1} \varphi(x_\kappa, 0, t^{n+1})$$

toward

$$B = \int_\Omega \int_{\mathbb{R}_+} \int_{\mathbb{R}_+} \left[\partial_t \varphi(x,\xi,t) + \partial_t h(x,t)\, \partial_\xi \varphi(x,\xi,t)\right] u(x,\xi,t)\, dt\, d\xi\, dx \\ + \int_\Omega \int_{\mathbb{R}_+} u^0(x,\xi)\varphi(x,\xi,0)\, d\xi\, dx$$

as $m \to \infty$. From (5.12) and (5.13), we have, for any $\varphi \in \mathcal{C}_c^\infty(\mathbb{R}^{d+2}) \supset \mathcal{A}_0$,

$$B'_m = \sum_{\kappa \in \mathcal{K}_m} |\kappa| \int_{\mathbb{R}_+} \int_0^T \left[\partial_t \varphi(x_\kappa,\xi,t) + \partial_t h_\kappa(t)\, \partial_\xi \varphi(x_\kappa,\xi,t)\right] u_\kappa(\xi,t)\, dt\, d\xi \\ + \sum_{\kappa \in \mathcal{K}_m} |\kappa| \int_{\mathbb{R}_+} u_\kappa^0(\xi)\varphi(x_\kappa,\xi,0)\, d\xi \to B \text{ as } m \to \infty,$$

and, from (5.11), $B'_m = -\sum_{\kappa\in\mathcal{K}_m} |\kappa| \int_0^T \partial_t h_\kappa(t) u_\kappa(0,t)\varphi(x_\kappa,0,t)\, dt$. Hence, it will suffice to show that $|A'_m - B'_m| \to 0$ as $m \to \infty$.

For given $\kappa \in \mathcal{K}_m$ and $n \in \{0,\dots,N_{\Delta t_m}\}$, let us recall that

$$\Delta\mathcal{M}_\kappa^{n+1} = \begin{cases} \int_{h_\kappa^n}^{h_\kappa^{n+1}} c_\kappa^{n+1}(z) dz & \text{if } h_\kappa^{n+1} \geq h_\kappa^n, \\ \int_{h_\kappa^n}^{h_\kappa^{n+1}} c_\kappa^n(z)\, dz & \text{if } h_\kappa^{n+1} < h_\kappa^n. \end{cases}$$

Considering the change of coordinates $z = h_\kappa(t)$ in these integrals, one can show that, in both the sedimentation ($h_\kappa^{n+1} \geq h_\kappa^n$) and erosion ($h_\kappa^{n+1} < h_\kappa^n$) cases, one has

$$\Delta\mathcal{M}_\kappa^{n+1} = \int_{t^n}^{t^{n+1}} c_\kappa(h_\kappa(t),t)\partial_t h_\kappa(t)\, dt = \int_{t^n}^{t^{n+1}} u_\kappa(0,t)\partial_t h_\kappa(t)\, dt.$$

Substituting this equality in the definition of A'_m leads to

$$B'_m - A'_m = \sum_{\kappa\in\mathcal{K}_m} |\kappa| \int_T^{t^{N_{\Delta t_m}+1}} \bar{u}_{\mathcal{K}_m,\Delta t_m}(x,0,t)\, \delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t)\varphi(x_\kappa,0,t) dt \\ - \sum_{\kappa\in\mathcal{K}_m} |\kappa| \sum_{n=0}^{N_{\Delta t_m}} \int_{t^n}^{t^{n+1}} \bar{u}_{\mathcal{K}_m,\Delta t_m}(x,0,t) \delta_t h_{\mathcal{K}_m,\Delta t_m}(x,t) [\varphi(x_\kappa,0,t^{n+1}) - \varphi(x_\kappa,0,t)]\, dt.$$

Thanks to the regularity of φ, there exists $C_1 > 0$, depending only on φ, such that $|\varphi(x_\kappa,0,t^{n+1}) - \varphi(x_\kappa,0,t)| \leq C_1\, \Delta t_m$ for all $t \in [t^n, t^{n+1}]$. Since the function $\delta_t h_{\mathcal{K}_m,\Delta t_m}$ is uniformly bounded in $L^2(\Omega \times (0, t^{N_{\Delta t_m}+1}))$, and $\bar{u}_{\mathcal{K}_m,\Delta t_m} \in [0,1]$, and $|t^{N_{\Delta t_m}+1} - T| < \Delta t_m$, the convergence of $|A'_m - B'_m|$ to 0 as $m \to \infty$ is obtained, which ends the proof of the theorem. □

6. Conclusion.

In this article, a fully implicit finite volume discretization of the multilithology stratigraphic model is considered in the simplified case for which the diffusion coefficients of all the lithologies are equal.

In such a case, the sediment thickness variable decouples from the other variables and satisfies a parabolic equation. A weak formulation has been defined for the remaining surface and basin concentration variables in order to cope with the difficulty to define the trace of the basin concentrations at the top of the basin. Then, the main result of this article is the convergence, up to a subsequence, of the discrete sediment thickness in $L^\infty(0,T;L^2(\Omega))$ and of the discrete concentrations in the L^∞ weak-$\star$ topology to a weak solution.

In particular, this proves the existence of at least one solution to the weak formulation for the coupled problem. The uniqueness of such a solution, and hence the full convergence of the discrete solutions, will be obtained in a forthcoming paper.

Appendix. Proof of Proposition 5.3.

To prove Proposition 5.3, the following weak-BV estimate will be used. It is an extension to the coupling of a parabolic and a hyperbolic equation of the result proved in [6] for the coupling of an elliptic and a hyperbolic equation in the case of a two phase Darcy flow.

LEMMA A.1. *Let us assume that Hypothesis* 1 *holds, and let* h *denote the solution of problem* (2.6). *Let* $i \in \{1,\dots,L\}$ $(\mathcal{K}, \Sigma_{int}, \mathcal{P})$ *be an admissible mesh of* Ω *in the sense of Definition* 3.1, $T > 0$, *and* $\Delta t \in (0,T)$. *Let* $\alpha > 0$ *be such that* $reg(\mathcal{K}) \leq \alpha$ *and* $\beta > 0$ *be such that* $\delta\mathcal{K} \leq \beta\sqrt{\Delta t}$. *Then, there exists* $H > 0$, *depending only on* T, Ω, $\|h\|_{W^{2,\infty}(\Omega\times(0,2T))}$, $\|g\|_{L^2(\partial\Omega\times\mathbb{R}_+)}$, β, *and* α, *such that the following inequality holds:*

$$\begin{aligned}(\text{A.1})\qquad &\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}\,|h_\kappa^{n+1} - h_{\kappa'}^{n+1}|\,|c_{i,\kappa}^{s,n+1} - c_{i,\kappa'}^{s,n+1}| \\ &\quad + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\,|c_{i,\kappa}^{s,n+1} - \tilde{c}_{i,\kappa}^{n+1}|\,g_\kappa^{(+),n+1} \leq \frac{H}{\sqrt{\delta\mathcal{K}}}.\end{aligned}$$

Proof. Let i belong to the set $\{1,\dots,L\}$. Again, the subscript i will be dropped in the proof, and c_i^s will be denoted by c. Multiplying (3.2) by c_κ^{n+1} and summing over $\kappa \in \mathcal{K}$ and $n \in \{0,\dots,N_{\Delta t}\}$ yield that

$$\begin{aligned}(\text{A.2})\qquad &\sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} |\kappa| c_\kappa^{*,n+1}\, c_\kappa^{n+1}(h_\kappa^{n+1} - h_\kappa^n) \\ &\quad + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c_{\kappa\kappa'}^{n+1}\, c_\kappa^{n+1}(h_\kappa^{n+1} - h_{\kappa'}^{n+1}) \\ &\quad - \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa\cap\partial\Omega|\, g_\kappa^{(+),n+1} \tilde{c}_\kappa^{n+1} c_\kappa^{n+1} \\ &\quad + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa\cap\partial\Omega|\, g_\kappa^{(-),n+1} (c_\kappa^{n+1})^2 = 0,\end{aligned}$$

where $c_\kappa^{*,n+1}$ is defined by $c_\kappa^{*,n+1}(h_\kappa^{n+1} - h_\kappa^n) = \Delta\mathcal{M}_\kappa^{n+1}$, such that $c_\kappa^{*,n+1} \in [0,1]$.

The upstream evaluation of the surface concentrations at the edges of the control volumes implies that, for all $\kappa \in \mathcal{K}$,

$$\begin{aligned}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c_{\kappa\kappa'}^{n+1}\, c_\kappa^{n+1}(h_\kappa^{n+1} - h_{\kappa'}^{n+1}) &= \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} (c_\kappa^{n+1})^2 (h_\kappa^{n+1} - h_{\kappa'}^{n+1})^+ \\ &\quad - \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c_{\kappa'}^{n+1}\, c_\kappa^{n+1}(h_\kappa^{n+1} - h_{\kappa'}^{n+1})^-.\end{aligned}$$

Therefore, since $(h_\kappa - h_{\kappa'})^+ = (h_{\kappa'} - h_\kappa)^-$, one has

$$\begin{aligned}&\sum_{\kappa\in\mathcal{K}} \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c_{\kappa\kappa'}^{n+1}\, c_\kappa^{n+1}(h_\kappa^{n+1} - h_{\kappa'}^{n+1}) \\ &\quad = \sum_{\kappa\in\mathcal{K}} \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}((c_\kappa^{n+1})^2 - c_{\kappa'}^{n+1}\, c_\kappa^{n+1})(h_\kappa^{n+1} - h_{\kappa'}^{n+1})^+.\end{aligned}$$

Then, using the equalities $(c_\kappa)^2 - c_\kappa\, c_{\kappa'} = \frac{1}{2}(c_\kappa - c_{\kappa'})^2 + \frac{1}{2}\big((c_\kappa)^2 - (c_{\kappa'})^2\big)$, $(h_\kappa - h_{\kappa'})^+ = (h_{\kappa'} - h_\kappa)^-$, and $(h_\kappa - h_{\kappa'}) = (h_\kappa - h_{\kappa'})^+ - (h_\kappa - h_{\kappa'})^-$ leads to the following successive equalities:

$$\begin{aligned}
&\sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c_{\kappa\kappa'}^{n+1}\, c_\kappa^{n+1}(h_\kappa^{n+1} - h_{\kappa'}^{n+1})\\
&\quad = \frac{1}{2}\sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}(c_\kappa^{n+1} - c_{\kappa'}^{n+1})^2(h_\kappa^{n+1} - h_{\kappa'}^{n+1})^+\\
&\quad +\frac{1}{2}\sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}(c_\kappa^{n+1})^2(h_\kappa^{n+1} - h_{\kappa'}^{n+1})^+\\
&\quad -\frac{1}{2}\sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}(c_{\kappa'}^{n+1})^2(h_\kappa^{n+1} - h_{\kappa'}^{n+1})^+\\
&\quad = \frac{1}{2}\sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}(c_\kappa^{n+1} - c_{\kappa'}^{n+1})^2(h_\kappa^{n+1} - h_{\kappa'}^{n+1})^+\\
&\quad +\frac{1}{2}\sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}(c_\kappa^{n+1})^2(h_\kappa^{n+1} - h_{\kappa'}^{n+1}).
\end{aligned}\tag{A.3}$$

Furthermore, summing (3.2) over $i \in \{1, \dots, L\}$, we obtain, for all $\kappa \in \mathcal{K}$ and $n \in \{0, \dots, N_{\Delta t}\}$,

$$|\kappa|(h_\kappa^{n+1} - h_\kappa^n) + \Delta t \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}(h_\kappa^{n+1} - h_{\kappa'}^{n+1}) - \Delta t\, |\partial\kappa \cap \partial\Omega|\, g_\kappa^{n+1} = 0. \tag{A.4}$$

Multiplying (A.4) by $(c_\kappa^{n+1})^2$ and summing over $\kappa \in \mathcal{K}$ gives in (A.3)

$$\begin{aligned}
&\sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c_{\kappa\kappa'}^{n+1}\, c_\kappa^{n+1}(h_\kappa^{n+1} - h_{\kappa'}^{n+1}) = -\frac{1}{2}\sum_{\kappa\in\mathcal{K}} |\kappa|(c_\kappa^{n+1})^2 \frac{h_\kappa^{n+1} - h_\kappa^n}{\Delta t}\\
&+\frac{1}{2}\sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\,(c_\kappa^{n+1})^2 g_\kappa^{n+1} + \frac{1}{2}\sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'}(c_\kappa^{n+1} - c_{\kappa'}^{n+1})^2(h_\kappa^{n+1} - h_{\kappa'}^{n+1})^+,
\end{aligned}$$

which finally results in the equality

$$\begin{aligned}
&\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}}\sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c_{\kappa\kappa'}^{n+1}\, c_\kappa^{n+1}(h_\kappa^{n+1} - h_{\kappa'}^{n+1})\\
&\qquad - \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1} \tilde{c}_\kappa^{n+1} c_\kappa^{n+1}\\
&\qquad + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(-),n+1} (c_\kappa^{n+1})^2\\
&\quad = \frac{1}{2}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}(c_\kappa^{n+1} - c_{\kappa'}^{n+1})^2 |h_\kappa^{n+1} - h_{\kappa'}^{n+1}|\\
&\qquad + \frac{1}{2}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1}(c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1})^2 - \frac{1}{2}\sum_{n=0}^{N_{\Delta t}}\sum_{\kappa\in\mathcal{K}} |\kappa|(c_\kappa^{n+1})^2(h_\kappa^{n+1} - h_\kappa^n)\\
&\qquad + \frac{1}{2}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} (|\partial\kappa \cap \partial\Omega|\, g_\kappa^{(-),n+1}(c_\kappa^{n+1})^2 - |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1}(\tilde{c}_\kappa^{n+1})^2).
\end{aligned}$$

Using this last result in (A.2), together with $g_\kappa^{(-),n+1} \geq 0$ for all $\kappa \in \mathcal{K}$ and $n \in \{0, \dots, N_{\Delta t}\}$, one obtains the estimate

$$\begin{aligned}
&\frac{1}{2}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}(c_\kappa^{n+1} - c_{\kappa'}^{n+1})^2 |h_\kappa^{n+1} - h_{\kappa'}^{n+1}| \\
&\quad + \frac{1}{2}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1} (c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1})^2 \\
&\quad \leq \frac{1}{2}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\kappa| \big[(c_\kappa^{n+1})^2 - 2\, c_\kappa^{*,n+1}\, c_\kappa^{n+1}\big] \frac{h_\kappa^{n+1} - h_\kappa^n}{\Delta t} \\
&\quad + \frac{1}{2}\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega| g_\kappa^{(+),n+1} (\tilde{c}_\kappa^{n+1})^2.
\end{aligned} \tag{A.5}$$

Noticing that, according to Corollary 1,

$$\begin{aligned}
&\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\kappa| \big[(c_\kappa^{n+1})^2 - 2\, c_\kappa^{*,n+1}\, c_\kappa^{n+1}\big] \frac{h_\kappa^{n+1} - h_\kappa^n}{\Delta t} \\
&\quad \leq C_1(T,\Omega) \left(\sum_{n=0}^{N_{\Delta t}} \Delta t \|\delta_t h_{\mathcal{K}}^n\|_{L^2(\Omega)}^2 \right)^{\frac{1}{2}} \leq C_1(T,\Omega) D_6
\end{aligned} \tag{A.6}$$

and

$$\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1}\, (\tilde{c}_\kappa^{n+1})^2 \leq C_2(\Omega, T)\, \|g^+\|_{L^2(\partial\Omega\times\mathbb{R}_+)}, \tag{A.7}$$

we deduce from (A.5), (A.6), and (A.7) the estimate

$$\begin{aligned}
&\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}(c_\kappa^{n+1} - c_{\kappa'}^{n+1})^2 |h_\kappa^{n+1} - h_{\kappa'}^{n+1}| \\
&\quad + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1} (c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1})^2 \leq C_1 \sqrt{D_6} + C_2\, \|g^+\|_{L^2(\partial\Omega\times\mathbb{R}_+)}.
\end{aligned}$$

Finally, the Cauchy–Schwarz inequality yields

$$\begin{aligned}
&\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'} |c_\kappa^{n+1} - c_{\kappa'}^{n+1}| |h_\kappa^{n+1} - h_{\kappa'}^{n+1}| \\
&\quad + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega| |c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1}|\, g_\kappa^{(+),n+1} \\
&\quad \leq \left(\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}(c_\kappa^{n+1} - c_{\kappa'}^{n+1})^2 |h_\kappa^{n+1} - h_{\kappa'}^{n+1}| \right. \\
&\quad \left. + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega| (c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1})^2 g_\kappa^{(+),n+1} \right)^{\frac{1}{2}} \\
&\quad \left(\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'} |h_\kappa^{n+1} - h_{\kappa'}^{n+1}| + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1} \right)^{\frac{1}{2}}.
\end{aligned}$$

The term

$$\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'} |h_{\kappa}^{n+1} - h_{\kappa'}^{n+1}| \leq \left(\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'} \right)^{\frac{1}{2}} \left(\sum_{n=0}^{N_{\Delta t}} \Delta t |h_{\mathcal{K}}^{n+1}|_{1,\mathcal{K}}^2 \right)^{\frac{1}{2}}$$

is estimated by Corollary 1 and the following bound from (3.1):

$$\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'} \leq \left(\sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} |\sigma|\, d(\kappa,\kappa') \right) \frac{2T\,\alpha^2}{\delta\mathcal{K}^2} \leq \frac{2Td\,\alpha^2\,|\Omega|}{\delta\mathcal{K}^2}. \tag{A.8}$$

We conclude from estimates similar to (A.7) that the inequality (A.1) holds. □

Proof of Proposition 5.3. Let i belong to the set $\{1,\dots,L\}$, and let $(\mathcal{K},\Sigma_{int},\mathcal{P},\Delta t)$ be an admissible discretization of $\Omega\times\mathbb{R}_+^*$ with $\Delta t < T$. For all $\kappa\in\mathcal{K}$, $x\in\partial\kappa\cap\partial\Omega$, $t\in\ (t^n,t^{n+1}]$, $n\geq 0$, let us define

$$\tilde{c}_{i,\mathcal{K},\Delta t}(x,t) = \tilde{c}_{i,\kappa}^{n+1}.$$

Throughout this proof we shall now drop the subscript i and use the simplified notation $c_i^s = c$.

Let us define the auxiliary expression E_3 by

$$E_3 = \sum_{n=0}^{N_{\Delta t}} \int_{t^n}^{t^{n+1}} \left(\int_{\Omega} c_{\mathcal{K},\Delta t}(x,t)\,\nabla h(x,t)\cdot\nabla\varphi(x,t^{n+1})\,dx \right. \\ \left. - \int_{\partial\Omega} \tilde{c}_{\mathcal{K},\Delta t}(x,t)\,g(x,t)\,\varphi(x,t^{n+1})\,d\gamma(x) \right) dt.$$

From the L^∞ weak-$\star$ convergence of $c_{\mathcal{K},\Delta t}$ to c and $\tilde{c}_{\mathcal{K},\Delta t}$ to $\tilde{c}$ as Δt and $\delta\mathcal{K}\to 0$, and their boundedness, it results that

$$E_3 \to \int_0^T \left(\int_{\Omega} c(x,t)\,\nabla h(x,t)\cdot\nabla\varphi(x,t)dx - \int_{\partial\Omega} \tilde{c}(x,t)g(x,t)\varphi(x,t)d\gamma(x) \right) dt$$

as $\Delta t\to 0$.

Multiplying (2.6) by $\varphi(x,t^{n+1})$ and integrating it over the time interval (t^n,t^{n+1}) and cell κ yield

$$\int_{t^n}^{t^{n+1}} \int_{\kappa} \partial_t h(x,t)\,\varphi(x,t^{n+1})\,dx\,dt - \int_{t^n}^{t^{n+1}} \int_{\kappa} \Delta h(x,t)\,\varphi(x,t^{n+1})\,dx\,dt = 0.$$

Since $\varphi\in\mathcal{C}_c^\infty(\mathbb{R}^{d+1})$, one obtains

$$\int_{t^n}^{t^{n+1}} \int_{\kappa} \nabla h(x,t)\cdot\nabla\varphi(x,t^{n+1})\,dx\,dt = -\int_{t^n}^{t^{n+1}} \int_{\kappa} \partial_t h(x,t)\,\varphi(x,t^{n+1})\,dx\,dt \\ + \int_{t^n}^{t^{n+1}} \int_{\partial\kappa} \nabla h(x,t)\cdot\vec{n}_\kappa\,\varphi(x,t^{n+1})d\gamma(x)\,dt,$$

where $\vec{n}_\kappa$ is the normal unit vector to $\partial\kappa$ outward to κ. Thus, one has

$$\begin{aligned} E_3 \quad &= \sum_{n=0}^{N_{\Delta t}} \sum_{\substack{\sigma\in\Sigma_{int} \\ \sigma=\kappa|\kappa'}} (c_\kappa^{n+1} - c_{\kappa'}^{n+1}) \int_{t^n}^{t^{n+1}} \int_\sigma \nabla h(x,t)\cdot \vec{n}_{\kappa\kappa'}\, \varphi(x,t^{n+1})\, d\gamma(x)\, dt \\ &+ \sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} \int_{t^n}^{t^{n+1}} \int_{\partial\kappa\cap\partial\Omega} (c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1})\, g(x,t)\, \varphi(x,t^{n+1})\, d\gamma(x)\, dt \\ &- \sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} \int_{t^n}^{t^{n+1}} \int_\kappa c_\kappa^{n+1}\, \partial_t h(x,t)\, \varphi(x,t^{n+1})\, dx\, dt. \end{aligned}$$

Defining the second auxiliary expression E_2 by

$$\begin{aligned} E_2 \quad &= -\sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} |\kappa| c_\kappa^{n+1} (h_\kappa^{n+1} - h_\kappa^n)\, \varphi(x_\kappa, t^{n+1}) \\ &+ \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int} \\ \sigma=\kappa|\kappa'}} (c_\kappa^{n+1} - c_{\kappa'}^{n+1}) T_{\kappa\kappa'} (h_{\kappa'}^{n+1} - h_\kappa^{n+1}) \frac{1}{|\sigma|} \int_\sigma \varphi(x,t^{n+1})\, d\gamma(x) \\ &+ \sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} \int_{t^n}^{t^{n+1}} \int_{\partial\kappa\cap\partial\Omega} (c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1})\, g(x,t)\, \varphi(x,t^{n+1})\, d\gamma(x)\, dt, \end{aligned}$$

we have

$$\begin{aligned} E_3 - E_2 = &-\sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} c_\kappa^{n+1} \int_{t^n}^{t^{n+1}} \int_\kappa \Big[\partial_t h(x,t)\, \varphi(x,t^{n+1}) \\ &- \frac{(h_\kappa^{n+1} - h_\kappa^n)}{\Delta t}\, \varphi(x_\kappa, t^{n+1}) \Big]\, dx\, dt + \sum_{n=0}^{N_{\Delta t}} \sum_{\substack{\sigma\in\Sigma_{int} \\ \sigma=\kappa|\kappa'}} (c_\kappa^{n+1} - c_{\kappa'}^{n+1}) \\ &\cdot \int_{t^n}^{t^{n+1}} \int_\sigma \left[\nabla h(x,t)\cdot \vec{n}_{\kappa\kappa'} - \frac{h_{\kappa'}^{n+1} - h_\kappa^{n+1}}{d(\kappa,\kappa')} \right] \varphi(x,t^{n+1}) d\gamma(x)\, dt. \end{aligned}$$

Multiplying (2.6) by $\varphi(x_\kappa, t^{n+1})$ and c_κ^{n+1} and integrating it over the time interval (t^n, t^{n+1}) and cell κ yield

$$\text{(A.9)} \qquad \begin{aligned} &\sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} \int_{t^n}^{t^{n+1}} \int_\kappa c_\kappa^{n+1}\, \partial_t h(x,t)\, \varphi(x_\kappa, t^{n+1})\, dx\, dt \\ &\quad - \sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} \int_{t^n}^{t^{n+1}} \int_{\partial\kappa} c_\kappa^{n+1}\, \nabla h(x,t)\cdot \vec{n}_\kappa\, \varphi(x_\kappa, t^{n+1})\, d\gamma(x)\, dt = 0. \end{aligned}$$

Similarly, multiplying (4.1) by c_κ^{n+1} and $\varphi(x_\kappa, t^{n+1})$ and summing the result over $\kappa\in\mathcal{K}$ and $n\in\{0,\dots,N_{\Delta t}\}$, we obtain

$$\text{(A.10)} \qquad \begin{aligned} &\sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} |\kappa| c_\kappa^{n+1} (h_\kappa^{n+1} - h_\kappa^n) \varphi(x_\kappa, t^{n+1}) \\ &\quad + \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} \sum_{\kappa'\in\mathcal{K}_\kappa} T_{\kappa\kappa'} c_\kappa^{n+1} (h_\kappa^{n+1} - h_{\kappa'}^{n+1}) \varphi(x_\kappa, t^{n+1}) \\ &\quad - \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa\cap\partial\Omega|\, g_\kappa^{n+1} c_\kappa^{n+1} \varphi(x_\kappa, t^{n+1}) = 0. \end{aligned}$$

Then, $E_3 - E_2 +$ (A.9) $-$ (A.10) yields the equality

$$E_3 - E_2 = \sum_{n=0}^{N_{\Delta t}} \sum_{\kappa \in \mathcal{K}} c_\kappa^{n+1} \int_{t^n}^{t^{n+1}} \int_\kappa \partial_t h(x,t) \left[\varphi(x_\kappa, t^{n+1}) - \varphi(x, t^{n+1})\right] dx\, dt$$
$$+ \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa \in \mathcal{K}} c_\kappa^{n+1} \sum_{\sigma \in \Sigma_\kappa \cap \Sigma_{\kappa'}} \int_\sigma \left[\frac{1}{\Delta t} \int_{t^n}^{t^{n+1}} \nabla h(x,t) \cdot \vec{n}_{\kappa\kappa'}\, dt - \frac{h_{\kappa'}^{n+1} - h_\kappa^{n+1}}{d(\kappa, \kappa')}\right]$$
$$\cdot \left[\varphi(x, t^{n+1}) - \varphi(x_\kappa, t^{n+1})\right] d\gamma(x).$$

Since φ is regular, there exists $C_1 > 0$ depending only on φ such that, for all $\kappa \in \mathcal{K}$ and $x \in \kappa$,

$$|\varphi(x, t^{n+1}) - \varphi(x_\kappa, t^{n+1})| \le C_1\, \delta\mathcal{K}. \tag{A.11}$$

Thanks to the regularity of h, there exists $C_2 > 0$ depending only on $\|h\|_{L^\infty(0,2T;W^{2,\infty}(\Omega))}$, such that, for all $\kappa \in \mathcal{K}$, $\sigma \in \Sigma_\kappa$, $x \in \sigma$, and $t \in (0, 2T)$,

$$\left| \frac{1}{|\sigma|} \int_\sigma \nabla h(u,t) \cdot \vec{n}_\kappa\, d\gamma(u) - \nabla h(x,t) \cdot \vec{n}_\kappa \right| \le C_2\, \delta\mathcal{K}.$$

Thus, the following estimate is derived:

$$|E_3 - E_2| \le C_3\, \delta\mathcal{K}\, \|\partial_t h\|_{L^\infty(\Omega \times [0,2T])} + 2C_1\, \delta\mathcal{K} \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma \in \Sigma_{int} \\ \sigma = \kappa|\kappa'}} \Bigg(|\sigma| C_2 \delta\mathcal{K}$$
$$+ \left| T_{\kappa\kappa'}(h_{\kappa'}^{n+1} - h_\kappa^{n+1}) - \frac{1}{\Delta t} \int_{t^n}^{t^{n+1}} \int_\sigma \nabla h(u,t) \cdot \vec{n}_{\kappa\kappa'}\, d\gamma(u)\, dt \right| \Bigg).$$

The last term in this estimate is bounded using Cauchy–Schwarz inequality as follows:

$$\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma \in \Sigma_{int} \\ \sigma = \kappa|\kappa'}} \left| T_{\kappa\kappa'}(h_{\kappa'}^{n+1} - h_\kappa^{n+1}) - \frac{1}{\Delta t} \int_{t^n}^{t^{n+1}} \int_\sigma \nabla h(u,t) \cdot \vec{n}_{\kappa\kappa'}\, d\gamma(u)\, dt \right|$$
$$\le \left[\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma \in \Sigma_{int} \\ \sigma = \kappa|\kappa'}} T_{\kappa\kappa'} \right]^{\frac{1}{2}} \left[\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma \in \Sigma_{int} \\ \sigma = \kappa|\kappa'}} d(\kappa, \kappa')\, |\sigma| \right.$$
$$\left. \left(\frac{h_{\kappa'}^{n+1} - h_\kappa^{n+1}}{d(\kappa, \kappa')} - \frac{1}{\Delta t} \frac{1}{|\sigma|} \int_{t^n}^{t^{n+1}} \int_\sigma \nabla h(u,t) \cdot \vec{n}_{\kappa\kappa'}\, d\gamma(u)\, dt \right)^2 \right]^{\frac{1}{2}}.$$

Finally, using (A.8), (4.5), and the bound $\sum_{\sigma \in \Sigma_{int}} |\sigma| \le \frac{d\, \alpha\, |\Omega|}{\delta\mathcal{K}}$, we obtain that

$$E_3 - E_2 \to 0 \text{ as } \Delta t \to 0.$$

It remains only to prove that $E_2 - E \to 0$ as $\Delta t \to 0$. Removing (A.10) from E yields

$$\begin{aligned} E = &\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} \sum_{\kappa'\in\mathcal{K}_\kappa} \underbrace{T_{\kappa\kappa'}(c_{\kappa\kappa'}^{n+1} - c_\kappa^{n+1})\,(h_\kappa^{n+1} - h_{\kappa'}^{n+1})\,\varphi(x_\kappa, t^{n+1})}_{(F)} \\ &+ \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1}(c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1})\,\varphi(x_\kappa, t^{n+1}) \\ &- \sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} |\kappa| c_\kappa^{n+1}(h_\kappa^{n+1} - h_\kappa^n)\,\varphi(x_\kappa, t^{n+1}). \end{aligned}$$

Thanks to the upstream evaluation of the concentrations at the edges, (F) vanishes if $h_\kappa^{n+1} \geq h_{\kappa'}^{n+1}$. In the opposite case, it is equal to $T_{\kappa\kappa'}(c_{k'}^{n+1} - c_\kappa^{n+1})\,(h_\kappa^{n+1} - h_{\kappa'}^{n+1})\,\varphi(x_\kappa, t^{n+1})$, and thus

$$\begin{aligned} E = &\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}(c_{\kappa'}^{n+1} - c_\kappa^{n+1})\,(h_\kappa^{n+1} - h_{\kappa'}^{n+1})\,\varphi(x_{\kappa\kappa'}, t^{n+1}) \\ &+ \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega|\, g_\kappa^{(+),n+1}(c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1})\,\varphi(x_\kappa, t^{n+1}) \\ &- \sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} |\kappa| c_\kappa^{n+1}(h_\kappa^{n+1} - h_\kappa^n)\,\varphi(x_\kappa, t^{n+1}), \end{aligned}$$

with

$$x_{\kappa\kappa'} = \begin{cases} x_\kappa & \text{if } h_\kappa \leq h_{\kappa'}, \\ x_{\kappa'} & \text{otherwise.} \end{cases}$$

Therefore, $E_2 - E$ writes

$$\begin{aligned} E_2 - E = &\sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'}(c_{\kappa'}^{n+1} - c_\kappa^{n+1})\,(h_\kappa^{n+1} - h_{\kappa'}^{n+1}) \\ &\left[\frac{1}{|\sigma|}\int_\sigma \varphi(x, t^{n+1})\,d\gamma(x) - \varphi(x_{\kappa\kappa'}, t^{n+1})\right] + \sum_{n=0}^{N_{\Delta t}} \sum_{\kappa\in\mathcal{K}} (c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1}) \\ &\int_{t^n}^{t^{n+1}} \int_{\partial\kappa\cap\partial\Omega} \Big[g(x,t)\,\varphi(x, t^{n+1}) - g_\kappa^{(+),n+1}\,\varphi(x_\kappa, t^{n+1})\Big] d\gamma(x)\,dt. \end{aligned}$$

Thanks to the regularity of φ, there exists $C_3 > 0$ depending only on φ such that

$$\left|\frac{1}{|\sigma|}\int_\sigma \varphi(x, t^{n+1})\,d\gamma(x) - \varphi(x_{\kappa\kappa'}, t^{n+1})\right| \leq C_3\,\delta\mathcal{K}. \tag{A.12}$$

Furthermore, since $\varphi \in \mathcal{A}_0^s$, one has

$$\int_{\partial\kappa\cap\partial\Omega} g(x, t^{n+1})\,\varphi(x, t^{n+1}) d\gamma(x) = \int_{\partial\kappa\cap\partial\Omega} g^+(x, t^{n+1})\,\varphi(x, t^{n+1}) d\gamma(x).$$

Finally, inequalities (A.11) and (A.12) and the definition of $g_\kappa^{(+),n+1}$ give the estimate

$$|E_2 - E| \leq C_3\,\delta\mathcal{K} \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\substack{\sigma\in\Sigma_{int}\\ \sigma=\kappa|\kappa'}} T_{\kappa\kappa'} |c_{\kappa'}^{n+1} - c_\kappa^{n+1}|\,|h_\kappa^{n+1} - h_{\kappa'}^{n+1}|$$

$$+ C_1\,\delta\mathcal{K} \sum_{n=0}^{N_{\Delta t}} \Delta t \sum_{\kappa\in\mathcal{K}} |\partial\kappa \cap \partial\Omega||c_\kappa^{n+1} - \tilde{c}_\kappa^{n+1}| g_\kappa^{(+),n+1}.$$

It results from Lemma A.1 that $|E_2 - E| \leq C_4\,\delta\mathcal{K}\,\frac{H}{\sqrt{\delta\mathcal{K}}}$, which ends the proof. □

DOMAIN DECOMPOSITION SPECTRAL APPROXIMATIONS FOR AN EIGENVALUE PROBLEM WITH A PIECEWISE CONSTANT COEFFICIENT*

M. S. MIN† AND D. GOTTLIEB†

Abstract. Consider a model eigenvalue problem with a piecewise constant coefficient. We split the domain at the discontinuity of the coefficient function and define the multidomain variational formulation for the eigenproblem. The discrete multidomain variational formulations are defined for Legendre–Galerkin and Legendre-collocation methods. The spectral rate of convergence of the approximate eigensolutions is proven for the Legendre–Galerkin method. The minmax principle is used for the convergence analysis.

The Legendre-collocation, Chebyshev-collocation, Legendre-collocation penalty, and Chebyshev-collocation penalty methods are also defined by using the multidomain approach, and their numerical results applied to the eigenproblem are demonstrated. The spectral convergence for the eigenvalues and eigenfunctions is confirmed for all the multidomain spectral techniques presented here.

Key words. discontinuous problems, multidomain variational formulation, minmax principle, domain decomposition, Legendre–Galerkin method, Legendre-collocation method, Legendre-collocation penalty method, Chebyshev-collocation method, Chebyshev-collocation penalty method

1. Introduction.

We consider Maxwell's equations governing the electromagnetic wave propagation in periodically structured dielectric arrays cast as an eigenvalue problem. The dielectric function corresponding to the periodic arrays is represented by a periodically piecewise constant function.

The electromagnetic wave propagation in a periodic dielectric medium was first studied by Rayleigh in 1887, identifying the fact that there exists a narrow frequency gap prohibiting light propagation through one-dimensional periodic twinning planes. A hundred years later, the concepts of omnidirectional forbidden frequency gaps in two and three dimensions were introduced, leading to many subsequent developments in the fabrication, theory, and application of electromagnetic wave propagation to optical fibers [14], [3], [15], [23]. Computation has become a primary tool for carrying out frequency gap calculation for various periodic dielectric structures.

Numerous numerical studies have focused on predicting the forbidden eigenfrequencies accurately by solving Maxwell's equations in the frequency domain [1], [6], [17], [16]. However, numerical analysis has been lacking, and high-order methods have not been applied to such problems yet.

In [18], Fourier–Galerkin and Fourier-collocation methods are applied to a single domain, and their theoretical and numerical convergence studies for the eigensolutions are demonstrated. As a result of the presence of the discontinuity in the coefficient function in a single domain, the solution is only in H_p^2, and the rates of convergence of the eigensolutions by Fourier methods are between *second order* and *third order*.

In this paper, we apply domain decomposition techniques for spectral methods. We obtain spectrally accurate eigensolutions by using multidomain Legendre and Chebyshev approximations. Implementations in two dimensions are extended in [19].

In the multidomain approach, we split the domain into subdomains in order for the discontinuous coefficient function to be smooth in each subdomain, so that the solutions are infinitely smooth in each subdomain. Then we reformulate the problem in multidomain variational form. The finite-dimensional space for each subdomain is defined by the Legendre polynomials of finite degrees, and boundary and interface conditions are imposed strongly for the Legendre–Galerkin, Legendre-collocation, and Chebyshev-collocation methods and weakly for the Legendre-collocation penalty and Chebyshev-collocation penalty methods.

We restrict the penalty parameter to a specific one in this paper and leave the study for the proper range of the parameters to future work. Convergence analysis for the eigenvalues and eigenfunctions is carried out for the Legendre–Galerkin method. For the collocation cases, two different methods are introduced by choosing two different test spaces for the same trial space.

The numerical results for Legendre–Galerkin, Legendre-collocation, Legendre-collocation penalty, Chebyshev-collocation, and Chebyshev-collocation penalty methods presented here show a spectral rate of convergence for the eigensolutions. In terms of accuracy, the results of the Legendre–Galerkin and the Legendre-collocation methods, which use the same space for the test and trial spaces, are comparable and more accurate than the results of the Legendre-collocation penalty and the Legendre-collocation methods, which use different spaces for the trial and test space. The penalty method is favorable because of the simplicity in implementation for the same magnitude of accuracy.

We organize this paper as follows. In section 2 we reformulate the eigenproblem into a multidomain variational formulation. We recall the minmax principle to characterize the lth eigenvalue by minimizing the maximum of the Rayleigh quotient over l-dimensional subspaces. In section 3 we present the finite-dimensional space used for the approximate solution. The procedure to find the basis for the finite approximant space is shown. In section 4 we define the multidomain variational formulation for the Legendre–Galerkin method. We provide a convergence analysis for the eigenvalues and eigenfunctions. The theory is confirmed by numerical results. In section 5 two different Legendre-collocation methods are defined, based on the test space chosen. The numerical results for eigensolutions by those methods show a spectral rate of convergence. In section 6, we discuss the Legendre-collocation penalty method by defining a multidomain variational formulation with the penalty approach [7] for the boundary and interface constraints. Chebyshev-collocation approximations are also tested and their numerical results presented. Section 7 discusses the asymptotic behavior of the largest approximate eigenvalues. Section 8 gives a brief conclusion.

2. The multidomain variational formulation.

The source-free Maxwell equations describing the transverse-magnetic mode in one-dimensional periodic media can be cast as the following generalized eigenvalue problem: find λ and u in $H_p^2(-\pi,\pi)$ (where p stands for periodic), such that

$$-u'' = \lambda \epsilon(x) u, \tag{2.1}$$

where $\epsilon(x) = 1$ in $(-\pi, 0)$ and $\epsilon(x) = \omega^2$ in $[0, \pi)$, $\omega \neq 1$. The function u represents the electric field pattern, and the dielectric function $\epsilon(x)$ describes a unit cell from a multilayer structure with 2π-periodicity. This problem was considered in [18].

Recall the variational formulation of (2.1) from [18]: Find λ and $u \in H^1_p(-\pi,\pi)$ such that

$$a(u,v) = \lambda(u,v) \quad \text{for } v \in H^1_p(-\pi,\pi), \tag{2.2}$$

where

$$a(u,v) = \int_{-\pi}^{\pi} u'v'dx \quad \text{and} \quad (u,v) = \int_{-\pi}^{\pi} u\,v\,\epsilon\,dx. \tag{2.3}$$

Since $a(u,v)$ is Hermitian, the eigenvalue can be characterized by the following two statements from [9], [18], [20], [21].

THEOREM 2.1. *Let λ_l denote the eigenvalues of* (2.1)*, and let S_l be any l-dimensional subspace of $H^1_p(\Omega)$. Then, for $\lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_l \cdots$,*

$$\lambda_l = \min_{S_l \subset H^1_p(\Omega)} \max_{v \in S_l} \frac{a(v,v)}{(v,v)}. \tag{2.4}$$

We also recall the following lemma from [9] and [18].

LEMMA 2.2. *Let λ_i be arranged in ascending order, and define*

$$E_{i,j} = span\{u_i, \ldots, u_j\}, \tag{2.5}$$

where u_i is the eigenfunction corresponding to the eigenvalue λ_i. Then

$$\lambda_l = \max_{v \in E_{k,l}} \frac{a(v,v)}{(v,v)}, \quad k \leq l, \tag{2.6}$$

$$\lambda_l = \min_{v \in E_{l,m}} \frac{a(v,v)}{(v,v)}, \quad l \leq m. \tag{2.7}$$

It is natural here to consider splitting the domain. Denote the domain by $\Omega = (-\pi,\pi)$ and divide it into two subdomains, say, $\Omega_- = (-\pi,0)$ and $\Omega_+ = (0,\pi)$, so that $\epsilon(x)$ is smooth in each subdomain. Denote the restrictions by $u_- = u\big|_{\Omega_-}$ and $u_+ = u\big|_{\Omega_+}$, which are distributional solutions to the given equation (2.1). Integrate by parts in Ω_1 and Ω_2, respectively, and define the following bilinear forms:

$$a(u,v)_- = \int_{-\pi}^{0} u'_-v'_-dx + u'_-v_-\Big|_0^{-\pi}, \qquad (u,v)_- = \int_{-\pi}^{0} u_-v_-\epsilon_-dx, \tag{2.8}$$

$$a(u,v)_+ = \int_{0}^{\pi} u'_+v'_+dx + u'_+v_+\Big|_\pi^{0}, \qquad (u,v)_+ = \int_{0}^{\pi} u_+v_+\epsilon_+dx. \tag{2.9}$$

Remark 1. It is clear to see that, for $u, v \in H^1_p(\Omega)$,

$$a(u,v) = a(u,v)_- + a(u,v)_+, \tag{2.10}$$

$$(u,v) = (u,v)_- + (u,v)_+. \tag{2.11}$$

3. Finite-dimensional subspace. In this section we present the finite-dimensional space used in our approximation. Denote by $\mathcal{P}_N = \text{span}\{L_k(\xi), \xi \in [-1,1]\}$ the space of Legendre polynomials of degree at most N. We define the local variables x_- and x_+ by

$$x_-(\xi) = \frac{\pi}{2}(\xi - 1) \quad \text{and} \quad x_+(\xi) = \frac{\pi}{2}(\xi + 1). \tag{3.1}$$

The approximation space V_{2N-2} is the $(2N-2)$-dimensional space defined by

$$V_{2N-2} = \{\phi \in H_p^2(\Omega) : \phi_-(x_-(\xi)) \in \mathcal{P}_N \ \text{ and } \ \phi_+(x_+(\xi)) \in \mathcal{P}_N\}. \tag{3.2}$$

To apply the Galerkin approximation, we need to find a basis of V_{2N-2}. This is done as follows.

Let ϕ in V_{2N-2} be expressed by

$$\phi_- = \phi\big|_{x_-(\xi)} = \sum_{k=0}^{N} c_k L_k(\xi), \tag{3.3}$$

$$\phi_+ = \phi\big|_{x_+(\xi)} = \sum_{k=0}^{N} d_k L_k(\xi). \tag{3.4}$$

Since ϕ and ϕ' are continuous at $x = 0$ and 2π-periodic, we apply the following conditions:

$$\phi_-(0) = \phi_+(0), \ \ \phi_-(-\pi) = \phi_+(\pi), \tag{3.5}$$

$$\phi'_-(0) = \phi'_+(0), \ \ \phi'_-(-\pi) = \phi'_+(\pi). \tag{3.6}$$

Letting $\alpha_k = L'_k(1) = \frac{k(k+1)}{2}$, and applying the boundary and the interface conditions (3.5) and (3.6), we obtain the following relations for the coefficients:

$$c_N = \sum_{k=1}^{\frac{N-2}{2}} \left[-\frac{(\alpha_N + \alpha_{2k})}{2\alpha_N} c_{2k} + \frac{(\alpha_N - \alpha_{2k})}{2\alpha_N} d_{2k} \right], \tag{3.7}$$

$$d_N = \sum_{k=1}^{\frac{N-2}{2}} \left[\ \frac{(\alpha_N - \alpha_{2k})}{2\alpha_N} c_{2k} - \frac{(\alpha_N + \alpha_{2k})}{2\alpha_N} d_{2k} \right], \tag{3.8}$$

$$c_{N-1} = \sum_{k=0}^{\frac{N-4}{2}} \left[-\frac{(\alpha_{N-1} + \alpha_{2k+1})}{2\alpha_{N-1}} c_{2k+1} - \frac{(\alpha_{N-1} - \alpha_{2k+1})}{2\alpha_{N-1}} d_{2k+1} \right], \tag{3.9}$$

$$d_{N-1} = \sum_{k=0}^{\frac{N-4}{2}} \left[-\frac{(\alpha_{N-1} - \alpha_{2k+1})}{2\alpha_{N-1}} c_{2k+1} - \frac{(\alpha_{N-1} + \alpha_{2k+1})}{2\alpha_{N-1}} d_{2k+1} \right]. \tag{3.10}$$

For simplicity, here we use the following notation:

$$\beta_k = \frac{\alpha_{N_k} + \alpha_k}{2\alpha_{N_k}} \qquad \text{and} \qquad \gamma_k = (-1)^k \frac{\alpha_{N_k} - \alpha_k}{2\alpha_{N_k}}, \tag{3.11}$$

$$N_k = \begin{cases} \ \ N & \text{for even } k, \\ N-1 & \text{for odd } k. \end{cases} \tag{3.12}$$

Then, substituting (3.7)–(3.10) into (3.3)–(3.4), we get

$$\phi_- = \phi\big|_{x_-(\xi)} = \sum_{k=0}^{N-2} c_k \{L_k(\xi) - \beta_k L_{N_k}(\xi)\} + \sum_{k=0}^{N-2} d_k \gamma_k L_{N_k}(\xi), \tag{3.13}$$

$$\phi_+ = \phi\big|_{x_+(\xi)} = \sum_{k=0}^{N-2} c_k \gamma_k L_{N_k}(\xi) + \sum_{k=0}^{N-2} d_k \{L_k(\xi) - \beta_k L_{N_k}(\xi)\}. \tag{3.14}$$

Thus, one can easily see the basis for V_{2N-2} given by

$$\{\phi_k, \psi_k\} \quad \text{for } 0 \le k \le N-2, \tag{3.15}$$

where the basis functions are defined by

$$(\phi_k)_- = L_k(\xi) - \beta_k L_{N_k}(\xi), \quad (\phi_k)_+ = \gamma_k L_{N_k}(\xi), \tag{3.16}$$

$$(\psi_k)_- = \gamma_k L_{N_k}(\xi), \quad (\psi_k)_+ = L_k(\xi) - \beta_k L_{N_k}(\xi). \tag{3.17}$$

Now, we are ready to construct the multidomain Legendre–Galerkin scheme in the following section.

4. Legendre–Galerkin method.

Find λ^N, $u^N \in V_{2N-2}$ such that

$$a(u^N, v^N) = \lambda^N (u^N, v^N) \quad \text{for all } v^N \in V_{2N-2}. \tag{4.1}$$

From the relations (2.10) and (2.11), the two inner products can be expressed by

$$a(u^N, v^N) = \int_{-\pi}^{0} (u_-^N)'(v_-^N)' dx + \int_0^{\pi} (u_+^N)'(v_+^N)' dx = \int_{-\pi}^{\pi} (u^N)'(v^N)' dx, \tag{4.2}$$

$$(u^N, v^N) = \int_{-\pi}^{0} (u_-^N)(v_-^N)(\epsilon_-) dx + \int_0^{\pi} (u_+^N)(v_+^N)(\epsilon_+) dx = \int_{-\pi}^{\pi} u^N v^N \epsilon\, dx. \tag{4.3}$$

4.1. Numerical scheme and its results.

The approximate eigenfunction $u^N \in V_{2N-2}$ can be expanded by the basis found in section 3 with an unknown set of $(2N-2)$ coefficients:

$$u^N = \sum_{k=0}^{N-2} [(\hat{u}_\phi^N)_k \phi_k + (\hat{u}_\psi^N)_k \psi_k]. \tag{4.4}$$

Take $v^N = \phi_n$ for $0 \le n \le N-2$, and substitute u^N in the form (4.4) to the variational formulation (4.2)–(4.3). We obtain the Legendre–Galerkin scheme as follows:

$$K \hat{\mathbf{u}}^N = \lambda^N M \hat{\mathbf{u}}^N. \tag{4.5}$$

The following are defined for the notation in scheme (4.5):

$$K = \begin{bmatrix} K_-^- & K_+^- \\ K_-^+ & K_+^+ \end{bmatrix}, \quad M = \begin{bmatrix} M_-^- & M_+^- \\ M_-^+ & M_+^+ \end{bmatrix}, \quad \text{and} \quad \hat{\mathbf{u}}^N = \begin{bmatrix} \hat{u}_\phi^N \\ \hat{u}_\psi^N \end{bmatrix}, \tag{4.6}$$

where

$$(K_-^-)_{k,n} = \int_{-\pi}^{\pi} (\phi_k)'(\phi_n)' dx, \quad (K_+^-)_{k,n} = \int_{-\pi}^{\pi} (\phi_k)'(\psi_n)' dx,$$
$$(K_-^+)_{k,n} = \int_{-\pi}^{\pi} (\psi_k)'(\phi_n)' dx, \quad (K_+^+)_{k,n} = \int_{-\pi}^{\pi} (\psi_k)'(\psi_n)' dx,$$

$$(M_-^-)_{k,n} = \int_{-\pi}^{\pi} \phi_k \phi_n \epsilon(x) dx, \quad (M_+^-)_{k,n} = \int_{-\pi}^{\pi} \phi_k \psi_n \epsilon(x) dx,$$
$$(M_-^+)_{k,n} = \int_{-\pi}^{\pi} \psi_k \phi_n \epsilon(x) dx, \quad (M_+^+)_{k,n} = \int_{-\pi}^{\pi} \psi_k \psi_n \epsilon(x) dx,$$

Table 1

Relative errors of eigenvalues for $\omega = 2$ and the discrete l_2-errors of $u_i - u_i^N$ for the multidomain Legendre–Galerkin method.

λ_i	N	$(\lambda_i^N - \lambda_i)/\lambda_i$	$\|u_i - u_i^N\|$
0.369875	4	2.94(-03)	2.61(-03)
	8	7.04(-10)	4.38(-07)
	16	6.15(-15)	1.03(-15)

1.937181	4	3.28(-01)	1.05(-01)
	8	1.45(-04)	4.71(-04)
	16	6.07(-15)	2.31(-10)
	32	2.64(-14)	8.45(-15)
	64	2.84(-13)	8.09(-14)

and

$$\hat{u}_\phi^N = [(\hat{u}_\phi^N)_0, (\hat{u}_\phi^N)_1, \ldots, (\hat{u}_\phi^N)_{N-2}]^T \quad \text{and} \quad \hat{u}_\psi^N = [(\hat{u}_\psi^N)_0, (\hat{u}_\psi^N)_1, \ldots, (\hat{u}_\psi^N)_{N-2}]^T.$$

Now, we solve the generalized matrix eigenproblem (4.5) numerically and obtain the approximate $l(\leq 2N-2)$th eigenvalues, λ_l^N, and the set of orthogonal vectors $\hat{\mathbf{u}}^N$, which approximates the lth eigenfunction u_l as the coefficients in the expansion of the basis of V_{2N-2}. In Table 1, the relative errors for $\lambda_l^N - \lambda_l$ and the discrete l_2-errors of $u_l - u_l^N$ as N increases are provided for the first few eigenvalues in an ascending order and the associated eigenfunctions. The numerical results demonstrate that the errors decay exponentially as N increases.

4.2. Error estimates for eigenvalues and eigenfunctions. We show the error estimates for the approximate eigenvalues and eigenfunctions for the multidomain Legendre–Galerkin method.

We first treat the approximate eigenvalues. Let $P_N u$ be defined by

$$P_N u = \sum_{k=0}^{N-2} [(\hat{u}_\phi)_k \phi_k + (\hat{u}_\psi)_k \psi_k], \tag{4.7}$$

where the expansion coefficients $(\hat{u}_\phi)_k$ and $(\hat{u}_\psi)_k$ will be defined later in this section.

From the minmax principle [9], [21], we can characterize the eigenvalue for the multidomain Legendre–Galerkin procedure by

$$\lambda_l^N = \min_{S_l \subset V_{2N-2}} \max_{v \in S_l} \frac{a(v,v)}{(v,v)}. \tag{4.8}$$

Lemma 4.1. *Let λ_l^N be the approximation to λ_l as obtained by the Legendre–Galerkin procedure* (4.5)*, and let $P_N u$ be defined as in* (4.7)*. Then*

$$\lambda_l \leq \lambda_l^N \leq \lambda_l \max_{v\in E_{1,l}} \frac{a(P_N v, P_N v)}{a(v,v)} \max_{v\in E_{1,l}} \frac{(v,v)}{(P_N v, P_N v)}. \tag{4.9}$$

Proof. Since V_{2N-2} is a subspace of $H_p^1(\Omega)$, it is true that $\lambda_l \leq \lambda_l^N$. Now, let $PE_{1,l}$ be spanned by $P_N u_1, \ldots, P_N u_l$. For simplicity, we denote $Pu = P_N u$. Clearly $PE_{1,l}$ is the l-dimensional subspace of V_{2N-2}. Using the minmax principle, we have

$$\begin{aligned}\lambda_l^N &\leq \max_{v\in PE_{1,l}} \frac{a(v,v)}{(v,v)}\\ &= \max_{v\in E_{1,l}} \frac{a(Pv,Pv)}{(Pv,Pv)}\\ &= \max_{v\in E_{1,l}} \frac{a(v,v)}{(v,v)}\frac{a(Pv,Pv)}{a(v,v)}\frac{(v,v)}{(Pv,Pv)}.\end{aligned}$$

From Lemma 2.2, the proof follows. □

Lemma 4.2. *For $u_{i=1,\ldots,l} \in H_p^1(\Omega)$, where $(u_i)_- \in H^m(\Omega_-)$ and $(u_i)_+ \in H^m(\Omega_+)$,*

$$\max_{v\in E_{1,l}} \frac{(v,v)}{(Pv,Pv)} \leq 1 + C(l)N^{-m}, \tag{4.10}$$

where the constant $C(l)$ is independent of N.

Proof. We follow the procedure in [18]. For $v = \sum_{i=1}^l \mu_i u_i$ in $E_{1,l}$, we have

$$\begin{aligned}\frac{(v,v)-(Pv,Pv)}{(v,v)} &\leq \frac{2|(v, v-Pv)|}{(v,v)}\\ &\leq \frac{2\sum_{i,j=1}^l |\mu_i||\mu_j||(u_i - Pu_i, u_j)|}{\sum_{i=1}^l |\mu_i|^2}\\ &= 2l \max_{i,j=1,\ldots,l} |(u_i - Pu_i, u_j)|.\end{aligned}$$

For the last term above, we have

$$|(u_i - Pu_i, u_j)| \leq |(u_i - Pu_i, u_j)_-| + |(u_i - Pu_i, u_j)_+|. \tag{4.11}$$

Now consider an eigenfunction $u = u_i$ and its projection Pu onto the space V_{2N-2}. Since

$$Pu_- = \sum_{k=0}^{N-2} \left[(\hat{u}_\phi)_k(\phi_k)_- + (\hat{u}_\psi)_k(\psi_k)_-\right], \tag{4.12}$$

$$Pu_+ = \sum_{k=0}^{N-2} \left[(\hat{u}_\phi)_k(\phi_k)_+ + (\hat{u}_\psi)_k(\psi_k)_+\right], \tag{4.13}$$

we can rewrite them in terms of Legendre polynomials as follows:

$$Pu_- = \sum_{k=0}^{N-2} (\hat{u}_\phi)_k L_k + c_{N-1}L_{N-1} + c_N L_N, \tag{4.14}$$

$$Pu_+ = \sum_{k=0}^{N-2} (\hat{u}_\psi)_k L_k + d_{N-1}L_{N-1} + d_N L_N, \tag{4.15}$$

where

$$c_{N-1} = \sum_{k=0}^{\frac{N-4}{2}} \left[-\beta_{2k+1}(\hat{u}_\phi)_{2k+1} + \gamma_{2k+1}(\hat{u}_\psi)_{2k+1}\right],$$

$$c_N = \sum_{k=1}^{\frac{N-2}{2}} \left[-\beta_{2k}(\hat{u}_\phi)_{2k} + \gamma_{2k}(\hat{u}_\psi)_{2k}\right],$$

$$d_{N-1} = \sum_{k=0}^{\frac{N-4}{2}} \left[\gamma_{2k+1}(\hat{u}_\phi)_{2k+1} - \beta_{2k+1}(\hat{u}_\psi)_{2k+1}\right],$$

$$d_N = \sum_{k=1}^{\frac{N-2}{2}} \left[\gamma_{2k}(\hat{u}_\phi)_{2k} - \beta_{2k}(\hat{u}_\psi)_{2k}\right].$$

Now we identify

$$(\hat{u}_\phi)_k = \frac{2k+1}{2}\int_{-1}^{1} u_-(x_-(\xi))L_k(\xi)d\xi, \tag{4.16}$$

$$(\hat{u}_\psi)_k = \frac{2k+1}{2}\int_{-1}^{1} u_+(x_+(\xi))L_k(\xi)d\xi, \tag{4.17}$$

which are exactly the Legendre coefficients for u_- and u_+, respectively. For clarity, we replace the notation $(\hat{u}_\phi)_k$ by $(\hat{u}_-)_k$, and similarly $(\hat{u}_\psi)_k$ by $(\hat{u}_+)_k$. Then, considering an eigenfunction u_i, the expansion coefficients of Pu_i are denoted by $(\hat{u}_{i_-})_k$ and $(\hat{u}_{i_+})_k$. Then we have

$$\begin{aligned}
&|(u_i - Pu_i, u_j)_-| \\
&= \left| \left(\sum_{k\geq N-1}^{\infty} (\hat{u}_{i_-})_k L_k - c_{N-1}L_{N-1} - c_N L_N, \sum_{n=0}^{\infty} (\hat{u}_{j_-})_n L_n \right)_- \right| \\
&\leq \frac{\pi}{2} \sum_{k\geq N-1}^{\infty} |(\hat{u}_{i_-})_k||(\hat{u}_{j_-})_k| \int_{-1}^{1} L_k^2 d\xi \\
&+ \frac{\pi}{2}|c_{N-1}||(\hat{u}_{j_-})_{N-1}| \int_{-1}^{1} L_{N-1}^2 d\xi + \frac{\pi}{2}|c_N||(\hat{u}_{j_-})_N| \int_{-1}^{1} L_N^2 d\xi = RHS(1).
\end{aligned}$$

We examine the two terms $|c_{N-1}|$ and $|c_N|$. From the Cauchy–Schwarz inequality, we have

$$|c_{N-1}| \leq \left\{ \sum_{k=0}^{\frac{N-4}{2}} (|\beta_{2k+1}|^2 + |\gamma_{2k+1}|^2) \right\}^{1/2} \left\{ \sum_{k=0}^{\frac{N-4}{2}} (|(\hat{u}_{i_-})_{2k+1}|^2 + |(\hat{u}_{i_+})_{2k+1}|^2) \right\}^{1/2},$$

$$|c_N| \leq \left\{ \sum_{k=1}^{\frac{N-2}{2}} (|\beta_{2k}|^2 + |\gamma_{2k}|^2) \right\}^{1/2} \left\{ \sum_{k=1}^{\frac{N-2}{2}} (|(\hat{u}_{i_-})_{2k}|^2 + |(\hat{u}_{i_+})_{2k}|^2) \right\}^{1/2}.$$

Since $|\beta_k|$, $|\gamma_k| < 1$, and $|(\hat{u}_{j_-})_k|$, $|(\hat{u}_{j_+})_k|$ decay like $O(k^{-m})$ in [4] and [5], it is clear that $|c_{N-1}|$ and $|c_N|$ are bounded by $O(N)$. Since $\int_{-1}^{1} L_k^2(\xi)d\xi = \frac{2}{2k+1}$, the second term of $RHS(1)$ which is the leading term decays like $O(N^{-m})$. Therefore we have

$$|(u_i - Pu_i, u_j)_-| \leq CN^{-m}. \tag{4.18}$$

Similarly, we get

$$|(u_i - Pu_i, u_j)_+| \leq CN^{-m}. \tag{4.19}$$

This completes the proof. □

LEMMA 4.3. *For $u_{i=1,\dots,l} \in H^1_p(\Omega)$, where $(u_i)_- \in H^m(\Omega_-)$ and $(u_i)_+ \in H^m(\Omega_+)$,*

$$\max_{v \in E1,l} \frac{a(Pv,Pv)}{a(v,v)} \leq 1 + C(l)N^{-m}, \tag{4.20}$$

where the constant $C(l)$ is independent of N.

Proof. Since

$$\frac{a(Pv,Pv)}{a(v,v)} = 1 - \frac{a(v,v) - a(Pv,Pv)}{a(v,v)}, \tag{4.21}$$

we examine the convergency of the last term of (4.21). Following the similar procedure as in Lemma 4.2, we obtain

$$\begin{aligned} |a(u_i - Pu_i, u_j)_-| &= \left| a\left(\sum_{k \geq N-1}^{\infty} (\hat{u}_{i_-})_k L_k - c_{N-1}L_{N-1} - c_N L_N, \sum_{n=0}^{\infty} (\hat{u}_{j_-})_n L_n \right)_- \right| \\ &\leq \frac{\pi}{2} \sum_{k \geq N-1}^{\infty} \sum_{n=0}^{\infty} |(\hat{u}_{i_-})_k||(\hat{u}_{j_-})_k| \int_{-1}^{1} L'_k L'_n d\xi \\ &+ \frac{\pi}{2} |c_{N-1}||(\hat{u}_{j_-})_{N-1}| \sum_{n=0}^{\infty} \int_{-1}^{1} L'_{N-1} L'_n d\xi \\ &+ \frac{\pi}{2} |c_N||(\hat{u}_{j_-})_N| \sum_{n=0}^{\infty} \int_{-1}^{1} L'_N L'_n d\xi = RHS(2). \end{aligned}$$

Since the leading term of $RHS(2)$ decays like $O(N^{-m})$, we have

$$|a(u_i - Pu_i, u_j)_-| \leq CN^{-m}. \tag{4.22}$$

Similarly, we get

$$|a(u_i - Pu_i, u_j)_+| \leq CN^{-m}. \tag{4.23}$$

This completes the proof. □

As consequences of Lemmas 4.2 and 4.3, we have the following theorems.

THEOREM 4.4. *For $u_{i=1,\dots,l} \in H^1_p(\Omega)$, where $(u_i)_- \in H^m(\Omega_-)$ and $(u_i)_+ \in H^m(\Omega_+)$, let λ^N_l be the lth eigenvalue obtained by the multidomain Legendre–Galerkin approximation from (4.1) to the eigenvalue λ_l. Then*

$$|\lambda^N_l - \lambda_l| \leq C(l)N^{-m}, \tag{4.24}$$

where $C(l)$ is independent of N.

For the approximate eigenvectors, we can state the following.

THEOREM 4.5. *For $u_{i=1,\dots,l} \in H^1_p(\Omega)$, where $(u_i)_- \in H^m(\Omega_-)$ and $(u_i)_+ \in H^m(\Omega_+)$, let u_l^N be the lth eigenfunction of the multidomain Legendre–Galerkin approximation* (4.1) *to the eigenfunction u_l. Then*

$$||u_l - u_l^N|| \le C(l)N^{-m}, \tag{4.25}$$

where $C(l)$ is independent of N.

The proof follows the same way as in [21].

5. Legendre-collocation methods. The Legendre–Gauss–Lobatto points ξ_i are defined by

$$\xi_0 = -1,\ \ \xi_N = 1,\ \ \xi_i (i = 1, \dots, N-1) \text{ zeros of } L'_N, \tag{5.1}$$

and the Legendre–Gauss–Lobatto weights are

$$w_i = \frac{2}{N(N+1)} \frac{1}{[L_N(\xi_i)]^2}. \tag{5.2}$$

Denoting

$$(u_-)_i = u\big|_{(x_-)_i} \qquad \text{for } (x_-)_i = \frac{\pi}{2}(\xi_i - 1), \tag{5.3}$$

$$(u_+)_i = u\big|_{(x_+)_i} \qquad \text{for } (x_+)_i = \frac{\pi}{2}(\xi_i + 1), \tag{5.4}$$

we define two discrete bilinear forms that approximate $a(u,v)_-$ and $a(u,v)_+$:

$$a(u,v)_{h-} = \sum_{i=0}^{N} (u_-)'_i (v_-)'_i w_i + (u_-)'_0 (v_-)_0 - (u_-)'_N (v_-)_N, \tag{5.5}$$

$$a(u,v)_{h+} = \sum_{i=0}^{N} (u_+)'_i (v_+)'_i w_i + (u_+)'_0 (v_+)_0 - (u_+)'_N (v_+)_N. \tag{5.6}$$

To approximate $(u,v)_-$ and $(u,v)_+$, define

$$(u,v)_{h-} = \sum_{i=0}^{N} (u_-)_i (v_-)_i (\epsilon_-)_i w_i, \tag{5.7}$$

$$(u,v)_{h+} = \sum_{i=0}^{N} (u_+)_i (v_+)_i (\epsilon_+)_i w_i. \tag{5.8}$$

It is natural to define the following discrete bilinear forms approximating the continuous bilinear forms $a(u,v)$ and (u,v):

$$a(u,v)_h = a(u,v)_{h-} + a(u,v)_{h+}, \tag{5.9}$$

$$(u,v)_h = (u,v)_{h-} + (u,v)_{h+}. \tag{5.10}$$

Now, we state the multidomain discrete variational formulation of (2.2): Find λ^c and u^c in V_{2N-2} such that

$$a(u^c, v)_h = \lambda^c (u^c, v)_h \qquad \text{for } \ v \in V, \tag{5.11}$$

where V is a suitable space that will be specified later. In the following subsections, we introduce two different Legendre-collocation methods by taking the space V differently.

5.1. Legendre-collocation method 1. Our first Legendre-collocation method takes the space V_{2N-2} as a test space. Find λ^c and u^c in V_{2N-2} such that

$$a(u^c, v^c)_h = \lambda^c (u^c, v^c)_h \text{ for } v^c \in V_{2N-2}. \tag{5.12}$$

To construct the scheme, we expand

$$(u_-^c)_i = \sum_{j=0}^{N} (u_-^c)_j l_j(\xi_i), \tag{5.13}$$

$$(u_+^c)_i = \sum_{j=0}^{N} (u_+^c)_j l_j(\xi_i), \tag{5.14}$$

where the Lagrange interpolation polynomials of degree N based on the Legendre–Gauss–Lobatto points [8], [10] are

$$l_j(\xi) = -\frac{1}{N(N+1)} \frac{(1-\xi^2)L_N'(\xi)}{(\xi-\xi_j)L_N(\xi_j)}. \tag{5.15}$$

Take $v^c = \phi_n(x)(0 \le n \le N-2)$, which is the basis for V_{2N-2}, and substitute u_-^c, u_+^c, and v^c in (5.5) and (5.6). Applying the continuity and the periodicity for u^c, that is, $(u_-^c)_0 = (u_+^c)_N$ and $(u_-^c)_N = (u_+^c)_0$, we get

$$\begin{aligned} a(u^c, v^c)_h = {} & (u_-^c)_0 \left(\sum_{i=0}^{N} [D_{i0} (\phi_{n_-})_i' w_0 + D_{iN} (\phi_{n_-})_i' w_N] \right) \\ & + (u_+^c)_0 \left(\sum_{i=0}^{N} [D_{i0} (\phi_{n_+})_i' w_0 + D_{iN} (\phi_{n_+})_i' w_N] \right) \\ & + \sum_{j=1}^{N-1} (u_-^c)_j \sum_{i=0}^{N} D_{ij} (\phi_{n_-})_i' w_i + \sum_{j=1}^{N-1} (u_+^c)_j \sum_{i=0}^{N} D_{ij} (\phi_{n_+})_i' w_i, \end{aligned}$$

where $D_{ij} = l_j'(\xi_i)$ is the differentiation matrix of Lagrange polynomials based on Legendre–Gauss–Lobatto points [10], [13]. Similarly, we have

$$\begin{aligned} (u^c, v^c)_h = {} & (u_-^c)_0 [(\phi_{0_-})_0 (\epsilon_-)_0 w_0 + (\phi_{0_+})_N (\epsilon_+)_N w_N] \\ & + (u_+^c)_0 [(\phi_{0_+})_0 (\epsilon_+)_0 w_0 + (\phi_{0_-})_N (\epsilon_-)_N w_N] \\ & + \sum_{j=1}^{N-1} (u_-^c)_j (\phi_{n_-})_j (\epsilon_-)_j w_j + \sum_{j=1}^{N-1} (u_+^c)_j (\phi_{n_+})_j (\epsilon_+)_j w_j. \end{aligned}$$

Applying the same procedure for $v^c = \psi_n(x)(0 \le n \le N-2)$, we have a system of $2N-2$ equations with the unknown vector

$$\mathbf{u}^c = [(u_-^c)_0, (u_-^c)_1, \ldots, (u_-^c)_{N-1}, (u_+^c)_0, (u_+^c)_1, \ldots, (u_+^c)_{N-1}]^T.$$

From the remaining boundary and the interface conditions, that is, $(u_-^c)_0' = (u_+^c)_N'$ and $(u_-^c)_N' = (u_+^c)_0'$, we get two more equations:

$$(u_-^c)_0 [D_{0N} - D_{N0}] + \sum_{j=1}^{N-1} (u_-^c)_j D_{jN} + (u_+^c)_0 [D_{NN} - D_{00}] - \sum_{j=1}^{N-1} (u_+^c)_j D_{j0} = 0,$$

$$(u_-^c)_0 [D_{0N} - D_{N0}] + \sum_{j=1}^{N-1} (u_-^c)_j D_{j0} + (u_+^c)_0 [D_{NN} - D_{00}] - \sum_{j=1}^{N-1} (u_+^c)_j D_{jN} = 0.$$

Table 2

Domain decomposition Legendre-collocation methods (LC1 = method 1, LC2 = method 2) for the relative errors of eigenvalues for $\omega = 2$ and the l_2-discrete errors of eigenfunctions.

Methods		LC1		LC2	
λ_i	N	$(\lambda_i^c - \lambda_i)/\lambda_i$	$\|u_i - u_i^c\|$	$(\lambda_i^{cc} - \lambda_i)/\lambda_i$	$\|u_i - u_i^{cc}\|$

	64	-2.68(-13)	1.24(-13)	1.85(-12)	3.32(-13)

Finally, we can represent the Legendre-collocation (method 1) scheme (5.11) in matrix form:

$$K\mathbf{u}^c = \lambda^c M\mathbf{u}^c, \tag{5.16}$$

where the dimension of the matrices K and M is $2N \times 2N$.

The numerical results are presented in Table 2 for the first few eigenvalues in ascending order and the corresponding eigenfunctions, showing that the relative errors for eigenvalues and l_2-errors of the eigenfunctions decay exponentially as N increases.

5.2. Legendre-collocation method 2.

Let us first define the $(N-1)$-dimensional space

$$\bar{\mathcal{L}}_{N-1} = \mathrm{span}\{l_j(\xi) | 1 \leq j \leq N-1, \ \ \xi \in [-1,1]\}, \tag{5.17}$$

where the Lagrange interpolation polynomials of degree N based on the Legendre–Gauss–Lobatto points are

$$l_j(\xi) = -\frac{1}{N(N+1)} \frac{(1-\xi^2)L_N'(\xi)}{(\xi - \xi_j)L_N(\xi_j)}. \tag{5.18}$$

Then we define

$$W_{2N-2} = \{\varphi \in C_p^0(\Omega) | \varphi_-(x_-(\xi)) \in \bar{\mathcal{L}}_{N-1} \ \text{ and } \ \varphi_+(x_+(\xi)) \in \bar{\mathcal{L}}_{N-1}\}, \tag{5.19}$$

the basis of which is given by $\{\varphi_n, \ \zeta_n\}_{n=1}^{N-1}$, where

$$\varphi_n = \begin{cases} l_n(\xi) & \text{in } [-\pi, 0], \\ 0 & \text{otherwise} \end{cases} \quad \text{and} \quad \zeta_n = \begin{cases} 0 & \text{in } [-\pi, 0], \\ l_n(\xi) & \text{otherwise.} \end{cases}$$

The multidomain discrete variational formulation of (2.2) for this method is to find λ^{cc} and u^{cc} in V_{2N-2} such that

$$a(u^{cc}, w^c)_h = \lambda^{cc}(u^{cc}, w^c)_h \text{ for } w^c \in W_{2N-2}. \tag{5.20}$$

Setting

$$(u_-^{cc})_i = \sum_{j=0}^{N} (u_-^{cc})_j l_j(\xi_i),$$
$$(u_+^{cc})_i = \sum_{j=0}^{N} (u_+^{cc})_j l_j(\xi_i)$$

and plugging them into (5.20) with $w^c = \varphi_n(x)$, $\zeta_n(x)$ $(1 \le n \le N-1)$, we get

$$K\mathbf{u}^{cc} = \lambda^{cc} M\mathbf{u}^{cc}, \tag{5.21}$$

where, denoting the second derivative matrix of Lagrange interpolation polynomials of degree N based on Legendre–Gauss–Lobatto points by D^2, the entries of $(2N \times 2N)$ matrices K and M are expressed by

$$K_{nj} = \begin{cases} D^2_{nj} \begin{cases} 1 \le n \le N-1, & 0 \le j \le N, \\ N+1 \le n \le 2N, & N \le j \le 2N, \end{cases} \\ 0 \quad \text{otherwise}, \end{cases} \tag{5.22}$$

and

$$M_{nj} = \operatorname{diag}\{(\epsilon_-)_1, \ldots, (\epsilon_-)_{N-1}, (\epsilon_+)_1, \ldots, (\epsilon_+)_{N-1}\}.$$

Additionally, two more equations are incorporated into the first and Nth rows of the matrices K and M, which are from the boundary and interface constraints:

$$(u_-^{cc})_0[D_{0N} - D_{N0}] + \sum_{j=1}^{N-1} (u_-^{cc})_j D_{jN} + (u_+^{cc})_0[D_{NN} - D_{00}] - \sum_{j=1}^{N-1} (u_+^{cc})_j D_{j0} = 0,$$
$$(u_-^{cc})_0[D_{0N} - D_{N0}] + \sum_{j=1}^{N-1} (u_-^{cc})_j D_{j0} + (u_+^{cc})_0[D_{NN} - D_{00}] - \sum_{j=1}^{N-1} (u_+^{cc})_j D_{jN} = 0,$$

where D is defined as in section 5.1.

Solving (5.21) numerically, one obtains the eigenvalues λ_l^{cc} $(l \le 2N)$ and the associated eigenvector

$$\mathbf{u}^{cc} = [(u_-^{cc})_0, (u_-^{cc})_1, \ldots, (u_-^{cc})_{N-1}, (u_+^{cc})_0, (u_+^{cc})_1, \ldots, (u_+^{cc})_{N-1}]^T.$$

The numerical results are presented in Table 2 for the first few eigenvalues in ascending order and the corresponding eigenfunctions, showing the exponential rate of convergence. Simply replacing the set of points and weights by the Chebyshev–Gauss–Lobatto points and weights, one can construct the multidomain Chebyshev-collocation method, the results of which are provided in Table 3.

TABLE 3

Relative errors of eigenvalues $\omega = 2$ and the l_2-discrete errors of eigenfunctions for multidomain Chebyshev-collocation method 2.

λ_i	N	$(\lambda_i^{cc} - \lambda_i)/\lambda_i$	$\|u_i - u_i^{cc}\|$

	64	-8.99(-13)	4.72(-13)

6. Legendre-collocation penalty method. In this section, the notation used in section 4 represents the same definition. Let $\mathcal{L}_{N+1}$ be the $(N+1)$-dimensional space of Legendre–Lagrange interpolation polynomials of degree N defined by

$$\mathcal{L}_{N+1} = \text{span}\{l_j(\xi) | 0 \le j \le N, \quad \xi \in [-1, 1]\}, \tag{6.1}$$

where

$$l_j(\xi) = -\frac{1}{N(N+1)} \frac{(1-\xi^2) L_N'(\xi)}{(\xi - \xi_j) L_N(\xi_j)}. \tag{6.2}$$

Let Y_{2N+2} be the $(2N+2)$-dimensional space of piecewise continuous interpolation polynomials defined as

$$Y_{2N+2} = \{\eta \in L^2(\Omega) | \eta_-(x_-(\xi)) \in \mathcal{L}_{N+1} \text{ and } \quad \eta_+(x_+(\xi)) \in \mathcal{L}_{N+1}\},$$

the basis of which is given by

$$\{\eta_n, \varsigma_n\} \quad \text{for} \quad 0 \le n \le N, \tag{6.3}$$

where

$$\eta_n = \begin{cases} l_n(\xi) & \text{in } [-\pi, 0], \\ 0 & \text{otherwise} \end{cases} \quad \text{and} \quad \varsigma_n = \begin{cases} 0 & \text{in } (-\pi, 0), \\ l_n(\xi) & \text{otherwise.} \end{cases}$$

Now, we define the discrete bilinear form approximating $a(u, v)$ with penalty boundary constraints:

$$\begin{aligned} a(u, v)_\tau = {} & a(u, v)_{h_-} + a(u, v)_{h_+} \\ & + \tau_1\{(u_+)_N - (u_-)_0\} \\ & + \tau_2\{(u_+)_0 - (u_-)_N\} \\ & + \tau_3\{(u_+)'_N - (u_-)'_0\} \\ & + \tau_4\{(u_-)'_N - (u_+)'_0\}, \end{aligned}$$

where τ_i $(1 \le i \le 4)$ are suitable constants depending on N, to be chosen later.

Now, we state the multidomain discrete variational formulation of (2.2) by penalty approach. Find λ^τ and u^τ in Y_{2N+2} such that

$$a(u^\tau, v^\tau)_\tau = \lambda^\tau (u^\tau, v^\tau)_h \ \text{ for } v^\tau \in Y_{2N+2}. \tag{6.4}$$

To construct the scheme, we expand

$$(u^\tau_-)_i = \sum_{j=0}^{N} (u^\tau_-)_j l_j(\xi_i), \tag{6.5}$$

$$(u^\tau_+)_i = \sum_{j=0}^{N} (u^\tau_+)_j l_j(\xi_i). \tag{6.6}$$

Take $v^\tau = \eta_n(x)$ and $v^\tau = \varsigma_n(x)$, and choose $\tau_1 = \tau_2 = \sigma_1^\tau$ and $\tau_3 = \tau_4 = \sigma_2^\tau$. Then we define the following matrix K, whose dimensions are $2N + 2$:

$$K = \begin{bmatrix} D^2 & O \\ O & D^2 \end{bmatrix}, \tag{6.7}$$

where the $(N + 1) \times (N + 1)$ matrix D^2 is the second derivative matrix of Lagrange interpolation polynomials based on Legendre–Gauss–Lobatto points. Also, defining the matrices

$$M = \operatorname{diag}\{(\epsilon_-)_0, \ldots, (\epsilon_-)_N, (\epsilon_+)_0, \ldots, (\epsilon_+)_N\},$$

$$B_1 = \begin{bmatrix} -1 & \ldots & 0 & 0 & \ldots & 1 \\ 0 & \ldots & 0 & 0 & \ldots & 0 \\ \vdots & \ldots & 0 & 0 & \ldots & \vdots \\ 0 & \ldots & -1 & 1 & \ldots & 0 \\ 0 & \ldots & -1 & 1 & \ldots & 0 \\ \vdots & \ldots & 0 & 0 & \ldots & \vdots \\ 0 & \ldots & 0 & 0 & \ldots & 0 \\ -1 & \ldots & 0 & 0 & \ldots & 1 \end{bmatrix} \tag{6.8}$$

Table 4

Relative errors of eigenvalues for $\omega = 2$ and the L_2-discrete errors of eigenfunctions for the Legendre-collocation penalty (LCP) method and the Chebyshev-collocation penalty (CCP) method.

	64	1.01(-11)	4.35(-12)	-2.51(-11)	1.61(-11)

and

$$B_2 = \begin{bmatrix} -D_{01} & \dots & -D_{0N} & D_{N1} & \dots & D_{NN} \\ 0 & \dots & 0 & 0 & \dots & 0 \\ \vdots & \dots & \vdots & \vdots & \dots & \vdots \\ 0 & \dots & 0 & 0 & \dots & 0 \\ D_{N1} & \dots & D_{NN} & -D_{01} & \dots & -D_{0N} \\ -D_{01} & \dots & -D_{0N} & D_{N1} & \dots & D_{NN} \\ 0 & \dots & 0 & 0 & \dots & 0 \\ \vdots & \dots & \vdots & \vdots & \dots & \vdots \\ 0 & \dots & 0 & 0 & \dots & 0 \\ D_{N1} & \dots & D_{NN} & -D_{01} & \dots & -D_{0N} \end{bmatrix}, \tag{6.9}$$

and letting

$$K_\tau = K + \sigma_1^\tau B_1 + \sigma_2^\tau B_2, \tag{6.10}$$

we can represent the Legendre-collocation penalty scheme for (6.4):

$$K_\tau \mathbf{u}^\tau = \lambda^\tau M \mathbf{u}^\tau, \tag{6.11}$$

where $\mathbf{u}^\tau = [(u_-^\tau)_0, \dots, (u_-^\tau)_N, (u_+^\tau)_0, \dots, (u_+^\tau)_N]^T$.

The numerical computations are carried out for the case $\sigma_1^\tau = \sigma_2^\tau = \left\{\frac{2}{\pi} N(N+1)\right\}^2$ [11], [12], which is chosen for the matrix K_τ to be symmetric positive definite [9], [20]. The results, shown in Table 4, demonstrate the exponential rate of convergence.

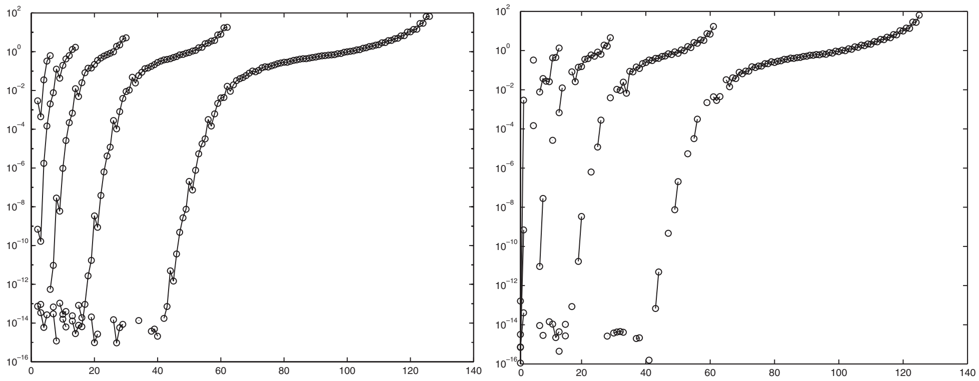

FIG. 1. *Legendre–Galerkin method (left) and Legendre-collocation method* 1 *(right): the relative errors of all the eigenvalues for* $N = 4, 8, 16, 32, 64$.

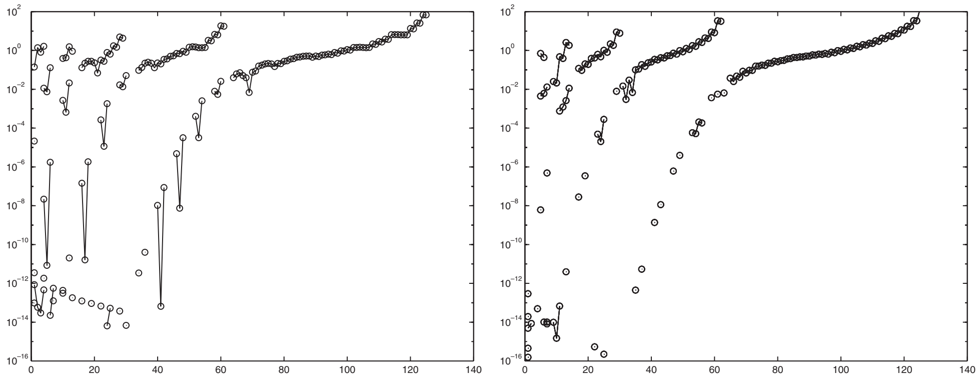

FIG. 2. *Legendre-collocation method* 2 *(left) and Legendre-collocation penalty method (right): the relative errors of all the eigenvalues for* $N = 4, 8, 16, 32, 64$.

Simply replacing the set of points and the weights by the Chebyshev–Gauss–Lobatto points and weights, one can construct the multidomain Chebyshev-collocation penalty method, whose results also are provided in Table 4.

The theoretical analysis of the convergence for the multidomain spectral penalty method is left for future study, as is the analysis for optimizing the parameter τ_i for this eigenvalue problem.

7. Discussion. In this section we discuss the asymptotic behavior of the largest approximate eigenvalues obtained by the multidomain spectral techniques for the eigenproblem with a discontinuous coefficient. Figures 1–2 demonstrate the relative errors of the eigenvalues with fixed $N = 4, 8, 16, 32, 64$ for each different method. The figures show that for the approximations with degree N, the fraction $\frac{2}{\pi}$ of the approximate eigenvalues converges to the analytic eigenvalues exponentially. Bernardi and Maday [2] and Vandeven [22] give rigorous proofs for finding the fraction of the approximate eigenvalues that approximate the eigenvalues of the second-order spectral differentiation operator.

We present the relative errors for the first 29 eigenvalues for a fixed $N = 16$ in

Table 5

Relative errors of eigenvalues for $\omega = 2$ for the domain decomposition Legendre–Galerkin (LG), Legendre-collocation method 1 (LC1), Legendre-collocation method 2 (LC2), Chebyshev-collocation method 2 (CC2), Legendre-collocation penalty method (LCP), Chebyshev-collocation penalty method (CCP): λ_l^* is the lth approximate eigenvalue and $N = 16$.

Table 5. One can see that $\frac{1}{\pi}$ of the eigenvalues approximate the analytic eigenvalues of the problem very accurately. One also can see that the Legendre–Galerkin method and the Legendre-collocation method 1 are more accurate than the other collocation methods. However, the Legendre-collocation method 2 and Legendre-collocation penalty method are relatively easier to implement because of their simplicity in dealing with the basis of the space used in the approximation.

8. Conclusion. In this paper, we have mainly discussed the Legendre–Galerkin, Legendre-collocation, and Legendre-collocation penalty methods with a domain decomposition approach in order to get exponentially accurate eigensolutions for a model eigenvalue problem with a piecewise continuous coefficient.

CONVERGENCE ANALYSIS OF WAVELET SCHEMES FOR CONVECTION-REACTION EQUATIONS UNDER MINIMAL REGULARITY ASSUMPTIONS*

JIANGGUO LIU[†], BOJAN POPOV[‡], HONG WANG[§], AND RICHARD E. EWING[†]

Abstract. In this paper, we analyze convergence rates of wavelet schemes for time-dependent convection-reaction equations within the framework of the Eulerian–Lagrangian localized adjoint method (ELLAM). Under certain minimal assumptions that guarantee H^1-regularity of exact solutions, we show that a generic ELLAM scheme has a convergence rate $\mathcal{O}(h/\sqrt{\Delta t} + \Delta t)$ in L^2-norm. Then, applying the theory of operator interpolation, we obtain error estimates for initial data with even lower regularity. Namely, it is shown that the error of such a scheme is $\mathcal{O}((h/\sqrt{\Delta t})^\theta + (\Delta t)^\theta)$ for initial data in a Besov space $B^\theta_{2,q}(0 < \theta < 1, 0 < q \leq \infty)$. The error estimates are a priori and optimal in some cases. Numerical experiments using orthogonal wavelets are presented to illustrate the theoretical estimates.

1. Introduction.

This paper is concerned with convergence rates of the wavelet schemes established in [24] for an initial value problem (IVP) to the following multidimensional linear convection-reaction equation

$$\begin{cases} u_t + \nabla \cdot (\mathbf{V}u) + Ru = f(\mathbf{x}, t), & (\mathbf{x}, t) \in \mathbb{R}^d \times (0, T], \\ u(\mathbf{x}, 0) = u_0(\mathbf{x}), & \mathbf{x} \in \mathbb{R}^d, \end{cases} \tag{1.1}$$

where $u(\mathbf{x}, t)$ is the unknown concentration function, $\mathbf{V}(\mathbf{x}, t)$ is a fluid velocity field, $R(\mathbf{x}, t)$ is a first order reaction coefficient, $f(\mathbf{x}, t)$ is a source/sink term, and $u_0(\mathbf{x})$ is a prescribed initial condition. It is assumed that $u_0(\mathbf{x})$ and $f(\mathbf{x}, t)$ are compactly supported, and hence so is the exact solution $u(\mathbf{x}, t)$ for any finite time.

Convection-dominated reactive transport equations arise from remediation of subsurface contamination, nuclear waste disposal, biodegradation, numerical simulation of petroleum reservoir, and many other applications. The solutions to these types of problems usually are not smooth and raise serious challenges to numerical methods. Standard finite difference or finite element methods (FEMs) produce either excessively oscillatory or smeared solutions. Therefore, many special schemes have been developed to overcome these difficulties.

Characteristics-based methods were developed in the late 1970s and the early 1980s to solve convection-dominated problems. Systematic study including error estimates for the FEM in the case of nondegenerate diffusion was given in [17]. Improved estimates for such problems were given in [12] with a special discussion for

degenerate diffusion. In the case of pure advection, [11] gives optimal rates of convergence for the piecewise linear FEM but with the restrictions of very small time steps ($\Delta t = \mathcal{O}(h^2)$) and sufficiently smooth exact solutions. There are many other results for convection-dominated diffusion problems, but in most cases the derived estimates adversely depend on the size of the diffusion parameter. In a recent paper [2], Bause and Knabner derived error estimates for Lagrangian–Galerkin methods, which are uniform with respect to the diffusion parameter, and therefore they remark that their results can carry over to the limit case of pure convection.

Among the existing characteristic methods, the Eulerian–Lagrangian localized adjoint method (ELLAM) [5] holds some advantages. It symmetrizes the governing equation, naturally incorporates boundary conditions, and conserves mass. However, ELLAM introduces further difficulties to the already fairly complicated analyses of characteristic methods. It was shown in [19, 25] that within the ELLAM framework, the piecewise linear FEM with uniform spatial partition has an optimal error estimate; in other words, it has a convergence rate $\mathcal{O}(h^2 + \Delta t)$, under the assumptions that $u \in L^\infty(0, T; H^3(\Omega))$ and $u_t \in L^2(0, T; H^2(\Omega))$. Many other papers also assume the exact solution is at least in H^2 in space. However, it is clear that the requirement $u \in L^\infty(0, T; H^s(\Omega))$ for any initial condition $u_0 \in H^s(\Omega)$ will imply that the fluid velocity is, roughly speaking, s times differentiable.

In this paper, requirements on regularity of the solution and the velocity field will be significantly reduced. We shall prove that under certain minimal assumptions that guarantee H^1-smoothness of the exact solution, ELLAM schemes including the orthogonal wavelet schemes satisfy

$$\max_{0\le n\le N} \|u(\mathbf{x}, t_n) - U_h^n(\mathbf{x})\|_{L^2(\mathbb{R}^d)} \le C(h/\sqrt{\Delta t} + \Delta t), \tag{1.2}$$

where $u(\mathbf{x}, t_n)$ is the exact solution at time t_n, and $U_h^n(\mathbf{x})$ is the corresponding numerical solution with spatial step size h and temporal step size Δt. The constant C depends only on the norms of the velocity, reaction, source, and initial data, but not on the norm of the exact solution $u(\mathbf{x}, t)$ itself.

Applying the theory of operator interpolation, we could obtain the error estimates

$$\max_{0\le n\le N} \|u(\mathbf{x}, t_n) - U_h^n(\mathbf{x})\|_{L^2(\mathbb{R}^d)} \le C\left[(h/\sqrt{\Delta t})^\theta + (\Delta t)^\theta\right] \tag{1.3}$$

for initial data u_0 in a Besov space $B^\theta_{2,q}(0 < \theta < 1, 0 < q \le \infty)$, where C could be additionally dependent on θ. This extends our results to a wide class of data, including discontinuous initial conditions, moving sharp fronts, or shocks. Generally speaking, Besov spaces provide subtler characterization on regularity of functions than Sobolev spaces do. Sometimes the exact order of approximation accuracy can be described only when Besov spaces are used, as illustrated by our Example 2 in section 8. Efforts in applying Besov spaces to other problems in numerical analysis can also be observed in literature, e.g., a recent work by Bacuta, Bramble, and Xu [1].

Errors in the wavelet schemes come from truncation, characteristic tracking, quadrature, and round-off. In this paper, we disregard quadrature rule error in the computations of wavelet coefficients. That is, we assume numerical integration is exact, following the common practices of most researchers [12, 17, 25]. The classic book [6] (see sections 4.1 and 4.4 of that work) has a full discussion on quadrature errors in the finite element method for elliptic problems. For time-dependent problems, some discussions can be found in [21].

The rest of this paper is organized as follows: Section 2 outlines the main ideas in the ELLAM weak formulation and establishes our numerical schemes, including the orthogonal wavelet schemes, within the ELLAM framework. Section 3 presents error estimates for the numerical schemes under some minimal regularity assumptions on the given data that guarantee H^1-stability of the exact solutions (Theorem 1). The proof of Theorem 1 is presented in section 4. In section 5, we state and prove the stability lemmas about the exact solutions used in section 4. Section 6 extends the results on convergence rates of the numerical schemes to initial data in Besov spaces. In section 7, we discuss optimality of our error estimates. Numerical experiments are presented in section 8 to illustrate the theoretical results. Finally, section 9 concludes the paper with some remarks.

2. ELLAM schemes.

In this section, we establish the ELLAM weak formulation for problem (1.1). Based on this weak formulation, we derive a generic (abstract) ELLAM scheme. Then we present the wavelet-ELLAM schemes using orthogonal wavelets.

2.1. ELLAM formulation.

Let $[0, T]$ be the time period, N a positive integer, $\Delta t := T/N$, and $t_n = n\Delta t$ $(n = 0, \dots, N)$ be a uniform partition of $[0, T]$. To establish a weak formulation for (1.1), we choose test function $w(\mathbf{x}, t)$ in such a way that it vanishes outside the space-time strip $\mathbb{R}^d \times (t_{n-1}, t_n]$ and is discontinuous in time at time t_{n-1}. Then integration by parts gives us

$$\begin{aligned}&\int_{\mathbb{R}^d} u(\mathbf{x}, t_n) w(\mathbf{x}, t_n) d\mathbf{x} - \int_{t_{n-1}}^{t_n} \int_{\mathbb{R}^d} (u(w_t + \mathbf{V}\cdot\nabla w - Rw))(\mathbf{x}, t) d\mathbf{x}dt \\ &\quad = \int_{\mathbb{R}^d} u(\mathbf{x}, t_{n-1}) w(\mathbf{x}, t_{n-1}^+) d\mathbf{x} + \int_{t_{n-1}}^{t_n} \int_{\mathbb{R}^d} f(\mathbf{x}, t) w(\mathbf{x}, t) d\mathbf{x}dt,\end{aligned} \tag{2.1}$$

where $w(\mathbf{x}, t_{n-1}^+) := \lim_{t\to t_{n-1}^+} w(\mathbf{x}, t)$ takes into account the fact that $w(\mathbf{x}, t)$ is discontinuous in time at time t_{n-1}.

To cancel the second term on the left side of (2.1), we require the test function to satisfy the adjoint equation

$$w_t + \mathbf{V}\cdot\nabla w - Rw = 0. \tag{2.2}$$

Solving the above problem yields an explicit expression for the test function:

$$w(\mathbf{y}(s; \mathbf{x}, t_n), s) = w(\mathbf{x}, t_n)\, e^{\int_{t_n}^{s} R(\mathbf{y}(r;\mathbf{x},t_n),r)dr}, \quad s \in (t_{n-1}, t_n], \tag{2.3}$$

where the characteristic $\mathbf{y}(s; \mathbf{x}, t_n)$ passing through $(\mathbf{x}, t_n)$ is determined by

$$\begin{cases} \dfrac{d\mathbf{y}}{ds} = \mathbf{V}(\mathbf{y}, s), \\ \mathbf{y}(s; \mathbf{x}, t_n)|_{s=t_n} = \mathbf{x}. \end{cases} \tag{2.4}$$

Then we are led to the reference equation

$$\begin{aligned}\int_{\mathbb{R}^d} u(\mathbf{x}, t_n) w(\mathbf{x}, t_n) d\mathbf{x} &= \int_{\mathbb{R}^d} u(\mathbf{x}, t_{n-1}) w(\mathbf{x}, t_{n-1}^+) d\mathbf{x} \\ &\quad + \int_{t_{n-1}}^{t_n} \int_{\mathbb{R}^d} f(\mathbf{x}, t) w(\mathbf{x}, t) d\mathbf{x}dt.\end{aligned} \tag{2.5}$$

Let $\mathbf{x}^* = \mathbf{y}(t_{n-1}; \mathbf{x}, t_n)$. Applying (2.3), we can rewrite the first term on the right side of (2.5) as

$$\begin{aligned}&\int_{\mathbb{R}^d} u(\mathbf{x}, t_{n-1}) w(\mathbf{x}, t_{n-1}^{+}) d\mathbf{x} \\ &\quad = \int_{\mathbb{R}^d} u(\mathbf{x}^*, t_{n-1}) w(\mathbf{x}, t_n) e^{\int_{t_n}^{t_{n-1}} R(\mathbf{y}(s;\mathbf{x},t_n),s)ds} \mathbf{J}(\mathbf{x}^*, \mathbf{x}) d\mathbf{x},\end{aligned} \tag{2.6}$$

where $\mathbf{J}(\mathbf{x}^*, \mathbf{x})$ is the Jacobian of $\mathbf{x}^*$ with respect to $\mathbf{x}$.

2.2. A generic ELLAM scheme. Based on (2.3), we first approximate the test function $w(\mathbf{y}(s; \mathbf{x}, t_n), s)$ in the space-time strip $\mathbb{R}^d \times (t_{n-1}, t_n]$ by

$$w(\mathbf{x}, t_n)\ e^{\int_{t_n}^{s} R(\mathbf{x},t_n)dr} \equiv w(\mathbf{x}, t_n)\ e^{R(\mathbf{x},t_n)(s-t_n)},$$

and then use it to approximate the second (source) term on the right side of (2.5),

$$\begin{aligned}&\int_{t_{n-1}}^{t_n} \int_{\mathbb{R}^d} f(\mathbf{y}, s) w(\mathbf{y}, s) d\mathbf{y} ds \\ &\quad = \int_{\mathbb{R}^d} \int_{t_{n-1}}^{t_n} f(\mathbf{y}, s) w(\mathbf{y}, s) \mathbf{J}(\mathbf{y}, \mathbf{x}) ds d\mathbf{x} \\ &\quad = \int_{\mathbb{R}^d} \int_{t_{n-1}}^{t_n} f(\mathbf{x}, t_n) w(\mathbf{x}, t_n) e^{R(\mathbf{x},t_n)(s-t_n)} ds d\mathbf{x} + E(f, w) \\ &\quad = \int_{\mathbb{R}^d} f(\mathbf{x}, t_n) w(\mathbf{x}, t_n) G_n(\mathbf{x}) d\mathbf{x} + E(f, w),\end{aligned} \tag{2.7}$$

where $\mathbf{J}(\mathbf{y}, \mathbf{x})$ is the Jacobian of $\mathbf{y}$ with respect to $\mathbf{x}$,

$$G_n(\mathbf{x}) := \int_{t_{n-1}}^{t_n} e^{R(\mathbf{x},t_n)(s-t_n)} ds = \begin{cases} \dfrac{1 - e^{-R(\mathbf{x},t_n)\Delta t}}{R(\mathbf{x}, t_n)} & \text{if } R(\mathbf{x}, t_n) \neq 0, \\ \Delta t & \text{otherwise,} \end{cases} \tag{2.8}$$

and $E(f, w)$ is the error term

$$E(f, w) := \int_{t_{n-1}}^{t_n} \int_{\mathbb{R}^d} f(\mathbf{y}, s) w(\mathbf{y}, s) d\mathbf{y} ds - \int_{\mathbb{R}^d} f(\mathbf{x}, t_n) w(\mathbf{x}, t_n) G_n(\mathbf{x}) d\mathbf{x}. \tag{2.9}$$

In practice, exact tracking of characteristics is usually unavailable, and we have to resort to numerical means. All commonly used numerical methods, e.g., Euler and Runge–Kutta methods, can be employed to solve (2.4). Let $(\mathbf{x}^{**}, t_{n-1})$ be the numerical back-tracking image of $(\mathbf{x}, t_n)$; then $w(\mathbf{x}^{**}, t_{n-1}^{+})$ can be approximated by $w(\mathbf{x}, t_n) e^{-R(\mathbf{x},t_n)\Delta t}$.

Now a generic ELLAM scheme can be established as follows: Let $V_h \subset L^2(\mathbb{R}^d)$ be an approximation subspace. Find $U_h^n(\mathbf{x}) \in V_h$ such that for any test function w with $w(\mathbf{x}, t_n) \in V_h$,

$$\begin{aligned}\int_{\mathbb{R}^d} U_h^n(\mathbf{x}) w(\mathbf{x}, t_n) d\mathbf{x} &= \int_{\mathbb{R}^d} U_h^{n-1}(\mathbf{x}^{**}) w(\mathbf{x}, t_n) e^{-R(\mathbf{x},t_n)\Delta t} \mathbf{J}(\mathbf{x}^{**}, \mathbf{x}) d\mathbf{x} \\ &\quad + \int_{\mathbb{R}^d} f(\mathbf{x}, t_n) w(\mathbf{x}, t_n) G_n(\mathbf{x}) d\mathbf{x},\end{aligned} \tag{2.10}$$

where $U_h^0(\mathbf{x})$ is an approximation to $u_0(\mathbf{x})$ from V_h obtained by some means. For example, it can be taken as the L^2-orthogonal projection of u_0 into V_h.

There are many choices for the approximation subspace V_h. It could be constructed through finite elements or wavelets.

2.3. Wavelet schemes. Let

$$\cdots \subset \mathcal{V}_{-1} \subset \mathcal{V}_0 \subset \mathcal{V}_1 \subset \cdots \subset \mathcal{V}_j \subset \mathcal{V}_{j+1} \subset \cdots \subset L^2(\mathbb{R})$$

be a multiresolution analysis in $L^2(\mathbb{R})$ generated by an orthogonal scaling function $\phi(x)$ and let $\psi(x)$ be the associated orthogonal wavelet [10]. We construct d-dimensional scaling function and wavelets through tensor products. Let $\mathbf{x} = (x_1, \ldots, x_d) \in \mathbb{R}^d, \mathbf{k} = (k_1, \ldots, k_d) \in \mathbb{Z}^d, \mathbf{e} = (e_1, \ldots, e_d) \in \{0, 1\}^d =: \hat{E}$, and $E := \hat{E} \setminus \{\mathbf{0}\}$. Then we define scaling function $\mathbf{\Phi}_{j,\mathbf{k}}(\mathbf{x}) := \prod_{i=1}^d \phi_{j,k_i}(x_i)$ and the wavelets

$$\Psi^{\mathbf{e}}_{j,\mathbf{k}}(\mathbf{x}) := \prod_{i=1}^{d} \Big(\phi_{j,k_i}(x_i)\Big)^{1-e_i} \Big(\psi_{j,k_i}(x_i)\Big)^{e_i}, \qquad \mathbf{e} \in E.$$

Furthermore, we define $V_j := \bigotimes_{i=1}^d \mathcal{V}_j$ as the closed linear span in $L^2(\mathbb{R}^d)$ of all functions of the form $f_1(x_1) \cdots f_d(x_d)$, where $f_i \in \mathcal{V}_j$ for $i = 1, \ldots, d$. Then $\langle V_j \rangle_{j \in \mathbb{Z}}$ forms a multiresolution analysis in $L^2(\mathbb{R}^d)$.

Clearly, we can use any subspace V_j in the above multiresolution analysis as an approximation subspace V_h in the ELLAM scheme (2.10). This gives us an orthogonal wavelet-ELLAM scheme.

For numerical implementations, we assume $\Omega \subset \mathbb{R}^d$ to be a rectangular domain such that the support of the solution $u(\mathbf{x}, t)$ to problem (1.1) is contained in Ω for all $t \in [0, T]$. Let $J_c < J_f$ be the chosen coarsest and finest resolution levels. For all j with $J_c \leq j \leq J_f$, we define

$$\Lambda_j := \{\mathbf{k} : \text{supp}\Phi_{j,\mathbf{k}} \cap \Omega \neq \emptyset\}, \tag{2.11}$$

$$\Lambda_{j,\mathbf{e}} := \{\mathbf{k} : \text{supp}\Psi^{\mathbf{e}}_{j,\mathbf{k}} \cap \Omega \neq \emptyset\}, \tag{2.12}$$

$$\mathcal{S}_j(\Omega) := \text{Span}\{\Phi_{j,\mathbf{k}}(\mathbf{x}) \mid \mathbf{k} \in \Lambda_j\}. \tag{2.13}$$

Then we set $V_h = \mathcal{S}_{J_f}(\Omega)$ with $h = 1/2^{J_f}$. There are two equivalent choices for the basis functions of V_h:

- only the scaling functions at the finest level J_f;
- the scaling functions at the coarsest level J_c plus all wavelets from level J_c to level $J_f - 1$.

When only the scaling functions at the finest level are used as the basis functions, we are seeking $U^n_h(\mathbf{x}) \in V_h$ with

$$U^n_h(\mathbf{x}) = \sum_{\mathbf{k} \in \Lambda_{J_f}} c^n_{J_f,\mathbf{k}} \Phi_{J_f,\mathbf{k}}(\mathbf{x}). \tag{2.14}$$

The orthogonality of scaling functions implies that we have an explicit scheme and the coefficients are given by

$$\begin{aligned} c^n_{J_f,\mathbf{k}} = &\int_\Omega U^{n-1}_h(\mathbf{x}^{**}) \Phi_{J_f,\mathbf{k}}(\mathbf{x}) e^{-R(\mathbf{x},t_n)\Delta t} \mathbf{J}(\mathbf{x}^{**}, \mathbf{x}) d\mathbf{x} \\ &+ \int_\Omega f(\mathbf{x}, t_n) \Phi_{J_f,\mathbf{k}}(\mathbf{x}) G_n(\mathbf{x}) d\mathbf{x}, \qquad \mathbf{k} \in \Lambda_{J_f}. \end{aligned} \tag{2.15}$$

This is the Scheme I discussed in [24].

When both the scaling functions at the coarsest level and the wavelets at fine levels are used as the basis functions, we get Scheme II with

$$U_h^n(\mathbf{x}) = \sum_{\mathbf{k}\in\Lambda_{J_c}} c_{J_c,\mathbf{k}}^n \Phi_{J_c,\mathbf{k}}(\mathbf{x}) + \sum_{j=J_c}^{J_f-1} \sum_{\mathbf{k}\in\Lambda_{j,\mathbf{e}}} d_{j,\mathbf{k}}^{n,\mathbf{e}} \Psi_{j,\mathbf{k}}^{\mathbf{e}}(\mathbf{x}). \tag{2.16}$$

Scheme II is also an explicit scheme. By choosing $w(\mathbf{x}, t_n) = \Phi_{J_c,\mathbf{k}}(\mathbf{x})$ or $\Psi_{j,\mathbf{k}}^{\mathbf{e}}(\mathbf{x})$, respectively, we obtain, again through the orthogonality,

$$\begin{aligned} c_{J_c,\mathbf{k}}^n &= \int_\Omega U_h^{n-1}(\mathbf{x}^{**})\Phi_{J_c,\mathbf{k}}(\mathbf{x})e^{-R(\mathbf{x},t_n)\Delta t}\mathbf{J}(\mathbf{x}^{**},\mathbf{x})d\mathbf{x} \\ &\quad + \int_\Omega f(\mathbf{x},t_n)\Phi_{J_c,\mathbf{k}}(\mathbf{x})G_n(\mathbf{x})d\mathbf{x}, \qquad \mathbf{k}\in\Lambda_{J_c}, \\ d_{j,\mathbf{k}}^{n,\mathbf{e}} &= \int_\Omega U_h^{n-1}(\mathbf{x}^{**})\Psi_{j,\mathbf{k}}^{\mathbf{e}}(\mathbf{x})e^{-R(\mathbf{x},t_n)\Delta t}\mathbf{J}(\mathbf{x}^{**},\mathbf{x})d\mathbf{x} \\ &\quad + \int_\Omega f(\mathbf{x},t_n)\Psi_{j,\mathbf{k}}^{\mathbf{e}}(\mathbf{x})G_n(\mathbf{x})d\mathbf{x}, \qquad \mathbf{k}\in\Lambda_{j,\mathbf{e}}, \ \ J_c \le j \le J_f - 1. \end{aligned} \tag{2.17}$$

In Scheme II, the first part on the right side of (2.16) provides a basic approximation. As more fine terms in the second part come in, we obtain better approximations.

As we know, solutions to convection-dominated transport equations often admit steep fronts and even jump discontinuities within very small regions but are smooth outside these regions. On the other hand, one prominent feature of wavelets is their localization capability. The terms in the wavelet expansion with noticeable coefficients correspond to the rough regions of the solution around those local singularities. We can drop the terms with small coefficients that correspond to the smooth regions of the solution. Therefore, the number of unknowns to be solved will be reduced. In other words, an adaptive multilevel scheme with mass-conservative compression can be constructed. This is the Scheme III presented in [24], which is, in some sense, equivalent to the traditional FEM with local refinement.

Due to compression, the wavelet basis functions (or elements) used in Scheme III vary at different time steps but are adapted to the solution we are looking for. This is a typical case of nonlinear approximation [14]. Of course, Schemes I and II are still in the category of linear approximation and are the main target of this paper. Theoretical analysis on convergence rates of Scheme III is much harder and will be addressed in our future work.

As proven in [24], all three wavelet schemes are explicit and unconditionally stable. In other words, they are not subject to the severe restriction of the Courant–Friedrichs–Lewy (CFL) condition. This allows us to use relatively large time steps.

3. Error estimate for solutions with H^1-regularity.

In this section, we derive an error estimate for the generic ELLAM scheme for exact solutions with only H^1-regularity.

Throughout this paper, we use L^p $(1 \le p \le \infty)$ to denote the standard Lebesgue spaces. Accordingly, W_p^k are the standard Sobolev spaces. When $p = 2$, we use H^k for W_2^k. For $1 \le q \le \infty$, we define

$$L^q(a,b;W_p^k) := \{u(\mathbf{x},t) | u(\cdot,t) : (a,b) \mapsto W_p^k, \|u(\cdot,t)\|_{W_p^k} \in L^q(a,b)\}.$$

In addition, $(W_\infty^1(\mathbb{R}^d \times [0,T]))^d$ is the space of vector-valued functions whose components are in the space $W_\infty^1(\mathbb{R}^d \times [0,T])$.

Assumption A. The approximation subspace V_h used in the generic ELLAM scheme (2.10) has the following approximation property:

$$\|u - P_h u\|_{L^2} \leq C_0 h \|u\|_{H^1} \qquad \forall u \in H^1(\mathbb{R}^d), \tag{3.1}$$

where C_0 is a constant independent of h and u. The above inequality is also called a Jackson-type inequality in literature.

Remark A. The above Jackson-type inequality is satisfied by commonly used wavelets, e.g., Daubechies' wavelets; see [14].

Assumption B.

(i) $\mathbf{V} \in (W^1_\infty(\mathbb{R}^d \times [0,T]))^d$.

(ii) $\mathrm{div}\mathbf{V} \in W^1_\infty(\mathbb{R}^d \times [0,T])$.

(iii) $R \in W^1_\infty(\mathbb{R}^d \times [0,T])$.

Now we state our first theorem on the error estimate for exact solutions with only H^1-regularity.

THEOREM 1. *Let $u(\mathbf{x},t)$ be the exact solution of problem* (1.1) *and let $U_h^n(\mathbf{x})$ be the numerical solution generated by the generic ELLAM scheme* (2.10)*. Then under Assumptions* A *and* B*, the following error estimate in L^2-norm holds:*

$$\begin{aligned} &\max_{0\leq n\leq N} \|u(\mathbf{x},t_n) - U_h^n(\mathbf{x})\|_{L^2(\mathbb{R}^d)} \\ &\leq C\Bigg[\frac{h}{\sqrt{\Delta t}}\left(\|u_0\|_{H^1(\mathbb{R}^d)} + \|f\|_{L^2(0,T;H^1(\mathbb{R}^d))}\right) \\ &\qquad +\Delta t\left(\|u_0\|_{L^2(\mathbb{R}^d)} + \|f\|_{L^2(0,T;L^2(\mathbb{R}^d))} + \|f_\tau\|_{L^2(0,T;L^2(\mathbb{R}^d))}\right)\Bigg], \end{aligned} \tag{3.2}$$

where Δt and h are the temporal and spatial step sizes, respectively, and f_τ is the total derivative, i.e., the derivative along the characteristic direction. The constant C depends only on the final time T and the norms of $\mathbf{V}, \mathrm{div}\mathbf{V}, R$ in the corresponding spaces in Assumption B*. When orthogonal wavelet schemes are used, $h = 1/2^J$ with J being the finest spatial resolution used in the wavelet schemes.*

4. Proof of Theorem 1. In this section, we first estimate the error $E_n(w)$ defined in (4.5). Then we estimate the error involving the source term defined in (2.9). Applying a discrete Gronwall inequality, we derive the final error estimate stated in Theorem 1.

Let $u_n(\mathbf{x}) := u(\mathbf{x},t_n)$ and let $P_h u_n$ be the L^2-orthogonal projection of u_n into the subspace V_h, that is,

$$(P_h u_n, v_h) = (u_n, v_h) \qquad \forall\, v_h \in V_h. \tag{4.1}$$

Now with $P_h u_n, U_h^n \in V_h$, we have the orthogonality

$$u_n - U_h^n = (u_n - P_h u_n) \oplus (P_h u_n - U_h^n), \tag{4.2}$$

$$\|u_n - U_h^n\|^2_{L^2(\mathbb{R}^d)} = \|u_n - P_h u_n\|^2_{L^2(\mathbb{R}^d)} + \|P_h u_n - U_h^n\|^2_{L^2(\mathbb{R}^d)}. \tag{4.3}$$

Here $u_n - P_h u_n$ is the approximation error, which is completely determined by u_n and the chosen approximation subspace V_h. It is independent of the numerical scheme being used: a wavelet method or a traditional finite element method. Therefore we only need to bound the second term on the right side of (4.3).

Let w be a test function such that $w(\mathbf{x}, t_n) \in V_h$. Subtracting (2.10) from (2.5) and then applying (2.6) and (2.9), we obtain

$$(P_h u_n - U_h^n, w(\mathbf{x}, t_n)) = E_n(w) + E(f, w), \tag{4.4}$$

where

$$\begin{aligned} E_n(w) := &\int_{\mathbb{R}^d} u(\mathbf{x}^*, t_{n-1}) w(\mathbf{x}, t_n) e^{\int_{t_n}^{t_{n-1}} R(\mathbf{y},s)ds} \mathbf{J}(\mathbf{x}^*, \mathbf{x}) d\mathbf{x} \\ &- \int_{\mathbb{R}^d} U_h^{n-1}(\mathbf{x}^{**}) w(\mathbf{x}, t_n) e^{-R(\mathbf{x},t_n)\Delta t} \mathbf{J}(\mathbf{x}^{**}, \mathbf{x}) d\mathbf{x}. \end{aligned} \tag{4.5}$$

From now on, we shall use C to denote a constant that is independent of the spatial and temporal mesh sizes but may depend on the final time T and the norms of the velocity field and the reaction in the corresponding spaces in Assumption B, whereas C_0 will be used for an absolute constant that does not depend on any of the aforementioned terms. All these constants may take different values in different occurrences.

The following basic estimates are easy to verify and shall be repeatedly used in this section. When Δt is small enough, we have

(i) $\mathbf{J}(\mathbf{x}^*, \mathbf{x}) \le 1 + C\Delta t$,

(ii) $\mathbf{J}(\mathbf{x}^{**}, \mathbf{x}) \le 1 + C\Delta t$,

(iii) $e^{\int_{t_n}^{t_{n-1}} R(\mathbf{y},s)ds} \le 1 + C\Delta t$,

(iv) $e^{-R(\mathbf{x},t_n)\Delta t} \le 1 + C\Delta t$.

Recall that Assumption B, part (i), implies that the velocity field is Lipschitz in both space and time. When the Euler method is used for tracking characteristics, we have

$$\mathbf{x}^{**} = \mathbf{x} + \mathbf{V}(\mathbf{x}, t_n)(t_{n-1} - t_n), \tag{4.6}$$

and hence

$$|\mathbf{x}^* - \mathbf{x}^{**}| \le C(\Delta t)^2, \tag{4.7}$$

where $C = C_0 \|\mathbf{V}\|_{(W_\infty^1(\mathbb{R}^d \times [0,T]))^d}$. Furthermore, the following estimate holds under Assumption B, parts (i) and (ii):

$$|\mathbf{J}(\mathbf{x}^*, \mathbf{x}) - \mathbf{J}(\mathbf{x}^{**}, \mathbf{x})| \le C(\Delta t)^2. \tag{4.8}$$

4.1. Estimate on error $E_n(w)$. For the error $E_n(w)$, we split it into 4 terms:

$$E_n(w) = I_n^{(1)} + I_n^{(2)} + I_n^{(3)} + I_n^{(4)}, \tag{4.9}$$

where

$$\begin{aligned} I_n^{(1)} &:= \int_{\mathbb{R}^d} \Big[u(\mathbf{x}^*, t_{n-1}) - u(\mathbf{x}^{**}, t_{n-1})\Big] w(\mathbf{x}, t_n) e^{\int_{t_n}^{t_{n-1}} R(\mathbf{y},s)ds} \mathbf{J}(\mathbf{x}^*, \mathbf{x}) d\mathbf{x}, \\ I_n^{(2)} &:= \int_{\mathbb{R}^d} u(\mathbf{x}^{**}, t_{n-1}) w(\mathbf{x}, t_n) e^{\int_{t_n}^{t_{n-1}} R(\mathbf{y},s)ds} \Big[\mathbf{J}(\mathbf{x}^*, \mathbf{x}) - \mathbf{J}(\mathbf{x}^{**}, \mathbf{x})\Big] d\mathbf{x}, \\ I_n^{(3)} &:= \int_{\mathbb{R}^d} u(\mathbf{x}^{**}, t_{n-1}) w(\mathbf{x}, t_n) \Big[e^{\int_{t_n}^{t_{n-1}} R(\mathbf{y},s)ds} - e^{-R(\mathbf{x},t_n)\Delta t}\Big] \mathbf{J}(\mathbf{x}^{**}, \mathbf{x}) d\mathbf{x}, \\ I_n^{(4)} &:= \int_{\mathbb{R}^d} \Big[u(\mathbf{x}^{**}, t_{n-1}) - U_h^{n-1}(\mathbf{x}^{**})\Big] w(\mathbf{x}, t_n) e^{-R(\mathbf{x},t_n)\Delta t} \mathbf{J}(\mathbf{x}^{**}, \mathbf{x}) d\mathbf{x}. \end{aligned} \tag{4.10}$$

Note that $I_n^{(1)}$ and $I_n^{(2)}$ in (4.10) reflect the error from inexact tracking of characteristics. These two terms will vanish when exact tracking of characteristics is available.

Estimate on $\boldsymbol{I_n^{(1)}}$ in (4.10). The H^1-stability of the exact solution (Lemma 4 in section 5) and estimate (4.7) yield

$$\left(\int_{\mathbb{R}^d} |u(\mathbf{x}^*, t_n) - u(\mathbf{x}^{**}, t_n)|^2 d\mathbf{x} \right)^{1/2} \leq C\|u_n\|_{H^1(\mathbb{R}^d)}(\Delta t)^2.$$

Therefore,

$$|I_n^{(1)}| \leq C(\Delta t)^2 \|u_n\|_{H^1(\mathbb{R}^d)} \|w(\mathbf{x}, t_n)\|_{L^2(\mathbb{R}^d)}. \tag{4.11}$$

Estimate on $\boldsymbol{I_n^{(2)}}$ in (4.10). Based on estimate (4.8), we have

$$|I_n^{(2)}| \leq C(\Delta t)^2 \|u_{n-1}\|_{L^2(\mathbb{R}^d)} \|w(\mathbf{x}, t_n)\|_{L^2(\mathbb{R}^d)}. \tag{4.12}$$

Estimate on $\boldsymbol{I_n^{(3)}}$ in (4.10). Let R_τ be the total derivative of R (along characteristic) and $\mathbf{z} = \mathbf{y}(r; \mathbf{x}, t_n)$ for $r \in [s, t_n]$; then

$$\left| e^{\int_{t_n}^{t_{n-1}} R(\mathbf{y},s)ds} - e^{-R(\mathbf{x},t_n)\Delta t} \right| \leq 2 \int_{t_{n-1}}^{t_n} \int_s^{t_n} |R_\tau(\mathbf{z}, r)| dr ds \leq \|R_\tau\|_\infty (\Delta t)^2.$$

But $R_\tau = \nabla R \cdot \mathbf{V} + R_t$, so we have

$$|I_n^{(3)}| \leq C(\Delta t)^2 \|u_{n-1}\|_{L^2(\mathbb{R}^d)} \|w(\mathbf{x}, t_n)\|_{L^2(\mathbb{R}^d)}. \tag{4.13}$$

Estimate on $\boldsymbol{I_n^{(4)}}$ in (4.10). It is easy to derive the following estimate:

$$|I_n^{(4)}| \leq (1 + C\Delta t) \|u_{n-1} - U_h^{n-1}\|_{L^2(\mathbb{R}^d)} \|w(\mathbf{x}, t_n)\|_{L^2(\mathbb{R}^d)}. \tag{4.14}$$

Substitution of estimates (4.11), (4.12), (4.13), and (4.14) into (4.9) gives us an estimate on the error $E_n(w)$ defined in (4.5):

$$\begin{aligned} |E_n(w)| \leq & \left(\frac{1}{2} + C\Delta t \right) \left(\|u_{n-1} - U_h^{n-1}\|^2_{L^2(\mathbb{R}^d)} + \|w(\mathbf{x}, t_n)\|^2_{L^2(\mathbb{R}^d)} \right) \\ & + C(\Delta t)^3 \|u_{n-1}\|^2_{L^2(\mathbb{R}^d)} + C\Delta t \|w(\mathbf{x}, t_n)\|^2_{L^2(\mathbb{R}^d)}, \end{aligned} \tag{4.15}$$

where C depends on the final time T and the norms of $\mathbf{V}, \mathrm{div}\mathbf{V}, R$ in the corresponding spaces in Assumption B.

4.2. Estimate on source term. Now we estimate the error in the approximation to the source term. Let $\mathbf{y} = \mathbf{y}(s; \mathbf{x}, t_n), s \in [t_{n-1}, t_n]$, and $\mathbf{z} = \mathbf{y}(r; \mathbf{x}, t_n), r \in [s, t_n]$. According to (2.3), (2.7), and (2.9), we have

$$E(f, w) = I_f^{(1)} + I_f^{(2)} + I_f^{(3)}, \tag{4.16}$$

where

$$\begin{aligned} I_f^{(1)} &:= \int_{t_{n-1}}^{t_n} \int_{\mathbb{R}^d} f(\mathbf{y}, s) e^{\int_{t_n}^s R(\mathbf{z},r)dr} w(\mathbf{x}, t_n) [\mathbf{J}(\mathbf{y}, \mathbf{x}) - 1] d\mathbf{x} ds, \\ I_f^{(2)} &:= \int_{t_{n-1}}^{t_n} \int_{\mathbb{R}^d} f(\mathbf{y}, s) \left[e^{\int_{t_n}^s R(\mathbf{z},r)dr} - e^{R(\mathbf{x},t_n)(s-t_n)} \right] w(\mathbf{x}, t_n) d\mathbf{x} ds, \\ I_f^{(3)} &:= \int_{t_{n-1}}^{t_n} \int_{\mathbb{R}^d} [f(\mathbf{y}, s) - f(\mathbf{x}, t_n)] \, e^{R(\mathbf{x},t_n)(s-t_n)} w(\mathbf{x}, t_n) d\mathbf{x} ds. \end{aligned} \tag{4.17}$$

For convenience, let $J_n := [t_{n-1}, t_n]$.

Estimate on $I_f^{(1)}$ in (4.17). Applying the Cauchy–Schwarz inequality first in space and then in time gives

$$\begin{aligned}\left|\int_{t_{n-1}}^{t_n}\int_{\mathbb{R}^d} f(\mathbf{y},s)e^{\int_{t_n}^{s} R(\mathbf{z},r)dr} w(\mathbf{x},t_n)[\mathbf{J}(\mathbf{y},\mathbf{x})-1]d\mathbf{x}ds\right| \\ \leq \int_{t_{n-1}}^{t_n} 4\sqrt{2}\|\mathrm{div}\mathbf{V}\|_\infty (t_n-s)\|f(\cdot,s)\|_{L^2(\mathbb{R}^d)}\|w(\mathbf{x},t_n)\|_{L^2(\mathbb{R}^d)}ds \\ \leq \frac{4\sqrt{2}}{\sqrt{3}}\|\mathrm{div}\mathbf{V}\|_\infty(\Delta t)^{\frac{3}{2}}\|f\|_{L^2(J_n;L^2(\mathbb{R}^d))}\|w(\mathbf{x},t_n)\|_{L^2(\mathbb{R}^d)}.\end{aligned}$$

Therefore, we have

$$|I_f^{(1)}| \leq \frac{2\sqrt{2}}{\sqrt{3}}\|\mathrm{div}\mathbf{V}\|_\infty\left[(\Delta t)^2\|f\|^2_{L^2(J_n,L^2(\mathbb{R}^d))}+\Delta t\|w(\mathbf{x},t_n)\|^2_{L^2(\mathbb{R}^d)}\right]. \tag{4.18}$$

Estimate on $I_f^{(2)}$ in (4.17). Similar to the above, we have

$$|I_f^{(2)}| \leq \frac{2\sqrt{2}}{\sqrt{3}}\|R\|_\infty\left[(\Delta t)^2\|f\|^2_{L^2(J_n;L^2(\mathbb{R}^d))}+\Delta t\|w(\mathbf{x},t_n)\|^2_{L^2(\mathbb{R}^d)}\right]. \tag{4.19}$$

Estimate on $I_f^{(3)}$ in (4.17). Let f_τ be the total derivative of f; then

$$\begin{aligned}\left|\int_{\mathbb{R}^d}[f(\mathbf{y},s)-f(\mathbf{x},t_n)]e^{R(\mathbf{x},t_n)(s-t_n)}w(\mathbf{x},t_n)d\mathbf{x}\right| \\ \leq 2\int_s^{t_n}\int_{\mathbb{R}^d}|f_\tau(\mathbf{z},r)|\,|w(\mathbf{x},t_n)|d\mathbf{x}dr \\ \leq 2\sqrt{2}(t_n-s)^{1/2}\|f_\tau\|_{L^2([s,t_n];L^2(\mathbb{R}^d))}\|w(\mathbf{x},t_n)\|_{L^2(\mathbb{R}^d)}.\end{aligned}$$

Therefore,

$$|I_f^{(3)}| \leq \frac{2\sqrt{2}}{3}\left[(\Delta t)^2\|f_\tau\|^2_{L^2(J_n;L^2(\mathbb{R}^d))}+\Delta t\|w(\mathbf{x},t_n)\|^2_{L^2(\mathbb{R}^d)}\right]. \tag{4.20}$$

Now we piece together the above estimates (4.18), (4.19), and (4.20) to obtain an estimate on the source term

$$\begin{aligned}|E(f,w)| \leq C\Delta t\|w(\mathbf{x},t_n)\|^2_{L^2(\mathbb{R}^d)} \\ +C(\Delta t)^2\left[\|f\|^2_{L^2(J_n;L^2(\mathbb{R}^d))}+\|f_\tau\|^2_{L^2(J_n;L^2(\mathbb{R}^d))}\right],\end{aligned} \tag{4.21}$$

where the constant C can be taken as $C=\frac{2\sqrt{2}}{\sqrt{3}}[\|\mathrm{div}\mathbf{V}\|_\infty+\|R\|_\infty+1]$.

4.3. Final estimate. Combining estimates (4.15) and (4.21) with (4.4) and taking $w(\mathbf{x},t_n)$ as $P_hu_n-U_h^n$, we get

$$\begin{aligned}\|P_hu_n-U_h^n\|^2_{L^2(\mathbb{R}^d)} \leq \left(\frac{1}{2}+C\Delta t\right)\left(\|P_hu_n-U_h^n\|^2_{L^2(\mathbb{R}^d)}+\|u_{n-1}-U_h^{n-1}\|^2_{L^2(\mathbb{R}^d)}\right) \\ +C(\Delta t)^3\|u_{n-1}\|^2_{L^2(\mathbb{R}^d)}+C(\Delta t)^2\left[\|f\|^2_{L^2(J_n;L^2(\mathbb{R}^d))}+\|f_\tau\|^2_{L^2(J_n;L^2(\mathbb{R}^d))}\right].\end{aligned}$$

Note that $\|u_{n-1}-U_h^{n-1}\|^2 = \|u_{n-1}-P_hu_{n-1}\|^2 + \|P_hu_{n-1}-U_h^{n-1}\|^2$. Taking Δt small enough such that $C\Delta t \le 1/2$, we obtain

$$\begin{aligned}\|P_hu_n-U_h^n\|^2 \le{}& \left(\frac{1}{2}+C\Delta t\right)\left(\|P_hu_n-U_h^n\|^2+\|P_hu_{n-1}-U_h^{n-1}\|^2\right)\\ &+\|u_{n-1}-P_hu_{n-1}\|^2+C(\Delta t)^3\|u_{n-1}\|^2\\ &+C(\Delta t)^2\left[\|f\|^2_{L^2(J_n;L^2(\mathbb{R}^d))}+\|f_\tau\|^2_{L^2(J_n;L^2(\mathbb{R}^d))}\right].\end{aligned}$$

Summing both sides for $n=1,2,\ldots,m$ ($m\le N$) and canceling identical terms (also $U_h^0=P_hu_0$), we get

$$\begin{aligned}\|P_hu_m-U_h^m\|^2 \le{}& \left(\frac{1}{2}+C\Delta t\right)\|P_hu_m-U_h^m\|^2+C\Delta t\sum_{n=1}^{m-1}\|P_hu_n-U_h^n\|^2\\ &+\sum_{n=0}^{m-1}\|u_n-P_hu_n\|^2+C(\Delta t)^3\sum_{n=0}^{m-1}\|u_n\|^2\\ &+C(\Delta t)^2\left[\|f\|^2_{L^2(0,T;L^2(\mathbb{R}^d))}+\|f_\tau\|^2_{L^2(0,T;L^2(\mathbb{R}^d))}\right].\end{aligned}$$

Taking Δt small enough such that $C\Delta t\le 1/4$, we have

$$\begin{aligned}\|P_hu_m-U_h^m\|^2 \le{}& C\Delta t\sum_{n=1}^{m-1}\|P_hu_n-U_h^n\|^2\\ &+C_0\sum_{n=0}^{m-1}\|u_n-P_hu_n\|^2+C(\Delta t)^3\sum_{n=0}^{m-1}\|u_n\|^2\\ &+C(\Delta t)^2\left[\|f\|^2_{L^2(0,T;L^2(\mathbb{R}^d))}+\|f_\tau\|^2_{L^2(0,T;L^2(\mathbb{R}^d))}\right].\end{aligned}$$

Applying the discrete Gronwall inequality, we obtain

$$\begin{aligned}\|P_hu_m-U_h^m\|^2_{L^2(\mathbb{R}^d)} \le{}& C\sum_{n=0}^{m-1}\|u_n-P_hu_n\|^2_{L^2(\mathbb{R}^d)}+C(\Delta t)^3\sum_{n=0}^{m-1}\|u_n\|^2_{L^2(\mathbb{R}^d)}\\ &+C(\Delta t)^2\left[\|f\|^2_{L^2(0,T;L^2(\mathbb{R}^d))}+\|f_\tau\|^2_{L^2(0,T;L^2(\mathbb{R}^d))}\right].\end{aligned} \tag{4.22}$$

The first two terms on the right side of the above estimate reflect the error buildup during the iterative process in numerical scheme (2.10). However, this can be controlled through the stability of the exact solution.

For the IVP to the linear convection-reaction equation in conservative form (1.1), Lemmas 3 and 4 in section 5 hold under the conditions in Assumption B and yield

$$\max_{0\le n\le N}\|u_n\|_{L^2(\mathbb{R}^d)} \le C\left(\|u_0\|_{L^2(\mathbb{R}^d)}+\|f\|_{L^2(0,T;L^2(\mathbb{R}^d))}\right), \tag{4.23}$$

$$\max_{0\le n\le N}\|u_n\|_{H^1(\mathbb{R}^d)} \le C\left(\|u_0\|_{H^1(\mathbb{R}^d)}+\|f\|_{L^2(0,T;H^1(\mathbb{R}^d))}\right), \tag{4.24}$$

where C depends only on the final time T and the norms of $\mathbf{V}, \mathrm{div}\mathbf{V}, R$ in the corresponding spaces in Assumption B.

Applying (4.23), we get

$$\sum_{n=0}^{m-1}\|u_n\|^2_{L^2(\mathbb{R}^d)} \le \frac{C}{\Delta t}\left(\|u_0\|^2_{L^2(\mathbb{R}^d)}+\|f\|^2_{L^2(0,T;L^2(\mathbb{R}^d))}\right). \tag{4.25}$$

Combining Assumption A with (4.24), we obtain

$$\sum_{n=0}^{m-1} \|u_n - P_h u_n\|_{L^2(\mathbb{R}^d)}^2 \le C\frac{h^2}{\Delta t}\left(\|u_0\|_{H^1(\mathbb{R}^d)}^2 + \|f\|_{L^2(0,T;H^1(\mathbb{R}^d))}^2\right). \tag{4.26}$$

Combining (3.1), (4.3), (4.22), and the above two estimates, we finish the proof of Theorem 1. □

5. Stability of exact solutions.

In this section, we prove the stability lemmas used in the last section about the exact solution to a linear convection-reaction equation. All results are first established for the solution to an IVP to the linear transport equation in nonconservative form:

$$\begin{cases} u_t + \mathbf{V}\cdot\nabla u = cu + f, & (\mathbf{x},t)\in\mathbb{R}^d\times(0,T],\\ u(\mathbf{x},0) = u_0(\mathbf{x}), & \mathbf{x}\in\mathbb{R}^d, \end{cases} \tag{5.1}$$

where $u_0 \in L^2(\mathbb{R}^d)$. However, the results can be easily passed to the linear convection-reaction equation in the conservative form (1.1) by simply setting $c = -(\mathrm{div}\mathbf{V} + R)$.

In this section, Assumption B, part (i), can be relaxed to $\mathbf{V}\in L^1(0,T;(W^1_\infty(\mathbb{R}^d))^d)$; that is, $\mathbf{V}$ is Lipschitz with respect to only spatial variables. Although it is possible to prove the existence, uniqueness, and regularity results below under even weaker assumptions, we restrict our attention to the case $\mathbf{V}\in L^1(0,T;(W^1_\infty(\mathbb{R}^d))^d)$ to keep the assumptions simple.

LEMMA 2 (existence and uniqueness). *Suppose* $\mathbf{V}\in L^1(0,T;(W^1_\infty(\mathbb{R}^d))^d)$, $c\in L^1(0,T;L^\infty(\mathbb{R}^d))$, *and* $f\in L^1(0,T;L^2(\mathbb{R}^d))$. *If* $u_0\in L^2(\mathbb{R}^d)$, *then there exists a unique solution to* (5.1) *in* $L^\infty(0,T;L^2(\mathbb{R}^d))$ *and the solution can be explicitly expressed as*

$$u(\mathbf{x},t) = u_0(\mathbf{y}(0;\mathbf{x},t))e^{\int_0^t c(\mathbf{y}(s;\mathbf{x},t),s)ds} + \int_0^t f(\mathbf{y}(s;\mathbf{x},t),s)e^{\int_s^t c(\mathbf{y}(r;\mathbf{x},t),r)dr}ds. \tag{5.2}$$

The uniqueness of the solution u in Lemma 2 is a corollary of the results in [16]. The solution formula (5.2) can be derived using the results in [16], the techniques in [22], and standard density arguments.

LEMMA 3 (L^2-stability). *Assume that* $\mathbf{V}, c,$ *and* f *satisfy the conditions of Lemma 2. If* $u_0\in L^2(\mathbb{R}^d)$, *then the unique solution satisfies*

$$\|u(\cdot,t)\|_{L^2(\mathbb{R}^d)} \le C\left[\|u_0\|_{L^2(\mathbb{R}^d)} + \|f\|_{L^1(0,t;L^2(\mathbb{R}^d))}\right] \qquad \forall t\in[0,T], \tag{5.3}$$

where C *can be taken as* $C = e^{\int_0^t[\|c(\cdot,r)\|_\infty + \frac{1}{2}\|\mathrm{div}\mathbf{V}(\cdot,r)\|_\infty]dr}$.

Proof. Applying the triangle and Minkowski inequalities to the representation formula (5.2), we obtain

$$\begin{aligned} \|u(\cdot,t)\|_2 \le e^{\int_0^t \|c(\cdot,s)\|_\infty ds}\Bigg[\left(\int_{\mathbb{R}^d}|u_0(\mathbf{y}(0;\mathbf{x},t))|^2 d\mathbf{x}\right)^{\frac{1}{2}} \\ + \int_0^t\left(\int_{\mathbb{R}^d}|f(\mathbf{y}(s;\mathbf{x},t),s)|^2 d\mathbf{x}\right)^{\frac{1}{2}} ds\Bigg]. \end{aligned} \tag{5.4}$$

Let $\mathbf{J}(\mathbf{y},\mathbf{x})$ be the Jacobian of mapping $\mathbf{x}\mapsto\mathbf{y} := \mathbf{y}(s;\mathbf{x},t)$. It is known [13] that

$$\mathbf{J}(\mathbf{y},\mathbf{x}) = e^{\int_t^s \mathrm{div}\mathbf{V}(\mathbf{y}(r;\mathbf{x},t),r)dr}. \tag{5.5}$$

Hence, for any $s \leq t \in [0,T]$, we have

$$e^{-\int_s^t \|\mathrm{div}\mathbf{V}(\cdot,r)\|_\infty dr} \leq \mathbf{J}(\mathbf{y},\mathbf{x}) \leq e^{\int_s^t \|\mathrm{div}\mathbf{V}(\cdot,r)\|_\infty dr}. \tag{5.6}$$

Of course, we can take $\mathbf{y} := \mathbf{y}(s;\mathbf{x},t)$ as the starting point. Then the reversibility of flow ensures that the Jacobian $\mathbf{J}(\mathbf{x},\mathbf{y})$ of the inverse mapping $\mathbf{y}(s;\mathbf{x},t) \mapsto \mathbf{x}$ satisfies the same estimate. A change of variables in (5.4) and then an application of the above estimates on Jacobians conclude the proof. ☐

Next we shall impose some additional conditions on c and f so that the solution $u \in L^\infty(0,T;H^1(\mathbb{R}^d))$, provided $u_0 \in H^1(\mathbb{R}^d)$. In other words, under these sufficient conditions on $\mathbf{V}$, c, and f, the solution operator $E_t : u_0 \mapsto u(\cdot,t)$ is a bounded operator from $H^1(\mathbb{R}^d)$ to $H^1(\mathbb{R}^d)$.

LEMMA 4 (H^1-stability). *Assume that* $\mathbf{V} \in L^1(0,T;(W^1_\infty(\mathbb{R}^d))^d)$*,* $c \in L^1(0,T;W^1_\infty(\mathbb{R}^d))$*, and* $f \in L^1(0,T;H^1(\mathbb{R}^d))$*. If* $u_0 \in H^1(\mathbb{R}^d)$*, then the unique weak solution satisfies*

$$\|u(\cdot,t)\|_{H^1(\mathbb{R}^d)} \leq C\big(\|u_0\|_{H^1(\mathbb{R}^d)} + \|f\|_{L^1(0,t;H^1(\mathbb{R}^d))}\big) \quad \forall t \in [0,T], \tag{5.7}$$

where the constant C *depends only on* $\|\mathbf{V}\|_{L^1(0,T;(W^1_\infty(\mathbb{R}^d))^d)}$ *and* $\|c\|_{L^1(0,T;W^1_\infty(\mathbb{R}^d))}$.

Proof. Using the chain rule to the solution formula (5.2), we can derive expressions for all partial derivatives $\frac{\partial u}{\partial x_i}, 1 \leq i \leq d$, which involve spatial partial derivatives of the flow $\mathbf{y}(s;\mathbf{x},t), c$, and f. Let $\mathbf{z}(s;\mathbf{x},t)$ be any partial derivative of $\mathbf{y} := \mathbf{y}(s;\mathbf{x},t)$ with respect to one of the variables $x_1,\ldots,x_d$. We shall derive a uniform bound for $\mathbf{z}(s;\cdot,t)$. Let $|\mathbf{z}(s;\mathbf{x},t)|$ be the usual Euclidean norm for a vector in $\mathbb{R}^d$. The following assertion was proven in [8, 22]: Let $\mathbf{V}$ satisfy

$$|(\mathbf{V}(\mathbf{x},t) - \mathbf{V}(\mathbf{y},t)) \cdot (\mathbf{x} - \mathbf{y})| \leq K(t)|\mathbf{x} - \mathbf{y}|^2;$$

then

$$|\mathbf{z}(s;\mathbf{x},t)| \leq |\mathbf{z}(t;\mathbf{x},t)|e^{\int_0^T K(r)dr} = e^{\int_0^T K(r)dr}.$$

Here we have used the fact $\mathbf{y}(t;\mathbf{x},t) = \mathbf{x}$ to get $|\mathbf{z}(t;\mathbf{x},t)| = 1$. It is not difficult to verify that if $\mathbf{V} \in L^1(0,T;(W^1_\infty(\mathbb{R}^d))^d)$, then the above inequality holds with $K(t) = \|\mathbf{V}(\cdot,t)\|_{W^1_\infty(\mathbb{R}^d)}$. Therefore,

$$\|\mathbf{z}(s,\cdot,t)\|_\infty := \text{ess sup}_{\mathbf{x}\in\mathbb{R}^d}|\mathbf{z}(s,\mathbf{x},t)| \leq e^{\|\mathbf{V}\|_{L^1(0,T;(W^1_\infty(\mathbb{R}^d))^d)}}. \tag{5.8}$$

This is the standard estimate for a Lipschitz flow; see (1.4) in [7]. Based on the uniform bound (5.8), we can estimate all partial derivatives as follows:

$$\Big\|\frac{\partial u}{\partial x_i}(\cdot,t)\Big\|_{L^2(\mathbb{R}^d)} \leq C\big(\|u_0\|_{H^1(\mathbb{R}^d)} + \|f\|_{L^1(0,T;H^1(\mathbb{R}^d))}\big),$$

where the constant C depends only on the norms of $\mathbf{V}$ in $L^1(0,T;(W^1_\infty(\mathbb{R}^d))^d)$ and c in $L^1(0,T;W^1_\infty(\mathbb{R}^d))$. We finish the proof by combining the above estimate and the result of Lemma 3. ☐

6. Extension to Besov spaces. Besov spaces provide subtle characterization of regularity of functions. Interpolation of spaces and operators is a classical topic in harmonic analysis and has many interesting applications. In this section, we cite only the minimal requisite for our discussion. Readers are referred to [3, 15] for complete accounts of these two topics.

Besov spaces involve moduli of smoothness rather than the distributional derivatives used for Sobolev spaces. Let $1 \leq p \leq \infty$, $f \in L^p(\mathbb{R}^d)$, $\mathbf{h} \in \mathbb{R}^d$, and let $\Delta_{\mathbf{h}}$ be the usual difference operator: $\Delta_{\mathbf{h}} f(\mathbf{x}) := f(\mathbf{x}+\mathbf{h}) - f(\mathbf{x})$. Let k be a positive integer and $t > 0$. The kth modulus of smoothness of function f is defined as

$$\omega_k(f,t)_p := \sup_{|\mathbf{h}| \leq t} \|\Delta^k_{\mathbf{h}}(f,\mathbf{x})\|_{L^p(\mathbb{R}^d)}. \tag{6.1}$$

Suppose $\alpha > 0$ and $0 < q \leq \infty$. Let k be a positive integer such that $k > \alpha$. The Besov space $B^\alpha_{p,q}(\mathbb{R}^d)$ consists of functions $f \in L^p(\mathbb{R}^d)$ (if $p < \infty$) or $C(\mathbb{R}^d)$ (if $p = \infty$) such that

$$\|f\|_{B^\alpha_{p,q}} := \begin{cases} \|f\|_{L^p} + \left\{ \int_0^\infty \left[t^{-\alpha}\omega_k(f,t)_p\right]^q \frac{dt}{t} \right\}^{1/q}, & 0 < q < \infty, \\ \|f\|_{L^p} + \sup\limits_{t>0} t^{-\alpha}\omega_k(f,t)_p, & q = \infty, \end{cases} \tag{6.2}$$

is finite.

It is known that $B^\alpha_{p,q_1} \subset B^\alpha_{p,q_2}$ if $q_1 < q_2$. When $p = 2$, one has $B^\alpha_{2,2} = H^\alpha$ with equivalent norms.

Interpolation of spaces can be defined by K-functionals. Let $X_1 \subset X_0$ be Banach spaces. For any $f \in X_0$ and $t > 0$,

$$K(f,t) := K(f,t;X_0,X_1) := \inf_{g \in X_1} \{\|f-g\|_{X_0} + t\|g\|_{X_1}\}. \tag{6.3}$$

Here t is viewed as a penalty factor. The intermediate space $[X_0, X_1]_{\theta,q}$ consists of all $f \in X_0$ for which

$$\|f\|_{\theta,q} := \begin{cases} \left\{ \int_0^\infty \left[t^{-\theta}K(f,t)\right]^q \frac{dt}{t} \right\}^{1/q}, & 0 < q < \infty, \\ \sup\limits_{t>0} t^{-\theta}K(f,t), & q = \infty, \end{cases} \tag{6.4}$$

is finite. Obviously, $X_1 \subset [X_0, X_1]_{\theta,q} \subset X_0$.

Amazingly, the K-functional for the pair (L^p, W^k_p) is equivalent to the modulus of smoothness, and hence we have the following (see [3, 15]).

Lemma 5 (interpolation of spaces). *Let $k > 0$ be an integer and let $1 \leq p \leq \infty$. For any $0 < \theta < 1, 0 < q \leq \infty$, we have*

$$\left[L^p(\mathbb{R}^d), W^k_p(\mathbb{R}^d)\right]_{\theta,q} = B^{\theta k}_{p,q}(\mathbb{R}^d). \tag{6.5}$$

Especially,

$$\left[L^2(\mathbb{R}^d), H^1(\mathbb{R}^d)\right]_{\theta,q} = B^{\theta}_{2,q}(\mathbb{R}^d). \tag{6.6}$$

Lemma 6 (interpolation of operators). *Suppose that $X_1 \subset X_0$ and Y are Banach spaces. If T is a linear operator from X_i to Y with norm M_i $(i = 0,1)$, then T is also a linear operator from $[X_0, X_1]_{\theta,q}$ to Y with norm not exceeding $M_0^{1-\theta}M_1^\theta$ for any $0 < \theta < 1, 0 < q \leq \infty$.*

THEOREM 7. *Suppose that Assumptions* A *and* B *are satisfied. Then for any* $0 < \theta < 1, 0 < q \leq \infty$, *the following error estimate holds:*

$$\begin{aligned}&\max_{0\leq n\leq N} \|u(\mathbf{x}, t_n) - U_h^n(\mathbf{x})\|_{L^2(\mathbb{R}^d)} \\ &\quad\leq C\Big\{ \Big[(h/\sqrt{\Delta t})^\theta + (\Delta t)^\theta\Big] \|u_0\|_{B^\theta_{2,q}(\mathbb{R}^d)} \\ &\qquad +(h/\sqrt{\Delta t} + \Delta t) \left[\|f\|_{L^2(0,T;H^1(\mathbb{R}^d))} + \|f_\tau\|_{L^2(0,T;L^2(\mathbb{R}^d))}\right] \Big\},\end{aligned} \tag{6.7}$$

where Δt *and* h *bear the same meaning as that in Theorem* 1, *but* C *may additionally depend on* θ.

Proof. We split the error as

$$u_n - U_h^n = [u_n^{(1)} - U_h^{(1),n}] + [u_n^{(2)} - U_h^{(2),n}],$$

where $u_n^{(1)}$ and $U_h^{(1),n}$ are the exact and numerical solutions for problem (1.1) without source term (i.e., $f \equiv 0$), whereas $u_n^{(2)}$ and $U_h^{(2),n}$ are the exact and numerical solutions for the problem with no initial data ($u_0 \equiv 0$).

Recall that in [24] we proved the numerical solution is L^2-stable. Here (4.23) is the L^2-stability of the exact solution. Combined, they imply

$$\|u_n^{(1)} - U_h^{(1),n}\|_{L^2(\mathbb{R}^d)} \leq C\|u_0\|_{L^2(\mathbb{R}^d)}$$

for $u_0 \in L^2(\mathbb{R}^d)$. If $u_0 \in H^1(\mathbb{R}^d)$, then by Theorem 1 we have

$$\|u_n^{(1)} - U_h^{(1),n}\|_{L^2(\mathbb{R}^d)} \leq C(h/\sqrt{\Delta t} + \Delta t)\|u_0\|_{H^1(\mathbb{R}^d)}.$$

Applying Lemmas 5 and 6 to the linear operator $E_n : u_0 \mapsto u_n^{(1)} - U_h^{(1),n}$, we obtain

$$\begin{aligned}\|u_n^{(1)} - U_h^{(1),n}\|_{L^2(\mathbb{R}^d)} &\leq C(h/\sqrt{\Delta t} + \Delta t)^\theta \|u_0\|_{B^\theta_{2,q}(\mathbb{R}^d)} \\ &\leq C\Big[(h/\sqrt{\Delta t})^\theta + (\Delta t)^\theta\Big] \|u_0\|_{B^\theta_{2,q}(\mathbb{R}^d)}.\end{aligned}$$

By Theorem 1 again, we have

$$\|u_n^{(2)} - U_h^{(2),n}\|_{L^2(\mathbb{R}^d)} \leq C(h/\sqrt{\Delta t} + \Delta t)\big(\|f\|_{L^2(0,T;H^1(\mathbb{R}^d))} + \|f_\tau\|_{L^2(0,T;L^2(\mathbb{R}^d))}\big).$$

Then the conclusion of Theorem 7 follows from a triangle inequality. □

7. Optimality of our error estimates. For solutions with H^1- or even lower regularity, we can use Haar wavelets to carry out our numerical approximations. Haar wavelets are the simplest wavelets and have only one vanishing moment. We know that the order of approximation accuracy is usually the minimum of the order of smoothness of the function being approximated and the order of the method, which is the number of vanishing moments for orthogonal wavelets. For a solution $u \in H^1$, Assumption A in section 3 is satisfied for the approximation subspace V_h generated by Haar wavelets.

However, in the original formulation of ELLAM discussed in subsection 2.1, the test function $w(\mathbf{x}, t)$ is assumed to be in $H^1(\mathbb{R}^d)$ for any $t \in (t_{n-1}, t_n]$ and required to satisfy the adjoint equation (2.2). But Haar scaling functions and wavelets are not in $H^1(\mathbb{R})$. However, mollifications with any cut-off function can be applied to Haar scaling functions or wavelets [18], so that (2.2) is satisfied for the mollifications. Then, based on the L^2-stability of the exact solution and density arguments, we can still get the reference equation (2.5) when the test function $w(x,t)$ is such that $w(x,t_n)$ is taken as a Haar scaling function or wavelet. Numerical scheme (2.10) can be established for Haar scaling functions and wavelets without difficulty. Moreover, when Haar scaling functions are used in the ELLAM formulation, the coefficients are exactly the cell averages of the unknown function on dyadic cells, thus we have local conservation of mass.

Let us consider a simple convection equation: $u_t - u_x = 0$, with a time step $\Delta t = \alpha h$ $(0 < \alpha < 1)$. For this case, the ELLAM scheme with Haar scaling functions becomes a monotone scheme, which is widely used for hyperbolic conservation laws. Monotone schemes are a special case of linear formal first order schemes; see [4] for details. According to Theorem 4.4 in [4], there exists a constant C_1 such that

$$\sup_{\|u_0\|_{H^1(\mathbb{R})}\leq 1} \|u(\mathbf{x},T) - U_h^N(\mathbf{x})\|_{L^2(\mathbb{R})} \geq C_1 h^{1/2}. \tag{7.1}$$

An explicit value for C_1 can be derived using a modification of the argument in [23].

On the other hand, for this equation with any initial condition $u_0 \in H^1(\mathbb{R})$ and $\Delta t = \alpha h$ $(0 < \alpha < 1)$, our Theorem 1 implies an upper bound for the error in the numerical solution at the final time T:

$$\|u(\mathbf{x},T) - U_h^N(\mathbf{x})\|_{L^2(\mathbb{R})} \leq C_2 h^{1/2}. \tag{7.2}$$

The above lower and upper bounds imply that our error estimate is optimal for this case for the class of initial conditions $u_0 \in H^1$. We also want to point out that it is possible to give more examples with an optimal rate 1/2: for a different equation or a different subspace generated by smooth basis functions.

Regarding the term $h/\sqrt{\Delta t}$ in the error estimates, our understanding is that it reflects the behavior of numerical schemes when only H^1-smoothness is assumed for exact solutions. From approximation theory, we know that only first order $\mathcal{O}(h)$ approximation accuracy can be achieved at each fixed time step. For time-marching schemes, error will accumulate. However, the buildup of error can be controlled by the stability of solutions. In our theoretical estimates, we derive an upper bound for the error in the form $h/\sqrt{\Delta t}$. A similar error estimate with adverse dependence on Δt in the form

$$\|u - u_h\|_{L^\infty(0,T;L^1(\mathbb{R}))} \leq \|u_0\|_{TV}\left(h + \frac{2\sqrt{T}}{\sqrt{3}}\frac{h}{\sqrt{\Delta t}}\right)$$

can also be found in [20] for one-dimensional nonlinear conservation law. Here u_h is the numerical solution and $\|\cdot\|_{TV}$ denotes the total variation.

To balance the two parts in our error estimates, the optimal choice for Δt is $\Delta t = Ch^{2/3}$. No lower bound for the error for the case $\Delta t = Ch^\beta$ $(\beta \neq 1)$ is covered in [4, 23]. It is also almost impossible to derive a general error estimate that is optimal for all schemes and all $0 < \beta < \infty$. But the rates observed in our numerical experiments in the next section are close to our theoretical rates for the case $\Delta t = Ch^{2/3}$.

It might not be exciting if small time steps Δt have to be used, e.g., for the traditional finite difference methods that are subject to the CFL condition. However, our ELLAM schemes are CFL-free [24]. So we are allowed to use relatively large time steps. This saves computations while retaining accuracy since information from characteristics are exploited.

8. Numerical experiments. In this section, we present one-dimensional numerical experiments to illustrate the theoretical results proven in previous sections.

We consider two examples with $V(x,t) = 1$, $R(x,t) = 0.2\sin t$, $f(x,t) = 0$, $\Omega = [0,2]$, and $T = 1$. The exact solution is then given by $u(x,t) = u_0(\xi)e^{0.2(\cos t-1)}$, where ξ is obtained by back-tracking the characteristic from (x,t) to $(\xi,0)$.

Example 1. The initial condition is specified as a cusp function:

$$u_0(x) = \begin{cases} A\Big(1 - \Big|\dfrac{x-\alpha}{\beta}\Big|^{\frac{1}{2}+\gamma}\Big) & \text{if } |x-\alpha| \le \beta, \\ 0 & \text{otherwise,} \end{cases} \tag{8.1}$$

where $\alpha \in \mathbb{R}, \beta > 0$, and $0 < \gamma \le 1/2$. It can be verified that $u_0 \in H^{1+\delta}(\mathbb{R})$ for any $0 < \delta < \gamma$.

In the numerical experiment, we take $A = 1, \alpha = 0.5, \beta = 0.25, \gamma = 0.01$. So the initial data is barely in $H^1(\mathbb{R})$, or, precisely, $u_0 \in H^{1+\delta}$ for $0 < \delta < 0.01$. The second order Daubechies scaling function and wavelet are used in the wavelet schemes.

We can attain only first order approximation in space for the initial data since it is barely in $H^1(\mathbb{R})$. The adverse dependence of the error estimate on Δt in section 3 indicates that time discretization has to be done carefully. More time steps do not necessarily mean better approximations. The best result can be attained when $\Delta t = h/\sqrt{\Delta t}$, that is, $\Delta t = h^{2/3}$, if the constants in the estimate are ignored. In other words, the wavelet schemes have convergence rate $h^{2/3}$. In Table 8.1, the numerical solution at the final time step has a convergence rate 0.74 in h, which is just about 10% better than the theoretical estimate 2/3.

TABLE 8.1
Convergence rates in h for Example 1.

h	$\Delta t = Ch^{2/3}$	$\|u_0 - U_0\|_{L^2}$	$\|u_T - U_T\|_{L^2}$
$1/2^6$	1/16	7.502E-3	5.134E-3
$1/2^9$	1/64	9.181E-4	1.114E-4
$1/2^{12}$	1/256	1.124E-4	2.457E-4
$1/2^{15}$	1/1024	1.376E-5	4.880E-5
Convergence rates		1.01	0.74

Example 2. The initial condition is the indicator function $\chi_{[\alpha,\beta]}$ of the interval $[\alpha,\beta]$:

$$u_0(x) = \chi_{[\alpha,\beta]} = \begin{cases} 1 & x \in [\alpha,\beta], \\ 0 & \text{otherwise.} \end{cases} \tag{8.2}$$

It is known that, for any interval I containing $[\alpha,\beta]$ in its interior, we have $\chi_{[\alpha,\beta]} \in H^{\frac{1}{2}-\delta}(I)$ for any $0 < \delta \le \frac{1}{2}$ but $\notin H^{\frac{1}{2}}(I)$. Direct calculations indicate that

$$\|\chi_{[\alpha,\beta]}\|_{H^{\frac{1}{2}-\delta}(I)} = \mathcal{O}(\delta^{-\frac{1}{2}}) \to \infty \quad \text{as } \delta \to 0. \tag{8.3}$$

Hence, the approximation order could not be characterized well using norms in Sobolev spaces. This is one place where we should use Besov spaces. It can be verified that $\chi_{[\alpha,\beta]} \in B^{\frac{1}{2}}_{2,\infty}(I)$ but $\notin B^{\frac{1}{2}}_{2,q}(I)$ for $q < \infty$.

The numerical results for $[\alpha,\beta] = [0.25, 0.75]$ are shown in Table 8.2. The order of approximation to the initial data (u_0) is exactly 1/2 because $u_0 \in B^{\frac{1}{2}}_{2,\infty}$. After the

Table 8.2
Convergence rates in h for Example 2.

h	$\Delta t = Ch^{2/3}$	$\|u_0 - U_0\|_{L^2}$	$\|u_T - U_T\|_{L^2}$
$1/2^7$	1/20	3.232E-2	5.375E-2
$1/2^{10}$	1/80	1.142E-2	2.248E-2
$1/2^{13}$	1/320	4.040E-3	1.151E-2
$1/2^{16}$	1/1280	1.428E-3	5.053E-3
Convergence rates		0.50	0.38

time-marching procedure, the approximation error at the final time step is of order 0.38, close to the theoretical estimate 1/3.

In these two numerical examples, convergence rates are a little better than the theoretically proven rates because the velocity field is nice (but we can easily compute the exact solutions in these cases). If the velocity field is exactly Lipschitz, i.e., it has minimal regularity, we expect numerical results to be even closer to the theoretical estimates.

9. Concluding remarks. Some similar results concerning convergence rates of Lagrangian–Galerkin methods for convection-dominated diffusion problems are presented in [2]. Their estimates are uniform in the small diffusion parameter and can be carried over to the hyperbolic limit case—linear convection equations without a reaction term. Their results are consistent with ours but require a smoother velocity field ($\mathbf{V} \in C(0, T; C^2(\overline{\Omega}))$).

The assumption $R \in W^1_\infty(\mathbb{R}^d \times [0, T])$ in our paper means some smoothness in the reaction term is required. Note that the test functions in ELLAM rely on the properties of the reaction along characteristics. Generally speaking, this type of smoothness is needed for time-marching schemes; otherwise we could not use well the information of the solutions at previous time steps.

In section 6, we did not discuss interpolations on the source term. The limitation is due to the way the source term is truncated in numerical scheme (2.10). Recall that in (2.7) we approximate the double integral for the source term by a single integral. This assumes some smoothness of the source term along the temporal direction or the characteristic direction. In return, the computational cost for the source term is reduced. Of course, the numerical scheme can be modified to allow even lower regularity for the source term, but accordingly the computational cost will increase.

For the wavelet scheme with adaptive compression, i.e., Scheme III in [24], computational cost will be significantly reduced through thresholding wavelet coefficients in the smooth regions. But the approximation will deteriorate as the threshold parameter is increased. A good choice of the threshold, in other words, a quantitative description of the trade-off between computational cost and approximation accuracy, is a delicate issue of nonlinear approximation and is already under our investigation.

ERROR BOUNDS FOR MONOTONE APPROXIMATION SCHEMES FOR HAMILTON–JACOBI–BELLMAN EQUATIONS[*]

GUY BARLES[†] and ESPEN R. JAKOBSEN[‡]

Abstract. We obtain error bounds for monotone approximation schemes of Hamilton–Jacobi–Bellman equations. These bounds improve previous results of Krylov and the authors. The key step in the proof of these new estimates is the introduction of a switching system which allows the construction of approximate, (almost) smooth supersolutions for the Hamilton–Jacobi–Bellman equation.

Key words. Hamilton–Jacobi–Bellman equations, switching system, viscosity solution, approximation schemes, finite difference methods, convergence rate, error bound

1. Introduction.

This paper is a continuation of a work started in [2] (see also Jakobsen [21]), whose aim is to prove results on the rate of convergence of monotone approximation schemes for possibly degenerate Hamilton–Jacobi–Bellman (HJB) equations by purely analytical methods. Krylov [26, 27] obtained such results in a rather general framework but by using a combination of PDE arguments and rather deep probabilistic estimates, which we want to avoid.

The strategy we used in [2] is based on the idea that the HJB equation and the approximation scheme should play symmetrical roles. Unfortunately, this leads to unnatural restrictions on the data when the scheme in consideration is a finite difference method. These restrictions do not appear in [27]. In the present paper, we use a more classical strategy, in which the HJB equation plays the central role. Our approach yields results in the full generality, improving those of [26, 27] and [2].

In order to be more specific, we introduce the HJB equation, which is written in the form

$$F(x,u,Du,D^2u)=0 \quad \text{in} \quad \mathbb{R}^N, \tag{1.1}$$

with

$$\begin{aligned} F(x,t,p,X) &= \sup_{\alpha\in\mathcal{A}} \mathcal{L}^\alpha(x,t,p,X),\\ \mathcal{L}^\alpha(x,t,p,X) &= -\mathrm{tr}[a^\alpha(x)X]-b^\alpha(x)p+c^\alpha(x)t-f^\alpha(x), \end{aligned}$$

where tr denotes the trace. The coefficients a, b, c, f are, at least, continuous functions defined on $\mathbb{R}^N\times\mathcal{A}$ with values, respectively, in the space $S(N)$ of symmetric $N\times N$ matrices, $\mathbb{R}^N$ and $\mathbb{R}$. The space of controls, $\mathcal{A}$, is assumed to be a compact metric space. Precise assumptions on the data will be given later on. Under classical

assumptions, it is well known that this equation is associated to a stochastic optimal control problem, and that the value function of this problem is the unique viscosity solution of the equation. Moreover, the value function is typically bounded and Hölder continuous, and the regularity depends on the properties of a, b, c, and f.

The monotone approximation schemes we consider are of the type

$$S(h, x, u_h(x), [u_h]_x) = 0 \quad \text{in} \quad \mathbb{R}^N, \tag{1.2}$$

where S is, loosely speaking, a consistent, monotone, and uniformly continuous approximation of F in (1.1). The approximate solution is u_h, $[u_h]_x$ is a function defined from u_h, and the approximation parameter is h. This abstract notation was introduced by Barles and Souganidis [3] to display clearly the monotonicity of the scheme: S is nondecreasing in u_h and nonincreasing in $[u_h]_x$ with the classical ordering for functions. Typical approximation schemes which we have in mind are finite difference methods (FDMs) and control schemes based on the dynamic programming principle. We refer to Dupuis and Kushner [11] and Camilli and Falcone [5] for more information about such schemes.

In the viscosity solutions setting the first results on convergence rates for monotone schemes were obtained by Crandall and Lions [10]. Later, the first-order case was studied by many authors considering different schemes and assumptions [7, 36, 37, 13, 1, 25, 29, 35, 28, 24]. Only recently did Krylov [26, 27] obtain the first results for second-order equations (for HJB equations), and these results were then partially extended by Barles and Jakobsen [2] and Jakobsen [21]. These results concern only HJB equations, or, equivalently, equations with convex/concave Lipschitz continuous nonlinearity F. In the nonconvex (or nonconcave) case, to the best of our knowledge, there are no general results. There exist results only in particular cases like, for example, in one space dimension [20] and for obstacle problems [19].

From a technical point of view, the upper estimate on $u - u_h$ is much easier to obtain than the lower estimate. Roughly speaking, a regularization of the solution u by convolution provides approximate smooth subsolutions of the equation because of the convexity of the equation. By inserting this smooth subsolution in the scheme and using consistency, one is led to the upper bound after choosing an optimal parameter of regularization. It is worth pointing out that a nontrivial difficulty in performing this argument is the x-dependence in the equation. This difficulty was solved by a very clever argument of Krylov [27] which is used extensively in [2] and in the present paper.

Unfortunately, this is clearly a one-sided argument working only for convex equations. In general, there is no simple way to build approximate smooth supersolutions which would lead to the lower estimate on $u - u_h$. It is precisely this difficulty that we overcome here. In fact, we do not really build a sequence of approximate smooth supersolutions, but rather a sequence of supersolutions which behave as if they were smooth. The key step here is to introduce switching system approximations of the HJB equation and study their rates of convergence. This admittedly strange idea leads us roughly speaking to consider equations that are linear (convex and concave) and from there to the solution of the above problem. Krylov [27] uses piecewise constant control approximations, which is more or less the interpretation of switching systems. Despite this similarity, the connection between his arguments and ours is not so clear. Our approach is inspired by Evans and Friedman [12] (see also [6]), and the rates of convergence are obtained by combining the above-mentioned clever argument of Krylov and an approach suggested by Lions [33]. Even if we do not make a point of proving general results in this direction, this part has an independent interest. It seems to be the first time that the rate of convergence is obtained for such switching system approximations in the case of second-order equations.

In order to give a flavor of our results, for HJB equation satisfying natural assumptions and with bounded Lipschitz continuous solutions, we prove a lower estimate of the form $h^{1/5}$ for a standard finite difference method. The corresponding result in Krylov [27] was $h^{1/27}$.

For control schemes, the results of this paper do not give the best error bounds available. They can be found in [2], where the richer structure of such schemes is fully exploited.

The paper is organized as follows: In section 2 we introduce the switching system and prove the rate of convergence. This result is then used in section 3 for obtaining the rate of convergence of the approximation scheme (1.2). In section 4, we apply the result of section 3 to a typical finite difference method for the HJB equation taken from Dupuis and Kushner [11]. In order to simplify the exposure, the proofs in the paper are presented in a context where all the solutions are Lipschitz continuous. In section 5, we provide without proofs extensions to the case of $C^{0,\delta}(\mathbb{R}^N)$-solutions. We also discuss the fact that our approach is rather close to provide results for the nonconvex (nonconcave) case. Finally, the appendix collects several results for switching systems (well-posedness, regularity, and continuous dependence) which are used throughout the paper.

We conclude this introduction by explaining the notation we will use throughout this paper. By $|\cdot|$ we mean the standard Euclidian norm in any $\mathbb{R}^p$-type space (including the space of $N \times P$ matrices). In particular, if $X \in S(N)$, then $|X|^2 = \mathrm{tr}(XX^T)$, where X^T denotes the transpose of X. Now if w is a bounded function from $\mathbb{R}^N$ into either $\mathbb{R}$, $\mathbb{R}^M$, or the space of $N \times P$ matrices, we set

$$|w|_0 = \sup_{y \in \mathbb{R}^N} |w(y)|.$$

If w is also Lipschitz continuous, we set

$$[w]_1 = \sup_{x \neq y} \frac{|w(x) - w(y)|}{|x-y|} \quad \text{and} \quad |w|_1 = |w|_0 + [w]_1.$$

We denote by $\leq$ the component-by-component ordering in $\mathbb{R}^M$ and the ordering in the sense of positive semidefinite matrices in $S(N)$. For the rest of this paper we let ρ denote the same, fixed, positive smooth function with support in $\{|x| < 1\}$ and mass 1. From this function ρ, we define the sequence of mollifiers $\{\rho_\varepsilon\}_{\varepsilon>0}$ as follows:

$$\rho_\varepsilon(x) = \frac{1}{\varepsilon^N}\rho\left(\frac{x}{\varepsilon}\right) \quad \text{in} \quad \mathbb{R}^N.$$

We also use the following spaces: $C_b(\mathbb{R}^N)$ and $C^{0,\delta}(\mathbb{R}^N)$, $\delta \in (0,1]$, denoting, respectively, the space of bounded continuous functions on $\mathbb{R}^N$ and the space of bounded δ-Hölder continuous functions on $\mathbb{R}^N$.

2. Convergence rate for a switching system.

In this section, we obtain the rate of convergence for certain switching system approximations to the HJB equation (1.1). Such approximations have been studied in [12, 6], and a viscosity solutions theory of switching systems can be found in [38, 18, 17]. We consider the following type of switching systems:

$$F_i(x, v, Dv_i, D^2 v_i) = 0 \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I} := \{1, \ldots, M\}, \tag{2.1}$$

where the solution $v = (v_1, \dots, v_M)$ is in $\mathbb{R}^M$, and for $i \in \mathcal{I}$, $x \in \mathbb{R}^N$, $r = (r_1, \dots, r_M) \in \mathbb{R}^M$, $p \in \mathbb{R}^N$, and $X \in \mathcal{S}^N$, F_i is given by

$$F_i(x, r, p, X) = \max \left\{ \sup_{\alpha \in \mathcal{A}_i} \mathcal{L}^\alpha(x, r_i, p, X);\ r_i - \mathcal{M}_i r \right\},$$

where $\mathcal{A}_i \subset \mathcal{A}$, $\mathcal{L}^\alpha$ is defined below (1.1), and for $k > 0$,

$$\mathcal{M}_i r = \min_{j \neq i} \{r_j + k\}.$$

Under suitable assumptions on the data, we have the existence and uniqueness of a solution v of this system. Moreover, it is not difficult to see that, as $k \to 0$, every component of v converges locally uniformly to the solution of the HJB equation

$$\sup_{\alpha \in \overline{\mathcal{A}}} \mathcal{L}^\alpha(x, u, Du, D^2 u) = 0 \quad \text{in} \quad \mathbb{R}^N\ , \tag{2.2}$$

where $\overline{\mathcal{A}} = \cup_i \mathcal{A}_i$.

The objective of this section is to obtain an error bound for this convergence. For the sake of simplicity, we restrict ourselves to the situation where the solutions are Lipschitz continuous. However, it is not difficult to adapt our approach to more general situations, and we give results in this direction in section 5.

We will use the following assumptions:

(A1) For any $\alpha \in \mathcal{A}$, $a^\alpha = \frac{1}{2}\sigma^\alpha \sigma^{\alpha T}$ for some $N \times P$ matrix σ^α. Furthermore, there are constants λ, K independent of α such that

$$c \geq \lambda > 0 \quad \text{and} \quad |\sigma^\alpha|_1 + |b^\alpha|_1 + |c^\alpha|_1 + |f^\alpha|_1 \leq K.$$

(A2) The constant λ in (A1) satisfies $\lambda > \sup_\alpha \left\{ [\sigma^\alpha]_1^2 + [b^\alpha]_1 \right\}$.

As the reader will see below and in the following sections, assumption (A1) ensures the well-posedness of all the equations and systems of equations we consider in this paper. If we assume in addition (A2), all solutions will belong to $C^{0,1}(\mathbb{R}^N)$. We refer to the appendix for a precise justification of these claims. In the present situation, we have the following well-posedness and regularity result.

PROPOSITION 2.1. (i) *Assume* (A1). *If w_1 and w_2 are sub- and supersolutions of* (2.1) *or* (2.2), *then $w_1 \leq w_2$.*

(ii) *Assume* (A1) *and* (A2). *Then there exist unique solutions v and u of* (2.1) *and* (2.2), *respectively, satisfying*

$$|v|_1 + |u|_1 \leq C,$$

where the constant C depends only on K, λ from (A1).

In order to obtain the rate of convergence for the switching approximation, we use the before-mentioned regularization procedure of Krylov [27, 2]. This procedure requires the introduction of the following auxiliary system:

$$F_i^\varepsilon(x, v^\varepsilon, Dv_i^\varepsilon, D^2 v_i^\varepsilon) = 0 \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I}, \tag{2.3}$$

where $v^\varepsilon = (v_1^\varepsilon, \dots, v_M^\varepsilon)$,

$$F_i^\varepsilon(x, r, p, M) = \max \left\{ \sup_{\alpha \in \mathcal{A}_i, |e| \leq \varepsilon} \mathcal{L}^\alpha(x + e, r_i, p, X);\ r_i - \mathcal{M}_i r \right\},$$

and $\mathcal{L}$ and $\mathcal{M}$ are defined below (1.1) and (2.1), respectively. By Theorems A.1 and A.3 in the appendix, we have the following result.

Proposition 2.2. (i) *Assume* (A1). *If w_1 and w_2 are sub- and supersolutions of* (2.3)*, then $w_1 \leq w_2$.*

(ii) *Assume* (A1) *and* (A2). *Then there exists a unique solution v^ε of* (2.3) *satisfying*

$$|v^\varepsilon|_1 + \frac{1}{\varepsilon}|v^\varepsilon - v|_0 \leq C,$$

where v solves (2.1) *and the constant C depends only on K, λ from* (A1).

We are now in position to state and prove the main result of this section.

Theorem 2.3. *Assume* (A1) *and* (A2). *If u and v are the solutions of* (2.2) *and* (2.1)*, respectively, then for k small enough,*

$$0 \leq v_i - u \leq Ck^{1/3} \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I},$$

where C depends only on λ, K from (A1).

Remark 2.1. This seems to be the first time the rate of convergence is obtained for switching system approximations of second-order equations.

Proof of Theorem 2.3. Since $w = (u, \dots, u)$ is a subsolution of (2.1), comparison for (2.1) (Proposition 2.1(i)) yields $u \leq v_i$ for $i \in \mathcal{I}$.

To get the other bound, we use an argument suggested by Lions [33] together with the regularization procedure of Krylov [27]. Consider first system (2.3). It follows that, for every $|e| \leq \varepsilon$,

$$\sup_{\alpha \in \mathcal{A}_i} \mathcal{L}^\alpha(x + e, v_i^\varepsilon(x), Dv_i^\varepsilon, D^2 v_i^\varepsilon) \leq 0 \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I}.$$

After a change of variables, we see that for every $|e| \leq \varepsilon$, $v^\varepsilon(x - e)$ is a subsolution of the following system of uncoupled equations:

$$\sup_{\alpha \in \mathcal{A}_i} \mathcal{L}^\alpha(x, w_i, Dw_i, D^2 w_i) = 0 \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I}. \tag{2.4}$$

Define $v_\varepsilon := v^\varepsilon * \rho_\varepsilon$, where $\{\rho_\varepsilon\}_\varepsilon$ is the sequence of mollifiers defined at the end of the introduction. A Riemann-sum approximation shows that $v_\varepsilon(x)$ can be viewed as the limit of convex combinations of $v^\varepsilon(x - e)$'s for $|e| < \varepsilon$. Since the $v^\varepsilon(x - e)$'s are subsolutions of the convex(!) equation (2.4), so are the convex combinations. By the stability result for viscosity subsolutions we can now conclude that v_ε is itself a subsolution of (2.4). We refer to the appendix in [2] for more details.

On the other hand, since v^ε is a continuous subsolution of (2.3), we have

$$v_i^\varepsilon \leq \min_{j \neq i} v_j^\varepsilon + k \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I}.$$

It follows that $\max_i v_i^\varepsilon(x) - \min_i v_i^\varepsilon(x) \leq k$, and hence

$$|v_i^\varepsilon - v_j^\varepsilon|_0 \leq k, \quad i, j \in \mathcal{I}.$$

Then, by the definition and properties of v_ε, we have

$$|D^n v_{\varepsilon i} - D^n v_{\varepsilon j}|_0 \leq C\frac{k}{\varepsilon^n}, \quad n \in \mathbb{N}, \quad i, j \in \mathcal{I},$$

where C depends only on ρ. Furthermore, from these bounds, we see that for $\varepsilon < 1$,

$$\left|\sup_{\alpha\in\mathcal{A}_i} \mathcal{L}^\alpha[v_{\varepsilon j}] - \sup_{\alpha\in\mathcal{A}_i} \mathcal{L}^\alpha[v_{\varepsilon i}]\right| \leq C\frac{k}{\varepsilon^2} \quad \text{in} \quad \mathbb{R}^N, \quad i,j\in\mathcal{I}.$$

Here C depends only on $|\sigma|_0, |b|_0, |c|_0$, and ρ. Since v_ε is a subsolution of (2.4), this means that

$$\sup_{\alpha\in\mathcal{A}} \mathcal{L}^\alpha(x, v_{\varepsilon i}, Dv_{\varepsilon i}, D^2 v_{\varepsilon i}) \leq C\frac{k}{\varepsilon^2} \quad \text{in} \quad \mathbb{R}^N, \quad i\in\mathcal{I}.$$

So by (A1) and the definition of $\mathcal{L}$, we see that $v_{\varepsilon i} - \frac{1}{\lambda}C\frac{k}{\varepsilon^2}$ is a subsolution of (2.2).

Comparison for (2.2) (Proposition 2.1(i)) yields

$$v_{\varepsilon i} - u \leq \frac{1}{\lambda}C\frac{k}{\varepsilon^2} \quad \text{in} \quad \mathbb{R}^N, \quad i\in\mathcal{I}.$$

Hence, by Proposition 2.2(ii) and properties of mollifiers, we have

$$v_i - u \leq v_i - v_{\varepsilon i} + v_{\varepsilon i} - u \leq C\varepsilon + \frac{1}{\lambda}C\frac{k}{\varepsilon^2} \quad \text{in} \quad \mathbb{R}^N, \quad i\in\mathcal{I}.$$

Minimizing with respect to ε yields the result. □

3. Convergence rate for the HJB equation. In this section we derive an error bound for the convergence of the solution of the scheme (1.2) to the solution of the HJB equation (1.1). This result is general and derived using only PDE methods, and it extends and improves earlier results by Krylov [26, 27], Barles and Jakobsen [2], and Jakobsen [21].

We assume that assumptions (A1) and (A2) of section 2 hold. As a special case of Proposition 2.1, we have the following well-posedness and regularity result for (1.1).

PROPOSITION 3.1. (i) *Assume* (A1). *If w_1 and w_2 are sub- and supersolutions of* (1.1)*, then $w_1 \leq w_2$.*

(ii) *Assume* (A1) *and* (A2). *Then there exists a unique solution u of* (1.1) *satisfying*

$$|u|_1 \leq C,$$

where the constant C depends only on K, λ from (A1).

For the scheme (1.2) we assume the following:

(S1) (Monotonicity.) For every $h > 0$, $x \in \mathbb{R}^N$, $r \in \mathbb{R}$, $m \geq 0$, and bounded continuous functions u, v such that $u \leq v$ in $\mathbb{R}^N$, the following holds:

$$S(h, x, r+m, [u+m]_x) \geq \lambda m + S(h, x, r, [v]_x).$$

(S2) (Regularity.) For every $h > 0$ and $\phi \in C_b(\mathbb{R}^N)$, $x \mapsto S(h, x, \phi(x), [\phi]_x)$ is bounded and continuous in $\mathbb{R}^N$ and the function $r \mapsto S(h, x, r, [\phi]_x)$ is uniformly continuous for bounded r, uniformly in $x \in \mathbb{R}^N$.

(S3) (Consistency.) There exist integers $n, k_i \geq 0$, $i = 1, 2, \ldots, n$, and a constant K_c such that for every $h \geq 0$, $x \in \mathbb{R}^N$, and smooth function ϕ,

$$\left|F(x, \phi(x), D\phi(x), D^2\phi(x)) - S(h, x, \phi(x), [\phi]_x)\right| \leq K_c \sum_{k_i\neq 0} |D^i\phi|_0 h^{k_i}.$$

Remark 3.1. Conditions (S1) and (S2) imply a comparison result for bounded continuous solutions of (1.2); see [2].

Before we continue, we mention that the upper bound on the error $u - u_h$ is known from [2]; see also [27, 21]. Let us state the result here.

PROPOSITION 3.2. *Assume* (A1), (A2), (S1)–(S3), *and that* (1.2) *has a unique solution* $u_h \in C_b(\mathbb{R}^N)$. *If* u *is the solution of* (1.1), *then, for sufficiently small* $h > 0$, *we have*

$$u - u_h \leq Ch^\gamma \quad in \quad \mathbb{R}^N,$$

where $\gamma := \min_{k_i \neq 0} \left\{ \frac{k_i}{i} \right\}$ *and* C *depends only on* λ, K, K_c *from* (A1), (S3).

Remark 3.2. Existence of $u_h \in C_b(\mathbb{R}^N)$ must be proved for each particular scheme S. We refer to [26, 27, 2, 21] for examples of such arguments.

As mentioned in the introduction, the proof of this proposition relies on the regularization procedure of Krylov, which was also used in section 2. The idea is to obtain a smooth subsolution of (1.1) which is close to the solution of this equation. This then yields the upper bound after classical computations. This approach, however, does not yield the lower bound unless you require much stronger assumptions on the scheme (1.2); see [2, 21, 26].

To avoid such restrictive assumptions, we use a different technique here. The key point is to obtain approximate "almost smooth" supersolutions by considering the following switching system approximation of (1.1):

$$F_i^\varepsilon(x, v^\varepsilon, Dv_i^\varepsilon, D^2 v_i^\varepsilon) = 0 \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I} := \{1, \ldots, M\}, \tag{3.1}$$

where $v^\varepsilon = (v_1^\varepsilon, \ldots, v_M^\varepsilon)$,

$$F_i^\varepsilon(x, r, p, X) = \max \left\{ \min_{|e| \leq \varepsilon} \mathcal{L}^{\alpha_i}(x + e, r_i, p, X);\ r_i - \mathcal{M}_i r \right\},$$

and $\mathcal{L}$ and $\mathcal{M}$ are defined below (1.1) and (2.1), respectively. The solution of this system is expected to be close to the solution of (1.1) if k and ε are small and $\{\alpha_i\}_{i \in \mathcal{I}} \subset \mathcal{A}$ is a sufficiently refined grid for $\mathcal{A}$. In fact, for this to be true we need to assume that the coefficients $\sigma^\alpha, b^\alpha, c^\alpha, f^\alpha$ can be approximated uniformly in x by $\sigma^{\alpha_i}, b^{\alpha_i}, c^{\alpha_i}, f^{\alpha_i}$. The precise assumption is as follows:

(A3) For every $\delta > 0$, there are $M \in \mathbb{N}$ and $\{\alpha_i\}_{i=1}^M \subset \mathcal{A}$, such that for any $\alpha \in \mathcal{A}$,

$$\inf_{1 \leq i \leq M} (|\sigma^\alpha - \sigma^{\alpha_i}|_0 + |b^\alpha - b^{\alpha_i}|_0 + |c^\alpha - c^{\alpha_i}|_0 + |f^\alpha - f^{\alpha_i}|_0) < \delta.$$

Remark 3.3. The typical cases where (A3) is satisfied are (i) when $\mathcal{A}$ is a finite set and (ii) when all coefficients are uniformly continuous in α, uniformly in x.

For (3.1), we have the following result.

LEMMA 3.3. *Assume* (A1) *and* (A2).

(a) *There exists a unique solution* v^ε *of* (3.1) *satisfying* $|v^\varepsilon|_1 \leq C$, *where* C *depends only on* λ, K *from* (A1).

(b) *Assume in addition* (A3), *and let* u *denote the solution of* (1.1). *Then for any* $\delta > 0$ *there are* $M \in \mathbb{N}$ *and* $\{\alpha_i\}_{i=1}^M \subset \mathcal{A}$ *such that the solution* v_ε *of* (3.1) *satisfy*

$$\max_i |u - v_i^\varepsilon|_0 \leq C(\varepsilon + k^{1/3} + \delta),$$

where C *depends only on* λ, K *from* (A1).

The (almost) smooth supersolutions of (1.1) we are looking for are built out of the v_i^ε's by mollification. Before giving the next lemma, we remind the reader that the sequence of mollifiers $\{\rho_\varepsilon\}_\varepsilon$ is defined at the end of the introduction.

LEMMA 3.4. *Assume* (A1), (A2), *and define* $v_{\varepsilon i} := \rho_\varepsilon * v_i^\varepsilon$ *for* $i \in \mathcal{I}$.

(a) *There is a constant C depending only on λ, K from* (A1), *such that*

$$|v_{\varepsilon j} - v_i^\varepsilon|_0 \le C(k+\varepsilon) \quad \textit{for} \quad i, j \in \mathcal{I}.$$

(b) *Assume in addition that $\varepsilon \le (4\sup_i [v_i^\varepsilon]_1)^{-1}k$. For every $x \in \mathbb{R}^N$, if $j := \mathrm{argmin}_{i\in\mathcal{I}} v_{\varepsilon i}(x)$, then*

$$\mathcal{L}^{\alpha_j}(x, v_{\varepsilon j}(x), Dv_{\varepsilon j}(x), D^2 v_{\varepsilon j}(x)) \ge 0\ .$$

Lemma 3.4(b) implies that $w := \min_{i\in\mathcal{I}} v_{\varepsilon i}$ is a viscosity supersolution of (1.1) in all of $\mathbb{R}^N$ (at least this follows from the proof). This function is an “almost smooth” supersolution in the sense that, at any point x, it is only the smooth function $v_{\varepsilon j}$ of Lemma 3.4(b) (which is a supersolution at this point) which is really playing a role. This can be seen from the proof of the rate of convergence below.

We will prove these two lemmas after having stated and proved the main result of this paper—the result giving the lower bound on the error $u - u_h$ for the scheme (1.2).

THEOREM 3.5. *Assume* (A1)–(A3), (S1), (S3) *and that* (1.2) *has a unique solution $u_h \in C_b(\mathbb{R}^N)$. If u is the solution of* (1.1), *then, for sufficiently small $h > 0$, we have*

$$-Ch^{\bar\gamma} \le u - u_h \quad \textit{in} \quad \mathbb{R}^N,$$

where $\bar\gamma := \min_{k_i \ne 0}\{\frac{k_i}{3i-2}\}$ and C depends only on λ, K, K_c from (A1), (S3).

Proof. We fix a $\delta > 0$ and pick the corresponding $\{\alpha_i\}_\mathcal{I}$ according to (A3). Then we consider the solution v^ε of (3.1) corresponding to this choice of $\{\alpha_i\}_\mathcal{I}$. Lemma 3.3 yields existence and properties of v^ε. Furthermore, we mollify this function to obtain v_ε as in Lemma 3.4.

We proceed to obtain an estimate for

$$m := \sup_{y\in\mathbb{R}^N}\{u_h(y) - w(y)\},$$

where $w := \min_{i\in\mathcal{I}} v_{\varepsilon i}$. In order to have a “max” instead of a “sup,” we approximate m by

$$m_\kappa := \sup_{y\in\mathbb{R}^N}\{u_h(y) - w(y) - \kappa\phi(y)\}, \tag{3.2}$$

where $\kappa > 0$ is a small constant and $\phi(y) = (1+|y|^2)^{1/2}$. Since u_h and w are continuous, it is clear that the supremum (3.2) is attained at some point $x \in \mathbb{R}^N$. Because of the definition of w, it is easy to see that x is also a maximum point of

$$\sup_{y\in\mathbb{R}^N}\{u_h(y) - v_{\varepsilon i}(y) - \kappa\phi(y)\} \tag{3.3}$$

when $i = \mathrm{argmin}_{j\in\mathcal{I}} v_{\varepsilon j}(x)$. Notice that this supremum is still m_κ.

Now take $\varepsilon = (4\sup_i [v_i^\varepsilon]_1)^{-1}k$. From Lemma 3.4(b), the properties of ϕ, and (A1), we see that

$$\sup_{\alpha\in\mathcal{A}} \mathcal{L}^\alpha(x, (v_{\varepsilon i} + \kappa\phi)(x), D(v_{\varepsilon i} + \kappa\phi)(x), D^2(v_{\varepsilon i} + \kappa\phi)(x)) \ge -C\kappa, \tag{3.4}$$

where C depends only on K from (A1) ($C = \sup_{\alpha,x}\{|\sigma^\alpha|_0^2 + |b^\alpha|_0\}$).

Let us estimate m_κ. By (3.4) and (S3) we have

$$-C\kappa \leq S(h, x, (v_{\varepsilon i} + \kappa\phi)(x), [v_{\varepsilon i} + \kappa\phi]_x) + K_c \sum_{k_i \neq 0} |D^i(v_{\varepsilon i} + \kappa\phi)|_0 h^{k_i}.$$

By the definitions of $v_{\varepsilon i}$ and ϕ, we can conclude that

$$-C \sum_{k_i \neq 0} \varepsilon^{1-i} h^{k_i} + \mathcal{O}(\kappa) \leq S(h, x, (v_{\varepsilon i} + \kappa\phi)(x), [v_{\varepsilon i} + \kappa\phi]_x), \tag{3.5}$$

where C depends only on the mollifier ρ and λ, K from (A1). On the other hand, using (S1), (3.3), and the definition of m_κ, we see that

$$\begin{aligned} S(h, x, (v_{\varepsilon i} + \kappa\phi)(x), [v_{\varepsilon i} + \kappa\phi]_x) &\leq S(h, x, u_h(x) - m_\kappa, [u_h - m_\kappa]_x) \\ &\leq -\lambda m_\kappa + S(h, x, u_h(x), [u_h]_x) = -\lambda m_\kappa, \end{aligned}$$

where the last equality follows since u_h is the solution of (1.2). From this inequality and (3.5), we have

$$\lambda m_\kappa \leq C \sum_{k_i \neq 0} \varepsilon^{1-i} h^{k_i} + \mathcal{O}(\kappa).$$

From this estimate, we obtain the estimate for m by sending $\kappa \to 0$ and noting that $m_\kappa \to m$.

Using the estimate for m, we now derive the lower bound on the error. Fix an arbitrary $y \in \mathbb{R}^N$. From the definition of m, we see that

$$\begin{aligned} u_h(y) - u(y) &\leq u_h(y) - v_{\varepsilon i}(y) + v_{\varepsilon i}(y) - u(y) \\ &\leq m + v_{\varepsilon i}(y) - u(y). \end{aligned}$$

Using the bound on m, and Lemmas 3.4(a) and 3.3(b), we obtain

$$u_h(y) - u(y) \leq C \left(\sum_{k_i \neq 0} \varepsilon^{1-i} h^{k_i} + \varepsilon + k + k^{1/3} + \delta \right).$$

The constant C does not depend on y, and therefore the right-hand side is a uniform in y upper bound for $u_h - u$.

The conclusion follows by choosing

$$\varepsilon = \max_{k_i \neq 0} h^{\frac{3k_i}{3i-2}} \quad \text{and} \quad k = 4 \sup_i [v_i^\varepsilon]_1 \varepsilon$$

and sending $\delta \to 0$ (since all constants are independent of the size of $\mathcal{I}$). □

Now we give the proofs of Lemmas 3.3 and 3.4.

Proof of Lemma 3.3.

1. First we approximate (1.1) by the following equation:

$$\sup_{i \in \mathcal{I}} \mathcal{L}^{\alpha_i}(x, v, Dv, D^2 v) = 0 \quad \text{in} \quad \mathbb{R}^N.$$

From assumption (A3) and Theorems A.1 and A.3 in the appendix, we have the following result: There exist a unique solution v of the above equation satisfying

$$|v - u|_0 \leq C\delta,$$

where C depends only on λ, K from (A1).

2. We continue by approximating the above equation by the following switching system:

$$\max\Big\{\mathcal{L}^{\alpha_i}(x, v_i, Dv_i, D^2 v_i);\ v_i - \mathcal{M}_i v\Big\} = 0 \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I},$$

where $\mathcal{M}$ is defined below (2.1). From Proposition 2.1 and Theorem 2.3, we have existence and uniqueness of a solution $\bar{v}$ of the above system satisfying

$$|\bar{v}_i - v|_0 \leq Ck^{1/3}, \quad i \in \mathcal{I},$$

where C depends only on the mollifier ρ and λ, K from (A1).

3. The switching system defined in the previous step is nothing but (3.1) with $\varepsilon = 0$ or (2.3) with the $\mathcal{A}_i$'s being singletons. Proposition 2.2 yields the existence and uniqueness of a solution v^ε of (3.1) satisfying

$$|v^\varepsilon|_1 + \frac{1}{\varepsilon}|v^\varepsilon - \bar{v}|_0 \leq C,$$

where C depends only on λ, K from (A1).

4. The proof is complete by combining the estimates in steps 1–3 and noting that (A3) is only needed in step 1. □

Proof of Lemma 3.4. We start with (a). From the properties of mollifiers and the Lipschitz continuity of v^ε, it is immediate that

$$|v_{\varepsilon i} - v_i^\varepsilon|_0 \leq C\varepsilon, \quad i \in \mathcal{I}, \tag{3.6}$$

where $C = \max_i [v_i^\varepsilon]_1$ depends only on K, λ from (A1). Furthermore we saw in the proof of Theorem 2.3 that

$$0 \leq \max_i v_i^\varepsilon - \min_i v_i^\varepsilon \leq k \quad \text{in} \quad \mathbb{R}^N.$$

From these two estimates, (a) follows.

Now consider (b). We consider an arbitrary point $x \in \mathbb{R}^N$ and set

$$j = \text{argmin}_{i \in \mathcal{I}} v_{\varepsilon i}(x).$$

Then, by definition of $\mathcal{M}$ and j, we have

$$v_{\varepsilon j}(x) - \mathcal{M}_j v_\varepsilon(x) = \max_{i \neq j}\big\{v_{\varepsilon j}(x) - v_{\varepsilon i}(x) - k\big\} \leq -k.$$

The bound (3.6) then leads to

$$v_j^\varepsilon(x) - \mathcal{M}_j v^\varepsilon(x) \leq -k + 2\max_i [v_i^\varepsilon]_1 \varepsilon,$$

and by using the Lipschitz continuity of v^ε (Lemma 3.3),

$$v_j^\varepsilon(y) - \mathcal{M}_j v^\varepsilon(y) \leq -k + 2\max_i [v_i^\varepsilon]_1(\varepsilon + |x - y|).$$

From this we conclude that if $|x - y| < \varepsilon$ and $\varepsilon \leq (4\max_i [v_i^\varepsilon]_1)^{-1}k$, then

$$v_j^\varepsilon(y) - \mathcal{M}_j v^\varepsilon(y) < 0.$$

Equation (3.1) then implies

$$\inf_{|e|\le\varepsilon} \mathcal{L}^{\alpha_j}(y+e, v_j^\varepsilon(y), Dv_j^\varepsilon(y), D^2 v_j^\varepsilon(y)) = 0.$$

After a change of variables we see that for every $|e| \le \varepsilon$,

$$\mathcal{L}^{\alpha_j}(x, v_j^\varepsilon(x-e), Dv_j^\varepsilon(x-e), D^2 v_j^\varepsilon(x-e)) \ge 0. \tag{3.7}$$

In other words, for every $|e| \le \varepsilon$, $v_j^\varepsilon(x-e)$ is a supersolution at x of

$$\mathcal{L}^{\alpha_j}(x, w, Dw, D^2 w) = 0. \tag{3.8}$$

By mollifying (3.7) we see formally that $v_{\varepsilon j}$ is also a supersolution of (3.8) at x and hence a (viscosity) supersolution of the HJB equation (1.1) at x. This is correct since $v_{\varepsilon j}$ can be viewed as the limit of convex combinations of supersolutions $v_j^\varepsilon(x-e)$ of the linear and hence concave equation (3.8); we refer to the proof of Theorem 2.3 and to the appendix in [2] for the details. We conclude the proof by noting that since $v_{\varepsilon j}$ is smooth, it is in fact a classical supersolution of (1.1) at x. □

4. Monotone finite difference methods. As an application of the results in the previous section we derive here the rate of convergence for a finite difference scheme proposed by Kushner [11, 14] for the N-dimensional HJB equation (1.1). The notation for these schemes is taken from [11, 14]. We start by naming the difference operators we need. Let $\{e_i\}_{i=1}^N$ denote the standard basis in $\mathbb{R}^N$ and define

$$\begin{aligned}
\Delta_{x_i}^{\pm} w(x) &= \pm\frac{1}{h}\{w(x \pm e_i h) - w(x)\},\\
\Delta_{x_i}^{2} w(x) &= \frac{1}{h^2}\{w(x + e_i h) - 2w(x) + w(x - e_i h)\},\\
\Delta_{x_i x_j}^{+} w(x) &= \frac{1}{2h^2}\{2w(x) + w(x + e_i h + e_j h) + w(x - e_i h - e_j h)\}\\
&\quad - \frac{1}{2h^2}\{w(x + e_i h) + w(x - e_i h) + w(x + e_j h) + w(x - e_j h)\},\\
\Delta_{x_i x_j}^{-} w(x) &= \frac{1}{2h^2}\{w(x + e_i h) + w(x - e_i h) + w(x + e_j h) + w(x - e_j h)\}\\
&\quad - \frac{1}{2h^2}\{2w(x) + w(x + e_i h - e_j h) + w(x - e_i h + e_j h)\}.
\end{aligned}$$

Now we define the schemes as follows:

$$\tilde{F}(x, u_h(x), \Delta_{x_i}^{\pm} u_h(x), \Delta_{x_i}^{2} u_h(x), \Delta_{x_i x_j}^{\pm} u_h(x)) = 0, \tag{4.1}$$

where

$$\begin{aligned}
\tilde{F}(x, t, p_i^{\pm}, A_{ii}, A_{ij}^{\pm}) = \sup_{\alpha\in\mathcal{A}} \Bigg\{ \sum_{i=1}^{N} \Bigg[-\frac{a_{ii}^{\alpha}}{2} A_{ii} + \sum_{j\neq i} \Bigg(-\frac{a_{ij}^{\alpha+}}{2} A_{ij}^{+} + \frac{a_{ij}^{\alpha-}}{2} A_{ij}^{-} \Bigg)\\
- b_i^{\alpha+}(x) p_i^{+} + b_i^{\alpha-}(x) p_i^{-} \Bigg] + c^{\alpha}(x) t - f^{\alpha}(x) \Bigg\},
\end{aligned}$$

and $b^+ = \max\{b, 0\}$ and $b^- = (-b)^+$ $(b = b^+ - b^-)$.

Assume that (A1) holds. In order to obtain the required monotonicity of these schemes, we need to assume in addition that the matrix a is diagonally dominant:

$$a_{ii}^{\alpha}(x) - \sum_{j\neq i} |a_{ij}^{\alpha}(x)| \geq 0 \quad \text{in} \quad \mathbb{R}^N, \quad i = 1, \dots, N. \tag{4.2}$$

We also assume that the coefficients are normalized so that

$$\sum_{i=1}^{N} \left\{ a_{ii}^{\alpha}(x) - \sum_{j\neq i} |a_{ij}^{\alpha}(x)| + |b_i^{\alpha}(x)| \right\} \leq 1 \quad \text{in} \quad \mathbb{R}^N. \tag{4.3}$$

Assumption (4.2) is standard in numerical analysis; see [11, 14]. We also refer to Lions and Mercier [34] and to Bonnans and Zidani [4] for a discussion of this condition. Assumption (4.3) is always satisfied after a multiplication in (1.1) by an appropriate positive constant.

From the results in section 3, we have the following bound on $u - u_h$.

THEOREM 4.1. *Assume* (A1)–(A3), (4.2), *and* (4.3) *hold. If u and $u_h \in C_b(\mathbb{R}^N)$ are solutions of* (1.1) *and* (4.1), *respectively, then for $h > 0$ sufficiently small,*

$$|u - u_h|_0 \leq C h^{1/5}.$$

Remark 4.1. Krylov [27] obtains the rate 1/27 using probabilistic methods. One contribution of this paper is to improve this rate to 1/5.

By Proposition 3.2 and Theorem 3.5 the above result holds if we can define S in (1.2), check that assumptions (S1)–(S3) hold with $k_2 = 1$, $k_4 = 2$, and $k_i = 0$ otherwise, and prove existence of $u_h \in C_b(\mathbb{R}^N)$. Let us proceed to write down S. In order to better see the monotonicity of the scheme and to fix some more notation, we are going to rewrite (4.1) as a discrete dynamical programming principle. We refer to [11] for the probabilistic interpretation. Define the following one-step transition probabilities:

$$\begin{aligned}
p^{\alpha}(x,x) &= 1 - \sum_{i=1}^{N} \left\{ a_{ii}^{\alpha}(x) - \sum_{j\neq i} |a_{ij}^{\alpha}(x)| + h|b_i^{\alpha}(x)| \right\}, \\
p^{\alpha}(x, x \pm e_i h) &= \frac{a_{ii}^{\alpha}(x)}{2} - \sum_{j\neq i} \frac{|a_{ij}^{\alpha}(x)|}{2} + h b_i^{\alpha\pm}(x), \\
p^{\alpha}(x, x + e_i h \pm e_j h) &= \frac{a_{ij}^{\alpha\pm}(x)}{2}, \\
p^{\alpha}(x, x - e_i h \pm e_j h) &= \frac{a_{ij}^{\alpha\mp}(x)}{2},
\end{aligned}$$

and $p^{\alpha}(x,y) = 0$ for all other y. Note that by (4.2) and (4.3), $0 \leq p^{\alpha}(x,y) \leq 1$ for all α, x, y if $h \leq 1$. Furthermore $\sum_{z\in h\mathbb{Z}^N} p^{\alpha}(x, x+z) = 1$ for all α, x. Tedious but straightforward computations show that the following equation is equivalent to (4.1):

$$u_h(x) = \inf_{\alpha\in\mathcal{A}} \left\{ \frac{1}{1 + h^2 c^{\alpha}(x)} \left(\sum_{z\in h\mathbb{Z}^N} p^{\alpha}(x, x+z) u_h(x+z) + h^2 f^{\alpha}(x) \right) \right\}.$$

This is the discrete dynamical programming principle. From this equation we define S. For $\phi \in C_b(\mathbb{R}^N)$, set $[\phi]_x^h(\cdot) := \phi(x+\cdot)$ and

$$S(h,y,t,[\phi]_x^h) := \sup_{\alpha\in\mathcal{A}} \left\{ -\frac{1}{h^2}\left[\sum_{z\in h\mathbb{Z}^N} p^\alpha(y,y+z)[\phi]_x^h(z) - t\right] + c^\alpha(x)t - f^\alpha(y) \right\}.$$

Using this definition of S, it is easy to check (S1)–(S3); see the lemma below (see also [2]). Existence of solutions $u_h \in C_b(\mathbb{R}^N)$ of (4.1) can be proved using the contraction mapping theorem; we refer to [26, 27, 2, 21] for such arguments. Thus, we may conclude that Theorem 4.1 holds.

Lemma 4.2. *Assume* (A1), (A2), (4.2), (4.3), *and* $0 < h < 1$. *Then the scheme* (4.1) *satisfies conditions* (S1)–(S3), *where* (S3) *takes the form*

$$|F(x,v,Dv,D^2v) - S(h,x,v(x),[v]_x)| \le \sup_\alpha |b^\alpha|_0 |D^2v|_0 h + \sup_\alpha |\sigma^\alpha|_0^2 |D^4v|_0 h^2.$$

5. Extensions and remarks. Let us first consider the case when (A2) is not satisfied. Then the solutions of the different equations are only Hölder continuous; e.g., for the HJB equation (1.1) we have the following result.

Lemma 5.1. *Assume* (A1) *and define* $\lambda_0 := \sup_{\mathcal{A}}\{[\sigma]_1^2 + [b]_1\}$. *If* $\lambda < \lambda_0$, *then there exists a unique solution* $u \in C^{0,\delta}(\mathbb{R}^N)$ *of* (1.1), *where* $\delta = \lambda/\lambda_0$.

This result was proved in [30]. We claim that under (A1), we have the same regularity (the same δ) for all equations considered in this paper. We skip the tedious proof of this claim. In the rest of this section, the solutions of the different equations are assumed to belong to $C^{0,\delta}(\mathbb{R}^N)$ with the same fixed $\delta \in (0,1]$.

Lower than Lipschitz regularity of solutions implies lower convergence rates than obtained in sections 2–4. We will now state the Hölder versions of these results without proofs. The proofs are not much different from the proofs given above, and, moreover, the Hölder case was extensively studied in [2]. We start with the convergence rate for the switching system approximation of section 2.

Proposition 5.2. *Assume* (A1). *If* $\bar{u}$ *and* v *are the solutions of* (2.2) *and* (2.1) *belonging to* $C^{0,\delta}(\mathbb{R}^N)$, *then for* k *small enough,*

$$0 \le v_i - \bar{u} \le Ck^{\frac{\delta}{2+\delta}} \quad in \quad \mathbb{R}^N, \quad i \in \mathcal{I},$$

where C *depends only on* λ, K *from* (A1).

The upper bound on the error for monotone approximation schemes (1.2) for the HJB equation (1.1) is given by the following result.

Proposition 5.3. *Assume* (A1), (S1)–(S3) *and that* (1.2) *has a unique solution* $u_h \in C_b(\mathbb{R}^N)$. *If* $u \in C^{0,\delta}(\mathbb{R}^N)$ *is the solution of* (1.1), *then for sufficiently small* $h > 0$, *we have*

$$u - u_h \le Ch^{\delta\gamma} \quad in \quad \mathbb{R}^N,$$

where γ *and* C *are defined in Proposition* 3.2.

This proposition was essentially proved in [2]; see [21] for this form of the result. Finally, we have come to the Hölder version of the main result of this paper.

Proposition 5.4. *Assume* (A1), (A3), (S1), (S3) *and that* (1.2) *has a unique solution* $u_h \in C_b(\mathbb{R}^N)$. *If* $u \in C^{0,\delta}(\mathbb{R}^N)$ *is the solution of* (1.1), *then for sufficiently small* $h > 0$, *we have*

$$-Ch^{\bar{\gamma}} \le u - u_h \quad in \quad \mathbb{R}^N,$$

where $\bar{\gamma} := \min_{k_i \neq 0}\{\frac{\delta^2 k_i}{(2+\delta)i - 2\delta}\}$ *and* C *depends only on* λ, K, K_c *from* (A1), (S3).

Remark 5.1. Above we removed assumption (A2). It is also possible to weaken assumption (A1) by assuming that c, f are only Hölder continuous. This would then lead to Hölder continuous solutions with lower Hölder exponents than above. The above results would continue to hold, however, but now with a different δ. We refer to [2] for results in this direction.

Next, we comment on a possible extension to the nonconvex/nonconcave case. We are interested in the Isaacs equations coming from stochastic differential games,

$$F(x, u, Du, D^2u) = 0 \quad \text{in} \quad \mathbb{R}^N, \tag{5.1}$$

where

$$\begin{aligned} F(x, t, p, X) &= \sup_{\alpha \in \mathcal{A}} \inf_{\beta \in \mathcal{B}} \mathcal{L}^{\alpha,\beta}(x, t, p, X), \\ \mathcal{L}^{\alpha,\beta}(x, t, p, X) &= -\text{tr}[a^{\alpha,\beta}(x)X] - b^{\alpha,\beta}(x)p + c^{\alpha,\beta}(x)t - f^{\alpha,\beta}(x), \end{aligned}$$

and $\mathcal{A}, \mathcal{B}$ are compact metric spaces. Assume that assumptions like (A1)–(A3) are satisfied for this problem. In this case we have well-posedness and Lipschitz regularity results for (5.1) (see the appendix).

Let $\{\alpha_i\}_{i=1}^M \subset \mathcal{A}$ be a suitable refined grid for $\mathcal{A}$, and consider the question of finding the rate of convergence for the following switching system approximation of (5.1):

$$F_i(x, v, Dv_i, D^2v_i) = 0 \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I} := \{1, \dots, M\}, \tag{5.2}$$

where $v = (v_1, \dots, v_M)$,

$$F_i(x, r, p, M) = \max\Big\{ \inf_{\beta \in \mathcal{B}} \mathcal{L}^{\alpha_i,\beta}(x, r_i, p, X);\ r_i - \mathcal{M}_i r \Big\},$$

and $\mathcal{M}$ is defined just below (2.1) in section 2. To the best of our knowledge, this question is still an open problem, and clearly the method used in section 2 cannot be extended to this case.

However, if we assume that this question has been resolved, then the proof of Theorem 3.5 can be extended to give a lower bound for the error of approximation schemes for (5.1). The only problem we face here is to extend the proof of Lemma 3.4(b). But this is trivial because of the concavity of the function $\inf_{\beta \in \mathcal{B}} \mathcal{L}^{\alpha_i,\beta}(x, t, p, X)$.

To get the upper bound on the error, we only need to assume that the Isaacs condition is satisfied, i.e.,

$$\sup_{\alpha \in \mathcal{A}} \inf_{\beta \in \mathcal{B}} \mathcal{L}^{\alpha,\beta}(x, t, p, X) = \inf_{\beta \in \mathcal{B}} \sup_{\alpha \in \mathcal{A}} \mathcal{L}^{\alpha,\beta}(x, t, p, X)$$

for any $x \in \mathbb{R}^N$, $t \in \mathbb{R}$, $p \in \mathbb{R}^N$, and $X \in \mathcal{S}^N$. The upper bound can then be obtained by a symmetric argument, changing "sup" to "inf," "max" to "min," and conversely.

Thus, the rate of convergence of approximation schemes for Isaacs equations would follow from our method if the rate of convergence of the corresponding switching system can be obtained.

Appendix. Well-posedness, regularity, and continuous dependence for switching systems. In this section we give well-posedness, regularity, and continuous dependence results for solutions of a very general switching system that has as special cases the scalar HJB and Isaacs equations (1.1) and (5.1), and the switching systems (2.1), (2.3), (3.1), (5.2).

We consider the following system:

$$F_i(x, u, Du_i, D^2u_i) = 0 \quad \text{in} \quad \mathbb{R}^N, \quad i \in \mathcal{I} := \{1, \dots, M\}, \tag{A.1}$$

with

$$F_i(x, r, p, X) = \max\Big\{ \sup_{\alpha\in\mathcal{A}} \inf_{\beta\in\mathcal{B}} \mathcal{L}_i^{\alpha,\beta}(x, r_i, p, X);\ r_i - \mathcal{M}_i r \Big\},$$
$$\mathcal{L}_i^{\alpha,\beta}(x, t, p, X) = -\mathrm{tr}[a_i^{\alpha,\beta}(x)X] - b_i^{\alpha,\beta}(x)p + c_i^{\alpha,\beta}(x)t - f_i^{\alpha,\beta}(x),$$

where $\mathcal{M}$ is defined below (2.1), $\mathcal{A}, \mathcal{B}$ are compact metric spaces, r is a vector $r = (r_1, \dots, r_M)$, and $k > 0$ is a constant (the switching cost). See [12, 6, 38, 18, 17] for more information about such systems.

We make the following assumptions:

(A1) For any α, β, i, $a_i^{\alpha,\beta} = \frac{1}{2}\sigma_i^{\alpha,\beta}\sigma_i^{\alpha,\beta T}$ for some $N \times P$ matrix $\sigma_i^{\alpha,\beta}$. Furthermore, there are constants λ, C independent of i, α, β, such that

$$c \geq \lambda > 0 \quad \text{and} \quad [\sigma_i^{\alpha,\beta}]_1 + [b_i^{\alpha,\beta}]_1 + [c_i^{\alpha,\beta}]_1 + |f_i^{\alpha,\beta}|_1 \leq C.$$

(A2) The constant λ in (A1) satisfies $\lambda > \sup_{i,\alpha,\beta}\{[\sigma_i^{\alpha,\beta}]_1^2 + [b_i^{\alpha,\beta}]_1\}$.

We start with comparison, existence, uniqueness, and L^∞ bounds on the solution and its gradient. Before stating the results, we first define $USC(\mathbb{R}^N; \mathbb{R}^M)$ and $LSC(\mathbb{R}^N; \mathbb{R}^M)$ to be the spaces of upper and lower semicontinuous functions from $\mathbb{R}^N$ into $\mathbb{R}^M$, respectively.

THEOREM A.1. *Assume* (A1) *holds.*

(i) *If $u \in USC(\mathbb{R}^N; \mathbb{R}^M)$ is a subsolution of* (A.1) *bounded above and $v \in LSC(\mathbb{R}^N; \mathbb{R}^M)$ is a supersolution of* (A.1) *bounded below, then $u \leq v$ in $\mathbb{R}^N$.*

(ii) *There exists a unique bounded continuous solution u of* (A.1) *satisfying*

$$\max_i |u_i|_0 \leq \sup_{i,\alpha,\beta} \frac{|f_i^{\alpha,\beta}|_0}{\lambda}.$$

(iii) *If in addition* (A2) *holds, then u is Lipschitz continuous and*

$$\max_i [u_i]_1 \leq \sup_{i,\alpha,\beta} \frac{|u^i|_0[c_i^{\alpha,\beta}]_1 + [f_i^{\alpha,\beta}]_1}{\lambda - [\sigma_i^{\alpha,\beta}]_1^2 - [b_i^{\alpha,\beta}]_1}.$$

Remark A.1. These bounds have the same form as those for linear equations [15] and HJB equations [30].

Before giving the proof, we state and prove a key technical lemma.

LEMMA A.2. *Let $u \in USC(\mathbb{R}^N; \mathbb{R}^M)$ be a bounded-above subsolution of* (A.1) *and $\bar{u} \in LSC(\mathbb{R}^N; \mathbb{R}^M)$ be a bounded-below supersolution of another equation* (A.1) *where the functions $\mathcal{L}_i^{\alpha,\beta}$ are replaced by functions $\bar{\mathcal{L}}_i^{\alpha,\beta}$ satisfying the same assumptions. Let $\phi \in C^2(\mathbb{R}^{2N})$ be a function bounded from below. We denote*

$$\psi_i(x, y) = u_i(x) - \bar{u}_i(y) - \phi(x, y)$$

and $M = \sup_{i,x,y} \psi_i(x, y)$. If there exists a maximum point for M, i.e., a point (i', x_0, y_0) such that $\psi_{i'}(x_0, y_0) = M$, then there exists $i_0 \in \mathcal{I}$ such that (i_0, x_0, y_0) is also a maximum point for M, and, in addition, $\bar{u}_{i_0}(y_0) < \mathcal{M}_{i_0}\bar{u}(y_0)$.

Loosely speaking this lemma means that whenever we do doubling of variables for systems of type (A.1), we can ignore the $u_i - \mathcal{M}_i u$ part of the equations. So we are more or less back in the scalar case with equations $\sup_\alpha \inf_\beta \mathcal{L}_{i_0}^{\alpha,\beta}[u^{i_0}] \le 0$ and $\sup_\alpha \inf_\beta \bar{\mathcal{L}}_{i_0}^{\alpha,\beta}[\bar{u}^{i_0}] \ge 0$.

Proof of Lemma A.2. The proof is a "no-loop" argument taken from Ishii and Koike [18]. We assume by contradiction that $\bar{u}_j(y_0) \ge \mathcal{M}_j \bar{u}(y_0)$ for every $j \in A$, where A is the set of j's such that (j, x_0, y_0) is a maximum point for ψ.

We pick a $j \in A$. By the definition of $\mathcal{M}_j$, there is $l \in \mathcal{I}$ such that

$$\mathcal{M}_j \bar{u}(y_0) = \bar{u}_l(y_0) + k.$$

By assumption, we have $\bar{u}_j(y_0) \ge \bar{u}_l(y_0) + k$. On the other hand, since u is a subsolution of (A.1), it follows that

$$u_j(x_0) \le \mathcal{M}_j u(x_0) \le u_l(x_0) + k.$$

Combining these inequalities yields

$$u_j(x_0) - u_l(x_0) \le k \le \bar{u}_j(y_0) - \bar{u}_l(y_0).$$

These inequalities first imply that $l \in A$, and therefore the last inequality is an equality. This, again, implies $\bar{u}_j(y_0) = \bar{u}_l(y_0) + k$.

Since A is finite we may find $j_1, \dots, j_K \in A$ such that $\bar{u}_{j_i}(y_0) = \bar{u}_{j_{i+1}}(y_0) + k$ for $i = 1, \dots, K-1$ and (importantly!) $j_1 = j_K$. But now

$$0 = \sum_{i=1}^{K-1} \big(\bar{u}_{j_i}(y_0) - \bar{u}_{j_{i+1}}(y_0)\big) = (K-1)k > 0,$$

which is a contradiction. The proof is complete. □

Proof of Theorem A.1. Comparison, uniqueness, and existence is proved in [18] for the Dirichlet problem for (1.1) on a bounded domain under assumptions that are satisfied for our problem. The key point here is the comparison principle. To extend this result to an unbounded domain, we only need to modify the test function used in [18] in the standard way. The proof remains practically unchanged.

Let

$$M := \sup_{i,\alpha,\beta} \frac{|f_i^{\alpha,\beta}|_0}{\lambda}.$$

Then the bound on $|u|_0$ follows from the comparison principle after checking that M $(-M)$ is a supersolution (subsolution) of (A.1). To get the bound on the gradient of u, consider

$$m := \sup_{i,x,y \in \mathbb{R}^N} \{u_i(x) - u_i(y) - L|x-y|\}.$$

If, by setting

$$L := \sup_{i,\alpha,\beta} \frac{|u_i|_0 [c_i^{\alpha,\beta}]_1 + [f_i^{\alpha,\beta}]_1}{\lambda - [\sigma_i^{\alpha,\beta}]_1^2 - [b_i^{\alpha,\beta}]_1},$$

we can conclude that $m \le 0$, then we are done. Assume for simplicity that the maximum is attained in $\bar{x}, \bar{y}$. If $\bar{x} = \bar{y}$, then $m = 0$ and we are done. If not, then

$L|x-y|$ is smooth at $\bar{x}, \bar{y}$ and a doubling of variables argument leads to $m \leq 0$. This argument is standard after an application of Lemma A.2 which reduces the problem to a scalar problem (see also the proof of Theorem A.3). We refer to the appendix of [15] for details in the (linear) scalar case. Since the maximum need not be attained, we must modify the test function in the standard way. We skip the details. □

Now we proceed to obtain continuous dependence on the coefficients.

THEOREM A.3. *Let u and $\bar{u}$ be solutions of* (A.1) *with coefficients σ, b, c, f and $\bar{\sigma}, \bar{b}, \bar{c}, \bar{f}$, respectively. If both sets of coefficients satisfy* (A1) *with the same λ, and $|u|_1 + |\bar{u}|_1 \leq M < \infty$, then*

$$\lambda \max_i |u_i - \bar{u}_i|_0 \leq K \sup_{i,\alpha,\beta} |\sigma - \bar{\sigma}|_0 + \sup_{i,\alpha,\beta} \Big\{ 2M|b-\bar{b}|_0 + M|c-\bar{c}|_0 + |f-\bar{f}|_0 \Big\},$$

where

$$K^2 \leq 8M \sup_{i,\alpha,\beta} \Big\{ 2M[\sigma]_1^2 \wedge [\bar{\sigma}]_1^2 + 2M[b]_1 \wedge [\bar{b}]_1 + M[c]_1 \vee [\bar{c}]_1 + [f]_1 \wedge [\bar{f}]_1 \Big\}.$$

Outline of proof. Define

$$m := \sup_{i,x,y} \psi^i(x,y) := \sup_{i,x,y} \left\{ u_i(x) - \bar{u}_i(y) - \frac{1}{\delta}|x-y|^2 - \varepsilon(|x|^2 + |y|^2) \right\}.$$

By the assumptions the supremum is attained at some point (i_0, x_0, y_0). By Lemma A.2, the index i_0 may be chosen so that $\bar{u}_{i_0}(y_0) < \mathcal{M}_{i_0}\bar{u}(y_0)$. With this in mind, the maximum principle for semicontinuous functions [8, 9] and the definition of viscosity solutions imply the following inequality:

$$\sup_\alpha \inf_\beta \mathcal{L}_{i_0}^{\alpha,\beta}(x_0, u_{i_0}, p_x, X) - \sup_\alpha \inf_\beta \bar{\mathcal{L}}_{i_0}^{\alpha,\beta}(y_0, \bar{u}_{i_0}, p_y, Y) \leq 0,$$

where $(p_x, X) \in \overline{D}^{2,+} u_{i_0}(x_0)$ and $(p_y, Y) \in \overline{D}^{2,-} \bar{u}_{i_0}(y_0)$ (see [8, 9] for the notation). Furthermore $p_x = \frac{2}{\delta}(x_0 - y_0) + 2\varepsilon x_0$, $p_y = \frac{2}{\delta}(x_0 - y_0) - 2\varepsilon y_0$, and

$$\begin{pmatrix} X & 0 \\ 0 & Y \end{pmatrix} \leq \frac{2}{\delta} \begin{pmatrix} I & -I \\ -I & I \end{pmatrix} + 2\varepsilon \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} + \mathcal{O}(\kappa)$$

for some $\kappa > 0$. In the end we will fix δ and ε and send $\kappa \to 0$, so we simply ignore the $\mathcal{O}(\kappa)$-term in the following. The first inequality implies

$$0 \leq \sup_{i,\alpha,\beta} \Big\{ -\operatorname{tr}[\bar{a}(y_0)Y] + \operatorname{tr}[a(x_0)X] + \bar{b}(y_0)p_x - b(x_0)p_y + \bar{c}(y_0)\bar{u}(y_0) - c(x)u(x_0) + \bar{f}(y_0) + f(x_0) \Big\}.$$

Note that Lipschitz regularity of the solutions and a standard argument yields

$$|x_0 - y_0| \leq \delta M.$$

So using Ishii's trick on the second-order terms [16, pp. 33, 34], and a few other manipulations, we get

$$0 \leq \sup_{i,\alpha,\beta} \left\{ \frac{2}{\delta}|\sigma(x_0) - \bar{\sigma}(y_0)|^2 + 2M|b(x_0) - \bar{b}(y_0)| + C\varepsilon(1 + |x_0|^2 + |y_0|^2) + M|c(x_0) - \bar{c}(y_0)| - \lambda m + |f(x_0) - \bar{f}(y_0)| \right\}.$$

Some more work leads to an estimate for m depending on δ and ε, and using the definition of m, we obtain an upper bound for $u - \bar{u}$. We finish the proof of the upper bound on $u - \bar{u}$ by minimizing this expression with respect to δ and sending $\varepsilon \to 0$. The lower bound follows in a similar fashion. □

Remark A.2. For more details on such manipulations, we refer to [22, 23].

CONVERGENCE OF UPWIND FINITE DIFFERENCE SCHEMES FOR A SCALAR CONSERVATION LAW WITH INDEFINITE DISCONTINUITIES IN THE FLUX FUNCTION*

SIDDHARTHA MISHRA[†]

Abstract. We consider the scalar conservation law with flux function discontinuous in the space variable, i.e.,

$$\begin{aligned} u_t + (H(x)f(u) + (1 - H(x))g(u))_x = 0 \quad \text{in } \mathbb{R} \times \mathbb{R}_+, \\ u(0, x) = u_0(x) \quad \text{in } \mathbb{R}, \end{aligned} \tag{0.1}$$

where H is the Heaviside function and f and g are smooth with the assumptions that either f is convex and g is concave or f is concave and g is convex. The existence of a weak solution of (0.1) is proved by showing that upwind finite difference schemes of Godunov and Enquist–Osher type converge to a weak solution. Uniqueness follows from a Kruzkhov-type entropy condition. We also provide explicit solutions to the Riemann problem for (0.1). At the level of numerics, we give easy-to-implement numerical schemes of Godunov and Enquist–Osher type. The central feature of this paper is the modification of the singular mapping technique (the main analytical tool for these types of equations) which allows us to show that the numerical schemes converge. Equations of type (0.1) with the above hypothesis on the flux may occur when considering the following scalar conservation law with discontinuous flux:

$$\begin{aligned} u_t + (k(x)f(u))_x = 0, \\ u(0, x) = u_0(x), \end{aligned} \tag{0.2}$$

with f convex and k of indefinite sign.

Key words. conservation laws, discontinuous fluxes, finite differences, singular mapping

DOI. 10.1137/030602745

1. Introduction.

We are interested in the following scalar conservation law:

$$\begin{aligned} u_t + (f(k(x), u))_x = 0 \quad \text{in } \mathbb{R} \times \mathbb{R}_+, \\ u(0, x) = u_0(x) \quad \text{in } \mathbb{R}. \end{aligned} \tag{1.1}$$

Here, the flux f is smooth in k and u but may depend discontinuously on the space variable through a coefficient k. Note that (0.2) and (0.1) are special cases of (1.1) and are referred to as the multiplicative case and the 2-flux case, respectively.

Equations of type (1.1) are of great practical interest in several areas of physics and engineering, e.g., in the water flooding model in the petroleum industry, in modeling continuous sedimentation in the ideal clarifier thickener units used in waste water treatment plants, in traffic flows on highways with changing road conditions, and in ion etching in the semiconductor industry. For more details on some of these applications, see [26].

As in the continuous case, i.e., when k is Lipschitz, weak solutions are sought for (1.1). For definitions, see section 2. As in the continuous case, we need to impose

*Received by the editors August 30, 2004; accepted for publication (in revised form) September 29, 2004; published electronically June 30, 2005. Part of this work appeared in the author's master's thesis as the chapter "Scalar Conservation Laws with Discontinuous Flux," IISc, 2003.

additional admissibility criteria or entropy conditions in order to obtain stability and uniqueness for the weak solutions. We note that at present, there is no complete theory for the entropy solutions of (1.1).

Equation (0.1) with both f and g convex was investigated by Adimurthi and Gowda in [1] by considering the corresponding Hamilton–Jacobi equation. They obtained an explicit Hopf–Lax-type formula for the solution and used it to prescribe a proper characteristic entropy condition at the interface ($x = 0$) which entailed the omission of undercompressive waves ($f' > 0, g' < 0$) at the interface. Coupled with a Kruzkhov-type entropy condition in the interior, the authors were able to show stability and uniqueness of weak solutions for (0.1). In [3], the authors developed a Godunov-type algorithm for approximating solutions of (0.1). They worked under the hypothesis that f and g have one minima (maxima) and no maxima (minima) in the phase space. It must be noted that the interface entropy condition of [3] is different in some cases from other prevailing entropy theories. In view of this, we are motivated to investigate (1.1) in detail by using [1], [3] as a starting point; the following questions have to be considered:

1. Can we extend the algorithm of [3] and the entropy theory of [1] to the more general equations of the form (1.1)?
2. Can we extend the algorithm of [3] and the entropy theory of [1] to a larger class of fluxes, including nonconvex and sign changing fluxes?
3. Can we develop numerical schemes for (1.1) based on fluxes other than Godunov, such as the Enquist–Osher and Lax–Friedrichs schemes and other higher order versions which are consistent with interface entropy conditions like that of [1]?
4. How does the entropy theory of [1], [3] compare with other entropy theories, and what is the correct notion of the entropy solution of (1.1)?

These questions are being investigated in a series of papers by Adimurthi, Gowda, and the author. This is the first paper in the series and looks at some aspects of questions 2 and 3. Other papers in this series are [4], [5], and [6].

In this paper, we consider the case when one of the fluxes is convex and the other is concave (see section 2 for precise hypotheses on the fluxes). We propose a notion of entropy solutions for (0.1) based on a Kruzkhov-type condition away from the interface. A special feature of the flux geometry considered in this paper is that no extra condition (except the usual Rankine–Hugoniot condition) is required at the interface. We report explicit solutions for the associated Riemann problem and use them to build up an easy-to-implement Godunov scheme. An Enquist–Osher scheme is also proposed and both schemes are shown to converge to the entropy solution of (0.1). It should be noted that a particular case of (0.2) is the case when $f = k_1 h$ and $g = k_2 h$ with h convex and k_1, k_2 of different signs. Thus, this case will serve as a building block for developing numerical methods for (1.1) when k is of indefinite sign. This will be done in a forthcoming paper [6].

Equations of type (1.1) have been dealt with extensively in the literature both from a theoretical as well as a numerical point of view. In [14], [15], Gimse and Risebro obtained solutions for the Riemann problem under the assumptions of convexity and used the solutions to develop a front tracking algorithm to show existence of a weak solution. Uniqueness was obtained by minimizing $|u_+ - u_-|$, the jump at the interface. Diehl investigated equations of type (0.1) with applications in the clarifier thickener unit in [11], [12]. He obtained solutions of the Riemann problem under extremely general hypotheses on the fluxes and showed uniqueness for the Riemann problem by using a variation condition which he termed the Γ condition. Results for the front tracking algorithm were obtained in [23], [24], [22], and [10] (including a time dependent discontinuous coefficient).

The first results for explicit finite difference schemes for (0.2) were obtained by Towers in [28], [29]. In [28], Towers developed a staggered grid scheme for (0.2) which just used the solution of a scalar Riemann problem for continuous flux. In that paper, he developed staggered versions of both the Godunov and the Enquist–Osher schemes for (0.2) when f is convex and k is assumed to be strictly positive. In [29], the author considered (0.2) with nonconvex fluxes and proved convergence for a staggered version of the Enquist–Osher scheme. These works are a motivation for this and other forthcoming papers where we develop and analyze numerical schemes for (1.1) based on exact or approximate Riemann solvers. In this paper, we tackle the question of the indefinite sign of the coefficient, which was left open in [28].

More recently, there has been a series of papers on (1.1). In [19], Karlsen, Risebro, and Towers studied (0.1) with an added degenerate parabolic term by using an Enquist–Osher-type scheme. In [20], the authors considered the vanishing viscosity limit of (0.2) and showed that it exists by using compensated compactness. They also included a degenerate parabolic term. A general entropy theory for (1.1) with degenerate parabolic terms was developed in [21], where well-posedness was shown for fluxes satisfying a certain "crossing condition" and a modified Kruzkhov-type entropy condition which agrees with that of [3] for (0.1) except in the undercompressive intersections case. Among other works are those of Burger et al. on the clarifier thickener model in [9] and of Karlsen, Klingenberg, and Risebro in [18], where a relaxation scheme for (0.2) was proposed and shown to converge.

A very recent paper of Karlsen and Towers [17] deals with (1.1) (including a time dependent discontinuity in the flux) by proposing a Lax–Friedrichs scheme and showing that the approximations converge the entropy solution. They were able to handle very general fluxes and sign-changing coefficients using compensated compactness. Another very recent work that has come to the notice of the author after this paper was completed is that of Audusse and Perthame in [7], in which they proposed an alternative concept of entropy solution for (1.1) by using adapted Kruzkhov entropies and showing uniqueness.

The concept of entropy solution proposed in this paper does not require extra assumptions at the interface on account of the special concave-convex flux geometry. Concepts of entropy solutions that do not require interface entropy conditions were noticed by Bagnerini and Rascle in [8] (with monotone fluxes) and more recently by Audusse and Perthame in [7]. The author wishes to clarify that the hypotheses on the fluxes considered in [7] are very different from the one in this paper. For example, in the special case of (0.1), the authors of [7] required that either both fluxes are monotone or both are convex (with same minimum value), which is different from the concave-convex flux geometry considered here. Similarly the results of [21] do not apply, as the "crossing condition" is not satisfied by the fluxes of this paper.

It is well known in the literature that it is difficult to handle the case of sign-changing coefficients. For instance, we quote the authors in [18]: "Also, sign changes in k are usually ruled out with the singular mapping due to the additional analytical difficulties." One way to overcome this difficulty is the use of compensated compactness such as with the vanishing viscosity and relaxation schemes for (0.2) in [20] and [18], respectively, and for the Lax–Friedrichs scheme in [17]. In this paper, we obtain the first convergence for Godunov and Enquist–Osher-type schemes (for sign-changing coefficients), which have their own place in the hierarchy of numerical methods. It should be emphasized that although the compensated compactness approach makes it easier to handle nonconvex fluxes and sign-changing coefficients, it is the singular mapping approach (with its derivative-type estimates) that gives more regular solutions. In particular, the singular mapping leads to solutions with traces that are required for the entropy theory, such as the BV_t solutions of [21], [9]. Hence, it is the belief of the author that each approach has its own utility and the singular mapping may be more useful keeping in mind the existing entropy theories.

We have organized this paper in the following way. In section 2, we will describe the continuous problem in detail, i.e., a precise description of the hypothesis on fluxes f and g and the initial data. We also define the entropy conditions and show that the entropy solutions of (0.1), if they exist, are unique. In section 3, we give explicit solutions of the Riemann problem for (0.1), in this case satisfying the entropy condition. In section 4, we describe our finite difference schemes of both Godunov and Enquist–Osher type and investigate some of their properties. Section 5 deals with the convergence of the schemes and is the core of this paper. Section 6 describes various numerical experiments comparing our schemes with those of Towers in [28]. In section 7, we derive certain conclusions from this paper.

2. The continuous problem.

As noted earlier, in this section we will describe the continuous problem for (0.1) in some detail. We begin with a precise description of the various hypotheses in this paper. First we give the hypotheses on the fluxes f and g. Let $s < S \in \mathbb{R}$, such that $[s, S]$ is the domain of definition of the fluxes (the phase space). The fluxes satisfy the following hypotheses:

(H_1) $f, g : [s, S] \to \mathbb{R}$ are Lipschitz continuous.

(H_2) $f(s) = g(s), f(S) = g(S)$.

(H_3) Either f is convex and g is concave on $[s, S]$ or f is concave and g is convex on $[s, S]$

As in [3], we can easily extend the convexity hypothesis to the following:

($\overline{H_3}$) Either f has one minima and no maxima and g has one maxima and no minima on $[s, S]$ or f has one maxima and no minima and g has one minima and no minima on $[s, S]$.

We remark that the hypothesis (H_2) is mostly to ensure that the solutions are bounded in L^∞, but this is a sufficient condition and is by no means necessary for boundedness and can be relaxed. The key hypotheses on the fluxes are (H_3) or ($\overline{H_3}$), which make the flux geometry of concave-convex or mixed type. We also need the following constant:

$$M = \max\{Lip(f), Lip(g)\}. \tag{2.1}$$

For any fixed $s < S$, we can have four possible cases of the fluxes, which we enumerate as follows.

Case A_1. f is convex and g is concave with $g(s) \leq g(S)$.

Case A_2. f is convex and g is concave with $g(s) > g(S)$.

Case B_1. f is concave and g is convex with $g(s) \leq g(S)$.

Case B_2. f is concave and g is convex with $g(s) > g(S)$.

Note that the hypothesis on the fluxes implies that the fluxes f and g only intersect at the endpoints of the domain of definition, i.e., s and S. Figure 2.1 depicts the various cases as given above.

Now we state our assumptions on the initial data. As in [3], we will need an estimator of the variation of the initial data, which we denote as $\overline{N}(f, g, u_0)$ and

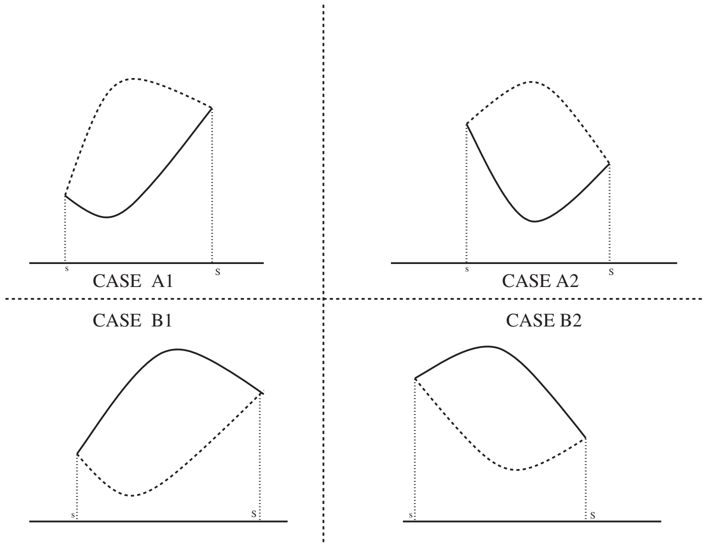

FIG. 2.1. *Various cases of fluxes f and g satisfying the hypotheses of this paper, with the thick line representing f and the dashed line g.*

which we define in section 4. The hypotheses on the initial data are as follows:

(IN_1) $s \leq u_0(x) \leq S \quad \forall x \in \mathbb{R}$.

(IN_2) $\overline{N}(f, g, u_0) \leq C < +\infty$.

We now come to the definition of the entropy solution of (0.1). We start by defining a weak solution of (0.1) as a function $u \in L^\infty_{\text{loc}}(\mathbb{R} \times \mathbb{R}_+)$ such that $\forall \varphi \in C_0^\infty(\overline{\mathbb{R} \times \mathbb{R}_+})$, the following holds:

$$\int_{\mathbb{R}} \int_{\mathbb{R}+} u\varphi_t + (H(x)f(u) + (1 - H(x))g(u))\varphi_x dxdt + \int_{\mathbb{R}} u_0(x)\varphi(0, x)dx = 0\,. \tag{2.2}$$

It is easy to check that u is a weak solution of (0.1) iff it satisfies in the weak sense

$$\begin{aligned} u_t + (g(u))_x &= 0, \quad x < 0, t > 0,\\ u_t + (f(u))_x &= 0, \quad x > 0, t > 0,\\ u(0, x) &= u_0(x) \end{aligned} \tag{2.3}$$

and the following interface Rankine–Hugoniot condition:

$$\begin{gathered} f(u^+(t)) \;=\; g(u^-(t)) \qquad \text{for a.e. } t,\\ u^+(t) = \lim_{x \to 0+} u(x, t), \qquad u^-(t) = \lim_{x \to 0-} u(x, t). \end{gathered} \tag{2.4}$$

We also need to specify a Kruzkhov-type interior entropy condition; for that we define the following:

Entropy pairs. → $\{\varphi_i, \psi_i\}_{i=1,2}$ is said to be a entropy pair for (0.1) if φ_i is convex in $[s, S]$ and $\psi_1'(\theta) = \phi_1'(\theta)f'(\theta), \psi_2'(\theta) = \phi_2'(\theta)g'(\theta)$.

Let $u_0 \in L^\infty(\mathbb{R})$ be the initial data with $s \leq u_0(x) \leq S$ $\forall x \in \mathbb{R}$; then u is said to satisfy the interior entropy condition if, for any entropy pairs $(\varphi_i, \psi_i)_{i=1,2}, u$ satisfies in the sense of distributions the following inequalities:

$$
\begin{aligned}
&\frac{\partial \varphi_1(u)}{\partial t} + \frac{\partial \psi_1(u)}{\partial x} \le 0 \quad \forall x > 0, t > 0,\\
&\frac{\partial \varphi_2(u)}{\partial t} + \frac{\partial \psi_2(u)}{\partial x} \le 0 \quad \forall x < 0, t > 0.
\end{aligned}
\tag{2.5}
$$

Now we define the entropy solution of (0.1) as follows: $u \in L^\infty(\mathbb{R} \times \mathbb{R}_+)$ is said to be an entropy solution for (0.1) if the following hold:

1. u is a weak solution of (0.1).
2. For all $t > 0$, $u^+(x,t)$ and $u^-(x,t)$ exist for a.e. x.
3. u satisfies the interior entropy condition (2.5).

Equipped with the above notation, we state the main existence and uniqueness theorem of this paper.

Theorem 2.1. *Let u_0 satisfy $(IN_1), (IN_2)$ and let the fluxes f and g satisfy H_1, H_2 and $\overline{H_3}$, respectively; then there exists a function $u \in L^\infty(\mathbb{R} \times \mathbb{R}_+)$ such that u is a weak solution of* (0.1) *and the following hold:*

1. *For almost all t and $x \in \mathbb{R}, u(x-,t)$ and $u(x+,t)$ exist.*
2. *u satisfies the interior entropy condition* (2.5) *and is hence unique.*

Remark. Note that unlike in [1], [3], we do not require any interface entropy condition at $x = 0$ for the entropy solutions. This is an interesting outcome of the flux geometry that we are considering, which leads to the fact that any solution that satisfies the interior entropy condition and the Rankine–Hugoniot condition at the interface is unique.

We will show the existence of a weak solution by showing that upwind finite difference schemes of Godunov and Enquist–Osher type converge to it. Currently, we show the uniqueness of the entropy solutions for (0.1). For that as in [1], [3], we need to define the interface entropy functional as

$$
\begin{aligned}
I(u,v,t) = {} & sgn(u^-(t) - v^-(t))(g(u^-(t)) - g(v^-(t)))\\
& - sgn(u^+(t) - v^+(t))(f(u^+(t)) - f(v^+(t))).
\end{aligned}
$$

We have the following lemma regarding the sign of I.

Lemma 2.2. *Let u and v be two entropy solutions of* (0.1)*; then for almost all $t > 0$, we have that $I(u,v,t) \equiv 0$.*

Proof. The proof follows easily from the Rankine–Hugoniot condition (2.4) and from the flux geometry. We leave the proof as an exercise.

Now we are in a position to prove the following uniqueness theorem.

Theorem 2.3. *Let $u, v \in L^\infty(\mathbb{R} \times \mathbb{R}_+)$ with $s \le u, v \le S$ be two solutions of* (0.1) *with initial data u_0, v_0, respectively. Assume that*

(i) *for a.e. $t, u(x+,t), v(x+,t), u(x-,t)$, and $v(x-,t)$ exist, and*

(ii) *u, v satisfy the interior entropy condition* (2.5).

Then for any $\overline{M} \ge M$, $a < 0, b > 0$, $b - a \ge 2\overline{M}t$, the function

$$
t \mapsto \int_{a+\overline{M}t}^{b-\overline{M}t} |u(x,t) - v(x,t)| dx
$$

is nonincreasing, and if $u_0 = v_0$ a.e., then it follows that $u = v$ a.e.

Proof. The proof of the above theorem follows exactly as in [1] and is also outlined in [3]. The proof is based on a doubling-of-variables argument (see [25]) coupled with a nonnegative sign of the interface entropy functional obtained in Lemma 2.2. ◻

So, in this section we have established the uniqueness part of the proof of Theorem 2.3 without any extra assumptions on the behavior of the solution at the interface. In the rest of the paper, we will show the existence part of Theorem 2.3.

3. Solutions to the Riemann problem. In this section, we give explicit solutions for the Riemann problem for (0.1) which satisfy both the interior entropy condition and the Rankine–Hugoniot condition (2.4) at the interface. For the sake of simplicity, we will deal only with fluxes satisfying (H_3) and $f, g \in C^2[s, S]$. For fluxes satisfying $(\overline{H_3},)$ the solutions to the Riemann problem can be similarly worked out. We remark that procedures for constructing the solutions of the Riemann problem have been described in [14] and [11]. We carry them out in this case. We are dealing with (0.1) with the following Riemann data:

$$u(x,0) = u_0(x) = \begin{cases} u_r & \text{if} \quad x > 0, \\ u_l & \text{if} \quad x < 0. \end{cases} \tag{3.1}$$

We start with the following case.

Case A_1. We have to distinguish the following subcases.

Case 1. $g(u_l) < g(S)$. From the shape of the fluxes, it is easy to see that there exists a unique $\theta \in (\theta_f, S]$ such that $f(\theta) = g(u_l)$. Let $s_0 = \frac{f(\theta)-f(u_r)}{\theta - u_r}$, $s_1 = \frac{g(u_l)-g(S)}{u_l - S}$, $s_2 = \frac{f(S)-f(u_r)}{S-u_r}$.

The solution in different subcases is given by the following:

Case 1.1. $\theta \leq u_r$.

$$u(x,t) = \begin{cases} u_l & \text{if} \quad x \leq 0, \\ \theta & \text{if} \quad 0 \leq x \leq tf'(\theta), \\ (f')^{-1}(\frac{x}{t}) & \text{if} \quad tf'(\theta) \leq x \leq tf'(u_r), \\ u_r & \text{if} \quad x \geq tf'(u_r). \end{cases}$$

Case 1.2. $\theta > u_r$.

$$\begin{cases} u_l & \text{if} \quad x \leq s_1 t, \\ S & \text{if} \quad s_1 t \leq x \leq s_2 t, \\ u_r & \text{if} \quad x \geq s_2 t. \end{cases}$$

Case 2. $g(u_l) \geq g(S)$. The solution in this case is given by the following:

$$u(x,t) = \begin{cases} u_l & \text{if} \quad x \leq s_1 t, \\ S & \text{if} \quad s_1 t \leq x \leq s_2 t, \\ u_r & \text{if} \quad x \geq s_2 t. \end{cases}$$

Case A_2. Again, we have to consider the following subcases.

Case 1. $f(u_r) > f(S)$. From the shape of the fluxes, it is easy to check that there exists a unique $\eta \in [\theta_g, S]$ such that $g(\eta) = f(u_r)$. Let $s_0 = \frac{g(\eta)-g(u_l)}{\eta - u_l}$, $s_1 = \frac{g(u_l)-g(S)}{u_l - S}$, $s_2 = \frac{f(S)-f(u_r)}{S-u_r}$.

The solution in different subcases is given by the following:

Case 1.1. $u_l > \eta$.

$$u(x,t) = \begin{cases} u_l & \text{if} \quad x \leq g'(u_l)t, \\ (g')^{-1}(\frac{x}{t}) & \text{if} \quad g'(u_l)t \leq x \leq g'(\eta)t, \\ \eta & \text{if} \quad g'(\eta)t \leq x \leq 0, \\ u_r & \text{if} \quad x \geq 0. \end{cases}$$

Case 1.2. $u_l \leq \eta$.

$$\begin{cases} u_l & \text{if} \quad x \leq s_0 t, \\ \eta & \text{if} \quad s_0 t \leq x \leq 0, \\ u_r & \text{if} \quad x \geq 0. \end{cases}$$

Case 2. $f(u_r) \leq f(S)$. The solution in this case is given by the following:

$$u(x,t) = \begin{cases} u_l & \text{if} \quad x \leq s_0 t, \\ \eta & \text{if} \quad s_0 t \leq x \leq 0, \\ u_r & \text{if} \quad x \geq 0. \end{cases}$$

Case B_1. Again, we have to consider the following cases.

Case 1. $g(u_l) \geq g(s)$. In this case, it is easy to see that there exists a unique $\theta \in [s, \theta_f]$ such that $f(\theta) = g(u_l)$. Let $s_0 = \frac{f(\theta)-f(u_r)}{\theta-u_r}$, $s_1 = \frac{g(s)-g(u_l)}{s-u_l}$, and $s_2 = \frac{f(s)-f(u_r)}{s-u_r}$.

The solution in different subcases is given by the following:

Case 1.1. $u_r < \theta$.

$$u(x,t) = \begin{cases} u_l & \text{if} \quad x \leq 0, \\ \theta & \text{if} \quad 0 \leq x \leq tf'(\theta), \\ (f')^{-1}(\frac{x}{t}) & \text{if} \quad tf'(\theta) \leq x \leq tf'(u_r), \\ u_r & \text{if} \quad x \geq tf'(u_r). \end{cases}$$

Case 1.2. $u_r \geq \theta$.

$$\begin{cases} u_l & \text{if} \quad x \leq 0, \\ \theta & \text{if} \quad 0 \leq x \leq s_0 t, \\ u_r & \text{if} \quad x \geq s_0 t. \end{cases}$$

Case 2. $g(u_l) < g(s)$. The solution is given by the following:

$$u(x,t) = \begin{cases} u_l & \text{if} \quad x \leq s_1 t, \\ s & \text{if} \quad s_1 t \leq x \leq s_2 t, \\ u_r & \text{if} \quad x \geq s_2 t. \end{cases}$$

Case B_2. We have to consider the following cases.

Case 1. $f(u_r) \leq f(s)$. In this case it is easy to see that there exists a unique $\eta \in [s, \theta_g]$ such that $f(u_r) = g(\eta)$. Let $s_0 = \frac{g(\eta)-g(u_l)}{\eta-u_l}$, $s_1 = \frac{g(s)-g(u_l)}{s-u_l}$, and $s_2 = \frac{f(s)-f(u_r)}{s-u_r}$.

The solution in different cases is given by the following:

Case 1.1. $u_l < \eta$.

$$u(x,t) = \begin{cases} u_l & \text{if} \quad x \leq g'(u_l)t, \\ (g')^{-1}(\frac{x}{t}) & \text{if} \quad g'(u_l)t \leq x \leq g'(\eta)t, \\ \eta & \text{if} \quad g'(\eta)t \leq x \leq 0, \\ u_r & \text{if} \quad x \geq 0. \end{cases}$$

Case 1.2. $u_l \geq \eta$.

$$\begin{cases} u_l & \text{if} \quad x \leq s_0 t, \\ \eta & \text{if} \quad s_0 t \leq x \leq 0, \\ u_r & \text{if} \quad x \geq 0. \end{cases}$$

Case 2. $f(u_r) > f(s)$.

$$u(x,t) = \begin{cases} u_l & \text{if} \quad x \leq s_1 t, \\ s & \text{if} \quad s_1 t \leq x \leq s_2 t, \\ u_r & \text{if} \quad x \geq s_2 t. \end{cases}$$

So we have given explicit solutions of the Riemann problem for (0.1) in all cases. The crucial fact about the solutions is that the solutions in some cases are the endpoints s and S, which are undercompressive in the sense that at s or S, we have $f' > 0, g' < 0$. A strange result of the flux geometry considered here is that we cannot avoid undercompressive waves at the interface, which is quite striking given that the interface entropy condition of [1], [3] essentially implies omitting undercompressive waves at the interface.

4. Description of the finite difference schemes. In this section, we seek to develop finite difference schemes for (0.1) which are of Godunov as well as Enquist–Osher type. As in [3], the key is to define the interface numerical fluxes; we start with the Godunov flux.

4.1. Godunov flux. Let h be a Lipschitz continuous function defined on $[s, S]$. We use the standard Godunov flux H defined by

$$\begin{aligned} H(a,b) &= \min_{\theta\in[a,b]} h(\theta) \quad \text{if } a \leq b \\ &= \max_{\theta\in[b,a]} h(\theta) \quad \text{if } a \geq b. \end{aligned}$$

We recall that H as defined above is Lipschitz in both its variables, nondecreasing in the first variable, and nonincreasing in the second variable. We use a similar method to define the interface Godunov flux. We use the explicit solutions of the Riemann problem in section 3 to define the interface Godunov flux. Let F and G be the standard Godunov flux corresponding to the fluxes f and g, respectively. We define the interface flux $\overline{F}$ in each case as follows.

Case A_1. $\overline{F}(a,b) = \min\{G(a,S), F(S,b)\}$.

Case A_2. $\overline{F}(a,b) = \max\{G(a,S), F(S,b)\}$.

Case B_1. $\overline{F}(a,b) = \max\{G(a,s), F(s,b)\}$.

Case B_2. $\overline{F}(a,b) = \min\{G(a,s), F(s,b)\}$.

Another way of writing down the above formulas is by defining the following function, which we define only in Case A_1 as follows: Let $\overline{f} : [s, S] \mapsto \mathbb{R}$, such that

$$\begin{aligned} \overline{f}(\theta) &= g(\theta) \quad \forall s \leq \theta \leq \overline{S} \\ &= g(S) \quad \text{otherwise.} \end{aligned} \tag{4.1}$$

We call the above-defined function $\overline{f}$ the interface function and claim that the interface Godunov flux $\overline{F}$ is the standard Godunov flux corresponding to $\overline{f}$. This fact is easy to check. The interface function corresponding to other cases can be easily constructed.

4.2. Enquist–Osher flux. One of the common approximate Riemann solvers that can be used in place of the Godunov flux is the Enquist–Osher flux developed in [13]. Let h be a lipschitz function; then the Enquist–Osher flux $\tilde{H}$ is given by

$$\tilde{H}(a,b) = \frac{1}{2}\left(h(a) + h(b) - \int_a^b |h'(\xi)|d\xi\right). \tag{4.2}$$

For a convex-type fluxes (fluxes with one minima and no maxima), we have a simple explicit formula given by

$$\tilde{H}(a,b) = h(\max(a,\theta)) + h(\min(\theta,b)) - h(\theta), \tag{4.3}$$

where θ is the unique minimum of the function h. The Enquist–Osher flux is similar to the Godunov flux except in the overcompressive case. Next, we have to define a suitable interface Enquist–Osher flux. As the Enquist–Osher fluxes are not based on exact solutions of the Riemann problem, we will employ the interface function $\overline{f}$ to construct the interface Enquist–Osher flux. Let $\tilde{F}$ and $\tilde{G}$ be the Enquist–Osher fluxes corresponding to f and g, respectively. We construct the interface Enquist–Osher flux only for Case A_1; other cases can be similarly treated. We define the interface Enquist–Osher flux ($\tilde{\overline{F}}$) in this case to be the standard Enquist–Osher flux corresponding to the interface function $\overline{f}$. We recall that the interface Godunov flux ($\overline{F}$) can be identified as the standard Godunov flux corresponding to the interface function ($\tilde{f}$), and we are following the same identification for defining the interface Enquist–Osher flux, but the concave-convex flux geometry in this case forces us to have the following proposition, which is easy to check.

PROPOSITION 4.1. *Let $\overline{F}$ and $\overline{\tilde{F}}$ be as defined above; then $\overline{F}(a,b) = \overline{\tilde{F}}(a,b)\ \forall a,b \in [s,S]$.*

Henceforth, we will also refer to the interface Enquist–Osher flux as $\overline{F}$. We collect some easy-to-verify facts regarding the interface flux in the following proposition.

PROPOSITION 4.2. *Let $\overline{F}$ be as given above and $a,b \in [s,S]$. Then the following holds:*

(a) *$\overline{F}$ is Lipschitz in each variable.*

(b) *$\overline{F}$ is nondecreasing in a and nonincreasing in b.*

(c) *$\overline{F}(s,s) = f(s) = g(s), \overline{F}(S,S) = f(s) = g(S)$.*

(d) *$\overline{F}$ is not consistent, i.e., there exists $a \in [s,S]$ such that $\overline{F}(a,a) \neq f(a) \neq g(a)$.*

Proof. (c) and (d) are easy to check from the definition of $\overline{F}$. (a) and (b) follow from the fact that $\overline{F}$ is the standard Godunov (Enquist–Osher) flux corresponding to the Lipschitz continuous function $\overline{f}$.

We remark that, in general, the interface Godunov and Enquist–Osher fluxes may not agree (for example, when both fluxes are convex), but in this case, on account of the flux geometry, they are exactly the same.

We are now in a position to describe the scheme. First, we describe the discretization in space and time as follows.

Let $h > 0$ and define the space grid points x_j as follows:

$$x_j = \left(\frac{2j-1}{2}\right)h \quad \text{for } j \geq 1, \quad x_j = \left(\frac{2j+1}{2}\right)h \quad \text{for } j \leq -1.$$

For time discretization, the time step $\Delta t > 0$, and let $t_n = n\Delta t$. We also introduce $\lambda = \frac{\Delta t}{h}$.

For a function $u_0 \in L^\infty(\mathbb{R})$ we define

$$u^0_{j+1} = \frac{1}{h}\int_{x_{j+1/2}}^{x_{j+3/2}} u_0(x)dx \quad \text{if } j \geq 0, \qquad u^0_{j-1} = \frac{1}{h}\int_{x_{j-3/2}}^{x_{j-1/2}} u_0(x)dx \quad \text{if } j \leq 0,$$

$$\begin{aligned} N_h(f,g,u_0) &= \sum_{i<-1} |G(u^0_i, u^0_{i+1}) - G(u^0_{i-1}, u^0_i)| + \sum_{i>1} |F(u^0_i, u^0_{i+1}) - F(u^0_{i-1}, u^0_i)| \\ &\quad + |\overline{F}(u^0_{-1}, u^0_1) - G(u^0_{-2}, u^0_{-1})| + |F(u^0_1, u^0_2) - \overline{F}(u^0_{-1}, u^0_1)|, \\ \tilde{N}_h(f,g,u_0) &= \sum_{i<-1} |\tilde{G}(u^0_i, u^0_{i+1}) - \tilde{G}(u^0_{i-1}, u^0_i)| + \sum_{i>1} |\tilde{F}(u^0_i, u^0_{i+1}) - \tilde{F}(u^0_{i-1}, u^0_i)| \\ &\quad + |\overline{F}(u^0_{-1}, u^0_1) - \tilde{G}(u^0_{-2}, u^0_{-1})| + |\tilde{F}(u^0_1, u^0_2) - \overline{F}(u^0_{-1}, u^0_1)|, \end{aligned}$$

$$N(f,g,u_0) = \sup_{h>0} \max\{N_h(f,g,u_0), \tilde{N}_h(f,g,u_0)\}.$$

It is easy to see that if $u_0 \in BV(\mathbb{R})$, then $N(f,g,u_0) \leq C||u_0||_{BV}$, where C is a constant depending only on the Lipschitz constants of f and g.

Now, we are in a position to describe our Godunov-type scheme. For every time level $(n+1)$, we calculate the discrete u_j^{n+1} as

$$\begin{aligned} u_j^{n+1} &= u_j^n - \lambda(F(u_j^n, u_{j+1}^n) - F(u_{j-1}^n, u_j^n)) \quad \forall j \geq 2, \\ u_1^{n+1} &= u_1^n - \lambda(F(u_1^n, u_2^n) - \overline{F}(u_{-1}^n, u_1^n)), \\ u_{-1}^{n+1} &= u_{-1}^n - \lambda(\overline{F}(u_{-1}^n, u_1^n) - G(u_{-2}^n, u_{-1}^n)), \\ u_j^{n+1} &= u_j^n - \lambda(G(u_i^n, u_{j+1}^n) - G(u_{j-1}^n, u_j^n)) \quad \forall j \leq -2. \end{aligned} \tag{4.4}$$

Similarly, we define the Enquist–Osher-type scheme for (0.1) as

$$\begin{aligned} u_j^{n+1} &= u_j^n - \lambda(\tilde{G}(u_j^n, u_{j+1}^n) - \tilde{G}(u_{j-1}^n, u_j^n)) \quad \forall j \leq -2, \\ u_{-1}^{n+1} &= u_{-1}^n - \lambda(\overline{F}(u_{-1}^n, u_1^n) - \tilde{G}(u_{-2}^n, u_{-1}^n)), \\ u_1^{n+1} &= u_1^n - \lambda(\tilde{F}(u_1^n, u_2^n) - \overline{F}(u_{-1}^n, u_1^n)), \\ u_j^{n+1} &= u_j^n - \lambda(\tilde{F}(u_j^n, u_{j+1}^n) - \tilde{F}(u_{j-1}^n, u_j^n)) \quad \forall j \geq 2. \end{aligned} \tag{4.5}$$

We now define the approximations in terms of the following piecewise constant functions:

$$u^h(x,t) = u_j^n \quad \text{if} \quad \tilde{u}^h(x,t) = \tilde{u}_j^n, \quad \text{if} \quad (x,t) \in [x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}}) \times [t^n, t^{n+1}). \tag{4.6}$$ □

In the next section, we shall show that these approximations u^h and $\tilde{u}^h$ are compact in the appropriate topology and converge to a weak solution of (0.1). In addition, the limit satisfies the interior entropy condition and is hence unique.

5. Convergence analysis. In this section, we carry out the convergence analysis for our schemes (4.4) and (4.5). We begin by showing that the solutions are bounded on account of the monotonicity of the scheme and the consistency of the fluxes at the endpoints. This gives compactness in the weak star topology which is not enough to pass to the limit in the nonlinear flux terms. In order to do so, we have to obtain derivative-type estimates, which for equations of type (1.1) is generally measured via the singular mapping introduced by Temple. This tool has been adopted in several papers on these equations. See [23], [28], [29]. To start with, we give some preliminary lemmas for convergence. We define the following functions to write our schemes in conservation form:

$$\begin{aligned} H_1(X,Y,Z) &= Y - \lambda(F(Y,Z) - F(X,Y)), \\ H_{-1}(X,Y,Z) &= Y - \lambda(G(Y,Z) - G(X,Y)), \\ H_2(X,Y,Z) &= Y - \lambda(F(Y,Z) - \overline{F}(X,Y)), \\ H_{-2}(X,Y,Z) &= Y - \lambda(\overline{F}(Y,Z) - G(X,Y)). \end{aligned}$$

Similarly we can define the corresponding $\overline{H}_i$'s for the Enquist–Osher scheme (4.5) by replacing the Godunov fluxes by the Enquist–Osher fluxes described in section 4. We have the following lemma.

LEMMA 5.1. *Let $2\lambda M \leq 1$ and $a \in [s,S]$; we have the following:*

1. $H_{\pm 1}(a,a,a) = \tilde{H}_{\pm 1}(a,a,a) = a, H_{\pm 2}(s,s,s) = \tilde{H}_{\pm 2}(s,s,s) = s$*,* $H_{\pm 2}(S,S,S) = \tilde{H}_{\pm 2}(S,S,S) = S$*.*
2. $H_i, \tilde{H}_i$ *are nondecreasing in each of their variables, and hence the schemes* (4.4), (4.5) *are monotone.*

Proof. Statement 1 follows directly from the definition of the fluxes and from Proposition 4.2. For statement 2, check that $H_{\pm 1}, \tilde{H}_{\pm 1}$ are monotone due to standard arguments. We check monotonicity only for (H_2); the other cases follow similarly. As (H_2) is Lipschitz, we differentiate it with respect to the variables and use Proposition 4.2 coupled with the CFL condition to get that

$$\begin{aligned}
\frac{\partial H_2}{\partial X} &= \lambda \frac{\partial(\overline{F})(X,Y)}{\partial a} \geq 0,\\
\frac{\partial H_2}{\partial Z} &= -\lambda \frac{\partial \overline{F}(Y,Z)}{\partial b} \geq 0,\\
\frac{\partial H_2}{\partial Y} &= 1 - \lambda \frac{\partial F(Y,Z)}{\partial a} + \frac{\partial \overline{F}(X,Y)}{\partial b} \geq 1 - 2\lambda M \geq 0;
\end{aligned}$$

hence we have shown that (H_2) is monotone in each variable and have proved the lemma. □

Now, we prove that the approximate solutions are uniformly bounded in L^∞ by the following invariant region principle.

LEMMA 5.2. *Let $u_0 \in L^\infty(\mathbb{R}, [s,S])$ be the initial data and let $u_j^n, \tilde{u}_j^n$ be the corresponding solutions calculated by the Godunov scheme* (4.4) *and the Enquist–Osher scheme* (4.5)*, respectively. Then*

$$s \leq u_j^n, \quad \tilde{u}_j^n \leq S \ \ \forall j, n. \tag{5.1}$$

Proof. We will prove for u_j^n only; the other case follows similarly. Since $s \leq u_0 \leq S$, and hence $\forall j,\ s \leq u_j^0 \leq S$. By induction, assume that (5.1) holds for n. Then from Lemma 5.1, we have

$$\begin{aligned}
&s = H_{-1}(s,s,s) \leq H_{-1}(u_{j-1}^n, u_j^n, u_{j+1}^n) = u_j^{n+1} \leq H_{-1}(S,S,S) = S \quad \text{if } \ j \leq -2,\\
&s = H_{1}(s,s,s) \leq H_{1}(u_{j-1}^n, u_j^n, u_{j+1}^n) = u_j^{n+1} \leq H_{1}(S,S,S) = S \quad \text{if } \ j \geq 2,\\
&s = H_{-2}(s,s,s) \leq H_{-2}(u_{-2}^n, u_{-1}^n, u_1^n) = u_{-1}^{n+1} \leq H_{-2}(S,S,S) = S,\\
&s = H_{2}(s,s,s) \leq H_{2}(u_{-1}^n, u_1^n, u_2^n) = u_1^{n+1} \leq H_{2}(S,S,S) = S.
\end{aligned}$$

This proves (5.1). □

Next we obtain the discrete L^1 contractivity estimate in the following.

LEMMA 5.3. *Let $u_0, v_0 \in L^\infty(\mathbb{R},\ [s,S])$ be the initial data and let $\{u_j^n\}$ and $\{v_j^n\}$ be the corresponding solutions calculated by the Godunov-type scheme* (4.4)*; let $\tilde{u_j^n}$ and $\tilde{v_j^n}$ be the corresponding solutions calculated by the Enquist–Osher scheme* (4.5)*. Then the following hold:*

$$\sum_{j\neq 0} |u_j^{n+1} - u_j^n| \leq \sum_{j\neq 0} |u_j^n - u_j^{n-1}|, \tag{5.2}$$

$$\sum_{j\neq 0} |\tilde{u}_j^{n+1} - \tilde{u}_j^n| \leq \sum_{j\neq 0} |\tilde{u}_j^n - \tilde{u}_j^{n-1}|. \tag{5.3}$$

Proof. The proof follows from monotonicity of the schemes and from the Crandall–Tartar lemma (see [16]).

Next we define the singular mappings. To start with, we use the standard notation $a \in \mathbb{R}$; then $a_+ = \max\{a,0\}, a_- = \min\{a,0\}, a = a_+ + a_-, |a| = a_+ - a_-$.

The singular mappings are given by

$$\psi_1(\theta) = \int_\alpha^\theta |g'(\xi)|d\xi, \quad \psi_2(\theta) = \int_\alpha^\theta |f'(\xi)|d\xi, \tag{5.4}$$

where $\alpha \in [s, S]$ is some number. Now we are in a position to define the transformed schemes for the discrete values of the solution as follows:

$$z_j^n = \begin{cases} \psi_1(u_j^n) & \text{if} \quad j \le -1, \\ \psi_1(u_{-1}^n) & \text{if} \quad j \ge -1, \end{cases} \qquad w_j^n = \begin{cases} \psi_2(u_1^n) & \text{if} \quad j \le 1, \\ \psi_2(u_j^n) & \text{if} \quad j \ge 1. \end{cases} \quad \square \tag{5.5}$$

We remark that unlike in [3], we define two sets of transformed variables in order to obtain the normalized variation bounds. This is a key difference in the analysis which enables us to show the convergence for finite difference approximations for the concave-convex case. This feature of using a set of singular mappings instead of the one considered so far in the literature appears to be novel and will be employed by us in the more general nonconvex case. We will show that the total variation of the approximate solutions under the above transformations is bounded in terms of the variation of the numerical fluxes. This is done in the following lemma, which gives a bound on the normalized variation in each cell.

LEMMA 5.4. *For all $j \in Z$, $\forall n \in \mathbb{N}$, we have the following inequalities:*

$$\forall j \le -3$$

$$(z_j^n - z_{j+1}^n)_+ \le |G(u_j^n, u_{j+1}^n) - G(u_{j-1}^n, u_j^n)| + |G(u_{j+1}^n, u_{j+2}^n) - G(u_j^n, u_{j+1}^n)|, \tag{5.6}$$

$$\forall j \ge 2$$

$$-(w_j^n - w_{j+1}^n)_- \le |F(u_j^n, u_{j+1}^n) - F(u_{j-1}^n, u_j^n)| + |F(u_{j+1}^n, u_{j+2}^n - F(u_j^n, u_{j+1}^n)|, \tag{5.7}$$

$$(z_{-2}^n - z_{-1}^n)_+ \le |G(u_{-2}^n, u_{-1}^n) - \overline{F}(u_{-1}^n, u_1^n)| + |G(u_{-3}^n, u_{-2}^n) - G(u_{-2}^n, u_{-1}^n)|, \tag{5.8}$$

$$-(w_1^n - w_2^n)_- \le |F(u_1^n, u_2^n) - \overline{F}(u_{-1}^n, u_1^n)| + |F(u_2^n, u_3^n) - F(u_1^n, u_2^n)|. \tag{5.9}$$

The above estimates also hold for the Enquist–Osher approximations by replacing u_j^n, z_j^n, w_j^n by $\tilde{u}_j^n, \tilde{z}_j^n, \tilde{w}_j^n$, respectively. We call these analogous estimates (5.6(a))*,* (5.7(a))*,* (5.8(a))*, and* (5.9(a))*, respectively.*

Proof. We provide proofs for (5.6), (5.8), and (5.7(a)). The other inequalities can be similarly proved.

Proof of (5.6). We fix t in the subsequent calculations and drop the superscript n in the notation. We have to consider three separate cases. First check that $(z_j - z_{j+1})_+ > 0$ iff $u_{j+1} < u_j$.

Case 1. $s \le u_{j+1} < u_j < \theta_g$. In this case, it is easy to check that we have the following:

$$(z_j - z_{j+1})_+ = g(u_j) - g(u_{j+1}), \quad G(u_j, u_{j+1}) = g(u_j). \tag{5.10}$$

For any $u_{j+2} \in [s, S]$, we have the following. If $u_{j+2} < u_{j+1}$, then we can check from the definition of G that $G(u_{j+1}, u_{j+2}) = g(u_{j+1})$, and if $u_{j+2} \ge u_{j+1}$, then by the fact that G is nonincreasing in the second variable and by its consistency, we get that $G(u_{j+1}, u_{j+2}) \le G(u_{j+1}, u_{j+1}) = g(u_{j+1})$. In either case, we have that $G(u_{j+1}, u_{j+2}) \le g(u_{j+1})$. By combining the above inequality with (5.10), we get the desired inequality:

$$(z_j^n - z_{j+1}^n)_+ \le |G(u_{j+1}^n, u_{j+2}^n) - G(u_j^n, u_{j+1}^n)|. \tag{5.11}$$

Case 2. $s \leq u_{j+1} < \theta_g \leq u_j$. In this case, we get directly from the definition that

$$(z_j - z_{j+1})_+ = g(\theta_g) - g(u_j) + g(\theta_g) - g(u_{j+1}), \quad G(u_j, u_{j+1}) = g(\theta_g). \tag{5.12}$$

For any $u_{j-1} \in [s, S]$, we have the following. If $u_{j-1} > u_j$, then we can check that $G(u_{j-1}, u_j) = g(u_j)$, and if $u_{j-1} \leq u_j$, then by the fact that G is nondecreasing in the first variable and by its consistency, we get that $G(u_{j-1}, u_j) \leq G(u_j, u_j) = g(u_j)$. In either case, we have that $G(u_{j-1}, u_j) \leq g(u_j)$. Now by combining the above estimate with (5.12) and the previous case, we get (5.6).

Case 3. $\theta_g \leq u_{j+1} < u_j \leq S$. In this case, from direct calculations we have that

$$(z_j - z_{j+1})_+ = g(u_{j+1}) - g(u_j), \quad G(u_j, u_{j+1}) = g(u_{j+1}). \tag{5.13}$$

Just by using (5.12) and (5.13), we get the desired inequality (5.8) and thus show it in all the three possible cases.

Proof of (5.8). As in the previous case, we have that $(z_{-2} - z_{-1})_+ > 0$ iff $u_{-2} > u_{-1}$, and we have to consider the following cases.

Case 1. $\theta_g \leq u_{-1} < u_{-2} \leq S$. The estimate (5.8) follows exactly as in Case 3 of the previous proof and we get

$$(z_{-2} - z_{-1})_+ \leq |G(u^n_{-2}, u^n_{-1}) - G(u^n_{-3}, u^n_{-2})|. \tag{5.14}$$

Case 2. $u_{-1} < u_{-2} \leq \theta_g$. In this case, from direct calculations we get that

$$(z_{-2} - z_{-1})_+ = g(u_{-2}) - g(u_{-1}), \quad G(u_{-2}, u_{-1}) = g(u_{-2}). \tag{5.15}$$

Now for any $u_1 \in [s, S]$, we have from the definition of the interface Godunov flux and its monotonicity properties that if $u_{-1} \leq \overline{S}$, $\overline{F}(u_{-1}, u_1) \leq \overline{F}(u_{-1}, s) = g(u_{-1})$; similarly, in the case $u_{-1} > \overline{S}$, we have $\overline{F}(u_{-1}, u_1) \leq g(S)$. In either case, we get that $\overline{F}(u_{-1}, u_1) \leq g(u_{-1})$. It is easy to check that (5.8) follows by combining the above inequality with (5.15).

Case 3. $u_{-1} \leq \theta_g < u_{-2}$. In this case, we verify that

$$(z_{-2} - z_{-1})_+ = g(\theta_g) - g(u_{-2}) + g(\theta_g) - g(u_{-1}), \quad G(u_{-2}, u_{-1}) = g(\theta_g). \tag{5.16}$$

By combining (5.16) with the estimates on the interface flux obtained in Case 2, we prove (5.8).

Proof of (5.7(a)). First check that $(\tilde{w}_j - \tilde{w}_{j+1})_- < 0$ iff $\tilde{u}_j < \tilde{u}_{j+1}$. We have to distinguish between three separate cases.

Case 1. $s \leq \tilde{u}_j < \tilde{u}_{j+1} \leq \theta_f$. In this case, we verify from direct calculations and the definition of the numerical flux $\tilde{F}$ that the following holds:

$$-(\tilde{w}_j - \tilde{w}_{j+1})_- = f(\tilde{u}_j) - f(\tilde{u}_{j+1}), \quad \tilde{F}(\tilde{u}_j, \tilde{u}_{j+1}) = f(\tilde{u}_{j+1}). \tag{5.17}$$

For any $\tilde{u}_{j-1} \in [s, S]$, we have the following three cases, i.e., if $\tilde{u}_{j-1} < \tilde{u}_j$, then from the definition of the Enquist–Osher flux it follows that $\tilde{F}(\tilde{u}_{j-1}, \tilde{u}_j) = f(\tilde{u}_j)$, and if $\tilde{u}_{j-1} > \tilde{u}_j$, then by the fact that the Enquist–Osher flux is nonincreasing in the first variable, it follows that $\tilde{F}(\tilde{u}_{j-1}, \tilde{u}_j) \geq \tilde{F}(\tilde{u}_j, \tilde{u}_j) = f(\tilde{u}_j)$. In either case we have $\tilde{F}(\tilde{u}_{j-1}, \tilde{u}_j) \geq f(\tilde{u}_j)$. So by combining this estimate with (5.17), we prove (5.7(a)) in this case.

Case 2. $\theta_f \leq \tilde{u}_j \leq \tilde{u}_{j+1} \leq S$. In this case, we verify from direct calculations and the definition of the numerical flux $\tilde{F}$ that the following holds:

$$-(\tilde{w}_j - \tilde{w}_{j+1})_- = f(\tilde{u}_{j+1}) - f(\tilde{u}_j), \quad \tilde{F}(\tilde{u}_j, \tilde{u}_{j+1}) = f(\tilde{u}_j). \tag{5.18}$$

For any $\tilde{u}_{j+2} \in [s, S]$, we have the following two cases, i.e., if $\tilde{u}_{j+1} < \tilde{u}_{j+2}$, then from the definition of the Enquist–Osher flux it follows that $\tilde{F}(\tilde{u}_{j+1}, \tilde{u}_{j+2}) = f(\tilde{u}_{j+1})$, and if $\tilde{u}_{j+2} \leq \tilde{u}_{j+1})$, then by the fact that the Enquist–Osher flux is nondecreasing in the first variable, it follows that $\tilde{F}(\tilde{u}_{j+1}, \tilde{u}_{j+2}) \geq \tilde{F}(\tilde{u}_{j+1}, \tilde{u}_{j+1}) = f(\tilde{u}_{j+1})$. In either case we have $\tilde{F}(\tilde{u}_{j+1}, \tilde{u}_{j+2}) \geq f(\tilde{u}_{j+1})$. So by combining the above with (5.18) we show (5.7(a)) in this case.

Case 3. $\tilde{u}_j \leq \theta_f \leq \tilde{u}_{j+1}$. In this case, we have that

$$-(\tilde{w}_j - \tilde{w}_{j+1})_- = f(\tilde{u}_j) - f(\theta_f) + f(\tilde{u}_{j+1}) - f\theta_f), \quad \tilde{F}(\tilde{u}_j, \tilde{u}_{j+1}) = f(\theta_f). \tag{5.19}$$

Now by combining (5.19) with the estimates obtained in the two previous cases, we prove (5.7(a)) in every case. Thus, we have shown the required estimates in all cases. Other estimates can be proved similarly, and we can complete the proof of Lemma 5.4. □

We use the above cell normalized variation inequalities in order to get the bounds on the total variation of the transformed schemes. More precisely, we have the following lemma.

LEMMA 5.5. *Let $z^n_j, w^n_j, \tilde{z}^n_j, \tilde{w}^n_j$ be as defined above. Then the following holds:*

$$\max\{TV(z^n_j), TV(\tilde{z}^n_j)\} \leq \frac{4}{\lambda} \max\left\{ \sum_{j\neq 0} |u^1_j - u^0_j|, \sum_{j\neq 0} |\tilde{u}^1_j - \tilde{u}^0_j| \right\}, \tag{5.20}$$

$$\max\{TV(\tilde{w}^n_j), TV(w^n_j)\} \leq \frac{4}{\lambda} \max\left\{ \sum_{j\neq 0} |u^1_j - u^0_j|, \sum_{j\neq 0} |\tilde{u}^1_j - \tilde{u}^0_j| \right\}.$$

Proof. We prove the above estimate for the sequence z^n_j. The other sequences are shown to satisfy the above inequality in the same way. First observe that $\forall j \geq -1$, we have $(z^n_j - z^n_{j+1})_+ \equiv 0$. So we have that $TV(z^n_j) = \sum |(z^n_j - z^n_{j+1}| = 2\sum(z^n_j - z^n_{j+1})_+$. Therefore by adding (5.6), (5.7), and the above inequality over all j, we get that

$$\begin{aligned}\sum(z^n_j - z^n_{j+1})_+ = 2\Bigg(&\sum_{j\leq -2} |G(u^n_j, u^n_{j+1}) - G(u^n_{j-1}, u^n_j)| + |G(u^n_{-2}, u^n_{-1}) - \overline{F}(u^n_{-1}, u^j_1)| \\ &+ |\overline{F}(u^n_{-1}, u^n_1) - F(u^n_1, u^n_2)| + \sum_{j\geq 2} |F(u^n_j, u^n_{j+1}) - F(u^n_{j-1}, u^n_j)|\Bigg) \\ &= \frac{2}{\lambda} \sum_{j\neq 0} |u^{n+1}_j - u^n_j|. \end{aligned} \tag{5.21}$$

From (5.2), we can get the required estimate on the right-hand side of (5.21), and the inequality follows. In a similar way, we can get the bounds for the other transformed sequences.

Now we define piecewise constant functions based on the transformed sequences and write some estimates on these functions, which follow in a straightforward way from Lemma 5.5. Define the piecewise constant functions $z^h, w^h, \tilde{z}^h, \tilde{w}^h$ by $z^h(x,t) = z^n_j, w^h(x,t) = w^n_j, \tilde{z}^h(x,t) = \tilde{z}^n_j, \tilde{w}^h(x,t) = \tilde{w}^n_j\ \forall (x,t) \in I^n_j$. Then the following estimates hold.

LEMMA 5.6. *With the functions defined as above and $\forall t \in \mathbb{R}_+$, we have*

$$\max\{TV(z^h), TV(w^h), TV(\tilde{z}^h), TV(\tilde{w}^h)\} \leq \frac{4}{\lambda} N(f, g, u_0). \tag{5.22}$$

Proof. The proof follows directly from Lemma 5.5.

We need time continuity estimates in L^1 for the approximations u^h, which is given in the following lemma.

LEMMA 5.7. *Let $u_0, v_0 \in L^\infty(\mathbb{R}, [s, S])$ such that $N(f, g, u_0) < \infty, N(f, g, v_0) < \infty$ are the initial data, let u_h and v_h be the corresponding solutions obtained by the Godunov scheme* (4.4)*, and let $\tilde{u}_h$ and $\tilde{v}_h$ be the corresponding solutions given by the Enquist–Osher-type scheme* (4.5)*. Then*

$$s \leq u_h(x,t), \tilde{u}_h(x,t) \leq S \qquad \forall (x,t) \in \mathbb{R} \times \mathbb{R}_+, \tag{5.23}$$

$$\max\left\{\int_{\mathbb{R}} |u_h(x,t) - u_h(x,\tau)|dx, \int_{\mathbb{R}} |\tilde{u}_h(x,t) - \tilde{u}^h(x,\tau)|dx\right\} \leq N(f,g,u_0)(2\Delta t + |t-\tau|).$$

Proof. The first inequality follows directly from (5.1). We prove the second inequality for the Godunov approximations; the Enquist–Osher approximations follow similarly.

Let $t_n \leq t < t_{n+1}$ and $t_m \leq \tau < t_{m+1}$, so

$$|n-m|\Delta t = |t_n - t_m| \leq |t_n - t| + |t - \tau| + |\tau - t_m| \leq 2\Delta t + |t - \tau|.$$

Hence from Lemma 5.3, we obtain

$$\begin{aligned}
\int_{\mathbb{R}} |u_h(x,t) - u_h(x,\tau)|dx &= h\sum_{j\neq 0} |u_j^n - u_j^m| \\
&\leq h\sum_{j\neq 0}\sum_{i=0}^{n-m+1} |u_j^{n-i} - u_j^{n-i-1}| \\
&\leq h|n-m|\sum_{j\neq 0} |u_j^1 - u_j^0| \\
&\leq \frac{\Delta t|n-m|}{\lambda}\sum_{j\neq 0} |u_j^1 - u_j^0| \\
&\leq (2\Delta t + |t-\tau|)N(f,g,u_0).
\end{aligned}$$

We complete the proof of the lemma. □

Now equipped with the above lemmas, we proceed to state and prove our main convergence theorem.

THEOREM 5.8. *Assume that λ, M satisfy the CFL condition $2\lambda M \leq 1$ and u_0 satisfy the hypotheses $(IN_1), (IN_2)$. Let $u_h, \tilde{u}_h$ be approximate solutions as defined above. Then there exists a subsequence (still denoted by h) such that u_h converge almost everywhere to a weak solution u of* (0.1)*. In fact, $u_h \to u$ in $L^\infty_{\text{loc}}(\mathbb{R}_+, L^1_{\text{loc}}(\mathbb{R}))$ as h goes to* 0*. Similarly, along a further subsequence still denoted by h, $\tilde{u_h}$ converge almost everywhere to a weak solution $\tilde{u}$ of* (0.1) *and, similarly, $\tilde{u_h} \to \tilde{u}$ in $L^\infty_{\text{loc}}(\mathbb{R}_+, L^1_{\text{loc}}(\mathbb{R}))$ as h goes to* 0*. Furthermore, both u and $\tilde{u}$ satisfy the Kruzkhov entropy condition and hence are identical to the entropy solution of* (0.1).

Proof. This is the main convergence theorem for our Godunov and Enquist–Osher-type schemes (4.4), (4.5). The proof follows easily from the BV bounds for the singular mappings and invertibility of ψ_1 in $x < 0$ and ψ_2 in $x > 0$. Entropy consistency follows from the Crandall–Majda entropy fluxes. We refer the reader to [28], [29] for details. □

We reiterate that the key step of the proof of convergence is Lemma 5.4, which used the set of singular mappings in order to get the normalized variation bounds.

Remark 5.1. The existence and uniqueness result presented in this paper and the Godunov and Enquist–Osher schemes can be extended to cover more general equations of the form (1.1) under the assumptions that

1. $k \in BV(\mathbb{R})$ with finitely many points of discontinuities and k being C^1 outside the set of discontinuities;
2. $f(k(x_1), s) = f(k(x_2), s), \quad f(k(x_1), S) = f(k(x_2), S) \quad \forall x_1, x_2 \in \mathbb{R}$;
3. $u \mapsto f(k, u)$ is Lipschitz and has at most one extrema in $[s, S]$ $\forall k \in \mathbb{R}$.

The proof of this general result is presented in a more general setting (by allowing finitely many extrema for the fluxes) in a forthcoming paper [6].

6. Numerical experience. We have tested the Godunov scheme (4.4) and the Enquist–Osher scheme (4.5) extensively and have compared the results with staggered mesh algorithms of Enquist–Osher type developed in [28], [29], and [19]. Due to the special nature of the fluxes considered in this paper, all entropy theories for (0.1) agree and the schemes give the same result.

In most of the test cases, we have observed that (4.4) and 4.5 resolve the interface discontinuity better than the staggered mesh algorithms. Regarding waves in the interior, both schemes of this paper as well as the staggered mesh algorithms seem to do equally well. Only when there is a rarefaction wave in the interior do the schemes (4.4) and (4.5) perform slightly better. This can be illustrated by the following example.

Consider the flux functions $f(u) = 2u^2 - u$ and $g(u) = 3u - 3u^2$ with the Riemann initial data of 0.25 when $x < 0$ and 1 when $x > 0$. From the exact solutions of the Riemann problem presented in section 3, the exact solution is given by a discontinuity at the interface and a rarefaction wave traveling to the right. The numerical results obtained by (4.4), which we have denoted the exact Riemann solver (ERS), and a staggered Godunov scheme developed in [28], which we denote as TS, are shown in Figure 6.1.

As seen in the figure, ERS resolves the solution very well even at low mesh sizes. TS also does well at approximating the solution, except that there is nonphysical nonmonotone traveling wave at the tip of the rarefaction. From the right side of Figure 6.1, we can observe that the wave decreases in amplitude as $h \to 0$, but its presence is puzzling. A way out of this nonphysical wave is suggested in [19] by moving

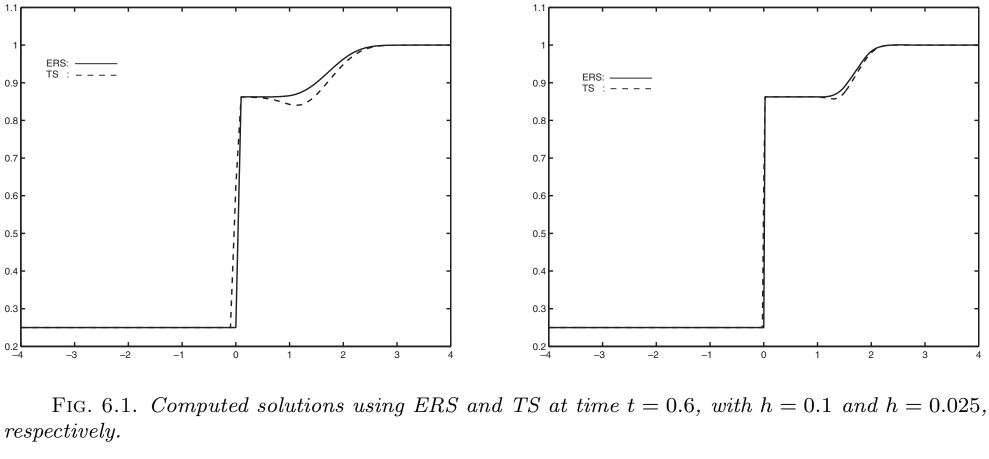

FIG. 6.1. *Computed solutions using ERS and TS at time* $t = 0.6$, *with* $h = 0.1$ *and* $h = 0.025$, *respectively.*

the interface discontinuity in the direction of the wave.

The main advantage of the staggered mesh algorithms as opposed to the 2 × 2 Riemann solvers is their simplicity. Although the scheme (4.4) is also based on exact solutions of the Riemann problem, it is as easy to implement as the staggered mesh schemes on account of the explicit formulae of the numerical fluxes. It also resolves the interface discontinuities better and avoids nonphysical waves and can be used as a substitute to the staggered mesh algorithms.

7. Conclusion.

Scalar conservation laws with discontinuous flux occur very frequently in physical and engineering applications, and hence we need to develop a well-posedness theory and stable numerical methods to approximate their solutions. An interesting case of such equations is when one of the fluxes is convex and the other concave, which can arise when the discontinuous coefficient is of indefinite sign. This case has received less attention in the literature on account of the difficulties in adapting the principal convergence tool of singular mapping.

In this paper, we have studied a scalar conservation law with discontinuous flux having the concave-convex flux geometry. The uniqueness of entropy solutions is shown by using a Kruzkhov-type argument. One strange feature of the flux geometry considered in this case is that we do not need to impose any additional entropy conditions at the interface. We give explicit solutions to the Riemann problem and use it to construct upwind finite difference schemes of Godunov and Enquist–Osher type. These schemes are shown to converge to the entropy solution by using a singular mapping technique. The novel feature of this paper is the use of a combination of singular mappings in order to show the convergence of our schemes to the entropy solutions. Numerical results are presented which show that our schemes resolve the solutions quite well. Comparison with the staggered mesh schemes indicate better performance of our schemes in some situations.

ERROR ESTIMATE AND THE GEOMETRIC CORRECTOR FOR THE UPWIND FINITE VOLUME METHOD APPLIED TO THE LINEAR ADVECTION EQUATION[*]

DANIEL BOUCHE[†], JEAN-MICHEL GHIDAGLIA[‡], AND FRÉDÉRIC PASCAL[§]

Abstract. This paper deals with the upwind finite volume method applied to the linear advection equation on a bounded domain and with natural boundary conditions. We introduce what we call the geometric corrector, which is a sequence associated with every finite volume mesh in $\mathbf{R}^{nd}$ and every nonvanishing vector $\mathbf{a}$ of $\mathbf{R}^{nd}$. First we show that if the continuous solution is regular enough and if the norm of this corrector is bounded by the mesh size, then an order one error estimate for the finite volume scheme occurs. Afterwards we prove that this norm is indeed bounded by the mesh size in several cases, including the one where an arbitrary coarse conformal triangular mesh is uniformly refined in two dimensions. Computing numerically exactly this corrector allows us to state that this result might be extended under conditions to more general cases, such as the one with independent refined meshes.

Key words. finite volume method, consistency and accuracy, geometric corrector, unstructured meshes

1. Introduction.

Finite volume methods (FVMs) were first used in the context of computational mechanics in situations in which solutions present discontinuities (see the monograph of Kröner [16], Godlewski and Raviart [13], and Eymard, Gallouët, and Herbin [10]). One reason for this is that they fundamentally rely on an integral version of the equations. This contrasts with finite difference methods (FDMs), for which smoothness of solutions is used in order to approximate derivatives by differential quotients. For finite element methods (FEMs), the situation is somewhat similar since trace theorems on hypersurfaces in H^1-type spaces exclude also the approximation of discontinuous solutions. It is the main reason why FVMs are widely used for the approximation of hyperbolic systems of conservation laws. Indeed, even when initial and boundary data are smooth, solutions of such equations produce in finite time discontinuous solutions. Let us also mention that other advantages of FVMs, like compact numerical stencil, effectiveness on unstructured grids, and simplicity in coding or data structures, are reasons for which these methods are used more and more often for elliptic and parabolic equations, albeit smoothness of the solution is guaranteed.

Concerning FVMs for hyperbolic equations, there are a lot of methods, and especially in computational fluid dynamics; historically these methods were natural

extensions of the famous Godunov method for the Euler equations of gas dynamics to multidimensional problems. The Godunov method was known to be too diffusive, and this was attributed to the fact that it is a first order method. In the beginning of the eighties, Bram Van Leer proposed MUSCL methods, which can be seen as corrections that lead to second order schemes.

However, it is an open problem to determine the optimal rate of convergence of FVMs. This contrasts strongly with FDMs and FEMs, where such rates are known. Hence there is an apparent paradox between the fact that some methods are termed "first order" or even "second order" and the fact that corresponding error estimates are not proved. Indeed, there is some confusion in the literature: what is usually called a "first order" method, for example, corresponds to methods with a first order truncation error on *uniform Cartesian* grids. In practice—and this is the main interest of FVMs—these methods are used on unstructured meshes, and therefore it is not known whether "first order" methods lead to first order error estimates. In fact the situation is even more puzzling since "first order" methods on unstructured grids *do not lead in general to a truncation error that goes to zero* as the mesh size goes to zero (see section 3.3).

Even for the scalar linear advection equation, obtaining a priori optimal error estimates is still a challenging task. One of the main difficulties, as said already, lies in the fact that the nonuniformity of the mesh brings up an apparent loss of consistency, as has been observed by Hoffman [14], Turkel [27], and Pike [24]. In fact this loss of consistency is an artifact of standard convergence proof: for instance, the Lax theorem states that stability and consistency are sufficient conditions for a scheme to be convergent at the same rate that the truncation error converges to zero. Actually, consistency is not necessary; the scheme maintains the accuracy and the global error behaves better than the local error would indicate. This property of enhancement of the truncation error is called supraconvergence, and for second and higher order boundary value problems, this phenomenon, discovered by Tikhonov and Samarskij [26], was widely analyzed in various cases by Manteuffel and his coauthors in [19], [20], [15], [21] and in Garcia-Archilla and Sanz-Serna [11].

In these papers, the analysis relies on the fact that the truncation error (defined by applying the discrete operator to the exact solution) can be rewritten in the special form $L_h\tau_1 + \tau_2$, where τ_1 and τ_2 are of the optimal order $\mathcal{O}(h^p)$, L_h is the discrete operator, and $L_h\tau_1$ is only $\mathcal{O}(h^{p-1})$. Then an optimal discrete energy estimate for the global error can be derived. This idea is extended to finite difference schemes for hyperbolic systems with nonuniform one-dimensional grids and with irregular Cartesian multidimensional grids in Levermore, Manteuffel, and White [18] and in Monk and Süli [22].

This way to rewrite the truncation error can be seen as a correction of the error in order to cancel the leading part of the local error due to the nonuniformity of the mesh. Actually, in Wendroff and White [31], [30] and Wendroff [29], a grid function is introduced for suitably smooth solutions of hyperbolic systems in order to prove the optimal order of convergence of upwind finite difference and Lax–Wendroff schemes in one space dimension, and in two dimensions when an alternate direction method is used. Berger et al. [3], [2] successfully used the idea to get the optimal rate of convergence of the "h-box" scheme defined on a nonuniform Cartesian grid with embedded irregular small cells.

Recently Després [9], [7], [8], by using energy estimates, gave an elegant proof of an order $h^{1/2}$ error estimate with respect to the L^2 norm for the linear advection equation on regular finite element meshes in the particular case of periodic boundary conditions.

Finally, let us mention that when no regularity conditions are imposed on the exact solution, by suitable application of Kuznetsov [17] approximation theory, for instance, it is possible to establish rate of convergence of $h^{1/2}$ in the L^1 norm for nonregular Cartesian grids: see Eymard, Gallouët, and Herbin [10], Cockburn and Gremaud [4], [5], Cockburn, Gremaud, and Yang [6], Vila and Villedieu [28], and Teng and Zhang [25]. All these results deal with data (and solutions) which belong to the set of functions with bounded variations. As shown in the aforementioned references, the $h^{1/2}$ is optimal for these solutions. However, these papers raise the question of whether such a rate is due to the irregularity of the mesh. Our present work answers this open question by showing that this is not the case: on irregular meshes, provided the solution is smooth, the error estimate behaves like h. Hence the poor convergence behavior is due to the lack of smoothness of solutions.

In this paper we study the initial and boundary value problem for the linear advection equation posed on a polygonal domain of $\mathbf{R}^{nd}$ (nd is the space dimension of the problem under consideration). We construct first what we call "geometric correctors." They form a family of vectors in $\mathbf{R}^{nd}$, $\Gamma = (\Gamma_j)_{j=1,\dots,N}$, where N is the number of control volumes. This set of geometric correctors depends only on the mesh and on the advection vector but not on the solutions to the advection equation. Our first result in section 3 shows that if the solution is regular and if this family of vectors is uniformly bounded by the mesh size, i.e., $||\Gamma|| \le Ch$, then under a Courant–Friedrichs–Lewy (CFL) condition, the classical explicit first order upwind scheme for the advection equation is indeed first order: $||u_h - u|| \le C'h$, where u is the exact solution and u_h the FVM approximation. Since we are able to compute exactly Γ, numerical simulations allow us to study in which cases the hypothesis $||\Gamma|| \le Ch$ is satisfied. We prove in section 4 this estimation in several cases, including the one where an arbitrary coarse conformal triangular mesh is refined. Finally in section 5, we present numerical experiments that lead us to conjecture that this result holds true in the case of independent refined meshes if the advection vector is not parallel to a side of the polygonal domain. On the other hand, on the basis of numerical evidence, we conjecture that if the advection vector is parallel to a side of the polygonal domain, then the best estimate should be in $h^{1/2}$.

2. The continuous problem. We consider Ω a polygonal domain in $\mathbf{R}^{nd}$ with $nd \ge 1$, and we denote by $\mathbf{n}$ the unitary external normal vector on $\partial\Omega$. Let $\mathbf{a}$ be a nonzero vector and let us denote $\partial\Omega^- = \{x \in \partial\Omega, \mathbf{a}\cdot\mathbf{n}(x) < 0\}$. Given a function φ defined on Ω and a function ψ defined on $\partial\Omega^- \times [0,+\infty[$, the initial and boundary value problem for the advection equation on $\bar\Omega \times [0,+\infty[$ reads

$$\frac{\partial u}{\partial t} + (\mathbf{a}\cdot\nabla)u = 0\,, \quad (x,t) \in \Omega \times]0,+\infty[\,, \tag{2.1}$$

$$u(x,0) = \varphi(x)\,, \quad x \in \Omega\,, \tag{2.2}$$

$$u(x,t) = \psi(x,t)\,, \quad (x,t) \in \partial\Omega^- \times [0,+\infty[\,. \tag{2.3}$$

As is well known and understood, this problem has a unique smooth solution, provided the data φ and ψ are smooth and satisfy the so-called compatibility conditions (for example, the first compatibility condition is given below in (2.6)). In fact there are several methods for obtaining this solution. The first one, which uses functional analysis, is due to Bardos [1]. It consists of considering smooth solutions to the parabolic equation ($\nu > 0$)

$$\frac{\partial u^\nu}{\partial t} + (\mathbf{a} \cdot \nabla) u^\nu = \nu \Delta u^\nu\,, \qquad (x,t) \in \Omega \times \,]0, +\infty[\,, \tag{2.4}$$

with the complete Dirichlet boundary conditions

$$u^\nu(x,t) = \psi^\nu(x,t)\,, \qquad (x,t) \in \partial\Omega \times [0, +\infty[, \tag{2.5}$$

where ψ^ν is a smooth extension of ψ to $\Omega \times [0, +\infty[$. Then the solution to (2.1)–(2.3) is obtained at the limit $\nu = 0$. This produces a weak solution, whose regularity is obtained using the compatibility conditions. This method has the great advantage of applying to general (i.e., with variable nonnecessarily smooth coefficients) first order linear hyperbolic equations. However, it is not constructive in contrast with the so-called method of characteristics. In the case of the linear advection equation (2.1), this last method consists of considering the backward characteristics, a straight line here, defined by $(x - s\mathbf{a}, t - s)_{s \geq 0}$ and starting from an arbitrary point $(x,t) \in \Omega \times [0, +\infty[$, and then in looking for its intersection with the boundary of this cylinder. One sees easily that this point belongs either to the set $\Omega \times \{0\}$ or to the set $\partial\Omega^- \times [0, +\infty[$, and since (2.1) simply means that u is constant along these characteristics, one finds $u(x,t)$ by using either (2.2) or (2.3). Let us be more precise. Given $x \in \Omega$, we denote by $s(x)$ the first positive real number τ such that $x - \tau\mathbf{a}$ meets the boundary of Ω (one sees easily that necessarily $x - s(x)\mathbf{a} \in \partial\Omega^-$). Then there are three cases:

(i) if $0 < s(x) < t$, then $u(x,t) = \psi(x - s(x)\mathbf{a}, t - s(x))$;

(ii) if $s(x) > t$, then $u(x,t) = \varphi(x - t\mathbf{a})$;

(iii) if $s(x) = t$, then $u(x,t) = \psi(x - t\mathbf{a}, 0) = \varphi(x - t\mathbf{a})$.

The last case sheds light on the first compatibility condition between ψ and φ:

$$\psi(x, 0) = \varphi(x) \quad \forall x \in \partial\Omega^-\,. \tag{2.6}$$

3. A cell-centered finite volume discretization and associated error estimates.

3.1. Notation and geometric properties of meshes. Let $\mathcal{T} = \{K_j \,:\, j = 1, \ldots, N\}$ be a partition of the domain Ω in polyhedral volumes K_j (the control volumes) that forms a structured or unstructured triangulation of Ω and such that the hyperface between two adjacent volumes is included in a hyperplane. For a given j between 1 and N, there are two cases:

- In the first one, the volume K_j has no hyperface on the boundary $\partial\Omega$. Then we denote by $\mathcal{N}(j)$ the set of indices $k \neq j$ between 1 and N such that $K_k \cap K_j$ has $(nd-1)$ positive measure.
- In the second one, the boundary of the volume K_j meets the boundary $\partial\Omega$ in a set of $(nd-1)$ positive measure. Then we denote by $\mathcal{N}_0(j)$ the set of indices $k \neq j$ between 1 and N such that $K_k \cap K_j$ has $(nd-1)$ positive measure, and we complete this set into $\mathcal{N}(j)$ by negative integers numbering the hyperfaces of K_j which are on the boundary $\partial\Omega$. We denote the set of these negative integers by $\mathcal{N}_b(j)$.

In both cases we have $\mathcal{N}(j) = \mathcal{N}_0(j) \cup \mathcal{N}_b(j)$, since $\mathcal{N}_b(j)$ is empty when K_j has no hyperface on the boundary $\partial\Omega$.

Let $k \in \mathcal{N}(j)$. If $k \in \mathcal{N}_0(j)$, we denote by $\mathbf{n}_{j,k}$ the unit normal on $K_j \cap K_k$, which points out from K_j and by $\mathbf{N}_{j,k}$ the product $\mathbf{N}_{j,k} = |K_j \cap K_k| \mathbf{n}_{j,k}$, where $|K_j \cap K_k|$ denotes the $(nd-1)$ positive measure of $K_j \cap K_k$. If $k \in \mathcal{N}_b(j)$, we denote by K_k the symmetric of K_j with respect to the hyperface $K_j \cap \partial\Omega$ and keep the same notation as above. We shall use in what follows the partition of $\mathcal{N}(j)$:

$$\mathcal{N}(j) = \mathcal{N}^+(j) \cup \mathcal{N}^-(j) \cup \mathcal{N}^0(j)\,, \tag{3.1}$$

where $\mathcal{N}^+(j) = \{k \in \mathcal{N}(j), \mathbf{a}\cdot\mathbf{n}_{j,k} > 0\}$, $\mathcal{N}^-(j) = \{k \in \mathcal{N}(j), \mathbf{a}\cdot\mathbf{n}_{j,k} < 0\}$, and $\mathcal{N}^0(j) = \{k \in \mathcal{N}(j), \mathbf{a}\cdot\mathbf{n}_{j,k} = 0\}$. Similar definitions are extended to $\mathcal{N}_0^\varepsilon(j)$ and $\mathcal{N}_b^\varepsilon(j)$, $\varepsilon \in \{0,+,-\}$. Last, the centroid of K_j will be denoted by g_j, while the one of $K_j \cap K_k$ will be denoted by $g_{j,k}$.

Since we are interested in convergence results, we are going to consider families of triangulation $\mathcal{T}^h$ indexed by the real number $h = \max_{K_j\in\mathcal{T}^h} h_j$, where h_j is the diameter of the volume K_j. By definition of the parameter h, we have $|K_j| \le h^{nd}$ and $|K_j \cap K_k| \le h^{nd-1}$ for all $K_j, K_k \in \mathcal{T}^h$, and we assume that there exist $h_0 > 0$ and positive constants κ_1 and κ_2 such that for every $h < h_0$ we have

$$\frac{h_j^{nd}}{|K_j|} \le \kappa_1 \quad \text{and} \quad \sharp\mathcal{N}(j) \le \kappa_2 \quad \forall K_j \in \mathcal{T}^h\,. \tag{3.2}$$

Remark 1. The first assumption is equivalent to the shape-regularity assumption, and the second one means that the number of neighbors of each volume remains bounded when h tends to zero.

Let us recall the following properties, applications of the divergence theorem.

Proposition 3.1. *With the previous notation, we have the two vector identities*

$$\sum_{k\in\mathcal{N}(j)} \mathbf{N}_{j,k} = 0 \quad \text{and} \quad \sum_{k\in\mathcal{N}(j)} \mathbf{X}\cdot\mathbf{N}_{j,k}\; g_{j,k} = \mathbf{X}\;|K_j| \quad \forall \mathbf{X} \in \mathbf{R}^{nd}\,. \tag{3.3}$$

A straightforward application of the previous proposition leads to the following.

Proposition 3.2. *For every nonvanishing vector* $\mathbf{a} \neq 0$*, we have*

$$\mathcal{N}^+(j) \neq \emptyset \quad \text{and} \quad \sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k} \neq 0\,. \tag{3.4}$$

Concerning the time discretization of (2.1), we use a *finite difference* approach, and therefore we consider an increasing sequence $0 = t_0 < t_1 < \cdots < t_n < t_{n+1} \longrightarrow \infty$ and set $\Delta t_n = t_{n+1} - t_n$.

We shall consider sequences $\xi = (\xi_j)_{j=1,\dots,N}$ of scalars and of vectors in $\mathbf{R}^{nd}$, and we will estimate the ℓ^p norm for $p \in [1,+\infty]$ with

$$||\xi||_\infty = \max_{1\le j\le N} |\xi_j| \quad \text{and} \quad ||\xi||_p = \left(\sum_{j=1}^{N} |K_j||\xi_j|^p\right)^{1/p} \quad \text{for } p \ge 1,$$

where $|\xi_j|$ is the ℓ^p norm in $\mathbf{R}^{nd}$ in the case of vectors.

3.2. The first order explicit upwind finite volume scheme. This scheme reads as follows:

$$\frac{u_j^{n+1} - u_j^n}{\Delta t_n} + \frac{1}{|K_j|}\left(\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k} u_j^n + \sum_{k\in\mathcal{N}^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k} u_k^n\right) = 0\,. \tag{3.5}$$

Indeed the underlying philosophy of the finite volume scheme is to approximate on each control volume K_j for $j \in 1, \ldots, N$ the mean value of the exact solution to the continuous equation (2.1)

$$U_j^n = \frac{1}{|K_j|} \int_{K_j} u(x, t_n) dx \tag{3.6}$$

by taking into account the direction from which the information comes. System (3.5) allows us to compute an approximation of U_j^n once the initial values, u_j^0 for $j \geq 1$, and the boundary ones, u_k^n for $k \in \cup_j \mathcal{N}_b^-(j)$ and for $n \geq 0$, have been provided.

The classical way to check if the goal is achieved is to evaluate the truncation error, which consists of replacing u_j^n by U_j^n in (3.5). Here we are going to use a truncation error based on the value $u(g_j, t_n)$ of the exact solution at the centroid of the control volumes. More precisely one computes

$$\begin{aligned} E_j^n = \frac{u(g_j, t_{n+1}) - u(g_j, t_n)}{\Delta t_n} + \frac{1}{|K_j|} \Bigg(& \sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} u(g_j, t_n) \\ & + \sum_{k \in \mathcal{N}_0^-(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} u(g_k, t_n) + \sum_{k \in \mathcal{N}_b^-(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} u_k^n \Bigg) . \end{aligned} \tag{3.7}$$

Then from (3.5) and (3.7), the error denoted by $\alpha_j^n = u_j^n - u(g_j, t_n)$ satisfies

$$\frac{\alpha_j^{n+1} - \alpha_j^n}{\Delta t_n} + \frac{1}{|K_j|} \left(\sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} \alpha_j^n + \sum_{k \in \mathcal{N}_0^-(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} \alpha_k^n \right) = -E_j^n , \tag{3.8}$$

which can also be written as

$$\alpha_j^{n+1} = (\mathcal{L}^n \alpha^n)_j - \Delta t_n E_j^n, \tag{3.9}$$

where we denote by $\mathcal{L}^n$ the following operator that acts on sequences $\xi = (\xi_j)_{j=1,\ldots,N}$:

$$(\mathcal{L}^n \xi)_j = \xi_j - \frac{\Delta t_n}{|K_j|} \left(\sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} \xi_j + \sum_{k \in \mathcal{N}_0^-(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} \xi_k \right) . \tag{3.10}$$

In classical finite difference theory, one transfers information on the smallness of the truncation error E_j^n to the error α_j^n via a stability property of the scheme, which amounts here to showing that the norm of the operator $\mathcal{L}^n$ is not greater than 1. Courant, Friedrichs, and Lewy, in their early study of the discretization of the one-dimensional advection equation by finite differences, introduced the CFL number as a limitation on the time step Δt_n in order to achieve stability. In the case of the scheme (3.5), their construction can be mimicked as follows. First we take on each volume the local time given by (observe that, thanks to Proposition 3.2, $\sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} \neq 0$)

$$\tau_j = \frac{|K_j|}{\sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k}} . \tag{3.11}$$

Then we set $\Delta t_* = \min_j \tau_j$ and assign to the CFL number the ratio

$$\lambda = \frac{\Delta t_n}{\Delta t_*} . \tag{3.12}$$

When $\lambda \leq 1$, the operator $\mathcal{L}^n$ has a norm not greater than 1. More precisely, we have the following result, whose proof is standard.

THEOREM 3.3. *Under the CFL condition $\lambda \leq 1$, for every $p \in [1, +\infty]$ the operator $\mathcal{L}^n$ satisfies*

$$||\mathcal{L}^n \xi||_p \leq ||\xi||_p \,. \tag{3.13}$$

This result, when combined with (3.9), has the following straightforward corollary.

COROLLARY 3.4. *Under the CFL condition $\lambda \leq 1$ and for every $p \in [1, +\infty]$ we have the estimate*

$$||\alpha^n||_p \leq ||\alpha^0||_p + \sum_{i=0}^{n-1} \Delta t_i ||E^i||_p \,. \tag{3.14}$$

This inequality shows that estimations on E^i transfer to ones on the error α^n.

3.3. On the truncation error. Let us consider the volume of control K_j. We see that the error E_j^n can be divided into three sums:

$$E_j^n = G_j^n + I_j^n + \frac{1}{|K_j|} \sum_{k \in \mathcal{N}_b^-(j)} \mathbf{a} \cdot \mathbf{N}_{j,k}(u_k^n - u(g_{j,k}, t_n)), \tag{3.15}$$

where

$$G_j^n = \frac{u(g_j, t_{n+1}) - u(g_j, t_n)}{\Delta t_n} + \frac{1}{|K_j|} \sum_{k \in \mathcal{N}(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} u(g_{j,k}, t_n) \tag{3.16}$$

and

$$\begin{aligned} |K_j| I_j^n = & \sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k}(u(g_j, t_n) - u(g_{j,k}, t_n)) \\ & + \sum_{k \in \mathcal{N}_0^-(j)} \mathbf{a} \cdot \mathbf{N}_{j,k}(u(g_k, t_n) - u(g_{j,k}, t_n)). \end{aligned} \tag{3.17}$$

Recalling the estimates (3.2) on the volumes, the third term in (3.15) that concerns the boundary conditions treatment behaves like $\mathcal{O}(h)$ if we assume, for instance, that

$$u_k^n = \frac{1}{\Delta t_n |K_j \cap K_k|} \int_{t_n}^{t_{n+1}} \int_{K_j \cap K_k} \psi(\sigma, t) d\sigma dt \,, \quad k \in \mathcal{N}_b^-(j) \,, \quad n \geq 0, \tag{3.18}$$

i.e., that the discrete numerical boundary treatment satisfies

$$|u_k^n - u(g_{j,k}, t_n)| = \mathcal{O}(h^2) \,, \quad k \in \mathcal{N}_b^-(j) \,, \quad n \geq 0 \,. \tag{3.19}$$

Using the relationship (3.3) on the normals, the assumptions (3.2) on the mesh, and, intensively, Taylor's expansions, we see that the second term in G_j^n can be written as

$$\begin{aligned} \sum_{k \in \mathcal{N}(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} u(g_{j,k}, t_n) &= \sum_{k \in \mathcal{N}(j)} \mathbf{a} \cdot \mathbf{N}_{j,k}(u(g_{j,k}, t_n) - u(g_j, t_n)) \,, \\ &= \sum_{k \in \mathcal{N}(j)} \mathbf{a} \cdot \mathbf{N}_{j,k}(g_{j,k} - g_j) \cdot \nabla u(g_j, t_n) + \mathcal{O}(h^{nd+1}) \,, \\ &= \left(\sum_{k \in \mathcal{N}(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} g_{j,k} \right) \cdot \nabla u(g_j, t_n) + \mathcal{O}(h^{nd+1}) \,, \\ &= |K_j| \mathbf{a} \cdot \nabla u(g_j, t_n) + \mathcal{O}(h^{nd+1}) \,. \end{aligned} \tag{3.20}$$

Finally, since

$$\frac{u(g_j,t_{n+1})-u(g_j,t_n)}{\Delta t_n}=\frac{\partial u}{\partial t}(g_j,t_n)+\mathcal{O}(\Delta t_n) \tag{3.21}$$

and since u is the solution of (2.1), we deduce that if $\Delta t_n \le ch$,

$$G_j^n=\mathcal{O}(h)\,. \tag{3.22}$$

But concerning I_j^n, a similar computation leads this time to $I_j^n=\mathcal{O}(1)$, and we find that $E_j^n=\mathcal{O}(1)$. Hence E_j^n does not even converge to zero as h goes to zero, so in a sense the scheme is inconsistent. One might think that the estimate above is not optimal, but in fact this is not the case since in the one-dimensional case the previous computations are much simpler and show that indeed E_j^n does not converge to zero as h goes to zero. This fact (the scheme is not pointwise-consistent) was already observed in two dimensions by Kröner [16, Lemma 3.2.8]. On the other hand, Lemma 4.1 of Chapter IV in Godlewski and Raviart [13] cannot be applied to the upwind scheme on a uniform triangulation by equilateral triangles, as they wrongly claim. In their proof, they use the identity $\frac{\partial\Phi}{\partial u}(u,u,\mathbf{n})+\frac{\partial\Phi}{\partial u}(u,u,-\mathbf{n})=0$, where $\Phi(u,v,\mathbf{n})$ denotes the numerical flux; that is, $\Phi(u,v,\mathbf{n})=(\mathbf{a}\cdot\mathbf{n})u$ for $\mathbf{a}\cdot\mathbf{n}>0$, $\Phi(u,v,\mathbf{n})=(\mathbf{a}\cdot\mathbf{n})v$ for $\mathbf{a}\cdot\mathbf{n}<0$ and $\Phi(u,v,\mathbf{n})=0$ for $\mathbf{a}\cdot\mathbf{n}=0$. And one can readily see that this identity is wrong. However, the result (that on such a triangulation the upwind scheme is first order accurate) is true, as it will follow from the proof of Theorem 4.2 in this paper.

3.4. A geometric corrector. Our goal is to construct a sequence of scalars $(\gamma_j^n)_{j=1,\dots,N}$ that satisfies the N equations

$$\sum_{k\in\mathcal{N}^+(j)}\mathbf{a}\cdot\mathbf{N}_{j,k}\gamma_j^n+\sum_{k\in\mathcal{N}_0^-(j)}\mathbf{a}\cdot\mathbf{N}_{j,k}\gamma_k^n=|K_j|I_j^n \tag{3.23}$$

in order to correct the errors $(\alpha_j^n)_{j=1,\dots,N}$ introduced in section 3.2 and to prove that under smoothness assumptions the finite volume scheme is first order accurate in spite of the fact that the truncation error is inconsistent. We first slightly modify the linear system (3.23) to be able to estimate in terms of h the norm of the sequence. Thus, we will consider the construction of a sequence of vectors in $\mathbf{R}^{nd}$, $(\Gamma_j)_{j=1,\dots,N}$ that satisfies the N following vector equations (we recall that g_j and $g_{j,k}$ belong to $\mathbf{R}^{nd}$):

$$\begin{aligned}&\sum_{k\in\mathcal{N}^+(j)}\mathbf{a}\cdot\mathbf{N}_{j,k}\Gamma_j+\sum_{k\in\mathcal{N}_0^-(j)}\mathbf{a}\cdot\mathbf{N}_{j,k}\Gamma_k\\&\qquad=\sum_{k\in\mathcal{N}^+(j)}\mathbf{a}\cdot\mathbf{N}_{j,k}(g_{j,k}-g_j)+\sum_{k\in\mathcal{N}_0^-(j)}\mathbf{a}\cdot\mathbf{N}_{j,k}(g_{j,k}-g_k)\,.\end{aligned} \tag{3.24}$$

We are going to prove, thanks to Theorem 3.8, that this system has one and only one solution, but let us first give the following definitions.

Definition 3.5. *Given a nonzero vector* $\mathbf{a}\in\mathbf{R}^{nd}$ *and a triangulation* $(K_j)_{j=1,\dots,N}$ *of a polygonal domain* Ω *in* $\mathbf{R}^{nd}$ *defined as in section* 3.1, *the geometric corrector for the advection equation* (2.1) *is the sequence of vectors in* $\mathbf{R}^{nd}$, $(\Gamma_j)_{j=1,\dots,N}$, *defined by the* $N\times N$ *system of equations* (3.24).

Definition 3.6. *For every control volume* $J\in\mathcal{T}$, *we denote by* $\mathcal{C}(J)$ *the cone of dependence of* J*:*

(3.25)
$$\mathcal{C}(J)=\{K\in\mathcal{T}\,/\,\exists\,J_1,\dots,J_p\in\mathcal{T}\,,\ \mathbf{a}\cdot\mathbf{N}_{J_1,K}<0,\ \mathbf{a}\cdot\mathbf{N}_{J_2,J_1}<0,\ \dots,\ \mathbf{a}\cdot\mathbf{N}_{J,J_p}<0\}\,.$$

Let us remark that

$$\forall K \in \mathcal{C}(J)\,,\ \big(j \in \mathcal{N}_0^-(K) \Rightarrow K_j \in \mathcal{C}(J)\big)\,. \tag{3.26}$$

PROPOSITION 3.7. *For every control volume $J \in \mathcal{T}$, there is at least one volume $K_k \in \mathcal{C}(J)$ that shares a face with $\partial\Omega^-$, i.e., such that*

$$\mathcal{N}_b^-(k) \neq \emptyset\,. \tag{3.27}$$

Proof. Indeed let us assume that there is no such volume in $\mathcal{C}(J)$. Since $\mathcal{C}(J)$ is composed of polyhedron, it is also a polyhedron, and there is at least one face (on the boundary of $\mathcal{C}(J)$) for which the external normal forms an obtuse angle with $\mathbf{a}$. Then for each volume $K \in \mathcal{C}(J)$ that meets this face, since from the assumption that K does not intersect $\partial\Omega^-$, there is an adjacent volume $L \in \mathcal{T} \setminus \mathcal{C}(J)$ such that $\mathbf{a} \cdot \mathbf{N}_{K,L} < 0$. From the definition of $\mathcal{C}(J)$, this last relation yields that L is in $\mathcal{C}(J)$, which is a contradiction. □

According to Proposition 3.2, $\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}$ does not vanish. We then define the $N \times N$ matrix B such that for an arbitrary sequence $X = (X_j)_{j=1,\dots,N}$ in $\mathbf{C}^N$ we have

$$(BX)_j = \frac{\sum_{k\in\mathcal{N}_0^-(j)}(-\mathbf{a}\cdot\mathbf{N}_{j,k})X_k}{\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}}\,. \tag{3.28}$$

We denote by $(\Delta_j)_{j=1,\dots,N}$ the sequence of vectors in $\mathbf{R}^{nd}$ defined by

$$\Delta_j = \frac{\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}(g_{j,k}-g_j) + \sum_{k\in\mathcal{N}_0^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}(g_{j,k}-g_k)}{\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}}\,. \tag{3.29}$$

It is clear that (3.24) can be written as

$$(Id - B)\Gamma = \Delta\,. \tag{3.30}$$

We are now able to prove that $Id - B$ is a nonsingular M-matrix.

THEOREM 3.8. *The spectrum $\sigma(B)$ of B satisfies*

$$\sigma(B) \subset \{z \in \mathbf{C}\,,\ |z| < 1\}\,, \tag{3.31}$$

i.e.,

$$(Id - B)^{-1} = \sum_{l=0}^{\infty} B^l\,. \tag{3.32}$$

Proof. (i) Let $X \neq 0$, $X \in \mathbf{C}^N$ such that $BX = \lambda X$. From definition (3.28), by observing that $-\mathbf{a}\cdot\mathbf{N}_{j,k} \geq 0$ for $k \in \mathcal{N}_0^-(j)$ and by using the relation $\sum_{k\in\mathcal{N}(j)} \mathbf{a}\cdot\mathbf{N}_{j,k} = 0$ rewritten as $\sum_{k\in\mathcal{N}_0^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k} + \sum_{k\in\mathcal{N}_b^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k} + \sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k} = 0$, we have

$$|(BX)_j| \leq \frac{\sum_{k\in\mathcal{N}_0^-(j)} -\mathbf{a}\cdot\mathbf{N}_{j,k}}{\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}} ||X||_\infty = \left(1 + \frac{\sum_{k\in\mathcal{N}_b^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}}{\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}}\right) ||X||_\infty. \tag{3.33}$$

Then $||BX||_\infty \leq ||X||_\infty$ and $|\lambda| \leq 1$.

(ii) Now let us assume that $\lambda \in \mathbf{C}$ with $|\lambda| = 1$ is an eigenvalue of B, i.e., that there is $X \neq 0$ such that $BX = \lambda X$ and $X \in \mathbf{C}^N$. Let us denote by $K_j \in \mathcal{T}$ a volume such that

$$|X_j| = \max_{1 \leq k \leq N} |X_k| \,. \tag{3.34}$$

From the jth component of $BX = \lambda X$, and since $\sum_{k \in \mathcal{N}(j)} \mathbf{N}_{j,k} = 0$, we get

$$\sum_{k \in \mathcal{N}_0^-(j)} (-\mathbf{a} \cdot \mathbf{N}_{j,k}) \left(|X_j| - \frac{X_k}{\lambda} \right) + \sum_{k \in \mathcal{N}_b^-(j)} (-\mathbf{a} \cdot \mathbf{N}_{j,k}) |X_j| = 0. \tag{3.35}$$

Thus

$$\sum_{k \in \mathcal{N}_0^-(j)} (-\mathbf{a} \cdot \mathbf{N}_{j,k}) \,\mathcal{R}e \left(|X_j| - \frac{X_k}{\lambda} \right) + \sum_{k \in \mathcal{N}_b^-(j)} (-\mathbf{a} \cdot \mathbf{N}_{j,k}) |X_j| = 0 \,, \tag{3.36}$$

$$\sum_{k \in \mathcal{N}_0^-(j)} (-\mathbf{a} \cdot \mathbf{N}_{j,k}) \,\mathcal{I}m \left(|X_j| - \frac{X_k}{\lambda} \right) = 0 \,. \tag{3.37}$$

Since $\mathcal{R}e(|X_j| - X_k/\lambda) \geq 0$ and $\mathcal{I}m(|X_j| - X_k/\lambda) \geq 0$, all the terms above are positive and thus equal to zero, so that $\mathcal{N}_b^-(j) = \emptyset$ and for all $k \in \mathcal{N}_0^-(j)$, $|X_j| = X_k/\lambda$, i.e., $|X_j| = |X_k|$. By induction, we find that for all k such that K_k belongs to $\mathcal{C}(K_j)$, $|X_k| = |X_j|$ and $\mathcal{N}_b^-(k) = \emptyset$, i.e., K_k does not meet $\partial\Omega^-$, which is in contradiction with Proposition 3.7. □

Remark 2. Let us denote

$$\delta_j = \sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} = \sum_{k \in \mathcal{N}^-(j)} |\mathbf{a} \cdot \mathbf{N}_{j,k}| > 0 \,, \tag{3.38}$$

so that (3.28) also reads as

$$(BX)_j = \frac{\sum_{k \in \mathcal{N}_0^-(j)} |\mathbf{a} \cdot \mathbf{N}_{j,k}| X_k}{\delta_j} \,. \tag{3.39}$$

We then observe that $(BX)_j$ is a barycenter of the X_k for $k \in \mathcal{N}^-(j)$ when K_j does not meet the boundary $\partial\Omega^-$, and of the X_k for $k \in \mathcal{N}_0^-(j)$ and 0 for $k \in \mathcal{N}_b^-(j)$ when K_j meets the boundary $\partial\Omega^-$. Now, given $m \geq 2$, we have

$$(B^m X)_j = \frac{\sum_{j_1 \in \mathcal{N}_0^-(j)} \cdots \sum_{j_m \in \mathcal{N}_0^-(j_{m-1})} |\mathbf{a} \cdot \mathbf{N}_{j,j_1}| \ldots |\mathbf{a} \cdot \mathbf{N}_{j_{m-1},j_m}| X_{j_m}}{\delta_j \delta_{j_1} \ldots \delta_{j_{m-1}}} \,. \tag{3.40}$$

Remark 3. The great advantage of the geometric corrector Γ_k defined by (3.24) on the corrector γ_j^n defined by (3.23) is that the former depends only on the advection vector $\mathbf{a}$ and on the geometry of the problem Ω and the elements K_j of the mesh and not on the initial and boundary data. On the other hand it might be that the introduction of this geometric corrector leads to a weaker estimate. We are going to show that this is not the case by considering the case where the data are affine functions. More precisely, we take for initial conditions (2.2) and boundary conditions (2.3)

$$\varphi(x) = \boldsymbol{\delta_1} \cdot x + \delta_2 \quad \text{and} \quad \psi(x,t) = \boldsymbol{\delta_1} \cdot x + \delta_2 - \boldsymbol{\delta_1} \cdot \mathbf{a} t \,, \quad t \geq 0, \tag{3.41}$$

where $\boldsymbol{\delta_1}$ is an arbitrary vector in $\mathbf{R}^{nd}$ and δ_2 is an arbitrary real number. Then the solution u to (2.1) is

$$u(x,t) = \boldsymbol{\delta_1} \cdot x + \delta_2 - \boldsymbol{\delta_1} \cdot \mathbf{a}t \tag{3.42}$$

with $\nabla u = \boldsymbol{\delta_1}$. In this case a straightforward computation yields that the exact solution of (3.23) has the form

$$\gamma_j^n = -\Gamma_j \cdot \boldsymbol{\delta_1} \equiv -\Gamma_j \cdot \nabla u \tag{3.43}$$

and indicates the optimality of the geometric corrector approach.

3.5. The error estimate. The previous remark suggests using the vector geometrical corrector $(\Gamma_j)_{j=1,\dots,N}$ defined by (3.24) to construct the scalar corrector γ_j^n by taking the formula

$$\gamma_j^n = -\Gamma_j \cdot \nabla u(g_j, t_n)\,. \tag{3.44}$$

Main result: we are now in a position to prove the following general result, where the required smoothness is due to the use of second order Taylor expansions.

THEOREM 3.9. *Let u be the smooth solution to* (2.1)–(2.3)*, where φ and ψ are arbitrary smooth functions satisfying the compatibility conditions (see Bardos* [1]*).*

Assume the local quasi uniformity of the family of meshes, i.e., that there is a positive constant κ_3 such that

$$\frac{1}{\kappa_3}|K_k| \le |K_j| \le \kappa_3 |K_k| \quad \forall h < h_0, \quad \forall K_j \in \mathcal{T}^h, \quad \forall k \in \mathcal{N}(j). \tag{3.45}$$

Let us make the following hypotheses on the discretization of the initial and boundary data: we assume that there exist two constants κ_4 and κ_5 such that for all $h < h_0$,

$$||(u_j^0 - \varphi(g_j))_{j=1,\dots,N}||_p \le \kappa_4 h\,, \tag{3.46}$$

$$|u_k^n - \psi(g_{j,k}, t_n)| \le \kappa_5 h^2 \quad \forall j\,, \quad \forall k \in \mathcal{N}_b^-(j) \text{ and } t_n \le T\,. \tag{3.47}$$

Under the CFL condition $\lambda \le 1$, for every $p \in [1, +\infty]$, if there exists C_p such that the geometric corrector Γ satisfies the estimate

$$||\Gamma||_p \le C_p h\,, \tag{3.48}$$

then the error for the explicit upwind finite volume scheme satisfies the first order estimate

$$||(u_j^n - U_j^n)_{j=1,\dots,N}||_p \le C_p' h, \quad t_n \le T\,. \tag{3.49}$$

Remark 4. If we have instead of (3.48) the weaker estimate

$$||\Gamma||_p \le C_p h^\alpha\,, \tag{3.50}$$

for some $\alpha \in]0,1]$, and provided we keep the same hypotheses, then the proof of Theorem 3.9 leads to the estimate

$$||(u_j^n - U_j^n)_{j=1,\dots,N}||_p \le C_p' h^\alpha, \quad t_n \le T\,. \tag{3.51}$$

Proof. Let us recall (3.9) about the error: $\alpha_j^{n+1} = (\mathcal{L}^n \alpha^n)_j - \Delta t_n E_j^n$. We propose to correct the error α with the corrector γ given by (3.44) as follows:

$$\underline{\alpha}_j^n = \alpha_j^n + \gamma_j^n \tag{3.52}$$

so that

$$\underline{\alpha}_j^{n+1} = (\mathcal{L}^n \underline{\alpha}^n)_j - \Delta t_n \underline{E}_j^n, \tag{3.53}$$

where the corrected truncation error has the form

$$\begin{aligned} \underline{E}_j^n &= E_j^n - \frac{1}{|K_j|}\left(\sum_{k \in \mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}\gamma_j^n + \sum_{k\in\mathcal{N}_0^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}\gamma_k^n \right) - \frac{\gamma_j^{n+1}-\gamma_j^n}{\Delta t_n} \\ &= G_j^n + \underline{I}_j^n + \frac{1}{|K_j|}\sum_{k\in\mathcal{N}_b^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}(u_k^n - u(g_{j,k},t_n)) - \frac{\gamma_j^{n+1}-\gamma_j^n}{\Delta t_n}\,. \end{aligned} \tag{3.54}$$

Now the previous bad behavior part in the error is changed to

$$\begin{aligned} \underline{I}_j^n = \frac{1}{|K_j|}\Bigg(&\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}\left(u(g_j,t_n) - u(g_{j,k},t_n) - \gamma_j^n\right) \\ &+ \sum_{k\in\mathcal{N}_0^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}\left(u(g_k,t_n) - u(g_{j,k},t_n) - \gamma_k^n\right)\Bigg)\,. \end{aligned} \tag{3.55}$$

Using the assumptions (3.2) and (3.45) on the mesh and the Taylor expansions

$$u(g_j,t_n) - u(g_{j,k},t_n) = (g_j - g_{j,k})\cdot\nabla u(g_j,t_n) + \mathcal{O}(h^2)\,, \tag{3.56}$$

$$u(g_k,t_n) - u(g_{j,k},t_n) = (g_k - g_{j,k})\cdot\nabla u(g_j,t_n) + \mathcal{O}(h^2)\,, \tag{3.57}$$

we have

$$\begin{aligned} \underline{I}_j^n = \frac{1}{|K_j|}\Bigg(&\sum_{k\in\mathcal{N}^+(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}\left((g_j - g_{j,k})\cdot\nabla u(g_j,t_n) - \gamma_j^n\right) \\ &+ \sum_{k\in\mathcal{N}_0^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}\left((g_k - g_{j,k})\cdot\nabla u(g_j,t_n) - \gamma_k^n\right)\Bigg) + \mathcal{O}(h)\,. \end{aligned} \tag{3.58}$$

The definitions (3.24) and (3.44) of the geometric corrector Γ and of γ_j^n yield that

$$\underline{I}_j^n = \frac{1}{|K_j|}\sum_{k\in\mathcal{N}_0^-(j)} \mathbf{a}\cdot\mathbf{N}_{j,k}\,\Gamma_k\cdot\left(\nabla u(g_k,t_n) - \nabla u(g_j,t_n)\right) + \mathcal{O}(h)\,. \tag{3.59}$$

Since Γ satisfies the estimate (3.48), we obtain

$$\underline{I}_j^n = \mathcal{O}(h). \tag{3.60}$$

On the other hand

$$\frac{\gamma_j^{n+1}-\gamma_j^n}{\Delta t_n} = \Gamma_j\cdot\left(\nabla\frac{\partial u}{\partial t}(g_j,t_n) + \mathcal{O}(\Delta t_n)\right)\,. \tag{3.61}$$

Then, again from the estimate (3.48) on Γ, we have

$$\frac{\gamma_j^{n+1}-\gamma_j^n}{\Delta t_n}=\mathcal{O}(h). \tag{3.62}$$

Thus using the assumption on the boundary conditions (3.47) and gathering results (3.22), (3.60), (3.62), we conclude that

$$\underline{E}_j^n=\mathcal{O}(h)\,. \tag{3.63}$$

According to the estimate (3.14) applied to (3.53) we deduce that

$$||(u_j^n-u(g_j,t_n)+\gamma_j^n)_{j=1,\dots,N}||_p\le||(u_j^0-u(g_j,0)+\gamma_j^0)_{j=1,\dots,N}||_p+\mathcal{O}(h)\,. \tag{3.64}$$

Now, the assumption on the initial values (3.46) shows that for $t_n\le T$,

$$||(u_j^n-u(g_j,t_n))_{j=1,\dots,N}||_p=\mathcal{O}(h)\,. \tag{3.65}$$

Finally the required results (3.49) follows from the Taylor expansion

$$U_j^n=u(g_j,t_n)+\mathcal{O}(h^2)\,. \qquad \square \tag{3.66}$$

Remark 5. All the results in this section extend to the implicit first order upwind scheme and to more general meshes where the intersection of two adjacent volumes are no longer included in a hyperplan but are composed of several $(nd-1)$-dimensional polygons. All these polygons have to be numbered and are distributed according to the angle they form with vector $\mathbf{a}$ as in (3.1). These extensions will be the subject of a forthcoming article.

Remark 6. In the definition (3.24) of the geometric corrector, the centroid g_j of the volume K_j can be replaced by any point $\tilde{g}_j$ such that $||g_j-\tilde{g}_j||\le C\,h$. Indeed, this will simply change Γ_j into $\Gamma_j+g_j-\tilde{g}_j$.

4. On the geometric corrector. We are now going to study from a theoretical point of view several cases where we have the following estimate on the geometric corrector: there exists C_p such that the sequence $\Gamma\equiv(\Gamma_j)_{j=1,\dots,N}$ satisfies

$$||\Gamma||_p\le C_p h\,. \tag{4.1}$$

4.1. The one-dimensional case. We consider the case $nd=1$. Here the advection vector is a scalar and we assume that $a>0$. The finite volume scheme reads here as

$$\frac{u_j^{n+1}-u_j^n}{\Delta t_n}+a\frac{u_j^n-u_{j-1}^n}{\Delta x_j}=0\,. \tag{4.2}$$

We have $\Omega=]A,B[$ and the "triangulation" of Ω is done by the control volumes $K_j=]x_{j-\frac12},x_{j+\frac12}[$ for $j=1,\dots,N$. The centroid of K_j is given by $g_j=x_j=(x_{j+\frac12}+x_{j-\frac12})/2$ and $|K_j|=\Delta x_j=x_{j+\frac12}-x_{j-\frac12}$. Equations (3.24) read in this case as

$$\left\{\begin{array}{rl} a\,\Gamma_1=a\,(x_{\frac32}-x_1)\,, & j=1\,,\\ a\,(\Gamma_j-\Gamma_{j-1})=a\,(x_{j+\frac12}-x_j)-a\,(x_{j-\frac12}-x_{j-1})\,, & j\ge2\,,\end{array}\right. \tag{4.3}$$

whose solution is simply $\Gamma_j = x_{j+\frac{1}{2}} - x_j = \frac{\Delta x_j}{2}$, $j \geq 1$. In this case, the estimation (4.1) is straightforward for all p and therefore Theorem 3.9 applies: the upwind FVM for the advection equation in one dimension leads to a first order approximation.

THEOREM 4.1. *We denote $h = \max_{j=1,\dots,N} \Delta x_j$ and assume that there is a constant κ_3 such that*

$$\frac{1}{\kappa_3} \leq \frac{\Delta x_j}{\Delta x_{j-1}} \leq \kappa_3 \quad \forall j \geq 2, \quad \forall h < h_0 . \tag{4.4}$$

If there exist two constants κ_4 and κ_5 such that the discretization of the initial and boundary data satisfies

$$|| \left(u_j^0 - \varphi(x_j)\right)_{j=1,\dots,N} ||_p \leq \kappa_4 h \quad \text{and} \quad |u_0^n - \psi(x_{\frac{1}{2}}, t_n)| \leq \kappa_5 h^2 , \quad t_n \leq T , \tag{4.5}$$

then under the CFL condition $\lambda \equiv a\Delta t_n / \min_{j=1,\dots,N} \Delta x_j \leq 1$, for every $p \in [1, +\infty]$, the error $u_j^n - U_j^n$ satisfies the first order estimate

$$||u^n - U^n||_p \leq C'_p h, \quad t_n \leq T . \tag{4.6}$$

Let us observe that the corrected error has the form

$$\underline{\alpha}_j^n = u_j^n - \Big(u(x_j, t_n) + (x_{j+\frac{1}{2}} - x_j) \cdot \nabla u(x_j, t_n)\Big) , \tag{4.7}$$

and this has a clear interpretation: u_j^n provided by the scheme should be compared to $u(x_{j+\frac{1}{2}}, t_n)$ rather than to $u(x_j, t_n)$. The upwinding introduces a bias which leads us to compare u_j^n with $u(x_{j+\frac{1}{2}}, t_n)$. In the case where $a < 0$ we would have found that u_j^n should be compared with $u(x_{j-\frac{1}{2}}, t_n)$. This has already been observed in Eymard, Gallouët, and Herbin [10] in their study of the one-dimensional linear advection equation.

Let us now make explicit the operator B in the one-dimensional case. For $a > 0$ one sees easily that for all $X \in \mathbf{C}^N$,

$$(BX)_1 = 0 \text{ and } (BX)_j = X_{j-1} \quad \text{for } j \geq 2 , \tag{4.8}$$

so that $B^N = 0$ while $B^{N-1} \neq 0$.

4.2. Back to the *nd*-dimensional case.

In this section, we show by straightforward computations that the geometric corrector is of order h for some two-dimensional structured meshes. We first consider the case of meshes composed of parallelograms.

4.2.1. Nonuniform nonorthogonal quadrilateral grid.

We consider a quadrilateral domain bounded from below by two half-lines, which we use as coordinate axes and that are uniquely defined such that the advection vector **a** is oriented from the exterior to the interior on these lines. Now we assume that the mesh is generated by half-lines parallel to these axes, as shown in Figure 4.1.

An element of the mesh is described by two indices (m, n), $m \geq 1$, along the x axis, $n \geq 1$ along the y axis, and $h(m)$ (respectively, $k(n)$) denotes the length of the element (m, n) along x (respectively, y). Here, for instance, sufficient conditions on the mesh to satisfy (3.2) and (3.45) read as

$$c_1 h \leq h(m) \leq c_2 h \quad \forall m \geq 1 , \quad c_3 h \leq k(n) \leq c_4 h \quad \forall n \geq 1 . \tag{4.9}$$

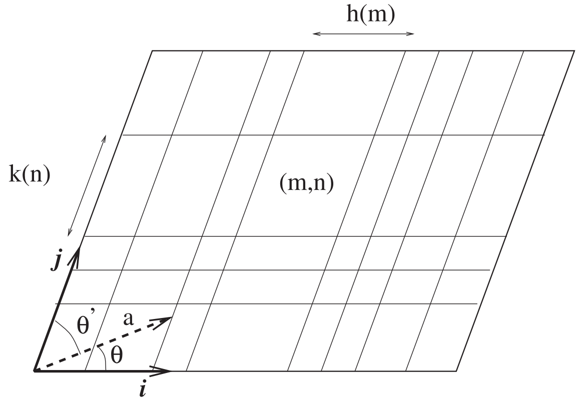

FIG. 4.1. *Nonuniform nonorthogonal quadrilateral grid.*

The corrector for the element (m,n) is therefore denoted by $\Gamma_{m,n}$, and the formula (3.24) for the geometric corrector suggests using

$$G_{m,n} = \Gamma_{m,n} - \frac{h(m)}{2}\vec{i} - \frac{k(n)}{2}\vec{j}, \tag{4.10}$$

where $\vec{i}$ (respectively, $\vec{j}$) denotes the unit vector along the x (respectively, y) axis. If we denote θ (respectively, θ') to be the angle of the advection vector $\mathbf{a}$ with the x axis (respectively, the y axis), it is straightforward to obtain that $G_{m,n}$ satisfy the following recursive formula:

$$G_{m,n} = \lambda_{m,n} G_{m,n-1} + (1-\lambda_{m,n}) G_{m-1,n} \quad \forall m \geq 1\,, \quad \forall n \geq 1, \tag{4.11}$$

where

$$\lambda_{m,n} = \frac{h(m)\sin(\theta)}{h(m) sin(\theta) + k(n)\sin(\theta')} \quad \forall m \geq 1, \quad \forall n \geq 1 \tag{4.12}$$

and where by convention we set

$$G_{m,0} = -\frac{h(m)}{2}\vec{i} \quad \text{and} \quad G_{0,n} = -\frac{h(n)}{2}\vec{j}\,. \tag{4.13}$$

Thus, $G_{m,n}$ is the barycenter of $G_{m,n-1}$ and $G_{m-1,n}$, with respective weights $\lambda_{m,n}$ and $1-\lambda_{m,n}$. Then a recursive computation leads $G_{m,n}$ to be a barycenter of $G_{p,0}$ with $1 \leq p \leq m$ and of $G_{0,q}$ with $1 \leq q \leq n$. From this property, we deduce that the absolute value of both components of $\Gamma_{m,n}$ is smaller than $h/2$ up to a multiplicative constant depending on c_i, $i = 1, \ldots, 4$, and that the estimate (4.1) is true for a nonuniform nonorthogonal quadrilateral mesh.

Remark 7. The above result can also be proved for quadrilateral meshes that satisfy only analogous conditions to (4.4) in each direction.

Remark 8. The above result is easily extended to a mesh composed of parallelepipeds in three dimensions.

4.2.2. Nonuniform nonorthogonal triangular grid. Let us divide each parallelogram of the previous mesh into two triangles according to Figure 4.2.

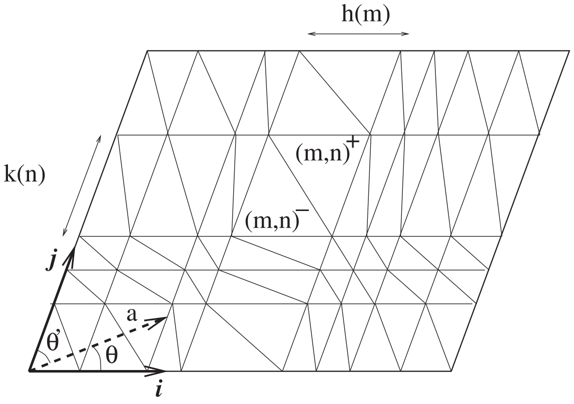

FIG. 4.2. *Nonuniform nonorthogonal triangular grid.*

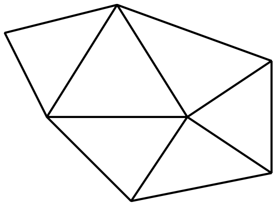

FIG. 4.3. $\mathcal{T}_0$*: a coarse triangular conformal mesh.*

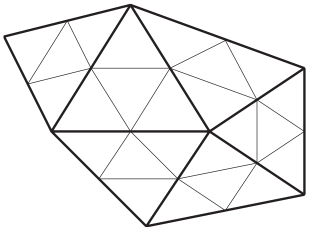

FIG. 4.4. $\mathcal{T}_1$*: 1-refinement of* $\mathcal{T}_0$*.*

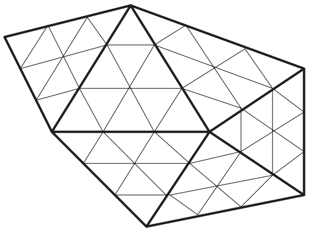

FIG. 4.5. $\mathcal{T}_2$*: 2-refinement of* $\mathcal{T}_0$*.*

The corrector for the downwind triangle of parallelogram (m, n) is denoted by $\Gamma^+_{m,n}$ and the corrector for the upwind one is denoted by $\Gamma^-_{m,n}$. Writing the equations that satisfy the geometric corrector in both triangles and eliminating $\Gamma^-_{m,n}$, we get an equation on $\Gamma^+_{m,n}$ of the same form as for the mesh composed of parallelogram. We now introduce

$$G^+_{m,n} = \Gamma^+_{m,n} - \frac{h(m)}{3}\vec{\imath} - \frac{k(n)}{3}\vec{\jmath} \tag{4.14}$$

and obtain that $G^+_{m,n}$ satisfy the recursive formula (4.11). As for the previous study, we conclude that $\Gamma^+_{m,n}$ is of order h. Using the expression of $\Gamma^-_{m,n}$, which is the sum of terms of order h, we prove estimate (4.1) for this type of meshes.

4.3. Asymptotically structured triangular meshes in two dimensions. The purpose of this section is to prove the estimate (4.1) in the case where a global refinement technique is applied to a given arbitrary and unstructured triangular conformal (in the finite element sense) mesh $\mathcal{T}_0$ as the one plotted in Figure 4.3. Given $\ell \in \mathbf{N}$ a positive integer, we denote by $\mathcal{T}_\ell$ the mesh obtained from $\mathcal{T}_0$ by dividing each triangle into $(\ell+1)^2$ congruent triangles, i.e., by introducing ℓ regularly spaced points on each edge, as can be seen in Figures 4.4 and 4.5.

THEOREM 4.2. *For every triangular conformal mesh* $\mathcal{T}_0$ *and for every nonvanishing vector* $\mathbf{a}$ *in* $\mathbf{R}^2$ *there exists a constant* $C(\mathbf{a}, \mathcal{T}_0)$ *such that for every* $\ell \in \mathbf{N}$ *we*

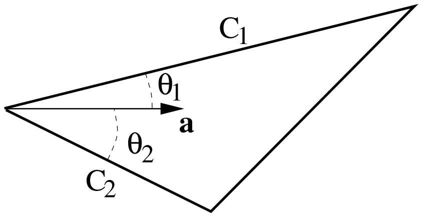

FIG. 4.6. *The case of* $\sharp\mathcal{N}^+(T) = 1$.

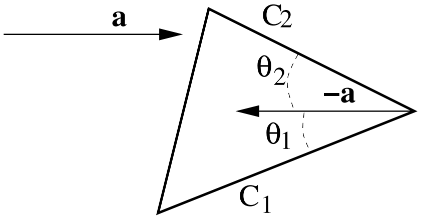

FIG. 4.7. *The case of* $\sharp\mathcal{N}^+(T) = 2$.

have the estimate

$$||\Gamma^{(\ell)}||_\infty \leq \frac{C(\mathbf{a}, \mathcal{T}_0)}{\ell + 1}\,, \tag{4.15}$$

where $\Gamma^{(\ell)}$ *denotes the geometric corrector sequence on* $\mathcal{T}_\ell$.

Denoting by $h^{(\ell)} = \max_{K_j \in \mathcal{T}_\ell} h_j > 0$, we have by construction $h^{(\ell)} = \frac{h^{(0)}}{\ell+1}$, and since $h^{(0)}$ depends only on $\mathcal{T}_0$, we deduce from (4.15) the proof of the estimate (4.1) in this case.

COROLLARY 4.3. *For every triangular conformal mesh* $\mathcal{T}_0$ *of a polygonal domain* Ω *and for every nonvanishing vector* $\mathbf{a}$ *in* $\mathbf{R}^2$*, there exists a constant* $C(\mathbf{a}, \mathcal{T}_0)$ *such that for every* $\ell \in \mathbf{N}$ *and for every real number* $p \in [1, \infty]$ *we have the estimate*

$$||\Gamma^{(\ell)}||_p \leq C(\mathbf{a}, \mathcal{T}_0)|\Omega|^{1/p} \max_{K_j \in \mathcal{T}_\ell} h_j\,. \tag{4.16}$$

Actually we are going to show a stronger result than Theorem 4.2. To state this result, we introduce the notation $\mathcal{N}^-(\Omega) = \{j$ such that K_j meets $\partial\Omega^-$ according a set of $nd - 1$ positive measure$\}$ and consider instead of (3.24)

$$\begin{aligned} &\sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} \Gamma_j + \sum_{k \in \mathcal{N}_0^-(j)} \mathbf{a} \cdot \mathbf{N}_{j,k} \Gamma_k \\ &\qquad = \sum_{k \in \mathcal{N}^+(j)} \mathbf{a} \cdot \mathbf{N}_{j,k}(g_{j,k} - g_j) + \sum_{k \in \mathcal{N}_0^-(j)} \mathbf{a} \cdot \mathbf{N}_{j,k}(g_{j,k} - g_k) + \epsilon_j\,, \end{aligned} \tag{4.17}$$

where ϵ_j vanishes for j not in $\mathcal{N}^-(\Omega)$.

THEOREM 4.4. *For every triangular conformal mesh* $\mathcal{T}_0$ *and for every nonvanishing vector* $\mathbf{a}$ *in* $\mathbf{R}^2$*, we consider on* $\mathcal{T}_\ell$ *a sequence* $\epsilon_j = \frac{\delta_j}{(\ell+1)^2}$*, where the sequence* δ_j *of vectors in* $\mathbf{R}^2$ *is uniformly bounded by a constant* $C_0(\mathbf{a}, \mathcal{T}_0)$ *and vanishes for* j *not in* $\mathcal{N}^-(\Omega)$*. Then there exists a constant* $C(a, \mathcal{T}_0)$ *such that for every* $\ell \in \mathbf{N}$ *we have the estimate* (4.15)*, where* $\Gamma^{(\ell)}$ *denotes the solution to* (4.17) *on* $\mathcal{T}_\ell$.

The proof of Theorem 4.4 proceeds by induction on M, the number of elements of $\mathcal{T}_0$.

4.3.1. The case where $\mathcal{T}_0$ has one element. In this case Ω is composed of a single triangle T and $\mathcal{T}_0 = T$. Besides the simpler case where the vector $\mathbf{a}$ is tangent to one of the edges of T, there are two cases that are presented in Figures 4.6 and 4.7, where $\theta_1 \neq 0$ and $\theta_2 \neq 0$: either $\sharp\mathcal{N}^+(T) = 1$ or $\sharp\mathcal{N}^+(T) = 2$. We index, as shown in

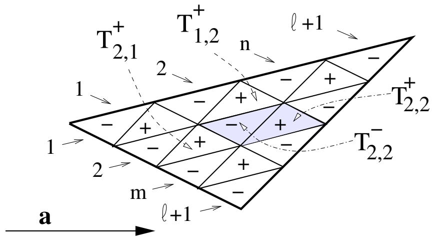

FIG. 4.8. $\sharp\mathcal{N}^+(T) = 1$*: an* ℓ*-refinement.*

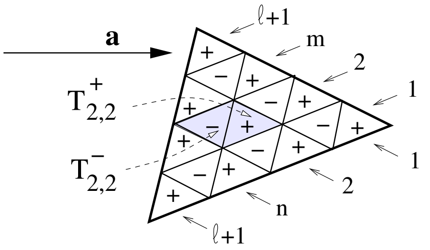

FIG. 4.9. $\sharp\mathcal{N}^+(T) = 2$*: an* ℓ*-refinement.*

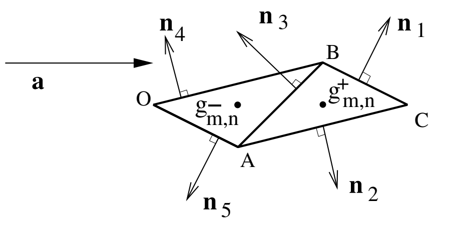

FIG. 4.10. $\sharp\mathcal{N}^+(T) = 1$*: the two subtriangles* $T^+_{m,n}$ *and* $T^-_{m,n}$ *(*$\mathbf{n}_i \equiv \mathbf{N}_i/||\mathbf{N}_i||$*).*

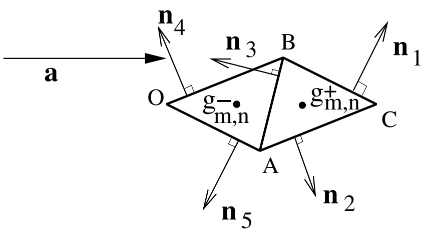

FIG. 4.11. $\sharp\mathcal{N}^+(T) = 2$*: the two subtriangles* $T^+_{m,n}$ *and* $T^-_{m,n}$ *(*$\mathbf{n}_i \equiv \mathbf{N}_i/||\mathbf{N}_i||$*).*

Figures 4.8 and 4.9, the $(\ell+1)^2$ triangles in $\mathcal{T}_\ell$, for $\ell \geq 1$, by a triplet (n, m, ϵ), where n and m are natural numbers satisfying $1 \leq n \leq \ell+1$, $1 \leq m \leq \ell+1$, $n+m \leq \ell+2$, and $\epsilon = \pm$. When $\epsilon = -$, we have $\sharp\mathcal{N}^+(T^\epsilon_{m,n}) = 1$, while when $\epsilon = +$, we have $\sharp\mathcal{N}^+(T^\epsilon_{m,n}) = 2$. We say that the triangle $T^\epsilon_{m,n}$ is interior when it has no edge on the boundary of T.

The case where $\sharp\mathcal{N}^+(T) = 1$*.*

- All the subtriangles $T^+_{m,n}$ (with $1 \leq m \leq \ell$, $1 \leq n \leq \ell$, and $m+n \leq \ell+1$) are interior ones. Hence if we adopt the notation explained in Figure 4.10, then we can write (4.17) in $T^+_{m,n}$ as follows:

$$\begin{aligned}(4.18)\qquad & \mathbf{a}\cdot\mathbf{N}_1\Gamma^+_{m,n} + \mathbf{a}\cdot\mathbf{N}_2\Gamma^+_{m,n} + \mathbf{a}\cdot\mathbf{N}_3\Gamma^-_{m,n} \\ &= \mathbf{a}\cdot\mathbf{N}_1\left(\frac{B+C}{2} - g^+_{m,n}\right) + \mathbf{a}\cdot\mathbf{N}_2\left(\frac{C+A}{2} - g^+_{m,n}\right) \\ &\quad + \mathbf{a}\cdot\mathbf{N}_3\left(\frac{A+B}{2} - g^-_{m,n}\right).\end{aligned}$$

If c_1, c_2, θ_1 and θ_2 are defined as in Figure 4.6, since $\mathbf{a}\cdot\mathbf{N}_1 + \mathbf{a}\cdot\mathbf{N}_2 = -\mathbf{a}\cdot\mathbf{N}_3 = \frac{c_1\sin\theta_1 + c_2\sin\theta_2}{l+1}$ and since the right-hand side of (4.18) is equal to $\frac{\boldsymbol{\zeta}_1}{(l+1)^2}$, where $\boldsymbol{\zeta}_1$ is a vector which depends only on T and $\mathbf{a}$, we deduce that

(4.19)
$$\Gamma^+_{m,n} - \Gamma^-_{m,n} = \frac{1}{\ell+1}\frac{\boldsymbol{\zeta}_1}{c_1\sin\theta_1 + c_2\sin\theta_2} \quad \text{for } 1 \leq m, n \leq \ell\,,\ m+n \leq \ell+1\,.$$

- Now let us consider the interior triangles $T^+_{m,n}$ for which we have $2 \leq m \leq \ell$, $2 \leq n \leq \ell$. Then the four triangles $T^+_{m,n}$, $T^-_{m,n}$, $T^+_{m-1,n}$, $T^+_{m,n-1}$ are also interior triangles and we can write (4.17) in the triangle $T^-_{m,n}$ as

$$\begin{aligned}(4.20)\qquad &\mathbf{a}\cdot\mathbf{N}_4\Gamma^+_{m-1,n} + \mathbf{a}\cdot\mathbf{N}_5\Gamma^+_{m,n-1} - \mathbf{a}\cdot\mathbf{N}_3\Gamma^-_{m,n}\\ &= \mathbf{a}\cdot\mathbf{N}_4\left(\frac{O+B}{2} - g^+_{m-1,n}\right) + \mathbf{a}\cdot\mathbf{N}_5\left(\frac{A+O}{2} - g^+_{m,n-1}\right)\\ &\quad - \mathbf{a}\cdot\mathbf{N}_3\left(\frac{A+B}{2} - g^-_{m,n}\right).\end{aligned}$$

By summing up (4.18) and (4.20), since their right-hand sides are opposite, we obtain

$$(4.21)\qquad \Gamma^+_{m,n} = \frac{c_1\sin\theta_1\Gamma^+_{m-1,n} + c_2\sin\theta_2\Gamma^+_{m,n-1}}{c_1\sin\theta_1 + c_2\sin\theta_2}.$$

- Let us now discuss the case where $T^-_{m,n}$ has at least one edge on the boundary of T. In this case the only change in (4.18) and (4.20) is that corresponding terms in the right- and left-hand sides are not present anymore when a triangle $T^\epsilon_{p,q}$ does not exist. Let us give these cases in full detail.
  - *The case* $T^-_{1,1}$. The analogue of (4.20) reads as

$$(4.22)\qquad -\mathbf{a}\cdot\mathbf{N}_3\Gamma^-_{1,1} = -\mathbf{a}\cdot\mathbf{N}_3\left(\frac{A+B}{2} - g^-_{1,1}\right) + \frac{\delta^-_{1,1}}{(\ell+1)^2}.$$

  Hence from (4.22) and (4.19)

$$(4.23)\qquad \Gamma^+_{1,1} = \frac{\boldsymbol{\zeta}_2}{\ell+1},$$

  where $\boldsymbol{\zeta}_2$ is a vector which depends only on T and $\mathbf{a}$.
  - *The case* $T^-_{m,1}$, $2 \leq m \leq \ell$. Equations (4.18), (4.20), and (4.21) are still valid in this case if we set $\Gamma^+_{m,0} \equiv \frac{B+C}{2} - g^+_{m,1} + \frac{\delta^-_{m,1}}{(\ell+1)c_2\sin\theta_2}$. Let us observe that this terms behaves like

$$(4.24)\qquad \Gamma^+_{m,0} = \frac{\boldsymbol{\zeta}_3}{\ell+1},$$

  where $\boldsymbol{\zeta}_3$ is a vector which depends only on T and $\mathbf{a}$.
  - *The case* $T^-_{1,n}$, $2 \leq n \leq \ell$. Here again (4.18), (4.20), and (4.21) are still valid in this case if we set $\Gamma^+_{0,n} \equiv \frac{A+C}{2} - g^+_{1,n} + \frac{\delta^-_{1,n}}{(\ell+1)c_1\sin\theta_1}$ and observe that

$$(4.25)\qquad \Gamma^+_{0,n} = \frac{\boldsymbol{\zeta}_4}{\ell+1},$$

  where $\boldsymbol{\zeta}_4$ is a vector which depends only on T and $\mathbf{a}$.
  - *The case* $T^-_{m,n}$ *with* $m+n = \ell+2$. Here we can only write (4.20), and we obtain

$$(4.26)\qquad \Gamma^-_{m,n} = \frac{c_1\sin\theta_1\Gamma^+_{m-1,n} + c_2\sin\theta_2\Gamma^+_{m,n-1}}{c_1\sin\theta_1 + c_2\sin\theta_2} + \frac{\boldsymbol{\zeta}_5}{\ell+1},$$

  where $\boldsymbol{\zeta}_5$ is a vector which depends only on T and $\mathbf{a}$ and where we set $\Gamma^+_{\ell+1,0} \equiv \frac{\delta^-_{\ell+1,1}}{(\ell+1)c_2\sin\theta_2}$ and $\Gamma^+_{0,\ell+1} \equiv \frac{\delta^-_{1,\ell+1}}{(\ell+1)c_1\sin\theta_1}$.

The barycenter structure of formula (4.21) is the key point and permits us to conclude. We find by induction on (m, n) the estimation on $\Gamma^+_{m,n}$ and then, by relation (4.19), the estimation on $\Gamma^-_{m,n}$ where the constant $C(\mathbf{a}, T)$ depends only on T and $\mathbf{a}$:

$$|\Gamma^\epsilon_{m,n}| \leq \frac{C(\mathbf{a}, T)}{\ell + 1}\,. \tag{4.27}$$

The case where $\sharp\mathcal{N}^+(T) = 2$. This case is slightly simpler because all the subtriangles $T^-_{m,n}$ are interior ones. Hence if we adopt the notation explained in Figure 4.11, for every (m, n) with $1 \leq n \leq \ell$, $1 \leq m \leq \ell$, $n + m \leq \ell + 1$, equation (4.17) in $T^-_{m,n}$ reads as

(4.28)

$$\begin{aligned}&\mathbf{a}\cdot\mathbf{N}_4\Gamma^+_{m+1,n} + \mathbf{a}\cdot\mathbf{N}_5\Gamma^+_{m,n+1} - \mathbf{a}\cdot\mathbf{N}_3\Gamma^-_{m,n}\\ &= \mathbf{a}\cdot\mathbf{N}_4\left(\frac{O+B}{2} - g^+_{m+1,n}\right) + \mathbf{a}\cdot\mathbf{N}_5\left(\frac{A+O}{2} - g^+_{m,n+1}\right) - \mathbf{a}\cdot\mathbf{N}_3\left(\frac{A+B}{2} - g^-_{m,n}\right).\end{aligned}$$

Concerning the subtriangles $T^+_{m,n}$, we have two cases.

- In the first one, $1 \leq n \leq \ell$, $1 \leq m \leq \ell$, $m + n \leq \ell + 1$. Then (4.17) in $T^+_{m,n}$ reads again as (4.18), and (4.19) is still valid. Combining (4.18) with (4.28), formula (4.21) is now replaced by

$$\Gamma^+_{m,n} = \frac{c_1 \sin\theta_1 \Gamma^+_{m+1,n} + c_2 \sin\theta_2 \Gamma^+_{m,n+1}}{c_1 \sin\theta_1 + c_2 \sin\theta_2}\,. \tag{4.29}$$

- In the second one, $m + n = \ell + 2$, and then (4.17) in $T^+_{m,n}$ reads as

  (4.30)

$$\begin{aligned}&\mathbf{a}\cdot\mathbf{N}_1\Gamma^+_{m,n} + \mathbf{a}\cdot\mathbf{N}_2\Gamma^+_{m,n}\\ &= \mathbf{a}\cdot\mathbf{N}_1\left(\frac{B+C}{2} - g^+_{m,n}\right) + \mathbf{a}\cdot\mathbf{N}_2\left(\frac{C+A}{2} - g^+_{m,n}\right) + \frac{\delta^+_{m,n}}{(\ell+1)^2}\,.\end{aligned}$$

  Hence we can say that

$$\Gamma^+_{m,n} = \frac{\boldsymbol{\zeta}}{\ell + 1} \text{ for } m + n = \ell + 2\,, \tag{4.31}$$

  where $\boldsymbol{\zeta}$ is a vector which depends only on T and $\mathbf{a}$.

In conclusion, we are able to show first by induction on $p = \ell + 3 - m - n$ that

$$|\Gamma^+_{m,n}| \leq \frac{|\boldsymbol{\zeta}|}{\ell + 1}\,. \tag{4.32}$$

Indeed, for $p = 1$ this assertion follows from (4.31). Assuming that (4.32) holds true for p, we take (m, n) with $m + n = \ell + 2 - p = \ell + 3 - (p + 1)$ and write (4.29). Since $m + n + 1 = \ell + 3 - p$ we can apply (4.32):

$$|\Gamma^+_{m+1,n}| \leq \frac{|\boldsymbol{\zeta}|}{\ell + 1}\,, |\Gamma^+_{m,n+1}| \leq \frac{|\boldsymbol{\zeta}|}{\ell + 1}\,. \tag{4.33}$$

So that thanks to (4.29), (4.32) holds true for $p + 1$. Now that (4.32) is shown, using (4.19) we conclude that (4.27) holds true in the case $\sharp\mathcal{N}^+(T) = 2$.

This ends the proof of Theorem 4.4 in the case where $\mathcal{T}_0$ has only one element.

4.3.2. The case where $\mathcal{T}_0$ has two elements. In this case, the domain Ω is the union of two triangles which share an edge. If $\mathbf{a}$ is tangent to this edge, then sequences of geometric correctors on one triangle are independent from sequences defined on the other one. Hence Theorem 4.4 follows in this case. Now when $\mathbf{a}$ is not tangent to this edge we denote these two triangles by T_1 and T_2 in order that $\mathbf{a}$ points from T_1 into T_2. We denote by $(\Gamma^{(\ell)})$ the solution to (4.17) on $\mathcal{T}_\ell$ the ℓ-refinement of $\mathcal{T}_0 = T_1 \cup T_2$. We also denote by $\mathcal{T}_{\ell,1}$ and $\mathcal{T}_{\ell,2}$ the ℓ-refinements of $\mathcal{T}_{0,1} = T_1$ and of $\mathcal{T}_{0,2} = T_2$. We are going to analyze subsequences of $(\Gamma^{(\ell)})$ associated to the triangle T_1 and the triangle T_2.

The first key observation is that since on $T_1 \cap T_2$ all the outer normals in subtriangles which are in T_1 form an acute angle with $\mathbf{a}$, the subsequence of $(\Gamma^{(\ell)})$ whose indices correspond to triangles which are in T_1 satisfies exactly (4.17) when it is written only for the refinement $\mathcal{T}_{\ell,1}$. But according to Theorem 3.8 we know that this solution is unique, and therefore this subsequence is equal to the sequence of geometric correctors defined on $\mathcal{T}_{\ell,1}$. We already proved that Theorem 4.4 applies to T_1 and deduce that

$$||\Gamma_j^{(\ell)}|| \le \frac{C_1(\mathbf{a}, \mathcal{T}_0)}{\ell+1} \quad \forall j \text{ corresponding to a subtriangle in } T_1 \,. \tag{4.34}$$

The next step is to estimate the remaining geometric correctors that correspond to subtriangles in T_2. By inspection of (4.17) when it is written for $\mathcal{T}_{\ell,2}$, one notices two facts:

1. If one considers a subtriangle which is in T_2 but which has no edge on $T_1 \cap T_2$, then the corrector of this subtriangle satisfies the same equation in both $\mathcal{T}_{\ell,2}$ and $\mathcal{T}_\ell$.
2. However, for a subtriangle j which is in T_2 and which has an edge on $T_1 \cap T_2$, we do not have the same equation since one term on each side of the equation is missing. But the difference is equal to

$$\mathbf{a} \cdot \mathbf{N}_{j,j_1} \left(\Gamma_{j_1}^{(\ell),1} + g_{j,j_1} - g_{j_1} \right) , \tag{4.35}$$

where we denote by j_1 the subtriangle in T_1 which shares an edge with the subtriangle j.

From (4.34), we observe that these differences slightly modify the right-hand side of equations associated to subtriangles of T_2 that share a boundary with ∂T_2^- by adding a term of the form $\frac{\delta(\mathbf{a},\mathcal{T}_0)}{(\ell+1)^2}$. Applying Theorem 4.4 to T_2, we deduce that

$$||\Gamma_j^{(\ell)}|| \le \frac{C_2(\mathbf{a}, \mathcal{T}_0)}{\ell+1} \quad \forall j \text{ corresponding to a subtriangle in } T_2 \,. \tag{4.36}$$

Then (4.34) and (4.36) allow us to conclude the proof of Theorem 4.4 in this case.

4.3.3. Proof of Theorem 4.4. Let $M \ge 1$ be given. We assume that this result is true for all triangulation $\mathcal{T}_0$ with a number of elements less than or equal to M. Let $\mathcal{T}_0$ be a triangulation with $M+1$ elements. First we are going to decompose this triangulation into two parts separated by a broken line made with consecutive edges having the same orientation with respect to $\mathbf{a}$ (see Figure 4.12). Then we will finish the proof by simply observing that it follows by extending the argument given in the case $M = 2$ in the previous section.

We prove the decomposition in two parts for a more general triangulation.

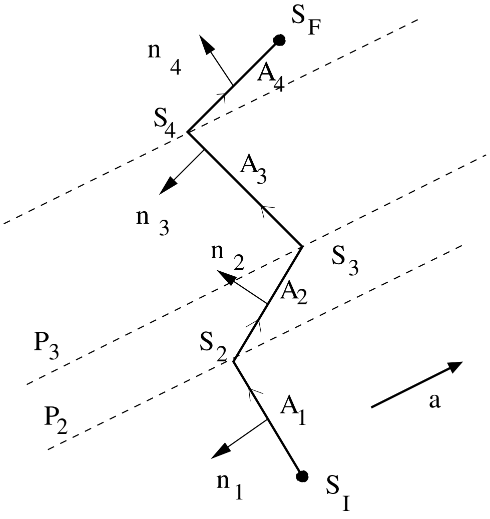

FIG. 4.12. *Broken line made with consecutive oriented edges* ($\mathbf{n}_i \equiv \mathbf{N}_i/||\mathbf{N}_i||$).

LEMMA 4.5. *Let $\mathcal{T}_0$ be a conformal mesh made with strictly convex polygons; i.e., the interior angle at vertices are strictly less than π. We assume that there is at least one interior edge not parallel to the vector* $\mathbf{a}$. *There exists a broken line made with consecutive oriented edges $A_1 = (S_I, S_2), \dots, A_i = (S_i, S_{i+1}), \dots, A_K = (S_K, S_F)$ which links two distinct vertices on the boundary S_I and S_F and such that $\mathbf{N}_i \cdot \mathbf{a} < 0$ for all $i = 1, \dots, K$, where the angle $(A_i, \mathbf{N}_i)$ is equal to $\frac{\pi}{2}$.*

Proof. First let us choose an arbitrary vertex on the boundary that is a vertex of an interior edge $A_1 = (S_I, S_2)$. We assume that the normal $\mathbf{N}_1$ to A_1 such that the angle $(A_1, \mathbf{N}_1)$ is equal to $\frac{\pi}{2}$ satisfies $\mathbf{N}_1 \cdot \mathbf{a} < 0$. If not, we take $\mathbf{a} = -\mathbf{a}$ and switch the role of S_I and S_F.

If S_2 is a vertex on the boundary, then we conclude with $S_F = S_2$. If not, let us denote by $\mathcal{P}_2$ the half-plane defined by the straight line $(S_2, \mathbf{a})$ (dashed line in Figure 4.12) and that does not contain the edge A_1. Since S_2 is an interior vertex and since interior angles of volumes sharing this vertex are strictly less than π, there is necessarily an edge $A_2 = (S_2, S_3)$ strictly in the half-plane $\mathcal{P}_2$. From the definition of $\mathcal{P}_2$, we have $\mathbf{N}_2 \cdot \mathbf{a} < 0$, where $\mathbf{N}_2$ is the normal to A_2 such that the angle $(A_2, \mathbf{N}_2)$ is equal to $\frac{\pi}{2}$.

Now, by induction we can determine a broken line of oriented edges $A_1, \dots, A_i$ such that $\mathbf{N}_1 \cdot \mathbf{a} < 0, \dots, \mathbf{N}_i \cdot \mathbf{a} < 0$ with the same convention for the orientation of $\mathbf{N}_i$. Since the distance of S_I to the line $(S_{i+1}, \mathbf{a})$ is strictly superior to the distance of S_I to the line $(S_i, \mathbf{a})$, there exists K such $S_{K+1} \equiv S_F$ is on the boundary. □

Thus we can realize Ω as the union of two adjacent polygonal sets Ω_1 and Ω_2 where $\mathbf{a}$ points from Ω_1 into Ω_2. Here again, the subsequence of geometric correctors on Ω whose indices correspond to triangles in Ω_1 is identical to the sequence of geometric correctors only defined in Ω_1. Since the coarse triangulation of Ω_1 has less than M elements, we can apply Theorem 4.4. For each subtriangle j of Ω_2 that shares an edge with the broken line defined in Lemma 4.5, the equation that satisfies the corrector in Ω and the equation that satisfies the corrector in Ω_2 differ from a combination of terms like (4.35), which are of the form $\frac{\delta_j}{(\ell+1)^2}$, and the δ_j are uniformly bounded by a constant which depends only on $\mathbf{a}$ and $\mathcal{T}_0$. Then, since Ω_2 has less than M elements, we can again apply Theorem 4.4 and therefore show this result for $M+1$. This concludes the proof of order h convergence of the upwind scheme for a uniform refinement of an arbitrary coarse conformal triangular mesh.

5. Numerical estimates for independent refinements. Since our analysis developed in section 3 is valid for arbitrary types of meshes, in order to validate from a numerical point of view the estimate (4.1), we perform some tests with a sequence of independent unstructured meshes where the mesh size decreases. In the present simulation, if we take two consecutive grids, one is not the refinement of the other one (by dividing, for instance, each triangle into four congruent subtriangles), but the mesh size is reduced. We consider a dodecagon with several meshes composed from 274 triangles to 286,514 triangles computed with the software Gmsh [12], developed by Jean-François Remacle and Christophe Geuzaine. In Figure 5.1, the pictures correspond to the three independent meshes of the sequence. We compute the corrector as solution of (3.24) for two advection vectors defined by the angle θ with the x axis: $\theta = 0$ and $\theta = \pi/4$.

In Figures 5.2, 5.3, and 5.4 the L^1 and L^∞ estimates of the geometric corrector and the L^1 norm of Δ defined by (3.29) are plotted versus the mesh size. The straight lines are the least-squares fits to the point and the slopes are 0.994 ($\theta = 0$) and 0.988 ($\theta = \pi/4$) for the L^1 norm of the corrector. We find 0.831 ($\theta = 0$) and 0.564 ($\theta = \pi/4$) for the L^∞ norm of the corrector and 0.969 ($\theta = 0$) and 0.954 ($\theta = \pi/4$) for $\|\Delta\|_1$. The L^1 norm of the geometric corrector and the norm of Δ behaves like $\mathcal{O}(h)$. Concerning the L^∞ norm of Γ, we have an unexpected behavior when the angle θ that defines the advection vector $\mathbf{a}$ is equal to $\pi/4$ (as shown in Figure 5.2), i.e., when the advection vector is parallel to two sides of the domain. Here, asymptotically we have $\|\Gamma\|_\infty = \mathcal{O}(h^{1/2})$, and although the right-hand side of (3.30) tends to zero with h in all cases, we observe that the estimation of the norm of the solution of this equation depends on the relative position of the advection vector with the boundary.

This behavior is similar to the loss of accuracy proved in Peterson [23]. More precisely, for the mesh and the subtle alignment with the direction of transport proposed by Peterson, we are able to prove that the L^∞ norm of the geometric corrector behaves like $\mathcal{O}(h^{1/2})$ and the L^1 norm is of order one. The technical proof is quite long and out of the scope of this paper and will be published elsewhere.

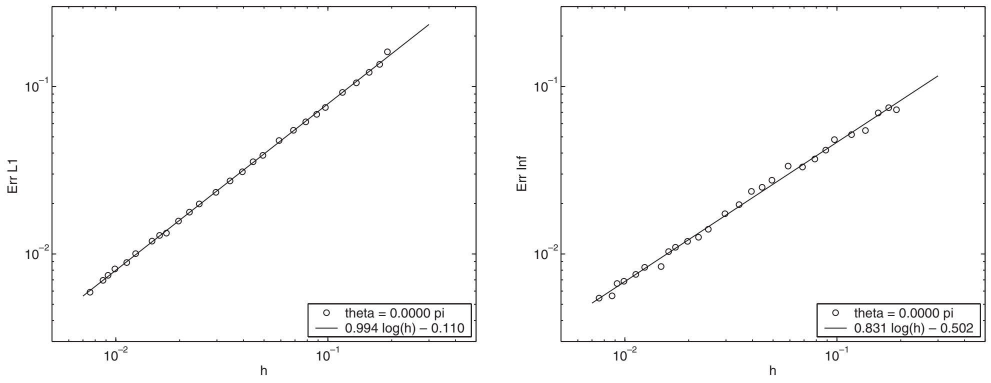

FIG. 5.2. *$\theta = 0$: $\|\Gamma\|_1$ and $\|\Gamma\|_\infty$ versus h for a sequence of independent meshes of the dodecagon domain.*

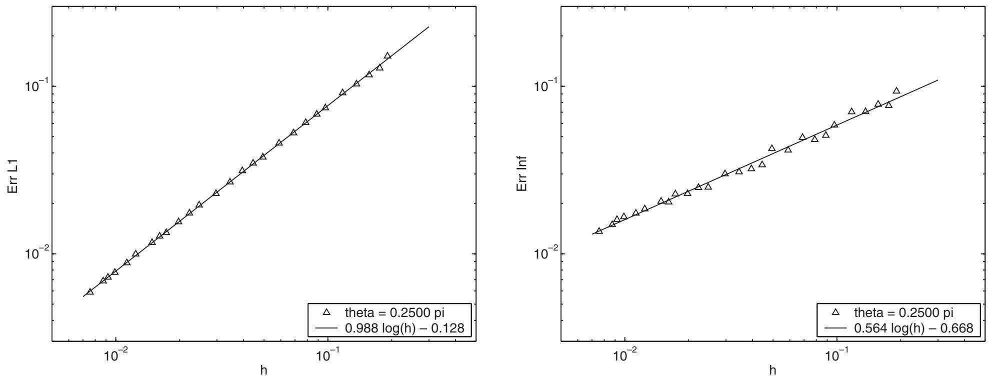

FIG. 5.3. *$\theta = \frac{\pi}{4}$: $\|\Gamma\|_1$ and $\|\Gamma\|_\infty$ versus h for a sequence of independent meshes of the dodecagon domain.*

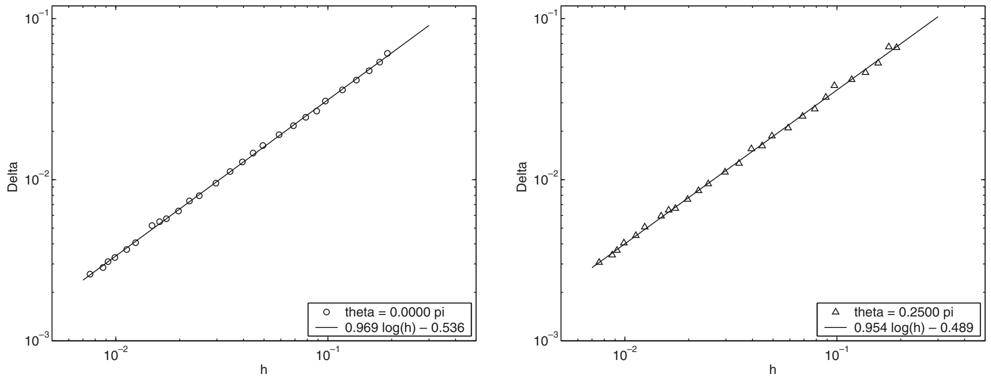

FIG. 5.4. *$\theta = 0$ and $\theta = \frac{\pi}{4}$: $\|\Delta\|_1$ versus h for a sequence of independent meshes of the dodecagon domain.*

6. Conclusion. For linear advection on bounded domain, we introduce the geometric corrector that depends only on the mesh and the velocity **a**. We first prove a general result that links the convergence of the finite volume scheme and the geometric corrector estimates. Then an analytical study of these correctors in the case of uniformly refined triangular meshes in two dimensions leads to the proof of the one order of convergence for the finite volume scheme applied to the linear advection with smooth solution and constant velocity. We plan to address the variable velocity case in a future work.

INEXACT NEWTON REGULARIZATION USING CONJUGATE GRADIENTS AS INNER ITERATION*

ANDREAS RIEDER[†]

Abstract. In our papers [*Inverse Problems*, 15 (1999), pp. 309–327] and [*Numer. Math.*, 88 (2001), pp. 347–365] we proposed algorithm `REGINN`, an inexact Newton iteration for the stable solution of nonlinear ill-posed problems. `REGINN` consists of two components: the outer iteration, which is a Newton iteration stopped by the discrepancy principle, and an inner iteration, which computes the Newton correction by solving the linearized system. The convergence analysis presented in both papers covers virtually any *linear* regularization method as inner iteration, especially Landweber iteration, ν-methods, and Tikhonov–Phillips regularization. In the present paper we prove convergence rates for `REGINN` when the conjugate gradient method, which is *nonlinear*, serves as inner iteration. Thereby we add to a convergence analysis of Hanke, who had previously investigated `REGINN` furnished with the conjugate gradient method [*Numer. Funct. Anal. Optim.*, 18 (1997), pp. 971–993]. By numerical experiments we illustrate that the conjugate gradient method outperforms the ν-method as inner iteration.

Key words. nonlinear ill-posed problems, inexact Newton iteration, conjugate gradients, ν-methods, regularization

1. Introduction.

Our goal is to find a stable approximate solution of the nonlinear ill-posed problem

$$F(x) = y^\delta, \tag{1.1}$$

where $F : \mathsf{D}(F) \subset X \to Y$ operates between the Hilbert spaces X and Y. Here, $\mathsf{D}(F)$ denotes the domain of definition of F, and y^δ is a noisy version of the exact but unknown data $y = F(x^+)$ satisfying

$$\|y - y^\delta\|_Y \leq \delta. \tag{1.2}$$

The nonnegative *noise level* δ is assumed to be known.

In [10, 11] we proposed algorithm `REGINN` for solving (1.1). As a Newton-type algorithm, `REGINN` updates the actual iterate x_n by adding a correction step s_n^δ obtained from solving a linearization of (1.1):

$$x_{n+1} = x_n + s_n^\delta, \quad n \in \mathbb{N}_0,$$

with an initial guess x_0. For obvious reasons we like to have s_n^δ as close as possible to the exact Newton step

$$s_n^{\mathrm{e}} = x^+ - x_n.$$

*Received by the editors August 2, 2004; accepted for publication (in revised form) September 27, 2004; published electronically June 30, 2005.

[†]Institut für Praktische Mathematik und Institut für Wissenschaftliches Rechnen und Mathematische Modellbildung, Universität Karlsruhe, 76128 Karlsruhe, Germany (andreas.rieder@math.uni-karlsruhe.de, www.mathematik.uni-karlsruhe.de/∼rieder).

Assuming F to be Fréchet differentiable with derivative $F' : \mathsf{D}(F) \to \mathcal{L}(X, Y)$, the exact Newton step satisfies the linear equation

$$F'(x_n)s_n^{\mathrm{e}} = y - F(x_n) - E(x^+, x_n) =: b_n, \tag{1.3}$$

where $E(v, w) := F(v) - F(w) - F'(w)(v - w)$ is the linearization error.

Unfortunately, the above right-hand side b_n is not available; however, we know a perturbed version

$$b_n^\varepsilon := y^\delta - F(x_n) \quad \text{with } \|b_n - b_n^\varepsilon\|_Y \le \delta + \|E(x^+, x_n)\|_Y.$$

Therefore, we determine the correction step s_n^δ as a solution of

$$F'(x_n)s = b_n^\varepsilon. \tag{1.4}$$

Here, we have to take into account that the ill-posedness of (1.1) is passed on to (1.4). For instance, if F is completely continuous, then $F'(x_n)$ is a compact operator (see, e.g., Zeidler [13, Proposition 7.33]); hence, (1.4) is ill-posed.

Depending on how s_n^δ is stably obtained from (1.4), different methods arise, for instance, the nonlinear Landweber method (Hanke, Neubauer, and Scherzer [6]), the Gauß–Newton method (see, e.g., Bakushinskii [1] and Kaltenbacher [7]), and the Levenberg–Marquardt scheme (Hanke [4]).

In the next few lines we recall briefly how `REGINN` works. First, a regularization scheme is applied to the linear system (1.4), obtaining

$$s_{n,r} := g_r(A_n^* A_n)A_n^* b_n^\varepsilon,$$

where $A_n = F'(x_n)$ and $g_r : [0, \|A_n\|^2] \to \mathbb{R}$ is the piecewise continuous filter function of the chosen regularization method. The parameter $r \in \mathbb{N}$ is called the regularization parameter. For instance, the filter functions belonging to the Tikhonov–Phillips regularization, the Landweber iteration, and the ν-methods are explicitly known; see, e.g., [2, 12], where more examples can be found. The filter functions g_r of both latter examples are polynomials of degree $r - 1$. The conjugate gradients method (cg-method) can also be described by filter polynomials g_r of degree $r - 1$, which, however, do depend on the right-hand side b_n^ε: $g_r(\cdot) = g_r(\cdot, b_n^\varepsilon)$. Therefore, the cg-method is a *nonlinear* scheme in contrast to the other mentioned examples.

Now we have to select a regularization parameter r_n. In `REGINN` r_n is picked as the smallest number at which the relative (linear) residual is smaller than a given tolerance $\mu_n \in \,]0, 1]$, that is,

$$\|A_n s_{n,r_n} - b_n^\varepsilon\|_Y < \mu_n \|b_n^\varepsilon\|_Y \le \|A_n s_{n,i} - b_n^\varepsilon\|_Y, \quad i = 1, \ldots, r_n - 1. \tag{1.5}$$

The tolerances should not be too small to guarantee existence of r_n; see Lemma 2.1 below. A meaningful strategy to adapt the μ_n's dynamically was proposed in [10]. Setting $s_n^\delta := s_{n,r_n}$ we end up with the Newton iteration

$$x_{n+1} = x_n + g_{r_n}(A_n^* A_n)A_n^* b_n^\varepsilon, \quad n \in \mathbb{N}_0,$$

which has to be stopped in time to avoid noise amplification. A well-established stopping rule is the discrepancy principle: Choose $R > 0$ and accept iterate x_N as an approximate solution of (1.1) that fulfills

$$\|y^\delta - F(x_N)\|_Y \le R\,\delta < \|y^\delta - F(x_k)\|_Y, \quad k = 0, \ldots, N - 1. \tag{1.6}$$

```
REGINN($x, R, \{\mu_n\}$)
$n := 0;\ x_0 := x;$
while $\|F(x_n) - y^\delta\|_Y > R\,\delta$ do
{   $i := 0;$
    repeat
      $i := i + 1;$
      $s_{n,i} := g_i\big(F'(x_n)^*F'(x_n)\big)F'(x_n)^*\big(y^\delta - F(x_n)\big);$
    until $\|F'(x_n)\,s_{n,i} + F(x_n) - y^\delta\|_Y < \mu_n\,\|F(x_n) - y^\delta\|_Y$
    $x_{n+1} := x_n + s_{n,i};$
    $n := n + 1;$
}
$x := x_n;$
```

FIG. 1.1. *Algorithmic realization of* REGINN *(*REG*ularization based on* IN*exact* N*ewton iterations).*

For an algorithmic realization of REGINN, see Figure 1.1. The inner repeat-loop provides the Newton update s_{n,r_n} and the outer while-loop implements the Newton iteration stopped by the discrepancy principle.

In [11] we were able to verify (under reasonable assumptions) that REGINN with a *linear* regularization scheme $\{g_r\}_{r\in\mathbb{N}}$ is well defined and indeed terminates. Moreover, we proved the existence of a positive $\kappa_{\min} < 1$ such that the source condition[1]

$$x^+ - x_0 \in \mathsf{R}\big(\big|F'(x^+)\big|^\kappa\big) \qquad \text{for a } \kappa \in \,]\kappa_{\min}, 1] \tag{1.7}$$

implies the suboptimal convergence rate[2]

$$\|x^+ - x_{N(\delta)}\|_X = \mathrm{O}\big(\delta^{\,(\kappa-\kappa_{\min})/(1+\kappa)}\big) \qquad \text{as } \delta \to 0. \tag{1.8}$$

In the present paper we will improve upon the convergence results for REGINN: We will verify that (1.7) implies (1.8) even when the cg-method serves as inner iteration of REGINN. Thus we supplement a convergence analysis of Hanke [5], who had previously investigated REGINN with the cg-method as inner iteration: Under a slightly weaker version of our general assumption on the nonlinearity (see (2.1) below), Hanke proved convergence of $\{x_{N(\delta)}\}_{\delta>0}$ to a set of solutions of $F(x) = y$ as $\delta \to 0$.

This paper is structured as follows. In the next two sections we compile facts about REGINN and the cg-method which we will need later on in our analysis. In section 4 we show that REGINN is well defined under (1.7) and terminates with an approximation to x^+. Then the regularization property (1.8) will be verified (section 5). Finally, we present numerical experiments for a parameter identification model problem and end with concluding remarks in section 7. Some lengthy and technical proofs from sections 3 and 4 are shifted to Appendices A and B, respectively.

[1] By $\mathsf{R}(B)$ we denote the range of the operator B, and $|B|$ is the square root of B^*B.

[2] For linear inverse problems $Ax = y^\delta$ the regularization error cannot decrease faster than $\mathrm{O}(\delta^{\kappa/(1+\kappa)})$ as $\delta \to 0$ under the source condition $x^+ - x_0 \in \mathsf{R}(|A|^\kappa)$ in general; see, e.g., [2, section 3.2] or [12, Kapitel 3.2.3]. Regularization schemes attaining the maximal order are therefore called *order-optimal*.

2. General assumptions and termination of the `repeat`-loop. Throughout the paper we assume $F : \mathsf{D}(F) \subset X \to Y$ to be continuously Fréchet differentiable with derivative $F' : \mathsf{D}(F) \to \mathcal{L}(X, Y)$. Moreover, let $x^+ \in \mathsf{D}(F)$, $y = F(x^+)$, $y^\delta \in Y$ with $\|y - y^\delta\|_Y \le \delta$, $A = F'(x^+)$, and $A_n = F(x_n)$.

Our analysis relies heavily on the local factorization (2.1) of F': Let $Q : X \times X \to \mathcal{L}(X, Y)$ be a mapping such that

$$F'(v) = Q(v, w)\, F'(w) \quad \text{with } \|I - Q(v, w)\| \le C_Q \, \|v - w\|_X \tag{2.1}$$

for all v, $w \in B_\rho(x^+) \subset \mathsf{D}(F)$, the open ball of radius ρ about x^+. Here, C_Q is a positive constant. For a discussion of the nontrivial factorization (2.1) and for examples of meaningful operators satisfying (2.1), we refer to [6, 10, 11], [12, Kapitel 7.3], and the literature cited therein.

Let $C_Q \, \rho < 1$. Then (2.1) gives

$$\|F(v) \, - \, F(w)\|_Y \; \ge \; (1 \, - \, C_Q \, \rho) \; \|F'(w)\,(v - w)\|_Y \tag{2.2}$$

as well as

$$\|E(v, w)\|_Y \; \le \; \omega \; \|F(v) \, - \, F(w)\|_Y \quad \text{for all } \; v, w \in B_\rho(x^+), \tag{2.3}$$

where $\omega \; := \; C_Q \, \rho/(1 - C_Q \, \rho)$; see [10, section 3] or [12, Lemma 7.3.9]. Observe that $\omega < 1$ for $C_Q \, \rho < 1/2$.

In our subsequent analysis we will frequently use the following estimate: For $x, y \in B_\rho(x^+)$ and $C_Q\rho < 1/2$ we have

$$\| |F'(x)|^{-\kappa} \, |F'(y)|^{\kappa} \| \; \le \; (1 - 2C_Q\rho)^{-\kappa} =: C_{K,\kappa} \quad \text{for all } \; \kappa \in [0, 1], \tag{2.4}$$

which is due to Kaltenbacher [7, Lemma 2.2]; see also [12, Lemma 7.5.16].

Using (2.3) we will bound the data error $\|b_n^\varepsilon - b_n\|_Y$ in terms of δ, ω, and the nonlinear defect

$$d_n := \|y^\delta - F(x_n)\|_Y \; = \; \|b_n^\varepsilon\|_Y.$$

For $x_n \in B_\rho(x^+)$ we find

$$\|b_n^\varepsilon - b_n\|_Y \; \le \; (1 + \omega)\, \delta \; + \; \omega \, d_n \; := \; \varepsilon \; = \; \varepsilon(x_n, \delta).$$

We recall a result from [10] which gives conditions on μ_n to stop the `repeat`-loop.

LEMMA 2.1. *Let $\{g_r\}_{r \in \mathbb{N}}$ be the filter function of a linear or nonlinear regularization scheme for which the discrepancy principle returns a well-defined stopping index; that is, for $\tau > 1$ there exists a smallest index r_S with $\|A_n s_{n,r_S} - b_n^\varepsilon\|_Y \le \tau \, \varepsilon$. Further let (2.1) hold true with $C_Q \, \rho < 1/2$ and assume $x_n \in B_\rho(x^+)$, where $n < N$. If $R \ge (1 + \omega)/(1 - \omega)$, then the `repeat`-loop of algorithm `REGINN` terminates for any*

$$\mu_n \in \; \left]\omega + \frac{(1 + \omega)\, \delta}{d_n}, \, 1\right].$$

The lower bound on R in Lemma 2.1 guarantees that the interval for μ_n is nonempty. Since $b_n \in \mathsf{R}(A_n)$ (see (1.3)), all regularization methods mentioned in section 1 (Tikhonov–Phillips, Landweber, ν-method, cg-method) satisfy the requirement of Lemma 2.1; see, e.g., Engl, Hanke, and Neubauer [2, Chapter 4.3] or [12, Kapitel 3.4].

3. The method of conjugate gradients: Preliminaries. Here we recall some basic facts of the cg-method which we will need later in the paper. More details as well as all proofs can be found in, e.g., Engl, Hanke, and Neubauer [2, Chapter 7] or [12, Kapitel 5.3].

Let $T \in \mathcal{L}(X,Y)$ and $\boldsymbol{\eta} \in Y$. The cg-method is an iteration for solving the normal equation $T^*T\,\boldsymbol{\zeta} = T^*\boldsymbol{\eta}$. Starting with $\boldsymbol{\xi}_0 \in X$ the cg-method produces a sequence $\{\boldsymbol{\xi}_m\}_{m\in\mathbb{N}_0}$ with the minimization property

$$\|\boldsymbol{\eta} - T\boldsymbol{\xi}_m\|_Y = \min\bigl\{\|\boldsymbol{\eta} - T\boldsymbol{\xi}\|_Y \bigm| \boldsymbol{\xi} \in X,\ \boldsymbol{\xi} - \boldsymbol{\xi}_0 \in U_m\bigr\}, \quad m \ge 1,$$

where U_m is the mth Krylov space,

$$U_m := \operatorname{span}\bigl\{T^*r^0, (T^*T)T^*r^0, (T^*T)^2T^*r^0, \dots, (T^*T)^{m-1}T^*r^0\bigr\}$$

with $r^0 := \boldsymbol{\eta} - T\boldsymbol{\xi}_0$. Therefore, $\boldsymbol{\xi}_m$, $m \ge 1$, can be expressed by

$$\boldsymbol{\xi}_m = \boldsymbol{\xi}_0 + q_{m-1}(T^*T)T^*(\boldsymbol{\eta} - T\boldsymbol{\xi}_0)$$

with a polynomial q_{m-1} of degree $m-1$. Closely related to q_{m-1} is the residual polynomial $p_m(\lambda) = 1 - \lambda\, q_{m-1}(\lambda)$ of degree m satisfying

$$\boldsymbol{\eta} - T\boldsymbol{\xi}_m = p_m(TT^*)(\boldsymbol{\eta} - T\boldsymbol{\xi}_0).$$

Both polynomials depend on $\boldsymbol{\eta}$: $q_{m-1}(\cdot) = q_{m-1}(\cdot,\boldsymbol{\eta})$ and $p_m(\cdot) = p_m(\cdot,\boldsymbol{\eta})$. As soon as $T^*(\boldsymbol{\eta} - T\boldsymbol{\xi}_k) = 0$ holds true, the cg-sequence is finite, that is, $\boldsymbol{\xi}_m = \boldsymbol{\xi}_k$ for all $m \ge k$. Accordingly,

$$\boldsymbol{m}_{\mathrm{T}} := \sup\{m \in \mathbb{N} \,|\, T^*(\boldsymbol{\eta} - T\boldsymbol{\xi}_{m-1}) \ne 0\}$$

is called the ultimate termination index of the cg-method ($\boldsymbol{m}_{\mathrm{T}} = \infty$ is allowed and the supremum of the empty set is understood as zero).

The residual polynomials are orthogonal with respect to the inner product $\langle\varphi,\psi\rangle_\Pi := \langle\varphi(T^*T)T^*\boldsymbol{\eta}, \psi(T^*T)T^*\boldsymbol{\eta}\rangle_X$, which is defined on the space of all polynomials:

$$\langle p_i, p_j\rangle_\Pi = 0 \quad \text{for all } 1 \le i,j \le \boldsymbol{m}_{\mathrm{T}} \text{ with } i \ne j.$$

The orthogonality of $\{p_m\}_{1\le m\le \boldsymbol{m}_{\mathrm{T}}}$ has several consequences. The residual polynomials satisfy a three-term recursion which can be used to compute $\boldsymbol{\xi}_m$ iteratively from $\boldsymbol{\xi}_{m-1}$ in a rather cheap way; see Figure 3.1. Moreover, p_m has m simple roots $\lambda_{m,j} \in\,]0, \|T\|^2[$, $j = 1,\dots,m$, which we order by

$$0 < \lambda_{m,1} < \lambda_{m,2} < \cdots < \lambda_{m,m} < \|A\|^2.$$

Because of its normalization $p_m(0) = 1$, p_m decomposes into the following linear factors:

$$p_m(\lambda) \;=\; \prod_{j=1}^{m}(1 - \lambda/\lambda_{m,j}) \;=\; \prod_{j=1}^{m}\frac{\lambda_{m,j} - \lambda}{\lambda_{m,j}}. \tag{3.1}$$

Although we know neither q_{m-1} nor p_m explicitly, some useful information about both polynomials is available.

Lemma 3.1. *For $0 < \Lambda \le \lambda_{m,1}$ and $1 \le m \le \boldsymbol{m}_{\mathrm{T}}$, we have that*

$$\sup_{0\le\lambda\le\Lambda} |q_{m-1}(\lambda,\boldsymbol{\eta})| \;=\; q_{m-1}(0,\boldsymbol{\eta}) \;=\; -p_m'(0,\boldsymbol{\eta}) \;=\; \sum_{j=1}^{m}\lambda_{m,j}^{-1}.$$

```
cg-algorithm for $T \in \mathcal{L}(X,Y)$, $\boldsymbol{\eta} \in Y$ and starting guess $\boldsymbol{\xi}_0 \in X$.
$r^0 := \boldsymbol{\eta} - T\boldsymbol{\xi}_0$; $p^1 = a^0 := T^* r^0$;
$m := 1$;
while ($a^{m-1} \neq 0$)
    { $q^m := Tp^m$;
      $\alpha_m := \|a^{m-1}\|_X^2 / \|q^m\|_Y^2$;
      $\boldsymbol{\xi}_m := \boldsymbol{\xi}_{m-1} + \alpha_m \; p^m$;
      $r^m := r^{m-1} - \alpha_m \; q^m$;
      $a^m := T^* r^m$;
      $\beta_m := \|a^m\|_X^2 / \|a^{m-1}\|_X^2$;
      $p^{m+1} := a^m + \beta_m \; p^m$;
      $m := m+1$; }
```

FIG. 3.1. *Conjugate gradients algorithm.*

The next result is proved in Appendix A and will be used twice in our convergence analysis of REGINN with the cg-method as inner iteration.

LEMMA 3.2. *Let* $\{\boldsymbol{\xi}_m\}_{0\le m\le m_{\rm T}}$, $\boldsymbol{\xi}_0 = 0$, *be the cg-sequence with respect to* $T \in \mathcal{L}(X,Y)$ *and* $\boldsymbol{\eta} \in Y$. *Further, let* $\boldsymbol{\xi}$ *be in* $\mathsf{D}(|T|^{-\mu})$ *for a* $\mu \in [0,1]$. *Then, for any* $\nu \in [0,\mu]$, *we have that*

$$\begin{aligned} \||T|^{-\nu}(\boldsymbol{\xi}_m - \boldsymbol{\xi})\|_X \le q_{m-1}(0,\boldsymbol{\eta})^{(\nu+1)/2}\big(\|T(\boldsymbol{\xi}_m - \boldsymbol{\xi})\|_Y + \|\boldsymbol{\eta} - T\boldsymbol{\xi}\|_Y\big) \\ + \; q_{m-1}(0,\boldsymbol{\eta})^{(\nu-\mu)/2}\,\||T|^{-\mu}\boldsymbol{\xi}\|_X. \end{aligned} \tag{3.2}$$

4. Termination of REGINN with conjugate gradients.

The convergence of REGINN will be established by bounding the Newton corrections s_{n,r_n} sharply enough. Indeed, we will show that the Newton corrections decrease geometrically in n. Thus, the Newton iterates stay in a ball about x_0.

Recall the assumptions and notation from section 2 and let the cg-method be the inner iteration of REGINN exclusively throughout this section.

LEMMA 4.1. *Suppose* s_{n,r_n} *is well defined. Then*

$$\|s_{n,r_n}\|_X < 3\; q_{r_n-1}(0,b_n^\varepsilon)^{1/2}\; d_n. \tag{4.1}$$

Proof. We apply Lemma 3.2 with $T = A_n$, $\mu = \nu = 0$, $\boldsymbol{\xi} = 0$, $\boldsymbol{\eta} = b_n^\varepsilon$, $\boldsymbol{\xi}_m = s_{n,r_n} = q_{r_n-1}(A_n^*A, b_n^\varepsilon)A_n^* b_n^\varepsilon$, that is, $m = r_n$. Thus,

$$\|s_{n,r_n}\|_X \le q_{r_n-1}(0,b_n^\varepsilon)^{1/2}\,\big(\|A_n s_{n,r_n}\|_Y + \|b_n^\varepsilon\|_Y\big).$$

We are done by $\|A_n s_{n,r_n}\|_Y \le \|A_n s_{n,r_n} - b_n^\varepsilon\|_Y + \|b_n^\varepsilon\|_Y \le (\mu_n + 1)\,\|b_n^\varepsilon\|_Y$. □

In the following we bound each of the factors on the right-hand side of (4.1). From [10, Lemma 4.1] (see also [12, Lemma 7.5.9]) we already know that the nonlinear residuals d_n decrease linearly.

LEMMA 4.2. *Suppose that the nth iterate* x_n *of* REGINN *is well defined and lies in* $B_\rho(x^+)$. *Further, let* (2.3) *hold true with*

$$\omega < \eta/(2+\eta) \quad \textit{for one} \quad \eta < 1.^3$$

[3] This restriction is satisfied, for instance, if (2.1) holds true and ρ is small enough.

If, moreover,

$$R \geq \frac{1+\omega}{\eta - (2+\eta)\,\omega} \quad \text{and} \quad \mu_n \in \left]\omega + \frac{(1+\omega)\,\delta}{d_n},\ \eta - (1+\eta)\,\omega\right]$$

as well as $x_{n+1} \in B_\rho(x^+)$, *then*

$$\frac{d_{n+1}}{d_n} \;=\; \frac{\|y^\delta - F(x_{n+1})\|_Y}{\|y^\delta - F(x_n)\|_Y} \;<\; \frac{\mu_n + \omega}{1-\omega} \;\leq\; \eta.$$

4.1. Bounding $q_{r_n-1}(0, b_n^\varepsilon)$.

We assume the existence of $w \in X$ and $\kappa \in [0,1]$ such that

$$s_0^{\mathrm{e}} \;=\; x^+ - x_0 \;=\; |A|^\kappa w, \tag{4.2}$$

where $A = F'(x^+)$. To formulate the bound for $q_{r_k-1}(0, b_k^\varepsilon)$ we introduce the ratio

$$\tau_k := \mu_k\, d_k / \varepsilon(x_k, \delta), \tag{4.3}$$

which is greater than 1 under the hypotheses of Lemma 2.1.

LEMMA 4.3. *Let* (2.1) *hold true with* $C_Q\rho < 1/2$ *(thus,* $\omega < 1$ *in* (2.3)*) and assume that the first* $n < N$ *iterates* $\{x_1, \ldots, x_n\}$ *of* `REGINN` *exist and stay in* $B_\rho(x^+)$. *Further, let* $x_0 \in B_\rho(x^+)$ *satisfy the source condition* (4.2).

Then $s_k^{\mathrm{e}} = x^+ - x_k \in \mathsf{D}(|A_k|^{-\kappa})$, $0 \leq k \leq n$. *Moreover, if* $R \geq (1+\omega)/(1-\omega)$ *and if* $\mu_k \in]\omega + (1+\omega)\delta/d_k, 1]$, $0 \leq k \leq n$, *then for any* $\Theta \in]0,1[$ *such that* $\Theta \min\{\tau_0, \ldots, \tau_n\} > 1$ *we have*

$$q_{r_k-1}(0, b_k^\varepsilon)^{(\kappa+1)/2} \leq \frac{a_\Theta}{\Theta\,\tau_k - 1}\ \varepsilon(x_k, \delta)^{-1}\ \||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X, \quad 0 \leq k \leq n,$$

where a_Θ *is a positive constant depending* only *on* Θ *and* κ.

Proof. See Appendix B for the proof. □

Let us summarize what we found so far. Starting from (4.1) we are able to bound the Newton steps under the assumptions of Lemma 4.3 by

$$\|s_{k,r_k}\|_X \;<\; 3\left(\frac{a_\Theta}{\Theta\,\tau_k - 1}\right)^{1/(\kappa+1)} \varepsilon(x_k, \delta)^{-1/(\kappa+1)}\ \||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X^{1/(\kappa+1)}\ d_k. \tag{4.4}$$

4.2. Bounding $\||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X$.

Before we are able to establish termination of `REGINN` by (4.4), we have to know how $\||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X$ behaves in k. Since $s_k^{\mathrm{e}} = x^+ - x_k = x^+ - x_{k-1} - s_{k-1,r_{k-1}} = s_{k-1}^{\mathrm{e}} - s_{k-1,r_{k-1}}$ we conclude that

$$\begin{aligned} \||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X \;&=\; \||A_k|^{-\kappa}(s_{k-1}^{\mathrm{e}} - s_{k-1,r_{k-1}})\|_X \\ &\overset{(2.4)}{\leq}\; C_{K,\kappa}\, \||A_{k-1}|^{-\kappa}(s_{k-1}^{\mathrm{e}} - s_{k-1,r_{k-1}})\|_X. \end{aligned}$$

We estimate the norm on the right by applying Lemma 3.2 with $T = A_{k-1}$, $\mu = \nu = \kappa$, $\boldsymbol{\xi} = s^{\mathrm{e}}_{k-1}$ $\boldsymbol{\eta} = b^{\varepsilon}_{k-1}$, and $\boldsymbol{\xi}_m = s_{k-1,r_{k-1}}$. Hence,

$$\begin{aligned}
\||A_k|^{-\kappa} s^{\mathrm{e}}_k\|_X &\le C_{K,\kappa}\, q_{r_{k-1}-1}(0, b^{\varepsilon}_{k-1})^{(\kappa+1)/2} \big(\|A_{k-1} s_{k-1,r_{k-1}} - b_{k-1}\|_Y \\
&\qquad\qquad + \|b^{\varepsilon}_{k-1} - b_{k-1}\|_Y\big) + \||A_{k-1}|^{-\kappa} s^{\mathrm{e}}_{k-1}\|_X \\
&\le C_{K,\kappa}\, q_{r_{k-1}-1}(0, b^{\varepsilon}_{k-1})^{(\kappa+1)/2} \big(\underbrace{\mu_{k-1}\, d_{k-1}}_{\overset{(4.3)}{=}\ \tau_{k-1}\,\varepsilon(x_{k-1},\delta)} + 2\,\varepsilon(x_{k-1},\delta)\big) \\
&\qquad\qquad + \||A_{k-1}|^{-\kappa} s^{\mathrm{e}}_{k-1}\|_X \\
&\le 3\, C_{K,\kappa}\, q_{r_{k-1}-1}(0, b^{\varepsilon}_{k-1})^{(\kappa+1)/2}\ \tau_{k-1}\ \varepsilon(x_{k-1},\delta) \\
&\qquad\qquad + \||A_{k-1}|^{-\kappa} s^{\mathrm{e}}_{k-1}\|_X \\
&\le \Big(3\, C_{K,\kappa}\, a_\Theta\, \frac{\tau_{k-1}}{\Theta\,\tau_{k-1} - 1} + 1\Big)\ \||A_{k-1}|^{-\kappa} s^{\mathrm{e}}_{k-1}\|_X,
\end{aligned}$$

where we used Lemma 4.3 in the last step. Inductively, we end up with the following lemma.

LEMMA 4.4. *Let* (2.1) *hold true with* $C_Q\rho < 1/2$ *(thus,* $\omega < 1$ *in* (2.3)*) and assume that the first* $n < N$ *iterates* $\{x_1, \dots, x_n\}$ *of* `REGINN` *exist and stay in* $B_\rho(x^+)$. *Further, choose* $R \ge (1+\omega)/(1-\omega)$ *and let* $x_0 \in B_\rho(x^+)$ *satisfy the source condition* (4.2).

If $\mu_k \in\,]\omega + (1+\omega)\delta/d_k, 1]$, $0 \le k \le n$, *and if* $\Theta \in\,]0,1[$ *is such that* $\Theta\,\tau_k > 1$, $0 \le k \le n$, *then*

$$\||A_k|^{-\kappa} s^{\mathrm{e}}_k\|_X \le C_{K,\kappa}\, \Lambda_n^k\ \|w\|_X \quad \textit{for}\ \ k = 0, \dots, n \tag{4.5a}$$

with

$$\Lambda_n = 1 + 3\, C_{K,\kappa}\ a_\Theta\ \frac{t_n}{\Theta\, t_n - 1} \quad \textit{and} \quad t_n = \min\{\tau_0, \dots, \tau_n\}. \tag{4.5b}$$

4.3. Termination. We are now able to verify termination of `REGINN` with conjugate gradients as inner iteration: under reasonable technical assumptions all iterates remain in $B_\rho(x_0)$ and `REGINN` delivers an approximation $x_{N(\delta)}$ to x^+. The following theorem is the counterpart of Theorem 3.3 from [11] (see also [12, Satz 7.5.14]) and will be proved along the same lines.

THEOREM 4.5. *Let* (2.1) *hold true with* $C_Q\rho < 1/2$ *(thus,* $\omega < 1$ *in* (2.3)*). Let* $\tau > 1$ *and let* $\Theta \in\,]0,1[$ *be such that* $\Theta\,\tau > 1$. *Set*

$$\Lambda = 1 + 3\, C_{K,\kappa}\ a_\Theta\ \frac{\tau}{\Theta\,\tau - 1},$$

where $C_{K,\kappa} = (1 - C_Q\rho)^{-\kappa}$ *(see* (2.4)*), and* a_Θ *comes from the estimate in Lemma* 4.3. *Suppose that* (2.3) *is satisfied with*

$$\omega < \frac{\eta}{\eta + \tau + 1}, \quad \textit{where} \quad \eta\,\Lambda < 1.^{4}$$

Assume that the starting guess $x_0 \in B_{\rho/2}(x^+)$ *is chosen such that the source condition* (4.2) *applies for* κ *restricted to* $]\log_{1/\eta}\Lambda, 1]$ *and that the product* $\|w\|_X\, \|y -$

[4] This restriction is satisfied, for instance, if (2.1) holds true and ρ is small enough.

$F(x_0)\|_Y^\kappa$ is sufficiently small. If

$$R \geq \frac{\tau\,(1+\omega)}{\eta - \omega\,\big(\eta + \tau + 1\big)} \quad \textit{and} \quad \mu_k \in \left[\tau\,\left(\omega + \frac{(1+\omega)\,\delta}{d_k}\right),\ \eta - (1+\eta)\,\omega\right]$$

for $k \geq 0$, then there is an $N(\delta) \in \mathbb{N}$ and a $\overline{\delta} > 0$ such that all iterates $\{x_1, \dots, x_{N(\delta)}\}$ are well defined and stay in $B_\rho(x^+)$ for all noise levels $\delta \in\ ]0, \overline{\delta}]$. Moreover, the final iterate $x_{N(\delta)}$ satisfies the discrepancy principle (1.6) *and, for $d_0 > R\,\delta$,*

$$N(\delta)\ \leq\ \lfloor \log_\eta(R\,\delta/d_0) \rfloor + 1.[5] \tag{4.6}$$

Proof. We will prove Theorem 4.5 by induction. Therefore, assume that the first n iterates $\{x_0, \dots, x_n\}$ are well defined under the hypotheses of Theorem 4.5 and stay in $B_\rho(x^+)$.

If $d_n \leq R\,\delta$, the iteration will be stopped by (1.6) with $N(\delta) = n$. Otherwise, $d_n > R\,\delta$, and we show that the interval determining μ_n is not empty. The bound on ω implies that the denominator of the lower bound of R is positive. The lower bound on R guarantees that $\tau(\omega + (1+\omega)\delta/d_n) < \tau(\omega + (1+\omega)/R) < \eta - (1+\eta)\,\omega$.

According to Lemma 2.1, r_n and thus the Newton step s_{n,r_n} are well defined. By (4.4) and (4.5),

$$\|s_{n,r_n}\|_X \leq 3\,\left(\frac{C_{K,\kappa}\,a_\Theta\,\|w\|_X}{\Theta\,\tau_n - 1}\right)^{1/(\kappa+1)}\ \Lambda_n^{n/(\kappa+1)}\ \varepsilon(x_n,\delta)^{-1/(\kappa+1)}\ d_n.$$

The lower bound on the μ_k's yields $\tau_k \geq \tau > 1$, $k = 0, \dots, n$ (cf. (4.3)), that is, $\Lambda_n \leq \Lambda$. Moreover, $d_n/\varepsilon(x_n,\delta) \leq 1/\omega$. Taking Lemma 4.2 into account, we obtain

$$\|s_{n,i_n}\|_X \leq C_S\ \|w\|_X^{1/(\kappa+1)}\ d_0^{\kappa/(\kappa+1)}\ \sigma(\kappa)^n,$$

where $C_S = 3\big(C_{K,\kappa}\,a_\Theta/(\Theta\,\tau - 1)/\omega\big)^{1/(\kappa+1)}$ and

$$\sigma(\kappa) := \big(\Lambda\,\eta^\kappa\big)^{1/(\kappa+1)}\ < 1.[6] \tag{4.7}$$

We define the quantity

$$\alpha(\delta) := C_S\ \|w\|_X^{1/(\kappa+1)}\ \|F(x_0) - y^\delta\|_X^{\kappa/(\kappa+1)}\Big/\big(1 - \sigma(\kappa)\,\big). \tag{4.8}$$

In our formulation of Theorem 4.5 we assumed the product $\|w\|_X\|F(x_0) - y\|_X^\kappa$ to be sufficiently small. Now we can be more precise: assume that $\|w\|_X\|F(x_0) - y\|_X^\kappa$ is so small that $\alpha(0) < \rho/2$. Then there exists a $\overline{\delta} > 0$ yielding $\alpha(\delta) < \rho/2$ for all $\delta \in\ ]0, \overline{\delta}]$ and the new iterate $x_{n+1} = x_n + s_{n,r_n} = x_0 + \sum_{k=0}^n s_{k,r_k}$ is in $B_\rho(x^+)$:

$$\|x^+ - x_{n+1}\|_X \leq \|x^+ - x_0\|_X + \sum_{k=0}^n \|s_{k,r_k}\|_X \leq \rho/2 + \alpha(\delta) \leq \rho.$$

Further, $d_{n+1} \leq \eta^{n+1} d_0$ uniformly in $\delta \in\ ]0, \overline{\delta}]$ (Lemma 4.2). This completes the inductive step, thereby finishing the proof of Theorem 4.5. □

[5] Here, $\lfloor t \rfloor \in \mathbb{Z}$ for $t \in \mathbb{R}$ denotes the greatest integer: $\lfloor t \rfloor \leq t < \lfloor t \rfloor + 1$.

[6] Note that $\sigma(\kappa)$ is smaller than 1 since $\kappa > \log_{1/\eta}\,\Lambda$.

5. Convergence with rates.

5. Convergence with rates. Finally, we are able to verify the regularization property of `REGINN` with conjugate gradients as inner iteration, that is, we will show convergence of $x_{N(\delta)}$ to x^+ as the noise level δ decreases.

As an additional tool we will use the *interpolation inequality* (5.1): If $T \in \mathcal{L}(X,Y)$, then

$$\big\|(T^*T)^\alpha x\big\|_X \le \|(T^*T)^\beta x\|_X^{\alpha/\beta}\, \|x\|_X^{1-\alpha/\beta} \quad \text{for } \ 0 < \alpha \le \beta; \tag{5.1}$$

see, e.g., [2, 12].

Under the hypotheses of Theorem 4.5 we have to control the reconstruction error $s_k^{\mathrm{e}} = x^+ - x_k$ of the kth iterate, $0 \le k \le N(\delta)$:

$$\begin{aligned} \|s_k^{\mathrm{e}}\|_X^2 &= \langle |A_k|^\kappa s_k^{\mathrm{e}}, |A_k|^{-\kappa} s_k^{\mathrm{e}}\rangle_X \le \||A_k|^\kappa s_k^{\mathrm{e}}\|_X\, \||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X \\ &\overset{(5.1)}{\le} \||A_k| s_k^{\mathrm{e}}\|_X^\kappa\, \|s_k^{\mathrm{e}}\|_X^{1-\kappa}\, C_{K,\kappa}\, \Lambda^k\, \|w\|_X, \end{aligned}$$

where we also applied (4.5) with $\Lambda_k \le \Lambda$ to obtain the last inequality. Thus,

$$\begin{aligned} \|s_k^{\mathrm{e}}\|_X &\le C_{K,\kappa}^{1/(\kappa+1)}\, \Lambda^{k/(\kappa+1)}\, \|w\|_X^{1/(\kappa+1)}\, \|A_k s_k^{\mathrm{e}}\|_Y^{\kappa/(\kappa+1)} \\ &\overset{(2.2)}{\le} C_{K,\kappa}^{1/(\kappa+1)}\, \Lambda^{k/(\kappa+1)}\, \|w\|_X^{1/(\kappa+1)} \left(\frac{\|y - F(x_k)\|_Y}{1 - C_Q\,\rho}\right)^{\kappa/(\kappa+1)}. \end{aligned} \tag{5.2}$$

Relying on the above estimate, we are now able to copy the proof of Theorem 4.1 from [11] (see also [12, Satz 7.5.17]) to yield the announced convergence result.

THEOREM 5.1. *Adopt the assumptions of Theorem* 4.5*; especially, let the source condition* (4.2) *be satisfied with κ restricted to* $]\log_{1/\eta} \Lambda, 1]$*. Additionally, assume that* $\alpha(0) < \rho/2$ *(see* (4.8)*), as well as* $F(x_0) \ne y = F(x^+)$*. Then*

$$\|x^+ - x_{N(\delta)}\|_X \le C_\kappa\, \|w\|_X^{1/(\kappa+1)}\, \delta^{(\kappa - \log_{1/\eta}\Lambda)/(\kappa+1)} \quad \text{as } \ \delta \to 0, \tag{5.3}$$

where C_κ is a suitable constant.

In the noise-free situation, that is, $\delta = 0$, we have that

$$\|x^+ - x_k\|_X = \mathrm{O}\big(\sigma(\kappa)^k\big) \quad \text{as } \ k \to \infty$$

with $\sigma(\kappa)$ from (4.7)*.*

Proof. Plugging $k = N(\delta)$ into (5.2) and taking (1.6) into account give

$$\|s_{N(\delta)}^{\mathrm{e}}\|_X \le C_{K,\kappa}^{1/(\kappa+1)}\, \|w\|_X^{1/(\kappa+1)} \left(\frac{R+1}{1 - C_Q\,\rho}\right)^{\kappa/(\kappa+1)} \Lambda^{N(\delta)/(\kappa+1)}\, \delta^{\kappa/(\kappa+1)}.$$

Thus, (5.3) follows from (4.6). Convergence in the noise-free setting is obtained from (5.2) in combination with Lemma 4.2. □

6. Computational example.

6. Computational example. By computational experiments we will demonstrate the increase in numerical efficiency of `REGINN` when replacing the ν-method by the conjugate gradient iteration as inner iteration. We distinguish the two variants by ν-`REGINN` and cg-`REGINN`. Throughout this section let $\nu = 1$.[7]

[7] Any $\nu \ge 1$ is admissible [11, Example 2.1]. However, larger ν slow down ν-`REGINN` in the numerical computations presented here.

For our numerical experiments we select a model problem which satisfies our main assumption (2.1). We like to identify the bivariate parameter $c \geq 0$ in the two-dimensional elliptic PDE

$$\begin{aligned} -\Delta u + c\,u &= f \quad \text{in } \Omega, \\ u &= g \quad \text{on } \partial\Omega \end{aligned} \tag{6.1}$$

from the knowledge of u in the box $\Omega =]0,1[^2$. In (6.1), $-\Delta$ is the Laplacian. Further, let f and g be continuous functions. If u has no zeros in Ω, then c can be recovered explicitly by $c = (f + \Delta u)/u$. Thus, c is uniquely determined by u but does not depend continuously on it. In the case of noise-corrupted data the inversion formula is useless. Further details about our model problem can be found in Hanke, Neubauer, and Scherzer [6, Example 4.2]. Since we already used our model problem for numerical experiments in [10, 11, 12] we will be brief in what follows.

We discretize (6.1) by finite differences with respect to the grid points $(x_i, y_j) = (i\,h, j\,h)$, $1 \leq i,j \leq m$, where $m \in \mathbb{N}$ and $h = 1/(m+1)$ is the discretization step size. Ordering the grid points lexicographically yields the $m^2 \times m^2$ linear system

$$\big(\mathbf{A} + \operatorname{diag}(\mathbf{c})\big)\,\mathbf{u} = \mathbf{f},$$

where $\mathbf{A}$ comes from the difference star of the Laplacian $-\Delta$ and where the components of $\mathbf{c} = (\mathbf{c}_1, \ldots, \mathbf{c}_{m^2})^t$ are given by $\mathbf{c}_{\ell(i,j)} = c(x_i, y_j)$ with $\ell : \{1, \ldots, m\}^2 \to \{1, \ldots, m^2\}$ denoting lexicographical ordering. The boundary values g are incorporated into the right-hand side $\mathbf{f}$. From the convergence theory for finite differences (see, e.g., Hackbusch [3]), we know that the solution $\mathbf{u}$ of the above linear system satisfies $\mathbf{u}_{\ell(i,j)} = u(x_i, y_j) + \mathrm{O}(h^2)$ as $h \to 0$ whenever u is sufficiently smooth.

In this discrete setting we like to reconstruct $\mathbf{c}$ from $\mathbf{u}$. Thus, we have to solve the nonlinear equation

$$F(\mathbf{c}) = \mathbf{u} \tag{6.2}$$

with $F : \mathbb{R}^{m^2}_{\geq 0} \to \mathbb{R}^{m^2}$, $F(\mathbf{c}) = (\mathbf{A} + \operatorname{diag}(\mathbf{c}))^{-1}\,\mathbf{f}$. The function F is differentiable with Jacobi-matrix $F'(\mathbf{c})w = -\big(\mathbf{A} + \operatorname{diag}(\mathbf{c})\big)^{-1}\big(F(\mathbf{c}) \odot w\big)$, where $\odot$ denotes componentwise multiplication of vectors. Moreover, F' can be factorized according to (2.1) in a neighborhood of any $\mathbf{c} > 0$ (componentwise), where also $F(\mathbf{c}) > 0$.[8] In our numerical experiments the parameter to be identified is

$$c^+(x,y) = 1.5\,\sin(2\pi\,x)\,\sin(3\pi\,y) + 3\,\big((x-0.5)^2 + (y-0.5)^2\big) + 2.$$

We have chosen f and g such that $u(x,y) = 16\,x\,(x-1)\,y\,(1-y) + 1$ solves (6.1) with respect to c^+. As perturbed right-hand side $\mathbf{u}^\delta$ for (6.2) we worked with $\mathbf{u}^\delta = \widetilde{\mathbf{u}} + \delta\,\mathbf{v}$, where $\widetilde{\mathbf{u}}_{\ell(i,j)} = u(x_i, y_j)$ and $\mathbf{v} = \mathbf{z}/\|\mathbf{z}\|_h$. The entries of the random vector $\mathbf{z}$ are uniformly distributed in $[-1,1]$. Therefore, $\|\mathbf{u} - \mathbf{u}^\delta\|_h \leq \delta + \mathrm{O}(h^2)$ measured in the weighted Euclidean norm $\|\mathbf{z}\|_h = h\,\big(\sum_{i=0}^{m^2} \mathbf{z}_i^2\big)^{1/2}$, which approximates the L^2-norm over Ω.

In all computations below we started `REGINN` with initial guess $\mathbf{c}_0$, where $(\mathbf{c}_0)_{\ell(i,j)} = c_0(x_i, x_j)$ and

$$c_0(x,y) = 3\,\big((x-0.5)^2 + (y-0.5)^2\big) + 2 + 128\,x\,(x-1)\,y\,(1-y).$$

[8] The implication $\mathbf{c} > 0 \Rightarrow F(\mathbf{c}) > 0$ holds true, for instance, if $\mathbf{f} > 0$ since $\mathbf{A} + \operatorname{diag}(\mathbf{c})$ is an M-matrix whose inverse has only nonnegative entries.

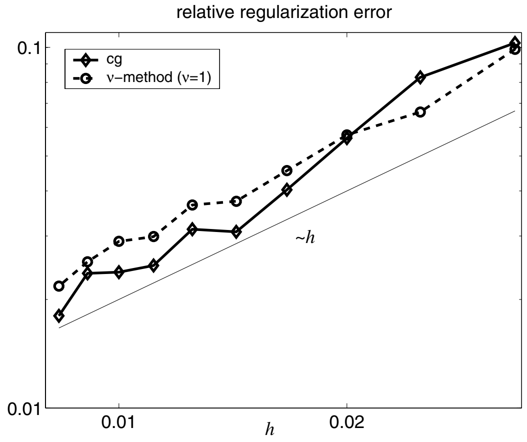

FIG. 6.1. *Relative reconstruction error* (6.4) *of* REGINN *as a function of* h *(solid line with* $\diamond$*: cg-method as inner iteration; dashed line with* $\circ$*:* ν*-method as inner iteration). The thin solid line indicates decay* $\mathrm{O}(h)$ *as* $h \to 0$.

Further, we always used $R = 1.5$, and we adapted the tolerances $\{\mu_k\}$ in (1.5) dynamically according to scheme (6.3) below, which was proposed in [10, section 6] (see also [12, Kapitel 7.5.3.4]): Initialize $\mu_{\text{start}} = 0.1$, $\gamma = 0.9$, $\mu_{\max} = 0.999$, and $\widetilde{\mu}_0 = \widetilde{\mu}_1 := \mu_{\text{start}}$. For $k = 0, \dots, N(\delta) - 1$ set

$$\mu_k := \mu_{\max} \max\big\{R\,\delta/\|F(\mathbf{c}_k) - \mathbf{u}^\delta\|_h,\, \widetilde{\mu}_k\big\}, \tag{6.3}$$

where $\mathbf{c}_k$ is the kth iterate and

$$\widetilde{\mu}_k := \begin{cases} 1 - \frac{r_{k-2}}{r_{k-1}}\,(1 - \mu_{k-1}) & : \quad r_{k-1} \geq r_{k-2}, \\ \gamma\,\mu_{k-1} & : \quad \text{else.} \end{cases}$$

Figure 6.1 shows relative reconstruction errors by ν-REGINN and cg-REGINN. More precisely, we plotted

$$\operatorname{err}(h) := \|\mathbf{c}_{N(\delta(h))} - \mathbf{c}^+\|_h / \|\mathbf{c}^+\|_h \quad \text{with } \delta(h) = 10\,h^2 \tag{6.4}$$

as a function of $h \in \{(10\,k)^{-1} \mid k = 3, \dots, 12\}$, where $\mathbf{c}^+_{\ell(i,j)} = c^+(x_i, y_j)$ and where $\mathbf{c}_{N(\delta(h))}$ is the output of either ν-REGINN or cg-REGINN. The auxiliary line in Figure 6.1 represents exact decay $\mathrm{O}(h)$ as $h \to 0$. Thus, our computations indicate that $\operatorname{err}(h) = \mathrm{O}(h)$ as $h \to 0$. Since $\|\mathbf{u} - \mathbf{u}^{\delta(h)}\|_h \leq \delta(h) + \mathrm{O}(h^2) := \boldsymbol{\delta}(h) = \mathrm{O}(h^2)$ the regularization error achieves maximal order of convergence according to Theorem 5.1, namely, $\operatorname{err}(\boldsymbol{\delta}) = \mathrm{O}(\boldsymbol{\delta}^{1/2})$ as $\boldsymbol{\delta} \to 0$, that is, $\kappa = 1$ and $\Lambda = 1$.

Both variants of REGINN deliver errors in comparable magnitude. In this respect there is not much difference between cg-REGINN and ν-REGINN. However, looking at the numerical efficiency we observe a significant difference. In Figure 6.2 we plotted the ratio

$$q(h) := \frac{\text{cpu-time of } \nu\text{-REGINN to compute } \mathbf{c}_{N(\delta(h))}}{\text{cpu-time of cg-REGINN to compute } \mathbf{c}_{N(\delta(h))}}, \tag{6.5}$$

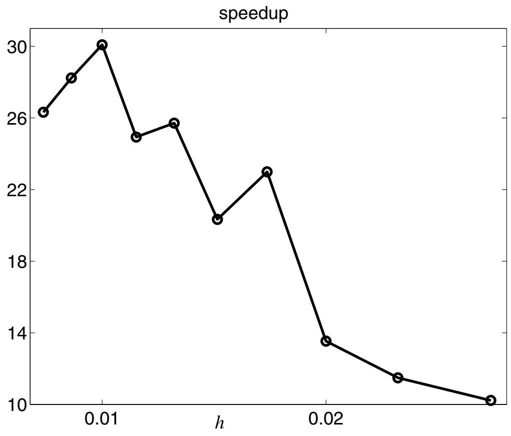

FIG. 6.2. *Speedup q (6.5) of cg-*`REGINN` *over ν-*`REGINN`.

TABLE 6.1

k	μ_{k-1}	r_{k-1}	d_k/d_{k-1}	$d_k/(R\,\delta)$	e_k
1	0.0999	1	0.3997	70.86	0.5598
2	0.0999	1	0.1188	8.418	0.3090
3	0.1187	6	0.1223	1.030	0.0239
4	0.9704	1	0.9629	0.991	0.0238

where we did not count cpu-time for preprocessing steps performed by both variants.[9] Figure 6.2 reveals that cg-`REGINN` is 10 to 30 times faster than ν-`REGINN` in our example.

Tables 6.1 and 6.2 record the convergence history of ν-`REGINN` and cg-`REGINN` in full detail for the discretization step size $h = 0.01$. In both tables

$$d_k := \|F(\mathbf{c}_k) - \mathbf{u}^{\delta(h)}\|_h \quad \text{and} \quad e_k := \|\mathbf{c}_k - \mathbf{c}^+\|_h / \|\mathbf{c}^+\|_h$$

denote the nonlinear defect and the relative L^2-error of the kth iterate, respectively.

Among all Krylov-subspace methods the conjugate gradient iteration is the most efficient one when the discrepancy principle is the used stopping rule; see, e.g., [2,

[9] The experiments were carried out under MATLAB 6.5 on a 2.6GHz Intel Pentium 4 processor.

Chapter 7.1] or [12, Kapitel 5.3.6]. As expected, cg-`REGINN` outperforms ν-`REGINN` since it takes much fewer inner iterations to yield the correction step which we can observe clearly in the tables (one iteration step of the cg-methods is only slightly more expensive than one iteration step of the ν-method).

7. Concluding remarks.

In this paper we proved local convergence with rates for a regularization scheme of inexact Newton type with the cg-method as inner iteration. Theoretical aspects are emphasized; ideas and techniques have been presented to cope with the nonlinearity of the conjugate gradient iteration.

As far as the author knows, the restrictive factorization assumption (2.1) has not been verified for real applications such as, e.g., impedance tomography, ultrasound tomography, and SPECT (single photon emission computed tomography). Therefore the most pressing improvement of the presented analysis is to weaken or to get rid of (2.1).

Nevertheless the practitioner may benefit from our theoretical results in at least two ways: (1) The adaptive tolerance selection scheme (6.3) has a sound justification for cg-`REGINN` and can be expected to perform well also for more general nonlinearities. (2) A potential convergence analysis of cg-`REGINN` for a specific application, which does not fall into the general category considered, can be based upon techniques developed here.

Appendix A. Proof of Lemma 3.2.

For the sake of simplicity we only prove Lemma 3.2 for a compact operator T (the general result will follow by integration over the spectral family of T^*T). Most of our arguments have been used before by Plato [9, Lemma 5.4] (see also [12, Lemma 5.3.11]) to prove another error estimate for the cg-method.

Let $\{(\sigma_j; v_j, u_j) | j \in \mathbb{N}\} \subset \,]0,\infty[\, \times X \times Y$ be the singular system of T, that is, $Tx = \sum_{j=1}^{\infty} \sigma_j \langle x, v_j \rangle_X u_j$ with $\lim_{j\to\infty} \sigma_j = 0$ monotonically, and $\{v_j\}$ and $\{u_j\}$ are orthonormal bases in $\mathsf{N}(T)^\perp$ and $\overline{\mathsf{R}(T)}$, respectively.[10]

We introduce the spectral family $\{\mathcal{E}_\Lambda\}_{\Lambda>0} \subset \mathcal{L}(X)$ of T^*T by[11]

$$\mathcal{E}_\Lambda x := \sum_{j\in\mathcal{J}(\Lambda)} \langle x, v_j \rangle_X v_j + P_{\mathsf{N}(T)} x, \qquad \mathcal{J}(\Lambda) := \{j \in \mathbb{N} \,|\, \sigma_j^2 \le \Lambda\}, \tag{A.1}$$

and start with

$$\||T|^{-\nu}(\boldsymbol{\xi}_m - \boldsymbol{\xi})\|_X \le \||T|^{-\nu}(I - \mathcal{E}_\Lambda)(\boldsymbol{\xi}_m - \boldsymbol{\xi})\|_X + \||T|^{-\nu}\mathcal{E}_\Lambda(\boldsymbol{\xi}_m - \boldsymbol{\xi})\|_X.$$

We proceed by

$$\begin{aligned}\||T|^{-\nu}(I - \mathcal{E}_\Lambda)(\boldsymbol{\xi}_m - \boldsymbol{\xi})\|_X^2 &= \sum_{k=1}^{\infty} \sigma_k^{-2(\nu+1)} \left|\left\langle |T|(I - \mathcal{E}_\Lambda)(\boldsymbol{\xi}_m - \boldsymbol{\xi}), v_k \right\rangle_X\right|^2 \\ &= \sum_{k\notin\mathcal{J}(\Lambda)} \sigma_k^{-2(\nu+1)} \left|\left\langle |T|(\boldsymbol{\xi}_m - \boldsymbol{\xi}), v_k \right\rangle_X\right|^2 \\ &\le \Lambda^{-(\nu+1)} \|T(\boldsymbol{\xi}_m - \boldsymbol{\xi})\|_Y^2\end{aligned}$$

[10] $\mathsf{N}(B)$ and $\mathsf{R}(B)$ denote the null space and the range of a linear operator, respectively.

[11] $P_M \in \mathcal{L}(X)$ denotes the orthogonal projection onto the closed subspace M of X.

and

$$
\begin{aligned}
&\||T|^{-\nu}\mathcal{E}_\Lambda(\boldsymbol{\xi}_m-\boldsymbol{\xi})\|_X\\
&\quad\le \||T|^{-\nu}\mathcal{E}_\Lambda p_m(T^*T,\boldsymbol{\eta})\boldsymbol{\xi}\|_X+\||T|^{-\nu}\mathcal{E}_\Lambda q_{m-1}(T^*T,\boldsymbol{\eta})T^*(\boldsymbol{\eta}-T\boldsymbol{\xi})\|_X\\
&\quad\le \|\mathcal{E}_\Lambda|T|^{\mu-\nu}p_m(T^*T,\boldsymbol{\eta})\|_X\,\||T|^{-\mu}\boldsymbol{\xi}\|_X\\
&\qquad\qquad\qquad+\||T|^{-\nu}\mathcal{E}_\Lambda q_{m-1}(T^*T,\boldsymbol{\eta})T^*\|_X\,\|\boldsymbol{\eta}-T\boldsymbol{\xi}\|_X\\
&\quad\le \||T|^{-\mu}\boldsymbol{\xi}\|_X\sup_{0\le\lambda\le\Lambda}\lambda^{(\mu-\nu)/2}\,|p_m(\lambda,\boldsymbol{\eta})|\\
&\qquad\qquad\qquad+\|\mathcal{E}_\Lambda q_{m-1}(T^*T,\boldsymbol{\eta})|T|^{-\nu}T^*\|_X\,\|\boldsymbol{\eta}-T\boldsymbol{\xi}\|_X.
\end{aligned}
$$

Further,

$$
\begin{aligned}
&\|\mathcal{E}_\Lambda q_{m-1}(T^*T,\boldsymbol{\eta})|T|^{-\nu}T^*\|^2\\
&\qquad=\|\mathcal{E}_\Lambda\,q_{m-1}(T^*T,\boldsymbol{\eta})|T|^{2(1-\nu)}q_{m-1}(T^*T,\boldsymbol{\eta})\mathcal{E}_\Lambda\|\\
&\qquad\le\|\mathcal{E}_\Lambda\,q_{m-1}(T^*T,\boldsymbol{\eta})\|\;\||T|^{2(1-\nu)}q_{m-1}(T^*T,\boldsymbol{\eta})\mathcal{E}_\Lambda\|\\
&\qquad\le\sup_{0\le\lambda\le\Lambda}|q_{m-1}(\lambda,\boldsymbol{\eta})|\sup_{0\le\lambda\le\Lambda}\lambda^{1-\nu}\,|q_{m-1}(\lambda,\boldsymbol{\eta})|.
\end{aligned}
$$

By Lemma 3.1 we have

$$
\sup_{0\le\lambda\le\Lambda}|q_{m-1}(\lambda,\boldsymbol{\eta})|\le q_{m-1}(0,\boldsymbol{\eta})\quad\text{whenever }0<\Lambda\le\lambda_{m,1}.
$$

The representation (3.1) of p_m shows that $0\le p_m(\lambda)\le 1$ for $\lambda\in[0,\lambda_{m,1}]$. Since $p_m(\lambda)=1-\lambda\,q_{m-1}(\lambda)$ we derive that

$$
\begin{aligned}
\sup_{0\le\lambda\le\Lambda}\lambda^{1-\nu}\,|q_{m-1}(\lambda,\boldsymbol{\eta})|&\le\big(\sup_{0\le\lambda\le\Lambda}\lambda\,|q_{m-1}(\lambda,\boldsymbol{\eta})|\big)^{1-\nu}\big(\sup_{0\le\lambda\le\Lambda}|q_{m-1}(\lambda,\boldsymbol{\eta})|\big)^{\nu}\\
&\le q_{m-1}(0,\boldsymbol{\eta})^{\nu}
\end{aligned}
$$

whenever $0<\Lambda\le\lambda_{m,1}$. Finally, for $0<\Lambda\le\lambda_{m,1}$, we obtain that

$$
\begin{aligned}
\||T|^{-\nu}(\boldsymbol{\xi}_m-\boldsymbol{\xi})\|_X\le\Lambda^{-(\nu+1)/2}\,\|T(\boldsymbol{\xi}_m-\boldsymbol{\xi})\|_Y+\||T|^{-\mu}\boldsymbol{\xi}\|_X\,\Lambda^{(\mu-\nu)/2}&\\
+\,q_{m-1}(0,\boldsymbol{\eta})^{(\nu+1)/2}\,\|\boldsymbol{\eta}-T\boldsymbol{\xi}\|_X&,
\end{aligned}
$$

which yields the stated inequality (3.2) by setting $\Lambda=1/q_{m-1}(0,\boldsymbol{\eta})$. This choice for Λ is admissible since $1/q_{m-1}(0,\boldsymbol{\eta})<\lambda_{m,1}$; see Lemma 3.1.

Appendix B. Proof of Lemma 4.3. Before we can prove Lemma 4.3, we need some auxiliary results (Lemmas B.1 and B.2 and Corollary B.3 below). Here we rely on arguments laid out by Plato [9, Kapitel 5] and Nemirovskii [8] (see also [12, Kapitel 5.3]).

Suppose that the first n iterates $\{x_1,\ldots,x_n\}$ of `REGINN` exist and stay in $B_\rho(x^+)$. Point of departure is the inequality

$$
\text{(B.1)}\qquad\|b_k^\varepsilon-A_k s_{k,m}\|_Y\le\|\mathcal{F}_{\lambda_{m,1}}\varphi_m(A_kA_k^*,b_k^\varepsilon)b_k\|_Y+\varepsilon,\quad 1\le m\le\boldsymbol{m}_{\mathrm{T}},
$$

where $0\le k\le n$, $\boldsymbol{m}_{\mathrm{T}}=\boldsymbol{m}_{\mathrm{T}}(k)$, and $\mathcal{F}_\Lambda\in\mathcal{L}(Y)$, $\Lambda>0$, is the orthogonal projection

$$
\text{(B.2)}\qquad\mathcal{F}_\Lambda y:=\sum_{i\in\mathcal{J}(\Lambda)}\langle y,u_i\rangle_Y\,u_i+P_{\mathsf{N}(A_k^*)}y
$$

with index set $\mathscr{J}$ as in (A.1). In defining $\mathcal{F}_\Lambda$ we used the singular system of A_k.[12] Further, the function $\varphi_m(\cdot, b_k^\varepsilon) \in \mathcal{C}(\mathbb{R})$ in (B.1) is

$$\varphi_m(\lambda, b_k^\varepsilon) := p_m(\lambda, b_k^\varepsilon)\,\Big(\frac{\lambda_{m,1}}{\lambda_{m,1}-\lambda}\Big)^{1/2},$$

where $\lambda_{m,1}$ is the smallest zero of the mth residual polynomial $p_m(\cdot, b_k^\varepsilon)$ of the cg-method with respect to A_k and b_k^ε. A proof of (B.1) is presented, e.g., by Engl, Hanke, and Neubauer [2, Proof of Theorem 7.10].

As $s_k^{\mathrm{e}} = x^+ - x_k = s_0^{\mathrm{e}} - \sum_{j=0}^{k-1} s_{j,r_j}$ we obtain

$$s_k^{\mathrm{e}} \overset{(4.2)}{=} |A|^\kappa w - \sum_{j=0}^{k-1} A_j^*\, q_{r_j-1}(A_jA_j^*, b_j^\varepsilon)\, b_j^\varepsilon.$$

Note that $s_k^{\mathrm{e}} \in \mathsf{D}(|A_i|^{-\kappa})$, $i = 0, \dots, n$. Indeed, in using $A_j = Q_{j,i}A_i$ with $Q_{j,i} = Q(x_j, x_i)$ (see (2.1)), we obtain that

$$\begin{aligned} \||A_i|^{-\kappa} s_k^{\mathrm{e}}\|_X \;&\leq\; \||A_i|^{-\kappa}|A|^\kappa w\|_X + \sum_{j=0}^{k-1} \||A_i|^{-\kappa} A_j^*\, q_{r_j-1}(A_jA_j^*, b_j^\varepsilon)\, b_j^\varepsilon\|_X \\ &\overset{(2.4)}{\leq}\; C_{K,\kappa}\,\|w\|_X + \underbrace{\||A_i|^{-\kappa}A_i^*\|}_{=\|A_i\|^{1-\kappa}} \sum_{j=0}^{k-1} \|Q_{j,i}^* q_{r_j-1}(A_jA_j^*, b_j^\varepsilon)\, b_j^\varepsilon\|_Y. \end{aligned}$$

Thus, by $A_k s_k^{\mathrm{e}} = b_k$,

$$\begin{aligned} &\|\mathcal{F}_{\lambda_{m,1}}\varphi_m(A_kA_k^*, b_k^\varepsilon) b_k\|_Y \\ &\qquad = \|\mathcal{F}_{\lambda_{m,1}}\varphi_m(A_kA_k^*, b_k^\varepsilon) A_k|A_k|^\kappa|A_k|^{-\kappa} s_k^{\mathrm{e}}\|_Y \\ &\qquad \leq \sup_{0\leq\lambda\leq\lambda_{m,1}} \lambda^{(\kappa+1)/2}\,\varphi_m(\lambda, b_k^\varepsilon)\; \||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X. \end{aligned} \tag{B.3}$$

Techniques from elementary calculus, together with Lemma 3.1, yield

$$\sup_{0\leq\lambda\leq\lambda_{m,1}} \lambda^{(\kappa+1)/2}\,\varphi_m(\lambda, b_k^\varepsilon) \leq 2\, q_{m-1}(0, b_k^\varepsilon)^{-(\kappa+1)/2}$$

for $\kappa \in [0,1]$; see, e.g., [2, (7.8)] or [12, (5.65)]. Hence,

$$\|\mathcal{F}_{\lambda_{m,1}}\varphi_m(A_kA_k^*, b_k^\varepsilon) b_k\|_Y \leq 2\, q_{m-1}(0, b_k^\varepsilon)^{-(\kappa+1)/2}\, \||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X. \tag{B.4}$$

Finally, (B.1) and (B.4) yield the following lemma.

LEMMA B.1. *Let* (2.1) *hold true and assume that the first n iterates $\{x_1, \dots, x_n\}$ of* `REGINN` *exist and stay in $B_\rho(x^+)$. If $x_0 \in B_\rho(x^+)$ satisfies* (4.2), *then, for $0 \leq k \leq n$ and $1 \leq m \leq \boldsymbol{m}_{\mathrm{T}}(k)$,*

$$\|b_k^\varepsilon - A_k s_{k,m}\|_Y \leq \varepsilon + 2\, q_{m-1}(0, b_k^\varepsilon)^{-(\kappa+1)/2}\; \||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X.$$

We need a second auxiliary lemma.

[12] More precisely, $\{\mathcal{F}_\Lambda\}_{\Lambda>0}$ is the spectral family of $A_kA_k^*$.

LEMMA B.2. *Let* (2.1) *hold true and assume that the first* n *iterates* $\{x_1, \ldots, x_n\}$ *of* `REGINN` *exist and stay in* $B_\rho(x^+)$. *Further, let* $x_0 \in B_\rho(x^+)$ *satisfy* (4.2). *Choose* $\vartheta > 2$ *and* $2 < r \leq 2(\vartheta - 1)$. *Let* $0 \leq k \leq n$ *and* $1 \leq m \leq \boldsymbol{m}_{\mathrm{T}}(k)$.

If $\vartheta\, q_{m-2}(0, b_k^\varepsilon) \leq q_{m-1}(0, b_k^\varepsilon)$, *then*

$$\frac{r-2}{r-1}\ \|b_k^\varepsilon - A_k s_{k,m-1}\|_Y \leq \varepsilon + \alpha^{(\kappa+1)/2}\, q_{m-1}(0, b_k^\varepsilon)^{-(\kappa+1)/2}\ \||A_k|^{-\kappa} s_k^{\mathrm{e}}\|_X,$$

where $\alpha = r/(1 - \vartheta^{-1})$.

Proof. Under our assumptions Plato [9, (5.16)] (see also [12, (5.67)]) established the bound

$$\frac{r-2}{r-1}\ \|b_k^\varepsilon - A_k s_{k,m-1}\|_Y \leq \|\mathcal{F}_{r\lambda_{m,1}} p(A_k A_k^*) b_k^\varepsilon\|_Y$$

with the polynomial $p(\lambda) = p_m(\lambda, b_k^\varepsilon)/(1 - \lambda/\lambda_{m,1})$ of degree $m - 1$. The triangle inequality leads to

$$\|\mathcal{F}_{r\lambda_{m,1}} p(A_k A_k^*) b_k^\varepsilon\|_Y \leq \varepsilon \sup_{0 \leq \lambda \leq r\lambda_{m,1}} |p(\lambda)| + \|\mathcal{F}_{r\lambda_{m,1}} p(A_k A_k^*) b_k\|_Y.$$

To bound $\|\mathcal{F}_{r\lambda_{m,1}} p(A_k A_k^*) b_k\|_Y$ we are able to apply exactly the same arguments as were used in estimating $\|\mathcal{F}_{\lambda_{m,1}} \varphi_m(A_k A_k^*) b_k\|_Y$; cf. (B.3). Accordingly, if

$$\sup_{0 \leq \lambda \leq r\lambda_{m,1}} |p(\lambda)| \leq 1 \tag{B.5a}$$

as well as

$$\sup_{0 \leq \lambda \leq r\lambda_{m,1}} \lambda^{(\kappa+1)/2}\, |p(\lambda)| \leq \alpha^{(\kappa+1)/2}\, q_{m-1}(0, b_k^\varepsilon)^{-(\kappa+1)/2}, \tag{B.5b}$$

then Lemma B.2 is true. Assume, for the moment, that

$$r\lambda_{m,1} < 2\,\lambda_{m,2} \quad \text{and} \quad \lambda_{m,1} \leq q_{m-1}(0, b_k^\varepsilon)^{-1}/(1 - \vartheta^{-1}) \tag{B.6}$$

hold true. The left inequality yields $r\lambda_{m,1}/\lambda_{m,j} < 2$, $j = 2, \ldots, m$, whence

$$|p(\lambda)| = \prod_{j=2}^{m} |1 - \lambda/\lambda_{m,j}| < 1 \quad \text{for } 0 < \lambda \leq r\lambda_{m,1}.$$

Therefore, (B.6) implies (B.5) and we are left with verifying (B.6).

First we look into the estimate on the right in (B.6). Since the residual polynomials $\{p_m(\cdot, b_k^\varepsilon)\}_{1 \leq m \leq \boldsymbol{m}_{\mathrm{T}}}$ are orthogonal, their zeros interlace, that is, $\lambda_{m-1,j} < \lambda_{m,j+1}$, $j = 1, \ldots, m-1$. By Lemma 3.1 we therefore have

$$\begin{aligned} q_{m-1}(0, b_k^\varepsilon) &= \lambda_{m,1}^{-1} + \sum_{j=1}^{m-1} \lambda_{m,j+1}^{-1} \\ &< \lambda_{m,1}^{-1} + \sum_{j=1}^{m-1} \lambda_{m-1,j}^{-1} = \lambda_{m,1}^{-1} + q_{m-2}(0, b_k^\varepsilon). \end{aligned} \tag{B.7}$$

The hypothesis $q_{m-2}(0, b_k^\varepsilon) \le \vartheta^{-1}\, q_{m-1}(0, b_k^\varepsilon)$ implies $q_{m-1}(0, b_k^\varepsilon) \le \lambda_{m,1}^{-1} + \vartheta^{-1} q_{m-1}(0, b_k^\varepsilon)$ and thus the right inequality in (B.6). Since

$$\begin{aligned}(\vartheta - 1)\ \lambda_{m-1,1}^{-1} \quad &< \quad (\vartheta - 1) \sum_{j=1}^{m-1} \lambda_{m-1,j}^{-1} \ = \ \vartheta\ q_{m-2}(0, b_k^\varepsilon) - q_{m-2}(0, b_k^\varepsilon) \\ &\overset{\substack{\text{by} \\ \text{assumpt.}}}{\le} \quad q_{m-1}(0, b_k^\varepsilon) - q_{m-2}(0, b_k^\varepsilon) \ \overset{\text{(B.7)}}{<} \ \lambda_{m,1}^{-1},\end{aligned}$$

we obtain $\lambda_{m,1} < (\vartheta - 1)^{-1}\, \lambda_{m-1,1} < (\vartheta - 1)^{-1}\, \lambda_{m,2}$ (interlacing property). In view of $r/(\vartheta - 1) \le 2$ we conclude that the left inequality in (B.6) holds true as well, thereby finishing the proof of Lemma B.2. $\square$

Both latter lemmas merge in the next corollary.

COROLLARY B.3. *Let* (2.1) *hold true and assume the first* n *iterates* $\{x_1, \ldots, x_n\}$ *of* REGINN *exist and stay in* $B_\rho(x^+)$. *Further, let* $x_0 \in B_\rho(x^+)$ *satisfy* (4.2). *Then, to any* $\Theta \in\,]0, 1[$, *there exists a number* a_Θ *such that, for* $0 \le k \le n$,

$$\Theta\, \| b_k^\varepsilon - A_k s_{k,m-1} \|_Y \le \varepsilon + a_\Theta\, q_{m-1}(0, b_k^\varepsilon)^{-(\kappa+1)/2}\ \| |A_k|^{-\kappa} s_k^{\mathrm{e}} \|_X ,$$

where $1 \le m \le \boldsymbol{m}_{\mathrm{T}}(k)$. *The number* a_Θ only *depends on* Θ *and* κ.

Proof. There is exactly one $r = r(\Theta) > 2$ such that $\Theta = \frac{r-2}{r-1}$. Let this r be fixed and define $\vartheta = r/2 + 1 > 2$, that is, $r = 2(\vartheta - 1)$. Exactly one of the following two cases holds true.

1. In the case of $\vartheta\, q_{m-2}(0, b_k^\varepsilon) \le q_{m-1}(0, b_k^\varepsilon)$ the assertion follows immediately from Lemma B.2 when setting

$$a_{\Theta,1} := \Big(\frac{r}{1 - \vartheta^{-1}} \Big)^{(\kappa+1)/2} = \Big(\frac{r}{1 - (r/2 + 1)^{-1}} \Big)^{(\kappa+1)/2} .$$

2. In the case of $q_{m-1}(0, b_k^\varepsilon) < \vartheta\, q_{m-2}(0, b_k^\varepsilon)$ we argue with Lemma B.1. Since $\Theta < 1$ and $q_{m-2}(0, b_k^\varepsilon)^{-1} < \vartheta\, q_{m-1}(0, b_k^\varepsilon)^{-1}$ we have

$$\begin{aligned}\Theta\, \| b_k^\varepsilon - A s_{k,m-1} \|_Y &\le \varepsilon + 2\, q_{m-2}(0, b_k^\varepsilon)^{-(\kappa+1)/2}\ \| |A_k|^{-\kappa} s_k^{\mathrm{e}} \|_X \\ &< \varepsilon + a_{\Theta,2}\, q_{m-1}(0, b_k^\varepsilon)^{-(\kappa+1)/2}\ \| |A_k|^{-\kappa} s_k^{\mathrm{e}} \|_X\end{aligned}$$

with

$$a_{\Theta,2} := 2\ \vartheta^{(\kappa+1)/2} = 2\, (r/2 + 1)^{(\kappa+1)/2} .$$

So, the assertion of Corollary B.3 is verified with $a_\Theta = \max\{a_{\Theta,1}, a_{\Theta,2}\}$. $\square$

Finally we are in a position to verify Lemma 4.3: The μ_k's and R satisfy the requirements of Lemma 2.1. Hence, $\tau_k > 1$ (see (4.3)), and $\tau_k\, \varepsilon \le \| b_k^\varepsilon - A_k s_{k, r_k - 1} \|_Y$ (see (1.5)). Since $1 \le r_k \le \boldsymbol{m}_{\mathrm{T}}(k)$ we obtain

$$\Theta\, \tau_k\, \varepsilon \le \Theta\, \| b_k^\varepsilon - A_k s_{k, r_k - 1} \|_Y \le \varepsilon + a_\Theta\, q_{r_k - 1}(0, b_k^\varepsilon)^{-(\kappa+1)/2}\ \| |A_k|^{-\kappa} s_k^{\mathrm{e}} \|_X$$

by Corollary B.3. A simple rearrangement of terms yields the assertion of Lemma 4.3.

SPECTRAL APPROXIMATION OF THE HELMHOLTZ EQUATION WITH HIGH WAVE NUMBERS*

JIE SHEN[†] AND LI-LIAN WANG[†]

Abstract. A complete error analysis is performed for the spectral-Galerkin approximation of a model Helmholtz equation with high wave numbers. The analysis presented in this paper does not rely on the explicit knowledge of continuous/discrete Green's functions and does not require any mesh condition to be satisfied. Furthermore, new error estimates are also established for multidimensional radial and spherical symmetric domains. Illustrative numerical results in agreement with the theoretical analysis are presented.

Key words. Helmholtz equation, high wave numbers, spectral-Galerkin approximation, error analysis

1. Introduction.

Time harmonic wave propagations appear in many applications, e.g., wave scattering and transmission, noise reduction, fluid-solid interaction, and sea and earthquake wave propagation. In many situations, time harmonic wave propagations are governed by the following Helmholtz equation in an exterior domain with the so-called Sommerfeld radiation boundary condition:

$$\begin{aligned} &-\Delta u - k^2 u = f \qquad \text{in } R^n \backslash D, \\ &u|_{\partial D} = 0, \;\; \partial_r u - \mathrm{i}ku = o\left(\|x\|^{\frac{1-n}{2}}\right) \qquad \text{as } \|x\| \to \infty, \end{aligned} \tag{1.1}$$

where D is a bounded domain in R^n $(n = 1, 2, 3)$, ∂_r is the radial derivative, and k is the nondimensional wave number: $k = \frac{\omega L}{c}$, where ω is a given frequency, L is the measure of the domain, and c is the sound speed in the acoustic medium.

Problem (1.1) presents a great challenge to numerical analysts and computational scientists because (i) the domain is unbounded, and (ii) the solution is highly oscillatory (when k is large) and decays slowly. There is abundant literature on different numerical techniques that have been developed for this problem, such as boundary element methods [5], infinite element methods [11], methods using nonreflecting boundary conditions [14], perfectly matched layers (PML) [2], among others. In many of these approaches, an essential step is to solve the following problem:

$$\begin{aligned} &-\Delta u - k^2 u = f \qquad \text{in } \Omega := B \backslash D, \\ &u|_{\partial D} = 0, \;\; (\partial_r u - \mathrm{i}ku)|_{\partial B} = g, \end{aligned} \tag{1.2}$$

where ∂_r is the outward normal derivative, f, g are given data, and B is a sufficiently large ball containing D.

The analysis and implementation of numerical schemes for (1.2) are challenging when the wave number k is large. The Galerkin finite element method (FEM) for (1.2)

in the one-dimensional case was first carried out in [8], where the well-posedness and error estimates of the Galerkin FEM were established under the condition $k^2h \lesssim 1$ using the Green's function and an argument due to Schatz [21]. A refined analysis for (1.2) in the one-dimensional case was performed in [18] (resp., [19]) for the h version (resp., hp version) of FEM, where the well-posedness and error estimates were established under the condition $kh \lesssim 1$ using the discrete Green's functions. The proofs in these works rely heavily on the use of explicit forms of continuous and/or discrete Green's functions. Hence, it is extremely complicated, if not impossible, to extend to more general cases and higher space dimensions.

On the other hand, the error estimates in the aforementioned papers concluded that the mesh condition $k^2h \lesssim 1$ has to be verified for the error estimates to be independent of k. This so-called pollution effect associated with high wave numbers was discussed in detail in [1]. It is well known [13] that spectral methods are suitable for problems with highly oscillatory solutions since they require fewer grid points per wavelength compared with finite difference methods and FEMs. Furthermore, since the convergence rate of spectral methods increases with the smoothness of the solution, the effect of pollution on the convergence rate of spectral methods is much less significant for smooth (but highly oscillatory) solutions. Hence, it is advantageous to use a spectral method for the Helmholtz equation (1.2) with high wave numbers.

In a recent work [7], Cummings and Feng obtained sharp regularity results for (1.2) in general two- or three-dimensional domains by using Rellich identities instead of using representations in terms of double-layer potentials (cf. [10]). Their analysis not only leads to sharper regularity results but also greatly simplifies the usual process for obtaining a priori estimates and is applicable to general and multidimensional star-shaped domains. Unfortunately, the technique used in [7] cannot be directly applied to Galerkin FEMs because the finite element subspaces do not contain the special test functions used in [7]. However, the situation is different in a spectral-Galerkin method, for which the procedure in [7] can be applied.

We consider in this paper the spectral-Galerkin method for the Helmholtz equation with high wave numbers. In the next section, we set up a prototypical one-dimensional Helmholtz equation which is derived from a multidimensional Helmholtz equation, and we establish its well-posedness; then we derive a priori estimates which are essential for the error analysis. In section 3, we introduce the spectral-Galerkin method and use the same arguments for the space continuous problem to establish the well-posedness and a priori estimates for the discrete problem; then we employ some new optimal Jacobi approximation results to carry out a complete error analysis. In section 4, we consider an alternative formulation which leads to an efficient numerical algorithm and present some illustrative numerical results. We extend our analysis to multidimensional domains in section 5.

We now introduce some notation. Let $\omega(x)$ be a given real weight function in $I = (a, b)$, which is not necessary in $L^1(I)$. We denote by $L^2_\omega(I)$ a Hilbert space of real or complex functions with inner product and norm

$$(u, v)_\omega = \int_I u(r)\overline{v(r)}\omega(r)dr, \qquad \|u\|_\omega = (u, u)_\omega^{\frac{1}{2}},$$

where $\bar{v}$ is the complex conjugate of v. Then the weighted Sobolev spaces $H^s_\omega(I)$ $(s = 0, 1, 2, \dots)$ can be defined as usual with inner products, norms, and seminorms denoted by $(\cdot, \cdot)_{s,\omega}$, $\|\cdot\|_{s,\omega}$, and $|\cdot|_{s,\omega}$, respectively. For real $s > 0$, $H^s_\omega(I)$ is defined by space interpolation. The subscript ω will be omitted from the notation in the case $\omega \equiv 1$. For simplicity, we denote $\partial^l_r v = \frac{d^l v}{dr^l}$, $l \geq 1$.

2. Model equation and a priori estimates. Since a global spectral method is most efficient on regular domains, we shall restrict our attention to the following special cases ($b > a \geq 0$):

- One-dimensional case (1-D): $D = (0, a)$ and $B = (0, b)$.
- Two-dimensional case (2-D): $D = \{(x, y) : x^2 + y^2 < a^2\}$ and $B = \{(x, y) : x^2 + y^2 < b^2\}$.
- Three-dimensional case (3-D): $D = \{(x, y, z) : x^2 + y^2 + z^2 < a^2\}$ and $B = \{(x, y, z) : x^2 + y^2 + z^2 < b^2\}$.

In the 2-D (resp., 3-D) case, we expand functions in polar (resp., spherical) coordinates, i.e., $u = \sum u_m(r)e^{im\theta}$ (resp., $u = \sum u_{lm}(r)Y_{l,m}(\theta, \phi)$, where $\{Y_{l,m}(\theta, \phi)\}$ are the usual spherical harmonic functions). Hence, the problem (1.2) reduces, after a polar (when $n = 2$) or spherical (when $n = 3$) transform, to a sequence (for each m in 2-D and (l, m) in 3-D) of 1-D equations (for brevity, we use u to denote u_m/u_{lm}, and likewise for f and g, below):

$$-\frac{1}{r^{n-1}}\partial_r(r^{n-1}\partial_r u) + d_m\frac{u}{r^2} - k^2 u = f, \quad r \in (a, b),\ n = 1, 2, 3,\ m \geq 0 \tag{2.1}$$

($d_m = 0, m^2, m(m+1)$ for $n = 1, 2, 3$, respectively), with suitable boundary conditions to be specified below.

If $a > 0$, the coefficients r^{n-1} and r^{-2} in (2.1) are uniformly bounded, so (2.1) with $a > 0$ is easier to handle than the case $a = 0$. Hence, for brevity of presentation, we shall be concerned mainly with the case $a = 0$, while some results for $a > 0$ will be stated without proof in section 5. On the other hand, the character of (2.1) does not change with the change of variable: $r \to rb$. Consequently, it suffices to consider the problem (2.1) in $I := (0, 1)$. The appropriate boundary conditions for (2.1) are the pole conditions at $r = 0$,

$$u(0) = 0 \quad \text{if } n = 1 \text{ and if } n = 2 \text{ with } m > 0, \tag{2.2}$$

and the Robin boundary condition (derived from the Sommerfeld radiation boundary condition) at $r = 1$,

$$u'(1) - \mathrm{i}ku(1) = g. \tag{2.3}$$

We note that error estimates for finite element approximations to the Helmholtz equation (2.1) with high wave numbers were derived in [8, 18, 19] for the 1-D case, and in [9, 6] for 2-D cases and in [12] for the 1-D Bessel equation reduced from a 3-D spherical domain, respectively.

Let $\mathbb{N}$ be the set of all nonnegative integers and let P_N be the space of all polynomials of degree at most N. We shall use c to denote a generic positive constant independent of any function, the wave frequency k, the radial/spherical frequency m, and the number of modes N. We use the expression $A \lesssim B$ to mean that there exists a generic positive constant c such that $A \leq cB$.

2.1. Variational formulation and weak solution. Let us denote $\omega^\alpha(r) = r^\alpha$ and $\omega(r) = r$. We define a Hilbert space,

$$X := X(m, n) := \{u \in H^1_{\omega^{n-1}}(I) :\ u \in L^2_{\omega^{n-3}}(I) \text{ for } n = 2, 3;\ u \text{ satisfies (2.2)}\},$$

and a sesquilinear form on $X \times X$,

$$\begin{aligned} \mathcal{B}(u, v) := \mathcal{B}_{mn}(u, v) := (\partial_r u, \partial_r v)_{\omega^{n-1}} + d_m(u, v)_{\omega^{n-3}} - k^2(u, v)_{\omega^{n-1}} \\ - \mathrm{i}ku(1)\overline{v(1)}. \end{aligned} \tag{2.4}$$

Note that to lighten the presentation, we will often omit m and n from the notation.

Then the weak formulation of (2.1)–(2.2) is to find $u \in X$ such that

$$\mathcal{B}(u,v) = (f,v)_{\omega^{n-1}} + g\overline{v(1)} \;\; \forall v \in X, \;\; n = 1,2,3. \tag{2.5}$$

THEOREM 2.1. *Given $f \in X'$, the problem* (2.5) *admits a unique weak solution.*

Proof. This result with $n = 1$ was established in [8, 18]. Hence, we shall prove only the cases with $n = 2$ and 3.

We first consider the uniqueness. It suffices to show that $u = 0$ is the only solution of the problem (2.5) with $f \equiv 0$ and $g = 0$.

Taking $v = u$ in (2.5) with $f \equiv 0$ and $g = 0$, we find from (2.4) that

$$\mathcal{B}(u,u) = \|\partial_r u\|^2_{\omega^{n-1}} + d_m\|u\|^2_{\omega^{n-3}} - k^2\|u\|^2_{\omega^{n-1}} - \mathrm{i}k|u(1)|^2 = 0, \tag{2.6}$$

which implies immediately $u(1) = 0$.

Next, let $J_\mu(r)$ be the Bessel function of the first kind of order μ. We recall that

$$\phi_m(r;h,n) := \begin{cases} J_m(hr), & n = 2, \; r,h > 0, \\ \frac{1}{\sqrt{r}} J_{m+\frac{1}{2}}(hr), & n = 3, \; r,h > 0, \end{cases} \tag{2.7}$$

is the solution of the modified Bessel equation (cf. [25]):

$$-\frac{1}{r^{n-1}}\partial_r(r^{n-1}\partial_r\phi_m) - \Big(h^2 - \frac{d_m}{r^2}\Big)\phi_m = 0, \;\; n = 2,3, \; m \geq 0. \tag{2.8}$$

Let $\{\xi_j\}_{j=1}^\infty$ be the set of all positive real zeros of the Bessel function $J_{m+\frac{n}{2}-1}(r)$. Then $\{\phi_m(r;\xi_j,n)\}_{j=1}^\infty$ forms a complete orthogonal system in $L^2_{\omega^{n-1}}(I)$ (cf. [26]), namely,

$$\begin{aligned} &\int_0^1 \phi_m(r;\xi_j,n)\phi_m(r;\xi_l,n) r^{n-1} dr \\ &= \int_0^1 J_{m+\frac{n}{2}-1}(r\xi_j) J_{m+\frac{n}{2}-1}(r\xi_l) r dr = \frac{1}{2} J^2_{m+\frac{n}{2}}(\xi_j)\delta_{j,l}. \end{aligned} \tag{2.9}$$

Since $u \in L^2_{\omega^{n-1}}(I)$, we can write

$$u(r) = \sum_{j=1}^\infty \tilde{u}_m^{(j)} \phi_m(r;\xi_j,n), \tag{2.10}$$

with

$$\tilde{u}_m^{(j)} = \frac{1}{\gamma_m^{(j)}} \int_0^1 u(r)\phi_m(r;\xi_j,n) r^{n-1} dr, \quad \gamma_m^{(j)} = \frac{1}{2} J^2_{m+\frac{n}{2}}(\xi_j). \tag{2.11}$$

Thanks to $u(1) = 0$, we derive from (2.8) with $h = \xi_j$, (2.11), and integration by parts that

$$\begin{aligned} 0 = \mathcal{B}(u,\phi_m) &= \int_0^1 u(r)\Big\{ -\frac{1}{r^{n-1}}\partial_r(r^{n-1}\partial_r\phi_m) - \Big(k^2 - \frac{d_m}{r^2}\Big)\phi_m\Big\} r^{n-1} dr \\ &= (\xi_j^2 - k^2)\int_0^1 u(r)\phi_m(r;\xi_j,n) r^{n-1} dr = (\xi_j^2 - k^2)\gamma_m^{(j)}\tilde{u}_m^{(j)}. \end{aligned} \tag{2.12}$$

If $J_{m+\frac{n}{2}-1}(k) \neq 0$ (i.e., $k \neq \xi_j$ for all $j \geq 1$), then (2.12) implies $\tilde{u}_m^{(j)} = 0$ for all j. Accordingly, we have $u \equiv 0$ (cf. (2.10)).

On the other hand, if $J_{m+\frac{n}{2}-1}(k) = 0$, then $k = \xi_{j_0}$ for some $j_0 \geq 1$. We then derive from (2.12) that $\tilde{u}_m^{(j)} = 0$ for all $j \neq j_0$. Thus, by (2.10),

$$u(r) = \tilde{u}_m^{(j_0)} \phi_m(r; \xi_{j_0}, n), \tag{2.13}$$

and it remains to verify $\tilde{u}_m^{(j_0)} = 0$. Due to $u(1) = 0$, integration by parts yields

$$\int_0^1 \partial_r u(r) \partial_r (r^m) r^{n-1} dr = -d_m \int_0^1 u(r) r^{m+n-3} dr, \quad n = 2, 3,\ m \geq 0. \tag{2.14}$$

Taking $v = r^m (\in X)$ in (2.5), we obtain from (2.13) that

$$\begin{aligned} 0 &= \mathcal{B}(u, r^m) = \tilde{u}_m^{(j_0)} \mathcal{B}(\phi_m(\cdot; \xi_{j_0}, n), r^m) \\ &= -k^2 \tilde{u}_m^{(j_0)} \int_0^1 \phi_m(r; \xi_{j_0}, n) r^{m+n-1} dr = -k^2 \tilde{u}_m^{(j_0)} \int_0^1 J_{m+\frac{n}{2}-1}(r\xi_{j_0}) r^{m+\frac{n}{2}} dr. \end{aligned} \tag{2.15}$$

We recall that $r^\mu,\ \mu \geq 0$, can be expanded as (see [26, p. 581])

$$r^\mu = \sum_{j=1}^{\infty} \frac{2 J_\mu(r\xi_j)}{\xi_j J_{\mu+1}(\xi_j)}, \quad 0 \leq r < 1. \tag{2.16}$$

Inserting (2.16) with $\mu = m + \frac{n}{2} - 1$ into (2.15) and using the orthogonality (2.9) lead to

$$0 = -k^2 \tilde{u}_m^{(j_0)} \int_0^1 J_{m+\frac{n}{2}-1}(r\xi_{j_0}) r^{m+\frac{n}{2}} dr = -k^2 \tilde{u}_m^{(j_0)} \frac{J_{m+\frac{n}{2}}(\xi_{j_0})}{\xi_{j_0}}.$$

This implies $\tilde{u}_m^{(j_0)} = 0$. Hence, we have $u \equiv 0$, which implies the uniqueness.

To prove the existence, we note from (2.6) that the following Gårding-type inequality holds:

$$\mathrm{Re}(\mathcal{B}(u, u)) \geq \|\partial_r u\|_{\omega^{n-1}}^2 + d_m \|u\|_{\omega^{n-3}}^2 - k^2 \|u\|_{\omega^{n-1}}^2. \tag{2.17}$$

Since all the arguments above apply also to the dual problem of (2.5), by the classical Fredholm alternative argument (see, for instance, [20, p. 194]); problem (2.5) either has a nontrivial solution with $f \equiv 0$ and $g = 0$ or it has at least one solution for every $f \in X'$. Since the uniqueness is proved, existence follows from the above argument. □

2.2. A priori estimates.

THEOREM 2.2. *If $f \in L^2_{\omega^{n-1}}(I)$, we have*

$$\|\partial_r u\|_{\omega^{n-1}} + \sqrt{d_m} \|u\|_{\omega^{n-3}} + k \|u\|_{\omega^{n-1}} \lesssim |g| + \|f\|_{\omega^{n-1}}, \quad n = 1, 2, 3. \tag{2.18}$$

Proof. The proof consists of taking two different test functions in (2.5). The first test function is the usual one. As in [7], the key step is to choose a suitable second test function which enables us to obtain a priori estimates without using the Green's functions as in [8, 18, 19]. In the following proof, $\varepsilon_j > 0,\ 1 \leq j \leq 5$, are adjustable real numbers.

Step 1. We take $v = u$ in (2.5) whose imaginary and real parts are as follows:

$$\begin{aligned} &-k|u(1)|^2 = \mathrm{Im}(g\overline{u(1)}) + \mathrm{Im}(f,u)_{\omega^{n-1}},\\ &\|\partial_r u\|^2_{\omega^{n-1}} + d_m\|u\|^2_{\omega^{n-3}} - k^2\|u\|^2_{\omega^{n-1}} = \mathrm{Re}(g\overline{u(1)}) + \mathrm{Re}(f,u)_{\omega^{n-1}}. \end{aligned} \tag{2.19}$$

Applying the Cauchy–Schwarz inequality to the imaginary part, we obtain

$$\begin{aligned} k|u(1)|^2 &\le |\mathrm{Im}(g\overline{u(1)})| + |\mathrm{Im}(f,u)_{\omega^{n-1}}|,\\ &\le \frac{k}{2}|u(1)|^2 + \frac{1}{2k}|g|^2 + \frac{\varepsilon_1 k}{2}\|u\|^2_{\omega^{n-1}} + \frac{1}{2\varepsilon_1 k}\|f\|^2_{\omega^{n-1}}; \end{aligned} \tag{2.20}$$

likewise, we obtain from the real part that

$$\begin{aligned} &\|\partial_r u\|^2_{\omega^{n-1}} + d_m\|u\|^2_{\omega^{n-3}} \le k^2\|u\|^2_{\omega^{n-1}} + |\mathrm{Re}(g\overline{u(1)})| + |\mathrm{Re}(f,u)_{\omega^{n-1}}|\\ &\quad\le k^2\|u\|^2_{\omega^{n-1}} + \varepsilon_2 k^2|u(1)|^2 + \frac{1}{4\varepsilon_2 k^2}|g|^2 + \frac{\varepsilon_3 k^2}{2}\|u\|^2_{\omega^{n-1}} + \frac{1}{2\varepsilon_3 k^2}\|f\|^2_{\omega^{n-1}}. \end{aligned} \tag{2.21}$$

Therefore, by (2.20),

$$|u(1)|^2 \le \varepsilon_1\|u\|^2_{\omega^{n-1}} + \frac{1}{k^2}|g|^2 + \frac{1}{\varepsilon_1 k^2}\|f\|^2_{\omega^{n-1}}, \tag{2.22}$$

and by (2.21)–(2.22) with $\varepsilon_2 = \frac{\varepsilon_3}{2\varepsilon_1}$,

$$\begin{aligned} \|\partial_r u\|^2_{\omega^{n-1}} + d_m\|u\|^2_{\omega^{n-3}} &\le (1+\varepsilon_3)k^2\|u\|^2_{\omega^{n-1}}\\ &+ \Big(\frac{\varepsilon_3}{2\varepsilon_1} + \frac{\varepsilon_1}{2\varepsilon_3 k^2}\Big)|g|^2 + \Big(\frac{\varepsilon_3}{2\varepsilon_1^2} + \frac{1}{2\varepsilon_3 k^2}\Big)\|f\|^2_{\omega^{n-1}}. \end{aligned} \tag{2.23}$$

It remains to bound $k^2\|u\|^2_{\omega^{n-1}}$.

Step 2. Using a usual regularity argument, one can easily derive that, for $f \in L^2_{\omega^{n-1}}(I)$, the weak solution of (2.5) satisfies $r\partial_r u \in X$, and we now consider the real part of (2.5) with $v = 2r\partial_r u$. After integrating by parts, the first three terms become

$$2\mathrm{Re}(\partial_r u, \partial_r(r\partial_r u))_{\omega^{n-1}} = |\partial_r u(1)|^2 + (2-n)\|\partial_r u\|^2_{\omega^{n-1}}; \tag{2.24a}$$

$$2\mathrm{Re}(u, r\partial_r u)_{\omega^{n-3}} = |u(1)|^2 + (2-n)\|u\|^2_{\omega^{n-3}}; \tag{2.24b}$$

$$-2k^2\mathrm{Re}(u, r\partial_r u)_{\omega^{n-1}} = -k^2|u(1)|^2 + nk^2\|u\|^2_{\omega^{n-1}}. \tag{2.24c}$$

Consequently, the real part of (2.5) with $v = 2r\partial_r u$ is

$$\begin{aligned} &(2-n)\Big(\|\partial_r u\|^2_{\omega^{n-1}} + d_m\|u\|^2_{\omega^{n-3}}\Big) + nk^2\|u\|^2_{\omega^{n-1}} + |\partial_r u(1)|^2 + d_m|u(1)|^2\\ &\qquad = k^2|u(1)|^2 + 2\mathrm{Re}\Big((\mathrm{i}ku(1) + g)\overline{\partial_r u(1)}\Big) + 2\mathrm{Re}(f, r\partial_r u)_{\omega^{n-1}}. \end{aligned} \tag{2.25}$$

We now proceed separately for the three different cases.

Case (i): $n = 1$. Thanks to $d_m = 0$, we derive from (2.25) and the Cauchy–Schwarz inequality that
