$$\begin{aligned} \|\partial_r u\|^2 + k^2\|u\|^2 + |\partial_r u(1)|^2 &\le k^2|u(1)|^2 + \frac{1}{2}|\partial_r u(1)|^2\\ &+ 2k^2|u(1)|^2 + 2|g|^2 + \frac{1}{2}\|\partial_r u\|^2 + 2\|f\|^2. \end{aligned} \tag{2.26}$$

Hence, we obtain from (2.22) that

$$\begin{aligned}\frac{1}{2}\|\partial_r u\|^2 + k^2\|u\|^2 + \frac{1}{2}|\partial_r u(1)|^2 &\le 3\varepsilon_1 k^2\|u\|^2 + c\Big(|g|^2 + (\varepsilon_1^{-1}+2)\|f\|^2\Big)\\ &\le \frac{k^2}{2}\|u\|^2 + c(|g|^2+\|f\|^2),\end{aligned} \tag{2.27}$$

where we have taken $\varepsilon_1 = \frac{1}{6}$ to derive the last inequality. This implies (2.18) with $n = 1$.

Case (ii): $n = 2$. Similarly, we have from (2.22), (2.23), and (2.25) that

$$\begin{aligned}2k^2\|u\|_\omega^2 + |\partial_r u(1)|^2 + d_m|u(1)|^2 &\le \frac{1}{2}|\partial_r u(1)|^2 + 3k^2|u(1)|^2\\ &\quad + 2|g|^2 + \varepsilon_4\|\partial_r u\|_\omega^2 + \varepsilon_4^{-1}\|f\|_\omega^2\\ &\le \frac{1}{2}|\partial_r u(1)|^2 + \Big(3\varepsilon_1 + \varepsilon_4(1+\varepsilon_3)\Big)k^2\|u\|_\omega^2 + C_1|g|^2 + C_2\|f\|_\omega^2,\end{aligned}$$

where C_1 and C_2 are two positive constants in terms of $\varepsilon_1, \varepsilon_3$, and ε_4. We take $\varepsilon_1 = 1/6$, $\varepsilon_3 = 1$, $\varepsilon_4 = 1/4$ and obtain that

$$k^2\|u\|_\omega^2 + d_m|u(1)|^2 + \frac{1}{2}|\partial_r u(1)|^2 \lesssim |g|^2 + \|f\|_\omega^2. \tag{2.28}$$

A combination of (2.23) and (2.28) leads to (2.18) with $n = 2$.

Case (iii): $n = 3$. As in the derivation of Case (ii), using (2.22), (2.23), and (2.25) yields

$$\begin{aligned}3k^2\|u\|_{\omega^2}^2 + |\partial_r u(1)|^2 + d_m|u(1)|^2 &\le \|\partial_r u\|_{\omega^2}^2 + d_m\|u\|^2 + \frac{1}{2}|\partial_r u(1)|^2 + 3k^2|u(1)|^2\\ &\quad + 2|g|^2 + \varepsilon_5\|\partial_r u\|_{\omega^2}^2 + \varepsilon_5^{-1}\|f\|_{\omega^2}^2\\ &\le \frac{1}{2}|\partial_r u(1)|^2 + \Big(3\varepsilon_1 + (1+\varepsilon_5)(1+\varepsilon_3)\Big)k^2\|u\|_{\omega^2}^2 + C_3|g|^2 + C_4\|f\|_{\omega^2}^2,\end{aligned}$$

where C_3 and C_4 are two positive constants depending only on $\varepsilon_1, \varepsilon_3$, and ε_5. Taking $\varepsilon_1 = 2/27$ and $\varepsilon_3 = \varepsilon_5 = 1/3$ such that $3\varepsilon_1 + (1+\varepsilon_5)(1+\varepsilon_3) = 2$ gives

$$k^2\|u\|_{\omega^2}^2 + d_m|u(1)|^2 + \frac{1}{2}|\partial_r u(1)|^2 \lesssim |g|^2 + \|f\|_{\omega^2}^2. \tag{2.29}$$

This completes the proof. □

Remark 2.1. We have also proved that

$$|\partial_r u(1)| + \sqrt{d_m}|u(1)| + k|u(1)| \lesssim |g| + \|f\|_{\omega^{n-1}}, \quad n = 1, 2, 3. \tag{2.30}$$

Remark 2.2. A combination of (2.1) and (2.18) leads to

$$|u|_2 \lesssim k|g| + (1+k)\|f\| \quad \text{if } n = 1, \tag{2.31a}$$

$$\|D^2 u\| \lesssim k|g| + (1+k)\|f\|_{\omega^{n-1}} \quad \text{if } n = 2, 3, \tag{2.31b}$$

where $D^2 u = -\partial_r(r^{n-1}\partial_r u) + d_m r^{n-3}u$.

3. Spectral-Galerkin approximation. In this section, we shall present the spectral-Galerkin scheme and analyze its errors in suitably weighted Sobolev spaces.

3.1. Spectral-Galerkin solution. Let us denote $X_N := X \cap P_N$, where P_N is the space of all polynomials of degree at most N. The spectral-Galerkin approximation of (2.5) is to find $u_N \in X_N$ such that

$$\mathcal{B}(u_N, v_N) = (f, v_N)_{\omega^{n-1}} + g\overline{v_N(1)} \quad \forall v_N \in X_N. \tag{3.1}$$

We observe that the sesquilinear form $\mathcal{B}(\cdot,\cdot)$ is not coercive in $X_N \times X_N$. To prove the well-posedness of (3.1) with $n = 1$, Douglas et al. [8] used an argument due to Schatz [21] for the (finite element) discrete system under the condition $k^2h \lesssim 1$, while Ihlenburg and Babuška [18] used an inf-sup argument due to Babuška and Brezzi under the condition $kh \lesssim 1$. However, the spectral-Galerkin approximation space X_N, unlike in the Galerkin FEM, has the following property: *For $u_N \in X_N$, we have $r\partial_r u_N \in X_N$. Hence, the proof of Theorem* 2.2 *is also valid for the discrete system* (3.1); i.e., we have the following.

THEOREM 3.1. *Let u_N be a solution of* (3.1). *Then Theorem* 2.2 *holds with u_N in place of u.*

An immediate consequence is the following.

COROLLARY 3.1. *The problem* (3.1) *admits a unique solution.*

Proof. Since (3.1) is a finite-dimensional linear system, it suffices to prove the uniqueness. Now, let u_N be a solution of (3.1) with $f \equiv 0$ and $g = 0$. We derive from Theorem 3.1 that $u_N \equiv 0$, which implies the uniqueness. □

Remark 3.1. It is interesting to note that while the existence of a solution for finite element approximations to the Helmholtz equation is guaranteed only under a mesh condition $kh \lesssim 1$ (see, for instance, [8, 18]), the spectral-Galerkin approximation (3.1) always admits a unique solution, just as (2.1) itself.

3.2. Error estimates. Thanks to Theorems 2.2 and 3.1, we can analyze the errors of the proposed scheme by comparing the numerical solution with some orthogonal projection of the exact solution as usual. For this purpose, let $\Pi^{1,m}_{N,n} : X \to X_N$ be an orthogonal projection, defined by

$$(\partial_r(u - \Pi^{1,m}_{N,n}u),\ \partial_r v_N)_{\omega^{n-1}} = 0 \quad \forall v_N \in X_N,\ \ n = 1, 3\ \ \forall m \text{ and } n = 2 \text{ with } m = 0. \tag{3.2}$$

In order to estimate the errors between u and u_N, we have to analyze the approximation properties of the projector $\Pi^{1,m}_{N,n}$ for functions in the following suitably weighted Sobolev spaces:

$$\widetilde{H}^s_{\omega^{n-1}}(I) := \{u\ :\ u \in L^2_{\omega^{n-1}}(I),\ (r - r^2)^{\frac{k-1}{2}}\partial^k_r u \in L^2_{\omega^{n-1}}(I),\ 1 \le k \le s\},$$

with the norm and seminorm

$$\|u\|_{\widetilde{H}^s_{\omega^{n-1}}} = \Big(\|u\|^2_{\omega^{n-1}} + \sum_{k=1}^{s} \|(r - r^2)^{\frac{k-1}{2}}\partial^k_r u\|^2_{\omega^{n-1}}\Big)^{\frac{1}{2}},$$
$$|u|_{\widetilde{H}^s_{\omega^{n-1}}} = \|(r - r^2)^{\frac{s-1}{2}}\partial^s_r u\|_{\omega^{n-1}}, \quad s \ge 1,\ s \in \mathbb{N}.$$

LEMMA 3.1. *For any $u \in X \cap \widetilde{H}^s_{\omega^{n-1}}(I)$, with $s \ge 1$ and $s \in \mathbb{N}$,*

$$\|\Pi^{1,m}_{N,n}u - u\|_{\mu,\omega^{n-1}} \lesssim N^{\mu-s}\|(r - r^2)^{\frac{s-1}{2}}\partial^s_r u\|_{\omega^{n-1}}, \tag{3.3}$$
$$\mu = 0, 1, \quad n = 1, 3\ \ \forall m \text{ and } n = 2 \text{ with } m = 0.$$

Proof. This result for $n = 1$ can be derived from [4] with an improvement of the norm in terms of the weights $(r - r^2)^{\frac{s-1}{2}}$ given in [16]. For $n = 2$ with $m = 0$ and $n = 3$, one can refer to [15, 16] for the proofs. □

Next, we shall estimate $e_N = u_N - \Pi^{1,m}_{N,n} u$. We denote $\tilde{e}_N = u - \Pi^{1,m}_{N,n} u$.

LEMMA 3.2. *Let u and u_N be, respectively, the solutions of* (2.5) *and* (3.1). *Then we have, for $n = 1, 3$ for all m and $n = 2$ with $m = 0$,*

$$\begin{aligned}(3.4)\qquad &\|\partial_r e_N\|_{\omega^{n-1}} + \sqrt{d_m}\|e_N\|_{\omega^{n-3}} + k\|e_N\|_{\omega^{n-1}} \\ &\quad\lesssim \sqrt{d_m}\Big(\|\partial_r \tilde{e}_N\|_{\omega^{n-1}} + \|\tilde{e}_N\|_{\omega^{n-3}}\Big) + k^2\|\tilde{e}_N\|_{\omega^{n-1}} + k(1 + d_m k^{-2})|\tilde{e}_N(1)|.\end{aligned}$$

Proof. By (2.5) and (3.1), we have $\mathcal{B}(u - u_N, v_N) = 0$ for all $v_N \in X_N$. Hence, we derive from (2.5) and (3.2) that, for any $v_N \in X_N$,

$$\begin{aligned}(3.5)\qquad \mathcal{B}(e_N, v_N) &= \mathcal{B}(u - \Pi^{1,m}_{N,n} u, v_N) \\ &= d_m(\tilde{e}_N, v_N)_{\omega^{n-3}} - k^2(\tilde{e}_N, v_N)_{\omega^{n-1}} - \mathrm{i}k\tilde{e}_N(1)\overline{v_N(1)}.\end{aligned}$$

We can view (3.5) in the form of (2.5) with $u = e_N$, $g = -\mathrm{i}k\tilde{e}_N(1)$, $f = -k^2\tilde{e}_N$ plus an extra term $d_m(\tilde{e}_N, v_N)_{\omega^{n-3}}$. Hence, as in the proof of Theorem 2.2, we take two different test functions $v_N = e_N, r\partial_r e_N \in X_N$ and estimate the extra term by

$$\begin{aligned} d_m|(\tilde{e}_N, e_N)_{\omega^{n-3}}| &\le \varepsilon_6 d_m\|e_N\|^2_{\omega^{n-3}} + \frac{d_m}{4\varepsilon_6}\|\tilde{e}_N\|^2_{\omega^{n-3}}, \\ d_m|(\tilde{e}_N, r\partial_r e_N)_{\omega^{n-3}}| &= d_m|\tilde{e}_N(1)\overline{e_N(1)} - (\partial_r\tilde{e}_N, e_N)_{\omega^{n-2}} - (n-2)(\tilde{e}_N, e_N)_{\omega^{n-3}}| \\ &\le \varepsilon_7 k^2|e_N(1)|^2 + \frac{d_m^2}{4k^2\varepsilon_7}|\tilde{e}_N(1)|^2 + \varepsilon_8 d_m\|e_N\|^2_{\omega^{n-3}} \\ &\quad + \frac{c d_m}{4\varepsilon_8}\Big(\|\partial_r\tilde{e}_N\|^2_{\omega^{n-1}} + \|\tilde{e}_N\|^2_{\omega^{n-3}}\Big).\end{aligned}$$

Thus, choosing suitable constants $\{\varepsilon_j\}_{j=6}^{8}$, and following a procedure similar to the proof of Theorem 2.2, we can derive

$$\begin{aligned}(3.6)\qquad &\|\partial_r e_N\|^2_{\omega^{n-1}} + d_m\|e_N\|^2_{\omega^{n-3}} + k^2\|e_N\|^2_{\omega^{n-1}} \\ &\quad\lesssim d_m(\|\partial_r\tilde{e}_N\|^2_{\omega^{n-1}} + \|\tilde{e}_N\|^2_{\omega^{n-3}}) + k^4\|\tilde{e}_N\|^2_{\omega^{n-1}} + k^2(1 + d_m^2 k^{-4})|\tilde{e}_N(1)|^2,\end{aligned}$$

which leads to the desired result. □

We now recall the following inequalities.

LEMMA 3.3.

$$(3.7a)\qquad |u(1)| \lesssim \|u\|^{\frac{1}{2}}_{\omega^{n-1}}\|u\|^{\frac{1}{2}}_{1,\omega^{n-1}} \quad \forall u \in H^1_{\omega^{n-1}}(I), \ \ n = 1, 2, 3,$$

$$(3.7b)\qquad \|u\| \lesssim \|u\|_{1,\omega^2} \quad \forall u \in H^1_{\omega^2}(I).$$

Proof. By the Sobolev inequality (see the appendix in [4]),

$$|u(1)| \lesssim \|u\|^{\frac{1}{2}}_{L^2(1/2,1)}\|u\|^{\frac{1}{2}}_{H^1(1/2,1)} \lesssim \|u\|^{\frac{1}{2}}_{L^2_{\omega^{n-1}}(1/2,1)}\|u\|^{\frac{1}{2}}_{H^1_{\omega^{n-1}}(1/2,1)} \lesssim \|u\|^{\frac{1}{2}}_{\omega^{n-1}}\|u\|^{\frac{1}{2}}_{1,\omega^{n-1}}.$$

Here, we used the fact that the weight function r^{n-1} is uniformly bounded on $[1/2, 1]$. The inequality (3.7b) follows directly from formula (13.5) of [3]. □

As a consequence of (3.7b) and Lemma 3.1, we derive that for $n=3$,

$$\|\Pi_{N,n}^{1,m}u-u\|_{\omega^{n-3}} \lesssim \|\Pi_{N,n}^{1,m}u-u\|_{1,\omega^{n-1}} \lesssim N^{1-s}\|(r-r^2)^{\frac{s-1}{2}}\partial_r^s u\|_{\omega^{n-1}}. \tag{3.8}$$

With the above preparations, we can now prove our main results.

THEOREM 3.2. *Let u and u_N be, respectively, the solutions of* (2.5) *and* (3.1) *such that $u \in X \cap \widetilde{H}^s_{\omega^{n-1}}(I)$ with $s \geq 1, s \in \mathbb{N}$.*

(i) *For $n=1$ or $n=2,3, m=0$,*

$$\|\partial_r(u-u_N)\|_{\omega^{n-1}} + k\|u-u_N\|_{\omega^{n-1}} \lesssim (1+k^2N^{-1})N^{1-s}\|(r-r^2)^{\frac{s-1}{2}}\partial_r^s u\|_{\omega^{n-1}}. \tag{3.9}$$

(ii) *For $n=3$ and $m>0$,*

$$\begin{aligned}&\|\partial_r(u-u_N)\|_{\omega^2} + \sqrt{d_m}\|u-u_N\| + k\|u-u_N\|_{\omega^2}\\ &\quad\lesssim \Big(\sqrt{d_m}+d_m^2k^{-4}+k^2N^{-1}\Big)N^{1-s}\|(r-r^2)^{\frac{s-1}{2}}\partial_r^s u\|_{\omega^2},\end{aligned} \tag{3.10}$$

where $d_m = m(m+1)$.

Proof. We first prove (3.9). Since

$$\begin{aligned}\|\partial_r(u-u_N)\|_{\omega^{n-1}} + k\|u-u_N\|_{\omega^{n-1}} &\lesssim \|\partial_r(\Pi_{N,n}^{1,m}u-u)\|_{\omega^{n-1}}\\ &\quad+ k\|\Pi_{N,n}^{1,m}u-u\|_{\omega^{n-1}} + \|\partial_r e_N\|_{\omega^{n-1}} + k\|e_N\|_{\omega^{n-1}},\end{aligned}$$

formula (3.9) follows from Lemmas 3.1 and 3.2 and (3.7a).

Similarly, for $n=3$ and $m>0$, we derive from (3.7a) and Lemmas 3.1 and 3.2 that

$$\begin{aligned}&\|\partial_r(u-u_N)\|_{\omega^{n-1}} + \sqrt{d_m}\|u-u_N\|_{\omega^{n-3}} + k\|u-u_N\|_{\omega^{n-1}}\\ &\quad\lesssim \sqrt{d_m}\Big(\|\partial_r(\Pi_{N,n}^{1,m}u-u)\|_{\omega^{n-1}} + \|\Pi_{N,n}^{1,m}u-u\|_{\omega^{n-3}}\Big)\\ &\qquad+ k^2\|\Pi_{N,n}^{1,m}u-u\|_{\omega^{n-1}} + k(1+d_mk^{-2})|(\Pi_{N,n}^{1,m}u-u)(1)|\\ &\quad\lesssim \sqrt{d_m}\Big(\|\partial_r(\Pi_{N,n}^{1,m}u-u)\|_{\omega^{n-1}} + \|\Pi_{N,n}^{1,m}u-u\|_{\omega^{n-3}}\Big)\\ &\qquad+ 2k^2\|\Pi_{N,n}^{1,m}u-u\|_{\omega^{n-1}} + (1+d_mk^{-2})^2\|\Pi_{N,n}^{1,m}u-u\|_{1,\omega^{n-1}}\\ &\quad\lesssim \Big(\sqrt{d_m}+(1+d_mk^{-2})^2+k^2N^{-1}\Big)N^{1-s}\|(r-r^2)^{\frac{s-1}{2}}\partial_r^s u\|_{\omega^{n-1}}\\ &\qquad+ \sqrt{d_m}\|\Pi_{N,n}^{1,m}u-u\|_{\omega^{n-3}}.\end{aligned} \tag{3.11}$$

Hence, we can obtain (3.10) by using (3.8) to estimate the last term in (3.11). □

Remark 3.2. For $n=1$, an error estimate of the same order as in (3.9) was derived in [19] for the *hp* FEM under the condition $kh \lesssim 1$. Our estimate is valid without any restriction on k and N and is bounded by a weaker weighted seminorm.

Although we believe that the estimate (3.10), modulo perhaps a logarithmic term, is also valid for the case $n=2$ with $m>0$, the above proof cannot be directly extended to this case due to a breakdown in the Hardy inequality (cf. [17]) as $\varepsilon \to 0$,

$$\int_0^1 \frac{u^2}{r^2}r^{1-\varepsilon}dr \leq \frac{4}{\varepsilon}\int_0^1 (\partial_r u)^2 r^{1-\varepsilon}dr, \tag{3.12}$$

which indicates that $\|\Pi^{1,m}_{N,n}u - u\|_{\omega^{-1}}$ in the last term of (3.11) cannot be bounded by $\|\partial_r(\Pi^{1,m}_{N,n}u - u)\|_\omega$.

Next, we perform the error estimate for the case $n = 2$ with $m > 0$ by using a different approach.

Let $a_m(u, v) := (\partial_r u, \partial_r v)_\omega + d_m(u, v)_{\omega^{-1}}$ and define the orthogonal projection $\pi^{1,m}_N : X \to X_N$ by

$$a_m(\pi^{1,m}_N u - u, v_N) = 0 \quad \forall v_N \in X_N. \tag{3.13}$$

To analyze the approximation properties of the above projector, we first consider an auxiliary projection. Let $\hat\omega = r(1-r)$, let $P^0_N := \{u \in P_N : u(0) = u(1) = 0\}$, and let π_N be the $L^2_{\hat\omega^{-1}}$-orthogonal projection onto P^0_N defined by

$$(\pi_N u - u, v_N)_{\hat\omega^{-1}} = 0 \quad \forall v_N \in P^0_N.$$

The following result can be derived directly from the generalized Jacobi approximation with parameters $\alpha = \beta = -1$ (cf. Theorem 3.1 of [24]).

Lemma 3.4. *For any $u \in L^2_{\hat\omega^{-1}}(I) \cap \widetilde{H}^s(I)$ with $s \geq 1, s \in \mathbb{N}$,*

$$\|\partial_r(\pi_N u - u)\| + N\|(\pi_N u - u)\|_{\hat\omega^{-1}} \lesssim N^{1-s}\|(r - r^2)^{\frac{s-1}{2}}\partial^s_r u\|. \tag{3.14}$$

Corollary 3.2. *There exists an operator $\pi^1_N : H^1(I) \to P_N$ such that $(\pi^1_N u)(r) = u(r)$ for $r = 0, 1$ and for any $u \in \widetilde{H}^s(I)$, with $s \geq 1, s \in \mathbb{N}$,*

$$\|\partial_r(\pi^1_N u - u)\| + N\|\pi^1_N u - u\|_{\hat\omega^{-1}} \lesssim N^{1-s}\|(r - r^2)^{\frac{s-1}{2}}\partial^s_r u\|. \tag{3.15}$$

Proof. Let $u_*(r) = (1-r)u(0) + ru(1) \in P_1$ for all $u \in H^1(I)$. By construction, we have $(u - u_*)(r) = 0$ for $r = 0, 1$. Next, we derive from the Hardy inequality (cf. [17]) that

$$\begin{aligned} \Big(\int_0^1 (u-u_*)^2(r-r^2)^{-1}dr\Big)^{\frac12} &\lesssim \Big(\int_0^1 (\partial_r(u-u_*))^2 dr\Big)^{\frac12} \\ &\lesssim \|\partial_r u\| + |u(1) - u(0)| \lesssim \|\partial_r u\| + \int_0^1 |\partial_r u| dr \lesssim \|\partial_r u\|. \end{aligned} \tag{3.16}$$

Hence, $u - u_* \in L^2_{\hat\omega^{-1}}(I)$ and we can define

$$\pi^1_N u = \pi_N(u - u_*) + u_* \in P_N \quad \forall u \in H^1(I).$$

Clearly, $(\pi^1_N u)(r) = u(r)$ for $r = 0, 1$, and by Lemma 3.4,

$$\|\partial_r(\pi^1_N u - u)\| + N\|(\pi^1_N u - u)\|_{\hat\omega^{-1}} \lesssim N^{1-s}\|(r - r^2)^{\frac{s-1}{2}}\partial^s_r(u - u_*)\|. \tag{3.17}$$

Since $\partial^s_r u_* \equiv 0$ for $s \geq 2$, and $\partial_r u_* = u(1) - u(0)$, which implies that

$$\|\partial_r u_*\| = |u(1) - u(0)| \lesssim \|\partial_r u\|,$$

the desired result follows from (3.17). □

Using the above corollary leads to the following lemma.

LEMMA 3.5. *For any $u \in X \cap \widetilde{H}^s(I)$ with $s \geq 1, s \in \mathbb{N}$,*

$$\begin{aligned}\|\partial_r(\pi_N^{1,m}u - u)\|_\omega + \sqrt{d_m}\|\pi_N^{1,m}u - u\|_{\omega^{-1}}&\\ \lesssim (1 + \sqrt{d_m}N^{-1})N^{1-s}\|(r-r^2)^{\frac{s-1}{2}}\partial_r^s u\|;&\end{aligned} \tag{3.18a}$$

$$\|\pi_N^{1,m}u - u\|_\omega \lesssim (d_m^{-\frac{1}{2}} + N^{-1})N^{1-s}\|(r-r^2)^{\frac{s-1}{2}}\partial_r^s u\|. \tag{3.18b}$$

Proof. The definition (3.13) implies that for any $\phi \in X_N$,

$$a_m(\pi_N^{1,m}u - u, \pi_N^{1,m}u - u) \leq a_m(\phi - u, \phi - u). \tag{3.19}$$

Taking $\phi = \pi_N^1 u \in X_N$ in (3.19), we obtain from Corollary 3.2 that

$$\begin{aligned}\|\partial_r(\pi_N^{1,m}u - u)\|_\omega + \sqrt{d_m}\|\pi_N^{1,m}u - u\|_{\omega^{-1}} &\lesssim \|\partial_r(\pi_N^1 u - u)\| + \sqrt{d_m}\|\pi_N^1 u - u\|_{\hat{\omega}^{-1}}\\ &\lesssim (1 + \sqrt{d_m}N^{-1})N^{1-s}\|(r-r^2)^{\frac{s-1}{2}}\partial_r^s u\|.\end{aligned}$$

Since $\|\pi_N^{1,m}u - u\|_\omega \leq \|\pi_N^{1,m}u - u\|_{\omega^{-1}}$, (3.18b) follows from (3.18a). □

We can now derive an error estimate for the case $n = 2$ with $m > 0$.

THEOREM 3.3. *If $u \in X \cap \widetilde{H}^s(I)$, with $s \geq 1$ and $s \in \mathbb{N}$, we have*

$$\begin{aligned}&\|\partial_r(u - u_N)\|_\omega + \sqrt{d_m}\|u - u_N\|_{\omega^{-1}} + k\|u - u_N\|_\omega\\ &\lesssim \Big((1 + \sqrt{d_m}N^{-1} + d_m^2 k^{-4}) + k^2(d_m^{-\frac{1}{2}} + N^{-1})\Big)N^{1-s}\|(r-r^2)^{\frac{s-1}{2}}\partial_r^s u\|.\end{aligned} \tag{3.20}$$

Proof. Let us still denote $e_N = u_N - \pi_N^{1,m}u$ and $\tilde{e}_N = u - \pi_N^{1,m}u$. Due to (3.13), the error equation (3.5) becomes

$$\mathcal{B}(e_N, v_N) = -k^2(\tilde{e}_N, v_N)_\omega - \mathrm{i}k\tilde{e}_N(1)\overline{v_N(1)}.$$

Consequently, (3.6) is changed to

$$\|\partial_r e_N\|_\omega^2 + d_m\|e_N\|_{\omega^{-1}}^2 + k^2\|e_N\|_\omega^2 \lesssim k^4\|\tilde{e}_N\|_\omega^2 + k^2(1 + d_m^2 k^{-4})|\tilde{e}_N(1)|^2.$$

Thus, following a procedure similar to that in the proof of Theorem 3.2, and thanks to Lemma 3.5, we can obtain (3.20). □

4. An alternate formulation and its numerical implementation.

In this section, we shall give an alternate formulation for problem (2.1)–(2.3), which is more suitable for implementation and also leads to a convergence rate similar to that of Theorem 3.2.

4.1. The formulation.

We make the transform

$$u(r) = v(r)e^{\mathrm{i}kr}, \quad f(r) = h(r)e^{\mathrm{i}kr}, \quad r \in I, \tag{4.1}$$

and we convert the problem (2.1)–(2.3) to

$$\begin{aligned}&-\frac{1}{r^{n-1}}\partial_r(r^{n-1}\partial_r v) + d_m\frac{v}{r^2} - \mathrm{i}k\Big(2\partial_r v + (n-1)\frac{v}{r}\Big) = h,\\ &r \in I := (0,1),\ n = 1,2,3,\ m \geq 0,\end{aligned} \tag{4.2}$$

where v satisfies the Dirichlet boundary condition (2.2) and the Neumann boundary condition:

$$v'(1) = \tilde{g} := ge^{-\mathrm{i}k}. \tag{4.3}$$

Let the spaces X and X_N be the same as before. The weak formulation of (4.2) with (2.2) and (4.3) is to find $v \in X$ such that

$$\begin{aligned}\widetilde{\mathcal{B}}(v,w) := (\partial_r v, \partial_r w)_{\omega^{n-1}} + d_m(v,w)_{\omega^{n-3}} - 2\mathrm{i}k(\partial_r v, w)_{\omega^{n-1}} \\ - (n-1)\mathrm{i}k(v,w)_{\omega^{n-2}} = (h,w)_{\omega^{n-1}} + \tilde{g}\overline{w(1)} \quad \forall w \in X.\end{aligned} \tag{4.4}$$

The well-posedness of this formulation is guaranteed by (4.1) and Theorem 2.1.

The spectral-Galerkin approximation to (4.4) is to seek $v_N \in X_N$ such that

$$\widetilde{\mathcal{B}}_N(v_N, w_N) = (h, w_N)_{\omega^{n-1}} + \tilde{g}\overline{w_N(1)} \quad \forall w_N \in X_N. \tag{4.5}$$

Using a procedure similar to the one used before, we can derive corresponding a priori estimates and error estimates. For simplicity, we consider the case $g = 0$.

THEOREM 4.1. *Let v and v_N be the solutions of* (4.4) *and* (4.5) *with $\tilde{g} = 0$ and $h \in L^2_{\omega^{n-1}}(I)$. Then*

$$\|\partial_r v\|_{\omega^{n-1}} + \sqrt{d_m}\|v\|_{\omega^{n-3}} \lesssim \|h\|_{\omega^{n-1}}, \tag{4.6}$$

$$\|\partial_r v_N\|_{\omega^{n-1}} + \sqrt{d_m}\|v_N\|_{\omega^{n-3}} \lesssim \|h\|_{\omega^{n-1}}. \tag{4.7}$$

Proof. As in the proof of Theorem 2.2, we take two different test functions in (4.4). We first take $w = v$ in (4.4), whose real part is

$$\|\partial_r v\|^2_{\omega^{n-1}} + d_m\|v\|^2_{\omega^{n-3}} + 2k\mathrm{Im}(\partial_r v, v)_{\omega^{n-1}} = \mathrm{Re}(h,v)_{\omega^{n-1}}, \tag{4.8}$$

and using integration by parts, its imaginary part becomes

$$-2k\mathrm{Re}(\partial_r v, v)_{\omega^{n-1}} - (n-1)k\|v\|^2_{\omega^{n-2}} = -k|v(1)|^2 = \mathrm{Im}(h,v)_{\omega^{n-1}}. \tag{4.9}$$

Here, in the derivation of (4.8) (likewise for (4.10) below), we have used the fact $\mathrm{Re}(\mathrm{i}(u,v)) = -\mathrm{Im}(u,v)$.

Next, we take $w = 2r\partial_r v$ ($\in X$) in (4.4), and thanks to (2.24a)–(2.24b), its real part becomes

$$\begin{aligned}(2-n)(\|\partial_r v\|^2_{\omega^{n-1}} + d_m\|v\|^2_{\omega^{n-3}}) + d_m|v(1)|^2 \\ + 2(n-1)k\mathrm{Im}(v, \partial_r v)_{\omega^{n-1}} = 2\mathrm{Re}(h, r\partial_r v)_{\omega^{n-1}}.\end{aligned} \tag{4.10}$$

As a consequence of (4.10), we have that for $n = 1$ (we recall that $d_m = 0$ in this case),

$$\|\partial_r v\|^2 \le 2\|h\|_{\omega^2}\|\partial_r v\| \le 2\|h\|\|\partial_r v\|, \tag{4.11}$$

which implies (4.6) with $n = 1$.

It remains to prove (4.6) with $n = 2, 3$. Since $\partial_r v(1) = 0$, it is easy to verify

$$\mathrm{Im}(\partial_r v, v)_{\omega^{n-1}} = -\mathrm{Im}(v, \partial_r v)_{\omega^{n-1}}. \tag{4.12}$$

Therefore, multiplying (4.8) by $n-1$ and adding the resulting equation to (4.10), we derive from the Cauchy–Schwarz inequality that

$$\begin{aligned}\|\partial_r v\|^2_{\omega^{n-1}} + d_m\|v\|^2_{\omega^{n-3}} + d_m|v(1)|^2 = (n-1)\mathrm{Re}(h,v)_{\omega^{n-1}} \\ + 2\mathrm{Re}(h, r\partial_r v)_{\omega^{n-1}} \le 2\|h\|_{\omega^{n-1}}\|v\|_{\omega^{n-1}} + \frac{1}{4}\|\partial_r v\|^2_{\omega^{n-1}} + 4\|h\|^2_{\omega^{n-1}}.\end{aligned} \tag{4.13}$$

Clearly, we have

$$|v(1)|^2 = \int_0^1 \partial_r(|v(r)|^2 r^n)dr = n\int_0^1 |v(r)|^2 r^{n-1}dr + 2\int_0^1 \partial_r v(r)\overline{v(r)}r^n dr,$$

and by the Cauchy–Schwarz inequality,

$$n\|v\|^2_{\omega^{n-1}} \le |v(1)|^2 + 2\|v\|_{\omega^{n-1}}\|\partial_r v\|_{\omega^{n+1}} \le |v(1)|^2 + \frac{n}{2}\|v\|^2_{\omega^{n-1}} + \frac{2}{n}\|\partial_r v\|^2_{\omega^{n-1}},$$

which together with (4.9) leads to

$$\begin{aligned}\|v\|^2_{\omega^{n-1}} &\le \frac{2}{n}|v(1)|^2 + \frac{4}{n^2}\|\partial_r v\|^2_{\omega^{n-1}} \le \frac{2}{nk}|\mathrm{Im}(h,v)_{\omega^{n-1}}| + \frac{4}{n^2}\|\partial_r v\|^2_{\omega^{n-1}}\\ &\le \frac{1}{2}\|v\|^2_{\omega^{n-1}} + \frac{2}{n^2k^2}\|h\|^2_{\omega^{n-1}} + \frac{4}{n^2}\|\partial_r v\|^2_{\omega^{n-1}}.\end{aligned} \tag{4.14}$$

As a result of (4.13) and (4.14), we obtain

$$\begin{aligned}\|\partial_r v\|^2_{\omega^{n-1}} + d_m\|v\|^2_{\omega^{n-3}} &\le 2\|h\|_{\omega^{n-1}}\Big(\frac{2}{nk}\|h\|_{\omega^{n-1}} + \frac{2\sqrt{2}}{n}\|\partial_r v\|_{\omega^{n-1}}\Big)\\ &+ \frac{1}{4}\|\partial_r v\|^2_{\omega^{n-1}} + 4\|h\|^2_{\omega^{n-1}} \le \frac{1}{2}\|\partial_r v\|^2_{\omega^{n-1}} + \Big(\frac{4}{nk} + \frac{32}{n^2} + 4\Big)\|h\|^2_{\omega^{n-1}}.\end{aligned}$$

This completes the proof of (4.6).

Since $r\partial_r v_N \in X_N$, we have the same results for the numerical solution v_N. □

Thanks to the above theorem, we can derive the following convergence result by using an argument similar to the proof of Theorem 3.2.

THEOREM 4.2. *Let* v *and* v_N *be, respectively, the solutions of* (4.4) *and* (4.5) *with* $\tilde{g} = 0$, *and we have*

(i) *for* $n = 1, 3$ *or* $n = 2, m = 0$, *and* $v \in X \cap \widetilde{H}^s_{\omega^{n-1}}(I)$ *with* $s \ge 1$ *and* $s \in \mathbb{N}$,

$$\|\partial_r(v - v_N)\|_{\omega^{n-1}} + \sqrt{d_m}\|v - v_N\|_{\omega^{n-3}} \lesssim (k + \sqrt{d_m})N^{1-s}\|(r - r^2)^{\frac{s-1}{2}}\partial_r^s v\|_{\omega^{n-1}}; \tag{4.15}$$

(ii) *for* $n = 2,\ m > 0$, *and* $v \in X \cap \widetilde{H}^s(I)$, *with* $s \ge 1$ *and* $s \in \mathbb{N}$,

$$\begin{aligned}&\|\partial_r(v - v_N)\|_{\omega} + \sqrt{d_m}\|v - v_N\|_{\omega^{-1}}\\ &\quad\lesssim \Big((1 + \sqrt{d_m}N^{-1}) + k^2(d_m^{-\frac{1}{2}} + N^{-1})\Big)N^{1-s}\|(r - r^2)^{\frac{s-1}{2}}\partial_r^s v\|.\end{aligned} \tag{4.16}$$

Proof. Let $\Pi^{1,m}_{N,n}$ be the orthogonal projection defined in (3.2), and denote $e_N = v_N - \Pi^{1,m}_{N,n}v$ and $\hat{e}_N = v - \Pi^{1,m}_{N,n}v$. Like (3.5), the error equation is

$$\widetilde{\mathcal{B}}(e_N, w_N) = d_m(\hat{e}_N, w_N)_{\omega^{n-3}} - 2\mathrm{i}k(\partial_r\hat{e}_N, w_N)_{\omega^{n-1}} - (n-1)\mathrm{i}k(\hat{e}_N, w_N)_{\omega^{n-2}}.$$

Therefore, taking the test function $w_N = e_N, r\partial_r e_N$, setting $h = -2\mathrm{i}k\partial_r\hat{e}_N - (n-1)\mathrm{i}kr^{-1}\hat{e}_N$ in (4.5), and dealing with the term $d_m(\hat{e}_N, w_N)_{\omega^{n-3}}$ the same as that in the proof of Lemma 3.2, we obtain

$$\|\partial_r e_N\|^2_{\omega^{n-1}} + d_m\|e_N\|^2_{\omega^{n-3}} \lesssim (k^2 + d_m)(\|\partial_r\hat{e}_N\|^2_{\omega^{n-1}} + \|\hat{e}_N\|^2_{\omega^{n-3}}).$$

The rest of the proof of (4.15) is similar to that of Theorem 3.2.

The estimate (4.16) can be proved in the same fashion by using the results in Lemma 3.5. □

4.2. Numerical implementations.

4.2.1. Choice of basis functions. Without loss of generality, we still assume that $\tilde{g} = 0$ in (4.2). For computational convenience, we transform $I = (0, 1)$ to the reference interval $\hat{I} = (-1, 1)$ with $x = 2r - 1$, $r = \frac{1}{2}(1 + x)$, $r \in I$, $x \in \hat{I}$. As demonstrated in [22, 23], it is advantageous to construct basis function satisfying the underlying homogeneous boundary conditions by using compact combinations of orthogonal polynomials. Hence, we define

$$W_N = W_N^{(m,n)} := \{w \in P_N : w'(1) = 0;\ \ w(-1) = 0 \text{ if } n = 1 \text{ and if } n = 2 \text{ with } m > 0\},$$

and we let $L_l(x)$ denote the Legendre polynomial of degree l. Define

$$\begin{aligned} &\phi_j(x) := (L_j(x) + L_{j+1}(x)) - \Big(\frac{j+1}{j+2}\Big)^2 (L_{j+1}(x) + L_{j+2}(x)); \\ &\psi_j(x) := L_j(x) - \frac{j}{j+2} L_{j+1}(x). \end{aligned} \tag{4.17}$$

Since $L_l(-1) = (-1)^l$ and $L_l'(1) = \frac{1}{2} l(l + 1)$, one can verify easily that

$$\phi_j(-1) = \phi_j'(1) = \psi_j'(1) = 0. \tag{4.18}$$

Hence, for $n = 1$ or $n = 2$ with $m > 0$, $W_N^{(m,n)} = \text{span}\{\phi_j : j = 0, 1, \ldots, N - 2\}$; and for $n = 3$ or $n = 2$ with $m = 0$, $W_N^{(m,n)} = \text{span}\{\psi_j : j = 0, 1, \ldots, N - 1\}$.

Now, let us write

$$v_N(r) := w_N^R(x) + \mathrm{i} w_N^I(x), \quad 2^{n-3} r^{n-1} h(r) := q^R(x) + \mathrm{i} q^I(x), \tag{4.19}$$

where w_N^R, w_N^I, q^R, and q^I are real functions in $\hat{I}$. Our spectral-Galerkin algorithm is to seek $w_N^R, w_N^I \in W_N$ such that for any real polynomials $\phi, \psi \in W_N$,

$$\begin{aligned} &((1 + x)^{n-1} \partial_x w_N^R, \partial_x \phi) + d_m((1 + x)^{n-3} w_N^R, \phi) + k((1 + x)^{n-1} \partial_x w_N^I, \phi) \\ &\qquad + \frac{n-1}{2} k((1 + x)^{n-2} w_N^I, \phi) = (q^R, \phi); \\ &((1 + x)^{n-1} \partial_x w_N^I, \partial_x \psi) + d_m((1 + x)^{n-3} w_N^I, \psi) - k((1 + x)^{n-1} \partial_x w_N^R, \psi) \\ &\qquad - \frac{n-1}{2} k((1 + x)^{n-2} w_N^R, \phi) = (q^I, \psi). \end{aligned} \tag{4.20}$$

Thanks to the nice properties of the Legendre polynomials, one can find that the coefficient matrix of the above system is sparse, and its nonzero entries can be determined exactly.

4.2.2. Numerical results. We present some numerical results for the problem (2.1)–(2.3) by using the schemes proposed above.

Example 1. We consider (2.1)–(2.3) with $n = 2$, $d_m = 100$, and $g = 0$ and set the exact solution to be

$$u(r) = v(r) e^{\mathrm{i}kr}, \quad r \in I, \tag{4.21}$$

where $v(r) = (\cos 2k - \cos(2k(1-r))) + \mathrm{i}(\frac{1}{k}(\sin 2k - \sin(2k(1-r))) - 2r \cos(2k(1-r)))$ is the exact solution of the transformed problem (4.2).

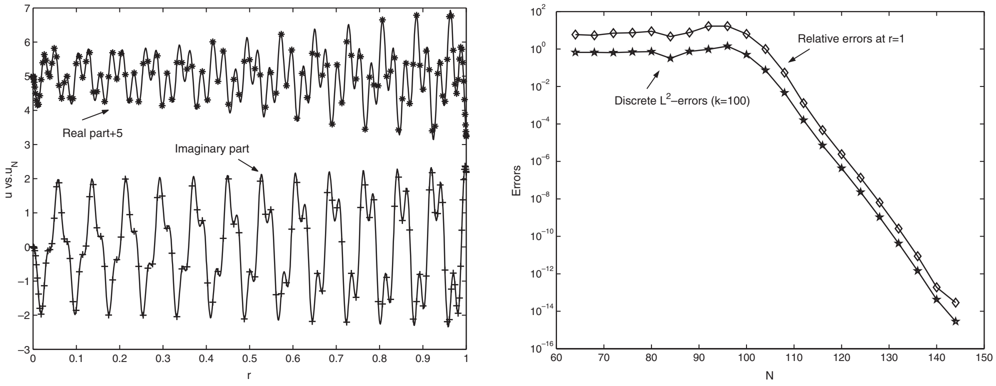

FIG. 4.1. *Left: exact solution vs. numerical solution. Right: errors vs. N $(k = 100)$.*

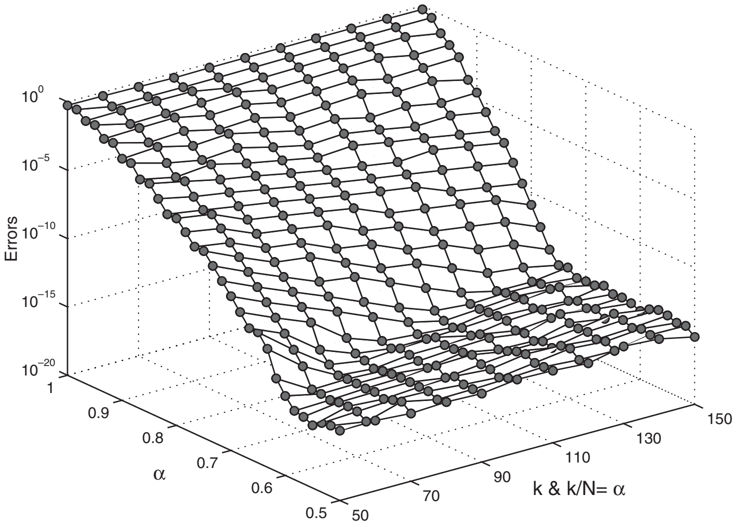

FIG. 4.2. *Errors vs. $\alpha \in [0.5, 1]$ and $k \in [50, 150]$ with $\frac{k}{N} = \alpha$.*

In Figure 4.1 (left), we plot the numerical solution at Legendre–Gauss–Lobatto points with $k = 80$ and $N = 96$ (asterisk-markers for the real part (raised by 5 unit) and plus-markers for the imaginary part) vs. the exact solution (solid line).

We now examine the convergence rate. According to Theorem 3.3, the predicted order of convergence for the exact solution (4.21) is

$$\|u - u_N\|_\omega \sim k^{1+s} N^{1-s}, \quad N \gg 1, \;\; k > 0, \;\; s \geq 1. \tag{4.22}$$

In Figure 4.1 (right), we fix the wave number $k = 100$ and plot the discrete L^2-errors and relative errors at $r = 1$ vs. different modes N. As expected, an exponential convergence rate is observed once N is large enough to resolve the oscillation.

Next, we fix $\alpha = \frac{k}{N}$ and examine the error behavior with respect to α. In Figure 4.2, we plot the discrete L^2-errors with $0.5 \leq \alpha \leq 1, \; 50 \leq k \leq 150$, and $N = \frac{k}{\alpha}$. The results indicate that the proposed scheme can provide very accurate approximations to highly oscillatory solutions under the condition $\frac{k}{N} = \alpha < 1$, which is necessary for

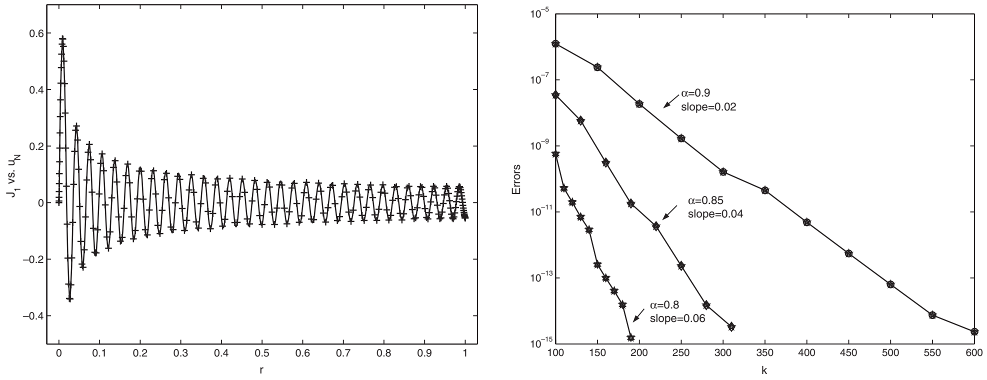

FIG. 4.3. *Left: exact solution vs. numerical solution. Right: errors vs. wave number k with* $\alpha = \frac{k}{N}$ *fixed.*

convergence (cf. [13]).

Example 2. We consider the problem (2.1)–(2.3) with $n = 2$ and $d_m = 1$. An exact solution is

$$u(r) = J_1(kr), \quad \text{with} \quad f \equiv 0 \;\text{ and }\; g = k(J_1'(k) - \mathrm{i}J_1(k)), \tag{4.23}$$

where $J_1(\cdot)$ is the first degree Bessel function of the first kind. As pointed out in [26], we have the following asymptotic property:

$$u(r) = J_1(kr) = \sqrt{\frac{2}{\pi kr}} \cos\left(kr - \frac{3}{4}\pi\right) + O((kr)^{-\frac{3}{2}}) \quad \text{if } kr \gg 1. \tag{4.24}$$

Hence, the solution is highly oscillating when the wave number k is large (see Figure 4.3 (left)). We derive from (4.24) that the expected convergence rate is $k^{\frac{1}{2}+s}N^{1-s}$. In Figure 4.3 (left), we plot the exact solution vs. the numerical solution with $k = 200$ and $N = 256$. In this case, the discrete L^2-error is 2.45×10^{-15} and relative error at $r = 1$ is 3.84×10^{-13}. The error behaviors with several fixed $\alpha = \frac{k}{N}$ are plotted in Figure 4.3 (right), which demonstrates that the spectral-Galerkin method is capable of providing very accurate results even for α close to 1.

5. Extensions to multidimensional cases. The results we derived for the prototypical 1-D problem (2.1)–(2.3) (with $n = 2, 3$) can be used to derive error estimates for the spectral-Galerkin approximation to the multidimensional problem (1.2). As an example, we consider the case $n = 3$:

$$\begin{aligned} -\Delta U - k^2 U = F \quad & \text{in } \hat{\Omega} := \{(x,y,z) \;:\; a^2 < x^2+y^2+z^2 < b^2\}, \\ \partial_r U - \mathrm{i}kU = G \quad & \text{on } S_b := \{(x,y,z) \;:\; x^2+y^2+z^2 = b^2\}, \\ U = 0 \quad & \text{on } \;S_a := \{(x,y,z) \;:\; x^2+y^2+z^2 = a^2\} \text{ if } a > 0. \end{aligned} \tag{5.1}$$

Applying the spherical transformation

$$x = r\cos\theta\sin\phi, \quad y = r\sin\theta\sin\phi, \quad z = r\cos\phi \tag{5.2}$$

to (5.1) and setting $u(r,\theta,\phi)=U(x,y,z),\ f(r,\theta,\phi)=F(x,y,z),\ g(\theta,\phi)=G(x,y,z)$, and $S:=[0,2\pi)\times[0,\pi)$, we obtain

$$\begin{aligned} -\Big(\frac{\partial^2}{\partial r^2}+\frac{2}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\Delta_S\Big)u-k^2u&=f \quad \text{in } \Omega:=(a,b)\times S,\\ \partial_r u-\mathrm{i}ku&=g \quad \text{on } S_b,\\ u&=0 \quad \text{on } S_a \ \text{ if } a>0, \end{aligned} \tag{5.3}$$

where Δ_S is the Laplace–Beltrami operator (the Laplacian on the unit sphere S):

$$\Delta_S=\frac{1}{\sin^2\phi}\frac{\partial^2}{\partial\theta^2}+\frac{\cos\phi}{\sin\phi}\frac{\partial}{\partial\phi}+\frac{\partial^2}{\partial^2\phi}. \tag{5.4}$$

We recall that the spherical harmonic functions $\{Y_{l,m}\}$ are the eigenfunctions of the Laplace–Beltrami operator (see [25])

$$-\Delta_S Y_{l,m}(\theta,\phi)=m(m+1)Y_{l,m}(\theta,\phi) \tag{5.5}$$

and are defined by

$$Y_{l,m}(\theta,\phi)=\sqrt{\frac{(2m+1)(m-l)!}{4\pi(m+l)!}}e^{il\theta}P_m^l(\cos\phi), \quad m\ge|l|\ge0,$$

where $P_m^l(x)$ is the associated Legendre functions given by

$$P_m^l(x)=\frac{(-1)^l}{2^m m!}(1-x^2)^{\frac{l}{2}}\frac{d^{m+l}}{dx^{m+1}}\{(x^2-1)^m\}.$$

The set of harmonic functions forms a complete orthonormal system in $L^2(S)$, i.e.,

$$\int_0^{2\pi}\int_0^{\pi}Y_{l,m}(\theta,\phi)\overline{Y_{l',m'}}(\theta,\phi)\sin\phi\, d\phi d\theta=\delta_{l,l'}\delta_{m,m'}. \tag{5.6}$$

Hence, for any function $U(x,y,z)\in L^2(\hat\Omega)$, the function $u(r,\theta,\phi)=U(x,y,z)$ can be expanded as

$$u=\sum_{|l|=0}^{\infty}\sum_{m\ge|l|}^{\infty}u_{lm}(r)Y_{l,m}(\theta,\phi), \ \text{ with } \ u_{lm}(r)=\int_S u(r,\theta,\phi)\overline{Y}_{l,m}(\theta,\phi)dS, \tag{5.7}$$

and we have

$$\|u\|^2_{L^2_{\omega^2}(\Omega)}=\sum_{|l|=0}^{\infty}\sum_{m\ge|l|}^{\infty}\|u_{lm}\|^2_{\omega^2}=\|U\|^2_{L^2(\hat\Omega)} \quad (\omega^2=r^2). \tag{5.8}$$

For a scalar function v on S, the gradient operator $\vec\nabla_S$ on the unit sphere is defined by $\vec\nabla_S v=\big(\frac{1}{\sin\phi}\partial_\theta v,\partial_\phi v\big)$. One can verify readily that

$$-(\Delta_S u,v)_S=(\vec\nabla_S u,\vec\nabla_S v)_S \quad \forall u,v\in\mathcal{D}(\Delta_S), \tag{5.9}$$

where $\mathcal{D}(\Delta_S)$ is the domain of the Laplace–Beltrami operator Δ_S. In particular, as a consequence of (5.5)–(5.9), we have

$$(\vec\nabla_S Y_{l,m},\vec\nabla_S Y_{l,m})_S=m(m+1), \quad m\ge|l|\ge0. \tag{5.10}$$

Accordingly, we can define the Sobolev space on S:

$$H^1(S) := \{u : u \text{ is measurable on } S \text{ and } \|u\|^2_{H^1(S)} < \infty\},$$

where $\|u\|_{H^1(S)} = \big(\|u\|^2_{L^2(S)} + \|\vec{\nabla}_S u\|^2_{L^2(S)}\big)^{\frac{1}{2}}$.

The variational formulation of (5.3) is to find $u \in V := H^1_{\omega^2}(I; L^2(S)) \cap L^2(I; H^1(S))$ such that $(\omega^2 = r^2)$

$$\begin{aligned} a(u, v) &:= (\partial_r u, \partial_r v)_{\omega^2,\Omega} + (\vec{\nabla}_S u, \vec{\nabla}_S v)_\Omega - k^2(u, v)_{\omega^2,\Omega} \\ &\quad - \mathrm{i}kb^2(u(b,\cdot), v(b,\cdot))_S = (f, v)_{\omega^2,\Omega} + b^2(g, v(b,\cdot))_S \quad \forall v \in V. \end{aligned} \tag{5.11}$$

The spectral-Galerkin approximation of (5.11) is to find $u_{MN} \in V_{MN}$ such that

$$a(u_{MN}, v) = (f, v)_{\omega^2,\Omega} + b^2(g, v(b,\cdot))_S \quad \forall v \in V_{MN}, \tag{5.12}$$

where $V_{MN} := W_M \times X_N$, and

$$W_M := \text{span}\{Y_{l,m} :\ 0 \le |l| \le m \le M\},\ X_N := \{u \in P_N\ :\ u(a) = 0 \ \text{ if }\ a > 0\}.$$

Hence, we can write

$$(u(r,\theta,\phi), f(r,\theta,\phi), g(\theta,\phi)) = \sum_{|l|=0}^{\infty} \sum_{m\ge|l|}^{\infty} (u_{lm}(r), f_{lm}(r), g_{lm}) Y_{l,m}(\theta,\phi); \tag{5.13a}$$

$$u_{MN}(r,\theta,\phi) = \sum_{|l|=0}^{M} \sum_{m\ge|l|}^{M} u^N_{lm}(r) Y_{l,m}(\theta,\phi). \tag{5.13b}$$

In order to describe the error bounds, we define a nonisotropic space $\widetilde{H}^s_{\omega^2}(I; H^t(S))$ as follows:

$$\widetilde{H}^s_{\omega^2}(I; H^t(S)) = \left\{ u \in L^2_{\omega^2}(\Omega) : \sum_{|l|=0}^{\infty} \sum_{m\ge|l|}^{\infty} m^t(m+1)^t \|u_{lm}\|^2_{\widetilde{H}^s_{\omega^2}(I)} < +\infty \right\}, \tag{5.14}$$

where $\{u_{lm}\}$ are the expansion coefficients of u in terms of $Y_{l,m}$ as in (5.7). Thanks to (5.10), we can define the norm on $\widetilde{H}^s_{\omega^2}(I; H^t(S))$ by

$$\|u\|_{\widetilde{H}^s_{\omega^2}(I;H^t(S))} = \left(\sum_{|l|=0}^{\infty} \sum_{m\ge|l|}^{\infty} m^t(m+1)^t \|u_{lm}\|^2_{\widetilde{H}^s_{\omega^2}(I)} \right)^{\frac{1}{2}} \tag{5.15}$$

and its seminorm by replacing $\|u_{lm}\|_{\widetilde{H}^s_{\omega^2}(I)}$ with $|u_{lm}|_{\widetilde{H}^s_{\omega^2}(I)}$. In particular, $L^2_{\omega^2}(I; H^t(S)) = \widetilde{H}^0_{\omega^2}(I; H^t(S))$ and $\widetilde{H}^s_{\omega^2}(I; L^2(S)) = \widetilde{H}^s_{\omega^2}(I; H^0(S))$.

5.1. In a sphere ($a = 0$). Without loss of generality, we assume that $b = 1$. In this case, we can show that $\{u_{lm}\}$ (resp., $\{u^N_{lm}\}$) satisfy the 1-D problem (2.5) (resp., (3.1)) with $n = 3$ and f, g being replaced by f_{lm} and g_{lm}, respectively.

THEOREM 5.1. *Let u and u_{MN} be, respectively, the solutions of* (5.11) *and* (5.12), *and denote $e = u - u_{MN}$. Then if*

$$u \in L^2(I; H^t(S)) \cap H^1_{\omega^2}(I; H^{t-1}(S)) \cap \widetilde{H}^s_{\omega^2}(I; L^2(S)), \quad s, t \ge 1,\ s, t \in \mathbb{N}, \tag{5.16}$$

we have

$$\begin{aligned} &\|\partial_r e\|_{L^2_{\omega^2}(\Omega)} + \|\vec{\nabla}_S e\|_{L^2(\Omega)} + k\|e\|_{L^2_{\omega^2}(\Omega)} \\ &\qquad \lesssim C_*\Big((M + M^4k^{-4} + k^2N^{-1})N^{1-s} + M^{1-t}(1 + kM^{-1})\Big), \end{aligned} \tag{5.17}$$

where C_* is a positive constant depending only on the seminorms of u in the spaces mentioned in (5.16).

Proof. Let $e_{lm}(r) = u_{lm}(r) - u_{lm}^N(r)$. We deduce from Theorem 3.2 that

$$\begin{aligned} &\|\partial_r e_{lm}\|_{L^2_{\omega^2}(I)} + \sqrt{d_m}\|e_{lm}\|_{L^2(I)} + k\|e_{lm}\|_{L^2_{\omega^2}(I)} \\ &\qquad \lesssim \Big(1 + \sqrt{d_m} + d_m^2k^{-4} + k^2N^{-1}\Big)N^{1-s}|e_{lm}|_{\widetilde{H}^s_{\omega^2}(I)}, \end{aligned} \tag{5.18}$$

where $d_m = m(m+1)$. Therefore, by (5.6)–(5.10) and (5.13b)–(5.14),

$$\begin{aligned} &\|\partial_r e\|^2_{L^2_{\omega^2}(\Omega)} + \|\vec{\nabla}_S e\|^2_{L^2(\Omega)} + k^2\|e\|^2_{L^2_{\omega^2}(\Omega)} \\ &\quad = \sum_{|l|=0}^{M}\sum_{m\ge|l|}^{M}\Big(\|\partial_r e_{lm}\|^2_{L^2_{\omega^2}(I)} + d_m\|e_{lm}\|^2_{L^2(I)} + k^2\|e_{lm}\|^2_{L^2_{\omega^2}(I)}\Big) \\ &\qquad + \left(\sum_{|l|=0}^{\infty}\sum_{m>M}^{\infty} + \sum_{|l|>M}^{\infty}\sum_{m\ge|l|}^{\infty}\right)\Big(\|\partial_r u_{lm}\|^2_{L^2_{\omega^2}(I)} + d_m\|u_{lm}\|^2_{L^2(I)} + k^2\|u_{lm}\|^2_{L^2_{\omega^2}(I)}\Big) \\ &\quad \lesssim \Big(1 + \sqrt{d_M} + d_M^2k^{-4} + k^2N^{-1}\Big)^2 N^{2-2s}\sum_{|l|=0}^{M}\sum_{m\ge|l|}^{M}|u_{lm}|^2_{\widetilde{H}^s_{\omega^2}(I)} \\ &\qquad + d_M^{1-t}\sum_{|l|=0}^{\infty}\sum_{m\ge|l|}^{\infty}\Big(d_m^{t-1}(\|\partial_r u_{lm}\|^2_{L^2_{\omega^2}(I)} + d_m\|u_{lm}\|^2_{L^2(I)} + k^2\|u_{lm}\|^2_{L^2_{\omega^2}(I)})\Big) \\ &\quad \lesssim (M + M^4k^{-4} + k^2N^{-1})^2N^{2-2s}|u|^2_{\widetilde{H}^s_{\omega^2}(I;L^2(S))} \\ &\qquad + d_M^{1-t}\Big(|u|^2_{H^1_{\omega^2}(I;H^{t-1}(S))} + |u|^2_{L^2(I;H^t(S))} + k^2d_m^{-1}|u|^2_{L^2_{\omega^2}(I;H^t(S))}\Big), \end{aligned}$$

which implies the desired result. □

5.2. In a spherical shell ($a > 0$). In this case, $\{u_{lm}\}$ are the solutions of

$$\widehat{\mathcal{B}}_{lm}(u_{lm}, v) = (f_{lm}, v)_{\omega^2} + b^2 g_{lm}\overline{v(b)} \quad \forall v \in X, \;\; 0 \le |l| \le m, \tag{5.19}$$

where $X := \{u \in H^1(I) \;:\; u(a) = 0\}$, and

$$\widehat{\mathcal{B}}_{lm}(u, v) := (\partial_r u, \partial_r v)_{\omega^2} + d_m(u, v) - k^2(u, v)_{\omega^2} - \mathrm{i}kb^2u(b)\overline{v(b)}, \tag{5.20}$$

with $\omega^2 = r^2$, $d_m = m(m+1)$. The numerical approximations u_{lm}^N $(0 \le |l| \le m,\ m = 0, 1, \ldots, M)$ are defined by

$$\widehat{\mathcal{B}}_{lm}(u_{lm}^N, v_N) = (f_{lm}, v_N)_{\omega^2} + b^2 g_{lm}\overline{v_N(b)} \quad \forall v_N \in X_N := X \cap P_N. \tag{5.21}$$

Since u_{lm}, $(r-a)u_{lm} \in X$ (resp., u_{lm}^N, $(r-a)u_{lm}^N \in X_N$), we can use them as test functions in (5.19) (resp., (5.21)), and derive the following results using an argument analogous to that in the proof of Theorem 2.2.

LEMMA 5.1. *Let* $\{u_{lm}\}$ *and* $\{u_{lm}^N\}$ *be, respectively, the solution of* (5.19) *and* (5.21)*. Then there exists* $\xi \in (a,b)$ *such that for* $C_\xi := (2-\frac{2a}{\xi})^{-1}$*, we have*

$$\|\partial_r u_{lm}\|^2_{L^2_{\omega^2}(I)} + d_m\|u_{lm}\|^2_{L^2(I)} + k^2\|u_{lm}\|^2_{L^2_{\omega^2}(I)} \lesssim C_\xi b^3(|g_{lm}|^2 + b^2\|f_{lm}\|^2_{L^2_{\omega^2}(I)}),$$
$$\|\partial_r u^N_{lm}\|^2_{L^2_{\omega^2}(I)} + d_m\|u^N_{lm}\|^2_{L^2(I)} + k^2\|u^N_{lm}\|^2_{L^2_{\omega^2}(I)} \lesssim C_\xi b^3(|g_{lm}|^2 + b^2\|f_{lm}\|^2_{L^2_{\omega^2}(I)}).$$

The above a priori estimates allow us to perform the error analysis for the spherical shell case. Similar to the case $a = 0$, we can prove the following.

THEOREM 5.2. *Let* u *and* u_{MN} *be, respectively, the solutions of* (5.11) *and* (5.12)*, and denote* $e = u - u_{MN}$*. Then if*

$$u \in L^2((a,b);H^t(S)) \cap H^1_{\omega^2}((a,b);H^{t-1}(S)) \cap \widetilde{H}^s_{\omega^2}((a,b);L^2(S)), \quad s,t \geq 1,\ s,t \in \mathbb{N},$$

there exists $\xi \in (a,b)$ *such that for* $C_\xi := (2-\frac{2a}{\xi})^{-1}$*, we have*

$$\|\partial_r e\|_{L^2_{\omega^2}(\Omega)} + \|\vec{\nabla}_S e\|_{L^2(\Omega)} + k\|e\|_{L^2_{\omega^2}(\Omega)}$$
$$\lesssim C_* b^2(1+\sqrt{C_\xi})\Big((M + M^4k^{-4} + k^2N^{-1})N^{1-s} + M^{1-t}(1+kM^{-1})\Big),$$

where C_* *is a positive constant depending only on the seminorms of* u *in the spaces mentioned in* (5.16)*.*

Remark 5.1. A similar procedure can be performed for the Helmholtz equation (1.2) in a 2-D axisymmetric domain ($n = 2$) by using a Fourier expansion in the θ-direction.

6. Concluding remarks. We presented in this paper a complete error analysis and an efficient numerical algorithm for the spectral-Galerkin approximation of the Helmholtz equation with high wave numbers in a 1-D domain as well as in multidimensional radial and spherical symmetric domains.

Our analysis is made possible by using two new arguments: (i) we employed a new procedure advocated in [7] which allowed us to obtain sharp (in terms of k) a priori estimates for both the continuous and discrete problems; (ii) we used new Jacobi and generalized Jacobi approximation results developed recently in [16, 24] which enabled us to derive optimal estimates for the cases $n = 2, 3$ which involve degenerate/singular coefficients.

Unlike in most of the previous studies on the approximation of the Helmholtz equation with high wave numbers, our analysis does not rely on explicit knowledge of continuous/discrete Green's functions and is valid without any restriction on the wave number k and the discretization parameter N. Hence, it is possible to extend our results to more complex problems such as Helmholtz equations in an inhomogeneous medium and to more complex domains through a suitable mapping or a domain perturbation technique.

Acknowledgment. The authors would like to thank Dr. Xiaobing Feng for many stimulating discussions and helpful suggestions.

AN ADAPTIVE PERFECTLY MATCHED LAYER TECHNIQUE FOR TIME-HARMONIC SCATTERING PROBLEMS*

ZHIMING CHEN† AND XUEZHE LIU‡

Abstract. We develop an adaptive perfectly matched layer (PML) technique for solving the time-harmonic scattering problems. The PML parameters such as the thickness of the layer and the fictitious medium property are determined through sharp a posteriori error estimates. The derived finite element a posteriori estimate for adapting meshes has the nice feature that it decays exponentially away from the boundary of the fixed domain where the PML layer is placed. This property makes the total computational costs insensitive to the thickness of the PML absorbing layers. Numerical experiments are included to illustrate the competitive behavior of the proposed adaptive method.

Key words. adaptivity, perfectly matched layer, a posteriori error analysis, scattering problems

1. Introduction.

We propose and study an adaptive perfectly matched layer (PML) technique for solving Helmholtz-type scattering problems with perfectly conducting boundary:

$$\Delta u + k^2 u = 0 \quad \text{in } \mathbb{R}^2 \backslash \bar{D}, \tag{1.1a}$$

$$\frac{\partial u}{\partial \mathbf{n}} = -g \quad \text{on } \Gamma_D, \tag{1.1b}$$

$$\sqrt{r}\left(\frac{\partial u}{\partial r} - \mathbf{i}ku\right) \to 0 \quad \text{as } r = |x| \to \infty. \tag{1.1c}$$

Here $D \subset \mathbb{R}^2$ is a bounded domain with Lipschitz boundary Γ_D, $g \in H^{-1/2}(\Gamma_D)$ is determined by the incoming wave, and $\mathbf{n}$ is the unit outer normal to Γ_D. We assume the wave number $k \in \mathbb{R}$ is a constant. We remark that the results in this paper can be easily extended to solve the scattering problems with other boundary conditions such as Dirichlet or the impedance boundary condition on Γ_D, or to solve the acoustic wave propagation through inhomogeneous media with a variable wave number $k^2(x)$ inside some bounded domain.

Since the work of Berenger [3] which proposed a PML technique for solving with the time-dependent Maxwell equations, various constructions of PML absorbing layers have been proposed and studied in the literature (cf., e.g., Turkel and Yefet [20], Teixeira and Chew [19] for the reviews). Under the assumption that the exterior solution is composed of outgoing waves only, the basic idea of the PML technique is to surround the computational domain by a layer of finite thickness with specially designed

model medium that would either slow down or attenuate all the waves that propagate from inside the computational domain. The PML equation for the time-harmonic scattering problem (1.1a) is derived in Collino and Monk [10] by a complex extension of the solution u in the exterior domain. It is proved in Lassas and Somersalo [13] and Hohage, Schmidt, and Zschiedrich [12] that the resultant PML solution converges exponentially to the solution of the original scattering problem as the thickness of the PML layer tends to infinity. We remark that in practical applications involving PML techniques, one cannot afford to use a very thick PML layer if uniform finite element meshes are used because it requires excessive grid points and hence more computer time and more storage. On the other hand, a thin PML layer requires a rapid variation of the artificial material property which deteriorates the accuracy if too coarse mesh is used in the PML layer.

A posteriori error estimates are computable quantities in terms of the discrete solution and data that measure the actual discrete errors without the knowledge of exact solutions. They are essential in designing algorithms for mesh modification which equidistribute the computational effort and optimize the computation. Ever since the pioneering work of Babuška and Rheinboldt [2], the adaptive finite element methods based on a posteriori error estimates have become a central theme in scientific and engineering computations. The ability of error control and the asymptotically optimal approximation property (see, e.g., Morin, Nochetto, and Siebert [17] and Chen and Dai [5]) make the adaptive finite element method attractive for complicated physical and industrial processes (cf., e.g., Chen and Dai [4] and Chen, Nochetto, and Schmidt [7]). For the efforts to solve scattering problems using adaptive methods based on a posterior error estimate, we refer to the recent work of Monk [15] and Monk and Süli [16].

It is proposed in Chen and Wu [8] for scattering problem by periodic structures (the grating problem) that one can use the a posteriori error estimate to determine the PML parameters. Moreover, the derived a posteriori error estimate in [8] has the nice feature of exponential decay in terms of the distance to the boundary of the fixed domain where the PML layer is placed. This property leads to coarse mesh size away from the fixed domain and thus makes the total computational costs insensitive to the thickness of the PML absorbing layer.

In this paper we extend the idea of using a posteriori error estimates to determine the PML parameters and propose an adaptive PML technique for solving the scattering problem (1.1a)–(1.1c). The main difficulty of the analysis is that in contrast to the grating problems in which there are only finite number of outgoing modes [8], now there are infinite number of outgoing modes expressed in terms of Hankel functions. We overcome this difficulty by exploiting the following uniform estimate for the Hankel functions H^1_ν, $\nu \in \mathbb{R}$:

$$|H_\nu^{(1)}(z)| \le e^{-\mathrm{Im}\,(z)\left(1-\frac{\Theta^2}{|z|^2}\right)^{1/2}} |H_\nu^{(1)}(\Theta)| \tag{1.2}$$

for any $z \in \mathbb{C}_{++}, \Theta \in \mathbb{R}$ such that $0 < \Theta \le |z|$, where $\mathbb{C}_{++} = \{z \in \mathbb{C} : \mathrm{Im}\,(z) \ge 0, \mathrm{Re}\,(z) \ge 0\}$. To our knowledge this sharp estimate is new and allows us to prove the exponentially decaying property of the PML solution without resorting to the integral equation technique in [13] or the representation formula in [12]. We remark that in [13], [12], it is required that the fictitious absorbing coefficient must be linear after certain distance away from the boundary where the PML layer is placed. The estimate (1.2) is proved in Lemma 2.2 which depends on the Macdonald formula for the modified Bessel functions. We also remark that since (1.2) is valid for all real order ν, the results of this paper can be extended directly to study three-dimensional Helmholtz-type scattering problems. We will report progress in this direction as well as the study of the electromagnetic scattering problems elsewhere in future.

Let $\Omega^{\rm PML} = B_\rho \backslash \bar{B}_R$, where $0 < R < \rho$ and B_a denotes the circle of radius $a > 0$. Let $\alpha(r) = 1 + \mathbf{i}\sigma(r)$ be the fictitious medium property. In practical applications, σ is usually taken as power functions:

$$\sigma = \sigma(r) = \sigma_0 \left(\frac{r-R}{\rho - R} \right)^m \quad \text{for some constant } \sigma_0 > 0 \text{ and integer } m \geq 1.$$

Under the assumption that the Dirichlet problem of the PML equation in the PML layer is uniquely solvable, we prove the following key estimate between the Dirichlet-to-Neumann mapping for the original scattering problem $T : H^{1/2}(\Gamma_R) \to H^{-1/2}(\Gamma_R)$ and the PML problem $\hat{T}$ (cf. Lemma 2.5), where $\Gamma_R = \partial B_R$,

$$\| T - \hat{T} \|_{L(H^{1/2}(\Gamma_R), H^{-1/2}(\Gamma_R))} \leq C(1+kR)^2 |\alpha_0|^2 e^{-k{\rm Im}\,(\tilde{\rho})\left(1 - \frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}},$$

where $\alpha_0 = 1 + \mathbf{i}\sigma_0$ and $\tilde{\rho} = \int_0^\rho \alpha(t)dt$ is the complex radius corresponding to ρ. We remark that the assumption of the unique solvability of the PML Dirichlet problem in the PML layer is rather mild in practical applications because standard Fredholm alternative theory implies that the PML Dirichlet problem in the PML layer is uniquely solvable for all but a discrete number of real k. Moreover, in the appendix of this paper, we show that for any given ρ, R, the Dirichlet PML problem in the PML layer is uniquely solvable for sufficiently large $\sigma_0 > 0$.

The layout of the paper is as follows. In section 2 we recall the PML formulation for (1.1a)–(1.1c), derive the key estimates for Hankel functions, and study the properties of the PML equation in the PML layer. Existence, uniqueness, and convergence of the PML formulation are considered. In section 3 we introduce the finite element discretization. In section 4 we derive the sharp a posteriori error estimate which lays down the basis of the combined adaptive PML and finite element methods. In section 5 we discuss the implementation of the adaptive method and present several numerical examples to illustrate the competitive behavior of the method. Finally in the appendix we show the unique solvability of the Dirichlet PML problem in the PML layer for sufficiently large σ_0.

2. The PML formulation. Let D be contained in the interior of the circle $B_R = \{x \in \mathbb{R}^2 : |x| < R\}$. We start by introducing an equivalent variational formulation of (1.1a)–(1.1c) in the bounded domain $\Omega_R = B_R \backslash \bar{D}$. In the domain $\mathbb{R}^2 \backslash \bar{B}_R$, the solution u of (1.1a)–(1.1c) can be written under the polar coordinates as follows:

$$u(r,\theta) = \sum_{n \in \mathbb{Z}} \frac{H_n^{(1)}(kr)}{H_n^{(1)}(kR)} \hat{u}_n e^{\mathbf{i}n\theta}, \quad \hat{u}_n = \frac{1}{2\pi} \int_0^{2\pi} u(R,\theta) e^{-\mathbf{i}n\theta} d\theta, \tag{2.1}$$

where $H_n^{(1)}$ is the Hankel function of the first kind and order n. The series in (2.1) converges uniformly for $r > R$ (cf., e.g., Colten and Kress [11]). Let $T : H^{1/2}(\Gamma_R) \to H^{-1/2}(\Gamma_R)$, where $\Gamma_R = \partial B_R$, be the Dirichlet-to-Neumann operator defined as follows: for any $f \in H^{1/2}(\Gamma_R)$,

$$Tf = \sum_{n \in \mathbb{Z}} k \frac{H_n^{(1)\prime}(kR)}{H_n^{(1)}(kR)} \hat{f}_n e^{\mathbf{i}n\theta}, \quad \hat{f}_n = \frac{1}{2\pi} \int_0^{2\pi} f e^{-\mathbf{i}n\theta} d\theta. \tag{2.2}$$

It is known that T is well-defined and the solution u written as in (2.1) satisfies

$$\frac{\partial u}{\partial \mathbf{n}}\Big|_{\Gamma_R} = Tu.$$

Let $a : H^1(\Omega_R) \times H^1(\Omega_R) \to \mathbb{C}$ be the sesquilinear form:

$$a(\varphi, \psi) = \int_{\Omega_R} \left(\nabla\varphi \cdot \nabla\bar{\psi} - k^2\varphi\bar{\psi}\right) dx - \langle T\varphi, \psi\rangle_{\Gamma_R}, \tag{2.3}$$

where $\langle\cdot,\cdot\rangle_{\Gamma_R}$ stands for the inner product on $L^2(\Gamma_R)$ or the duality pairing between $H^{-1/2}(\Gamma_R)$ and $H^{1/2}(\Gamma_R)$. Similar notation applies for $\langle\cdot,\cdot\rangle_{\Gamma_D}$, $\langle\cdot,\cdot\rangle_{\Gamma_\rho}$. The scattering problem (1.1a)–(1.1c) is equivalent to the following weak formulation (cf., e.g., [11]): given $g \in H^{-1/2}(\Gamma_D)$, find $u \in H^1(\Omega_R)$ such that

$$a(u, \psi) = \langle g, \psi\rangle_{\Gamma_D} \quad \forall \psi \in H^1(\Omega_R). \tag{2.4}$$

The existence of a unique solution of the variational problem (2.4) is known (cf., e.g., Colton and Kress [11] and McLean [14]). Then the general theory in Babuška and Aziz [1, Chapter 5] implies that there exists a constant $\mu > 0$ such that the following inf-sup condition holds:

$$\sup_{0\neq\psi\in H^1(\Omega_R)} \frac{|a(\varphi,\psi)|}{\|\,\psi\,\|_{H^1(\Omega_R)}} \geq \ \mu\|\,\varphi\,\|_{H^1(\Omega_R)} \quad \forall \varphi \in H^1(\Omega_R). \tag{2.5}$$

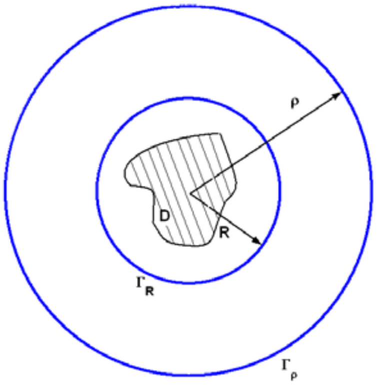

FIG. 2.1. *Setting of the scattering problem with the PML layer.*

Now we turn to the introduction of the absorbing PML layer. We surround the domain Ω_R with a PML layer $\Omega^{\mathrm{PML}} = \{x \in \mathbb{R}^2 : R < |x| < \rho\}$. The specially designed model medium in the PML layer should basically be so chosen that either the wave never reaches its external boundary or the amplitude of the reflected wave is so small that it does not essentially contaminate the solution in Ω_R. Throughout the paper we assume $\rho \leq CR$ for some generic fixed constant $C > 0$.

Let $\alpha(r) = 1 + \mathbf{i}\sigma(r)$ be the model medium property which satisfies

$$\sigma \in C(\mathbb{R}), \quad \sigma \geq 0, \quad \sigma = 0 \quad \text{for } r \leq R.$$

Denote by $\tilde{r}$ the complex radius defined by

$$\tilde{r} = \tilde{r}(r) = \begin{cases} r & \text{if } r \leq R, \\ \displaystyle\int_0^r \alpha(t)dt = r\beta(r) & \text{if } r \geq R. \end{cases} \tag{2.6}$$

Following [10], we introduce the PML equation

$$\nabla \cdot (A\nabla w) + \alpha\beta k^2 w = 0 \quad \text{in } \Omega^{\text{PML}}, \tag{2.7}$$

where $A = A(x)$ is a matrix which satisfies, in polar coordinates,

$$\nabla \cdot (A\nabla) = \frac{1}{r}\frac{\partial}{\partial r}\left(\frac{\beta r}{\alpha}\frac{\partial}{\partial r}\right) + \frac{\alpha}{\beta r^2}\frac{\partial^2}{\partial \theta^2}. \tag{2.8}$$

The PML solution $\hat{u}$ in $\Omega_\rho = B_\rho \backslash \bar{D}$ is defined as the solution of the following system:

$$\nabla \cdot (A\nabla \hat{u}) + \alpha\beta k^2 \hat{u} = 0 \quad \text{in } \Omega_\rho, \tag{2.9a}$$

$$\frac{\partial \hat{u}}{\partial \mathbf{n}} = -g \quad \text{on } \Gamma_D, \qquad \hat{u} = 0 \quad \text{on } \Gamma_\rho. \tag{2.9b}$$

This problem can be reformulated in the bounded domain Ω_R by imposing the boundary condition

$$\frac{\partial \hat{u}}{\partial \mathbf{n}}\Big|_{\Gamma_R} = \hat{T}\hat{u},$$

where the operator $\hat{T} : H^{1/2}(\Gamma_R) \to H^{-1/2}(\Gamma_R)$ is defined as follows: given $f \in H^{1/2}(\Gamma_R)$,

$$\hat{T}f = \frac{\partial \zeta}{\partial \mathbf{n}}\Big|_{\Gamma_R},$$

where $\zeta \in H^1(\Omega^{\text{PML}})$ satisfies

$$\nabla \cdot (A\nabla \zeta) + \alpha\beta k^2 \zeta = 0 \quad \text{in } \Omega^{\text{PML}}, \tag{2.10a}$$

$$\zeta = f \quad \text{on } \Gamma_R, \qquad \zeta = 0 \quad \text{on } \Gamma_\rho. \tag{2.10b}$$

The existence and uniqueness of the solutions of the PML problems (2.10a)–(2.10b) will be studied in the subsection 2.2 below.

On the basis of operator $\hat{T}$, we introduce the sesquilinear form $\hat{a} : H^1(\Omega_R) \times H^1(\Omega_R) \to \mathbb{C}$ by

$$\hat{a}(\varphi, \psi) = \int_{\Omega_R} \left(A\nabla\varphi \cdot \nabla\bar{\psi} - k^2\alpha\beta\varphi\bar{\psi}\right) dx - \langle \hat{T}\varphi, \psi \rangle_{\Gamma_R}. \tag{2.11}$$

Then the weak formulation for (2.9a)–(2.9b) is, given $g \in H^{-1/2}(\Gamma_D)$, find $\hat{u} \in H^1(\Omega_R)$ such that

$$\hat{a}(\hat{u}, \psi) = \langle g, \psi \rangle_{\Gamma_D} \quad \forall \psi \in H^1(\Omega_R). \tag{2.12}$$

The well-posedness of the PML problem (2.12) and the convergence of its solution to the solution of the original scattering problem (2.4) will be studied in the subsection 2.3. In the following we first derive some basic estimates for the Hankel function $H_n^{(1)}$ which play a key role in the analysis in this paper.

2.1. Hankel functions. For $\nu \in \mathbb{C}$, the two Hankel functions $H_\nu^{(1)}(z), H_\nu^{(2)}(z)$, where $z \in \mathbb{C}$, are two fundamental solutions of the Bessel equation for functions of order ν:

$$z^2\frac{d^2y}{dz^2} + z\frac{dy}{dz} + (z^2 - \nu^2)y = 0, \tag{2.13}$$

which satisfy the following asymptotic behaviors as $|z| \to \infty$:

$$H_\nu^{(1)}(z) \sim \left(\frac{2}{\pi z}\right)^{\frac{1}{2}} e^{\mathbf{i}\left(z-\frac{1}{2}\nu\pi-\frac{1}{4}\pi\right)}, \quad H_\nu^{(2)}(z) \sim \left(\frac{2}{\pi z}\right)^{\frac{1}{2}} e^{-\mathbf{i}\left(z-\frac{1}{2}\nu\pi-\frac{1}{4}\pi\right)}. \tag{2.14}$$

We also need the Bessel functions of purely imaginary argument $K_\nu(z)$, also called the modified Bessel functions, which is the solution of the differential equation

$$z^2\frac{d^2y}{dz^2} + z\frac{dy}{dz} - (z^2 + \nu^2)y = 0. \tag{2.15}$$

It is connected with $H_\nu^{(1)}(z)$ through the relation

$$K_\nu(z) = \frac{1}{2}\pi\mathbf{i}e^{\frac{1}{2}\nu\pi\mathbf{i}}H_\nu^{(1)}(\mathbf{i}z). \tag{2.16}$$

The importance of the function $K_\nu(z)$ in mathematical physics lies in the fact that it is a solution of (2.15) which tends to zero exponentially as $z \to \infty$ through positive values. We refer to the treatise by Watson [21] for extensive studies on the functions $H_\nu^{(1)}(z), H_\nu^{(2)}(z)$, and $K_\nu(z)$.

The following lemma is proved in [21, p. 439].

LEMMA 2.1 (Macdonald formula). *For any $\nu \in \mathbb{C}$ and $z_1, z_2 \in \mathbb{C}$ satisfying*

$$|\arg z_1| < \pi, \quad |\arg z_2| < \pi, \quad |\arg(z_1 + z_2)| < \frac{1}{4}\pi,$$

we have

$$K_\nu(z_1)K_\nu(z_2) = \frac{1}{2}\int_0^\infty e^{-\frac{v}{2}-\frac{z_1^2+z_2^2}{2v}} K_\nu\left(\frac{z_1z_2}{v}\right)\frac{dv}{v}.$$

An important consequence of this lemma is that for real ν, $K_\nu(z)$ has no zeros if $|\arg z| \le \frac{1}{2}\pi$ [21, p. 511], which, by (2.16), implies that $H_\nu^{(1)}(z)$ has no zeros when $\mathrm{Im}\,(z) \le 0$. In particular, we have $H_n^{(1)}(kR) \neq 0$ for any $n \in \mathbb{Z}, R > 0$. This justifies the writing of $H_n^{(1)}(kR)$ in the denominator in (2.1), (2.2).

LEMMA 2.2. *For any $\nu \in \mathbb{R}, z \in \mathbb{C}_{++} = \{z \in \mathbb{C} : \mathrm{Im}\,(z) \ge 0, \mathrm{Re}\,(z) \ge 0\}$, and $\Theta \in \mathbb{R}$ such that $0 < \Theta \le |z|$, we have*

$$|H_\nu^{(1)}(z)| \le e^{-\mathrm{Im}\,(z)\left(1-\frac{\Theta^2}{|z|^2}\right)^{1/2}}|H_\nu^{(1)}(\Theta)|. \tag{2.17}$$

This estimate, which to our knowledge is new, will play an important role in the analysis of this paper. The importance of the estimate (2.17) lies in the fact that it is uniform with respect to ν. We remark that the large argument asymptotic expansions such as (2.14) in the literature usually depend on ν and thus are insufficient for our purpose.

Proof. By (2.16) we know that

$$|H_\nu^{(1)}(z)|^2 = H_\nu^{(1)}(z)\overline{H_\nu^{(1)}(z)} = \frac{4}{\pi^2} K_\nu(-\mathbf{i}z)\overline{K_\nu(-\mathbf{i}z)} = \frac{4}{\pi^2} K_\nu(-\mathbf{i}z)K_\nu(\mathbf{i}\bar{z}),$$

where we have used the formula $K_\nu(\bar{z}) = \overline{K_\nu(z)}$ for real ν. Since $z \in \mathbb{C}_{++}$, we know that $|\arg(-\mathbf{i}z)| < \pi$, $|\arg(\mathbf{i}\bar{z})| < \pi$, and $|\arg(-\mathbf{i}z + \mathbf{i}\bar{z})| = 0 < \frac{\pi}{4}$. Thus by Lemma 2.1 we obtain

$$|H_\nu^{(1)}(z)|^2 = \frac{2}{\pi^2} \int_0^\infty e^{-\frac{v}{2} - \frac{-z^2 - \bar{z}^2}{2v}} K_\nu\left(\frac{|z|^2}{v}\right) \frac{dv}{v}.$$

After the change of variable $w = |z|^2/v$, we get

$$|H_\nu^{(1)}(z)|^2 = \frac{2}{\pi^2} \int_0^\infty e^{-\frac{|z|^2}{2w} + \frac{z^2 + \bar{z}^2}{2|z|^2} w} K_\nu(w) \frac{dw}{w},$$

which, for any $\Theta > 0$, we rewrite as

$$|H_\nu^{(1)}(z)|^2 = \frac{2}{\pi^2} \int_0^\infty e^{-\frac{|z|^2 - \Theta^2}{2w} - \frac{2|z|^2 - z^2 - \bar{z}^2}{2|z|^2} w} \cdot e^{-\frac{\Theta^2}{2w} + w} K_\nu(w) \frac{dw}{w}.$$

Now for $0 < \Theta \le |z|$, by Cauchy–Schwarz inequality, we deduce that

$$e^{-\frac{|z|^2 - \Theta^2}{2w} - \frac{2|z|^2 - z^2 - \bar{z}^2}{2|z|^2} w} = e^{-\frac{|z|^2 - \Theta^2}{2w} - \frac{2\mathrm{Im}\,(z)^2}{|z|^2} w} \le e^{-2\mathrm{Im}\,(z)\left(1 - \frac{\Theta^2}{|z|^2}\right)^{1/2}}.$$

Therefore,

$$\begin{aligned} |H_\nu^{(1)}(z)|^2 &\le e^{-2\mathrm{Im}\,(z)\left(1 - \frac{\Theta^2}{|z|^2}\right)^{1/2}} \frac{2}{\pi^2} \int_0^\infty e^{-\frac{\Theta^2}{2w} + w} K_\nu(w) \frac{dw}{w} \\ &= e^{-2\mathrm{Im}\,(z)\left(1 - \frac{\Theta^2}{|z|^2}\right)^{1/2}} |H_\nu^{(1)}(\Theta)|^2. \end{aligned}$$

This completes the proof. □

To proceed further, we recall the following Nicholson integral [21, p. 441]:

$$J_\nu^2(z) + Y_\nu^2(z) = \frac{8}{\pi^2} \int_0^\infty K_0(2z \sinh t) \cosh(2\nu t) dt \quad \text{for } z \in \mathbb{C}, \mathrm{Re}\,(z) > 0.$$

Here $K_0(z)$ is the modified Bessel function of order zero in (2.16). Since $\cosh(t) = (e^t + e^{-t})/2$ is an increasing function in $\mathbb{R}^+$, we have, for $\Theta > 0$, $n \ge 1$, that

$$\begin{aligned} J_{n-1}^2(\Theta) + Y_{n-1}^2(\Theta) &= \frac{8}{\pi^2} \int_0^\infty K_0(2\Theta \sinh t) \cosh(2(n-1)t) dt \\ &\le \frac{8}{\pi^2} \int_0^\infty K_0(2\Theta \sinh t) \cosh(2nt) dt \\ &= J_n^2(\Theta) + Y_n^2(\Theta). \end{aligned}$$

Thus,

$$|H_{n-1}^{(1)}(\Theta)| \le |H_n^{(1)}(\Theta)| \quad \text{for any } \Theta > 0, n \ge 1. \tag{2.18}$$

LEMMA 2.3. *For any $z \in \mathbb{C}_{++}$ and $\Theta \in \mathbb{R}$ such that $0 < \Theta \le |z|$, we have*

$$|H_n^{(1)\prime}(z)| \le e^{-\mathrm{Im}\,(z)\left(1-\frac{\Theta^2}{|z|^2}\right)^{1/2}}\left(1+\frac{|n|}{|z|}\right)|H_n^{(1)}(\Theta)| \quad \text{for } n \in \mathbb{Z}, |n| \ge 1, \tag{2.19}$$

$$|H_0^{(1)\prime}(z)| \le e^{-\mathrm{Im}\,(z)\left(1-\frac{\Theta^2}{|z|^2}\right)^{1/2}}|H_0^{(1)\prime}(\Theta)|. \tag{2.20}$$

Proof. Since $H_{-n}^{(1)} = e^{\mathbf{i}n\pi}H_n^{(1)}(z)$, we only need to prove (2.19) for $n \in \mathbb{Z}$, $n \ge 1$. By the formula

$$z\frac{dH_n^{(1)}(z)}{dz} + nH_n^{(1)}(z) = zH_{n-1}^{(1)}(z),$$

Lemma 2.2, and (2.18), we know that

$$\begin{aligned}|H_n^{(1)\prime}(z)| &\le |H_{n-1}^{(1)}(z)| + \frac{n}{|z|}|H_n^{(1)}(z)|\\ &\le e^{-\mathrm{Im}\,(z)\left(1-\frac{\Theta^2}{|z|^2}\right)^{1/2}}\left(|H_{n-1}^{(1)}(\Theta)| + \frac{n}{|z|}|H_n^{(1)}(\Theta)|\right)\\ &\le e^{-\mathrm{Im}\,(z)\left(1-\frac{\Theta^2}{|z|^2}\right)^{1/2}}\left(1+\frac{n}{|z|}\right)|H_n^{(1)}(\Theta)|.\end{aligned}$$

This proves (2.19). The estimate (2.20) can be proved similarly by using the formula $dH_0^{(1)}(z)/dz = -H_1^{(1)}(z)$. This completes the proof. □

2.2. The PML equation in the layer. In this subsection we consider the Dirichlet problem of the PML equation in the layer Ω^{PML}:

$$\nabla \cdot (A\nabla w) + \alpha\beta k^2 w = 0 \quad \text{in } \Omega^{\mathrm{PML}}, \tag{2.21a}$$

$$w = 0 \quad \text{on } \Gamma_R, \qquad w = q \quad \text{on } \Gamma_\rho, \tag{2.21b}$$

where $q \in H^{1/2}(\Gamma_\rho)$. Let $\hat{b} : H^1(\Omega^{\mathrm{PML}}) \times H^1(\Omega^{\mathrm{PML}}) \to \mathbb{C}$ be the sesquilinear form:

$$\hat{b}(\varphi,\psi) = \int_R^\rho\int_0^{2\pi}\left(\frac{\beta r}{\alpha}\frac{\partial\varphi}{\partial r}\frac{\partial\bar{\psi}}{\partial r} + \frac{\alpha}{\beta r}\frac{\partial\varphi}{\partial\theta}\frac{\partial\bar{\psi}}{\partial\theta} - \alpha\beta k^2 r\varphi\bar{\psi}\right)dr\,d\theta. \tag{2.22}$$

Then from (2.8) we know that the weak formulation for (2.21a)–(2.21b) is the following: Given $q \in H^{1/2}(\Gamma_\rho)$, find $w \in H^1(\Omega^{\mathrm{PML}})$ such that $w = 0$ on Γ_R, $w = q$ on Γ_ρ, and

$$\hat{b}(w,\varphi) = 0 \quad \forall\varphi \in H_0^1(\Omega^{\mathrm{PML}}). \tag{2.23}$$

We make the following assumption on the fictitious medium property σ, which is rather mild in the practical application of the PML techniques:

(H1) $\sigma = \sigma_0\left(\frac{r-R}{\rho-R}\right)^m$ for some constant $\sigma_0 > 0$ and some integer $m \ge 1$.

From (H1) we know that $\beta(r) = 1 + \mathbf{i}\hat{\sigma}(r)$, where

$$\hat{\sigma}(r) = \frac{1}{r}\int_R^r \sigma(t)dt = \frac{\sigma_0}{m+1}\frac{r-R}{r}\left(\frac{r-R}{\rho-R}\right)^m.$$

Thus $\hat{\sigma} \leq \sigma$ for all $r \geq R$. Notice that for $\alpha = 1 + \mathbf{i}\sigma$, $\beta = 1 + \mathbf{i}\hat{\sigma}$, we have

$$\operatorname{Re}\left(\frac{\beta}{\alpha}\right) = \frac{1+\sigma\hat{\sigma}}{1+\sigma^2}, \qquad \operatorname{Re}\left(\frac{\alpha}{\beta}\right) = \frac{1+\sigma\hat{\sigma}}{1+\hat{\sigma}^2}, \qquad \operatorname{Re}(\alpha\beta) = 1 - \sigma\hat{\sigma}$$

and, consequently,

$$\operatorname{Re}[\hat{b}(v,v)] = \int_R^\rho \int_0^{2\pi} \left[\frac{1+\sigma\hat{\sigma}}{1+\sigma^2} r \left|\frac{\partial v}{\partial r}\right|^2 + \frac{1+\sigma\hat{\sigma}}{1+\hat{\sigma}^2} \frac{1}{r} \left|\frac{\partial v}{\partial \theta}\right|^2 + (\sigma\hat{\sigma} - 1)k^2 r |v|^2 \right] dr\, d\theta.$$

Since

$$\frac{1+\sigma\hat{\sigma}}{1+\sigma^2} \geq \frac{1}{1+\sigma^2} \geq |\alpha_0|^{-2}, \qquad \frac{1+\sigma\hat{\sigma}}{1+\hat{\sigma}^2} \geq 1 \geq |\alpha_0|^{-2}, \tag{2.24}$$

where $\alpha_0 = 1 + \mathbf{i}\sigma_0$, by using the analytic Fredholm alternative theorem we know that the PML problem in the layer (2.23) exists a unique solution for every real k except possibly for a discrete set of values of k (cf., e.g., the argument in [10, Theorem 2]). In this paper we will not elaborate on this issue and simply make the following assumption:

(H2) There exists a unique solution to the Dirichlet PML problem (2.23) in the layer.

For any $\varphi \in H^1(\Omega^{\mathrm{PML}})$, define

$$\|\varphi\|_{*,\Omega^{\mathrm{PML}}} = \left[\int_R^\rho \int_0^{2\pi} \left(\frac{1+\sigma\hat{\sigma}}{1+\sigma^2} r \left|\frac{\partial \varphi}{\partial r}\right|^2 + \frac{1+\sigma\hat{\sigma}}{1+\hat{\sigma}^2} \frac{1}{r} \left|\frac{\partial \varphi}{\partial \theta}\right|^2 + (1+\sigma\hat{\sigma})k^2 r |\varphi|^2 \right) \right]^{1/2}.$$

It is easy to see that $\|\cdot\|_{*,\Omega^{\mathrm{PML}}}$ is an equivalent norm on $H^1(\Omega^{\mathrm{PML}})$. By using the general theory in [1, Chapter 5], (H2) implies that there exists a constant $\hat{C} > 0$ such that

$$\sup_{0 \neq \psi \in H_0^1(\Omega^{\mathrm{PML}})} \frac{|\hat{b}(\varphi,\psi)|}{\|\psi\|_{*,\Omega^{\mathrm{PML}}}} \geq \hat{C} \|\varphi\|_{*,\Omega^{\mathrm{PML}}} \quad \forall \varphi \in H_0^1(\Omega^{\mathrm{PML}}). \tag{2.25}$$

The constant $\hat{C}$ depends in general on the domain Ω^{PML} and the wave number k. In the appendix of the paper, however, we will show that for sufficiently large σ_0, (H2) can be proved and $\hat{C}$ can be chosen as independent of Ω^{PML} and k. Without loss of generality we assume $\hat{C} \leq 1$.

To proceed, we introduce the following notation. For any function ξ defined on a circle $\Gamma_a = \{x \in \mathbb{R}^2 : |x| = a\}$ having the Fourier expansion:

$$\xi = \sum_{n \in \mathbb{Z}} \hat{\xi}_n e^{\mathbf{i}n\theta}, \qquad \hat{\xi}_n = \frac{1}{2\pi} \int_0^{2\pi} \xi e^{-\mathbf{i}n\theta} d\theta,$$

we define

$$\|\xi\|^2_{H^{1/2}(\Gamma_a)} = 2\pi \sum_{n \in \mathbb{Z}} (1+n^2)^{1/2} |\hat{\xi}_n|^2, \qquad \|\xi\|^2_{H^{-1/2}(\Gamma_a)} = 2\pi \sum_{n \in \mathbb{Z}} (1+n^2)^{-1/2} |\hat{\xi}_n|^2.$$

The following theorem is the main objective of this subsection.

THEOREM 2.4. *Let* (H1)–(H2) *be satisfied. There exists a constant* $C > 0$ *independent of* k, R, ρ, *and* σ_0 *such that the following estimates are satisfied:*

$$\| \, |\alpha|^{-1} \nabla w \, \|_{L^2(\Omega^{\rm PML})} \le C\hat{C}^{-1}(1+kR)|\alpha_0| \| \, q \, \|_{H^{1/2}(\Gamma_\rho)}, \tag{2.26}$$

$$\left\| \frac{\partial w}{\partial \mathbf{n}} \right\|_{H^{-1/2}(\Gamma_R)} \le C\hat{C}^{-1}(1+kR)^2|\alpha_0|^2 \| \, q \, \|_{H^{1/2}(\Gamma_\rho)}, \tag{2.27}$$

where $\alpha_0 = 1 + \mathbf{i}\sigma_0$.

Proof. We first show that there exists a constant C independent of k, ρ, R, and σ_0 such that

$$|\hat{b}(\varphi,\psi)| \le C(1+kR)|\alpha_0| \| \, \psi \, \|_{*,\Omega^{\rm PML}} |||\varphi|||_{H^1(\Omega^{\rm PML})}, \tag{2.28}$$

where $|||\varphi|||_{H^1(\Omega^{\rm PML})} = (\| \, \nabla\varphi \, \|^2_{L^2(\Omega^{\rm PML})} + R^{-2} \| \, \varphi \, \|^2_{L^2(\Omega^{\rm PML})})^{1/2}$ is the weighted H^1-norm. In fact, since $\hat{\sigma} \le \sigma \le \sigma_0$, we have

$$\begin{aligned}
&\left| \int_R^\rho \int_0^{2\pi} \left(\frac{\beta}{\alpha} r \frac{\partial\varphi}{\partial r}\frac{\partial\bar{\psi}}{\partial r} + \frac{\alpha}{\beta r}\frac{\partial\varphi}{\partial\theta}\frac{\partial\bar{\psi}}{\partial\theta} - \alpha\beta k^2 r\varphi\bar{\psi} \right) dr\, d\theta \right| \\
&\le \left(\int_R^\rho \int_0^{2\pi} \frac{1+\sigma\hat{\sigma}}{1+\sigma^2} r \left| \frac{\partial\psi}{\partial r} \right|^2 \right)^{1/2} \left(\int_R^\rho \int_0^{2\pi} \frac{1+\hat{\sigma}^2}{1+\sigma\hat{\sigma}} r \left| \frac{\partial\varphi}{\partial r} \right|^2 \right)^{1/2} \\
&\quad + \left(\int_R^\rho \int_0^{2\pi} \frac{1+\sigma\hat{\sigma}}{1+\hat{\sigma}^2} \frac{1}{r} \left| \frac{\partial\psi}{\partial\theta} \right|^2 \right)^{1/2} \left(\int_R^\rho \int_0^{2\pi} \frac{1+\sigma^2}{1+\sigma\hat{\sigma}} \frac{1}{r} \left| \frac{\partial\varphi}{\partial\theta} \right|^2 \right)^{1/2} \\
&\quad + \left(\int_R^\rho \int_0^{2\pi} k^2(1+\sigma\hat{\sigma}) r|\psi|^2 \right)^{1/2} \left(\int_R^\rho \int_0^{2\pi} k^2 r \frac{|\alpha\beta|^2}{1+\sigma\hat{\sigma}} |\varphi|^2 \right)^{1/2} \\
&\le C(1+kR)|\alpha_0| \| \, \psi \, \|_{*,\Omega^{\rm PML}} |||\varphi|||_{H^1(\Omega^{\rm PML})}.
\end{aligned}$$

This implies the estimate (2.28).

Now we turn to the proof the estimate (2.26). Let $\psi \in H^1(\Omega^{\rm PML})$ such that $\psi = 0$ on Γ_R and $\psi = q$ on Γ_ρ. By taking $\varphi = w - \psi \in H^1_0(\Omega^{\rm PML})$ in (2.23), we know from (2.28) that

$$|\hat{b}(\varphi,\varphi)| = |\hat{b}(w-\psi,\varphi)| = |\hat{b}(\psi,\varphi)| \le C(1+kR)|\alpha_0| \| \, \varphi \, \|_{*,\Omega^{\rm PML}} |||\psi|||_{H^1(\Omega^{\rm PML})},$$

which implies by (2.25) that

$$\| \, \varphi \, \|_{*,\Omega^{\rm PML}} \le C\hat{C}^{-1}(1+kR)|\alpha_0| |||\psi|||_{H^1(\Omega^{\rm PML})}.$$

Notice that

$$\| \, \psi \, \|_{*,\Omega^{\rm PML}} \le C(1+kR)|\alpha_0| |||\psi|||_{H^1(\Omega^{\rm PML})},$$

we get

$$\| \, w \, \|_{*,\Omega^{\rm PML}} = \| \, \varphi + \psi \, \|_{*,\Omega^{\rm PML}} \le C\hat{C}^{-1}(1+kR)|\alpha_0| |||\psi|||_{H^1(\Omega^{\rm PML})}.$$

Since the above estimate is valid for any $\psi \in H^1(\Omega^{\rm PML})$ such that $\psi = 0$ on Γ_R, $\psi = q$ on Γ_ρ, we deduce by standard scaling argument using the assumption $\rho \le CR$ that

$$\| \, w \, \|_{*,\Omega^{\rm PML}} \le C\hat{C}^{-1}(1+kR)|\alpha_0| \| \, q \, \|_{H^{1/2}(\Gamma_\rho)}. \tag{2.29}$$

This shows the estimate (2.26) upon using (2.24).

To show (2.27) we multiply the (2.21a) by any function $\varphi \in H^1(\Omega^{\rm PML})$ such that $\varphi = 0$ on Γ_ρ and integrate over $\Omega^{\rm PML}$ to obtain

$$-\int_{\Omega^{\rm PML}} A\nabla w \cdot \nabla\varphi dx - \int_{\Gamma_R} \frac{\partial w}{\partial r}\varphi ds + \int_{\Omega^{\rm PML}} \alpha\beta k^2 w\varphi dx = 0.$$

Thus

$$\left|\int_{\Gamma_R} \frac{\partial w}{\partial r}\varphi ds\right| = |\hat{b}(w,\bar{\varphi})| \le C(1+kR)|\alpha_0| \|\, w \,\|_{*,\Omega^{\rm PML}} |||\varphi|||_{H^1(\Omega^{\rm PML})}$$

for any $\varphi \in H^1(\Omega^{\rm PML})$ such that $\varphi = 0$ on Γ_ρ. This implies by (2.29) that

$$\left|\int_{\Gamma_R} \frac{\partial w}{\partial r}\varphi ds\right| \le C\hat{C}^{-1}(1+kR)^2|\alpha_0|^2 \|\, q \,\|_{H^{1/2}(\Gamma_\rho)} \|\varphi\|_{H^{1/2}(\Gamma_R)} \qquad \forall \varphi \in H^{1/2}(\Gamma_R).$$

This completes the proof of the theorem. □

2.3. Convergence of the PML problem. In this subsection we consider the convergence of the PML problem (2.12) to the original scattering problem (2.4). Following an idea in [13], for any function $f \in H^{1/2}(\Gamma_R)$, we introduce the propagation operator $P : H^{1/2}(\Gamma_R) \to H^{1/2}(\Gamma_\rho)$:

$$P(f) = \sum_{n\in\mathbb{Z}} \frac{H_n^{(1)}(k\tilde{\rho})}{H_n^{(1)}(kR)} \hat{f}_n e^{\mathbf{i}n\theta}, \qquad \hat{f}_n = \frac{1}{2\pi}\int_0^{2\pi} f e^{-\mathbf{i}n\theta} d\theta. \tag{2.30}$$

By Lemma 2.2, it is easy to see that $P : H^{1/2}(\Gamma_R) \to H^{1/2}(\Gamma_\rho)$ is well-defined, and

$$\|\, P(f) \,\|_{H^{1/2}(\Gamma_\rho)} \le e^{-k{\rm Im}\,(\tilde{\rho})\left(1-\frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \|\, f \,\|_{H^{1/2}(\Gamma_R)} \qquad \forall r \ge R. \tag{2.31}$$

Moreover, by Theorem 2.4, under the assumptions (H1)–(H2), the operator $\hat{T} : H^{1/2}(\Gamma_R) \to H^{-1/2}(\Gamma_R)$, which is defined through the Dirichlet problem of the PML equation in the layer, is also well-defined. Furthermore, we have the following estimate.

Lemma 2.5. *Let* (H1)–(H2) *be satisfied. We have*

$$\|\, Tf - \hat{T}f \,\|_{H^{-1/2}(\Gamma_R)} \le C\hat{C}^{-1}(1+kR)^2|\alpha_0|^2 e^{-k{\rm Im}\,(\tilde{\rho})\left(1-\frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \|\, f \,\|_{H^{1/2}(\Gamma_R)}.$$

Proof. For any $f \in H^{1/2}(\Gamma_R)$, we know that

$$Tf - \hat{T}f = \frac{\partial w}{\partial \mathbf{n}}\Big|_{\Gamma_R},$$

where $w \in H^1(\Omega^{\rm PML})$ satisfies

$$\nabla\cdot(A\nabla w) + \alpha\beta k^2 w = 0 \quad \text{in } \Omega^{\rm PML},$$
$$w = 0 \ \text{ on } \Gamma_R, \qquad w = P(f) \quad \text{on } \Gamma_\rho.$$

By (2.27) and (2.31) we then have

$$\begin{aligned}\left\|\frac{\partial w}{\partial \mathbf{n}}\right\|_{H^{-1/2}(\Gamma_R)} &\le C\hat{C}^{-1}(1+kR)^2|\alpha_0|^2 \|\, P(f) \,\|_{H^{1/2}(\Gamma_\rho)} \\ &\le C\hat{C}^{-1}(1+kR)^2|\alpha_0|^2 e^{-k{\rm Im}\,(\tilde{\rho})\left(1-\frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \|\, f \,\|_{H^{1/2}(\Gamma_R)}.\end{aligned}$$

This completes the proof. □

The following theorem is the main result of this section.

THEOREM 2.6. *Let* (H1)–(H2) *be satisfied. Then for sufficiently large $\sigma_0 > 0$, the PML problem* (2.12) *has a unique solution $\hat{u} \in H^1(\Omega_\rho)$. Moreover, we have the following estimate:*

$$\| u - \hat{u} \|_{H^1(\Omega_R)} \le C\hat{C}^{-1}(1+kR)^2|\alpha_0|^2 e^{-k\mathrm{Im}\,(\tilde{\rho})\left(1-\frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \| \hat{u} \|_{H^{1/2}(\Gamma_R)}. \tag{2.32}$$

Proof. The existence of a unique solution for (2.12) follows from Lemma 2.5 by using the same argument as in [8, Theorem 2.4]. Next, by (2.4) and (2.12), we have

$$a(u-\hat{u},\varphi) = \hat{a}(\hat{u},\varphi) - a(\hat{u},\varphi) = \langle T\hat{u} - \hat{T}\hat{u}, \varphi\rangle_{\Gamma_R} \quad \forall \varphi \in H^1(\Omega^{\mathrm{PML}}).$$

This implies the desired estimate (2.32) upon using Lemma 2.5 and (2.5). □

3. Finite element approximations. In this section we introduce the finite element approximations of the PML problems (2.9a)–(2.9b). From now on we assume $g \in L^2(\Gamma_D)$. Let $b : H^1(\Omega_\rho) \times H^1(\Omega_\rho) \to \mathbb{C}$ be the sesquilinear form given by

$$b(\varphi,\psi) = \int_{\Omega_\rho} \left(A\nabla\varphi \cdot \nabla\bar{\psi} - \alpha\beta k^2 \varphi\bar{\psi}\right) dx. \tag{3.1}$$

Denote by $H^1_{(0)}(\Omega_\rho) = \{v \in H^1(\Omega_\rho) : v = 0 \text{ on } \Gamma_\rho\}$. Then the weak formulation of (2.9a)–(2.9b) is, given $g \in L^2(\Gamma_D)$, find $\hat{u} \in H^1_{(0)}(\Omega_\rho)$ such that

$$b(\hat{u},\psi) = \int_{\Gamma_D} g\bar{\psi} ds \qquad \forall \psi \in H^1_{(0)}(\Omega_\rho). \tag{3.2}$$

Let Γ^h_ρ, which consists of piecewise segments whose vertices lie on Γ_ρ, be an approximation of Γ_ρ. Let Ω^h_ρ be the subdomain of Ω_ρ bounded by Γ_D and Γ^h_ρ. Let $\mathcal{M}_h$ be a regular triangulation of the domain Ω^h_ρ. We assume the elements $K \in \mathcal{M}_h$ may have one curved edge align with Γ_D so that $\Omega^h_\rho = \cup_{K\in\mathcal{M}_h} K$.

Let $V_h \subset H^1(\Omega^h_\rho)$ be the conforming linear finite element space over Ω^h_ρ, and $\overset{\circ}{V}_h = \{v_h \in V_h : v_h = 0 \text{ on } \Gamma^h_\rho\}$. In the following we will always assume that the functions in $\overset{\circ}{V}_h$ are extended to the domain Ω_ρ by zero so that any function $v_h \in \overset{\circ}{V}_h$ is also a function in $H^1_{(0)}(\Omega_\rho)$. The finite element approximation to the PML problems (2.9a)–(2.9b) reads as follows: Find $u_h \in \overset{\circ}{V}_h$ such that

$$b(u_h,\psi_h) = \int_{\Gamma_D} g\bar{\psi}_h ds \qquad \forall\ \psi_h \in \overset{\circ}{V}_h. \tag{3.3}$$

Following the general theory in [1, Chapter 5], the existence of unique solution of the discrete problem (3.3) and the finite element convergence analysis depend on the following discrete inf-sup condition:

$$\sup_{0\neq\psi_h\in\overset{\circ}{V}_h} \frac{|b(\varphi_h,\psi_h)|}{\| \psi_h \|_{H^1(\Omega_\rho)}} \ge \hat{\mu}\ \| \varphi_h \|_{H^1(\Omega_\rho)} \quad \forall\ \varphi_h \in \overset{\circ}{V}_h, \tag{3.4}$$

where the constant $\hat{\mu} > 0$ is independent of the finite element mesh size. Since the continuous problem (3.2) has a unique solution by Theorem 2.6, the sesquilinear form

$b : H^1_{(0)}(\Omega_\rho) \times H^1_{(0)}(\Omega_\rho) \to \mathbb{C}$ satisfies the continuous inf-sup condition. Then a general argument of Schatz [18] implies (3.4) is valid for sufficiently small mesh size $h < h^*$. On the basis of (3.4), appropriate a priori error estimate can also be derived which depends on the regularity of the PML solution $\hat{u}$. In this paper, we are interested in a posterior error estimates and the associated adaptive algorithm. Thus in the following we simply assume the discrete problem (3.3) has a unique solution $u_h \in \overset{\circ}{V}_h$.

For any $K \in \mathcal{M}_h$, we denote by h_K its diameter. Let $\mathcal{B}_h$ denote the set of all sides that do not lie on Γ_D and Γ^h_ρ. For any $e \in \mathcal{B}_h$, h_e stands for its length. For any $K \in \mathcal{M}_h$, we introduce the residual:

$$R_h := \nabla \cdot (A \nabla u_h|_K) + \alpha\beta k^2 u_h|_K. \tag{3.5}$$

For any interior side $e \in \mathcal{B}_h$ which is the common side of K_1 and $K_2 \in \mathcal{M}_h$, we define the jump residual across e:

$$J_e := (A\nabla u_h|_{K_1} - A\nabla u_h|_{K_2}) \cdot \nu_e, \tag{3.6}$$

using the convention that the unit normal vector ν_e to e points from K_2 to K_1. If $e = \Gamma_D \cap \partial K$ for some element $K \in \mathcal{M}_h$, then we define the jump residual:

$$J_e := 2(\nabla u_h|_K \cdot \mathbf{n} + g). \tag{3.7}$$

For any $K \in \mathcal{M}_h$, denote by η_K the local error estimator which is defined by

$$\eta_K = \max_{x \in \tilde{K}} \omega(x) \cdot \left(\|h_K R_h\|^2_{L^2(K)} + \frac{1}{2} \sum_{e \subset \partial K} h_e \| \, J_e \, \|^2_{L^2(e)} \right)^{1/2}, \tag{3.8}$$

where $\tilde{K}$ is the union of all elements having nonempty intersection with K, and

$$\omega(x) = \begin{cases} 1 & \text{if } x \in \overline{\Omega_R}, \\ |\alpha_0 \alpha| e^{-k \mathrm{Im}\,(\tilde{r}) \left(1 - \frac{r^2}{|\tilde{r}|^2}\right)^{1/2}} & \text{if } x \in \Omega^{\mathrm{PML}}. \end{cases}$$

The following theorem is the main result of this paper.

THEOREM 3.1. *There exists a constant C depending only on the minimum angle of the mesh $\mathcal{M}_h$ such that the following a posterior error estimate is valid:*

$$\begin{aligned} \| \, u - u_h \, \|_{H^1(\Omega_R)} \le\; & C\hat{C}^{-1} \Lambda(kR)^{1/2}(1 + kR) \left(\sum_{K \in \mathcal{M}_h} \eta_K^2 \right)^{1/2} \\ & + C\hat{C}^{-1}(1 + kR)^2 |\alpha_0|^2 e^{-k \mathrm{Im}\,(\tilde{\rho}) \left(1 - \frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \| \, u_h \, \|_{H^{1/2}(\Gamma_R)}. \end{aligned} \tag{3.9}$$

Here $\Lambda(kR)$ is defined in Lemma 4.3 *below.*

The proof of this theorem will be given in section 4. The important exponentially decaying factor $e^{-k\mathrm{Im}\,(\tilde{r})\left(1 - \frac{r^2}{|\tilde{r}|^2}\right)^{1/2}}$ in the PML region Ω^{PML} allows us to take thicker PML layers without introducing unnecessary fine meshes away from the fixed domain Ω_R. Recall that thicker PML layers allow smaller PML medium property, which enhances numerical stability.

4. A posteriori error estimates.

In this section we prove the a posteriori error estimates in Theorem 3.1.

4.1. Error representation formula. For any $\varphi \in H^1(\Omega_R)$, let $\tilde{\varphi}$ be its extension in $\Omega^{\rm PML}$ such that

$$\nabla\cdot(\bar{A}\nabla\tilde{\varphi}) + \overline{\alpha\beta}k^2\tilde{\varphi} = 0 \quad \text{in } \Omega^{\rm PML}, \tag{4.1a}$$

$$\tilde{\varphi} = \varphi \quad \text{on } \Gamma_R, \qquad \tilde{\varphi} = 0 \quad \text{on } \Gamma_\rho. \tag{4.1b}$$

Lemma 4.1. *Let* (H2) *be satisfied. For any $\varphi, \psi \in H^1(\Omega^{\rm PML})$, we have*

$$\langle \hat{T}\varphi, \psi\rangle_{\Gamma_R} = \langle \hat{T}\bar{\psi}, \bar{\varphi}\rangle_{\Gamma_R}.$$

Proof. By definition, $\hat{T}\varphi = \partial w/\partial\mathbf{n}$ on Γ_R, where w satisfies

$$\nabla\cdot(A\nabla w) + \alpha\beta k^2 w = 0 \quad \text{in } \Omega^{\rm PML},$$
$$w = \varphi \quad \text{on } \Gamma_R, \qquad w = 0 \quad \text{on } \Gamma_\rho.$$

Thus

$$w(x) = \sum_{n\in\mathbb{Z}} \left(a_n H_n^{(1)}(k\tilde{r}) + b_n H_n^{(2)}(k\tilde{r})\right) e^{\mathbf{i}n\theta}$$

with the coefficients a_n, b_n being determined by the boundary conditions in (4.1b)

$$a_n H_n^{(1)}(kR) + b_n H_n^{(2)}(kR) = \hat{\varphi}_n, \qquad a_n H_n^{(1)}(k\tilde{\rho}) + b_n H_n^{(2)}(k\tilde{\rho}) = 0,$$

where $\hat{\varphi}_n = \frac{1}{2\pi}\int_0^{2\pi}\varphi(R,\theta)e^{-\mathbf{i}n\theta}d\theta$ is the nth Fourier coefficient of $\varphi|_{\Gamma_R}$. Denote by

$$H_n(k\tilde{r}) = H_n^{(1)}(k\tilde{r})H_n^{(2)}(k\tilde{\rho}) - H_n^{(2)}(k\tilde{r})H_n^{(1)}(k\tilde{\rho}).$$

Then since by (H2) the Dirichlet PML problem in the layer has a unique solution, we get $H_n(kR) \neq 0$, and

$$a_n = \frac{H_n^{(2)}(k\tilde{\rho})}{H_n(kR)}\hat{\varphi}_n, \qquad b_n = -\,\frac{H_n^{(1)}(k\tilde{\rho})}{H_n(kR)}\hat{\varphi}_n.$$

Thus

$$w = w(r,\theta) = \sum_{n\in\mathbb{Z}} \frac{H_n(k\tilde{r})}{H_n(kR)}\hat{\varphi}_n e^{\mathbf{i}n\theta},$$

which, since $\tilde{r}'(R) = \alpha(R) = 1$ and $\tilde{R} = R$, implies

$$\hat{T}\varphi|_{\Gamma_R} = \sum_{n\in\mathbb{Z}} k\frac{H_n'(kR)}{H_n(kR)}\hat{\varphi}_n e^{\mathbf{i}n\theta}.$$

Therefore,

$$\langle \hat{T}\varphi, \psi\rangle_{\Gamma_R} = \sum_{n\in\mathbb{Z}} k\frac{H_n'(kR)}{H_n(kR)}\hat{\varphi}_n\bar{\hat{\psi}}_n \qquad \forall \varphi, \psi \in H^1(\Omega^{\rm PML}).$$

This completes the proof. □

Whenever no confusion of the notation incurred, we shall write in the following $\tilde{\varphi}$ as φ in $\Omega^{\rm PML}$.

LEMMA 4.2 (error representational formula). *For any $\varphi \in H^1(\Omega_R)$, which is extended to be a function in $H^1(\Omega_\rho)$ according to* (4.1a)–(4.1b), *and $\varphi_h \in \overset{\circ}{V}_h$, we have*

$$a(u-u_h,\varphi) = \int_{\Gamma_D} g(\overline{\varphi-\varphi_h}) - b(u_h,\varphi-\varphi_h) + \langle Tu_h - \hat{T}u_h, \varphi\rangle_{\Gamma_R}. \tag{4.2}$$

Proof. By (2.4) and the definitions (2.3) and (3.1),

$$\begin{aligned} &a(u-u_h,\varphi)\\ &\quad = \int_{\Gamma_D} g\bar{\varphi} - \int_{\Omega_R} (A\nabla u_h\cdot\nabla\bar{\varphi} - \alpha\beta k^2 u_h\bar{\varphi}) + \langle Tu_h,\varphi\rangle_{\Gamma_R}\\ &\quad = \int_{\Gamma_D} g\bar{\varphi} - b(u_h,\varphi) + \int_{\Omega^{\rm PML}} (A\nabla u_h\cdot\nabla\bar{\tilde{\varphi}} - \alpha\beta k^2 u_h\bar{\tilde{\varphi}}) + \langle Tu_h,\varphi\rangle_{\Gamma_R}. \end{aligned} \tag{4.3}$$

On the other hand, by multiplying (4.1a) by $\bar{u}_h$, integrating by parts, and recalling that $\mathbf{n}$ is the unit outer normal to Γ_R which points outside Ω_R, we deduce that

$$-\int_{\Omega^{\rm PML}} (\bar{A}\nabla\tilde{\varphi}\cdot\nabla\bar{u}_h - \overline{\alpha\beta}k^2\tilde{\varphi}\bar{u}_h) - \left\langle \frac{\partial\tilde{\varphi}}{\partial\mathbf{n}}, u_h\right\rangle_{\Gamma_R} = 0,$$

which is equivalent to

$$\int_{\Omega^{\rm PML}} (A\nabla u_h\cdot\nabla\bar{\tilde{\varphi}} - \alpha\beta k^2 u_h\bar{\tilde{\varphi}}) = -\left\langle \frac{\partial\bar{\tilde{\varphi}}}{\partial\mathbf{n}}, \bar{u}_h\right\rangle_{\Gamma_R}. \tag{4.4}$$

Since by the definition of $\hat{T}: H^{1/2}(\Gamma_R)\to H^{-1/2}(\Gamma_R)$,

$$\frac{\partial\bar{\tilde{\varphi}}}{\partial\mathbf{n}}\Big|_{\Gamma_R} = \hat{T}\bar{\varphi},$$

we obtain by substituting (4.4) into (4.3) that

$$a(u-u_h,\varphi) = \int_{\Gamma_D} g\bar{\varphi} - b(u_h,\varphi) + \langle Tu_h,\varphi\rangle - \langle \hat{T}\bar{\varphi},\bar{u}_h\rangle.$$

This completes the proof upon using Lemma 4.1 and (3.3). □

4.2. Estimates for the extension. For any $\varphi\in H^1(\Omega_R)$, we define, for $r\ge R$,

$$\phi = \phi(r,\theta) = \sum_{n\in\mathbb{Z}} \frac{H_n^{(1)}(k\tilde{r})}{H_n^{(1)}(kR)}\bar{\hat{\varphi}}_n e^{\mathbf{i}n\theta}, \qquad \hat{\varphi}_n = \frac{1}{2\pi}\int_0^{2\pi} \varphi(R,\theta)e^{-\mathbf{i}n\theta}d\theta. \tag{4.5}$$

The function ϕ satisfies

$$\nabla\cdot(A\nabla\phi) + \alpha\beta k^2\phi = 0 \quad \text{in } \mathbb{R}^2\backslash\bar{B}_R, \tag{4.6a}$$

$$\phi = \bar{\varphi} \quad \text{on } \Gamma_R, \tag{4.6b}$$

$$|\phi| \text{ is uniformly bounded as } r = |x| \to \infty. \tag{4.6c}$$

By Lemma 2.2, it is easy to see that

$$\| \phi \|_{H^{1/2}(\Gamma_\rho)} \le e^{-k\mathrm{Im}\,(\tilde\rho)\left(1-\frac{R^2}{|\tilde\rho|^2}\right)^{1/2}} \| \varphi \|_{H^{1/2}(\Gamma_R)}. \tag{4.7}$$

Set

$$\gamma(r) = e^{k\mathrm{Im}\,(\tilde r)\left(1-\frac{r^2}{|\tilde r|^2}\right)^{1/2}}.$$

Since $\tilde r = r(1+\mathbf{i}\hat\sigma)$, we obatin by simple calculation that

$$\gamma'(r) = \gamma(r)\cdot k\left(\frac{\sigma\hat\sigma}{(1+\hat\sigma^2)^{1/2}} + \frac{r\hat\sigma\hat\sigma'}{(1+\hat\sigma^2)^{3/2}}\right),$$

which, together with $r\hat\sigma' = \sigma - \hat\sigma \le \sigma$, implies

$$0 \le \gamma'(r) \le 2\sigma k\gamma(r) \quad \forall r \ge R. \tag{4.8}$$

Lemma 4.3. *Let $\Lambda(kR) = \max(1, \frac{|H_0^{(1)\prime}(kR)|}{|H_0^{(1)}(kR)|})$. Then there exists a constant $C > 0$ independent of k, R, ρ, and σ_0 such that*

$$\| |\alpha|^{-1}\gamma\nabla\phi \|_{L^2(\Omega^{\mathrm{PML}})} \le C\Lambda(kR)^{1/2}(1+kR)|\alpha_0|\| \varphi \|_{H^{1/2}(\Gamma_R)}.$$

Proof. We multiply (4.6a) by $\gamma^2\bar\phi$ and integrate over Ω^{PML} to obtain

$$\begin{aligned}
&\int_R^\rho\int_0^{2\pi}\gamma^2\left(\frac{\beta r}{\alpha}\left|\frac{\partial\phi}{\partial r}\right|^2 + \frac{\alpha}{\beta r}\left|\frac{\partial\phi}{\partial\theta}\right|^2\right)dr\,d\theta\\
&\quad = -\int_R^\rho\int_0^{2\pi}\left(\frac{\beta r}{\alpha}\frac{\partial\phi}{\partial r}(\gamma^2)'\bar\phi - \alpha\beta k^2 r\gamma^2|\phi|^2\right)dr\,d\theta\\
&\qquad + \int_0^{2\pi}\left[\frac{\beta r}{\alpha}\gamma^2\frac{\partial\phi}{\partial r}\bar\phi\right](\rho)d\theta - \int_0^{2\pi}\left[\frac{\beta r}{\alpha}\gamma^2\frac{\partial\phi}{\partial r}\bar\phi\right](R)d\theta.
\end{aligned}$$

Taking the real part of the equation we get

$$\begin{aligned}
&\int_R^\rho\int_0^{2\pi}\gamma^2\left(\frac{1+\sigma\hat\sigma}{1+\sigma^2}r\left|\frac{\partial\phi}{\partial r}\right|^2 + \frac{1+\sigma\hat\sigma}{1+\hat\sigma^2}\frac{1}{r}\left|\frac{\partial\phi}{\partial\theta}\right|^2\right)dr\,d\theta\\
&\quad \le \int_R^\rho\int_0^{2\pi}\left|\frac{\beta r}{\alpha}\frac{\partial\phi}{\partial r}2\gamma\gamma'\bar\phi\right|dr\,d\theta + \int_R^\rho\int_0^{2\pi}|\alpha\beta|k^2r\gamma^2|\phi|^2dr\,d\theta\\
&\qquad + \int_0^{2\pi}\left|\left[\frac{\beta r}{\alpha}\gamma^2\frac{\partial\phi}{\partial r}\bar\phi\right](\rho)\right|d\theta + \int_0^{2\pi}\left|\left[\frac{\beta r}{\alpha}\gamma^2\frac{\partial\phi}{\partial r}\bar\phi\right](R)\right|d\theta\\
&\quad := \mathrm{I}_1 + \cdots + \mathrm{I}_4.
\end{aligned} \tag{4.9}$$

Since $\gamma' \le 2k\sigma\gamma$ by (4.8), we obtain by Cauchy–Schwarz inequality and the fact $\hat\sigma \le \sigma$ that

$$\begin{aligned}
\mathrm{I}_1 &\le \left(\int_R^\rho\int_0^{2\pi}\gamma^2\frac{1+\sigma\hat\sigma}{1+\sigma^2}r\left|\frac{\partial\phi}{\partial r}\right|^2\right)^{1/2}\left(\int_R^\rho\int_0^{2\pi}16k^2\sigma^2\gamma^2\left|\frac{\beta}{\alpha}\right|^2\frac{1+\sigma^2}{1+\sigma\hat\sigma}\ r|\phi|^2\right)^{1/2}\\
&\le 4\left(\int_R^\rho\int_0^{2\pi}\gamma^2\frac{1+\sigma\hat\sigma}{1+\sigma^2}r\left|\frac{\partial\phi}{\partial r}\right|^2dr\,d\theta\right)^{1/2}\left(\int_R^\rho\int_0^{2\pi}k^2\sigma^2\gamma^2r|\phi|^2dr\,d\theta\right)^{1/2}.
\end{aligned}$$

On the other hand, by (4.5) and Lemma 2.2, we know that

$$\begin{aligned}\int_R^\rho \int_0^{2\pi} k^2\sigma^2\gamma^2 r|\phi|^2 dr\,d\theta &= 2\pi\sum_{n\in\mathbb{Z}}\int_R^\rho k^2\sigma^2\gamma^2 r\left|\frac{H_n^{(1)}(k\tilde r)}{H_n^{(1)}(kR)}\right|^2 dr\cdot|\hat\phi_n|^2\\ &\le 2\pi\sum_{n\in\mathbb{Z}}\int_R^\rho k^2\sigma^2 r dr\cdot|\hat\phi_n|^2\\ &\le C(1+kR)^2|\alpha_0|^2\|\,\phi\,\|^2_{L^2(\Gamma_R)}.\end{aligned}\tag{4.10}$$

Hence

$$\mathrm{I}_1 \le \frac{1}{2}\int_R^\rho\int_0^{2\pi}\gamma^2\frac{1+\sigma\hat\sigma}{1+\sigma^2}r\left|\frac{\partial\phi}{\partial r}\right|^2 dr\,d\theta + C(1+kR)^2|\alpha_0|^2\|\,\phi\,\|^2_{L^2(\Gamma_R)}.$$

By (4.10) we also have

$$\mathrm{I}_2 \le C(1+kR)^2|\alpha_0|^2\|\,\phi\,\|^2_{L^2(\Gamma_R)}.$$

Next, since $\tilde r'(r)=\alpha(r)$, by (4.5) and Lemma 2.3, we have

$$\begin{aligned}\mathrm{I}_3 &\le 2\pi\sum_{n\in\mathbb{Z}}\left|k\rho\beta(\rho)\gamma(\rho)^2\frac{H_n^{(1)\prime}(k\tilde\rho)}{H_n^{(1)}(kR)}\frac{H_n^{(1)}(k\tilde\rho)}{H_n^{(1)}(kR)}\right|\cdot|\hat\phi_n|^2\\ &\le 2\pi|\alpha_0|\sum_{n\ne0}k\rho\left(1+\frac{|n|}{|k\tilde\rho|}\right)|\hat\phi_n|^2 + 2\pi|\alpha_0|k\rho\left|\frac{H_0^{(1)\prime}(kR)}{H_0^{(1)}(kR)}\right|\cdot|\hat\phi_0|^2\\ &\le 2\pi|\alpha_0|\sum_{n\ne0}(k\rho+|n|)|\hat\phi_n|^2 + 2\pi|\alpha_0|k\rho\Lambda(kR)|\hat\phi_0|^2,\end{aligned}$$

where in the last inequality we have used the relation $\rho\le|\tilde\rho|$. Since $k\rho+|n|\le(1+k\rho)(1+n^2)^{1/2}$, we deduce finally

$$\mathrm{I}_3 \le C\Lambda(kR)(1+k\rho)|\alpha_0|\|\,\phi\,\|^2_{H^{1/2}(\Gamma_R)} \le C\Lambda(kR)(1+kR)|\alpha_0|\|\,\phi\,\|^2_{H^{1/2}(\Gamma_R)}.$$

Similarly, we can prove

$$\mathrm{I}_4 \le C\Lambda(kR)(1+kR)\|\,\phi\,\|^2_{H^{1/2}(\Gamma_R)}.$$

Substituting the estimates for $\mathrm{I}_1,\dots,\mathrm{I}_4$ into (4.9), we conclude that

$$\begin{aligned}&\int_R^\rho\int_0^{2\pi}\gamma^2\left(\frac{1+\sigma\hat\sigma}{1+\sigma^2}r\left|\frac{\partial\phi}{\partial r}\right|^2+\frac{1+\sigma\hat\sigma}{1+\hat\sigma^2}\frac{1}{r}\left|\frac{\partial\phi}{\partial\theta}\right|^2\right)dr\,d\theta\\ &\quad\le C\Lambda(kR)(1+kR)^2|\alpha_0|^2\|\,\phi\,\|^2_{H^{1/2}(\Gamma_R)}.\end{aligned}$$

This completes the proof. □

The following lemma is the main objective of this subsection.

LEMMA 4.4. *For any $\varphi\in H^1(\Omega_R)$, which is extended to be a function $\tilde\varphi\in H^1(\Omega^{\mathrm{PML}})$ according to* (4.1a)–(4.1b), *we have the following estimate:*

$$\|\,|\alpha|^{-1}\gamma\nabla\tilde\varphi\,\|_{L^2(\Omega^{\mathrm{PML}})} \le C\hat C^{-1}\Lambda(kR)^{1/2}(1+kR)|\alpha_0|\|\,\varphi\,\|_{H^{1/2}(\Gamma_R)}.$$

Proof. Let $w = \tilde{\varphi} - \bar{\phi}$; then from (4.1a)–(4.1b) and (4.6a)–(4.6b) we know that w satisfies

$$\nabla \cdot (A\nabla w) + \alpha\beta k^2 w = 0 \quad \text{in } \Omega^{\mathrm{PML}},$$
$$w = 0 \ \text{ on } \Gamma_R, \qquad w = -\bar{\phi} \quad \text{on } \Gamma_\rho.$$

By Theorem 2.4 and (4.7) we have

$$\begin{aligned}\| \,|\alpha|^{-1}\nabla w \,\|_{L^2(\Omega^{\mathrm{PML}})} &\le C\hat{C}^{-1}(1+kR)|\alpha_0|\| \,w\, \|_{H^{1/2}(\Gamma_\rho)}\\ &= C\hat{C}^{-1}(1+kR)|\alpha_0|\| \,\phi\, \|_{H^{1/2}(\Gamma_\rho)}\\ &\le C\hat{C}^{-1}(1+kR)|\alpha_0|e^{-k\mathrm{Im}\,(\tilde{\rho})\left(1-\frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}}\| \,\varphi\, \|_{H^{1/2}(\Gamma_R)}.\end{aligned}$$

By (4.8), γ is a increasing function, and we know that, for $r \le \rho$,

$$\gamma(r)e^{-k\mathrm{Im}\,(\tilde{\rho})\left(1-\frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \le \gamma(\rho)e^{-k\mathrm{Im}\,(\tilde{\rho})\left(1-\frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \le 1.$$

Hence

$$\| \,|\alpha|^{-1}\gamma\nabla w \,\|_{L^2(\Omega^{\mathrm{PML}})} \le C\hat{C}^{-1}(1+kR)|\alpha_0|\| \,\varphi\, \|_{H^{1/2}(\Gamma_R)}.$$

This completes the proof upon using Lemma 4.3. ◻

To conclude this subsection we remark that a direct consequence of this lemma is that

$$\| \,\omega^{-1}\nabla\varphi \,\|_{L^2(\Omega^{\mathrm{PML}})} \le C\hat{C}^{-1}\Lambda(kR)^{1/2}(1+kR)\| \,\varphi\, \|_{H^{1/2}(\Gamma_R)}. \tag{4.11}$$

4.3. Proof of Theorem 3.1. Since we are going to interpolate nonsmooth functions, we resort to an interpolation operator $\Pi_h : H^1_{(0)}(\Omega_\rho) \to \overset{\circ}{V}_h$ of Clement-type [9], where $H^1_{(0)}(\Omega_\rho) = \{v \in H^1(\Omega_\rho) : v = 0 \ \text{ on } \Gamma_\rho\}$. Let $\mathcal{N}_h = \{a_i\}_{i=1}^N$ be the set of the nodes of $\mathcal{M}_h$ which is interior to Ω^h_ρ or on the boundary Γ_D, and let $\{\phi_i\}_{i=1}^N$ be the corresponding nodal basis of V_h. Define $\Delta_i = \operatorname{supp}\phi_i \cap \Omega_\rho$. Then the interpolation operator $\Pi_h : H^1_{(0)}(\Omega_\rho) \to V_h$ is defined by

$$\Pi_h v(x) = \sum_{i=1}^N \left(\frac{1}{|\Delta_i|}\int_{\Delta_i} v(x)dx\right)\phi_i(x).$$

Since the nodes on Γ^h_ρ are not included in the definition of Π_h, we know that $\Pi_h v \in \overset{\circ}{V}_h$. Moreover, by slightly modifying the argument in [6, Lemmas 3.1 and 3.2], one can show that the operator Π_h enjoys the following interpolation estimates, for any $v \in H^1_{(0)}(\Omega_\rho)$,

$$\| \,v - \Pi_h v\, \|_{L^2(K)} \le Ch_K\| \,\nabla v\, \|_{L^2(\tilde{K})}, \quad \| \,v - \Pi_h v\, \|_{L^2(e)} \le Ch_e^{1/2}\| \,\nabla v\, \|_{L^2(\tilde{e})}, \tag{4.12}$$

where $\tilde{K}$ and $\tilde{e}$ are the union of all elements in $\mathcal{M}_h$ having nonempty intersection with $K \in \mathcal{M}_h$ and the side e, respectively.

Now we take $\varphi_h = \Pi_h\varphi \in \overset{\circ}{V}_h$ in the error representation formula (4.2) to get

$$\begin{aligned}a(u-u_h,\varphi) &= \int_{\Gamma_D} g(\overline{\varphi - \Pi_h\varphi}) - b(u_h, \varphi - \Pi_h\varphi) + \langle Tu_h - \hat{T}u_h, \varphi\rangle_{\Gamma_R}\\ &:= \mathrm{II}_1 + \mathrm{II}_2 + \mathrm{II}_3.\end{aligned} \tag{4.13}$$

We observe that, by integration by parts and using (3.5)–(3.7),

$$\mathrm{II}_1 + \mathrm{II}_2 = \sum_{K \in \mathcal{M}_h} \left(\int_K R_h (\overline{\varphi - \Pi_h \varphi}) dx + \sum_{e \subset \partial K} \frac{1}{2} \int_e J_e (\overline{\varphi - \Pi_h \varphi}) ds \right).$$

Standard argument in the a posteriori error analysis using (4.12) and (4.11) implies

$$\begin{aligned} |\mathrm{II}_1 + \mathrm{II}_2| &\leq C \sum_{K \in \mathcal{M}_h} \left(\| h_K R_h \|^2_{L^2(K)} + \frac{1}{2} \sum_{e \subset \partial K} \| h_e^{1/2} J_e \|^2_{L^2(e)} \right)^{1/2} \| \nabla \varphi \|_{L^2(\tilde{K})} \\ &\leq C \sum_{K \in \mathcal{M}_h} \eta_K \| \omega^{-1} \nabla \varphi \|_{L^2(\tilde{K})} \\ &\leq C \hat{C}^{-1} \Lambda (kR)^{1/2} (1 + kR) \left(\sum_{K \in \mathcal{M}_h} \eta_K^2 \right)^{1/2} \| \varphi \|_{H^{1/2}(\Gamma_R)}. \end{aligned}$$

By Lemma 2.5, we obtain

$$|\mathrm{II}_3| \leq C \hat{C}^{-1} (1 + kR)^2 |\alpha_0|^2 e^{-k \mathrm{Im}\,(\tilde{\rho}) \left(1 - \frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \| u_h \|_{H^{1/2}(\Gamma_R)} \| \varphi \|_{H^{1/2}(\Gamma_R)}.$$

Therefore, by the inf-sup condition (2.5), we finally get

$$\begin{aligned} \| u - u_h \|_{H^1(\Omega_R)} &\leq C \sup_{0 \neq \varphi \in H^1(\Omega_R)} \frac{|a(u - u_h, \varphi)|}{\| \varphi \|_{H^1(\Omega_R)}} \\ &\leq C \hat{C}^{-1} \Lambda (kR)^{1/2} (1 + kR) \left(\sum_{K \in \mathcal{M}_h} \eta_K^2 \right)^{1/2} \\ &\quad + C \hat{C}^{-1} (1 + kR)^2 |\alpha_0|^2 e^{-k \mathrm{Im}\,(\tilde{\rho}) \left(1 - \frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \| u_h \|_{H^{1/2}(\Gamma_R)}. \end{aligned}$$

This completes the proof. ◻

5. Implementation and numerical examples. The implementation of the adaptive algorithm in this section is based on the PDE toolbox of MATLAB. We use the a posteriori error estimate in Theorem 3.1 to determine the PML parameters. According to the discussion in section 2, we choose the PML medium property as the power function and thus we need only to specify the thickness $\rho - R$ of the layer and the medium parameter σ_0. Recall from Theorem 3.1 that the a posteriori error estimate consists of two parts: the PML error and the finite element discretization error. In our implementation we first choose ρ and σ_0 such that the exponentially decaying factor:

$$\hat{\omega} = e^{-k \mathrm{Im}\,(\tilde{\rho}) \left(1 - \frac{R^2}{|\tilde{\rho}|^2}\right)^{1/2}} \leq 10^{-8}, \tag{5.1}$$

which makes the PML error negligible compared with the finite element discretization errors. Once the PML region and the medium property are fixed, we use the standard finite element adaptive strategy to modify the mesh according to the a posteriori error estimate. Now we describe the adaptive algorithm we used in the paper.

ALGORITHM 5.1. Given tolerance TOL > 0. Let $m = 2$.

- Choose ρ and σ_0 such that the exponentially decaying factor $\hat{\omega} \leq 10^{-8}$.

- Set the computational domain $\Omega_\rho = B_\rho \backslash \bar{\Gamma}_D$ and generate an initial mesh $\mathcal{M}_h$ over Ω_ρ.
- While $\mathcal{E}_{FEM} = \left(\sum_{K\in\mathcal{M}_h} \eta_K^2\right)^{1/2} > \text{TOL}$ do

  – refine the mesh $\mathcal{M}_h$ according to the strategy:

  $$\text{if } \eta_K > \tfrac{1}{2}\max_{K\in\mathcal{M}_h}\eta_K, \text{ refine the element } K \in \mathcal{M}_h$$

  – solve the discrete problem (3.3) on $\mathcal{M}_h$
  – compute error estimators on $\mathcal{M}_h$
  end while

In the following we report two numerical examples to demonstrate the competitive behavior of the proposed algorithm. In the computations we first prescribe ρ and then determine σ_0 according to (5.1). We scale the error estimator for determining finite element meshes by a factor 0.15 as in the PDE toolbox of MATLAB.

Example 1. Let the scatter D be unit circle. We consider the scattering problem whose exact solution is known: $u = H_0^{(1)}(kr)$, where $r = |x|$. We take $R = 2$ and $k = 1$. Table 5.1 shows the different choices of the PML parameters ρ and σ_0 determined by the relation (5.1).

TABLE 5.1
The PML parameters for Examples 1 *and* 2.

Example 1		Example 2	
ρ	σ_0	ρ	σ_0
2R	30	2R	4
3R	15	3R	2
4R	10	4R	1
8R	5		

Figure 5.1 shows the $\log N_k$-$\log \| \nabla(u-u_k) \|_{L^2(\Omega_R)}$ curves, where N_k is the number of nodes of the mesh $\mathcal{M}_k$ and u_k is the finite element solution of (3.3) over the mesh $\mathcal{M}_k$. It indicates that the meshes and the associated numerical complexity are quasi-optimal: $\| \nabla(u - u_k) \|_{L^2(\Omega_R)} = CN_k^{-1/2}$ is valid asymptotically.

One of the important quantities in the scattering problems is the far field pattern:

$$u_\infty(\hat{x}) = \frac{e^{i\frac{\pi}{4}}}{\sqrt{8\pi k}} \int_{\partial D} \left(u(y) \frac{\partial e^{-ik\hat{x}\cdot y}}{\partial v(y)} - \frac{\partial u(y)}{\partial v(y)} e^{-ik\hat{x}\cdot y} \right) ds(y), \qquad \hat{x} = \frac{x}{|x|}.$$

We compute the far field $u_\infty(\hat{x})$, $\hat{x} = (\cos(\theta), \sin(\theta))^T$ in the observation direction $\theta = \pi/4$. Figure 5.2 shows the far fields for different choices of PML parameters ρ and σ_0. We observe that our adaptive algorithm is robust with respect to the choice of the thickness of PML layer: the far fields of the scattering solutions are insensitive to the choices of the PML parameters.

Example 2. This example is taken from [10] which concerns the scattering of the plane wave $u_I = e^{\mathbf{i}kx_1}$ from a perfectly conducting metal. The scatter D is contained in the box $\{x \in \mathbb{R} :\ -2 < x_1 < 2.2, -0.7 < x_2 < 0.7\}$ as plotted in Figure 5.3. We take $R = 3$ and $k = 2\pi$. The different choices of PML parameters ρ and σ_0 determined by the relation (5.1) are shown in Table 5.1.

Figure 5.4 shows the $\log N_k$–$\log \mathcal{E}_k$ curves, where N_k is the number of nodes of the mesh $\mathcal{M}_k$ and the $\mathcal{E}_k = (\sum_{K\in\mathcal{M}_k} \eta_K^2)^{1/2}$ is the associated a posteriori error estimate. It indicates that the meshes and the associated numerical complexity are quasi-optimal: $\mathcal{E}_k = CN_k^{-1/2}$ is valid asymptotically.

Figures 5.5 and 5.6 show the far fields in the incident direction $\theta = 0$ and the reflective direction $\theta = \pi$. Again we observe that the far fields are insensitive to the choices of PML parameters.

In Figure 5.7 we show the mesh after 13 adaptive iterations when $\rho = 3R$. We observe that the mesh near the boundary Γ_ρ is rather coarse, as a consequence of the exponentially decaying factor in our finite element a posteriori error estimator.

Appendix. The PML equation in the layer for large σ_0. The purpose of the appendix is to show that for sufficiently large σ_0, the PML problem in the layer (2.23) has a unique solution w. Moreover, the constant $\hat{C}$ in (2.25) can be chosen independent of Ω^{PML} and k.

From (H1) we know that $\beta(r) = 1 + \mathbf{i}\hat{\sigma}(r)$, where

$$\hat{\sigma}(r) = \frac{1}{r}\int_R^r \sigma(t)dt = \frac{\sigma_0}{m+1}\frac{r-R}{r}\left(\frac{r-R}{\rho-R}\right)^m.$$

Define

$$\zeta(r) := \frac{2\sigma_0^2}{\sigma\hat{\sigma}(r)} = \frac{2(m+1)r(\rho-R)^{2m}}{(r-R)^{2m+1}} \qquad \forall r > R.$$

It is clear that $\zeta : (R,\infty) \to \mathbb{R}$ is strictly monotone decreasing and $\zeta(r) \to \infty$ as $r \to R$, $\zeta(r) \to 0$ as $r \to \infty$. Thus, for any $\sigma_0 > 0$, there exists a unique $\hat{R} = \hat{R}(\sigma_0) > R$ such that

$$\sigma_0^2 = \zeta(\hat{R}) = \frac{2(m+1)\hat{R}(\rho-R)^{2m}}{(\hat{R}-R)^{2m+1}}. \tag{5.1}$$

Hence, since $\sigma\hat{\sigma} : (R,\infty) \to \mathbb{R}$ is increasing, we have

$$\sigma\hat{\sigma}(r) \ge \sigma\hat{\sigma}(\hat{R}) = \frac{2\sigma_0^2}{\zeta(\hat{R})} = 2 \qquad \text{for } r \ge \hat{R}. \tag{5.2}$$

In this appendix we make the following assumption on the choice of σ_0:

(H3) $\sigma_0^2 \ge \zeta(\hat{R}_{\max})$, where $\hat{R}_{\max} := \max\{r \in (R,\rho) : \theta(r) \le 1\}$ with

$$\theta(r) = k^2R^2\left[\left(\frac{r^2}{R^2} - 1\right)\ln\frac{r}{R} + \frac{2r^2(r-R)}{(2m+1)R^3}\right] \qquad \forall r \ge R.$$

Since the function $\theta : (R, \rho) \to \mathbb{R}$ is strictly monotone increasing and $\theta(R) = 0$, $\hat{R}_{\max}$ is well-defined.

LEMMA 5.1. *Let* (H1) *and* (H3) *be satisfied. Then*

$$\int_R^{\hat{R}} k^2 r \left(\int_R^r \frac{1 + \sigma^2(t)}{t} dt \right) dr \leq \frac{1}{2}.$$

Proof. First we have

$$\int_R^{\hat{R}} r \left(\int_R^r \frac{1}{t} dt \right) dr = \int_R^{\hat{R}} r \ln \frac{r}{R} dr \leq \frac{1}{2}(\hat{R}^2 - R^2) \ln \frac{\hat{R}}{R}.$$

Next by (H1) and (5.1) we know that

$$\begin{aligned}
\int_R^{\hat{R}} r \left(\int_R^r \frac{\sigma^2}{t} dt \right) dr &\leq \frac{\hat{R}}{R} \int_R^{\hat{R}} \left(\int_R^r \sigma^2(t) dt \right) dr \\
&= \frac{\hat{R}}{R} \int_R^{\hat{R}} \frac{\sigma_0^2}{2m+1} \frac{(r - R)^{2m+1}}{(\rho - R)^{2m}} dr \\
&= \frac{\hat{R}}{R} \frac{\sigma_0^2}{(2m+1)(2m+2)} \frac{(\hat{R} - R)^{2m+2}}{(\rho - R)^{2m}} \\
&= \frac{\hat{R}^2(\hat{R} - R)}{(2m+1)R}.
\end{aligned}$$

Thus

$$\begin{aligned}
\int_R^{\hat{R}} k^2 r \left(\int_R^r \frac{1 + \sigma^2(t)}{t} dt \right) dr &\leq \frac{1}{2} k^2 R^2 \left[\left(\frac{\hat{R}^2}{R^2} - 1 \right) \ln \frac{\hat{R}}{R} + \frac{2\hat{R}^2(\hat{R} - R)}{(2m+1)R^3} \right] \\
&= \frac{1}{2} \theta(\hat{R}).
\end{aligned}$$

Now if $\sigma_0^2 \geq \zeta(\hat{R}_{\max})$, we know from the monotonicity of ζ that $\hat{R} = \hat{R}(\sigma_0) \leq \hat{R}_{\max}$. Thus $\theta(\hat{R}) \leq \theta(\hat{R}_{\max}) \leq 1$ by (H3). This completes the proof. □

Now we are ready to prove the main result of this appendix.

THEOREM 5.2. *Under the assumptions* (H1) *and* (H3) *there exists a constant* $C > 0$ *independent of* k, R, ρ, *and* σ_0 *such that*

$$\operatorname{Re}[\hat{b}(v, v)] \geq C \| v \|^2_{*, \Omega^{\mathrm{PML}}} \qquad \forall v \in H_0^1(\Omega^{\mathrm{PML}}).$$

Proof. For any $v \in H_0^1(\Omega^{\mathrm{PML}})$, we have

$$\operatorname{Re}[\hat{b}(v, v)] = \int_R^{\rho} \int_0^{2\pi} \left[\frac{1 + \sigma\hat{\sigma}}{1 + \sigma^2} r \left| \frac{\partial v}{\partial r} \right|^2 + \frac{1 + \sigma\hat{\sigma}}{1 + \hat{\sigma}^2} \frac{1}{r} \left| \frac{\partial v}{\partial \theta} \right|^2 + (\sigma\hat{\sigma} - 1) k^2 r |v|^2 \right].$$

By (5.2) we know that

$$\begin{aligned}
&\int_R^{\rho} \int_0^{2\pi} (\sigma\hat{\sigma} - 1) k^2 r |v|^2 dr \, d\theta \\
&\quad = \int_R^{\hat{R}} \int_0^{2\pi} (\sigma\hat{\sigma} - 1) k^2 r |v|^2 dr \, d\theta + \int_{\hat{R}}^{\rho} \int_0^{2\pi} (\sigma\hat{\sigma} - 1) k^2 r |v|^2 dr \, d\theta \\
&\quad \geq -\frac{3}{2} \int_R^{\hat{R}} \int_0^{2\pi} k^2 r |v|^2 dr \, d\theta + \frac{1}{4} \int_R^{\rho} \int_0^{2\pi} (1 + \sigma\hat{\sigma}) k^2 r |v|^2 dr \, d\theta.
\end{aligned}$$

Notice that since $v = 0$ on Γ_R,

$$|v(r)| = \left| \int_R^r \frac{\partial v}{\partial r} dr \right| \leq \left(\int_R^r \frac{1+\sigma\hat{\sigma}}{1+\sigma^2} t \left| \frac{\partial v}{\partial r} \right|^2 dt \right)^{1/2} \left(\int_R^r \frac{1}{t} \frac{1+\sigma^2}{1+\sigma\hat{\sigma}} dt \right)^{1/2},$$

which, by Lemma 5.1, yields

$$\begin{aligned} \int_R^{\hat{R}} \int_0^{2\pi} k^2 r |v|^2 dr &\leq \left(\int_R^{\hat{R}} \int_0^{2\pi} \frac{1+\sigma\hat{\sigma}}{1+\sigma^2} r \left| \frac{\partial v}{\partial r} \right|^2 \right) \cdot \int_R^{\hat{R}} k^2 r \left(\int_R^r \frac{1}{t} \frac{1+\sigma^2}{1+\sigma\hat{\sigma}} dt \right) \\ &\leq \frac{1}{2} \int_R^{\hat{R}} \int_0^{2\pi} \frac{1+\sigma\hat{\sigma}}{1+\sigma^2} r \left| \frac{\partial v}{\partial r} \right|^2. \end{aligned}$$

Thus

$$\operatorname{Re}[\hat{b}(v,v)] \geq \frac{1}{4} \int_R^{\rho} \int_0^{2\pi} \left[\frac{1+\sigma\hat{\sigma}}{1+\sigma^2} r \left| \frac{\partial v}{\partial r} \right|^2 + \frac{1+\sigma\hat{\sigma}}{1+\hat{\sigma}^2} \frac{1}{r} \left| \frac{\partial v}{\partial \theta} \right|^2 + (1+\sigma\hat{\sigma}) k^2 r |v|^2 \right].$$

This completes the proof. □

ANALYSIS OF FIRST ORDER ERRORS IN SHOCK CALCULATIONS IN TWO SPACE DIMENSIONS*

MALIN SIKLOSI† AND GUNILLA EFRAIMSSON‡

Abstract. Numerical computations show that solutions of hyperbolic conservation laws obtained by second or higher order shock capturing methods in many cases are only first order accurate downstream of shocks (see, e.g., [M. H. Carpenter and J. H. Casper, *AIAA J.*, 37 (1999), pp. 1072–1079]). We use matched asymptotic expansions to analyze the degeneration in order of accuracy for stationary solutions of hyperbolic conservation laws in two space dimensions.

1. Introduction.

Numerical results presented in this and other papers (see, e.g., [2], [3], [4], [5], [7], and [16]) show that solutions of hyperbolic conservation laws in one and two space dimensions obtained by formally second or higher order accurate shock capturing schemes degenerate to first order downstream of shock layers. A numerical study by Carpenter and Casper [3] shows that the error depends on flow conditions and generally increases with increasing shock strength. They further conclude that the first order error terms seem to be nearly independent of the design order of accuracy of the method.

The first order term for reasonable mesh-sizes seems to be small in many cases. However, in applications where the small scale behavior is of significance, such as aeroacoustics, the degeneration to first order accuracy can be troublesome. It is also important to understand the phenomenon more deeply in order, hopefully, to be able to design new methods which do not suffer from this deficiency.

This paper is the fourth in a series of papers. In [5], an explanation of the degeneracy in accuracy was given for the case of steady-state solutions of systems with source terms in one space dimension, and, in [16], it was shown how to raise the accuracy and remove the first order error with a specific choice of a matrix valued artificial viscosity. In [23], the same method of analysis was extended to time-dependent solutions of hyperbolic systems in one space dimension. Also in that case, it was possible to avoid the downstream error by using a specific matrix valued artificial viscosity. In this paper we consider steady-state solutions of hyperbolic conservation laws in two space dimensions. We present an analysis which reveals how the downstream error is related to the dissipative terms in the numerical scheme.

Shock capturing methods for hyperbolic conservation laws consist of a discretization of the conservation law, augmented by some mechanism for adding dissipation in the vicinity of discontinuities in the solution without explicitly keeping track of

the position of the discontinuities. The dissipative terms are either intrinsic in the scheme or explicitly added (artificial viscosity). In order to avoid spurious oscillations around shocks, the dissipative terms must be $\mathcal{O}(h)$ in the shock layer. Here, h is the grid size. In smooth regions, the dissipative terms are of order $\mathcal{O}(h^p)$ or smaller, where p is the order of accuracy of the discretization of the conservation law. Many shock capturing schemes for problems in several space dimensions are obtained as a straightforward generalization of the corresponding one-dimensional scheme. This means that the dissipative terms are turned on separately in the x- and y-directions. Hence, at shocks aligned to one of the coordinate axes, dissipative terms only act normally to the shock. For shocks that are oblique relative to the grid, dissipative terms are switched on in both space directions.

A widely used technique to model the behavior of numerical schemes is to study the solutions of the so-called modified equation; see [19]. The modified equation is obtained by Taylor series expansions. The goal is to obtain a PDE which approximates the discrete numerical solution better than the original, continuous PDE. The technique has mostly been used to investigate the dispersive and dissipative properties of PDE schemes. It has, in particular, been widely used to investigate the behavior of numerical schemes in the vicinity of shocks. In the shock region, the modified equation can be proved to be valid only for weak shocks; see [9]. Due to the strong gradients in the shock region, it is not obvious what terms in the Taylor expansion will be dominant; see, e.g., [14]. Considering the wide use, there is surprisingly little literature considering the validity and scope of the method of modified equations; see [10], [24], and references therein.

Many shock capturing schemes that are in wide use, such as the scheme due to Jameson, Schmidt, and Turkel [12], are based on a relatively simple finite difference/finite volume discretization of the conservation law. Mechanisms for the extra dissipation that is needed at discontinuities are then explicitly added. The dissipation mechanisms usually consist of some kind of a switch function multiplying a finite difference/finite volume discretization of a second derivative term. It is straightforward to obtain a modified equation, modeling the finite difference/finite volume discretizations of the conservation law and the second derivative term. The construction of the switch functions is often rather complicated and it is not as easy to obtain a good model. However, e.g., for the switch introduced by Jameson, Schmidt, and Turkel in [12], it is reasonable to model the switch function by a smooth function, which is one in the shock region and vanishes a fixed number of grid points away from the shock; see computations in [6].

For more advanced schemes, where the dissipative mechanisms are more intrinsic in the scheme, e.g., higher order WENO schemes, it is difficult to find an analytic formulation of the modified equation and, hence, to construct a model for the numerical scheme. Theoretical studies of "continuous discrete shock profiles" (see [13], [20], [22], and references therein) and numerical investigations, such as the work by Arora and Roe [1], indicate, however, that for many of these more advanced methods, the numerical solution, also in the vicinity of shock waves, can be modeled by a continuous PDE.

In section 2, we suggest a model for numerical solutions obtained by shock capturing schemes. The model consists of the modified equation with boundary conditions. We then analyze this modified problem by a matched asymptotic analysis. It is assumed that an inner solution is valid in the shock layer and an outer solution is valid elsewhere. The two solutions are matched in a region of overlap. From the analysis, we see that generally the outer solution contains a term of $\mathcal{O}(h)$ downstream of the shock.

The phenomenon has also been studied by other methods in [7] and [4]. In [7], analytic examples in one dimension are constructed where the numerical solution is only first order accurate downstream of a shock, although the numerical scheme is formally second order. It is also shown that a converging numerical method will yield solutions having the formal order of accuracy in domains where no characteristics have passed through a shock. In [4], the first order downstream error is numerically detected in solutions of a one-dimensional (1D) shock–sound interaction problem solved by a fourth order ENO method. A scalar, linear equation is used to model the problem. It can be seen that the solution of the model problem computed with the fourth order ENO method behaves qualitatively differently depending on if the discontinuity is located on a cell interface or in the interior of a cell. In the first case, the solution is fourth order in all of the domain, but in the second case the solution is only first order downstream of the discontinuity. On the basis of this observation, the numerical method is modified such that the shock position will always be on a cell interface, and the fourth order accuracy of the solution of the shock–sound interaction problem is obtained both upstream and downstream.

2. Analysis.

In this section we will consider a hyperbolic system in two space dimensions with a stationary solution containing a shock. We will model the numerical solution and present an analysis that shows how the $\mathcal{O}(1)$ error in the shock region causes an $\mathcal{O}(h)$ error downstream of the shock. From the analysis, we see that the first order downstream error can only appear if there is a variation of the solution tangentially to the shock, i.e., if the solution is truly two-dimensional (2D).

Many numerical schemes for problems in several space dimensions are obtained as a straightforward generalization of the corresponding 1D scheme. This means that the dissipative terms are turned on separately in the x- and y-directions. Hence, at shocks aligned to one of the coordinate axes, dissipative terms only act normally to the shock. At a shock which is oblique relative to the grid, however, there are dissipative terms in both coordinate directions.

First, we consider a straight shock which is aligned with the y-axis. Then, we show how the analysis can be extended to a more general shock. The essential conclusion is the same in both cases; downstream the solution is only first order accurate.

2.1. The inviscid problem.

We consider a system of conservation laws

$$\mathbf{u}_t + \mathbf{f}(\mathbf{u})_x + \mathbf{g}(\mathbf{u})_y = 0, \quad (x, y) \in \Omega, \quad t > 0, \tag{2.1}$$

where $\mathbf{u}(x, y, t) \in \mathbf{R}^m$ and $\mathbf{f}, \mathbf{g} : \mathbf{R}^m \to \mathbf{R}^m$. We assume that the linearization of (2.1) is strongly hyperbolic, i.e., there exists a smooth matrix function $S(\mathbf{u}, \bar{\omega})$ such that $S\breve{\mathbf{f}}'S^{-1}$ is diagonal with real entries. The Jacobian $\breve{\mathbf{f}}'$ is defined by $\breve{\mathbf{f}}'(\mathbf{u}, \bar{\omega}) = \omega^x \mathbf{f}'(\mathbf{u}) + \omega^y \mathbf{g}'(\mathbf{u})$, and $\bar{\omega} = (\omega^x, \omega^y)$ is an arbitrary unit vector. The eigenvalues of $\breve{\mathbf{f}}'$ are denoted by $\breve{\lambda}_k(\mathbf{u}, \bar{\omega})$, $k = 1, 2, \ldots, m$, and are in the increasing order.

Across discontinuities, $\mathbf{u}$ satisfies the Rankine–Hugoniot condition; see, e.g., [11]. If $\mathbf{u}$ has a discontinuity across a curve Σ in the (x, y)-plane, the Rankine–Hugoniot condition can be formulated as

$$n^x[\mathbf{f}] + n^y[\mathbf{g}] + s[\mathbf{u}] = 0, \tag{2.2}$$

where $\bar{n} = (n^x, n^y)$ is the unit normal of Σ, and $s = -\bar{v} \cdot \bar{n}$ is the speed of the discontinuity in the negative normal direction; see Figure 2.1. By the notation $[\mathbf{u}]$,

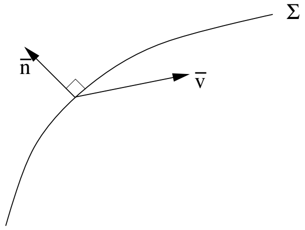

FIG. 2.1. *A discontinuity surface Σ moving with velocity $\bar{v}$. Here, $\bar{n}$ denotes the unit normal of Σ.*

we denote the jump in $\mathbf{u}$ across the discontinuity. We will define this notation in a precise way later.

We call the discontinuity a k-shock if it satisfies the Lax entropy condition, i.e., there is an integer k, $1 \leq k \leq m$, such that

$$\breve{\lambda}_k(\mathbf{u}^-, \bar{n}) > s > \breve{\lambda}_k(\mathbf{u}^+, \bar{n})$$

so that the k-characteristic impinges on the discontinuity from both sides, while the other characteristics cross the discontinuity:

$$\begin{aligned} &\breve{\lambda}_j(\mathbf{u}^-, \bar{n}) < s \quad \text{and} \quad \breve{\lambda}_j(\mathbf{u}^+, \bar{n}) < s \quad \text{for } j = 1, 2, \dots, k-1, \\ &\breve{\lambda}_j(\mathbf{u}^-, \bar{n}) > s \quad \text{and} \quad \breve{\lambda}_j(\mathbf{u}^+, \bar{n}) > s \quad \text{for } j = k+1, k+2, \dots, m. \end{aligned}$$

Here, $\mathbf{u}^\pm$ denotes the value of $\mathbf{u}$ on each side of the shock, and this notation will be made precise later. The Lax entropy condition is a necessary condition for linearized stability of the shock front; see, e.g., [21]. It is also necessary for linearized stability of the shock front that the diagonalization matrix S at the shock front satisfies a certain determinant condition. For the general formulation of this determinant condition; see, e.g., [25] or [21]. In Assumption 1, we will formulate the determinant condition for the special case we consider.

We let the domain Ω be a strip along the positive y-axis, which has width $2a$ and is infinitely long, i.e.,

$$\Omega = \{(x, y) : |x| \leq a, y > 0\}.$$

Assumption 1. We assume that there exists a steady-state solution of (2.1) which satisfies the Rankine–Hugoniot condition (2.2) at discontinuities. We denote the steady-state solution $\mathbf{u} = \mathbf{u}(x, y)$. We further assume that the initial and boundary conditions are chosen such that $\mathbf{u}$ contains a single 1-shock, which is straight and aligned with the y-axis, where the y-dependence is introduced via the boundary conditions. Also,

$$\mathbf{u}(x, 0) = \begin{cases} \mathcal{U}^+(x) & \text{for } x > 0, \\ \mathcal{U}^-(x) & \text{for } x < 0, \end{cases}$$

where $\mathcal{U}^\pm(x) \in \mathbf{R}^m$ are smooth functions.

We will use the following notation:

$$[\mathbf{u}(\cdot, y)] = \mathbf{u}^+(y) - \mathbf{u}^-(y), \quad \text{where } \mathbf{u}^\pm(y) = \lim_{\xi \to 0^+} \mathbf{u}(\pm\xi, y).$$

Corresponding notation for other quantities will be used frequently.

Let the $m \times m$ matrix D be defined by

$$D = (S_{II}^{+} \quad [\mathbf{g}]). \tag{2.3}$$

Here the columns of S_{II}^{+} are the eigenvectors of $\mathbf{f}'(\mathbf{u}^{+}(y))$ corresponding to the eigenvalues $\lambda_j(\mathbf{u}^{+}),\ j = 2, 3, \dots, m$. We assume

$$\det D \neq 0.$$

We consider a boundary condition at $x = \pm a$ of the form

$$\mathbf{u} = \mathbf{h}(y) \quad \text{at } x = -a, \tag{2.4}$$

$$R(\mathbf{u}) = r(y) \quad \text{at } x = a, \tag{2.5}$$

where $\mathbf{h}(y) \in \mathbf{R}^n$ and $r(y) \in \mathbf{R}$ are given. Here, $R(\mathbf{u}) : \mathbf{R}^n \to \mathbf{R}$ is a nonlinear function. Hence, one boundary condition is given for each ingoing characteristic. On both sides of the y-axis, $\mathbf{u}(x, y)$ is assumed to be smooth without discontinuities. We assume that the eigenvalues of $\mathbf{f}'(\mathbf{u})$ have constant sign on each side of the shock interface.

Under the conditions in Assumption 1, the Rankine–Hugoniot conditions simplify to

$$[\mathbf{f}(\cdot, y)] = 0, \tag{2.6}$$

and the shock is a 1-shock if

$$\begin{gathered} \lambda_1(\mathbf{u}^-) > 0 > \lambda_1(\mathbf{u}^+), \\ \lambda_j(\mathbf{u}^-) > 0, \quad \text{and} \quad \lambda_j(\mathbf{u}^+) > 0 \quad \text{for } j = 2, 3, \dots, m, \end{gathered}$$

where $\lambda_j(\mathbf{u}),\ j = 1, 2, \dots, m$, are the eigenvalues of the Jacobian $\mathbf{f}'(\mathbf{u})$.

Remark. For 1-shocks and n-shocks there is just one downstream side. Hence, the first order error appears only on one side of the shock. For other Lax shocks, both sides of the shock are downstream sides, and the first order error appears on both sides. The phenomenon can be analyzed by the same method in both cases, but the analysis becomes less involved when only one side must be considered. For clarity and without loss of generality, we analyze a 1-shock.

Remark. Instead of boundary conditions of the form (2.4) and (2.5), one could use more general boundary conditions. This would not change the result of the analysis.

2.2. The modified problem. On the basis of the considerations in the introduction, we use the equations given below to model a generic second order shock capturing scheme for solving (2.1) in the case specified in Assumption 1.

Assumption 2. Let $\mathbf{u}^{\varepsilon}$ be the solution of

$$\mathbf{f}(\mathbf{u}^{\varepsilon})_x + \mathbf{g}(\mathbf{u}^{\varepsilon})_y = \varepsilon \left(\phi \left(\frac{x - x^{\varepsilon}(y)}{\varepsilon} \right) \mathbf{u}_x^{\varepsilon} \right)_x + c_2 \varepsilon^2 (\mathbf{u}_{xx}^{\varepsilon} + \mathbf{u}_{yy}^{\varepsilon}), \quad (x, y) \in \Omega, \tag{2.7}$$

where $\varepsilon = c_1 h$ and c_1 and c_2 are scalar constants. The function $\phi(z)$ is a smooth one-variable function which models the switch mechanism, i.e.,

$$\phi(z) = \begin{cases} 1 & \text{for } |z| \leq K_0, \\ 0 & \text{for } |z| \geq K_1, \end{cases}$$

where $K_0 < K_1$ are positive constants with K_0 sufficiently large.

The boundary conditions for $\mathbf{u}^\varepsilon$ are

$$\mathbf{u}^\varepsilon = \mathbf{h}(y) \quad \text{at } x = -a, \tag{2.8}$$

$$R(\mathbf{u}^\varepsilon) = r(y) \quad \text{at } x = a \tag{2.9}$$

together with boundary conditions that model the numerical boundary conditions, such as extrapolation of outgoing characteristic variables. We assume that the numerical boundary conditions are chosen such that the possible boundary layer effects are $\mathcal{O}(h^2)$ or smaller. Also,

$$\mathbf{u}^\varepsilon(x,0) = \begin{cases} \mathcal{U}^+(x) & \text{for } \frac{x}{\varepsilon} > K_1, \\ \hat{\mathbf{U}}(x/\varepsilon, 0) & \text{for } |\frac{x}{\varepsilon}| \leq K_1, \\ \mathcal{U}^-(x) & \text{for } \frac{x}{\varepsilon} < K_1, \end{cases}$$

where $\hat{\mathbf{U}}(\tilde{x}, y)$ is the solution of (2.27). We define the position of the viscous shock layer as the smallest x-value such that $\mathbf{u}^{\varepsilon(1)}(x,y) = (\mathbf{u}^{-(1)}(y)+\mathbf{u}^{+(1)}(y))/2$ and denote this x-value by $x^\varepsilon(y)$. That is, the viscous shock position is described by $(x^\varepsilon(y), y)$. Hence we have

$$x^\varepsilon(0) = 0. \tag{2.10}$$

Remark. We consider the same boundary condition for $\mathbf{u}^\varepsilon$ as for $\mathbf{u}$. When (2.1) is solved numerically, the boundary conditions must be augmented by $m-1$ numerical boundary conditions at $x = a$. Correspondingly, additional boundary conditions that model the numerical boundary conditions are needed for the parabolic PDE (2.7). Numerical boundary conditions can introduce boundary layers in the solution. We consider numerical boundary conditions where such effects are $\mathcal{O}(h^2)$ or smaller. Extrapolation of outgoing characteristic variables is a commonly used numerical boundary condition, but other numerical boundary conditions are also possible, and would not change the result of the analysis.

2.3. Exploring the modified problem using asymptotic expansions. To explore the behavior of the model stated in Assumption 2, we will use the technique of matched asymptotic expansions. In [8], an introduction on how to use asymptotics and matching for internal layers is given. For a comprehensive description of asymptotic techniques, see, e.g., [15] or [18]. In this subsection, we will follow the methods outlined in [8] and use asymptotic expansions and matching for constructing an alternative formulation of the model stated in Assumption 2.

Assumption 3. We assume that $\mathbf{u}^\varepsilon$ can be approximated by truncations of a formal power series

$$\mathbf{u}^\varepsilon(x,y) \sim \sum_{i=0}^{\infty} \varepsilon^i \mathbf{u}_i(x,y) \tag{2.11}$$

in regions away from the inviscid shock interface at $x = 0$. The "outer" functions $\mathbf{u}_i$ may be discontinuous at $x = 0$ but are uniformly smooth up to $x = 0$. We assume that $\mathbf{u}_0 = \mathbf{u}$, i.e., the leading order term of the outer expansion is equal to the solution of the corresponding inviscid problem stated in Assumption 1.

Near $x = 0$, $\mathbf{u}^\varepsilon$ can be approximated by truncations of another formal power series:

$$\mathbf{u}^\varepsilon(x, y) \sim \sum_{i=0}^{\infty} \varepsilon^i \mathbf{U}_i(\tilde{x}, y). \tag{2.12}$$

The "inner" representation of $\mathbf{u}^\varepsilon$ is expressed using the variables $(\tilde{x}, y)$, where

$$\tilde{x} = \frac{x}{\varepsilon}.$$

Also, the position of the viscid shock interface, $x^\varepsilon(y)$, can be expanded in ε:

$$x^\varepsilon(y) \sim 0 + \varepsilon \tilde{x}_1 + \varepsilon^2 \tilde{x}_2 + \cdots .$$

The two expansions (2.11) and (2.12) can be matched in a region of overlap. The more the terms included in the truncated series, the better the approximation. Also, the region of overlap depends on how many terms are included in the truncated series; if more terms are included, the region of overlap decreases. Let $\Sigma_\delta = \{(x, y) : |x| \leq \delta\}$. Let $\mathcal{D}_\delta$ be the complement of Σ_δ in Ω. We denote truncations of series (2.11) including terms up to order ε^N by $\mathbf{u}^{\varepsilon(N)}_{\text{outer}}$, i.e.,

$$\mathbf{u}^{\varepsilon(N)}_{\text{outer}} = \sum_{i=0}^{N} \varepsilon^i \mathbf{u}_i(x, y),$$

and use the corresponding notation for truncations of series (2.12). We assume that there exists a function $\delta(N, \varepsilon)$, with $\delta \to 0$ as $\varepsilon \to 0$, such that

$$|\mathbf{u}^\varepsilon - \mathbf{u}^{\varepsilon(N)}_{\text{outer}}| = \mathcal{O}(\varepsilon^{N+1}) \quad \text{as } \varepsilon \to 0 \tag{2.13}$$

uniformly for $(x, y) \in \mathcal{D}_{\delta(N,\varepsilon)}$. This is to be true for all N up to some integer N_0 that depends on the context. We also assume that there is a function $\tilde{K}(\varepsilon, N)$ such that $\tilde{K} \to \infty$ as $\varepsilon \to 0$ so that

$$|\mathbf{u}^\varepsilon - \mathbf{u}^{\varepsilon(N)}_{\text{inner}}| = \mathcal{O}(\varepsilon^{N+1}) \quad \text{as } \varepsilon \to 0$$

uniformly for $|\tilde{x}| < \tilde{K}(\varepsilon, N)$. Again, this is to be true for all N up to N_0.

The asymptotic expansions above can be viewed as an alternative formulation of the model of the numerical solution, as described in Assumption 2. Hence, instead of analyzing the differential equation (2.7), we can analyze the different terms in the truncated expansions. We model a numerical method which gives a formally second order accurate approximation of the solution of (2.1) away from the shock region. We claim that the solution will be second order accurate upstream of the shock, but only first order accurate downstream, i.e., we must show that $\mathbf{u}_1 = 0$ is upstream and $\mathbf{u}_1 \neq 0$ is downstream. Hence, for our purposes, it is sufficient to truncate the asymptotic expansions after the first two terms and then analyze the truncated expansions with the purpose to show $\mathbf{u}_1 \neq 0$ downstream. Therefore, we choose $N_0 = 1$.

To obtain equations for the terms in the outer and inner expansions, we substitute the expansions into (2.7), Taylor expand and collect terms multiplying the same power of ε. The equation for $\mathbf{U}_0$ is

$$(\phi(\tilde{x} - \tilde{x}_0)\mathbf{U}_{0\tilde{x}})_{\tilde{x}} - \mathbf{f}(\mathbf{U}_0)_{\tilde{x}} = 0, \tag{2.14}$$

where we have used that

$$\frac{\partial}{\partial x} = \frac{1}{\varepsilon}\frac{\partial}{\partial \tilde{x}}.$$

We have also used the fact that in the $(\tilde{x}, y)$-coordinate system, all derivatives of $\mathbf{U}_i$ are $\mathcal{O}(1)$. If $\tilde{x}_0$ denotes the position of the shock layer in $\mathbf{U}_0$, i.e.,

$$\mathbf{U}_0^{(1)}(\tilde{x}_0, y) = (\mathbf{u}^{-(1)}(y) + \mathbf{u}^{+(1)}(y))/2,$$

then Assumption 3 gives $\tilde{x}_0 = \tilde{x}_1 + \mathcal{O}(\varepsilon)$. On each side of $x = 0$ the equation for $\mathbf{u}_1$ is

$$(\mathbf{f}'(\mathbf{u})\mathbf{u}_1)_x + (\mathbf{g}'(\mathbf{u})\mathbf{u}_1)_y = 0. \tag{2.15}$$

We also need boundary conditions for $\mathbf{u}_1$ on the two domains $[-a, 0]$ and $[0, a]$. Using (2.4) and (2.8) in (2.13) we obtain

$$\mathbf{u}_1(-a, y) = 0.$$

No further boundary conditions are needed (or allowed) for $\mathbf{u}_1$ on the upstream side, since all characteristics of (2.15) are going into the domain at $x = -a$ and going out of the domain at $x = 0$. Hence, $\mathbf{u}_1 \equiv 0$ in the upstream region. By using (2.5) and (2.9) in (2.13) we obtain the boundary condition for $\mathbf{u}_1$ at $x = a$,

$$R'(\mathbf{u})\mathbf{u}(a, y) = 0.$$

The boundary condition for $\mathbf{u}_1^+(y)$ remains to be determined. We will do that in the next subsection.

We will now construct the region of overlap on the downstream side. The region of overlap is obtained analogously on the upstream side. Expressed in the stretched variable $\tilde{x}$, the region of overlap, which we will denote by $\mathcal{J}$, is defined by

$$\mathcal{J}: \quad \varepsilon^{-1}\delta(\varepsilon, 1) \le \tilde{x} \le \tilde{K}(\varepsilon, 1).$$

Both the inner and outer expansions are valid in $\mathcal{J}$; hence they must be equal in $\mathcal{J}$, i.e.,

$$\mathbf{U}_0(\tilde{x}, y) + \varepsilon\mathbf{U}_1(\tilde{x}, y) = \mathbf{u}(\varepsilon\tilde{x}, y) + \varepsilon\mathbf{u}_1(\varepsilon\tilde{x}, y) + \mathcal{O}(\varepsilon^2) \quad \text{in } \mathcal{J}.$$

Both $\mathbf{u}$ and $\mathbf{u}_1$ are assumed to be smooth up to $x = 0$. Using the Taylor series expansion around $\tilde{x} = 0$, we arrive at

$$\left(\mathbf{U}_0(\tilde{x}, y) - \mathbf{u}^+(y)\right) + \varepsilon\left(\mathbf{U}_1(y) - \mathbf{u}_x^+(y)\tilde{x} - \mathbf{u}_1^+(y)\right) = \mathcal{O}(\varepsilon^2\tilde{x}^2) \quad \text{in } \mathcal{J}. \tag{2.16}$$

We will need $\varepsilon^{-1}\delta(\varepsilon, 1) \to \infty$ as $\varepsilon \to 0$. Hence, we make the ansatz

$$\delta = \varepsilon^{\alpha}, \quad K = \varepsilon^{-\beta}, \quad 0 < \alpha < 1, \quad 1 - \alpha < \beta,$$

i.e.,

$$\mathcal{J}: \quad \varepsilon^{\alpha-1} < \tilde{x} < \varepsilon^{-\beta}.$$

Both the terms $(\mathbf{U}_0(\tilde{x}, y) - \mathbf{u}^+(y))$ and $\varepsilon\left(\mathbf{U}_1(\tilde{x}, y) - \mathbf{u}_x^+(y)\tilde{x} - \mathbf{u}_1^+(y)\right)$ in (2.16) are individually $\mathcal{O}(\varepsilon^2\tilde{x}^2)$ in $\mathcal{J}$. To see this, we now consider ε as a function of $\tilde{x}$. In

$\mathcal{J}$ we have $\varepsilon = \tilde{x}^{-\gamma}$, where $\gamma \in (1/\beta, 1/(1-\alpha))$. Substituting this on the left-hand side of (2.16), we arrive at

$$\big(\mathbf{U}_0(\tilde{x}, y) - \mathbf{u}^+(\cdot, y)\big) + \tilde{x}^{-\gamma}\left(\mathbf{U}_1(\tilde{x}, y) - \mathbf{u}_x^+(y)\tilde{x} - \mathbf{u}_1^+(y)\right) = \mathcal{O}(\varepsilon^2\tilde{x}^2) \quad \text{in } \mathcal{J}. \tag{2.17}$$

We may then write (2.17) in the form

$$\frac{V_0(\tilde{x}, y) + V_1(\tilde{x}, y)}{\varepsilon^2\tilde{x}^2}, \quad \text{which is bounded in } \mathcal{J}. \tag{2.18}$$

If γ is chosen such that $\tilde{x}$ is strictly within $\mathcal{J}$ for $\varepsilon = \tilde{x}^{-\gamma}$, $\tilde{x}$ will remain inside $\mathcal{J}$, also for $\varepsilon = \tilde{x}^{-\gamma'}$, if $\gamma' = \gamma + \eta$ for $\eta > 0$ sufficiently small, i.e.,

$$\frac{V_0(\tilde{x}, y) + \tilde{x}^{-\eta}V_1(\tilde{x}, y)}{\varepsilon^2\tilde{x}^2} \quad \text{is bounded in } \mathcal{J}. \tag{2.19}$$

Subtracting (2.19) from (2.18) and resubstituting $\tilde{x}^{-\gamma} = \varepsilon$, we obtain

$$\mathbf{U}_1(\tilde{x}, y) - \mathbf{u}_x^+(y)\tilde{x} - \mathbf{u}_1^+(y) = \mathcal{O}(\varepsilon\tilde{x}^2).$$

Then it follows that

$$\mathbf{U}_0(\tilde{x}, y) - \mathbf{u}^+(y) = \mathcal{O}(\varepsilon^2\tilde{x}^2).$$

Hence, in $\mathcal{J}$, we must have $\varepsilon\tilde{x}^2 = \mathbf{o}(1)$. This is true, e.g., if $\beta = 1/3$. We can then choose, e.g., $\alpha = 1/4$. The construction of $\mathcal{J}$ is then complete. The matching conditions are

$$\begin{aligned} &\mathbf{U}_0(\pm\infty, y) = \mathbf{u}^\pm(y), \\ &\mathbf{U}_1(\tilde{x}, y) - \mathbf{u}_x^\pm(y)\tilde{x} - \mathbf{u}_1^\pm(y) = \mathbf{o}(1) \quad \text{as } \tilde{x} \to \pm\infty. \end{aligned} \tag{2.20}$$

Since $\phi(z)$ vanishes for $|z| \geq K_1$, we conclude from (2.14) that $\mathbf{U}_0$ must have reached $\mathbf{u}^\pm(y)$ at $\tilde{x}_0 \pm K_1$. Hence, the matching condition (2.20) can be reformulated as

$$\mathbf{U}_0(\tilde{x}_0 - K_1, y) = \mathbf{u}^-(y), \quad \mathbf{U}_0(\tilde{x}_0 + K_1, y) = \mathbf{u}^+(y).$$

2.4. Downstream boundary condition for the first order term. In this subsection, we will derive the necessary boundary conditions for $\mathbf{u}_1$ at $x = 0^+$.

Let x_m^- denote one point in the upstream matching region and x_m^+ denote one point in the downstream matching region. Integration of the viscous (2.7) from x_m^- to x_m^+ gives

$$[\mathbf{f}(\mathbf{u}^\varepsilon)]_{x_m^-}^{x_m^+} + \int_{x_m^-}^{x_m^+} \mathbf{g}(\mathbf{u}^\varepsilon)_y - c_2\varepsilon^2\mathbf{u}_{yy}^\varepsilon \, dx = \mathcal{O}(\varepsilon^2), \tag{2.21}$$

where we have used that $\phi(x)$ vanishes in the matching regions. Using the outer expansion of $\mathbf{u}^\varepsilon$ we obtain

$$[\mathbf{f}(\mathbf{u}^\varepsilon)]_{x_m^-}^{x_m^+} = [\mathbf{f}(\mathbf{u})]_{x_m^-}^{x_m^+} + \varepsilon[\mathbf{f}'(\mathbf{u})\mathbf{u}_1]_{x_m^-}^{x_m^+} + \mathcal{O}(\varepsilon^2). \tag{2.22}$$

By integrating the inviscid (2.1) over the same interval we find

$$[\mathbf{f}(\mathbf{u})]_{x_m^-}^{x_m^+} = -\int_{x_m^-}^{0^-} \mathbf{g}(\mathbf{u})_y \, dx - \int_{0^+}^{x_m^+} \mathbf{g}(\mathbf{u})_y \, dx. \tag{2.23}$$

Note that $\mathbf{u}$ is discontinuous at $x=0$ and that the Rankine–Hugoniot condition (2.6) applies across the discontinuity. Taking into account that $\mathbf{u}_1 \equiv 0$ upstream of the shock layer and introducing (2.22) and (2.23) into (2.21), and Taylor expanding $\mathbf{u}$ and $\mathbf{u}_1$ around $\tilde{x} = 0$, we arrive at

$$\varepsilon \mathbf{f}'(\mathbf{u}^+(y))\mathbf{u}_1^+(y) + I_1(y) - I_2(y) = \mathcal{O}(\varepsilon^2), \tag{2.24}$$

where I_1 and I_2 are defined by

$$\begin{aligned} I_1 &= \int_{x_m^-}^{0^-} (\mathbf{g}(\mathbf{u}^\varepsilon) - \mathbf{g}(\mathbf{u}))_y \, dx + \int_{0^+}^{x_m^+} (\mathbf{g}(\mathbf{u}^\varepsilon) - \mathbf{g}(\mathbf{u}))_y \, dx, \\ I_2 &= \int_{x_m^-}^{x_m^+} c_2 \varepsilon^2 \mathbf{u}_{yy}^\varepsilon \, dx. \end{aligned} \tag{2.25}$$

First, we consider I_2. Expressed using the inner expansion of $\mathbf{u}^\varepsilon$ and the $(\tilde{x}, y)$-coordinate system, we have

$$I_2 = \varepsilon \int_{\tilde{x}_m^-}^{\tilde{x}_m^+} c_2 \varepsilon^2 (\mathbf{U}_0 + \varepsilon \mathbf{U}_1 + \mathcal{O}(\varepsilon^2))_y \, d\tilde{x}.$$

In the $(\tilde{x}, y)$-coordinate system, all derivatives of $\mathbf{U}_i$ are $\mathcal{O}(1)$. Hence,

$$I_2 = \mathbf{o}(\varepsilon^2), \tag{2.26}$$

where we have used that $\varepsilon \tilde{x} = \mathbf{o}(1)$ in the matching region.

Next, we consider I_1. We use the inner expansion of $\mathbf{u}^\varepsilon$, the Taylor expansion of $\mathbf{u}$ around $x = 0^\pm$ and change coordinates. Then we obtain

$$\begin{aligned} I_1 &= \varepsilon \tilde{I}_1, \\ \tilde{I}_1 &= \int_{\tilde{x}_m^-}^{0} \big(\mathbf{g}(\mathbf{U}_0) - \mathbf{g}(\mathbf{u}^-)\big)_y \, d\tilde{x} + \int_{0}^{\tilde{x}_m^+} \big(\mathbf{g}(\mathbf{U}_0) - \mathbf{g}(\mathbf{u}^+)\big)_y \, d\tilde{x} + \mathbf{o}(1), \end{aligned}$$

where we have used that $\varepsilon \tilde{x}^2 = \mathbf{o}(1)$ in the matching region.

For the further analysis, it is convenient to introduce $\hat{\mathbf{U}}(\tilde{x}, y)$ defined by

$$\begin{aligned} \big(\phi(\tilde{x})\hat{\mathbf{U}}_{\tilde{x}}\big)_{\tilde{x}} - \mathbf{f}(\hat{\mathbf{U}})_{\tilde{x}} &= 0, \\ \hat{\mathbf{U}}(-K_1, y) &= \mathbf{u}^-, \\ \hat{\mathbf{U}}(K_1, y) &= \mathbf{u}^+, \end{aligned} \tag{2.27}$$

i.e., $\mathbf{U}_0(\tilde{x}, y) = \hat{\mathbf{U}}(\tilde{x} - \tilde{x}_0, y)$. Hence, using $\hat{\mathbf{U}}$ we obtain

$$\begin{aligned} \tilde{I}_1 = &\int_{\tilde{x}_m^-}^{0} (\mathbf{g}(\hat{\mathbf{U}}(\tilde{x} - \tilde{x}_0(y)) - \mathbf{g}(\mathbf{u}^-))_y \, d\tilde{x} \\ &+ \int_{0}^{\tilde{x}_m^+} (\mathbf{g}(\hat{\mathbf{U}}(\tilde{x} - \tilde{x}_0(y)) - \mathbf{g}(\mathbf{u}^+))_y \, d\tilde{x} + \mathbf{o}(1). \end{aligned}$$

We now again change the coordinate system, introducing $\hat{x} = \tilde{x} - \tilde{x}_0(y), \hat{y} = y$. The relations between derivatives in the $(\tilde{x}, y)$-coordinate system and the $(\hat{x}, \hat{y})$-coordinate system are

$$\begin{aligned}\frac{\partial}{\partial \tilde{x}} &= \frac{\partial}{\partial \hat{x}},\\ \frac{\partial}{\partial y} &= -\tilde{x}_0'(\hat{y})\frac{\partial}{\partial \hat{x}} + \frac{\partial}{\partial \hat{y}}.\end{aligned}$$

After applying the change of coordinates, we arrive at

$$\tilde{I}_1 = (-\tilde{x}_0(\hat{y})[\mathbf{g}])_{\hat{y}} + \hat{I}_{1\hat{y}} + \mathbf{o}(1),$$

where

$$\hat{I}_1 = \int_{-K_1}^{0} \mathbf{g}(\hat{\mathbf{U}}) - \mathbf{g}(\mathbf{u}^-)\,d\hat{x} + \int_0^{K_1} \mathbf{g}(\hat{\mathbf{U}}) - \mathbf{g}(\mathbf{u}^+)\,d\hat{x}.$$

The leading terms of (2.24) together with condition (2.10) give that the equations for $\mathbf{u}_1^+(y)$ and $\tilde{x}_1(y)$ are

$$\mathbf{f}'(\mathbf{u}^+)\mathbf{u}_1^+ - (\tilde{x}_1[\mathbf{g}])_y = -\hat{I}_{1y}, \tag{2.28}$$

$$\tilde{x}_1(0) = 0. \tag{2.29}$$

We have used that $\tilde{x}_0 = \tilde{x}_1 + \mathcal{O}(\varepsilon)$ and that $\mathbf{u}$ and $\mathbf{u}_1$ are independent of ε. Note that the terms $\tilde{x}_1[\mathbf{g}(\cdot, y)]$ and $\hat{I}_1$ are one-variable functions; hence there is no difference between $\hat{y}$ and y.

(2.28) and (2.29) constitute the boundary condition for $\mathbf{u}_1$ at $x = 0^+$. To make (2.28) and (2.29) easier to understand, we rewrite them using the characteristic variables of $\mathbf{u}_1$. Let w_I be the characteristics of $\mathbf{u}_1$ going into the shock, and let $\mathbf{w}_{II}$ be the characteristic variables going out of the shock. We then have

$$\mathbf{u}^+ = (S_I^+ S_{II}^+)\begin{pmatrix}\mathrm{w}_I\\ \mathbf{w}_{II}\end{pmatrix}.$$

Expressed in characteristic variables, (2.28) can be written as

$$\begin{pmatrix}\mathbf{w}_{II}\\ \tilde{x}_1'\end{pmatrix} = D^{-1}\begin{pmatrix}\Lambda_{II}^+ & 0\\ 0 & -1\end{pmatrix}^{-1}(\tilde{x}_1[\mathbf{g}] - S_I^+\mathrm{w}_I - \hat{I}_{1y}), \tag{2.30}$$

where D is defined in (2.3) and $\Lambda_{II}^+ = \mathrm{diag}(\lambda_2^+, \lambda_3^+, \ldots, \lambda_m^+)$. By solving (2.30) and (2.29) for $\tilde{x}_1$, we can express $\mathbf{w}_{II}$ in w_I and known functions of time. The Laplace transform method (see, e.g., [17]) shows that the equation and boundary conditions for $\mathbf{w}$ constitute a well-posed problem. Well-posedness implies that for any $\hat{I}_{1y}$ there exists a unique solution. The boundary condition for $\mathbf{w}$ at $x = 0^+$ is homogeneous if $\hat{I}_{1y} \equiv 0$, and nonhomogeneous otherwise. Since $\mathbf{w}$ is a transformation of $\mathbf{u}_1$, the same applies for $\mathbf{u}_1$.

2.5. Main result.

We summarize the conclusions from the analysis in the following theorem.

THEOREM 2.1. *If Assumptions* 1–3 *are satisfied, then* $\mathbf{u}_1 \equiv 0$ *on the upstream side and* $\mathbf{u}_1$ *together with* $\tilde{x}_1$ *on the downstream side satisfy the well-posed problem consisting of* (2.15) *with the boundary conditions* (2.28) *and* (2.29) *on the domain*

$$0 < x < a, \quad y > 0.$$

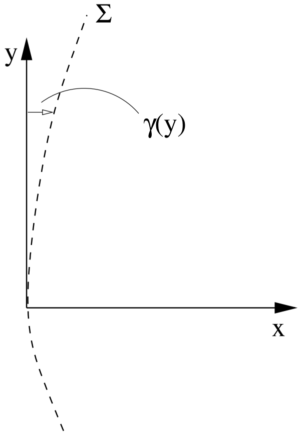

FIG. 2.2. *For a curved shock, we define the shock curve* Σ *by* $\Sigma = \{(x, y) : x = \gamma(y)\}$.

If $\hat{I}_{1y} \equiv 0$*, then* $\mathbf{u}_1 \equiv 0$*, and* $\mathbf{u}^\varepsilon$ *is a second order accurate approximation of* $\mathbf{u}$*. In the general case* $\mathbf{u}_1 \neq 0$*, and* $\mathbf{u}^\varepsilon$ *will be a first order accurate approximation of* $\mathbf{u}$*.*

Remark. In [16] and [23], similar analysis was presented for steady-state solutions of systems with source terms in one space dimension and time-dependent solutions of systems in one space dimension, respectively. In both cases, integral conditions similar to $\hat{I}_{1y} = 0$ are necessary for second order accuracy of the numerical schemes. In the 1D cases, we were able to design a matrix valued viscosity coefficient such that the integral condition is satisfied. Numerical computations verified that the numerical solutions obtained are indeed second order accurate both upstream and downstream of the shock. In the 1D cases, however, the integral condition involved $\mathbf{u}$ and $\hat{U}$, while the integral condition in two dimensions involved $\mathbf{g}(\mathbf{u})$ and $\mathbf{g}(\hat{U})$. In general, $\mathbf{g}$ is a complicated nonlinear function. We have not been able to design a matrix valued viscosity coefficient such that the integral condition $\hat{I}_{1y} = 0$ is satisfied.

2.6. Curved shocks. In this subsection we sketch how the analysis in the previous sections is altered if we consider curved shocks. The shock curve Σ is defined by $\Sigma = \{(x, y) : x = \gamma(y)\}$; see Figure 2.2.

The normal of Σ is $(-1, \gamma')/\sqrt{1 + |\gamma'|^2}$. As long as $|\gamma'|$ is bounded we have from (2.2)

$$-[\mathbf{f}] + \gamma'[\mathbf{g}] = 0.$$

After the coordinate transformation

$$\hat{x} = x - \gamma(y), \quad \hat{y} = y, \tag{2.31}$$

the inviscid steady-state solution

$$\mathbf{f}(\mathbf{u})_x - \mathbf{g}(\mathbf{u})_y = 0$$

becomes

$$(\mathbf{f}(\mathbf{u}) - \gamma'(\hat{y})\mathbf{g}(\mathbf{u}))_{\hat{x}} + \mathbf{g}(\mathbf{u})_{\hat{y}} = 0.$$

In numerical computations the dissipation is usually treated separately in each grid direction. Therefore, instead of (2.7), we now consider the model equation

$$\mathbf{f}(\mathbf{u}^\varepsilon)_x + \mathbf{g}(\mathbf{u}^\varepsilon)_y = \varepsilon\big(\phi_1 \mathbf{u}^\varepsilon_x\big)_x + \varepsilon\big(\phi_2 \mathbf{u}^\varepsilon_y\big)_y + c_2\varepsilon^2\big(\mathbf{u}^\varepsilon_{xx} + \mathbf{u}^\varepsilon_{yy}\big) \tag{2.32}$$

with the appropriate changes of boundary conditions, etc. The functions ϕ_1 and ϕ_2 are smooth functions of one variable modeling the switch mechanism. The model equation (2.32) expressed in the $(\hat{x}, \hat{y})$-variables is

$$\begin{aligned}(2.33)\quad &(\mathbf{f}(\mathbf{u}^\varepsilon) - \gamma'(\hat{y})\mathbf{g}(\mathbf{u}^\varepsilon))_{\hat{x}} + \mathbf{g}(\mathbf{u}^\varepsilon)_{\hat{y}} \\ &\quad = \varepsilon\big(\big(\phi_1 \mathbf{u}^\varepsilon_{\hat{x}}\big)_{\hat{x}} - \gamma'\big(\phi_2\big(-\gamma'\mathbf{u}^\varepsilon_{\hat{x}} + \mathbf{u}^\varepsilon_{\hat{y}}\big)\big)_{\hat{x}} + \big(\phi_2\big(-\gamma'\mathbf{u}^\varepsilon_{\hat{x}} + \mathbf{u}^\varepsilon_{\hat{y}}\big)\big)_{\hat{y}}\big) + \mathcal{O}(\varepsilon^2).\end{aligned}$$

One of the most important assumptions in the analysis in the previous subsections was that the derivatives in the x-direction were $\mathcal{O}(1/\varepsilon)$, whereas the y-derivatives were $\mathcal{O}(1)$. As long as $|\gamma'| \ll 1$, this also applies in this more general setting. After introducing

$$\hat{\mathbf{f}}(\mathbf{u}) = \mathbf{f}(\mathbf{u}) - \gamma'(\hat{y})\mathbf{g}(\mathbf{u})$$

the same analysis as before can be performed. Consequently, the downstream boundary condition for the first order term is of the same form as (2.28) and (2.29).

In the case with a straight shock, the first order downstream error was driven only by the variation along the shock of the states in the inviscid solution. From (2.27), however, we see that in the case of a curved shock, the first order downstream error is also driven by the curvature of the shock.

For a general shock, the analysis presented in this section can be applied after a rotation. There is no essential difference in the analysis, but the calculations become more tedious. The conclusion is still that the solution will be only first order accurate downstream of a shock interface.

3. Summary.

In this paper we present an analysis that yields a possible explanation to the reduction in order of accuracy, when formally second and higher order shock capturing schemes are used for solutions containing shocks. A detailed analysis of the so-called modified equation for a generic shock capturing scheme is presented for the case of a steady-state solution containing a shock that is straight and aligned with one of the grid directions. We then show how the analysis can be extended to curved shocks. The analysis yields that a reduction to first order accuracy in 2D steady-state solutions in general is due to the variation of the solution in the direction tangential to the shock layer in the vicinity of the shock. Note that in the 1D case the reduction to first order accuracy in a steady-state solution is only possible with a lower order term present in the conservation law. Such a term is not necessary in the 2D case.

Acknowledgment. The authors would like to thank Prof. Gunilla Kreiss for fruitful discussions and helpful suggestions throughout the work on this paper.

MULTILEVEL PRECONDITIONERS FOR NON–SELF-ADJOINT OR INDEFINITE ORTHOGONAL SPLINE COLLOCATION PROBLEMS*

RAKHIM AITBAYEV†

Abstract. Efficient numerical algorithms are developed and analyzed that implement symmetric multilevel preconditioners for the solution of an orthogonal spline collocation (OSC) discretization of a Dirichlet boundary value problem with a non–self-adjoint or an indefinite operator. The OSC solution is sought in the Hermite space of piecewise bicubic polynomials. It is proved that the proposed additive and multiplicative preconditioners are uniformly spectrally equivalent to the operator of the normal OSC equation. The preconditioners are used with the preconditioned conjugate gradient method, and numerical results are presented that demonstrate their efficiency.

Key words. orthogonal spline collocation, multilevel methods, preconditioner, non–self-adjoint or indefinite operator, elliptic boundary value problem

1. Introduction.

Let Ω be a unit square $(0,1)\times(0,1)$ with boundary $\partial\Omega$, and let $x=(x_1,x_2)$. We consider a Dirichlet boundary value problem (BVP)

$$Lu = f \text{ in } \Omega \quad \text{and} \quad u=0 \text{ on } \partial\Omega, \tag{1.1}$$

where we let

$$Lu\,(x) = \sum_{i,j=1}^{2} a_{ij}(x)u_{x_ix_j}(x) + \sum_{i=1}^{2} b_i(x)u_{x_i}(x) + c(x)u(x). \tag{1.2}$$

With respect to BVP (1.1), we make the following assumptions. The functions $\{a_{ij}\}_{i,j=1}^2$, $\{b_i\}_{i=1}^2$, c, and f are sufficiently smooth, and $a_{12}=a_{21}$. The differential operator L satisfies the uniform ellipticity condition; that is, there is $\nu>0$ such that

$$\sum_{i,j=1}^{2} a_{ij}(x)\,\eta_i\,\eta_j \ge \nu(\eta_1^2+\eta_2^2), \quad x\in\Omega,\ (\eta_1,\eta_2)\in R^2. \tag{1.3}$$

For any $f\in L^2(\Omega)$, BVP (1.1) has a unique solution $u(x)$ in

$$\tilde{H}_0^2(\Omega) = \{v\in H^2(\Omega):\ v=0 \text{ on } \partial\Omega\}, \tag{1.4}$$

where $L^2(\Omega)$ and $H^2(\Omega)$ are the Sobolev spaces.

We approximate BVP (1.1) by an orthogonal spline collocation (OSC) scheme, in which the discrete solution is sought in the Hermite space of piecewise bicubic polynomials, and it satisfies the differential equation exactly at the special set of collocation points. The primary advantages of the OSC method are as follows: it has low computational cost of forming a linear system of algebraic equations; it has relatively easy

application of higher order finite elements; the OSC solution possesses optimal order error estimates [7]; and the solution exhibits the so-called superconvergence property [8, 15]. The matrix of a linear system resulting from the OSC discretization is sparse and can be expressed as a sum of tensor products of so-called almost block diagonal matrices [2].

The solution of the OSC equations by a banded Gaussian elimination requires $\mathrm{O}(N^2)$ arithmetic operations, where N is the number of unknowns [22, 23, 34]. If the differential operator is separable and the partition is uniform in one direction, then the OSC problem can be solved by a fast direct algorithm with the cost $\mathrm{O}(N \log N)$ [10].

Classical iterative methods, such as Jacobi, Gauss–Seidel, and SOR, for the OSC solution of Poisson's equation on a uniform partition were studied in [21, 26, 37]. ADI methods for solving OSC problems with separable operators were investigated in [5, 14, 18].

Modern techniques are underdeveloped for the solution of OSC equations in comparison with finite element Galerkin or finite difference methods. Only a few optimal cost algorithms have been proposed to solve the OSC discretization of self-adjoint positive definite BVPs. In [19], the multigrid method was applied to the OSC problem and compared with a multigrid finite difference method. The author concluded that the proposed multigrid OSC method is less efficient than a multigrid finite difference method. A domain decomposition–based fast solver for the OSC discretization of the Dirichlet problem for Poisson's equation was developed in [6] requiring $\mathrm{O}(N \log\log N)$ arithmetic operations. In [13], multigrid methods were developed and analyzed for quadratic spline collocation equations. Numerical results were presented indicating that a multigrid iteration is an efficient solver for the quadratic spline collocation equations.

It is well known that the primary issue in the efficient application of an iterative algorithm for solving a BVP is the construction of a good preconditioner. In [24], the authors studied preconditioning of a non–self-adjoint or an indefinite OSC operator by a finite element operator and investigated H^1 condition numbers and the distribution of singular values of the preconditioned matrices. Additive and multiplicative multilevel preconditioners were proposed in [9] for the iterative solution of the OSC discretization of a self-adjoint positive definite Dirichlet BVP. It was proved that the preconditioners are uniformly spectrally equivalent to the OSC operator corresponding to a BVP with the Laplacian and require $\mathrm{O}(N)$ arithmetic operations. An efficient two-level domain decomposition–type "edge" preconditioner was proposed in [29] that requires $\mathrm{O}(N)$ arithmetic operations. The preconditioner is applied with the GMRES method, and the number of iterations is independent of the partition stepsize h.

Numerical techniques developed for self-adjoint positive definite BVPs are usually inefficient or even fail when applied to non–self-adjoint or indefinite BVPs, and hence, special, more sophisticated methods are required to obtain the solution [4, 11, 12, 27, 28]. A fast direct preconditioning algorithm for the solution of the normal OSC equation approximating non–self-adjoint or indefinite BVPs was proposed in [1].

In this work, we develop additive and multiplicative multilevel preconditioners for the computation of the solution of the normal OSC equation. Results and algorithms presented in this paper are closely related to those in [1, 7, 9, 31, 32, 39, 40]. To prove uniform spectral equivalence of our preconditioners, we use the approach described in [31] and [32] based on the equivalence of a norm of a certain Besov space with the Sobolev H^2-norm. We note that the approach used in [39] and [40] requires higher regularity of the solution of BVP (1.1). Our main conclusion in this work is that the general framework of multilevel methods can be applied to the OSC discretization of BVPs to construct efficient preconditioners. Rather general non–self-adjoint or indefinite OSC problems can be preconditioned quite well by the proposed multilevel OSC preconditioners.

The outline of this article is as follows. We introduce our notation and define the OSC problem in section 2. In section 3, we present auxiliary facts that are used to prove main results of this work. In section 4, we define additive and multiplicative OSC preconditioners and prove that they are uniformly spectrally equivalent to the operator of the normal OSC equation. In section 5, we introduce the matrix-vector form of the OSC problem in the standard Hermite finite element basis and obtain recurrence relations for the computation of the OSC approximations and other quantities required by the multilevel algorithms. In section 6, we describe implementations of the additive and the multiplicative preconditioners, and in section 7, we present numerical results of the application of the preconditioners with the preconditioned conjugate gradient (PCG) method to solve test problems.

2. OSC problem.

In this section, we introduce our notation and define the OSC problem. Throughout this paper, C, C_1, and $C_2 \geq C_1$ denote generic positive constants independent of the partition stepsize, the number of partition levels, and other variables in the expressions where the constants appear. By $\|\cdot\|_{L^2(\Omega)}$ and $\|\cdot\|_{H^2(\Omega)}$ we denote the standard Sobolev norms.

Construction of nested spaces. We set $\pi_0 = \Omega$ and, for integer $K > 0$, we construct a sequence of partitions $\{\pi_k\}_{k=0}^{K}$ by subdividing each rectangular element of partition π_{k-1} into four congruent rectangular elements of partition π_k. Let $h_k = 2^{-k}$ denote the stepsize of partition π_k. In what follows, if not stated otherwise, the index variable k takes all values in $\{0, 1, \ldots, K\}$. We note that there are $K + 1$ partition levels, and integer K is an important parameter in our analysis.

Let V_k be the vector space of Hermite piecewise bicubic polynomials that vanish on $\partial\Omega$, which has the dimension $N_k = 4^{k+1}$ (see Chapter 3 in [35]). The sequence of vector spaces $\{V_k\}$ is nested as follows:

$$V_0 \subset V_1 \subset \cdots \subset V_K \subset \tilde{H}_0^2(\Omega). \tag{2.1}$$

We denote $h = h_K$, $N = N_K$, $\pi_h = \pi_K$, and $V_h = V_K$.

Original OSC equation. Let $\mathcal{G}_h$ be the set of nodes of the two-dimensional composite Gaussian quadrature on partition π_h with 4 nodes in each element of π_h. In the OSC discretization of BVP (1.1), we seek $u_h \in V_h$ that satisfies the OSC equations

$$Lu_h(\xi) = f(\xi), \quad \xi \in \mathcal{G}_h, \tag{2.2}$$

where the differential operator L is defined in (1.2). Existence and uniqueness of a solution and a convergence analysis of problem (2.2) are given in [7].

The OSC problem (2.2) can be written as the operator equation

$$L_h u_h = f_h, \tag{2.3}$$

where the OSC operator L_h from V_h into V_h and the vector $f_h \in V_h$ are defined by

$$\begin{aligned} (L_h v)(\xi) &= Lv(\xi), \quad \text{for any } \xi \in \mathcal{G}_h \text{ and for any } v \in V_h, \\ f_h(\xi) &= f(\xi), \quad \text{for any } \xi \in \mathcal{G}_h. \end{aligned} \tag{2.4}$$

Both L_h and f_h are well defined since a function in V_h is uniquely determined by its values at $\mathcal{G}_h$ (see Lemma 5.1 in [33]). We call (2.3) the original OSC equation.

Normal OSC equation. The vector space V_h is a Hilbert space with the inner product

$$(v,w)_h = \frac{h^2}{4} \sum_{\xi \in \mathcal{G}_h} v(\xi) w(\xi), \tag{2.5}$$

which corresponds to the composite Gaussian quadrature on π_h. Let L_h^* be the adjoint to L_h with respect to the inner product $(\cdot,\cdot)_h$. Applying L_h^* on (2.3), we obtain the normal OSC equation

$$L_h^* L_h u_h = L_h^* f_h. \tag{2.6}$$

We introduce a bilinear form

$$a_h(w,v) = (L_h^* L_h w, v)_h, \quad w, v \in V_h, \tag{2.7}$$

and consider the following variational form of problem (2.6): find $u_h \in V_h$ that satisfies

$$a_h(u_h, v) = (L_h^* f_h, v)_h \ \text{ for all } \ v \in V_h. \tag{2.8}$$

The problems (2.8) and (2.2) are equivalent; hence, problem (2.8) has a unique solution. In this work, we develop and analyze multilevel preconditioners for the iterative solution of (2.8).

Space decompositions. In what follows, we denote $\sum_k$ and $\sum_{k,i}$ for $\sum_{k=0}^K$ and $\sum_{k=0}^K \sum_{i=1}^{N_k}$, respectively, where N_k is the dimension of V_k.

Let $\{\psi_i^k\}_{i=1}^{N_k}$ be a finite element basis of V_k that satisfies

$$C_1 h_k^{1-|\alpha|} \le \|\partial^\alpha \psi_i^k\|_{L^2(\Omega)} \le C_2 h_k^{1-|\alpha|}, \quad |\alpha| \le 2, \tag{2.9}$$

where $\alpha = (\alpha_1, \alpha_2)$ is a multi-index (see Theorem 5.7 in [3]). Let

$$V_{ki} = \operatorname{span}(\psi_i^k), \quad 1 \le i \le N_k, \tag{2.10}$$

be one-dimensional subspaces of V_k. Based on (2.1), we consider the following two space decompositions:

$$\sum_k V_k = V_h \quad \text{and} \quad \sum_{k,i} V_{ki} = V_h.$$

For $v \in V_h$, let

$$\mathcal{V}_1(v) = \left\{ \{v_k\} : \sum_k v_k = v,\ v_k \in V_k,\ 0 \le k \le K \right\},$$

$$\mathcal{V}_2(v) = \left\{ \{v_{ki}\} : \sum_{ki} v_{ki} = v,\ v_{ki} \in V_{ki},\ 1 \le i \le N_k,\ 0 \le k \le K \right\}.$$

We call an element in $\mathcal{V}_1(v)$ and in $\mathcal{V}_2(v)$ a representation of v. The sets $\mathcal{V}_1(v)$ and $\mathcal{V}_2(v)$ will be used to define auxiliary equivalent norms on V_h.

3. Auxiliary results.

In this section we present auxiliary facts that are used to prove main results of this work. The following inequalities are proved in Theorem 3.1 in [1].

Lemma 3.1. *For h sufficiently small,*

$$C_1 \|v\|^2_{H^2(\Omega)} \le a_h(v,v) \le C_2 \|v\|^2_{H^2(\Omega)}, \quad v \in V_h. \tag{3.1}$$

Remark. In what follows, by sufficiently small h, we mean values of h for which the statement of Lemma 3.1 holds.

It follows from (3.1) and (2.7) that, for h sufficiently small, the bilinear form $a_h(\cdot,\cdot)$ is an inner product on V_h. The following is the estimate (8.24) in Chapter 3 of [25].

LEMMA 3.2.

$$\|v\|_{H^2(\Omega)} \leq C\|\Delta v\|_{L^2(\Omega)}, \quad v \in \tilde{H}_0^2(\Omega). \tag{3.2}$$

Inequalities (3.1), (3.2), and

$$\|\Delta v\|^2_{L^2(\Omega)} \leq C \int_\Omega (v^2_{x_1x_1} + v^2_{x_2x_2})dx, \quad v \in \tilde{H}_0^2(\Omega), \tag{3.3}$$

imply that, for h sufficiently small,

$$C_1\|\Delta v\|^2_{L^2(\Omega)} \leq a_h(v,v) \leq C_2\|\Delta v\|^2_{L^2(\Omega)}, \quad v \in V_h. \tag{3.4}$$

LEMMA 3.3. *Let $v \in V_k$, and let*

$$v = \sum_{i=1}^{N_k} c_j\psi_i^k \ \ \textit{and} \ \ \vec{c}_v = (c_1,\ldots,c_{N_k})^t. \tag{3.5}$$

Then,

$$C_1h_k|\vec{c}_v| \leq \|v\|_{L^2(\Omega)} \leq C_2h_k|\vec{c}_v|, \quad v \in V_k, \tag{3.6}$$

where $|\cdot|$ is the 2-norm on R^{N_k}.

Proof. Using (3.5), we obtain

$$\|v\|^2_{L^2(\Omega)} = \int_\Omega \sum_{i=1}^{N_k} c_i\psi_i^k \sum_{j=1}^{N_k} c_j\psi_j^k\,dx = \sum_{i,j=1}^{N_k} c_ic_j \int_\Omega \psi_i^k\psi_j^k\,dx.$$

The inequalities in (3.6) follow from the last identity and the fact that the eigenvalues of the mass matrix corresponding to the finite element basis $\{\psi_i^k\}_{i=1}^{N_k}$ belong to the interval $[C_1h_k^2, C_2h_k^2]$ (see (5.103) in [3]). □

Let

$$\|v\|_{*,h} = \left(\inf_{\mathcal{V}_1(v)} \sum_{k=0}^{K} h_k^{-4}\|v_k\|^2_{L^2(\Omega)}\right)^{1/2}, \quad v \in V_h, \tag{3.7}$$

where $\inf_{\mathcal{V}_1(v)}$ denotes the infimum with respect to all representations $\{v_k\}$ in $\mathcal{V}_1(v)$. The following important statement is similar to Corollary 2.1 in [32] and Lemma 2 in [31].

LEMMA 3.4. *The norms $\|\cdot\|_{H^2(\Omega)}$ and $\|\cdot\|_{*,h}$ are uniformly equivalent on V_h; that is,*

$$C_1\|v\|_{H^2(\Omega)} \leq \|v\|_{*,h} \leq C_2\|v\|_{H^2(\Omega)}, \quad v \in V_h. \tag{3.8}$$

Proof. First, we prove the second inequality in (3.8). It is known that the Besov space $B^2_{2,2}(\Omega)$ coincides, up to equivalent norms, with the Sobolev space $H^2(\Omega)$ (see part (b) of Theorem 4.6.1 and (3) of section 4.2.1 in [38]). Since $\tilde{H}_0^2(\Omega)$ is a closed subspace of $H^2(\Omega)$, it is a closed subspace of $B^2_{2,2}(\Omega)$. We note that functions in $\tilde{H}_0^2(\Omega)$ are continuous on $\overline{\Omega}$, and therefore, for any $v \in \tilde{H}_0^2(\Omega)$, $v(x) = 0$ for all $x \in \partial\Omega$; in particular, the trace of $v \in \tilde{H}_0^2(\Omega)$ is continuous. In a natural way, we extend the definition of $\{V_k\}$ for $k > K$. It follows from Theorem 5.1 in [16] that

$$\|v\|_{A^2_{2,2}} = \left(\|v\|^2_{L^2(\Omega)} + \sum_{k=0}^{\infty} 2^{4k} \left(\inf_{z \in V_k} \|v - z\|_{L^2(\Omega)} \right)^2 \right)^{1/2}$$

is a norm on $\tilde{H}_0^2(\Omega)$ equivalent to the standard norm in $B^2_{2,2}(\Omega)$ (see [30] for a definition of the approximation space $A^2_{2,2}$). Therefore, using the equivalence of norms $\|\cdot\|_{H^2(\Omega)}$ and $\|\cdot\|_{A^2_{2,2}}$ on $\tilde{H}_0^2(\Omega)$ and the fact $V_h \subset \tilde{H}_0^2(\Omega)$, we get

$$\|v\|_{A^2_{2,2}} \le C\|v\|_{H^2(\Omega)}, \quad v \in V_h. \tag{3.9}$$

Let us prove

$$\|v\|_{*,h} \le C\|v\|_{A^2_{2,2}}, \quad v \in V_h. \tag{3.10}$$

We note that

$$\|v\|_{A^2_{2,2}} = \left(\|v\|^2_{L^2(\Omega)} + \sum_{k=0}^{K-1} 2^{4k} \left(\inf_{z \in V_k} \|v - z\|_{L^2(\Omega)} \right)^2 \right)^{1/2}, \quad v \in V_h, \tag{3.11}$$

since

$$\inf_{z \in V_k} \|v - z\|_{L^2(\Omega)} = 0, \;\; k \ge K, \;\; v \in V_h.$$

Take any $v \in V_h$ and set $v_0 = z_0$ and $v_k = z_k - z_{k-1}$ for $1 \le k \le K$, where z_k is the orthogonal L^2-projection of v into V_k. Note that $v = z_K = \sum_{k=0}^K v_k$. Using $\|v_0\|_{L^2(\Omega)} \le \|v\|_{L^2(\Omega)}$, the triangle inequality, the definition of $\{z_k\}$, and (3.11), we obtain

$$\begin{aligned} \sum_{k=0}^{K} h_k^{-4} \|v_k\|^2_{L^2(\Omega)} &= \|v_0\|^2_{L^2(\Omega)} + \sum_{k=1}^{K} h_k^{-4} \|z_k - v + v - z_{k-1}\|^2_{L^2(\Omega)} \\ &\le \|v\|^2_{L^2(\Omega)} + 4 \sum_{k=0}^{K-1} h_k^{-4} \|v - z_k\|^2_{L^2(\Omega)} \\ &= \|v\|^2_{L^2(\Omega)} + 4 \sum_{k=0}^{K-1} 2^{4k} \left(\inf_{z \in V_k} \|v - z\|_{L^2(\Omega)} \right)^2 \le 4\|v\|^2_{A^2_{2,2}}. \end{aligned}$$

Taking the infimum over $\mathcal{V}_1(v)$, we get (3.10). Inequalities (3.10) and (3.9) imply the second inequality in (3.8).

Let us prove the first inequality in (3.8). Take any $v \in V_h$ and let $\{v_k\} \in \mathcal{V}_1(v)$. Using the strengthened Cauchy–Schwarz inequality,

$$\left| \int_\Omega \Delta v_k \, \Delta v_l dx \right| \le C 2^{-|k-l|/2} (h_k h_l)^{-2} \|v_k\|_{L^2(\Omega)} \|v_l\|_{L^2(\Omega)}, \quad v_k \in V_k, \;\; v_l \in V_l,$$

(see Lemma 5.1 in [40]) and the fact that the spectral radius of matrix $B = (b_{kl})$ with the entries

$$b_{kl} = 2^{-|k-l|/2}, \quad 0 \le k, l \le K,$$

is bounded by the maximum norm $\|B\|_\infty \le 3 + 2\sqrt{2}$, we get

$$\begin{aligned}\|\Delta v\|^2_{L^2(\Omega)} &= \int_\Omega (\Delta v)^2 dx = \int_\Omega \left(\sum_{k=0}^K \Delta v_k\right)\left(\sum_{l=0}^K \Delta v_l\right) dx = \sum_{k,\, l=0}^K \int_\Omega \Delta v_k \, \Delta v_l dx \\ &\le C \sum_{k,\, l=0}^K 2^{-|k-l|/2}(h_k h_l)^{-2} \|v_k\|_{L^2(\Omega)} \|v_l\|_{L^2(\Omega)} \\ &\le C(3 + 2\sqrt{2}) \sum_k h_k^{-4} \|v_k\|^2_{L^2(\Omega)}.\end{aligned}$$

From the last estimate, using (3.2) and taking the infimum over $\mathcal{V}_1(v)$, we obtain the first inequality in (3.8).

To finish the proof of the lemma, we establish that $\|\cdot\|_{*,h}$ is a norm on V_h. It follows from the inequalities in (3.8) that $\|v\|_{*,h} \ge 0$ for any $v \in V_h$, and $\|v\|_{*,h} = 0$ if and only if $v = 0$. Let us show that $\|cv\|_{*,h} = |c| \, \|v\|_{*,h}$ for any $v \in V_h$ and $c \in R$. Since the case $c = 0$ is trivial, assume $c \ne 0$. Using the fact that the infimum over $\mathcal{V}_1(cv)$ equals the infimum over $\mathcal{V}_1(v)$, we obtain

$$\|cv\|^2_{*,h} = \inf_{\{w_k\} \in \mathcal{V}_1(cv)} \sum_{k=0}^K h_k^{-4} \|w_k\|^2_{L^2(\Omega)} = \inf_{\{v_k\} \in \mathcal{V}_1(v)} \sum_{k=0}^K h_k^{-4} \|cv_k\|^2_{L^2(\Omega)} = c^2 \|v\|^2_{*,h},$$

which implies the required identity.

To prove the triangle inequality for $\|\cdot\|_{h,*}$, using the triangle inequality for the L^2-norm and the Minkowski inequality, we obtain, for any v and w in V_h,

$$\begin{aligned}\|v + w\|^2_{*,h} &= \inf_{\{z_k\} \in \mathcal{V}_1(v+w)} \sum_{k=0}^K h_k^{-4} \|z_k\|^2_{L^2(\Omega)} \le \inf_{\mathcal{V}_1(v)} \inf_{\mathcal{V}_1(w)} \sum_{k=0}^K h_k^{-4} \|v_k + w_k\|^2_{L^2(\Omega)} \\ &\le \inf_{\mathcal{V}_1(v)} \inf_{\mathcal{V}_1(w)} \sum_{k=0}^K h_k^{-4} (\|v_k\|_{L^2(\Omega)} + \|w_k\|_{L^2(\Omega)})^2 \le (\|v\|_{*,h} + \|w\|_{*,h})^2.\end{aligned}$$

Thus, $\|\cdot\|_{*,h}$ is a norm on V_h which is equivalent to the H^2-norm. □

Remark. The result of Lemma 3.4 is analogous to those formulated in [32, Corollary 2.1] and [31, Lemma 2], where relations similar to (3.8) were proved first for Sobolev spaces with equivalent norms involving infinite number series, and then the versions for finite-dimensional subspaces were obtained. Our proof of Lemma 3.4 is somewhat different since it is based on the representation (3.11).

Let

$$\|v\|_{\Sigma,\Delta} = \left(\inf_{\mathcal{V}_2(v)} \sum_{k,i} \|\Delta v_{ki}\|^2_{L^2(\Omega)} \right)^{1/2}, \quad v \in V_h. \tag{3.12}$$

Lemma 3.5.

$$C_1 \|v\|_{H^2(\Omega)} \le \|v\|_{\Sigma,\Delta} \le C_2 \|v\|_{H^2(\Omega)}, \quad v \in V_h. \tag{3.13}$$

Proof. We call nonnegative quantities $A(h)$ and $B(h)$ uniformly equivalent with respect to h and write $A(h) \approx B(h)$ if

$$C_1 B(h) \leq A(h) \leq C_2 B(h).$$

Our proof consists of establishing the following sequence of equivalence relations:

$$\|v\|^2_{\Sigma,\Delta} \approx \inf_{\mathcal{V}_2(v)} \sum_{k,i} h_k^{-4} \|v_{ki}\|^2_{L^2(\Omega)} \approx \|v\|^2_{*,h} \approx \|v\|^2_{H^2(\Omega)}. \tag{3.14}$$

The last equivalence relation in (3.14) is stated and proved in Lemma 3.4.

Let us prove the first equivalence relation in (3.14). Take any $v \in V_h$ and consider a representation $\{v_{ki}\} \in \mathcal{V}_2(v)$. Using (2.10), (3.3), (3.2), and (2.9) with $|\alpha| = 2$ and $\alpha = (0,0)$, we obtain

$$C_1 \|\Delta v_{ki}\|^2_{L^2(\Omega)} \leq h_k^{-4} \|v_{ki}\|^2_{L^2(\Omega)} \leq C_2 \|\Delta v_{ki}\|^2_{L^2(\Omega)}.$$

Summing these inequalities with respect to k and i and taking the infimum over $\mathcal{V}_2(v)$, we obtain the first equivalence relation in (3.14).

We now prove the second equivalence relation in (3.14):

$$C_1 \inf_{\mathcal{V}_2(v)} \sum_{k,i} h_k^{-4} \|v_{ki}\|^2_{L^2(\Omega)} \leq \|v\|^2_{*,h} \leq C_2 \inf_{\mathcal{V}_2(v)} \sum_{k,i} h_k^{-4} \|v_{ki}\|^2_{L^2(\Omega)}, \quad v \in V_h. \tag{3.15}$$

Take any $v \in V_h$. Using uniqueness of the representation

$$v_k = \sum_{i=1}^{N_k} v_{ki}, \quad v_{ki} \in V_{ki}, \quad 1 \leq i \leq N_k,$$

for $v_k \in V_k$, we define injection mappings $\mathcal{V}_1(v) \to \mathcal{V}_2(v)$ and $\mathcal{V}_2(v) \to \mathcal{V}_1(v)$ by

$$\sum_k v_k = \sum_{ki} v_{ki}.$$

The Schroeder–Bernstein theorem implies that there is a bijection $\mathcal{V}_1(v) \to \mathcal{V}_2(v)$.

Consider any representation $\{v_k\} \in \mathcal{V}_1(v)$ and the representation $\{v_{ki}\} \in \mathcal{V}_2(v)$ given by the bijection $\mathcal{V}_1(v) \to \mathcal{V}_2(v)$. Let c_{ki} be such that $v_{ki} = c_{ki}\psi_i^k$. Using (2.9) with $\alpha = (0,0)$, we have

$$C_1\, c_{ki}^2 h_k^2 \leq \|v_{ki}\|^2_{L^2(\Omega)} \leq C_2\, c_{ki}^2 h_k^2.$$

Summing the last inequalities with respect to i and using (3.6), we obtain

$$C_1 \sum_{i=1}^{N_k} \|v_{ki}\|^2_{L^2(\Omega)} \leq \|v_k\|^2_{L^2(\Omega)} \leq C_2 \sum_{i=1}^{N_k} \|v_{ki}\|^2_{L^2(\Omega)}. \tag{3.16}$$

Multiplying (3.16) by h_k^{-4}, summing for $k = 0, 1, \ldots, K$, taking the infimum over $\mathcal{V}_1(v)$, and using (3.7), we obtain

$$C_1 \inf_{\mathcal{V}_1(v)} \sum_{k,i} h_k^{-4} \|v_{ki}\|^2_{L^2(\Omega)} \leq \|v\|^2_{*,h} \leq C_2 \inf_{\mathcal{V}_1(v)} \sum_{k,i} h_k^{-4} \|v_{ki}\|^2_{L^2(\Omega)}. \tag{3.17}$$

Since there is a bijection $\mathcal{V}_1(v) \to \mathcal{V}_2(v)$, the infimum over $\mathcal{V}_1(v)$ is equal to the infimum over $\mathcal{V}_2(v)$; hence, (3.17) implies (3.15). □

4. Uniform spectral equivalence. In this section, we define additive and multiplicative OSC preconditioners and prove that they are uniformly spectrally equivalent to the OSC operator $L_h^* L_h$.

Additive preconditioner. For $0 \leq k \leq K$ and $1 \leq i \leq N_k$, let T_i^k be a linear operator from V_h into V_{ki} defined as follows: for any $w \in V_h$, $T_i^k w$ satisfies

$$a_h(T_i^k w, v) = a_h(w, v) \quad \text{for all} \quad v \in V_{ki}. \tag{4.1}$$

The following is our main result for the additive preconditioner.

Theorem 4.1. *Assume that h is sufficiently small. Linear operator*

$$T_A = \sum_{k,i} T_i^k \tag{4.2}$$

is self-adjoint positive definite on V_h in the inner product $a_h(\cdot,\cdot)$. Linear operator

$$B_A = L_h^* L_h T_A^{-1} \tag{4.3}$$

is self-adjoint positive definite on V_h in the inner product $(\cdot,\cdot)_h$, and

$$C_1 (B_A v, v)_h \leq (L_h^* L_h v, v)_h \leq C_2 (B_A v, v)_h, \quad v \in V_h. \tag{4.4}$$

Proof. Let

$$\|v\|^2_{\Sigma,a_h} = \inf_{\mathcal{V}_2(v)} \sum_{k,i} a_h(v_{ki}, v_{ki}), \quad v \in V_h. \tag{4.5}$$

First, let us prove the equivalence relation

$$C_1 a_h(v,v) \leq \|v\|^2_{\Sigma,a_h} \leq C_2 a_h(v,v), \quad v \in V_h. \tag{4.6}$$

Using (3.4), (3.12), and (4.5), we obtain inequalities

$$C_1 \|v\|_{\Sigma,\Delta} \leq \|v\|_{\Sigma,a_h} \leq C_2 \|v\|_{\Sigma,\Delta}, \quad v \in V_h,$$

which, by Lemma 3.5, imply

$$C_1 \|v\|_{H^2(\Omega)} \leq \|v\|_{\Sigma,a_h} \leq C_2 \|v\|_{H^2(\Omega)}, \quad v \in V_h.$$

The last inequalities and Lemma 3.1 imply (4.6). We note that the second inequality in (4.6) is one of the key assumptions in the abstract theory of Schwarz methods (see Assumption 1 in section 5.2 of [36]).

Using (4.2), (4.1), the second inequality in (4.6), and (3.1), we obtain

$$a_h(T_A v, v) \geq C a_h(v,v) \geq C \|v\|^2_{H^2(\Omega)}, \quad v \in V_h$$

(see Theorem 1 in [17]). Therefore, operator T_A is positive definite. Operators T_i^k are self-adjoint since $a_h(\cdot,\cdot)$ is a symmetric bilinear form; hence, T_A is self-adjoint (see Lemma 2 in section 5.2 of [36]). Thus, operator T_A^{-1} is self-adjoint positive definite. It follows from (4.3), (2.7), and Lemma 1 in section 5.2 of [36] that

$$(B_A v, v)_h = a_h(T_A^{-1} v, v) = \|v\|^2_{\Sigma,a_h}, \quad v \in V_h.$$

The last relation, along with (4.6) and (2.7), gives (4.4). $\square$

Multiplicative preconditioner. Let

$$T_M = I_h - \left[\prod_{k=K}^{0} \prod_{i=1}^{N_k} \left(I_h - T_i^k\right) \right] \left[\prod_{k=0}^{K} \prod_{i=N_k}^{1} \left(I_h - T_i^k\right) \right], \tag{4.7}$$

where I_h is the identity operator on V_h.

THEOREM 4.2. *Assume that h is sufficiently small. Linear operator T_M is self-adjoint positive definite on V_h in the inner product $a_h(\cdot,\cdot)$. Linear operator*

$$B_M = L_h^* L_h T_M^{-1} \tag{4.8}$$

is self-adjoint positive definite on V_h in the inner product $(\cdot,\cdot)_h$, and

$$C_1(B_M v, v)_h \le (L_h^* L_h v, v)_h \le C_2(B_M v, v)_h, \quad v \in V_h. \tag{4.9}$$

Proof. Since operators $\{T_i^k\}$ are self-adjoint on V_h with respect to the inner product $a_h(\cdot,\cdot)$, it is easy to see that T_M is also a self-adjoint operator. Hence, B_M is self-adjoint in the inner product $(\cdot,\cdot)_h$. Inequalities in (4.9) follow from Lemma 4 in section 5.2 of [36] with $\omega = 1$, the second inequality in (4.6), and Lemma 6.1 in [40] formulated for $\{V_k\}$. □

Remark. Using the multigrid terminology, we note that the multiplicative preconditioner B_M corresponds to the V-cycle multigrid algorithm with the Gauss–Seidel smoother.

Iterative method. Since the operator of (2.6) is self-adjoint positive definite, we can use our multilevel preconditioners with the PCG algorithm to compute the OSC solution (see Algorithm 9.4.14 in [20]).

Let $\lambda_{\min,h}$ and $\lambda_{\max,h}$ be, respectively, the smallest and the largest eigenvalues of the preconditioned operator

$$\tilde{A}_h = M_h^{-1/2} L_h^* L_h M_h^{-1/2},$$

where M_h is a preconditioner. It is well known that the convergence rate of the PCG is bounded from above by

$$(\sqrt{\kappa_h} - 1)/(\sqrt{\kappa_h} + 1),$$

where $\kappa_h = \lambda_{\max,h}/\lambda_{\min,h}$ is the spectral condition number of $\tilde{A}_h$ (see Theorem 9.4.14 in [20]). It follows from Theorems 4.1 and 4.2 that

$$\kappa_h \le C_2/C_1 < \infty \ \text{ as } \ h \to \infty. \tag{4.10}$$

The estimate (4.10) implies that it takes $O(|\ln \epsilon|)$ iterations of the PCG algorithm with the multilevel OSC preconditioners to approximate the solution of (2.6) with tolerance ϵ; that is, the number of iterations is bounded by a constant independent of h and K.

5. OSC matrix-vector representation.

In this section, we introduce the matrix-vector representation of the OSC problem in the standard Hermite finite element basis and obtain recurrence relations for the computation of the OSC approximations and other required quantities.

Representation of Hermite piecewise cubic polynomials. Let V_k^1 denote a vector space of Hermite piecewise cubic polynomials vanishing at $t = 0$ and $t = 1$ and corresponding to the partition $\{t_i^k = i/2^k\}_{i=0}^{2^k}$ of the interval $[0,1]$. The dimension of V_k^1 is $M_k = 2^{k+1}$. Let

$$\Phi_k = \{s_0^k, v_1^k, s_1^k, \dots, v_{2^k-1}^k, s_{2^k-1}^k, s_{2^k}^k\} \equiv \{\phi_i\}_{i=1}^{M_k} \tag{5.1}$$

be the standard basis of V_k^1 consisting of nodal value and nodal slope basis functions $v_i(t)$ and $s_i(t)$, respectively, defined for $0 \le i \le 2^k$ by

$$\begin{aligned} &v_i^k(t_j^k) = \delta_{ij}, \quad (v_i^k)'(t_j^k) = 0, \quad 0 \le j \le 2^k, \\ &s_i^k(t_j^k) = 0, \quad (s_i^k)'(t_j^k) = h_k^{-1}\delta_{ij}, \quad 0 \le j \le 2^k, \end{aligned} \tag{5.2}$$

where δ_{ij} is the Kronecker delta. We note that the basis functions v_0^k and $v_{2^k}^k$ corresponding to the boundary points $t = 0$ and $t = 1$ are not included in Φ_k.

The value and the slope basis functions in Φ_k corresponding to an interior partition node are uniquely expressed as a linear combination of five basis functions in Φ_{k+1} as follows:

$$\begin{aligned} v_i^k &= \tfrac{1}{2}v_{2i-1}^{k+1} + \tfrac{3}{4}s_{2i-1}^{k+1} + v_{2i}^{k+1} + \tfrac{1}{2}v_{2i+1}^{k+1} - \tfrac{3}{4}s_{2i+1}^{k+1}, \\ s_i^k &= -\tfrac{1}{8}v_{2i-1}^{k+1} - \tfrac{1}{8}s_{2i-1}^{k+1} + \tfrac{1}{2}s_{2i}^{l+1} + \tfrac{1}{8}v_{2i+1}^{k+1} - \tfrac{1}{8}s_{2i+1}^{k+1}. \end{aligned} \tag{5.3}$$

Let

$$P = \begin{pmatrix} 4 & -1 \\ 6 & -1 \end{pmatrix}, \; Q = \begin{pmatrix} 8 & 0 \\ 0 & 4 \end{pmatrix}, \; \text{and } R = \begin{pmatrix} 4 & 1 \\ -6 & -1 \end{pmatrix} \tag{5.4}$$

be matrices corresponding to the representation (5.3). Let P_k^1 be a $2M_k \times M_k$ matrix obtained from

$$\frac{1}{8}\begin{pmatrix} Q & O & O & \dots & O \\ R & P & O & & \\ O & Q & O & & \\ O & R & P & & \\ \vdots & & & \ddots & \vdots \\ O & & & \dots & Q \end{pmatrix} \in R^{(2M_k+2)\times(M_k+2)}, \tag{5.5}$$

where O is the 2×2 zero matrix, by removing the first and next-to-last rows and columns. For $v \in V_k^1$, let $[v]_{\mathcal{H},k}$ denote the vector representation of v in the basis Φ_k. It follows from (5.3), (5.4), and (5.5) that

$$[v]_{\mathcal{H},k+1} = P_k^1[v]_{\mathcal{H},k}, \quad v \in V_k^1, \quad k \in \{0,1,2,\dots,K-1\}. \tag{5.6}$$

Representation of Hermite piecewise bicubic polynomials. We note that $V_k = V_k^1 \otimes V_k^1$, where the symbol $\otimes$ denotes a vector space tensor product. Set

$$\psi_{M_k(i-1)+j}^k(x) = \phi_i(x_1)\phi_j(x_2) \quad \text{for } 1 \le i,j \le M_k, \tag{5.7}$$

where basis functions ϕ_i, for $1 \le i \le M_k$, are defined by (5.1) and (5.2). The set $\Psi_k = \{\psi_j^k\}_{j=1}^{N_k}$, where $N_k = M_k^2 = 4^{k+1}$, is the standard basis for V_k in the standard ordering.

It follows from (5.3) and (5.7) that a basis function in Ψ_k corresponding to an interior partition node is uniquely expressed as a linear combination of 25 basis functions in Ψ_{k+1}. Let $[v]_{\mathcal{H},k}$ denote the vector representation of $v \in V_k$ in the basis Ψ_k, and let $[v]_{\mathcal{H}} = [v]_{\mathcal{H},K}$ for $v \in V_h$. It is obvious that

$$[\psi_j^k]_{\mathcal{H},k} = \vec{e}_j^{\,k}, \quad 1 \le j \le N_k, \tag{5.8}$$

where $\vec{e}_j^{\,k}$ is the jth standard basis vector in R^{N_k}.

We set

$$P_k = P_k^1 \otimes P_k^1 \in R^{2N_k \times N_k}, \tag{5.9}$$

where P_k^1 is the one-dimensional interpolation matrix in (5.6) and the symbol $\otimes$ now denotes the matrix tensor product. Matrix P_k corresponds to the piecewise bicubic Hermite interpolation in V_{k+1}, and we call P_k the interpolation matrix from level k to level $k+1$. It follows from (5.6), (5.7), and (5.9) that

$$[v]_{\mathcal{H},k+1} = P_k [v]_{\mathcal{H},k} \quad \text{for } \ 0 \le k \le K-1 \ \text{ and } \ v \in V_k. \tag{5.10}$$

Applying formula (5.10) recurrently, we obtain

$$[v]_{\mathcal{H}} = P_{K-1} \cdots P_k [v]_{\mathcal{H},k}, \quad v \in V_k. \tag{5.11}$$

In particular, replacing v in (5.11) by ψ_j^k and using (5.8), we get

$$[\psi_j^k]_{\mathcal{H}} = P_{K-1} \cdots P_k \vec{e}_j^{\,k}, \quad 1 \le j \le N_k. \tag{5.12}$$

Matrix-vector form of the OSC problem. Assume that the set of Gauss points $\mathcal{G}_h = \{\xi_i\}_{i=1}^N$ is ordered, and let

$$[v]_{\mathcal{G}} = [v(\xi_1), \dots, v(\xi_N)]^t$$

for any function v defined on $\mathcal{G}_h$. From (2.5), we have

$$(v, w)_h = (h^2/4)[w]_{\mathcal{G}}^t [v]_{\mathcal{G}}, \quad v, w \in V_h. \tag{5.13}$$

Let $[L_h]$ be the OSC matrix of size $N \times N$, corresponding to the differential operator L in (1.2), with entries $L\psi_j^K(\xi_i)$, where i is the row index. For a continuous function $g(x)$, let

$$D(g) = \operatorname{diag}\left(g(\xi_1), \dots, g(\xi_N)\right)$$

be a diagonal matrix. We note that

$$\begin{aligned}[L_h] = {} & D(a_{11})(\hat{A} \otimes \hat{B}) + 2D(a_{12})(\hat{C} \otimes \hat{C}) + D(a_{22})(\hat{B} \otimes \hat{A}) \\ & + D(b_1)(\hat{C} \otimes \hat{B}) + D(b_2)(\hat{B} \otimes \hat{C}) + D(c)(\hat{B} \otimes \hat{B}),\end{aligned}$$

and the matrices $\hat{A}$, $\hat{C}$, and $\hat{B}$ have the following almost block diagonal structure:

$$\begin{pmatrix} \tilde{W} & Z & O & O & \cdots & O & \tilde{O} \\ \tilde{O} & W & Z & O & & & \\ \tilde{O} & O & W & Z & & & \\ \vdots & \vdots & & & \ddots & \vdots & \vdots \\ \tilde{O} & O & & & \dots & W & \tilde{Z} \end{pmatrix} \in R^{M_K \times M_K},$$

where W, Z, O and $\tilde{W}$, $\tilde{Z}$, $\tilde{O}$ are, respectively, 2×2 and 2×1 blocks; O and $\tilde{O}$ are zero matrices. The (i,j) entries of matrices $\hat{A}$, $\hat{C}$, and $\hat{B}$ are $\phi_i''(\eta_j)$, $\phi_i'(\eta_j)$, and $\phi_i(\eta_j)$, respectively, where $\{\eta_j\}_{j=1}^{M_K}$ is the set of Gauss points in interval $[0,1]$ corresponding to partition π_h.

It is easy to see that

$$[L_h v]_{\mathcal{G}} = [L_h][v]_{\mathcal{H}}, \quad v \in V_h. \tag{5.14}$$

Using (2.7), (5.13), and (5.14), we obtain, for any v and w in V_h,

$$a_h(v,w) = (L_h v, L_h w)_h = (h^2/4)[L_h w]_{\mathcal{G}}^t [L_h v]_{\mathcal{G}} = (h^2/4)[w]_{\mathcal{H}}^t [L_h]^t [L_h][v]_{\mathcal{H}}. \tag{5.15}$$

Let $A_k = (a_{ij}^k)$ be an $N_k \times N_k$ matrix with entries

$$a_{ij}^k = (4/h^2) a_h(\psi_j^k, \psi_i^k), \tag{5.16}$$

and let $A = A_K$. From (5.16), using (5.15), we get

$$a_{ij}^k = [\psi_j^k]_{\mathcal{H}}^t [L_h]^t [L_h][\psi_i^k]_{\mathcal{H}}. \tag{5.17}$$

From (5.17) for $k = K$, using (5.8), we obtain

$$A = [L_h]^t [L_h]. \tag{5.18}$$

Similarly, using (5.13), (5.14), the relation $[f]_{\mathcal{G}} = [f_h]_{\mathcal{G}}$, and (5.8), we obtain

$$\begin{aligned}(4/h^2)(L_h^* f_h, \psi_i^K)_h &= (4/h^2)(f_h, L_h \psi_i^K)_h = [f_h]_{\mathcal{G}}^t [L_h \psi_i^K]_{\mathcal{G}} \\ &= [f]_{\mathcal{G}}^t [L_h][\psi_i^K]_{\mathcal{H}} = (\vec{e}_i^{\,K})^t [L_h]^t [f]_{\mathcal{G}}.\end{aligned}$$

Thus, the variational OSC equation (2.8) has the matrix-vector form

$$A\,[u_h]_{\mathcal{H}} = [L_h]^t [f]_{\mathcal{G}}. \tag{5.19}$$

6. Implementation.

In this section, we describe implementations of both the additive and the multiplicative OSC preconditioners.

Additive preconditioner. Let us describe the computation of $w = B_A^{-1} v$ for $v \in V_h$, where B_A is defined by (4.3). Let

$$w_k = \sum_{i=1}^{N_k} w_{ki}, \quad \text{where } \; w_{ki} = T_i^k (L_h^* L_h)^{-1} v. \tag{6.1}$$

Using (4.3), (4.2), and (6.1), we get

$$w = T_A (L_h^* L_h)^{-1} v = \left(\sum_{k,i} T_i^k \right) (L_h^* L_h)^{-1} v = \sum_{k,i} w_{ki} = \sum_k w_k. \tag{6.2}$$

Thus, to compute w, we need to compute and sum w_k for $k = 0, 1, \ldots, K$.

Using (4.1) and (2.7), we obtain, for $1 \le i \le N_k$,

$$a_h(w_{ki}, \psi_i^k) = a_h(T_i^k (L_h^* L_h)^{-1} v, \psi_i^k) = a_h((L_h^* L_h)^{-1} v, \psi_i^k) = (v, \psi_i^k)_h. \tag{6.3}$$

Let

$$w_{ki} = c_{ki} \psi_i^k, \quad c_{ki} \in R, \tag{6.4}$$

$$[v]_k = (4/h^2)[(v, \psi_1^k)_h, \ldots, (v, \psi_{N_k}^k)_h]^t \in R^{N_k}. \tag{6.5}$$

Substituting (6.4) into (6.3) and using (6.5) and (5.16), we rewrite (6.3) in the form

$$\operatorname{diag}(A_k)\vec{w}_k = [v]_k, \tag{6.6}$$

where $\vec{w}_k = (c_{k1}, \ldots, c_{kN_k})^t = [w_k]^t_{\mathcal{H},k}$ and $\operatorname{diag}(A_k) = \operatorname{diag}(a^k_{11}, \ldots, a^k_{N_kN_k})$.

Let $[I_h]$ be an $N \times N$ matrix with entries $\psi^K_j(\xi_i)$, where i is the row index. Matrix $[I_h]$ is nonsingular and maps $[v]_{\mathcal{H}}$ to $[v]_{\mathcal{G}}$, that is,

$$[v]_{\mathcal{G}} = [I_h]\,[v]_{\mathcal{H}}, \quad v \in V_h. \tag{6.7}$$

For $[v]_k$ defined by (6.5), let us show

$$[v]_K = [I_h]^t[v]_{\mathcal{G}}, \tag{6.8}$$

$$[v]_k = P^t_k[v]_{k+1} \quad \text{for} \quad k = K-1, K-2, \ldots, 0, \tag{6.9}$$

where the interpolation matrix P_k is defined by (5.9) and (5.5). Using (6.5), (5.13), and (6.7), we obtain

$$(\vec{e}^{\,k}_j)^t[v]_k = (4/h^2)(v, \psi^k_j)_h = [\psi^k_j]^t_{\mathcal{G}}[v]_{\mathcal{G}} = [\psi^k_j]^t_{\mathcal{H}}[I_h]^t[v]_{\mathcal{G}}, \quad 1 \le j \le N_k. \tag{6.10}$$

Relation (6.8) follows from (6.10) with $k = K$ and (5.8). Using (6.10), (5.12), and (6.8), we obtain

$$[v]_k = P^t_k \cdots P^t_{K-1}[v]_K,$$

which implies (6.9).

The multiplication by P^t_k is carried out using the representation

$$P^t_k = ((P^1_k)^t \otimes I_k)(I_k \otimes (P^1_k)^t),$$

where I_k is the identity matrix of size $M_k \times M_k$. Matrices $\{A_k\}$ can be precomputed using the recurrence formula

$$A_k = P^t_k A_{k+1} P_k \quad \text{for} \quad k = K-1, K-2, \ldots, 0, \tag{6.11}$$

which follows from (5.17), (5.12), and (5.18). Finally, to compute $w = \sum_k w_k$, that is, $[w]_{\mathcal{H}}$, we implement

$$\vec{w}_{k+1} \leftarrow \vec{w}_{k+1} + P_k\vec{w}_k, \quad k = 0, 1, \ldots, K-1.$$

The additive preconditioning algorithm is presented in Figure 6.1. It is easy to see that the computational cost of the additive algorithm is $O(h^{-2}) = O(4^K)$.

Multiplicative preconditioner. We now consider the computation of $w = B^{-1}_M v$ for $v \in V_h$, where B_M is defined in (4.8). Let

$$u = (L^*_h L_h)^{-1}v. \tag{6.12}$$

Using (4.8) and (6.12), we get

$$w = B^{-1}_M v = T_M(L^*_h L_h)^{-1}v = T_M u,$$

which, by (4.7), implies

$$u - w = \left[\prod_{k=K}^{0}\prod_{i=1}^{N_k}(I_h - T^k_i)\right]\left[\prod_{k=0}^{K}\prod_{i=N_k}^{1}(I_h - T^k_i)\right]u. \tag{6.13}$$

```
input: $K$, $[v]_K$, $\{\mathrm{diag}(A_k)\}_{k=0}^K$
output: $[w]_{\mathcal{H}}$
$\vec{v}_K \leftarrow [v]_K$
for $k = K, K-1, \ldots, 0$
    if $(k < K)$ $\vec{v}_k = P_k^t \vec{v}_{k+1}$ end
    solve $\mathrm{diag}(A_k)\vec{w}_k = \vec{v}_k$
end
for $k = 0, 1, \ldots, K-1$
    $\vec{w}_{k+1} \leftarrow \vec{w}_{k+1} + P_k \vec{w}_k$
end
$[w]_{\mathcal{H}} \leftarrow \vec{w}_K$
```

FIG. 6.1. *Additive preconditioning algorithm.*

Let S be an ordered set of pairs (k, i) with the ordering corresponding to that of factors in (6.13) from right to left. Setting $y = u - w$, we see that $u - w$ can be computed by

$$y \leftarrow u; \;\; y \leftarrow (I_h - T_i^k)y \;\text{ for }\; (k, i) \in S,$$

which is equivalent to

$$w \leftarrow 0; \;\; w \leftarrow w + T_i^k(u - w) \;\text{ for }\; (k, i) \in S. \tag{6.14}$$

Let us develop an efficient implementation of the algorithm in (6.14). Using (4.1), (2.7), and (6.12), we obtain

$$a_h(T_i^k(u - w), \psi_i^k) = a_h(u - w, \psi_i^k) = (v, \psi_i^k)_h - a_h(w, \psi_i^k), \quad \psi_i^k \in V_{ki}. \tag{6.15}$$

Substituting $T_i^k(u - w) = c_{ki}\psi_i^k$ into (6.15) and (6.14), we get

$$c_{ki} = g_i^k(w)/a_{ii}^k, \tag{6.16}$$

$$w \leftarrow w + c_{ki}\psi_i^k, \tag{6.17}$$

where a_{ii}^k is as defined in (5.16), and

$$g_{ki}(w) = (4/h^2)\left[(v, \psi_i^k)_h - a_h(w, \psi_i^k)\right], \quad 1 \le i \le N_k. \tag{6.18}$$

Let $\vec{g}_k(w) = (g_{k1}(w), \ldots, g_{kN_k}(w))^t$. We note that, each time the value of w is changed by (6.17), all entries of vector $\vec{g}^k(w)$ should be updated by (6.18), and such computation requires a matrix-vector product. It is more efficient to use a recurrent assignment

$$\vec{g}_k(w) \leftarrow \vec{g}_k(w) - c_{ki}(a_{1i}^k, \ldots, a_{N_k,i}^k)^t, \tag{6.19}$$

which is obtained by multiplying (6.17) by ψ_j^k in the $a_h(\cdot,\cdot)$ inner product and subtracting $(v, \psi_j^k)_h$ from both sides of the resulting assignment.

For $k = K-1, K-2, \ldots, 0$, let w_k be the value of w after implementing

$$w \leftarrow w + T_i^l(u - w), \quad i = 1, \ldots, N_l, \;\; l = K, K-1, \ldots, k+1,$$

```
input: $K$, $[v]_K$, $\{A_k\}_{k=0}^K$
output: $[w]_{\mathcal{H}}$
$\vec{g}_K \leftarrow [v]_K$
for $k = K, \dots, 0$
    solve $L_k \vec{w}_k = \vec{g}_k$
    if $(k > 0)$ $\vec{g}_{k-1} \leftarrow P_{k-1}^t(\vec{g}_k - A_k \vec{w}_k)$ end
end
for $k = 0, \dots, K$
    if $(k > 0)$ $\vec{w}_k \leftarrow \vec{w}_k + P_{k-1} \vec{w}_{k-1}$ end
    solve $L_k^t \vec{w} = \vec{g}_k - A_k \vec{w}_k$
    $\vec{w}_k \leftarrow \vec{w}_k + \vec{w}$
end
$[w]_{\mathcal{H}} \leftarrow \vec{w}_K$
```

FIG. 6.2. *Multiplicative preconditioning algorithm.*

and let

$$\vec{g}_k = \vec{g}_k(w_k). \tag{6.20}$$

We note that (6.16) followed by (6.19) for $i = 1, \dots, N_k$ is the column-oriented algorithm of solving a lower triangular linear system $L_k \vec{w}_k = \vec{g}_k$, where matrix L_k contains the lower triangular part of A_k and $\vec{w}_k = (c_{k1}, \dots, c_{k,N_k})^t$.

Let us show that vectors $\{\vec{g}_k\}$ can be computed by the recurrence formula

$$\vec{g}_{k-1} = P_{k-1}^t\,(\vec{g}_k - A_k \vec{w}_k). \tag{6.21}$$

Using (6.19), the definition of w_{k-1}, and (6.20), we obtain

$$\vec{g}_k(w_{k-1}) = \vec{g}_k - A_k \vec{w}_k. \tag{6.22}$$

Applying (6.18), (6.5), (5.15), (5.12), we get

$$\vec{g}_k(w) = [v]_k - P_k^t \cdots P_{K-1}^t [L_h]^t [L_h][w]_{\mathcal{H}}. \tag{6.23}$$

From (6.23) with k replaced by $k-1$ and (6.9), we have

$$\vec{g}_{k-1}(w) = P_{k-1}^t \left([v]_k - P_k^t \cdots P_{K-1}^t [L_h]^t [L_h][w]_{\mathcal{H}}\right) = P_{k-1}^t \vec{g}_k(w),$$

which, by (6.22), implies (6.21).

In the ascend phase, for $k = 0, \dots, K$, an upper triangular linear system with the matrix L_k^t is solved. The algorithm implementing the multiplicative preconditioning is given in Figure 6.2. It is easy to see that the cost of the multiplicative algorithm is $O(h^{-2}) = O(4^K)$.

7. Numerical results. In this section, we present numerical results for solving test problems by the PCG method with the multilevel OSC preconditioners developed in this work. For a chosen exact solution $u(x)$ of BVP (1.1), we set $f = Lu$. PCG iterations are stopped when the relative residual norm, that is, the ratio of the 2-norm of the residual of (5.19) to the 2-norm of the right-hand side, becomes less than tolerance ϵ.

Table 7.1

Comparison of multilevel preconditioners to solve the normal and the original OSC equations by PCG ($L = \Delta$, $\epsilon = 10^{-12}$).

	Normal OSC equation				Original OSC equation			
	Additive		Multiplicative		Additive		Multiplicative	
h	κ_h	Iter.	κ_h	Iter.	κ_h	Iter.	κ_h	Iter.
1/16	4.490	26	1.434	12	7.551	30	1.169	9
1/32	5.016	29	1.476	13	7.794	30	1.167	9
1/64	5.488	32	1.501	13	7.908	30	1.165	9
1/128	5.845	34	1.516	14	7.962	29	1.164	9
1/256	6.162	35	1.525	14	7.991	28	1.162	9

The spectral condition number κ_h of the preconditioned OSC operator satisfies (4.10), that is, $\kappa_h < C_2/C_1$ as $h \to 0$. To demonstrate this fact numerically, we compute quantities that approximate κ_h on a sequence of nested partitions using the PCG iteration parameters and present these approximations in the following tables under κ_h. Under "Iter.", we report the numbers of iterations to reduce the relative residual norm within the specified tolerance.

In the first set of experiments, we compare our preconditioners with those proposed in [9], where both additive and multiplicative multilevel preconditioners were developed to solve the original OSC equation (2.3) for a self-adjoint L. As in [9], we take $L = \Delta$, the Laplacian, and

$$u(x) = 10x_1^2(1 - x_1)x_2^2(1 - x_2).$$

Since $u(x)$ is a bicubic polynomial, it is also the solution of the OSC problem; hence, the discretization error is zero. The numerical results are presented in Table 7.1, and they indicate that, for $L = \Delta$, PCG with multilevel preconditioners for the original OSC equation is slightly more efficient than that for the normal OSC equation. For smaller values of h, the approximations to κ_h and the numbers of iterations are relatively small and change insignificantly.

In the next set of experiments, we solve the same problems as in [1], where the PCG algorithm was tested with a direct solver preconditioner. The operator L in (1.2) is taken with the coefficients

$$\begin{aligned} &a_{11}(x) = e^{x_1x_2}, && b_1(x) = x_2e^{x_1x_2} + \beta_1 \cos[\pi(x_1 + x_2)], \\ &a_{12}(x) = \alpha/(1 + x_1 + x_2), && b_2(x) = -x_1e^{-x_1x_2} + \beta_2 \sin(2\pi x_1x_2), \\ &a_{22}(x) = e^{-x_1x_2}, && c(x) = \gamma[1 + 1/(1 + x_1 + x_2)], \end{aligned} \tag{7.1}$$

where α, β_1, β_2, and γ are parameters, and the exact solution of BVP (1.1) is set to

$$u(x) = e^{x_1+x_2}x_1x_2(1 - x_1)(1 - x_2).$$

Using the PCG with the multiplicative preconditioner, we solve the following four test problems corresponding to the differential operator L, which is defined in each problem:

P1 – self-adjoint negative definite, $\alpha = \beta_1 = \beta_2 = \gamma = 0$.

P2 – self-adjoint indefinite, $\alpha = \beta_1 = \beta_2 = 0$ and $\gamma = 100$.

P3 – non–self-adjoint indefinite, $\beta_2 = 100$ and $\alpha = \beta_1 = \gamma = 0$.

P4 – non–self-adjoint indefinite, $\alpha = 0.5$, $\beta_1 = 10$, $\beta_2 = \gamma = 50$.

Table 7.2

Approximations to the spectral condition number κ_h and PCG iteration numbers for the variable coefficient L ($\epsilon = 10^{-10}$). Top part: multilevel preconditioner. Bottom part: additive preconditioner.

	P1		P2		P3		P4	
h	κ_h	Iter.	κ_h	Iter.	κ_h	Iter.	κ_h	Iter.
1/16	2.570	15 (26)	363.0	68 (46)	624.5	43 (34)	516.1	51 (68)
1/32	3.646	17 (30)	363.2	70 (51)	499.8	42 (38)	457.8	61 (75)
1/64	4.922	20 (33)	361.6	71 (54)	459.3	46 (40)	402.9	56 (81)
1/128	6.189	23 (34)	361.5	72 (55)	398.6	52 (42)	382.0	58 (84)
1/256	7.253	25	360.3	73	376.0	54	377.8	59

1/32	50.9	58	5802.3	117	7396.7	79	5999.5	83
1/64	75.6	70	5801.5	128	6562.9	98	5131.5	104
1/128	99.9	81	5803.4	140	5414.9	122	5008.0	121
1/256	117.6	89	5805.2	147	5025.1	139	5213.8	137

In the top part of Table 7.2, we report results with the multiplicative preconditioner, and, in parentheses, we reproduce results reported in [1].

For all four problems, the numbers of iterations increase slowly with decreasing h. It takes the least number of iterations to solve the self-adjoint negative definite problem P1, and the most number of iterations to solve P2, the "most indefinite" problem of P1–P4. For P1, approximations to the spectral ratio κ_h are much smaller than those for P2–P4, where the approximations to κ_h are about the same for smaller values of h. It is interesting to note that κ_h monotonically increases for P1 and decreases for P2–P4 as h decreases. We observe that the approximations to κ_h for P2–P4 are significantly larger than those for P1. The numbers of iterations for P1 and P4 favor the multilevel multiplicative preconditioner rather than the direct solver preconditioner developed in [1], although the preconditioner in [1] produces smaller numbers of iterations for P2 and P3.

Results for the additive preconditioner are presented in the bottom part of Table 7.2, and they suggest that, for the tested problems, the additive preconditioner is less efficient, in terms of numbers of iterations, than the multiplicative preconditioner. The approximations of κ_h computed with the additive preconditioner are approximately 15 times larger than those computed with the multiplicative preconditioner, and the indicated difference is reflected by a larger number of iterations for the additive preconditioner. This result is intuitively expected based on known properties of Jacobi and Gauss–Seidel smoothers for finite difference operators.

In Figure 7.1, we display plots of residual curves for $h = 1/256$. We observe monotone convergence only for the self-adjoint negative definite problem P1; for P2–P4, the residual curves are plotted relatively close to each other.

In the last set of experiments, we solve the Helmholtz equation $\Delta u + k^2 u = f$ for several values of k^2. Numerical results were obtained using the multiplicative preconditioner, and they are presented in Table 7.3. We see that the approximations to κ_h change insignificantly when h is decreased for all taken values of k^2. For $k^2 = 1000$, the approximations to k_h are very large; however, for $k^2 = 1400$ they are the smallest. The approximations to k_h are large because of small values of the smallest eigenvalue $\lambda_{\min,h}$ of the preconditioned operator. In Figure 7.2, we plot the eigenvalues of the OSC matrix $[L_h]$ with $h = 1/32$ ($N = 4,096$) for the Helmholtz equation with $k^2 = 1400$. We note that the eigenvalues are widely spread over the complex plane.

ADAPTIVE MULTIVARIATE APPROXIMATION USING BINARY SPACE PARTITIONS AND GEOMETRIC WAVELETS[*]

S. DEKEL[†] AND D. LEVIATAN[‡]

Abstract. The binary space partition (BSP) technique is a simple and efficient method to adaptively partition an initial given domain to match the geometry of a given input function. As such, the BSP technique has been widely used by practitioners, but up until now no rigorous mathematical justification for it has been offered. Here we attempt to put the technique on sound mathematical foundations, and we offer an enhancement of the BSP algorithm in the spirit of what we are going to call *geometric wavelets*. This new approach to sparse geometric representation is based on recent developments in the theory of multivariate nonlinear piecewise polynomial approximation. We provide numerical examples of n-term geometric wavelet approximations of known test images and compare them with dyadic wavelet approximation. We also discuss applications to image denoising and compression.

Key words. binary space partitions, geometric wavelets, piecewise polynomial approximation, nonlinear approximation, adaptive multivariate approximation

1. Introduction.

The binary space partition (BSP) technique is widely used in image processing and computer graphics [15, 17, 19], and can be described as follows. Given an initial convex domain in $\mathbb{R}^d$, such as $[0,1]^d$, and a function $f \in L_p([0,1]^d)$, $0 < p < \infty$, one subdivides the initial domain into two subdomains by intersecting it with a hyperplane. The subdivision is performed so that a given cost function is minimized. This subdivision process then proceeds recursively on the subdomains until some exit criterion is met. To be specific, we describe the algorithm of [17], which is a BSP algorithm, for the purpose of finding a compact geometric description of the target function, in this case a digital image ($d = 2$).

In [17], at each stage of the BSP process, for a given convex polytope Ω, the algorithm finds two subdomains Ω', Ω'' and two bivariate (linear) polynomials $Q_{\Omega'}$, $Q_{\Omega''}$ that minimize the quantity

$$\|f - Q_{\Omega'}\|^p_{L_p(\Omega')} + \|f - Q_{\Omega''}\|^p_{L_p(\Omega'')}$$

over all pairs Ω', Ω'' of polyhedral domains that are the result of a binary space partition of Ω. The polynomials $Q_{\Omega'}$, $Q_{\Omega''}$ are found using the least-squares technique with $p = 2$. The goal in [17] is to encode a *cut* of the BSP tree, i.e., a sparse piecewise polynomial approximation of the original digital image based on a union of disjoint polytopes from the BSP tree. Also, to meet a given bit target, rate-distortion optimization strategies are used (see also [21]).

Inspired by recent progress in multivariate piecewise polynomial approximation, made by Karaivanov, Petrushev, and collaborators [13, 14], we propose a modification to the above method which can be described as a *geometric wavelets* approach. Let

Ω' be a *child* of Ω in a BSP tree; i.e., $\Omega' \subset \Omega$ and Ω' has been created by a BSP partition of Ω. We use the polynomial approximations Q_Ω, $Q_{\Omega'}$ that were found for these domains by the local optimization algorithm above and define

$$\psi_{\Omega'} := \psi_{\Omega'}(f) := \mathbf{1}_{\Omega'}(Q_{\Omega'} - Q_\Omega) \tag{1.1}$$

as the geometric wavelet associated with the subdomain Ω' and the function f. A reader familiar with wavelets (see, e.g., [3, 7]) will notice that $\psi_{\Omega'}$ is a "local difference" component that belongs to the detail space between two levels in the BSP tree, a "low resolution" level associated with Ω and a "high resolution" level associated with Ω'. Also, these wavelets have what may be regarded as the "zero moments" property; i.e., if f is locally a polynomial over Ω, then we get $Q_{\Omega'} = Q_\Omega = f$ and $\psi_{\Omega'} = 0$. However, the BSP method is highly nonlinear; both the partition and the geometric wavelets are so dependent on the function f that one cannot expect some of the familiar properties of wavelets like a two-scale relation, a partition of unity, or spanning of some a priori given spaces.

Our modified BSP algorithm proceeds as follows. We apply the BSP algorithm and create a "full" BSP tree $\mathcal{P}$. Obviously, in applications, the subdivision process is terminated when the leaves of the tree are subdomains of sufficiently small volume, or equivalently, in image processing, when the subdomains contain only a few pixels. We shall see that under certain mild conditions on the partition $\mathcal{P}$ and the function f we have

$$f = \sum_{\Omega \in \mathcal{P}} \psi_\Omega(f) \quad \text{a.e. in } [0,1]^d,$$

where

$$\psi_{[0,1]^d} := \psi_{[0,1]^d}(f) := \mathbf{1}_{[0,1]^d} Q_{[0,1]^d}.$$

We then compute all the geometric wavelets (1.1) and sort them according to their L_p norms, i.e.,

$$\|\psi_{\Omega_{k_1}}\|_p \geq \|\psi_{\Omega_{k_2}}\|_p \geq \|\psi_{\Omega_{k_3}}\|_p \cdots . \tag{1.2}$$

Given an integer $n \in \mathbb{N}$, we approximate f by the n-term geometric wavelet sum

$$\sum_{j=1}^{n} \psi_{\Omega_{k_j}}. \tag{1.3}$$

The sum (1.3) is, in some sense, a generalization of the classical n-term wavelet approximation (see [7] and references therein), where the wavelets are constructed over dyadic cubes.

A key observation is that the BSP algorithm described above is a *geometric greedy* algorithm. At each stage of the algorithm we try to find a locally optimal partition of a given subdomain. Indeed, the problem of finding an optimal triangulation or partition is associated with an NP-hard problem (see the discussion in [6, section 4] and references therein).

It is known in classical wavelet theory (see, e.g., [7]) that the energy of the wavelet basis coefficients in some l_τ-norm, $0 < \tau < p$, is a valid gauge for the "sparseness" of the wavelet representation of the given function. We follow this idea, extending it to our geometric wavelet setup. Thus we take as a reasonable benchmark by which to measure the efficiency of the greedy algorithm, a BSP partition that "almost" minimizes, over all possible partitions, the sum of energies of the geometric wavelets of a given function, namely,

$$\left(\sum_{\Omega\in\mathcal{P}}\|\psi_\Omega\|_p^\tau\right)^{1/\tau}, \tag{1.4}$$

for some $0<\tau<p$.

We note the following geometric suboptimality of the BSP algorithm (see [12, 25] and references therein). We say that a BSP for n disjoint objects in a given convex domain is a recursive dissection of the domain into convex regions such that each object (or part of an object) is in a distinct region. Ideally, every object should be in one convex region, but sometimes it is inevitable that some of the objects are dissected. The size of the BSP is defined as the number of leaves in the resulting BSP tree.

It can be shown that for a collection of n disjoint line segments in the plane, there exists a BSP of complexity $O(n\log n)$. Recently, Tóth [24] showed a lower bound of $\Omega(n\log n/\log\log n)$, meaning that for $d=2$, in the worst case, the BSP algorithm might need slightly more elements to "capture" arbitrary linear geometry. In higher dimensions, the performance of the BSP in the worst case decreases. For example, the known lower bound for the BSP of a collection of n disjoint rectangles in $\mathbb{R}^3$ is $\Omega(n^2)$.

The paper is organized as follows. In section 2, we outline the algorithmic aspects of the geometric wavelet approach so that the reader who is less interested in the rigorous mathematics may skip section 3 and proceed directly to section 4. In section 3, we review the more theoretical aspects of our approach, and we provide some details on the approximation spaces that are associated with the method. It is interesting to note that, while the approximation spaces corresponding to nonlinear n-term wavelet approximation are linear Besov spaces (see [7] for details), the adaptive nature of the geometric wavelets implies that the corresponding approximation spaces are nonlinear. Nevertheless, it turns out that the problem at hand is "tamed" enough so as to enable the application of the classical machinery of the Jackson and Bernstein inequalities (see, e.g., [7]). Specifically, the analysis can be carried out because we are adaptively selecting one nested fixed partition for a given function, from which we select n-term geometric wavelets for any n. (In contrast, general adaptive piecewise polynomial n-term approximation [6] allows for each n, the selection of any n pieces, with no assumptions that they are taken from a fixed partition.) We conclude the paper with section 4, where we provide some numerical examples of n-term geometric wavelet approximation of digital images and discussion of possible applications in image denoising and compression.

2. Adaptive BSP partitions and the geometric wavelet approximation algorithm. Let $\Pi_{r-1}:=\Pi_{r-1}(\mathbb{R}^d)$ denote the multivariate polynomials of total degree $r-1$ (order r) in d variables. Given a bounded domain $\Omega\subset\mathbb{R}^d$, we denote the *degree (error) of polynomial approximation* of a function $f\in L_p(\Omega)$, $0<p\le\infty$, by

$$E_{r-1}(f,\Omega)_p:=\inf_{P\in\Pi_{r-1}}\|f-P\|_{L_p(\Omega)}.$$

Recall that the greedy BSP algorithm consists of finding, at each step, an optimal dissection of some domain Ω, and computing the polynomials $Q_{\Omega'}$ and $Q_{\Omega''}$ that best approximate the target function f in the p-norm over the children $\Omega', \Omega'' \subset \Omega$. In practice, we will have a suboptimal dissection, and *near-best* approximation. Thus, we are going to assume that for each $\Omega \in \mathcal{P}$, Q_Ω is a near-best approximation, i.e.,

$$\|f - Q_\Omega\|_{L_p(\Omega)} \le CE_{r-1}(f, \Omega)_p, \tag{2.1}$$

where C is independent of f and Ω but may depend on parameters like d, r, and possibly p. We shall see in section 3 that for the purpose of analysis when $p \le 1$, we need the stronger assumption that Q_Ω is a (possibly not unique) best approximation.

Let $\mathcal{P}$ be a partition of $[0,1]^d$, and let Ω' be a child of $\Omega \in \mathcal{P}$. For $f \in L_p([0,1]^d)$, $0 < p < \infty$, we set $\psi_{\Omega'}$ as in (1.1). As noted in the introduction, the function $\psi_{\Omega'}$ in (1.1) may be regarded as a local wavelet component of the function f that corresponds to the partition $\mathcal{P}$. For $0 < \tau \le p$ we denote the τ-energy of the sequence of geometric wavelets by the l_τ-norm of its L_p-norms,

$$\mathcal{N}_\tau(f, \mathcal{P}) := \left(\sum_{\Omega \in \mathcal{P}} \|\psi_\Omega\|_p^\tau \right)^{1/\tau}. \tag{2.2}$$

We will show that, under some mild conditions, the geometric wavelet expansion converges to the function. Namely, we introduce a weak constraint on the BSP partitions, which allows the analysis below to be carried out (see, for example, the proof of Theorem 3.5 below). We say that $\mathcal{P}$ is in $BSP(\rho)$, $3/4 < \rho < 1$, if for any child Ω' of Ω we have

$$|\Omega'| \le \rho |\Omega|, \tag{2.3}$$

where $|V|$ denotes the volume of a bounded set $V \subset \mathbb{R}^d$.

THEOREM 2.1. *Assume that* $\mathcal{N}_\tau(f, \mathcal{P}) < \infty$*, for some* $f \in L_p([0,1]^d)$, $0 < p < \infty$, $0 < \tau < p$*, and* $\mathcal{P} \in \mathrm{BSP}(\rho)$*. Then*

1. $f = \sum_\Omega \psi_\Omega$*, absolutely, a.e. in* $[0,1]^d$,
2. $\|f\|_p \le C(d, r, p, \tau, \rho) \mathcal{N}_\tau(f, \mathcal{P})$.

Proof. The proof is almost identical to the proof of [13, Theorem 2.17], except that here we take $\eta = p$, and we replace [13, Lemma 2.7] by Lemma 2.4 below. □

Thus, it is expedient to look for partitions (and τ) that yield finite energy or, better still, that minimize the energy. Obviously, this is not always possible or it may be too costly, and we are willing to settle for somewhat less. To this end, we define the following.

DEFINITION 2.2. *For* $f \in L_p([0,1]^d)$ *and* $0 < \tau < p < \infty$*, we say that* $\mathcal{P}_\tau(f) \in \mathrm{BSP}(\rho)$ *is a* near-best partition *if*

$$\mathcal{N}_\tau(f, \mathcal{P}_\tau(f)) \le C \inf_{\mathcal{P} \in \mathrm{BSP}(\rho)} \mathcal{N}_\tau(f, \mathcal{P}). \tag{2.4}$$

Let $\mathcal{P}_D$ be the BSP partition that gives the classical subdivision of $[0,1]^d$ into dyadic cubes. This can be done, for example, in the case $d = 2$ by partitioning $[0,1]^2$ along the line $x_1 = 1/2$ and then partitioning the two resulting rectangles along the line $x_2 = 1/2$. We get four dyadic cubes, and we proceed on each one recursively in the same manner. In section 3 we show the following relationship between $\mathcal{N}_\tau(f, \mathcal{P}_\tau(f))$ and the Besov seminorm of f (compare with the classical dyadic wavelet-type characterization of Besov spaces [10] and, in particular, the quantities $N_3(f)$ and $N_4(f)$ therein).

We will show that for $f \in L_p([0,1]^d)$, $0 < p < \infty$, $\alpha > 0$, and $1/\tau = \alpha + 1/p$, we have

$$\mathcal{N}_\tau(f, \mathcal{P}_\tau(f)) \le C\mathcal{N}_\tau(f, \mathcal{P}_D) \approx |f|_{B^{d\alpha,r}_\tau}, \tag{2.5}$$

where $B^{\gamma,r}_\tau$, $\gamma > 0$, is the classical Besov space (see Definition 3.1 below). The proof follows from the discussion beyond (3.6), and especially from (3.16).

We note that (2.2) was already defined in [16] for the special case of partitions over dyadic boxes. Also in [16], the author gives an algorithm to find the best dyadic box partition (see also [11]), thereby providing a complete solution to a restricted version of (2.4).

For $1 < p < \infty$, a more subtle but sharper definition of $\mathcal{P}_\tau(f)$ would be to define it as an "almost" minimizer of the weak ℓ_τ-norm of its corresponding geometric wavelets instead of the ℓ_τ-norm (2.2). Recall that the weak ℓ_τ-norm of a sequence $\{a_k\}$ is defined by

$$\|\{a_k\}\|_{w\ell_\tau} := \inf\{M : \#\{k : |a_k| > M\varepsilon^{1/\tau}\} \le \varepsilon^{-1}\ \forall \varepsilon > 0\}$$

and satisfies $\|\{a_k\}\|_{w\ell_\tau} \le \|\{a_k\}\|_{\ell_\tau}$. This corresponds to a well-known fact that n-term wavelet approximation can be estimated using the weaker p-norm when $1 < p < \infty$ (see [13, Theorem 3.3] for details, and see [7, Theorem 7.2.5] for the case of classic dyadic wavelets).

As we shall see, $\mathcal{N}_\tau(f, \mathcal{P})$ may serve as a "quality gauge" for partitions, when τ takes certain values strictly smaller than p. The following example demonstrates the role of τ.

Example 2.3. Let $\widetilde{\Omega} \subset [0,1]^d$ be a convex polytope, and define $f(x) := \mathbf{1}_{\widetilde{\Omega}}(x)$. Assume $\mathcal{P}$ is a partition such that for each $\Omega \in \mathcal{P}$ either $\widetilde{\Omega} \subseteq \Omega$, $\Omega \subseteq \widetilde{\Omega}$, or $\operatorname{int}(\Omega \cap \widetilde{\Omega}) = \emptyset$, where $\operatorname{int}(E)$ denotes the interior of $E \subset \mathbb{R}^d$. Then for $p = 2$ and $r = 1$ it is easy to see that

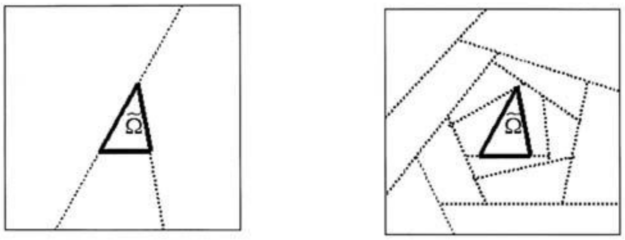
$$Q_\Omega = \begin{cases} \dfrac{|\widetilde{\Omega}|}{|\Omega|}, & \widetilde{\Omega} \subseteq \Omega, \\ 0, & \operatorname{int}(\Omega \cap \widetilde{\Omega}) = \emptyset. \end{cases}$$

Therefore we have $\psi_{[0,1]^d} = |\widetilde{\Omega}|\mathbf{1}_{[0,1]^d}$ and, for $\Omega, \Omega' \in \mathcal{P}$ with Ω' a child of Ω,

$$\|\psi_{\Omega'}\|_2^\tau = \|Q_{\Omega'} - Q_\Omega\|_{L_2(\Omega')}^\tau = \begin{cases} |\widetilde{\Omega}|^\tau \left(\dfrac{1}{|\Omega'|} - \dfrac{1}{|\Omega|}\right)^\tau |\Omega'|^{\tau/2}, & \widetilde{\Omega} \subseteq \Omega', \\ |\widetilde{\Omega}|^\tau \dfrac{1}{|\Omega|^\tau} |\Omega'|^{\tau/2}, & \operatorname{int}(\widetilde{\Omega}) \subset \Omega \setminus \Omega', \\ 0, & \operatorname{int}(\Omega \cap \widetilde{\Omega}) = \emptyset \text{ or } \Omega \subseteq \widetilde{\Omega}. \end{cases}$$

Thus, the energy of the geometric wavelets is given by the formal sum

$$\begin{aligned} \mathcal{N}_\tau^\tau(f, \mathcal{P}) &= \sum_{\Omega \in \mathcal{P}} \|\psi_\Omega\|_2^\tau \\ &= |\widetilde{\Omega}|^\tau \left(1 + \sum_{\substack{\widetilde{\Omega} \subseteq \Omega' \\ \Omega' \text{ child of } \Omega}} \left(\frac{1}{|\Omega'|} - \frac{1}{|\Omega|}\right)^\tau |\Omega'|^{\tau/2} + \frac{1}{|\Omega|^\tau}(|\Omega| - |\Omega'|)^{\tau/2}\right). \end{aligned} \tag{2.6}$$



$\mathcal{P}^{(1)}$: "Good" BSP

$\mathcal{P}^{(2)}$: "Bad" BSP

FIG. 1. *Two BSPs with* $\mathcal{N}_2(f,\mathcal{P}^{(1)}) = \mathcal{N}_2(f,\mathcal{P}^{(2)}) = \|f\|_2$.

The above sum converges, for example, if $\mathcal{P}$ is in BSP(ρ), for some $\rho < 1$. In the special case $\tau = 2$ we get

$$\begin{aligned}\mathcal{N}_2^2(f,\mathcal{P}) &= |\widetilde{\Omega}|^2\left(1 + \sum_{\substack{\widetilde{\Omega}\subseteq\Omega' \\ \Omega' \text{ child of } \Omega}} \left(\frac{1}{|\Omega'|} - \frac{1}{|\Omega|}\right)^2 |\Omega'| + \frac{1}{|\Omega|^2}(|\Omega| - |\Omega'|)\right)\\ &= |\widetilde{\Omega}|^2\left(1 + \sum_{\substack{\widetilde{\Omega}\subseteq\Omega' \\ \Omega' \text{ child of } \Omega}} \left(\frac{1}{|\Omega'|} - \frac{1}{|\Omega|}\right)\right)\\ &= |\widetilde{\Omega}|,\end{aligned}$$

which implies that $\mathcal{N}_2(f,\mathcal{P}) = \|f\|_2$. Since this equality holds for any partition that satisfies the above conditions, it follows that $\mathcal{N}_2(f,\mathcal{P})$ is not a good sparsity gauge for adaptive partitions when $p = 2$.

Referring to Figure 1, we see that the partition $\mathcal{P}^{(1)}$ is optimal since its BSP lines coincide with the hyperplanes that describe $\partial\widetilde{\Omega}$, while $\mathcal{P}^{(2)}$ contains "unnecessary" subdomains. Nevertheless, the equality $\mathcal{N}_2(f,\mathcal{P}^{(1)}) = \mathcal{N}_2(f,\mathcal{P}^{(2)}) = \|f\|_2$ holds. However, things change dramatically when we choose a sufficiently small τ. In this case, the ℓ_τ-norm serves almost as a counting measure, and since the sum (2.6) contains significantly fewer nonzero elements in the case of $\mathcal{P}^{(1)}$, we obtain that $\mathcal{N}_\tau(f,\mathcal{P}^{(1)})$ is much smaller than $\mathcal{N}_\tau(f,\mathcal{P}^{(2)})$.

Thus, we wish to address the issue of the expected range of the parameter τ for digital images and $p = 2$. If the image contains a curve singularity that is not a straight line, then the theory of section 3 below suggests that we should take $\tau \geq 2/5$. Since, in a way, dyadic wavelets are a special case of geometric wavelets, we can obtain an upper bound estimate on τ using the ideas of [8]. One needs to compute the discrete dyadic wavelet transform of the image and then compute the rate of convergence of the n-term wavelet approximation, by fitting the error function with the exponent $e(f,n) := C(f)n^{-\alpha(f)}$. Since we expect geometric wavelets to perform at least at the rate of dyadic wavelets, we should take $\tau \leq 2/(2\alpha(f)+1)$.

Going back to the greedy BSP step described in the introduction, let $(\Omega',\Omega'') \in \mathrm{BSP}(\Omega)$, and let Q_Ω, $Q_{\Omega'}$, $Q_{\Omega''}$ be the near-best polynomial approximations for their corresponding subdomains. Then we have, by (1.1),

$$\begin{aligned}&\|\psi_{\Omega'}\|_p^\tau + \|\psi_{\Omega''}\|_p^\tau\\ &\quad\leq C(\|f - Q_\Omega\|_{L_p(\Omega)}^p + \|f - Q_{\Omega'}\|_{L_p(\Omega')}^p + \|f - Q_{\Omega''}\|_{L_p(\Omega'')}^p).\end{aligned} \tag{2.7}$$

Observing that Q_Ω has been already been determined at a previous (greedy) step, we have that the local greedy optimization step of [17] will capture the geometry in which the local geometric wavelet components of f are relatively small. If we denote the levels of a BSP partition $\mathcal{P}$ of $[0,1]^d$ by $\{\mathcal{P}_m\}_{m\in\mathbb{N}}$, we say that $\Omega' \in \mathcal{P}_{m+1}$ is a *child* of $\Omega \in \mathcal{P}_m$ if $\Omega' \subset \Omega$. Then we note that our analysis also suggests that a significant improvement may be obtained if the local optimization step is carried out for several levels at once. Namely, given $\Omega \in \mathcal{P}_m$, try to minimize, for some (small) $J \geq 2$,

$$\sum_{j=1}^{J} \sum_{\substack{\tilde{\Omega}\subset\Omega \\ \tilde{\Omega}\in\mathcal{P}_{m+j}}} \|f - Q_{\tilde{\Omega}}\|^p_{L_p(\tilde{\Omega})}. \tag{2.8}$$

Finally, we return to the proof of Theorem 2.1. Condition (2.3) implies that

$$(1-\rho)|\Omega| \leq |\Omega'| \leq \rho|\Omega|. \tag{2.9}$$

This condition for BSPs corresponds to the *weak local regularity (WLR)* condition that is assumed for triangulations in [13]. Observe that a BSP still allows the polytopes of the partition to be adaptive to the geometry of the function to be approximated; i.e., the polytopes may become as thin as one may wish, so long as the "thinning" process occurs over a sequence of levels of the partition. Also, note that we have not limited the complexity of the polytopes. Indeed, polytopes at the mth level may be of complexity m.

We need the following results on norms of polynomials over convex domains.

LEMMA 2.4. *Let $P \in \Pi_{r-1}(\mathbb{R}^d)$, and let $0 < \rho < 1$ and $0 < p, q \leq \infty$.*

(a) *Assume that $\Omega', \Omega \subset \mathbb{R}^d$ are bounded convex domains such that $\Omega' \subseteq \Omega$ and $(1-\rho)|\Omega| \leq |\Omega'|$. Then*

$$\|P\|_{L_p(\Omega)} \leq C(d,r,p,\rho)\|P\|_{L_p(\Omega')}.$$

(b) *For any bounded convex domain $\Omega \subset \mathbb{R}^d$,*

$$\|P\|_{L_q(\Omega)} \approx |\Omega|^{1/q-1/p}\|P\|_{L_p(\Omega)},$$

with constants of equivalency depending only on d, r, p, and q.

(c) *If Ω' is a child of Ω in a* BSP *partition $\mathcal{P} \in \mathrm{BSP}(\rho)$, then*

$$\|P\|_{L_q(\Omega)} \approx \|P\|_{L_q(\Omega')} \approx |\Omega|^{1/q-1/p}\|P\|_{L_p(\Omega')},$$

with constants of equivalency depending only on d, r, p, q, and ρ.

Proof. The proof of (a) and (b) can be found in [5, Lemma 3.1] and the first part of the proof of [5, Lemma 3.2], respectively. Assertion (c) follows from (a) and (b), since, by the properties of $\mathcal{P}$, we have that all the domains concerned are convex, and the following equivalence of volumes holds:

$$(1-\rho)|\Omega| \leq |\Omega'| \leq (1-\rho)^{-1}|\Omega \setminus \Omega'|. \qquad \square$$

We conclude this section by outlining the steps of the adaptive geometric wavelet approximation algorithm:

1. Given $f \in L_p([0,1]^d)$, find a BSP using local steps of optimal partitions and polynomial approximations (see discussion above (2.8)).

2. For each subdomain of the partition, $\Omega \in \mathcal{P}$, compute the p-norm of the corresponding geometric wavelet ψ_Ω.

3. Sort the geometric wavelets according their energy as in (1.2). As in the case of classical dyadic wavelets, this step can be simplified by using thresholding (see [7, section 7.8]).

4. For any $n \geq 1$, construct the n-term geometric wavelet sum (1.3).

3. Theoretical aspects of the geometric wavelet approach. One of the greatest challenges in approximation theory is the characterization of adaptive multivariate piecewise polynomial approximation (see the discussion in [7, section 6.5] and [6]). Given $f \in L_p([0,1]^d)$, we wish to understand the behavior of the degree of nonlinear approximation

$$\inf_{S \in \Sigma_n^r} \|f - S\|_{L_p([0,1]^d)}, \tag{3.1}$$

where Σ_n^r is the collection $\sum_{k=1}^n \mathbf{1}_{\Omega_k} P_k$; $\{\Omega_k\}$ are convex polytopes with disjoint interiors such that $\bigcup_{k=1}^n \Omega_k = [0,1]^d$; and $P_k \in \Pi_{r-1}$, $1 \leq k \leq n$. Usually $\{\Omega_k\}$ are assumed to be simplices (triangles in the bivariate case), so as to keep their complexity bounded. However, when using the BSP approach, the polytopes $\{\Omega_k\}$ can be of arbitrary complexity, and descendant polytopes are contained in their ancestors.

In the univariate case there is a certain equivalence between the two n-term approximation methods, wavelets and piecewise polynomials. Namely, the approximation spaces associated with the two methods are characterized by the same Besov spaces [7]. The advantage of wavelet approximation over piecewise polynomial approximation is the simplicity and efficiency with which one can implement it. When $d \geq 2$, these two methods are no longer equivalent. Wavelet approximation is still characterized by the (linear) Besov spaces, while the approximation spaces associated with piecewise polynomials are known to be nonlinear spaces [6], and their characterization remains an open problem.

While the geometric wavelet algorithm of section 2 is highly adaptive and geometrically flexible, it is nothing but a "tamed" version of the piecewise polynomial method (see also discussion in [13]). To explain this, for a given BSP partition $\mathcal{P}$, denote by $\Sigma_n^r(\mathcal{P})$ the collection

$$\sum_{k=1}^n \mathbf{1}_{\Omega_k} P_k, \quad \Omega_k \in \mathcal{P}, \quad P_k \in \Pi_{r-1}, \quad 1 \leq k \leq n. \tag{3.2}$$

Observe that the n-term geometric wavelet sum (1.3) is in $\Sigma_n^r(\mathcal{P})$, for the given partition $\mathcal{P}$. Let $\mathcal{P}_\tau(f) \in \mathrm{BSP}(\rho)$ be the near-best partition of Definition 2.2 for $f \in L_p([0,1]^d)$, $0 < \tau < p$. Then, the degree of nonlinear approximation from the near-best partition is given by

$$\sigma_{n,r,\tau}(f)_p := \inf_{S \in \Sigma_n^r(\mathcal{P}_\tau(f))} \|f - S\|_p. \tag{3.3}$$

We see that the main difference between (3.1) and (3.3) is that in the latter the n-term approximations are taken from a fixed partition. This is a major advantage, as one of the main difficulties one encounters when trying to analyze the degree of approximation of n-term piecewise polynomial approximation (where the supports have disjoint interiors) is that for $S_1, S_2 \in \Sigma_n^r$ we may have, in the worst case, that $S_1 + S_2$ is of complexity $O(n^d)$, that is, supported on n^d domains with disjoint interiors.

On the other hand, if we have a fixed partition $\mathcal{P}$, and two piecewise polynomials $S_1, S_2 \in \Sigma_n^r(\mathcal{P})$, then $S_1 + S_2 \in \Sigma_{2n}^r(\mathcal{P})$. Still, even for a fixed partition, it is hard to find a solution to (3.3). As we demonstrate below, a good method for computing an n-term piecewise polynomial approximation is to take the n-term geometric wavelet sum (1.3) (see the proof of Theorem 3.6).

The goal of this section is to provide some characterization of the adaptive geometric wavelet approximation, where the n-terms are taken from a near-best adaptive partition $\mathcal{P}_\tau(f)$, which we consider as a benchmark to any of the greedy algorithms discussed above. To this end we denote by $A_{q,\tau}^{\gamma,r}(L_p)$, $\gamma > 0$, $0 < q \le \infty$, $0 < \tau < p$, the *approximation space* corresponding to nonlinear approximation from $\mathcal{P}_\tau(f)$. This is the collection of all functions $f \in L_p([0,1]^d)$ for which the error (3.3) roughly "decays" at the rate $n^{-\gamma}$, i.e., $f \in L_p([0,1]^d)$ for which

$$(f)_{A_{q,\tau}^{\gamma,r}(L_p)} := \begin{cases} \left(\sum_{m=0}^{\infty} (2^{m\gamma} \sigma_{2^m,r,\tau}(f)_p)^q \right)^{1/q}, & 0 < q < \infty, \\ \sup_{m \ge 0} (2^{m\gamma} \sigma_{2^m,r,\tau}(f)_p), & q = \infty, \end{cases}$$

is finite.

Recall that for $f \in L_\tau(\Omega)$, $0 < \tau \le \infty$, $h \in \mathbb{R}^d$, and $r \in \mathrm{N}$, we denote the rth order difference operator by

$$\Delta_h^r(f, x) := \Delta_h^r(f, \Omega, x) := \begin{cases} \sum_{k=0}^{r} (-1)^{r+k} \binom{r}{k} f(x + kh), & [x, x + rh] \subset \Omega, \\ 0, & \text{otherwise}, \end{cases}$$

where $[x, y]$ denotes the line segment connecting the points $x, y \in \mathbb{R}^d$. The *modulus of smoothness of order* r of $f \in L_\tau(\Omega)$ (see, e.g., [7, 9]) is defined by

$$\omega_r(f, t)_{L_\tau(\Omega)} := \sup_{|h| \le t} \|\Delta_h^r(f, \Omega, \cdot)\|_{L_\tau(\Omega)}, \quad t > 0,$$

where for $h \in \mathbb{R}^d$, $|h|$ denotes the length of h. We also define

$$\omega_r(f, \Omega)_\tau := \omega_r(f, \operatorname{diam}(\Omega))_{L_\tau(\Omega)}. \tag{3.4}$$

Definition 3.1. *For $\gamma > 0$, $\tau > 0$, and $r \in N$, the* Besov space $B_\tau^{\gamma,r}$ *is the collection of functions $f \in L_\tau([0,1]^d)$ for which*

$$|f|_{B_\tau^{\gamma,r}} := \left(\sum_{m=0}^{\infty} \left(2^{\gamma m} \omega_r \left(f, 2^{-m} \right)_{L_\tau([0,1]^d)} \right)^\tau \right)^{1/\tau} < \infty.$$

Definition 3.2. *For $0 < p < \infty$, $\alpha > 0$, $\rho > 0$, and $1/\tau := \alpha + 1/p$, we define the* geometric B-space $\mathcal{GB}_\tau^{\alpha,r}$, *$r \in N$, as the set of functions $f \in L_p([0,1]^d)$ for which*

$$(f)_{\mathcal{GB}_\tau^{\alpha,r}} := \left(\inf_{\mathcal{P} \in \mathrm{BSP}(\rho)} \sum_{\Omega \in \mathcal{P}} (|\Omega|^{-\alpha} \omega_r(f, \Omega)_\tau)^\tau \right)^{1/\tau} < \infty. \tag{3.5}$$

Note that the smoothness measure $(\cdot)_{\mathcal{GB}_\tau^{\alpha,r}}$ is not a (quasi-)seminorm, since the triangle inequality, in general, is not satisfied. However, it is easy to show that for $\alpha_1 \le \alpha_2$ and $1/\tau_k = \alpha_k + 1/p$, $k = 1, 2$, we have $\mathcal{GB}_{\tau_2}^{\alpha_2,r} \subseteq \mathcal{GB}_{\tau_1}^{\alpha_1,r}$, so just as in the case of Besov spaces, a larger α implies a smaller class of functions with "more smoothness." Also, the smoothness measure $(\cdot)_{\mathcal{GB}_\tau^{\alpha,r}}$ of a function is bounded by the Besov (quasi-)seminorm of the function in $B_\tau^{d\alpha,r}$. Indeed, let $\mathcal{P}_D$ denote the BSP partition that gives the classical dyadic partition. If we denote the collection of dyadic cubes of side length 2^{-m} by $\mathcal{D}_m$, then

$$\begin{aligned}(f)_{\mathcal{GB}_\tau^{\alpha,r}} &\le \left(\sum_{\Omega\in\mathcal{P}_D} (|\Omega|^{-\alpha}\omega_r(f,\Omega)_\tau)^\tau\right)^{1/\tau} \\ &\le C\left(\sum_{m=0}^{\infty}\sum_{I\in\mathcal{D}_m} (2^{d\alpha m}\omega_r(f,I)_\tau)^\tau\right)^{1/\tau} \\ &\le C|f|_{B_\tau^{d\alpha,r}}.\end{aligned} \tag{3.6}$$

For a geometric B-space $\mathcal{GB}$ we introduce the (nonlinear) *K-functional* corresponding to the pair L_p and $\mathcal{GB}$

$$K(f,t) := K(f,t,L_p,\mathcal{GB}) := \inf_{g\in\mathcal{GB}}\{\|f-g\|_p + t\cdot(g)_{\mathcal{GB}}\}, \quad t>0. \tag{3.7}$$

The (nonlinear) *interpolation space* $(L_p,\mathcal{GB})_{\lambda,q}$, $\lambda>0$, $0<q\le\infty$, is defined as the set of all $f\in L_p([0,1]^d)$ such that

$$(f)_{(L_p,\mathcal{GB})_{\lambda,q}} := \begin{cases}\left(\sum_{m=0}^{\infty}(2^{m\lambda}K(f,2^{-m}))^q\right)^{1/q}, & 0<q<\infty,\\ \sup_{m\ge 0} 2^{m\lambda}K(f,2^{-m}), & q=\infty,\end{cases}$$

is finite. Although the interpolation spaces $(L_p,\mathcal{GB})_{\lambda,q}$ are nonlinear, we can still apply the Jackson and Bernstein machinery that one usually applies in the case of linear spaces defined over fixed geometry, such as dyadic partitions [7] or fixed triangulations [13, 5]. We obtain the following characterization.

THEOREM 3.3. *Let* $0<\gamma<\alpha$, $0<q\le\infty$, *and* $0<p<\infty$; *then*

$$A_{q,\tau}^{\gamma,r}(L_p) = (L_p,\mathcal{GB}_\tau^{\alpha,r})_{\frac{\gamma}{\alpha},q}, \tag{3.8}$$

where $1/\tau := \alpha + 1/p$.

The remainder of this section is devoted to the proof of Theorem 3.3.

In [5] we proved that for all bounded convex domains $\Omega\subset\mathbb{R}^d$ and functions $f\in L_\tau(\Omega)$, $0<\tau\le\infty$, we have the equivalence

$$E_{r-1}(f,\Omega)_\tau \approx \omega_r(f,\Omega)_\tau, \tag{3.9}$$

where the constants of equivalency depend only on d, r, and τ.

To proceed with our analysis, we have to show that the polynomial approximations Q_Ω in (2.1), which are near-best approximations in the p-norm, are also near-best approximations for some $0<\eta<p$. Indeed we show the following.

LEMMA 3.4. *Let $\Omega \subset \mathbb{R}^d$ be a bounded convex domain and let $f \in L_p(\Omega)$, $0 < p < \infty$. Then for any $r \in \mathrm{N}$ there exists a polynomial $Q \in \Pi_{r-1}$ such that for all $0 < \eta \le p$ if $0 < p \le 1$, and for all $1 \le \eta \le p$ if $1 < p < \infty$, we have*

$$\|f - Q\|_{L_\eta(\Omega)} \le C E_{r-1}(f, \Omega)_\eta, \tag{3.10}$$

where for $1 < p < \infty$, $C = C(r, d)$, and for $0 < p \le 1$, $C = C(r, d, \eta) \le C(r, d, \eta_0)$, $\eta_0 \le \eta \le p$.

Proof. We begin with the case $1 < p < \infty$. Given a convex domain $\Omega \subset \mathbb{R}^d$, in [4] we have constructed for any $g \in C^r(\Omega)$ a near-best polynomial $\widetilde{Q} \in \Pi_{r-1}$ such that

$$\|g - \widetilde{Q}\|_{L_\eta(\Omega)} \le C(r, d) E_{r-1}(g, \Omega)_\eta, \quad 1 \le \eta < \infty. \tag{3.11}$$

Let $f \in L_p(\Omega)$, and let $\{g_n\}$ be a sequence in $C^r(\Omega)$ such that $\|f - g_n\|_p \to 0$ as $n \to \infty$. By Hölder's inequality, it follows that for all $1 \le \eta \le p$, $\|f - g_n\|_\eta \to 0$ as $n \to \infty$. Now let Q_n be the near-best approximation to g_n guaranteed by (3.11). Then $\|g_n - Q_n\|_p \le C(r, d)\|g\|_p$, and since we may assume that $\|f - g_n\|_p \le \|f\|_p$, we obtain

$$\|Q_n\|_\infty \le C(r, d)|\Omega|^{-1/p}\|Q_n\|_p \le C(r, d)|\Omega|^{-1/p}\|f\|_p.$$

Hence, the set of polynomials Q_n is compact in $C(\Omega)$, and we may assume that $\{Q_n\}$ converges in the uniform norm to a polynomial Q. Now

$$\|f - Q\|_\eta \le \|f - g_n\|_\eta + \|g_n - Q_n\|_\eta + \|Q_n - Q\|_\eta, \quad 1 \le \eta \le p,$$

whence

$$\|f - Q\|_\eta \le \lim_{n \to \infty} C(r, d) E_{r-1}(g_n, \Omega)_\eta = C(r, d) E_{r-1}(f, \Omega)_\eta, \quad 1 \le \eta \le p.$$

This proves (3.10) for $1 < p < \infty$.

For the case $0 < p \le 1$, we first make the following observation. Let A be a nonsingular affine mapping on $\mathbb{R}^d$, given by $A(x) := Mx + b$, where M is a nonsingular $d \times d$ matrix, and let $f \in L_p(\Omega)$. Define $\tilde{f} := f(A\cdot)$, $\tilde{Q} := Q(A\cdot)$, and $\widetilde{\Omega} := A^{-1}\Omega$. Then $\tilde{f} \in L_p(\widetilde{\Omega})$, and

$$\|f - Q\|_{L_\eta(\Omega)} = |\det M|^{1/\eta} \|\tilde{f} - \tilde{Q}\|_{L_\eta(\widetilde{\Omega})}, \quad 0 < \eta \le p. \tag{3.12}$$

Therefore

$$E_{r-1}(f, \Omega)_\eta = |\det M|^{1/\eta} E_{r-1}(\tilde{f}, \widetilde{\Omega})_\eta, \quad 0 < \eta \le p. \tag{3.13}$$

By John's theorem (see [4, 5] and references therein), for any bounded convex domain $\Omega \subset \mathbb{R}^d$ there exists a nonsingular affine mapping A such that

$$B(0, 1) \subseteq \widetilde{\Omega} \subseteq B(0, d), \tag{3.14}$$

where $B(x_0, R)$ denotes the ball of radius R with center at x_0. Then we follow [1] (see also [9, Theorem 3.10.4]), and for $\tilde{f} \in L_p(\widetilde{\Omega})$ obtain $\tilde{Q} \in \Pi_{r-1}$, a so-called polynomial of best approximation in $L_1(\widetilde{\Omega})$, which satisfies

$$\|\tilde{f} - \tilde{Q}\|_{L_\eta(\widetilde{\Omega})} \le C(r, d, \eta) E_{r-1}(\tilde{f}, \widetilde{\Omega})_\eta, \quad \eta \le 1, \tag{3.15}$$

where $C(r, d, \eta) \le C(r, d, \eta_0)$, $\eta_0 < \eta \le p$. Now, (3.10) for $0 < p \le 1$ follows by virtue of (3.12) and (3.13). $\square$

THEOREM 3.5. *For $0 < p < \infty$, $\alpha > 0$, $1/\tau = \alpha + 1/p$, and $f \in L_p([0,1]^d)$, we have the equivalence*

$$(f)_{\mathcal{GB}_\tau^{\alpha,r}} \approx \mathcal{N}_\tau(f, \mathcal{P}_\tau(f)), \tag{3.16}$$

with constants of equivalency depending only on α, d, r, p, and ρ.

Proof. Let $\mathcal{P} \in \mathrm{BSP}(\rho)$ be a given partition. For $0 < \mu \le p$ and $\Omega \in \mathcal{P}$, denote by $Q_{\Omega,\mu}$ a near-best polynomial approximation of $f \in L_\mu(\Omega)$. Note that with this notation, the near-best polynomials used in (1.1) are $Q_\Omega = Q_{\Omega,p}$. We define

$$\mathcal{N}_{\tau,\mu}(f,\mathcal{P}) := \left(\sum_{\Omega\in\mathcal{P}} \|\psi_{\Omega,\mu}\|_p^\tau\right)^{1/\tau},$$

where $\psi_{\Omega,\mu}$ are defined in (1.1) with the near-best polynomials $Q_{\Omega,\mu}$, and

$$\widetilde{\mathcal{N}}_{\tau,\mu}(f,\mathcal{P}) := \left(\sum_{\Omega\in\mathcal{P}} (|\Omega|^{1/p-1/\mu}\omega_r(f,\Omega)_\mu)^\tau\right)^{1/\tau}.$$

By Lemma 3.4 we know that there is a $\tau < \eta < p$ such that for any $\Omega \in \mathcal{P}$ we may take $\psi_{\Omega,\eta} = \psi_{\Omega,p} = \psi_\Omega$. Therefore, in order to prove (3.16), it suffices to prove that for any $\mathcal{P} \in \mathrm{BSP}(\rho)$

$$\mathcal{N}_{\tau,\eta}(f,\mathcal{P}) \approx \widetilde{\mathcal{N}}_{\tau,\tau}(f,\mathcal{P}) \tag{3.17}$$

holds with constants of equivalency that depend only on d, r, p, τ, η, and ρ.

To this end, take $\tau \le \mu \le \eta$, and recall that if Ω' is a child of Ω, then

$$\begin{aligned} \|\psi_{\Omega',\mu}\|_\mu &\le C(\|f - Q_{\Omega,\mu}\|_{L_\mu(\Omega')} + \|f - Q_{\Omega'},\mu\|_{L_\mu(\Omega')}) \\ &\le C(E_{r-1}(f,\Omega)_\mu + E_{r-1}(f,\Omega')_\mu), \end{aligned} \tag{3.18}$$

where $C = C(r,d,\mu)$. Hence

$$\begin{aligned} \mathcal{N}_{\tau,\mu}(f,\mathcal{P}) &= \left(\sum_{\Omega\in\mathcal{P}} \|\psi_{\Omega,\mu}\|_p^\tau\right)^{1/\tau} \\ &\le C\left(\sum_{\Omega\in\mathcal{P}} (|\Omega|^{1/p-1/\mu}\|\psi_{\Omega,\mu}\|_\mu)^\tau\right)^{1/\tau} \\ &\le C\left(\sum_{\Omega\in\mathcal{P}} (|\Omega|^{1/p-1/\mu}E_{r-1}(f,\Omega)_\mu)^\tau\right)^{1/\tau} \\ &\le C\left(\sum_{\Omega\in\mathcal{P}} (|\Omega|^{1/p-1/\mu}\omega_r(f,\Omega)_\mu)^\tau\right)^{1/\tau} \\ &= C\widetilde{\mathcal{N}}_{\tau,\mu}(f,\mathcal{P}), \end{aligned} \tag{3.19}$$

where for the first inequality we applied Lemma 2.4, for the second we applied (3.18) and (2.9), and finally for the third inequality we applied (3.9).

Next we show that for $\tau \le \mu \le \eta$

$$\widetilde{\mathcal{N}}_{\tau,\eta}(f,\mathcal{P}) \le \mathcal{N}_{\tau,\mu}(f,\mathcal{P}). \tag{3.20}$$

We may assume that $\mathcal{N}_{\tau,\mu}(f,\mathcal{P}) < \infty$, because otherwise there is nothing to prove. Since $\mu < p$, we have that $f \in L_\mu([0,1]^d)$, and Theorem 2.1 implies

$$f = \sum_{\Omega\in\mathcal{P}} \psi_{\Omega,\mu} \quad \text{a.e.}$$

Therefore,

$$\begin{aligned}
\omega_r(f,\Omega)_\eta^\tau &= \omega_r\left(f - \sum_{\widetilde{\Omega}\in\mathcal{P},\,\widetilde{\Omega}\supseteq\Omega} \psi_{\widetilde{\Omega},\mu}, \Omega\right)_\eta^\tau \\
&\le C\left\|\sum_{\widetilde{\Omega}\in\mathcal{P},\,\widetilde{\Omega}\subset\Omega} |\psi_{\widetilde{\Omega},\mu}|\right\|_\eta^\tau \\
&\le C\sum_{\widetilde{\Omega}\in\mathcal{P},\,\widetilde{\Omega}\subset\Omega} \|\psi_{\widetilde{\Omega},\mu}\|_\eta^\tau \\
&\le C\sum_{\widetilde{\Omega}\in\mathcal{P},\,\widetilde{\Omega}\subset\Omega} |\widetilde{\Omega}|^{\tau(1/\eta-1/\tau)}\|\psi_{\widetilde{\Omega},\mu}\|_\tau^\tau,
\end{aligned}$$

where for the equality we used the fact that for $\Omega \subseteq \widetilde{\Omega}$ the geometric wavelet $\psi_{\widetilde{\Omega},\mu}$ is a polynomial of total degree $\le r-1$, for the second inequality we applied [13, Theorem 3.3], and for the third inequality we applied Lemma 2.4. Therefore,

$$\begin{aligned}
\widetilde{\mathcal{N}}_{\tau,\eta}(f,\mathcal{P})^\tau &\le C\sum_{\Omega\in\mathcal{P}} |\Omega|^{\tau(1/p-1/\eta)} \sum_{\widetilde{\Omega}\subset\Omega} |\widetilde{\Omega}|^{\tau(1/\eta-1/\tau)}\|\psi_{\widetilde{\Omega},\mu}\|_\tau^\tau \\
&= C\sum_{\Omega\in\mathcal{P}}\sum_{\widetilde{\Omega}\subset\Omega}\left(\frac{|\widetilde{\Omega}|}{|\Omega|}\right)^{\tau(1/\eta-1/p)} (|\widetilde{\Omega}|^{1/p-1/\tau}\|\psi_{\widetilde{\Omega},\mu}\|_\tau)^\tau \\
&= C\sum_{\widetilde{\Omega}\in\mathcal{P}} (|\widetilde{\Omega}|^{1/p-1/\tau}\|\psi_{\widetilde{\Omega},\mu}\|_\tau)^\tau \sum_{\substack{\Omega\in\mathcal{P}\\ \Omega\supset\widetilde{\Omega}}}\left(\frac{|\widetilde{\Omega}|}{|\Omega|}\right)^{\tau(1/\eta-1/p)}.
\end{aligned}$$

Now, if $\widetilde{\Omega} \in \mathcal{P}_m$ and $\Omega \in \mathcal{P}_{m-k}$, $k > 0$, is one of its ancestors, then by (2.9),

$$|\widetilde{\Omega}| \le |\Omega|\rho^k.$$

Hence

$$\sum_{\Omega\in\mathcal{P},\,\Omega\supset\widetilde{\Omega}}\left(\frac{|\widetilde{\Omega}|}{|\Omega|}\right)^{\tau(1/\eta-1/p)} \le C\sum_{k=1}^{\infty}\rho^{k\tau(1/\eta-1/p)} \le C(p,\eta,\tau,\rho).$$

We conclude that

$$\begin{aligned}
\widetilde{\mathcal{N}}_{\tau,\eta}(f,\mathcal{P})^\tau &\le C\sum_{\widetilde{\Omega}\in\mathcal{P}} (|\widetilde{\Omega}|^{1/p-1/\tau}\|\psi_{\widetilde{\Omega},\mu}\|_\tau)^\tau \\
&\le C\sum_{\widetilde{\Omega}\in\mathcal{P}} \|\psi_{\widetilde{\Omega},\mu}\|_p^\tau = C\mathcal{N}_{\tau,\mu}(f,\mathcal{P})^\tau,
\end{aligned}$$

where for the last inequality we again applied Lemma 2.4. This proves (3.20).

Now combining (3.19) with $\mu = \eta$, (3.20) with $\mu = \tau$, and then (3.19) with $\mu = \tau$, we obtain

$$\mathcal{N}_{\tau,\eta}(f,\mathcal{P}) \le C\widetilde{\mathcal{N}}_{\tau,\eta}(f,\mathcal{P}) \le C\mathcal{N}_{\tau,\tau}(f,\mathcal{P}) \le C\widetilde{\mathcal{N}}_{\tau,\tau}(f,\mathcal{P}),$$

which proves one direction in (3.17). In order to prove the opposite direction, we observe that it follows from Hölder's inequality that

$$\widetilde{\mathcal{N}}_{\tau,\tau}(f,\mathcal{P}) \le \widetilde{\mathcal{N}}_{\tau,\eta}(f,\mathcal{P}).$$

Using (3.20) with $\mu = \eta$ yields

$$\widetilde{\mathcal{N}}_{\tau,\eta}(f,\mathcal{P}) \le C\mathcal{N}_{\tau,\eta}(f,\mathcal{P}),$$

which gives

$$\widetilde{\mathcal{N}}_{\tau,\tau}(f,\mathcal{P}) \le \widetilde{\mathcal{N}}_{\tau,\eta}(f,\mathcal{P}) \le C\mathcal{N}_{\tau,\eta}(f,\mathcal{P}).$$

This completes the proof of the opposite direction in (3.17) and concludes our proof. □

In view of the above, one may draw the following conclusion. There are cases of functions that are not in the Besov space of scale $d\alpha$ and therefore cannot be approximated by n-term wavelet approximation at the "rate" $n^{-\alpha}$ (see [7]). Yet, there might exist an adaptive partition which captures the geometry (if it exists!) of the function's singularities and leads to a finite smoothness measure (3.5) for the scale α. In fact we show that such a partition can also provide n-term geometric wavelet approximation at the rate $n^{-\alpha}$.

Theorem 3.6 (Jackson estimate). *Let $0 < p < \infty$, $\alpha > 0$, and $r \in \mathrm{N}$. If $f \in \mathcal{GB}_\tau^{\alpha,r}$, $1/\tau = \alpha + 1/p$, then*

$$\sigma_{n,r,\tau}(f)_p \le Cn^{-\alpha}(f)_{\mathcal{GB}_\tau^{\alpha,r}}, \tag{3.21}$$

where $C := C(\alpha,d,r,p,\rho)$.

Proof. Given f, p, and τ, we select the near-best adaptive partition $\mathcal{P}_\tau(f)$. Applying [13, Theorem 3.4] with the collection $\{\Phi_m\} := \{\psi_\Omega\}_{\Omega\in\mathcal{P}_\tau(f)}$ and then (3.16), we obtain

$$\begin{aligned}\sigma_{n,r,\tau}(f)_p &\le Cn^{-\alpha}\mathcal{N}_\tau(f,\mathcal{P}_\tau(f))\\ &\le Cn^{-\alpha}(f)_{\mathcal{GB}_\tau^{\alpha,r}}. \qquad \square\end{aligned}$$

Let $\phi \in L_p([0,1]^d)$ and let $\mathcal{P} \in \mathrm{BSP}(\rho)$ be a *fixed* partition. Then, the smoothness of ϕ with respect to the fixed partition $\mathcal{P}$ is

$$|\phi|_{\mathcal{B}_\tau^{\alpha,r}(\mathcal{P})} := \left(\sum_{\Omega\in\mathcal{P}} (|\Omega|^{-\alpha}\omega_r(\phi,\Omega)_\tau)^\tau\right)^{1/\tau}.$$

For a fixed partition $\mathcal{P}$, the smoothness quantity $|\cdot|_{\mathcal{B}_\tau^{\alpha,r}(\mathcal{P})}$ is a quasi seminorm. Therefore we obtain the Bernstein estimate for BSPs in much the same way that it was proved for triangulations in the bivariate case in [13], and in arbitrary dimension $d \ge 2$ in [5]. Namely, we have the following.

THEOREM 3.7 (Bernstein estimate). *Let $\mathcal{P} \in \mathrm{BSP}(\rho)$, and let $\phi \in \Sigma_n^r(\mathcal{P})$. Then for all $0 < p < \infty$, $\alpha > 0$, and $1/\tau = \alpha + 1/p$,*

$$|\phi|_{\mathcal{B}_\tau^{\alpha,r}(\mathcal{P})} \le C n^\alpha \|\phi\|_p, \tag{3.22}$$

where $C := C(\alpha, d, r, p, \rho)$.

We are now ready to prove Theorem 3.3.

Proof of Theorem 3.3. The proof is similar to the proof of [9, Theorem 7.9.1]. The proof that the right-hand side of (3.8) is contained in the left-hand side readily follows by the Jackson inequality. Indeed, it is a standard technique to show that (3.21) implies that for every $f \in L_p$

$$\sigma_{n,r,\tau}(f)_p \le CK(f, n^{-\alpha}, L_p, \mathcal{GB}_\tau^{\alpha,r}).$$

Hence by the first part of the proof of [9, Theorem 7.9.1]

$$(f)_{A_{q,\tau}^{\gamma,r}} \le C\Big(\|f\|_p + (f)_{(L_p, \mathcal{GB}_\tau^{\alpha,r})_{\frac{\gamma}{\alpha},q}}\Big).$$

In order to prove that the left-hand side of (3.8) is contained in the right-hand side, we have to estimate the appropriate K-functional. Namely, we replace the proof of [9, Theorem 7.5.1(ii)] with the estimate

$$K(f, 2^{-m\alpha}, L_p, \mathcal{GB}_\tau^{\alpha,r}) \le C 2^{-m\alpha} \left(\sum_{j=1}^m (2^{j\alpha} \sigma_{2^{j-1}}(f)_p)^\mu + \|f\|_p^\mu \right)^{1/\mu}, \tag{3.23}$$

where $K(f, \cdot, L_p, \mathcal{GB}_\tau^{\alpha,r})$ is defined by (3.7), $\sigma_{2^j}(f)_p := \sigma_{2^j,r,\tau}(f)_p$, $m \ge 1$, and $\mu := \min(\tau, 1)$. Note that, in proving this, special attention is needed to circumvent the fact that $(\cdot)_{\mathcal{GB}_\tau^{\alpha,r}}$ is not a (quasi-)seminorm. Indeed, for each $j \ge 0$ we take a geometric wavelet sum $S_j \in \Sigma_{2^j}^r(\mathcal{P}_\tau(f))$ such that

$$\|f - S_j\|_{L_p([0,1]^d)} \le 2\sigma_{2^j}(f)_p.$$

Since $\mathcal{P}_\tau(f)$ is a fixed nested partition, we have that $\phi_j := S_j - S_{j-1} \in \Sigma_{2^{j+1}}^r(\mathcal{P}_\tau(f))$, $j \ge 1$, and

$$\|\phi_j\|_p \le \|f - S_j\|_p + \|f - S_{j-1}\|_p \le 2\sigma_{2^{j-1}}(f)_p, \quad j \ge 1.$$

We also set $\phi_0 := S_0$. Since S_0 is a single geometric wavelet component, we conclude that (3.9) implies that $\|\phi_0\|_p \le C\|f\|_p$. Now, we substitute $g := S_m = \sum_{j=0}^m \phi_j$ in (3.7) and apply the Bernstein inequality (3.22) on the fixed partition $\mathcal{P}_\tau(f)$ to obtain

$$\begin{aligned}
K(f, 2^{-m\alpha}, L_p, \mathcal{GB}_\tau^{\alpha,r}) &\le \|f - S_m\|_p + 2^{-m\alpha}(S_m)_{\mathcal{GB}_\tau^{\alpha,r}} \\
&\le C(\sigma_{2^m}(f)_p + 2^{-m\alpha}|S_m|_{B_\tau^{\alpha,r}(P_\tau(f))}) \\
&\le C\left(\sigma_{2^m,r}(f)_p + 2^{-m\alpha}\left(\sum_{j=0}^m |\phi_j|^\mu_{B_\tau^{\alpha,r}(\mathcal{P}_\tau(f))}\right)^{1/\mu}\right) \\
&\le C\left(\sigma_{2^m}(f)_p + 2^{-m\alpha}\left(\sum_{j=0}^m (2^{(j+1)\alpha}\|\phi_j\|_p)^\mu\right)^{1/\mu}\right) \\
&\le C 2^{-m\alpha}\left(\sum_{j=1}^m (2^{j\alpha}\sigma_{2^{j-1}}(f)_p)^\mu + \|f\|_p^\mu\right)^{1/\mu}.
\end{aligned}$$

We leave the rest of the proof to the reader. □

4. Simulation results and discussion. We implemented the geometric wavelet algorithm for the purpose of finding sparse representations of digital images with $r = 2$ (linear polynomials) and $p = 2$. We point out that, in our current implementation, condition (2.3) does not come into play.

To reduce the time complexity of the implementation, the images were subdivided into tiles of size 64×64, and a BSP tree was constructed over each of the tiles separately. Although JPEG-like artifacts, resulting from the tiles' boundaries, are visible in the examples below, this approach ensures that the time complexity of the algorithm is almost linear with respect to the image size. Once all the BSP trees were constructed over the 64×64 tiles, and the geometric wavelets were computed, we extracted a global n-term approximation (1.3) from the joint list of all the geometric wavelets over all the tiles. Our experiments show that in most cases increasing the tile size does not have a significant impact on the results.

To further improve the time complexity of the algorithm, we performed coarse

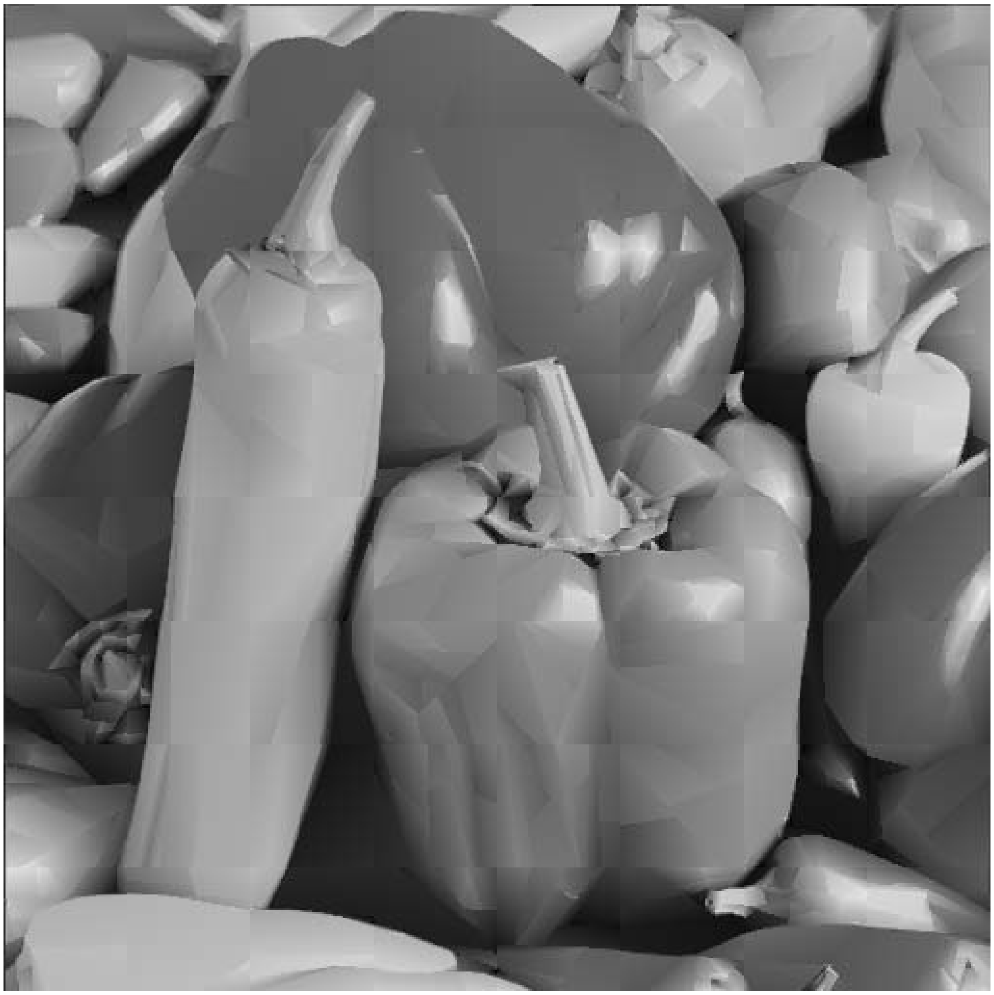

FIG. 3. *Geometric wavelet approximation of the peppers image with* $n = 2048$, PSNR $= 31.32$.

partition searches at lower levels of the BSP tree and fine searches at the higher levels. The search for the optimal partition was done by advancing two points on a domain's boundary, computing the two subdomains created by the line that goes through these points, and then computing the two least-squares linear polynomials over each of these subdomains. In lower levels of the BSP tree, this march was done in larger steps and in finer levels, and the step size was set to 1, the pixel resolution. In some sense, the idea of finer partitions at higher resolutions is related to the way curvelets [2] have "more directions" at higher resolutions.

In Figure 3 we see an n-term geometric wavelet approximation of the known test image peppers (cf. original in Figure 2) of size 512×512 with 2048 elements and PSNR (peak signal-to-noise ratio) 31.32. In Figure 4 we see an n-term dyadic wavelet approximation with twice as many elements, 4096, and still somewhat worse PSNR, 29.22. In all the examples below, we used a ratio of 1:2 (peppers, Figures 3–4; Lena, Figures 6–7), 1:3 (Barbara, Figures 13–14) or 1:4 (cameraman, Figures 9–11)

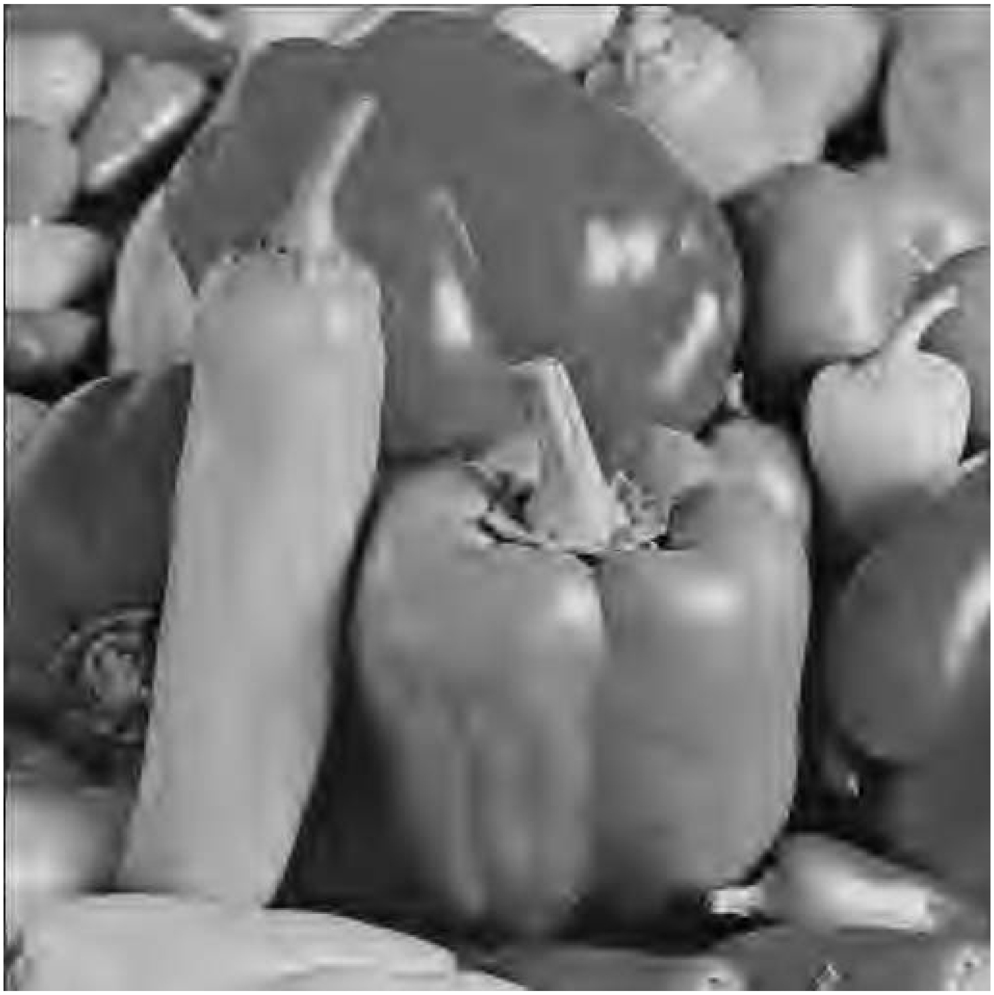

FIG. 4. *Dyadic biorthogonal wavelet approximation of the peppers image with* $n = 4096$*,* PSNR = 29.22*.*

between the number of geometric wavelets and dyadic wavelets, so as to make the comparison more relevant. Observe that on the more "geometric" images, peppers and cameraman, i.e., images that are roughly composed of smooth regions and strong distinct edges, the geometric wavelets seem to perform relatively better. For example, for the cameraman image the 512-term geometric wavelet approximation gives the same PSNR as the 2048-term dyadic wavelet approximation.

For the dyadic wavelets approximation we used the MATLAB wavelet toolbox, where we selected the well-known biorthogonal wavelet basis $(4, 4)$ (see [3]), also known as the "nine-seven" in the engineering community. This biorthogonal wavelet has four zero moments, corresponding to $r = 4$. We note that we actually allowed the dyadic wavelet approximation to use even slightly more elements than claimed in the figures, so as to compensate for MATLAB handling of the image boundaries by a somewhat overredundant wavelet decomposition. The results are summarized in Table 1.

In Figure 15 we see an example of image denoising using geometric wavelets. To

Fig. 5. *The "Lena" image* 512 × 512.

Table 1
Comparison of n-term dyadic and geometric wavelets.

Image	N-term dyadic	N-term geometric	Ratio	PSNR dyadic	PSNR geometric
peppers	4096	2048	2:1	29.22	31.32
Lena	4096	2048	2:1	30.18	31.26
cameraman	2048	512	4:1	26.72	26.71
		1024			28.93
Barbara	12288	4096	3:1	27.54	27.10

compare with results in [22], we added Gaussian white noise to the Lena test image with standard deviation of 20, which gives a noisy image with PSNR = 22.14. Following the usual "sparse representation" methodology [22], we applied the geometric wavelet algorithm to the noisy image and extracted an n-term approximation (1.3) to the original image. We see that geometric features are recovered quite well in the pro-

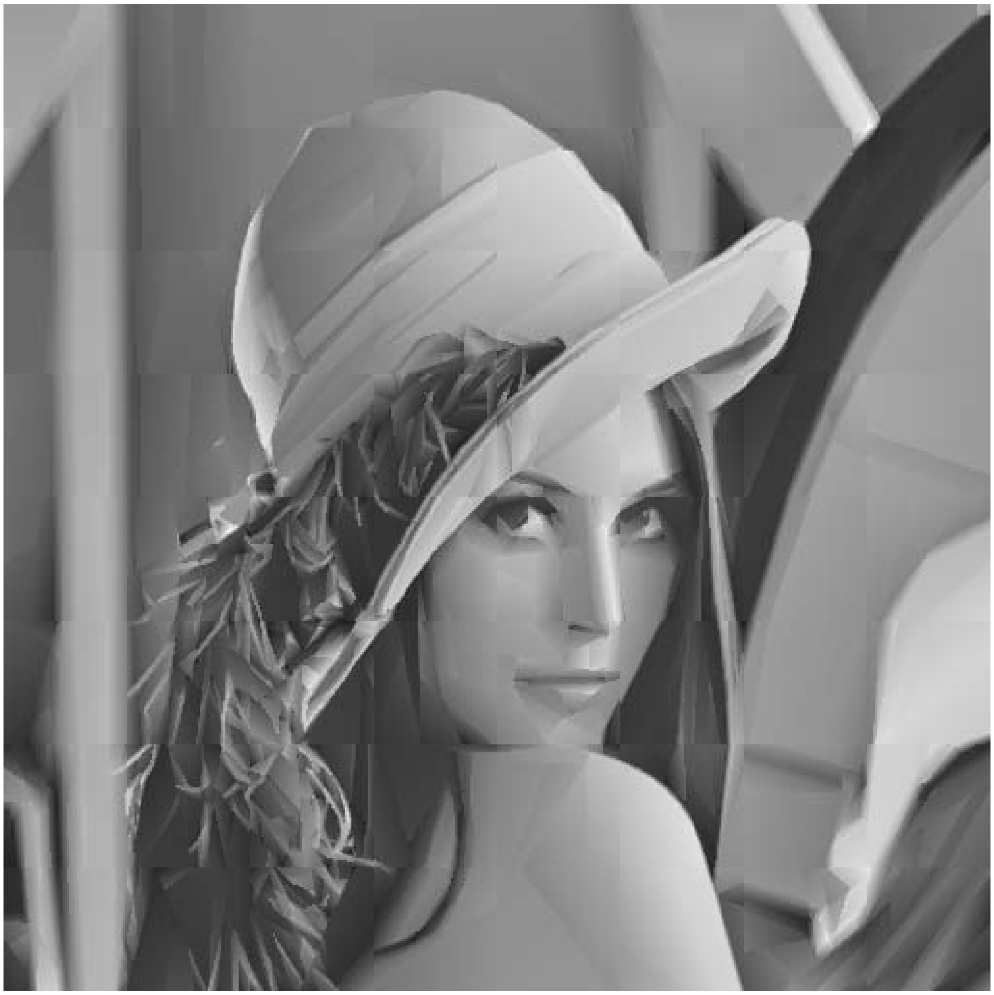

FIG. 6. *Geometric wavelet approximation of the Lena image with* $n = 2048$, PSNR $= 31.26$.

cess, in a manner which is very competitive with curvelets. The algorithm produced a restored image with PSNR $= 29.76$.

As with classical wavelets, the n-term strategy can be used for progressive coding and rate-distortion control, where more geometric wavelets are added according to their order of appearance in (1.2). It is important to note that when trying to encode the approximation (1.3) it should be remembered that for a geometric wavelet located in a "deep" level of the BSP tree, one needs to encode the sequence of binary partitions that created it. Thus, if the wavelet ψ_Ω is located at the mth level of the BSP partition, $O(m)$ bits are required to encode its location. Therefore, encoding geometric wavelets at higher levels is more expensive when considering bit allocation. However, this is no different from dyadic wavelet compression, where encoding the index of a dyadic wavelet located at the resolution m also requires $O(m)$ bits. Recall that at lower levels of the BSP tree we perform coarse partitions and at higher levels, fine partitions. As pointed out in [17], this also improves the coding performance, since it facilitates the quantization and encoding of the partitions.

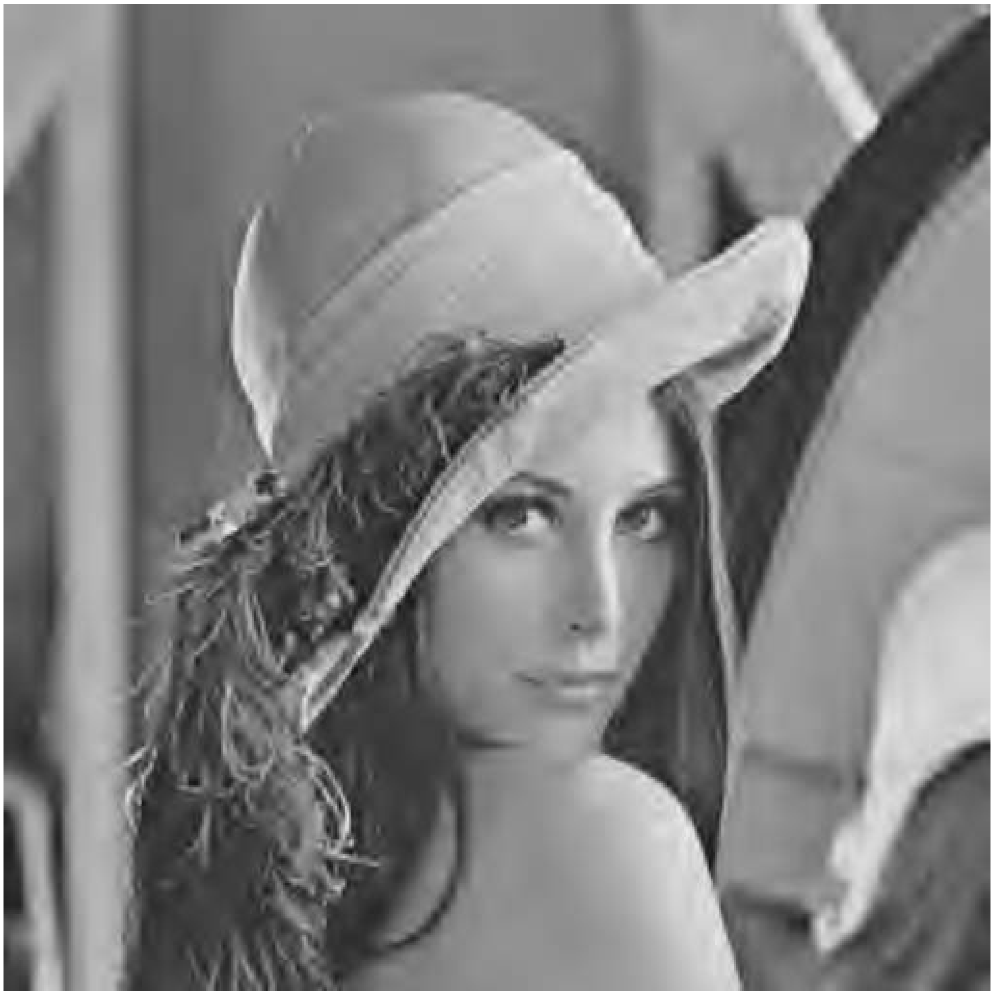

FIG. 7. *Dyadic biorthogonal wavelet approximation of the Lena image with* $n = 4096$*,* PSNR $=$ 30.18*.*

Although image coding using geometric wavelets is ongoing work, we anticipate that the problem of encoding geometric side-information can be solved by using zerotree-type encoding [18, 20] and rate-distortion optimization techniques [21, 23]. Furthermore, we plan to incorporate a geometric rate-distortion optimization technique borrowed from the wavelet coding algorithm WedgePrints [26]. Namely, at each node of the BSP tree, one may allocate a flag (bit) to signal to the decoder a decision about whether all further partitions of this domain are uniform (nonadaptive) or geometrically adaptive. Encoding geometric wavelets whose supports lie in a "uniform" ancestor domain is similar to dyadic wavelet encoding, where only an index of the geometric wavelet in a uniform partition needs to be encoded and the support of the geometric wavelet is known from the uniform partition of the ancestor. Thus, using rate-distortion optimization techniques, one would choose at each node of the BSP whether to use an adaptive partition whose geometry needs to be encoded, or a uniform nonadaptive partition.

OPTIMAL ERROR ESTIMATES FOR LINEAR PARABOLIC PROBLEMS WITH DISCONTINUOUS COEFFICIENTS*

RAJEN KUMAR SINHA† AND BHUPEN DEKA†

Abstract. A finite element discretization is proposed and analyzed for a linear parabolic problems with discontinuous coefficients. Due to low global regularity of the solution, it seems difficult to achieve optimal order of convergence with classical finite element methods [*Numer. Math.*, 79 (1998), pp. 175–202]. In this paper, we have used a finite element discretization, where interface triangles are assumed to be curved triangles instead of straight triangles as in classical finite element methods. Optimal order error estimates in L^2 and H^1 norms are shown to hold even if the regularity of the solution is low on the whole domain. While the continuous time Galerkin method is discussed for the spatially discrete scheme, the discontinuous Galerkin method is analyzed for the fully discrete scheme. The interfaces and boundaries of the domains are assumed to be smooth for our purpose.

Key words. parabolic, interface, discontinuous coefficients, finite element approximation, semidiscrete and fully discrete schemes, optimal error estimates, discontinuous Galerkin method

1. Introduction.

In this paper, we consider a linear parabolic interface problem of the form

$$u_t + \mathcal{L}u = f(x,t) \quad \text{in } \Omega \times (0,T] \tag{1.1}$$

with initial and boundary conditions

$$u(x,0) = u_0 \ \text{ in } \Omega; \ \ u(x,t) = 0 \quad \text{on } \partial\Omega \times (0,T] \tag{1.2}$$

and interface conditions

$$[u] = 0, \ \ \left[\mathcal{A}\frac{\partial u}{\partial \mathbf{n}}\right] = g(x,t) \quad \text{along } \Gamma, \tag{1.3}$$

where Ω is a bounded domain in $\mathbb{R}^2$ with smooth boundary $\partial\Omega$, $\Omega_1 \subset \Omega$ is an open domain with C^2 boundary Γ, and $\Omega_2 = \Omega\backslash\Omega_1$ (see Figure 1). The operator $\mathcal{L}$ is a second order elliptic partial differential operator of the form

$$\mathcal{L}v = -\nabla \cdot (\mathcal{A}\nabla v).$$

The symbol $[v]$ is a jump of a quantity v across the interface Γ and $\mathbf{n}$ denotes the unit outward normal to the boundary $\partial\Omega_1$. We assume that the coefficient matrix $\mathcal{A} = (a_{ij}(x))_{i,j=1}^2$ is symmetric and uniformly positive definite in Ω. Moreover, the matrix $\mathcal{A}$ is assumed to be discontinuous along Γ but piecewise smooth in each subdomain Ω_1 and Ω_2, i.e.,

$$\mathcal{A} = \mathcal{A}_l = (a_{ij}^l(x))_{i,j=1}^2 \quad \text{for } x \in \Omega_l, \ l = 1, 2.$$

Here for each l, $\mathcal{A}_l$ is a uniformly positive definite matrix.

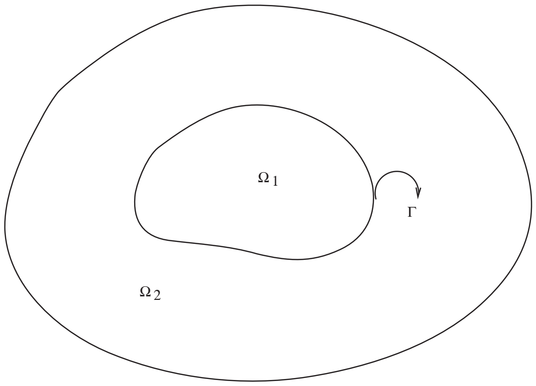

FIG. 1. *Domain Ω and its subdomains Ω_1, Ω_2 with interface Γ.*

Parabolic equations (1.1) with discontinuous coefficients occur in many applications, such as in material sciences and fluid dynamics, where domains consist of two or more heterogeneous media, i.e., when two distinct materials or fluids with different conductivities, densities, or diffusions are involved. Because of the discontinuity of the coefficients along the interface, the solution of such a problem has low regularity on the whole physical domain (cf. [10] and [5]).

In recent years, numerical methods for solving parabolic problems, by means of finite element methods under minimal regularity assumption on the true solutions, are the subject of much interest; see [5] and [6]. Due to low global regularity of the true solution, achieving higher order accuracy by the classical finite element method seems very difficult (cf. [2] and [5]). In [5], the authors studied the convergence of the finite element method for the elliptic and parabolic problems by approximating the smooth interface by a polygon and the interface function by its interpolant. They obtained suboptimal order error estimates in both energy and L^2 norms. It is also mentioned [5, p. 177] that classical analysis is difficult to apply in the convergence analysis for the interface problem. Subsequently, the author of [13] analyzed the error in the finite element method applied to self-adjoint elliptic interface problems and obtained optimal order error estimate in the H^1 norm. More recently, in [16] the authors studied elliptic interface type problems by means of the finite element method and proved optimal rates of convergence when the global regularity of the solution is low.

In the present paper, we propose a finite element discretization for the parabolic interface problem (1.1)–(1.3) by allowing interface triangles to be curved triangles instead of straight triangles. The analysis presented shows that the finite element solutions approximate the true solutions with an optimal order even if the global regularity is very low. More precisely, for the spatially discrete scheme, optimal order error estimates are derived in L^2 and H^1 norms. The key to the present analysis is the introduction of some auxiliary projections and duality arguments. Further, the discontinuous Galerkin method is analyzed for the time discretization, and related error estimates are obtained. To the best of our knowledge, optimal error estimates using conforming finite element methods for the parabolic interface problem have not been established earlier.

The previous work on finite element analysis of elliptic and parabolic problems without interface can be found in [7], [8], [9], [12], [17], and references therein. For literature on the discontinuous Galerkin methods, we refer to [3], [11], [14], [15], and [17].

A brief outline of this paper is as follows. In section 2, we introduce some notation, recall some basic results from the literature, and obtain the a priori estimate for the solution. In section 3, we describe a finite element discretization for the problem (1.1)–(1.3) and prove some approximation properties related to the auxiliary projection used in our analysis. Section 4 is devoted to the error estimates for the spatially discrete scheme. Finally, the discontinuous Galerkin method is analyzed for the fully discrete scheme, and related error estimates are derived in section 5.

Throughout this paper, C denotes a generic positive constant that does not depend on the spatial and time discretization parameters h and k, respectively.

2. Preliminaries.

2.1. Basic notation. We shall use standard notation for Sobolev spaces and norms. For $m \geq 0$ and real p with $1 \leq p \leq \infty$, we use $W^{m,p}(\Omega)$ to denote a Sobolev space of order m with norm $\|.\|_m$ and, in particular, for $p = 2$, we write $W^{m,2}(\Omega) = H^m(\Omega) = H^m$. $H_0^m(\Omega)$ is a closed subspace of $H^m(\Omega)$, which is also a closure of $C_0^\infty(\Omega)$ (the set of all C^∞ functions with compact support) with respect to the norm of $H^m(\Omega)$. For a fractional number s, Sobolev space H^s is defined in [1]. For a given Banach space $\mathcal{B}$, we define for $m = 0, 1$,

$$H^m(0,T;\mathcal{B}) = \left(u(t) \in \mathcal{B} \text{ for a.e. } t \in (0,T) \text{ and } \sum_{j=0}^{m} \int_0^T \left\| \frac{\partial^j u(t)}{\partial t^j} \right\|_{\mathcal{B}}^2 dt < \infty \right)$$

equipped with the norm

$$\|u\|_{H^m(0,T;\mathcal{B})} = \left(\sum_{j=0}^{m} \int_0^T \left\| \frac{\partial^j u(t)}{\partial t^j} \right\|_{\mathcal{B}}^2 dt \right)^{\frac{1}{2}}.$$

We write $\|u\|_{H^1(\Omega)}^2 \equiv \|u\|_{H^1(\Omega_1)}^2 + \|u\|_{H^1(\Omega_2)}^2$ and $L^2(0,T;\mathcal{B}) = H^0(0,T;\mathcal{B})$.

In addition, we shall also work on the following spaces:

$$X = H^1(\Omega) \cap H^2(\Omega_1) \cap H^2(\Omega_2) \quad \text{and} \quad Y = L^2(\Omega) \cap H^1(\Omega_1) \cap H^1(\Omega_2)$$

equipped with the norms

$$\|v\|_X = \|v\|_{H^1(\Omega)} + \|v\|_{H^2(\Omega_1)} + \|v\|_{H^2(\Omega_2)}$$

and

$$\|v\|_Y = \|v\|_{L^2(\Omega)} + \|v\|_{H^1(\Omega_1)} + \|v\|_{H^1(\Omega_2)},$$

respectively.

In order to introduce the weak formulation of the problem, we now define the bilinear form $A(\cdot,\cdot) : H^1(\Omega) \times H^1(\Omega) \to \mathbb{R}$ by

$$A(u,v) = \int_\Omega \mathcal{A}\nabla u \cdot \nabla v dx \quad \forall u, v \in H^1(\Omega).$$

Then the weak formulation of the interface problem (1.1)–(1.3) is stated as follows. Find $u \in H_0^1(\Omega)$ such that

$$(u_t, v) + A(u,v) = (f,v) + \langle g, v\rangle_\Gamma \quad \forall v \in H_0^1(\Omega), \;\; t \in (0,T], \tag{2.1}$$

with $u(0) = u_0$. Here, $(\cdot,\cdot)$ and $\langle\cdot,\cdot\rangle$ are used to denote the inner products of the $L^2(\Omega)$ and $L^2(\Gamma)$ spaces, respectively.

2.2. A priori estimate. Due to the presence of discontinuous coefficients, the solution u, in general, does not belong to $H^2(\Omega)$. But one can expect higher local regularity of the solution when the coefficients are locally smoother (cf. [10]). In the theorem below, we prove the a priori estimate for the solution u of the interface problem (1.1)–(1.3) under appropriate regularity conditions on f and g.

THEOREM 2.1. *Let $f \in H^1(0,T;L^2(\Omega))$, $g \in H^1(0,T;H^{\frac{1}{2}}(\Gamma))$, and $u_0 \in H_0^1(\Omega)$. Then the problem (1.1)–(1.3) has a unique solution $u \in L^2(0,T;X) \cap H^1(0,T;Y)$. Further, u satisfies the a priori estimate*

$$\|u\|_{L^2(0,T;X)} \leq C\Big\{\|f\|_{L^2(0,T;L^2(\Omega))} + \|u_0\|_{H^1(\Omega)} + \|g(0)\|_{H^{\frac{1}{2}}(\Gamma)} + \|g(T)\|_{H^{\frac{1}{2}}(\Gamma)} + \|g\|_{H^1(0,T;H^{\frac{1}{2}}(\Gamma))}\Big\}. \tag{2.2}$$

Proof. The proof of the existence of a unique solution is in [10]. Next, to obtain the a priori estimate (2.2), we first transform the problem (1.1)–(1.3) into the following equivalent problem.

For a.e. $t \in (0,T]$, find $u = u(x,t) \in H_0^1(\Omega) \cap X$ satisfying

$$\begin{aligned} \mathcal{L}u &= f(x,t) - u_t \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega, \\ [u] = 0, \quad \left[\mathcal{A}\frac{\partial u}{\partial \mathbf{n}}\right] &= g(x,t) \quad \text{along } \Gamma. \end{aligned} \tag{2.3}$$

From the elliptic regularity estimate for the elliptic interface problem (cf. [5]), it follows that

$$\|u\|_X \leq C\left(\|f - u_t\|_{L^2(\Omega)} + \|g\|_{H^{\frac{1}{2}}(\Gamma)}\right). \tag{2.4}$$

Multiply both sides of (2.3) by u_t and then integrate over Ω to obtain

$$\|u_t\|^2_{L^2(\Omega)} + (\mathcal{L}u, u_t) = (f, u_t). \tag{2.5}$$

Note that $u \in H^1(0,T;X)$ and $[u] = 0$ on Γ imply $[u_t] = 0$ on Γ. Hence, an integration by parts leads to

$$\begin{aligned} (\mathcal{L}u, u_t) &= \int_{\Omega_1} \mathcal{A}_1 \nabla u \cdot \nabla u_t dx + \int_{\Omega_2} \mathcal{A}_2 \nabla u \cdot \nabla u_t dx + \int_\Gamma \left[\mathcal{A}\frac{\partial u}{\partial \mathbf{n}}\right] u_t dS \\ &= A^1(u, u_t) + A^2(u, u_t) + \langle g, u_t\rangle_\Gamma, \end{aligned} \tag{2.6}$$

where $A^l(.,.) : H^1(\Omega_l) \times H^1(\Omega_l) \to \mathbb{R}$ is given by

$$A^l(w, v) = \int_{\Omega_l} \mathcal{A}_l \nabla w \cdot \nabla v dx, \quad l = 1, 2.$$

Equation (2.5), together with (2.6), yields

$$\|u_t\|^2_{L^2(\Omega)} + \frac{1}{2}\frac{d}{dt}\left(\sum_{i=1}^2 A^i(u,u)\right) = (f, u_t) - \frac{d}{dt}\langle g, u\rangle_\Gamma + \langle g_t, u\rangle_\Gamma.$$

Integrate the above equation from 0 to T. Then apply the Cauchy–Schwarz inequality and the trace theorem (cf. [1]) to obtain

$$\begin{aligned}
&\int_0^T \|u_t\|^2_{L^2(\Omega)}ds + \|u(T)\|^2_{H^1(\Omega_1)} + \|u(T)\|^2_{H^1(\Omega_2)}\\
&\le C\left(\int_0^T \|f\|_{L^2(\Omega)}\|u_t\|_{L^2(\Omega)}ds\right.\\
&\qquad + \|g(T)\|_{L^2(\Gamma)}\|u(T)\|_{L^2(\Gamma)} + \|g(x,0)\|_{L^2(\Gamma)}\|u_0\|_{L^2(\Gamma)}\\
&\qquad \left. + \int_0^T \|g_t\|_{L^2(\Gamma)}\|u\|_{L^2(\Gamma)}ds + \|u_0\|^2_{H^1(\Omega_1)} + \|u_0\|^2_{H^1(\Omega_2)}\right)\\
&\le C\left(\int_0^T \|f\|_{L^2(\Omega)}\|u_t\|_{L^2(\Omega)}ds + \|g(T)\|_{H^{\frac{1}{2}}(\Gamma)}\|u(T)\|_{H^1(\Omega)}\right.\\
&\qquad \left. + \|g(x,0)\|_{H^{\frac{1}{2}}(\Gamma)}\|u_0\|_{H^1(\Omega)} + \int_0^T \|g_t\|_{H^{\frac{1}{2}}(\Gamma)}\|u\|_{H^1(\Omega)}ds + \|u_0\|^2_{H^1(\Omega)}\right).
\end{aligned}$$

Use a standard kickback argument to obtain

$$\begin{aligned}
&\|u_t\|^2_{L^2(0,T;L^2(\Omega))} + \|u(T)\|^2_{H^1(\Omega)}\\
&\le C\left(\int_0^T \|f\|^2_{L^2(\Omega)}ds + \|g(T)\|^2_{H^{\frac{1}{2}}(\Gamma)}\right.\\
&\qquad \left. + \|g(0)\|^2_{H^{\frac{1}{2}}(\Gamma)} + \int_0^T \|g_t\|^2_{H^{\frac{1}{2}}(\Gamma)}ds + \|u_0\|^2_{H^1(\Omega)}\right)\\
&\quad + C\int_0^T \|u(s)\|^2_{H^1(\Omega)}ds.
\end{aligned}$$

Finally, an application of Gronwall's lemma completes the proof. □

3. Finite element discretization and some auxiliary results. In this section, we shall describe a finite element discretization, introduce some auxiliary projections, and prove their approximation properties.

For the purpose of finite element approximation we now describe the triangulation of Ω as follows: Let $\mathcal{T}_h$ be a triangulation of Ω with mesh parameter h, $0 < h < 1$. We first approximate the domain Ω_1 by a domain Ω_1^h with the polygonal boundary Γ_h whose vertices all lie on the interface Γ. Let Ω_2^h be the approximation for the domain Ω_2 with polygonal exterior $\partial\Omega_2^h$ and interior boundary Γ_h. Further, let $\{P_j\}_{j=1}^{m_h}$ be the set of all nodes of the triangulation $\mathcal{T}_h$ lying on the interface Γ, and let $\{e_j\}(j = 1, \ldots, m_h)$ be the edge connecting the two neighboring points P_j and P_{j+1} such that $P_{m_h+1} = P_1$. Let $\mathcal{T}_h^*$ be a triangulation obtained with a modification of $\mathcal{T}_h$. $\mathcal{T}_h^*$ is obtained by changing those triangles of $\mathcal{T}_h$ having one e_j edge (for some $1 \le j \le m_h$) into curved triangles having two original edges unchanged but having their third edge e_j replaced with the curved segment (cf. Figure 2). The element $K \in \mathcal{T}_h^*$ with one curved edge along the interface Γ is called the interface curved triangle.

Triangulation $\mathcal{T}_h^*$ of the domain Ω satisfies the following conditions:

($\mathcal{A}1$) $\overline{\Omega} = \cup_{K\in\mathcal{T}_h^*}K$.

($\mathcal{A}2$) If K_1, $K_2 \in \mathcal{T}_h^*$, and $K_1 \ne K_2$, then either $K_1 \cap K_2 = \emptyset$ or $K_1 \cap K_2$ is a common vertex, or edge, or one curved edge of both triangles.

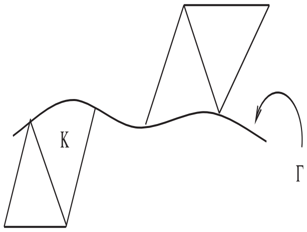

FIG. 2. *Interface curved triangle K.*

($\mathcal{A}3$) Each interface triangle K intersects Γ (interface) in at most two vertices and has at most one curved edge.

($\mathcal{A}4$) For each triangle $K \in \mathcal{T}_h^*$, let r_K, $\overline{r}_K$ be the radii of its inscribed and circumscribed circles, respectively. Let $h = \max\{\overline{r}_K : K \in \mathcal{T}_h^*\}$. We assume that, for some fixed $h_0 > 0$, there exists two positive constants C_0 and C_1 independent of h such that

$$C_0 h \leq diam(K) \leq C_1 h \quad \forall K \in \mathcal{T}_h^*, \quad \forall h \in (0, h_0).$$

Assumption ($\mathcal{A}4$) allows us to relate L^2 and H^1 norms of the polynomials in each element of $\mathcal{T}_h^*$ by

$$\|v\|_{H^1(K)} \leq Ch^{-1}\|v\|_{L^2(K)} \quad \forall K \in \mathcal{T}_h^* \tag{3.1}$$

for any polynomial $v \in P_1(K)$ (cf. [4, Lem. 4.5.3]).

Let V_h be a family of finite element subspaces of $H_0^1(\Omega)$ defined on $\mathcal{T}_h^*$ consisting of piecewise linear polynomials vanishing on the boundary $\partial\Omega$. Note that the construction of such finite element spaces is not straightforward. We refer to [13] for the construction and examples of various types of finite element spaces V_h.

Further, we assume that V_h satisfy the inverse estimate

$$\|\phi\|_{H^1(\Omega)} \leq Ch^{-1}\|\phi\|_{L^2(\Omega)} \quad \forall\, \phi \in V_h, \tag{3.2}$$

and this follows immediately from the estimate (3.1).

For $v \in X$, let

$$f^* = -\nabla \cdot (\mathcal{A}_l \nabla v) \quad \text{in } \Omega_l,\ l = 1, 2.$$

We now define an operator $R_h : X \cap H_0^1(\Omega) \to V_h$ by

$$A(R_h v, \phi) = (f^*, \phi) \quad \forall \phi \in V_h,\ v \in X \cap H_0^1(\Omega). \tag{3.3}$$

It now follows from the definition of f^* that

$$(f^*, \phi) = A(v, \phi) \quad \forall \phi \in V_h,\ v \in X \cap H_0^1(\Omega) \tag{3.4}$$

which, together with (3.3), yields

$$A(R_h v, \phi) = (f^*, \phi) = A(v, \phi) \quad \forall \phi \in V_h,\ v \in X \cap H_0^1(\Omega). \tag{3.5}$$

Below, we present a proof that shows optimal error bounds for the projection operator R_h. This lemma is very crucial for our later analysis.

LEMMA 3.1. *Let R_h be defined by* (3.5). *Then there is a positive constant C independent of h such that*

$$\|v - R_h v\| + h\|v - R_h v\|_1 \le Ch^2 \|v\|_X \quad \forall v \in X \cap H_0^1(\Omega).$$

Proof. By the definition of f^*, it is easy to see that

$$A(v, \phi) = (f^*, \phi) \quad \forall \phi \in H_0^1(\Omega). \tag{3.6}$$

For $k = 1, 2$, define $f_k : \Omega \to \mathbb{R}$ by

$$f_k = \begin{cases} f^*|_{\Omega_k} & \text{in } \Omega_k, \\ 0 & \text{otherwise.} \end{cases}$$

Clearly, $f_k \in L^2(\Omega)$ and $f^* = f_1 + f_2$ a.e. in Ω. We now consider the following interface problems: Let $w_k \in H_0^1(\Omega)$ be the solution of the interface problem

$$A(w_k, \phi) = (f_k, \phi) \quad \forall \phi \in H_0^1(\Omega). \tag{3.7}$$

Then by the coercivity of the operator A it follows immediately that $v = w_1 + w_2$.

Let $w_h^k \in V_h$ be the finite element approximation to w_k defined by

$$A(w_h^k, \phi) = (f_k, \phi) \quad \forall \phi \in V_h. \tag{3.8}$$

Again by the coercivity of the operator A and definition (3.5) of the R_h operator, it follows that $R_h v = w_h^1 + w_h^2$.

Since $f_k|_{\Omega_s} = 0$, $s = 1(2)$ if $k = 2(1)$, we have for the elliptic interface problem (3.7)–(3.8) (see [13, Thm. 6.1])

$$\begin{aligned} \|w_k - w_h^k\|_{H^1(\Omega)} &\le Ch(\|w_k\|_{H^2(\Omega_1)} + \|w_k\|_{H^2(\Omega_2)}) \\ &\le Ch\|w_k\|_X. \end{aligned} \tag{3.9}$$

Then by the elliptic regularity (cf. [5]) we have

$$\begin{aligned} \|w_k\|_X &\le C\|f_k\|_{L^2(\Omega)} \\ &\le C\|f^*\|_{L^2(\Omega_k)} \le C\|v\|_{H^2(\Omega_k)}. \end{aligned}$$

This, together with (3.9), yields

$$\|w_k - w_h^k\|_{H^1(\Omega)} \le Ch\|v\|_{H^2(\Omega_k)}. \tag{3.10}$$

Then

$$\begin{aligned} \|v - R_h v\|_{H^1(\Omega)} &\le \|w_1 - w_h^1\|_{H^1(\Omega)} + \|w_2 - w_h^2\|_{H^1(\Omega)} \\ &\le C\,(h\|w_1\|_X + h\|w_2\|_X) \\ &\le Ch\left(\|v\|_{H^2(\Omega_1)} + \|v\|_{H^2(\Omega_2)}\right) \\ &\le Ch\|v\|_X \quad \forall v \in X \cap H_0^1(\Omega). \end{aligned} \tag{3.11}$$

For the L^2 norm estimate, let us consider the following problem: Find $w \in H_0^1(\Omega)$ such that

$$A(w, \phi) = (v - R_h v, \phi) \quad \forall \phi \in H_0^1(\Omega). \tag{3.12}$$

By setting $\phi = v - R_h v \in H_0^1(\Omega)$ in (3.12) and using definition (3.5) of the R_h operator, we have

$$\begin{aligned}\|v - R_h v\|^2_{L^2(\Omega)} &= A(w, v - R_h v)\\ &= A(w - R_h w, v - R_h v) + A(R_h w, v - R_h v)\\ &= A(w - R_h w, v - R_h v)\\ &\le C\|w - R_h w\|_{H^1(\Omega)}\|v - R_h v\|_{H^1(\Omega)}\\ &\le Ch^2\|v\|_X\|w\|_X;\end{aligned}$$

in the last inequality, we used (3.11). Then applying the elliptic regularity estimate for the interface problem (3.12), we get

$$\begin{aligned}\|v - R_h v\|^2_{L^2(\Omega)} &\le Ch^2\|v\|_X\|w\|_X\\ &\le Ch^2\|v - R_h v\|_{L^2(\Omega)}\|v\|_X.\end{aligned}$$

This completes the proof of Lemma 3.1. □

Let $L_h : L^2(\Omega) \to V_h$ be the standard L^2 projection defined by

$$(L_h v, \phi) = (v, \phi) \quad \forall v \in L^2(\Omega), \ \ \phi \in V_h, \tag{3.13}$$

satisfying the stability estimate

$$\|L_h v\|_{H^1(\Omega)} \le C\|v\|_{H^1(\Omega)} \quad \forall v \in H_0^1(\Omega). \tag{3.14}$$

It is well known that $L_h v \in V_h$ is the best approximation in the L^2 norm to $v \in L^2(\Omega)$. The following lemma shows that $L_h v$ is a quasi-best approximation to $v \in H_0^1(\Omega) \cap X$ in the H^1 norm.

Lemma 3.2. *Let R_h and L_h be defined by* (3.5) *and* (3.13)*, respectively. Then we have*

$$\|L_h v - v\|_{H^1(\Omega)} \le C\|R_h v - v\|_{H^1(\Omega)} \quad \forall v \in H_0^1(\Omega) \cap X.$$

Proof. For any $v \in H_0^1(\Omega) \cap X$, we know that there exists a unique solution $w \in H_0^1(\Omega)$ for the elliptic interface problem

$$A(w, \phi) = (R_h v - v, \phi) \quad \forall \phi \in H_0^1(\Omega). \tag{3.15}$$

Equation (3.15), together with (3.5) and Lemma 3.1, leads to

$$\begin{aligned}\|R_h v - v\|^2_{L^2(\Omega)} &= A(w - R_h w, R_h v - v) + A(R_h w, R_h v - v)\\ &\le C\|w - R_h w\|_{H^1(\Omega)}\|v - R_h v\|_{H^1(\Omega)}\\ &\le Ch\|w\|_X\|v - R_h v\|_{H^1(\Omega)}\\ &\le Ch\|v - R_h v\|_{L^2(\Omega)}\|v - R_h v\|_{H^1(\Omega)}.\end{aligned}\tag{3.16}$$

Here we used the fact that $\|w\|_X \le C\|v - R_h v\|_{L^2(\Omega)}$. Use of the triangle inequality and (3.2) yields

$$\begin{aligned}\|L_h v - v\|_{H^1(\Omega)} &\le \|R_h v - v\|_{H^1(\Omega)} + \|L_h v - R_h v\|_{H^1(\Omega)}\\ &\le \|R_h v - v\|_{H^1(\Omega)} + Ch^{-1}\|L_h v - R_h v\|_{L^2(\Omega)}\\ &\le \|R_h v - v\|_{H^1(\Omega)} + Ch^{-1}\{\|v - R_h v\|_{L^2(\Omega)} + \|L_h v - v\|_{L^2(\Omega)}\}.\end{aligned}\tag{3.17}$$

We know $L_h v$ is the best approximation of $v \in L^2(\Omega)$ with respect to the L^2 norm. Since $v \in X \cap H_0^1(\Omega)$, $R_h v \in V_h$. Thus, $\|v - L_h v\|_{L^2(\Omega)} \le C\|v - R_h v\|_{L^2(\Omega)}$. Therefore, (3.17) implies

$$\|L_h v - v\|_{H^1(\Omega)} \le \|R_h v - v\|_{H^1(\Omega)} + Ch^{-1}\|v - R_h v\|_{L^2(\Omega)}. \tag{3.18}$$

The desired estimate now follows from (3.16) and (3.18). □

4. The continuous time Galerkin approximation. This section deals with the error analysis for the spatially discrete scheme. Optimal order of convergence in both L^2 and H^1 norms is established when the global regularity of the solution is low on the entire domain.

The continuous time Galerkin finite element approximation to (2.1) is stated as follows: Find $u_h(t) \in V_h$ such that

$$(u_{ht}, v_h) + A(u_h, v_h) = (f, v_h) + \langle g, v_h\rangle_\Gamma \quad \forall v_h \in V_h, \quad t \in (0, T], \tag{4.1}$$

with $u_h(0) = L_h u_0$. Subtracting (4.1) from (2.1) we have

$$(u_t - u_{ht}, v_h) + A(u - u_h, v_h) = 0 \quad \forall v_h \in V_h. \tag{4.2}$$

Define the error $e(t)$ as $e(t) = u(t) - u_h(t)$. Setting $v_h = L_h u$ in (4.2) and using (3.13), we obtain

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}\|e\|^2_{L^2(\Omega)} &+ A(e, e)\\
&= A(u - u_h, u - L_h u) + (u_t - u_{ht}, u - L_h u)\\
&= A(u - u_h, u - L_h u) + (u_t - L_h u_t, u - L_h u)\\
&\quad + (L_h u_t - u_{ht}, u - L_h u)\\
&= A(u - u_h, u - L_h u) + (u_t - (L_h u)_t, u - L_h u)\\
&\quad + (L_h u_t - u_{ht}, u - L_h u)\\
&= A(u - u_h, u - L_h u) + \frac{1}{2}\frac{d}{dt}(u - L_h u, u - L_h u).
\end{aligned} \tag{4.3}$$

In the last equality we used the fact that $L_h u_t - u_{ht} \in V_h$ and the definition (3.13) of the L_h operator. Integrate the above equation from 0 to t. Then apply the Cauchy–Schwarz inequality and Young's inequality to obtain

$$\begin{aligned}
\|e\|^2_{L^2(\Omega)} &+ \int_0^t \|e\|^2_{H^1(\Omega)} ds\\
&\le C\left(\int_0^t \|u - L_h u\|^2_{H^1(\Omega)} ds + \|u - L_h u\|^2_{L^2(\Omega)} + \|u_0 - L_h u_0\|^2_{L^2(\Omega)}\right).
\end{aligned}$$

An application of Lemma 3.2 leads to

$$\begin{aligned}
\|e\|^2_{L^2(\Omega)} &+ \int_0^t \|e\|^2_{H^1(\Omega)} ds\\
&\le C\left(\int_0^t \|u - R_h u\|^2_{H^1(\Omega)} ds + \|u - L_h u\|^2_{L^2(\Omega)} + \|u_0 - L_h u_0\|^2_{L^2(\Omega)}\right),
\end{aligned}$$

which, together with Lemma 3.1 and the fact $\|L_h v - v\|_{L^2(\Omega)} \le Ch\|v\|_{H^1(\Omega)} \forall v \in H^1_0(\Omega)$ yields

$$\int_0^t \|e\|^2_{H^1(\Omega)} ds \le h^2 \left\{\|u_0\|^2_{H^1(\Omega)} + \|u\|^2_X + \|u\|^2_{L^2(0,T;X)}\right\}.$$

Thus we have proved the following optimal H^1 norm estimate.

THEOREM 4.1. *Let u and u_h be the solutions of the problem* (1.1)–(1.3) *and* (4.1), *respectively. Then, for $u_0 \in H^1_0(\Omega)$, $f \in H^1(0, T; L^2(\Omega))$, and $g \in H^1(0, T; H^{\frac{1}{2}}(\Gamma))$, we have*

$$\|u - u_h\|_{L^2(0,T;H^1(\Omega))} \le Ch\left\{\|u_0\|_{H^1(\Omega)} + \|u\|_X + \|u\|_{L^2(0,T;X)}\right\}.$$

Next, for the L^2 norm error estimate, we shall use the duality argument. For this purpose, we now consider the following auxiliary problem: Find $z \in H_0^1(\Omega)$ such that

$$A(z, v) = (u - u_h, v) \quad \forall v \in H_0^1(\Omega), \quad t \in (0, T], \tag{4.4}$$

with $[\mathcal{A}\frac{\partial z}{\partial \mathbf{n}}] = 0$ across the interface Γ. Then its finite element approximation is defined to be a function $z_h \in V_h$ satisfying

$$A(z_h, v_h) = (u - u_h, v_h) \quad \forall v_h \in V_h, \quad t \in (0, T]. \tag{4.5}$$

Setting $v = u - u_h$ in (4.4) and using (4.2), we obtain

$$\begin{aligned} \|u - u_h\|^2_{L^2(\Omega)} &= A(z, u - u_h) \\ &= A(z - z_h, u - u_h) + A(z_h, u - u_h) \\ &= A(z - z_h, u - u_h) - (u_t - u_{ht}, z_h). \end{aligned} \tag{4.6}$$

Differentiating (4.5) with respect to t, we obtain

$$A(z_{ht}, v_h) = (u_t - u_{ht}, v_h).$$

Thus, we have

$$\frac{1}{2}\frac{d}{dt}A(z_h, z_h) = A(z_{ht}, z_h) = (u_t - u_{ht}, z_h),$$

and hence, integrating (4.6) from 0 to T we obtain

$$\begin{aligned} &\|u - u_h\|^2_{L^2(0,T;L^2(\Omega))} + \frac{1}{2}A(z_h, z_h) \\ &\leq C\int_0^T \|z - z_h\|_{H^1(\Omega)}\|u - u_h\|_{H^1(\Omega)}ds + \frac{1}{2}A(z_h(0), z_h(0)). \end{aligned}$$

Further, using the regularity estimate for the elliptic interface problem (4.4)–(4.5) and Lemma 3.1, we obtain

$$\begin{aligned} \|z - z_h\|_{H^1(\Omega)} &\leq C\|z - R_h z\|_{H^1(\Omega)} \\ &\leq Ch\|z\|_X \\ &\leq Ch\|u - u_h\|_{L^2(\Omega)}, \end{aligned}$$

and hence

$$\begin{aligned} &\|u - u_h\|^2_{L^2(0,T;L^2(\Omega))} \\ &\leq C\int_0^T h\|u - u_h\|_{L^2(\Omega)}\|u - u_h\|_{H^1(\Omega)}ds + \frac{1}{2}A(z_h(0), z_h(0)). \end{aligned} \tag{4.7}$$

Taking $t \to 0$, it now follows from (4.5) that

$$A(z_h(0), z_h(0)) = (u_0 - L_h u_0, z_h(0)) = 0.$$

This, together with (4.7) and Theorem 4.1, leads to

$$\begin{aligned} &\|u - u_h\|^2_{L^2(0,T;L^2(\Omega))} \\ &\leq Ch\left(\int_0^T \|u - u_h\|^2_{L^2(\Omega)}ds\right)^{\frac{1}{2}}\left(\int_0^T \|u - u_h\|^2_{H^1(\Omega)}ds\right)^{\frac{1}{2}} \\ &\leq Ch^2\|u - u_h\|_{L^2(0,T;L^2(\Omega))}\left\{\|u_0\|_{H^1(\Omega)} + \|u\|_X + \|u\|_{L^2(0,T;X)}\right\}. \end{aligned}$$

Thus we have proved the following optimal L^2 norm estimate.

THEOREM 4.2. *Let u and u_h be the solutions of the problems* (1.1)–(1.3) *and* (4.1), *respectively. Then, for $u_0 \in H_0^1(\Omega)$, $f \in H^1(0,T;L^2(\Omega))$, $g \in H^1(0,T;H^{\frac{1}{2}}(\Gamma))$, we have*

$$\|u-u_h\|_{L^2(0,T;L^2(\Omega))} \leq Ch^2 \left\{ \|u_0\|_{H^1(\Omega)} + \|u\|_X + \|u\|_{L^2(0,T;X)} \right\}.$$

Remark 4.1. Note that Theorems 4.1 and 4.2 yield an optimal order of convergence, assuming that the interface triangles are curved instead of straight. In contrast to [5] we do not require the interface function $g \in C(\Gamma)$, but $g \in H^1(0,T;H^{1/2}(\Gamma))$ suffices for the present analysis.

5. Discrete time discontinuous Galerkin method. In this section, we apply the discontinuous Galerkin method in the direction of the time variable. In this method an approximation to the solution is sought as a piecewise constant polynomial function in t, which is not necessarily continuous at the nodes of the defining partition.

We first divide the interval $[0,T]$ into M equally spaced subintervals by the points

$$0 = t_0 < t_1 < \cdots < t_M = T$$

with $t_n = nk$, $k = T/M$ being the time step. Let $I_n = (t_{n-1}, t_n]$ be the nth subinterval. In order to discretize (2.1) in time, we shall use the finite dimensional space

$$V_{hk} = \{\phi : [0,T] \to V_h \ : \phi|_{I_n} \in V_h \text{ is constant in time}\}.$$

For $\phi \in V_{hk}$, we denote ϕ^n and ϕ_+^n to be the value of ϕ and its limit from the above at t_n, respectively. Further, we write V_{hk}^n for the restriction to I_n of the functions in V_{hk}.

Remark 5.1. The functions belonging to V_{hk} need not be continuous at the nodes but are taken to be continuous to the left there.

Now we introduce the backward difference quotient

$$\Delta_k \phi^n = \frac{\phi^n - \phi^{n-1}}{k}$$

for a given sequence $\{\phi^n\}_{n=0}^M \subset L^2(\Omega)$. For a given Banach space $\mathcal{B}$ and some function $\xi \in L^2(0,T;\mathcal{B})$, we write

$$\overline{\xi}^{\,n} = k^{-1} \int_{I_n} \xi(x,t)dt. \tag{5.1}$$

The fully discrete finite element approximation to the problem (2.1) is defined as follows: Find $U^n \in V_{hk}$, for $n = 1, 2, \ldots, M$, such that

$$(\Delta_k U^n, v_h) + A(U^n, v_h) = (\overline{f}^{\,n}, v_h) + \langle \overline{g}^{\,n}, v_h \rangle_\Gamma \quad \forall v_h \in V_{hk}^n \tag{5.2}$$

with $U^0 = R_h u_0$ and $\overline{f}^{\,n}$ defined as in (5.1).

Below we prove the stability result for the solution U^n satisfying (5.2).

LEMMA 5.1. *Let U^n be satisfy* (5.2). *Then we have*

$$\|U^M\|_{L^2(\Omega)}^2 + \sum_{n=1}^M k\|U^n\|_{H^1(\Omega)}^2 \leq C\left(\|f\|_{L^2(0,T;L^2(\Omega))}^2 + \|u_0\|_{H^1(\Omega)}^2 + \|g\|_{L^2(0,T;H^{\frac{1}{2}}(\Gamma))}^2 \right).$$

Proof. Setting $v_h = U^n$ in (5.2) and then using the Cauchy–Schwarz inequality we obtain

$$\begin{aligned}\|U^n\|^2_{L^2(\Omega)} &+ k\|U^n\|^2_{H^1(\Omega)}\\ &\le k(\overline{f}^{\,n}, U^n) + k\langle\overline{g}^{\,n}, U^n\rangle_\Gamma + (U^{n-1}, U^n)\\ &\le k\|\overline{f}^{\,n}\|_{L^2(\Omega)}\|U^n\|_{L^2(\Omega)} + k\|\overline{g}^{\,n}\|_{L^2(\Gamma)}\|U^n\|_{L^2(\Gamma)}\\ &\qquad + \|U^{n-1}\|_{L^2(\Omega)}\|U^n\|_{L^2(\Omega)}.\end{aligned}$$

Applying Young's inequality, summing over n from $n = 1$ to $n = M$, and noting that $\|R_h u_0\|_{H^1(\Omega)} \le C\|u_0\|_{H^1(\Omega)}$, we obtain

$$\begin{aligned}\|U^M\|^2_{L^2(\Omega)} &+ \sum_{n=1}^{M} k\|U^n\|^2_{H^1(\Omega)}\\ &\le C\left(\|u_0\|^2_{H^1(\Omega)} + \sum_{n=1}^{M} k\|\overline{f}^{\,n}\|^2_{L^2(\Omega)} + \sum_{n=1}^{M} k\|\overline{g}^{\,n}\|^2_{L^2(\Gamma)}\right).\end{aligned}$$

It follows from simple calculation that

$$\sum_{n=1}^{M} k\|\overline{f}^{\,n}\|^2_{L^2(\Omega)} \le C\|f\|^2_{L^2(0,T;L^2(\Omega))} \quad \text{and} \quad \sum_{n=1}^{M} k\|\overline{g}^{\,n}\|^2_{L^2(\Gamma)} \le C\|g\|^2_{L^2(0,T;H^{\frac{1}{2}}(\Gamma))}.$$

Altogether these estimates lead to the desired result and complete the proof. □

Now we introduce the interpolant $P_k \in V_{hk}$ of u defined by

$$\begin{aligned}\int_{I_n} A(P_k - u, \phi)\, ds &= 0 \quad \forall \phi \in V_{hk},\\ \text{i.e. } P_k|_{I_n} &= k^{-1}\int_{I_n} R_h u ds\\ &= \overline{P}_k^{\,n}.\end{aligned} \tag{5.3}$$

It is easy to notice from Lemma 3.1 that

$$\left(\sum_{n=1}^{M} k\|\overline{u}^{\,n} - \overline{P}_k^{\,n}\|^2_{H^m(\Omega)}\right)^{\frac{1}{2}} \le Ch^{2-m}\|u\|_{L^2(0,T;X)}, \quad m = 0, 1. \tag{5.4}$$

Now we state the main results of this section in the following theorems.

THEOREM 5.2. *Let u and U be the solutions of* (1.1)–(1.3) *and* (5.2), *respectively. Then, for $u_0 \in X \cap H^1_0(\Omega)$, $f \in H^1(0,T;L^2(\Omega))$, and $g \in H^1(0,T;H^{\frac{1}{2}}(\Gamma))$, there exists a constant C independent of h and k such that*

$$\|u - U\|_{L^2(0,T;L^2(\Omega))} \le C(k + h^2)\left\{\|u_0\|_X + \|u\|_{L^2(0,T;X)} + \|u_t\|_{L^2(0,T;L^2(\Omega))}\right\}.$$

THEOREM 5.3. *Let u and U be the solutions of* (1.1)–(1.3) *and* (5.2), *respectively. Then, for $u_0 \in X \cap H^1_0(\Omega)$, $f \in H^1(0,T;L^2(\Omega))$, and $g \in H^1(0,T;H^{\frac{1}{2}}(\Gamma))$, there exists a positive constant C independent of h and k such that*

$$\|u - U\|_{L^2(0,T;H^1(\Omega))} \le C(k + h)\left\{\|u_0\|_X + \|u\|_{L^2(0,T;X)} + \|u_t\|_{L^2(0,T;Y)}\right\}.$$

The proofs of the above theorems require some preparation. We now appeal to the parabolic duality arguments. Consider the following auxiliary problem: Find $z^n \in V_{hk}$ such that

$$(5.5)\qquad (-\nabla_k z^n, v_h) + A(z_+^{n-1}, v_h) = (\overline{u}^{\,n} - U^n, v_h) \quad \forall v_h \in V_{hk}^n,\ 1 \le n \le M,$$

with $z_+^M = 0$, $\nabla_k z^n = \frac{z_+^n - z_+^{n-1}}{k}$. The following stability result of the solution z^n of (5.5) is very crucial for the convergence analysis.

LEMMA 5.4. *Let z^n be the solution of* (5.5). *Then we have*

$$\sum_{n=1}^{M} k\|\nabla_k z^n\|_{L^2(\Omega)}^2 + \|z_+^0\|_{H^1(\Omega)}^2 \le C \sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|_{L^2(\Omega)}^2.$$

Proof. Taking $v_h = -k\nabla_k z^n$ in (5.5) and applying the Cauchy–Schwarz inequality, we obtain

$$(5.6)\qquad k\|\nabla_k z^n\|_{L^2(\Omega)}^2 + A(z_+^{n-1}, z_+^{n-1} - z_+^n) \le Ck\|\overline{u}^{\,n} - U^n\|_{L^2(\Omega)}^2.$$

It is easy to notice that

$$A(z_+^{n-1}, z_+^{n-1} - z_+^n) = \frac{k^2}{2} A(\nabla_k z^n, \nabla_k z^n) - \frac{1}{2} A(z_+^n, z_+^n) + \frac{1}{2} A(z_+^{n-1}, z_+^{n-1}).$$

This, combined with (5.6), yields

$$k\|\nabla_k z^n\|_{L^2(\Omega)}^2 + \frac{k^2}{2} A(\nabla_k z^n, \nabla_k z^n) - \frac{1}{2} A(z_+^n, z_+^n) + \frac{1}{2} A(z_+^{n-1}, z_+^{n-1}) \le Ck\|\overline{u}^{\,n} - U^n\|_{L^2(\Omega)}^2.$$

Summing over n from $n = 1$ to $n = M$, we obtain

$$\sum_{n=1}^{M} k\|\nabla_k z^n\|_{L^2(\Omega)}^2 + A(z_+^0, z_+^0) \le \sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|_{L^2(\Omega)}^2.$$

This completes the proof. □

Proof of Theorem 5.2. Choose $v_h = k(\overline{P}_k^{\,n} - U^n) \in V_{hk}^n$ in (5.5). Observing that $A(z_+^{n-1}, \overline{P}_k^{\,n}) = A(z_+^{n-1}, \overline{u}^{\,n})$, we have

$$\begin{aligned}
&k\|\overline{u}^{\,n} - U^n\|_{L^2(\Omega)}^2 \\
&= k(\overline{u}^{\,n} - U^n, \overline{u}^{\,n} - \overline{P}_k^{\,n}) + k(-\nabla_k z^n, \overline{P}_k^{\,n} - U^n) + kA(z_+^{n-1}, \overline{P}_k^{\,n} - U^n) \\
&= k(\overline{u}^{\,n} - U^n, \overline{u}^{\,n} - \overline{P}_k^{\,n}) + k(-\nabla_k z^n, \overline{P}_k^{\,n} - U^n) + kA(z_+^{n-1}, \overline{u}^{\,n} - U^n) \\
&= k(\overline{u}^{\,n} - \overline{P}_k^{\,n}, \overline{u}^{\,n} - U^n) + k(-\nabla_k z^n, \overline{P}_k^{\,n} - u^n) \\
(5.7)\quad &+ k(-\nabla_k z^n, u^n - U^n) + kA(z_+^{n-1}, \overline{u}^{\,n} - U^n).
\end{aligned}$$

Now summing over n from $n=1$ to $n=M$, we obtain

$$\begin{aligned}\sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|^2_{L^2(\Omega)} &= \sum_{n=1}^{M}\Big\{k(\overline{u}^{\,n} - \overline{P}_k^{\,n}, \overline{u}^{\,n} - U^n)\Big\}\\ &\quad + \sum_{n=1}^{M}\Big\{k(-\nabla_k z^n, \overline{P}_k^{\,n} - u^n)\Big\}\\ &\quad + \sum_{n=1}^{M} k\left\{(-\nabla_k z^n, u^n - U^n) + A(z_+^{n-1}, \overline{u}^{\,n} - U^n)\right\}\\ &=: I_1 + I_2 + I_3. \end{aligned}\tag{5.8}$$

Before estimating the three terms in (5.8), we first rewrite the term I_3. Note that for all $v \in H_0^1(\Omega)$, we have

$$(\Delta_k u^n, v) + A(\overline{u}^{\,n}, v) = (\overline{f}^{\,n}, v) + \langle \overline{g}^{\,n}, v\rangle_\Gamma, \quad 1 \le n \le M. \tag{5.9}$$

Now, taking $v_h = v = z_+^{n-1}$ in both (5.2) and (5.9), subtracting one from the other, and summing the resulting equation over n, we obtain

$$\sum_{n=1}^{M} k\left\{(\Delta_k(u^n - U^n), z_+^{n-1}) + A(\overline{u}^{\,n} - U^n, z_+^{n-1})\right\} = 0 \tag{5.10}$$

which, together with (5.8), yields

$$\begin{aligned}&\sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|^2_{L^2(\Omega)}\\ &= I_1 + I_2 + \sum_{n=1}^{M} k\bigg((-\nabla_k z^n, u^n - U^n) + (-\Delta_k(u^n - U^n), z_+^{n-1})\bigg)\\ &=: I_1 + I_2 + I_4.\end{aligned}\tag{5.11}$$

Using the fact that $z_+^M = 0$, and applying the identity

$$\sum_{n=1}^{M}(a_n - a_{n-1})b_n = a_M b_M - a_0 b_0 - \sum_{n=1}^{M} a_{n-1}(b_n - b_{n-1})$$

to I_4 with $a_n = z_+^n$ and $b_n = u^n - U^n$, we obtain

$$\begin{aligned} I_4 &= \sum_{n=1}^{M} k\left\{(-\nabla_k z^n, u^n - U^n) + (-\Delta_k(u^n - U^n), z_+^{n-1})\right\}\\ &= (z_+^0, u_0 - R_h u_0).\end{aligned}\tag{5.12}$$

Using (5.4) and the Cauchy–Schwarz inequality, it now follows that

$$\begin{aligned}|I_1| &\le \left(\sum_{n=1}^{M} k\|\overline{u}^{\,n} - \overline{P}_k^{\,n}\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}} \left(\sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}}\\ &\le Ch^2\|u\|_{L^2(0,T;X)} \left(\sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}}.\end{aligned}\tag{5.13}$$

Similarly, for I_2, use of (5.4) and Lemma 5.4 leads to

$$\begin{aligned}|I_2| &\le C\left(\sum_{n=1}^{M} k\|\nabla_k z^n\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}} \\ &\quad\times\left[\left(\sum_{n=1}^{M} k\|\overline{P}_k{}^n - \overline{u}^{\,n}\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}} + \left(\sum_{n=1}^{M} k\|\overline{u}^{\,n} - u^n\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}}\right] \\ &\le C(k+h^2)\left(\|u\|^2_{L^2(0,T;X)} + \|u_t\|^2_{L^2(0,T;L^2(\Omega))}\right)^{\frac{1}{2}}\left(\sum_{n=1}^{M} k\|\nabla_k z^n\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}} \\ &\le C(k+h^2)\left(\|u\|^2_{L^2(0,T;X)} + \|u_t\|^2_{L^2(0,T;L^2(\Omega))}\right)^{\frac{1}{2}} \\ &\quad\times\left(\sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}}. \qquad (5.14)\end{aligned}$$

Finally, using Lemmas 3.1 and 5.4, the term I_4 is estimated as

$$\begin{aligned}|I_4| &\le \|z_+^0\|_{H^1(\Omega)}\|u_0 - R_h u_0\|_{L^2(\Omega)} \\ &\le h^2\|u_0\|_X\left(\sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}}. \qquad (5.15)\end{aligned}$$

By simple calculation, it follows that

$$\begin{aligned}\|u-U\|_{L^2(0,T;L^2(\Omega))} &\le Ck\|u_t\|_{L^2(0,T;L^2(\Omega))} \\ &\quad + C\left(\sum_{n=1}^{M} k\|\overline{u}^{\,n} - U^n\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}}, \qquad (5.16)\end{aligned}$$

and hence, the desired result now follows from (5.11) and the estimates (5.13)–(5.16). This completes the proof. □

For the H^1 norm estimate, as for the L^2 norm, we analyze the following auxiliary discrete problem: For $1 \le n \le M$, find $w^n \in V_{hk}$ such that

$$(-\nabla_k w^n, v_h) + A(w_+^{n-1}, v_h) = (\nabla(\overline{u}^{\,n} - U^n), \nabla v_h) \quad \forall v_h \in V_{hk}^n, \qquad (5.17)$$

with $w_+^M = 0$. Applying the standard arguments (cf. [5]) and (3.14), we have the following stability result of the solution w satisfying (5.17). This stability result is crucial for the H^1 norm estimate.

LEMMA 5.5. *Let w^n satisfy* (5.17). *Then the following stability results hold:*

$$\max_{1\le n\le M}\|w_+^{n-1}\|^2_{L^2(\Omega)} + \sum_{n=1}^{M} k\|w^{n-1}\|^2_{H^1(\Omega)} \le \sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - U^n)\|^2_{L^2(\Omega)}$$

and

$$\sum_{n=1}^{M} k\|\nabla_k w^n\|^2_{H^{-1}(\Omega)} \le \sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - U^n)\|^2_{L^2(\Omega)}.$$

Proof of Theorem 5.3. Now choose $v_h = k(\overline{P}_k^{\,n} - U^n)$ in (5.17) and repeat the same analysis as for deriving I_4 in (5.12) to obtain

$$\begin{aligned}
&\sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - U^n)\|^2_{L^2(\Omega)} \\
&= \sum_{n=1}^{M} k(\nabla(\overline{u}^{\,n} - \overline{P}_k^{\,n}), \nabla(\overline{u}^{\,n} - U^n)) + \sum_{n=1}^{M} k(-\nabla_k w^n, \overline{P}_k^{\,n} - u^n) \\
&\quad + \sum_{n=1}^{M} \left(k(-\nabla_k w^n, u^n - U^n) + kA(w_+^{n-1}, \overline{u}^{\,n} - U^n)\right) \\
&= \sum_{n=1}^{M} k(\nabla(\overline{u}^{\,n} - \overline{P}_k^{\,n}), \nabla(\overline{u}^{\,n} - U^n)) + \sum_{n=1}^{M} k(-\nabla_k w^n, \overline{P}_k^{\,n} - u^n) \\
&\quad + (w_+^0, u_0 - R_h u_0) \\
&=: II_1 + II_2 + II_3. \qquad (5.18)
\end{aligned}$$

For the term II_1, use the Cauchy–Schwarz inequality and (5.4) to obtain

$$\begin{aligned}
|II_1| &\le \sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - \overline{P}_k^{\,n})\|_{L^2(\Omega)} \|\nabla(\overline{u}^{\,n} - U^n)\|_{L^2(\Omega)} \\
&\le \left\{\sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - \overline{P}_k^{\,n})\|^2_{L^2(\Omega)}\right\}^{\frac{1}{2}} \left\{\sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - U^n)\|^2_{L^2(\Omega)}\right\}^{\frac{1}{2}} \\
&\le Ch\|u\|_{L^2(0,T;X)} \left\{\sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - U^n)\|^2_{L^2(\Omega)}\right\}^{\frac{1}{2}}. \qquad (5.19)
\end{aligned}$$

The term II_2 is estimated in a manner similar to I_2 as in (5.14). Thus, using (5.4) and Lemma 5.5, we obtain

$$\begin{aligned}
|II_2| &\le \left(\sum_{n=1}^{M} k\|\nabla_k w^n\|^2_{H^{-1}(\Omega)}\right)^{\frac{1}{2}} \\
&\quad \cdot \left[\left\{\sum_{n=1}^{M} k\|\overline{u}^{\,n} - \overline{P}_k^{\,n}\|^2_{H^1(\Omega)}\right\}^{\frac{1}{2}} + \left\{\sum_{n=1}^{M} k\|\overline{u}^{\,n} - u^n\|^2_{H^1(\Omega)}\right\}^{\frac{1}{2}}\right] \\
&\le C(k+h)\left(\|u\|^2_{L^2(0,T;X)} + \|u_t\|^2_{L^2(0,T;Y)}\right)^{\frac{1}{2}} \\
&\quad \cdot \left(\sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - U^n)\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}}. \qquad (5.20)
\end{aligned}$$

An application of Lemmas 3.1 and 5.5 yields

$$|II_3| \le Ch\|u_0\|_X \left(\sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n} - U^n)\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}}. \qquad (5.21)$$

Again, by an easy calculation (cf. [5]), it follows that

$$(5.22)\ \|u-U\|_{L^2(0,T;H^1(\Omega))} \leq k\|u_t\|_{L^2(0,T;Y)} + \left(\sum_{n=1}^{M} k\|\nabla(\overline{u}^{\,n}-U^n)\|^2_{L^2(\Omega)}\right)^{\frac{1}{2}},$$

and hence, the desired estimate now follows from (5.18)–(5.22). This completes the proof. □

Acknowledgments. The authors wish to thank the anonymous referees for their careful reading of the manuscript and for their valuable comments and suggestions that improved some results as well as the presentation.

POLYNOMIALS AND POTENTIAL THEORY FOR GAUSSIAN RADIAL BASIS FUNCTION INTERPOLATION*

RODRIGO B. PLATTE† AND TOBIN A. DRISCOLL†

Abstract. We explore a connection between Gaussian radial basis functions and polynomials. Using standard tools of potential theory, we find that these radial functions are susceptible to the Runge phenomenon, not only in the limit of increasingly flat functions, but also in the finite shape parameter case. We show that there exist interpolation node distributions that prevent such phenomena and allow stable approximations. Using polynomials also provides an explicit interpolation formula that avoids the difficulties of inverting interpolation matrices, while not imposing restrictions on the shape parameter or number of points.

Key words. Gaussian radial basis functions, RBF, potential theory, Runge phenomenon, convergence, stability

1. Introduction.

Radial basis functions (RBFs) have been popular for some time in high-dimensional approximation [3] and are increasingly being used in the numerical solution of partial differential equations [7, 14, 17, 20]. Given a set of *centers* $\xi_0, \dots, \xi_N$ in R^d, an RBF approximation takes the form

$$F(x) = \sum_{k=0}^{N} \lambda_k \, \phi\big(\|x - \xi_k\|\big), \tag{1.1}$$

where $\|\cdot\|$ denotes the Euclidean distance between two points and $\phi(r)$ is a function defined for $r \geq 0$. The coefficients $\lambda_0, \dots, \lambda_N$ may be chosen by interpolation or other conditions at a set of *nodes* that typically coincide with the centers. In this article, however, we give special attention to the case in which the locations of centers and nodes differ. Moreover, we shall consider equally spaced centers in most parts of this exposition.

Common choices for ϕ fall into two main categories:

- infinitely smooth and containing a free parameter, such as multiquadrics ($\phi(r) = \sqrt{r^2 + c^2}$) and Gaussians ($\phi(r) = e^{-(r/c)^2}$);
- piecewise smooth and parameter-free, such as cubics ($\phi(r) = r^3$) and thin plate splines ($\phi(r) = r^2 \ln r$).

Convergence analysis of RBF interpolation has been carried out by several researchers—see, e.g., [18, 19, 25]. For smooth ϕ, spectral convergence has been proved for functions belonging to a certain reproducing kernel Hilbert space $\mathcal{F}_\phi$ [19]. This space, however, is rather small since the Fourier transform of functions in $\mathcal{F}_\phi$ must decay very quickly or have compact support [25]. More recently, in [26] Yoon obtained spectral orders on Sobolev spaces, and in [11] error analysis was performed by considering the simplified case of equispaced periodic data. In this article, we use standard

†Department of Mathematical Sciences, University of Delaware, Newark, DE 19716 (platte@math.udel.edu, driscoll@math.udel.edu).

tools of polynomial interpolation and potential theory to study several properties of Gaussian RBF (GRBF) interpolation in one dimension, including convergence and stability.

As is well known in polynomial interpolation, a proper choice of interpolation nodes is essential for good approximations. It is also known that, for fixed N in the limit $c \to \infty$, RBF interpolation is equivalent to polynomial interpolation on the same nodes [6]; hence, the classical Runge phenomenon, and its remedy through node spacing, applies. For practical implementations it is well appreciated that node clustering near the boundaries is helpful [10, 20], but to our knowledge there has been no clear statement about the Runge phenomenon or asymptotically stable interpolation nodes for finite-parameter RBFs. The question has perhaps been obscured somewhat by the fact that the straightforward approach to computing the λ_k is itself numerically ill-conditioned when the underlying approximations are accurate [22].

In this paper we explore the fact that GRBFs with equally spaced centers are related to polynomials through a simple change of variable. Using this connection, in section 2 we demonstrate a Runge phenomenon using GRBFs on equispaced and classical Chebyshev nodes, and we compute asymptotically optimal node densities using potential theory. Numerical calculations suggest that these node densities give Lebesgue constants that grow at logarithmic rates, allowing stable approximations. In section 3 we explore the algorithmic implications of the connections we have made and derive a barycentric interpolation formula that circumvents the difficulty of inverting a poorly conditioned matrix, so approximations can be carried out to machine precision without restrictions on the values of the shape parameter c and number of centers N. Finally, section 4 contains observations on multiquadrics and other possible extensions of the methods presented.

2. Gaussian RBFs as polynomials.

In (1.1) we now choose $d = 1$, Gaussian shape functions, and centers $\xi_k = -1 + 2k/N = -1 + kh$, $k = 0, \ldots, N$. Hence the GRBF approximation is

$$F(x) = \sum_{k=0}^{N} \lambda_k e^{-(x+1-kh)^2/c^2} = e^{-(x+1)^2/c^2} \sum_{k=0}^{N} \lambda_k e^{(2kh-k^2h^2)/c^2} e^{2kxh/c^2}. \tag{2.1}$$

Making the definition $\beta = 2h/c^2 = 4/(Nc^2)$ and using the transformation

$$s = e^{\beta x}, \quad s \in [e^{-\beta}, e^{\beta}],$$

we find that

$$G(s) = F\left(\frac{\log(s)}{\beta}\right) = e^{-\frac{N}{4\beta}(\log s + \beta)^2} \sum_{k=0}^{N} \tilde{\lambda}_k s^k = \psi_\beta^N(s) \sum_{k=0}^{N} \tilde{\lambda}_k s^k, \tag{2.2}$$

where the $\tilde{\lambda}_k$ are independent of s. In this section we regard β as a fixed parameter of the GRBF method. In the literature this is sometimes called the stationary case [2].

From (2.2) it is clear that G/ψ_β^N is a polynomial of degree no greater than N. If F is chosen by interpolation to a given f at $N+1$ nodes, then we can apply standard potential theory to find necessary convergence conditions on the singularities of f in the complex plane $z = x + iy$.

LEMMA 2.1. *Suppose that f is analytic in a closed simply connected region R that lies inside the strip $-\pi/(2\beta) < \mathrm{Im}(z) < \pi/(2\beta)$ and that C is a simple, closed,* *rectifiable curve that lies in R and contains the interpolation points $x_0, x_1, \dots, x_N$. Then the remainder of the GRBF interpolation for f at x can be represented as the contour integral*

$$f(x) - F(x) = \frac{\beta \eta_N(x)}{2\pi i} \int_C \frac{f(z) e^{\beta z}}{\eta_N(z)(e^{\beta z} - e^{\beta x})} dz,$$

where $\eta_N(x) = e^{-\frac{N\beta}{4}(x+1)^2} \prod_{k=0}^{N} (e^{\beta x} - e^{\beta x_k})$.

Proof. Consider the conformal map $w = e^{\beta z}$, and let $g(s) = f(\log(s)/\beta)$. Under this transformation, the region R is mapped to a closed simply connected region that lies in the half-plane $\mathrm{Re}(w) > 0$. Thus g/ψ_β^N is analytic in this region in the w-plane, and we can use the Hermite formula for the error in polynomial interpolation [5],

$$\begin{aligned} g(s) - G(s) &= \psi_\beta^N(s) \left(\frac{g(s)}{\psi_\beta^N(s)} - \sum_{k=0}^{N} \tilde{\lambda}_k s^k \right) \\ &= \frac{\psi_\beta^N(s) \prod_{k=0}^{N}(s - s_k)}{2\pi i} \int_{\mathcal{C}} \frac{g(w)}{(w-s)\psi_\beta^N(w) \prod_{k=0}^{N}(w - s_k)} dw, \end{aligned}$$

where $s_k = e^{\beta x_k}$ and $\mathcal{C}$ is the image of C in the w-plane. A change of variables completes the proof. □

We now turn our attention to necessary conditions for uniform convergence of the interpolation process. To this end, we need the concept of limiting node density functions. These functions describe how the density of node distributions varies over $[-1, 1]$ as $N \to \infty$ [10, 16]. Given a node density function μ, it follows that the node locations x_j satisfy [10]

$$\frac{j}{N} = \int_{-1}^{x_j} \mu(x) dx, \qquad j = 0, \dots, N.$$

Since our analysis parallels the convergence proof for polynomial interpolation (see, e.g., [5, 16, 24]), define

$$u_\beta(z) = \frac{\beta}{4} \mathrm{Re}\left[(z+1)^2\right] - \int_{-1}^{1} \log(|e^{\beta z} - e^{\beta t}|) \mu(t) dt. \tag{2.3}$$

We shall refer to this function as the *logarithmic potential* and to its level curves as *equipotentials.*

In the theorem below we shall assume that μ is such that there exist a and b, $a < b$, with the property that if $K \in [a, b]$, then there exists a simple, closed, rectifiable curve that satisfies $u_\beta(z) = K$ and contains the interval $[-1, 1]$ in its interior. We denote this curve by C_K and by R_K the part of the plane which lies inside it. We also require that if $K_1 > K_2$, then $R_{K_1} \subset R_{K_2}$. To illustrate this feature, consider the logarithmic potential for uniformly distributed nodes on $[-1, 1]$ and $\beta = 1$. In this case we have that $\mu(t) = 1/2$. The level curves of u_1 are presented in Figure 2.1. In this instance one could choose $a = 0.5$ and $b = 0.7$.

THEOREM 2.2. *Suppose μ satisfies the properties above, and let B be the closure of R_b. If f is an analytic function in an open region R which lies inside the strip $-\pi/(2\beta) < \mathrm{Im}(z) < \pi/(2\beta)$ and contains B in its interior, then the GRBF interpolation described above converges uniformly with respect to $z \in B$.*

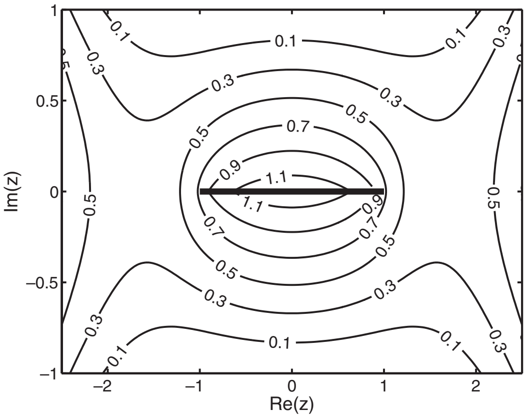

FIG. 2.1. *Level curves of the logarithmic potential for* $\beta = 1$ *and* $\mu(t) = 1/2$. *The straight line represents the interval* $[-1, 1]$.

Proof. Since R is open and B is closed, there exist K_1 and K_2 such that $K_1 < K_2 < b$ and $R_{K_1} \cup C_{K_1}$ lies inside R. Using Lemma 2.1, we have that for any x on C_{K_2},

$$|f(x) - F(x)| \leq \frac{\beta M}{2\pi\delta} \int_{C_{K_1}} \frac{|\eta_N(x)|}{|\eta_N(z)|} dz, \tag{2.4}$$

where M is the largest value of $|f(z)e^{\beta z}|$ on C_{K_1} and δ is the smallest value of $|e^{\beta z} - e^{\beta x}|$ for $z \in C_{K_1}$ and $x \in C_{K_2}$.

We also have that

$$\frac{|\eta_N(x)|}{|\eta_N(z)|} = \exp\left\{-N\left(\log|\eta_N(z)|^{\frac{1}{N}} - \log|\eta_N(x)|^{\frac{1}{N}}\right)\right\}. \tag{2.5}$$

A bound on this exponential can be obtained using the limiting logarithmic potential. Notice that

$$\lim_{N\to\infty} \log|\eta_N(z)|^{\frac{1}{N}} = -u_\beta(z) = -K_1 \quad \text{for } z \in C_{K_1}$$

and

$$\lim_{N\to\infty} \log|\eta_N(x)|^{\frac{1}{N}} = -u_\beta(x) = -K_2 \quad \text{for } x \in C_{K_2}.$$

Hence, for any given ϵ, $0 < \epsilon < (K_2 - K_1)/2$, there exists N_ϵ such that for $N > N_\epsilon$

$$\begin{aligned} &-K_1 - \epsilon < \log|\eta_N(z)|^{\frac{1}{N}} < -K_1 + \epsilon, \\ &-K_2 - \epsilon < \log|\eta_N(x)|^{\frac{1}{N}} < -K_2 + \epsilon, \end{aligned}$$

which implies that

$$\log|\eta_N(z)|^{\frac{1}{N}} - \log|\eta_N(x)|^{\frac{1}{N}} < m_\epsilon, \tag{2.6}$$

where $m_\epsilon = K_2 - K_1 + 2\epsilon > 0$.

Combining (2.4), (2.5), and (2.6) gives

$$|f(x) - F(x)| \leq \frac{\beta M \kappa}{2\pi\delta} e^{-Nm_\epsilon}, \quad N > N_\epsilon,\ x \in C_{K_2}, \tag{2.7}$$

where κ is the length of C_{K_1}.

This last inequality implies that $|f - F| \to 0$ uniformly as $N \to \infty$ on C_{K_2}. Since $f - F$ is analytic in R_{K_2}, by the maximum modulus principle we have that F converges uniformly to f in R_{K_2}. □

We point out that, as happens in polynomial interpolation, the convergence in (2.7) is exponential with a rate that is governed by the equipotentials induced by the nodes.

2.1. The Runge phenomenon. The Runge phenomenon is well understood in polynomial interpolation in one dimension [5, 9] . Even if a function is smooth on the interpolation interval $[-1, 1]$, polynomial interpolants will not converge to it uniformly as $N \to \infty$ unless the function is analytic in a larger complex region whose shape depends on the interpolation nodes. Clustering nodes more densely near the ends of the interval avoids this difficulty. Specifically, points distributed with density $\pi^{-1}(1 - x^2)^{-1/2}$, such as Chebyshev extreme points $x_j = -\cos(j\pi/N)$ and zeros of Chebyshev and Legendre polynomials, are common choices of interpolation nodes on $[-1, 1]$. Uniform convergence of polynomial interpolants is guaranteed for these nodes as long as the function being interpolated is analytic inside an ellipse with foci ± 1 and semiminor larger than δ, for some $\delta > 0$ [9].

In this section we show that for GRBFs uniform convergence may be lost, not only in the polynomial limit $c \to \infty$ but also for constant β (which implies $c \to 0$ as $N \to \infty$), if the distribution of interpolation nodes is not chosen appropriately. Theorem 2.2 can be used to state the regularity requirements of the function being interpolated using a given node distribution, enabling us to determine whether the interpolation process is convergent.

We point out that, for $\beta \ll 1$,

$$u_\beta(z) = -\log(\beta) - \int_{-1}^{1} \log|z - t| \mu(t) dt + O(\beta). \tag{2.8}$$

In this case, the level curves of u_β are similar to equipotentials of polynomial interpolation, and the convergence of the GRBF interpolation process can be predicted from the well-known behavior of polynomial interpolation.

Equipotentials for $\beta = 0.1, 0.8, 2, 5$ are presented in Figure 2.2. On the left of this figure, we present contour maps obtained with a uniform node distribution, and on the right, contour maps obtained with the Chebyshev extreme points. Equipotentials for $\beta = 0.1$ are similar to equipotentials for polynomial interpolation [9], as expected. By Theorem 2.2, convergence is guaranteed if the function is analytic inside the contour line that surrounds the smallest equipotential domain that includes $[-1, 1]$, whereas any singularity inside this region leads to spurious oscillations that usually grow exponentially. Therefore, it is desirable to have the region where the function is required to be analytic be as small as possible. In this sense, we note that for $\beta = 0.1$ the Chebyshev distribution is close to optimal, and for $\beta = 5$ a uniform distribution seems to be more appropriate. We also note that, for large β, Chebyshev density overclusters the nodes near the ends of the interval. In fact, if this clustering is used with $\beta = 5$, even the interpolation of $f \equiv 1$ is unstable; in this case there is no equipotential region that encloses $[-1, 1]$.

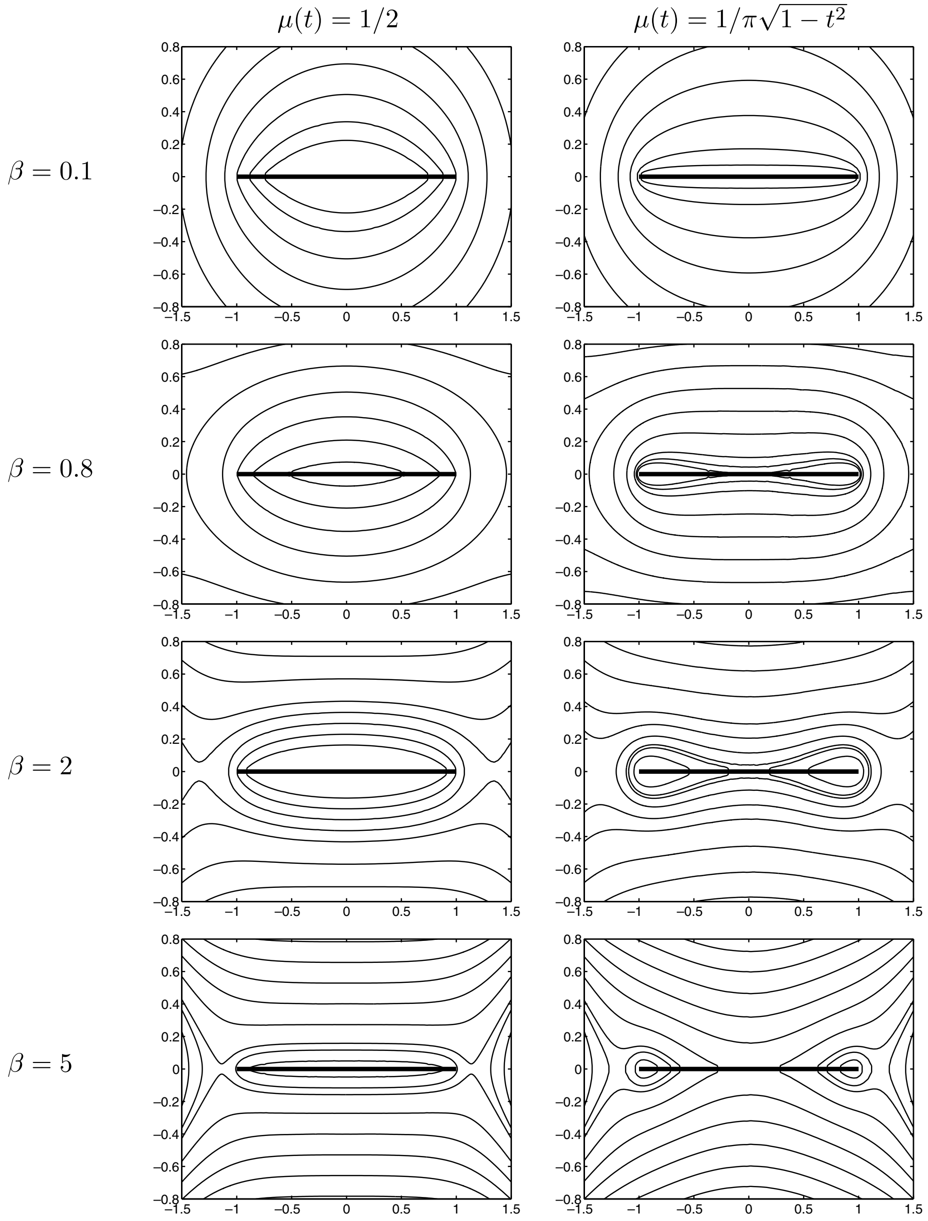

Fig. 2.2. *Contour maps of the logarithmic potential. Plots on the left were obtained with uniform node distribution. Plots on the right were obtained with Chebyshev distribution.*

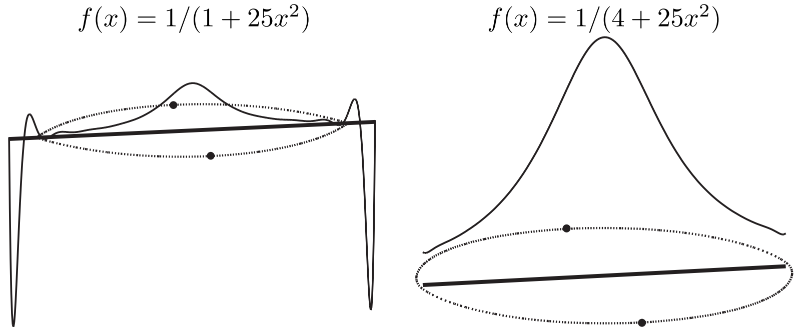
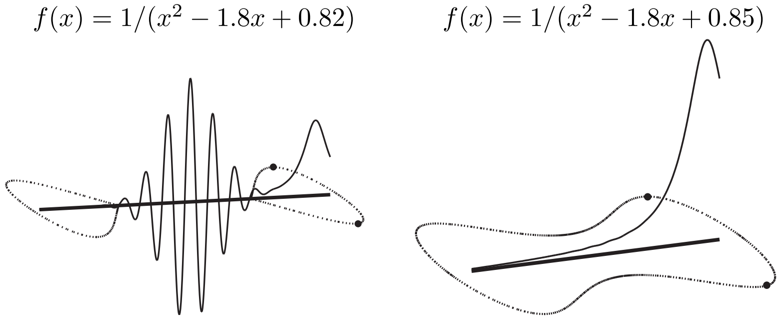
To demonstrate how the equipotentials and singularities of the interpolated function restrict the convergence of GRBF interpolation, in Figures 2.3 and 2.4 we show two pairs of interpolants. Each pair consists of one function that leads to the Runge phenomenon and one that leads to a stable interpolation process. In Figure 2.3, equispaced nodes were used. The interpolation of $f(x) = 1/(4 + 25x^2)$ is convergent, while the interpolation of $f(x) = 1/(1 + 25x^2)$ is not. Notice from Figure 2.2 that the former function is singular at points inside the smallest equipotential domain,



$f(x) = 1/(1+25x^2)$ $f(x) = 1/(4+25x^2)$

FIG. 2.3. *Interpolation of f with 25 equispaced nodes and $\beta = 0.8$. Closed curves are level curves of the logarithmic potential, dots mark the singularities of f, and straight lines represent the interval* $[-1, 1]$.



$f(x) = 1/(x^2 - 1.8x + 0.82)$ $f(x) = 1/(x^2 - 1.8x + 0.85)$

FIG. 2.4. *Interpolation of f with 41 Chebyshev nodes and $\beta = 2$. Closed curves are level curves of the logarithmic potential, dots mark the singularities of f, and straight lines represent the interval* $[-1, 1]$.

and the singularities of the latter function lie outside this region. For Chebyshev nodes and $\beta = 2$, interpolation of $f(x) = 1/(x^2 - 1.8x + 0.82)$ generates spurious oscillation in the center of the interval. Interpolation of a slightly different function, $f(x) = 1/(x^2 - 1.8x + 0.85)$, gives a well-behaved interpolant.

2.2. Lebesgue constants. Although Theorem 2.2 guarantees convergence for sufficiently smooth functions and properly chosen interpolation points, approximations may not converge in the presence of rounding errors due to the rapid growth of the Lebesgue constant. For GRBF interpolation, we define the Lebesgue constant by

$$\Lambda_N^{GRBF} = \max_{x\in[-1,1]} \sum_{k=0}^{N} |L_k(x)|, \tag{2.9}$$

where

$$L_k(x) = e^{-\frac{N\beta}{4}\left((x+1)^2-(x_k+1)^2\right)} \prod_{\substack{j=0\\ j\neq k}}^{N} \frac{(e^{\beta x} - e^{\beta x_j})}{(e^{\beta x_k} - e^{\beta x_j})} \tag{2.10}$$

is the GRBF cardinal function. Notice that $L_k(x_k) = 1$, $L_k(x_j) = 0$ $(j \neq k)$, and by (2.2), $L_k(x) \in \operatorname{Span}\{e^{-(x-\xi_k)^2/c^2}\}$. Thus, the unique GRBF interpolant can be

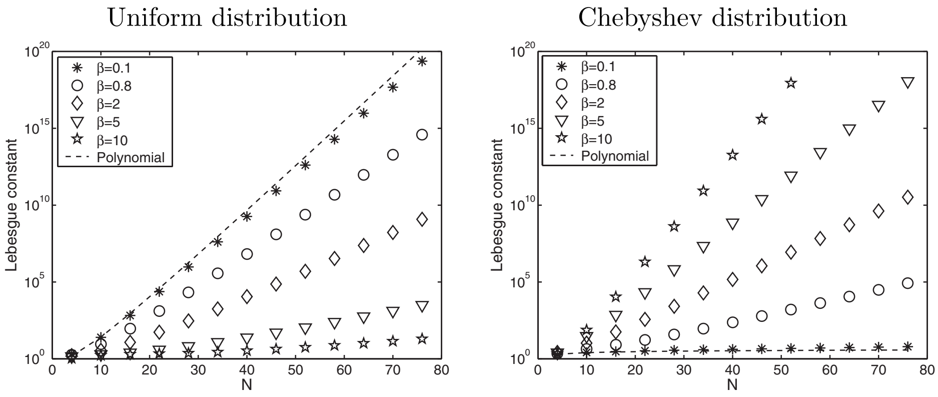


FIG. 2.5. *Lebesgue constant for different values of β. Dashed lines mark the Lebesgue constant values for polynomial interpolation.*

written as

$$F(x) = \sum_{k=0}^{N} L_k(x) f(x_k), \tag{2.11}$$

and it follows that

$$\|F - f\|_\infty \le (1 + \Lambda_N^{GRBF}) \|F^{opt} - f\|_\infty, \tag{2.12}$$

where F^{opt} is the best approximation to f in the GRBF subspace with respect to the infinity norm.

Figure 2.5 illustrates how the GRBF Lebesgue constant grows with N for equispaced nodes (left) and Chebyshev nodes (right). As expected, for small β the GRBF Lebesgue constants approximate the polynomial Lebesgue constants, which behave asymptotically as $O(2^N/(N \log N))$ for equispaced nodes and $O(\log N)$ for Chebyshev nodes [9, 23]. This figure shows that the Lebesgue constants grow exponentially for both node distributions, except for large values of β for uniform nodes and small values of β for Chebyshev nodes.

In the presence of rounding errors, (2.12) indicates that if computations are carried out with precision ε, then the solution will generally be contaminated by errors of size $\varepsilon \Lambda_N^{GRBF}$ [23]. For instance, if $f(x) = 1/(x^2 - 1.8x + 0.85)$ and $\beta = 2$, the convergence of the interpolation process on Chebyshev nodes in double precision stops at $N = 80$, with a minimum residue of $O(10^{-7})$ due to rounding error. Similar results have been observed on equispaced nodes if β is small.

2.3. Stable interpolation nodes. Our goal now is to find node distributions that lead to a convergent interpolation process whenever the function is analytic on $[-1, 1]$. This happens only if $[-1, 1]$ is itself an equipotential, as is the case for Chebyshev density in polynomial interpolation. Therefore, we seek a density function μ that satisfies

$$\frac{\beta}{4}(x+1)^2 = \int_{-1}^{1} \log(|e^{\beta x} - e^{\beta t}|)\mu(t)dt \ + \ \text{constant}, \quad x \in [-1, 1]. \tag{2.13}$$

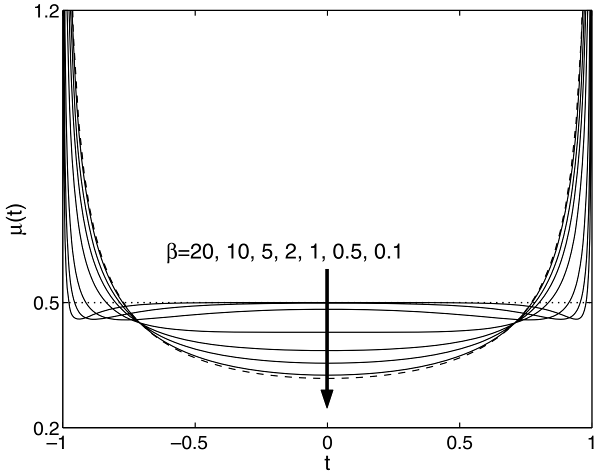

FIG. 2.6. *Numerical approximations of the optimal density functions for several values of β. The dashed line shows the Chebyshev density function.*

In order to find a numerical solution to this integral equation, we assume that the optimal μ can be approximated by

$$\mu(t) \cong \sum_{k=0}^{N_\mu} a_k \frac{T_{2k}(t)}{\sqrt{1-t^2}}, \tag{2.14}$$

where T_{2k} is the Chebyshev polynomial of order $2k$. We consider only even functions in our expansion because we expect the density function to be even due to symmetry. This generalizes the Chebyshev density function $\mu(t) = \pi^{-1}(1-t^2)^{-1/2}$. We also tried more general expressions, replacing $\sqrt{1-t^2}$ with $(1-t^2)^{-\alpha}$, and found that $\alpha = 1/2$ was suitable.

Figure 2.6 shows density functions computed with the expression above. We computed the coefficients a_k by discrete least-squares, and the integral in (2.13) was approximated by Gaussian quadrature. We used $N_\mu = 9$ and 50 points to evaluate the residue in the least-squares process. With this choice of parameters, the residual was less than 10^{-7} in all computations.

In Figure 2.7 we show 21 nodes computed using (2.13) and (2.14) for several values of β. For large values of β the nodes are nearly equally spaced, and for small values they are approximately equal to Chebyshev extreme points. The optimal equipotentials obtained for $\beta = 0.1, 0.8, 2, 5$ are presented in Figure 2.8. For all these values of β, $[-1, 1]$ seems to be a level curve of the logarithmic potential.

As mentioned in section 2.2, in the presence of rounding errors the Lebesgue constant also plays a crucial role. Fortunately, for the optimal nodes computed numerically in this section, experiments suggest that the Lebesgue constant grows at a logarithmic rate. Figure 2.9 presents computed Lebesgue constants for different values of β on optimal nodes.

Figure 2.10 shows the convergence of the GRBF interpolation to the four functions used to illustrate the Runge phenomenon in section 2.1. Now all four functions can be approximated nearly to machine precision. The algorithm used to obtain these

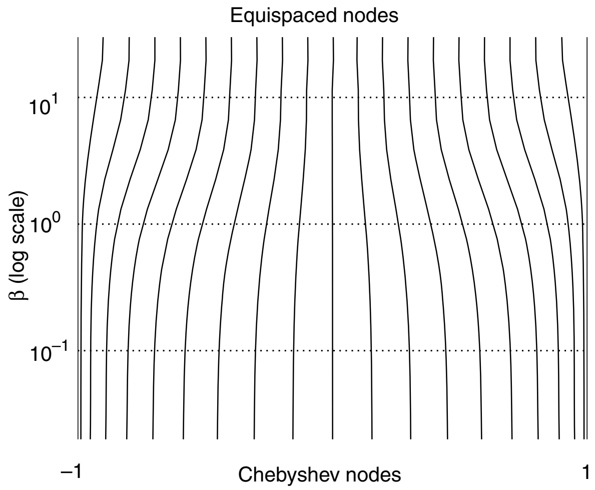

FIG. 2.7. *Node locations obtained using a density function computed by solving the integral equation* (2.13) *for* $N = 20$ *and several values of* β.

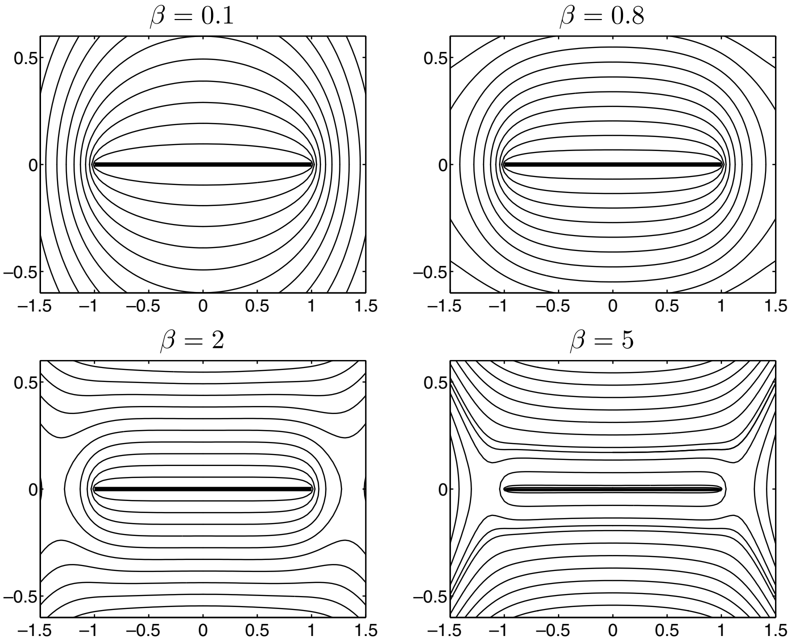

FIG. 2.8. *Contour maps of the logarithmic potential obtained with a numerically approximated optimal density function.*

data is presented in section 3. Notice that the convergence rates are determined by the singularities of the function being interpolated. Dashed lines in this figure mark the convergence rates predicted by (2.7). For instance, if $f(x) = 1/(1 + 25x^2)$ and $\beta = 0.8$, then m_ϵ is approximately the difference between the value of the potential in $[-1, 1]$ and the potential at $z = 0.2i$ (where f is singular), giving $m_\epsilon \cong 0.23$.

Notice that for $\beta = 2$ the equipotentials that enclose the interval $[-1, 1]$ are

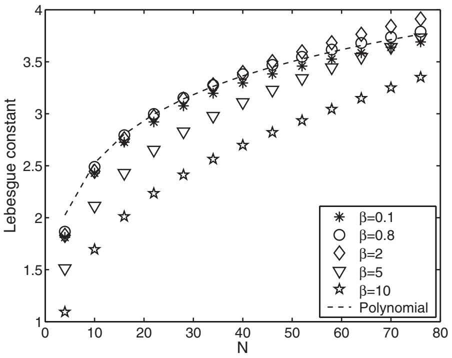

FIG. 2.9. *Lebesgue constant for different values of β and optimal node distribution.*

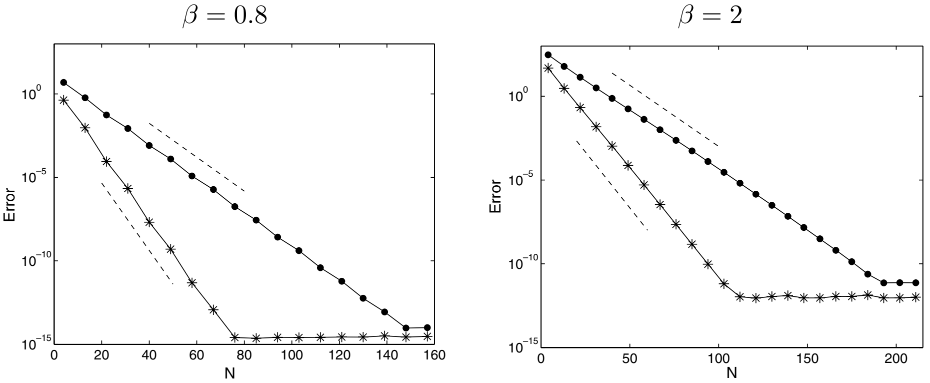

$\beta = 0.8$

$\beta = 2$

FIG. 2.10. *Maximum error of the interpolation process using optimal nodes. Left:* $f(x) = 1/(1+25x^2)$ *(*$\bullet$*) and* $f(x) = 1/(4+25x^2)$ *(*$*$*). Right:* $f(x) = 1/(x^2 - 1.8x + 0.82)$ *(*$\bullet$*) and* $f(x) = 1/(x^2 - 1.8x + 0.85)$ *(*$*$*). Dashed lines mark convergence rates predicted by* (2.7).

contained in a bounded region (Figure 2.8). This indicates that the convergence rate given by (2.7) is the same for *all* functions that have singularities outside this region. In polynomial interpolation, convergence to entire functions is much faster than to functions with finite singularities. This is not the case for GRBFs. With $\beta = 2$ we found that the rate of convergence of interpolants of $1/(1+4x^2)$, $1/(100+x^2)$, $\sin(x)$, and $|x+2|$ were all about the same. What these functions have in common is that they are analytic inside the smallest region that includes all equipotentials that enclose $[-1,1]$.

It is also worth noting that the one-parameter family μ_γ of node density functions proportional to $(1-t^2)^{-\gamma}$ [9] was used in [10] and [20] to cluster nodes near boundaries in RBF approximations. Although numerical results there showed improvement in accuracy, no clear criteria for choosing γ was provided in those papers. By using these node density functions and minimizing the residue in (2.13) with respect to γ, we found that optimal values of γ are approximately given by $\gamma \cong 0.5e^{-0.3\beta}$. We point out, however, that interpolations using these density functions may not converge if large values of N are required.

2.4. Location of centers. Up to this point we have assumed that the centers are uniformly distributed on $[-1,1]$. Here we briefly investigate the consequences of

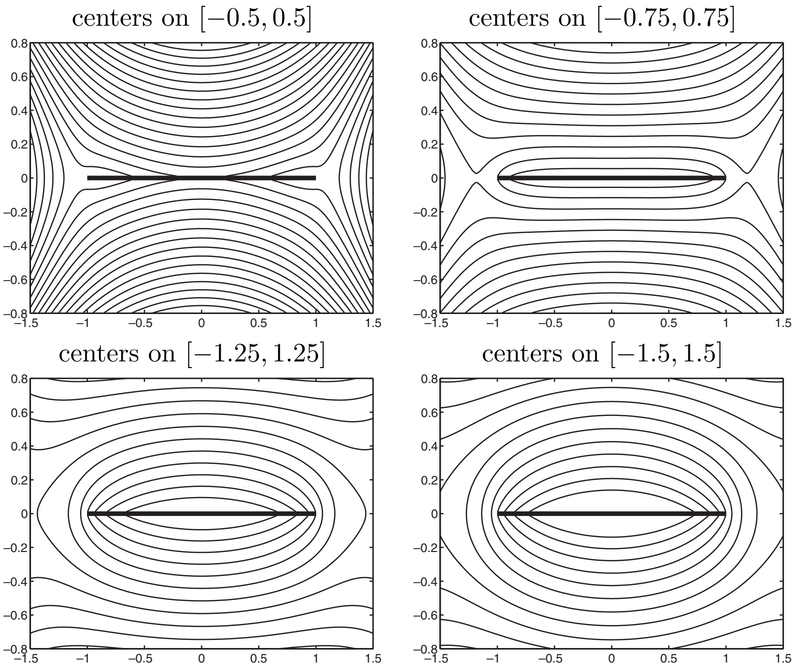

FIG. 2.11. *Equipotentials for $\beta = 2$ (compare with Figure 2.2). Uniformly distributed centers on interval specified above. Interpolation points are uniformly distributed on* $[-1, 1]$.

choosing centers ξ_k that are equispaced on the interval $[-L, L]$, where $L \neq 1$, and also discuss results where centers are not equally spaced. Taking centers outside the interval of approximation, as was suggested in [10, 17] to improve edge accuracy, is of practical interest.

For equispaced centers on $[-L, L]$, a straightforward modification of (2.2) gives

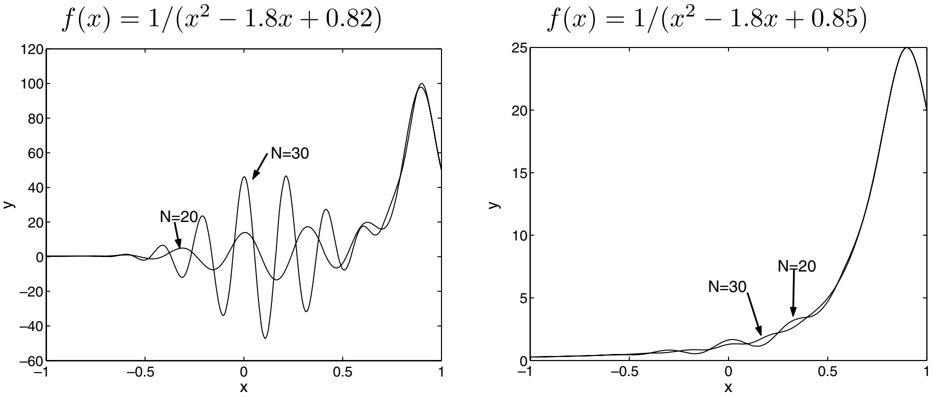
$$F(x) = e^{\frac{-N\beta}{4L}(x+L)^2} \sum_{k=0}^{N} \tilde{\lambda}_k e^{k\beta x},$$

where $\beta = 4L/Nc^2$. In this case the logarithmic potential becomes

$$u_\beta^L(z) = \frac{\beta}{4L} \operatorname{Re}\left[(z+L)^2\right] - \int_{-1}^{1} \log(|e^{\beta z} - e^{\beta t}|)\mu(t)dt.$$

Equipotentials for different values of L are presented in Figure 2.11. We considered equispaced interpolation nodes on $[-1, 1]$. Notice that if $L = 0.5$, there is no guarantee of convergence, as no equipotential encloses $[-1, 1]$. For $L =$0.75, 1.25, and 1.5, there are equipotentials enclosing this interval. The region where f is required to be smooth seems to increase with L. We also point out that the asymptotic behavior for small β, given in (2.8), holds independently of L, indicating that center location is irrelevant in the polynomial limit.

It is common practice to choose the same nodes for centers and interpolation. In Figure 2.12 we show the graphs of the GRBF interpolants, for $f(x) = 1/(x^2 - 1.8x + 0.82)$ and $f(x) = 1/(x^2 - 1.8x + 0.85)$, where both centers and interpolation nodes are Chebyshev points. These data suggest that interpolation with Chebyshev centers also



$f(x) = 1/(x^2 - 1.8x + 0.82)$

$f(x) = 1/(x^2 - 1.8x + 0.85)$

FIG. 2.12. *GRBF interpolation using Chebyshev points for centers and interpolation nodes, $\beta = 2$.*

suffers from the Runge phenomenon. These results are similar to the ones obtained in Figure 2.4 for equispaced centers. Notice that we cannot use the definition involving h for β if the centers are not equispaced; in this case we use the definition $\beta = 4/(Nc^2)$.

3. Algorithmic implications. It is well known that most RBF-based algorithms suffer from ill-conditioning. The interpolation matrix $[\phi(\|x_i - \xi_j\|)]$ in most conditions becomes ill-conditioned as the approximations get more accurate, to the extent that global interpolants are rarely computed for more than a couple of hundred nodes. Based on numerical and theoretical observations, in [22] Schaback states that for RBFs, "Either one goes for a small error and gets a bad sensitivity, or one wants a stable algorithm and has to take a comparably larger error." Several researchers have addressed this issue [4, 8, 15, 21]. In particular, Fornberg and Wright [12] recently presented a contour-integral approach that allows numerically stable computations of RBF interpolants for all values of the free parameter c, but this technique is expensive and has been applied only for experimental purposes.

For GRBFs with equispaced centers, (2.11) provides an explicit interpolation formula through the use of the cardinal functions L_k, so the difficulty of inverting the interpolation matrix can be avoided. This is equivalent to Lagrange polynomial interpolation.

Notice that the exponential term $e^{-\frac{N\beta}{4}((x+1)^2-(x_k+1)^2)}$ in (2.10) becomes very close to zero for certain values of x if N is large, affecting the accuracy of the approximations. A simple modification of (2.10) improves matters:

$$L_k(x) = \prod_{\substack{j=0 \\ j\neq k}}^{N} \frac{e^{-\frac{\beta}{4}\left((x+1)^2-(x_k+1)^2\right)}\left(e^{\beta x} - e^{\beta x_j}\right)}{\left(e^{\beta x_k} - e^{\beta x_j}\right)}. \tag{3.1}$$

The direct implementation of (3.1) together with (2.11) provides a simple algorithm for computing the GRBF interpolant for moderate values of N. In our experiments, effective computations were carried out up to $N = 300$. We shall next derive a more stable formula to handle larger problems.

In [1] Berrut and Trefethen point out the difficulties of using the standard Lagrange formula for practical computations and argue that the barycentric form of Lagrange interpolation should be the method of choice for polynomial interpolation.

For GRBFs we define the barycentric weights by

$$w_k = \left(\prod_{\substack{j=0 \\ j \neq k}}^{N} e^{-\frac{\beta}{4}(x_k+1)^2} \left(e^{\beta x_k} - e^{\beta x_j} \right) \right)^{-1}, \tag{3.2}$$

and thus we have that

$$L_k(x) = L(x) \frac{w_k}{e^{-\frac{\beta}{4}(x+1)^2} \left(e^{\beta x} - e^{\beta x_k} \right)} \qquad (x \neq x_k),$$

where

$$L(x) = \prod_{j=0}^{N} e^{-\frac{\beta}{4}(x+1)^2} \left(e^{\beta x} - e^{\beta x_j} \right).$$

Therefore, the GRBF interpolant can be written as

$$F(x) = L(x) \sum_{k=0}^{N} \frac{w_k}{e^{-\frac{\beta}{4}(x+1)^2} \left(e^{\beta x} - e^{\beta x_k} \right)} f(x_k). \tag{3.3}$$

For reasons of numerical stability, it is desirable to write L as a sum involving the barycentric weights. For polynomial interpolation this is done by considering that 1 can be exactly written in terms of interpolation formulas, since it is itself a polynomial. Unfortunately, a constant function is not exactly represented in terms of GRBFs. Nevertheless, this difficulty can be circumvented if we properly choose a function that belongs to the GRBF space. In our implementation, we consider the function

$$v(x) = \frac{1}{N} \sum_{k=0}^{N} e^{-\frac{N\beta}{4}(x-\xi_k)^2}.$$

Notice that in this case,

$$L(x) = \frac{v(x)}{\sum_{k=0}^{N} \frac{w_k}{e^{-\frac{\beta}{4}(x+1)^2} \left(e^{\beta x} - e^{\beta x_k} \right)} v(x_k)}.$$

Combining the last expression with (3.3) gives our *GRBF barycentric formula*:

$$F(x) = v(x) \frac{\sum_{k=0}^{N} \frac{w_k}{\left(e^{\beta x} - e^{\beta x_k} \right)} f(x_k)}{\sum_{k=0}^{N} \frac{w_k}{\left(e^{\beta x} - e^{\beta x_k} \right)} v(x_k)}. \tag{3.4}$$

As mentioned in [1], the fact that the weights w_k appear symmetrically in the denominator and in the numerator means that any common factor in all the weights may be canceled without affecting the value of F. In some cases it is necessary to rescale terms in (3.2) to avoid overflow. In our implementation we divided each term by $\prod_{j=1}^{N} |e^{\beta x_j} - e^{-\beta}|^{1/N}$.

In [13] Higham shows that for polynomials the barycentric formula is forward stable for any set of interpolation points with a small Lebesgue constant. Our numerical experiments suggest that the GRBF barycentric formula is also stable.

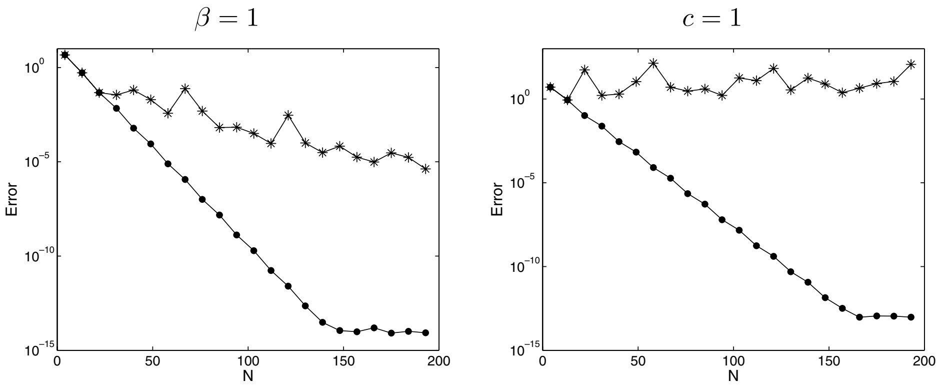


FIG. 3.1. *Maximum error of the interpolation of $f(x) = 1/(1+25x^2)$ using barycentric interpolation (●) and the standard RBF algorithm ($*$). Left: β fixed. Right: c fixed.*

Figure 2.10 was obtained using the barycentric formula. We point out that the direct inversion of the interpolation matrix becomes unstable even for moderate values of N. In Figure 3.1 we compare the convergence of the GRBF interpolant computed with the barycentric formula with that found by inverting the interpolation matrix (standard RBF algorithm). We first computed approximations with β fixed (left graph). Notice that for the standard implementation, convergence rate changes at a level around 10^{-2}, and the method becomes very inefficient for larger values of N. For the barycentric formula, on the other hand, convergence continues to machine precision. For these approximations we used nodes computed with an approximate optimal density function, as in section 2.3.

We also compared the algorithms for fixed c (right graph). In this instance we used Chebyshev nodes, as c constant implies that $\beta \to 0$ as N becomes large and approximations become polynomial. The performance of the standard algorithm is even worse in this case.

4. Final remarks. GRBFs using equally spaced centers are easily related to polynomials in a transformed variable through (2.2). This connection allows us to apply polynomial interpolation and potential theory to draw a number of precise conclusions about the convergence of GRBF interpolation. In particular, for a given interpolation node density, one can derive spectral convergence (or divergence) rates based on the singularity locations of the target function. Conversely, one can easily compute node densities for which analyticity of the function in $[-1, 1]$ is sufficient for convergence and for which the Lebesgue constant is controlled. Furthermore, the polynomial connection allows us to exploit barycentric Lagrange interpolation to construct a simple explicit interpolation algorithm that avoids the ill-conditioning of the interpolation matrix. We stress that the convergence illustrated in Figure 3.1 is made possible only through the use of *both* the stable nodes and the stable algorithm.

Numerical evidence suggests that other RBFs such as multiquadrics may also be susceptible to the Runge phenomenon and dependent on node location for numerically stable interpolations. Figure 4.1 shows graphs of multiquadric interpolants of two functions. We first considered the small β case (nearly polynomial) with the same function that caused the Runge phenomenon for GRBFs on equispaced nodes. The high oscillations of the interpolant at the ends of the interval indicates that this function also causes the Runge phenomenon for multiquadrics. The multiquadric

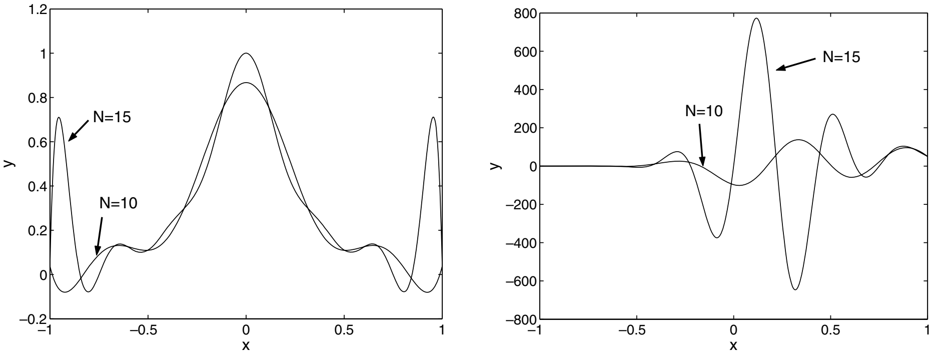

Fig. 4.1. *Runge phenomenon in multiquadric RBF interpolation. Left: Interpolation of $f(x) = 1/(1+25x^2)$ using equispaced nodes and $\beta = 0.1$. Right: Interpolation of $f(x) = 1/(x^2-1.8x+0.82)$ using Chebyshev nodes and $\beta = 2$.*

interpolant of $f(x) = 1/(x^2 - 1.8x + 0.82)$ with $\beta = 2$ and equispaced centers also presented spurious oscillations, as its GRBF counterpart did, when Chebyshev interpolation nodes were used.

Practical interest in RBF methods is fueled by their flexibility in the node and center locations and by their simple use in higher-dimensional approximation. The results of this paper do not extend immediately in either of those directions, except to a tensor-product situation of uniform center locations in a box. Still, we believe that the explicit GRBF interpolation algorithm, in particular, may be adaptable to selective resolution requirements and geometric flexibility.

ANALYSIS OF REGULARIZATION METHODS FOR THE SOLUTION OF ILL-POSED PROBLEMS INVOLVING DISCONTINUOUS OPERATORS*

F. FRÜHAUF†, O. SCHERZER†, and A. LEITÃO‡

Abstract. We consider a regularization concept for the solution of ill-posed operator equations, where the operator is composed of a continuous and a discontinuous operator. A particular application is level set regularization, where we develop a novel concept of minimizers. The proposed level set regularization is capable of handling changing topologies. A functional analytic framework explaining the splitting of topologies is given. The asymptotic limit of the level set regularization method is an evolution process, which is implemented numerically, and the quality of the proposed algorithm is demonstrated by solving an inverse source problem.

Key words. ill-posed problems, regularization methods, level set methods

1. Introduction.

The goal of this paper is to analyze *regularization* models for the *stable* solution of *ill-posed* operator equations

$$F(P(\phi)) = y. \tag{1.1}$$

Here F is a continuous operator between Banach spaces X and Y, and P is a probably *discontinuous operator* into an admissible class $\mathcal{P} \subset X$. Classical results on convergence and stability of variational regularization principles for solving *nonlinear* ill-posed problems (see, e.g., [19, 20, 10]) in a Hilbert spaces setting such as

1. existence of a regularized solution,
2. stability of the regularized approximations,
3. approximation properties of the regularized solutions

are applicable if the operator P is

1. bounded and linear or
2. nonlinear, continuous, and weakly closed.

In this paper we particularly emphasize operator equations (1.1), where the operator P is discontinuous. Of particular interest for this paper is

$$P(t) := \begin{cases} 0 & \text{for} \quad t < 0, \\ 1 & \text{for} \quad t \geq 0. \end{cases} \tag{1.2}$$

With P there is associated the *admissible class*

$$\mathcal{P} := \left\{ u : u = \chi_D, \text{ where } D \subseteq \Omega \text{ is measurable and } \mathcal{H}^{n-1}(\partial D) < \infty \right\}. \tag{1.3}$$

Here

1. $\mathcal{H}^{n-1}(\partial D)$ denotes the $n-1$-dimensional Hausdorff-measure of the boundary of D;
2. χ_D denotes the characteristic function of the set D.

We refer to a regularization approach involving this projection as a *level set regularization* since we recover the boundary of an object ∂D, which is a level set (for instance, with value 0) of a function ϕ. The idea of considering characteristic functions as level sets of higher-dimensional data has been used before in the context of *multiphase flow* (see, e.g., [18, 26, 8]) and segmentation (see, e.g., [7]). Level set methods have been used successively in many applications since the pioneering work of Osher and Sethian [22]. For solving inverse problems applications with level sets, we refer to Santosa [24] and Burger [5].

In this work we base our considerations on ideas from nonlinear convex semigroup theory (cf. Brezis [4]), which allows us to characterize the solution of an evolution process by implicit time steps of regularization models. Since our regularization models appear to be nonconvex, the theoretical results of nonlinear semigroup theory are not available. Simulating this approach, we show in this work that iterated regularization is well posed, and (aside from the lack of theoretical results) we can interpret the iterated regularized solutions as time instance of an evolution process.

Various other models fit in the general framework of this paper but are not particularly emphasized: for instance, for $a \in \mathbb{R}$ let us consider the projection operator

$$P^a(t) := \begin{cases} -a & \text{for} \quad t < -a, \\ t & \text{for} \quad -a \leq t \leq a, \\ a & \text{for} \quad t > a, \end{cases}$$

with the admissible class

$$\mathcal{P}_a := \left\{ u : u = P^a(\phi) \text{ with } \phi \in H^1(\Omega) \right\}. \tag{1.4}$$

The operator P^a ensures that the recovered functions are absolutely bounded by a. The operator

$$P^+(t) := \exp(t)$$

with the *admissible class*

$$\mathcal{P}_+ := \left\{ u : 0 < u = P^+(\phi) \right\} \tag{1.5}$$

can be used to guarantee *nonnegativity.* Depending on the operator P, we actually solve a constraint optimization problem. With P_+, P_a, P we guarantee that the solution is in the corresponding admissible class.

The outline of this paper is as follows. In section 2 we introduce the concept of *level set regularization*, based on considerations in [24, 5, 17]. The level set regularization functionals derived in [17] are modified such that a convergence analysis becomes tractable (cf. section 2.1). That is, we show that each implicit time step is well defined. This a prerequisite step in showing that the corresponding gradient flow equation (cf. section 2.1) is well defined. To this end, we introduce a novel concept of a minimizer of regularization functionals involving discontinuous operators (cf. section 2.2). A convergence analysis is presented in section 2.3. The problem of numerical minimization is discussed in section 3, and in section 4 a relation to iterative regularization is considered. Finally, numerical examples are presented in section 5.

2. Analysis of level set regularization. In the following we pose the general assumptions which we assume to hold throughout this paper:

1. $\Omega \subseteq \mathbb{R}^n$ is bounded with $\partial\Omega$ piecewise C^1 (see, e.g., [2]).
2. The operator $F : L^1(\Omega) \to Y$ is continuous and Fréchet-differentiable. Y is a Banach space.
3. $\varepsilon, \alpha, \beta$ denote positive parameters.
4. We use the following notation:
   (i) $\to$ denotes strong convergence.
   (ii) $\overset{(*)}{\rightharpoonup}$ denotes weak(*) convergence.
   (iii) $L^p(\Omega)$ denotes the space of measurable p-times-integrable functions.
   (iv) $W^{1,p}(\Omega)$ denotes the Sobolev space of one time weakly differentiable functions where the function and its derivative are in L^p; in particular we set $H^1 = W^{1,2}$.
   (v) $\mathtt{BV}(\Omega)$ denotes the space of functions of *bounded variation*.
5. We assume that (1.1) has a solution; i.e., there exists a $z \in \mathcal{P}$ satisfying $F(z) = y$ and a function $\phi \in H^1(\Omega)$ satisfying $|\nabla\phi| \neq 0$ in a neighborhood of $\{\phi = 0\}$ and $P(\phi) = z$. If $z = \chi_A$ and $\emptyset \neq A$, then we let

$$\phi = -d_{\overline{A}} + d_{\overline{CA}},$$

where $d_{\overline{A}}$ and $d_{\overline{CA}}$ denote the distance functions from $\overline{A}$, and $\overline{CA}$, respectively. Since $d_{\overline{A}}$ and $d_{\overline{CA}}$ are uniformly Lipschitz-continuous (see, e.g., [9]), they are in $L^\infty(\Omega)$. Moreover, $|\nabla d_{\overline{A}}| \leq 1$ and $|\nabla d_{\overline{CA}}| \leq 1$ (see again, e.g., [9]). In particular this shows that $d_{\overline{A}}, d_{\overline{CA}} \in W^{1,\infty}(\Omega) \subseteq H^1(\Omega)$. Thus $z \in \mathcal{P}$ if $z = \chi_A$ and A satisfies that the closure of the interior of A is the closure of A.

We consider the unconstrained inverse problem of solving (1.1) with

$$\begin{aligned} P : H^1(\Omega) &\to \mathcal{P}\ , \\ \phi &\mapsto \frac{1}{2} + \frac{1}{2}\mathrm{sgn}(\phi) =: \frac{1}{2} + \frac{1}{2}\left\{ \begin{array}{rl} 1 & \text{for } \phi \geq 0, \\ -1 & \text{for } \phi < 0. \end{array} \right. \end{aligned}$$

The standard form of Tikhonov regularization for solving (1.1) consists of minimizing the functional

$$\mathcal{F}_\alpha(\phi) := \|F(P(\phi)) - y^\delta\|_Y^2 + \alpha\|\phi - \phi_0\|_{H^1(\Omega)}^2 \tag{2.1}$$

over $H^1(\Omega)$. Actually, we understand the minimizer ϕ_α of this functional as

$$\phi_\alpha = \lim_{\varepsilon\to 0+} \phi_{\varepsilon,\alpha},$$

where the limit is understood in an appropriate sense (weak, weak* convergence) and $\phi_{\varepsilon,\alpha}$ minimizes the functional over $H^1(\Omega)$:

$$\mathcal{F}_{\varepsilon,\alpha}(\phi) := \|F(P_\varepsilon(\phi)) - y^\delta\|_Y^2 + \alpha\|\phi - \phi_0\|_{H^1(\Omega)}^2, \tag{2.2}$$

where we use

$$P_\varepsilon(\phi) := \begin{cases} 0 & \text{for} \quad \phi < -\varepsilon, \\ 1 + \frac{\phi}{\varepsilon} & \text{for} \quad \phi \in [-\varepsilon, 0], \\ 1 & \text{for} \quad \phi > 0, \end{cases}$$

for approximating P as $\varepsilon \to 0^+$. In this case we define

$$P'(t) := \lim_{\varepsilon \to 0+} P'_\varepsilon(t) = \delta(t).$$

Here and in the following, $\delta(t)$ denotes the one-dimensional δ-distribution.

Taking into account that

$$\|P_\varepsilon(\phi_k) - P_\varepsilon(\phi)\|_{L^1(\Omega)} \leq \frac{1}{\varepsilon}\sqrt{\text{meas}(\Omega)}\|\phi_k - \phi\|_{L^2(\Omega)},$$

the proof of existence of a minimizer of the functional $\mathcal{F}_{\varepsilon,\alpha}$ is similar to the proof of existence of regularized solutions of Tikhonov functionals for approximately minimizing nonlinear ill-posed problems in [11, 25] (see also [10]).

THEOREM 2.1. *For any $\phi_0 \in H^1(\Omega)$ the functional $\mathcal{F}_{\varepsilon,\alpha}$ (cf. (2.2)) attains a minimizer $\phi_{\varepsilon,\alpha}$ in $H^1(\Omega)$.*

2.1. Towards an analysis of level set regularization techniques. In the following we outline the difficulties in performing a rigorous analysis for the functional $\mathcal{F}_\alpha$, defined in (2.1).

1. $\phi_{\varepsilon,\alpha}$ satisfies

$$\|P(\phi_{\varepsilon,\alpha})\|_{L^\infty} \leq 1 \quad \text{and} \quad \|\phi_{\varepsilon,\alpha} - \phi_0\|_{H^1(\Omega)} < \infty.$$

Since $L^\infty(\Omega)$ is the dual of $L^1(\Omega)$, i.e., $L^{1*}(\Omega) = L^\infty(\Omega)$, we find that there exists a subsequence $\{\phi_{\varepsilon_k,\alpha_k}\}_{k\in\mathbb{N}}$ such that

$$\phi_{\varepsilon_k,\alpha_k} \rightharpoonup \phi \text{ in } H^1(\Omega) \quad \text{and} \quad P(\phi_{\varepsilon_k,\alpha_k}) \overset{*}{\rightharpoonup} z \text{ in } L^\infty(\Omega).$$

There is no analytical evidence for $z \in \mathcal{P}$; i.e., it may not be in the range of the operator P.

2. To overcome this difficulty let us assume that the sequence $\{\phi_{\varepsilon_k,\alpha_k}\}_{k\in\mathbb{N}}$ satisfies the condition that the Hausdorff-measure of the boundary of the set

$$\{x : \phi_{\varepsilon_k,\alpha_k}(x) \geq 0\}$$

is uniformly bounded. Then the bounded variation seminorm of $P(\phi_{\varepsilon_k,\alpha_k})$ is uniformly bounded, and consequently $P(\phi_{\varepsilon_k,\alpha_k})$ has a convergent subsequence in $L^1(\Omega)$, showing that z is admissible.

This suggests that we incorporate in the functional (2.1) as an additional regularization term the bounded variation seminorm of $P(\phi)$, penalizing the length of the zero level set of ϕ. Actually in design problems the necessity of incorporating such a term is well documented in [14, 15, 16]. This leads to the following modified regularization method of minimizing

$$\mathcal{G}_\alpha(\phi) := \|F(P(\phi)) - y^\delta\|_Y^2 + 2\beta\alpha|P(\phi)|_{\mathtt{BV}} + \alpha\|\phi - \phi_0\|_{H^1(\Omega)}^2. \tag{2.3}$$

In order to guarantee existence of a minimizer of $\mathcal{G}_\alpha$ we introduce a novel concept of a minimizer in the next subsection.

2.2. Minimizing concept.

Definition 2.2. 1. *A* pair *of functions*

$$(z, \phi) \in L^\infty(\Omega) \times H^1(\Omega)$$

is called admissible

(i) *if there exists a sequence $\{\phi_k\}_{k\in\mathbb{N}}$ in $H^1(\Omega)$ such that $\phi_k \to \phi$ with respect to the $L^2(\Omega)$-norm and*

(ii) *if there exists a sequence $\{\varepsilon_k\}_{k\in\mathbb{N}}$ of positive numbers converging to zero such that*

$$P_{\varepsilon_k}(\phi_k) \to z \textit{ in } L^1(\Omega).$$

2. *A minimizer of $\mathcal{G}_\alpha$ is considered any admissible pair of functions (z, ϕ) minimizing*

$$\mathcal{G}_\alpha(z, \phi) = \|F(z) - y^\delta\|_Y^2 + \alpha\rho(z, \phi) \tag{2.4}$$

over all admissible pairs. Here

$$\rho(z, \phi) := \inf \liminf_{k\to\infty} \left\{ 2\beta |P_{\varepsilon_k}(\phi_k)|_{\mathtt{BV}} + \|\phi_k - \phi_0\|_{H^1(\Omega)}^2 \right\}, \tag{2.5}$$

where the infimum is taken with respect to all sequences $\{\varepsilon_k\}_{k\in\mathbb{N}}$ satisfying item 1(ii) *and $\{\phi_k\}_{k\in\mathbb{N}}$ satisfying item* 1(i).

A generalized minimizer of $\mathcal{G}_\alpha(\phi)$ is a minimizer of $\mathcal{G}_\alpha(z, \phi)$ on the set of admissible pairs.

The following lemma shows that the functional ρ is coercive on the set of admissible pairs.

Lemma 2.3. *For each (z, ϕ) admissible,*

$$2\beta |z|_{\mathtt{BV}} + \|\phi - \phi_0\|_{H^1(\Omega)}^2 \le \rho(z, \phi).$$

Proof. Let (z, ϕ) be an admissible pair; then there exists sequences $\{\varepsilon_k\}_{k\in\mathbb{N}}$ and $\{\phi_k\}_{k\in\mathbb{N}}$ satisfying items 1(i) and 1(ii) and

$$\rho(z, \phi) = \lim_{k\to\infty} 2\beta |P_{\varepsilon_k}(\phi_k)|_{\mathtt{BV}} + \|\phi_k - \phi_0\|_{H^1(\Omega)}^2.$$

By the weak lower semicontinuity of the $\mathtt{BV}$ and H^1-norms, it follows that

$$\|\phi - \phi_0\|_{H^1(\Omega)}^2 \le \liminf_{k\in\mathbb{N}} \|\phi_k - \phi_0\|_{H^1(\Omega)}^2,$$
$$|z|_{\mathtt{BV}} \le \liminf_{k\in\mathbb{N}} |P_{\varepsilon_k}(\phi_k)|_{\mathtt{BV}},$$

which proves the assertion. □

The definition of $\rho(z, \phi)$ is impractical, since it is defined via a relaxation procedure. The following arguments allow an explicit characterization of this functional. From several experiments which we outline below, we conjecture the following characterization of the functional $\rho(z, \phi)$.

Conjecture 2.4. *We define*

$$\Phi_+ = \{x \in \Omega : \phi(x) > 0\} \quad \textit{and} \quad \Phi_- = \{x \in \Omega : \phi(x) < 0\}$$

and

$$C\Phi = \Omega \backslash (\Phi_+ \cup \Phi_-).$$

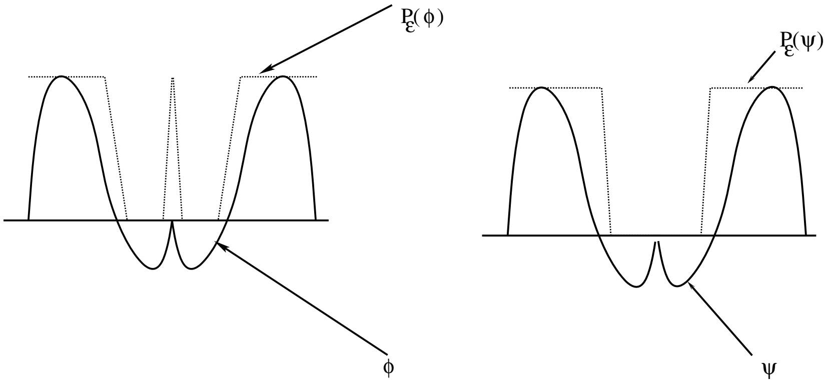

FIG. 2.1. *(Left)* $n = 1$*: The functions* ϕ *and* $P_\varepsilon(\phi)$*:* $|P_\varepsilon(\phi)|_{\mathtt{BV}} = 4$*. (Right) A slight perturbation:* ψ *and* $P_\varepsilon(\psi)$*:* $|P_\varepsilon(\psi)|_{\mathtt{BV}} = 2$*.*

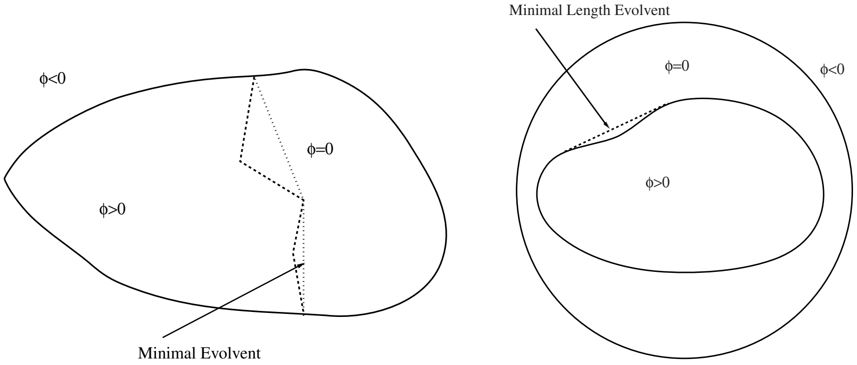

FIG. 2.2. *The minimal evolvent in* $C\Phi$*.*

(i) *If* $\partial\Phi_+ \cap \Omega = \partial\Phi_- \cap \Omega$*, then*

$$\begin{aligned}\rho(z, \phi) &= 2\beta\mathcal{H}^{n-1}(\partial\Phi_- \cap \Omega) + \|\phi - \phi_0\|^2_{H^1(\Omega)}\\ &= 2\beta\mathcal{H}^{n-1}(\partial\Phi_+ \cap \Omega) + \|\phi - \phi_0\|^2_{H^1(\Omega)}\ .\end{aligned}$$

(ii) *If the* n*-dimensional Lebesgue measure* $\lambda^n(C\Phi) > 0$*, then* z *is not uniquely identified; in particular,* z *can attain all values in* $[0, 1]$ *in* $C\Phi$*. We conjecture that*

$$\inf_{z\ admissible} \rho(z, \phi) = 2\beta\mathcal{H}^{n-1}(S) + \|\phi - \phi_0\|^2_{H^1(\Omega)}.$$

The problem consists of finding the surface S *of minimal* $n-1$*-dimensional Hausdorff-measure, which is contained in* $C\Phi$ *and divides* Ω *in two sets. One set completely contains* Φ_+ *and the other set contains* Φ_- *(cf. Figures* 2.1 *and* 2.2*).*

Intuitively the conjecture is quite obvious. Assuming the conjecture to be true, we are further led to conjecture that the functional ρ is independent of the choice of the approximation P_ε. Thus any other approximation of P with Lipschitz-continuous functions P_ε approximating the δ-distribution is suitable as well.

Remark 2.5. For $\phi \in H^1(\Omega)$, where $\{\phi = 0\}$ is a set of positive Lebesgue measure (cf. Figure 2.3), it is possible to find sequences $\{\phi_k\}_{k\in\mathbb{N}}$ and $\{\tilde{\phi}_k\}_{k\in\mathbb{N}}$, which converge

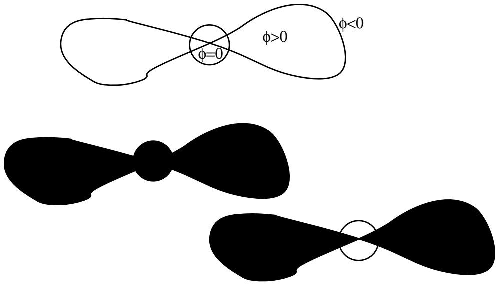

FIG. 2.3. Top: *The level set function has critical values (i.e.,* $|\nabla\phi| = 0$ *in a circle).* Bottom: *Two possible functions* z *and* $\tilde{z}$*. The black value corresponds to a value of* $z = 1$*.*

strongly to ϕ in $L^2(\Omega)$. However, the limits of the projections are different; i.e., $z = \lim_{k\to\infty} P_{\varepsilon_k}(\phi_k) \neq \tilde{z} = \lim_{k\to\infty} P_{\varepsilon_k}(\tilde{\phi}_k)$; cf. Figure 2.3. In such a situation we have $\rho(z,\phi) \neq \rho(\tilde{z},\phi)$.

In the following we summarize some properties of the functional ρ.

LEMMA 2.6. *The functional* ρ *satisfies*

$$\rho(z,\phi) \leq \liminf_{n\in\mathbb{N}} \rho(z_n,\phi_n)$$

if $z_n \to z$ *in* $L^1(\Omega)$ *and if* $\phi_n \rightharpoonup \phi$ *in* $H^1(\Omega)$ *and* (z_n,ϕ_n) *is admissible.*

Proof. From the definition of the functional ρ and Lemma 2.3 it follows that the functional ρ is a Γ^--limit (see, e.g., [3]), and thus we conclude that it is weak lower semicontinuous. □

Remark 2.7. Suppose for the moment that P is a continuous operator, in which case we can set $P_\varepsilon := P$. Then the admissible class is just the set of pairs (z,ϕ) satisfying $P(\phi) = z$. This is just another formulation of constraint optimization. In our context P is discontinuous, and therefore we consider the more general concept of admissible pairs.

Example 2.8. Let $\phi \in H^1(\Omega)$ satisfying $|\nabla\phi| > 0$ in a neighborhood of $\{\phi = 0\}$.

1. Let $\phi_k = \phi \in H^1(\Omega)$ and let $z = P(\phi_k)$. Since for any sequence $\varepsilon_k \to 0$

$$P_{\varepsilon_k}(\phi_k) \to z \quad \text{in } L^1(\Omega),$$

it follows that (z,ϕ) is admissible.

2. Let $\phi \in H^1(\Omega)$ and define $\phi_k = \frac{1}{k}\phi$. Then there is a sequence $\varepsilon_k \to 0$ with

$$P_{\varepsilon_k}(\phi_k) \to z \quad \text{in } L^1(\Omega).$$

Consequently, $(z,0)$ is admissible.

The consequence of the second item is striking. Suppose that $\phi_0 = 0$ and that there exists a minimizer $\phi_\alpha \neq 0$ of (2.3). Then for any $k \in \mathbb{N}$

$$\mathcal{G}_\alpha(\phi_\alpha/k) < \mathcal{G}_\alpha(\phi)\,,$$

showing that a minimizer of $\mathcal{G}_\alpha$ is not attained in a common setting. However, the pair $(z = P(\phi_\alpha), 0)$ is admissible and can be considered as the generalized solution.

Note that in this example we consider only functions $\phi \in H^1(\Omega)$ without critical points along the zero level set.

2.3. Well-posedness and convergence analysis.

THEOREM 2.9 (well-posedness). *Both the functional $\mathcal{G}_\alpha$ and the functional*

$$\tilde{\mathcal{G}_\alpha}(z,\phi) := \|F(z) - y^\delta\|_Y^2 + 2\beta\alpha|z|_{\mathtt{BV}} + \alpha\|\phi - \phi_0\|_{H^1(\Omega)}^2$$

attain minimizers on the set of admissible pairs.

Proof. 1. Since $(0,0)$ is admissible, the set of admissible pairs is not empty.

2. Suppose that $\{(z_k,\phi_k)\}_{k\in\mathbb{N}}$ is a sequence of admissible pairs such that

$$\mathcal{G}_\alpha(z_k,\phi_k) \to \inf \mathcal{G}_\alpha \le \mathcal{G}_\alpha(0,0) < \infty.$$

From Lemma 2.3 it follows that $\{(z_k,\phi_k)\}_{k\in\mathbb{N}}$ is uniformly bounded in $\mathtt{BV} \times H^1(\Omega)$. By the Sobolev embedding theorem there exists a subsequence, denoted again by $\{\phi_k\}_{k\in\mathbb{N}}$, such that

$$\begin{gathered}\phi_k \rightharpoonup \phi \text{ in } H^1(\Omega) \quad \text{and} \quad \phi_k \to \phi \text{ in } L^2(\Omega),\\ z_k \to z \text{ in } L^1(\Omega), \qquad 2\beta|z|_{\mathtt{BV}} \le \rho(z,\phi) \le \liminf_{k\to\infty} \rho(z_k,\phi_k).\end{gathered}$$

Since ρ is weakly lower semicontinuous (cf. Lemma 2.6) it follows that

$$\begin{aligned}\inf \mathcal{G}_\alpha &= \lim_{k\to\infty} \mathcal{G}_\alpha(z_k,\phi_k)\\ &= \lim_{k\to\infty} \left\{\|F(z_k) - y^\delta\|_Y^2 + \alpha\rho(z_k,\phi_k)\right\}\\ &\ge \|F(z) - y^\delta\|_Y^2 + \alpha\rho(z,\phi)\\ &= \mathcal{G}_\alpha(z,\phi).\end{aligned} \tag{2.6}$$

3. It remains to prove that (z,ϕ) is admissible. For k fixed, since (z_k,ϕ_k) is admissible, there exists a sequence $\{\varepsilon_{k,l}\}_{l\in\mathbb{N}}$ of positive numbers and a sequence $\{\phi_{k,l}\}_{l\in\mathbb{N}}$ in $H^1(\Omega)$ such that

$$\phi_{k,l} \to_{l\to\infty} \phi_k \text{ in } L^2(\Omega), \quad P_{\varepsilon_{k,l}}(\phi_{k,l}) \to_{l\to\infty} z_k \text{ in } L^1(\Omega).$$

Thus there exists an index $l(k) \in \mathbb{N}$ such that

(i) $\varepsilon_{k,l(k)} < \frac{1}{2}\varepsilon_{k-1,l(k-1)}$;

(ii) $\|\phi_{k,l(k)} - \phi_k\|_{L^2(\Omega)} \le \frac{1}{k}$;

(iii) $\|P_{\varepsilon_{k,l(k)}}(\phi_{k,l(k)}) - z_k\|_{L^1(\Omega)} \le \frac{1}{k}$.

Define

$$\psi_k := \phi_{k,l(k)} \quad \text{and} \quad \eta_k := \varepsilon_{k,l(k)}.$$

Then, since

$$\psi_k \to \phi \text{ in } L^2(\Omega) \quad \text{and} \quad P_{\eta_k}(\psi_k) \to z \text{ in } L^1(\Omega),$$

we see that (z,ϕ) is admissible.

The proof of existence of a minimizer of $\tilde{\mathcal{G}_\alpha}$ is analogous to that for $\mathcal{G}_\alpha$ and is thus omitted. □

We have shown that for any positive parameters α,β the functionals $\mathcal{G}_\alpha$ and $\tilde{\mathcal{G}_\alpha}$ both attain a minimizer.

In what follows we denote by (z_α,ϕ_α) a minimizer of $\mathcal{G}_\alpha$.

In the following we summarize some convergence results for regularized minimizers, which are based on the existence of a *minimum norm solution.*

THEOREM 2.10 (existence of a minimum norm solution). *Under the general assumptions of this paper there exists a minimum norm solution* $(z^\dagger, \phi^\dagger)$*, that is, an admissible pair of functions that satisfies*

1. $F(z^\dagger) = y$,
2. $\rho(z^\dagger, \phi^\dagger) = ms := \inf\{\rho(z,\phi) : (z,\phi) \text{ admissible and } F(z) = y\}$.

Proof. 1. According to assumption 5 in section 2, there exists a function $\tilde{z} \in \mathcal{P}$ and a function $\tilde{\phi} \in H^1(\Omega)$ such that $P(\tilde{\phi}) = \tilde{z}$ and $F(\tilde{z}) = y$. Then the pair $(\tilde{z}, \tilde{\phi})$ is admissible for the sequence $\tilde{\phi}_k = \tilde{\phi}$, because $P_{\varepsilon_k}(\tilde{\phi}_k) \to \tilde{z}$ converges in $L^1(\Omega)$ for every sequence $\varepsilon_k \to 0$ due to the fact that P_{ε_k} is a convolution of P with a δ-distribution; i.e., $P_{\varepsilon_k} = P * \delta_k$. Thus the set of admissible pairs with $F(z) = y$ is not empty.

2. Suppose that $\{(z_k, \phi_k)\}_{k\in\mathbb{N}}$ is a sequence of admissible pairs with $F(z_k) = y$ such that

$$\rho(z_k, \phi_k) \to \mathrm{ms} \le \rho(\tilde{z}, \tilde{\phi}) < \infty.$$

From Lemma 2.3 it follows that the sequences $\{\phi_k\}_{k\in\mathbb{N}}$ and $\{z_k\}_{k\in\mathbb{N}}$ are uniformly bounded in $H^1(\Omega)$ and $\mathtt{BV}(\Omega)$, respectively. Thus there exists subsequences, again denoted by $\{\phi_k\}_{k\in\mathbb{N}}$ and $\{z_k\}_{k\in\mathbb{N}}$, such that

$$\phi_k \to \phi^\dagger \text{ in } L^2(\Omega), \qquad z_k \to z^\dagger \text{ in } L^1(\Omega).$$

Since ρ is weakly lower semicontinuous, it follows that

$$\mathrm{ms} = \lim_{k\to\infty} \rho(z_k, \phi_k) \ge \rho(z^\dagger, \phi^\dagger).$$

Since F is continuous on $L^1(\Omega)$, $F(z^\dagger) = \lim_{k\to\infty} F(z_k) = y$. Analogous to the proof of Theorem 2.9 it follows that $(z^\dagger, \phi^\dagger)$ is admissible and therefore a minimal norm solution. □

Below, we summarize a stability and convergence result. The proof uses classical techniques from the analysis of Tikhonov-type regularization methods (e.g., see [11, 25, 1, 10, 21]) and thus is omitted.

THEOREM 2.11 (convergence and stability). *Let* $\|y^\delta - y\|_Y \le \delta$. *If* $\alpha = \alpha(\delta)$ *satisfies*

$$\lim_{\delta\to 0} \alpha(\delta) = 0 \quad \textit{and} \quad \lim_{\delta\to 0} \frac{\delta^2}{\alpha(\delta)} = 0,$$

then, for a sequence $\{\delta_k\}_{k\in\mathbb{N}}$ *converging to* 0*, there exists a sequence* $\{\alpha_k := \alpha(\delta_k)\}_{k\in\mathbb{N}}$ *such that* $(z_{\alpha_k}, \phi_{\alpha_k})$ *converges in* $L^1(\Omega) \times L^2(\Omega)$ *to a minimal norm solution.*

3. Numerical solution.

We consider a stabilized functional

$$\mathcal{G}_{\varepsilon,\alpha}(\phi) := \|F(P_\varepsilon(\phi)) - y^\delta\|_Y^2 + 2\beta\alpha|P_\varepsilon(\phi)|_{\mathtt{BV}} + \alpha\|\phi - \phi_0\|_{H^1(\Omega)}^2. \tag{3.1}$$

This functional is well posed, as the following lemma shows.

LEMMA 3.1. *For any* $\phi_0 \in H^1(\Omega)$ *the functional* (3.1) *attains a minimizer.*

Proof. The proof is similar to that of Theorem 2.1, taking into account that, for any sequence $\{\phi_k\}_{k\in\mathbb{N}}$ converging weakly to ϕ in the $H^1(\Omega)$-norm, there exists a strongly convergent subsequence in $L^2(\Omega)$. Denoting the subsequence again by $\{\phi_k\}_{k\in\mathbb{N}}$, we find

1.

$$\|P_\varepsilon(\phi_k) - P_\varepsilon(\phi)\|_{L^1(\Omega)} \le \frac{1}{\varepsilon}\sqrt{\mathrm{meas}(\Omega)}\|\phi_k - \phi\|_{L^2(\Omega)} \to 0.$$

2. Therefore

$$|P_\varepsilon(\phi)|_{\mathtt{BV}} \le \liminf_{k\to\infty} |P_\varepsilon(\phi_k)|_{\mathtt{BV}}.$$

Now, the assertion can be proved as for Theorem 2.1. □

In the following we show that for $\varepsilon \to 0$ the minimizer of $\mathcal{G}_{\varepsilon,\alpha}$ approximates a minimizer of $\mathcal{G}_\alpha$; i.e., it approximates an admissible pair.

THEOREM 3.2. *Let $\phi_{\varepsilon,\alpha}$ be a minimizer of $\mathcal{G}_{\varepsilon,\alpha}$. Then for $\varepsilon_k \to 0$ there exists a convergent subsequence $(P_{\varepsilon_k}(\phi_{\varepsilon_k,\alpha}), \phi_{\varepsilon_k,\alpha}) \to (\tilde{z}, \tilde{\phi})$ in $L^1(\Omega) \times L^2(\Omega)$, and the limit minimizes $\mathcal{G}_\alpha$ in the set of admissible pairs.*

Proof. 1. The infimum of $\mathcal{G}_\alpha$ is attained (cf. Theorem 2.9); i.e., there exists (z_α, ϕ_α) minimizing $\mathcal{G}_\alpha$ over all admissible pairs. In particular, taking into account the definition of admissible pairs, there exists a sequence $\{\varepsilon_k\}_{k\in\mathbb{N}}$ of positive numbers converging to zero and a corresponding sequence $\{\phi_k\}_{k\in\mathbb{N}}$ in $H^1(\Omega)$ satisfying

$$\begin{aligned}(P_{\varepsilon_k}(\phi_k), \phi_k) &\to (z_\alpha, \phi_\alpha) \quad \text{in } L^1(\Omega)\times L^2(\Omega),\\ \rho(z_\alpha, \phi_\alpha) &= \lim_{k\to\infty} \left\{ 2\beta |P_{\varepsilon_k}(\phi_k)|_{\mathtt{BV}} + \|\phi_k - \phi_0\|^2_{H^1(\Omega)} \right\}.\end{aligned}$$

2. Let ϕ_{ε_k} be a minimizer of $\mathcal{G}_{\varepsilon_k,\alpha}$. The sequence $\{\phi_{\varepsilon_k}\}_{k\in\mathbb{N}}$ is uniformly bounded in $H^1(\Omega)$. Thus it has a weakly convergent subsequence (which is again denoted by the same indices), and the weak limit is denoted $\tilde{\phi}$. Moreover, $\{P_{\varepsilon_k}(\phi_{\varepsilon_k})\}_{k\in\mathbb{N}}$ is uniformly bounded in $\mathtt{BV}(\Omega)$. Thus, by the compact Sobolev embedding theorem there exists a subsequence $\{\phi_{\varepsilon_k}\}_{k\in\mathbb{N}}$ (again denoted with the same indices) satisfying

$$\phi_{\varepsilon_k} \to \tilde{\phi} \text{ in } L^2(\Omega) \quad \text{and} \quad P_{\varepsilon_k}(\phi_{\varepsilon_k}) \to \tilde{z} \text{ in } L^1(\Omega).$$

Thus $(\tilde{z}, \tilde{\phi}) \in \mathcal{P} \times H^1(\Omega)$ is admissible.

3. From the definition of ρ and the continuity of $F : L^1(\Omega) \to Y$ it follows that

$$\begin{aligned}\|F(\tilde{z}) - y^\delta\|^2_Y &= \lim_{k\to\infty} \|F(P_{\varepsilon_k}(\phi_{\varepsilon_k})) - y^\delta\|^2_Y,\\ \rho(\tilde{z}, \tilde{\phi}) &\le \liminf_{k\to\infty} \left\{ 2\beta |P_{\varepsilon_k}(\phi_{\varepsilon_k})|_{\mathtt{BV}} + \|\phi_{\varepsilon_k} - \phi_0\|^2_{H^1(\Omega)} \right\}.\end{aligned}$$

This shows that

$$\begin{aligned}\mathcal{G}_\alpha(\tilde{z}, \tilde{\phi}) &\le \liminf_{k\to\infty} \mathcal{G}_{\varepsilon_k,\alpha}(\phi_{\varepsilon_k})\\ &\le \liminf_{k\to\infty} \mathcal{G}_{\varepsilon_k,\alpha}(\phi_k)\\ &= \|F(z_\alpha) - y^\delta\|^2_Y + \alpha\rho(z_\alpha, \phi_\alpha)\\ &= \inf \mathcal{G}_\alpha.\end{aligned}$$

Therefore the infimum of $\mathcal{G}_\alpha$ is attained at $(\tilde{z}, \tilde{\phi})$. □

Theorem 3.2 justifies using the functionals $\mathcal{G}_{\varepsilon,\alpha}$ for approximation of the minimizer of $\mathcal{G}_\alpha$. In contrast to the minimizer of $\mathcal{G}_{\varepsilon,\alpha}$, which is a function in $H^1(\Omega)$, the minimizer of $\mathcal{G}_\alpha$ is an admissible pair (z_α, ϕ_α). Recall that the function z_α is not uniquely defined by ϕ_α if it attains critical values in a neighborhood of the zero level set (cf. Remark 2.5).

For numerical purposes it is convenient to derive the optimality conditions of a minimizer of this functional. To this end we consider the functional $\mathcal{G}_{\varepsilon,\alpha}$ with $Y = L^2(\partial\Omega)$.

Since $P_\varepsilon'(\phi)$ is self-adjoint, we can write the formal optimality condition for a minimizer of the functional $\mathcal{G}_{\varepsilon,\alpha}$ as follows:

$$\alpha(\Delta - I)(\phi - \phi_0) = R_{\varepsilon,\alpha,\beta}(\phi), \tag{3.2}$$

where

$$R_{\varepsilon,\alpha,\beta}(\phi) = P_\varepsilon'(\phi)F'(P_\varepsilon(\phi))^*(F(P_\varepsilon(\phi)) - y^\delta) - \beta\alpha P_\varepsilon'(\phi)\nabla \cdot \left(\frac{\nabla P_\varepsilon(\phi)}{|\nabla P_\varepsilon(\phi)|}\right).$$

4. Iterative regularization and the relation to dynamic level set methods. For $n = 1$ set $\mathcal{G}_\alpha^{(1)}(z,\phi) = \mathcal{G}_\alpha(z,\phi)$ (cf. (2.4)). Iterative regularization consists of minimizing the family of functionals

$$\mathcal{G}_\alpha^{(n)}(z,\phi) = \|F(z) - y^\delta\|_Y^2 + \alpha\rho^{(n)}(z,\phi), \tag{4.1}$$

where $\rho^{(n)}$ is the functional ρ (as defined in (2.5)) with ϕ_0 replaced by ϕ_{n-1}. The minimizer of $\mathcal{G}_\alpha^{(n)}(z,\phi)$ is denoted by ϕ_n.

Proceeding as before, we find that ϕ_n can be realized by solving the formal optimality condition

$$\alpha(\Delta - I)(\phi - \phi_{n-1}) = R_{\varepsilon,\alpha,\beta}(\phi). \tag{4.2}$$

Identifying $\alpha = 1/\Delta t$, $t_n = n\Delta t$, and $\phi_n = \phi(t_n)$, $n = 0, 1, \dots,$ we find

$$(\Delta - I)\left(\frac{\phi(t_n) - \phi(t_{n-1})}{\Delta t}\right) = R_{\varepsilon,1/\Delta t,\beta}(\phi(t_n)). \tag{4.3}$$

Considering Δt as a time discretization and using $\beta = b_\Delta \Delta t$, we find that in a formal sense the iterative regularized solution ϕ_n is a solution of an implicit time step for the dynamic system

$$(\Delta - I)\left(\frac{\partial\phi(t)}{\partial t}\right) = R_{\varepsilon,1/\Delta t,b_\Delta\Delta t}(\phi(t)). \tag{4.4}$$

In our numerical experiments we have calculated the solution of the dynamic system (4.4).

Each time step requires solving (4.3). Then $\phi(t_n)$ in (4.3) can be solved with a fixed point iteration: setting $\phi(t_{n-1}) = \phi^{(0)}$, we get $\phi(t_n) = \lim_{k\to\infty}\phi^{(k)}$

$$(\Delta - I)\left(\frac{\phi^{(k+1)} - \phi^{(0)}}{\Delta t}\right) = R_{\varepsilon,1/\Delta t,b_\Delta\Delta t}(\phi^{(k)})\ . \tag{4.5}$$

In our numerical experiments we observed that the iteration starts oscillating after the first iteration (cf. Figure 4.1). This behavior becomes transparent by noting that the H^1-seminorm typically dominates the L^2-norm in the quadratic regularization term. The H^1-seminorm difference of the regularized solution and $\phi^{(0)}$ is small if it is just shifted up or down. In numerical experiments it is observed that the first iteration almost corresponds to a horizontal shift of $\phi^{(0)}$ such that the residual functional is minimized (cf. Figure 4.2), and also the further iterations are again nearly horizontally shifted versions of $\phi^{(0)}$ (cf. Figure 4.3).

In almost all test examples the residual $\|F(P_\varepsilon(\phi^{(k)})) - y^\delta\|^2$ is oscillating in a way dependent on k (cf. Figure 4.2) and smallest for $k = 1$.

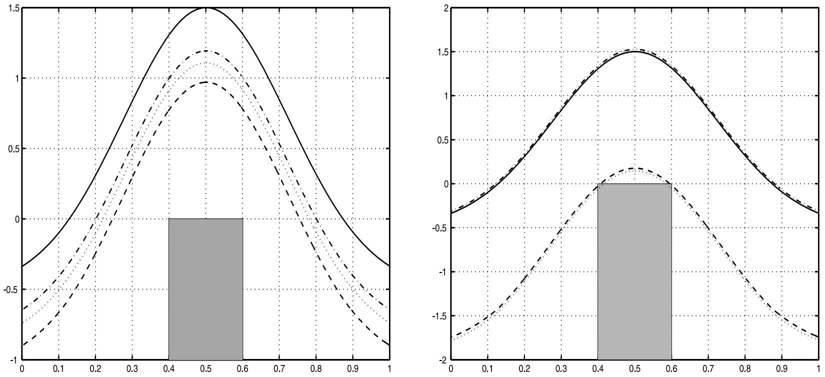

FIG. 4.1. *The functions $\phi^{(0)}$ (solid line), $\phi^{(1)}$ (dashed line), $\phi^{(2)}$ (dash-dot line), and $\phi^{(3)}$ (dotted line). To recover is the interval $[0.4, 0.6]$, which is displayed by the grey rectangle. The first iteration is the best. In the right picture α is smaller than in the left picture.*

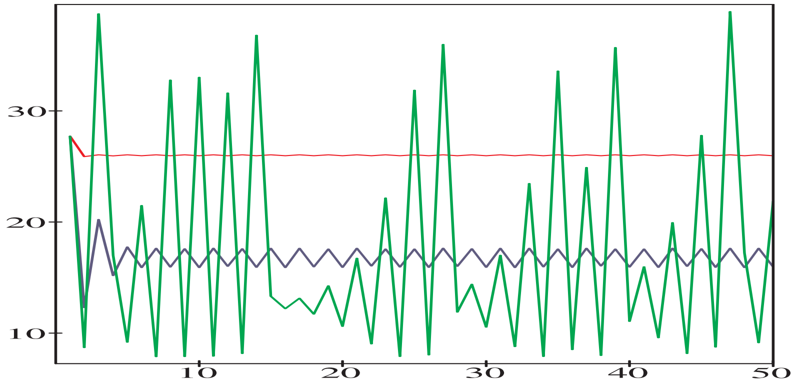

FIG. 4.2. *Decay of the residual $\|F(P_\varepsilon(\phi^{(k)})) - y^\delta\|_Y^2$ dependent on the number of iterations (residual evaluated for the first experiment—noise-free data in section 5). After the first iteration the fixed-point iteration stagnates.*

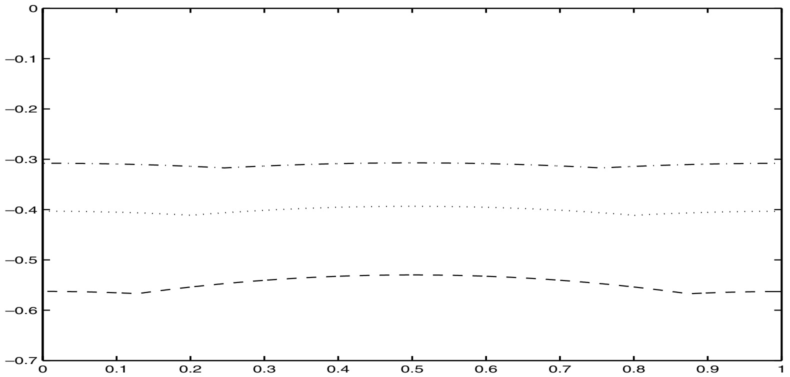

FIG. 4.3. *The differences between $\phi^{(0)}$ and the functions $\phi^{(1)}$ (dashed line), $\phi^{(2)}$ (dash-dot line), and $\phi^{(3)}$ (dotted line) from the left picture of Figure 4.1.*

The above consideration justifies our restricting attention to the approximate solution of the dynamic system (4.2), where in each time step only one iteration step of (4.5) is used; i.e., we use an explicit Euler method for solving the evolution process. In this case numerical instabilities may occur by dividing by small absolute values of the gradient in the differential $\nabla \cdot \left(\frac{\nabla P_\varepsilon(\phi)}{|\nabla P_\varepsilon(\phi)|}\right)$. Thus, for numerical purposes it is convenient to introduce a small positive number h and replace the differential by

$$\nabla \cdot \left(\frac{\nabla P_\varepsilon(\phi)}{\sqrt{|\nabla P_\varepsilon(\phi)|^2 + h^2}} \right) .$$

Usually semiimplicit iteration schemes require a less restrictive time marching. (This approach is commonly referred to as Dziuk's method.) The implementation would require solving

$$\begin{aligned}(\Delta - I)\left(\frac{\phi^{(k+1)} - \phi^{(0)}}{\Delta t}\right) &= P_\varepsilon'(\phi^{(k)})F'(P_\varepsilon(\phi^{(k)}))^*(F(P_\varepsilon(\phi^{(k)})) - y^\delta) \\ &\quad - b_\Delta P_\varepsilon'(\phi^{(k)})\nabla \cdot \left(\frac{\nabla P_\varepsilon(\phi^{(k+1)})}{\sqrt{|\nabla P_\varepsilon(\phi^{(k)})|^2 + h^2}} \right) .\end{aligned} \tag{4.6}$$

In implementation of this approach the difficulty arises that the function in front of $\nabla \cdot \left(\nabla P_\varepsilon(\phi^{(k+1)})/\sqrt{|\nabla P_\varepsilon(\phi^{(k)})|^2 + h^2}\right)$ vanishes outside of a neighborhood of the zero level set, which makes it almost impossible to implement this scheme efficiently.

5. Numerical experiments. In this section we shall consider an inverse potential problem of recovering the shape of a domain D using the knowledge of its (constant) density and the measurements of the Cauchy data of the corresponding potential on the boundary of a fixed Lipschitz domain $\Omega \subset \mathbb{R}^2$, which contains $\overline{D}$. This is the same problem as considered by Hettlich and Rundell [12], which used iterative methods for recovering a single star-shaped object.

To achieve an analogous problem, a certain definition of the operator F is necessary:

$$\begin{aligned} F : L^2(\Omega) &\to L^2(\partial\Omega), \\ \chi_D &\to \ F(\chi_D). \end{aligned}$$

This is possible because we consider only characteristic functions χ_D. The $L^2(\Omega)$-norm is then equivalent to the $L^1(\Omega)$-norm of χ_D. Therefore the necessary properties are retained.

The problem introduced above can mathematically be described as follows:

$$\Delta u = \chi_D \ \text{ in } \Omega, \qquad u|_{\partial\Omega} = 0, \tag{5.1}$$

where χ_D is the characteristic function of the domain $D \subset \Omega$, which has to be reconstructed. Since $\chi_D \in L^2(\Omega)$, the Dirichlet boundary value problem in (5.1) has a unique solution, the potential $u \in H^2(\Omega) \cap H_0^1(\Omega)$. Here $H_0^1(\Omega)$ is defined as the closure with respect to $H^1(\Omega)$ of functions in $C^\infty(\Omega)$ with compact support in Ω.

The inverse problem that we are concerned with consists of determining the shape of D from measurements of the Neumann trace of u at $\partial\Omega$, i.e., from $[\partial u/\partial \nu]_{\partial\Omega}$, where ν represents the outer normal vector to $\partial\Omega$.

Notice that this problem can be considered in the framework of an inverse problem for the *Dirichlet-to-Neumann map.* For given $h \in L^2(\Omega)$, the Dirichlet-to-Neumann operator maps a Dirichlet boundary datum onto the Neumann trace of the potential, i.e., $\Lambda : H^{1/2}(\partial\Omega) \to H^{-1/2}(\partial\Omega)$, $\Lambda(\varphi) := [\partial\tilde{u}/\partial\nu]_{\partial\Omega}$, where $\tilde{u}$ solves

$$\Delta\tilde{u} = h \text{ in } \Omega, \qquad \tilde{u}|_{\partial\Omega} = \varphi\,.$$

The inverse problem for the Λ operator consists of determining the unknown parameter (i.e., the function h) from different pairs of Dirichlet Neumann boundary data. The general case with $h \in L^2(\Omega)$ has already been considered by many authors, including [6, 23], who introduced numerical methods based on Tikhonov regularization, and [12], who used iterative regularization methods.

Hettlich and Rundell [12] observe that, in the particular case $h = \chi_D$, one pair of Dirichlet–Neumann measurement data furnishes as much information as the full Dirichlet–Neumann operator; i.e., it is sufficient to consider only one pair of Cauchy data for the inverse problem. Therefore, no further information on D can be gained by using various pairs of Dirichlet–Neumann data, since we can always reduce the reconstruction problem to the homogeneous Dirichlet case.

For the particular case $h = \chi_D$, it has been observed by Hettlich and Rundell [12] that the Cauchy data may not furnish enough information to reconstruct the boundary of D, e.g., if D is not simply connected. On the other hand, Isakov observed in [13] that star-like domains D are uniquely determined by their potentials.

The inverse potential problem is discussed within the general framework introduced in section 1. In particular, we allow domains that consist of a number of connected inclusions. For this general class we do not have unique identifiability, and we restrict our attention to "minimum-norm solutions." Recall that in this case a minimum-norm solution is a level set function ϕ, where $P(\phi)$ determines the inclusion. A minimum-norm solution satisfies the requirement that it minimize the functional $\rho(z, \phi)$ in the class of level set functions such that the corresponding Neumann boundary values $\frac{\partial u}{\partial \nu}$ fit the data y^δ.

5.1. The level set regularization algorithm. In the following we describe the level set regularization algorithm. This method is comparable with the Landweber iteration as proposed by Hettlich and Rundell [12]. In our context the operator F' can be considered as an approximation of the *domain derivative operator* for multiple connected domains (cf. Figure 5.1).

The complexity of our algorithm is as follows: at each iteration of the level set method, three elliptic boundary value problems are solved (two of Dirichlet type and one of Neumann type).

In Figure 5.1 the iteration procedure for the solution of the formal optimality condition (3.2) is outlined. The algorithm can be implemented using finite element codes (as we did) or finite difference methods for the solution of partial differential equations.

5.2. Reconstruction of a density function with non–simply connected support. In this first experiment we consider the inverse problem of reconstructing the right-hand-side χ_D in (5.1) from the knowledge of a single pair of boundary data $(u, \Lambda u) = (0, y^\delta)$ at $\partial\Omega$. In the examples considered below we always use the squared domain $\Omega = (0,1)^2 \subset \mathbb{R}^2$. Additionally, $\chi_D \in L^2(\Omega)$ is the characteristic function as represented in Figure 5.2.

The overdetermined boundary measurement data y^δ for solving the inverse problem is obtained by solving the elliptic boundary value problem in (5.1). Notice that χ_D corresponds to the characteristic function of a not-connected proper subset of Ω.

1. Evaluate the residual $r_k := F(P_\varepsilon(\phi_k)) - y^\delta = \frac{\partial u_k}{\partial \nu} - y^\delta$, where u_k solves

$$\Delta u_k = P_\varepsilon(\phi_k) \ \texttt{in} \ \Omega, \qquad u_k|_{\partial\Omega} = 0.$$

2. Evaluate $v_k := F'(P_\varepsilon(\phi_k))^*(r_k) \in L^2(\Omega)$, solving

$$\Delta v_k = 0 \ \texttt{in} \ \Omega, \quad v_k|_{\partial\Omega} = r_k\,.$$

3. Evaluate $w_k \in H^1(\Omega)$, satisfying

$$(I - \Delta) w_k = -P'_\varepsilon(\phi_k)\, v_k + \beta\alpha P'_\varepsilon(\phi_k) \nabla \cdot \left(\frac{\nabla P_\varepsilon(\phi_k)}{|\nabla P_\varepsilon(\phi_k)|} \right) \ \texttt{in} \ \Omega,$$
$$\frac{\partial w_k}{\partial \nu}|_{\partial\Omega} = 0.$$

4. Update the level set function $\phi_{k+1} = \phi_k + \frac{1}{\alpha}\, w_k\,.$

FIG. 5.1. *Implementation of a single iteration step for minimizing the level set regularization.*

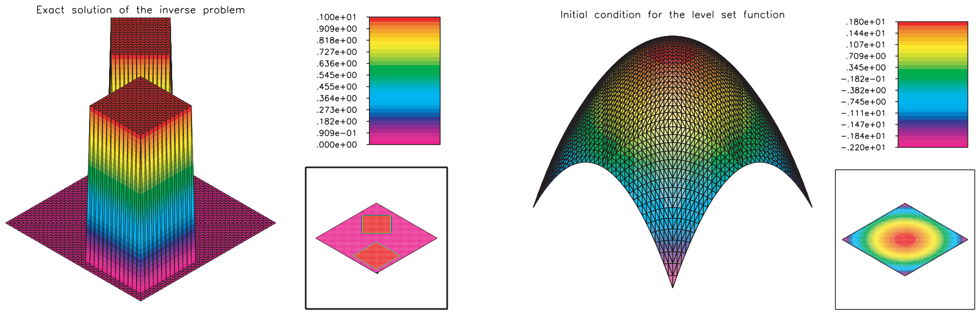

FIG. 5.2. *The picture on the left-hand side shows the coefficient to be reconstructed. In the other picture, the initial condition for the level set regularization method is given.*

The initial condition for the level set function is shown in Figure 5.2. In order to avoid inverse crimes, the direct problem (5.1) is solved on an adaptively refined grid with 8.807 nodes (three levels of adaptive refinement). Alternatively, in the numerical implementation of the level set method, all boundary value problems are solved on a uniformly refined grid with 2.113 nodes.

When the data is given exactly, we tested the iterative level set regularization without the additional regularization term $|P_\varepsilon(\phi_k)|_{\mathtt{BV}}$, i.e., $\beta = 0$.

In all computed experiments we use the operator P_ε defined in section 2 with $\varepsilon = 1/8$. This seems to be compatible with the size of our mesh, since the diameter of the triangles in the uniform grid (used in the finite element method) is approximately $\sqrt{2}/32$.

In Figure 5.3 we present the evolution of the level set function for given exact data for the first 3000 iterative steps. As one can see in this figure, the original level set splits into two convex components after approximately 800 iterations. After 1000 iterations, the level set function still changes but very slowly. We performed similar tests for different initial conditions and observed that, after 1000 iterations, the corresponding pictures look very much alike.

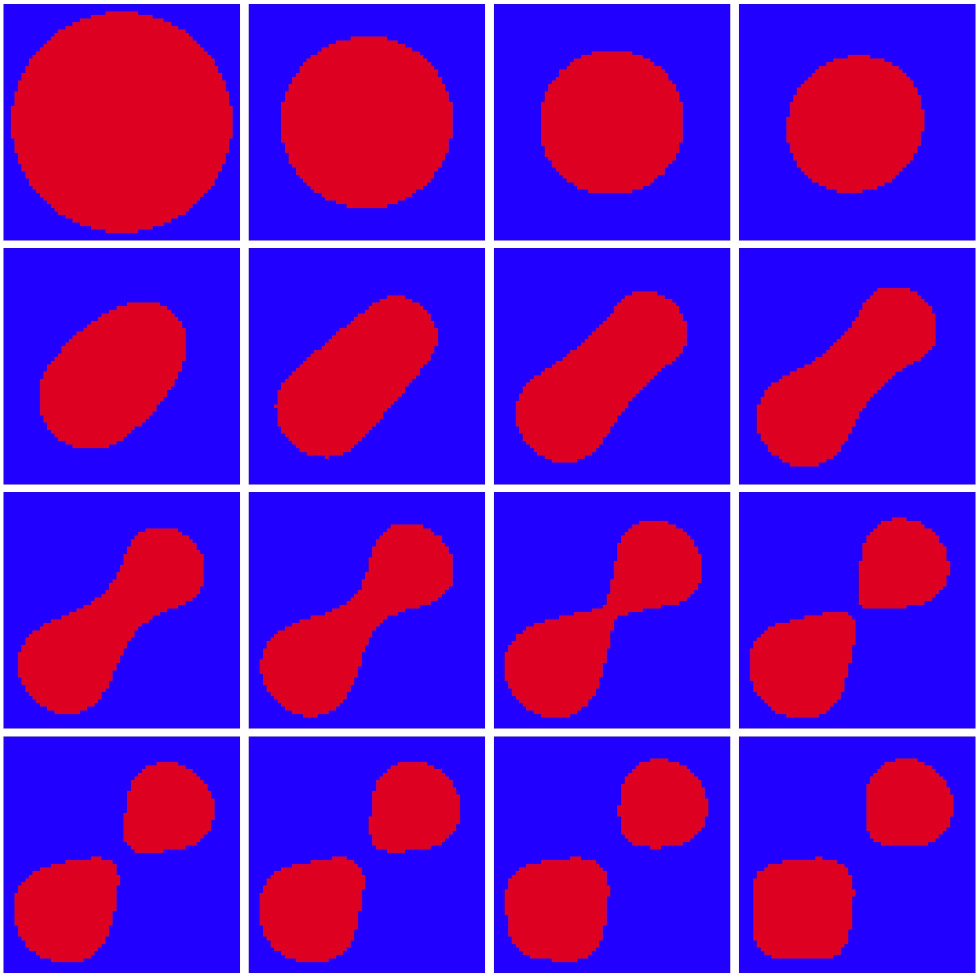

FIG. 5.3. *Level set evolution for exact data. Plots after (grouped by row)* $0, 1, 2, 10$; $100, 200, 300, 400$; $500, 600, 700, 800$; $900, 1000, 2000, 3000$ *iterative steps.*

For the second part of this experiment, the density function to be reconstructed is still the one shown in Figure 5.2. This time, however, we add randomly generated noise to the data y^δ used in the first part of the experiment.

The exact boundary data y^δ is shown in Figure 5.4 as the square-dotted (blue) line. We consider actually two distinct sets of perturbed data. For the first experiment we add to the exact data a white noise of 10% (in the l_∞-norm). For the second experiment we use a noise level of 50%. Both sets of inaccurate data are plotted in Figure 5.4 and correspond to the solid (red) line.

As in the noise-free experiment, care was taken to avoid inverse crimes. The choice of the parameter ε (operator P_ε) also follows the same criteria as before. However, since we are now dealing with noisy data, we have to develop a strategy for choosing the regularization parameter β. For this proposal we opted for the fit-to-data strategy; i.e., $\beta\alpha$ is chosen such that the regularization term (see Figure 5.1) has the same order as the noise level.

The corresponding results generated by the level set method were surprisingly stable, as one can observe in Figures 5.5 and 5.6. In the first case (noise level of 10%)

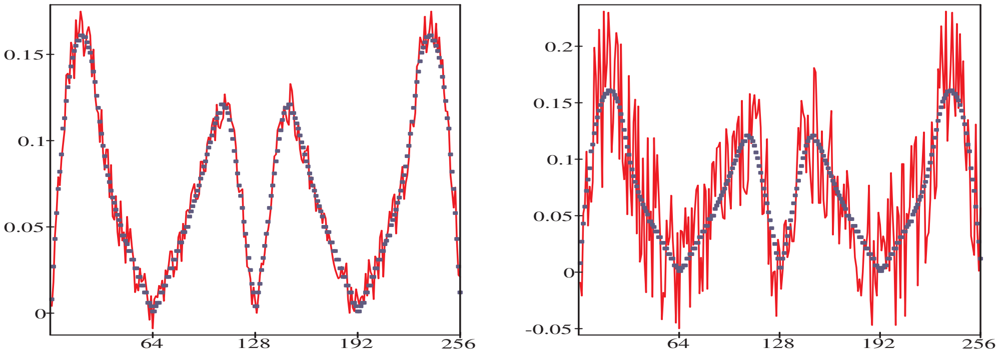

FIG. 5.4. *The square-dotted (blue) line represents the exact data* y^δ*; the solid (red) line represents the perturbed data. The noise level corresponds to* 10% *at the left-hand side and* 50% *at the right-hand side.*

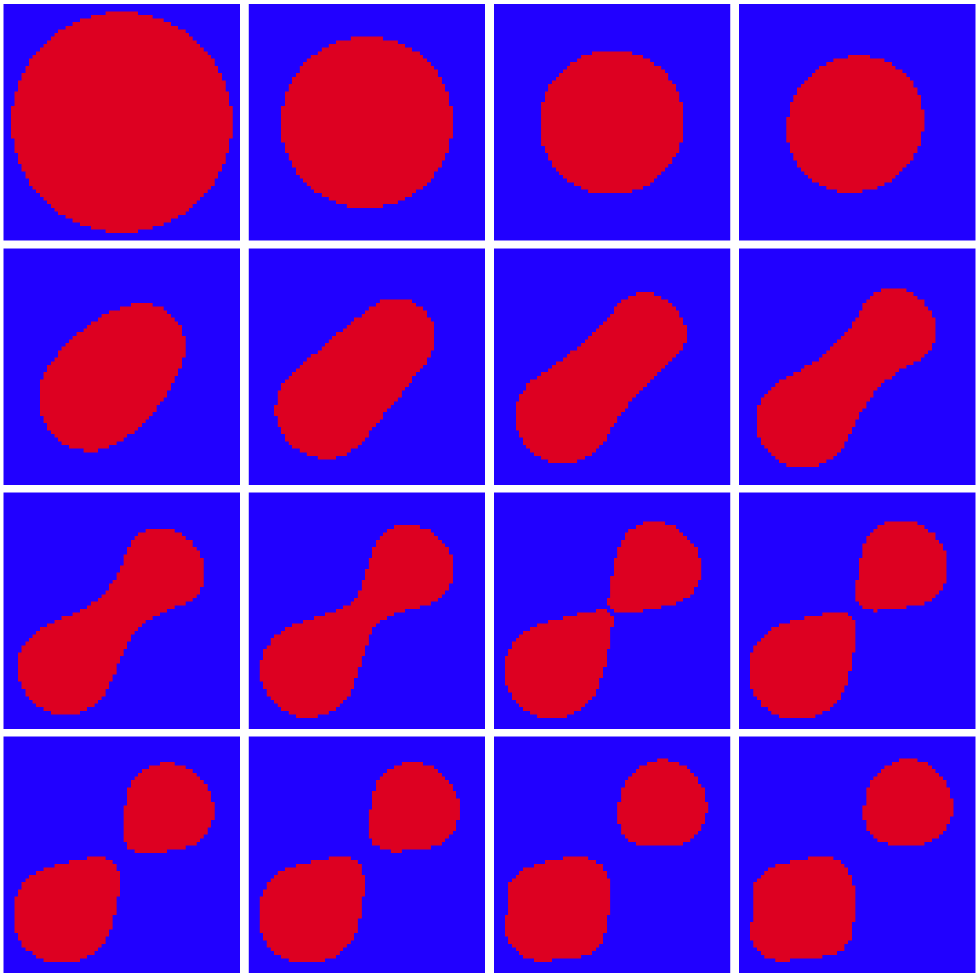

FIG. 5.5. *Level set evolution for inaccurate data; noise level of* 10%. *Plots after* $0, 1, 2, 10$; $100, 200, 300, 400$; $500, 600, 700, 800$; $900, 1000, 2000, 3000$ *iterative steps.*

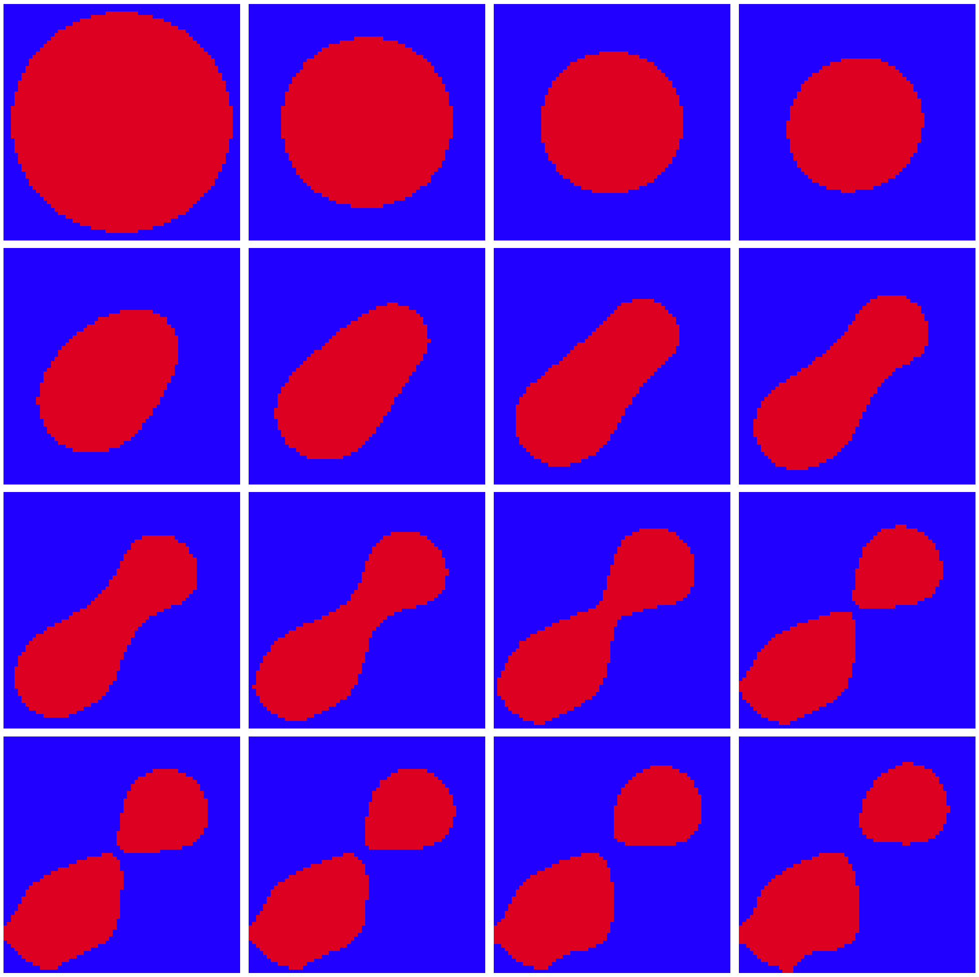

FIG. 5.6. *Level set evolution for inaccurate data; noise level of* 50%. *Plots after* $0, 1, 2, 10$; $100, 200, 300, 400$; $500, 600, 700, 800$; $900, 1000, 1300, 1600$ *iterative steps.*

the results are comparable with the previous experiment, where exact data was available. In the second case (noise level of 50%) we are not able to precisely recover the shape of the set D, corresponding to the characteristic function shown in Figure 5.2. However, we are still able to identify the number of connected components of D, as well as their relative positions inside the domain Ω.

5.3. Reconstruction of a density function with nonconvex support. In this second experiment we consider the problem of reconstructing the density function shown in Figure 5.7. The main goal now is to investigate the difficulty of the level set method in recovering nonconvex domains. The domain Ω is the same used in subsection 5.2, and again we aim to reconstruct the density function in (5.1) from boundary measurements.

As in the first part of the previous experiment, the data is given almost exactly, and the velocity w_k is again obtained by solving the boundary value problem with $\beta = 0$. The evolution of the level set function is shown in Figure 5.8.

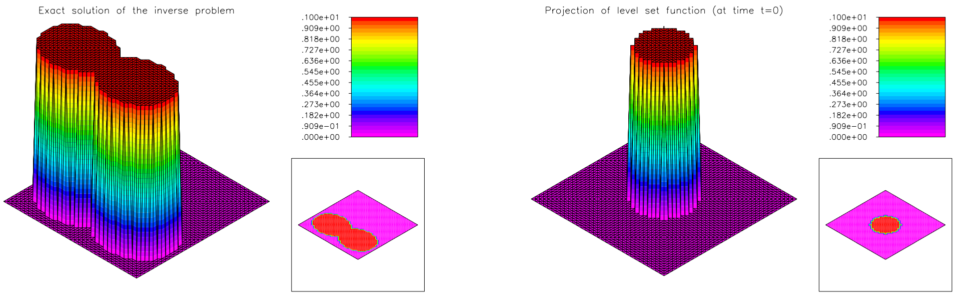

FIG. 5.7. *(Left) The coefficient to be reconstructed. (Right) The (projection of the) initial condition for the level set regularization method.*

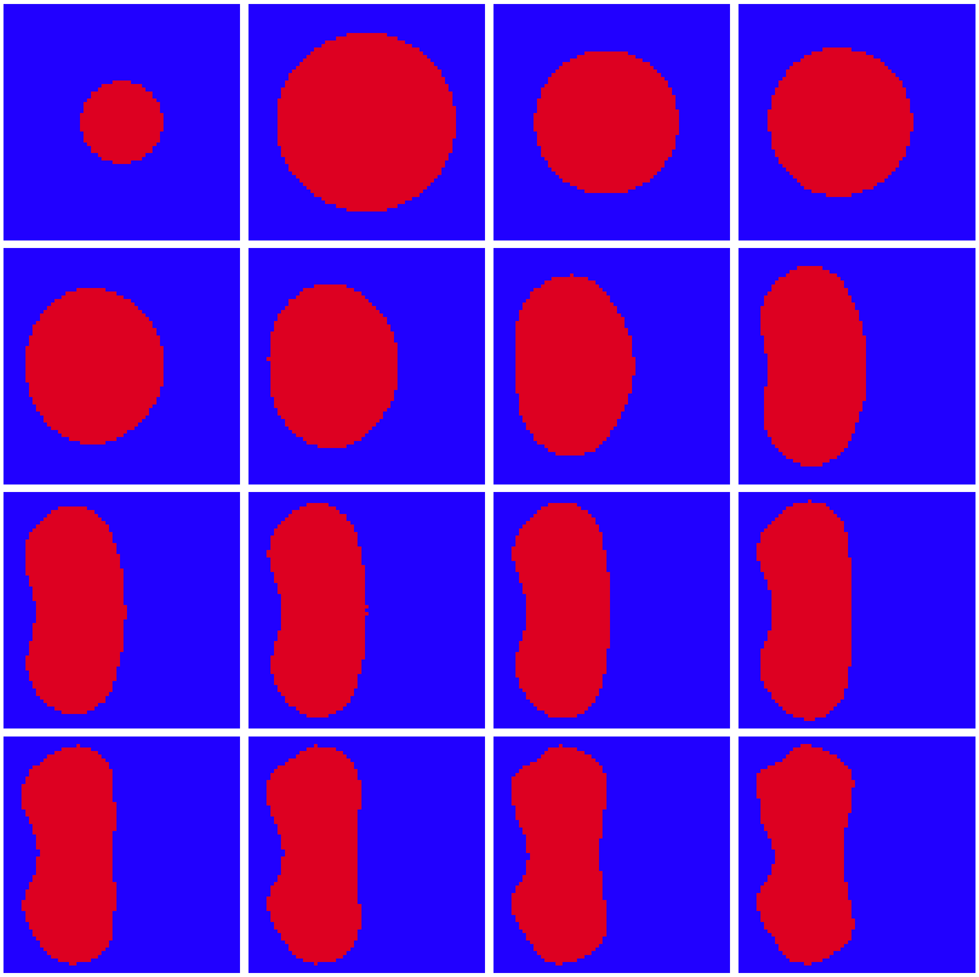

FIG. 5.8. *Level set evolution for the second experiment. Plots after* $0, 1, 5, 20;$ $50, 100, 200, 400;$ $600, 800, 1000, 2000;$ $5000, 10000, 20000, 50000$ *iterative steps.*

Remark 5.1. *The effect of parameter changes.* In our numerical observations we observed that in numerical simulations the minimizer is not severely affected by the choice of $\beta\alpha$ and can, in fact, be neglected.

GAUSSIAN INTERVAL QUADRATURE FORMULAE FOR TCHEBYCHEFF SYSTEMS[*]

BORISLAV BOJANOV[†] AND PETAR PETROV[†]

Abstract. For any given system of continuously differentiable functions $\{u_k\}_{k=1}^{2n}$ that constitute an extended Tchebycheff system of order 2 on $[a, b]$ we prove the existence and uniqueness of the Gaussian interval quadrature formula based on n weighted integrals over nonoverlapping subintervals of $[a, b]$ of preassigned lengths. This supplies an analogue of the result of Krein about canonical representation of linear positive functionals.

Key words. Gaussian quadrature, Tchebycheff systems, interval analysis, polynomials

DOI. 10.1137/040606521

1. Introduction.

The classical Gauss quadrature formula was extended over the years in various directions. The present paper concerns an interesting development of the subject, initiated by Krein in [5]. He proved that for any given system $U_{2n} := \{u_1, u_2, \dots, u_{2n}\}$ of continuous functions that form a Tchebycheff system on $[a, b]$, there exists a unique set of points $x_1 < \cdots < x_n$ in $[a, b]$ such that the interpolatory quadrature formula

$$\int_a^b f(t)\,dt \approx \sum_{k=1}^{n} C_k f(x_k)$$

is exact for every generalized polynomial

$$u(t) = c_1 u_1(t) + \cdots + c_{2n} u_{2n}(t)$$

with real coefficients $\{c_j\}$. Actually, his result is slightly stronger and covers the canonical representation of a general linear positive functional $L[f]$ on $C[a, b]$. Simplified proofs of Krein's result can be found in [4] and [1].

A significant effort was made in the last few decades in extending the Gauss formula to other natural types of data, in addition to the standard one of sampling function values. Recently, we proved in [2], [3] the existence and uniqueness of a formula of the form

$$\int_a^b f(t)\,dt \approx \sum_{k=1}^{n} A_k \frac{1}{h_k} \int_{x_k}^{x_k+h_k} f(t)\,dt$$

of highest degree of precision with respect to the class of algebraic polynomials, for any fixed system of lengths $\{h_k\}$, $h_1 + \cdots + h_n \le b - a$. The problem stayed open for quite a long time (see [7], [9], [10], [11], [12] for previous results). In [8], Milovanović and Cvetković showed that the proof from [3] can be modified to cover the case of

Jacobi weight function. The purpose of this paper is to go further and show that the result also holds for Tchebycheff systems and thus supplies an interval analogue of Krein's result. In case all lengths $\{h_k\}$ are supposed equal to zero, the quadrature reduces to Krein's canonical representation.

Throughout this paper we assume that n is a natural number, $[a,b]$ is a fixed finite interval, and $U_{2n} := \{u_1, u_2, \dots, u_{2n}\}$ is a given system of continuously differentiable functions which constitute an extended Tchebycheff (ET) system of order 2 on $[a,b]$. Recall that the system U_{2n} constitutes an ET system of order 2 on $[a,b]$ if any nonzero generalized polynomial u with respect to U_{2n} possesses no more than $2n-1$ zeros in $[a,b]$ (counting twice every common zero of u and u') (see [4, Chapter II]). We shall denote by $\mathcal{U}_{2n}$ the linear space of all generalized polynomials with respect to the system U_{2n}, that is,

$$\mathcal{U}_{2n} := \text{span}\,\{u_1, u_2, \dots, u_{2n}\}.$$

Further, assume that $\mu(t)$ is a given integrable function on $[a,b]$, which is continuous and strictly positive on (a,b), and denote by $L[f]$ the integral

$$L[f] := \int_a^b \mu(t) f(t)\,dt.$$

We are going to give a canonical representation of $L[f]$ in $\mathcal{U}_{2n}$ of the form

$$L[f] = \sum_{k=1}^{n} a_k \frac{1}{I_k} I_k[f]\,,$$

where

$$I_k[g] := \int_{x_k}^{x_k+h_k} \mu(t) g(t)\,dt, \qquad I_k := I_k[1].$$

Here we assume that

$$\Delta_k := [x_k, x_k + h_k]$$

are n nonoverlapping subintervals of $[a,b]$ of preassigned lengths $|\Delta_k| := h_k \geq 0$.

In case $h_k = 0$ the quantity $I_k[f]/I_k$ is defined by continuity, that is,

$$\frac{1}{I_k} I_k[f]\Big|_{h_k=0} := \lim_{h_k \to 0} \frac{1}{I_k} I_k[f] = f(x_k).$$

Keeping the notation from [3], we introduce the set H of admissible lengths $\mathbf{h} = (h_1, \dots, h_n)$,

$$H := \left\{ \mathbf{h} \in \mathbb{R}^n \,:\, h_k \geq 0,\, k = 1, \dots, n,\, \sum_{k=1}^{n} h_k < b - a \right\},$$

the associated set

$$D = D(\mathbf{h}) := \{\mathbf{x} \in \mathbb{R}^n \,:\, a < x_1 \leq x_1 + h_1 < \cdots < x_n \leq x_n + h_n < b\}$$

of admissible nodes, and its closure

$$\bar{D} = \bar{D}(\mathbf{h}) := \{\mathbf{x} \in \mathbb{R}^n \,:\, a \leq x_1 \leq x_1 + h_1 \leq \cdots \leq x_n \leq x_n + h_n \leq b\}.$$

Let us denote by ∂D the boundary of D. We prove the following.

THEOREM 1. *Let $U_{2n} = \{u_1, \dots, u_{2n}\}$ be any ET system of order 2 of continuously differentiable functions on $[a,b]$ and let μ be an integrable function on $[a,b]$ which is continuous and positive on (a,b). Then, for every given set of numbers $\mathbf{h} \in H$ there exists a unique set of nodes $\mathbf{x} \in D(\mathbf{h})$ such that*

$$L[f] = \sum_{k=1}^{n} a_k \frac{1}{I_k} \int_{x_k}^{x_k+h_k} \mu(t) f(t)\, dt \tag{1}$$

for every f from the space $\mathcal{U}_{2n}$.

We shall call (1) a Gaussian formula.

Note that Theorem 1 also holds in the trivial case $h_1 + \cdots + h_n = b - a$ since the uniqueness of the best coefficients $a_k = I_k$, $k = 1, \dots, n$, can be easily verified.

The proof of Theorem 1 is given in section 3 and is based on some auxiliary results contained in section 2.

2. Auxiliary results. The lemmas in this section hold under weakened conditions on the space $\mathcal{U}_{2n}$ and the weight μ. It is enough to assume that the Tchebycheff system U_{2n} consists of continuous functions on $[a,b]$ and $\mu(t)$ is any given continuous weight function on (a,b) such that $\int_\alpha^\beta \mu(t)\, dt > 0$ for every $a \le \alpha < \beta \le b$.

We begin with two lemmas concerning interpolation properties of the Tchebycheff space $\mathcal{U}_{2n}$.

LEMMA 1. *Let*

$$a \le t_1 \le t_1 + h_1 \le \cdots \le t_{2n} \le t_{2n} + h_{2n} \le b$$

be given points such that $t_i < t_{i+1}$ in case $h_i = h_{i+1} = 0$. Then the interpolation problem

$$\left(\int_{t_k}^{t_k+h_k} \mu(t)\, dt \right)^{-1} \cdot \int_{t_k}^{t_k+h_k} \mu(t) u(t)\, dt = f_k\,, \quad k = 1, \dots, 2n, \tag{2}$$

is uniquely solvable in $\mathcal{U}_{2n}$ for any values $f_k \in \mathbb{R}$.

Proof. It is sufficient to show that the corresponding homogeneous interpolation problem admits only the zero solution $u \equiv 0$. In order to do this, suppose that $u \in \mathcal{U}_{2n}$ satisfies conditions (2) with $f_k = 0$. Note that in case $h_k = 0$ the corresponding homogeneous condition reduces to $u(t_k) = 0$, and if $h_k > 0$, it implies that $u(t)$ must change sign on $(t_k, t_k + h_k)$. Then u must have at least one zero in every interval $[t_k, t_k + h_k]$, i.e., at least $2n$ zeros in total. But this means that $u \equiv 0$, since $\mathcal{U}_{2n}$ is a Tchebycheff space, and the proof is complete. □

LEMMA 2. *Let $\mathbf{h} \in H$ be fixed. Then for every $\mathbf{x} \in \partial D$ there exists a generalized polynomial $u \in \mathcal{U}_{2n}$ which is positive on $[a,b] \setminus \cup_{k=1}^n \Delta_k$ and*

$$\frac{I_k[u]}{I_k} = 0\,, \quad \textit{for } k = 1, \dots, n. \tag{3}$$

Proof. We consider only the case $x_j + h_j = x_{j+1}$ for some $j \in \{1, \dots, n-1\}$, $h_j > 0$, $h_{j+1} > 0$, $x_k + h_k < x_{k+1}$ for all $k \ne j$. The other cases follow similarly.

Any generalized polynomial w from $\mathcal{U}_{2n}$,

$$w = c_1 u_1 + \cdots + c_{2n} u_{2n}\,,$$

is completely determined by its coefficients $\{c_i\}$. We shall look for a generalized polynomial w satisfying the conditions (3) and, in addition,

$$w(x_k + h_k) = 0 \quad \text{for every} \quad k \neq j, j+1.$$

If some $h_k = 0$, we interpret the conditions $I_k[w]/I_k = 0$, $w(x_k + h_k) = 0$ as "x_k is a double zero of w" (see [4, Chapter I, Theorems 5.1 and 5.2] for handling "double zeros" of Tchebycheff systems). Thus, we have imposed $2n-2$ zero conditions on w. Now, if one of the end points, say a, is not among the prescribed nodes $x_1, \ldots, x_n$, we define one more condition, $w(a) = 0$. If $a = x_1$ and $b = x_n + h_n$, then we delete the condition $w(x_1 + h_1) = 0$, choose two distinct points ξ_1 and ξ_2 outside any of the subintervals Δ_k, $k = 1, \ldots, n$, and impose the conditions "w has a double zero at ξ_1," $w(\xi_2) = 1$. In this way, we have a system of $2n$ linear equations with respect to the coefficients of w. It is easy to see that the corresponding homogeneous system admits only the zero solution since any of the $2n$ homogeneous equations leads to a zero of w. Thus the system of conditions imposed on u determine it uniquely. All zeros of w lie in the intervals $\{\Delta_i\}_{i=1}^n$ and also at ξ_1. Constructing similarly another polynomial $v \in \mathcal{U}_{2n}$ with different point ξ_1, we conclude that $u = w + v$ is positive outside $\{\Delta_i\}_{i=1}^n$ and satisfies (3). The lemma is proved. □

The next observation is a simple consequence from known properties of the Tchebycheff systems.

Lemma 3. *For all* $\mathbf{h} \in H$*, the coefficients* a_k *of the Gaussian formula* (1) *are uniformly bounded.*

Proof. It is a well-known fact (see, for example, [6, Chapter II, Theorem 1.4]) that every Tchebycheff space contains a strictly positive function. Let $\tilde{u} \in \mathcal{U}_{2n}$ and $\tilde{u}(t) > 0$ on $[a, b]$. Since (1) holds for $\tilde{u}$ and the coefficients a_k are strictly positive (see [2, Theorem 1]), then

$$a_k < \frac{\int_a^b \mu(x)\tilde{u}(x)\,dx}{\min_{\,x\in[a,b]}\tilde{u}(x)}, \quad k = 1, \ldots, n. \qquad \square$$

Further, we prove a lemma similar to Lemma 2 from [3] , which asserts that the node subintervals of any Gaussian formula are uniformly distant from each other and from the end points of the interval $[a, b]$.

For each $0 < \varepsilon < b - a$ we define

$$H_\varepsilon := \left\{ \mathbf{h} \in H \, : \, \sum_{k=1}^n h_k \leq b - a - \varepsilon \right\}. \qquad \square$$

Lemma 4. *Let* $0 < \varepsilon < b - a$*. Then there exists an* $\varepsilon_0 \in (0, \varepsilon)$ *such that all* $\mathbf{h} \in H_\varepsilon$ *and the corresponding nodes* $\mathbf{x} \in D(\mathbf{h})$ *which define a Gaussian formula* (1) *satisfy the conditions*

$$(4) \quad x_1 - a > \varepsilon_0, \quad x_{j+1} - x_j - h_j > \varepsilon_0, \; j = 1, \ldots, n-1, \quad b - x_n - h_n > \varepsilon_0.$$

Proof. Assume the contrary. Then for each $0 < \delta < \varepsilon$ there exist numbers $\mathbf{h}_\delta \in H_\varepsilon$ and nodes $\mathbf{x}_\delta \in D(\mathbf{h}_\delta)$ which define a Gaussian quadrature formula (1) with coefficients $a_{k,\delta}$, but at least one of the conditions in (4) (with $\varepsilon_0 = \delta$) is violated.

Since the sequences $\{\mathbf{h}_\delta\}$ and $\{\mathbf{x}_\delta\}$ are bounded, and according to Lemma 3 the corresponding coefficients $a_{k,\delta}$ are bounded, there exist subsequences $\{\mathbf{h}^{(i)}\}_{i=1}^\infty$,

$\{\mathbf{x}^{(i)}\}_{i=1}^{\infty}$, and $\{a_k^{(i)}\}_{i=1}^{\infty}$, with $\mathbf{x}^{(i)} \in D(\mathbf{h}^{(i)})$, which converge to certain $\mathbf{h}^{(0)} \in H_\varepsilon$, $\mathbf{x}^{(0)} \in \partial D(\mathbf{h}^{(0)})$, and $a_k^{(0)}$, respectively. They define a Gaussian formula

$$L[u] = \sum_{k=1}^{n} a_k^{(0)} \frac{1}{I_k^{(0)}} I_k^{(0)}[u] \tag{5}$$

(with $I_k^{(0)}$ and $I_k^{(0)}[u]$, defined by $x_k^{(0)}$ and $h_k^{(0)}$). In addition, since $\mathbf{x}^{(0)} \in \partial D(\mathbf{h}^{(0)})$, at least one of the following equalities holds:

$$x_1^{(0)} = a, \quad x_{j+1}^{(0)} = x_j^{(0)} + h_j^{(0)},\ j = 1, \dots, n-1, \quad x_n^{(0)} + h_n^{(0)} = b.$$

Using Lemma 2, in any of the above cases we can construct a generalized polynomial $u \in \mathcal{U}_{2n}$ for which the right-hand side of (5) is zero, but the integral in the left-hand side is positive. This leads to a contradiction, and the proof is complete. □

3. Proof of Theorem 1. Let $\mathbf{h} \in H_\varepsilon$ be a fixed vector. First we shall find a system of equations for the nodes $\mathbf{x} \in D(\mathbf{h})$ ensuring the Gaussian property of formula (1). Lemma 4 implies that the nodes of any Gaussian formula (1) belong to the set $D_{\varepsilon_0}(\mathbf{h})$ defined by (4). Let us choose arbitrary points

$$a < s_1 < \cdots < s_n < a + \varepsilon_0/2 \quad \text{and} \quad b - \varepsilon_0/2 < t_1 < \cdots < t_n < b.$$

According to Lemma 1, for each $i \in \{1, \dots, n\}$, there exist a unique pair of generalized polynomials p_i, q_i from $\mathcal{U}_{2n}$ such that

$$p_i(s_k) = 0\,, \quad \frac{1}{I_k} I_k[p_i] = \delta_{ik}\,, \quad i, k = 1, \dots, n\,, \tag{6}$$

and

$$q_i(t_k) = 0\,, \quad \frac{1}{I_k} I_k[q_i] = \delta_{ik}\,, \quad i, k = 1, \dots, n. \tag{7}$$

It is easily seen that $\{p_i, q_i\}_{i=1}^{n}$ are linearly independent and thus form a basis in $\mathcal{U}_{2n}$. Thus, the interval formula (1) is Gaussian if and only if

$$a_i = L[p_i] = L[q_i]\,, \quad i = 1, \dots, n\,,$$

and the latter is equivalent to the system

$$\Psi_i(\mathbf{x}) := \Psi_i(\mathbf{x}, \mathbf{h}) := L[p_i - q_i] = 0\,, \quad i = 1, \dots, n. \tag{8}$$

Let

$$p_i(t) = \sum_{m=1}^{2n} \alpha_{im} u_m(t), \quad q_i(t) = \sum_{m=1}^{2n} \beta_{im} u_m(t).$$

We have to show that the system (8) possesses a unique solution in $D_{\varepsilon_0}(\mathbf{h})$. To this aim, we prove first that the Jacobian of (8) is distinct from zero and has a constant sign at any solution of (8). In order to compute the elements of the Jacobian matrix, we note that, in view of Lemma 1, the matrix D (which does not depend on i) of the linear system (6) with respect to the coefficients $\{\alpha_{im}\}$ possesses a nonzero determinant.

Moreover, by the implicit function theorem, the coefficients are differentiable functions of x_j and

$$\frac{\partial \alpha_{im}}{\partial x_j} = -C_{ij}\,\frac{\det D_{jm}}{\det D},$$

where D_{jm} is the matrix obtained from D by replacing the $(n+j)$th element of its mth column by 1 and the other elements of the column by zero. The constant C_{ij} is given by

$$C_{ij} = \frac{\partial}{\partial x_j}\left\{\frac{I_j[p_i]}{I_j}\right\}.$$

But, by Cramer's rule,

$$\alpha_{im} = \frac{\det D_{im}}{\det D}.$$

Therefore

$$\frac{\partial \alpha_{im}}{\partial x_j} = -\frac{\partial}{\partial x_j}\left\{\frac{I_j[p_i]}{I_j}\right\}\alpha_{jm}.$$

This implies the relation

$$\frac{\partial p_i(t)}{\partial x_j} = -\frac{\partial}{\partial x_j}\left\{\frac{I_j[p_i]}{I_j}\right\}p_j(t).$$

Similarly we obtain

$$\frac{\partial q_i(t)}{\partial x_j} = -\frac{\partial}{\partial x_j}\left\{\frac{I_j[q_i]}{I_j}\right\}q_j(t).$$

Using the last relations and the equality

$$L[p_i] = L[q_i] = a_i,$$

we easily compute the elements of the Jacobian matrix

$$J := J(\mathbf{x},\mathbf{h}) := \left\{\frac{\partial \Psi_i}{\partial x_j}\right\}_{i,j=1}^{n}.$$

We have

$$\begin{aligned}\frac{\partial \Psi_i}{\partial x_j} &= \frac{\partial}{\partial x_j}L[p_i(t)-q_i(t)]\\ &= L\left[\frac{\partial}{\partial x_j}(p_i(t)-q_i(t))\right]\\ &= -\frac{\partial}{\partial x_j}\left\{\frac{I_j[p_i]}{I_j}\right\}L[p_j] + \frac{\partial}{\partial x_j}\left\{\frac{I_j[q_i]}{I_j}\right\}L[q_j]\\ &= a_j d_j[r_i]\,,\end{aligned}$$

where $r_i := q_i - p_i$ and

$$d_j[g] := \frac{\partial}{\partial x_j}\left\{\frac{I_j[g]}{I_j}\right\}.$$

Thus,

$$\det J(\mathbf{x},\mathbf{h}) = a_1 \cdots a_n \det J_1(\mathbf{x},\mathbf{h}) \,,$$

J_1 being the matrix

$$J_1(\mathbf{x},\mathbf{h}) := \begin{bmatrix} d_1[r_1] & d_2[r_1] & \cdots & d_n[r_1] \\ d_1[r_2] & d_2[r_2] & \cdots & d_n[r_2] \\ \vdots & \vdots & \vdots & \vdots \\ d_1[r_n] & d_2[r_n] & \cdots & d_n[r_n] \end{bmatrix}.$$

Besides, the coefficients of any Gaussian formula are positive (see [2]). Thus $a_j > 0$ at any solution $\mathbf{x}$ of (8). Next we examine the sign of $J_1(\mathbf{y},\mathbf{v})$ in the set

$$E_{\varepsilon_0} := \{(\mathbf{y},\mathbf{v}) \,:\, \mathbf{v} \in H \,,\ \mathbf{y} \in D_{\varepsilon_0}(\mathbf{v})\}.$$

E_{ε_0} is a bounded connected set with nonempty interior which contains all the points $(\mathbf{x},\mathbf{h})$ corresponding to any Gaussian formula (1).

Now we show that $\det J_1(\mathbf{y},\mathbf{v}) \neq 0$ at every point $(\mathbf{y},\mathbf{v}) \in E_{\varepsilon_0}$. Assume the contrary, i.e., $\det J_1(\mathbf{x},\mathbf{h}) = 0$ for some $(\mathbf{x},\mathbf{h}) \in E_{\varepsilon_0}$. Then there exists a linear dependence between the rows of $J_1(\mathbf{x},\mathbf{h})$, and thus there exists a nonzero vector $(b_1,\ldots,b_n)$ such that

$$\text{(9)} \qquad d_j[r] = \frac{\partial}{\partial x_j}\left\{\frac{I_j[r]}{I_j}\right\} = 0\,, \quad j = 1,\ldots,n\,,$$

where $r := \sum_{i=1}^{n} b_i r_i$. In case $h_j = 0$ the last condition reduces to $r'(x_j) = 0$. Besides, by (6) and (7), $r(x_j) = 0$ and thus r has a double zero at x_j. If $h_j > 0$, then $I_j > 0$ and (9) leads to

$$\left(\frac{\partial}{\partial x_j} I_j[r]\right) I_j - I_j[r] \frac{\partial}{\partial x_j} I_j = 0.$$

On the other hand, (6) and (7) yield

$$I_j[r] = 0\,, \quad j = 1,\ldots,n.$$

Therefore, if $h_j > 0$, (9) reduces to

$$\frac{\partial}{\partial x_j} I_j[r] = 0.$$

Performing the differentiation we obtain

$$\frac{\partial}{\partial x_j} I_j[r] = \mu(x_j + h_j) r(x_j + h_j) - \mu(x_j) r(x_j) = 0.$$

Since $I_j[r] = 0$ and $\mu(t) > 0$, the function $r(t)$ must have at least two zeros in $[x_j, x_j + h_j]$ (counting the multiplicities up to 2). And this holds for every $j = 1,\ldots,n$. Therefore r has at least $2n$ zeros in (a,b), and hence $r \equiv 0$. This was the point at which we used that $\mathcal{U}_{2n}$ is an ET space of order 2. Then

$$r = \sum_{i=1}^{n} b_i (q_i - p_i) \equiv 0,$$

and thus $\sum_{i=1}^{n} b_i p_i$ must vanish at $s_1, \ldots, s_n, t_1, \ldots, t_n$. This means that $b_1 = \cdots = b_n = 0$, which is a contradiction. Therefore $\det J_1(\mathbf{y}, \mathbf{v})$ does not vanish in E_{ε_0}, and consequently $\det J(\mathbf{x}, \mathbf{h}) \neq 0$ (and even has a constant sign) at any solution $\mathbf{x}$ of system (8).

Now we are ready to complete the proof of Theorem 1. The existence of (1) was proved in [2] in a more general case. It can also be derived easily from the implicit function theorem. Indeed, for any given $\mathbf{h} \in H_\varepsilon$ we consider the family of lengths $\alpha\mathbf{h}$, parameterized by α, $0 \leq \alpha \leq 1$. According to Krein's theorem (see [5]), the Gaussian quadrature exists for $\alpha = 0$. We shall use this fact to extend the solution $(\mathbf{x}(\alpha), \alpha\mathbf{h})$ to any $0 \leq \alpha \leq 1$. And this can be done by the implicit function theorem since the Jacobian J is different from zero at any solution $(\mathbf{x}(\alpha), \alpha\mathbf{h})$ of (8) (since $\alpha\mathbf{h} \in H_\varepsilon$ for $0 \leq \alpha \leq 1$).

It remains to prove that the Gaussian quadrature is unique. Assume the contrary, that is, assume that system (8) has two distinct solutions $\mathbf{x}$ and $\mathbf{y}$. Consider the unique extensions $\mathbf{x}(\alpha)$, $\mathbf{y}(\alpha)$ of these solutions for α going back from 1 to 0. We have $\mathbf{x}(1) = \mathbf{x}$, $\mathbf{y}(1) = \mathbf{y}$, and $\mathbf{x}(1) \neq \mathbf{y}(1)$. On the other hand, by Krein's theorem $\mathbf{x}(0) = \mathbf{y}(0)$. Let us set

$$\alpha_0 := \max\{\alpha \in [0,1) : \mathbf{x}(\alpha) = \mathbf{y}(\alpha)\}.$$

Then, there must be two different extensions of $\mathbf{x}(\alpha_0) = \mathbf{y}(\alpha_0)$ in a neighborhood of α_0, which is a contradiction to the implicit function theorem. This ends the proof. $\square$

It is worth mentioning explicitly the important particular case of interval quadrature formula of Gauss–Christoffel type.

Corollary 1. *Let μ be any integrable function on $[a, b]$ that is continuous and positive on (a, b). Then, for every given set of nonnegative numbers $\mathbf{h}$ satisfying the condition*

$$h_1 + \cdots + h_n < b - a,$$

there exists a unique set of nodes $\mathbf{x} \in D(\mathbf{h})$ such that

$$\int_a^b \mu(t) f(t)\, dt = \sum_{k=1}^{n} a_k \frac{1}{I_k} \int_{x_k}^{x_k + h_k} \mu(t) f(t)\, dt$$

for every algebraic polynomial of degree less than or equal to $2n - 1$.

NUMERICAL SOLUTIONS TO COMPRESSIBLE FLOWS IN A NOZZLE WITH VARIABLE CROSS-SECTION*

DIETMAR KRÖNER† AND MAI DUC THANH‡

Abstract. Compressible flows in a nozzle can be modeled by the gas dynamics equations in one-dimensional space with source terms. It turns out that along stationary waves, the entropy is conserved. Investigating properties of the system leads us to the determination of stationary waves. Relying on this analysis, we construct a numerical scheme which takes into account the use of stationary waves. Our scheme is shown to be capable of maintaining equilibrium states. This demonstrates the efficiency of the new scheme over classical ones, which usually give unsatisfactory results when reducing the refinement of the mesh-size. Moreover, our scheme converges much faster than the classical ones in most cases.

Key words. gas dynamics, nozzle, conservation law, weak solution, stationary wave, modified Lax–Friedrichs scheme

1. Introduction.

In this paper we consider the following one-dimensional space gas dynamics equations that describe the evolution of a gas flow in a nozzle with cross-sectional area $a = a(x) > 0, x \in \boldsymbol{R}$:

$$\begin{aligned} &\partial_t(a\rho) + \partial_x(a\rho u) \;=\; 0, \\ &\partial_t(a\rho u) + \partial_x(a(\rho u^2 + p)) \;=\; p\partial_x a, \\ &\partial_t(a\rho e) + \partial_x(au(\rho e + p)) = 0, \quad x \in \boldsymbol{R},\, t > 0. \end{aligned} \tag{1.1}$$

As usual, the thermodynamical variables $\varepsilon, \rho, v = 1/\rho, p, T, S$ are the internal energy, density, specific volume, pressure, absolute temperature, and entropy, respectively; u is the velocity; and $e = \varepsilon + u^2/2$ is the total energy. The system (1.1) has the form of a system of conservation laws with source terms. It is nonconservative due to the effect of the geometry.

An efficient way to deal with system (1.1) is to supplement it with an additional trivial equation,

$$\partial_t a = 0 \tag{1.2}$$

(see [24, 21]), and then treat a (nontrivially) as an unknown. This step drives out the obstacle of the nonconservativeness in producing another characteristic field which turns out to be linearly degenerate. However, the system is then nonstrictly hyperbolic. Consequently, this causes the ill-posedness of the initial value problem. The

reader is referred to the related works in [24, 14, 15, 9, 22, 1]. In [22], the Riemann problem for isentropic flows with discontinuous cross-section area was solved.

Due to the geometry, system (1.1) has the form of conservation laws with source terms. There is another familiar form of systems of conservation laws with sources: the model of shallow water equations. There have recently been lots of contribution studies of hyperbolic systems of conservation laws with source terms. A well-balanced scheme was proposed for a single conservation law by [12, 13]. In [23], the author proposed modified Riemann problems for the Godunov method. Recently, well-balanced schemes aimed at dealing with conservation laws with sources were constructed in [6, 11, 4, 5, 2, 16]. In particular, for a single conservation law with sources, the method in [4, 5] actually gives a high accuracy, and seems to be efficient at capturing stationary solutions. The computations and comparisons with two-dimensional averaged computing were carried out in [1].

Our main purpose in this paper is to construct a new scheme for the system of conservation laws with source terms (1.1) which is capable of maintaining equilibrium states. The idea was originally proposed by Greenberg and Leroux [12] (see also [13]) for scalar conservation laws. Here, we first provide some background and investigate properties of the system (1.1). The motivation is given and the notion of stationary contact waves for ideal isentropic gas flows [22] is reviewed and is formulated for general nonisentropic fluid flows. It turns out that the entropy is conserved across any stationary solution. Based on this step, we propose a new scheme which is capable of capturing stationary contact waves whenever available. The new scheme is constructed from the following arguments: first we take care of the effect of the source terms which produce equilibrium states resulted by stationary contact waves; second, using any standard finite difference scheme for gas dynamics equations (without source terms) in one-dimensional space, we take into account all the available equilibrium states. Our method can be seen as being composed of two steps, in which the first one deals with stationary waves, which are independent of time. Thus, we can argue that the first step provides an *immediate response* that gives us equilibrium states. Therefore, the first step does not delay the evolution of the fluid described by system (1.1), roughly speaking. Since the first step provides us with the exact equilibrium states produced from the source terms, our method has advantage over the standard finite difference schemes for gas dynamics equations with a usual discretization of the source terms, referred in the following as classical schemes. This explains the reason why the new scheme converges much faster than the classical schemes as seen from our test cases. Although our method can be applied to any standard finite difference scheme, for simplicity, in the test cases we just take the Lax–Friedrichs scheme which has the numerical flux of the form

$$g^{\mathrm{L}}(U,V) := \frac{1}{2}(f(U)+f(V)) - \frac{1}{2\lambda}(V-U). \tag{1.3}$$

Here, we use the definition of numerical fluxes as the one in standard books of conservation laws (see [18, 10], for example).

Our scheme is determined for a broad class of fluids which satisfy

$$2p_\rho(\rho,S) + \rho p_{\rho\rho}(\rho,S) \; > \; 0 \tag{1.4}$$

in the domain under consideration. The condition (1.3) is fulfilled by the *stiffened gas* equation of state (see Menikoff and Plohr [25])

$$p = (\gamma-1)\rho(\varepsilon-\varepsilon_\infty) - \gamma p_\infty, \quad \gamma > 1, \tag{1.5}$$

where $\varepsilon_\infty, p_\infty$ are constants, depending on the material under consideration, and by *van der Waals fluid* equations of states in a certain domain where the system may not be genuinely nonlinear, but necessarily strictly hyperbolic. Notice that a stiffened gas equation of state reduces to an ideal polytropic gas when $p_\infty = 0$ and $\varepsilon_\infty = 0$. And, as mentioned in [25], for some materials, p_∞ can be quite large.

To demonstrate the efficiency of our scheme, we consider test cases for polytropic gases which have equations of state of the form

$$p = (\gamma - 1)\rho\varepsilon, \quad \gamma > 1, \tag{1.6}$$

for nonisentropic gases and

$$p = \kappa\rho^\gamma, \quad \kappa > 0, \gamma > 1, \tag{1.7}$$

for isentropic gases, which for simplicity, we take $\kappa = 1$. Precisely, the test cases include the following: two tests for stationary waves for a nonisentropic polytropic gas (1.6) and for an isentropic ideal gas (1.7); seven tests for nonstationary waves for an isentropic ideal gas (1.7); and two tests for nonstationary waves for a nonisentropic polytropic gas (1.6). We note that the seven test cases for the isentropic gas (1.7) cover all the possibilities of the location of left- and right-hand states of the Riemann problem: either the left- and right-hand states lying in the same phase or in different phases. Here, we call a *phase* the biggest region of the phase domain where the system remains strictly hyperbolic. As shown in [22], there are exactly three such phases.

The paper is organized as follows. Section 2 provides a simple way of modeling of fluid flows in a nozzle. Although the model has been known for a long time, to our knowledge the complete derivation is not available in the literature. Therefore, we want to review it for the sake of completeness. We assume the nozzle is smooth with small variation so that the flow through it would have some symmetry and relatively uniform properties. We note here that for fluid flows in an arbitrary nozzle, and in particular a nozzle with discontinuous cross-sections, we can consider the same model, but the derivation presented here may not be applied. In section 3 we will investigate the properties of general fluid flows, and we will give the definition of elementary waves. We will show that the entropy is conserved across any stationary wave. This will help us construct the new scheme by solving the jump relations of a system as if it were of isentropic gases. Section 4 will deal with the analysis of stationary waves which yields their determination at the end. In section 5 we will construct the numerical scheme, relying on the use of stationary waves. Section 6 will show the evidence of the advantage of the new scheme over the classical ones. Here we compare the CPU times of the two schemes: The modified Lax–Friedrichs scheme, which takes the Lax–Friedrichs scheme together with a usual cell average discretization of the source term, and our new one.

The model of fluid flows in a nozzle (1.1) is closely related to the model of multiphase flows which has a vast domain of applications. Formally, the previous one can be obtained from the last one by restricting it to a single fluid. Both systems share common features such as the lack of strict hyperbolicity, systems of conservation laws with sources, ill-posedness, etc. A two-phase mixture theory for reactive granular materials was introduced by [3]. We note that a theory of multiphase flows was established in the book [8]. An overview of the ill-posedness of the two-fluid model was observed in [7]. In recent research [17], the authors investigated properties of the two-fluid model which lacks hyperbolicity. See also the references therein.

Several important properties of the numerical scheme presented in this paper concerning the *minimum principle* of the numerical entropy and the *nonnegativity* of the numerical density can be found in [20]. A well-balanced scheme for the nonreactive version of the Baer–Nunziato (BN) model of two-phase fluids which aim to maintain equilibrium states has been under study in [19].

2. A simple way of modeling. The model (1.1) is well known and one could easily find it in the literature. However, we do not know whether it was derived in a complete form. The derivation in the stationary case can be found in the standard book of Zucrow and Hoffman [26]. Here, for the sake of completeness, we present a simple way of modeling the physical phenomenon. To validate our analysis below, *we restrict our attention to a given smooth nozzle with small variation.*

Let the Euler equations in a two-dimensional tube with height $a(x) > 0$ be given:

$$\begin{aligned} &\partial_t \rho + \partial_x(\rho u) + \partial_y(\rho v) \;=\; 0,\\ &\partial_t(\rho u) + \partial_x(\rho u^2 + p) + \partial_y(\rho uv) \;=\; 0,\\ &\partial_t(\rho v) + \partial_x(\rho uv) + \partial_y(\rho v^2 + p) \;=\; 0,\\ &\partial_t(\rho e) + \partial_x(u(\rho e + p)) + \partial_y(v(\rho e + p)) = 0, \quad x, y \in \boldsymbol{R},\ t > 0. \end{aligned} \tag{2.1}$$

Let us assume that the nozzle is put in the x-direction (see Figure 2.1). First, we consider the first and the second equations. Integrating the first and the second equations of (2.1) in y we obtain, respectively,

$$\begin{aligned} &\int_0^{a(x)} [\partial_t \rho + \partial_x(\rho u) + \partial_y(\rho v)]\, dy \;=\; 0,\\ &\int_0^{a(x)} \big[\partial_t(\rho u) + \partial_x(\rho u^2 + p) + \partial_y(\rho uv)\big]\, dy \;=\; 0, \quad x \in \boldsymbol{R},\ t > 0, \end{aligned}$$

or

$$\begin{aligned} &\partial_t\bigg(\int_0^{a(x)} \rho(x,y,t)\, dy\bigg) + \int_0^{a(x)} \partial_x(\rho u)\, dy + \int_0^{a(x)} \partial_y(\rho v)\, dy \;=\; 0,\\ &\partial_t\bigg(\int_0^{a(x)} \rho u(x,y,t)\, dy\bigg) + \int_0^{a(x)} \partial_x(\rho u^2 + p)\, dy + \int_0^{a(x)} \partial_y(\rho uv)\, dy \;=\; 0. \end{aligned} \tag{2.2}$$

Clearly,

$$\begin{aligned} &\int_0^{a(x)} \partial_y(\rho v)\, dy = \rho v(x, a(x), t) - \rho v(x, 0, t),\\ &\int_0^{a(x)} \partial_y(\rho uv)\, dy = \rho uv(x, a(x), t) - \rho uv(x, 0, t). \end{aligned} \tag{2.3}$$

In addition, at the boundary, particles are moving along the boundary and thus their trajectories follow the shape of the boundary. Thus, the particle velocity (u, v) at each point on the boundary, which has the coordinate $(x, y = a(x))$, is the tangent of the nozzle at that point. In other words, it holds that

$$v(x, a(x), t) = u(x, a(x), t) \tan\alpha,$$

where α is the angle between the tangent of the graph of $a(x)$ and the x-axis. Since

$$\tan\alpha = a'(x),$$

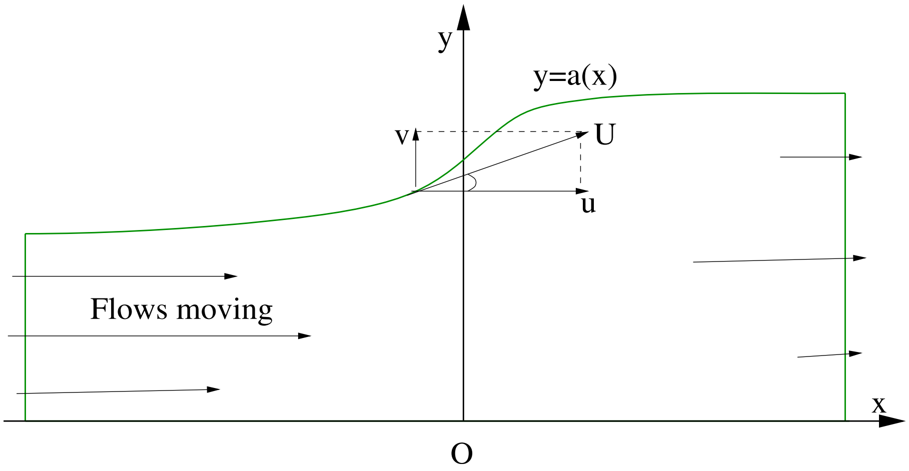

FIG. 2.1. *Flows moving inside a nozzle.*

we have from the last two equations

$$v(x, a(x), t) = a'(x)u(x, a(x), t). \tag{2.4}$$

Similarly,

$$v(x, y = 0, t) = 0, \tag{2.5}$$

since the boundary of the nozzle at the bottom $y = 0$ is parallel to the x-direction. It is derived from (2.3) to (2.5) that

$$\begin{aligned} &\int_0^{a(x)} \partial_y(\rho v)\, dy = a'(x)\rho u(x, a(x), t),\\ &\int_0^{a(x)} \partial_y(\rho uv)\, dy = a'(x)\rho u^2(x, a(x), t). \end{aligned} \tag{2.6}$$

On the other hand, we have

$$\begin{aligned} \partial_x\left(\int_0^{a(x)} \rho u(x,y,t)\, dy\right) &= \int_0^{a(x)} \partial_x(\rho u)(x,y,t)\, dy + a'(x)\rho u(x, a(x), t),\\ \partial_x\left(\int_0^{a(x)} \rho u^2(x,y,t)\, dy\right) &= \int_0^{a(x)} \partial_x(\rho u^2)(x,y,t)\, dy + a'(x)\rho u^2(x, a(x), t),\\ \partial_x\left(\int_0^{a(x)} p(x,y,t)\, dy\right) &= \int_0^{a(x)} \partial_x p(x,y,t)\, dy + a'(x)p(x, a(x), t). \end{aligned} \tag{2.7}$$

From (2.2) and (2.7), we obtain

$$\begin{aligned} &\partial_t\left(\int_0^{a(x)} \rho(x,y,t)\, dy\right) + \partial_x\left(\int_0^{a(x)} \rho u(x,y,t)\, dy\right) = 0,\\ &\partial_t\left(\int_0^{a(x)} \rho u(x,y,t)\, dy\right) + \partial_x\left(\int_0^{a(x)} (\rho u^2 + p)(x,y,t)\, dy\right) = a'(x)p(x, a(x), t). \end{aligned} \tag{2.8}$$

To obtain the first two equations of (1.1) from (2.8), we make the following assumptions.

- The cross-section average density and pressure $\bar{\rho}, \bar{p}$ play the role of ρ, p, respectively, where, for example,

$$\bar{\rho}(x,t) := \frac{1}{a(x)} \int_0^{a(x)} \rho(x,y,t)\,dy, \quad x \in \boldsymbol{R}, t > 0.$$

- The u-component of the particle velocity is uniform in each cross-section, i.e.,

$$u(x,y,t) \;=\; u(x,y',t) := \bar{u}(x,t) \quad \forall y,y' \in (0,a(x)) \quad \forall x \in \boldsymbol{R}, t > 0.$$

- The average pressure $\bar{p}$ is approximated by $p(x,a(x),t)$.

We observe that these assumptions are quite limited, since the nozzle then should be smooth with small variation so that the flow through it would approximately have the symmetry and uniform properties. Since the system (1.1) serves only the component u of the velocity in the x-direction, we can ignore the third equation of (2.1). The third equation of (1.1) can be similarly derived as the first equation. The modeling is complete.

3. Basic properties and stationary waves. In this section we recall basic properties of system (1.1)–(1.2) and draw elementary conclusions for stationary waves which will be used in the next sections. Together with shock waves and rarefaction waves in genuinely nonlinear characteristic fields, and contact discontinuities in the linearly degenerate field of the usual gas dynamics equations, stationary waves will be defined as one kind of *elementary wave*. We will show that *the entropy remains constant across stationary waves*. This result enables us to determine stationary waves as in the isentropic case (see [22]).

Precisely, we are studying the following system:

$$\begin{aligned}
&\partial_t(a\rho) + \partial_x(a\rho u) \;=\; 0,\\
&\partial_t(a\rho u) + \partial_x(a(\rho u^2 + p)) \;=\; p\partial_x a,\\
&\partial_t(a\rho e) + \partial_x(au(\rho e + p)) = 0,\\
&\partial_t a = 0, \quad x \in \boldsymbol{R},\, t > 0.
\end{aligned} \tag{3.1}$$

In what follows, the density and the entropy are chosen as independent thermodynamics variables. Note that other thermodynamics variables can always be expressed in terms of any two thermodynamics variables. Thus, we can write $p = p(\rho, S), \varepsilon = \varepsilon(\rho, S)$, etc. Let us be given a smooth solution $U(x,t) = (\rho(x,t), u(x,t), S(x,t), a(x))$ of the system (4.1). A straightforward calculation shows that the smooth solution U satisfies the following system of conservation laws in nonconservative form:

$$\begin{aligned}
&\rho_t + u\rho_x + \rho u_x + \frac{u\rho}{a} a_x \;=\; 0,\\
&u_t + uu_x + \frac{1}{\rho} p_x \;=\; 0,\\
&S_t + uS_x \;=\; 0,\\
&a_t = 0, \quad x \in \boldsymbol{R},\, t > 0.
\end{aligned} \tag{3.2}$$

The Jacobian matrix of the system (3.2) is given by

$$B(U) = \begin{pmatrix} u & \rho & 0 & \frac{u\rho}{a} \\ \frac{p_\rho}{\rho} & u & \frac{p_S}{\rho} & 0 \\ 0 & 0 & u & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{3.3}$$

The characteristic equation is given by

$$\lambda(u-\lambda)[(u-\lambda)^2 - p_\rho] = 0. \tag{3.4}$$

Note. In fact, (3.4) is obtained by multiplying a factor λ, which represents an additional linearly degenerate field, to the characteristic equation of the usual gas dynamics equations.

Thus, we obtain four real eigenvalues,

$$\lambda_0 = 0, \quad \lambda_1 = u - c, \quad \lambda_2 = u, \quad \lambda_3 = u + c, \tag{3.5}$$

where c is the *local sound speed*

$$c = \sqrt{p_\rho} \geq 0.$$

The associated eigenvectors of $B(U)$ can be chosen as

$$r_0 = \begin{pmatrix} u^2\rho \\ -up_\rho \\ 0 \\ a(p_\rho - u^2) \end{pmatrix}, \quad r_1 = \begin{pmatrix} \rho \\ -c \\ 0 \\ 0 \end{pmatrix}, \quad r_2 = \begin{pmatrix} -p_S \\ 0 \\ p_\rho \\ 0 \end{pmatrix}, \quad r_3 = \begin{pmatrix} \rho \\ c \\ 0 \\ 0 \end{pmatrix}.$$

In the following we will assume that the local sound speed is positive:

$$c = \sqrt{p_\rho} > 0.$$

The system (3.1) is in general *not strictly hyperbolic*, since the characteristic field associated with λ_0 may coincide with any other field. The phase domain is in fact divided into four regions in which the system is strictly hyperbolic:

$$\begin{aligned} G_1 &= \{U : \lambda_1(U) < \lambda_2(U) < \lambda_3(U) < \lambda_0(U)\}, \\ G_2 &= \{U : \lambda_1(U) < \lambda_2(U) < \lambda_0(U) < \lambda_3(U)\}, \\ G_3 &= \{U : \lambda_1(U) < \lambda_0(U) < \lambda_2(U) < \lambda_3(U)\}, \\ G_4 &= \{U : \lambda_0(U) < \lambda_1(U) < \lambda_2(U) < \lambda_3(U)\}. \end{aligned} \tag{3.6}$$

In what follows, we will call each of these regions a *phase*. The phases are separated by three isolated surfaces on which the system fails to be strictly hyperbolic:

$$\begin{aligned} \Sigma_+ &= \{U : \lambda_1(U) = \lambda_0(U)\}, \\ \Sigma_0 &= \{U : \lambda_2(U) = \lambda_0(U)\}, \\ \Sigma_- &= \{U : \lambda_3(U) = \lambda_0(U)\}. \end{aligned} \tag{3.7}$$

We will refer to each of these surfaces a *hyperbolic boundary*.

Clearly, the 0- and the 2-characteristic fields are linearly degenerate. And under the condition that

$$\frac{\partial c}{\partial \rho} \geq 0,$$

one can easily check that the 1- and the 3-characteristic fields are genuinely nonlinear.

A stationary smooth solution U of (1.1) is a time-independent smooth solution. Thus, the derivative in t in (1.1) can be omitted. Stationary solutions of the initial value problem for (1.1) are, therefore, the ones for the following ordinary differential equations:

$$\begin{aligned} &(a\rho u)' = 0, \\ &(a(\rho u^2 + p))' = pa', \\ &(au(\rho e + p))' = 0, \end{aligned} \tag{3.8}$$

with the smooth initial data

$$U(x,0) = U_0(x), \tag{3.9}$$

where we denote

$$\frac{d(.)}{dx} = (.)'.$$

The following lemma will help us in computing stationary contacts.

LEMMA 3.1. *The system* (3.8) *for smooth solutions is equivalent to*

$$\begin{aligned} (a\rho u)' &= 0, \\ uu' + \frac{p'}{\rho} &= 0, \\ S' &= 0. \end{aligned} \tag{3.10}$$

In other words, the entropy is conserved across any stationary smooth solution of the initial value problem for (1.1).

Consequently, the nonisentropic system is reduced to the isentropic case for stationary solutions. Therefore, we can define a *stationary contact of* (3.1) as the limit of sequences of stationary smooth solutions in a similar way of the isentropic gases (see [22]).

Proof. Let us be given initial data U_0. The first equation of (4.8) can be expressed as

$$a\rho u = C$$

for some constant C dependent only on U_0. Therefore, the second equation can be written as

$$(C \cdot u + a \cdot p)' = p \cdot a'$$

or

$$C \cdot u' + a \cdot p' = 0.$$

Restoring C from its original definition, we obtain

$$a\rho\biggl(uu' + \frac{p'}{\rho}\biggr) = 0.$$

Since the cross-section is assumed to be positive, the last equation can be written as the second equation of (3.10). Besides, the third equation of (3.8) can be written as

$$C \cdot \biggl(e + \frac{p}{\rho}\biggr)' = 0. \tag{3.11}$$

Recall the thermodynamics identity that

$$TdS = d\varepsilon + pdv, \quad v = \frac{1}{\rho}.$$

Since we are considering stationary waves, i.e., solutions independent of time, the thermodynamics identity applied to this kind of wave gives

$$TS' = \varepsilon' + pv'. \tag{3.12}$$

It is derived from the definition of the total energy and from (3.12) that (3.11) can be written as

$$\varepsilon' + uu' + (pv)' = 0$$

or

$$TS' + \frac{p'}{\rho} + uu' = 0.$$

In view of the second equation of (3.10) we just established, the last equation takes the simpler form

$$S' = \frac{dS}{dx} = 0.$$

Thus, we have demonstrated that system (3.8) is equivalent to (3.10).

Furthermore, since we are considering stationary waves, we have

$$dS = \frac{dS}{dx}dx + \frac{dS}{dt}dt = 0, \tag{3.13}$$

which implies the rest of Lemma 3.1. □

Let us now discuss the notion of shock waves of the system (3.1). A shock wave from a left-hand state $U_- = (\rho_-, u_-, S_-, a_-)$ to a right-hand state $U_+ = (\rho_+, u_+, S_+, a_+)$, which propagates with a speed $\bar{\lambda}$, should satisfy the Rankine–Hugoniot relation for the last equation of (3.1), which yields

$$\bar{\lambda}[a] \; = \; 0, \tag{3.14}$$

where $[a] = a_+ - a_-$. This implies that either

- the component a must be constant, or
- the shock speed is equal to zero (*stationary contact*).

Assume first that this shock corresponds to a constant level of the cross-section a. The right-hand side of the system (3.1) thus vanishes, and system (3.1) is reduced to the usual form of conservation laws. It is not difficult to check that the left- and right-hand states of the shock are constraint by the Rankine–Hugoniot relations for the usual form of gas dynamics equations:

$$\begin{aligned}
&\partial_t \rho + \partial_x(\rho u) \; = \; 0,\\
&\partial_t(\rho u) + \partial_x(\rho u^2 + p) \; = \; 0,\\
&\partial_t(\rho e) + \partial_x(u(\rho e + p)) = 0, \quad x \in \boldsymbol{R},\, t > 0.
\end{aligned} \tag{3.15}$$

Assume next that the shock speed $\bar{\lambda}$ is zero. Then, we define this kind of shock wave as the ones provided by Lemma 3.1. Let us introduce the *specific enthalpy*

$$h = \varepsilon + pv, \tag{3.16}$$

which satisfies

$$dh = T\,dS + v\,dp.$$

In view of Lemma 3.1, the left- and right-hand states of the shock are constraint by the jump relations

$$\begin{aligned} &S = S_- = S_+,\\ &p = p(\rho, S_-),\\ &[a\rho u] = 0,\\ &\Big[\frac{u^2}{2} + h(\rho, S_-)\Big] = 0, \end{aligned} \tag{3.17}$$

where h is the specific enthalpy (3.16). Observe in this case that

$$\frac{\partial}{\partial\rho} h(\rho, S_-) = v \frac{\partial}{\partial\rho} p(\rho, S_-).$$

For rarefaction waves of (3.1), which are smooth solutions, it is not difficult to see that they are the ones of the usual gas dynamics equations (3.15). Similar arguments can be applied for contact discontinuities. Finally, we can define the elementary waves of (3.1) as follows.

DEFINITION 3.2. *Elementary waves for the system* (3.1) *are the following ones.*

- *If* $a = \text{const}$, *all the elementary waves* (*shock waves, rarefaction waves, contact discontinuities*) *are the ones of the usual gas dynamics equations* (3.15).
- *The stationary contacts which have zero propagation speed and are given by* (3.17).

4. Equilibrium states. We will describe in this section how to get the exact equilibrium states, i.e., the two left- and right-hand states of a stationary contact. In other words, we search for an exact solution of (3.17) for given data U_- and given cross-sections on the left and right of the stationary contact. This exact solution will be used in the second part for the construction of the new scheme.

Let us be given a state $U_- = (\rho_-, u_-, a_-)$ with a level of cross-section a_- and another level cross-section a_+. As seen in the previous section, a state $U_+ = (\rho_+, u_+, a_+)$ with the level cross-section a_+ which can be connected with U_- via a stationary wave is determined by the system

$$\begin{aligned} &S = S_- = S_+,\\ &p = p(\rho, S_-),\\ &[a\rho u] = 0,\\ &\Big[\frac{u^2}{2} + h(\rho, S_-)\Big] = 0, \end{aligned} \tag{4.1}$$

where h is the specific enthalpy (3.16), which satisfies

$$\frac{\partial}{\partial\rho} h(\rho, S_-) = v \frac{\partial}{\partial\rho} p(\rho, S_-). \tag{4.2}$$

To solve system (4.1) for $\rho_+ = \rho$, we solve the equation

$$\Phi(\rho) := (u_-^2 + 2h(\rho_-, S_-))\rho^2 - 2\rho^2 h(\rho, S_-) \ = \ \Big(\frac{a_- u_- \rho_-}{a_+}\Big)^2. \tag{4.3}$$

To this end, we investigate properties of the function Φ. We have due to (4.2)

$$\begin{aligned}\Phi'(\rho) &= 2(u_-^2 + 2h(\rho_-, S_-))\rho - 4\rho h(\rho, S_-) - 2\rho^2 h_\rho(\rho, S_-)\\ &= 2(u_-^2 + 2h(\rho_-, S_-))\rho - 4\rho h(\rho, S_-) - 2\rho p_\rho(\rho, S_-)\\ &= 2\rho\Big(u_-^2 + 2\int_\rho^{\rho_-} h_\rho(\tau, S_-)\,d\tau - p_\rho(\rho, S_-)\Big)\\ &= 2\rho\Big(u_-^2 + 2\int_\rho^{\rho_-} \frac{p_\rho(\tau, S_-)}{\tau}\,d\tau - p_\rho(\rho, S_-)\Big),\end{aligned}$$

which has the same sign as

$$\Psi(\rho) := \frac{\Phi'(\rho)}{2\rho} = u_-^2 + 2\int_\rho^{\rho_-} \frac{p_\rho(\tau, S_-)}{\tau}\,d\tau - p_\rho(\rho, S_-). \tag{4.4}$$

Assumption (1.4) implies

$$\begin{aligned}\Psi'(\rho) &:= -(2h_\rho(\rho, S_-) + p_{\rho\rho}(\rho, S_-))\\ &= -\frac{1}{\rho}\Big(2p_\rho(\rho, S_-) + \rho p_{\rho\rho}(\rho, S_-)\Big) \ < \ 0 \quad \forall\,\rho.\end{aligned} \tag{4.5}$$

In addition, we can always have

$$\begin{aligned}&\Psi(\rho) > 0 \qquad \text{as} \quad \rho \to 0,\\ &\Psi(\rho) < 0 \qquad \text{for large } \rho,\end{aligned} \tag{4.6}$$

for example, under the assumptions that

$$\begin{aligned}&p_\rho(\rho = 0, S_-) = 0,\\ &p_\rho(\rho, S_-) \to +\infty \quad \text{as} \quad \rho \to +\infty.\end{aligned} \tag{4.7}$$

It is, therefore, derived from (4.4) to (4.6) that there exists exactly one value $\rho = \rho_{\max}$ such that

$$\begin{aligned}&\Phi'(\rho) > 0, \quad \rho < \rho_{\max},\\ &\Phi'(\rho) < 0, \quad \rho > \rho_{\max},\\ &\Phi'(\rho) = 0, \quad \rho = \rho_{\max}.\end{aligned} \tag{4.8}$$

Observe that

$$\begin{aligned}&\Phi(\rho = 0) = 0,\\ &\Phi(\rho) \to -\infty \quad \text{as} \quad \rho \to +\infty,\end{aligned} \tag{4.9}$$

and that the right-hand side of (4.3) is nonnegative. It is thus derived from (4.8) to (4.9) that (4.3) has a solution iff

$$\Phi(\rho_{\max}) \geq \Big(\frac{a_- u_- \rho_-}{a_+}\Big)^2 \tag{4.10}$$

or, equivalently,

$$a_+ \geq a_{\min}(U_-) := \frac{a_- u_- \rho_-}{\sqrt{\Phi(\rho_{\max})}}. \tag{4.11}$$

In this case, we can easily see that (4.3), and, therefore, system (4.1), has two roots, denoted by $\varphi_1(U_-, a_+) \leq \varphi_2(U_-, a_+)$, which coincide iff $a_+ = a_{\min}(U_-)$. The fact that $a = a_-$ still gives us a solution of (4.1) and, therefore, of (4.3), a_- has to satisfy

$$a_{\min}(U_-) \leq a_-. \tag{4.12}$$

For polytropic ideal gases (1.6), it is not difficult to check that $a_{\min}(U_-) = a_-$ iff the state U_- belongs to the hyperbolic boundaries (3.7) (see Lemma 2.3 of [22]). Therefore, we can conclude from (4.11) to (4.12) that *the capturing stationary waves can always be done when a_+ is closed to a_-*, which holds for nozzles with small sudden changes.

In order to select one solution $\varphi_1(U_-, a_+)$ or $\varphi_2(U_-, a_+)$ of (5.1), we will use the following admissibility criterion. Observe that for a given state U_-, the last equation of (4.1) also determines a curve $u = u(\rho)$ in the plan (ρ, u), called *stationary curve*, and, therefore, the third equation of (4.1) implies the component a can be expressed as a function $a = a(\rho)$ of the variable ρ along this curve. Let us impose an additional admissibility criterion (see [14, 22]).

Admissibility Criterion 4.1. *Along the stationary curve in the (ρ, u)-plan between left- and right-hand states of any stationary wave, the component a obtained from* (4.1) *and expressed as a function of ρ has to be monotone in ρ.*

We know by the previous section that entropy is constant along stationary curves. Thus, we arrive at the following lemma as in the case of isentropic gases [22], and, therefore, we omit the proof.

Lemma 4.1. *Admissibility Criterion* 4.1 *is equivalent to the statement that any stationary wave has to remain in the closure of only one phase.*

Remark 1. Without such an admissibility condition, the Riemann problem for piecewise constant cross-sections may admit a one-parameter family of solutions; when this condition is used, the Riemann problem may have at most three solutions (see [14, 22, 9]). Here, it is interesting that the approximate solutions given by our scheme and the chosen standard Lax–Friedrichs scheme will both converge to the same exact solution in all the tests (see section 6).

Remark 2. It is derived from (4.1) that, under Admissibility Criterion 4.1, the equilibrium states depend continuously on the cross-section component in the sense that when the left- and the right-hand cross-sections $a_\pm$ of a stationary wave are closed, the corresponding states $U_\pm$ remain closed as well. That implies the continuous dependence on the data of our numerical scheme defined in the next section when the nozzle is a continuous function of $x \in \boldsymbol{R}$. If the nozzle is discontinuous, this conclusion may not be held. In fact, let one state U_0 of the stationary wave with fixed distinct cross-sections $a_\pm$ belong to the hyperbolic boundaries. Then, a small perturbation to this state U_0 would cause a considerable difference. For example, let a small $\varepsilon > 0$ and $U_0 \in \Sigma_+$ be given (see (3.7)). We consider the stationary wave with the cross-sections $a_\pm$ from any fixed left-hand state $U_1 \in B(U_0, \varepsilon) \cap G_3$, and the stationary wave from any fixed left-hand state $U_2 \in B(U_0, \varepsilon) \cap G_4$, where $B(U_0, \varepsilon)$ is the open ball with center U_0 and radius ε. The stationary wave from U_1 remains in G_3 while the one from U_2 belongs to G_4 in view of Lemma 4.1. As a consequence, the structures of solutions (e.g., the number and the order of waves) are thus different as observed from the constructions of the Riemann solutions in [22, 9].

Since a is positive, the function $a = a(\rho)$ is decreasing (increasing) in ρ between ρ_- and ρ_+ if the function

$$\left(\frac{a_- u_- \rho_-}{a(\rho)}\right)^2 = (u_-^2 + 2h(\rho_-, S_-))\rho^2 - 2\rho^2 h(\rho, S_-) \ = \Phi(\rho) \tag{4.13}$$

is increasing (decreasing, respectively) in ρ between ρ_- and ρ_+. Hence, Admissibility Criterion 4.1 selects only one root $\rho = \varphi_i(U_-, a_+)$, $i \in \{1, 2\}$, of (4.1) such that the function Φ is monotone between ρ_- and $\varphi_i(U_-, a_+)$. That means ρ_- and $\varphi_i(U_-, a_+)$ must be located in the same side with respect to $\rho_{\max}$ obtained from (4.8), i.e.,

$$(\varphi_i(U_-, a_+) - \rho_{\max})(\rho_- - \rho_{\max}) \ \geq \ 0. \tag{4.14}$$

Let us now discuss the geometrical sense of the condition (4.14). Let $u = u(\rho)$ be the stationary curve defined by the last equation of (4.1). Then, since $a(\rho)\rho u(\rho) = a_-\rho_- u_-$ for all ρ, we have

$$\begin{aligned} &u(\rho_{\max}) \cdot u_- \geq 0, \\ &u(\rho_{\max})^2 - p_\rho(\rho_{\max}) = \Psi(\rho_{\max}) = 0. \end{aligned} \tag{4.15}$$

The relations (4.15) imply that the point $U_{\max} := (\rho_{\max}, u(\rho_{\max}), S_-)$ belongs to the hyperbolic boundaries. More precisely,

$$\begin{aligned} U_{\max} &\in \Sigma_+ \quad \text{for} \quad u_- > 0, \\ U_{\max} &\in \Sigma_0 \quad \text{for} \quad u_- = 0, \\ U_{\max} &\in \Sigma_- \quad \text{for} \quad u_- < 0. \end{aligned} \tag{4.16}$$

Now, the condition (4.14) simply implies that the *stationary contact wave remains in the same phase* whenever U_- belongs to one of the phase domains $G_i, i = 1, 2, 3, 4$, or the hyperbolic boundary Σ_0. When U_- belongs to the hyperbolic boundaries $\Sigma_\pm$, in the following scheme, we can avoid the situation of multiple choices by skipping to the next space-step, which means we do not use stationary jump at U_-. Another way, following our experience in the construction of composite wave curves of the Riemann problem [22], is the following:

- choose $\varphi_1(U_-, a_+)$ when $U_- \in \Sigma_+$, choose $\varphi_2(U_-, a_+)$ when $U_- \in \Sigma_-$ for forward construction, i.e., when U_- is the left-hand state and we look for a right-hand state of a stationary contact;
- vice versa for backward construction: given a right-hand state U_+ and another cross-section level a_-, we look for a left-hand state U_- of a stationary contact; then, we choose $\varphi_2(U_+, a_-)$ when $U_+ \in \Sigma_+$, and choose $\varphi_1(U_+, a_-)$ when $U_+ \in \Sigma_-$.

5. Numerical schemes. In this section we will present a new scheme for approximating solutions of the system (1.1), relying on the arguments in the previous sections. Given a uniform time step Δt and a special mesh size Δx, setting $x_j = j\Delta x, j \in \mathbf{Z}$, and $t_n = n\Delta t, n \in \mathbf{N}$, we denote by U_j^n in what follows the approximation of the values $U(x_j, t_n)$ of the exact solution $U = (a\rho, a\rho u, a\rho e)$ of (1.1).

Set

$$\lambda = \frac{\Delta t}{\Delta x}.$$

Let us take any standard finite difference scheme for gas dynamics equations with the numerical flux g^{C}. The *classical scheme* is of the form

$$U_j^{n+1} = U_j^n - \lambda\Big(g^{\mathrm{C}}\big(U_j^n, U_{j+1}^n\big) - g^{\mathrm{C}}\big(U_{j-1}^n, U_j^n\big)\Big) + \frac{\lambda}{2}\big(0, p_j^n(a_{j+1} - a_{j-1}), 0\big), \tag{5.1}$$

where p_j^n is given by suitable equations of state, and $a_j := a(x_j)$. The *modified Lax–Friedrichs scheme* is the one of (5.1) with the Lax–Friedrichs numerical flux:

$$\begin{aligned} &g^{\mathrm{C}}(U,V) := \frac{1}{2}(f(U) + f(V)) - \frac{1}{2\lambda}(V - U),\\ &U := (a\rho, a\rho u, a\rho e), \quad f(U) := (a\rho u, a(\rho u^2 + p), au(\rho e + p)). \end{aligned} \tag{5.2}$$

The constant λ is also required to satisfy the so-called *CFL stability condition*

$$\lambda \max_U |f'(U)| \le 1. \tag{5.3}$$

The motivation of our study in the following new scheme is to take into account the effect of stationary waves. The method was originally developed in [12, 13], and extended to more general problems in [4, 5, 2]. It can be described by two steps.

- First, at each grid node $x_j, j \in \mathbf{Z}$, we determine two stationary waves of (1.1) in which one stationary wave arrives at x_j with the cross-section level a_j from the given left-hand state U_{j-1}^n (with $a = a_{j-1}$) by a right-hand state, denoted by $U_{j-1,+}^n$, and another stationary wave arrives at x_j with the cross-section level a_j from the given right-hand state U_{j+1}^n (with $a = a_{j+1}$) by a left-hand state, denoted by $U_{j+1,-}^n$.
- Second, taking the Lax–Friedrichs scheme for the usual gas dynamics equations (3.15) for computing U_j^{n+1} at time $t = (n+1)h$, we substitute U_{j+1}^n by $U_{j+1,-}^n$ and U_{j-1}^n by $U_{j-1,+}^n$.

Precisely, the new scheme is defined by

$$U_j^{n+1} = U_j^n - \lambda\big(g^{\mathrm{N}}(U_j^n, U_{j+1,-}^n) - g^{\mathrm{N}}(U_{j-1,+}^n, U_j^n)\big), \tag{5.4}$$

where $g^{\mathrm{N}}(U,V)$ can be any standard numerical flux for gas dynamics equations, and $U_{j+1,-}^n, U_{j-1,+}^n$ are given shortly below. In the next section devoted to numerical tests, we take the Lax–Friedrichs numerical flux:

$$\begin{aligned} &g^{\mathrm{N}}(U,V) := g^{\mathrm{C}}(U,V) = \frac{1}{2}\big(f(U) + f(V)\big) - \frac{1}{2\lambda}(V - U),\\ &U := (\rho, \rho u, \rho e), \quad f(U) := \big(\rho u, (\rho u^2 + p), u(\rho e + p)\big). \end{aligned}$$

In the scheme (5.4), the states

$$U_{j+1,-}^n = (\rho, \rho u, \rho e)_{j+1,-}^n, \quad U_{j-1,+}^n = (\rho, \rho u, \rho e)_{j-1,+}^n$$

are defined by observing that the entropy is constant across each stationary jump, and by computing $\rho_{j+1,-}^n, u_{j+1,-}^n$ from the equations

$$\begin{aligned} &a_{j+1}^n \rho_{j+1}^n u_{j+1}^n = a_j^n \rho_{j+1,-}^n u_{j+1,-}^n,\\ &\frac{(u_{j+1}^n)^2}{2} + h(\rho_{j+1}^n) = \frac{(u_{j+1,-}^n)^2}{2} + h(\rho_{j+1,-}^n), \end{aligned} \tag{5.5}$$

and computing $\rho^n_{j-1,+}, u^n_{j-1,+}$ from the equations

$$\begin{aligned} a^n_{j-1}\rho^n_{j-1}u^n_{j-1} &= a^n_j\rho^n_{j-1,+}u^n_{j-1,+}, \\ \frac{(u^n_{j-1})^2}{2} + h(\rho^n_{j-1}) &= \frac{(u^n_{j-1,+})^2}{2} + h(\rho^n_{j-1,+}). \end{aligned} \tag{5.6}$$

Remember that we have for stationary solutions

$$\begin{aligned} a^n_{j+1}\rho^n_{j+1}u^n_{j+1} &= a^n_j\rho^n_j u^n_j, \\ \frac{(u^n_{j+1})^2}{2} + h(\rho^n_{j+1}) &= \frac{(u^n_j)^2}{2} + h(\rho^n_j). \end{aligned} \tag{5.7}$$

Therefore, the definition of $U^n_{j+1,-}, U^n_{j-1,+}$ in (5.5) and (5.6), respectively, implies that in the stationary case the unique solutions of (5.5) and (5.6) will be

$$\begin{aligned} \rho^n_{j+1,-} &= \rho^n_j, \quad u^n_{j+1,-} = u^n_j, \\ \rho^n_{j-1,+} &= \rho^n_j, \quad u^n_{j-1,+} = u^n_j, \end{aligned} \tag{5.8}$$

i.e.,

$$U^n_{j+1,-} = U^n_j, \quad U^n_{j-1,+} = U^n_j,$$

and, therefore (see (5.4)),

$$U^{n+1}_j = U^n_j. \tag{5.9}$$

This means that we exactly recover the stationary solution.

In a domain where a is a constant, it is easy to verify from (5.5) and (5.6) that

$$U^n_{j+1,-} = U^n_{j+1}, \quad U^n_{j-1,+} = U^n_{j-1}, \tag{5.10}$$

which implies that in this case (a constant) the scheme (5.4) as well as the modified scheme (5.1) both reduce to the chosen standard scheme for gas dynamics equations (3.15) without source term effects.

The convergence of numerical approximations given by this method was established in [12, 4] for (scalar) single conservation laws in one-dimensional space, and in [5] for single conservation laws in multidimensional space.

6. Test cases. In this section we will provide some test cases to demonstrate the efficiency of our new scheme (5.4) by using MATLAB. To compare between two kinds of schemes, we take the standard Lax–Friedrichs numerical flux. We first compute solutions by using the modified Lax–Friedrichs scheme (5.1)–(5.2) and the new scheme (5.4). Then, we compare the numerical solutions with the corresponding exact solutions, which were obtained in [22] for the isentropic gases. We provide the exact Riemann solutions for the nonisentropic test cases only for special data. In that case, the exact Riemann solution can be easily computed.

The first subsection, consisting of two test cases, is devoted to computing stationary waves for both nonisentropic polytropic and isentropic ideal gases (1.6), (1.7), respectively. The second subsection consists of seven test cases of nonstationary waves for isentropic gases (1.7). The third subsection consists of test cases of nonstationary waves for nonisentropic polytropic gases (1.6). For all test cases, the exact solutions are available (see also [22]) and we will compute the error and the corresponding CPU times. The notation $U_h^{\mathrm{C}}, U_h^{\mathrm{N}}$ refer to Lax–Friedrichs solutions obtained by (5.1)–(5.2) and the new scheme (5.4), respectively.

Solutions $U(x,t)$ of the Riemann problem for system (1.1) will be computed for

$$x \in [-1,1], \quad t = 0.2.$$

We note the left- and right-hand states of the Riemann problem by U_L, U_R, respectively.

6.1. Stationary contacts. In this subsection, our new scheme will be shown to maintain equilibrium states resulted by stationary waves.

6.1.1. Test case 1. Nonisentropic polytropic ideal gases. Let us denote $U = (\rho, u, p, a)$. The Riemann initial data

$$U_L = (3.4718, -2.5923, 5.7118, 1), \quad U_R = (2, -3, 2.639, 1.5), \quad CFL = 0.5$$

can be easily verified from the relations (3.17) to correspond to a stationary contact.

The two columns on the left of Figure 6.1 shows an approximation with a visible distinction from describing a stationary contact for the modified Lax–Friedrichs scheme (5.1)–(5.2) after 156 s of CPU time with 1000 mesh-points. Meanwhile, the two columns on the right of Figure 6.1 show an immediate recovery of the stationary wave by our new scheme after 112 s of CPU time with 400 mesh-points.

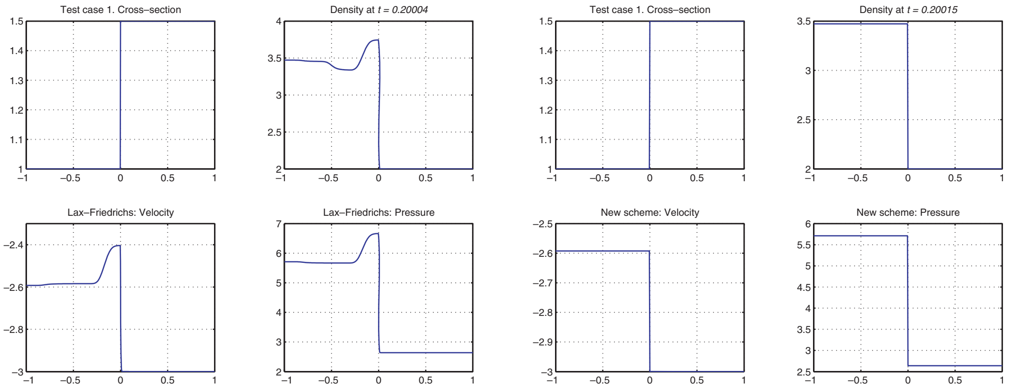

FIG. 6.1. *Test case* 1*: A stationary contact approximated by the two schemes. Left four plots: Lax–Friedrichs. Right four plots: New scheme.*

6.1.2. Test case 2. Isentropic ideal gases. We denote $U = (\rho, u, a)$ and take

$$U_L = (3.4718, -2.5923, 1), \quad U_R = (2, -3, 1.5), \quad CFL = 0.5.$$

Description. The solution is just a stationary wave from U_L to U_R; see Figure 6.2 (see [22]).

(6.1)

N	$\lVert U_h^{\mathrm{C}} - U \rVert_{L^1}$	CPU time (s)
500	0.0522	44
1000	0.0538	141
2000	0.0550	473

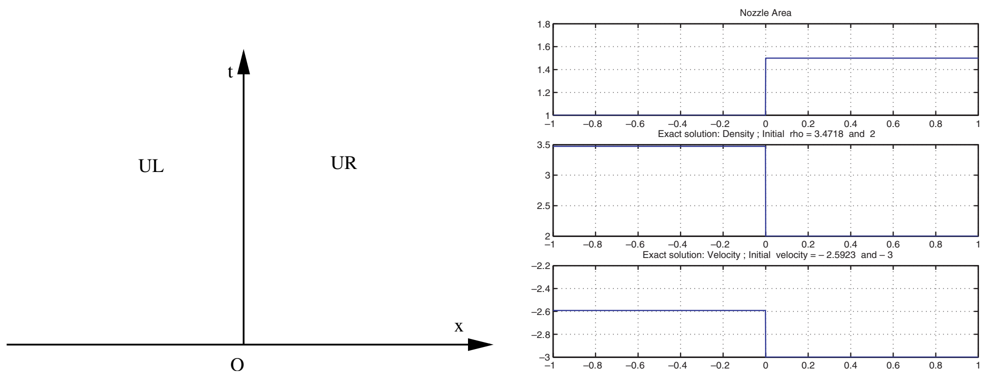

FIG. 6.2. *Test case 1: Exact Riemann solution at $t = 0.2$.*

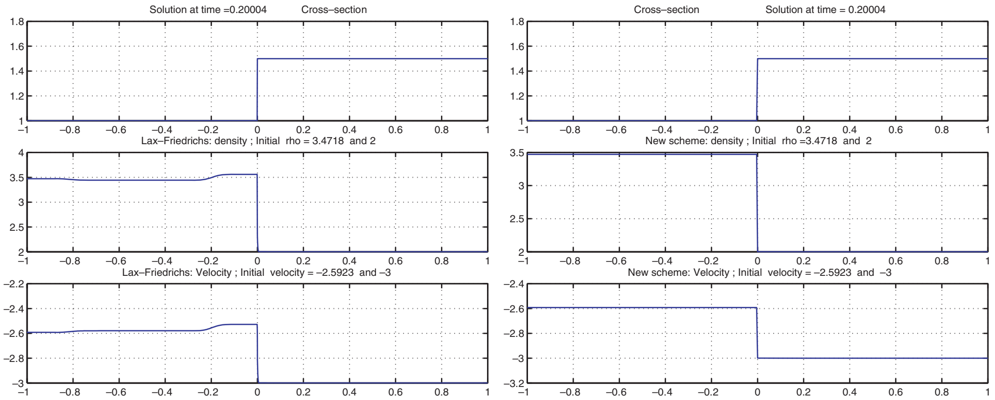

FIG. 6.3. *Test case 2: Isentropic gases: A stationary contact approximated by the two schemes.*

Looking at table (6.1), we can see that the Lax–Friedrichs scheme gives unsatisfactory results: while *decreasing the mesh-size, the errors increase*. In this case the numerical results show that our scheme can maintain the equilibrium states, i.e., the states before and after a stationary jump, while there is a visible oscillation for the modified Lax–Friedrichs scheme (see Figure 6.3).

(6.2)

N	$\|\|U_h^{\mathrm{N}} - U\|\|_{L^1}$	CPU time (s)
500	0.000016	91

6.2. Nonstationary waves for isentropic gases. To provide the comparison of CPU time between the two schemes, we need exact solutions of the Riemann problem which were all constructed in [22] for isentropic ideal gases, where the pressure is given by

$$p = \kappa\, \rho^{\gamma}, \qquad \kappa > 0,\, 1 < \gamma < 5/3. \tag{6.3}$$

The exact solutions of the Riemann problem will be used as reference solutions to compare the CPU times of convergence between the modified Lax–Friedrichs scheme and the new scheme.

As seen in section 3, there are three regions separated by two curves, in which the system is strictly hyperbolic, and the order of eigenvalues in each region is different

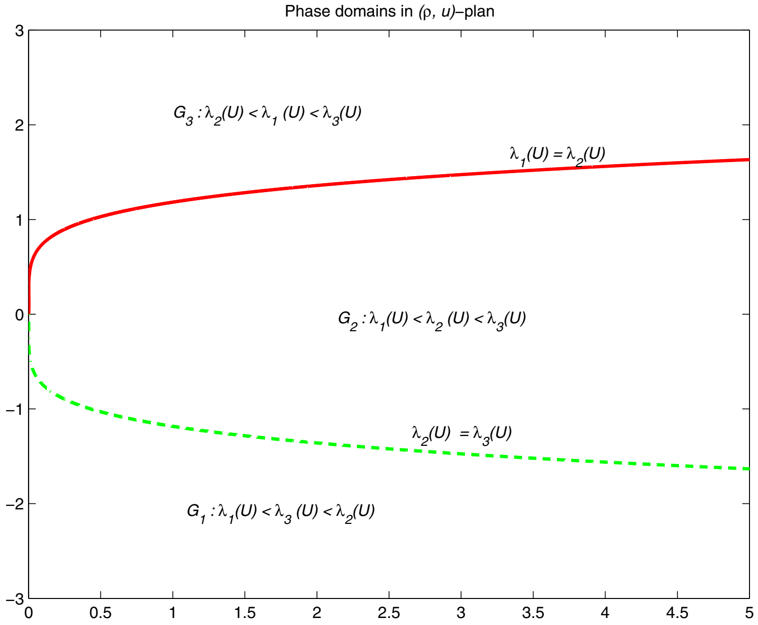

FIG. 6.4. *Hyperbolic boundaries and the three phases.*

(see Figure 6.4). Precisely, let us define

$$\begin{aligned} G_1 &:= \{(\rho,u) \ : \ \lambda_1(\rho,u) \ < \ \lambda_3(\rho,u) \ < \ \lambda_2(\rho,u)\},\\ G_2 &:= \{(\rho,u) \ : \ \lambda_1(\rho,u) \ < \ \lambda_2(\rho,u) \ < \ \lambda_3(\rho,u)\}, \qquad (6.4)\\ G_3 &:= \{(\rho,u) \ : \ \lambda_2(\rho,u) \ < \ \lambda_1(\rho,u) \ < \ \lambda_3(\rho,u)\}. \end{aligned}$$

The tests in this subsection consist of seven cases which cover all possible locations of the left- and right-hand states of the Riemann data with respect to the hyperbolic boundaries.

- Test case 3: $U_L \in G_1, \quad U_R \in G_1.$
- Test case 4: $U_L \in G_1, \quad U_R \in G_2.$
- Test case 5: $U_L \in G_2, \quad U_R \in G_1.$
- Test case 6: $U_L \in G_2, \quad U_R \in G_2.$
- Test case 7: $U_L \in G_2, \quad U_R \in G_3.$
- Test case 8: $U_L \in G_3, \quad U_R \in G_2.$
- Test case 9: $U_L \in G_3, \quad U_R \in G_3.$

6.2.1. Test case 3.

$$U_L = (0.5, -1, 1) \in G_1, \quad U_R = (2, -3, 1.5) \in G_1, \quad CFL = 0.5.$$

Description. The solution is a 1-shock from U_L to a state U_1, followed by a 3-rarefaction wave from U_1 to a state U_2, then followed by a stationary contact from U_2 to U_R. All these states belong to the same phase G_1 (see Figures 6.5 and 6.6).

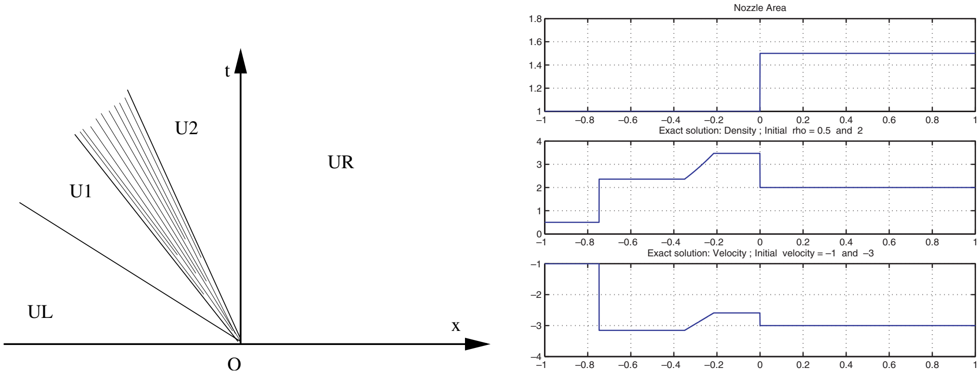

FIG. 6.5. *Test case 3: Exact Riemann solution at* $t = 0.2$.

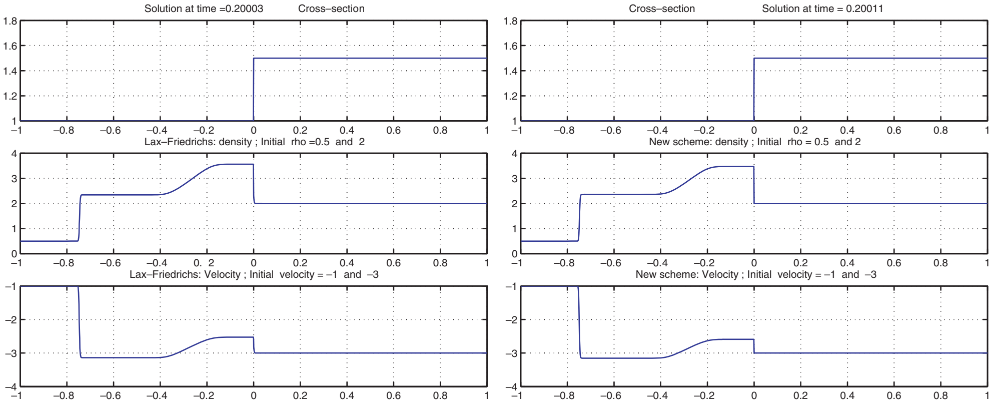

FIG. 6.6. Test case 3: *Numerical solutions by schemes with* 2000 *mesh-points.*

(6.5)

N	$\|\|U_h^{\mathrm{C}} - U\|\|_{L^1}$	CPU time (s)

6.2.2. Test case 4.

$$U_L = (1, -3, 1) \in G_1, \quad U_R = (5, 0.5, 1.5) \in G_2, \quad CFL = 0.75.$$

Description. The states U_L, U_R belong to the different phases. The solution is a 1-rarefaction wave from U_L to a state U_1, followed by a 3-rarefaction wave from U_1 to a state U_2 on the hyperbolicity boundary, then jumps to a state U_3 by a stationary contact, followed by a 3-rarefaction wave from U_3 to U_R (see Figures 6.7 and 6.8).

AN ERROR ANALYSIS OF CONSERVATIVE SPACE-TIME MESH REFINEMENT METHODS FOR THE ONE-DIMENSIONAL WAVE EQUATION[*]

PATRICK JOLY[†] AND JERÓNIMO RODRÍGUEZ[†]

Abstract. We study two space-time mesh refinement methods as the one introduced in [F. Collino, T. Fouquet, and P. Joly, *Numer. Math.*, 95 (2003), pp. 197–221]. The stability of such methods is guaranteed by construction through the conservation of a discrete energy. In this paper, we show the L^2 convergence of these schemes and provide optimal error estimates. The proof is based on energy techniques and bootstrap arguments. Our results are validated with numerical simulations and compared with results from plane wave analysis [F. Collino, T. Fouquet, and P. Joly, *Numer. Math.*, 95 (2003), pp. 223–251].

Key words. mesh refinement, local time stepping, error estimates, stability, energy conservation, wave equation

1. Introduction.

For the numerical solution of time-dependent wave propagation problems, in which one often has to deal with complex geometries in diffraction problems, it is natural to try to use local mesh refinements with nonmatching grids. One initial idea consists in using only spatial refinement (see [1] for acoustic waves, [8] and [22] for Maxwell's equations). However, with explicit schemes, when a uniform time step is used, it is the finest mesh that imposes the time step because of the stability condition. There are two problems with this. First, the computational cost is increased. Second, the ratio $c\Delta t/h$ (where h is the space step size) in the coarser grid will be much smaller than its optimal value. With standard numerical schemes (such as Yee's scheme for Maxwell's equations) this generates dispersion errors. To avoid these problems, it is useful to be able to work with a local time step in order to keep the ratio $c\Delta t/h$ constant (or almost constant) in the whole computational domain.

The use of local time stepping raises new practical and theoretical problems, especially for hyperbolic equations, that are much more delicate than those raised by a simple spatial refinement.

The solutions suggested in the electromagnetic literature are primarily based on interpolation techniques (in time and/or in space) especially designed to guarantee the consistency of the scheme at the coarse grid/fine grid interface (see [20], [18], [24], [9]). Unfortunately, the resulting schemes appear to be very difficult to analyze and may suffer from some instability phenomena [11]. Another possible solution for local time stepping is to use a domain decomposition approach such as that recently developed in [14]. However, the stability and convergence analysis of these techniques remain to be completed.

It seems that very few papers in the mathematical literature have been devoted to space-time mesh refinement for the specific case of Maxwell's equations (and more generally for linear wave propagation problems). However, these questions have been treated in many articles in the conservation laws community during the 1980s. Let us mention, for instance, the work of Osher and Sanders [23] based on finite volume methods or, closer to what we are doing here, the works of Berger and her coauthors [3, 4, 7, 5] on finite differences schemes. These works are devoted to various space-time mesh refinement techniques for first order hyperbolic systems. These techniques are mainly based on interpolation-type procedures and concern both overlapping and nonoverlapping grids (see [7, 5] for a general presentation). In [3], Berger has developed a stability analysis of such methods in the cases of the one-dimensional (1D) linear advection equations using the GKS theory [19, 15]. She was able to establish the results in the case where dissipative interior schemes (typically Lax–Wendroff scheme) were used or when conservative (typically leap-frog) schemes are used provided that overlapping grids are considered. However, it is also mentioned in [3] that using leap-frog-type schemes and nonoverlapping grids may lead to instability, as has already been mentioned for Maxwell's equations.

Recently, we developed alternative solutions to these interpolation procedures that we call conservative space-time mesh refinement methods. These methods, originally invented for the 1D wave equation, have been developed for Maxwell's equations [13] and recently extended to the elastodynamic equations [2]. A general presentation of these kinds of methods can be found in [16]. The main ideas and properties of these methods have been treated in more detail in [10] for the model problem of the 1D wave equation written as the first order system

$$(1.1)\qquad \begin{cases} \dfrac{\partial u}{\partial t} + \dfrac{\partial v}{\partial x} = 0, & \dfrac{\partial v}{\partial t} + \dfrac{\partial u}{\partial x} = 0, \qquad x \in \mathbb{R}, \qquad t > 0, \\ u(x,0) = u_0(x), & v(x,0) = v_0(x), \end{cases}$$

when one uses the FDTD Yee [26] scheme as the reference interior scheme in each subdomain

$$(1.2)\qquad \begin{cases} \dfrac{u_j^{n+1} - u_j^n}{\Delta t} + \dfrac{v_{j+\frac{1}{2}}^{n+\frac{1}{2}} - v_{j-\frac{1}{2}}^{n+\frac{1}{2}}}{h} = 0, \quad j \in \mathbb{Z}, \quad n \geq 0, \\ \dfrac{v_{j+\frac{1}{2}}^{n+\frac{1}{2}} - v_{j+\frac{1}{2}}^{n-\frac{1}{2}}}{\Delta t} + \dfrac{u_{j+1}^n - u_j^n}{h} = 0, \quad j \in \mathbb{Z}, \quad n \geq 0. \end{cases}$$

In particular the construction of the scheme and stability analysis based on energy conservation properties is presented in [10]. An important fact is that the stability CFL condition, namely, in the 1D case,

$$(1.3)\qquad \alpha = \frac{\Delta t}{h} < 1,$$

is not affected by the mesh refinement process. A plane wave analysis for measuring the accuracy of the method is detailed in [12]. The present article, whose purpose is essentially theoretical, is the sequel to [12]. Our goal is to derive optimal error estimates and to validate them through numerical tests. More precisely, we present a convergence analysis for two different conservative space-time mesh refinement schemes introduced in [11].

We mention that in [4] and more recently in [6] the authors have constructed space-time mesh refinement schemes devoted to the conservation of a discrete equivalent of the integral of the solution of a first order hyperbolic system. Such schemes are also called conservative schemes in the conservation laws community, but they are not necessarily stable (the integral of the solution is not a norm!). However, such conservation properties are highly desirable for the approximation of solutions with shocks.

The outline of the rest of the article is as follows. In section 2, we define our two grids model problem, present the two mesh refinement schemes (I and II) and recall the main stability theorems. In section 3, we state our main convergence Theorem 3.1. Section 4, devoted to the proof of this theorem, is the main section of this article. We think that one of the contributions of the present paper is precisely the proof that appears rather nonstandard, although based on energy techniques. Finally, in section 5, the theoretical results are compared to numerical ones and those obtained in [12] by Fourier-like techniques. This analysis did not result in rigorous error estimates, as did that of Theorem 3.1, but permitted us to predict the order of convergence that we prove in the present paper. The other interest of the energy proof we develop here is that it can be generalized to spatially variable coefficients and higher space dimensions with only purely technical additional difficulties.

2. Conservative space-time mesh refinement schemes.

We recall the construction of the method presented in [11]. In order to solve system (1.1) with a local space-time mesh refinement, the computational domain is split into two half-spaces, $\Omega_c = \{x < 0\}$ and $\Omega_f = \{x > 0\}$. Denoting by (u_c, v_c) and (u_f, v_f) the restrictions of (u, v) to Ω_c and Ω_f respectively, problem (1.1) can be rewritten as a transmission problem through the interface $x = 0$ as follows:

$$\left\{\begin{aligned} &\frac{\partial u_c}{\partial t} + \frac{\partial v_c}{\partial x} = 0,\\ &\frac{\partial v_c}{\partial t} + \frac{\partial u_c}{\partial x} = 0, \end{aligned}\right. \quad \text{in } \Omega_c, \tag{2.1}$$

$$\left\{\begin{aligned} &\frac{\partial u_f}{\partial t} + \frac{\partial v_f}{\partial x} = 0,\\ &\frac{\partial v_f}{\partial t} + \frac{\partial u_f}{\partial x} = 0, \end{aligned}\right. \quad \text{in } \Omega_f, \tag{2.2}$$

coupled by the interface conditions

$$u_c(0,t) = u_f(0,t), \tag{2.3}$$

$$v_c(0,t) = v_f(0,t), \tag{2.4}$$

to obtain a solution of the global problem.

2.1. The interior scheme.

Assume that we have a mesh with step size $(2h, 2\Delta t)$ for Ω_c and a mesh with step size $(h, \Delta t)$ for Ω_f. It is important to note that the ratio of the time step to the space step is the same in both domains. With the obvious notation, the unknowns of our scheme will be the following:

- for the coarse grid,

$$u_{2j}^{2n}, \quad j \le 0, \quad n \ge 0, \qquad v_{2j+1}^{2n+1}, \quad j \le -1, \quad n \ge 0;$$

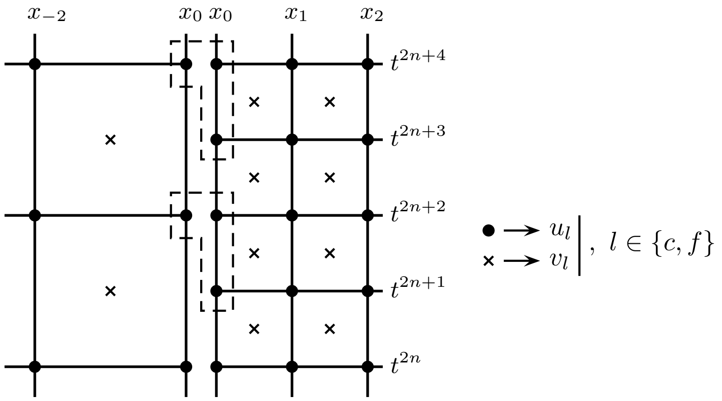

FIG. 2.1. *Distribution of the unknowns over* Γ.

- for the fine grid,

$$u_j^n, \qquad j \geq 0, \qquad n \geq 0, \qquad\qquad v_{j+\frac{1}{2}}^{n+\frac{1}{2}}, \qquad j \geq 0, \qquad n \geq 0.$$

At the interior of each subdomain, the standard Yee scheme [26, 25] is considered. The discrete equations in the coarse and in the fine grids between the instants t^{2n} and t^{2n+2} are

$$\text{(2.5)} \quad \begin{cases} \dfrac{(u_c)_{2j}^{2n+2} - (u_c)_{2j}^{2n}}{2\Delta t} + \dfrac{(v_c)_{2j+1}^{2n+1} - (v_c)_{2j-1}^{2n+1}}{2h} = 0, \quad j \leq -1, \quad n \geq 0, \\ \dfrac{(v_c)_{2j+1}^{2n+1} - (v_c)_{2j+1}^{2n-1}}{2\Delta t} + \dfrac{(u_c)_{2j+2}^{2n} - (u_c)_{2j}^{2n}}{2h} = 0, \quad j \leq -1, \quad n \geq 0, \end{cases}$$

$$\text{(2.6)} \quad \begin{cases} \dfrac{(u_f)_j^{2n+1} - (u_f)_j^{2n}}{\Delta t} + \dfrac{(v_f)_{j+\frac{1}{2}}^{2n+\frac{1}{2}} - (v_f)_{j-\frac{1}{2}}^{2n+\frac{1}{2}}}{h} = 0, \quad j \geq 1, \quad n \geq 0, \\ \dfrac{(v_f)_{j+\frac{1}{2}}^{2n+\frac{1}{2}} - (v_f)_{j+\frac{1}{2}}^{2n-\frac{1}{2}}}{\Delta t} + \dfrac{(u_f)_{j+1}^{2n} - (u_f)_j^{2n}}{h} = 0, \quad j \geq 0, \quad n \geq 0, \end{cases} \\ \begin{cases} \dfrac{(u_f)_j^{2n+2} - (u_f)_j^{2n+1}}{\Delta t} + \dfrac{(v_f)_{j+\frac{1}{2}}^{2n+\frac{3}{2}} - (v_f)_{j-\frac{1}{2}}^{2n+\frac{3}{2}}}{h} = 0, \quad j \geq 1, \quad n \geq 0, \\ \dfrac{(v_f)_{j+\frac{1}{2}}^{2n+\frac{3}{2}} - (v_f)_{j+\frac{1}{2}}^{2n+\frac{1}{2}}}{\Delta t} + \dfrac{(u_f)_{j+1}^{2n+1} - (u_f)_j^{2n+1}}{h} = 0, \quad j \geq 0, \quad n \geq 0, \end{cases}$$

completed with discrete initial conditions.

$$\text{(2.7)} \quad \begin{array}{llll} (u_c)_{2j}^0, & j \leq 0, & (v_c)_{2j+1}^1, & j \leq -1\,, \\ (u_f)_j^0, & j \geq 0, & (v_f)_{j+\frac{1}{2}}^{\frac{1}{2}}, & j \geq 0\,. \end{array}$$

As is shown in Figure 2.1, two values of the solution are allowed along the interface $\Gamma = \{x = 0\}$ at the even time steps. The continuity of the unknown u is imposed in a weak way: this seems to be useful for guaranteeing the stability of the scheme [11].

2.2. The discrete transmission conditions. For coupling (2.5) and (2.6), the idea is to approximate the transmission conditions (2.3) and (2.4) in such a way that the stability of the method is ensured a priori. A simple way to do that is to impose a discrete version of the energy conservation property

$$E(t) = E(0), \qquad \text{where} \quad E(t) = \frac{1}{2}\int_{\mathbb{R}} u(x,t)^2 \mathrm{d}x + \frac{1}{2}\int_{\mathbb{R}} v(x,t)^2 \mathrm{d}x,$$

satisfied by the exact solution of (1.1). In our case, it is natural to define the total discrete energy only at the even instants by

$$E^{2n} = E_c^{2n} + E_f^{2n}, \tag{2.8}$$

where E_c^{2n} and E_f^{2n} are, respectively, the coarse grid and fine grid energies:

$$E_c^{2n} = \frac{1}{2}\left(\sum_{j\leq -1} |(u_c)_{2j}^{2n}|^2\; 2h + \sum_{j\leq -1} (v_c)_{2j+1}^{2n+1}(v_c)_{2j+1}^{2n-1}\; 2h + |(u_c)_0^{2n}|^2\; h\right),$$

$$E_f^{n} = \frac{1}{2}\left(\sum_{j\geq 1} |(u_f)_{j}^{n}|^2\; h + \sum_{j\geq 0} (v_f)_{j+\frac{1}{2}}^{n+\frac{1}{2}}(v_f)_{j+\frac{1}{2}}^{n-\frac{1}{2}}\; h + |(u_f)_0^{n}|^2\; \frac{h}{2}\right).$$

This is the most natural extension to the "two grids" scheme of the discrete energy which is conserved with the Yee scheme on a single grid. The idea pursued in [11] is to impose the conservation of E^{2n}. To state the main result of [11], it is useful to introduce the following "discrete traces" of u_c, v_c, u_f, and v_f:

$$\begin{cases} (U_c)_0^{2n+1} &= \dfrac{1}{2}\left((u_c)_0^{2n+2} + (u_c)_0^{2n}\right), \\[2ex] (V_c)_0^{2n+1} &= (v_c)_{-1}^{2n+1} - h\dfrac{(u_c)_0^{2n+2} - (u_c)_0^{2n}}{2\Delta t}, \end{cases} \tag{2.9}$$

$$\begin{cases} (U_f)_0^{n+\frac{1}{2}} &= \dfrac{1}{2}\left((u_f)_0^{n+1} + (u_f)_0^{n}\right), \\[2ex] (V_f)_0^{n+\frac{1}{2}} &= (v_f)_{\frac{1}{2}}^{n+\frac{1}{2}} + \dfrac{h}{2}\dfrac{(u_f)_0^{n+1} - (u_f)_0^{n}}{\Delta t}. \end{cases} \tag{2.10}$$

THEOREM 2.1. *Consider a solution of* (2.5) *and* (2.6), *the discrete energy* (2.8) *is conserved if and only if*

$$\frac{1}{2}\left((U_f)_0^{2n+\frac{1}{2}}(V_f)_0^{2n+\frac{1}{2}} + (U_f)_0^{2n+\frac{3}{2}}(V_f)_0^{2n+\frac{3}{2}}\right) = (U_c)_0^{2n+1}(V_c)_0^{2n+1}. \tag{2.11}$$

Let us come back to the approximation of the continuity conditions (2.3) and (2.4). We first remark that, assuming the discrete unknowns have been computed up to time t^{2n}, the interior scheme given by (2.5) and (2.6) permits us to obtain all the unknowns up to time t^{2n+2} except the three following values:

$$(u_c)_0^{2n+2}, \qquad (u_f)_0^{2n+1}, \qquad (u_f)_0^{2n+2}.$$

So, three additional (linear) equations consistent with the transmission conditions (2.3) and (2.4) and compatible with (2.11) should be added. A first natural choice consists in imposing the following discrete continuity conditions:

$$(2.12)\qquad \begin{cases} (V_f)_0^{2n+\frac{1}{2}} = (V_f)_0^{2n+\frac{3}{2}} = (V_c)_0^{2n+1}, \\ \dfrac{1}{2}\left((U_f)_0^{2n+\frac{1}{2}} + (U_f)_0^{2n+\frac{3}{2}}\right) = (U_c)_0^{2n+1}. \end{cases}$$

The scheme given by (2.5), (2.6), and (2.12) will be called scheme I. The continuity of u is imposed once and that of v twice. A second possible choice is given by

$$(2.13)\qquad \begin{cases} (U_f)_0^{2n+\frac{1}{2}} = (U_f)_0^{2n+\frac{3}{2}} = (U_c)_0^{2n+1}, \\ \dfrac{1}{2}\left((V_f)_0^{2n+\frac{1}{2}} + (V_f)_0^{2n+\frac{3}{2}}\right) = (V_c)_0^{2n+1}, \end{cases}$$

which gives us scheme II. Unlike in the previous scheme, the continuity of u is written twice and that of v once.

Remark 2.1. Using the two first equations of (2.13) we can easily prove that $(u_f)_0^{2n+2} = (u_f)_0^{2n}$ and so the discrete trace of u in the fine side at the even instants is always the same. As a consequence, this scheme cannot be L^∞-convergent. However the numerical simulations will show us that scheme II gives a "good" approximation of the solution "except at the interface," and the L^2-convergence will be proven in section 4.

3. Error analysis: The main results.

Notation. We first introduce some notation for discrete sequences. In order to show the L^2-stability and convergence of both schemes, some discrete norms and spaces must be introduced. Let us define the discrete coarse and fine L^2 spaces for u,

$$(3.1)\qquad \begin{aligned} L^2_{c,u} &= \Big\{ u_{c,h} = \{(u_c)_{2j}\}_{j\le 0} \text{ such that } \sum_{j\le 0} |(u_c)_{2j}|^2 < +\infty \Big\}, \\ L^2_{f,u} &= \Big\{ u_{f,h} = \{(u_f)_{j}\}_{j\ge 0} \text{ such that } \sum_{j\ge 0} |(u_f)_{j}|^2 < +\infty \Big\}, \end{aligned}$$

and their natural Hilbert norms,

$$(3.2)\qquad \begin{aligned} \|u_{c,h}\|^2 &= \sum_{j\le -1} |(u_c)_{2j}|^2 2h + |(u_c)_0|^2\, h, \\ \|u_{f,h}\|^2 &= \sum_{j\ge 1} |(u_f)_{j}|^2 h + |(u_f)_0|^2\, \frac{h}{2}. \end{aligned}$$

In the same way, we have the discrete coarse and fine L^2 spaces for v,

$$(3.3)\qquad \begin{aligned} L^2_{c,v} &= \Big\{ v_{c,h} = \{(v_c)_{2j+1}\}_{j\le -1} \text{ such that } \sum_{j\le -1} |(v_c)_{2j+1}|^2 < +\infty \Big\}, \\ L^2_{f,v} &= \Big\{ v_{f,h} = \{(v_f)_{j+\frac{1}{2}}\}_{j\ge 0} \text{ such that } \sum_{j\ge 0} |(v_f)_{j+\frac{1}{2}}|^2 < +\infty \Big\}, \end{aligned}$$

and the norms,

$$\|v_{c,h}\|^2 = \sum_{j\leq -1} |(v_c)_{2j+1}|^2 \; 2h, \qquad \|v_{f,h}\|^2 = \sum_{j\geq 1} |(v_f)_{j+\frac{1}{2}}|^2 \; h. \tag{3.4}$$

It is immediate to check that our schemes are well posed in these spaces; i.e., as soon as the discrete initial data $u^0_{c,h}, v^1_{c,h}, u^0_{f,h}$, and $v^{\frac{1}{2}}_{f,h}$ belong, respectively, to $L^2_{c,u}$, $L^2_{c,v}$, $L^2_{f,u}$, and $L^2_{f,v}$, then the discrete solution is such that

$$\left(u^{2n}_{c,h}, v^{2n+1}_{c,h}, u^n_{f,h}, v^{n+\frac{1}{2}}_{f,h}\right) \in L^2_{c,u} \times L^2_{c,v} \times L^2_{f,u} \times L^2_{f,v}.$$

For the convergence study, we assume that our solution is at least continuous and we introduce the pointwise exact values

$$\tilde{u}^s_r = u(rh, s\Delta t), \quad \tilde{v}^s_r = v(rh, s\Delta t), \quad (r,s) \in \mathbb{R} \times \mathbb{R}^+.$$

We will assume that the corresponding sequences $\tilde{u}^{2n}_{c,h}, \tilde{v}^{2n+1}_{c,h}, \tilde{u}^n_{f,h}$, and $\tilde{v}^{n+\frac{1}{2}}_{c,h}$ belong, respectively, to $L^2_{c,u}$, $L^2_{c,v}$, $L^2_{f,u}$, and $L^2_{f,v}$. We then define the pointwise errors:

$$\left| \begin{array}{ll} \left(e^u_{c,h}\right)^{2n} = \tilde{u}^{2n}_{c,h} - u^{2n}_{c,h}, & \left(e^u_{f,h}\right)^n = \tilde{u}^n_{f,h} - u^n_{f,h}, \\[2ex] \left(e^v_{c,h}\right)^{2n+1} = \tilde{v}^{2n}_{c,h} - v^{2n}_{c,h}, & \left(e^v_{f,h}\right)^{n+\frac{1}{2}} = \tilde{v}^{n+\frac{1}{2}}_{f,h} - v^{n+\frac{1}{2}}_{f,h}. \end{array} \right.$$

We shall denote by a *superscript h* sequences in both discrete space and time. More precisely, we set

$$\begin{cases} u^h_c = \left(u^{2n}_{c,h}\right)_{n\geq 0}, & u^h_f = \left(u^n_{f,h}\right)_{n\geq 0}, \qquad u^h = \left(u^h_c, u^h_f\right), \\[2ex] v^h_c = \left(v^{2n+1}_{c,h}\right)_{n\geq 0}, & v^h_f = \left(v^{n+\frac{1}{2}}_{f,h}\right)_{n\geq 0}, \qquad v^h = \left(v^h_c, v^h_f\right), \end{cases}$$

for the discrete solutions and, in the same way,

$$\begin{cases} e^{u,h}_c = \left(\left(e^u_{c,h}\right)^{2n}\right)_{n\geq 0}, & e^{u,h}_f = \left(\left(e^u_{f,h}\right)^n\right)_{n\geq 0}, \quad e^{u,h} \; (\equiv u - u^h) = \left(e^{u,h}_c, e^{u,h}_f\right), \\[2ex] e^{v,h}_c = \left(\left(e^v_{c,h}\right)^{2n+1}\right)_{n\geq 0}, & e^{v,h}_f = \left(\left(e^v_{f,h}\right)^{n+\frac{1}{2}}\right)_{n\geq 0}, \quad e^{v,h} \; (\equiv v - v^h) = \left(e^{v,h}_c, e^{v,h}_f\right), \end{cases}$$

for the errors.

For a given $T > 0$, we can introduce the discrete $L^\infty(0,T;L^2)$ norms (that we define here for the errors $e^{u,h} = u - u^h$ and $e^{v,h} = v - v^h$)

$$\begin{cases} \|e^{u,h}\|^*_{\infty,2,T} = \displaystyle\sup_{t^{2n+\frac{3}{2}}\leq T} \left(\, \|\left(e^u_{c,h}\right)^{2n}\| + \|\left(e^u_{f,h}\right)^{2n}\| \, \right), \\[3ex] \|e^{u,h}\|_{\infty,2,T} = \|e^{u,h}\|^*_{\infty,2,T} + \displaystyle\sup_{t^{2n+\frac{3}{2}}\leq T} \|\left(e^u_{f,h}\right)^{2n+1}\|, \\[3ex] \|e^{v,h}\|_{\infty,2,T} = \displaystyle\sup_{t^{2n+\frac{3}{2}}\leq T} \left(\, \|\left(e^v_{c,h}\right)^{2n+1}\| + \|\left(e^v_{f,h}\right)^{2n+\frac{1}{2}}\| + \|\left(e^v_{f,h}\right)^{2n+\frac{3}{2}}\| \, \right). \end{cases} \tag{3.5}$$

Remark 3.1. Note that $\|u^h\|^*_{\infty,2,T}$ is only a seminorm since the odd instants are not concerned. The complete norm is $\|u^h\|_{\infty,2,T}$. The interest of the introduction of the seminorm $\|u^h\|^*_{\infty,2,T}$ will appear in the proof of Theorem 3.1 (cf. section 4).

We also need to introduce some notation for norms in spaces of continuous functions. For any $a > 0$ and any integer $k \geq 0$, we shall denote

$$\|f\|_{\mathcal{C}^k_{a,T}} = \sup_{x\in[-a,a],\ 0\leq t\leq T} \ \sup_{i+j\leq k} \left| \frac{\partial^{i+j} f}{\partial x^i \partial t^j}(x,t) \right| \quad \forall\ f \in \mathcal{C}^k([-a,a]\times[O,T]), \tag{3.6}$$

$$\|(u,v)\|_{\mathcal{C}^k_{a,T}} = \|u\|_{\mathcal{C}^k_{a,T}} + \|v\|_{\mathcal{C}^k_{a,T}} \quad \forall\ (u,v) \in \mathcal{C}^k([-a,a]\times[O,T])^2. \tag{3.7}$$

It will also be useful to introduce the class of functions

$$\mathbf{C}^\infty_{a,T} = \{(u,v) \in \mathcal{C}^\infty([-a,a]\times[O,T])^2 \text{ such that (3.9) holds}\}. \tag{3.8}$$

Property (3.9) expresses in some sense that the successive derivatives of the functions do not increase too quickly with the order of derivation. More precisely, that

$$|||(u,v)|||_{\mathbf{C}^\infty_{a,T}} \equiv \sup_{k\geq 0} |||(u,v)|||_{\mathcal{C}^k_{a,T}} < +\infty, \tag{3.9}$$

where, for each integer k,

$$|||(u,v)|||_{\mathcal{C}^k_{a,T}} = \|(u,v)\|^{\frac{1}{2^k}}_{\mathcal{C}^k_{a,T}} \prod_{j=1}^{k} \|(u,v)\|^{\frac{1}{2^j}}_{\mathcal{C}^{j+1}_{a,T}}. \tag{3.10}$$

In what follows, if (u,v) is defined for $x \in \mathbb{R}, t \geq 0$, we shall say that $(u,v) \in \mathbf{C}^\infty_{a,T}$ if its restriction to $[-a,a]\times[O,T]$ belongs to $\mathbf{C}^\infty_{a,T}$.

Remark 3.2. The introduction of the set $\mathbf{C}^\infty_{a,T}$ as well as the "norms" $|||(\cdot,\cdot)|||_{\mathcal{C}^k_{a,T}}$ and $|||(\cdot,\cdot)|||_{\mathbf{C}^\infty_{a,T}}$ is rather surprising in such a simple context as the 1D wave equation, and we are not sure that it is really necessary (see also the comments that follow the statement of the theorem at the end of this section). However, these notions will naturally appear in the proof of the theorem. It is interesting to note the following here:

- From the remark that

$$\forall\ k \geq 1, \quad \sum_{j=1}^{k} \frac{1}{2^j} + \frac{1}{2^k} = 1, \tag{3.11}$$

it follows that the maps $(u,v) \to |||(u,v)|||_{\mathcal{C}^k_{a,T}}$ and $(u,v) \to ||(u,v)|||_{\mathcal{C}^\infty_{a,T}}$ are homogeneous of degree 1, and that the set $\mathbf{C}^\infty_{a,T}$ is a cone. It also possesses a *homogeneity property.* Let (u,v) be defined for all real x and all positive t. For any real $\lambda > 0$, we set

$$(u_\lambda(x,t), v_\lambda(x,t)) = (u(\lambda x, \lambda t), v(\lambda x, \lambda t));$$

then

$$(u,v) \in \mathbf{C}^\infty_{a,T} \Longrightarrow (u_\lambda, v_\lambda) \in \mathbf{C}^\infty_{a/\lambda, T/\lambda}.$$

It suffices to remark that if $\hat{\lambda} = \max(1, \lambda)$, then

$$|||(u_\lambda, v_\lambda)|||_{\mathcal{C}^k_{a/\lambda, T/\lambda}} \leq \left(\hat{\lambda}^{\frac{1}{2^k}} \prod_{j=1}^{k} \hat{\lambda}^{\frac{j+1}{2^j}} \right) |||(u,v)|||_{\mathcal{C}^k_{a,T}},$$

and that $\lim_{k \to +\infty} \hat{\lambda}^{\frac{1}{2^k}} = 1$, $\prod_{j=1}^{+\infty} \hat{\lambda}^{\frac{j+1}{2^j}} < +\infty$. Note also that $|||(u,v)|||_{\mathcal{C}^k_{a,T}} = 0 \Longrightarrow (u,v) = 0$.

- However, $|||(\cdot,\cdot)|||_{\mathcal{C}^k_{a,T}}$ and $|||(\cdot,\cdot)|||_{\mathcal{C}^\infty_{a,T}}$ are not norms since they do not satisfy the triangular inequality. As a consequence, it is not so clear that the set $\mathbf{C}^\infty_{a,T}$ is a vector set (this point may be interesting but not central to this paper). Clearly, the fact that u belongs to $\mathbf{C}^\infty_{a,T}$ implies that the successive derivatives of u must not increase too quickly with the order of derivation. It is easy to see that $\mathbf{C}^\infty_{a,T}$ contains some well-known functional spaces such as the *Gevrey* spaces $\mathcal{G}^s_{a,T}$, $s \geq 1$ that can be defined as (see [21] for instance)

$$\mathcal{G}^s_{a,T} = \left\{ (u,v) \in \mathcal{C}^\infty_{a,T} \ / \ \exists \ (\mathcal{C}, \gamma) \ / \ \|(u,v)\|_{\mathcal{C}^j_{a,T}} \leq \mathcal{C} \ \gamma^j \ (j!)^s \right\}. \tag{3.12}$$

The set $\mathcal{G}^1_{a,T}$ is made up of analytic functions while the set $\mathcal{G}^s_{a,T}$ for $s > 1$ contains functions with compact support such as

$$f(x,t) = e^{\frac{1}{(x-t)^2 - \alpha^2}} \chi_{[-\alpha,\alpha]},$$

which is easily shown to belong to $\mathcal{G}^3_{a,T}$.

Let us introduce the spaces

$$H^k(\mathbb{R}) = \left\{ f \in L^2(\mathbb{R}) \text{ such that } \partial_x^{\tilde{k}} f \in L^2(\mathbb{R}), \ 0 \leq \tilde{k} \leq k \right\},$$

equipped by the natural norm (in particular $H^0(\mathbb{R}) = L^2(\mathbb{R})$). Let us also define for any Hilbert space H

$$W^{k,\infty}([0,T], H) = \left\{ w : [0,T] \mapsto H, \text{ such that } \sup_{t \in [0,T]} \|\partial_t^{\tilde{k}} w(t)\|_H \leq \infty, \ 0 \leq \tilde{k} \leq k \right\},$$

also equipped by the natural norm. In that way, we set the space

$$E = W^{3,\infty}([0,T], L^2(\mathbb{R})) \cap W^{0,\infty}([0,T], H^3(\mathbb{R})),$$

and we introduce the following notation:

$$\|f\|_E = \max\left\{ \|f\|_{W^{3,\infty}([0,T],L^2(\mathbb{R}))}, \|f\|_{W^{0,\infty}([0,T],H^3(\mathbb{R}))} \right\} \quad \forall \ f \in E,$$

$$\|(u,v)\|_E = \|u\|_E + \|v\|_E \qquad \forall \ (u,v) \in E^2.$$

For technical reasons we will assume that the initial conditions of problem (1.1) are such that

$$(u_0, v_0) \in \left(H^3(\mathbb{R})\right)^2, \quad \text{supp}(u_0, v_0) \cap \{0\} = \varnothing, \tag{3.13}$$

so that the exact solution $(u,v) \in E^2$. In particular, this implies that

$$\tilde{u}^{2n}_{c,h} \in L^2_{c,u}, \quad \tilde{v}^{2n+1}_{c,h} \in L^2_{c,v}, \quad u^n_{f,h} \in L^2_{f,u}, \quad v^{n+\frac{1}{2}}_{f,h} \in L^2_{f,v} \tag{3.14}$$

for all $n \in \mathbb{N}$. Let us also assume that the discrete initial conditions (2.7) satisfy

$$u^0_{c,h} \in L^2_{c,u}, \quad v^1_{c,h} \in L^2_{c,v}, \quad u^0_{f,h} \in L^2_{f,u}, \quad v^{\frac{1}{2}}_{f,h} \in L^2_{f,v}, \tag{3.15}$$

and that they are a good approximation of the exact initial conditions, for example,

$$\begin{aligned}
(u_c)^0_{2j} &= \frac{1}{2h}\int_{x_{2j-1}}^{x_{2j+1}} u_0(x)\mathrm{d}x,\\
(v_c)^1_{2j+1} &= \frac{1}{2h}\int_{x_{2j}}^{x_{2j+2}} v_0(x)\mathrm{d}x - \Delta t\frac{(u_c)^0_{2j+2}-(u_c)^0_{2j}}{2h},\\
(u_f)^0_j &= \frac{1}{h}\int_{x_{j-\frac{1}{2}}}^{x_{j+\frac{1}{2}}} u_0(x)\mathrm{d}x,\\
(v_f)^{\frac{1}{2}}_{j+\frac{1}{2}} &= \frac{1}{h}\int_{x_j}^{x_{j+1}} v_0(x)\mathrm{d}x - \frac{\Delta t}{2}\frac{(u_f)^0_{j+1}-(u_f)^0_j}{h},
\end{aligned} \tag{3.16}$$

or

$$\begin{aligned}
(u_c)^0_{2j} &= u_0(2jh), & (v_c)^1_{2j+1} &= v_0((2j+1)h) - \Delta t\frac{(u_c)^0_{2j+2}-(u_c)^0_{2j}}{2h},\\
(u_f)^0_j &= u_0(jh), & (v_f)^{\frac{1}{2}}_{j+\frac{1}{2}} &= v_0((n+\tfrac{1}{2})h) - \frac{\Delta t}{2}\frac{(u_f)^0_{j+1}-(u_f)^0_j}{h}.
\end{aligned} \tag{3.17}$$

Statement of the main results.

THEOREM 3.1. *Assume that the discretization parameters h and Δt are related by the strict CFL condition* (1.3) *and that the initial condition (u_0, v_0) of equations* (1.1) *satisfies* (3.13) (*so that the exact solution (u, v) belongs to E^2*). *Let us consider initial data given by* (3.16) *or* (3.17). *Then the following hold:*

(i) *The discrete solutions (u^h, v^h) given by the schemes* I *and* II *satisfy the error estimates*

$$\left|\begin{aligned}
\|u-u^h\|_{\infty,2,T} + \|v-v^h\|_{\infty,2,T} &\le \mathcal{C}\ (1-\alpha^2)^{-1}\ T\ h^{\frac{1}{2}}\ \|(u,v)\|_{\mathcal{C}^1_{a,T}}\\
&\quad + \mathcal{C}\ (1-\alpha^2)^{-1}\ (1+T)\ h^2\ \|(u,v)\|_E.
\end{aligned}\right. \tag{3.18}$$

(ii) *If moreover $(u, v) \in \mathcal{C}^{k+1}([-a, a] \times [0, T])$ for some real $a > 0$ and integer $k \ge 1$, the discrete solution given by the scheme* I *satisfies*

$$\left|\begin{aligned}
\|u-u^h\|_{\infty,2,T} + \|v-v^h\|_{\infty,2,T} &\le \mathcal{C}\ (1-\alpha^2)^{-1} T\ h^{\left(\frac{3}{2}-\frac{1}{2^k}\right)}\ |||(u,v)|||_{\mathcal{C}^k_{a,T}}\\
&\quad + \mathcal{C}\ (1-\alpha^2)^{-1}\ (1+T)\ h^2\ \|(u,v)\|_E.
\end{aligned}\right. \tag{3.19}$$

(iii) *If, finally, $(u, v) \in E^2 \cap \mathbf{C}^\infty_{a,T}$, the discrete solution given by the scheme* I *satisfies*

$$\left|\begin{aligned}
\|u-u^h\|_{\infty,2,T} + \|v-v^h\|_{\infty,2,T} &\le \mathcal{C}\ (1-\alpha^2)^{-1}\ T\ h^{\frac{3}{2}}\ |||(u,v)|||_{\mathbf{C}^\infty_{a,T}}\\
&\quad + \mathcal{C}\ (1-\alpha^2)^{-1}\ (1+T)\ h^2\ \|(u,v)\|_E.
\end{aligned}\right. \tag{3.20}$$

Let us complete this theorem by the following comments:

- This theorem expresses the fact that, in the $L^\infty(0,T;L^2)$ norm, scheme I is of order 3/2 while scheme II is of order 1/2. In (3.18), (3.19), and (3.20), the right-hand side is the sum of two terms: the first one measures the error introduced by the transmission scheme while the second one (of second order) is due to the interior scheme.
- The coefficients appearing in the right-hand side of estimates (3.18) through (3.20) blow up when α goes to 1. This is coherent with what one observes numerically: the two schemes are not strongly convergent for $\alpha = 1$. Nevertheless, as has been explained in [12], good results are obtained with the values of α close to 1 (see also section 5).
- One can define the discrete $L^\infty(0,T;L^\infty)$ norm of the error, namely, $\|u - u^h\|_{\infty,T}$ and $\|v-v^h\|_{\infty,T}$, by replacing in definition (3.5) the discrete L^2 norms $\|u_{f,h}\|$, $\|v_{f,h}\|$, $\|u_{c,h}\|$, and $\|v_{c,h}\|$ by the discrete L^∞ norms

$$|u_{f,h}|_\infty = \sup_{j\geq 0}|u_j|, \quad |v_{f,h}|_\infty = \sup_{j\geq 0}|v_{j+\frac{1}{2}}|,$$
$$|u_{c,h}|_\infty = \sup_{j\leq 0}|u_{2j}|, \quad |v_{f,h}|_\infty = \sup_{j\leq -1}|v_{2j+1}|.$$

From the obvious inequality (see also Lemma 4.5)

$$\|u - u^h\|_{\infty,T} \leq \frac{C}{\sqrt{h}}\,\|u - u^h\|_{\infty,2,T}, \tag{3.21}$$

we deduce that

$$\begin{cases} \|u - u^h\|_{\infty,T} + \|v - u^h\|_{\infty,T} = O(h) & \text{with scheme I.} \\ \|u - u^h\|_{\infty,T} + \|v - u^h\|_{\infty,T} = O(1) & \text{with scheme II.} \end{cases}$$

- From Remark 2.1, we already know that scheme II cannot be convergent in the (discrete) $L^\infty(0,T;L^\infty)$ space. As a consequence, using (3.21), we deduce that the error estimate (3.18) is sharp (see also section 5). We also conjecture that the $O(h^{3/2})$ estimate for scheme I is optimal. This is more or less implicit in the plane wave analysis (see [12] and section 5.2) and in good agreement with the numerical results.
- If our results are optimal in terms of powers of h, it is not clear that it is the case concerning the required regularity of the solution, for instance, that we need the C^∞ regularity to obtain the $O(h^{3/2})$ error estimate with scheme I. However, the Fourier analysis (see [12]) does suggest that, at least, time regularity is needed. Moreover, the "norms" $|||(u,v)|||_{\mathcal{C}^k_{\alpha,T}}$ naturally appears in the proof of the theorem (see section 3.1).
- If the solution of the continuous problem is regular enough, scheme I is of order $h^{\frac{3}{2}}$ in the $L^\infty(0,T;L^2)$ norm. As is strongly suggested by the plane wave reflection-transmission analysis (see [12]) as well as numerical results (cf. section 5), we conjecture that scheme I (resp., scheme II) provides $O(h^2)$ (resp., $O(h)$) errors when these are measured in space regions that do not contain a neighborhood of the origin. The proof of such a result remains an open question for us.
- We have considered here the case of the 1D wave equation with constant coefficients. However, it is not difficult to see that the proofs of section 4 (based on energy methods) can be adapted to the case of the 1D wave equation with spatially variable coefficients.

Remark 3.3. The hypotheses demanded in Theorem 3.1 can be rewritten in terms of the regularity of the initial condition. In this way we have the following:

- Estimation (3.19) is satisfied since the initial condition satisfies (3.13) and belongs to $\mathcal{C}^{k+1}(-a-T, a+T)$.
- We define the class of functions

  $$\mathbf{C}_b^\infty = \{(u,v) \in \mathcal{C}^\infty([-b,b])^2 \text{ such that (3.22) holds}\},$$

  where

  $$|||(u,v)|||_{\mathbf{C}_b^\infty} \equiv \sup_{k\geq 0} |||(u,v)|||_{\mathcal{C}_b^k} < +\infty, \tag{3.22}$$

  with

  $$|||(u,v)|||_{\mathcal{C}_b^k} = \|(u,v)\|_{\mathcal{C}_b^k}^{\frac{1}{2^k}} \prod_{j=1}^{k} \|(u,v)\|_{\mathcal{C}_b^{j+1}}^{\frac{1}{2^j}},$$

  and

  $$\|f\|_{\mathcal{C}_b^k} = \sup_{x\in[-b,b]} \sup_{i+j\leq k} \left| \frac{\partial^{i+j} f}{\partial x^i \partial t^j}(x,t) \right| \quad \forall\, f \in \mathcal{C}^k([-b,b]).$$

  Then the hypothesis demanded in statement (iii) is satisfied since $(u_0, v_0) \in \mathbf{C}_{a+T}^\infty$.

4. Proof of the error estimates.

4.1. The equations satisfied by the errors. The first step of the proof consists, of course, in writing the scheme satisfied by the errors. This is also the opportunity to define some useful notation. We introduce "discrete traces" for the exact solution,

$$\begin{cases} (\widetilde{U}_c)_0^{2n+1} = \dfrac{1}{2}\left(\tilde{u}_0^{2n+2} + \tilde{u}_0^{2n}\right), \\[2ex] (\widetilde{V}_c)_0^{2n+1} = \tilde{v}_{-1}^{2n+1} - h\dfrac{\tilde{u}_0^{2n+2} - \tilde{u}_0^{2n}}{2\Delta t}, \end{cases} \tag{4.1}$$

$$\begin{cases} (\widetilde{U}_f)_0^{n+\frac{1}{2}} = \dfrac{1}{2}\left(\tilde{u}_0^{n+1} + \tilde{u}_0^{n}\right), \\[2ex] (\widetilde{V}_f)_0^{n+\frac{1}{2}} = \tilde{v}_{\frac{1}{2}}^{n+\frac{1}{2}} + \dfrac{h}{2}\dfrac{\tilde{u}_0^{n+1} - \tilde{u}_0^{n}}{\Delta t}, \end{cases} \tag{4.2}$$

and for the error,

$$\begin{cases} \left(e_c^U\right)_0^{2n+1} = \dfrac{1}{2}\left(\left(e_c^u\right)_0^{2n+2} + \left(e_c^u\right)_0^{2n}\right), \\[2ex] \left(e_c^V\right)_0^{2n+1} = \left(e_c^v\right)_{-1}^{2n+1} - h\dfrac{\left(e_c^u\right)_0^{2n+2} - \left(e_c^u\right)_0^{2n}}{2\Delta t}, \end{cases} \tag{4.3}$$

$$\begin{cases} \left(e_f^U\right)_0^{n+\frac{1}{2}} = \dfrac{1}{2}\left(\left(e_f^u\right)_0^{n+1} + \left(e_f^u\right)_0^{n}\right), \\[2ex] \left(e_f^V\right)_0^{n+\frac{1}{2}} = \left(e_f^v\right)_{\frac{1}{2}}^{n+\frac{1}{2}} + \dfrac{h}{2}\dfrac{\left(e_f^u\right)_0^{n+1} - \left(e_f^u\right)_0^{n}}{\Delta t}. \end{cases} \tag{4.4}$$

The interior equations satisfied by the error are

$$\tag{4.5} \begin{cases} \dfrac{\left(e_c^u\right)_{2j}^{2n+2} - \left(e_c^u\right)_{2j}^{2n}}{2\Delta t} + \dfrac{\left(e_c^v\right)_{2j+1}^{2n+1} - \left(e_c^v\right)_{2j-1}^{2n+1}}{2h} = \left(\eta_c^u\right)_{2j}^{2n+1}, \quad j \leq -1, \\ \dfrac{\left(e_c^v\right)_{2j+1}^{2n+1} - \left(e_c^v\right)_{2j+1}^{2n-1}}{2\Delta t} + \dfrac{\left(e_c^u\right)_{2j+2}^{2n} - \left(e_c^u\right)_{2j}^{2n}}{2h} = \left(\eta_c^v\right)_{2j+1}^{2n}, \quad j \leq -1, \end{cases}$$

in the coarse grid, and

$$\tag{4.6} \begin{array}{l} \begin{cases} \dfrac{\left(e_f^u\right)_j^{2n+1} - \left(e_f^u\right)_j^{2n}}{\Delta t} + \dfrac{\left(e_f^v\right)_{j+\frac12}^{2n+\frac12} - \left(e_f^v\right)_{j-\frac12}^{2n+\frac12}}{h} = \left(\eta_f^u\right)_j^{2n+\frac12}, \quad j \geq 1, \\ \dfrac{\left(e_f^v\right)_{j+\frac12}^{2n+\frac12} - \left(e_f^v\right)_{j+\frac12}^{2n-\frac12}}{\Delta t} + \dfrac{\left(e_f^u\right)_{j+1}^{2n} - \left(e_f^u\right)_j^{2n}}{h} = \left(\eta_f^v\right)_{j+\frac12}^{2n}, \quad j \geq 0, \end{cases} \\ \begin{cases} \dfrac{\left(e_f^u\right)_j^{2n+2} - \left(e_f^u\right)_j^{2n+1}}{\Delta t} + \dfrac{\left(e_f^v\right)_{j+\frac12}^{2n+\frac32} - \left(e_f^v\right)_{j-\frac12}^{2n+\frac32}}{h} = \left(\eta_f^u\right)_j^{2n+\frac32}, \quad j \geq 1, \\ \dfrac{\left(e_f^v\right)_{j+\frac12}^{2n+\frac32} - \left(e_f^v\right)_{j+\frac12}^{2n+\frac12}}{\Delta t} + \dfrac{\left(e_f^u\right)_{j+1}^{2n+1} - \left(e_f^u\right)_j^{2n+1}}{h} = \left(\eta_f^v\right)_{j+\frac12}^{2n+1}, \quad j \geq 0, \end{cases} \end{array}$$

in the fine grid. In (4.5) and (4.6), the terms on the right-hand side are classical *interior truncation errors* that are completely defined from the exact solution: they are nothing but the quantities in the left-hand sides of (4.5) and (4.6) after the substitution

$$\left(e_c^u\right)_{2j}^{2n}, \left(e_c^v\right)_{2j+1}^{2n+1}, \left(e_f^u\right)_j^n, \left(e_f^v\right)_{j+\frac12}^{n+\frac12} \longrightarrow (\tilde u_c)_{2j}^{2n}, (\tilde v_c)_{2j+1}^{2n+1}, (\tilde u_f)_j^n, (\tilde v_f)_{j+\frac12}^{n+\frac12}.$$

The equations on the interface are

$$\tag{4.7} \begin{cases} \left(e_c^V\right)_0^{2n+1} - \left(e_f^V\right)_0^{2n+\frac12} = \left(\varepsilon_r^v\right)^{2n+\frac12}, \\ \left(e_c^V\right)_0^{2n+1} - \left(e_f^V\right)_0^{2n+\frac32} = \left(\varepsilon_r^v\right)^{2n+\frac32}, \\ \left(e_c^U\right)_0^{2n+1} - \dfrac12\left(\left(e_f^U\right)_0^{2n+\frac12} + \left(e_f^U\right)_0^{2n+\frac32}\right) = \left(\varepsilon_r^u\right)^{2n+1} \end{cases}$$

for scheme I, and

$$\tag{4.8} \begin{cases} \left(e_c^U\right)_0^{2n+1} - \left(e_f^U\right)_0^{2n+\frac12} = \left(\widetilde\varepsilon_r^u\right)^{2n+\frac12}, \\ \left(e_c^U\right)_0^{2n+1} - \left(e_f^U\right)_0^{2n+\frac32} = \left(\widetilde\varepsilon_r^u\right)^{2n+\frac32}, \\ \left(e_c^V\right)_0^{2n+1} - \dfrac12\left(\left(e_f^V\right)_0^{2n+\frac12} + \left(e_f^V\right)_0^{2n+\frac32}\right) = \left(\widetilde\varepsilon_r^v\right)^{2n+1} \end{cases}$$

for scheme II. The quantities on the right-hand side of (4.7) (resp., (4.8)) are the *interface truncation errors* for scheme I (resp., scheme II). Once again, they are completely defined by the exact solution, as the terms in the left-hand side of (4.7) (resp., (4.8)) in which we have made the substitution

$$\left(e_c^U\right)_0^{2n+1}, \left(e_c^V\right)_0^{2n+1}, \left(e_f^U\right)_0^{n+\frac12}, \left(e_f^V\right)_0^{n+\frac12} \longrightarrow (\widetilde U_c)_0^{2n+1}, (\widetilde V_c)_0^{2n+1}, (\widetilde U_f)_0^{n+\frac12}, (\widetilde V_f)_0^{n+\frac12}.$$

4.2. Outline of the proof. It is clear that, by exploiting the linearity of the equations, the error can be separated into two parts:

- the error due to the *interior truncation errors* and *initial conditions*;
- the error due to the *interface truncation errors.*

Let us formalize this setting:

$$\delta^h := \Big\{ \big(e_c^u\big)^0_{2j}, \big(e_c^v\big)^1_{2j+1}, \big(e_f^u\big)^0_j, \big(e_f^v\big)^{\frac{1}{2}}_{j+\frac{1}{2}} \Big\}, \qquad \text{the } \textit{initial errors,}$$

$$\eta^h := \Big\{ \big(\eta_c^u\big)^{2n}_{2j}, \big(\eta_c^v\big)^{2n+1}_{2j+1}, \big(\eta_f^u\big)^{n+\frac{1}{2}}_j, \big(\eta_f^v\big)^{n}_{j+\frac{1}{2}} \Big\}, \qquad \text{the } \textit{interior truncation errors,}$$

$$\varepsilon^h_I := \big\{ \big(\varepsilon_r^u\big), \big(\varepsilon_r^v\big) \ \big\}, \quad \varepsilon^h_{II} := \big\{ \big(\widetilde{\varepsilon}_r^u\big), \big(\widetilde{\varepsilon}_r^v\big) \big\}, \qquad \text{the } \textit{interface truncation errors.}$$

It is clear that if $(\delta^h, \eta^h, \varepsilon^h)$ are known, the sequences $(e^{u,h}, e^{v,h})$ are completely characterized by the interior equations and the transmission scheme I or II. In this way, we define two maps $\Phi_l, l = I, II$,

$$\big(\delta^h, \eta^h, \varepsilon^h_l\big) \xrightarrow{\Phi_l} (e^{u,h}, e^{v,h}),$$

which are linear. In particular

$$\Big(\big(e_c^{u,h}\big), \big(e_c^{v,h}\big), \big(e_f^{u,h}\big), \big(e_f^{v,h}\big) \Big) = \Phi_l(\delta^h, \eta^h, 0) + \Phi_l\big(0, 0, \varepsilon^h_l\big).$$

- The estimate of $\Phi_l(\delta^h, \eta^h, 0)$, due to the *interior truncation errors* and the approximations of *initial data*, does not really depend on the *transmission scheme*, provided that this scheme is conservative in the sense of Theorem 2.1, which is the case for schemes I and II. As a consequence of the centered nature of the scheme, this *error* is $O(h^2)$ provided that the initial conditions are approximated to $O(h^2)$. The precise result is the following.

  Proposition 4.1. *Let h and Δt be constants such that*

  $$\alpha := \frac{\Delta t}{h} < 1$$

  and let $T > 0$. Assume that the initial condition (u_0, v_0) of equations (1.1) *satisfies* (3.13) *(so that the exact solution (u, v) belongs to E^2). Let us consider initial data given by* (3.16) *or* (3.17). *Then, $(e^{u,h}, e^{v,h}) = \Phi_l(\delta^h, \eta^h, 0)$ satisfies the following estimate:*

  $$\|e^{u,h}\|_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T} \leq \mathcal{C}(1-\alpha^2)^{-1}\,(1+T)\,h^2\|(u,v)\|_E. \tag{4.9}$$

  The analysis of this error is very similar to that (rather standard) of the "pure" Yee scheme (i.e., without any mesh refinement) and, as this point is not central to this paper, we have chosen not to give the proof here. We refer to the reader to [17] for more details.

- The estimate of $\Phi_l(0, 0, \varepsilon^h_l)$ does depend on the *transmission scheme.* The analysis, presented in sections 4.3 and 4.4, is much less classical and consists in two main steps:
  - For both schemes I and II, a direct analysis combining the use of *energy techniques* (as for the stability analysis), *consistency estimates* for the

transmission conditions (*globally* in $O(h)$—see Lemma 4.3), and the use of a *discrete trace inequality* (which results in the loss of one half-power of h—see Lemma 4.5) permits us to show an $O(\sqrt{h})$ estimate for both schemes I and II. This is Lemma 4.2. The proof stops here for scheme II.

– For scheme I, one can use a *bootstrap* argument to improve iteratively the obtained rate of convergence: the estimate that will lead to (3.19) is proved by *induction* on k (this is Lemma 4.8) and that leading to (3.20) by passing to the limit when $k \to +\infty$ (this is Lemma 4.9). This demands a closer look at the structure of the *transmission truncation error* ε_I that has some properties that the error ε_{II} does not.

In summary, estimate (3.18) is obtained by combining Proposition 4.1 with Lemma 4.2, (3.19) is obtained by regrouping Proposition 4.1 with Lemma 4.8, and (3.20) is obtained by regrouping Proposition 4.1 with Lemma 4.9.

4.3. Proof of the $\mathcal{O}(\sqrt{h})$ estimates. Provided that similar techniques can be applied to the analysis of scheme II, only the estimate for scheme I will be proven. The main difference between the two proofs will be pointed out in Remark 4.1.

What we are going to derive here is the equivalent of estimate (3.18) for $\Phi_I(0,0,\varepsilon_l)$. For the sake of simplicity, we shall still denote in this section

$$\Phi_I\big(0,0,\varepsilon_l^h\big) = \Big(\big(e_c^{u,h}\big),\big(e_c^{v,h}\big),\big(e_f^{u,h}\big),\big(e_f^{v,h}\big)\Big).$$

We shall also use the notation

$$e^{u,h} = \Big(\big(e_c^{u,h}\big),\big(e_f^{u,h}\big)\Big), \quad e^{v,h} = \Big(\big(e_c^{v,h}\big),\big(e_f^{v,h}\big)\Big)$$

and refer to definition (3.5) for the discrete norms. Throughout this section we will use only the last two norms of (3.5). The first one (that we call norm-star) will be useful for the proof of (3.19). The estimate we want to prove here is the following.

LEMMA 4.2. *If the solution of the continuous problem* (1.1) *belongs to* $\mathcal{C}^1_{a,T}$ *for* $a > 0$*, then*

$$\|e^{u,h}\|_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T} \;\leq\; \mathcal{C}\,(1-\alpha^2)^{-1}\,T\,h^{\frac{1}{2}}\,\|(u,v)\|_{\mathcal{C}^1_{a,T}}. \tag{4.10}$$

The rest of this section is devoted to the proof of this lemma. By definition,

$$\big(e_c^{u,h}\big),\big(e_c^{v,h}\big),\big(e_f^{u,h}\big), \text{ and } \big(e_f^{v,h}\big)$$

satisfy the *homogeneous* interior equations (4.5) and (4.6) (i.e., with *zero* right-hand sides), and we recall below the equations at the interface,

$$\begin{cases} \big(e_c^V\big)_0^{2n+1} - \big(e_f^V\big)_0^{2n+\frac{1}{2}} = (\varepsilon_r^v)^{2n+\frac{1}{2}}, \\ \big(e_c^V\big)_0^{2n+1} - \big(e_f^V\big)_0^{2n+\frac{3}{2}} = \big(\varepsilon_r^v\big)^{2n+\frac{3}{2}}, \\ \big(e_c^U\big)_0^{2n+1} - \dfrac{1}{2}\Big(\big(e_f^U\big)_0^{2n+\frac{1}{2}} + \big(e_f^U\big)_0^{2n+\frac{3}{2}}\Big) = (\varepsilon_r^u)^{2n+1}, \end{cases} \tag{4.11}$$

where the *interface truncation errors* are given by (we indicate the order of magnitude of each term obtained by a Taylor expansion)

$$\big(\varepsilon_r^v\big)^{2n+\frac{1}{2}} = (\widetilde{V}_c)_0^{2n+1} - (\widetilde{V}_f)_0^{2n+\frac{1}{2}} = \mathcal{O}(\Delta t),$$

$$\big(\varepsilon_r^v\big)^{2n+\frac{3}{2}} = (\widetilde{V}_c)_0^{2n+1} - (\widetilde{V}_f)_0^{2n+\frac{3}{2}} = \mathcal{O}(\Delta t),$$

$$\big(\varepsilon_r^u\big)^{2n+1} = (\widetilde{U}_c)_0^{2n+1} - \tfrac{1}{2}\Big((\widetilde{U}_f)_0^{2n+\frac{1}{2}} + (\widetilde{U}_f)_0^{2n+\frac{3}{2}}\Big) = \mathcal{O}(\Delta t^2),$$

where the quantities $(\widetilde{U}_c)_0^{2n+1}, (\widetilde{V}_c)_0^{2n+1}, (\widetilde{V}_f)_0^{2n+\frac{1}{2}}, (\widetilde{V}_f)_0^{2n+\frac{1}{2}}$ are defined from the exact solution (u,v) by ((4.1) and (4.2)). The following lemma, whose immediate proof is omitted here (it is based on a simple Taylor expansion), gives us the magnitude of these quantities.

LEMMA 4.3. *Assume that, for some $a > 0$, u and v belong to $\mathcal{C}^1_{a,T}$. Then, provided that $\alpha \leq 1$,*

$$\text{(4.12)} \quad \sup_{t^{2n}\leq T} |\big(\varepsilon_r^v\big)^{n+\frac{1}{2}}| \leq \mathcal{C}\ h\ \|(u,v)\|_{\mathcal{C}^1_{a,T}}, \qquad \sup_{t^{2n}\leq T} |\big(\varepsilon_r^u\big)^{2n+1}| \leq \mathcal{C}\ \alpha\ h\ \|u\|_{\mathcal{C}^1_{a,T}}.$$

If moreover $(u,v) \in \mathcal{C}^2_{a,T}$, then

$$\sup_{t^{2n}\leq T} |(\varepsilon_r^u)^{2n+1}| \leq \mathcal{C}\ \alpha^2\ h^2\ \|u\|_{\mathcal{C}^2_{a,T}}, \qquad \sup_{t^{2n}\leq T} |\big(\varepsilon_r^v\big)^{2n+\frac{1}{2}} + \big(\varepsilon_r^v\big)^{2n+\frac{3}{2}}| \leq \mathcal{C}\ h^2\ \|(u,v)\|_{\mathcal{C}^2_{a,T}}.$$
(4.13)

Next, as for to the discrete energy (2.8), we introduce the discrete energy of the error at even instants:

$$\text{(4.14)} \qquad \mathcal{E}^{2n} = \mathcal{E}_c^{2n} + \mathcal{E}_f^{2n},$$

$$\text{where} \quad \left| \begin{aligned} \mathcal{E}_c^{2n} &= \frac{1}{2} \sum_{j\leq -1} |\big(e_c^u\big)_{2j}^{2n}|^2\ 2h + \frac{1}{2} \sum_{j\leq -1} \big(e_c^v\big)_{2j+1}^{2n+1} \big(e_c^v\big)_{2j+1}^{2n-1}\ 2h + \frac{1}{2}\ |\big(e_c^u\big)_0^{2n}|^2\ h, \\ \mathcal{E}_f^n &= \frac{1}{2} \sum_{j\geq 1} |\big(e_f^u\big)_j^n|^2\ h + \frac{1}{2} \sum_{j\geq 0} \big(e_f^v\big)_{j+\frac{1}{2}}^{n+\frac{1}{2}} \big(e_f^v\big)_{j+\frac{1}{2}}^{n-\frac{1}{2}}\ h + \frac{1}{2}\ |\big(e_f^u\big)_0^n|^2\ \frac{h}{2}. \end{aligned} \right.$$

Our goal will be to obtain an estimate for $\sqrt{\mathcal{E}^{2n}}$. This will provide an L^2-estimate for the error with the aid of the following lemma.

LEMMA 4.4. *Assume that* (1.3) *holds and that*

$$\Big(\big(e_{f,h}^u\big)^n, \big(e_{f,h}^v\big)^{n+\frac{1}{2}}\Big) \in L^2_{f,u} \times L^2_{f,v} \quad \text{ and } \quad \Big(\big(e_{c,h}^u\big)^{2n}, \big(e_{c,h}^v\big)^{2n+1}\Big) \in L^2_{c,u} \times L^2_{c,v}.$$

Then, there exists a positive constant $\mathcal{C}$ independent of Δt, h, and α such that for any $n > 0$

$$\text{(4.15)} \quad \|\big(e_{c,h}^u\big)^{2n}\|^2 + \|\big(e_{c,h}^v\big)^{2n+1}\|^2 + \|\big(e_{c,h}^v\big)^{2n-1}\|^2 \leq \mathcal{C}\ (1-\alpha^2)^{-1}\ \mathcal{E}_c^{2n},$$

$$\text{(4.16)} \quad \|\big(e_{f,h}^u\big)^{2n}\|^2 + \|\big(e_{f,h}^v\big)^{2n+\frac{1}{2}}\|^2 + \|\big(e_{f,h}^v\big)^{2n-\frac{1}{2}}\|^2 \leq \mathcal{C}\ (1-\alpha^2)^{-1}\ \mathcal{E}_f^{2n},$$

$$\text{(4.17)} \quad \|\big(e_{f,h}^u\big)^{2n+1}\|^2 \leq \mathcal{C}\ (1-\alpha^2)^{-1}\ \big(\mathcal{E}^{2n} + \mathcal{E}^{2n+2}\big) + \mathcal{C}\ h\ |\big(\varepsilon_r^u\big)^{2n+1}|^2.$$

Proof. We first prove (4.15). Using the identity $4ab = (a+b)^2 - (a-b)^2$, we obtain

$$\text{(4.18)} \quad \left| \begin{aligned} \mathcal{E}_c^{2n} = \frac{1}{2} \left(\sum_{j\leq -1} |\big(e_c^u\big)_{2j}^{2n}|^2\ 2h + |\big(e_c^u\big)_0^{2n}|^2\ h \right) &+ \frac{1}{2} \sum_{j\leq -1} \left| \frac{\big(e_c^v\big)_{2j+1}^{2n+1} + \big(e_c^v\big)_{2j+1}^{2n-1}}{2} \right|^2\ 2h \\ &- \frac{1}{2} \sum_{j\leq -1} \left| \frac{\big(e_c^v\big)_{2j+1}^{2n+1} - \big(e_c^v\big)_{2j+1}^{2n-1}}{2} \right|^2\ 2h. \end{aligned} \right.$$

Using the second equation of scheme (4.5), we observe that

$$\left|\frac{\left(e_c^v\right)_{2j+1}^{2n+1}-\left(e_c^v\right)_{2j+1}^{2n-1}}{2}\right|^2=\frac{\alpha^2}{4}\,\left|\left(e_c^u\right)_{2j+2}^{2n}-\left(e_c^u\right)_{2j}^{2n}\right|^2\leq\frac{\alpha^2}{2}\,\left(\left|\left(e_c^u\right)_{2j+2}^{2n}\right|^2+\left|\left(e_c^u\right)_{2j}^{2n}\right|^2\right).$$

We use this in (4.18) to deduce that

$$\mathcal{E}_c^{2n}\geq\frac{1}{2}\left\|\frac{\left(e_{c,h}^v\right)^{2n-1}+\left(e_{c,h}^v\right)^{2n+1}}{2}\right\|^2+\frac{1-\alpha^2}{2}\left\|\left(e_{c,h}^u\right)^{2n}\right\|^2, \tag{4.19}$$

which implies in particular

$$\|\left(e_{c,h}^u\right)^{2n}\|^2\leq 2\,(1-\alpha^2)^{-1}\,\mathcal{E}_c^{2n}. \tag{4.20}$$

Next, we remark that the second equality of (4.5) can be rewritten as

$$\left(e_c^v\right)_{2j+1}^{2n\pm1}=\frac{\left(e_c^v\right)_{2j+1}^{2n+1}+\left(e_c^v\right)_{2j+1}^{2n-1}}{2}\mp\frac{\Delta t}{2h}\left(\left(e_c^u\right)_{2j+2}^{2n}-\left(e_c^u\right)_{2j}^{2n}\right).$$

Then, using the inequality $(a+b)^2\leq 2(a^2+b^2)$ twice, we obtain

$$\|\left(e_{c,h}^v\right)^{2n\pm1}\|^2\leq 2\,\|\frac{\left(e_{c,h}^v\right)^{2n-1}+\left(e_{c,h}^v\right)^{2n+1}}{2}\|^2+2\alpha^2\,\|\left(e_{c,h}^u\right)^{2n}\|^2.$$

Using now (4.19) and (4.20), we deduce the existence of a constant C such that

$$\|\left(e_{c,h}^u\right)^{2n}\|^2+\|\left(e_{c,h}^v\right)^{2n+1}\|^2+\|\left(e_{c,h}^v\right)^{2n-1}\|^2\leq\mathcal{C}(1-\alpha^2)^{-1}\mathcal{E}_c^{2n}, \tag{4.21}$$

and (4.15) is proven.

If we use techniques similar to those used above, it is easy (we omit the details) to show that, for any integer k,

$$\|\left(e_{f,h}^u\right)^{k}\|^2+\|\left(e_{f,h}^v\right)^{k+\frac{1}{2}}\|^2+\|\left(e_{f,h}^v\right)^{k-\frac{1}{2}}\|^2\leq\mathcal{C}(1-\alpha^2)^{-1}\mathcal{E}_f^{k},$$

which gives (4.16) for $k=2n$.

If we take $k=2n+1$, we are only able to bound $\|(e_{f,h}^u)^{2n+1}\|$ in terms of $\mathcal{E}_f^{2n+1}$ but not in terms of $\mathcal{E}^{2n}$ and $\mathcal{E}^{2n+2}$ (the conserved energy).

In order to do so, we use the first equality of (4.6) for $j\geq 1$ to obtain

$$|\left(e_f^u\right)_j^{2n+1}|\leq|\left(e_f^u\right)_j^{2n}|+\alpha\left(|\left(e_f^v\right)_{j+\frac{1}{2}}^{2n+\frac{1}{2}}|+|\left(e_f^v\right)_{j-\frac{1}{2}}^{2n+\frac{1}{2}}|\right).$$

Therefore, using $(a+b)^2\leq 2(a^2+b^2)$ once again,

$$\|\left(e_{f,h}^u\right)^{2n+1}\|^2\leq\mathcal{C}\left(\|\left(e_{f,h}^u\right)^{2n}\|^2+\|\left(e_{f,h}^v\right)^{2n+\frac{1}{2}}\|^2\right)+\frac{h}{2}\,|\left(e_f^u\right)_0^{2n}|^2,$$

which yields, with the aid of (4.16),

$$\|\left(e_{f,h}^u\right)^{2n+1}\|^2\leq\mathcal{C}\left(1-\alpha^2\right)^{-1}\mathcal{E}_f^{2n}+\frac{h}{2}|\left(e_f^u\right)_0^{2n+1}|^2. \tag{4.22}$$

To conclude we use the third equality of (4.7) rewritten as

$$\left(e_f^u\right)_0^{2n+1} = \left(e_c^u\right)_0^{2n+2} + \left(e_c^u\right)_0^{2n} - \frac{1}{2}\left(\left(e_f^u\right)_0^{2n+2} + \left(e_f^u\right)_0^{2n}\right) - 2(\varepsilon_r^u)^{2n+1}.$$

This obviously implies that

$$|\left(e_f^u\right)_0^{2n+1}|^2 \leq \frac{\mathcal{C}}{h}(\ \|\left(e_{c,h}^u\right)^{2n+2}\|^2 + \|\left(e_{c,h}^u\right)^{2n}\|^2 + \|\left(e_{f,h}^u\right)^{2n+2}\|^2 + \|\left(e_{f,h}^u\right)^{2n}\|^2) + |\left(\varepsilon_r^u\right)^{2n+1}|^2,$$

which yields, using this time (4.15) and (4.16), that

$$\frac{h}{2}\ |\left(e_f^u\right)_0^{2n+1}|^2 \leq \mathcal{C}\ (1-\alpha^2)^{-1}\ \left(\mathcal{E}^{2n} + \mathcal{E}^{2n+2}\right) + \mathcal{C}\ h\ |\left(\varepsilon_r^u\right)^{2n+1}|^2. \tag{4.23}$$

Finally, (4.17) is a direct consequence of (4.22) and (4.23). □

For the estimation of the energy, we use the following identity which is the equivalent for the error of the estimate of Theorem 2.1 for the discrete solution:

$$\left|\begin{aligned} \frac{1}{2\Delta t}\left(\mathcal{E}^{2n+2} - \mathcal{E}^{2n}\right) = {} & \frac{1}{2}\left(\left(e_f^U\right)_0^{2n+\frac{1}{2}}\left(e_f^V\right)_0^{2n+\frac{1}{2}} + \left(e_f^U\right)_0^{2n+\frac{3}{2}}\left(e_f^V\right)_0^{2n+\frac{3}{2}}\right) \\ & - \left(e_c^U\right)_0^{2n+1}\left(e_c^V\right)_0^{2n+1}. \end{aligned}\right. \tag{4.24}$$

The rest of the proof consists in deducing from (4.24) an appropriate estimate for the energy $\mathcal{E}^{2n}$ and then applying Lemma 4.3 to get an estimate of the error. In order to do this, we reorganize the three terms using (4.7) in order to exhibit the consistency errors (see Remark 4.1)

$$\left|\begin{aligned} \frac{1}{2\Delta t}\left(\mathcal{E}^{2n+2} - \mathcal{E}^{2n}\right) = {} & -\frac{1}{2}\left(\left(e_f^U\right)_0^{2n+\frac{1}{2}}\left(\varepsilon_r^v\right)^{2n+\frac{1}{2}} + \left(e_f^U\right)_0^{2n+\frac{3}{2}}\left(\varepsilon_r^v\right)^{2n+\frac{3}{2}}\right) \\ & - \left(\varepsilon_r^u\right)^{2n+1}\left(e_c^V\right)_0^{2n+1}. \end{aligned}\right. \tag{4.25}$$

According to Lemma 4.3, the quantities $(\varepsilon_r^v)^{2n+\frac{1}{2}}$, $(\varepsilon_r^v)^{2n+\frac{3}{2}}$, and $(\varepsilon_r^u)^{2n+1}$ are small. In order to bound the other terms appearing on the right-hand side of (4.25) (and defined in (4.3) and (4.4)) by a function of the error norm, we use a discrete trace lemma.

LEMMA 4.5. *Under the hypotheses of Lemma* 4.4*, there exists a positive constant* $\mathcal{C}$ *independent of* Δt *and* h *such that, for each* $n > 0$*,*

$$\begin{aligned} &|\left(e_f^u\right)_0^n| \leq \tfrac{\sqrt{2}}{\sqrt{h}}\|\left(e_{f,h}^u\right)^n\|, && |\left(e_f^v\right)_0^{n+\frac{1}{2}}| \leq \tfrac{1}{\sqrt{h}}\|\left(e_{f,h}^v\right)^{n+\frac{1}{2}}\|, \\ &|\left(e_c^u\right)_0^{2n}| \leq \tfrac{1}{\sqrt{h}}\|\left(e_{c,h}^u\right)^{2n}\|, && |\left(e_c^v\right)_0^{2n+1}| \leq \tfrac{1}{\sqrt{2h}}\|\left(e_{c,h}^v\right)^{2n+1}\|. \end{aligned} \tag{4.26}$$

Proof. The result is trivial. □

For simplicity of exposition, it is useful to introduce a local measure of the error on the time interval $I_{2n+1} = [t^{2n}, t^{2n+2}]$. Thus we set

$$\left\{\begin{aligned} \|e^{u,h}\|_{h,I_{2n+1}}^2 = {} & \|\left(e_{c,h}^u\right)^{2n}\|^2 + \|\left(e_{c,h}^u\right)^{2n+2}\|^2 \\ & + \|\left(e_{f,h}^u\right)^{2n}\|^2 + \|\left(e_{f,h}^u\right)^{2n+1}\|^2 + \|\left(e_{f,h}^u\right)^{2n+2}\|^2, \\ \|e^{v,h}\|_{h,I_{2n+1}}^2 = {} & \|\left(e_{c,h}^v\right)^{2n+1}\|^2 + \|\left(e_{f,h}^v\right)^{2n+\frac{1}{2}}\|^2 + \|\left(e_{f,h}^v\right)^{2n+\frac{3}{2}}\|^2. \end{aligned}\right. \tag{4.27}$$

Note that these are the quantities appearing in the left-hand sides of inequalities (4.15) through (4.17) of Lemma 4.4. By definition of the discrete $L^\infty(0,T;L^2)$ norm, we have, for $t^{2n+2} \leq T$,

$$\left\{\begin{array}{ll} \|e^{u,h}\|_{h,I_{2n+1}} \leq C\ \|e^{u,h}\|_{\infty,2,T}, & \|e^{v,h}\|_{h,I_{2n+1}} \leq C\ \|e^{v,h}\|_{\infty,2,T}, \\ \|e^{u,h}\|_{\infty,2,T} \leq \displaystyle\sup_{t^{2n+2}\leq T} \|e^{u,h}\|_{h,I_{2n+1}}, & \|e^{v,h}\|_{\infty,2,T} \leq \displaystyle\sup_{t^{2n+2}\leq T} \|e^{v,h}\|_{h,I_{2n+1}}. \end{array}\right. \tag{4.28}$$

Using elementary manipulations on expression (4.25) and Lemma 4.5, the following inequality can be obtained (note that the factor $1/\alpha$ appearing below comes from the right-hand side of the second equation of (4.3)):

$$\left| \begin{array}{l} \displaystyle\frac{\mathcal{E}^{2n+2}-\mathcal{E}^{2n}}{2\Delta t} \leq \frac{\mathcal{C}}{\sqrt{h}}\ \|e^{u,h}\|_{h,I_{2n+1}}\ \left\{|(\varepsilon_r^v)^{2n+\frac{1}{2}}| + |(\varepsilon_r^v)^{2n+\frac{3}{2}}|\right\} \\ \qquad\qquad\qquad \displaystyle + \frac{\mathcal{C}}{\alpha\sqrt{h}}\ \left\{\|e^{u,h}\|_{h,I_{2n+1}} + \alpha\|e^{v,h}\|_{h,I_{2n+1}}\right\}\ |(\varepsilon_r^u)^{2n+1}|. \end{array}\right.$$

Then, by Lemma 4.3 (inequalities (4.12)) and (4.28)

$$\frac{\mathcal{E}^{2n+2}-\mathcal{E}^{2n}}{2\Delta t} \leq \mathcal{C}\ \sqrt{h}\ \|(u,v)\|_{\mathcal{C}^1_{a,T}} \left(\|e^{u,h}\|_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T}\right). \tag{4.29}$$

Adding the above inequalities from $n = 0$ to $m-1$, for any integer $m > 1$, we obtain ($\mathcal{E}_0 = 0$)

$$\mathcal{E}^{2m} \leq \mathcal{C}\ t^{2m}\ \sqrt{h}\ \|(u,v)\|_{\mathcal{C}^1_{a,T}} \left\{\|e^{u,h}\|_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T}\right\}.$$

Now, using Lemma 4.4, we can write, for $t^{2n+2} \leq T$,

$$\left| \begin{array}{l} \|e^{u,h}\|^2_{h,I_{2n+1}} + \|e^{v,h}\|^2_{h,I_{2n+1}} \leq \mathcal{C}\ (1-\alpha^2)^{-1} \left(\mathcal{E}^{2n} + \mathcal{E}^{2n+2}\right) + \mathcal{C}\ h\ |(\varepsilon_r^u)^{2n+1}|^2 \\ \quad \leq \mathcal{C}\ (1-\alpha^2)^{-1}\ T\ \sqrt{h}\ \|(u,v)\|_{\mathcal{C}^1_{a,T}} \left\{\|e^{u,h}\|_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T}\right\} + \mathcal{C}\ h^3\ \|(u,v)\|^2_{\mathcal{C}^1_{a,T}}. \end{array}\right.$$

Therefore, taking the supremum over $t^{2n+2} \leq T$, using (4.28) and classical manipulations based on Young's inequality, one proves the final estimate (4.10) (we omit the details).

Remark 4.1. Let us give some details concerning the derivation of (4.25). We start from the identities

$$\left(e_f^U\right)_0^{2n+\frac{1}{2}} \left(e_f^V\right)_0^{2n+\frac{1}{2}} = \left(e_f^U\right)_0^{2n+\frac{1}{2}} \left[\left(e_f^V\right)_0^{2n+\frac{1}{2}} - \left(e_c^V\right)_0^{2n+1}\right] + \left(e_f^U\right)_0^{2n+\frac{1}{2}} \left(e_c^V\right)_0^{2n+1},$$

$$\left(e_f^U\right)_0^{2n+\frac{3}{2}} \left(e_f^V\right)_0^{2n+\frac{3}{2}} = \left(e_f^U\right)_0^{2n+\frac{3}{2}} \left[\left(e_f^V\right)_0^{2n+\frac{3}{2}} - \left(e_c^V\right)_0^{2n+1}\right] + \left(e_f^U\right)_0^{2n+\frac{3}{2}} \left(e_c^V\right)_0^{2n+1}.$$

After summation, we obtain, using (4.11),

$$\begin{array}{l} \displaystyle\frac{1}{2}\left\{\left(e_f^U\right)_0^{2n+\frac{1}{2}} \left(e_f^V\right)_0^{2n+\frac{1}{2}} + \left(e_f^U\right)_0^{2n+\frac{3}{2}} \left(e_f^V\right)_0^{2n+\frac{3}{2}}\right\} = \left(e_c^V\right)_0^{2n+1} \left[\frac{\left(e_f^U\right)_0^{2n+\frac{1}{2}} + \left(e_f^U\right)_0^{2n+\frac{3}{2}}}{2}\right] \\ \qquad\qquad\qquad\qquad \displaystyle - \frac{1}{2}\ \left(e_f^U\right)_0^{2n+\frac{1}{2}} \left(\varepsilon_r^v\right)_0^{2n+\frac{1}{2}} - \frac{1}{2}\ \left(e_f^U\right)_0^{2n+\frac{3}{2}} \left(\varepsilon_r^v\right)_0^{2n+\frac{3}{2}}. \end{array} \tag{4.30}$$

On the other hand, one has the identity

$$\left|\ \begin{aligned} \left(e_c^U\right)_0^{2n+1}\left(e_c^V\right)_0^{2n+1} = \ & \left[\left(e_c^U\right)_0^{2n+1} - \frac{1}{2}\ \left\{\left(e_f^U\right)_0^{2n+\frac{3}{2}} + \left(e_f^U\right)_0^{2n+\frac{3}{2}}\right\}\right]\left(e_c^V\right)_0^{2n+1} \\ & + \frac{1}{2}\ \left[\left(e_f^U\right)_0^{2n+\frac{3}{2}} + \left(e_f^U\right)_0^{2n+\frac{3}{2}}\right]\left(e_c^V\right)_0^{2n+1}, \end{aligned}\right.$$

that is to say, with the aid of (4.11),

$$\left(e_c^U\right)_0^{2n+1}\left(e_c^V\right)_0^{2n+1} = \left(e_c^V\right)_0^{2n+1}\left(\varepsilon_r^u\right)_0^{2n+1} + \frac{1}{2}\left[\left(e_f^U\right)_0^{2n+\frac{3}{2}} + \left(e_f^U\right)_0^{2n+\frac{3}{2}}\right]\left(e_c^V\right)_0^{2n+1}. \tag{4.31}$$

Finally, (4.25) is obtained as the difference between (4.30) and (4.31).

If scheme II is used, we have

$$\frac{\mathcal{E}^{2n+2} - \mathcal{E}^{2n}}{2\Delta t} = -\frac{1}{2}\left(\left(e_f^V\right)_0^{2n+\frac{1}{2}}\left(\widetilde{\varepsilon}_r^u\right)^{2n+\frac{1}{2}} + \left(e_f^V\right)_0^{2n+\frac{3}{2}}\left(\widetilde{\varepsilon}_r^u\right)^{2n+\frac{3}{2}}\right) - \left(\widetilde{\varepsilon}_r^v\right)^{2n+1}\left(e_c^U\right)_0^{2n+1}, \tag{4.32}$$

and the proof of estimate (3.18) is similar to that presented for scheme I.

4.4. Proof of estimate (3.19). Apart from the results of section 4.4.1, which are essentially generalizations of estimate (3.18), what we do in this section is valid only when we use scheme I to do the coupling. The real novelty in the proof will appear in section 4.4.2. The main differences between scheme I and scheme II will be explained in Remark 4.3.

4.4.1. Estimate of coarse discrete derivatives. Our goal in this paragraph is to derive estimates similar to (3.18) for which we shall call the successive *coarse time discrete derivatives* of the error $(e^{u,h}, e^{v,h})$. The proof is essentially a repetition of the proof of section 4.3, but the statement of the precise result requires some notation.

We define the *coarse discrete derivative* operator D by defining its action on a sequence $w^h = (w)_s^t$ (where t and s are integers or integers plus one half—negative indices t are allowed):

$$(Dw)_s^{t+1} := \frac{(w)_s^{t+2} - (w)_s^t}{2\Delta t}.$$

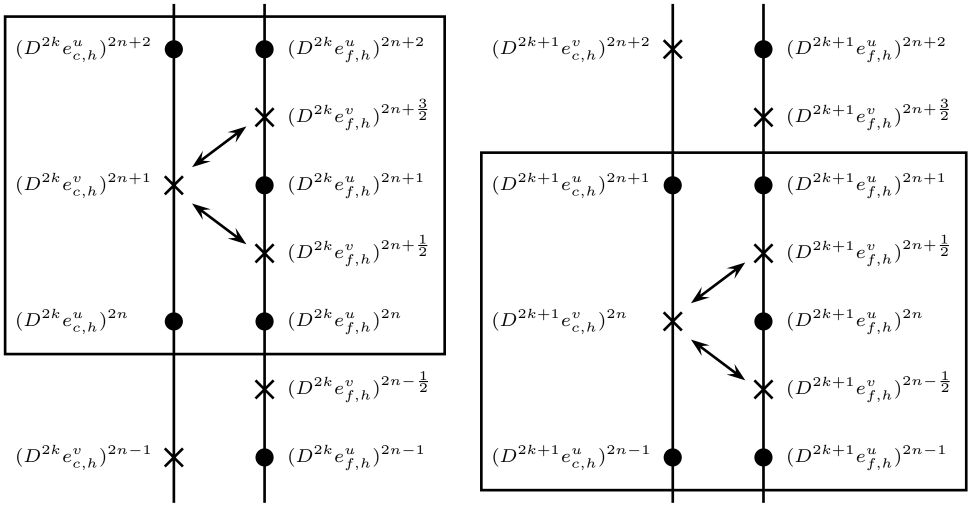
We also define D^m as the mth successive power of D:

$$D^m w^h = D\ (D^{m-1} w^h).$$

We shall now write the numerical scheme satisfied by the mth discrete derivative of $e^{u,h}$ and $e^{v,h}$ (these sequences are implicitly extended by 0 for negative times). Note that the sequences $D^m e^{u,h}$ and $D^m e^{v,h}$ are naturally defined on a grid shifted by $m\Delta t$ (the initial grid is supposed to contain negative discrete instants), so that the fine grids differ depending whether m is odd or even. As the scheme (4.5), (4.6), and (4.7) is "invariant" under a translation by $2\Delta t$, it is easy to see that the *odd* discrete coarse derivative of the sequences $(e_c^{u,h}), (e_c^{v,h}), (e_f^{u,h})$, and $(e_f^{v,h})$, namely,

$$\left(D^{2q+1} e_c^{u,h}\right), \left(D^{2q+1} e_c^{v,h}\right), \left(D^{2q+1} e_f^{u,h}\right), \text{ and } \left(D^{2q+1} e_f^{v,h}\right),$$

satisfies a similar but different set of equations. More precisely, at the instants at which the odd discrete derivative are defined, the only change concerns the coarse grid and corresponds to the substitutions $e_{c,h}^u \leftrightarrow D^{2q+1} e_{c,h}^v$ and $e_{c,h}^v \leftrightarrow D^{2q+1} e_{c,h}^u$.



$(D^{2k}e^u_{c,h})^{2n+2}$
$(D^{2k}e^u_{f,h})^{2n+2}$
$(D^{2k}e^v_{f,h})^{2n+\frac{3}{2}}$
$(D^{2k}e^v_{c,h})^{2n+1}$
$(D^{2k}e^u_{f,h})^{2n+1}$

$(D^{2k+1}e^u_{f,h})^{2n-1}$

FIG. 4.1. *Time distribution of the unknowns.*

Other than this change, the scheme for the time intervals $[t^{2n-1}, t^{2n+1}]$ for the odd coarse discrete derivative is the same as that satisfied by $e^{u,h}$ and $e^{v,h}$ in the time intervals $[t^{2n}, t^{2n+2}]$. This is illustrated by Figure 4.1 in which the arrows represent the discrete transmission conditions. We shall find two types of schemes that are easily deduced from each other. In order to avoid repetition, it is useful to introduce

$$\overline{m} = 1 \quad \text{if } m \text{ is odd }, \qquad \overline{m} = 0 \quad \text{if } m \text{ is even.}$$

Then the equations of the scheme in a characteristic interval $[t^{2n-\overline{m}}, t^{2n+2-\overline{m}}]$ are

$$\left\{\begin{aligned} &\frac{\left(D^m e^u_c\right)^{2n+2-\overline{m}}_{2j} - \left(D^m e^u_c\right)^{2n-\overline{m}}_{2j}}{2\Delta t} + \frac{\left(D^m e^v_c\right)^{2n+1-\overline{m}}_{2j+1} - \left(D^m e^v_c\right)^{2n+1-\overline{m}}_{2j-1}}{2h} = 0,\\ &\frac{\left(D^m e^v_c\right)^{2n+1-\overline{m}}_{2j+1} - \left(D^m e^v_c\right)^{2n-1-\overline{m}}_{2j+1}}{2\Delta t} + \frac{\left(D^m e^u_c\right)^{2n-\overline{m}}_{2j+2} - \left(D^m e^u_c\right)^{2n-\overline{m}}_{2j}}{2h} \quad = 0 \end{aligned}\right. \tag{4.33}$$

on the coarse grid (i.e., for $j \leq -1$), and

$$\begin{gathered} \left\{\begin{aligned} &\frac{\left(D^m e^u_f\right)^{2n+1}_{j} - \left(D^m e^u_f\right)^{2n}_{j}}{\Delta t} + \frac{\left(D^m e^v_f\right)^{2n+\frac{1}{2}}_{j+\frac{1}{2}} - \left(D^m e^v_f\right)^{2n+\frac{1}{2}}_{j-\frac{1}{2}}}{h} = 0, \quad j \geq 1,\\ &\frac{\left(D^m e^v_f\right)^{2n+\frac{1}{2}}_{j+\frac{1}{2}} - \left(D^m e^v_f\right)^{2n-\frac{1}{2}}_{j+\frac{1}{2}}}{\Delta t} + \frac{\left(D^m e^u_f\right)^{2n}_{j+1} - \left(D^m e^u_f\right)^{2n}_{j}}{h} \quad = 0, \quad j \geq 0, \end{aligned}\right. \\ \left\{\begin{aligned} &\frac{\left(D^m e^u_f\right)^{2n+2}_{j} - \left(D^m e^u_f\right)^{2n+1}_{j}}{\Delta t} + \frac{\left(D^m e^v_f\right)^{2n+\frac{3}{2}}_{j+\frac{1}{2}} - \left(D^m e^v_f\right)^{2n+\frac{3}{2}}_{j-\frac{1}{2}}}{h} = 0, \quad j \geq 1,\\ &\frac{\left(D^m e^v_f\right)^{2n+\frac{3}{2}}_{j+\frac{1}{2}} - \left(D^m e^v_f\right)^{2n+\frac{1}{2}}_{j+\frac{1}{2}}}{\Delta t} + \frac{\left(D^m e^u_f\right)^{2n+1}_{j+1} - \left(D^m e^u_f\right)^{2n+1}_{j}}{h} = 0, \quad j \geq 0, \end{aligned}\right. \end{gathered} \tag{4.34}$$

on the fine grid. Finally the discrete transmission conditions read

$$
(4.35)\quad \begin{cases}
\big(D^m e_c^V\big)_0^{2n+1-\overline{m}} - \big(D^m e_f^V\big)_0^{2n+\frac{1}{2}-\overline{m}} = \big(D^m \varepsilon_r^v\big)^{2n+\frac{1}{2}-\overline{m}}, \\
\big(D^m e_c^V\big)_0^{2n+1-\overline{m}} - \big(D^m e_f^V\big)_0^{2n+\frac{3}{2}-\overline{m}} = \big(D^m \varepsilon_r^v\big)^{2n+\frac{3}{2}-\overline{m}}, \\
\big(D^m e_c^U\big)_0^{2n+1-\overline{m}} - \dfrac{1}{2}\Big(\big(D^m e_f^U\big)_0^{2n+\frac{1}{2}-\overline{m}} + \big(D^m e_f^U\big)_0^{2n+\frac{3}{2}-\overline{m}}\Big) = \big(D^m \varepsilon_r^u\big)^{2n+1-\overline{m}}.
\end{cases}
$$

If we assume that the exact solution (u, v) belongs to $\mathcal{C}_{a,T}^{m+1}$, using a Taylor–Lagrange expansion, it is easy to show that the truncation errors appearing on the right-hand side of (4.35) satisfy (this is the analog of (4.12) of Lemma 4.3)

$$
(4.36)\quad \sup_{t^{2n}\le T} \big|\big(D^m \varepsilon_r^u\big)^{2n+1}\big| \le \mathcal{C}\ \alpha\ h\ \|u\|_{\mathcal{C}_{a,T}^{m+1}}, \quad \sup_{t^{2n}\le T} \big|\big(D^m \varepsilon_r^v\big)^{n+\frac{1}{2}}\big| \le \mathcal{C}\ h\ \|(u,v)\|_{\mathcal{C}_{a,T}^{m+1}}.
$$

If we define the discrete $L^\infty(0, T; L^2)$ norms of the discrete coarse derivatives as

$$
(4.37)\quad \left|\begin{aligned}
&\|D^m e^{u,h}\|_{\infty,2,T}^* = \sup_{t^{2n+\frac{3}{2}}\le T} \Big(\ \big\|\big(D^m e_{c,h}^u\big)^{2n-\overline{m}}\big\| + \big\|\big(D^m e_{f,h}^u\big)^{2n-\overline{m}}\big\|\Big) \\
&\|D^m e^{u,h}\|_{\infty,2,T} = \|D^m e^{u,h}\|_{\infty,2,T}^* + \sup_{t^{2n+\frac{3}{2}}\le T} \ \big\|\big(D^m e_{f,h}^u\big)^{2n+1-\overline{m}}\big\| \\
&\|D^m e^{v,h}\|_{\infty,2,T} = \sup_{t^{2n+\frac{3}{2}}\le T} \Big(\ \big\|\big(D^m e_{c,h}^v\big)^{2n+1-\overline{m}}\big\| \\
&\qquad\qquad + \big\|\big(D^m e_{f,h}^v\big)^{2n+\frac{1}{2}-\overline{m}}\big\| + \big\|\big(D^m e_{f,h}^v\big)^{2n+\frac{3}{2}-\overline{m}}\big\|\ \Big),
\end{aligned}\right.
$$

we can apply the proof of section 4.3 to prove the following lemma.

LEMMA 4.6. *If the solution of the continuous problem* (1.1) *belongs to* $\mathcal{C}_{a,T}^{m+1}$ *for* $a > 0$*, then*

$$
(4.38)\quad \|D^m e^{u,h}\|_{\infty,2,T} + \|D^m e^{v,h}\|_{\infty,2,T} \le \mathcal{C}\ (1-\alpha^2)^{-1}\ T\ h^{\frac{1}{2}}\ \big\|\big(\partial_t^m u, \partial_t^m v\big)\big\|_{\mathcal{C}_{a,T}^1}.
$$

4.4.2. The bootstrap argument.

Step 1*: Derivation of an* $\mathcal{O}(h)$ *estimate.* In order to improve estimate (4.10), we note that equations (4.11) can be rewritten as

$$
(4.39)\quad \begin{cases}
\big(e_f^V\big)_0^{2n+\frac{3}{2}} - \big(e_f^V\big)_0^{2n+\frac{1}{2}} = \big(\varepsilon_r^v\big)^{2n+\frac{1}{2}} - \big(\varepsilon_r^v\big)^{2n+\frac{3}{2}} = \mathcal{O}(\Delta t) \\
2(e_c^V)_0^{2n+1} - \Big(\big(e_f^V\big)_0^{2n+\frac{3}{2}} + \big(e_f^V\big)_0^{2n+\frac{1}{2}}\Big) = \big(\varepsilon_r^v\big)^{2n+\frac{1}{2}} + \big(\varepsilon_r^v\big)^{2n+\frac{3}{2}} = \mathcal{O}(\Delta t^2) \\
\big(e_c^U\big)_0^{2n+1} - \dfrac{1}{2}\Big(\big(e_f^U\big)_0^{2n+\frac{1}{2}} + \big(e_f^U\big)_0^{2n+\frac{3}{2}}\Big) = \big(\varepsilon_r^u\big)^{2n+1} = \mathcal{O}(\Delta t^2).
\end{cases}
$$

Now, we reorganize the right-hand side of (4.24) in a clever way so that the left-hand sides of (4.39) appear as (see Remark 4.2)

$$
(4.40)\quad \left|\begin{aligned}
\frac{\mathcal{E}^{2n+2} - \mathcal{E}^{2n}}{2\Delta t} = &- \frac{1}{2}\ \big(\varepsilon_r^u\big)^{2n+1}\Big(\big(e_f^V\big)_0^{2n+\frac{1}{2}} + \big(e_f^V\big)_0^{2n+\frac{3}{2}}\Big) \\
&- \frac{1}{2}\ \Big(\big(\varepsilon_r^v\big)^{2n+\frac{1}{2}} + \big(\varepsilon_r^v\big)^{2n+\frac{3}{2}}\Big)\big(e_c^U\big)_0^{2n+1} \\
&+ \frac{1}{4}\ \Big(\big(\varepsilon_r^v\big)^{2n+\frac{3}{2}} - \big(\varepsilon_r^v\big)^{2n+\frac{1}{2}}\Big)\Big(\big(e_f^U\big)_0^{2n+\frac{3}{2}} - \big(e_f^U\big)_0^{2n+\frac{1}{2}}\Big).
\end{aligned}\right.
$$

Let us analyze the equality in detail. In order to bound the terms appearing on the right-hand side by an L^2 norm of the error, we first point out that from (4.3) and (4.4) it follows that

$$\left\{\begin{aligned} \big(e_f^V\big)_0^{2n+\frac{1}{2}} + \big(e_f^V\big)_0^{2n+\frac{3}{2}} &= \big(e_f^v\big)_{\frac{1}{2}}^{2n+\frac{1}{2}} + \big(e_f^v\big)_{\frac{1}{2}}^{2n+\frac{3}{2}} + h\frac{\big(e_f^u\big)_0^{2n+2} - \big(e_f^u\big)_0^{2n}}{2\Delta t},\\ \big(e_c^U\big)_0^{2n+1} &= \frac{1}{2}\left(\big(e_c^u\big)_0^{2n+2} + \big(e_c^u\big)_0^{2n}\right),\\ \big(e_f^U\big)_0^{2n+\frac{3}{2}} - \big(e_f^U\big)_0^{2n+\frac{1}{2}} &= \frac{1}{2}\left(\big(e_f^u\big)_0^{2n+2} - \big(e_f^u\big)_0^{2n}\right). \end{aligned}\right. \tag{4.41}$$

It is important to note that the quantity $(e_f^u)_0^{2n+1}$ does not appear in expression (4.40). This fact allows us to work with the norm $\|e^{u,h}\|^*_{\infty,2,T}$, which uses only the even time steps of the error of u. This will permit us to use only inequalities (4.15) and (4.16) of Lemma 4.4. Obtaining an estimate using the norm-star yields a similar estimate for the other norm because of the following lemma.

LEMMA 4.7. *Assume the hypothesis of Lemma* 4.4. *Then*

$$\sup_{t^{2n+\frac{3}{2}}\le T} \|\big(e_{f,h}^u\big)^{2n+1}\|_{\infty,2,T} \le \mathcal{C}\left(\|e^{u,h}\|^*_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T} + h^{\frac{5}{2}}\|(u,v)\|_{\mathcal{C}^2_{a,T}}\right). \tag{4.42}$$

Proof. Using the first equality of (4.6) for $j \ge 1$ we get

$$\big(e_f^u\big)_j^{2n+1} = \big(e_f^u\big)_j^{2n} - \alpha\left(\big(e_f^v\big)_{j+\frac{1}{2}}^{2n+\frac{1}{2}} - \big(e_f^v\big)_{j-\frac{1}{2}}^{2n+\frac{1}{2}}\right),$$

and in this way we also get

$$\|\big(e_{f,h}^u\big)^{2n+1}\|^2 \le \mathcal{C}\left(\|\big(e_{f,h}^u\big)^{2n}\|^2 + \|\big(e_{f,h}^v\big)^{2n+\frac{1}{2}}\|^2\right) + \frac{h}{2}|\big(e_f^u\big)_0^{2n+1}|^2. \tag{4.43}$$

In order to estimate the last term we use the last equation in (4.7) to obtain

$$\big(e_f^u\big)_0^{2n+1} = -2\big(\varepsilon_r^u\big)^{2n+1} + \big(e_c^u\big)_0^{2n} + \big(e_c^u\big)_0^{2n+2} - \left(\big(e_f^u\big)_0^{2n} + \big(e_f^u\big)_0^{2n+2}\right)/2.$$

Thus it is clear that

$$\begin{aligned}\frac{h}{2}|\big(e_f^u\big)_0^{2n+1}|^2 \le \mathcal{C}\Big(&\|\big(e_{f,h}^u\big)^{2n}\|^2 + \|\big(e_{f,h}^u\big)^{2n+2}\|^2 + \|\big(e_{c,h}^u\big)^{2n}\|^2\\ &+ \|\big(e_{c,h}^u\big)^{2n+2}\|^2 + h|\big(\varepsilon_r^u\big)^{2n+1}|^2\Big).\end{aligned}$$

Introducing this inequality in (4.43) and using (4.13) of Lemma 4.3 we obtain

$$\|\big(e_{f,h}^u\big)^{2n+1}\|^2 \le \mathcal{C}\left(\|e^{u,h}\|^{*\,2}_{\infty,2,T} + \|e^{v,h}\|^2_{\infty,2,T} + h^5\|(u,v)\|^2_{\mathcal{C}^2_{a,T}}\right),$$

which easily implies (4.42). □

Returning to (4.40), we use successively the trace Lemma 4.5 and the inequalities

(4.13) of Lemma 4.3 to obtain

$$\left|\begin{aligned}&\frac{1}{2}\left|\big(e_f^V\big)_0^{2n+\frac{1}{2}}+\big(e_f^V\big)_0^{2n+\frac{3}{2}}\right|\left|\big(\varepsilon_r^u\big)^{2n+1}\right|+\frac{1}{2}\left|\big(e_c^U\big)_0^{2n+1}\right|\left|\big(\varepsilon_r^v\big)^{2n+\frac{1}{2}}+\big(\varepsilon_r^v\big)^{2n+\frac{3}{2}}\right|\\&\qquad\le\frac{\mathcal{C}}{\alpha\sqrt{h}}\left(\|e^{u,h}\|^*_{\infty,2,T}+\alpha\|e^{v,h}\|_{\infty,2,T}\right)|\big(\varepsilon_r^u\big)^{2n+1}|\\&\qquad\quad+\frac{\mathcal{C}}{\sqrt{h}}\left(|\big(\varepsilon_r^v\big)^{2n+\frac{1}{2}}+\|e^{u,h}\|^*_{\infty,2,T}\big(\varepsilon_r^v\big)^{2n+\frac{3}{2}}|\right)\|e^{u,h}\|^*_{\infty,2,T}\\&\qquad\le\mathcal{C}\;h^{\frac{3}{2}}\;\|(u,v)\|_{\mathcal{C}^2_{a,T}}\left(\|e^{u,h}\|^*_{\infty,2,T}+\|e^{v,h}\|_{\infty,2,T}\right).\end{aligned}\right. \tag{4.44}$$

The third term of the right-hand side of (4.40) is more complicated to treat, and this is where we need the result on *coarse discrete derivatives.* Indeed, we can write, using estimate (4.12) of Lemma 4.3 and the discrete trace Lemma 4.5,

$$\left|\begin{aligned}&\frac{1}{4}|\big(\varepsilon_r^v\big)^{2n+\frac{1}{2}}-\big(\varepsilon_r^v\big)^{2n+\frac{3}{2}}|\;|\big(e_f^U\big)_0^{2n+\frac{3}{2}}-\big(e_f^U\big)_0^{2n+\frac{1}{2}}|\\&\qquad=\frac{\Delta t}{4}|\big(\varepsilon_r^v\big)^{2n+\frac{1}{2}}-\big(\varepsilon_r^v\big)^{2n+\frac{3}{2}}|\;|\big(De_f^u\big)_0^{2n+1}|\\&\qquad\le\;\mathcal{C}\;h^{\frac{3}{2}}\;\|(u,v)\|_{\mathcal{C}^1_{a,T}}\;\|De^{u,h}\|^*_{\infty,2,T}.\end{aligned}\right. \tag{4.45}$$

Substituting (4.44) and (4.45) into (4.40) and using inequalities (4.10) and (4.38) (for $m=1$) from Lemmas 4.2 and 4.6, we finally obtain

$$\frac{\mathcal{E}^{2n+2}-\mathcal{E}^{2n}}{2\Delta t}\le\;\mathcal{C}\;(1-\alpha^2)^{-1}\;T\;h^2\;\|(u,v)\|_{\mathcal{C}^2_{a,T}}\;\|(u,v)\|_{\mathcal{C}^1_{a,T}}. \tag{4.46}$$

As a consequence, after summation over n, we have

$$\mathcal{E}^{2n}\le\mathcal{C}\;(1-\alpha^2)^{-1}\;T^2\;h^2\;\|(u,v)\|_{\mathcal{C}^2_{a,T}}\;\|(u,v)\|_{\mathcal{C}^1_{a,T}},$$

and similar computations to those of the previous section lead to

$$\|e^{u,h}\|^*_{\infty,h,T}+\|e^{v,h}\|_{\infty,h,T}\le\mathcal{C}_1\;(1-\alpha^2)^{-1}\;T\;h\;\|(u,v)\|^{\frac{1}{2}}_{\mathcal{C}^2_{a,T}}\;\|(u,v)\|^{\frac{1}{2}}_{\mathcal{C}^1_{a,T}}. \tag{4.47}$$

That is, using (4.47), (4.42), and Proposition 4.1, we obtain estimate (3.19) for $k=1$; i.e., the scheme is of order h.

To initiate the recurrence that will be the object of step 2 of the proof, we shall also need similar estimates for the successive discrete coarse derivatives of the error $(e^{u,h},e^{v,h})$ (where we assume more regularity for the exact solution). Such estimates are easily obtained along the same lines as (4.47). Clearly, if the exact solution belongs to $\mathcal{C}^{2+m}_{a,T}$, we have that

$$\begin{aligned}&\sup_{t^{2n}\le T}|\big(D^m\varepsilon_r^u\big)^{2n+1-\overline{m}}|\;\le\;\mathcal{C}\;\alpha^2\;h^2\;\|\partial_t^k u\|_{\mathcal{C}^2_{a,T}},\\&\sup_{t^{2n}\le T}|\big(D^m\varepsilon_r^v\big)^{2n+\frac{1}{2}-\overline{m}}+\big(D^m\varepsilon_r^v\big)^{2n+\frac{3}{2}-\overline{m}}|\;\le\;\mathcal{C}\;h^2\;\|\big(\partial_t^k u,\partial_t^k v\big)\|_{\mathcal{C}^2_{a,T}},\end{aligned} \tag{4.48}$$

and so we can apply in the case of the mth discrete coarse derivatives $(D^m e^{u,h},D^m e^{v,h})$ a proof similar to that used for proving (4.47) and obtain

$$\begin{aligned}&\|D^m e^{u,h}\|^*_{\infty,2,T}+\|D^m e^{v,h}\|_{\infty,2,T}\le\mathcal{C}\;(1-\alpha^2)^{-1}\;T\;h\\&\qquad\qquad\times\|\big(\partial_t^m u,\partial_t^m v\big)\|^{\frac{1}{2}}_{\mathcal{C}^2_{a,T}}\|\big(\partial_t^m u,\partial_t^m v\big)\|^{\frac{1}{2}}_{\mathcal{C}^1_{a,T}}.\end{aligned} \tag{4.49}$$

Step 2: The recurrence proof. Assume the following by induction.

Assumption $\mathcal{R}_k$. If (u,v) belongs to $\mathcal{C}^{m+k+1}_{a,T}$, for $m \geq 0$,

$$\left|\begin{aligned}&\|D^m e^{u,h}\|^*_{\infty,h,T} + \|D^m e^{v,h}\|_{\infty,h,T} \leq \mathcal{C}_k\ (1-\alpha^2)^{-1}\ T\ h^{p_k}\\ &\qquad\qquad\qquad \times \|(\partial_t^m u, \partial_t^m v)\|^{\frac{1}{2^k}}_{\mathcal{C}^k_{a,T}} \prod_{j=1}^{k} \|(\partial_t^m u, \partial_t^m v)\|^{\frac{1}{2^j}}_{\mathcal{C}^{j+1}_{a,T}}.\end{aligned}\right.$$

In what follows, the constant $\mathcal{C}$ should change from one line to another, but it is always independent of k. From (4.40), using (4.44) and (4.45) we obtain

$$\left|\begin{aligned}&\frac{\mathcal{E}^{2n+2}-\mathcal{E}^{2n}}{2\Delta t} \leq \mathcal{C}\ h^{\frac{3}{2}}\ \|(u,v)\|_{\mathcal{C}^2_{a,T}}\ \Big(\ \|e^{u,h}\|^*_{\infty,h,T} + \|e^{v,h}\|_{\infty,h,T}\Big)\\ &\qquad\qquad + \mathcal{C}\ h^{\frac{3}{2}} \|(u,v)\|_{\mathcal{C}^1_{a,T}}\ \Big(\ \|De^{u,h}\|^*_{\infty,h,T} + \|De^{v,h}\|_{\infty,h,T}\Big).\end{aligned}\right. \tag{4.50}$$

We assume that $(u,v) \in \mathcal{C}^{k+2}_{a,T}$. Using Assumption $\mathcal{R}_k$ for $m=0$ and for $m=1$, we obtain

$$\left|\begin{aligned}\frac{\mathcal{E}^{2n+2}-\mathcal{E}^{2n}}{2\Delta t} \leq \mathcal{C}\ \mathcal{C}_k\ (1-\alpha^2)^{-1}\ T\ h^{p_k+\frac{3}{2}} \Bigg(&\|(u,v)\|_{\mathcal{C}^2_{a,T}}\ \|(u,v)\|^{\frac{1}{2^k}}_{\mathcal{C}^k_{a,T}} \prod_{j=1}^{k} \|(u,v)\|^{\frac{1}{2^j}}_{\mathcal{C}^{j+1}_{a,T}}\\ &+ \|(u,v)\|_{\mathcal{C}^1_{a,T}}\ \|(u,v)\|^{\frac{1}{2^k}}_{\mathcal{C}^{k+1}_{a,T}} \prod_{j=1}^{k} \|(u,v)\|^{\frac{1}{2^j}}_{\mathcal{C}^{j+2}_{a,T}}\Bigg).\end{aligned}\right.$$

From the inequalities

$$\|(u,v)\|_{\mathcal{C}^2_{a,T}} \geq \|(u,v)\|_{\mathcal{C}^1_{a,T}},\ \|(u,v)\|_{\mathcal{C}^k_{a,T}} \leq \|(u,v)\|_{\mathcal{C}^{k+1}_{a,T}} \text{ and } \|(u,v)\|_{\mathcal{C}^{j+1}_{a,T}} \leq \|(u,v)\|_{\mathcal{C}^{j+2}_{a,T}}\ ,$$

we deduce that

$$\frac{\mathcal{E}^{2n+2}-\mathcal{E}^{2n}}{2\Delta t} \leq \mathcal{C}\ \mathcal{C}_k\ (1-\alpha^2)^{-1}\ T\ h^{p_k+\frac{3}{2}} \left(\ \|(u,v)\|_{\mathcal{C}^2_{a,T}}\ \|(u,v)\|^{\frac{1}{2^k}}_{\mathcal{C}^{k+1}_{a,T}} \prod_{j=1}^{k} \|(u,v)\|^{\frac{1}{2^j}}_{\mathcal{C}^{j+2}_{a,T}}\right).$$

Summing over n, we obtain after some manipulations (including a shift of index in the product)

$$\mathcal{E}^{2n} \leq \mathcal{C}\ \mathcal{C}_k\ (1-\alpha^2)^{-1}\ T^2\ h^{p_k+\frac{3}{2}} \left(\ \|(u,v)\|^{\frac{1}{2^k}}_{\mathcal{C}^{k+1}_{a,T}} \prod_{j=1}^{k+1} \|(u,v)\|^{\frac{1}{2^{j-1}}}_{\mathcal{C}^{j+1}_{a,T}}\right).$$

To conclude, it suffices to use once again (4.15) and (4.16) of Lemma 4.4, which gives

$$\|e^{u,h}\|^*_{\infty,h,T} + \|e^{v,h}\|_{\infty,h,T} \leq (\mathcal{C}\ \mathcal{C}_k)^{\frac{1}{2}}\ (1-\alpha^2)^{-1}\ T\ h^{\frac{p_k}{2}+\frac{3}{4}} \left(\ \|(u,v)\|^{\frac{1}{2^{k+1}}}_{\mathcal{C}^{k+1}_{a,T}} \prod_{j=1}^{k+1} \|(u,v)\|^{\frac{1}{2^j}}_{\mathcal{C}^{j+1}_{a,T}}\right),$$

which is what we wanted to prove with

$$p_{k+1} = \frac{p_k}{2} + \frac{3}{4}, \quad C_{k+1} = (\mathcal{C}\ \mathcal{C}_k)^{\frac{1}{2}}.$$

In order to finish the recurrence proof we should obtain similar estimates for the mth discrete coarse derivative of the error assuming more regularity of the solution. Suppose that $(u,v) \in \mathcal{C}^{m+k+2}_{a,T}$. Using similar techniques to those used in the present section (and using $\mathcal{R}_k$ with m and $m+1$) it is easy to show that

$$\begin{aligned}\|D^m e^{u,h}\|^*_{\infty,h,T} + \|D^m e^{v,h}\|_{\infty,h,T} \leq \mathcal{C}_k \ (1-\alpha^2)^{-1} \ T \ h^{p_{k+1}} \\ \times \|\big(\partial_t^m u, \partial_t^m v\big)\|^{\frac{1}{2^{k+1}}}_{\mathcal{C}^{k+1}_{a,T}} \prod_{j=1}^{k+1} \|\big(\partial_t^m u, \partial_t^m v\big)\|^{\frac{1}{2^j}}_{\mathcal{C}^{j+1}_{a,T}}.\end{aligned}$$

Since the result of Step 1, namely, estimates (4.47) and (4.49), is nothing but Assumption $\mathcal{R}_1$, we see easily that

$$p_k = \frac{3}{2} - \frac{1}{2^k}, \quad \mathcal{C}_k = \mathcal{C} \ \left(\mathcal{C}_1/\mathcal{C}\right)^{\frac{1}{2^{k-1}}} .$$

As the sequence $\mathcal{C}_k$ is convergent, it is in particular bounded. Finally we obtain the estimate

$$\|e^{u,h}\|^*_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T} \leq \mathcal{C} \ (1-\alpha^2)^{-1} \ T \ h^{\left(\frac{3}{2}-\frac{1}{2^k}\right)} \ |||(u,v)|||_{\mathcal{C}^k_{a,T}} \tag{4.51}$$

and using Lemma 4.7 we complete the proof of the following lemma.

Lemma 4.8. *If the solution of the continuous problem* (1.1) *belongs to* $\mathcal{C}^k_{a,T}$ *for* $a > 0$*, then*

$$\|e^{u,h}\|_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T} \leq \mathcal{C} \ (1-\alpha^2)^{-1} \ \ T \ h^{\left(\frac{3}{2}-\frac{1}{2^k}\right)} \ |||(u,v)|||_{\mathcal{C}^k_{a,T}} + \mathcal{C} \ h^{\frac{5}{2}} \ \|(u,v)\|_{\mathcal{C}^2_{a,T}}. \tag{4.52}$$

Step 3*: Case* $(u,v) \in \mathbf{C}^{\infty}_{a,T}$. Under this hypothesis, and using the previous part of the proof, we have that

$$\begin{aligned}\|e^{u,h}\|^*_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T} &\leq \mathcal{C} \ (1-\alpha^2)^{-1} \ T \ h^{\left(\frac{3}{2}-\frac{1}{2^k}\right)} \ |||(u,v)|||_{\mathcal{C}^k_{a,T}} \\ &\leq \mathcal{C} \ (1-\alpha^2)^{-1} \ T \ h^{\left(\frac{3}{2}-\frac{1}{2^k}\right)} \ |||(u,v)|||_{\mathbf{C}^{\infty}_{a,T}}\end{aligned}$$

for all $k \in \mathbb{N}$. Passing to the limit when $k \to +\infty$ and using Lemma 4.7, we get the following.

Lemma 4.9. *If the solution of the continuous problem* (1.1) *belongs to* $\mathbf{C}^{\infty}_{a,T}$ *for* $a > 0$*, then*

$$\|e^{u,h}\|_{\infty,2,T} + \|e^{v,h}\|_{\infty,2,T} \leq \mathcal{C} \ (1-\alpha^2)^{-1} \ T \ h^{\frac{3}{2}} \ |||(u,v)|||_{\mathbf{C}^{\infty}_{a,T}} + \mathcal{C} \ h^{\frac{5}{2}} \ \|(u,v)\|_{\mathcal{C}^2_{a,T}}. \tag{4.53}$$

Remark 4.2. To see how (4.40) can be derived, we start from the two following identities:

$$\begin{aligned}\big(e_f^U\big)_0^{2n+1\pm\frac{1}{2}} \big(e_f^V\big)_0^{2n+1\pm\frac{1}{2}} = \big(e_f^V\big)_0^{2n+1\pm\frac{1}{2}} &\left[\frac{\big(e_f^U\big)_0^{2n+\frac{1}{2}} + \big(e_f^U\big)_0^{2n+\frac{3}{2}}}{2} - \big(e_c^U\big)_0^{2n+1}\right] \\ + \big(e_f^V\big)_0^{2n+1\pm\frac{1}{2}} &\left[\big(e_c^U\big)_0^{2n+1} \pm \frac{\big(e_f^U\big)_0^{2n+\frac{3}{2}} - \big(e_f^U\big)_0^{2n+\frac{1}{2}}}{2}\right].\end{aligned}$$

Adding and identifying the consistency errors we obtain

$$\begin{aligned}\frac{1}{2}\left(\left(e_f^U\right)_0^{2n+\frac{1}{2}}\left(e_f^V\right)_0^{2n+\frac{1}{2}}+\left(e_f^U\right)_0^{2n+\frac{3}{2}}\left(e_f^V\right)_0^{2n+\frac{3}{2}}\right)=&-\frac{1}{2}(\varepsilon_r^u)^{2n+1}\left(\left(e_f^V\right)_0^{2n+\frac{1}{2}}+\left(e_f^V\right)_0^{2n+\frac{3}{2}}\right)\\&+\frac{1}{2}\left(e_c^U\right)_0^{2n+1}\left(\left(e_f^V\right)_0^{2n+\frac{3}{2}}+\left(e_f^V\right)_0^{2n+\frac{1}{2}}\right)\\&+\frac{1}{4}\left(\left(\varepsilon_r^v\right)^{2n+\frac{3}{2}}-\left(\varepsilon_r^v\right)^{2n+\frac{1}{2}}\right)\left(\left(e_f^U\right)_0^{2n+\frac{3}{2}}-\left(e_f^U\right)_0^{2n+\frac{1}{2}}\right).\end{aligned}$$

Finally subtracting the term $(e_c^U)_0^{2n+1}(e_c^V)_0^{2n+1}$ we obtain the desired expression.

Remark 4.3. Let us explain why we cannot use the same proof for scheme II. Following the same steps as for scheme I we rewrite the transmission conditions (4.8) as

$$(4.54)\quad\begin{cases}\left(e_f^U\right)_0^{2n+\frac{3}{2}}-\left(e_f^U\right)_0^{2n+\frac{1}{2}}=(\tilde{\varepsilon}_r^u)^{2n+\frac{1}{2}}-\left(\tilde{\varepsilon}_r^u\right)^{2n+\frac{3}{2}}=\mathcal{O}(\Delta t),\\ 2\left(e_c^U\right)_0^{2n+1}-\left(\left(e_f^U\right)_0^{2n+\frac{3}{2}}+\left(e_f^U\right)_0^{2n+\frac{1}{2}}\right)=\left(\tilde{\varepsilon}_r^u\right)^{2n+\frac{1}{2}}+\left(\tilde{\varepsilon}_r^u\right)^{2n+\frac{3}{2}}=\mathcal{O}(\Delta t^2),\\ \left(e_c^V\right)_0^{2n+1}-\frac{1}{2}\left(\left(e_f^V\right)_0^{2n+\frac{1}{2}}+\left(e_f^V\right)_0^{2n+\frac{3}{2}}\right)=\left(\tilde{\varepsilon}_r^v\right)^{2n+1}=\mathcal{O}(\Delta t^2)\end{cases}$$

in order to have two consistency errors of order two and only one of first order. We rewrite (4.32) using this last truncation errors obtaining

$$(4.55)\quad\left|\begin{aligned}\frac{1}{2\Delta t}\left(\mathcal{E}^{2n+2}-\mathcal{E}^{2n}\right)=&-\frac{1}{2}\left(\left(e_f^U\right)_0^{2n+\frac{1}{2}}+\left(e_f^U\right)_0^{2n+\frac{3}{2}}\right)\left(\widetilde{\varepsilon}_r^v\right)^{2n+1}\\&-\frac{1}{2}\left(e_c^V\right)_0^{2n+1}\left(\left(\widetilde{\varepsilon}_r^u\right)^{2n+\frac{1}{2}}+\left(\widetilde{\varepsilon}_r^u\right)^{2n+\frac{3}{2}}\right)\\&+\frac{1}{4}\left(\left(\widetilde{\varepsilon}_r^u\right)^{2n+\frac{1}{2}}-\left(\widetilde{\varepsilon}_r^u\right)^{2n+\frac{3}{2}}\right)\left(\left(e_f^V\right)_0^{2n+\frac{3}{2}}-\left(e_f^V\right)_0^{2n+\frac{1}{2}}\right),\end{aligned}\right.$$

which is an analog of (4.40) for scheme II. The term that is most complicated to treat is, as for scheme I, the last one. However, its expression in this case is not as easy as for scheme I because

$$(e_f^V)_0^{2n+\frac{3}{2}}-(e_f^V)_0^{2n+\frac{1}{2}}=(e_f^v)_{\frac{1}{2}}^{n+\frac{3}{2}}-(e_f^v)_{\frac{1}{2}}^{n+\frac{1}{2}}+\frac{h}{2}\frac{(e_f^u)_0^{2n+2}-2(e_f^u)_0^{2n+1}+(e_f^u)_0^{2n}}{\Delta t}.$$

In fact we cannot use similar arguments as before to estimate the last term. We recall that for scheme I we had an simpler expression (third equation of (4.41)).

5. Comparison between theory and numerics.

5. Comparison between theory and numerics. The results obtained in section 3 are compared in subsection 5.2 to those obtained in [12] using the Fourier technique (see subsection 5.1 for a brief recap of these results) and with some numerical results in subsection 5.3.

5.1. Fourier analysis results. This study is based on the behavior of plane wave solutions in the presence of a space-time mesh refinement. More precisely, we study the reflection and transmission through the artificial interface between the coarse grid and the fine grid of an incident wave in Ω_c, of amplitude 1 and frequency ω. One reflected wave and one transmitted wave each of frequency ω and of amplitude R_c (reflection coefficient) and T_c (transmission coefficient), respectively, are generated in the coarse and fine grids, respectively. Due to the aliasing phenomena (namely,

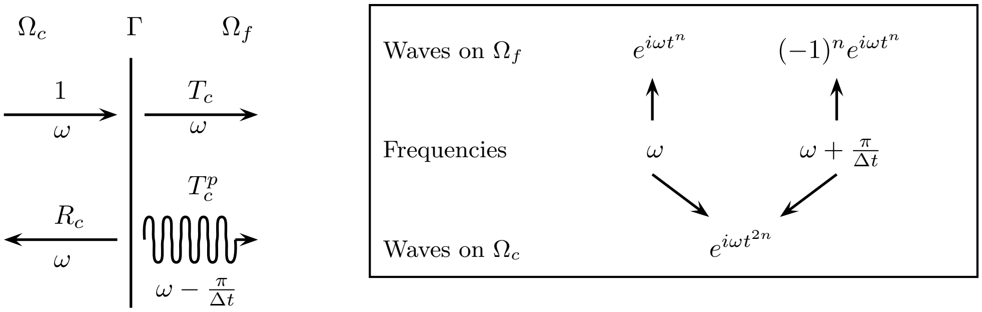

FIG. 5.1. *Schematic representation of the aliasing phenomena.*

that the frequencies ω and $\omega + \frac{\pi}{\Delta t}$ coincide in the coarse grid but are distinct in the fine grid—see Figure 5.1) a parasitic transmitted wave of frequency $\omega + \frac{\pi}{\Delta t}$ is generated in the fine grid. If ωh is small enough and α is less than 1, this parasitic wave is highly oscillatory in space (with space frequency $\frac{\pi}{h}$) and evanescent (i.e., decaying exponentially with distance from the interface) with a penetration depth $l(h, \alpha)$ which satisfies

$$l(h, \alpha) = \frac{h}{2\text{argch}(1/\alpha)} + \mathcal{O}(h^3). \tag{5.1}$$

The amplitude of this parasitic wave at the interface is given by a coefficient T_c^p, the parasitic transmission coefficient. The particular solution one looks for is thus given by the following expressions for u (the wave numbers k_c and k_f appearing in the formula below depend on α and h and are deduced from the dispersion relation on each grids—see [12] for more details):

$$\begin{cases} (u_c)_{2j}^{2n} = e^{i(k_c x_{2j} - \omega t^{2n})} + R_c \; e^{i(-k_c x_{2j} - \omega t^{2n})}, & j \leq 0, \\ (u_f)_j^n = T_c \; e^{i(k_f x_j - \omega t^n)} + T_c^p \; (-1)^{j+n} \; e^{-i\omega t^n} \; e^{-\frac{x_j}{l(h,\alpha)}}, & j \geq 0. \end{cases}$$

The expressions for v are similar. The unknown coefficients R_c, T_c, and T_c^p can be determined from the coupling equations (2.12) or (2.13). As the interface $x = 0$ is purely artificial, if we consider the continuous case, we should find

$$R_c = 0, \quad T_c = 1, \quad T_c^p = 0,$$

the *physical values* of the parameters. In the discrete case the coefficients R_c, T_c, and T_c^p depend only on ωh and α, and, for fixed $0 < \alpha < 1$, their Taylor expansions for small ωh are given by

$$\begin{aligned} R_c(\omega h, \alpha) &= \frac{1}{16} \big(\alpha^2 - 3\big) (\omega h)^2 + \mathcal{O}\big((\omega h)^3\big), \\ T_c(\omega h, \alpha) &= 1 - \frac{3}{16} \big(\alpha^2 + 1\big) (\omega h)^2 + \mathcal{O}\big((\omega h)^3\big), \\ T_c^p(\omega h, \alpha) &= \frac{1}{2} \frac{i\alpha^2}{\sqrt{1 - \alpha^2}} (\omega h) + \mathcal{O}\big((\omega h)^3\big) \end{aligned} \tag{5.2}$$

if scheme I is used and

$$\begin{aligned} R_c(\omega h,\alpha) &= -\frac{i\sqrt{1-\alpha^2}}{4}(\omega h)+\mathcal{O}(\omega^2h^2),\\ T_c(\omega h,\alpha) &= 1-\frac{i\sqrt{1-\alpha^2}}{4}(\omega h)+\mathcal{O}(\omega^2h^2),\\ T_c^p(\omega h,\alpha) &= -1+\frac{i\sqrt{1-\alpha^2}}{4}(\omega h)+\mathcal{O}(\omega^2h^2) \end{aligned} \tag{5.3}$$

if scheme II is used.

Remark 5.1. When one considers the limit case $\alpha = 1$, one can show that the parasitic wave becomes propagative ($l(h,\alpha)$ tends to infinity when α tends to one) and we have for both schemes

$$R_c = 0, \quad T_c = 1+\mathcal{O}(\omega^2h^2), \quad T_c^p = -1+\mathcal{O}(\omega^2h^2).$$

5.2. Comparing our results with the Fourier analysis results. Let us summarize the main information provided by the Fourier analysis. First of all we consider scheme I with $\alpha < 1$. In this case we have the following:

- The discrete reflection and transmission coefficients are second order approximations of the physical ones. The contribution to the error is of order two in the L^∞ and L^p, $p > 1$, norms.
- The L^∞ norm of the error coming from the parasitic transmitted wave is approximately (for h small enough)

$$\frac{\alpha^2\omega h}{\sqrt{1-\alpha^2}}, \tag{5.4}$$

  that is, the method should be first order accurate for this norm. Due to the exponential decay of this wave, the L^p error is approximately

$$\left(\int_0^\infty \frac{(\alpha^2\omega h)^p}{(1-\alpha^2)^{\frac{p}{2}}}\, e^{-\frac{2px\,\mathrm{argch}(\alpha^{-1})}{h}}\,\mathrm{d}x\right)^{\frac{1}{p}} \approx \frac{h^{\frac{p+1}{p}}}{(1-\alpha)^{\frac{p+1}{2p}}} \quad (\alpha \longrightarrow 1). \tag{5.5}$$

  Taking $p = 2$ we remark that the order of convergence is in conformity with that given by Theorem 3.1 and the comments following it. It seems that the Fourier techniques allow us to obtain a sharper estimate for the dependence on $1-\alpha$ when α goes to 1. The best estimate is obtained in the L^1 norm, where the error should be of order two.
- We also remark that this last error is localized at the artificial interface. In effect, computing the L^∞ and L^p, $p \geq 1$, norms on the complement of a neighborhood of the artificial interface, this error is exponentially decreasing with the space step. The method should be of order two in these norms.

Concerning scheme II with $\alpha < 1$, the Fourier analysis allows us to make the following conclusions:

- The error coming from the reflected and (not parasitic) transmitted waves is of order one in the L^∞ and L^p, $p \geq 1$, norms.
- The amplitude of the parasitic transmitted wave does not go to zero when the discretization parameters go to zero. This means that the method does

not converge in the L^∞ norm. Due to the exponential decay of this wave, a simple computation allows us to estimate its L^p error,

$$\frac{h^{\frac{1}{p}}}{\operatorname{argch}^{\frac{1}{p}}(\alpha^{-1})} \approx \frac{h^{\frac{1}{p}}}{(1-\alpha)^{\frac{1}{2p}}} \quad (\alpha \longrightarrow 1).$$

Again, the results obtained for $p = 2$ are coherent with those of Theorem 3.1 and the comments given later on. The L^1 error should be of order one. The estimate for the dependence on $1 - \alpha$ seems to be more precise with the Fourier techniques.

- As for scheme I, this last error is localized. If we consider the L^∞ and $L^p,\ p \geq 1$, norms on the complement of a neighborhood of the point $x = 0$, the method should be of first order, because the error provided by the transmitted parasitic wave is exponentially decreasing.

For $\alpha = 1$, the amplitude of the transmitted parasitic wave does not tend to zero and the wave is not evanescent. Neither method should be strongly convergent.

5.3. Numerical results. In this section we will obtain numerically the orders of convergence of schemes I and II for several norms to compare them with the theoretical ones provided by Theorem 3.1 and the Fourier analysis. We consider the 1D wave equation

$$(5.6)\quad \begin{cases} \dfrac{\partial u}{\partial t} + \dfrac{\partial v}{\partial x} = 0, \\ \dfrac{\partial v}{\partial t} + \dfrac{\partial u}{\partial x} = 0, \end{cases} \quad (x,t) \in \mathbb{R} \times \mathbb{R}^+, \qquad \begin{cases} u(x,t=0) = u_0(\frac{x-x_0}{L}), \\ v(x,t=0) = 0, \end{cases} \quad x \in \mathbb{R},$$

where $x_0 = -0.25$, $L = 0.25$, and

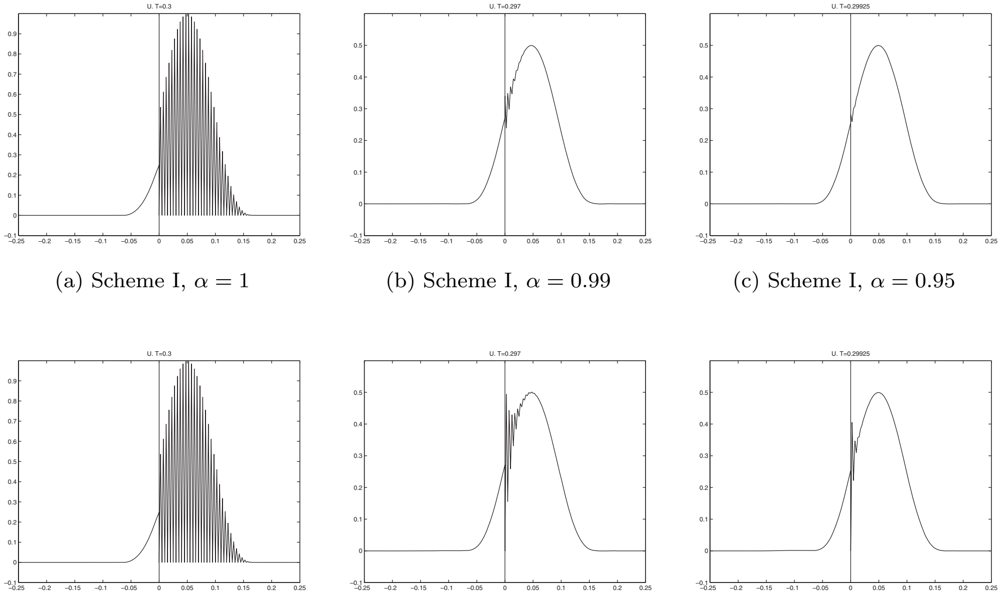
$$u_0(x) \quad = \quad \begin{cases} 256(x-1/2)^4(x+1/2)^4 & \text{if } x \in [-1/2, 1/2], \\ 0 & \text{otherwise.} \end{cases}$$

The exact solution of the problem is given by

$$u(x,t) = \frac{1}{2}u_0\left((x - x_0 - t)/L\right) + \frac{1}{2}u_0\left((x - x_0 + t)/L\right),$$

$$v(x,t) = \frac{1}{2}u_0\left((x - x_0 - t)/L\right) - \frac{1}{2}u_0\left((x - x_0 + t)/L\right).$$

The computational domain for the numerical resolution of the equations is the interval $\Omega = [-0.5, 0.5]$. We use transparent boundary conditions to simulate the unbounded domain. A space step of size h is used in $\Omega_c = [-0.5, 0]$ and of size $h/2$ in $\Omega_f = [0, 0.5]$. We recall that both schemes also depend on the parameter $\alpha = \Delta t/h$ that we must choose in the interval $(0,1)$ to ensure the stability of the method. In practice, it is interesting to choose α to be as large as possible to reduce the computational costs. The problem is that all the error and stability estimates given in section 3 blow up when α tends to 1. In Figures 5.2 and 5.3 we can note this phenomenon as well. For $\alpha = 1$ both schemes give us similar results. A high frequency wave appears when the waves cross the artificial boundary (see Figures 5.2(a) and 5.2(d)). Even so, the method seems to be L^2 stable. Taking $\alpha < 1$ most of oscillatory parasitic waves become evanescent and we obtain a good solution if we remove the behavior near



(a) Scheme I, $\alpha = 1$ (b) Scheme I, $\alpha = 0.99$ (c) Scheme I, $\alpha = 0.95$

(d) Scheme II, $\alpha = 1$ (e) Scheme II, $\alpha = 0.99$ (f) Scheme II, $\alpha = 0.95$

FIG. 5.2. *Dependence on α of u^h. $T \approx 0.3$. Zoom around $x = 0$.*

$x = 0$. The penetration depth of the transmitted parasitic wave increases as α goes to the limit value 1. As we can see in Figures 5.2(c) and 5.2(f), $\alpha = 0.95$ is sufficient to obtain a good result. We can also see that the amplitude of the parasitic wave is higher for scheme II than for scheme I (see Figure 5.3). In particular, scheme II does not converge in the L^∞ norm (see Remark 2.1).

In order to measure the error between the exact solution (u, v) and the numerical solution (u^h, v^h) we consider the discrete equivalent of the norms

$$\begin{aligned} &L_t^\infty([0,T], L_x^p(\Omega)), \qquad && L_t^\infty([0,T], L_x^\infty(\Omega)), \\ &L_t^\infty([0,T], L_x^p(\Omega^\star)), \qquad && L_t^\infty([0,T], L_x^\infty(\Omega^\star)) \end{aligned} \tag{5.7}$$

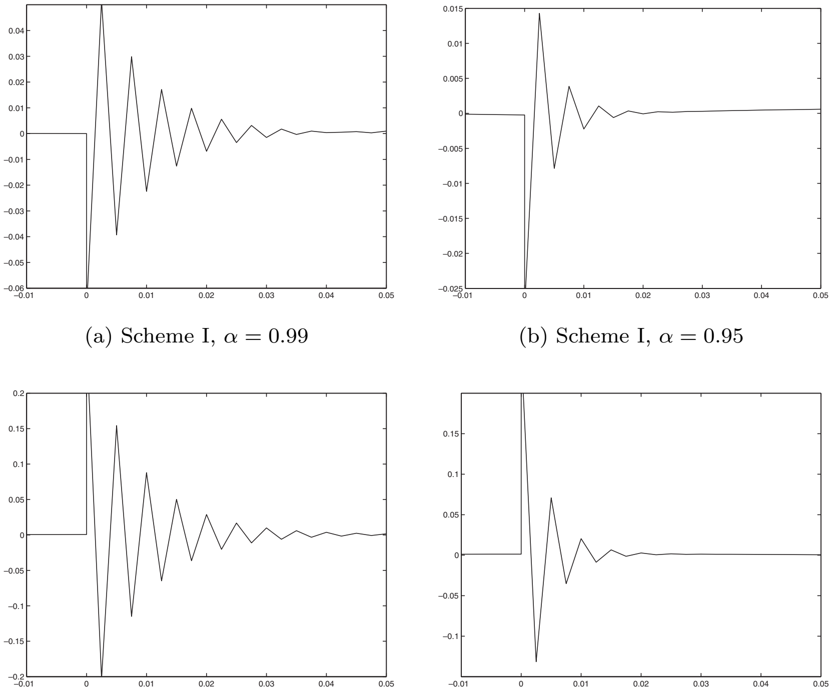
(with $\Omega^\star = \Omega \setminus [0, 0.1]$, and $p \in \mathbb{N}$), which we will denote by

$$\|e^h\|_{\infty,p,T}, \qquad \|e_h\|_{\infty,T}, \qquad \|e_h\|^\star_{\infty,p,T}, \qquad \|e_h\|^\star_{\infty,T}.$$

Let us assume that the error has approximately the form

$$\|e_h\| \approx \mathcal{C}(u, v)(1 - \alpha)^{-k_2} h^{k_1}. \tag{5.8}$$

Fixing a value of the parameter α and computing the different norms at $T = 0.5$ (where the wave has already crossed the artificial interface) for $h = 0.005$, $0.00\hat{3}$, 0.0025, and 0.002 we obtain the value of k_1 for each norm. The results for $\alpha = 0.95$, using the discrete $L_t^\infty([0,T], L_x^1(\Omega))$, $L_t^\infty([0,T], L_x^2(\Omega))$, and $L_t^\infty([0,T], L_x^\infty(\Omega))$ norms, are plotted in Figures 5.4(a), 5.5(a), and 5.6(a), respectively. We can see that the slopes are coherent with the estimates predicted in section 3 and subsection 5.2. As we pointed



(a) Scheme I, $\alpha = 0.99$

(b) Scheme I, $\alpha = 0.95$

(c) Scheme II, $\alpha = 0.99$

(d) Scheme II, $\alpha = 0.95$

out in section 5.2, the most important part of the error is localized at the interface as we can see in Figure 5.7, where the $L_t^\infty([0, T], L_x^2(\Omega^\star))$, and $L_t^\infty([0, T], L_x^p(\Omega^\star))$ errors have been computed.

The same computations have been done with $\alpha = 0.85$, 0.9, 0.97, and 0.99 and the same orders of convergence have been obtained (see Table 5.1). This allows us to compute the dependence on α of the method when this parameter goes to 1. In Figures 5.4(b), 5.5(b), and 5.6(b), we represent the results obtained for the $L_t^\infty([0, T], L_x^1(\Omega))$, $L_t^\infty([0, T], L_x^2(\Omega))$, and $L_t^\infty([0, T], L_x^\infty(\Omega))$ norms that are in cor-

respondence with the Fourier analysis (that gives sharper estimates) and, in consequence, also with Theorem 3.1. We have also noted that the hypotheses demanded in Theorem 3.1 concerning the smoothness of the exact solution of (1.1) are in practice too strong. We have observed the same rates of convergence for initial conditions that are $\mathcal{C}_2(\mathbb{R} \times [0, T])^2$.

FINITE VOLUME METHODS FOR DOMAIN DECOMPOSITION ON NONMATCHING GRIDS WITH ARBITRARY INTERFACE CONDITIONS*

L. SAAS†, I. FAILLE†, F. NATAF‡, and F. WILLIEN†

Abstract. We are interested in a robust and accurate domain decomposition method with arbitrary interface conditions on nonmatching multiblock grids using a finite volume discretization. To take into account the nonmatching grids at the interface, we introduce transmission operators, Dirichlet–Neumann interface conditions, and arbitrary equivalent interface conditions (for example, Robin interface conditions). Under a compatibility assumption on the transmission operators, we prove the equivalence between the different types of interface conditions and the well posedness of the local and global problems. Then two error estimates are proven in terms of the discrete H^1-norm: the first in $O(h)^{1/2}$ with transmission operators based on piecewise constant functions and the second in $O(h)$ (as in the matching case) with transmission operators using a piecewise linear rebuilding. In conclusion, numerical results are presented in confirmation of the theory.

Key words. nonmatching grids, finite volume, domain decomposition methods, optimized Schwarz method

1. Introduction.

Our aim is to develop numerical methods which combine a finite volume method [21] and a domain decomposition [1] algorithm on nonmatching multiblock grids with arbitrary interface conditions. The goal is to obtain a numerical scheme as accurate as the finite volume scheme on matching grids ($O(h)$ in discrete H^1-norm). Finite volume schemes are used for their conservation property and are well adapted to deal with convective terms. A particular case of arbitrary interface conditions is the Robin interface conditions ($\frac{\partial}{\partial n}+\alpha$) which were introduced in domain decomposition methods in [18]. They enable the use of nonoverlapping subdomains and speed up the convergence of iterative domain decomposition algorithms [20] and [17]. Nonmatching grids make grid generation much easier and faster, since it is then a parallel task, and enable sliding blocks.

Some domain decomposition methods use the same numerical schemes in each subdomain as in the matching case. They define transmission operators and interface conditions to impose weak continuity of the primary unknown and its normal derivative across the nonmatching interface. The first introduced, the mortar method [7], is based on a finite element discretization [12] and introduces a mortar space at the interface to define interface conditions of Dirichlet–Neumann-type (mortar interface conditions). An extension to mixed finite elements with different Dirichlet–Neumann interface conditions is done in [4]. In [13], the mortar method is extended to the finite volume method after formulating the discretization as a finite element method using the dual mesh. In all these methods, error estimates are proven (order 1 ($O(h)$) in H^1-norm with P^1 finite element, with RT0 mixed finite element, or with vertex cen-

tered finite volume), but the use of Robin interface conditions does not seem possible. In [3] a finite volume scheme with Robin interface conditions is proposed (see [5] for the mixed finite element case). The error estimate depends on the Robin interface conditions ($\frac{\partial .}{\partial n} + \alpha\ .$): if $\alpha = O(1/h)^{\gamma}$, the error estimate is in $O(h)^{1-\gamma/2}$, and optimized Robin interface coefficients with respect to the convergence rate of the iterative domain decomposition algorithm [20], $\alpha_{opt} = O(1/h)^{1/2}$, give an error of $O(h)^{3/4}$ (less than that in the matching case). Moreover the Robin coefficients must be constant along the interface. These methods enable the use of Robin interface conditions but not arbitrary ones involving, for instance, second-order tangential derivatives.

Other domain decomposition methods for nonmatching grids consist of introducing a matching subgrid at the interface. They use classical interface conditions on this subgrid but need a modified numerical scheme in each subdomain. In the two-point flux approximation (TPFA) method, the intersection grids at the interface are introduced and classical Robin conditions are used. This method has already been used in oil engineering applications [6] and has been studied in [11] and [10]. A two-point scheme is used on the subgrid leading to an error estimate in $O(h)^{1/2}$ [10] because of the lack of consistency of the flux (a more general error estimate is performed depending on the number of nonmatching elements). In [8] the previous method is extended using interpolation near the subgrid to ensure a consistent flux approximation: stability and an error estimate are not proven but it seems to be in $O(h)$. In [2] a multipoint flux approximation (MPFA) is used near the nonmatching interface to ensure weak continuity of the principal unknown and of its normal derivative, but no theoretical results are proven.

All those methods either do not use arbitrary interface conditions or do not have finite volume accuracy or a mathematical basis. In this paper, we present and study, for a second-order elliptic problem, a domain decomposition method on nonmatching multiblock grids using finite volume and arbitrary interface conditions. For instance, the interface conditions used in the domain decomposition method could involve the discrete Steklov–Poincaré operator (see [20]), Robin interface conditions as in [5] or in [19], or second-order tangential derivatives as in [17], [16]. The reason for using such interface conditions is that they lead to faster domain decomposition methods.

The paper is organized as follows. In section 2, we introduce the domain decomposition formulation of a problem and its discretization by a finite volume scheme. Section 2.3 gives the finite volume discretization on the nonmatching grids. In section 3, we define transmission operators, Dirichlet–Neumann interface conditions, and equivalent arbitrary interface conditions. Section 4 deals with the wellposedness of the global and local problems. We give two examples of transmission operators in section 5. In section 6 error estimates are performed. The first transmission operators are piecewise constant projections and lead to an error estimate in $O(h^{1/2})$. The second transmission operators are based on the linear rebuilding of [4] and lead to an error estimate in $O(h)$ as in the matching case. In section 7 numerical results are shown. Finally, in section 8 we give our conclusion.

2. Formulation of the problem.

2.1. Domain decomposition.

Let Ω be a bounded domain in $\mathbb{R}^d$ $(d = 2, 3)$, $\eta > 0$ and $\operatorname{div}(\vec{a}) \geq 0$ with $\vec{a} \in C^1(\Omega)$. We consider the following second-order elliptic problem:

$$\eta p - \Delta p + \operatorname{div}(\vec{a} p) = f \text{ in } \Omega, \tag{2.1}$$

$$p = g \text{ on } \partial\Omega, \tag{2.2}$$

where f and g are given data. The assumption $\eta > 0$ is made throughout the paper. It may probably be relaxed but at the expense of longer and more tedious proofs. The domain Ω is decomposed into N ($N \geq 2$) nonoverlapping subdomains Ω_i, and we introduce the set $\mathcal{I} = \{i \in \mathbb{N} \mid 1 \leq i \leq N\}$ such that $\overline{\Omega} = \cup_{i\in\mathcal{I}}\overline{\Omega_i}$ (with $\Omega_i \cap \Omega_j = \emptyset$). We also introduce for all $i \in \mathcal{I}$, $\mathcal{V}_i = \{j \in \mathcal{I} \mid i \neq j \text{ and } \dim(\overline{\Omega}_i \cap \overline{\Omega}_j) = d-1\}$ and for all $j \in \mathcal{V}_i$, we denote $\Gamma_{ij} = \overline{\Omega}_i \cap \overline{\Omega}_j$ (we have the following property: $i \in \mathcal{V}_j \iff j \in \mathcal{V}_i$). At the continuous level, for all $i \in \mathcal{I}$, for all $j \in \mathcal{V}_i$ given arbitrary positive definite interface operators $\tilde{S}^i_j$ acting on functions living on the interface between two subdomains Ω_i and Ω_j, the above problem (2.1)–(2.2) can be reformulated as the following domain decomposition problem with arbitrary continuous interface conditions (2.5): for all $i \in \mathcal{I}$

$$\eta p_i - \Delta p_i + \operatorname{div}(\vec{a}p_i) = f \quad \text{in } \Omega_i, \tag{2.3}$$

$$p_i = g \quad \text{on } \partial\Omega \cap \partial\Omega_i, \tag{2.4}$$

$$\frac{\partial p_i}{\partial n_i} + \tilde{S}^i_j(p_i) = -\frac{\partial p_j}{\partial n_j} + \tilde{S}^i_j(p_j) \text{ on } \Gamma_{ij} \quad \forall j \in \mathcal{V}_i. \tag{2.5}$$

A simple iterative method for solving the above domain decomposition method is the additive Schwarz method:

$$\eta p_i^{n+1} - \Delta p_i^{n+1} + \operatorname{div}(\vec{a}p_i^{n+1}) = f \quad \text{in } \Omega, \tag{2.6}$$

$$p_i^{n+1} = g \quad \text{on } \partial\Omega \cap \partial\Omega_i, \tag{2.7}$$

$$\frac{\partial p_i^{n+1}}{\partial n_i} + \tilde{S}^i_j(p_i^{n+1}) = -\frac{\partial p_j^n}{\partial n_j} + \tilde{S}^i_j(p_j^n) \text{ on } \Gamma_{ij} \quad \forall j \in \mathcal{V}_i. \tag{2.8}$$

The wellposedness and convergence of the above problems have been studied in [18] for Robin interface conditions ($\tilde{S}^j_i(p) = \alpha^j_i p$ with $\alpha^j_i > 0$). It is also possible to use (2.6)–(2.8) as a preconditioner for Krylov-type methods; see, for example, [1], [22]. In this paper, we present a finite volume counterpart of problem (2.1)–(2.2) on nonmatching multiblock grids with discrete arbitrary interface conditions. We want to solve it with an iterative domain decomposition algorithm of the same type as (2.6)–(2.8). In the next subsection, we give the classical finite volume that we use inside a subdomain Ω_i.

2.2. Finite volume discretization.

(2.1)–(2.2) are discretized using a cell centered finite volume scheme in each subdomain [21]. We choose this scheme as an example but other schemes would be possible as well.

2.2.1. Mesh and definition.

For $i \in \mathcal{I}$, let $\mathcal{T}_i$ be a set of closed polygonal subsets associated with Ω_i such that $\Omega_i = \cup_{K\in\mathcal{T}_i} K$. We shall use the following notation for all $i \in \mathcal{I}$.

- $\mathcal{E}_{\Omega_i}$ is the set of faces of $\mathcal{T}_i$.
- $\mathcal{E}_{iD}$ is the set of faces such that $\partial\Omega_i \cap \partial\Omega = \cup_{\epsilon\in\mathcal{E}_{iD}}\epsilon$ (let us recall that a Dirichlet boundary condition will be imposed on $\partial\Omega_i \cap \partial\Omega$).
- $\mathcal{E}_i$ is the set of faces such that $\partial\Omega_i \backslash \partial\Omega = \cup_{\epsilon\in\mathcal{E}_i}\epsilon$ (let us recall that a Dirichlet–Neumann or an arbitrary boundary condition will be imposed on $\partial\Omega_i \backslash \partial\Omega$).
- For all $j \in \mathcal{V}_i$, $\mathcal{E}_{i\to j} = \{\epsilon \in \mathcal{E}_i | \epsilon \cap \Gamma_{ij} \neq \emptyset\}$, the grid of Γ_{ij} for the subdomain Ω_i, $\mathcal{E}_i = \cup_{j\in\mathcal{V}_i}\mathcal{E}_{i\to j}$ (because the grids are nonmatching at the interface Γ_{ij}, we have $\mathcal{E}_{i\to j} \neq \mathcal{E}_{j\to i}$).
- For all $j \in \mathcal{V}_i$, $\mathcal{E}_{ij} = \{\epsilon_i \cap \epsilon_j | \epsilon_i \in \mathcal{E}_{i\to j} \text{ and } \epsilon_j \in \mathcal{E}_{j\to i}\}$, the subgrid intersection of $\mathcal{E}_{i\to j}$ and $\mathcal{E}_{j\to i}$. For any $\epsilon \in \mathcal{E}_{ij}$, there exists a unique pair $(K_i, K_j) \in \mathcal{T}_i \times \mathcal{T}_j$ such that $\epsilon = K_i \cap K_j$. We shall use the notation $K_i = K_i(\epsilon)$ and $K_j = K_j(\epsilon)$.

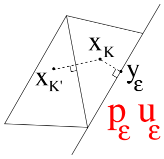

FIG. 1. *Assumption* 1.

- $\forall K \in \mathcal{T}_i$,

  $\mathcal{E}(K)$ denotes the set of faces of K.

  $\mathcal{E}_{iD}(K) = \mathcal{E}(K) \cap \mathcal{E}_{iD}$ is the set of faces of K which are on $\partial\Omega_i \cap \partial\Omega$.

  $\mathcal{E}_i(K) = \mathcal{E}(K) \cap \mathcal{E}_i$ is the set of faces of K which are on $\partial\Omega_i \backslash \partial\Omega$.

  $\mathcal{N}_i(K) = \{K' \in \mathcal{T}_i | K \cap K' \in \mathcal{E}_{\Omega_i}\}$ is the set of the control cells adjacent to K in Ω_i.

  $\mathcal{N}_{ij}(K) = \{K' \in \mathcal{T}_j | K \cap K' \in \mathcal{E}_{ij}\}$ is the set of the control cells adjacent to K which belongs to Ω_j.

  $\mathcal{N}(K) = \mathcal{N}_i(K) \cup (\cup_{j \in \mathcal{V}_i} \mathcal{N}_{ij}(K))$ and we note for all $K' \in \mathcal{N}(K)$, $[K, K'] = K \cap K'$.

We make the following geometrical assumptions on the meshes (see Figure 1).

Assumption 1. For all $i \in \mathcal{I}$, $\mathcal{T}_i$ is a finite volume admissible mesh, i.e., $\mathcal{T}_i$ is a set of closed subsets of dimension d such that

- for any $(K, K') \in \mathcal{T}_i^2$ with $K \neq K'$, one has either $K \cap K' \in \mathcal{E}_{\Omega_i}$ or $\dim(K \cap K') < d - 1$
- there exist points $(y_\epsilon)_{\epsilon \in \mathcal{E}_{\Omega_i}}$ on the faces and points $(x_K)_{K \in \mathcal{T}_i}$ inside the cells such that
  - for any adjacent cells K and K', the straight line $[x_K, x_{K'}]$ is perpendicular to the face $[K, K']$ and $[x_K, x_{K'}] \cap [K, K'] = \{y_{[K,K']}\}$
  - for any face $\epsilon \in \mathcal{E}_{iD}$, let $K(\epsilon) \in \mathcal{T}_i$ be such that $\epsilon \subset K$: then the straight line $[x_{K(\epsilon)}, y_\epsilon]$ is perpendicular to ϵ
- for all $i \in \mathcal{I}$, no face intersects both $\partial\Omega_i \backslash \partial\Omega$ and $\partial\Omega_i \cap \partial\Omega$ ($\mathcal{E}_i \cap \mathcal{E}_{iD} = \emptyset$)
- for all $j \in \mathcal{V}_i$, $\Gamma_{ij} = \partial\Omega_i \cap \partial\Omega_j$ can be written as the union of faces of $\mathcal{E}_{i \to j}$ and of $\mathcal{E}_{j \to i}$

Remark 2.1. As a result, $\bigcup_{i \in \mathcal{I}} \partial\Omega_i \cap \partial\Omega$ can be written as a union of (whole) faces. The same holds for $\partial\Omega_i \backslash \partial\Omega$. For all $j \in \mathcal{V}_i$ and for all $k \in \mathcal{V}_i$ ($j \neq k$), we have $\mathcal{E}_{i \to j} \cap \mathcal{E}_{i \to k} = \emptyset$. We note $\mathcal{T} = \cup_{i \in \mathcal{I}} \mathcal{T}_i$ and $h = \max_{i \in \mathcal{I}, K \in \mathcal{T}_i} diam(K)$ its mesh size.

2.2.2. Cell centered finite volume scheme in the subdomains.

Let $i \in \mathcal{I}$; we shall use the primary unknowns $(p_K^i)_{K \in \mathcal{T}_i}$ which aim at being approximations of $p(x_K)$ and for $\epsilon \in \mathcal{E}_i$, $(p_\epsilon^i,\, u_\epsilon^i)$ which aim at being approximations of

$$(p(y_\epsilon),\, \partial p / \partial n_i(y_\epsilon)).$$

The scheme is obtained by integrating (2.6) over each control volume $K \in \mathcal{T}_i$:

$$\int_K \eta p - \int_{\partial K} \frac{\partial p}{\partial \vec{n}_K} + \int_{\partial K} \vec{a} \cdot \vec{n}_K p = \int_K f, \tag{2.9}$$

where $\vec{n}_K$ is the outward normal on ∂K of K. If we introduce F_K such that

$$S_K = \frac{1}{meas(K)} \int_K f - F_K = O(diam(K)). \tag{2.10}$$

(2.9) is discretized by

$$\begin{aligned}&\eta\, meas(K)p_K^i - \sum_{K'\in\mathcal{N}_i(K)} [u_{K,K'}^i meas([K,K']) + v_{K,K'}^i] - \sum_{\epsilon\in\mathcal{E}_{iD}(K)\cup\mathcal{E}_i(K)} u_\epsilon^i meas(\epsilon)\\ &\quad + \sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} v_{[K,K']}^{i,j} + \sum_{\epsilon\in\mathcal{E}_{iD}(K)} v_{\epsilon,K^+}^i = F_K meas(K),\end{aligned} \tag{2.11}$$

where $meas(\cdot)$ denotes the Lebesgue measure and u^i and v^i are defined in what follows. For an interior face $[K,K'] \in \mathcal{E}_{\Omega_i}\backslash(\mathcal{E}_{iD}\cup\mathcal{E}_i)$, we define

$$u_{K,K'}^i = \frac{p_{K'}^i - p_K^i}{d(x_{K'},x_K)}, \tag{2.12}$$

where $d(x,y)$ is the Euclidean distance between x and y. For a face $\epsilon\in\mathcal{E}_{iD}(K)$ on the boundary $\partial\Omega_i\cap\Omega$, the Dirichlet boundary condition (2.7) is taken into account by using

$$u_\epsilon^i = \frac{g_\epsilon^i - p_K^i}{d(y_\epsilon,x_K)}, \tag{2.13}$$

where $g_\epsilon^i = g(y_\epsilon)$. On each interface face $\epsilon\in\mathcal{E}_i(K)$, we have

$$u_\epsilon^i = \frac{p_\epsilon^i - p_K^i}{d(y_\epsilon,x_K)}. \tag{2.14}$$

As for the convective terms, for any adjacent cells K, K', let

$$v_{K,K'}^i = a_{[K,K']}p_{[K,K']^+}^i, \tag{2.15}$$

where $a_{[K,K']} = \int_{[K,K']}\vec{a}\cdot\vec{n}_K$. If $a_{[K,K']}\geq 0$, then $p_{[K,K']^+}^i = p_K^i$; else $p_{[K,K']^+}^i = p_{K'}^i$ (upwind scheme). Note that (2.15) will even be used for cells adjacent to the interfaces between subdomains. We have the useful properties that $u_{K,K'}^i = -u_{K',K}^i$, $a_{[K,K']} = -a_{[K',K]}$, and $p_{[K,K']^+}^i = p_{[K',K]^+}^i$. For the discretization of the convective term on $\epsilon\in\mathcal{E}_{iD}(K)$, we introduce $a_{\epsilon,K} = \int_\epsilon \vec{a}\cdot\vec{n}_K$, and if $a_{\epsilon,K}\geq 0$, then $p_{\epsilon,K^+}^i = p_K^i$; else $p_{\epsilon,K^+}^i = g(y_\epsilon)$. We define

$$v_{\epsilon,K^+}^i = a_{\epsilon,K}p_{\epsilon,K^+}^i. \tag{2.16}$$

When there is no domain decomposition, this scheme has been analyzed in [21] in the more general case of discontinuous coefficients, and it is proven to be of order 1 for a discrete H^1-norm.

In order to define the domain decomposition discretization scheme, we shall define in section 2.3 the convective fluxes on the interface and the matching conditions for the diffusive fluxes.

To simplify the notation, for all $i\in\mathcal{I}$, we associate with any discrete values $(p_\epsilon^i)_{\epsilon\in\mathcal{E}_i}$, p_i its natural piecewise constant extrapolation in $P^0(\mathcal{E}_i)$:

$$\begin{aligned} p_i:\quad &\partial\Omega_i\backslash\partial\Omega \longrightarrow \mathbb{R},\\ &y \longmapsto p_i(y) = p_\epsilon^i \quad \text{if } y\in\epsilon\subset\mathcal{E}_i\end{aligned}$$

and also for all $j \in \mathcal{V}_i$, p_i^j the restriction of p_i to $\partial\Omega_i \cap \partial\Omega_j$.

We define the spaces of discretization and the associated discrete norms for all $i \in \mathcal{I}$:

$$\begin{aligned} P^0(\mathcal{E}_{i\to j}) &= \{p : \Gamma_{ij} \longrightarrow \mathbb{R} \mid p \text{ is constant on all } \epsilon \in \mathcal{E}_{i\to j}\}, \\ P^0(\mathcal{E}_i) &= \{p \text{ is constant on all } \epsilon \in \mathcal{E}_i\}, \\ Z_i &= \{p : \Omega_i \longrightarrow \mathbb{R} \mid \forall K \in \mathcal{T}_i, p \text{ is constant on } K\}, \\ Z &= \prod_{i\in\mathcal{I}} Z_i. \end{aligned}$$

The discrete L^2-norms and H^1-norms are defined by the following: for all $p \in Z_i$,

$$\|p\|^2_{L^2(\Omega_i)} = \sum_{K\in\mathcal{T}_i} (p_K)^2 meas(K)$$

and for all $q \in P^0(\mathcal{E}_i)$,

$$\|q\|^2_{L^2(\partial\Omega_i)} = \sum_{\epsilon\in\mathcal{E}_{iD}\cup\mathcal{E}_i} (q_\epsilon)^2 meas(\epsilon).$$

Let $X_i = Z_i \times P^0(\mathcal{E}_i)$ be endowed with the following seminorms: for $\tilde{p} = (p, p_b) \in X_i$,

$$\begin{aligned} |\tilde{p}|^2_{1,\mathcal{T}_i} = \sum_{K\in\mathcal{T}_i} \Bigg[&\sum_{K'\in\mathcal{N}_i(K)} \frac{(p_K - p_{K'})^2}{d(x_K, x_{K'})} meas([K,K']) \\ &+ \sum_{\epsilon\in\mathcal{E}_{iD}(K)} \frac{(p_K)^2}{d(x_K, y_\epsilon)} meas(\epsilon) + \sum_{\epsilon\in\mathcal{E}_i(K)} \frac{(p_{b_\epsilon} - p_K)^2}{d(x_K, y_\epsilon)} meas(\epsilon) \Bigg] \end{aligned}$$

and

$$\|\tilde{p}\|_{L^2(\partial\Omega_i)} = \Big(\sum_{\epsilon\in\mathcal{E}_i} |p_{b\epsilon}|^2 \, meas(\epsilon) \Big)^{1/2}.$$

In what follows, we shall drop the subscript b.

For all $p = (p_i)_{i\in\mathcal{I}} \in Z$, let $\|p\|^2_{L^2(\Omega)} = \sum_{i=1}^N \|p_i\|^2_{L^2(\Omega_i)}$. Let the product space $X = \Pi_{i\in\mathcal{I}} X_i$ be endowed with the following seminorm: for $\tilde{p} = (\tilde{p}_i)_{i\in\mathcal{I}} \in X$, $|\tilde{p}|^2_{1,\mathcal{T}} = \sum_{i=1}^N |\tilde{p}_i|^2_{1,\mathcal{T}_i}$.

2.3. Finite volume scheme on the interfaces.

We first give the discretization of the convective flux through the interface on the nonmatching grids. Then in order to enforce the weak continuity of the primary unknown p and of its normal derivative (denoted by u) through the interface on the nonmatching grids, we introduce transmission operators.

Convective flux. The convective flux on the nonmatching grids is discretized as in the matching case by an upwind scheme [21]. For all $K \in \mathcal{T}_i$, for all $j \in \mathcal{V}_i$, for all $K' \in \mathcal{N}_{ij}(K)$, we define

$$v^{i,j}_{[K,K']} = a_{[K,K']} p^{i,j}_{[K,K']^+}, \tag{2.17}$$

where $a_{[K,K']} = \int_{[K,K']} \vec{a} \cdot \vec{n}_K$ and $p^{i,j}_{[K,K']^+} = p^i_K$ if $a_{[K,K']} \geq 0$, and $p^{i,j}_{[K,K']^+} = p^j_K$ otherwise.

Transmission operators and Dirichlet–Neumann interface conditions. In order to enforce a weak continuity across the interface Γ_{ij} of the principal unknown p and of its normal derivative (denoted by u), we introduce the linear transmission operators $Q_i^j : P^0(\mathcal{E}_{j\to i}) \longrightarrow P^0(\mathcal{E}_{i\to j})$. They satisfy the following compatibility condition.

Assumption 2. For all $i \in \mathcal{I}$, $j \in \mathcal{V}_i$ and $u \in P^0(\mathcal{E}_{i\to j})$ and $v \in P^0(\mathcal{E}_{j\to i})$,

$$\langle Q_j^i(u), v\rangle_{L^2(\Gamma_{ij})} = \langle u, Q_i^j(v)\rangle_{L^2(\Gamma_{ij})}$$

As in mortar methods [7], we consider that one subdomain enforces the weak continuity of the primary unknown which is interpreted as the Dirichlet interface condition. This subdomain is called the master. The other subdomain enforces the weak continuity of the normal derivative which corresponds to a Neumann interface condition and is called the slave. The conditions are interpreted and considered in the following as Dirichlet–Neumann interface conditions. We introduce the following definition.

DEFINITION 2.2. *For all $i \in \mathcal{I}$, $\mathcal{V}_i$ is partitioned as $\mathcal{V}_i = \mathcal{S}_i \cup \mathcal{M}_i$ such that $\mathcal{S}_i \cap \mathcal{M}_i = \emptyset$ and for all $j \in \mathcal{I}$, $i \in \mathcal{S}_j \Longleftrightarrow j \in \mathcal{M}_i$.*

We define for all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$, $p_i, u_i \in P^0(\mathcal{E}_{j\to i})$, and $p_j, u_j \in P^0(\mathcal{E}_{i\to j})$ the Dirichlet–Neumann interface conditions on Γ_{ij} by

$$p_j = Q_j^i(p_i), \tag{2.18}$$

$$u_i = Q_i^j(-u_j), \tag{2.19}$$

where, if $j \in \mathcal{S}_i$, subdomain Ω_i is the master of subdomain Ω_j which is the slave. On each interface between two subdomains, one side has to be the master and the other one the slave. This choice is arbitrary. In what follows, when there is no ambiguity, we shall drop the superscripts in the above equalities. Two types of transmission operators will be given in section 5.

3. Interface boundary conditions.

To define more general interface conditions that have an impact on the convergence rate of the iterative domain decomposition algorithm (2.6)–(2.8) but not on the converged solution, we introduce the linear interface operator $S_{i,j} : P^0(\mathcal{E}_{i\to j}) \longrightarrow P^0(\mathcal{E}_{i\to j})$. The interface operators satisfy the following hypothesis.

Assumption 3. For all $i \in \mathcal{I}$, $j \in \mathcal{V}_i$, $i \neq j$, $S_{i,j}$ is positive definite (for all $u \in P^0(\mathcal{E}_{i\to j})$, $u \neq 0$, $\langle S_{i,j}(u), u\rangle_{L^2(\Gamma_{ij})} > 0$).

Assumption 3 implies that $S_{i,j}$ is invertible. For example $S_{i,j}$ can be

- the discrete Steklov–Poincaré operator (see [20]);
- a diagonal operator ($S_{i,j} = diag(\alpha_\epsilon)$, with $\alpha_\epsilon > 0$ a constant Robin coefficient on $\epsilon \in \mathcal{E}_{i\to j}$);
- optimized Robin interface coefficients of order 0 ($S_{i,j} = diag(\alpha_\epsilon^{opt})$, with $\alpha_\epsilon^{opt} > 0$ Robin optimized coefficients on $\epsilon \in \mathcal{E}_{i\to j}$) (see [19]);
- the discretization of $(\alpha - \frac{\partial}{\partial\tau}(\beta\frac{\partial}{\partial\tau}))$, where τ is the tangential vector of the interface ($S_{i,j}$ is a tridiagonal operator with $\alpha_\epsilon^{opt} > 0$ and β_ϵ^{opt} for $\epsilon \in \mathcal{E}_{i\to j}$) (see [17], [16]).

In what follows, when there is no ambiguity, we shall denote $S_{i,j}$ by S_i.

3.1. Dirichlet–Neumann and arbitrary interface conditions.

The arbitrary interface conditions are defined by the following: for all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$,

$$u_i + Q_i(S_jQ_j(p_i)) = Q_i(-u_j + S_j(p_j)) \quad \text{on } \Gamma_{i,j}, \tag{3.1}$$

$$Q_j(S_i^{-1}Q_i(u_j)) + p_j = Q_j(-S_i^{-1}(u_i) + p_i) \quad \text{on } \Gamma_{i,j}. \tag{3.2}$$

Theorem 3.1 proves that conditions (2.19) and (2.18) and conditions (3.1) and (3.2) are equivalent.

THEOREM 3.1. *Assume that for all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$, the transmission operators Q_i^j satisfy Assumption 2 and that the interface operators $S_{i,j}$ satisfy Assumption 3; then we have the following equivalence: for all $(p_i, u_i) \in P^0(\mathcal{E}_{i\to j}) \times P^0(\mathcal{E}_{i\to j})$ and for all $(p_j, u_j) \in P^0(\mathcal{E}_{j\to i}) \times P^0(\mathcal{E}_{j\to i})$,*

$$\begin{cases} u_i + Q_i(S_{j,i}Q_j(p_i)) & = & Q_i(-u_j + S_{j,i}(p_j)) \\ Q_j(S_{i,j}^{-1}Q_i(u_j)) + p_j & = & Q_j(-S_{i,j}^{-1}(u_i) + p_i) \end{cases} \iff \begin{cases} u_i & = & Q_i(-u_j), \\ p_j & = & Q_j(p_i). \end{cases}$$

Proof. ($\Rightarrow$) We introduce the auxiliary variables

$$\begin{cases} \delta p_j = Q_j(p_i) - p_j, \\ \delta u_i = Q_i(u_j) + u_i. \end{cases}$$

Then conditions (3.1) and (3.2) are rewritten with δp_j and δu_i as

$$\begin{cases} Q_i(S_j(\delta p_j)) + \delta u_i & = 0, \\ -Q_j(S_i^{-1}(\delta u_i)) + \delta p_j & = 0. \end{cases}$$

By multiplying the first equation by $S_i^{-1}(\delta u_i)$ and the second by $S_j(\delta p_j)$, integrating over Γ_{ij}, and summing we obtain

$$\begin{aligned} &\int_{\Gamma_{ij}} Q_i(S_j(\delta p_j))S_i^{-1}(\delta u_i) - \int_{\Gamma_{ij}} Q_j(S_i^{-1}(\delta u_i))S_j(\delta p_j) \\ &\quad + \int_{\Gamma_{ij}} (\delta u_i)S_i^{-1}(\delta u_i) + \int_{\Gamma_{ij}} (\delta p_j)S_j(\delta p_j) = 0. \end{aligned} \tag{3.3}$$

From Assumption 2, we deduce

$$\int_{\Gamma_{ij}} Q_i(S_j(\delta p_j))S_i^{-1}(\delta u_i) = \int_{\Gamma_{ij}} S_j(\delta p_j)Q_jS_i^{-1}(\delta u_i).$$

Consequently (3.3) becomes

$$\int_{\Gamma_{ij}} \delta u_i S_i^{-1}(\delta u_i) + \int_{\Gamma_{ij}} \delta p_j S_j(\delta p_j) = 0.$$

S_i and S_j satisfying Assumption 3, we have $\delta u_i = \delta p_j = 0$, and thus $u_i = Q_i(-u_j)$ and $p_j = Q_j(p_i)$.

($\Leftarrow$) Equation (2.18) yields

$$p_j^i = Q_j^i(p_i^j) \Rightarrow S_{j,i}(p_j^i) = S_{j,i}Q_j^i(p_i^j) \Rightarrow Q_i^j(S_{j,i}(p_j^i)) = Q_i^j(S_{j,i}Q_j^i(p_i^j)); \tag{3.4}$$

then combining (3.4) and (2.19) we get (3.1). Proceeding in the same way with (2.19), we get (3.2). ∎

4. Wellposedness. Before proving that the global problem defined by (2.11)–(2.19) is well posed, we state the following lemma.

LEMMA 4.1. *In each subdomain Ω_i $(i \in \mathcal{I})$, if $(p, u_\epsilon) \in X_i \times P^0(\mathcal{E}_i)$ satisfy* (2.11)–(2.16)*, then the following estimate holds:*

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_i}\Bigg(\eta\, meas(K)(p_K^i)^2+\frac{1}{2}\sum_{K'\in\mathcal{N}_i(K)}\frac{(p_K^i-p_{K'}^i)^2}{d(x_K,x_{K'})}meas([K,K'])\\
&\quad+\sum_{\epsilon\in\mathcal{E}_{iD}(K)}\frac{(p_K^i)^2}{d(y_\epsilon,x_K)}meas(\epsilon)+\sum_{\epsilon\in\mathcal{E}_i(K)}d(y_\epsilon,x_K)(u_\epsilon^i)^2 meas(\epsilon)-\sum_{\epsilon\in\mathcal{E}_i(K)}u_\epsilon^i p_\epsilon^i meas(\epsilon)\\
&\quad+\frac{1}{2}\sum_{\epsilon\in\mathcal{E}(K)\setminus\mathcal{E}_i(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_K\right](p_K^i)^2+\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)}v^{i,j}_{[K,K']}p_K^i\Bigg)\\
&\quad\le\sum_{K\in\mathcal{T}_i}F_K p_K^i meas(K)+\sum_{\epsilon\in\mathcal{E}_{iD}}\frac{p_K^i g_\epsilon^i}{d(y_\epsilon,x_K)}meas(\epsilon)-\sum_{\epsilon\in\mathcal{E}_{iD}}1_{[a_{\epsilon,K}\le 0]}\;a_{\epsilon,K}g_\epsilon^i p_K^i.
\end{aligned}$$

Remark 4.2. For any K such that $\mathcal{E}(K)\subset[\mathcal{E}_{\Omega_i}\setminus(\mathcal{E}_i\cup\mathcal{E}_{iD})]$, thanks to div $(\vec{a})\ge 0$, we have

$$\sum_{\epsilon\in\mathcal{E}(K)}\int_\epsilon \vec{a}\cdot\vec{n}_{K(\epsilon)}(p_{K(\epsilon)}^i)^2=\int_K(\mathrm{div}(\vec{a}))(p_{K(\epsilon)}^i)^2\ge 0.$$

Proof. The summation over $K\in\mathcal{T}_i$ in (2.11) multiplied by p_K^i yields

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_i}\Bigg(\eta\, meas(K)(p_K^i)^2-\sum_{K'\in\mathcal{N}_i(K)}\left[u_{K,K'}^i p_K^i meas([K,K'])+v^i_{[K,K']^+}p_K^i\right]\\
&\quad-\sum_{\epsilon\in\mathcal{E}_{iD}(K)\cup\mathcal{E}_i(K)}u_\epsilon^i p_K^i meas(\epsilon)+\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)}v^{i,j}_{[K,K']}p_K^i+\sum_{\epsilon\in\mathcal{E}_{iD}(K)}v^i_{\epsilon,K^+}p_K^i\Bigg)\\
&\qquad=\sum_{K\in\mathcal{T}_i}F_K p_K^i meas(K).
\end{aligned}\tag{4.1}$$

Taking into account (2.12)–(2.16), (4.1) reads as

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_i}\Bigg(\eta\, meas(K)(p_K^i)^2+\sum_{K'\in\mathcal{N}_i(K)}\left[p_K^i\frac{p_K^i-p_{K'}^i}{d(x_K,x_{K'})}meas([K,K'])+a_{[K,K']}p^i_{[K,K']^+}p_K^i\right]\\
&\qquad+\sum_{\epsilon\in\mathcal{E}_{iD}(K)}p_K^i\frac{p_K^i-g_\epsilon^i}{d(y_\epsilon,x_K)}\;meas(\epsilon)+\sum_{\epsilon\in\mathcal{E}_i(K)}d(y_\epsilon,x_K)(u_\epsilon^i)^2 meas(\epsilon)\\
&\qquad+\sum_{\epsilon\in\mathcal{E}_{iD}(K)}a_{\epsilon,K}p^i_{\epsilon,K^+}p_K^i-\sum_{\epsilon\in\mathcal{E}_i(K)}u_\epsilon^i p_\epsilon^i meas(\epsilon)+\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)}v^{i,j}_{[K,K']}p_K^i\Bigg)\\
&=\sum_{K\in\mathcal{T}_i}F_K p_K^i meas(K).
\end{aligned}\tag{4.2}$$

The second term of (4.2) can be replaced by

$$\sum_{K'\in\mathcal{N}_i(K)}p_K^i\frac{p_K^i-p_{K'}^i}{d(x_K,x_{K'})}meas([K,K'])=\frac{1}{2}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_i(K)}\frac{(p_K^i-p_{K'}^i)^2}{d(x_K,x_{K'})}meas([K,K']).$$

The third term of (4.2) corresponds to the convective term inside the subdomain Ω_i, and proceeding as in [21], we obtain

$$\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_i(K)} a_{[K,K']}p^i_{[K,K']^+}p^i_K \geq \frac{1}{2}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}(K)\setminus(\mathcal{E}_{iD}(K)\cup\mathcal{E}_i(K))}\int_\epsilon \vec{a}\cdot\vec{n}_K|p^i_K|^2. \tag{4.3}$$

For the convection fluxes on the Dirichlet boundary $\partial\Omega_i\cap\partial\Omega$, we have

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_{iD}(K)} a_{\epsilon,K}p^i_{\epsilon,K^+}p^i_K\\
&\quad=\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_{iD}(K)} 1_{[a_{\epsilon,K}\geq 0]}\ a_{\epsilon,K}(p^i_K)^2+\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_{iD}(K)} 1_{[a_{\epsilon,K}\leq 0]}\ a_{\epsilon,K}g^i_\epsilon p^i_K\\
&\quad\geq\frac{1}{2}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_{iD}(K)} 1_{[a_{\epsilon,K}\geq 0]}\ a_{\epsilon,K}(p^i_K)^2+\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_{iD}(K)} 1_{[a_{\epsilon,K}\leq 0]}\ a_{\epsilon,K}g^i_\epsilon p^i_K\\
&\quad\geq\sum_{K\in\mathcal{T}_i}\Bigg(\frac{1}{2}\sum_{\epsilon\in\mathcal{E}_{iD}(K)}\left[\int_\epsilon\vec{a}\cdot\vec{n}_K\right](p^i_K)^2+\sum_{\epsilon\in\mathcal{E}_{iD}(K)} 1_{[a_{\epsilon,K}\leq 0]}\ a_{\epsilon,K}g^i_\epsilon p^i_K\Bigg). \qquad (4.4)
\end{aligned}$$

Thus combining (4.2)–(4.4), we get the inequality of Lemma 4.1. □

4.1. Global wellposedness.

THEOREM 4.3. *Under Assumptions* 2 *and* 3*, the finite volume discretization defined by* (2.11)–(2.19) *is well posed and if* $(g^i_\epsilon)_{\epsilon\in\mathcal{E}_{iD}}=0$*, there exists* $C\geq 0$ *such that its unique solution* $p\in X$ *satisfies*

$$\eta\|p\|^2_{L^2(\Omega)}+|p|^2_{1,\mathcal{T}}\leq C\|F\|^2_{L^2(\Omega)}. \tag{4.5}$$

Remark 4.4. The assumptions of Theorem 3.1 are satisfied, so the interface conditions (2.19) and (2.18) are equivalent to the interface conditions (3.1) and (3.2), which are easier to use. The global problem is defined also with (2.19) and (2.18) instead of (3.1) and (3.2).

Proof. The global system is a linear square, so we just have to prove that the solution of the global homogeneous problem ($(F_K)_{K\in\mathcal{T}_i}=0$ and $(g^i_\epsilon)_{\epsilon\in\mathcal{E}_{iD}}=0$ for all $\in\mathcal{I}$) is zero. We sum over $i\in\mathcal{I}$ the equality of Lemma 4.1 and with (2.17) for all $i\in\mathcal{I}$, for all $j\in\mathcal{V}_i$, it yields

$$\begin{aligned}
&\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\Bigg(\eta\ meas(K)(p^i_K)^2+\frac{1}{2}\sum_{K'\in\mathcal{N}_i(K)}\frac{(p^i_K-p^i_{K'})^2}{d(x_K,x_{K'})}\ meas([K,K'])\\
&\quad+\sum_{\epsilon\in\mathcal{E}_{iD}(K)}\frac{(p^i_K)^2}{d(y_\epsilon,x_K)}meas(\epsilon)+\sum_{\epsilon\in\mathcal{E}_i(K)} d(y_\epsilon,x_K)(u^i_\epsilon)^2meas(\epsilon)\\
&\quad-\sum_{\epsilon\in\mathcal{E}_i(K)} u^i_\epsilon p^i_\epsilon meas(\epsilon)+\sum_{\epsilon\in\mathcal{E}(K)\setminus\mathcal{E}_i(K)}\left[\int_\epsilon\vec{a}\cdot\vec{n}_K\right](p^i_K)^2\\
&\quad+\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} a_{[K,K']}p^{i,j}_{[K,K']^+}p^i_K\Bigg)\leq\sum_{i\in\mathcal{I}}\Bigg(\sum_{K\in\mathcal{T}_i}F_Kp^i_Kmeas(K)\\
&\quad+\sum_{\epsilon\in\mathcal{E}_{iD}}\frac{p^i_Kg^i_\epsilon}{d(y_\epsilon,x_K)}meas(\epsilon)-\sum_{\epsilon\in\mathcal{E}_{iD}} 1_{[a_{\epsilon,K}\leq 0]}\ a_{\epsilon,K}g^i_\epsilon p^i_K\Bigg). \qquad (4.6)
\end{aligned}$$

The term of the diffusive fluxes could be rewritten as

$$\begin{aligned}
-\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} u^i_\epsilon p^i_\epsilon meas(\epsilon) &= -\sum_{i\in\mathcal{I}}\int_{\Gamma_i} u_i p_i = -\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\int_{\Gamma_{ij}} u^j_i p^j_i \\
&= -\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}} \left[u^j_i p^j_i + u^i_j p^i_j\right] \\
&= -\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}} \left[u^j_i Q^j_i(p^i_j) - Q^i_j(u^j_i) p^i_j\right]
\end{aligned}$$

and using Assumption 2

$$= -\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}} \left[u^j_i Q^j_i(p^i_j) - u^j_i Q^j_i(p^i_j)\right] = 0. \tag{4.7}$$

For the convective fluxes on the interface, we obtain

$$\begin{aligned}
T_1 &= \sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} a_{[K,K']} p^{i,j}_{[K,K']^+} p^i_K \\
&= \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} \big(a_{[K,K']} p^{i,j}_{[K,K']^+} p^i_K + a_{[K',K]} p^{j,i}_{[K',K]^+} p^j_{K'}\big).
\end{aligned}$$

Since $p^{i,j}_{[K,K']^+} = p^{j,i}_{[K',K]^+}$ and $a_{[K,K']} = -a_{[K',K]}$, we write

$$T_1 = \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} a_{[K,K']} p^{i,j}_{[K,K']^+}(p^i_K - p^j_{K'}). \tag{4.8}$$

We introduce the downstream value $p^{i,j}_{[K,K']^-}$ to $[K,K']$ with respect to $\vec{a}$, i.e., if $a_{[K,K']} \leq 0$, then $p^{i,j}_{[K,K']^-} = p^i_K$ else $p^{i,j}_{[K,K']^-} = p^j_{K'}$. We transform the term $a_{[K,K']} p^{i,j}_{[K,K']^+}(p^i_K - p^j_{K'})$ as follows:

$$a_{[K,K']} p^{i,j}_{[K,K']^+}(p^i_K - p^j_{K'}) = |a_{[K,K']}| p^{i,j}_{[K,K']^+}(p^{i,j}_{[K,K']^+} - p^{i,j}_{[K,K']^-}).$$

Then (4.8) becomes

$$\begin{aligned}
T_1 &= \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} |a_{[K,K']}| p^{i,j}_{[K,K']^+}\big(p^{i,j}_{[K,K']^+} - p^{i,j}_{[K,K']^-}\big) \\
&= \frac{1}{4}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} |a_{[K,K']}|\big[\big(p^{i,j}_{[K,K']^+} - p^{i,j}_{[K,K']^-}\big)^2\big] \\
&\quad + \big(\big(p^{i,j}_{[K,K']^+}\big)^2 - \big(p^{i,j}_{[K,K']^-}\big)^2\big),
\end{aligned}$$

and then we write

$$\begin{aligned}
T_1 &\geq \frac{1}{4}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} |a_{[K,K']}|\big[\big(p^{i,j}_{[K,K']^+}\big)^2 - \big(p^{i,j}_{[K,K']^-}\big)^2\big] \\
&\geq \frac{1}{4}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} \big[a_{[K,K']}(p^i_K)^2 + a_{[K',K]}(p^j_{K'})^2\big] \\
&\geq \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} a_{[K,K']}(p^i_K)^2
\end{aligned}$$

$$\geq \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_{ij}(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_K\right](p_K^i)^2 = \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_K\right](p_K^i)^2.$$

Let us denote by T_2 the convective terms that are not on the interfaces. Using the same method for the convective term inside the subdomains and on the Dirichlet boundary as in [21], we have

$$T_2 \geq \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\left[\sum_{\epsilon\in\mathcal{E}(K)\backslash\mathcal{E}_i(K)}\int_\epsilon \vec{a}\cdot\vec{n}_{K(\epsilon)}\right](p_{K(\epsilon)}^i)^2 + \sum_{\epsilon\in\mathcal{E}_{iD}} 1_{[a_{\epsilon,K}\leq 0]}\; a_{\epsilon,K}g_\epsilon^i p_K^i.$$

Consequently for the convective term, we obtain thanks to $\mathrm{div}(\vec{a})\geq 0$

$$\begin{aligned}T_1+T_2 &\geq \sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_{K(\epsilon)}\right](p_{K(\epsilon)}^i)^2 + \sum_{\epsilon\in\mathcal{E}_{iD}} 1_{[a_{\epsilon,K}\leq 0]}\; a_{\epsilon,K}g_\epsilon^i p_K^i \\ &\geq \sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\int_K[\mathrm{div}(\vec{a})(p_{K(\epsilon)}^i)^2] + \sum_{\epsilon\in\mathcal{E}_{iD}} 1_{[a_{\epsilon,K}\leq 0]}\; a_{\epsilon,K}g_\epsilon^i p_K^i \\ &\geq \sum_{\epsilon\in\mathcal{E}_{iD}} 1_{[a_{\epsilon,K}\leq 0]}\; a_{\epsilon,K}g_\epsilon^i p_K^i.\end{aligned}$$

(4.6) leads to

$$\begin{aligned}&\sum_{i\in\mathcal{I}}\Bigg(\sum_{K\in\mathcal{T}_i}\Bigg(\eta\, meas(K)(p_K^i)^2 + \frac{1}{2}\sum_{K'\in\mathcal{N}_i(K)}\frac{(p_K^i-p_{K'}^i)^2}{d(x_K,x_{K'})}meas([K,K']) \\ &\quad + \sum_{\epsilon\in\mathcal{E}_{iD}(K)}\frac{(p_K^i)^2}{d(y_\epsilon,x_K)}meas(\epsilon) + \sum_{\epsilon\in\mathcal{E}_i(K)} d(y_\epsilon,x_K)(u_\epsilon^i)^2 meas(\epsilon)\Bigg)\Bigg) \\ &\quad \leq \sum_{i\in\mathcal{I}}\Bigg(\sum_{K\in\mathcal{T}_i}F_K p_K^i meas(K) + \sum_{\epsilon\in\mathcal{E}_{iD}}\frac{p_K^i g_\epsilon^i}{d(y_\epsilon,x_K)}meas(\epsilon) \\ &\quad - \sum_{\epsilon\in\mathcal{E}_{iD}} 1_{[a_{\epsilon,K}\leq 0]}\; a_{\epsilon,K}g_\epsilon^i p_K^i\Bigg).\end{aligned} \tag{4.9}$$

For the homogeneous problem ($(F_K)_{K\in\mathcal{T}_i}=0$ and $(g_\epsilon^i)_{\epsilon\in\mathcal{E}_{iD}}=0$), all the terms on the right-hand side of (4.9) are nonnegative. We conclude that for all $i\in\mathcal{I}$

$$p_K^i = 0\ \forall K\in\mathcal{T}_i \tag{4.10}$$

$$u_\epsilon^i = 0\ \forall \epsilon\in\mathcal{E}_i. \tag{4.11}$$

Using (2.14), (4.10), and (4.11), we obtain $p_\epsilon^i = 0$ for all $\epsilon\in\mathcal{E}_i$. Consequently the global system is invertible and the wellposedness of the scheme for the global domain is proven.

Moreover if $(g_\epsilon^i)_{\epsilon\in\mathcal{E}_{iD}}=0$ for all $i\in\mathcal{I}$ and using the Young inequality, for all $C_f>0$, we have for all $i\in\mathcal{I}$

$$\begin{aligned}\sum_{K\in\mathcal{T}_i}F_K p_K^i meas(K) &\leq \frac{1}{2C_f}\sum_{K\in\mathcal{T}_i}(p_K^i)^2 meas(K) + \frac{C_f}{2}\sum_{K\in\mathcal{T}_i}(F_K)^2 meas(K) \\ &\leq \frac{1}{2C_f}\|p_i\|^2_{L^2(\Omega_i)} + \frac{C_f}{2}\|F\|^2_{L^2(\Omega_i)}.\end{aligned} \tag{4.12}$$

Then (4.9)–(4.12) give

$$\left(\eta - \frac{1}{2C_f}\right)\sum_{i\in\mathcal{I}} \|p_i\|^2_{L^2(\Omega_i)} + \sum_{i\in\mathcal{I}}\Bigg(\frac{1}{2} \sum_{K'\in\mathcal{N}_i(K)} \frac{(p^i_K - p^i_{K'})^2}{d(x_K,x_{K'})} meas([K,K'])$$
$$+ \sum_{\epsilon\in\mathcal{E}_{iD}(K)} \frac{(p^i_K)^2}{d(y_\epsilon,x_K)} meas(\epsilon) + \sum_{\epsilon\in\mathcal{E}_i(K)} d(y_\epsilon,x_K)(u^i_\epsilon)^2 meas(\epsilon)\Bigg) \le \frac{C_f}{2}\sum_{i\in\mathcal{I}}\|F\|^2_{L^2(\Omega_i)}.$$

Taking $C_f > 1/\eta$ with (2.14) we obtain with $C \geq C_f$

$$\frac{\eta}{2}\|p\|^2_{L^2(\Omega)} + \frac{1}{2}|p|^2_{1,\mathcal{T}} \le C\|F\|^2_{L^2(\Omega)}. \qquad \square \tag{4.13}$$

4.2. Local wellposedness. We want to solve the global problem on Ω with an iterative domain decomposition method based on the computation of successive local boundary problems on Ω_i for $i \in \mathcal{I}$. Given $(R_\epsilon)_{\epsilon\in\mathcal{E}_i}$ and $(C_\epsilon)_{\epsilon\in\cup_j\mathcal{E}^+_{ij}}$ where, for all $j \in \mathcal{V}_i$, $\mathcal{E}^+_{ij}$ is the subset of $\mathcal{E}_{ij}$ where $a_\epsilon < 0$. The local problem on Ω_i is defined by the boundary conditions on Γ_{ij} for all $j \in \mathcal{V}_i$, for all $\epsilon \in \mathcal{E}_{i\to j}$:

$$u^{i,j}_\epsilon + [Q^j_i S_{j,i} Q^i_j(p^j_i)]_\epsilon = R_\epsilon \quad \text{if } j \in \mathcal{S}_i, \tag{4.14}$$

$$\left[Q^j_i S^{-1}_{j,i} Q^i_j(u^j_i)\right]_\epsilon + p^{i,j}_\epsilon = R_\epsilon \quad \text{if } j \in \mathcal{M}_i, \tag{4.15}$$

and by (2.11)–(2.16) where in (2.11), we have for all $j \in \mathcal{V}_i$, for any $K' \in \mathcal{N}_{ij}(K)$,

$$v^{i,j}_{[K,K']} = \begin{cases} a_\epsilon\, p^i_{K(\epsilon)} & \text{if } a_\epsilon \geq 0 \\ C_\epsilon & \text{if } a_\epsilon < 0. \end{cases} \tag{4.16}$$

where $\epsilon = [K,K']$. We have the following theorem

THEOREM 1. *Assume Assumptions* 2 *and* 3 *hold. Then, there exists a unique* $p^i \in X_i$ *and* $(v^{i,j}_\epsilon)_{\epsilon\in\mathcal{E}_{i\to j}}$ *satisfying the local problem on* Ω_i *defined by* (2.11)–(2.16) *and* (4.14)–(4.16).

Proof. The system in p^i and $v^{i,j}_\epsilon$ is linear and square, so it suffices to prove that the solution of the homogeneous local problem is zero. The homogeneous form of the equation of Lemma 4.1 is

(4.17)
$$\sum_{K\in\mathcal{T}_i}\Bigg(\eta\, meas(K)(p^i_K)^2 + \frac{1}{2}\sum_{K'\in\mathcal{N}_i(K)} \frac{(p^i_K - p^i_{K'})^2}{d(x_K,x_{K'})} d(x_K,x_{K'})\ meas([K,K'])$$
$$+\frac{1}{2}\sum_{\epsilon\in\mathcal{E}_{\Omega_i}(K)\setminus\mathcal{E}_i(K)} \left[\int_\epsilon \vec{a}\cdot\vec{n}_K\right](p^i_K)^2 + \sum_{\epsilon\in\mathcal{E}_{iD}(K)} \frac{(p^i_K)^2}{d(y_\epsilon,x_K)} meas(\epsilon)$$
$$+ \sum_{\epsilon\in\mathcal{E}_i(K)} d(y_\epsilon,x_K)(u^i_\epsilon)^2 meas(\epsilon) + \sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} v^{i,j}_{[K,K']} p^i_K\Bigg) \le \sum_{\epsilon\in\mathcal{E}_i} u^i_\epsilon p^i_\epsilon meas(\epsilon).$$

The homogeneous boundary conditions on $\mathcal{E}_{i\to j}$ are

$$\begin{aligned} p^j_i + Q^j_i(S^{-1}_{j,i}Q^i_j(u^j_i)) &= 0 \quad \forall j \in \mathcal{S}_i, \\ u^j_i + Q^j_i(S_{j,i}Q^i_j(p^j_i)) &= 0 \quad \forall j \in \mathcal{M}_i \end{aligned}$$

and give

$$\begin{aligned} p_i^j &= -Q_i^j(S_{j,i}^{-1}Q_j^i(u_i^j)) \quad \forall j \in \mathcal{S}_i,\\ u_i^j &= -Q_i^j(S_{j,i}Q_j^i(p_i^j)) \quad \forall j \in \mathcal{M}_i \end{aligned}$$

so the term on the interface reads

$$\begin{aligned} \sum_{\epsilon\in\mathcal{E}_i} u_\epsilon^i p_\epsilon^i meas(\epsilon) &= \int_{\Gamma_i} u_i p_i = \sum_{j\in\mathcal{V}_i}\int_{\Gamma_{ij}} u_i^j p_i^j = \sum_{j\in\mathcal{S}_i}\int_{\Gamma_{ij}} u_i^j p_i^j + \sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}} u_i^j p_i^j\\ &= -\sum_{j\in\mathcal{S}_i}\int_{\Gamma_{ij}} Q_i^j(S_{j,i}Q_j^i(p_i^j))p_i^j - \sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}} Q_i^j(S_{j,i}^{-1}Q_j^i(u_i^j))u_i^j\\ &= -\sum_{j\in\mathcal{S}_i}\int_{\Gamma_{ij}} S_{j,i}Q_j^i(p_i^j)Q_j^i(p_i^j) - \sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}} S_{j,i}^{-1}Q_j^i(u_i^j)Q_j^i(u_i^j) \le 0 \end{aligned}$$

because Q_i^j and Q_j^i satisfy Assumption 2 and $S_{j,i}$ satisfies Assumption 3. For the homogeneous convective term on the interface, we have

$$\begin{aligned} T_1 &= \sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} 1_{[a_{[K,K']}\ge 0]}a_{[K,K']}(p_K^i)^2\\ &\ge \frac{1}{2}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} 1_{[a_{[K,K']}\ge 0]}a_{[K,K']}(p_K^i)^2 \ge \frac{1}{2}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} a_{[K,K']}(p_K^i)^2\\ &\ge \frac{1}{2}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{K'\in\mathcal{N}_{ij}(K)}\int_{[K,K']}\vec{a}\cdot\vec{n}_K(p_K^i)^2 \ge \frac{1}{2}\sum_{j\in\mathcal{V}_i}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}\int_\epsilon \vec{a}\cdot\vec{n}_K(p_{K(\epsilon)}^i)^2. \end{aligned}$$

For the convective term inside the subdomains Ω_i and on the homogeneous Dirichlet boundary, we have

$$T_2 = \frac{1}{2}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_(K)\setminus\mathcal{E}_i(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_{K(\epsilon)}\right](p_K^i)^2.$$

So using $\operatorname{div}(\vec{a}) \ge 0$, we have

$$\begin{aligned} T_1 + T_2 &\ge \frac{1}{2}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_{K(\epsilon)}\right](p_K^i)^2\\ &= \sum_{K\in\mathcal{T}_i}\int_K[\operatorname{div}(\vec{a})(p_{K(\epsilon)}^i)^2] \ge 0. \end{aligned}$$

Then inequality (4.17) could be rewritten as

$$\begin{aligned} \sum_{K\in\mathcal{T}_i}\Bigg(\eta\, meas(K)(p_K^i)^2 &+ \frac{1}{2}\sum_{K'\in\mathcal{N}_i(K)}\frac{(p_K^i - p_{K'}^i)^2}{d(x_K,x_{K'})}d(x_K,x_{K'})\ meas([K,K'])\\ &+ \sum_{\epsilon\in\mathcal{E}_{iD}(K)}\frac{(p_K^i)^2}{d(y_\epsilon,x_K)}\ meas(\epsilon) + \sum_{\epsilon\in\mathcal{E}_i(K)} d(y_\epsilon,x_K)(u_\epsilon^i)^2\ meas(\epsilon)\Bigg) \le 0. \end{aligned} \tag{4.18}$$

All the left-hand-side terms of (4.18) are ≥ 0, so this implies

$$p_K^i = 0 \qquad \forall K \in \mathcal{T}_i, \tag{4.19}$$

$$u_\epsilon^i = 0 \qquad \forall \epsilon \in \mathcal{E}_i. \tag{4.20}$$

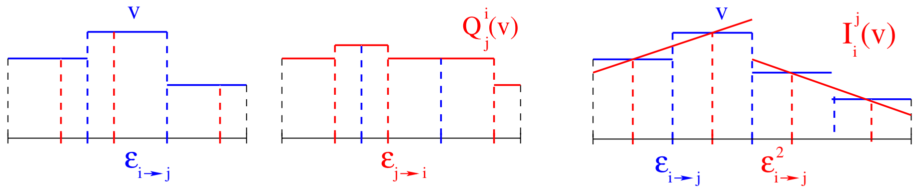

FIG. 2. *Projection on $P^0(\mathcal{E}_{j\to i})$ and interpolation on $P^1_d(\mathcal{E}^2_{i\to j})$ via the coarsened grid.*

Using (2.14), (4.19), and (4.20), we obtain $p^i_\epsilon = 0$ for all $\epsilon \in \mathcal{E}_i$. Then, from (4.16), we have $v^{i,j}_{[K,K']} = 0$ for $j \in \mathcal{V}_i$, $K' \in \mathcal{N}_{ij}(K)$. So the solution of the homogeneous problem on Ω_i is zero. □

5. Examples of transmission operators. We give two types of transmission operators which satisfy Assumption 2, but other transmission operators may be used. In the next section, an error estimate is performed for general transmission operators and then applied to the two types of transmission operators defined in the following.

5.1. Orthogonal L^2 projection on $P^0(\mathcal{E}_{i\to j})$. For $i \in \mathcal{I}$, $j \in \mathcal{V}_i$, let $P^C_{i,j}$ be the L^2 orthogonal projection onto $P^0(\mathcal{E}_{i\to j})$. The first type of operator is the restriction of $P^C_{i,j}$ to $P^0(\mathcal{E}_{j\to i})$. Let $u_j \in P^0(\mathcal{E}_{j\to i})$ and $\epsilon \in \mathcal{E}_{i\to j}$; it is defined by

$$[P^C_{i,j}(u_j)]_\epsilon = \frac{1}{meas(\epsilon)}\int_\epsilon u_j = \sum_{\epsilon'\in\mathcal{E}_j} \frac{meas(\epsilon\cap\epsilon')}{meas(\epsilon)} u_{j,\epsilon'}. \tag{5.1}$$

Assumption 2 is satisfied.

5.2. Transmission operators with linear rebuilding. The second type of operator, inspired by [4], uses a linear rebuilding process to have a more accurate transmission; see Figure 2. We shall use the following assumption.

Assumption 4. For all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$, there exists a coarsened grid $\mathcal{E}^2_{i\to j}$ of $\mathcal{E}_{i\to j}$ (with half the number of edges in two dimensions and one fourth the number of faces in three dimensions) such that

- if $d = 2$, for all $\epsilon \in \mathcal{E}^2_{i\to j}$, there exists $(\epsilon_1, \epsilon_2) \in (\mathcal{E}_{i\to j})^2$ such that $\epsilon = \epsilon_1 \cup \epsilon_2$ and $\bar\epsilon_1 \cap \bar\epsilon_2 \neq \emptyset$
- if $d = 3$, for all $\epsilon \in \mathcal{E}^2_{i\to j}$, there exists $(\epsilon_1, \epsilon_2, \epsilon_3, \epsilon_4) \in (\mathcal{E}_{i\to j})^4$ such that $\epsilon = \cup^4_{k=1}\epsilon_k$ and for all $1 \le k \le 4$, $card(\{l | 1 \le l \le 4,\ l \neq k,\ \text{and } \dim(\bar\epsilon_l \cap \bar\epsilon_k) = 1\}) = 2$.

For $d = 3$, some examples of mesh $\mathcal{E}_{i\to j}$ which satisfy Assumption 4 are corner point geometry mesh or quasi-uniform rectangular mesh. We introduce $P^1_d(\mathcal{E}^2_{i\to j})$, the space of discontinuous piecewise linear functions on $\mathcal{E}^2_{i\to j}$ if $d = 2$, or the space of discontinuous piecewise bilinear functions on $\mathcal{E}^2_{i\to j}$ if $d = 3$. The interpolation operator $I^j_i : P^0(\mathcal{E}_{i\to j}) \longrightarrow P^1_d(\mathcal{E}^2_{i\to j})$ is defined for all $p \in P^0(\mathcal{E}_{i\to j})$ by $[I^j_i(p)](y_\epsilon) = p(y_\epsilon)$, where y_ϵ is the barycenter of $\epsilon \in \mathcal{E}_{i\to j}$ and $(I^j_i)^T : P^1_d(\mathcal{E}^2_{i\to j}) \longrightarrow P^0(\mathcal{E}_{i\to j})$ is its transpose with respect to the $L^2(\Gamma_{ij})$ inner product. We also introduce $P^L_{i,j}$, the $L^2(\Gamma_{ij})$ orthogonal projection onto $P^1_d(\mathcal{E}^2_{i\to j})$. For $i \in \mathcal{I}$, $j \in \mathcal{S}_i$, the transmission operator is

$$Q^i_j = [P^C_{j,i|P^1_d(\mathcal{E}^2_{i\to j})}] I^j_i \qquad \text{(for the primary unknown)}. \tag{5.2}$$

In order to satisfy Assumption 2, we have

$$Q_i^j = (I_i^j)^T [P^L_{i,j|P^0(\mathcal{E}_{j\to i})}] \quad \text{(for the normal derivative).} \tag{5.3}$$

When the grids match, Q_i^j is the identity operator.

6. Error estimates. In this section, we study the accuracy of the finite volume scheme defined by (2.11)–(2.18) on nonmatching grids. The first subsection is an error estimate without taking into account the terms of the interface Γ_{ij}. The second subsection proves the error estimate in the general case with an additional assumption on transmission errors. In the other subsections we compute the transmission error in order to obtain the error estimate in the discrete H^1-norm. For the L^2 orthogonal projection on piecewise constant functions, we obtain an error in $O(h)^{1/2}$ in the general case and in $O(h)$ if the master sides are subgrids of the slave sides (subsection 5.1) and for the transmission operator with linear rebuilding (subsection 5.2), we get an error in $O(h)$. We denote the interface interpolation operators for all $i \in \mathcal{I}$, for all $j \in \mathcal{V}_i$ on Γ_{ij}, by

$$\begin{aligned} \mathcal{P}_i^j &: C^2(\overline{\Omega}) \longrightarrow P^0(\mathcal{E}_{i\to j}), \\ \mathcal{U}_i^j &: C^2(\overline{\Omega}) \longrightarrow P^0(\mathcal{E}_{i\to j}). \end{aligned}$$

We note $\mathcal{P}_\epsilon^{i,j}(p) = [\mathcal{P}_i^j(p)]_\epsilon$ and $\mathcal{U}_\epsilon^{i,j}(\frac{\partial f}{\partial n_i}) = [\mathcal{U}_i^j(\frac{\partial f}{\partial n_i})]_\epsilon$. These error interpolation operators allow us to introduce with flexibility an interpolated solution of p, the exact solution of (2.1)–(2.2), and of its normal derivative on Γ_{ij} (for all $i \in \mathcal{I}$, for all $j \in \mathcal{V}_i$) which is used to define the discrete error. The interpolated solution is defined by the following, for all $i \in \mathcal{I}$:

- $\tilde{p}_K^i = p(x_K)$ for any cell K in $\mathcal{T}_i$.
- $\tilde{p}_\epsilon^i = p(y_\epsilon)$ and $\tilde{u}_\epsilon^i = \frac{\partial p}{\partial n_i}(y_\epsilon)$ for any $\epsilon \in \mathcal{E}_{iD}$.
- For all $K \in \mathcal{T}_i$, for all $K' \in \mathcal{N}_i(K)$, if $a_{[K,K']} \geq 0$, then $\tilde{p}^i_{[K,K']+} = p(x_K)$; else $\tilde{p}^i_{[K,K']+} = p(x_{K'})$.
- For all $K \in \mathcal{T}_i$, for all $\epsilon \in \mathcal{E}_{iD}(K)$, if $a_{\epsilon,K} \geq 0$, then $\tilde{p}^i_{\epsilon,K+} = p(x_K)$; else $\tilde{p}^i_{\epsilon,K+} = p(y_\epsilon)$.
- For all $K \in \mathcal{T}_i$, for all $j \in \mathcal{V}_i$, for all $K \in \mathcal{N}_{ij}(K)$, if $a_{[K,K']} \geq 0$, then $\tilde{p}^{i,j}_{[K,K']+} = p(x_K)$; else $\tilde{p}^{i,j}_{[K,K']+} = p(x_{K'})$.

For the interface edges, the interpolated solution is adapted to the transmission operators:

- for $j \in \mathcal{V}_i$ and $\epsilon \in \mathcal{E}_{i\to j}$, $\tilde{p}_\epsilon^i = \mathcal{P}_i^j(p)_\epsilon$ and $\tilde{u}_\epsilon^i = \mathcal{U}_i^j(\frac{\partial p}{\partial n_i})_\epsilon$.

The discrete errors are defined by $e_K^i = p_K^i - \tilde{p}_K^i$ (for all $K \in \mathcal{T}_i$), $e_\epsilon^i = p_\epsilon^i - \tilde{p}_\epsilon^i$ (for all $\epsilon \in \mathcal{E}_{iD} \cup \mathcal{E}_i$), $q_\epsilon^i = u_\epsilon^i - \tilde{u}_\epsilon^i$ (for all $\epsilon \in \mathcal{E}_i \cup \mathcal{E}_{iD}$), $e^i_{[K,K']+} = p^i_{[K,K']+} - \tilde{p}^i_{[K,K']+}$ (for all $K \in \mathcal{T}_i$, for all $K' \in \mathcal{N}_i(K)$), $e^i_{\epsilon,K+} = p^i_{\epsilon,K+} - \tilde{p}^i_{\epsilon,K+}$ (for all $K \in \mathcal{T}_i$, for all $\epsilon \in \mathcal{E}_{iD}(K)$), and $e^{i,j}_{[K,K']+} = p^{i,j}_{[K,K']+}\tilde{p}^{i,j}_{[K,K']+}$ (for all $K \in \mathcal{T}_i$, for all $j \in \mathcal{V}_i$, for all $K' \in \mathcal{N}_{ij}(K)$). To simplify, we note for all $i \in \mathcal{I}$

- $R_K^i = \dfrac{1}{meas(K)} \displaystyle\int_K \eta(p_i - \tilde{p}_K^i)$ for all $K \in \mathcal{T}_i$,
- $R_{K,K'}^i = \dfrac{1}{meas([K,K'])} \displaystyle\int_{[K,K']} \frac{\partial p_i}{\partial n_i} - \frac{\tilde{p}^i_{K'} - \tilde{p}^i_K}{d(x_K, x_{K'})}$ for all $K \in \mathcal{T}_i$, for all $K' \in \mathcal{N}_i(K)$,
- $R_\epsilon^i = \dfrac{1}{meas(\epsilon)} \displaystyle\int_\epsilon \frac{\partial p_i}{\partial n_i} - \tilde{u}_\epsilon^i$ for all $\epsilon \in \mathcal{E}_i \cup \mathcal{E}_{iD}$,

- $r^i_{K,K'} = \dfrac{1}{meas([K,K'])}\displaystyle\int_{[K,K']} \vec{a}\cdot\vec{n}_K(p - \tilde{p}^i_{[K,K']^+})$ for all $K \in \mathcal{T}_i$ for all $K' \in \mathcal{N}_i$,
- $r^i_{K,\epsilon} = \dfrac{1}{meas(\epsilon)}\displaystyle\int_\epsilon \vec{a}\cdot\vec{n}_{K(\epsilon)}(p - \tilde{p}^i_{\epsilon,K^+})$ for all $K \in \mathcal{T}_i$, for all $\epsilon \in \mathcal{E}_{iD}(K)$,
- $r^{i,j}_{K,K'} = \dfrac{1}{meas([K,K'])}\displaystyle\int_{[K,K']} \vec{a}\cdot\vec{n}_K(p - \tilde{p}^{i,j}_{[K,K']^+})$ for all $K \in \mathcal{T}_i$, for all $j \in \mathcal{V}_i$, for all $K' \in \mathcal{N}_{ij}(K)$.

For $\epsilon \in \mathcal{E}_{i\to j}$, let us define

$$\begin{aligned}
T^i_\epsilon &= e^i_{K(\epsilon)} - e^i_\epsilon - d(x_K, y_\epsilon)q^i_\epsilon,\\
R^i_\epsilon &= \tfrac{1}{meas(\epsilon)}\textstyle\int_\epsilon \tfrac{\partial p}{\partial n_i} - \left[\mathcal{U}^j_i\left(\tfrac{\partial p}{\partial n}\right)\right]_\epsilon,\\
\Delta e^j_{i,\epsilon} &= \left[Q^j_i(\mathcal{P}^i_j(p)) - \mathcal{P}^j_i(p)\right]_\epsilon \quad \text{if } j \in \mathcal{M}_i,\\
\Delta q^j_{i,\epsilon} &= \left[Q^j_i(\mathcal{U}^i_j(\tfrac{\partial p}{\partial n_j})) + \mathcal{U}^j_i(\tfrac{\partial p}{\partial n_i})\right]_\epsilon \quad \text{if } j \in \mathcal{S}_i.
\end{aligned}$$

We introduce the global transmission errors:

- $R = \max_{i\in\mathcal{I},\epsilon\mathcal{E}_i} |R^i_\epsilon|$,
- $T = \max_{i\in\mathcal{I},\epsilon\mathcal{E}_i} |T^i_\epsilon|$,
- $T^2_d = \max_{i\in\mathcal{I},\epsilon\in\mathcal{E}_i} \frac{(T^i_\epsilon)^2}{d(x_{K(\epsilon)},y_\epsilon)}$,
- $\delta e = \max_{i\in\mathcal{I},j\in\mathcal{M}_i,\epsilon\in\mathcal{E}_i} |\Delta e^j_{i,\epsilon}|$,
- $\delta e^2_d = \max_{i\in\mathcal{I},j\in\mathcal{M}_i,\epsilon\in\mathcal{E}_i} \frac{(\Delta e^j_{i,\epsilon})^2}{d(x_{K(\epsilon)},y_\epsilon)}$,
- $\delta q = \max_{i\in\mathcal{I},j\in\mathcal{M}_i,\epsilon\in\mathcal{E}_j} |\Delta q^i_{j,\epsilon}|$.

6.1. Error analysis without the terms due to nonmatching grids.

In this section we give Lemma 6.1 in which we study the classical term of error without taking into account the term on the interface Γ_{ij} due to the nonmatching grids ($\mathcal{E}_{i\to j} \neq \mathcal{E}_{j\to i}$). This lemma will be used in the next subsection to estimate the interface error and thus the global error.

LEMMA 6.1. *Assuming that p the solution of* (2.1)–(2.2) *belongs to $C^2(\overline{\Omega})$ for each domain Ω_i $(i \in \mathcal{I})$, there exists $C > 0$ depending only on p, Ω_i, d, f, g, η such that*

(6.1)

$$\begin{aligned}
&\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\Bigg(\frac{\eta}{2}meas(K)(e^i_K)^2 + \frac{1}{4}\sum_{K'\in\mathcal{N}_i(K)}\frac{(e^i_K - e^i_{K'})^2}{d(x_K,x_{K'})}meas([K,K'])\\
&\quad + \sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} a_{[K,K']}e^{i,j}_{[K,K']^+} + \frac{1}{2}\sum_{\epsilon\in\mathcal{E}_{iD}(K)}\frac{(e^i_K)^2}{d(x_K,y_\epsilon)}meas(\epsilon)\\
&\quad - \sum_{\epsilon\in\mathcal{E}_i(K)} q^i_\epsilon e^i_K meas(\epsilon) + \frac{1}{2}\sum_{\epsilon\in\mathcal{E}(K)\setminus\mathcal{E}_i(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_K\right](e^i_K)^2\Bigg)\\
&\quad \le Ch^2 + \sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\left(\sum_{\epsilon\in\mathcal{E}_i(K)} R^i_\epsilon e^i_K meas(\epsilon) + \sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} e^i_K r^{i,j}_{K,K'} meas([K,K'])\right).
\end{aligned}$$

The proof is based on standard arguments; see [3] or more generally [21].

6.2. Error analysis with interface terms.

In order to have as far as possible a common treatment of the error analysis for the two transmission operators we consider, we first derive a general estimate making the following extra assumption.

Assumption 5. There exist $\gamma_1 > 0$, $\gamma_2 > 0$, $\gamma_3 > 0$, $\gamma_4 > 0$, $\gamma_5 > 0$, and $\gamma_6 > 0$ such that $R = O(h)^{\gamma_1}$, $T = O(h)^{\gamma_2}$, $\delta e = O(h)^{\gamma_3}$, $\delta q = O(h)^{\gamma_4}$, $T_d^2 = O(h)^{\gamma_5}$, and $\delta e_d^2 = O(h)^{\gamma_6}$.

The values of the parameters γ depend on the transmission operator and will be analyzed in sections 6.3 and 6.4. To estimate the interface term due to the nonmatching grids, we need the following theorem which is proven in [15].

THEOREM 6.2. *For all $p \in X_i$, there exists $C(\Omega_i) > 0$ depending only on Ω_i and d such that*

$$\|p\|_{L^2(\partial\Omega_i)} \leq C(\Omega_i)(\|p\|_{L^2(\Omega_i)} + |p|_{1,\mathcal{T}_i}). \tag{6.2}$$

We shall also use the following formula (see [21]):

$$\sum_{K\in\mathcal{T}_i}\Big(\sum_{K'\in\mathcal{N}_i(K)} d(x_K, x_{K'})meas([K,K']) + \sum_{\epsilon\in\mathcal{E}_{iD}(K)\cup\mathcal{E}_i(K)} d(x_K, y_\epsilon)meas(\epsilon)\Big) = dmeas(\Omega_i). \tag{6.3}$$

We have the following theorem.

THEOREM 6.3. *Let us consider a family of admissible meshes $\mathcal{T}_i$ (for all $i \in \mathcal{I}$) which satisfy Assumption* 1. *We assume that the solution p of* (2.1)–(2.2) *is $C^2(\overline{\Omega})$ and that Assumptions* 2, 5, *and* 3 *are satisfied; then there exists $C > 0$ independent of h such that*

$$\big(\eta\|e\|^2_{L^2(\Omega)} + |e|^2_{1,\mathcal{T}}\big)^{1/2} \leq Ch^{\beta},$$

where $h = \max_{i\in\mathcal{I},K\in\mathcal{T}_i} diam(K)$ and $\beta = \frac{1}{2}\min(2, 2\gamma_1, \gamma_2+\gamma_3, 2\gamma_4, \gamma_5, \gamma_6)$.

Proof. Lemma 6.1 is satisfied for all $i \in \mathcal{I}$, so we sum over $i \in \mathcal{I}$ (6.1):

$$\begin{aligned}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\Bigg(&\frac{\eta}{2}meas(K)(e_K^i)^2 + \frac{1}{4}\sum_{K'\in\mathcal{N}_i(K)}\frac{(e_K^i - e_{K'}^i)^2}{d(x_K, x_{K'})}meas([K,K'])\\ &+\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} a_{[K,K']}e^{i,j}_{[K,K']^+} + \frac{1}{2}\sum_{\epsilon\in\mathcal{E}_{iD}(K)}\frac{(e_K^i)^2}{d(y_\epsilon, x_K)}meas(\epsilon)\\ &-\sum_{\epsilon\in\mathcal{E}_i(K)} q_\epsilon^i e_K^i meas(\epsilon) + \frac{1}{2}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_{\Omega_i}(K)\setminus\mathcal{E}_i(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_K\right](e_K^i)^2\Bigg)\\ \leq \sum_{i\in\mathcal{I}} C_i h^2 + \sum_{i\in\mathcal{I}}\Bigg(&\sum_{\epsilon\in\mathcal{E}_i} R_\epsilon^i e_{K(\epsilon)}^i meas(\epsilon) + \sum_{K\in\mathcal{T}_i}\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} r^{i,j}_{K,K'}e_K^i meas([K,K'])\Bigg).\end{aligned} \tag{6.4}$$

For the term $E_1 = \sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} R_\epsilon^i e_{K(\epsilon)}^i meas(\epsilon)$, we have used the Young inequality for all $C_6 > 0$:

$$\begin{aligned}E_1 &= \sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} R_\epsilon^i(e_{K(\epsilon)}^i - e_\epsilon^i)meas(\epsilon) + \sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} R_\epsilon^i e_\epsilon^i meas(\epsilon)\\ &\leq \sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} R_\epsilon^i e_\epsilon^i meas(\epsilon) + \frac{C_6}{2}\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} d(x_{K(\epsilon)}, y_\epsilon)(R_\epsilon^i)^2 meas(\epsilon)\\ &\quad+\frac{1}{2C_6}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}\frac{(e_\epsilon^i - e_K^i)^2}{d(x_K, y_\epsilon)}meas(\epsilon).\end{aligned} \tag{6.5}$$

The first right-hand-side term of (6.5) becomes, with the Young inequality for all $C_7 > 0$ and Theorem 6.2,

$$\begin{aligned} E_2 = \sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} R^i_\epsilon e^i_\epsilon meas(\epsilon) &\leq \frac{C_7}{2}\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i}(R^i_\epsilon)^2 meas(\epsilon) + \frac{1}{2C_7}\|e\|^2_{L^2(\partial\Omega_i)} \\ &\leq \frac{C_7}{2}\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i}(R^i_\epsilon)^2 meas(\epsilon) + \sum_{i\in\mathcal{I}}\frac{C(\Omega_i)}{2C_7}(\|e\|^2_{L^2(\Omega_i)} + |e|^2_{1,\mathcal{T}_i}). \end{aligned} \tag{6.6}$$

We estimate $E_3 = \sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} r^{i,j}_{K,K'} e^i_K meas([K,K'])$. For any positive constants C^1_c and C^2_c, we have

$$\begin{aligned} E_3 \leq &\frac{1}{2C^1_c}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)}\frac{(e^i_\epsilon - e^i_K)^2}{d(x_K,y_\epsilon)} meas([K,K']) \\ &+\frac{C^1_c}{2}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)} d(x_K,y_\epsilon)(r^{i,j}_{K,K'})^2 meas([K,K']) \\ &+\frac{1}{2C^2_c}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}(e^i_\epsilon)^2 meas(\epsilon) \\ &+\frac{C^2_c}{2}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)}(r^{i,j}_{K,K'})^2 meas([K,K']). \end{aligned}$$

By the Taylor expansion there exists $C > 0$ such that $|r^{i,j}_{K,K'}| \leq Ch$ so that together with (6.3), we have

$$\begin{aligned} E_3 \leq &\frac{1}{2C^1_c}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)}\frac{(e^i_\epsilon - e^i_K)^2}{d(x_K,y_\epsilon)} meas([K,K']) \\ &+\frac{C^1_c}{2}C^2h^2d\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i} meas(\Omega_j) \\ &+\frac{1}{2C^2_c}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}(e^i_\epsilon)^2 meas(\epsilon) + \frac{C^2_c}{2}C^2h^2\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i} meas(\Gamma_{ij}). \end{aligned}$$

With Theorem 6.2, we obtain

$$\begin{aligned} E_3 \leq &\frac{1}{2C^1_c}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{j\in\mathcal{V}_i}\sum_{K'\in\mathcal{N}_{ij}(K)}\frac{(e^i_\epsilon - e^i_K)^2}{d(x_K,y_\epsilon)} meas([K,K']) \\ &+\sum_{i\in\mathcal{I}}\frac{C(\Omega_i)}{2C^2_c}(\|e\|^2_{L^2(\Omega_i)} + |e|^2_{1,\mathcal{T}_i}) + \frac{C^1_c}{2}C^2h^2d\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i} meas(\Omega_j) \\ &+\frac{C_c}{2}C^2h^2\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{V}_i} meas(\Gamma_{ij}). \end{aligned} \tag{6.7}$$

For the term $T_1 = \sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)} e^i_K q^i_\epsilon meas(\epsilon)$, one has

$$\begin{aligned} T_1 &= -\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} q^i_\epsilon e^i_\epsilon meas(\epsilon) - \sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)} q^i_\epsilon(e^i_K - e^i_\epsilon) meas(\epsilon) \\ &= -\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i} q^i_\epsilon e^i_\epsilon meas(\epsilon) + \sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}\frac{(e^i_K - e^i_\epsilon)^2}{d(x_K,y_\epsilon)} meas(\epsilon) \end{aligned}$$

$$-\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}\frac{(e^i_K-e^i_\epsilon)T^i_\epsilon}{d(x_K,y_\epsilon)}meas(\epsilon).$$

Then by the Young inequality for all $C_8>0$,

$$\begin{aligned}T_1\geq{}&-\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i}q^i_\epsilon e^i_\epsilon meas(\epsilon)-\frac{C_8}{2}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}\frac{(T^i_\epsilon)^2}{d(x_K,y_\epsilon)}meas(\epsilon)\\&+\left(1-\frac{1}{2C_8}\right)\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}\frac{(e^i_K-e^i_\epsilon)^2}{d(x_K,y_\epsilon)}meas(\epsilon).\end{aligned}\tag{6.8}$$

Using the definition of the sets $\mathcal{M}_i$ and $\mathcal{S}_i$, the term $T_2=-\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i}q^i_\epsilon e^i_\epsilon meas(\epsilon)$ is rewritten as

$$T_2=-\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}}\left[q^j_ie^j_i+q^i_je^i_j\right].\tag{6.9}$$

By definition we have on Γ_{ij} for all $i\in\mathcal{I}$ and for all $j\in\mathcal{V}_i$

$$e^{i,j}_\epsilon=p^{i,j}_\epsilon-\tilde{p}^{i,j}_\epsilon=p^{i,j}_\epsilon-\mathcal{P}^{i,j}_\epsilon(p).$$

Using the interface conditions (2.18), the discrete error on the primary unknown $e^{i,j}_\epsilon$ corresponds to, for all $j\in\mathcal{M}_i$,

$$\begin{aligned}e^{i,j}_\epsilon&=\left[Q^j_i(p^i_j)\right]_\epsilon-\mathcal{P}^{i,j}_\epsilon(p)=\left[Q^j_i\left(e^i_j+\mathcal{P}^i_j(p)\right)\right]_\epsilon-\mathcal{P}^{i,j}_\epsilon(p)\\&=\left[Q^j_i\left(e^i_j\right)\right]_\epsilon+\left[Q^j_i\left(\mathcal{P}^i_j(p)\right)\right]_\epsilon-\mathcal{P}^{i,j}_\epsilon(p)=\left[Q^j_i\left(e^i_j\right)\right]_\epsilon+\Delta e^{i,j}_\epsilon\end{aligned}\tag{6.10}$$

or, in compact form, $e^j_i=Q^j_i(e^i_j)+\Delta e^j_i$. In the same way, we have for all $j\in\mathcal{M}_i$

$$q^{j,i}_\epsilon=\left[Q^i_j\left(-q^j_i\right)\right]_\epsilon+\Delta q^{i,j}_\epsilon\tag{6.11}$$

or, in compact form, $q^i_j=Q^i_j(q^j_i)+\Delta q^i_j$. From (6.9)–(6.11) and Assumption 2, we have

$$T_2=-\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}}\left[q^j_i\Delta e^j_i+\Delta q^j_ie^i_j\right].\tag{6.12}$$

By the Young inequality, for all $C_9>0$, and by definition of T^ϵ_i, we have

$$\begin{aligned}T_3={}&-\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}}q^j_i\Delta e^j_i=-\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{j\to i}}q^{i,j}_\epsilon\Delta e^{i,j}_\epsilon meas(\epsilon)\\\geq{}&-\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{j\to i}}|T^i_\epsilon||\Delta e^{i,j}_\epsilon|meas(\epsilon)-\frac{1}{2C_9}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{j\to i}}\frac{(e^i_\epsilon-e^i_{K(\epsilon)})^2}{d(x_{K(\epsilon)},y_\epsilon)}meas(\epsilon)\\&-\frac{C_9}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{j\to i}}\frac{(\Delta e^{i,j}_\epsilon)^2}{d(x_{K(\epsilon)},y_\epsilon)}meas(\epsilon).\end{aligned}\tag{6.13}$$

Using Theorem 6.2 on Ω_i, the second term becomes, with the Young inequality for all $C_{10}>0$,

$$\begin{aligned}-\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}}\Delta q^j_ie^i_j\geq{}&-\frac{1}{2C_{10}}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\|e\|^2_{L^2(\partial\Omega_j)}\\&-\frac{C_{10}}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{i\to j}}(\Delta q^{j,i}_\epsilon)^2meas(\Gamma_{ij}).\end{aligned}$$

With Theorem 6.2, we get

$$(6.14)\qquad -\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\int_{\Gamma_{ij}}\Delta q_i^j e_j^i \ \geq\ \sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\frac{C(\Omega_j)}{2C_{10}}(\|e\|^2_{L^2(\Omega_j)}+|e|^2_{1,\mathcal{T}_j}) - \frac{C_{10}}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{i\to j}}(\Delta q_\epsilon^{j,i})^2 meas(\Gamma_{ij}).$$

For the convective fluxes on the interfaces we proceed as in the proof of Theorem 4.3: we have

$$(6.15)\qquad \sum_{i\in\mathcal{I},j\in\mathcal{V}_i,K\in\mathcal{T}_i,K'\in\mathcal{N}_{ij}(K)} a_{[K,K']}e^{i,j}_{[K,K']^+}e^i_K \geq \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{\epsilon\in\mathcal{E}_i}\left[\int_\epsilon \vec{a}\cdot\vec{n}_{K(\epsilon)}\right](e^i_{K(\epsilon)})^2.$$

Let T be the convective terms of (6.4); thanks to (6.15) and $\operatorname{div}(\vec{a})\geq 0$, we have

$$T \geq \frac{1}{2}\sum_{i\in\mathcal{I}}\left(\sum_{\epsilon\in\mathcal{E}_i}\left[\int_\epsilon \vec{a}\cdot\vec{n}_{K(\epsilon)}\right](e^i_{K(\epsilon)})^2 + \sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}(K)\setminus\mathcal{E}_i(K)}\left[\int_\epsilon \vec{a}\cdot\vec{n}_K\right](e^i_K)^2\right)$$

$$(6.16)\qquad \geq \frac{1}{2}\sum_{i\in\mathcal{I}}\sum_{K\in\mathcal{T}_i}\int_K[\operatorname{div}(\vec{a})](e^i_{K(\epsilon)})^2 \geq 0.$$

So we obtain for the global error estimate, thanks to (6.4)–(6.6), (6.8), (6.13), (6.14), and (6.16),

$$\begin{aligned}
&\sum_{i\in\mathcal{I}}\left[\sum_{K\in\mathcal{T}_i}\left(\frac{\eta}{2}meas(K)(e^i_K)^2 + \frac{1}{4}\sum_{K'\in\mathcal{N}_i(K)}\frac{(e^i_K-e^i_{K'})^2}{d(x_K,x_{K'})}meas([K,K'])\right.\right.\\
&\quad+\left(1-\frac{1}{2C_6}-\frac{1}{2C_8}-\frac{1}{2C_9}\right)\sum_{\epsilon\in\mathcal{E}_i(K)}\frac{(e^i_\epsilon-e^i_K)^2}{d(y_\epsilon,x_K)}meas(\epsilon)\\
&\quad\left.\left.+\frac{1}{2}\sum_{\epsilon\in\mathcal{E}_{iD}(K)}\frac{(e^i_K)^2}{d(y_\epsilon,x_K)}meas(\epsilon)\right)\right]-\sum_{i\in\mathcal{I}}C(\Omega_i)\left(\frac{1}{2C_7}+\frac{1}{2C_{10}}\right)(\|e\|^2_{L^2(\Omega_i)}+|e|^2_{1,\mathcal{T}_i})\\
&\leq \sum_{i\in\mathcal{I}}\left[C_ih^2+\frac{C_7}{2}\sum_{\epsilon\in\mathcal{E}_i}(R^i_\epsilon)^2meas(\epsilon)+\frac{C_6}{2}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}d(x_K,y_\epsilon)(R^i_\epsilon)^2meas(\epsilon)\right.\\
&\quad\left.+\frac{C_8}{2}\sum_{K\in\mathcal{T}_i}\sum_{\epsilon\in\mathcal{E}_i(K)}\frac{(T^i_\epsilon)^2}{d(x_K,y_\epsilon)}meas(\epsilon)\right]+\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{j\to i}}|T^i_\epsilon||\Delta e^{i,j}_\epsilon|meas(\epsilon)\\
&\quad+\frac{C_9}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{j\to i}}\frac{(\Delta e^{i,j}_\epsilon)^2}{d(x_{K(\epsilon)},y_\epsilon)}meas(\epsilon)+\frac{C_{10}}{2}\sum_{i\in\mathcal{I}}\sum_{j\in\mathcal{M}_i}\sum_{\epsilon\in\mathcal{E}_{i\to j}}(\Delta q^{i,j}_\epsilon)^2meas(\epsilon).
\end{aligned}$$

We conclude the proof of Theorem 6.3 by using Assumption 5. □

We are now interested in the consistency of the diffusive fluxes. For all $\epsilon\in\mathcal{E}_i(K)$, using (2.14) and the Taylor expansion, we get

$$\begin{aligned}
T^i_\epsilon &= e^i_K - e^i_\epsilon + d(x_K,y_\epsilon)q^i_\epsilon = (p^i_K-\tilde{p}^i_K)-(p^i_\epsilon-\tilde{p}^i_\epsilon)+d(x_K,y_\epsilon)(u^i_\epsilon-\tilde{u}^i_\epsilon)\\
&= -\tilde{p}^i_K+\tilde{p}^i_\epsilon-d(x_K,y_\epsilon)\tilde{u}^i_\epsilon\\
&= -p(y_\epsilon)+d(x_K,y_\epsilon)\frac{\partial p}{\partial n_i}(y_\epsilon)+\tilde{p}^i_\epsilon-d(x_K,y_\epsilon)\tilde{u}^i_\epsilon+O(d(x_K,y_\epsilon))^2
\end{aligned}$$

$$= [\mathcal{P}^i_\epsilon(p) - p(y_\epsilon)] + d(x_K, y_\epsilon)\left[\frac{\partial p}{\partial n_i}(y_\epsilon) - \mathcal{U}^i_\epsilon\left(\frac{\partial p}{\partial n_i}\right)\right] + O(d(x_K, y_\epsilon))^2$$

$$= [\mathcal{P}^i_\epsilon(p) - p(y_\epsilon)] + d(x_K, y_\epsilon)\left[\frac{\partial p}{\partial n_i}(y_\epsilon) - \mathcal{U}^i_\epsilon\left(\frac{\partial p}{\partial n_i}\right)\right] + O(d(x_K, y_\epsilon))^2. \tag{6.17}$$

6.3. Error estimate for orthogonal L^2 projection on $P^0(\mathcal{E}_{i\to j})$. In order to give the error estimate for the transmission operators defined by (5.1), we define the interpolation error operator for all $f \in C^2(\overline{\Omega})$, $i \in \mathcal{I}$, and $j \in \mathcal{V}_i$, $\epsilon \in \mathcal{E}_{i\to j}$ as

$$\mathcal{P}^{i,j}_\epsilon(f) = [P^C_{i,j}(f)]_\epsilon = \frac{1}{meas(\epsilon)}\int_\epsilon f,$$

$$\mathcal{U}^{i,j}_\epsilon\left(\frac{\partial f}{\partial n_i}\right) = \left[Q^j_i\left(\frac{\partial f}{\partial n_i}\right)\right]_\epsilon = \left[P^C_{i,j}\left(\frac{\partial f}{\partial n_i}\right)\right]_\epsilon = \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial f}{\partial n_i}.$$

We have to estimate the transmission error of Assumption 5 due to the transmission operator (5.1) to state the following theorem.

THEOREM 6.4. *We assume that the solution p of* (2.1)–(2.2) *is $C^2(\overline{\Omega})$. Let us consider a family of admissible meshes $\mathcal{T}_i$ (for all $i \in \mathcal{I}$) which satisfy Assumption 1.*

We assume that the transmission operators are defined by (5.1)*, that the interface operators satisfy Assumption* 3*, and that $C > 0$ independent of the mesh such that*

$$\forall i \in \mathcal{I}, \forall \epsilon \in \mathcal{E}_i \quad diam(\epsilon) \le C(d(x_{K(\epsilon)}, y_\epsilon)); \tag{6.18}$$

then there exists $C_1 > 0$ such that

$$\left(\eta\|e\|^2_{L^2(\Omega)} + |e|^2_{1,\mathcal{T}}\right)^{1/2} \le C_1 h^{1/2}.$$

Moreover if for all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$, $\mathcal{E}_{i\to j}$ is a subgrid of $\mathcal{E}_{j\to i}$ (the grids of the masters are subgrids of the slaves) and $(y_\epsilon)_{\epsilon\in\mathcal{E}_i}$ are the barycenter of ϵ and there exists $C > 0$ independent of the mesh such that

$$\forall i \in \mathcal{I}, \forall \epsilon \in \mathcal{E}_i \; diam(\epsilon) \le C(d(x_{K(\epsilon)}, y_\epsilon))^{1/2}, \tag{6.19}$$

then there exists $C_2 > 0$ such that

$$\left(\eta\|e\|^2_{L^2(\Omega)} + |e|^2_{1,\mathcal{T}}\right)^{1/2} \le C_2 h.$$

Remark 6.5. The assumption that the master sides are subgrids of the slave sides allows both a weaker assumption on the mesh ((6.19) is weaker than (6.18)) and a better error estimate. This result is assessed in the numerical tests; see Figure 6.

Proof. For all $i \in \mathcal{I}$, for all $\epsilon \in \mathcal{E}_i$, we have

$$R^i_\epsilon = \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial p}{\partial n_i} - \left[\mathcal{U}_i\left(\frac{\partial p}{\partial n_i}\right)\right]_\epsilon = 0.$$

Then $R = 0$ and we can take any $\gamma_1 > 0$. Using (6.17), we get

$$\begin{aligned} T^i_\epsilon &= \left[p(y_\epsilon) - \frac{1}{meas(\epsilon)}\int_\epsilon p\right] + d(x_{K(\epsilon)}, y_\epsilon)\left[\frac{\partial p_i}{\partial n_i}(y_\epsilon) - \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial p}{\partial n_i}\right] \\ &\quad - O(d(x_{K(\epsilon)}, y_\epsilon))^2 \\ &= [O(diam(\epsilon))] + d(x_{K(\epsilon)}, y_\epsilon)O(diam(\epsilon)) - O(d(x_{K(\epsilon)}, y_\epsilon))^2 = O(h). \end{aligned}$$

It implies that $\gamma_2 = 1$. For all $\epsilon \in \mathcal{E}_{i\to j}$, we write

$$\begin{aligned}\Delta e^j_{i,\epsilon} &= \left[Q^j_i\big(\mathcal{P}^i_j(p)\big) - \mathcal{P}^j_i(p)\right]_\epsilon = \left[P^C_{i,j}P^C_{j,i}(p) - P^C_{i,j}(p)\right]_\epsilon = \left[P^C_{i,j}\big(P^C_{j,i} - I\big)(p)\right]_\epsilon \\ &= \frac{1}{meas(\epsilon)}\int_\epsilon \big(P^C_{j,i} - I\big)(p) = O\big(\max_{\epsilon'\in\mathcal{E}_{j\to i}} diam(\epsilon')\big) = O(h).\end{aligned}$$

Hence we get $\gamma_3 = 1$. For all $\epsilon \in \mathcal{E}_{j\to i}$, we have

$$\begin{aligned}\Delta q^i_{j,\epsilon} &= \left[Q^i_j\left(\mathcal{U}^j_i\left(\frac{\partial p}{\partial n_i}\right)\right) + \mathcal{U}^i_j\left(\frac{\partial p}{\partial n_j}\right)\right]_\epsilon = \left[P^C_{j,i}P^C_{i,j}\left(\frac{\partial p}{\partial n_i}\right) + P^C_{j,i}\left(\frac{\partial p}{\partial n_j}\right)\right]_\epsilon \\ &= \left[P^C_{j,i}(P^C_{i,j} - I)\left(\frac{\partial p}{\partial n_j}\right)\right]_\epsilon \\ &= \frac{1}{meas(\epsilon)}\int_\epsilon (P^C_{i,j} - I)\left(\frac{\partial p}{\partial n_j}\right) = O\left(\max_{\epsilon'\in\mathcal{E}_{i\to j}} diam(\epsilon')\right) = O(h).\end{aligned}$$

It gives $\gamma_4 = 1$. Using (6.18), we have

$$\begin{aligned}\frac{(T^i_\epsilon)^2}{d(x_{K(\epsilon)}, y_\epsilon)} &= \frac{O(diam(\epsilon))^2}{d(x_{K(\epsilon)}, y_\epsilon)} + d(x_{K(\epsilon)}, y_\epsilon)O(diam(\epsilon))^2 + O(d(x_{K(\epsilon)}, y_\epsilon))^3 \\ &+O(diam(\epsilon)) + O(d(x_K, y_\epsilon))O(diam(\epsilon))^2 + O(d(x_{K(\epsilon)}, y_\epsilon))^2 O(diam(\epsilon)) = O(h).\end{aligned}$$

We have for $T^2_d = O(h)$, so we have $\gamma_5 = 1$. Using (6.18), we obtain the following estimate:

$$\frac{(\Delta e^{i,j}_\epsilon)^2}{d(x_{K(\epsilon)}, y_\epsilon)} = \frac{O(diam(\epsilon))^2}{d(x_{K(\epsilon)}, y_\epsilon)} = O(h).$$

We get $\delta e^2_d = O$ so that $\gamma_6 = 1$. Consequently due to $\gamma_6 = 1$ we obtain $\frac{1}{2}\min(2, 2\gamma_1, \gamma_2 + \gamma_3, 2\gamma_4, \gamma_5, \gamma_6) = \frac{1}{2}$. This proves the first part of Theorem 6.4.

As for the second part of Theorem 6.4, we assume that for all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$, $\mathcal{E}_{i\to j}$ is a subgrid of $\mathcal{E}_{j\to i}$ (the grids of the masters are subgrids of the slaves). This assumption implies that for all $j \in \mathcal{S}_i$, $P^C_{i,j} = P^C_{i,j}P^C_{j,i}$ and consequently

$$\Delta e^{i,j}_\epsilon = [P^C_{i,j}(P^C_{j,i} - I)(p)]_\epsilon = 0.$$

We get $\delta e = 0$ and $\delta e^2_d = 0$. For all $\epsilon \in \mathcal{E}_i$, y_ϵ is the barycenter of ϵ and p is $C^2(\overline{\Omega})$, so we get $p(\epsilon) - \frac{1}{meas(\epsilon)}\int_\epsilon p = O(diam(\epsilon))^2$, and consequently the consistency error on the fluxes becomes

$$\begin{aligned}T^i_\epsilon &= [p(y_\epsilon) - \mathcal{P}^i_\epsilon(p)] + d(x_{K(\epsilon)}, y_\epsilon)\left[\frac{\partial p_i}{\partial n_i}(y_\epsilon) - \mathcal{U}^i_\epsilon\left(\frac{\partial p}{\partial n_i}\right)\right] - O(d(x_{K(\epsilon)}, y_\epsilon))^2 \\ &= \left[p(y_\epsilon) - \frac{1}{meas(\epsilon)}\int_\epsilon p\right] + d(x_{K(\epsilon)}, y_\epsilon)\left[\frac{\partial p_i}{\partial n_i}(y_\epsilon) - \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial p}{\partial n_i}\right] - O(h)^2 \\ &= [O(diam(\epsilon))^2] + d(x_{K(\epsilon)}, y_\epsilon)O(diam(\epsilon)) - O(h)^2 = O(h)^2;\end{aligned}$$

then $\gamma_2 = 2$. For T^2_d, we have using (6.19)

$$\frac{(T^i_\epsilon)^2}{d(x_{K(\epsilon)}, y_\epsilon)} = \frac{O(diam(\epsilon))^4}{d(x_{K(\epsilon)}, y_\epsilon)} + d(x_{K(\epsilon)}, y_\epsilon)O(diam(\epsilon))^2 + O(d(x_{K(\epsilon)}, y_\epsilon))^3 = O(h^2).$$

Then γ_1 and γ_4 are unchanged, $\gamma_2 = 2$, $\gamma_5 = 2$, and we can take any $\gamma_3 > 0$ and $\gamma_6 > 0$ (for example, $\gamma_3 = \gamma_6 = 2$), which gives

$$\frac{1}{2}\min(2, 2\gamma_1, \gamma_2 + \gamma_3, 2\gamma_4, \gamma_5, \gamma_6) = 1. \qquad \square$$

6.4. Error estimate for transmission operators with linear rebuilding. For the error estimate with transmission operators defined by (5.3) and (5.2), we assume the following geometrical additional assumption is satisfied.

Assumption 6. For all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$, the grid of the master $\mathcal{E}_{i\to j}$ is Cartesian and there exists δ independent of the mesh such that for all $\epsilon \in \mathcal{E}^2_{i\to j}$ $\max_{\epsilon' \in \mathcal{E}_{i\to j} | \epsilon' \subset \epsilon} \text{meas}(\epsilon') \le \delta \min_{\epsilon' \in \mathcal{E}_{i\to j} | \epsilon' \subset \epsilon} \text{meas}(\epsilon')$.

We define a local operator $E^j_i = (I^j_i)^T - P^C_{i,j|P^0(\mathcal{E}_{j\to i})} = (I^j_i)^T - (I^j_i)^{-1}$ and prove the following lemma.

LEMMA 6.6. *For $d = \{2,3\}$ and under Assumption 6, for all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$, I^j_i is invertible, $(I^j_i)^{-1} = P^C_{i,j|P^1_d(\mathcal{E}_{i\to j})}$, $\ker(E^j_i) = P^0(\mathcal{E}^2_{i\to j})$, and there exists $C_E(\delta) > 0$ such that $\|E^j_i\|_{L^2(\Gamma_{ij})} < C_E(\delta)$.*

Proof. From the locality of the operators, it suffices to consider $\epsilon_1, \epsilon_2 \in (\mathcal{E}_{i\to j})^2$ such that $\epsilon = \epsilon_1 \cup \epsilon_2 \in \mathcal{E}^2_{i\to j}$ and the restriction $E^j_{i,\epsilon}$ of E^j_i from $P^0(\epsilon_1) \times P^0(\epsilon_2)$ to $P^1_d(\epsilon)$. Let

$$
\begin{aligned}
e_1(y) &= 1 \qquad \text{if } y \in \epsilon_1 \cup \epsilon_2,\\
e_2(y) &= \begin{cases} -meas(\epsilon_2) & \text{if } y \in \epsilon_1,\\ \ \ meas(\epsilon_1) & \text{if } y \in \epsilon_2,\end{cases}\\
f_1 &= I^j_i(e_1) = 1,\\
f_2 &= I^j_i(e_2) = 2y - (meas(\epsilon_2) - meas(\epsilon_1))/2,
\end{aligned}
$$

and $\tilde{e}_i = e_i / \|e_i\|_{L^2(\epsilon)}$, $\tilde{f}_i = f_i / \|f_i\|_{L^2(\epsilon)}$ for $i = 1, 2$. The bases $(\tilde{e}_1, \tilde{e}_2)$ of $P^0(\epsilon_1) \times P^0(\epsilon_2)$ and $(\tilde{f}_1, \tilde{f}_2)$ of $P^1_d(\epsilon)$ are orthonormal. In these bases, the matrix of $E^j_{i,\epsilon}$ is

$$
\frac{\|f_2\|_{L^2}}{\|e_2\|_{L^2}} \left[\begin{array}{cc} 0 & 0 \\ 0 & 1 - \dfrac{(meas(\epsilon_1) + meas(\epsilon_2))^2}{3meas(\epsilon_1)meas(\epsilon_2)} \end{array} \right].
$$

Since $1 - \frac{(meas(\epsilon_1)+meas(\epsilon_2))^2}{3meas(\epsilon_1)meas(\epsilon_2)} < 0$, we have $\ker(E^j_{i,\epsilon}) = \mathbb{R}e_1 = P^0(\epsilon)$. By Assumption 6, we have that there exists $C(\delta) > 0$ independent of ϵ such that $\|E^j_{i,\epsilon}\|_{L^2(\epsilon)} \le C(\delta)$. Lemma 6.6 holds locally for $E^j_{i,\epsilon}$ and therefore globally for E^j_i.

For $d = 3$, the proof is very similar. Let us just indicate that we consider in local coordinates four faces $\epsilon_1 = [-h_1, 0] \times [-k_1, 0], \epsilon_2 = [-h_1, 0] \times [0, k_2], \epsilon_3 = [0, h_2] \times [-k_1, 0], \epsilon_4 = [0, h_2] \times [0, k_2]$ such that $\cup^4_{i=1} \epsilon_i \in \mathcal{E}^2_{i\to j}$. It is convenient to introduce (e_1, e_2, e_3, e_4) a local basis of the space of piecewise constant functions $\prod^4_{i=1} P^0(\epsilon_i)$:

$$
\begin{array}{rclcrcl}
e_1(y,z) &=& 1 \text{ on } E = \cup^4_{i=1}\epsilon_i, & & e_2(y,z) &=& \begin{cases} -h_2 & \text{on } \epsilon_1,\\ -h_2 & \text{on } \epsilon_2,\\ \ \ h_1 & \text{on } \epsilon_3,\\ \ \ h_1 & \text{on } \epsilon_4,\end{cases}\\
e_3(y,z) &=& \begin{cases} -k_2 & \text{on } \epsilon_1,\\ \ \ k_1 & \text{on } \epsilon_2,\\ -k_2 & \text{on } \epsilon_3,\\ \ \ k_1 & \text{on } \epsilon_4\end{cases} & \text{and} & e_4(y,z) &=& \begin{cases} \ \ h_2k_2 & \text{on } \epsilon_1,\\ -k_1h_2 & \text{on } \epsilon_2,\\ -k_2h_1 & \text{on } \epsilon_3,\\ \ \ h_1k_1 & \text{on } \epsilon_4.\end{cases}
\end{array}
$$

As in the case $d = 2$, let $f_i = I^j_i(e_i)$, $\tilde{e}_i = e_i/\|e_i\|_{L^2}$, and $\tilde{f}_i = f_i / \|f_i\|_{L^2}$ for $i = 1, \ldots, 4$. The theorem is proved by considering the matrix of the restriction of E^j_i in the orthonormal bases $(\tilde{e}_i)_{i=1,\ldots,4}$ and $(\tilde{f}_i)_{i=1,\ldots,4}$. □

We now define the transmission interpolations operator by

$$\mathcal{P}_\epsilon^{i,j}(f) = P_{i,j}^C(f) = \frac{1}{meas(\epsilon)}\int_\epsilon f \quad \mathcal{U}_\epsilon^{i,j}\left(\frac{\partial f}{\partial n_i}\right) = P_{i,j}^C\left(\frac{\partial f}{\partial n_i}\right) = \frac{1}{meas(\epsilon)}\frac{\partial f}{\partial n_i}$$

for all $f \in C^2(\overline{\Omega})$, for all $i \in \mathcal{I}$, for all $j \in \mathcal{M}_i$, for any $\epsilon \in \mathcal{E}_{i\to j}$ and by

$$\mathcal{P}_\epsilon^{i,j}(f) = (I_i^j)^{-1}P_{i,j}^L(f) = \frac{1}{meas(\epsilon)}P_{i,j}^L(f) \qquad \mathcal{U}_\epsilon^{i,j}\left(\frac{\partial f}{\partial n_i}\right) = (I_i^j)^T P_{i,j}^L P_{j,i}^C\left(\frac{\partial f}{\partial n_i}\right)$$

for all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$.

THEOREM 6.7. *We assume that the solution p of* (2.1)–(2.2) *is $C^2(\overline{\Omega})$. Let us consider a family of admissible meshes for all $i \in \mathcal{I}$ $\mathcal{T}_i$ which satisfies Assumptions* 1–4 *and* 6. *Assume that for all $\epsilon \in \mathcal{E}_i$ y_ϵ is the barycenter of ϵ and that there exists $C' > 0$, independent of the family of meshes, such that*

$$\forall i \in \mathcal{I}, \forall \epsilon \in \mathcal{E}_i \quad diam(\epsilon) \le C'\, d(y_\epsilon, x_K)^{1/2}. \tag{6.20}$$

We assume that the transmission operators are defined by (5.3) *and* (5.2) *and that the interface operators satisfy Assumption* 3*; then there exists $C > 0$ such that*

$$\left(\eta\|e\|^2_{L^2(\Omega)} + |e|^2_{1,\mathcal{T}}\right)^{1/2} \le Ch.$$

Proof. For all $i \in \mathcal{I}$, for all $j \in \mathcal{M}_i$, for all $\epsilon \in \mathcal{E}_{i\to j}$, we have

$$R_\epsilon^i = \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial p}{\partial n_i} - \left[\mathcal{U}_i\left(\frac{\partial p}{\partial n_i}\right)\right]_\epsilon = 0,$$

and using the fact that y_ϵ is the barycenter of $\epsilon \in \mathcal{E}_i$

$$\begin{aligned} T_\epsilon^i &= [p(y_\epsilon) - P_{i,j}^C(p)] + d(x_{K(\epsilon)}, y_\epsilon)\left[\frac{\partial p}{\partial n_i}(y_\epsilon) - P_{i,j}^C\left(\frac{\partial p}{\partial n_i}\right)\right] - O(d(x_{K(\epsilon)}, y_\epsilon))^2 \\ &= O(diam(\epsilon))^2 + d(x_{K(\epsilon)}, y_\epsilon)O(diam(\epsilon)) - O(d(x_{K(\epsilon)}, y_\epsilon))^2 = O(h)^2. \end{aligned}$$

We introduce P_{ij}^C, the $L^2(\Gamma_{ij})$ orthogonal projection on $P^0(\mathcal{E}^2_{i\to j})$. Then we have

$$\begin{aligned} R_\epsilon^i &= \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial p}{\partial n_i} - \left[\mathcal{U}_i^j\left(\frac{\partial p}{\partial n_i}\right)\right]_\epsilon \\ &= \left[P_{i,j}^C\left(\frac{\partial p}{\partial n_i}\right) - (I_i^j)^{-1}P_{i,j}^L P_{j,i}^C\left(\frac{\partial p}{\partial n_i}\right)\right]_\epsilon \\ &\quad + \left[(I_i^j)^{-1}P_{i,j}^L P_{j,i}^C\left(\frac{\partial p}{\partial n_i}\right) - (I_i^j)^T P_{i,j}^L P_{j,i}^C\left(\frac{\partial p}{\partial n_i}\right)\right]_\epsilon. \end{aligned}$$

Thanks to Lemma 6.6, we have $(I_i^j)^{-1} = P^C_{i,j|P^1_d(\mathcal{E}^2_{i\to j})}$ and by definition $E_i^j = (I_i^j)^{-1} - (I_i^j)^T$ so that

$$R_\epsilon^i = \left[P_{i,j}^C\left(\frac{\partial p}{\partial n_i} - P_{i,j}^L P_{j,i}^C\left(\frac{\partial p}{\partial n_i}\right)\right)\right]_\epsilon + \left[E_i^j P_{i,j}^L P_{j,i}^C\left(\frac{\partial p}{\partial n_i}\right)\right]_\epsilon.$$

Since $\ker(E_i^j) = P^0(\mathcal{E}^2_{i\to j})$ and $P^C_{ij} P^L_{i,j} P^C_{j,i}(\frac{\partial p}{\partial n_i}) \in P^0(\mathcal{E}^2_{i\to j})$ we get

$$\begin{aligned}
R^i_\epsilon &= \left[P^C_{i,j}\left(\left(\frac{\partial p}{\partial n_i}\right) - P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right) + P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right) - P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right)\right]_\epsilon \\
&\quad + \left[E_i^j\left[P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right) - P^C_{ij}P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right]\right]_\epsilon \\
&= \left[P^C_{i,j}\left[(I - P^C_{j,i})\left(\frac{\partial p}{\partial n_i}\right)\right]\right]_\epsilon + \left[P^C_{i,j}\left[(I - P^L_{i,j})P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right]\right]_\epsilon \\
&\quad + \left[E_i^j\left[(I - P^C_{ij})P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right]\right]_\epsilon \\
&= O(\max_{\epsilon_j \in \mathcal{E}_{j\to i}} diam(\epsilon_j)) + \left[P^C_{i,j}\left[(I - P^L_{i,j})P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right]\right]_\epsilon \\
&\quad + \left[E_i^j\left[(I - P^C_{ij})P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right]\right]_\epsilon .
\end{aligned}$$

For all $i \in \mathcal{I}$, for all $j \in \mathcal{S}_i$, for all $\epsilon \in \mathcal{E}_{i\to j}$, we denote by ϵ_2 the unique $\epsilon_2 \in \mathcal{E}_{i\to j}$ such that $\epsilon \subset \epsilon_2$. The second term gives

$$\begin{aligned}
\left[P^C_{i,j}\left[(I - P^L_{i,j})P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right]\right]_\epsilon &= \frac{1}{meas(\epsilon)}\int_\epsilon \left[(I - P^L_{i,j})P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right] \\
&\le \frac{1}{(meas(\epsilon))^{1/2}}\left\|(I - P^L_{i,j})P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right\|_{L^2(\epsilon_2)} \\
&\le \left(\frac{meas(\epsilon_2)}{meas(\epsilon)}\right)^{1/2} O(diam(\epsilon_2))^2 \\
&\le O(diam(\epsilon))^2 \text{ (thanks to Assumption 6).}
\end{aligned}$$

By the definition of E_i^j, the third term becomes

$$\begin{aligned}
&\left[E_i^j\left[(I - P^C_{ij})P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right]\right]_\epsilon \\
&\quad = \frac{1}{meas(\epsilon)}\int_\epsilon E_i^j\left[(I - P^C_{ij})P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right] \\
&\quad \le \frac{1}{(meas(\epsilon))^{1/2}}\left\|E_i^j[(I - P^C_{ij})P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right\|_{L^2(\epsilon_2)} \\
&\quad \le \frac{1}{(meas(\epsilon))^{1/2}}\|E_i^j\|_{L^2(\epsilon_2)}\left\|(I - P^C_{ij})P^L_{i,j}P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right\|_{L^2(\epsilon_2)} \\
&\quad \le \left(\frac{meas(\epsilon_2)}{meas(\epsilon)}\right)^{1/2} C_E(\delta)O(diam(\epsilon_2)) = O(h).
\end{aligned}$$

The last line comes from Lemma 6.6. Thus we have $R^i_\epsilon = O(diam(\epsilon))$.

From (6.17), we have

$$\begin{aligned}
T^i_\epsilon &= [p(y_\epsilon) - \mathcal{P}^i_\epsilon(p)] + d(x_{K(\epsilon)}, y_\epsilon)\left[\frac{\partial p_i}{\partial n_i}(y_\epsilon) - \mathcal{U}^i_\epsilon\left(\frac{\partial p}{\partial n_i}\right)\right] - O(d(x_{K(\epsilon)}, y_\epsilon))^2 \\
&= [p(y_\epsilon) - \mathcal{P}^i_\epsilon(p)] + d(x_{K(\epsilon)}, y_\epsilon)
\end{aligned}$$

$$\times \left[\frac{\partial p_i}{\partial n_i}(y_\epsilon) - \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial p}{\partial n_i} + \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial p}{\partial n_i} - \mathcal{U}^i_\epsilon\left(\frac{\partial p}{\partial n_i}\right)\right] - O(h)^2$$

$$= [p(y_\epsilon) - (I^j_i)^{-1}P^L_{i,j}(p)] + d(x_{K(\epsilon)}, y_\epsilon)\left[\frac{\partial p_i}{\partial n_i}(y_\epsilon) - \frac{1}{meas(\epsilon)}\int_\epsilon \frac{\partial p}{\partial n_i} + R^i_\epsilon\right] - O(h)^2;$$

by assumption y_ϵ is the barycenter of $\epsilon \in \mathcal{E}_i$, so

$$= [p(y_\epsilon) - (I^j_i)^{-1}P^L_{i,j}(p)] + d(x_{K(\epsilon)}, y_\epsilon)[R^i_\epsilon + O(diam(\epsilon))^2] - O(h)^2;$$

using Lemma 6.6, we get

$$= [P^C_{i,j}[I - P^L_{i,j}](p)]_\epsilon + d(x_{K(\epsilon)}, y_\epsilon)O(diam(\epsilon)) - O(h)^2$$
$$= O(diam(\epsilon))^2 + d(x_{K(\epsilon)}, y_\epsilon)O(diam(\epsilon)) - O(d(x_{K(\epsilon)}, y_\epsilon))^2 = O(h)^2.$$

Thus for all $i \in \mathcal{I}$, for all $\epsilon \in \mathcal{E}_i$, we have shown that $R^i_\epsilon = O(h)$ and $T^i_\epsilon = O(h)^2$ and consequently $\gamma_1 = 1$ and $\gamma_2 = 2$. Now we estimate δe, δq, T^2_d, and δe^2_d only for all $i \in \mathcal{I}$, for all $j \in \mathcal{M}_i$, for all $\epsilon \in \mathcal{E}_{i\to j}$:

$$\Delta e^{i,j}_\epsilon = \left[Q^j_i(\mathcal{P}^i_j(f)) - \mathcal{P}^j_i(f)\right]_\epsilon = [P^C_{i,j}I^i_jP^C_{j,i}(p)] - P^C_{i,j}I^i_jP^C_{j,i}(p) = 0 \tag{6.21}$$

and similarly

$$\Delta q^{j,i}_\epsilon = \left[(I^i_j)^T P^L_{j,i}\left(P^C_{j,i}\left(\frac{\partial p}{\partial n_i}\right)\right) + (I^i_j)^T P^L_{j,i}\left(P^C_{j,i}\left(\frac{\partial p}{\partial n_j}\right)\right)\right]_\epsilon = 0. \tag{6.22}$$

(6.21) and (6.22) allow us to take any γ_3, $\gamma_4 > 0$, for example, $\gamma_3 = 2$ and $\gamma_4 = 2$. With (6.21) and (6.20), we estimate γ_5:

$$\frac{(T^i_\epsilon)^2}{d(x_{K(\epsilon)}, y_\epsilon)} = \frac{1}{d(x_{K(\epsilon)}, y_\epsilon)}[O(diam(\epsilon))^2 + d(x_{K(\epsilon)}, y_\epsilon)O(diam(\epsilon)) - O(d(x_{K(\epsilon)}, y_\epsilon))^2]^2$$
$$= \frac{1}{d(x_{K(\epsilon)}, y_\epsilon)}[O(diam(\epsilon))^2 + d(x_{K(\epsilon)}, y_\epsilon)O(h)]^2$$
$$= \frac{O(diam(\epsilon))^4}{d(x_{K(\epsilon)}, y_\epsilon)} + O(h)O(diam(\epsilon))^2 + d(x_{K(\epsilon)}, y_\epsilon)O(h)^2 = O(h)^2.$$

Hence we have $\gamma_5 = 2$. (6.21) implies that $\frac{(\Delta e^{i,j}_\epsilon)^2}{d(x_{K(\epsilon)}, y_\epsilon)} = 0$, and so we can take, for example, $\gamma_6 = 2$. We conclude that $\min(2, 2\gamma_1, \gamma_2 + \gamma_3, 2\gamma_4, \gamma_5, \gamma_6) = 2$. □

7. Numerical results. We consider the domain $\Omega =]0,1[\times]0,1[$ with the problem defined by $\eta = 1$, $f(x,y) = x^3y^2 - 6x^2y^2 - 2x^3 + (1 + x^2 + y^2)\sin(xy)$ and $g(x,y) = x^3y^2 + \sin(xy)$. The associated analytical solution is $p(x,y) = x^3y^2 + \sin(xy)$. We have tested a two-domain decomposition and a four-domain decomposition with a corner in order to compare the following methods on nonmatching grids: TPFA [9] (or [11]), Ceres (like TPFA but a linear interpolation is done to have a consistent flux on the interface; see [24], [8], which tested only for a two-domain decomposition because of an implementation too complex when there is a corner), New Cement [3], and our two methods associated with the transmission operators (5.1) (method Constant) and (5.3) and (5.2) (method Linear). In [3], the interface conditions (3.1) and (3.2) are replaced by a more symmetric form:

$$u_i + S_i(p_i) = Q_i(-u_j + S_i(p_j)) \qquad \text{on } \Gamma_{i,j}, \tag{7.1}$$

$$u_j + S_j(p_j) = Q_j(-u_i + S_j(p_i)) \qquad \text{on } \Gamma_{i,j} \tag{7.2}$$

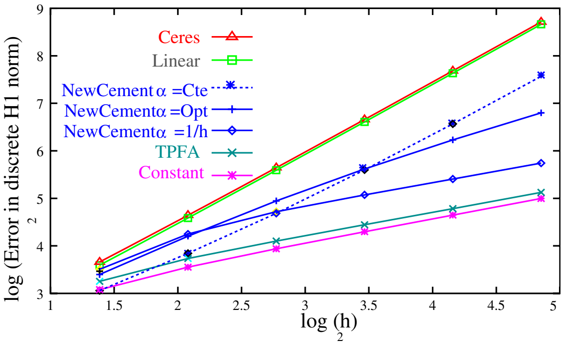

FIG. 3. *Two domains: log of the error H^1-norm vs. log of the mesh size (h).*

with the peculiarity that the solution depends on the choice of the Robin parameters in $S_{i,j}$. We study the dependency of the error estimate in discrete H^1-norm and of the number of GMRES iterations as a function of the mesh size and for Robin interface conditions corresponding to different diagonal interface operators: $S_i = \text{diag}(\alpha^i_\epsilon)$ with for all $\epsilon \in \mathcal{E}_i$ $\alpha^i_\epsilon = 1$ or $\alpha^i_\epsilon = \alpha^i_{opt,\epsilon} = O(1/\sqrt{h_i})$ or $\alpha^i_\epsilon = 1/h_i$ with h_i the size of the mesh of Ω_i.

7.1. Domain decomposition solver. The algorithm that we used is defined in detail in [23]. When no interface grid is a subgrid of the other, the Robin interface conditions (3.1) and (3.2) introduce a dependency of the interface conditions on Ω_i with the grid of the neighboring subdomain Ω_j. To cancel this dependency a subgrid based on $\mathcal{E}_{i\to j}$ and $\mathcal{E}_{j\to i}$ and new unknowns are introduced on Γ_{ij} to write arbitrary interface conditions equivalent to interface conditions (3.1) and (3.2). As a result, we get a new finite volume discretization equivalent to (2.11)–(2.13), (3.1), and (3.2), which is locally and globally well posed, but an additional interface band linear system has to be solved [23] at each domain decomposition iteration. Then the problem is formulated as a substructuring method and is solved by a GMRES algorithm.

7.2. Two-subdomain decomposition. For the decomposition into two subdomains, we use two regular Cartesian meshes on $\Omega = \Omega_1 \cup \Omega_2 =]0,1[\times]0,1[$. Figure 4 shows the solution and the error for the different methods. We see that the error is located on the interface and on the Dirichlet boundary. Figure 3 gives the asymptotic behavior of the log of the error as a function of the log of the mesh size h for the different interface operators. We observe that the solution and the error do not depend on the interface operators except for the method New Cement. This is in agreement with Theorem 3.1. For Ceres and Linear we obtain an order of 1.8 (higher than what is expected, maybe because we use regular Cartesian meshes in each subdomain). For New Cement, as predicted by theory, the order depends on the choice of α^i_ϵ ($\alpha^i_\epsilon = 1$, order 1.8; $\alpha^i_{opt,\epsilon}$, order 0.8; and $\alpha^i_\epsilon = 1/h_i$, order 0.5). For TPFA and Constant we obtain an order of 0.5 as expected.

7.3. Four-subdomain decomposition with a corner. We cut the domain $\Omega = \cup^4_{i=1}\Omega_i =]0,1[\times]0,1[$ into four subdomains with a corner. The method Ceres is not tested in this decomposition because the scheme does not extend easily to this situation. In Figure 7.3, we observe the H^1-norm of the error for the different methods and for the different interface operators. As in the decomposition into two subdomains only the error and the solution for New Cement depend on the interface

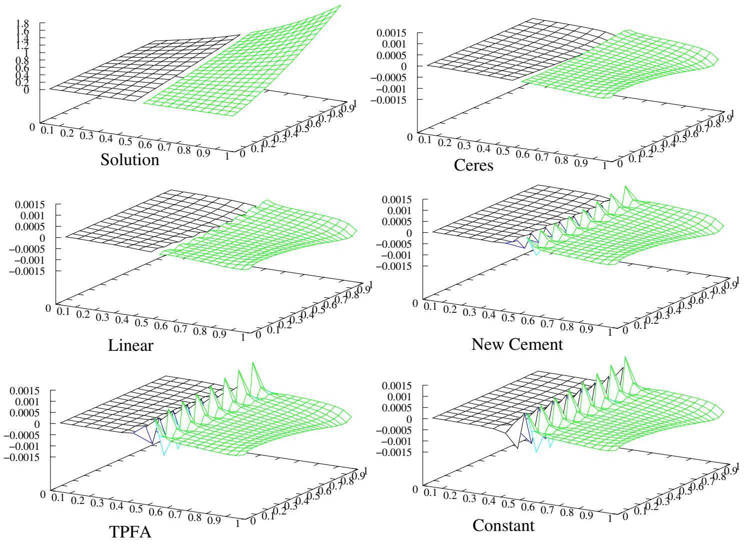

FIG. 4. *Solution $x^3y^2 + sin(xy)$ and the error for different methods for two subdomains.*

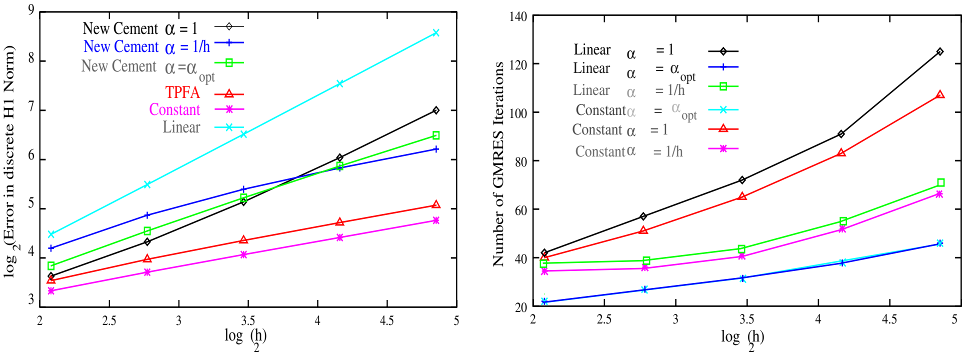

FIG. 5. *Left: Log of the error H^1-norm vs. log of the mesh size (h) for four subdomains. Right: Number of GMRES iterations vs. mesh size for different Robin coefficients for four subdomains.*

operators. For Linear we have an error order of 1.5. This is better than the error in $O(h)$ proved in Theorem 6.7. This is most probably due to the regular meshes in each subdomain which yield a superconvergence effect. For New Cement the order is 1.3 with $\alpha_\epsilon^i = 1$, 0.9 with $\alpha_{opt,\epsilon}^i$, and 0.6 with $\alpha_\epsilon^i = 1/h_i$. For TPFA and Constant we see an order of 0.5. As an illustration of the second error estimate in Theorem 6.4, we show Figure 6, which illustrates the need to have the master grid as a subgrid of the slave grid in order to have an error of order $O(h)$ when using only piecewise constant projections. Figure 7.3 represents the number of GMRES iterations for the different interface operators as a function of the log of the mesh size, and we note that the number of GMRES iterations is always the lowest for $\alpha_i = \alpha_{opt,\epsilon}^i$ as expected.

8. Conclusion. We have presented a finite volume method for a domain decomposition with nonmatching grids that allows for the use of arbitrary interface conditions. This last feature is important for a fast convergence of the iterative domain decomposition algorithm. Contrary to [5] or [3] the discrete solution does not

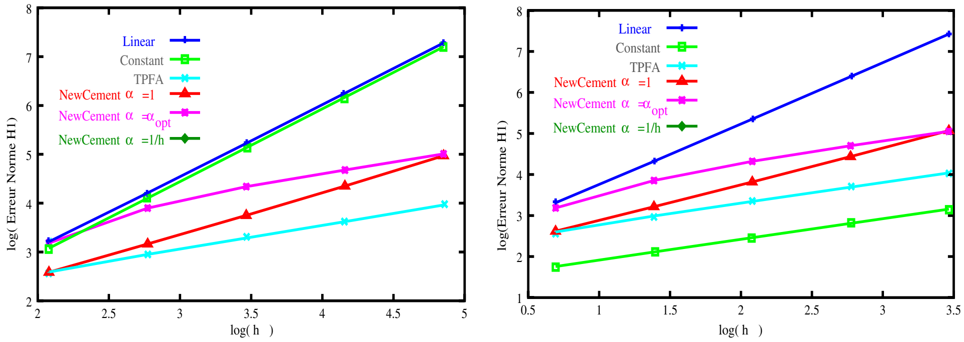

FIG. 6. *Piecewise constant projection. Left: the master grid is a subgrid of the slave. Right: the slave grid is a subgrid of the master.*

depend on the interface conditions. In practical computations in porous media flow, the diffusion operator is not a scalar nor a smooth function. It is typical to have jumps in the coefficients of diffusion of four orders of magnitude that do not match across the interface. In order to still have good results, the proposed method has to be enhanced by the introduction of a thin subdomain at each interface; see [14]. Numerical results are very satisfactory but the corresponding analysis still demands further investigation.

AN EFFICIENT AND STABLE METHOD FOR COMPUTING MULTIPLE SADDLE POINTS WITH SYMMETRIES[*]

ZHI-QIANG WANG[†] AND JIANXIN ZHOU[‡]

Abstract. In this paper, an efficient and stable numerical algorithm for computing multiple saddle points with symmetries is developed by modifying the local minimax method established in [Y. Li and J. Zhou, *SIAM J. Sci. Comput.* 23 (2001), pp. 840–865; Y. Li and J. Zhou, *SIAM J. Sci. Comput.*, 24 (2002), pp. 840–865]. First an invariant space is defined in a more general sense and a principle of invariant criticality is proved for the generalization. Then the orthogonal projection to the invariant space is used to preserve the invariance and to reduce computational error across iterations. Simple averaging formulas are used for the orthogonal projections. Numerical computations of examples with various symmetries, of which some can and others cannot be characterized by a compact group of linear isomorphisms, are carried out to confirm the theory and to illustrate applications. The mathematical features of various problems demonstrated in these examples fall into two categories: nodal solutions of saddle-point type with large Morse indices and nonradial positive solutions via symmetry breaking in radially symmetric elliptic problems. The new numerical algorithm generates these rather unstable solutions in an efficient and stable way. The existence of many unstable solutions and their behavior found in this paper remain to be investigated.

Key words. multiple saddle points, Morse index, symmetry, invariance, local minimax method, semilinear PDE

1. Introduction.

Let H be a Hilbert space and let $J : H \to \mathbb{R}$ be Fréchet differentiable; let J' be its Fréchet derivative and let ∇J be the gradient and J'' its second Fréchet derivative if it exists. A point $u^* \in H$ is a *critical point* of J if u^* solves the Euler–Lagrange equation $J'(u^*) = 0$. A critical point u^* is *nondegenerate* if $J''(u^*)$ is invertible; otherwise u^* is *degenerate*. According to the Morse theory, the *Morse index* (MI) of a critical point u^* of J is the maximal dimension of a subspace of H on which the operator $J''(u^*)$ is negative definite. The first candidates for a critical point are the local extrema to which the classical critical point theory was devoted in calculus of variations [22]. Most conventional numerical algorithms focus on finding such stable solutions. Critical points that are not local extrema are *unstable* and called *saddle points*. Because of unstable nature, saddle points are too elusive to be numerically captured.

It is interesting for both theory and applications to develop *efficient* and *stable* numerical algorithms for finding multiple saddle points. Minimax principle is one of the most popular approaches in critical point theory. However, most minimax theorems in the literature (see [1], [2], [3], [6], [16], [18], [19], [20], [21], [24]), such as the mountain pass, various linking and saddle point theorems, require one to solve a two-level *global* optimization problem and, therefore, are not useful for algorithm implementation.

Efforts for numerically computing saddle points have been made in [7] for MI = 1 and in [10] for MI = 2 which were motivated by theoretical (global minimax) characterizations of saddle points in [1] and [23], respectively. Inspired by [7], [10], and an idea in [9], [17], a local minimax method (LMM) was developed in [12], [13] and many multiple solutions were numerically computed for a class of semilinear elliptic equations. Its convergence results are obtained in [13]. Several results in instability analysis of saddle points are established in [14], [25].

Let us briefly recall LMM. Its basic idea is to define a local peak selection and a solution set. Let $L \subset H$ be a closed subspace, called a support to the critical point u^* to be found, $S_{L^\perp} = \{v \in L^\perp : \|v\| = 1\}$ and denote $[L, v] = \{tv + v_L : t \in \mathbb{R}, v_L \in L\}\,\forall v \in S_{L^\perp}$. A set-valued mapping $P\colon S_{L^\perp} \to 2^H$ is called a *peak mapping* of J if $P(v)$ is the set of all local maximum points of J in $[L, v]$. A single-valued mapping $p\colon S_{L^\perp} \to H$ is called a *peak selection* if $p(v) \in P(v)\,\forall v \in S_{L^\perp}$. Let $v \in S_{L^\perp}$ be a point. p is said to be a *local peak selection* of J with respect to (w.r.t.) L at v if a peak selection p is locally defined near v.

A local minimax theorem which characterizes a saddle point as a local minimax solution has been established in [12]. It states the following: let a solution set be defined by

$$\mathcal{M} = \{p(v) : v \in S_{L^\perp}\}; \tag{1.1}$$

then a point $u^* = p(v^*) \in \mathcal{M}$ is a saddle point of J if p is continuous at v^*, $p(v^*) \notin L$, and

$$v^* = \arg \underset{v \in S_{L^\perp}}{\text{loc-min}}\, J(p(v)) = \arg \underset{v \in S_{L^\perp}}{\text{loc-min}}\ \underset{u \in [L,v]}{\text{loc-max}}\, J(u).$$

It becomes a local minimization problem on the solution set $\mathcal{M}$, which can be numerically approximated by, e.g., the steepest descent method.

A numerical LMM.

Step 1. Given positive ε and λ, let $n-1$ critical points $w_1, w_2, \ldots, w_{n-1}$ of J be given, of which w_{n-1} has the highest critical value. Set the support $L = \operatorname{span}\{w_1, w_2, \ldots, w_{n-1}\}$. Let $v_n^1 \in S_{L^\perp}$ be an ascent direction at w_{n-1}. Let $t_0^0 = 1$ and $v_L^0 = w_{n-1}$ and set $k = 0$.

Step 2. Use the initial guess $w = t_0^k v^k + v_L^k$; solve for

$$w^k \equiv p(v^k) \equiv t_0^k v^k + v_L^k = \arg \max_{w \in [L, v^k]} J(w) \text{ and denote } t_0^k v^k + v_L^k = w^k \equiv p(v^k).$$

Step 3. Compute the steepest descent vector $d^k = -\nabla J(w^k)$.

Step 4. If $\|d^k\| \le \varepsilon$, then output $w_n = w^k$, stop; else go to Step 5.

Step 5. Set $v^k(s) = \frac{v^k + sd^k}{\|v^k + sd^k\|}$ and find

$$s^k = \max\left\{\frac{\lambda}{2^m} \,\middle|\, m \in \mathbb{N}, J\Big(p\Big(v^k\Big(\frac{\lambda}{2^m}\Big)\Big)\Big) - J(w^k) \le -\frac{t_0^*}{2}\|d^k\| \left\|v^k\Big(\frac{\lambda}{2^m}\Big) - v^k\right\|\right\}.$$

Initial guess $u = t_0^k v^k(\frac{\lambda}{2^m}) + v_L^k$, where t_0^k and v_L^k are found in Step 2, is used to find the local maximum point $p(v^k(\frac{\lambda}{2^m}))$ in $[L, v^k(\frac{\lambda}{2^m})]$, similar to Step 2.

Step 6. Set $v^{k+1} = v^k(s^k)$ and update $k = k + 1$, then go to Step 2.

The subspace L containing critical points previously found serves as a support to a saddle point u^* to be found at a higher critical level. A support to u^* is said to be *sufficient* if it contains all critical points below u^*'s critical level. When MI of u^* gets larger, the dimension of L grows larger [25]. Solving the local maximization problem in the space $[L, v^k]$ in Step 2 of LMM becomes more expensive. Since $u^* = p(v^*)$ and $v^* = \arg\max_{v \in S_{L^\perp}} J(p(v))$, the solution set $\mathcal{M}$ is a stable set, i.e., when J is restricted to $\mathcal{M}$, u^* is a stable solution.

Symmetries exist in many natural phenomena, such as in crystals, elementary particle physics, symmetry of the Schrödinger equation for the atomic nucleus and the electron shell w.r.t. permutations and rotations, energy conservation law for systems which are invariant w.r.t. time translation, etc. Symmetry properties are usually studied by group actions in mathematics. Symmetries described by compact group actions in variational problems have been used in the literature to prove the existence of *multiple critical points*, typically in the Ljusternik–Schnirelman theory (see recent results in [5], [15], [11], and others). It is known that symmetries in a nonlinear variational problem can lead to the existence of more solutions of saddle type and can also cause degeneracy. In this paper, we study the impact of the presence of symmetries on LMM in finding multiple saddle points. By modifying LMM, we shall develop an efficient and stable numerical algorithm for computing multiple critical points with general symmetries. Consider a semilinear elliptic BVP and its energy function J,

$$\begin{cases} \Delta u(x) + F(u(x), x) = 0, & x \in \Omega \subset R^n, \\ u(x) = 0, & x \in \partial\Omega, \end{cases} \qquad J(u) = \int_\Omega \left\{ \frac{1}{2}|\nabla u(x)|^2 - f(u(x), x) \right\} dx,$$

where $f(t, x) = \int_0^t F(\tau, x) d\tau$ satisfies some standard conditions. When $L = \{0\}$, the solution set becomes $\mathcal{M} = \{t_u u : u \in H, \|u\| = 1, t_u \neq 0, \langle \nabla J(t_u u), u\rangle = 0\}$, which is called the Nehari manifold. Under some standard conditions, it can be shown that $\mathcal{M}$ is smooth, or the peak selection p is continuously differentiable [12].

Several researchers have tried to use certain symmetry of a problem to capture a solution of higher MI. For example, odd symmetry is used in [7] to capture sign-changing solutions (MI = 2) by a minimization on the Nehari manifold with an odd symmetric initial guess. When a negative gradient-type minimax algorithm is used, the symmetry is inherited but not enforced, and the sequence generated by the algorithm will get close to a saddle point. However, when computational error builds up or $\|\nabla J(u)\|$ becomes small, computational error will dominate and break the symmetry of $\nabla J(u)$. Eventually the symmetry of the sequence collapses. Therefore, the sequence will not stop near a sign-changing solution; instead it will slide down to a positive solution (MI = 1), unless a forcing stop action is taken. Thus such an approximation is unstable and no convergence can be established. Even rotational symmetry is considered in [8] to capture sign-changing solutions (MI = 3) by a high-linking algorithm. Action to preserve the symmetry is taken, so the algorithm is stable.

In this paper, we consider more general symmetries and try to establish some mathematical justifications. In particular, we are concerned with not only preserving the symmetry but also reducing computational error across iterations. There are at least three motivations for one to use symmetries to define an invariant space H_I in computing a saddle point:

(1) a sufficient support is available in H, but one wants to reduce its dimension by using a sufficient support L in H_I to enhance the efficiency of the algorithm;
(2) no sufficient support is available in H; one has to use the symmetries to find a sufficient support L in H_I;
(3) to use symmetries to bypass the degeneracy of a problem.

To find a critical point u^* at a higher critical level by LMM, one needs to know if the support L is sufficient or not. If the answer is yes, one can expect a stable convergence even without using any symmetry. If the answer is no, the minimization process will sooner or later find a slider and bypass u^*. The algorithm becomes unstable and fails to reach u^*.

Assume one has identified symmetries of a problem and defined an invariant subspace H_I. Then one can restrict the problem in H_I, i.e., the support L contains critical points at lower critical level only in H_I. By doing so, the dimension of the support L can be greatly reduced. Since LMM with an insufficient support in H_I is unstable, we assume the support L in H_I is sufficient. When computational error builds up or $\|\nabla J(w^k)\|$ becomes small, computational error will dominate and break the symmetry of $\nabla J(w^k)$. That is, $\nabla J(w^k)$, eventually w^{k+1} goes outside of H_I. There are two possibilities. If the support L in H_I is also sufficient in H, there is no slider around u^*. Thus the symmetry has no effect on the algorithm and, therefore, the collapse of the symmetry has no effect either; the algorithm will still converge to u^*. If the support L in H_I is not sufficient in H, and w^{k+1} is outside H_I, the minimization process will sooner or later find a slider and then fail to reach u^*. A projection of $\nabla J(w^k)$ onto H_I will pull $\nabla J(w^k)$ and then w^{k+1} back to H_I and resolve the problem.

These types of projections into an invariant space have been used in the literature to preserve the symmetry, where computational error is not a concern. In this case any projection operator onto H_I will serve the purpose. However, computational error is a main concern in numerical computation, particularly in multilevel iterations for finding unstable saddle points at a higher critical level, which is rather sensitive to computational error. It is, therefore, a main concern of this paper. There are infinitely many projection operators onto H_I. Some of them are poor at handling computational error. Only the orthogonal projection operator onto H_I is the optimal one to handle computational error. Thus in this paper, we look for the orthogonal projection operator onto H_I. It is known that finding an orthogonal projection onto a subspace is equivalent to an infinite-dimensional minimization problem, which is very expensive. It is in particular very difficult, since there is no explicit expression for H_I. The average formula defined by the Haar integral has been used in the literature to project a point onto an invariant subspace. Here we expose a fact that the Haar integral operator is actually the orthogonal projection operator onto H_I. Implementation of this formula with LMM for numerical computations of multiple critical points with symmetries at higher critical levels will be discussed in detail by using typical numerical examples.

The numerical examples we choose also serve to reveal new phenomena in the corresponding mathematical problems. Here we are mainly interested in two directions: nodal solutions of saddle-point type for nonlinear elliptic problems and nonradial positive solutions in radially symmetric elliptic equations. In both cases, people expect that many unstable solutions exist, that these solutions should have large MIs, and that degeneracy occurs in general. Using LMM with symmetry we shall not only demonstrate solutions that are known to exist in theory but also exhibit many cases for which the existence is still open in theory. Some of these examples give surprising, new mathematical features and should shed light on the study of the nonlinear elliptic PDEs.

2. Invariant space and its orthogonal projection.

2.1. Invariant spaces and LMM in invariant spaces. In order to let LMM handle symmetry we need the concept of invariant spaces. The following is a more general one without reference to symmetry.

DEFINITION 2.1. *Let H be a Hilbert space and $J \in C^1(H,R)$. A closed subspace H_I of H is said to be a J-invariant space if for every $u \in H_I$ it holds that $\nabla J(u) \in H_I$.*

Along the line of the classical principle of symmetric criticality by Palais, we have the following principle of invariant criticality (PIC) without reference to symmetry.

THEOREM 2.1. *Let H be a Hilbert space, $J \in C^1(H,R)$ and H_I a J-invariant space. If $u^* \in H_I$ is a critical point of J restricted to H_I, then u^* is a critical point of J in H.*

Proof. That u^* is a critical point of J restricted to H_I implies $\langle \nabla J(u^*), v\rangle = 0\ \forall v \in H_I$, i.e., $\nabla J(u^*) \perp H_I$. On the other hand, H_I is a J-invariant space, i.e., $u^* \in H_I$ implies $\nabla J(u^*) \in H_I$. Therefore, $\nabla J(u^*) \in H_I \cap H_I^{\perp} = \{0\}$. □

Thus we can restrict solving the problem only in H_I. It is clear that H is trivially a J-invariant space. Since the smaller the dimension of H_I is, the smaller the MI of u^* relative to H_I is—which implies that the smaller the dimension of the support L [25] in H_I is, the more efficient and stable is the numerical computation—we always look for the smallest such J-invariant space. In this way, LMM can be used, in a much more efficient and stable way, to find multiple saddle points with certain symmetries at higher critical level.

Let L be a closed subspace of H_I and denote $S_{L^\perp} = \{v \in H_I : \|v\| = 1, v \perp L\}$. Let $k = 0$; started from a point $v^k \in S_{L^\perp}$ we have $p(v^k) = t^k v^k + v_L^k \in H_I$ for some $t^k \neq 0$ and $v_L^k \in L \subset H_I$. Then $d^k = -\nabla J(p(v^k)) \in H_I$ and $v^{k+1} = \frac{v^k + s^k d^k}{\|v^k + s^k d^k\|} \in H_I$, where $s^k > 0$ is the stepsize. If $v^0 \in H_I$ and $d^k = -\nabla J(p(v^k)) \neq 0$, we have [12]

$$J(p(v^{k+1})) - J(p(v^k)) < -\frac{t^k}{2}\|d^k\|\|v^{k+1} - v^k\|.$$

This brings us to the conclusion that, in theory, LMM is closed in an invariant space H_I and generates a strict minimizing sequence $\{p(v^k)\} = \{t^k v^k + v_L^k\}$ in $\mathcal{M} \cap H_I$, where $\mathcal{M}$ is the solution set defined in (1.1). The limit of the sequence is a critical point of J in H_I by the convergence results in [13] and thus a critical point of J in H by PIC. However, in numerical computation of the negative gradient $d^k = -\nabla J(p(v^k))$, it involves discretization, approximation, round-off error, etc. It generates numerical error and then breaks the invariance of d^k. To preserve the invariance, we use the decomposition $H = H_I \oplus H_I^c$ for some complement space H_I^c of H_I in H and

$$d^k = d_I^k + (d^k)_I^c, \quad d_I^k \in H_I, \quad (d^k)_I^c \in H_I^c.$$

Note that if $p(v^k) \in H_I$ and $d^k = -\nabla J(p(v^k))$ is computed exactly, we should have

$$d^k = (d^k)_I \in H_I \quad \text{and} \quad (d^k)_I^c = 0.$$

When numerical error is involved, we use $(d^k)_I$ to replace d^k in Step 3 of LMM, the updated point v^{k+1} is now in H_I, and the invariance is preserved.

The above decomposition for H needs to find a projection operator T from H to H_I. There are infinitely many such projection operators. If preserving the invariance is the only concern, by PIC, any one of them will serve the purpose. However, when error analysis is concerned, the case is different. Note that the term $(d^k)_I^c = d^k - (d^k)_I$ represents computational error. In numerical computation, we have to not only preserve the invariance, but also reduce error which will be carried to the next iteration. Among all those projection operators, some of them are very poor at dealing with error and there is the optimal one that minimizes the distance from d^k to H_I, the error term, that is, the orthogonal projection. In this case, the maximum invariant part of d^k has been carried to $(d^k)_I$ and $(d^k)_I^c$ becomes $(d^k)_I^\perp$, i.e.,

$$d^k = (d^k)_I + (d^k)_I^\perp \quad \text{and} \quad (d^k)_I \perp (d^k)_I^\perp .$$

For this reason, in this paper we will do our best to adopt the orthogonal projection.

EXAMPLE 2.1. *Let $X = R^2$, $X_2 = \{(0, x_2)^T\}$. Both $A = \left[\begin{smallmatrix} 0 & 0 \\ 100 & 1 \end{smallmatrix}\right]$ and $B = \left[\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right]$ are projection operators of X onto X_2. Let $(\epsilon_1, \epsilon_2)^T$ represents computational error in computing $(0,1)^T \in X_2$; we get $u = (\epsilon_1, \epsilon_2 + 1)^T \notin X_2$. To do projection, we have*

$$Au = (0, 100\epsilon_1 + 1 + \epsilon_2)^T \in X_2 \quad \textit{and} \quad Bu = (0, 1 + \epsilon_2)^T \in X_2.$$

It is clear that A greatly enlarges error while B does not. As a matter of fact, where error analysis is concerned, B is the optimal operator that minimizes error, i.e., B is the orthogonal projection operator from $X \to X_2$ and Bu is the best approximation one can get.

2.2. Invariant spaces from symmetries. Invariant spaces appear naturally when the problems considered possess certain symmetry, e.g., when the function J is invariant w.r.t. certain symmetry. There are two usual ways in numerical computations to preserve symmetry. By dividing the domain into several subdomains along the axes of symmetry, one may solve the problem only on one subdomain with an additional continuity condition with the Neumann data across the cuts; the problem may become much harder to solve, but the size of the problem becomes smaller; one may also solve the problem on the entire domain, but use the solution data only on one subdomain. Then in either case, one can produce a solution on the entire domain according to the symmetry. Note that either way, it preserves the symmetry, but carries computational error with the solution to the next iteration. Indeed it forces computational error to be of the same symmetry. However, computational error is usually asymmetric and even random.

In contrast to the usual method, our new method separates a solution from computational error (at least the asymmetric part), and then carries only the solution, not the error, in iterations. Thus the advantage is clear that it makes the algorithm more efficient and more stable. Our numerical examples confirm the analysis.

Let us start with the most studied symmetries in the literature, i.e., those symmetries that can be characterized by a compact group of linear isomorphisms.

Let H be a Hilbert space and G be a compact group of linear isomorphisms of H, i.e., the map from $G \times H \to H$ evaluated by $(g, u) \to gu$ is continuous such that for each $h \in G$,

$$1 \cdot u = u, \quad (gh)u = g(hu), \quad u \to gu \quad \text{is linear}, \quad \|gu\| = \|u\|.$$

The identification of G as a subgroup of linear isomorphisms of H is called a representation of G, and we shall still use G to stand for a representation of it.

For a representation of G we may define its invariant subspace. A set $A \subset H$ is G-invariant if $g(A) = A \, \forall g \in G$. The *$G$-invariant subspace* of H is the subspace $H_G = \{u \in H : gu = u \, \forall g \in G\}$. Let $J \in C^1(H, R)$. J is said to be G-invariant if $J(gu) = J(u)$ for every $(g, u) \in G \times H$. A map $F : H \to H$ is G-equivariant if $g \circ F = F \circ g$ for every $g \in G$. Since $J \in C^1(H, R)$ is G-invariant implies that ∇J is G-equivariant, i.e., $\nabla J(gu) = g \nabla J(u) \; \forall u \in H$, when $u \in H_G$, we have $g \nabla J(u) = \nabla J(gu) = \nabla J(u) \; \forall g \in G$ or $\nabla J(u) = \nabla J(u)_G$.

The above definition for an invariant space separates the space H from the function J, which may have other applications. On the other hand, Definition 2.1 combines the space H with the function J in the definition of a J-invariant space, which serves precisely the purpose of applications in this research. It is clear that if J is G-invariant, then H_G is a J-invariant space as in Definition 2.1. Thus the following classical result follows from Theorem 2.1.

THEOREM 2.2 (principle of symmetric criticality (Palais, 1979)). *Let H be a Hilbert space and G a compact group of linear isomorphisms of H. If $J \in C^1(H, R)$ is G-invariant and if $u \in H_G$ is a critical point of J restricted to H_G, then u is a critical point of J.*

2.3. Orthogonal projections. Note that the invariant space H_G is usually infinite-dimensional and in particular does not have an explicit formula; finding the orthogonal projection of d^k onto H_G is very expensive and difficult. However, for many usual symmetries, the orthogonal projection onto H_G turns out to be simple algebraic computations. Let us first cite the following theorem.

THEOREM 2.3 (Haar, 1933). *Let G be a compact group and $C(G)$ the vector space of real-valued continuous functions on G. Then there exists a unique positive integral (the Haar integral) such that the map $C(G) \to R$ by $f \mapsto \int_G f(g)\,dg$ is*

(a) *linear, monotone, and normalized ($\int_G 1\,dg = 1$);*

(b) *left-invariant, i.e., $\int_G f(h^{-1}g)\,dg = \int_G f(g)\,dg\,\forall h \in G$.*

The Haar integral operator $\mathcal{H}$ from H to H_G defined by $\mathcal{H}u = \int_G gu\,dg\,\forall u \in H$ has been used in the literature as a projection from H onto H_G to preserve an invariance, where computational error is not a concern. When reducing computational error across iterations is a concern, we are interested mainly in the orthogonal projection onto H_G. Since for $u, v \in H$,

$$\begin{aligned}\langle \mathcal{H}u, \mathcal{H}v\rangle &= \int_G \langle gu, \mathcal{H}v\rangle\,dg = \int_G \langle u, g^*\mathcal{H}v\rangle\,dg\\ &= \int_G \langle u, \mathcal{H}v\rangle\,dg = \langle u, \mathcal{H}v\rangle,\end{aligned}$$

we have $\langle u-\mathcal{H}u, v\rangle = \langle u-\mathcal{H}u, \mathcal{H}v\rangle = 0\,\forall v \in H_G$, i.e., $\mathcal{H}$ turns out to be the orthogonal projection operator from H onto H_G and $u = \mathcal{H}u + (u - \mathcal{H}u)$ is the orthogonal direct sum.

2.4. Examples. We give some examples that will be used in our numerical computations.

EXAMPLE 2.2. *Let H be a Hilbert space with inner product $\langle , \rangle$ and G a finite group of linear isomorphisms of H with m elements. Then for each $u \in H$, the Haar integral operator on u is given by $\mathcal{H}u = u_G = \frac{1}{m}\sum_{g \in G} gu \in H_G$ and $u_G^\perp = u - u_G \in H_G^\perp$.*

EXAMPLE 2.3. *Let $\Omega \subset R^n$ $(n \geq 1)$ be a bounded open set and $H = W^{k,2}(\Omega)$, where $k \geq 0$ be the Sobolev space. Let $\mathcal{O}(n)$ be the set of all orthogonal matrices in $R^{n\times n}$. $\mathcal{O}(n)$ is a compact group. Let G be the set of all orthogonal matrices $g \in \mathcal{O}(n)$ such that $g(\Omega) = \Omega$. For each $g \in G$ and $u \in H$, let $gu(x) = u(gx)\,\forall x \in \Omega$; then G is a compact group of linear isomorphisms of H. The Haar integral operator $\mathcal{H}$ defines the orthogonal projection operator from H onto H_G. Indeed, if g is represented by an orthogonal matrix, then g is an isomorphism of H, or in other words, the inner* *product is g-invariant, i.e.,*

$$\begin{aligned}\langle gu, gv\rangle &= \int_\Omega \sum_{|\alpha|\le k} (D^\alpha u(gx))^T (D^\alpha v(gx))\,dx \\ &\quad (\textit{by substituting } y = gx \textit{ and } g(\Omega) = \Omega, g^T g = I) \\ &= \int_\Omega \sum_{|\alpha|\le k} (D^\alpha u(y))^T (g^T)^\alpha (g)^\alpha (D^\alpha v(y))|g|\,dy = \langle u, v\rangle \quad \forall u, v \in H.\end{aligned}$$

Example 2.4. *Let $\Omega \subset R^n$ be a bounded open domain. Assume that Ω is symmetric about the reflections w.r.t. the first $n-1$ axes. Let $H = W^{k,2}(\Omega)$. Define $g : H \to H$ by $(gu)(x_1, \dots, x_{n-1}, x_n) = -u(-x_1, \dots, -x_{n-1}, x_n)$. Then $G = \{id, g\} \cong \mathbb{Z}_2$.*

Example 2.5. *Let $\Omega \subset R^2$ be a bounded open domain. Let $m > 1$ be an integer. For each point $x = (r, \theta) \in \Omega$ denote $gx \equiv g(r, \theta) = (r, \theta + \frac{2\pi}{m})$ and $\bar h x \equiv \bar h(r, \theta) = (r, -\theta)$, i.e., for $\alpha = \frac{2\pi}{m}, g = \left[\begin{smallmatrix}\cos(\alpha) & -\sin(\alpha)\\ \sin(\alpha) & \cos(\alpha)\end{smallmatrix}\right]$ and $\bar h = \left[\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right]$. Let $g(\Omega) = \Omega$, $\bar h(\Omega) = \Omega$ and $H = W^{1,2}(\Omega)$ be the Sobolev space of functions on Ω with the inner product $\langle u, v\rangle = \int_\Omega (\nabla u \cdot \nabla v + uv)\,dx$. Let $\mathbf{eo} = \pm 1$ be fixed. For each $u \in H$, we define*

$$g(u)(x) = u(gx) \quad \textit{and} \quad h(u)(x) = \mathbf{eo}(\bar h x).$$

It is clear that g represents a rotation and h represents an even ($\mathbf{eo} = 1$) or an odd ($\mathbf{eo} = -1$) reflection. The inner product is invariant under both linear operators g and h. To see this let f denote the operator g or h and the matrix g or $\bar h$. We have $f^T f = I$, and thus

$$\begin{aligned}\langle fu, fv\rangle &= \int_\Omega (\nabla u(fx)^T f^T f \nabla v(fx) + u(fx)v(fx))\,dx \\ &\quad (\textit{substituting } y = fx \textit{ and note } f(\Omega) = \Omega, |f| = 1) \\ &= \int_\Omega (\nabla u(y)\nabla v(y) + u(y)v(y))|f|\,dy = \langle u, v\rangle.\end{aligned}$$

We have a finite group $G = \{g, g^2, \dots, g^m, hg, hg^2, \dots, hg^m\}$ of linear isomorphisms of H which has two generators g and h. The invariant subspace H_G of H is defined by

$$H_G = \{u \in H : g^i u = u \;\; \textit{and} \;\; hg^i u = u\, \forall i = 1, 2, \dots, m\}.$$

For each $u \in H$, the Haar integral operator on u is given by

$$\mathcal{H}u = u_G \equiv \frac{1}{2m}\left(\sum_{i=1}^m g^i u + \sum_{i=1}^m hg^i u\right) \in H_G \quad \textit{and} \quad u_G^\perp \equiv u - u_G \in H_G^\perp.$$

There are symmetries that cannot be defined by a compact group of linear isomorphisms of H, such as composite symmetries involving partially defined symmetries. We may identify those symmetries by using several projections, among which the first one is orthogonal with which computational error is expected to be minimized.

Example 2.6. *Let $\Omega = [-a, a] \times [-a, a]$ in R^2 and $H = H_0^1(\Omega)$. We are interested in finding a critical point u^* with the following symmetries. The profile of u^* is even symmetric about the line $y = -x$, even symmetric about the x-axis for points (x, y) with $0 \ge y \ge -x \ge -a$, and even symmetric about the y-axis for points (x, y) with*

$0 \geq -x \geq y \geq -a$. To define the invariant space, we combine two projection operators $T = T_2 \cdot T_1$, where

$$\begin{cases} (T_1u)(x,y) = \frac{1}{2}(u(x,y) + u(-y,-x)), \\ \qquad (x,y) \in \Omega, \end{cases} \quad (T_2u)(x,y) = \begin{cases} u(x,-y), & 0 \geq y \geq -x, \\ u(-x,y), & 0 \geq -x \geq y, \\ u(x,y) & \textit{otherwise.} \end{cases}$$

T_1 is an orthogonal projection from H to H_{T_1} with which computational error is minimized and T_2 is a projection from H_{T_1} to H_T. Note that T_2 can map H to outside of H. However, T_2 projects H_{T_1} into H. Thus $T = T_2 \cdot T_1$ projects H into $H_T \subset H$.

Remark 2.1. When certain symmetries cannot be described by a compact group of linear isomorphisms, such as the case in Example 2.6, it is difficult to analytically verify whether or not a point u having the symmetries will imply that $\nabla J(u)$ has the same symmetries. But it can be numerically checked as follows. Let T represent the projection operator onto H_I. The term $\nabla J(u) - T(\nabla J(u))$ represents the asymmetric part of $\nabla J(u)$ together with the computational error. Let ε represent the order of the computational error. If $\|\nabla J(u) - T(\nabla J(u))\| \approx \varepsilon \|\nabla J(u)\|$, it means that the asymmetric part is caused by the computational error, not the asymmetric part of $\nabla J(u)$. Thus $\nabla J(u)$ has the same symmetries. Otherwise $\nabla J(u)$ does not have the same symmetries.

3. Numerical examples. In this section, we present several typical examples to illustrate the theory and numerical algorithm. Each of these examples has its own feature in symmetry and other properties. These examples also exhibit two types of mathematical phenomena. The first is about symmetry breaking in terms of some parameters of the problems. In general, for the problems with the full radial symmetry in $\mathbf{R}^n$, there is always a radial solution for all parameters. When we vary the parameters the problems may or may not have nonradial solutions. If nonradial solutions appear, we say symmetry breaking occurs. We demonstrate this feature by using autonomous equations with the Dirichlet boundary condition (the Lane–Emden equation) on thin annular domains as well as for the Henon equation in ball domains. For the existence of these solutions, some have been proved theoretically and others are still open (see [5], [4] for more references of theoretical studies). These nonradial solutions tend to have higher energy and possess large MIs. The second is about nodal solutions (sign-changing solutions) for nonlinear Dirichlet problems. Again these solutions tend to have higher energy and large MIs. The existence of most of these solutions are still open (see [11] for more references of theoretical studies on nodal solutions). As these examples show our new numerical algorithm is very powerful in dealing with multiple saddle points with large MIs and is very efficient and stable in dealing with the presence of symmetries.

To find a saddle point of J, when H is replaced by a J-invariant space H_I in LMM, whether or not the algorithm is stable depends on whether or not the support L in H_I is sufficient. We will pay special attention to the case where $L = \{0\}$, the smallest possible support. So we have tried to explore the symmetries of a problem to the maximum. It is known that when $L = \{0\}$, our solution set coincides with the Nehari manifold in H_G defined by

$$\mathcal{M} = \{t_u u : u \in H_G, \|u\| = 1, t_u \neq 0, \langle \nabla J(t_u u), u \rangle = 0\}.$$

Under some standard conditions, it can be shown [12] that $\mathcal{M}$ is smooth and the peak selection p is unique and C^1, which gives us a great advantage to show the convergence of LMM [13].

Let $\Omega \subset R^2$ be a bounded open domain. Consider the Henon equation ($p = 3, q \geq 0$)

$$\Delta u(x) + |x|^q u^p(x) = 0, \quad x \in \Omega, \quad u(x) = 0, \quad x \in \partial\Omega. \tag{2.0}$$

When $q = 0$, (2.0) reduces to the Lane–Emden equation. When $q > 0$, due to an explicit dependency on x, the well-known Gidas–Ni–Nirenberg theorem on symmetry does not apply. Thus it is interesting to examine the symmetry breaking phenomena.

Though the abstract theory asserts the invariance under general conditions of the group action, we demonstrate as an example for the Henon equation how to verify this for certain symmetries. We show here if u has a symmetry, then $\nabla J(u)$ possesses the same symmetry, where J is the corresponding functional to the Henon equation. Let $G \subset \mathcal{O}(n)$ be a closed subgroup, and Ω is invariant under the action of G. Let $\lambda_1 < \lambda_2 < \lambda_3 < \cdots$ be the eigenvalues of $-\Delta$ with Dirichlet boundary condition and E_i the eigenspace corresponding to λ_i. Then for $u \in E_i$, $-\Delta u = \lambda_i u$. It follows from this that for $g \in G$ we also have $-\Delta gu = \lambda_i gu$. That is, E_i is invariant subspace under G. This means H_G, the invariant space of group G, and $H_G^\perp$ are both generated by G-invariant eigenspaces. Now it is easy to verify that

$$(\nabla J(u), v) = \int_\Omega \nabla(u - (-\Delta)^{-1}|x|^q u^p)\nabla v \, dx,$$

which implies $\nabla J(u) = u - (-\Delta)^{-1}|x|^q u^p$. Assume $u \in H_G$ is in the G-invariant subspace. Then $|x|^q u^p \in H_G$ and we have $\nabla J(u) \in H_G$ if and only if $w = (-\Delta)^{-1}|x|^q u^p \in H_G$. Let $w = w_G + w_G^\perp$ with $w_G \in H_G$ and $w_G^\perp \in H_G^\perp$. Since w solves for $-\Delta w = |x|^q u^p \in H_G$ we have $-\Delta w_G^\perp = 0$. Thus $w_G^\perp = 0$ and $w \in H_G$. This gives $\nabla J(u) \in H_G$.

In the examples we consider four types of domains:

(a) $\Omega_s = [-1, 1] \times [-1, 1]$, (c) $\Omega_d = \{(x, y) \in R^2 : x^2 + y^2 \leq 1\}$,
(b) $\Omega_r = [-1.5, 1.5] \times [-1, 1]$, (d) $\Omega_a = \{(x, y) \in R^2 : 0.7 \leq \sqrt{x^2 + y^2} \leq 1\}$.

Domains Ω_s and Ω_r are used to exploit the structure of nodal solutions which are saddle points with large MIs. Domains Ω_d and Ω_a are discs and annulars which will be used to demonstrate symmetry breaking phenomena and to find nonradial positive solutions while radial positive solutions always exist. Disks and annular domains are the most symmetric domains in R^2, i.e., they are invariant under the full $\mathcal{O}(2)$ symmetry. But the symmetry causes degeneracy, due to the fact that a rotation of a nonradial solution about any angle is still a solution. Thus the solutions are not isolated in the whole space H. When symmetry is properly used to define an invariant space H_I, a solution in H_I can be isolated.

It is known that on a disk, the Lane–Emden equation has a unique positive solution as the ground state which is radially symmetric and has a single peak; while the Henon equation, in addition to the radially symmetric positive solution which has the highest critical level among all other positive solutions if exist, may have a nonradially symmetric positive solution. The existence of a nonradial solution to the Henon equation depends on the parameter q, which is a typical symmetry breaking phenomenon. There may have multipeak positive solutions. The number of peaks that a positive solution may have depends on the parameter q. This may be considered a bifurcation problem with parameter q. Because of high critical level, the

radially symmetric positive solution is the most unstable and, therefore, most elusive to capture among all positive solutions by LMM, since it will never get a sufficient support, unless one uses the radial symmetry to convert it into solving an ordinary differential equation. However, the method developed in this paper can easily capture this radially symmetric solution.

We point out that for a numerical computation using symmetry to be successful, it is important that its discretized mesh points must match the symmetry. In the numerical examples, $\varepsilon < 10^{-4}$ is used to terminate iterations, an initial guess v_0^1 is obtained from solving

$$\Delta v(x) = c(x), \quad x \in \Omega, \qquad \text{and} \qquad v(x) = 0, \quad x \in \partial\Omega,$$

where $c(x)$ is equal to -1 $(+1)$ if one wants $v(x)$ to be convex down (up) at x and is

equal to 0 if the profile of $v(x)$ is not of concern at x, and $L = \{0\}$, i.e., the smallest possible invariant subspace is used unless it is otherwise specified. In all the figures, J is the critical value. Figures 1, 2, and 3 are solutions to the Lane–Emden equation and we mainly want to demonstrate a variety of nodal solutions which are saddle points having large MIs. Figure 4 contains two positive solutions of the Lane-Emden equation on annular domains. Figures 5, 6, 7, 8, 9, and 10 are solutions to the Henon equation. For Figures 5 and 6, we explore the symmetry breaking phenomenon by showing that as the parameter q increases more and more nonradial positive solutions

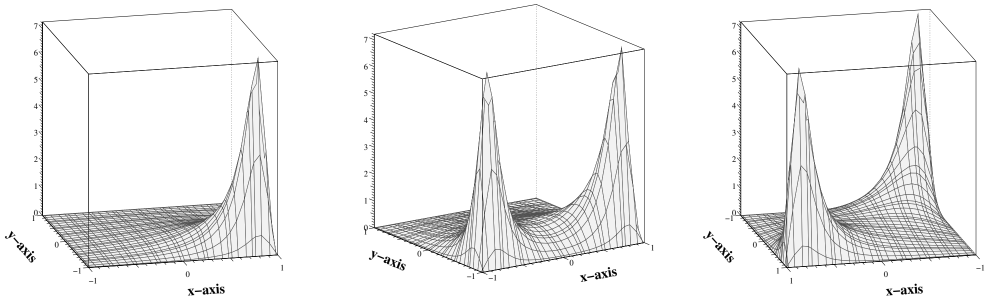

FIG. 7. *Solutions to the Henon equation on* Ω_s $(q = 9)$ *with* $J = 43.44$ (*left*), $J = 86.34$ (*center*), *and* $J = 86.61$ (*right*).

appear which should also have large MIs. For Figures 7, 8, and 9, we show how to handle various even and/or odd symmetries. The symmetry in Figure 10 is partial and cannot be described by a compact group. The following list contains details on how we use symmetries to find each of the solutions, i.e., a formula is given in each case for us to compute $\mathcal{H}(d^k)$ and then to replace d^k in LMM.

(1) Cf. Figure 1 (left). No symmetry is needed or $(\mathcal{H}u)(x, y) = u(x, y)$. This is a mountain-pass solution with $\mathrm{MI} = 1$.

(2) Cf. Figure 1 (center). Either odd reflection about the line $y = x$ or odd re-

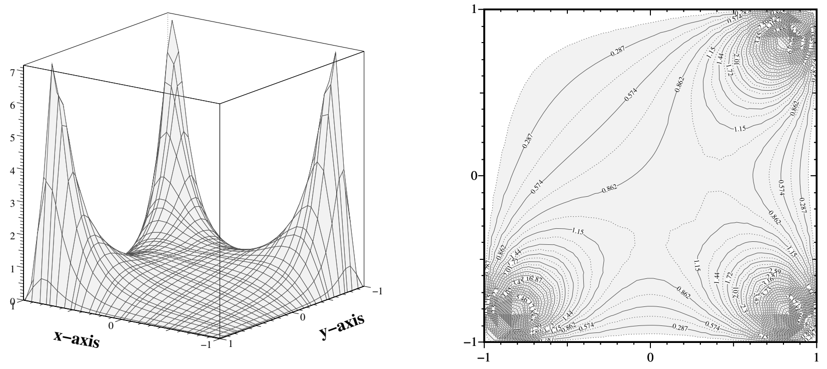

FIG. 10. *A solution to the Henon equation on Ω_s and its contours with $q = 9, J = 129.1$.*

flection about the origin. $(\mathcal{H}u)(x,y) = \frac{1}{2}(u(x,y) - u(-y,-x))$ or $(\mathcal{H}u)(x,y) = \frac{1}{2}(u(x,y) - u(-x,-y))$. This is a solution whose MI is at least 2 in H, and its MI is 1 when restricted in H_I.

(3) Cf. Figure 1 (right). Odd reflection about the x-axis. $(\mathcal{H}u)(x,y) = \frac{1}{2}(u(x,y) - u(x,-y))$.

(4) Cf. Figure 2 (left). Either odd reflections about the x-axis and the y-axis, or odd symmetry about the rotation by $\frac{\pi}{2}$. $(\mathcal{H}u)(x,y) = \frac{1}{4}(u(x,y) - u(-x,y) + u(-x,-y) - u(x,-y))$ or $(\mathcal{H}u)(\theta,r) = \frac{1}{4}(u(\theta,r) - u(\theta+\frac{\pi}{2},r) + u(\theta+\pi,r) - u(\theta+\frac{3\pi}{2},r))$. This solution has MI at least 4 in H though the MI $= 1$ in H_I.

(5) Cf. Figure 2 (center). Odd reflections about the lines $y = x$ and $y = -x$. $(\mathcal{H}u)(x,y) = \frac{1}{4}(u(x,y) - u(y,x) + u(-x,-y) - u(-y,-x))$.

(6) Cf. Figure 2 (right). Either even reflections about the x-axis and the y-axis, or even symmetry about the rotation by $\frac{\pi}{2}$. $L = \{u_1\}$ and u_1 is the solution in (1). $(\mathcal{H}u)(x,y) = \frac{1}{4}(u(x,y) + u(-x,y) + u(-x,-y) + u(x,-y))$ or $(\mathcal{H}u)(\theta,r) = \frac{1}{4}(u(\theta,r) + u(\theta+\frac{\pi}{2},r) + u(\theta+\pi,r) + u(\theta+\frac{3\pi}{2},r))$.

(7) Cf. Figure 3 (left). Odd reflections about the x-axis, the y-axis, the lines $y = x$ and $y = -x$. $\mathcal{H} = \mathcal{H}_4\mathcal{H}_3\mathcal{H}_2\mathcal{H}_1$, where $(\mathcal{H}_1u)(x,y) = \frac{1}{2}(u(x,y) - u(x,-y))$, $(\mathcal{H}_2u)(x,y) = \frac{1}{2}(u(x,y) - u(-x,y))$, $(\mathcal{H}_3u)(x,y) = \frac{1}{2}(u(x,y) - u(y,x))$, $(\mathcal{H}_4u)(x,y) = \frac{1}{2}(u(x,y) - u(-y,-x))$. Such a solution has a vary large MI in H and is too expensive to compute without using the symmetry.

(8) Cf. Figure 3 (center). Odd reflections about the x-axis and the y-axis. $(\mathcal{H}u)(x,y) = \frac{1}{4}(u(x,y) - u(-x,y) + u(-x,-y) - u(x,-y))$. Since the domain is a rectangle, the rotation by $\frac{\pi}{2}$ is not applicable. Contrast to Figure 2 (left).

(9) Cf. Figure 3 (right). Even reflections about the x-axis and the y-axis. $(\mathcal{H}u)(x,y) = \frac{1}{4}(u(x,y) + u(-x,y) + u(-x,-y) + u(x,-y))$. $L = \{u_1\}$, where u_1 is the single peak positive solution in the rectangle. This is the same symmetry used in the example shown in Figure 2 (right). It is interesting to compare this to Figure 2 (right). If we let the rectangle $[-1.5, 1.5] \times [-1, 1]$ change gradually to the square $[-1, 1] \times [-1, 1]$, e.g., $[-1.01, 1.01] \times [-1, 1]$, the solution remains of the same profile; it is an interesting observation. If we compare the critical values, profiles and symmetries of Figure 2 (left) and (right) with that of Figure 3 (center) and (right), we note that their sequential orders in critical level and profiles have changed drastically due to even a slight change in the geometry of the domain.

(10) Cf. Figure 4 (left). Rotation symmetry by $\frac{2\pi}{3}$. $(\mathcal{H}u)(\theta,r) = \frac{1}{3}(u(\theta,r) + u(\theta +$

$\frac{2\pi}{3}, r) + u(\theta + \frac{4\pi}{3}, r))$. Such a solution failed to be captured in [12] due to the fact that without using the symmetry, a sufficient support L in H contains infinitely many saddle points at lower critical level. We observe that the solution generated not only has the Z_3 symmetry it also has the additional symmetry of being even about the rotation by $\frac{2\pi}{3}$. Thus the solution has D_3 symmetry as well. With our new algorithm we may capture, in a stable way, solutions with D_k symmetry for any prime number k. The MIs of these solutions should be large depending upon the number of peaks k. This is related to the symmetry breaking phenomena for radially symmetric elliptic problems. The existence and qualitative behavior of these solutions can be found in [5] and the references therein. A rotation of the solution by any angle is still a solution. It is a degenerate case. However, adding an even symmetry about the x-axis can bypass the degeneracy.

(11) Cf. Figure 4 (right). Same symmetry as in Example 2.6. The existence of such a solution is still open. By Remark 2.1, we numerically checked that for each $v^k = p(u^k) \in H_I$ generated by LMM, $\nabla J(v^k) \in H_I$, i.e., the invariant subspace H_I is well defined. However, this problem is degenerate and also ill-conditioned in the sense that if we fix one peak and move another peak around, the change in J is almost invisible.

(12) Cf. Figure 5 (left). No symmetry is needed. This radial solution should be the unique positive solution to the Henon equation. A nonradial solution can be found for $q \geq 1$.

(13) Cf. Figure 5 (center). No symmetry is needed. However, adding an even symmetry about the x-axis will bypass the degeneracy. This is the least energy solution of the problem and this exhibits the phenomenon of symmetry breaking of ground state solutions (see [4]).

(14) Cf. Figure 5 (right). Even symmetry about the origin or rotation by π. $(\mathcal{H}u)(x,y) = \frac{1}{2}(u(x,y) + u(-x,-y))$. Such a radially symmetric solution is impossible to capture without using the symmetry since it has the highest critical value among all positive solutions and a sufficient support L in H needs to contain infinitely many positive solutions. A traditional way to find this solution is to use the radial symmetry to convert it into an ODE. On the other hand, this also shows that for small q (in this case $q = 3$) the radial solution is still the least energy solution in the class of even functions, and when we increase q to $q = 4$ as in the next example, the radial solution is going to lose its stability and the least energy solution becomes nonradial again.

(15) Cf. Figure 6 (left). Either even symmetry about the origin or even symmetry about the rotation by π. $(\mathcal{H}u)(x,y) = \frac{1}{2}(u(x,y) + u(-x,-y))$. Adding an even symmetry about the x-axis or y-axis will bypass the degeneracy. A symmetry about the rotation by $\frac{2\pi}{3}$ will generate the radially symmetric solution. From this example onward, the solutions demonstrated should have large MI depending upon the number of peaks of the solutions.

(16) Cf. Figure 6 (center). Symmetry about the rotation by $\frac{2\pi}{3}$. $(\mathcal{H}u)(\theta,r) = \frac{1}{3}(u(\theta,r) + u(\theta + \frac{2\pi}{3}, r) + u(\theta + \frac{4\pi}{3}, r))$. Adding an even symmetry about the x-axis will bypass the degeneracy. A symmetry about the rotation by $\frac{\pi}{2}$ will generate the radially symmetric solution. This implies the radial solution is the ground state in the class of functions invariant under Z_4, but is not the ground state in the class of Z_3-invariant functions.

(17) Cf. Figure 6 (right). Symmetry about the rotation by $\frac{\pi}{2}$. $(\mathcal{H}u)(\theta,r) = \frac{1}{4}(u(\theta,r)+$

$u(\theta+\frac{\pi}{4},r)+u(\theta+\frac{\pi}{2},r)+u(\theta+\frac{3\pi}{4},r))$. Adding an even symmetry about the x-axis or y-axis will bypass the degeneracy.

(18) Cf. Figure 7 (left). No symmetry is needed or $\mathcal{H}u(x,y)=u(x,y)$.

(19) Cf. Figure 7 (center). Even reflection about the y-axis. $(\mathcal{H}u)(x,y)=\frac{1}{2}(u(x,y)+u(-x,y))$.

(20) Cf. Figure 7 (right). Even reflection about the line $y=-x$. $(\mathcal{H}u)(x,y)=\frac{1}{2}(u(x,y)+u(-y,-x))$.

(21) Cf. Figure 8 (left). Even reflection about the x-axis and the y-axis. $(\mathcal{H}u)(x,y)=\frac{1}{4}(u(x,y)+u(-x,y)+u(-x,-y)+u(x,-y))$.

(22) Cf. Figure 8 (center). Odd reflection about the y-axis. $(\mathcal{H}u)(x,y)=\frac{1}{2}(u(x,y)-u(-x,y))$.

(23) Cf. Figure 8 (right). Odd reflection about the line $y=-x$. $(\mathcal{H}u)(x,y)=\frac{1}{2}(u(x,y)-u(-y,-x))$.

(24) Cf. Figure 9 (left). Even reflection about the y-axis and odd reflection about the x-axis.

(25) Cf. Figure 9 (center). Odd reflections about the x-axis and the y-axis. $(\mathcal{H}u)(x,y)=\frac{1}{4}(u(x,y)+u(-x,y)-u(-x,-y)-u(x,-y))$.

(26) Cf. Figure 9 (right). The same symmetry used in finding the solution in (7). Such a solution has a vary large MI in H and is too expensive to compute without using the symmetry.

(27) Cf. Figure 10. The same symmetry as in Example 2.6 and also in (11). It is an interesting example, since its symmetry is partial and cannot be described by a compact group. Theoretically the existence of such a solution is still open. However, we are able to follow Remark 2.1 to numerically verify the invariant subspace in the sense of Definition 2.1. For each $v^k=p(u^k)\in H_I$ generated in LMM, we find that the asymmetric part of $d^k=\nabla J(v^k)$ satisfies $\|\text{asymmetric part of } d^k\|_{H_0^1}\cong 2\times 10^{-4}\|d^k\|_{H_0^1}$. Thus we are very optimistic about the existence of this solution.

SHARP ERROR ESTIMATES FOR INTERPOLATORY APPROXIMATION ON CONVEX POLYTOPES*

ALLAL GUESSAB† AND GERHARD SCHMEISSER‡

Abstract. Let $\mathfrak{P}$ be a convex polytope in the d-dimensional Euclidean space. We consider an interpolation of a function f at the vertices of $\mathfrak{P}$ and compare it with the interpolation of f and its derivative at a fixed point $y \in \mathfrak{P}$. The two methods may be seen as multivariate analogues of an interpolation by secants and tangents, respectively. For twice continuously differentiable functions, we establish sharp error estimates with respect to a generalized L^p norm for $1 \leq p \leq \infty$. The case $p = 1$ is of special interest since it provides analogues of the midpoint rule and the trapezoidal rule for approximate integration over the polytope $\mathfrak{P}$. In the case where $\mathfrak{P}$ is a simplex and $p > 1$, this investigation covers recent results by S. Waldron [*SIAM J. Numer. Anal.*, 35 (1998), pp. 1191–1200] and by M. Stämpfle [*J. Approx. Theory*, 103 (2000), pp. 78–90].

Key words. interpolation on convex polytopes, sharp error estimates, approximation of functions, approximate integration, approximation of functionals

1. Introduction and notation.

Denote by $\mathcal{P}_1$ the class of all polynomials in d real variables of degree at most 1, also called the class of *affine functions* on $\mathbb{R}^d$. Let $\mathfrak{P} \subset \mathbb{R}^d$ be a convex polytope of positive measure with vertices $v_1, \ldots, v_n$, and let $B_1, \ldots, B_n$ be an associated system of continuous functions on $\mathfrak{P}$ with the following properties.

Nonnegativity. For $i = 1, \ldots, n$, we have

$$B_i(x) \geq 0 \qquad (x \in \mathfrak{P}). \tag{1.1}$$

Linear precision. For every $\lambda \in \mathcal{P}_1$, we have

$$\lambda(x) = \sum_{i=1}^{n} \lambda(v_i) B_i(x). \tag{1.2}$$

Warren [10] showed that $B_1, \ldots, B_n$ can be chosen as rational functions, which are uniquely determined if one requires that each B_i have minimal degree. Furthermore, for an arbitrary convex polytope, he presented an algorithm for constructing these functions $B_1, \ldots, B_n$ in a finite number of steps.

Since vertices of a convex polytope are extremal points, it is easily deduced from the "linear precision" that

$$B_i(v_j) = \delta_{ij} \qquad (i, j \in \{1, \ldots, n\}), \tag{1.3}$$

where we use Kronecker's delta. As a consequence of (1.2) and (1.3), the functions $B_1, \ldots, B_n$ are linearly independent and span an n-dimensional linear space $\mathcal{R}_n$ which contains $\mathcal{P}_1$ as a subspace.

By $C(\mathfrak{P})$, $C^1(\mathfrak{P})$, and $C^2(\mathfrak{P})$, we denote the spaces of functions which are defined on $\mathfrak{P}$ and are continuous, continuously differentiable, and twice continuously differentiable, respectively.

Next, let $\mathcal{L}$ be a positive linear functional on $C(\mathfrak{P})$. The positivity means that $\mathcal{L}(f) > 0$ for every nontrivial nonnegative function $f \in C(\mathfrak{P})$.

Examples of such functionals are weighted integrals

$$\mathcal{L}(f) := \int_{\mathfrak{P}} w(x)f(x)\mathrm{d}x \qquad \bigl(f \in C(\mathfrak{P})\bigr), \tag{1.4}$$

where w is integrable and positive on $\mathfrak{P}$ except for a set of measure zero.

For $f \in C(\mathfrak{P})$, we introduce

$$\|f\|_p := \bigl(\mathcal{L}(|f|^p)\bigr)^{1/p} \qquad (1 \le p < \infty) \tag{1.5}$$

and

$$\|f\|_\infty := \sup_{x\in\mathfrak{P}} |f(x)|\,, \tag{1.6}$$

which define norms on $C(\mathfrak{P})$. When $\mathcal{L}$ is given by (1.4) and $w = 1$, then $\|\cdot\|_p$ is the familiar L^p norm. For general $\mathcal{L}$, we may think of $\mathfrak{P}$ as being equipped with a mass distribution such that $\mathcal{L}(1)$ is the total mass of $\mathfrak{P}$. The possibility of having an arbitrary $\mathcal{L}$ is of interest mainly in our applications of the case $p = 1$ (see section 4). For this reason, we do not use a weighted supremum norm.

By $\|\cdot\|$, *without* any subscript, and by $\langle\cdot,\cdot\rangle$, we want to denote the Euclidean norm and the standard inner product in $\mathbb{R}^d$.

In this paper, we shall study the linear interpolation operator Λ^{v}, defined by

$$\Lambda^{\mathrm{v}}[f] := \sum_{i=1}^{n} f(v_i)B_i \qquad \bigl(f \in C(\mathfrak{P})\bigr), \tag{1.7}$$

which interpolates f at the vertices of $\mathfrak{P}$, and shall compare it with

$$\Lambda_y[f] := f(y) + Df(y)(\cdot - y) \qquad \bigl(f \in C^1(\mathfrak{P})\bigr), \tag{1.8}$$

where $y \in \mathfrak{P}$. Clearly, $\Lambda_y[f]$ interpolates f at y, and the same holds for the first derivative.

As regards our notation, we want to follow the convention that a superscript in roman type indicates an abbreviation for a word, while a subscript in italic type is a mathematical quantity. In particular, the superscript v shall always refer to interpolation at the *vertices*. Similarly, we shall use the superscripts sb for *smallest ball* and cm for *center of mass*.

2. Auxiliary results. For convenient reference, we first state some properties of the operators Λ_y and Λ^{v} as lemmas.

LEMMA 2.1. *For $y \in \mathfrak{P}$, the operator Λ_y has the following properties:*

(i) *It maps $C^1(\mathfrak{P})$ into $\mathcal{P}_1$.*

(ii) *It reproduces functions from $\mathcal{P}_1$.*

(iii) *It approximates convex functions from below.*

Proof. The properties (i) and (ii) are obvious. Property (iii) is a well-known fact about differentiable, convex functions; see [5, Theorem A, p. 98]. ◻

LEMMA 2.2. *The operator Λ^{v} has the following properties:*

(i) *It maps $C(\mathfrak{P})$ into $\mathcal{R}_n$.*
(ii) *It reproduces functions from $\mathcal{R}_n$.*
(iii) *It approximates convex functions from above.*
(iv) *If $f, g \in C(\mathfrak{P})$ and $f(v_i) \le g(v_i)$ for $i = 1, \dots, n$, then $\Lambda^{\mathrm{v}}[f] \le \Lambda^{\mathrm{v}}[g]$.*

Proof. Since $\{B_1, \dots, B_n\}$ is a basis of $\mathcal{R}_n$, the properties (i) and (ii) are obvious consequences of the definition of Λ^{v}.

Next, it follows from (1.2) that

$$x \,=\, \sum_{i=1}^{n} v_i B_i(x) \qquad (x \in \mathfrak{P}),$$

which is a representation of x as a convex combination of the vertices of $\mathfrak{P}$. Hence, for a convex function f,

$$f(x) \,=\, f\left(\sum_{i=1}^{n} v_i B_i(x)\right) \,\le\, \sum_{i=1}^{n} f(v_i) B_i(x) \,=\, \Lambda^{\mathrm{v}}[f](x) \qquad (x \in \mathfrak{P}),$$

and so statement (iii) is verified.

Finally, recalling (1.1), we see that, under the hypothesis of statement (iv),

$$\Lambda^{\mathrm{v}}[f] \,=\, \sum_{i=1}^{n} f(v_i) B_i \,\le\, \sum_{i=1}^{n} g(v_i) B_i \,=\, \Lambda^{\mathrm{v}}[g].$$

This completes the proof. □

It will turn out that the constants in our error estimates are determined by the interpolation error of the quadratic function $\|\cdot\|^2$. We therefore introduce the (nonnegative) functions

$$e_y \,:=\, \|\cdot\|^2 - \Lambda_y\left[\|\cdot\|^2\right], \tag{2.1}$$

where $y \in \mathfrak{P}$, and

$$e^{\mathrm{v}} \,:=\, \Lambda^{\mathrm{v}}\left[\|\cdot\|^2\right] - \|\cdot\|^2 \,=\, \sum_{i=1}^{n} \|v_i\|^2 B_i - \|\cdot\|^2. \tag{2.2}$$

Representations, interrelations, and estimates for these functions are stated in the following lemma.

LEMMA 2.3. *The functions e_y and e^{v} are nonnegative and vanish at the interpolation points of Λ_y and Λ^{v}, respectively. They satisfy the equations*

$$e_y = \|\cdot - y\|^2, \tag{2.3}$$

$$e^{\mathrm{v}} = \sum_{i=1}^{n} \|\cdot - v_i\|^2 B_i, \tag{2.4}$$

$$e^{\mathrm{v}} + e_y = \sum_{i=1}^{n} e_y(v_i) B_i. \tag{2.5}$$

Furthermore, denoting by

$$\mathfrak{B}^{\mathrm{sb}} \,=:\, \{x \in \mathbb{R}^d \,:\, \|x - x^{\mathrm{sb}}\| \le r^{\mathrm{sb}}\} \tag{2.6}$$

the smallest ball that contains $\mathfrak{P}$*, we have*

$$e^{\mathrm{v}}(x) \le (r^{\mathrm{sb}})^2 - \|x - x^{\mathrm{sb}}\|^2 \le (r^{\mathrm{sb}})^2 \tag{2.7}$$

for all $x \in \mathfrak{P}$.

For notational simplicity, we write

$$\Lambda^{\mathrm{sb}} := \Lambda_y \quad \text{and} \quad e^{\mathrm{sb}} := e_y \quad \text{if } y = x^{\mathrm{sb}}. \tag{2.8}$$

Proof. From the definition of the functions e_y and e^{v}, it is clear that they vanish at the interpolation points of Λ_y and Λ^{v}, respectively. Since $\|\cdot\|^2$ is a convex function, the statements (iii) of Lemmas 2.1 and 2.2 show that e_y and e^{v} are nonnegative.

Next, from the definition of e_y, we deduce that

$$e_y(x) = \|x\|^2 - \big(\|y\|^2 + 2\langle y, x - y\rangle\big) = \|x\|^2 + \|y\|^2 - 2\langle y, x\rangle = \|x - y\|^2,$$

which is (2.3).

Since $e^{\mathrm{v}} + e_y$ belongs to $\mathcal{R}_n$, statement (ii) of Lemma 2.2 shows that, for any $x \in \mathfrak{P}$, we have

$$e^{\mathrm{v}}(x) + e_y(x) = \sum_{i=1}^{n} \big(e^{\mathrm{v}}(v_i) + e_y(v_i)\big)\, B_i(x) = \sum_{i=1}^{n} e_y(v_i) B_i(x), \tag{2.9}$$

which is (2.5).

Substituting $y = x$ in (2.9) and using (2.3), we obtain (2.4).

For a proof of (2.7), we first note that $x^{\mathrm{sb}} \in \mathfrak{P}$, as a consequence of the convexity of $\mathfrak{P}$. Since

$$h^{\mathrm{sb}} := (r^{\mathrm{sb}})^2 - \|\cdot - x^{\mathrm{sb}}\|^2 \tag{2.10}$$

is nonnegative on $\mathfrak{P}$, while e^{v} vanishes at *all* the vertices of $\mathfrak{P}$, we clearly have

$$h^{\mathrm{sb}}(v_i) - e^{\mathrm{v}}(v_i) \ge 0 \qquad (i = 1, \ldots, n).$$

Therefore statement (iv) of Lemma 2.2 implies that $\Lambda^{\mathrm{v}}[h^{\mathrm{sb}} - e^{\mathrm{v}}] \ge 0$. Furthermore, using (2.3), (2.5), and the notation (2.8), we find that

$$h^{\mathrm{sb}} - e^{\mathrm{v}} = (r^{\mathrm{sb}})^2 - e^{\mathrm{sb}} - e^{\mathrm{v}} = (r^{\mathrm{sb}})^2 - \sum_{i=1}^{n} e^{\mathrm{sb}}(v_i) B_i, \tag{2.11}$$

which obviously belongs to $\mathcal{R}_n$. Hence statement (ii) of Lemma 2.2 allows us to conclude that

$$h^{\mathrm{sb}} - e^{\mathrm{v}} = \Lambda^{\mathrm{v}}\big[h^{\mathrm{sb}} - e^{\mathrm{v}}\big] \ge 0, \tag{2.12}$$

which gives (2.7) immediately. □

Remark 2.4. Inequality (2.7) is of interest for the following reason. As we shall see, the best constants in our error estimates for $\Lambda^{\mathrm{v}}[f]$ are determined by norms of e^{v}. If e^{v} is complicated, then we may use the simpler function (2.10) instead and obtain a constant which is possibly somewhat worse, but which may still be good enough for practical applications. In the case where $\mathfrak{P}$ is a simplex, it can even be shown that

$$\sup_{x \in \mathfrak{P}} e^{\mathrm{v}}(x) = \sup_{x \in \mathfrak{P}} h^{\mathrm{sb}}(x) = (r^{\mathrm{sb}})^2;$$

see [6, Lemma 4.2].

3. Approximation of functions. We are mainly interested in approximation of functions from $C^2(\mathfrak{P})$. However, in the case where $\mathcal{P}$ is a simplex, Stämpfle [6, Theorem 4.1, statements (i)–(iv)] also presented results for functions belonging to lower regularity classes. These statements extend to Λ^{v} by exactly the same arguments as in [6]. We only mention a result for a Lipschitz class which is more general than the one considered in [6].

For $\alpha \in (0,1]$ and $L > 0$, we write $f \in \mathrm{Lip}_L(\alpha, \mathfrak{P})$ and say that f satisfies a *Lipschitz condition* of *order* α with *Lipschitz constant* L on $\mathfrak{P}$ if $f \in C(\mathfrak{P})$ and

$$|f(x) - f(y)| \,\leq\, L\|x-y\|^{\alpha} \qquad (x, y \in \mathfrak{P}).$$

THEOREM 3.1. *Let* $f \in \mathrm{Lip}_L(\alpha, \mathfrak{P})$. *Then*

$$\big|f(x) - \Lambda^{\mathrm{v}}[f](x)\big| \,\leq\, L\left(e^{\mathrm{v}}(x)\right)^{\alpha/2} \qquad (x \in \mathfrak{P}) \tag{3.1}$$

and, for each $p \in [1, \infty]$,

$$\big\|f - \Lambda^{\mathrm{v}}[f]\big\|_p \,\leq\, L\,\big\|(e^{\mathrm{v}})^{\alpha/2}\big\|_p. \tag{3.2}$$

Proof. From (1.2) and the definition of Λ^{v}, it is clear that

$$f(x) - \Lambda^{\mathrm{v}}[f](x) \,=\, \sum_{i=1}^{n}\big(f(x) - f(v_i)\big)\,B_i(x),$$

and so, by the triangle inequality and the Lipschitz condition,

$$\big|f(x) - \Lambda^{\mathrm{v}}[f](x)\big| \,\leq\, L\sum_{i=1}^{n}\|x - v_i\|^{\alpha}B_i(x). \tag{3.3}$$

Next, using Hölder's inequality with $p := 2/\alpha$ and $q := 2/(2-\alpha)$, which is an admissible pair of exponents, and recalling (1.2) and (2.4), we find that

$$\begin{aligned}\sum_{i=1}^{n}\|x-v_i\|^{\alpha}B_i(x) &= \sum_{i=1}^{n}\|x-v_i\|^{\alpha}B_i(x)^{1/p}\cdot B_i(x)^{1/q}\\ &\leq \left(\sum_{i=1}^{n}\|x-v_i\|^{\alpha p}B_i(x)\right)^{1/p}\cdot\left(\sum_{i=1}^{n}B_i(x)\right)^{1/q}\\ &= \left(\sum_{i=1}^{n}\|x-v_i\|^{2}B_i(x)\right)^{\alpha/2} \,=\, \left(e^{\mathrm{v}}(x)\right)^{\alpha/2}.\end{aligned}$$

Combining this with (3.3), we obtain (3.1). Clearly, (3.2) is an immediate consequence of (3.1). □

For twice differentiable functions $f : \mathfrak{P} \to \mathbb{R}$, we denote by

$$H[f](x) \,:=\, \left(\frac{\partial^2 f}{\partial x_i \partial x_j}(x)\right)_{i,j=1,\ldots,d}$$

the Hessian matrix of f at x and introduce

$$\boldsymbol{|}D^2 f\boldsymbol{|} \,:=\, \sup_{x\in\mathfrak{P}}\,\sup_{\substack{y\in\mathbb{R}^d\\ \|y\|=1}}\left|y^{\top}H[f](x)y\right|, \tag{3.4}$$

agreeing that the elements of $\mathbb{R}^d$ are column vectors so that $y^\top$, which denotes the transpose of y, becomes a row vector. Clearly, $\left|D^2 f\right| = 0$ for $f \in \mathcal{P}_1$, and $\left|D^2 f\right| = 2\,|c|$ for $f = c\|\cdot\|^2$.

Subsequently, we shall often refer to the space

$$\mathcal{F}_2 := \left\{ f := \lambda + c\,\|\cdot\|^2 \;:\; \lambda \in \mathcal{P}_1,\, c \in \mathbb{R} \right\}. \tag{3.5}$$

The following theorem for Λ_y is not more than an easy exercise in calculus. We formulate it as a theorem only in order to compare it with the corresponding result for Λ^{v}.

Theorem 3.2. *Let* $f \in C^2(\mathfrak{P})$. *Then,*

$$\left|f(x) - \Lambda_y[f](x)\right| \le \frac{1}{2}\,\|x-y\|^2\,\left|D^2 f\right| \qquad (x, y \in \mathfrak{P}). \tag{3.6}$$

Furthermore, for each $p \in [1, \infty]$,

$$\left\|f - \Lambda_y[f]\right\|_p \le c_{y,p}\,\left|D^2 f\right|, \tag{3.7}$$

where

$$c_{y,p} := \frac{1}{2}\,\|e_y\|_p. \tag{3.8}$$

Both inequalities are sharp. Equality is attained for every $f \in \mathcal{F}_2$.

Proof. By the Taylor formula of order two, we have

$$f(x) - \Lambda_y[f](x) = \frac{1}{2}\,(x-y)^\top H[f]\big(y + \theta(x-y)\big)(x-y)$$

for some $\theta \in (0,1)$. Now the definition of $\left|D^2 f\right|$, given in (3.4), shows that (3.6) holds. Inequality (3.7) is an immediate consequence of (3.6). Finally, the case of equality is easily verified. □

Theorem 3.3. *Let* $f \in C^2(\mathfrak{P})$. *Then,*

$$\left|f(x) - \Lambda^{\mathrm{v}}[f](x)\right| \le \frac{1}{2}\,e^{\mathrm{v}}(x)\,\left|D^2 f\right| \qquad (x \in \mathfrak{P}). \tag{3.9}$$

Furthermore, for each $p \in [1, \infty]$,

$$\left\|f - \Lambda^{\mathrm{v}}[f]\right\|_p \le c_p^{\mathrm{v}}\,\left|D^2 f\right|, \tag{3.10}$$

where

$$c_p^{\mathrm{v}} := \frac{1}{2}\,\|e^{\mathrm{v}}\|_p. \tag{3.11}$$

Both inequalities are sharp. Equality is attained for every $f \in \mathcal{F}_2$.

Proof. Inequality (3.6) may be rewritten as

$$-\frac{1}{2}\,\|x-y\|^2\,\left|D^2 f\right| \le f(x) - \Lambda_y[f](x) \le \frac{1}{2}\,\|x-y\|^2\,\left|D^2 f\right| \quad (x, y \in \mathfrak{P}). \tag{3.12}$$

Next, from statement (iv) of Lemma 2.2, it follows that inequalities between continuous functions on $\mathfrak{P}$ are preserved when the operator Λ^{v} is applied on both sides.

Moreover, statement (i) of Lemma 2.1 together with statement (ii) of Lemma 2.2 shows that

$$\Lambda^{\mathrm{v}}\big[\Lambda_y[f]\big] \,=\, \Lambda_y[f].$$

Hence (3.12) implies that

$$-\frac{1}{2}\,\Lambda^{\mathrm{v}}\big[\|\cdot - y\|^2\big](x)\,\,\big|D^2 f\big| \,\le\, \Lambda^{\mathrm{v}}[f](x) - \Lambda_y[f](x) \,\le\, \frac{1}{2}\,\Lambda^{\mathrm{v}}\big[\|\cdot - y\|^2\big](x)\,\,\big|D^2 f\big|.$$

Now, taking $y = x$ and noting that $\Lambda_x[f](x) = f(x)$ and, by (2.4),

$$\Lambda^{\mathrm{v}}\big[\|\cdot - x\|^2\big](x) \,=\, \sum_{i=1}^{n} \|v_i - x\|^2 B_i(x) \,=\, e^{\mathrm{v}}(x),$$

we obtain

$$-\frac{1}{2}\,e^{\mathrm{v}}(x)\,\,\big|D^2 f\big| \,\le\, \Lambda^{\mathrm{v}}[f](x) - f(x) \,\le\, \frac{1}{2}\,e^{\mathrm{v}}(x)\,\,\big|D^2 f\big|,$$

which is equivalent to (3.9). Inequality (3.10) is an immediate consequence of (3.9). The statement on the occurrence of equality is easily verified by a calculation. ∎

Remark 3.4. Since Λ^{v} is a positive operator which reproduces affine functions, inequality (3.9) can also be deduced from [9, Theorem 1.4] in conjunction with the above Lemma 2.3.

The operator Λ_y has just one interpolation point, which is of multiplicity two. Such an interpolation can be described by $d+1$ scalar equations. The interpolation of the operator Λ^{v}, which has n simple interpolation points, can be described by n scalar equations. Since $n \ge d+1$, we may expect that the operator Λ^{v} is at least as precise as Λ_y. In the following proposition, we compare the constants (3.8) and (3.11) when $p = \infty$.

PROPOSITION 3.5. *For $p = \infty$, the constants* (3.8) *and* (3.11) *satisfy the relations*

$$c^{\mathrm{v}}_{\infty} \,\le\, c_{y,\infty} \qquad (y \in \mathfrak{P}) \tag{3.13}$$

and

$$\inf_{y\in\mathfrak{P}} c_{y,\infty} \,=\, \frac{(r^{\mathrm{sb}})^2}{2}, \tag{3.14}$$

the infimum being attained for $y = x^{\mathrm{sb}}$, where r^{sb} and x^{sb} specify the smallest ball $\mathfrak{B}^{\mathrm{sb}}$ which contains $\mathfrak{P}$, as introduced in (2.6).

If all the vertices of $\mathfrak{P}$ lie on the boundary of $\mathfrak{B}^{\mathrm{sb}}$, then

$$c^{\mathrm{v}}_{\infty} \,=\, \frac{(r^{\mathrm{sb}})^2}{2}. \tag{3.15}$$

Proof. It follows from (2.5) that

$$e^{\mathrm{v}}(x) \,\le\, \sum_{i=1}^{n} e_y(v_i) B_i(x) \,\le\, \max_{1\le i\le n} e_y(v_i) \qquad (x \in \mathfrak{P}), \tag{3.16}$$

which implies (3.13).

Since a convex function, defined on a convex set, attains its supremum at an extreme point (see, for example, [4, p. 91]), we have

$$\max_{1\le i\le n} e_y(v_i) \;=\; \sup_{x\in\mathfrak{P}} e_y(x) \;=\; 2c_{y,\infty}. \tag{3.17}$$

This shows that $c_{y,\infty}$ attains its smallest value at a point where

$$\phi(y) \;:=\; \max_{1\le i\le n} e_y(v_i) \;=\; \max_{1\le i\le n} \|y-v_i\|^2$$

attains its minimum. Clearly, this is the center of the smallest ball $\mathfrak{B}^{\rm sb}$ that contains $\mathfrak{P}$, and so

$$\min_{y\in\mathfrak{P}} \phi(y) \;=\; \phi(x^{\rm sb}) \;=\; (r^{\rm sb})^2.$$

Thus (3.14) is verified.

If *all* the vertices of $\mathfrak{P}$ lie on the boundary of $\mathfrak{B}^{\rm sb}$, then $\|x^{\rm sb}-v_i\| = r^{\rm sb}$ for $i=1,\dots,n$. Therefore, by (2.4),

$$e^{\rm v}(x^{\rm sb}) \;=\; \sum_{i=1}^n \|x^{\rm sb}-v_i\|^2 B_i(x^{\rm sb}) \;=\; (r^{\rm sb})^2 \sum_{i=1}^n B_i(x^{\rm sb}) \;=\; (r^{\rm sb})^2,$$

which shows that $c_\infty^{\rm v} \ge (r^{\rm sb})^2/2$. Combining this inequality with (3.13) and (3.14), we obtain (3.15). □

In the univariate case, where $\mathfrak{P}$ is an interval $[a,b]$, it is known and also seen from (3.15) that, for $y=(b+a)/2$, we have

$$c_\infty^{\rm v} \;=\; c_{y,\infty} \;=\; \frac{(b-a)^2}{8}.$$

Moreover, the mean value

$$\frac{1}{2}\left(\Lambda_y[f] + \Lambda^{\rm v}[f]\right) \qquad \left(y = \frac{a+b}{2}\right)$$

gives an approximation whose constant in the error bound is $(b-a)^2/16$. A generalization is given in the following proposition.

PROPOSITION 3.6. *Let $f\in C^2(\mathfrak{P})$. Then, for every $y\in\mathfrak{P}$ and $\alpha\in[0,1]$, we have*

$$\left\|f-\alpha\Lambda_y[f]-(1-\alpha)\Lambda^{\rm v}[f]\right\|_\infty \;\le\; c(\alpha,y)\;\left|D^2 f\right|, \tag{3.18}$$

where

$$c(\alpha,y) \;:=\; \frac{1}{2}\sup_{x\in\mathfrak{P}}\left(\alpha e_y(x) + (1-\alpha)e^{\rm v}(x)\right). \tag{3.19}$$

Furthermore,

$$\inf_{0\le\alpha\le1}\,\inf_{y\in\mathfrak{P}} c(\alpha,y) \;\le\; \frac{(r^{\rm sb})^2}{4} \;=\; c\left(\frac{1}{2},x^{\rm sb}\right), \tag{3.20}$$

where $r^{\rm sb}$ and $x^{\rm sb}$ are the radius and the center, respectively, of the smallest ball $\mathfrak{B}^{\rm sb}$ that contains $\mathfrak{P}$. Equality occurs in (3.20) *if all the vertices of $\mathfrak{P}$ lie on the boundary* *of* $\mathfrak{B}^{\mathrm{sb}}$. *In this case, inequality* (3.18) *is sharp when* $\alpha = 1/2$ *and* $y = x^{\mathrm{sb}}$, *and equality is attained for every function* $f \in \mathcal{F}_2$.

Proof. The estimates (3.6) and (3.9) may be rewritten as

$$-\frac{1}{2}e_y(x)\ \left|D^2 f\right|\ \le\ f(x) - \Lambda_y[f](x)\ \le\ \frac{1}{2}e_y(x)\ \left|D^2 f\right|$$

and

$$-\frac{1}{2}e^{\mathrm{v}}(x)\ \left|D^2 f\right|\ \le\ f(x) - \Lambda^{\mathrm{v}}[f](x)\ \le\ \frac{1}{2}e^{\mathrm{v}}(x)\ \left|D^2 f\right|.$$

Multiplying the first inequalities by α and the second by $1-\alpha$, and adding the results, we obtain

$$\left|f(x) - \alpha\Lambda_y[f](x) - (1-\alpha)\Lambda^{\mathrm{v}}[f](x)\right|\ \le\ \frac{1}{2}\left(\alpha e_y(x) + (1-\alpha)e^{\mathrm{v}}(x)\right)\ \left|D^2 f\right|.$$

This implies (3.18).

Next, using (2.5) and the notation (2.8), we find that

$$c\left(\frac{1}{2}, x^{\mathrm{sb}}\right)\ =\ \frac{1}{4}\sup_{x\in\mathfrak{P}}\left(e^{\mathrm{v}}(x) + e^{\mathrm{sb}}(x)\right)\ =\ \frac{1}{4}\sup_{x\in\mathfrak{P}}\sum_{i=1}^{n}\|x^{\mathrm{sb}} - v_i\|^2 B_i(x).$$

If v_j is a vertex on the boundary of $\mathfrak{B}^{\mathrm{sb}}$, then, by (1.1), (1.3), (2.11), and (2.12),

$$\sum_{i=1}^{n}\|x^{\mathrm{sb}} - v_i\|^2 B_i(v_j)\ =\ \|x^{\mathrm{sb}} - v_j\|^2\ =\ (r^{\mathrm{sb}})^2\ \ge\ \sum_{i=1}^{n}\|x^{\mathrm{sb}} - v_i\|^2 B_i(x)$$

for all $x \in \mathfrak{P}$. This shows that

$$\sup_{x\in\mathfrak{P}}\sum_{i=1}^{n}\|x^{\mathrm{sb}} - v_i\|^2 B_i(x)\ =\ (r^{\mathrm{sb}})^2$$

and completes the proof of (3.20).

Using (3.19), we deduce that

$$c(\alpha, y)\ \ge\ \frac{1-\alpha}{2}\sup_{x\in\mathfrak{P}} e^{\mathrm{v}}(x)\ =\ (1-\alpha)\,c^{\mathrm{v}}_{\infty}\ \ge\ \frac{c^{\mathrm{v}}_{\infty}}{2}\qquad \text{if } \alpha \in \left[0, \frac{1}{2}\right]$$

and, in conjunction with (3.14),

$$c(\alpha, y)\ \ge\ \frac{\alpha}{2}\sup_{x\in\mathfrak{P}} e_y(x)\ =\ \alpha\, c_{y,\infty}\ \ge\ \frac{(r^{\mathrm{sb}})^2}{4}\qquad \text{if } \alpha \in \left[\frac{1}{2}, 1\right].$$

Under the hypothesis that all the vertices of $\mathfrak{P}$ lie on the boundary of $\mathfrak{B}^{\mathrm{sb}}$, we know from Proposition 3.5 that

$$c^{\mathrm{v}}_{\infty}\ =\ \frac{(r^{\mathrm{sb}})^2}{2}.$$

Hence

$$c(\alpha, y)\ \ge\ \frac{(r^{\mathrm{sb}})^2}{4}\qquad (\alpha \in [0,1],\ y \in \mathfrak{P}),$$

which shows that equality occurs in (3.20).

Finally, we have to verify the statement on the occurrence of equality for functions f from the class $\mathcal{F}_2$. For this, it is clearly enough to consider the function $f := \|\cdot\|^2$ only.

Using the notation (2.8), we may rewrite (2.1) and (2.2) as

$$\begin{aligned} f(x) - \Lambda^{\mathrm{sb}}[f](x) &= e^{\mathrm{sb}}(x), \\ f(x) - \Lambda^{\mathrm{v}}[f](x) &= -e^{\mathrm{v}}(x). \end{aligned}$$

Therefore,

$$f(x) - \frac{1}{2}\,\Lambda^{\mathrm{sb}}[f](x) - \frac{1}{2}\,\Lambda^{\mathrm{v}}[f](x) \;=\; \frac{1}{2}\left(e^{\mathrm{sb}}(x) - e^{\mathrm{v}}(x)\right)$$

and consequently,

$$\left\| f - \frac{1}{2}\,\Lambda^{\mathrm{sb}}[f] - \frac{1}{2}\,\Lambda^{\mathrm{v}}[f]\right\|_\infty \;=\; \frac{1}{2}\,\sup_{x\in\mathfrak{P}} \left|e^{\mathrm{sb}}(x) - e^{\mathrm{v}}(x)\right|.$$

If all the vertices of $\mathfrak{P}$ lie on the boundary of $\mathfrak{B}^{\mathrm{sb}}$, then

$$\sup_{x\in\mathfrak{P}} \left|e^{\mathrm{sb}}(x) - e^{\mathrm{v}}(x)\right| \;\geq\; \left|e^{\mathrm{sb}}(x^{\mathrm{sb}}) - e^{\mathrm{v}}(x^{\mathrm{sb}})\right| \;=\; e^{\mathrm{v}}(x^{\mathrm{sb}}) \;=\; (r^{\mathrm{sb}})^2,$$

where the last equation follows from (2.4) and (1.2), and so

$$\left\| f - \frac{1}{2}\,\Lambda^{\mathrm{sb}}[f] - \frac{1}{2}\,\Lambda^{\mathrm{v}}[f]\right\|_\infty \;\geq\; \frac{(r^{\mathrm{sb}})^2}{2}.$$

On the other hand, (3.18) and (3.20) show that

$$\left\| f - \frac{1}{2}\,\Lambda^{\mathrm{sb}}[f] - \frac{1}{2}\,\Lambda^{\mathrm{v}}[f]\right\|_\infty \;\leq\; \frac{(r^{\mathrm{sb}})^2}{2}.$$

Hence equality occurs for $f = \|\cdot\|^2$. □

4. Approximation of linear functionals. In the case $p = 1$, Theorems 3.1–3.3 provide an approximation of $\mathcal{L}(f)$, defined in (1.4), by the values of f (and possibly of Df) at the interpolation points of Λ_y and Λ^{v}, respectively. Indeed, if Λ is any of the two operators Λ_y and Λ^{v}, and $I(f) := \mathcal{L}(\Lambda[f])$, then, using that $\mathcal{L}$ is linear and positive, we have

$$\left|\mathcal{L}(f) - I(f)\right| \;=\; \left|\mathcal{L}(f - \Lambda[f])\right| \;\leq\; \mathcal{L}\big(\,|f - \Lambda[f]|\big) \;=\; \left\|f - \Lambda[f]\right\|_1.$$

Let us now turn to details. Denoting by id the identity mapping on $\mathfrak{P}$ and observing that $\mathcal{L}(\mathrm{id})$ is a mapping from $\mathfrak{P}$ into $\mathbb{R}^d$, we shall consider the operators

$$I_y(f) \;:=\; \mathcal{L}(\Lambda_y[f]) \;=\; \mathcal{L}(1)\left[f(y) + Df(y)\left(\frac{\mathcal{L}(\mathrm{id})}{\mathcal{L}(1)} - y\right)\right] \tag{4.1}$$

and

$$I^{\mathrm{v}}(f) \;:=\; \mathcal{L}(\Lambda^{\mathrm{v}}[f]) \;=\; \sum_{i=1}^{n} f(v_i)\mathcal{L}(B_i). \tag{4.2}$$

In the case $p = 1$, the constants (3.8) and (3.11) can be expressed as

$$c_{y,1} \;=\; \frac{1}{2}\,\mathcal{L}(e_y) \qquad \text{and} \qquad c_1^{\mathrm{v}} \;=\; \frac{1}{2}\left(I^{\mathrm{v}}(e_y) - \mathcal{L}(e_y)\right). \tag{4.3}$$

Note that the last equation, which is deduced with the help of (2.5), is independent of y. Now Theorems 3.2 and 3.3 imply the following corollaries.

COROLLARY 4.1. *Let $f \in C^2(\mathfrak{P})$. Then, for any $y \in \mathfrak{P}$, we have*

$$|\mathcal{L}(f) - I_y(f)| \;\le\; \frac{\mathcal{L}(e_y)}{2}\;\big|D^2 f\big|.$$

Equality is attained for every $f \in \mathcal{F}_2$.

COROLLARY 4.2. *Let $f \in C^2(\mathfrak{P})$. Then, for any $y \in \mathfrak{P}$, we have*

$$|\mathcal{L}(f) - I^{\mathrm{v}}(f)| \;\le\; \frac{I^{\mathrm{v}}(e_y) - \mathcal{L}(e_y)}{2}\;\big|D^2 f\big|.$$

Equality is attained for every $f \in \mathcal{F}_2$.

Remark 4.3. The conclusions of Corollaries 4.1 and 4.2 can be refined when, in addition, f is known to be a convex function. In fact, in this case, we also have

$$I_y(f) \;\le\; \mathcal{L}(f) \;\le\; I^{\mathrm{v}}(f)$$

as a consequence of the statements (iii) of Lemmas 2.1 and 2.2.

The "cubature rule" $I^{\mathrm{v}}(f)$ may be seen as a multivariate analogue of the trapezoidal rule. As (4.1) shows, the "cubature rule" $I_y(f)$ simplifies and does not depend on Df if y is chosen as

$$x^{\mathrm{cm}} \;:=\; \frac{\mathcal{L}(\mathrm{id})}{\mathcal{L}(1)}.$$

In this case, $I_y(f)$ is a multivariate analogue of the midpoint rule.

The point x^{cm} will be called the *center of mass* of $\mathfrak{P}$ with respect to the functional $\mathcal{L}$. Note that x^{cm} always belongs to $\mathfrak{P}$. Indeed, if x^{cm} were outside $\mathfrak{P}$, then there would exist a separating hyperplane

$$\lambda(x) \;:=\; a + \langle b, x\rangle \;=\; 0,$$

where $a \in \mathbb{R}$ and $b \in \mathbb{R}^d$, such that $\lambda(x) > 0$ for $x \in \mathfrak{P}$ and $\lambda(x^{\mathrm{cm}}) < 0$. Since $\mathcal{L}$ is positive, we would have $\mathcal{L}(\lambda) > 0$. On the other hand, the linearity of $\mathcal{L}$ implies that

$$\mathcal{L}(\lambda) = a\mathcal{L}(1) + \langle b, \mathcal{L}(\mathrm{id})\rangle = a\mathcal{L}(1) + \langle b, \mathcal{L}(1)x^{\mathrm{cm}}\rangle = \mathcal{L}(1)\lambda(x^{\mathrm{cm}}) < 0,$$

which is a contradiction.

For notational simplicity, we now write

$$\Lambda^{\mathrm{cm}} := \Lambda_y, \quad I^{\mathrm{cm}} := I_y, \quad e^{\mathrm{cm}} := e_y, \quad c_p^{\mathrm{cm}} := c_{y,p} \qquad \text{if } y = x^{\mathrm{cm}}. \tag{4.4}$$

Since

$$e_y(x) = \|x - y\|^2 = \|x - x^{\mathrm{cm}}\|^2 + \|x^{\mathrm{cm}} - y\|^2 + 2\langle x - x^{\mathrm{cm}},\, x^{\mathrm{cm}} - y\rangle,$$

we find, using the definition of x^{cm}, that

$$c_{y,1} \;=\; \mathcal{L}(e_y) \;=\; \mathcal{L}(e^{\mathrm{cm}}) + \mathcal{L}(1)\|x^{\mathrm{cm}} - y\|^2.$$

This shows that the constant in the error estimate of Corollary 4.1 becomes smallest if and only if $y = x^{\mathrm{cm}}$.

Remark 4.4. It may be interesting to compare the operators I^{cm} and I^{v}. Recalling that c_1^{v} in (4.3) does not depend on y, we may take $y = x^{\mathrm{cm}}$. Then Corollaries 4.1 and 4.2 show that the quotient

$$\kappa := \frac{\mathcal{L}(e^{\mathrm{cm}})}{I^{\mathrm{v}}(e^{\mathrm{cm}})} \tag{4.5}$$

indicates which one of the two operators I^{cm} and I^{v} has the smaller constant in its error estimate. We see that $c_1^{\mathrm{cm}} < c_1^{\mathrm{v}}$ if and only if $\kappa \in (0, 1/2)$. Since, for convex functions, I^{v} approximates $\mathcal{L}$ from above, we always have $\kappa \in (0, 1)$. In all the standard examples considered by us, we found that $\kappa \in (0, 1/2)$. However, $\kappa \in [1/2, 1)$ will occur when $\mathcal{L}$ is of the form (1.4) and the weight function w is large near the vertices.

5. Examples. We illustrate our results by considering three special classes of convex polytopes for which interpolation and approximation problems have been studied in the literature.

5.1. Intervals (the univariate case). Let $d := 1$, $\mathfrak{P} := [a, b]$, and $\mathcal{L}(f) := \int_a^b f(x)\,\mathrm{d}x$. Then $x^{\mathrm{sb}} = x^{\mathrm{cm}} = \frac{1}{2}(a + b)$,

$$\Lambda^{\mathrm{cm}}[f](x) = f\left(\frac{a+b}{2}\right) + f'\left(\frac{a+b}{2}\right)\left(x - \frac{a+b}{2}\right),$$

and

$$\Lambda^{\mathrm{v}}[f](x) = \frac{b-x}{b-a}\,f(a) + \frac{x-a}{b-a}\,f(b).$$

Moreover, $\left|D^2 f\right| = \sup_{a \le x \le b} |f''(x)|$. For the constants (3.8) with $y = x^{\mathrm{cm}}$ and (3.11), we find that

$$c_p^{\mathrm{cm}} = \frac{1}{2}\left[\frac{(b-a)^{2p+1}}{2^{2p}(2p+1)}\right]^{1/p} \qquad (1 \le p < \infty)$$

and

$$c_p^{\mathrm{v}} = \frac{1}{2}\left[B(p+1, p+1)(b-a)^{2p+1}\right]^{1/p} \qquad (1 \le p < \infty),$$

where

$$B(s, t) := \int_0^1 x^{s-1}(1-x)^{t-1}\,\mathrm{d}x$$

is the beta function. Furthermore,

$$c_\infty^{\mathrm{cm}} = c_\infty^{\mathrm{v}} = \frac{(b-a)^2}{8}.$$

It can be shown that $c_p^{\mathrm{cm}} < c_p^{\mathrm{v}}$ for $1 \le p < \infty$. In particular, $c_1^{\mathrm{v}}/c_1^{\mathrm{cm}} = 2$, which expresses the well-known fact that the constant in the error term of the trapezoidal rule is twice as large as that of the midpoint rule.

5.2. Multidimensional simplices. Let $\mathfrak{S} \subset \mathbb{R}^d$ be a nondegenerate simplex with vertices $v_0, \dots, v_d$. The uniquely determined rational basis functions $B_0, \dots, B_d$ of minimal degree are the classical barycentric coordinates, which may be constructed as follows. Let $\lambda_i(x) = 0$ be the equation of a hyperplane that contains all the vertices of $\mathfrak{S}$ other than v_i. Then

$$B_i(x) \;=\; \frac{\lambda_i(x)}{\lambda_i(v_i)} \qquad (i = 0, \dots, d).$$

For $\mathcal{L}(f) := \int_{\mathfrak{S}} f(x)\,\mathrm{d}x$, we obtain

$$x^{\mathrm{cm}} \;=\; \frac{1}{|\mathfrak{S}|} \int_{\mathfrak{S}} x \,\mathrm{d}x \;=\; \frac{1}{d+1} \sum_{i=0}^{d} v_i,$$

where we write $|\mathfrak{S}|$ for the d-dimensional volume of $\mathfrak{S}$. This gives a representation of e^{cm} in terms of the vertices, which, via (4.4) and (3.17), leads us to

$$c_\infty^{\mathrm{cm}} \;=\; \frac{1}{2(d+1)^2} \max_{0 \le i \le d} \left\| \sum_{j=0}^{d} (v_i - v_j) \right\|^2 .$$

Since the basis functions B_i belong to $\mathcal{P}_1$, the function e^{v}, defined in (2.2), is now of the form $e^{\mathrm{v}} = \lambda - \|\cdot\|^2$, where $\lambda \in \mathcal{P}_1$. Therefore $e^{\mathrm{v}}(x) = 0$ is the equation of the uniquely defined sphere that contains all the vertices of $\mathfrak{S}$ (see, e.g., Stämpfle [6, Proposition 3.1]). Thus e^{v} can be represented as

$$e^{\mathrm{v}}(x) \;=\; \widehat{r}^2 - \|x - \widehat{x}\|^2$$

for some $\widehat{r} > 0$ and $\widehat{x} \in \mathbb{R}^d$.

The case of the approximation by Λ^{v} with respect to the norm $\|\cdot\|_\infty$ is covered by the papers of Waldron [8, Theorem 2.1] and Stämpfle [6, Theorem 4.1]; also see de Boor [1]. Clearly, $c_\infty^{\mathrm{v}} = \widehat{r}^2/2$ when $\widehat{x} \in \mathfrak{S}$. Otherwise, it can be shown that $c_\infty^{\mathrm{v}} = \frac{1}{2}(\widehat{r}^2 - \rho^2)$, where ρ is the distance of $\widehat{x}$ from $\mathfrak{S}$. Geometrically, $2c_\infty^{\mathrm{v}}$ may be interpreted as the square of the radius of the smallest ball that contains $\mathfrak{S}$ (see [6, Lemma 4.2]).

For the standard unit simplex of dimension $d \ge 2$, a straightforward calculation gives

$$c_\infty^{\mathrm{cm}} \;=\; \frac{d^2 + d - 1}{2(d+1)^2} \qquad \text{and} \qquad c_\infty^{\mathrm{v}} \;=\; \frac{d-1}{2d},$$

and so

$$\frac{c_\infty^{\mathrm{v}}}{c_\infty^{\mathrm{cm}}} \;=\; 1 - \frac{1}{d(d^2 + d - 1)} \;<\; 1.$$

For the calculation of the constants (4.3) for $y = x^{\mathrm{cm}}$, we first determine $\mathcal{L}(e^{\mathrm{cm}})$ with the help of a cubature rule which is exact for all polynomials of degree less than or equal to 2, taken from the book of Stroud [7, formula $T_n : 2$-2, p. 307]. This gives

$$\begin{aligned} \mathcal{L}(e^{\mathrm{cm}}) = \int_{\mathfrak{S}} e^{\mathrm{cm}}(x)\,\mathrm{d}x = \frac{(2-d)\,|\mathfrak{S}|}{(d+2)(d+1)} & \sum_{i=0}^{d} e^{\mathrm{cm}}(v_i) \\ + \frac{4\,|\mathfrak{S}|}{(d+2)(d+1)} & \sum_{0 \le i < j \le d} e^{\mathrm{cm}}(v_{ij}), \end{aligned}$$

where $v_{ij} = \frac{1}{2}(v_i + v_j)$. Simplifying the second sum by making use of the special form of e^{cm}, we arrive at

$$\mathcal{L}(e^{\mathrm{cm}}) = \frac{|\mathfrak{S}|}{(d+2)(d+1)} \sum_{i=0}^{d} e^{\mathrm{cm}}(v_i).$$

Since the basis functions $B_0, \ldots, B_d$ belong to $\mathcal{P}_1$, we conclude that

$$\mathcal{L}(B_i) \;=\; \mathcal{L}(1)B_i(x^{\mathrm{cm}}) \;=\; \frac{\mathcal{L}(1)}{d+1} \;=\; \frac{|\mathfrak{S}|}{d+1} \qquad (i = 0, \ldots, d)$$

and therefore

$$I^{\mathrm{v}}(e^{\mathrm{cm}}) = \frac{|\mathfrak{S}|}{d+1} \sum_{i=0}^{d} e^{\mathrm{cm}}(v_i).$$

Thus, by (4.3), the definition of e^{cm} in (4.4), and the representation in (2.3), we have

$$c_1^{\mathrm{cm}} \;=\; \frac{|\mathfrak{S}|}{2(d+2)(d+1)} \sum_{i=0}^{d} \|v_i - x^{\mathrm{cm}}\|^2$$

and

$$c_1^{\mathrm{v}} \;=\; \frac{|\mathfrak{S}|}{2(d+2)} \sum_{i=0}^{d} \|v_i - x^{\mathrm{cm}}\|^2.$$

These values for c_1^{cm} and c_1^{v} also follow from [3, Corollary 6.2, formulae (6.4) and (6.5)]. We see that $c_1^{\mathrm{v}} = (d+1)c_1^{\mathrm{cm}}$ and $\kappa = 1/(d+2)$ in (4.5).

5.3. Hyperrectangles. Let

$$\mathfrak{R} \;:=\; [a_1, b_1] \times \cdots \times [a_d, b_d]$$

be a rectangle in $\mathbb{R}^d$ with vertices

$$v_i \;:=\; (v_{i1}, \ldots, v_{id}) \qquad (i = 1, \ldots, 2^d).$$

To each vertex v_i, there corresponds exactly one vertex of maximal distance, which we call the *diametrically opposite* vertex and which we denote by $\overline{v}_i := (\overline{v}_{i1}, \ldots, \overline{v}_{id})$. Any two vertices v_i and v_j have at least one common component unless they are a pair of diametrically opposite vertices. Therefore

$$B_i(x) \;:=\; \prod_{j=1}^{d} \frac{x_j - \overline{v}_{ij}}{v_{ij} - \overline{v}_{ij}} \qquad (i = 1, \ldots, 2^d),$$

where $x = (x_1, \ldots, x_d)$, are the rational basis functions of smallest degree, spanning a polynomial space of dimension 2^d, which contains $\mathcal{P}_1$ as a subspace.

For $\mathcal{L}(f) := \int_{\mathfrak{R}} f(x)\,\mathrm{d}x$, the center of mass is

$$x^{\mathrm{cm}} \;=\; \frac{1}{2}(a_1 + b_1, \ldots, a_d + b_d).$$

With this, we find that

$$e^{\mathrm{cm}}(v_i) \;=\; \frac{1}{4}\sum_{i=1}^{d}(a_i-b_i)^2 \;=:\; (r^{\mathrm{cm}})^2 \qquad (i=1,\dots,2^d).$$

Therefore (2.5) implies that

$$e^{\mathrm{cm}}(x)+e^{\mathrm{v}}(x) \;=\; (r^{\mathrm{cm}})^2$$

for all x. Consequently,

$$\sup_{x\in\mathfrak{R}} e^{\mathrm{cm}}(x) \;=\; \sup_{x\in\mathfrak{R}} e^{\mathrm{v}}(x) \;=\; (r^{\mathrm{cm}})^2,$$

or equivalently,

$$c_\infty^{\mathrm{cm}} \;=\; c_\infty^{\mathrm{v}} \;=\; \frac{(r^{\mathrm{cm}})^2}{2}.$$

For determining the best constants in the case $p=1$, we first calculate

$$\mathcal{L}(e^{\mathrm{cm}}) \;=\; \int_{\mathfrak{R}} \|x-x^{\mathrm{cm}}\|^2\,\mathrm{d}x \;=\; \frac{(r^{\mathrm{cm}})^2}{3}\,|\mathfrak{R}|\,,$$

where $|\mathfrak{R}| = \prod_{i=1}^{d}(b_i-a_i)$, and note that

$$I^{\mathrm{v}}(e^{\mathrm{cm}}) \;=\; (r^{\mathrm{cm}})^2\,|\mathfrak{R}|\,.$$

Hence (4.3) with $y=x^{\mathrm{cm}}$ implies that

$$c_1^{\mathrm{cm}} = \frac{(r^{\mathrm{cm}})^2}{6}\,|\mathfrak{R}| \qquad \text{and} \qquad c_1^{\mathrm{v}} = \frac{(r^{\mathrm{cm}})^2}{3}\,|\mathfrak{R}|\,.$$

Thus, $c_1^{\mathrm{v}}/c_1^{\mathrm{cm}} = 2$ and $\kappa = 1/3$, as in the univariate case.

In the literature, analogues of the trapezoidal rule for hyperrectangles have been studied in the context of tensor product rules (see, e.g., [2, section 8.2]).

REPRESENTATIONS OF RUNGE–KUTTA METHODS AND STRONG STABILITY PRESERVING METHODS*

INMACULADA HIGUERAS[†]

Abstract. Over the last few years a great effort has been made to develop monotone high order explicit Runge–Kutta methods by means of their Shu–Osher representations. In this context, the stepsize restriction to obtain numerical monotonicity is normally computed using the optimal representation. In this paper we extend the Shu–Osher representations for any Runge–Kutta method giving sufficient conditions for monotonicity. We show how optimal Shu–Osher representations can be constructed from the Butcher tableau of a Runge–Kutta method.

The optimum stepsize restriction for monotonicity is given by the radius of absolute monotonicity of the Runge–Kutta method [L. Ferracina and M. N. Spijker, *SIAM J. Numer. Anal.*, 42 (2004), pp. 1073–1093], and hence if this radius is zero, the method is not monotone. In the Shu–Osher representation, methods with zero radius require negative coefficients, and to deal with them, an extra associate problem is considered. In this paper we interpret these schemes as representations of perturbed Runge–Kutta methods. We extend the concept of radius of absolute monotonicity and give sufficient conditions for monotonicity. Optimal representations can be constructed from the Butcher tableau of a perturbed Runge–Kutta method.

1. Introduction.

We consider initial value problems for ordinary differential systems (ODEs) of the form

$$\begin{aligned} \frac{d}{dt}u(t) &= f(u(t)), \qquad t \geq t_0, \\ u(t_0) &= u_0. \end{aligned} \tag{1.1}$$

We assume that $t_0 \in \mathbb{R}$, $u_0 \in \mathbb{R}^m$, and f is a function from $\mathbb{R}^m$ to $\mathbb{R}^m$ such that for each $t_0 \in \mathbb{R}$ and $u_0 \in \mathbb{R}^m$ the problem (1.1) has a unique solution $u : [t_0, \infty) \to \mathbb{R}^m$. We assume too that $\| \cdot \| : \mathbb{R}^m \to \mathbb{R}$ is a convex functional (e.g., a norm, a seminorm, etc.) such that for any $t_0 \in \mathbb{R}$ and any solution $u(t)$ to (1.1) we have

$$\|u(t)\| \leq \|u(t_0)\| \qquad \forall\, t \geq t_0. \tag{1.2}$$

On $(f, \| \cdot \|)$ we impose the condition

$$\left\| y + \frac{1}{\rho} f(y) \right\| \leq \|y\| \qquad \forall\, y \in \mathbb{R}^m \tag{1.3}$$

for some fixed $\rho > 0$, and we denote this class of problems by $\mathcal{F}(\rho)$. From [10, Lemma II.5.1], we get that if (1.3) holds, condition

$$\|y + \tau f(y)\| \leq \|y\|, \qquad 0 \leq \tau \leq \frac{1}{\rho}, \tag{1.4}$$

*Received by the editors May 1, 2003; accepted for publication (in revised form) January 6, 2005; published electronically September 20, 2005. This research was supported by the Ministerio de Ciencia y Tecnología, Project BFM2001-2188.

http://www.siam.org/journals/sinum/43-3/42706.html

[†]Departamento de Matemática e Informática, Universidad Pública de Navarra 31006, Pamplona, Navarra, Spain (higueras@unavarra.es).

also holds. Denoting by D_+ the right-hand derivative, for $u(t)$, the solution of (1.1), we obtain [1, Lemma 1.5.3]

$$D_+\|u(t)\| = \lim_{\tau\to 0^+} \frac{\|u(t)+\tau u'(t)\| - \|u(t)\|}{\tau} = \lim_{\tau\to 0^+} \frac{\|u(t)+\tau f(u(t))\| - \|u(t)\|}{\tau} \le 0.$$

Hence assumption (1.3) with $\rho > 0$ gives the monotonicity inequality (1.2) for the solution of the ODE (1.1). Later on, we will also use the inequality

$$\|y\| \le \|y + \tau f(y)\| \qquad \forall\, \tau < 0,\ \forall\, y \in \mathbb{R}^m. \tag{1.5}$$

From [10, Lemma II.5.1], it can be concluded that condition (1.3) implies condition (1.5). In the rest of the paper we assume that f in (1.1) satisfies $(f, \|\cdot\|) \in \mathcal{F}(\rho)$.

Given the initial value problem (1.1), a common class of one-step methods to solve it numerically is the Runge–Kutta (RK) methods. An s-stage RK method is defined by an $s \times s$ real matrix $\mathcal{A}$ and a real vector $b \in \mathbb{R}^s$; we will refer to it as $(\mathcal{A}, b)$. From u_n, the numerical approximation of the solution $u(t)$ at $t = t_n$, we obtain u_{n+1}, the numerical approximation of the solution at $t_{n+1} = t_n + h$ from

$$u_{n+1} = u_n + h \sum_{i=1}^{s} b_i f(U_i), \tag{1.6}$$

$$U_i = u_n + h \sum_{j=1}^{s} a_{ij} f(U_j). \tag{1.7}$$

The internal stage U_i approximates $u(t_n + c_i h)$, where $c_i = \sum_{j=1}^{s} a_{ij}$. Furthermore, for many methods $c_i \ge 0$, $i = 1, \dots, s$, and thus $t_n + c_i h \ge t_n$.

If we solve numerically an ODE (1.1) with $(f, \|\cdot\|) \in \mathcal{F}(\rho)$ with an RK method, a natural requirement for the internal stages and the numerical solution is

$$\|U_i\| \le \|u_n\|, \quad i = 1, \dots, s, \quad \|u_{n+1}\| \le \|u_n\|, \tag{1.8}$$

for all $n \ge 0$, probably under a stepsize restriction $h \le \Delta t_{MAX}$.

1.1. SSP methods. Over the last few years ([13], [14], [5], [11], [16], [6]; see [4], [15] for reviews on this topic) a great effort has been done to develop high order methods satisfying (1.8) when the forward Euler discretization of (1.1) satisfies (1.8),

$$\|u_n + h f(u_n)\| \le \|u_n\| \qquad \text{for } h \le \Delta t_{FE}. \tag{1.9}$$

These methods are called strong stability preserving methods (SSP methods). The class of ODEs considered in this context arise from a method-of-lines approximation of hyperbolic conservation laws. A simple numerical example given in [4] shows that the use of non-SSP methods for the time discretization of these ODEs has the potential to produce an undesirable overshoot.

As the forward Euler method has the drawback of a low order of accuracy, higher order SSP methods are of great interest. The idea in [14], [13] is to derive conditions (1.8) from condition (1.9) for the forward Euler method by means of convex combinations of it. In [13], Shu and Osher write explicit s-stage RK methods as

$$\begin{aligned} u^{(1)} &= u_n, \\ u^{(i)} &= \sum_{k=1}^{i-1} (\alpha_{ik} u^{(k)} + h\, \beta_{ik}\, f(u^{(k)})), \qquad i = 2, \dots, s+1, \\ u_{n+1} &= u^{(s+1)}, \end{aligned} \tag{1.10}$$

where $\alpha_{ik} \geq 0$ for all i, j, and $\sum_{k=1}^{i-1} \alpha_{ik} = 1$, $i = 2, \ldots, s+1$. It is also imposed that

$$\beta_{i,j} = 0 \qquad \text{whenever} \qquad \alpha_{ij} = 0. \tag{1.11}$$

Proceeding in this way, the new method will also be strongly stable, perhaps with a modified stepsize restriction

$$h \leq c\,\Delta t_{FE}. \tag{1.12}$$

The coefficient c in (1.12) is known as a CFL coefficient. Convex combinations of the forward Euler method are obtained in (1.10) if $\beta_{ij} \geq 0$. In this case, the CFL coefficient is given by

$$c = \min_{ik} \frac{\alpha_{ik}}{\beta_{ik}}. \tag{1.13}$$

The representation of RK methods in the form (1.10) is not unique [16]. Different representations give rise to different values for the CFL coefficient (1.13).

If some $\beta_{ij} < 0$, then f is replaced by an associated operator $\tilde{f}$ corresponding to stepping backward in time. The requirement for $\tilde{f}$ is that it approximate the same spatial derivatives as f, and that (1.8) hold with the same stepsize restriction for the explicit Euler scheme solved backwards, $u_{n+1} = u_n - h\tilde{f}(u_n)$; i.e.,

$$\|u_n - h\tilde{f}(u_n)\| \leq \|u_n\| \qquad \text{for } h \leq \Delta t_{FE}. \tag{1.14}$$

In this case [13], the RK method is SSP under the stepsize restriction (1.12) with

$$c = \min_{ik} \frac{\alpha_{ik}}{|\beta_{ik}|}. \tag{1.15}$$

For example, the classical fourth order four-stage RK method can be written [13] as

$$\begin{aligned}
u^{(1)} &= u^{(0)},\\
u^{(2)} &= u^{(1)} + \frac{1}{2}hf(u^{(1)}),\\
u^{(3)} &= \frac{1}{2}u^{(1)} - \frac{1}{4}h\tilde{f}(u^{(1)}) + \frac{1}{2}u^{(2)} + \frac{1}{2}hf(u^{(2)}),\\
u^{(4)} &= \frac{1}{9}u^{(1)} - \frac{1}{9}h\tilde{f}(u^{(1)}) + \frac{2}{9}u^{(2)} - \frac{1}{3}h\tilde{f}(u^{(2)}) + \frac{2}{3}u^{(3)} + hf(u^{(3)}),\\
u^{(5)} &= \frac{1}{3}u^{(2)} + \frac{1}{6}hf(u^{(2)}) + \frac{1}{3}u^{(3)} + \frac{1}{3}u^{(4)} + \frac{1}{6}hf(u^{(4)}).
\end{aligned} \tag{1.16}$$

The CFL coefficient given by (1.15) is $c = 2/3$. A better definition of $u^{(4)}$ allows us to raise the CFL coefficient to $c = 137/200$ [13].

A particular class of implicit RK methods is also considered in [4, section 6.2]:

$$\begin{aligned}
u^{(1)} &= u_n,\\
u^{(i)} &= \sum_{k=1}^{i-1} \alpha_{ik}u^{(k)} + h\,\beta_i\,f(u^{(i)}), \qquad i = 2, \ldots, s+1,\\
u_{n+1} &= u^{(s+1)},
\end{aligned} \tag{1.17}$$

with $\alpha_{ik} \geq 0$ and $\sum_{k=1}^{i-1} \alpha_{ik} = 1$. In this case, monotonicity, or more precisely unconditional monotonicity, is assumed on the implicit Euler method; i.e., for

$$u_{n+1} = u_n + h\, f(u_{n+1}),$$

it holds that $\|u_{n+1}\| \leq \|u_n\|$ for any stepsize h; i.e.,

$$\|u_{n+1}\| \leq \|u_{n+1} - h\, f(u_{n+1})\| \qquad \forall\, h > 0. \tag{1.18}$$

At this point we would like to establish a link between the class of problems considered in this paper and SSP methods. If we compare the condition (1.3) (see also (1.4)) imposed on the problem, with the condition (1.9) assumed in the SSP context for the explicit Euler method, we get that $\Delta t_{FE} = 1/\rho$; i.e., the stepsize restriction for the forward Euler method is determined by the class of problem considered. Furthermore, condition (1.18) imposed for implicit problems in the SSP context is precisely (1.5). Remember that (1.3) implies (1.5).

Therefore the class of problems considered in the SSP context is also $(f, \|\cdot\|) \in \mathcal{F}(\rho)$. For these problems, the explicit Euler method is monotone under stepsize restriction $h \leq 1/\rho$, whereas the implicit Euler method is unconditionally monotone.

1.2. Radius of absolute monotonicity. In the context of contractive RK methods, the concept of radius of absolute monotonicity plays an important role [7]. Recently, Ferracina and Spijker [2] have proved that this concept is also relevant for monotone methods. We remember the definitions of absolute monotonicity and radius of absolute monotonicity.

Definition 1.1 (see [7, Definition 2.4]). *An s-stage RK method with coefficients $(\mathcal{A}, b)$ is said to be absolutely monotonic at a given point $\xi \leq 0$ if $I - \xi\mathcal{A}$ is nonsingular, the stability function $\phi(\xi) = 1 + \xi\, b^t(I - \xi\mathcal{A})^{-1}e \geq 0$, $\mathcal{A}(\xi) = \mathcal{A}(I - \xi\mathcal{A})^{-1} \geq 0$, $b(\xi)^t = b^t(I - \xi\mathcal{A})^{-1} \geq 0$, and $e(\xi) = (I - \xi\mathcal{A})^{-1}e \geq 0$, where $e = (1, 1, \ldots, 1) \in \mathbb{R}^s$, and the vector inequalities are understood componentwise. Further, the method is said to be absolutely monotonic on a given set $\Omega \subset \mathbb{R}$ if it is absolutely monotonic at each $\xi \in \Omega$. The radius of absolute monotonicity $R(\mathcal{A}, b)$ is defined by*

$$R(\mathcal{A}, b) = \sup\{r \mid r \geq 0 \text{ and } (\mathcal{A}, b) \text{ is absolutely monotonic on } [-r, 0]\}. \tag{1.19}$$

If there is no $r > 0$ such that $(\mathcal{A}, b)$ is absolutely monotonic on $[-r, 0]$, we set $R(\mathcal{A}, b) = 0$.

Observe that the four conditions on $\phi(\xi)$, $\mathcal{A}(\xi)$, $b(\xi)$, and $e(\xi)$ in Definition 1.1 can be written in compact form as

$$\begin{pmatrix} (I - \xi\mathcal{A})^{-1} & 0 \\ \xi\, b^t(I - \xi\mathcal{A})^{-1} & 1 \end{pmatrix} \begin{pmatrix} e \\ 1 \end{pmatrix} \geq 0, \qquad \begin{pmatrix} (I - \xi\mathcal{A})^{-1} & 0 \\ \xi\, b^t(I - \xi\mathcal{A})^{-1} & 1 \end{pmatrix} \begin{pmatrix} \mathcal{A} & 0 \\ b^t & 0 \end{pmatrix} \geq 0. \tag{1.20}$$

Denoting the coefficients of an RK method by

$$\mathbb{A} = \begin{pmatrix} \mathcal{A} & 0 \\ b^t & 0 \end{pmatrix},$$

we can write (1.20) as

$$(I - \xi\mathbb{A})^{-1}\mathbb{A} \geq 0, \qquad (I - \xi\mathbb{A})^{-1}e \geq 0, \tag{1.21}$$

where now $e = (1, 1, \ldots, 1)^t \in \mathbb{R}^{s+1}$. In the following we will denote $R(\mathcal{A}, b)$ in (1.19) by $R(\mathbb{A})$.

1.3. Scope of the paper. Recently, Ferracina and Spijker [2] have established a link between the radius of absolute stability and the stepsize restriction (1.12). More precisely, in [2] it is proved that if (1.9) holds, irreducible RK methods are monotone with stepsize restriction $h \leq c\,\Delta t_{FE}$ if and only if $c \leq R(\mathbb{A})$. In other words, the optimal CFL coefficient in (1.12) is $R(\mathbb{A})$. As the CFL coefficient in (1.13) is normally obtained using a numerical optimal representation, a natural question that arises is whether, given the Butcher tableau of an explicit RK method, there exists a representation such that the CFL coefficient (1.13) is the maximum one $R(\mathbb{A})$. On the other hand, representations (1.10) and (1.17) are given for explicit methods and a class of implicit methods, respectively, whereas $R(\mathbb{A})$ is defined for general RK methods. This suggests that more general representations can be considered, and from them a notion of CFL coefficient like the one in (1.13) can be computed. In this paper we study these issues. The rest of the paper is organized as follows.

In section 2 we define a kind of representation of the RK methods that contains schemes (1.10) and (1.17) as particular cases, and we extend the CFL coefficient (1.13). We also prove that if $R(\mathbb{A}) > 0$, it is possible to obtain an optimal representation such that the CFL coefficient computed from it is equal to $R(\mathbb{A})$.

Section 3 is devoted to RK methods $\mathbb{A}$ with $R(\mathbb{A}) = 0$. In the Shu–Osher representation, methods with negative coefficients β_{ij} imply that $R(\mathbb{A}) = 0$, and to deal with them, an extra associate problem is considered. In this paper we interpret these schemes as representations of perturbed RK methods. An extension of the CFL coefficient (1.15) is defined. We also extend the concept of radius of absolute monotonicity and give sufficient conditions for monotonicity. Optimal representations can be constructed from the Butcher tableau of a perturbed RK method.

The paper ends with some conclusions and some open questions for future work.

2. Representations of an RK method. We consider methods of the form

$$U = \alpha \otimes u_n + (\Lambda \otimes I)U + h(\Gamma \otimes I)F(U), \tag{2.1}$$

where $\alpha \in \mathbb{R}^{s+1}$, Λ and Γ are $(s+1) \times (s+1)$ matrices such that $\Lambda e + \alpha = e$, the matrix $I - \Lambda$ is invertible, and the last column in Γ, Λ is zero. We have defined $e = (1, \ldots, 1)^t \in \mathbb{R}^{s+1}$, $U = (U_1^t, \ldots, U_s^t, u_{n+1}^t)^t \in \mathbb{R}^{(s+1)m}$, and $F(U) = (f(U_1)^t, \ldots, f(U_s)^t, 0)^t \in \mathbb{R}^{(s+1)m}$. The symbol $\otimes$ denotes the Kronecker product (see, e.g., [9, section 12.1]).

Method (1.10) is a particular case of (2.1), with $\alpha = (1, 0, \ldots, 0)^t$ and

(2.2)
$$\Lambda = \begin{pmatrix} 0 & 0 & \cdots & \cdots & 0 \\ \alpha_{21} & 0 & \ddots & & \vdots \\ \alpha_{31} & \alpha_{32} & 0 & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ \alpha_{s+1,1} & \alpha_{s+1,2} & \cdots & \alpha_{s+1,s} & 0 \end{pmatrix}, \qquad \Gamma = \begin{pmatrix} 0 & 0 & \cdots & \cdots & 0 \\ \beta_{21} & 0 & \ddots & & \vdots \\ \beta_{31} & \beta_{32} & 0 & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ \beta_{s+1,1} & \beta_{s+1,2} & \cdots & \beta_{s+1,s} & 0 \end{pmatrix}.$$

Method (1.17) is also a particular case of (2.1) with $\alpha = (\alpha_{21}, \alpha_{31}, \ldots, \alpha_{s+1,1}, 0)^t$ and

(2.3)
$$\Lambda = \begin{pmatrix} 0 & 0 & \cdots & \cdots & \cdots & 0 \\ \alpha_{32} & 0 & \ddots & & & \vdots \\ \alpha_{42} & \alpha_{43} & 0 & \ddots & & \vdots \\ \vdots & \vdots & \ddots & \ddots & \ddots & 0 \\ \alpha_{s+1,2} & \alpha_{s+1,3} & \cdots & \alpha_{s+1,s} & 0 & 0 \\ 0 & \cdots & \cdots & 0 & 1 & 0 \end{pmatrix}, \quad \Gamma = \begin{pmatrix} \beta_2 & 0 & \cdots & \cdots & \cdots & 0 \\ 0 & \beta_3 & \ddots & & & \vdots \\ 0 & \ddots & \beta_4 & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & \cdots & 0 & \beta_{s+1} & 0 \\ 0 & \cdots & \cdots & 0 & 0 & 0 \end{pmatrix}.$$

Remark 1. Observe that in (2.2), $U_1 = u_n$, and hence the elements $\alpha_{21}, \ldots, \alpha_{s+1,1}$ in Λ can appear either in Λ or in α.

In compact form, (1.6)–(1.7) can be written as

$$U = e \otimes u_n + h\, (\mathbb{A} \otimes I)\, F(U). \tag{2.4}$$

It is straightforward to obtain that (2.1) can be written as

$$U = e \otimes u_n + h\, (((I - \Lambda)^{-1}\Gamma) \otimes I)\, F(U).$$

Comparing this expression with (2.4), we obtain that (2.1) is an RK method with $\mathbb{A} = (I - \Lambda)^{-1}\Gamma$, and for this reason we will refer to (2.1) as a representation of the RK method $\mathbb{A}$. On the other hand, if the RK coefficient matrix $\mathbb{A}$ can be factorized as $\mathbb{A} = (I - \Lambda)^{-1}\Gamma$, we can write (2.4) in the form of (2.1). Observe that such a representation is always possible. For example, we can always take a trivial one with $\Lambda = 0$ and $\Gamma = \mathbb{A}$. More interesting representations can also be given.

Example 1. For the classical four-stage order four method we can write $\mathbb{A} = (I - \Lambda_i)^{-1}\Gamma_i$, $i = 1, 2$, with

(2.5)
$$\Lambda_1 = \begin{pmatrix} 0 & & & & \\ 1 & 0 & & & \\ 1/2 & 1/2 & 0 & & \\ 1/9 & 2/9 & 2/3 & 0 & \\ 0 & 1/3 & 1/3 & 1/3 & 0 \end{pmatrix}, \qquad \Gamma_1 = \begin{pmatrix} 0 & & & & \\ 1/2 & 0 & & & \\ -1/4 & 1/2 & 0 & & \\ -1/9 & -1/3 & 1 & 0 & \\ 0 & 1/6 & 0 & 1/6 & 0 \end{pmatrix},$$

(2.6)
$$\Lambda_2 = \begin{pmatrix} 0 & & & & \\ 1/3 & 0 & & & \\ 2/9 & 1/3 & 0 & & \\ 2/27 & 2/9 & 2/3 & 0 & \\ 40/243 & 22/81 & 4/27 & 1/9 & 0 \end{pmatrix}, \qquad \Gamma_2 = \begin{pmatrix} 0 & & & & \\ 1/2 & 0 & & & \\ -1/6 & 1/2 & 0 & & \\ -1/9 & -1/3 & 1 & 0 & \\ 5/162 & 7/27 & 2/9 & 1/6 & 0 \end{pmatrix}.$$

Observe that in both cases, $\Lambda \geq 0$ but Γ contains negative elements.

Once we have defined the representations (2.1), the next step is to extend the CFL coefficient (1.13) that gives the stepsize restriction for monotonicity.

PROPOSITION 2.1. *Consider a method of the form* (2.1) *such that* $\Lambda\, e \leq e$, $\Lambda \geq 0$, $\Gamma \geq 0$, *and*

$$\Lambda - c\,\Gamma \geq 0 \qquad \textit{for some } c > 0. \tag{2.7}$$

Then for

$$h \leq c\,\frac{1}{\rho}, \tag{2.8}$$

it holds that $\|U_i\| \leq \|u_n\|$, $i = 1, \dots, s$, $\|u_{n+1}\| \leq \|u_n\|$.

Proof. The proof is the same as that for Proposition 3.9 below, with $\tilde{\Lambda} = 0$ and $\tilde{\Gamma} = 0$. □

Remark 2.

1. Observe that (2.7) implies condition (1.11).
2. Observe that the maximum c in (2.7) is

   $$c = \min_{ij} \frac{\alpha_{ij}}{\beta_{ij}}. \tag{2.9}$$

   As a particular case we get the CFL coefficient (1.13) obtained in the SSP context.
3. As $\alpha + \Lambda\, e = e$, with $\alpha \geq 0$, $\Lambda \geq 0$, the proof is also valid for a convex functional $\| \cdot \|$.

Observe that, whereas the CFL coefficient (1.13) was defined only for explicit methods, the CFL coefficient c in (2.7) can also be computed for implicit methods.

Example 2. We consider the methods of the form (2.1) with $\alpha = (1, 0, 0)^t$ and

$$\Lambda = \begin{pmatrix} 0 & 0 & 0 \\ 1/2 & 1/2 & 0 \\ 1/2 & 1/2 & 0 \end{pmatrix}, \qquad \Gamma = \begin{pmatrix} 0 & 0 & 0 \\ 1/4 & 1/4 & 0 \\ 1/4 & 1/4 & 0 \end{pmatrix}. \tag{2.10}$$

It corresponds to the RK method $\mathbb{A}$ with

$$\mathbb{A} = \begin{pmatrix} 0 & 0 & 0 \\ 1/2 & 1/2 & 0 \\ 1/2 & 1/2 & 0 \end{pmatrix}. \tag{2.11}$$

We get $\Lambda - c\Gamma = 0$ for $c = 2$. Hence Proposition 2.1 gives that the method is monotone under stepsize restriction (2.8) with $c = 2$.

The next goal is to establish a relationship between representations of an RK method $\mathbb{A}$, $\mathbb{A} = (I - \Lambda)^{-1}\Gamma$, the CFL coefficient c in (2.7), and $R(\mathbb{A})$. Although from the study done by Ferracina and Spijker [2] we can conclude that, for irreducible RK methods, for the CFL coefficient c dictated by (2.7) we have $c \leq R(\mathbb{A})$, this fact can easily be obtained directly for arbitrary RK schemes.

Proposition 2.2. *Consider an RK method* $\mathbb{A}$. *Assume that it can be written in terms of* Λ *and* Γ *with*

$$\Lambda\, e \leq e, \qquad \Gamma \geq 0, \qquad \Lambda - c\,\Gamma \geq 0,$$

and the matrix $I - (\Lambda - c\,\Gamma)$ *invertible for some coefficient* $c \geq 0$. *Then the method is absolutely monotonic at* $-c$.

Proof. The proof is the same as that for Proposition 3.11 below, with $\tilde{\Lambda} = 0$ and $\tilde{\Gamma} = 0$. □

In particular, if for an RK method it holds that $R(\mathbb{A}) = 0$, then it is not possible to get a representation with $\Lambda \geq 0$, $\Gamma \geq 0$, $\alpha \geq 0$, and $\Lambda - c\Gamma \geq 0$ for some $c > 0$.

An algebraic criterion for obtaining $R(\mathbb{A}) > 0$ for irreducible methods is given in [7, Theorem 4.2]. See [1, Definitions 4.4.1 and 4.4.3] for the definition of reducible methods, and [7] for a complete study of order barriers and stage order barriers when $R(\mathbb{A}) > 0$. Taking into account the extension we plan to do in section 3, we are going to obtain algebraic criteria for obtaining $R(\mathbb{A}) > 0$ for any reducible or irreducible RK methods. To proceed we need the following definition.

DEFINITION 2.3. *For matrix $F = (f_{ij})$ we define its incidence matrix* $\mathrm{Inc}(F) = (g_{ij})$ *by $g_{ij} = 1$ if $f_{ij} \neq 0$ and by $g_{ij} = 0$ if $f_{ij} = 0$.*

We give an algebraic criterion for getting $R(\mathbb{A}) > 0$.

PROPOSITION 2.4. *Consider an RK method with coefficients $\mathbb{A}$. Then $R(\mathbb{A}) > 0$ if and only if $\mathbb{A} \geq 0$ and*

$$\mathrm{Inc}(\mathbb{A}^2) \leq \mathrm{Inc}(\mathbb{A}). \tag{2.12}$$

Proof. See the proof of Proposition 3.7 below for $\tilde{\mathbb{A}} = 0$. □

Recall that Proposition 2.4 is not exactly Theorem 4.2 in [7], as we have not assumed the irreducibility of the RK method. In the following lemma we study some of the conditions involved in Proposition 2.4 for irreducible methods.

LEMMA 2.5. *Consider an irreducible RK method $\mathbb{A}$ with $\mathbb{A} \geq 0$. Then $b > 0$ if and only if* $\mathrm{Inc}(b^t\mathcal{A}) \leq \mathrm{Inc}(b^t)$.

Proof. If $b > 0$, then trivially $\mathrm{Inc}(b^t\mathcal{A}) \leq \mathrm{Inc}(b^t)$. We assume now that $\mathrm{Inc}(b^t\mathcal{A}) \leq \mathrm{Inc}(b^t)$. We consider the sets $S = \{j \mid b_j = 0\}$ and $T = \{j \mid b_j \neq 0\}$. If there is an index j such that $b_j = 0$, then $S \neq \emptyset$. Condition $\mathrm{Inc}(b^t\mathcal{A}) \leq \mathrm{Inc}(b^t)$ gives $\sum_{i=1}^{s} b_i a_{ij} = 0$ for all $j \in S$, and hence, as $\mathbb{A} \geq 0$, we get $b_i a_{ij} = 0$, $i = 1, \dots, s$, for all $j \in S$. Thus we obtain $a_{ij} = 0$ for all $i \in T$, $j \in S$. This implies that the method is DJ-reducible [1, Definition 4.4.1], that contradicts the irreducibility assumption, and therefore $b > 0$. □

With this lemma, we get the result in [7] for irreducible methods.

COROLLARY 2.6 (see [7, Theorem 4.2]). *For an irreducible coefficient scheme $\mathbb{A}$ we have $R(\mathbb{A}) > 0$ if and only if $\mathcal{A} \geq 0$, $b > 0$, and* $\mathrm{Inc}(\mathcal{A}^2) \leq \mathrm{Inc}(\mathcal{A})$.

Proof. In terms of $(\mathcal{A}, b)$, the conditions in Proposition 2.4 are $\mathcal{A} \geq 0$, $b \geq 0$, $\mathrm{Inc}(\mathcal{A}^2) \leq \mathrm{Inc}(\mathcal{A})$, $\mathrm{Inc}(b^t\mathcal{A}) \leq \mathrm{Inc}(b^t)$. By Lemma 2.5, for irreducible methods, conditions $b > 0$ and $\mathrm{Inc}(b^t\mathcal{A}) \leq \mathrm{Inc}(b^t)$ are equivalent. □

The algebraic criterion in Proposition 2.4 is extremely useful to determine whether, for a given method, the condition $R(\mathbb{A}) > 0$ holds. For example, for the classical four-stage order four method it is straightforward to prove that condition $\mathrm{Inc}(\mathbb{A}^2) \leq \mathrm{Inc}(\mathbb{A})$ does not hold and thus $R(\mathbb{A}) = 0$.

So far we have obtained that, given a representation, the CFL coefficient c computed in (2.7) satisfies $c \leq R(\mathbb{A})$. Remember that the representation of an RK method is not unique, and hence the CFL coefficient computed in (2.7) depends on the representation available. Next we study whether, given the Butcher tableau of an RK method $\mathbb{A}$ with radius $R(\mathbb{A})$, there is a representation such that the CFL coefficient computed from (2.7) is equal to $R(\mathbb{A})$. We will refer to such representations as optimal ones. We remark that our study for optimal representations is done for a given method, and it differs from the study done in [16], where an optimization process over the CFL coefficient within classes of explicit methods, with a given number of stages and order, is done.

PROPOSITION 2.7. *We consider an RK method $\mathbb{A}$. If $0 < r = R(\mathbb{A}) < \infty$, then there exist matrices Λ and Γ such that $\mathbb{A} = (I - \Lambda)^{-1}\Gamma$ with $\Lambda \geq 0$, $\Gamma \geq 0$, $\Lambda e \leq e$, $I - (\Lambda - r\Gamma)$ invertible, and $\Lambda - r\Gamma \geq 0$.*

Proof. See the proof of Proposition 3.7 below for $\tilde{\mathbb{A}} = 0$. □

The proof of the above result is constructive and can be used to get, for a given method, an optimal representation. We remark that we can construct a representation such that $\Lambda - r\Gamma = 0$, namely,

$$\Lambda = r\,\mathbb{A}(I + r\mathbb{A})^{-1}, \qquad \Gamma = \mathbb{A} - \Lambda\mathbb{A}, \tag{2.13}$$

and $\alpha = e - \Lambda e$.

Example 3. Consider the method

$$\begin{array}{c|ccc} 0 & 0 & & \\ 1 & 1 & 0 & \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} & 0 \\ \hline & \frac{1}{6} & \frac{1}{6} & \frac{2}{3} \end{array} .$$

For this method, $R(\mathbb{A}) = 1$. From (2.13) we compute

$$\Lambda = r\,\mathbb{A}(I + r\mathbb{A})^{-1} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & \frac{1}{4} & 0 & 0 \\ 0 & 0 & \frac{2}{3} & 0 \end{pmatrix}, \qquad \Gamma = \mathbb{A} - \Lambda\mathbb{A} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & \frac{1}{4} & 0 & 0 \\ 0 & 0 & \frac{2}{3} & 0 \end{pmatrix},$$

and $\alpha = e - \Lambda e = (1, 0, 3/4, 1/3)^t$. This is essentially the representation given in [16, Table A1]. See Remark 1.

Example 4. For the method (2.11) the radius of absolute monotonicity is $R(\mathbb{A}) = 2$. The representation obtained from (2.13) is (2.10).

In Proposition 2.1 we have given conditions to ensure conditional monotonicity. The rest of the section is devoted to unconditional monotonicity issues.

The concept of M-matrix will be used. We remember that a matrix A is said to be an M-matrix if A is nonsingular, $A^{-1} \geq 0$, and the off-diagonal elements of A are nonpositive. In the following results, Γ_* denotes the matrix Γ, where the last column has been changed to $(0, \dots, 0, 1)^t$.

PROPOSITION 2.8. *Consider a representation* (2.1) *such that* Γ_* *is invertible,* $\Gamma_*^{-1}\alpha \geq 0$, *and* $\Gamma_*^{-1}(I - \Lambda)$ *is an* M*-matrix. Then for any stepsize it holds that* $\|U_i\| \leq \|u_n\|$, $i = 1, \dots, s$, $\|u_{n+1}\| \leq \|u_n\|$.

Proof. The proof is similar to the one done in [7, Theorem 6.1]. We remark that it is also valid for a convex functional $\|\cdot\|$. □

For RK methods, unconditional monotonicity is obtained when $R(\mathbb{A}) = \infty$. If we define

$$\mathbb{A}_* = \begin{pmatrix} \mathcal{A} & 0 \\ b^t & 1 \end{pmatrix},$$

and assume that the matrix $\mathbb{A}_*$ is nonsingular, then $R(\mathbb{A}) = \infty$ if and only if $\mathbb{A}_*^{-1}$ is an M-matrix and $\mathbb{A}_*^{-1}e \geq 0$ [7, Lemma 4.5].

Observe that if $\mathbb{A} = (I - \Lambda)^{-1}\Gamma$, then $\mathbb{A}_* = (I - \Lambda)^{-1}\Gamma_*$. Hence it is straightforward to prove that if the conditions of Proposition 2.8 hold, then $R(\mathbb{A}) = \infty$.

If $R(\mathbb{A}) = \infty$, an optimal representation can be given trivially,

$$\Gamma = \mathbb{A}, \qquad \Lambda = 0. \tag{2.14}$$

Unfortunately methods with $R(\mathbb{A}) = \infty$ have at most order one [7, Theorem 8.3], and therefore they are not of great interest.

Remark 3. Some of the results contained in this section have also been obtained independently by Ferracina and Spijker [3]. The main difference is how the case of unconditional monotonicity is handled. We briefly summarize the analogies and differences between both papers. Formula (2.1) in [3] is essentially our representation (2.1). The relationship between the matrices in [3, formula (2.2)] and our matrices Λ and Γ is

$$\Lambda = \begin{pmatrix} L_0 & 0 \\ L_1 & 0 \end{pmatrix}, \qquad \Gamma = \begin{pmatrix} M_0 & 0 \\ M_1 & 0 \end{pmatrix}.$$

The regularity assumption for the matrix $I - \Lambda$ is equivalent to the regularity of $I - L_0$ in [3], our relationship $\mathbb{A} = (I - \Lambda)^{-1}\Gamma$ is expression (2.5) in [3], and our conditions $\Lambda \geq 0$ and $\Lambda\, e \leq e$ are assumption (2.8) in [3]. There are two differences between the definition of the coefficient c in formula (2.9) in [3] and our CFL coefficient c in (2.7): at this point we do not consider unconditional monotonicity, and in $\Lambda - c\Gamma \geq 0$ we do not make distinctions between diagonal and nondiagonal elements. However, for explicit methods both definitions are the essentially the same. Part I in Theorem 2.2 in [3] is contained in the introduction of section 2. Our Propositions 2.1 and 2.8 on conditional and unconditional monotonicity are part II in Theorem 2.2 in [3]. We remark that Theorem 2.2 in [3] is proved simultaneously for $R(\mathbb{A}) < \infty$ and $R(\mathbb{A}) = \infty$, whereas we have obtained the results separately with different techniques. With regard to optimal representations, if $R(\mathbb{A}) < \infty$, the ones given in (3.2b) in [3, Theorem 3.4] are the same as the ones given in this paper (see (2.13) in Proposition 2.7). If $R(\mathbb{A}) = \infty$, we have given the trivial representation (2.14) that fulfills our requirements, whereas in [3] another representation is given, as it is intended to obtain the CFL coefficient ∞ in formula (2.9) in [3]. Finally, irreducibility of the RK scheme is imposed in Theorem 3.4 in [3], whereas in this paper this condition is not assumed. A detailed reading of its proof gives that irreducibility is required to prove parts I and II, where some maximal properties of CFL coefficients obtained from representations are stated. Parts I and II in [3, Theorem 3.4] are closely related with the fact that for irreducible RK methods the maximum CFL coefficient for monotonicity is $R(\mathbb{A})$ [2].

3. Perturbed RK methods. In this section we consider RK methods $\mathbb{A}$ with $R(\mathbb{A}) = 0$. In this case (see Proposition 2.1), it is not possible to obtain a representation (2.1) with positive CFL coefficient (2.7). When $R(\mathbb{A}) = 0$, we can try to perturb the method so that the new numerical solution $u_n^{(p)}$ satisfies the monotonicity condition

$$\|U_i^{(p)}\| \leq \|u_n^{(p)}\|, \quad i = 1, \dots, s, \qquad \|u_{n+1}^{(p)}\| \leq \|u_n^{(p)}\|.$$

To do so, we consider an auxiliary problem

$$\frac{d}{dt}u(t) = -\tilde{f}(u(t)), \qquad t \geq t_0, \tag{3.1}$$

and assume that, like the original problem, $(-\tilde{f}, \|\cdot\|) \in \mathcal{F}(\rho)$; i.e.,

$$\left\| y - \frac{1}{\rho}\,\tilde{f}(y) \right\| \leq \|y\| \qquad \forall\, y \in \mathbb{R}^m. \tag{3.2}$$

Given an RK method $\mathbb{A}$, we define the perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$

$$U^{(p)} = e \otimes u_n^{(p)} + h(\mathbb{A} \otimes I)F(U^{(p)}) + h(\tilde{\mathbb{A}} \otimes I)\left(F(U^{(p)}) - \tilde{F}(U^{(p)})\right), \tag{3.3}$$

with $\tilde{\mathbb{A}}$ an $(s+1) \times (s+1)$ matrix with the last column equal to $(0, \ldots, 0)^t$, and $\tilde{F}(U) = (\tilde{f}(U_1)^t, \ldots, \tilde{f}(U_s)^t, 0^t) \in \mathbb{R}^{(s+1)m}$. As far as we know, this is a new concept.

Assuming stability of the RK method $\mathbb{A}$, it is easy to prove that if the perturbations are small enough, then the perturbed method $(\mathbb{A}, \tilde{\mathbb{A}})$ will retain the order of the unperturbed problem. The standard stability bounds [8, p. 32] give

$$\|u_n^{(p)} - u_n\| \leq M\varepsilon,$$

provided that

$$h\|F(U) - \tilde{F}(U)\| \leq \varepsilon. \tag{3.4}$$

Hence, if the method $\mathbb{A}$ has order p, we have

$$\|u_n^{(p)} - u(t_n)\| \leq \|u_n^{(p)} - u_n\| + \|u_n - u(t_n)\| \leq M\varepsilon + Ch^p,$$

and therefore we obtain order p whenever $M\varepsilon = \vartheta(h^p)$. In the following we drop the exponent (p) for the perturbed solution.

In the context of SSP methods, where the ODE comes from a semidiscretization of the hyperbolic conservation laws, the auxiliary problem (3.1) is obtained with another semidiscretization such that (3.2) holds. For example [13, p. 444], for $u_t = u_x$ we can semidiscretize u_x as

$$u_x(x_j, t) \approx \frac{u(x_j + \Delta x, t) - u(x_j, t)}{\Delta x} := f(u)_j$$

and

$$u_x(x_j, t) \approx \frac{u(x_j, t) - u(x_j - \Delta x, t)}{\Delta x} := \tilde{f}(u)_j,$$

obtaining, respectively, properties (1.3) and (3.2) for $\rho = 1/\Delta x$. In this case (3.4) holds with ε depending on the space discretization step Δx.

3.1. The radius of absolute monotonicity for perturbed RK methods. The radius of absolute monotonicity had an important role in monotonicity. In this section we extend this concept to perturbed RK methods $(\mathbb{A}, \tilde{\mathbb{A}})$ and analyze some of its properties. For a better understanding of that extension, we briefly show how conditions in Definition 1.1 arise in [7].

In [7] the scalar linear problems $u' = \lambda u$, $u' = \lambda(t)u$ and the vectorial linear problem $u' = L(t)u(t)$, with $L(t)$ an $m \times m$ matrix, are considered. An RK method $\mathbb{A}$ for these problems gives, respectively, $U = \phi(h\lambda)u_n$ with $\phi(z) = (I_{s+1} - z\mathbb{A})^{-1}e$, $U = K(\operatorname{diag}(h\lambda_1, \ldots, h\lambda_s, 0))\, u_n$ with $K(Z) = (I_{s+1} - \mathbb{A}Z)^{-1}e$ and Z a diagonal matrix, and $U = \mathbb{K}(\operatorname{diag}(hL_1, \ldots, hL_s, 0)) \otimes u_n$ with

$$\mathbb{K}(\mathbb{Z}) = \left(I_{(s+1)\cdot m} - (\mathbb{A} \otimes I_m)\mathbb{Z}\right)^{-1}(e \otimes I_m)$$

and $\mathbb{Z}$ a block diagonal matrix. The concepts of absolute monotonicity at a given point $\xi \in \mathbb{R}$ for ϕ, K, and $\mathbb{K}$ are given in [7, p. 487]. Roughly speaking, they mean the nonnegativity of all coefficients of the Taylor expansion of ϕ, K, and $\mathbb{K}$ about $z=\xi$, $Z=\xi I_{s+1}$, or $\mathbb{Z}=\xi I_{(s+1)\cdot m}$, respectively. In particular, for $\mathbb{Z}=\xi I_{(s+1)\cdot m}+\mathbb{W}$ with $\mathbb{W}$ sufficiently close to zero, we obtain

$$\mathbb{K}(\mathbb{Z})=\left[I_{(s+1)\cdot m}-(\mathsf{A}(\xi)\otimes I_m)\mathbb{W}\right]^{-1}\mathsf{e}(\xi)\otimes I_m$$

with $\mathsf{A}(\xi)=(I_{s+1}-\xi\mathbb{A})^{-1}\mathbb{A}$ and $\mathsf{e}(\xi)=(I_{s+1}-\xi\mathbb{A})^{-1}e$. Thus with $\mathsf{A}(\xi)\geq 0$ and $\mathsf{e}(\xi)\geq 0$ (see (1.21)), we obtain the absolute monotonicity of $\mathbb{K}$ at $\xi I_{(s+1)\cdot m}$.

Similarly, if we consider now the perturbed problems, $u'=-\tilde{\lambda}u$, $u'=-\tilde{\lambda}(t)u$, and $u'=-\tilde{L}(t)u(t)$, with $\tilde{L}(t)$ an $m\times m$ matrix, a perturbed RK method $(\mathbb{A},\tilde{\mathbb{A}})$ gives, respectively, $U=\phi(h\lambda,h\tilde{\lambda})u_n$ with $\phi(z,\tilde{z})=(I_{s+1}-z(\mathbb{A}+\tilde{\mathbb{A}})-\tilde{z}\tilde{\mathbb{A}})^{-1}e$, $U=K\left(\operatorname{diag}(h\lambda_1,\ldots,h\lambda_s,0),\operatorname{diag}(h\tilde{\lambda}_1,\ldots,h\tilde{\lambda}_s,0)\right)u_n$ with

$$K(Z,\tilde{Z})=(I_{s+1}-(\mathbb{A}+\tilde{\mathbb{A}})Z-\tilde{\mathbb{A}}\tilde{Z})^{-1}e$$

and $Z,\tilde{Z}$ diagonal matrices, and

$$U=\mathbb{K}\left(\operatorname{diag}(hL_1,\ldots,hL_s,0),\operatorname{diag}(h\tilde{L}_1,\ldots,h\tilde{L}_s,0)\right)\otimes u_n$$

with

$$\mathbb{K}(\mathbb{Z},\tilde{\mathbb{Z}})=(I_{(s+1)\cdot m}-((\mathbb{A}+\tilde{\mathbb{A}})\otimes I_m)\mathbb{Z}-(\tilde{\mathbb{A}}\otimes I_m)\tilde{\mathbb{Z}})^{-1}(e\otimes I_m)$$

and $\mathbb{Z},\tilde{\mathbb{Z}}$ block diagonal matrices. For $\mathbb{Z}=\xi I_{(s+1)\cdot m}+\mathbb{W}$, $\tilde{\mathbb{Z}}=\xi I_{(s+1)\cdot m}+\tilde{\mathbb{W}}$ with $\mathbb{W},\tilde{\mathbb{W}}$ sufficiently close to zero, we obtain

$$\mathbb{K}(\mathbb{Z},\tilde{\mathbb{Z}})=[I_{(s+1)\cdot m}-(\mathsf{A}(\xi)\otimes I_m)\mathbb{W}-(\tilde{\mathsf{A}}(\xi)\otimes I_m)\tilde{\mathbb{W}}]^{-1}\left(\mathsf{e}(\xi)\otimes I_m\right)$$

with $\mathsf{A}(\xi)$, $\tilde{\mathsf{A}}(\xi)$, and $\mathsf{e}(\xi)$ defined by (3.5)–(3.7) below. Thus with $\mathsf{A}(\xi)\geq 0$, $\tilde{\mathsf{A}}(\xi)\geq 0$, $\mathsf{e}(\xi)\geq 0$, we obtain that all the coefficients in the Taylor expansion of $\mathbb{K}$ at $\xi I_{(s+1)\cdot m}$ are nonnegative. This analysis leads us to the extension of Definition 1.1 as follows.

Definition 3.1. *An s-stage perturbed RK method $(\mathbb{A},\tilde{\mathbb{A}})$ is said to be absolutely monotonic at a given point $\xi\leq 0$ if $I-\xi(\mathbb{A}+2\tilde{\mathbb{A}})$ is invertible and*

$$\mathsf{A}(\xi)=(I-\xi(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}(\mathbb{A}+\tilde{\mathbb{A}})\geq 0, \tag{3.5}$$

$$\tilde{\mathsf{A}}(\xi)=(I-\xi(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}}\geq 0, \tag{3.6}$$

$$\mathsf{e}(\xi)=(I-\xi(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}e\geq 0. \tag{3.7}$$

Further, the perturbed method is said to be absolutely monotonic on a given set $\Omega\in\mathbb{R}$ if it is absolutely monotonic at each $\xi\in\Omega$. The radius of absolute monotonicity $R(\mathbb{A},\tilde{\mathbb{A}})$ is defined by

$$R(\mathbb{A},\tilde{\mathbb{A}})=\sup\{r\mid r\geq 0 \textit{ and } (\mathbb{A},\tilde{\mathbb{A}}) \textit{ is absolutely monotonic on } [-r,0]\}.$$

If there is no $r>0$ such that $(\mathbb{A},\tilde{\mathbb{A}})$ is absolutely monotonic on $[-r,0]$, we set $R(\mathbb{A},\tilde{\mathbb{A}})=0$.

We go deeper into the concept of radius of absolute monotonicity. In [7, Lemma 4.4] it is proved that for checking the absolute monotonicity of an RK method $\mathbb{A}$ on a given interval $[-r,0]$ it is sufficient to consider the left endpoint $-r$ only. Our next goal is to prove that a similar result is also true for perturbed RK methods $(\mathbb{A},\tilde{\mathbb{A}})$. We begin with some technical lemmas.

Lemma 3.2. *Consider an order m matrix $B \geq 0$ such that for a given $r \geq 0$ the matrix $I + rB$ is nonsingular and $B(I+rB)^{-1} \geq 0$. Then $I - \xi B$ is nonsingular for all $\xi \in [-2r, 0]$.*

Proof. As $B(I+rB)^{-1} \geq 0$ and $B \geq 0$, then $(I+rB)^{-1} = I - rB(I+rB)^{-1}$ is an M-matrix, and hence [9, section 15.2], denoting by $\sigma(C)$ the spectral radius of the matrix C, we have $\sigma\left(rB(I+rB)^{-1}\right) < 1$. Therefore $\det\left(\lambda I - rB(I+rB)^{-1}\right) \neq 0$ for all λ with $|\lambda| \geq 1$. For $\xi \neq -r$, $r \neq 0$, we have that

$$\det\left(I - (\xi + r)B(I+rB)^{-1}\right) = \frac{(\xi+r)^m}{r^m} \det\left(\frac{r}{\xi + r} I - rB(I+rB)^{-1}\right),$$

obtaining $\det\left(I - (\xi+r)B(I+rB)^{-1}\right) \neq 0$ for all ξ with $|\xi + r| \leq r$. Finally, as $I - \xi B = \left(I - (\xi+r)B(I+rB)^{-1}\right) \cdot (I+rB)$, we can write

$$\det(I - \xi B) = \det\left(I - (\xi+r)B(I+rB)^{-1}\right) \cdot \det(I + rB)$$

to obtain that $I - \xi B$ is nonsingular for all $\xi \in [-2r, 0]$. □

For the next result we recall the concept of absolutely monotonic function [7, Definition 2.1]. A function $\psi(z)$ is said to be absolutely monotonic at a given point $\xi \in \mathbb{R}$ if $(d^k\psi/dz^k)(\xi) \geq 0$, $k = 0, 1, \dots$. For matrices or vectors whose components are functions, we will say that they are absolutely monotonic at a given point ξ if each element or component is absolutely monotonic at ξ.

Lemma 3.3. *Consider the functions $\mathsf{A}(\xi)$, $\tilde{\mathsf{A}}(\xi)$, and $\mathsf{e}(\xi)$, defined by* (3.5), (3.6), *and* (3.7), *respectively. Then the perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$ is absolutely monotonic at ξ_0 if and only if the functions $\mathsf{A}(\xi)$, $\tilde{\mathsf{A}}(\xi)$, and $\mathsf{e}(\xi)$ are absolutely monotonic at ξ_0.*

Proof. Recall that from the definition the perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$ is absolutely monotonic at ξ_0 if and only if $\mathsf{A}(\xi_0) \geq 0$, $\tilde{\mathsf{A}}(\xi_0) \geq 0$, and $\mathsf{e}(\xi_0) \geq 0$. The if part is trivial. For the only if part we simply have to observe that $(d^k\mathsf{A}/d\xi^k)(\xi_0) = k!\,[\mathsf{A}(\xi_0) + \tilde{\mathsf{A}}(\xi_0)]^k \mathsf{A}(\xi_0)$, and similarly for $(d^k\tilde{\mathsf{A}}/d\xi^k)(\xi_0)$ and $(d^k\mathsf{e}/d\xi^k)(\xi_0)$. Thus from $\mathsf{A}(\xi_0) \geq 0$, $\tilde{\mathsf{A}}(\xi_0) \geq 0$, and $\mathsf{e}(\xi_0) \geq 0$ we obtain the absolute monotonicity of $\mathsf{A}(\xi)$, $\tilde{\mathsf{A}}(\xi)$, and $\mathsf{e}(\xi)$ at ξ_0. □

We are in position to prove for the perturbed RK methods an analogous result to Lemma 4.4 in [7].

Proposition 3.4. *Consider a perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$ and a real positive number r. Then $R(\mathbb{A}, \tilde{\mathbb{A}}) \geq r$ if and only if $(\mathbb{A}, \tilde{\mathbb{A}})$ is absolutely monotonic at $\xi = -r$ and $\mathbb{A} + \tilde{\mathbb{A}} \geq 0$, $\tilde{\mathbb{A}} \geq 0$.*

Proof. 1. We begin by assuming that $R(\mathbb{A}, \tilde{\mathbb{A}}) \geq r$. Then $(\mathbb{A}, \tilde{\mathbb{A}})$ is absolutely monotonic on $(-r, 0]$, and hence by Lemma 3.3 the functions $\mathsf{A}(\xi)$, $\tilde{\mathsf{A}}(\xi)$, and $\mathsf{e}(\xi)$ are absolutely monotonic on $(-r, 0]$. We can now apply componentwise Lemma 3.6 in [7] to get that they are also absolutely monotonic on $[-r, 0]$. In particular, the method is absolutely monotonic at $\xi = 0$, and hence $\mathbb{A} + \tilde{\mathbb{A}} \geq 0$ and $\tilde{\mathbb{A}} \geq 0$.

2. We assume now that $(\mathbb{A}, \tilde{\mathbb{A}})$ is absolutely monotonic at $\xi = -r$ and $\mathbb{A} + \tilde{\mathbb{A}} \geq 0$, $\tilde{\mathbb{A}} \geq 0$. Using Lemma 3.2 for $B = \mathbb{A} + 2\tilde{\mathbb{A}}$, we get that $I - \xi(\mathbb{A} + 2\tilde{\mathbb{A}})$ is nonsingular for all $\xi \in [-r, 0]$, and hence the functions $\mathsf{A}(\xi)$, $\tilde{\mathsf{A}}(\xi)$, and $\mathsf{e}(\xi)$ are well defined for $\xi \in [-r, 0]$. We can apply componentwise Lemma 3.1 in [7] to obtain that these functions are absolutely monotonic on $[-r, 0]$, and hence, by Lemma 3.3, $R(\mathbb{A}, \tilde{\mathbb{A}}) \geq r$. □

Example 5. For the classical fourth order RK method we consider the perturbed RK method

$$U_1 = u_n,$$
$$U_2 = u_n + \frac{1}{2} h f(U_1),$$

$$
\begin{aligned}
U_3 &= u_n + \frac{1}{2}hf(U_2) + \frac{1}{4}h[f(U_1) - \tilde{f}(U_1)],\\
U_4 &= u_n + hf(U_3) + \frac{5}{18}h[f(U_1) - \tilde{f}(U_1)] + \frac{1}{3}h[f(U_2) - \tilde{f}(U_2)],\\
u_{n+1} &= u_n + \frac{1}{6}hf(U_1) + \frac{1}{3}hf(U_2) + \frac{1}{3}hf(U_3) + \frac{1}{6}hf(U_4) + \frac{19}{108}h[f(U_1) - \tilde{f}(U_1)]\\
&\quad + \frac{1}{9}h[f(U_2) - \tilde{f}(U_2)].
\end{aligned}
$$

The coefficient matrices $(\mathbb{A}, \tilde{\mathbb{A}})$ are

$$
\mathbb{A} = \begin{pmatrix} 0 & & & & \\ 1/2 & 0 & & & \\ 0 & 1/2 & 0 & & \\ 0 & 0 & 1 & 0 & \\ 1/6 & 1/3 & 1/3 & 1/6 & 0 \end{pmatrix}, \qquad \tilde{\mathbb{A}} = \begin{pmatrix} 0 & & & & \\ 0 & 0 & & & \\ 1/4 & 0 & 0 & & \\ 5/18 & 1/3 & 0 & 0 & \\ 19/108 & 1/9 & 0 & 0 & 0 \end{pmatrix}. \tag{3.8}
$$

It can be checked that for this perturbed RK method $R(\mathbb{A}, \tilde{\mathbb{A}}) = 2/3$.

We are in position to obtain a conditional monotonicity result for the perturbed method.

THEOREM 3.5. *Assume that the perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$ is absolutely monotonic at $-r$. Then for*

$$h \le r\,\frac{1}{\rho}$$

it holds that $\|U_i\| \le \|u_n\|$, $i = 1, \dots, s$, $\|u_{n+1}\| \le \|u_n\|$.

Proof. The perturbed RK method can be written as

$$U = e \otimes u_n + h((\mathbb{A} + \tilde{\mathbb{A}}) \otimes I)F(U) - h(\tilde{\mathbb{A}} \otimes I)\tilde{F}(U). \tag{3.9}$$

Observe that the conditions on the problems imply, for $h \le r/\rho$, that

$$\left\| U_i + \frac{h}{r}F(U_i) \right\| \le \|U_i\|, \qquad \left\| U_i - \frac{h}{r}\tilde{F}(U_i) \right\| \le \|U_i\|. \tag{3.10}$$

In (3.9) we add to both sides $r((\mathbb{A} + 2\tilde{\mathbb{A}}) \otimes I)U$, obtaining

$$
\begin{aligned}
&(I + r((\mathbb{A} + 2\tilde{\mathbb{A}}) \otimes I))\, U\\
&= e \otimes u_n + r\,((\mathbb{A} + \tilde{\mathbb{A}}) \otimes I) \left(U + \frac{h}{r}F(U) \right) + r\,(\tilde{\mathbb{A}} \otimes I) \left(U - \frac{h}{r}\tilde{F}(U) \right),
\end{aligned}
$$

or equivalently

$$U = \mathsf{e}(-r) \otimes u_n + r\,(\mathsf{A}(-r) \otimes I) \left(U + \frac{h}{r}F(U) \right) + r\,(\tilde{\mathsf{A}}(-r)) \otimes I) \left(U - \frac{h}{r}\tilde{F}(U) \right),$$

where $\mathsf{e}(\xi)$, $\mathsf{A}(\xi)$, and $\tilde{\mathsf{A}}(\xi)$ are given by (3.5)–(3.7). If we take norms, the conditions on $\mathsf{e}(-r)$, $\mathsf{A}(-r)$, and $\tilde{\mathsf{A}}(-r)$ imply

$$
\begin{aligned}
[\|U\|] &\le \mathsf{e}(-r) \otimes \|u_n\| + r\,(\mathsf{A}(-r) \otimes I) \left[\left\| U + \frac{h}{r}F(U) \right\| \right]\\
&\quad + r\,(\tilde{\mathsf{A}}(-r) \otimes I) \left[\left\| U - \frac{h}{r}\tilde{F}(U) \right\| \right],
\end{aligned} \tag{3.11}
$$

where $[\|U\|]^t = (\|U_1\|, \dots, \|U_s\|, \|u_{n+1}\|)^t \in \mathbb{R}^{s+1}$. Conditions (3.10) now imply

$$[\|U\|] \le \mathsf{e}(-r) \otimes \|u_n\| + r\,((\mathsf{A}(-r) + \tilde{\mathsf{A}}(-r)) \otimes I)[\|U\|],$$

and hence

$$((I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1} \otimes I)\,[\|U\|] \le ((I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1} e) \otimes \|u_n\|, \tag{3.12}$$

where we have used that $I - r(\mathsf{A}(-r) + \tilde{\mathsf{A}}(-r)) = (I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}$. We simply have to multiply (3.12) by $I + r(\mathbb{A} + 2\tilde{\mathbb{A}}) \ge 0$ to get $\|U_i\| \le \|u_n\|$, $i = 1, \dots, s+1$. Observe that $U_{s+1} = u_{n+1}$, and thus we obtain the desired result. $\square$

Remark 4. As $\mathsf{e}(-r) + \mathsf{A}(-r)\,e + \tilde{\mathsf{A}}(-r)\,e = e$, with $\mathsf{e}(-r) \ge 0$, $\mathsf{A}(-r) \ge 0$, and $\tilde{\mathsf{A}}(-r) \ge 0$, inequality (3.11) is also valid for a convex functional $\|\cdot\|$.

The above result gives us monotonicity under the stepsize restriction

$$h \le R(\mathbb{A}, \tilde{\mathbb{A}})\,\frac{1}{\rho}. \tag{3.13}$$

Hence, given a method $\mathbb{A}$ with $R(\mathbb{A}) = 0$, we should find $\tilde{\mathbb{A}}$ such that $R(\mathbb{A}, \tilde{\mathbb{A}}) > 0$, because in this case we have a positive stepsize restriction for monotonicity.

We prove the following auxiliary lemma.

LEMMA 3.6. *Consider matrices $A = (a_{ij})$ and $B = (b_{ij})$ such that $A \ge 0$, $B \ge 0$, and* $\mathrm{Inc}(BA) \le \mathrm{Inc}(A)$. *Then* $\mathrm{Inc}(B^k A) \le \mathrm{Inc}(A)$ *for all $k \ge 2$.*

Proof. We prove it by induction. For $k = 1$ the statement is true. We assume that it is also true for k, and we will prove it for $k+1$. If $(B^{k+1}A)_{ij} \ne 0$, then $b_{il}(B^k A)_{lj} \ne 0$ for some l, and hence $b_{il} \ne 0$ and $(B^k A)_{lj} \ne 0$. From $(B^k A)_{lj} \ne 0$ and $\mathrm{Inc}(B^k A) \le \mathrm{Inc}(A)$, we get that $a_{lj} \ne 0$. Now from $b_{il} \ne 0$ and $a_{lj} \ne 0$ we obtain that $(BA)_{ij} \ne 0$. Finally, from $\mathrm{Inc}(BA) \le \mathrm{Inc}(A)$ we obtain that $a_{ij} \ne 0$. $\square$

We are in position to give a criterion for getting $R(\mathbb{A}, \tilde{\mathbb{A}}) > 0$.

PROPOSITION 3.7. *We have $R(\mathbb{A}, \tilde{\mathbb{A}}) > 0$ if and only if $\mathbb{A} + \tilde{\mathbb{A}} \ge 0$, $\tilde{\mathbb{A}} \ge 0$, and*

$$\mathrm{Inc}((\mathbb{A} + 2\tilde{\mathbb{A}})(\mathbb{A} + \tilde{\mathbb{A}})) \le \mathrm{Inc}(\mathbb{A} + \tilde{\mathbb{A}}), \tag{3.14}$$

$$\mathrm{Inc}((\mathbb{A} + 2\tilde{\mathbb{A}})\tilde{\mathbb{A}}) \le \mathrm{Inc}(\tilde{\mathbb{A}}). \tag{3.15}$$

Proof. The proof is similar to that of Theorem 4.2 in [7]. For real ξ close to zero, the matrix $(I - \xi(\mathbb{A} + 2\tilde{\mathbb{A}}))$ is nonsingular and

$$(I - \xi(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1} = I + \xi(\mathbb{A} + 2\tilde{\mathbb{A}}) + \xi^2(\mathbb{A} + 2\tilde{\mathbb{A}})^3 + \cdots,$$

and hence

$$(I - \xi(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}(\mathbb{A} + \tilde{\mathbb{A}}) = \mathbb{A} + \tilde{\mathbb{A}} + \xi(\mathbb{A} + 2\tilde{\mathbb{A}})(\mathbb{A} + \tilde{\mathbb{A}}) + \cdots, \tag{3.16}$$

$$(I - \xi(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}} = \tilde{\mathbb{A}} + \xi(\mathbb{A} + 2\tilde{\mathbb{A}})\tilde{\mathbb{A}} + \cdots. \tag{3.17}$$

From (3.16) and (3.17) we see that $\mathbb{A} + \tilde{\mathbb{A}} \ge 0$, $\tilde{\mathbb{A}} \ge 0$, and (3.14)–(3.15) are necessary conditions for (3.5) and (3.6) to hold on a left neighborhood of $\xi = 0$. To see that they are also sufficient we use Lemma 3.6 with $B = \mathbb{A} + 2\tilde{\mathbb{A}}$, $A = \mathbb{A} + \tilde{\mathbb{A}}$, and $A = \tilde{\mathbb{A}}$ to state that for $k \ge 2$ we have

$$\mathrm{Inc}((\mathbb{A} + 2\tilde{\mathbb{A}})^k(\mathbb{A} + \tilde{\mathbb{A}})) \le \mathrm{Inc}(\mathbb{A} + \tilde{\mathbb{A}}), \qquad \mathrm{Inc}((\mathbb{A} + 2\tilde{\mathbb{A}})^k\tilde{\mathbb{A}}) \le \mathrm{Inc}(\tilde{\mathbb{A}}).$$

Hence as $\mathbb{A}+\tilde{\mathbb{A}} \geq 0$ and $\tilde{\mathbb{A}} \geq 0$, in (3.16) and (3.17) we get (3.5) and (3.6), respectively. Observe that inequality (3.7) always holds for r close to zero. □

Given a method $\mathbb{A}$ with $R(\mathbb{A}) = 0$, we want to find $\tilde{\mathbb{A}}$ such that $R(\mathbb{A}, \tilde{\mathbb{A}}) > 0$. In terms of computation and storage it is expensive to deal with $f(U_i)$ and $\tilde{f}(U_i)$. Furthermore, as it is pointed out in [12, p. 978], the differences $f(U_i) - \tilde{f}(U_i)$ contribute to artificial dissipation and smearing. Therefore the matrix $\tilde{\mathbb{A}}$ should have as few nonzero columns as possible, although, on the other hand, with more nonzero columns, perhaps better CFL coefficients can be found.

Example 6. Consider the family of four-stage order four methods with $w \neq 0$,

$$\mathbb{A} = \begin{pmatrix} 0 & 0 & \cdots & \cdots & 0 \\ 1/2 & 0 & \ddots & & 0 \\ 1/2 - 1/(6w) & 1/(6w) & 0 & \ddots & 0 \\ 0 & 1-3w & 3w & 0 & 0 \\ 1/6 & 2/3 - w & w & 1/6 & 0 \end{pmatrix}. \tag{3.18}$$

As we should have $\mathbb{A}+\tilde{\mathbb{A}} \geq 0$, whenever $a_{ij} < 0$ we require that $\tilde{a}_{ij} \neq 0$. Hence the sign pattern of the coefficient matrix $\mathbb{A}$ determines the compulsory nonzero elements in $\tilde{\mathbb{A}}$. Furthermore, from conditions (3.14) we obtain that $\tilde{a}_{31} \neq 0$ implies that $\tilde{a}_{41} \neq 0$; $\tilde{a}_{32} \neq 0$ implies that $\tilde{a}_{42} \neq 0$; $\tilde{a}_{41} \neq 0$ implies that $\tilde{a}_{51} \neq 0$; $\tilde{a}_{42} \neq 0$ implies that $\tilde{a}_{52} \neq 0$; and $\tilde{a}_{43} \neq 0$ implies that $\tilde{a}_{53} \neq 0$. For $w < 0$ or $w > 1/3$ from (3.15) we get that $\tilde{a}_{42} \neq 0$ implies that $\tilde{a}_{41} \neq 0$. Hence, we conclude the following.

w	Compulsory nonzero elements	Implied nonzero elements
$w < 0$	$\tilde{a}_{32}, \tilde{a}_{43}, \tilde{a}_{53}$	$\tilde{a}_{41}, \tilde{a}_{42}, \tilde{a}_{51}, \tilde{a}_{52}$
$0 < w < \frac{1}{3}$	$\tilde{a}_{31}$	$\tilde{a}_{41}, \tilde{a}_{51}$
$w = \frac{1}{3}$		$\tilde{a}_{31}, \tilde{a}_{41}, \tilde{a}_{51}, \tilde{a}_{42}, \tilde{a}_{52}$
$\frac{1}{3} < w < \frac{2}{3}$	$\tilde{a}_{42}$	$\tilde{a}_{41}, \tilde{a}_{51}, \tilde{a}_{52}$
$w = \frac{2}{3}$	$\tilde{a}_{42}$	$\tilde{a}_{41}, \tilde{a}_{51}, \tilde{a}_{52}$
$\frac{2}{3} < w$	$\tilde{a}_{42}, \tilde{a}_{52}$	$\tilde{a}_{41}, \tilde{a}_{51}$

Observe that for $0 < w < 1/3$ in $\tilde{\mathbb{A}}$ only one column is required, whereas for the rest we must consider two or three columns. Recall that the classical fourth order four-stage method is obtained for $w = 1/3$.

3.2. Representations of perturbed RK methods. We consider now perturbed methods of the form

$$U = \alpha \otimes u_n + ((\Lambda + \tilde{\Lambda}) \otimes I)U + h(\Gamma \otimes I)F(U) - h(\tilde{\Gamma} \otimes I)\tilde{F}(U), \tag{3.19}$$

with $\alpha \in \mathbb{R}^{s+1}$; Λ, $\tilde{\Lambda}$, Γ, and $\tilde{\Gamma}$ are $(s+1) \times (s+1)$ matrices such that $(\Lambda + \tilde{\Lambda})\, e + \alpha = e$, the matrix $I - (\Lambda + \tilde{\Lambda})$ is invertible, and the last column in Λ, $\tilde{\Lambda}$, Γ, and $\tilde{\Gamma}$ is zero. The elements in $\tilde{\Lambda}$, $\tilde{\Gamma}$ will be denoted by $\tilde{\alpha}_{ij}$ and $\tilde{\beta}_{ij}$, respectively. The elements in $\Lambda + \tilde{\Lambda}$ will be denoted by λ_{ij}.

We remark that in (3.19) we have considered the matrix $\Lambda + \tilde{\Lambda}$. We have used this notation because later on this matrix will be split into Λ and $\tilde{\Lambda}$.

It is straightforward to get that (3.19) can be written as

$$U = e \otimes u_n + h\left(((I-(\Lambda+\tilde{\Lambda}))^{-1}\Gamma)\otimes I\right)F(U) - h\left(((I-(\Lambda+\tilde{\Lambda}))^{-1}\tilde{\Gamma})\otimes I\right)\tilde{F}(U).$$

Comparing this expression with (3.3), we obtain that (3.19) is a perturbed RK method with

$$\mathbb{A} = (I-(\Lambda+\tilde{\Lambda}))^{-1}(\Gamma-\tilde{\Gamma}), \qquad \tilde{\mathbb{A}} = (I-(\Lambda+\tilde{\Lambda}))^{-1}\tilde{\Gamma}. \tag{3.20}$$

Example 7. Method (1.16) is a perturbed RK method (3.19) with

$$\Lambda+\tilde{\Lambda} = \begin{pmatrix} 0 & & & & \\ 1 & 0 & & & \\ 1/2 & 1/2 & 0 & & \\ 1/9 & 2/9 & 2/3 & 0 & \\ 0 & 1/3 & 1/3 & 1/3 & 0 \end{pmatrix}, \tag{3.21}$$

$\alpha = (1,0,0,0,0)^t$, and

$$\Gamma = \begin{pmatrix} 0 & & & & \\ 1/2 & 0 & & & \\ 0 & 1/2 & 0 & & \\ 0 & 0 & 1 & 0 & \\ 0 & 1/6 & 0 & 1/6 & 0 \end{pmatrix}, \qquad \tilde{\Gamma} = \begin{pmatrix} 0 & & & & \\ 0 & 0 & & & \\ 1/4 & 0 & 0 & & \\ 1/9 & 1/3 & 0 & 0 & \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{3.22}$$

Later on we will split (3.21) into Λ and $\tilde{\Lambda}$. Observe that in $\Gamma = (\beta_{ij})$ and $\tilde{\Gamma} = (\tilde{\beta}_{ij})$ whenever $\beta_{ij} \neq 0$, then $\tilde{\beta}_{ij} = 0$, and whenever $\tilde{\beta}_{ij} \neq 0$, then $\beta_{ij} = 0$.

From (3.20) we obtain the matrices $\mathbb{A}$ and $\tilde{\mathbb{A}}$ in (3.8). The matrices Λ_1 and Γ_1 in the factorization (2.5) are $\Lambda_1 = \Lambda + \tilde{\Lambda}$ and $\Gamma_1 = \Gamma - \tilde{\Gamma}$, with $\Lambda + \tilde{\Lambda}$, Γ, and $\tilde{\Gamma}$ from (3.21)–(3.22).

For some results in the rest of the paper, the following technical lemma will be useful.

LEMMA 3.8. *If a matrix $B \in \mathbb{R}^{m\times m}$ satisfies $B \geq 0$, $B\,e \leq e$ and $I - B$ is invertible, then $(I-B)^{-1} \geq 0$.*

Proof. As $B\,e \leq e$, by the Gershgorin theorem, the spectral radius $\rho(B)$ satisfies $\rho(B) \leq 1$. As $B \geq 0$, the matrix B has a real eigenvalue r, equal to the spectral radius of B [9, Theorem 15.5.1]. Thus if $\rho(B) = 1$, the matrix B would have the eigenvalue $r = 1$, which contradicts the invertibility of $I - B$. Hence $\rho(B) < 1$. In this case, the matrix $I - B$ is an M-matrix [9, Theorem 15.2.2]; i.e., $(I-B)^{-1} \geq 0$. □

We study stepsize restrictions to get monotonicity for the schemes (3.19). We get an extension of the CFL coefficient (1.15) for the Shu–Osher representations (1.10).

PROPOSITION 3.9. *Consider a method of the form* (3.19) *such that $(\Lambda+\tilde{\Lambda})e \leq e$, $\Lambda \geq 0$, $\tilde{\Lambda} \geq 0$, $\Gamma \geq 0$, $\tilde{\Gamma} \geq 0$, and*

$$\Lambda - c\,\Gamma \geq 0, \qquad \tilde{\Lambda} - c\,\tilde{\Gamma} \geq 0 \qquad \textit{for some } c > 0. \tag{3.23}$$

Then for

$$h \leq c\,\frac{1}{\rho} \tag{3.24}$$

it holds that $\|U_i\| \leq \|u_n\|$, $i = 1,\dots,s$, $\|u_{n+1}\| \leq \|u_n\|$.

Proof. Conditions on the problems imply that

$$\left\| U_j + h\frac{\beta_{ij}}{\alpha_{ij}} F(U_j) \right\| \le \|U_j\| \qquad \text{for } h\,\frac{\beta_{ij}}{\alpha_{ij}} \le \frac{1}{\rho},$$
$$\left\| U_j - h\frac{\tilde\beta_{ij}}{\tilde\alpha_{ij}} \tilde F(U_j) \right\| \le \|U_j\| \qquad \text{for } h\,\frac{\tilde\beta_{ij}}{\tilde\alpha_{ij}} \le \frac{1}{\rho}.$$

From (3.19), using that $\alpha \ge 0$, $\Lambda \ge 0$, $\tilde\Lambda \ge 0$, $\Gamma \ge 0$, and $\tilde\Gamma \ge 0$, we immediately obtain

$$\|U_i\| \le \alpha_i \|u_n\| + \sum_{j=1}^{s} \alpha_{ij} \left\| U_j + h\frac{\beta_{ij}}{\alpha_{ij}} F(U_j) \right\| + \sum_{j=1}^{s} \tilde\alpha_{ij} \left\| U_j - h\frac{\tilde\beta_{ij}}{\tilde\alpha_{ij}} \tilde F(U_j) \right\|$$
$$\le \alpha_i \|u_n\| + \sum_{j=1}^{s} (\alpha_{ij} + \tilde\alpha_{ij}) \|U_j\|, \tag{3.25}$$

for h satisfying (3.24), or in vectorial form

$$[\|U\|] \le \alpha \otimes \|u_n\| + ((\Lambda + \tilde\Lambda) \otimes I)\, [\|U\|]\,,$$

i.e.,

$$((I - (\Lambda + \tilde\Lambda)) \otimes I)\, [\|U\|] \le \alpha \otimes \|u_n\|.$$

We can apply Lemma 3.8 to $\Lambda + \tilde\Lambda$ to obtain that $(I - (\Lambda + \tilde\Lambda))^{-1} \ge 0$, and thus we obtain the desired result. □

Remark 5.

1. Observe that from (3.23) we get that $\alpha_{ij} = 0$ implies $\beta_{ij} = 0$, and $\tilde\alpha_{ij} = 0$ implies $\tilde\beta_{ij} = 0$.
2. Observe that the maximum c in (3.23) is
$$c = \min_{ij} \left\{ \frac{\alpha_{ij}}{\beta_{ij}}, \frac{\tilde\alpha_{ij}}{\tilde\beta_{ij}} \right\}. \tag{3.26}$$
3. Given any factorization $\mathbb{A} = (I - \Lambda)^{-1}\Gamma$, where Γ has positive and negative coefficients, we can consider the sign splitting $\Gamma = \Gamma_+ - \Gamma_-$, with $\Gamma_+ \ge 0$ and $\Gamma_- \ge 0$. According to this splitting we take the corresponding terms in Λ to split it into $\Lambda = \Lambda_+ - \Lambda_-$. This is essentially the way of proceeding in the SSP context. It turns out that (3.26) is precisely the CFL coefficient (1.15) obtained in the SSP context.
4. As $\alpha + \Lambda\, e + \tilde\Lambda\, e = e$, with $\alpha \ge 0$, $\Lambda \ge 0$, and $\tilde\Lambda \ge 0$, the first inequality in (3.25) is also valid for a convex functional $\|\cdot\|$.

Example 8. We consider the representation (3.21)–(3.22) in Example 7 for the perturbed four-stage order four RK method. To split $\Lambda + \tilde\Lambda = (\lambda_{ij})$ in (3.21) we follow the zeros pattern in Γ and $\tilde\Gamma$ in (3.22); i.e., if $\beta_{ij} \ne 0$, we take $\alpha_{ij} = \lambda_{ij}$ and $\tilde\alpha_{ij} = 0$, and in a similar way if $\tilde\beta_{ij} \ne 0$. In this way we obtain

$$\Lambda = \begin{pmatrix} 0 & & & & \\ 1 & 0 & & & \\ 0 & 1/2 & 0 & & \\ 0 & 0 & 2/3 & 0 & \\ 0 & 1/3 & 1/3 & 1/3 & 0 \end{pmatrix}, \qquad \tilde\Lambda = \begin{pmatrix} 0 & & & & \\ 0 & 0 & & & \\ 1/2 & 0 & 0 & & \\ 1/9 & 2/9 & 0 & 0 & \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

It can be checked that condition (3.23) holds for $c = 2/3$.

Example 9. The numerically optimized four-stage order four RK method in [5, formula (3.4)] has

$$\Lambda+\tilde{\Lambda}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0\\ 1 & 0 & 0 & 0 & 0\\ \frac{649}{1600} & \frac{951}{1600} & 0 & 0 & 0\\ \frac{53989}{2500000} & \frac{4806213}{20000000} & \frac{23619}{32000} & 0 & 0\\ \frac{1}{5} & \frac{6127}{30000} & \frac{7873}{30000} & \frac{1}{3} & 0 \end{pmatrix},$$

$\alpha=(1,0,0,0,0)^t$, and

$$\Gamma=\begin{pmatrix} 0 & 0 & 0 & 0 & 0\\ \frac{1}{2} & 0 & 0 & 0 & 0\\ 0 & \frac{5000}{7873} & 0 & 0 & 0\\ 0 & 0 & \frac{7873}{10000} & 0 & 0\\ \frac{1}{10} & \frac{1}{6} & 0 & \frac{1}{6} & 0 \end{pmatrix},\qquad \tilde{\Gamma}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0\\ \frac{10890423}{25193600} & 0 & 0 & 0 & 0\\ \frac{102261}{5000000} & \frac{5121}{20000} & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

Following the zeros pattern in Γ and $\tilde{\Gamma}$, we can split $\Lambda+\tilde{\Lambda}$ into

$$\Lambda=\begin{pmatrix} 0 & 0 & 0 & 0 & 0\\ 1 & 0 & 0 & 0 & 0\\ 0 & \frac{951}{1600} & 0 & 0 & 0\\ 0 & 0 & \frac{23619}{32000} & 0 & 0\\ \frac{1}{5} & \frac{6127}{30000} & \frac{7873}{30000} & \frac{1}{3} & 0 \end{pmatrix},\qquad \tilde{\Lambda}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0\\ \frac{649}{1600} & 0 & 0 & 0 & 0\\ \frac{53989}{2500000} & \frac{4806213}{20000000} & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

It can be checked that condition (3.23) holds for $c=\frac{7487223}{8000000}\approx 0.936$. If we compute the matrices $\mathbb{A}$ and $\tilde{\mathbb{A}}$ from (3.20), we obtain a perturbed RK method $(\mathbb{A},\tilde{\mathbb{A}})$ with

$$\mathbb{A}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0\\ \frac{1}{2} & 0 & 0 & 0 & 0\\ -\frac{2127}{15746} & \frac{5000}{7873} & 0 & 0 & 0\\ 0 & \frac{2127}{10000} & \frac{7873}{10000} & 0 & 0\\ \frac{1}{6} & \frac{12127}{30000} & \frac{7873}{30000} & \frac{1}{6} & 0 \end{pmatrix},\qquad \tilde{\mathbb{A}}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0\\ \frac{10890423}{25193600} & 0 & 0 & 0 & 0\\ \frac{869139357}{2560000000} & \frac{5121}{20000} & 0 & 0 & 0\\ \frac{580124399}{2560000000} & \frac{1707}{20000} & 0 & 0 & 0 \end{pmatrix}.$$

The matrix $\mathbb{A}$ is the four-stage order four method in the family (3.18) for $w=\frac{7873}{30000}$. It can be computed that $R(\mathbb{A},\tilde{\mathbb{A}})=\frac{7487223}{8000000}$. Observe that, for this value of w, the coefficient a_{31} in $\mathbb{A}$ is negative, and therefore, although $\tilde{\mathbb{A}}$ has two nontrivial columns, only the elements $\tilde{a}_{31}$, $\tilde{a}_{41}$, and $\tilde{a}_{51}$ in $\tilde{\mathbb{A}}$ are required in order to get $R(\mathbb{A},\tilde{\mathbb{A}})>0$.

Under some conditions on Λ and Γ, Proposition 3.9 ensures monotonicity under the stepsize restriction

$$h\le c\,\frac{1}{\rho}, \tag{3.27}$$

where c is such that $\Lambda - c\Gamma \geq 0$ and $\tilde{\Lambda} - c\tilde{\Gamma} \geq 0$. If we compare the stepsize restriction (3.27) with the stepsize restriction (3.13) obtained in terms of $R(\mathbb{A}, \tilde{\mathbb{A}})$, it is natural to wonder about the relationship between c in (3.27) and $R(\mathbb{A}, \tilde{\mathbb{A}})$. We begin expressing the concept of absolute monotonicity for the perturbed RK method in terms of the representation (3.19). The proof is omitted because it is straightforward.

LEMMA 3.10. *Consider a perturbed RK method* $(\mathbb{A}, \tilde{\mathbb{A}})$ *such that it can be factorized as* $\mathbb{A} = (I - (\Lambda + \tilde{\Lambda}))^{-1}(\Gamma - \tilde{\Gamma})$, $\tilde{\mathbb{A}} = (I - (\Lambda + \tilde{\Lambda}))^{-1}\tilde{\Gamma}$. *Then the method is absolutely monotonic at* ξ *if and only if*

1. *the matrix* $I - (\Lambda + \tilde{\Lambda} + \xi\,(\Gamma + \tilde{\Gamma}))$ *is invertible,*
2. *the following inequalities hold:*

$$\begin{aligned}
&(I - (\Lambda + \tilde{\Lambda} + \xi\,(\Gamma + \tilde{\Gamma}))^{-1}\Gamma \geq 0,\\
(3.28)\qquad &(I - (\Lambda + \tilde{\Lambda} + \xi\,(\Gamma + \tilde{\Gamma}))^{-1}\tilde{\Gamma} \geq 0,\\
&(I - (\Lambda + \tilde{\Lambda} + \xi\,(\Gamma + \tilde{\Gamma})))^{-1}(I - (\Lambda + \tilde{\Lambda}))\,e \geq 0.
\end{aligned}$$

The following result relates conditions in Proposition 3.9 with absolute monotonicity at a given point.

PROPOSITION 3.11. *Consider a perturbed RK method* $(\mathbb{A}, \tilde{\mathbb{A}})$. *Assume that it can be written in terms of* Λ, $\tilde{\Lambda}$, Γ, *and* $\tilde{\Gamma}$ *with*

$$(I - (\Lambda + \tilde{\Lambda}))\,e \geq 0, \qquad \Gamma \geq 0, \qquad \tilde{\Gamma} \geq 0, \qquad \Lambda + \tilde{\Lambda} - c\,(\Gamma + \tilde{\Gamma}) \geq 0,$$

and $I - (\Lambda + \tilde{\Lambda} - c\,(\Gamma + \tilde{\Gamma}))$ *invertible for some coefficient* $c \geq 0$. *Then the method is absolutely monotonic at* $-c$.

Proof. We will get the absolute monotonicity at $-c$ from Lemma 3.10. Some of the conditions imposed give part 1 in Lemma 3.10, and hence we simply have to check part 2. As $c\,(\Gamma + \tilde{\Gamma}) \geq 0$ and $(\Lambda + \tilde{\Lambda})\,e \leq e$, we obtain

$$(\Lambda + \tilde{\Lambda} - c\,(\Gamma + \tilde{\Gamma}))\,e \leq (\Lambda + \tilde{\Lambda})\,e \leq e.$$

This inequality, together with the assumption $\Lambda + \tilde{\Lambda} - c\,(\Gamma + \tilde{\Gamma}) \geq 0$ and the regularity of the matrix $I - (\Lambda + \tilde{\Lambda} - c\,(\Gamma + \tilde{\Gamma}))$, allows us to apply Lemma 3.8 with $B = \Lambda + \tilde{\Lambda} - c\,(\Gamma + \tilde{\Gamma})$, obtaining

$$(I - (\Lambda + \tilde{\Lambda} - c\,(\Gamma + \tilde{\Gamma})))^{-1} \geq 0.$$

In this way, as $\Gamma \geq 0$, $\tilde{\Gamma} \geq 0$, and $(I - (\Lambda + \tilde{\Lambda}))\,e \geq 0$, we get (3.28) and thus the desired result. □

From Proposition 3.11 we get that the CFL coefficient (3.23) obtained from a representation satisfies $c \leq R(\mathbb{A}, \tilde{\mathbb{A}})$. The next step is to study whether, given a perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$, there exists a representation such that the CFL coefficient (3.23) satisfies $c = R(\mathbb{A}, \tilde{\mathbb{A}})$. We will refer to these representations as optimal ones.

3.3. Optimal perturbed representations. In the next result we prove that optimal representations exist, and we show how to construct them.

PROPOSITION 3.12. *We consider a perturbed RK method* $(\mathbb{A}, \tilde{\mathbb{A}})$. *If* $r = R(\mathbb{A}, \tilde{\mathbb{A}}) > 0$, *then there exist matrices* $\Lambda, \tilde{\Lambda}, \Gamma, \tilde{\Gamma}$ *such that* $\mathbb{A} = (I - (\Lambda + \tilde{\Lambda}))^{-1}(\Gamma - \tilde{\Gamma})$, $\tilde{\mathbb{A}} = (I - (\Lambda + \tilde{\Lambda}))^{-1}\tilde{\Gamma}$, *with* $\Lambda + \tilde{\Lambda} \geq 0$, $\Gamma \geq 0$, $\tilde{\Gamma} \geq 0$, *and* $(I - (\Lambda + \tilde{\Lambda}))e \geq 0$, $I - (\Lambda + \tilde{\Lambda} - r(\Gamma + \tilde{\Gamma}))$ *invertible and* $\Lambda - r\Gamma \geq 0$, $\tilde{\Lambda} - r\tilde{\Gamma} \geq 0$.

Proof. Remember that $R(\mathbb{A}, \tilde{\mathbb{A}}) > 0$ implies that $\mathbb{A} + \tilde{\mathbb{A}} \geq 0$ and $\tilde{\mathbb{A}} \geq 0$. As $(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1} = I - r(\mathbb{A} + 2\tilde{\mathbb{A}})(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}$, we can write

$$\begin{aligned}
&\mathbb{A}+\tilde{\mathbb{A}}-r(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}(\mathbb{A}+\tilde{\mathbb{A}})=(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}(\mathbb{A}+\tilde{\mathbb{A}})\geq 0,\\
&\tilde{\mathbb{A}}-r(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}}=(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}}\geq 0,\\
&e-r(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}e=(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}e\geq 0.
\end{aligned}$$

Thus

$$r(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}(\mathbb{A}+\tilde{\mathbb{A}})\leq\mathbb{A}+\tilde{\mathbb{A}}, \tag{3.29}$$

$$r(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}}\leq\tilde{\mathbb{A}}, \tag{3.30}$$

$$r(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}e\leq e. \tag{3.31}$$

As $r>0$, conditions (3.5)–(3.6) give

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\geq 0.$$

Thus, taking this together with (3.31), we get

$$0\leq r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\leq\mathbb{E},$$

with $\mathbb{E}$ the matrix whose elements are all equal to one. We can take matrices $\Lambda+\tilde{\Lambda}$ such that

$$0\leq r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\leq\Lambda+\tilde{\Lambda}\leq\mathbb{E}. \tag{3.32}$$

If we multiply (3.32) by e, we obtain

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}e\leq(\Lambda+\tilde{\Lambda})\,e\leq s\,e.$$

As $e\leq s\,e$, inequality (3.31) gives

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}e\leq e\leq s\,e,$$

and hence we can impose for $(\Lambda+\tilde{\Lambda})e$ the condition

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}e\leq(\Lambda+\tilde{\Lambda})\,e\leq e. \tag{3.33}$$

If we now multiply (3.32) by $\mathbb{A}+\tilde{\mathbb{A}}\geq 0$, we obtain

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}(\mathbb{A}+\tilde{\mathbb{A}})\leq(\Lambda+\tilde{\Lambda})(\mathbb{A}+\tilde{\mathbb{A}})\ \leq\mathbb{E}\,(\mathbb{A}+\tilde{\mathbb{A}}).$$

As $\mathbb{A}+\tilde{\mathbb{A}}\leq\mathbb{E}\,(\mathbb{A}+\tilde{\mathbb{A}})$, inequality (3.29) gives

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}(\mathbb{A}+\tilde{\mathbb{A}})\leq\mathbb{A}+\tilde{\mathbb{A}}\ \leq\mathbb{E}\,(\mathbb{A}+\tilde{\mathbb{A}}),$$

and therefore we can impose for $(\Lambda+\tilde{\Lambda})(\mathbb{A}+\tilde{\mathbb{A}})$ the condition

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}(\mathbb{A}+\tilde{\mathbb{A}})\leq(\Lambda+\tilde{\Lambda})(\mathbb{A}+\tilde{\mathbb{A}})\leq\mathbb{A}+\tilde{\mathbb{A}}. \tag{3.34}$$

Finally, if we multiply (3.32) by $\tilde{\mathbb{A}}\geq 0$, we obtain

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}}\leq(\Lambda+\tilde{\Lambda})\tilde{\mathbb{A}}\ \leq\mathbb{E}\,\tilde{\mathbb{A}}.$$

As $\tilde{\mathbb{A}}\leq\mathbb{E}\,\tilde{\mathbb{A}}$, inequality (3.30) gives

$$r\,(\mathbb{A}+2\tilde{\mathbb{A}})(I+r(\mathbb{A}+2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}}\leq\tilde{\mathbb{A}}\ \leq\mathbb{E}\,\tilde{\mathbb{A}}.$$

We can impose for $(\Lambda + \tilde{\Lambda})\tilde{\mathbb{A}}$ the condition

$$r\,(\mathbb{A} + 2\tilde{\mathbb{A}})(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}} \leq (\Lambda + \tilde{\Lambda})\tilde{\mathbb{A}} \leq \tilde{\mathbb{A}}. \tag{3.35}$$

It is possible to impose conditions (3.32)–(3.35). For example, we can take

$$\Lambda = r\,(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}(\mathbb{A} + \tilde{\mathbb{A}}), \qquad \tilde{\Lambda} = r\,(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}}. \tag{3.36}$$

In this case, the matrix $I - (\Lambda + \tilde{\Lambda})$ is invertible. Some other choices of $\Lambda + \tilde{\Lambda}$ are possible. Once that $\Lambda + \tilde{\Lambda}$ has been chosen satisfying (3.32)–(3.35), with $I - (\Lambda + \tilde{\Lambda})$ invertible, we define

$$\Gamma = \mathbb{A} + \tilde{\mathbb{A}} - (\Lambda + \tilde{\Lambda})(\mathbb{A} + \tilde{\mathbb{A}}), \qquad \tilde{\Gamma} = \tilde{\mathbb{A}} - (\Lambda + \tilde{\Lambda})\tilde{\mathbb{A}}, \qquad \alpha = e - (\Lambda + \tilde{\Lambda})e. \tag{3.37}$$

Respectively from (3.34), (3.35), and (3.33) we get $\Gamma \geq 0$, $\tilde{\Gamma} \geq 0$, and $(\Lambda + \tilde{\Lambda})e \leq e$.

In order to prove that $\Lambda + \tilde{\Lambda} - r(\Gamma + \tilde{\Gamma}) \geq 0$, we compute

$$(\Lambda + \tilde{\Lambda} - r(\Gamma + \tilde{\Gamma}))(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1} = \Lambda + \tilde{\Lambda} - r(\mathbb{A} + 2\tilde{\mathbb{A}})(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1} \geq 0,$$

where we have used (3.32). If we right-multiply this expression by $I + r(\mathbb{A} + 2\tilde{\mathbb{A}}) \geq 0$, we obtain that

$$\Lambda + \tilde{\Lambda} - r(\Gamma + \tilde{\Gamma}) \geq 0. \tag{3.38}$$

If we choose Λ and $\tilde{\Lambda}$ from (3.36), we obtain $\Lambda - r\Gamma = 0$, $\tilde{\Lambda} - r\tilde{\Gamma} = 0$. Otherwise, we have to prove that

$$\Lambda - r\Gamma \geq 0 \quad \text{and} \quad \tilde{\Lambda} - r\tilde{\Gamma} \geq 0. \tag{3.39}$$

Observe that so far the different conditions imposed and the definitions of Γ, $\tilde{\Gamma}$, and α depend on $\Lambda + \tilde{\Lambda}$. Thus, once the matrix $\Lambda + \tilde{\Lambda}$ has been determined, we have to obtain Λ and $\tilde{\Lambda}$ such that (3.39) holds. We proceed componentwise as follows. We take, for example, $\alpha_{ij} = r\beta_{ij}$; in this way $(\Lambda - r\Gamma)_{ij} = 0$, and using (3.38), we have

$$\tilde{\alpha}_{ij} - r\tilde{\beta}_{ij} = \alpha_{ij} + \tilde{\alpha}_{ij} - r\tilde{\beta}_{ij} - r\beta_{ij} \geq 0.$$

We can alternatively take $\tilde{\alpha}_{ij} = r\tilde{\beta}_{ij}$ to get $(\tilde{\Lambda} - r\tilde{\Gamma})_{ij} = 0$ and $\alpha_{ij} - r\beta_{ij} \geq 0$.

Finally, remember that $r = R(\mathbb{A}, \tilde{\mathbb{A}})$ implies the invertibility of $I + r(\mathbb{A} + 2\tilde{\mathbb{A}})$, and hence by Lemma 3.10 the invertibility of $I - (\Lambda - r\Gamma)$. □

Remark 6.

1. We can construct matrices Λ, $\tilde{\Lambda}$, Γ, and $\tilde{\Gamma}$ such that $\Lambda - r\Gamma = 0$ and $\tilde{\Lambda} - r\tilde{\Gamma} = 0$, namely Λ and $\tilde{\Lambda}$ from (3.36), and Γ, $\tilde{\Gamma}$, and α from (3.37).
2. Inequality (3.32) has been used to prove (3.38). However, when a representation is constructed, if we ensure (3.38), we can drop (3.32).

Example 10. We consider again the classical four-stage fourth order RK method and its perturbation (3.8) with $R(\mathbb{A}, \tilde{\mathbb{A}}) = 2/3$ (see Example 5). According to Proposition 3.12, if we construct Λ and $\tilde{\Lambda}$ from (3.36), and Γ, $\tilde{\Gamma}$, and α from (3.37), we obtain Λ, $\tilde{\Lambda}$, Γ, and $\tilde{\Gamma}$ such that $\Lambda - 2/3\Gamma = \tilde{\Lambda} - 2/3\tilde{\Gamma} = 0$, and thus the CFL coefficient (3.23) is also 2/3. Simple computations give that

$$\Lambda = \begin{pmatrix} 0 & & & & \\ 1/3 & 0 & & & \\ 1/18 & 1/3 & 0 & & \\ 0 & 0 & 2/3 & 0 & \\ 5/54 & 2/9 & 4/27 & 1/9 & 0 \end{pmatrix}, \qquad \Gamma = \begin{pmatrix} 0 & & & & \\ 1/2 & 0 & & & \\ 1/12 & 1/2 & 0 & & \\ 0 & 0 & 1 & 0 & \\ 5/36 & 1/3 & 2/9 & 1/6 & 0 \end{pmatrix},$$

$$\tilde{\Lambda} = \begin{pmatrix} 0 & & & & \\ 0 & 0 & & & \\ 1/6 & 0 & 0 & & \\ 2/27 & 2/9 & 0 & 0 & \\ 35/486 & 4/81 & 0 & 0 & 0 \end{pmatrix}, \qquad \tilde{\Gamma} = \begin{pmatrix} 0 & & & & \\ 0 & 0 & & & \\ 1/4 & 0 & 0 & & \\ 1/9 & 1/3 & 0 & 0 & \\ 35/324 & 2/27 & 0 & 0 & 0 \end{pmatrix},$$

and $\alpha = (1, 2/3, 4/9, 1/27, 74/243)^t$. From $\mathbb{A} = (I - (\Lambda + \tilde{\Lambda}))^{-1}(\Gamma - \tilde{\Gamma})$, we get the factorization given in (2.6), i.e., $\Lambda_2 = \Lambda + \tilde{\Lambda}$ and $\Gamma_2 = \Gamma - \tilde{\Gamma}$. However, from the implementation point of view, such a representation is not optimal as it requires one to store $f(u_n)$, $f(U_2)$, $f(U_3)$, $f(U_4)$, $\tilde{f}(u_n)$, and $\tilde{f}(U_2)$ until the computation of u_{n+1}. The computational cost can be decreased if the matrices Γ and $\tilde{\Gamma}$ have as many zeros as possible and the nonzeros appear in optimal positions. We will try to impose $\tilde{\beta}_{ij} = 0$ whenever $\beta_{ij} \neq 0$, and vice versa: $\beta_{ij} = 0$ whenever $\tilde{\beta}_{ij} \neq 0$.

Denoting the elements of $\Lambda + \tilde{\Lambda}$ by λ_{ij}, if we compute inequality (3.34), we obtain that $\lambda_{43} = 2/3$ and $\lambda_{42} = 2/9$. Next we construct $\Gamma = (\beta_{ij})$ and $\tilde{\Gamma} = (\beta_{ij})$ from (3.37). As $\tilde{\beta}_{31} \neq 0$, we impose $\beta_{31} = 0$, which gives $\lambda_{32} = 1/2$. We can get $\tilde{\beta}_{52} = 0$ if we set $\lambda_{54} = 1/3$. Similarly, we can obtain $\tilde{\beta}_{51} = 0$, imposing $\lambda_{53} = 1/3$. Finally we can get $\beta_{51} = 0$, imposing $\lambda_{52} = 1/3$. If we impose $\alpha = (1, 0, 0, 0, 0)^t$, we get $\lambda_{21} = 1$, $\lambda_{31} = 1/2$, $\lambda_{41} = 1/9$, and $\lambda_{51} = 0$. So far we have obtained the matrix $\Lambda + \tilde{\Lambda}$ in (3.21), and the matrices Γ and $\tilde{\Gamma}$ in (3.22) in Example 7.

They satisfy (3.38), although condition (3.32) does not hold (see Remark 6). We can take into account the zeros distribution in Γ and $\tilde{\Gamma}$ to split out $\Lambda + \tilde{\Lambda}$ into Λ and $\tilde{\Lambda}$ (see Example 8). We have that $\Lambda - 2/3\Gamma \geq 0$, $\tilde{\Lambda} - 2/3\tilde{\Gamma} \geq 0$. This is the representation (1.16) taken from [13].

We finish the section showing how the theory developed in this paper applies to the schemes in [12].

Example 11. In [12], explicit RK schemes are represented in terms of coefficient matrices $\Lambda = (\alpha_{ij}) \geq 0$ and $\Gamma = (\beta_{ij})$. The matrix Γ is such that the nonzero coefficients β_{ik} for a given k are all of the same sign. If a sign splitting is done for Γ, i.e., $\Gamma = \Gamma_+ - \Gamma_-$, the RK method is applied as follows:

$$U = \alpha \otimes u_n + h(\Lambda \otimes I)U + h(\Gamma_+ \otimes I)F(U) - h(\Gamma_- \otimes I)\tilde{F}(U), \tag{3.40}$$

where $\alpha = (1, 0, \ldots, 0)^t$. The same sign splitting can be done in Λ, $\Lambda = \Lambda_+ - \Lambda_-$, and then the CFL coefficient in the SSP context (1.15) is the same as that given in expression (3.23) of Proposition 3.9 (see Remark 5). Scheme (3.40) can also be written as

$$U = e \otimes u_n + h(\mathbb{A}_+ \otimes I)F(U) - h(\mathbb{A}_- \otimes I)\tilde{F}(U), \tag{3.41}$$

where $\mathbb{A}_+ = (I - \Lambda)^{-1}\Gamma_+$ and $\mathbb{A}_- = (I - \Lambda)^{-1}\Gamma_-$. Observe that by Lemma 3.8 we have $\mathbb{A}_+ \geq 0$ and $\mathbb{A}_- \geq 0$. Observe too that (3.41) can also be formulated as a perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$, with $\mathbb{A} = \mathbb{A}_+ - \mathbb{A}_-$ and $\tilde{\mathbb{A}} = \mathbb{A}_-$. The sign distribution of the matrix Γ gives that $\mathbb{A}_+$ and $\mathbb{A}_-$ are a sign splitting of $\mathbb{A}$. As has been pointed out above, the coefficient c computed from (3.23) (or (1.15) from the SSP context) satisfies $c \leq R(\mathbb{A}, \mathbb{A}_-)$.

Three optimal fifth order methods, denoted by SSP(7,5), SSP(8,5), and SSP(9,5), are constructed in [12]. For these methods it has been checked that the CFL coefficient c given in [12], computed from (1.15), is the radius of absolute monotonicity of the perturbed method $(\mathbb{A}, \mathbb{A}_-)$, i.e., $c = R(\mathbb{A}, \mathbb{A}_-)$. We remark that for these methods only one column in the matrix $\mathbb{A}_-$ is different from zero. This is enough to obtain schemes with $R(\mathbb{A}, \mathbb{A}_-) > 0$.

4. Conclusions and future work. In this paper we have extended the Shu–Osher representations to general RK methods, and we have related the stepsize restrictions for monotonicity with the radius of absolute monotonicity giving optimal representations. The case of Shu–Osher representations with positive coefficients corresponds to the case $R(\mathbb{A}) > 0$. Optimal representations are given by

$$\Lambda = r(I - r\mathbb{A})^{-1}\mathbb{A}, \qquad \Gamma = (I - \Lambda)\mathbb{A}, \qquad \alpha = (I - \Lambda)e,$$

with $r = R(\mathbb{A})$. In this case $\Lambda - r\Gamma = 0$.

The case of Shu–Osher representations with negative coefficients corresponds to the case $R(\mathbb{A}) = 0$. To deal with this case, we have interpreted the numerical integration as perturbations of the original RK method $\mathbb{A}$ with some coefficients $\tilde{\mathbb{A}}$, and we have referred to $(\mathbb{A}, \tilde{\mathbb{A}})$ as perturbed RK methods. These perturbed RK methods have perturbed representations.

A new definition of radius of absolute monotonicity for the perturbed RK method $(\mathbb{A}, \tilde{\mathbb{A}})$ has been given, and some of its properties have been investigated. In this way it is possible to have a positive generalized radius $R(\mathbb{A}, \tilde{\mathbb{A}}) > 0$ if RK methods with $R(\mathbb{A}) = 0$ are used. For $R(\mathbb{A}, \tilde{\mathbb{A}}) > 0$, we obtain monotonicity under nontrivial stepsize restrictions. Optimal representations are given by

$$\begin{aligned}
&\Lambda = r\,(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}(\mathbb{A} + \tilde{\mathbb{A}}), &&\tilde{\Lambda} = r\,(I + r(\mathbb{A} + 2\tilde{\mathbb{A}}))^{-1}\tilde{\mathbb{A}},\\
&\Gamma = \mathbb{A} + \tilde{\mathbb{A}} - (\Lambda + \tilde{\Lambda})(\mathbb{A} + \tilde{\mathbb{A}}), &&\tilde{\Gamma} = \tilde{\mathbb{A}} - (\Lambda + \tilde{\Lambda})\tilde{\mathbb{A}},\\
&\alpha = e - (\Lambda + \tilde{\Lambda})e,
\end{aligned}$$

with $r = R(\mathbb{A}, \tilde{\mathbb{A}})$. In this case $\Lambda - r\Gamma = 0$ and $\tilde{\Lambda} - r\tilde{\Gamma} = 0$.

With regard to the new concept $R(\mathbb{A}, \tilde{\mathbb{A}})$, at least two questions remain open for future work. The first one concerns the possibility of getting $R(\mathbb{A}, \tilde{\mathbb{A}}) = \infty$ and hence unconditional monotonicity for high order methods. The second one is how to construct $\tilde{\mathbb{A}}$ for a given RK method $\mathbb{A}$ so that $R(\mathbb{A}, \tilde{\mathbb{A}})$ is as large as possible.

Acknowledgment. The author thanks the anonymous referees for their valuable remarks and comments on the paper.

A STABILIZED MIXED FINITE ELEMENT METHOD FOR ELLIPTIC SYSTEMS OF FIRST ORDER*

MANFRED DOBROWOLSKI[†] AND MANUEL VILLEGAS[‡]

Abstract. A quasilinear elliptic equation of second order can be split into a first order system in various ways. We present and analyze a stabilized finite element method for the system, which is well suited for any of these possible splittings. Under minimal assumptions on the continuous solution, existence and (nearly) optimal convergence in L^∞ of the discrete solutions is established. This result holds for any choice of the stabilization parameter $\omega > 0$. Moreover, the paper presents a framework for investigating other mixed methods for unsymmetric first order systems.

Key words. finite elements, elliptic systems

DOI. 10.1137/S0036142902408829

1. Introduction.

Let $\Omega \subset \mathbb{R}^n$, $n = 2, 3$, be a bounded domain. Consider the first order system with unknown functions $u = (u^1, \ldots, u^n)$ and p,

$$u^\alpha = b^\alpha(x, p, \nabla p) \quad \text{in } \Omega, \quad \alpha = 1, \ldots, n, \tag{1.1}$$

$$\partial_i c_i(x, p, u) = g(x, p, \nabla p) \quad \text{in } \Omega, \quad p = 0 \quad \text{on } \partial\Omega. \tag{1.2}$$

Here and in the following we use the usual summation convention for small Latin ($i, j = 0, \ldots, n$, $\partial_0 := 1$) and Greek ($\alpha, \beta = 1, \ldots, n$) indices. It is assumed that the functions b^α, g, c_i are sufficiently smooth with respect to the arguments u, p, and $q = \nabla p$. The system is equivalent to the second order equation

$$\partial_i c_i(x, p, b(x, p, \nabla p)) = g(x, p, \nabla p), \tag{1.3}$$

which is quasilinear; i.e., it is linear in the second derivatives of p. The coefficient function of the main part of (1.3) is given by

$$a_{ij} = c_i^\alpha b_j^\alpha, \quad i, j = 1, \ldots, n, \tag{1.4}$$

with

$$c_i^\alpha(x, p, u) = \frac{\partial}{\partial u^\alpha} c_i(x, p, u), \quad \alpha = 1, \ldots, n,$$

$$b_j^\alpha(x, p, q) = \frac{\partial}{\partial q^j} b^\alpha(x, p, q), \quad j = 1, \ldots, n.$$

Now we can formulate our existence and ellipticity condition, as follows.

ASSUMPTION A. *There exists a solution* $(u, p) \in C^0(\overline{\Omega})^n \times C^1(\overline{\Omega})$ *of* (1.1), (1.2) *such that the coefficient function*

$$a_{ij}(x) := a_{ij}(x, u(x), p(x), \nabla p(x))$$

in (1.4) *satisfies*

$$m_0|\xi|^2 \leq \sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \leq M_0|\xi|^2 \quad \forall \xi \in \mathbb{R}^n \tag{1.5}$$

with constants $m_0, M_0 > 0$ *independent of* $x \in \Omega$.

Note that (1.5) is a purely local condition. Hence, no growth conditions for the functions c_i^α, b_j^α are required.

Our next condition is concerned with the linearized operator of (1.1), (1.2). Writing

$$b_0^\alpha = \frac{\partial}{\partial p} b^\alpha, \quad c_i^0 = \frac{\partial}{\partial p} c_i,$$

$$g_0 = \frac{\partial}{\partial p} g, \quad g_i = \frac{\partial}{\partial q_i} g \quad (g = g(x, p, q)),$$

we define the linear first order operators

$$Bq(x) = (b_i^\alpha \partial_i q(x))_{\alpha=1,\ldots,n,}$$

$$C_i(v(x), q(x)) = c_i^0 q(x) + c_i^\alpha v^\alpha(x),$$

$$Dq(x) = g_i \partial_i q(x).$$

Note that b_i^α, c_i^α are evaluated in $p, \nabla p$ or p, u. The linearized operator of (1.1), (1.2) can be written in weak form. For

$$(v, q), (\varphi, \psi) \in L^2(\Omega)^n \times H_0^{1,2}(\Omega)$$

we define the bilinear form

$$a((v, q), (\varphi, \psi)) = (v, \varphi) - (Bq, \varphi) - (C_i(v, q), \partial_i \psi) - (Dq, \psi).$$

Obviously, the operator L corresponding to $a(\cdot, \cdot)$ is a continuous mapping

$$L : L^2(\Omega)^n \times H_0^{1,2}(\Omega) \to (L^2(\Omega)^n \times H_0^{1,2}(\Omega))'.$$

Here and below we use the usual Lebesgue and Sobolev spaces with norms

$$\|v\|_{H^{m,p}(\Omega)} = \|v\|_{m,p} = \left(\sum_{i=0}^{m} \|\nabla^i v\|_p^p \right)^{1/p}.$$

Theorem 1.1. *Assume that condition* A *holds. Then the operator L satisfies Fredholm's alternative: Either the problem*

$$L(v, q) = (f, g) \tag{1.6}$$

is uniquely solvable for all $(f, g) \in (L^2(\Omega)^n \times H_0^{1,2}(\Omega))'$ or $\lambda = 0$ is an eigenvalue of L.

This theorem is a simple consequence of the ellipticity condition (1.5) and will be proved in section 2. Usually, the second alternative in Theorem 1.1 signifies that (u, p) lies in a singularity of the bifurcation diagram of (1.1), (1.2). In this case, however, the system cannot be discretized by a direct finite element method. Hence, we state our next condition.

Assumption B. *$\lambda = 0$ is not an eigenvalue of the linearized operator L.*

In view of the fact that L can also be written as a second order elliptic operator, H^2-regularity can be assumed in the following form.

Assumption C. *For $(f, g) \in H^{1,2}(\Omega)^n \times L^2(\Omega)$ the solution of* (1.6) *satisfies $(v, q) \in H^{1,2}(\Omega)^n \times H^{2,2}(\Omega)$ and*

$$||v||_{1,2} + ||q||_{2,2} \leq c\{||f||_{1,2} + ||g||_2\}.$$

Let us describe our finite element method for approximating the system (1.1), (1.2). Let $S^m \subset C^0(\overline{\Omega})$ be a standard Lagrangian finite element space (see [9]) containing the polynomials of degree $\leq m$ on each element Λ of a quasi-regular subdivision Π of $\overline{\Omega}$, possibly isoperimetrically modified at the boundary $\partial\Omega$. It is assumed that each element Λ is contained in a ball of radius h and contains a ball of radius ch. Here and in the following the generic constant c does not depend on the mesh parameter h. Set $S_0^m = S^m \cap H_0^{1,2}$. The discrete solution (u_h, p_h) will be defined in the space $X_h \times Y_h$ with $X_h = (S^l)^n$, $Y_h = S_0^m$. In view of the fact that u is coupled with ∇p, we assume that $l \geq m - 1$. $(u_h, p_h) \in X_h \times Y_h$ is defined by

$$(u_h, \varphi_h) = (b(\cdot, p_h, \nabla p_h), \varphi_h) \quad \forall \varphi_h \in X_h, \tag{1.7}$$

$$\begin{aligned}(\partial_i c_i(\cdot, p_h, u_h), \psi_h) + \omega(u_h - b(\cdot, p_h, \nabla p_h), B(p_h)\psi_h)& \\ = (g(\cdot, p_h, \nabla p_h), \psi_h) \quad \forall \psi_h \in Y_h.&\end{aligned} \tag{1.8}$$

Here, $\omega > 0$ is the (uncritical) *stabilization parameter* and

$$B(p_h)\psi_h(x) = (b_i^\alpha(x, p_h(x), \nabla p_h(x))\partial_i \psi_h(x))_{\alpha=1,\ldots,n}$$

according to our notation introduced above. Note that, in contrast to stabilized mixed methods for the Stokes equation (see [7]), the stabilizing term is conforming; i.e., the solution (u, p) of the continuous system satisfies (1.7), (1.8) as well.

Now we can state the main result of this paper.

Theorem 1.2. *Assume that Assumptions* A, B, C *hold. Assume further that the solution (u, p) of* (1.1), (1.2) *is in the space $H^{m,\infty}(\Omega)^n \times H^{m+1,\infty}(\Omega)$, and that the stabilization parameter $\omega > 0$ is chosen independent of h. Then there exists a $h_0 > 0$ such that for $0 < h \leq h_0$ the discrete system* (1.7), (1.8) *has a local solution in a neighborhood of (u, p) which satisfies the error estimate*

$$h||u - u_h||_\infty + ||p - p_h||_\infty \leq ch^{m+1-\epsilon}\{||u||_{m,\infty} + ||p||_{m+1,\infty}\}$$

for all $\epsilon > 0$ with a constant $c = c(\epsilon)$.

The proof of this theorem will be given in the next sections.

Since our results are also new in the linear case, we study the corresponding linear problem

$$(u,\varphi) + b(p,\varphi) = f(\varphi), \tag{1.9}$$

$$c(u,\psi) = g(\psi), \tag{1.10}$$

where the bilinear forms $b(\cdot,\cdot)$, $c(\cdot,\cdot)$ correspond to linear first order operators. Again, we do not assume that $b(\psi,\varphi) = c(\varphi,\psi)$. The problem (1.9), (1.10) is discretized by the method analogous to (1.7), (1.8),

$$(u_h,\varphi_h) + b(p_h,\varphi_h) = f(\varphi_h) \quad \forall \varphi_h \in X_h, \tag{1.11}$$

$$c(u_h,\psi_h) + \omega(u_h + Bp_h, B\psi_h) = g(\psi_h) + \omega f(B\psi_h) \quad \forall \psi_h \in Y_h, \tag{1.12}$$

where $(Bp,\varphi) = b(p,\varphi)$. It is now obvious that the stabilization term is the first variation of

$$\|u + Bp - f\|_2$$

with respect to p. Hence, the method is a Galerkin least squares method already considered in [13] for the elasticity problem. It is the object of this paper to demonstrate that the Galerkin least squares approach allows nearly arbitrary, in particular unsymmetric, splittings of the second order equation. For the classical and other least squares methods, we refer to [8] and [3].

With a proof similar to that for Theorem 1.2 we can show the following.

Theorem 1.3. *Assume that* (1.5) *and Assumptions* B *and* C *hold. Assume further that the solution* (u,p) *of* (1.9), (1.10) *is in the space* $H^{m,2}(\Omega)^n \times H^{m+1,2}(\Omega)$ *and that the stabilization parameter* $\omega > 0$ *is chosen independent of* h*. Then there exists a* $h_0 > 0$ *such that for* $0 < h \leq h_0$ *the discrete system* (1.11), (1.12) *has a solution which satisfies the error estimate*

$$h||u-u_h||_2 + ||p-p_h||_2 \leq ch^{m+1}\{||u||_{m,2} + ||p||_{m+1,2}\}.$$

We remark that we have assumed only that $\lambda = 0$ is not an eigenvalue of the continuous system. This carries over to the discretized system only for sufficiently small h. Thus, the condition $0 < h \leq h_0$ cannot be removed in the linear case.

A further object of this paper is to present a framework for analyzing other mixed methods for first order systems of the type (1.9), (1.10). The classical mixed finite element theory (see, e.g., [4], [6]) requires a symmetry condition for the forms $b(\cdot,\cdot)$ and $c(\cdot,\cdot)$, but what can be done if this condition is violated? Our improvement in the analysis of first order systems is Lemma 2.1, which states that any elliptic first order system can be transformed into a first order system with "nearly" adjoint forms $b(\cdot,\cdot)$ and $c(\cdot,\cdot)$. Using this lemma, it is a simple exercise to prove convergence for the classical mixed elements introduced in [22], [5] for general first order systems. Mixed methods for unsymmetric systems are also treated in [18], but the methodology presented there is different. The idea of Lemma 2.1 can also be applied to generalized Stokes equations [11].

Mixed methods for nonlinear first order systems are also treated in [17], [20], [16]. In all of these papers, only the symmetric case is considered. Moreover, the convergence proofs are based on L^2-estimates, which restricts the results to space dimension $n = 2$ or higher order elements.

Theorem 1.2 states that for an elliptic second order equation

$$\partial_i F_i(x, p, \nabla p) = 0 \tag{1.13}$$

any splitting of the form (1.1), (1.2) is allowed. For example, the coefficient function a_{ij} in (1.4) of Poisson's equation

$$\Delta p = g$$

is the identity matrix. If we use the splitting

$$u^1 = \partial_1 p + \partial_2 p, \quad u^2 = -\partial_1 p + \partial_2 p, \quad \partial_1 u^1 + \partial_2 u^2 = g,$$

we again obtain Poisson's equation, but now with coefficient matrix

$$A = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}.$$

In contrast to the direct finite element method for the second order equation, the corresponding mixed method is different from the mixed method of the standard splitting

$$u = \nabla p, \quad \partial_1 u^1 + \partial_2 u^2 = g.$$

More natural splittings for (1.13) are

$$u = \nabla p, \quad \partial_i F_i(x, p, u) = 0$$

and

$$u^i = F_i(x, p, \nabla p) \ \text{ for } i = 1, \dots, n, \quad \sum_{i=1}^{n} \partial_i u^i = -F_0(x, p, \nabla p).$$

Numerical examples for both splittings are given in [23]. These splittings also give an idea of how to discretize the general elliptic equation

$$F(x, q, \nabla q, \nabla^2 q) = 0,$$

which can be treated by

$$u = \nabla p, \quad F(x, p, u, \nabla u) = 0.$$

We remark that in this case our convergence proof works only for higher order elements, i.e., $m \geq 2$.

2. Linear systems of first order. We consider the system

$$v^\alpha - b_i^\alpha \partial_i q = f^\alpha \ \text{ in } \Omega, \quad \alpha = 1, \dots, n, \tag{2.1}$$

$$\partial_i (c_i^\alpha v^\alpha) + d_i \partial_i q = g \ \text{ in } \Omega, \quad q = 0 \ \text{ on } \partial\Omega, \tag{2.2}$$

where the coefficient functions $b_i^\alpha, c_i^\alpha, d_i$ are assumed to be smooth functions of $x \in \Omega$. Introducing the bilinear forms

$$\begin{aligned} b(q,\varphi) &= -\left(b_i^\alpha \partial_i q, \varphi^\alpha\right), \\ c(v,\psi) &= -\left(\sum_{i=1}^n c_i^\alpha v^\alpha, \partial_i \psi\right) + \left(c_0^\alpha v^\alpha, \psi\right), \\ d(q,\psi) &= (d_i \partial_i q, \psi), \end{aligned}$$

the weak solution $(v,q) \in L^2(\Omega)^n \times H_0^{1,2}(\Omega)$ is defined by

$$(v,\varphi) + b(q,\varphi) = (f,\varphi) \quad \forall \varphi \in L^2(\Omega)^n, \tag{2.3}$$

$$c(v,\psi) + d(q,\psi) = (g,\psi) \quad \forall \psi \in H_0^{1,2}(\Omega). \tag{2.4}$$

The characteristic problem in the finite element analysis of (2.1), (2.2) is that we have the condition of ellipticity in (1.5), but we need conditions for the forms $b(\cdot,\cdot)$ and $c(\cdot,\cdot)$. Therefore, the following lemma is the basis of the finite element analysis of (2.1), (2.2) and the corresponding nonlinear case in (1.7), (1.8).

LEMMA 2.1. *The following statements are equivalent:*

(i) *The system* (2.1), (2.2) *is elliptic in the sense of* (1.5); *i.e., the coefficients*

$$a_{ij} = c_i^\alpha b_j^\alpha, \quad i,j = 1,\dots,n, \tag{2.5}$$

satisfy

$$m_0|\xi|^2 \le a_{ij}(x)\xi_i\xi_j \le M_0|\xi|^2 \quad \forall \xi \in \mathbb{R}^n. \tag{2.6}$$

(ii) *The following two conditions hold:*

(a) *There exists a matrix $M(x) \in \mathbb{R}^{n\times n}$ which is as smooth as the coefficient functions b_i^α, c_i^α such that with a constant $m_1 > 0$*

$$m_1||v||_2^2 \le (v, Mv) \quad \forall v \in L^2(\Omega)^n \tag{2.7}$$

and

$$|b(q,Mv) - c(v,q)| \le c||v||_2||q||_2, \quad \forall v \in L^2(\Omega)^n,\ \forall q \in H_0^{1,2}(\Omega). \tag{2.8}$$

(b) *Setting*

$$Bq = (b_i^\alpha \partial_i q)_{\alpha=1,\dots,n},$$

we have with a constant $m_2 > 0$

$$m_2||\nabla q||^2 \le ||Bq||_2^2 + c||q||_2^2 \quad \forall q \in H_0^{1,2}(\Omega). \tag{2.9}$$

Remarks. (i) Condition (2.7) is satisfied if M is uniformly real positive. (ii) The forms $b(\cdot,\cdot)$ and $c(\cdot,\cdot)$ are of first order, but the right-hand side in (2.8) is not. The intuitive meaning of condition (2.8) is that (2.3) can be transformed by the matrix M such that the transformed form of $b(\cdot,\cdot)$ is adjoint to $c(\cdot,\cdot)$ in the leading terms; i.e.,

$$b(q,Mv) = c(v,q) + l.o.t.$$

Proof. Introducing the matrices

$$\tilde{C} = (c_i^\alpha)_{i,\alpha=1,\dots,n}, \quad \tilde{B} = (b_i^\alpha)_{i,\alpha=1,\dots,n}, \quad A = (a_{ij})_{i,j=1,\dots,n},$$

formula (2.5) can be written in the form

$$A = \tilde{C}\tilde{B}^T. \tag{2.10}$$

In the next step, we derive a representation of the matrix M from condition (2.8). Since it is stated that M is as smooth as the coefficient functions, we can assume that at least $M \in C(\overline{\Omega})^{n\times n}$. Let $x_0 \in \Omega$, $B_\epsilon(x_0) \subset \Omega$, and $\varphi \in C_0^\infty(B_\epsilon(x_0))$ with $||\varphi||_2 = 1$. For $r, s \in \mathbb{R}^n$ set ($\mathbf{i} = \sqrt{-1}$)

$$q(x) = e^{2\pi \mathbf{i} r\cdot x}\varphi(x), \quad v(x) = e^{-2\pi \mathbf{i} r\cdot x}\varphi(x)s.$$

Then

$$\nabla q(x) = 2\pi \mathbf{i} r q(x) + e^{2\pi \mathbf{i} r\cdot x}\nabla\varphi(x),$$

and hence

$$b(q, Mv) - c(v, q) = \int_\Omega \sum_{i=1}^n \{-2\pi \mathbf{i} b_i^\alpha r_i \varphi M_{\alpha\beta}\varphi s_\beta + 2\pi \mathbf{i} c_i^\alpha s_\alpha \varphi r_i \varphi\}\, dx + R, \tag{2.11}$$

where the lower order terms in R satisfy the estimate

$$|R| \leq c|s|\ ||\varphi||_{1,2}^2$$

with a constant c independent of r, s. We replace r in (2.11) by λr, $\lambda \in \mathbb{R}$, and apply the mean value theorem which gives, for $x_1 \in B_\epsilon(x_0)$,

$$b(q, Mv) - c(v, q) = -\lambda 2\pi \mathbf{i} S + R, \tag{2.12}$$

where

$$S = \sum_{i=1}^n \{b_i^\alpha(x_1) r_i M_{\alpha\beta}(x_1) s_\beta - c_i^\alpha(x_1) s_\alpha r_i\}.$$

In view of the fact that condition (2.8) must hold for all $\lambda \in \mathbb{R}$ and

$$||q||_2 ||v||_2 \leq c|s|,$$

we have $S = 0$ or

$$r^T \tilde{B}(x_1) M(x_1) s = r^T \tilde{C}(x_1) s \quad \forall r, s \in \mathbb{R}^n,$$

and, since $\tilde{B}, \tilde{C}, M$ are continuous and ϵ can be chosen arbitrary small,

$$\tilde{C} = \tilde{B}M \ \text{ in } \Omega.$$

Comparing this with (2.10), we obtain that $A = \tilde{B}M\tilde{B}^T$ is real positive. This implies that M is also real positive.

Finally, we show that condition (2.9) is equivalent to the uniform regularity of the matrix $\tilde{B}$. Let $\tilde{B}(x)$ be uniformly regular, i.e.,

$$|\tilde{B}(x)^{-T} r|^2 \leq c|r|^2 \quad \forall x \in \Omega,\ \forall r \in \mathbb{R}^n.$$

Inserting $r = \tilde{B}(x)^T \nabla q(x)$ and integrating gives

$$||\nabla q||_2 \leq c||\tilde{B}^T \nabla q||_2. \tag{2.13}$$

From

$$(Bq)^\alpha = b_i^\alpha \partial_i q = (\tilde{B}^T \nabla q)^\alpha + b_0^\alpha q,$$

it follows that

$$\|Bq\|_2 \geq \|\tilde{B}^T \nabla q\|_2 - \|b_0 q\|_2,$$

and condition (2.9) is proved by (2.13). Conversely, if condition (2.9) is satisfied, we proceed with similar arguments as before. Let $x_0 \in \Omega$ and $\epsilon > 0$ such that $B_\epsilon(x_0) \subset \Omega$. Let $\varphi \in C_0^\infty(B_\epsilon(x_0))$ with $||\varphi||_2 = 1$. For $r \in \mathbb{R}^n$ set

$$q(x) = e^{2\pi \mathbf{i} r\cdot x}\varphi(x).$$

Then

$$\nabla q(x) = 2\pi \mathbf{i} r q(x) + e^{2\pi \mathbf{i} r\cdot x}\nabla\varphi(x)$$

and

$$||q||_2 = ||\varphi||_2 = 1.$$

For the terms in (2.9) we obtain

$$m_2||\nabla q||^2 \geq \frac{m_2}{2}||2\pi \mathbf{i} r\varphi||^2 - m_2||\nabla\varphi||^2 = \frac{m_2}{2}(|r|^2 - 2||\nabla\varphi||^2),$$

$$||Bq|| \leq ||b_i^\alpha \partial_i q|| \leq ||\tilde{B}^T rq||_2 + c||\varphi||_{1,2}.$$

Using the mean value theorem, we obtain for $x_1 \in B_\epsilon(x_0)$

$$||\tilde{B}^T rq||_2 = |\tilde{B}^T(x_1)r|.$$

From (2.9) and the above estimates it follows that

$$\frac{m_2}{2}(|r|^2 - 2||\nabla\varphi||_2^2) \leq 2|\tilde{B}(x_1)r|^2 + c||\varphi||_{1,2}^2.$$

Replacing r by λr, we conclude that $\tilde{B}$ is uniformly regular in Ω. □

Proof of Theorem 1.1. The theorem can clearly be proved by considering the second order equation corresponding to (2.3), (2.4). Here we want to show how the methodology of Lemma 2.1 can be applied. The finite element analysis in Lemma 4.2 is more complicated but uses the same arguments.

We consider (2.3) and a compactly perturbed (2.4), namely,

$$c(v, \psi) + d(q, \psi) - \lambda(q, \psi) = (g, \psi) \quad \forall \psi \in H_0^{1,2}(\Omega), \tag{2.14}$$

with a parameter $\lambda > 0$. Assume that $(v, q) \in L^2(\Omega)^n \times H_0^{1,2}(\Omega)$ is a solution of (2.3), (2.14). Inserting $\varphi = Mv$ into (2.3) and $\psi = q$ into (2.14) and subtracting the resulting equations yields

$$(v, Mv) + b(q, Mv) - c(v, q) - d(q, q) + \lambda||q||_2^2 = (f, Mv) - (g, q),$$

and hence, by conditions (2.7) and (2.8),

$$m_1||v||_2^2 + \lambda||q||_2^2 \le c||v||_2||q||_2 + c||q||_{1,2}||q||_2 + c||f||_2||v||_2 + ||g||_{-1,2}||q||_{1,2}. \tag{2.15}$$

From the strong formulation of (2.3) we conclude that

$$||Bq||_2^2 \le 2||v||_2^2 + 2||f||_2^2$$

and, by condition (2.9),

$$m_2||\nabla q||^2 \le 2||v||_2^2 + 2||f||_2^2 + c||q||_2^2.$$

Combining this estimate with (2.15) gives the a priori bound for sufficiently large $\lambda > 0$,

$$||v||_2^2 + ||q||_{1,2}^2 \le c\{||f||_2^2 + ||g||_{-1,2}^2\}. \tag{2.16}$$

From the bound (2.16) we conclude an inf-sup condition for the bilinear form

$$B_\lambda((v,q),(\varphi,\psi)) = (v,\varphi) + b(q,\varphi) - c(v,\psi) - d(q,\psi) + \lambda(q,\psi),$$

since

$$\begin{aligned} ||f||_2 + ||g||_{-1} &= \sup_{\varphi \in L^2(\Omega)^n} \frac{(v,\varphi) + b(q,\varphi)}{||\varphi||_2} + \sup_{\psi \in H_0^{1,2}(\Omega)} \frac{-c(v,\psi) - d(q,\psi) + \lambda(q,\psi)}{||\psi||_{1,2}} \\ &= \sup_{||\varphi||_2 = 1, ||\psi||_{1,2} = 1} B_\lambda((v,q),(\varphi,\psi)), \end{aligned}$$

and hence, by (2.16),

$$||v||_2 + ||q||_{1,2} \le c \sup_{||\varphi||_2 = 1, ||\psi||_{1,2} = 1} B_\lambda((v,q),(\varphi,\psi)).$$

In order to prove existence of a solution of (2.3), (2.14), an a priori bound analogous to (2.16) for the adjoint problem is required (see [2]). This can be done by the same method by observing that the adjoint forms satisfy condition (2.8),

$$|c(M^{-1}v,q) - b(q,v)| \le c||v||_2||q||_2$$

and M^{-1} is real positive. Thus, we have proved that the system (2.3), (2.14) has a uniquely determined solution. In view of the fact that $\lambda(q,\psi)$ is a compact perturbation of the bilinear form B_0, we obtain from standard arguments (see, e.g., [1, p. 102]) that (2.3), (2.4) satisfies Fredholm's alternative.

3. Standard finite element spaces and weighted Sobolev norms.

Throughout the rest of the paper we assume that Ω is a polygonal or polyhedral domain and that $\overline{\Omega} = \cup\Lambda$. The interpolation operator $I_h : C^0(\overline{\Omega}) \to S^m$ of a standard Lagrangian finite element space S^m satisfies

$$||\nabla^k(u - I_h u)||_{p;\Lambda} \le ch^{l-k}||\nabla^l u||_{p;\Lambda} \quad \forall u \in H^{l,p}(\Lambda), \tag{3.1}$$

for $0 \le k \le l \le m+1$ and $1 \le p \le \infty$ with $lp > n$ (see, e.g., [9]). Moreover, the inverse estimates hold,

$$||\nabla^k u_h||_{p;\Lambda} \le ch^{-k}||u_h||_{p;\Lambda} \quad \forall u_h \in S^m,\ 0 \le k \le m,\ 1 \le p \le \infty, \tag{3.2}$$

$$||u_h||_{\infty;\Lambda} \le ch^{-n/2}||u_h||_{2;\Lambda} \quad \forall u_h \in S^m. \tag{3.3}$$

For nonsmooth functions we use the approximation operator $R_h : L^1(\Omega) \to S^m$ defined in [10] with the properties

$$||\nabla^k(u - R_h u)||_{p;\Lambda} \leq ch^{l-k}||\nabla^l u||_{p;U(\Lambda)}, \quad 0 \leq k \leq l \leq m+1,\ 1 \leq p \leq \infty, \tag{3.4}$$

$$||\nabla^k R_h u||_{p;\Lambda} \leq c||\nabla^k u||_{p;U(\Lambda)}, \quad 0 \leq k \leq m,\ 1 \leq p \leq \infty, \tag{3.5}$$

where $U(\Lambda)$ denotes a neighborhood of Λ of diameter ch. Since Π is assumed to be a quasi-uniform partition, the estimates (3.4), (3.5) carry over to the domain Ω.

For $x_0 \in \Omega$ we define the weight function

$$\sigma(x) = (|x - x_0|^2 + \rho^2)^{1/2},$$

where $\rho = c^* h^\beta$ and $c^* \geq 1$, $\beta \geq 1$ will be determined later. σ satisfies

$$\sigma^{-1} \leq \rho^{-1}, \quad |\nabla^k \sigma| \leq c\sigma^{-k+1} \quad \forall k \in \mathbb{N} \tag{3.6}$$

and, in view of $\operatorname{diam}(\Lambda) \leq h$,

$$\max_{x\in\Lambda} \sigma(x) \leq c \min_{x\in\Lambda} \sigma(x). \tag{3.7}$$

Using polar coordinates, one can easily show that

$$\int_\Omega \sigma^{-\alpha}\, dx \leq \begin{cases} c & \text{for} \quad \alpha < n, \\ c|\ln\rho| & \text{for} \quad \alpha = n, \\ c\rho^{n-\alpha} & \text{for} \quad \alpha > n. \end{cases} \tag{3.8}$$

For $k \in \mathbb{N}$ and $\alpha \in \mathbb{R}$ the corresponding weighted Sobolev norms are defined by

$$||v||^2_{(\alpha)} = \sum_\Lambda \int_\Lambda |v|^2 \sigma^\alpha\, dx, \quad ||v||^2_{(k,\alpha)} = \sum_{i=0}^k ||\nabla^i v||^2_{(\alpha)}.$$

Estimate (3.7) is the crucial point which allows us to prove the interpolation and inverse estimates (3.1)–(3.5) also in weighted norms; for example,

$$\begin{aligned} ||\nabla^k(u - I_h u)||^2_{(\alpha)} &= \sum_\Lambda \int_\Lambda |\nabla^k(u - I_h u)|^2 \sigma^\alpha\, dx \\ &\leq \sum_\Lambda \max_{x\in\Lambda} \sigma^\alpha(x) ||\nabla^k(u - I_h u)||^2_{2;\Lambda} \\ &\leq ch^{2(l-k)} \sum_\Lambda \min_{x\in\Lambda} \sigma^\alpha(x) ||\nabla^l u||^2_{2;\Lambda} \\ &\leq ch^{2(l-k)} ||\nabla^l u||^2_{(\alpha)}, \end{aligned}$$

and hence,

$$||\nabla^k(u - I_h u)||_{(\alpha)} \leq ch^{l-k}||\nabla^l u||_{(\alpha)}, \quad 0 \leq k \leq l \leq m+1,\ 2l > n, \tag{3.9}$$

$$||\nabla^k(u - R_h u)||_{(\alpha)} \leq ch^{l-k}||\nabla^l u||_{(\alpha)}, \quad 0 \leq k \leq l \leq m+1, \tag{3.10}$$

$$||\nabla^k R_h u||_{(\alpha)} \leq c||\nabla^k u||_{(\alpha)}, \tag{3.11}$$

$$||\nabla^k u_h||_{(\alpha)} \leq ch^{-k}||u_k||_{(\alpha)}. \tag{3.12}$$

The next lemma presents the key idea of the weighted Sobolev norms, namely the control of the L^∞-norm by a weighted L^2-norm.

LEMMA 3.1. *Let $v \in H^{l,\infty}(\Omega)$, $1 \le l \le m+1$, and $v_h \in S^m$. Then there exists a point x_0 such that for the corresponding weighted norm*

$$||v - v_h||_\infty \le ch^{-n/2}\rho^{n/2}||v - v_h||_{(-n)} + ch^{-n/2}\rho^{n/2}h^l|\ln\rho|^{1/2}||v||_{l,\infty}.$$

Proof. Using (3.4) and (3.3), we obtain for some $x_0 \in \Lambda$

$$\begin{aligned}||v - v_h||_\infty &\le ||v - R_hv||_\infty + ||R_hv - v_h||_\infty\\ &\le ch^l||v||_{l,\infty} + |R_hv - v_h|(x_0)\\ &\le ch^l||v||_{l,\infty} + ch^{-n/2}||R_hv - v_h||_{2;\Lambda}.\end{aligned}$$

The second term on the right-hand side can be bounded by a weighted norm,

$$\begin{aligned}||R_hv - v_h||_{2;\Lambda} &\le c\rho^{n/2}||R_hv - v_h||_{(-n)}\\ &\le c\rho^{n/2}\left(||v - R_hv||_{(-n)} + ||v - v_h||_{(-n)}\right).\end{aligned}$$

Now we use (3.10), (3.8),

$$||v - R_hv||_{(-n)} \le ch^l||\nabla^l v||_{(-n)} \le ch^l|\ln\rho|^{1/2}||v||_{l,\infty},$$

which completes the proof of the lemma. □

For the duality argument in finite element analysis an a priori estimate in weighted Sobolev norms is required.

LEMMA 3.2. *Assume that conditions* B *and* C *hold for the linear problem* (1.6). *Then, for $f \in H^{1,2}(\Omega)^n$, $g \in L^2(\Omega)$, the solution $(v,q) \in L^2(\Omega)^n \times H_0^{1,2}(\Omega)$ of $L(v,q) = (f,g)$ satisfies*

$$||v||_{(1,n)} + ||q||_{(2,n)} \le c\rho^{-\kappa}(||f||_{(1,n)} + ||g||_{(n)})$$

for all $\kappa > 0$ with a constant $c = c(\kappa)$. The estimate also holds for the adjoint system.

Proof. The result is well known for second order equations (see, e.g., [19], [21]). It also holds with $\rho^{-\kappa}$ replaced by $|\ln\rho|^{1/2}$. Since our system can equivalently be transformed into a second order equation, the result follows. □

4. Finite element approximation of linear systems.

We return to the linear system (2.1), (2.2), but assume that $d_i = 0$ in view of the fact that this term is definitely of lower order. Using again the notation

$$Bq(x) = (b_i^\alpha \partial_i q)_{\alpha=1,\dots,n},$$

the solution of (2.1), (2.2) satisfies

$$(u,\varphi) + b(p,\varphi) = (f,\varphi) \quad \forall\varphi \in L^2(\Omega)^n, \tag{4.1}$$

$$c(u,\psi) + \omega\{(u,B\psi) + b(p,B\psi) - (f,B\psi)\} = (g,\psi) \quad \forall\psi \in H_0^{1,2}(\Omega). \tag{4.2}$$

The stabilized finite element approximation is defined by an analogous set of equations. Subtracting the defining equations for (u,p) and (u_h,p_h) gives

$$(u - u_h,\varphi_h) + b(p - p_h,\varphi_h) = F(\varphi_h) \quad \forall\varphi_h \in X_h, \tag{4.3}$$

$$c(u - u_h,\psi_h) + \omega(u - u_h,B\psi_h) + \omega b(p - p_h,B\psi_h) = G(\psi_h) \quad \forall\psi_h \in Y_h \tag{4.4}$$

with $F = 0, G = 0$. The functionals F, G are introduced for treating the nonlinear case described in the next section. F is a continuous linear functional on $L^2(\Omega)^n$, whereas G is continuous on $H_0^{1,2}(\Omega)$. The corresponding weighted norms of the functionals are defined by

$$||F||_{(-n)} = \sup_{v \in L^2(\Omega)^n} \frac{|F(v)|}{||v||_{(n)}},$$

$$||G||_{(-1,-n)} = \sup_{q \in H_0^{1,2}(\Omega)} \frac{|G(q)|}{||q||_{(1,n)}}.$$

In the following, we assume that the system (4.1), (4.2) for $\omega = 0$ satisfies the assumptions of the first section.

In order to simplify the presentation we assume that $l = m - 1$ and $m \geq 2$. The proof for the case $l = m = 1$ is given in [23]. The latter case does not really differ in this section, but the treatment of the nonlinearities in the next section requires a special technique already described in [15], [12].

In the following we use the weighted norm technique introduced in [19]. It allows an easy treatment of the nonlinearities, but the results are not as sharp as those obtained from the methods using regularized Green's functions (see, e.g., [14]).

We start with a technical estimate which is used only in the proof of Lemma 4.2.

LEMMA 4.1. *For $u \in H^{m,\infty}(\Omega)^n$, $u_h \in X_h$, and $\varphi_h = I_h(M(u - u_h)\sigma^{-n})$ with a smooth matrix M we have*

$$||M(u - u_h)\sigma^{-n} - \varphi_h||_{(n)} \leq ch\rho^{-1}||u - u_h||_{(-n)} + ch^m||\nabla^m u||_{(-n)}. \tag{4.5}$$

Proof. We use the interpolation estimate for I_h in (3.9):

$$||M(u - u_h)\sigma^{-n} - \varphi_h||_{(n)} \leq ch^m||\nabla^m(M(u - u_h)\sigma^{-n})||_{(n)}. \tag{4.6}$$

Recall that the weighted norm is defined for piecewise smooth functions. In view of the fact that $u_h\,|_\Lambda \in \mathbb{P}_{m-1}$ we have

$$||\nabla^m(u - u_h)||_{(-n)} = ||\nabla^m u||_{(-n)},$$

and hence, by Leibniz' rule and (3.6),

$$||\nabla^m(M(u - u_h)\sigma^{-n})||_{(n)} \leq c\sum_{i=0}^{m-1}||u - u_h||_{(i,-n-2m+2i)} + c||\nabla^m u||_{(-n)}.$$

Using (3.9) and (3.12), we immediately obtain

$$\begin{aligned}||\nabla^k(u - u_h)||_{(\alpha)} &\leq ||\nabla^k(u - u_h - I_h(u - u_h))||_{(\alpha)} + ||\nabla^k I_h(u - u_h)||_{(\alpha)} \\ &\leq ch^{m-k}||\nabla^m u||_{(\alpha)} + ch^{-k}||I_h(u - u_h) - (u - u_h)||_{(\alpha)} + ch^{-k}||u - u_h||_{(\alpha)} \\ &\leq ch^{-k}||u - u_h||_{(\alpha)} + ch^{m-k}||\nabla^m u||_{(\alpha)}.\end{aligned}$$

From this estimate we have

$$\begin{aligned}||\nabla^m(M(u - u_h)\sigma^{-n}||_{(n)} \leq c\sum_{i=0}^{m-1} h^{-i}||u - u_h||_{(-n-2m+2i)} \\ + c\sum_{i=0}^{m-1} h^{m-i}||\nabla^m u||_{(-n-2m+2i)} + c||\nabla^m u||_{(-n)}.\end{aligned}$$

Now we use the estimates

$$||v||_{(-n-2\beta)} \leq c\rho^{-\beta}||v||_{(-n)}$$

and $\rho^{-1} \leq h^{-1}$,

$$||\nabla^m(M(u-u_h)\sigma^{-n}||_{(n)} \leq ch^{-m+1}\rho^{-1}||u-u_h||_{(-n)} + c||\nabla^m u||_{(-n)}.$$

This estimate and (4.6) complete the proof of the lemma. □

LEMMA 4.2. *For pairs* (u,p) *and* $(u_h,p_h) \in X_h \times Y_h$ *satisfying* (4.3), (4.4) *we have the error estimates*

$$(4.7)\quad ||u-u_h||^2_{(-n)} + ||p-p_h||^2_{(1,-n)} \leq c||p-p_h||^2_{(-n-2)} + c\{||F||^2_{(-n)} + ||G||^2_{(-1,-n)}\} + ch^{2m-\epsilon}\left\{||u||^2_{m,\infty} + ||p||^2_{m+1,\infty}\right\}$$

for all $\epsilon > 0$ *with a constant* $c = c(\epsilon)$.

Proof. The proof follows the lines of the proof of Theorem 1.1. Lemma 4.2 can be regarded as the energy estimate of the error in a weighted norm. The terms on the right-hand side of (4.7) are denoted by

$$R = ||p-p_h||^2_{(-n-2)} + ||F||^2_{(-n)} + ||G||^2_{(-1,-n)} + h^{2m-\epsilon}\{||u||^2_{m,\infty} + ||p||^2_{m+1,\infty}\}.$$

In view of the fact that the system is elliptic, we can apply condition (2.7) in Lemma 2.1, and we obtain with a smooth matrix M

$$\begin{aligned}(4.8)\qquad m_1||u-u_h||^2_{(-n)} &\leq (u-u_h, M(u-u_h)\sigma^{-n}) \\ &= (u-u_h, M(u-u_h)\sigma^{-n} - \varphi_h) + F(\varphi_h) \\ &\quad - b(p-p_h, \varphi_h - M(u-u_h)\sigma^{-n}) \\ &\quad - b(p-p_h, M(u-u_h)\sigma^{-n}) \\ &= \text{(i)} + \text{(ii)} + \text{(iii)} + \text{(iv)}.\end{aligned}$$

Here we have used (4.3) with $\varphi_h = I_h(M(u-u_h)\sigma^{-n})$.

The first term in (4.8) is estimated by Cauchy's inequality,

$$\text{(i)} \leq ||u-u_h||_{(-n)}||M(u-u_h)\sigma^{-n} - \varphi_h||_{(n)}.$$

From Lemma 4.1 and Young's inequality $ab \leq \frac{\epsilon}{2}a^2 + \frac{1}{2\epsilon}b^2$ we conclude

$$\text{(i)} \leq \left(ch\rho^{-1} + \frac{m_1}{16}\right)||u-u_h||^2_{(-n)} + ch^{2m}||\nabla^m u||^2_{(-n)}$$

and, by $\rho = c^*h$ and c^* sufficiently large,

$$\text{(i)} \leq \frac{m_1}{8}||u-u_h||^2_{(-n)} + ch^{2m}||\nabla^m u||^2_{(-n)}.$$

For the second term, we obtain from the definition of the weighted norm of F

$$\begin{aligned}\text{(ii)} = F(\varphi_h) &\leq ||F||_{(-n)}||\varphi_h||_{(n)} \\ &\leq ||F||_{(-n)}\left(||\varphi_h - M(u-u_h)\sigma^{-n}||_{(n)} + ||M(u-u_h)\sigma^{-n}||_{(n)}\right).\end{aligned}$$

Using Lemma 4.1 and

$$||M(u-u_h)\sigma^{-n}||_{(n)} \leq c||u-u_h||_{(-n)},$$

we get

$$\text{(ii)} \leq \frac{m_1}{8}||u-u_h||^2_{(-n)} + c||F||^2_{(-n)} + ch^{2m}||\nabla^m u||^2_{(-n)}.$$

For the third term we conclude similarly from (4.5)

$$\begin{aligned}\text{(iii)} &\leq ||p-p_h||_{(1,-n)}||M(u-u_h)\sigma^{-n} - \varphi_h||_{(n)} \\ &\leq ch\rho^{-1}||p-p_h||_{(1,-n)}||u-u_h||_{(-n)} + ch^m||p-p_h||_{(1,-n)}||\nabla^m u||_{(-n)} \\ &\leq \eta||p-p_h||^2_{(1,-n)} + \frac{m_1}{8}||u-u_h||^2_{(-n)} + ch^{2m}||\nabla^m u||^2_{(-n)},\end{aligned}$$

with an $\eta > 0$ which will be determined later sufficiently small.

Collecting the preceding estimates, it follows from (4.8) that

$$(4.9)\qquad \frac{m_1}{2}||u-u_h||^2_{(-n)} \leq \eta||p-p_h||^2_{(1,-n)} + cR - b(p-p_h, M(u-u_h)\sigma^{-n}).$$

In order to estimate the last term on the right-hand side we use condition (2.8) in Lemma 2.1 in the form

$$|b(q,Mv) - c(v,q)| \leq c||v||_{(\alpha)}||q||_{(-\alpha)},$$

which can be proved in the same way as (2.8). Now

$$\begin{aligned}-b(p-&p_h, M(u-u_h)\sigma^{-n}) \\ &= -b(p-p_h, M(u-u_h)\sigma^{-n}) + c((u-u_h)\sigma^{-n}, p-p_h) - c((u-u_h)\sigma^{-n}, p-p_h) \\ &\leq c||(u-u_h)\sigma^{-n}||_{(n)}||p-p_h||_{(-n)} - c((u-u_h)\sigma^{-n}, p-p_h).\end{aligned}$$

Thus we have proved that

$$(4.10)\qquad -b(p-p_h, M(u-u_h)\sigma^{-n}) \leq \frac{m_1}{8}||u-u_h||^2_{(-n)} + c||p-p_h||^2_{(-n)} + A,$$

where $A = -c((u-u_h)\sigma^{-n}, p-p_h)$. Since we want to apply the error relation (4.4) to A, we have to shift the weight function σ^{-n} to the second argument of $c(\cdot,\cdot)$,

$$\begin{aligned}A &= \int_\Omega \sum_{i=1}^n c_i^\alpha (u-u_h)^\alpha \sigma^{-n}\partial_i(p-p_h)\,dx - \int_\Omega c_0^\alpha(u-u_h)^\alpha\sigma^{-n}(p-p_h)\,dx \\ &\leq -c(u-u_h,(p-p_h)\sigma^{-n}) + c\int_\Omega |u-u_h||\nabla\sigma^{-n}||p-p_h|\,dx \\ &\leq -c(u-u_h,(p-p_h)\sigma^{-n}) + \frac{m_1}{8}||u-u_h||^2_{(-n)} + c||p-p_h||^2_{(-n-2)}.\end{aligned}$$

Combining this estimate with (4.10) and using the fact that $||p-p_h||^2_{(-n)} \leq c||p-p_h||^2_{(-n-2)}$, we obtain

$$(4.11)\qquad -b((p-p_h), M(u-u_h)\sigma^{-n}) \leq \frac{m_1}{4}||u-u_h||^2_{(-n)} + c||p-p_h||^2_{(-n-2)} + B$$

with

$$B = -c(u - u_h, (p - p_h)\sigma^{-n}),$$

and hence, by (4.9), (4.11),

$$\frac{m_1}{4}||u - u_h||^2_{(-n)} \leq \eta||p - p_h||^2_{(1,-n)} + cR + B. \tag{4.12}$$

Term B is estimated by (4.4):

$$\begin{aligned} B = {} & -c(u - u_h, (p - p_h)\sigma^{-n} - \psi_h) + \omega(u - u_h, B(\psi_h - (p - p_h)\sigma^{-n})) \\ & + \omega b(p - p_h, B(\psi_h - (p - p_h)\sigma^{-n})) - G(\psi_h - (p - p_h)\sigma^{-n}) \\ & + \omega(u - u_h, B((p - p_h)\sigma^{-n})) + \omega b(p - p_h, B((p - p_h)\sigma^{-n})) \\ & - G((p - p_h)\sigma^{-n}), \end{aligned} \tag{4.13}$$

where $\psi_h = I_h((p - p_h)\sigma^{-n})$. In view of the fact that we gain a factor $h\rho^{-1}$ in terms containing $v - I_h v$ in contrast to the terms containing v, we restrict ourselves to the estimation of the last three terms in (4.13), namely

$$\begin{aligned} \text{(i)} &= \omega(u - u_h, B((p - p_h)\sigma^{-n})), \\ \text{(ii)} &= \omega b(p - p_h, B((p - p_h)\sigma^{-n})), \\ \text{(iii)} &= -G((p - p_h)\sigma^{-n}); \end{aligned} \tag{4.14}$$

the other terms in (4.13) can be bounded by

$$\frac{m_1}{16}||u - u_h||^2_{(-n)} + \eta||p - p_h||^2_{(1,-n)} + cR, \tag{4.15}$$

since the constant $\omega > 0$ is assumed to be fixed.

For the first term in (4.14) we obtain

$$\begin{aligned} \text{(i)} = {} & -\omega\int_\Omega (u - u_h)^\alpha b_i^\alpha \partial_i(p - p_h)\sigma^{-n}\,dx - \omega\sum_{i=1}^n \int_\Omega (u - u_h)^\alpha b_i^\alpha (p - p_h)\partial_i\sigma^{-n}\,dx \\ & \leq \omega||u - u_h||_{(-n)}||B(p - p_h)||_{(-n)} + \frac{m_1}{16}\|u - u_h\|^2_{(-n)} + c\|p - p_h\|^2_{(-n-2)}. \end{aligned}$$

The second term in (4.14) gives us the second term with the "right" sign,

$$\begin{aligned} \text{(ii)} &= -\omega\int_\Omega b_i^\alpha \partial_i(p - p_h) b_j^\alpha \partial_j((p - p_h)\sigma^{-n})\,dx \\ &\leq -\omega||B(p - p_h)||^2_{(-n)} + c||p - p_h||_{(1,-n)}||p - p_h||_{(-n-2)} \\ &\leq -\omega||B(p - p_h)||^2_{(-n)} + \eta||p - p_h||^2_{(1,-n)} + cR. \end{aligned}$$

The third term in (4.14) is simply bounded by

$$\text{(iii)} \leq ||G||_{(-1,-n)}||p - p_h||_{(1,-n)} \leq \eta||p - p_h||^2_{(1,-n)} + cR.$$

These estimates together with (4.12), (4.13), (4.15) give

$$\begin{aligned}(4.16)\qquad \frac{m_1}{8}||u-u_h||^2_{(-n)} &+ \omega||B(p-p_h)||^2_{(-n)}\\ &\le \omega||u-u_h||_{(-n)}||B(p-p_h)||_{(-n)} + 3\eta||p-p_h||^2_{(1,-n)} + cR.\end{aligned}$$

It is obvious that the term

$$\omega||u-u_h||_{(-n)}||B(p-p_h)||_{(-n)}$$

cannot be put into the left-hand side of (4.16) for all $\omega > 0$. Since we will prove the lemma for all $\omega > 0$, we will estimate $||u-u_h||_{(-n)}$ by $||B(p-p_h)||_{(-n)}$. Similar to the method described at the beginning of the proof, we use (4.3) with $\varphi_h = I_h((u-u_h)\sigma^{-n})$,

$$\begin{aligned}||u-u_h||^2_{(-n)} &= (u-u_h,(u-u_h)\sigma^{-n}-\varphi_h) + b(p-p_h,(u-u_h)\sigma^{-n}-\varphi_h)\\ &\quad + F(\varphi_h) - b(p-p_h,(u-u_h)\sigma^{-n}).\end{aligned}$$

Using Lemma 4.1 with $M = E$, the first three terms of the right-hand side can be bounded by

$$\epsilon_1||u-u_h||^2_{(-n)} + \epsilon_1||B(p-p_h)||^2_{(-n)} + cR$$

with arbitrarily small $\epsilon_1 > 0$, and for the last term we have trivially

$$-b(p-p_h,(u-u_h)\sigma^{-n}) \le ||B(p-p_h)||_{(-n)}||u-u_h||_{(-n)},$$

and hence

$$(4.17)\qquad ||u-u_h||^2_{(-n)} \le (1+\epsilon)||B(p-p_h)||^2_{(-n)} + cR$$

with $c = c(\epsilon)$ and ϵ can be chosen arbitrary small. We obtain from (4.16) and (4.17) for all $\omega > 0$

$$||u-u_h||^2_{(-n)} + ||B(p-p_h)||^2_{(-n)} \le c\eta||p-p_h||^2_{(1,-n)} + cR.$$

The lemma follows by applying the analogue of (2.9) in Lemma 2.1 and choosing η sufficiently small. □

LEMMA 4.3. *For pairs (u,p) and $(u_h,p_h) \in X_h \times Y_h$ satisfying* (4.3), (4.4) *we have the error estimates*

$$\begin{aligned}(4.18)\qquad ||p-p_h||_{(-n)} &\le c\rho^{-\kappa}h\{||u-u_h||_{(-n)} + ||p-p_h||_{(1,-n)}\}\\ &\quad + c\rho^{-\kappa}\{||F||_{(-n)} + ||G||_{(-1,-n)}\}\end{aligned}$$

with an arbitrarily small $\kappa > 0$ and a constant $c = c(\kappa)$.

Proof. Let $(v,q) \in L^2(\Omega)^n \times H_0^{1,2}(\Omega)$ be the solution of the adjoint problem

$$(\varphi,v) + c(\varphi,q) + \omega(\varphi,Bq) = 0 \quad \forall\varphi \in L^2(\Omega)^n,$$

$$b(\psi,v) + \omega b(\psi,Bq) = ((p-p_h)\sigma^{-n},\psi) \quad \forall\psi \in H_0^{1,2}(\Omega).$$

Inserting $\varphi = u - u_h$, $\psi = p - p_h$ and using the error relations (4.3), (4.4) gives

$$\begin{aligned} ||p-p_h||^2_{(-n)} &= (u-u_h, v-R_hv) + c(u-u_h, q-R_hq) \\ &\quad + \omega(u-u_h, B(q-R_hq)) + b(p-p_h, v-R_hv) \\ &\quad + \omega b(p-p_h, B(q-R_hq)) + F(R_hv) + G(R_hq). \end{aligned} \tag{4.19}$$

The bilinear forms are estimated by Cauchy's inequality and (3.10); for example,

$$\begin{aligned} (u-u_h, v-R_hv) &\leq ||u-u_h||_{(-n)}||v-R_hv||_{(n)} \\ &\leq ch||u-u_h||_{(-n)}||v||_{(1,n)}, \\ \omega b(p-p_h, B(q-R_hq)) &\leq c||p-p_h||_{(1,-n)}||q-R_hq||_{(1,n)} \\ &\leq ch||p-p_h||_{(1,-n)}||q||_{(2,n)}. \end{aligned}$$

The functionals are simply bounded by their norms and (3.11):

$$\begin{aligned} F(R_hv) + G(R_hq) &\leq ||F||_{(-n)}||R_hv||_{(n)} + ||G||_{(-1,-n)}||R_hq||_{(1,n)} \\ &\leq c||F||_{(-n)}||v||_{(1,n)} + c||G||_{(-1,-n)}||q||_{(2,n)}. \end{aligned}$$

Inserting these estimates into (4.19) gives

$$\begin{aligned} ||p-p_h||^2_{(-n)} \leq c(&h||u-u_h||_{(-n)} + h||p-p_h||_{(1,-n)} + ||F||_{(-n)} + ||G||_{(-1,-n)}) \\ &\times(||v||_{(1,n)} + ||q||_{(2,n)}). \end{aligned}$$

The lemma follows by applying Lemma 3.2,

$$||v||_{(1,n)} + ||q||_{(2,n)} \leq c\rho^{-\kappa}||(p-p_h)\sigma^{-n}||_{(n)} = c\rho^{-\kappa}||p-p_h||_{(-n)}. \qquad \square$$

LEMMA 4.4. *There exists an $h_0 > 0$ such that for all $h \leq h_0$ all solutions $(u_h, p_h) \in X_h \times Y_h$ of* (4.3), (4.4) *satisfy the error estimates*

$$\begin{aligned} h||u-u_h||_\infty + h||p-p_h||_{1,\infty} + ||p-p_h||_\infty &\leq ch^{m+1-\epsilon}(||u||_{m,\infty} + ||p||_{m+1,\infty}) \\ &\quad + ch^{-\epsilon}\{||F||_{(-n)} + ||G||_{(-1,-n)}\} \end{aligned}$$

for all $\epsilon > 0$ with constants $c = c(\epsilon)$.

Proof. We add $\rho^{-2}||p-p_h||^2_{(-n)}$ to both sides of (4.7) in Lemma 4.2, use the estimate

$$||p-p_h||^2_{(-n-2)} \leq \rho^{-2}||p-p_h||^2_{(-n)}$$

on the right-hand side of (4.7), and insert the estimate (4.18) into the resulting estimate,

$$\begin{aligned} ||u-u_h||^2_{(-n)} &+ ||p-p_h||^2_{(-1,-n)} + \rho^{-2}||p-p_h||^2_{(-n)} \\ &\leq c\rho^{-2-2\kappa}h^2\{||u-u_h||^2_{(-n)} + ||p-p_h||^2_{(1,-n)}\} \\ &\quad + c\rho^{-2-2\kappa}\{||F||^2_{(-n)} + ||G||^2_{(-1,-n)}\} \\ &\quad + ch^{2m-\epsilon}\{||u||^2_{m,\infty} + ||p||^2_{m+1,\infty}\}, \end{aligned} \tag{4.20}$$

where κ and ϵ can be chosen arbitrarily small. For small κ we choose $\rho = c^* h = h^{1-2\kappa}$ such that

$$c\rho^{-2-2\kappa}h^2 = ch^{(1-2\kappa)(-2-2\kappa)}h^2 \leq \frac{1}{2}$$

for $h \leq h_0$. By this procedure, the first term on the right-hand side of (4.20) can be put into the left-hand side. We determine

$$\max(||u-u_h||_\infty, ||p-p_h||_{1,\infty}, \rho^{-1}||p-p_h||_\infty)$$

and choose x_0 such that Lemma 3.1 can be applied to the corresponding term. In view of the fact that κ can be chosen arbitrarily small, the lemma is proved. □

5. Proof of Theorem 1.2. We return to the definition of the discrete solution in (1.7), (1.8). Subtracting this system from the corresponding continuous system yields

$$(u-u_h, \varphi_h) = (b(\cdot, p, \nabla p) - b(\cdot, p_h, \nabla p_h), \varphi_h) \quad \forall \varphi_h \in X_h, \tag{5.1}$$

$$\begin{aligned} -\sum_{i=1}^n (c_i(\cdot,p,u) - c_i(\cdot,p_h,u_h), \partial_i\psi_h) + (c_0(\cdot,p,u) - c_0(\cdot,p_h,u_h), \psi_h) \\ + \omega(u-u_h-b(\cdot,p,\nabla p) + b(\cdot,p_h,\nabla p_h), B(p_h)\psi_h) \\ = (g(\cdot,p,\nabla p) - g(\cdot,p_h,\nabla p_h), \psi_h) \quad \forall \psi_h \in Y_h. \end{aligned} \tag{5.2}$$

Setting

$$\bar{b}_i^\alpha = \int_0^1 b_i^\alpha(x, tp + (1-t)p_h, t\nabla p + (1-t)\nabla p_h)\,dt,$$

we have

$$\begin{aligned} (b(\cdot,p,\nabla p) - b(\cdot,p_h,\nabla p_h), \varphi_h) &= (\bar{b}_i^\alpha \partial_i(p-p_h), \varphi_h^\alpha) \\ &= -b(p-p_h, \varphi_h) + F(p_h;\varphi_h), \end{aligned}$$

where

$$b(q,v) = -\int_\Omega b_i^\alpha \partial_i q\, v\, dx$$

and

$$F(p_h;\varphi_h) = ((\bar{b}_i^\alpha - b_i^\alpha)\partial_i(p-p_h), \varphi_h)$$

satisfies

$$|F(p_h;\varphi_h)| \leq c\int_\Omega (|p-p_h|^2 + |\nabla(p-p_h)|^2)|\varphi_h|\,dx. \tag{5.3}$$

Thus we have shown that (5.1) is of the form

$$(u-u_h,\varphi_h) + b(p-p_h,\varphi_h) = F(p_h;\varphi_h) \quad \forall \varphi_h \in X_h, \tag{5.4}$$

which is exactly (4.3). The first two terms in (5.2) are treated by the same method

$$-\sum_{i=1}^{n}(c_i(\cdot,p,u)-c_i(\cdot,p_h,u_h),\partial_i\psi_h)+(c_0(\cdot,p,u)-c_0(\cdot,p_h,u_h),\psi_h)$$

$$=c(u-u_h,\psi_h)+d_1(p-p_h,\psi_h)-G_1(u_h,p_h;\psi_h),$$

where G_1 satisfies

$$|G_1(u,p;\psi_h)|\le c\int_\Omega(|p-p_h|+|u-u_h|)^2(|\psi_h|+|\nabla\psi_h|)\,dx. \tag{5.5}$$

For the right-hand side we obtain similarly

$$(g(\cdot,p,\nabla p)-g(\cdot,p_h,\nabla p_h),\psi_h)=-d_2(p-p_h,\psi_h)+G_2(p_h;\psi_h)$$

with

$$|G_2(p_h;\psi_h)|\le c\int_\Omega(|p-p_h|+|\nabla p-\nabla p_h|)^2|\psi_h|\,dx. \tag{5.6}$$

For the remaining term in (5.2) we obtain

$$\begin{aligned}\omega(u-u_h&-b(\cdot,p,\nabla p)+b(\cdot,p_h,\nabla p_h),B(p_h)\psi_h)\\ &=\omega(u-u_h-b(\cdot,p,\nabla p)+b(\cdot,p_h,\nabla p_h),(B(p_h)-B(p))\psi_h)\\ &\quad+\omega(u-u_h-b(\cdot,p,\nabla p)+b(\cdot,p_h,\nabla p_h),B(p)\psi_h)\\ &=-G_3(u_h,p_h;\psi_h)+\omega(u-u_h,B(p)\psi_h)\\ &\quad+\omega b(p-p_h,B(p)\psi_h)-G_4(u_h,p_h;\psi_h)\end{aligned}$$

with G_3,G_4 satisfying

$$\begin{aligned}&|G_3(u_h,p_h;\psi_h)|+|G_4(u_h,p_h;\psi_h)|\\ &\qquad\le c\int_\Omega(|u-u_h|^2+|p-p_h|^2+|\nabla p-\nabla p_h|^2)(|\psi_h|+|\nabla\psi_h|)\,dx.\end{aligned} \tag{5.7}$$

Now (5.1), (5.2) are exactly of the form (4.3), (4.4) with $G=G_1+G_2+G_3+G_4$, $d=d_1+d_2$. From (5.3), (5.5), (5.6), (5.7), it follows with the aid of Cauchy's inequality that

$$\begin{aligned}||F(u_h;\cdot)||_{(-n)}&\le\left(\int_\Omega(|p-p_h|^2+|\nabla(p-p_h)|^2)^2\sigma^{-n}\,dx\right)^{1/2}\\ &\le c|\ln h|^{1/2}||p-p_h||_{1,\infty}^2,\end{aligned} \tag{5.8}$$

$$||G(u_h,p_h;\cdot)||_{(-1,-n)}\le c|\ln h|^{1/2}(||u-u_h||_\infty^2+||p-p_h||_{1,\infty}^2). \tag{5.9}$$

Define the set

$$K_R = \{(v_h, q_h) \in X_h \times Y_h : \ ||u - v_h||_\infty + ||p - q_h||_{1,\infty} \le R\}$$

and the operator $T : K_R \to X_h \times Y_h$, $T(v_h, q_h) = (u_h, p_h)$ by

$$(u - u_h, \varphi_h) + b(p - p_h, \varphi_h) = F(v_h; \varphi_h) \quad \forall \varphi_h \in X_h, \tag{5.10}$$

$$\begin{aligned} c(u - u_h, \psi_h) + \omega(u - u_h, B\psi_h) + \omega b(p - p_h, B\psi_h) \\ = G(v_h, q_h; \psi_h) \ \ \forall \psi_h \in Y_h, \end{aligned} \tag{5.11}$$

where $B = B(p)$. In order to demonstrate that T is well defined let $h \le h_0$ such that Lemma 4.4 can be applied. Set $F = 0$, $G = 0$, $u = 0$, $p = 0$. Then it follows from Lemma 4.4 that $u_h = 0$ and $p_h = 0$. This proves that (5.10), (5.11) is a regular system for h sufficiently small.

By Lemma 4.4, (u_h, p_h) satisfies

$$\begin{aligned} ||u - u_h||_\infty + ||p - p_h||_{1,\infty} &\le c(u,p)h^{m-\epsilon} \\ &\quad + ch^{-1-\epsilon}\left\{||F(v_h; \cdot)||_{(-n)} + ||G(v_h, q_h; \cdot)||_{(-1,-n)}\right\} \\ &\le c(u,p)h^{m-\epsilon} + ch^{-1-2\epsilon}R^2, \end{aligned}$$

where we have used (5.8), (5.9) and that $(v_h, q_h) \in K_R$. Choosing $R = 2c(u,p)h^{m-\epsilon}$ and recalling $m \ge 2$, the last estimate demonstrates that $T : K_R \to K_R$ for sufficiently small h. By Brouwer's fixed point theorem, T has a fixed point, which is a solution of (1.7), (1.8). The better estimate for $||p - p_h||_\infty$ follows from Lemma 4.4.

THE IMPLICIT UPWIND METHOD FOR 1-D SCALAR CONSERVATION LAWS WITH CONTINUOUS FLUXES[*]

MICHAEL BREUẞ[†]

Abstract. We present the first part of a theory of monotone implicit methods for scalar conservation laws. In this paper, we focus on the implicit upwind scheme. The theoretical investigation of this method is centered around a rigorously verified implicit monotonicity criterion. The relation between the upwind scheme and a discrete entropy inequality is constructed analogously to the classical approach of Crandall and Majda [M. G. Crandall and A. Majda, *Math. Comp.*, 34 (1980), pp. 1–21]. A proof of convergence is given which does not rely on a classical compactness argument. The theoretical results are complemented by a discussion of numerical aspects.

Key words. conservation laws, implicit methods, monotone methods, upwind methods

1. Introduction.

The aim of this paper is to describe the first part of a constructive approach to the entropy solution of hyperbolic conservation laws in the sense of Kružkov for the most general case possible in 1-D, i.e., essentially for merely continuous flux functions. Finally, we seek to develop a theory of implicit finite difference methods which is centered around a rigorously verified implicit monotonicity notion.

The validation of the monotonicity property is not trivial in the implicit case. We restrict our attention in this note on the upwind method, i.e., on continuous nonstrictly growing monotone fluxes. The extension to the mentioned more general case is the subject of a forthcoming paper. In contrast to fundamental works within this field; see, e.g., [4, 3, 16, 13], we do not rely on the Lipschitz continuity of the flux, nor on the boundedness of the solution in space, nor on boundedness with respect to the total variation of the solution. In the nonconstructive sense, the existence and uniqueness results of corresponding solutions are documented within a number of papers of Kružkov and his co-workers; see [1, 11, 12] and the references therein. Related to the subject of the present work are also problems with discontinuous fluxes; see, e.g., [6] for a useful presentation.

In order to point out the difficulties encountered when approaching the described task, let us briefly discuss the consequences of our basic assumptions.

If the flux function of a nonlinear conservation law is not Lipschitz continuous, it may happen that information is propagated with infinite speed. This is, e.g., the case in the example given by Kružkov and Panov in [12], which is concerned with the equation

$$\frac{\partial}{\partial t}u(x,t)+\frac{\partial}{\partial x}\left(\frac{|u(x,t)|^{\alpha}}{\alpha}\right)=0,\quad \alpha\in(0,1),\, t>0,\, x\in\mathbf{R}. \tag{1.1}$$

Given the initial condition

$$u_0(x) \;=\; \begin{cases} 0 & : \quad x < -1, \\ 1 & : \quad -1 \le x \le 0, \\ 0 & : \quad x > 0, \end{cases} \tag{1.2}$$

the exact solution defined over a time interval depending on the exact choice of α reads

$$u(x,t) \;=\; \begin{cases} 0 & : \quad t > \alpha(x+1), \\ 1 & : \quad x < t \le \alpha(x+1), \\ \left(\frac{t}{x}\right)^{1/(1-\alpha)} & : \quad t \le x. \end{cases} \tag{1.3}$$

As can easily be seen, this solution incorporates a rarefaction wave extending to infinity after arbitrarily small time. Mathematically, two properties of special interest are contained within this example: the flux features a pole at $u = 0$, and the domain of the solution is infinite even for an initial condition with compact support. The first property yields that the CFL number would be effectively zero when using an explicit scheme. Also, the Kuznetsov approach to convergence [13] does not work since it explicitly uses the Lipschitz continuity of the flux (as well as the boundedness of the domain of the solution). The second property implies that the main other traditional approaches to the convergence of numerical methods are also not suitable, as can be seen as follows. There are essentially two further approaches to be noted: the first one relies on Helly's theorem, using the compactness of the space of functions of bounded variations to extract a converging sequence of numerical solutions as the grid is refined. This is, e.g., the case in the convergence proofs of TVD methods. As described in detail by LeVeque [14], this function space is only compact when employing the BV concept over a fixed compact space-time-domain, thus the compactness property of this function space is in general not applicable in the discussed case. Note that also within the paper of Crandall and Majda [4] on explicit monotone methods, the properties of this function space are used to obtain a compactness argument. The second approach relies on the concept of measure valued solutions introduced by DiPerna [5]. Also here, the compactness of the space-time-domain of the solution is assumed which is, e.g., already noted in [3].

By this discussion, it is evident that we have to employ implicit schemes in a framework which enables the use of a convergence strategy different from the mentioned classical ones. We achieve this by using the monotonicity of an implicit method as a means of nonlinear stability. It is then verified that the monotonicity property is enough to guarantee the convergence of such methods to the entropy solution in the sense of Kružkov.

The need to be sure about the monotonicity property needs to be addressed in detail within this paper. In fact, within the literature about numerical methods for conservation laws, the monotonicity of numerical schemes is generally discussed for explicit schemes; see, e.g., [7, 14] and the references therein. It makes no sense to cite here numerous more practically oriented papers on implicit methods, where the numerical flux function of a scheme which is monotone under a CFL condition in the explicit case is employed in some context, and where an implicit time-stepping procedure is applied for evaluating the fluxes, e.g., to ensure the stability of an algorithm, or, e.g., to enhance the effectiveness of a method for computing steady state solutions, etc.. Since the aim of these works is typically a totally different one from ours, it is also not at all our objective to criticize them. However, an existing mathematically rigorous investigation of the monotonicity property of implicit schemes is not known by the author. Furthermore, with respect to the continuity of the flux, it is necessary that the validation of an implicit monotonicity criterion does not involve any derivative of the flux. Consequently, we develop a monotonicity notion which is verified by comparing data sets using the induction principle.

One further point of interest is the validity of a discrete entropy condition. Since we are interested in the Kružkov entropy notion, it is adequate to use a discrete version of the corresponding entropy inequality. We found that the relation between a monotone method and a discrete entropy inequality used by Crandall and Majda [4] (which is in turn based on the previous work of Harten, Hyman, and Lax [9]) can also be used in the implicit case. This is not at all self-evident; it is based on the fact that even in the original derivation of this relation no technique is used which relies on the Lipschitz property of the flux. This was also already noted in the original paper [4]. However, the validity of this relation of course has to be verified rigorously since there are some differences with respect to the explicit case within the techniques in use. It is mandatory to stress that only the relation between the implicit upwind method and the discrete entropy condition is derived similarly to the proceeding in [4]. The remainder of the content of this paper including the convergence proof is technically completely different than the theory presented in [4].

The proof of convergence can be sketched as follows. Using pointwise comparison of data sets, the monotone implicit upwind method yields a monotonously growing approximative sequence of numerical solutions corresponding to a constructed sequence of monotonously growing discrete initial data. The sequence is L_∞-bounded by the monotonicity of the method for L_∞-bounded initial data. Thus, it is possible to use the theorem of monotone convergence by Beppo Levi to obtain strong convergence a.e. of the whole sequence to a unique limit over any arbitrarily chosen compact domain. Since the approximative sequence satisfies a discrete entropy inequality, convergence to the entropy condition of Kružkov follows by the established strong convergence a.e. of the sequence. To the knowledge of the author, this principle is not used up to now in any other work.

According to the discussion above, this paper is organized as follows. At first, implicit notions are developed which are centered around the monotonicity notion for the implicit upwind schemes. A minor stability result is established which is needed within the convergence proof. The upwind method is investigated with respect to its monotonicity. The proof of convergence to the entropy solution is illustrated. Finally, we discuss numerical approximations followed by conclusive remarks and acknowledgements.

2. The implicit upwind method.

In the following, u_m^l denotes the value of the numerical solution at $m\Delta x$ and $l\Delta t$. The presence of a uniform grid with a constant mesh ratio $\lambda = \Delta t/\Delta x$ is assumed, but this is only for a more transparent notation and is not essential.

In order to avoid some inconveniences within the notation, implicit 3-point-methods of the form

$$u_0^{n+1} = \tilde{H}(u_{-1}^{n+1}, u_0^{n+1}, u_1^{n+1}; u_0^n)$$

are sometimes addressed which includes both possible upwind schemes

$$u_j^{n+1} \;=\; u_j^n - \lambda\big[f(u_j^{n+1}) - f(u_{j-1}^{n+1})\big] \tag{2.1}$$

and

$$u_j^{n+1} \;=\; u_j^n - \lambda\big[f(u_j^{n+1}) - f(u_{j+1}^{n+1})\big].$$

However, in this paper we only discuss in detail the upwind scheme (2.1). All statements given within the paper can easily be adapted in an identical fashion to the other possible implicit upwind scheme.

Since we restrict our attention in the following to (2.1), it is convenient to use as the abbreviated form of the method

$$u_0^{n+1} = H(u_{-1}^{n+1}, u_0^{n+1}; u_0^n). \tag{2.2}$$

2.1. Implicit notions. For the completeness of the presentation, we give the definitions of the conservation form, the numerical flux function, and consistency. These notions are completely analogous to the corresponding ones for explicit schemes.

Definition 2.1 (conservation form, numerical flux function). *A* 3*-point numerical scheme is in conservation form if a continuous numerical flux function $g : \mathbf{R}^2 \to \mathbf{R}$ exists, so that the method reads*

$$\tilde{H}(u_{-1}^{n+1}, u_0^{n+1}, u_1^{n+1}; u_0^n) = u_0^n - \lambda\big[g(u_0^{n+1}, u_1^{n+1}) - g(u_{-1}^{n+1}, u_0^{n+1})\big].$$

Definition 2.2 (consistency). *A* 3*-point numerical method described by g is consistent if $g(v,v) = f(v)$ holds for all $v \in \mathbf{R}$.*
Obviously, the implicit upwind scheme (2.1) is a consistent and conservative scheme with

$$g \equiv g(u,v) \equiv g(u) = f(u). \tag{2.3}$$

The key to nonlinear stability is the notion of monotonicity.

Definition 2.3 (monotonicity). *Let two data sequences v^n and w^n be given. Let the upwind scheme* (2.1) *produce new sequences of data v^{n+1} and w^{n+1} out of the given data v^n and w^n, respectively. Then the method is monotone iff the implication*

$$v^n \geq w^n \quad \Rightarrow \quad v^{n+1} \geq w^{n+1} \tag{2.4}$$

holds in the sense of the comparison of components.
Note that Definition 2.3 captures the essence of the notion of monotonicity and is free of derivatives of H.

In the following, we use the abbreviations $w_{j-1}^{n+1} =: a$, $w_j^{n+1} =: b$ and $w_j^n =: d$ when appropriate to simplify the notation.

Theorem 2.1 (monotonicity of the upwind scheme). *The upwind method* (2.1) *is monotone if the following conditions hold:*

$$H(a + \Delta a, b; d) \geq H(a, b, c; d), \tag{2.5}$$

$$H(a, b; d + \Delta d) \geq H(a, b; d), \tag{2.6}$$

with $\Delta a, \Delta d \;\geq 0$, respectively. Thereby, the condition (2.5) *has the meaning that the scheme* (2.1) *is monotone if the flux is a nonstrictly growing monotonous function.*
Before we proceed with the proof, let us give an insight into the meaning of the properties of the mapping H which follow from (2.5) and (2.6).

In the case of explicit 3-point schemes, the monotonicity of a scheme is verified by computing the derivatives of the function k of the method,

$$u_j^{n+1} = k(u_{j-1}^n, u_j^n, u_{j+1}^n).$$

The monotonicity condition is then

$$\frac{\partial}{\partial a_i} k(a_1, a_2, a_3) \geq 0 \quad \forall\, i \in \{1, 2, 3\}.$$

Note that this means not to investigate concrete changes in u^{n+1} due to changes in a given data set u^n. Rather than that, the effects of changes in u^n are studied this way, answering the question: If we change the given data set u^n in a positive way, is the effect a nonnegative change in u^{n+1} or not?

Since we deal with continuous fluxes in this paper, we cannot generally compute a derivative. However, if we fix, for instance, our attention on the first monotonicity requirement (2.5)

$$H(a + \Delta a, b; d) \geq H(a, b; d)$$

for $\Delta a > 0$, then we may subtract the right-hand side from this inequality and divide by Δa to obtain the condition

$$\frac{H(a + \Delta a, b; d) - H(a, b; d)}{\Delta a} \geq 0$$

which takes the form of a discretized derivative. We observe the connection between the explicit and the implicit monotonicity notion.

Proof of Theorem 2.1. Let us first verify the validity of the conditions (2.5) and (2.6) before we proceed further.
To condition (2.5)*,*

$$\begin{aligned} &H(a + \Delta a, b; d) - H(a, b; d) \\ &= \big[d - \lambda\big[f(b) - f(a + \Delta a)\big]\big] - \big[d - \lambda\big[f(b) - f(a)\big]\big] \\ &= \lambda\left[f(a + \Delta a) - f(a)\right]. \end{aligned}$$

The condition (2.5) is only valid if f grows monotonously.
To condition (2.6)*,*

$$\begin{aligned} &H(a, b, c; d + \Delta d) - H(a, b, c; d) \\ &= \big[d + \Delta d - \lambda\big[f(b) - f(a)\big]\big] - \big[d - \lambda\big[f(b) - f(a)\big]\big] \\ &= \Delta d \quad (\geq 0). \end{aligned}$$

The latter condition seems to be redundant by the general form of the discussed methods. However, the condition (2.6) fixes the necessary coupling mechanism needed to obtain a comparison principle as given in Definition 2.3. Note that f does not need to be Lipschitz continuous in order to fulfill the stated monotonicity conditions. Let us now prepare the main part of the proof and let us note that (2.1) is defined for the indices $j > J$ and $n \geq 0$, whereby u_J^{n+1} must be given for some index J.

In the notation used before, the scheme (2.1) reads

$$b = d - \lambda\left(f(b) - f(a)\right),$$

or, equivalently,

$$b + \lambda f(b) = d + \lambda f(a).$$

Let us define the function

$$\mathcal{F}(b) := b + \lambda f(b).$$

For $\delta b > 0$ we have

$$\begin{aligned}&\mathcal{F}(b+\delta b) - \mathcal{F}(b)\\ &= \big[b + \delta b + \lambda f(b+\delta b)\big] - \big[b + \lambda f(b)\big]\\ &= \underbrace{\delta b}_{>0} + \lambda \underbrace{\left(f(b+\delta b) - f(b)\right)}_{\geq 0}\end{aligned}$$

since f is a nonstrictly growing monotone function. Thus, $\mathcal{F}$ is a strictly growing monotone function so that there exists a strictly increasing inverse function $\mathcal{F}^{-1}$. Now, let two sequences v^n, w^n be given with $v^n \mapsto v^{n+1}$ and $w^n \mapsto w^{n+1}$ by application of the considered scheme. Furthermore, let $(v^n = w^n) \Rightarrow \big(v^{n+1} = w^{n+1}\big)$ hold. According to the assertion of the theorem, we seek to establish the comparison principle $v^{n+1} \geq w^{n+1}$ for any two given sequences $v^n \geq w^n$ by using the properties (2.5) and (2.6) of the mapping H. The idea of the proof worked out in the following is to assume inductively $a \geq a'$ and $d \geq d'$ resulting in

$$b = \mathcal{F}^{-1}\left[d + \lambda f\left(a\right)\right] \geq \mathcal{F}^{-1}\left[d' + \lambda f\left(a'\right)\right] = b', \tag{2.7}$$

which is nothing but the pointwise realization of the sought monotone comparison principle.

Let $\mathbf{I}$ be the set of indices k with $v^n_k > w^n_k$, $v^n_k \in v^n$, $w^n_k \in w^n$. There are only a few possibilities for the composition of the set $\mathbf{I}$: It may consist of the empty set or a finite or infinite subset of $\mathbf{Z}$. The proof of the assertion of the theorem follows by diversion of cases and induction by the number of indices in $\mathbf{I}$. The aim is to show in each step of the induction the validity of the defined comparison principle.

Note that we neglect the choice of the value u^{n+1}_J which must be given within an algorithm. For our purpose, the index J can be considered as the minimum index in the index set $\mathbf{I}$ if $\mathbf{I}$ is not empty.

Case: $\mathbf{I} = \mathbf{I_0} = \emptyset$. The validity of the assertion is trivial for $\mathbf{I_0} = \emptyset$ since v^n is equal to w^n in that case.

Case: $\mathbf{I} \neq \emptyset$. As already indicated, the proof is done by induction.

Beginning of the induction (induction level 1): $\sharp\mathbf{I_1} = 1$ (*i.e.,* $\mathbf{I} = \mathbf{I_1}$).

Let $k =: J$ be the index in the arbitrarily chosen but fixed index set $\mathbf{I_1}$. By definition, this is equivalent to

$$v^n_J > w^n_J \quad \text{and} \quad v^n_i = w^n_i \;\forall\, i > J.$$

The indices i' with $i' < J$ are not important since we discuss nonstrictly growing monotone fluxes, i.e., any signal will be transported from left to right and

$$v^{n+1}_{i'} = v^n_{i'} \equiv w^n_{i'} \quad \forall\, i' < J$$

will hold for all considered time level indices n, $n+1$. We prove the comparison principle sought here by induction over the indices $\tilde{i} \geq J$.

Beginning of the induction (induction level 2*):* $\tilde{i} = J$.

By the properties of $\mathcal{F}$ worked out above, we have

$$v^{n+1}_J = \mathcal{F}^{-1}\left[v^n_J + \lambda f\left(v^{n+1}_{J-1}\right)\right]$$

$$\begin{aligned}
&\geq \mathcal{F}^{-1}\left[w_J^n + \lambda f\left(v_{J-1}^{n+1}\right)\right] \\
&= \mathcal{F}^{-1}\left[w_J^n + \lambda f\left(w_{J-1}^{n+1}\right)\right] \\
&= w_J^{n+1}.
\end{aligned}$$

Assumption of the induction (induction level 2*): For all indices* $\tilde{i} \geq J$ *but* $\tilde{i} \leq \bar{i}$ *it holds* $v_{\tilde{i}}^{n+1} \geq w_{\tilde{i}}^{n+1}$.
Induction step (induction level 2*):* $\bar{i} \mapsto \bar{i} + 1$.
Let us consider the situation at the index $\bar{i} + 1$. As before, we employ the properties of G to obtain

$$\begin{aligned}
v_{\bar{i}+1}^{n+1} &= \mathcal{F}^{-1}\left[v_{\bar{i}+1}^n + \lambda f\left(v_{\bar{i}}^{n+1}\right)\right] \\
&= \mathcal{F}^{-1}\left[w_{\bar{i}+1}^n + \lambda f\left(v_{\bar{i}}^{n+1}\right)\right] \\
&\geq \mathcal{F}^{-1}\left[w_{\bar{i}+1}^n + \lambda f\left(w_{\bar{i}}^{n+1}\right)\right] \\
&= w_{\bar{i}+1}^{n+1}.
\end{aligned}$$

This proves the assertion of the beginning of the induction over $\mathbf{I}$.
Assumption (induction level 1*):*
Consider $\sharp\mathbf{I_m} = m$ with $m > 1$, $m \in \mathbf{N}$ (i.e., $\mathbf{I} = \mathbf{I_m}$). Let the upwind scheme under consideration be monotone with respect to the proceeding for all subsets of $\mathbf{I_m}$, i.e., it holds $v^{n+1} \geq w^{n+1}$ for perturbations $v_i^n > w_i^n$, $i \in \tilde{\mathbf{I}}$, for any arbitrarily chosen but fixed subset $\tilde{\mathbf{I}}$ of $\mathbf{I_m}$.
Induction step (induction level 1*):* $m \mapsto m + 1$.
Now, $\sharp\mathbf{I_{m+1}} = m + 1$ is considered. For the following proceeding, it is useful to have in mind that the construction of the induction step has to be well defined, i.e., the proceeding does not rely on any specific choice of indices.

We first choose (in a well-defined fashion) two indices m_1, m_2 useful for the procedure.

Let $\mathbf{I_m} \subset \mathbf{I_{m+1}}$ hold without limitation of generality. Let m_1 be an arbitrary but fixed index with

$$m_1 \ \in \ \left[\mathbf{I_m} \subset \mathbf{I_{m+1}}\right].$$

Moreover, let m_2 be the index by which

$$m_2 \ \in \ \left[\mathbf{I_{m+1}} \setminus \mathbf{I_m}\right]$$

holds. In other words, m_1 is an index in both $\mathbf{I_m}$ and $\mathbf{I_{m+1}}$, while m_2 corresponds exactly to the difference between the given index set $\mathbf{I_m}$ and the new index set $\mathbf{I_{m+1}}$.

By the assumption of the induction, the implicit upwind scheme is monotone with respect to positive changes in values corresponding to the index set $\mathbf{I_m}$. This means in particular that a positive change in $v_{m_1}^n$ together with positive changes in other values v_k^n, $k \in \mathbf{I_m} \setminus \{m_1\}$, leads to nonnegative changes in the sequence v^{n+1}.

In order to undertake the induction step, we have to consider now the effect of the additional nonnegative perturbation in the index m_2.

Thus, simultaneous positive changes in $v_{m_1}^n$ and $v_{m_2}^n$ are considered while in the background there are arbitrary but fixed positive changes in the values corresponding to

$$\bar{\mathbf{I}}_{\mathbf{m}} \ := \ \mathbf{I_{m+1}} \setminus \{m_1, m_2\} \quad \subset \quad \mathbf{I_m}$$

due to the assumption of the induction.

Let us briefly consider the effects of the latter positive perturbations in the values corresponding to $\bar{\mathbf{I}}_{\mathbf{m}}$. We recall that by the assumption of the induction, the application of the upwind scheme has the effect that the comparison principle $v^{n+1} \geq w^{n+1}$ holds for positive changes in v_k^n, $k \in \bar{\mathbf{I}}_{\mathbf{m}}$. Let us fix these influences by denoting the data computed by positive perturbations in v_k^n, $k \in \bar{\mathbf{I}}_{\mathbf{m}}$, by $\bar{v}^{n+1}$. Having defined this notion, we know that $\bar{v}^{n+1} \geq w^{n+1}$ holds by the assumption of the induction step because of $\bar{\mathbf{I}}_{\mathbf{m}} \subset \mathbf{I}_{\mathbf{m}}$. Furthermore, we have achieved that $\bar{v}^{n+1}$ denotes the state before taking into account further changes caused by nonnegative perturbations in $v_{m_1}^n$ and $v_{m_2}^n$.

We now focus our attention especially on the indices m_1 and m_2 defined above. Let Δ_j^1 be a change in $\bar{v}_j^{n+1}$ induced by a positive change in $v_{m_1}^n$. Then Δ_j^1 is always nonnegative by the assumption of the induction since $m_1 \in \mathbf{I}_{\mathbf{m}}$. Analogously, let Δ_j^2 be a change in $\bar{v}_j^{n+1}$ induced by a positive change in $v_{m_2}^n$. The change Δ_j^2 is also nonnegative because of the assumed validity of condition (2.6) and application of the procedure within the level two induction.

Thus, the single effects of separately considered nonnegative perturbations at m_1 and m_2 are nonnegative. Now, for the mutual effects of such changes in data corresponding to an arbitrary but fixed index i, $i \notin \{m_1, m_2\}$, there are only two possibilities because of $m_1 \neq m_2$:

1. $m_1 > m_2$:
   We set $J := m_2$. The procedure within the level two induction especially reveals $v_{m_1-1}^{n+1} \geq w_{m_1-1}^{n+1}$, thus we obtain the estimate $v_{m_1}^{n+1} \geq w_{m_1}^{n+1}$ in the same fashion as in (2.7). Then the assertion follows by the same type of induction as in the level two induction over $\mathbf{I}$.
2. $m_2 > m_1$:
   We set $J := m_1$. The assertion follows analogously to the case $m_1 > m_2$.

Thus, the mutual effects cannot result in a different situation as investigated up to now. Note the arbitrary choice of m_1 and m_2 together with simultaneous changes in the data corresponding to the index set $\bar{\mathbf{I}}_{\mathbf{m}}$. Since there are no limitations concerning the choice of the index set $\mathbf{I}_{\mathbf{m}}$, the proceeding as a whole is well defined and so the proof is finished. □

By the monotonicity of the implicit upwind method, one can easily derive the following stability statement. This is not the nonlinear stability we seek, but it is needed as a technical assertion in the convergence proof.

Theorem 2.2 (L_∞-stability). *Let the flux f be a nonstrictly growing monotone function. Then the numerical solution obtained by the implicit upwind scheme* (2.1) *satisfies*

$$||u^n||_{L_\infty} \quad \leq \quad ||u_0||_{L_\infty}.$$

Proof. Let a sequence $u^n \in L_\infty$ be given. With $a_k := \inf_{j\in\mathbf{Z}}(u_j^k)$ and $b_k := \sup_{j\in\mathbf{Z}}(u_j^k)$ we define sequences a^n, a^{n+1} and b^n, b^{n+1} by $a_j^k := a_k$ and $b_j^k := b_k$ for all $j \in \mathbf{Z}$. Since the method is conservative,

$$a_{n+1} \;=\; u_j^n - \lambda\left\{g(a_{n+1}, a_{n+1}) - g(a_{n+1}, a_{n+1})\right\} \;\geq\; a_n \tag{2.8}$$

$$\text{and} \quad b_{n+1} \;=\; u_j^n - \lambda\left\{g(b_{n+1}, b_{n+1}) - g(b_{n+1}, b_{n+1})\right\} \;\leq\; b_n \tag{2.9}$$

holds for the sequences a^{n+1} and b^{n+1}, respectively. Consequently, by the monotonicity of the method established in Theorem 2.1 follows $(b^n \geq u^n) \Rightarrow \left(b^{n+1} \geq u^{n+1}\right)$ and

$(u^n \geq a^n) \Rightarrow \left(u^{n+1} \geq a^{n+1}\right)$ which implies the L_∞-stability of the method by (2.8) and (2.9). □

Note that the proof given above is valid for general monotone 3-point schemes.

Concerning convergence of the scheme (2.1) to the entropy solution, the following definition is useful.

Definition 2.4 (entropy consistency). *The implicit upwind scheme* (2.1) *is consistent with the entropy condition of Kružkov if there exists a continuous numerical entropy flux G which satisfies for all $l \in \mathbf{R}$ the following assertions:*

1. *Consistency with the entropy flux of Kružkov*

$$G(v;l) = sgn(v-l)\,[f(v)-f(l)]\ \ \forall v. \tag{2.10}$$

2. *Validity of a discrete entropy inequality*

$$\frac{U(u_j^{n+1};l)-U(u_j^n;l)}{\Delta t} \leq -\frac{G(u_j^{n+1};l)-G(u_{j-1}^{n+1};l)}{\Delta x}, \tag{2.11}$$

where $U(v;l) = |v-l|$ is chosen due to Kružkov.

For the sake of brevity, let

$$a \vee b := \max(a,b) \quad \text{and} \quad a \wedge b := \min(a,b) \tag{2.12}$$

hold. The important connection between the numerical entropy flux G and the numerical flux function g of the scheme (2.1) can now be established.

Lemma 2.1. *Consider the implicit upwind scheme* (2.1) *and nonstrictly growing monotone fluxes. Then the numerical entropy flux defined by*

$$G(v;l) \ := \ g(v \vee l) - g(v \wedge l) \tag{2.13}$$

is consistent with the entropy flux of Kružkov.

Proof. By use of g as in (2.3) we immediately obtain

$$G(v;l) = f(v \vee l) - f(v \wedge l) = sgn(v-l)[f(v)-f(l)]$$

by use of (2.12) for all $l \in \mathbf{R}$. □

Now follow one of the main assertions described in this paper. The proceeding within the proof is a variation of a procedure employed by Crandall and Majda [4].

Theorem 2.3. *Consider the implicit upwind scheme* (2.1) *which is consistent, conservative, and monotone for nonstrictly growing monotone fluxes. Then the scheme is also consistent with the entropy condition of Kružkov.*

Proof. By Lemma 2.1 a numerical entropy flux can be associated with the considered scheme. Thus, the consistency with the entropy flux of Kružkov is given. It remains to show the validity of a discrete entropy inequality in the sense of (2.11). Therefore, let $l \in \mathbf{R}$ be chosen arbitrarily but fixed. Using (2.12), one can derive

$$\begin{aligned} -\lambda\left\{G(u_j^{n+1};l) - G(u_{j-1}^{n+1};l)\right\} = \\ H\left(u_{j-1}^{n+1} \vee l, u_j^{n+1} \vee l; u_j^n \vee l\right) \\ -H\left(u_{j-1}^{n+1} \wedge l, u_j^{n+1} \wedge l; u_j^n \wedge l\right) - \left|u_j^n - l\right|. \end{aligned} \tag{2.14}$$

We now show the validity of

$$H\left(u_{j-1}^{n+1} \vee l, u_j^{n+1} \vee l; u_j^n \vee l\right) \ \geq \ u_j^{n+1} \vee l \tag{2.15}$$

and

$$H(u_{j-1}^{n+1} \wedge l, u_j^{n+1} \wedge l; u_j^n \wedge l) \ \leq \ u_j^{n+1} \wedge l. \tag{2.16}$$

As we will see, these relations follow straightforwardly by diversion of the cases $u_j^{n+1} \geq l$ and $u_j^{n+1} < l$ using the monotonicity conditions (2.5) and (2.6).
For the validation of (2.15) we compute the following cases.
Case $u_j^{n+1} \geq l$,

$$\begin{aligned}
&H\left(u_{j-1}^{n+1} \vee l, u_j^{n+1} \vee l; u_j^n \vee l\right) \\
&\overset{case}{=} H\left(u_{j-1}^{n+1} \vee l, u_j^{n+1}; u_j^n \vee l\right) \\
&\overset{(2.5)}{\geq} H\left(u_{j-1}^{n+1}, u_j^{n+1}; u_j^n \vee l\right) \\
&\overset{(2.6)}{\geq} H\left(u_{j-1}^{n+1}, u_j^{n+1}; u_j^n\right) \\
&= \ u_j^{n+1} \\
&\overset{case}{=} u_j^{n+1} \vee l, \text{ and}
\end{aligned}$$

Case $u_j^{n+1} < l$,

$$\begin{aligned}
&H\left(u_{j-1}^{n+1} \vee l, u_j^{n+1} \vee l; u_j^n \vee l\right) \\
&\overset{case}{=} H\left(u_{j-1}^{n+1} \vee l, l; u_j^n \vee l\right) \\
&\overset{(2.5)}{\geq} H\left(l, l; u_j^n \vee l\right) \\
&\overset{(2.6)}{\geq} H\left(l, l; l\right) \\
&= \ l \\
&\overset{case}{=} u_j^{n+1} \vee l.
\end{aligned}$$

Analogously, we compute for the validation of (2.16).
Case $u_j^{n+1} \geq l$,

$$\begin{aligned}
&H\left(u_{j-1}^{n+1} \wedge l, u_j^{n+1} \wedge l; u_j^n \wedge l\right) \\
&\overset{case}{=} H\left(u_{j-1}^{n+1} \wedge l, l; u_j^n \wedge l\right) \\
&\overset{(2.5)}{\leq} H\left(l, l; u_j^n \wedge l\right) \\
&\overset{(2.6)}{\leq} H\left(l, l; l\right) \\
&= \ l \\
&\overset{case}{=} u_j^{n+1} \wedge l, \text{ and}
\end{aligned}$$

Case $u_j^{n+1} < l$,

$$\begin{aligned}
&H\left(u_{j-1}^{n+1} \wedge l, u_j^{n+1} \wedge l; u_j^n \wedge l\right) \\
&\overset{case}{=} H\left(u_{j-1}^{n+1} \wedge l, u_j^{n+1}; u_j^n \wedge l\right) \\
&\overset{(2.5)}{\leq} H\left(u_{j-1}^{n+1}, u_j^{n+1}; u_j^n \wedge l\right)
\end{aligned}$$

$$\begin{aligned} &\overset{(2.6)}{\leq} H\left(u_{j-1}^{n+1}, u_j^{n+1}; u_j^n\right) \\ &= u_j^{n+1} \\ &\overset{case}{=} u_j^{n+1} \wedge l. \end{aligned}$$

Using $|a-b| = a \vee b - a \wedge b$, one can easily derive from (2.14) via the estimates (2.15) and (2.16) the desired discrete entropy inequality. $\square$

2.2. Convergence. We now give the convergence proof for the method (2.1) under the usual assumption of nonstrictly growing monotone fluxes.

Since the proof relies on the theorem of monotone convergence of Beppo Levi which is not common in the conservation laws literature, we first state it for convenience.

THEOREM 2.4 (Beppo Levi). *Let $h_k : \mathbf{R} \to \mathbf{R}$, $k \in \mathbf{N}$, be a sequence of integrable functions with $h_k \leq h_{k+1}$ (in the sense of pointwise comparison a.e.) for all $k \in \mathbf{N}$. If*

$$\lim_{k\to\infty} \int h_k(x)\,dx =: C < \infty$$

holds, then the function

$$h := \lim_{k\to\infty} h_k$$

is integrable and it holds

$$\int h(x)\,dx = \lim_{k\to\infty} \int h_k(x)\,dx.$$

The basic idea behind the convergence proof is the following: corresponding to a sequence $\Delta x_k \downarrow 0$, we construct a monotonously growing sequence of initial data. Then, by the monotonicity of the method, we obtain a monotonously growing sequence of numerical solutions. Since we multiply the initial function u_0 with an arbitrarily chosen but fixed test function with compact support, we only have to consider u_0 over a compact domain. Because of the assumption $u_0 \in L_\infty$ and since we have L_∞-stability, the function sequence corresponding to the numerical solutions obtained in the limit $k \to \infty$ is integrable and bounded from above. Then we can use the theorem of monotone convergence of Beppo Levi to show convergence (almost everywhere) to a limit function. More formally, we state the following theorem.

THEOREM 2.5 (Convergence of the implicit upwind method). *Let $u_0(x)$ be in $L_\infty^{loc}(\mathbf{R})$. Let the flux function of a given conservation law grow in a nonstrictly monotone fashion and be at least continuous. Consider a sequence of nested grids indexed by $k = 1, 2, \ldots$, with mesh parameters $\Delta t_k, \Delta x_k \to 0$ as $k \to \infty$, and let $u_k(x,t)$ be the numerical approximation obtained via the implicit upwind scheme. Then u_k converges to the unique entropy solution of the given conservation law as $k \to \infty$.*

Proof. For brevity of the notation, we omit the arguments (x,t) when appropriate in the following within this proof.

The most important technical detail is the special discretization of the initial condition $u_0 \in L_\infty^{loc}(\mathbf{R})$. Therefore, we use nested grids in order to compare data sets of values; i.e., refined grids always inherit cell borders.

After a suitable manipulation of u_0 on a set of Lebesgue measure zero if necessary, the initial condition is discretized on cell j by

$$u_j^0 \ := \ \inf_{x \in (\Delta x_0 (j-1), j\Delta x_0]} u_0(x). \tag{2.17}$$

Corresponding to the initial data we also define a piecewise constant function

$$u_k(x,0) := u_j^0 \quad \text{for} \quad (j-1)\Delta x_k < x \leq j\Delta x_k. \tag{2.18}$$

It is a simple matter of classical analysis not described in this paper to verify that the discretization (2.17) together with (2.18) gives on any compact interval on the x-axis a monotonously growing function sequence with

$$\lim_{k\to\infty} u_k(x,0) \ = \ u_0(x) \text{ almost everywhere} \tag{2.19}$$

by application of the theorem of monotone convergence.

Similarly, we extract discrete test elements ϕ_j^0 out of a given test function $\phi \in C_0^\infty(\mathbf{R} \times \mathbf{R}_+)$, where $\phi \geq 0$ holds in a pointwise sense, by setting

$$\begin{aligned} \phi_j^0 \ &:= \ \phi(x_j, 0) \quad \text{and} \\ \phi_k(x,0) &= \phi_j^0 \quad \text{for} \quad x_j - \Delta x_k < x \leq x_j. \end{aligned} \tag{2.20}$$

Also, we define for $n \geq 1$ the step function

$$u_k(x,t) = u_j^n \quad \text{for} \quad x_j - \Delta x_k < x \leq x_j \quad \text{and} \quad t^{n-1} < t \leq t^n.$$

Analogously, the definition of the function $\phi_k(x,0)$ can be extended to arguments $t > 0$.

Let the test function ϕ be chosen arbitrarily but fixed. Multiplication of the discrete entropy condition (2.11) corresponding to the implicit upwind scheme (2.1) with $\Delta x_k \Delta t_k$ as well as with the discrete test element ϕ_j^{n+1}, summation over $j \in \mathbf{Z}$ and $n \geq 0$ and finally summation by parts yields

$$\begin{aligned} -\Delta x \sum_{j\in\mathbf{Z}} |u_j^0 - l|\phi_j^0 \ \leq \ \Delta x \Delta t \sum_{j\in\mathbf{Z}} \sum_{n\geq 0} \Bigg[& |u_j^n - l| \frac{\phi_j^{n+1} - \phi_j^n}{\Delta t} \\ & + sgn\left(u_j^{n+1} - l\right) \left[f(u_j^{n+1}) - f(l)\right] \frac{\phi_{j+1}^{n+1} - \phi_j^{n+1}}{\Delta x} \Bigg]. \end{aligned} \tag{2.21}$$

We now prove convergence of (2.21) towards the weak form of the entropy condition due to Kružkov,

$$\int_0^\infty \int_{-\infty}^\infty \Big[|u-l|\phi_t + sgn\,(u-l)\,[f(u) - f(l)]\,\phi_x \Big]\, dxdt \geq - \int_{-\infty}^\infty |u_0 - l|\phi_0 \, dx. \tag{2.22}$$

Therefore, we have to consider an arbitrarily chosen but fixed test element which consists of a 2-tupel (ϕ, l) composed of a test function ϕ with $\phi \geq 0$, $\phi \in C_0^\infty(\mathbf{R}\times\mathbf{R}_+)$, and a test number $l \in \mathbf{R}$.

By (2.18) and (2.20) as well as by the developed notions, the inequality (2.21) is equivalent to

$$\begin{aligned} - \int_{-\infty}^\infty |u_k(x,0) - l| \, \phi_k(x,0) \, dx \leq \int_0^\infty \int_{-\infty}^\infty \Big[& |u_k(x,t) - l| \phi_t' \\ & + sgn\,(u_k(x, t+\Delta t_k) - l)\, [f(u_k(x,t+\Delta t_k)) - f(l)]\, \phi_x' \Big]\, dxdt \end{aligned} \tag{2.23}$$

with

$$\phi'_t := \frac{\phi_k(x, t + \Delta t_k) - \phi_k(x,t)}{\Delta t_k} \tag{2.24}$$

and

$$\phi'_x := \frac{\phi_k(x + \Delta x_k, t + \Delta t_k) - \phi_k(x, t + \Delta t_k)}{\Delta x_k}. \tag{2.25}$$

We first investigate the left-hand side of (2.23). Therefore, let

$$\begin{aligned} &K_\phi := \mathit{support}(\phi) \cap \{(x,t) \,|\, t = 0\} \quad \text{and} \\ &K := \{x \,|\, \exists y \in K_\phi :\ y - \Delta x_0 \le x \le y + \Delta x_0\}. \end{aligned}$$

By construction, K is compact and gives the largest possible interval on the x-axis where nonzero discrete data may occur.

Adding zero, we now cast the problem in a first step into the form

$$\begin{aligned} &\int_K |u_k(x,0) - l| \phi_k(x,0)\,dx \\ &= \int_K |u_k(x,0) - l| \big[\phi_k(x,0) - \phi(x,0) + \phi(x,0)\big]\,dx \\ &= \underbrace{\int_K |u_k(x,0) - l| \big[\phi_k(x,0) - \phi(x,0)\big]\,dx}_{=:(a)} + \underbrace{\int_K |u_k(x,0) - l| \phi(x,0)\,dx}_{=:(b)}. \end{aligned} \tag{2.26}$$

We now discuss the value of (2.26)(a) in the limit $k \to \infty$. Because of $u_0 \in L^\infty(\mathbf{R})$ and since l is chosen arbitrarily but fixed (i.e., $l < \infty$), we can estimate the term $|u_k(x,0) - l|$ in (2.26)(a) by the help of a constant $M_{u,l} < \infty$ as

$$\left| \int_K |u_k(x,0) - l| \big[\phi_k(x,0) - \phi(x,0)\big]\,dx \right| \le M_{u,l} \int_K |\phi_k(x,0) - \phi(x,0)|\;dx. \tag{2.27}$$

Since ϕ is a smooth test function, it is a simple but technical exercise of classical analysis to prove

$$\sup_{x \in K} |\phi_k(x,0) - \phi(x,0)| \overset{k\to\infty}{\longrightarrow} 0;$$

i.e., $||\phi_k(x,0) - \phi(x,0)||_\infty \to 0$ for $k \to \infty$. Using this, we receive from (2.27)

$$M_{u,l} \int_K |\phi_k(x,0) - \phi(x,0)|\;dx \le M_{u,l}\,|K| \sup_{x \in K} |\phi_k(x,0) - \phi(x,0)|\,. \tag{2.28}$$

The estimations (2.27) and (2.28) imply that the Limes for $k \to \infty$ of the investigated term goes to zero. We now turn to (2.26)(b). It is useful to add zero again in order to obtain

$$\begin{aligned} &\int_K |u_k(x,0) - l| \phi(x,0)\,dx \\ &= \int_K \big|u_k(x,0) - u(x,0) + u(x,0) - l\big| \phi(x,0)\,dx \\ &\le \underbrace{\int_K |u(x,0) - l| \phi(x,0)\,dx}_{=:(b_1)} + \underbrace{\int_K |u_k(x,0) - u(x,0)| \phi(x,0)\,dx}_{=:(b_2)}. \end{aligned} \tag{2.29}$$

Our aim is to prove that (2.29)(b_2) vanishes in the limit for $k \to \infty$. Since ϕ is continuous, we can estimate the absolute of the term (2.29)(b_2) with the help of a constant $M_\phi < \infty$ by

$$\left| \int_K |u_k(x,0) - u(x,0)| \, \phi(x,0) \, dx \right| \le M_\phi \int_K |u_k(x,0) - u_0(x)| \, dx.$$

By our construction (2.17), (2.18), $u_k(x,0)$ approaches $u_0(x)$ from below; i.e.,

$$M_\phi \int_K |u_k(x,0) - u_0(x)| \, dx = M_\phi \int_K u_0(x) - u_k(x,0) \, dx \quad \forall k.$$

Using the theorem of monotone convergence, i.e., (2.19), implies that

$$\int_K u_0(x) - u_k(x,0) \, dx$$

vanishes in the limit for $k \to \infty$. Thus, the term (2.29)(b_2) goes to zero for $k \to \infty$. To condense these results, we get by the described procedure and use of the identity $u(x,0) \equiv u_0(x)$

$$\lim_{k\to\infty} \int_{\mathbf{R}} u_k(x,0)\phi_k(x,0) \, dx \le \int_{\mathbf{R}} u_0(x)\phi(x,0) \, dx,$$

i.e.,

$$-\lim_{k\to\infty} \int_{\mathbf{R}} u_k(x,0)\phi_k(x,0) \, dx \ge -\int_{\mathbf{R}} u_0(x)\phi(x,0) \, dx$$

which displays the appropriate order with respect to the underlying relation (2.21) and the sought inequality (2.22). By analogously defining a compact domain S including the support of ϕ in space and time and using the attributes of test functions, it remains to be shown that

$$\begin{aligned} &\int_S sgn\,(u_k(x,t+\Delta t_k) - l)\,\big[f(u(x,t)) - f(l)\big]\phi_x(x,t)\,dxdt \\ \text{(2.30)} \qquad &\overset{k\to\infty}{\longrightarrow} \int_S sgn\,(u(x,t) - l)\,\big[f(u(x,t)) - f(l)\big]\phi_x(x,t)\,dxdt \end{aligned}$$

as well as

$$\text{(2.31)} \qquad \int_S \big|u(x,t) - u_k(x,t)\big| \, |\phi_t(x,t)| \, dxdt \overset{k\to\infty}{\longrightarrow} 0$$

whereby (2.31) was obtained after adding zeros in a similar fashion as within the proceeding before.

Let us first discuss the latter expression (2.31). Since ϕ_t is continuous on S, we can estimate $|\phi_t|$ in (2.31) by a constant $M_t < \infty$.

Since we obtain in the limit $k \to \infty$ a monotonously growing sequence of numerical approximations in the sense of pointwise comparison and since it is bounded from above because of $u_0 \in L_\infty(S)$ and the monotonicity of the method, the function sequence $(u_k(x,t))_{k\in\mathbf{N}}$ converges almost everywhere to an integrable limit function on S by the theorem of monotone convergence due to Levi. We set

$$u(x,t) := \lim_{k\to\infty} u_k(x,t).$$

Introducing exactly this limit function as the function $u(x,t)$ used up to now, the expression on the left-hand side of (2.31) becomes zero in the limit

$$\lim_{k\to\infty}\int_S \big|u(x,t)-u_k(x,t)\big|\,|\phi_t(x,t)|\;dxdt \le M_t\int_S u(x,t)-\lim_{k\to\infty}u_k(x,t)\,dxdt=0.$$

Note that the pointwise convergence $u_k\to u$ almost everywhere is now established and can be used in the following.

By definition of the symbols "$\vee$" and "$\wedge$" from (2.12), it holds that

$$\begin{aligned}
&\lim_{k\to\infty}\Big|\int_S sgn\,(u_k(x,t+\Delta t_k)-l)\,\big[f(u_k(x,t+\Delta t_k))-f(l)\big]\phi_x(x,t)\,dxdt\\
&-sgn\,(u(x,t)-l)\,\big[f(u(x,t))-f(l)\big]\phi_x(x,t)\,dxdt\Big|\\
\le{}&\lim_{k\to\infty}\int_S\Big|\Big[sgn\,(u_k(x,t+\Delta t_k)-l)\,\big[f(u_k(x,t+\Delta t_k))-f(l)\big]\\
&-sgn\,(u(x,t)-l)\,\big[f(u(x,t))-f(l)\big]\Big]\phi_x(x,t)\Big|\,dxdt\\
={}&\lim_{k\to\infty}\int_S\Big|\Big[\big[f(u_k(x,t+\Delta t_k)\vee l)-f(u_k(x,t+\Delta t_k)\wedge l)\big]\\
&-\big[f(u(x,t)\vee l)-f(u(x,t)\wedge l)\big]\Big]\phi_x(x,t)\Big|\,dxdt.
\end{aligned}\tag{2.32}$$

By adding zero, we obtain equivalently to (2.32) the expression

$$\begin{aligned}
\lim_{k\to\infty}\int_S\Big|\Big[&\big[f(u_k(x,t+\Delta t_k)\vee l)-f(u_k(x,t)\vee l)\big]\\
&-\big[f(u_k(x,t+\Delta t_k)\wedge l)-f(u_k(x,t)\wedge l)\big]\\
&-\big[f(u(x,t)\vee l)-f(u_k(x,t)\vee l)\big]\\
&+\big[f(u(x,t)\wedge l)-f(u_k(x,t)\wedge l)\big]\Big]\phi_x(x,t)\Big|\,dxdt.
\end{aligned}\tag{2.33}$$

The latter expression (2.33) can be estimated from above using $|\phi_x(x,t)|<M_x<\infty$ by

$$M_x\lim_{k\to\infty}\int_S\big|f(u_k(x,t+\Delta t_k)\vee l)-f(u_k(x,t)\vee l)\big|\,dxdt \tag{2.34}$$

$$+M_x\lim_{k\to\infty}\int_S\big|f(u_k(x,t+\Delta t_k)\wedge l)-f(u_k(x,t)\wedge l)\big|\,dxdt \tag{2.35}$$

$$+M_x\lim_{k\to\infty}\int_S\big|f(u(x,t)\vee l)-f(u_k(x,t)\vee l)\big|\,dxdt \tag{2.36}$$

$$+M_x\lim_{k\to\infty}\int_S\big|f(u(x,t)\wedge l)-f(u_k(x,t)\wedge l)\big|\,dxdt. \tag{2.37}$$

Let us discuss now the terms (2.34)–(2.37). The terms denoted via (2.34) and (2.35) vanish because of the continuity in the mean of the combined function $f\circ u_k$. Because of Theorem 2.2 it holds that $u_k\in L_\infty$, and since we have chosen an arbitrary but fixed test number l ($<\infty$), we can find finite estimates from above for the integrands in (2.36) and (2.37). Thus, these terms vanish when using the established pointwise convergence $u_k\to u$ almost everywhere and the theorem of Lebesgue. Thus, convergence to the entropy solution is shown. $\square$

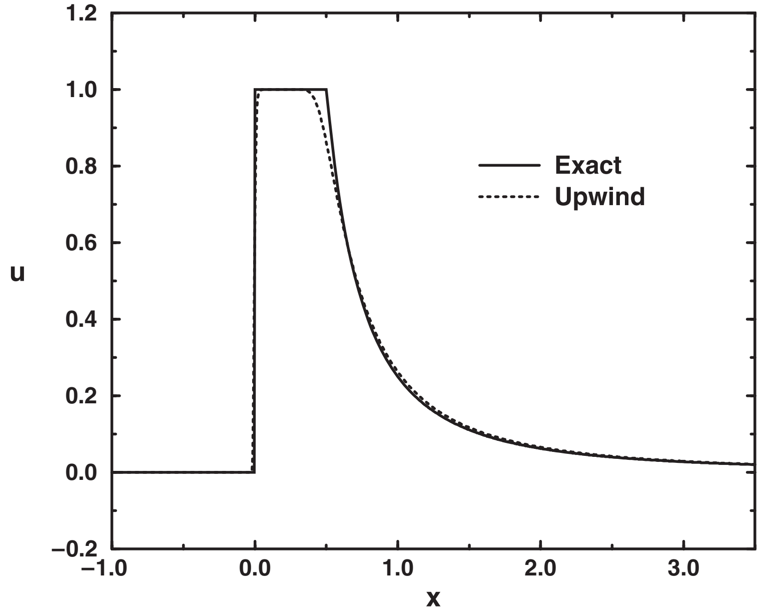

Fig. 3.1. *Numerical solution of the described example due to Kružkov, obtained by the implicit upwind method.*

3. Numerical tests.

In order to show the usefulness of the developed notions, we investigate the truly nonstandard conservation law developed by Kružkov and Panov [12] we already mentioned in the introduction, i.e., we investigate exactly the example given by (1.1), (1.2), and (1.3). For the numerical solution we use a grid of 1000 points with $\Delta x = 0.005$ and a time step size of $\Delta t = 0.00075$. We set $\alpha = 0.5$ within the flux function described above.

The solution obtained by the use of the implicit upwind scheme is displayed in Figure 3.1. The ansatz of the rarefaction wave is a bit smeared which can be explained by the monotonicity property and the employed relatively coarse grid.

4. Conclusive remarks.

We have described the fundament of a theory of implicit methods for conservation laws, extending the rigorously verified range of applicability of numerical methods. The scheme we focused our attention on is the upwind scheme, the monotonicity property of other implicit methods is the subject of a forthcoming paper.

Acknowledgements. The author is very thankful for the constructive comments of the referees which helped to improve the paper. He would also like to express his gratitude to Professor Rainer Ansorge from the University of Hamburg.

ON THE CONVERGENCE OF A GENERAL CLASS OF FINITE VOLUME METHODS*

HOLGER WENDLAND†

Abstract. In this paper we investigate numerical methods for solving hyperbolic conservation laws based on finite volumes and optimal recovery. These methods can, for example, be applied in certain ENO schemes. Their approximation properties depend in particular on the reconstruction from cell averages. Hence, this paper is devoted to prove convergence results for such reconstruction processes from cell averages.

Key words. optimal recovery, finite volumes, positive definite kernels, approximation orders

AMS subject classifications. 65M20 65M15 41A30

DOI. 10.1137/040612993

1. Introduction. Finite volume methods are well-established tools for solving hyperbolic conservation laws of the form

$$\frac{\partial}{\partial t}u + \sum_{\ell=1}^{d} \frac{\partial}{\partial x_\ell} f_\ell(u) = 0 \tag{1.1}$$

numerically. Here, $u : \mathbb{R}^d \times [0, \infty) \to \mathbb{R}^n$ is the vector-valued solution containing the quantity to be conserved while $f_\ell : \mathbb{R}^n \to \mathbb{R}^n$ denote the so-called flux functions.

For discretizing in space, finite volume methods use cell average information. To be more precise, for a fixed time such cell averages are employed to reconstruct the unknown function u approximately. For a good reconstruction in regions where the solution of (1.1) is known or expected to be smooth, a higher order reconstruction scheme is desirable. Hence, such high order schemes currently form a major research direction in the theory of finite volumes.

The first higher order reconstruction schemes employed were based on polynomials and suffered from the typical behavior of multivariate polynomials, such as oscillation and ill-conditioning.

Sonar and Iske [4] and Sonar [9, 10, 11] proposed to employ optimal recovery based on conditionally positive definite kernels instead. Sonar's numerical examples indicate that these recovery processes indeed lead to higher order schemes. Nonetheless, up to now there has been no mathematical proof given for this observation. In [11], he concluded with "[...] nearly nothing is known about approximation orders in the case of recovery from cell average data. [...] At the moment, however, we are faced with the fact that important theoretical results are missing in this area of research."

It is the goal of this paper to fill this theoretical gap and to show that the recovery process can lead to arbitrary high orders, provided the target function u is sufficiently smooth and the correct (conditionally) positive definite kernel is employed.

However, since our analysis is based upon approximation properties of polynomials, our proof will need slightly larger *stencils* than those proposed by Sonar. On the

†Institut für Numerische und Angewandte Mathematik, Universität Göttingen, Lotzestr. 16-18, D-37083 Göttingen, Germany (wendland@math.uni-goettingen.de).

other hand, since the "correct" selection of stencils is still under investigation, our results might also contribute to this problem.

Moreover, the results we will achieve are not restricted to (conditionally) positive definite kernels at all. On the contrary, they will work for every interpolatory and stable reconstruction process. Finally, our results are established for an *arbitrary* space dimension.

This paper is organized as follows. In the rest of the section we will introduce some general notations we will need to state our convergence results. Section 2 is devoted to a short review on finite volume and ENO (essentially nonoscillatory) schemes. Section 3 describes how such schemes can be derived using optimal recovery. Sections 4 and 5 are the main sections where we provide our error analysis. In section 6 we take a special look at thin-plate spline approximation, which is one of the most popular reconstruction methods in this context. For numerical examples we refer the reader to the previously mentioned papers by Sonar.

We will establish our error estimates using a variety of Sobolev spaces, which we want to introduce now. Let $\Omega \subseteq \mathbb{R}^d$ be a domain. For $k \in \mathbb{N}_0$ and $1 \le p < \infty$, we define the Sobolev spaces $W_p^k(\Omega)$ to consist of all u with distributional derivatives $D^\alpha u \in L_p(\Omega)$, $|\alpha| \le k$. Associated with these spaces are the (semi-)norms

$$|u|_{W_p^k(\Omega)} = \left(\sum_{|\alpha|=k} \|D^\alpha u\|_{L_p(\Omega)}^p \right)^{1/p} \text{ and } \|u\|_{W_p^k(\Omega)} = \left(\sum_{|\alpha|\le k} \|D^\alpha u\|_{L_p(\Omega)}^p \right)^{1/p}.$$

The case $p = \infty$ is defined in the following obvious way:

$$|u|_{W_p^k(\Omega)} = \sup_{|\alpha|=k} \|D^\alpha u\|_{L_\infty(\Omega)} \text{ and } \quad \|u\|_{W_\infty^k(\Omega)} = \sup_{|\alpha|\le k} \|D^\alpha u\|_{L_\infty(\Omega)}.$$

We will also be dealing with fractional order Sobolev spaces. Let $1 \le p < \infty$, $k \in \mathbb{N}_0$, and $0 < s < 1$. We define the fractional order Sobolev spaces $W_p^{k+s}(\Omega)$ to be all u for which the following (semi-)norms are finite:

$$|u|_{W_p^{k+s}(\Omega)} := \left(\sum_{|\alpha|=k} \int_\Omega \int_\Omega \frac{|D^\alpha u(x) - D^\alpha u(y)|^p}{\|x-y\|_2^{d+ps}} dxdy \right)^{1/p},$$
$$\|u\|_{W_p^{k+s}(\Omega)} := \left(\|u\|_{W_p^k(\Omega)}^p + |u|_{W_p^{k+s}(\Omega)}^p \right)^{1/p}.$$

2. Finite volume and ENO schemes.

Finite volume schemes introduce weak solutions to (1.1) in the following sense. If $V \subseteq \mathbb{R}^d$ is an arbitrary compact, small region, called the *control volume*, then u has to satisfy the weak form of the conservation law (1.1) in the form

$$\frac{d}{dt} \int_V u(x,t)dx = -\int_{\partial V} \sum_{\ell=1}^d f_\ell(u(x,t))\eta_\ell(x)dS, \tag{2.1}$$

where $\eta(x)$ denotes the outer normal vector to the boundary ∂V. This form of (1.1) often directly results from the physical conservation law and is then in a certain sense even more natural than (1.1).

To convert (2.1) into a numerical procedure, the region $\Omega \subseteq \mathbb{R}^d$ of interest is subdivided into nonoverlapping subregions $\mathcal{T}_h = \{V_j\}$, i.e.,

$$\Omega = \bigcup_{j=1}^{N} V_j,$$

where the V_j are simplices having size $\mathcal{O}(h)$. Then, (2.1) can obviously be rewritten using the *cell averages*

$$\lambda_j(u)(t) := \overline{u}_j(t) = \frac{1}{|V_j|}\int_{V_j} u(x,t)dx, \qquad 1 \leq j \leq N.$$

Moreover, if $\mathcal{N}_j$ denotes the set of the neighboring simplices to the simplex $V_j \in \mathcal{T}_h$, we have

$$\frac{d}{dt}\lambda_j(u)(t) = -\frac{1}{|V_j|}\sum_{V\in\mathcal{N}_j}\int_{\partial V\cap\partial V_j}\sum_{\ell=1}^{d} f_\ell(u)\eta_\ell^{(V)}dS,$$

where $\eta^{(V)}$ denotes the outer unit normal vector to the boundary face $\partial V \cap \partial V_j$ of V.

If the flux is replaced by a numerical flux function or an approximate Riemann solver $H : \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^d \to \mathbb{R}^n$, satisfying

$$H(u,u;\eta) = \sum_{\ell=1}^{d} f_\ell(u)\eta_\ell,$$

and if the integration on the boundary hyperplane $\partial V \cap \partial V_j$ is replaced by a quadrature rule having weights w_ν and points $x_\nu(V)$, $1 \leq \nu \leq n_Q$, we derive

$$\frac{d}{dt}\lambda_j(u)(t) = -\frac{1}{|V_j|}\sum_{V\in\mathcal{N}_j}\sum_{\nu=1}^{n_Q} w_\nu H(u(x_\nu(V),t), u(x_\nu(V),t); \eta_\ell^{(V)}) + \mathcal{O}(h^{m_Q}),$$

where m_Q denotes the order of the employed quadrature rule.

Replacing the unknown values $u(x_\nu(V),t)$ simply by the cell averages spoils the approximation order and leads only to a first order scheme. However, if these values are replaced by a more accurate reconstruction $s_u(x_\nu(V),t)$, which satisfies

$$\lambda_j(s_u)(t) = \lambda_j(u)(t), \qquad 1 \leq j \leq N, \tag{2.2}$$

$$\|u - s_u\|_{L_\infty(\Omega)} = \mathcal{O}(h^p), \qquad h \to 0, \tag{2.3}$$

for all sufficiently smooth functions u, then we get for smooth f_ℓ via

$$\begin{aligned}\|H(u,u;n) - H(s_u,s_u;n)\|_2 &\leq \sum_{\ell=1}^{d}\|[f_\ell(u) - f_\ell(s_u)]\eta_\ell\|_2 \leq \sum_{\ell=1}^{d}\|[f_\ell(u) - f_\ell(s_u)]\|_2\\ &\leq C_f\|u - s_u\|_2\end{aligned}$$

finally,

$$\frac{d}{dt}\lambda_j(u)(t) = -\frac{1}{|V_j|}\sum_{V\in\mathcal{N}_j}\sum_{\nu=1}^{n_Q} w_\nu H(s_u(x_\nu(V),t), s_u(x_\nu(V),t); \eta_\ell^{(V)}) + \mathcal{O}(h^{\min\{p,m_Q\}}).$$

Hence, it is crucial to have reconstruction processes satisfying (2.2) and (2.3). In the next section, we will describe one possibility, which is based upon optimal recovery. However, the error estimate (2.3) is actually intrinsic to the reconstruction requirements (2.2), at least if the reconstruction process is stable in a sense which we will soon make precise. This is a consequence of the following result, which we will prove in this paper.

THEOREM 2.1. *Let k be a positive integer, $0 < s \le 1, 1 \le p < \infty, 1 \le q \le \infty$ and let α be a multi-index satisfying $k > |\alpha| + d/p$ or, for $p = 1, k \ge |\alpha| + d$. Let Ω be a bounded set satisfying an interior cone condition. Suppose Ω is decomposed into finitely many, nonoverlapping subdomains V_j such that every ball $B \subseteq \Omega$ with radius h contains at least one subdomain V_j. If the function $u \in W_p^{k+s}(\Omega)$ satisfies $\lambda_j(u) = 0$, $1 \le j \le N$, then*

$$|u|_{W_q^{|\alpha|}(\Omega)} \le ch^{k+s-|\alpha|-d(1/p-1/q)_+}|u|_{W_p^{k+s}(\Omega)},$$

where c is a constant independent of u and h, and $(x)_+ = \max\{x, 0\}$.

The condition that every ball $B \subseteq \Omega$ of radius h contains at least one volume V_j is automatically satisfied if the volumes form a uniform decomposition of Ω consisting of volumes of size h.

From this theorem we can conclude that any reconstruction process in the sense of (2.2) immediately satisfies

$$\|u - s_u\|_{L_\infty(\Omega)} \le Ch^{k+s-d/p}|u - s_u|_{W_p^{k+s}(\Omega)},$$

so that the stability assumption on the reconstruction process has to be something like

$$|u - s_u|_{W_p^{k+s}(\Omega)} \le C|u|_{W_p^{k+s}(\Omega)}. \tag{2.4}$$

Of course, the (semi-)norm on the right-hand side might be replaced by a norm or a stronger (semi-)norm; (2.2) and (2.4) together now yield the approximation error (2.3).

However, in most applications it is not reasonable to build a reconstruction using *all* cell averages. Instead, for each cell a local reconstruction is computed using all the cell averages of cells in a neighborhood of the current cell. Moreover, to avoid unwanted oscillations, the ENO approach chooses for each cell V_j different sets of neighboring volumes, which are usually called *stencils*, computes for all theses sets a local reconstruction and then chooses the reconstruction, where the oscillation of the solution is least.

3. Optimal recovery. In this section we shortly review the idea of using optimal recovery to solve the reconstruction problem (2.2). It has initially been introduced by Sonar in [9]. It is based upon (conditionally) positive definite functions and has the advantage of satisfying a stability condition such as (2.4) automatically. For simplicity, we will from now on suppress the time variable and restrict ourselves to functions $u : \mathbb{R}^d \to \mathbb{R}$, i.e., we assume $n = 1$.

In what follows, we will denote the space of d-variate polynomials of degree less than or equal to m by $\pi_m(\mathbb{R}^d)$.

DEFINITION 3.1. *A function $\Phi : \mathbb{R}^d \to \mathbb{R}$ is said to be conditionally positive definite of order m, if for all $N \in \mathbb{N}_0$, all sets $X = \{x_1 \ldots, x_N\}$ of pairwise distinct* *points, and all $\alpha \in \mathbb{R}^N \setminus \{0\}$ satisfying $\sum_{j=1}^N \alpha_j p(x_j) = 0$ for all $p \in \pi_{m-1}(\mathbb{R}^d)$, it is satisfied that*

$$\sum_{i,j=1}^N \alpha_i \alpha_j \Phi(x_i - x_j) > 0.$$

A function that is conditionally positive definite of order $m = 0$, where no constraints on α are imposed, is called positive definite.

A positive definite function Φ gives rise to a *reproducing kernel Hilbert space* $\mathcal{H} = \mathcal{H}_\Phi$, for which Φ is the reproducing kernel. In case of a conditionally positive definite function this remains true modulo $\pi_{m-1}(\mathbb{R}^d)$, which is the null space of the semi-inner product defined by Φ. In this context, this space is also called the *native space* associated to Φ.

Now suppose we are given functionals $\mu_1, \ldots, \mu_N$, which are continuous and linearly independent over $\mathcal{H}$ (modulo $\pi_{m-1}(\mathbb{R}^d)$.) Suppose further these functionals are $\pi_{m-1}(\mathbb{R}^d)$-unisolvent meaning that $p = 0$ is the only polynomial from $\pi_{m-1}(\mathbb{R}^d)$ with $\mu_j(p) = 0$ for all $1 \leq j \leq N$. Then, there exists exactly one function of the form

$$s_u(x) = \sum_{j=1}^N \alpha_j \mu_j^y \Phi(x - y) + p(x),$$

where $p \in \pi_{m-1}(\mathbb{R}^d)$ and μ_j^y means acting with respect to the variable y, which satisfies the interpolation conditions

$$\mu_j(s_u) = \mu_j(u), \qquad 1 \leq j \leq N,$$

together with

$$\sum_{j=1}^N \alpha_j \mu_j(q) = 0, \qquad q \in \pi_{m-1}(\mathbb{R}^d).$$

Moreover, the solution s_u satisfies the stability estimates

$$\|s_u\|_{\mathcal{H}} \leq \|u\|_{\mathcal{H}}, \qquad \|u - s_u\|_{\mathcal{H}} \leq \|u\|_{\mathcal{H}},$$

and the latter leads to (2.4), if $\mathcal{H}$ is either a Sobolev or a Beppo–Levi space. Examples for (conditionally) positive definite functions are the compactly supported functions, constructed and investigated in [12, 13] by this author, for Sobolev spaces, and the thin-plate or surface splines, investigated in [2] by Duchon, for Beppo–Levi spaces. We will come back to these examples later on.

For more details on optimal recovery and scattered data approximation, we refer the reader to the recent book [14].

4. Local estimates. Let us describe the main idea for proving Theorem 2.1. Our analysis is based upon the following approach. First of all, we consider u only on small subregions Ω_ℓ of Ω and derive estimates in terms of the diameter of Ω_ℓ. These subregions can, for example, be the stencils of the ENO schemes previously described. For our matters, it is only important that Ω_ℓ itself is the union of some of the volumes V_j. If interested in estimates on all of Ω, we have to glue these local estimates together to retrieve our final error bound.

In accordance with Theorem 2.1 we assume that the smooth function u satisfies

$$\lambda_j(u) = \frac{1}{|V_j|}\int_{V_j} u(x)dx = 0, \qquad j \in \mathcal{M}_\ell,$$

where $\mathcal{M}_\ell$ contains all indices j with $V_j \subseteq \Omega_\ell$.

On the local domain Ω_ℓ we approximate u by a polynomial $P \in \pi_k(\mathbb{R}^d)$, i.e., we write

$$u = u - P + P.$$

If u is smooth, the term $u - P$ can locally be bounded in a sound way by using an averaged Taylor polynomial to u as P. To bound this specific P we have to study the action of the functionals λ_j on the space of polynomials $\pi_k(\mathbb{R}^d)$ of degree k. Suppose our functionals allow a reconstruction of the form

$$p(x) = \sum_{j\in\mathcal{M}_\ell} a_j(x)\lambda_j(p), \qquad x \in \Omega_\ell, p \in \pi_k(\mathbb{R}^d)$$

with certain numbers $a_j(x)$, $j \in \mathcal{M}_\ell$, having a uniformly bounded ℓ_1-norm. Then, using $\lambda_j(u) = 0$, we can derive

$$\begin{aligned}|p(x)| &\le \sum_{j\in\mathcal{M}_\ell} |a_j(x)||\lambda_j(p-u)| = \sum_{j\in\mathcal{M}_\ell} |a_j(x)|\frac{1}{|V_j|}\int_{V_j} |p(x) - u(x)|dx \\ &\le \|p-u\|_{L_\infty(\Omega_\ell)} \sum_{j\in\mathcal{M}_\ell} |a_j(x)|.\end{aligned}$$

Hence, we can control the norm of P again by the norm of $u - P$. Moreover, this shows that we first have to investigate polynomial approximation on local sets.

4.1. Polynomial approximation. To simplify notation in the rest of the section, we denote our current local set Ω_ℓ by $\mathcal{D}$ and assume that $\mathcal{M}_\ell = \{1, \dots, N\}$. This short section is meant to collect all necessary results on local polynomial approximation. It is based upon Brenner and Scott's book [1, Chapter 4] and on the recent article [7]. We start by introducing star-shaped regions.

DEFINITION 4.1. *A domain $\mathcal{D}$ is* star-shaped with respect to a ball $B(x_c, r) := \{x \in \mathbb{R}^d : \|x - x_c\|_2 < r\}$ *if for every $x \in \mathcal{D}$, the closed convex hull of $\{x\} \cup B$ is contained in $\mathcal{D}$.*

It should be apparent, that a bounded region which is star-shaped with respect to a ball automatically satisfies a uniform interior cone condition. To be more precise, the following result has been established in [7].

LEMMA 4.2. *If $\mathcal{D}$ is star-shaped with respect to a ball $B(x_c, r)$ and contained in a ball $B(x_c, R)$, then it satisfies an interior cone condition with radius r and angle $\theta = 2\arcsin\left(\frac{r}{2R}\right)$.*

Brenner and Scott [1, Chapter 4] discuss approximating a function $u \in W_p^k(\mathcal{D})$ by averaged Taylor polynomials $Q_k u \in \pi_{k-1}(\mathbb{R}^d)$. These results have been extended and generalized to the case of fractional Sobolev spaces by Narcowich et al. [7]. In this section, we briefly summarize these results.

The averaged Taylor polynomials are defined as follows. Let B_r be a ball relative to which $\mathcal{D}$ is star-shaped and having radius $r \ge \frac{1}{2}r_{max}$, where r_{max} is the largest radius of a ball relative to which $\mathcal{D}$ is star-shaped. The averaged Taylor polynomials are then given by

$$Q_k u(x) := \sum_{|\alpha|<k} \frac{1}{\alpha!} \int_{B_r} D^\alpha u(y)(x-y)^\alpha \phi(y)dy,$$

where ϕ is a nonnegative C^∞ "bump" function supported on B_r, satisfying both $\int_{B_r} \phi(y)dy = 1$ and $\max \phi \leq Cr^{-d}$, where $C = C_d$. The result we need is a generalization of [1, Proposition 4.3.2] and comes from [7]. It utilizes the *chunkiness parameter* γ of a star-shaped domain $\mathcal{D}$, which is defined to be $\gamma = \rho_{\mathcal{D}}/r_{max}$, where $\rho_{\mathcal{D}}$ is the diameter of $\mathcal{D}$.

LEMMA 4.3. *Let $0 < s \leq 1$. Assume that $1 < p < \infty$ and $k > |\alpha| + d/p$, or $p = 1$ and $k \geq |\alpha| + d$. Then, we have for $u \in W_p^{k+s}(\mathcal{D})$ the estimate*

$$\|D^\alpha u - D^\alpha Q_{k+1} u\|_{L_\infty(\mathcal{D})} \leq C_{k,d,p}(1+\gamma)^{d(1+1/p)} \rho_{\mathcal{D}}^{k+s-|\alpha|-d/p} |u|_{W_p^{k+s}(\mathcal{D})},$$

where $\rho_{\mathcal{D}}$ denotes the diameter of $\mathcal{D}$.

It is important to realize that the involved constant here depends on the domain $\mathcal{D}$ only via its chunkiness parameter γ.

4.2. Norming sets. To reconstruct polynomials from cell averages in a controlled way we employ *norming sets*. Norming sets have been introduced in the context of scattered data approximation on spheres [5]. The idea behind them can be described in a rather abstract setting; see [6, 14].

Let V be a finite dimensional vector space with norm $\|\cdot\|_V$ and let $Z \subseteq V^*$ be a finite set consisting of N functionals. Here, V^* denotes the dual space of V consisting of all linear and continuous functionals defined on V.

DEFINITION 4.4. *We will say that Z is a norming set for V if the mapping $T : V \to T(V) \subseteq \mathbb{R}^N$ defined by $T(v) = (z(v))_{z \in Z}$ is injective. We will call T the sampling operator.*

If Z is a norming set for V, the mapping $T : V \to T(V) \subseteq \mathbb{R}^{|Z|}$ is bijective and the norm of its inverse is given by

$$\|T^{-1}\| = \sup_{v \neq 0} \frac{\|v\|}{\|Tv\|}.$$

THEOREM 4.5. *Suppose V is a finite dimensional normed linear space and $Z = \{z_1, \dots, z_N\}$ is a norming set for V with T being the corresponding sampling operator. For every $\psi \in V^*$ there exists a vector $a \in \mathbb{R}^N$ depending only on ψ such that for every $v \in V$,*

$$\psi(v) = \sum_{j=1}^N a_j z_j(v),$$

and

$$\|a\|_{\mathbb{R}^{N*}} \leq \|\psi\|_{V^*} \|T^{-1}\|.$$

We can apply Theorem 4.5 to our situation by choosing $V = \pi_k(\mathbb{R}^d)$, $\psi = \delta_x$, or more generally $\psi = \delta_x \circ D^\alpha$ with $x \in \mathcal{D}$ and $T : \pi_k(\mathbb{R}^d) \to \mathbb{R}^N$ defined by $T(p) := (\lambda_1(p), \dots, \lambda_N(p))^T$, where λ_j denotes once again the cell average operator to the cell V_j. Thus, we have to find a bound on $\|T^{-1}\|$, which means we have to determine a constant $C > 0$ with

$$\|p\|_{L_\infty(\mathcal{D})} \le C\|T(p)\|_\infty, \qquad p \in \pi_k(\mathbb{R}^d). \tag{4.1}$$

Before providing such a result in general, let us have a look at two examples.

Example 4.6. In the first case we consider the case of linear polynomials in the univariate setting with equidistant points. Hence, our cell averages are given by

$$\lambda_j(u) = \frac{1}{h}\int_{jh}^{(j+1)h} u(x)dx.$$

Now, let our local $\mathcal{D}$ be $\mathcal{D} = [0, 2h]$. If $p \in \pi_1(\mathbb{R})$ satisfies $\|p\|_{L_\infty(\mathcal{D})} = 1$, then it obviously attains its absolute maximum either in 0 or in $2h$. In the first case (the other one is dealt with in the same way) p satisfies (without restriction) $p(0) = 1$ and $p'(0) \le 0$. Hence, we can express p as $p(x) = 1 - ax$ with $a \ge 0$ and for this p we find

$$|\lambda_1(p)| = \left|1 - \frac{1}{h}\int_0^h axdx\right| = \left|1 - a\frac{h}{2}\right| = 1 - a\frac{h}{2} \ge 1 - \frac{1}{2} = \frac{1}{2},$$

since we can conclude from $|p(2h)| \le 1$ that $|a| < 1/h$. Hence, we can choose the constant C in (4.1) as $C = 2$.

Example 4.7. Our second example deals still with linear polynomials but this time on $\mathbb{R}^2$. Again, we assume that our cells form an equidistant grid $h\mathbb{Z}^2$. Suppose our stencil consists of the four volumes $V_1 = [0,h]^2$, $V_2 = [h,2h]\times[0,h]$, $V_3 = [0,h]\times[h,2h]$, and $V_4 = [h,2h]^2$. Again, without restriction we can assume that $p \in \pi_1(\mathbb{R}^2)$ attains its maximum in $(0,0)$. Hence, we have $p(x,y) = 1 - ax - by$ with $a, b \ge 0$. A simple computation shows that

$$\lambda_1(p) = 1 - \frac{h}{2}(a+b), \quad \lambda_2(p) = \lambda_1(p) - ha, \quad \lambda_3(p) = \lambda_1(p) - hb.$$

Now if $|\lambda_1(p)| \le 1/3$, then we find $4/3 \le h(a+b) \le 8/3$ giving

$$-\frac{10}{3} \le \lambda_2(p) + \lambda_3(p) = 2\lambda_1(p) - h(a+b) \le -\frac{2}{3}.$$

Hence, if we have in addition $|\lambda_2(p)| \le 1/3$, we must have $|\lambda_3(p)| \ge 1/3$. Thus we can choose the constant C in (4.1) to be $C = 3$.

From the second example it should already be clear that the multidimensional case is in general harder to be dealt with. Moreover, if higher degree polynomials are under investigation, we cannot expect the maximum to be attained in a vertex of our simplices. Furthermore, we do not want to restrict ourselves to uniform grids. Hence, we need a somewhat more general approach. The price we have to pay for this is to use slightly larger stencils than probably really necessary.

LEMMA 4.8. *Suppose $\mathcal{D}$ is compact and satisfies a cone condition with angle θ and radius $r > 0$. Suppose $\mathcal{D}$ is disjointly decomposed into $\mathcal{D} \subseteq \cup_{j=1}^N V_j$ with subregions V_j. Suppose every ball $B(x_0, h) \subseteq \mathcal{D}$ with radius h contains at least one V_j. Then, provided that*

$$h \le \frac{r\sin\theta}{4k^2(1+\sin\theta)}, \tag{4.2}$$

the mapping $T : \pi_k(\mathbb{R}^d) \to \mathbb{R}^N$, $T(p) = (\lambda_1(p), \dots, \lambda_N(p))^T$ *is injective with*

$$\|T(p)\|_\infty = \max_{1 \le j \le N} |\lambda_j(p)| \ge \frac{1}{2}\|p\|_{L_\infty(\mathcal{D})}, \qquad p \in \pi_k(\mathbb{R}^d).$$

Proof. Suppose $p \in \pi_k(\mathbb{R}^d)$ with $\|p\|_{L_\infty(\mathcal{D})} = 1$ is given. Then there exists a point $x_0 \in \mathcal{D}$ with $|p(x_0)| = 1$. To point x_0, we can choose a cone $C(x_0)$ with angle θ and radius r which is completely contained in $\mathcal{D}$. If $\xi \in \mathbb{R}^d$ with $\|\xi\|_2 = 1$ gives the axis of the cone, it is easy to see that $C(x_0)$ completely contains the ball $B(y, h)$ with $y = x_0 + (h/\sin\theta)\xi$, provided $h \le r\sin\theta/(1+\sin\theta)$ is satisfied. Hence, by assumption, we find a volume V_j with

$$V_j \subseteq B(y, h) \subseteq C(x_0) \subseteq \mathcal{D}.$$

Moreover, the line segment $x_0 + t(x - x_0)/\|x - x_0\|_2$, $t \in [0, r]$, which joins x_0 with any $x \in V_j$ and beyond is entirely contained in $\mathcal{D}$. Hence, if we define the univariate polynomial $q(t) = p(x_0 + t(x - x_0)/\|x - x_0\|_2)$, $t \in [0, r]$, we can apply Markov's inequality for univariate polynomials in the form

$$|q'(s)| \le \frac{2k^2}{r}\|q\|_{L_\infty[0,r]}, \qquad s \in [0, r],$$

to derive

$$|p(x_0) - p(x)| = |q(0) - q(\|x - x_0\|_2)| \le \int_0^{\|x - x_0\|_2} |q'(s)| ds \le \frac{2k^2}{r}\|x - x_0\|_2$$

for every $x \in V_j \subseteq B(y, h)$. For such an x we also have the bound

$$\|x - x_0\|_2 \le \|x - y\|_2 + \|y - x_0\|_2 \le h + \frac{h}{\sin\theta} = h\left(\frac{1 + \sin\theta}{\sin\theta}\right),$$

so that we can conclude

$$\begin{aligned} |p(x_0) - \lambda_j(p)| &\le \frac{1}{|V_j|}\int_{V_j} |p(x_0) - p(x)| dx \le \frac{2k^2}{r|V_j|}\int_{V_j} \|x - x_0\|_2 dx \\ &\le \frac{2k^2(1 + \sin\theta)}{r\sin\theta} h \le \frac{1}{2}, \end{aligned}$$

provided (4.2) is satisfied. This means $\lambda_j(p) \ge \|p\|_{L_\infty(\mathcal{D})}/2$ for this particular j. □

Note that for deriving our result only those volumes V_j were necessary with $V_j \subseteq \mathcal{D}$, as long as all other assumptions are satisfied.

Now that we know the bound on the inverse of the sampling operator we still need a bound on the norm of the evaluation functional ψ; this situation is again provided in [7].

LEMMA 4.9. *Suppose* $\mathcal{D}$ *is bounded and satisfies an interior cone condition with angle* θ *and radius* r*. Then, for every* $p \in \pi_k(\mathbb{R}^d)$ *and every* $|\alpha| \le k$ *we have*

$$\|D^\alpha p\|_{L_\infty(\mathcal{D})} \le \left(\frac{2k^2}{r\sin\theta}\right)^{|\alpha|} \|p\|_{L_\infty(\mathcal{D})}.$$

As a consequence, Theorem 4.5 guarantees for every $x \in \mathcal{D}$ and every $\alpha \in \mathbb{N}_0^d$ with $|\alpha| \le k$ the existence of numbers $a_1^\alpha(x), \dots, a_N^\alpha(x)$ such that

$$D^\alpha p(x) = \sum_{j=1}^N \lambda_j(p) a_j^\alpha(x), \qquad p \in \pi_k(\mathbb{R}^d), \tag{4.3}$$

and

$$\sum_{j=1}^{N} |a_j^\alpha(x)| \le 2 \left(\frac{2k^2}{r \sin\theta} \right)^{|\alpha|}. \tag{4.4}$$

For our next result, we use the fact that a domain $\mathcal{D} \subseteq B(x_c, R)$ which is star-shaped with respect to a ball $B(x_c, r) \subseteq \mathcal{D}$ satisfies an interior cone condition with radius r and angle $\theta = 2\arcsin(r/(2R))$.

PROPOSITION 4.10. *Let k be a positive integer, $1 \le p < \infty$, $0 < s \le 1$, and let α be a multi-index satisfying $k > |\alpha| + d/p$, or, for $p = 1$, $k \ge |\alpha| + d$. Let $1 \le q \le \infty$. Suppose $\mathcal{D} = \cup V_j \subseteq B(x_c, R)$ is star-shaped with respect to $B(x_c, r)$ and covered with volumes V_j such that every ball $B \subseteq \mathcal{D}$ with radius h contains at least one of these volumes V_j. Let $\rho_{\mathcal{D}}$ denote the diameter of $\mathcal{D}$. If h satisfies* (4.2)*, then we have for every $u \in W_p^{k+s}(\mathcal{D})$ satisfying $\lambda_j(u) = 0$, $1 \le j \le N$, the error estimate*

$$\|D^\alpha u\|_{L_q(\mathcal{D})} \le C \rho_D^{k+s-|\alpha|+d(1/q-1/p)} |u|_{W_p^{k+s}(\mathcal{D})},$$

and the constant C depends only on $k, d, p, |\alpha|$, and $\theta = 2\arcsin(r/2R)$.

Proof. We use the decomposition $D^\alpha u = D^\alpha u - D^\alpha Q_{k+1} + D^\alpha Q_{k+1}$ with $Q_{k+1} \in \pi_k(\mathbb{R}^d)$ being the averaged Taylor polynomial to u.

Since the chunkiness parameter γ can be bounded by

$$1 \le \gamma \le \rho_{\mathcal{D}}/r \le 2R/r = 1/\sin(\theta/2), \tag{4.5}$$

Lemma 4.3 yields a constant C depending only on $k, d, |\alpha|, \theta$ with

$$\|D^\alpha u - D^\alpha Q_{k+1} u\|_{L_\infty(\mathcal{D})} \le C \rho_{\mathcal{D}}^{k+s-|\alpha|-d/p} |u|_{W_p^{k+s}(\mathcal{D})}.$$

On the other hand, since (4.2) is satisfied, Lemma 4.8 and Theorem 4.5 yield stable polynomial reproduction in the sense of (4.3) and (4.4). Hence, because of $\lambda_j(u) = 0$ we have for any polynomial $p \in \pi_k(\mathbb{R}^d)$,

$$\begin{aligned} |D^\alpha p(x)| &= \left| \sum_{j=1}^{N} \lambda_j(p) a_j^\alpha(x) \right| = \left| \sum_{j=1}^{N} a_j^\alpha(x) \left[\lambda_j(p) - \lambda_j(u) \right] \right| \\ &\le \sum_{j=1}^{N} |a_j^\alpha(x)| \frac{1}{|V_j|} \int_{V_j} |p(y) - u(y)| dy \\ &\le 2 \left(\frac{2k^2}{r \sin\theta} \right)^{|\alpha|} \|p - u\|_{L_\infty(\mathcal{D})}. \end{aligned}$$

Specifying $p = Q_{k+1}$ and using Lemma 4.3 and (4.5) yields

$$\begin{aligned} |D^\alpha Q_{k+1}(x)| &\le 2 C_{k,d,p} (1+\gamma)^{d(1+1/p)} \left(\frac{2k^2 \rho_{\mathcal{D}}}{r \sin\theta} \right)^{|\alpha|} \rho_{\mathcal{D}}^{k+s-|\alpha|-d/p} |u|_{W_p^{k+s}(\mathcal{D})} \\ &\le C \rho_{\mathcal{D}}^{k+s-|\alpha|-d/p} |u|_{W_p^{k+s}(\mathcal{D})} \end{aligned}$$

with a constant depending only on $k, d, p, |\alpha|$ and θ. Hence, we have established the result

$$\|D^\alpha u\|_{L_\infty(\mathcal{D})} \le C \rho_{\mathcal{D}}^{k+s-|\alpha|-d/p} |u|_{W_p^{k+s}(\mathcal{D})}$$

for $q = \infty$. Next, integrating this inequality and using the fact that $\mathcal{D}$ has volume $\mathcal{O}(\rho_{\mathcal{D}}^d)$, leads to

$$\|u\|_{L_q(\mathcal{D})} \leq C\rho_{\mathcal{D}}^{k+s-|\alpha|+d(1/q-1/p)}|u|_{W_p^{k+s}(\mathcal{D})},$$

which finishes the proof. □

Note that this result remains true even if $\mathcal{D}$ itself is not the union of its volumes. More precisely, if $\mathcal{D} \subseteq \cup V_j$ it suffices that the collection $\{V_j : V_j \subseteq \mathcal{D}\}$ satisfies the assumptions. In particular, in this situation the recovery function should only be based upon these volumes.

Proposition 4.10 yields our first main result. It covers the situation of ENO approximation whenever a sufficiently large stencil is chosen. Note, however, that the assumption on the size of the stencil can even be improved in case of linear polynomials and regular meshes, using the ideas of Examples 4.6 and 4.7.

DEFINITION 4.11. *We say that a stencil $\mathcal{D} = \cup_{j=1}^M V_j$ with volumes V_j is* admissible *if there exist constants $C_1 > 0$ and $L \geq 1$ such that*

- *$\mathcal{D}$ is star-shaped with respect to a ball $B(x_c, C_1 h)$,*
- *$\mathcal{D}$ is contained in the ball $B(x_c, LC_1 h)$,*
- *each ball of radius h contains at least one V_j.*

If a stencil is admissible in this sense, it yields convergence of the reconstruction process using cell averages.

THEOREM 4.12. *Suppose the assumption on $k, p, s, |\alpha|$, and q from Proposition* 4.10 *hold. Suppose $\mathcal{D} = \cup_{j=1}^M V_j \subseteq \mathbb{R}^d$ is an admissible stencil with constants C_1, L. Set $\theta = 2\arcsin(1/(2L))$. If*

$$C_1 \geq \frac{4k^2(1+\sin\theta)}{\sin\theta},$$

then for every $u \in W_p^{k+s}(\mathcal{D})$, which satisfies $\lambda_j(u) = 0$ for $1 \leq j \leq N$, the error estimate

$$\|D^\alpha u\|_{L_q(\mathcal{D})} \leq Ch^{k+s-|\alpha|+d(1/q-1/p)}|u|_{W_p^{k+s}(\mathcal{D})}$$

is satisfied, where C is a constant independent of u and h.

Proof. From Lemma 4.2 we know that $\mathcal{D}$ satisfies a cone condition with radius $r = C_1 h$ and angle $\theta = 2\arcsin(1/(2L))$. Our assumption on C_1 assures that condition (4.2) is satisfied, so that Proposition 4.10 yields the result. □

It is important here to note that all involved constants depend on the region $\mathcal{D}$ only by their cone condition. This will be of importance for deriving our general result in the next section.

The assumptions $k > |\alpha| + d/p$ can be weakened in case of $p = q$ using interpolation theory to $k > d/p$.

Finally, note that for Proposition 4.10 it is not important for $\mathcal{D}$ to be the collection of all local V_j. It suffices that every ball of radius h contained in $\mathcal{D}$ contains a V_j itself.

5. Global estimates.

Now we work our way towards proving Theorem 2.1. To this end, we cover our region Ω by small regions $\mathcal{D}$. The key ingredient is that the involved constants depend on the local regions only via their cone condition. Hence, if we fix r and R and use local domains $\mathcal{D}$ for which we can find an x_c such that $\mathcal{D} \subseteq B(x_c, R)$ is star-shaped with respect to $B(x_c, r)$, the chunkiness parameter and thus the angle θ of the cone condition are all the same. This means in particular that we can use the same constant C in Proposition 4.10 for any such domain.

Interestingly, the procedure which now follows is identical to the one employed in the point evaluation case, which was studied in [7]. Hence, we will rely heavily on that paper; see also [14].

Let us suppose our global region Ω is bounded and satisfies a cone condition with radius r and angle θ. We introduce the following quantities. As usual, let h be the typical size of our finite volumes. Let

$$\begin{aligned} \vartheta &:= 2\arcsin\left(\frac{\sin\theta}{4(1+\sin\theta)}\right), \\ Q(k,\theta) &:= \frac{\sin\theta\sin\vartheta}{8k^2(1+\sin\theta)(1+\sin\vartheta)} \\ R &:= Q(k,\theta)^{-1}h, \\ r &:= \frac{\sin\theta}{2(1+\sin\theta)}R. \end{aligned}$$

With these settings we define the sets $T_r := \{t \in \frac{2r}{\sqrt{d}}\mathbb{Z}^d : B(t,r) \subseteq \Omega\}$ and

$$\mathcal{D}_t = \{x \in \Omega : \mathrm{co}(\{x\} \cup B(t,r)) \subseteq \Omega \cap B(t,R)\}, \qquad t \in T_r,$$

where co(A) denotes the closed convex hull of the set A.

LEMMA 5.1 (see [7]). *With the just introduced quantities, suppose the number $h > 0$ satisfies $h \le Q(k,\theta)r$. Then, the following holds true:*

1. *Each $\mathcal{D}_t$ is star-shaped with respect to the ball $B(t,r)$ and satisfies $B(t,r) \subseteq \mathcal{D}_t \subseteq \Omega \cap B(t,R)$.*
2. *Each $\mathcal{D}_t$ satisfies a cone condition with angle ϑ and radius r.*
3. *$\Omega = \bigcup_{t\in T_r} \mathcal{D}_t$ and $\rho_{\mathcal{D}_t} \le 2R = 2h/Q(k,\theta)$.*
4. *There is a constant $M_1 > 0$ such that $\sum_{t\in T_r} \chi_{\mathcal{D}_t} \le M_1$.*
5. *There is a constant $M_2 > 0$ such that $\#T_r \le M_2 r^{-d}$.*

Here, $\chi_{\mathcal{D}_t}(x)$ is 1 if $x \in \mathcal{D}_t$ and 0 elsewhere and $\#T_r$ denotes the cardinality of T_r.

Now that we have the local sets we can formulate and prove our main result of this section; Theorem 2.1.

THEOREM 5.2. *Suppose Ω is bounded and satisfies an interior cone condition with radius $r > 0$ and angle θ. Let k be a positive integer, $0 < s \le 1$, $1 \le p < \infty$, $1 \le q \le \infty$, and let $m \in \mathbb{N}_0$ satisfy $k > m + d/p$ for $p > 1$, or $k \ge m + d$ for $p = 1$. Also, let $\{V_1, \dots, V_N\} \subseteq \Omega$ such that each ball $B \subseteq \Omega$ of radius $h \le Q(k,\theta)r$ contains at least one volume V_j. If $u \in W_p^{k+s}(\Omega)$ satisfies $\lambda_j(u) = 0$, $1 \le j \le N$, then*

$$|u|_{W_q^m(\Omega)} \le Ch^{k+s-m-d(1/p-1/q)_+}|u|_{W_p^{k+s}(\Omega)}, \tag{5.1}$$

where $(x)_+ = \max\{x, 0\}$.

Proof. We use the notation introduced in the paragraph before Lemma 5.1. First of all note that, since $h \le Q(k,\theta)r$, Lemma 5.1 is applicable. Furthermore, our definition of r, R, and $Q(k,\theta)$ establish $h = \frac{r\sin\vartheta}{4k^2(1+\sin\vartheta)}$, which allows us to apply Proposition 4.10 to the local sets $\mathcal{D}_t$. The just mentioned lemma and proposition immediately establish the result in the case $q = \infty$. On the other hand, for $1 \le q < \infty$

the decomposition of Ω implies that we have

$$\begin{aligned}|u|^q_{W^m_q(\Omega)} &= \sum_{|\alpha|=m}\int_\Omega |D^\alpha u(x)|^q dx\\ &\le \sum_{t\in T_r}\sum_{|\alpha|=m}\int_{\mathcal{D}_t}|D^\alpha u(x)|^q dx = \sum_{t\in T_r}|u|^q_{W^m_q(\mathcal{D}_t)}\\ &\le (\#T_r)^{q\left(\frac{1}{q}-\frac{1}{p}\right)_+}\left(\sum_{t\in T_r}|u|^p_{W^m_q(\mathcal{D}_t)}\right)^{q/p},\end{aligned}$$

where the last bound follows from standard inequalities relating p and q norms on finite dimensional spaces. Proposition 4.10 together with $\rho_{\mathcal{D}_t}\le 2R = 2Q(k,\theta)^{-1}h$ gives the bound

$$\left(\sum_{t\in T_r}|u|^p_{W^m_q(\mathcal{D}_t)}\right)^{1/p} \le Ch^{k+s-m+d(\frac{1}{q}-\frac{1}{p})}\left(\sum_{t\in T_r}|u|^p_{W^{k+s}_p(\mathcal{D}_t)}\right)^{1/p}.$$

Here, it has been essential that all involved constants depend only on the cone condition, which is the same for all $\mathcal{D}_t$. Now, using Lemma 5.1 again yields

$$\begin{aligned}\sum_{t\in T_r}|u|^p_{W^{k+s}_p(\mathcal{D}_t)} &\le \sum_{|\alpha|=k}\int_\Omega\sum_{t\in T_r}\chi_{\mathcal{D}_t}(x)\int_{\mathcal{D}_t}\frac{|D^\alpha u(x)-D^\alpha u(y)|^p}{\|x-y\|_2^{d+sp}}dydx\\ &\le M_1\sum_{|\alpha|=k}\int_\Omega\int_\Omega\frac{|D^\alpha u(x)-D^\alpha u(y)|^p}{\|x-y\|_2^{d+sp}}dydx\\ &\le M_1|u|^p_{W^{k+s}_p(\Omega)}.\end{aligned}$$

A final application of Lemma 5.1 together with $r=\frac{\sin\theta}{2Q(k,\theta)(1+\sin\theta)}h$ shows $\#T_r\le Ch^{-d}$. Putting all these things together and taking

$$d\left(\frac{1}{q}-\frac{1}{p}\right)-d\left(\frac{1}{q}-\frac{1}{p}\right)_+ = -d\left(\frac{1}{p}-\frac{1}{q}\right)_+$$

into account establishes the desired result. □

Let us apply this result to the compactly supported functions of minimal degree [12, 13]. They are radial functions $\Phi_{d,k}(x)=\phi_{d,k}(\|x\|_2)$, $x\in\mathbb{R}^d$, where each univariate function $\phi_{d,k}$ consists of a univariate polynomial on its support. Moreover, the d-variate function $\Phi_{d,k}$ is in $C^{2k}(\mathbb{R}^d)$. The functions $\Phi_{d,k}$ generate Sobolev spaces $W^\sigma_2(\mathbb{R}^d)$ with $\sigma = d/2+k+1/2$ as their associated reproducing kernel Hilbert spaces since their Fourier transforms $\widehat{\Phi}=\widehat{\Phi}_{d,k}$ decay like

$$C_1(1+\|\omega\|_2^2)^{-\sigma}\le\widehat{\Phi}(\omega)\le C_2(1+\|\omega\|_2^2)^{-\sigma}. \tag{5.2}$$

Corollary 5.3. *Suppose $\Omega\subseteq\mathbb{R}^d$ is bounded, satisfies a cone condition, and has a Lipschitz boundary. Suppose $\Phi\in L_1(\mathbb{R}^d)$ is positive definite and has a Fourier transform $\widehat{\Phi}$ satisfying* (5.2) *with $\sigma>d/2$. Let $1\le q\le\infty$ and $u\in W^\sigma_2(\Omega)$. If Ω is covered by volumes $\{V_j\}$ such that every ball $B\subseteq\Omega$ of radius h contains at least* *one V_j, then the error between u and its optimal recovery s_u from cell averages can be bounded by*

$$\|u - s_u\|_{L_q(\Omega)} \le Ch^{\sigma - d(1/2-1/q)_+}\|u\|_{W_2^\sigma(\Omega)}.$$

Proof. We need to extend $u \in W_2^\sigma(\Omega)$ to a function $Eu \in W_2^\sigma(\mathbb{R}^d)$. This is under the assumptions on Ω continuously possible; see the discussion in [7]. Hence, there exists a constant $C > 0$ such that $\|Eu\|_{W_2^\sigma(\mathbb{R}^d)} \le C\|u\|_{W_2^\sigma(\Omega)}$ and optimal recovery leads to

$$\|u - s_u\|_{W_2^\sigma(\Omega)} \le \|Eu - s_{Eu}\|_{W_2^\sigma(\mathbb{R}^d)} \le C\|Eu\|_{W_2^\sigma(\mathbb{R}^d)} \le C\|u\|_{W_2^\sigma(\Omega)}. \tag{5.3}$$

Since we have for the cell averages $\lambda_j(u - s_u) = 0$, we can apply Theorem 5.2 to $u - s_u$, which yields, together with (5.3), the desired result. □

For simplicity, we have stated the result only for the nonderivative case. The reader should have no problems restating it, including estimates on the derivatives.

If the target function u is known to be analytic so that it belongs even to the reproducing Hilbert space of *Gaussians* $\phi(r) = \exp(-\alpha r^2)$, $\alpha > 0$ or *multiquadrics* $\phi(r) = \sqrt{1 + r^2}$, then *any* Sobolev norm can be used, giving arbitrary convergence order. However, this is true only under rather restrictive assumptions on the target function.

6. Improved estimates for thin-plate splines. In this section we will improve the estimates derived in Theorem 5.2 in the particular situation of thin-plate splines. The ideas employed can also be used for other basis functions. However, the additional assumptions that have to be imposed on the target function are in other cases often only implicitly given.

We start by applying Theorem 5.2 to thin-plate splines. To be more precise, for $x \in \mathbb{R}^d$, we let

$$\Phi_{d,k}(x) := c_{d,k}\begin{cases} \|x\|_2^{2k-d} & \text{for } d \text{ odd}, \\ \|x\|_2^{2k-d}\log\|x\|_2 & \text{for } d \text{ even}, \end{cases}$$

where $c_{d,k}$ is a constant chosen so that $\Phi_{d,k}$ is a fundamental solution of the iterated Laplacian. In terms of the distributional Fourier transform, this is equivalent to requiring that $\widehat{\Phi}_{d,k}(\omega) = \|\omega\|_2^{-2k}$, if $\omega \neq 0$.

The reproducing kernel semi-Hilbert space associated with $\Phi_{d,k}$ is the Beppo–Levi space,

$$\mathrm{BL}_k(\mathbb{R}^d) := \{f \in C(\mathbb{R}^d) : D^\alpha f \in L_2(\mathbb{R}^d) \text{ for all } |\alpha| = k\},$$

which is equipped with the semi-inner product

$$(f, g)_{\mathrm{BL}_k(\mathbb{R}^d)} = \sum_{|\alpha|=k} \frac{k!}{\alpha!}(D^\alpha f, D^\alpha g)_{L_2(\mathbb{R}^d)},$$

i.e., BL_k is equipped with a semi-Hilbert norm comparable to $|\cdot|_{W_2^k(\mathbb{R}^d)}$. In particular, choosing $k = 2$ in case of $d = 2$ leads to the well-known thin-plate splines $\phi(r) = r^2 \log r$.

As in the case of the compactly supported functions, we need to extend the function $f \in W_2^k(\Omega)$ to a function $E_k f \in \mathrm{BL}_k(\mathbb{R}^d)$. This is possible due to Duchon

[2]. To be more precise there exists an extension operator $E_k : W_2^k(\Omega) \to \mathrm{BL}_k(\mathbb{R}^d)$ with $E_k u|\Omega = u$ and $|E_k u|_{\mathrm{BL}_k(\mathbb{R}^d)} \le \|E_k\| |u|_{\mathrm{BL}_k(\Omega)}$.

Again, we state our result only for the nonderivative case.

COROLLARY 6.1. *Suppose $\Omega \subseteq \mathbb{R}^d$ is bounded and satisfies an interior cone condition. Suppose further $k > d/2$ and $1 \le q \le \infty$. If Ω is covered by volumes $\{V_j\}$ such that every ball $B \subseteq \Omega$ of radius h contains at least one volume V_j. Then, the error between $u \in W_2^k(\Omega)$ and its optimal recovery s_u from cell averages using the thin-plate spline $\Phi_{d,k}$ has the error estimate*

$$\|u - s_u\|_{L_q(\Omega)} \le C h^{k-d(1/2-1/q)_+} |u|_{\mathrm{BL}_k(\Omega)}.$$

Proof. We extend $u \in W_2^k(\Omega)$ to a function $u = E_k u \in \mathrm{BL}_k(\mathbb{R}^d)$. Since $\mathrm{BL}_k(\mathbb{R}^d)$ is the associated reproducing kernel semi-Hilbert space, we have

$$|u - s_u|_{\mathrm{BL}_k(\mathbb{R}^d)} \le |u|_{\mathrm{BL}_k(\mathbb{R}^d)} \le C_e |u|_{\mathrm{BL}_k(\Omega)}.$$

Since the function $u - s_u$ satisfies $\lambda_j(u) = 0$ we can apply Theorem 5.2 to it, which gives the desired result. □

For here the mainly interesting case of $q = \infty$ gives

$$\|u - s_u\|_{L_\infty(\Omega)} \le C h^{k-d/2} |u|_{\mathrm{BL}_k(\Omega)}.$$

Hence, in the bivariate case $d = 2$ using classical thin-plate splines $\phi(r) = r^2 \log r$ this leads only to a first order approximation scheme. This recovers an unpublished result [3] by Gutzmer.

However, under additional assumptions on the target function u improved error estimates can be established.

THEOREM 6.2. *Under the assumptions of Corollary* 6.1, *assume that $u \in W_2^{2k}(\Omega)$ has support in Ω. Then, the error between u and its optimal recovery s_u can be bounded by*

$$\|u - s_u\|_{L_q(\Omega)} \le C h^{2k-d(1/2-1/q)_+} \|\Delta u^k\|_{L_2(\Omega)}.$$

Proof. Since u is supported in Ω it is actually globally defined. Moreover, we have the estimate

$$\|u - s_u\|_{L_q(\Omega)} \le C h^{k-d(1/2-1/q)_+} |u - s_u|_{\mathrm{BL}_k(\Omega)} \tag{6.1}$$

by Theorem 5.2. The improved estimate follows from bounding $|u - s_u|_{\mathrm{BL}_k(\Omega)}$. To this end, we use the fact that s_u is the best approximation to u from

$$\mathrm{span}\{\lambda_j^y \Phi_{d,k}(\cdot - y) : 1 \le j \le N\}.$$

Hence, using also the compact support of u, we deduce

$$|u - s_u|^2_{\mathrm{BL}_k(\Omega)} = (u - s_u, u)_{\mathrm{BL}_k(\Omega)} = \sum_{|\alpha|=k} \frac{k!}{\alpha!} \int_\Omega D^\alpha (u - s_u)(x) D^\alpha u(x) dx,$$

so that integration by parts results in

$$\begin{aligned} |u - s_u|^2_{\mathrm{BL}_k(\Omega)} &= (-1)^k \sum_{|\alpha|=k} \frac{k!}{\alpha!} \int_\Omega (u - s_u)(x) D^{2\alpha} u(x) dx \\ &= (-1)^k \int_\Omega (u - s_u)(x) \Delta^k u(x) dx, \end{aligned}$$

which can be bounded by

$$|u - s_u|^2_{\mathrm{BL}_k(\Omega)} \le \|u - s_u\|_{L_2(\Omega)} \|\Delta^k u\|_{L_2(\Omega)}.$$

Applying Theorem 5.2 to $\|u - s_u\|_{L_2(\Omega)}$ and inserting the result into (6.1) finishes the proof. □

This gives the estimate

$$\|u - s_u\|_{L_\infty(\Omega)} \le Ch^{2k-d/2} \|\Delta^k u\|_{L_2(\Omega)},$$

so that we have for thin-plate splines in $\mathbb{R}^2$ now a third order scheme, provided the target function is smooth enough and compactly supported.

This naturally raises the question of how good the approximation order can become under the best possible conditions. As in the case of pure point evaluation functionals (see [8]) it can be shown that any smooth function u with

$$\|u - s_u\|_{L_\infty(K)} = o(h^{2k})$$

for every compact subset $K \subseteq \Omega$ must already satisfy $\Delta^k u = 0$ and is in this sense trivial.

A PIECEWISE CONSTANT ALGORITHM FOR WEIGHTED L_1 APPROXIMATION OVER BOUNDED OR UNBOUNDED REGIONS IN $\mathbb{R}^s$*

FRED J. HICKERNELL[†], IAN H. SLOAN[‡], and GRZEGORZ W. WASILKOWSKI[§]

Abstract. Using Smolyak's construction [S. A. Smolyak, *Dokl. Akad. Nauk SSSR,* 4 (1963), pp. 240–243], we derive a new algorithm for approximating multivariate functions over bounded or unbounded regions in $\mathbb{R}^s$ with the error measured in a weighted L_1-norm. We provide upper bounds for the algorithm's cost and error for a class of functions whose mixed first order partial derivatives are bounded in the L_1-norm. In particular, we prove that the error and the cost (measured in terms of the number of function evaluations) satisfy the relation

$$\text{error} \le \frac{s\ \exp\left(\frac{1}{12(s-1)}\right)}{(s-1)\pi} \left(\frac{e\ \ln(\text{cost})}{(s-1)\sqrt{2}\ln(2)}\right)^{2(s-1)} \frac{1}{\text{cost}}$$

whenever the cost is sufficiently large relative to the number s of variables. More specifically, the inequality holds when $q \ge 2(s-1)$, where q is a special parameter defining the refinement level in Smolyak's algorithm, and hence the number of function evaluations used by the algorithm. We also discuss extensions of the results to the spaces with the derivatives bounded in L_p-norms.

1. Introduction.

In this paper, we derive a simple-to-use, piecewise constant algorithm for approximating functions in a weighted L_1 sense. Function approximation has been studied quite extensively; see, e.g., [13, 17, 22, 24] and the papers cited therein. However, such problems were considered mainly for functions with a bounded domain D, say $D = [0,1]^s$.

The worst case complexity of weighted approximation over unbounded domains D has recently been studied in, e.g., [11, 27], assuming that the corresponding function classes $\mathcal{F}$ are isotropic. The analysis of the approximation problem for tensor product spaces $\mathcal{F}$ is quite straightforward if $\mathcal{F}$ is a Hilbert space, since then desirable properties of Smolyak's construction could be used; see, e.g., [25].

In this paper, we study a weighted approximation problem with an emphasis on unbounded domains D and tensor product function classes $\mathcal{F}$ in a non-Hilbert-space setting. More specifically, we study a ρ-weighted L_1 approximation problem with the

error between f and the approximation $\mathcal{A}(f)$ measured in the following seminorm:

$$\|(f-\mathcal{A}(f))\,\rho\|_{L_1(D)} = \int_D \rho(\mathbf{x})\,|f(\mathbf{x})-\mathcal{A}(f)(\mathbf{x})|\,d\mathbf{x}. \tag{1}$$

We have chosen the L_1-norm here (as opposed to the L_r-norm for $r > 1$) since then the approximation problem is related to weighted integration. This relation is briefly discussed in section 6; here we only mention that any algorithm $\mathcal{A}$ for L_1 approximation yields an integration algorithm with the error at least as small as the error of $\mathcal{A}$. Another reason for choosing $r = 1$ is the simplicity of analysis; for $r \neq 1, 2$ the corresponding weighted L_r approximation problem is more difficult to analyze.

Throughout this article, it is assumed that $\rho(\mathbf{x}) = \prod_{k=1}^{s} \rho_k(x_k)$ is a given integrable weight function. The domain D of functions can be an arbitrary box, even $D = \mathbb{R}^s$. The class $\mathcal{F}$ is a space of functions whose dominating mixed first order derivatives are bounded in the L_1-norm. This seems to be about the minimum amount of smoothness needed to get a convergence rate of essentially $O(n^{-1})$. For example, if only the functions have bounded L_1-norm, then function values may not even be finite, and algorithms depending on function values are not be to guaranteed to converge. The case of derivatives bounded in L_p-norms seems to be harder than the case with the L_1-norm (especially for unbounded D), and is briefly addressed in section 5.

We stress that classes $\mathcal{F}$ as defined here are commonly assumed in the context of integration problems over $D = [0, 1]^s$, especially when dealing with quasi-Monte Carlo methods and discrepancy; see, e.g., [5, 12, 19] and papers cited therein. This point is further discussed in section 2. These $\mathcal{F}$ have been used even for integration problems with unbounded domains [9]. Moreover, for bounded D, these classes contain the classes MW_p^1 of periodic functions considered for approximation in [22, Chap. 4].

Instead of a condition on the dominating mixed derivatives, one sometimes assumes that all derivatives of total order α are bounded in the L_1-norm. Error analysis using such conditions suffer from the "curse of dimensionality." For example, to have a convergence rate of $O(n^{-1})$ requires all derivatives of total order s to be bounded in the L_1-norm. The condition assumed here is weaker.

The main result of the paper is the derivation and analysis of a family $\{\mathcal{A}_{q,s}\}_{q=s}^{\infty}$ of algorithms that provide approximations that are special piecewise constant functions. They are obtained by applying Smolyak's construction (see [21]) to scalar piecewise constant interpolation methods. As we shall see, given a number s of variables and a parameter $q \geq s$, the algorithm has the worst case error bounded by

$$\mathrm{error}(\mathcal{A}_{q,s}) \leq \begin{cases} s\,2^{-2q+2s-3}\binom{2q-2s+3}{q-s+1} & \text{if } q < 2(s-1), \\ s\,2^{-q}\binom{q}{s-1} & \text{if } q \geq 2(s-1). \end{cases}$$

Here q is the refinement parameter in Smolyak's algorithm. Under an additional symmetry assumption (4) that is stated later, we get

$$\mathrm{error}(\mathcal{A}_{q,s}) \leq s\,2^{-q+s-1-a}\binom{q-s}{a} \quad \text{with} \quad a = \begin{cases} \lfloor \frac{q-s+1}{3} \rfloor & \text{if } q < 4(s-1), \\ s-1 & \text{otherwise.} \end{cases}$$

Let $n = \mathrm{card}(\mathcal{A}_{q,s})$ denote the number of function evaluations used by $\mathcal{A}_{q,s}$. From [25, Lem. 7] we have $n \leq 2^{q-s+1}\binom{q-1}{s-1}$, and we conclude that for every $s \geq 2$ and $q \geq 2(s-1)$,

$$\mathrm{error}(\mathcal{A}_{q,s}) \leq \frac{s}{(s-1)\pi}\left(\frac{e\,\ln(n)}{(s-1)\sqrt{2}\ln(2)}\right)^{2(s-1)}\frac{1}{n}.$$

This rate $n^{-1}\ln^{2(s-1)}(n)$ of convergence is as good as the best known rate for L_1 approximation of periodic functions from the class $\mathcal{F} = MW_1^1$; see [22, Thm. 5.1 of Chap. 4] and [23]. Recall that MW_1^1 is contained in $\mathcal{F}$ when D^s is bounded and the approximation is with $\rho \equiv 1$. Hence $\mathcal{A}_{q,s}$ works for more general classes of problems and spaces of functions. Moreover, the result above shows in an explicit way the dependence of the errors on the dimension s.

We do not know whether $n^{-1}\ln^{2(s-1)}(n)$ is the best possible rate. However, because the Kolmogorov width for the corresponding problem over MW_1^1 equals $\Theta(n^{-1}\ln^{3(s-1)/2}(n))$ (see [22, Thm. 4.5 of Chap. 3]), the difference could only be in the exponent of the $\ln(n)$-term.

Since $\mathcal{A}_{q,s}(f)$ is a piecewise constant function, the algorithm is easy to implement. Its only drawback is in exponential gaps between consecutive numbers $\mathrm{card}(\mathcal{A}_{q,s})$ of function evaluations. However, we believe that it is of a practical interest, especially for small to moderate values of s. Implementation of the algorithm and numerical tests will be reported later.

We stress that Smolyak's construction, also referred to as *sparse grid*, *hyperbolic cross*, and *Boolean blending*, has been applied to many problems, including differential and integral equations, integration and approximation of multivariate functions, and to wavelets construction; see, e.g., [1, 2, 3, 4, 6, 7, 8, 10, 16, 18, 14, 22, 23, 25, 26] and the papers cited therein. However, with only a few exceptions, the considered functions are defined over bounded domains (e.g., $D = [0,1]^s$), and sometimes are of a special form (e.g., $f = g * B$ for a fixed function B as in MW_p^α classes). By analyzing ρ-weighted L_1 approximation, we are able to propose a simple algorithm that works well for any probability density function ρ of a tensor product form and even for $D = \mathbb{R}^s$. The proposed algorithm uses a finite number n of function values and approximates the function with error $O(n^{-1}\ln^{2(s-1)}(n))$. It is linear, simple, and easy to implement.

We would like to contrast this to a possible wavelet approach with $D = \mathbb{R}^s$ as proposed in [4]. There, the approximating algorithm is defined as the function from a special linear subspace $\mathcal{H}_n$ that minimizes the L_p distance from f, and the space $\mathcal{H}_n$ has infinite dimension. Hence, it is very difficult to implement. This should explain our interest in ρ-weighted approximation. We have chosen the L_1-norm since for the L_r-norm ($r > 1$) the analysis would be much harder and getting sharp bounds (including explicit constants) rather impossible.

We now explain the choice of low regularity $\alpha = 1$. Recall that we assume first order mixed derivatives to be bounded. As in the papers cited in the previous paragraph that deal with classes of functions of arbitrary (but fixed) regularity and bounded domains, it is possible to extend the results even to the case of $D = \mathbb{R}^s$. Indeed, using general properties of Smolyak's construction (e.g., from [25]) and results on the complexity of scalar ($s = 1$) weighted L_r approximation over $\mathbb{R}$ (see [27]), it is possible to achieve a convergence rate $O(n^{-(\alpha+(1/r-1/p)_-)}\ln^{(\alpha+1)(s-1)}(n))$. This is when the mixed partial derivatives of order α are bounded in the (weighted) L_p-norm. However, this extension to general α would (i) hold only under special assumptions on ρ (see [27, Thm. 1]), (ii) make explicit dependence on the dimension s very difficult to obtain, and (iii) make the resulting algorithms more difficult to implement and less applicable. In particular, the gaps between consecutive values of $\mathrm{card}(\mathcal{A}_{q,s})$ would increase with increasing regularity α, making the algorithm applicable only for very small values of s (say $s \le 3$). Moreover, by assuming $\alpha = 1$ we make our algorithm applicable to a larger class of functions also because the classes with $\alpha > 1$ are contained in the class with $\alpha = 1$. The explicitness of the results, as well as the simplicity and applicability of the algorithm, were our primary reasons for choosing $\alpha = 1$.

We summarize the content of this paper. Section 2 provides some basic definitions and assumptions, as well as an error bound for an arbitrary algorithm $\mathcal{A}$. Since Smolyak's construction depends on the specific choice of scalar algorithms, section 3 considers very special scalar algorithms based on a piecewise constant interpolation. The corresponding algorithm and its properties are presented in section 4. An extension to functions with derivatives bounded in L_p-norm is provided in section 5. Section 6 briefly explains why the error bounds obtained for the ρ-weighted L_1 approximation also hold for the corresponding ρ-weighted integration problem.

2. Basic definitions.

In this section, we briefly present some definitions and basic facts concerning the worst case setting. A more detailed discussion can be found, e.g., in [13, 24].

We consider a weighted L_1 approximation of functions of s variables whose domain D is a box,

$$D = \overline{(a_1, b_1)} \times \cdots \times \overline{(a_s, b_s)}.$$

The values a_i and b_i might be infinite; this is why we write $\overline{(a_i, b_i)}$ instead of $[a_i, b_i]$.

Let $\mathcal{F}$ be a Banach space of functions $f : D \to \mathbb{R}$ that will be specified later. The approximation problem depends on a weight function ρ which is assumed to have the following properties:

$$\rho(\mathbf{x}) = \prod_{k=1}^{s} \rho_k(x_k) \quad \text{and} \quad \rho_k \geq 0. \tag{2}$$

For simplicity of presentation, we also assume that

$$\int_{a_k}^{b_k} \rho_k(t)\, dt = 1 \quad \forall\, k = 1, \ldots, s.$$

However, it is enough to assume that the integrals of ρ_k are finite; in such a case, all error bounds derived in this paper should be multiplied by the constant $c = \int_D \rho(\mathbf{x})\, d\mathbf{x}$.

Functions from $\mathcal{F}$ are approximated by an algorithm $\mathcal{A}$,

$$f \sim \mathcal{A}(f) = \sum_{i=1}^{n} f(\mathbf{x}^i)\, g_i$$

for some points $\mathbf{x}^i$ and functions g_i, with the error between f and $\mathcal{A}(f)$ measured in the ρ-weighted L_1-norm; see (1). The *worst case error* (with respect to $\mathcal{F}$) of $\mathcal{A}$ is defined by

$$\text{error}(\mathcal{A}) := \sup_{\|f\| \leq 1} \|(f - \mathcal{A}(f))\, \rho\|_{L_1(D)},$$

where $\|f\|$ denotes the norm of f in the space $\mathcal{F}$. The importance of this definition is that due to linearity of $\mathcal{A}$ we have

$$\|(f - \mathcal{A}(f))\, \rho\|_{L_1} \leq \|f\|\ \text{error}(\mathcal{A}) \quad \forall\, f \in \mathcal{F}.$$

Each algorithm uses a finite number n of function evaluations. That number is called the *cardinality* and is denoted by $\mathrm{card}(\mathcal{A})$.

With the exception of sections 5 and 6, the following space $\mathcal{F}=\mathcal{F}_{1,s}$ is considered. Let $\mathcal{H}_k$ be the space of absolutely continuous functions on $\overline{(a_k,b_k)}$ whose first derivative is in $L_1((a_k,b_k))$. Let $\mathcal{H}^s = \bigotimes_{k=1}^s \mathcal{H}_k$ be the space consisting of linear combinations of functions f of the tensor product form

$$f : D \to \mathbb{R} \qquad \text{and} \qquad f(\mathbf{x}) = \prod_{k=1}^{s} h_k(x_k) \quad \text{with} \quad h_k \in \mathcal{H}_k.$$

The space $\mathcal{F}_{1,s}$ is the completion of $\mathcal{H}^s$ with respect to the following norm:

$$\|f\|_{1,s} := |f(\mathbf{c})| + \sum_{U\neq\emptyset} \|f'_U\|_{L_1(D_U)}. \tag{3}$$

Here $\mathbf{c} = [c_1,\dots,c_s] \in D$ is a fixed point, called an *anchor*. The summation is with respect to nonempty subsets U of $\{1,\dots,s\}$, and

$$f'_U(\mathbf{x}_U) := \frac{\partial^{|U|}}{\prod_{k\in U}\partial x_k} f(\mathbf{x}_U,\mathbf{c}),$$

where $(\mathbf{x}_U,\mathbf{c})$ denotes the s-dimensional vector whose kth component is x_k if $k \in U$, and c_k otherwise. By $\mathbf{x}_U$ we mean the $|U|$-dimensional vector obtained from $\mathbf{x}$ by removing all components x_k with $k \notin U$. This means that f'_U is a function defined on $D_U := \prod_{k\in U} \overline{(a_k,b_k)}$ and $\mathbf{x}_U \in D_U$. To simplify the notation, we will also write $f'_\emptyset$ and $\|f'_\emptyset\|_{L_1}$ to denote $f(\mathbf{c})$ and $|f(\mathbf{c})|$, respectively; and we often drop D_U by writing $\|\cdot\|_{L_1}$ instead of $\|\cdot\|_{L_1(D_U)}$. This allows the more concise formula

$$\|f\|_{1,s} = \sum_U \|f'_U\|_{L_1}.$$

We illustrate this for $s = 2$:

$$\begin{aligned}\|f\|_{1,2} = |f(c_1,c_2)| &+ \int_{a_1}^{b_1} \left|\frac{\partial}{\partial x_1} f(x_1,c_2)\right| dx_1 + \int_{a_2}^{b_2} \left|\frac{\partial}{\partial x_2} f(c_1,x_2)\right| dx_2 \\ &+ \int_{a_1}^{b_1}\int_{a_2}^{b_2} \left|\frac{\partial^2}{\partial x_1 \partial x_2} f(x_1,x_2)\right| dx_2\, dx_1.\end{aligned}$$

Although in general the anchor $\mathbf{c}$ and the weight ρ are not related, we shall obtain stronger results under the following symmetry condition:

$$\int_{a_k}^{c_k} \rho_k(x)\, dx = \frac{1}{2} \quad \forall k = 1,\dots,s. \tag{4}$$

Of course, this condition is satisfied if (a_k,b_k) and ρ_k are symmetric with respect to c_k ($k = 1,\dots,s$), e.g., if $a_k = -b_k$, $c_k = 0$, and $\rho_k(x) = \rho_k(-x)$. In general, for a given ρ_k one may always choose c_k to satisfy (4).

We now comment on the norm (3) and the role of the anchor $\mathbf{c}$.

Remark 1. As already mentioned in the introduction, the norm (3) and the space $\mathcal{F}_{1,s}$ are frequently assumed/studied in the context of quasi-Monte Carlo integration and discrepancies when the domain D is bounded, $D = [0,1]^s$. Then, classically, the anchor $\mathbf{c} = [1, \dots, 1]$. Of course, when $D = \mathbb{R}^s$ such a choice of the anchor seems unjustified and this is why we prefer to deal with arbitrary $\mathbf{c}$; see [9] for additional discussion.

There are a number of important results when, instead of the norm (3), a seminorm

$$|||f|||_{\alpha,p,s} := \|f^{(\alpha,\dots,\alpha)}\|_{L_p} \quad \text{with} \quad f^{(\alpha,\dots,\alpha)} = \left(\prod_{k=1}^{s} \frac{\partial^\alpha}{\partial x_k^\alpha} \right) f$$

is assumed. Of course, for $\alpha = 1$ and $p = 1$ this seminorm is very much related to (3) since it is equivalent to $\|f'_U\|_{L_1}$ with $U = \{1, \dots, s\}$. In particular, for $s = 1$, the complexities of problems with bounded $\|f\|_{1,s}$ or $|||f|||_{1,1,s}$ are equivalent. The situation changes drastically in the the multivariate case $s \geq 2$. This is because the subspace of functions with vanishing $|||\cdot|||_{\alpha,p,s}$-seminorm has infinite dimension. Therefore, to guarantee finite errors, one has to add additional restrictions on the considered class of functions. Examples of such restrictions include periodicity as in classes MW_p^α, or boundary conditions such as the vanishing of f and its partial derivatives at the points $\mathbf{x}$ with at least one component equal to zero. The presence of $\|f'_U\|_{L_1}$-terms in the definition of (3) guarantees that it is a well-defined norm without additional restrictions on the class of functions.

The following fact will play an important role. Let

$$M_k(x,t) := \begin{cases} 1 & \text{if } c_k < t < x, \\ -1 & \text{if } x < t < c_k, \\ 0 & \text{otherwise,} \end{cases}$$

$$M(\mathbf{x},\mathbf{t}) := \prod_{k=1}^{s} M_k(x_k, t_k) \quad \text{and} \quad M_U(\mathbf{x}_U, \mathbf{t}_U) := \prod_{k \in U} M_k(x_k, t_k),$$

with the convention that $M_\emptyset \equiv 1$. Then for every $f \in \mathcal{F}_{1,s}$ and every $\mathbf{x} \in D$,

$$f(\mathbf{x}) = \sum_U \int_{D_U} f'_U(\mathbf{t}_U)\, M_U(\mathbf{x}_U, \mathbf{t}_U)\, d\mathbf{t}_U. \tag{5}$$

The representation (5) has been used, at least implicitly, in a number of papers, and its short proof can be found in [9]. From it we have

$$\|f\,\rho\|_{L_1} \leq \sum_U \int_{D_U} |f'_U(\mathbf{t}_U)| \int_D |\rho(\mathbf{x})\, M_U(\mathbf{x}_U, \mathbf{t}_U)|\, d\mathbf{x}\, d\mathbf{t}_U \leq \|f\|_{1,s}.$$

This means that the approximation problem is well defined since the corresponding embedding operator is bounded. Actually, the following theorem, when applied to the zero algorithm $\mathcal{A} \equiv 0$, implies that the norm of the embedding is equal to one, i.e.,

$$\sup_{f \in \mathcal{F}} \frac{\|f\,\rho\|_{L_1}}{\|f\|_{1,s}} = 1.$$

THEOREM 1. *The error of any $\mathcal{A}$ is bounded by*

$$\text{error}(\mathcal{A}) \leq \sup_{\mathbf{t} \in D} \max_U \int_{D_U} h_U(\mathbf{x}_U, \mathbf{t}_U)\, d\mathbf{x}_U, \tag{6}$$

where

$$h_U(\mathbf{x}_U,\mathbf{t}_U) = \rho_U(\mathbf{x}_U)\,|M_U(\mathbf{x}_U,\mathbf{t}_U) - \mathcal{A}(M_U(\cdot,\mathbf{t}_U))(\mathbf{x}_U)|.$$

If $\mathcal{A}$ is based on piecewise constant interpolation then (6) *holds with equality.*

Proof. We defer the proof to section 5, where a more general result is proven. □

3. Scalar functions.

Since Smolyak's construction depends on specific algorithms for the scalar cases, we consider now approximating univariate functions whose domain is $\overline{(a_k,b_k)}$ and whose weight function is ρ_k. To simplify the notation in this section, we write a, b, and ω instead of a_k, b_k, and ρ_k.

For $i = 1, 2, \dots$, consider the set of points $x^k_{i,j}$ $(j = 0, \dots, 2^i)$ such that

$$a = x^k_{i,0} < x^k_{i,1} < \cdots < x^k_{i,2^i} = b$$

and

$$\int_{x^k_{i,j-1}}^{x^k_{i,j}} \omega(t)\,dt = 2^{-i}. \tag{7}$$

For simplicity, we will write in this section $x_{i,j}$ instead $x^k_{i,j}$.

Of course, $x_{i-1,j} = x_{i,2j}$. We take the following family of algorithms A_i $(i = 1, 2, \dots)$ based on piecewise constant interpolation:

$$A_i(f)(x) = f(x_{i,j}) \qquad \text{if } c_k \le x_{i,j} \le x < x_{i,j+1} \quad \text{or} \quad x_{i,j-1} < x \le x_{i,j} \le c_k.$$

Moreover, when $x, c_k \in (x_{i,j}, x_{i,j+1})$ then $A_i(f)(x)$ equals $f(x_{i,j})$ or $f(x_{i,j+1})$ depending on whether or not $x \le c_k$. Note that under the symmetry condition (4), $x_{1,1} = x_{i,2^{i-1}} = c_k$ and $A_i(f)(x) = f(c_k)$ for $x \in (x_{i,2^{i-1}-1}, x_{i,2^{i-1}+1})$.

For given k, define

$$\delta_{k,1}(x,t) := A_1(M_k(\cdot,t))(x)$$

and

$$\delta_{k,i}(x,t) := A_i(M_k(\cdot,t))(x) - A_{i-1}(M_k(\cdot,t))(x), \quad i \ge 2. \tag{8}$$

The following result is needed in section 4.

PROPOSITION 1. *For every t, we have*

$$\|\omega\,\delta_{k,i}(\cdot,t)\|_{L_1} \le 2^{-i} \quad \forall\, i \ge 2.$$

Moreover, $A_1(M_k(\cdot,t))$ is a constant function equal to ± 1 or zero, and if (4) *holds, then*

$$A_1(M_k(\cdot,t)) = 0.$$

The second part of the proposition can be directly checked. The first part of the proposition is an immediate consequence of the following lemma that will be used in section 5. For simplicity of presentation, we state the lemma only for arguments x and t greater than c_k. The analogous result is true for arguments smaller than c_k with the only difference being that $\delta_{i,k}(x,t) \in \{-1, 0\}$. Moreover, $\delta_{k,i}(x,t) = 0$ when c_k is between x and t.

Lemma 1. *The following statements hold for any $i \ge 2$ and $x, t > c_k$.*

(i) $\delta_{k,i}(x,t) \in \{0,1\}$.

(ii) *If $\delta_{k,i}(x,t) = 1$, then there exists $j \le 2^{i-1} - 1$ such that*

$$t \in (x_{i,2j}, x_{i,2j+1}] \qquad \textit{and} \qquad x \in (x_{i,2j+1}, x_{i,2j+2}].$$

(iii) *There is at most one $i \ge 2$ such that $\delta_{k,i}(x,t) = 1$.*

Proof. (i) follows immediately from the facts that $M_k(x,t) \in \{0,1\}$, $M_k(\cdot,t)$ is nondecreasing, and A_i uses the points used by A_{i-1}.

(ii) Let $x \in (x_{i,\ell}, x_{i,\ell+1}]$ for some ℓ. Then $A_i(M_k(\cdot,t))(x) = 1$ only if $t < x_{i,\ell}$. However, for $A_{i-1}(M_k(\cdot,t))(x) = 0$, $x_{i,\ell}$ has to be different than any point $x_{i-1,j}$ used by A_{i-1}. This means that ℓ has to be odd.

(iii) follows from (ii). Indeed, let (x,t) be fixed. If $\delta_{k,i}(x,t) = 1$, then t and x are in two neighboring subintervals with the evaluation point $x_{i,\ell}$ between them and $\ell = 2j+1$. Consider now $\delta_{k,i+n}(x,t)$ for positive n. Then the points $x_{i,\ell} = x_{i+n,m}$ with $m = 2^n \ell$ is between t and x, yet m is even. Hence, due to part (ii), $\delta_{k,i+n}(x,t)$ cannot be equal to one. This completes the proof. □

4. The algorithm.

Let $\{A_{k,i}\}$ be the families of algorithms from the previous section, each for $\omega = \rho_k$ and $(a,b) = (a_k, b_k)$, respectively. Recall that $A_{k,i}$ uses function values at points $x^k_{i,1}, \dots, x^k_{i,2^i-1}$. Define

$$\Delta_{k,1} := A_{k,1}, \qquad \Delta_{k,i} := A_{k,i} - A_{k,i-1} \quad \text{for} \quad i \ge 2$$

and

$$\mathcal{A}_{q,s} := \sum_{|\mathbf{i}| \le q} \bigotimes_{k=1}^{s} \Delta_{k,i_k} \tag{9}$$

for $q \ge s$. Here and elsewhere, $\mathbf{i} = [i_1, \dots, i_s] \in \mathbb{N}^s_+$ is a multi-index with $i_k \ge 1$ and $|\mathbf{i}| = \sum_{k=1}^s i_k$.

Theorem 2. *Let $s \ge 2$ and $q \ge s$. Then*

$$\mathrm{error}(\mathcal{A}_{q,s}) \le \begin{cases} s\, 2^{-q} \binom{q}{\lfloor \frac{q+1}{2} \rfloor} & \textit{if } q < 2(s-1), \\ s\, 2^{-q} \binom{q}{s-1} & \textit{if } q \ge 2(s-1). \end{cases}$$

If, additionally, (4) *holds, then*

$$\mathrm{error}(\mathcal{A}_{q,s}) \le s\, 2^{-q+s-1-a} \binom{q-s}{a} \quad \textit{with} \quad a = \begin{cases} \lfloor \frac{q-s+1}{3} \rfloor & \textit{if } q < 4(s-1), \\ s-1 & \textit{if } q \ge 4(s-1). \end{cases}$$

To prove this theorem, we need the following lemma. We think it is known; however, we have not found it in the literature. For $q \ge s-1$, define

$$\mathrm{B}(q,s) := \sum_{|\mathbf{i}| \ge q+1} 2^{-|\mathbf{i}|}. \tag{10}$$

Lemma 2. *For every $q \ge s-1$,*

$$\mathrm{B}(q,s) = 2^{-q} \sum_{j=0}^{s-1} \binom{q}{j} \le \overline{\mathrm{B}}(q,s), \tag{11}$$

where

$$\overline{\mathrm{B}}(q,s) := s\,2^{-q} \begin{cases} \binom{q}{\lfloor \frac{q+1}{2} \rfloor} & \textit{if } 2s \geq q+3, \\ \binom{q}{s-1} & \textit{otherwise.} \end{cases} \tag{12}$$

Proof of Lemma 2. Indeed,

$$\mathrm{B}(q,s) = \sum_{j=q+1}^{\infty} 2^{-j} \binom{j-1}{s-1}$$

and

$$\begin{aligned} 2^{-j}\binom{j-1}{s-1} &= 2^{-s} \cdot 2^{-(j-s)} \cdot \frac{(j-1)\cdots(j-s+1)}{(s-1)!} \\ &= \frac{x^s}{(s-1)!} \cdot \left(x^{j-1}\right)^{(s-1)} \Big|_{x=1/2}. \end{aligned}$$

Taking the summation with respect to j inside the differentiation, we get

$$\begin{aligned} \mathrm{B}(q,s) &= \frac{x^s}{(s-1)!} \left(\sum_{j=q+1}^{\infty} x^{j-1} \right)^{(s-1)} \Bigg|_{x=1/2} = \frac{x^s}{(s-1)!} \left(\frac{x^q}{1-x} \right)^{(s-1)} \Bigg|_{x=1/2} \\ &= \frac{x^s}{(s-1)!} \sum_{j=0}^{s-1} \binom{s-1}{j} \left(x^q\right)^{(j)} \left((1-x)^{-1}\right)^{(s-1-j)} \Bigg|_{x=1/2} \\ &= x^s \sum_{j=0}^{s-1} \frac{1}{j!(s-1-j)!} \cdot x^{q-j} \cdot q \cdots (q-j+1) \cdot \frac{(s-1-j)!}{(1-x)^{s-j}} \Bigg|_{x=1/2}, \end{aligned}$$

which, after some elementary manipulation, can be shown to be equal to $2^{-q} \sum_{j=0}^{s-1} \binom{q}{j}$. This completes the proof of (11). The upper bound $\overline{\mathrm{B}}(q,s)$ follows from this and the well-known fact that $\binom{q}{j-1} \leq \binom{q}{j}$ iff $2j \leq q+1$. This completes the proof of Lemma 2. □

Proof of Theorem 2. Note that for any scalar function $f \in \mathcal{H}_k$, $A_{k,n}(f)$ converges pointwise to f with $n \to \infty$ and that $\sum_{i=1}^{n} \Delta_{k,i} = A_{k,n}$. Therefore,

$$f(\mathbf{x}) = \sum_{\mathbf{i} \in \mathbb{N}_+^s} \bigotimes_{k=1}^{s} \Delta_{k,i_k}(f)(\mathbf{x})$$

for any $\mathbf{x}$ and any $f \in \mathcal{F}_{1,s}$. Here and elsewhere, by $\sum_{\mathbf{i} \in \mathbb{N}^s}$ we mean a double sum $\sum_{\ell=s}^{\infty} \sum_{|\mathbf{i}|=\ell}$. Hence

$$f - \mathcal{A}_{q,s}(f) = \mathcal{E}_{q,s}(f) \quad \text{with} \quad \mathcal{E}_{q,s}(f) := \sum_{|\mathbf{i}| \geq q+1} \bigotimes_{k=1}^{s} \Delta_{k,i_k}(f).$$

Due to (5) and the fact that $\mathcal{E}_{q,s}$ vanishes on constant functions,

$$\mathcal{E}_{q,s}(f) = \sum_{U \neq \emptyset} \int_{D_U} f'_U(\mathbf{t}_U)\, \mathcal{E}_{q,s}(M_U(\cdot, \mathbf{t}_U))\, d\mathbf{t}_U,$$

which yields

$$\|(f-\mathcal{A}_{q,s}(f))\,\rho\|_{L_1} \le \|f\|_{1,s}\cdot \sup_{\mathbf{t}\in D}\max_{U\neq\emptyset}\|\rho\,\mathcal{E}_{q,s}(M_U(\cdot,\mathbf{t}_U))\|_{L_1}.$$

Hence, to complete the proof, we only need to estimate the above supremum. For that purpose, note that

$$\bigotimes_{k=1}^{s}\Delta_{k,i_k}(M_U(\cdot,\mathbf{t}_U))\equiv 0 \quad \text{if } i_k\ge 2 \text{ for some } k\notin U.$$

This follows from the fact that $\Delta_{k,i}(1)\equiv 0$ for any $i\ge 2$, which, in turn, is a consequence of the fact that $A_{k,i}(1)\equiv 1$ for any $i\ge 1$. Otherwise, i.e., when $i_k=1$ for all $k\notin U$,

$$\left\|\rho\bigotimes_{k=1}^{s}\Delta_{k,i_k}(M_U(\cdot,\mathbf{t}_U))\right\|_{L_1} = \prod_{k\in U}\|\rho_k\,\Delta_{k,i_k}(M_k(\cdot,t_k))\|_{L_1} \le \prod_{k\in U}2^{-i_k},$$

independently of $\mathbf{t}$, due to Proposition 1. Therefore

$$(13)\qquad \|\rho\,\mathcal{E}_{q,s}(M_U(\cdot,\mathbf{t}_U))\|_{L_1} \le \sum_{\mathbf{i}}2^{-|\mathbf{i}|} \le \mathrm{B}(q-s+|U|,|U|) \le \overline{\mathrm{B}}(q-s+|U|,|U|)$$

with the summation in (13) over $\mathbf{i}\in\mathbb{N}^{|U|}$ such that $|\mathbf{i}|\ge q+1-(s-|U|)$. The first result in the theorem is proved by showing that $\overline{\mathrm{B}}(q-s+|U|,|U|)$ is increasing with $|U|$, i.e., $\max_U\overline{\mathrm{B}}(q-s+|U|,|U|)=\overline{\mathrm{B}}(q,s)$.

Consider first $q\ge 2(s-1)$. To see that $\overline{\mathrm{B}}(q-s+|U|,|U|)$ is increasing with $|U|$, note that

$$\begin{aligned}\frac{\overline{\mathrm{B}}(q-s+|U|+1,|U|+1)}{\overline{\mathrm{B}}(q-s+|U|,|U|)} &= \frac{(|U|+1)(q-s+|U|+1)}{2|U|^2}\\ &\ge \frac{q-s+|U|+1}{2|U|}\ge 1\end{aligned}$$

with the last inequality due to the fact that $|U|+1\le s$ and hence $|U|\le s-1\le q-s+1$.

Suppose now $q<2(s-1)$. To show that $\overline{\mathrm{B}}(q-s+|U|,|U|)$ increases with $|U|$ also in this case, we need to consider three different cases. Consider first $|U|>q-s+3$ (i.e., $2|U|>q-s+|U|+3$). Then

$$\begin{aligned}\frac{\overline{\mathrm{B}}(q-s+|U|+1,|U|+1)}{\overline{\mathrm{B}}(q-s+|U|,|U|)} &= \frac{|U|+1}{2|U|}\binom{q-s+|U|+1}{\lfloor\frac{q-s+|U|+2}{2}\rfloor}\Big/\binom{q-s+|U|}{\lfloor\frac{q-s+|U|+1}{2}\rfloor}\\ &= \frac{|U|+1}{|U|}\,\frac{2\ell+1}{2\ell+2}>1\end{aligned}$$

with the last equality due to an extra assumption that $q-s+|U|=2\ell$ (the proof for odd $q-s+|U|$ is very similar).

Consider next the case of $|U|=q-s+2$. Then

$$\frac{\overline{\mathrm{B}}(q-s+|U|+1,|U|+1)}{\overline{\mathrm{B}}(q-s+|U|,|U|)} = \frac{(q-s+3)(2q-2s+3)}{(q-s+2)(2q-2s+4)}\ge 1.$$

Consider now $|U|+1<q-s+3$. Then

$$\begin{aligned}\frac{\overline{\mathrm{B}}(q-s+|U|+1,|U|+1)}{\overline{\mathrm{B}}(q-s+|U|,|U|)} &= \frac{|U|+1}{2|U|}\binom{q-s+|U|+1}{|U|}\Big/\binom{q-s+|U|}{|U|-1}\\ &= \frac{(|U|+1)(q-s+|U|+1)}{2|U|^2}\geq 1.\end{aligned}$$

This completes the proof of the first part of the theorem.

Assume now that (4) holds. Then

$$\bigotimes_{k=1}^{s}\Delta_{k,i_k}(M_U(\cdot,\mathbf{t}_U))\equiv 0 \quad \text{if } i_k=1 \text{ for some } k\in U$$

as follows directly from the second part of Proposition 1. This means that the sum in (13) is now over $\mathbf{i}\in\mathbb{N}^{|U|}$ such that $|\mathbf{i}|\geq\max\{q+1-s+|U|,2|U|\}$ and $\mathbf{i}\geq\mathbf{2}$. Replacing $\mathbf{i}$ by $\mathbf{j}=\mathbf{i}-\mathbf{1}$, the sum becomes

$$(14)\qquad 2^{-|U|}\sum_{|\mathbf{j}|\geq\max\{q+1-s,|U|\}}2^{-|\mathbf{j}|}=2^{-|U|}\cdot\mathrm{B}(\max\{q-s,|U|-1\},|U|).$$

Therefore, for $|U|<q-s+1$ we have

$$(15)\qquad \|\rho\,\mathcal{E}_{q,s}(M_U(\cdot,\mathbf{t}_U))\|_{L_1}\leq 2^{-q-|U|+s}\sum_{j=0}^{|U|-1}\binom{q-s}{j}$$

and for $|U|\geq q-s+1$ we have

$$(16)\qquad \|\rho\,\mathcal{E}_{q,s}(M_U(\cdot,\mathbf{t}_U))\|_{L_1}\leq 2^{-|U|}\leq 2^{-q+s-1}.$$

Since $|U|\leq s$, we have to have $q\leq 2s-1$ for the latter case to happen. To estimate the maximum of the upper bound with respect to $|U|$, we consider the following cases.

Case $q\geq 3(s-1)$. Then, because $q-s\geq 2|U|-3$, the right-hand side of (15) is bounded from above by $s\,2^{-q-|U|+s}\binom{q-s}{|U|-1}$, which can be shown to increase with $|U|$ as long as $|U|\leq 1+\lfloor(q-s+1)/3\rfloor$. Since $|U|\leq s$, this yields the upper bounds

$$\|\rho\,\mathcal{E}_{q,s}(M_U(\cdot,\mathbf{t}_U))\|_{L_1}\leq s\,2^{-q}\binom{q-s}{s-1},$$

if $q\geq 4(s-1)$, and

$$\|\rho\,\mathcal{E}_{q,s}(M_U(\cdot,\mathbf{t}_U))\|_{L_1}\leq s\,2^{-q+s-1-\lfloor\frac{q-s+1}{3}\rfloor}\binom{q-s}{\lfloor(q-s+1)/3\rfloor},$$

if $q/(s-1)\in[3,4)$.

Case $2(s-1)<q<3(s-1)$. First note that the right-hand side of (15) decreases with $|U|$ when $|U|>(q-s)/2$. This follows from the fact that the value of the right-hand side for $|U|$ minus the value for $|U|+1$ equals

$$2^{-q-|U|-1+s}\left(\sum_{j=0}^{|U|-1}\binom{q-s}{j}-\binom{q-s}{|U|}\right)\geq 0$$

as claimed. Moreover, for $|U| \le (q-s)/2$, the right-hand side of (15) is bounded by $s\,2^{-q-|U|+s}\binom{q-s}{|U|-1}$, which attains its maximum for $|U| = 1 + \lfloor (q-s+1)/3 \rfloor$. Hence again,

$$\|\rho\,\mathcal{E}_{q,s}(M_U(\cdot,\mathbf{t}_U))\|_{L_1} \le s\,2^{-q+s-1-\lfloor \frac{q-s+1}{3} \rfloor}\binom{q-s}{\lfloor (q-s+1)/3 \rfloor}.$$

Case $q \le 2(s-1)$. Due to (16), we need only to estimate the right-hand side of (15) for $|U| < q-s+1$. However, as in the previous case, it is bounded by $s\,2^{-q-|U^*|+s}\binom{q-s}{|U^*|-1}$ with $|U^*| = 1 + \lfloor (q-s+1)/3 \rfloor$. Since

$$s\,2^{-q+s-1-\lfloor \frac{q-s+1}{3} \rfloor}\binom{q-s}{\lfloor (q-s+1)/3 \rfloor} \ge 2^{-q+s-1},$$

the left-hand side of the above inequality is an upper bound on $\|\rho\,\mathcal{E}_{q,s}(M_U(\cdot_U,\mathbf{t}_U))\|_{L_1}$ also in this case. This completes the proof. □

We end this section by relating the error of $\mathcal{A}_{q,s}$ to its cardinality $\mathrm{card}(\mathcal{A}_{q,s})$.

THEOREM 3. *For every* $s \ge 2$ *and* $q \ge 2(s-1)$,

$$\text{(17)} \qquad \mathrm{error}(\mathcal{A}_{q,s}) \le \frac{s\,\exp\left(\frac{1}{12(s-1)}\right)}{(s-1)\pi}\left(\frac{e\,\ln(\mathrm{card}(\mathcal{A}_{q,s}))}{(s-1)\sqrt{2}\ln(2)}\right)^{2(s-1)}\frac{1}{\mathrm{card}(\mathcal{A}_{q,s})}.$$

Proof. Since the information used by $\mathcal{A}_{q,s}$ is nested, we know from [25, Lem. 7] that

$$\text{(18)} \qquad 2^{q-s}\binom{q-1}{s-1} \le \mathrm{card}(\mathcal{A}_{q,s}) \le 2^{q-s+1}\binom{q-1}{s-1}.$$

Let's represent q as $q = (t+1)(s-1)$ with $t \ge 1$. We apply Stirling's formula ($n! = (n/e)^n\sqrt{2\pi n}\exp(\theta/(12n))$ for $\theta \in (0,\pi)$) to the error bound from Theorem 2; one can show that

$$\begin{aligned}\mathrm{error}(\mathcal{A}_{q,s}) &\le s\,2^{-(t+1)(s-1)}\binom{(t+1)(s-1)}{s-1}\\ &\le s\,2^{-(t+1)(s-1)}\,((t+1)e)^{s-1}\sqrt{\frac{t+1}{t2\pi(s-1)}}\,\exp\left(\frac{1}{12q}\right)\\ &\le s\,2^{-(t+1)(s-1)}\,((t+1)e)^{s-1}\sqrt{\frac{\exp\left(\frac{1}{12(s-1)}\right)}{\pi(s-1)}},\end{aligned}$$

with the last inequality due to the fact that $t \ge 1$. Similarly,

$$\mathrm{card}(\mathcal{A}_{q,s}) \le 2^{t(s-1)}\,(e(t+1))^{s-1}\sqrt{\frac{\exp\left(\frac{1}{12(s-1)}\right)}{\pi(s-1)}}.$$

Since $x/(\ln(x))^{2(s-1)}$ increases for $x \ge e^{2(s-1)}$, and since $\mathrm{card}(\mathcal{A}_{q,s}) \ge e^{2(s-1)}$ due to (18), we can replace $\mathrm{card}(\mathcal{A}_{q,s})$ by the right-hand side of the above inequality in the following estimation:

$$\begin{aligned}L &:= \frac{\mathrm{card}(\mathcal{A}_{q,s})\ \mathrm{error}(\mathcal{A}_{q,s})}{(\ln(\mathrm{card}(\mathcal{A}_{q,s})))^{2(s-1)}}\\ &\le \frac{s\,\exp\left(\frac{1}{12(s-1)}\right)}{\pi(s-1)}\,2^{-(s-1)}\left(\frac{e}{s-1}\,g(t)\right)^{2(s-1)},\end{aligned}$$

with

$$g(t) := \frac{t+1}{t\ln(2)+\ln(t+1)}$$

since $s-1-\ln(\pi(s-1))/2$ is positive. It is easy to verify that $\max_{t\geq 1} g(t) = 1/\ln(2)$. This yields

$$\begin{aligned} L &\leq \frac{s\ \exp\left(\frac{1}{12(s-1)}\right)}{(s-1)\pi}\, 2^{-(s-1)} \left(\frac{e}{(s-1)\ln(2)}\right)^{2(s-1)} \\ &= \frac{s\ \exp\left(\frac{1}{12(s-1)}\right)}{(s-1)\pi} \left(\frac{e}{(s-1)\sqrt{2}\ln(2)}\right)^{2(s-1)}, \end{aligned}$$

which completes the proof. □

5. Extensions. In this section, we extend some of the previous results assuming now that the functions f are from the space $\mathcal{F} = \mathcal{F}_{p,s,\gamma}$, which is the completion of $\mathcal{H}^s$ with respect to the norm

$$\|f\|_{p,s,\gamma} := \left(|f(\mathbf{c})|^p + \sum_{U\neq\emptyset} \gamma_{s,U}^{-p}\, \|f'_U\|_{L_p}^p\right)^{1/p} = \left(\sum_U \gamma_{s,u}^{-p} \|f'_U\|_{L_p}^p\right)^{1/p},$$

where $p \in [1,\infty]$ and $\gamma = \{\gamma_{s,u}\}_{s,U}$ is a family of nonnegative numbers, called weights. By a convention $0/0 = 0$. Of course, for $p = \infty$ we have $\|f\|_{\infty,s} = \max_U \gamma_{s,U}^{-1} \|f'_U\|_{L_\infty}$. This norm differs from $\|\cdot\|_{1,s}$ by using L_p instead of L_1-norms and by adding the weights $\gamma_{s,U}$.

The role of $\gamma_{s,U}$ is that they model how important certain variables and their groups are. For instance, the condition of small enough $\gamma_{s,U}$ means that $\|f'_U\|_{L_p}$ cannot be too large, and $\gamma_{s,U} = 0$ implies that $\|f'_U\|_{L_p} = 0$. Since the introduction of weighted norms in [20], high dimensional problems with such norms have been investigated in a number of papers; see, e.g., [15] and papers cited there. It is often the case that if the weights are small enough, then the error in solving a high dimensional problem is essentially no worse than that for solving a one-dimensional problem.

To stress that now a different space from $\mathcal{F}_{1,s}$ is being considered, we will write error$(\mathcal{A}; \mathcal{F}_{p,s,\gamma})$ instead error$(\mathcal{A})$. When all weights equal 1, we will simply write $\mathcal{F}_{p,s}$. For simplicity, we assume throughout this section that (4) is satisfied and that $\mathbf{c} = \mathbf{0}$. Hence, in particular $a_k < 0 < b_k$.

Note that for $p > 1$ and unbounded D it could happen that the approximation problem is not well defined since the corresponding embedding operator could be unbounded. As follows from [27, Thm. 1], the problem is well defined iff

$$\left(\int_{a_k}^{b_k} \psi_k^{p^*}(x)\,dx\right)^{1/p^*} < \infty \quad \forall k, \tag{19}$$

with

$$\psi_k(t) = \begin{cases} \int_t^{b_k} \rho_k(x)\,dx & \text{for } t \geq 0, \\ \int_{a_k}^{t} \rho_k(x)\,dx & \text{otherwise,} \end{cases} \tag{20}$$

where here and elsewhere p^* denotes the conjugate to p, i.e.,

$$\frac{1}{p}+\frac{1}{p^*}=1.$$

This is why we assume (19) throughout the rest of this paper. Of course, (19) trivially holds when D is bounded. It also holds for $p=1$ since then $p^*=\infty$ and the left-hand side of (19) should formally be replaced by $\operatorname{ess\,sup}_{t\ge c_k}\int_t^{b_k}\rho_k(x)\,dx$, which obviously is equal to $1/2$.

THEOREM 4. *The error of any algorithm $\mathcal{A}$ is bounded by*

$$\text{(21)}\qquad \operatorname{error}(\mathcal{A};\mathcal{F}_{p,s,\gamma})\le\left(\sum_U\gamma_{s,U}^{p^*}\int_{D_U}\left(\int_{D_U}h_U(\mathbf{x}_U,\mathbf{t}_U)\,d\mathbf{x}_U\right)^{p^*}d\mathbf{t}_U\right)^{1/p^*},$$

where

$$h_U(\mathbf{x}_U,\mathbf{t}_U)=\rho_U(\mathbf{x}_U)\,|M_U(\mathbf{x}_U,\mathbf{t}_U)-\mathcal{A}(M_U(\cdot,\mathbf{t}_U))(\mathbf{x}_U)|.$$

If $\mathcal{A}$ is based on piecewise constant interpolation, then we have equality in (21).

Proof. To simplify the notation, we write $m(\mathbf{x}_U,\mathbf{t}_U)$ to denote

$$m(\mathbf{x}_U,\mathbf{t}_U):=M(\mathbf{x}_U,\mathbf{t}_U)-\mathcal{A}(M(\cdot,\mathbf{t}_U))(\mathbf{x}_U).$$

Of course, $h_U(\mathbf{x}_U,\mathbf{t}_U)=\rho_U(\mathbf{x}_U)\,|m_U(\mathbf{x}_U,\mathbf{t}_U)|$.

Suppose that $p>1$. We begin with the proof of (21). Using (5), we have by Hölder's inequality

$$\begin{aligned}
&\int_D\rho(\mathbf{x})\,|f(\mathbf{x})-\mathcal{A}(f)(\mathbf{x})|\,d\mathbf{x}\\
&\quad=\int_D\rho(\mathbf{x})\left|\sum_U\int_{D_U}f_U'(\mathbf{t}_U)\,m_U(\mathbf{x}_U,\mathbf{t}_U)\,d\mathbf{t}_U\right|\,d\mathbf{x}_U\\
&\quad\le\sum_U\int_{D_U}\rho_U(\mathbf{x}_U)\int_{D_U}|f_U'(\mathbf{t}_U)\,m_U(\mathbf{x}_U,\mathbf{t}_U)|\,d\mathbf{t}_U\,d\mathbf{x}_U\\
&\quad=\sum_U\int_{D_U}|f_U'(\mathbf{t}_U)|\int_{D_U}h_U(\mathbf{x}_U,\mathbf{t}_U)\,d\mathbf{x}_U\,d\mathbf{t}_U\\
&\quad\le\sum_U\|f_U'\|_{L_p}\,\gamma_{s,U}^{-1}\left(\gamma_{s,U}^{p^*}\int_{D_U}\left(\int_{D_U}h_U(\mathbf{x}_U,\mathbf{t}_U)\,d\mathbf{x}_U\right)^{p^*}d\mathbf{t}_U\right)^{1/p^*}\\
&\quad\le\|f\|_{p,s,\gamma}\left(\sum_U\gamma_{s,U}^{p^*}\int_{D_U}\left(\int_{D_U}h_U(\mathbf{x}_U,\mathbf{t}_U)\,d\mathbf{x}_U\right)^{p^*}d\mathbf{t}_U\right)^{1/p^*}.
\end{aligned}$$

This proves (21) for $p>1$. We now show equality when $\mathcal{A}(m_U(\cdot,\mathbf{t}_U))$ is a piecewise constant function interpolating $m_U(\cdot,t_U)$. To that end, define

$$g_U(\mathbf{t}_U):=\operatorname{sign}(\mathbf{t}_U)\left(\int_{D_U}h(\mathbf{x}_U,\mathbf{t}_U)\,d\mathbf{x}_U\right)^{p^*-1}\quad\text{with}\quad\operatorname{sign}(\mathbf{t}_U):=\prod_{k\in U}\operatorname{sign}(t_k),$$

and

$$\widetilde{f}(\mathbf{y}):=\sum_U\gamma_{s,U}^{p^*}\int_{D_U}g_U(\mathbf{t}_U)\,M_U(\mathbf{y}_U,\mathbf{t}_U)\,d\mathbf{t}_U.$$

Of course, from (5), $\widetilde{f} \in \mathcal{F}_{p,s,\gamma}$ and $\widetilde{f}'_U = \gamma_{s,U}^{p^*} g_U$. Since $p p^* - p = p^*$, it is easy to check that

$$\|\widetilde{f}\|_{p,s,\gamma}, = \left(\sum_U \gamma_{s,U}^{p^*} \int_{D_U} \left(\int_{D_U} h_U(\mathbf{x}_U, \mathbf{t}_U)\, d\mathbf{x}_U \right)^{p^*} d\mathbf{t}_U \right)^{1/p}.$$

Moreover,

$$\begin{aligned}
\|(\widetilde{f} - \mathcal{A}(\widetilde{f}))\,\rho\|_{L_1} &= \int_D \rho(\mathbf{y})\, |\widetilde{f}(\mathbf{y}) - \mathcal{A}(\widetilde{f})(\mathbf{y})|\, d\mathbf{y} \\
&= \int_D \rho(\mathbf{y}) \left| \sum_U \gamma_{s,U}^{p^*} \int_{D_U} g_U(\mathbf{t}_U)\, m(\mathbf{y}_U, \mathbf{t}_U)\, d\mathbf{t}_U \right| d\mathbf{y} \\
&= \int_D \rho(\mathbf{y}) \left| \sum_U \gamma_{s,U}^{p^*} \int_{D_U} \left(\int_{D_U} h(\mathbf{x}_U, \mathbf{t}_U)\, d\mathbf{x}_U \right)^{p^*-1} \operatorname{sign}(\mathbf{t}_U)\, m(\mathbf{y}_U, \mathbf{t}_U)\, d\mathbf{t}_U \right| d\mathbf{y} \\
&= \sum_U \gamma_{s,U}^{p^*} \int_{D_U} \left(\int_{D_U} h(\mathbf{x}_U, \mathbf{t}_U)\, d\mathbf{x}_U \right)^{p^*-1} \int_{D_U} h(\mathbf{y}_U, \mathbf{t}_U)\, d\mathbf{y}_U\, d\mathbf{t}_U \\
&= \sum_U \gamma_{s,U}^{p^*} \int_{D_U} \left(\int_{D_U} h_U(\mathbf{x}_U, \mathbf{t}_U)\, d\mathbf{x}_U \right)^{p^*} d\mathbf{t}_U = \|\widetilde{f}\|_{p,s,\gamma}^p,
\end{aligned}$$

with the third-to-last equality due to the fact that

$$\operatorname{sign}(\mathbf{t}_U)\, m(\mathbf{y}_U, \mathbf{t}_U) = |m(\mathbf{y}_U, \mathbf{t}_U)| \ge 0 \quad \forall \mathbf{y}, \mathbf{t}.$$

Dividing $\|(\widetilde{f} - \mathcal{A}(\widetilde{f}))\,\rho\|_{L_1}$ by $\|\widetilde{f}\|_{p,s,\gamma}$ to obtain $\|\widetilde{f}\|_{p,s,\gamma}^{p-1} = \|\widetilde{f}\|_{p,s,\gamma}^{p/p^*}$ on the right completes the proof of the equality for $p > 1$.

For $p = 1$ the proof technique is the same with obvious modifications. □

Let $\mathcal{A}_{q,s}$ be the algorithm from section 4 and denote

$$\delta_{U,\mathbf{i}_U}(\mathbf{x}_U, \mathbf{t}_U) := \Delta_{U,\mathbf{i}_U}(M_U(\cdot, \mathbf{t}_U))(\mathbf{x}_U) = \prod_{k \in U} \delta_{k,i_k}(x_{i_k}, t_{i_k}).$$

From Lemma 1, we have the following proposition.

PROPOSITION 2. *Let $U \neq \emptyset$ and $\mathbf{t}_U \in D_U$. Then the following hold.*

(i) *For every $\mathbf{x}_U \in D_U$, $\delta_{U,\mathbf{i}_U}(\mathbf{x}_U, \mathbf{t}_U) \in \{-1, 0, 1\}$.*

(ii) *For every $\mathbf{x} \in D_U$ there exists at most one $\mathbf{i}_U$ such that $|\delta_{U,\mathbf{i}_U}(\mathbf{x}_U, \mathbf{t}_U)| = 1$.*

(iii) *For every $\mathbf{i}$, the ρ_U-probability of the set of $\mathbf{x}_U$'s with $|\delta_{U,\mathbf{i}_U}(\mathbf{x}_U, \mathbf{t}_U)| = 1$ is at most $2^{-|\mathbf{i}_U|}$.*

(iv) *If $\delta_{U,\mathbf{i}_U}(\mathbf{x}_U, \mathbf{t}_U) \neq 0$ for some $\mathbf{x}$ and $\mathbf{i}$, then $t_k \in [x_{i_k,1}^k, x_{i_k,2^{i_k}-1}^k]$ for every $k \in U$.*

As in the proof of Theorem 2, let $\mathcal{E}_{q,s}(f) = \sum_{|\mathbf{i}| \ge q+1} \bigotimes_{k=1}^s \Delta_{k,i_k}(f)$. Recall that $\Delta_{\mathbf{i}}(M_U(\cdot, \mathbf{t}_U)) \equiv 0$ if either $i_k = 1$ for some $k \in U$, or $i_k \ge 2$ for some $k \notin U$. Hence

$$\mathcal{E}_{q,s}(M_U(\cdot, \mathbf{t}_U))(\mathbf{x}_U) = \sum_{\mathbf{i}_U \in P(q,s,U)} \delta_{U,\mathbf{i}_U}(\mathbf{x}_U, \mathbf{t}_U)$$

with

$$P(q,s,U) = \left\{ \mathbf{j} \in \mathbb{N}_+^{|U|} \,:\, \mathbf{j} \ge \mathbf{2}, |\mathbf{j}| \ge q + 1 - s + |U| \right\}.$$

From Theorem 4, this yields

$$\mathrm{error}(\mathcal{A}_{q,s}, \mathcal{F}) = \left(\sum_{U \neq \emptyset} \gamma_{s,U}^{p^*} \int_{D_U} b_U^{p^*}(\mathbf{t}_U)\, d\mathbf{t}_U \right)^{1/p^*},$$

where

$$b_U(\mathbf{t}_U) := \left| \int_{D_U} \rho_U(\mathbf{x}_U) \sum_{\mathbf{i}_U \in P(q,s,U)} \delta_{U,\mathbf{i}_U}(\mathbf{x}_U, \mathbf{t}_U)\, d\mathbf{x}_U \right|. \tag{22}$$

Due to its definition (20), $\psi_k(t)$ converges to zero with $t \to b_k$ and/or $t \to a_k$. Moreover, from (iv) of Proposition 2, we know that

$$\delta_{U,\mathbf{i}_U}(\mathbf{x}_U, \mathbf{t}_U) \neq 0 \quad \text{implies } \psi_k(t_k) \geq 2^{-i_k} \text{ for every } k \in U.$$

This means that we can replace the set $P(q, s, U)$ by the even smaller set

$$P(q, s, U, \mathbf{t}_U) = \left\{ \mathbf{j} \in \mathbb{N}_+^{|U|} \,:\, \mathbf{j} \geq \mathbf{2},\ |\mathbf{j}| \geq q + 1 - s + |U|, \text{ and } 2^{-j_k} \leq \psi_k(t_k),\ \forall\, k \in U \right\}.$$

This leads to

$$\begin{aligned} b_U(\mathbf{t}_U) &\leq \sum_{\mathbf{j} \in P(q,s,U,\mathbf{t}_U)} 2^{-\mathbf{j}} \\ &\leq \min \left\{ 2^{|U|}\, \psi_U(\mathbf{t}_U)\, ,\, 2^{-|U|}\ \mathrm{B}(\max\{q - s, |U| - 1\}, |U|) \right\}, \end{aligned}$$

where, as always, $\psi_U(\mathbf{t}_U) = \prod_{k \in U} \psi_k(t_k)$. We summarize this in the following proposition.

PROPOSITION 3. *Let* (4) *hold. Then for any $s \geq 2$ and any $q \geq s$,*

$$\mathrm{error}(\mathcal{A}_{q,s,\gamma}; \mathcal{F}_{p,s,\gamma}) = \left(\sum_{U \neq \emptyset} \gamma_{s,U}^{p^*} \int_{D_U} b_U^{p^*}(\mathbf{t}_U)\, d\mathbf{t}_U \right)^{1/p^*}.$$

Moreover,

$$b_U(\mathbf{t}_U) \leq \min \left\{ 2^{|U|}\, \psi_U(\mathbf{t}_U)\, ,\, \frac{\mathrm{B}(\max\{q - s, |U| - 1\}, |U|)}{2^{|U|}} \right\}.$$

For $p > 1$ and unbounded D, the above error bound is quite complicated, due to the presence of integrals of $b_U^{p^*}$. Suppose now that D is bounded, say

$$D = [0, 1]^s.$$

Then the integrals of b_U^* can be replaced by $\mathrm{B}(\max\{q - s, |U| - 1\}, |U|)\, 2^{-|U|}$ leading to the following upper bound:

$$\mathrm{error}(\mathcal{A}_{q,s}; \mathcal{F}_{p,s,\gamma}) \leq \left(\sum_{U \neq \emptyset} \left(2^{-|U|}\, \gamma_{s,U}\ \mathrm{B}(\max\{q - s, |U| - 1\}, |U|) \right)^{p^*} \right)^{1/p^*}. \tag{23}$$

Of course, if $p = 1$, then $p^* = \infty$ and the bound (23) takes the form

$$\mathrm{error}(\mathcal{A}_{q,s}; \mathcal{F}_{1,s}) \le \max_{U \neq \emptyset} 2^{-|U|}\, \gamma_{s,U}\ \mathrm{B}(\max\{q-s, |U|-1\}, |U|),$$

which coincides with the bound from section 4 for the case when (3) holds. For $p > 1$, (23) can be further estimated from above, leading to

$$\mathrm{error}(\mathcal{A}_{q,s}; \mathcal{F}_{p,s,\gamma}) \le 2^{s/p^*} \max_{U \neq \emptyset} 2^{-|U|}\, \gamma_{s,U}\ \mathrm{B}(\max\{q-s, |U|-1\}, |U|).$$

This means that error upper bounds from section 4 also hold for $p > 1$ modulo the multiplicative factor $2^{s/p^*}$. In particular, we have the following consequence of Theorem 3.

THEOREM 5. *Let $p > 1$, $\gamma_{s,U} \equiv 1$, and $D = [0,1]^s$. Then for every $s \ge 2$ and $q \ge 2(s-1)$,*

$$\mathrm{error}(\mathcal{A}_{q,s}; \mathcal{F}_{p,s}) \le \frac{s \exp\left(\frac{1}{12(s-1)}\right), 2^{1/p^*}}{(s-1)\pi} \left(\frac{e \ln(\mathrm{card}(\mathcal{A}_{q,s}))}{(s-1)\, 2^{1/(2p^*)} \ln(2)}\right)^{2(s-1)} \frac{1}{\mathrm{card}(\mathcal{A}_{q,s})}.$$

6. Integration problem.

In this section, we briefly discuss the problem of approximating weighted integrals

$$I_\rho(f) = \int_D f(\mathbf{x})\, \rho(\mathbf{x})\, d\mathbf{x}$$

by algorithms (often called quadratures) $\mathcal{Q}$ of the form $\mathcal{Q}(f) = \sum_{i=1}^n f(\mathbf{x}^i)\, g_i$. The *worst case error* of $\mathcal{Q}$ (with respect to $\mathcal{F}_{p,s}$) is defined by

$$\mathrm{error}(\mathcal{Q}; \mathcal{F}_{p,s}, \mathrm{Int}) := \sup_{\|f\|_{p,s} \le 1} |I_\rho(f) - \mathcal{Q}(f)|.$$

Consider now the following quadrature

$$\mathcal{Q}_{q,s}(f) := I_\rho(\mathcal{A}_{q,s}(f)). \tag{24}$$

It is easy to see that

$$\mathcal{Q}_{q,s} = \sum_{|\mathbf{i}| \le q} \bigotimes_{k=1}^{s} \left(Q_{k,i_k} - Q_{k,i_k-1}\right), \quad \text{where} \quad Q_{k,i}(f) = 2^{-i} \left(f(c_k) + \sum_{j=1}^{2^i-1} f(x_{i,j}^k)\right)$$

$x_{i,j}^k$ defined by (7). Clearly,

$$\mathrm{error}(\mathcal{Q}_{q,s}; \mathcal{F}_{p,s}, \mathrm{Int}) \le \mathrm{error}(\mathcal{A}_{q,s}; \mathcal{F}_{p,s}).$$

Hence all error bounds for $\mathcal{A}_{q,s}$ obtained in the previous sections also hold for $\mathcal{Q}_{q,s}$.

A POSTERIORI ERROR ESTIMATES FOR THE MORTAR MIXED FINITE ELEMENT METHOD[*]

MARY F. WHEELER[†] AND IVAN YOTOV[‡]

Abstract. Several a posteriori error estimators for mortar mixed finite element discretizations of elliptic equations are derived. A residual-based estimator provides optimal upper and lower bounds for the pressure error. An efficient and reliable estimator for the velocity and mortar pressure error is also derived, which is based on solving local (element) problems in a higher-order space. The interface flux-jump term that appears in the estimators can be used as an indicator for driving an adaptive process for the mortar grids only.

Key words. mixed finite element, mortar finite element, nonmatching grids, a posteriori error estimates, adaptive mesh refinement

AMS subject classifications. 65N12, 65N15, 65N30, 65N50

DOI. 10.1137/S0036142903431687

1. Introduction.

We consider the second order elliptic problem written as a system of two first order equations

$$\mathbf{u} = -K\nabla p \quad \text{in } \Omega, \tag{1.1}$$

$$\nabla \cdot \mathbf{u} = f \quad \text{in } \Omega, \tag{1.2}$$

$$p = g \quad \text{on } \Gamma_D, \tag{1.3}$$

$$\mathbf{u} \cdot \nu = 0 \quad \text{on } \Gamma_N, \tag{1.4}$$

where $\Omega \subset \mathbf{R}^d$, $d = 2$ or 3, is a multiblock domain with a boundary $\partial\Omega = \overline{\Gamma}_D \cup \overline{\Gamma}_N$, $\Gamma_D \cap \Gamma_N = \emptyset$, measure $(\Gamma_D) > 0$, ν is the outward unit normal on $\partial\Omega$, and K is a symmetric, uniformly positive definite tensor satisfying, for some $0 < k_0 \leq k_1 < \infty$,

$$k_0\xi^T\xi \leq \xi^T K(x)\xi \leq k_1\xi^T\xi \quad \forall x \in \Omega \quad \forall \xi \in \mathbf{R}^d. \tag{1.5}$$

In flow in porous media the above system models single-phase flow where p is the pressure, $\mathbf{u}$ is the Darcy velocity, and K represents the permeability divided by the viscosity.

A number of papers in recent years have studied the numerical solution of the above and related problems on multiblock domains with nonmatching grids across the interfaces. This growing interest is driven by the flexibility provided by the multiblock paradigm. Complicated geometries can be modeled as unions of relatively simple subdomains with locally constructed grids. Local features of the solution such as

corner singularities or large gradients can be resolved by finer grids in the local region. Large scale features such as geological faults and layers in subsurface flow can be modeled with nonmatching grids. Moreover, the resulting algebraic problem can be efficiently solved via parallel domain decomposition algorithms.

In a multiblock formulation, the equations are imposed locally on each subdomain and appropriate interface matching conditions are enforced on the interfaces. The use of mortar finite elements to impose the interface conditions is a popular approach due to its excellent stability and accuracy. For the use of mortars, the reader is referred to [10, 8, 20] and references therein for Galerkin finite element and finite volume methods, and to [40, 3, 9] in the context of mixed finite element methods.

An integral part of any successful computational method is the development of a posteriori error estimators and adaptive mesh refinement strategies. Although there is an enormous amount of literature on a posteriori error estimation and adaptivity on conforming grids (seminal works include [5, 7, 2, 35]), few papers deal with this issue for mortar finite element methods. In the case of Galerkin finite elements, error estimators have been developed in [37, 38, 30]. Even fewer results are available for the mortar mixed finite element method. Goal-oriented estimates and adaptivity are developed in [6]. Computational results from [36, 29] indicate that a judicious choice of mortar grids can lead to an accurate solution at low computational cost, but no rigorous justification is given. The goal of this paper is to develop a posteriori error estimators and an adaptive mesh refinement strategy for the mortar mixed finite element method.

Previous works on error estimation for mixed finite element methods on conforming grids include [11, 12, 17, 24, 39, 25]. In [11], mesh-dependent norms are utilized to obtain optimal residual-based error estimators. Estimators based on superconvergence error estimates are developed in [12, 24]. In [17, 39], the Helmholtz decomposition is used to derive optimal residual-based error estimators in the natural pressure and velocity norms. Hierarchical estimates and implicit estimates based on solving local problems are also investigated in [39]. Only the three-dimensional results are given in [25], where a duality argument is employed to obtain residual-based estimates. However, the velocity bounds derived there depend on a saturation assumption that may not hold in general.

In this paper we derive a posteriori error estimates that provide lower and upper bounds for the pressure, velocity, and mortar error in two and three dimensions. According to the widely accepted terminology, an estimator is referred to as *reliable* if it provides an upper bound of the error, whereas it is called *efficient* if it gives a lower bound. We employ a duality-type argument to obtain an efficient and reliable residual-based estimator for the pressure error. In addition to the usual element residual terms, the estimator involves a flux-jump term and a mortar pressure difference term on subdomain interfaces. A closely related estimator of the velocity and mortar error is also derived, which provides an optimal upper bound, but suboptimal (yet sharp) lower bound. We then proceed to derive an optimal efficient and reliable implicit estimator for the velocity based on solving local (element) problems in a higher-order space. Throughout the paper we make several reasonable saturation assumptions which are motivated by known a priori error estimates.

It was observed in [36, 29] that varying the mortar degrees of freedom while keeping the subdomain grids fixed has a substantial effect on the convergence of the interface algorithm employed to solve the algebraic system. At the same time mortar grids that are too coarse lead to deterioration of the accuracy of the method. Therefore, finding "optimal" mortar grids for given subdomain grids is an important question. The flux-jump term that appears in all estimators provides a stand-alone indicator of the nonconformity error in the mortar discretization. It can be used to drive an adaptive mesh refinement process for the mortar grids.

The rest of the paper is organized as follows. In the next section the mortar mixed finite element method is defined along with its equivalent interface formulation. In section 3, the residual-based error estimators are derived and analyzed. The implicit estimator for the velocity is developed in section 4. Computational results are presented in section 5, followed by some remarks and conclusions in section 6.

2. Formulation of the method and preliminaries. We will make use of the following standard notation. For a subdomain $G \subset \mathbf{R}^d$, the $L^2(G)$ inner product (or duality pairing) and norm are denoted by $(\cdot,\cdot)_G$ and $\|\cdot\|_G$, respectively, for scalar and vector valued functions. The Sobolev spaces $W_p^k(G)$, $k \in \mathbf{R}$, $1 \le p \le \infty$, are defined in the usual way [1] with the usual norm $\|\cdot\|_{k,p,G}$. Let $\|\cdot\|_{k,G}$ be the norm of the Hilbert space $H^k(G) = W_2^k(G)$. We omit G in the subscript if $G = \Omega$. For a section of a subdomain boundary $S \subset \cup_{i=1}^n \partial\Omega_i$ we write $\langle\cdot,\cdot\rangle_S$ and $\|\cdot\|_S$ for the $L^2(S)$ inner product (or duality pairing) and norm, respectively.

We assume that problem (1.1)–(1.4) is H^2-regular, i.e., there exists a positive constant C depending only on K and Ω such that

$$\|p\|_2 \le C(\|f\| + \|g\|_{3/2,\Gamma_D}). \tag{2.1}$$

We refer the reader to [23, 26, 21] for sufficient conditions for H^2-regularity.

To give the weak formulation of (1.1)–(1.4) we recall the usual velocity space [16]

$$H(\mathrm{div};\Omega) = \{\mathbf{v} \in (L^2(\Omega))^d : \nabla\cdot\mathbf{v} \in L^2(\Omega)\}$$

with a norm

$$\|\mathbf{v}\|_{H(\mathrm{div})} = (\|\mathbf{v}\|^2 + \|\nabla\cdot\mathbf{v}\|^2)^{1/2}$$

and define

$$\bar{\mathbf{V}} = \{\mathbf{v} \in H(\mathrm{div};\Omega) : \mathbf{v}\cdot\nu = 0 \text{ on } \Gamma_N\}.$$

A weak solution of (1.1)–(1.4) is $\mathbf{u} \in \bar{\mathbf{V}}$, $p \in L^2(\Omega)$ such that

$$(K^{-1}\mathbf{u},\mathbf{v}) = (p,\nabla\cdot\mathbf{v}) - \langle g,\mathbf{v}\cdot\nu\rangle_{\Gamma_D}, \quad \mathbf{v} \in \bar{\mathbf{V}}, \tag{2.2}$$

$$(\nabla\cdot\mathbf{u},w) = (f,w), \quad w \in L^2(\Omega). \tag{2.3}$$

It is well known (see, e.g., [16, 32]) that (2.2) and (2.3) have a unique solution.

Let $\Omega = \cup_{i=1}^n \Omega_i$ be a union of nonoverlapping subdomains. Let

$$\Gamma_{i,j} = \partial\Omega_i \cap \partial\Omega_j, \quad \Gamma = \cup_{i,j=1}^n \Gamma_{i,j}, \quad \Gamma_i = \partial\Omega_i \cap \Gamma = \partial\Omega_i \backslash \partial\Omega.$$

Let

$$\mathbf{V}_i = \{\mathbf{v} \in H(\mathrm{div};\Omega_i) : \mathbf{v}\cdot\nu_i \in L^2(\partial\Omega_i) \text{ and } \mathbf{v}\cdot\nu_i = 0 \text{ on } \partial\Omega_i \cap \Gamma_N\}, \quad \mathbf{V} = \bigoplus_{i=1}^n \mathbf{V}_i,$$

$$W_i = L^2(\Omega_i), \quad W = \bigoplus_{i=1}^n W_i = L^2(\Omega), \quad M = L^2(\Gamma).$$

It is easy to see that if the solution of (2.2) and (2.3) satisfies $\mathbf{u}\cdot\nu|_\Gamma \in L^2(\Gamma)$ and $p \in H^1(\Omega)$, then for $1 \le i \le n$

$$(K^{-1}\mathbf{u},\mathbf{v})_{\Omega_i} = (p,\nabla\cdot\mathbf{v})_{\Omega_i} - \langle \lambda, \mathbf{v}\cdot\nu_i\rangle_{\Gamma_i} - \langle g, \mathbf{v}\cdot\nu\rangle_{\partial\Omega_i\cap\Gamma_D}, \quad \mathbf{v}\in\mathbf{V}_i, \tag{2.4}$$

$$(\nabla\cdot\mathbf{u}, w)_{\Omega_i} = (f,w)_{\Omega_i}, \quad w \in W_i, \tag{2.5}$$

$$\sum_{i=1}^n \langle \mathbf{u}\cdot\nu_i, \mu\rangle_{\Gamma_i} = 0, \quad \mu \in M, \tag{2.6}$$

where $\lambda = p|_\Gamma$. (2.4)–(2.6) imply that $(\mathbf{u}, p, \lambda) \in \mathbf{V}\times W\times M$ satisfy

$$A(\mathbf{u},p,\lambda;\mathbf{v},w,\mu) = L(\mathbf{v},w,\mu) \quad \forall\ (\mathbf{v},w,\mu)\in\mathbf{V}\times W\times M, \tag{2.7}$$

where

$$\begin{aligned} &A(\mathbf{u},p,\lambda;\mathbf{v},w,\mu) \\ &\quad = \sum_{i=1}^n \big((K^{-1}\mathbf{u},\mathbf{v})_{\Omega_i} - (p,\nabla\cdot\mathbf{v})_{\Omega_i} + \langle\lambda,\mathbf{v}\cdot\nu_i\rangle_{\Gamma_i} + \sigma(\nabla\cdot\mathbf{u},w)_{\Omega_i} - \sigma\langle\mathbf{u}\cdot\nu_i,\mu\rangle_{\Gamma_i}\big)\end{aligned}$$

and

$$L(\mathbf{v},w,\mu) = \sigma(f,w) - \langle g, \mathbf{v}\cdot\nu\rangle_{\Gamma_D}.$$

Here $\sigma = 1$ or $\sigma = -1$. If $\sigma = -1$, $A(\cdot;\cdot)$ is a symmetric bilinear form, which we denote by $A^s(\cdot;\cdot)$. If $\sigma = 1$, we denote $A(\cdot;\cdot)$ by $A^c(\cdot;\cdot)$ and note that

$$A^c(\mathbf{v},w,\mu;\mathbf{v},w,\mu) = (K^{-1}\mathbf{v},\mathbf{v});$$

thus $A^c(\cdot;\cdot)$ is nonsymmetric, but coercive. Note that the solution does not depend on the choice of σ.

Let $\{\mathcal{T}_{h,i}\}_h$ be a family of finite element partitions of Ω_i, $1\le i\le n$. Let, for any $E\in\mathcal{T}_{h,i}$, $h_E = \operatorname{diam}(E)$ and let

$$h_i = \max_{E\in\mathcal{T}_{h,i}} h_E, \quad h = \max_{1\le i\le n} h_i.$$

Define ρ_E to be the largest diameter of a ball contained in $\overline{E}$. We require that each subdomain grid satisfies the nondegeneracy condition

$$\max_{E\in\mathcal{T}_{h,i}} \frac{h_E}{\rho_E} \le c_0,$$

where the constant c_0 is independent of h_i. The partitions $\mathcal{T}_{h,i}$ and $\mathcal{T}_{h,j}$ may be nonmatching along $\Gamma_{i,j}$. Let $\mathcal{T}_h = \cup_{i=1}^n \mathcal{T}_{h,i}$ and let $\mathcal{E}_h$ be the union of all interior edges (faces) not including the interfaces and the outer boundary. Let

$$\mathbf{V}_{h,i}\times W_{h,i} \subset \mathbf{V}_i\times W_i$$

be any of the usual mixed finite element spaces (i.e., the RTN spaces [34, 31, 27], BDM spaces [15], BDFM spaces [14], BDDF spaces [13], or CD spaces [18]). The order of the spaces is assumed to be the same on every subdomain. Let

$$\mathbf{V}_h = \bigoplus_{i=1}^n \mathbf{V}_{h,i}, \quad W_h = \bigoplus_{i=1}^n W_{h,i}.$$

Note that this choice leads to a nonconforming approximation since the normal components of vectors in $\mathbf{V}_h$ do not have to be continuous across Γ. Throughout the paper we will abuse notation when using the $H(\text{div})$-norm. In particular, for $\mathbf{v} \in H(\text{div}; \Omega_i)$, $i = 1, \ldots, n$,

$$\|\mathbf{v}\|_{H(\text{div})} = \left(\|\mathbf{v}\|^2 + \sum_{i=1}^{n} \|\nabla \cdot \mathbf{v}\|_{\Omega_i}^2 \right)^{1/2},$$

and for $\mathbf{v} \in H(\text{div}; E)$, $E \in \mathcal{T}_h$,

$$\|\mathbf{v}\|_{H(\text{div})} = \left(\|\mathbf{v}\|^2 + \sum_{E \in \mathcal{T}_h} \|\nabla \cdot \mathbf{v}\|_{E}^2 \right)^{1/2}.$$

For all of the above spaces

$$\nabla \cdot \mathbf{V}_{h,i} = W_{h,i}$$

and there exists a projection operator $\Pi_{h,i}$ of $(H^1(\Omega_i))^d$ onto $\mathbf{V}_{h,i}$ satisfying for any $\mathbf{q} \in (H^1(\Omega_i))^d$

$$(\nabla \cdot (\Pi_{h,i}\mathbf{q} - \mathbf{q}), w)_{\Omega_i} = 0, \quad w \in W_{h,i}, \tag{2.8}$$

$$\langle (\mathbf{q} - \Pi_{h,i}\mathbf{q}) \cdot \nu_i, \mathbf{v} \cdot \nu_i \rangle_{\partial\Omega_i} = 0, \quad \mathbf{v} \in \mathbf{V}_{h,i}. \tag{2.9}$$

Let $\Pi_h : \bigoplus (H^1(\Omega_i))^d \to \mathbf{V}_h$ be such that $\Pi_h \mathbf{q}|_{\Omega_i} = \Pi_{h,i}\mathbf{q}$ for all $\mathbf{q} \in \bigoplus (H^1(\Omega_i))^d$.

Let the mortar interface mesh $\mathcal{T}_{h,i,j}$ be a quasi-uniform finite element partition of $\Gamma_{i,j}$ and let $\mathcal{T}^{\Gamma,h} = \cup_{1 \le i < j \le n} \mathcal{T}_{h,i,j}$. For any $\tau \in \mathcal{T}_{h,i,j}$, let

$$E_\tau = \cup (E \in \mathcal{T}_h : \partial E \cap \tau \neq \emptyset).$$

We will assume that there exist constants c_1 and c_2 such that

$$c_1 h_E \le h_\tau \le c_2 h_E \quad \forall E \in E_\tau, \tag{2.10}$$

where the notation $h_S = \text{diam}(S)$ is used. Denote by $M_{h,i,j} \subset L^2(\Gamma_{i,j})$ the mortar space on $\Gamma_{i,j}$ containing at least either the continuous or discontinuous piecewise polynomials of degree $k+1$ on $\mathcal{T}_{h,i,j}$, where k is associated with the degree of the polynomials in $\mathbf{V}_h \cdot \nu$. More precisely, if $d = 3$ and e is a triangle of the mesh, we take $M_{h,i,j}|_e = P_{k+1}(e)$, the set of polynomials of degree less than or equal to $k+1$ on e. If e is a rectangle, we take $M_{h,i,j}|_e = Q_{k+1}(e)$, the set of polynomials on e for which the degree in each variable separately is less than or equal to $k+1$. Now let

$$M_h = \bigoplus_{1 \le i < j \le n} M_{h,i,j}$$

be the mortar finite element space on Γ.

In the mortar mixed finite element method for approximating (2.4)–(2.6) we seek $\mathbf{u}_h \in \mathbf{V}_h$, $p_h \in W_h$, and $\lambda_h \in M_h$ such that, for $1 \le i \le n$,

$$(K^{-1}\mathbf{u}_h, \mathbf{v})_{\Omega_i} = (p_h, \nabla \cdot \mathbf{v})_{\Omega_i} - \langle \lambda_h, \mathbf{v} \cdot \nu_i \rangle_{\Gamma_i} - \langle g, \mathbf{v} \cdot \nu_i \rangle_{\partial\Omega_i \cap \Gamma_D}, \quad \mathbf{v} \in \mathbf{V}_{h,i}, \tag{2.11}$$

$$(\nabla \cdot \mathbf{u}_h, w)_{\Omega_i} = (f, w)_{\Omega_i}, \quad w \in W_{h,i}, \tag{2.12}$$

$$\sum_{i=1}^{n} \langle \mathbf{u}_h \cdot \nu_i, \mu \rangle_{\Gamma_i} = 0, \quad \mu \in M_h. \tag{2.13}$$

(2.13) enforces weak (with respect to the mortar space M_h) continuity of the flux across the block interfaces. Existence and uniqueness of a solution of (2.11)–(2.13) are shown in [40, 3] along with optimal convergence and superconvergence for both pressure and velocity under the assumption that for all $\mu \in M_{h,i,j}$ there exists a constant C independent of h such that

$$\|\mu\|_{\Gamma_{i,j}} \le C(\|\mathcal{Q}_{h,i}\mu\|_{\Gamma_{i,j}} + \|\mathcal{Q}_{h,j}\mu\|_{\Gamma_{i,j}}), \tag{2.14}$$

where $\mathcal{Q}_{h,i} : L^2(\partial\Omega_i) \to \mathbf{V}_{h,i}\cdot\nu_i|_{\partial\Omega_i}$ is the L^2-orthogonal projection satisfying for any $\phi \in L^2(\partial\Omega_i)$

$$\langle \phi - \mathcal{Q}_{h,i}\phi, \mathbf{v}\cdot\nu_i\rangle_{\Gamma_i} = 0 \quad \forall \mathbf{v} \in \mathbf{V}_{h,i}. \tag{2.15}$$

Remark 2.1. Condition (2.14) imposes a limit on the number of mortar degrees of freedom and is easily satisfied in practice [40, 28].

We recall some a priori error estimates from [3] which will later motivate some of the saturation assumptions needed in the a posteriori error analysis. Herein l is associated with the degree of the polynomials in W_h and $\|\cdot\|_{d_h}$ is a mortar space norm defined in the next subsection. Throughout the paper C denotes a generic constant independent of h.

THEOREM 2.1. *For the solution of* (2.11)–(2.13) *if* (2.14) *holds, then*

$$\|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)\| \le C\sum_{i=1}^n \|\nabla\cdot\mathbf{u}\|_{r,\Omega_i}h^r, \quad 1 \le r \le l+1,$$

$$\|\mathbf{u}-\mathbf{u}_h\| \le C\sum_{i=1}^n (\|p\|_{r+1,\Omega_i} + \|\mathbf{u}\|_{r,\Omega_i})h^r, \quad 1 \le r \le k+1,$$

$$\|p-p_h\| \le C\sum_{i=1}^n (\|p\|_{r+1,\Omega_i} + \|\mathbf{u}\|_{r,\Omega_i} + \|\nabla\cdot\mathbf{u}\|_{r,\Omega_i})h^r, \quad 1 \le r \le \min(k+1, l+1),$$

$$\|\lambda-\lambda_h\|_{d_h} \le C\sum_{i=1}^n (\|p\|_{r+1,\Omega_i} + \|\mathbf{u}\|_{r,\Omega_i})h^r, \quad 1 \le r \le k+1.$$

2.1. Interface formulation.

Method (2.11)–(2.13) can be reduced to an equivalent interface (mortar) problem. We recall this interface formulation from [22, 40, 3], as it will be used in estimating the mortar error.

Define $d_h : L^2(\Gamma)\times L^2(\Gamma) \to \mathbf{R}$ for $\varphi, \mu \in L^2(\Gamma)$ by

$$d_h(\varphi,\mu) = \sum_{i=1}^n d_{h,i}(\varphi,\mu) = -\sum_{i=1}^n \langle \mathbf{u}_h^*(\varphi)\cdot\nu_i, \mu\rangle_{\Gamma_i}, \tag{2.16}$$

where $(\mathbf{u}_h^*(\varphi), p_h^*(\varphi)) \in \mathbf{V}_h \times W_h$ solve, for $1 \le i \le n$,

$$(K^{-1}\mathbf{u}_h^*(\varphi), \mathbf{v})_{\Omega_i} = (p_h^*(\varphi), \nabla\cdot\mathbf{v})_{\Omega_i} - \langle \varphi, \mathbf{v}\cdot\nu_i\rangle_{\Gamma_i}, \quad \mathbf{v} \in \mathbf{V}_{h,i}, \tag{2.17}$$

$$(\nabla\cdot\mathbf{u}_h^*(\varphi), w)_{\Omega_i} = 0, \quad w \in W_{h,i}. \tag{2.18}$$

Define $g_h : L^2(\Gamma) \to \mathbf{R}$ by

$$g_h(\mu) = \sum_{i=1}^n g_{h,i}(\mu) = \sum_{i=1}^n \langle \bar{\mathbf{u}}_h\cdot\nu_i, \mu\rangle_{\Gamma_i},$$

where $(\bar{\mathbf{u}}_h, \bar{p}_h) \in \mathbf{V}_h \times W_h$ solve, for $1 \le i \le n$,

$$\begin{aligned}(K^{-1}\bar{\mathbf{u}}_h, \mathbf{v})_{\Omega_i} &= (\bar{p}_h, \nabla\cdot\mathbf{v})_{\Omega_i} - \langle g, \mathbf{v}\cdot\nu_i\rangle_{\partial\Omega_i\cap\Gamma_D}, \quad \mathbf{v}\in\mathbf{V}_{h,i},\\ (\nabla\cdot\bar{\mathbf{u}}_h, w)_{\Omega_i} &= (f, w)_{\Omega_i}, \quad w \in W_{h,i}.\end{aligned}$$

Then $(\mathbf{u}_h, p_h, \lambda_h)$ satisfies

$$d_h(\lambda_h, \mu) = g_h(\mu) \quad \forall \mu \in M_h, \quad \mathbf{u}_h = \mathbf{u}_h^*(\lambda_h) + \bar{\mathbf{u}}_h, \quad p_h = p_h^*(\lambda_h) + \bar{p}_h.$$

It is easy to see from (2.16) and (2.17) that

$$d_{h,i}(\varphi,\varphi) = (K^{-1}\mathbf{u}_h^*(\varphi), \mathbf{u}_h^*(\varphi))_{\Omega_i}, \tag{2.19}$$

which implies that $d_h(\cdot,\cdot)$ is positive semidefinite in $M \times M$ and, assuming (2.14), positive definite in $M_h \times M_h$. We define the norm in M_h:

$$\|\mu\|_{d_h} := d_h(\mu,\mu)^{1/2}.$$

It is shown in [40, 28] for RT_0 rectangular elements and very general hanging interface nodes and mortar grid configurations satisfying (2.14) that

$$\sum_{\tau\in\mathcal{T}^{\Gamma,h}} \|\mu\|_{1/2,\tau}^2 \le C d_h(\mu,\mu) \quad \forall \mu \in M_h. \tag{2.20}$$

The proofs in [40, 28] can be generalized in a relatively straightforward way to the other mixed finite element spaces under consideration and to higher-order elements.

The following construction will also be useful in the analysis of the mortar error. Define, for $\varphi \in L^2(\Gamma)$,

$$\mathbf{u}_h(\varphi) = \mathbf{u}_h^*(\varphi) + \bar{\mathbf{u}}_h, \quad p_h(\varphi) = p_h^*(\varphi) + \bar{p}_h.$$

We note that $(\mathbf{u}_h(\varphi), p_h(\varphi)) \in \mathbf{V}_h \times W_h$ satisfy, for $1 \le i \le n$,

$$\begin{aligned}(K^{-1}\mathbf{u}_h(\varphi), \mathbf{v})_{\Omega_i} &= (p_h(\varphi), \nabla\cdot\mathbf{v})_{\Omega_i} - \langle \varphi, \mathbf{v}\cdot\nu\rangle_{\Gamma_i}\\ &\quad - \langle g, \mathbf{v}\cdot\nu\rangle_{\partial\Omega_i\cap\Gamma_D}, \quad \mathbf{v}\in\mathbf{V}_{h,i}, \qquad (2.21)\\ (\nabla\cdot\mathbf{u}_h(\varphi), w)_{\Omega_i} &= (f, w)_{\Omega_i}, \quad w\in W_{h,i}. \qquad (2.22)\end{aligned}$$

In particular, $\mathbf{u}_h(\lambda_h) = \mathbf{u}_h$ and $p_h(\lambda_h) = p_h$.

The a priori error bounds from Theorem 2.1 motivate the following assumption on the mortar error.

Saturation assumption. There exists a constant γ such that

$$|||\lambda - \lambda_h||| := \left(\sum_{\tau\in\mathcal{T}^{\Gamma,h}} h_\tau^{-1}\|\lambda-\lambda_h\|_\tau^2\right)^{1/2} \le \gamma\|\mathbf{u}-\mathbf{u}_h\|. \tag{2.23}$$

For further justification of (2.23), note that $|||\lambda-\lambda_h|||$ is closely related to the discrete $H^{1/2}(\Gamma)$ norm and, by (2.20), to $\|\lambda-\lambda_h\|_{d_h}$. Now, assuming that

$$\|\mathbf{u}-\mathbf{u}_h(\lambda)\| \le \gamma_1\|\mathbf{u}-\mathbf{u}_h\|,$$

which is reasonable, since $\mathbf{u}_h(\lambda)$ is the numerical solution based on the true interface data, we have, using (2.19),

$$\begin{aligned}C\|\lambda-\lambda_h\|_{d_h} &\le \|\mathbf{u}_h^*(\lambda) - \mathbf{u}_h^*(\lambda_h)\| = \|\mathbf{u}_h(\lambda) - \mathbf{u}_h(\lambda_h)\| = \|\mathbf{u}_h(\lambda) - \mathbf{u}_h\|\\ &\le \|\mathbf{u}-\mathbf{u}_h(\lambda)\| + \|\mathbf{u}-\mathbf{u}_h\| \le (1+\gamma_1)\|\mathbf{u}-\mathbf{u}_h\|.\end{aligned}$$

Remark 2.2. Condition (2.14) is necessary for the solvability and accuracy of the method and for the validity of (2.23). See [40, 28] for examples of grids that satisfy (2.14). Note that (2.14) excludes the case of matching subdomain grids and a mortar grid that coincides with them. In the case of matching subdomain grids, the mortar grid has to be at least twice as coarse as their trace on the interface. Another possibility in the case of matching grids is to use the standard Lagrange multipliers from the hybrid mixed method [4], in which case the conforming mixed method solution is recovered. This trivial case is not a special case of the mortar mixed finite element method, since the mortar spaces consist of polynomials of one degree higher than the Lagrange multipliers.

2.2. Residual representation and orthogonality of error. Using the notation from (2.7), the solution of (2.11)–(2.13) $(\mathbf{u}_h, p_h, \lambda_h) \in \mathbf{V}_h \times W_h \times M_h$ satisfies

$$A(\mathbf{u}_h, p_h, \lambda_h; \mathbf{v}, w, \mu) = L(\mathbf{v}, w, \mu) \quad \forall\, (\mathbf{v}, w, \mu) \in \mathbf{V}_h \times W_h \times M_h. \tag{2.24}$$

Our goal is to derive a posteriori estimates of the error functions

$$\xi = \mathbf{u} - \mathbf{u}_h, \quad \eta = p - p_h, \quad \text{and} \quad \delta = \lambda - \lambda_h.$$

Using (2.7), $(\xi, \eta, \delta) \in \mathbf{V} \times W \times M$ satisfies the residual equation

(2.25)
$$A(\xi, \eta, \delta; \mathbf{v}, w, \mu) = L(\mathbf{v}, w, \mu) - A(\mathbf{u}_h, p_h, \lambda_h; \mathbf{v}, w, \mu) \quad \forall\, (\mathbf{v}, w, \mu) \in \mathbf{V} \times W \times M,$$

which, together with (2.24), implies the orthogonality condition

$$A(\xi, \eta, \delta; \mathbf{v}, w, \mu) = 0 \quad \forall\, (\mathbf{v}, w, \mu) \in \mathbf{V}_h \times W_h \times M_h. \tag{2.26}$$

2.3. Approximation properties. We present below some of the approximation properties of the finite element spaces. In addition to the operators defined above, we will make use of the interpolant $\mathcal{I}_h$ in the mortar space M_h, and the L^2-projection onto W_h, defined as

$$(w - \hat{w}, w_h) = 0 \quad \forall w_h \in W_h.$$

The following approximation properties hold true. For all $E \in \mathcal{T}_h$, $\tau \in \mathcal{T}^{\Gamma,h}$, $e \in \mathcal{T}_{h,i}|_{\partial\Omega_i}$, and smooth enough functions $\mathbf{v}$, w, and μ,

$$\|\mathbf{v} - \Pi_h \mathbf{v}\|_E \le C h_E \|\mathbf{v}\|_{1,E}, \tag{2.27}$$
$$\|(\mathbf{v} - \Pi_h \mathbf{v}) \cdot \nu_E\|_{\partial E} \le C h_E^s \|\mathbf{v} \cdot \nu_E\|_{s,\partial E}, \quad s = 0, 1/2, \tag{2.28}$$
$$\|w - \hat{w}\|_E \le C h_E \|w\|_{1,E}, \tag{2.29}$$
$$\|\mu - \mathcal{I}_h \mu\|_\tau \le C h_\tau^{3/2} \|\mu\|_{3/2,\tau}, \tag{2.30}$$
$$\|\mu - \mathcal{Q}_{h,i} \mu\|_e \le C h_e \|\mu\|_{1,e}. \tag{2.31}$$

Bound (2.27) can be found in [16, 33]; bounds (2.28)–(2.31) are standard interpolation and L^2-projection approximation results [19].

2.4. Some useful inequalities. In the analysis below we will make use of the trace inequalities

$$\forall E \in \mathcal{T}_h, \quad e \in \partial E, \quad \|\phi\|_e \le C(h_E^{-1/2} \|\phi\|_E + h_E^{1/2} \|\nabla \phi\|_E) \quad \forall \phi \in H^1(E), \tag{2.32}$$

$$\forall E \in \mathcal{T}_h, \quad e \in \partial E, \quad \|\phi\|_{1/2,e} \le C\|\phi\|_{1,E} \quad \forall \phi \in H^1(E), \tag{2.33}$$

$$\forall E \in \mathcal{T}_h, \quad e \in \partial E, \quad \|\mathbf{v}\cdot\nu\|_e \le C h_E^{-1/2}\|\mathbf{v}\|_E \quad \forall \mathbf{v} \in \mathbf{V}_h, \tag{2.34}$$

and the well-known inequality

$$ab \le \epsilon a^2 + \frac{1}{4\epsilon}b^2 \quad \forall \epsilon > 0. \tag{2.35}$$

3. Residual-based error estimators. In this section we derive upper and lower bounds on the error in terms of local residuals. The resulting estimators are often called explicit estimators as they involve only residual terms that depend explicitly on the input data and the computed solution and do not require the solution of additional finite element problems.

3.1. Upper bounds. Let, for all $E \in \mathcal{T}_h$, $\tau \in \mathcal{T}^{\Gamma,h}$,

$$\omega_E^2 = \|K^{-1}\mathbf{u}_h + \nabla p_h\|_E^2 h_E^2 + \|f - \nabla\cdot\mathbf{u}_h\|_E^2 h_E^2 + \|\lambda_h - p_h\|_{\partial E\cap\Gamma}^2 h_E, \tag{3.1}$$

$$\omega_\tau^2 = \|[\mathbf{u}_h\cdot\nu]\|_\tau^2 h_\tau^3, \tag{3.2}$$

where for any $\mathbf{v} \in \mathbf{V}$, $\mathbf{v}|_{\Omega_i} = \mathbf{v}_i$,

$$[\mathbf{v}\cdot\nu]|_{\Gamma_{i,j}} = \mathbf{v}_i\cdot\nu_i + \mathbf{v}_j\cdot\nu_j$$

is the jump operator. We first derive an upper bound on the pressure error η.

THEOREM 3.1. *There exists a constant C independent of h such that*

$$\|\eta\|^2 \le C\bigg\{\sum_{E\in\mathcal{T}_h}\omega_E^2 + \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\omega_\tau^2 + \sum_{e\in\mathcal{T}_h|_{\Gamma_D}}\|g - \mathcal{Q}_h g\|_e^2 h_e\bigg\}.$$

Proof. The proof is based on a duality argument. Consider the auxiliary problem

$$\begin{aligned} -\nabla\cdot K\nabla w &= \eta \quad \text{in } \Omega,\\ w &= 0 \quad \text{on } \Gamma_D,\\ K\nabla w\cdot\nu &= 0 \quad \text{on } \Gamma_N. \end{aligned}$$

The elliptic regularity assumption (2.1) implies that

$$\|w\|_2 \le C\|\eta\|. \tag{3.3}$$

Let $\mathbf{v} = -K\nabla w$ and $\mu = w|_\Gamma$. With (2.7), $(\mathbf{v}, w, \mu)$ satisfy

$$A^s(\mathbf{v}, w, \mu; \tilde{\mathbf{v}}, \tilde{w}, \tilde{\mu}) = -(\eta, \tilde{w}) \quad \forall\ (\tilde{\mathbf{v}}, \tilde{w}, \tilde{\mu}) \in \mathbf{V}\times W\times M.$$

Then, using (2.26) and (2.26),

$$\begin{aligned} \|\eta\|^2 &= -A^s(\mathbf{v}, w, \mu; \xi, \eta, \delta) = -A^s(\xi, \eta, \delta; \mathbf{v}, w, \mu)\\ &= -A^s(\xi, \eta, \delta; \mathbf{v} - \Pi_h\mathbf{v}, w - \hat{w}, \mu - \mathcal{I}_h\mu)\\ &= A^s(\mathbf{u}_h, p_h, \lambda_h; \mathbf{v} - \Pi_h\mathbf{v}, w - \hat{w}, \mu - \hat{\mu}) + (f, w - \hat{w}) + \langle g, (\mathbf{v} - \Pi_h\mathbf{v})\cdot\nu\rangle_{\Gamma_D}\\ &= \sum_{E\in\mathcal{T}_h}\big((K^{-1}\mathbf{u}_h, \mathbf{v} - \Pi_h\mathbf{v})_E - (p_h, \nabla\cdot(\mathbf{v} - \Pi_h\mathbf{v}))_E - (\nabla\cdot\mathbf{u}_h, w - \hat{w})_E\big)\\ &\quad + \sum_{i=1}^n\big(\langle\lambda_h, (\mathbf{v} - \Pi_h\mathbf{v})\cdot\nu_i\rangle_{\Gamma_i} + \langle\mathbf{u}_h\cdot\nu_i, \mu - \mathcal{I}_h\mu\rangle_{\Gamma_i}\big)\\ &\quad + (f, w - \hat{w}) + \langle g, (\mathbf{v} - \Pi_h\mathbf{v})\cdot\nu\rangle_{\Gamma_D}. \end{aligned}$$

Applying Green's formula and using (2.9),

$$\begin{aligned}\|\eta\|^2 = &\sum_{E\in\mathcal{T}_h} \big((K^{-1}\mathbf{u}_h + \nabla p_h, \mathbf{v} - \Pi_h\mathbf{v})_E + (f - \nabla\cdot\mathbf{u}_h, w - \hat{w})_E\big)\\ &+ \sum_{i=1}^{n} \big(\langle \lambda_h - p_h, (\mathbf{v} - \Pi_h\mathbf{v})\cdot\nu_i\rangle_{\Gamma_i} + \langle \mathbf{u}_h\cdot\nu_i, \mu - \mathcal{I}_h\mu\rangle_{\Gamma_i}\big)\\ &+ \langle g - \mathcal{Q}_h g, (\mathbf{v} - \Pi_h\mathbf{v})\cdot\nu\rangle_{\Gamma_D}.\end{aligned}$$

Using the Cauchy–Schwartz inequality and the approximation properties (2.27)–(2.31),

$$\begin{aligned}\|\eta\|^2 \le C\bigg\{ &\sum_{E\in\mathcal{T}_h} \big(\|K^{-1}\mathbf{u}_h + \nabla p_h\|_E h_E \|\mathbf{v}\|_{1,E} + \|f - \nabla\cdot\mathbf{u}_h\|_E h_E \|w\|_{1,E}\\ &+ \|\lambda_h - p_h\|_{\partial E\cap\Gamma} h_E^{1/2}\|\mathbf{v}\|_{1,E}\big) + \sum_{\tau\in\mathcal{T}^{\Gamma,h}} \|[\mathbf{u}_h\cdot\nu]\|_\tau h_\tau^{3/2}\|\mu\|_{3/2,\tau}\\ &+ \sum_{e\in\mathcal{T}_h|_{\Gamma_D}} \|g - \mathcal{Q}_h g\|_e h_e^{1/2}\|\mathbf{v}\|_{1/2,e}\bigg\}.\end{aligned}$$

An application of the discrete Cauchy–Schwartz inequality, the trace inequality (2.33), and (3.3) completes the proof. □

Remark 3.1. Because of the approximation property (2.31) of $\mathcal{Q}_h$ the last term in the bound of Theorem 3.1 is of higher order than the other terms. Therefore, its effect becomes negligible for small h.

To derive a bound on $\xi = \mathbf{u} - \mathbf{u}_h$ we need a saturation assumption. Let $\mathbf{V}'_h$, W'_h, and M'_h be the finite element spaces of one order higher than $\mathbf{V}_h$, W_h, and M_h, respectively. Let $\mathbf{u}'_h \in \mathbf{V}'_h$, $p'_h \in W'_h$, and $\lambda'_h \in M'_h$ be the mortar mixed finite element solution in these higher-order spaces (see (2.11)–(2.13)). The a priori error estimates from Theorem 2.1 motivate the following.

Saturation assumption. There exist constants $\beta < 1$, $\beta_{\mathrm{div}} < 1$, and $\beta_p < \infty$ such that

$$\|\mathbf{u} - \mathbf{u}'_h\| \le \beta\|\mathbf{u} - \mathbf{u}_h\|, \tag{3.4}$$

$$\|\nabla\cdot(\mathbf{u} - \mathbf{u}'_h)\| \le \beta_{\mathrm{div}}\|\nabla\cdot(\mathbf{u} - \mathbf{u}_h)\|, \tag{3.5}$$

$$\|p - p'_h\| \le \beta_p\|p - p_h\|. \tag{3.6}$$

Let

$$\xi' = \mathbf{u}'_h - \mathbf{u}_h, \quad \eta' = p'_h - p_h, \quad \text{and} \quad \delta' = \lambda'_h - \lambda_h.$$

Similar to (2.26) and (2.26), we have that $(\xi', \eta', \delta') \in \mathbf{V}'_h \times W'_h \times M'_h$ satisfy the residual equation

$$\begin{aligned}A(\xi', \eta', \delta'; \mathbf{v}'_h, w'_h, \mu'_h) = L(\mathbf{v}'_h, w'_h, \mu'_h) - A(\mathbf{u}_h, p_h, \lambda_h; \mathbf{v}'_h, w'_h, \mu'_h)&\\ \forall\ (\mathbf{v}'_h, w'_h, \mu'_h) \in \mathbf{V}'_h \times W'_h \times M'_h&\end{aligned} \tag{3.7}$$

and the orthogonality condition

$$A(\xi', \eta', \delta'; \mathbf{v}, w, \mu) = 0 \quad \forall\ (\mathbf{v}, w, \mu) \in \mathbf{V}_h \times W_h \times M_h. \tag{3.8}$$

The bounds on ξ and δ will be expressed in terms of weighted local residuals, for all $E \in \mathcal{T}_h$, $\tau \in \mathcal{T}^{\Gamma,h}$,

$$\begin{aligned}&\tilde{\omega}_E^2 = h_E^{-2}\omega_E^2 = \|K^{-1}\mathbf{u}_h + \nabla p_h\|_E^2 + \|f - \nabla\cdot\mathbf{u}_h\|_E^2 + \|\lambda_h - p_h\|_{\partial E\cap\Gamma}^2 h_E^{-1},\\ &\tilde{\omega}_\tau^2 = h_\tau^{-2}\omega_\tau^2 = \|[\mathbf{u}_h\cdot\nu]\|_\tau^2 h_\tau.\end{aligned}$$

Theorem 3.2. *Assume that the saturation assumptions* (2.23) *and* (3.4) *hold. Then there exists a constant C independent of β such that*

$$\|\xi\|^2_{H(\mathrm{div})} \le \frac{C}{(1-\beta)^2}\left\{ \sum_{E\in\mathcal{T}_h} \tilde\omega_E^2 + \sum_{\tau\in\mathcal{T}^{\Gamma,h}} \tilde\omega_\tau^2 + \sum_{e\in\mathcal{T}_h|_{\Gamma_D}} \|g-\mathcal{Q}_h g\|_e^2 h_e^{-1}\right\}.$$

Proof. The bound on $\|\nabla\cdot\xi\|$ is trivial. Indeed, for all $E\in\mathcal{T}_h$,

$$\|\nabla\cdot\xi\|_E = \|f-\nabla\cdot\mathbf{u}_h\|_E \le \tilde\omega_E.$$

To bound $\|\xi\|$, since (3.4) implies that

$$\|\xi\| \le \frac{1}{1-\beta}\|\xi'\|, \tag{3.9}$$

it is enough to bound $\|\xi'\|$. Using (3.8) and (3.7),

$$\begin{aligned}
\|K^{-1/2}\xi'\|^2 &= A^c(\xi',\eta',\delta';\xi',\eta',\delta') = A^c(\xi',\eta',\delta';\xi'-\Pi_h\xi',\eta',\delta')\\
&= L^c(\xi'-\Pi_h\xi',\eta',\delta') - A^c(\mathbf{u}_h,p_h,\lambda_h;\xi'-\Pi_h\xi',\eta',\delta')\\
&= -\sum_{E\in\mathcal{T}_h}\big((K^{-1}\mathbf{u}_h,\xi'-\Pi_h\xi')_E - (p_h,\nabla\cdot(\xi'-\Pi_h\xi'))_E + (\nabla\cdot\mathbf{u}_h,\eta')_E\big)\\
&\quad -\sum_{i=1}^n\big(\langle\lambda_h,(\xi'-\Pi_h\xi')\cdot\nu_i\rangle_{\Gamma_i} - \langle\mathbf{u}_h\cdot\nu_i,\delta'\rangle_{\Gamma_i}\big)\\
&\quad + (f,\eta') - \langle g,(\xi'-\Pi_h\xi')\cdot\nu\rangle_{\Gamma_D}.
\end{aligned}$$

The use of Green's formula and (2.9) gives

$$\begin{aligned}
\|K^{-1/2}\xi'\|^2 = &-\sum_{E\in\mathcal{T}_h}\big((K^{-1}\mathbf{u}_h+\nabla p_h,\xi'-\Pi_h\xi')_E + (\nabla\cdot\mathbf{u}_h - f,\eta')_E\big)\\
&-\sum_{i=1}^n\big(\langle\lambda_h-p_h,(\xi'-\Pi_h\xi')\cdot\nu_i\rangle_{\Gamma_i} - \langle\mathbf{u}_h\cdot\nu_i,\delta'\rangle_{\Gamma_i}\big)\\
&-\langle g-\mathcal{Q}_h g,(\xi'-\Pi_h\xi')\cdot\nu\rangle_{\Gamma_D} = T_1+\cdots+T_5.
\end{aligned}\tag{3.10}$$

For T_1, using the Cauchy–Schwartz inequality, (2.27), the inverse inequality, and (2.35), we have

$$|(K^{-1}\mathbf{u}_h+\nabla p_h,\xi'-\Pi_h\xi')_E| \le C\left(\frac{1}{4\epsilon_1}\|K^{-1}\mathbf{u}_h+\nabla p_h\|_E^2 + \epsilon_1\|\xi'\|_E^2\right). \tag{3.11}$$

Similarly for T_2,

$$|(\nabla\cdot\mathbf{u}_h - f,\eta')_E| \le \frac{1}{2}\|\nabla\cdot\mathbf{u}_h - f\|_E^2 + \frac{1}{2}\|\eta'\|_E^2. \tag{3.12}$$

To bound T_3, the use of (2.28) with $s=0$ gives, for $e\in\Gamma_i$, $e\in\partial E$,

$$|\langle\lambda_h-p_h,(\xi'-\Pi_h\xi')\cdot\nu_i\rangle_e| \le C\left(\frac{1}{4\epsilon_3}\|\lambda_h-p_h\|_e^2 h_E^{-1} + \epsilon_3\|\xi'\|_E^2\right). \tag{3.13}$$

Similarly for T_5,

$$|\langle g-\mathcal{Q}_h g,(\xi'-\Pi_h\xi')\cdot\nu\rangle_e| \le C\left(\frac{1}{4\epsilon_5}\|g-\mathcal{Q}_h g\|_e^2 h_e^{-1} + \epsilon_5\|\xi'\|_E^2\right). \tag{3.14}$$

Finally for T_4, using (2.35),

$$\begin{aligned}\left|\sum_{i=1}^{n}\langle \mathbf{u}_h\cdot\nu_i,\delta'\rangle_{\Gamma_i}\right| &= \left|\sum_{\tau\in\mathcal{T}^{\Gamma,h}}\langle[\mathbf{u}_h\cdot\nu],\delta'\rangle_\tau\right| \le \sum_{\tau\in\mathcal{T}^{\Gamma,h}} h_\tau^{1/2}\|[\mathbf{u}_h\cdot\nu]\|_\tau h_\tau^{-1/2}\|\delta'\|_\tau \\ &\le \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\left(\frac{1}{4\epsilon_4}\|[\mathbf{u}_h\cdot\nu]\|_\tau^2 h_\tau + \epsilon_4\|\delta'\|_\tau^2 h_\tau^{-1}\right).\end{aligned} \tag{3.15}$$

Combining (1.5) with (3.10)–(3.15) for small enough ϵ_1, ϵ_3, and ϵ_5,

$$\begin{aligned}\|\xi'\|^2 \le C\Bigg\{&\sum_{E\in\mathcal{T}_h}(\|K^{-1}\mathbf{u}_h+\nabla p_h\|_E^2 + \|f-\nabla\cdot\mathbf{u}_h\|_E^2 + \|\lambda_h - p_h\|_{\partial E\cap\Gamma}^2 h_E^{-1} + \|\eta'\|_E^2) \\ &+ \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\left(\frac{1}{4\epsilon_4}\|[\mathbf{u}_h\cdot\nu]\|_\tau^2 h_\tau + \epsilon_4\|\delta'\|_\tau^2 h_\tau^{-1}\right) + \sum_{e\in\mathcal{T}_h|_{\Gamma_D}}\|g-\mathcal{Q}_h g\|_e^2 h_e^{-1}\Bigg\}.\end{aligned} \tag{3.16}$$

Because of (3.6), the bound on $\|\eta\|$ from Theorem 3.1 applies to $\|\eta'\|$ as well. It remains to estimate $|||\delta'|||^2 = \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\|\delta'\|_\tau^2 h_\tau^{-1}$. Using (2.23) (with a constant γ' in the case of the higher-order spaces) and (3.4), we have

$$\begin{aligned}|||\delta'||| &\le |||\lambda-\lambda_h||| + |||\lambda-\lambda_h'||| \le \gamma\|\mathbf{u}-\mathbf{u}_h\| + \gamma'\|\mathbf{u}-\mathbf{u}_h'\| \\ &\le (\gamma+\gamma'\beta)\|\mathbf{u}-\mathbf{u}_h\|.\end{aligned} \tag{3.17}$$

Using (3.17), (3.9) and taking ϵ_4 in (3.16) small enough completes the proof. □

3.2. Lower bounds. Next, we establish lower bounds on the error, which indicate that the residual error estimators can be used effectively in an adaptive mesh refinement algorithm.

THEOREM 3.3. *There exists a constant C independent of h such that*

$$\sum_{E\in\mathcal{T}_h}\omega_E^2 + \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\omega_\tau^2 \le C\left(\|\eta\|^2 + \sum_{E\in\mathcal{T}_h} h_E^2\|\xi\|_{H(\mathrm{div};E)}^2 + \sum_{\tau\in\mathcal{T}^{\Gamma,h}} h_\tau\|\delta\|_\tau^2\right) \tag{3.18}$$

and, assuming that the saturation assumption (2.23) *holds,*

$$\sum_{E\in\mathcal{T}_h}\tilde\omega_E^2 + \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\tilde\omega_\tau^2 \le C\left(\sum_{E\in\mathcal{T}_h} h_E^{-2}\|\eta\|_E^2 + \|\xi\|_{H(\mathrm{div})}^2\right). \tag{3.19}$$

Moreover, the following local bounds hold for any $E\in\mathcal{T}_h$, $e\in\partial E$, and $\tau\in\mathcal{T}^{\Gamma,h}$:

$$\|K^{-1}\mathbf{u}_h+\nabla p_h\|_E^2 h_E^2 + \|f-\nabla\cdot\mathbf{u}_h\|_E^2 h_E^2 \le C(\|\eta\|_E^2 + \|\xi\|_{H(\mathrm{div};E)}^2 h_E^2), \tag{3.20}$$

$$\|[\mathbf{u}_h\cdot\nu]\|_\tau^2 h_\tau^3 \le C\|\xi\|_{H(\mathrm{div};E_\tau)}^2 h_\tau^2, \tag{3.21}$$

$$\|\lambda_h - p_h\|_e^2 h_E \le C(\|\eta\|_E^2 + \|\xi\|_{H(\mathrm{div};E)}^2 h_E^2 + \|\delta\|_e^2 h_E). \tag{3.22}$$

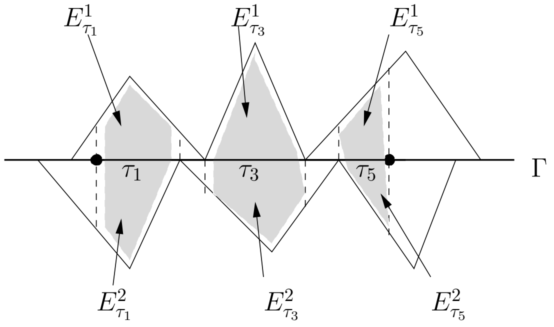

FIG. 3.1. *Construction of* E_{τ_k}.

Proof. It has been shown in [17], using a bubble function argument, that

$$\|K^{-1}\mathbf{u}_h + \nabla p_h\|_E h_E \le C(\|\eta\|_E + \|\xi\|_E h_E),$$

which, combined with

$$\|f - \nabla\cdot\mathbf{u}_h\|_E h_E = \|\nabla\cdot\xi\|_E h_E,$$

gives (3.20). To prove (3.21), consider any $\tau \in \mathcal{T}^{\Gamma,h}$. Let τ be divided by the intersection of the two traces of $\mathcal{T}_h$ on Γ into elements $\tau_1, \dots, \tau_l$. Because of (2.10) there exists $c > 0$ such that

$$h_{\tau_k} \ge c h_\tau, \quad k = 1, \dots, l. \tag{3.23}$$

Next, let us translate any point in τ_k in both directions orthogonal to Γ until an interior edge (face) of an element of $\mathcal{T}_h$ is reached. Let E_{τ_k} be the union of all such trajectories. Figure 3.1 illustrates this construction in the case of triangular grids in $\mathbf{R}^2$, where the neighboring domains are Ω_1 and Ω_2. Note that

$$E_{\tau_k} = E^1_{\tau_k} \cup E^2_{\tau_k},$$

where $E^i_{\tau_k}$, $i = 1, 2$, is a subset of an element of $\mathcal{T}_{h,i}$. Let φ_k be a continuous piecewise linear bubble function such that $0 \le \varphi_k(x) \le 1$ in E_{τ_k}, $\varphi_k = 1$ at the gravity center of τ_k and $\varphi_k = 0$ on ∂E_{τ_k}. Such a function can be easily constructed by decomposing E_{τ_k} into triangles if $d = 2$ or tetrahedra if $d = 3$. We also need an extension of $[\mathbf{u}_h\cdot\nu]_{\tau_k}$ to E_{τ_k}. Given $\psi \in H^{1/2}(\tau_k)$, define $\mathcal{R}\psi \in H^1(E_{\tau_k})$ such that $\mathcal{R}\psi$ is constant along lines perpendicular to Γ. Let

$$\phi_k = \varphi_k \mathcal{R}[\mathbf{u}_h\cdot\nu]_{\tau_k} \in H^1(E_{\tau_k}).$$

Note that $\phi_k = 0$ on ∂E_{τ_k}. Using a scaling argument similar to the one in [35] it can be shown that

$$\|\phi_k\|_{\tau_k} \le \|[\mathbf{u}_h\cdot\nu]\|_{\tau_k}, \tag{3.24}$$

$$\|\nabla\phi_k\|_{E_{\tau_k}} \le C h_{\tau_k}^{-1}\|\phi_k\|_{E_{\tau_k}}, \tag{3.25}$$

$$\|\phi_k\|_{E_{\tau_k}} \le C h_{\tau_k}^{1/2}\|\phi_k\|_{\tau_k}, \tag{3.26}$$

$$C\|[\mathbf{u}_h\cdot\nu]\|^2_{\tau_k} \le \langle\phi_k, [\mathbf{u}_h\cdot\nu]\rangle_{\tau_k}. \tag{3.27}$$

Using (3.27) and that $[\mathbf{u} \cdot \nu] = 0$,

$$
\begin{aligned}
C\|[\mathbf{u}_h \cdot \nu]\|_{\tau_k}^2 &\le \langle \mathbf{u}_{h,1} \cdot \nu_1 + \mathbf{u}_{h,2} \cdot \nu_2, \phi_k \rangle_{\tau_k} \\
&= \langle (\mathbf{u}_{h,1} - \mathbf{u}) \cdot \nu_1, \phi_k \rangle_{\tau_k} + \langle (\mathbf{u}_{h,2} - \mathbf{u}) \cdot \nu_2, \phi_k \rangle_{\tau_k}.
\end{aligned} \tag{3.28}
$$

Using Green's formula for the first term on the right-hand side, we have

$$
\begin{aligned}
\left| \langle \xi_1 \cdot \nu_1, \phi_k \rangle_{\tau_k} \right| &= \left| (\nabla \phi_k, \xi_1)_{E^1_{\tau_k}} + (\phi_k, \nabla \cdot \xi_1)_{E^1_{\tau_k}} \right| \\
&\le \|\nabla \phi_k\|_{E^1_{\tau_k}} \|\xi_1\|_{E^1_{\tau_k}} + \|\phi_k\|_{E^1_{\tau_k}} \|\nabla \cdot \xi_1\|_{E^1_{\tau_k}} \\
&\le C h_{\tau_k}^{-1} \|\phi_k\|_{E^1_{\tau_k}} \|\xi_1\|_{E^1_{\tau_k}} + \|\phi_k\|_{E^1_{\tau_k}} \|\nabla \cdot \xi_1\|_{E^1_{\tau_k}} \\
&\le C(h_{\tau_k}^{-1/2} \|\xi_1\|_{E^1_{\tau_k}} + h_{\tau_k}^{1/2} \|\nabla \cdot \xi_1\|_{E^1_{\tau_k}}) \|[\mathbf{u}_h \cdot \nu]\|_{\tau_k},
\end{aligned} \tag{3.29}
$$

where we have used (3.25) for the second inequality and (3.26), (3.24) for the third inequality. The second term on the right-hand side of (3.28) can be bounded similarly in terms of $\|\xi_2\|_{H(\mathrm{div}; E^2_{\tau_k})}$. A combination of (3.28), (3.29), and (3.23) gives (3.21).

It remains to show (3.22). By the triangle inequality,

$$
\|\lambda_h - p_h\|_e \le \|\lambda_h - \lambda\|_e + \|p - p_h\|_e. \tag{3.30}
$$

For the second term on the right-hand side we employ the trace inequality (2.32)

$$
\begin{aligned}
\|p - p_h\|_e &\le C\big(h_E^{-1/2} \|p - p_h\|_E + h_E^{1/2} \|\nabla (p - p_h)\|_E \big) \\
&\le C\big(h_E^{-1/2} \|p - p_h\|_E + h_E^{1/2} \|K^{-1} \mathbf{u}_h + \nabla p_h\|_E + h_E^{1/2} \|K^{-1}(\mathbf{u} - \mathbf{u}_h)\|_E \big) \\
&\le C\big(h_E^{-1/2} \|\eta\|_E + h_E^{1/2} \|\xi\|_{H(\mathrm{div}; E)} \big),
\end{aligned} \tag{3.31}
$$

using (3.20) for the last inequality. A combination of (3.30), (3.31), and (2.10) completes the proof of (3.22). The global bound (3.18) follows immediately from (3.20) to (3.22), using (2.10), and so does (3.19), using (2.23). □

Remark 3.2. The last two terms in (3.18) are of higher order, so $\|\eta\|$ dominates for small enough h. Therefore, this bound, combined with Theorem 3.1, implies that $\sum_{E \in \mathcal{T}_h} \omega_E^2 + \sum_{\tau \in \mathcal{T}^{\Gamma,h}} \omega_\tau^2$ is an efficient and reliable estimator for the pressure error. Because of the negative power of h in the first term on the right-hand side of (3.19), the estimator $\sum_{E \in \mathcal{T}_h} \tilde{\omega}_E^2 + \sum_{\tau \in \mathcal{T}^{\Gamma,h}} \tilde{\omega}_\tau^2$ provides only a suboptimal bound for the velocity error.

4. Error estimators based on solving local problems.

In this section we derive an implicit error estimator which requires solving local (element) boundary value problems. These problems approximate the local residual equations satisfied by the true error. The motivation for considering implicit estimators comes from the unknown generic constants that appear in the explicit estimators, as well as the suboptimality in the lower bound for the velocity error. We show that the implicit estimator provides both optimal upper and lower bounds of the error.

4.1. Global approximation to the error.

Similar to the approach in [39], we first construct a global approximation to the error based on higher-order finite element spaces. Using (2.4)–(2.6), the true error satisfies the residual equations:

$$(K^{-1}\xi, \mathbf{v})_{\Omega_i} - (\eta, \nabla\cdot\mathbf{v})_{\Omega_i} + \langle\delta, \mathbf{v}\cdot\nu_i\rangle_{\Gamma_i} = -\langle g, \mathbf{v}\cdot\nu\rangle_{\partial\Omega_i\cap\Gamma_D}$$
$$- (K^{-1}\mathbf{u}_h, \mathbf{v})_{\Omega_i} + (p_h, \nabla\cdot\mathbf{v})_{\Omega_i} - \langle\lambda_h, \mathbf{v}\cdot\nu_i\rangle_{\Gamma_i} \equiv r(\mathbf{v}), \quad \mathbf{v}\in\mathbf{V}_i, \tag{4.1}$$
$$(\nabla\cdot\xi, w)_{\Omega_i} = (f - \nabla\cdot\mathbf{u}_h, w)_{\Omega_i}, \quad w\in W_i, \tag{4.2}$$
$$\sum_{i=1}^{n}\langle\xi\cdot\nu_i, \mu\rangle_{\Gamma_i} = -\sum_{i=1}^{n}\langle\mathbf{u}_h\cdot\nu_i, \mu\rangle_{\Gamma_i}, \quad \mu\in M. \tag{4.3}$$

Recall from the previous section that $\mathbf{V}'_h \times W'_h \times M'_h$ are the mortar mixed finite element spaces of one order higher than $\mathbf{V}_h\times W_h\times M_h$ and $(\xi', \eta', \delta') \in \mathbf{V}'_h\times W'_h\times M'_h$ is the finite element approximation to (ξ, η, δ) satisfying

$$(K^{-1}\xi', \mathbf{v})_{\Omega_i} - (\eta', \nabla\cdot\mathbf{v})_{\Omega_i} + \langle\delta', \mathbf{v}\cdot\nu_i\rangle_{\Gamma_i} = r(\mathbf{v}), \quad \mathbf{v}\in\mathbf{V}'_{h,i}, \tag{4.4}$$
$$(\nabla\cdot\xi', w)_{\Omega_i} = (f - \nabla\cdot\mathbf{u}_h, w)_{\Omega_i}, \quad w\in W'_{h,i}, \tag{4.5}$$
$$\sum_{i=1}^{n}\langle\xi'\cdot\nu_i, \mu\rangle_{\Gamma_i} = -\sum_{i=1}^{n}\langle\mathbf{u}_h\cdot\nu_i, \mu\rangle_{\Gamma_i}, \quad \mu\in M'_h. \tag{4.6}$$

Note that (4.4)–(4.6) implies that $(\mathbf{u}'_h = \mathbf{u}_h + \xi', p'_h = p_h + \eta', \lambda'_h = \lambda_h + \delta')$ is the finite element approximation to $(\mathbf{u}, p, \lambda)$ in $\mathbf{V}'_h\times W'_h\times M'_h$ satisfying

$$(K^{-1}\mathbf{u}'_h, \mathbf{v})_{\Omega_i} = (p'_h, \nabla\cdot\mathbf{v})_{\Omega_i} - \langle\lambda'_h, \mathbf{v}\cdot\nu_i\rangle_{\Gamma_i} - \langle g, \mathbf{v}\cdot\nu_i\rangle_{\partial\Omega_i\cap\Gamma_D}, \quad \mathbf{v}\in\mathbf{V}'_{h,i}, \tag{4.7}$$
$$(\nabla\cdot\mathbf{u}'_h, w)_{\Omega_i} = (f, w)_{\Omega_i}, \quad w\in W'_{h,i}, \tag{4.8}$$
$$\sum_{i=1}^{n}\langle\mathbf{u}'_h\cdot\nu_i, \mu\rangle_{\Gamma_i} = 0, \quad \mu\in M'_h. \tag{4.9}$$

The saturation assumptions (3.4) and (3.5) imply

$$(1-\beta)\|\xi\| \le \|\xi'\| \le (1+\beta)\|\xi\|, \tag{4.10}$$
$$(1-\beta_{\mathrm{div}})\|\nabla\cdot\xi\| \le \|\nabla\cdot\xi'\| \le (1+\beta_{\mathrm{div}})\|\nabla\cdot\xi\|, \tag{4.11}$$

so it is enough to estimate ξ'.

4.2. Local (element) approximation to the error. For any $E\in\mathcal{T}_h$, the true error satisfies the local equations:

$$(K^{-1}\xi, \mathbf{v})_E - (\eta, \nabla\cdot\mathbf{v})_E = r_E(\mathbf{v}) - \langle p, \mathbf{v}\cdot\nu_E\rangle_{\partial E}, \quad \mathbf{v}\in\mathbf{V}(E), \tag{4.12}$$
$$(\nabla\cdot\xi, w)_E = (f - \nabla\cdot\mathbf{u}_h, w)_E, \quad w\in W(E), \tag{4.13}$$

where

$$r_E(\mathbf{v}) = -(K^{-1}\mathbf{u}_h, \mathbf{v})_E + (p_h, \nabla\cdot\mathbf{v})_E.$$

We construct a higher-order local approximation of the error by solving element subproblems: find $\psi'\in\mathbf{V}'_h(E)$ and $\theta'\in W'_h(E)$ such that

$$(K^{-1}\psi', \mathbf{v})_E - (\theta', \nabla\cdot\mathbf{v})_E = r_E(\mathbf{v}) - \langle p_A, \mathbf{v}\cdot\nu_E\rangle_{\partial E}, \quad \mathbf{v}\in\mathbf{V}'_h(E), \tag{4.14}$$
$$(\nabla\cdot\psi', w)_E = (f - \nabla\cdot\mathbf{u}_h, w)_E, \quad w\in W'_h(E), \tag{4.15}$$

where $p_A = g$ on Γ_D, $p_A = \lambda_h$ on $\partial E \cap \Gamma$, and $p_A = \tilde{p}_h$ on $\partial E \cap \mathcal{E}_h$, where $\tilde{p}_h$ is the Lagrange multiplier for $\mathbf{V}_h$ and W_h defined as

$$\langle \tilde{p}_h, \mathbf{v}\cdot\nu_E\rangle_{\partial E} = -(K^{-1}\mathbf{u}_h, \mathbf{v})_E + (p_h, \nabla\cdot\mathbf{v})_E, \quad \mathbf{v}\in\mathbf{V}_h(E). \tag{4.16}$$

Let $\tilde{p}'$ be the Lagrange multiplier for the higher-order spaces $\mathbf{V}'_h$ and W'_h satisfying

$$\langle \tilde{p}', \mathbf{v}\cdot\nu_E\rangle_{\partial E} = -(K^{-1}\mathbf{u}'_h, \mathbf{v})_E + (p'_h, \nabla\cdot\mathbf{v})_E, \quad \mathbf{v}\in V'_h(E). \tag{4.17}$$

We make the following.

Saturation assumption. There exists a constant σ such that

$$\left(\sum_{e\in\mathcal{E}_h} h_e^{-1}\|\tilde{p}' - \tilde{p}_h\|_e^2\right)^{1/2} \le \sigma\|\mathbf{u}-\mathbf{u}_h\|. \tag{4.18}$$

Assumption (4.18) is motivated by the a priori error estimate for the Lagrange multiplier [16]

$$\left(\sum_{e\in\mathcal{E}_h} h_e^{-1}\|\bar{p} - \tilde{p}_h\|_e^2\right)^{1/2} \le Ch^{k+1},$$

where $\bar{p}$ is the L^2-projection of p onto $\mathbf{V}_h\cdot\nu|_{\mathcal{E}_h}$.

THEOREM 4.1. *Assume that the saturation assumptions* (2.23), (3.4), (3.5), *and* (4.18) *hold. Then there exist constants C_1 and C_2 independent of β and β_{div} such that*

$$\begin{aligned} C_1\left(\|\psi'\|_{H(\mathrm{div})} + \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\|[\mathbf{u}_h\cdot\nu]\|_\tau h_\tau^{1/2}\right) &\le \|\xi\|_{H(\mathrm{div})} \\ &\le \frac{C_2}{1-\beta_{max}}\left(\|\psi'\|_{H(\mathrm{div})} + \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\|[\mathbf{u}_h\cdot\nu]\|_\tau h_\tau^{1/2}\right), \end{aligned} \tag{4.19}$$

where $\beta_{max} = \max\{\beta,\beta_{\mathrm{div}}\}$.

Proof. We first note that (4.5) and (4.15) imply that on every $E\in\mathcal{T}_h$,

$$\nabla\cdot\psi' = \nabla\cdot\xi'. \tag{4.20}$$

Taking $\mathbf{v} = \psi' - \xi'$ in (4.14) and summing over all elements, we have

(4.21)
$$\begin{aligned} &\sum_{E\in\mathcal{T}_h}\big((K^{-1}(\psi'-\xi'), \psi'-\xi')_E - (\theta'-\eta', \nabla\cdot(\psi'-\xi'))_E\big) \\ &\quad= \sum_{E\in\mathcal{T}_h}\big(-(K^{-1}\xi', \psi'-\xi')_E + (\eta', \nabla\cdot(\psi'-\xi'))_E \\ &\qquad + r_E(\psi'-\xi') - \langle p_A, (\psi'-\xi')\cdot\nu_E\rangle_{\partial E}\big) \\ &\quad= \sum_{E\in\mathcal{T}_h}\big(-(K^{-1}\mathbf{u}'_h, \psi'-\xi')_E + (p'_h, \nabla\cdot(\psi'-\xi'))_E - \langle\tilde{p}_h, (\psi'-\xi')\cdot\nu_E\rangle_{\partial E\cap\mathcal{E}_h} \\ &\qquad - \langle g, (\psi'-\xi')\cdot\nu\rangle_{\partial E\cap\Gamma_D} - \langle\lambda_h, (\psi'-\xi')\cdot\nu_E\rangle_{\partial E\cap\Gamma}\big) \\ &\quad= \sum_{E\in\mathcal{T}_h}\big(\langle\tilde{p}'-\tilde{p}_h, (\psi'-\xi')\cdot\nu_E\rangle_{\partial E\cap\mathcal{E}_h} + \langle\lambda'_h - \lambda_h, (\psi'-\xi')\cdot\nu_E\rangle_{\partial E\cap\Gamma}\big), \end{aligned}$$

using (4.7) and (4.17) for the last equality. For the first term on the right-hand side, using the saturation assumption (4.18) and (2.34), we have

$$\begin{aligned}\left|\sum_{E\in\mathcal{T}_h}\langle\tilde{p}'-\tilde{p}_h,(\psi'-\xi')\cdot\nu_E\rangle_{\partial E\cap\mathcal{E}_h}\right| &\le \sum_{e\in\mathcal{E}_h} h_e^{-1/2}\|\tilde{p}'-\tilde{p}_h\|_e h_e^{1/2}\|(\psi'-\xi')\cdot\nu_e\|_e\\ &\le C\|\xi\|\|\psi'-\xi'\|.\end{aligned}\tag{4.22}$$

For the second term on the right-hand side of (4.21) we write, using (2.34), (2.23), and (3.17),

$$\begin{aligned}\left|\sum_{E\in\mathcal{T}_h}\langle\lambda_h'-\lambda_h,(\psi'-\xi')\cdot\nu_E\rangle_{\partial E\cap\Gamma}\right| &= \left|\sum_{i=1}^n\langle\delta',(\psi'-\xi')\cdot\nu_i\rangle_{\Gamma_i}\right|\\ \le \sum_{\tau\in\mathcal{T}^{\Gamma,h}} h_\tau^{-1/2}\|\delta'\|_\tau h_\tau^{1/2}\|[(\psi'-\xi')\cdot\nu]\|_\tau&\\ \le |||\delta'|||\,\|\psi'-\xi'\| \le C\|\xi\|\|\psi'-\xi'\|.&\end{aligned}\tag{4.23}$$

Combining (4.21)–(4.23) and using (4.20), we obtain

$$\|\psi'-\xi'\|\le C\|\xi\|,$$

which implies, using the triangle inequality and (4.10),

$$\|\psi'\|\le C\|\xi\|.\tag{4.24}$$

Taking $w=\nabla\cdot\psi'$ in (4.15) immediately gives

$$\|\nabla\cdot\psi'\|\le\|\nabla\cdot\xi\|,$$

which, combined with (4.24), implies

$$\|\psi'\|_{H(\mathrm{div})}\le C\|\xi\|_{H(\mathrm{div})}.$$

Combining the above bound with (3.21) completes the proof of the left inequality in (4.19). To show the right inequality in (4.19), taking $\mathbf{v}=\xi'$ in (4.4), and using (4.14), we have

$$(K^{-1}(\xi'-\psi'),\xi')=\sum_{i=1}^n\big((\eta'-\theta',\nabla\cdot\xi')_{\Omega_i}-\langle\delta',\xi'\cdot\nu_i\rangle_{\Gamma_i}\big).\tag{4.25}$$

For the first term on the right-hand side of (4.25) we use (4.20) and the argument from (4.21) to obtain

$$\begin{aligned}\sum_{i=1}^n(\eta'-\theta',\nabla\cdot\xi')_{\Omega_i} &= \sum_{E\in\mathcal{T}_h}(\eta'-\theta',\nabla\cdot\psi')_E\\ &= \big(K^{-1}(\xi'-\psi'),\psi'\big)-\sum_{E\in\mathcal{T}_h}\big(\langle\tilde{p}'-\tilde{p}_h,\psi'\cdot\nu_E\rangle_{\partial E\cap\mathcal{E}_h}\\ &\quad+\langle\lambda_h'-\lambda_h,\psi'\cdot\nu_E\rangle_{\partial E\cap\Gamma}\big),\end{aligned}\tag{4.26}$$

which, combined with (4.25), implies

$$\begin{aligned}&\big(K^{-1}(\xi'-\psi'),\xi'-\psi'\big)=-\langle\delta',\xi'\cdot\nu_i\rangle_{\Gamma_i}\\ &\quad-\sum_{E\in\mathcal{T}_h}\big(\langle\tilde{p}'-\tilde{p}_h,\psi'\cdot\nu_E\rangle_{\partial E\cap\mathcal{E}_h}+\langle\lambda_h'-\lambda_h,\psi'\cdot\nu_E\rangle_{\partial E\cap\Gamma}\big).\end{aligned}\tag{4.27}$$

For the first term on the right-hand side we have, using (4.6),

$$\left|\sum_{i=1}^{n}\langle \delta', \xi'\cdot\nu_i\rangle_{\Gamma_i}\right| = \left|\sum_{i=1}^{n}\langle \delta', \mathbf{u}_h\cdot\nu_i\rangle_{\Gamma_i}\right| \le \epsilon_1\|\xi\|^2 + \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\frac{1}{4\epsilon_1}\|[\mathbf{u}_h\cdot\nu]\|_\tau^2 h_\tau, \tag{4.28}$$

where the inequality is obtained using the argument in (3.15) and (3.17). The last two terms on the right-hand side of (4.27) can be bounded similarly to (4.22) and (4.23):

(4.29)

$$\left|\sum_{E\in\mathcal{T}_h}\left(\langle \tilde{p}' - \tilde{p}_h, \psi'\cdot\nu_E\rangle_{\partial E\cap\mathcal{E}_h} + \langle \lambda_h' - \lambda_h, \psi'\cdot\nu_E\rangle_{\partial E\cap\Gamma}\right)\right| \le C\left(\epsilon_2\|\xi\|^2 + \frac{1}{4\epsilon_2}\|\psi'\|^2\right).$$

Combining (4.27)–(4.29),

$$\|\xi' - \psi'\|^2 \le C\left((\epsilon_1+\epsilon_2)\|\xi\|^2 + \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\frac{1}{4\epsilon_1}\|[\mathbf{u}_h\cdot\nu]\|_\tau^2 h_\tau + \frac{1}{4\epsilon_2}\|\psi'\|^2\right),$$

which implies, using the triangle inequality, (4.10), and taking ϵ_1 and ϵ_2 small enough,

$$\|\xi\| \le \frac{C}{1-\beta}\left(\|\psi'\| + \sum_{\tau\in\mathcal{T}^{\Gamma,h}}\|[\mathbf{u}_h\cdot\nu]\|_\tau h_\tau^{1/2}\right).$$

An application of (4.11) and (4.20) completes the proof. ∎

5. Numerical results.

In this section we test the performance of the residual-based error estimator. The estimator is used as a local error indicator that drives an adaptive mesh refinement process. The following algorithm describes the adaptive procedure.

ALGORITHM.

1. Solve the problem on a coarse (both subdomain and mortar) grid.
2. For each subdomain Ω_i
   (a) Compute
   $$\omega_i = \left(\sum_{E\in\mathcal{T}_{h,i}}\omega_E^2 + \sum_{\tau\in\mathcal{T}^{\Gamma_i,h}}\omega_\tau^2\right)^{1/2}.$$
   (b) If $\omega_i > 0.5\max_{1\le j\le n}\omega_j$, refine $\mathcal{T}_{h,i}$.
   (c) If any neighboring subdomain grid has been refined two times more than Ω_i, refine $\mathcal{T}_{h,i}$.
3. For each interface $\Gamma_{i,j}$, if either Ω_i or Ω_j has been refined, refine $\mathcal{T}_{h,i,j}$.
4. Solve the problem on the refined grid. If either the desired error tolerance or the maximum refinement level has been reached, exit; otherwise go to step 2.

Several comments are in order. First, we employ the pressure error estimator based on ω_E and ω_τ, defined in (3.1) and (3.2), since it provides an efficient and reliable estimate of the L^2 pressure error, due to Theorems 3.1 and 3.3. Second, the refinement rule 2(c) is needed to reduce the effect of discretization error due to large ratios between grid sizes in neighboring subdomains. Third, according to rule 3, mortar grids are refined if either adjacent subdomain grid is refined.

In the examples below, the subdomains are discretized by the lowest-order Raviart–Thomas spaces. Discontinuous piecewise linear mortar spaces are used on the interfaces.

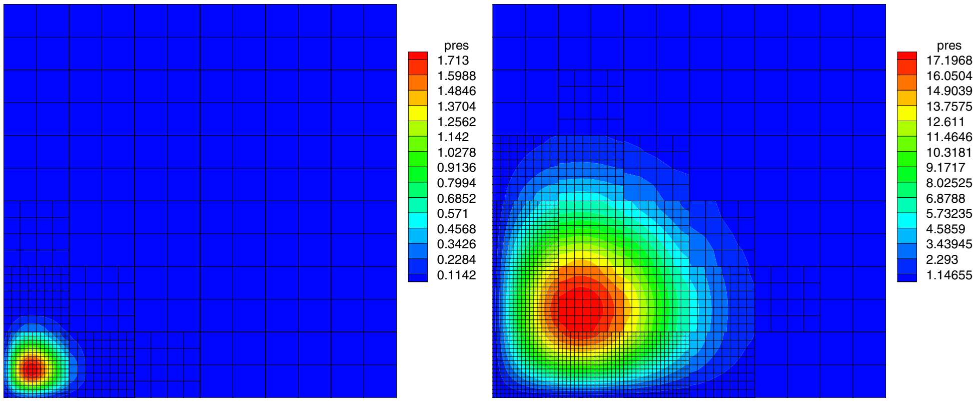

Fig. 5.1. *Computed pressure on the fourth grid level for examples* 1 *and* 2.

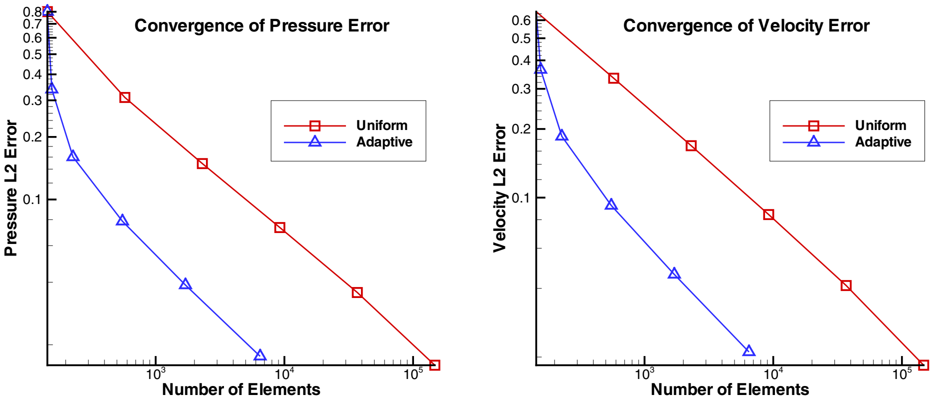

Fig. 5.2. *Convergence of pressure and velocity error for example* 1.

We first illustrate the above algorithm for several two-dimensional problems. In all examples the domain is the unit square, decomposed into 6×6 subdomains. The coarse grid in each subdomain is 2×2 with a single mortar element on each interface. In the first two examples we test problems with boundary layers. The true pressure solution is

$$p(x, y) = 1000\, x\, y\, e^{-k(x^2+y^2)},$$

where $k = 100$ in example 1 and $k = 10$ in example 2. In both cases $K = I$. The computed pressure after three refinements is shown in Figure 5.1. We note that in both cases the grids are appropriately refined along the boundary layers. In the second example the exponential drop is less steep. This causes an extended boundary layer, which is resolved by a strip of fine subdomain grids along the boundary. In Figure 5.2, the pressure and velocity errors in example 1 are plotted as functions of the total number of finite elements. The convergence of the error for all other examples is similar and is not shown. We observe that the adaptive solution needs about 20 times fewer elements to provide the same accuracy.

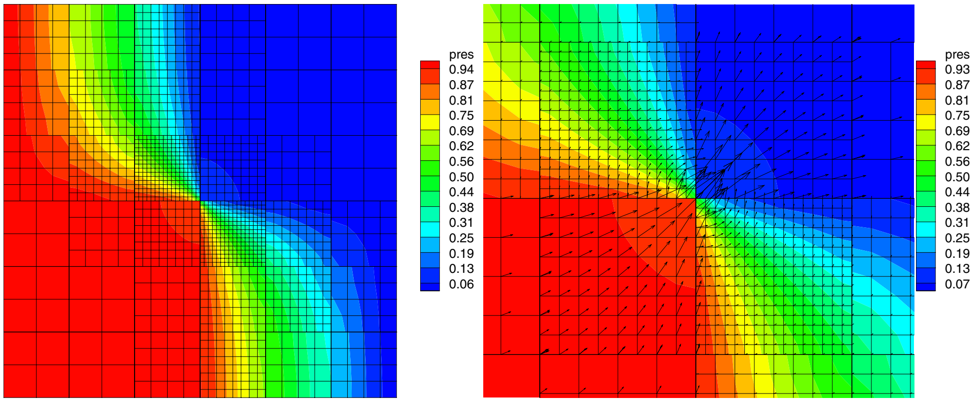

Fig. 5.3. *Computed solution on the fourth grid level for example* 3. *Left: pressure on the full grid. Right: pressure and velocity near the singularity.*

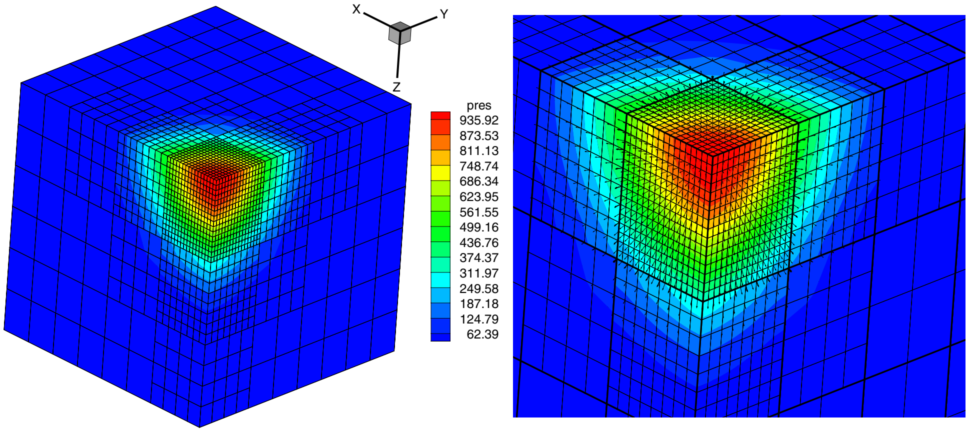

Fig. 5.4. *Computed solution on the fourth grid level for example* 4. *Left: pressure on the full grid. Right: pressure and velocity zoom.*

In the next example, motivated by the modeling flow in heterogeneous porous media, we test a problem with a discontinuous permeability tensor K. The domain is divided into four subregions by the lines $x = 0.5$ and $y = 0.5$. The permeability is $K = 100I$ in the lower-left and upper-right regions and $K = I$ in the other two regions. Dirichlet boundary conditions $p = 1$ on the left and $p = 0$ on the right and no-flow boundary conditions on the top and bottom force the flow from left to right. It is known for the true solution that $p \in H^{1+\alpha}$ for some $0 < \alpha < 1$ with singularity occurring at the cross-point. The computed solution after three refinements is shown in Figure 5.3. As expected the grids are finest near the singularity and are also refined in the low permeability region to resolve the high pressure gradient. Some of the grids in the high permeability region are refined as well, due to the refinement rule 2(c).

Finally, a three-dimensional example is presented. The unit cube is divided into $4 \times 4 \times 3$ subdomains. The true pressure

$$p = 1000\, e^{-10(x^2+y^2+z^2)}$$

exhibits a steep exponential decay near the origin. The computed pressure and velocity on the fourth grid level are given in Figure 5.4. The steep pressure gradient and large velocity are well resolved by the fine computational grids near the origin.

6. Conclusions. In this paper, several two- and three-dimensional a posteriori error estimators for mortar mixed finite element methods for elliptic equations have been derived. A residual-based error estimator provides optimal upper and lower bounds for the pressure error. A closely related error estimator for the velocity gives an optimal upper bound, but suboptimal lower bound. The negative power of h that appears is due to the different order of derivatives involved in the L^2-norm and the $H(\text{div})$-norm. An efficient and reliable implicit estimator for the velocity is also derived, which is based on solving local (element) problems. All estimators include a term that measures the jump of flux across subdomain interfaces. This term provides a measure of nonconformity in the mortar discretization. In cases where the subdomain grids are fixed and optimal mortar grids need to be obtained, this flux-jump term can be used to drive an adaptive process for the mortar grids independently of the subdomain grids.

Acknowledgment. The authors thank Wolfgang Bangerth for his useful comments.

THE GAUGE–UZAWA FINITE ELEMENT METHOD. PART I: THE NAVIER–STOKES EQUATIONS*

RICARDO H. NOCHETTO† AND JAE-HONG PYO‡

Abstract. The gauge–Uzawa FEM is a new first order fully discrete projection method which combines advantages of both the gauge and Uzawa methods within a variational framework. A time step consists of a sequence of $d+1$ Poisson problems, d being the space dimension, thereby avoiding both the incompressibility constraint as well as dealing with boundary tangential derivatives as in the gauge method. This allows for a simple finite element discretization in space of any order in both two and three dimensions. This first part introduces the method for the Navier–Stokes equations of incompressible fluids and shows unconditional stability and error estimates for both velocity and pressure via a variational approach under realistic regularity assumptions. Several numerical experiments document performance of the gauge–Uzawa FEM and compare it with other projection methods.

1. Introduction.

Given an open bounded polygon (or polyhedron) Ω in $\mathbb{R}^d$ with $d = 2$ (or 3), we consider the time-dependent Navier–Stokes equations

$$\begin{aligned} \mathbf{u}_t + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p - \mu\triangle\mathbf{u} &= \mathbf{f} \quad \text{in } \Omega, \\ \operatorname{div}\mathbf{u} &= 0 \quad \text{in } \Omega, \\ \mathbf{u}(\mathbf{x},0) &= \mathbf{u}^0 \quad \text{in } \Omega \end{aligned} \tag{1.1}$$

with a vanishing Dirichlet boundary condition $\mathbf{u} = \mathbf{0}$ on $\partial\Omega$ and a pressure mean-value $\int_\Omega p = 0$. This system models the dynamics of an incompressible viscous Newtonian fluid. The viscosity $\mu = Re^{-1}$ is the reciprocal of the Reynolds number. The unknowns are a vector function $\mathbf{u}$ (velocity) and a scalar function p (pressure).

The incompressibility condition $\operatorname{div}\mathbf{u} = 0$ in (1.1) leads to a saddle point structure, which requires compatibility between the discrete spaces for $\mathbf{u}$ and p [1, 2, 10] (*inf-sup condition*). To circumvent this difficulty, projection methods have been studied since the late 1960s which exploit the time dependence in (1.1) [4, 9, 11, 18, 21, 24, 25]. However, such methods

- yield momentum equations inconsistent with the first equation in (1.1);
- impose artificial boundary conditions on pressure (or related variables), which are responsible for boundary layers and reduced accuracy [4, 9];
- require sometimes knowing a suitable initial pressure which is incompatible with the elliptic nature of the Lagrange multiplier p and equation $\operatorname{div}\mathbf{u} = 0$ [11, 18];

- are often studied without space discretization [3, 4, 18, 20, 21, 25], and the ensuing analysis may not apply to full discretizations;
- often require unrealistic regularity assumptions in their analysis, particularly so for fully discrete schemes; for instance, $\mathbf{u}_{tt} \in L^\infty(\mathbf{H}^2)$, $\mathbf{u}_{ttt} \in L^\infty(\mathbf{H}^1)$, $p_{tt} \in L^\infty(H^2)$, $p_{ttt} \in L^\infty(L^2)$ are required in [11] for a Chorin finite element method, and similar strong assumptions are made in [27] for a gauge finite difference method.

The gauge method is a projection method, due to Osedelets [17] and E and Liu [7], meant to circumvent these difficulties. It introduces new variables $\mathbf{a}$ and ϕ (gauge) such that $\mathbf{u} = \mathbf{a} + \nabla\phi$ and couple them via the boundary condition $\mathbf{u} = \mathbf{0}$. The method has been studied in [27] using asymptotic methods and in [16] employing variational techniques. The boundary coupling is responsible for accuracy degradation in problems with singular solutions (due to reentrant corners), as will be illustrated below. It also makes the use of finite element methods (FEM) problematic for space discretization. In this paper, we construct a gauge–Uzawa FEM (GU-FEM) which inherits some beneficial properties of both the gauge method and the Uzawa method and which avoids dealing with boundary derivatives. We also prove that the fully discrete method is unconditionally stable and derive error estimates for both velocity and pressure under realistic regularity requirements.

1.1. The gauge–Uzawa finite element method. To motivate the new method we start from the gauge method of Oseledets [17] and E and Liu [7]; see also [16, 19]. Let ϕ be an auxiliary scalar variable, the so-called *gauge* variable, and $\mathbf{a}$ be an unknown vector such that $\mathbf{u} = \mathbf{a} + \nabla\phi$. If ϕ and p satisfy the heat equation $\partial_t\phi - \mu\Delta\phi = -p$, then the momentum and incompressibility equations become

$$\begin{aligned} \partial_t\mathbf{a} + (\mathbf{u}\cdot\nabla)\mathbf{u} - \mu\triangle\mathbf{a} &= \mathbf{f} \quad \text{in } \Omega,\\ -\triangle\phi &= \operatorname{div}\mathbf{a} \quad \text{in } \Omega. \end{aligned}$$

This formulation is equivalent to (1.1) at the PDE level. We are now free to choose boundary conditions for the nonphysical variables $\mathbf{a}$ and ϕ for as long as $\mathbf{u} = \mathbf{0}$ is enforced. Hereafter, we employ a Neumann condition on ϕ which, according to [7, 16, 19, 27], is the most advantageous:

$$\partial_{\boldsymbol{\nu}}\phi = 0, \quad \mathbf{a}\cdot\boldsymbol{\nu} = 0, \quad \mathbf{a}\cdot\boldsymbol{\tau} = -\partial_{\boldsymbol{\tau}}\phi;$$

$\boldsymbol{\nu}$ and $\boldsymbol{\tau}$ are the unit vectors in the normal and tangential directions, respectively. Upon discretizing in time via the backward Euler method [7, 27] and a semi-implicit treatment of the convection term, we end up with the following unconditionally stable method [16, 19].

Algorithm 1 (gauge method). Start with $\phi^0 = 0$ and $\mathbf{a}^0 = \mathbf{u}^0$. Repeat the steps.
Step 1: Find $\mathbf{a}^{n+1}$ as the solution of

$$\text{(1.2)} \qquad \begin{aligned} \frac{\mathbf{a}^{n+1} - \mathbf{a}^n}{\tau} + (\mathbf{u}^n\cdot\nabla)(\mathbf{a}^{n+1} + \nabla\phi^n) - \mu\triangle\mathbf{a}^{n+1} &= \mathbf{f}(t^{n+1}) \quad \text{in } \Omega,\\ \mathbf{a}^{n+1}\cdot\boldsymbol{\nu} = 0, \qquad \mathbf{a}^{n+1}\cdot\boldsymbol{\tau} &= -\partial_{\boldsymbol{\tau}}\phi^n \quad \text{on } \partial\Omega. \end{aligned}$$

Step 2: Find ϕ^{n+1} as the solution of

$$\begin{aligned} -\triangle\phi^{n+1} &= \operatorname{div}\mathbf{a}^{n+1} \qquad \text{in } \Omega,\\ \partial_{\boldsymbol{\nu}}\phi^{n+1} &= 0 \qquad \text{on } \partial\Omega. \end{aligned}$$

Step 3: Update $\mathbf{u}^{n+1}$ according to

$$\mathbf{u}^{n+1} = \mathbf{a}^{n+1} + \nabla\phi^{n+1}. \tag{1.3}$$

We point out that the momentum equation is linear in $\mathbf{a}^{n+1}$, and that the explicit boundary condition $\mathbf{a}^{n+1}\cdot\boldsymbol{\tau} = -\partial_{\boldsymbol{\tau}}\phi^n$ is crucial to decouple the equations for $\mathbf{a}^{n+1}$ and ϕ^{n+1}. Since this formulation is consistent with (1.1), except for $\mathbf{u}^{n+1}\cdot\boldsymbol{\tau} = \partial_{\boldsymbol{\tau}}(\phi^{n+1}-\phi^n)$, normal mode analysis can be used to show full accuracy for smooth solutions [3, 20]. However, several deficiencies of this algorithm are now apparent.

- The boundary term $\partial_{\boldsymbol{\tau}}\phi^n$ is nonvariational and thus difficult to implement within a finite element context, especially in three dimensions.
- The computation of $\partial_{\boldsymbol{\tau}}\phi^n$, which involves numerical differentiation, yields loss of accuracy and is problematic at corners of $\partial\Omega$ where $\boldsymbol{\tau}$ is not well defined. This is remarkably important for reentrant corners as illustrated in the comparisons below.
- The computation of $p^{n+1} = \mu\Delta\phi^{n+1} - \tau^{-1}(\phi^{n+1}-\phi^n)$ is also unstable. This yields a reduced rate of convergence or lack of convergence altogether [16, 19, 27].
- Numerical experiments indicate that the polynomial degree for ϕ must be of higher order than that for p [19]. A suitable combination of finite element spaces for $(\mathbf{a},\mathbf{u},\phi,p)$ is continuous piecewise polynomials $(\mathcal{P}^2,\mathcal{P}^2,\mathcal{P}^3,\mathcal{P}^1)$, which is consistent with (1.3) and the previous expression for p^{n+1}. This computation is, however, rather costly since ϕ is just an auxiliary variable without intrinsic interest [19].

The purpose of this paper is to construct and study the gauge–Uzawa FEM, which overcomes these shortcomings without losing advantages of the gauge method. We start by introducing a new vector variable $\widehat{\mathbf{u}}^{n+1}$ having zero boundary values

$$\widehat{\mathbf{u}}^{n+1} = \mathbf{a}^{n+1} + \nabla\phi^n.$$

Inserting this into (1.2), we readily get

$$\frac{\widehat{\mathbf{u}}^{n+1}-\mathbf{u}^n}{\tau} + (\mathbf{u}^n\cdot\nabla)\widehat{\mathbf{u}}^{n+1} - \mu\triangle\widehat{\mathbf{u}}^{n+1} + \mu\nabla\triangle\phi^n = \mathbf{f}(t^{n+1}) \quad \text{in } \Omega. \tag{1.4}$$

To deal with the third order term $\nabla\triangle\phi^n$, which is a source of trouble due to lack of commutativity of the differential operators at the discrete level, we introduce the variable $s^{n+1} = \triangle\phi^{n+1}$ and note the connection with the *Uzawa iteration*:

$$s^{n+1} = \triangle\phi^{n+1} = -\operatorname{div}\mathbf{a}^{n+1} = \triangle\phi^n - \operatorname{div}\widehat{\mathbf{u}}^{n+1} = s^n - \operatorname{div}\widehat{\mathbf{u}}^{n+1}. \tag{1.5}$$

If we also set $\rho^{n+1} = \phi^{n+1} - \phi^n$, then

$$-\triangle\rho^{n+1} = -\triangle(\phi^{n+1}-\phi^n) = \operatorname{div}\widehat{\mathbf{u}}^{n+1}. \tag{1.6}$$

Combining (1.4), (1.5), and (1.6) we arrive at the discrete-time gauge–Uzawa method.

In order to introduce the finite element discretization we need further notation. Let $H^s(\Omega)$ be the Sobolev space with s derivatives in $L^2(\Omega)$, set $\mathbf{L}^2(\Omega) = (L^2(\Omega))^d$ and $\mathbf{H}^s(\Omega) = (H^s(\Omega))^d$, where $d = 2$ or 3, and denote by $L^2_0(\Omega)$ the subspace of $L^2(\Omega)$ of functions with vanishing mean value. We indicate with $\|\cdot\|_s$ the norm in $H^s(\Omega)$ and with $\langle\cdot\,,\cdot\rangle$ the inner product in $L^2(\Omega)$. Let $\mathfrak{T} = \{K\}$ be a shape-regular quasi-uniform partition of Ω of mesh size h into closed elements K [1, 2, 10]. The vector and scalar finite element spaces are

$$\begin{aligned}
&\mathbb{W}_h := \{\mathbf{v}_h \in \mathbf{L}^2(\Omega) : \mathbf{v}_h|_K \in \mathcal{P}(K) \quad \forall K \in \mathfrak{T}\}, \quad \mathbb{V}_h := \mathbb{W}_h \cap \mathbf{H}^1_0(\Omega),\\
&\mathbb{P}_h := \{q_h \in L^2_0(\Omega) \cap C^0(\Omega) : q_h|_K \in \mathcal{Q}(K) \quad \forall K \in \mathfrak{T}\},
\end{aligned}$$

where $\mathcal{P}(K)$ and $\mathcal{Q}(K)$ are spaces of polynomials with degree bounded uniformly with respect to $K \in \mathfrak{T}$ [2, 10]. We stress that the space $\mathbb{P}_h$ is composed of continuous functions for (1.6) to make sense. This implies the crucial equality

$$\langle \operatorname{div} \mathbf{v}_h \,,\, q_h \rangle = -\langle \mathbf{v}_h \,,\, \nabla q_h \rangle \quad \forall \mathbf{v}_h \in \mathbb{V}_h, \quad q_h \in \mathbb{P}_h.$$

Using the following discrete counterpart of the form $\mathfrak{N}(\mathbf{u}, \mathbf{v}, \mathbf{w}) = \langle (\mathbf{u} \cdot \nabla)\mathbf{v} \,,\, \mathbf{w} \rangle$:

$$\mathfrak{N}_h(\mathbf{u}_h, \mathbf{v}_h, \mathbf{w}_h) = \frac{1}{2} \langle (\mathbf{u}_h \cdot \nabla)\mathbf{v}_h \,,\, \mathbf{w}_h \rangle - \frac{1}{2} \langle (\mathbf{u}_h \cdot \nabla)\mathbf{w}_h \,,\, \mathbf{v}_h \rangle, \tag{1.7}$$

we are ready to write the gauge–Uzawa finite element method.

Algorithm 2 (gauge–Uzawa FEM). Start with $s_h^0 = 0$ and $\mathbf{u}_h^0$ as a solution of $\langle \mathbf{u}_h^0 \,,\, \mathbf{w}_h \rangle = \langle \mathbf{u}^0 \,,\, \mathbf{w}_h \rangle$ for all $\mathbf{w}_h \in \mathbb{V}_h$.

Step 1: Find $\widehat{\mathbf{u}}_h^{n+1} \in \mathbb{V}_h$ as the solution of

$$\begin{aligned} \tau^{-1} \langle \widehat{\mathbf{u}}_h^{n+1} - \mathbf{u}_h^n \,,\, \mathbf{w}_h \rangle + \mathfrak{N}_h(\mathbf{u}_h^n, \widehat{\mathbf{u}}_h^{n+1}, \mathbf{w}_h) + \mu \langle \nabla \widehat{\mathbf{u}}_h^{n+1} \,,\, \nabla \mathbf{w}_h \rangle \\ - \mu \langle s_h^n \,,\, \operatorname{div} \mathbf{w}_h \rangle = \langle \mathbf{f}(t^{n+1}) \,,\, \mathbf{w}_h \rangle \quad \forall \mathbf{w}_h \in \mathbb{V}_h. \end{aligned} \tag{1.8}$$

Step 2: Find $\rho_h^{n+1} \in \mathbb{P}_h$ as the solution of

$$\langle \nabla \rho_h^{n+1} \,,\, \nabla \psi_h \rangle = \langle \operatorname{div} \widehat{\mathbf{u}}_h^{n+1} \,,\, \psi_h \rangle \qquad \forall \psi_h \in \mathbb{P}_h. \tag{1.9}$$

Step 3: Update $s_h^{n+1} \in \mathbb{P}_h$ according to

$$\langle s_h^{n+1} \,,\, q_h \rangle = \langle s_h^n \,,\, q_h \rangle - \langle \operatorname{div} \widehat{\mathbf{u}}_h^{n+1} \,,\, q_h \rangle \qquad \forall q_h \in \mathbb{P}_h. \tag{1.10}$$

Step 4: Update $\mathbf{u}_h^{n+1} \in \mathbb{V}_h + \nabla \mathbb{P}_h$ according to

$$\mathbf{u}_h^{n+1} = \widehat{\mathbf{u}}_h^{n+1} + \nabla \rho_h^{n+1}. \tag{1.11}$$

We note that $\mathbf{u}_h^{n+1}$ is a discontinuous function across interelement boundaries and that, in light of (1.9), $\mathbf{u}_h^{n+1}$ is discrete divergence free in the sense that

$$\langle \mathbf{u}_h^{n+1} \,,\, \nabla \psi_h \rangle = 0 \qquad \forall \psi_h \in \mathbb{P}_h. \tag{1.12}$$

In addition, the discrete pressure $p_h^{n+1} \in \mathbb{P}_h$ can be computed via

$$p_h^{n+1} = \mu s_h^{n+1} - \tau^{-1} \rho_h^{n+1}. \tag{1.13}$$

Consequently, the ensuing momentum equations for either $(\widehat{\mathbf{u}}^{n+1}, p^n)$ or $(\mathbf{u}^{n+1}, p^{n+1})$ are fully consistent with (1.1), a distinctive feature of this new formulation:

$$\begin{aligned} \tau^{-1} \langle \widehat{\mathbf{u}}_h^{n+1} - \widehat{\mathbf{u}}_h^n \,,\, \mathbf{w}_h \rangle + \mathfrak{N}_h(\mathbf{u}_h^n, \widehat{\mathbf{u}}_h^{n+1}, \mathbf{w}_h) + \mu \langle \nabla \widehat{\mathbf{u}}_h^{n+1} \,,\, \nabla \mathbf{w}_h \rangle \\ - \langle p_h^n \,,\, \operatorname{div} \mathbf{w}_h \rangle = \langle \mathbf{f}(t^{n+1}) \,,\, \mathbf{w}_h \rangle \quad \forall \mathbf{w}_h \in \mathbb{V}_h. \end{aligned} \tag{1.14}$$

1.2. Comparison with other projection methods. We now compare the gauge–Uzawa FEM of Algorithm 2 with the original Chorin method [4, 25], the Chorin–Uzawa method [18], and the gauge method of Algorithm 1 [7, 16, 19] using finite elements of degree 2 for $\mathbf{u}, \widehat{\mathbf{u}}, \mathbf{a}$, of degree 1 for p, s, ρ, and of degree 3 for ϕ.

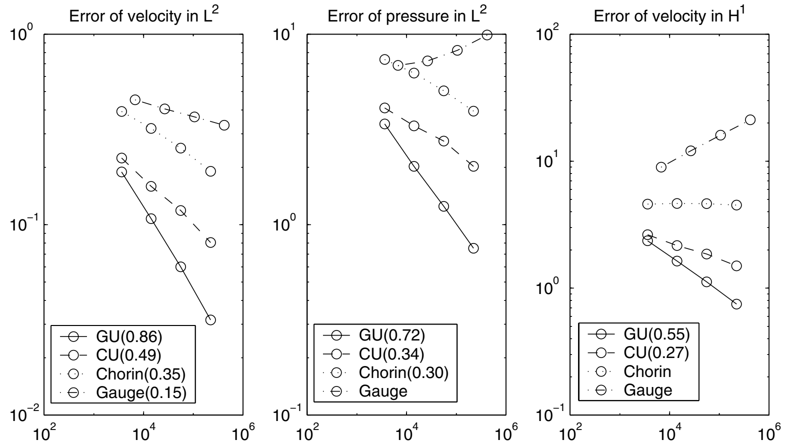

FIG. 1.1. *Error decay vs. number of degrees of freedom for four projection methods; the errors are measured in $L^2(\mathbf{L}^2)$ and $L^2(\mathbf{H}^1)$ for velocity and $L^2(L^2)$ for pressure. Velocity and pressure do not always converge for the gauge method, even though we use the best finite element combination $(\mathcal{P}^2, \mathcal{P}^1, \mathcal{P}^3)$ for $(\mathbf{u}, p, \phi)$. The gauge–Uzawa FEM exhibits a superior performance overall. Numbers in parentheses are the experimental orders of convergence.*

We consider the L-shaped domain $\Omega = ((-1,1)\times(-1,1)) - ([0,1)\times(-1,0])$ and the corresponding time-dependent singular solution of the Stokes equation ($\mathfrak{N}_h = 0$) [26]

$$\mathbf{u}(r,\theta) = \frac{3-\cos(5t)}{4} r^{\alpha} \begin{bmatrix} \cos(\theta)\psi'(\theta) + (1+\alpha)\sin(\theta)\psi(\theta) \\ \sin(\theta)\psi'(\theta) - (1+\alpha)\cos(\theta)\psi(\theta) \end{bmatrix},$$

$$p(r,\theta) = -\frac{3-\cos(5t)}{4} r^{\alpha-1} \frac{(1+\alpha)^2\psi'(\theta) + \psi'''(\theta)}{1-\alpha},$$

where $\omega = \frac{3\pi}{2}, \alpha = 0.544,$

$$\psi(\theta) = \frac{\sin((1+\alpha)\theta)\cos(\alpha\omega)}{1+\alpha} - \cos((1+\alpha)\theta) + \frac{\sin((\alpha-1)\theta)\cos(\alpha\omega)}{1-\alpha} + \cos((\alpha-1)\theta),$$

and $T = 5$. This example is not covered by theory because $(\mathbf{u}, p)(\cdot, t) \notin \mathbf{H}^2(\Omega)\times H^1(\Omega)$ due to $\alpha < 1$ (see Lemma 2.1); it provides, however, quite strong computational support to GU-FEM and hints at the need for further analysis. The initial mesh and time steps are $\tau = h = 1/8$ and are subsequently halved for every experiment.

Figure 1.1 clearly shows the superior performance of the gauge–Uzawa FEM, particularly so in regard to pressure approximation for which the gauge method fails to converge. These experiments, as well as those in section 7, were carried out within the software platform ALBERT of Schmidt and Siebert [22].

1.3. The main results. We now summarize our theoretical results of the rest of this paper for the gauge–Uzawa FEM. In section 3 we prove stability.

Theorem 1.1 (stability). *The gauge–Uzawa FEM is unconditionally stable in the sense that, for all $\tau > 0$, the following a priori bound holds:*

$$\begin{aligned}\left\|\mathbf{u}_h^{N+1}\right\|_0^2 + \sum_{n=0}^{N}\left\|\mathbf{u}_h^{n+1}-\mathbf{u}_h^{n}\right\|_0^2 + \frac{\mu\tau}{2}\sum_{n=0}^{N}\left\|\nabla\widehat{\mathbf{u}}_h^{n+1}\right\|_0^2 \\ + 2\sum_{n=0}^{N}\left\|\nabla\rho_h^{n+1}\right\|_0^2 + \mu\tau\left\|s_h^{N+1}\right\|_0^2 \le \left\|\mathbf{u}_h^0\right\|_0^2 + C\tau\sum_{n=0}^{N}\left\|\mathbf{f}(t^{n+1})\right\|_{-1}^2.\end{aligned} \tag{1.15}$$

We then study the rate of convergence of various unknowns under appropriate assumptions A1–A6 described in section 2. In section 4 we prove error estimates for velocity.

Theorem 1.2 (error estimates for velocity). *If* A1–A6 *hold and $h^2 \le C\tau$, with $C > 0$ arbitrary, then we have the error estimates*

$$\tau\sum_{n=0}^{N}\left\|\nabla\left(\mathbf{u}(t^{n+1})-\widehat{\mathbf{u}}_h^{n+1}\right)\right\|_0^2 \le C(\tau+h^2),$$

$$\tau\sum_{n=0}^{N}\left(\left\|\mathbf{u}(t^{n+1})-\mathbf{u}_h^{n+1}\right\|_0^2 + \left\|\mathbf{u}(t^{n+1})-\widehat{\mathbf{u}}_h^{n+1}\right\|_0^2\right) \le C(\tau+h^2)^2.$$

Given a sequence $\{W^n\}_{n=0}^N$, we define its discrete time derivative to be

$$\delta W^{n+1} := \frac{W^{n+1}-W^n}{\tau}.$$

We also define the discrete weight $\sigma^n := \min(t^n, 1)$ for $1 \le n \le N$. In section 5 we derive an error estimate for time derivative of velocity and utilize it in section 6 to prove and error estimate for pressure.

Theorem 1.3 (error estimates for time derivative of velocity and pressure). *Let* A1–A6 *hold and $C_1h^2 \le \tau \le C_2h^{\frac{d}{3}(1+\varepsilon)}$ be valid with arbitrary constants $C_1 > 0$ and $C_2 > 0$, where d is the space dimension. Then the following weighted estimates hold:*

$$\tau\sum_{n=0}^{N}\sigma^{n+1}\left(\left\|\delta(\mathbf{u}(t^{n+1})-\mathbf{u}_h^{n+1})\right\|_0^2 + \left\|p(t^{n+1})-p_h^{n+1}\right\|_0^2\right) \le C(\tau+h^2).$$

If NLC of section 2 *is also satisfied, then the following uniform error estimates are valid:*

$$\tau\sum_{n=0}^{N}\left(\left\|\delta(\mathbf{u}(t^{n+1})-\mathbf{u}_h^{n+1})\right\|_0^2 + \left\|p(t^{n+1})-p_h^{n+1}\right\|_0^2\right) \le C(\tau+h^2).$$

Proofs of Theorems 1.1–1.3 follow the variational approach of [16, 19]. These error estimates are similar to those known for the Chorin method [11, 18, 21], but require realistic and thus provable regularity when $t \downarrow 0$. They do not explain, though, the rates observed in practice for smooth solutions, as reported in section 7.1, which remains an open question. We also show in section 7.2 how to accommodate other boundary conditions.

2. Basic assumptions and regularity. This section is mainly devoted to stating assumptions and basic regularity results. We refer the reader to Constantin and Foias [5], Heywood and Rannacher [12], and Prohl [18] for details.

2.1. Regularity. We start with three basic assumptions about data Ω, $\mathbf{u}^0$, $\mathbf{f}$, and $\mathbf{u}$. We consider first the stationary Stokes equations which will be used in a duality argument:

$$\begin{aligned} -\triangle \mathbf{v} + \nabla q &= \mathbf{g} \quad \text{in } \Omega, \\ \operatorname{div} \mathbf{v} &= 0 \quad \text{in } \Omega, \\ \mathbf{v} &= \mathbf{0} \quad \text{on } \partial\Omega. \end{aligned} \tag{2.1}$$

Assumption A1 (regularity of $(\mathbf{v}, q)$). The unique solution $(\mathbf{v}, q) \in H_0^1(\Omega) \times L_0^2(\Omega)$ of the stationary Stokes equations (2.1) satisfies

$$\|\mathbf{v}\|_2 + \|q\|_1 \leq C\|\mathbf{g}\|_0.$$

We notice that A1 is valid provided $\partial\Omega$ is of class C^2 [5], or if Ω is a *convex* two-dimensional polygon [13] or three-dimensional polyhedron [6].

Assumption A2 (data regularity). The initial velocity $\mathbf{u}^0$ and the forcing term $\mathbf{f}$ in (1.1) satisfy

$$\mathbf{u}^0 \in \mathbf{H}^2(\Omega) \cap \mathbf{Z}(\Omega) \qquad \text{and} \qquad \mathbf{f},\, \mathbf{f}_t \in \mathbf{L}^\infty(0, T; \mathbf{L}^2(\Omega)),$$

where $\mathbf{Z}(\Omega) := \{\mathbf{z} \in \mathbf{H}_0^1(\Omega) : \operatorname{div} \mathbf{z} = 0\}$.

Assumption A3 (regularity of the solution $\mathbf{u}$). There exists $M > 0$ such that

$$\sup_{t\in[0,T]} \|\nabla \mathbf{u}(t)\|_0 \leq M.$$

We note that A3 is always satisfied in two dimensions, whereas it is valid in three dimensions provided $\left\|\mathbf{u}^0\right\|_1$ and $\|\mathbf{f}\|_{L^\infty(0,T;\mathbf{L}^2(\Omega))}$ are sufficiently small [12].

Lemma 2.1 (uniform and weighted a priori estimates [12]). *Let* $\sigma(t) = \min\{t, 1\}$ *be a weight function and* $0 < T \leq \infty$. *If* A1–A3 *holds, the solution* $(\mathbf{u}, p)$ *of* (1.1)

$$\sup_{0<t<T} \left(\|\mathbf{u}\|_2 + \|\mathbf{u}_t\|_0 + \|p\|_1\right) \leq M, \qquad \int_0^T \|\mathbf{u}_t\|_1^2\, dt \leq M, \tag{2.2}$$

$$\sup_{0<t<T} \left(\sigma(t)\|\mathbf{u}_t\|_1^2\right) \leq M, \qquad \int_0^T \sigma(t)\left(\|\mathbf{u}_t\|_2^2 + \|\mathbf{u}_{tt}\|_0^2 + \|p_t\|_1^2\right) dt \leq M. \tag{2.3}$$

Consequently, $(\mathbf{u}, p) \in L^\infty(0, T; \mathbf{H}^2(\Omega) \times H^1(\Omega))$ provided A1–A3 are valid.

The following *nonlocal* assumption is used to remove the weight $\sigma(t)$ for the error estimates for $\mathbf{u}_t$ in section 5 and pressure in section 6.

Assumption NLC (nonlocal compatibility). The data $\mathbf{u}^0$ and $\mathbf{f}^0 = \mathbf{f}(0, \cdot)$ are such that $\|\nabla \mathbf{u}_t(0)\|_0 \leq M$.

In view of [12, Corollary 2.1], we realize that NLC is equivalent to the initial data $\mathbf{u}^0, p^0 = p(0, \cdot), \mathbf{f}^0$ satisfying the overdetermined system

$$\Delta p^0 = \operatorname{div}(\mathbf{f}^0 - (\mathbf{u}^0 \cdot \nabla)\mathbf{u}^0) \quad \text{in } \Omega, \qquad \nabla p^0 = \Delta \mathbf{u}^0 + \mathbf{f}^0 - (\mathbf{u}^0 \cdot \nabla)\mathbf{u}^0 \quad \text{on } \partial\Omega.$$

This is true if $\mathbf{u}^0 = \mathbf{f}^0 = \mathbf{0}$, in which case also $p^0 = 0$ and $\|\nabla \mathbf{u}_t(0)\|_0 = 0$. However, $\|\nabla \mathbf{u}_t(t)\|_0$ blows-up in general as $t \downarrow 0$, thereby uncovering the practical limitations of results based on higher regularity than (2.2) and (2.3) uniformly for $t \downarrow 0$ [11, 27].

LEMMA 2.2 (uniform a priori estimates [12, Corollary 2.1]). *Suppose* A1–A3 *hold and let* $0 < T \leq \infty$. *Then NLC is valid if and only if*

$$\int_0^T \|\mathbf{u}_{tt}(t)\|_0^2\, dt + \sup_{0<t<T} \|\nabla \mathbf{u}_t(t)\|_0^2 \leq M. \tag{2.4}$$

Furthermore, if NLC holds, then $\int_0^T (\|p_t(t)\|_1^2 + \|\mathbf{u}_t(t)\|_2^2)\, dt \leq M$.

LEMMA 2.3 (a priori estimates on $\mathbf{Z}(\Omega)^*$ [16, 19]). *If* A1–A3 *hold, then we have*

$$\int_0^T \|\mathbf{u}_{tt}(t)\|_*^2\, dt \leq M, \tag{2.5}$$

where $\mathbf{Z}(\Omega)^*$ *is a dual space of* $\mathbf{Z}(\Omega)$. *If NLC also holds, then* $\sup_{0<t<T} \|\mathbf{u}_{tt}(t)\|_*^2 \leq M$.

LEMMA 2.4 (div-grad relation [15, 16, 19, 24]). *If* $\mathbf{v} \in \mathbf{H}_0^1(\Omega)$, *then*

$$\|\text{div } \mathbf{v}\|_0 \leq \|\nabla \mathbf{v}\|_0.$$

2.2. Properties of FEM.

We impose the following properties on $\mathbb{V}_h, \mathbb{P}_h$.

Assumption A4 (discrete inf-sup). There exists a constant $\beta > 0$ such that

$$\inf_{q_h \in \mathbb{P}_h} \sup_{\mathbf{v}_h \in \mathbb{V}_h} \frac{\langle \text{div } \mathbf{v}_h\, ,\, q_h \rangle}{\|\mathbf{v}_h\|_1 \|q_h\|_0} \geq \beta.$$

Assumption A5 (shape regularity and quasi-uniformity [1, 2, 10]). There exists a constant $C > 0$ such that the ratio between the diameter h_K of an element $K \in \mathfrak{T}$ and the diameter of the largest ball contained in K is bounded uniformly by C, and h_K is comparable with the mesh size h for all $K \in \mathfrak{T}$.

Assumption A6 (approximability [1, 2, 10]). For each $(\mathbf{v}, q) \in \mathbf{H}^2(\Omega) \times H^1(\Omega)$, there exist approximations $(\mathbf{v}_h, q_h) \in \mathbb{V}_h \times \mathbb{P}_h$ such that

$$\|\mathbf{v} - \mathbf{v}_h\|_0 + h\|\mathbf{v} - \mathbf{v}_h\|_1 \leq Ch^2 \|\mathbf{v}\|_2 \quad \text{and} \quad \|q - q_h\|_0 \leq Ch\|q\|_1.$$

The low order accuracy of A6 is consistent with the regularity setting of A1–A3. A higher order FEM could be used as well, particularly so if $(\mathbf{u}, p)$ is sufficiently smooth, and in this case the space error estimates below would accordingly be of a higher order.

Now let $(\mathbf{v}_h, q_h) \in \mathbb{V}_h \times \mathbb{P}_h$ indicate the finite element solution of (2.1), namely,

$$\begin{aligned} \langle \nabla \mathbf{v}_h\, ,\, \nabla \mathbf{w}_h \rangle - \langle q_h\, ,\, \text{div } \mathbf{w}_h \rangle = \langle \mathbf{g}\, ,\, \mathbf{w}_h \rangle \quad & \forall \mathbf{w}_h \in \mathbb{V}_h, \\ \langle r_h\, ,\, \text{div } \mathbf{v}_h \rangle = 0 \qquad\qquad & \forall r_h \in \mathbb{P}_h. \end{aligned} \tag{2.6}$$

LEMMA 2.5 (error estimates for mixed FEM [1, 2, 10]). *Let* $(\mathbf{v}, q) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ *be the solutions of* (2.1) *and* $(\mathbf{v}_h, q_h) = \mathfrak{S}_h(\mathbf{v}, q) \in \mathbb{V}_h \times \mathbb{P}_h$ *be the Stokes projections defined by* (2.6), *respectively. If* A4–A6 *hold, then*

$$\|\mathbf{v} - \mathbf{v}_h\|_0 + h\|\mathbf{v} - \mathbf{v}_h\|_1 + h\|q - q_h\|_0 \leq Ch^2 \left(\|\mathbf{v}\|_2 + \|q\|_1\right). \tag{2.7}$$

If A1 *also holds, then the right-hand side is bounded by* $Ch^2\|\mathbf{g}\|_0$ *and*

$$\|\mathbf{g}\|_* \le C\|\nabla\mathbf{v}\|_0 \le Ch\|\mathbf{g}\|_0 + C\|\nabla\mathbf{v}_h\|_0, \tag{2.8}$$

$$|\!|\!|\mathbf{v}-\mathbf{v}_h|\!|\!| := \|\mathbf{v}-\mathbf{v}_h\|_{\mathbf{L}^\infty(\Omega)} + \|\nabla(\mathbf{v}-\mathbf{v}_h)\|_{\mathbf{L}^3(\Omega)} \le C\|\mathbf{g}\|_0. \tag{2.9}$$

Proof. Inequality (2.7) is standard [1, 2, 10]. To prove (2.8) we simply test (2.1) with an arbitrary $\mathbf{z} \in \mathbf{Z}(\Omega)$ for the first inequality, and next use (2.7) for the second one. To establish (2.9) we just deal with the L^∞-norm since the other can be treated similarly. If I_h denotes the Clement interpolant, then $\|\mathbf{v} - I_h\mathbf{v}\|_{\mathbf{L}^\infty(\Omega)} \le C\|\mathbf{v}\|_2$ and

$$\|I_h\mathbf{v}-\mathbf{v}_h\|_{\mathbf{L}^\infty(\Omega)} \le Ch^{-d/2}\|I_h\mathbf{v}-\mathbf{v}_h\|_{\mathbf{L}^2(\Omega)} \le C\|\mathbf{v}\|_2$$

as a consequence of an inverse estimate and (2.7). This completes the proof. ∎

Remark 2.6 (H^1 stability of q_h). The bound $\|\nabla q_h\|_0 \le C(\|\mathbf{v}\|_2 + \|q\|_1)$ is a simple by-product of (2.7). To see this, we add and subtract I_hq, use the stability of I_h in H^1, and observe that (2.7) implies $\|\nabla(q_h - I_hq)\|_0 \le Ch^{-1}\|q_h - I_hq\| \le C$.

We finally state without proof several properties of the nonlinear form $\mathfrak{N}_h$. In view of (1.7), we have the following properties of $\mathfrak{N}_h$ for all $\mathbf{u}_h, \mathbf{v}_h\mathbf{w}_h \in \mathbb{V}_h$:

$$\mathfrak{N}_h(\mathbf{u}_h,\mathbf{v}_h,\mathbf{w}_h) = -\mathfrak{N}_h(\mathbf{u}_h,\mathbf{w}_h,\mathbf{v}_h), \qquad \mathfrak{N}_h(\mathbf{u}_h,\mathbf{v}_h,\mathbf{v}_h) = 0 \tag{2.10}$$

and

$$\operatorname{div}\mathbf{u} = 0 \Rightarrow \mathfrak{N}_h(\mathbf{u},\mathbf{v}_h,\mathbf{w}_h) = \mathfrak{N}(\mathbf{u},\mathbf{v}_h,\mathbf{w}_h) = -\mathfrak{N}(\mathbf{u},\mathbf{w}_h,\mathbf{v}_h).$$

Applying Sobolev imbedding lemma yields the following useful results.

LEMMA 2.7 (bounds on nonlinear convection [11, 12]). *Let* $\mathbf{u}, \mathbf{v} \in \mathbf{H}^2(\Omega)$ *with* $\operatorname{div}\mathbf{u} = 0$*, and let* $\mathbf{u}_h, \mathbf{v}_h, \mathbf{w}_h \in \mathbb{V}_h$*. Then*

$$\mathfrak{N}_h(\mathbf{u},\mathbf{v}_h,\mathbf{w}_h) \le C\begin{cases}\|\mathbf{u}\|_1\|\mathbf{v}_h\|_1\|\mathbf{w}_h\|_1,\\ \|\mathbf{u}\|_2\|\nabla\mathbf{v}_h\|_0\|\mathbf{w}_h\|_0,\\ \|\mathbf{u}\|_2\|\mathbf{v}_h\|_0\|\nabla\mathbf{w}_h\|_0,\end{cases} \tag{2.11}$$

$$\mathfrak{N}_h(\mathbf{u}_h,\mathbf{v},\mathbf{w}_h) \le \|\mathbf{u}_h\|_0\|\mathbf{v}\|_2\|\nabla\mathbf{w}_h\|_0. \tag{2.12}$$

In addition,

$$\mathfrak{N}_h(\mathbf{u}_h,\mathbf{v}_h,\mathbf{w}_h) \le C\begin{cases}\|\mathbf{u}_h\|_0|\!|\!|\mathbf{v}_h|\!|\!|\|\nabla\mathbf{w}_h\|_0,\\ \|\mathbf{u}_h\|_{\mathbf{L}^3(\Omega)}\|\mathbf{v}_h\|_1\|\nabla\mathbf{w}_h\|_0.\end{cases} \tag{2.13}$$

3. Theorem 1.1: Stability.

In this section, we show that the gauge–Uzawa FEM is unconditionally stable via a standard energy method. We choose $\mathbf{w}_h = 2\tau\widehat{\mathbf{u}}_h^{n+1}$ in (1.8) and observe the following relation for the first term in (1.8):

$$\left\langle \widehat{\mathbf{u}}_h^{n+1} - \mathbf{u}_h^n\,,\, \widehat{\mathbf{u}}_h^{n+1}\right\rangle = \left\langle \mathbf{u}_h^{n+1} - \mathbf{u}_h^n\,,\, \mathbf{u}_h^{n+1}\right\rangle + \left\langle \nabla\rho_h^{n+1}\,,\, \nabla\rho_h^{n+1}\right\rangle$$

because of (1.11). Since the convection term vanishes from (2.10), we then obtain

$$\begin{aligned}\left\|\mathbf{u}_h^{n+1}\right\|_0^2 - \|\mathbf{u}_h^n\|_0^2 + \left\|\mathbf{u}_h^{n+1} - \mathbf{u}_h^n\right\|_0^2 + 2\left\|\nabla\rho_h^{n+1}\right\|_0^2 + 2\mu\tau\left\|\nabla\widehat{\mathbf{u}}_h^{n+1}\right\|_0^2 \\ = 2\mu\tau\left\langle s_h^n\,,\, \operatorname{div}\widehat{\mathbf{u}}_h^{n+1}\right\rangle + 2\tau\left\langle \mathbf{f}(t^{n+1})\,,\, \widehat{\mathbf{u}}_h^{n+1}\right\rangle.\end{aligned}$$

According to (1.10), we can write

$$2\left\langle s_h^n\,,\,\mathrm{div}\;\widehat{\mathbf{u}}_h^{n+1}\right\rangle = 2\left\langle s_h^n\,,\,s_h^n - s_h^{n+1}\right\rangle = \|s_h^n\|_0^2 - \left\|s_h^{n+1}\right\|_0^2 + \left\|s_h^n - s_h^{n+1}\right\|_0^2.$$

Combining now (1.10) with Lemma 2.4, we infer that $\left\|s_h^{n+1} - s_h^n\right\|_0 \le \left\|\mathrm{div}\;\widehat{\mathbf{u}}_h^{n+1}\right\|_0 \le \left\|\nabla\widehat{\mathbf{u}}_h^{n+1}\right\|$, whence

$$\begin{aligned}\left\|\mathbf{u}_h^{n+1}\right\|_0^2 - \|\mathbf{u}_h^n\|_0^2 + \left\|\mathbf{u}_h^{n+1} - \mathbf{u}_h^n\right\|_0^2 + 2\left\|\nabla\rho_h^{n+1}\right\|_0^2 + 2\mu\tau\left\|\nabla\widehat{\mathbf{u}}_h^{n+1}\right\|_0^2 \\ + \mu\tau\left\|s_h^{n+1}\right\|_0^2 - \mu\tau\|s_h^n\|_0^2 \le \frac{\tau}{2}\left\|\mathbf{f}(t^{n+1})\right\|_{-1}^2 + \frac{3\mu\tau}{2}\left\|\nabla\widehat{\mathbf{u}}_h^{n+1}\right\|_0^2.\end{aligned}$$

Adding over n from 0 to N, we obtain (1.15) and complete the proof of Theorem 1.1. It is important to notice that it is the *semi-implicit* treatment of convection in (1.8) that is responsible for unconditional stability.

4. Theorem 1.2: Error analysis for velocity.

In this section, we prove weak and strong error estimates for velocity for the gauge–Uzawa FEM of Algorithm 2. The proof is rather intricate because of the limited regularity of section 2.1, particularly that $\mathbf{u}_{tt} \notin L^2(0,T;\mathbf{L}^2(\Omega))$, and consists of three steps as follows.

- *Time-discrete Stokes.* We first consider a sequence of Stokes equations with the exact forcing and convection, namely, $\mathbf{U}^{n+1} \in \mathbf{H}_0^1(\Omega), P^{n+1} \in L_0^2(\Omega)$ satisfy $\mathbf{U}^0 = \mathbf{u}^0$ and

  (4.1)
  $$\delta\mathbf{U}^{n+1} - \mu\Delta\mathbf{U}^{n+1} + \nabla P^{n+1} = \mathbf{f}(t^{n+1}) - \big((\mathbf{u}\cdot\nabla)\mathbf{u}\big)(t^{n+1}), \qquad \mathrm{div}\;\mathbf{U}^{n+1} = 0.$$

  In Lemma 4.1, we derive estimates for the errors

  $$\mathbf{G}^{n+1} := \mathbf{u}(t^{n+1}) - \mathbf{U}^{n+1}, \qquad g^{n+1} := p(t^{n+1}) - P^{n+1},$$

  which rely solely on the regularity $\mathbf{u}_{tt} \in L^2([0:T]:\mathbf{Z}(\Omega)^*)$ of Lemma 2.3. This is possible because the test function $\mathbf{w} = \mathbf{u}(t^{n+1}) - \mathbf{U}^{n+1}$ is divergence free and thus allows us to work on the spaces $\mathbf{Z}(\Omega)$ and $\mathbf{Z}(\Omega)^*$.
- *Stokes projection.* We define $(\mathbf{U}_h^{n+1}, P_h^{n+1}) := \mathfrak{S}_h(\mathbf{u}(t^{n+1}), p(t^{n+1})) \in \mathbb{V}_h \times \mathbb{P}_h$ to be the Stokes projection of the true solution at time t^{n+1}, and derive error estimates in Lemma 4.3 for the errors

  $$\mathbf{G}_h^{n+1} := \mathbf{u}(t^{n+1}) - \mathbf{U}_h^{n+1}, \qquad g_h^{n+1} := p(t^{n+1}) - P_h^{n+1}.$$

  We point out that this choice of space discretization is more handy than discretizing (4.1) by finite elements, and still gives estimates for the errors $\mathbf{F}^{n+1} := \mathbf{U}^{n+1} - \mathbf{U}_h^{n+1}$ and $f^{n+1} := P^{n+1} - P_h^{n+1}$ by combining the first two steps.
- *Comparing* (4.1) *with* (1.8)–(1.11). We derive strong estimates of order 1/2 and use then to prove weak estimates of order 1 for the errors

  $$\text{(4.2)} \quad \mathbf{E}^{n+1} := \mathbf{U}^{n+1} - \mathbf{u}_h^{n+1}, \quad \widehat{\mathbf{E}}^{n+1} := \mathbf{U}^{n+1} - \widehat{\mathbf{u}}_h^{n+1}, \quad e^{n+1} := P^{n+1} - p_h^{n+1}.$$

  This is the most technical step; therefore, we now must deal with the fact that $\widehat{\mathbf{u}}_h^{n+1}$ is not divergence free, whereas $\mathbf{u}_h^{n+1}$ does not vanish on $\partial\Omega$; this is carried out in section 4.3. Upon combining the estimates of these three steps, we readily obtain Theorem 1.2.

4.1. Time-discrete Stokes problem. We now show error bounds for (4.1).

LEMMA 4.1 (uniform estimates). *Let* A1–A3 *hold. Then*

$$\left\|\mathbf{G}^{N+1}\right\|_0^2+\sum_{n=0}^{N}\left\|\mathbf{G}^{n+1}-\mathbf{G}^n\right\|_0^2+\mu\tau\sum_{n=0}^{N}\left\|\nabla\mathbf{G}^{n+1}\right\|_0^2\le C\tau^2, \tag{4.3}$$

$$\tau\sum_{n=0}^{N}\left\|g^{n+1}\right\|_0^2\le C\tau. \tag{4.4}$$

Proof. We subtract (4.1) from (1.1) at $t=t^{n+1}$ and thereby write

$$\delta\mathbf{G}^{n+1}-\mu\Delta\mathbf{G}^{n+1}+\nabla g^{n+1}=\mathbf{R}^{n+1}:=\frac{1}{\tau}\int_{t^n}^{t^{n+1}}(t-t^n)\mathbf{u}_{tt}(\cdot,t)\,dt, \tag{4.5}$$

where $\mathbf{R}^{n+1}$ is the truncation error. We multiply this elliptic PDE by the admissible test function $2\tau\mathbf{G}^{n+1}\in\mathbf{Z}(\Omega)$ to arrive at

$$\left\|\mathbf{G}^{n+1}\right\|_0^2-\left\|\mathbf{G}^n\right\|_0^2+\left\|\mathbf{G}^{n+1}-\mathbf{G}^n\right\|_0^2+2\mu\tau\left\|\nabla\mathbf{G}^{n+1}\right\|_0^2\le 2\tau\left\|\mathbf{R}^{n+1}\right\|_*\left\|\nabla\mathbf{G}^{n+1}\right\|_0.$$

Adding over n and using (2.5) yield (4.3). To prove (4.4) we use the error equation (4.5) to obtain any $\mathbf{w}\in\mathbf{H}_0^1(\Omega)$

$$\left\langle g^{n+1}\,,\,\mathrm{div}\,\mathbf{w}\right\rangle\le\frac{1}{\tau}\left\|\mathbf{G}^{n+1}-\mathbf{G}^n\right\|_0\|\mathbf{w}\|_0+\mu\left\|\nabla\mathbf{G}^{n+1}\right\|_0\|\nabla\mathbf{w}\|_0+\left\|\mathbf{R}^{n+1}\right\|_0\|\mathbf{w}\|_0.$$

Since $\left\|\mathbf{R}^{n+1}\right\|_0^2\le\frac{1}{2}\int_{t^n}^{t^{n+1}}\sigma\|\mathbf{u}_{tt}\|_0^2$, (2.3) and (4.3) together with the continuous inf-sup condition imply (4.4). ∎

LEMMA 4.2 (weighted estimates). *Let* A1–A3 *hold. Then*

$$\sigma^{N+1}\left\|\delta\mathbf{G}^{N+1}\right\|_0^2+\sum_{n=1}^{N}\sigma^{n+1}\left\|\delta\mathbf{G}^{n+1}-\delta\mathbf{G}^n\right\|_0^2+\frac{\mu\tau}{2}\sum_{n=1}^{N}\sigma^{n+1}\left\|\nabla\delta\mathbf{G}^{n+1}\right\|_0^2\le C\tau, \tag{4.6}$$

$$\sup_{0\le n\le N+1}\sigma^n\|g^n\|_0^2+\sum_{n=0}^{N}\sigma^{n+1}\left(\left\|g^{n+1}\right\|_0^2+\left\|\delta g^{n+1}\right\|_0^2\right)\le C\tau. \tag{4.7}$$

If NLC is also valid, then (4.6) *and* (4.7) *become uniform, namely, without weights.*

Proof. To prove (4.6) we subtract two consecutive equations (4.5) and thus derive an equation for $\delta\mathbf{G}^{n+1}$. We next multiply this equation by $2\sigma^{n+1}\delta\mathbf{G}^{n+1}$ and proceed as in Lemma 4.1 to discover that $I^{n+1}:=2\sigma^{n+1}\left\langle\delta(\mathbf{G}^{n+1}-\mathbf{G}^n)\,,\,\delta\mathbf{G}^{n+1}\right\rangle$ and $II^{n+1}:=2\tau\sigma^{n+1}\left\langle\delta\mathbf{R}^{n+1}\,,\,\delta\mathbf{G}^{n+1}\right\rangle$ must be estimated. We see that

$$I^{n+1}=\sigma^{n+1}\left\|\delta\mathbf{G}^{n+1}\right\|_0^2-\sigma^n\left\|\delta\mathbf{G}^n\right\|_0^2+\sigma^{n+1}\left\|\delta\mathbf{G}^{n+1}-\delta\mathbf{G}^n\right\|_0^2-(\sigma^{n+1}-\sigma^n)\|\delta\mathbf{G}^n\|_0^2$$

and realize that, upon summation over n, the first two terms on the right-hand side telescope, whereas the last one leads to $\frac{1}{\tau}\sum_{n=1}^{N}\left\|\mathbf{G}^{n+1}-\mathbf{G}^n\right\|_0^2\le C\tau$ in view of (4.3). On the other hand, II^{n+1} can be written equivalently as follows:

$$\begin{aligned}II^{n+1}&=2\sigma^{n+1}\left\langle\mathbf{R}^{n+1}\,,\,\delta\mathbf{G}^{n+1}\right\rangle-2\sigma^n\left\langle\mathbf{R}^n\,,\,\delta\mathbf{G}^n\right\rangle\\&\quad+2\sigma^n\left\langle\mathbf{R}^n\,,\,\delta\mathbf{G}^n-\delta\mathbf{G}^{n+1}\right\rangle+2(\sigma^n-\sigma^{n+1})\left\langle\mathbf{R}^n\,,\,\delta\mathbf{G}^{n+1}\right\rangle.\end{aligned}$$

We now add on n and observe that the first two terms telescope. The third term can be handled via the estimate $\sum_{n=1}^{N}\sigma^n\|\mathbf{R}^n\|_0^2 \le C\tau\int_0^T\sigma\|\mathbf{u}_{tt}\|_0^2 \le C\tau$, which results from (2.3), together with the bound for $\sum_{n=1}^{N} I^{n+1}$. Using again $\sum_{n=1}^{N}\sigma^n\|\mathbf{R}^n\|_0^2 \le C\tau$, now coupled with $\sum_{n=1}^{N}\|\delta\mathbf{G}^n\|_0^2 \le C$ from (4.3), takes care of the last term in II^{n+1}.

We finally observe that the presence of weights allows us to employ regularity (2.3) for $\mathbf{u}_{tt}$. If we further assume NLC, then we could omit weights and instead resort to regularity (2.4) to establish uniform bounds. This completes the proof. □

4.2. Stokes projection. We now establish simple estimates for $(\mathbf{G}_h^{n+1}, g_h^{n+1})$.

LEMMA 4.3 (Stokes projection). *Let* A1–A6 *hold. Then*

$$\big\|\mathbf{G}_h^{n+1}\big\|_0 + h\big\|\mathbf{G}_h^{n+1}\big\|_1 + h\big\|g_h^{n+1}\big\|_0 \le Ch^2, \tag{4.8}$$

$$\tau\sum_{n=0}^{N}\sigma^{n+1}\Big(\big\|\delta\mathbf{G}_h^{n+1}\big\|_0^2 + h^2\big\|\delta\mathbf{G}_h^{n+1}\big\|_1^2 + h^2\big\|\delta g_h^{n+1}\big\|_0^2\Big) \le Ch^4. \tag{4.9}$$

If NLC also holds, then (4.9) *becomes* uniform*, namely, without weights.*

Proof. Estimate (4.8) is a direct consequence of Lemma 2.5 and (2.2). Since the Stokes operator $\mathfrak{S}_h$ is linear, we readily have $(\delta\mathbf{U}_h^n, \delta P_h^n) = \mathfrak{S}_h(\delta\mathbf{u}(t^n), \delta p(t^n))$, and Lemma 2.5 applies again. Upon multiplying by $\tau\sigma^{n+1}$, the square of the right-hand side of (2.7) can be bounded by

$$h^4\tau^{-1}\sum_{n=0}^{N}\sigma^{n+1}\Big(\big\|\mathbf{u}(t^{n+1}) - \mathbf{u}(t^n)\big\|_2^2 + \big\|p(t^{n+1}) - p(t^n)\big\|_1^2\Big).$$

We examine the velocity term only since the other one is similar. For $n = 0$ we recall (2.2), along with $\sigma^1 = \tau$, to write $\sigma^1\big\|\mathbf{u}(t^1) - \mathbf{u}(t^0)\big\|_2^2 \le C\tau$. For $n \ge 1$, instead, we use that $\sigma^{n+1} \le 2\sigma(t)$ for $t^n \le t \le t^{n+1}$, whence

$$\sum_{n=1}^{N}\sigma^{n+1}\big\|\mathbf{u}(t^{n+1}) - \mathbf{u}(t^n)\big\|_2^2 \le C\tau\int_0^T\sigma\|\mathbf{u}_t\|_2^2 \le C\tau$$

because of (2.3). This completes the proof. □

4.3. Comparing (4.1) with (1.8)–(1.11). We derive strong estimates of order 1/2 and use them to prove weak estimates of order 1 for the errors in (4.2), namely,

$$\mathbf{E}^{n+1} = \mathbf{U}^{n+1} - \mathbf{u}_h^{n+1}, \quad \widehat{\mathbf{E}}^{n+1} = \mathbf{U}^{n+1} - \widehat{\mathbf{u}}_h^{n+1}, \quad e^{n+1} = P^{n+1} - p_h^{n+1}.$$

Before embarking on this discussion, we mention several useful properties of the error functions. If $\mathbf{E}_h^{n+1} := \mathbf{U}_h^{n+1} - \mathbf{u}_h^{n+1}$, $\widehat{\mathbf{E}}_h^{n+1} := \mathbf{U}_h^{n+1} - \widehat{\mathbf{u}}_h^{n+1}$, and $\mathbf{F}^{n+1} = \mathbf{U}^{n+1} - \mathbf{U}_h^{n+1}$, then

$$\widehat{\mathbf{E}}^{n+1} = \mathbf{E}^{n+1} + \nabla\rho_h^{n+1}, \qquad \widehat{\mathbf{E}}_h^{n+1} = \mathbf{E}_h^{n+1} + \nabla\rho_h^{n+1},$$
$$\widehat{\mathbf{E}}^{n+1} = \mathbf{F}^{n+1} + \widehat{\mathbf{E}}_h^{n+1}, \qquad \mathbf{E}^{n+1} = \mathbf{F}^{n+1} + \mathbf{E}_h^{n+1},$$

as well as

$$\big\langle\mathbf{E}^{n+1}, \nabla q_h\big\rangle = \big\langle\mathbf{E}_h^{n+1}, \nabla q_h\big\rangle = \big\langle\mathbf{F}^{n+1}, \nabla q_h\big\rangle = 0 \qquad \forall q_h \in \mathbb{P}_h, \tag{4.10}$$

whence we deduce crucial orthogonality properties:

$$\|\widehat{\mathbf{E}}^{n+1}\|_0^2 = \|\mathbf{E}^{n+1}\|_0^2 + \|\nabla\rho_h^{n+1}\|_0^2, \qquad \|\widehat{\mathbf{E}}_h^{n+1}\|_0^2 = \|\mathbf{E}_h^{n+1}\|_0^2 + \|\nabla\rho_h^{n+1}\|_0^2. \tag{4.11}$$

Since $\mathbf{F}^{n+1} = \mathbf{G}_h^{n+1} - \mathbf{G}^{n+1}, f^{n+1} = g_h^{n+1} - g^{n+1}$, Lemmas 4.1 and 4.3 give rise to the following estimates provided A1–A6 hold:

$$\|\mathbf{F}^{n+1}\|_0^2 \le C(\tau^2 + h^4), \quad \mu\tau \sum_{n=1}^{N} \|\nabla \mathbf{F}^{n+1}\|_0^2 \le C(\tau^2 + h^2),$$
$$\tau \sum_{n=1}^{N} \|f^{n+1}\|_0^2 \le C(\tau + h^2). \tag{4.12}$$

We also point out that, owing to Lemma 2.4, $s_h^{n+1} \in \mathbb{P}_h$ defined in (1.10) satisfies

$$\left\|s_h^{n+1} - s_h^n\right\|_0 \le \|\nabla \widehat{\mathbf{E}}^{n+1}\|_0. \tag{4.13}$$

LEMMA 4.4 (reduced rate of convergence for velocity). *Let* A1–A6 *and* $h^2 \le C\tau$ *be valid with an arbitrary constant* $C > 0$. *Then the velocity error functions satisfy*

$$\|\mathbf{E}^{N+1}\|_0^2 + \|\widehat{\mathbf{E}}^{N+1}\|_0^2 + \mu\tau\left\|s_h^{N+1}\right\|_0^2 + \frac{1}{2}\sum_{n=0}^{N}\left\|\mathbf{E}^{n+1} - \mathbf{E}^n\right\|_0^2$$
$$+ \sum_{n=0}^{N}\left\|\nabla\rho_h^{n+1}\right\|_0^2 + \frac{\mu\tau}{2}\sum_{n=0}^{N}\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2 \le C(\tau + h^2). \tag{4.14}$$

Proof. Subtracting (1.8) from (4.1) yields, for all $\mathbf{w}_h \in \mathbb{V}_h$,

$$\tau^{-1}\left\langle \widehat{\mathbf{E}}^{n+1} - \mathbf{E}^n\, , \, \mathbf{w}_h\right\rangle + \mu\left\langle \nabla\widehat{\mathbf{E}}^{n+1}\, , \, \nabla\mathbf{w}_h\right\rangle = \left\langle P^{n+1}\, , \, \mathrm{div}\ \mathbf{w}_h\right\rangle \tag{4.15}$$
$$-\mu\left\langle s_h^n\, , \, \mathrm{div}\ \mathbf{w}_h\right\rangle - \mathfrak{N}_h(\mathbf{u}(t^{n+1}), \mathbf{u}(t^{n+1}), \mathbf{w}_h) + \mathfrak{N}_h(\mathbf{u}_h^n, \widehat{\mathbf{u}}_h^{n+1}, \mathbf{w}_h).$$

Choosing $\mathbf{w}_h = 2\tau\widehat{\mathbf{E}}_h^{n+1} = 2\tau(\widehat{\mathbf{E}}^{n+1} - \mathbf{F}^{n+1})$ in (4.15) and using (4.10), we easily get

$$\left\|\mathbf{E}^{n+1}\right\|_0^2 - \|\mathbf{E}^n\|_0^2 + \left\|\mathbf{E}^{n+1} - \mathbf{E}^n\right\|_0^2 + 2\mu\tau\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2 + 2\left\|\nabla\rho_h^{n+1}\right\|_0^2 = \sum_{i=1}^{4} A_i \tag{4.16}$$

with

$$A_1 := 2\left\langle \mathbf{E}^{n+1} - \mathbf{E}^n\, , \, \mathbf{F}^{n+1}\right\rangle + 2\mu\tau\left\langle \nabla\widehat{\mathbf{E}}^{n+1}\, , \, \nabla\mathbf{F}^{n+1}\right\rangle,$$
$$A_2 := 2\tau\left\langle P^{n+1}\, , \, \mathrm{div}\ \widehat{\mathbf{E}}_h^{n+1}\right\rangle,$$
$$A_3 := -2\tau\left(\mathfrak{N}_h(\mathbf{u}(t^{n+1}), \mathbf{u}(t^{n+1}), \widehat{\mathbf{E}}_h^{n+1}) - \mathfrak{N}_h(\mathbf{u}_h^n, \widehat{\mathbf{u}}_h^{n+1}, \widehat{\mathbf{E}}_h^{n+1})\right),$$
$$A_4 := -2\mu\tau\left\langle s_h^n\, , \, \mathrm{div}\ \widehat{\mathbf{E}}_h^{n+1}\right\rangle.$$

We now estimate each term A_i separately. Applying the Hölder inequality, we find a bound of the first term

$$A_1 \le \frac{1}{2}\left\|\mathbf{E}^{n+1} - \mathbf{E}^n\right\|_0^2 + C\left\|\mathbf{F}^{n+1}\right\|_0^2 + \frac{\mu\tau}{4}\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2 + C\mu\tau\left\|\nabla\mathbf{F}^{n+1}\right\|_0^2. \tag{4.17}$$

Since $\mathbf{U}_h^{n+1}$ is discrete divergence free, but not so $\widehat{\mathbf{u}}_h^{n+1}$, we add and subtract P_h^{n+1} and $p(t^{n+1})$, and recall (1.9) and Remark 2.6 to derive

$$A_2 = 2\tau\left\langle f^{n+1}\, , \, \mathrm{div}\ \widehat{\mathbf{E}}_h^{n+1}\right\rangle + 2\tau\left\langle \nabla g_h^{n+1}\, , \, \nabla\rho_h^{n+1}\right\rangle - 2\tau\left\langle \nabla p(t^{n+1})\, , \, \nabla\rho_h^{n+1}\right\rangle \tag{4.18}$$
$$\le C\tau^2 B^{n+1} + \frac{C\tau}{\mu}\left\|f^{n+1}\right\|_0^2 + \frac{\mu\tau}{8}\left(\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2 + \left\|\nabla\mathbf{F}^{n+1}\right\|_0^2\right) + \left\|\nabla\rho_h^{n+1}\right\|_0^2,$$

where $B^{n+1} := \left\|\mathbf{u}(t^{n+1})\right\|_2^2 + \left\|\nabla p(t^{n+1})\right\|_0^2$. To tackle A_3 we first add and subtract $\mathbf{u}(t^{n+1}), \mathbf{u}_h^n$, and realize that $\mathfrak{N}_h(\mathbf{u}_h^n, \widehat{\mathbf{E}}_h^{n+1}, \widehat{\mathbf{E}}_h^{n+1}) = 0$ according to (2.10). This yields

$$\begin{aligned}A_3 = &- 2\tau\mathfrak{N}_h(\mathbf{u}(t^{n+1}) - \mathbf{u}(t^n), \mathbf{u}(t^{n+1}), \widehat{\mathbf{E}}_h^{n+1})\\ &- 2\tau\mathfrak{N}_h(\mathbf{u}(t^n) - \mathbf{u}_h^n, \mathbf{u}(t^{n+1}), \widehat{\mathbf{E}}_h^{n+1}) - 2\tau\mathfrak{N}_h(\mathbf{u}_h^n, \mathbf{G}_h^{n+1}, \widehat{\mathbf{E}}_h^{n+1}).\end{aligned}$$

Since $\left\|\mathbf{u}(t^{n+1})\right\|_2 + \left|\!\left|\!\left|\mathbf{G}_h^{n+1}\right|\!\right|\!\right| \le C$ in view of (2.2) and (2.9), and $\widehat{\mathbf{E}}_h^{n+1} = \widehat{\mathbf{E}}^{n+1} - \mathbf{F}^{n+1}$, (2.11) and (2.13) give

$$A_3 \le \frac{C\tau^2}{\mu} D^{n+1} + \frac{C\tau}{\mu}\left(\|\mathbf{E}^n\|_0^2 + \|\mathbf{G}^n\|_0^2 + \left\|\mathbf{G}_h^{n+1}\right\|_0^2\right) + \frac{\mu\tau}{8}\|\nabla\widehat{\mathbf{F}}^{n+1}\|_0^2 + \frac{\mu\tau}{8}\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2$$

with $D^{n+1} := \int_{t^n}^{t^{n+1}} \|\mathbf{u}_t(t)\|_0^2\, dt$. Next, making use of (1.10) and (4.13), we arrive at

$$\begin{aligned}A_4 &= 2\mu\tau\left\langle s_h^n\,,\, \operatorname{div}\, \widehat{\mathbf{u}}_h^{n+1}\right\rangle = 2\mu\tau\left\langle s_h^n - s_h^{n+1}\,,\, s_h^n\right\rangle\\ &\le \mu\tau\left(\|s_h^n\|_0^2 - \left\|s_h^{n+1}\right\|_0^2\right) + \mu\tau\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2.\end{aligned}$$

Inserting the above estimates into (4.16), summing over n from 0 to N gives

$$\begin{aligned}\text{(4.19)}\qquad &\left\|\mathbf{E}^{N+1}\right\|_0^2 + \frac{1}{2}\sum_{n=0}^{N}\left\|\mathbf{E}^{n+1} - \mathbf{E}^n\right\|_0^2 + \frac{\mu\tau}{2}\sum_{n=0}^{N}\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2\\ &+ \mu\tau\left\|s_h^{N+1}\right\|_0^2 + \sum_{n=0}^{N}\left\|\nabla\rho_h^{n+1}\right\|_0^2 \le C(\tau + h^2) + \frac{C\tau}{\mu}\sum_{n=0}^{N}\|\mathbf{E}^n\|_0^2,\end{aligned}$$

where we have used (2.2) to bound B^{n+1}, D^{n+1}, together with (4.3) and (4.8) to estimate $\|\mathbf{G}^n\|_0$ and $\|\mathbf{G}_h^{n+1}\|_0$, respectively, and (4.12) as well as $h^2 \le C\tau$ to bound $\|\mathbf{F}^{n+1}\|_0, \|\mathbf{F}^{n+1}\|_0$, and $\|f^{n+1}\|_0$. The discrete Gronwall lemma finally yields (4.14) except for $\|\widehat{\mathbf{E}}^{n+1}\|_0^2$. The latter results from (4.11) and completes the proof. □

Remark 4.5 (initial errors). If $N = 0$ in (4.19), then Lemmas 4.1 and 4.3 give

$$\begin{aligned}&\left\|\mathbf{E}^1\right\|_0^2 + \frac{1}{2}\left\|\mathbf{E}^1 - \mathbf{E}^0\right\|_0^2 + \frac{\mu\tau}{2}\|\nabla\widehat{\mathbf{E}}^1\|_0^2 + \mu\tau\left\|s_h^1\right\|_0^2 + \left\|\nabla\rho_h^1\right\|_0^2\\ &\quad\le C(\tau^2 + \tau h^2 + h^4) + \frac{C\tau}{\mu}\left\|f^1\right\|_0^2 \le C(\tau + \tau h^2 + h^4)\end{aligned}$$

or $\le C(\tau^2 + \tau h^2 + h^4)$ provided NLC holds in conjunction with (4.7).

Remark 4.6 (suboptimal order). The suboptimal order $\mathcal{O}(\tau + h^2)$ of Lemma 4.4 is due to terms $\|\mathbf{F}^{n+1}\|_0^2 + \tau\|\nabla\mathbf{F}^{n+1}\|_0^2$ in (4.17) and the fact that $\widehat{\mathbf{E}}_h^{n+1}$ in (4.18) is not discrete divergence free. To improve upon this we must get rid of both terms.

Lemma 4.7 (full rate of convergence for velocity). *Let* A1–A6 *hold and* $h^2 \le C\tau$ *be valid with an arbitrary constant* $C > 0$. *Then we have*

$$\text{(4.20)}\qquad \left\|\mathbf{E}^{N+1}\right\|_*^2 + \sum_{n=0}^{N}\left\|\mathbf{E}^{n+1} - \mathbf{E}^n\right\|_*^2 + \left(\mu\tau\left\|\mathbf{E}^{n+1}\right\|_0^2 + \|\widehat{\mathbf{E}}^{n+1}\|_0^2\right) \le C(\tau^2 + h^4).$$

Proof. Let $(\mathbf{v}^n, q^n)$ and $(\mathbf{v}_h^n, q_h^n)$ be solutions of the Stokes equations (2.1) and (2.6) with $\mathbf{g} = \mathbf{E}^n$. Then Lemma 2.5 and A1 yield a crucial inequality

$$\|\mathbf{v}^n - \mathbf{v}_h^n\|_0 + h\|\mathbf{v}^n - \mathbf{v}_h^n\|_1 + h\|q^n - q_h^n\|_0 \le Ch^2\|\mathbf{E}^n\|_0. \tag{4.21}$$

Since $\mathbf{v}_h^{n+1}$ is discrete divergence free, then $\langle \nabla\rho_h^{n+1}, \mathbf{v}_h^{n+1}\rangle = 0$ and

$$\left\langle \widehat{\mathbf{E}}^{n+1} - \mathbf{E}^n , \mathbf{v}_h^{n+1} \right\rangle = \langle \mathbf{E}^{n+1} - \mathbf{E}^n , \mathbf{v}_h^{n+1}\rangle = \langle \nabla(\mathbf{v}_h^{n+1} - \mathbf{v}_h^n) , \nabla\mathbf{v}_h^{n+1}\rangle .$$

Choosing $\mathbf{w}_h = 2\tau\mathbf{v}_h^{n+1}$ in (4.15) yields

$$\left\|\nabla\mathbf{v}_h^{n+1}\right\|_0^2 - \|\nabla\mathbf{v}_h^n\|_0^2 + \left\|\nabla(\mathbf{v}_h^{n+1} - \mathbf{v}_h^n)\right\|_0^2 + 2\mu\tau\left\|\mathbf{E}^{n+1}\right\|_0^2 = \sum_{i=1}^4 A_i \tag{4.22}$$

with

$$\begin{aligned}
A_1 &:= -2\mu\tau\langle\nabla\mathbf{F}^{n+1} , \nabla\mathbf{v}_h^{n+1}\rangle,\\
A_2 &:= 2\mu\tau(\langle\mathbf{F}^{n+1} , \mathbf{E}^{n+1}\rangle + \langle\nabla\rho_h^{n+1} , \nabla q_h^{n+1}\rangle),\\
A_3 &:= 2\tau\langle P^{n+1} , \operatorname{div} \mathbf{v}_h^{n+1}\rangle,\\
A_4 &:= -2\tau(\mathfrak{N}_h(\mathbf{u}(t^{n+1}), \mathbf{u}(t^{n+1}), \mathbf{v}_h^{n+1}) - \mathfrak{N}_h(\mathbf{u}_h^n, \widehat{\mathbf{u}}_h^{n+1}, \mathbf{v}_h^{n+1})).
\end{aligned}$$

We now estimate A_1–A_4 separately. We use inequality (4.21) to get

$$\begin{aligned}
A_1 &= 2\mu\tau\left\langle\nabla\mathbf{F}^{n+1} , \nabla\left(\mathbf{v}^{n+1} - \mathbf{v}_h^{n+1}\right) - \nabla\mathbf{v}^{n+1}\right\rangle\\
&\le C\mu\tau\left(h^2\left\|\nabla\mathbf{F}^{n+1}\right\|_0^2 + \left\|\mathbf{F}^{n+1}\right\|_0^2\right) + \frac{\mu\tau}{6}\left\|\mathbf{E}^{n+1}\right\|_0^2
\end{aligned}$$

as well as

$$A_2 \le C\mu\tau\left(\left\|\mathbf{F}^{n+1}\right\|_0^2 + \left\|\nabla\rho_h^{n+1}\right\|_0^2\right) + \frac{\mu\tau}{6}\left\|\mathbf{E}^{n+1}\right\|_0^2.$$

We next use the fact that $\mathbf{v}_h^{n+1}$ is discrete divergence free and $\mathbf{v}^{n+1}$ is divergence free. Hence

$$\begin{aligned}
A_3 &= 2\tau\left\langle P^{n+1} - P_h^{n+1} , \operatorname{div}\left(\mathbf{v}_h^{n+1} - \mathbf{v}^{n+1}\right)\right\rangle\\
&\le C\tau h\left\|f^{n+1}\right\|_0\left\|\mathbf{v}^{n+1}\right\|_2 \le \frac{C\tau h^2}{\mu}\left\|f^{n+1}\right\|_0^2 + \frac{\mu\tau}{6}\left\|\mathbf{E}^{n+1}\right\|_0^2.
\end{aligned}$$

At the same time, the convection term A_4 can be rewritten as $A_4 = \sum_{i=1}^3 A_{4,i}$ with

$$\begin{aligned}
A_{4,1} &:= -2\tau\mathfrak{N}_h((\mathbf{u}(t^{n+1}) - \mathbf{u}(t^n)) + (\mathbf{u}(t^n) - \mathbf{u}_h^n), \mathbf{u}(t^{n+1}), \mathbf{v}_h^{n+1}),\\
A_{4,2} &:= 2\tau\mathfrak{N}_h(\mathbf{u}(t^n) - \mathbf{u}_h^n, \mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}, (\mathbf{v}_h^{n+1} - \mathbf{v}^{n+1}) + \mathbf{v}^{n+1}),\\
A_{4,3} &:= -2\tau\mathfrak{N}_h(\mathbf{u}(t^n), \mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}, \mathbf{v}_h^{n+1}).
\end{aligned}$$

Since $\mathbf{u}(t^n) - \mathbf{u}_h^n = \mathbf{E}^n + \mathbf{G}^n$, (2.2) in conjunction with (2.12) yields

$$A_{4,1} \le C\tau^2\mu\int_{t^n}^{t^{n+1}} \|\mathbf{u}_t(t)\|_0^2\, dt + \frac{\mu\tau}{6}\left(\|\mathbf{E}^n\|_0^2 + \|\mathbf{G}^n\|_0^2\right) + \frac{C\tau}{\mu}\left\|\nabla\mathbf{v}_h^{n+1}\right\|_0^2.$$

Before tacking $A_{4,2}$ we observe that (4.3) and (4.14) imply $\|\mathbf{u}(t^n)-\mathbf{u}_h^n\|_0 \le C(h+\tau^{1/2})$, and that (2.9) and (4.21) yield

$$\left\|\left\|\mathbf{v}_h^{n+1}-\mathbf{v}^{n+1}\right\|\right\| \le C\|\mathbf{v}^{n+1}\|_2 \le C\|\mathbf{E}^{n+1}\|_0.$$

Therefore, (2.12) and (2.13) lead to

$$A_{4,2} \le \frac{C\tau}{\mu}\left(\tau+h^2\right)\left(\left\|\nabla\mathbf{G}^{n+1}\right\|_0^2+\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2\right)+\frac{\mu\tau}{6}\left\|\mathbf{E}^{n+1}\right\|_0^2.$$

Since $\mathbf{u}(t^n)$ is divergence free, we can resort to (2.11) and (4.11) to obtain

$$A_{4,3} \le \frac{\mu\tau}{6}\left(\left\|\mathbf{E}^{n+1}\right\|_0^2+\left\|\nabla\rho_h^{n+1}\right\|_0^2+\left\|\mathbf{G}^{n+1}\right\|_0^2\right)+\frac{C\tau}{\mu}\left\|\nabla\mathbf{v}_h^{n+1}\right\|_0^2.$$

Inserting the above estimates into (4.22) and summing over n from 0 to N, we deduce

$$\begin{aligned}(4.23)\qquad &\left\|\nabla\mathbf{v}_h^{N+1}\right\|_0^2+\sum_{n=0}^{N}\left\|\nabla(\mathbf{v}_h^{n+1}-\mathbf{v}_h^n)\right\|_0^2+\mu\tau\sum_{n=0}^{N}\left\|\mathbf{E}^{n+1}\right\|_0^2\\ &\le C\left(\tau^2+h^4\right)+\frac{C\tau}{\mu}\sum_{n=0}^{N}\left\|\nabla\mathbf{v}_h^{n+1}\right\|_0^2\end{aligned}$$

because of (4.3), (4.12), and (4.14) bound the remaining terms. The discrete Gronwall lemma and (2.8) allow us to remove the rightmost term in (4.23), and thereby arrive at (4.20) upon invoking (2.8). However, this does not give a bound for $\|\widehat{\mathbf{E}}^{n+1}\|_0$, which comes from (4.11) and (4.14) instead. The proof is thus complete. □

Proof of Theorem 1.2. This is a consequence of Lemmas 4.1, 4.4, and 4.7. □

Remark 4.8 (estimates for $\left\|\nabla\mathbf{v}_h^1\right\|_0$). These estimates will be crucial in section 5 and can be extracted from (4.23) upon invoking Remark 4.5 and choosing $N=0$. Since $\mathbf{v}_h^0=0$ because $\mathbf{E}^0$ is orthogonal to $\mathbb{V}_h$, (4.23) reduces to

$$\left\|\nabla\mathbf{v}_h^1\right\|_0^2 \le C\tau(\tau^2+h^4)+\frac{C\tau h^2}{\mu}\left\|f^1\right\|_0^2 \le C\tau(\tau^2+h^2).$$

On the other hand, if NLC is also valid, then $\|f^1\|_0^2 \le C\tau$ and $\left\|\nabla\mathbf{v}_h^1\right\|_0^2 \le C\tau(\tau^2+h^4)$.

5. Theorem 1.3: Error analysis for time derivative of velocity.

In this section we embark on an error analysis for the time derivative of velocity.

LEMMA 5.1 (stability of time-derivative of velocity). *Let* A1–A6 *hold and* $h^2 \le C_1h^2 \le \tau \le C_2h^{\frac{d}{3}(1+\varepsilon)}$ *be valid with arbitrary constants* $C_1, C_2 > 0$. *Then the error functions satisfy the weighted estimates*

$$\begin{aligned}(5.1)\qquad &\sigma^{N+1}\left\|\delta\mathbf{E}^{N+1}\right\|_0^2+\sum_{n=1}^{N}\sigma^{n+1}\left\|\delta\mathbf{E}^{n+1}-\delta\mathbf{E}^n\right\|_0^2+\sum_{n=1}^{N}\sigma^{n+1}\left\|\nabla\delta\rho_h^{n+1}\right\|_0^2\\ &+\mu\tau\sigma^{N+1}\left\|\delta s_h^{N+1}\right\|_0^2+\mu\tau\sum_{n=1}^{N}\sigma^{n+1}\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\|_0^2 \le C.\end{aligned}$$

If NLC is also valid, then (5.1) *becomes uniform, namely, without weights.*

Proof. Subtracting two consecutive expressions (4.15) yields

$$
\begin{aligned}
(5.2)\qquad &\left\langle \delta\widehat{\mathbf{E}}^{n+1} - \delta\mathbf{E}^{n} \,,\, \mathbf{w}_h \right\rangle + \mu\tau \left\langle \nabla\delta\widehat{\mathbf{E}}^{n+1} \,,\, \nabla\mathbf{w}_h \right\rangle \\
&\quad = \tau \left\langle \delta P^{n+1} \,,\, \operatorname{div} \mathbf{w}_h \right\rangle - \mu\tau \left\langle \delta s_h^{n} \,,\, \operatorname{div} \mathbf{w}_h \right\rangle \\
&\qquad - \mathfrak{N}_h(\mathbf{u}(t^{n+1}), \mathbf{u}(t^{n+1}), \mathbf{w}_h) + \mathfrak{N}_h(\mathbf{u}_h^{n}, \widehat{\mathbf{u}}_h^{n+1}, \mathbf{w}_h) \\
&\qquad + \mathfrak{N}_h(\mathbf{u}(t^{n}), \mathbf{u}(t^{n}), \mathbf{w}_h) - \mathfrak{N}_h(\mathbf{u}_h^{n-1}, \widehat{\mathbf{u}}_h^{n}, \mathbf{w}_h).
\end{aligned}
$$

Choosing $\mathbf{w}_h = 2\delta\widehat{\mathbf{E}}_h^{n+1} = 2\delta(\widehat{\mathbf{E}}^{n+1} - \mathbf{F}^{n+1})$ in (5.2) and using (4.10) implies

$$
\begin{aligned}
(5.3)\qquad &\left\|\delta\mathbf{E}^{n+1}\right\|_0^2 - \left\|\delta\mathbf{E}^{n}\right\|_0^2 + \left\|\delta\mathbf{E}^{n+1} - \delta\mathbf{E}^{n}\right\|_0^2 \\
&\quad + 2\left\|\nabla\delta\rho_h^{n+1}\right\|_0^2 + 2\mu\tau\left\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\right\|_0^2 = \sum_{i=1}^{4} A_i
\end{aligned}
$$

with

$$
\begin{aligned}
A_1 &:= 2\langle \delta\mathbf{E}^{n+1} - \delta\mathbf{E}^{n} \,,\, \delta\mathbf{F}^{n+1}\rangle + 2\mu\tau\langle \nabla\delta\widehat{\mathbf{E}}^{n+1} \,,\, \nabla\delta\mathbf{F}^{n+1}\rangle, \\
A_2 &:= 2\tau\left\langle \delta P^{n+1} \,,\, \operatorname{div} \delta\widehat{\mathbf{E}}_h^{n+1}\right\rangle, \\
A_3 &:= -2\mu\tau\left\langle \delta s_h^{n} \,,\, \operatorname{div} \delta\widehat{\mathbf{E}}_h^{n+1}\right\rangle, \\
A_4 &:= -2\mathfrak{N}_h(\mathbf{u}(t^{n+1}), \mathbf{u}(t^{n+1}), \delta\widehat{\mathbf{E}}_h^{n+1}) + 2\mathfrak{N}_h(\mathbf{u}_h^{n}, \widehat{\mathbf{u}}_h^{n+1}, \delta\widehat{\mathbf{E}}_h^{n+1}), \\
&\quad + 2\mathfrak{N}_h(\mathbf{u}(t^{n}), \mathbf{u}(t^{n}), \delta\widehat{\mathbf{E}}_h^{n+1}) - 2\mathfrak{N}_h(\mathbf{u}_h^{n-1}, \widehat{\mathbf{u}}_h^{n}, \delta\widehat{\mathbf{E}}_h^{n+1}).
\end{aligned}
$$

We now estimate each term A_i separately. First, we easily find out that

$$
\begin{aligned}
A_1 &\le \frac{\mu\tau}{14}\left\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\right\|_0^2 + C\mu\tau\left\|\nabla\delta\mathbf{F}^{n+1}\right\|_0^2 + \frac{1}{2}\left\|\delta\mathbf{E}^{n+1} - \delta\mathbf{E}^{n}\right\|_0^2 + C\left\|\delta\mathbf{F}^{n+1}\right\|_0^2, \\
A_2 &= 2\tau\left\langle \delta p(t^{n+1}) - \delta g^{n+1} \,,\, \operatorname{div} \delta\widehat{\mathbf{E}}_h^{n+1}\right\rangle \\
&\le \frac{C}{\mu}\int_{t^n}^{t^{n+1}} \|p_t(t)\|_0^2 \, dt + \frac{C\tau}{\mu}\left\|\delta g^{n+1}\right\|_0^2 + \frac{\mu\tau}{14}\left\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\right\|_0^2 + \frac{\mu\tau}{14}\left\|\nabla\delta\mathbf{F}^{n+1}\right\|_0^2.
\end{aligned}
$$

Since $\mathbf{U}_h^{n+1}$ is discrete divergence free, $A_3 = 2\mu\tau\left\langle \delta s_h^{n} \,,\, \operatorname{div} \delta\widehat{\mathbf{u}}_h^{n+1}\right\rangle$. Consequently, making use of (1.10) and (4.13), we arrive at

$$
A_3 = 2\mu\tau\left\langle \delta s_h^{n} \,,\, \delta s_h^{n} - \delta s_h^{n+1}\right\rangle \le \mu\tau\left(\left\|\delta s_h^{n}\right\|_0^2 - \left\|\delta s_h^{n+1}\right\|_0^2\right) + \mu\tau\left\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\right\|_0^2.
$$

At the same time, we further split A_4 to read $A_4 = A_{4,1} + A_{4,2}$ with

$$
\begin{aligned}
A_{4,1} &:= -2\tau\Big(\mathfrak{N}_h\big(\delta\mathbf{u}(t^{n+1}), \mathbf{u}(t^{n+1}), \delta\widehat{\mathbf{E}}_h^{n+1}\big) - \mathfrak{N}_h\big(\delta\mathbf{u}(t^{n}), \mathbf{u}(t^{n}), \delta\widehat{\mathbf{E}}_h^{n+1}\big) \\
&\qquad - \mathfrak{N}_h\big(\mathbf{u}(t^{n}) - \mathbf{u}_h^{n}, \mathbf{u}(t^{n+1}), \delta\widehat{\mathbf{E}}_h^{n+1}\big) + \mathfrak{N}_h\big(\mathbf{u}(t^{n-1}) - \mathbf{u}_h^{n-1}, \mathbf{u}(t^{n}), \delta\widehat{\mathbf{E}}_h^{n+1}\big)\Big), \\
A_{4,2} &:= -2\Big(\mathfrak{N}_h(\mathbf{u}_h^{n}, \mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}, \delta\widehat{\mathbf{E}}_h^{n+1}) - \mathfrak{N}_h\big(\mathbf{u}_h^{n-1}, \mathbf{u}(t^{n}) - \widehat{\mathbf{u}}_h^{n}, \delta\widehat{\mathbf{E}}_h^{n+1}\big)\Big).
\end{aligned}
$$

In light of (2.2) and definitions of $\mathbf{G}^i$ and $\mathbf{E}^i$, (2.12) produces

$$
A_{4,1} \le \frac{C}{\mu}D^{n+1} + \frac{\mu\tau}{14}\left\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\right\|_0^2 + \frac{\mu\tau}{14}\left\|\nabla\delta\mathbf{F}^{n+1}\right\|_0^2 + \frac{C}{\mu\tau}\sum_{i=n-1}^{n}\left(\left\|\mathbf{G}^i\right\|_0^2 + \left\|\mathbf{E}^i\right\|_0^2\right)
$$

with $D^{n+1} := \int_{t^{n-1}}^{t^{n+1}} \|\mathbf{u}_t(t)\|_0^2\,dt$. To bound $A_{4,2}$ we rewrite as $A_{4,2} = \sum_{i=1}^3 B_i$ with

$$\begin{aligned}
B_1 &:= -2\mathfrak{N}_h\big(\mathbf{u}_h^n, \mathbf{G}_h^{n+1}, \delta\widehat{\mathbf{E}}_h^{n+1}\big),\\
B_2 &:= 2\mathfrak{N}_h\big(\mathbf{u}_h^{n-1}, \mathbf{G}_h^{n}, \delta\widehat{\mathbf{E}}_h^{n+1}\big),\\
B_3 &:= -2\mathfrak{N}_h\big(\mathbf{u}_h^n, \widehat{\mathbf{E}}_h^{n+1}, \delta\widehat{\mathbf{E}}_h^{n+1}\big) + 2\mathfrak{N}_h(\mathbf{u}_h^{n-1}, \widehat{\mathbf{E}}_h^{n}, \delta\widehat{\mathbf{E}}_h^{n+1}).
\end{aligned}$$

Since $\big|\!\big|\!\big|\mathbf{G}_h^{n+1}\big|\!\big|\!\big| \le C\big(\|\mathbf{u}(t^{n+1})\|_2 + \|p(t^{n+1})\|_1\big) \le C$, (2.11) and (2.13) give

$$\begin{aligned}
B_1 &= 2\mathfrak{N}_h\left((\mathbf{u}(t^n) - \mathbf{u}_h^n) - \mathbf{u}(t^n), \mathbf{G}_h^{n+1}, \delta\widehat{\mathbf{E}}_h^{n+1}\right)\\
&\le \frac{C}{\mu\tau}\left(\|\mathbf{E}^n\|_0^2 + \|\mathbf{G}^n\|_0^2 + \big\|\mathbf{G}_h^{n+1}\big\|_0^2\right) + \frac{\mu\tau}{14}\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\|_0^2 + \frac{\mu\tau}{14}\big\|\nabla\delta\mathbf{F}^{n+1}\big\|_0^2,
\end{aligned}$$

as well as

$$B_2 \le \frac{C}{\mu\tau}\left(\big\|\mathbf{E}^{n-1}\big\|_0^2 + \big\|\mathbf{G}^{n-1}\big\|_0^2 + \|\mathbf{G}_h^n\|_0^2\right) + \frac{\mu\tau}{14}\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\|_0^2 + \frac{\mu\tau}{14}\big\|\nabla\delta\mathbf{F}^{n+1}\big\|_0^2.$$

Invoking crucial properties of $\mathfrak{N}_h$, written in (2.10), we infer that

$$B_3 = \frac{2}{\tau}\big(\mathfrak{N}_h\big(\mathbf{u}_h^n, \widehat{\mathbf{E}}_h^{n+1}, \widehat{\mathbf{E}}_h^n\big) + \mathfrak{N}_h\big(\mathbf{u}_h^{n-1}, \widehat{\mathbf{E}}_h^{n}, \widehat{\mathbf{E}}_h^{n+1}\big)\big) = 2\tau\mathfrak{N}_h\big(\delta\mathbf{u}_h^n, \delta\widehat{\mathbf{E}}_h^{n+1}, \widehat{\mathbf{E}}_h^n\big).$$

Hence

$$B_3 = -2\tau\mathfrak{N}_h\big(\delta\mathbf{G}_h^n - \delta\mathbf{u}(t^n), \delta\widehat{\mathbf{E}}_h^{n+1}, \widehat{\mathbf{E}}_h^n\big) - 2\tau\mathfrak{N}_h\big(\delta\mathbf{E}_h^n, \delta\widehat{\mathbf{E}}_h^{n+1}, \widehat{\mathbf{E}}_h^n\big) = B_4 + B_5.$$

Since $\|\widehat{\mathbf{E}}_h^n\|_1 \le C$ according to (4.12) and (4.14), (2.11) yields

$$\begin{aligned}
B_4 &\le C\tau\left(\|\delta\mathbf{G}_h^n\|_1 + \|\delta\mathbf{u}(t^n)\|_1\right)\big\|\delta\widehat{\mathbf{E}}_h^{n+1}\big\|_1\big\|\widehat{\mathbf{E}}_h^n\big\|_1\\
&\le \frac{C\tau}{\mu}\|\nabla\delta\mathbf{G}_h^n\|_0^2 + \frac{C}{\mu}\int_{t^n}^{t^{n+1}} \|\mathbf{u}_t(t)\|_1^2\,dt + \frac{\mu\tau}{14}\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\|_0^2 + \frac{\mu\tau}{14}\big\|\nabla\delta\mathbf{F}^{n+1}\big\|_0^2.
\end{aligned}$$

We now deal with B_5 via (2.13), namely, $B_5 \le C\tau\|\delta\mathbf{E}_h^n\|_{\mathbf{L}^3(\Omega)}\|\delta\widehat{\mathbf{E}}_h^{n+1}\|_1\|\widehat{\mathbf{E}}_h^n\|_1$. In contrast to [16], here we no longer have $\mathbf{E}_h^{n+1} \in \mathbf{H}_0^1$ and we have to resort to the inverse inequality $\|\delta\mathbf{E}_h^n\|_{\mathbf{L}^3(\Omega)} \le Ch^{-\frac{d}{6}}\|\delta\mathbf{E}_h^n\|_0$, whence

$$B_5 \le \underbrace{\frac{C\tau h^{-\frac{d}{3}}}{\mu}\|\delta\mathbf{E}_h^n\|_0^2\big\|\nabla\widehat{\mathbf{E}}_h^n\big\|_0^2}_{=:\Lambda^n} + \frac{\mu\tau}{14}\big\|\nabla\delta\widehat{\mathbf{E}}^{n+1}\big\|_0^2 + \frac{\mu\tau}{14}\big\|\nabla\delta\mathbf{F}^{n+1}\big\|_0^2.$$

We postpone the discussion of Λ^n until the end since it is rather delicate. We now insert the above estimates into (5.3), multiply by the weight σ^{n+1}, and add over n from 1 to N. Arguing as in Lemma 4.4, we see that the first two terms in (5.3) become

$$\sigma^{N+1}\big\|\delta\mathbf{E}^{N+1}\big\|_0^2 - \sigma^1\big\|\delta\mathbf{E}^1\big\|_0^2 - \tau\sum_{n=1}^N \|\delta\mathbf{E}^n\|_0^2 \ge -C + \sigma^{N+1}\big\|\delta\mathbf{E}^{n+1}\big\|_0^2. \tag{5.4}$$

On the other hand, we resort to the property $\frac{\sigma^{n+1}}{\sigma^n} \le 2$ for $n \ge 1$ to write

$$\sum_{n=1}^{N} \sigma^{n+1} A_2 \le \frac{C\tau}{\mu} \sum_{n=1}^{N} \sigma^{n+1} \big\|\delta g^{n+1}\big\|_0^2 + \frac{C}{\mu} \int_{t^1}^{t^{N+1}} \sigma(t) \|p_t(t)\|_0^2 \, dt \\ + \frac{\mu\tau}{14} \sum_{n=1}^{N} \sigma^{n+1} \big(\|\nabla \delta \widehat{\mathbf{E}}^{n+1}\|_0^2 + \|\nabla \delta \mathbf{F}^{n+1}\|_0^2\big). \tag{5.5}$$

Collecting these estimates, and using Lemmas 4.1–4.4 and 4.7, we get, for $D_1, D_2 > 0$,

$$\sigma^{N+1} \big\|\delta \mathbf{E}^{N+1}\big\|_0^2 + \frac{1}{2} \sum_{n=1}^{N} \sigma^{n+1} \big\|\delta \mathbf{E}^{n+1} - \delta \mathbf{E}^n\big\|_0^2 + \frac{\mu\tau}{2} \sum_{n=1}^{N} \sigma^{n+1} \big\|\nabla \delta \widehat{\mathbf{E}}^{n+1}\big\|_0^2 \\ + \sum_{n=1}^{N} \sigma^{n+1} \big\|\nabla \delta \rho_h^{n+1}\big\|_0^2 + \mu\tau\sigma^{N+1} \big\|\delta s_h^{N+1}\big\|_0^2 \le D_1 + D_2 \sum_{n=1}^{N} \sigma^{n+1} \Lambda^n.$$

To complete this proof, it suffices to show $\sum_{n=1}^{N} \sigma^{n+1} B_6^n \le C$. To do so, we start with a simpler form of the above estimate, namely,

$$\sigma^{N+1} \big\|\delta \mathbf{E}^{N+1}\big\|_0^2 \le D_1 + D_2 \tau h^{-\frac{d}{3}} \sum_{n=1}^{N} \sigma^{n+1} \|\delta \mathbf{E}_h^n\|_0^2 \big\|\nabla \widehat{\mathbf{E}}_h^n\big\|_0^2. \tag{5.6}$$

Since $\tau^2 \sum_{n=1}^{N} \|\delta \mathbf{E}^n\|_0^2 = \sum_{n=1}^{N} \big\|\mathbf{E}^n - \mathbf{E}^{n-1}\big\|_0^2 \le C\tau$ and $\|\nabla \widehat{\mathbf{E}}_h^n\|_0^2 \le C$ according to Lemma 4.4, we readily obtain the rough estimate

$$\sigma^{N+1} \big\|\delta \mathbf{E}^{N+1}\big\|_0^2 \le C h^{-\frac{d}{3}}.$$

To improve upon this, we utilize $\sum_{n=1}^{N} \|\nabla \widehat{\mathbf{E}}_h^n\|_0^2 \le C$, a by-product of (4.12) and (4.14). Hence

$$\sigma^{N+1} \big\|\delta \mathbf{E}^{N+1}\big\|_0^2 \le D_1 + D_2 \tau h^{-\frac{2d}{3}} \sum_{n=1}^{N} \big\|\nabla \widehat{\mathbf{E}}_h^n\big\|_0^2 \le C\tau h^{-\frac{2d}{3}}.$$

We realize that the net effect is a an additional factor $C\tau h^{-d/3}$ in (5.6). After m iterations, we obtain

$$\sigma^{N+1} \big\|\delta \mathbf{E}^{N+1}\big\|_0^2 \le M(m) \big(\tau h^{-\frac{d}{3}}\big)^m h^{-\frac{d}{3}},$$

where $M(m) > 0$ possibly grows with m. Since $\tau h^{-\frac{d}{3}} \le C_2 h^{\frac{d\varepsilon}{3}}$ for $m > \varepsilon^{-1}$ we obtain $\sum_{n=1}^{N} \sigma^{n+1} \Lambda^n \le C$. This shows our assertion (5.1).

If NLC is valid, so is Lemma 2.2, thereby making unnecessary the use of weight σ^{n+1} in (5.4) and (5.5). This yields an inequality similar to (5.1) without weights, and implies the asserted uniform estimate. ∎

Lemma 5.2 (rate of convergence for time-derivative of velocity). *Let* A1–A6 *hold and* $C_1 h^2 \le \tau \le C_2 h^{\frac{d}{3}(1+\varepsilon)}$ *be valid with arbitrary constants* $C_1, C_2 > 0$. *Then the error function* $\mathbf{E}^n$ *satisfies the weighted estimates*

$$\sigma^{N+1} \big\|\delta \mathbf{E}^{N+1}\big\|_*^2 + \sum_{n=1}^{N} \sigma^{n+1} \left(\big\|\delta \mathbf{E}^{n+1} - \delta \mathbf{E}^n\big\|_*^2 + \mu\tau \big\|\delta \mathbf{E}^{n+1}\big\|_0^2 \right) \le C(\tau + h^2). \tag{5.7}$$

If NLC is also valid, then the following uniform error estimates hold:

$$\left\|\delta\mathbf{E}^{N+1}\right\|_*^2 + \frac{1}{2}\sum_{n=1}^{N}\left\|\delta\mathbf{E}^{n+1} - \delta\mathbf{E}^{n}\right\|_*^2 + \mu\tau\sum_{n=1}^{N}\left\|\delta\mathbf{E}^{n+1}\right\|_0^2 \le C(\tau + h^2). \tag{5.8}$$

Proof. Let $(\mathbf{v}^n, q^n)$ and $(\mathbf{v}_h^n, q_h^n)$ be solutions of the Stokes equations (2.1) and (2.6) with $\mathbf{g} = \mathbf{E}^{n+1}$. Choosing $\mathbf{w}_h = 2\delta\mathbf{v}_h^{n+1}$ in (5.2), we arrive at

$$\left\|\nabla\delta\mathbf{v}_h^{n+1}\right\|_0^2 - \|\nabla\delta\mathbf{v}_h^{n}\|_0^2 + \left\|\nabla(\delta\mathbf{v}_h^{n+1} - \delta\mathbf{v}_h^{n})\right\|_0^2 + 2\mu\tau\left\|\delta\mathbf{E}^{n+1}\right\|_0^2 = \sum_{i=1}^{4} A_i \tag{5.9}$$

with

$$\begin{aligned}
A_1 &:= -2\mu\tau\big\langle\nabla\delta\mathbf{F}^{n+1}\,,\,\nabla\delta\mathbf{v}_h^{n+1}\big\rangle,\\
A_2 &:= 2\mu\tau\big(\langle\delta\mathbf{E}^{n+1}\,,\,\delta\mathbf{F}^{n+1}\rangle + \big\langle\nabla\delta q_h^{n+1}\,,\,\nabla\delta\rho_h^{n+1}\big\rangle\big),\\
A_3 &:= 2\tau\langle\delta P^{n+1}\,,\,\mathrm{div}\ \delta\mathbf{v}_h^{n+1}\rangle,\\
A_4 &:= 2\mathfrak{N}_h\big(\mathbf{u}_h^n, \widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}_h^{n+1}\big) - 2\mathfrak{N}_h\big(\mathbf{u}_h^{n-1}, \widehat{\mathbf{u}}_h^{n}, \delta\mathbf{v}_h^{n+1}\big)\\
&\quad - 2\mathfrak{N}_h\big(\mathbf{u}(t^{n+1}), \mathbf{u}(t^{n+1}), \delta\mathbf{v}_h^{n+1}\big) + 2\mathfrak{N}_h\big(\mathbf{u}(t^{n}), \mathbf{u}(t^{n}), \delta\mathbf{v}_h^{n+1}\big).
\end{aligned}$$

Except for A_4, we can proceed as in Lemma 4.7 to estimate A_1–A_3, whence

$$\begin{aligned}
A_1 &\le C\mu\tau\left(h^2\left\|\nabla\delta\mathbf{F}^{n+1}\right\|_0^2 + \left\|\delta\mathbf{F}^{n+1}\right\|_0^2\right) + \frac{\mu\tau}{6}\left\|\delta\mathbf{E}^{n+1}\right\|_0^2,\\
A_2 &\le C\mu\tau\left(\left\|\delta\mathbf{F}^{n+1}\right\|_0^2 + \left\|\nabla\delta\rho_h^{n+1}\right\|_0^2\right) + \frac{\mu\tau}{6}\left\|\delta\mathbf{E}^{n+1}\right\|_0^2,\\
A_3 &\le \frac{C\tau h^2}{\mu}\left\|\delta f^{n+1}\right\|_0^2 + \frac{\mu\tau}{6}\left\|\delta\mathbf{E}^{n+1}\right\|_0^2.
\end{aligned}$$

The remaining term A_4 gives rise to rather technical calculations. A tedious but simple rearrangement yields $A_4 = \sum_{i=1}^{6} A_{4,i}$ with each term A_i to be examined separately:

$$\begin{aligned}
A_{4,1} &:= -2\mathfrak{N}_h(\mathbf{u}(t^{n+1}) - 2\mathbf{u}(t^n) + \mathbf{u}(t^{n-1}), \mathbf{u}(t^{n+1}), \delta\mathbf{v}_h^{n+1}),\\
A_{4,2} &:= -2\mathfrak{N}_h((\mathbf{u}(t^n) - \mathbf{u}_h^n) - (\mathbf{u}(t^{n-1}) - \mathbf{u}_h^{n-1}), \mathbf{u}(t^{n+1}), \delta\mathbf{v}_h^{n+1}),\\
A_{4,3} &:= -2\mathfrak{N}_h(\mathbf{u}_h^n - \mathbf{u}_h^{n-1}, \mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}_h^{n+1}),\\
A_{4,4} &:= -2\mathfrak{N}_h(\mathbf{u}(t^n) - \mathbf{u}(t^{n-1}), \mathbf{u}(t^{n+1}) - \mathbf{u}(t^n), \delta\mathbf{v}_h^{n+1}),\\
A_{4,5} &:= -2\mathfrak{N}_h(\mathbf{u}(t^{n-1}) - \mathbf{u}_h^{n-1}, \mathbf{u}(t^{n+1}) - \mathbf{u}(t^n), \delta\mathbf{v}_h^{n+1}),\\
A_{4,6} &:= -2\mathfrak{N}_h(\mathbf{u}_h^{n-1}, (\mathbf{u}(t^{n+1}) - \mathbf{u}(t^n)) - (\widehat{\mathbf{u}}_h^{n+1} - \widehat{\mathbf{u}}_h^{n}), \delta\mathbf{v}_h^{n+1}).
\end{aligned}$$

Since $\left\|\mathbf{u}(t^{n+1}) - 2\mathbf{u}(t^n) + \mathbf{u}(t^{n-1})\right\|_0^2 \le C\tau^2\int_{t^{n-1}}^{t^{n+1}}\sigma\|\mathbf{u}_{tt}\|_0^2\,dt$, (2.2) and (2.12) yield

$$A_{4,1} \le C\tau\int_{t^{n-1}}^{t^{n+1}}\sigma(t)\|\mathbf{u}_{tt}(t)\|_0^2\,dt + C\tau\left\|\nabla\delta\mathbf{v}_h^{n+1}\right\|_0^2,$$

as well as

$$A_{4,2} \le \frac{\mu\tau}{8}\big(\|\delta\mathbf{G}^n\|_0^2 + \|\delta\mathbf{E}^n\|\big) + \frac{C\tau}{\mu}\left\|\nabla\delta\mathbf{v}_h^{n+1}\right\|_0^2.$$

Dealing with $A_{4,3}$ entails further rearrangement as follows:

$$\begin{aligned}A_{4,3} &= 2\tau\mathfrak{N}_h\big(\delta\mathbf{u}(t^n) - \delta\mathbf{u}_h^n, \mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}_h^{n+1} - \delta\mathbf{v}^{n+1}\big)\\ &\quad + 2\tau\mathfrak{N}_h\big(\delta\mathbf{u}(t^n) - \delta\mathbf{u}_h^n, \mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}^{n+1}\big)\\ &\quad - 2\tau\mathfrak{N}_h\big(\delta\mathbf{u}(t^n), \mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}_h^{n+1} - \delta\mathbf{v}^{n+1}\big)\\ &\quad - 2\tau\mathfrak{N}_h\big(\delta\mathbf{u}(t^n), \mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}^{n+1}\big).\end{aligned}$$

In view of (2.12) and (2.13), we can thus write

$$\begin{aligned}A_{4,3} &\le C\tau\|\delta\mathbf{u}(t^n) - \delta\mathbf{u}_h^n\|_{\mathbf{L}^3(\Omega)}\big\|\mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}\big\|_1\big\|\delta\mathbf{v}^{n+1} - \delta\mathbf{v}_h^{n+1}\big\|_1\\ &\quad + C\tau\|\delta\mathbf{u}(t^n) - \delta\mathbf{u}_h^n\|_0\big\|\mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}\big\|_1\big\|\delta\mathbf{v}^{n+1}\big\|_2\\ &\quad + C\tau\|\delta\mathbf{u}(t^n)\|_1\big\|\mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}\big\|_1\big\|\delta\mathbf{v}^{n+1} - \delta\mathbf{v}_h^{n+1}\big\|_1\\ &\quad + C\tau\|\delta\mathbf{u}(t^n)\|_1\big\|\mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1}\big\|_0\big\|\delta\mathbf{v}^{n+1}\big\|_2.\end{aligned}$$

Since $\|\delta(\mathbf{v}^{n+1} - \mathbf{v}_h^{n+1})\|_1 \le Ch\|\mathbf{E}^{n+1}\|_0$, because of (2.7), we see that the problematic term with $\mathbf{L}^3$ norm can be easily handled. In fact, invoking Lemma 5.1 together with an inverse inequality from L^3 to L^2 gives

$$\sigma^n\|\delta\mathbf{u}(t^n) - \delta\mathbf{u}_h^n\|_0^2 + \sigma^n h^2\|\delta\mathbf{u}(t^n) - \delta\mathbf{u}_h^n\|_{\mathbf{L}^3(\Omega)}^2 \le C.$$

We note that this inequality also holds without weight σ^n if NLC is valid. Since, according to (2.2), we have $\|\delta\mathbf{u}(t^n)\|_0^2 \le M$ and $\|\delta\mathbf{u}(t^n)\|_1^2 \le \tau^{-1}\int_{t^n}^{t^{n+1}} \|\mathbf{u}_t(t)\|_1^2\,dt \le M\tau^{-1}$, after a simple calculation we get

$$A_{4,3} \le \frac{C}{\mu}(\tau + h^2)D^n + \frac{C\tau}{\sigma^n\mu}\left(\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0^2 + \big\|\nabla\mathbf{G}^{n+1}\big\|_0^2\right) + \frac{\mu\tau}{8}\big\|\delta\mathbf{E}^{n+1}\big\|_0^2,$$

where $D^n := \int_{t^{n-1}}^{t^n} \|\nabla\mathbf{u}_t(t)\|_0^2\,dt$. We again use the bound for $\|\delta\mathbf{u}(t^n)\|_1$ to get

$$A_{4,4} \le C\tau^2\|\delta\mathbf{u}(t^n)\|_1\big\|\delta\mathbf{u}(t^{n+1})\big\|_1\big\|\delta\mathbf{v}_h^{n+1}\big\|_1 \le C\tau D^n + C\tau\big\|\nabla\delta\mathbf{v}_h^{n+1}\big\|_0^2.$$

To estimate $A_{4,5}, A_{4,6}$ we again have to handle an L^3 norm, this time for $\mathbf{u}(t^n) - \mathbf{u}_h^n$. Combining once again Lemma 5.1 with an inverse estimate yields $h\|\mathbf{u}(t^n) - \mathbf{u}_h^n\|_{\mathbf{L}^3(\Omega)} \le C\|\mathbf{u}(t^n) - \mathbf{u}_h^n\|_0 \le C(\tau + h^2)^{\frac{1}{2}}$. Consequently,

$$\begin{aligned}A_{4,5} &\le C\tau\big\|\mathbf{u}(t^{n-1}) - \mathbf{u}_h^{n-1}\big\|_{\mathbf{L}^3(\Omega)}\big\|\delta\mathbf{u}(t^{n+1})\big\|_1\big\|\delta\mathbf{v}^{n+1} - \delta\mathbf{v}_h^{n+1}\big\|_1\\ &\quad + C\tau\big\|\mathbf{u}(t^{n-1}) - \mathbf{u}_h^{n-1}\big\|_0\big\|\delta\mathbf{u}(t^{n+1})\big\|_1\big\|\delta\mathbf{v}^{n+1}\big\|_2\\ &\le \frac{C}{\mu}(\tau + h^2)D^{n+1} + \frac{\mu\tau}{8}\big\|\delta\mathbf{E}^{n+1}\big\|_0^2.\end{aligned}$$

In addition, since

$$\begin{aligned}A_{4,6} &= 2\tau\mathfrak{N}_h(\mathbf{u}(t^{n-1}) - \mathbf{u}_h^{n-1}, \delta\mathbf{u}(t^{n+1}) - \delta\widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}_h^{n+1} - \delta\mathbf{v}^{n+1})\\ &\quad + 2\tau\mathfrak{N}_h(\mathbf{u}(t^{n-1}) - \mathbf{u}_h^{n-1}, \delta\mathbf{u}(t^{n+1}) - \delta\widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}^{n+1})\\ &\quad - 2\tau\mathfrak{N}_h(\mathbf{u}(t^{n-1}), \delta\mathbf{u}(t^{n+1}) - \delta\widehat{\mathbf{u}}_h^{n+1}, \delta\mathbf{v}_h^{n+1}),\end{aligned}$$

a similar argument leads to

$$A_{4,6} \le \frac{C\tau}{\mu}\left(\|\delta\widehat{\mathbf{E}}^{n+1} + \delta\mathbf{G}^{n+1}\|_0^2 + (\tau + h^2)\|\delta\widehat{\mathbf{E}}^{n+1} + \delta\mathbf{G}^{n+1}\|_1^2\right) + \frac{\mu\tau}{8}\|\delta\mathbf{E}^{n+1}\|_0^2.$$

We now multiply both sides of (5.9) by the weight σ^{n+1} and sum over n for $1 \leq n \leq N$. We first examine the ensuing first two terms on the left-hand side of (5.9). In light of $\sigma^1 = \tau$, $h^2 \leq C\tau$, $\sum_{n=1}^N \|\nabla\delta\mathbf{v}_h^n\|_0^2 \leq C$ (see Lemma 4.7) and $\sigma^1 \big\|\nabla\delta\mathbf{v}_h^1\big\|_0^2 \leq C\tau$ (see Remark 4.8), we deduce

$$\sum_{n=1}^N \Big(\sigma^{n+1}\big\|\nabla\delta\mathbf{v}^{n+1}\big\|_0^2 - \sigma^n\big\|\nabla\delta\mathbf{v}_h^n\big\|_0^2 - (\sigma^{n+1}-\sigma^n)\big\|\nabla\delta\mathbf{v}_h^n\big\|_0^2\Big)$$
$$\geq \sigma^{N+1}\big\|\nabla\delta\mathbf{v}_h^{N+1}\big\|_0^2 - \sigma^1\big\|\nabla\delta\mathbf{v}_h^1\big\|_0^2 - \tau\sum_{n=1}^N \|\nabla\delta\mathbf{v}_h^n\|_0^2 \geq \sigma^{N+1}\big\|\nabla\delta\mathbf{v}_h^{N+1}\big\|_0^2 - C\tau.$$

Since $\frac{\sigma^{n+1}}{\sigma^n} \leq 2$ for $n \geq 1$, we can replace σ/σ^n in $A_{4,3}$ by a constant. Therefore, we can achieve an estimate for $\sigma^{n+1}\|\nabla\delta\mathbf{v}_h^{n+1}\|_0^2$ with the aid of Lemmas 4.1, 4.7, and 5.1, as well as the discrete Gronwall lemma. The asserted *weighted* error estimate follows from (2.8).

If NLC is valid, we do not need to multiply (5.9) by σ^{n+1} to derive the *uniform* error estimate (5.8). In this case, we have, instead, $\|\delta\mathbf{G}^n\|_0 + \|\delta\mathbf{E}^n\|_0 \leq C$ (see Lemmas 4.2 and 5.1). We finally proceed as before to obtain (5.8). $\square$

6. Theorem 1.3: Error analysis for pressure. We derive here the error of pressure of Theorem 1.3 by exploiting all previous results.

Lemma 6.1 (rate of convergence for pressure). *Let* A1–A6 *hold and* $C_1h^2 \leq \tau \leq C_2h^{\frac{d}{3}(1+\varepsilon)}$ *be valid with arbitrary constants* $C_1, C_2 > 0$. *Then the pressure error function satisfies the weighted estimates*

$$\tau\sum_{n=0}^N \sigma^{n+1}\big\|e_h^{n+1}\big\|_0^2 \leq C\left(\tau + h^2\right). \tag{6.1}$$

If NLC is also valid, then the following uniform error estimate holds:

$$\tau\sum_{n=0}^N \big\|e_h^{n+1}\big\|_0^2 \leq C(\tau + h^2). \tag{6.2}$$

Proof. Since $p_h^{n+1} = \mu s_h^{n+1} - \tau^{-1}\rho_h^{n+1}$ and $\widehat{\mathbf{E}}_h^{n+1} = \mathbf{E}_h^{n+1} + \nabla\rho_h^{n+1}$ according to (1.11) and (1.13), we can rearrange (4.15) to read $\big\langle e_h^{n+1}\,,\,\mathrm{div}\,\mathbf{w}_h\big\rangle = A_1 + A_2$ with

$$\begin{aligned} A_1 &:= \langle\delta\mathbf{E}^{n+1}\,,\,\mathbf{w}_h\rangle + \mu\langle\nabla\widehat{\mathbf{E}}^{n+1}\,,\,\nabla\mathbf{w}_h\rangle - \langle\mu(s_h^{n+1} - s_h^n) + f^{n+1}\,,\,\mathrm{div}\,\mathbf{w}_h\rangle,\\ A_2 &:= \mathfrak{N}_h\left(\mathbf{u}(t^{n+1}),\mathbf{u}(t^{n+1}),\mathbf{w}_h\right) - \mathfrak{N}_h\big(\mathbf{u}_h^n,\widehat{\mathbf{u}}_h^{n+1},\mathbf{w}_h\big). \end{aligned}$$

In view of (4.13), A_1 can be bounded as follows:

$$\sup_{\mathbf{w}_h\in\mathbb{V}_h}\frac{|A_1|}{\|\nabla\mathbf{w}_h\|_0} \leq C\|\delta\mathbf{E}^{n+1}\|_0 + C\mu\|\nabla\widehat{\mathbf{E}}^{n+1}\|_0 + C\big\|f^{n+1}\big\|_0.$$

The remaining term A_2 can be further split as follows:

$$\begin{aligned} A_2 = &-\mathfrak{N}_h\big(\mathbf{u}(t^{n+1}) - \mathbf{u}(t^n),\mathbf{u}(t^{n+1}),\mathbf{z}_h^{n+1}\big)\\ &-\mathfrak{N}_h\big(\mathbf{u}(t^n) - \mathbf{u}_h^n,\mathbf{u}(t^{n+1}),\mathbf{z}_h^{n+1}\big)\\ &-\mathfrak{N}_h\big(\mathbf{u}(t^n),\mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1},\mathbf{z}_h^{n+1}\big)\\ &-\mathfrak{N}_h\big(\mathbf{u}_h^n - \mathbf{u}(t^n),\mathbf{u}(t^{n+1}) - \widehat{\mathbf{u}}_h^{n+1},\mathbf{z}_h^{n+1}\big). \end{aligned}$$

The only problematic term is the last one because it requires use of (2.13). To this end, note that $\|\mathbf{u}(t^n) - \mathbf{u}_h^n\|_{\mathbf{L}^3(\Omega)} \le C + Ch^{-\frac{d}{6}}(\tau^{\frac{1}{2}} + h) \le C$, as results from adding and subtracting $I_h\mathbf{u}(t^n)$, and employing an inverse inequality together with (4.14). Therefore, since (2.2) implies $\int_{t^n}^{t^{n+1}} \|\mathbf{u}_t(t)\|_0 \, dt \le C\tau$,

$$\sup_{\mathbf{w}_h \in \mathbb{V}_h} \frac{|A_2|}{\|\nabla \mathbf{w}_h\|_0} \le C\tau + C\big(\|\mathbf{E}^n\|_0 + \|\mathbf{G}^n\|_0 + \|\widehat{\mathbf{E}}^{n+1}\|_1 + \|\mathbf{G}^{n+1}\|_1\big).$$

Altogether, invoking the inf-sup condition $A4$ in conjunction with (4.3) and (4.14), we obtain

$$\begin{aligned} \beta\|e_h^{n+1}\|_0 &\le \sup_{\mathbf{w}_h \in \mathbb{V}_h} \frac{\langle e_h^{n+1}, \operatorname{div} \mathbf{w}_h\rangle}{\|\nabla \mathbf{w}_h\|_0} \\ &\le C\big(\tau^{\frac{1}{2}} + h\big) + C\big(\|\delta\mathbf{E}^{n+1}\|_0 + \|\widehat{\mathbf{E}}^{n+1}\|_1 + \|\mathbf{G}^{n+1}\|_1 + \|f^{n+1}\|_0\big). \end{aligned}$$

What remains now is to square, multiply by $\tau\sigma^{n+1}$ (resp., τ in case NLC is valid), and sum over n from 0 to N. Recalling (4.3), (4.12), (4.14), and (5.7), assertion (6.1) (resp., (6.2)) follows immediately. This concludes the proof. □

7. Numerical experiments.

7. Numerical experiments. In this section, we document the computational performance of the gauge–Uzawa FEM with two relevant examples. They were both computed within the finite element toolbox ALBERT of Schmidt and Siebert [22].

7.1. Example 1: Smooth solution. We first test the performance of GU-FEM with a smooth solution. Let $\Omega = [0,1] \times [0,1]$ and the solution be given by

$$\begin{cases} u(x,y,t) = \cos(t)(x^2 - 2x^3 + x^4)(2y - 6y^2 + 4y^3), \\ v(x,y,t) = -\cos(t)(y^2 - 2y^3 + y^4)(2x - 6x^2 + 4x^3), \\ p(x,y,t) = \cos(t)\left(x^2 + y^2 - \dfrac{2}{3}\right). \end{cases}$$

The forcing term $\mathbf{f}(t)$ is determined accordingly for any μ; here $\mu = 1$. Computations are carried out with the Taylor–Hood $(\mathcal{P}^2, \mathcal{P}^1)$ finite element pair on quasi-uniform meshes of size h. However, the coarsest mesh is quite distorted to avoid superconvergence effects. In view of the error estimates of Theorems 1.2 and 1.3, we adopt the parabolic relation $\tau = h^2$ to avoid dominance of either space or time error over the other. Table 7.1 shows second order accuracy for both velocity and pressure in $L^2(\mathbf{H}^1(\Omega) \times L^2(\Omega))$. This is better than predicted by the theory for solutions with minimal regularity, especially when $t \downarrow 0$, and hints at the need for further analysis beyond the present techniques, perhaps involving also other norms as suggested in Table 7.1.

7.2. Example 2: Backward step and do-nothing boundary condition. In order to explore the applicability of the gauge–Uzawa FEM beyond the theory, we consider the backward step flow problem with *do-nothing boundary condition*; this is a natural boundary condition for the stress, namely,

$$(-\nabla \mathbf{u} + \mathbf{I}p) \cdot \boldsymbol{\nu} = 0 \quad \text{on } \Gamma_{out}, \tag{7.1}$$

where $\Gamma_{out} \subset \partial\Omega$. This condition can be imposed on fluid problems with an open outlet without forcing. Conditions involving the stress and geometric quantities such

Table 7.1

Example 7.1*: The error decay of the gauge–Uzawa FEM for a smooth solution and several norms for velocity and pressure. The computations are performed with the Taylor–Hood* ($\mathcal{P}^2, \mathcal{P}^1$) *finite element pair on quasi-uniform meshes. The meshes are distorted though to prevent superconvergence effects. The table shows second order accuracy for both velocity and pressure for the relation* $\tau = h^2$.

as mean curvature are ubiquitous in dealing with free boundary problems for fluids. The mere fact that projection methods decouple velocity and pressure computations, and that both $\mathbf{u}$ and p appear together in (7.1) makes its implementation a challenge. This is the case for several projections methods such as the Chorin method [4, 21, 18] and the gauge method [7, 8, 27].

Since the momentum equation (1.8) is consistent for the pair $(\widehat{\mathbf{u}}_h^{n+1}, p_h^n)$, as written in (1.14), to impose (7.1) on the gauge–Uzawa method, we use the modified form $(-\nabla \mathbf{u}^{n+1} + \mathbf{I}p^n) \cdot \boldsymbol{\nu} = 0$. This amounts to solving (1.14), namely,

$$\tau^{-1} \left\langle \widehat{\mathbf{u}}_h^{n+1} - \widehat{\mathbf{u}}_h^n \, , \, \mathbf{w}_h \right\rangle + \mathfrak{N}_h(\mathbf{u}_h^n, \widehat{\mathbf{u}}_h^{n+1}, \mathbf{w}_h) + \mu \left\langle \nabla \widehat{\mathbf{u}}_h^{n+1} \, , \, \nabla \mathbf{w}_h \right\rangle$$
$$- \mu \langle p_h^n \, , \, \mathrm{div} \, \mathbf{w}_h \rangle = \langle \mathbf{f}(t^{n+1}) \, , \, \mathbf{w}_h \rangle,$$

but with test function $\mathbf{w}_h$ free on Γ_{out}. This leads, however, to an incompatible Poisson problem (1.9) if we insist on a homogeneous Neumann condition; note that now it is plausible that $\int_{\partial\Omega} \widehat{\mathbf{u}}_h^{n+1} \cdot \boldsymbol{\nu} \neq 0$.

To circumvent this issue, we consider a space-continuous gauge–Uzawa formulation. In view of (1.9) and (1.12), we can write

$$\left\langle \nabla \rho^{n+1} \, , \, \nabla \psi \right\rangle = - \left\langle \widehat{\mathbf{u}}^{n+1} \, , \, \nabla \psi \right\rangle = \left\langle \mathbf{u}^{n+1} - \widehat{\mathbf{u}}^{n+1} \, , \, \nabla \psi \right\rangle \qquad \forall \psi \in \mathbb{P}.$$

This amounts to the natural boundary condition $\partial_{\boldsymbol{\nu}} \rho^{n+1} = (\mathbf{u}^{n+1} - \widehat{\mathbf{u}}^{n+1}) \cdot \boldsymbol{\nu}$, which is not computable since we do not yet know $\mathbf{u}^{n+1}$. We now decompose $\partial\Omega$ into an inflow part Γ_{in}, where we prescribe velocity, an outflow part Γ_{out}, where we impose (7.1), and the rest where $\widehat{\mathbf{u}}^{n+1} \cdot \boldsymbol{\nu} = \mathbf{u}^{n+1} \cdot \boldsymbol{\nu} = 0$. Since $\int_{\partial\Omega} \mathbf{u}^{n+1} \cdot \boldsymbol{\nu} = \int_\Omega \mathrm{div} \, \mathbf{u}^{n+1} = 0$,

$$\int_{\Gamma_{out}} \mathbf{u}^{n+1} \cdot \boldsymbol{\nu} = - \int_{\Gamma_{in}} \mathbf{u}^{n+1} \cdot \boldsymbol{\nu} = - \int_{\Gamma_{in}} \widehat{\mathbf{u}}^{n+1} \cdot \boldsymbol{\nu},$$

whence $\int_{\Gamma_{out}} (\mathbf{u}^{n+1} - \widehat{\mathbf{u}}^{n+1}) \cdot \boldsymbol{\nu} = - \int_{\partial\Omega} \widehat{\mathbf{u}}^{n+1} \cdot \boldsymbol{\nu}$. We thus solve (1.9) with a constant flux condition, namely,

$$\partial_{\boldsymbol{\nu}} \rho^{n+1} = -|\Gamma_{out}|^{-1} \int_{\partial\Omega} \widehat{\mathbf{u}}^{n+1} \cdot \boldsymbol{\nu} \quad \text{on } \Gamma_{out}.$$

We consider a simple geometry consisting of a backward step flow with *do-nothing boundary condition.* This example has been studied extensively and our results are consistent with those in the literature [14, 23]. The computational domain Ω is $[0, 6] \times$

$[0,1]$ with an obstacle $[1.2,1.6]\times[0,0.4]$ (see Figure 7.1). No slip boundary condition is imposed except on the inflow boundary Γ_{in} and on the outflow boundary Γ_{out}. We assign $\mathbf{u}=(1,0)$ on Γ_{in} and (7.1) on Γ_{out} for all time t. The viscosity is $\mu=0.005$ and the discretization parameters are $\tau=0.05$ and $h=1/32$.

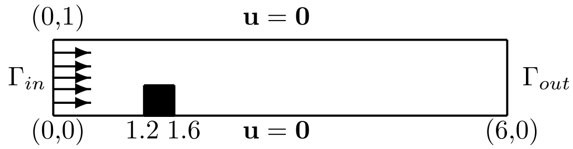

FIG. 7.1. *Example 7.2: The computational domain and boundary values. The viscosity is $\mu=0.005$ and the discretization parameters are $\tau=0.05$ and $h=1/32$.*

Figure 7.2 is a time sequence of streamlines and velocity vector fields for $t=1$, 2, 5, and 50. For $t=50$ the evolution already became stationary. Figure 7.3 displays zooms of the recirculation zone behind the step.

EXPLICIT EXPONENTIAL RUNGE–KUTTA METHODS FOR SEMILINEAR PARABOLIC PROBLEMS*

MARLIS HOCHBRUCK† AND ALEXANDER OSTERMANN‡

Abstract. The aim of this paper is to analyze explicit exponential Runge–Kutta methods for the time integration of semilinear parabolic problems. The analysis is performed in an abstract Banach space framework of sectorial operators and locally Lipschitz continuous nonlinearities. We commence by giving a new and short derivation of the classical (nonstiff) order conditions for exponential Runge–Kutta methods, but the main interest of our paper lies in the stiff case. By expanding the errors of the numerical method in terms of the solution, we derive new order conditions that form the basis of our error bounds for parabolic problems. We show convergence for methods up to order four, and we analyze methods that were recently presented in the literature. These methods have classical order four, but they do not satisfy some of the new conditions. Therefore, an order reduction is expected. We present numerical experiments which show that this order reduction in fact arises in practical examples. Based on our new conditions, we finally construct methods that do not suffer from order reduction.

Key words. exponential integrators, Runge–Kutta methods, semilinear parabolic problems, stiff order conditions, explicit high-order methods, convergence, order reduction

1. Introduction.

Motivated by recent interest in exponential integrators for stiff problems [3, 9, 11, 12] and inspired by the promising numerical experiments reported in those papers, we present error bounds for a class of explicit exponential Runge–Kutta methods for semilinear parabolic problems

$$u'(t) + Au(t) = g(t, u(t)), \qquad u(t_0) = u_0. \tag{1.1}$$

The idea behind exponential integrators is an old one and dates back to the 1960s. The early literature on exponential one-step methods comprises [4, 6, 14, 23, 24, 25]. In most of those papers, the methods were constructed by making use of the variation-of-constants formula for the solution of (1.1). All of them use the exponential function of the matrix $-hA$ in order to step from time t to time $t+h$, or some rational approximations thereof. Exponential multistep methods have been considered in [13, 21, 26].

Although the first exponential integrators were proposed many years ago, such methods have not been regarded as practical for a long time. This view, however, has changed recently as new methods for computing or approximating the product of a matrix exponential function with a vector have been developed; see the review [19] and references therein. For large problems, polynomial approximations have to be applied, in general, either based on Chebyshev polynomials or using variants of the Lanczos process or the Arnoldi method. (These techniques are also reviewed in [19].) For parabolic problems it has been shown recently that one can achieve grid independent convergence of the Lanczos process by working with a shifted and inverted matrix

[5, 20]. The linear systems arising in each step of the Lanczos process can either be solved directly (if fast direct solvers are available) or with a preconditioned iterative method. Details can be found in [5].

The numerical comparisons presented in [11, 12, 18] reveal a number of examples where explicit exponential integrators outperform standard integrators. However, while the convergence behavior of implicit or linearly implicit Runge–Kutta or multistep methods for parabolic problems is nowadays well understood [15, 16], no analysis is known so far for explicit exponential integrators. In our paper [10] we analyzed implicit exponential Runge–Kutta methods. There, a crucial step in the convergence proofs was to show that all stages have a sufficiently small defect when the true solution is inserted in place of the numerical solution. This is no longer true for explicit schemes of order at least three. Therefore, new techniques have to be used for proving error bounds in this case. Our aim with this paper is to derive new order conditions for stiff problems and, based on these, to give error bounds for parabolic problems. The new conditions will then enable us to analyze the methods presented in the literature and, further, to construct new methods that do not suffer from order reduction.

The outline of the paper is as follows. In section 2, we define a general class of exponential Runge–Kutta methods and give conditions under which these methods preserve equilibria. We further give a simple and short derivation of the classical order conditions for arbitrary order. Our convergence analysis of (1.1) will be performed in the standard framework of analytic semigroups and locally Lipschitz continuous nonlinearities in a Banach space. This abstract framework is recalled in section 3. Our main results are contained in section 4, where we derive new order conditions for explicit exponential Runge–Kutta methods applied to parabolic problems. These conditions, which comprise the classical order conditions, are given in Table 2 up to order four. Based on them, we show convergence for explicit exponential Runge–Kutta methods up to order four, under appropriate temporal smoothness of the exact solution. The convergence results for the exponential Euler method and for second-order methods are given in Theorems 4.2 and 4.3, respectively, and our main result is Theorem 4.7. The new order conditions are further used in section 5 to analyze methods from the literature and to construct new methods. In particular, we will show that neither of the exponential classical Runge–Kutta methods from [3, 12] is of order four, in general, when applied to parabolic problems. Our order conditions enable us, however, to construct a new exponential variant of the classical Runge–Kutta method which is of full order four. In section 6 we present numerical experiments which show that the order reductions predicted by our theory may in fact arise in practical examples.

2. Order conditions and general properties.

We consider the following general class of one-step methods for solving (1.1):

$$u_{n+1} = \chi(-hA)u_n + h\sum_{i=1}^{s} b_i(-hA)G_{ni}, \tag{2.1a}$$

$$U_{ni} = \chi_i(-hA)u_n + h\sum_{j=1}^{s} a_{ij}(-hA)G_{nj}, \tag{2.1b}$$

$$G_{nj} = g(t_n + c_j h, U_{nj}). \tag{2.1c}$$

Here, the method coefficients χ, χ_i, a_{ij}, and b_i are constructed from exponential functions, or rational approximations of such functions evaluated at the matrix or operator $-hA$.

For consistency reasons, we always assume that $\chi(0) = \chi_i(0) = 1$. It seems worth mentioning that (2.1) reduces to a Runge–Kutta method with coefficients $b_i = b_i(0)$ and $a_{ij} = a_{ij}(0)$ if we consider the limit $A \to 0$. The latter method will be called the *underlying Runge–Kutta method* henceforth, while (2.1) will be referred to as an *exponential Runge–Kutta method* in the following. We suppose throughout the paper that the underlying Runge–Kutta method satisfies

$$\sum_{j=1}^{s} b_j(0) = 1, \qquad \sum_{j=1}^{s} a_{ij}(0) = c_i, \quad i = 1, \dots, s,$$

which makes it invariant under the transformation of (1.1) to autonomous form.

A desirable property of numerical methods is that they preserve equilibria $u^\star$ of the autonomous problem $u'(t) + Au(t) = g(u(t))$. Requiring $U_{ni} = u_n = u^\star$ for all i and $n \geq 0$ immediately yields the necessary and sufficient conditions. It turns out that the coefficients of the method have to satisfy

$$\sum_{j=1}^{s} b_j(z) = \frac{\chi(z) - 1}{z}, \qquad \sum_{j=1}^{s} a_{ij}(z) = \frac{\chi_i(z) - 1}{z}, \quad i = 1, \dots, s. \tag{2.2}$$

Without further mention, we will assume throughout the paper that these conditions are fulfilled.

With the help of (2.2), the functions χ and χ_i can be eliminated in (2.1). The numerical scheme then takes the form

$$u_{n+1} = u_n + h \sum_{i=1}^{s} b_i(-hA)\big(G_{ni} - Au_n\big), \tag{2.3a}$$

$$U_{ni} = u_n + h \sum_{j=1}^{s} a_{ij}(-hA)\big(G_{nj} - Au_n\big). \tag{2.3b}$$

Conditions (2.2) also imply that we can restrict ourselves to autonomous problems

$$u'(t) + Au(t) = g(u(t)), \qquad u(t_0) = u_0, \tag{2.4}$$

since all methods satisfying (2.2) are invariant under the transformation of (1.1) to autonomous form.

For $A = 0$, the methods reduce to classical Runge–Kutta methods, for which the order conditions are well known. In the case of $A \neq 0$, nonstiff order conditions of order up to 5 have been presented by Friedli [6] using Taylor series expansion of the exact and the numerical solutions; see also [25] and references therein. Our approach below is based on trees, which allows us to extract the order conditions for arbitrary orders in a systematic and simple way, very similar to classical Runge–Kutta methods. A more technical approach based on the theory of B-series is chosen in [1].

Writing (2.4) in the form

$$u' = g(u) - Au = F(u)$$

shows that the Taylor expansion of the exact solution contains the elementary differentials of F which are represented by the usual trees. Note that these differentials coincide with those of g except for $F' = g' - A$ and F itself. Splitting the trees that contain F', we obtain trees with two kinds of nodes. The nodes corresponding to A

are represented by open (white) circles in Table 1, whereas the evaluation of F and of derivatives of g is represented by filled (black) circles. This gives the subclass of bicolored trees with black branching nodes and black leaves.

For the numerical scheme written in the form (2.3), we define $\widetilde{F}(u) = g(u) - Au_n$. Then, (2.3) can be formally interpreted as an ordinary Runge–Kutta method with the usual trees corresponding to the elementary differentials of $\widetilde{F}$. The differentials of $\widetilde{F}$ coincide with those of g except for the evaluation of the functions themselves where $F(u_n) = \widetilde{F}(u_n)$. Moreover, taking the series expansion of the coefficients a_{ij} and b_i into account leads to the same bicolored trees as for the exact solution.

The derivation of the order conditions from the trees proceeds as follows. For sake of simplicity in presentation, we formally define

$$a_{ij}(z) = \sum_{k\geq 0} \alpha_{ij}^{(k)} z^k, \qquad b_i(z) = \sum_{k\geq 0} \beta_i^{(k)} z^k. \tag{2.5}$$

A black node preceded by another black node is interpreted as $\alpha_{ij}^{(0)}$, whereas a black root is interpreted as $\beta_i^{(0)}$. This is exactly the same interpretation as for the underlying Runge–Kutta method. Moreover, k subsequent white nodes followed by a black node are interpreted as $\beta_i^{(k)}$ or $\alpha_{ij}^{(k)}$, respectively, depending on whether they appear at the root or not, respectively. This is seen directly from (2.5) with $z = -hA$. The order conditions up to order four are displayed in Table 1.

3. Analytical framework.

Our analysis below will be based on an abstract formulation of (1.1) as an evolution equation in a Banach space $(X, \|\cdot\|)$. Let $\mathcal{D}(A)$ denote the domain of A in X. Our basic assumptions on the operator A are those of [8].

Assumption 1. Let $A : \mathcal{D}(A) \to X$ be sectorial; i.e., A is a densely defined and closed linear operator on X satisfying the resolvent condition

$$\|(\lambda I - A)^{-1}\|_{X\leftarrow X} \leq \frac{M}{|\lambda - a|} \tag{3.1}$$

on the sector $\{\lambda \in \mathbb{C} : \vartheta \leq |\arg(\lambda - a)| \leq \pi,\ \lambda \neq a\}$ for $M \geq 1$, $a \in \mathbb{R}$, and $0 < \vartheta < \pi/2$.

Under this assumption, the operator $-A$ is the infinitesimal generator of an analytic semigroup $\{\mathrm{e}^{-tA}\}_{t\geq 0}$. For $\omega > -a$, the fractional powers of $\widetilde{A} = A + \omega I$ are well defined. The following stability bounds are proved in [10]. They are crucial in our analysis.

Lemma 3.1. *Under Assumption* 1 *and for fixed* $\omega > -a$, *the following bounds hold uniformly on* $0 \leq t \leq T$:

$$\|\mathrm{e}^{-tA}\|_{X\leftarrow X} + \|t^\gamma \widetilde{A}^\gamma \mathrm{e}^{-tA}\|_{X\leftarrow X} \leq C, \qquad \gamma \geq 0, \tag{3.2a}$$

$$\left\| hA \sum_{j=1}^{n-1} \mathrm{e}^{-jhA} \right\|_{X\leftarrow X} \leq C. \tag{3.2b}$$

The next lemma (often called Abel's partial summation) is a discrete version of the integration-by-parts formula. Its proof is straightforward.

Lemma 3.2. *For* $W_k = \sum_{j=0}^{k} w_j$ *the following summation-by-parts formula holds:*

$$\sum_{j=0}^{n-1} w_j v_{n-j} = W_{n-1} v_1 - \sum_{j=0}^{n-2} W_j (v_{n-j-1} - v_{n-j}). \tag{3.3}$$

Table 1
Order trees and nonstiff order conditions for exponential Runge–Kutta methods.

No.	Tree	Order	Differential	Order condition
1		1	F	$\sum \beta_i^{(0)} = 1$
2		2	$g'F$	$\sum \beta_i^{(0)} \alpha_{ij}^{(0)} = \frac{1}{2}$

18		4	$g'AAF$	$\sum \beta_i^{(0)} \alpha_{ij}^{(2)} = \frac{1}{24}$
19		4	$Ag'AF$	$\sum \beta_i^{(1)} \alpha_{ij}^{(1)} = \frac{1}{24}$
20		4	$AAg'F$	$\sum \beta_i^{(2)} \alpha_{ij}^{(0)} = \frac{1}{24}$
21		4	$AAAF$	$\sum \beta_i^{(3)} = \frac{1}{24}$

The stability estimate (3.2a) enables us to define the bounded operators

$$\varphi_j(-tA) = \frac{1}{t^j}\int_0^t \mathrm{e}^{-(t-\tau)A}\frac{\tau^{j-1}}{(j-1)!}\,\mathrm{d}\tau, \qquad j \geq 1. \tag{3.4}$$

We note for later use that $\varphi_0(z) = \mathrm{e}^z$ and

$$\varphi_{k+1}(z) = \frac{\varphi_k(z) - 1/k!}{z}, \qquad \varphi_k(0) = \frac{1}{k!}, \qquad k \geq 0. \tag{3.5}$$

Our basic assumptions on g are those of [8] and [22]. We thus choose $0 \leq \alpha < 1$ and define $V = \mathcal{D}(\widetilde{A}^\alpha) \subset X$, where $\widetilde{A}$ denotes the shifted operator $\widetilde{A} = A + \omega I$ with $\omega > -a$. The linear space V is a Banach space with norm $\|v\|_V = \|\widetilde{A}^\alpha v\|$. Note that V does not depend on ω, since different choices of ω lead to equivalent norms. Our main hypothesis on the nonlinearity g is the following.

Assumption 2. Let $g : [0,T] \times V \to X$ be locally Lipschitz-continuous in a strip along the exact solution u. Thus there exists a real number $L(R,T)$ such that

$$\|g(t,v) - g(t,w)\| \leq L\|v - w\|_V \tag{3.6}$$

for all $t \in [0,T]$ and $\max(\|v - u(t)\|_V, \|w - u(t)\|_V) \leq R$.

Example. It is well known that reaction-diffusion equations fit into this abstract framework, as well as the incompressible Navier–Stokes equations in two and three space dimensions; see, e.g., [8, Chapter 3] and [17, section 7.3].

For high-order convergence results, we have to assume more regularity.

Assumption 3. We suppose that (1.1) possesses a sufficiently smooth solution $u : [0,T] \to V$ with derivatives in V, and that $g : [0,T] \times V \to X$ is sufficiently often Fréchet differentiable in a strip along the exact solution. All occurring derivatives are supposed to be uniformly bounded.

Note that, under the above assumption, the composition

$$f : [0,T] \to X : t \mapsto f(t) = g(t,u(t))$$

is a smooth mapping, too. This will be used frequently.

4. Convergence results for exponential methods. In this section, we discuss the exponential counterparts of classical Runge–Kutta methods and study their convergence properties for the semilinear problem (1.1). More precisely, we consider methods with

$$\chi(z) = \mathrm{e}^z \qquad \text{and} \qquad \chi_i(z) = \mathrm{e}^{c_i z}, \quad 1 \leq i \leq s. \tag{4.1}$$

Our main interest lies in *explicit* methods for which, due to $c_1 = 0$,

$$\chi_1(z) = 1 \qquad \text{and} \qquad a_{ij}(z) = 0, \qquad 1 \leq i \leq j \leq s. \tag{4.2}$$

Implicit methods have been analyzed in detail in our recent paper [10]. The scheme (2.1) satisfying (4.1) and (4.2) is called an *explicit exponential Runge–Kutta method* henceforth. For the coefficients of the exponential Runge–Kutta method (2.1) we assume stability assumptions similar to (3.2a)

$$\|\phi(-tA)\|_{X \leftarrow X} + \left\|t^\gamma \widetilde{A}^\gamma \phi(-tA)\right\|_{X \leftarrow X} \leq C, \qquad 0 \leq \gamma \leq 1, \tag{4.3}$$

for $\phi = b_i$ or $\phi = a_{ij}$, $i,j = 1,\ldots,s$. This assumption is satisfied by all methods considered below, since $b_i(z)$ and $a_{ij}(z)$ are (linear) combinations of the functions $\varphi_k(z)$ and $\varphi_k(c_l z)$, respectively.

4.1. Error recursion and representation of the defects. In order to simplify the notation, we again set $f(t) = g(t, u(t))$. Our proofs are heavily based on the representation of the exact solution by the variation-of-constants formula

$$u(t_n + \theta h) = \mathrm{e}^{-\theta h A} u(t_n) + \int_0^{\theta h} \mathrm{e}^{-(\theta h - \tau)A} f(t_n + \tau)\, \mathrm{d}\tau. \tag{4.4}$$

We expand f into a Taylor series with remainder in integral form to get

$$f(t_n + \tau) = \sum_{j=1}^{q} \frac{\tau^{j-1}}{(j-1)!} f^{(j-1)}(t_n) + \int_0^{\tau} \frac{(\tau - \sigma)^{q-1}}{(q-1)!} f^{(q)}(t_n + \sigma)\, \mathrm{d}\sigma. \tag{4.5}$$

On the one hand, inserting this into the right-hand side of (4.4) yields

$$\begin{aligned} u(t_n + c_i h) = \mathrm{e}^{-c_i h A} u(t_n) &+ \sum_{j=1}^{q_i} (c_i h)^j \varphi_j(-c_i h A) f^{(j-1)}(t_n) \\ &+ \int_0^{c_i h} \mathrm{e}^{-(c_i h - \tau)A} \int_0^{\tau} \frac{(\tau - \sigma)^{q_i - 1}}{(q_i - 1)!} f^{(q_i)}(t_n + \sigma)\, \mathrm{d}\sigma\, \mathrm{d}\tau. \end{aligned} \tag{4.6}$$

On the other hand, inserting the exact solution into the numerical scheme gives

$$u(t_n + c_i h) = \mathrm{e}^{-c_i h A} u(t_n) + h \sum_{j=1}^{i-1} a_{ij}(-hA) f(t_n + c_j h) + \Delta_{ni}, \tag{4.7a}$$

$$u(t_{n+1}) = \mathrm{e}^{-hA} u(t_n) + h \sum_{i=1}^{s} b_i(-hA) f(t_n + c_i h) + \delta_{n+1} \tag{4.7b}$$

with defects Δ_{ni} and δ_{n+1}. Substituting (4.5) into (4.7a), we obtain

$$\begin{aligned} u(t_n + c_i h) = \mathrm{e}^{-c_i h A} u(t_n) &+ h \sum_{k=1}^{i-1} a_{ik}(-hA) \sum_{j=1}^{q_i} \frac{(c_k h)^{j-1}}{(j-1)!} f^{(j-1)}(t_n) \\ &+ h \sum_{k=1}^{i-1} a_{ik}(-hA) \int_0^{c_k h} \frac{(c_k h - \sigma)^{q_i - 1}}{(q_i - 1)!} f^{(q_i)}(t_n + \sigma)\, \mathrm{d}\sigma + \Delta_{ni}. \end{aligned} \tag{4.8}$$

Subtracting (4.6) from (4.8) gives the following explicit representation of the defects,

$$\Delta_{ni} = \sum_{j=1}^{q_i} h^j \psi_{j,i}(-hA) f^{(j-1)}(t_n) + \Delta_{ni}^{[q_i]}, \tag{4.9}$$

with remainders $\Delta_{ni}^{[q_i]}$ and with

$$\psi_{j,i}(-hA) = \varphi_j(-c_i h A) c_i^j - \sum_{k=1}^{i-1} a_{ik}(-hA) \frac{c_k^{j-1}}{(j-1)!}. \tag{4.10}$$

Similarly, we get for the defects at time t_{n+1}

$$\delta_{n+1} = \sum_{j=1}^{q} h^j \psi_j(-hA) f^{(j-1)}(t_n) + \delta_{n+1}^{[q]}, \tag{4.11}$$

where

$$\psi_j(-hA) = \varphi_j(-hA) - \sum_{k=1}^{s} b_k(-hA)\frac{c_k^{j-1}}{(j-1)!}. \tag{4.12}$$

For the remainders in (4.9) and (4.11), we have the following estimate.

LEMMA 4.1. *Let* $0 < \nu \le 1$ *and* $\widetilde{A}^{\nu-1} f^{(r)} \in L^\infty(0,T;V)$. *Then,*

$$h^{1-\nu}\|\Delta_{ni}^{[r]}\|_V + \|\widetilde{A}^{\nu-1}\Delta_{ni}^{[r]}\|_V \le Ch^{r+1} \sup_{0\le\tau\le 1} \|\widetilde{A}^{\nu-1} f^{(r)}(t_n+\tau h)\|_V, \tag{4.13a}$$

$$\left\| \sum_{j=0}^{n-1} \mathrm{e}^{-jhA}\delta_{n-j}^{[r]} \right\|_V \le Ch^r \sup_{0\le t\le t_n} \|\widetilde{A}^{\nu-1} f^{(r)}(t)\|_V \tag{4.13b}$$

holds with a constant C, *uniformly in* $0 \le t_n \le T$.

Proof. Both estimates follow at once from the stability bound

$$\left\|t^\gamma \widetilde{A}^\gamma \mathrm{e}^{-tA}\right\|_{V\leftarrow V} + \left\|t^\gamma \widetilde{A}^\gamma \phi(-tA)\right\|_{V\leftarrow V} \le C, \qquad 0 \le \gamma \le 1,$$

for $\phi = b_i$ or $\phi = a_{ij}$, $i,j = 1,\dots,s$. The latter is a consequence of (3.2a) and (4.3), respectively. □

Let $e_n = u_n - u(t_n)$ and $E_{ni} = U_{ni} - u(t_n + c_i h)$ denote the differences between the numerical and the exact solutions. Subtracting (4.7) from the numerical method (2.1) satisfying (4.1) and (4.2) gives the error recursion

$$E_{ni} = \mathrm{e}^{-c_i hA} e_n + h\sum_{j=1}^{i-1} a_{ij}(-hA)\Big(g(t_n+c_jh, U_{nj}) - f(t_n+c_jh)\Big) - \Delta_{ni}, \tag{4.14a}$$

$$e_{n+1} = \mathrm{e}^{-hA} e_n + h\sum_{i=1}^{s} b_i(-hA)\Big(g(t_n+c_ih, U_{ni}) - f(t_n+c_ih)\Big) - \delta_{n+1}. \tag{4.14b}$$

We will derive bounds for these errors.

4.2. Convergence of the exponential Euler method. For $s = 1$, the only reasonable choice is the exponential form of Euler's method. Applied to (1.1), it is

$$u_{n+1} = \mathrm{e}^{-hA} u_n + h\varphi_1(-hA) g(t_n, u_n). \tag{4.15}$$

For this method, we have the following convergence result.

THEOREM 4.2. *Let the initial value problem* (1.1) *satisfy Assumptions* 1–2 *and consider for its numerical solution the exponential Euler method* (4.15). *Further assume that* $f : [0,T] \to X$ *is differentiable and that* $\beta \in (0,1]$ *is such that* $\widetilde{A}^{\beta-1} f' \in L^\infty(0,T;V)$. *Then, the error bound*

$$\|u_n - u(t_n)\|_V \le C\cdot h \sup_{0\le t\le t_n} \|\widetilde{A}^{\beta-1} f'(t)\|_V$$

holds uniformly in $0 \le nh \le T$. *The constant* C *depends on* T, *but it is independent of* n *and* h.

Proof. The exponential Euler method satisfies the error recursion

$$e_{n+1} = \mathrm{e}^{-hA} e_n + h\varphi_1(-hA)\big(g(t_n,u_n) - f(t_n)\big) - \delta_{n+1} \tag{4.16}$$

with defects $\delta_{n+1} = \delta_{n+1}^{[1]}$ given by (4.7b) and (4.11). Solving recursion (4.16) gives

$$e_n = h \sum_{j=0}^{n-1} \mathrm{e}^{-(n-j-1)hA} \varphi_1(-hA)\big(g(t_j, u_j) - f(t_j)\big) - \sum_{j=0}^{n-1} \mathrm{e}^{-jhA} \delta_{n-j}.$$

Using (3.2a), Assumption 2, and Lemma 4.1, we may estimate this in V by

$$\|e_n\|_V \le Ch \sum_{j=0}^{n-2} t_{n-j-1}^{-\alpha} \|e_j\|_V + Ch^{1-\alpha}\|e_{n-1}\|_V + Ch \sup_{0\le t\le t_n} \|\widetilde{A}^{\beta-1} f'(t)\|_V.$$

The application of a discrete Gronwall lemma [10, Lemma 4] now concludes the proof. □

Remark. The above theorem can also be deduced from [10], since the exponential Euler method is a collocation method with $s = 1$ and $c_1 = 0$.

4.3. Convergence results for second-order methods. We first derive a bound for the errors of the internal stages. Due to (2.2) and (4.1), we always have $\psi_{1,j} = 0$. From (4.9) and (4.14a) we thus get, with the help of Assumption 2,

$$\|E_{ni}\|_V \le C\,\|e_n\|_V + Ch^{1-\alpha} \max_{2\le j\le i-1} \|E_{nj}\|_V + \|\Delta_{ni}^{[1]}\|_V.$$

Applying Lemma 4.1 then shows the a priori bound

$$\|E_{ni}\|_V \le C\,\|e_n\|_V + Ch^{1+\nu} \sup_{0\le\tau\le 1} \|\widetilde{A}^{\nu-1} f'(t_n+\tau h)\|_V. \tag{4.17}$$

For second-order methods, we will satisfy the order conditions

$$\psi_1(-hA) = 0, \qquad \psi_2(-hA) = 0 \tag{4.18}$$

and take $q = 2$ in (4.11). We are now in the position to state the convergence theorem.

THEOREM 4.3. *Let the initial value problem* (1.1) *satisfy Assumptions* 1 *and* 2*, and consider for its solution an exponential Runge–Kutta method* (2.1) *satisfying* (4.1)*,* (4.2)*, and* (4.18)*. Further assume that $f : [0, T] \to X$ is twice differentiable and that $\beta, \kappa \in (0, 1]$ are such that $\widetilde{A}^{\beta-1} f' \in L^\infty(0, T; V)$ and $\widetilde{A}^{\kappa-1} f'' \in L^\infty(0, T; V)$. Then, the error bound*

$$\|u_n - u(t_n)\|_V \le C \cdot h^{1+\beta} \sup_{0\le t\le t_n} \|\widetilde{A}^{\beta-1} f'(t)\|_V + C \cdot h^2 \sup_{0\le t\le t_n} \|\widetilde{A}^{\kappa-1} f''(t)\|_V$$

holds uniformly in $0 \le nh \le T$. The constant C depends on T, but it is independent of n and h.

Remark. If $f', f'' \in L^\infty(0, T; X)$, the above theorem is applicable with $\beta = \kappa = 1 - \alpha$. For $\beta = 1$, the theorem yields order 2. Under the slightly weaker regularity assumptions $f'(0) \in V$ and $f'' \in L^1(0, T; V)$, we obtain an alternative second-order error bound

$$\|u_n - u(t_n)\|_V \le C \cdot h^2 \left(\|f'(0)\|_V + \int_0^{t_n} \|f''(\tau)\|_V \,\mathrm{d}\tau \right).$$

This follows easily from the proof of Theorem 4.3.

Proof. Solving the error recursion (4.14b) in the same way as in the proof of Theorem 4.2 gives

$$\|e_n\|_V \le Ch^{1-\alpha}\|E_{n-1}\|_V + Ch\sum_{j=0}^{n-2} t_{n-j-1}^{-\alpha}\|E_j\|_V + \Big\|\sum_{j=0}^{n-1} \mathrm{e}^{-jhA}\delta_{n-j}\Big\|_V$$

with $\|E_j\|_V = \max_{2\le k\le s}\|E_{jk}\|_V$. After inserting the bounds (4.17) and (4.13b), the proof is concluded by applying a discrete Gronwall lemma. □

If $g : [0,T]\times V \to X$ is twice differentiable, its derivatives

$$J_n = \frac{\partial g}{\partial u}\big(t_n, u(t_n)\big), \qquad K_n = \frac{\partial^2 g}{\partial t\partial u}\big(t_n, u(t_n)\big)$$

are bounded operators from V to X.

Lemma 4.4. *Under Assumption* 3*, we have*

$$g(t_n + c_ih, U_{ni}) - f(t_n + c_ih) = J_nE_{ni} + c_ihK_nE_{ni} + Q_{ni}, \tag{4.19a}$$

$$g(t_n, u_n) - f(t_n) = J_ne_n + Q_n \tag{4.19b}$$

with remainders Q_{ni} *and* Q_n *satisfying the bounds*

$$\|Q_{ni}\| \le C\cdot\big(h^2 + \|E_{ni}\|_V\big)\|E_{ni}\|_V, \qquad \|Q_n\| \le C\cdot\|e_n\|_V^2,$$

as long as the errors E_{ni} *and* e_n *remain in a sufficiently small neighborhood of 0.*

Proof. Using Taylor series expansion, we get

$$\begin{aligned} g(t_n + c_ih, U_{ni}) - f(t_n + c_ih) &= \frac{\partial g}{\partial u}\big(t_n + c_ih, u(t_n + c_ih)\big)E_{ni} \\ &+ \int_0^1 (1-\tau)\frac{\partial^2 g}{\partial u^2}\big(t_n + c_ih, u(t_n + c_ih) + \tau E_{ni}\big)(E_{ni}, E_{ni})\,\mathrm{d}\tau. \end{aligned}$$

Expanding the first term on the right-hand side at t_n yields the desired result. □

Inserting (4.19a) into the recursion (4.14b) shows that the main contribution of the defects to the global error is given by the term

$$h\sum_{j=0}^{n-1}\mathrm{e}^{-jhA}\sum_{i=1}^{s} b_i(-hA)J_n\Delta_{n-j-1,i}^{[1]}. \tag{4.20}$$

Let $\gamma < 1$ and $0 \le \mu \le 1-\beta$ be such that

$$\big\|\widetilde{A}^{-\gamma}J_n\,\widetilde{A}^{\mu}\big\|_{V\leftarrow V} \le C. \tag{4.21}$$

This estimate holds trivially for $\gamma = \alpha$ and $\mu = 0$. But there are more favorable situations in which $\mu > 0$. Then, the expression (4.20) is bounded by

$$C\cdot h^{1+\beta+\mu}\sup_{0\le t\le t_n}\|\widetilde{A}^{\beta-1}f'(t)\|_V, \tag{4.22}$$

which slightly improves the error bound of the theorem. We do not elaborate this point here further.

4.4. Convergence results for higher-order methods. An explicit expansion of E_{ni} in terms of Δ_{ni} and e_n is easily obtained with the help of Lemma 4.4 by inserting the expressions of the lemma recursively into (4.14a). Depending on the size of s and α, however, this expansion will consist of a great number of terms that all give rise to order conditions for the method. For example, the arising term

$$h^{\ell+2}\sum_{j_1=1}^{i-1} a_{ij_1}(-hA)J_n\cdots\sum_{j_\ell=1}^{j_{\ell-1}} a_{j_{\ell-1}j_\ell}(-hA)J_n\cdot\psi_{2,j_\ell}(-hA)f'(t_n) \tag{4.23}$$

has classical order $\ell+2$ and can be neglected for $\ell\ge 2$ in a fourth-order method. In our context, however, it has only order $1+(\ell+1)(1-\alpha)$, and this might be a small number, even for large ℓ. In that case, the term can no longer be neglected.

To keep our presentation simple, we will consider in the remainder of this section only the case $\alpha=0$. It is therefore no longer necessary to distinguish between the spaces V and X.

LEMMA 4.5. *Under the assumptions of Lemma* 4.4 *and* $\alpha=0$, *there exist bounded operators* $\mathcal{N}_{ni}(e_n)$ *on* X *such that*

$$\begin{aligned}E_{ni} = \mathcal{N}_{ni}(e_n)e_n &- h^2\psi_{2,i}(-hA)f'(t_n) - h^3\psi_{3,i}(-hA)f''(t_n)\\ &- h^3\sum_{j=2}^{i-1} a_{ij}(-hA)J_n\psi_{2,j}(-hA)f'(t_n) + h^4\mathcal{R}_{ni},\end{aligned}$$

with uniformly bounded remainders $\|\mathcal{R}_{ni}\|\le C$.

Proof. The formula follows easily from recursion (4.14a), the representation of the defects (4.9), and from Lemma 4.4 by an induction argument. □

An important consequence of the above lemma is the following representation of the errors e_n. It is the key result for obtaining the stiff order conditions.

LEMMA 4.6. *Under the assumptions of Lemma* 4.4 *and* $\alpha=0$, *there exist uniformly bounded operators* $\mathcal{N}_n(e_n)$ *on* X *such that the global errors* e_n *satisfy the recursion*

$$\begin{aligned}e_{n+1} = \mathrm{e}^{-hA}e_n &+ h\mathcal{N}_n(e_n)e_n - h^2\psi_2(-hA)f'(t_n)\\ &- h^3\psi_3(-hA)f''(t_n) - h^3\sum_{i=1}^{s} b_i(-hA)J_n\psi_{2,i}(-hA)f'(t_n)\\ &- h^4\psi_4(-hA)f'''(t_n) - h^4\sum_{i=1}^{s} b_i(-hA)J_n\psi_{3,i}(-hA)f''(t_n)\\ &- h^4\sum_{i=1}^{s} b_i(-hA)J_n\sum_{j=2}^{i-1} a_{ij}(-hA)J_n\psi_{2,j}(-hA)f'(t_n)\\ &- h^4\sum_{i=1}^{s} b_i(-hA)c_iK_n\psi_{2,j}(-hA)f'(t_n) + h^5\mathcal{R}_n,\end{aligned} \tag{4.24}$$

with uniformly bounded remainders $\|\mathcal{R}_n\|\le C$.

Proof. The formula follows easily from recursion (4.14b), the representation of the defects (4.11), and Lemma 4.5. □

The stiff order conditions can easily be identified in (4.24). For clarity, we have collected them in Table 2. With these preparations, we are now in the position to formulate a more general convergence result.

TABLE 2

Stiff order conditions for explicit exponential Runge–Kutta methods for $\alpha = 0$. Here J and K denote arbitrary bounded operators on X. The functions ψ_i and $\psi_{k,\ell}$ are defined in (4.12) *and* (4.10)*, respectively.*

No.	Order	Order condition
1	1	$\psi_1(-hA) = 0$
2	2	$\psi_2(-hA) = 0$
3	2	$\psi_{1,i}(-hA) = 0$
4	3	$\psi_3(-hA) = 0$
5	3	$\sum_{i=1}^{s} b_i(-hA) J \psi_{2,i}(-hA) = 0$
6	4	$\psi_4(-hA) = 0$
7	4	$\sum_{i=1}^{s} b_i(-hA) J \psi_{3,i}(-hA) = 0$
8	4	$\sum_{i=1}^{s} b_i(-hA) J \sum_{j=2}^{i-1} a_{ij}(-hA) J \psi_{2,j}(-hA) = 0$
9	4	$\sum_{i=1}^{s} b_i(-hA) c_i K \psi_{2,i}(-hA) = 0$

THEOREM 4.7. *Let the initial value problem* (1.1) *satisfy Assumptions* 1–3 *with* $\alpha = 0$*, and consider for its numerical solution an explicit exponential Runge–Kutta method* (2.1) *satisfying* (4.1) *and* (4.2)*. For* $2 \le p \le 4$*, assume that the order conditions of Table* 2 *hold up to order* $p-1$ *and that* $\psi_p(0) = 0$*. Further assume that the remaining conditions of order* p *hold in a weaker form with* $b_i(0)$ *instead of* $b_i(-hA)$ *for* $2 \le i \le s$*. Then, the numerical solution* u_n *satisfies the error bound*

$$\|u_n - u(t_n)\| \le C \cdot h^p,$$

uniformly in $0 \le nh \le T$*. The constant* C *depends on* T*, but it is independent of* n *and* h*.*

Proof. Inserting the order conditions into the recursion of Lemma 4.6 yields

$$e_{n+1} = \mathrm{e}^{-hA} e_n + h\mathcal{N}_n(e_n)e_n + h^p \mathcal{T}_n + h^{p+1}\mathcal{R}_n$$

with bounded remainders $\mathcal{R}_n$ depending on p. Here, $\mathcal{T}_n$ denotes the terms multiplying h^p in Lemma 4.6. Solving the above error recursion gives

$$e_n = h \sum_{j=0}^{n-1} \mathrm{e}^{-(n-j)hA} \mathcal{N}_j(e_j)e_j + h^p \sum_{j=0}^{n-1} \mathrm{e}^{-jhA} \mathcal{T}_{n-j-1} + h^{p+1} \sum_{j=0}^{n-1} \mathrm{e}^{-jhA} \mathcal{R}_{n-j-1}.$$

In order to bound the second term on the right-hand side, we use the assumptions on the conditions of order p and apply Lemma 4.8 below. Using further the stability estimate (3.2a) and the bounds for $\mathcal{R}_j$ and for $\mathcal{N}_j(e_j)$ finally yields

$$\|e_n\| \le Ch \sum_{j=0}^{n-1} \|e_j\| + Ch^p.$$

Thus, an application of the classical Gronwall lemma concludes the proof. ∎

The following lemma was used in the above proof.

Lemma 4.8. *Under the above assumptions, let $\varrho_i : [0,T] \to X$ for $1 \le i \le s$ denote differentiable functions with bounded derivatives. Then*

$$\Big\| \sum_{j=0}^{n-1} \mathrm{e}^{-jhA} \sum_{i=1}^{s} \big(b_i(-hA) - b_i(0)\big) \varrho_i(t_{n-j-1}) \Big\| \le C. \tag{4.25}$$

Proof. We first note that there exist bounded operators $\widetilde{b}_i(-hA)$ with

$$b_i(-hA) - b_i(0) = hA \cdot \widetilde{b}_i(-hA).$$

The bound (4.25) now follows at once from Lemma 3.2 with $w_j = \mathrm{e}^{-jhA} hA \cdot \widetilde{b}_i(-hA)$ and $v_j = \varrho_i(t_{j-1})$ by using the stability bound (3.2b). □

Remark. The proof of Theorem 4.7 does not extend immediately to variable step sizes. The reason for this lies in the use of the summation-by-parts formula (3.3). Assuming, however, that the method satisfies the conditions of order p in the strong sense of Table 2, then Lemma 4.8 is no longer needed. In that case, the theorem obviously holds for variable step sizes, too.

4.5. Existence of explicit methods of arbitrarily high order. In our recent paper [10] we have shown that, under the above assumptions, an s-stage exponential Runge–Kutta method of collocation type with coefficients $\widehat{a}_{ij}(-hA)$ and $\widehat{b}_i(-hA)$ satisfies the error bound

$$\|\widehat{u}_n - u(t_n)\|_V \le C\, h^s \sup_{0 \le t \le T} \|f^{(s)}(t)\|,$$

uniformly on $0 \le t_n \le T$. It is further shown there that the equations for the internal stages can be solved by fixed-point iteration,

$$\widehat{U}_{ni}^{(k)} = \mathrm{e}^{-c_i hA} \widehat{u}_n + h \sum_{i=1}^{s} \widehat{a}_{ij}(-hA)\, g\big(t_n + c_j h, \widehat{U}_{nj}^{(k-1)}\big), \qquad \widehat{U}_{nj}^{(0)} = \widehat{u}_n.$$

For $\alpha = 0$, we obviously gain one power of h in each iteration. Performing s iterations and setting $U_{ni} = \widehat{U}_{ni}^{(s)}$, $1 \le i \le s$, and

$$u_{n+1} = \mathrm{e}^{-hA} u_n + h \sum_{i=1}^{s} \widehat{b}_i(-hA)\, g\big(t_n + c_j h, U_{nj}\big)$$

thus defines an *explicit* exponential Runge–Kutta method of order s with s^2 stages. The construction shows that there exist explicit exponential Runge–Kutta methods of arbitrarily high order. For general α, however, we gain only $h^{1-\alpha}$ in each iteration. Therefore, a lot of explicit stages might be necessary for obtaining order s.

5. A discussion of explicit methods of orders up to four. In this section, we consider some examples of methods up to order four. Since the first-order exponential Euler method has already been analyzed in section 4.2, we commence here with second-order methods. In the Butcher tableaus below, we use the abbreviations

$$\varphi_{i,j} = \varphi_{i,j}(-hA) = \varphi_i(-c_j hA), \qquad 2 \le j \le s. \tag{5.1}$$

5.1. Second-order methods. Second-order methods require two internal stages at least. For two stages, the order conditions are

$$b_1(-hA) + b_2(-hA) = \varphi_1(-hA), \tag{5.2a}$$

$$b_2(-hA)c_2 = \varphi_2(-hA), \tag{5.2b}$$

$$a_{21}(-hA) = c_2\varphi_1(-c_2hA). \tag{5.2c}$$

A straightforward elimination leads to the following one-parameter family of exponential Runge–Kutta methods

$$\begin{array}{c|cc} 0 & & \\ c_2 & c_2\,\varphi_{1,2} & \\ \hline & \varphi_1 - \frac{1}{c_2}\varphi_2 & \frac{1}{c_2}\varphi_2 \end{array}. \tag{5.3}$$

The coefficients are displayed as usual in a Butcher tableau. It is also possible to omit the function φ_2 by weakening condition (5.2b) to $b_2(0)c_2 = \varphi_2(0) = \frac{1}{2}$. This yields another one-parameter family of methods

$$\begin{array}{c|cc} 0 & & \\ c_2 & c_2\,\varphi_{1,2} & \\ \hline & (1-\frac{1}{2c_2})\varphi_1 & \frac{1}{2c_2}\varphi_1 \end{array}. \tag{5.4}$$

Note that the choice $c_2 = \frac{1}{2}$ yields $b_1 = 0$.

Methods (5.3) and (5.4) have been proposed already by Strehmel and Weiner [25, Example 4.2.2] in the context of adaptive Runge–Kutta methods, where the functions φ_j are usually approximated by certain rational functions. It is shown in [25, Section 4.5.3] that both methods are B-consistent of order one.

Method (5.3) satisfies the assumptions of Theorem 4.3 and thus converges with order $1+\beta$, in general. Method (5.4) can be analyzed in a similar way, as it differs from (5.3) in the choice of the quadrature rule for u_{n+1} only. The defects at the grid points now have the form

$$\begin{aligned} \delta_{n+1} &= \frac{h^2}{2}\big(2\varphi_2(-hA) - \varphi_1(-hA)\big)f'\left(t_n + \frac{h}{2}\right) \\ &\quad + \int_0^h \mathrm{e}^{-(h-\tau)A}\int_{h/2}^{\tau}(\tau-\xi)f''\left(t_n+\xi\right)\,\mathrm{d}\xi. \end{aligned} \tag{5.5}$$

Since $2\varphi_2(0) - \varphi_1(0) = 0$, the first term of (5.5) contributes with

$$C\cdot h^{1+\beta}\left(\|\widetilde{A}^{\beta-1}f'(0)\|_V + \int_0^{t_n}\|\widetilde{A}^{\beta-1}f''(t)\|_V\,\mathrm{d}t\right) \tag{5.6}$$

to the global error. This is seen with the help of Lemma 3.2. Thus, Theorem 4.3 holds with the additional error term (5.6) for the modified method (5.4), too. In particular, we get a second-order error bound for $\beta = 1$. Note, however, that (5.6) cannot be improved under a condition of the type (4.21). For situations in which $f'(t), f''(t) \notin V$, method (5.3) is therefore preferable to method (5.4), which can be affected by an order reduction; see also Figure 6.3 below.

5.2. Third-order methods. We will continue with 3-stage methods. In the following, we assume $\alpha = 0$. The order conditions for 3-stage methods are

$$b_1(-hA) + b_2(-hA) + b_3(-hA) = \varphi_1(-hA), \tag{5.7a}$$

$$b_2(-hA)c_2 + b_3(-hA)c_3 = \varphi_2(-hA), \tag{5.7b}$$

$$a_{21}(-hA) = c_2\varphi_1(-c_2hA), \tag{5.7c}$$

$$a_{31}(-hA) + a_{32}(-hA) = c_3\varphi_1(-c_3hA), \tag{5.7d}$$

$$b_2(-hA)c_2^2 + b_3(-hA)c_3^2 = 2\varphi_3(-hA), \tag{5.7e}$$

$$b_2(-hA)Jc_2^2\varphi_2(-c_2hA) + b_3(-hA)J\psi_{2,3} = 0, \tag{5.7f}$$

where

$$\psi_{2,3} = c_3^2\varphi_2(-c_3hA) - c_2a_{32}(-hA).$$

Condition (5.7f) can be satisfied by $b_2 = 0$ and $\psi_{2,3} = 0$ or $b_2 = \gamma b_3$ and $c_2^2\varphi_{2,2} + \gamma\psi_{2,3} = 0$. However, both choices contradict conditions (5.7b) and (5.7e). We thus weaken (5.7e) to

$$b_2(0)c_2^2 + b_3(0)c_3^2 = 2\varphi_3(0) = \frac{1}{3}. \tag{5.7g}$$

The choice $b_2 = 0$ leads to the following one-parameter family of third-order methods:

$$\begin{array}{c|ccc} 0 & & & \\ c_2 & c_2\varphi_{1,2} & & \\ \frac{2}{3} & \frac{2}{3}\varphi_{1,3} - \frac{4}{9c_2}\varphi_{2,3} & \frac{4}{9c_2}\varphi_{2,3} & \\ \hline & \varphi_1 - \frac{3}{2}\varphi_2 & 0 & \frac{3}{2}\varphi_2 \end{array} . \tag{5.8}$$

The other choice $b_2 = \gamma b_3$ leads to the two-parameter family of methods of order three

$$\begin{array}{c|ccc} 0 & & & \\ c_2 & c_2\varphi_{1,2} & & \\ c_3 & c_3\varphi_{1,3} - a_{32} & \gamma c_2\varphi_{2,2} + \frac{c_3^2}{c_2}\varphi_{23} & \\ \hline & \varphi_1 - b_2 - b_3 & \frac{\gamma}{\gamma c_2 + c_3}\varphi_2 & \frac{1}{\gamma c_2 + c_3}\varphi_2 \end{array} , \tag{5.9}$$

where γ, c_2, and c_3 have to satisfy the restriction

$$2(\gamma c_2 + c_3) = 3(\gamma c_2^2 + c_3^2). \tag{5.10}$$

Another possibility is to weaken (5.7f) to

$$b_2(0)c_2^2\varphi_2(-c_2hA) + b_3(0)\big(c_3^2\varphi_2(-c_3hA) - c_2a_{32}(-hA)\big) = 0. \tag{5.11}$$

The order conditions of the underlying Runge–Kutta method of order three show that

$$b_2(0) = \frac{2 - 3c_3}{6c_2(c_2 - c_3)}, \qquad b_3(0) = \frac{2 - 3c_2}{6c_3(c_3 - c_2)};$$

see [7, Exercise II.1.4]. Here, we have to choose $c_2 \neq 2/3$ and $c_2 \neq c_3$ except for $c_2 = c_3 = 2/3$ where $b_2(0) + b_3(0) = 3/4$.

A three-parameter family of methods that involve φ_1 and φ_2 only is given by

$$\begin{array}{c|ccc} 0 & & & \\ c_2 & c_2\varphi_{1,2} & & \\ c_3 & c_3\varphi_{1,3} - a_{32} & \frac{c_3^2}{c_2}\varphi_{2,3} - \frac{2-3c_3}{2-3c_2}c_3\varphi_{2,2} & \\ \hline & \varphi_1 - b_2 - b_3 & \alpha_2\varphi_1 + \beta_2\varphi_2 & \alpha_3\varphi_1 + \beta_3\varphi_2 \end{array} . \tag{5.12}$$

In addition to c_2 and c_3, one of the coefficients α_i, β_i can be chosen arbitrarily, and the remaining ones are determined by the linear system

$$c_2\alpha_2 + c_3\alpha_3 = 0, \qquad \alpha_3 + \frac{1}{2}\beta_3 = b_3(0), \qquad c_2\beta_2 + c_3\beta_3 = 1.$$

Note that for $\alpha_2 = 0$ and $\beta_2 = \gamma\beta_3$ we recover condition (5.10) and obtain the scheme (5.9). Setting $\alpha_2 = \beta_2 = 0$ leads to $b_2(-hA) = 0$ and the condition $c_3 = 2/3$, which results in the scheme (5.8).

We next discuss some related methods which can be found in the literature.

Strehmel and Weiner [25, Example 4.5.4] proved that for a 3-stage adaptive Runge–Kutta method with second-order B-consistency, the condition $b_2 = 0$ is necessary. They proposed the following family of such methods:

$$\begin{array}{c|ccc} 0 & & & \\ c_2 & c_2\varphi_{1,2} & & \\ 1 & \varphi_{1,3} - \frac{1}{c_2}\varphi_{2,3} & \frac{1}{c_2}\varphi_{2,3} & \\ \hline & \varphi_1 - \varphi_2 & 0 & \varphi_2 \end{array} .$$

These methods satisfy conditions (5.7a), (5.7b), (5.7c), and (5.7d), i.e., all conditions of Table 2 up to order two. However, the conditions (5.7f) and (5.7g) of order three are not satisfied, not even in a weak form. Therefore, these methods are of second order only. Since they are more expensive than the 2-stage methods proposed in the previous section, the latter should be preferred for semilinear parabolic problems.

Cox and Matthews [3] constructed a method called ETD3RK, which reads

$$\begin{array}{c|ccc} 0 & & & \\ \frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & \\ 1 & -\varphi_{1,3} & 2\varphi_{1,3} & \\ \hline & 4\varphi_3 - 3\varphi_2 + \varphi_1 & -8\varphi_3 + 4\varphi_2 & 4\varphi_3 - \varphi_2 \end{array} . \tag{5.13}$$

This method uses φ_3 and satisfies conditions (5.7a), (5.7b), (5.7c), (5.7d), and (5.7g). However, condition (5.7f) is satisfied only in a very weak form (where all arguments are evaluated for $A = 0$). This leads to an order reduction to order two in the worst case. The same conditions are satisfied by ETD2RK3 from [3].

The method ETD2CF3 is a variant of the commutator-free Lie group method CF3 due to Celledoni, Marthinsen, and Owren [2]. It is given by

$$\begin{array}{c|ccc} 0 & & & \\ \frac{1}{3} & \frac{1}{3}\varphi_{1,2} & & \\ \frac{2}{3} & \frac{2}{3}\varphi_{1,3} - \frac{4}{3}\varphi_{2,3} & \frac{4}{3}\varphi_{2,3} & \\ \hline & \varphi_1 - \frac{9}{2}\varphi_2 + 9\varphi_3 & 6\varphi_2 - 18\varphi_3 & -\frac{3}{2}\varphi_2 + 9\varphi_3 \end{array} .$$

This method satisfies (5.7a)–(5.7c) and weak forms of (5.7d) and (5.7f), where $b_i(-hA)$ is evaluated for $A = 0$. Therefore this method is of order three for $\alpha = 0$.

5.3. Fourth-order methods. Again we assume $\alpha = 0$. The order conditions for s-stage methods up to order four are

$$\sum_{i=1}^{s} b_i(-hA) = \varphi_1(-hA), \tag{5.14a}$$

$$\sum_{i=2}^{s} b_i(-hA)c_i = \varphi_2(-hA), \tag{5.14b}$$

$$\sum_{j=1}^{i-1} a_{ij}(-hA) = c_i\varphi_1(-c_ihA), \tag{5.14c}$$

$$\sum_{i=2}^{s} b_i(-hA)c_i^2 = 2\varphi_3(-hA), \tag{5.14d}$$

$$\sum_{i=2}^{s} b_i(-hA)J\Bigg(\varphi_2(-c_ihA)c_i^2 - \sum_{j=2}^{i-1} a_{ij}(-hA)c_j\Bigg) = 0, \tag{5.14e}$$

$$\sum_{i=2}^{s} b_i(-hA)c_i^3 = 6\varphi_4(-hA), \tag{5.14f}$$

$$\sum_{i=2}^{s} b_i(-hA)J\Bigg(\varphi_3(-c_ihA)c_i^3 - \frac{1}{2}\sum_{j=2}^{i-1} a_{ij}(-hA)c_j^2\Bigg) = 0, \tag{5.14g}$$

$$\sum_{i=2}^{s} b_i(-hA)J\sum_{j=2}^{i-1} a_{ij}(-hA)J\Bigg(\varphi_2(-c_jhA)c_j^2 - \sum_{k=2}^{j-1} a_{jk}(-hA)c_k\Bigg) = 0, \tag{5.14h}$$

$$\sum_{i=2}^{s} b_i(-hA)c_iK\Bigg(\varphi_2(-c_ihA)c_i^2 - \sum_{j=2}^{i-1} a_{ij}(-hA)c_j\Bigg) = 0. \tag{5.14i}$$

From (5.14a), (5.14b), and (5.14d) we deduce that any fourth-order method has to involve φ_1, φ_2, and φ_3. By Theorem 4.7 it is sufficient to satisfy condition 6 of Table 2 in the weakened form $\psi_4(0) = 0$, i.e., to replace (5.14f) by

$$\sum_{i=2}^{s} b_i(0)c_i^3 = \frac{1}{4}. \tag{5.14j}$$

Cox and Matthews [3] proposed the following exponential variant of the classical Runge–Kutta method:

$$\begin{array}{c|cccc}
0 & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & & \\
\frac{1}{2} & 0 & \frac{1}{2}\varphi_{1,3} & & \\
1 & \frac{1}{2}\varphi_{1,3}\big(\varphi_{0,3}-1\big) & 0 & \varphi_{1,3} & \\
\hline
 & \varphi_1 - 3\varphi_2 + 4\varphi_3 & 2\varphi_2 - 4\varphi_3 & 2\varphi_2 - 4\varphi_3 & 4\varphi_3 - \varphi_2
\end{array}\ . \tag{5.15}$$

This method satisfies conditions 1–4 of Table 2, the weakened but sufficient condition 6 ($\psi_4(0) = 0$), but not conditions 5, 7, 8, and 9. However, it satisfies a weakened form of conditions 5 and 9 (because $\psi_{2,2}(0) + \psi_{2,3}(0) = 0$ and $\psi_{2,4}(0) = 0$), and a very weak form of conditions 7 and 8 (where all arguments are evaluated for $A = 0$). In the worst case, this leads to an order reduction to order two only.

Krogstad's method [12] for (1.1) is given by

$$\begin{array}{c|cccc}
0 & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,3} - \varphi_{2,3} & \varphi_{2,3} & & \\
1 & \varphi_{1,4} - 2\varphi_{2,4} & 0 & 2\varphi_{2,4} & \\
\hline
 & \varphi_1 - 3\varphi_2 + 4\varphi_3 & 2\varphi_2 - 4\varphi_3 & 2\varphi_2 - 4\varphi_3 & -\varphi_2 + 4\varphi_3
\end{array}\,. \tag{5.16}$$

This method satisfies conditions 1–5 and 9 of Table 2, the weakened but sufficient condition 6 ($\psi_4(0) = 0$), but not conditions 7 and 8, which are only satisfied in a very weak form (where all arguments are evaluated for $A = 0$). In the worst case, this leads to an order reduction to order three.

Strehmel and Weiner's method [25, Example 4.5.5] can be written as

$$\begin{array}{c|cccc}
0 & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,3} - \frac{1}{2}\varphi_{2,3} & \frac{1}{2}\varphi_{2,3} & & \\
1 & \varphi_{1,4} - 2\varphi_{2,4} & -2\varphi_{2,4} & 4\varphi_{2,4} & \\
\hline
 & \varphi_1 - 3\varphi_2 + 4\varphi_3 & 0 & 4\varphi_2 - 8\varphi_3 & -\varphi_2 + 4\varphi_3
\end{array}\,. \tag{5.17}$$

This method satisfies the conditions of Table 2 in exactly the same way as Krogstad's method. It thus converges in our situation with order three in the worst case. Strehmel and Weiner proved that the method is B-consistent of order two.

Remark. Under favorable circumstances, each of the above methods can show a higher order of convergence (generically up to order four). We will shortly discuss a typical situation when this happens. For instance, the method of Cox and Matthews satisfies condition 5 of Table 2 only in the very weak form

$$\sum_{i=1}^{s} b_i(0) J_n \psi_{2,i}(0) = 0.$$

According to Theorem 4.7, this may result in an order reduction down to order two. The term corresponding to condition 5 contributes to the global error via

$$h^3 \sum_{j=0}^{n-1} \mathrm{e}^{-(n-j-1)hA} \sum_{i=1}^{s} b_i(-hA) J_j \psi_{2,i}(-hA) f''(t_j)$$

$$= h^3 \sum_{j=0}^{n-1} \mathrm{e}^{-(n-j-1)hA} \sum_{i=1}^{s} \Big(b_i(-hA) - b_i(0) \Big) J_j \psi_{2,i}(0) f''(t_j) \tag{5.18a}$$

$$+\, h^3 \sum_{j=0}^{n-1} \mathrm{e}^{-(n-j-1)hA} \sum_{i=1}^{s} b_i(-hA) J_j \Big(\psi_{2,i}(-hA) - \psi_{2,i}(0) \Big) f''(t_j). \tag{5.18b}$$

The first part (5.18a) has order three by Lemma 4.8. In order to improve the second term, we assume that the operators A and J_j are such that $A^{-1}J_j\widetilde{A}^{\mu}$ is bounded on X for some $0 \le \mu \le 1$. Then, due to

$$\begin{aligned}&\big\|A^{-1}J_j\big(\psi_{2,i}(-hA)-\psi_{2,i}(0)\big)\big\|_{X\leftarrow X}\\ &\quad= \big\|A^{-1}J_j(h\widetilde{A})^{\mu}\cdot(h\widetilde{A})^{-\mu}\big(\psi_{2,i}(-hA)-\psi_{2,i}(0)\big)\big\|_{X\leftarrow X} \le Ch^{\mu},\end{aligned}$$

one gains (by applying Lemma 4.8 once more) an additional order μ in the term (5.18b). Exactly this happens in the numerical examples of section 6.

One might ask whether it is possible to modify the above methods in such a way that they have order four for semilinear parabolic problems. In fact this cannot be done without adding further stages, which is seen as follows. Assume $s = 4$, $c_2 = c_3 = 1/2$, and $c_4 = 1$. Due to the order conditions of the underlying method, we have $b_4(0) \neq 0$ and $|b_2(0)| + |b_3(0)| > 0$. Condition 5 of Table 2 immediately yields $\psi_{2,4} = 0$. Moreover, $b_3 \neq 0$ since $\psi_{2,2} \neq 0$. Hence, condition 5 can be satisfied only if $b_2 = \gamma b_3$. This leads to $\gamma\psi_{2,2} + \psi_{2,3} = 0$, which gives $a_{32} = (1+\gamma)\frac{1}{2}\varphi_{2,3}$. This choice of a_{32} contradicts condition 8 even in the weakened form, where $b_i(-hA)$ is replaced by $b_i(0)$.

Thus we consider the case $s = 5$ and add the node $c_5 = 1/2$. In order to avoid the difficulty encountered above, we have to choose $b_2 = b_3 = 0$. This requires $b_4b_5 \neq 0$, and therefore we have to enforce $\psi_{2,4} = \psi_{2,5} = 0$ by condition 5 for a method of order three. Thus condition 9 is satisfied automatically. Condition 8 shows that $a_{42} = \gamma a_{43}$ and $a_{52} = \gamma a_{53}$. For simplicity, we choose $\gamma = 1$. This gives $\psi_{2,2} + \psi_{2,3} = 0$, which leads to $a_{32} = \varphi_{2,3}$. Unfortunately, condition 7 cannot be satisfied in a strong form, because $\psi_{3,4} = \psi_{3,5} = 0$ contradicts $\psi_{2,4} = \psi_{2,5} = 0$. Hence we require only the weak form with $b_i(0)$ instead of $b_i(-hA)$. This yields the following fourth-order scheme:

$$\begin{array}{c|ccccc}
0 & & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,2} & & & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,3}-\varphi_{2,3} & \varphi_{2,3} & & & \\
1 & \varphi_{1,4}-2\varphi_{2,4} & \varphi_{2,4} & \varphi_{2,4} & & \\
\frac{1}{2} & \frac{1}{2}\varphi_{1,5}-2a_{5,2}-a_{5,4} & a_{5,2} & a_{5,2} & \frac{1}{4}\varphi_{2,5}-a_{5,2} & \\
\hline
 & \varphi_1-3\varphi_2+4\varphi_3 & 0 & 0 & -\varphi_2+4\varphi_3 & 4\varphi_2-8\varphi_3
\end{array} \tag{5.19}$$

with

$$a_{5,2} = \frac{1}{2}\varphi_{2,5} - \varphi_{3,4} + \frac{1}{4}\varphi_{2,4} - \frac{1}{2}\varphi_{3,5}.$$

6. Numerical experiments.

In this section we present some numerical experiments in order to verify the sharpness of our error bounds.

As a first example we consider the semilinear parabolic problem

$$\frac{\partial U}{\partial t}(x,t) - \frac{\partial^2 U}{\partial x^2}(x,t) = \frac{1}{1+U(x,t)^2} + \Phi(x,t) \tag{6.1}$$

for $x \in [0,1]$ and $t \in [0,1]$, subject to homogeneous Dirichlet boundary conditions. The source function Φ is chosen in such a way that the exact solution of the problem is $U(x,t) = x(1-x)\,\mathrm{e}^t$.

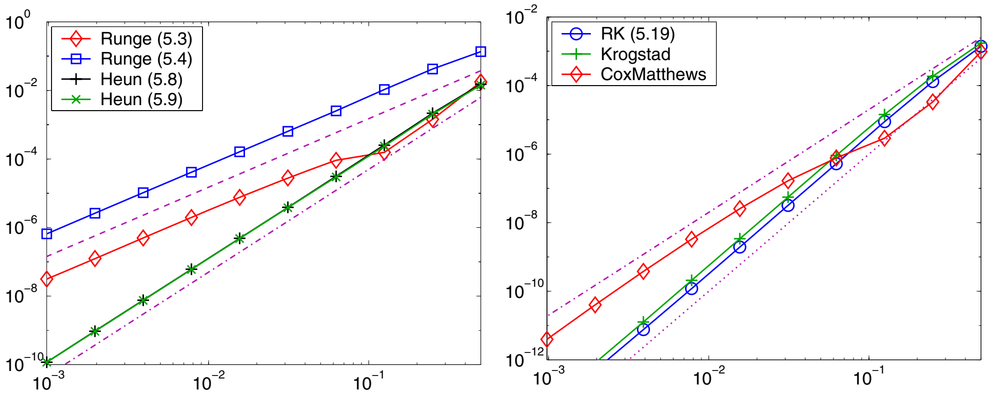

FIG. 6.1. *The errors of various explicit exponential Runge–Kutta methods of orders two to four when applied to* (6.1)*. The errors are measured in the maximum norm at* $t = 1$ *and plotted as functions of the step size. For comparison, we added lines with slope two* (*dashed*)*, three* (*dash-dotted*)*, and four* (*dotted*)*.*

We discretize this problem in space by standard finite differences with 200 grid points. Due to our theory, we expect to see order two for the two variants (5.3) and (5.4) with $c_2 = \frac{1}{2}$ of the exponential Runge method, and order three for the two variants (5.8) and (5.9) of the exponential Heun method with $c_2 = 1/3$ and $\gamma = 1.52$. Note that for this example $\|A^{-1}JA\|$ is bounded. This gives us order four for Krogstad's method and order three for the Cox and Matthews method. All these orders are confirmed by the results illustrated in Figure 6.1, where the errors are measured in the maximum norm.

Next we consider the semilinear parabolic problem

$$\frac{\partial U}{\partial t}(x,t) - \frac{\partial^2 U}{\partial x^2}(x,t) = \int_0^1 U(x,t)\,\mathrm{d}x + \Phi(x,t) \tag{6.2}$$

for $x \in [0,1]$ and $t \in [0,1]$, subject to homogeneous Dirichlet boundary conditions. The source function Φ is again chosen such that $U(x,t) = x(1-x)\,\mathrm{e}^t$ is the exact solution.

We discretize this problem in space as in the first example, with the trapezoidal rule for the approximation of the integral. The numerical results are displayed in Figure 6.2. Again we can see order two for the two variants of the exponential Runge method and order three for the two variants of the exponential Heun method. However, since in this example only $\|A^{-1}JA^{1/2}\|$ is bounded, Krogstad's method and the Cox and Matthews method suffer from an order reduction. For Krogstad's method, we thus obtain order 3.5, while for the Cox–Matthews method we have order 2.5 only. The new exponential variant of the classical Runge–Kutta method is of full order four in this example.

In Figure 6.3 we present the errors of the 2- and 3-stage methods in the V-norm for the choice $X = L^2$ and $\alpha = 1/2$. It can be seen that method (5.3) is of order two, while method (5.4) only is of order 1.75. The order reduction for (5.4) is perfectly explained by Theorem 4.3 with $\beta = 3/4 - \varepsilon$ for arbitrary $\varepsilon > 0$, since the derivatives of f are smooth functions that do not satisfy the boundary conditions. Method (5.3), however, has full order two, since condition (4.21) holds with $\gamma = 1$ and $\mu = 1/2$. See also our detailed discussion on this topic at the end of section 4.3. By similar

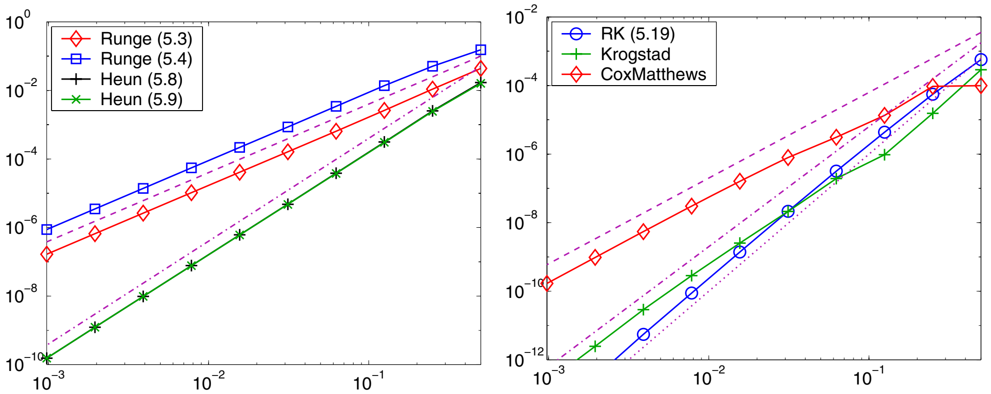

FIG. 6.2. *The errors of various explicit exponential Runge–Kutta methods of orders two to four when applied to* (6.2). *The errors are measured in the maximum norm at* $t = 1$ *and plotted as functions of the step size. For comparison, we added lines with different slopes. In the left panel, slope two is represented by a dashed line and slope three by a dash-dotted line. In the right panel, slope* 2.5 *is represented by a dashed line, slope* 3.5 *by a dash-dotted line, and slope* 4 *by a dotted line.*

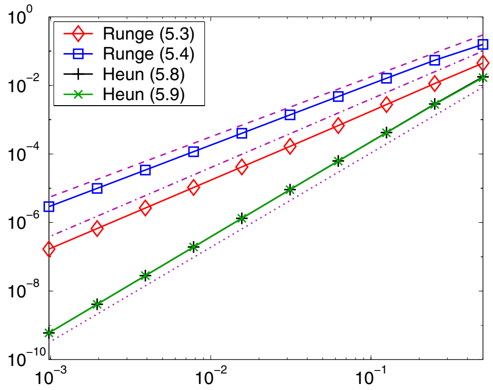

FIG. 6.3. *The errors of various explicit exponential Runge–Kutta methods up to order three when applied to* (6.2). *The errors are measured at* $t = 1$ *in a discrete* V*-norm for* $X = L^2$ *and* $\alpha = 1/2$. *They are plotted as a function of the step size. For comparison, we added lines with different slopes: slope* 1.75 *is represented by a dashed line, slope* 2 *by a dash-dotted line, and slope* 2.75 *by a dotted line.*

considerations it can be explained why the 3-stage methods show order 2.75 instead of order three in this norm.

It is beyond the scope of this paper to discuss implementation details and to compare the efficiency of exponential methods with standard implicit schemes. Such comparisons have been presented in [3, 11, 12]. Our aim here was to understand the convergence behavior of explicit methods and to present new order conditions which allow us to construct methods up to order four in a systematic way.

Acknowledgments. The authors thank Ch. Lubich and J. Schweitzer for their continuous interest in our work and for inspiring discussions.

THE POSTPROCESSED MIXED FINITE-ELEMENT METHOD FOR THE NAVIER–STOKES EQUATIONS[*]

BLANCA AYUSO[†], BOSCO GARCÍA-ARCHILLA[‡], AND JULIA NOVO[†]

Abstract. A postprocessing technique for mixed finite-element methods for the incompressible Navier–Stokes equations is studied. The technique was earlier developed for spectral and standard finite-element methods for dissipative partial differential equations. The postprocessing amounts to solving a Stokes problem on a finer grid (or higher-order space) once the time integration on the coarser mesh is completed. The analysis presented here shows that this technique increases the convergence rate of both the velocity and the pressure approximations. Numerical experiments are presented that confirm both this increase in the convergence rate and the corresponding improvement in computational efficiency.

Key words. Navier–Stokes equations, mixed finite-element methods

1. Introduction.

This paper in a sense culminates the development of a postprocessing technique to increase the accuracy and computational efficiency of Galerkin methods for dissipative partial differential equations introduced in [18]. We turn to the equations which gave rise to this postprocessing technique, the incompressible Navier–Stokes equations, and we address those Galerkin methods for these equations which, when complex-shaped bodies are present, are acknowledged to be of wider applicability, mixed finite-element (MFE) methods.

The postprocessing technique we study here was originally developed for spectral methods [18], [19]. At that moment, either its analysis and understanding or its development seemed to depend heavily on the properties of the Fourier modes, although this was not a shortcoming to prove its usefulness in the study of nonlinear shell vibrations [27]. In later works [13], [14], the dependence on the Fourier modes was overcome. Of particular importance to the present work, besides [14], has been the development of the postprocessing technique for finite-element methods in [20], [15]. In [20], it was devised how to carry out the postprocessing without the help of an approximate inertial manifold [11], [12], a concept more suited to spectral methods and eigenfunction expansion. In [15], it is shown what gains can be expected when postprocessing low-order elements.

As is usually the case with MFE methods, it is the experience and understanding gained in previous works (see [14], [15], [16], [17], [18], [19], [20], and the references cited therein) with simpler equations and methods which has allowed the present one to be written. Furthermore, although for simplicity we focus on Hood–Taylor [26] elements, the postprocessing technique can be easily adapted to other kinds of mixed

elements. In fact, in [3] (see also [5]) the so-called mini-element is shown to render similar gains as Hood–Taylor elements when postprocessed if the provisions in [15] are taken into account.

Let us describe what this postprocessing technique is. We consider the incompressible Navier–Stokes equations, which, in appropriate dimensionless variables, can be written as

$$\begin{aligned} u_t - \nu\Delta u + (u\cdot\nabla)u + \nabla p &= f, \\ \operatorname{div}(u) &= 0 \end{aligned} \tag{1.1}$$

in a bounded domain $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$ with smooth boundary subject to homogeneous Dirichlet boundary conditions $u = 0$ on $\partial\Omega$. In (1.1), u is the velocity field, p the pressure, and f a given force field. Suppose that for the solution u and p corresponding to a given initial condition

$$u(\cdot, 0) = u_0; \tag{1.2}$$

we are interested in its value at a certain time $T > 0$. We first compute MFE approximations u_h and p_h to the velocity and pressure, respectively, by integrating in time the corresponding discretization of (1.1)–(1.2) from $t = 0$ to $t = T$. Then, in the postprocessing step, we obtain an approximation to the solution $\tilde{u}$, $\tilde{p}$ of the Stokes problem

$$\begin{aligned} \left.\begin{aligned} -\nu\Delta\tilde{u} + \nabla\tilde{p} = f - \tfrac{d}{dt}u_h(T) - (u_h(T)\cdot\nabla)u_h(T) \\ \operatorname{div}(\tilde{u}) = 0 \end{aligned}\right\} \quad & \text{in } \Omega, \\ \tilde{u} = 0 \quad & \text{on } \partial\Omega. \end{aligned} \tag{1.3}$$

The MFE of this last step is either the same-order Hood–Taylor element over a finer grid or a higher-order Hood–Taylor element over the same grid. The rate of convergence of the discrete velocity and pressure in the resulting method is proved to be the same as the rate of convergence of the MFE used in the postprocessed step. The overcost of the postprocessed procedure is nearly negligible since the Stokes problem using the enhanced MFE is solved only once, when the time integration has been completed. In this respect, it radically differs from some other research [2], [32], with low-order MFEs for the Navier–Stokes equations that also developed from the ideas in [11] and [12], since in [2] and [32] computations with the enhanced element or on the finer grid are carried out all the way through the interval $(0, T]$.

Some superconvergence results are obtained in the paper and are used as a tool to get the rate of convergence of the postprocessed method. In particular, we derive a superconvergence result for the error between the MFE approximation to the velocity and the discrete Stokes projection introduced in [24]. For simplicity of analysis, we derive these results under the strong regularity hypotheses in (2.2), which, as pointed out in [24], are unrealistic in practical situations. In a more practical setting, assumptions (2.2) should be assumed from some positive time $t_0 > 0$ onwards, and, as we comment in section 2, computations (and their analysis) up to this time should take into account the lower regularity at $t = 0$.

Finally, we remark that recent research [16], [17] has shown the usefulness of the postprocessing technique in obtaining efficient a posteriori error estimators in partial differential equations of evolution, a field much less developed than in the case of steady problems. The application of the postprocessing technique to get a posteriori error estimates for Navier–Stokes equations using the results obtained in this paper will be the subject of future work.

The rest of the paper is as follows. In section 2 we recall some properties of MFE methods and collect some inequalities to be used later. In section 3 we first specify the postprocessing technique and then carry out the convergence analysis. Finally, in section 4 numerical experiments are presented to assess the capabilities of the new technique.

2. Preliminaries and notations. Let Ω be a bounded domain in $\mathbb{R}^d$, $d = 2, 3$, not necessarily convex, but of class $\mathcal{C}^m$, $m \geq 3$, and let H and V be the Hilbert spaces $H = \{u \in \big(L^2(\Omega)\big)^d, \,|\, \mathrm{div}(u) = 0,\ u \cdot n_{|\partial\Omega} = 0\}$, $V = \{u \in \big(H_0^1(\Omega)\big)^d, \,|\, \mathrm{div}(u) = 0\}$, endowed with the inner product of $L^2(\Omega)^d$ and $H_0^1(\Omega)^d$, respectively. For $1 \leq q \leq \infty$ and $l \geq 0$, we consider the standard Sobolev spaces, $W^{l,q}(\Omega)^d$, of functions with derivatives up to order l in $L^q(\Omega)$, and $H^l(\Omega)^d = W^{l,2}(\Omega)^d$. The norm in $H^l(\Omega)^d$ will be denoted by $\|\cdot\|_l$ while $\|\cdot\|_{-l}$ will represent the norm of its dual space. We consider also the quotient spaces $H^l(\Omega)/\mathbb{R}$ with norm $\|p\|_{H^l/\mathbb{R}} = \inf\{\|p + c\|_l \mid c \in \mathbb{R}\}$.

We shall frequently use the following Sobolev's imbeddings [1]. There exists a constant $C = C(\Omega, q)$ such that for $q \in [1, \infty)$, $q' < \infty$, it holds that

$$\|v\|_{L^{q'}(\Omega)^d} \leq C\|v\|_{W^{s,q}(\Omega)^d}, \qquad \frac{1}{q} \geq \frac{1}{q'} \geq \frac{1}{q} - \frac{s}{d} > 0, \quad v \in W^{s,q}(\Omega)^d. \tag{2.1}$$

For $q' = \infty$, (2.1) holds with $\frac{1}{q} < \frac{s}{d}$.

Let $\Pi : L^2(\Omega)^d \longrightarrow H$ be the Leray projector that maps each function in $L^2(\Omega)^d$ onto its divergence-free part. We denote by $\mathcal{A}$ the Stokes operator in Ω:

$$\mathcal{A} : \mathcal{D}(\mathcal{A}) \subset H \longrightarrow H, \quad \mathcal{A} = -\Pi\Delta, \quad \mathcal{D}(\mathcal{A}) = H^2(\Omega)^d \cap V.$$

Applying Leray's projector to (1.1), the equations can be written in the form

$$u_t + \nu\mathcal{A}u + B(u, u) = \Pi f \qquad \text{in } \Omega,$$

where $B(u, u) = \Pi((u \cdot \nabla)u)$.

In what follows we will assume that the solution (u, p) of (1.1)–(1.2) satisfies

$$\max_{0\leq t\leq T} \big(\|u(t)\|_r + \|p(t)\|_{H^{r-1}/\mathbb{R}}\big) < \infty, \quad \max_{0\leq t\leq T} \big(\|u_t(t)\|_r + \|p_t(t)\|_{H^{r-1}/\mathbb{R}}\big) < \infty. \tag{2.2}$$

We refer the reader to [30] for a study about the regularity of the solutions of the Navier–Stokes equations. Notice, however, that, as pointed out in [24], it is unrealistic to assume such a strong regularity up to time $t = 0$. The assumption in (2.2) is for simplicity in the analysis. In a more realistic setting, $t = 0$ should be replaced by some positive time t_0, and error bounds requiring less regularity such as those in [24] and [25] should be considered from $t = 0$ to $t = t_0$. In order to maintain the accuracy levels that a higher regularity would allow from t_0 onwards, computations up to $t = t_0$ should be carried out on an adequate finer grid. Notice also that among the conditions to ensure (2.2) (see, e.g., Theorem 4 in [23]) is that Ω is of class $\mathcal{C}^r$.

Let $\mathcal{T}_h = (\tau_i^h, \phi_i^h)_{i\in I_h}$, $h > 0$, be a family of partitions of suitable domains Ω_h, where the parameter h is the maximum diameter of the elements $\tau_i^h \in \mathcal{T}_h$ and ϕ_i^h are the mappings of the reference simplex τ_0 onto τ_i^h. We restrict ourselves to quasi-uniform and regular meshes $\mathcal{T}_h$.

Let $r \geq 2$, we consider the finite-element spaces

$$\widehat{S}_{h,r} = \big\{\chi_h \in \mathcal{C}^0(\overline{\Omega_h}) \,|\, \chi_{h|_{\tau_i^h}} \circ \phi_i^h \in P^{r-1}(\tau_0)\big\} \subset H^1(\Omega_h),$$

$$\overset{\circ}{S}_{h,r} = \big\{\chi_h \in \mathcal{C}^0(\overline{\Omega_h}) \,|\, \chi_{h|_{\tau_i^h}} \circ \phi_i^h \in P^{r-1}(\tau_0),\ \chi_h(x) = 0\ \forall x \in \partial\Omega_h\big\} \subset H_0^1(\Omega_h),$$

where $P^{r-1}(\tau_0)$ denotes the space of polynomials of degree at most $r-1$ on τ_0. As a consequence of restricting our study to quasi-uniform partitions, the following inverse inequality holds (see, e.g., [9, Theorem 3.2.6]) $\forall \tau = \tau_i^h \in \mathcal{T}_h$, with $\operatorname{diam}(\tau) = h_\tau \le h$, $v_h \in (\overset{\circ}{S}_{h,r})^d$:

(2.3)
$$\|v_h\|_{W^{m,q}(\tau)^d} \le Ch^{l-m-d(\frac{1}{q'}-\frac{1}{q})}\|v_h\|_{W^{l,q'}(\tau)^d}, \quad 0 \le l \le m \le 2, \quad 1 \le q' \le q \le \infty.$$

In order to guarantee convergence of the MFE approximation, we choose a stable combination of two finite-element spaces (see [7]). We introduce the finite-element spaces in which our MFE approximation to (u, p) will be carried out. We shall denote by $(X_{h,r}, Q_{h,r-1})$ the so-called Hood–Taylor element, where

$$X_{h,r} = \left(\overset{\circ}{S}_{h,r}\right)^d, \quad Q_{h,r-1} = \widehat{S}_{h,r-1} \cap L^2(\Omega_h)/\mathbb{R}, \qquad r \ge 3.$$

For this mixed element a uniform inf-sup condition is satisfied (see [26], [6]), that is, there exists a constant $\beta > 0$ independent of the mesh grid size h such that

$$\inf_{q_h \in Q_{h,r-1}} \sup_{v_h \in X_{h,r}} \frac{(q_h, \nabla \cdot v_h)}{\|v_h\|_1 \|q_h\|_{L^2/\mathbb{R}}} \ge \beta. \tag{2.4}$$

The approximate velocity solution belongs to the discretely divergence-free space

$$V_{h,r} = X_{h,r} \cap \left\{ \chi_h \in H_0^1(\Omega_h) \ : \ \int_{\Omega_h} q_h \operatorname{div}(\chi_h) = 0 \ \ \forall q_h \in Q_{h,r-1} \right\}.$$

We observe that for the Hood–Taylor element, $V_{h,r}$ is not a subspace of V.

For any $v \in C_0(\Omega)^d$, we consider the standard interpolant operator $I_h : C_0(\Omega)^d \longrightarrow X_{h,r}$. Let $v \in H^r(\Omega)^d \cap H_0^1(\Omega)^d$; it is well known that I_h satisfies

$$\|v - I_h(v)\|_{L^2(\Omega\cap\Omega_h)^d} + h\|v - I_h(v)\|_{H^1(\Omega\cap\Omega_h)^d} \le Ch^r\|v\|_{H^r(\Omega)^d}. \tag{2.5}$$

We briefly discuss next under what circumstances (2.5) can be extended to a global estimate (i.e., to an estimate in Ω and not just in $\Omega \cap \Omega_h$). The interpolation operator $I_h(v)$ is extended by zero in $\Omega \setminus \Omega_h$, and defining $\delta(h) = \max_{x\in\partial\Omega_h} \operatorname{dist}(x, \partial\Omega)$, one obtains

$$\|v - I_h(v)\|_{L^2(\Omega)^d} + h\|v - I_h(v)\|_{H^1(\Omega\cap\Omega_h)^d} \le C(h^r + \delta(h))\|v\|_{H^r(\Omega)^d}. \tag{2.6}$$

For $x \in \Omega \cap \Omega_h$, (2.5) (and so (2.6)) follows from standard theory of interpolation and the Bramble–Hilbert lemma (see, e.g., [9, p. 192]). For $x \in \Omega \setminus \Omega_h$, $v(x)$ can be bounded by means of the mean-value theorem,

$$\|v - I_h(v)\|_{L^2(\Omega\setminus\Omega_h)^d} = \|v\|_{L^2(\Omega\setminus\Omega_h)^d} \le \delta(h)\|\nabla v\|_{L^2(\Omega)^d}.$$

We observe that using isoparametric elements $\delta(h) \le Ch^r$, and so in (2.6) the right-hand side is further bounded by $Ch^r\|v\|_{W^{r,q}(\Omega)^d}$ (see [9, section 4.4]). As regards the global estimate for the gradient, isoparametric modification is not enough to preserve the optimal approximability properties of the finite-element space. Following [3], we shall assume in what follows the use of superparametric elements at the boundary. By this type of approximation we mean that $\delta(h) \le Ch^{2r-2}$ so that the outside effects will not pollute the optimal estimate. Under these assumptions [3], [4], the interpolant I_h satisfies

$$\|v - I_h(v)\|_{L^2(\Omega)^d} + h\|v - I_h(v)\|_{H^1(\Omega)^d} \leq Ch^r \|v\|_{H^r(\Omega)^d}. \tag{2.7}$$

Notice then that the condition $\delta(h) \leq Ch^{2r-2}$ allows us to forget about the discrepancies between Ω and Ω_h in most of the arguments that follow. Observe, however, that one must then assume that Ω is piecewise of class $\mathcal{C}^{2r-2}$.

For each fixed time $t \in [0, T]$ the solution (u, p) of (1.1)–(1.2) is also the solution of a Stokes problem with right-hand side $f - u_t - (u \cdot \nabla)u$. We will denote by $(s_h, q_h) \in (X_{h,r}, Q_{h,r-1})$, its MFE approximation satisfying

$$\begin{aligned} \nu(\nabla s_h, \nabla \phi_h) - (q_h, \nabla \cdot \phi_h) &= \nu(\nabla u, \nabla \phi_h) - (p, \nabla \cdot \phi_h) \\ &= (f - u_t - (u \cdot \nabla u), \phi_h) \quad \forall \phi_h \in X_{h,r}, \\ (\nabla \cdot s_h, \psi_h) &= 0 \quad \forall \psi_h \in Q_{h,r-1}. \end{aligned} \tag{2.8}$$

We observe that $s_h = S_h(u) : V \longrightarrow V_{h,r}$ is the so-called discrete Stokes projection of the solution (u, p) of (1.1)–(1.2) (see [24]) and satisfies

$$(\nabla S_h(u), \nabla \chi_h) = (\nabla u, \nabla \chi_h) - (p, \nabla \cdot \chi_h) = (f - u_t - (u \cdot \nabla)u, \chi_h) \quad \forall\ \chi_h \in V_{h,r}.$$

The following bound holds for $2 \leq l \leq r$:

$$\|u - s_h\|_0 + h\|u - s_h\|_1 \leq Ch^l \left(\|u\|_l + \|p\|_{H^{l-1}/\mathbb{R}}\right). \tag{2.9}$$

The proof of (2.9) for $\Omega = \Omega_h$ can be found in [25]. For the general case superparametric approximation at the boundary is assumed; see [3], [4]. Under the same conditions, the bound for the pressure is [21]

$$\|p - q_h\|_{L^2/\mathbb{R}} \leq C_\beta h^{l-1} \left(\|u\|_l + \|p\|_{H^{l-1}/\mathbb{R}}\right), \tag{2.10}$$

where the constant C_β depends on the constant β in the inf-sup condition (2.4).

Since we are assuming that Ω is of class $\mathcal{C}^m$ with $m \geq 3$ (and that $\delta(h) \leq Ch^{2r-2}$) using standard duality arguments and (2.9), one obtains [3], [4]

$$\|u - s_h\|_{-s} \leq Ch^{r+s}(\|u\|_r + \|p\|_{H^{r-1}/\mathbb{R}}), \qquad 0 \leq s \leq \min(r-2, 1). \tag{2.11}$$

Let $\Pi_{h,r} : L^2(\Omega)^d \longrightarrow V_{h,r}$ be the discrete Leray's projection defined by demanding that $(\Pi_{h,r}(u), \chi_h) = (u, \chi_h)\ \forall \chi_h \in V_{h,r}$. By definition, the projection is stable in the L^2 norm. For divergence-free functions, by writing $\Pi_{h,r}u = (\Pi_{h,r}u - S_h(u)) + S_h(u)$ and using the quasi-uniformity of the meshes, one easily shows that

$$\|\Pi_{h,r}u\|_1 \leq C\|u\|_1 \qquad \forall\, u \in V. \tag{2.12}$$

We will denote by $\mathcal{A}_h$ the discrete Stokes operator defined by

$$(\nabla v_h, \nabla \phi_h) = (\mathcal{A}_h v_h, \phi_h) = \left(\mathcal{A}_h^{1/2} v_h, \mathcal{A}_h^{1/2} \phi_h\right) \qquad \forall v_h, \phi_h \in V_{h,r}.$$

Since $\mathcal{A}_h$ is a discrete self-adjoint operator, it is easy to show that, for each $0 \leq \alpha < 1$, there exists a positive constant C_α, which is independent of h, such that

$$\|\mathcal{A}_h^\alpha e^{-t\mathcal{A}_h}\|_0 \leq C_\alpha t^{-\alpha} \qquad \forall\ 0 \leq \alpha < 1. \tag{2.13}$$

In our analysis we shall frequently use the following relations for $f \in L^2(\Omega)^d$:

$$\|\mathcal{A}_h^{-s/2}\Pi_{h,r}f\|_0 \le Ch^s\|f\|_0 + \|\mathcal{A}^{-s/2}\Pi f\|_0, \quad s = 1,2, \tag{2.14}$$

$$\|\mathcal{A}^{-s/2}\Pi f\|_0 \le Ch^s\|f\|_0 + \|\mathcal{A}_h^{-s/2}\Pi_{h,r}f\|_0, \quad s = 1,2. \tag{2.15}$$

These inequalities are readily deduced from the estimates $\|\mathcal{A}^{-s/2} - \mathcal{A}_h^{-s/2}\Pi_{h,r}\|_0 \le Ch^s$ for $s = 1,2$ [29]. Similarly, since $\forall v_h \in V_{h,r}$, $(\mathcal{A}_h^{-1/2}\Pi_{h,r}f, v_h) = (f, \mathcal{A}_h^{-1/2}v_h)$, it follows that

$$\|\mathcal{A}_h^{-1/2}\Pi_{h,r}f\|_0 \le C\|f\|_{-1}, \tag{2.16}$$

and since $\forall v \in V$, we have $(\mathcal{A}^{-1/2}\Pi(\Pi_{h,r}f), v) = (\Pi_{h,r}f, \mathcal{A}^{-1/2}v) = (f, \Pi_{h,r}\mathcal{A}^{-1/2}v)$, from (2.12) it follows that

$$\|\mathcal{A}^{-1/2}\Pi(\Pi_{h,r}f)\|_0 \le C\|f\|_{-1}, \qquad f \in L^2(\Omega)^2. \tag{2.17}$$

2.1. The suggested method. Let us suppose that we want to approximate the solution of (1.1)–(1.2) at time T. For $d = 3$, the final time T is assumed to satisfy $0 < T < T^*$, where T^* is the critical time until which the existence and uniqueness of a strong solution of (1.1)–(1.2) has been proven. The postprocessing technique can be seen as a two-level method. We first compute the MFE approximation to (1.1)–(1.2) at time T. Given $u^h(0)$ an initial approximation to $u(0)$, we find that $u_h : [0,T] \longrightarrow X_{h,r}$ and $p_h : [0,T] \longrightarrow Q_{h,r-1}$ satisfy

$$(\dot{u}_h, \phi_h) + \nu(\nabla u_h, \nabla\phi_h) + b_h(u_h, u_h, \phi_h) + (\nabla p_h, \phi_h) = (f, \phi_h) \quad \forall\, \phi_h \in X_{h,r}, \tag{2.18}$$

$$(\nabla \cdot u_h, \psi_h) = 0 \quad \forall\, \psi_h \in Q_{h,r-1}, \tag{2.19}$$

where $b_h(\cdot,\cdot,\cdot)$ is a suitable discrete approximation to its continuous counterpart. As an initial condition we will take $u_h(0) = S_h(u_0)$, although other choices are possible.

In the second step, the discrete velocity and pressure $(u_h(T), p_h(T))$ are postprocessed. Basically, we enhance this approximation by solving a single discrete Stokes problem, via MFE. The MFE in this step, denoted by $(\widetilde{X}, \widetilde{Q})$, is either

- the same-order Hood–Taylor element over a finer grid $(\widetilde{X}, \widetilde{Q}) = (X_{\tilde{h},r}, Q_{\tilde{h},r-1})$, $r \ge 3$, $\tilde{h} < h$, or
- a higher-order Hood–Taylor element over the same grid $(\widetilde{X}, \widetilde{Q}) = (X_{\tilde{h},r+1}, Q_{\tilde{h},r})$, $r \ge 3$, $\tilde{h} = h$.

That is, we shall search for $(\tilde{u}_h, \tilde{p}_h) \in (\widetilde{X}, \widetilde{Q})$ satisfying

$$\nu\big(\nabla\tilde{u}_{\tilde{h}}, \nabla\tilde{\phi}\big) + \big(\nabla\tilde{p}_{\tilde{h}}, \tilde{\phi}\big) = (f, \tilde{\phi}) - b_{\tilde{h}}(u_h(T), u_h(T), \tilde{\phi}) - (\dot{u}_h(T), \tilde{\phi}) \quad \forall\, \tilde{\phi} \in \widetilde{X}, \tag{2.20}$$

$$\big(\nabla \cdot \tilde{u}_{\tilde{h}}, \tilde{\psi}\big) = 0 \quad \forall\, \tilde{\psi} \in \widetilde{Q}. \tag{2.21}$$

We will denote by $\widetilde{V}$ the corresponding discretely divergence-free space that can be either $\widetilde{V} = V_{\tilde{h},r}$ or $\widetilde{V} = V_{h,r+1}$ depending on the selection of the postprocessed space. The discrete Leray's projection into $\widetilde{V}$ will be denoted by $\widetilde{\Pi}_{\tilde{h}}$, and we will represent by $\widetilde{\mathcal{A}}_{\tilde{h}}$ the discrete Stokes operator acting on functions in $\widetilde{V}$.

The postprocessed Hood–Taylor approximation to the velocity, $\tilde{u}_{\tilde{h}}$, is the solution of the pressure-free formulation

$$\nu\big(\nabla\tilde{u}_{\tilde{h}}, \nabla\tilde{\chi}_h\big) = \big(f, \tilde{\chi}_h\big) - b_{\tilde{h}}\big(u_h(T), u_h(T), \tilde{\chi}_h\big) - \big(\dot{u}_h(T), \tilde{\chi}_h\big) \quad \forall\, \tilde{\chi}_h \in \widetilde{V}. \tag{2.22}$$

In the next section, we show that the solution $(\tilde{u}_h, \tilde{p}_h)$ of (2.20)–(2.21) is a more accurate approximation to the solution of (1.1)–(1.2) than the Galerkin MFE approximation (u_h, p_h) that solves (2.18)–(2.19).

For the discrete approximation to the nonlinear term, following [24], we define b_h in the following way:

$$b_h(u_h, v_h, \phi_h) = ((u_h \cdot \nabla)v_h, \phi_h) + \frac{1}{2}(\operatorname{div}(u_h)v_h, \phi_h) \quad \forall\, u_h, v_h, \phi_h \in X_{h,r} \subset H_0^1(\Omega)^d.$$

For all $u, v \in H_0^1(\Omega)^d$, the corresponding continuous operator will be denoted by $F(u, v) = (u \cdot \nabla)v + (1/2)\operatorname{div}(u)v$. Extending the definition of b_h to functions in $H_0^1(\Omega)^d$ (not necessarily in $X_{h,r}$), we observe that $\forall\, u, v, w \in H_0^1(\Omega)^d$, $b_h(u, v, w) = (F(u, v), w)$. It is straightforward to verify that b_h enjoys the skew-symmetry property

$$b_h(u, v, w) = -b_h(u, w, v) \qquad \forall\, u, v, w \in H_0^1(\Omega)^d. \tag{2.23}$$

Let us observe that $B(u, v) = \Pi F(u, v)$ if $u \in V$. Finally, we shall denote by

$$B_h(u, v) = \Pi_{h,r} F(u, v) \qquad \forall\, u,\, v\, \in\, H_0^1(\Omega)^d.$$

3. Analysis of the postprocessed method.

This section is devoted to the analysis of convergence of the postprocessed MFE method. Our first aim will be to show a superconvergence result for the error between the MFE approximation to the velocity u_h and the Stokes projection of the velocity field u, s_h. This superconvergence behavior occurs for both the L^2 and H^1 norms, as will be shown in Theorem 3.7 and Corollary 3.8, respectively. In the first part of the section, we shall concentrate our efforts in Theorem 3.7. It will be achieved by a stability plus consistency argument (Propositions 3.2 and 3.6, respectively). For the purpose of analysis, we shall mainly be concerned with the pressure-free formulation associated with (2.18)–(2.19). If (u_h, p_h) is the MFE approximation to the solution (u, p) of (1.1)–(1.2), then $u_h \in V_{h,r}$ is the solution of

$$(\dot{u}_h, \chi_h) + \nu(\nabla u_h, \nabla \chi_h) + b_h(u_h, u_h, \chi_h) = (f, \chi_h) \qquad \forall \chi_h \in V_{h,r}, \tag{3.1}$$

which can also be expressed in abstract operator form as

$$\dot{u}_h + \nu \mathcal{A}_h u_h + B_h(u_h, u_h) = \Pi_{h,r} f. \tag{3.2}$$

The Stokes projection s_h satisfies the abstract equation

$$\dot{s}_h + \nu \mathcal{A}_h s_h + B_h(s_h, s_h) = \Pi_{h,r} f + T_h, \tag{3.3}$$

where $T_h(t)$ is the truncation error, defined as

$$T_h(t) = \dot{s_h} - \Pi_{h,r}(u_t) + B_h(s_h, s_h) - B_h(u, u). \tag{3.4}$$

Let us now consider mappings $v_h : [0, T] \longrightarrow V_{h,r}$ satisfying the following threshold condition:

$$\|s_h(t) - v_h(t)\|_0 \le c_\tau h^2 \qquad \forall\, t \in [0, t_1], \quad 0 < t_1 \le T. \tag{3.5}$$

We define their truncation error as

$$\widehat{T}_h = \dot{v}_h + \nu \mathcal{A}_h v_h + B_h(v_h, v_h) - \Pi_{h,r} f. \tag{3.6}$$

Prior to establishing the stability restricted to the threshold (3.5) (Proposition 3.2), we prove a lemma which provides some estimates for the convective term.

LEMMA 3.1. *Let (u,p) be the solution of the Navier–Stokes problem* (1.1)–(1.2). *Let $s_h = S_h(u)$ be the discrete Stokes projection of the velocity field u and let $v_h : [0,T] \longrightarrow V_{h,r}$ satisfy the threshold condition* (3.5). *Then, there exists a constant $K>0$, independent of t_1 in* (3.5), *such that $\forall\, t \in [0,t_1]$,*

$$\|F(s_h(t),s_h(t)) - F(v_h(t),v_h(t))\|_0 \le K\|s_h(t)-v_h(t)\|_1, \tag{3.7}$$
$$\|F(s_h(t),s_h(t)) - F(v_h(t),v_h(t))]\|_{-1} \le K\|s_h(t)-v_h(t)\|_0, \tag{3.8}$$

where the constant $K = K\big(c_\tau, \max_{0\le t\le T}(\|u(t)\|_2 + \|p(t)\|_{H^1/\mathbb{R}})\big)$.

Proof. In order to simplify the notation, we shall omit the dependence on t in the proof. Denote by $e_h = v_h - s_h$. We proceed by standard duality arguments, using the splitting

$$F(v_h,v_h) - F(s_h,s_h) = F(v_h,e_h) + F(e_h,s_h). \tag{3.9}$$

We start by showing (3.7). We first observe that

$$\begin{aligned}\|F(e_h,s_h)\|_0 &= \sup_{\|\phi\|_0=1}\left|(e_h\cdot\nabla s_h,\phi) + \frac{1}{2}((\nabla\cdot e_h)s_h,\phi)\right|\\ &\le C\|e_h\|_{L^{2d/(d-1)}(\Omega)^d}\|\nabla s_h\|_{L^{2d}(\Omega)^d} + C\|e_h\|_1\|s_h\|_\infty.\end{aligned}$$

Let us show that both $\|s_h\|_\infty$, $\|\nabla s_h\|_{L^{2d}(\Omega)^d}$ are bounded. Since, by virtue of Sobolev's imbeddings (2.1), we have $\|s_h\|_\infty \le C\|\nabla s_h\|_{L^{2d}(\Omega)^d}$, we only need to bound the second term. Application of the inverse inequality (2.3) and the error estimates (2.9) and (2.7) together with (2.1) give

$$\begin{aligned}\|\nabla s_h\|_{L^{2d}(\Omega)^d} &\le Ch^{\frac{-(1+d)}{2}}(\|s_h-u\|_0 + \|u-I_hu\|_0) + \|\nabla I_h u\|_{L^{2d}(\Omega)^d}\\ &\le Ch^{(3-d)/2}(\|u\|_2 + \|p\|_{H^1/\mathbb{R}}) + C\|u\|_{W^{1,2d}(\Omega)^d} \le K.\end{aligned} \tag{3.10}$$

Using again (2.1) we obtain

$$\|e_h\|_{L^{2d/(d-1)}(\Omega)^d} \le C\|e_h\|_{1/2} \le C\|e_h\|_1,$$

and so $\|F(e_h,s_h)\|_0 \le K\|e_h\|_1$. As regards the other term in (3.9), the same arguments lead to

$$\begin{aligned}\|F(v_h,e_h)\|_0 &= \sup_{\|\phi\|_0=1}\left|(v_h\cdot\nabla e_h,\phi) + \frac{1}{2}((\nabla\cdot v_h)e_h,\phi)\right|\\ &\le C\|v_h\|_\infty\|e_h\|_1 + C\|\nabla v_h\|_{L^{2d}(\Omega)^d}\|e_h\|_{L^{2d/(d-1)}(\Omega)^d}.\end{aligned}$$

As before, to conclude we must show that the above norms of v_h are bounded. We only need to handle $\|\nabla v_h\|_{L^{2d}(\Omega)^d}$. Using the inverse inequality (2.3) and the threshold conditions (3.5) and (3.10), we find

$$\|\nabla v_h\|_{L^{2d}(\Omega)^d} \le h^{\frac{-(1+d)}{2}}\|v_h - s_h\|_0 + \|\nabla s_h\|_{L^{2d}(\Omega)^d} \le c_\tau h^{(3-d)/2} + K \le K.$$

Therefore, (3.7) follows. We now show (3.8). Applying (3.9), we find

$$\|F(v_h,v_h) - F(s_h,s_h)\|_{-1} \le \|F(v_h,e_h)\|_{-1} + \|F(e_h,s_h)\|_{-1}, \tag{3.11}$$

so that the proof is reduced to estimate each of the above negative norms on the right-hand side. Using the skew-symmetry property (2.23), one gets for the first term:

$$\begin{aligned}\|F(v_h,e_h)\|_{-1} &= \sup_{\|\phi\|_1=1}\left|-((v_h\cdot\nabla)\phi,e_h)-\frac{1}{2}((\nabla\cdot v_h)\phi,e_h)\right|\\ &\le \sup_{\|\phi\|_1=1}\left(\|e_h\|_0\|v_h\|_\infty\|\phi\|_1+\|e_h\|_0\|\nabla\cdot v_h\|_{L^{2d/(d-1)}}\|\phi\|_{L^{2d}(\Omega)^d}\right)\le K\|e_h\|_0.\end{aligned}$$

Regarding the other term in (3.11), integrating by parts, we obtain

$$\begin{aligned}\|F(e_h,s_h)\|_{-1} &= \sup_{\|\phi\|_1=1}\left|\frac{1}{2}\big((e_h\cdot\nabla)s_h,\phi\big)-\frac{1}{2}\big((e_h\cdot\nabla)\phi,s_h\big)\right|\\ &\le \sup_{\|\phi\|_1=1}(\|e_h\|_0\|\nabla s_h\|_{L^{2d/(d-1)}(\Omega)^d}\|\phi\|_{L^{2d}(\Omega)^d}+\|e_h\|_0\|\phi\|_1\|s_h\|_\infty)\le K\|e_h\|_0.\end{aligned}$$

This finishes the proof of (3.8). □

PROPOSITION 3.2 (stability). *Let $T>0$ be fixed; let $s_h=S_h(u)$ be the discrete Stokes projection of the velocity field u solution of* (1.1)–(1.2) *and let $v_h:[0,T]\longrightarrow V_{h,r}$ satisfy the threshold condition* (3.5). *Then, there exists a positive constant $K_s>0$ such that $\forall\, t_1\le T$, the following estimate holds:*

$$\max_{0\le t\le t_1}\|s_h(t)-v_h(t)\|_0\le e^{K_st_1}\Bigg(\|s_h(0)-v_h(0)\|_0 + \max_{0\le t\le t_1}\left\|\int_0^t e^{-\nu(t-s)\mathcal{A}_h}[T_h(s)-\widehat{T}_h(s)]ds\right\|_0\Bigg), \tag{3.12}$$

where $T_h(s)$ and $\widehat{T}_h(s)$ are the truncation errors given in (3.4) *and* (3.6), *respectively.*

Proof. We denote by $e_h=s_h-v_h$. Subtracting (3.6) from (3.3), it follows that e_h satisfies the error equation

$$\dot{e}_h(t)+\nu\mathcal{A}_he_h(t)=B_h(v_h(t),v_h(t))-B_h(s_h(t),s_h(t))+T_h(t)-\widehat{T}_h(t).$$

Then, by integrating the above error equation from time 0 up to time t, we find that

$$\begin{aligned}e_h(t)&=e^{-\nu t\mathcal{A}_h}\Pi_{h,r}e_h(0)+\int_0^t e^{-\nu(t-s)\mathcal{A}_h}\Pi_{h,r}[B_h(v_h,v_h)-B_h(s_h,s_h)]ds\\ &\quad+\int_0^t e^{-\nu(t-s)\mathcal{A}_h}\Pi_{h,r}[T_h(s)-\widehat{T}_h(s)]ds.\end{aligned}$$

Since $\{e^{-\nu t\mathcal{A}_h}\Pi_{h,r}\}_{t>0}$ is a contraction $\|e^{-\nu t\mathcal{A}_h}\Pi_{h,r}e_h(0)\|_0\le\|e_h(0)\|_0$. As regards the second term, estimates (2.13), (2.16), and (3.8) from Lemma 3.1 lead to

$$\begin{aligned}&\left\|\int_0^t e^{-\nu(t-s)\mathcal{A}_h}[B_h(s_h,s_h)-B_h(v_h,v_h)]ds\right\|_0\\ &\quad\le\frac{C_{1/2}}{\sqrt{\nu}}\int_0^t\frac{\left\|\mathcal{A}_h^{-1/2}\big(\Pi_{h,r}F(s_h,s_h)-\Pi_{h,r}F(v_h,v_h)\big)\right\|_0}{\sqrt{t-s}}ds\le\frac{KC_{1/2}}{\sqrt{\nu}}\int_0^t\frac{\|e_h(s)\|_0}{\sqrt{t-s}}ds.\end{aligned}$$

Then,

$$\|e_h(t)\|_0\le\|e_h(0)\|_0+\frac{KC_{1/2}}{\sqrt{\nu}}\int_0^t\frac{\|e_h(s)\|_0}{\sqrt{t-s}}ds+\int_0^t e^{-\nu(t-s)\mathcal{A}_h}[T_h(s)-\widehat{T}_h(s)]ds.$$

And now, a standard application of the generalized Gronwall lemma (see [22, pp. 188–189]) allows us to conclude the proof. □

Proposition 3.2 is an example of stability restricted to h-dependent thresholds. This kind of stability is an alternative to establishing the a priori bounds for the approximate solution u_h required in order to handle the nonlinear term [28].

The following lemmas will be required in the proof of Proposition 3.6.

LEMMA 3.3. *For any $f \in C([0,T];L^2(\Omega)^d)$, the following estimate holds $\forall\, t \in [0,T]$:*

$$\int_0^t \left\|\mathcal{A}_h e^{-\nu(t-s)\mathcal{A}_h}\Pi_{h,r} f(s)\right\|_0 ds \le \frac{C}{\nu}|\log(h)| \max_{0\le t\le T}\|f(t)\|_0.$$

Proof. The proof follows essentially the same steps as in [14] and [20]. □

LEMMA 3.4. *Let $v \in (H^2(\Omega))^d \cap V$. Then, there exists a constant $K = K(\|v\|_2)$ such that $\forall\, w \in H_0^1(\Omega)^d$, we have that*

$$\|\mathcal{A}^{-1}\Pi[F(v,v) - F(w,w)]\|_0 \le K\big(\|v-w\|_{-1} + \|v-w\|_1\|v-w\|_0\big). \tag{3.13}$$

Proof. Throughout the proof, we shall designate $e = v - w$. We rewrite the difference of the nonlinear terms as

$$\mathcal{A}^{-1}\Pi\left(F(v,v) - F(w,w)\right) = \mathcal{A}^{-1}\Pi F(v,e) + \mathcal{A}^{-1}\Pi F(e,v) - \mathcal{A}^{-1}\Pi F(e,e). \tag{3.14}$$

Let us first estimate the last term in (3.14). Using (2.23) and (2.1), we have

$$\begin{aligned}\|\mathcal{A}^{-1}\Pi F(e,e)\|_0 &\le \sup_{\|\phi\|_0=1}\left| -\big((e\cdot\nabla)\mathcal{A}^{-1}\Pi\phi, e\big) - \frac{1}{2}\big((\nabla\cdot e)(\mathcal{A}^{-1}\Pi\phi), e\big)\right| \\ &\le \sup_{\|\phi\|_0=1}\Big(\|e\|_{L^{2d/(d-1)}(\Omega)^d}\|\nabla\mathcal{A}^{-1}\Pi\phi\|_{L^{2d}(\Omega)^d} + \|e\|_1\|\mathcal{A}^{-1}\Pi\phi\|_\infty\Big)\|e\|_0 \\ &\le \sup_{\|\phi\|_0=1}\Big(C\|e\|_{1/2}\|\mathcal{A}^{-1}\Pi\phi\|_2 + C\|e\|_1\|\mathcal{A}^{-1}\Pi\phi\|_2\Big)\|e\|_0 \le C\|e\|_1\|e\|_0.\end{aligned}$$

For the first term in the splitting (3.14), taking into account that $\mathrm{div}(v) = 0$, we find

$$\|\mathcal{A}^{-1}\Pi F(v,e)\|_0 = \sup_{\|\phi\|_0=1}\left|\big((v\cdot\nabla)\mathcal{A}^{-1}\Pi\phi, e\big)\right| \le \|e\|_{-1}\sup_{\|\phi\|_0=1}\|\nabla((v\cdot\nabla)\mathcal{A}^{-1}\Pi\phi)\|_0.$$

Therefore, we must show that the last supremum above is bounded. Using again Sobolev's imbeddings (2.1) for $\phi \in L^2(\Omega)$ with $\|\phi\|_0 = 1$, we obtain

$$\begin{aligned}\|\nabla\big((v\cdot\nabla)\mathcal{A}^{-1}\Pi\phi\big)\|_0^2 &\le \sum_{k=1}^d \|\big(\partial_k v\cdot\nabla\big)(\mathcal{A}^{-1}\Pi\phi) + (v\cdot\nabla)\big(\partial_k(\mathcal{A}^{-1}\Pi\phi)\big)\|_0^2 \\ &\le \sum_{k=1}^d \|\partial_k v\|^2_{L^{2d/(d-1)}(\Omega)^d}\|\nabla\mathcal{A}^{-1}\Pi\phi\|^2_{L^{2d}(\Omega)^d} + \|v\|_\infty^2\|\partial_k(\nabla\mathcal{A}^{-1}\Pi\phi)\|_0^2 \\ &\le C\big[\|\nabla v\|_{1/2}^2\|\mathcal{A}^{-1}\Pi\phi\|_2^2 + \|v\|_2^2\|\mathcal{A}^{-1}\Pi\phi\|_2^2\big] \le C\|v\|_2^2,\end{aligned}$$

so that $\|\mathcal{A}^{-1}\Pi F(v,e)\|_0 \le K\|e\|_{-1}$. Finally, we deal with the second term in (3.14). Integrating by parts, we get

$$\|\mathcal{A}^{-1}\Pi F(e,v)\|_0 = \sup_{\|\phi\|_0=1}\left|\frac{1}{2}((e\cdot\nabla)v, \mathcal{A}^{-1}\Pi\phi) - \frac{1}{2}((e\cdot\nabla)\mathcal{A}^{-1}\Pi\phi, v)\right|.$$

We shall estimate each supremum in the above equation separately. For the first term, we have

$$\begin{aligned}\big|(e\cdot\nabla)v,\mathcal{A}^{-1}\Pi\phi)\big| &\le \|e\|_{-1}\|\big((\mathcal{A}^{-1}\Pi\phi)\cdot\nabla\big)v\|_1\\ &\le \|e\|_{-1}\Big(\|\nabla v\|_1\|\mathcal{A}^{-1}\Pi\phi\|_\infty+\|\nabla v\|_{L^{2d/(d-1)}(\Omega)^d}\|\nabla\mathcal{A}^{-1}\Pi\phi\|_{L^{2d}(\Omega)^d}\Big)\\ &\le C\|e\|_{-1}\Big(\|v\|_2\|\mathcal{A}^{-1}\Pi\phi\|_2+\|v\|_2\|\mathcal{A}^{-1}\Pi\phi\|_2\Big)\le C\|v\|_2\|e\|_{-1}\le K\|e\|_{-1}.\end{aligned}$$

As regards the other supremum, we note that

$$\begin{aligned}\big|(e\cdot\nabla)\mathcal{A}^{-1}\Pi\phi,v)\big| &\le \sum_{k=1}^{d}\|e^k\|_{-1}\Big(\|\nabla(\partial_k\mathcal{A}^{-1}\Pi\phi)\cdot v\|_0+\|\partial_k(\mathcal{A}^{-1}\Pi\phi)\cdot(\nabla v)\|_0\Big)\\ &\le \|e\|_{-1}\Big(\|\mathcal{A}^{-1}\Pi\phi\|_2\|v\|_\infty+\|\partial_k(\mathcal{A}^{-1}\Pi\phi)\|_{L^{2d}(\Omega)^d}\|\nabla v\|_{L^{2d/(d-1)}(\Omega)^d}\Big)\\ &\le \|e\|_{-1}\Big(\|\mathcal{A}^{-1}\Pi\phi\|_2\|v\|_2+\|\mathcal{A}^{-1}\Pi\phi)\|_2\|v\|_2\Big)\le C\|v\|_2\|e\|_{-1}\le K\|e\|_{-1},\end{aligned}$$

which concludes the proof. □

LEMMA 3.5. *Let* (u,p) *be the solution of* (1.1)–(1.2). *Then, there exists a positive constant* $K=K(u,p)$ *such that,* $\forall\, t\in[0,T]$, *the truncation error defined in* (3.4) *satisfies the following bound:*

$$\|\mathcal{A}_h^{-1}T_h(t)\|_0\le Kh^{r+1}. \tag{3.15}$$

Proof. In view of definition (3.4), we observe that

$$\|\mathcal{A}_h^{-1}T_h(t)\|_0\le\|\mathcal{A}_h^{-1}\Pi_{h,r}(\dot s_h-u_t)\|_0+\|\mathcal{A}_h^{-1}\Pi_{h,r}(F(s_h,s_h)-F(u,u))\|_0.$$

We will use (2.14) with $s=2$ to bound both terms on the right-hand side. For the first, we obtain

$$\begin{aligned}\|\mathcal{A}_h^{-1}\Pi_{h,r}(\dot s_h-u_t)\|_0 &\le Ch^2\|\dot s_h-u_t\|_0+\|\mathcal{A}^{-1}\Pi(\dot s_h-u_t)\|_0\\ &\le Ch^2\|\dot s_h-u_t\|_0+\|\dot s_h-u_t\|_{-2}\le Ch^{r+1}(\|u_t\|_r+\|p_t\|_{H^{r-1}/\mathbb{R}}),\end{aligned}$$

where in the last inequality we have used that $\|\cdot\|_{-2}\le\|\cdot\|_{-1}$ and applied (2.11). As regards the second term, applying (3.7) from Lemma 3.1 and (3.13) from Lemma 3.4, we get

$$\begin{aligned}&\|\mathcal{A}_h^{-1}\Pi_{h,r}\left(F(s_h,s_h)-F(u,u)\right)\|_0\\ &\quad\le Ch^2\|F(s_h,s_h)-F(u,u)\|_0+\|\mathcal{A}^{-1}\Pi(F(s_h,s_h)-F(u,u))\|_0\\ &\quad\le Kh^2\|s_h-u\|_1+K(\|s_h-u\|_{-1}+\|s_h-u\|_1\|s_h-u\|_0).\end{aligned}$$

We observe that although Lemma 3.1 has been stated for functions $v_h\in V_{h,r}$ satisfying (3.5) can equally be applied for $v_h=u$. To conclude, we apply estimates (2.9) and (2.11) to get

$$\|\mathcal{A}_h^{-1}\Pi_{h,r}\left(F(s_h,s_h)-F(u,u)\right)\|_0\le Kh^{r+1}\left(\|u\|_r+\|p\|_{H^{r-1}/\mathbb{R}}\right). \qquad \square$$

Proposition 3.6 (consistency). *Let (u,p) be the solution of* (1.1)–(1.2). *Then, there exists a positive constant $K=K(u,p,\nu)$ such that*

$$\max_{0\le t\le T}\left\| \int_0^t e^{-\nu(t-s)\mathcal{A}_h} T_h(s)ds\right\|_0 \le Kh^{r+1}|\log(h)|. \tag{3.16}$$

Proof. Let us start by noticing that

$$\left\| \int_0^t e^{-\nu(t-s)\mathcal{A}_h} T_h(s)ds\right\|_0 \le \int_0^t \left\| \mathcal{A}_h e^{-\nu(t-s)\mathcal{A}_h} \mathcal{A}_h^{-1} T_h(s)\right\|_0 ds.$$

By virtue of Lemma 3.3, the last integral reduces to

$$\int_0^t \left\| \mathcal{A}_h e^{-\nu(t-s)\mathcal{A}_h} \Pi_{h,r}\mathcal{A}_h^{-1} T_h(s)\right\|_0 ds \le \frac{C}{\nu}|\log(h)| \max_{0\le t\le T}\left\|\mathcal{A}_h^{-1}T_h(t)\right\|_0,$$

and then, since Lemma 3.5 provides the required estimate for the truncation error, we reach (3.16). □

Theorem 3.7 (superconvergence for the velocity). *Let (u,p) be the solution of* (1.1)–(1.2)*, let s_h be the Stokes projection of u, and let u_h be the Hood–Taylor element approximation to u. Then, there exist positive constants $K(u,p,\nu)$ and h_0 such that, for every $h\in(0,h_0]$,*

$$\max_{0\le t\le T}\|s_h(t)-u_h(t)\|_0 \le K(u,p,\nu)h^{r+1}|\log(h)|. \tag{3.17}$$

Proof. Since $u_h(0)=s_h(0)$, the proof follows from Proposition 3.2 (applied to $v_h=u_h$) and Proposition 3.6. The threshold condition (3.5) needed for Proposition 3.2 to be valid is easily proved by a standard bootstrap argument (see, e.g., [20] and [3]). □

Next, we derive the superconvergence result for the error between the MFE approximation u_h to the velocity and the Stokes projection s_h in the H^1 norm.

Corollary 3.8. *Let (u,p) be the solution of the Navier–Stokes problem* (1.1)–(1.2)*, let s_h be the discrete Stokes projection of u, and let u_h be the Hood–Taylor element approximation to u. Then, there exist positive constants $K(u,p,\nu)$ and h_0 such that, for every $h\in(0,h_0]$, the following bound holds:*

$$\max_{0\le t\le T}\|s_h(t)-u_h(t)\|_1 \le K(u,p,\nu)h^{r}|\log(h)|. \tag{3.18}$$

Proof. The result follows from Theorem 3.7 and the inverse inequality (2.3). □

As a consequence of Theorem 3.7 and Corollary 3.8, the optimal rate of convergence for u_h is obtained.

Corollary 3.9. *Let (u,p) be the solution of the Navier–Stokes problem* (1.1)–(1.2)*, and let the conditions of Theorem* 3.7 *be satisfied. Then, for $s=0,1$,*

$$\max_{0\le t\le T}\|u(t)-u_h(t)\|_s \le Ch^{r-s}\Big(\max_{0\le t\le T}(\|u\|_r+\|p\|_{H^{r-1}/\mathbb{R}})+K(u,p,\nu)h|\log(h)|\Big). \tag{3.19}$$

Proof. By rewriting $u-u_h=(u-s_h)+(s_h-u_h)$, and appealing to Theorem 3.7 and Corollary 3.8 together with estimate (2.9), we reach (3.19). □

The following lemma provides several estimations (in different norms) for the time derivative of the error in the MFE approximation to the velocity.

LEMMA 3.10. *Let (u,p) be the solution of* (1.1)–(1.2), *and let $u_h : [0,T] \to V_{h,r}$ be the Hood–Taylor approximation to the velocity. Then, the following estimates hold:*

$$\max_{0<t\le T} \left\| u_t(t) - \dot{u}_h(t)\right\|_0 \le K(u,p,\nu) h^{r-1} |\log(h)|, \tag{3.20}$$

$$\max_{0<t\le T} \left\| \mathcal{A}^{-1}\Pi(u_t(t) - \dot{u}_h(t))\right\|_0 \le K(u,p,\nu) h^{r+1} |\log(h)|, \tag{3.21}$$

$$\max_{0<t\le T} \left\| u_t(t) - \dot{u}_h(t)\right\|_{-1} \le K(u,p,\nu) h^{r} |\log(h)|. \tag{3.22}$$

Proof. For simplicity, we shall drop the explicit dependence on the time t in the proof. We consider the splitting

$$u_t - \dot{u}_h = (u_t - \dot{s}_h) + (\dot{s}_h - \dot{u}_h).$$

Since the first term can be readily estimated in the different norms by means of (2.9) and (2.11), we will concentrate only on the second one in the rest of the proof. Let us denote $e_h = s_h - u_h$. The time derivative of e_h satisfies the equation

$$\dot{e}_h = -\nu \mathcal{A}_h e_h + B_h(u_h,u_h) - B_h(u,u) + \Pi_{h,r}(\dot{s}_h - u_t).$$

We shall start by proving (3.20). Applying the inverse inequality (2.3), the stability of $\Pi_{h,r}$ in the L^2 norm, (3.7) from Lemma 3.1 and (2.9), we get

$$\begin{aligned}
\|\dot{e}_h\|_0 &\le \nu \left\|\mathcal{A}_h^{1/2}\mathcal{A}_h^{1/2} e_h\right\|_0 + \|B_h(u_h,u_h) - B_h(u,u)\|_0 + \|\Pi_{h,r}(\dot{s}_h - u_t)\|_0 \\
&\le C\nu h^{-1}\left\|\mathcal{A}_h^{1/2} e_h\right\|_0 + K\|e_h\|_1 + Ch^r(\|u_t\|_r + \|p_t\|_{H^{r-1}/\mathbb{R}}) \\
&\le (C\nu h^{-1} + K)\|e_h\|_1 + O(h^r) \le (C\nu h^{-1} + K)K(u,p,\nu)h^r|\log(h)| + O(h^r)
\end{aligned}$$

after applying Corollary 3.8 in the last inequality, and so (3.20) is shown. Notice that Lemma 3.1 has been applied for $v_h = u_h$ and taking u instead of s_h. It is immediate to check that the proof of the lemma remains valid in this case.

We deal next with (3.21). We first observe that

$$\begin{aligned}
\|\mathcal{A}^{-1}\Pi\dot{e}_h\|_0 \le{}& \nu\|\mathcal{A}^{-1}\Pi A_h e_h\|_0 + \|\mathcal{A}^{-1}\Pi(B_h(u_h,u_h) - B_h(u,u))\|_0 \\
&+\|\mathcal{A}^{-1}\Pi(\dot{s}_h - \Pi_{h,r}u_t)\|_0.
\end{aligned} \tag{3.23}$$

Let us now bound each term on the right-hand side of (3.23). For the first, taking into account the relation (2.15), and applying the inverse inequality (2.3) and Theorem 3.7, we obtain

$$\|\mathcal{A}^{-1}\Pi\mathcal{A}_h e_h\|_0 \le Ch^2\|\mathcal{A}_h e_h\|_0 + \left\|\mathcal{A}_h^{-1}\mathcal{A}_h e_h\right\|_0 \le C\|e_h\|_0 \le K(u,p,\nu)h^{r+1}|\log(h)|.$$

As regards the second term, by writing $\mathcal{A}^{-1}\Pi\Pi_{h,r} = (\mathcal{A}^{-1}\Pi - \mathcal{A}_h^{-1}\Pi_{h,r})\Pi_{h,r} + (\mathcal{A}_h^{-1}\Pi_{h,r} - \mathcal{A}^{-1}\Pi) + \mathcal{A}^{-1}\Pi$, then (3.7) and Lemma 3.4 give

$$\begin{aligned}
\left\|\mathcal{A}^{-1}\Pi(B_h(u_h,u_h) - B_h(u,u))\right\|_0 &= \left\|\mathcal{A}^{-1}\Pi[\Pi_{h,r}(F(u_h,u_h) - F(u,u))]\right\|_0 \\
&\le Ch^2\left\|F(u_h,u_h) - F(u,u)\right\|_0 + K(\|u_h - u\|_{-1} + \|u_h - u\|_1\|u_h - u\|_0) \\
&\le Kh^2\|u_h - u\|_1 + K(\|e_h\|_0 + \|s_h - u\|_{-1} + \|u_h - u\|_1\|u_h - u\|_0),
\end{aligned}$$

so that applying Theorem 3.7, (2.11), and (3.19) the desired bound for this term is reached. Finally, for the last term on the right-hand side of (3.23), we use (2.17) and (2.11) to get

$$\|\mathcal{A}^{-1}\Pi(\dot{s}_h - \Pi_{h,r}u_t)\|_0 \leq \left\|\mathcal{A}^{-1/2}\Pi(\dot{s}_h - \Pi_{h,r}u_t)\right\|_0 \leq C\|s_h - u_t\|_{-1}$$
$$\leq Ch^{r+1}(\|u_t\|_r + \|p_t\|_{H^{r-1}/\mathbb{R}}).$$

To conclude, we now show (3.22). As we show in Lemma 3.11

$$\|\dot{e}_h\|_{-1} \leq Ch\|\dot{e}_h\|_0 + C\left\|\mathcal{A}^{-1/2}\Pi\dot{e}_h\right\|_0.$$

We have already proved that $\|\dot{e}_h\|_0 \leq Kh^{r-1}|\log(h)|$. Reasoning exactly as we did with $\|\mathcal{A}^{-1}\Pi\dot{e}_h\|_0$, we also get $\|A^{-1/2}\Pi\dot{e}_h\|_0 \leq Kh^r|\log(h)|$, and then the proof is complete. □

Lemma 3.11. *There exists a positive constant independent of h such that*

$$\|f_h\|_{-1} \leq Ch\|f_h\|_0 + C\left\|\mathcal{A}^{-1/2}\Pi f_h\right\|_0 \qquad \forall f \in V_{h,r}.$$

Proof. For $\phi \in H_0^1(\Omega)$ we have the (L^2-orthogonal) decomposition $\phi = \Pi\phi + (I - \Pi)\phi$, for which we have that $(I - \Pi)\phi = \nabla\chi$ for some $\chi \in H^2(\Omega)$ and, for some constant $C > 0$,

$$\|\Pi\phi\|_1 \leq C\,\|\phi\|_1\,, \qquad \|\nabla\chi\|_1 \leq C\,\|\phi\|_1 \tag{3.24}$$

(see, e.g., [10]). Thus, $(f_h, \phi) = (f_h, \Pi\phi) + (f_h, \nabla\chi)$. But, on the one hand, $(f_h, \Pi\phi) = (\Pi f_h, \Pi\phi) = (\mathcal{A}^{-1/2}\Pi f_h, \mathcal{A}^{1/2}\Pi\phi)$; on the other hand, since $f_h \in V_{h,r}$, we may write $(f_h, \nabla(\chi - I_h(\chi))$, where $I_h(\chi)$ is the standard interpolant of χ in $\hat{S}_{h,r-1}$. Now, standard interpolation bounds and (3.24) finish the proof. □

Theorem 3.12 (superconvergence for the pressure). *Let (u, p) be the solution of the Navier–Stokes equations* (1.1)–(1.2)*; let p_h be the Hood–Taylor approximation to the pressure p, and let q_h be the MFE approximation to p in the Stokes problem* (2.8). *Then, there exist positive constants $K(u, p, \nu)$ and h_0 such that, for every $h \in (0, h_0]$,*

$$\max_{0\leq t\leq T}\|p_h(t) - q_h(t)\|_{L^2/\mathbb{R}} \leq \frac{1}{\beta}K(u, p, \nu)h^r|\log(h)|, \tag{3.25}$$

where β is the constant in the inf-sup *condition* (2.4).

Proof. Subtracting (2.8) from (2.18), we obtain for the difference $p_h - q_h$

$$(p_h - q_h, \nabla\cdot\phi_h) = \nu(\nabla(u_h - s_h), \nabla\phi_h) + (F(u_h, u_h) - F(u, u), \phi_h) + (\dot{u}_h - u_t, \phi_h)$$

$\forall\phi_h \in X_{h,r}$. Using the inf-sup condition (2.4),

$$\beta\|p_h - q_h\|_{L^2/\mathbb{R}} \leq \nu\|u_h - s_h\|_1 + \|F(u_h, u_h) - F(u, u)\|_{-1} + \|\dot{u}_h - u_t\|_{-1}.$$

Applying Corollary 3.8, (3.8) from Lemma 3.1, and (3.20) from Lemma 3.10, we get

$$\beta\|p_h - q_h\|_{L^2/\mathbb{R}} \leq \nu Kh^r|\log(h)| + \|u - u_h\|_0 + Kh^r|\log(h)|.$$

Finally, thanks to Corollary 3.9, (3.25) is reached. □

As a consequence of Theorem 3.12 and (2.10), and by writing $p - p_h = (p - q_h) + (q_h - p_h)$, we also obtain the optimal rate of convergence for of the pressure.

Corollary 3.13. *Let (u, p) be the solution of the Navier–Stokes equations* (1.1)–(1.2)*, and let the conditions of Theorem* 3.12 *be satisfied. Then,*

$$\max_{0\leq t\leq T}\|p(t) - p_h(t)\|_{L^2/\mathbb{R}} \leq Ch^{r-1}\max_{0\leq t\leq T}\left(\|u\|_r + \|p\|_{H^{r-1}/\mathbb{R}}\right) + K(u, p, \nu)h^r. \tag{3.26}$$

Next, we state the rate of convergence of the postprocessed MFE approximation $(\tilde u_{\tilde h}, \tilde p_{\tilde h}) \in (\widetilde X, \widetilde Q)$ that solves (2.20)–(2.21).

THEOREM 3.14. *Let $T > 0$ be fixed. Let (u_h, p_h) be the MFE approximation to the solution (u, p) of* (1.1)–(1.2)*, and let $(\tilde u_{\tilde h}, \tilde p_{\tilde h})$ be the postprocessed MFE approximation at time T. Then, there exist constants $K_1(u, p, \nu)$, $K_0(u, p, \nu)$ such that*

(i) *if the postprocessing element is $(\widetilde X, \widetilde Q) = (X_{\tilde h,r}, Q_{\tilde h,r-1})$, then*

$$\|u(T) - \tilde u_{\tilde h}\|_1 \le C(\tilde h)^{r-1}\big(\|u(T)\|_r + \|p(T)\|_{H^{r-1}/\mathbb{R}}\big) + K_1(u, p, \nu) h^r |\log(h)|, \tag{3.27}$$

$$\|u(T) - \tilde u_{\tilde h}\|_0 \le C(\tilde h)^{r}\big(\|u(T)\|_r + \|p(T)\|_{H^{r-1}/\mathbb{R}}\big) + K_0(u, p, \nu) h^{r+1} |\log(h)|; \tag{3.28}$$

(ii) *if at time T the solution $(u(T), p(T))$ belongs to $(H^{r+1}(\Omega)^d \cap V) \times H^r(\Omega)/\mathbb{R}$, and the postprocessing element is $(\widetilde X, \widetilde Q) = (X_{h,r+1}, Q_{h,r})$, then*

$$\|u(T) - \tilde u_{\tilde h}\|_1 \le C h^{r}\big(\|u(T)\|_{r+1} + \|p(T)\|_{H^{r}/\mathbb{R}}\big) + K_1(u, p, \nu) h^r |\log(h)|, \tag{3.29}$$

$$\|u(T) - \tilde u_{\tilde h}\|_0 \le C h^{r+1}\big(\|u(T)\|_{r+1} + \|p(T)\|_{H^{r}/\mathbb{R}}\big) + K_0(u, p, \nu) h^{r+1} |\log(h)|. \tag{3.30}$$

Proof. Let $\widetilde S_{\tilde h}(u) \in \widetilde V$ be the Stokes projection of the solution of (1.1)–(1.2) at time T that satisfies

$$\begin{aligned} \Big(\nabla \widetilde S_{\tilde h}(u), \nabla \tilde\chi_h\Big) &= \big(\nabla u(T), \nabla \tilde\chi_h\big) - \big(p(T), \nabla\cdot \tilde\chi_h\big) \\ &= \big(f(T) - u_t(T) - F(u(T), u(T)), \tilde\chi_h\big) \quad \forall \tilde\chi_h \in \widetilde V. \end{aligned} \tag{3.31}$$

Then, we consider the splitting $\|u(T) - \tilde u_{\tilde h}\|_l \le \|u(T) - \widetilde S_{\tilde h}(u)\|_l + \|\widetilde S_{\tilde h}(u) - \tilde u_{\tilde h}\|_l$, $l = 0, 1$. The first term can be readily estimated by using (2.9), so that, for $l = 0, 1$,

$$\|u(T) - \widetilde S_{\tilde h}(u)\|_l \le \begin{cases} C(\tilde h)^{r-l}(\|u(T)\|_r + \|p(T)\|_{H^{r-1}/\mathbb{R}}), & \widetilde V = \widetilde V_{\tilde h,r}, \\ C h^{r+1-l}(\|u(T)\|_{r+1} + \|p(T)\|_{H^{r}/\mathbb{R}}), & \widetilde V = \widetilde V_{h,r+1}. \end{cases}$$

We will concentrate now on the second term. Subtracting (3.31) from (2.22), one finds

$$\begin{aligned} \nu(\nabla(\tilde u_{\tilde h} - \widetilde S_{\tilde h}(u)), \nabla \tilde\chi_h) &= b_{\tilde h}(u(T), u(T), \tilde\chi_h) - b_{\tilde h}(u_h(T), u_h(T), \tilde\chi_h) \\ &\quad + (u_t(T) - \dot u_h(T), \tilde\chi_h) \quad \forall \tilde\chi_h \in \widetilde V. \end{aligned} \tag{3.32}$$

Then, by setting $\tilde\chi_h = \tilde u_{\tilde h} - \widetilde S_{\tilde h}(u) \in \widetilde V$, we find

$$\nu\|\nabla(\tilde u_{\tilde h} - \widetilde S_{\tilde h}(u))\|_0 \le \big\|F(u(T), u(T)) - F(u_h(T), u_h(T))\big\|_{-1} + \|u_t(T) - \dot u_h(T)\|_{-1}.$$

For the first term above, applying (3.8) from Lemma 3.1 and Corollary 3.9, we get

$$\begin{aligned} \big\|F(u(T), u(T)) - F(u_h(T), u_h(T))\big\|_{-1} &\le K\|u(T) - u_h(T)\|_0 \\ &\le K h^r(\|u(T)\|_r + \|p(T)\|_{H^{r-1}/\mathbb{R}}). \end{aligned}$$

For the second term, (3.22) from Lemma 3.10 gives $\|u_t - \dot u_h\|_{-1} \le K h^r |\log(h)|$. Then

$$\|\tilde u_{\tilde h} - \widetilde S_{\tilde h}(u)\|_1 \le K_1(u, p, \nu) h^r |\log(h)|, \tag{3.33}$$

and the proof for the H^1 norm is complete. We next deal with the estimate in the L^2 norm. Writing (3.32) in abstract operator form, we find that

$$\nu \widetilde{\mathcal A}_{\tilde h}(\tilde u_{\tilde h} - \widetilde S_{\tilde h}(u)) = \widetilde\Pi_{\tilde h}[F(u(T), u(T)) - F(u_h(T), u_h(T))] + \widetilde\Pi_{\tilde h}[u_t(T) - \dot u_h(T)].$$

Then, applying $\widetilde{\mathcal{A}}_{\tilde h}^{-1}$ to both sides of the above equation, we obtain

$$\begin{aligned}\|\tilde u_{\tilde h} - \widetilde S_{\tilde h}(u)\|_0 \le \frac{1}{\nu}\Big(&\big\|\widetilde{\mathcal{A}}_{\tilde h}^{-1}\widetilde\Pi_{\tilde h}[F(u(T),u(T)) - F(u_h(T),u_h(T))]\big\|_0\\ &+\big\|\widetilde{\mathcal{A}}_{\tilde h}^{-1}\widetilde\Pi_{\tilde h}[u_t(T)-\dot u_h(T)]\big\|_0\Big).\end{aligned}$$

Thus, our aim is reduced to estimate each of the above norms. As regards the nonlinear term, taking into account (2.14), with $s=2$, we find

$$\begin{aligned}\big\|\widetilde{\mathcal{A}}_{\tilde h}^{-1}\widetilde\Pi_{\tilde h}[F(u,u)-F(u_h,u_h)]\big\|_0 \le{}& C\tilde h^2\big\|F(u,u)-F(u_h,u_h)\big\|_0\\ &+\big\|\mathcal{A}^{-1}\Pi[F(u,u)-F(u_h,u_h)]\big\|_0.\end{aligned}$$

Now, using estimates (3.7) from Lemma 3.1 and (3.13) from Lemma 3.4, we get

$$\|\widetilde{\mathcal{A}}_{\tilde h}^{-1}\widetilde\Pi_{\tilde h}[F(u,u)-F(u_h,u_h)]\big\|_0 \le C\tilde h^2\|u-u_h\|_1 + C(\|u-u_h\|_{-1}+\|u-u_h\|_0\|u-u_h\|_1).$$

To conclude, we shall estimate each term in both sums. The required estimates in the L^2 and H^1 norms are granted by Corollary 3.9. As regards the estimate in the H^{-1} norm, note that by means of (2.11) and (3.17), one readily finds

$$\begin{aligned}\|u-u_h\|_{-1} &\le \|u-s_h\|_{-1} + \|s_h-u_h\|_{-1} \le \|u-s_h\|_{-1}+\|s_h-u_h\|_0\\ &\le Ch^{r+1}(\|u\|_r + \|p\|_{H^{r-1}/\mathbb{R}}) + Kh^{r+1}|\log(h)|.\end{aligned}$$

Then, we finally get $\big\|\widetilde{\mathcal{A}}_{\tilde h}^{-1}\widetilde\Pi_{\tilde h}[F(u,u)-F(u_h,u_h)]\big\|_0 \le Kh^{r+1}|\log(h)|$. We next deal with the estimate for the time derivative. Applying again (2.14) with $s=2$ together with estimates (3.20) and (3.21) from Lemma 3.10, we reach

$$\begin{aligned}\big\|\widetilde{\mathcal{A}}_{\tilde h}^{-1}\widetilde\Pi_{\tilde h}\,[u_t(T)-\dot u_h(T)]\big\|_0 &\le \tilde h^2\,\|u_t(T)-\dot u_h(T)\|_0 + \|\mathcal{A}^{-1}\Pi[u_t(T)-\dot u_h(T)]\|_0\\ &\le K\tilde h^2 h^{r-1}|\log(h)| + Kh^{r+1}|\log(h)| \le Kh^{r+1}|\log(h)|.\end{aligned}$$

Hence the proof for the L^2 norm is also finished. □

THEOREM 3.15. *Let $T>0$ be fixed. Let (u_h,p_h) be the MFE approximation to the solution (u,p) of* (1.1)–(1.2). *Let $(\tilde u_{\tilde h},\tilde p_{\tilde h})$ be the postprocessed MFE approximation at time T. Then, there exists a constant $K(u,p,\nu)$ such that*

(i) *if the postprocessing element is $(\widetilde X,\widetilde Q) = (X_{\tilde h,r},Q_{\tilde h,r-1})$, then*

$$\begin{aligned}\|p(T)-\tilde p_{\tilde h}\|_{L^2/\mathbb{R}} \le{}& C_\beta(\tilde h)^{r-1}\big(\|u(T)\|_r + \|p(T)\|_{H^{r-1}/\mathbb{R}}\big)\\ &+K(u,p,\nu,\beta)h^r|\log(h)|;\end{aligned}\tag{3.34}$$

(ii) *if at time T the solution $(u(T),p(T))$ belongs to $(H^{r+1}(\Omega)^d\cap V)\times H^r(\Omega)/\mathbb{R}$, and the postprocessing element is $(\widetilde X,\widetilde Q)=(X_{h,r+1},Q_{h,r})$, then*

$$\|p(T)-\tilde p_{\tilde h}\|_{L^2/\mathbb{R}} \le C_\beta h^r\big(\|u(T)\|_{r+1}+\|p(T)\|_{H^r/\mathbb{R}}\big) + K(u,p,\nu,\beta)h^r|\log(h)|.\tag{3.35}$$

Proof. Let us denote by $\tilde q_{\tilde h}$ the MFE approximation to the pressure $p(T)$ obtained by solving the Stokes problem (2.8) at time T in the postprocessed space $(\widetilde X,\widetilde Q)$. Adding and subtracting $\tilde q_{\tilde h}$, we get

$$\|p(T)-\tilde p_{\tilde h}\|_{L^2/\mathbb{R}} \le \|p(T)-\tilde q_{\tilde h}\|_{L^2/\mathbb{R}} + \|\tilde q_{\tilde h}-\tilde p_{\tilde h}\|_{L^2/\mathbb{R}}.$$

The first term can easily be estimated applying (2.10):

$$\|p(T)-\tilde q_{\tilde h}\|_{L^2/\mathbb{R}} \le \begin{cases} C_\beta(\tilde h)^{r-1}\big(\|u(T)\|_r \\ +\|p(T)\|_{H^{r-1}/\mathbb{R}}\big), & \big(\widetilde X,\widetilde Q\big)=(X_{\tilde h,r},Q_{\tilde h,r-1}),\\ C_\beta h^r\big(\|u(T)\|_{r+1} \\ +\|p(T)\|_{H^r/\mathbb{R}}\big), & \big(\widetilde X,\widetilde Q\big)=(X_{h,r+1},Q_{\tilde h,r}).\end{cases}$$

Let us now bound the second term. Using the equations that satisfy $\tilde p_{\tilde h}$ and $\tilde q_{\tilde h}$ ((2.20), (2.8), respectively), we deduce

$$\Big(\tilde p_{\tilde h}-\tilde q_{\tilde h},\nabla\cdot\tilde\phi\Big)=\nu\Big(\nabla\big(\tilde u_{\tilde h}-\widetilde S_{\tilde h}(u)\big),\nabla\tilde\phi\Big)+\big(F(u_h,u_h)\\ -F(u,u),\tilde\phi\big)+\big(\dot u_h-u_t,\tilde\phi\big)\qquad\forall\tilde\phi\in\widetilde X.$$

Using the inf-sup condition (2.4), we obtain

$$\beta\|\tilde p_{\tilde h}-\tilde q_{\tilde h}\|_{L^2/\mathbb{R}}\le\nu\|\tilde u_{\tilde h}-\widetilde S_{\tilde h}\|_1+\|F(u_h,u_h)-F(u,u)\|_{-1}+\|u_h-u_t\|_{-1}.$$

Taking into account (3.33), (3.8) from Lemma 3.1, and (3.22) from Lemma 3.10, we reach

$$\|\tilde p_{\tilde h}-\tilde q_{\tilde h}\|_{L^2/\mathbb{R}}\le\frac{1}{\beta}\left(Kh^r|\log(h)|+\|u-u_h\|_0+Kh^r|\log(h)|\right),$$

so that, applying Corollary 3.8, we have completed the proof. □

Remark 3.1. Observe that for the velocity we used piecewise polynomials of degree at least 2. In general, the postprocessed method does not increase the rate of convergence in the L^2 norm in the linear case although an improvement in the energy norm is obtained. The application of the postprocessing technique to the mini-element approximation to Navier–Stokes equations is studied in [3], [5].

4. Numerical experiments. In this section, we present some numerical experiments in order to support the analysis developed in the paper and to assess the merit of the postprocessed method when compared with the standard MFE method. We consider the Navier–Stokes equations (1.1) over the domain $\Omega=[0,1]\times[0,1]$ subject to homogeneous Dirichlet boundary conditions. The value of the viscosity in the experiments is $\nu=1$, and the final time is $T=1.2$. We set to zero the initial velocity field u_0 (1.2) and choose the external force f so that the exact solution is

$$\begin{aligned} u^1(x,y,t)&=-6\cdot[1-\cos(\pi t)]\big(\sin^3(\pi x)\sin^2(\pi y)\cos(\pi y)\big),\quad (x,y,t)\in\Omega\times[0,T],\\ u^2(x,y,t)&=6\cdot\big(1-\cos(\pi t)\big)\big(\sin^2(\pi x)\sin^3(\pi y)\cos(\pi x)\big),\quad (x,y,t)\in\Omega\times[0,T],\\ p(x,y,t)&=(\sin(2\pi t)/2)\big(\sin^4(\pi x)+\sin^3(\pi y)\big)-\mathfrak{p}_0,\quad (x,y,t)\in\Omega\times[0,T],\end{aligned}$$

where $\mathfrak{p}_0$ denotes the mean of the pressure. In spite of the simplicity of this solution and its lack of physical meaning, we remark that our main interest has been to check the improvement in the rate of convergence achieved with the postprocessing technique and whether this also increases the efficiency of the standard MFE approximation.

In our calculations we take the so-called regular pattern triangulations of Ω, which are induced by the set of nodes $(i/N,j/N)$, $0\le i,\ j\le N$, where $N=|\Omega|/h$ is an integer. The MFE approximation to (1.1)–(1.2) is carried out using the Hood–Taylor element $(X_{h,3},Q_{h,2})$ that we will denote by $P2P1$. That is, we use Lagrange quadratic

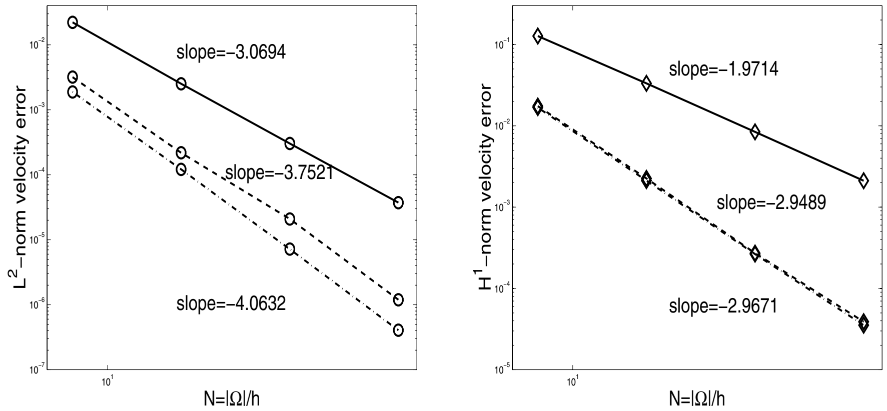

FIG. 4.1. *Convergence diagrams for the first component of the velocity with $P2P1$ (continuous line), $P3P2$ (dashed-dotted line), and the postprocessed method with $P3P2$ (dashed line). On the left the errors are measured in the L^2 norm (circles $\circ$) and on the right in the H^1 norm (diamonds $\diamondsuit$).*

elements for the approximation to the velocity and linear elements to approximate the pressure. For the postprocessing step, due to the smoothness of the solution (u, p), we perform the experiments not only with the same MFE over a finer grid, $(X_{h',3}, Q_{h',2})$, $h' < h$, but also with the higher-order Hood–Taylor element over the same grid, $(X_{h,4}, Q_{h,3})$; i.e., Lagrange cubic for the velocity and Lagrange quadratic for the pressure. This element will be denoted by $P3P2$.

For the time integration we use the well-known semi-implicit method where linear terms are approximated by the implicit midpoint rule (i.e., the Crank–Nicolson method) and nonlinear terms by the two-step explicit Adams formula (see, e.g., [8, p. 105]). The modified Stokes problems that arise at each step are solved by means of a standard projection method [31, pp. 27–28] (see also [3, section 4.6]).

For each h used in the triangulations of Ω, every experiment was carried out with different values of the time step dt. There is always a point, depending on h, at which further reduction of the time step dt does not reduce the errors anymore. This means that the error arising from the time discretization is smaller than the error arising from the MFE discretization. To avoid wrong conclusions from our numerical experiments, we have been careful to ensure that the dominant error in all the computations presented here is the spatial discretization error. For the computational cost in the efficiency diagrams shown here, we use the largest time step among those in which the spatial discretization error is dominant.

In what follows, we use the same symbols in all the plots to represent the relative errors. For the velocity we plot the errors in the first component. Similar errors are obtained for the second. The different methods are distinguished by the line used to join the symbols. For the MFE-$P2P1$ approximation, we use continuous line, and for the MFE-$P3P2$ dashed-dotted line. The MFE-$P2P1$ has been postprocessed in two different ways: using $P3P2$ (dashed line) and refining the mesh (dotted line).

In Figure 4.1 we present two convergence diagrams showing the errors committed by the methods when used with $h = |\Omega|/N$, $N = 8, 16, 32, 64$, both in the L^2 norm (left) and the H^1 norm (right). We have plotted the errors of the MFE-$P2P1$ and $P3P2$ methods and the postprocessed errors with $P3P2$. One can observe that the postprocessing technique with $P3P2$ provides an approximate velocity with about the

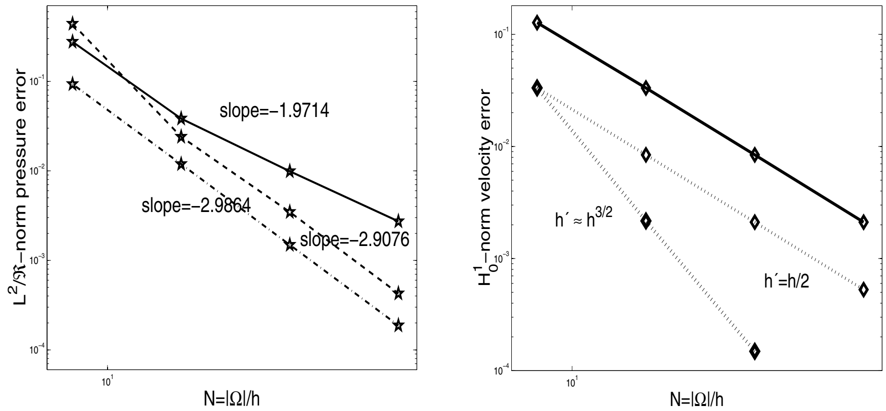

Fig. 4.2. *Left: convergence diagram for the pressure approximation with $P2P1$ (continuous line), $P3P2$ (dashed-dotted lines), and the postprocessed method with $P3P2$ (dashed lines). Right: convergence diagram for the first component of the velocity approximation with $P2P1$ (continuous line) and the postprocessed $P2P1$ over finer grids.*

same accuracy as that corresponding to the MFE-$P3P2$ method. This is especially true for the H^1 norm, in which the two methods produce virtually the same errors. Measures of the slopes of the plots confirm the rates predicted by the theory (i.e., the errors in the plots decrease like $N^{\text{slope}} = \text{const}.h^{-\text{slope}}$).

Similar conclusions can be reached from the errors of the approximations to the pressure in Figure 4.2 (left). Except for the first point, which correspond to $h = 1/8$, the postprocessed errors lies on a line (almost) parallel to the one joining the MFE-$P3P2$ errors. The rate of convergence of these two methods is one unit larger than that of the MFE-$P2P1$ in agreement with what the theory predicts.

In Figure 4.2 (right), we plot the errors obtained postprocessing the MFE-$P2P1$ refining the grid. We have represented the errors measured in the H^1 norm; similar results have been obtained for the L^2 norm. In view of Theorem 3.14, in order to get a gain of one order of convergence in the H^1 norm, we should use a mesh of size $h' \approx h^{3/2}$. The improvement in the rate of convergence of the postprocessed method can be observed in the figure. We can also observe in the plot that using a refined mesh of size $h' = h/2$ (only one regular refinement), the errors are considerably reduced. In fact, observe that the postprocessed error with $h' = h/2$ is almost the same as that of the standard MFE-$P2P1$ carried out using a mesh of size $h/2$ over the full interval $[0, T]$. This fact can be of interest when the cost of the postprocessing step with a refined mesh of size a power of h is not affordable for computational reasons.

The relevant question now is whether the improvement in the rate of convergence also implies improved efficiency. In Figure 4.3, we have represented the same errors as in Figure 4.1 (right) and Figure 4.2 (left) against the smallest amount of time needed to achieve them. We have also plotted the errors of the postprocessed method refining the mesh (Figure 4.2 (right)). In the plot we observe that the efficiency of the two postprocessing procedures is very similar. We can conclude that the postprocessed method really improves the efficiency of the standard MFE method for both approximations to the velocity and to the pressure. For any error that we may demand, the postprocessed method achieves that error in less computing time than the standard $P2P1$ and $P3P2$-MFE methods. The reason for this improvement is that the error of

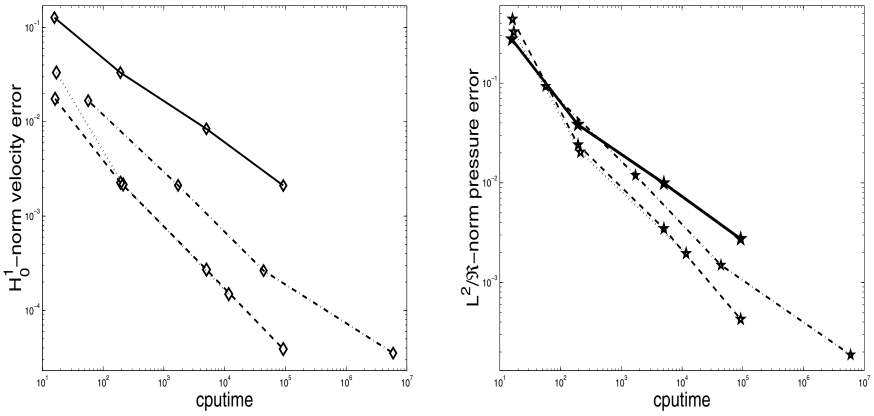

FIG. 4.3. *Efficiency diagrams for the first component of the velocity in the H^1 norm (left) and the pressure (right) with $P2P1$ (continuous line), $P3P2$ (dashed-dotted line) and the postprocessed method with $P3P2$ (dashed line) and refining the grid (dotted line).*

the MFE-$P2P1$ method is reduced when the postprocessing is done, but this is done at very little cost: that of solving a single discrete Stokes problem at the final time.

All numerical experiments were carried out on a Pentium IV, with 1 GB of Rimm memory, under the Solaris8 (Intel) operating system, with SUN Workshop 5 compilers. The programs were written in Fortran 77.

FULLY DISCRETE FINITE ELEMENT APPROXIMATION FOR ANISOTROPIC SURFACE DIFFUSION OF GRAPHS*

KLAUS DECKELNICK†, GERHARD DZIUK‡, AND CHARLES M. ELLIOTT§

Abstract. We analyze a fully discrete numerical scheme for approximating the evolution of graphs for surfaces evolving by anisotropic surface diffusion. The scheme is based on the idea of second order operator splitting for the nonlinear geometric fourth order equation. This yields two coupled spatially second order problems, which are approximated by linear finite elements. The time discretization is semi-implicit. We prove error bounds for the resulting scheme and present numerical test calculations that confirm our analysis and illustrate surface diffusion.

Key words. surface diffusion, anisotropic, geometric motion, second order operator splitting, nonlinear partial differential equation, finite element, fully discrete, error estimates, fourth order parabolic equation

1. Introduction.

This article is concerned with the geometric problem of determining an evolving surface $\Gamma(t)$ whose motion is governed by the highly nonlinear fourth order geometric anisotropic surface diffusion equation

$$V = \Delta_\Gamma \mathcal{H}_\gamma \quad \text{on } \Gamma(t), \tag{1.1}$$

where V and Δ_Γ denote, respectively, the normal velocity and the Laplace–Beltrami (surface Laplacian) operator for $\Gamma(t)$. Furthermore, $\mathcal{H}_\gamma$ denotes the anisotropic mean curvature of the surface with respect to the positive, convex, and 1-homogeneous surface energy density $\gamma : \mathbb{R}^{n+1}\backslash\{0\} \to \mathbb{R}$. We can introduce $\mathcal{H}_\gamma$ formally as the first variation of the surface energy

$$A_\gamma(\Gamma) = \int_\Gamma \gamma(\nu), \tag{1.2}$$

where ν denotes the unit normal to Γ.

Modelling morphological surface evolution and growth is fundamental in materials science and the study of microstructure. The surface evolution law (1.1) is referred to as surface diffusion because it models the diffusion of mass within the bounding surface of a solid body. At the atomistic level atoms on the surface move along the

surface due to a driving force consisting of a chemical potential difference. For a surface with surface energy density $\gamma(\nu)$ the appropriate chemical potential in this setting is the anisotropic curvature $\mathcal{H}_\gamma$. This leads to the flux law

$$\rho V = -\operatorname{div}_\Gamma \mathbf{j},$$

where ρ is the mass density and $\mathbf{j}$ is the mass flux in the surface, with the constitutive flux law [19], [21]

$$\mathbf{j} = -D\nabla_\Gamma \mathcal{H}_\gamma.$$

Here, D is the diffusion constant. From these equations we obtain the law (1.1) after an appropriate nondimensionalization. The notion of surface diffusion is due to Mullins [21] and for a review we refer the reader to [5].

Our sign convention is that $\mathcal{H}_\gamma$ with respect to the outer normal is positive for the Wulff shape $\mathcal{W} := \{p \in \mathbb{R}^{n+1} \mid \langle p, q\rangle \le \gamma(q)\ \forall q \in \mathbb{R}^{n+1}\}$.

This evolution has interesting geometrical properties: if $\Gamma(t)$ is a closed surface bounding a domain $\Omega(t)$, then the volume of $\Omega(t)$ is preserved and the surface energy (or weighted surface area) of $\Gamma(t)$ decreases. The corresponding result in the graph case is given in Lemma 2.2. At present, the existence and uniqueness theory for surface diffusion is limited to the isotropic case $\gamma(q) := |q|$, $q \in \mathbb{R}^{n+1}$. For example, it is known that for closed curves in the plane or closed surfaces in $\mathbb{R}^3$ balls are asymptotically stable subject to small perturbations; see [15], [17]. However, topological changes such as pinch-off are possible [18], [20], and a one-dimensional graph may lose its graph property in finite time whilst the surface evolves smoothly [16].

In what follows we shall study evolving surfaces $\Gamma(t)$ which can be described, for each $t \ge 0$, as the graph of a height function $u(\cdot, t)$ over some base domain $\Omega \subset \mathbb{R}^n$, i.e., $\Gamma(t) = \{(x, u(x,t)) \in \mathbb{R}^{n+1} \mid x \in \Omega\}$. The area element and a unit normal, denoted by $Q(u)$ and $\nu(u)$, are then given by

$$Q(u) = \sqrt{1 + |\nabla u|^2}, \qquad \nu(u) = \frac{(\nabla u, -1)}{\sqrt{1+|\nabla u|^2}} = \frac{(\nabla u, -1)}{Q(u)}$$

so that we can calculate the surface energy or weighted area for a graph Γ given by the height function u as

$$A_\gamma(\Gamma) = \mathcal{I}_\gamma(u) := \int_\Omega \gamma(\nu(u))Q(u) = \int_\Omega \gamma(\nabla u, -1)$$

in view of the homogeneity of γ. Thus the first variation of A_γ in the direction of a function $\phi \in C_0^\infty(\Omega)$ is

$$\begin{aligned}\frac{d}{d\epsilon}\mathcal{I}_\gamma(u + \epsilon\phi)_{|\epsilon=0} &= \sum_{i=1}^n \int_\Omega \gamma_{p_i}(\nabla u, -1)\phi_{x_i} = -\sum_{i,j=1}^n \int_\Omega \gamma_{p_ip_j}(\nabla u, -1)u_{x_ix_j}\phi \\ &= -\int_\Omega \mathcal{H}_\gamma \phi = \int_\Omega w\phi,\end{aligned}$$

where we use $-w$ to denote the anisotropic or weighted mean curvature of the surface in the graph case so that

$$w := -\sum_{i,j=1}^n \gamma_{p_ip_j}(\nabla u, -1)u_{x_ix_j}. \tag{1.3}$$

In order to translate (1.1) into a differential equation for $u = u(x,t)$, we observe that the normal velocity V of $\Gamma(t)$ is given by $V = -\frac{u_t}{Q(u)}$. Furthermore, if $v : \Omega \to \mathbb{R}$, then the Laplace–Beltrami operator on $\Gamma(t)$ is given by (see (2.5) below)

$$\Delta_\Gamma v = \frac{1}{Q(u)} \nabla \cdot \left(\left(Q(u) I - \frac{\nabla u \otimes \nabla u}{Q(u)} \right) \nabla v \right),$$

where $\otimes$ denotes the usual tensor product of two vectors in $\mathbb{R}^n$. Thus, anisotropic surface diffusion for graphs is defined by the following highly nonlinear fourth order evolutionary equation:

$$u_t = -\nabla \cdot \left(\left(Q(u) I - \frac{\nabla u \otimes \nabla u}{Q(u)} \right) \nabla \left(\sum_{i,j=1}^{n} \gamma_{p_i p_j}(\nabla u, -1) u_{x_i x_j} \right) \right). \tag{1.4}$$

The aim of this paper is to analyze a fully discrete finite element approximation of the initial-boundary value problem in the case of *graphs.* We use the second order splitting method for fourth order problems proposed by Elliott, French, and Milner [14] for the fourth order Cahn–Hilliard equation and subsequently employed for surface diffusion by Deckelnick, Dziuk, and Elliott [12]. Thus the space discretization is accomplished using H^1 conforming finite element spaces. For example, continuous piecewise linear elements on triangulations are sufficient. On the other hand, in time we use a novel semi-implicit discretization which requires only the solution of linear algebraic equations but which preserves the Liapunov structure. This ensures the natural stability properties of the scheme with a time step independent of the spatial mesh size. The scheme involves stabilizing the explicit Euler scheme by adding a semi-implicit linear form which involves the discrete time derivative. This stabilizing form has two terms. One involves the anisotropy and is designed to yield a stable linearization. The second term is of higher order with respect to the time step and is based on the Laplace–Beltrami form. It is designed to yield the L^2 stability bound, (3.11), on the discrete solution similar to that enjoyed by the solution of the partial differential equation. A similar idea was previously used in [11] for the anisotropic mean curvature flow of graphs and in [23] for surface diffusion. The main achievement of the paper is the derivation of a priori geometric error bounds. We prove optimal order bounds for the difference of the normals measured in the L^2 norm over either the continuous surface $\Gamma(t)$ or the discrete surface $\Gamma_h(t)$ and the L^2 norm on the discrete surface of the difference of the tangential gradients of the anisotropic mean curvature. This latter bound is equivalent to an H^{-1} bound on the difference in normal velocities. Some numerical computations are presented which confirm the analysis and which illustrate the effect of anisotropy.

A second order splitting finite element scheme for axially symmetric surfaces was presented by Coleman, Falk, and Moakher [7], [8] together with some stability results and interesting numerical computations illustrating pinch-off and the formation of beads. A first finite element error analysis for the second order splitting method for surface diffusion in the axially symmetric case was presented by Deckelnick, Dziuk, and Elliott [12]. Subsequently, Bänsch, Morin, and Nochetto [1] developed an optimal order continuous in time finite element error analysis for the second order splitting method in the case of multidimensional graphs. Our work has the distinctive feature of analyzing a fully discrete second order splitting finite element method for nonlinear surface anisotropy using a stable semi-implicit time stepping scheme.

Remark 1.1. The analysis is easily extended to the more general evolution law

$$V = \Delta_\Gamma(\mathcal{H}_\gamma - f) + g, \tag{1.5}$$

where f is a force arising from an extra term in the energy and g is a surface growth term. For example, including mechanical energy leads to the appearance of f and in epitaxial growth g models the deposition of atoms.

Remark 1.2. Our results are presented for zero Neumann boundary conditions with exact quadrature. The results and arguments also hold without change for the case of Ω being a box and periodic boundary conditions. Minor modifications are required for homogeneous Dirichlet boundary conditions. These three sets of conditions have the property of being variationally separated and allow the second order splitting method to work.

Remark 1.3. The approach to surface diffusion in this paper is entirely analogous to the work of Elliott, French, and Milner [14] for the Cahn–Hilliard equation where u is an order or phase field variable and w is the chemical potential. The variational gradient flow structure is identical in each setting. Indeed the degenerate Cahn–Hilliard equation yields a diffuse interface approximation to surface diffusion [4].

The paper is organized as follows. In section 2 we introduce some notation and assumptions. We set up the numerical scheme and derive some preliminary estimates in section 3, whilst section 4 contains the proof of the error bounds. Finally, section 5 contains some numerical results.

2. Notation and assumptions.

2.1. Differential geometry. Let Γ be a C^2 hypersurface in $\mathbb{R}^{n+1}$ with unit normal ν. For any function $\bar{\eta} = \bar{\eta}(x_1, \dots, x_{n+1})$ defined in a neighborhood $\mathcal{N} \subset \mathbb{R}^{n+1}$ of Γ we define its tangential gradient on Γ by

$$\nabla_\Gamma \bar{\eta} := D\bar{\eta} - \langle D\bar{\eta}, \nu\rangle \nu,$$

where on $\mathbb{R}^{n+1}$ $\langle \cdot, \cdot \rangle$ denotes the usual scalar product and $D\bar{\eta}$ denotes the usual gradient. The tangential gradient $\nabla_\Gamma \bar{\eta}$ depends only on the values of $\bar{\eta}$ on Γ and $\langle \nabla_\Gamma \bar{\eta}, \nu \rangle = 0$. The Laplace–Beltrami operator on Γ is defined as the tangential divergence of the tangential gradient, i.e.,

$$\Delta_\Gamma \bar{\eta} = \langle \nabla_\Gamma, \nabla_\Gamma \bar{\eta} \rangle.$$

Let Γ have a boundary $\partial\Gamma$ whose intrinsic unit outer normal, tangential to Γ, is denoted by μ. Then the surface Green's formula is

$$\int_\Gamma \langle \nabla_\Gamma \bar{\xi}, \nabla_\Gamma \bar{\eta} \rangle = \int_{\partial\Gamma} \bar{\xi} \langle \nabla_\Gamma \bar{\eta}, \mu \rangle - \int_\Gamma \bar{\xi} \Delta_\Gamma \bar{\eta}. \tag{2.1}$$

We now turn to the situation in hand where $\Gamma(t) = \{(x, u(x,t)) \in \mathbb{R}^{n+1} \mid x \in \Omega\}$. For functions $v = v(x)$, $x \in \Omega$, we use the extension $\bar{v}(x, x_{n+1}) = v(x)$ and define

$$\nabla_\Gamma v := \nabla_\Gamma \bar{v} = D\bar{v} - \langle D\bar{v}, \nu(u) \rangle \nu(u) = P(\nu(u)) D\bar{v},$$

where we observe that $D\bar{v} = (\nabla v, 0)$, $\nu(u) = (\nabla u, -1)/Q(u)$ and $P(\nu(u))$ is given by

$$P(\nu(u)) := I - \nu(u) \otimes \nu(u).$$

Here, we have used the tensor product notation $y \otimes y := yy^T$. It follows that

$$\langle \nabla_\Gamma v, \nabla_\Gamma \eta \rangle = \nabla v \cdot \nabla \eta - \frac{1}{Q(u)^2} \nabla v \cdot \nabla u \nabla \eta \cdot \nabla u = \frac{1}{Q(u)} (\nabla v)^t E(\nabla u) \nabla \eta, \tag{2.2}$$

where

$$E(\nabla u) := Q(u) I - \frac{\nabla u \otimes \nabla u}{Q(u)}.$$

For later use we note that

$$\langle P(\nu(u)) D\bar{v}, D\bar{w} \rangle Q(u) = (\nabla v)^t E(\nabla u) \nabla w, \tag{2.3}$$

$$(\nabla v)^t E(\nabla u) \nabla v \geq \frac{|\nabla v|^2}{Q(u)}. \tag{2.4}$$

Integrating (2.2) over Γ we derive

$$\int_\Gamma \langle \nabla_\Gamma \bar{v}, \nabla_\Gamma \bar{\eta} \rangle = \int_\Omega \langle \nabla_\Gamma v, \nabla_\Gamma \eta \rangle Q(u) = \int_\Omega (\nabla v)^t E(\nabla u) \nabla \eta.$$

If we combine this relation with (2.1) we obtain for test functions η, which vanish on $\partial\Omega$

$$\int_\Gamma \bar{\eta}\, \Delta_\Gamma \bar{v} = \int_\Omega \eta \nabla \cdot (E(\nabla u) \nabla v) = \int_\Omega \eta \frac{1}{Q(u)} \nabla \cdot (E(\nabla u) \nabla v) Q(u),$$

so that

$$\Delta_\Gamma v := \Delta_\Gamma \bar{v} = \frac{1}{Q(u)} \nabla \cdot (E(\nabla u) \nabla v). \tag{2.5}$$

2.2. The anisotropy. We suppose that $\gamma : \mathbb{R}^{n+1} \setminus \{0\} \to \mathbb{R}$ is smooth with $\gamma(p) > 0$ for $p \in \mathbb{R}^{n+1} \setminus \{0\}$ and that γ is positively homogeneous of degree one, i.e.,

$$\gamma(\lambda p) = |\lambda| \gamma(p) \quad \forall\, \lambda \neq 0,\ p \neq 0. \tag{2.6}$$

Here, $|\cdot|$ denotes the Euclidean norm. It is not difficult to verify that (2.6) implies

$$\langle \gamma'(p), p \rangle = \gamma(p), \qquad \langle \gamma''(p) p, q \rangle = 0, \tag{2.7}$$

$$\gamma_{p_i}(\lambda p) = \frac{\lambda}{|\lambda|} \gamma_{p_i}(p), \qquad \gamma_{p_i p_j}(\lambda p) = \frac{1}{|\lambda|} \gamma_{p_i p_j}(p) \tag{2.8}$$

for all $p \in \mathbb{R}^{n+1} \setminus \{0\}$, $q \in \mathbb{R}^{n+1}$, $\lambda \neq 0$, and $i, j \in \{1, \dots, n+1\}$. Finally, we assume that there exists $\gamma_0 > 0$ such that

$$\langle D^2 \gamma(p) q, q \rangle \geq \gamma_0 |q|^2 \quad \forall\, p, q \in \mathbb{R}^{n+1},\ |p| = 1,\ \langle p, q \rangle = 0. \tag{2.9}$$

Further information about the geometric properties and physical relevance of anisotropic energy functionals can be found, respectively, in [2] and [24].

2.3. Function spaces. By $(\cdot,\cdot)$ we denote the $L^2(\Omega)$ inner product $(v, \eta) := \int_\Omega v(x)\eta(x)dx$ for $v, \eta \in L^2(\Omega)$ with norm $\|v\| := (v,v)^{\frac{1}{2}}$. Also $H^{m,p}(\Omega)$ denotes the usual Sobolev space with the corresponding norm being given by $\|u\|_{H^{m,p}(\Omega)} = (\sum_{k=0}^m \|D^k u\|_{L^p(\Omega)}^p)^{\frac{1}{p}}$ with the usual modification for $p = \infty$. For $p = 2$ we simply write $H^m(\Omega) = H^{m,2}(\Omega)$ with norm $\|\cdot\|_{H^m(\Omega)}$.

2.4. The variational formulation and initial-boundary value problem. Rather than discretizing the fourth order equation (1.4) we use the height u of the graph and the anisotropic curvature of the graph w as variables and consider the two second order equations (1.1), (1.3),

$$u_t = \nabla \cdot (E(\nabla u)\nabla w), \tag{2.10}$$

$$w = -\sum_{i,j=1}^{n} \gamma_{p_i p_j}(\nabla u, -1) u_{x_i x_j}. \tag{2.11}$$

The system is closed using Neumann boundary conditions and an initial condition for u.

$$E(\nabla u)\nabla w \cdot \nu_{\partial\Omega} = 0, \tag{2.12}$$

$$\langle \gamma'(\nu(u)), (\nu_{\partial\Omega}, 0)\rangle = 0, \tag{2.13}$$

$$u(\cdot, 0) = u_0. \tag{2.14}$$

The first equation, (2.12), is the zero mass flux condition whereas the second equation, (2.13), is the natural variational boundary condition which defines w as the variational derivative or chemical potential for the surface energy functional. Note that an initial condition on w is not required.

In order to write down the variational formulation it is convenient to introduce the following forms:

Laplace–Beltrami (LB) form,

$$\mathcal{E}(u; w, \eta) := \int_\Omega (\nabla w)^t E(\nabla u)\nabla \eta dx$$

Anisotropic mean curvature (AMC) form,

$$\mathcal{A}(u, \eta) := \sum_{i=1}^{n} \int_\Omega \gamma_{p_i}(\nu(u))\eta_{x_i} dx.$$

Then it is straightforward to show the following equivalence between the classical form of the initial-boundary value problem and the variational formulation.

LEMMA 2.1. *Let $u \in C^1([0, T]; C^4(\bar{\Omega}))$, $u(\cdot, 0) = u_0$, and $w \in C^0([0, T]; C^2(\bar{\Omega}))$. Then (u, w) is a solution of* (2.10)–(2.13) *iff* $u(\cdot, 0) = u_0$ *and the following variational equations are satisfied:*

$$(\partial_t u, \eta) + \mathcal{E}(u; w, \eta) = 0 \quad \forall\, \eta \in H^1(\Omega), \tag{2.15}$$

$$(w, \eta) - \mathcal{A}(u, \eta) = 0 \quad \forall\, \eta \in H^1(\Omega). \tag{2.16}$$

LEMMA 2.2. *The solution (u, w) satisfies for each $t \in [0, T]$ the surface energy equation*

$$\mathcal{I}_\gamma(u) + \int_0^t \mathcal{E}(u; w, w)\, ds = \mathcal{I}_\gamma(u_0) \tag{2.17}$$

and the conservation laws

$$(u, 1) = (u_0, 1), \qquad (w, 1) = 0. \tag{2.18}$$

Furthermore, for each $t \in [0,T]$ we have the bound

$$\|u(t)\|^2 + \int_0^t \|w\|^2 \, ds \le C(\gamma, u_0, T). \tag{2.19}$$

Proof. Taking $\eta = w$ in (2.15) and $\eta = \partial_t u$ in (2.16) and subtracting the resulting equations yields (2.17). Taking $\eta = 1$ in (2.15) and (2.16) yields (2.18).

In order to prove the first part of (2.19), we use $\eta = u$ in (2.15) and apply (2.29) which gives

$$\frac{1}{2}\frac{d}{dt}\|u\|^2 = -\mathcal{E}(u;w,u) \le \mathcal{E}(u;w,w)^{\frac{1}{2}}\mathcal{E}(u;u,u)^{\frac{1}{2}} \le \frac{1}{2}\mathcal{E}(u;w,w) + \frac{1}{2}\int_\Omega Q(u).$$

Integrating this inequality with respect to time we obtain with the help of (2.17),

$$\|u(t)\|^2 \le \|u_0\|^2 + \int_0^t \mathcal{E}(u;w,w)ds + \frac{1}{\inf_{|p|=1}\gamma(p)}\int_0^t I_\gamma(u)\, ds \le C(\gamma, u_0, T).$$

Using $\eta = w$ in (2.16) we deduce

$$\|w\|^2 = \mathcal{A}(u,w) \le \sup_{|p|=1}|\gamma'(p)| \int_\Omega |\nabla w| \le C\left(\int_\Omega \frac{|\nabla w|^2}{Q(u)}\right)^{\frac{1}{2}}\left(\int_\Omega Q(u)\right)^{\frac{1}{2}},$$

so that (2.4) and similar arguments as above yield

$$\int_0^t \|w\|^2 ds \le C\int_0^t \mathcal{E}(u;w,w)ds + C\int_0^t Q(u)\, ds \le C(\gamma, u_0, T). \qquad \square$$

Remark 2.3. The surface energy equation (2.17) can be written as

$$\int_{\Gamma(t)} \gamma(\nu) + \int_0^T \int_{\Gamma(t)} |\nabla_\Gamma \mathcal{H}_\gamma|^2 = \int_{\Gamma(0)} \gamma(\nu). \tag{2.20}$$

The conservation of u is equivalent to the conservation of the volume lying below the graph of the surface. That the integral over Ω of the anisotropic mean curvature is zero is a consequence of the fact that constant vertical variations in the height of the graph do not change the anisotropic surface area.

2.5. Geometric lemmas. The following algebraic relations are elementary.

LEMMA 2.4.

$$|\nabla(u-v)|^2 = (Q(u)-Q(v))^2 + |\nu(u)-\nu(v)|^2 Q(u)Q(v), \tag{2.21}$$

$$\left|\frac{1}{Q(u)} - \frac{1}{Q(v)}\right| \le |\nu(u)-\nu(v)|, \tag{2.22}$$

$$|Q(u)-Q(v)| \le Q(u)Q(v)|\nu(u)-\nu(v)|. \tag{2.23}$$

LEMMA 2.5 (properties of the anisotropy and the AMC form $\mathcal{A}$). *Let $u, v \in H^{1,\infty}(\Omega)$. Then*

$$\mathcal{A}(v, u-v) \ge \mathcal{I}_\gamma(u) - \mathcal{I}_\gamma(v) - \bar{\gamma}\int_\Omega |\nu(u)-\nu(v)|^2 Q(u), \tag{2.24}$$

where

$$\bar{\gamma} := \frac{1}{\sqrt{5}-1} \max\left\{ \sup_{|p|=1} |\gamma'(p)|, \sup_{|p|=1} |\gamma''(p)| \right\}. \tag{2.25}$$

If in addition $|\nabla u| \leq K$ *a.e. in* Ω*, then*

$$|\mathcal{A}(u,\eta) - \mathcal{A}(v,\eta)| \leq C(\gamma, K) \int_\Omega |\nu(u) - \nu(v)||\nabla\eta|. \tag{2.26}$$

Proof. The first inequality follows from the estimate

$$\sum_{i=1}^{n} \gamma_{p_i}(\nu(v))(u-v)_{x_i} \geq \gamma(\nu(u))Q(u) - \gamma(\nu(v))Q(v) - \bar{\gamma}|\nu(u) - \nu(v)|^2 Q(u) \tag{2.27}$$

which is contained in the proof of Theorem 3.1 in [11, p. 430]. Let us next turn to (2.26). Lemma 6.1 in [11] implies that there exists $c_0 = c_0(K) > 0$ such that

$$|s\nu(u) + (1-s)\nu(v)| \geq c_0 \quad \text{a.e. in } \Omega \quad \forall\, s \in [0,1]. \tag{2.28}$$

Note that c_0 is independent of v. As a consequence,

$$\begin{aligned} |\gamma_{p_i}(\nu(u)) - \gamma_{p_i}(\nu(v))| &= \left| \sum_{j=1}^{n+1} \int_0^1 \gamma_{p_i p_j}(s\nu(u) + (1-s)\nu(v)) ds (\nu_j(u) - \nu_j(v)) \right| \\ &\leq \frac{1}{c_0} \max_{|p|=1} |D^2\gamma(p)||\nu(u) - \nu(v)| \leq C(\gamma, K)|\nu(u) - \nu(v)|, \end{aligned}$$

since $D^2\gamma$ is positively homogeneous of degree -1. This yields (2.26). □

LEMMA 2.6 (properties of the LB form $\mathcal{E}$). *Let* $u, v \in H^{1,\infty}(\Omega)$*. Then*

$$|\mathcal{E}(u; w, \eta)| \leq \mathcal{E}(u; w, w)^{\frac{1}{2}} \mathcal{E}(u; \eta, \eta)^{\frac{1}{2}}. \tag{2.29}$$

If in addition $|\nabla u| \leq K$ *a.e. in* Ω*, then*

$$\mathcal{E}(v; u-v, u-v) \leq C(K) \int_\Omega |\nu(u) - \nu(v)|^2 Q(v), \tag{2.30}$$

$$|\mathcal{E}(u; \eta_1, \eta_2) - \mathcal{E}(v; \eta_1, \eta_2)| \leq C(K)\|\nabla\eta_1\|_\infty \int_\Omega |\nu(u) - \nu(v)||\nabla\eta_2|Q(v), \tag{2.31}$$

$$\begin{aligned} |\mathcal{E}(u; \eta_1, \eta_2) - \mathcal{E}(v; \eta_1, \eta_2)| &\leq \epsilon\mathcal{E}(v; \eta_1, \eta_1) \\ &\quad + \frac{C(K)}{\epsilon} \|\nabla\eta_2\|_\infty^2 \int_\Omega |\nu(u) - \nu(v)|^2 Q(v). \end{aligned} \tag{2.32}$$

Proof. Using (2.3) together with Young's inequality we have

$$\begin{aligned} |\mathcal{E}(u; w, \eta)| &= \left| \int_\Omega \langle P(\nu(u))D\bar{w}, D\bar{\eta}\rangle Q(u) \right| \\ &\leq \int_\Omega \langle P(\nu(u))D\bar{w}, D\bar{w}\rangle^{\frac{1}{2}} \langle P(\nu(u))D\bar{\eta}, D\bar{\eta}\rangle^{\frac{1}{2}} Q(u) \\ &\leq \mathcal{E}(u; w, w)^{\frac{1}{2}} \mathcal{E}(u; \eta, \eta)^{\frac{1}{2}}. \end{aligned}$$

Next, observing that $(\nabla(u-v),0) = Q(u)\nu(u) - Q(v)\nu(v)$ we obtain

$$\begin{aligned}
&\langle P(\nu(v))(\nabla(u-v),0),(\nabla(u-v),0)\rangle \\
&\quad = \langle (I-(\nu(v)\otimes\nu(v)))(Q(u)\nu(u)-Q(v)\nu(v)),(Q(u)\nu(u)-Q(v)\nu(v))\rangle \\
&\quad = Q(u)^2(1-\langle\nu(u),\nu(v)\rangle^2) = Q(u)^2(1-\langle\nu(u),\nu(v)\rangle)(1+\langle\nu(u),\nu(v)\rangle) \\
&\quad \le Q(u)^2|\nu(u)-\nu(v)|^2,
\end{aligned}$$

since $1-\langle\nu(u),\nu(v)\rangle = \frac{1}{2}|\nu(u)-\nu(v)|^2$. Multiplication of the above inequality by $Q(v)$ followed by integration over Ω yields (2.30). From the definition of $P(\nu(u))$ and (2.23) we infer

$$|P(\nu(u))Q(u) - P(\nu(v))Q(v)| \le C(K)|\nu(u)-\nu(v)|Q(v),$$

which implies (2.31). Finally, writing $D\bar\eta = (\nabla\eta,0)$ and using (2.23) as well as (2.4) we have

$$\begin{aligned}
|\mathcal{E}(u;\eta_1,\eta_2) - \mathcal{E}(v;\eta_1,\eta_2)| &\le \int_\Omega |\langle P(\nu(v))D\bar\eta_1, D\bar\eta_2\rangle||Q(v)-Q(u)| \\
&\quad + \int_\Omega |\langle (P(\nu(v)) - P(\nu(u)))D\bar\eta_1, D\bar\eta_2\rangle|Q(u) \\
&\le \int_\Omega \langle P(\nu(v))D\bar\eta_1, D\bar\eta_1\rangle^{\frac{1}{2}}\langle P(\nu(v))D\bar\eta_2, D\bar\eta_2\rangle^{\frac{1}{2}}|\nu(u)-\nu(v)|Q(u)Q(v) \\
&\quad + C(K)\int_\Omega |\nu(u)-\nu(v)|\sqrt{Q(v)}\frac{|\nabla\eta_1|}{\sqrt{Q(v)}}|\nabla\eta_2| \\
&\le \epsilon\mathcal{E}(v;\eta_1,\eta_1) + \frac{C(K)}{\epsilon}\|\nabla\eta_2\|_\infty^2\int_\Omega |\nu(u)-\nu(v)|^2Q(v).
\end{aligned}$$

This concludes the proof of (2.32). □

Remark 2.7. We note that inequalities (2.30) and (2.32) were proved in [1] as Lemmas 4.7 and 4.5, respectively. The argument used above, employing the projection P, is more direct and slightly simpler than the one used in [1] in that it avoids the splitting of Ω into subsets.

LEMMA 2.8. *Let $u,v \in H^{1,\infty}(\Omega)$ with $|\nabla u| \le K$ a.e. in Ω. There exists a constant $c_1 > 0$ which depends only on K and γ_0 from* (2.9) *such that for*

$$D := \int_\Omega (\gamma(\nu(v)) - \langle\gamma'(\nu(u)),\nu(v)\rangle)Q(v)$$

we have

$$D \ge c_1\int_\Omega |\nu(u)-\nu(v)|^2Q(v).$$

Proof. This is just a reformulation of Lemma 3.2 in [9]. □

3. Discretization.

3.1. The finite element approximation.

We now turn to the discretization of (2.15), (2.16). Let $\mathcal{T}_h$ be a family of triangulations of Ω with maximum mesh size $h := \max_{\tau\in\mathcal{T}_h}\operatorname{diam}(\tau)$. We suppose that $\bar\Omega$ is the union of the elements of $\mathcal{T}_h$ so that element edges lying on the boundary are curved. Furthermore, we suppose that the triangulation is nondegenerate in the sense that $\max_{\tau\in\mathcal{T}_h}\frac{\operatorname{diam}(\tau)}{\rho_\tau} \le \kappa$, where the constant $\kappa > 0$ is independent of h and ρ_τ denotes the radius of the largest ball which is contained in $\bar{\tau}$. The discrete space is defined by

$$\mathcal{S}^h := \{v_h \in C^0(\bar{\Omega}) \mid v_h \text{ is a linear polynomial on each } \tau \in \mathcal{T}_h\}.$$

There exists an interpolation operator $\Pi^h : H^2(\Omega) \to \mathcal{S}^h$ such that

$$\|v - \Pi^h v\| + h\|\nabla(v - \Pi^h v)\| \le ch^2\|v\|_{H^2(\Omega)} \quad \forall\, v \in H^2(\Omega). \tag{3.1}$$

We are now in position to give a precise formulation of our numerical scheme. Let $\Delta t := \frac{T}{N}$ for an integer N and $t_m := m\Delta t$, $m = 0, \dots, N$. We denote by U^m, W^m the approximations to $u(\cdot, t_m)$ and $w(\cdot, t_m)$, respectively. Furthermore, let

$$\delta_t v^m := \frac{v^{m+1} - v^m}{\Delta t}.$$

In order to formulate a semi-implicit scheme requiring just the solution of linear equations we introduce the following form.

Stabilizing Anisotropic (SA) form,

$$\mathcal{B}(u; v, \eta) := \lambda \mathcal{B}_0(u; v, \eta) + \Delta t \mathcal{E}(u; v, \eta), \tag{3.2}$$

where

$$\mathcal{B}_0(u; v, \eta) := \int_\Omega \frac{\gamma(\nu(u))}{Q(u)} \nabla v \cdot \nabla w dx. \tag{3.3}$$

Remark 3.1. The purpose of the form $\mathcal{B}_0$ is to stabilize $\mathcal{A}$, which will be evaluated at the old time step. The second part in $\mathcal{B}$ is introduced in order to gain control on $\|U^m\|$ (see the proof of Lemma 3.4 below, in particular (3.14) and (3.15)) and the corresponding error in the convergence analysis.

Scheme 3.2. *We seek for each $m \in [1, N]$ a pair $\{U^m, W^m\} \in \mathcal{S}^h \times \mathcal{S}^h$ satisfying for $m \ge 0$*

$$(\delta_t U^m, \eta) + \mathcal{E}(U^m; W^{m+1}, \eta) = 0 \quad \forall\, \eta \in \mathcal{S}^h, \tag{3.4}$$

$$(W^{m+1}, \eta) - \mathcal{A}(U^m, \eta) - \Delta t \mathcal{B}(U^m; \delta_t U^m, \eta) = 0 \quad \forall\, \eta \in \mathcal{S}^h. \tag{3.5}$$

For simplicity we impose the initial condition,

$$U^0 := \Pi^h u_0. \tag{3.6}$$

The scheme does not require W^0. The constant λ is chosen to satisfy

$$\lambda \gamma_{\min} > \bar{\gamma}, \quad \text{where } \gamma_{\min} = \inf_{|p|=1} \gamma(p) > 0 \tag{3.7}$$

in order to ensure stability (see Lemma 3.4 below).

Lemma 3.3 (properties of the SA form $\mathcal{B}$). *Suppose that $u, v \in H^{1,\infty}(\Omega)$. Then*

$$\mathcal{B}(u; v, v) \le \left(\lambda \sup_{|p|=1} \gamma(p) + \Delta t\right) \mathcal{E}(u; v, v). \tag{3.8}$$

If in addition $|\nabla u| \le K$ a.e. in Ω, then

$$\begin{aligned} &|\mathcal{B}(u; \eta_1, \eta_2) - \mathcal{B}(v; \eta_1, \eta_2)| \\ &\quad \le C\|\nabla \eta_1\|_{L^\infty} \left(\int_\Omega |\nu(u) - \nu(v)||\nabla \eta_2| + \Delta t \int_\Omega |\nu(u) - \nu(v)||\nabla \eta_2| Q(v) \right). \end{aligned} \tag{3.9}$$

Proof. The inequality (3.8) follows immediately from (2.4). Next, if $|\nabla u| \le K$ a.e. in Ω, we deduce from (2.28) that

$$\begin{aligned}&\left|\frac{\gamma(\nu(u))}{Q(u)} - \frac{\gamma(\nu(v))}{Q(v)}\right| \\ &\quad \le \frac{1}{Q(u)}\left|\int_0^1 \langle\gamma'(s\nu(u)+(1-s)\nu(v))ds, \nu(u)-\nu(v)\rangle\right| + C\left|\frac{1}{Q(u)} - \frac{1}{Q(v)}\right| \\ &\quad \le C|\nu(u)-\nu(v)|.\end{aligned}$$

Combining this inequality with (2.31) implies (3.9). □

3.2. Stability.

Lemma 3.4. *Suppose that* (3.7) *holds. Then the unique discrete solution satisfies*

$$\max_{m\in[0,N]} \mathcal{I}_\gamma(U^m) + \Delta t\sum_{k=1}^N \mathcal{E}(U^{k-1}; W^k, W^k) \le C(\gamma, U^0), \tag{3.10}$$

$$\max_{m\in[0,N]} \|U^m\|^2 + \Delta t\sum_{k=1}^N \|W^k\|^2 \le C(\lambda,\gamma,U^0,T). \tag{3.11}$$

Proof. Taking $\eta = \Delta t W^{m+1}$ in (3.4), $\eta = \Delta t\delta_t U^m$ in (3.5) and adding yields

$$\begin{aligned}&\Delta t\mathcal{E}(U^m; W^{m+1}, W^{m+1}) + \mathcal{A}(U^m, U^{m+1}-U^m) \\ &\qquad + (\Delta t)^2\mathcal{B}(U^m; \delta_t U^m, \delta_t U^m) = 0.\end{aligned} \tag{3.12}$$

Lemma 2.5 implies

$$\begin{aligned}\mathcal{A}(U^m, U^{m+1}-U^m) &\ge I_\gamma(U^{m+1}) - I_\gamma(U^m) - \bar\gamma\int_\Omega |\nu(U^{m+1})-\nu(U^m)|^2 Q(U^{m+1}) \\ &\ge I_\gamma(U^{m+1}) - I_\gamma(U^m) - (\Delta t)^2\frac{\bar\gamma}{\gamma_{\min}}\mathcal{B}_0(U^m; \delta_t U^m, \delta_t U^m),\end{aligned}$$

where we have used (2.21). Inserting the above inequality into (3.12) and recalling the definition of $\mathcal{B}$ we infer

$$\begin{aligned}&\mathcal{I}_\gamma(U^{m+1}) - \mathcal{I}_\gamma(U^m) + \Delta t\mathcal{E}(U^m; W^{m+1}, W^{m+1}) \\ &\quad + \left(\lambda - \frac{\bar\gamma}{\gamma_{\min}}\right)(\Delta t)^2\mathcal{B}_0(U^m; \delta_t U^m, \delta_t U^m) + (\Delta t)^3\mathcal{E}(U^m, \delta_t U^m, \delta_t U^m) \le 0.\end{aligned} \tag{3.13}$$

Summation over m yields (3.10) as well as

$$\begin{aligned}&(\Delta t)^2\sum_{m=0}^{N-1}\mathcal{B}_0(U^m; \delta_t U^m, \delta_t U^m) \\ &\qquad + (\Delta t)^3\sum_{m=0}^{N-1}\mathcal{E}(U^m; \delta_t U^m, \delta_t U^m) \le C(\lambda,\gamma,U^0).\end{aligned} \tag{3.14}$$

Next, using $\eta = \Delta t U^{m+1}$ in (3.4) we deduce

$$\begin{aligned}
&\frac{1}{2}\|U^{m+1}\|^2 - \frac{1}{2}\|U^m\|^2 + \frac{1}{2}\|U^{m+1} - U^m\|^2 = \Delta t \mathcal{E}(U^m; W^{m+1}, U^{m+1})\\
&\quad \le \Delta t \mathcal{E}(U^m; W^{m+1}, W^{m+1})^{\frac{1}{2}} \mathcal{E}(U^m; U^{m+1}, U^{m+1})^{\frac{1}{2}}\\
&\quad \le \Delta t \mathcal{E}(U^m; W^{m+1}, W^{m+1})^{\frac{1}{2}} \left(\mathcal{E}(U^m; U^m, U^m)^{\frac{1}{2}} + \Delta t \mathcal{E}(U^m; \delta_t U^m, \delta_t U^m)^{\frac{1}{2}}\right)\\
&\quad \le \Delta t \mathcal{E}(U^m; W^{m+1}, W^{m+1}) + \Delta t \int_\Omega Q(U^m) + (\Delta t)^3 \mathcal{E}(U^m; \delta_t U^m, \delta_t U^m).
\end{aligned} \tag{3.15}$$

Finally, using $\eta = \Delta t W^{m+1}$ in (3.5) we obtain with the help of (2.4) and (3.8) that

$$\begin{aligned}
\Delta t \|W^{m+1}\|^2 &= \Delta t \mathcal{A}(U^m, W^{m+1}) + (\Delta t)^2 \mathcal{B}(U^m; \delta_t U^m, W^{m+1})\\
&\le \Delta t \sup_{|p|=1} |\gamma'(p)| \left(\int_\Omega \frac{|\nabla W^{m+1}|^2}{Q(U^m)}\right)^{\frac{1}{2}} \left(\int_\Omega Q(U^m)\right)^{\frac{1}{2}} \qquad (3.16)\\
&\quad + (\Delta t)^2 \mathcal{B}(U^m; \delta_t U^m, \delta_t U^m)^{\frac{1}{2}} \mathcal{B}(U^m; W^{m+1}, W^{m+1})^{\frac{1}{2}}\\
&\le \Delta t \mathcal{E}(U^m; W^{m+1}, W^{m+1}) + C(\gamma) \Delta t \int_\Omega Q(U^m) \qquad (3.17)\\
&\quad + C(\Delta t)^2 \mathcal{B}(U^m; \delta_t U^m, \delta_t U^m).
\end{aligned}$$

Now (3.11) follows from summing (3.15), (3.16) over m, the inequality $\int_\Omega Q(U^m) \le C(\gamma) I_\gamma(U^m)$, and (3.10), (3.14). □

Remark 3.5. It follows in particular that

$$\max_{m \in [0,N]} \int_\Omega Q(U^m) \le C(\gamma, U^0). \tag{3.18}$$

3.3. Boundary conditions, domain perturbation, and quadrature.

For Neumann boundary conditions it is sufficient for the union of the elements to contain Ω, provided exact quadrature is used. The above analysis can be easily extended to higher order elements. On the other hand, when using piecewise linear elements it is convenient to use a quadrature rule based on mass lumping for the L^2 inner products. The other integrals require just the measure of the regions of integration. In the case of Dirichlet boundary conditions it is necessary either to analyze the effect of domain perturbation in the case of linear finite elements with a polygonal interpolation of Ω or to analyze isoparametric approximations for higher order elements.

4. Error bounds.

We set

$$u^m := u(\cdot, t_m), \qquad w^m := w(\cdot, t_m), \qquad S^m := \delta_t u^m - \partial_t u(\cdot, t_{m+1}).$$

Then we have for the continuous problem the analogue of the discrete scheme,

$$(\delta_t u^m, \eta) + \mathcal{E}(u^{m+1}; w^{m+1}, \eta) = (S^m, \eta) \quad \forall \eta \in H^1(\Omega), \tag{4.1}$$

$$(w^m, \eta) - \mathcal{A}(u^m, \eta) = 0 \quad \forall \eta \in H^1(\Omega). \tag{4.2}$$

It is convenient to introduce the errors

$$e_u^m := u^m - U^m =: \rho_u^m + \theta_u^m, \qquad e_w^m := w^m - W^m := \rho_w^m + \theta_w^m,$$

where

$$\rho_u^m := u^m - \Pi^h u^m, \qquad \rho_w^m := w^m - \Pi^h w^m$$

are the interpolation errors. It is our goal to prove the following error bounds.

Theorem 4.1. *Let (u,w) solve (2.10)–(2.14) and satisfy the regularity $u \in H^{1,\infty}(0,T;H^{2,\infty}(\Omega))$, $u_{tt} \in L^\infty(0,T;H^{1,\infty}(\Omega))$, $w \in H^{1,\infty}(0,T;H^{2,\infty}(\Omega))$, $w_{tt} \in L^2(0,T;L^2(\Omega))$. Suppose also that (3.7) holds. Then there exists $\delta > 0$ such that for $0 < \Delta t \le \delta$*

$$\max_{m\in[0,N]} \left(\|e_u^m\|^2 + \int_\Omega |\nu(u^m) - \nu(U^m)|^2 Q(U^m) \right) \\ + \Delta t \sum_{k=1}^{N} (\|e_w^k\|^2 + \mathcal{E}(U^{k-1}; e_w^k, e_w^k)) \le C(h^2 + (\Delta t)^2),$$

where C and δ depend on γ, Ω, T, λ and the solution u.

The rest of this section will be devoted to the proof of Theorem 4.1. Subtracting (3.4), (3.5) and (4.1), (4.2) yields, for all $\eta \in \mathcal{S}^h$, the error equations

$$(\delta_t e_u^m, \eta) + \mathcal{E}(u^{m+1}; w^{m+1}, \eta) - \mathcal{E}(U^m; W^{m+1}, \eta) = (S^m, \eta), \tag{4.3}$$

$$(e_w^{m+1}, \eta) - \mathcal{A}(u^m, \eta) + \mathcal{A}(U^m, \eta) + \Delta t \mathcal{B}(U^m; \delta_t U^m, \eta) = (w^{m+1} - w^m, \eta). \tag{4.4}$$

4.1. An a priori estimate in the energy norm. The first step is to emulate the energy bounds obtained for the continuous and discrete solutions by testing (4.3) and (4.4) with $e_w^{m+1} - \rho_w^{m+1} \in \mathcal{S}^h$ and $\delta_t e_u^m - \delta_t \rho_u^m \in \mathcal{S}^h$ yielding

$$\begin{aligned}(\delta_t e_u^m, e_w^{m+1}) &+ \mathcal{E}(u^{m+1}; w^{m+1}, e_w^{m+1}) - \mathcal{E}(U^m; W^{m+1}, e_w^{m+1}) \\ &= (\delta_t e_u^m, \rho_w^{m+1}) + \mathcal{E}(u^{m+1}; w^{m+1}, \rho_w^{m+1}) \\ &\quad - \mathcal{E}(U^m; W^{m+1}, \rho_w^{m+1}) + (S^m, e_w^{m+1} - \rho_w^{m+1}),\end{aligned} \tag{4.5}$$

$$\begin{aligned}(e_w^{m+1}, \delta_t e_u^m) &- \mathcal{A}(u^m, \delta_t e_u^m) + \mathcal{A}(U^m, \delta_t e_u^m) + \Delta t \mathcal{B}(U^m; \delta_t U^m, \delta_t e_u^m) \\ &= (e_w^{m+1}, \delta_t \rho_u^m) - \mathcal{A}(u^m, \delta_t \rho_u^m) + \mathcal{A}(U^m, \delta_t \rho_u^m) + \Delta t \mathcal{B}(U^m; \delta_t U^m, \delta_t \rho_u^m) \\ &\quad + \Delta t(\delta_t w^m, \delta_t e_u^m - \delta_t \rho_u^m).\end{aligned} \tag{4.6}$$

Combining these equations and multiplying by Δt yields

$$\begin{aligned}\Delta t(\mathcal{A}(u^m, \delta_t e_u^m) &- \mathcal{A}(U^m, \delta_t e_u^m)) \\ &+ \Delta t(\mathcal{E}(u^{m+1}; w^{m+1}, e_w^{m+1}) - \mathcal{E}(U^m; W^{m+1}, e_w^{m+1})) \\ &+ (\Delta t)^2 \mathcal{B}(U^m; \delta_t e_u^m, \delta_t e_u^m) = \Delta t(\mathcal{A}(u^m, \delta_t \rho_u^m) - \mathcal{A}(U^m, \delta_t \rho_u^m)) \\ &+ \Delta t(\mathcal{E}(u^{m+1}; w^{m+1}, \rho_w^{m+1}) - \mathcal{E}(U^m; W^{m+1}, \rho_w^{m+1})) \\ &+ \Delta t(S^m, e_w^{m+1} - \rho_w^{m+1}) - \Delta t(e_w^{m+1}, \delta_t \rho_u^m) \\ &+ \Delta t(\delta_t e_u^m, \rho_w^{m+1}) - (\Delta t)^2(\delta_t w^m, \delta_t e_u^m - \delta_t \rho_u^m) \\ &+ (\Delta t)^2(\mathcal{B}(U^m; \delta_t u^m, \delta_t e_u^m) - \mathcal{B}(U^m; \delta_t U^m, \delta_t \rho_u^m)) := \sum_{j=1}^{7} R_j^m.\end{aligned} \tag{4.7}$$

The proof of the error bounds is based on estimating the terms on both sides of the above equation. We begin with the left-hand side of (4.7) which we denote by L^m. First we recall the following lemma.

Lemma 4.2. *Let*

$$\mathcal{D}^m := \int_\Omega (\gamma(\nu(U^m)) - \langle \gamma'(\nu(u^m)), \nu(U^m) \rangle) Q(U^m).$$

Then we have for $m \in [0, N-1]$ *and small* Δt

$$\begin{aligned}\Delta t(\mathcal{A}(u^m, \delta_t e_u^m) - \mathcal{A}(U^m, \delta_t e_u^m)) &\geq \mathcal{D}^{m+1} - \mathcal{D}^m \\ &- (\bar{\gamma} + C\Delta t)\int_\Omega \frac{|\nabla(e_u^{m+1} - e_u^m)|^2}{Q(U^m)} \\ &- C\Delta t\left((\Delta t)^2 + \int_\Omega |\nu(u^{m+1}) - \nu(U^{m+1})|^2 Q(U^{m+1})\right).\end{aligned}$$

Proof. See [11, Lemma 4.2]. □

Lemma 4.2 and the definition of $\mathcal{B}_0$ now imply

$$\begin{aligned}&\Delta t(\mathcal{A}(u^m, \delta_t e_u^m) - \mathcal{A}(U^m, \delta_t e_u^m)) \\ &\quad\geq \mathcal{D}^{m+1} - \mathcal{D}^m - (\Delta t)^2\left(\frac{\bar{\gamma}}{\gamma_{\min}} + C\Delta t\right)\mathcal{B}_0(U^m; \delta_t e_u^m, \delta_t e_u^m) \\ &\qquad - C\Delta t\left((\Delta t)^2 + \int_\Omega |\nu(u^{m+1}) - \nu(U^{m+1})|^2 Q(U^{m+1})\right).\end{aligned} \tag{4.8}$$

Next we examine

$$\begin{aligned}&\Delta t(\mathcal{E}(u^{m+1}; w^{m+1}, e_w^{m+1}) - \mathcal{E}(U^m; W^{m+1}, e_w^{m+1})) \\ &\quad= \Delta t\mathcal{E}(U^m; e_w^{m+1}, e_w^{m+1}) + \Delta t(\mathcal{E}(u^{m+1}; w^{m+1}, e_w^{m+1}) - \mathcal{E}(u^m; w^{m+1}, e_w^{m+1})) \\ &\qquad + \Delta t(\mathcal{E}(u^m; w^{m+1}, e_w^{m+1}) - \mathcal{E}(U^m; w^{m+1}, e_w^{m+1})) \\ &\quad=: \alpha_1^m + \alpha_2^m + \alpha_3^m.\end{aligned}$$

We infer from (3.18) and (2.4) that

$$\begin{aligned}|\alpha_2^m| &\leq C(\Delta t)^2\|\nabla w^{m+1}\|_{L^\infty}\int_\Omega |\nabla e_w^{m+1}| \leq C(\Delta t)^2\left(\int_\Omega Q(U^m)\right)^{\frac{1}{2}}\left(\int_\Omega \frac{|\nabla e_w^{m+1}|^2}{Q(U^m)}\right)^{\frac{1}{2}} \\ &\leq \epsilon\Delta t\mathcal{E}(U^m, e_w^{m+1}, e_w^{m+1}) + \frac{C}{\epsilon}(\Delta t)^3.\end{aligned}$$

Furthermore, (2.32) yields

$$|\alpha_3^m| \leq \epsilon\Delta t\mathcal{E}(U^m, e_w^{m+1}, e_w^{m+1}) + \frac{C}{\epsilon}\|\nabla w^{m+1}\|_{L^\infty}^2 \int_\Omega |\nu(u^m) - \nu(U^m)|^2 Q(U^m).$$

Combining (4.8) and the estimates for α_2^m, α_3^m we derive

$$\begin{aligned}L^m &\geq \mathcal{D}^{m+1} - \mathcal{D}^m + (1 - 2\epsilon)\Delta t\mathcal{E}(U^m; e_w^{m+1}, e_w^{m+1}) \\ &\quad + (\Delta t)^2\left(\lambda - \frac{\bar{\gamma}}{\gamma_{\min}} - C\Delta t\right)\mathcal{B}_0(U^m; \delta_t e_u^m, \delta_t e_u^m) + (\Delta t)^3\mathcal{E}(U^m; \delta_t e_u^m, \delta_t e_u^m) \\ &\quad - \frac{C}{\epsilon}\Delta t\Bigg((\Delta t)^2 + \int_\Omega |\nu(u^m) - \nu(U^m)|^2 Q(U^m) \\ &\qquad\qquad + \int_\Omega |\nu(u^{m+1}) - \nu(U^{m+1})|^2 Q(U^{m+1})\Bigg).\end{aligned} \tag{4.9}$$

4.2. L^2-estimates.

In order to proceed and estimate the terms R_j^m on the right-hand side of (4.7), we need to derive bounds on the L^2-norms of e_w^{k+1} and e_u^{k+1}.

LEMMA 4.3. *We have for* $m \in [0, N-1]$

$$\|e_w^{m+1}\|^2 \le \mathcal{E}(U^m; e_w^{m+1}, e_w^{m+1}) + C(\Delta t)^2 \mathcal{B}(U^m; \delta_t e_u^m, \delta_t e_u^m) \\ + C \int_\Omega |\nu(u^m) - \nu(U^m)|^2 Q(U^m) + C(h^2 + (\Delta t)^2).$$

Proof. Inserting $\eta = e_w^{m+1} - \rho_w^{m+1}$ into (4.4) and using (2.26) we infer

$$\begin{aligned} &\|e_w^{m+1}\|^2 \\ &\quad = (e_w^{m+1}, e_w^{m+1} - \rho_w^{m+1}) + (e_w^{m+1}, \rho_w^{m+1}) \\ &\quad = \mathcal{A}(u^m, e_w^{m+1} - \rho_w^{m+1}) - \mathcal{A}(U^m, e_w^{m+1} - \rho_w^{m+1}) \\ &\qquad -\Delta t \mathcal{B}(U^m; \delta_t U^m, e_w^{m+1} - \rho_w^{m+1}) + \Delta t(\delta_t w^m, e_w^{m+1} - \rho_w^{m+1}) \\ &\qquad + (e_w^{m+1}, \rho_w^{m+1}) \le C \int_\Omega |\nu(u^m) - \nu(U^m)|(|\nabla e_w^{m+1}| + |\nabla \rho_w^{m+1}|) \\ &\qquad + \Delta t |\mathcal{B}(U^m; \delta_t U^m, e_w^{m+1} - \rho_w^{m+1})| + C\Delta t(\|e_w^{m+1}\| + \|\rho_w^{m+1}\|) \\ &\qquad + \|e_w^{m+1}\| \|\rho_w^{m+1}\| \le \frac{1}{2}\|e_w^{m+1}\|^2 + \Delta t |\mathcal{B}(U^m; \delta_t U^m, e_w^{m+1} - \rho_w^{m+1})| \\ &\qquad + C((\Delta t)^2 + h^2) + \frac{1}{4}\int_\Omega \frac{|\nabla e_w^{m+1}|^2}{Q(U^m)} + C\int_\Omega |\nu(u^m) - \nu(U^m)|^2 Q(U^m). \end{aligned}$$

It remains to bound the term involving $\mathcal{B}$. Clearly,

$$\begin{aligned} &|\mathcal{B}(U^m; \delta_t U^m, e_w^{m+1})| \\ &\quad \le \mathcal{B}(U^m; \delta_t U^m, \delta_t U^m)^{\frac{1}{2}} \mathcal{B}(U^m; e_w^{m+1}, e_w^{m+1})^{\frac{1}{2}} \\ &\quad \le \left(\mathcal{B}(U^m; \delta_t u^m, \delta_t u^m)^{\frac{1}{2}} + \mathcal{B}(U^m; \delta_t e_u^m, \delta_t e_u^m)^{\frac{1}{2}}\right) \mathcal{B}(U^m; e_w^{m+1}, e_w^{m+1})^{\frac{1}{2}} \\ &\quad \le C\left(\left(\int_\Omega Q(U^m)\right)^{\frac{1}{2}} + \mathcal{B}(U^m; \delta_t e_u^m, \delta_t e_u^m)^{\frac{1}{2}}\right) \mathcal{E}(U^m; e_w^{m+1}, e_w^{m+1})^{\frac{1}{2}}, \end{aligned}$$

by (3.8). Recalling (3.18) we deduce

$$\begin{aligned} &\Delta t |\mathcal{B}(U^m; \delta_t U^m, e_w^{m+1})| \\ &\qquad \le \frac{1}{4}\mathcal{E}(U^m; e_w^{m+1}, e_w^{m+1}) + C((\Delta t)^2 + (\Delta t)^2 \mathcal{B}(U^m; \delta_t e_u^m, \delta_t e_u^m)). \end{aligned}$$

Similarly,

$$\Delta t |\mathcal{B}(U^m; \delta_t U^m, \rho_w^{m+1})| \le C((\Delta t)^2 + h^2) + C(\Delta t)^2 \mathcal{B}(U^m; \delta_t e_u^m, \delta_t e_u^m).$$

If we insert these inequalities into the estimate for $\|e_w^{m+1}\|$ and use (2.4) we arrive at the desired bound. □

LEMMA 4.4. *We have for* $0 \le m \le N$

$$\max_{k \in [0,m]} \|e_u^k\|^2 \le C\left(\Delta t \sum_{k=0}^{m-1} \mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1}) + (\Delta t)^3 \sum_{k=0}^{m-1} \mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k)\right) \\ + C((\Delta t)^2 + h^2) + C\Delta t \sum_{k=0}^{m-1} \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k).$$

Proof. Clearly,

$$\begin{aligned}
&\frac{1}{2}\|e_u^{k+1}\|^2 - \frac{1}{2}\|e_u^k\|^2 + \frac{1}{2}\|e_u^{k+1} - e_u^k\|^2 \\
&\qquad = \Delta t(\delta_t e_u^k, e_u^{k+1}) = \Delta t(\delta_t e_u^k, \theta_u^{k+1}) + \Delta t(\delta_t e_u^k, \rho_u^{k+1}) \\
&\qquad = \Delta t(\mathcal{E}(U^k; W^{k+1}, \theta_u^{k+1}) - \mathcal{E}(u^{k+1}; w^{k+1}, \theta_u^{k+1})) \\
&\qquad\quad + \Delta t(S^k, \theta_u^{k+1}) + \Delta t(\delta_t e_u^k, \rho_u^{k+1}),
\end{aligned} \tag{4.10}$$

where the last inequality follows from (4.3) with the choice $\eta = \Delta t \theta_u^{k+1}$. To begin,

$$\begin{aligned}
&|\mathcal{E}(U^k; W^{k+1}, \theta_u^{k+1}) - \mathcal{E}(u^{k+1}; w^{k+1}, \theta_u^{k+1})| \\
&\quad \le |\mathcal{E}(U^k; e_w^{k+1}, \theta_u^{k+1})| + |\mathcal{E}(U^k; w^{k+1}, \theta_u^{k+1}) - \mathcal{E}(u^k; w^{k+1}, \theta_u^{k+1})| \\
&\qquad + |\mathcal{E}(u^k; w^{k+1}, \theta_u^{k+1}) - \mathcal{E}(u^{k+1}; w^{k+1}, \theta_u^{k+1})| \\
&\quad = I + II + III.
\end{aligned}$$

Before we estimate these terms we first note that (2.30) and (3.18) imply

$$\begin{aligned}
&\mathcal{E}(U^k; \theta_u^{k+1}, \theta_u^{k+1}) \\
&\quad \le 2\mathcal{E}(U^k; e_u^{k+1}, e_u^{k+1}) + 2\mathcal{E}(U^k; \rho_u^{k+1}, \rho_u^{k+1}) \\
&\quad \le 4\mathcal{E}(U^k; e_u^k, e_u^k) + 4(\Delta t)^2\mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k) + C\|\nabla \rho_u^{k+1}\|_{L^\infty}^2 \int_\Omega Q(U^k) \\
&\quad \le C\int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k) + 4(\Delta t)^2\mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k) + Ch^2.
\end{aligned} \tag{4.11}$$

We then infer from (2.29) and (4.11)

$$\begin{aligned}
I &\le \mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1})^{\frac{1}{2}} \mathcal{E}(U^k; \theta_u^{k+1}, \theta_u^{k+1})^{\frac{1}{2}} \le \mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1}) \\
&\quad + C\biggl((\Delta t)^2\mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k) + h^2 + \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k)\biggr).
\end{aligned}$$

Next, (2.32) together with (4.11) implies

$$\begin{aligned}
II &\le \mathcal{E}(U^k; \theta_u^{k+1}, \theta_u^{k+1}) + C\|\nabla w^{k+1}\|_{L^\infty}^2 \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k) \\
&\le C\left((\Delta t)^2\mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k) + h^2 + \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k)\right),
\end{aligned}$$

as well as

$$\begin{aligned}
III &\le \mathcal{E}(U^k; \theta_u^{k+1}, \theta_u^{k+1}) + C\|\nabla w^{k+1}\|_{L^\infty}^2 \int_\Omega |\nu(u^{k+1}) - \nu(u^k)|^2 Q(u^k) \\
&\le C\left((\Delta t)^2\mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k) + (\Delta t)^2 + h^2 + \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k)\right).
\end{aligned}$$

Collecting the above estimates we derive

$$\begin{aligned}
&\Delta t|\mathcal{E}(U^k; W^{k+1}, \theta_u^{k+1}) - \mathcal{E}(u^{k+1}; w^{k+1}, \theta_u^{k+1})| \le \Delta t\mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1}) \\
&\quad + C\Delta t\left((\Delta t)^2\mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k) + (\Delta t)^2 + h^2 + \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k)\right).
\end{aligned}$$

Next,

$$\Delta t|(S^k,\theta_u^{k+1})| \le C(\Delta t)^2(\|e_u^k\| + \|e_u^{k+1}-e_u^k\| + \|\rho_u^{k+1}\|)$$
$$\le \frac{1}{4}\|e_u^{k+1}-e_u^k\|^2 + C\Delta t\|e_u^k\|^2 + C\Delta t((\Delta t)^2+h^4).$$

If we insert the above estimates into (4.10), sum from $k=0$ to $m-1$, and rearrange terms, we obtain

$$\begin{aligned}\frac{1}{2}\|e_u^m\|^2 \le{}& \frac{1}{2}\|e_u^0\|^2 + \Delta t\sum_{k=0}^{m-1}\mathcal{E}(U^k;e_w^{k+1},e_w^{k+1}) + C(\Delta t)^3\sum_{k=0}^{m-1}\mathcal{E}(U^k;\delta_t e_u^k,\delta_t e_u^k)\\ &+ C((\Delta t)^2+h^2) + C\Delta t\sum_{k=0}^{m-1}\int_\Omega |\nu(u^k)-\nu(U^k)|^2 Q(U^k)\\ &+ C\Delta t\sum_{k=0}^{m-1}\|e_u^k\|^2 + \Delta t\sum_{k=0}^{m-1}(\delta_t e_u^k,\rho_u^{k+1}).\end{aligned}$$

Integrating by parts discretely in time we infer

$$\left|\Delta t\sum_{k=0}^{m-1}(\delta_t e_u^k,\rho_u^{k+1})\right| = \left|-\Delta t\sum_{k=0}^{m-1}(e_u^k,\delta_t\rho_u^k) + (e_u^m,\rho_u^m) - (e_u^0,\rho_u^0)\right| \le Ch^2,$$

since $\max_{k\in[0,N]}\|e_u^k\|^2 \le C$ by Lemma 3.4. Thus,

$$\begin{aligned}\|e_u^m\|^2 \le{}& 2\Delta t\sum_{k=0}^{m-1}\mathcal{E}(U^k;e_w^{k+1},e_w^{k+1}) + C(\Delta t)^3\sum_{k=0}^{m-1}\mathcal{E}(U^k;\delta_t e_u^k,\delta_t e_u^k) + C((\Delta t)^2+h^2)\\ &+ C\Delta t\sum_{k=0}^{m-1}\int_\Omega|\nu(u^k)-\nu(U^k)|^2Q(U^k) + C\Delta t\sum_{k=0}^{m-1}\|e_u^k\|^2.\end{aligned}$$

The result now follows with the help of a discrete Gronwall argument. □

4.3. Estimating the right-hand side of (4.7). Invoking (2.26) we obtain

$$\begin{aligned}|R_1^k| &= \Delta t|\mathcal{A}(u^k,\delta_t\rho_u^k) - \mathcal{A}(U^k,\delta_t\rho_u^k)|\\ &\le C\Delta t\int_\Omega|\nu(u^k)-\nu(U^k)||\nabla\delta_t\rho_u^k| \le C\Delta t h\Big(\int_\Omega|\nu(u^k)-\nu(U^k)|^2\Big)^{\frac{1}{2}}\\ &\le C\Delta t h^2 + C\Delta t\int_\Omega|\nu(u^k)-\nu(U^k)|^2Q(U^k).\end{aligned}\tag{4.12}$$

Lemma 2.6 and (3.18) imply

$$
\begin{aligned}
|R_2^k| &\le \Delta t|\mathcal{E}(u^{k+1}; w^{k+1}, \rho_w^{k+1}) - \mathcal{E}(u^k; w^{k+1}, \rho_w^{k+1})| \\
&\quad + \Delta t|\mathcal{E}(u^k; w^{k+1}, \rho_w^{k+1}) - \mathcal{E}(U^k; w^{k+1}, \rho_w^{k+1})| \\
&\quad + \Delta t|\mathcal{E}(U^k; e_w^{k+1}, \rho_w^{k+1})| \le C\Delta t\|\nabla w^{k+1}\|_{L^\infty} \\
&\quad \times\bigg(\int_\Omega |\nu(u^{k+1}) - \nu(u^k)||\nabla \rho_w^{k+1}|Q(u^k) \\
&\qquad + \int_\Omega |\nu(u^k) - \nu(U^k)||\nabla \rho_w^{k+1}|Q(U^k)\bigg) \\
&\quad + \Delta t\mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1})^{\frac{1}{2}}\mathcal{E}(U^k; \rho_w^{k+1}, \rho_w^{k+1})^{\frac{1}{2}} \\
&\le \epsilon\Delta t\mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1}) + \frac{C}{\epsilon}\Delta t((\Delta t)^2 + h^2) \\
&\quad + C\Delta t\int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k).
\end{aligned}
\tag{4.13}
$$

Next, Lemma 4.3 gives

$$
\begin{aligned}
|R_3^k + R_4^k| &\le C(\Delta t)^2(\|e_w^{k+1}\| + \|\rho_w^{k+1}\|) + \Delta t\|e_w^{k+1}\|\|\delta_t \rho_u^k\| \\
&\le \epsilon\Delta t\|e_w^{k+1}\|^2 + \frac{C}{\epsilon}\Delta t((\Delta t)^2 + h^4) \\
&\le \epsilon\Delta t\mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1}) + \epsilon(\Delta t)^3\mathcal{B}(U^k; \delta_t e_u^k, \delta_t e_u^k) \\
&\quad + \epsilon\Delta t\int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k) + \frac{C}{\epsilon}\Delta t((\Delta t)^2 + h^2).
\end{aligned}
\tag{4.14}
$$

Integrating by parts discretely in time yields

$$
\begin{aligned}
\left|\sum_{k=0}^{m-1} R_5^k\right| &= \left|-\Delta t\sum_{k=0}^{m-1}(e_u^k, \delta_t \rho_w^k) + (e_u^m, \rho_w^m) - (e_u^0, \rho_w^0)\right| \\
&\le \epsilon \max_{k\in[0,m]}\|e_u^k\|^2 + \frac{C}{\epsilon}h^4.
\end{aligned}
\tag{4.15}
$$

Similarly,

$$
\begin{aligned}
\left|\sum_{k=0}^{m-1} R_6^k\right| &\le \left|-(\Delta t)^2\sum_{k=0}^{m-1}(\delta_t w^k, \delta_t e_u^k)\right| + (\Delta t)^2\left|\sum_{k=0}^{m-1}(\delta_t w^k, \delta_t \rho_u^k)\right| \\
&\le (\Delta t)^2\Bigg|\sum_{k=1}^{m-1}\left(\frac{w^{k+1} - 2w^k + w^{k-1}}{(\Delta t)^2}, e_u^k\right) \\
&\qquad - \Delta t(\delta_t w^{m-1}, e_u^m) + \Delta t(\delta_t w^0, e_u^0)\Bigg| + Ch^2\Delta t \\
&\le C\Delta t\max_{k\in[0,m]}\|e_u^k\| + Ch^2\Delta t \le \epsilon\max_{k\in[0,m]}\|e_u^k\|^2 + \frac{C}{\epsilon}((\Delta t)^2 + h^4).
\end{aligned}
\tag{4.16}
$$

Finally, let us write

$$
\begin{aligned}
R_7^k &= (\Delta t)^2(\mathcal{B}(U^k; \delta_t u^k, \delta_t e_u^k) - \mathcal{B}(U^k; \delta_t u^k, \delta_t \rho_u^k) + \mathcal{B}(U^k; \delta_t e_u^k, \delta_t \rho_u^k)) \\
&= I + II + III.
\end{aligned}
$$

In view of the definition of $\mathcal{B}$ we have

$$\begin{aligned} I &= (\Delta t)^2 \lambda \int_\Omega \frac{\gamma(\nu(u^k))}{Q(u^k)} \nabla \delta_t u^k \cdot \nabla \delta_t e_u^k \\ &\quad + (\Delta t)^2 \lambda \int_\Omega \left(\frac{\gamma(\nu(U^k))}{Q(U^k)} - \frac{\gamma(\nu(u^k))}{Q(u^k)} \right) \nabla \delta_t u^k \cdot \nabla \delta_t e_u^k \\ &\quad + (\Delta t)^3 \mathcal{E}(U^k; \delta_t u^k, \delta_t e_u^k) = (\Delta t)^2 \lambda (G^k, \nabla \delta_t e_u^k) + I_2 + I_3, \end{aligned}$$

where we have written $G^k := \frac{\gamma(\nu(u^k))}{Q(u^k)} \nabla \delta_t u^k$. We infer from (2.28) and (2.4) that

$$\begin{aligned} |I_2| &\le C(\Delta t)^2 \int_\Omega |\nu(u^k) - \nu(U^k)| |\nabla \delta_t e_u^k| \\ &\le \epsilon (\Delta t)^3 \int_\Omega \frac{|\nabla \delta_t e_u^k|^2}{Q(U^k)} + \frac{C}{\epsilon} \Delta t \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k) \\ &\le \epsilon (\Delta t)^3 \mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k) + \frac{C}{\epsilon} \Delta t \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k). \end{aligned}$$

Furthermore, (2.29) and (3.18) yield

$$|I_3| \le \epsilon (\Delta t)^3 \mathcal{E}(U^k; \delta_t e_u^k, \delta_t e_u^k) + \frac{C}{\epsilon} (\Delta t)^3.$$

Observing that $\mathcal{B}(U^k; \delta_t \rho_u^k, \delta_t \rho_u^k) \le Ch^2$ we finally have

$$\begin{aligned} |II| &\le (\Delta t)^2 \mathcal{B}(U^k; \delta_t u^k, \delta_t u^k)^{\frac{1}{2}} \mathcal{B}(U^k; \delta_t \rho_u^k, \delta_t \rho_u^k)^{\frac{1}{2}} \le C \Delta t ((\Delta t)^2 + h^2), \\ |III| &\le (\Delta t)^2 \mathcal{B}(U^k; \delta_t e_u^k, \delta_t e_u^k)^{\frac{1}{2}} \mathcal{B}(U^k; \delta_t \rho_u^k, \delta_t \rho_u^k)^{\frac{1}{2}} \\ &\le \epsilon (\Delta t)^2 \mathcal{B}(U^k; \delta_t e_u^k, \delta_t e_u^k) + \frac{C}{\epsilon} \Delta t ((\Delta t)^2 + h^2). \end{aligned}$$

Summing the above estimates, integrating the first term in I by parts in time, and taking into account the estimate (which follows from (2.21) and (2.23))

$$\|\nabla e_u^k\|_{L^1} \le \left(\int_\Omega \frac{|\nabla e_u^k|^2}{Q(U^k)} \right)^{\frac{1}{2}} \left(\int_\Omega Q(U^k) \right)^{\frac{1}{2}} \le C \left(\int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k) \right)^{\frac{1}{2}},$$

we derive

$$\begin{aligned} \left| \sum_{k=0}^{m-1} R_7^k \right| &\le \lambda \left| -(\Delta t)^2 \sum_{k=0}^{m-1} (\delta_t G^k, \nabla e_u^k) + \Delta t (G^m, \nabla e_u^m) - \Delta t (G^0, \nabla e_u^0) \right| \\ &\quad + \frac{C}{\epsilon} ((\Delta t)^2 + h^2) + \epsilon (\Delta t)^2 \sum_{k=0}^{m-1} \mathcal{B}(U^k, \delta_t e_u^k, \delta_t e_u^k) \\ &\quad + \frac{C}{\epsilon} \Delta t \sum_{k=0}^{m-1} \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k) \\ &\le \epsilon \int_\Omega |\nu(u^m) - \nu(U^m)|^2 Q(U^m) + \epsilon (\Delta t)^2 \sum_{k=0}^{m-1} \mathcal{B}(U^k, \delta_t e_u^k, \delta_t e_u^k) \\ &\quad + \frac{C}{\epsilon} ((\Delta t)^2 + h^2) + \frac{C}{\epsilon} \Delta t \sum_{k=0}^{m-1} \int_\Omega |\nu(u^k) - \nu(U^k)|^2 Q(U^k). \end{aligned} \tag{4.17}$$

Collecting (4.12)–(4.17) and recalling Lemma 2.8 finally yields

$$\begin{aligned}\left|\sum_{k=0}^{m-1}\sum_{j=1}^{7} R_j^k\right| &\le \epsilon\Delta t\sum_{k=0}^{m-1}\mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1})\\ &\quad + \epsilon(\Delta t)^2\sum_{k=0}^{m-1}\mathcal{B}_0(U^k;\delta_t e_u^k, \delta_t e_u^k) + \epsilon\max_{k\in[0,N]}\|e_u^k\|^2\\ &\quad + \epsilon(\Delta t)^3\sum_{k=0}^{m-1}\mathcal{E}(U^k;\delta_t e_u^k,\delta_t e_u^k) + \frac{C}{\epsilon}((\Delta t)^2+h^2)\\ &\quad + C\Delta t\sum_{k=0}^{m}\mathcal{D}^k + \epsilon\mathcal{D}^m.\end{aligned}\tag{4.18}$$

4.4. Completion of the proof of the error bound. We are now in position to complete the proof of the error estimate. Starting from the relation $\sum_{k=0}^{m-1} L^k = \sum_{k=0}^{m-1}\sum_{j=1}^{7} R_j^k$ and using (4.9) together with (4.18) and Lemma 4.4 we deduce

$$\begin{aligned}&(1-\epsilon)\mathcal{D}^m + (\Delta t)^2\left(\lambda - \frac{\bar\gamma}{\gamma_{\min}} - \epsilon - C\Delta t\right)\sum_{k=0}^{m-1}\mathcal{B}_0(U^k;\delta_t e_u^k,\delta_t e_u^k)\\ &\qquad + (1-C\epsilon)\Delta t\sum_{k=0}^{m-1}\mathcal{E}(U^k; e_w^{k+1}, e_w^{k+1}) + (1-C\epsilon)(\Delta t)^3\sum_{k=0}^{m-1}\mathcal{E}(U^k;\delta_t e_u^k,\delta_t e_u^k)\\ &\quad \le \mathcal{D}^0 + \frac{C}{\epsilon}((\Delta t)^2+h^2) + \frac{C}{\epsilon}\Delta t\sum_{k=0}^{m}\mathcal{D}^k.\end{aligned}$$

It follows from (2.7) that $\mathcal{D}^0 = \int_\Omega(\gamma(\nu(U^0)) - \gamma(\nu(u^0)) - \langle\gamma'(\nu(u^0)), (\nu(U^0)-\nu(u^0))\rangle)Q(U^0)$ so that by Taylor expansion and (2.28) $\mathcal{D}^0 \le Ch^2$. After choosing ϵ and Δt sufficiently small we obtain

$$\begin{aligned}\mathcal{D}^m + \frac{\Delta t}{2}\sum_{k=1}^{m}\mathcal{E}(U^k, e_w^{k+1}, e_w^{k+1}) + c_0(\Delta t)^2\sum_{k=0}^{m-1}\mathcal{B}(U^k;\delta_t e_u^k,\delta_t e_u^k)\\ \le C((\Delta t)^2+h^2) + C\Delta t\sum_{k=0}^{m-1}\mathcal{D}^k.\end{aligned}$$

Gronwall's lemma together with Lemma 2.8 implies that

$$\begin{aligned}\max_{m\in[0,N]}\int_\Omega|\nu(u^m)-\nu(U^m)|^2 Q(U^m) + \Delta t\sum_{k=1}^{N}\mathcal{E}(U^{k-1}, e_w^k, e_w^k)\\ + (\Delta t)^2\sum_{k=0}^{N-1}\mathcal{B}(U^k;\delta_t e_u^k,\delta_t e_u^k) \le C((\Delta t)^2+h^2)\end{aligned}$$

and the remainder of the proof of Theorem 4.1 now follows from Lemmas 4.3 and 4.4.

5. Numerical results.

5.1. The algebraic problem. Let $\{\chi_j\}$ denote the usual nodal basis functions for $\mathcal{S}^h$. Set

$$M_{i,j} = (\chi_i, \chi_j), \qquad E^m_{i,j} = \mathcal{E}(U^m; \chi_i, \chi_j), \qquad B^m_{i,j} = \mathcal{B}(U^m; \chi_i, \chi_j)$$

and

$$F^m_j = -\mathcal{A}(U^m, \chi_j) + \mathcal{B}(U^m; U^m, \chi_j).$$

It follows that the nodal values $\mathbf{U}^{m+1}$, $\mathbf{W}^{m+1}$ solve the linear algebraic system

$$\begin{aligned} \frac{1}{\Delta t} M\mathbf{U}^{m+1} + E^m \mathbf{W}^{m+1} &= \frac{1}{\Delta t} M\mathbf{U}^m, \\ B^m \mathbf{U}^{m+1} - M\mathbf{W}^{m+1} &= \mathbf{F}^m. \end{aligned}$$

Note that the structure of this system is of the same form as that arising in discretizations of the Cahn–Hilliard equation. Eliminating $\mathbf{W}^{m+1}$ by inverting the mass matrix in the second equation leads to the "fourth order" system

$$\frac{1}{\Delta t} M\mathbf{U}^{m+1} + E^m M^{-1} B^m \mathbf{U}^{m+1} = \frac{1}{\Delta t} M\mathbf{U}^m + E^m M^{-1}\mathbf{F}^m. \tag{5.1}$$

In our practical computations we have used mass lumping, so that M becomes a diagonal matrix. Although the system is unsymmetric, both the biconjugate gradient (BICG) and conjugate gradient (CG) methods were used to solve the linear equations. Remarkably, it was discovered that CG converged.

5.2. Convergence tests. We measured the actual error in different norms for several quantities for test problems, for which we know the continuous solutions. For this we have to extend our method to include right-hand sides f and g as indicated in (1.5). The tables contain the errors for the graph $u = u(x,t)$,

$$\begin{aligned} E_{\infty,2,u} &= \max_{m\in[0,N]} \|u^m - U^m\|, \\ E_{\infty,2,\nu} &= \max_{m\in[0,N]} \left(\int_\Omega |\nu(u^m) - \nu(U^m)|^2 Q(U^m) \right)^{\frac{1}{2}}, \end{aligned}$$

and for the curvature $w = w(x,t)$,

$$\begin{aligned} E_{2,2,w} &= \left(\Delta t \sum_{m=0}^{N} \|w^m - W^m\|^2 \right)^{\frac{1}{2}}, \\ E_{2,\mathcal{E},\nabla w} &= \left(\Delta t \sum_{m=0}^{M-1} \mathcal{E}(U^m; w^m - W^m, w^m - W^m) \right)^{\frac{1}{2}}. \end{aligned}$$

These are the errors which were estimated in Theorem 4.1. Additionally we provide the errors

$$E_{\infty,\infty,u} = \max_{m\in[0,N]} \|u^m - U^m\|_{L^\infty}, \qquad E_{\infty,2,\nabla u} = \max_{m\in[0,N]} \|\nabla u^m - \nabla U^m\|.$$

Table 5.1

Errors for the isotropic test problem with $\Delta t = 0.1h$.

h	$E_{\infty,2,u}$	*eoc*	$E_{\infty,2,\nu}$	*eoc*	$E_{2,2,w}$	*eoc*	$E_{2,\mathcal{E},\nabla w}$	*eoc*
1.0	8.495	-	0.4538	-	0.2264	-	5.534	-
0.7368	3.299	3.10	0.1702	3.21	0.6294	-3.35	2.965	2.04
0.4203	0.6255	2.96	0.06580	1.69	0.2343	1.76	1.097	1.77
0.2219	0.1564	2.17	0.03241	1.11	0.06291	2.06	0.4664	1.34
0.1137	0.04360	1.91	0.01622	1.04	0.01597	2.05	0.2234	1.10
0.05754	0.01306	1.77	0.008113	1.02	0.003942	2.05	0.1109	1.03

We also measure the error

$$E_{2,2,\nabla w} = \left(\Delta t \sum_{m=0}^{M-1} \int_\Omega \frac{|\nabla w^m - \nabla W^m|^2}{Q(U^m)} \right)^{\frac{1}{2}},$$

which is bounded from above by $E_{2,\mathcal{E},\nabla w}$. The error in the normal velocity is given by

$$E_{2,2,V} = \left(\Delta t \sum_{m=1}^{N} \int_\Omega (V(u^m) - V(U^m))^2 Q(U^m) \right)^{\frac{1}{2}},$$

where

$$V(u^m) = -\frac{u_t(\cdot, t_m)}{Q(u^m)}, \qquad V(U^m) = -\frac{U^m - U^{m-1}}{\Delta t\, Q(U^m)}.$$

Between two spatial discretization levels with grid sizes h_1 and h_2 we compute the experimental order of convergence

$$eoc(h_1, h_2) = \log \frac{E(h_1)}{E(h_2)} \left(\log \frac{h_1}{h_2} \right)^{-1}$$

for the errors $E(h_1)$ and $E(h_2)$ for each of the error norms.

For isotropic surface diffusion we used the function

$$u(x,t) = \frac{1}{2} \cos(t) \left(1 + |x|^2 - \frac{3}{4}|x|^4 + \frac{1}{6}|x|^6 \right)$$

as continuous solution on the domain $\Omega = \{x \in \mathbb{R}^2 \mid |x| < 1\}$ and on the time interval $[0,T] = [0,1]$. We calculated the right-hand side g from the equation

$$g = V - \Delta_\Gamma \mathcal{H}_\gamma,$$

and used this function as a right-hand side in our algorithm to compute U^m and W^m. We have chosen $\lambda = 1$. In Tables 5.1 and 5.2 we show the results for the time step size $\Delta t = 0.1\,h$ and Tables 5.3 and 5.4 contain the results for $\Delta t = h^2$. The results confirm the theoretical estimates from Theorem 4.1. Obviously the errors $E_{\infty,2,\nu}$ and $E_{\infty,2,\nabla u}$ as well as the errors $E_{2,\mathcal{E},\nabla w}$ and $E_{2,2,\nabla w}$ exhibit the same orders of convergence.

The anisotropic case was tested, see Tables 5.5 and 5.6, with the exact solution

$$u(x,t) = \sqrt{1 - 4t - 4x_1^2 - x_2^2}$$

on the domain $\Omega = \{x \in \mathbb{R}^2 \mid |x| < 0.125\}$ and for $t \in [0, 0.125]$. Domain and time interval have to be relatively small in order to remain in the setting of a graph. As in the isotropic case we have used a right-hand side g, and since u does not satisfy the natural boundary condition, we have extended the concept to include the inhomogeneous Neumann boundary condition $\langle \gamma'(\nabla u, -1), (\nu_{\partial\Omega}, 0)\rangle = c$ for a given

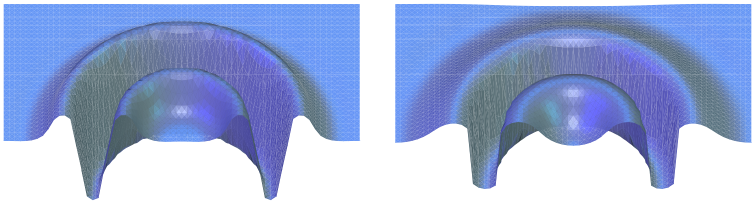

FIG. 5.1. *Initial function which leads to loss of the graph property after short time and solution becoming vertical (cut along the x_1-x_3 plane of symmetry).*

function c on $\partial\Omega$. As anisotropy we have used

$$\gamma(p) = \sqrt{0.25p_1^2 + p_2^2 + p_3^2}$$

and the stabilizing parameter was $\lambda = 1$.

We add an example of a surface which moves under isotropic surface diffusion and which loses its graph property in finite time. Nevertheless the discrete solution exists for all times. In Figure 5.1 two steps of the evolution are shown. In Figure 5.2 the maxima of the moduli of the gradients of the discrete solution is plotted as a function of time. The computational domain is $\Omega = (-1, 1)^2$ and the time interval is $[0, 0.0005]$. The graph of the solution becomes vertical after a short time, but the discrete solution continues to exist. We show the maximal gradient for the discretization levels 9, 10, 11, and 12. Observe that the number $1/h$ is 8.0, 11.32, 16.0, and 22.63 for these levels and by comparison with peaks in the graph of Figure 5.2 we see the suggestion of "infinite" gradients.

5.3. Numerical experiments. We end this section with two illustrative computations. First, we demonstrate the smoothing property of isotropic surface diffusion by choosing a highly oscillatory initial function u_0,

$$u_0(x) = 1 + 0.1\big(\sin(2(m+1)\pi x_1) + \sin(2m\pi x_1)(\sin(2(m+1)\pi x_2) + \sin(2m\pi x_2))\big) \tag{5.2}$$

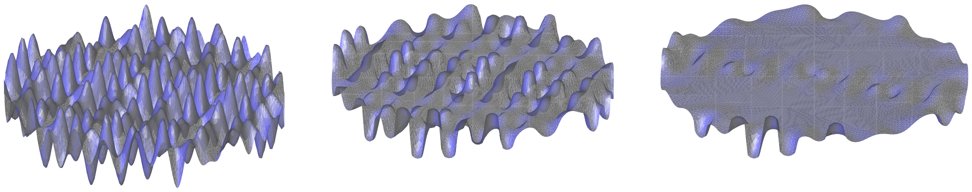

FIG. 5.3. *Solution u for the initial data* (5.2) *at times* 0.0, 3.5×10^{-6}, *and* 6.3×10^{-6}.

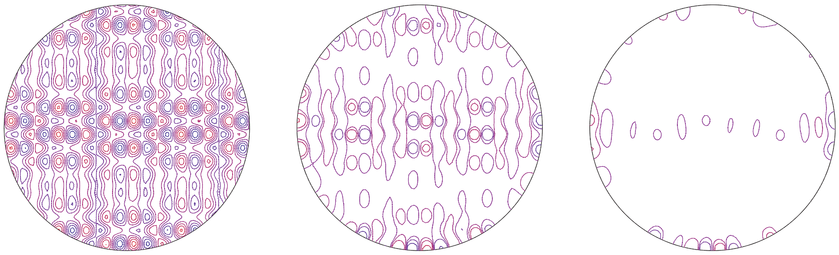

FIG. 5.4. *Level lines of the solution from Figure* 5.3.

with $m = 4$. The computational domain is the unit disk $\Omega = \{x \in \mathbb{R}^2 \mid |x| < 1\}$, and we have used natural boundary conditions. The grid has to be fine in order to capture the frequency of the initial function. In order to show the rapid smoothing of u_0 we have chosen an extremely small time step proportional to h^4. In Figure 5.3 we show the solution at the times 0.0, 7.0×10^{-6} and 1.4×10^{-5}. Figure 5.4 shows level lines of the solution for these time steps. The level lines are equally distributed between the values 0.65 and 1.35 and are the same in all three cases.

Second, we computed an example for anisotropic surface diffusion with an extremely strong anisotropy. The anisotropy is chosen to be a regularized l^1 norm,

$$\gamma(p) = \sum_{j=1}^{3} \sqrt{p_j^2 + \varepsilon^2 |p|^2}, \tag{5.3}$$

where we have chosen $\varepsilon = 10^{-3}$. Thus the Frank diagram is a smoothed octahedron and the Wulff shape is a smoothed cube. The initial data were taken to depend on three random numbers $r_1, r_2, r_3 \in (0, 1)$,

$$\begin{aligned} u_0(x) = {} & \frac{1}{4}\left(\sin(2\pi r_1 x_1) + \frac{1}{4}\sin(3\pi r_2 x_2)\right)(0.1\sin(2\pi r_3 x_1) + \sin(5\pi r_1 x_2)) \\ & \times \sin(2\pi r_2 x_1 x_2). \end{aligned} \tag{5.4}$$

We used Neumann boundary conditions and the right-hand side (for the curvature equation) $f = 1 - x_1^2 - x_2^2$. The domain is given as $\Omega = (-1, 1) \times (-1, 1)$, and the triangulation contains 16641 vertices and 32768 triangles. We chose $\lambda = 4$. In Figure 5.5 we show the graph of the solution u in the direction of the x_1-axis. Figure 5.6 shows the graph for the time steps 0, 50, and 200. The Wulff shape (a smooth cube) appears in the solution as a consequence of the right-hand side f.

NUMERICAL INTEGRATION OF STOCHASTIC DIFFERENTIAL EQUATIONS WITH NONGLOBALLY LIPSCHITZ COEFFICIENTS*

G. N. MILSTEIN†‡ AND M. V. TRETYAKOV‡

Abstract. We propose a new concept which allows us to apply any numerical method of weak approximation to a very broad class of stochastic differential equations (SDEs) with nonglobally Lipschitz coefficients. Following this concept, we discard the approximate trajectories which leave a sufficiently large sphere. We prove that accuracy of any method of weak order p is estimated by $\varepsilon + O(h^p)$, where ε can be made arbitrarily small with increasing radius of the sphere. The results obtained are supported by numerical experiments.

Key words. SDEs with nonglobally Lipschitz coefficients, numerical integration of SDEs in the weak sense

DOI. 10.1137/040612026

1. Introduction.

Stochastic differential equations (SDEs) with nonglobally Lipschitz coefficients possessing unique solutions make up a very important class in applications. For instance, Langevin-type equations and gradient systems with noise belong to this class [10, 9, 1, 5, 11]. At the same time, most numerical methods for SDEs are derived under the global Lipschitz condition [3, 7]. If this condition is violated, the behavior of many standard numerical methods in the whole space can lead to incorrect conclusions (see, for instance, [9, 1, 5, 11, 4]). This situation is very alarming since we are forced to refuse many effective methods and/or to resort to some comparatively complicated and inefficient numerical procedures. In [6] (see also Example 3.3 here), applying an explicit quasi-symplectic method of weak approximation to a Langevin equation with nonglobally Lipschitz coefficients for calculating an ergodic limit, the authors found an explosive behavior of some approximate trajectories. The explosions are observed outside of a comparatively large sphere after a relatively large time and very rarely. Clearly, the exploding approximate trajectories badly reproduce the actual behavior of the considered system. We have also found that if these rare trajectories are discarded, then the explicit quasi-symplectic method gives much better results than the implicit Euler method, which does not have any exploding trajectories. From the heuristic point of view, this is rather natural. Roughly speaking, the value of an ergodic limit depends, on the whole, on the behavior of trajectories in a bounded (though large) domain on a finite (though large) time interval. Consequently, any method that is effective for systems with globally Lipschitz coefficients has to work well for systems with nonglobally Lipschitz coefficients as well if one rejects a small number of "bad" trajectories.

In this paper, we propose a new concept which allows us to apply any method of weak approximation to a very broad class of SDEs with nonglobally Lipschitz coef-

ficients. Roughly speaking, we require for SDEs from this class just to have regular solutions on a time interval $[t_0, T]$ and to have sufficiently smooth coefficients; i.e., the assumptions made (which are given in terms of Lyapunov functions in section 2) usually hold for SDEs of applicable interest. (We note that convergence of the explicit Euler method is proved under more restrictive assumptions in [1].) Following the concept proposed here, we discard the approximate trajectories which leave a sufficiently large sphere $S_R := \{x : |x| < R\}$. The theoretical justification of the concept is given in section 2. We prove that accuracy of any method of weak order p is estimated by $\varepsilon + O(h^p)$, where ε can be made arbitrarily small with growing R, and $|O(h^p)| \leq Kh^p$ can be made arbitrarily small with decreasing h (of course, K depends on R). Thus, we obtain that the violation of the global Lipschitz condition is not fatal for applying any method of numerical integration. Since the Monte Carlo technique is used for simulation of a mean $Ef(X(T))$, the error estimation $\varepsilon + O(h^p)$ should be increased by the Monte Carlo error. It turns out that in practice the error given by ε is much smaller than the joint numerical integration and Monte Carlo error. Furthermore, in principle, due to the concept of rejecting "bad" trajectories, we can choose a suitable method for solving a system of SDEs with nonglobally Lipschitz coefficients, taking into account all the known methods of numerical integration [3, 7]. The application of the concept is discussed in section 3, where some numerical experiments are presented.

An implication of the concept proposed here for the calculation of ergodic limits will be considered in a separate publication.

2. Integration via paths in a bounded domain. Consider the system of Ito SDEs

$$dX = a(t, X)dt + \sum_{l=1}^{q} \sigma_l(t, X)dw_l(t), \qquad X(t_0) = x, \tag{2.1}$$

where X, a, σ_l are d-dimensional column-vectors and $w_l(t)$, $l = 1, \ldots, q$, are independent standard Wiener processes.

We suppose the coefficients of (2.1) to be sufficiently smooth functions in $[t_0, T] \times \mathbf{R}^d$, and any solution $X(t; t_0, x)$ of (2.1) to be regular on $[t_0, T]$. We recall that a process is called regular if it is defined for all $t_0 \leq t \leq T$. Denote by $\mathbf{C}^2$ the class of functions defined on $[t_0, T] \times \mathbf{R}^d$ and twice continuously differentiable with respect to x and once with respect to t. A sufficient condition of regularity (see [2]) consists of the existence of a Lyapunov function $V \in \mathbf{C}^2$, $V \geq 0$, which satisfies the inequality

$$LV(t, x) \leq c_0 V(t, x) + c_1, \qquad (t, x) \in [t_0, T] \times \mathbf{R}^d, \tag{2.2}$$

and

$$V_R := \min_{t_0 \leq t \leq T,\ |x| \geq R} V(t, x), \qquad \lim_{R \to \infty} V_R = \infty, \tag{2.3}$$

where c_0 and c_1 are some constants and L is the following generating operator:

$$LV(t, x) = \frac{\partial V}{\partial t}(t, x) + \sum_{i=1}^{d} a^i(t, x) \frac{\partial V}{\partial x^i}(t, x) + \frac{1}{2} \sum_{i,j=1}^{d} a^{ij}(t, x) \frac{\partial^2 V}{\partial x^i \partial x^j}(t, x), \tag{2.4}$$

$$a^{ij} := \sum_{l=1}^{q} \sigma_l^i \sigma_l^j.$$

Moreover, if (2.2) and (2.3) are fulfilled and if an initial distribution for x (x can be random) is such that $EV(t_0, x)$ exists, then $EV(t, X(t; t_0, x))$ exists for all $t_0 \le t \le T$. For instance, if V has an m-polynomial growth at infinity, then there exist the moments of order m for X. We note that it is not required that c_0 be negative. For definiteness, we consider $c_0 > 0$ and $c_1 > 0$.

Let $S_R := \{x : |x| < R\}$ be an open sphere in $\mathbf{R}^d$, $Q_R = [t_0, T) \times S_R$ be a cylinder in $\mathbf{R}^{d+1}$, $\Gamma_R = \bar{Q}_R \backslash Q_R$, where $\bar{Q}_R$ is the closure of Q_R. The set Γ_R is a part of the boundary of cylinder Q_R consisting of the upper base and the lateral surface. Let τ_R be the first-passage time of the process $(t, X(t; t_0, x))$, $t_0 \le t \le T$, to Γ_R. Clearly, $t_0 \le \tau_R \le T$. We introduce the following events:

$$\begin{aligned} \Omega_R &: = \{\omega : |X(s; t_0, x)| < R,\ t_0 \le s < T\} = \{\omega : \tau_R = T\}, \\ \Lambda_R &: = \{\omega : \exists\ s \in [t_0, T) \ \text{ such that } \ |X(s; t_0, x)| \ge R\} = \{\omega : \tau_R < T\}. \end{aligned} \tag{2.5}$$

Let us obtain an upper bound for the probability

$$p_R := P(\tau_R < T) = P(\Lambda_R), \tag{2.6}$$

assuming (2.2) and (2.3) (see [2]). Introduce the nonnegative function

$$U(t, x) = (c_1 + 1)(T - t) + \exp(c_0(t_0 - t))V(t, x), \tag{2.7}$$

where $V(t, x)$ is a function satisfying (2.2)–(2.3). We get

$$LU(t, x) = -(c_1 + 1) - c_0 \exp(c_0(t_0 - t))V(t, x) + \exp(c_0(t_0 - t))LV(t, x) \le -1. \tag{2.8}$$

Due to the Ito formula, we have

$$\begin{aligned} dU(t, X(t; t_0, x)) &= LU(t, X(t; t_0, x))dt \\ &+ \exp(c_0(t_0 - t)) \sum_{i=1}^{d} \frac{\partial V}{\partial x^i}(t, X(t; t_0, x)) \sum_{l=1}^{q} \sigma_l^i(X(t; t_0, x))dw_l(t). \end{aligned} \tag{2.9}$$

Hence

$$U(\tau_R, X(\tau_R; t_0, x)) - U(t_0, x) = \int_0^{\tau_R} LU dt + \int_0^{\tau_R} \exp(c_0(t_0 - t)) \sum_{i=1}^{d} \frac{\partial V}{\partial x^i} \sum_{l=1}^{q} \sigma_l^i \ dw_l(t). \tag{2.10}$$

The expectation of the second integral on the right-hand side of (2.10) is equal to zero according to the martingale property. Therefore, due to (2.8), we get

$$EU(\tau_R, X(\tau_R; t_0, x)) \le U(t_0, x) = (c_1 + 1)(T - t_0) + V(t_0, x). \tag{2.11}$$

By Chebyshev's inequality, we obtain from (2.11)

$$\begin{aligned} p_R \exp(c_0(t_0 - T)) \min_{t_0 \le t \le T,\ |x| \ge R} V(t, x) &\le p_R \min_{t_0 \le t \le T,\ |x| \ge R} U(t, x) \\ &\le (c_1 + 1)(T - t_0) + V(t_0, x), \end{aligned} \tag{2.12}$$

whence

$$p_R \le \exp(c_0(T-t_0))\frac{(c_1+1)(T-t_0)+V(t_0,x)}{\min_{t_0\le t\le T,\ |x|\ge R} V(t,x)}, \tag{2.13}$$

and therefore

$$\lim_{R\to\infty} p_R = 0.$$

PROPOSITION 2.1. *Let* (2.2) *and* (2.3) *be fulfilled. Let $f(x)$ be a function such that*

$$|f(x)| \le V(t,x), \qquad t_0 \le t \le T,\ x\in \mathbf{R}^d. \tag{2.14}$$

Then for any $x\in R^d$ and $\varepsilon>0$ there exists $R(x,\varepsilon)>0$ such that for any $R>R(x,\varepsilon)$

$$|Ef(X(T;t_0,x)) - E[f(X(T;t_0,x))\chi_{\Omega_R}(\omega)]| < \varepsilon. \tag{2.15}$$

Proof. Clearly,

$$\lim_{R\to\infty} f(X(T;t_0,x))\chi_{\Omega_R}(\omega) = f(X(T;t_0,x)),\ \text{a.s.}$$

Now the conclusion of this proposition follows from the existence of $EV(T,X(T;t_0,x))$ and the Lebesgue theorem on majorized convergence. □

The significance of this proposition consists of the capability to disregard the trajectories running off too far. We are about to show that when systems under consideration are numerically integrated, the approximating trajectories running off too far can also be discarded. Due to this possibility, we are able, in principle, to use any known method of numerical integration for calculating means. In this respect we shall rest on the developed theory of weak approximation for SDEs with globally Lipschitz coefficients [3, 7]. To this aim we introduce an auxiliary system with globally Lipschitz coefficients, which coincides with the original system in a sphere $S_{R'}$ somewhat wider than S_R: $S_{R'}\supset S_R$, where $R'=R+r$ and $r>0$ is a constant.

Let the coefficients a^i, σ^i_l and the function f have continuous derivatives up to some order. The requirement on smoothness depends on a particular numerical method used; in general, the higher the order of the method, the more derivatives are needed. We construct coefficients $a^i_R, (\sigma^i_l)_R$ and function f_R so that in $[t_0,T]\times S_{R'}$ they coincide with a^i, σ^i_l and f, respectively, and, in addition, they are bounded in $[t_0,T]\times\mathbf{R}^d$ together with their derivatives up to the same order. This can be done in the following way. Introduce the function $\varphi(z)$ of one variable z:

$$\varphi(z) = \begin{cases} z, & -R'\le z\le R', \\ R' + \displaystyle\int_{R'}^{z}\frac{dz'}{1+(z'-R')^k}, & z>R', \\ -R' - \displaystyle\int_{z}^{-R'}\frac{dz'}{1+(-R'-z')^k}, & z<-R', \end{cases} \tag{2.16}$$

where $k\ge 2$ is a natural number. Clearly, $\varphi(z)$ is bounded on $\mathbf{R}^1$ together with its derivatives up to order k. Let $g(t,x^1,\dots,x^d)$ be a function with some continuous derivatives defined in $[t_0,T]\times\mathbf{R}^d$. It is easily seen that

$$g_R(t,x^1,\dots,x^d) := g(t,\varphi(x^1),\dots,\varphi(x^d))$$

satisfies the above-mentioned conditions. Moreover, there exists a constant $\rho > r$ (which does not depend on R) such that for any $x = (x^1, \dots, x^d) \in \mathbf{R}^d$ the point $(\varphi(x^1), \dots, \varphi(x^d)) \in S_{R+\rho}$. Therefore

$$\sup_{x\in\mathbf{R}^d} |f_R(x)| \le \max_{|x|\le R+\rho} |f(x)| \,. \tag{2.17}$$

Introduce the auxiliary system of SDEs

$$dX_R = a_R(X_R)dt + \sum_{l=1}^{q} (\sigma_l^i)_R(X_R)dw_l(t) \,. \tag{2.18}$$

We emphasize that this system is used in our theoretical proofs only; it is not used in simulation.

Proposition 2.2. *Assume that* $V(t,x)$ *satisfies* (2.2), (2.3), *and*

$$\frac{\min_{t_0\le t\le T,\ |x|\ge R+\rho} V(t,x)}{\min_{t_0\le t\le T,\ |x|\ge R} V(t,x)} \le c, \tag{2.19}$$

where c *is a constant which is independent of* R. *Let* $f(x)$ *be a function such that*

$$\lim_{R\to\infty} \frac{\max_{|x|\le R} |f(x)|}{\min_{t_0\le t\le T,\ |x|\ge R} V(t,x)} = 0. \tag{2.20}$$

Then for any $x \in R^d$ *and* $\varepsilon > 0$ *there exists* $R(x,\varepsilon) > 0$ *such that for any* $R > R(x,\varepsilon)$

$$|Ef_R(X_R(T;t_0,x)) - Ef(X(T;t_0,x))| < \varepsilon. \tag{2.21}$$

Proof. Since the solutions $X(t;t_0,x)$ and $X_R(t;t_0,x)$ and also the functions $f(X(t;t_0,x))$ and $f_R(X_R(t;t_0,x))$ coincide on the interval $t \in [t_0, \tau_R]$, we have

$$E[f_R(X_R(T;t_0,x))\chi_{\Omega_R}(\omega)] = E[f(X(T;t_0,x))\chi_{\Omega_R}(\omega)]. \tag{2.22}$$

Hence

$$\begin{aligned} &|Ef_R(X_R(T;t_0,x)) - Ef(X(T;t_0,x))| \\ &\le |E[f_R(X_R(T;t_0,x))\chi_{\Lambda_R}(\omega)]| + |E[f(X(T;t_0,x))\chi_{\Lambda_R}(\omega)]|. \end{aligned} \tag{2.23}$$

Proposition 2.1 implies

$$\lim_{R\to\infty} |E[f(X(T;t_0,x))\chi_{\Lambda_R}(\omega)]| = 0. \tag{2.24}$$

Further, due to (2.17) and (2.13), we obtain

$$\begin{aligned} E|f_R(X_R(T;t_0,x))\chi_{\tau_R<T}(\omega)| &\le \sup_{x\in\mathbf{R}^d} |f_R(x)| p_R \le \max_{|x|\le R+\rho} |f(x)| p_R \\ &\le \frac{\max_{|x|\le R+\rho} |f(x)|}{\min_{t_0\le t\le T,\ |x|\ge R+\rho} V(t,x)} \times \frac{\min_{t_0\le t\le T,\ |x|\ge R+\rho} V(t,x)}{\min_{t_0\le t\le T,\ |x|\ge R} V(t,x)} \\ &\quad \times \exp(c_0(T-t_0))[(c_1+1)(T-t_0) + V(t_0,x)]. \end{aligned} \tag{2.25}$$

Now, by using the conditions (2.19) and (2.20), we complete the proof. □

Our next step is to show that approximating paths obtained by a numerical method applied to the system (2.1) belong to the bounded domain with a large probability and that averaging via these paths gives a good approximation for the mean $Ef(X(T;t_0,x))$.

Let us start with some necessary auxiliary knowledge of the Markov chains generated by numerical methods. Consider the system of SDEs in the sense of Ito:

$$dY = b(t,Y)dt + \sum_{l=1}^{q} \gamma_l(t,Y)dw_l(t). \tag{2.26}$$

We assume that the functions $b(t,y)$ and $\gamma_l(t,y),\ (t,y) \in [t_0,T] \times \mathbf{R}^d$, have bounded derivatives with respect to t, y up to some order. In particular, the system (2.18) satisfies this assumption. In most cases a method (both mean-square and weak) can be defined by a one-step approximation of the form

$$\bar{Y}(t+h;t,y) = y + A(t,y,h;\xi), \qquad t_0 \le t < t+h \le T, \tag{2.27}$$

where ξ is a random vector having moments of a sufficiently high order and A is a vector function of dimension d.

Partition the interval $[t_0,T]$ into N equal parts with the step $h = (T-t_0)/N$: $t_0 < t_1 < \cdots < t_N = T$, $t_{k+1} - t_k = h$. According to (2.27), we construct the sequence

$$\bar{Y}_0 = Y(t_0) = y, \quad \bar{Y}_{k+1} = \bar{Y}_k + A(t_k,\bar{Y}_k,h;\xi_k), \qquad k = 0,\ldots,N-1, \tag{2.28}$$

where ξ_0 is independent of $\bar{Y}_0$, while ξ_k for $k > 0$ are independent of $\bar{Y}_0,\ldots,\bar{Y}_k$, $\xi_0,\ldots,\xi_{k-1}$. The sequence $\bar{Y}_k$ is a Markov chain. Its transition probability function is defined by

$$P(t,y,s,D) = P(\bar{Y}(s;t,y) \in D), \qquad s \ge t,\ t,s = t_0, t_0+h,\ldots,T, \tag{2.29}$$

where $\bar{Y}(s;t,y)$ is the process with discrete time starting at the moment t from y and defined by (2.28). The generating operator of the Markov chain is defined by

$$\begin{aligned} L_h U(t,y) &= \frac{1}{h}\int P(t,y,t+h,dz)[U(t+h,z) - U(t,y)] \\ &= \frac{1}{h}[EU(t+h,\bar{Y}(t+h;t,y)) - U(t,y)]. \end{aligned} \tag{2.30}$$

Denote by $\bar{\tau}_R$ the first exit time of the process $(t_k, \bar{Y}(t_k;t_0,y))$, $k = 0,\ldots,N$, from $[t_0,T) \times S_R$. Due to (2.30), we have (see [8])

$$EU(\bar{\tau}_R, \bar{Y}(\bar{\tau}_R;t_0,y)) - U(t_0,y) = E\sum_{k=0}^{\kappa-1} L_h U(t_k,\bar{Y}(t_k;t_0,y))h, \tag{2.31}$$

where κ is defined by $t_\kappa = \bar{\tau}_R$.

In what follows we use the following assumption.

(A1) *The one-step approximation* (2.27) *is at least of order two in the weak sense, and the method defined by this approximation converges at least with order one.*

By the definition of weak approximation

$$|EU(t+h,\bar{Y}(t+h;t,y)) - EU(t+h,Y(t+h;t,y))| \le Kh^2, \tag{2.32}$$

where K is a positive constant, provided that y belongs to a compact set. At the same time (see [7])

$$EU(t+h,Y(t+h;t,y)) = U(t,y) + hLU(t,y) + O(h^2), \tag{2.33}$$

where $|O(h^2)| \le Kh^2$ and K is again independent of y belonging to a compact set. Using (2.32) and (2.33), we get

$$|EU(t+h,\bar{Y}(t+h;t,y)) - U(t,y) - hLU(t,y)| \le Kh^2,$$

and then we obtain from (2.30)

$$|L_hU(t,y) - LU(t,y)| \le Kh. \tag{2.34}$$

Let us proceed to the system (2.18). Apply a numerical method of weak order $p \ge 1$ to the systems (2.1) and (2.18). As a result, we obtain two Markov chains $\bar{X}_k$ and $(\bar{X}_R)_k$. For the Markov chain $(\bar{X}_R)_k$ (but not for $\bar{X}_k$) we have for $(t,x) \in [t_0,T] \times S_R$ (see [7])

$$|Ef(X_R(T;t_0,x)) - Ef(\bar{X}_R(T;t_0,x))| \le Kh^p. \tag{2.35}$$

Let L_R be the generating operator for (2.18), and $(L_R)_h$ for $\bar{X}_R$. According to (2.34), we get

$$|(L_R)_hU(t,x) - L_RU(t,x)| \le Kh, \qquad (t,x) \in [t_0,T] \times S_R. \tag{2.36}$$

If $(t,x) \in [t_0,T] \times S_R$, then

$$L_RU(t,x) = LU(t,x). \tag{2.37}$$

Due to (2.8), we obtain that $LU \le -1$. It follows from this inequality together with (2.36) and (2.37) that for all h small enough

$$(L_R)_hU(t,x) \le 0, \qquad (t,x) \in [t_0,T] \times S_R. \tag{2.38}$$

In future we need the following assumption.

(A2) *If $(\bar{X}_R)_i \in S_R$, $i = 0,\dots,k$, then $\bar{X}_k = (\bar{X}_R)_k$, $k \le N$. (Of course, the approximating trajectories are starting from the same point: $\bar{X}_0 = (\bar{X}_R)_0 = x$.)*

The assumption is evidently true, for instance, for the explicit Euler method. Moreover, for this method even $\bar{X}_{k+1} = (\bar{X}_R)_{k+1}$ if only $\bar{X}_k = (\bar{X}_R)_k \in S_R$, though $\bar{X}_{k+1}$ may not belong to S_R. The definition of φ (see (2.16)) ensures coincidence of the coefficients of (2.1) and (2.18) in the wider domain S_{R+r}. Due to this fact, (A2) is fulfilled for h small enough if ξ_k are bounded. This is the most typical case for weak methods, while, applying mean-square methods, we can use random variables such that $\xi_k h^{1/2}$ are small if h is small (see [7]). Thus, the condition (A2) is fulfilled for typical mean-square methods as well. Nevertheless, we should pay attention that a method of the type (2.27) with initial data from $[t_0,T] \times S_R$ may depend on behavior of a system's coefficients not only in $[t_0,T] \times S_{R+r}$ but, generally speaking, in $[t_0,T] \times \mathbf{R}^d$.

Let us take h ensuring (2.38). Denote by $\bar{\tau}_R$ the first exit time of the chain $(t_k, \bar{X}_R(t_k;t_0,x))$ from $[t_0,T) \times S_R$, i.e., $\bar{X}_R(t_k;t_0,x) \in S_R$, $k = 0,1,\ldots,\kappa-1$, and either $\bar{X}_R(t_\kappa;t_0,x) = \bar{X}_R(\bar{\tau}_R;t_0,x) \notin S_R$, where $\bar{\tau}_R = t_\kappa$, or $t_\kappa = T$. Applying (2.31) to $\bar{X}_R$ and using (2.38), we obtain

$$EU(\bar{\tau}_R, \bar{X}_R(\bar{\tau}_R;t_0,x)) \le U(t_0,x) = (c_1+1)(T-t_0) + V(t_0,x). \tag{2.39}$$

Introduce the events

$$\begin{aligned} \tilde{\Omega}_R \; :&= \{\omega : |\bar{X}_R(t_k;t_0,x)| < R,\ k = 0,\ldots,N-1, \ \text{ and } \ |\bar{X}_R(T;t_0,x)| \le R\} \\ &= \{\omega : (\bar{\tau}_R = T) \setminus \big((\bar{\tau}_R = T) \cap \big(|\bar{X}_R(T;t_0,x)| > R\big)\big)\}, \\ \tilde{\Lambda}_R \; :&= \{\omega : (\exists\ t_k,\ k = 0,\ldots,N-1, \ \text{ such that} \\ &\qquad |\bar{X}_R(t_k;t_0,x)| \ge R) \cup (|\bar{X}_R(T;t_0,x)| > R)\} \\ &= \{\omega : (\bar{\tau}_R < T) \cup \big((\bar{\tau}_R = T) \cap \big(|\bar{X}_R(T;t_0,x)| > R\big)\big)\}. \end{aligned} \tag{2.40}$$

The event $\tilde{\Lambda}_R$ consists of leaving S_R by $\bar{X}_R$ at one of the moments $t_0,\ldots,t_{N-1}$ or leaving $\bar{S}_R$ at $t_N = T$. We note that in the continuous case (see (2.5)) the set $(\tau_R = T) \cap (|X_R(T;t_0,x)| > R)$ is empty.

Let

$$\bar{p}_R = P(\tilde{\Lambda}_R).$$

Analogously to (2.12) and (2.13), we apply Chebyshev's inequality and obtain from (2.39)

$$\bar{p}_R \le \exp(c_0(T-t_0)) \frac{(c_1+1)(T-t_0) + V(t_0,x)}{\min_{t_0 \le t \le T,\ |x| \ge R} V(t,x)}. \tag{2.41}$$

Further, analogously to (2.25), we obtain

$$E|f_R(\bar{X}_R(T;t_0,x))\chi_{\tilde{\Lambda}_R}(\omega)| \le \max_{|x| \le R+\rho} |f(x)|\bar{p}_R. \tag{2.42}$$

We see from the two last inequalities that the expectation $E|f_R(\bar{X}_R(T;t_0,x))\chi_{\tilde{\Lambda}_R}(\omega)|$ is as small as $E|f_R(X_R(T;t_0,x))\chi_{\tilde{\Lambda}_R}(\omega)|$ (cf. (2.25)) if only h ensures (2.38).

THEOREM 2.3. *Consider any method satisfying* (A1) *which is weakly convergent with order* p *for systems with sufficiently smooth and bounded derivatives up to some order. Let the conditions of Propositions* 2.1 *and* 2.2 *and the assumption* (A2) *be fulfilled. Then for any* $x \in R^d$ *and* $\varepsilon > 0$ *there exists* $R(x,\varepsilon) > 0$ *such that for all* $R \ge R(x,\varepsilon)$ *and sufficiently small* h

$$|Ef(X(T;t_0,x)) - E[f(\bar{X}(T;t_0,x))\chi_{\tilde{\Omega}_R}(\omega)]| \le Kh^p + \varepsilon, \tag{2.43}$$

where $K > 0$ *depends on* x *and* R.

Proof. It has been proved (see Proposition 2.2) that for any $\varepsilon > 0$

$$|Ef(X(T;t_0,x)) - Ef_R(X_R(T;t_0,x))| \le \frac{\varepsilon}{2} \tag{2.44}$$

if R is sufficiently large.

Since the coefficients of system (2.18) and the function f_R can be taken so that they have bounded derivatives up to a sufficiently high order, the mentioned method gives for sufficiently small h (see [7])

$$|Ef_R(X_R(T;t_0,x)) - Ef_R(\bar{X}_R(T;t_0,x))| \le Kh^p. \tag{2.45}$$

Let us choose $R(x,\varepsilon)$ so that for $R \geq R(x,\varepsilon)$ and sufficiently small h both inequality (2.44) and inequality

$$E|f_R(\bar{X}_R(T;t_0,x))\chi_{\tilde{\Lambda}_R}(\omega)| \leq \frac{\varepsilon}{2} \tag{2.46}$$

(see (2.41) and (2.42)) are fulfilled.

Since the assumption (A2) holds, $f_R(x) = f(x)$ for $x \in S_R$, and $\bar{X}_R = \bar{X}$ for $\omega \in \tilde{\Omega}_R$, we get

$$\begin{aligned} Ef_R(\bar{X}_R(T;t_0,x)) &= E[f_R(\bar{X}_R(T;t_0,x))\chi_{\tilde{\Omega}_R}(\omega)] + E[f_R(\bar{X}_R(T;t_0,x))\chi_{\tilde{\Lambda}_R}(\omega)] \\ &= E[f(\bar{X}(T;t_0,x))\chi_{\tilde{\Omega}_R}(\omega)] + E[f_R(\bar{X}_R(T;t_0,x))\chi_{\tilde{\Lambda}_R}(\omega)]. \end{aligned} \tag{2.47}$$

Inequality (2.43) follows from (2.44)–(2.47). Theorem 2.3 is proved. □

Remark 2.1. If a method for a particular stochastic system converges, then K in (2.43) is bounded for all R (and ε). However, as was discussed in the Introduction, a method applied to SDEs with nonglobally Lipschitz coefficients can be divergent. It is obvious that in this case K goes to infinity as $R \to \infty$ ($\varepsilon \to 0$). In practice (see, e.g., our experiments and also a comment on the choice of R in section 3), for a not too big R (and, consequently, not large K) the ε is negligibly small since the divergence is usually due to rare exploding approximate trajectories which have to be discarded. This concept of rejecting exploding trajectories is very practical; it allows us, in particular, to guarantee the accuracy of numerical results obtained even by "divergent" methods. We emphasize that the value of K depends on the choice of a numerical method, as is usual in the global Lipschitz case. Thanks to the above concept, we can exploit the whole arsenal of methods [3, 7] and choose an appropriate scheme depending on the system we are solving.

Remark 2.2. It is possible to prove that the proposed concept is also applicable in the case of the Talay–Tubaro extrapolation [12, 7]; i.e., for a sufficiently large R and all sufficiently small h the error can be expanded in powers of h:

$$\begin{aligned} &Ef(X(T;t_0,x)) - E[f(\bar{X}(T;t_0,x))\chi_{\tilde{\Omega}_R}(\omega)] \\ &\quad = \rho(R,h) + C_0h^p + \cdots + C_nh^{p+n} + O(h^{p+n+1})\,, \end{aligned} \tag{2.48}$$

where the constants $C_0,\dots,C_n$ are independent of h and $\rho(R,h) \to 0$ as $R \to \infty$ uniformly with respect to h.

Due to Remark 2.1, ρ is negligibly small for a fixed R in comparison with the term $O(h^{p+n+1})$ (for realistic, not too small h, of course). Therefore it can be supposed that $|\rho| \leq Ch^{p+n+1}$, where C is a positive constant. Then we can use (2.48) in practice to estimate the global error as well as to improve the accuracy of the method [12, 7]. For example, simulating $u = Ef(X(T;t_0,x))$ twice by a first-order scheme (i.e., $p = 1$) with two different time steps $h_1 = h$, $h_2 = \alpha h$, $\alpha > 0$, $\alpha \neq 1$, we obtain $\bar{u}^{h_1} = E[f(\bar{X}^{h_1}(T;t_0,x))\chi_{\tilde{\Omega}_R}(\omega)]$ and $\bar{u}^{h_2} = E[f(\bar{X}^{h_2}(T;t_0,x))\chi_{\tilde{\Omega}_R}(\omega)]$, respectively. We can expand (see (2.48) with $p = 1$, $n = 0$):

$$u = \bar{u}^{h_1} + C_0h_1 + \delta_1\,, \quad u = \bar{u}^{h_2} + C_0h_2 + \delta_2\,,$$

where $|\delta_i| \leq Ch^2$, $i = 1,2$. Hence C_0 can be estimated as $C_0 \simeq -\frac{\bar{u}^{h_2}-\bar{u}^{h_1}}{h_2-h_1}$, and we get the improved value

$$\bar{u}_{imp} = \bar{u}^{h_1}\frac{h_2}{h_2-h_1} - \bar{u}^{h_2}\frac{h_1}{h_2-h_1}, \qquad u = \bar{u}_{imp} + \delta,$$

where $|\delta| \leq Ch^2$.

Example 2.1. Consider the following system:

$$\begin{aligned} dP &= -\nabla F(Q)dt - \nu P dt + \sum_{l=1}^{n} \sigma_l dw_l(t), \\ dQ &= P dt, \end{aligned} \tag{2.49}$$

where ν is a positive constant and σ_l, $l = 1, \dots, n$, are n-dimensional constant linearly independent vectors. The authors of [5] prove exponential ergodicity of (2.49) assuming that $F \in \mathbf{C}^{\infty}(\mathbf{R}^n, \mathbf{R})$, $F(q) \geq 0$ for all $q \in \mathbf{R}^n$ and that there exist an $\alpha > 0$ and $0 < \beta < 1$ such that

$$\frac{1}{2}(\nabla F(q), q) \geq \beta F(q) + \nu^2 \frac{\beta(2-\beta)}{8(1-\beta)} |q|^2 - \alpha. \tag{2.50}$$

The Lyapunov function

$$\begin{aligned} V(x) = V(p,q) &= \frac{1}{2}|p|^2 + F(q) + \frac{\nu}{2}(p,q) + \frac{\nu^2}{4}|q|^2 + 1 \\ &\geq 1 + \frac{1}{8}|p|^2 + \frac{\nu^2}{12}|q|^2 \end{aligned} \tag{2.51}$$

is used to prove that for any $m \geq 1$ there exist positive $c_m,\ d_m$ such that

$$L[V(x)]^m \leq -c_m [V(x)]^m + d_m. \tag{2.52}$$

The exponential ergodicity means that for any function f with a polynomial growth the following inequality holds:

$$\left| Ef(X(t;0,x)) - \int f(z) d\mu(z) \right| \leq Ce^{-\lambda t}, \tag{2.53}$$

where $C > 0$ and $\lambda > 0$ are some constants. In (2.51)–(2.53), $x := (p,q),\ X := (P,Q)$, and μ is an invariant measure for the Markov process defined by (2.49).

Resting on (2.52), it is not difficult to verify all the assumptions of Theorem 2.3 that concern the system under consideration. Due to (2.53), application of this theorem to calculation of $Ef(X(t;0,x))$ gives an approximate value of the ergodic limit. In [6] (see also Example 3.3 below) a numerical example connected with calculation of an ergodic limit is given.

3. Numerical experiments.

3. Numerical experiments. Theorem 2.3 has the following practical implication for evaluating expectations of functionals of solutions to SDEs. We pick up a numerical method suitable for a stochastic system under consideration. We choose $R > 0$ such that the solution of the stochastic system equipped with some initial data leaves the sphere S_R of the radius R during a fixed time interval with a relatively small probability. In a lot of cases interesting from the applicable point of view (e.g., Langevin-type equations and gradient systems with noise) it is usually not difficult to guess this value of R by physical reasoning. Anyway, we can test the choice of R in practice as explained below. For the chosen R, we select a time step h for the numerical method, which ensures an accuracy appropriate for our purposes. As usual, the choice of time step h_* is appropriate if, by further decrease of the time step, we obtain a result which is close enough to the one obtained with h_*. The expectation of a functional which we are aiming to find is evaluated according to the Monte Carlo technique by running M independent realizations of the numerical solution to the considered system. According to the concept proposed in this paper, the value of the functional corresponding to sample trajectories that left the sphere S_R is set to be zero when counted to the expectation. Finally, we say that the choice of R is appropriate if its increase does not essentially affect the result. We also note that there is Monte Carlo error in this procedure, which is controlled in the standard way by choosing an appropriate M. In practice, the procedure can be modified by assigning a certain value (not zero as we do here) for the trajectories which leave the sphere S_R. This value can be chosen/adjusted in response to experimental results or by physical reasoning.

As we will see in the numerical experiments presented below, the numerical integration and Monte Carlo errors affect accuracy of simulation much more than error due to canceling "bad" trajectories (ε in (2.43)), which is usually negligibly small.

Example 3.1. Consider the stochastic differential equation

$$dX = -X^3 dt + \sigma dw(t), \quad X(0) = X_0. \tag{3.1}$$

It is demonstrated in [5] (see also [9, 11]) that the explicit Euler method for (3.1),

$$X_{k+1} = X_k - X_k^3 h + \sigma \Delta_k w, \qquad \Delta_k w := w(t_{k+1}) - w(t_k), \tag{3.2}$$

can explode.

For test purposes, we evaluate the functional

$$F = \frac{1}{2} E X^2(T) + E \int_0^T X^4(t) dt. \tag{3.3}$$

It can be shown that

$$F = \frac{1}{2}\sigma^2 T.$$

To simulate this functional, we introduce the additional equation

$$dZ = X^4(t) dt, \qquad Z(0) = 0. \tag{3.4}$$

Then

$$F = E\left(\frac{1}{2}X^2(T) + Z(T)\right). \tag{3.5}$$

The solution of (3.4) is approximated as

$$Z_{k+1} = Z_k + X_k^4 h. \tag{3.6}$$

By taking $V(x,z) = x^6 + z^2$, it is not difficult to check that the conditions of Propositions 2.1 and 2.2 are satisfied for the system (3.1), (3.4). Also, the condition (A2) holds for the explicit Euler method (3.2). Then Theorem 2.3 is applicable here; i.e., we can evaluate F from (3.3) by using approximate trajectories $(\bar{X}(t), \bar{Z}(t))$, $0 \le t \le T$, which belong to the ball $\{(x,z) : x^2 + z^2 < R^2\}$. In fact, in the case of functionals like that in (3.3) it is enough to control the paths $\bar{X}(t)$ only; i.e., the following estimate takes place (cf. (2.43)):

$$\left| E\left(\frac{1}{2}X^2(T) + Z(T)\right) - E\left(\frac{1}{2}\bar{X}^2(T) + \bar{Z}(T)\right)\chi_{\tilde{\Omega}_R}(\omega)\right| \le Kh + \varepsilon, \tag{3.7}$$

where $\tilde{\Omega}_R$ is defined by $\bar{\tau}_R$ being the first exit time of $(t, \bar{X}(t))$ from the rectangle $[0,T) \times (-R,R)$. This result is valid thanks to the fact that the right-hand sides of (3.1), (3.4) do not depend on Z. The proof is almost a word-by-word repetition of the proof of Theorem 2.3.

We also consider the weak Euler method:

$$X_{k+1} = X_k - X_k^3 h + \sigma \xi_k \sqrt{h}, \tag{3.8}$$

where ξ_k are i.i.d. (independently and identically distributed) random variables with the law $P(\xi = \pm 1) = 1/2$.

Let us choose a time step $h > 0$ for (3.8) such that

$$|X_0| \le \frac{1}{\sqrt{h}} \quad \text{and} \quad h < \frac{1}{\sigma}\left(1 - \frac{2}{3\sqrt{3}}\right).$$

Then one can directly show that $|X_1| \le \frac{1}{\sqrt{h}}$ and therefore $|X_k| \le \frac{1}{\sqrt{h}}$ for all k. Thus, trajectories of (3.8) do not explode, provided that the above conditions on the step h hold. The authors do not exclude a possibility that methods using bounded random variables (like the weak Euler method (3.8)) can weakly converge in some nonglobally Lipschitz cases. In general this question concerning convergence is rather complicated (see, e.g., the third example below and also [6]) and requires further investigation. We should stress that convergence of methods does not undermine the concept proposed in this paper. Indeed, suppose that a weak method converges but for a not very small time step it may have exploding trajectories; then results obtained with this time step should be disregarded unless this concept is applied. This is well illustrated in our examples. Further, the concept is universal. It allows us to use any numerical method in the nonglobally Lipschitz case straightaway for a very broad class of SDEs, without any additional analysis at all.

In our experiments we simulate F from (3.5) as follows:

$$\bar{F} = \frac{1}{M} \sum_{m=1}^{M} \left(\frac{1}{2} \left[\bar{X}^{(m)}(T) \right]^2 + \bar{Z}^{(m)}(T) \right) \chi_{\tilde{\Omega}_R}(\omega) + \rho_{mc}, \tag{3.9}$$

where M is the number of independent realizations $\bar{X}^{(m)}(T)$, $\bar{Z}^{(m)}(T)$ of $\bar{X}(T)$, $\bar{Z}(T)$ that are found due to a numerical method of our choice. The Monte Carlo error ρ_{mc} has zero bias, and its variance equals

$$Var(\rho_{mc}) = \frac{Var\ \left(\left(\frac{1}{2}\bar{X}^2(T) + \bar{Z}(T) \right) \chi_{\tilde{\Omega}_R}(\omega) \right)}{M}; \tag{3.10}$$

i.e., the simulated

$$\hat{F} := \frac{1}{M} \sum_{m=1}^{M} \left(\frac{1}{2} \left[\bar{X}^{(m)}(T) \right]^2 + \bar{Z}^{(m)}(T) \right) \chi_{\tilde{\Omega}_R}(\omega)$$

belongs to the confidence interval

$$\hat{F} \in (E\bar{F} - c\sqrt{Var(\rho_{mc})}, E\bar{F} + c\sqrt{Var(\rho_{mc})}) \tag{3.11}$$

with the fiducial probability, for example, 0.997 for $c = 3$ and 0.95 for $c = 2$. For definiteness, we set $c = 2$ here.

Table 1

Simulation of (3.1), (3.4) *by the Euler methods* (3.2), (3.6) *and* (3.8), (3.6) *with various time steps h. See the other parameters in the text. The exact value $F = 5$. The "±" reflects the Monte Carlo error only; it does not reflect the error of the methods.*

h	(3.2), (3.6) $\bar{F}$	(3.2), (3.6) Trajectories left $(-R, R)$	(3.8), (3.6) $\bar{F}$
0.25	6.640 ± 0.010	0.03%	5.962 ± 0.006
0.1	5.409 ± 0.007	0%	5.371 ± 0.007
0.02	5.069 ± 0.007	0%	5.073 ± 0.007
0.01	5.032 ± 0.007	0%	5.037 ± 0.007

In Table 1 some results of our numerical experiments are presented. We take $\sigma = 1$, $X_0 = 0$, $M = 400000$, $T = 10$, and $R = 50$. The "±" reflects the Monte Carlo error only; it gives the confidence interval with $c = 2$ (see (3.11)). If our concept were not applied in the case of the Euler method (3.2), (3.6) with $h = 0.25$, then there would be an overflow in computer calculations. We also note in passing that both Euler methods produce quite similar results. Of course, the Euler method (3.2) is computationally more expensive than (3.8) due to the need to simulate Gaussian random variables instead of very simple random variables for (3.8).

Example 3.2. As the second test model, we choose the equation

$$dX = -X \exp(X^2) dt + dw(t), \quad X(0) = X_0, \tag{3.12}$$

and evaluate $EX^2(t)$. See also some experiments and discussion concerning (3.12) in [5].

By taking $V(x) = x^4$, it is easy to check that the conditions of Propositions 2.1 and 2.2 are satisfied for this equation. Therefore Theorem 2.3 is applicable again for methods satisfying the condition (A2). Further, (3.12) is exponentially ergodic, and the second moment evaluated with respect to the invariant measure is equal to 0.2539 up to 4 decimal points (d.p.).

We simulate (3.12) by the explicit Euler method

$$X_{k+1} = X_k - X_k \exp(X_k^2)\, h + \Delta_k w \tag{3.13}$$

on the time interval $[0, 100]$ with $X_0 = 0$. In our numerical experiments we choose $R = 5$ (we note that the force $-x \exp(x^2)$ produces a very sharp "barrier"); the number of independent realizations $M = 400000$, and as the result the Monte Carlo error $2\sqrt{Var(\rho_{mc})} \leq 0.001$. Figure 1 gives the averaged trajectories of $EX^2(t)$ for various time steps h. For $h = 0.2$, there are 356390 trajectories (i.e., 89%) that leave the interval $(-5, 5)$. Obviously, the obtained result cannot be considered reliable, and it is not presented in Figure 1. For $h = 0.1$, we have 36676 trajectories (i.e., 9%) that leave the interval $(-5, 5)$; for $h = 0.05$, 130 trajectories (i.e., 0.03%); and for $h = 0.02$, there are no trajectories out of 400000 that leave the interval $(-5, 5)$. An increase of R has almost no effect on the results. This indicates that our choice of R is appropriate. We see from Figure 1 that for $h = 0.05$ and $h = 0.02$ we obtain a quite good approximation of the ergodic limit. At the same time, we note that if our concept were not applied in this experiment, then the average trajectories for $h = 0.1$ and $h = 0.05$ would blow up. In the case of $h = 0.02$ we have not observed exploding trajectories, but this does not mean that if we continued the experiment further, we would not observe any exploding trajectories that lead to blow-up of the average trajectories. Further, we should note that the weak Euler method (cf. (3.8)) applied

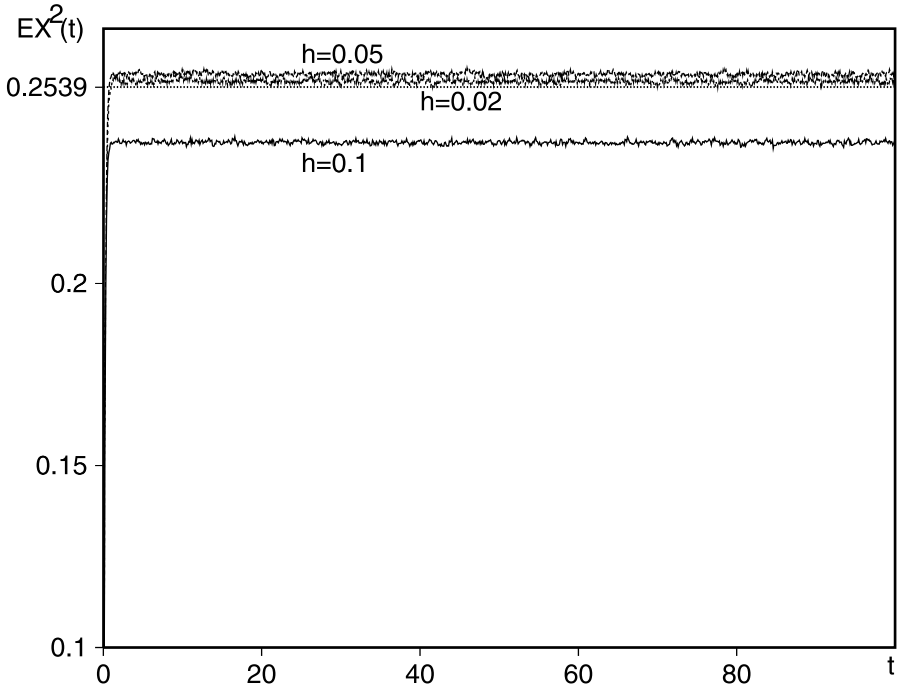

FIG. 1. *Result of simulations of* (3.12) *by the Euler method* (3.13) *with various time steps* h. *We take* $R = 5$; *see the other parameters in the text.*

to (3.12) does not explode even for $h = 0.2$. This can be explained by arguments similar to those used in the first example.

Example 3.3. Consider the oscillator with cubic restoring force and additive noise

$$dQ = Pdt,\qquad dP = \left(Q - Q^3\right)dt - \nu Pdt + \sigma dw(t), \tag{3.14}$$

where $w(t)$ is a standard Wiener process and ν and σ are positive constants. This system is exponentially ergodic, and the second moment EQ^2 evaluated with respect to the invariant measure is equal to 2.435 up to 3 d.p.

The system (3.14) belongs to the class of Langevin equations, for which quasi-symplectic methods are the most effective [6] (see also [7]). We apply an explicit quasi-symplectic method of weak order one to (3.14):

$$P_{k+1} = (1 - \nu h)\left(P_k + h\left(Q_k - Q_k^3\right) + h^{1/2}\sigma\xi_k\right),\qquad Q_{k+1} = Q_k + h\left(P_k + h\left(Q_k - Q_k^3\right)\right), \tag{3.15}$$

where ξ_k are i.i.d. random variables with the law $P(\xi = \pm 1) = 1/2$.

The results of simulating $EQ^2(t)$ by this method are presented in Figure 2. We take the parameters of (3.14) as follows: $Q(0) = P(0) = 0$, $\nu = 0.05$, and $\sigma = 1$. For realization of the proposed concept, we choose $R = 50$. The number of independent realizations M used to produce the picture is equal to 400000, which ensures the Monte Carlo error $2\sqrt{Var(\rho_{mc})} \leq 0.008$. For $h = 0.2$, there are 28 trajectories (i.e., 0.007%) that leave the ball of radius 50. We see that, applying the proposed concept

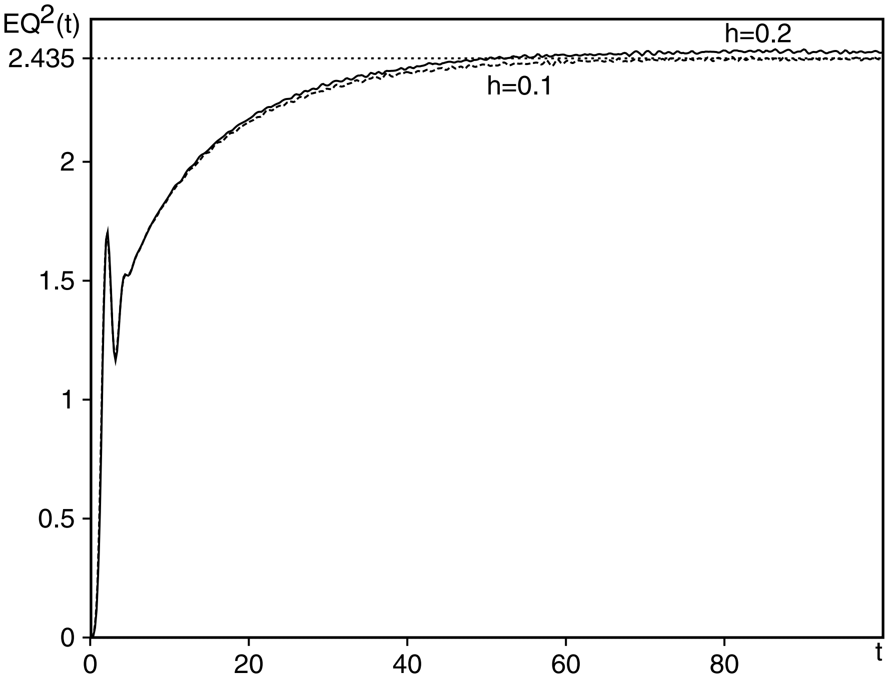

FIG. 2. *Result of simulations of* (3.14) *by the quasi-symplectic method* (3.15) *with various time steps h. We take $R = 50$; see the other parameters in the text.*

(i.e., not taking into account these 28 “bad” trajectories), we obtain a quite accurate approximation of the ergodic limit. If one did not exploit the concept here, then the results obtained with $h = 0.2$ could not be used, since the exploding trajectories lead to numerical overflow in computing the average. For $h = 0.1$, there are no trajectories out of 400000 that leave the ball of radius 50, but this does not exclude the possibility of having exploding trajectories in another series of Monte Carlo runs. Such uncertainty made it uncomfortable to use the results of such experiments before the concept developed in this paper. This concept gives us a rigorous basis for making use of any numerical method to solve nonlinear SDEs and for interpreting experiments in which occurrence of exploding trajectories is not excluded. Some other experiments with the model (3.14) are available in [6] and [5]. We also note that a further development of the concept of rejecting exploding trajectories specifically for calculation of ergodic limits will be addressed in a separate publication.

VARIABLE ACCURACY OF MATRIX-VECTOR PRODUCTS IN PROJECTION METHODS FOR EIGENCOMPUTATION*

V. SIMONCINI†

Abstract. We analyze the behavior of projection-type schemes, such as the Arnoldi and Lanczos methods, for the approximation of a few eigenvalues and eigenvectors of a matrix A, when A cannot be applied exactly but only with a possibly large perturbation. This occurs, for instance, in shift-and-invert procedures or when dealing with large generalized eigenvalue problems. We theoretically show that the accuracy with which A is applied at each iteration can be relaxed, as convergence to specific eigenpairs takes place. We show that the size of the perturbation is allowed to be inversely proportional to the current residual norm, in a way that also depends on the sensitivity of the matrix A. This result provides a complete understanding of reported experimental evidence in the recent literature. Moreover, we adapt our theoretical results to devise a practical relaxation criterion to achieve convergence of the inexact procedure. Numerical experiments validate our analysis.

Key words. eigenvalues, projection methods, Krylov subspaces, inexact methods, Ritz values

1. Introduction.

We are interested in the behavior of projection-type procedures, such as the Arnoldi or Lanczos methods (see, e.g., [18, 2]), for the approximation of a few of the eigenvalues and corresponding eigenvectors in the eigenvalue problem

$$Ax = \lambda x, \quad \|x\| = 1, \tag{1.1}$$

where A is an $n \times n$ non-Hermitian matrix and $\|\cdot\|$ is the Euclidean norm.We focus on the case in which A cannot be applied exactly, but only with a perturbation; that is, at each iteration the operation $y = Av$ is replaced by

$$y = Av + f, \tag{1.2}$$

where f can change at each iteration and $\|f\|$ can be monitored. In general, we expect $\|f\|$ to be much larger than machine precision, so that the standard techniques of round-off error analysis are not appropriate. This is indeed the case when, for instance, shift-and-invert procedures are used to find interior eigenvalues of the given matrix, or when a generalized eigenvalue problem is considered. On large problems, both these procedures require the (approximate) solution of a linear system before applying the matrix A. Finally, inaccurate products occur when the matrix itself is an operator that needs to be estimated each time it is applied. As an alternative to a fixed perturbation tolerance, methods based on shift-and-invert power iterations have for a long time focused on increasing the accuracy as convergence was taking place; see, e.g., [9, 27] and [2, section 11.2] and references therein; see also [29] for a recent analysis of perturbed power iterations. On the other hand, in the context of projection-type methods, more recently the case of *decreasing* accuracy has been considered

[5, 21, 7, 15]. We notice that an analogous problem has received considerable attention in the linear system setting; see, e.g., [4, 6, 32, 22, 25].

An approximate matrix-vector multiplication significantly perturbs the method, but in a way that is apparently far less dramatic than the norm of the perturbation would suggest. A large number of experiments in [5] showed that in many cases convergence towards eigenpairs of A can be achieved despite the fact that $\|f\|$ is allowed to grow as the iteration progresses. In other words, it was shown in [5] that the accuracy with which A is applied at each iteration can be relaxed as convergence takes place. It was argued that the size of the perturbation can be related to the inverse of the residual norm of the current eigenvalue approximation. However, these arguments were not supported by theoretical justifications in [5]; the not always consistent behavior of the methods under the analyzed perturbations did not allow the authors to make conclusive statements as to the reliability of using variable accuracy. We aim to fill this gap in this paper.

The aim of this paper is twofold. First, we provide a theoretical understanding of the experimental evidence reported in [5], together with an analysis of the spectral properties that may influence the inexact process. Then, we adapt our theoretical results to devise a practical relaxation criterion to achieve convergence of the inexact procedure. Assuming that the unperturbed process converges, given an approximate eigenpair (θ, z) obtained by the perturbed process, we will show that the deviation of the computable residual from the true (unobservable) residual $Az - \theta z$ can be kept below a fixed small tolerance. This result will imply that the final attainable true residual will also fall below the required tolerance.

Our analysis of variable accuracy in the matrix-vector products includes both Ritz and harmonic Ritz approximations obtained with the Arnoldi method, as well as Ritz spectral information computed by the Lanczos procedure. Although these methods usually provide different approximation quantities and satisfy different optimality properties (see, e.g., [2]), the analysis of their performance under matrix-vector perturbations can be unified within the presented framework.

In this paper we restrict our analysis to the case when the considered method is not restarted. In practice, projection-type schemes require possibly sophisticated restarting procedures such as *implicit restarting* (see [28] and also [10]), to limit memory requirements while improving the current available approximation. The problem of handling inexactness when some form of restarting is included will be the topic of future research.

The key idea beyond the success of inexact processes is related to an intrinsic property of Krylov subspace methods. Approximations are generated as $V_m u$, where the m columns of the matrix V_m span the Krylov subspace of dimension m, and u is the approximate solution of the projected problem. The perturbations f's affecting the matrix-vector operation in (1.2) at each iteration may be collected as subsequent columns of a "perturbation matrix" F_m. It turns out that the fundamental relation associated with the inexact process formally differs from the unperturbed one by an additional term $F_m u$. Ideally, if one is able to show that the components of u decrease with m—that is, for instance, that the ith component of u goes towards zero as ρ_m^i for some $0 < \rho_m < 1$—then the norm of the corresponding columns of F_m is allowed to grow, that is, larger perturbations are allowed in later iterations, while still yielding a small perturbation term $F_m u$ in norm. As a result, the perturbed fundamental relation remains significantly close to the unperturbed one, and the approximation process does not appear to be influenced. Therefore, given a problem to be solved by means of projection onto a Krylov subspace, the inexact matrix-vector product in (1.2) can be conveniently exploited if one can show that the approximation vector u has a decreasing pattern. Intuitively, a decreasing pattern is associated with a "marginal approximation" property, as the Krylov subspace grows. However, a rigorous treatment of this step is far from obvious. As one may suspect, both the difficulty in proving the existence of this pattern, as well as the constraints under which this pattern does settle down, depend on the possible complexity and nonlinearity of the problem. In the linear system setting, the decreasing pattern of u (in this case the projected system approximate solution) was proved in [22, 32]. In this paper, we solve this problem within eigenvalue computation. We will show that the matrix sensitivity and the nonlinearity of the problem play a crucial role: the conditions under which the pattern arises are different and significantly more stringent than in the linear system setting. Moreover, the analysis becomes even more complex when more than one eigenpair, or more generally an invariant subspace, is sought. Finally, deep results from matrix perturbation theory need to be employed, making the approach and the conclusions of this paper significantly different from what has been done in [22, 32] for linear systems.

In section 2 we show that some of the eigenvectors of the representation matrix of A in the approximation subspace have a decreasing pattern. This key result will be used in section 3 to show that, in the inexact Arnoldi method, the matrix-vector multiplication can be perturbed in a way that is inversely proportional to this pattern. A practical relaxation strategy for the Arnoldi method is proposed in section 3.1 and numerically tested in section 4. Our theoretical results are subsequently applied to related methods that are currently used as alternatives to general Arnoldi and that are based on the same key relations [2]. In particular, we will discuss the inexact harmonic Ritz approximations in section 5, and the inexact Lanczos method in section 6. Finally, section 7 summarizes our results and discusses some related issues.

The following notation will be used throughout. For a vector u, $\bar{u}$ denotes its conjugate, u^* its conjugate transpose, and $\|u\|$ its 2-norm. For a given $k \times k$ matrix T, an eigenpair (λ, u) consists of $\lambda \in \mathbb{C}$ and $u \in \mathbb{C}^k$ such that $Tu = \lambda u$, $\|u\| = 1$. An eigentriple (λ, u, v) of T is such that $Tu = \lambda u$ and $v^*T = \lambda v^*$ such that $\|u\| = 1$ and $v^*u = 1$. Here u indicates a right eigenvector and v a left eigenvector. Moreover, I_k denotes the identity matrix of size k (the subscript is omitted if clear from the context), while e_j is the jth column of the identity matrix of given dimension not smaller than j. Finally, Range(X) is the space generated by the columns of X, while $\Lambda(H)$ is the set of eigenvalues of a square matrix H. Exact precision arithmetic is assumed throughout the paper, and the term inexact refers to an inaccurate computation, whose error is significantly larger than the finite precision arithmetic unit. All experiments were run using MATLAB [11].

2. Bounds for the eigenvector components of the Arnoldi matrix.

2.1. Notation. Starting with a unit norm vector v_1, the Arnoldi method builds a basis V_m for the Krylov subspace $K_m(A, v_1) = \text{span}\{v_1, Av_1, \ldots, A^{m-1}v_1\}$ satisfying the following *Arnoldi relation*:

$$AV_m = V_m H_m + v_{m+1} h_{m+1,m} e_m^* = V_{m+1} \begin{bmatrix} H_m \\ h_{m+1,m} e_m^* \end{bmatrix}, \quad V_{m+1}^* V_{m+1} = I. \tag{2.1}$$

Matrix H_m is an $m \times m$ upper Hessenberg matrix, and it is the orthogonal projection and restriction of the matrix A onto the Krylov subspace. An eigenpair (θ, u) of H_m

defines the Ritz value, θ, and Ritz vector, $V_m u$, which may be used to approximate some of the eigenpairs of A [2, 18]. The accuracy in the approximation is usually monitored by means of some relative quantity involving the residual $r_m = AV_m u - \theta V_m u$; we refer to [2] and its references for a detailed discussion on stopping criteria for eigenvalue solvers. It is also important to recall that for ill-conditioned problems, small residuals do not necessarily imply small errors in the approximate eigenpair [8]; additional care should be taken in this case.

Given the eigenpair (θ, u) and using (2.1), the residual r_m and its norm can be cheaply computed as

$$r_m = v_{m+1} h_{m+1,m}\, e_m^* u, \qquad \|r_m\| = |h_{m+1,m}|\, |e_m^* u|. \tag{2.2}$$

This relation emphasizes that for the residual to be small, at least one of $h_{m+1,m}$ or $|e_m^* u|$ have to be small. In the former case, the Krylov subspace is close to an invariant subspace. On the other hand, a small $|e_m^* u|$ indicates that the mth component of the eigenvector u of H_m is small. No other knowledge of the eigenvector components is commonly employed in the convergence test, although it can be experimentally observed that the absolute values of the components of u tend to exhibit a decreasing pattern if $(\theta, V_m u)$ is a good approximation to an eigenpair of A; see, e.g., [17, 19].

In Proposition 2.2 we will show that there exists a strong relation between the magnitude of the $(k+1)$st component of u and the residual of some Ritz pair after k Arnoldi iterations, with $k < m$. This relation can be derived as a consequence of a general approximation theorem for nonnormal matrices; cf., e.g., [30]. Below we report the result with our notation. To this end, we introduce some definitions. Given an orthogonal basis U for an invariant subspace of a matrix H, and given Y so that $[U, Y]$ is unitary, Range(U) is called a simple invariant subspace of H if the spectra of $U^* H U$ and of $Y^* H Y$ do not intersect; cf. [30, Definition V.1.2]. Moreover, for two square matrices L_1, L_2 with disjoint spectra, the function $\mathrm{sep}(L_1, L_2)$ is defined as (see, e.g., [30, p. 231])

$$\mathrm{sep}(L_1, L_2) := \inf_{\|P\|=1} \|PL_1 - L_2 P\|.$$

The definition holds for $\|\cdot\|$ being any consistent family of norms; in the following we shall use the 2-norm for vectors and the induced 2-norm for matrices. If L_1 is a scalar, then $\mathrm{sep}(L_1, L_2) = \sigma_{\min}(L_2 - L_1 I)$. An analogous relation holds whenever L_2 is a scalar.

Theorem 2.1 (see [30, Theorem V.2.1, p. 230]). *Let $\mathcal{X} = [U, Y]$ be a unitary matrix and let*

$$\mathcal{X}^* H_m \mathcal{X} = \begin{bmatrix} L_1 & K \\ G & L_2 \end{bmatrix}.$$

Set $\gamma = \|G\|$, $\eta = \|K\|$. Assume that L_1 and L_2 have distinct spectra, so that $\delta := \mathrm{sep}(L_1, L_2) > 0$. Then if $\gamma\eta/\delta^2 < \frac{1}{4}$, there is a unique matrix P satisfying $\|P\| < 2\frac{\gamma}{\delta}$ such that the columns of $\widetilde{U} = (U + YP)(I + P^*P)^{-\frac{1}{2}}$ form an orthonormal basis of a simple right invariant subspace of H_m. The representation of the matrix H_m with respect to $\widetilde{U}$ is given by $\widetilde{L}_1 = (I + P^*P)^{\frac{1}{2}}(L_1 + KP)(I + P^*P)^{-\frac{1}{2}}$.

2.2. Spectral properties of the Arnoldi matrix.

We first use the result of Theorem 2.1 in the case of the approximation of one eigenpair, and then generalize it to the approximation of an invariant subspace.

Consider the principal submatrix of H_m of size k, H_k, i.e.,

$$H_m = \left[\begin{array}{cc} H_k & H_\star \\ h_{k+1,k}e_1e_k^* & * \end{array} \right], \quad H_k \in \mathbb{C}^{k\times k}, \tag{2.3}$$

and let $u^{(k)}$ be an eigenvector of H_k. Let Y be a matrix such that the matrix

$$\mathcal{X} = \left[\left[\begin{array}{c} u^{(k)} \\ \underline{0} \end{array} \right], Y \right] \in \mathbb{C}^{m\times m}$$

is unitary, where here and in the following, $\underline{0}$ pads with zeros the bottom part of a vector with a total of m components. Then

$$\underline{H_m} := Y^* H_m Y \in \mathbb{C}^{(m-1)\times(m-1)} \tag{2.4}$$

is the orthogonal projection and restriction of H_m onto the range of Y, the space orthogonal to the space spanned by $[\begin{smallmatrix} u^{(k)} \\ \underline{0} \end{smallmatrix}]$.

Proposition 2.2. *Let $(\theta^{(k)}, u^{(k)})$ be an eigenpair of H_k, $r_k = v_{k+1}h_{k+1,k}e_k^*u^{(k)}$, $\delta_{m,k} = \sigma_{\min}(\underline{H_m} - \theta^{(k)}I) > 0$ with $\underline{H_m}$ defined in* (2.4)*, and $s_m^* = [(u^{(k)})^*, \underline{0}^*]H_m - \theta^{(k)}[(u^{(k)})^*, \underline{0}^*]$. If*

$$\|r_k\| < \frac{\delta_{m,k}^2}{4\|s_m\|}, \tag{2.5}$$

then there exists a unit norm eigenvector $u = [\begin{smallmatrix} u_1 \\ u_2 \end{smallmatrix}]$ of H_m with $u_1 \in \mathbb{C}^k$ such that

$$\|u_2\| \le \frac{\tau}{\sqrt{1+\tau^2}}, \quad \textit{with} \quad \tau \in \mathbb{R}, \quad 0 \le \tau < 2\frac{\|r_k\|}{\delta_{m,k}}. \tag{2.6}$$

Moreover, if θ is the eigenvalue associated with u, we have

$$|\theta - \theta^{(k)}| \le \|s_m\|\tau. \tag{2.7}$$

Proof. Let $Y = [\begin{smallmatrix} Y_1 \\ Y_2 \end{smallmatrix}]$ be such that the matrix $\mathcal{X} = [[\begin{smallmatrix} u^{(k)} \\ \underline{0} \end{smallmatrix}], Y] \in \mathbb{C}^{m\times m}$ is unitary. Note that this implies $Y_1^*u^{(k)} = 0$ and $Y_2Y_2^* = I$. Using (2.3) gives

$$\mathcal{X}^*H_m\mathcal{X} = \left[\begin{array}{cc} \theta^{(k)} & K \\ G & \underline{H_m} \end{array} \right], \qquad \begin{array}{l} G = Y_2^*h_{k+1,k}e_1e_k^*u^{(k)}, \\ K = (u^{(k)})^*\,[H_k, H_\star]\,Y. \end{array}$$

Since Y_2 has orthonormal rows,

$$\gamma := \|G\| = \|Y_2^*h_{k+1,k}e_1e_k^*u^{(k)}\| = |h_{k+1,k}e_k^*u^{(k)}| = \|r_k\|. \tag{2.8}$$

Moreover, since $[(u^{(k)})^*, \underline{0}^*]Y = 0$, $\|K\| = \|[(u^{(k)})^*, \underline{0}^*]\,H_mY\| = \|s_m^*Y\| \le \|s_m\|$. Using Theorem 2.1, if $\frac{\gamma\|s_m\|}{\delta_{m,k}^2} < \frac{1}{4}$, i.e., if (2.5) holds, then there exists a vector $p \in \mathbb{C}^{m-1}$ satisfying

$$\tau := \|p\| < 2\frac{\gamma}{\delta_{m,k}}$$

such that the unit norm vector

$$u = \left[\begin{array}{c} u_1 \\ u_2 \end{array} \right] = \frac{1}{\sqrt{1+\|p\|^2}} \left(\left[\begin{array}{c} u^{(k)} \\ \underline{0} \end{array} \right] + \left[\begin{array}{c} Y_1 \\ Y_2 \end{array} \right] p \right)$$

is an eigenvector of H_m. To complete the proof, we notice that

$$\|u_2\| = \frac{1}{\sqrt{1+\|p\|^2}}\|Y_2 p\| \le \frac{1}{\sqrt{1+\|p\|^2}}\|p\|.$$

The bound for $|\theta - \theta^{(k)}|$ follows from the representation of H_m with respect to u in Theorem 2.1, that is, $|\theta - \theta^{(k)}| = \|Kp\| \le \|K\|\,\|p\| \le \|s_m\|\,\tau$. □

Proposition 2.2 shows that if the residual r_k is sufficiently small, then there exists an eigenvector u of H_m whose last $m-k$ components can be bounded by a quantity involving $\|r_k\|$, and thus they are also small. Each of the last $m-k$ components of u is bounded by $\tau/\sqrt{1+\tau^2}$, and hence

$$|e_j^* u| \le \frac{\tau}{\sqrt{1+\tau^2}} \le \tau \le 2\frac{\|r_k\|}{\delta_{m,k}}, \quad j = k+1,\dots,m. \tag{2.9}$$

The bound (2.9) is most interesting for $j = k+1$. Indeed, Proposition 2.2 can be applied to other principal submatrices of H_m, of size k_1 larger than k. In this case, and if a more accurate Ritz pair is computed with H_{k_1}, the last $m-k_1$ components of the corresponding eigenvector are smaller than those for H_k. In practice, this implies that for k sufficiently large, so that $\|r_k\|$ satisfies (2.5), the last $m-k$ components of u have an almost monotonically decreasing pattern.

It is remarkable that, in our setting, $\|r_k\|$ has a double role. On the one hand, $\|r_k\| = \|G\|$ (cf. (2.8)), which measures the accuracy of

$$\left(\theta^{(k)}, \begin{bmatrix} u^{(k)} \\ \underline{0} \end{bmatrix}\right) \tag{2.10}$$

as an approximate eigenpair of H_m in connection with the general approximation theorem. On the other hand,

$$r_k = v_{k+1}h_{k+1,k}e_k^* u^{(k)} = AV_k u^{(k)} - \theta^{(k)} V_k u^{(k)}$$

is the residual of $(\theta^{(k)}, V_k u^{(k)})$ as approximate eigenpair of A. This double role is what makes our eigenvector component analysis possible.

In Proposition 2.2, s_m is the *left* residual vector of the approximate pair (2.10) of H_m. For nonnormal problems, $\|s_m\|$ is bound not to be small, and in general the estimate $\|s_m\| \approx \|A\|$ can be used.

Remark 2.3. The function $\delta_{m,k}$ provides a condition number of the eigenvector problem [30, p. 241], and it reflects the proximity of $\theta^{(k)}$ to $\underline{H_m}$, although it may be much smaller than the distance between the spectrum of $\underline{H_m}$ and $\theta^{(k)}$ for nonnormal matrices [30, Example 2.4, p. 234]. We notice that if (2.10) is a good approximation to the eigenpair (θ, u) of H_m, then $\delta_{m,k}$ is close to the norm of the reduced resolvent of H_m. These comments will be used when we derive a practical relaxation criterion for the matrix-vector product with A. □

Remark 2.4. Proposition 2.2 states the *existence* of an eigenvector u of H_m satisfying (2.6). On the other hand, we are interested in the characterization of the components of a specific eigenvector u of H_m. To be able to correctly identify the eigenvector determined by Proposition 2.2 as the analyzed vector u, we will need some further hypotheses. In particular, we will require that after k iterations, $\theta^{(k)}$ and $u^{(k)}$ provide sufficiently good approximations to an eigenpair of H_m and of A. Unfortunately this apparently restrictive condition is observed to be required in practice.

In particular, eigenvector components do not exhibit a decreasing pattern until the Ritz pair reaches its final, possibly superlinear, asymptotic convergence rate; see [3] for a discussion on the occurrence of superlinear convergence rates. □

We next generalize our result to the case of an invariant subspace.

PROPOSITION 2.5. *Let the columns of $U^{(k)}$ be an orthonormal basis for a simple invariant subspace of H_k of dimension ℓ, with representation matrix $L^{(k)} = (U^{(k)})^* H_k U^{(k)}$. Let $\delta_{m,k} = \mathrm{sep}(L^{(k)}, L_2) > 0$, $R_k = v_{k+1} h_{k+1,k} e_k^* U^{(k)}$, and $S_m = [(U^{(k)})^*, O^*] H_m - L^{(k)} [(U^{(k)})^*, O^*]$, where O is the $(m-k) \times \ell$ zero matrix. If $\|R_k\| < \frac{\delta_{k,m}^2}{4\|S_m\|}$, then there exists a matrix $U = [\begin{smallmatrix} U_1 \\ U_2 \end{smallmatrix}]$, $U^*U = I$, with $U_1 \in \mathbb{C}^{k \times \ell}$ and whose columns span a simple invariant subspace of H_m, such that*

$$\|U_2\| \leq \frac{\tau}{\sqrt{1+\tau^2}}, \quad \textit{with} \quad \tau \in \mathbb{R}, \quad 0 \leq \tau < 2\frac{\|R_k\|}{\delta_{k,m}}. \tag{2.11}$$

Proof. The proof follows the lines of that of Proposition 2.2. □

The setting of Proposition 2.5 is most appropriate whenever the sought-after eigenvalues form a cluster separated from the rest of the spectrum. Indeed, $\|R_k\|$ is required to be less than $\delta_{m,k}^2 / \|S_m\|$, and $\delta_{m,k}$ may be very small if the whole cluster is not sufficiently well captured by Range$(U^{(k)})$. The result of Proposition 2.5 is particularly helpful when dealing with close to defective eigenvalues, whose eigenvector bases can be very ill-conditioned. The use of invariant subspaces considerably simplifies the analysis [30].

We would also like to comment on the case when H_m, and thus H_k, is tridiagonal. Whenever H_m is tridiagonal, e.g., for Hermitian problems and in the non-Hermitian Lanczos process, the relation between the $(k+1)$st component of an eigenvector of H_m and the residual at step k can be derived directly [20]. However, in the context of inexact matrix-vector multiplication, the resulting matrix H_m is not tridiagonal but upper Hessenberg, even in the inexact Lanczos recurrence (cf. section 6); therefore the more general result is required.

As an alternative to Proposition 2.2, van den Eshof [31] noticed that a related result could be obtained as follows. Let $(\theta^{(k)}, u^{(k))})$ be as before, with associated residual r_k, and let $\hat{u}^{(k)} = [u^{(k)}; \underline{0}]$. If $H_m = QTQ^*$ is the Schur decomposition of H_m, with $Q = [u, Q_2]$ unitary and

$$T = \begin{bmatrix} \theta & a^* \\ \underline{0} & T_{22} \end{bmatrix},$$

then we have (cf. [2, formula (7.107), p. 230])

$$\sin\theta(\hat{u}^{(k)}, u) \leq \frac{\|r_k\|}{\sigma_{\min}(T_{22} - \theta^{(k)} I)}.$$

Therefore, using $u = [u_1; u_2]$, we can write $u = \hat{u}^{(k)}(\hat{u}^{(k)})^* u + (I - \hat{u}^{(k)}(\hat{u}^{(k)})^*)u$ so that $u_2 = [0, I](I - \hat{u}^{(k)}\hat{(}u^{(k)})^*)u$, from which we obtain

$$\|u_2\| \leq \|(I - \hat{u}^{(k)}(\hat{u}^{(k)})^*)u\| = \sin\theta(\hat{u}^{(k)}, u) \leq \frac{\|r_k\|}{\sigma_{\min}(T_{22} - \theta^{(k)} I)}.$$

This relation is very similar to that in (2.6); however, $\sigma_{\min}(T_{22} - \theta^{(k)} I)$ is not the same quantity as $\delta_{m,k}$, as in the former the matrix T_{22} is completely specified by the spectral properties of the target matrix H_m and does not take into account the approximate eigenvector. Nonetheless, it is not clear whether the bound in (2.6), which also includes a condition on the residual, is sharper than the one above. Other characterizations using perturbation theorems can be found, e.g., in [30, section V.2.2]. We would also like to stress that, as shown in Proposition 2.5, the result we have used can be naturally generalized to the case of a simple invariant subspace.

3. Inexact Arnoldi method.

When A is not applied exactly, at each iteration the operation $y = Av$ is replaced by (1.2). Letting $F_m = [f_1, \dots, f_m]$ be the matrix whose columns collect all perturbations, we obtain the following inexact (perturbed) Arnoldi relation:

$$AV_m + F_m = V_m H_m + h_{m+1,m} v_{m+1} e_m^*. \tag{3.1}$$

As in the exact case, matrix V_m has orthonormal columns; however, the space generated by its columns is no longer a Krylov subspace associated with A. Moreover, both V_m and the upper Hessenberg matrix H_m are different from those one would obtain with the exact process, and F_m measures the inexactness of the perturbed Arnoldi relation. When looking for specific eigenpairs, large perturbations may be allowed and still maintain the convergence of the eigenvalue residual to a low final accuracy. Let (θ, u) be an eigenpair of H_m. We have

$$\begin{aligned} AV_m u - \theta V_m u &= V_m H_m u - \theta V_m u + h_{m+1,m} v_{m+1} e_m^* u - F_m u \\ &= h_{m+1,m} v_{m+1} e_m^* u - F_m u. \end{aligned}$$

We call the quantity $AV_m u - \theta V_m u$ the *true residual*, whereas we call the vector $r_m = h_{m+1,m} v_{m+1} e_m^* u$ the *computed residual*, which can be monitored during the recurrence. Note that the true residual cannot be computed when A is not applied exactly. In particular, in the inexact case, the true and computed residuals differ by the vector $F_m u$. We have

$$\begin{aligned} \|(AV_m u - \theta V_m u) - r_m\| &= \|F_m u\| = \|[f_1, \dots, f_m]u\| \\ &= \left\| \sum_{k=1}^m f_k (e_k^* u) \right\| \le \sum_{k=1}^m \|f_k\| \, |e_k^* u|. \end{aligned} \tag{3.2}$$

The distance between the true and the computed residuals is small when each addend $\|f_k\| \, |e_k^* u|$, $k = 1, \dots, m$, in the last sum is small. This occurs when either of the two terms $\|f_k\|$ and $|e_k^* u|$ is small, and not necessarily both, as long as the other term remains bounded by some $O(1)$, say, constant. Therefore, if $|e_k^* u|$ is small, $\|f_k\|$ is allowed to be large and still provide a small gap between true and computed residuals. We next make this statement more precise.

Assume that a maximum of m iterations of inexact Arnoldi can be carried out, and let $(\theta, V_m u)$ be the best Ritz approximation with H_m to the sought-after eigenpair of A. Relaxation in the matrix-vector product at step $k < m$ is possible if there exists an eigenpair of H_{k-1}, denoted by $(\theta^{(k-1)}, u^{(k-1)})$, that is sufficiently close to the eigenpair (θ, u) of H_m or to an eigenpair of A. More precisely, using the notation introduced in Proposition 2.2, for relaxation to take place at step k, it must hold that

$$\|r_{k-1}\| < \frac{\delta_{m,k-1}^2}{4\|s_m\|}, \tag{3.3}$$

$$\forall \theta_j \in \Lambda(H_m), \quad \theta_j \neq \theta, \quad |\theta^{(k-1)} - \theta_j| > 2 \frac{\|s_m\| \, \|r_{k-1}\|}{\delta_{m,k-1}}. \tag{3.4}$$

Condition (3.4) ensures that the eigenpair $(\theta^{(k-1)}, u^{(k-1)})$ in Proposition 2.2 is indeed a perturbation of the analyzed eigenpair (θ, u) of H_m; cf. Remark 2.4. This requires that $\theta^{(k-1)}$ be closer to θ than to other eigenvalues of H_m. This closeness is measured in terms of the quantities $\|r_{k-1}\|$ and $\delta_{m,k-1}$, associated with $\theta^{(k-1)}$. If both (3.3) and (3.4) hold, then (θ, u) is the only eigenpair of H_m such that (2.6) and (2.7) hold at iteration $k-1$. When

$$\theta^{(k-1)} \approx \theta, \qquad \begin{bmatrix} u^{(k-1)} \\ \underline{0} \end{bmatrix} \approx u,$$

we can write

$$\delta_{m,k-1} \leq \min_{\theta_i \in \Lambda(\underline{H_m})} |\theta_i - \theta^{(k-1)}| \approx \min_{\theta_j \in \Lambda(H_m) \setminus \{\theta\}} |\theta_j - \theta^{(k-1)}|,$$

in which case (3.4) follows from (3.3). For simplicity, here and below we assume that θ is a simple eigenvalue of H_m. A generalization of the result of Theorem 3.1 can be obtained by using Proposition 2.5.

Theorem 3.1. *Assume that m inexact Arnoldi iterations have been carried out, and let (θ, u) be an eigenpair of H_m with θ simple Ritz value and $\|u\| = 1$. Given any $\varepsilon \in \mathbb{R}$, $\varepsilon > 0$, assume that for $k = 1, \ldots, m$,*

$$\|f_k\| \leq \begin{cases} \frac{\delta_{m,k-1}}{2m\|r_{k-1}\|}\varepsilon & \text{if } k > 1 \text{ and there exists } (\theta^{(k-1)}, u^{(k-1)}) \text{ of } H_{k-1} \\ & \quad \text{satisfying (3.3) and (3.4),} \\ \frac{1}{m}\varepsilon & \text{otherwise.} \end{cases} \tag{3.5}$$

Then

$$\|(AV_m u - \theta V_m u) - r_m\| \leq \varepsilon.$$

Proof. If at step $k-1$ there exists an eigenpair $(\theta^{(k-1)}, u^{(k-1)})$ of H_{k-1} satisfying (3.3), (3.4), then θ is the only eigenvalue of H_m such that

$$|\theta - \theta^{(k-1)}| \leq 2\frac{\|s_m\|\,\|r_{k-1}\|}{\delta_{m,k-1}}.$$

Hence, Proposition 2.2 ensures that $\theta^{(k-1)}$ is a perturbation of the considered eigenvalue θ of H_m.

Let $\mathcal{K}$ be the subset of $\{2, \ldots, m\}$ such that for each $k \in \mathcal{K}$ there exists an eigenpair $(\theta^{(k-1)}, u^{(k-1)})$ of H_{k-1} satisfying (3.3) and (3.4). Then, using (3.2),

$$\begin{aligned} \|(AV_m u - \theta V_m u) - r_m\| &= \|F_m u\| \leq \sum_{k=1}^{m} \|f_k\|\,|e_k^* u| \\ &= \sum_{k \in \mathcal{K}} \|f_k\|\,|e_k^* u| + \sum_{k \notin \mathcal{K}, k \leq m} \|f_k\|\,|e_k^* u| \\ &\leq \sum_{k \in \mathcal{K}} \frac{\delta_{m,k-1}}{2m\|r_{k-1}\|}\varepsilon\,|e_k^* u| + \sum_{k \notin \mathcal{K}, k \leq m} \frac{1}{m}\varepsilon\,|e_k^* u| \\ &\leq \sum_{k \in \mathcal{K}} \frac{\delta_{m,k-1}}{2m\|r_{k-1}\|}\varepsilon\, 2\frac{\|r_{k-1}\|}{\delta_{m,k-1}} + \sum_{k \notin \mathcal{K}, k \leq m} \frac{1}{m}\varepsilon \qquad \text{(see (2.9))} \\ &= \frac{|\mathcal{K}|}{m}\varepsilon + \frac{m - |\mathcal{K}|}{m}\varepsilon = \varepsilon. \qquad \square \end{aligned}$$

If the conditions of Theorem 3.1 hold, then the difference between the two residuals is less than some fixed value ε. For a sufficiently good starting vector, the norm of the computed residual tends to zero as m goes to infinity; therefore, ε also provides a bound for the final attainable accuracy of the true residual. For this reason, it is natural to relate the value of ε to the threshold in the eigenvalue problem stopping criterion.

Note that $\delta_{m,k-1}$ may dramatically influence the size of the perturbation. For a sensitive matrix H_m, $\delta_{m,k-1}$ may be very small and thus force high accuracy in the matrix-vector product to maintain convergence. On the other hand, it is also important to realize that $\delta_{m,k-1}$ is related to the sensitivity of H_m and not of the original matrix A. Since H_m is a projection of A onto a possibly much smaller space, in general we expect H_m to be less sensitive to perturbations than A.

3.1. A practical relaxation strategy. The result of Theorem 3.1 suggests that we could derive a practical criterion for relaxing the accuracy with which A is applied at each iteration. Unfortunately, the criterion in (3.5) requires crucial information that is not available at iteration k, namely $\delta_{m,k-1} = \sigma_{\min}(\underline{H_m} - \theta^{(k-1)} I)$. This quantity emphasizes the sensitivity of the eigenproblem with H_m and cannot cheaply be replaced. We therefore suggest a relaxation strategy that mimics (3.5), while sacrificing some accuracy in $\delta_{m,k-1}$.

Assume that a maximum of m inexact iterations are to be carried out. At the first iteration, we require that $\|f_1\|$ be less than or equal to $\frac{1}{m}\varepsilon$. At iteration $k > 1$ we require that the perturbation satisfy

$$\|f_k\| \leq \frac{\min\{\alpha, \delta^{(k-1)}\}}{2m\|r_{k-1}\|}\varepsilon, \qquad \delta^{(k-1)} := \min_{\theta_j \in \Lambda(H_{k-1})\setminus\{\theta^{(k-1)}\}} |\theta^{(k-1)} - \theta_j|, \tag{3.6}$$

where α is an estimate of $\|A\|$ and is included to make the condition invariant[1] with respect to a scaling of A. The quantity $\delta^{(k-1)}$ is related to the distance of the Ritz value $\theta^{(k-1)}$ from the rest of the spectrum of H_{k-1}. Clearly, $\delta^{(k-1)}$ may in general be very different from $\delta_{m,k-1}$ (cf. also Remark 2.3). On the other hand, $\delta_{m,k-1}$ will not be too overestimated when $\theta^{(k-1)}$ and its nearby eigenvalues have stabilized to the corresponding eigenvalues of a matrix H_m that is not very sensitive to perturbations.

We should add that, in our numerical experiments, we assume that conditions (3.3) and (3.4) are always satisfied. We require only that the residual be less than one; otherwise the unit value is used instead of the residual in the test.

In (3.6), ε is some fixed constant, naturally related to the final stopping tolerance for the eigenvalue computation. In the numerical experiments of section 4, we require that the final residual be less than ε in norm. In general, ε may include some information about the eigenproblem; one could, for instance, let ε depend on the current approximation, that is, $\varepsilon_{k-1} = |\theta^{(k-1)}|\epsilon$, with ϵ fixed. This choice of ε_{k-1} is associated with the following stopping criterion for the eigenvalue solver,

$$\frac{\|r_{k-1}\|}{|\theta^{(k-1)}|} \leq \epsilon,$$

which is commonly employed in practical implementations; see, e.g., Example 4.2.

[1] We thank Julien Langou, University of Tennessee, for pointing this out.

Remark 3.2. The proposed dynamic perturbation criterion is tailored to the sought-after invariant subspace of A. Assuming that convergence is achieved in the unperturbed case, our analysis shows that specific Ritz pairs obtained by the inexact procedure can still converge to the wanted eigenpairs of A, up to a certain tolerance. Other Ritz pairs may be significantly perturbed, if in the exact scheme they approximate eigenpairs of A with a slower convergence rate. In Example 4.1 we report an experiment where eigenvalues do converge at different rates and the inexact method delivers significantly different results from the exact process (cf. Table 4.1). Our theory formalizes a similar consideration stated in [22, section 11]. □

4. Numerical experiments.

4. Numerical experiments. In this section we report on some numerical experiments that support our theoretical results for the inexact Arnoldi method using Ritz pairs.

Extensive computational experiments were carried out in [5], where the family of relaxation criteria

$$\|f_k\| \leq \frac{10^{-\alpha_0}}{\|r_{k-1}\|}\varepsilon \tag{4.1}$$

was introduced, with $\alpha_0 = 0, 1, 2$, while $\varepsilon = \|A\|\epsilon$, with ϵ equal to the required final residual accuracy. The authors reported the number of times the inexact procedure successfully achieved the required accuracy in approximating the selected eigenpairs of a wide range of matrices. They showed that in 42% of the tests the criterion (4.1) was fulfilled for $\alpha_0 = 0$, up to 81% for $\alpha_0 = 2$. In the following we shall report experiments for $\alpha_0 = 0$. We remark that our theory provides an understanding of the role of the numerator $10^{-\alpha_0}$, and it explains the reason why for $\alpha_0 = 0$ the effect of the perturbation may be severely underestimated.

Example 4.1. We consider the 900×900 matrix stemming from the centered finite difference discretization of the operator

$$Lu = -\Delta u + 100((x+y)u)_x + 100((x+y)u)_y$$

on the unit square, and we seek the eigenvalue with largest real part, $\lambda \approx 7.5127$; cf. Figure 4.1(left). In Figure 4.1(right) we report the convergence history for the exact Arnoldi method for $m = 130$ (dash-dotted line), the inexact method with the flexible accuracy criterion in (3.6) with $\alpha = 10$ (solid line), and the flexible accuracy criterion adopted by Bouras and Frayssé (dashed line); cf. (4.1). The two increasing curves report the values of $\|f_k\|$ for the two inexact methods, with $\varepsilon = 10^{-8}$. The starting vector for the iterative process was taken to be the normalized vector of all ones. Inexactness of A was simulated by adding a random perturbation vector f_k, whose norm was equal to the right-hand side of (3.5) and (4.1) (with $\alpha_0 = 0$), for our criterion and for that of Bouras and Frayssé, respectively.

Both inexact approaches replicate the exact convergence curve until they reach their final attainable accuracy. Note that the original Bouras and Frayssé criterion does not allow the method to fall below the required final residual accuracy, while this is achieved by the criterion in (3.6).

In Table 4.1 we report the last seven computed Ritz values after $m = 100$ iterations, with the exact Arnoldi method and with the inexact method, when either the new relaxation strategy or strategy (4.1) is employed. The first column reports the corresponding eigenvalues of A. We notice that for the two inexact procedures most Ritz values differ from those computed by the exact Arnoldi method, and only the

The increasing curves report the values of the perturbation norms, $\|f_k\|$, in* (3.6) *and* (4.1) *(labeled BF).*

TABLE 4.1

Example 4.1. *Ritz values of exact and inexact Arnoldi methods at iteration m =* 100. *Both flexible strategies* (3.6) *and* (4.1) *are considered. The underlined digits are as accurate as those obtained with the exact Arnoldi method.*

Exact eigenvalues	Arnoldi Ritz values	Flexible accuracy $\|\|f_{100}\|\| = 9.38\,10^{-5}$	Flexible accuracy BF $\|\|f_{100}\|\| = 4.91\,10^{-2}$
6.528963528	$6.5012 + 0.7235i$	$6.5010 + 0.7208i$	$6.5012 + 0.7238i$
6.553808631	$6.5012 - 0.7235i$	$6.5010 - 0.7208i$	$6.5012 - 0.7238i$
6.714551208	$6.6933 + 0.3818i$	$6.6949 + 0.3793i$	$6.6929 + 0.3821i$
6.825884813	$6.6933 - 0.3818i$	$6.6949 - 0.3793i$	$6.6929 - 0.3821i$
6.863220504	$6.8832 + 0.1068i$	$6.8846 + 0.1070i$	$6.8828 + 0.1066i$
7.122198478	$6.8832 - 0.1068i$	$6.8846 - 0.1070i$	$6.8828 - 0.1066i$
7.185702959	7.123532521	$\underline{7.123}544655$	$\underline{7.1235}21753$
7.512696262	7.512695900	$\underline{7.51269590}4$	$\underline{7.5126959}12$

first 3–4 digits remain unaltered. This is not the case for the sought-after eigenvalue $\lambda \approx 7.5126$, for which the exact and inexact Ritz values coincide with several digits of accuracy. We can thus confirm that the perturbation does affect the convergence of Ritz values that do not converge with the same rate as those that guided the perturbation magnitude; see Remark 3.2.

We next report the results obtained when looking for a group of eigenvalues, namely the three largest eigenvalues of A, with both the exact and inexact methods. We considered a starting vector with random entries normally distributed (MATLAB function `randn`, with initial state random number generator), since the previously chosen constant vector had small components onto the second largest eigenvalue. In the table below we display the *four* largest Ritz values obtained after m = 150 iterations of the exact Arnoldi and inexact Arnoldi methods, with $\varepsilon = 10^{-8}$.

Method	θ_4	θ_3	θ_2	θ_1
Exact Arnoldi	6.856543090	7.12220153908	7.18570250215	7.51269626278988
Inexact Arnoldi	6.856516751	7.12220154236	7.18570250124	7.51269626278483

In the inexact process, the perturbation was monitored by using the Frobenius norm of the residual matrix of the three largest Ritz values. The final perturbation norm was equal to $\|f_{150}\| = 2 \cdot 10^{-4}$. We observe in the table that these three Ritz values deviate from those of the exact process of at most $O(10^{-9})$. On the other hand, the fourth Ritz value matches only that of the exact Arnoldi process, to five decimal digits. Therefore, the accuracy in the inexact recurrence is again lost for the approximate eigenpairs that are not involved in the perturbation tolerance. We also note that the largest eigenvalue has more accurate digits with respect to the exact process than the other eigenvalues. In particular, it has almost full accuracy, in spite of a $2 \cdot 10^{-4}$ perturbation in norm. This phenomenon confirms the fact that for groups of eigenvalues, it is the slowest one converging that drives the allowed perturbation.

Example 4.2. We next present a typical setting where the flexible accuracy in the matrix-vector product can be fully appreciated. We consider the matrix SHERMAN5 from the Matrix Market repository [12]. This is a non-Hermitian indefinite real matrix of size $n = 3312$, and was also employed in [14] to analyze the performance of Arnoldi-type methods. The spectrum of the matrix is reported in the left plot of Figure 4.2. We approximate the (real) eigenvalue closest to zero, $\lambda \approx 4.6925 \cdot 10^{-2}$, by means of an inverted Arnoldi process. The generating vector v_1 was the normalized vector of all ones. At each inverted Arnoldi iteration, the operation $y = A^{-1}v$ should be carried out. At each (outer) inexact iteration, a system with A, namely $Ay = v$, is approximately solved with preconditioned GMRES with zero starting guess. The MATLAB incomplete LU factorization with `tol` $= 10^{-3}$ was used as right preconditioner. The GMRES iteration terminated as soon as the system residual norm reached a certain tolerance `tol`. The inner stopping criterion that we used to approximately solve $Ay = v_k$ at step k is

$$\|v_k - Ay\| \leq \frac{\min\{\alpha, \delta^{(k-1)}\}}{2m\|r_{k-1}\|/|\theta^{(k-1)}|}\varepsilon, \qquad \varepsilon = 10^{-10}, \qquad \alpha = 400.$$

In the *exact* case, we assume that we cannot afford to solve with A exactly; therefore we approximately solve the inner system with a fixed tolerance, `tol` $= 10^{-10}$. A total of $m = 12$ outer iterations was carried out. The results of our experiment are reported

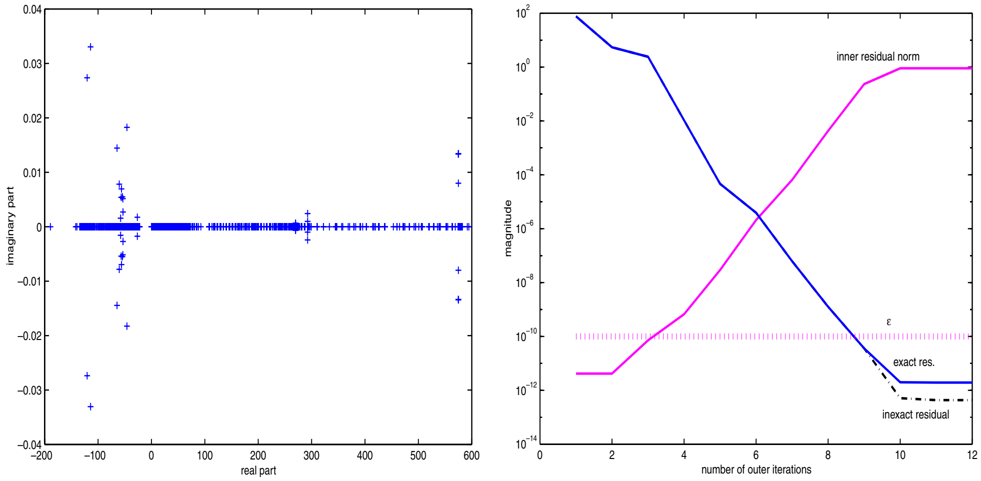

FIG. 4.2. *Example* 4.2. *Left: spectrum of A. Right: convergence curves for inverted Arnoldi (dash-dotted curve) and inexact inverted Arnoldi (solid curve). The right panel also reports the fixed tolerance $\varepsilon = 10^{-10}$ (dotted line).*

in the right plot of Figure 4.2, where the magnitude of the final inner residual at each iteration is also plotted. The eigenvalue convergence curves cannot be distinguished until the final accuracy is reached. Note that in the case of variable inner tolerance, preconditioned GMRES took 22 iterations to solve the first inner system at the required accuracy, whereas only 5 iterations were needed at the 8th inverted Arnoldi iteration, to reach a residual of the order of 10^{-2}.

5. Harmonic Ritz approximation. It has been shown [13, 16, 24] that when looking for interior eigenvalues of Hermitian as well as of non-Hermitian matrices, harmonic Ritz values may be preferred to Ritz values. Harmonic Ritz pairs are pairs $(\theta, V_m u)$, where θ and u are the eigenvalues and corresponding eigenvectors of the generalized eigenvalue problem

$$(H_m^* H_m + |h_{m+1,m}|^2 e_m e_m^*)u = \theta H_m^* u, \quad \|u\| = 1,$$

or, equivalently, of the standard eigenvalue problem

$$(H_m + |h_{m+1,m}|^2 (H_m^*)^{-1} e_m e_m^*)u = \theta u, \quad \|u\| = 1. \tag{5.1}$$

In the following, we let

$$\widetilde{H}_m = H_m + |h_{m+1,m}|^2 (H_m^*)^{-1} e_m e_m^*. \tag{5.2}$$

It was observed in [14] that a better choice as approximation to eigenpairs of A is the pair $(\rho, V_m u)$, where ρ is the Rayleigh quotient of u, that is, $\rho = u^* H_m u$. Using (5.1), for the associated residual we have

$$\begin{aligned} AV_m u - \rho V_m u &= V_m H_m u + h_{m+1,m} v_{m+1} e_m^* u - \rho V_m u \\ &= V_{m+1} \begin{pmatrix} H_m u - \rho u \\ h_{m+1,m} e_m^* u \end{pmatrix}. \end{aligned} \tag{5.3}$$

In the following we will use the *computed* residual in (5.3); namely, we define

$$r_m := V_{m+1} \begin{pmatrix} H_m u - \rho u \\ h_{m+1,m} e_m^* u \end{pmatrix}, \tag{5.4}$$

which differs from the *true* residual $AV_m u - \rho V_m u$ in the inexact case.

A result similar to that of Proposition 2.2 can be derived in terms of the matrix $\widetilde{H}_m$ in (5.2).

PROPOSITION 5.1. *For $k < m$, let $V_k u^{(k)}$ be a harmonic Ritz vector associated with H_k, with $\|u^{(k)}\| = 1$, and let $\rho^{(k)} = (u^{(k)})^* H_k u^{(k)}$. Moreover, let $\mathcal{X} = [[\begin{smallmatrix} u^{(k)} \\ \underline{0} \end{smallmatrix}], Y]$ be a unitary matrix and $\underline{\widetilde{H}_m} = Y^* \widetilde{H}_m Y$. Let $\delta_{m,k} = \sigma_{\min}(\underline{\widetilde{H}_m} - \rho^{(k)} I)$,*

$$r_k = V_{k+1} \begin{pmatrix} H_k u^{(k)} - \rho^{(k)} u^{(k)} \\ h_{k+1,k} e_k^* u^{(k)} \end{pmatrix}, \quad s_m^* = [(u^{(k)})^*, \underline{0}^*] \widetilde{H}_m - \rho^{(k)} [(u^{(k)})^*, \underline{0}^*].$$

If $\delta_{m,k} > 0$ *and*

$$\|r_k\| < \frac{\delta_{m,k}^2}{4\|s_m\|}, \tag{5.5}$$

then there exists a unit norm eigenvector $u = \left[\begin{smallmatrix} u_1 \\ u_2 \end{smallmatrix}\right]$ *of* $\widetilde{H}_m$ *with* $u_1 \in \mathbb{C}^k$ *such that*

$$\|u_2\| \le \frac{\tau}{\sqrt{1+\tau^2}} \le \tau, \quad \textit{where} \quad \tau \in \mathbb{R}, \quad 0 \le \tau < 2\frac{\|r_k\|}{\delta_{m,k}}.$$

Proof. Let Y be such that $\mathcal{X} = [\left[\begin{smallmatrix} u^{(k)} \\ \underline{0} \end{smallmatrix}\right], Y] \in \mathbb{C}^{m\times m}$ is unitary. Recalling that $e_m^*[(u^{(k)}); \underline{0}] = 0$ so that $[(u^{(k)})^*, \underline{0}^*]\widetilde{H}_m[(u^{(k)}); \underline{0}] = \rho^{(k)}$, and following the proof of Proposition 2.2, we can write

$$\mathcal{X}^*\widetilde{H}_m\mathcal{X} = \left[\begin{array}{cc} \rho^{(k)} & K \\ G & \underline{\widetilde{H}_m} \end{array}\right], \qquad \begin{array}{l} G = Y^*\widetilde{H}_m \left[\begin{array}{c} u^{(k)} \\ \underline{0} \end{array}\right], \\ K = [(u^{(k)})^*, \underline{0}^*]\widetilde{H}_m Y. \end{array}$$

Once again, we use $[(u^{(k)})^*, \underline{0}^*]e_m = 0$ and, in addition, $[(u^{(k)})^*, \underline{0}^*]Y = 0$, to obtain

$$\begin{aligned} \gamma := \|G\| &= \left\| Y^*\widetilde{H}_m \left[\begin{array}{c} u^{(k)} \\ \underline{0} \end{array}\right] \right\| = \left\| Y^* \left[\begin{array}{c} H_k u^{(k)} \\ h_{k+1,k}e_1 e_k^* u^{(k)} \end{array}\right] \right\| \\ &= \left\| Y^* \left[\begin{array}{c} H_k u^{(k)} - \rho^{(k)}u^{(k)} \\ h_{k+1,k}e_1 e_k^* u^{(k)} \end{array}\right] \right\| \le \|r_k\|. \end{aligned}$$

Moreover, $\|K\| = \|s_m^* Y\| \le \|s_m\|$. Using Theorem 2.1, if (5.5) holds, so that $\frac{\gamma\|s_m\|}{\delta_{m,k}^2} < \frac{1}{4}$, then there exists $p \in \mathbb{C}^{m-1}$ satisfying $\tau := \|p\| < 2\frac{\gamma}{\delta_{m,k}}$ such that the vector

$$u = \left[\begin{array}{c} u_1 \\ u_2 \end{array}\right] = \frac{1}{\sqrt{1+\|p\|^2}} \left(\left[\begin{array}{c} u^{(k)} \\ \underline{0} \end{array}\right] + \left[\begin{array}{c} Y_1 \\ Y_2 \end{array}\right] p \right)$$

is an eigenvector of $\widetilde{H}_m$ with unit norm, so that $\|u_2\| \le \frac{\|p\|}{\sqrt{1+\|p\|^2}}$. □

Using Proposition 5.1, we can provide a flexible criterion for the accuracy with which the matrix A is applied in the case of harmonic Ritz approximation. We first notice that, in the inexact case, (5.3) becomes

$$AV_m u - \rho V_m u = V_{m+1} \left(\begin{array}{c} H_m u - \rho u \\ h_{m+1,m}e_m^* u \end{array} \right) - F_m u = r_m - F_m u.$$

With the notation of Proposition 5.1, to bound the distance between the true and computed residuals, we require that the best harmonic Ritz approximation $(\rho^{(k-1)}, u^{(k-1)})$ after $k-1$ iterations satisfies

$$\|r_{k-1}\| < \frac{\delta_{m,k-1}^2}{4\|s_m\|}, \tag{5.6}$$

$$\left\{ \begin{array}{l} \forall\rho_j \text{ Rayleigh quotient of eigenvectors of } \widetilde{H}_m, \ \ \rho_j \ne \rho, \\ \quad |\rho^{(k-1)} - \rho_j| > 2\frac{\|s_m\|\,\|r_{k-1}\|}{\delta_{m,k-1}}. \end{array} \right. \tag{5.7}$$

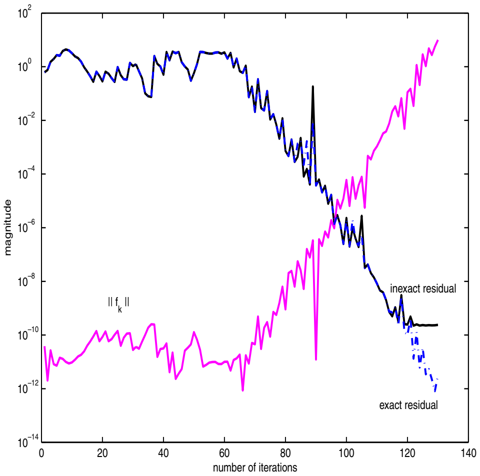

FIG. 5.1. *Matrix in Example* 4.1 *and harmonic Ritz approximation of the largest eigenvalue in modulo. Convergence curves of the exact method (dash-dotted) and inexact Harmonic approximation with* (5.9) *(solid). The increasing curve reports the values of the perturbation norms,* $\|f_k\|$*, in* (5.9).

The following result is similar to Theorem 3.1, and its proof is therefore omitted.

THEOREM 5.2. *Assume that m inexact Arnoldi iterations have been carried out, and let $V_m u$ be a harmonic Ritz vector associated with H_m, with $\|u\| = 1$, and let ρ be the Rayleigh quotient of u, $\rho = u^* H_m u$. Given any $\varepsilon \in \mathbb{R}$, $\varepsilon > 0$, assume that for $k = 1, \ldots, m$,*

$$\|f_k\| \leq \begin{cases} \dfrac{\delta_{m,k-1}}{2m\|r_{k-1}\|}\varepsilon & \begin{array}{l}\textit{if } k > 1 \textit{ and there exists } V_{k-1}u^{(k-1)} \textit{ harmonic Ritz}\\ \textit{vector of } H_{k-1} \textit{ satisfying } (5.6) \textit{ and } (5.7) \textit{ with}\\ \rho^{(k-1)} = (u^{(k-1)})^* H_{k-1} u^{(k-1)},\end{array} \\[2ex] \dfrac{1}{m}\varepsilon & \textit{otherwise.} \end{cases} \tag{5.8}$$

Then $\|(AV_m u - \rho V_m u) - r_m\| \leq \varepsilon$.

The deviation of the inexact harmonic process from its unperturbed counterpart does not significantly differ from that of inexact and exact Arnoldi. As an example, we report the convergence behavior of the exact and inexact harmonic Ritz approximations for the matrix in Example 4.1. In Figure 5.1 the convergence to the largest eigenvalue in modulo is depicted. The matrix-vector product was perturbed by using the following variant of (3.6):

$$\|f_k\| \leq \frac{\min\{\alpha, \delta^{(k-1)}\}}{2m\|r_{k-1}\|}\varepsilon, \qquad \delta^{(k-1)} := \min_{\text{all } \rho_j \neq \rho^{(k-1)}} |\rho^{(k-1)} - \rho_j|, \tag{5.9}$$

where each ρ_j is the Rayleigh quotient associated with the jth unit norm harmonic Ritz vector $u^{(j)}$ of H_{k-1}.

We also report the results after $m = 150$ iterations with the same matrix, when looking for the first three eigenvalues. Similar strategies as in Example 4.1 were used.

Method	ρ_4	ρ_3	ρ_2	ρ_1
Exact harmonic	6.8572788458	7.1222009509	7.18570255184	7.5126962627829
Inexact harmonic	6.8571791230	7.1222009690	7.18570254871	7.5126962627823

The same considerations as for the Arnoldi process apply here. The magnitude of the perturbation at the last iteration was $9 \cdot 10^{-5}$.

6. Exact and inexact Lanczos methods. In this section we show that our analysis carries over to the case of the inexact Lanczos method. In the standard nonsymmetric Lanczos method the following relations hold:

$$AQ_k = Q_k T_k + t_{k+1,k} q_{k+1} e_k^*, \quad A^* P_k = P_k T_k^* + \bar{t}_{k,k+1} p_{k+1} e_k^*, \quad P_k^* Q_k = I_k. \tag{6.1}$$

Writing $Q_{k+1} = [q_1, q_2, \dots, q_{k+1}]$, we assume $\|q_i\| = 1$, $i = 1, \dots, k+1$. This condition, together with the biorthogonality of P_k, Q_k, completely defines the column vectors in P_k, Q_k. Different normalizations would be possible, such as $\|q_i\| = 1 = \|p_i\|$, $i = 1, \dots, k$. In (6.1), T_k is a $k \times k$ nonsymmetric tridiagonal matrix; see, e.g., [2].

When the matrix-vector products with A and A^* are performed inexactly, that is,

$$q = Aq_i + f_i, \qquad p = A^* p_i + g_i, \quad i = 1, \dots, k,$$

the original Lanczos relations (6.1) transform as follows:

$$AQ_k = Q_k H_k + h_{k+1,k} q_{k+1} e_k^* + F_k, \tag{6.2}$$

$$A^* P_k = P_k K_k + \bar{h}_{k,k+1} p_{k+1} e_k^* + G_k, \quad P_k^* Q_k = I_k, \tag{6.3}$$

where we used $F_k = [f_1, \dots, f_k]$ and $G_k = [g_1, \dots, g_k]$. Here matrices H_k and K_k^* are upper Hessenberg and no longer tridiagonal. Their diagonal and near-diagonal elements are the same, whereas the remaining upper parts of the two matrices differ. Clearly, the special properties of the Lanczos iteration are lost. Indeed, the inexact Lanczos iteration is a paired long-term recurrence, as opposed to the paired three-term recurrence of the Lanczos iteration (6.1). Moreover, while in the exact recurrence the matrix T_k provides approximations to both right and left eigenvectors of A, this is no longer the case in the inexact method. Since H_k and K_k^* differ, both eigenvalue problems with H_k and K_k^* need to be solved to obtain right and left Ritz vectors. Another property not inherited by the inexact process concerns convergence. Under certain conditions, the exact Lanczos recurrence determines quadratically converging Ritz values [1, 20].[2] Since neither H_k nor K_k alone provides right and left eigenvector approximations, convergence is only linear in the inexact case.

Proposition 2.2 can be applied to each of the two matrices H_k and K_k^*, to show that the components of converging Ritz vectors have a decreasing pattern. Owing to the similarity between the inexact relations of (6.2), (6.3) with (3.1), we can thus apply the result on dynamic accuracy stated in Theorem 3.1 to each of the two inexact Lanczos recurrences. This provides us with a way to monitor the gap $\|(AQ_k u - \theta Q_k u) - r_k\|$, where (θ, u) is a right eigenpair of H_k in (6.2) and r_k is the associated computed residual. An analogous result holds for left Ritz pairs.

Example 6.1. We consider the 900×900 matrix arising from the centered finite difference approximation of the operator $Lu = -u_{xx} - u_{yy} + (x+y)u_x$ on the unit square. The starting vector is the normalized vector of all ones, for both the Q_k and P_k sequences. We are interested in the approximation of the smallest (real) eigenvalue, $\lambda \approx 2.0276 \cdot 10^{-2}$, with a final residual tolerance of $\varepsilon = 10^{-8}$. The whole spectrum is depicted in the left plot of Figure 6.1. The convergence of the exact and

[2] We thank David Day, Sandia National Laboratories, for pointing us to [1].

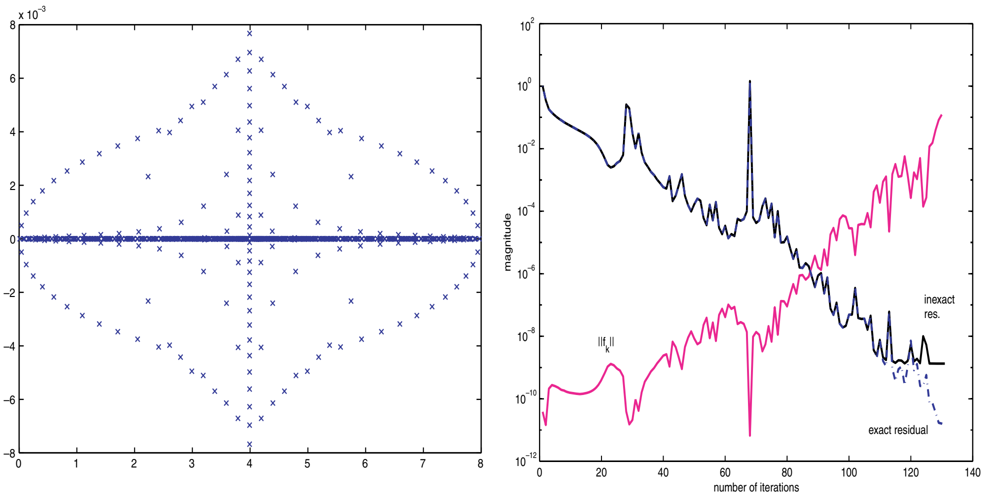

Fig. 6.1. *Example* 6.1. *Left: spectrum of A. Right: convergence curves of right residual norms of exact and inexact Lanczos. The increasing (solid) curve represents the norm of the right matrix-vector perturbation at each iteration.*

inexact Lanczos right residual norms is reported in the right plot of Figure 6.1. The perturbations in the matrix-vector products were enforced by adding random vectors f_i, g_i, $i = 1, \ldots, k$. Their norms were monitored by means of (3.6), applied distinctly to the eigenpairs of the matrices H_{i-1}, K_{i-1}. The convergence curve in the inexact case agrees with that of the exact procedure until final accuracy is reached.

7. Further comments. It was empirically observed in the literature that when approximating the eigenpairs of a matrix by means of the Arnoldi method, the accuracy in the application of the operator may in some cases be relaxed while maintaining the convergence to the sought-after eigenpairs. In this paper we have presented the theoretical foundation for the justification of this phenomenon, and provided a more robust relaxation criterion. Our results indicate that flexible accuracy can be safely employed when the approximate eigenpair is sufficiently close to the target eigenpair, depending on the sensitivity of the given matrix.

Our analysis highlights that reasonably accurate results can be obtained in spite of large perturbations. The inexact Arnoldi relation (3.1) could be written as follows:

$$(A + \mathcal{E}_m)V_m = V_m H_m + h_{m+1,m} v_{m+1} e_m^*, \qquad \mathcal{E}_m = \sum_{k=1}^{m} f_k v_k^*.$$

A backward error analysis would suggest the rather pessimistic picture that a Ritz pair $(\theta, V_m u)$ would be an approximation to an eigenpair of $A + \mathcal{E}_m$ but not of A. We have shown that the perturbation is performed in such a way that the approximation to the target eigenpairs of A is not affected. However, other inexact Ritz pairs may be perturbed by a quantity fully influenced by $\|\mathcal{E}_m\|$.

A related question that we have not answered is whether the rate of convergence could be affected by the perturbation. More precisely, even though our theory ensures that the norm of the true residual of some selected Ritz pairs still converges to a small quantity, it is not clear whether it does so with the same convergence rate as in the unperturbed process. A similar problem is encountered in the inexact linear system setting [22, 32, 25]. In [23] it was shown that no convergence delay is observed in the inexact linear system case, unless the coefficient matrix and the right-hand side are very sensitive to perturbations. Although we expect these conclusions to carry over to the eigenvalue setting, an ad hoc analysis remains to be done.

Practical implementations require (implicit) restarting and locking of converged eigenpairs [10]. As already mentioned in the introduction, we have not addressed these important issues, which need special attention, since our theory predicts that flexible accuracy should take into account the occurrence of Ritz pairs converging to target eigenpairs of A at different rates. In the linear system setting, the problem of restarting has been recently addressed in [26].

Acknowledgments. We thank Jasper van den Eshof for his insightful remarks, and the two anonymous referees for their comments.

CONVERGENCE OF THE SUPERCELL METHOD FOR DEFECT MODES CALCULATIONS IN PHOTONIC CRYSTALS[*]

SOFIANE SOUSSI[†]

Abstract. We present a rigorous study of the convergence of the *supercell* method used for determing defect modes in photonic crystals with compactly supported perturbations. Transverse electric and transverse magnetic polarized waves are investigated in 2-D structures. We prove an exponential convergence of the defect frequencies with the *supercell* size and give a justification of the quasi-independence of the corresponding eigenfunctions on the wave vector. We also give a characterization of the *supercell* eigenvalues corresponding to the background photonic crystal.

Key words. photonic crystal, supercell, Helmholtz equation, defect modes

AMS subject classifications. 45C05, 45L05

DOI. 10.1137/040616875

1. Introduction.

Photonic crystals are periodic structures composed of dielectric materials and designed to exhibit interesting properties, such as spectral band gaps, in the propagation of classical electromagnetic waves. In other words, monochromatic electromagnetic waves of certain frequencies do not exist in these structures. Media with band gaps have many potential applications, for example, in optical communications, filters, lasers, and microwaves; see [18], [19], [23], [29] for an introduction to photonic crystals. While necessary conditions under which band gaps exist in general are not known, Figotin and Kuchment have produced an example of high-contrast periodic medium where band gaps exist and can be characterized [16], [17]. Other band gap structures have been found through computational and physical experiments; see [2], [8], [9], [10], [12].

In order to achieve lasers, filters, fibers, or waveguides, allowed modes are required in the band gaps. These modes are obtained by creating localized defects in the periodicity and correspond to isolated eigenvalues with finite multiplicity inside the gaps. The defect mode frequency strongly depends on the defect nature. Figotin and Klein rigorously proved that when a defect is introduced into the periodic structure, i.e., a perturbation with compact support, it is possible to create a defect mode, which is an exponentially confined standing wave whose frequency lies in the band gap [13], [14], [15]; see also Ammari and Santosa [1] and Kuchment and Ong [24] for the issue of existence of exponentially confined modes guided by line defects in photonic crystals.

The defect modes as well as the guided modes associated with compact and line defects, respectively, are computed via the supercell technique. This technique consists of restricting the computation on a domain surrounding the defect with sufficient bulk crystal, called the *supercell*, with periodic conditions on its boundary. The boundary conditions on the supercell are, in principle, irrelevant if the mode is sufficiently confined. Since one would like to compute only the defect or the guided modes in the band gap, without the waste of computation and memory of finding all the eigenvalues associated with the supercell belonging to the continuous spectrum,

one states the problem as one of finding the eigenvalues and eigenvectors closest to the mid-gap frequency.

The supercell method demonstrates very good concordance with experimental results and seems to be very accurate. However, analytic studies and rigorous proofs of convergence of this technique are essentially absent.

In this paper we address some of the basic issues of the supercell method and prove the convergence of this technique. Although one can obtain analogous results for the case of full Maxwell equations, we only address the cases of transverse electric (TE) and transverse magnetic (TM) polarized electromagnetic waves in two-dimensional photonic structures.

The outline of this paper is as follows. In the next section we review some basic facts on the spectra of periodic elliptic operators, emphasizing the Floquet–Bloch theory. We then describe in section 3 the supercell method and investigate its mathematical foundations in the TM case. Section 4 is devoted to the TE case. Finally, in section 5 the results of numerical experiments are presented to illustrate our main findings.

2. Notation and preliminary results.

Consider a photonic crystal characterized by its dielectric permittivity ε_{p}, which is a real valued, piecewise constant and periodic function belonging to the set $\{\varepsilon_{\mathrm{p}} \in L^\infty(\mathbb{R}^2/\mathbb{Z}^2) :\ 0 < \varepsilon_1 \le \varepsilon_{\mathrm{p}} \le \varepsilon_2 \text{ a.e.}\}$, where ε_1 and ε_2 are constants. The magnetic permeability is supposed constant and equal to unity throughout this paper.

We assume that the crystal is periodic with period $[0,1]^2$, i.e., that $\varepsilon_{\mathrm{p}}(x+n) = \varepsilon(x)$ for almost all $x \in \mathbb{R}^2$ and all $n \in \mathbb{Z}^2$.

The propagation of electromagnetic waves is governed by the Maxwell's equations. It is common to reduce these equations in a 2-D medium to two sets of scalar equations in the TM and TE cases. Each one can be solved by solving one scalar partial differential equation and the other scalar functions follow immediately from that solution.

These equations are the Helmholtz equation

$$\Delta u + \omega^2 \varepsilon_{\mathrm{p}} u = 0, \tag{2.1}$$

for the TM polarization, and the acoustic equation

$$\nabla \cdot \frac{1}{\varepsilon_{\mathrm{p}}} \nabla u + \omega^2 u = 0, \tag{2.2}$$

for the TE polarization.

We now recall some well-known results on the spectrum of the TM and TE operators in the periodic medium. Since we deal with a partial differential equation with periodic coefficients, it is natural to make a Floquet transform and apply the Floquet–Bloch theory.

First we briefly present the Floquet–Bloch theory applied to the TM and TE operators in periodic media.

Let $A(x,D)$ denote the TM or TE operator on $L^2(\mathbb{R}^2)$ in a periodic medium characterized by ε_{p}, where $D = -i\nabla$. This operator is invariant with respect to the discrete group of translations $\mathbb{Z}^2$ acting on $\mathbb{R}^2$. It is then natural to apply the Fourier transform on $\mathbb{Z}^2$, that is the transform assigning to a sufficiently decaying function $h(n)$ on $\mathbb{Z}^2$, the Fourier series

$$\widehat{h}(\xi) = \sum_{j \in \mathbb{Z}^2} h(j) e^{i\xi\cdot j},$$

where $\xi \in \mathbb{R}^2$. However, since we deal with functions defined on $\mathbb{R}^2$, we use the Floquet transform which is the appropriate transform in this case.

Consider a function v defined on $\mathbb{R}^2$, sufficiently decaying at infinity. We can then define its Floquet transform by

$$\mathcal{F}v(x,\xi) = \sum_{j\in\mathbb{Z}^2} v(x-j)e^{i\xi\cdot j} = \widehat{v(x-\cdot)}. \tag{2.3}$$

It is easy to check that $\mathcal{F}v(\cdot,\xi)$ is ξ-quasi-periodic with respect to the first variable, that is

$$(\mathcal{F}v)(x+n,\xi) = (\mathcal{F}v)(x,\xi)e^{i\xi\cdot n} \quad \forall x \in \mathbb{R}^2, n \in \mathbb{Z}^2.$$

Moreover, it is periodic with respect to the variable ξ, called quasi-momentum, with period lattice $[0,2\pi]^2$. It is then sufficient to know the function $\mathcal{F}v$ for $(x,\xi) \in Y \times \mathcal{B}$, where $Y = [0,1[^2$ and $\mathcal{B} = [-\pi,\pi[^2$ (called in the literature the first Brillouin zone), to recover it on $\mathbb{R}^2 \times \mathbb{R}^2$.

It turns out that the Floquet transform commutes with partial differential operators with periodic coefficients. In particular, we notice that

$$\mathcal{F}(A(x,D)u) = A(x,D)(\mathcal{F}u).$$

The Floquet transform allows us to represent a function on $L^2(\mathbb{R}^2)$ as a continuous sum of quasi-periodic functions. In fact, the Floquet theory defines an isometric mapping between $L^2(\mathbb{R}^2)$ and $L^2(\mathcal{B}, L^2_\xi(\mathbb{R}^2))$, $L^2_\xi(\mathbb{R}^2)$ being the space of ξ-quasi-periodic L^2- functions. The inverse of the Floquet transform is given by the following formula:

$$(\mathcal{F}^{-1}v)(x) = \frac{1}{|\mathcal{B}|}\int_B v(x,\xi)d\xi, \tag{2.4}$$

for any v in $L^2(\mathcal{B}, L^2_\xi(\mathbb{R}^2))$.

The isometric character of the Floquet transform, together with its commutation properties on partial differential operators with periodic coefficients, make it very useful to study spectral problems. Indeed, the spectral problem for the operator $A(x,D)$ becomes a family of spectral problems for operators $A_\xi(x,D)$ (having formally the same expression but with domains depending on ξ), acting on functions defined on a bounded set (the period lattice of the photonic crystal), with ξ-quasi-periodicity.

An alternative version to the Floquet transform is the transform Φ defined as

$$\Phi v(x,\xi) = \sum_{j\in\mathbb{Z}^2} v(x-j)e^{-i\xi\cdot(x-j)} = e^{-i\xi\cdot x}\mathcal{F}v(x,\xi).$$

The function Φv is periodic with respect to x and $(-x)$-quasi-periodic with respect to ξ with 2π-quasi-period,

$$\begin{cases} \Phi v(x+n,\xi) = \Phi v(x,\xi), & n \in \mathbb{Z}^2, \\ \Phi v(x,\xi+\zeta) = e^{-i\zeta\cdot x}\Phi v(x,\xi), & \zeta \in 2\pi\mathbb{Z}^2. \end{cases} \tag{2.5}$$

With this transform, we now deal with functions defined on a fixed space $L^2(\mathcal{B}, L^2(\mathbb{R}^2/\mathbb{Z}^2))$, while the operator $A(x,D)$ is split into a sum of operators $A(x,D-\xi)$, depending on ξ,

$$\Phi(A(x.D)u)(x,\xi) = A(x,D-\xi)(\Phi u)(x,\xi).$$

The transform Φ is still an isometric mapping between $L^2(\mathbb{R}^2)$ and $L^2(\mathcal{B}, L^2(\mathbb{R}^2/\mathbb{Z}^2))$, and its inverse transform is

$$(\Phi^{-1}v)(x) = \frac{1}{|\mathcal{B}|}\int_{\mathcal{B}} e^{ix\cdot\xi} v(x,\xi)d\xi.$$

Let Σ be the spectrum of $A(x,D)$ on $L^2(\mathbb{R}^2)$ and Σ^ξ the spectrum of $A(x, D-\xi)$ on $L^2(\mathbb{R}^2/\mathbb{Z}^2)$, then we can deduce immediately the following identity:

$$\Sigma = \cup_{\xi\in\mathcal{B}}\Sigma^\xi. \tag{2.6}$$

Now, with these tools, we are in the position to explore the spectrum of the TM and TE operators in periodic media.

In the case of the TE polarization, the operator we are studying is

$$A(x,D) = -\nabla\cdot\frac{1}{\varepsilon_{\mathrm{p}}}\nabla.$$

After the transform Φ, we get the following spectral problem:

$$-(\nabla_x - i\xi)\cdot\frac{1}{\varepsilon_{\mathrm{p}}}(\nabla_x - i\xi)v(x,\xi) = \omega^2 v(x,\xi), \quad v(\cdot,\xi)\in L^2(\mathbb{R}^2/\mathbb{Z}^2). \tag{2.7}$$

We remark that $A(x, D-\xi)$ is an elliptic self-adjoint operator on $L^2(\mathbb{R}^2/\mathbb{Z}^2)$ with compact resolvent. It follows that its spectrum is discrete with countably many positive eigenvalues denoted $\lambda_n(\xi)$ and ordered increasingly. It is easy to prove the continuity of $\lambda_n(\xi)$ on $\xi\in\mathcal{B}$. Finally, defining the intervals I_n by

$$I_n = \left[\min_{\xi\in\mathcal{B}}\lambda_n(\xi), \max_{\xi\in\mathcal{B}}\lambda_n(\xi)\right],$$

we deduce the spectrum of the TE operator

$$\Sigma_{\mathrm{TE}} = \cup_{n\in\mathbb{N}} I_n.$$

We then see clearly the band structure of the spectrum since it is a union of the intervals formed by the values of each eigenvalue when the quasi-momentum varies in the Brillouin zone. In fact, if two successive intervals are disjoint, which means that the maximal value of an eigenvalue is smaller than the minimal value of the following one, then there is a gap in the spectrum Σ_{TE} and no propagation is possible for TE waves at the corresponding frequencies. This makes all the interest of photonic crystals.

In what follows, we make the following assumption: *the spectrum of the TM operator and the TE operator in the periodic medium are absolutely continuous.* This is always assumed in photonic crystal studies. There exists a proof of absolute continuity of Maxwell operator spectrum in periodic media with smooth coefficients in [25].

Another important property of photonic crystals is a consequence of the characterization of the decay of functions in $L^2(\mathbb{R}^2)$ in terms of the smoothness of their Floquet transform in the same spirit as the Paley–Wiener theorem. Suppose that the spectrum contains some gaps, that is $\Sigma_{TE} \neq \mathbb{R}^2$ and let ω be a frequency lying in a band gap. Let G_{p} be the Green's function of the TE operator defined by

$$\nabla\cdot\frac{1}{\varepsilon_{\mathrm{p}}}\nabla G_{\mathrm{p}}(\omega;x,y) + \omega^2 G_{\mathrm{p}}(\omega;x,y) = \delta(x-y), \quad x\in\mathbb{R}^2. \tag{2.8}$$

It has been established in [3], [7] that the Floquet transform of G_{p} is analytic with respect to ω in a complex neighborhood of the real axis. In view of Paley–Wiener-type theorems, the analyticity of $\mathcal{F}G_{\mathrm{p}}$ is the key ingredient of the proof of the following result [13], [14], [15].

Lemma 2.1. *For any $\omega_0^2 > 0$, there exist two positive constants C_1 and C_2 depending only on ω_0^2 such that for any $\omega^2 \notin \Sigma_{\mathrm{TE}} \cap (0, \omega_0^2)$,*

$$|G_{\mathrm{p}}(\omega; x, y)| \leq C_1 e^{-C_2\, dist(\omega^2, \Sigma_{\mathrm{TE}})|x-y|}, \quad \textit{for } |x-y| \to +\infty. \tag{2.9}$$

Remark 2.1. The behavior of the Green's function at infinity is the essential feature of PBG materials: it explains why localized defects in photonic crystals may act as perfect cavities, when the frequency lies in a band gap. Electromagnetic waves can be represented in terms of G_{p} and thus inherit the exponential decay property.

In the case of the TM polarization, the operator we are studying is

$$A(x, D) = -\frac{1}{\varepsilon_{\mathrm{p}}}\Delta.$$

Taking the transform Φ, we get the following spectral problem:

$$-\frac{1}{\varepsilon_{\mathrm{p}}}(\nabla_x - i\xi)\cdot(\nabla_x - i\xi)v(x,\xi) = \omega^2 v(x,\xi), \quad v(\cdot,\xi) \in L^2(\mathbb{R}^2/\mathbb{Z}^2). \tag{2.10}$$

The difference with the TE case is that this operator is elliptic, self-adjoint with compact resolvent on the space of square measurable functions provided with the measure $\varepsilon_{\mathrm{p}}(x)\, dx$ instead of dx.

The results are therefore the same as for the TE case, and we get a spectrum with band structure

$$\Sigma_{\mathrm{TM}} = \cup_{n\in\mathbb{N}} I_n,$$

where $(I_n)_{n\in\mathbb{N}}$ are defined in the same way as for the TE case.

Analogous properties to the TE case hold. In particular, Lemma 2.1 holds with the Green's function associated with the TM polarization.

From now on and until otherwise mentioned, we deal with TM-polarized electromagnetic waves. We consider a background medium characterized by its dielectric permittivity ε_{p}.

First, we introduce some simplified notations. For any domain $D \subset \mathbb{R}^2$ and any measurable positive function $\rho \in L^\infty(D)$ bounded and away from 0 (i.e., $\exists \rho_-, \rho_+ \in \mathbb{R}_+$ s.t. $0 < \rho_- \leq \rho(x) \leq \rho_+ < \infty$, a.e. $x \in D$) we define the weighted L^2 space denoted by $L^2_\rho(D)$ and corresponding to square mesurable functions on D provided with the scalar product $(f,g)_{L^2_\rho(D)} = \int_D f(x)\bar{g}(x)\rho(x)\mathrm{d}x$ and the norm $\|f\|_{L^2_\rho(D)} = \int_D |f(x)|^2\rho(x)\, dx$.

Definition 2.1. *We define the self-adjoint operator A_{p} by*

$$A_{\mathrm{p}} = -\frac{1}{\varepsilon_{\mathrm{p}}}\Delta, \quad \textit{on } L^2_{\varepsilon_{\mathrm{p}}}(\mathbb{R}^2),$$

and denote by Σ_{p} its spectrum.

For $\xi \in [0, 2\pi[^2$ we define A^ξ_{p} on $L^2_{\varepsilon_{\mathrm{p}}}(\mathbb{R}^2/\mathbb{Z}^2)$ by

$$A^\xi_{\mathrm{p}} = -\frac{1}{\varepsilon_{\mathrm{p}}}(\nabla_x - i\xi)\cdot(\nabla_x - i\xi),$$

and denote by $\Sigma_{\mathrm{p}}^{\xi}$ *its spectrum.*

We create a perturbation of the background medium by modifying its dielectric permittivity into ε as follows:

$$\varepsilon(x) = \varepsilon_{\mathrm{p}}(x) - (\delta\varepsilon)\chi_{\Omega}(x), \tag{2.11}$$

where $(\delta\varepsilon)$ is a real constant and Ω is a bounded domain in $\mathbb{R}^2$.

The perturbation of the dielectric permittivity induces a modification of the TM operator into

$$A = -\frac{1}{\varepsilon}\Delta, \tag{2.12}$$

and, consequently, the spectrum Σ of A is different from the spectrum Σ_{p} of A_{p}. However, it has been proved that the perturbation of the TM operator is relatively compact and therefore it keeps the essential spectrum of A_{p} unchanged; see [14]. Since the spectrum Σ_{p} is purely continuous, the perturbation will result in the addition of eigenvalues of finite multiplicity to Σ_{p}.

The following theorem from [14] is of importance to us.

THEOREM 2.1. *Suppose that, for some* $\omega_0^2 > 0$*, the spectrum* $\Sigma_{\mathrm{p}} \cap (0, \omega_0^2)$ *of the operator* A_{p} *has a gap and suppose that the defect* $(\Omega, (\delta\varepsilon))$ *has created an isolated eigenvalue* ω^2 *in the gap. Let* u *be an associated eigenvector. Then, there exists two constants* C_1 *and* C_2*, depending only on* ω_0^2*, such that*

$$\|u\|_{L^2(B_x)} \leq C_1 e^{-C_2\, dist(\omega^2, \Sigma_{\mathrm{p}})\, dist(x,\Omega)} \|u\|_{L^2(\Omega)},$$

where B_x *is the ball of center* x *and radius one.*

Proof. The eigenmode u is solution of the following equation:

$$\Delta u + \omega^2 \varepsilon(x) u = 0. \tag{2.13}$$

It is easy then to see that u is solution of the following integral equation:

$$u(x) = (\delta\varepsilon)\omega^2 \int_{\Omega} G_{\mathrm{p}}(\omega; x, y) u(y)\, dy. \tag{2.14}$$

The proof of the theorem is then a direct consequence of the exponential decay of the Green's function in Lemma 2.1. □

Remark 2.2. This theorem has very important consequences. It explains why we can confine electromagnetic waves in defects or guide them along a defect. The use of dielectric material that has very low loss and the exponential decrease of the electromagnetic field away from the defect ensures a very efficient confinement with a cladding of few periods of the photonic crystal.

3. The supercell method. We start this section by giving a mathematical description of the supercell method.

3.1. Definitions and preliminary results. We consider the background and perturbed media introduced in the previous section with their corresponding TM operators and spectra. Since the perturbed medium is not periodic, the Floquet's theory does not apply.

To recover a periodic medium, we define an artificial medium in the following way. Without loss of generalization, we can suppose that the defect support Ω is centered at 0. For $N \in \mathbb{N}$ large enough to have $\Omega \in]-N, N[^2$, we define the $(2N)$-periodic L^∞-function ε_N by

$$\begin{cases} \varepsilon_N(x) = \varepsilon(x) \quad \forall x \in]-N, N[^2, \\ \varepsilon_N(x + 2Nj) = \varepsilon_N(x) \quad \forall x \in \mathbb{R}^2 \, \forall j \in \mathbb{N}^2. \end{cases} \tag{3.1}$$

Definition 3.1. *We define the self-adjoint operator A_N on $L^2_{\varepsilon_N}(\mathbb{R}^2)$ by*

$$A_N = -\frac{1}{\varepsilon_N}\Delta, \tag{3.2}$$

and let Σ_N be its spectrum.

For $\xi \in \mathcal{B_N} = [-\frac{\pi}{2N}, \frac{\pi}{2N}[^2$, we define the self-adjoint operator A_N^ξ on $L^2_{\varepsilon_N}\mathbb{R}^2/2N\mathbb{Z}^2)$ by:

$$A_N^\xi = -\frac{1}{\varepsilon_N}(\nabla - i\xi) \cdot (\nabla - i\xi),$$

and denote by Σ_N^ξ its spectrum.

The function ε_N defines a photonic crystal formed by the defect repeated with a $2N$-period inside the original photonic crystal. It is therefore obvious that the spectrum Σ_N is an absolutely continuous spectrum. The question is: what happens when N goes to infinity?

A natural answer is that since the repeated defects will be away from each other, they will not interact and, in the neighborhood of one defect, the operator will see almost an infinite crystal. We expect then a kind of convergence of Σ_N to the spectrum Σ corresponding to one defect in the infinite photonic crystal. So for N large enough, after taking the Floquet transform in the supercell and computing the spectrum, we will find a spectrum divided into wide bands very close to those corresponding to the background medium and very narrow bands (almost a horizontal line when plotted against the quasi-momentum) that should correspond to the defect modes of the perturbed crystal. This is what will be proved in the following subsections.

To give a characterization of the convergence of the spectrum of the supercell, we will use the Hausdorff distance denoted $\text{dist}_\mathcal{H}$, that is a measure of the resemblance of two (fixed) sets.

Definition 3.2. *Let E and F be two nonempty subsets of a metric set. We define the Hausdorff distance denoted $dist_\mathcal{H}$ between E and F as*

$$dist_\mathcal{H}(E, F) = \inf\{d \geq 0 \; \forall (x, y) \in E \times F, \; dist(x, F) < d \text{ and } dist(y, E) < d\}.$$

This means that if $\text{dist}_\mathcal{H}(E, F) = d$, then any point of one of the two sets is within distance d from some point of the other set.

Finally, we give in the following proposition an important result from the spectral theory, see [28], that will be useful for the convergence results.

Proposition 3.1. *Let A be a self-adjoint operator with a domain $\mathcal{D}(A)$ and a spectrum $\sigma(A)$, then, for $\mu \in \mathbb{R}$,*

$$dist(\mu, \sigma(A)) = \min_{\phi \in \mathcal{D}(A)} \frac{\|(A - \mu I)\phi\|}{\|\phi\|}. \tag{3.3}$$

3.2. Convergence of the "continuous spectrum." Here we give a characterization of the convergence of the part corresponding to the spectrum of the unperturbed crystal.

THEOREM 3.1. *For any $\omega_0 > 0$ and $N_0 \in \mathbb{N}$, there exists $C > 0$, depending only on ω_0, N_0 and Ω, such that*

$$\max_{\omega^2 \in \cup_{k\in[-N+1,N-1[^2\cap\mathbb{N}^2} \Sigma_{\mathrm{p}}^{\xi+k\pi/N} \cap [0,\omega_0^2]} dist(\omega^2, \Sigma_N^{\xi}) \leq \frac{C}{N^2}, \tag{3.4}$$

for any $N \geq N_0$ and any $\xi \in \mathcal{B}_{\mathcal{N}}$.

Proof. Let $k \in [-N+1, N-1[^2\cap\mathbb{N}^2$ and $\xi \in \mathcal{B}_{\mathcal{N}}$. Let ω^2 be in $\Sigma_{\mathrm{p}}^{\xi+k\pi/N} \cap [0, \omega_0^2]$. Since $\xi + k\pi/N \in \mathcal{B}$, there exists $\phi \in L^2_{\varepsilon_{\mathrm{p}}}(\mathbb{R}^2/\mathbb{Z}^2)$ with unit norm such that

$$\left(\nabla - i\left(\xi + \frac{k\pi}{N}\right)\right) \cdot \left(\nabla - i\left(\xi + \frac{k\pi}{N}\right)\right)\phi + \omega^2\varepsilon_{\mathrm{p}}\phi = 0. \tag{3.5}$$

Let $\tilde{\phi}$ be defined in $L^2_{\varepsilon_N}(\mathbb{R}^2/2N\mathbb{Z}^2)$ as

$$\tilde{\phi}(x) = \phi(x)e^{-i\frac{\pi}{N}k\cdot x}. \tag{3.6}$$

There exists a constant $0 < C_0 < 4$ such that for some integer $N_0 > 0$,

$$\|\tilde{\phi}\|_{L^2_{\varepsilon_N}(\mathbb{R}^2/2N\mathbb{Z}^2)} > C_0 N^2$$

for any $N \geq N_0$, where C_0 and N_0 are independent of $\tilde{\phi}$. The function $\tilde{\phi}$ satisfies the following equation:

$$(\nabla - i\xi) \cdot (\nabla - i\xi)\tilde{\phi} + \omega^2\varepsilon_{\mathrm{p}}\tilde{\phi} = 0, \tag{3.7}$$

which can be rewritten as follows:

$$(\nabla - i\xi) \cdot (\nabla - i\xi)\tilde{\phi} + \omega^2\varepsilon_N\tilde{\phi} = -\chi_\Omega(\delta\varepsilon)\omega^2\tilde{\phi}. \tag{3.8}$$

Let C_1 be the minimal number of unit squares in which Ω can be strictly included. Since the $L^2_{\varepsilon_{\mathrm{p}}}$-norm of $\tilde{\phi}$ in a unit square is 1, we have

$$\|\tilde{\phi}\|_{L^2(\Omega)} \leq \frac{C_1}{\sqrt{\min(\varepsilon_{\mathrm{p}})}}.$$

Thus

$$\begin{aligned} \frac{\|\frac{1}{\varepsilon_N}(\nabla - i\xi) \cdot (\nabla - i\xi)\tilde{\phi} + \omega^2\tilde{\phi}\|_{L^2_{\varepsilon_N}(\mathbb{R}^2/(2N)\mathbb{Z}^2)}}{\|\tilde{\phi}\|_{L^2_{\varepsilon_N}(\mathbb{R}^2/2N\mathbb{Z}^2)}} &= (\delta\varepsilon)\omega^2 \frac{(\int_\Omega |\tilde{\phi}|^2 \frac{1}{\varepsilon_N}\, dx)^{1/2}}{\|\tilde{\phi}\|_{L^2_{\varepsilon_N}(\mathbb{R}^2/2N\mathbb{Z}^2)}} \\ &\leq \frac{C_2}{N^2}, \end{aligned}$$

where $C_2 = |(\delta\varepsilon)|\omega_0^2 \frac{C_1}{C_0\sqrt{\min(\varepsilon_{\mathrm{p}})\min(\varepsilon_N)}}$.

It follows from Proposition 3.1 that there exists an eigenvalue ω_ξ^2 belonging to the spectrum Σ_N^ξ of the operator A_N^ξ such that

$$|\omega^2 - \omega_\xi^2| \leq \frac{C_2}{N^2},$$

which ends the proof. □

Remark 3.1. This theorem tells us that $\mathrm{card}\big(\Sigma_N^\xi \cap [0, \omega_0^2]\big)$ for $\xi \in \mathcal{B}_\mathcal{N}$ will grow at least as fast as $N^2 \mathrm{card}\big(\Sigma_p^{\xi'} \cap [0, \omega_0^2]\big)$ for any $\xi' \in \mathcal{B}$. So when we use the supercell method to determine the defect modes, we are in front of a dilemma; larger is the size of the supercell, better is the approximation of the defect eigenvalues. But this will take much more time and need much more memory size because of the size of the computational domain and the growing number of useless (in the sense that they do not correspond to the defect) eigenvalues. It is important then to determine the convergence rate of the eigenvalues corresponding to the defect.

Since we know that the spectrum $\Sigma_N = \cup_{\xi \in \mathcal{B}_\mathcal{N}} \Sigma_N^\xi$ is absolutely continuous, we deduce that each connected component of $(\mathbb{R}^2 \setminus \Sigma_N) \cap \Sigma_\mathrm{p} \cap [0, \omega_0]$ has a width smaller than $\frac{2C}{N^2}$.

In practice, because of the growth of degeneracy of the eigenvalues located in Σ_p with N, there will be almost no visible gap inside the bands of Σ_N but the remark remains useful for the perturbation brought to the edges of the bands. In particular, it is useful to check if a perturbation of the edges of a band in Σ_p is due to the presence of a defect eigenvalue in Σ close to the band or not.

3.3. Convergence of the defect eigenvalues.

Here we are concerned with the behavior of the part of the spectrum Σ_N that will give us an approximation of the defect modes (eigenvalues with finite multiplicity in Σ). Let us first try to give a characterization of this part.

DEFINITION 3.3. *For $\eta > 0$, we define $\Sigma_{\mathrm{d},N}^\eta$ as the union of the connected components of Σ_N that are at least η-distant from Σ_p.*

We also define Σ_d as the set of the defect eigenvalues of the perturbed photonic crystal

$$\Sigma_\mathrm{d} = \Sigma \setminus \Sigma_\mathrm{p}.$$

Finally, we introduce $\Sigma_{\mathrm{d},N}^{\xi,\eta}$ and Σ_d^η as

$$\Sigma_{\mathrm{d},N}^{\xi,\eta} = \{\omega^2 \in \Sigma_N^\xi : dist(\omega^2, \Sigma_\mathrm{p}) \geq \eta\}.$$
$$\Sigma_\mathrm{d}^\eta = \{\omega_\mathrm{d}^2 \in \Sigma_\mathrm{d} : dist(\omega_\mathrm{d}^2, \Sigma_\mathrm{p}) \geq \eta\}.$$

The following proposition holds.

PROPOSITION 3.2. *For every gap $]a, b[$ in Σ_p $(0 < a < b)$ satisfying $]a, b[\cap \Sigma = \emptyset$, there exists $N_1 \in \mathbb{N}$ such that, for $N \geq N_1$, $\Sigma_N \cap]a, b[= \emptyset$.*

Proof. Suppose that the proposition is false. Then for any $N_0 \in \mathbb{N}$ there exists $N \geq N_0$ and $\omega_N^2 \in]a, b[\cap \Sigma_N$. This means that there exist $\xi_N \in \mathcal{B}_\mathcal{N}$ and $\phi_N \in L_{\varepsilon_N}^2(\mathbb{R}^2/2N\mathbb{Z}^2)$ with unit norm such that

$$(\nabla - i\xi_N) \cdot (\nabla - i\xi_N)\phi_N + \omega_N^2 \varepsilon_N \phi_N = 0 \quad \text{in } L_{\varepsilon_N}^2(\mathbb{R}^2/2N\mathbb{Z}^2). \tag{3.9}$$

Now, we define $\tilde{\phi}_N$ in $L^2_\varepsilon(\mathbb{R}^2)$ by

$$\tilde{\phi}_N(x) = \int_\Omega G(\omega_N^2; x, y) e^{-i\xi_N \cdot y} \phi_N(y)\, dy. \tag{3.10}$$

The following lemma is needed.

Lemma 3.1. *There exist $N_0 > 0$ depending only on a, b and $\Sigma_{\rm p}$, such that for $N \geq N_0$, we have*

$$\|\tilde{\phi}_N\|_{L^2_\varepsilon(\mathbb{R}^2)} \geq \frac{1}{2}.$$

Proof. From the expression of $\tilde{\phi}_N$ we deduce that

$$\begin{aligned}
(\delta\varepsilon)\omega_N^2 \tilde{\phi}_N(x) &= (\delta\varepsilon)\omega_N^2 \int_\Omega G(\omega_N^2; x, y) e^{-i\xi_N \cdot y} \phi_N(y)\, dy \\
&= \int_{\mathbb{R}^2} G(\omega_N^2; x, y)(\Delta + \omega_N^2 \varepsilon_{\rm p})\big(e^{-i\xi_N \cdot y}\phi_N(y)\big)\, dy \\
&\quad - \int_{\mathbb{R}^2} G(\omega_N^2; x, y)(\Delta + \omega_N^2 \varepsilon)\big(e^{-i\xi_N \cdot y}\phi_N(y)\big)\, dy \\
&= \int_{\mathbb{R}^2} (\Delta + \omega_N^2 \varepsilon_{\rm p}) G(\omega_N^2; x, y) e^{-i\xi_N \cdot y}\phi_N(y)\, dy \\
&\quad - \int_{\mathbb{R}^2} G(\omega_N^2; x, y) e^{-i\xi_N \cdot y}((\nabla - i\xi_N)\cdot(\nabla - i\xi_N) + \omega_N^2\varepsilon)\phi_N(y)\, dy \\
&= e^{-i\xi_N \cdot x}\phi_N(x) \\
&\quad - \int_\Omega \sum_{j\in\mathbb{Z}^2, j\neq 0} (G(\omega_N^2; x, y + Nj) e^{-iN\xi_N \cdot j}) e^{-i\xi_N \cdot y}\phi_N(y) dy.
\end{aligned}$$

Let us now prove that the L^2-norm of the last term in $]-N, N[^2$ converges to 0. From the exponential decay of the Green's function, we deduce that there exist positive constants C_1 and C_2 depending only on the distance of a and b to $\Sigma_{\rm p}$ such that, for any $\omega^2 \in]a, b[$, we have [1]

$$\sum_{j\in\mathbb{Z}^2, j\neq 0} \big|G(\omega^2; x, y + Nj)\big| \leq C_1 e^{-C_2 N} \qquad \forall x \in]-N, N[^2\ \forall y \in \Omega. \tag{3.11}$$

It follows then, since $\|\phi_N\|_{L^2_{\varepsilon_N}(]-N,N[^2)} = 1$, that for any $x \in]-N, N[^2$, we have

$$\begin{aligned}
&\Big| \int_\Omega \sum_{j\in\mathbb{Z}^2, j\neq 0} (G(\omega_N^2; x, y + Nj) e^{-iN\xi_N \cdot j}) e^{-i\xi_N \cdot y}\phi_N(y) dy \Big| \\
&\quad \leq C_1 e^{-C_2 N} \int_\Omega |\phi_N(y)|\, dy \\
&\quad \leq C_1 e^{-C_2 N} \frac{|\Omega|^{\frac{1}{2}}}{\sqrt{\min(\varepsilon_N)}} ||\phi_N||_{L^2_{\varepsilon_N}(\Omega)} \\
&\quad \leq C_1 e^{-C_2 N} \frac{|\Omega|^{\frac{1}{2}}}{\sqrt{\min(\varepsilon_N)}}.
\end{aligned}$$

We then deduce that:

$$\left\| \int_\Omega \sum_{j\in\mathbb{Z}^2, j\neq 0} (G(\omega_N^2; x, y+Nj)e^{-iN\xi_N\cdot j})e^{-i\xi_N\cdot y}\phi_N(y)dy \right\|_{L^2_\varepsilon(]-N,N[^2)} \\ \leq \frac{\sqrt{\max(\varepsilon)}|\Omega|^{\frac{1}{2}}}{\sqrt{\min(\varepsilon_N)}} 2NC_1e^{-C_2N}.$$

Hence, recalling that $\|e^{-i\xi_N\cdot x}\phi_N(x)\|_{L^2_{\varepsilon_N}(]-N,N[^2)} = 1$, there exists $N_0 > 0$ such that for any $N \geq N_0$, we have

$$\|\tilde{\phi}_N\|_{L^2_\varepsilon(\mathbb{R}^2)} \geq \|\tilde{\phi}_N\|_{L^2_\varepsilon(]-N,N[^2)} \geq \frac{1}{2}. \tag{3.12}$$

Lemma 3.1 is then proved. □

We now turn to the proof of Proposition 3.2. We have

$$\begin{aligned}
\Delta\tilde{\phi}_N + \omega_N^2\varepsilon\tilde{\phi}_N &= \int_\Omega (\Delta_x + \omega_N^2\varepsilon)G(\omega_N^2; x, y)e^{-i\xi_N\cdot y}\phi_N(y)\, dy \\
&= \int_\Omega (\Delta_x + \omega_N^2\varepsilon_{\mathrm{p}})G(\omega_N^2; x, y)e^{-i\xi_N\cdot y}\phi_N(y)\, dy \\
&\quad -(\delta\varepsilon)\chi_\Omega(x)\omega_N^2 \int_\Omega G(\omega_N^2; x, y)e^{-i\xi_N\cdot y}\phi_N(y)\, dy \\
&= \chi_\Omega(x)e^{-i\xi_N\cdot x}\phi_N(x) \\
&\quad -\chi_\Omega(x)\int_{\mathbb{R}^2} G(\omega_N^2; x, y)(\Delta_y + \omega_N^2\varepsilon_{\mathrm{p}})(e^{-i\xi_N\cdot y}\phi_N(y))\, dy \\
&\quad +\chi_\Omega(x)\int_{\mathbb{R}^2} G(\omega_N^2; x, y)(\Delta_y + \omega_N^2\varepsilon)(e^{-i\xi_N\cdot y}\phi_N(y))\, dy \\
&= \chi_\Omega(x)e^{-i\xi_N\cdot x}\phi_N(x) \\
&\quad -\chi_\Omega(x)\int_{\mathbb{R}^2} (\Delta_y + \omega_N^2\varepsilon_{\mathrm{p}})G(\omega_N^2; x, y)e^{-i\xi_N\cdot y}\phi_N(y)\, dy \\
&\quad +\chi_\Omega(x)\int_{\mathbb{R}^2} G(\omega_N^2; x, y)e^{-i\xi_N\cdot y}((\nabla - i\xi_N)\cdot(\nabla - i\xi_N) + \omega_N^2\varepsilon)\phi_N(y)dy \\
&= (\delta\varepsilon)\omega_N^2\chi_\Omega(x) \\
&\qquad \int_\Omega \Bigg(\sum_{j\in\mathbb{Z}^2, j\neq 0} G(\omega_N^2; x, y+Nj)e^{-i\xi_N\cdot(y+Nj)} \Bigg)\phi_N(y)\, dy.
\end{aligned}$$

Using estimate (3.11), we deduce the existence of positive constants C_1 and C_2 depending only on the distance of a and b to Σ_{p} such that

$$\left| \sum_{j\in\mathbb{Z}^2, j\neq 0} G(\omega_N^2; x, y+Nj)e^{-i\xi_N\cdot(y+Nj)} \right| \leq C_1e^{-C_2N}, \tag{3.13}$$

for any $x, y \in \Omega$. We then obtain that

$$\begin{aligned}&\left| \int_\Omega \left(\sum_{j\in\mathbb{Z}^2, j\neq 0} G(\omega_N^2; x, y+Nj) e^{-i\xi_N\cdot(y+Nj)} \right) \phi_N(y)\, dy \right| \\ &\quad \le C_1 e^{-C_2 N} |\Omega|^{\frac{1}{2}} \|\phi_N\|_{L^2(\Omega)} \\ &\quad \le C_1 e^{-C_2 N} |\Omega|^{\frac{1}{2}}.\end{aligned}$$

This yields the following result:

$$\left\| \frac{1}{\varepsilon} \Delta \tilde{\phi}_N + \omega_N^2 \tilde{\phi}_N \right\|_{L^2_\varepsilon(\mathbb{R}^2)} \le \frac{|(\delta\varepsilon)|\omega_N^2|\Omega|}{\sqrt{\min(\varepsilon)}} C_1 e^{-C_2 N}. \tag{3.14}$$

Lemma 3.1 yields the estimate

$$\operatorname{dist}(\omega_N^2, \Sigma) \le \frac{2|(\delta\varepsilon)|\ b\ |\Omega|}{\sqrt{\min(\varepsilon)}} C_1 e^{-C_2 N},$$

from which we conclude that $\operatorname{dist}(]a,b[,\Sigma) = 0$. This is a contradiction with the assumption. The proof of the proposition is complete. ∎

Now we can prove the following result concerning the convergence to the defect modes.

Theorem 3.2. *Suppose that the perturbation has created defect eigenvalues. Then, there exist $\eta_0 > 0$ and $N_0 \in \mathbb{N}$ such that for any $\eta \le \eta_0$ and $N \ge N_0$,*

$$\Sigma_{\mathrm{d},N}^{\xi,\eta} \neq \emptyset \quad \forall \xi \in \mathcal{B}_{\mathcal{N}}.$$

Moreover, for any $\omega_0^2 > 0$ and $\eta \le \eta_0$, there exist two positive constants C_1 and C_2, depending only on ω_0^2, such that for any $\xi \in \mathcal{B}_{\mathcal{N}}$,

$$dist_{\mathcal{H}}(\Sigma_{\mathrm{d},N}^{\xi,\eta} \cap [0, \omega_0^2], \Sigma_{\mathrm{d}}^{\eta} \cap [0, \omega_0^2]) \le C_1 e^{-C_2 \eta N}. \tag{3.15}$$

Proof. Let ω_{d}^2 be a defect eigenvalue in Σ_{d}. It follows that there exists a function u in $L^2_\varepsilon(\mathbb{R}^2)$ with unit norm such that

$$\Delta u + \omega_{\mathrm{d}}^2 \varepsilon u = 0 \quad \text{in } \mathbb{R}^2. \tag{3.16}$$

Let ξ be in $\mathcal{B}_{\mathcal{N}}$. We define u^ξ in $L^2_{\varepsilon_N}(\mathbb{R}^2/2N\mathbb{Z}^2)$ by

$$u^\xi(x) = \sum_{j\in\mathbb{Z}^2} u(x+Nj) e^{i\xi\cdot(x+Nj)}.$$

Then for $x \in]-N, N[^2$, we have

$$\begin{aligned}&((\nabla - i\xi)\cdot(\nabla - i\xi) + \omega_{\mathrm{d}}^2 \varepsilon_N) u^\xi(x) \\ &\qquad = \sum_{j\in\mathbb{Z}^2} e^{i\xi\cdot(x+Nj)} (\Delta + \omega_{\mathrm{d}}^2 \varepsilon_N) u(x+Nj) \\ &\qquad = \sum_{j\in\mathbb{Z}^2} e^{i\xi\cdot(x+Nj)} (\Delta + \omega_{\mathrm{d}}^2 \varepsilon(x+Nj)) u(x+Nj) \\ &\qquad\quad + (\delta\varepsilon)\omega_{\mathrm{d}}^2 \sum_{j\in\mathbb{Z}^2} e^{i\xi\cdot(x+Nj)} (\varepsilon_N(x) - \varepsilon(x+Nj)) u(x+Nj) \\ &\qquad = -(\delta\varepsilon)\omega_{\mathrm{d}}^2 \chi_\Omega(x) \sum_{j\in\mathbb{Z}^2, j\neq 0} e^{i\xi\cdot(x+Nj)} u(x+Nj).\end{aligned}$$

On the other hand, for $x \in \mathbb{R}^2$,

$$\begin{aligned} u(x) &= \int_{\mathbb{R}^2} \delta(x-y)u(y)\,dy \\ &= \int_{\mathbb{R}^2} (\Delta + \varepsilon_{\mathrm{p}}\omega_{\mathrm{d}}^2) G(\omega_{\mathrm{d}}^2; x, y) u(y)\,dy \\ &= \int_{\mathbb{R}^2} G(\omega_{\mathrm{d}}^2; x, y)(\Delta + \varepsilon_{\mathrm{p}}\omega_{\mathrm{d}}^2) u(y)\,dy \\ &= (\delta\varepsilon)\omega_{\mathrm{d}}^2 \int_{\Omega} G(\omega_{\mathrm{d}}^2; x, y) u(y)\,dy. \end{aligned}$$

Therefore

$$\begin{aligned} &((\nabla - i\xi)\cdot(\nabla - i\xi) + \omega_{\mathrm{d}}^2\varepsilon_N)u^\xi(x) \\ &\quad -(\delta\varepsilon)^2\omega_{\mathrm{d}}^4\chi_\Omega(x)\int_\Omega \left(\sum_{j\in\mathbb{Z}^2, j\neq 0} G(\omega_{\mathrm{d}}^2; x+Nj, y) e^{i\xi\cdot(x+Nj)}\right) u(y)\,dy. \end{aligned}$$

From (3.11), it follows that there exist two positive constants C_1 and C_2, depending only on ω_0^2, such that

$$\begin{aligned} \left| \int_\Omega \left(\sum_{j\in\mathbb{Z}^2, j\neq 0} G(\omega_{\mathrm{d}}^2; x+Nj, y) e^{i\xi\cdot(x+Nj)}\right) u(y)\,dy \right| &\leq C_1 e^{-C_2 \mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_{\mathrm{p}})N} \int_\Omega |u(y)|\,dy \\ &\leq C_1 e^{-C_2 \mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_{\mathrm{p}})N} |\Omega|^{\frac{1}{2}} \|u\|_{L^2(\Omega)} \\ &\leq |\Omega|^{\frac{1}{2}} C_1 e^{-C_2 \mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_{\mathrm{p}})N}. \end{aligned}$$

Therefore

$$\left\| \frac{1}{\varepsilon_N}(\nabla - i\xi)\cdot(\nabla - i\xi)u^\xi(x) + \omega_{\mathrm{d}}^2 u^\xi(x) \right\|_{L^2_{\varepsilon_N}(]-N,N[^2)} \leq \frac{(\delta\varepsilon)^2\omega_{\mathrm{d}}^4|\Omega|}{\sqrt{\min(\varepsilon_N)}} C_1 e^{-C_2 \mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_{\mathrm{p}})N}, \tag{3.17}$$

since

$$\begin{aligned} u^\xi(x) &= u(x)e^{i\xi\cdot x} + \sum_{j\in\mathbb{Z}^2, j\neq 0} u(x+Nj)e^{i\xi\cdot(x+Nj)}, x \in]-N, N[^2, \\ \lim_{N\to+\infty} &\|u(x)e^{i\xi\cdot x}\|_{L^2_{\varepsilon_N}(]-N,N[^2)} = 1, \end{aligned}$$

and

$$\left\| \sum_{j\in\mathbb{Z}^2, j\neq 0} u(x+Nj)e^{i\xi\cdot(x+Nj)} \right\|_{L^2_{\varepsilon_N}(]-N,N[^2)} \leq |\Omega|^{\frac{1}{2}} N C_1 e^{-C_2 \mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_{\mathrm{p}})N},$$

we deduce that for N large enough,

$$\|u^\xi\|_{L^2_{\varepsilon_N}(]-N,N[^2)} \geq \frac{1}{2}.$$

Thus, we conclude that

$$\mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_N^\xi) \leq C_1 e^{-C_2 \mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_{\mathrm{p}}) N},$$

for two positive constants C_1 and C_2, depending only on ω_0^2.

It follows that

$$\max_{\omega_{\mathrm{d}} \in \Sigma_{\mathrm{d}}^\eta \cap [0, \omega_0^2]} \mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_N^\xi) \leq C_1 e^{-C_2 \eta N}, \tag{3.18}$$

uniformly for $\xi \in \mathcal{B}_{\mathcal{N}}$. Hence, any defect eigenvalue $\omega_{\mathrm{d}}^2 \in \Sigma_{\mathrm{d}}$ is a limit point of $(\Sigma_N^\xi)_{N \in \mathbb{N}}$.

Let $\eta > 0$ be small enough to get $\Sigma_{\mathrm{d}}^\eta \neq \emptyset$. Applying Proposition 3.2, we may see that there exists $N_0 \in \mathbb{N}$, depending only on ω_0^2 and η, such that $\Sigma_{\mathrm{d},N}^{\xi,\eta} \cap [0, \omega_0^2]$ has at least as many connected components as $\mathrm{card}(\Sigma_{\mathrm{d}}^\eta \cap [0, \omega_0^2])$ for $N \geq N_0$. To prove this, we take a neighborhood of $\Sigma_{\mathrm{d}}^\eta \cap [0, \omega_0^2]$ formed by disjoint intervals and away from Σ_{p}, each one of them containing exactly one defect eigenvalue. Then from Proposition 3.2, we deduce that for N large enough, the edges of these intervals will be strictly distant from Σ_N. On the other hand, we have proved here that for N large enough, the intersection of every interval with Σ_N^ξ is not empty. This means that $\Sigma_{\mathrm{d},N}^{\xi,\eta}$ is not empty if we take η small enough and then let N be large enough. By the same manner, (3.18) can be written as

$$\max_{\omega_{\mathrm{d}} \in \Sigma_{\mathrm{d}}^\eta \cap [0, \omega_0^2]} \mathrm{dist}(\omega_{\mathrm{d}}^2, \Sigma_{\mathrm{d},N}^{\xi,\eta}) \leq C_1 e^{-C_2 \eta N}, \tag{3.19}$$

uniformly for $\xi \in \mathcal{B}_{\mathcal{N}}$. The proof of the first part of the theorem is then done.

Now, let $\xi \in \mathcal{B}_{\mathcal{N}}$ and let $\omega^2 \in \Sigma_{\mathrm{d},N}^{\xi,\eta}$. There exists $\phi \in L^2_{\varepsilon_N}(\mathbb{R}^2/2N\mathbb{Z}^2)$ with unit norm such that

$$(\nabla - i\xi) \cdot (\nabla - i\xi)\phi + \omega^2 \varepsilon_N \phi = 0.$$

Then, we define u in $L^2_\varepsilon(\mathbb{R}^2)$ by

$$u(x) = \int_\Omega G(\omega^2; x, y)\phi(y) e^{-i\xi \cdot y}\, dy.$$

Let us now find a lower bound for $\|u\|_{L^2_\varepsilon(\mathbb{R}^2)}$. We compute

$$\begin{aligned}
(\delta\varepsilon)\omega^2 u(x) &= \int_{\mathbb{R}^2} G(\omega^2; x, y)\big(\Delta + \omega^2 \varepsilon_{\mathrm{p}}\big)\big(\phi(y) e^{-i\xi \cdot y}\big)\, dy \\
&\quad - \int_{\mathbb{R}^2} G(\omega^2; x, y)\big(\Delta + \omega^2 \varepsilon\big)\big(\phi(y) e^{-i\xi \cdot y}\big)\, dy \\
&= \phi(x) e^{-i\xi \cdot x} \\
&\quad - \int_{\mathbb{R}^2} G(\omega^2; x, y) e^{-i\xi \cdot y}\big((\nabla - i\xi) \cdot (\nabla - i\xi) + \omega^2 \varepsilon\big)\phi(y)\, dy \\
&= \phi(x) e^{-i\xi \cdot x} \\
&\quad -(\delta\varepsilon)\omega^2 \int_\Omega \sum_{j \in \mathbb{Z}^2, j \neq 0} (G(\omega^2; x, y + Nj) e^{-i\xi \cdot (y + Nj)})\phi(y)\, dy.
\end{aligned}$$

Since there exist positive constants C_1 and C_2, depending only on ω_0^2, such that

$$\left| \sum_{j\in\mathbb{Z}^2, j\neq 0} (G(\omega^2; x, y+Nj)e^{-i\xi\cdot(y+Nj)}) \right| \leq C_1 e^{-C_2\eta N} \ \forall x \in]-N,N[^2 \ \forall y \in \Omega, \tag{3.20}$$

for any $\omega^2 \in [0, \omega_0^2]$ such that $\operatorname{dist}(\omega^2, \Sigma_{\mathrm{p}}) \geq \eta$, we deduce that

$$\left\| \int_\Omega \sum_{j\in\mathbb{Z}^2, j\neq 0} (G(\omega^2; x, y+Nj)e^{-i\xi\cdot(y+Nj)})\phi(y)\, dy \right\|_{L^2_\varepsilon(]-N,N[^2)} \leq N C_1 e^{-C_2\eta N}, \tag{3.21}$$

where the constants C_1 and C_2 are different from the previous ones but have the same dependence. Recalling that $\|\phi\|_{L^2_{\varepsilon_N}(]-N,N[^2)} = 1$, we deduce the existence of $N_0 > 0$ such that

$$\|\phi\|_{L^2_\varepsilon(\mathbb{R}^2)} \geq \|\phi\|_{L^2_\varepsilon(]-N,N[^2)} \geq \frac{1}{2}. \tag{3.22}$$

On the other hand,

$$\begin{aligned}
(\Delta + \omega^2\varepsilon)u(x) &= \int_\Omega (\Delta_x + \omega^2\varepsilon) G(\omega^2; x, y)\phi(y)e^{-i\xi\cdot y}\, dy \\
&= \chi_\Omega(x)\phi(x)e^{-i\xi\cdot x} - (\varepsilon_{\mathrm{p}}(x) - \varepsilon(x))\,\omega^2 \int_\Omega G(\omega^2; x, y)\phi(y)e^{-i\xi\cdot y}\, dy \\
&= \chi_\Omega(x)\phi(x)e^{-i\xi\cdot x} - \chi_\Omega(x)(\delta\varepsilon)\omega^2 \int_\Omega G(\omega^2; x, y)\phi(y)e^{-i\xi\cdot y}\, dy \\
&= \chi_\Omega(x)\phi(x)e^{-i\xi\cdot x} \\
&\quad -\chi_\Omega(x) \int_{\mathbb{R}^2} G(\omega^2; x, y) \left(\Delta + \omega^2\varepsilon_{\mathrm{p}}\right) \left(\phi(y)e^{-i\xi\cdot y}\right)\, dy \\
&\quad +\chi_\Omega(x) \int_{\mathbb{R}^2} G(\omega^2; x, y) \left(\Delta + \omega^2\varepsilon\right) \left(\phi(y)e^{-i\xi\cdot y}\right)\, dy \\
&= \chi_\Omega(x)\phi(x)e^{-i\xi\cdot x} \\
&\quad -\chi_\Omega(x) \int_{\mathbb{R}^2} \left(\Delta_y + \omega^2\varepsilon_{\mathrm{p}}\right) G(\omega^2; x, y)\phi(y)e^{-i\xi\cdot y}\, dy \\
&\quad +\chi_\Omega(x) \int_{\mathbb{R}^2} G(\omega^2; x, y)e^{-i\xi\cdot y} \left((\nabla - i\xi)\cdot(\nabla - i\xi) + \omega^2\varepsilon\right)\phi(y)\, dy \\
&= \chi_\Omega(x)(\delta\varepsilon)\omega^2 \int_{\mathbb{R}^2} G(\omega^2; x, y)e^{-i\xi\cdot y}\phi(y) \left(\sum_{j\in\mathbb{Z}^2, j\neq 0} \chi_\Omega(y - Nj) \right) dy \\
&= \chi_\Omega(x)(\delta\varepsilon)\omega^2 \int_\Omega \sum_{j\in\mathbb{Z}^2, j\neq 0} (G(\omega^2; x, y+Nj)e^{-i\xi\cdot(y+Nj)})\phi(y)\, dy.
\end{aligned}$$

Therefore, it follows from (3.20) that

$$\left|\Delta u(x) + \omega^2\varepsilon u(x)\right| \leq |(\delta\varepsilon)|\omega_0^2|\Omega|^{\frac{1}{2}} C_1 e^{-C_2\eta N},$$

for any $x \in \Omega$. Consequently,

$$\left\| \frac{1}{\varepsilon}\Delta u + \omega^2 u \right\|_{L^2_\varepsilon(\mathbb{R}^2)} \leq \frac{|(\delta\varepsilon)|\omega_0^2|\Omega|}{\sqrt{\min(\varepsilon)}} C_1 e^{-C_2\eta N}. \tag{3.23}$$

From (3.22), we readily get

$$\operatorname{dist}(\omega^2, \Sigma) \leq C_1 e^{-C_2 \eta N},$$

where C_1 and C_2 are different from the previous ones but have the same dependence.

Since $\operatorname{dist}(\omega^2, \Sigma_{\mathrm{p}}) \geq \eta$, we easily arrive at

$$\operatorname{dist}(\omega^2, \Sigma_{\mathrm{d}}^{\eta}) \leq C_1 e^{-C_2 \eta N},$$

which ends the proof of the theorem. □

An immediate consequence of this theorem is the following corollary.

Corollary 3.1. *Suppose that the perturbation has created defect eigenvalues. Then, there exists $\eta_0 > 0$ and $N_0 \in \mathbb{N}$ such that $\Sigma_{\mathrm{d},N}^{\eta} \neq \emptyset$ for $\eta \leq \eta_0$ and $N \geq N_0$.*

Moreover, there exists $N_1 \in \mathbb{N}$ depending only on η such that the number of connected components of $\Sigma_{\mathrm{d},N}^{\eta} \cap [0, \omega_0^2]$ is at least equal to card$\left(\Sigma_{\mathrm{d}}^{\eta} \cap [0, \omega_0^2]\right)$ and the width of each component decays exponentially with N.

Proof. The proof follows immediately from the fact that each eigenvalue in $\Sigma_{\mathrm{d},N}^{\xi,\eta}$ is continuous with respect to ξ, and

$$\Sigma_N = \cup_{\xi \in \mathcal{B}_{\mathcal{N}}} \Sigma_N^{\xi}. \qquad \square$$

Remark 3.2. These results are very important and practical for determining the defect modes of 2-D photonic crystals. Indeed, after identifying the background continuous spectrum by computing numerically $\Sigma_{\mathrm{p}}^{\xi}$ for $\xi \in \mathcal{B}$, we have the gaps and we can have constants C_1 and C_2 such that

$$\left|G(\omega^2; x, y)\right| \leq C_1 e^{-C_2 \operatorname{dist}(\omega^2, \Sigma_{\mathrm{p}}) N}.$$

Then we compute Σ_N^{ξ} for some $\xi \in \mathcal{B}_{\mathcal{N}}$, and from the eigenvalues that are not located in Σ_{p} we deduce an approximation of the defect eigenvalues.

4. The TE polarization.

In this section we deal with the TE polarization. The same results hold, but the proofs are slightly different. This is a consequence of the dependence of the domain of the acoustic operator on the inverse of the dielectric function. So when we perturb ε_{p} into ε, the operator $-\nabla.\frac{1}{\varepsilon_{\mathrm{p}}}\nabla$ is transformed into $-\nabla.\frac{1}{\varepsilon}\nabla$ and we see clearly that, in general, these operators do not have the same domain. So the proofs have to be adjusted.

4.1. Definition and preliminary results.

First, we introduce some analogous notations to those in Definition 2.1.

Definition 4.1. *Let A_{p} be the self-adjoint operator defined by*

$$A_{\mathrm{p}} = -\nabla.\frac{1}{\varepsilon_{\mathrm{p}}}\nabla, \quad \text{on } L^2(\mathbb{R}^2),$$

and let Σ_p denote its spectrum.

For $\xi \in [0, 2\pi[^2$, we define A_{p}^{ξ} on $L^2(\mathbb{R}^2/\mathbb{Z}^2)$ by

$$A_{\mathrm{p}}^{\xi} = -(\nabla_x - i\xi) \cdot \frac{1}{\varepsilon_{\mathrm{p}}}(\nabla_x - i\xi),$$

and denote by $\Sigma_{\mathrm{p}}^{\xi}$ its spectrum.

We perturb the background periodic medium on a bounded domain as done in (2.11).

It has been proved that the spectrum of A_{p} is absolutely continuous and that the perturbation is relatively compact and so does not affect the essential spectrum of A_{p}. The perturbation will then result in the addition of eigenvalues of finite multiplicity to Σ_{p}.

We define ε_N, A_N, A_N^ξ, Σ_N, and Σ_N^ξ in the same manner as in section 3.1. To avoid the problem of the dependence of the domain on ε, we introduce a new operator that will have the same spectral properties as those of A_{p}.

DEFINITION 4.2. *Let B_{p} be the self-adjoint operator defined on $L^2_{\varepsilon_{\mathrm{p}}}(\mathbb{R}^2)^2$ by*

$$B_{\mathrm{p}} = -\frac{1}{\varepsilon_{\mathrm{p}}}\nabla\nabla\cdot$$

For $\xi \in [0, 2\pi[^2$, we define B_{p}^ξ on $L^2_{\varepsilon_{\mathrm{p}}}(\mathbb{R}^2/\mathbb{Z}^2)^2$ by

$$B_{\mathrm{p}}^\xi = -\frac{1}{\varepsilon_{\mathrm{p}}}(\nabla - i\xi)(\nabla - i\xi)\cdot$$

We also define B_N and B_N^ξ analogously as done for A_{p}.

The operator B_{p} is a self-adjoint periodic differential operator on $L^2_{\varepsilon_{\mathrm{p}}}(\mathbb{R}^2/\mathbb{Z}^2)^2$ but is not elliptic since its kernel has infinite dimension. Actually, the kernel is the subspace of divergence free vectors. We cannot apply the same technique as for A_{p} to prove that the spectrum of B_{p}^ξ is a set of positive eigenvalues that accumulate at infinity and that the spectrum of B_{p} is an absolutely continuous spectrum with band structure located in $\mathbb{R}^+$. It is, however, possible to extend this operator into a larger elliptic self-adjoint operator that will coincide with B_{p} on a subspace that is complementary with the kernel of B_{p} (see [23]). We can deduce then that the spectrum of B_{p} in $\mathbb{R}^+ \setminus \{0\}$ is absolutely continuous and that 0 is an eigenvalue with infinite multiplicity. This technique is used to prove the band structure of the Maxwell operator. Another way to characterize the structure of the spectrum of B_{p} is to relate it to the spectrum of A_{p}. This is given by the following theorem.

THEOREM 4.1. *For any $\xi \in [0, 2\pi[^2$, the spectra of B_{p}^ξ, B_{p}, B_N^ξ, B_N, and B are $\Sigma_{\mathrm{p}}^\xi \cup \{0\}$, Σ_{p}, $\Sigma_N^\xi \cup \{0\}$, Σ_N, and Σ, respectively. Moreover,*

(i) *The operators B_{p}^ξ and B_N^ξ have exactly the same eigenvalues as A_{p}^ξ and A_N^ξ, respectively, except for* 0 *which is an eigenvalue of A_{p}^0 and A_N^0 of multiplicity* 1 *and is not an eigenvalue of A_{p}^ξ and A_N^ξ when $\xi \neq 0$ while it is an eigenvalue of B_{p}^ξ and B_N^ξ for any ξ with infinite multiplicity.*

(ii) *The spectra of B_{p} and B_N are absolutely continuous spectra in $\mathbb{R}^+ \setminus \{0\}$ and* 0 *is an eigenvalue of infinite multiplicity.*

(iii) *The operators A and B have the same absolutely continuous spectrum and the eigenvalues have exactly the same multiplicity for A and B except for* 0 *that is an eigenvalue of B with infinite multiplicity.*

Proof. Let $\xi \in [0, 2\pi[^2$ and $\omega^2 \geq 0$. Suppose that either $\xi \neq 0$ or $\omega^2 \neq 0$ and that ω^2 is in the spectrum of A_{p}^ξ. Then there exists $\phi \in L^2(\mathbb{R}^2/\mathbb{Z}^2)$ such that $\phi \neq 0$ and

$$(\nabla - i\xi)\cdot\frac{1}{\varepsilon_{\mathrm{p}}}(\nabla - i\xi)\phi + \omega^2\phi = 0.$$

We can easily see that since ξ and ω^2 are not simultaneously equal to 0, $(\nabla - i\xi)\phi \neq 0$.

Let $\psi = \dfrac{1}{\varepsilon_{\rm p}}(\nabla - i\xi)\phi \in L^2_{\varepsilon_{\rm p}}(\mathbb{R}^2/\mathbb{Z}^2)^2$. Then

$$(\nabla - i\xi)(\nabla - i\xi)\cdot\psi + \omega^2\varepsilon_{\rm p}\psi = 0,$$

which means that ω^2 is an eigenvalue of $B^\xi_{\rm p}$. Moreover, if ϕ_1 and ϕ_2 are two linearly independent eigenvectors related to the same eigenvalue $\omega^2 \neq 0$, then $\psi_1 = \frac{1}{\varepsilon_{\rm p}}(\nabla - i\xi)\phi_1$ and $\psi_2 = \frac{1}{\varepsilon_{\rm p}}(\nabla - i\xi)\phi_2$ are linearly independent.

We conclude that all the eigenvalues of $A^\xi_{\rm p}$ except for the eigenvalue 0 of $A^0_{\rm p}$ are eigenvalues of $B^\xi_{\rm p}$. We will see that 0 is an infinite multiplicity eigenvalue of $A^0_{\rm p}$.

Conversely, let ω^2 be an eigenvalue of $B^\xi_{\rm p}$ and let $\psi \in L^2_{\varepsilon_{\rm p}}(\mathbb{R}^2/\mathbb{Z}^2)^2$ be such that $\psi \neq 0$ and satisfies

$$(\nabla - i\xi)(\nabla - i\xi)\cdot\psi + \omega^2\varepsilon_{\rm p}\psi = 0.$$

Suppose that $(\nabla - i\xi)\cdot\psi = 0$. Then, since $\psi \neq 0$, we have $\omega^2 = 0$. We also obtain that $\nabla\cdot(e^{-i\xi\cdot x}\psi) = 0$, or, equivalently, that there exists $\alpha \in L^2(\mathbb{R}^2/\mathbb{Z}^2)$ such that

$$e^{-i\xi\cdot x}\psi = \nabla\times(\alpha e^{-i\xi\cdot x}),$$

where $\nabla\times\alpha = (\partial_2\alpha, -\partial_1\alpha)$. It follows that

$$\psi = \nabla\times\alpha - i\begin{pmatrix}\xi_2\\ -\xi_1\end{pmatrix}\alpha.$$

Hence, 0 is an eigenvalue of $B^\xi_{\rm p}$ with infinite multiplicity.

In the case where $(\nabla - i\xi)\cdot\psi \neq 0$, let $\phi = (\nabla - i\xi)\cdot\psi \in L^2(\mathbb{R}^2/\mathbb{Z}^2)$. Then,

$$(\nabla - i\xi)\cdot\frac{1}{\varepsilon_{\rm p}}(\nabla - i\xi)\phi + \omega^2\phi = 0,$$

which means that ω^2 is an eigenvalue of $A^\xi_{\rm p}$. We can also show that if ψ_1 and ψ_2 are two linearly independent eigenvectors of $B^\xi_{\rm p}$ related to the same eigenvalue $\omega^2 \neq 0$, then $\phi_1 = (\nabla - i\xi)\cdot\psi_1$ and $\phi_2 = (\nabla - i\xi)\cdot\psi_2$ are linearly independent.

The same proof holds for A^ξ_N and B^ξ_N and for the eigenvalues of A and B. □

As a consequence of the above theorem, we can recover the properties of the spectra of A^ξ_N and A_N by studying those of B^ξ_N and B_N to which we can apply mainly the same technique as in the TM case since their domain does not depend on ε.

To this end we need to give an analogous result to Lemma 2.1 for the operator $B_{\rm p}$.

LEMMA 4.1. *For any $z \notin \Sigma_{\rm p}$ and $l > 0$ we have*

$$\|\chi_{x,l}R(z)\chi_{y,l}\| \leq \left(\frac{9}{\eta}\right)e^{(\sqrt{2}l/4)}e^{-m_z|x-y|} \quad \forall x, y \in \mathbb{R}^2, \tag{4.1}$$

with

$$m_z = \frac{\eta}{4(2\varepsilon_-^{-1} + |z| + \eta)}, \tag{4.2}$$

where $\eta = dist(z, \Sigma_{\rm p})$, $\varepsilon_- = \min_{x\in\mathbb{R}^2}\varepsilon_{\rm p}(x)$, and $\chi_{x,l}$ is the characteristic function of the cube $\{y = (y_1, y_2) \in \mathbb{R}^2 : |y_1 - x_1| < \frac{l}{2}$ and $|y_2 - x_2| < \frac{l}{2}\}$.

Proof. The proof is exactly the same as the one for the Helmholtz operator which uses a Combe–Thomas argument and can be found in [13], [14], [15].

Let B_a denote the operators formally given by

$$B_a = e^{a\cdot x} B_p e^{-a\cdot x}, \quad a \in \mathbb{R}^2, \tag{4.3}$$

as the closed densely defined operators (uniquely) introduced by the corresponding quadratic forms defined on $C_0^1(\mathbb{R}^2)$ by

$$\mathcal{B}_a[\psi] = \left\langle \nabla\cdot(e^{a\cdot x}\psi), \frac{1}{\varepsilon_{\mathrm{p}}(x)}\nabla\cdot(e^{-a\cdot x}\psi)\right\rangle = \left\langle (\nabla + a)\cdot\psi, \frac{1}{\varepsilon_{\mathrm{p}}(x)}(\nabla - a)\cdot\psi\right\rangle. \tag{4.4}$$

We also introduce the quadratic form $\mathcal{Q}_a$ as

$$\begin{aligned}\mathcal{Q}_a[\psi] &= \mathcal{B}_a[\psi] - \mathcal{B}_0[\psi]\\ &= \left\langle a\cdot\psi, \frac{1}{\varepsilon_{\mathrm{p}}(x)}\nabla\cdot\psi\right\rangle - \left\langle \nabla\cdot\psi, \frac{1}{\varepsilon_{\mathrm{p}}(x)}a\cdot\psi\right\rangle\\ &\quad - \left\langle a\cdot\psi, \frac{1}{\varepsilon_{\mathrm{p}}(x)}a\cdot\psi\right\rangle.\end{aligned}$$

Since

$$\left|\left\langle a\cdot\psi, \frac{1}{\varepsilon_{\mathrm{p}}(x)}\nabla\cdot\psi\right\rangle\right| \le \frac{1}{2}|a|\left(\left\langle \psi, \frac{1}{\varepsilon_{\mathrm{p}}(x)}\psi\right\rangle + \left\langle \nabla\cdot\psi, \frac{1}{\varepsilon_{\mathrm{p}}(x)}\nabla\cdot\psi\right\rangle\right), \tag{4.5}$$

we have

$$|\mathcal{Q}_a[\psi]| \le |a|\mathcal{B}_0[\psi] + |a|(1+|a|)\varepsilon_-^{-1}\|\psi\|^2 \quad \forall\psi \in C_0^1(\mathbb{R}^2). \tag{4.6}$$

Then we require $|a| < 1$ and use Theorem VI.3.9 in [21] to conclude that $\mathcal{B}_a$ is a closable sectorial form and define B_a as the unique m-sectorial operator associated with it. If, in addition, $z \notin \Sigma_p$ and

$$\Lambda \equiv 2\left\|(|a|(1+|a|)\varepsilon_-^{-1} + |a|B_{\mathrm{p}})(B_{\mathrm{p}} - zI)^{-1}\right\| < 1, \tag{4.7}$$

we can conclude that $z \notin \Sigma_a$ (the spectrum of B_a) and

$$\|R_a(z) - R_0(z)\| \le \frac{4\Lambda}{(1-\Lambda)^2}\|R_0(z)\|, \tag{4.8}$$

where $R_a(z) = (B_a - zI)^{-1}$.

Since

$$\begin{aligned}\Lambda &= 2\left\|(|a|(1+|a|)\varepsilon_-^{-1} + |a|z)(B_{\mathrm{p}} - zI)^{-1} + |a|\right\|\\ &\le 2|a|(((1+|a|)\varepsilon_-^{-1} + |z|)\eta^{-1} + 1)\\ &\le 2|a|((2\varepsilon_-^{-1} + |z|)\eta^{-1} + 1),\end{aligned}$$

it is sufficient to take

$$|a| < \frac{\eta}{2(2\varepsilon_-^{-1} + |z| + \eta)}, \tag{4.9}$$

to ensure $\Lambda < 1$. In fact, we take

$$|a| < m_z = \frac{\eta}{4(2\varepsilon_-^{-1} + |z| + \eta)}, \tag{4.10}$$

so that we get $\Lambda < \frac{1}{2}$. It follows that

$$\|R_a(z)\| \leq \left(1 + \frac{4\Lambda}{(1-\Lambda)^2}\right) \|R_0(z)\| \leq \frac{9}{\eta}. \tag{4.11}$$

Now, let $x_0, y_0 \in \mathbb{R}^2$, $l > 0$, and take

$$a = \frac{m_z}{|x_0 - y_0|}(x_0 - y_0).$$

We have

$$\begin{aligned}\|\chi_{x_0,l} R_0(z) \chi_{y_0,l}\| &= \|\chi_{x_0,l} e^{-a\cdot x} R_a(z) e^{a\cdot x} \chi_{y_0,l}\| \\ &= e^{-m_z\cdot|x_0-y_0|} \|\chi_{x_0,l} e^{-a\cdot(x-x_0)} R_a(z) e^{a\cdot(x-y_0)} \chi_{y_0,l}\| \\ &\leq \frac{9}{\eta} e^{-m_z\cdot|x_0-y_0|} \|\chi_{x_0,l} e^{-a\cdot(x-x_0)}\|_\infty \|\chi_{y_0,l} e^{-a\cdot(x-y_0)}\|_\infty.\end{aligned}$$

We also notice that

$$\|\chi_{x_0,l} e^{\pm a\cdot(x-x_0)}\|_\infty \leq e^{\frac{l}{\sqrt{2}} m_z},$$

and since $m_z \leq \frac{1}{4}$, the theorem is proved. □

As a consequence, the matricial Green's kernel of B_p has a similar exponential decay as the Green's kernel of A_p. Let $\omega^2 \notin \Sigma_p$, we define the matricial Green's kernel $K(\omega^2; x, y)$ as the solution to

$$\nabla\nabla \cdot K(\omega^2; x, y) + \omega^2 \varepsilon_\mathrm{p} K(\omega^2; x, y) = \delta(x-y) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{4.12}$$

Here we shall impose an outgoing radiation condition on $\nabla \cdot K$ in order to ensure uniqueness. As a direct consequence of the previous lemma the following result holds.

Corollary 4.1. *For any $\omega_0^2 > 0$, there exist two positive constants C_1 and C_2, depending only on $\omega_0^2 > 0$, such that for any $\omega^2 \notin \Sigma_\mathrm{p} \cap (0, \omega_0^2)$,*

$$|K(\omega^2; x, y)| \leq C_1 e^{-C_2 \, dist(\omega^2, \Sigma_\mathrm{p})|x-y|}, \quad \text{for } |x-y| \to +\infty. \tag{4.13}$$

Now we are ready to prove the analogous results to those concerning the TM polarization.

4.2. Convergence of the "continuous spectrum." As done for the TM polarization, we give an estimate of the perturbation brought to the continuous spectrum of A_p by the supercell method.

Theorem 4.2. *For any $\omega_0 > 0$ and $N_0 \in \mathbb{N}$, there exists $C > 0$, depending only on ω_0, N_0 and Ω, such that*

$$\max_{\omega^2 \in \cup_{k\in]-N+1,N-1[^2\cap\mathbb{N}^2} \Sigma_\mathrm{p}^{\xi+k\pi/N} \cap [0,\omega_0^2]} dist(\omega^2, \Sigma_N^\xi) \leq \frac{C}{N^2}, \tag{4.14}$$

for any $N \geq N_0$ *and any* $\xi \in \mathcal{B}_{\mathcal{N}}$.

Proof. Let $k \in]-N+1, N-1[^2 \cap \mathbb{N}^2$ and $\xi \in \mathcal{B}_{\mathcal{N}}$. Let ω^2 be in $\Sigma_{\mathrm{p}}^{\xi+k\pi/N} \cap [0, \omega_0^2]$. If $\omega^2 = 0$, then necessarily $\xi = 0$ and $k = 0$ and in that case we know that $0 \in \Sigma_N^{\xi}$.

Let us consider now $\omega^2 \neq 0$. From Theorem 4.1, we deduce that ω^2 is in the spectrum of $B_{\mathrm{p}}^{\xi+k\pi/N}$.

Since $\xi + k\pi/N \in \mathcal{B}$, there exists $\phi \in L^2_{\varepsilon_{\mathrm{p}}}(\mathbb{R}^2/\mathbb{Z}^2)^2$ with unit norm such that

$$\left(\nabla - i\left(\xi + \frac{k\pi}{N}\right)\right)\left(\nabla - i\left(\xi + \frac{k\pi}{N}\right)\right) \cdot \phi + \omega^2 \varepsilon_{\mathrm{p}} \phi = 0. \tag{4.15}$$

Let $\tilde{\phi}$ be defined in $L^2_{\varepsilon}(\mathbb{R}^2/2N\mathbb{Z}^2)^2$ as

$$\tilde{\phi}(x) = \phi(x) e^{-i\frac{\pi}{N}k\cdot x}. \tag{4.16}$$

For any $0 < C_0 < 4$, there exits an integer N_0 independent of $\tilde{\phi}$, such that for any $N > N_0$, we have $\|\tilde{\phi}\|_{L^2_{\varepsilon}(\mathbb{R}^2/2N\mathbb{Z}^2)^2} > C_0 N^2$, and it satisfies the following equation:

$$(\nabla - i\xi)(\nabla - i\xi) \cdot \tilde{\phi} + \omega^2 \varepsilon_{\mathrm{p}} \tilde{\phi} = 0, \tag{4.17}$$

which can be written as

$$(\nabla - i\xi)(\nabla - i\xi) \cdot \tilde{\phi} + \omega^2 \varepsilon \tilde{\phi} = -\chi_{\Omega}(\delta\varepsilon)\omega^2 \tilde{\phi}. \tag{4.18}$$

We prove then in the same way as done for the TM case that there exists an eigenvalue ω_ξ^2 belonging to the spectrum of B_N^{ξ}, that is $\Sigma_N^{\xi} \cup \{0\}$, satisfying

$$|\omega^2 - \omega_\xi^2| \leq \frac{C}{N^2},$$

since we considered $\omega^2 \neq 0$, for N large enough $\omega_\xi^2 \neq 0$ and then $\omega_\xi^2 \in \Sigma_N^{\xi}$. This means that

$$\mathrm{dist}(\omega^2, \Sigma_N^{\xi}) \leq \frac{C}{N^2}.$$

The theorem is then proved. □

4.3. Convergence of the defect eigenvalues. Analogously to the TM polarization, we give a characterization of the part of the spectrum Σ_N corresponding to the defect eigenvalues of Σ. We use the notations introduced in Definition 3.3. The following proposition holds.

PROPOSITION 4.1. *For every gap* $]a, b[$ *in* Σ_{p} *(*$0 < a < b$*) satisfying* $]a, b[\cap \Sigma = \emptyset$*, there exists* $N_1 \in \mathbb{N}$ *such that, for* $N \geq N_1$, $\Sigma_N \cap]a, b[= \emptyset$.

Proof. Suppose that the proposition is false. Then for any $N_0 \in \mathbb{N}$ there exists $N \geq N_0$ and $\omega_N^2 \in]a, b[\cap \Sigma_N$. This means that ω_N^2 is in the spectrum of B_N. Then there exist $\xi_N \in \mathcal{B}_{\mathcal{N}}$ and $\phi_N \in L^2_{\varepsilon_N}(\mathbb{R}^2/2N\mathbb{Z}^2)^2$ with unit norm such that

$$(\nabla - i\xi_N)(\nabla - i\xi_N) \cdot \phi_N + \omega_N^2 \varepsilon_N \phi_N = 0, \quad \text{in } L^2_{\varepsilon_N}(\mathbb{R}^2/2N\mathbb{Z}^2)^2. \tag{4.19}$$

Now, define $\tilde{\phi}_N$ in $L^2_{\varepsilon}(\mathbb{R}^2)$ as

$$\tilde{\phi}_N(x) = \int_{\Omega} K(\omega_N^2; x, y) e^{-i\xi_N \cdot y} \phi_N(y)\, dy. \tag{4.20}$$

Using $\tilde{\phi}_N$, we prove in a similar way as for Proposition 3.2 that

$$\frac{\|\frac{1}{\varepsilon}\nabla\nabla\cdot\tilde{\phi}_N+\omega_N^2\tilde{\phi}_N\|_{L^2_\varepsilon(\mathbb{R}^2)^2}}{\|\tilde{\phi}_N\|_{L^2_\varepsilon(\mathbb{R}^2)^2}}\leq C_1e^{-C_2N}, \tag{4.21}$$

for some positive constants C_1 and C_2. Since ω_N^2 is away from 0, then

$$\operatorname{dist}(\omega_N^2,\Sigma)\leq C_1e^{-C_2N}, \tag{4.22}$$

which leads to a contradiction. □

Now we give the main result for the TE case about the convergence of the eigenvalues of the supercell corresponding to the defect.

THEOREM 4.3. *Suppose that the perturbation has created defect eigenvalues. Then, there exists $\eta_0>0$ and $N_0\in\mathbb{N}$ such that for any $\eta\leq\eta_0$ and $N\geq N_0$,*

$$\Sigma_{\mathrm{d},N}^{\xi,\eta}\neq\emptyset\quad\forall\xi\in\mathcal{B}_{\mathcal{N}}.$$

Moreover, for any $\omega_0^2>0$ and $\eta\leq\eta_0$, there exists two positive constants C_1 and C_2 depending only on ω_0^2 such that for any $\xi\in\mathcal{B}_{\mathcal{N}}$,

$$dist_{\mathcal{H}}(\Sigma_{\mathrm{d},N}^{\xi,\eta}\cap[0,\omega_0^2],\Sigma_{\mathrm{d}}^{\eta}\cap[0,\omega_0^2])\leq C_1e^{-C_2\eta N}. \tag{4.23}$$

Proof. Since we deal with a part of the spectrum that is away from 0, the statements are exactly the same when considering the spectra related to B_{p} instead of A_{p}. The proof then becomes similar to the one of Theorem 3.2. □

Note that the Corollary 3.1 holds for the TE polarization.

5. Numerical experiments.

The numerical simulations presented in this section are computed with the *MIT Photonic-Bands* (MPB) package [20]. We consider a 2-D photonic crystal in which the dielectric permittivity takes the values of 1 and 12. The structure of the crystal is shown in Figure 5.1 where the dark area corresponds to dielectric permittivity 12.

We investigate only the TE polarization. We compute the TE-spectrum of this structure for the first 8 bands. This is shown in Figure 5.2 where we notice the presence of two gaps between the first and the second bands and between the second and the third bands. The singularities of the last band come from the fact that it crosses the following band, which is not represented on the diagram.

Then we introduce a defect to this periodic structure by changing the dielectric permittivity in one disc from 1 into 12. The corresponding 7×7 supercell is represented in Figure 5.3. We compute the TE-spectrum in the supercell for a fixed wave number

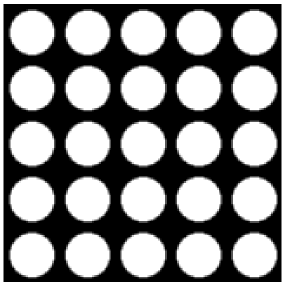

FIG. 5.1. *The periodic structure.*

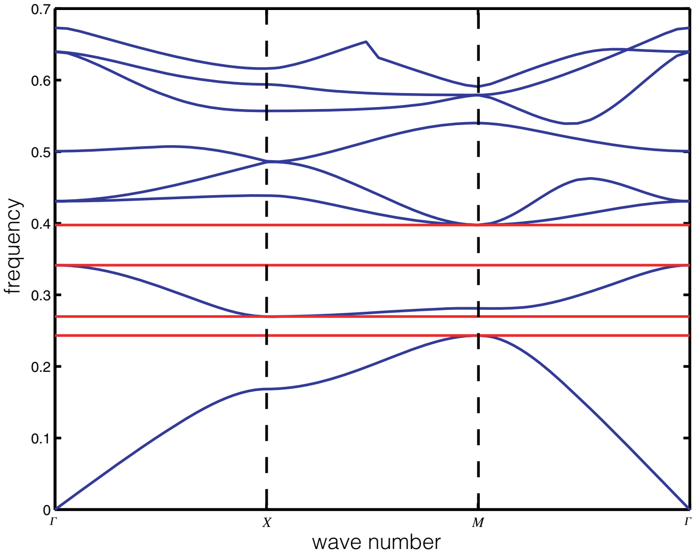

Fig. 5.2. *TE-spectrum of the periodic structure.*

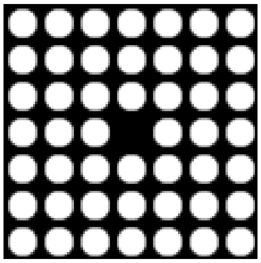

Fig. 5.3. *The 7×7 supercell.*

Table 5.1
Defect frequencies and relative difference with the 7×7 supercell.

Supercell size	3×3	5×5	7×7
Defect frequency 1	0.3706 0.6%	0.3687 0.05%	0.3685
Defect frequency 2	0.3574 0.3%	0.3563 ≤00.3%	0.3563

and for different sizes of the supercell (3,5,7). The results are shown in Figure 5.4. The horizontal dashed lines delimit the gaps of the periodic medium.

We notice clearly the presence of two defect eigenvalues in the second gap. The values of the defect frequencies and the relative difference with the 7×7 supercell results are shown in Table 5.1.

The convergence of the continuous spectrum is in $1/N$ but the multiplicative constant depends on the dispersion of the band considered (the differential of the frequency with respect to the wave vector). This explains why the convergence in the first band (the most dispersive) is the lowest.

In Figure 5.5 we plotted the defect frequencies against the wave number. In the 3×3 supercell, the defect frequencies oscillate with an amplitude about 1% while the oscillation is about 0.1% in the 5×5 supercell and about 0.05% in the 7×7 supercell.

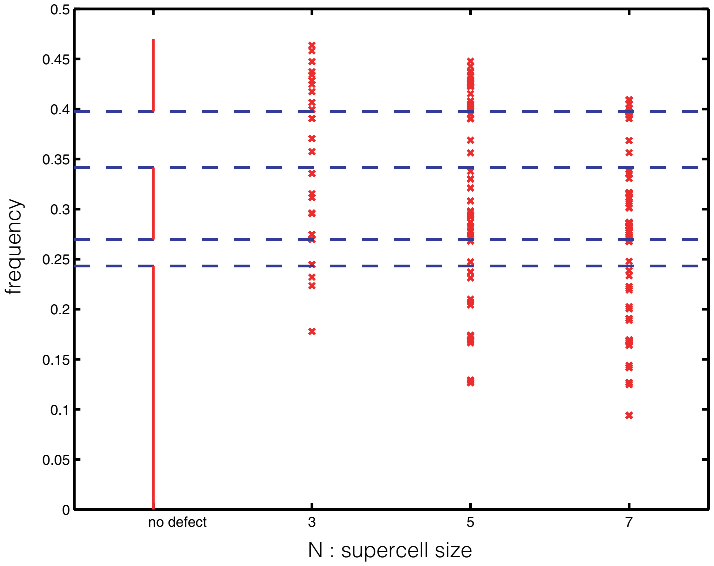

Fig. 5.4. *TE-spectrum of the supercell.*

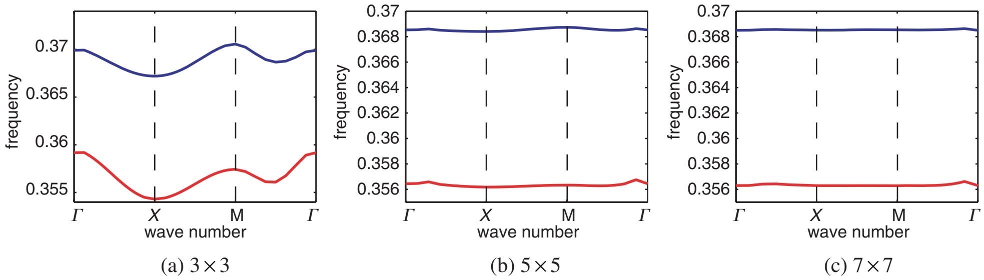

(a) 3×3

(b) 5×5

(c) 7×7

Fig. 5.5. *Dependence of the defect frequencies on the wave number.*

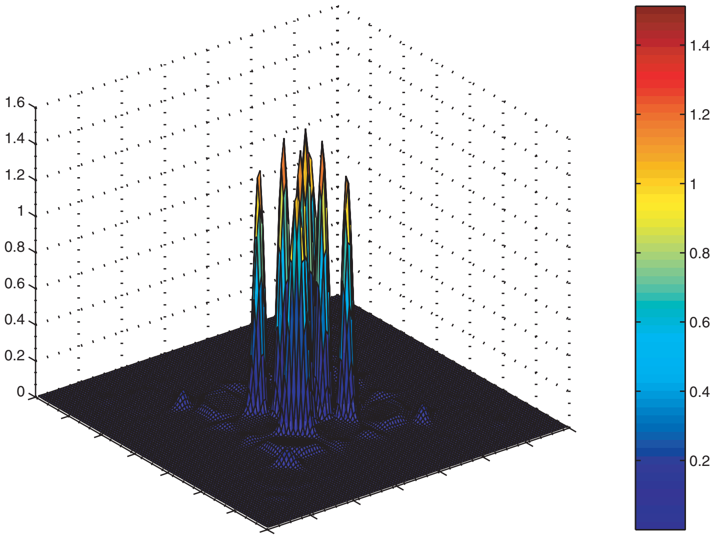

Fig. 5.6. *Energy distribution in the first defect mode.*

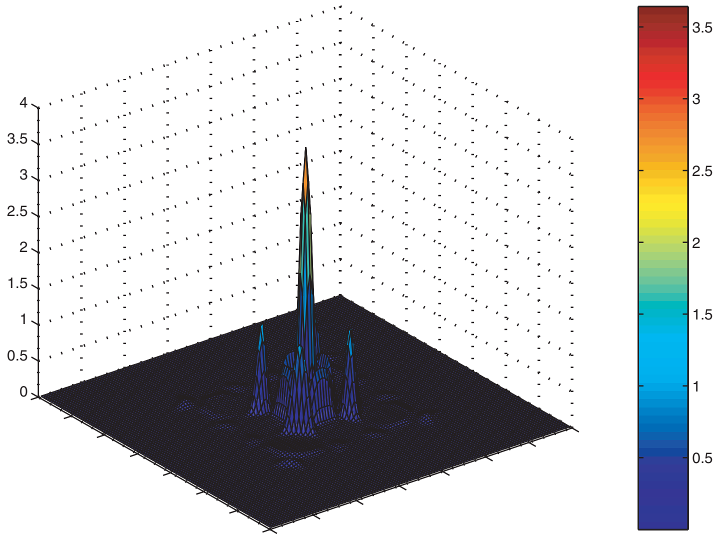

FIG. 5.7. *Energy distribution in the second defect mode.*

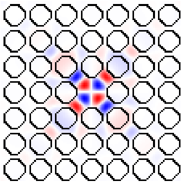

FIG. 5.8. *Magnetic field distribution in the first defect mode.*

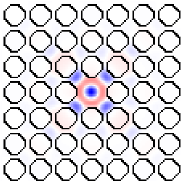

FIG. 5.9. *Magnetic field distribution in the second defect mode.*

Finally, in Figures 5.6–5.9 we represent the energy distribution and the magnetic field for the defect modes in the case of the 7 × 7 supercell.

6. Conclusion. In this paper we presented a rigorous proof of the convergence of the supercell method. The convergence speed is related to the exponential decay of the Green's function. If (ω_a^2, ω_b^2) is a gap of the photonic crystal (ω_a^2, ω_b^2 belong to the spectrum), then it was proved that for $\omega^2 \in (\omega_a^2, \omega_b^2)$, the exponential decay of the Green's function is of the form

$$O\Big(\exp\Big(-C\sqrt{|\omega^2-\omega_a^2||\omega^2-\omega_b^2|}\;|x|\Big)\Big). \tag{6.1}$$

It follows that the convergence of the defect eigenvalues will be slower when they are closer to the edges of the gap. This is not an important problem since these modes are useless. Actually, we are interested in the localization property of the defect modes which is weak for such eigenvalues.

Finally, we remark that this method becomes very costly when looking for defects lying over few bands. For example, if we look for a defect eigenvalue lying in a gap between the fourth and the fifth band, when computing the spectrum of the 5×5 supercell, every band will contribute with 5^2 eigenvalues and the defect eigenvalue will be the 101st eigenvalue which requires many calculations. We believe that it should be possible to determine such eigenvalues in a faster way with integral operator methods.

THE COMPUTATION OF CONICAL DIFFRACTION COEFFICIENTS IN HIGH-FREQUENCY ACOUSTIC WAVE SCATTERING*

B. D. BONNER†, I. G. GRAHAM†, AND V. P. SMYSHLYAEV†

Abstract. When a high-frequency acoustic or electromagnetic wave is scattered by a surface with a conical point, the component of the asymptotics of the scattered wave corresponding to diffraction by the conical point can be represented as an asymptotic expansion, valid as the wave number $k \to \infty$. The *diffraction coefficient* is the coefficient of the principal term in this expansion and is of fundamental interest in high-frequency scattering. It can be computed by solving a family of homogeneous boundary value problems for the Laplace–Beltrami–Helmholtz equation (parametrized by a complex wave number–like parameter ν) on a portion of the unit sphere bounded by a simple closed contour ℓ, and then integrating the resulting solutions with respect to ν. In this paper we give the numerical analysis of a method for carrying out this computation (in the case of acoustic waves) via the boundary integral method applied on ℓ, emphasizing the practically important case when the conical scatterer has lateral edges. The theory depends on an analysis of the integral equation on ℓ, which shows its relation to the corresponding integral equation for the planar Helmholtz equation. This allows us to prove optimal convergence for piecewise polynomial collocation methods of arbitrary order. We also discuss efficient quadrature techniques for assembling the boundary element matrices. We illustrate the theory with computations on the classical canonical open problem of a trihedral cone.

1. Introduction.

When an incident plane acoustic or electromagnetic wave is scattered by a bounded impenetrable (three-dimensional) obstacle, the asymptotic behavior of the scattered wave when the frequency is large is described by the classical geometric theory of diffraction (GTD) [28]. The asymptotics of the scattered field when the wave number $k \to \infty$ is known from the GTD to be composed of a number of components corresponding to "reflections" or "diffractions" by particular parts of the boundary. Along with the component corresponding to simple reflection of nongrazing incident waves at smooth parts of the obstacle, or a more complicated grazing incidence which leads to asymptotics in the shadow [27] and special boundary-layer asymptotics in the "penumbra" (see, e.g., [7] and the references therein), the scattered wave's asymptotics may also contain components arising from diffraction by nonsmooth "singular" points of the scattering surface, such as edges or conical points. From the GTD [28] (and its further developments), the principal parts of those components are known to be described by the (diffracted component of the) far field of waves scattered by the *tangent cone* at the singular point(s). This is due to the so-called principle of localization (which is the essence of the GTD). Many authors

http://www.siam.org/journals/sinum/43-3/60335.html

†Department of Mathematical Sciences, University of Bath, Bath BA2 7AY, UK (bradley_bonner@yahoo.co.uk, I.G.Graham@bath.ac.uk, vps@maths.bath.ac.uk).

have considered the problem of describing the asymptotics of the diffracted wave for various "canonical" cones (see, e.g., [12, 15, 16, 11, 6] and the references therein).

This problem has been studied in detail when the obstacle is a cone with a smooth lateral surface, and ideal boundary conditions are applied; see, e.g., [12, 6] and the references therein, where explicit formulae for the principal asymptotics of the diffracted wave were derived. (By "ideal" we mean pure Dirichlet or Neumann boundary conditions in the acoustic case and perfectly conducting boundary conditions in the electromagnetic case. See [9, 2, 10] for some results on nonideal boundary conditions.)

For example, consider the scalar (acoustic) case, with an incident plane wave $U^{inc}(\mathbf{x}) = \exp(-ik\boldsymbol{\omega}_0 \cdot \mathbf{x})$, with the point $\boldsymbol{\omega}_0 \in S^2$ (the unit sphere in $\mathbb{R}^3$), describing the direction of incidence. Then both the scattered wave U^{sc} and the total wave $U := U^{inc} + U^{sc}$ satisfy the three-dimensional Helmholtz equation, $(\Delta + k^2)U = 0$, in the domain of propagation, and U^{sc} satisfies an appropriate version of the radiation conditions. The theory in [33, 4, 6] describes the behavior of the diffracted component $U^{diff}(\mathbf{x})$ of $U^{sc}(\mathbf{x})$ at any point $\mathbf{x}$ in the domain of propagation. Using spherical coordinates centered at the conical point—$\mathbf{x} = r\boldsymbol{\omega}$ with $\boldsymbol{\omega} \in S^2$ and $r > 0$ denoting the distance of $\mathbf{x}$ from the conical point—it follows from the general recipes of the GTD that (with either Dirichlet or Neumann conditions imposed on the surface of the scatterer) U^{diff} has the asymptotic representation

$$U^{diff}(\mathbf{x}, k, \boldsymbol{\omega}_0) = 2\pi \frac{\exp(ikr)}{kr} f(\boldsymbol{\omega}, \boldsymbol{\omega}_0) + O((kr)^{-2}), \qquad k \to \infty. \tag{1.1}$$

Here the distribution $f(\boldsymbol{\omega}, \boldsymbol{\omega}_0)$, which is infinitely smooth everywhere except at the so-called *singular directions* (where it is typically infinite), is the important *diffraction coefficient* (also known as the kernel of the *scattering matrix*) and describes the intensity of the diffracted wave in the particular direction $\boldsymbol{\omega}$. (See, e.g., [6, 13] and the references therein for precise descriptions of the distributional spaces.)

This paper deals with the numerical analysis and implementation of methods for computing $f(\boldsymbol{\omega}, \boldsymbol{\omega}_0)$. Following [4] and [6], to obtain a formula for f, we take O to be the vertex of the conical obstacle, Ξ (which is indicated by dotted lines in Figure 1), and let M denote the portion of the unit sphere S^2 which is exterior to Ξ. M is a submanifold of S^2 with boundary, which we denote by ℓ (see Figure 1 again). Let Δ^* denote the Laplace–Beltrami operator on S^2 and introduce the *spherical* Green's function $g(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu)$ on M (also known as a "spectral function"), satisfying

$$(\Delta^* + \nu^2 - 1/4) g(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) = \delta(\boldsymbol{\omega} - \boldsymbol{\omega}_0), \quad \boldsymbol{\omega}, \boldsymbol{\omega}_0 \in M \text{ and } \nu \in \mathbb{C}\ , \tag{1.2}$$

where δ denotes the Dirac delta function and the differentiation on the left-hand side is with respect to $\boldsymbol{\omega}$. As a function of $\boldsymbol{\omega}$, g is also required to satisfy a Dirichlet or Neumann boundary condition on ℓ (whichever is given in the original scattering problem). Once g is known, the diffraction coefficient in (1.1) is then given by the formula (see [33, 6])

$$f(\boldsymbol{\omega}, \boldsymbol{\omega}_0) = \lim_{s \to 0+} \frac{i}{\pi} \int_\gamma \exp(-i\nu\pi - s\nu) g(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) \nu d\nu. \tag{1.3}$$

The integrals in (1.3) are known to converge uniformly as $s \to 0+$ away from the singular directions; cf. [8]. The infinite integration contour γ in (1.3) has to be chosen in the complex plane, so that the (positive) numbers $\sqrt{\lambda_j}$ (where λ_j ranges over all eigenvalues of the self-adjoint operator $-\Delta^* + 1/4$ on M, subject to the appropriate

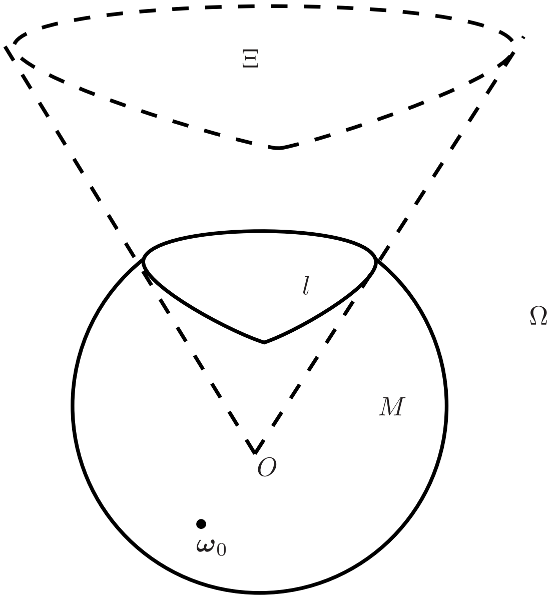

FIG. 1. *Geometry of obstacle.*

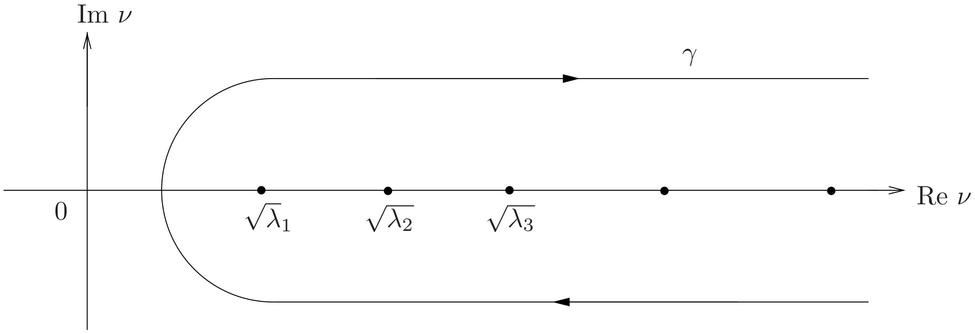

FIG. 2. *Contour of integration.*

boundary condition on ℓ) lie on its right and also so that when $\text{Re}(\nu) \to \infty$, along γ, $\text{Im}(\nu) \to \pm a$ for some constant $a > 0$ (see [6]). The function $g(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu)$ is known from spectral theory to be analytic in ν, except for poles at $\nu = \sqrt{\lambda_j}$, provided $\boldsymbol{\omega} \neq \boldsymbol{\omega}_0$—see Figure 2.

Thus the computational procedure for realizing the asymptotic formula (1.1) requires the following: (i) the computation of the Green's function $g(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu)$ for all required incidence directions $\boldsymbol{\omega}_0$ and observation directions $\boldsymbol{\omega} \in M$ and (ii) the computation of the integral in (1.3) for sufficiently small positive s, by quadrature. Note that (ii) in turn implies that $g(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu)$ must be evaluated for sufficiently many $\nu \in \gamma$ to ensure an accurate answer.

The Green's function g in (1.3) can be replaced (see [33, 4]) by its regular part $g^r := g - g_0$, where g_0 is the (known) fundamental solution for the operator $(\Delta^* + \nu^2 - 1/4)$ on all of S^2 (see section 2). Moreover, for certain configurations of $\boldsymbol{\omega}, \boldsymbol{\omega}_0$ (which, say, in the case of a smooth, fully illuminated, and convex cone corresponds to the direction of observation $\boldsymbol{\omega}$ with no reflected wave [33, 4, 25]—see (2.1) for a precise statement), the right-hand side of (1.3) can be transformed by deforming the contour of integration γ onto the imaginary axis and then interchanging the limit with the integral. These modifications yield the simpler formula

$$f(\boldsymbol{\omega},\boldsymbol{\omega}_0) = -\frac{i}{\pi}\int_{-\infty}^{\infty} \exp(\tau\pi) g^r(\boldsymbol{\omega},\boldsymbol{\omega}_0, i\tau)\tau d\tau, \tag{1.4}$$

with the integral convergent absolutely. In fact it can be shown (see [13, section 6.4] and the references therein) that

$$\exp(\tau\pi) g^r(\boldsymbol{\omega},\boldsymbol{\omega}_0, i\tau) \sim \left\{ \begin{array}{ll} \exp(\alpha_1\tau) \ , & \tau \to -\infty \ , \\ \exp(-\alpha_2\tau) \ , & \tau \to \infty \ , \end{array} \right. \tag{1.5}$$

where α_1, α_2 are positive numbers depending on the location of $\boldsymbol{\omega}$ and $\boldsymbol{\omega}_0$, provided $\boldsymbol{\omega}$ and $\boldsymbol{\omega}_0$ satisfy the technical condition (2.1) below.

The configurations of $\boldsymbol{\omega}$ and $\boldsymbol{\omega}_0$ for which the formulation (1.4) is possible are described by a geometrical condition (see [6, section 2.3]). All our computations in this paper are for cases in which (1.4) is valid. In other cases one must compute the limit (1.3) as it stands, leading to a more complicated approximation problem directly employing (1.3) with sufficiently small s [6].

In [4] and [6] a numerical method was proposed for the computation of (1.4) and (1.3). The boundary integral method was used to compute g^r. (g^r satisfies the homogeneous PDE $(\Delta^* + \nu^2 - 1/4)g^r(\boldsymbol{\omega},\boldsymbol{\omega}_0,\nu) = 0$, on the manifold M, subject to an inhomogeneous boundary condition on its boundary ℓ.) This was implemented in [4] and [6] in the case when Ξ is a smooth cone (i.e., ℓ is a smooth contour) using, in effect, a simple trapezoidal-Nyström-type integral equation solver combined with the trapezoidal rule for computing (1.3) or (1.4). The approach of [33, 4, 6] was also extended to the electromagnetic case [34], which was implemented numerically in [5].

The papers [4] and [6] contained no convergence analysis of the method and, moreover, dealt only with the case of a smooth cone Ξ. The case of a cone with lateral edges is of fundamental importance in both the high-frequency theory of diffraction (where it is one of the unsolved canonical problems [28]) and in practice, where high-frequency scattering by antennas or corners of buildings is a key problem in microwave engineering. In such cases ℓ contains corners.

Although the integral equation method reduces the computation of $g(\boldsymbol{\omega},\boldsymbol{\omega}_0,\nu)$ to a computation on the (one-dimensional) contour ℓ on the surface of the unit sphere S^2, this equation has to be solved many times for different values of ν (and also more times if different $\boldsymbol{\omega}$ and $\boldsymbol{\omega}_0$ are to be considered). Moreover, as we shall see, the evaluation of the kernel in the integral equation arising from the spherical PDE (1.2) is much more costly than for typical boundary integral equations in planar scattering theory. Thus there is strong practical demand for the development of an efficient algorithm, in particular one which solves the integral equation with the highest accuracy and the minimal number of kernel evaluations. Thus the purposes of this paper are as follows:

(i) To propose an efficient method for computing diffraction coefficients which is robust even when the cone Ξ has lateral edges and to analyze its convergence.

(ii) To minimize the number of kernel evaluations required in the implementation.

(iii) To demonstrate its use in the computation of diffraction coefficients in several sample cases.

The plan of the paper is as follows. In section 2 we describe briefly the boundary integral method for computing g^r. This leads to nonstandard integral equations posed on the spherical contour ℓ, which possibly contains corners. In section 3 we obtain the important properties of the integral operators which arise, including the case when the cone Ξ has lateral edges. In section 4 we describe a flexible numerical method based on collocation with piecewise polynomials and prove its convergence as a means of approximating $g^r(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu)$. Finally in section 5 we provide computations of diffraction coefficients for several sample problems. We also give in section 5 outline descriptions of various technical issues such as the computation of the contour integral in (1.3) and the evaluation of the kernel which appears in the integral operator. In particular, we note that because of the exponential decay (1.5), the domain of integration in (1.4) can be replaced by $[-N_1, N_2]$ with $N_i = O(r \log(n))$ at the cost of an error of $O(1/n^r)$. Therefore very large values of N_i (equivalently very large values of $|\tau|$) are not required in our computations.

Although this paper considers only diffraction coefficients for acoustic scattering, the related and more difficult electromagnetic case is described in [13] and the references therein.

2. Formulae for the conical diffraction coefficients. Throughout the paper we shall assume that the cone Ξ has a finite number of smooth (analytic) faces, joined at lateral edges, and that the angle between pairs of adjacent faces lies in $(0, 2\pi)$ (i.e., cuspoid edges are excluded). As in [13], we also assume that M and $S^2\backslash\overline{M}$ are simply connected subsets of S^2 and that the contour ℓ is a simple closed curve, consisting of a finite number of analytic arcs, also joined at noncuspoid corners. (For much of what we are going to do below, weaker smoothness assumptions away from edges would suffice, but we suppress this extra generality in the interest of readability.)

For $\boldsymbol{\omega}, \boldsymbol{\omega}' \in S^2$ we define $\theta(\boldsymbol{\omega}, \boldsymbol{\omega}')$ to be the geodesic distance between two points $\boldsymbol{\omega}$ and $\boldsymbol{\omega}'$ on the sphere S^2 (i.e., $\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}') = \boldsymbol{\omega} \cdot \boldsymbol{\omega}'$, $0 \leq \theta(\boldsymbol{\omega}, \boldsymbol{\omega}') \leq \pi$). The configurations of $\boldsymbol{\omega}$ and $\boldsymbol{\omega}_0$ which ensure that (1.3) can be rewritten as (1.4) can now be described (for a convex fully illuminated cone) by the following condition (see also [33]):

$$\theta_1(\boldsymbol{\omega}, \boldsymbol{\omega}_0) := \min_{\boldsymbol{\omega}' \in \ell} \{\theta(\boldsymbol{\omega}, \boldsymbol{\omega}') + \theta(\boldsymbol{\omega}', \boldsymbol{\omega}_0)\} > \pi. \tag{2.1}$$

When $\theta_1(\boldsymbol{\omega}, \boldsymbol{\omega}_0) \leq \pi$ the formula (1.3) may either be undefined on the so-called singular directions or have to be interpreted in an appropriate distributional sense; for more details see [6, 25, 8]. We will not discuss this here, but the reader may refer to [6] and [13] for more detail, including the case when the cone is not fully illuminated.

As mentioned in section 1, the regular part g^r of the Green's function g in (1.2) is defined by

$$g^r(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) = g(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) - g_0(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu), \tag{2.2}$$

where g_0 is given by

$$g_0(\boldsymbol{\omega}, \boldsymbol{\omega}', \nu) = -\frac{1}{4\cos(\pi\nu)} P_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}')), \tag{2.3}$$

with P_k denoting the Legendre special function of the first kind of index k (see, e.g., [1, p. 332]). It is well known (see, e.g., [33, 4, 6]) that g_0 satisfies

$$(\Delta^* + \nu^2 - 1/4) g_0(\boldsymbol{\omega}, \boldsymbol{\omega}', \nu) = \delta(\boldsymbol{\omega} - \boldsymbol{\omega}')\ ,\ \ \boldsymbol{\omega}, \boldsymbol{\omega}' \in S^2 \tag{2.4}$$

(where the differentiation is with respect to $\boldsymbol{\omega}$); i.e., it is the fundamental solution for the operator $\Delta^* + \nu^2 - 1/4$ on all of the sphere S^2. Comparing (2.4) and (1.2), we see that for each $\boldsymbol{\omega}_0 \in M$ and $\nu \in \mathbb{C}$, the function g^r, as a function of $\boldsymbol{\omega}$, satisfies the homogeneous PDE (see [4, 6])

$$(\Delta^* + \nu^2 - 1/4)g^r(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) = 0, \quad \boldsymbol{\omega} \in M, \tag{2.5}$$

subject to the boundary condition on ℓ,

$$\left.\begin{array}{lll} \text{either} & g^r(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) = -g_0(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu), & \text{the Dirichlet case} \\ \text{or} & (\partial g^r/\partial \mathbf{m})(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) = -(\partial g_0/\partial \mathbf{m})(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu), & \text{the Neumann case} \end{array}\right\} \text{for all } \boldsymbol{\omega} \in \ell . \tag{2.6}$$

The boundary condition to be imposed on g^r is inherited from the boundary condition imposed on the original scattering problem. In (2.6) and throughout the paper, we make use of the following notational convention.

NOTATION 2.1. *With each $\boldsymbol{\omega} \in \ell$, not a corner point, we associate a unit normal $\mathbf{m} = \mathbf{m}(\boldsymbol{\omega})$ to ℓ at $\boldsymbol{\omega}$ which lies in the plane tangent to the unit sphere S^2 at $\boldsymbol{\omega}$ and is oriented outward from M. We also associate with $\boldsymbol{\omega}$ the unit tangent to ℓ at $\boldsymbol{\omega}$ denoted by $\mathbf{t} = \mathbf{t}(\boldsymbol{\omega})$, oriented so that $\mathbf{t}(\boldsymbol{\omega})$, $\mathbf{m}(\boldsymbol{\omega})$, $\boldsymbol{\omega}$ form an orthogonal right-handed triple (see Figure 3). (We usually suppress the dependence on $\boldsymbol{\omega}$ from the notation for simplicity.) Then $\partial/\partial\mathbf{m}$ denotes the (outward) normal derivative with respect to $\boldsymbol{\omega} \in \ell$. For any other point $\boldsymbol{\omega}'$ in ℓ, we analogously define the unit normal and tangent vectors $\mathbf{m}'$ and $\mathbf{t}'$ and normal derivative $\partial/\partial\mathbf{m}'$.*

The problem (2.5), (2.6) can now be solved by an integral equation method on ℓ. Here we follow the classical indirect approach, e.g., [3], adapted to the present problem in [4] and [6], although we note that a direct approach based on Green's formula would also be possible.

In the Dirichlet case, we seek the solution in the form of a double layer potential,

$$g^r(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) = \int_\ell \frac{\partial g_0}{\partial \mathbf{m}'}(\boldsymbol{\omega}, \boldsymbol{\omega}', \nu) u(\boldsymbol{\omega}', \nu) d\boldsymbol{\omega}', \qquad \boldsymbol{\omega} \in M \ . \tag{2.7}$$

Taking limits as $\boldsymbol{\omega}$ tends to the contour ℓ in (2.7) and using the jump conditions of the double layer potential and the Dirichlet boundary condition from (2.6), we obtain the second-kind integral equation:

$$\frac{1}{2}u(\boldsymbol{\omega}, \nu) + \int_\ell \frac{\partial g_0}{\partial \mathbf{m}'}(\boldsymbol{\omega}, \boldsymbol{\omega}', \nu) u(\boldsymbol{\omega}', \nu) d\boldsymbol{\omega}' = -g_0(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) \tag{2.8}$$

for all smooth points $\boldsymbol{\omega} \in l$. This equation is given in [4]. A rigorous justification for potential theory on manifolds with smooth boundaries is given in a very general context in [19]. For corner points the factor $1/2$ has to be replaced by a factor related to the corner angle; cf. [14]. However, since we will estimate errors for our boundary integral equations in L^2-type spaces, these points are unimportant. Notice that since $\boldsymbol{\omega} \in \ell$ and $\boldsymbol{\omega}_0 \in M$, the right-hand side (2.8) is never singular.

Analogously, the Neumann problem is solved with the single layer potential:

$$g^r(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) = \int_\ell g_0(\boldsymbol{\omega}, \boldsymbol{\omega}', \nu) u(\boldsymbol{\omega}', \nu) d\boldsymbol{\omega}', \qquad \boldsymbol{\omega} \in M \ . \tag{2.9}$$

Taking the normal derivative and fitting the boundary condition leads to

$$-\frac{1}{2}u(\boldsymbol{\omega}, \nu) + \int_\ell \frac{\partial g_0}{\partial \mathbf{m}}(\boldsymbol{\omega}, \boldsymbol{\omega}', \nu) u(\boldsymbol{\omega}', \nu) d\boldsymbol{\omega}' = -\frac{\partial g_0}{\partial \mathbf{m}}(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) \ . \tag{2.10}$$

We can write (2.8), (2.10) (almost everywhere) in operator form as

$$\Big(I + \mathcal{L}_B\Big)u = b_B \ , \quad \text{with} \ \ (\mathcal{L}_B u)(\boldsymbol{\omega}) = \int_\ell L_B(\boldsymbol{\omega}, \boldsymbol{\omega}')u(\boldsymbol{\omega}')d\boldsymbol{\omega}' \ , \quad B = D, N, \tag{2.11}$$

with solution $u(\boldsymbol{\omega}, \nu)$ abbreviated by $u(\boldsymbol{\omega})$. In the Dirichlet case the data are

$$b_D(\boldsymbol{\omega}) := -2g_0(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) \ , \quad L_D(\boldsymbol{\omega}, \boldsymbol{\omega}') := 2\frac{\partial g_0}{\partial \mathbf{m}'}(\boldsymbol{\omega}, \boldsymbol{\omega}', \nu) \ , \tag{2.12}$$

and in the Neumann case,

$$b_N(\boldsymbol{\omega}) := 2\frac{\partial g_0}{\partial \mathbf{m}}(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu), \quad L_N(\boldsymbol{\omega}, \boldsymbol{\omega}') := -2\frac{\partial g_0}{\partial \mathbf{m}}(\boldsymbol{\omega}, \boldsymbol{\omega}', \nu) \ . \tag{2.13}$$

Although the operators in (2.11), with the kernels from (2.12) or (2.13), are not classical, we will show that their properties are analogous to those of the standard layer potentials for the Helmholtz equation on the boundary of a planar domain.

3. Integral operators.

3.1. Preliminary results.

3.1. Preliminary results. The aim of this subsection is to identify the principal parts of the kernels L_D and L_N. This is done in Theorem 3.3. To prove this we need two technical lemmas.

LEMMA 3.1. *Using Notation* 2.1, *we have*

$$L_D(\boldsymbol{\omega}, \boldsymbol{\omega}') = \frac{1}{2\cos(\pi\nu)} \ P'_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}')) \ \mathbf{t}'.(\boldsymbol{\omega} \wedge \boldsymbol{\omega}') \ , \tag{3.1}$$

$$L_N(\boldsymbol{\omega}, \boldsymbol{\omega}') = -\frac{1}{2\cos(\pi\nu)} \ P'_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}')) \ \mathbf{t}.(\boldsymbol{\omega}' \wedge \boldsymbol{\omega}) \ . \tag{3.2}$$

Proof. By employing spherical polar coordinates $\boldsymbol{\omega}' = (\sin\theta'\cos\phi', \sin\theta'\sin\phi', \cos\theta')^T$, for any $v : S^2 \to \mathbb{R}$, we have the representation

$$\frac{\partial v}{\partial \mathbf{m}'}(\boldsymbol{\omega}') = \nabla_{\boldsymbol{\omega}'} \{v \circ \boldsymbol{\omega}'\} \cdot \mathbf{m}' \ ,$$

where $\nabla_{\boldsymbol{\omega}'}$ is the spherical gradient

$$\nabla_{\boldsymbol{\omega}'} = \frac{1}{\sin\theta'}\mathbf{e}_{\phi'}\frac{\partial}{\partial\phi'} + \mathbf{e}_{\theta'}\frac{\partial}{\partial\theta'} \ ,$$

with

$$\mathbf{e}_{\phi'} = (-\sin\phi', \cos\phi', 0)^T \quad \text{and} \quad \mathbf{e}_{\theta'} = (\cos\theta'\cos\phi', \cos\theta'\sin\phi', -\sin\theta')^T \ .$$

Since $\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}') = \boldsymbol{\omega} \cdot \boldsymbol{\omega}'$, we have

$$\frac{\partial}{\partial \mathbf{m}'}P_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}')) = -P'_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}')) \ \nabla_{\boldsymbol{\omega}'} \{\boldsymbol{\omega} \cdot \boldsymbol{\omega}'\} \cdot \mathbf{m}'. \tag{3.3}$$

Now an easy calculation shows that

$$\nabla_{\boldsymbol{\omega}'}\Big\{\boldsymbol{\omega} \cdot \boldsymbol{\omega}'\Big\} \cdot \mathbf{m}' = \Big\{(\boldsymbol{\omega} \cdot \mathbf{e}_{\phi'}) \ \mathbf{e}_{\phi'} + (\boldsymbol{\omega} \cdot \mathbf{e}_{\theta'}) \ \mathbf{e}_{\theta'}\Big\} \cdot \mathbf{m}' \ = \boldsymbol{\omega} \cdot \mathbf{m}'.$$

Thus from (3.3), (2.3), and (2.12), we have

$$L_D(\boldsymbol{\omega},\boldsymbol{\omega}') = \frac{1}{2\cos(\pi\nu)}\ P'_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\omega},\boldsymbol{\omega}'))\ \boldsymbol{\omega}\cdot\mathbf{m}'\ . \tag{3.4}$$

Since $\mathbf{t}'$, $\mathbf{m}'$, and $\boldsymbol{\omega}'$ form a right-handed triple, we have $\mathbf{m}' = \boldsymbol{\omega}' \wedge \mathbf{t}'$, and so

$$L_D(\boldsymbol{\omega},\boldsymbol{\omega}') = \frac{1}{2\cos(\pi\nu)}\ P'_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\omega},\boldsymbol{\omega}'))\ \boldsymbol{\omega}\cdot(\boldsymbol{\omega}'\wedge\mathbf{t}')\ ,$$

which is equivalent to (3.1) by cyclic permutation. Since $L_N(\boldsymbol{\omega},\boldsymbol{\omega}') = -L_D(\boldsymbol{\omega}',\boldsymbol{\omega})$, (3.2) follows easily. □

The next lemma identifies the asymptotic behavior of $P'_{\nu+\frac{1}{2}}(x)$ for x close to -1. In Theorem 3.3, we will combine this with (3.1), (3.2) to identify the behavior of L_D and L_N near $\boldsymbol{\omega} = \boldsymbol{\omega}'$.

Lemma 3.2. *For all $k \in \mathbb{C}$, $P_k(x)$ is an analytic function of $x \in (-1,3)$. Moreover, for $x \in (-3,1)$,*

$$P_k(x) = a_k(x)\log\left(\frac{1+x}{2}\right) + b_k(x),$$

where $a_k(x)$ and $b_k(x)$ are both analytic on $(-3,1)$, with

$$a_k(-1) = \frac{\sin(\pi k)}{\pi} \qquad \text{and} \qquad b_k(-1) = \frac{\sin(\pi k)}{\pi}\ \{\psi(k)+\psi(-k-1)+2\gamma\},$$

where $\psi(k) = -\gamma - \sum_{r=1}^{\infty}(1/(k+r) - 1/r)$ and γ is the Euler constant [1, p. 255].

Proof. From [1, equation (8.1.2)] we get the following representation of P_k:

$$P_k(x) = F\left(-k, k+1; 1; \frac{1-x}{2}\right), \tag{3.5}$$

where F is the hypergeometric function. It follows from [1, p. 556] that $F(-k,k+1;1;z)$ is a convergent power series for $-1 \le z < 1$. Therefore, by (3.5), $P_k(x)$ is analytic for $x \in (-1,3)$ and in particular for $x \in (-1,1)$. This proves the first statement in the theorem.

Furthermore, from [24, Chapter V, equation (53)] we have that

$$P_k(x) = a_k(x)\log\left(\frac{1+x}{2}\right) + b_k(x),$$

where

$$a_k(x) = \frac{\sin(\pi k)}{\pi}F(-k,k+1;1;(1+x)/2) \tag{3.6}$$

and

$$\begin{aligned} b_k(x) = \frac{\sin(\pi k)}{\pi}\Bigg\{&[\psi(k)+\psi(-k-1)+2\gamma]F(-k,k+1;1;(1+x)/2) \\ &+\sum_{r=1}^{\infty}B(k,r)\phi(k,r)\left(\frac{1+x}{2}\right)^r\Bigg\}\ . \end{aligned} \tag{3.7}$$

Here

$$B(k,r) = \frac{(-k)\dots(-k+r-1)(k+1)\dots(k+r)}{(r!)^2}$$

and

$$\phi(k,r) = \sum_{j=1}^{r} \left\{ \frac{2k(k+1)+j}{(j^2-k^2-k-j)j} \right\}.$$

As remarked above, $F(-k,k+1;1;(1+x)/2)$ is a convergent power series for $-1 \le (1+x)/2 < 1$, so $a_k(x)$ is analytic for $x \in (-3,1)$. Moreover $a_k(-1) = \sin(\pi k)/\pi$ follows from [1, p. 556]).

Turning to b_k, it is clear that the first term on the right-hand side of (3.7) is also analytic for $x \in (-3,1)$ and that the assertions about b_k will then follow, provided the domain of convergence of the power series

$$\sum_{r=1}^{\infty} B(k,r)\phi(k,r)\left(\frac{1+x}{2}\right)^r \tag{3.8}$$

can be shown to be $(-3,1)$. To obtain this result, note that $\lim_{r\to\infty}\phi(k,r)$ is clearly finite. If $\lim_{r\to\infty}\phi(k,r) \neq 0$, then it follows that $|\phi(k,r+1)/\phi(k,r)| \to 1$ as $r \to \infty$. Then

$$\begin{aligned}&\lim_{r\to\infty} \frac{|B(k,r+1)\ \phi(k,r+1)((1+x)/2)^{r+1}|}{|B(k,r)\ \phi(k,r)((1+x)/2)^r|}\\ &= \left|\frac{1+x}{2}\right| \lim_{r\to\infty}\left|\frac{(-k+r)(k+r+1)}{(r+1)^2}\,\frac{\phi(k,r+1)}{\phi(k,r)}\right| = \left|\frac{1+x}{2}\right|,\end{aligned} \tag{3.9}$$

and (3.8) is convergent for $x \in (-3,1)$ by the ratio test. However, if $\lim_{r\to\infty}\phi(k,r) = 0$, then, for large enough r, $|\phi(k,r)| < 1$. Since (3.9) also shows that the power series $\sum_{r=1}^{\infty} B(k,r)((1+x)/2)^r$ converges for $x \in (-3,1)$, the comparison test then ensures that (3.8) also converges for $x \in (-3,1)$. □

We now combine Lemmas 3.1 and 3.2 to obtain the following theorem.

THEOREM 3.3. *Recall Notation* 2.1.

(i) *For* $\boldsymbol{\omega}, \boldsymbol{\omega}' \in \ell$,

$$L_D(\boldsymbol{\omega},\boldsymbol{\omega}') = -\frac{\mathbf{t}'\cdot(\boldsymbol{\omega}\wedge\boldsymbol{\omega}')}{\pi|\boldsymbol{\omega}-\boldsymbol{\omega}'|^2} + F_D(\boldsymbol{\omega},\boldsymbol{\omega}'), \tag{3.10}$$

$$L_N(\boldsymbol{\omega},\boldsymbol{\omega}') = \frac{\mathbf{t}\cdot(\boldsymbol{\omega}'\wedge\boldsymbol{\omega})}{\pi|\boldsymbol{\omega}-\boldsymbol{\omega}'|^2} + F_N(\boldsymbol{\omega},\boldsymbol{\omega}'), \tag{3.11}$$

where F_D *and* F_N *are bounded functions on* $\ell \times \ell$.

(ii) *When* $\boldsymbol{\omega}$ *is* not *a corner point of* ℓ,

$$\frac{\mathbf{t}'\cdot(\boldsymbol{\omega}\wedge\boldsymbol{\omega}')}{\pi|\boldsymbol{\omega}-\boldsymbol{\omega}'|^2} \quad \text{and} \quad \frac{\mathbf{t}\cdot(\boldsymbol{\omega}'\wedge\boldsymbol{\omega})}{\pi|\boldsymbol{\omega}-\boldsymbol{\omega}'|^2} \tag{3.12}$$

are both $\mathcal{C}^\infty$ *functions of* $\boldsymbol{\omega}'$ *in a neighborhood of* $\boldsymbol{\omega}$ *and, for* $B = D$ *or* N,

$$F_B(\boldsymbol{\omega},\boldsymbol{\omega}') = O(|\boldsymbol{\omega}-\boldsymbol{\omega}'|^2 \log|\boldsymbol{\omega}-\boldsymbol{\omega}'|) \quad \text{as} \quad \boldsymbol{\omega}' \to \boldsymbol{\omega}\ . \tag{3.13}$$

Proof. We give the proof for L_D; the argument for L_N is analogous.

(i) From Lemma 3.2 with $k = \nu - 1/2$, we have, for $x \in (-1, 1)$,

$$P'_{\nu-\frac{1}{2}}(x) = \frac{-\cos(\pi\nu)}{\pi}\left\{\frac{1}{x+1}\right\} + r(x), \tag{3.14}$$

where

$$r(x) = \left[\frac{a_{\nu-\frac{1}{2}}(x) - a_{\nu-\frac{1}{2}}(-1)}{x-(-1)} + a'_{\nu-\frac{1}{2}}(x)\log\left(\frac{x+1}{2}\right) + b'_{\nu-\frac{1}{2}}(x)\right] . \tag{3.15}$$

Also note that since $\boldsymbol{\omega}, \boldsymbol{\omega}' \in S^2$, we have

$$-\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}') + 1 = -\boldsymbol{\omega}.\boldsymbol{\omega}' + 1 = \frac{1}{2}|\boldsymbol{\omega} - \boldsymbol{\omega}'|^2 . \tag{3.16}$$

Hence

$$P'_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}')) = -\frac{2\cos(\pi\nu)}{\pi|\boldsymbol{\omega} - \boldsymbol{\omega}'|^2} + r(-1 + |\boldsymbol{\omega} - \boldsymbol{\omega}'|^2/2). \tag{3.17}$$

Therefore combining (3.1) with (3.15) and (3.17), we obtain the formula (3.10), where

$$F_D(\boldsymbol{\omega}, \boldsymbol{\omega}') = \frac{1}{2\cos(\pi\nu)}\ r(-1 + |\boldsymbol{\omega} - \boldsymbol{\omega}'|^2/2)\ \mathbf{t}' \cdot (\boldsymbol{\omega} \wedge \boldsymbol{\omega}') . \tag{3.18}$$

To complete the proof of (i) we now show that F_D is bounded on $\ell \times \ell$. To do this, choose a fixed δ satisfying $0 < \delta < \pi/2$ and first consider $\boldsymbol{\omega}, \boldsymbol{\omega}'$ in the range

$$0 \le \theta(\boldsymbol{\omega}, \boldsymbol{\omega}') \le \pi - \delta . \tag{3.19}$$

Then there exists $\epsilon > 0$ such that $-1 \le -\cos\theta(\boldsymbol{\omega}, \boldsymbol{\omega}') \le 1 - \epsilon$, and hence it follows from (3.16) that

$$-1 \le -1 + |\boldsymbol{\omega} - \boldsymbol{\omega}|^2/2 \le 1 - \epsilon. \tag{3.20}$$

Substituting (3.15) into (3.18) we obtain

$$\begin{aligned} &2\cos(\pi\nu)F_D(\boldsymbol{\omega}, \boldsymbol{\omega}') \\ &= \mathbf{t}' \cdot (\boldsymbol{\omega} \wedge \boldsymbol{\omega}')\left\{\frac{a_{\nu-\frac{1}{2}}(-1+|\boldsymbol{\omega} - \boldsymbol{\omega}'|^2/2) - a_{\nu-\frac{1}{2}}(-1)}{|\boldsymbol{\omega} - \boldsymbol{\omega}'|^2/2} + b'_{\nu-\frac{1}{2}}(-1+|\boldsymbol{\omega} - \boldsymbol{\omega}'|^2/2)\right\} &(3.21)\\ &+ a'_{\nu-\frac{1}{2}}(-1 + |\boldsymbol{\omega} - \boldsymbol{\omega}'|^2/2)\ \left\{\mathbf{t}' \cdot (\boldsymbol{\omega} \wedge \boldsymbol{\omega}')\log(|\boldsymbol{\omega} - \boldsymbol{\omega}'|^2/4)\right\} . &(3.22)\end{aligned}$$

Recall from Lemma 3.2 that $a_{\nu-\frac{1}{2}}$ and $b'_{\nu-\frac{1}{2}}$ are both analytic on $(-3, 1)$. Since $|\boldsymbol{\omega} - \boldsymbol{\omega}'|^2$ is a smooth function of $\boldsymbol{\omega}, \boldsymbol{\omega}'$, it follows that the terms inside the braces in (3.21) are smooth functions of $\boldsymbol{\omega}, \boldsymbol{\omega}' \in \ell$. Moreover

$$\begin{aligned} |\mathbf{t}' \cdot (\boldsymbol{\omega} \wedge \boldsymbol{\omega}')| \le |\mathbf{t}'||\boldsymbol{\omega} \wedge \boldsymbol{\omega}'| &= \sin\theta(\boldsymbol{\omega}, \boldsymbol{\omega}') = \{1 - \cos^2\theta(\boldsymbol{\omega}, \boldsymbol{\omega}')\}^{1/2} \\ &= \{1 - (\boldsymbol{\omega} \cdot \boldsymbol{\omega}')^2\}^{1/2} = \{(1 - \boldsymbol{\omega} \cdot \boldsymbol{\omega}')(1 + \boldsymbol{\omega} \cdot \boldsymbol{\omega}')\}^{1/2} \\ &= \frac{1}{2}|\boldsymbol{\omega} - \boldsymbol{\omega}'||\boldsymbol{\omega} + \boldsymbol{\omega}'|, \end{aligned} \tag{3.23}$$

which ensures the boundedness of (3.21). The boundedness of (3.22) follows in a similar way, using (3.23) and the analyticity of $a'_{\nu-\frac{1}{2}}$ on $(-3,1)$.

To complete the proof, consider the case when (3.19) fails, i.e., $\pi-\delta \le \theta(\boldsymbol{\omega},\boldsymbol{\omega}') \le \pi$. For this case recall from (3.5) that $P_{\nu-1/2}(x)$ is analytic for $x \in (-1,3)$. Therefore (3.1) implies that $L_D(\boldsymbol{\omega},\boldsymbol{\omega}')$ is bounded for $\pi-\delta \le \theta(\boldsymbol{\omega},\boldsymbol{\omega}') \le \pi$. Thus setting

$$F_D(\boldsymbol{\omega},\boldsymbol{\omega}) = L_D(\boldsymbol{\omega},\boldsymbol{\omega}') + \frac{\mathbf{t}'\cdot(\boldsymbol{\omega}\wedge\boldsymbol{\omega}')}{\pi|\boldsymbol{\omega}-\boldsymbol{\omega}'|^2}$$

ensures that (3.10) holds, with $F_D(\boldsymbol{\omega},\boldsymbol{\omega})$ bounded for $\pi-\delta \le \theta(\boldsymbol{\omega},\boldsymbol{\omega}') \le \pi$.

(ii) Now suppose that $\boldsymbol{\omega}$ is not a corner point and that $\boldsymbol{\omega}'$ is sufficiently close to $\boldsymbol{\omega}$ so as to ensure that there is no corner point between $\boldsymbol{\omega}$ and $\boldsymbol{\omega}'$ on ℓ. Let $\boldsymbol{\rho}$ denote an arclength parameterization of ℓ from any fixed reference point; then setting $\boldsymbol{\omega}=\boldsymbol{\rho}(s)$, the unit tangent $\mathbf{t}$ at $\boldsymbol{\omega}$ is given by $\mathbf{t}=\boldsymbol{\rho}_s(s)$, the derivative of $\boldsymbol{\rho}(s)$. Then for $\boldsymbol{\omega}'$ near $\boldsymbol{\omega}$ with $\boldsymbol{\omega}'=\boldsymbol{\rho}(\sigma)$, we have

$$(3.24)\quad |\boldsymbol{\omega}-\boldsymbol{\omega}'|/|s-\sigma| = O(1) \quad\text{and}\quad |s-\sigma|/|\boldsymbol{\omega}-\boldsymbol{\omega}'| = O(1) \qquad \text{as } \sigma\to s.$$

Also,

$$\boldsymbol{\omega}\wedge\boldsymbol{\omega}' = \boldsymbol{\rho}(s)\wedge\boldsymbol{\rho}(\sigma) = (\boldsymbol{\rho}(s)-\boldsymbol{\rho}(\sigma))\wedge\boldsymbol{\rho}(\sigma).$$

Hence

$$(3.25)\qquad \mathbf{t}'\cdot(\boldsymbol{\omega}\wedge\boldsymbol{\omega}') = \boldsymbol{\rho}_s(\sigma)\cdot((\boldsymbol{\rho}(s)-\boldsymbol{\rho}(\sigma)-(s-\sigma)\boldsymbol{\rho}_s(\sigma))\wedge\boldsymbol{\rho}(\sigma)).$$

Since $|\boldsymbol{\omega}-\boldsymbol{\omega}'|^2 = (\boldsymbol{\rho}(s)-\boldsymbol{\rho}(\sigma))\cdot(\boldsymbol{\rho}(s)-\boldsymbol{\rho}(\sigma))$, it follows that (3.12) are smooth functions as $\sigma\to s$ (i.e., $\boldsymbol{\omega}'\to\boldsymbol{\omega}$). Moreover (3.24) and (3.25) imply that $|\mathbf{t}'\cdot(\boldsymbol{\omega}\wedge\boldsymbol{\omega}')| = O(|\boldsymbol{\omega}-\boldsymbol{\omega}'|^2)$ and so (3.13) follows from (3.21) and (3.22). □

We see from Theorem 3.3 that if there are no corner points on ℓ, then L_D and L_N are bounded (in fact continuous), so in both the Dirichlet and Neumann cases the integral operator $\mathcal{L}_B$ will be compact on most standard spaces, e.g., $C(\ell), L^2(\ell)$. Then standard stability proofs for the numerical method will follow. However, if ℓ does contain a corner, compactness is lost and so another approach is needed to show stability of a numerical method. The approach we will use is to compare the integral operator $\mathcal{L}_B$ with a corresponding plane Laplace integral operator $\mathcal{K}_B$ and then use stability results which are known for the planar Laplace problem. This is done in the following subsection.

3.2. Relation to planar Laplace case. To simplify the presentation, we assume that the contour ℓ has one corner which we will denote by the point $\boldsymbol{\omega}_c \in S^2$. The case of several corners is obtained analogously. Without loss of generality, we assume $\boldsymbol{\omega}_c = (0,0,1)^T$. Suppose that $\boldsymbol{\rho}(s)$ travels around ℓ with M on the right-hand side (as indicated by the arrow in Figure 3), as s travels from $-\Lambda$ to Λ, where 2Λ is the length of ℓ. Then we can introduce the *wedge* w in the tangent plane to S^2 at $\boldsymbol{\omega}_c$ as follows.

DEFINITION 3.4. *The wedge w is defined to be the union of two straight line segments: $w = w^- \cup w^+$, where*

$$w^- = \{(0,0,1)^T + s\mathbf{t}_c^- : s\in[-\Lambda,0]\}, \qquad w^+ = \{(0,0,1)^T + s\mathbf{t}_c^+ : s\in[0,\Lambda]\},$$

and $\mathbf{t}_c^\pm = \lim_{s\to 0\pm}\boldsymbol{\rho}_s(s)$ (see Figure 3). The angle between the tangents $\mathbf{t}_c^+$ and $-\mathbf{t}_c^-$ is measured "counterclockwise" about the z axis (when viewed from outside the sphere)

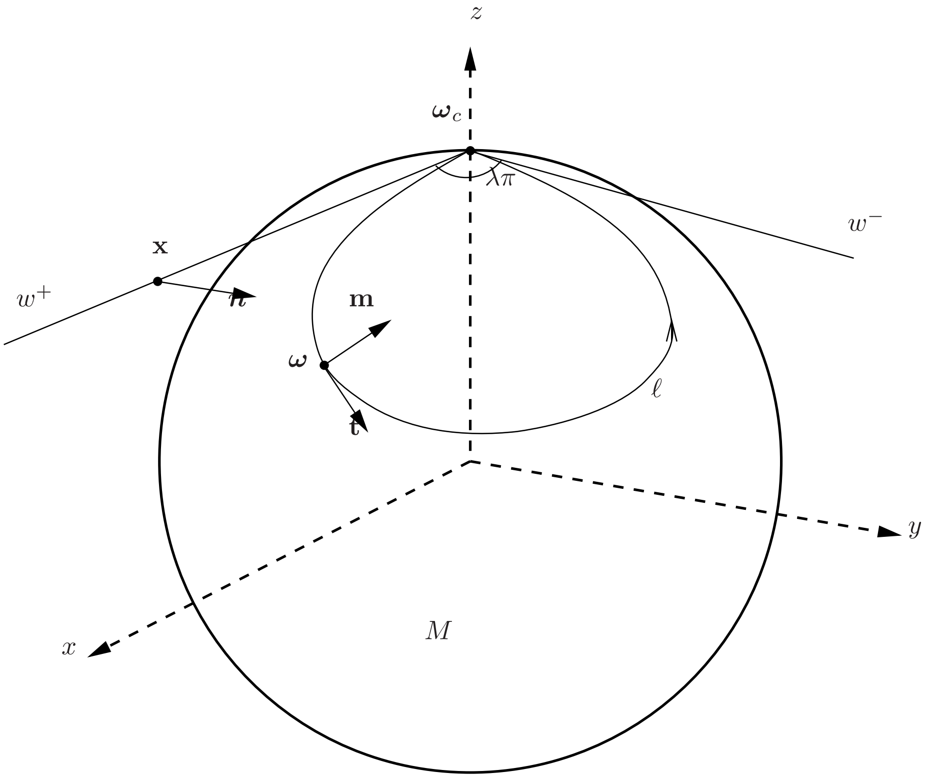

FIG. 3. *Wedge w and contour ℓ.*

from w^+ to w^- and is denoted $\lambda\pi$, where $\lambda \in (0,2)\backslash\{1\}$. Without loss of generality we choose our coordinate system so that $\mathbf{t}_c^+$ is in the direction of the x axis. Each $\mathbf{x} = s\mathbf{t}_c^\pm \in w^\pm$ can be associated with a unique $\boldsymbol{\omega} = \boldsymbol{\rho}(s) \in \ell$, and with a unit normal $\mathbf{m}$ at $\boldsymbol{\omega} \in \ell$ orientated outward from M. To $\mathbf{x}$ we associate a unit normal $\boldsymbol{n}$ to w in the plane tangent to S^2 at $\boldsymbol{\omega}_c$, orientated so that $\boldsymbol{n}\cdot\mathbf{m} \to 1$ as $s \to 0$. (See Figure 3.)

The fundamental solution of Laplace's equation on the plane is $(1/2\pi)\log|\mathbf{x}-\mathbf{x}'|$. Using this we introduce the operators

$$(\mathcal{K}_B u)(\mathbf{x}) = \int_w K_B(\mathbf{x},\mathbf{x}')u(\mathbf{x}')d\mathbf{x}' \ , \qquad B = D, N \ .$$

Analogously to (2.12), (2.13), the Dirichlet and Neumann kernels are

$$K_D(\mathbf{x},\mathbf{x}') := \frac{1}{\pi}\frac{\partial}{\partial \boldsymbol{n}'}\left\{\log|\mathbf{x}-\mathbf{x}'|\right\} = -\frac{(\mathbf{x}-\mathbf{x}')\cdot\boldsymbol{n}'}{\pi|\mathbf{x}-\mathbf{x}'|^2}, \tag{3.26}$$

$$K_N(\mathbf{x},\mathbf{x}') := -\frac{1}{\pi}\frac{\partial}{\partial \boldsymbol{n}}\left\{\log|\mathbf{x}-\mathbf{x}'|\right\} = -\frac{(\mathbf{x}-\mathbf{x}')\cdot\boldsymbol{n}}{\pi|\mathbf{x}-\mathbf{x}'|^2}. \tag{3.27}$$

Here $\boldsymbol{n}, \boldsymbol{n}'$ are unit normals to $\boldsymbol{\omega}$ at $\mathbf{x}, \mathbf{x}' \in w$, as described in Definition 3.4.

Theorem 3.5 will show that the principal singularity of L_B near $\boldsymbol{\omega} = \boldsymbol{\omega}' = \boldsymbol{\omega}_c$ is the same as K_B near $\mathbf{x} = \mathbf{x}' = \boldsymbol{\omega}_c$. This is useful because the properties of the integral operator $\mathcal{K}_B$ with kernel K_B are well understood [17, 14, 20, 22, 31].

To prepare for Theorem 3.5, we use the arclength parameterization, $\boldsymbol{\rho}(\sigma)$, of ℓ, introduced above, to rewrite (2.11) on $[-\Lambda,\Lambda]$. Putting $\boldsymbol{\omega} = \boldsymbol{\rho}(s)$ and $\boldsymbol{\omega}' = \boldsymbol{\rho}(\sigma)$ we obtain

$$(3.28)\quad (I+\widehat{\mathcal{L}}_B)\widehat{u}=\widehat{b}_B\ ,\quad \text{with}\ \ (\widehat{\mathcal{L}}_B\widehat{u})(s)=\int_{-\Lambda}^{\Lambda}\widehat{L}_B(s,\sigma)\widehat{u}(\sigma)d\sigma,\quad s\in[-\Lambda,\Lambda],$$

where $\widehat{u}(s)=u(\boldsymbol{\rho}(s))$. In the case of Dirichlet boundary data, using (2.12) and Lemma 3.1 we have

$$\widehat{b}_D(s):=-2g_0(\boldsymbol{\rho}(s),\boldsymbol{\omega}_0,\nu)\quad\text{and}$$
$$(3.29)\quad \widehat{L}_D(s,\sigma):=\frac{1}{2\cos(\pi\nu)}\ P'_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\rho}(s),\boldsymbol{\rho}(\sigma)))\ \boldsymbol{\rho}_s(\sigma)\cdot(\boldsymbol{\rho}(s)\wedge\boldsymbol{\rho}(\sigma)).$$

(Note that since $\boldsymbol{\rho}$ is the arclength parameterization, the Jacobian satisfies $|\boldsymbol{\rho}_s(\sigma)|=1$ and therefore does not appear explicitly in the kernel.) For Neumann boundary data, using (2.13) and Lemma 3.1 we obtain

$$\widehat{b}_N(s):=2\frac{\partial g_0}{\partial\mathbf{m}(s)}(\boldsymbol{\rho}(s),\boldsymbol{\omega}_0,\nu)\quad\text{and}$$
$$(3.30)\quad \widehat{L}_N(s,\sigma):=-\frac{1}{2\cos(\pi\nu)}\ P'_{\nu-\frac{1}{2}}(-\cos\theta(\boldsymbol{\rho}(s),\boldsymbol{\rho}(\sigma)))\ \boldsymbol{\rho}_s(s)\cdot(\boldsymbol{\rho}(\sigma)\wedge\boldsymbol{\rho}(s)),$$

where $\mathbf{m}(s)$ is the corresponding normal to ℓ at $\boldsymbol{\rho}(s)$.

If we now denote the arclength parameterization of w by $\boldsymbol{r}$, with $\boldsymbol{r}(-\Lambda)=(0,0,1)^T-\Lambda\mathbf{t}_c^-$, $\boldsymbol{r}(0)=\boldsymbol{\omega}_c$, and $\boldsymbol{r}(\Lambda)=(0,0,1)^T+\Lambda\mathbf{t}_c^+$, then we can also rewrite $\mathcal{K}_B$ as an operator:

$$(\widehat{\mathcal{K}}_B\widehat{u})(s)=\int_{-\Lambda}^{\Lambda}\widehat{K}_B(s,\sigma)\widehat{u}(\sigma)d\sigma,\qquad s\in[-\Lambda,\Lambda]\ ,\quad B=D,N\ ,$$

where, from (3.26), (3.27),

$$(3.31)\qquad \widehat{K}_D(s,\sigma):=-\frac{(\boldsymbol{r}(s)-\boldsymbol{r}(\sigma))\cdot\boldsymbol{n}(\sigma)}{\pi|\boldsymbol{r}(s)-\boldsymbol{r}(\sigma)|^2},$$
$$(3.32)\qquad \widehat{K}_N(s,\sigma):=-\frac{(\boldsymbol{r}(s)-\boldsymbol{r}(\sigma))\cdot\boldsymbol{n}(s)}{\pi|\boldsymbol{r}(s)-\boldsymbol{r}(\sigma)|^2}$$

for the Dirichlet and Neumann problems, respectively. Here $\boldsymbol{n}(\sigma)$ is the normal to w at $\mathbf{x}=\boldsymbol{r}(\sigma)$. The following theorem shows that $\widehat{K}_B$ contains the principal singularity of $\widehat{L}_B$ near the corner point $s=\sigma=0$ in both the Dirichlet and Neumann cases, $B=D,N$.

THEOREM 3.5. *Let $B=D$ or N. Then for $(s,\sigma)\in[-\Lambda,\Lambda]\times[-\Lambda,\Lambda]$, $\widehat{L}_B(s,\sigma)-\widehat{K}_B(s,\sigma)$ is a bounded function.*

Proof. We give the proof for the case $B=D$. The case $B=N$ is analogous. First we consider the kernel $\widehat{K}_D$. From Definition 3.4 the parametric equation, $\boldsymbol{r}$, for w is given by

$$(3.33)\qquad \boldsymbol{r}(\sigma)=\begin{cases}(-\sigma\cos(\lambda\pi),-\sigma\sin(\lambda\pi),1)^T, & \sigma\in[-\Lambda,0],\\ (\sigma,0,1)^T, & \sigma\in[0,\Lambda].\end{cases}$$

Notice that if $-\Lambda\le s,\sigma\le 0$ or $0\le s,\sigma\le\Lambda$, then $\boldsymbol{r}(s)$ and $\boldsymbol{r}(\sigma)$ lie on the same arm of w, and so it follows from (3.31) that $\widehat{K}_D(s,\sigma)=0$ and, by Theorem 3.3(ii),

$\widehat{L}_D(s,\sigma)$ is bounded. So we have to consider only the case when s and σ are on different sides of 0.

First consider the case $-\Lambda \le s \le 0 \le \sigma \le \Lambda$. Then (3.33) implies that $\boldsymbol{r}(s) - \boldsymbol{r}(\sigma) = (-s\cos(\lambda\pi) - \sigma, -s\sin(\lambda\pi), 0)^T$ and $\boldsymbol{n}(\sigma) = (0,1,0)^T$. Therefore $(\boldsymbol{r}(s) - \boldsymbol{r}(\sigma))\cdot \boldsymbol{n}(\sigma) = -s\sin(\lambda\pi)$ and $|\boldsymbol{r}(s) - \boldsymbol{r}(\sigma)|^2 = s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2$. So from (3.31),

$$\widehat{K}_D(s,\sigma) = \frac{1}{\pi}\frac{s\sin(\lambda\pi)}{(s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2)}, \quad -\Lambda \le s \le 0 \le \sigma \le \Lambda. \tag{3.34}$$

A similar calculation shows analogously that

$$\widehat{K}_D(s,\sigma) = -\frac{1}{\pi}\frac{s\sin(\lambda\pi)}{(s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2)}, \quad -\Lambda \le \sigma \le 0 \le s \le \Lambda. \tag{3.35}$$

Now we turn our attention to the kernel, $\widehat{L}_D(s,\sigma)$. Using Taylor's theorem we can write the parameterization $\boldsymbol{\rho}$ as

$$\boldsymbol{\rho}(\sigma) = \begin{cases} \boldsymbol{r}(\sigma) + \sigma^2(\alpha_1(-\sigma), \beta_1(-\sigma), \gamma_1(-\sigma))^T, & \sigma \in [-\Lambda, 0], \\ \boldsymbol{r}(\sigma) + \sigma^2(\alpha_2(\sigma), \beta_2(\sigma), \gamma_2(\sigma))^T, & \sigma \in [0, \Lambda], \end{cases} \tag{3.36}$$

where $\alpha_i(s), \beta_i(s)$, and $\gamma_i(s)$ are smooth functions on $[0,\Lambda]$ for $i = 1,2$. Thus, for $-\Lambda \le s \le 0 \le \sigma \le \Lambda$, we have, from (3.36),

$$\boldsymbol{\rho}(s) \wedge \boldsymbol{\rho}(\sigma) = (-s\sin(\lambda\pi), s\cos(\lambda\pi) + \sigma, 0)^T + O(\max\{|s|,|\sigma|\}^2)$$

as $\max\{|s|,|\sigma|\} \to 0$. Hence with $\boldsymbol{\omega} = \boldsymbol{\rho}(s)$ and $\boldsymbol{\omega}' = \boldsymbol{\rho}(\sigma)$, we have

$$\mathbf{t}' = \boldsymbol{\rho}_s(\sigma) = (1,0,0)^T + O(|\sigma|) \,, \tag{3.37}$$

$$-\mathbf{t}'\cdot(\boldsymbol{\omega}\wedge\boldsymbol{\omega}') = s\sin(\lambda\pi) + O(\max\{|s|,|\sigma|\}^2) \,,$$

$$\text{and } |\boldsymbol{\omega} - \boldsymbol{\omega}'|^2 = s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2 + O(\max\{|s|,|\sigma|\}^3) \tag{3.38}$$

as $\max\{|s|,|\sigma|\} \to 0$. Therefore we have, from (3.10),

$$\widehat{L}_D(s,\sigma) = \frac{\sin(\lambda\pi)}{\pi}\frac{s + \eta_2(s,\sigma)}{s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2 + \eta_3(s,\sigma)} + \widehat{F}_D(s,\sigma),$$

where $\widehat{F}_D(s,\sigma) = F_D(\boldsymbol{\rho}(s), \boldsymbol{\rho}(\sigma))$ and

$$\eta_i(s,\sigma) = O(\max\{|s|,|\sigma|\}^i), \quad i = 2,3. \tag{3.39}$$

Hence, for $-\Lambda \le s \le 0 \le \sigma \le \Lambda$,

$$(\widehat{L}_D - \widehat{K}_D)(s,\sigma) = \frac{\sin(\lambda\pi)}{\pi}\left\{\frac{s + \eta_2(s,\sigma)}{s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2 + \eta_3(s,\sigma)} - \frac{s}{s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2}\right\} + \widehat{F}_D(s,\sigma), \tag{3.40}$$

which is clearly continuous for $(s,\sigma) \ne (0,0)$.

In order to show that $(\widehat{L}_D - \widehat{K}_D)(s,\sigma)$ is bounded near $(s,\sigma) = (0,0)$ we need to show that the limit (as $(s,\sigma) \to (0,0)$) of the first term on the right-hand side of

(3.40) is bounded. We do this for $0 < -s \leq \sigma$. The case $0 < \sigma \leq -s$ is analogous. To obtain the result, write

$$\begin{aligned}
&\frac{s + \eta_2(s,\sigma)}{s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2 + \eta_3(s,\sigma)} - \frac{s}{s^2 + 2s\sigma\sin(\lambda\pi) + \sigma^2} \\
&\qquad = \frac{\eta_2(s,\sigma)(s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2) - \eta_3(s,\sigma)s}{(s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2)(s^2 + 2s\sigma\cos(\lambda\pi) + \sigma^2 + \eta_3(s,\sigma))} \\
&\qquad = \frac{\frac{\eta_2(s,\sigma)}{\sigma^2}((\frac{s}{\sigma})^2 + 2\frac{s}{\sigma}\cos(\lambda\pi) + 1) - \frac{\eta_3(s,\sigma)}{\sigma^3}\frac{s}{\sigma}}{((\frac{s}{\sigma})^2 + 2\frac{s}{\sigma}\cos(\lambda\pi) + 1)((\frac{s}{\sigma})^2 + 2\frac{s}{\sigma}\cos(\lambda\pi) + 1 + \frac{\eta_3(s,\sigma)}{\sigma^2})}. \qquad (3.41)
\end{aligned}$$

Now, when $0 < -s \leq \sigma$ we have $0 < |s| \leq |\sigma|$ and from (3.39) it follows that $\eta_2(s,\sigma)/\sigma^2 = O(1)$, $\eta_3(s,\sigma)/\sigma^3 = O(1)$, and $\eta_3(s,\sigma)/\sigma^2 \to 0$ as $(s,\sigma) \to (0,0)$. Moreover, since $\lambda \in (0,2)\backslash\{1\}$, we have

$$x^2 + 2x\cos(\lambda\pi) + 1 \ \geq \ \sin^2(\lambda\pi) \ > \ 0 \quad \text{for all } \ x \in \mathbb{R} \ .$$

Combining all these facts with (3.41) shows that the first term in (3.40) is bounded as $(s,\sigma) \to (0,0)$. Since $\widehat{F}_D$ is a bounded function, it follows that $\widehat{L}_D(s,\sigma) - \widehat{K}_D(s,\sigma)$ is bounded for $-\Lambda \leq s \leq 0 \leq \sigma \leq \Lambda$.

For $-\Lambda \leq \sigma \leq 0 \leq s \leq \Lambda$ the result follows analogously. □

We shall analyze (3.28) in the space $L^2[-\Lambda,\Lambda]$, equipped with the norm $\|v\|_{L^2[-\Lambda,\Lambda]} = \{\int_{-\Lambda}^{\Lambda} |v(\sigma)|^2 d\sigma\}^{1/2}$. This allows us to cover the Neumann and Dirichlet problems in a unified setting. (There is a corresponding theory in the space $L^\infty[-\Lambda,\Lambda]$ which applies to the Dirichlet problem but not to the Neumann problem.) The next result follows directly from Theorem 3.5, using, e.g., [26, p. 326].

COROLLARY 3.6. *For $B = D$ or N, $\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B$ is a compact operator on $L^2[-\Lambda,\Lambda]$.*

The remainder of this section is devoted to proving the well-posedness of (3.28) in $L^2[-\Lambda,\Lambda]$. This is done in Corollary 3.8. Since $\widehat{\mathcal{L}}_B$ is a compact perturbation of $\widehat{\mathcal{K}}_B$, the key part of the proof of Corollary 3.8 is contained in the following theorem, which is of key importance also when we come to the numerical analysis in section 4.

THEOREM 3.7. *For $B = D$ or N, $(I + \widehat{\mathcal{K}}_B)^{-1}$ exists and is bounded on $L^2[-\Lambda,\Lambda]$.*

Proof. Since the proof follows standard procedures for dealing with Mellin convolution operators, we will be brief. More detail is in [13]. The first step is to write the operator $v \mapsto (I + \widehat{\mathcal{K}}_B)v$ on $L^2[-\Lambda,\Lambda]$ as two coupled convolution operators on $[0,\Lambda]$. For $(w_1,w_2) \in L^2[0,\Lambda] \times L^2[0,\Lambda]$ we introduce the norm $\|(w_1,w_2)\| = \{\|w_1\|^2_{L^2[0,\Lambda]} + \|w_2\|^2_{L^2[0,\Lambda]}\}^{1/2}$. Also we define the map $\Pi : L^2[-\Lambda,\Lambda] \to L^2[0,\Lambda] \times L^2[0,\Lambda]$ by

$$\Pi v := (v_1, v_2), \text{ where } v_1(s) = v(-s) + v(s) \quad \text{and} \quad v_2(s) = v(-s) - v(s), \quad s \in [0,\Lambda].$$

Clearly Π is a bijection and $\|\Pi v\|^2 = 2\|v\|^2_{L^2[-\Lambda,\Lambda]}$. Moreover, an elementary calculation using (3.34) and (3.35) and the analogous kernels for $B = N$ (see [13] for details) shows that

$$\Pi\widehat{\mathcal{K}}_B = \tilde{\mathbb{K}}_B\Pi, \quad B = D \text{ or } N. \qquad (3.42)$$

Here $\tilde{\mathbb{K}}_B$ is the matrix operator

$$\tilde{\mathbb{K}}_B = \begin{pmatrix} \widetilde{\mathcal{K}}_B & 0 \\ 0 & -\widetilde{\mathcal{K}}_B \end{pmatrix},$$

and $\widetilde{\mathcal{K}}_B$ is the *Mellin convolution* operator on $L^2[0,\Lambda]$ defined by

$$(\widetilde{\mathcal{K}}_B v)(s) = \int_0^\Lambda \tilde{\kappa}_B(s/\sigma)v(\sigma)\frac{d\sigma}{\sigma},$$

with kernels

$$\tilde{\kappa}_D(s) = -\frac{\sin(\lambda\pi)}{\pi}\frac{s}{1-2s\cos\lambda\pi+s^2}, \qquad \tilde{\kappa}_N(s) = \frac{\sin(\lambda\pi)}{\pi}\frac{1}{1-2s\cos\lambda\pi+s^2} \ .$$

Hence, for all $v \in L^2[-\Lambda,\Lambda]$, we have

$$(I+\widehat{\mathcal{K}}_B)v = \Pi^{-1}(I+\mathbb{K}_B)\Pi v. \tag{3.43}$$

It can be shown, using Mellin integral transform techniques [20], that $\|\widetilde{\mathcal{K}}_B\|_{L^2[0,\Lambda]} < 1$ (see [13] for further details). Hence by Banach's lemma $I \pm \widetilde{\mathcal{K}}_B$ has a bounded inverse on $L_2[0,\Lambda]$ and the result follows from (3.43). □

Corollary 3.6 and Theorem 3.7 can now be combined to obtain the well-posedness of (2.11) via the Fredholm alternative. The proof requires the injectiveness of $(I+\hat{\mathcal{L}}_B)$; i.e., we need to show that for all ν on the contour γ (see Figure 2), the implication

$$(I+\widehat{\mathcal{L}}_B)\widehat{u} = 0 \ \Rightarrow\ \widehat{u} = 0 \quad \text{for} \ \ \widehat{u} \in L^2[-\Lambda,\Lambda] \tag{3.44}$$

holds.

This implication is established in a standard way using uniqueness results for boundary-value problems for the PDE $\Delta^* + \nu^2 - 1/4$ on the manifolds M and $S^2\backslash\{M \cup \ell\}$ and the jump relations for the corresponding layer potentials on ℓ. The uniqueness can be easily established because the contour γ is constructed to avoid the eigenvalues of $-\Delta^* + 1/4$, while the jump relations may be found in [19] or [4] for the case of smooth ℓ, and a standard local analysis at corners will provide the extension of the jump relations to corner domains.

Corollary 3.8. *For $B = D$ or N, $(I+\widehat{\mathcal{L}}_B)^{-1}$ exists and is bounded on $L^2[-\Lambda,\Lambda]$.*

Proof. Using Theorem 3.7, the left-hand equation in (3.28) can be rewritten as

$$(I+(I+\widehat{\mathcal{K}}_B)^{-1}(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B))\widehat{u} = (I+\widehat{\mathcal{K}}_B)^{-1}\widehat{b}_B. \tag{3.45}$$

Since, by Corollary 3.6, $(I+\widehat{\mathcal{K}}_B)^{-1}(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)$ is a compact operator, it follows from the Fredholm alternative and the injectiveness property (3.44) that (3.45) has a unique solution. It also follows that the operator on the left-hand side of (3.45) has a bounded inverse. Therefore,

$$\|\widehat{u}\|_{L^2[-\Lambda,\Lambda]} \le C\|(I+\widehat{\mathcal{K}}_B)^{-1}\widehat{b}\|_{L^2[-\Lambda,\Lambda]} \le C'\|\widehat{b}_B\|_{L^2[-\Lambda,\Lambda]}$$

for some constants C and C', and the result follows. □

Remark 3.9. If the cone Ξ contains more than one lateral edge, then the contour ℓ will contain several corners. All the results of this subsection remain true in this case. In particular the analogue of Corollary 3.8 ensures the well-posedness of (3.28), or equivalently (2.11) in the multiple corner case. The proof is entirely analogous to the proof above, except that a pair of coupled Mellin convolution equations local to each corner has to be considered. Such systems are standard—see, e.g., [14].

Remark 3.10. The operator $\hat{\mathcal{L}}_B$ depends on the parameter ν, and further analysis will be required if one wishes to obtain a "stability bound" (i.e., a bound on $\|(I-\hat{\mathcal{L}}_B)^{-1}\|_{L_2[-\Lambda,\Lambda]}$ as a function of ν). However, we note that for the case $\nu = i\tau$ the corresponding Helmholtz operator on the plane was analyzed in [30], where a stability bound independent of τ was proved. The case $\nu = i\tau$ is particularly important in our computations—see section 5.

4. Numerical method. In this section we shall discuss the piecewise polynomial collocation method for (3.28) and obtain its convergence, using the results of section 3. We also describe briefly its efficient implementation. The performance of this scheme will be illustrated in section 5.

The basic collocation scheme is entirely standard, so we will be brief. First introduce a mesh:

$$-\Lambda = x_0 < x_1 < \cdots < x_m < x_{m+1} < \cdots < x_n = \Lambda\ . \tag{4.1}$$

We assume here that ℓ has a single corner situated at $x_m = 0$ in parameter space and that $n = 2m$. The case of several corners is similar (see Remark 3.9 and the remarks below (4.5)), and that of a smooth boundary is straightforward (see [13]). We define $I_i = [x_{i-1}, x_i]$ and $h_i = x_i - x_{i-1}$ for $i = 1, \dots, n$. We assume that for each integer $r \geq 1$, we have chosen, a priori, r points: $0 < \xi_1^r < \xi_2^r < \cdots < \xi_r^r < 1$. Then we introduce the approximation space

$$S_n^r[-\Lambda,\Lambda] = \{v \in L^\infty[-\Lambda,\Lambda] : v|_{I_i} \in P_r\}\ , \tag{4.2}$$

where P_r denotes the set of polynomials of order $r \geq 1$ (i.e., of degree $r-1$). Also, on each I_i, we define the r collocation points $x_{ij}^r = x_{i-1} + h_i \xi_j^r$, and we define the basis functions of $S_n^r[-\Lambda,\Lambda]$ by

$$\phi_{ij}(x) = \begin{cases} \displaystyle\prod_{\substack{1\le k\le r \\ k\neq j}} \frac{x - x_{ik}^r}{x_{ij}^r - x_{ik}^r}\chi_i(x) & \text{when} \quad r > 1 \\ \chi_i(x) & \text{when} \quad r = 1 \end{cases}$$

for $j = 1, \dots, r$ and $i = 1, \dots, n$, where χ_i is the characteristic function on I_i. Clearly $\phi_{ij}|_{I_i} \in P_r$ and $\phi_{ij}(x_{i'j'}) = \delta_{ii'}\delta_{jj'}$.

In the collocation method for (3.28), we seek an approximate solution

$$\widehat{u}_n(s) := \sum_{i=1}^n \sum_{j=1}^r \mu_{ij}\phi_{ij}(s),$$

where μ_{ij} are chosen so that the residual vanishes at the collocation points:

$$\mu_{i'j'} + \sum_{i=1}^n \sum_{j=1}^r \mu_{ij} \int_{I_i} \widehat{L}_B(x_{i'j'}^r, \sigma)\phi_{ij}(\sigma)d\sigma = \widehat{b}_B(x_{i'j'}^r) \ \text{ for } \ i' = 1, \dots, n\ ,\ j' = 1, \dots, r\ . \tag{4.3}$$

Equivalently,

$$(I + \widehat{\mathcal{P}}_n\widehat{\mathcal{L}}_B)\widehat{u}_n = \widehat{\mathcal{P}}_n\widehat{b}_B\ , \tag{4.4}$$

where $\widehat{\mathcal{P}}_n$ denotes the operator onto $S_n^r[-\Lambda,\Lambda]$ defined by interpolation at the points $\{x_{i,j}\}$. Because the ξ_j^r are chosen interior to $[0,1]$, none of the points x_{ij} are corner points, and so $\widehat{\mathcal{P}}_n\widehat{\mathcal{L}}_B\widehat{u}_n$ and $\widehat{\mathcal{P}}_n\widehat{b}_B$ are well-defined in (4.3).

In the *h version* of the collocation method (with r fixed and $n \to \infty$), we adopt the usual a priori mesh grading:

$$x_{m\pm i} = \pm(i/m)^q \Lambda \qquad \text{for } i = 0, \dots, m, \tag{4.5}$$

where $q \geq 1$ is the grading exponent. Note that the corner point in parameter space ($x_m = 0$) is a mesh point. This is important. If ℓ has several corners, we would simply use meshes like (4.5) local to each corner, joined together with quasi-uniform refinement away from the corners in an obvious way.

To obtain the stability of the collocation scheme, we need the concept of a *modification parameter* $i* \geq 0$ (first introduced in [14]). The *modified collocation scheme* is exactly the same as (4.3) when $i* = 0$. But when $i* \geq 1$, $\widehat{u}_n$ is set to 0 on each of the subintervals $I_i, i = m - i* + 1, \dots, m + i*$, and equations (4.3) are required to hold only for $i' \notin \{m - i* + 1, \dots m + i*\}$. (In other words, the collocation solution is set to 0 on each of the $2i*$ subintervals nearest the corner and (4.3) is not required to hold on those subintervals.) For notational convenience we shall continue to write the collocation equations as (4.4), thus suppressing $i*$ from the notation.

THEOREM 4.1. *Let r and q be fixed and let $B = D$ or N. Then there exists a modification parameter $i* \geq 1$ independent of n, and a constant C which may depend on r, q, and $i*$ but not on n such that $\|(I + \widehat{\mathcal{P}}_n \widehat{\mathcal{L}}_B)^{-1}|_{S_n^r[-\Lambda,\Lambda]}\|_{L^2[-\Lambda,\Lambda]} \leq C$ for all sufficiently large n; i.e., the collocation method* (4.4) *is stable in* $L^2[-\Lambda, \Lambda]$.

Proof. We shall show that, for each $\epsilon > 0$, there exists a modification such that, for n sufficiently large,

$$\|(I - \widehat{\mathcal{P}}_n)\widehat{\mathcal{L}}_B v_n\|_{L^2[-\Lambda,\Lambda]} \leq \epsilon \|v_n\|_{L^2[-\Lambda,\Lambda]} \tag{4.6}$$

for all $v_n \in S_n^r[-\Lambda, \Lambda]$. Then, since

$$I + \widehat{\mathcal{P}}_n \widehat{\mathcal{L}}_B = (I + \widehat{\mathcal{L}}_B) - (I - \widehat{\mathcal{P}}_n)\widehat{\mathcal{L}}_B,$$

existence and stability of $(I + \widehat{\mathcal{P}}_n \widehat{\mathcal{L}}_B)^{-1}$ on $S_n^r[-\Lambda, \Lambda]$ follow from Corollary 3.8.

To obtain (4.6), note that by the triangle inequality,

$$\begin{aligned} \|(I - \widehat{\mathcal{P}}_n)\widehat{\mathcal{L}}_B v_n\|_{L^2[-\Lambda,\Lambda]} \leq{} & \|(I - \widehat{\mathcal{P}}_n)\widehat{\mathcal{K}}_B v_n\|_{L^2[-\Lambda,\Lambda]} \\ & + \|(I - \widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B) v_n\|_{L^2[-\Lambda,\Lambda]}. \end{aligned} \tag{4.7}$$

Now recall that $\widehat{\mathcal{P}}_n$ projects to zero on the $2i*$ intervals nearest 0. Thus

$$\begin{aligned} \|(I - \widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B) v_n\|^2_{L^2[-\Lambda,\Lambda]} \leq{} & \|(\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B) v_n\|^2_{L^2[x_{m-i*}, x_{m+i*}]} \\ & + \|(I - \widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B) v_n\|^2_{L^2([-\Lambda,\Lambda]\setminus[x_{m-i*}, x_{m+i*}])}. \end{aligned} \tag{4.8}$$

By Theorem 3.5, $\widehat{L}_B - \widehat{K}_B$ is a bounded function, and this implies that $(\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B)$ is compact from $L^2[-\Lambda, \Lambda]$ to $L^\infty[-\Lambda, \Lambda]$ (see [26, pp. 534–535]). Thus the first term on the right-hand side of (4.8) may be estimated by

$$\begin{aligned} \|(\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B) v_n\|^2_{L^2[x_{m-i*}, x_{m+i*}]} & \leq 2x_{m+i*} \|(\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B) v_n\|^2_{L^\infty[x_{m-i*}, x_{m+i*}]} \\ & \leq C n^{-q} \|v_n\|^2_{L^2[-\Lambda,\Lambda]}. \end{aligned} \tag{4.9}$$

(Throughout the proof, C denotes a generic constant which is independent of n but may depend on the other parameters.)

We now consider the second term on the right-hand side of (4.8). First we write

$$\begin{aligned}\|(I-\widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|^2_{L^2([-\Lambda,\Lambda]\setminus[x_{m-i*},x_{m+i*}])} &= \sum_{i\leq m-i*}\|(I-\widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|^2_{L^2(I_i)} \\ &\quad + \sum_{i\geq m+i*+1}\|(I-\widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|^2_{L^2(I_i)}.\end{aligned} \tag{4.10}$$

We will estimate the second sum in (4.10). (The first sum can be dealt with in a similar way.) To do this we recall the standard results for piecewise polynomial interpolation and write

$$\begin{aligned}\sum_{i\geq m+i*+1}\|(I-\widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|^2_{L^2(I_i)} &\leq C\sum_{i\geq m+i*+1} h_i^2\|D(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|^2_{L^2(I_i)} \\ &\leq C\sum_{i\geq m+i*+1} h_i^3\|s^{-1}sD(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|^2_{L^\infty(I_i)}.\end{aligned}$$

It can be shown, using the same argument as in the proof of Theorem 3.5, that the operator $sD(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)$ has a bounded kernel. Hence, noting that $h_i\leq Cn^{-1}$, we obtain

$$\begin{aligned}\sum_{i\geq m+i*+1}\|(I-\widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|^2_{L^2(I_i)} &\leq Cn^{-1}\sum_{i\geq m+i*+1}(h_i x_{i-1}^{-1})^2\|v_n\|^2_{L^2[-\Lambda,\Lambda]} \\ &\leq C\max_{i\geq m+i*+1}(h_i x_{i-1}^{-1})^2\|v_n\|^2_{L^2[-\Lambda,\Lambda]}.\end{aligned} \tag{4.11}$$

Now for $i\geq i*+1$, (4.5) implies

$$h_{m+i}=\Big(\frac{i}{m}\Big)^q\Lambda-\Big(\frac{i-1}{m}\Big)^q\Lambda\leq q\Lambda\frac{1}{m}\Big(\frac{i}{m}\Big)^{q-1}.$$

Hence, since $i*$ satisfies $i*\geq 1$,

$$h_{m+i}x_{m+i-1}^{-1}\leq q\frac{1}{m}\Big(\frac{i}{m}\Big)^{q-1}\Big(\frac{m}{i-1}\Big)^q\leq Cq\frac{1}{i-1}\leq Cq\frac{1}{i*}. \tag{4.12}$$

By substituting (4.12) into (4.11) it follows that

$$\sum_{i\geq m+i*+1}\|(I-\widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|^2_{L^2(I_i)}\leq C\Big(\frac{1}{i*}\Big)^2\|v_n\|^2_{L^2[-\Lambda,\Lambda]}.$$

A similar estimate holds for the first sum in (4.10) and so

$$\begin{aligned}\|(I-\widehat{\mathcal{P}}_n)(\widehat{\mathcal{L}}_B-\widehat{\mathcal{K}}_B)v_n\|_{L^2([-\Lambda,\Lambda]\setminus[x_{m-i*},x_{m+i*}])} &\leq C\frac{1}{i*}\|v_n\|_{L^2[-\Lambda,\Lambda]} \\ &\leq \frac{\epsilon}{2}\|v_n\|_{L^2[-\Lambda,\Lambda]}\end{aligned} \tag{4.13}$$

for sufficiently large $i*$.

By (4.7), (4.8), (4.9), and (4.13), we see that to prove (4.6) it is sufficient to prove it with $\widehat{\mathcal{L}}_B$ replaced by $\widehat{\mathcal{K}}_B$. However, this follows from now-classical results about numerical methods for Mellin convolution equations. To explain briefly, we first employ the operators Π and $\tilde{\mathbb{K}}_B$ defined in the proof of Theorem 3.7, as well as the fact that the mesh (4.1) is symmetric about 0, to obtain $\Pi\widehat{\mathcal{P}}_n\widehat{\mathcal{K}}_B = \tilde{\mathbb{P}}_n\tilde{\mathbb{K}}_B\Pi$, where

$$\tilde{\mathbb{P}}_n = \begin{pmatrix} \tilde{\mathcal{P}}_n & 0 \\ 0 & \tilde{\mathcal{P}}_n \end{pmatrix},$$

with $\tilde{\mathcal{P}}_n$ defined as the restriction of $\widehat{\mathcal{P}}_n$ to functions on $[0,\Lambda]$. Since $(I - \widehat{\mathcal{P}}_n)\widehat{\mathcal{K}}_B = \Pi^{-1}(I - \widetilde{\mathbb{P}}_n)\widetilde{\mathbb{K}}_B\Pi$, the result follows if, for all $\epsilon > 0$, there exists a modification $i*$ such that

$$\|(I - \tilde{\mathcal{P}}_n)\tilde{\mathcal{K}}_B v_n\|_{L^2[0,\Lambda]} \leq \epsilon\|v_n\|_{L^2[0,\Lambda]} \tag{4.14}$$

for all $v_n \in S_n^r[0,\Lambda]$ and for sufficiently large n. However, result (4.14) follows (even for all n) from the general results in the survey [22]. (See Theorem 3.1 there, and the remarks following it. Note that $\tilde{\kappa}_B$ and $\tilde{\kappa}_N$ both satisfy conditions (A1) and (A2) of [22], with $p = 2$.) See [23, 14, 20] and also [13] for more details. □

Remark 4.2. The introduction of the parameter $i*$ is solely a device to prove stability of the collocation method for (2.11) when ℓ contains a corner. No unmodified practical collocation method has ever been observed to be unstable. However, the proof that these methods are stable without modification has eluded researchers for 15 years. For this reason, and to simplify the presentation, we assume that Theorem 4.1 holds for $i* = 0$ (i.e., no modification) for the remainder of this section. All the following results also hold for $i* \geq 1$, but the proofs require slightly different technicalities.

Theorem 4.1 implies that the collocation equation (4.4) is uniquely solvable for all n sufficiently large. An easy manipulation using (3.28) and (4.4) shows that $(I + \widehat{\mathcal{P}}_n\widehat{\mathcal{L}}_B)(\widehat{\mathcal{P}}_n\widehat{u} - \widehat{u}_n) = -\widehat{\mathcal{P}}_n\widehat{\mathcal{L}}_B(I - \widehat{\mathcal{P}}_n)\widehat{u}$. Theorem 4.1 then implies

$$\|\widehat{\mathcal{P}}_n\widehat{u} - \widehat{u}_n\|_{L^2[-\Lambda,\Lambda]} \leq C\|\widehat{\mathcal{P}}_n\widehat{\mathcal{L}}_B(I - \widehat{\mathcal{P}}_n)\widehat{u}\|_{L^2[-\Lambda,\Lambda]}. \tag{4.15}$$

After some technical manipulations using properties of $\widehat{\mathcal{L}}_B = \widehat{\mathcal{K}}_B + (\widehat{\mathcal{L}}_B - \widehat{\mathcal{K}}_B)$ it can be shown that the right-hand side of (4.15) can be bounded by a constant multiple of $\|(I - \widehat{\mathcal{P}}_n)\widehat{u}\|_{L^2[-\Lambda,\Lambda]}$ (see [13]). Then the triangle inequality implies

$$\|\widehat{u} - \widehat{u}_n\|_{L^2[-\Lambda,\Lambda]} \leq \|\widehat{u} - \widehat{\mathcal{P}}_n\widehat{u}\|_{L^2[-\Lambda,\Lambda]} + \|\widehat{\mathcal{P}}_n\widehat{u} - \widehat{u}_n\|_{L^2[-\Lambda,\Lambda]} \leq C\|(I - \widehat{\mathcal{P}}_n)\widehat{u}\|_{L^2[-\Lambda,\Lambda]}. \tag{4.16}$$

Therefore to obtain convergence rates we need estimates for $\|(I - \widehat{\mathcal{P}}_n)\widehat{u}\|_{L^2[-\Lambda,\Lambda]}$. These of course depend on the regularity of the solution. To describe this regularity we introduce the weighted Sobolev space for an interval $J \subset \mathbb{R}$ and for $k \in \mathbb{N}$ and $\alpha \in \mathbb{R}$,

$$L_\alpha^{2,k}(J) = \{v : |x|^{j-\alpha}D^j v \in L^2(J),\ j = 0, 1, \dots, k\},$$

equipped with the norm $\|v\|_{L_\alpha^{2,k}(J)} = \sum_{j=0}^k \|x^{j-\alpha}D^j v\|_{L^2(J)}$ (see [20]).

Examples 4.3.

(i) The function

$$\widehat{u}(x) = C' + C''|x|^\theta, \quad \text{where} \quad 1/2 < \theta < 1, \tag{4.17}$$

satisfies $\widehat{u}(x) - C' \in L_\alpha^{2,k}[-\Lambda,\Lambda]$ for all $k \geq 0$ and $\alpha < \theta + 1/2$.

(ii) The function

$$\widehat{u}(x) = C|x|^{\theta-1}, \quad \text{where} \quad 1/2 < \theta < 1, \tag{4.18}$$

satisfies $\widehat{u}(x) \in L^{2,k}_{\alpha}[-\Lambda, \Lambda]$ for all $k \geq 0$ and $\alpha < \theta - 1/2$.

Remark 4.4. When we solve the Dirichlet problem for the Laplace equation in the region interior to a planar polygon using the indirect boundary integral method, the solution of the resulting integral equation has its principal singularity in the form (4.17), where the corner is at $x = 0$ and $\theta = 1/(1 + |\chi|)$, where$(1 - \chi)\pi$ is the angle between the tangents at the corner ($\chi \in (-1, 1)\backslash\{0\}$). When we solve the Neumann problem with the same geometry again using the indirect boundary integral method, the density has its principal singularity in the form (4.18), again with $\theta = 1/(1 + |\chi|)$ (see, e.g, [17, 23, 20]). It can be shown by standard local analysis (see, e.g., [32]) that the solutions of our integral equations have the same principal singularity as identified in Examples 4.3.

Estimates for $\|(I - \widehat{\mathcal{P}}_n)\widehat{u}\|_{L^2[-\Lambda,\Lambda]}$ under assumptions which encapsulate Examples 4.3(i) and (ii) are well known (see, e.g., [22]). Combining these with (4.16), we obtain the final result given below (see also [13] for more details).

Theorem 4.5. *Consider the collocation method* (4.4) *and assume that stability holds in the sense of Theorem* 4.1.

(i) *Suppose that $B = D$ and that the exact solution to* (3.28) *satisfies $\widehat{u} - C' \in L^{2,r}_{\alpha}[-\Lambda, \Lambda]$ with $1 < \alpha < 3/2$. Then for sufficiently large n the collocation method described by* (4.4) *converges with error*

$$\|\widehat{u} - \widehat{u}_n\|_{L^2[-\Lambda,\Lambda]} \leq Cn^{-r}\|\widehat{u} - C'\|_{L^{2,r}_{\alpha}[-\Lambda,\Lambda]} \quad \textit{as} \quad n \to \infty, \tag{4.19}$$

provided the grading parameter $q \geq \max\{r/\alpha, 1\}$.

(ii) *Suppose that $B = N$ and that the exact solution to* (3.28) *satisfies $\widehat{u} \in L^{2,r}_{\alpha}[-\Lambda, \Lambda]$ for some $0 < \alpha < 1/2$. Then for sufficiently large n the collocation method described by* (4.4) *converges with error*

$$\|\widehat{u} - \widehat{u}_n\|_{L^2[-\Lambda,\Lambda]} \leq Cn^{-r}\|\widehat{u}\|_{L^{2,r}_{\alpha}[-\Lambda,\Lambda]} \quad \textit{as} \quad n \to \infty, \tag{4.20}$$

provided the grading parameter $q \geq r/\alpha$.

The implementation of the collocation method (4.3) requires the efficient calculation of the stiffness matrix entries

$$\widehat{\mathbb{L}}_{i'j',ij} := \int_{I_i} \widehat{L}_B(x^r_{i'j'}, \sigma)\phi_{ij}(\sigma)d\sigma. \tag{4.21}$$

Each evaluation of the kernel $\widehat{L}_B$ in (4.21) requires an evaluation of (the derivative) of the Legendre function with complex index (see (3.29), (3.30)). We do this by integrating Legendre's differential equation using a Runge–Kutta method (cf. [4, 5, 6, 18]—details are in [13]). Thus efficient quadrature methods for (4.21) are of the utmost importance. This is especially true when we remember that (2.11) needs to be solved many times over (for different values of ν on the imaginary axis) in order to allow the approximate integration of (1.4). The main difficulty in evaluating (4.21) is the singularity which arises when $i' = i$. (This is strongest when I_i contains the origin in parameter space, corresponding to the corner on ℓ.) In [13] a detailed study of quadrature for (4.21) is carried out. Here we have room to mention only the most useful result from [13], as follows.

Theorem 4.6. *Suppose the collocation points x^r_{ij}, $j = 1,\ldots,r$, are chosen to be the r Gauss–Legendre points on* $[0,1]$*, shifted to I_i. Suppose that* (4.21) *is approximated by the Gauss–Legendre rule based at these points for all i, i' satisfying*

$$\mathrm{dist}(I'_i, I_i) \geq h_i^{1/(r+2)}, \tag{4.22}$$

and the remaining entries of (4.21) *are computed exactly. Then the $O(n^{-r})$ convergence rate reported in Theorem* 4.5 *continues to hold.*

Since ϕ_{ij} vanishes at all the points x^r_{ik}, except $k = j$, the implementation of the rule in Theorem 4.6 requires only one kernel evaluation, and (4.22) shows that this can be done for most of the matrix as the mesh is refined. It also turns out that even when (4.22) is not satisfied, rules with $O(\log(n))$ kernel evaluations can be employed and the $O(n^{-r})$ rate in Theorem 4.5 remains unperturbed—for more details see section 5 and also [13].

5. Numerical results. We shall illustrate the performance of the numerical method described above in the case of the diffraction of acoustic waves by a *trihedral cone*. In the diffraction literature this is an unsolved *canonical problem*; i.e., it is a relatively simple geometry which often occurs in applications, but there is no known closed form expression for the diffraction coefficients.

Our trihedral cone is determined by three edges which emanate from the origin and pass through the points $\boldsymbol{\omega}_{c_i} \in S^2$, $i = 1, 2, 3$, which are specified by spherical polar coordinates $(\theta^*, 0), (\theta^*, 2\pi/3)$, and $(\theta^*, 4\pi/3)$, respectively, where $\cos\theta^* = 1/\sqrt{3}$. Hence the edges are mutually perpendicular. The conical scatterer Ξ therefore has its surface composed of three mutually perpendicular planar segments determined by each pair of edges, and the contour ℓ is made up of three smooth geodesic curves in S^2, with each pair of smooth curves meeting at an angle of $\pi/2$ at one of the points $\boldsymbol{\omega}_{c_i}$. The geometry is depicted in Figure 4. The contour ℓ is drawn in bold. (This corresponds to the practically important case of the corner of a rectangular building.)

Throughout the computations we used collocation at the Gauss points of subintervals. For the evaluation of the boundary integrals (4.21), we used Gauss quadrature at the collocation points in the "far field," i.e., when i, i' satisfy (4.22). When (4.22) does not hold we increase the number of quadrature points, d, logarithmically. More precisely, we choose d to be the smallest integer satisfying

$$d \geq \frac{(r+1)\log(n)}{2\log(2)}.$$

This heuristic is motivated by an analysis in [13]. Note that for this geometry, when $\boldsymbol{\omega}, \boldsymbol{\omega}'$ lie on the same edge of the geodesic triangle ℓ, then $L_B(\boldsymbol{\omega}, \boldsymbol{\omega}') = 0$. Hence one-third of the matrix entries are zero. Included in these zero entries are the integrals that occur when the collocation point lies in the interval of integration. Note that our procedure uses only one kernel evaluation for most matrix entries, as mentioned in section 4. We shall see that our numerical results coincide with the theoretical predictions of Theorem 4.5.

Our first set of results illustrate the accuracy of methods for solving the integral equation (2.11) (equivalently (3.28)) arising from the boundary value problem (2.5), (2.6). For these tests we set $\boldsymbol{\omega}_0 = -\boldsymbol{\omega}_{c_1}$ and set the parameter $\nu = i$.

The density $\widehat{u}$ in (3.28) is not smooth near the corner. In fact, in the case of the Dirichlet problem, we expect from Remark 4.4 that there exists a constant C' such that $\widehat{u} - C' \in L^{2,r}_{\alpha}$, with $\alpha < 7/6$. (This is because for the corners in this example

Table 1

Estimated errors for densities $\hat{u}$ using the piecewise constant collocation method for (3.28) *on a uniform mesh, $q = 1$.*

	Dirichlet problem		Neumann problem	
n	err_n^1	Ratio	err_n^1	Ratio
24	9.957E-2		1.609E-3	
48	5.285E-2	1.88	1.530E-3	1.05
96	2.472E-2	2.14	1.229E-3	1.24
192	1.074E-2	2.30	1.077E-3	1.14
384	4.992E-3	2.15	9.589E-4	1.12

$\chi = 1/2$, so $\theta = 2/3$ and hence $\theta + 1/2 = 7/6$.) When Neumann boundary conditions are prescribed, we expect $\widehat{u} \in L^{2,r}_{\alpha}$, $\alpha < 1/6$. So, for the Dirichlet problem, piecewise constant approximation ($r = 1$) should (by Theorem 4.5) yield optimal convergence (i.e., $O(n^{-1})$ in the L^2 norm) on a uniform mesh ($q = 1$ in (4.5)). On the other hand for the Neumann problem we expect (by a generalization of Theorem 4.5) a rate of convergence close to $O(n^{-1/6})$ on a uniform mesh.

To illustrate convergence, for each case we have computed an "exact" solution $\widehat{u}^*$ by using piecewise linear collocation on a mesh with 498 nodes. (To obtain the "exact" Dirichlet solution we grade the mesh towards the corners with $q = 2$, and for the "exact" Neumann solution, since the grading required to obtain optimal convergence is rather severe, we use here a grading exponent $q = 3$.) We computed the approximate L^2 error $\mathrm{err}_n^1 := \|\widehat{u}^* - \widehat{u}_n\|_2$ using midpoint quadrature with respect to the mesh with n subintervals. The results are given in Table 1. As expected, a convergence rate of close

Table 2
Estimated errors for densities $\hat{u}$*, using the piecewise constant collocation method for* (3.28) *on a graded mesh,* $q = 3$*.*

	Dirichlet problem		Neumann problem	
n	err_n^1	Ratio	err_n^1	Ratio
24	1.257E-2		6.307E-3	
48	4.948E-3	2.54	6.106E-3	1.03
96	2.147E-3	2.30	4.744E-3	1.29

to $O(n^{-1})$ is observed for the Dirichlet problem and close to $O(n^{-1/6})$ for the Neumann problem. (In Tables 1–4, “ratio” is defined to be $\mathrm{err}_n^i/\mathrm{err}_{n-1}^i$ for $i = 1$ or 2.) As we have shown, mesh grading will improve suboptimal rates of convergence. Consider the integral equation arising from the Neumann problem. Because its solution satisfies $\widehat{u} \in L_\alpha^{2,r}$, with $\alpha < 1/6$, it can be shown (by the methods of Theorem 4.5) that with $q' \leq 6r$ a rate of convergence of $O(n^{-q'/6})$ in the L^2 norm can be attained when a graded mesh is used with grading exponent $q > q'$ for collocation onto piecewise polynomials of order r. We illustrate the correctness of this result with $q = 3$. The results are in Table 2. Here we find that the Neumann problem now converges with rate close to $O(n^{-1/2})$, as expected. The Dirichlet problem now appears to converge with a superoptimal rate, but this could be expected to subside back to $O(n^{-1})$ asymptotically. These results indicate that our integral equation solver is working as predicted by the theory.

Our next set of results illustrates the convergence of the approximate solutions to the spherical boundary-value problem (2.5), (2.6). We consider the same problem as above with $\boldsymbol{\omega}_0 = -\boldsymbol{\omega}_{c_1}$ and $\nu = i$. In Tables 3 and 4, we tabulate the errors in approximate solutions to (2.5), (2.6) obtained by substituting $u_n(\boldsymbol{\rho}(s), \nu) = \widehat{u}_n(s)$ into (2.7) (in the Dirichlet case) and (2.9) (in the Neumann case) and computing the resulting integrals by the Gauss quadrature rule based at the points used in the computation of $\widehat{u}_n$. For illustration we have chosen to observe the solution at the particular observation direction $\boldsymbol{\omega} = (0, 0, -1)$. The error err_n^2 is computed by $|g_n^r(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu) - \widetilde{g}^r(\boldsymbol{\omega}, \boldsymbol{\omega}_0, \nu)|$, where $\widetilde{g}^r$ is computed with a large n $(= 330)$ and $q = 3$.

The results illustrate the superconvergence of the method (well documented in the case of planar problems; see, e.g., [14, 3, 22]), with close to $O(n^{-2})$ convergence attained for $q = 3$. The extreme gradings needed for optimal convergence of the density may not be needed for the potential, and in fact better than optimal convergence may be obtained because of the smoothness of the fundamental solution away from the boundary ℓ.

We emphasize that the results in Tables 1–4 illustrate not only the convergence theory in section 4, but also show that the algorithm used to compute the Legendre functions with complex index (by applying a Runge–Kutta method to Legendre’s differential equation), which is described in detail in [13], is working in a stable manner.

The results given here involve approximation with piecewise constant basis functions. Results for piecewise linears are given in [13]. An important point is that, since only one kernel evaluation is needed for most matrix entries *independent* of the order of the basis functions, the cost of implementation does not increase much as the order of the basis functions is increased. This suggests that the h-p version of the boundary element method should be very competitive for this application, and our next set of

results concern this method.

For fixed $\sigma \in (0,1)$ we define a geometrically graded mesh on $[-\Lambda, \Lambda]$ by

$$(5.1) \qquad x_{m+i} = \sigma^{m-i}\Lambda, \qquad -x_{m-i} = \sigma^{m-i}\Lambda, \qquad i = 1, \dots, m, \qquad x_m = 0.$$

Instead of seeking an approximate solution in the space S_n^r of piecewise polynomials of fixed order r on each subinterval, we allow a variable order r_i on each subinterval I_i (see (4.1) and the remarks following). A typical distribution of orders would be

$$r = \lceil (m+1-i)\beta \rceil \quad \text{for } i < m, \qquad r = \lceil (i-m)\beta \rceil \quad \text{for } i > m+1$$

for some fixed parameter $\beta > 0$, where, for $x \in \mathbb{R}$, $\lceil x \rceil$ denotes the smallest integer which is strictly greater that x. On the intervals I_i, $i = m, m+1$, the approximate solution is set to zero. Thus, on intervals close to the corner we approximate the solution on small subintervals, using low order methods, while further away we use higher orders on larger subintervals. The maximum order increases linearly with m and hence also with n. This is a standard prescription (e.g., [21]).

By making use of the fundamental results of Elschner [21] for the Laplace case, and combining these with our results in section 3, it can be shown [13] that the h-p method is stable. By making further assumptions about the regularity of the solution to (3.28), it can be shown that the h-p method converges exponentially. In Figure 5 we illustrate the convergence of the h-p method, compared with the piecewise constant and piecewise linear cases for the potentials (2.7) arising from the Dirichlet problem with $\boldsymbol{\omega}_0 = -\boldsymbol{\omega}_{c_1}$, $\boldsymbol{\omega} = (0, 0, -1)$, and $\nu = i$.

In these computations, the parameter values $\sigma = 0.25$ and $\beta = 0.5$ were employed in the h-p method. For these results we naively used the r-point Gauss–Legendre rule to calculate the matrix entries $\widehat{\mathbb{L}}_{i'j',ij}$; i.e., in this case *all* of the matrix entries were computed using one kernel evaluation. Observe the exponential convergence of the h-p method in Figure 5. (For another way to obtain exponential convergence for this type of integral equation, see [29].)

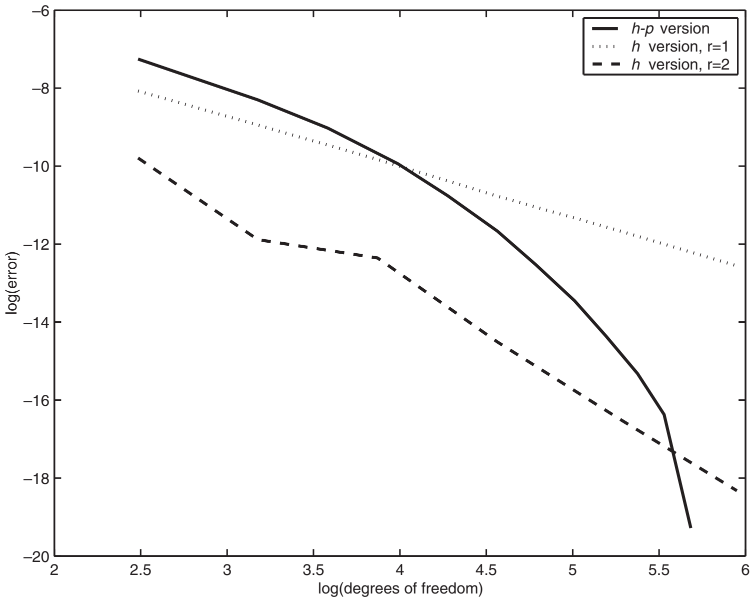

FIG. 5. *Errors for the potential* (2.7) *for the h version and h-p version of collocation.*

Finally, in order to illustrate the computations of the diffraction coefficients for this geometry, we shall show graphically how the computed $f(\boldsymbol{\omega}, \boldsymbol{\omega}_0)$ in (1.4) varies for three different incidence directions $\boldsymbol{\omega}_0$, and many observation directions $\boldsymbol{\omega}$ ranging over a subdomain of M. In this illustration we restrict ourselves to the Dirichlet problem, and we consider the incident directions given in spherical polar coordinates (θ, ϕ) by

$$\boldsymbol{\omega}_0 = (\pi, 0),\ (11\pi/12, 0),\ \text{and}\ (5\pi/6, 0), \tag{5.2}$$

and a range of observation directions

$$\boldsymbol{\omega} = ((\pi - \theta), \phi), \quad \text{with} \quad 0 \le \theta \le \pi/3,\ \ 0 \le \phi \le 2\pi. \tag{5.3}$$

In Figure 6 we illustrate how $|f(\boldsymbol{\omega}, \boldsymbol{\omega}_0)|$ varies as a function of θ and ϕ for each of the three different incident angles. The quantity $|f(\boldsymbol{\omega}, \boldsymbol{\omega}_0)|$ is plotted on the x_3 axis against the projection of $\boldsymbol{\omega}$ onto the x_1x_2-plane given by $\boldsymbol{\omega} = (\pi - \theta, \phi) \mapsto (\theta \cos\phi, \theta \sin\phi)$.

Observe in the first row of Figure 6 that when $\boldsymbol{\omega}_0 = (\pi, 0)$, i.e., the incident wave propagates in an "axial" direction, then the magnitude of the diffraction coefficients is smallest in the backscattering direction. This is in qualitative agreement with results for the circular cone [4]. Also note when $\boldsymbol{\omega}_0 = (\pi, 0)$ that if we fix $\theta > 0$, then the distance between $\boldsymbol{\omega} = (\pi - \theta, \phi)$ and the boundary of the nonsingular region, given by $\theta_1(\boldsymbol{\omega}, \boldsymbol{\omega}_0) = \pi$—see (2.1)—is smallest when $\phi = 0, 2\pi/3, 4\pi/3$. At the singular directions f is infinitely large; hence the three peaks appear in the first row of Figure 6.

As expected, the results are symmetric with respect to rotations by $\pm 2\pi/3$ about the axis. As we vary the angle of incidence, the symmetry breaks and the position of the singular directions will vary. In particular it can be shown from (2.1) that for $\boldsymbol{\omega}_0 = (11\pi/12, 0)$ and $(5\pi/6, 0)$ and fixed $\theta > 0$, the distance between $\boldsymbol{\omega}$ and the

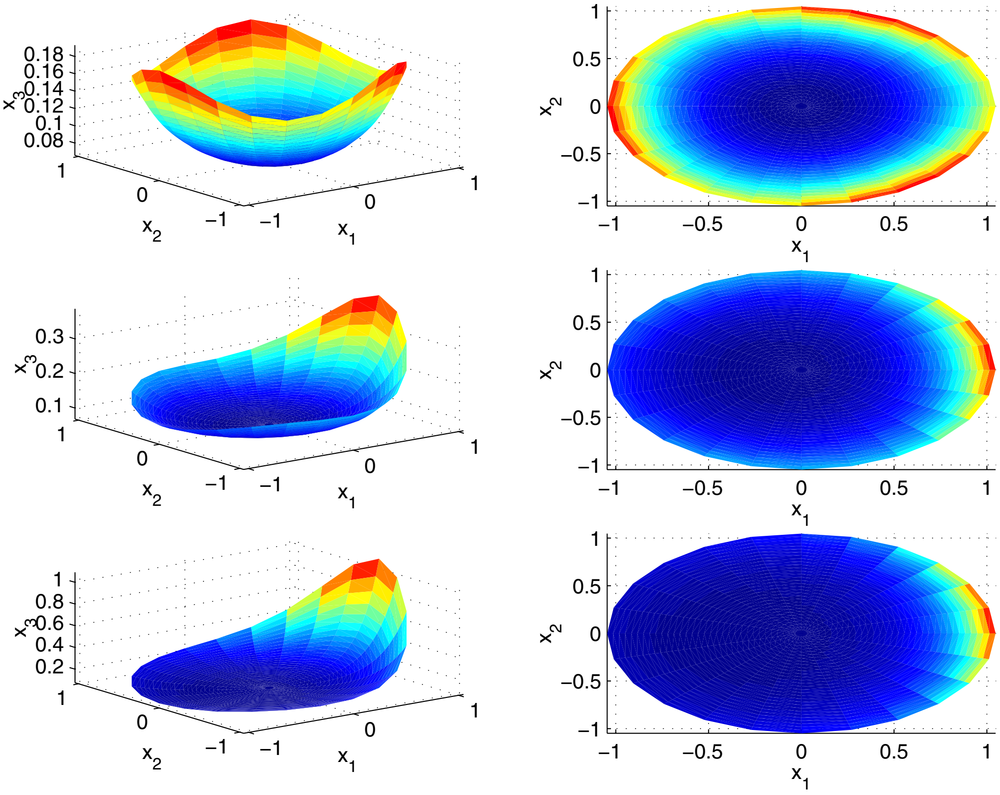

FIG. 6. *Diffraction coefficients for a trihedral cone.*

singular directions is smallest when $\phi = 0$. This explains the faster growth, as θ increases, of $|f(\boldsymbol{\omega}, \boldsymbol{\omega}_0)|$ along $\phi = 0$ (i.e., along the line $x_2 = 0$)—see the second and third rows of Figure 6.

The numerical method used for these computations was the piecewise constant collocation method with $n = 48$ subintervals on a uniform mesh (cf. Theorem 4.5). To produce each picture in Figure 6 the density in the integral equation (3.28) was approximated for 80 values of ν. Then using these densities we computed the solution to the boundary-value problem (2.5), (2.6) for the same 80 values of ν at ~ 800 observation points $\boldsymbol{\omega}$. Therefore $\sim$64,000 evaluations of the double layer potential were required. The diffraction coefficient f was computed from formula (1.4) by truncation to a finite domain of integration with respect to $\nu = i\tau$ and then applying the trapezoidal rule. The truncation points are chosen according to an analysis of the asymptotics of the integrand in (1.4) for large $|\tau|$ and are designed to yield an overall method which converges at the same rate as the method for computing g^r (see [13]). Clearly this is a very computationally intensive problem and the efficiency of our algorithm is of prime importance.

WELL-POSED BOUNDARY CONDITIONS FOR THE NAVIER–STOKES EQUATIONS*

JAN NORDSTRÖM[†] AND MAGNUS SVÄRD[‡]

Abstract. In this article we propose a general procedure that allows us to determine both the number and type of boundary conditions for time dependent partial differential equations. With those, well-posedness can be proven for a general initial-boundary value problem. The procedure is exemplified on the linearized Navier–Stokes equations in two and three space dimensions on a general domain.

Key words. well-posed problems, boundary conditions, Navier–Stokes equations, energy estimates, initial boundary value problems, stability

AMS subject classifications. 35M10, 65M99, 76N99

DOI. 10.1137/040604972

1. Introduction.

The problem of well-posed boundary conditions is an essential question in many areas of physics. In fluid dynamics, characteristic boundary conditions for the Euler equations have long been accepted as one way to impose boundary conditions since the specification of the ingoing variable at a boundary implies well-posedness. Often the Euler boundary conditions are used as a guidance when boundary conditions are chosen for the Navier–Stokes equations as well (see [1, 2, 3, 4, 5]). In [6] characteristic boundary conditions for the one-dimensional linearized Navier–Stokes equations were derived.

For the two- and three-dimensional Navier–Stokes equations, the number of boundary conditions implying well-posedness can be obtained using the Laplace transform technique. (See [7] for an introduction of the Laplace transform technique.) Although possible to use, the Laplace transform technique is usually a very complicated procedure for systems of partial differential equations such as the Navier–Stokes equations. However, the exact form of the boundary conditions that lead to a well-posed problem is still an open question and will be the issue addressed in this article.

In this paper we assume that we have unlimited access to accurate boundary data. We do not engage in the elaborate, difficult, and stimulating procedure of deriving artificial (or radiation or absorbing) boundary conditions. Examples of extensive research on these matters are given in [8, 9].

We propose a self-contained procedure to obtain both the number and type of boundary conditions for a general time dependent partial differential equation. The procedure is based on the energy method and has substantial similarities to the derivation of characteristic boundary conditions, since it involves a splitting of the boundary terms into ingoing and outgoing parts by a diagonalization. Compared to the Laplace transform technique, our procedure yields a much simpler analysis.

[‡]Department of Information Technology, Uppsala University, SE-751 05 Uppsala, Sweden (Magnus.Svard@it.uu.se).

As was already mentioned, boundary conditions for the Navier–Stokes equations have been the subject of many investigations, and still there is no theory for the general case. Hence, the linearized and symmetrized Navier–Stokes equations derived in [10] will serve as an example to which our proposed procedure is applied. Since the procedure involves a significant amount of work, we will not treat other equations in this article.

Well-posedness of the continuous problem is a necessary requirement for all numerical methods. Even for well-posed boundary conditions, numerous difficulties arise, and virtually all numerical schemes have their own way of handling boundary conditions. Hence, we will refrain from numerical calculations for a particular discretization technique and focus on the mathematical groundwork.

The contents of this article are divided as follows. In section 2 a general procedure for determining well-posed boundary conditions is presented. Section 3 applies the procedure to the three-dimensional Navier–Stokes equations on a general domain. In section 4 conclusions are drawn.

2. Well-posed boundary conditions.

Throughout this paper, the analysis will deal with linear constant coefficient equations. Frequently, the equations of interest are not linear constant coefficient equations but rather variable coefficient or even nonlinear equations (such as the Navier–Stokes equations). We will start with a brief discussion on the relevance of analyzing the constant coefficient case.

Consider a nonlinear initial-boundary value problem on a domain D with boundary ∂D. By linearizing around a solution u and freezing the coefficients, we obtain

$$\begin{aligned} \tilde{w}_t &= P(u)\tilde{w} + \delta F(x,t), \quad x \in D,\, t \geq 0, \\ \tilde{w} &= \delta f(x), \quad x \in D,\, t = 0, \\ L\tilde{w} &= \delta g(t), \quad x \in \partial D, t \geq 0, \end{aligned} \tag{1}$$

where P is the (nonlinear) differential operator and L a boundary operator. Here $\delta F, \delta f$, and δg are perturbations of the forcing, initial, and boundary functions. $\tilde{w}$ is the perturbation from the exact solution.

DEFINITION 2.1. *The linear problem* (1) *is well posed if there exists a unique solution bounded by the data $\delta F, \delta f$, and δg.*

Remark 1. There are many definitions of well-posedness. Our choice is sometimes referred to as strongly well-posed since it involves all types of data (see, for example, [7]).

Both existence and uniqueness are strongly coupled to the boundedness of the solution. In fact, it suffices to prove that a solution is bounded using a minimal number of boundary conditions; then both existence and uniqueness follow. (See, for example, [11].)

In short, the following principle holds: If (1) is well posed for all values of u, then the original nonlinear problem is well posed (see [12] for more details).

Before considering well-posedness of a problem of the type (1), we will briefly state some additional mathematical theory that is the basis of the forthcoming analysis. First we give a definition from [13].

DEFINITION 2.2. *Let A be a Hermitian matrix. The* inertia *of A is the ordered triple*

$$i(A) = (i_+(A), i_-(A), i_0(A)), \tag{2}$$

where $i_+(A)$ is the number of positive eigenvalues of A, $i_-(A)$ is the number of negative eigenvalues of A, and $i_0(A)$ is the number of zero eigenvalues of A, counting multiplicities.

We will also need the following theorem from [13], and we refer to that textbook for the proof. The theorem is also known as *Sylvester's law of inertia*.

THEOREM 2.3. *Let A, B be Hermitian matrices. There is a nonsingular matrix S such that $A = SBS^*$ if and only if A and B have the same inertia.*

S^* denotes the Hermitian adjoint of S. The following corollary is merely a rephrasing of Theorem 2.3.

COROLLARY 2.4. *Suppose that R is a nonsingular matrix and that A is a real symmetric matrix. Then the number of positive/negative eigenvalues of R^TAR is the same as the number of positive/negative eigenvalues of A.*

Proof. The claim follows immediately from Theorem 2.3 with $B = R^TAR$. □

Finally, we state another definition from [13].

DEFINITION 2.5. *If A is a real m-by-n matrix, we set $I(A) = [\mu_{ij}]$, where $\mu_{ij} = 1$ if $a_{ij} \neq 0$ and $\mu_{ij} = 0$ if $a_{ij} = 0$. The matrix $I(A)$ is called the* indicator matrix *of A.*

Now we turn to the main theory of this article. We will give general principles of how to determine boundary conditions such that the constant coefficient problem is well posed. Thus, assuming that linearization and freezing of coefficients have already been carried out, we consider a linear constant coefficient problem with n space dimensions and $\bar{x} = (x_1, \ldots, x_n)$,

$$\begin{aligned} \tilde{u}_t + \sum_{i=1}^{n} A_i \tilde{u}_{x_i} &= \sum_{i=1}^{n}\sum_{j=1}^{n} B_{ij}\tilde{u}_{x_i x_j} + F(\bar{x}, t), \quad \bar{x} \in D,\, t \geq 0, \\ \tilde{u}(\bar{x}, 0) &= f(\bar{x}), \quad \bar{x} \in D, \\ L\tilde{u}(\bar{x}, t) &= g(t), \quad \bar{x} \in \partial D,\, t \geq 0. \end{aligned} \tag{3}$$

The definition (3) of an initial-boundary value problem covers hyperbolic, parabolic, and incompletely parabolic partial differential equations depending on the rank of the matrices. Let $\|\cdot\|$ denote some norm for functions on D. Our approach of analyzing the well-posedness of (3) comprises the following steps.

(i) Symmetrize (3).

(ii) Apply the energy method. The energy estimate will have the structure

$$\|\tilde{u}\|_t^2 + c_i \sum_{i=1}^{n} \|\tilde{u}_{x_i}\|^2 + \oint_{\partial D} \tilde{v}^T \mathbf{A} \tilde{v} ds \leq 0, \tag{4}$$

where $c_i \geq 0$, $i = 1, \ldots, n$, are constants and $\tilde{v}$ a vector formed by combinations of $\tilde{u}$ and $\tilde{u}_{x_i}$. Further, $\mathbf{A}$ is reduced to a full rank matrix. The boundedness of $\tilde{u}$ now depends on the boundedness of $\tilde{v}^T \mathbf{A} \tilde{v}$ in boundary data.

(iii) Find a diagonalizing matrix, M, such that $M^T \mathbf{A} M = \Lambda$ is diagonal. ($\mathbf{A}$ is symmetric due to step (i) above.) Then we also have the variable transformation $M^{-1}\tilde{v} = \tilde{w}$.

(iv) Split $\Lambda = \Lambda^+ + \Lambda^-$ such that Λ^+ is positive semidefinite and Λ^- is negative semidefinite. Also, split $\tilde{w}$ into $\tilde{w} = \tilde{w}^+ + \tilde{w}^-$ corresponding to the nonzero entries of $\Lambda^{+,-}$. More precisely, let $\tilde{w}^- = I(\Lambda^-)\tilde{w}$ and $\tilde{w}^+ = \tilde{w} - \tilde{w}^-$.

(v) Supply boundary data to the negative part. That is, specify $\tilde{w}^-$ by g.

Remark 2. In step (iv) the number of boundary conditions is given as the number of negative eigenvalues of $\mathbf{A}$ or Λ. Further, the type of boundary conditions is given by the matrix M, derived in step (iii).

This implies boundedness of $\|\tilde{u}\|_t$ and hence of $\|\tilde{u}\|$. The difficult part of this scheme is step (iii). However, we know that $\mathbf{A}$ is symmetric, and we can prove the following proposition regarding steps (iii)–(v).

Proposition 2.6. *Assume that steps* (i) *and* (ii) *are fulfilled; then the matrix* $\mathbf{A}$ *and the vector* $\tilde{v}$ *can be split such that* $\tilde{v}^T\mathbf{A}\tilde{v} = \tilde{w}^{+T}\Lambda^+\tilde{w}^+ + \tilde{w}^{-T}\Lambda^-\tilde{w}^-$, *where* Λ^+ *is positive semidefinite,* Λ^- *is negative semidefinite, and* $M^{-1}\tilde{v} = \tilde{w} = \tilde{w}^+ + \tilde{w}^-$ *for some matrix* M^{-1}. *Further, by specifying* $\tilde{w}^- = I(\Lambda^-)w$ *at the boundary, we find that* (3) *is well posed.*

Proof. Since $\mathbf{A}$ is symmetric, the eigenvalues are real and there exists a full set of eigenvectors. If Z contains the eigenvectors, we have

$$\tilde{v}^T\mathbf{A}\tilde{v} = \tilde{v}^T ZZ^T\mathbf{A}ZZ^T\tilde{v} = \tilde{w}^T\Lambda_{\mathbf{Z}}\tilde{w} = \tilde{w}^{+T}\Lambda^+_{\mathbf{Z}}\tilde{w}^+ + \tilde{w}^{-T}\Lambda^-_{\mathbf{Z}}\tilde{w}^-, \tag{5}$$

where $\Lambda_{\mathbf{Z}}^{-/+}$ are diagonal negative/positive semidefinite. We define $\tilde{w}^- = I(\Lambda^-)\tilde{w}$ and $\tilde{w}^+ = \tilde{w} - \tilde{w}^-$. This proves the first part of Proposition 2.6.

Another way to prove the first part of Proposition 2.6 is to apply Corollary 2.4, to conclude that any nonsingular matrix R can be used as a transformation, $\mathbf{B} = R^T\mathbf{A}R$, such that $\mathbf{A}$ and $\mathbf{B}$ have the same inertia. By construction, $\mathbf{B}$ is symmetric. Then $\mathbf{B}$ may be diagonalized by its eigenvectors, and we have another diagonalization of $\mathbf{A}$. Denote by X the matrix containing the eigenvectors of $\mathbf{B}$ as columns such that

$$\begin{aligned}\tilde{v}^T\mathbf{A}\tilde{v} &= \tilde{v}^T R^{-1,T}R^T\mathbf{A}RR^{-1}\tilde{v} = \tilde{v}^T R^{-1,T}\mathbf{B}R^{-1}\tilde{v}\\ &= \tilde{v}^T R^{-1,T}X\Lambda_{\mathbf{M}}X^T R^{-1}\tilde{v} = \tilde{w}^T\Lambda^+_{\mathbf{M}}\tilde{w} + \tilde{w}^T\Lambda^-_{\mathbf{M}}\tilde{w}\end{aligned}$$

or

$$\tilde{v}^T M^{-1,T}M^T\mathbf{A}MM^{-1}\tilde{v} = \tilde{w}^T\Lambda_{\mathbf{M}}\tilde{w} = \tilde{w}^{+T}\Lambda^+_{\mathbf{M}}\tilde{w}^+ + \tilde{w}^{-T}\Lambda^-_{\mathbf{M}}\tilde{w}^-, \tag{6}$$

where $\tilde{w} = M^{-1}\tilde{v}$, $M = RX$, and $\Lambda_{\mathbf{M}}^{-/+}$ are diagonal negative/positive semidefinite. Further, $\tilde{w}^- = I(\Lambda^-_{\mathbf{M}})\tilde{w}$ and $\tilde{w}^+ = \tilde{w} - \tilde{w}^-$. We conclude that there are several different ways of diagonalizing $\mathbf{A}$, but in all cases $\Lambda_{\mathbf{Z}}$ and $\Lambda_{\mathbf{M}}$ have the same inertia. The fundamental difference between Z and another diagonalizing matrix, M, is that M is not orthogonal. We may regard Z as a specific M.

Next, we turn to the proof of the second part of the proposition. Specify $\tilde{w}^- = g$ at the boundary. Equation (4) can be rewritten as

$$\|\tilde{u}\|^2_t + \oint_{\partial D}\tilde{w}^{+T}\Lambda^+_{\mathbf{M}}\tilde{w}^+ ds + c_i\sum_{i=1}^{n}\|\tilde{u}_{x_i}\|^2 = -\oint_{\partial D} g^T\Lambda^-_{\mathbf{M}}g\,ds. \tag{7}$$

All the terms on the left-hand side of (7) are positive, implying that $\|\tilde{u}\|_t$, and hence $\|\tilde{u}\|$, are bounded. □

Remark 3. The assumption that steps (i) and (ii) in Proposition 2.6 can be fulfilled is true for many important partial differential equations. For example, it is true for the Euler, Navier–Stokes, and Maxwell equations.

Remark 4. The procedure that diagonalizes $\mathbf{A}$, with its eigenvectors and bounds the negative part, is what we mean by characteristic boundary conditions.

For Proposition 2.6 to be practically useful, a crucial point is to find a diagonalizing matrix. That is why we gave two examples of diagonalizing matrices. In the first example we used the eigenvalues and eigenvectors directly. For a system of equations, the matrix A can be large (9-by-9 for the Navier–Stokes equations in three dimensions). The eigenvalues of $\mathbf{A}$ are given as the roots of a polynomial of high degree, for which in general there do not exist roots in closed form.

In the second example, we can proceed in a different way. We will seek a diagonalizing matrix to $\mathbf{A}$ that is not orthogonal. By choosing R such that $\mathbf{B}$ has a simpler structure than $\mathbf{A}$, we may be able to find the eigenvalues and eigenvectors to $\mathbf{B}$. In fact, we will show that this is possible for the three-dimensional Navier–Stokes equations on general domains.

Certainly, not all of the points are novel in the above procedure. For example, in [10] a symmetrization of the linearized Navier–Stokes equations is presented. For the Euler equations, the whole procedure has been carried out when deriving the well-known characteristic boundary conditions. However, the idea of diagonalizing the boundary terms with a nonorthogonal matrix is, to the knowledge of the present authors, new. Furthermore, it is important to formalize the whole procedure since it should be possible to find well-posed boundary conditions to any problem of type (3).

3. The Navier–Stokes equations.

3.1. Step (i): Symmetrize the equations.

We will consider the Navier–Stokes equations as an example of how to use the procedure presented above to derive well-posed boundary conditions. We begin by rescaling the three-dimensional Navier–Stokes equations to nondimensional form. Consider the Navier–Stokes equations in primitive variables $\tilde{V} = [\tilde{\rho}, \tilde{u}_1, \tilde{u}_2, \tilde{u}_3, \tilde{p}]$ as stated in [10],

$$\begin{aligned} &\tilde{V}_t + \tilde{A}_1^p \tilde{V}_x + \tilde{A}_2^p \tilde{V}_y + \tilde{A}_3^p \tilde{V}_z \\ &= \tilde{B}_{11}^p \tilde{V}_{xx} + \tilde{B}_{22}^p \tilde{V}_{yy} + \tilde{B}_{33}^p \tilde{V}_{zz} + \tilde{B}_{xy}^p \tilde{V}_{xy} + \tilde{B}_{yz}^p \tilde{V}_{yz} + \tilde{B}_{zx}^p \tilde{V}_{zx}, \end{aligned} \tag{8}$$

where the tilde sign emphasizes that the entity depends on the solution. Further, $\tilde{\rho}$ is the density; $\tilde{u}_1, \tilde{u}_2, \tilde{u}_3$ are the velocities in the x, y, and z directions, respectively; and $\tilde{p}$ is the pressure. We will also use the ratio between the specific heat capacities, $\gamma = c_p/c_v$, and the speed of sound, c; μ the dynamic viscosity, λ the bulk viscosity, and $\nu = \frac{\mu}{\rho}$ the kinematic viscosity; $Pr = \frac{\nu}{\alpha}$ denoting the Prandtl number, where α is the thermal diffusivity. Let $Re = \frac{\rho_\infty U_\infty L}{\mu_\infty}$ denote the Reynolds number. The infinity subscript denotes free stream conditions, and L is some characteristic length scale.

The equations (8) are nondimensionalized and the coefficients are frozen, which corresponds to the linearization of the Navier–Stokes equations. The tilde signs are dropped on the matrices as they no longer depend on the solution. Using the parabolic symmetrizer S_p derived in [10] and letting $\epsilon = \frac{1}{Re}$ yields

$$\begin{aligned} &\tilde{u}_t + A_1 \tilde{u}_x + A_2 \tilde{u}_y + A_3 \tilde{u}_z \\ &= \epsilon (B_{11} \tilde{u}_{xx} + B_{22} \tilde{u}_{yy} + B_{33} \tilde{u}_{zz} + B_{xy} \tilde{u}_{xy} + B_{yz} \tilde{u}_{uz} + B_{zx} \tilde{u}_{zx}). \end{aligned} \tag{9}$$

The transformed nondimensionalized variables are

$$\begin{aligned} S_p^{-1} \tilde{V} &= \begin{pmatrix} \frac{c}{\sqrt{\gamma}\rho} & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ -\frac{c}{\rho\sqrt{\gamma}\sqrt{\gamma-1}} & 0 & 0 & 0 & \sqrt{\frac{\gamma}{\gamma-1}}\frac{1}{\rho c} \end{pmatrix} \begin{pmatrix} \tilde{\rho} \\ \tilde{u}_1 \\ \tilde{u}_2 \\ \tilde{u}_3 \\ \tilde{p} \end{pmatrix} \\ &= \begin{pmatrix} \frac{c}{\sqrt{\gamma}\rho}\tilde{\rho} \\ \tilde{u}_1 \\ \tilde{u}_2 \\ \tilde{u}_3 \\ -\frac{c}{\sqrt{\gamma}\sqrt{\gamma-1}}\frac{\tilde{\rho}}{\rho} + \sqrt{\frac{\gamma}{\gamma-1}}\frac{1}{\rho c}\tilde{p} \end{pmatrix} = \tilde{u}. \end{aligned} \tag{10}$$

The symmetrized matrices are derived in [10] and are repeated here for convenience. Let $a = \sqrt{\frac{\gamma-1}{\gamma}}c$ and $b = \frac{c}{\sqrt{\gamma}}$. Then

$$A_1 = \begin{pmatrix} u_1 & b & 0 & 0 & 0 \\ b & u_1 & 0 & 0 & a \\ 0 & 0 & u_1 & 0 & 0 \\ 0 & 0 & 0 & u_1 & 0 \\ 0 & a & 0 & 0 & u_1 \end{pmatrix}, \qquad A_2 = \begin{pmatrix} u_2 & 0 & b & 0 & 0 \\ 0 & u_2 & 0 & 0 & 0 \\ b & 0 & u_2 & 0 & a \\ 0 & 0 & 0 & u_2 & 0 \\ 0 & 0 & a & 0 & u_2 \end{pmatrix}, \tag{11}$$

$$A_3 = \begin{pmatrix} u_3 & 0 & 0 & b & 0 \\ 0 & u_3 & 0 & 0 & 0 \\ 0 & 0 & u_3 & 0 & 0 \\ b & 0 & 0 & u_3 & a \\ 0 & 0 & 0 & a & u_3 \end{pmatrix}, \qquad B_{xy} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{\lambda+\mu}{\rho} & 0 & 0 \\ 0 & \frac{\lambda+\mu}{\rho} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \tag{12}$$

$$B_{yz} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{\lambda+\mu}{\rho} & 0 \\ 0 & 0 & \frac{\lambda+\mu}{\rho} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \qquad B_{zx} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{\lambda+\mu}{\rho} & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{\lambda+\mu}{\rho} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \tag{13}$$

$$B_{11} = \operatorname{diag}\left(0, \frac{\lambda+2\mu}{\rho}, \frac{\mu}{\rho}, \frac{\mu}{\rho}, \frac{\gamma\mu}{Pr\rho}\right), \tag{14}$$

$$B_{22} = \operatorname{diag}\left(0, \frac{\mu}{\rho}, \frac{\lambda+2\mu}{\rho}, \frac{\mu}{\rho}, \frac{\gamma\mu}{Pr\rho}\right), \tag{15}$$

$$B_{33} = \operatorname{diag}\left(0, \frac{\mu}{\rho}, \frac{\mu}{\rho}, \frac{\lambda+2\mu}{\rho}, \frac{\gamma\mu}{Pr\rho}\right). \tag{16}$$

3.2. Step (ii): Apply the energy method. Next, we turn to the analysis of boundary conditions for the Navier–Stokes equations. Consider a general domain D with boundary ∂D in three space dimensions. From (9), the symmetrized and nondimensionalized Navier–Stokes equations are

$$\tilde{u}_t + (A_1\tilde{u} - \epsilon\tilde{F}_v)_x + (A_2\tilde{u} - \epsilon\tilde{G}_v)_y + (A_3\tilde{u} - \epsilon\tilde{H}_v)_z, \tag{17}$$

where

$$\tilde{F}_v = B_{11}\tilde{u}_x + B_{21}\tilde{u}_y + B_{31}\tilde{u}_z, \tag{18}$$

$$\tilde{G}_v = B_{22}\tilde{u}_y + B_{32}\tilde{u}_z + B_{12}\tilde{u}_x, \tag{19}$$

$$\tilde{H}_v = B_{33}\tilde{u}_z + B_{23}\tilde{u}_y + B_{13}\tilde{u}_x, \tag{20}$$

and

$$B_{21} = B_{12} = \frac{B_{xy}}{2}, \quad B_{32} = B_{23} = \frac{B_{yz}}{2}, \quad B_{31} = B_{13} = \frac{B_{zx}}{2}.$$

Applying the energy method (step (ii)),

$$\begin{aligned}\int_D \tilde{u}^T\tilde{u}_t dxdydz + \int_D \frac{\partial}{\partial x}\left(\frac{1}{2}\tilde{u}^T A_1\tilde{u} - \epsilon\tilde{u}^T\tilde{F}_v\right)&\\ + \frac{\partial}{\partial y}\left(\frac{1}{2}\tilde{u}^T A_2\tilde{u} - \epsilon\tilde{u}^T\tilde{G}_v\right) + \frac{\partial}{\partial z}\left(\frac{1}{2}\tilde{u}^T A_3\tilde{u} - \epsilon\tilde{u}^T\tilde{H}_v\right) dxdydz&\\ = -\epsilon\int_D (\tilde{u}_x^T\tilde{F}_v + \tilde{u}_y^T\tilde{G}_v + \tilde{u}_z^T\tilde{H}_v)dxdydz.&\end{aligned} \tag{21}$$

The right-hand side in (21) is negative definite and denoted by $-DI$.

Remark 5. It is easily verified that the last term in (21) is dissipation,

$$DI = \epsilon\int_D \left(\begin{array}{ccc} \tilde{u}_x^T & \tilde{u}_y^T & \tilde{u}_z^T \end{array}\right)\left(\begin{array}{ccc} B_{11} & B_{12} & B_{13}\\ B_{21} & B_{22} & B_{23}\\ B_{31} & B_{32} & B_{33}\end{array}\right)\left(\begin{array}{c}\tilde{u}_x\\ \tilde{u}_y\\ \tilde{u}_z\end{array}\right) dxdydz.$$

The matrix is symmetric with positive or zero diagonal entries. With $\lambda \leq \mu$, the matrix is diagonally dominant. Thus, it is positive semidefinite.

Denote by $\|\tilde{u}\|^2$ the integral $\int_D \tilde{u}^T\tilde{u}dxdydz$. Using Gauss' theorem, we obtain

$$\begin{aligned}\|\tilde{u}\|_t^2 + \oint_{\partial D}\left(\tilde{u}^T(A_1\tilde{u} - 2\epsilon\tilde{F}_v), \tilde{u}^T(A_2\tilde{u} - 2\epsilon\tilde{G}_v), \tilde{u}^T(A_3\tilde{u} - 2\epsilon\tilde{H}_v)\right)\cdot\hat{\mathbf{n}}\, ds&\\ = -2DI,&\end{aligned} \tag{22}$$

where $\hat{\mathbf{n}} = (n_1, n_2, n_3)$ is the outward-pointing unit normal on the surface ∂D and $ds = \sqrt{dx^2 + dy^2 + dz^2}$. Equation (22) can be rewritten as

$$\begin{aligned}\|\tilde{u}\|_t^2 + \oint_{\partial D}\left(\begin{array}{c}\tilde{u}\\ \tilde{F}^V\end{array}\right)^T\left(\begin{array}{cc} A_1n_1 + A_2n_2 + A_3n_3 & -\epsilon I_5\\ -\epsilon I_5 & 0_5\end{array}\right)\left(\begin{array}{c}\tilde{u}\\ \tilde{F}^V\end{array}\right)ds&\\ = -2DI,&\end{aligned} \tag{23}$$

where I_n denotes the n-by-n identity matrix, and similarly 0_n the n-by-n zero matrix and $\tilde{F}^V = \tilde{F}_v n_1 + \tilde{G}_v n_2 + \tilde{H}_v n_3$.

To prove well-posedness we have to split the matrix in the boundary integral into positive definite and negative definite parts. The negative part of the boundary term in (23) caused by

$$\mathbf{A_1} = \left(\begin{array}{cc} A_1n_1 + A_2n_2 + A_3n_3 & -\epsilon I_5\\ -\epsilon I_5 & 0_5\end{array}\right) \tag{24}$$

has to be supplied with boundary conditions, which in turn bounds the growth of $\|\tilde{u}\|_t^2$ in (21).

We note that the first component of $\tilde{F}^V$ is zero, and hence we can reduce the system by omitting that component and denoting the resulting vector by $\tilde{G}^V$. By this procedure $\mathbf{A_1}$ is also reduced from a 10-by-10 matrix to a 9-by-9 matrix by deleting the sixth row and column. With $\mathbf{u} = (u_1, u_2, u_3)$, we have

$$\left(\begin{array}{c}\tilde{u}\\ \tilde{F}^V\end{array}\right)^T\left(\begin{array}{cc} A_1n_1 + A_2n_2 + A_3n_3 & -\epsilon I_5\\ -\epsilon I_5 & 0_5\end{array}\right)\left(\begin{array}{c}\tilde{u}\\ \tilde{F}^V\end{array}\right) = \left(\begin{array}{c}\tilde{u}\\ \tilde{G}^V\end{array}\right)^T\mathbf{A}\left(\begin{array}{c}\tilde{u}\\ \tilde{G}^V\end{array}\right),$$

where

$$\mathbf{A} = \begin{pmatrix} \mathbf{u}\cdot\hat{\mathbf{n}} & bn_1 & bn_2 & bn_3 & 0 & 0 & 0 & 0 & 0 \\ bn_1 & \mathbf{u}\cdot\hat{\mathbf{n}} & 0 & 0 & an_1 & -\epsilon & 0 & 0 & 0 \\ bn_2 & 0 & \mathbf{u}\cdot\hat{\mathbf{n}} & 0 & an_2 & 0 & -\epsilon & 0 & 0 \\ bn_3 & 0 & 0 & \mathbf{u}\cdot\hat{\mathbf{n}} & an_3 & 0 & 0 & -\epsilon & 0 \\ 0 & an_1 & an_2 & an_3 & \mathbf{u}\cdot\hat{\mathbf{n}} & 0 & 0 & 0 & -\epsilon \\ 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 \end{pmatrix} = \begin{pmatrix} A_{11} & A_{12} & 0_{14} \\ A_{21} & A_{22} & -\epsilon I_4 \\ 0_{41} & -\epsilon I_4 & 0_4 \end{pmatrix}, \tag{25}$$

using the notation 0_{nm} for the n-by-m zero matrix. We will also use the notation $u_n = \mathbf{u}\cdot\hat{\mathbf{n}}$. Since $\hat{\mathbf{n}}$ is the outward-pointing normal, $u_n < 0$ implies inflow. Further, note that A_{11} in (25) is a scalar.

3.3. Step (iii): Find a diagonalizing matrix.

Next, we state and prove the following proposition, where $M_n = u_n/c$ is the Mach number.

PROPOSITION 3.1. *If $|M_n| \neq 1, 0$ and $u_n < 0$, there are four positive and five negative eigenvalues of $\mathbf{A}$. If $|M_n| \neq 1, 0$ and $u_n > 0$, there are five positive and four negative eigenvalues of $\mathbf{A}$.*

Proposition 3.1 states that an inflow demands five and an outflow four boundary conditions. The number of boundary conditions can also be derived using the Laplace transform technique, which is shown in [14, 15]. However, to prove well-posedness of specific boundary conditions using the Laplace transform technique is algebraically very complex, as shown in [15]. In the proof of Proposition 3.1 we will continue with the procedure outlined in section 2 and find a diagonalizing matrix to A (step (iii)). However, finding the eigenvalues of A corresponds to solving a ninth degree polynomial. Besides the algebraic difficulty of finding roots to ninth degree polynomials, it is probable that the roots in this particular case do not exist in closed form. Instead, we will derive another diagonalizing matrix. That matrix gives the explicit form of the well-posed boundary conditions.

Proof of Proposition 3.1. Rotate $\mathbf{A}$ by

$$R^T\mathbf{A}R = \begin{pmatrix} 1 & 0_{14} & 0_{14} \\ \bar{\alpha}^T & I_4 & 0_4 \\ \bar{\beta}^T & \bar{\gamma}^T & I_4 \end{pmatrix} \begin{pmatrix} A_{11} & A_{12} & 0_{14} \\ A_{21} & A_{22} & -\epsilon I_4 \\ 0_{41} & -\epsilon I_4 & 0_4 \end{pmatrix} \begin{pmatrix} 1 & \bar{\alpha} & \bar{\beta} \\ 0_{41} & I_4 & \bar{\gamma} \\ 0_{41} & 0_4 & I_4 \end{pmatrix} = \begin{pmatrix} E_{11} & E_{12} & E_{13} \\ E_{21} & E_{22} & E_{23} \\ E_{31} & E_{32} & E_{33} \end{pmatrix} = \mathbf{E}, \tag{26}$$

where

$$\begin{aligned} E_{11} &= A_{11}, \\ E_{12} &= A_{11}\bar{\alpha} + A_{12}, \\ E_{13} &= A_{11}\bar{\beta} + A_{12}\bar{\gamma}, \\ E_{21} &= \bar{\alpha}^T A_{11} + A_{21}, \\ E_{22} &= \bar{\alpha}^T(A_{11}\bar{\alpha} + A_{12}) + (A_{21}\bar{\alpha} + A_{22}), \end{aligned}$$

$$E_{23} = \bar{\alpha}^T(A_{11}\bar{\beta} + A_{12}\bar{\gamma}) + A_{21}\bar{\beta} + A_{22}\bar{\gamma} - \epsilon I_3,$$
$$E_{31} = \bar{\beta}^T A_{11} + \bar{\gamma}^T A_{21},$$
$$E_{32} = \bar{\beta}^T(A_{11}\bar{\alpha} + A_{12}) + \bar{\gamma}^T(A_{21}\bar{\alpha} + A_{22}) - \epsilon I_3,$$
$$E_{33} = \bar{\beta}^T(A_{11}\bar{\beta} + A_{12}\bar{\gamma}) + \bar{\gamma}^T(A_{21}\bar{\beta} + A_{22}\bar{\gamma} - \epsilon I_3) - \epsilon I_3\bar{\gamma}.$$

Using $A_{12}^T = A_{21}$, we cancel the off-diagonal blocks and solve for $\bar{\alpha}, \bar{\beta}$, and $\bar{\gamma}$. We obtain

$$\text{(27)} \qquad \bar{\alpha} = -A_{11}^{-1}A_{12}, \quad \bar{\beta} = \epsilon A_{11}^{-1}A_{12}E_{22}^{-1}, \quad \bar{\gamma} = -\epsilon E_{22}^{-1},$$

$$\text{(28)} \qquad \mathbf{E} = \begin{pmatrix} A_{11} & 0_{14} & 0_{14} \\ 0_{41} & E_{22} & 0_4 \\ 0_{41} & 0_4 & -\epsilon^2 E_{22}^{-1} \end{pmatrix}, \quad E_{22} = A_{22} - A_{21}A_{11}^{-1}A_{12}.$$

The conditions for this procedure to hold are that $\det(A_{11}) \neq 0$ and $\det(E_{22}) \neq 0$.

We know from Corollary 2.4 that $i(\mathbf{A}) = i(\mathbf{E})$. Thus, we can instead determine the sign of the eigenvalues of $\mathbf{E}$. Note that the upper-left entry of $\mathbf{E}$ is a scalar and hence an eigenvalue. We denote that by

$$\text{(29)} \qquad \lambda_1 = A_{11} = u_n.$$

If $\det(E_{22}) \neq 0$, we know that E_{22} has four real nonzero eigenvalues, since E_{22} is symmetric by construction. The signs of those do not change as E_{22} is inverted such that from the second and third block there are always four negative and four positive eigenvalues of $\mathbf{E}$. Including λ_1, we have for $u_n > 0$ four negative and five positive eigenvalues, and for $u_n < 0$, five negative and four positive eigenvalues of $\mathbf{E}$, as stated in the proposition (assuming that $\det(A_{11}) \neq 0$ and $\det(E_{22}) \neq 0$).

We will now show that $\det(A_{11}) \neq 0$ and $\det(E_{22}) \neq 0$ for $M_n \neq \pm 1, 0$. Since $A_{11} = u_n$, we have $\det(A_{11}) \neq 0$ for $M_n \neq 0$. To evaluate the second condition, we compute the eigenvalues of E_{22} explicitly. From (25) and (28) we have

$$\text{(30)} \qquad E_{22} = \begin{pmatrix} -\frac{b^2n_1^2}{u_n} + u_n & -\frac{b^2n_1n_2}{u_n} & -\frac{b^2n_1n_3}{u_n} & an_1 \\ -\frac{b^2n_1n_2}{u_n} & -\frac{b^2n_2^2}{u_n} + u_n & -\frac{b^2n_2n_3}{u_n} & an_2 \\ -\frac{b^2n_1n_3}{u_n} & -\frac{b^2n_2n_3}{u_n} & -\frac{b^2n_3^2}{u_n} + u_n & an_3 \\ an_1 & an_2 & an_3 & u_n \end{pmatrix},$$

and the eigenvalues are

$$\text{(31)} \qquad \lambda_{2,3} = \frac{-b^2 + 2u_n^2 \pm \sqrt{b^4 + 4a^2u_n^2}}{2u_n},$$

$$\text{(32)} \qquad \lambda_4 = \lambda_5 = u_n,$$

where $n_1^2 + n_2^2 + n_3^2 = 1$ has been used to simplify the expressions. λ_4 and λ_5 obviously shift sign at $u_n = 0$. Also, since $\lambda_4 = \lambda_5 = 0$ with $M_n = u_n = 0$, we have that $\det(E_{22}) = 0$. Thus, to rotate $\mathbf{A}$ by R we once more need $M_n \neq 0$. λ_2 and λ_3 can be expressed as

$$\text{(33)} \qquad \lambda_{2,3} = \frac{c}{2\gamma M_n}\left(-1 + 2\gamma M_n^2 \pm \sqrt{1 + 4(\gamma - 1)\gamma M_n^2}\right).$$

Consider λ_2, and note that $\gamma \geq 1$. Then $\sqrt{1-4\gamma M_n^2+4\gamma^2 M_n^2} \geq 1$ such that the sign of λ_2 is the same as the sign of the denominator, i.e., M_n or u_n. This means that $\lambda_2 \neq 0$ for all $M_n \neq 0$, and $\lambda_2 = 0$ for $M_n = 0$.

At last, λ_3 is considered. λ_3 shifts sign when

$$2\gamma M_n^2 - 1 - \sqrt{1-4\gamma M_n^2+4\gamma^2 M_n^2} = 0.$$

Alternatively, $(2\gamma M_n^2-1)^2 = (1-4\gamma M_n^2+4\gamma^2 M_n^2)$, which has the solutions $M_n = 0, 1, -1$, but $M_n = 0$ is discarded due to the original equality. Thus, $\lambda_3 \neq 0$, and hence $\det(E_{22}) \neq 0$ for $|M_n| \neq 1$. Note that, λ_3 is singular for $M_n = 0$. □

We have now derived the number of positive and negative eigenvalues of $\mathbf{A}$, and hence the number of boundary conditions, and their dependence on M_n. This was done by calculating the eigenvalues of $\mathbf{E}$ explicitly.

To obtain a set of boundary conditions we also need the eigenvectors of $\mathbf{E}$. Given the eigenvectors of $\mathbf{E}$, it is a simple task to derive a diagonalizing matrix to $\mathbf{A}$. The eigenvectors of E_{22} are able to be explicitly derived since the eigenvalues are explicitly given and they are $Y = (y_2, y_3, y_4, y_5)$, where

$$\begin{aligned} y_2 &= \left(n_1, n_2, n_3, -\frac{-b^4-\sqrt{b^2+4a^2u_n^2}}{2au_n}\right)^T \\ &= \left(n_1, n_2, n_3, \frac{-\lambda_3+u_n}{a}\right)^T, \qquad (34) \\ y_3 &= \left(n_1, n_2, n_3, -\frac{-b^4+\sqrt{b^2+4a^2u_n^2}}{2au_n}\right)^T \\ &= \left(n_1, n_2, n_3, \frac{-\lambda_2+u_n}{a}\right)^T, \qquad (35) \\ y_4 &= (-n_2, n_1, 0, 0)^T, \qquad (36) \\ y_5 &= (-n_3, 0, n_1, 0). \qquad (37) \end{aligned}$$

Remark 6. We omit the normalization of the eigenvectors to keep the expressions (34)–(37) simple.

Now, we can derive a specific diagonalizing matrix M and conclude step (iii). For convenience, we restate (6),

$$\tilde{v}^T M^{-1,T} M^T \mathbf{A} M M^{-1} \tilde{v} = \tilde{w}^T \Lambda_{\mathbf{M}} \tilde{w},$$

where $M = RX$ and $\tilde{v} = (\tilde{u}^T\, (\tilde{G}^V)^T)^T$. R is given in (26), (27), and (28). Further,

$$X = \begin{pmatrix} 1 & 0_{14} & 0_{14} \\ 0_{41} & Y & 0_4 \\ 0_{41} & 0_4 & Y \end{pmatrix}, \qquad \Lambda_{\mathbf{M}} = \begin{pmatrix} u_n & 0_{14} & 0_{14} \\ 0_{41} & \Lambda & 0_4 \\ 0_{41} & 0_4 & -\epsilon^2\Lambda^{-1} \end{pmatrix},$$

where $\Lambda = \operatorname{diag}(\lambda_2, \lambda_3, \lambda_4, \lambda_5)$. Inverting R and M yields

$$R^{-1} = \begin{pmatrix} 1 & -\bar{\alpha} & 0_{14} \\ 0_{41} & I_4 & -\bar{\gamma} \\ 0_{41} & 0_4 & I_4 \end{pmatrix}, \qquad M^{-1} = X^T R^{-1} = \begin{pmatrix} 1 & -\bar{\alpha} & 0_{14} \\ 0_{41} & Y^T & -Y^T\bar{\gamma} \\ 0_{41} & 0_4 & Y^T \end{pmatrix}. \qquad (38)$$

To simplify the computation of M^{-1} we use (27) and obtain

$$-Y^T\gamma = \epsilon Y^T E_{22}^{-1} = \epsilon Y^T Y \Lambda^{-1} Y^T = \epsilon \Lambda^{-1} Y^T = \epsilon \begin{pmatrix} \lambda_2^{-1} y_2^T \\ \lambda_3^{-1} y_3^T \\ \lambda_4^{-1} y_4^T \\ \lambda_5^{-1} y_5^T \end{pmatrix}, \tag{39}$$

yielding

$$M^{-1} = \begin{pmatrix} 1 & -\bar{\alpha} & 0_{14} \\ 0_{41} & Y^T & \epsilon\Lambda^{-1}Y^T \\ 0_{41} & 0_4 & Y^T \end{pmatrix}, \quad \text{where } \bar{\alpha} = \left(-\frac{b}{u_n}\hat{\mathbf{n}}, 0\right). \tag{40}$$

We proceed by computing the variables, $\tilde{w} = X^T R^{-1} \tilde{v} = M^{-1}\tilde{v}$, to which boundary conditions should be applied. Let $\tilde{G}_i^V$ be the ith component of $\tilde{G}^V$. Define $\tilde{v}_{i\ldots j} = (\tilde{v}_i, \ldots, \tilde{v}_j)^T$ and $\tilde{u}_n = (\tilde{u}_1, \tilde{u}_2, \tilde{u}_3) \cdot \hat{\mathbf{n}}$. For convenience, we restate $\tilde{v}$,

$$\tilde{v} = \left(\frac{b}{\rho}\tilde{\rho}, \tilde{u}_1, \tilde{u}_2, \tilde{u}_3, -\frac{b}{\sqrt{\gamma-1}}\frac{\tilde{\rho}}{\rho} + \frac{1}{\rho a}\tilde{p}, \tilde{G}_1^V, \tilde{G}_2^V, \tilde{G}_3^V, \tilde{G}_4^V\right)^T. \tag{41}$$

Then,

$$\tilde{w} = M^{-1}\tilde{v} = \begin{pmatrix} \tilde{v}_1 - \bar{\alpha}\cdot\tilde{v}_{2\ldots5} \\ y_2^T(\tilde{v}_{2\ldots5} - \epsilon\lambda_2^{-1}\tilde{G}^V) \\ y_3^T(\tilde{v}_{2\ldots5} - \epsilon\lambda_3^{-1}\tilde{G}^V) \\ y_4^T(\tilde{v}_{2\ldots5} - \epsilon\lambda_4^{-1}\tilde{G}^V) \\ y_5^T(\tilde{v}_{2\ldots5} - \epsilon\lambda_5^{-1}\tilde{G}^V) \\ y_2^T\tilde{G}^V \\ y_3^T\tilde{G}^V \\ y_4^T\tilde{G}^V \\ y_5^T\tilde{G}^V \end{pmatrix}, \tag{42}$$

by using (34)–(37).

For completeness we also give the reverse transformation. It is $\tilde{v} = RX\tilde{w} = M\tilde{w}$,

$$M = \begin{pmatrix} 1 & \bar{\alpha}Y & \bar{\beta}Y \\ 0_{31} & Y & \bar{\gamma}Y \\ 0_{31} & 0_3 & Y \end{pmatrix} = \begin{pmatrix} 1 & \bar{\alpha}Y & \bar{\alpha}\Lambda^{-1}Y^T \\ 0_{31} & Y & -\epsilon Y\Lambda \\ 0_{31} & 0_3 & Y \end{pmatrix}. \tag{43}$$

The corresponding diagonalizing matrices in the two-dimensional case are given in Appendix A.

Remark 7. Note that we have found one of possibly several diagonalizing matrices. M is not orthogonal, which means that $\Lambda_{\mathbf{M}}$ does not hold the eigenvalues of $\mathbf{A}$.

Remark 8. Note that the only condition involved with finding a diagonalizing matrix M is that $\mathbf{A}$ be nonsingular. Then we can choose to rotate $\mathbf{A}$ to block diagonal form with blocks of arbitrary size. If the blocks are small enough, we can derive their eigenvalues analytically.

3.4. Step (iv) and (v): Split $\Lambda_{\mathbf{M}}$ and $\tilde{w}$. In order to know which components of $\tilde{w}$ to bound with boundary conditions we need to investigate the sign of the diagonal entries of $\Lambda_{\mathbf{M}}$, i.e., the eigenvalues of $\mathbf{E}$ (step (iv)).

Table 1
The sign of the eigenvalues for different Mach numbers.

Eigenvalue	$M_n < -1$	$-1 < M_n < 0$	$0 < M_n < 1$	$M_n > 1$

Supersonic outflow	4

Table 3
The number of boundary conditions to be specified at different flow cases for the three-dimensional Euler equations.

Supersonic inflow	5
Subsonic inflow	4
Subsonic outflow	1
Supersonic outflow	0

In the proof of Proposition 3.1, λ_3 given by (33) was analyzed. It was shown that λ_3 changes sign at $M_n = 0$ and $|M_n| = 1$. The eigenvalues $\lambda_1, \lambda_2, \lambda_4$, and λ_5 only change signs at $M_n = 0$. Thus, the different cases are inflow or outflow and sub- or supersonic flow. A consequence is that sub- or supersonic flow affects which boundary conditions to choose but not the number of them. In fact, only the boundary condition corresponding to λ_3 (and hence $-\epsilon^2\lambda_3^{-1} \equiv \lambda_7$) changes sign at $|M_n| = 1$. With $\Lambda = \mathrm{diag}(\lambda_2, \lambda_3, \lambda_4, \lambda_5)$, the diagonal form of $\mathbf{E}$ is $\Lambda_{\mathbf{M}} = \mathrm{diag}(\lambda_1, \Lambda, -\epsilon^2\Lambda^{-1})$. In Table 1 the signs of the different eigenvalues are summarized, where $\lambda_6, \ldots, \lambda_9$ denotes the diagonal entries of $-\epsilon^2\Lambda^{-1}$. Those with negative signs have to be supplied with boundary conditions. As mentioned above, since $\hat{\mathbf{n}}$ is the outward-pointing normal, negative values of M_n indicate inflow and positive values mean outflow.

In Table 2 the numbers of boundary conditions deduced from Table 1 for different flow cases are shown. They are in full agreement with the results from the Laplace transform technique derived in [14] and also in [15]. Note that in the Euler limit, i.e., $\epsilon \to 0$, the last four eigenvalues will become zero, and there are five nontrivial eigenvalues. In Table 3 the numbers of boundary conditions are displayed for the Euler case, $\epsilon \to 0$. The result agrees with the well-known theory for Euler equations.

At last, we can split $\tilde{w}$ given by (42) into $\tilde{w}^+$ and w^- corresponding to the positive and negative eigenvalues and perform step (v), such that well-posedness follows.

Remark 9. Though there are no numerical computations in this article, we would like to comment on some computational aspects. We assume that we know the exact boundary data ahead of time. This implies knowledge of the type of boundary (inflow/outflow, subsonic/supersonic) that we have at each point on the boundary as well as when one boundary type changes to another.

However, in computations, the numerical result might indicate that the assumed data are erroneous. In such a case, this procedure as well as other boundary condition procedures require an adjustment of the given data or location of the boundary for better accuracy.

3.5. Special case: $\boldsymbol{u_n = 0}$. The above derivation gives a set of boundary conditions that leads to a well-posed mathematical problem. However, it is assumed that $u_n \neq 0$, which excludes two cases: tangential flow and the important solid wall condition. We will treat the case $u_n = 0$ separately and redo the steps (iii)–(v). Throughout this paper, we have considered the Navier–Stokes equations linearized around the solution at the boundary, in this case $u_n = 0$. We obtain

$$\mathbf{A} = \begin{pmatrix} 0 & bn_1 & bn_2 & bn_3 & 0 & 0 & 0 & 0 & 0 \\ bn_1 & 0 & 0 & 0 & an_1 & -\epsilon & 0 & 0 & 0 \\ bn_2 & 0 & 0 & 0 & an_2 & 0 & -\epsilon & 0 & 0 \\ bn_3 & 0 & 0 & 0 & an_2 & 0 & 0 & -\epsilon & 0 \\ 0 & an_1 & an_2 & an_3 & 0 & 0 & 0 & 0 & -\epsilon \\ 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 \end{pmatrix}, \tag{44}$$

to which the previous rotation does not apply, since $\mathbf{A}$ is now singular. This leaves us with no other choice but to seek the eigenvalues and eigenvectors of this matrix. It turns out that it is now a simpler task than with $u_n \neq 0$. The result is presented below, and the details of the derivation are found in Appendix B.

Define $\mathbf{m_1}$ and $\mathbf{m_2}$ such that $\hat{\mathbf{n}}^T\mathbf{m_1} = 0$, $\hat{\mathbf{n}}^T\mathbf{m_2} = \mathbf{m_1}^T\mathbf{m_2} = 0$, and

$$\mu_{1,2} = -\frac{c^2}{2} \pm \sqrt{\frac{c^4}{4} + a^2\epsilon^2}.$$

Then,

$$\begin{aligned}
\lambda_1 &= -\epsilon, & e_1 &= (0, \mathbf{m_1}^T, 0, \mathbf{m_1}^T, 0)^T, \\
\lambda_2 &= -\epsilon, & e_2 &= (0, \mathbf{m_2}^T, 0, \mathbf{m_2}^T, 0)^T, \\
\lambda_3 &= \epsilon, & e_3 &= (0, \mathbf{m_1}^T, 0, -\mathbf{m_1}^T, 0)^T, \\
\lambda_4 &= \epsilon, & e_4 &= (0, \mathbf{m_2}^T, 0, -\mathbf{m_2}^T, 0)^T, \\
\lambda_5 &= 0, & e_5 &= \left(1, 0, 0, 0, 0, \frac{b}{\epsilon}\hat{\mathbf{n}}, 0^T\right), \\
\lambda_6 &= \sqrt{\epsilon^2 - \mu_1}, & e_6 &= \left(b, \lambda_6\hat{\mathbf{n}}^T, -\frac{a\lambda_6^2}{\mu_1^2}, -\epsilon\hat{\mathbf{n}}^T, \frac{\epsilon a\lambda_6}{\mu_1^2}\right)^T, \\
\lambda_7 &= -\sqrt{\epsilon^2 - \mu_1}, & e_7 &= \left(b, \lambda_7\hat{\mathbf{n}}^T, -\frac{a\lambda_7^2}{\mu_1^2}, -\epsilon\hat{\mathbf{n}}^T, \frac{\epsilon a\lambda_7}{\mu_1^2}\right)^T, \\
\lambda_8 &= \sqrt{\epsilon^2 - \mu_2}, & e_8 &= \left(b, \lambda_8\hat{\mathbf{n}}^T, -\frac{a\lambda_8^2}{\mu_2^2}, -\epsilon\hat{\mathbf{n}}^T, \frac{\epsilon a\lambda_8}{\mu_2^2}\right)^T, \\
\lambda_9 &= -\sqrt{\epsilon^2 - \mu_2}, & e_9 &= \left(b, \lambda_9\hat{\mathbf{n}}^T, -\frac{a\lambda_9^2}{\mu_2^2}, -\epsilon\hat{\mathbf{n}}^T, \frac{\epsilon a\lambda_9}{\mu_2^2}\right)^T.
\end{aligned} \tag{45}$$

Remark 10. With some algebra one can show that $\epsilon^2 \geq \mu_{1,2}$ such that the eigenvalues $\lambda_6, \dots, \lambda_9$ are real. In fact, since $\mathbf{A}$ is symmetric and the vectors $e_1, \dots, e_9$ are orthogonal and diagonalize $\mathbf{A}$, $\lambda_1, \dots, \lambda_9$ have to be real.

Above, step (iii) is performed and we turn to step (iv). We have

$$\begin{aligned}\Lambda^- &= \mathrm{diag}(\lambda_1, \lambda_2, 0, 0, 0, 0, \lambda_7, 0, \lambda_9),\\ \Lambda^+ &= \mathrm{diag}(0, 0, \lambda_3, \lambda_4, 0, \lambda_6, 0, \lambda_8, 0).\end{aligned}$$

Remark 11. Note that we have four negative eigenvalues. This means that a boundary with $u_n = 0$ is classified as an outflow boundary.

Further, $\tilde{w} = X^T v$, where the column vectors of X are the eigenvectors. With $\tilde{\mathbf{u}} = (\tilde{u}_1, \tilde{u}_2, \tilde{u}_3)^T$, $\tilde{G}^V_{i \dots j} = (\tilde{G}^V_i, \dots, \tilde{G}^V_j)^T$, and the ith component of $\tilde{v}$ denoted by $\tilde{v}_i$, we obtain

$$\tilde{w} = \begin{pmatrix} \mathbf{m_1}^T(\tilde{\mathbf{u}} + \tilde{G}^V_{1\dots 3}) \\ \mathbf{m_2}^T(\tilde{\mathbf{u}} + \tilde{G}^V_{1\dots 3}) \\ \mathbf{m_1}^T(\tilde{\mathbf{u}} - \tilde{G}^V_{1\dots 3}) \\ \mathbf{m_2}^T(\tilde{\mathbf{u}} - \tilde{G}^V_{1\dots 3}) \\ v_1 + \frac{b}{\epsilon}\hat{\mathbf{n}}^T(\tilde{G}^V)_{1\dots 3} \\ bv_1 + \hat{\mathbf{n}}^T(\lambda_6\tilde{\mathbf{u}} - \epsilon\tilde{G}^V_{1\dots 3}) - \frac{a\lambda_6}{\mu_1^2}(\lambda_6 v_4 - \epsilon\tilde{G}^V_4) \\ bv_1 + \hat{\mathbf{n}}^T(\lambda_7\tilde{\mathbf{u}} - \epsilon\tilde{G}^V_{1\dots 3}) - \frac{a\lambda_7}{\mu_1^2}(\lambda_7 v_4 - \epsilon\tilde{G}^V_4) \\ bv_1 + \hat{\mathbf{n}}^T(\lambda_8\tilde{\mathbf{u}} - \epsilon\tilde{G}^V_{1\dots 3}) - \frac{a\lambda_8}{\mu_2^2}(\lambda_8 v_4 - \epsilon\tilde{G}^V_4) \\ bv_1 + \hat{\mathbf{n}}^T(\lambda_9\tilde{\mathbf{u}} - \epsilon\tilde{G}^V_{1\dots 3}) - \frac{a\lambda_9}{\mu_2^2}(\lambda_9 v_4 - \epsilon\tilde{G}^V_4) \end{pmatrix}. \tag{46}$$

Finally, we can split $\tilde{w}$ into $\tilde{w}^+$ and $\tilde{w}^-$ as before and perform step (v), i.e., supply $\tilde{w}^-$ with boundary conditions to obtain a well-posed system.

Remark 12. There are two more cases where $u_n \neq 0$. Those are tangential flows with $|M_n| = 1$. To find the eigenvalues of $\mathbf{A}$ directly for $M_n = 1, -1$ is equally difficult as the general case, and we did not find roots in closed form.

3.6. Curvilinear coordinates. Until now, we have analyzed well-posed boundary conditions for the Navier–Stokes equations in a Cartesian coordinate system and a general domain. Considering numerical computations, that derivation suffices when using unstructured methods such as finite volume schemes. However, for structured methods, such as finite difference schemes, the Navier–Stokes equations are usually expressed in a curvilinear coordinate system. We have included a brief analysis in Appendix C showing that the Cartesian results are directly applicable in the curvilinear case through metric transformations.

4. Conclusions. We have proposed a step-by-step procedure to analyze a general time dependent partial differential equation in terms of well-posedness including boundary conditions. The procedure applied to the Euler equations results in the well-known characteristic boundary conditions. In this article we have applied the procedure to the three-dimensional Navier–Stokes equations on a general domain and obtained a novel set of well-posed boundary conditions.

Appendix A. The two-dimensional matrices. With very few comments and leaving out most details, we show the differences of the derivation in section 3 for the two-dimensional case.

With

$$B_{21} = B_{12} = \frac{B_{xy}}{2},$$

the symmetrized equations are

$$\tilde{u}_t + A_1\tilde{u}_x + A_2\tilde{u}_y = \epsilon(B_{11}\tilde{u}_{xx} + B_{22}\tilde{u}_{yy} + B_{12}\tilde{u}_{xy} + B_{21}\tilde{u}_{yx}).$$

The matrices are obtained by deleting the row and column referring to the u_3 component (see [10]). We introduce

$$\tilde{F}_v = B_{11}\tilde{u}_x + B_{21}\tilde{u}_y, \quad \tilde{G}_v = B_{22}\tilde{u}_y + B_{12}\tilde{u}_x,$$

such that

$$\frac{1}{2}\|\tilde{u}\|_t^2 + \oint_{\partial D} \frac{1}{2}\begin{pmatrix} \tilde{u} \\ \tilde{F}^V \end{pmatrix}^T \begin{pmatrix} A_1 n_1 + A_2 n_2 & -\epsilon I_4 \\ -\epsilon I_4 & 0_4 \end{pmatrix}\begin{pmatrix} \tilde{u} \\ \tilde{F}^V \end{pmatrix} = DI,$$

where $\hat{\mathbf{n}} = [n_1, n_2]$, $ds = \sqrt{dx^2 + dy^2}$, and $\tilde{F}^V = \tilde{F}_v n_1 + \tilde{G}_v n_2$.

By deleting the first component of $\tilde{F}^V$ yielding $\tilde{G}^V$, the matrix is reduced from an 8-by-8 matrix to a 7-by-7 matrix. With $\mathbf{u} = (u_1, u_2)$, we obtain

$$\begin{pmatrix} \tilde{u} \\ \tilde{F}^V \end{pmatrix}^T \begin{pmatrix} A_1 n_1 + A_2 n_2 & -\epsilon I_4 \\ -\epsilon I_4 & 0_4 \end{pmatrix}\begin{pmatrix} \tilde{u} \\ \tilde{F}^V \end{pmatrix} = \begin{pmatrix} \tilde{u} \\ \tilde{G}^V \end{pmatrix}^T \mathbf{A} \begin{pmatrix} \tilde{u} \\ \tilde{G}^V \end{pmatrix},$$

where

$$\mathbf{A} = \begin{pmatrix} \mathbf{u}\cdot\hat{\mathbf{n}} & bn_1 & bn_2 & 0 & 0 & 0 & 0 \\ bn_1 & \mathbf{u}\cdot\hat{\mathbf{n}} & 0 & an_1 & -\epsilon & 0 & 0 \\ bn_2 & 0 & \mathbf{u}\cdot\hat{\mathbf{n}} & an_2 & 0 & -\epsilon & 0 \\ 0 & an_1 & an_2 & \mathbf{u}\cdot\hat{\mathbf{n}} & 0 & 0 & -\epsilon \\ 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\epsilon & 0 & 0 & 0 \end{pmatrix}$$
$$= \begin{pmatrix} A_{11} & A_{12} & 0_{14} \\ A_{21} & A_{22} & -\epsilon I_4 \\ 0_{41} & -\epsilon I_4 & 0_4 \end{pmatrix}.$$

The rotation of $\mathbf{A}$ is precisely similar,

$$\mathbf{R}^T\mathbf{A}\mathbf{R} = \begin{pmatrix} 1 & 0_{13} & 0_{13} \\ \bar{\alpha}^T & I_3 & 0_3 \\ \bar{\beta}^T & \bar{\gamma}^T & I_3 \end{pmatrix}\begin{pmatrix} A_{11} & A_{12} & 0_{13} \\ A_{21} & A_{22} & -\epsilon I_3 \\ 0_{31} & -\epsilon I_3 & 0_3 \end{pmatrix}\begin{pmatrix} 1 & \bar{\alpha} & \bar{\beta} \\ 0_{31} & I_3 & \bar{\gamma} \\ 0_{31} & 0_3 & I_3 \end{pmatrix}$$
$$= \begin{pmatrix} E_{11} & E_{12} & E_{13} \\ E_{21} & E_{22} & E_{23} \\ E_{31} & E_{32} & E_{33} \end{pmatrix} = \mathbf{E}.$$

The same solution is obtained,

$$\bar{\alpha} = -A_{11}^{-1}A_{12}, \quad \bar{\beta} = A_{11}^{-1}A_{12}E_{22}^{-1}, \quad \bar{\gamma} = -\epsilon E_{22}^{-1},$$

$$\mathbf{E} = \begin{pmatrix} A_{11} & 0_{14} & 0_{14} \\ 0_{41} & E_{22} & 0_4 \\ 0_{41} & 0_4 & -\epsilon^2 E_{22}^{-1} \end{pmatrix}, \qquad E_{22} = A_{22} - A_{21}A_{11}^{-1}A_{12}.$$

The first eigenvalue of $\mathbf{E}$ is $\lambda_1 = A_{11} = u_n$, and the others are given by the eigenvalues of E_{22},

$$E_{22} = \begin{pmatrix} -\frac{b^2 n_1^2}{u_n} + u_n & -\frac{b^2 n_1 n_2}{u_n} & a n_1 \\ -\frac{b^2 n_1 n_2}{u_n} & -\frac{b^2 n_2^2}{u_n} + u_n & a n_2 \\ a n_1 & a n_2 & u_n \end{pmatrix},$$

$$\lambda_{2,3} = \frac{-b^2 + 2u_n^2 \pm \sqrt{b^4 + 4a^2 u_n^2}}{2u_n}, \quad \lambda_4 = u_n,$$

where $n_1^2 + n_2^2 = 1$ and $u_n = \mathbf{u} \cdot \hat{\mathbf{n}}$. These can be simplified similarly as for the three-dimensional case.

The eigenvectors $Y = (y_2, y_3, y_4)$ are

$$y_2 = \begin{pmatrix} n_1 \\ n_2 \\ \frac{-\lambda_3 + u_n}{a} \end{pmatrix}, \quad y_3 = \begin{pmatrix} n_1 \\ n_2 \\ \frac{-\lambda_2 + u_n}{a} \end{pmatrix}, \quad y_4 = \begin{pmatrix} -n_2, \\ n_1 \\ 0 \end{pmatrix}. \tag{47}$$

Introduce the block matrix, $X = \operatorname{diag}(1, Y, Y)$, such that $X^T \mathbf{E} X = \Lambda$, where $\Lambda = \operatorname{diag}(u_n, \Lambda, -\epsilon^2\Lambda)$. Let $\tilde{v} = (\tilde{u}^T, (\tilde{G}^V)^T)^T$; then $\tilde{v}^T \mathbf{A} \tilde{v} = \tilde{w}^T \Lambda \tilde{w}$, where $\tilde{w} = X^T R^{-1} \tilde{v} = M^{-1}\tilde{v}$ and $\Lambda = M^T \mathbf{A} M$. The matrices are

$$R^{-1} = \begin{pmatrix} 1 & -\bar{\alpha} & 0_{13} \\ 0_{31} & I_3 & -\bar{\gamma} \\ 0_{31} & 0_3 & I_3 \end{pmatrix}, \qquad M^{-1} = \begin{pmatrix} 1 & -\bar{\alpha} & 0_{14} \\ 0_{41} & Y^T & \epsilon\Lambda^{-1}Y^T \\ 0_{41} & 0_4 & Y^T \end{pmatrix},$$

where

$$\Lambda^{-}Y^T = \begin{pmatrix} \lambda_2^{-1} y_2 \\ \lambda_3^{-1} y_3 \\ \lambda_4^{-1} y_4 \end{pmatrix}, \quad \bar{\alpha} = \left(-\frac{b}{u_n}\hat{\mathbf{n}}, 0\right), \quad M = \begin{pmatrix} 1 & \bar{\alpha}Y & \bar{\alpha}\Lambda^{-1}Y^T \\ 0_{31} & Y & -\epsilon Y \Lambda \\ 0_{31} & 0_3 & Y \end{pmatrix}.$$

In two dimensions, $\tilde{v}$ is

$$\tilde{v} = \left(\frac{b}{\rho}\frac{\tilde{\rho}}{\rho}, \tilde{u}_1, \tilde{u}_2, -\frac{b}{\sqrt{\gamma - 1}}\tilde{\rho} + \frac{1}{\rho a}\tilde{p}, \tilde{G}_1^V, \tilde{G}_2^V, \tilde{G}_3^V\right).$$

Then,

$$\tilde{w} = M^{-1}\tilde{v} = \begin{pmatrix} \tilde{v}_1 - \bar{\alpha} \cdot \tilde{v}_{2\ldots4} \\ y_2^T(\tilde{v}_{2\ldots4} - \epsilon\lambda_2^{-1}\tilde{G}^V) \\ y_3^T(\tilde{v}_{2\ldots4} - \epsilon\lambda_3^{-1}\tilde{G}^V) \\ y_4^T(\tilde{v}_{2\ldots4} - \epsilon\lambda_4^{-1}\tilde{G}^V) \\ y_2^T\tilde{G}^V \\ y_3^T\tilde{G}^V \\ y_4^T\tilde{G}^V \end{pmatrix}. \tag{48}$$

Appendix B. Diagonalization with $\boldsymbol{u_n = 0}$. Consider

$$\mathbf{A}e = \lambda e, \tag{49}$$

where $\mathbf{A}$ is given by (44), repeated here for convenience,

$$\mathbf{A} = \begin{pmatrix} 0 & bn_1 & bn_2 & bn_3 & 0 & 0 & 0 & 0 & 0 \\ bn_1 & 0 & 0 & 0 & an_1 & -\epsilon & 0 & 0 & 0 \\ bn_2 & 0 & 0 & 0 & an_2 & 0 & -\epsilon & 0 & 0 \\ bn_3 & 0 & 0 & 0 & an_2 & 0 & 0 & -\epsilon & 0 \\ 0 & an_1 & an_2 & an_3 & 0 & 0 & 0 & 0 & -\epsilon \\ 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -\epsilon & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{50}$$

The structure of $\mathbf{A}$ suggests the following ansatz:

$$e_1 = (0, m_1, m_2, m_3, 0, m_1, m_2, m_3, 0)^T, \tag{51}$$

$$e_2 = (0, m_1, m_2, m_3, 0, -m_1, -m_2, -m_3, 0)^T, \tag{52}$$

$$e_3 = (m_4, m_5n_1, m_5n_2, m_5n_3, m_6, m_7n_1, m_7n_2, m_7n_3, m_8). \tag{53}$$

We will use the notation $\mathbf{m} = (m_1, m_2, m_3)^T$. With (51), equation (49) becomes

$$\begin{pmatrix} b\mathbf{\hat{n}^T m} \\ -\epsilon m_1 \\ -\epsilon m_2 \\ -\epsilon m_3 \\ a\mathbf{\hat{n}^T m} \\ -\epsilon m_1 \\ -\epsilon m_2 \\ -\epsilon m_3 \\ 0 \end{pmatrix} = \lambda \begin{pmatrix} 0 \\ m_1 \\ m_2 \\ m_3 \\ 0 \\ m_1 \\ m_2 \\ m_3 \\ 0 \end{pmatrix}. \tag{54}$$

With $\lambda = \lambda_1$ and $\mathbf{m} = \mathbf{m}_1$, the following choice satisfies the above equation, $\mathbf{\hat{n}}^T\mathbf{m_1} = 0$, and $\lambda_1 = -\epsilon$. Further, we may also choose a second solution $\mathbf{m} = \mathbf{m}_2$ and $\lambda_2 = -\epsilon$ such that $\mathbf{\hat{n}}^T\mathbf{m_2} = 0$ and $\mathbf{m_2}^T\mathbf{m_1} = 0$. Similarly, ansatz (52) yields

$$\lambda_3 = \epsilon, \quad \mathbf{\hat{n}}^T\mathbf{m_3} = 0, \tag{55}$$

$$\lambda_4 = \epsilon, \quad \mathbf{\hat{n}}^T\mathbf{m_4} = 0, \quad \mathbf{m_3}^T\mathbf{m_4} = 0. \tag{56}$$

In fact, we can let $\mathbf{m}_1 = \mathbf{m}_3$ and $\mathbf{m}_2 = \mathbf{m}_4$. It is obvious that the vectors (51) and (52) will be orthogonal, and, by definition, they are orthogonal to (53). So far, four eigenvalues and eigenvectors out of nine are derived when we turn to the last ansatz (53). In this case (49) becomes

$$\begin{pmatrix} m_5b \\ (bm_4 + am_6 - \epsilon m_7)n_1 \\ (bm_4 + am_6 - \epsilon m_7)n_2 \\ (bm_4 + am_6 - \epsilon m_7)n_3 \\ am_5 - \epsilon m_8 \\ -\epsilon m_5n_1 \\ -\epsilon m_5n_2 \\ -\epsilon m_5n_3 \\ -\epsilon m_6 \end{pmatrix} = \lambda \begin{pmatrix} m_4 \\ m_5n_1 \\ m_5n_2 \\ m_5n_3 \\ m_6 \\ m_7n_1 \\ m_7n_2 \\ m_7n_3 \\ m_8 \end{pmatrix}, \tag{57}$$

where $n_1^2+n_2^2+n_3^3$ has been used. Note that the above system of equations reduces to only five equations by the choice of the eigenvector. Further, we have five unknowns, including λ. (One of the unknowns of the eigenvector drops out since it should only enter as a scaling.) We have

$$m_5 b = \lambda m_4, \tag{58}$$

$$b m_4 + a m_6 - \epsilon m_7 = \lambda m_5, \tag{59}$$

$$a m_5 - \epsilon m_8 = \lambda m_6, \tag{60}$$

$$-\epsilon m_5 = \lambda m_7, \tag{61}$$

$$-\epsilon m_6 = \lambda m_8. \tag{62}$$

In this case it turns out that the ansatz was satisfactory since five solutions to the system (58)–(62) exist.

The case we examine is the marginal case with $u_n = 0$, which leads us to expect one eigenvalue to be zero. Thusly, with $\lambda_5 = 0$ the following eigenvector is obtained:

$$e_5 = \left(1, 0, 0, 0, 0, \frac{b}{\epsilon} n_1, \frac{b}{\epsilon} n_2, \frac{b}{\epsilon} n_3, 0\right)^T. \tag{63}$$

Next, we solve full system (58)–(62) without assumptions on the solution. With $\mu = \epsilon^2 - \lambda^2$, a second degree equation in μ is obtained,

$$\mu^2 + (b + a^2)\mu - a^2\epsilon^2 = 0, \tag{64}$$

with the solutions

$$\mu_{1,2} = -\frac{b + a^2}{2} \pm \sqrt{\frac{(b + a^2)^2}{4} + a^2\epsilon^2} = -\frac{c^2}{2} \pm \sqrt{\frac{c^4}{4} + a^2\epsilon^2} \tag{65}$$

such that $\lambda_{6,7} = \pm\sqrt{\epsilon^2 - \mu_1}$ and $\lambda_{8,9} = \pm\sqrt{\epsilon^2 - \mu_2}$. For any of these λ's the eigenvector is given by

$$e = \begin{pmatrix} b \\ \lambda n_1 \\ \lambda n_2 \\ \lambda n_3 \\ -\frac{a\lambda^2}{\epsilon^2 - \lambda^2} \\ -\epsilon n_1 \\ -\epsilon n_2 \\ -\epsilon n_3 \\ \frac{\epsilon a \lambda}{\epsilon^2 - \lambda^2} \end{pmatrix}. \tag{66}$$

Next, we have to show that the different eigenvectors obtained from (66) are orthogonal to each other. We distinguish between two cases: 1. any of the eigenvalues derived from μ_1, denoted by ξ_1, and another eigenvalue ξ_2 derived from μ_2; 2. both eigenvalues $\xi_{1,2}$ derived from the same μ.

The scalar product is

$$e(\xi_1)^T \cdot e(\xi_2) = b + \xi_1\xi_2 + \frac{a^2\xi_1^2\xi_2^2}{(\epsilon^2 - \xi_1^2)(\epsilon^2 - \xi_2^2)} + \epsilon^2 + \frac{\epsilon^2 a^2 \xi_1 \xi_2}{(\epsilon^2 - \xi_1^2)(\epsilon^2 - \xi_2^2)}. \tag{67}$$

Case 1. For a general quadratic equation $x^2+px+q=0$ the roots fulfill $x_1x_2=q$ and $x_1+x_2=-p$. When applied to (64) this implies

$$\mu_1\mu_2=(\epsilon^2-\xi_1^2)(\epsilon^2-\xi_2^2)=-a^2\epsilon^2, \tag{68}$$

$$\mu_1+\mu_2=-(b+a^2). \tag{69}$$

Thus, (67) is

$$\begin{aligned} & b+\xi_1\xi_2-\frac{\xi_1^2\xi_2^2}{\epsilon^2}+\epsilon^2-\xi_1\xi_2 \\ &= b+\epsilon^2+\frac{(\epsilon^2-\mu_1)(\epsilon^2-\mu_2)}{\epsilon^2} \\ &= b+\epsilon^2-(\epsilon^2-(\mu_1+\mu_2)-a^2) \\ &= b-(b+a^2)+a^2=0. \end{aligned} \tag{70}$$

Case 2. In this case the following relations hold:

$$\lambda^2=\xi_1^2=\xi_2^2, \tag{71}$$

$$\lambda=\xi_1=-\xi_2, \tag{72}$$

$$\lambda^2=-\xi_1\xi_2=(\mu-\epsilon^2),$$

$$(\epsilon^2-\xi_{1,2}^2)=\mu. \tag{73}$$

Then (67) becomes, after multiplying by $(\epsilon^2-\lambda^2)^2$,

$$\begin{aligned} & (\epsilon^2-\lambda^2)^2(b-\lambda^2+\epsilon^2)+a^2\lambda^4-\epsilon^2a^2\lambda^2 \\ &= (b-\lambda^2+\epsilon^2)(\epsilon^2-\lambda^2)^2+a^2\lambda^2(\lambda^2-\epsilon^2) \\ &= (\lambda^2-\epsilon^2)((b+(\epsilon-\lambda^2))(\epsilon^2-\lambda^2)+a^2\lambda^2) \\ &= -\mu((b+\mu)\mu+a^2(\mu-\epsilon^2)) \\ &= -\mu(\mu^2+(b+a^2)\mu-a^2\epsilon^2)=0, \end{aligned}$$

where the last equality is due to (64).

One should also normalize these vectors to formally obtain the eigenvectors of the matrix $\mathbf{A}$. With this done, we conclude that in the case of neither inflow nor outflow, the above derivation gives the eigenvalues and eigenvectors of the linearized Navier–Stokes equations in three dimensions.

Appendix C. Curvilinear coordinates.

C.1. Metric relations.

Let x, y, z denote the usual Cartesian coordinates. Consider the following coordinate transformation:

$$\xi=\xi(x,y,z), \quad \eta=\eta(x,y,z), \quad \zeta=\zeta(x,y,z).$$

The Jacobian is defined as

$$\mathbf{J}=\begin{pmatrix} x_\xi & x_\eta & x_\zeta \\ y_\xi & y_\eta & y_\zeta \\ z_\xi & z_\eta & z_\zeta \end{pmatrix}. \tag{74}$$

Let $\bar{x}=(x,y,z)=(x_1,x_2,x_3)$ and $\bar{\xi}=(\xi,\eta,\zeta)=(\xi_1,\xi_2,\xi_3)$. Then we can formally express the Jacobian as $\mathcal{D}_{\bar{\xi}}\bar{x} = \mathbf{J}$. The following relation holds:

$$I = \mathcal{D}_{\bar{x}}\bar{x}(\bar{\xi}) = \mathcal{D}_{\bar{\xi}}\bar{x}\mathcal{D}_{\bar{x}}\bar{\xi}. \tag{75}$$

Hence,

$$\mathbf{J}^{-1} = \mathcal{D}_{\bar{x}}\xi = \begin{pmatrix} \xi_x & \xi_y & \xi_z \\ \eta_x & \eta_y & \eta_z \\ \zeta_x & \zeta_y & \zeta_z \end{pmatrix}. \tag{76}$$

However, $\mathbf{J}^{-1}$ can also be obtained directly by inverting (74),

$$\mathbf{J}^{-1} = \mathcal{D}_{\bar{x}}\xi = \frac{1}{J}\begin{pmatrix} y_\eta z_\zeta - y_\zeta z_\eta & -(x_\eta z_\zeta - x_\zeta z_\eta) & x_\eta y_\zeta - x_\zeta y_\eta \\ -(y_\xi z_\zeta - y_\zeta z_\xi) & x_\xi z_\zeta - x_\zeta z_\xi & -(x_\xi y_\zeta - x_\zeta y_\xi) \\ y_\xi z_\eta - y_\eta z_\xi & -(x_\xi z_\eta - x_\eta z_\xi) & x_\xi y_\eta - x_\eta y_\xi \end{pmatrix}, \tag{77}$$

where J denotes the determinant of the Jacobian. Then (76) and (77) give relations between the different metric coefficients. For example, we note that

$$\begin{aligned} (J\xi_x)_\xi + (J\eta_x)_\eta + (J\zeta_x)_\zeta &= (y_\eta z_\zeta - y_\zeta z_\eta)_\xi - (y_\xi z_\zeta - y_\zeta z_\xi)_\eta + (y_\xi z_\eta - y_\eta z_\xi)_\zeta = 0, \\ (J\xi_y)_\xi + (J\eta_y)_\eta + (J\zeta_y)_\zeta &= -(x_\eta z_\zeta - x_\zeta z_\eta)_\xi + (x_\xi z_\zeta - x_\zeta z_\xi)_\eta - (x_\xi z_\eta - x_\eta z_\xi)_\zeta = 0, \\ (J\xi_z)_\xi + (J\eta_z)_\eta + (J\zeta_z)_\zeta &= (x_\eta y_\zeta - x_\zeta y_\eta)_\xi - (x_\xi y_\zeta - x_\zeta y_\xi)_\eta + (x_\xi y_\eta - x_\eta y_\xi)_\zeta = 0, \end{aligned} \tag{78}$$

which will be used below.

C.2. Curvilinear Navier–Stokes equations. Consider the linearized and symmetrized Navier–Stokes equations (9), restated here for convenience,

$$\begin{aligned} \tilde{u}_t + \quad & (A_1\tilde{u} - \epsilon(B_{11}\tilde{u}_x + B_{12}\tilde{u}_y + B_{13}\tilde{u}_z))_x \\ & + (A_2\tilde{u} - \epsilon(B_{22}\tilde{u}_y + B_{23}\tilde{u}_z + B_{12}\tilde{u}_x))_y \\ & + (A_3\tilde{u} - \epsilon(B_{33}\tilde{u}_z + B_{32}\tilde{u}_y + B_{13}\tilde{u}_x))_z = 0 \end{aligned}$$

or

$$\begin{aligned} \tilde{u}_t + (F^I - \epsilon\tilde{F}_v)_x + (G^I - \epsilon\tilde{G}_v)_y + (H^I - \epsilon\tilde{H}_v)_z \\ = \tilde{u}_t + F_x + G_y + H_z = 0. \end{aligned} \tag{79}$$

Multiply (79) by J and make the change of coordinates,

$$\begin{aligned} 0 &= (J\tilde{u})_t + JF_x + JG_y + JH_z \\ &= (J\tilde{u})_t + J\xi_x F_\xi + J\eta_x F_\eta + J\zeta_x F_\zeta \\ &\quad + J\xi_y G_\xi + J\eta_y G_\eta + J\zeta_y G_\zeta \\ &\quad + J\xi_z H_\xi + J\eta_z H_\eta + J\zeta_z H_\zeta. \end{aligned} \tag{80}$$

Reformulating (80) yields

$$\begin{aligned} (J\tilde{u})_t &+ (J\xi_x F + J\xi_y G + J\xi_z H)_\xi - R_1 \\ &+ (J\eta_x F + J\eta_y G + J\eta_z H)_\eta - R_2 \\ &+ (J\zeta_x F + J\zeta_y G + J\zeta_z H)_\zeta - R_3, \end{aligned}$$

where

$$\begin{aligned}R_1 &= (J\xi_x)_\xi F + (J\xi_y)_\xi G + (J\xi_z)_\xi H,\\ R_2 &= (J\eta_x)_\eta F + (J\eta_y)_\eta G + (J\eta_z)_\eta H,\\ R_3 &= (J\zeta_x)_\zeta F + (J\zeta_y)_\zeta G + (J\zeta_z)_\zeta H.\end{aligned}$$

By using the metric relations in (78), we obtain

$$\begin{aligned}R_1 + R_2 + R_3 = F(&(J\xi_x)_\xi + (J\eta_x)_\eta + (J\zeta_x)_\zeta)\\ + G(&(J\xi_y)_\xi + (J\eta_y)_\eta + (J\zeta_y)_\zeta)\\ + H(&(J\xi_z)_\xi + (J\eta_z)_\eta + (J\zeta_z)_\zeta) = 0.\end{aligned}$$

Define

$$\begin{aligned}\hat{F} &= (J\xi_x F + J\xi_y G + J\xi_z H),\\ \hat{G} &= (J\eta_x F + J\eta_y G + J\eta_z H),\\ \hat{H} &= (J\zeta_x F + J\zeta_y G + J\zeta_z H)\end{aligned}$$

such that

$$0 = (J\tilde{u})_t + JF_x + JG_y + JH_z = (J\tilde{u})_t + \hat{F}_\xi + \hat{G}_\eta + \hat{H}_\zeta. \tag{81}$$

Next, we express the new fluxes in curvilinear coordinates. We obtain

$$\begin{aligned}\hat{F}^I &= (J\xi_x F^I + J\xi_y G^I + J\xi_z H^I) = J(\xi_x A_1 + \xi_y A_2 + \xi_z A_3)u,\\ \hat{G}^I &= (J\eta_x F^I + J\eta_y G^I + J\eta_z H^I) = J(\eta_x A_1 + \eta_y A_2 + \eta_z A_3)u,\\ \hat{H}^I &= (J\zeta_x F^I + J\zeta_y G^I + J\zeta_z H^I) = J(\zeta_x A_1 + \zeta_y A_2 + \zeta_z A_3)u,\end{aligned} \tag{82}$$

and

$$\begin{aligned}\hat{F}_v &= (J\xi_x \tilde{F}_v + J\xi_y \tilde{G}_v + J\xi_z \tilde{H}_v),\\ \hat{G}_v &= (J\eta_x \tilde{F}_v + J\eta_y \tilde{G}_v + J\eta_z \tilde{H}_v),\\ \hat{H}_v &= (J\zeta_x \tilde{F}_v + J\zeta_y \tilde{G}_v + J\zeta_z \tilde{H}_v),\end{aligned} \tag{83}$$

where

$$\begin{aligned}\tilde{F}_v &= \tilde{B}_{11}\tilde{u}_\xi + \tilde{B}_{12}\tilde{u}_\eta + \tilde{B}_{13}\tilde{u}_\zeta,\\ \tilde{G}_v &= \tilde{B}_{22}\tilde{u}_\eta + \tilde{B}_{23}\tilde{u}_\zeta + \tilde{B}_{12}\tilde{u}_\xi,\\ \tilde{H}_v &= \tilde{B}_{33}\tilde{u}_\zeta + \tilde{B}_{32}\tilde{u}_\eta + \tilde{B}_{13}\tilde{u}_\xi,\end{aligned}$$

and

$$\begin{aligned}\tilde{B}_{11} &= B_{11}\xi_x + B_{12}\xi_y + B_{13}\xi_z, & \tilde{B}_{12} &= B_{11}\eta_x + B_{12}\eta_y + B_{13}\eta_z,\\ \tilde{B}_{13} &= B_{11}\zeta_x + B_{12}\zeta_y + B_{13}\zeta_z, & \tilde{B}_{22} &= B_{22}\xi_y + B_{23}\xi_z + B_{12}\xi_x,\\ \tilde{B}_{23} &= B_{22}\eta_y + B_{23}\eta_z + B_{12}\eta_x, & \tilde{B}_{21} &= B_{22}\zeta_y + B_{23}\zeta_z + B_{12}\zeta_x,\\ \tilde{B}_{33} &= B_{33}\xi_z + B_{32}\xi_y + B_{13}\xi_x, & \tilde{B}_{32} &= B_{33}\eta_z + B_{32}\eta_y + B_{13}\eta_x,\\ \tilde{B}_{31} &= B_{33}\zeta_z + B_{32}\zeta_y + B_{13}\zeta_x.\end{aligned}$$

C.3. Energy estimate. Next, we turn to the well-posedness of (81). We apply the energy method and derive the boundary terms. Our aim is to relate the boundary terms in curvilinear coordinates to those derived in $\bar{x}$-space.

First we note that

$$dxdydz = Jd\xi d\eta d\zeta. \tag{84}$$

Further, we use the notation $D_{\bar{\xi}}$ in $\bar{\xi}$-space for the image of the domain $D_{\bar{x}}$ in $\bar{x}$-space.

Apply the energy method to (81) to obtain

$$\begin{aligned} 0 = \int_{D_{\bar{\xi}}} \tilde{u}^T \tilde{u}_t J d\xi d\eta d\zeta + \int_{D_{\bar{\xi}}} \tilde{u}^T (\hat{F}^I_\xi + \hat{G}^I_\eta + \hat{H}^I_\zeta) d\xi d\eta d\zeta \\ -\epsilon \int_{D_{\bar{\xi}}} \tilde{u}^T ((\hat{F}_v)_\xi + (\hat{G}_v)_\eta + (\hat{H}_v)_\zeta) d\xi d\eta d\zeta = \int_{D_{\bar{x}}} \tilde{u}^T \tilde{u}_t dxdydz + I_1 - \epsilon I_2, \end{aligned} \tag{85}$$

$$\begin{aligned} I_2 &= \int_{D_{\bar{\xi}}} (\tilde{u}^T \hat{F}_v)_\xi + (\tilde{u}^T \hat{G}_v)_\eta + (\tilde{u}^T \hat{H}_v)_\zeta d\xi d\eta d\zeta \\ &\quad - \int_{D_{\bar{\xi}}} \tilde{u}^T_\xi (\hat{F}_v)_\xi + \tilde{u}^T_\eta (\hat{G}_v)_\eta + \tilde{u}^T_\zeta (\hat{H}_v)_\zeta d\xi d\eta d\zeta \\ &= \int_{D_{\bar{\xi}}} (\tilde{u}^T \hat{F}_v)_\xi + (\tilde{u}^T \hat{G}_v)_\eta + (\tilde{u}^T \hat{H}_v)_\zeta d\xi d\eta d\zeta - DI \\ &= \oint_{\Gamma_{\bar{\xi}}} (\tilde{u}^T \hat{F}_v, \tilde{u}^T \hat{G}_v, \tilde{u}^T \hat{H}_v) \cdot \mathbf{n}_{\bar{\xi}} ds_{\bar{\xi}} - DI \\ &= \oint_{\Gamma_{\bar{\xi}}} \tilde{u}^T \hat{F}^V ds_{\bar{\xi}} - DI, \end{aligned} \tag{86}$$

where $\mathbf{n}_{\bar{\xi}} = (n_\xi, n_\eta, n_\zeta)$ and $ds_{\bar{\xi}}$ denote the outward-pointing normal and surface element in $\bar{\xi}$-space, respectively. Further, $\hat{F}^V = \hat{F}_v n_\xi + \hat{G}_v n_\eta + \hat{H}_v n_\zeta$. DI denotes a dissipative term and is equal to DI defined in subsection 3.2.

$$\begin{aligned} I_1 &= \int_{D_{\bar{\xi}}} \tilde{u}^T (\hat{F}^I_\xi + \hat{G}^I_\eta + \hat{H}^I_\zeta) d\xi d\eta d\zeta \\ &= \int_{D_{\bar{\xi}}} \tilde{u}^T (J\xi_x A_1 \tilde{u} + J\xi_y A_2 \tilde{u} + J\xi_z A_3 \tilde{u})_\xi \\ &\quad + \tilde{u}^T (J\eta_x A_1 \tilde{u} + J\eta_y A_2 \tilde{u} + J\eta_z A_3 \tilde{u})_\eta \\ &\quad + \tilde{u}^T (J\zeta_x A_1 \tilde{u} + J\zeta_y A_2 \tilde{u} + J\zeta_z A_3 \tilde{u})_\zeta d\xi d\eta d\zeta. \end{aligned}$$

Next, we use relations of the type

$$\begin{aligned} \tilde{u}^T (J\xi_x A_1 \tilde{u})_\xi &= (J\xi_x)_\xi \tilde{u}^T A_1 \tilde{u} + (J\xi_x) \left(\frac{1}{2} \tilde{u}^T A_1 \tilde{u}\right)_\xi \\ &= (J\xi_x)_\xi \tilde{u}^T A_1 \tilde{u} + \left(J\xi_x \frac{1}{2} \tilde{u}^T A_1 \tilde{u}\right)_\xi - (J\xi_x)_\xi \left(\frac{1}{2} \tilde{u}^T A_1 \tilde{u}\right) \\ &= \left(J\xi_x \frac{1}{2} \tilde{u}^T A_1 \tilde{u}\right)_\xi + (J\xi_x)_\xi \left(\frac{1}{2} \tilde{u}^T A_1 \tilde{u}\right) \end{aligned}$$

to obtain

$$\begin{aligned} I_1 = \int_{D_{\bar{\xi}}} & \left(J\xi_x \frac{1}{2}\tilde{u}^T A_1 \tilde{u}\right)_\xi + \left(J\xi_y \frac{1}{2}\tilde{u}^T A_2 \tilde{u}\right)_\xi + \left(J\xi_z \frac{1}{2}\tilde{u}^T A_3 \tilde{u}\right)_\xi \\ & + \left(J\eta_x \frac{1}{2}\tilde{u}^T A_1 \tilde{u}\right)_\eta + \left(J\eta_y \frac{1}{2}\tilde{u}^T A_2 \tilde{u}\right)_\eta + \left(J\eta_z \frac{1}{2}\tilde{u}^T A_3 \tilde{u}\right)_\eta \\ & + \left(J\zeta_x \frac{1}{2}\tilde{u}^T A_1 \tilde{u}\right)_\zeta + \left(J\zeta_y \frac{1}{2}\tilde{u}^T A_2 \tilde{u}\right)_\zeta + \left(J\zeta_z \frac{1}{2}\tilde{u}^T A_3 \tilde{u}\right)_\zeta \\ & + \frac{1}{2}\tilde{u}^T A_1 \tilde{u}(J\xi_x)_\xi + \frac{1}{2}\tilde{u}^T A_1 \tilde{u}(J\eta_x)_\eta + \frac{1}{2}\tilde{u}^T A_1 \tilde{u}(J\zeta_x)_\zeta \\ & + \frac{1}{2}\tilde{u}^T A_2 \tilde{u}(J\xi_y)_\xi + \frac{1}{2}\tilde{u}^T A_2 \tilde{u}(J\eta_y)_\eta + \frac{1}{2}\tilde{u}^T A_2 \tilde{u}(J\zeta_y)_\zeta \\ & + \frac{1}{2}\tilde{u}^T A_3 \tilde{u}(J\xi_z)_\xi + \frac{1}{2}\tilde{u}^T A_3 \tilde{u}(J\eta_z)_\eta + \frac{1}{2}\tilde{u}^T A_3 \tilde{u}(J\zeta_z)_\zeta \, d\xi d\eta d\zeta. \end{aligned} \tag{87}$$

Hence, by using (78), the last three rows of (87) are identically zero:

$$I_1 = \oint_{\Gamma_{\bar{\xi}}} \frac{1}{2}(\tilde{u}^T(\hat{A}_1)\tilde{u}, \tilde{u}^T(\hat{A}_2)\tilde{u}, \tilde{u}^T(\hat{A}_3)\tilde{u}) \cdot \mathbf{n}_{\bar{\xi}} ds_{\bar{\xi}}, \tag{88}$$

where

$$\begin{aligned} \hat{A}_1 &= (A_1 J\xi_x + A_2 J\xi_y + A_3 J\xi_z), \\ \hat{A}_2 &= (A_1 J\eta_x + A_2 J\eta_y + A_3 J\eta_z), \\ \hat{A}_3 &= (A_1 J\zeta_x + A_2 J\zeta_y + A_3 J\zeta_z). \end{aligned}$$

By inserting (86) and (88) into (85), we obtain

$$\begin{aligned} & 2\int_{D_{\bar{x}}} \tilde{u}^T \tilde{u}_t dxdydz \\ & + \oint_{\Gamma_{\bar{\xi}}} (\tilde{u}^T(\hat{A}_1)\tilde{u}, \tilde{u}^T(\hat{A}_2)\tilde{u}, \tilde{u}^T(\hat{A}_3)\tilde{u}) \cdot \mathbf{n}_{\bar{\xi}} ds_{\bar{\xi}} - \epsilon\left(\oint_{\Gamma_{\bar{\xi}}} 2\tilde{u}^T \hat{F}^V ds_{\bar{\xi}} - DI\right) \\ & = \|\tilde{u}\|_t^2 + \oint_{\Gamma_{\bar{\xi}}} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \begin{pmatrix} (\hat{A}_1, \hat{A}_2, \hat{A}_3) \cdot \mathbf{n}_{\bar{\xi}} & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} - DI \\ & = \|\tilde{u}\|_t^2 + \oint_{\Gamma_{\bar{\xi}}} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \hat{\mathbf{A}} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} - DI = 0. \end{aligned} \tag{89}$$

The form (89) is completely similar to the one in the $\bar{x}$-system. As mentioned earlier, the domain in $\bar{\xi}$-space is a cube. Hence, $\mathbf{n}_{\bar{\xi}}$ is particularly simple. It is a unit vector in the coordinate directions, $\pm e_\xi, \pm e_\eta, \pm e_\zeta$, on the boundary of the computational domain, $0 \leq \xi \leq 1$, $0 \leq \eta \leq 1$, $0 \leq \zeta \leq 1$. The full formulation for the cube is

$$\begin{aligned}
\|\tilde{u}\|_t^2 - & \int_{\xi=0} \begin{pmatrix} \tilde{u} \\ \hat{\mathbf{F}}_{\mathbf{v}} \end{pmatrix} \begin{pmatrix} \hat{A}_1 & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} \\
& + \int_{\xi=1} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \begin{pmatrix} \hat{A}_1 & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} \\
& - \int_{\eta=0} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \begin{pmatrix} \hat{A}_2 & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} \\
& + \int_{\eta=1} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \begin{pmatrix} \hat{A}_2 & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} \\
& - \int_{\zeta=0} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \begin{pmatrix} \hat{A}_3 & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} \\
& + \int_{\zeta=1} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \begin{pmatrix} \hat{A}_3 & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} = DI.
\end{aligned} \tag{90}$$

Note that $ds_{\bar{\xi}}$ is different in the different coordinate directions. As a last step we will express one of the integrals in (90) in $\bar{x}$- space. Consider, for example,

$$\begin{aligned}
& - \int_{\xi=0} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \begin{pmatrix} \hat{A}_1 & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} \\
&= \int_{\xi=0} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} \begin{pmatrix} -A_1 J\xi_x - A_2 J\xi_y - A_3 J\xi_z & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \hat{F}^V \end{pmatrix} ds_{\bar{\xi}} \\
&= \int_{\xi=0} \begin{pmatrix} \tilde{u} \\ \frac{\hat{F}^V}{JT_1} \end{pmatrix} \begin{pmatrix} -A_1 \frac{\xi_x}{T_1} - A_2 \frac{\xi_y}{T_1} - A_3 \frac{\xi_z}{T_1} & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \frac{\hat{F}^V}{JT_1} \end{pmatrix} JT_1 ds_{\bar{\xi}} \\
&= \int_{\xi=0} \begin{pmatrix} \tilde{u} \\ \frac{\hat{F}^V}{JT_1} \end{pmatrix} \begin{pmatrix} A_1 n_1 + A_2 n_2 + A_3 n_3 & -\epsilon I \\ -\epsilon I & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \frac{\hat{F}^V}{JT_1} \end{pmatrix} JT_1 ds_{\bar{\xi}},
\end{aligned} \tag{91}$$

where $T_1 = \sqrt{(\xi_x)^2 + (\xi_y)^2 + (\xi_z)^2}$ and $n_1^2 + n_2^2 + n_3^2 = 1$. In fact, (n_1, n_2, n_3) is equal to the normal in the $\bar{x}$- system. This is easily seen by the following. Denote by $\mathbf{r} = (x, y, z)$ a position vector in space. The unnormalized normal vector at $\xi = 0$ is

$$\begin{aligned}
& \frac{\partial \mathbf{r}}{\partial \eta} \times \frac{\partial \mathbf{r}}{\partial \zeta} = (x_\eta, y_\eta, z_\eta) \times (x_\zeta, y_\zeta, z_\zeta) \\
&= (y_\eta z_\zeta - z_\eta y_\zeta, -(x_\eta z_\zeta - z_\eta x_\zeta), x_\eta y_\zeta - y_\eta x_\zeta) = JT_1(n_1, n_2, n_3),
\end{aligned} \tag{92}$$

where (76) and (77) have been used. Hence the matrices appearing in (91) and (23) are equal. Next, we will show that the vectors in (91) and (23) are also equal. We have

$$\begin{aligned}
\frac{\hat{F}^V}{JT_1} &= \frac{\hat{F}_v \cdot 1 + \hat{G}_v \cdot 0 + \hat{H}_v \cdot 0}{JT_1} = \frac{\hat{F}_v}{JT_1} \\
&= \frac{(\xi_x \tilde{F}_v + \xi_y \tilde{G}_v + \xi_z \tilde{H}_v)}{T_1} = \tilde{F}_v n_1 + \tilde{G}_v n_2 + \tilde{H}_v n_3 = \tilde{F}^V.
\end{aligned}$$

At last, we find

$$ds_{\bar{x}} = \left| \frac{\partial \mathbf{r}}{\partial \eta} \times \frac{\partial \mathbf{r}}{\partial \zeta} \right| ds_{\bar{\xi}} = JT_1 ds_{\bar{\xi}}, \tag{93}$$

implying that (91) and (23) are equal.

The other boundaries can be treated similarly. To summarize, we have shown that the relations in $\bar{x}$-space are completely equivalent to those in $\bar{\xi}$-space.

SEQUENTIAL CONTROL VARIATES FOR FUNCTIONALS OF MARKOV PROCESSES*

EMMANUEL GOBET[†] AND SYLVAIN MAIRE[‡]

Abstract. Using a sequential control variates algorithm, we compute Monte Carlo approximations of solutions of linear partial differential equations connected to linear Markov processes by the Feynman–Kac formula. It includes diffusion processes with or without absorbing/reflecting boundary and jump processes. We prove that the bias and the variance decrease geometrically with the number of steps of our algorithm. Numerical examples show the efficiency of the method on elliptic and parabolic problems.

Key words. sequential Monte Carlo, Feynman–Kac formula, variance reduction

1. Introduction.

We are concerned with the numerical evaluation of $\mathbf{E}(\Psi(X_s : s \geq t)|X_t = x)$, where $(X_t)_t$ is a Markov process (with linear dynamics) and where Ψ belongs to a class of functionals related to Feynman–Kac representations. These issues arise, for example, in physics in the computations of the solution of diffusion equations (see [CDL$^+$89]), or in finance in the pricing of European options (see [DG95] and the references therein). Monte Carlo methods are usually used to evaluate these expectations for high-dimensional problems or when the functionals are complex. They give a rather poor approximation because of a slow convergence as $\sigma/\sqrt{M}$, M being the number of simulations and σ^2 the relative variance. A better accuracy can nevertheless be reached by using relevant variance-reduction tools like, for instance, the control variates method or importance sampling [Hal70, New94]. One of the most performing tools is the sequential Monte Carlo approach which consists in using iteratively these variance-reduction ideas [Hal62, Hal70, Boo89]. Using, respectively, importance sampling and control variates, this approach has been recently developed in [BCP00] for Markov chains and in [Mai03] for the numerical integration of multivariate smooth functions. We have introduced in [GM04] a sequential Monte Carlo method to solve the Poisson equation with Dirichlet boundary conditions over square domains. This method was based on Feynman–Kac computations of pointwise solutions combined with a global approximation on Tchebychef polynomials [BM97]. Pointwise solutions were computed using walk-on-spheres (WOS) simulations of stopped Brownian motion, which induces a simulation error due to the absorption layer thickness. We have nevertheless observed a geometric reduction up to a limit of both the simulation error and the variance with the number of steps of the algorithm. The global error was comparable to standard deterministic spectral methods [BM97] while avoiding the resolution of a linear system. Our goal here is twofold:

- to extend the scope of the approach to general Markov processes connected to linear elliptic and parabolic Dirichlet problems;

- to analyze mathematically the convergence of both the bias and the variance. This will be achieved for general discretization schemes for the stochastic processes and also for general global approximations of the solution (not only using Tchebychef polynomials). We also emphasize two major improvements compared to [BCP00] where analogous geometric convergences are proved for Markov chains. First we incorporate in our analysis the influence of the discretization error on the underlying process. Second we allow the global solution not to be in the right approximation space.

In section 2, we make a complete study of the algorithm on elliptic problems with general boundary conditions. At each step of the algorithm, the Monte Carlo computation of $\mathbf{E}(\Psi(X_s : s \geq 0)|X_0 = x)$ at some points x in the domain is required. Then, we build a global approximation using the values at these points. This approximation is used as a control variate at the next step and so on. If the discretization step is small enough, we first prove that the error on the mean value of the global solution reduces geometrically up to a limit directly linked to the approximation error of the exact solution. If furthermore the number of drawings at each step is large enough, we also prove that the variance of the solution reduces in the same way. The proofs of convergence mainly rely on independence properties of the different simulations, on the connection with a linear partial differential equation (PDE), and on the linearity of the functionals with respect to (w.r.t.) the data. This means that the algorithm can be used for Brownian stochastic differential equations (SDEs) with or without absorbing/reflecting boundary, or for Lévy-driven SDEs. The last two sections describe the practical implementation of the algorithm. We first make a discussion on the discretization schemes and on the approximation problems. We then give numerical examples on elliptic and parabolic problems after having precisely studied the speed of convergence of the algorithm on the relative approximation bases. The numerical results confirm the efficiency of the method and the phenomenon of geometric convergence on both the bias and the variance up to a limit.

2. Statement of the problem.

2.1. Elliptic problems. Before giving a general formulation, we prefer listing relevant examples. The Markov process underlying our study is denoted by $X(x) = [X_t(x)]_{t\geq 0}$ and its initial value x belongs to a domain $D \subset \Re^d$. The functionals $\Psi(X_t(x) : t \geq 0) := \Psi(f, g, X(x))$ are related to Feynman–Kac formulas and represented by two continuous functions f and g, respectively defined on $\bar{D}$ and its boundary ∂D. We especially consider the following.

Ex. 1: Brownian SDEs [RY94]: $X_t = x + \int_0^t b(X_s)ds + \int_0^t \sigma(X_s)dW_s$, where W is a Brownian motion. Set $Z_t = e^{-\int_0^t c(X_r)dr}$ and $\tau = \inf\{t \geq 0 : X_t \notin D\}$: we can take $\Psi(f, g, X(x)) = g(X_\tau)Z_\tau - \int_0^\tau f(X_s)Z_s ds$ (provided that $\tau < +\infty$ a.s.). If $D = \Re^d$, we may consider $\Psi(f, g, X(x)) = -\int_0^\infty f(X_s)Z_s ds$ $(g \equiv 0)$ (see [Fre85]).

Ex. 2: SDEs with reflection on ∂D in the nontangential direction γ [Fre85]: $X_t = x+\int_0^t b(X_r)dr+\int_0^t \sigma(X_r)dW_r+\int_0^t \gamma(X_r)d\Lambda_r$, where X_t takes values in $\bar{D}$ and where the so-called local time $(\Lambda_t)_t$ is increasing only when X_t is on ∂D. Set $Z_s = e^{-\int_0^s c(X_r)dr-\int_0^s \lambda(X_r)d\Lambda_r}$: we can take $\Psi(f, g, X(x)) = -\int_0^\infty f(X_s)Z_s ds - \int_0^\infty g(X_s)Z_s d\Lambda_s$.

Ex. 3: Lévy-driven SDEs (see [BL84, GM92]): $X_t = x+\int_0^t b(X_r)dr+\int_0^t \sigma(X_r)dW_r+ \int_0^t \int_{\Re^p} \Upsilon(X_r, z)\mu(dr, dz)$, where μ is a martingale normalized Poisson measure on $\Re^p$, with Lévy measure $m(dz)$. We can take $\Psi(f, g, X(x)) =$

$-\int_0^\tau f(X_s)Z_s ds$ ($g \equiv 0$) where τ and Z are defined as in the Brownian case. Note that reflections could be included [BL84]. Similar situations also occur with transport equations [CDL$^+$89].

The processes above are well defined under, for example, Lipschitz assumptions on their coefficients. For the first two cases, the relative infinitesimal generator is given by $L_0\phi = \sum_{i=1}^d b_i(x)\partial_{x_i}\phi + \frac{1}{2}\sum_{i,j=1}^d [\sigma\sigma^*(x)]_{i,j}\partial^2_{x_i,x_j}\phi$. For the last one, jumps are taken into account by an extra integral kernel. Thus, the associated infinitesimal generator is defined by $L_0\phi(y) + \int_{\Re^p}\left[\phi(y+z) - \phi(y) - z\cdot\nabla\phi(y)\mathbf{1}_{|z|\leq 1}\right]M(y,dz)$ (here the measure $M(y,\cdot)$ is defined by $M(y,A) = m\{z : \Upsilon(y,z) \in A\}$). The key point is that these operators are linear. The goal of this section is to describe how to evaluate efficiently the quantity

$$u(x) = \mathbf{E}\big(\Psi(f,g,X(x))\big). \tag{2.1}$$

We assume the following.

(H1) The process X, the domain D, and the data (f,g) are such that $\Psi(f,g,X(x))$ is a linear map w.r.t. the data (f,g) and that $\mathbf{V}\mathrm{ar}(\Psi(f,g,X(x))) < +\infty$.

This assumption is natural in view of the previous examples. Usually, it imposes restrictions on the domain, on the sign of c arising in Z. See Proposition 4.1 for explicit conditions about absorbed Brownian SDEs. We now assume that u solves an elliptic PDE with appropriate boundary conditions, using the connection between Markov processes and PDEs.

(H2) The process X, the domain D, and the data (f,g) are such that u is a classic[1] solution of

$$\begin{cases}\mathcal{A}u = f & \text{in } D,\\ \mathcal{B}u = g & \text{on } \partial D,\end{cases} \tag{2.2}$$

where $\mathcal{A}$ and $\mathcal{B}$ are second order linear operators.

The domain may be bounded or unbounded in some cases, the diffusion processes may be elliptic or hypo-elliptic. We refer the reader to [Fri75, BL84, Fre85] for details and references. For the first example, we have $\mathcal{A}u = L_0u - cu$ and $\mathcal{B}u = u$ (Dirichlet boundary condition), for the second example $\mathcal{B}u = \nabla_x u.\gamma - \lambda u$ (Neumann boundary condition). Second order operators $\mathcal{B}$ arise with Ventcel's boundary conditions corresponding to processes having a diffusion part on ∂D (see [Cat92]). These different boundary conditions can also be mixed.

2.2. Parabolic problems. The extension to problems with a terminal time T is straightforward. Formally, it is achieved by considering the time-space process $(t, X_t)_t$ in the domain $]0,T[\times D$. Then the operator $\mathcal{A}$ has to replaced by $\partial_t + \mathcal{A}$. In that case, we can take $D = \Re^d$ (this is the so-called Cauchy problem). The coefficients of X and the domain D may also be time-dependent [BL84, Lie96]. The reader can check that the following algorithm and its convergence proof are derived in the same way.

3. Study of the algorithm.

3.1. Description. We now describe our algorithm, which computes iterative approximations $(u_n)_{n\geq 0}$ of the global solution u. These approximations rely on the computations of $\mathbf{E}[\Psi(\tilde{f},\tilde{g},X(x))]$ (for data $\tilde{f}$ and $\tilde{g}$ possibly different from f and g) at some points $(x_i)_{1\leq i\leq N}$.

[1] The regularity of u depends on the type of the boundary condition.

Initialization. We begin with $u_0 \equiv 0$.

***Iteration n*, step 1.** Assume that an approximated solution u_{n-1} of class $C^2(\bar{D})$ is built at stage $n-1$ and that the representation $u_{n-1}(x)=\mathbf{E}(\Psi[\mathcal{A}u_{n-1},\mathcal{B}u_{n-1},X(x)])$ holds (which simply means that u_{n-1} solves (2.2) with $f=\mathcal{A}u_{n-1}$ and $g=\mathcal{B}u_{n-1}$). The idea is to compute a correction $y_n = u - u_{n-1}$ on this approximation. Using (2.1), we have

$$y_n(x) = \mathbf{E}(\Psi[f-\mathcal{A}u_{n-1}, g-\mathcal{B}u_{n-1}, X(x)]). \tag{3.1}$$

In the above equation, the expectation is relative to the law of X and not to the law of u_{n-1}, which can be random. We intend to compute a Monte Carlo approximation of $y_n(x_i)$. For this, we replace the simulations of the random variable $\Psi[f-\mathcal{A}u_{n-1}, g-\mathcal{B}u_{n-1}, X(x_i)]$ by $\Psi[f-\mathcal{A}u_{n-1}, g-\mathcal{B}u_{n-1}, X^{\Delta}(x_i)]$ using a suitable discretization procedure $X^{\Delta}(x_i)$ for the stochastic process $X(x_i)$. For the moment, we prefer keeping quite abstract notations concerning the discretization scheme, since mild assumptions are required (see assumption (H4) below). We just mention that Δ usually represents the discretization parameter which tends to 0 (for instance, for the WOS procedure [Sab91], Δ is the space step; for the Euler procedure [CPS98, Gob01], Δ is the time step). Consequently, $y_n(x_i)$ is approximated by

$$\bar{y}_n(x_i) = \frac{1}{M}\sum_{m=1}^{M} \Psi[f-\mathcal{A}u_{n-1}, g-\mathcal{B}u_{n-1}, X^{\Delta,n,m}(x_i)] \tag{3.2}$$

using M independent simulations of the paths $X^{\Delta,n,m}(x_i)$. They are also generated independently of everything else. In fact, the independence of simulations at different points is not crucial to ensure the convergence of the algorithm. Nevertheless, we think that dependent drawings slow down the convergence of the method and are less adapted to parallel computations.

***Iteration n*, step 2.** In order to build a global approximation y_n based on the values $(\bar{y}_n(x_i))_i$, we use a linear approximation [CHQZ88, BM97]. The linear approximation of a function $w(\cdot)$ at some points $(x_j)_j$ can always be written

$$\mathcal{P}w(x) = \sum_{j=1}^{N} w(x_j)\mathcal{C}_j(x) \tag{3.3}$$

for some functions $(\mathcal{C}_j)_j$. In addition we assume a stability property:

$$\mathcal{P}[\mathcal{P}w] = \mathcal{P}w \quad \text{for any function } w. \tag{3.4}$$

If we use an interpolation, the functions $(\mathcal{C}_j)_j$ simply verify $\mathcal{C}_j(x_i) = \delta_{i,j}$. This is, for example, the case of interpolation in dimension one on Lagrange polynomials $L_j(x) = \frac{\prod_{i\neq j}(x-x_j)}{\prod_{i\neq j}(x_i-x_j)}$. This approximation can also come from a problem of fitting an approximation model $\sum_{k=1}^{K}\alpha_k\varphi_k$ on some basis functions $(\varphi_k)_k$ to the values $(w(x_i))_i$. This leads to a discrete least-squares problem [Bjö96], using the norm associated to the discrete inner product $\langle u,v\rangle_\mu = \sum_{j=1}^{N}\mu_j v(x_j)u(x_j)$ for some positive weights $(\mu_j)_j$, which consists in the minimization of the squared norm $\|\sum_{k=1}^{K}\alpha_k\varphi_k - w\|_\mu^2$. The optimal coefficients $(\alpha_k)_k$ are hence solutions of a linear system $A\alpha = b$ with $A_{ik} =$

$\langle \varphi_i, \varphi_k \rangle_\mu$, $b_k = \langle w, \varphi_k \rangle_\mu$. As $\alpha = A^{-1}b$, we get $\alpha_k = \sum_{i=1}^N A^{-1}_{ik} \sum_{j=1}^N \mu_j \varphi_k(x_j) w(x_j)$ and we are still in a linear form of type (3.3) in letting

$$\mathcal{C}_j(x) = \mu_j \sum_{k=1}^K \sum_{i=1}^N A^{-1}_{ik} \varphi_k(x_j) \varphi_k(x).$$

If the $(\varphi_k)_k$ are, moreover, orthonormal w.r.t. $\langle \cdot, \cdot \rangle_\mu$, then we simply have $\mathcal{C}_j(x) = \mu_j \sum_{k=1}^K \varphi_k(x_j)\varphi_k(x)$. A slightly different situation is the computation of the projection of the function w on orthonormal polynomials $(T_n)_n$ w.r.t. the inner product $\langle u, v \rangle_\nu = \int_{[a,b]} v(x)u(x)\nu(x)dx$, where ν is a positive weight function on the interval $D = [a, b]$. We have $w(x) \simeq \sum_{k=0}^N \alpha_k T_k(x)$ with $\alpha_k = \langle w, T_k \rangle_\nu$ and the points $(x_i)_i$ are used to build quadrature formulas to compute accurately the coefficients $(\alpha_k)_k$. These points are usually chosen as the zeros of T_{N+1} which makes the quadrature formula exact for all polynomials of degree $\leq 2N+1$. Note that in this case, this approximation is equal to the interpolation at the same points. Another possibility is the Gauss–Lobatto formulas where the boundaries of the interval are chosen as quadrature points. In higher dimensions, the approximations are built using tensor products. In any case the approximations are still linear and they will be described in detail in section 4. Note that the stability property (3.4) holds for all of these approximations. Once one of the above approximations has been chosen we just write

$$u_n = u_{n-1} + \mathcal{P}\bar{y}_n = u_{n-1} + \sum_{j=1}^N \bar{y}_n(x_j)\mathcal{C}_j \tag{3.5}$$

and we can proceed to the next iteration. Furthermore, we assume the following throughout the remainder of the paper.

(H3) The functions $(\mathcal{C}_j)_{1 \leq j \leq N}$ are of class $C^2(\bar{D})$. Furthermore, for any $x \in D$ we have $\mathbf{V}\mathrm{ar}(\Psi(\mathcal{A}\mathcal{C}_j, \mathcal{B}\mathcal{C}_j, X(x))) < +\infty$ and

$$\mathbf{E}(\Psi(\mathcal{A}\mathcal{C}_j, \mathcal{B}\mathcal{C}_j, X(x))) = \mathcal{C}_j(x). \tag{3.6}$$

In other words, $\mathcal{C}_j$ (formally) solves (2.2) with data $f = \mathcal{A}\mathcal{C}_j$ and $g = \mathcal{B}\mathcal{C}_j$. Hence, $\mathcal{P}w \in C^2(\bar{D})$ for any function w. In particular, u_n is of class $C^2(\bar{D})$ for any n and satisfies the representation $u_n(x) = \mathbf{E}(\Psi[\mathcal{A}u_n, \mathcal{B}u_n, X(x)])$, which makes our algorithm valid. Note also that the stability property (3.4) written for u_n gives

$$\mathcal{P}u_n = u_n \quad \text{for any } n \geq 0. \tag{3.7}$$

Note that the numerical computations of $\mathcal{A}u_{n-1}$ in (3.2) (and analogously those of $\mathcal{B}u_{n-1}$) are performed using the evaluations of $(\mathcal{A}\mathcal{C}_j)_j$ through the equality $\mathcal{A}u_{n-1} = \sum_{j=1}^N u_{n-1}(x_j)\mathcal{A}\mathcal{C}_j$ (see [GM04]).

3.2. Convergence results.

Our goal is now to estimate the convergence of

$$m_n := \sup_{1 \leq i \leq N} |\mathbf{E}(u_n(x_i) - u(x_i))|, \quad v_n := \sup_{1 \leq i \leq N} \mathbf{V}\mathrm{ar}(u_n(x_i)). \tag{3.8}$$

It is possible to derive other measures of the error, like $\frac{1}{N}\sum_{i=1}^N |\mathbf{E}(u_n(x_i) - u(x_i))|$, without major differences. However, in this work, rather than finding the optimal way to measure the error, we prefer studying in detail the convergence. We need to introduce some extra notation regarding the scheme X^{Δ}. For a deterministic smooth function $\tilde{g}$ we set

$$\begin{aligned} e(\tilde{g},\Delta,x) &= \mathbf{E}\big(\Psi[\mathcal{A}\tilde{g},\mathcal{B}\tilde{g},X^{\Delta}(x)]\big)-\mathbf{E}\big(\Psi[\mathcal{A}\tilde{g},\mathcal{B}\tilde{g},X(x)]\big),\\ V(\tilde{g},\Delta,x) &= \mathbf{V}\mathrm{ar}\big(\Psi[\mathcal{A}\tilde{g},\mathcal{B}\tilde{g},X^{\Delta}(x)]\big). \end{aligned}$$

We state mild assumptions on the discretization scheme X^{Δ}, which allows great generality on the procedures that can be used.

(H4) (1) The map $(\tilde{f},\tilde{g})\mapsto\Psi(\tilde{f},\tilde{g},X^{\Delta}(x))$ is linear.
(2) The discretization errors $[e(\mathcal{C}_j,\Delta,x_i)]_{1\le i,j\le N}$ converge to 0 as $\Delta\to 0$.
(3) The variances $[V(u,\Delta,x_i)]_i$ and $[V(\mathcal{C}_k,\Delta,x_i)]_{i,k}$ are finite.
(4) The latter are uniformly bounded for Δ close to 0:
$\limsup_{\Delta\to 0} V(\mathcal{C}_k,\Delta,x_i)<\infty$ for any i and k.

The first assumption is natural since the initial map $(\tilde{f},\tilde{g})\mapsto\Psi(\tilde{f},\tilde{g},X(x))$ is linear. The second one is minimal since it requires only the weak convergence of the discretization scheme for the $C^2(\bar{D})$-functions $(\mathcal{C}_k)_k$. The last two ones are also very natural since they are satisfied for X (see (H1)–(H3)). A practical verification of (H4) will be given in section 4.1. It easily follows from statement (3) that $V(u-\mathcal{P}u,\Delta,x_i)<+\infty$ for any i. This justifies the finiteness of the terms which appear in Theorem 3.2.

We first state a convergence result for the bias.

Theorem 3.1. *Assume* (H1)–(H2)–(H3)–(H4). *Then, for any $n\ge 1$, one has*

$$m_n \le \rho_m\ m_{n-1}+\sup_{1\le i\le N}|[\mathcal{P}u-u](x_i)+\mathcal{P}[e(u-\mathcal{P}u,\Delta,\cdot)](x_i)|, \tag{3.9}$$

where $\rho_m=\sup_{1\le i\le N}\big[\sum_{j=1}^N|\mathcal{P}[e(\mathcal{C}_j,\Delta,\cdot)](x_i)|\big]$. For Δ small enough, one has $\rho_m<1$. Thus, the convergence of $(m_n)_n$ is geometric at rate ρ_m, up to a threshold equal to

$$\limsup_n m_n \le \frac{1}{1-\rho_m}\sup_{1\le i\le N}|[\mathcal{P}u-u](x_i)+\mathcal{P}[e(u-\mathcal{P}u,\Delta,\cdot)](x_i)|. \tag{3.10}$$

The upper limit for the bias strongly depends on the quality of the approximation of u by the operator $\mathcal{P}$. Note that if u is in the right approximation space ($\mathcal{P}u\equiv u$), the first term on the right-hand side of (3.10) cancels and the bias m_n converges geometrically to 0. In other words, even if the simulations are biased because of Δ, the bias vanishes at the limit. This is a surprising and very interesting phenomenon. However, unlike the direct Monte Carlo procedure, there is no guarantee that $\lim_{\Delta\to 0}\limsup_n m_n=0$, except in the case of the interpolation operator $\mathcal{P}$ (i.e., $\mathcal{P}u(x_i)=u(x_i)$ for any x_i). We now state the convergence of the variance $(v_n)_n$.

Theorem 3.2. *Assume* (H1)–(H2)–(H3)–(H4) *and set*

$$\begin{aligned} C(\Delta,N) &= 2\sup_{1\le i\le N}\sum_{j=1}^N \mathcal{C}_j^2(x_i)\Big[\sum_{k=1}^N\sqrt{V(\mathcal{C}_k,\Delta,x_j)}\ \Big]^2,\\ \rho_v &= \sup_{1\le i\le N}\left(\sum_{j=1}^N|\mathcal{P}[e(\mathcal{C}_j,\Delta,\cdot)](x_i)|\right)^2+\frac{C(\Delta,N)}{M}. \end{aligned}$$

Then, for any $n\ge 1$, one has

$$v_n\le\rho_v v_{n-1}+\frac{1}{M}\Big\{2\sup_{1\le i\le N}\sum_{j=1}^N\mathcal{C}_j^2(x_i)V(u-\mathcal{P}u,\Delta,x_j)+C(\Delta,N)m_{n-1}^2\Big\}. \tag{3.11}$$

For Δ small enough and M large enough, one has $\rho_v < 1$. Thus, the convergence of $(v_n)_n$ is geometric at rate ρ_v, up to a threshold equal to

$$\limsup_n v_n \le \frac{1}{(1-\rho_v)M}\left\{2\sup_{1\le i\le N}\sum_{j=1}^{N}\mathcal{C}_j^2(x_i)V(u-\mathcal{P}u,\Delta,x_j)+C(\Delta,N)\limsup_n m_n^2\right\}. \tag{3.12}$$

Note that when $\rho_v < 1$, $\rho_m < 1$, so that the convergence holds simultaneously for the bias and for the variance. As for the bias, if $\mathcal{P}u = u$, then $\limsup_n m_n = 0$ and thus $\limsup_n v_n = 0$: the variance v_n converges geometrically to 0, provided that $1/\Delta$ and M are large enough.

3.3. Proofs of convergence. To make the distinction between what is simulated before stage n and at stage n, we define the usual conditional expectations and variances

$$\mathbf{E}^{n-1}(Y) = \mathbf{E}\big(Y\big|\sigma(X^{\Delta,n',m}(x_i) : 1 \le n' \le n-1; 1 \le m \le M; 1 \le i \le N)\big)$$

and $\mathbf{V}\text{ar}^{n-1}(Y) = \mathbf{E}^{n-1}(Y^2) - [\mathbf{E}^{n-1}(Y)]^2$. Note that the construction of the algorithm yields that the discretized processes $[X^{\Delta,n,m}(x_i)]_{m,i,n}$ are independent.

3.3.1. Proof of Theorem 3.1. Formula (3.10) is a straightforward consequence of (3.9). Before proving (3.9), we transform the expression of $u_n(x_i)$ for a fixed x_i. Using (3.5), (3.2), and the PDE solved by u, we get $u_n(x_i) = u_{n-1}(x_i) + \frac{1}{M}\sum_{j=1}^{N}\sum_{m=1}^{M}\Psi[\mathcal{A}(u-u_{n-1}),\mathcal{B}(u-u_{n-1}),X^{\Delta,n,m}(x_j)]\mathcal{C}_j(x_i)$. In view of (3.7), note that

$$u - u_{n-1} = u - \mathcal{P}u + \sum_{k=1}^{N}(u-u_{n-1})(x_k)\mathcal{C}_k \tag{3.13}$$

and that $\Psi[\mathcal{A}(u-u_{n-1}),\mathcal{B}(u-u_{n-1}),X^{\Delta,n,m}(x_j)]$ equals

$$\Psi[\mathcal{A}(u-\mathcal{P}u),\mathcal{B}(u-\mathcal{P}u),X^{\Delta,n,m}(x_j)] + \sum_{k=1}^{N}(u-u_{n-1})(x_k)\Psi[\mathcal{A}\mathcal{C}_k,\mathcal{B}\mathcal{C}_k,X^{\Delta,n,m}(x_j)],$$

because of the linearity of $\Psi[(\cdot,\cdot),X^{\Delta}(x)]$ under (H4). Thus, we obtain

$$\begin{aligned} u_n(x_i) = u_{n-1}(x_i) + \frac{1}{M}\sum_{j=1}^{N}\sum_{m=1}^{M}&\Bigg[\Psi[\mathcal{A}(u-\mathcal{P}u),\mathcal{B}(u-\mathcal{P}u),X^{\Delta,n,m}(x_j)] \\ &+ \sum_{k=1}^{N}(u-u_{n-1})(x_k)\Psi[\mathcal{A}\mathcal{C}_k,\mathcal{B}\mathcal{C}_k,X^{\Delta,n,m}(x_j)]\Bigg]\mathcal{C}_j(x_i). \end{aligned} \tag{3.14}$$

Computation of $\mathbf{E}^{n-1}$ $(u_n(x_i))$. As $[X^{\Delta,n,m}(x_j)]_{m,j}$ is independent of u_{n-1}, we readily get

$$\begin{aligned} \mathbf{E}^{n-1}(u_n(x_i)) = u_{n-1}(x_i) &+ \sum_{j=1}^{N}\mathbf{E}\left(\Psi[\mathcal{A}(u-\mathcal{P}u),\mathcal{B}(u-\mathcal{P}u),X^{\Delta}(x_j)]\right)\mathcal{C}_j(x_i) \\ &+ \sum_{k=1}^{N}(u-u_{n-1})(x_k)\sum_{j=1}^{N}\mathbf{E}\left(\Psi[\mathcal{A}\mathcal{C}_k,\mathcal{B}\mathcal{C}_k,X^{\Delta}(x_j)]\right)\mathcal{C}_j(x_i). \end{aligned} \tag{3.15}$$

Note that

(a) using (2.1) and (3.6), we have $\mathbf{E}\big(\Psi[\mathcal{A}(u-\mathcal{P}u),\mathcal{B}(u-\mathcal{P}u),X^{\Delta}(x_j)]\big) = e(u-\mathcal{P}u,\Delta,x_j)+(u-\mathcal{P}u)(x_j)$;

(b) using (3.6), we have $\mathbf{E}\left(\Psi[\mathcal{A}\mathcal{C}_k,\mathcal{B}\mathcal{C}_k,X^{\Delta}(x_j)]\right) = e(\mathcal{C}_k,\Delta,x_j)+\mathcal{C}_k(x_j)$;

(c) owing to (3.4), we have $\sum_{j=1}^{N}\mathcal{C}_k(x_j)\mathcal{C}_j(x_i)=\mathcal{C}_k(x_i)$ (indeed, a choice of $w(\cdot)$ such that $w(x_i)=\delta_{i,k}$ leads to $\mathcal{P}w=\mathcal{C}_k$, and thus $\mathcal{P}\mathcal{C}_k=\mathcal{C}_k$ by (3.4)).

Plugging these identities in (3.15), it readily follows that

$$\begin{aligned}\mathbf{E}^{n-1}(u_n(x_i)) &= u_{n-1}(x_i)+\sum_{j=1}^{N}\big[e(u-\mathcal{P}u,\Delta,x_j)+(u-\mathcal{P}u)(x_j)\big]\mathcal{C}_j(x_i)\\ &\quad+\sum_{k=1}^{N}(u-u_{n-1})(x_k)\left[\mathcal{C}_k(x_i)+\sum_{j=1}^{N}e(\mathcal{C}_k,\Delta,x_j)\mathcal{C}_j(x_i)\right]\\ &= \mathcal{P}u(x_i)+\mathcal{P}[e(u-\mathcal{P}u,\Delta,\cdot)](x_i)+\sum_{k=1}^{N}(u-u_{n-1})(x_k)\mathcal{P}[e(\mathcal{C}_k,\Delta,\cdot)](x_i), \qquad (3.16)\end{aligned}$$

simplifications at the last line arising from (3.4).

Computation of $\mathbf{E}(u_n(x_i))$. Taking the expectation in (3.16) we obtain

$$\begin{aligned}\mathbf{E}\big(u_n(x_i)-u(x_i)\big) &= \mathcal{P}u(x_i)-u(x_i)+\mathcal{P}[e(u-\mathcal{P}u,\Delta,\cdot)](x_i)\\ &\quad+\sum_{k=1}^{N}\mathbf{E}((u-u_{n-1})(x_k))\mathcal{P}[e(\mathcal{C}_k,\Delta,\cdot)](x_i).\end{aligned}$$

It remains to take absolute values and the supremum over i on both sides to complete the proof of (3.9). □

3.3.2. Proof of Theorem 3.2. Note that the inequality $\rho_v<1$ holds for Δ small enough and M large enough. Indeed, under (H4) $C(\Delta,N)$ remains uniformly bounded w.r.t. Δ close to 0. We prove only (3.11). Taking some fixed x_i, we have

$$\mathbf{V}\mathrm{ar}(u_n(x_i)) = \mathbf{V}\mathrm{ar}\big[\mathbf{E}^{n-1}(u_n(x_i))\big]+\mathbf{E}\big[\mathbf{V}\mathrm{ar}^{n-1}(u_n(x_i))\big]. \qquad (3.17)$$

Computation of $\mathbf{Var}[\mathbf{E}^{n-1}(u_n(x_i))]$. In view of (3.16), we have

$$\begin{aligned}\mathbf{V}\mathrm{ar}\big[\mathbf{E}^{n-1}(u_n(x_i))\big] &= \mathbf{V}\mathrm{ar}\left[\sum_{j=1}^{N}u_{n-1}(x_j)\mathcal{P}[e(\mathcal{C}_j,\Delta,\cdot)](x_i)\right]\\ &\le v_{n-1}\left(\sum_{j=1}^{N}|\mathcal{P}[e(\mathcal{C}_j,\Delta,\cdot)](x_i)|\right)^2, \qquad (3.18)\end{aligned}$$

where we have used the standard inequality

$$\begin{aligned}\mathbf{V}\mathrm{ar}\left(\sum_{j=1}^{N}\alpha_jY_j\right) &= \sum_{j_1,j_2=1}^{N}\alpha_{j_1}\alpha_{j_2}\mathbf{C}\mathrm{ov}(Y_{j_1},Y_{j_2})\\ &\le \sum_{j_1,j_2=1}^{N}|\alpha_{j_1}|\,|\alpha_{j_2}|\sqrt{\mathbf{V}\mathrm{ar}(Y_{j_1})}\sqrt{\mathbf{V}\mathrm{ar}(Y_{j_2})} = \left[\sum_{j=1}^{N}|\alpha_j|\sqrt{\mathbf{V}\mathrm{ar}(Y_j)}\right]^2 \qquad (3.19)\end{aligned}$$

for any real numbers $(\alpha_j)_j$ and any square integrable real random variables $(Y_j)_j$.

Computation of $\mathbf{Var}^{n-1}(u_n(x_i))$. We invoke the independence of $[X^{\Delta,n,m}(x_i)]_{m,i}$ and u_{n-1} in (3.14) to derive

$$\begin{aligned}\mathbf{V}\mathrm{ar}^{n-1}(u_n(x_i)) &= \sum_{j=1}^{N}\frac{\mathcal{C}_j^2(x_i)}{M}\mathbf{V}\mathrm{ar}^{n-1}\Bigg[\Psi[\mathcal{A}(u-\mathcal{P}u),\mathcal{B}(u-\mathcal{P}u),X^{\Delta}(x_j)]\\ &\qquad+\sum_{k=1}^{N}(u-u_{n-1})(x_k)\Psi[\mathcal{A}\mathcal{C}_k,\mathcal{B}\mathcal{C}_k,X^{\Delta}(x_j)]\Bigg]\\ &\le \sum_{j=1}^{N}\frac{\mathcal{C}_j^2(x_i)}{M}\Bigg[\sqrt{V(u-\mathcal{P}u,\Delta,x_j)}+\sum_{k=1}^{N}|u-u_{n-1}|(x_k)\sqrt{V(\mathcal{C}_k,\Delta,x_j)}\Bigg]^2,\end{aligned}$$

using (3.19) at the last inequality. Applying the inequality $\mathbf{E}(\alpha_0+\sum_{k=1}^N\alpha_kY_k)^2\le 2\alpha_0^2+2\big(\sum_{k=1}^N|\alpha_k|\sqrt{\mathbf{E}(Y_k^2)}\big)^2$, which can be proved as (3.19), we get

$$\begin{aligned}\mathbf{E}(\mathbf{V}\mathrm{ar}^{n-1}(u_n(x_i))) &\le 2\sup_{1\le i\le N}\sum_{j=1}^{N}\frac{\mathcal{C}_j^2(x_i)}{M}\Bigg\{V(u-\mathcal{P}u,\Delta,x_j)\\ &\qquad+\sup_{1\le k\le N}\mathbf{E}((u-u_{n-1})^2(x_k))\Bigg[\sum_{k=1}^{N}\sqrt{V(\mathcal{C}_k,\Delta,x_j)}\Bigg]^2\Bigg\}.\end{aligned}$$

Combine this estimate with (3.18) and (3.17), use $\sup_{1\le k\le N}\mathbf{E}((u-u_{n-1})^2(x_k))\le v_{n-1}+m_{n-1}^2$, and take the supremum over i to complete the proof of (3.11). □

4. Influence of parameters of the algorithm.

We focus mainly on the first example of Brownian SDEs with a Dirichlet boundary condition. This means (see section 2) that $X_t=x+\int_0^t b(X_s)ds+\int_0^t\sigma(X_s)dW_s$, $\Psi(f,g,X(x))=g(X_\tau)Z_\tau-\int_0^\tau f(X_s)Z_sds$ (with $Z_t=e^{-\int_0^t c(X_r)dr}$ and $\tau=\inf\{t\ge 0: X_t\notin D\}$), $\mathcal{A}u=\sum_{i=1}^d b_i\partial_{x_i}u+\frac{1}{2}\sum_{i,j=1}^d[\sigma\sigma^*]_{i,j}\partial^2_{x_i,x_j}u-cu$, and $\mathcal{B}u=u$. We first give a set of explicit assumptions implying (H1)–(H2) and (3.6) in this case.

(H2′) (i) The functions b and σ are Lipschitz continuous on $\bar{D}$ and $\sigma\sigma^*(x)\ge\epsilon_0\mathrm{I}_d$ uniformly w.r.t. $x\in D$ ($\epsilon_0>0$).

(ii) D is a bounded domain and each point of its boundary ∂D satisfies the *exterior cone condition*: for any $x\in\partial D$, there exists a finite right circular cone $\mathcal{K}$, with vertex x, such that $\bar{\mathcal{K}}\cap\bar{D}=\{x\}$.

(iii) The function g is continuous on ∂D, f and $c\ge 0$ are uniformly Hölder continuous in $\bar{D}$ (with exponent $\alpha\in]0,1[$).

PROPOSITION 4.1. *Under* (H2′), (H1) *and* (H2) *are fulfilled. Furthermore, if* $\mathcal{C}_j$ *is of class* $C^2(\bar{D})$, (H3) *holds.*

Proof. The variance in (H1) is finite. Indeed, on the one hand the functions g and f are bounded and c is nonnegative. On the other hand, we have $\mathbf{E}_x(\tau)<+\infty$ (which automatically induces exponential moments for τ; see [Fre85, section 3.3]).

The proof of (H2) is somewhat classic except that D is not smooth here. We just recall the two main steps. First, the existence of a solution to (2.2) follows from the remark after [GT83, Theorem 6.13], noting that under (H2′) every point of the boundary has a barrier (see Problem 6.3 in [GT83]). Second, [Fre85, Theorem 2.1, section 2.2] states that the solution is given by (2.1). This is achieved by applying Itô's formula to u and using some careful localization procedures because derivatives of u explode near the boundary (see also Appendix B). (H3) is proved analogously. □

4.1. Verification of assumption (H4). We propose to check it when we use the so-called *discrete Euler scheme* [Gob00], which is the simplest procedure that can be used for general stopped diffusions. An alternative is the WOS scheme, which is especially efficient when we are dealing with the Brownian motion (see [HMG03] and the references therein). Some refinements to the discrete Euler scheme are also possible, using Brownian bridge simulations [Bal95, Gob00, Gob01].

For a given time step Δ and discretization times $t_k = k\Delta$, the Euler scheme is defined by $X_0^\Delta = x$ and $X_{t_{k+1}}^\Delta - X_{t_k}^\Delta = b(X_{t_k}^\Delta)(t_{k+1} - t_k) + \sigma(X_{t_k}^\Delta)(W_{t_{k+1}} - W_{t_k})$, which can be written in continuous time as

$$X_t^\Delta = x + \int_0^t b(X_{\phi(s)}^\Delta)ds + \int_0^t \sigma(X_{\phi(s)}^\Delta)dW_s. \tag{4.1}$$

Here, $\phi(s) = t_k$ for $t_k \leq s < t_{k+1}$. The approximated exit time is defined by $\tau^\Delta = \inf\{t_k \geq 0 : X_{t_k}^\Delta \notin D\}$. Thus, to approximate $\Psi(f, g, X(x))$, we simply propose

$$\Psi(f, g, X^\Delta(x)) = g(X_{\tau^\Delta}^\Delta)Z_{\tau^\Delta}^\Delta - \int_0^{\tau^\Delta} f(X_{\phi(s)}^\Delta)Z_{\phi(s)}^\Delta ds, \quad Z_s^\Delta = e^{-\int_0^s c(X_{\phi(u)}^\Delta)du}. \tag{4.2}$$

Here, g is evaluated at $X_{\tau^\Delta}^\Delta$ which is not a priori on ∂D: hence, in (4.2) g has to be understood as a bounded continuous function on the whole space. In view of (4.2), (H4)-(1) is clearly fulfilled. To verify (2)–(4) of (H4), our main tool is the following theorem, which is original in this context of elliptic problems and whose proof is postponed to Appendix A.

THEOREM 4.2. *Assume* (H2′). *Then, the following assertions hold.*

(a) *For any* $p \geq 1$, $\sup_{x\in\bar{D}} \mathbf{E}_x(\tau^p) + \limsup_{\Delta\to 0} \sup_{x\in\bar{D}} \mathbf{E}_x([\tau^\Delta]^p) < \infty$.

(b) $\lim_{\Delta\to 0} \tau^\Delta = \tau$ *in* $\mathbf{L}_p$ *for any* $p \geq 1$.

(c) $\lim_{\Delta\to 0} X_{\tau^\Delta}^\Delta = X_\tau$ *in probability.*

(d) *For any bounded continuous* γ, $\limsup_{\Delta\to 0} \int_0^{\tau^\Delta\wedge\tau} |\gamma(X_s) - \gamma(X_{\phi(s)}^\Delta)|ds = 0$ *in* $\mathbf{L}_p$ *for any* $p \geq 1$.

Since $|\Psi[\mathcal{A}u, u, X^\Delta(x)]| = |\Psi[f, u, X^\Delta(x)]| \leq C(1+\tau^\Delta)$ and $|\Psi[\mathcal{A}\mathcal{C}_k, \mathcal{C}_k, X^\Delta(x)]| \leq C(k)(1 + \tau^\Delta)$, we easily get that (H4)-(3) and (H4)-(4) are fulfilled in view of (a). It remains to prove that $e(\mathcal{C}_k, \Delta, x) = \mathbf{E}\big(\Psi[\mathcal{A}\mathcal{C}_k, \mathcal{C}_k, X^\Delta(x)] - \Psi[\mathcal{A}\mathcal{C}_k, \mathcal{C}_k, X(x)]\big)$ converges to 0 when $\Delta \to 0$, for any $\mathcal{C}_k$ of class $C^2(\bar{D})$. Using (c), we get the convergence of $\mathcal{C}_k(X_{\tau^\Delta}^\Delta)$ to $\mathcal{C}_k(X_\tau)$ in probability, and thus in $\mathbf{L}_1$ since $\mathcal{C}_k$ is bounded. Since $\exp(\cdot)$ is 1-Lipschitz on $\Re^-$ and $c(\cdot)$ is nonnegative, we have $|Z_{\tau^\Delta}^\Delta - Z_\tau| \leq |\int_0^{\tau^\Delta} c(X_{\phi(u)}^\Delta)du - \int_0^\tau c(X_u)du|$, which converges to 0 in $\mathbf{L}_1$, using (b) and (d). For the convergence in $\mathbf{L}_1$ of $\int_0^{\tau^\Delta} f(X_{\phi(s)}^\Delta)Z_{\phi(s)}^\Delta ds$ to $\int_0^\tau f(X_s)Z_s ds$, the previous arguments apply and this completes the verification of (H4)-(2).

4.2. Impact of the approximation operator. The discretization parameter Δ has to be chosen small enough to ensure the convergence of the bias. This convergence depends on the approximation operator as we must have $\rho_m < 1$. As it is mainly described by the sensitivity of regular functions to the discretization error, it actually depends very little on the approximation operator. The convergence of the variance (described by the condition $\rho_v < 1$) depends a lot more on the choice of the approximation, but in the same way concerning the discretization parameter. In order to study this convergence, we can hence focus on the case $\Delta = 0$. In this ideal case, we have

$$v_n \leq v_{n-1}\frac{C(0, N)}{M} + \frac{2}{M}\sup_{1\leq i\leq N}\sum_{j=1}^N \mathcal{C}_j^2(x_i)V(u - \mathcal{P}u, 0, x_j)$$

with

$$C(0,N) = 2 \sup_{1\le i\le N} \sum_{j=1}^{N} \mathcal{C}_j^2(x_i) \left(\sum_{k=1}^{N} \sqrt{V(\mathcal{C}_k, 0, x_j)} \right)^2 .$$

The quantities $V(u-\mathcal{P}u, 0, x_j)$ and $V(\mathcal{C}_k, 0, x_j)$ can be computed as

$$V(u-\mathcal{P}u,0,x_j) = \mathbf{E}_{x_j}\left[\int_0^\tau Z_s^2 \left|\nabla_x(u-\mathcal{P}u)\sigma\right|^2 (X_s)ds\right],$$
$$V(\mathcal{C}_k,0,x_j) = \mathbf{E}_{x_j}\left[\int_0^\tau Z_s^2 \left|\nabla_x \mathcal{C}_k\sigma\right|^2 (X_s)ds\right],$$

using Lemma B.1 given in Appendix B. The first term enables us to control the final error and the second one the speed of convergence of the algorithm. Both depend only on the gradient of the basis functions and not on the second derivatives of these functions. It is quite difficult to make a general discussion on the optimal choice of the approximation in a general domain. We prefer focusing on polynomial interpolations on square domains and give explicit computations of the convergence parameters in this case. The process X remains general.

4.3. Gauss–Tchebychef interpolation on $]-1,1[^d$. The Tchebychef polynomials $T_n(x) = \cos(n \arccos(x))$ are the orthogonal polynomials on $]-1,1[$ with respect to the inner product $\langle P,Q\rangle_w = \int_{-1}^{1} P(x)Q(x)w(x)dx$, where $w(x) = \frac{1}{\sqrt{1-x^2}}$. We have $\|T_0\|_w^2 = \pi$ and $\|T_n\|_w^2 = \frac{\pi}{2}$ if $n \ge 1$. In dimension one, the interpolation polynomial $\mathcal{P}_N(u)$ of the function u at the Tchebychef abscissae

$$x_k = \cos\left(\frac{2k+1}{N+1}\frac{\pi}{2}\right), \qquad k = 0,1,\dots,N,$$

is given by [Bjö96]

$$\mathcal{P}_N(u) = \sum_{n=0}^{N} \alpha_n T_n$$

with

$$\alpha_n = \frac{\pi}{\|T_n\|_w^2 (N+1)} \sum_{k=0}^{N} u(x_k) T_n(x_k).$$

This interpolation is optimal w.r.t. the sup norm. The control of u and of its derivative is given in the following theorem (see [CHQZ88, p. 298]).

THEOREM 4.3. *Denote by H_w^m the w-weighted Sobolev space with regularity $m \in \mathbf{N}^*$. Then $\exists\, c_1, c_2 > 0$ such that $\forall u \in H_w^m$, we have*

$$\|u - \mathcal{P}_N(u)\|_w \le c_1 N^{-m} \|u\|_{H_w^m}, \qquad \|u - \mathcal{P}_N(u)\|_{H_w^1} \le c_2 N^{2-m} \|u\|_{H_w^m} .$$

The Tchebychef interpolation of a function $u : D =]-1,1[^d \mapsto \mathbf{R}$ is built using the same process as in dimension one. The interpolation polynomial $\mathcal{P}_N(u)$ at the N^d points of a tensored Tchebychef grid and evaluated at $z = (z_1,\dots,z_d)$ is

$$\mathcal{P}_N(u)(z) = \sum_{n_1,\dots,n_d=1}^{N} \alpha_{n_1,\dots,n_d} T_{n_1}(z_1)\cdots T_{n_d}(z_d),$$

where the $\alpha_{n_1,\dots,n_d}$ are defined by

$$\alpha_{n_1,\dots,n_d} = \prod_{i=1}^{d}\left(\frac{\pi}{\|T_{n_i}\|_w^2(N+1)}\right)\sum_{m_1,\dots,m_d=1}^{N} u(x_{m_1},\dots,x_{m_d})T_{n_1}(x_{m_1})\cdots T_{n_d}(x_{m_d}).$$

The quality of this interpolation is exactly the same as that in Theorem 4.3. In dimension one, the basis functions $\mathcal{C}_k$ write

$$\mathcal{C}_k(x) = \sum_{n=0}^{N}\frac{\pi}{\|T_n\|_w^2(N+1)}T_n(x_k)T_n(x).$$

As $T_n^{'}(x) = \frac{-n\sin(n\arccos(x))}{\sqrt{1-x^2}}$ and because $\frac{\pi}{\|T_n\|_w^2(N+1)}T_n(x_k) \leq \frac{2}{N+1}$, we have $|\nabla_x\mathcal{C}_k(x)|^2 \leq [\sum_{n=0}^{N}\frac{2}{N+1}\frac{n}{\sqrt{1-x^2}}]^2 = \frac{N^2}{1-x^2} \leq \frac{N^2}{1-|x|}$. Using $Z_s^2 \leq 1$, the occupation time formula [RY94], and Lemma 4.4 (which is proved in Appendix C), we finally have $V(\mathcal{C}_k, 0, x_j) \leq \int_{-1}^{1}|\nabla_x\mathcal{C}_k(y)|^2\mathbf{E}_{x_j}(L_\tau^y(X))dy \leq CN^2$.

Lemma 4.4. *For $D =]-1,1[$ and under* (H2$'$)*, we have* $\mathbf{E}_x(L_\tau^y(X)) \leq C(1-|y|)$ *uniformly in $x \in D$.*

As furthermore $\mathcal{C}_k(x_j) = \delta_{k,j}$, we have

$$C(0,N) = 2\sup_{0\leq j\leq N}\left(\sum_{k=0}^{N}\sqrt{V(\mathcal{C}_k,0,x_j)}\right)^2 \leq 2\left(\sum_{k=0}^{N}\sqrt{C}N\right)^2 = O(N^4).$$

This means that we need to take $M \geq CN^4$ (with C large enough) to ensure the convergence. Using the same tools, we can also prove that if $u \in H_w^m$,

$$V(u-\mathcal{P}_N(u),0,x_j) \leq C\int_{-1}^{1}|\nabla_x(u-\mathcal{P}_N(u))|^2(y)dy \leq C\|u-\mathcal{P}_N(u)\|_{H_w^1}^2 = O(N^{-2m+4})$$

and so that the final error on the solution is a

$$O\left(\sqrt{\sup_{1\leq i\leq N}\sum_{j=1}^{N}\mathcal{C}_j^2(x_i)\frac{V(u-\mathcal{P}u,0,x_j)}{M}}\right) = O(N^{-m}).$$

We now go back to the interpolation on the multidimensional Tchebychef grid. In this case, the basis functions simply write $\mathcal{C}_{k_1,\dots,k_d}(x_1,\dots,x_d) = \mathcal{C}_{k_1}(x_1)\cdots\mathcal{C}_{k_d}(x_d)$. As $|\nabla_x\mathcal{C}_{k_1,\dots,k_d}(x)|^2 \leq C\sum_{i=1}^{d}|\nabla_x\mathcal{C}_{k_i}(x_i)|^2$, we deduce immediately that $V(\mathcal{C}_{k_1,\dots,k_d},0,x) = O(N^2)$ and that $C(0,N) = O(N^{2+2d})$. The error estimates, using the order m of regularity of u, are the same in dimension d as they are in dimension one. As the convergence is geometric and the solution is computed at N^d points with a source term constituted of N^d terms, the complexity of the algorithm is essentially $C(0,N)N^{2d}$. The upper bound on $C(0,N)$ may not be tight. We shall especially see that in all the numerical experiments $C(0,N)$ is a lot smaller than N^{2+2d}, and we should also keep in mind that the spectral methods are used for very smooth solutions so that N is usually small. As a comparison, the usual spectral method requires us to solve a linear system of size N^d which involves a complexity of a $O(N^{3d})$ using a direct method and of N^{2d} at each step of an iterative method. The resolution induces moreover an additional error on the solution due to the condition number of the matrix which can grow very quickly with N [BM97]. This can also make the speed of convergence of the iterative method quite slow. A big advantage of our method is that it keeps all the advantages of the Monte Carlo method in terms of parallel computing. One can, for example, use one processor for each of the N^d points of the grid.

4.4. Gauss–Lobatto–Tchebychef interpolation. To reach a slightly better accuracy, one can also use the Gauss–Lobatto points [BM97]

$$y_k = \cos\left(\frac{N-k}{N}\pi\right), \qquad k = 0, 1, \dots, N,$$

where the boundaries of the interval are taken as interpolation points. The coefficients (β_n) of the interpolation polynomial $\mathcal{Q}_N(u) = \sum_{n=0}^{N} \beta_n T_n$ satisfy the relation $\beta_n \|T_n\|_w^2 = \int_{-1}^{1} \mathcal{Q}_N(u)(x) T_n(x) w(x) dx$. For $n < N$, the integral equals

$$\frac{\pi}{N}\left(\frac{u(-1)T_n(-1) + u(1)T_n(1)}{2} + \sum_{k=1}^{N-1} u(y_k) T_n(y_k)\right)$$

using the relative quadrature formula, which is exact on polynomials of degree smaller than $2N-1$. This gives the values of β_n for $n < N$. Moreover, as $T_n(1) = 1$, we have $\beta_N = u(1) - \sum_{n=0}^{N-1} \beta_n$. Hence, the basis functions write

$$\mathcal{C}_N = T_N + \sum_{n=0}^{N-1} \frac{\pi(T_n - T_N)}{2N\|T_n\|_w^2}, \qquad \mathcal{C}_0 = \sum_{n=0}^{N-1} \frac{\pi(-1)^n (T_n - T_N)}{2N\|T_n\|_w^2}$$

and if $j \neq 0, N$,

$$\mathcal{C}_j = \sum_{n=0}^{N-1} \frac{\pi T_n(y_j)}{N\|T_n\|_w^2}(T_n - T_N).$$

As for the Gauss–Tchebychef case, the d-dimensional extension on tensored domains is obtained by setting $\mathcal{C}_{k_1,\dots,k_d}(x_1, \dots, x_d) = \mathcal{C}_{k_1}(x_1) \cdots \mathcal{C}_{k_d}(x_d)$. This interpolation enables a better control of the derivative of u than the previous one, as we can see in the following theorem [BM97] (valid in any dimension).

THEOREM 4.5. *For all $m \in \mathbf{N}^*$, $\exists c_1, c_2 > 0$ such that $\forall u \in H_w^m$, we have*

$$\|u - \mathcal{Q}_N(u)\|_w \leq c_1 N^{-m} \|u\|_{H_w^m}, \qquad \|u - \mathcal{Q}_N(u)\|_{H_w^1} \leq c_2 N^{1-m} \|u\|_{H_w^m}.$$

Using the previous tools, one can easily prove that $C(0, N) = O(N^{2+2d})$ and $V(u - \mathcal{P}u, 0, x_j) = O(N^{-2m+2})$ so that the final error on the solution is an $O(N^{-m-1})$ which is compared to an $O(N^{-m})$ for the previous interpolation.

5. Numerical results.

The aim of this numerical part is not to give the optimal way to solve a general problem using our algorithm. We study various classic situations only to illustrate the convergence and the accuracy of our algorithm. Different approximations and discretization schemes are tested to confirm our theoretical estimates and the great efficiency and generality of our approach.

5.1. Poisson equation in dimension one. Our first example is the numerical resolution of the Poisson equation in dimension one using a Monte Carlo scheme with no discretization error [GM04] and Tchebychef interpolations on either the $(x_k)_k$ or the $(y_k)_k$. The solution of this Poisson equation

$$\frac{1}{2}u'' = f \qquad \text{in }]-1, 1[$$

with boundary conditions $u(-1) = a, u(1) = b$ is $u(x) = a\mathbf{P}_x(W_{\tau_D} = -1) + b(1 - \mathbf{P}_x(W_{\tau_D} = -1)) - \mathbf{E}_x(\int_0^{\tau_D} f(W_s)ds)$. As $\mathbf{P}_x(W_{\tau_D} = -1) = \frac{1-x}{2}$ the contribution of the boundary conditions to the solution can be easily simulated. To achieve the contribution of the source term with no discretization error, we use the representation $\mathbf{E}_x(\int_0^{\tau_D} f(W_s)ds) = (1-x^2)\mathbf{E}(f(Y_x))$ where the density of the random variable Y_x is $\frac{1+r}{1+x}1_{-1\leq r\leq x} + \frac{1-r}{1-x}1_{x\leq r\leq 1}$.

We study the example $f(x) = (x+2)\exp(x)/2, a = -\frac{1}{e}, b = e$, so that the solution of this equation is $u(x) = x\exp(x)$. We give in the following table the error

$$e(j) = \sup_{0\leq k\leq N} |u(x_k) - u_j(x_k)|$$

as a function of the number j of steps and of the number M of sample values to compute the pointwise approximation at the x_k. Even if our algorithm is based on independent random drawings, we have observed in [GM04] that one could use low-discrepancy sequences to speed up the convergence of the algorithm. We hence use here a version of the algorithm based on Halton sequences, which is twice as fast as the Monte Carlo version. The accuracy of the crude quasi–Monte Carlo method with M sample values is given by $e(1)$. L is the number of steps until convergence for a given value of M. All the CPU times are less than one second.

N	M	L	$e(1)$	$e(5)$	$e(L)$
5	80	16	2×10^{-1}	2×10^{-2}	5×10^{-4}
7	200	30	1×10^{-1}	9×10^{-3}	4×10^{-6}
10	800	45	9×10^{-2}	2×10^{-3}	8×10^{-10}

M has to be chosen large enough with respect to N to make the algorithm converge but is significantly smaller than N^4. The error at convergence $e(L)$ corresponds exactly to the interpolation error of the interpolation polynomial $\mathcal{P}_N(u)$ of the exact solution at the Tchebychef abscissae. We now study the same example using the Gauss–Lobatto–Tchebychef interpolation.

N	M	L	$e(1)$	$e(5)$	$e(L)$
5	40	10	4×10^{-1}	1×10^{-3}	7×10^{-4}
7	100	26	2×10^{-1}	2×10^{-2}	2×10^{-6}
10	400	35	1×10^{-1}	1×10^{-2}	2×10^{-9}

We can see that we can take half as many drawings to achieve the same final accuracy for similar number of steps. This means that the convergence is twice as fast using this kind of interpolation, maybe because there is no error on the correction at the two boundary points. We do not notice any major difference on the final error, as we might have expected.

5.2. The bidimensional case. We consider the Poisson equation on the square domain $D =]-1,1[^2$ with Dirichlet boundary conditions. We use an interpolation at the bidimensional Tchebychef grid, two types of discretization schemes, and Monte Carlo simulations. The first one is the modified WOS method [HMG03, GM04] which can take into account the source term f. This walk goes from one sphere to another until the motion reaches the ε-absorption layer. The second one is based on the continuous Euler scheme with parameter $\triangle t$ [Gob01]. We study the equation $\frac{1}{2}\triangle u = \frac{1}{2}(4x^2+3)\exp(x^2+y)$ with Dirichlet boundary conditions chosen so that the solution of this equation is $u(x, y) = \exp(x^2 + y)$. We begin with the WOS scheme taking, respectively, $\varepsilon_1 = 10^{-2}$ and $\varepsilon_2 = 10^{-3}$ for the absorption layer thickness and use the same notation as in the previous examples.

N	M	L	$e_1(1)$	$e_1(L)$	CPU	$e_2(1)$	$e_2(L)$	CPU
6	200	11	0.24	1×10^{-3}	1.4	0.18	1×10^{-3}	2.4
8	400	13	0.17	8×10^{-5}	6.7	0.14	7×10^{-5}	10.5
10	800	17	0.13	3×10^{-6}	28	0.14	4×10^{-6}	44

We observe a geometric convergence on both the bias and the variance up to the interpolation error of the exact solution. We do not notice any difference on the final accuracy for the two values ε_1 and ε_2. CPU times are of course smaller for ε_1 and also about eight times smaller than in [GM04] by using a recursive computation of the Tchebychef polynomials instead of their trigonometric expression. We now use the corrected Euler scheme with discretization parameters $\triangle t_1 = 0.005$ and $\triangle t_2 = 0.002$.

N	M	L	$e_1(1)$	$e_1(L)$	CPU	L	$e_2(1)$	$e_2(L)$	CPU
6	30	10	0.7	3×10^{-3}	1.4	12	0.6	2×10^{-3}	4
8	100	40	0.37	2×10^{-4}	28	10	0.38	1×10^{-4}	16
10	200	10	0.4	5	27	50	0.3	3×10^{-5}	300

We observe the same kind of convergence as in the previous examples except in the case $\triangle t_1 = 0.005$ and $N = 10$ because the discretization parameter is not small enough (see the condition $\rho_v < 1$). Nevertheless, we do not achieve the same accuracy at the limit. A bias due to the discretization scheme still remains. When $\triangle t$ decreases this bias decreases and the convergence is faster. Using the naive Euler scheme on the same example, the bias at the limit was twice as big and the convergence twice as slow. We can take M a lot smaller than using the WOS method to achieve the convergence.

5.3. Parabolic problem. We consider a regular up and out call option with maturity $T = 1$, corresponding to the domain $D =]0, 2[$ (actually, 0 is a natural boundary) and the Cauchy–Dirichlet boundary condition $g(t, x) = (x - 1)_+$ if $t = 1$ and $g(t, x) = 1$ if $x = 2$. The dynamics is given by $X_t = x \exp(\sigma W_t - \frac{1}{2}\sigma^2 t)$. The quantity $u(0, x) = \mathbf{E}_x((X_\tau - 1)_+)$ (with $\tau = \inf\{t : X_t \notin]0, 2[\} \wedge 1$) gives the risk-neutral price of the option at time 0, when the interest rate equals 0. The solution u can be computed by a closed formula [Zha97]. The derivatives of u have singularities around $(t, x) = (1, 1)$. Thus, the solution is less smooth than in previous examples and the numerical results below show that the benefit of our method is less important in that case. For the interpolation procedure, we propose a piecewise linear interpolation w.r.t. the time variable and a Tchebychef interpolation w.r.t. the space variable. The interpolation times are $(t_i = iT/(K - 1))_{0 \leq i < K}$ and the $N + 1$ Tchebychef points at each interpolation time are the (x_n) or (y_n) (on the interval $[0, 2]$ instead of $[-1, 1]$).

Notation relative to the errors remains the same. We first compare the accuracy of the Gauss–Tchebychef (GT) and Gauss–Lobatto–Tchebychef (GLT) interpolations, in the case $K = 5$, $N = 5$. The simulation of X can be exactly performed at discretization times $(k\triangle t)$, from which we can derive a naive approximation of τ. Here, we take $\triangle t = 0.05$ and $M = 10$ simulated paths. All the CPU times are less than one second.

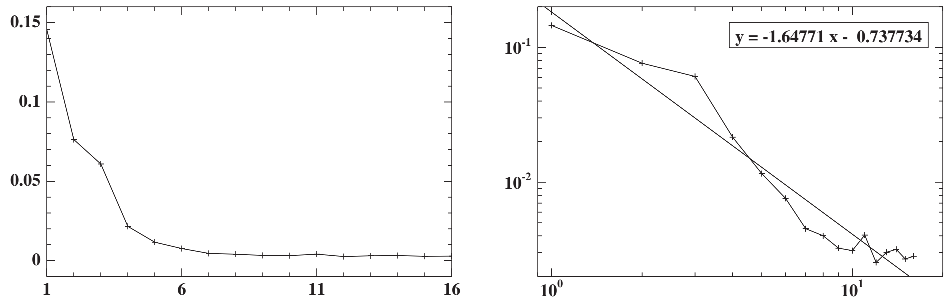

FIG. 5.1. *On the left, error $e(j)$ w.r.t. the number of iterations. On the right, the same in logarithmic scales.*

	K	N	M	$\triangle t$	L	$e(1)$	$e(2)$	$e(L)$
GT	5	5	10	0.05	4	1.32×10^{-1}	7.92×10^{-2}	3.88×10^{-2}
GLT	5	5	10	0.05	4	1.72×10^{-1}	4.7×10^{-2}	1.44×10^{-2}

The GLT interpolation converges faster and the relative final error is slightly smaller. Note also that from the first iteration, the accuracy of our method compared to a crude Monte Carlo method is improved by a factor of 3.6 using the GLT interpolation: this accuracy could be achieved using 13 times more crude Monte Carlo simulations. To diminish the bias, we now use Brownian bridge corrections to simulate the exit event. To obtain more evidence of the better convergence of the GLT interpolation, we increase the value of N to 15: the contraction constant ρ_v should increase (from Theorem 3.2 and sections 4.2 and 4.3, one has $\rho_v \approx O(\frac{N^4}{M}))$ and may become larger than 1 (to recover $\rho_v < 1$, one can increase M). This is confirmed by the following result, where for the GLT interpolation, the convergence still holds but not for the GT interpolation.

	K	N	M	$\triangle t$	L	$e(1)$	$e(2)$	$e(L)$
GT	5	15	10	0.01	–	1.98×10^{-1}	5.64×10^{-1}	2.7 for $L = 15$
GLT	5	15	10	0.01	10	2.13×10^{-1}	1.24×10^{-1}	5.65×10^{-3}

In view of this nice behavior, the following experiments are done using GLT interpolation. Figure 5.1 illustrates the geometric convergence till the interpolation error. It has been obtained with $K = 10$, $N = 20$, $M = 20$, and $\triangle t = 0.001$. The optimal choice of (K, N) will be analyzed in future research.

6. Conclusion. We developed and studied a sequential Monte Carlo method for the numerical solution of linear PDEs. This method provides a regular global approximation of this solution by combining pointwise approximations via the Feynman–Kac formula and a linear approximation on some basis functions. As the pointwise approximations are computed by means of a Monte Carlo method, statistical and discretization errors occur. We have proved the geometric reduction of these two kinds of errors up to a limit linked to the linear approximation. Numerical experiments on simple diffusion equations using various discretization schemes and different kinds of approximations have confirmed this geometric reduction and the efficiency of our method. Further numerical examples should be developed on more complex domains, in higher dimensions, or for less regular solutions. In higher dimensions, one needs to diminish the dimensional effect by making a good choice of the basis functions [Mai03]. For more complex domains or less regular solutions, new versions of the algorithm based on finite elements approximations or domain decomposition methods can certainly be developed. In all those situations, our algorithm could at least be a variance reduction tool by computing a rather poor approximation on few basis functions. As a final remark, we think that our method could advantageously replace the usual deterministic methods in many situations, especially if it is used in a parallel version.

Appendix A. Proof of Theorem 4.2.

Statement (a). Since D is bounded, it is sufficient to prove the result when $D = D_R = [-R, R]^d$ for an arbitrary R. We proceed in several steps.

Step 1. τ^Δ has exponential moments, not necessarily uniformly bounded in Δ. If we use the Markov property at time $(t_k)_k$ for the Euler scheme, we get the rough estimate $\mathbf{P}(\tau^\Delta > m\Delta) \le [\sup_{x\in\bar{D}} \mathbf{P}_x(X^\Delta_\Delta \in D)]^m$. Under (H2′), $\sup_{x\in\bar{D}} \mathbf{P}_x(X^\Delta_\Delta \in D) < 1$, and thus τ^Δ has exponential moments. The point is to prove that they are uniformly bounded w.r.t. Δ, which is not clear from the computations above.

Step 2. The first moment $\sup_{x\in\bar{D}} \mathbf{E}_x(\tau^\Delta)$ is uniformly bounded w.r.t. Δ close to 0. We adapt the arguments from [Fre85], where it is proved that $\sup_{x\in\bar{D}} \mathbf{E}_x(\tau) < \infty$. Take $x \in D$ and set $\mathbf{1} = (1, \ldots, 1)^*$; the ellipticity assumption combined with Itô's formula applied to $e^{\lambda\mathbf{1}.x}$ (for λ large enough such that $-\lambda|b|_\infty d + \frac{1}{2}\lambda^2\epsilon_0 d \ge 1$) gives

$$\begin{aligned}\mathbf{E}_x(e^{\lambda\mathbf{1}.X^\Delta_{\tau^\Delta}}) &\ge e^{\lambda\mathbf{1}.x} + \mathbf{E}_x\left(\int_0^{\tau^\Delta} e^{\lambda\mathbf{1}.X^\Delta_s} ds\right)\\ &\ge e^{\lambda\mathbf{1}.x} + \min_{z\in D_{R+1}} e^{\lambda\mathbf{1}.z}\left[\mathbf{E}_x(\tau^\Delta) - \mathbf{E}_x\left(\int_0^{\tau^\Delta} \mathbf{1}_{X^\Delta_s \notin D_{R+1}} ds\right)\right]. \qquad \text{(A.1)}\end{aligned}$$

On the one hand, we have

$$\mathbf{E}_x(e^{\lambda\mathbf{1}.X^\Delta_{\tau^\Delta}}) \le \sup_{z\in D_{R+1}} e^{\lambda\mathbf{1}.z} + \sum_{k=0}^{\infty} \mathbf{E}_x\big[\mathbf{1}_{t_k<\tau^\Delta}\mathbf{1}_{X^\Delta_{t_{k+1}}\notin D_{R+1}} e^{\lambda\mathbf{1}.X^\Delta_{t_{k+1}}}\big].$$

Standard large deviation estimates (see Lemma 4.1 in [Gob00]) give

$$\mathbf{E}\left(e^{\lambda\mathbf{1}.X^\Delta_{t_{k+1}}}\mathbf{1}_{X^\Delta_{t_{k+1}}\notin D_{R+1}}|\mathcal{F}_{t_k}\right) \le C(\lambda)e^{-c/\Delta}$$

for some constants $c > 0$ and $C(\lambda)$ uniform w.r.t. $\Delta \le 1$ and $X^\Delta_{t_k} \in D_R$. For Δ small enough such that $\frac{C(\lambda)e^{-c/\Delta}}{\Delta} \le \frac{1}{3}\min_{z\in D_{R+1}} e^{\lambda\mathbf{1}.z}$, we obtain

$$\mathbf{E}_x(e^{\lambda\mathbf{1}.X^\Delta_{\tau^\Delta}}) \le \sup_{z\in D_{R+1}} e^{\lambda\mathbf{1}.z} + \mathbf{E}_x(\tau^\Delta)\,\frac{1}{3}\min_{z\in D_{R+1}} e^{\lambda\mathbf{1}.z}.$$

On the other hand, from Fubini's theorem, we have $\mathbf{E}_x(\int_0^{\tau^\Delta} \mathbf{1}_{X^\Delta_s\notin D_{R+1}} ds) = \int_0^\infty \mathbf{P}_x(\phi(s) < \tau^\Delta; X^\Delta_s \notin D_{R+1}) ds$. The previous arguments give $\mathbf{E}_x(\int_0^{\tau^\Delta} \mathbf{1}_{X^\Delta_s\notin D_{R+1}} ds) \le Ce^{-c/\Delta}\int_0^\infty \mathbf{P}_x(\phi(s) < \tau^\Delta) ds \le \frac{1}{3}\mathbf{E}_x\tau^\Delta$ for Δ small enough. Plugging all these estimates into (A.1), we get

$$\sup_{z\in D_{R+1}} e^{\lambda\mathbf{1}.z} \ge e^{\lambda\mathbf{1}.x} + \mathbf{E}_x(\tau^\Delta)\,\frac{1}{3}\min_{z\in D_{R+1}} e^{\lambda\mathbf{1}.z}$$

uniformly in $x \in D$ for Δ small enough. This proves our assertion.

Step 3. The pth moment $\sup_{x\in\bar{D}} \mathbf{E}_x([\tau^\Delta]^p)$ $(p \geq 1)$ is uniformly bounded w.r.t. Δ close to 0. This is a standard consequence of the boundedness of $\sup_{x\in\bar{D}} \mathbf{E}_x(\tau^\Delta)$ and of the Markov property at times $(k\Delta)_k$. We refer to section 3.3 in [Fre85] for a proof in the diffusion case, which can be adapted to the discrete Euler scheme in a straightforward way. Statement (a) is proved.

Statement (b). In view of the uniform integrability conditions (a), it is enough to prove that τ^Δ converges in probability to τ, which follows from the weak convergence of (τ^Δ, τ) to (τ, τ) (stable convergence). Thus, we aim at showing that for any s_1, s_2, we have

$$\lim_{\Delta\to 0} \mathbf{P}_x(\tau^\Delta \leq s_1, \tau \leq s_2) = \mathbf{P}_x(\tau \leq s_1, \tau \leq s_2). \tag{A.2}$$

We introduce the signed distance to ∂D, defined by $F(x) = d(x, \partial D)$ if $x \in D$ and $F(x) = -d(x, \partial D)$ if $x \notin D$. Without additional regularity on D, F is at least a Lipschitz continuous function. Note that $\{\tau^\Delta \leq s_1\} = \{\inf_{t\leq s_1} F(X^\Delta_{\phi(t)}) \leq 0\}$ and $\{\tau \leq s_1\} = \{\inf_{t\leq s_1} F(X_t) \leq 0\}$. From the a.s. uniform convergence of $(X^\Delta_{\phi(t)})_t$ to $(X_t)_t$ on $[0, s_1]$ (see [Gob00], for instance), we have $\lim_{\Delta\to 0} \inf_{t\leq s_1} F(X^\Delta_{\phi(t)}) = \inf_{t\leq s_1} F(X_t)$ a.s. Thus, (A.2) holds true if $0 = \mathbf{P}(\inf_{t\leq s_1} F(X_t) = 0)$, and we obtain, using the strong Markov property,

$$0 = \mathbf{E}(\mathbf{1}_{\tau<s_1} \mathbf{P}_{X_\tau}(\forall t \leq s_1 - \tau : X_t \in \bar{D})) + \mathbf{P}(\tau = s_1). \tag{A.3}$$

In fact, for any $r > 0$ and $x \in \partial D$, under (H2$'$) we have $\mathbf{P}_x(\forall t \leq r : X_t \in \bar{D}) \leq \mathbf{P}_x(X_r \in \bar{D}) < 1$ (in [Gob00], see inequality (68) and the comments before Remark 5.1). Thus, by the Blumenthal zero-one law, the probability $\mathbf{P}_x(\forall t \leq r : X_t \in \bar{D})$ must be equal to 0. Hence, (A.3) is reduced to $\mathbf{P}(\tau = s_1) = 0$. This equality is true except for the countable number of points of discontinuity of $s_1 \mapsto \mathbf{P}(\tau \leq s_1)$, which is enough to derive (A.2) for any s_1.

Statements (c) and (d). Both statements easily follow from the a.s. uniform convergence of X^Δ to X on compact sets, from the uniform integrability in (a) and from the convergence (b). □

Appendix B. A technical lemma.

LEMMA B.1. *Assume* (H2$'$) *and that $\hat{u}$ is the $C^0(\bar{D}) \cap C^2(D)$-solution of $L_0\hat{u} - c\hat{u} = \hat{f}$ in D and $\hat{u} = \hat{g}$ on ∂D, where $\hat{f}$ and $\hat{g}$ are bounded continuous functions. Then*

$$V(\hat{u}, 0, x) = \mathbf{E}_x \left[\int_0^\tau Z_s^2 \ |\nabla_x \hat{u}\ \sigma|^2(X_s) ds \right] < +\infty.$$

Proof. The technical difficulty comes from the fact that $\hat{u}$ may have derivatives exploding near the boundary. To circumvent this problem, set $D_\varepsilon = \{x \in D : d(x, \partial D) > \varepsilon\}$ for $\varepsilon > 0$ and denote by τ_ε the associated exit time. By standard interior estimates [GT83], $\hat{u}$ has a bounded gradient in D_ε. Furthermore, it is straightforward to see that $\tau_\varepsilon \uparrow \tau$ a.s. as $\varepsilon \downarrow 0$. An application of Itô's formula gives

$$\hat{u}(X_{\tau_\varepsilon}) Z_{\tau_\varepsilon} + \int_0^{\tau_\varepsilon} Z_s(-L_0\hat{u} + c\hat{u})(X_s) ds = \hat{u}(x) + \int_0^{\tau_\varepsilon} Z_s\ [\nabla_x \hat{u}\ \sigma](X_s) dW_s.$$

Owing to the localization in D_ε, it is easy to see that $\mathbf{E}_x\big[\int_0^{\tau_\varepsilon} Z_s^2\ |\nabla_x\hat{u}\ \sigma|^2(X_s)ds\big] < \infty$. Hence, by the isometry property, we obtain

$$\mathbf{E}_x\left[\int_0^{\tau_\varepsilon} Z_s^2\ |\nabla_x\hat{u}\ \sigma|^2(X_s)ds\right] = \mathbf{V}\mathrm{ar}_x\left[\hat{u}(X_{\tau_\varepsilon})Z_{\tau_\varepsilon} + \int_0^{\tau_\varepsilon} Z_s(-L_0\hat{u}+c\hat{u})(X_s)ds\right].$$

Take the limit when ε goes to 0: the left-hand side converges using the monotone convergence theorem and the right-hand side using the dominated convergence theorem. The limit writes $\mathbf{E}_x\big[\int_0^{\tau} Z_s^2\ |\nabla_x\hat{u}\ \sigma|^2(X_s)ds\big] = V(\hat{u},0,x)$, which is our statement. □

Appendix C. Proof of Lemma 4.4. We can assume $y \geq 0$. Tanaka's formula [RY94] yields

$$\frac{1}{2}\mathbf{E}_x(L_\tau^y(X)) = \mathbf{E}_x(X_\tau - y)_+ - (x-y)_+ - \mathbf{E}_x\left(\int_0^\tau b(X_s)\mathbf{1}_{X_s\geq y}ds\right).$$

Hence, we get $\mathbf{E}_x(L_\tau^y(X)) \leq C$ uniformly in x, y. Using the occupation time formula in the equality above and the previous uniform estimate, we obtain $\frac{1}{2}\mathbf{E}_x(L_\tau^y(X)) \leq (1-y)+C\int_y^1 \mathbf{E}_x(L_\tau^z(X))dz \leq C(1-y)$. If $y<0$, then the same arguments apply. □

ON THE CONVERGENCE OF MORTAR EDGE ELEMENT METHODS IN $\mathbb{R}^3$*

XUEJUN XU[†] AND R. H. W. HOPPE[‡]

Abstract. In this paper, we are concerned with mortar element methods for the numerical solution of the eddy currents equations based on domain decompositions on nonmatching grids using individual subdomain discretizations by the lowest order edge elements of Nédélec's first family. The main results are optimal a priori error estimates of the global discretization error and the Lagrange multipliers that take care of the weak continuity constraints on the tangential traces across interior subdomain boundaries. These estimates are derived under moderate regularity assumptions.

Key words. mortar edge elements, domain decomposition on nonmatching grids, eddy currents equations

1. Introduction.

Mortar element methods have attracted considerable attention in recent years, since they can handle situations where meshes on different subdomains need not align across interfaces, and the matching of discretizations on adjacent subdomains is only enforced weakly. In [8], Bernardi, Maday, and Patera first introduced basic concepts of general mortar element methods, including the coupling of spectral elements with finite elements. Subsequently, they have been extensively used and analyzed by many authors. In [4], Ben Belgacem studied the mortar element method within a primal hybrid finite element formulation. Some extensions and convergence results in three dimensions have been considered in [5], [10], and [22].

In the framework of edge element discretizations, the mortar element method has been studied for two-dimensional problems in [3] and [6]. However, similar to second order elliptic problems (cf., e.g., [5], [10], [22]), the situation in the three-dimensional case is much more complicated, since it particularly requires a subtle specification of the multiplier space. Recently, the second author of this paper considered a mortar element method for three-dimensional Maxwell equations in [20], where the edge element of the first family has been studied (see also [21]). Related work for mortar edge elements has been proposed by Ben Belgacem, Buffa, and Maday in [7], but their result holds only for the lowest order edge elements of Nédélec's second family [26]. Furthermore, their error estimate of order $O(hlog(h))$ is not optimal and requires a somewhat high regularity of the solution, i.e., the solution is assumed to belong to $H^2(\mathbf{curl};\Omega)$.

In this paper, we will give an optimal error estimate for the mortar edge element method based on the lowest order edge elements of Nédélec's first family. Our convergence results are established under a weaker regularity assumption, i.e., the solution

is assumed to belong to $H^1(\mathbf{curl};\Omega)$. On the other hand, on the basis of the discrete inf-sup condition constructed in [20], we also obtain an optimal error estimate for the Lagrange multiplier.

The paper is organized as follows. Section 2 describes the model problem under consideration. Section 3 introduces the mortar edge element method followed by the derivation of the optimal energy error estimate in section 4. Finally, section 5 is devoted to an optimal error estimate for the Lagrange multiplier.

2. Model problem. Given a bounded simply connected domain Ω in R^3 with polyhedral boundary $\partial\Omega$, we consider the following elliptic boundary value problem:

$$\begin{cases} \mathbf{curl}\ \mathbf{A}\ \mathbf{curl}\ \mathbf{j} + \mathbf{B}\ \mathbf{j} = \mathbf{f} & \text{in } \Omega, \\ \mathbf{j} \wedge \mathbf{n} = \mathbf{g} & \text{on } \partial\Omega, \end{cases} \tag{2.1}$$

where $\mathbf{n}$ denotes the exterior unit normal vector on $\partial\Omega$. We note that the above problem arises, for instance, in the computation of eddy currents and can be deduced from the time-dependent equations by using an implicit finite difference scheme (cf. [9], [18], [23]).

We assume $\mathbf{A} = \{a_{ij}\}_{i,j=1}^3$ and $\mathbf{B} = \{b_{ij}\}_{i,j=1}^3$ to be symmetric matrix-valued functions, with $a_{ij} \in C^1(\bar{\Omega}),\ b_{ij} \in L^\infty(\Omega),\ 1 \le i,j \le 3$, satisfying

$$c|\xi|^2 \le \sum_{i,j=1}^3 a_{ij}(x)\xi_i\xi_j \le C|\xi|^2, \qquad c|\xi|^2 \le \sum_{i,j=1}^3 b_{ij}(x)\xi_i\xi_j \le C|\xi|^2, \quad \xi \in R^3,$$

for almost all $x \in \Omega$. In this paper, the constants c and C with or without subscript always denote general positive constants independent of the mesh size. Moreover, we assume $\mathbf{f} \in L^2(\Omega)^3$ and suppose, for simplicity, that $\mathbf{g} = 0$.

We denote by $H(\mathbf{curl};\Omega)$ the Hilbert space

$$H(\mathbf{curl};\Omega) := \{\mathbf{q} \in L^2(\Omega)^3 \mid \mathbf{curl}\mathbf{q} \in L^2(\Omega)^3\}$$

equipped with the norm

$$\|\mathbf{q}\|_{\mathbf{curl},\Omega} := (\|\mathbf{q}\|_{0,\Omega}^2 + \|\mathbf{curl}\mathbf{q}\|_{0,\Omega}^2)^{\frac{1}{2}}.$$

Here and in what follows, $\|\cdot\|_{k,\Omega}, k \in \mathbb{N}_0$, stands for the norm of the Sobolev space $H^k(\Omega)^3$. Moreover, we define the space

$$H^1(\mathbf{curl};\Omega) := \{\mathbf{q} \in H^1(\Omega)^3 | \mathbf{curl}\mathbf{q} \in H^1(\Omega)^3\}$$

equipped with the norm

$$\|\mathbf{q}\|_{1,\mathbf{curl},\Omega} := (\|\mathbf{q}\|_{1,\Omega} + \|\mathbf{curl}\mathbf{q}\|_{1,\Omega})^{\frac{1}{2}}.$$

Similarly, if G is a subdomain of Ω, we can define the space $H^1(\mathbf{curl};G)$ over the subdomain G. The corresponding norm is denoted by $\|\mathbf{q}\|_{1,\mathbf{curl},G}$.

We refer to

$$\mathbf{V} := H_0(\mathbf{curl};\Omega) = \{\mathbf{q} \in H(\mathbf{curl};\Omega) \mid \mathbf{n} \wedge (\mathbf{q} \wedge \mathbf{n})|_{\partial\Omega} = 0\}$$

as the subspace of vector fields with vanishing tangential components trace on $\partial\Omega$.

Then, the variational formulation of (2.1) is to find $\mathbf{j} \in \mathbf{V}$ such that

$$a_\Omega(\mathbf{j},\mathbf{q}) \ = \ l(\mathbf{q}) \quad \forall \mathbf{q} \in \mathbf{V}, \tag{2.2}$$

where the bilinear form $a_\Omega(\cdot,\cdot) : H(\mathbf{curl};\Omega) \times H(\mathbf{curl};\Omega) \to \mathbb{R}$ and the functional $l(\cdot) : H(\mathbf{curl};\Omega) \to R$ are given by

$$a_\Omega(\mathbf{j},\mathbf{q}) := \int_\Omega (\mathbf{A}\ \mathbf{curl}\ \mathbf{j} \cdot \mathbf{curl}\ \mathbf{q} + \mathbf{B}\ \mathbf{j} \cdot \mathbf{q})\, dx,$$
$$l(\mathbf{q}) := \int_\Omega \mathbf{f} \cdot \mathbf{q}\, dx.$$

We further have to introduce the tangential traces of $H(\mathbf{curl};\Omega)$. In particular, we denote by div_τ and curl_τ the surfacic divergence and the adjoint of the surfacic rotational $\mathbf{curl}_\tau$ (cf. [1]). For $B \subset \partial\Omega$, the space $H_{00}^{\frac{1}{2}}(B)$ is the subspace of functions $u \in H^{\frac{1}{2}}(\Omega)$ whose extension $\tilde{u}$ by zero to $\partial\Omega\backslash B$ belongs to $H^{\frac{1}{2}}(\partial\Omega)$ with norm $\|u\|_{H_{00}^{\frac{1}{2}}(B)} := \|\tilde{u}\|_{\frac{1}{2},\partial\Omega}$. We refer to $H^{-\frac{1}{2}}(B)$ as the dual space of $H_{00}^{\frac{1}{2}}(B)$ (cf. [19] for details).

The tangential trace $(\mathbf{q} \wedge \mathbf{n})|_B$ belongs to the Hilbert space

$$H^{-\frac{1}{2}}(\mathrm{div}_\tau; B) \ := \ \{\mathbf{q} \in H^{-\frac{1}{2}}(B)^3 \mid \mathbf{n} \cdot \mathbf{q}|_B = 0 \text{ and } \mathrm{div}_\tau \mathbf{q} \in H^{-\frac{1}{2}}(B)\}$$

equipped with the norm

$$\|\mathbf{q}\|_{-\frac{1}{2},\mathrm{div}_\tau,B} \ := \ (\|\mathbf{q}\|^2_{-\frac{1}{2},B} + \|\mathrm{div}_\tau \mathbf{q}\|^2_{-\frac{1}{2},B})^{1/2},$$

whereas the tangential components trace $(\mathbf{n} \wedge (\mathbf{q} \wedge \mathbf{n}))|_B$ lives in the Hilbert space

$$H^{-\frac{1}{2}}(\mathrm{curl}_\tau; B) \ := \ \{\mathbf{q} \in H^{-\frac{1}{2}}(B)^3 \mid \mathbf{n} \cdot \mathbf{q}|_B = 0 \quad \text{and} \quad \mathrm{curl}_\tau \mathbf{q} \in H^{-\frac{1}{2}}(B)\}$$

equipped with the norm

$$\|\mathbf{q}\|_{-\frac{1}{2},\mathrm{curl}_\tau,B} \ := \ (\|\mathbf{q}\|^2_{-\frac{1}{2},B} + \|\mathrm{curl}_\tau \mathbf{q}\|^2_{-\frac{1}{2},B})^{1/2}.$$

The spaces $H^{-\frac{1}{2}}(\mathrm{div}_\tau; B)$ and $H^{-\frac{1}{2}}(\mathrm{curl}_\tau; B)$ are dual to each other with $\mathbf{L}^2_\mathbf{t}(B) := \{\mathbf{q} \in L^2(B)^3 \mid \mathbf{n} \cdot \mathbf{q}|_B = 0\}$ as the pivot space (cf. [13], [14], and [15] for details).

3. The mortar edge element method. We now introduce a mortar finite element method for the solution of (2.1). First, we partition Ω into nonoverlapping subdomains such that

$$\overline{\Omega} = \bigcup_{i=1}^N \overline{\Omega}_i \quad \text{and} \quad \Omega_i \cap \Omega_j = \emptyset, \quad i \neq j.$$

We assume this decomposition to be geometrically conforming in the sense that the intersection of $\bar{\Omega}_i \cap \bar{\Omega}_j$ for $i \neq j$ is either empty, a vertex, an edge, or a face. The skeleton of the decomposition

$$S = \bigcup_{i=1}^N \partial\Omega_i \backslash \partial\Omega$$

is partitioned into a set of disjoint open faces γ_m $(1 \leq m \leq M)$ called mortars, i.e.,

$$S = \bigcup_{m=1}^M \bar{\gamma}_m, \quad \gamma_m \cap \gamma_n = \emptyset \ \text{ if } \ m \neq n.$$

We denote the common interface between Ω_i and Ω_j by γ_m. We refer to $\gamma_{m(i)}$ as the mortar associated with subdomain Ω_i, while the other face, which geometrically occupies the same place, is denoted by $\delta_{m(j)}$ and is called the nonmortar.

Let $\mathcal{T}_i$ be a regular and quasi-uniform triangulation of the subdomain Ω_i with mesh size $h_i := \max_{K\in\mathcal{T}_i} h_K$ made of tetrahedra. The triangulations generally do not align at the interfaces. We denote the global mesh $\cup_i \mathcal{T}_i$ by $\mathcal{T}_h$ with mesh size $h := \max_i h_i$. We refer to $\mathcal{T}_{\gamma_{m(i)}}$ and $\mathcal{T}_{\delta_{m(j)}}$ as the triangulations which are inherited from the triangulations $\mathcal{T}_i$ and $\mathcal{T}_j$ on the mortar and nonmortar sides, respectively. We further denote by $h_{\gamma_{m(i)}}$ and $h_{\delta_{m(j)}}$ the global mesh sizes with respect to the triangulations $\mathcal{T}_{\gamma_{m(i)}}$ and $\mathcal{T}_{\delta_{m(j)}}$. Moreover, for $\Sigma_i \subset \bar{\Omega}_i$ we define $\mathcal{F}_h(\Sigma_i)$ and $\mathcal{E}_h(\Sigma_i)$ as the sets of faces, respectively, edges, of $\mathcal{T}_i$ in Σ_i. Likewise, for $\Sigma_{\gamma_{m(i)}}$ and $\Sigma_{\delta_{m(j)}} \subset \gamma_m$ we refer to $\mathcal{E}_h(\Sigma_{\gamma_{m(i)}})$ and $\mathcal{E}_h(\Sigma_{\delta_{m(j)}})$ as the set of edges of $\mathcal{T}_{\gamma_{m(i)}}$, respectively, $\mathcal{T}_{\delta_{m(j)}}$, in $\Sigma_{\gamma_{m(i)}}$, respectively, $\Sigma_{\delta_{m(j)}}$.

We assume that there exist constants c, C independent of $h_{\gamma_{m(i)}}$ and $h_{\delta_{m(j)}}$ such that

$$c\, h_{\gamma_{m(i)}} \;\le\; h_{\delta_{m(j)}} \;\le\; C\, h_{\gamma_{m(i)}}. \tag{3.1}$$

For the discretization of $H(\mathbf{curl};\Omega_i)$, we introduce Nédélec's **curl**-conforming edge elements of the first family as described in [25], i.e., for a tetrahedron $K \in \mathcal{T}_i$ the lowest order edge element $\mathrm{ND_1(K)}$ is defined as

$$\mathrm{ND_1(K)} \;:=\; \{\mathbf{q} = \mathbf{a} + \mathbf{b} \wedge \mathbf{x} \mid \mathbf{a},\ \mathbf{b} \in R^3,\ \mathbf{x} \in K\}.$$

Note that any $\mathbf{q} \in \mathrm{ND_1(K)}$ is uniquely determined by the degrees of freedom

$$l_e(\mathbf{q}) \;:=\; \int_e \mathbf{t_e} \cdot \mathbf{q}\, ds, \quad e \in \mathcal{E}_h(K), \tag{3.2}$$

where $\mathbf{t_e}$ stands for the tangential unit vector along e.

Then, the spaces $\mathrm{ND}_1(\Omega_i;\mathcal{T}_i)$ are given as follows:

$$\mathrm{ND}_1(\Omega_i;\mathcal{T}_i) \;:=\; \{\mathbf{q_h} \in H(\mathbf{curl};\Omega_i) \mid \mathbf{q_h}|_K \in \mathrm{ND}_1(K),\ K \in \mathcal{T}_i\}.$$

On the basis of the above definition, we consider the product space

$$\tilde{\mathbf{V}}_\mathbf{h} \;:=\; \{\mathbf{q_h} \in L^2(\Omega)^3 \mid \mathbf{q_h}|_{\Omega_i} \in \mathrm{ND}_{1,0}(\Omega_i;\mathcal{T}_i),\ 1 \le i \le n\},$$

where we refer to $\mathrm{ND}_{1,0}(\Omega_i;\mathcal{T}_i)$ as the subspace of vector fields with vanishing tangential component traces on $\partial\Omega \cap \partial\Omega_i$.

It is clear that we cannot expect $\tilde{\mathbf{V}}_\mathbf{h}$ to be a subspace of $H_0(\mathbf{curl};\Omega)$, since the tangential traces $(\mathbf{q_h} \wedge \mathbf{n})|_F, \mathbf{q_h} \in \tilde{\mathbf{V}}_\mathbf{h}$, are not continuous across the common face F of two adjacent subdomains. Therefore, in order to guarantee consistency of the approximation, we have to impose some weak continuity constraints on the tangential traces. We note that $(\mathbf{q_h} \wedge \mathbf{n})|_{\gamma_{m(i)}}$ and $(\mathbf{q_h} \wedge \mathbf{n})|_{\delta_{m(j)}}$ are elements of the lowest order Raviart–Thomas finite element spaces $\mathrm{RT}_0(\gamma_{m(i)};\mathcal{T}_{\gamma_{m(i)}})$ and $\mathrm{RT}_0(\delta_{m(j)};\mathcal{T}_{\delta_{m(j)}})$. We recall the definition of the lowest order Raviart–Thomas conforming finite element (cf. [12], [27]). For a triangle $T \in \mathcal{T}_{\gamma_{m(i)}}$, we define $\mathrm{RT_0(T)}$ by means of

$$\mathrm{RT_0(T)} \;:=\; \{\mathbf{q} = \mathbf{a} + b\mathbf{x} \mid \mathbf{a} \in \mathbb{R}^2,\ b \in \mathbb{R},\ \mathbf{x} \in T\}.$$

Any $\mathbf{q} \in \mathrm{RT_0(T)}$ is uniquely defined by the degrees of freedom

$$l_e(\mathbf{q}) \;:=\; \int_e \mathbf{n_e} \cdot \mathbf{q}\, ds, \quad e \in \mathcal{E}_h(T), \tag{3.3}$$

where $\mathbf{n_e}$ stands for the exterior unit normal vector with respect to e.

Then, $\mathrm{RT}_0(\gamma_{m(i)}; \mathcal{T}_{\gamma_{m(i)}})$ is given as

$$\mathrm{RT}_0(\gamma_{m(i)}; \mathcal{T}_{\gamma_{m(i)}}) \ := \ \{\mathbf{q_h} \in H(\mathrm{div}; \gamma_{m(i)}) \mid \mathbf{q_h}|_T \in \mathrm{RT}_0(T),\ T \in \mathcal{T}_{\gamma_{m(i)}}\},$$

and we can similarly define $\mathrm{RT}_0(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$.

For the Lagrange multiplier space we choose

$$\mathbf{M_h} := \prod_{\delta_{m(j)}} \mathbf{M_h}(\delta_{m(j)})$$

with

$$\dim\ \mathbf{M_h}(\delta_{m(j)}) = \dim\ \mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}}),$$

where $\mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$ denotes the subspace of vector fields with vanishing normal components along the boundary $\partial\delta_{m(j)}$.

For the proper definition of $\mathbf{M_h}(\delta_{m(j)})$ we need a more detailed specification of the basis fields of $\mathrm{RT}_0(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$. In view of (3.3), we specify the basis field $\mathbf{q}_\gamma$ associated with the edge $e_\gamma \in \mathcal{E}_h(\bar{\delta}_{m(j)})$ according to

$$\int_{e_\mu} \mathbf{n}_\mu \cdot \mathbf{q}_\gamma \ ds \ = \ h_{\delta_{m(j)}} \delta_{\gamma\mu}, \quad e_\mu \in \mathcal{E}_h(\bar{\delta}_{m(j)}). \tag{3.4}$$

We now define $\mathbf{M_h}(\delta_{m(j)})$ by an extension of the basis field $\mathbf{q_e} \in \mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$ with respect to those edges in $\delta_{m(j)}$ that have at least one neighboring edge on the boundary $\partial\delta_{m(j)}$. The precise specification requires some notation:

1. For an interior edge $e \in \mathcal{E}_h(\delta_{m(j)})$, we denote by

$$\mathcal{E}_h^{\partial\delta_{m(j)}}(e) \ := \ \{f \in \mathcal{E}_h(\partial\delta_{m(j)}) \mid f \subset \mathrm{supp}\ \mathbf{q}_e\} \tag{3.5}$$

the set of the neighboring edges on $\partial\delta_{m(j)}$.

2. For a boundary edge $f \in \mathcal{E}_h(\partial\delta_{m(j)})$, we refer to

$$\mathcal{E}_h^{\delta_{m(j)}}(f) \ := \ \{e \in \mathcal{E}_h(\delta_{m(j)}) \mid e \subset \mathrm{supp}\ \mathbf{q}_f\} \tag{3.6}$$

as the set of neighboring edges in the interior of $\delta_{m(j)}$.

Finally we define

$$\mathcal{E}_h^{\delta_{m(j)}}(\partial\delta_{m(j)}) \ := \bigcup_{f \in \mathcal{E}_h(\partial\delta_{m(j)})} \mathcal{E}_h^{\delta_{m(j)}}(f) \tag{3.7}$$

as the set of interior edges with a neighboring edge on $\partial\delta_{m(j)}$.

Then, for $e \in \mathcal{E}_h^{\delta_{m(j)}}(\partial\delta_{m(j)})$, we choose appropriate weighting factors $\lambda_{e,f} \in \mathbb{R}$, $f \in \mathcal{E}_h^{\partial\delta_{m(j)}}(e)$, and define the basis field $\tilde{\mathbf{q}}_\mathbf{e}$, $e \in \mathcal{E}_h(\delta_{m(j)})$, according to

$$\tilde{\mathbf{q}}_e = \begin{cases} \mathbf{q}_e, & e \in \mathcal{E}_h(\delta_{m(j)}) \backslash \mathcal{E}_h^{\delta_{m(j)}}(\partial\delta_{m(j)}) \\ \mathbf{q}_e + \sum_{f \in \mathcal{E}_h^{\partial\delta_{m(j)}}(e)} \lambda_{e,f} \mathbf{q}_f, & e \in \mathcal{E}_h^{\delta_{m(j)}}(\partial\delta_{m(j)}), \end{cases} \tag{3.8}$$

where the weighting factors are assumed to satisfy

$$\begin{cases} \lambda_{e,f} \geq 0, \\ \sum_{e \in \mathcal{E}_h^{\delta_{m(j)}}(f)} \lambda_{e,f} = 1, \quad f \in \mathcal{E}_h(\partial\delta_{m(j)}). \end{cases} \tag{3.9}$$

The thus specified basis fields define

$$\mathbf{M_h}(\delta_{m(j)}) \ := \ \operatorname{span}\{\tilde{\mathbf{q}}_e | e \in \mathcal{E}_h(\delta_{m(j)})\}. \tag{3.10}$$

Remark 3.1. In view of (3.9) it is easy to check that $\mathbf{M_h}(\delta_{m(j)})$ contains the constant vectors.

Next, we introduce the L^2-projection $Q_h^{\delta_{m(j)}} : L^2(\gamma_m)^2 \rightarrow \mathbf{M_h}(\delta_{m(j)})$ as follows:

$$(Q_h^{\delta_{m(j)}}\mathbf{q}, \mathbf{w}) = (\mathbf{q}, \mathbf{w}), \quad \mathbf{w} \in \mathbf{M_h}(\delta_{m(j)}). \tag{3.11}$$

LEMMA 3.1. *Let* $Q_h^{\delta_{m(j)}}$ *be given by* (3.11). *Then there holds*

$$\|\mathbf{q} - Q_h^{\delta_{m(j)}}\mathbf{q}\|_{0,\gamma_m} \leq C \ h_{\delta_{m(j)}}^{\frac{1}{2}} \ |\mathbf{q}|_{\frac{1}{2},\delta_{m(j)}}, \quad \mathbf{q} \in (H^{\frac{1}{2}}(\delta_{m(j)}))^2.$$

Proof. Let $\mathbf{I_h}$ denote the global interpolation operator associated with the space $\mathbf{M_h}(\delta_{m(j)})$, i.e.,

$$\mathbf{I_h q} = \sum_{e \in \mathcal{E}_h(\delta_{m(j)})} l_e(\mathbf{q})\tilde{\mathbf{q}}_e,$$

where $l_e(\mathbf{q}) = \int_e \mathbf{n}_e \cdot \mathbf{q}\, ds \ \forall \mathbf{q} \in (H^1(\delta_{m(j)}))^2$.

In view of Remark 3.1 we know that $\mathbf{I_h}$ preserves constant vectors, i.e., for any $\mathbf{C} \in R^2$,

$$\mathbf{I}_h\mathbf{C} = \mathbf{C}.$$

Consequently, by the standard Bramble–Hilbert lemma and scaling argument we get

$$\begin{aligned} \|(\mathbf{I} - \mathbf{I_h})\mathbf{q}\|_{0,\gamma_m}^2 &= \|(\mathbf{I} - \mathbf{I_h})(\mathbf{q} + \mathbf{C})\|_{0,\gamma_m}^2 \\ &= \sum_{T \in \mathcal{T}_{\delta_{m(j)}}} \|(\mathbf{I} - \mathbf{I_h})(\mathbf{q} + \mathbf{C})\|_{0,T}^2 \\ &\leq \ Ch_{\delta_{m(j)}}^2 |\mathbf{q}|_{1,\delta_{m(j)}}^2, \qquad \mathbf{q} \in (H^1(\delta_{m(j)}))^2, \end{aligned}$$

whence

$$\|(\mathbf{I} - \mathbf{I_h})\mathbf{q}\|_{0,\gamma_m} \ \leq \ Ch_{\delta_{m(j)}} |\mathbf{q}|_{1,\delta_{m(j)}}, \quad \mathbf{q} \in (H^1(\delta_{m(j)}))^2.$$

It follows from the definition of $Q_h^{\delta_{m(j)}}$ that

$$\|(\mathbf{I} - Q_h^{\delta_{m(j)}})\mathbf{q}\|_{0,\gamma_m} \leq \|(\mathbf{I} - \mathbf{I_h})\mathbf{q}\|_{0,\gamma_m} \ \leq \ Ch_{\delta_{m(j)}} |\mathbf{q}|_{1,\delta_{m(j)}}, \quad \mathbf{q} \in (H^1(\delta_{m(j)}))^2.$$

On the other hand,

$$\|(\mathbf{I} - Q_h^{\delta_{m(j)}})\mathbf{q}\|_{0,\gamma_m} \leq 2\|\mathbf{q}\|_{0,\delta_{m(j)}}.$$

The assertion then follows from a standard interpolation of the preceding inequalities. □

We now introduce the following mortar edge element space:

$$\begin{aligned} \mathbf{V_h} = \{\mathbf{q_h} \mid \mathbf{q_h} \in \tilde{\mathbf{V}}_\mathbf{h}, \text{ and for any } \gamma_m = \gamma_{m(i)} = \delta_{m(j)}, \\ Q_h^{\delta_{m(j)}}(\mathbf{q_h} \wedge \mathbf{n}|_{\gamma_{m(i)}}) = Q_h^{\delta_{m(j)}}(\mathbf{q_h} \wedge \mathbf{n}|_{\delta_{m(j)}})\}. \end{aligned} \tag{3.12}$$

We define the bilinear form $a_h(\cdot,\cdot) : \mathbf{V_h} \times \mathbf{V_h} \rightarrow \mathbb{R}$ by means of

$$a_h(\mathbf{j_h}, \mathbf{q_h}) \;=\; \sum_{i=1}^{N} \int_{\Omega_i} (\mathbf{A\ curl\ j_h} \cdot \mathbf{curl\ q_h} + \mathbf{B\ j_h} \cdot \mathbf{q_h})\ dx. \tag{3.13}$$

Then the mortar finite element method for the solution of (2.4) can be stated as follows: Find $\mathbf{j_h} \in \mathbf{V_h}$ such that

$$a_h(\mathbf{j_h}, \mathbf{q_h}) \;=\; l(\mathbf{q_h}), \quad \mathbf{q_h} \in \mathbf{V_h}. \tag{3.14}$$

4. Error estimates.

We first recall the well-known Strang lemma (cf., e.g., [17]).

LEMMA 4.1 (Strang's lemma). *Let* $\mathbf{j}, \mathbf{j_h}$ *be the solutions of* (2.2) *and* (3.14), *respectively. Then there holds*

$$\begin{aligned}\|\mathbf{j} - \mathbf{j_h}\|_{a_h} \;\le\; &\left(\inf_{\mathbf{q_h} \in \mathbf{V_h}/\{0\}} \|\mathbf{j} - \mathbf{q_h}\|_{a_h} + \sup_{\mathbf{q_h} \in \mathbf{V_h}\setminus\{0\}} \frac{|a_h(\mathbf{j}, \mathbf{q_h}) - (f, \mathbf{q_h})|}{\|\mathbf{q_h}\|_{a_h}} \right) \\ &:= C(E_a + E_c),\end{aligned}$$

where $\|\cdot\|_{a_h} = a_h(\cdot,\cdot)^{\frac{1}{2}}$.

We are now in a position to estimate the two terms on the right side of the above inequality. As usual, we refer to the first one as the approximation error and to the second one as the consistency error.

4.1. Consistency error.

For $\mathbf{curl\ j} \in (H^1(\Omega_i))^3$, $\mathbf{q_h} \in ND_1(\Omega_i; \mathcal{T}_i)$, by Stokes' theorem we get

$$\begin{aligned}&\int_{\Omega_i} \mathbf{curl} \cdot \mathbf{Acurl\ j} \cdot \mathbf{q_h}\ dx \\ &\quad - \int_{\Omega_i} \mathbf{Acurl\ j} \cdot \mathbf{curl\ q_h}\ dx \;=\; (\mathbf{n} \wedge (\mathbf{Acurl\ j} \wedge \mathbf{n}), \mathbf{q_h} \wedge \mathbf{n})_{0,\partial\Omega_i},\end{aligned}$$

where $\mathbf{n} \wedge (\mathbf{Acurl\ j} \wedge \mathbf{n})$ is the tangential components trace of $\mathbf{Acurl\ j}$. Rearranging the right-hand term in the above equality, for any $\mathbf{q_h} \in \tilde{\mathbf{V}}_\mathbf{h}$, and $\mathbf{curl\ j} \in (H^1(\Omega_i))^3$, $i = 1, \ldots, N$, we have (cf. [7] for details)

$$\begin{aligned}&\sum_{i=1}^{N} \left(\int_{\Omega_i} \mathbf{curl} \cdot \mathbf{Acurl\ j} \cdot \mathbf{q_h}\ dx \;-\; \int_{\Omega_i} \mathbf{Acurl\ j} \cdot \mathbf{curl\ q_h}\ dx \right) \\ &\quad = \sum_{m=1}^{M} (\mathbf{n} \wedge (\mathbf{Acurl\ j} \wedge \mathbf{n}), [\mathbf{q_h} \wedge \mathbf{n}])_{0,\gamma_m},\end{aligned} \tag{4.1}$$

where $[\cdot]$ denotes the jump across the interface γ_m, i.e.,

$$[\mathbf{q_h} \wedge \mathbf{n}] = \mathbf{q_h} \wedge \mathbf{n}|_{\delta_{m(j)}} - \mathbf{q_h} \wedge \mathbf{n}|_{\gamma_{m(i)}}.$$

On the basis of the above equality, we can easily show that

$$E_c \;=\; \sup_{\mathbf{q_h} \in \mathbf{V_h}\setminus\{0\}} \left| \sum_{m=1}^{M} \frac{(\mathbf{n} \wedge (\mathbf{Acurl\ j} \wedge \mathbf{n}), [\mathbf{q_h} \wedge \mathbf{n}])_{0,\gamma_m}}{\|\mathbf{q_h}\|_{a_h}} \right|.$$

THEOREM 4.1. *Assume* $\mathbf{j} \in H^1(\mathbf{curl};\Omega)$. *Then the consistency error can be estimated as follows*:

$$E_c \leq C \left(\sum_{j=1}^{N} h_j^2 \ \|\mathbf{curl}\,\mathbf{j}\|_{1,\Omega_j}^2 \right)^{\frac{1}{2}}.$$

Proof. It follows from Lemma 3.1, (3.12), and the trace inequality that

$$\begin{aligned}
&|(\mathbf{n} \wedge (\mathbf{A}\mathbf{curl}\,\mathbf{j} \wedge \mathbf{n}), [\mathbf{q_h} \wedge \mathbf{n}])_{0,\gamma_m}| \\
&\quad = |(\mathbf{n} \wedge (\mathbf{A}\mathbf{curl}\,\mathbf{j} \wedge \mathbf{n}) - Q_h^{\delta_{m(j)}}(\mathbf{n} \wedge (\mathbf{A}\mathbf{curl}\,\mathbf{j} \wedge \mathbf{n})), [\mathbf{q_h} \wedge \mathbf{n}])_{0,\gamma_m}| \\
&\quad \leq \|\mathbf{n} \wedge (\mathbf{A}\mathbf{curl}\,\mathbf{j} \wedge \mathbf{n}) - Q_h^{\delta_{m(j)}}(\mathbf{n} \wedge (\mathbf{A}\mathbf{curl}\,\mathbf{j} \wedge \mathbf{n}))\|_{0,\gamma_m} \ \|[\mathbf{q_h} \wedge \mathbf{n}]\|_{0,\gamma_m} \\
&\quad \leq Ch_{\delta_{m(j)}}^{\frac{1}{2}} \ |\mathbf{n} \wedge (\mathbf{A}\mathbf{curl}\,\mathbf{j} \wedge \mathbf{n})|_{\frac{1}{2},\delta_{m(j)}} \ \|[\mathbf{q_h} \wedge \mathbf{n}]\|_{0,\gamma_m} \\
&\quad \leq Ch_j^{\frac{1}{2}} \ \|\mathbf{curl}\,\mathbf{j}\|_{1,\Omega_j} \ \|[\mathbf{q_h} \wedge \mathbf{n}]\|_{0,\gamma_m}.
\end{aligned}$$

On the other hand, for $\mathbf{q_h} \in \mathbf{V_h}$, Theorem 3.2 in [20] yields

$$\|[\mathbf{q_h} \wedge \mathbf{n}]\|_{0,\gamma_m} \ \leq \ C \ h_{\delta_{m(j)}}^{\frac{1}{2}} \ (\|\mathbf{curl}\,\mathbf{q_h}\|_{0,\Omega_i} + \|\mathbf{curl}\,\mathbf{q_h}\|_{0,\Omega_j}). \tag{4.2}$$

On the basis of the preceding inequalities, we get

$$\begin{aligned}
E_c &\leq \left[\sum_{j=1}^{N} C \ h_j \ \|\mathbf{curl}\,\mathbf{j}\|_{1,\Omega_j} (\|\mathbf{curl}\,\mathbf{q_h}\|_{0,\Omega_i} + \|\mathbf{curl}\,\mathbf{q_h}\|_{0,\Omega_j}) \right] / \|\mathbf{q_h}\|_{a_h} \\
&\leq C \ \left[\|\mathbf{curl}\,\mathbf{q_h}\|_{0,\Omega} \left(\sum_{j=1}^{N} h_j^2 \ \|\mathbf{curl}\,\mathbf{j}\|_{1,\Omega_j}^2 \right)^{\frac{1}{2}} \right] / \|\mathbf{q_h}\|_{a_h} \\
&\leq C \ \left(\sum_{j=1}^{N} h_j^2 \ \|\mathbf{curl}\,\mathbf{j}\|_{1,\Omega_j}^2 \right)^{\frac{1}{2}}. \qquad \square
\end{aligned}$$

4.2. Approximation error. We first introduce the extension operator $E_h^{\delta_{m(j)}}$: $\mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}}) \rightarrow \mathrm{ND}_1(\Omega_j; \mathcal{T}_j)$, defined according to

$$(E_h^{\delta_{m(j)}} \lambda_h^j) \wedge \mathbf{n} = \lambda_h^j \text{ on } \delta_{m(j)}, \quad \lambda_h^j \in \mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}}),$$

where all degrees of freedom that are not located on $\delta_{m(j)}$ are set equal to zero.

In order to estimate $E_h^{\delta_{m(j)}} \lambda_h^j$, $\lambda_h^j \in \mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$, we need some auxiliary results.

LEMMA 4.2. *For any* $\mathbf{q_h} \in \mathrm{ND}_1(\Omega_i; \mathcal{T}_i)$, *there holds*

$$ch_i^3 \sum_{T \in \mathcal{F}_h(\bar{\Omega}_i)} |(\mathbf{n_T} \cdot \mathbf{curl}\mathbf{q_h})|_T|^2 \leq \|\mathbf{curl}\mathbf{q_h}\|_{0,\Omega_i}^2 \leq Ch_i^3 \sum_{T \in \mathcal{F}_h(\bar{\Omega}_i)} |(\mathbf{n_T} \cdot \mathbf{curl}\mathbf{q_h})|_T|^2,$$

and

$$ch_i^3 \sum_{e \in \mathcal{E}_h(\bar{\Omega}_i)} |(\mathbf{t_e} \cdot \mathbf{q_h})(x_e^M)|^2 \leq \|\mathbf{q_h}\|_{0,\Omega_i}^2 \leq Ch_i^3 \sum_{e \in \mathcal{E}_h(\bar{\Omega}_i)} |(\mathbf{t_e} \cdot \mathbf{q_h})(x_e^M)|^2,$$

where $\mathbf{n_T}$ *denotes the exterior unit normal vector with respect to* $T \in \mathcal{F}_h(\bar{\Omega}_i)$, *and* x_e^M *is the midpoint of the edge e. Similarly, for any* $\delta_{m(j)} \subset S$, *and any* $\mathbf{q_h} \in \mathrm{RT}_0(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$, *we have*

$$ch^2_{\delta_{m(j)}} \sum_{T \in \mathcal{T}_{\delta_{m(j)}}} |(\mathrm{div}_\tau \mathbf{q_h})|_T|^2 \leq \|\mathrm{div}_\tau \mathbf{q_h}\|^2_{0,\delta_{m(j)}} \leq Ch^2_{\delta_{m(j)}} \sum_{T \in \mathcal{T}_{\delta_{m(j)}}} |(\mathrm{div}_\tau \mathbf{q_h})|_T|^2,$$

and

$$ch^2_{\delta_{m(j)}} \sum_{e \in \mathcal{E}_h(\bar{\delta}_{m(j)})} |(\mathbf{n_e} \cdot \mathbf{q_h})(x_e^M)|^2 \leq \|\mathbf{q_h}\|^2_{0,\delta_{m(j)}} \leq Ch^2_{\delta_{m(j)}} \sum_{e \in \mathcal{E}_h(\bar{\delta}_{m(j)})} |(\mathbf{n_e} \cdot \mathbf{q_h})(x_e^M)|^2.$$

Proof. We first prove the second inequality. In the reference tetrahedron $\hat{K}$, it is easy to see that

$$\|\hat{\mathbf{q}}_h\|_{0,\hat{K}} \quad \text{and} \quad \left(\sum_{e \in \mathcal{E}_h(\bar{K})} |(\mathbf{t}_e \cdot \hat{\mathbf{q}}_\mathbf{h})(x_e^M)|^2 \right)^{\frac{1}{2}}$$

are equivalent norms over the finite dimension space. By a scaling argument and summing up all $e \in \mathcal{E}_h(\bar{\Omega}_i)$, we can get the second inequality. Similarly, the fourth inequality can be verified. Moreover, the first and third inequalities are easy consequences of the following fact:

$$\mathbf{curl}\ \mathbf{q_h}|_K \in P_0(K)^3,\ K \in \mathcal{T}_i, \quad \text{and} \quad \mathrm{div}_\tau \mathbf{q_h}|_T \in P_0(T),\ T \in \mathcal{T}_{\delta_{m(j)}}. \qquad \square$$

On the basis of Lemma 4.2 we can derive the following lemma.

LEMMA 4.3. *For* $\lambda_h^j \in \mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$ *there holds*

$$\|E_h^{\delta_{m(j)}} \lambda_h^j\|_{\mathbf{curl},\Omega_j} \leq C\ h^{\frac{1}{2}}_{\delta_{m(j)}}\ \|\lambda_h^j\|_{\mathrm{div}_\tau,\delta_{m(j)}},$$

where $\|\mathbf{v}\|_{\mathrm{div}_\tau,\delta_{m(j)}} := (\|\mathbf{v}\|^2_{0,\delta_{m(j)}} + \|\mathrm{div}_\tau \mathbf{v}\|^2_{0,\delta_{m(j)}})^{\frac{1}{2}}, \quad \forall \mathbf{v} \in \mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$.

Proof. It follows from the definition of the extension operator $E_h^{\delta_{m(j)}}$ and Lemma 4.2 that

$$\begin{aligned} \|\mathbf{curl}(E_h^{\delta_{m(j)}} \lambda_h^j)\|^2_{0,\Omega_j} &\leq Ch_j^3 \sum_{T \in \mathcal{T}_{\delta_{m(j)}}} |\mathbf{n_T} \cdot \mathbf{curl}(E_h^{\delta_{m(j)}} \lambda_h^j)|_T|^2 \\ &= Ch_j^3 \sum_{T \in \mathcal{T}_{\delta_{m(j)}}} |\mathrm{div}_\tau (E_h^{\delta_{m(j)}} \lambda_h^j \wedge \mathbf{n})|_T|^2 \\ &= Ch_j^3 \sum_{T \in \mathcal{T}_{\delta_{m(j)}}} |\mathrm{div}_\tau (\lambda_h^j)|_T|^2 \\ &\leq Ch_j\ \|\mathrm{div}_\tau (\lambda_h^j)\|^2_{0,\delta_{m(j)}}. \end{aligned}$$

Using Lemma 4.2 again, we have

$$\begin{aligned} \|E_h^{\delta_{m(j)}} \lambda_h^j\|^2_{0,\Omega_j} &\leq Ch_j^3 \sum_{e \in \mathcal{E}_h(\bar{\Omega}_j)} |(\mathbf{t_e} \cdot \mathbf{E_h^{\delta_{m(j)}}} \boldsymbol{\lambda}_\mathbf{h}^\mathbf{j})(x_e^M)|^2 \\ &= Ch_j^3 \sum_{e \in \mathcal{E}_h(\bar{\Omega}_j)} |\mathbf{n_e} \cdot (\mathbf{E_h^{\delta_{m(j)}}} \boldsymbol{\lambda}_\mathbf{h}^\mathbf{j} \wedge \mathbf{n})(x_e^M)|^2 \end{aligned}$$

$$
\begin{aligned}
&= Ch_j^3 \sum_{e\in\mathcal{E}_h(\delta_{m(j)})} |(\mathbf{n_e}\cdot\lambda_h^j)(x_e^M)|^2 \\
&\le h_j\|\lambda_h^j\|^2_{0,\delta_{m(j)}}.
\end{aligned}
$$

Then, Lemma 4.3 follows from the above two inequalities. □

LEMMA 4.4. *Let $\Pi_h^j : H^1(\mathbf{curl};\Omega_j)\to \mathrm{ND}_1(\Omega_j;\mathcal{T}_j)$ be the standard interpolation operator associated with subdomain Ω_j. Then there holds*

(i)$\|\mathbf{n_T}\cdot(\mathbf{curl}\ \Pi_h^j\mathbf{j}-\mathbf{curl}\ \mathbf{j})\|_{0,T}\le Ch_K^{\frac12}\|\mathbf{curl}\ \mathbf{j}\|_{1,K},\quad K\in\mathcal{T}_j,$

(ii) $\|\Pi_h^j\mathbf{j}-\mathbf{j}\|_{0,T}\le Ch_K^{\frac12}\|\mathbf{j}\|_{1,\mathbf{curl},K},\quad T\in\partial K.$

Proof. We first prove (i). For $K\in\mathcal{T}_i$ and $T\in\partial K$ let $F_K(\hat x)=B_K\hat x+b_K,\ \hat x\in\hat K$, be the affine transformation mapping the reference element $\hat K$ onto K. Further, choose $\hat T\in\partial\hat K$ such that $T=F_K(\hat T)$ and denote by $F_T=F_K|_{\hat T}$ the associated affine transformation $F_T(\hat x)=B_T\hat x+b_T$, $\hat x\in\hat T$, mapping $\hat T$ onto T. Setting $\hat{\mathbf{j}}=B_K^*\mathbf{j}$, it is easy to check that

$$\mathbf{n_T}\cdot(\mathbf{curl}\ \Pi_h^j\mathbf{j}-\mathbf{curl}\ \mathbf{j})|_T=\mathrm{curl}_\tau\Pi_h^j\mathbf{j}|_T-\mathrm{curl}_\tau\mathbf{j}|_T.$$

We note (cf. Lemma 3.57 of [24] for details) that

$$\mathrm{curl}_\tau\ \mathbf{j}|_T\ =\ (B_T^*)^{-1}\ \mathrm{curl}_\tau\ \hat{\mathbf{j}}|_{\hat T}\ B_T^{-1},$$

where $\mathrm{curl}_\tau\ \mathbf{u}$ denotes the 2×2 matrix with entries

$$[\mathrm{curl}_\tau\ \mathbf{u}]_{i,j}=\frac{\partial u_i}{\partial x_j}-\frac{\partial u_j}{\partial x_i},\quad \mathbf{u}:=(u_1,u_2).$$

It follows that

$$
\begin{aligned}
(4.3)\qquad &\|\mathbf{n_T}\cdot(\mathbf{curl}\ \Pi_h^j\mathbf{j}-\mathbf{curl}\ \mathbf{j})\|^2_{0,T}\\
&=\|\mathrm{curl}_\tau\Pi_h^j\mathbf{j}|_T-\mathrm{curl}_\tau\mathbf{j}|_T\|^2_{0,T}\\
&\le C\ |\det\ B_T|\|B_T^{-1}\|^4\ \|\mathbf{n}_{\hat{\mathbf{T}}}\cdot\mathbf{curl}(\hat\Pi_h^j\hat{\mathbf{j}}-\hat{\mathbf{j}})\|^2_{0,\hat T}\\
&\le C\ |\det\ B_T|\|B_T^{-1}\|^4\ \|\mathbf{curl}(\hat\Pi_h^j\hat{\mathbf{j}}-\hat{\mathbf{j}})\|^2_{0,\hat T}\\
&\le C|\det\ B_T|\|B_T^{-1}\|^4\ \|(I-\hat W_h^j)\mathbf{curl}\ \hat{\mathbf{j}}\|^2_{0,\hat T}.
\end{aligned}
$$

Here, we have used $\mathbf{curl}\ \hat\Pi_h^j\hat{\mathbf{j}}=\hat W_h^j\mathbf{curl}\ \hat{\mathbf{j}}$ with $\hat W_h^j$ being the L^2-projection onto the space of elementwise constants. It follows that

$$(4.4)\qquad \|(I-\hat W_h^j)\mathbf{curl}\ \hat{\mathbf{j}}\|^2_{0,\hat T}\ \le\ C\ |\mathbf{curl}\ \hat{\mathbf{j}}|^2_{1,\hat K}.$$

We note that

$$\mathbf{curl}\ \hat{\mathbf{j}}\ =\ B_K^*\ \mathbf{curl}\ \mathbf{j}\ B_K,$$

where $\mathbf{curl}\ \mathbf{j}$ stands for the 3×3 matrix with entries

$$[\mathbf{curl}\ \mathbf{j}]_{i,j}=\frac{\partial j_i}{\partial x_j}-\frac{\partial j_j}{\partial x_i},\quad \mathbf{j}:=(j_1,j_2,j_3).$$

Hence, by backtransformation we obtain (cf. Lemma 5.5 in [1] for details)

$$(4.5)\qquad |\mathbf{curl}\ \hat{\mathbf{j}}|^2_{1,\hat K}\ \le\ C\ |\det\ B_K|^{-2}\ \|B_K\|^7\|B_K^*\|^2\ |\mathbf{curl}\ \mathbf{j}|^2_{1,K}.$$

Summarizing (4.3), (4.4), and (4.5), it follows that

$$\begin{aligned}(4.6)\quad &\|\mathbf{n_T}\cdot(\mathbf{curl}\,\Pi_h^j\,\mathbf{j}-\mathbf{curl}\,\mathbf{j})\|_{0,T}^2\\ &\leq\; C\frac{|\det\,B_T|}{|\det\,B_K|}\,(\|B_T^{-1}\|\;\|B_K\|)^4\;\|B_K\|^3\|B_K^*\|^2|\det\,B_K|^{-1}\;|\mathbf{curl}\,\mathbf{j}|_{1,K}^2.\end{aligned}$$

Finally, taking into account that $\mathcal{T}_i$ is a regular triangulation, we have

$$(4.7)\qquad \|B_T^{-1}\|\;\|B_K\|\;\leq\;C,\quad \|B_K\|,\|B_K^*\|\;\leq\;C\;h_K.$$

Moreover,

$$(4.8)\qquad |\det\,B_T|\;=\;\frac{\text{meas}(T)}{\text{meas}(\hat{T})},\quad |\det\,B_K|\;=\;\frac{\text{meas}(K)}{\text{meas}(\hat{K})}.$$

Using (4.7) and (4.8) in (4.6) gives the assertion.

We now prove (ii). Observing

$$\mathbf{j}|_T=(B_T^*)^{-1}\hat{\mathbf{j}}|_{\hat{T}},$$

we have

$$\|\Pi_h^j\mathbf{j}-\mathbf{j}\|_{0,T}^2\leq|\text{det}B_T|\|(B_T^*)^{-1}\|^2\|\hat{\Pi}_h^j\hat{\mathbf{j}}-\hat{\mathbf{j}}\|_{0,\hat{T}}^2.$$

Using the trace inequality and similar arguments as in the proof of Theorem 5.41 of [24], we can derive that

$$\|\hat{\Pi}_h^j\hat{\mathbf{j}}-\hat{\mathbf{j}}\|_{0,\hat{T}}^2\leq C(|\hat{\mathbf{j}}|_{1,\hat{K}}+|\mathbf{curl}\,\hat{\mathbf{j}}|_{1,\hat{K}}).$$

On the other hand,

$$|\hat{\mathbf{j}}|_{1,\hat{K}}^2\leq\|B_K\|^5\|B_K^*\|^2|\text{det}B_K^{-1}|^2|\mathbf{j}|_{1,K}^2.$$

Combining the above three inequalities with (4.5), (4.7), and (4.8) yields Lemma 4.4(ii). □

We further introduce a special projection operator $\pi_h^{\delta_{m(j)}}$ which will play an important role in analyzing the approximate error of the mortar edge element method. We define $\pi_h^{\delta_{m(j)}}:L^2(\gamma_m)^2\to\text{RT}_{0,0}(\delta_{m(j)};\mathcal{T}_{\delta_{m(j)}})$ according to

$$(4.9)\qquad \int_{\delta_{m(j)}}\pi_h^{\delta_{m(j)}}(\mathbf{p})\cdot\mathbf{q_h}\;dx\;=\;\int_{\delta_{m(j)}}\mathbf{p}\cdot\mathbf{q_h}\;dx,\quad \mathbf{q_h}\in\mathbf{M_h}(\delta_{m(j)}).$$

The boundedness of $\pi_h^{\delta_{m(j)}}$ is a direct consequence of the following result.

Lemma 4.5. *The following* inf-sup *condition holds true:*

$$\inf_{\mathbf{q_h}\in RT_0(\delta_{m(j)};\mathcal{T}_{\delta_{m(j)}})}\;\sup_{\mu_h\in\mathbf{M_h}(\delta_{m(j)})}\;\frac{(\mathbf{q_h},\mu_h)_{0,\delta_{m(j)}}}{\|\mathbf{q_h}\|_{0,\delta_{m(j)}}\;\|\mu_h\|_{0,\delta_{m(j)}}}\;\geq\;C\;>\;0.$$

Proof. Taking the construction (3.8) on the basis of $\mathbf{M_h}(\delta_{m(j)})$ into account, for $\mathbf{q_h}\in RT_0(\delta_{m(j)};\mathcal{T}_{\delta_{m(j)}})$ we determine $\mu_h\in\mathbf{M_h}(\delta_{m(j)})$ by specifying its degrees of freedom according to

$$\ell_e(\mu_h)=\begin{cases}\ell_e(\mathbf{q_h}), & e\in\mathcal{E}_h(\delta_{m(j)})\setminus\mathcal{E}_h^{\delta_{m(j)}}(\partial\delta_{m(j)}),\\ \ell_e(\mathbf{q_h})+\sum_{f\in\mathcal{E}_h^{\delta_{m(j)}}(e)}\lambda_{e,f}\;\ell_f(\mathbf{q_h}), & e\in\mathcal{E}_h^{\delta_{m(j)}}(\partial\delta_{m(j)}).\end{cases}$$

The assertion can then be verified by following lines of proof analogous to those of [20, Lemma 3.2]. □

Furthermore, by Lemma 3.2 in [20], we know that the following inf-sup condition also true

COROLLARY 4.6. *There holds*

$$\inf_{\mu_h \in \mathbf{M_h}(\delta_{m(j)})} \sup_{\mathbf{q_h} \in RT_{0,0}(\delta_{m(j)};\mathcal{T}_{\delta_{m(j)}})} \frac{(\mathbf{q_h}, \mu_h)_{0,\delta_{m(j)}}}{\|\mathbf{q_h}\|_{0,\delta_{m(j)}} \; \|\mu_h\|_{0,\delta_{m(j)}}} \;\geq\; C \;>\; 0.$$

On the basis of Lemma 4.5, we have the following.

COROLLARY 4.7. *Let $\pi_h^{\delta_{m(j)}}$ be given by* (4.9)*. Then there holds*

$$\|\pi_h^{\delta_{m(j)}}(\mathbf{p})\|_{0,\delta_{m(j)}} \;\leq\; C\;\|\mathbf{p}\|_{0,\gamma_m}, \quad \mathbf{p} \in L^2(\gamma_m)^2.$$

Proof. Using Lemma 4.5, straightforward computation reveals

$$\begin{aligned}
\|\pi_h^{\delta_{m(j)}}(\mathbf{p})\|_{0,\delta_{m(j)}} &\leq C \sup_{\mu_h \in \mathbf{M_h}(\delta_{m(j)})} \frac{(\pi_h^{\delta_{m(j)}}(\mathbf{p}), \mu_h)_{0,\delta_{m(j)}}}{\|\mu_h\|_{0,\delta_{m(j)}}} \\
&= C \sup_{\mu_h \in \mathbf{M_h}(\delta_{m(j)})} \frac{(\mathbf{p}, \mu_h)_{0,\delta_{m(j)}}}{\|\mu_h\|_{0,\delta_{m(j)}}} \\
&\leq C\;\|\mathbf{p}\|_{0,\gamma_m}. \qquad □
\end{aligned}$$

As a further consequence of the inf-sup condition in Lemma 4.5, we obtain the following.

LEMMA 4.8. *Let $\Pi_h \,:\, H^1(\mathbf{curl};\Omega) \cap \mathbf{V} \;\to\; \tilde{\mathbf{V}}_\mathbf{h}$ be the standard interpolation operator. Then we have*

$$\|\mathrm{div}_\tau \pi_h^{\delta_{m(j)}}[\Pi_h \mathbf{j} \wedge \mathbf{n}]\|_{0,\gamma_m} \;\leq\; C\;\|\mathrm{div}_\tau[\Pi_h \mathbf{j} \wedge \mathbf{n}]\|_{0,\gamma_m}.$$

Proof. We denote by $P_h^{\delta_{m(j)}}$ the $\mathrm{RT}_0(\delta_{m(j)};\mathcal{T}_{\delta_{m(j)}})$-interpolation operator. Observing that $P_h^{\delta_{m(j)}}|_T,\; T \in \mathcal{T}_{\delta_{m(j)}}$, preserves constant tangential traces, by a Bramble–Hilbert argument we obtain

$$\begin{aligned}
&\|(I - P_h^{\delta_{m(j)}})[\Pi_h \mathbf{j} \wedge \mathbf{n}]\|^2_{0,\gamma_m} \\
&\quad \leq C h^2_{\delta_{m(j)}} \sum_{T \in \mathcal{T}_{\delta_{m(j)}}} \; \sum_{T' \cap T \neq \emptyset, T' \in \mathcal{T}_{\gamma_{m(i)}}} |[\Pi_h \mathbf{j} \wedge \mathbf{n}]|^2_{1,T' \cap T} \\
&\quad = C h^2_{\delta_{m(j)}} \sum_{T \in \mathcal{T}_{\delta_{m(j)}}} \|\mathrm{div}_\tau[\Pi_h \mathbf{j} \wedge \mathbf{n}]\|^2_{0,T} \\
&\quad = C\; h^2_{\delta_{m(j)}}\;\|\mathrm{div}_\tau[\Pi_h \mathbf{j} \wedge \mathbf{n}]\|^2_{0,\gamma_m},
\end{aligned}$$

where we have used the fact that $\Pi_h \mathbf{j} \wedge \mathbf{n}|_{\gamma_m}$ belongs to the lowest order Raviart–Thomas space. Similar arguments for the proof of the first inequality can be found in [16] . So we get

$$\|(I - P_h^{\delta_{m(j)}})[\Pi_h \mathbf{j} \wedge \mathbf{n}]\|_{0,\gamma_m} \leq C\; h_{\delta_{m(j)}}\;\|\mathrm{div}_\tau[\Pi_h \mathbf{j} \wedge \mathbf{n}]\|_{0,\gamma_m}. \tag{4.10}$$

Moreover, in view of

$$\mathrm{div}_\tau P_h^{\delta_{m(j)}}[\Pi_h \mathbf{j} \wedge \mathbf{n}] \;=\; W_h^{\delta_{m(j)}}\;\mathrm{div}_\tau[\Pi_h \mathbf{j} \wedge \mathbf{n}],$$

where $W_h^{\delta_{m(j)}}$ is the L^2-projection onto the elementwise constants, we obtain

$$\|\mathrm{div}_\tau P_h^{\delta_{m(j)}}[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m} \;\leq\; C\;\|\mathrm{div}_\tau[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m}. \tag{4.11}$$

We have $(\pi_h^{\delta_{m(j)}} - P_h^{\delta_{m(j)}})[\Pi_h\mathbf{j}\wedge\mathbf{n}] \in \mathrm{RT}_0(\delta_{m(j)};\mathcal{T}_{\delta_{m(j)}})$, and hence, by Lemma 4.5 and (4.10),

$$\begin{aligned}\|(\pi_h^{\delta_{m(j)}} - P_h^{\delta_{m(j)}})[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m} &\leq\; C \sup_{\psi\in\mathbf{M_h}(\delta_{m(j)})}\frac{((\pi_h^{\delta_{m(j)}} - P_h^{\delta_{m(j)}})[\Pi_h\mathbf{j}\wedge\mathbf{n}],\psi)}{\|\psi\|_{0,\delta_{m(j)}}}\\ &=\; C \sup_{\psi\in\mathbf{M_h}(\delta_{m(j)})}\frac{((I - P_h^{\delta_{m(j)}})[\Pi_h\mathbf{j}\wedge\mathbf{n}],\psi)}{\|\psi\|_{0,\delta_{m(j)}}}\\ &\leq\; C\;h_{\delta_{m(j)}}\;\|\mathrm{div}_\tau[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m}.\end{aligned} \tag{4.12}$$

Combining (4.11) and (4.12), we get

$$\begin{aligned}&\|\mathrm{div}_\tau\pi_h^{\delta_{m(j)}}[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m}\\ &\quad\leq\; \|\mathrm{div}_\tau(\pi_h^{\delta_{m(j)}} - P_h^{\delta_{m(j)}})[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m} + \|\mathrm{div}_\tau P_h^{\delta_{m(j)}}[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m}\\ &\quad\leq C\;h_{\delta_{m(j)}}^{-1}\;\|(\pi_h^{\delta_{m(j)}} - P_h^{\delta_{m(j)}})[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m} + \|\mathrm{div}_\tau[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m}\\ &\quad\leq\; C\;\|\mathrm{div}_\tau[\Pi_h\mathbf{j}\wedge\mathbf{n}]\|_{0,\gamma_m}. \qquad \square\end{aligned}$$

We are now in a position to estimate the discretization error of the mortar edge element method.

THEOREM 4.2. *For any* $\mathbf{j}\in H^1(\mathbf{curl};\Omega)$ *there exists a function* $\mathbf{q_h}\in\mathbf{V_h}$ *such that*

$$\|\mathbf{j}-\mathbf{q_h}\|_{a_h} \leq C\left(\sum_{j=1}^{N} h_j^2\;\|\mathbf{j}\|_{1,\mathbf{curl},\Omega_j}^2\right)^{\frac{1}{2}}.$$

Proof. We define $\mathbf{q_h}$ as

$$\mathbf{q_h} = \Pi_h\mathbf{j} - \sum_{m=1}^{M} E_h^{\delta_{m(j)}}\{\pi_h^{\delta_{m(j)}}[(\Pi_h^j\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\Pi_h^i\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}}]\}$$

and remark that $\mathbf{q_h}\in\mathbf{V_h}$ can be easily seen.

For each $\delta_{m(j)}$, by Lemma 4.3, Corollary 4.7, and Lemma 4.8, we get

$$\begin{aligned}&\|E_h^{\delta_{m(j)}}(\pi_h^{\delta_{m(j)}}((\Pi_h^j\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\Pi_h^i\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}}))\|_{\mathbf{curl},\Omega_j}\\ &\quad\leq C\;h_{\delta_{m(j)}}^{\frac{1}{2}}\;\|\mathrm{div}_\tau\big(\pi_h^{\delta_{m(j)}}((\Pi_h^j\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\Pi_h^i\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}})\big)\|_{0,\gamma_m}\\ &\qquad + C\;h_{\delta_{m(j)}}^{\frac{1}{2}}\;\|\pi_h^{\delta_{m(j)}}\big((\Pi_h^j\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\Pi_h^i\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}}\big)\|_{0,\gamma_m}\\ &\quad\leq\; C\;h_{\delta_{m(j)}}^{\frac{1}{2}}\;\|\mathrm{div}_\tau\big((\Pi_h^j\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\Pi_h^i\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}}\big)\|_{0,\gamma_m}\\ &\qquad + C\;h_{\delta_{m(j)}}^{\frac{1}{2}}\;\|(\Pi_h^j\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\Pi_h^i\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}}\|_{0,\gamma_m}\\ &\quad:=\; I_1\;+\;I_2.\end{aligned} \tag{4.13}$$

As far as the first term I_1 is concerned, applying Lemma 4.4 results in

$$\begin{aligned} I_1 \le& \; C\ h_j^{\frac{1}{2}}\ \big(\|\mathrm{div}_\tau\big((\Pi_h^j \mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}}\big)\|_{0,\gamma_m} \\ &+\|\mathrm{div}_\tau\big((\Pi_h^i \mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}} - (\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}}\big)\|_{0,\gamma_m}\big) \\ \le& \; C\ h_j^{\frac{1}{2}}\ \left(\sum_{T\in\mathcal{T}(\delta_{m(j)})} (\|\mathbf{n}_T\cdot(\mathbf{curl}\ \Pi_h^j\ \mathbf{j} - \mathbf{curl}\ \mathbf{j})|_T\|_{0,T}^2\right)^{\frac{1}{2}} \\ &+\ \left(\sum_{T\in\mathcal{T}(\gamma_{m(i)})} (\|\mathbf{n}_T\cdot(\mathbf{curl}\ \Pi_h^i\ \mathbf{j} - \mathbf{curl}\ \mathbf{j})|_T\|_{0,T}^2)^{\frac{1}{2}}\right) \\ \le& \; C\ h_j^{\frac{1}{2}}\ \big(h_j^{\frac{1}{2}}\|\mathbf{curl}\ \mathbf{j}\|_{1,\Omega_j} + h_i^{\frac{1}{2}}\|\mathbf{curl}\ \mathbf{j}\|_{1,\Omega_i}\big). \end{aligned} \tag{4.14}$$

For the second term I_2, using Lemma 4.4, we obtain

$$\begin{aligned} I_2 \le& \; C\ h_{\delta_{m(j)}}^{\frac{1}{2}}\ \big(\|(\Pi_h^j\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}}\|_{0,\gamma_m}\big) \\ &+\|(\Pi_h^i\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}} - (\mathbf{j}\wedge\mathbf{n})|_{\gamma_{m(i)}}\|_{0,\gamma_m} \\ \le& \; C\ h_j^{\frac{1}{2}}\ \big(h_j^{\frac{1}{2}}\|\mathbf{j}\|_{1,\mathbf{curl},\Omega_j} + h_i^{\frac{1}{2}}\|\mathbf{j}\|_{1,\mathbf{curl},\Omega_i}\big). \end{aligned} \tag{4.15}$$

Observing the standard approximation property

$$\|\mathbf{j}-\Pi_h\mathbf{j}\|_{a_h} \le C\left(\sum_{j=1}^N h_j^2\ \|\mathbf{j}\|_{1,\mathbf{curl},\Omega_j}^2\right)^{\frac{1}{2}}$$

and using (4.13), (4.14), and (4.15) results in

$$\begin{aligned} \|\mathbf{j}-\mathbf{q_h}\|_{a_h}^2 \ \le&\ C\ \big(\|\mathbf{j}-\Pi_h\mathbf{j}\|_{a_h}^2 \\ &+\ \sum_{m=1}^{m}\|E_h^{\delta_{m(j)}}(\pi_h^{\delta_{m(j)}}((\Pi_h^j\mathbf{j}\wedge\mathbf{n})|_{\delta_{m(j)}} - (\Pi_h^i\mathbf{j}\wedge\mathbf{n}))\|_{\mathbf{curl},\Omega_j}^2\big) \\ \le&\ C\ \sum_{j=1}^N h_j^2\ \|\mathbf{j}\|_{1,\mathbf{curl},\Omega_j}^2. \qquad \square \end{aligned}$$

Finally, Theorems 4.1 and 4.2 imply the main result of this paper.

THEOREM 4.3. *Let* $\mathbf{j}\in H^1(\mathbf{curl};\Omega)$ *and* $\mathbf{j_h}\in\mathbf{V_h}$ *be the solutions of* (2.2) *and* (3.14), *respectively. Then there holds*

$$\|\mathbf{j}-\mathbf{j_h}\|_{a_h}\ \le\ C\ \left(\sum_{j=1}^N h_j^2\ \|\mathbf{j}\|_{1,\mathbf{curl},\Omega_j}^2\right)^{\frac{1}{2}}.$$

5. Saddle point formulation.

A saddle point formulation for mortar element methods associated with second order elliptic problems has been introduced in [4]. In particular, an a priori estimate for the Lagrange multiplier in the $(H_{00}^{\frac{1}{2}})'$-norm has been established there, whereas related estimates in mesh-dependent norms have been given in [28], [29], [30]. In this section, we will derive an a priori estimate for the Lagrange multiplier of the mortar edge element method.

First, we introduce a macrohybrid variational formulation for the continuous problem (2.1).

Using the domain decomposition as presented in the preceding section, we introduce the product space

$$\mathbf{X} \;:=\; \{\mathbf{q} \in L^2(\Omega)^3 \mid \mathbf{q}|_{\Omega_i} \in H(\mathbf{curl};\Omega_i),\; (\mathbf{n} \wedge (\mathbf{q} \wedge \mathbf{n}))|_{\partial\Omega_i \cap \partial\Omega} = \mathbf{0}\}$$

equipped with the norm

$$\|\mathbf{q}\|_{\mathbf{X}} \;:=\; \left(\sum_{i=1}^{N} \|\mathbf{q}\|^2_{\mathbf{curl},\Omega_i} \right)^{\frac{1}{2}}.$$

We further consider the subspace

$$\tilde{\mathbf{V}} \;:=\; \left\{ \mathbf{q} \in \mathbf{X} \mid [\mathbf{q} \wedge \mathbf{n}]|_{\gamma_m} \in (H^{\frac{1}{2}}_{00}(\gamma_m))^2 \right\}$$

provided with the norm

$$\|\mathbf{q}\|_{\tilde{\mathbf{V}}} \;:=\; \left(\|\mathbf{q}\|^2_{\mathbf{X}} + \|[\mathbf{q} \wedge \mathbf{n}]\|^2_{\frac{1}{2},S} \right)^{\frac{1}{2}},$$

where

$$\|[\mathbf{q} \wedge \mathbf{n}]\|_{\frac{1}{2},S} \;:=\; \left(\sum_{\gamma_m \in S} \|[\mathbf{q} \wedge \mathbf{n}]\|^2_{(H^{\frac{1}{2}}_{00}(\gamma_m))^2} \right)^{\frac{1}{2}}.$$

A natural candidate for the multiplier space is then

$$\mathbf{M} \;:=\; \prod_{\gamma_m} (H^{-\frac{1}{2}}(\delta_{m(j)}))^2$$

equipped with the norm

$$\|\mu\|_{\mathbf{M}} \;:=\; \left(\sum_{\delta_{m(j)} \in S} \|\mu|_{\delta_{m(j)}}\|^2_{-\frac{1}{2},\delta_{m(j)}} \right)^{\frac{1}{2}},$$

where $H^{-\frac{1}{2}}(\delta_{m(j)}) := (H^{\frac{1}{2}}_{00}(\delta_{m(j)}))'$.

We introduce the bilinear form $a(\cdot,\cdot)\mathbf{X} \times \mathbf{X} \to \mathbb{R}$ as the sum of the bilinear forms associated with the subdomain problems according to

$$a(\mathbf{j},\mathbf{q}) \;:=\; \sum_{i=1}^{N} a_{\Omega_i}(\mathbf{j}|_{\Omega_i},\mathbf{q}|_{\Omega_i}) = \sum_{i=1}^{N} \int_{\Omega_i} \left[\mathbf{A}\mathbf{curl}\;\mathbf{j} \cdot \mathbf{curl}\;\mathbf{q} + \mathbf{B}\mathbf{j} \cdot \mathbf{q} \right] dx.$$

Furthermore, we define the bilinear form $b(\cdot,\cdot) : \tilde{\mathbf{V}} \times \mathbf{M} \to \mathbf{R}$ by means of

$$b(\mathbf{q},\mu) := \langle [\mathbf{q} \wedge \mathbf{n}], \mu \rangle_{\frac{1}{2},S},$$

where $\langle \cdot,\cdot \rangle_{\frac{1}{2},S} := \sum_{\delta_{m(j)} \in S} \langle \cdot,\cdot \rangle_{\frac{1}{2},\delta_{m(j)}}$.

Then the appropriate macrohybrid variational formulation of (2.1) can be formulated as follows:

Find $(\mathbf{j},\lambda) \in \tilde{\mathbf{V}} \times \mathbf{M}$ such that

$$\begin{aligned} a(\mathbf{j},\mathbf{q}) \;+\; b(\mathbf{q},\lambda) &= l(\mathbf{q}), \quad \mathbf{q} \in \tilde{\mathbf{V}}, \\ b(\mathbf{j},\mu) &= 0, \quad \mu \in \mathbf{M}. \end{aligned} \tag{5.1}$$

Denote by $B : \tilde{\mathbf{V}} \to \mathbf{M}$ the operator associated with the bilinear form $b(\cdot,\cdot)$, i.e.,

$$\langle B\mathbf{q}, \mu \rangle_{\frac{1}{2},S} = b(\mathbf{q}, \mu), \quad \mu \in \mathbf{M}.$$

It is proved in Theorem 2.1 of [20] that the bilinear form $a(\cdot,\cdot)$ is Ker$B$-elliptic and the bilinear form $b(\cdot,\cdot)$ satisfies the LBB condition. So the saddle point problem (5.1) admits a unique solution. For $\mathbf{q} \in \mathbf{V} \subset \tilde{\mathbf{V}}$, the first equation of (5.1) reduces to (2.2). Hence, the solution $\mathbf{j}$ of (5.1) is also the solution of (2.2). Finally, by (4.1) we know that $\lambda|_{\gamma_m} = \mathbf{n} \wedge (\mathbf{A}\ \mathbf{curl}\ \mathbf{j} \wedge \mathbf{n})|_{\gamma_m}$.

Next, we consider the discrete version of (5.1). On $\tilde{\mathbf{V}}_\mathbf{h}$, we define the norm

$$\|\mathbf{q_h}\|_{\tilde{\mathbf{V}}_\mathbf{h}} \ := \ \left(\|\mathbf{q_h}\|^2_{\mathbf{X}} \ + \ \|[\mathbf{q_h} \wedge \mathbf{n}]|_S\|^2_{\frac{1}{2},h,S}\right)^{\frac{1}{2}}, \quad \mathbf{q_h} \in \tilde{\mathbf{V}}_\mathbf{h},$$

where $\|\cdot\|_{\frac{1}{2},h,S}$ is given by

$$\|[\mathbf{q_h} \wedge \mathbf{n}]|_S\|_{\frac{1}{2},h,S} \ := \ \left(\sum_{\gamma_m \subset S} \|[\mathbf{q_h} \wedge \mathbf{n}]\|^2_{\frac{1}{2},h,\gamma_m}\right)^{\frac{1}{2}}$$

and $\|\cdot\|_{\frac{1}{2},h,\gamma_m}$ stands for the mesh-dependent norm:

$$\|[\mathbf{q_h} \wedge \mathbf{n}]\|_{\frac{1}{2},h,\gamma_m} \ := \ h^{-\frac{1}{2}}_{\delta_{m(j)}} \ \|[\mathbf{q_h} \wedge \mathbf{n}]\|_{0,\gamma_m}.$$

The Lagrange multiplier space $\mathbf{M_h}$ will be provided with the following mesh-dependent norm:

$$\|\mu_h\|_{\mathbf{M_h}} \ := \ \|\mu_h\|_{-\frac{1}{2},h,S}, \quad \mu_h \in \mathbf{M_h},$$

where

$$\|\mu_h\|_{-\frac{1}{2},h,S} \ := \ \left(\sum_{\delta_{m(j)} \subset S} \|\mu_h\|^2_{-\frac{1}{2},h,\delta_{m(j)}}\right)^{\frac{1}{2}}$$

and $\|\cdot\|_{-\frac{1}{2},h,\delta_{m(j)}}$ is given by

$$\|\mu_h|_{\delta_{m(j)}}\|_{-\frac{1}{2},h,\delta_{m(j)}} \ := \ h^{\frac{1}{2}}_{\delta_{m(j)}} \ \|\mu_h\|_{0,\delta_{m(j)}}.$$

In addition to the bilinear form $a_h(\cdot,\cdot) : \tilde{\mathbf{V}}_\mathbf{h} \times \tilde{\mathbf{V}}_\mathbf{h} \to \mathbb{R}$ as defined by (3.13), we introduce the bilinear form $b_h(\cdot,\cdot) : \tilde{\mathbf{V}}_\mathbf{h} \times \mathbf{M_h} \to \mathbb{R}$ according to

$$b_h(\mathbf{q_h}, \mu_h) \ := \ \sum_{\gamma_m \in S} ([\mathbf{q_h} \wedge \mathbf{n}]|_{\gamma_m}, \mu_h)_{0,\delta_{m(j)}}.$$

Then the mortar edge element approximation of (5.1) amounts to the solution of the following problem: Find $(\mathbf{j_h}, \lambda_h) \in \tilde{\mathbf{V}}_\mathbf{h} \times \mathbf{M_h}$ such that

$$\begin{aligned} a_h(\mathbf{j_h}, \mathbf{q_h}) \ + \ b_h(\mathbf{q_h}, \lambda_h) &= \ l(\mathbf{q_h}), \quad \mathbf{q_h} \in \tilde{\mathbf{V}}_\mathbf{h}, \\ b_h(\mathbf{j_h}, \mu_h) &= \ 0, \quad \mu_h \in \mathbf{M_h}. \end{aligned} \tag{5.2}$$

The saddle point problem (5.2) admits a unique solution which follows from the following LBB condition for the bilinear form $b_h(\cdot,\cdot)$.

LEMMA 5.1. *The bilinear form* $b_h(\cdot,\cdot) : \tilde{\mathbf{V}}_\mathbf{h} \times \mathbf{M}_\mathbf{h} \to \mathbf{R}$ *satisfies a discrete* inf-sup *condition (LBB condition) uniformly in* h_i, *i.e., there exists a constant* $c > 0$ *independent of the mesh size* h_i *such that*

$$\sup_{\mathbf{q_h} \in \tilde{\mathbf{V}}_\mathbf{h}} \frac{b_h(\mathbf{q_h}, \mu_h)}{\|\mathbf{q_h}\|_{\tilde{\mathbf{V}}_\mathbf{h}}} \;\geq\; c\;\|\mu_h\|_{\mathbf{M_h}}.$$

Proof. For any $\mu_h \in \mathbf{M_h}(\delta_{m(j)})$ we define $\mathbf{p_h^j} \in \mathrm{RT}_{0,0}(\delta_{m(j)}; \mathcal{T}_{\delta_{m(j)}})$ according to

$$\ell_e(\mathbf{p_h^j}) \;=\; \ell_e(\mu_h), \quad e \in \mathcal{E}_h(\delta_{m(j)})$$

and refer to $\mathbf{q_h^j} \in \mathrm{ND}_1(\Omega_j; \mathcal{T}_j)$ as the trivial extension, i.e.,

$$\mathbf{q_h^j} \wedge \mathbf{n} \;=\; \mathbf{p_h^j} \quad \text{on} \quad \delta_{m(j)},$$

where all degrees of freedom that are not located on $\delta_{m(j)}$ are set equal to zero, especially $[\mathbf{q_h^j} \wedge \mathbf{n}] = \mathbf{p_h^j}$. On the basis of Lemma 4.3, we have

$$\begin{aligned}
\|\mathbf{q_h^j}\|_{\mathbf{curl},\Omega_j} &\leq C\; h_j^{\frac{1}{2}}\;\|\mathbf{p_h^j}\|_{\mathrm{div}_\tau,\delta_{m(j)}} \\
&\leq C\; h_j^{-\frac{1}{2}}\;\|\mathbf{p_h^j}\|_{0,\delta_{m(j)}} \\
&= C\; h_j^{-\frac{1}{2}}\;\|[\mathbf{q_h^j} \wedge \mathbf{n}]\|_{0,\delta_{m(j)}}.
\end{aligned}$$

By Corollary 4.6 and the above inequality, we obtain

$$\begin{aligned}
(\mu_h, [\mathbf{q_h^j} \wedge \mathbf{n}]|_{\delta_{m(j)}})_{0,\delta_{m(j)}} &\geq C\;\|\mu_h\|_{0,\delta_{m(j)}} \|[\mathbf{q_h^j} \wedge \mathbf{n}]\|_{0,\delta_{m(j)}} \\
&\geq C\; h_j^{\frac{1}{2}}\;\|\mu_h\|_{0,\delta_{m(j)}} \|\mathbf{q_h^j}\|_{\mathbf{curl},\Omega_j} \\
&\geq C\;\|\mu_h\|_{-\frac{1}{2},h,\delta_{m(j)}}\;\|\mathbf{q_h^j}\|_{\mathbf{curl},\Omega_j}.
\end{aligned}$$

On the other hand,

$$\begin{aligned}
(\mu_h, [\mathbf{q_h^j} \wedge \mathbf{n}]|_{\delta_{m(j)}})_{0,\delta_{m(j)}} &\geq C\;\|\mu_h\|_{0,\delta_{m(j)}}\;\|[\mathbf{n} \wedge \mathbf{q_h^j}]\|_{0,\delta_{m(j)}} \\
&= C\; h_j^{\frac{1}{2}}\;\|\mu_h\|_{0,\delta_{m(j)}}\; h_j^{-\frac{1}{2}}\;\|[\mathbf{q_h^j} \wedge \mathbf{n}]\|_{0,\delta_{m(j)}} \\
&= C\;\|\mu_h\|_{-\frac{1}{2},h,\delta_{m(j)}}\;\|[\mathbf{q_h^j} \wedge \mathbf{n}]\|_{\frac{1}{2},h,\delta_{m(j)}}.
\end{aligned}$$

Adding the above inequalities and summing over all $\delta_{m(j)} \subset \Gamma$ gives the assertion. □

Finally, we obtain the following.

THEOREM 5.2. *Let* $\mathbf{j} \in H^1(\mathbf{curl}; \Omega)$ *and* $(\mathbf{j_h}, \lambda_h) \in \tilde{\mathbf{V}}_\mathbf{h} \times \mathbf{M_h}$ *be the solutions of* (2.2) *and* (5.2), *respectively. Then there holds*

$$\|\lambda - \lambda_h\|_{-\frac{1}{2},h,S} \leq C \left(\sum_{j=1}^{N} h_j^2\;\|\mathbf{j}\|^2_{1,\mathbf{curl},\Omega_j} \right)^{\frac{1}{2}}.$$

Proof. On the basis of the inf-sup condition developed in Lemma 5.1 and arguments similar to those in [12] for the mixed finite element methods and [30] for the saddle point method for mortar element methods, we get

$$\|\lambda - \lambda_h\|_{-\frac{1}{2},h,S} \leq C(\|\mathbf{j} - \mathbf{j_h}\|_{a_h} + \inf_{\mu_h \in \mathbf{M_h}} \|\lambda - \mu_h\|_{-\frac{1}{2},h,S}).$$

By Theorem 4.3, we have

$$\|\mathbf{j}-\mathbf{j_h}\|_{a_h} \le C\left(\sum_j^N h_j^2\|\mathbf{j}\|^2_{1,\mathbf{curl},\Omega_j}\right)^{\frac{1}{2}}. \tag{5.3}$$

Moreover, by Lemma 3.1

$$\begin{aligned}\inf_{\mu_h\in\mathbf{M_h}(\delta_{m(j)})}\|\lambda-\mu_h\|_{-\frac{1}{2},h,\delta_{m(j)}} &= h^{\frac{1}{2}}_{\delta_{m(j)}}\inf_{\mu_h\in\mathbf{M_h}(\delta_{m(j)})}\|\lambda-\mu_h\|_{0,\delta_{m(j)}}\\ &\le C\,h_j\;\|\mathbf{n}\wedge(\mathbf{A}\ \mathbf{curl}\ \mathbf{j}\wedge\mathbf{n})\|_{\frac{1}{2},\delta_{m(j)}}\\ &\le C\,h_j\;\|\mathbf{curl}\ \mathbf{j}\|_{1,\Omega_j}.\end{aligned}$$

Summing over all $\delta_{m(j)}$ results in

$$\inf_{\mu_h\in\mathbf{M_h}}\|\lambda-\mu_h\|_{-\frac{1}{2},h,S} \le C\left(\sum_j^N h_j^2\|\mathbf{curl}\ \mathbf{j}\|^2_{1,\Omega_j}\right)^{\frac{1}{2}}. \tag{5.4}$$

Finally, combining (5.3) and (5.4) gives the assertion. □

Acknowledgment. We thank the anonymous referees who meticulously read through the paper and made many helpful suggestions which led to an improved presentation of this paper.

MIXED FINITE ELEMENT METHODS FOR SMOOTH DOMAIN FORMULATION OF CRACK PROBLEMS*

Z. BELHACHMI†, J. M. SAC-EPÉE†, AND J. SOKOLOWSKI‡

Abstract. The discretization by finite element methods of a new variational formulation of crack problems is considered. The new formulation, called the smooth domain method, is derived for crack problems in the case of an elastic membrane. Inequality type boundary conditions are prescribed at the crack faces. The resulting model takes the form of a unilateral contact problem on the crack. We study and implement various mixed finite element methods for the numerical approximation of the model. A priori error estimates are derived, and results of computations are provided. The convergence rates obtained from the numerical simulations are in agreement with the theoretical estimates.

Key words. crack problems, variational inequalities, mixed finite element methods, a priori error estimates

1. Introduction.

The smooth domain method is based on a new approach [25] to the crack modelling of linear elastic bodies with inequality type boundary conditions prescribed on the crack faces. By a crack problem we mean the boundary value problem defined in the geometrical domain $\Omega_c = \Omega \setminus \Gamma_c$ with the cut Γ_c. The cut is called a crack provided that some boundary conditions are specified on both sides $\Gamma_c^{\pm}$ of the set Γ_c [24]. In general, such conditions are only an approximation of the exact contact conditions derived for the displacement and stress fields in the framework of the elasticity theory. We restrict ourselves to a model problem with the unilateral conditions for scalar unknown functions. More realistic boundary conditions for the elasticity boundary value problem are the subject of further investigations from the numerical point of view in a forthcoming work. The boundary conditions of unilateral type on $\Gamma_c^{\pm}$ describe the mutual nonpenetration between the crack faces. In the smooth domain method the elements of the convex cone of admissible displacements and stresses used in the mixed variational formulation are extended to the crack surface. Therefore, the admissible displacements and stresses are defined in the smooth domain Ω, with the removed cut Γ_c. However, the restrictions imposed on the admissible functions are still present and can be considered as internal constraints prescribed on the given subset Γ_c of the smooth geometrical domain Ω. The resulting weak formulation of the nonlinear boundary value problem is defined over the smooth domain of integration. Such a formulation includes integral equations and inequalities. Applying this new approach to the elastic membrane problem in the domain with a cut, we analyze and implement the discretization by mixed finite element methods. The internal constraint in the model, which requires the nonpositivity of normal derivatives at crack faces, is expressed by means of a Lagrange multiplier.

The analysis of contact problems and their approximation by finite elements, or mixed finite elements methods, were performed by several authors (e.g., in [21], [22], [26], [9], [10], [19], [35], and the references therein). More recently, significant progress in the numerical analysis of such problems has been made. We refer the reader to, for example, [23], [3], [4] for the discretization by the mortar affine finite element method. In [14], [29] the mixed finite elements method is analyzed and implemented. We also refer to [34], [33] for a general setting to study some mixed variational formulations and the application to the discretization by the Raviart–Thomas elements of lowest order. In [33], an extension of the analysis of some mixed formulations arising in contact problems to the case where the first bilinear form is not coercive on the whole space is proposed and the numerical analysis is performed. Even if the problem we consider is set in a non-Lipschitzian domain, the mixed variational formulation that we obtain in the entire domain fits within the framework of [33]. However, our approach is different since we prefer to work with the hybrid mixed formulation. The tools of the numerical analysis and the results that we obtain in this article for our specific problem appear to be a complementary contribution to the analysis and discretization of contact problems already deeply performed in [5], [14], [34], [33].

The important feature of these approaches is the specific approximation of the nonpenetration conditions in the discrete model. For mixed finite element methods, the unilateral conditions can be expressed by introduction of either a piecewise constant [29], [33] or a piecewise continuous Lagrange multiplier [5], [14]. Such a construction is also crucial for the convergence analysis and numerical solution of the crack problem with the smooth domain formulation.

In this paper, we perform the convergence analysis and derive a priori error estimates for some mixed finite element methods that are also implemented numerically. Each approach among those considered in this work is characterized by the specific space of approximation for the Lagrangian multipliers. We obtain for the smooth domain method the convergence rate $O(h^{\frac{3}{4}})$ for the best choice of continuous piecewise affine approximation of the multipliers, exactly the same as the rate derived for the classical unilateral problems arising in contact mechanics. In fact, the smooth domain method can be considered as a mixed variational formulation, which takes into consideration the inequality conditions for the normal derivatives on the crack faces rather than the unilateral conditions for the jump of the displacement over the crack.

The paper is organized as follows. In section 2, the crack problem for an elastic membrane is introduced. The smooth domain formulation is given, and its well-posedness is established. Section 3 is devoted to the discretization of the continuous problem. First of all, a new formulation, based on the mixed variational method, is introduced and analyzed. The convergence analysis is performed in section 4. The error estimates and the convergence rates are established for the proposed approximations. In section 5, the numerical implementation is described in details, and some numerical examples are presented. Finally, some concluding remarks and perspectives are given.

2. Model problem.

We present the smooth domain method for a scalar model problem. First, appropriate notations are introduced.

Let Ω be a bounded domain in $\mathbb{R}^2$ with smooth boundary Γ, and $\Gamma_c \subset \Omega$ be a smooth curve without self-intersections. We assume that Γ_c can be extended to a closed smooth curve $\Sigma \subset \Omega$, with Σ of class $C^{1,1}$, and $\Omega = \Omega^1 \cup \Sigma \cup \Omega^2$ divided into two subdomains Ω^1, Ω^2 (see Figure 1). In this case, $\Sigma = \partial\Omega^1$ is the boundary of

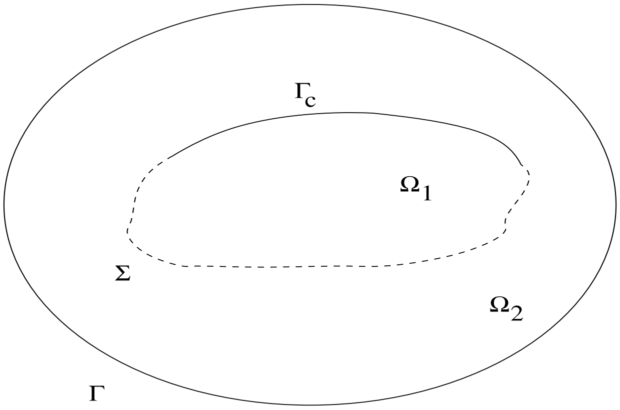

FIG. 1. *Domain with a cut.*

Ω^1 and $\Sigma \cup \Gamma = \partial\Omega^2$ is the boundary of Ω^2. Let Ω_c be the domain $\Omega \setminus \overline{\Gamma_c}$; then Γ_c is called a crack in the elastic body of the reference configuration Ω_c (see Figure 2). The static equilibrium problem for the elastic membrane in the domain Ω_c with the interior crack Γ_c can be formulated as follows.

Find u such that

$$-\Delta u = f \qquad \text{in } \Omega_c, \tag{1}$$

$$u = 0 \qquad \text{on } \Gamma, \tag{2}$$

$$[u] \geq 0, \qquad \left[\frac{\partial u}{\partial \nu}\right] = 0, \qquad [u]\,\frac{\partial u}{\partial \nu} = 0 \qquad \text{on } \Gamma_c, \tag{3}$$

$$\frac{\partial u}{\partial \nu} \leq 0 \qquad \text{on } \Gamma_c^{\pm}, \tag{4}$$

where f is a given function in $L^2(\Omega_c)$. The jump of the function u on Γ_c is denoted by $[u] = u^+ - u^-$, where $u^\pm = u|_{\Gamma_c^\pm}$ are the traces of u on $\Gamma_c^\pm$.

Boundary value problem (1)–(4) can be considered as a free boundary problem since the coincidence set $\Xi = \{x \in \Gamma_c | \, [u] = 0\}$ is an unknown part of Γ_c. When using the modelling in the framework of linear elasticity, similar boundary value problems arise in the crack theory for elastic bodies [25], [28]. In such a case the inequality type boundary conditions are imposed on Γ_c to describe mutual nonpenetration between the crack faces. It is the so-called frictionless contact problem on the crack. It is well-known that problem (1)–(4) admits a unique weak solution that minimizes the energy functional

$$\frac{1}{2}\int_{\Omega_c} |\nabla v|^2\, dx - \int_{\Omega_c} fv\, dx$$

over the closed convex cone

$$\mathbb{C}(\Gamma_c) = \{v \in H^1(\Omega_c) | v = 0 \quad \text{on} \quad \Gamma, \ [v] \geq 0 \quad \text{on} \quad \Gamma_c\}$$

including the functions in the Sobolev space $H^1(\Omega_c)$ which vanish on Γ and satisfy the unilateral condition $[v] \geq 0$ on Γ_c.

We denote by $V = V(\Omega_c)$ the space $L^2(\Omega_c)$ and consider the vector space $\mathbf{X} = \mathbf{X}(\Omega_c)$,

$$\mathbf{X} = \left\{\mathbf{q} \in L^2(\Omega_c)^2, \ \operatorname{div} \mathbf{q} \in L^2(\Omega_c)\right\}$$

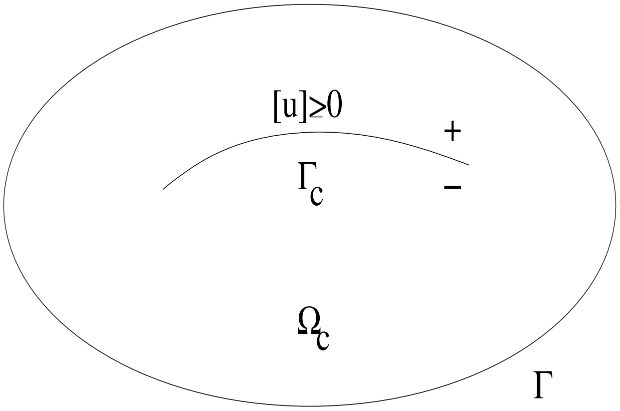

FIG. 2. *Elastic membrane.*

equipped with the norm

$$\|\mathbf{q}\|_{\mathbf{X}} = \left(\|\mathbf{q}\|^2_{(L^2(\Omega_c))^2} + \|\operatorname{div} \mathbf{q}\|^2_{L^2(\Omega_c)}\right)^{\frac{1}{2}}.$$

Remark 2.1. For the sake of simplicity, in the smooth domain formulation over Ω, we use the same notation for $V = V(\Omega)$ and for $\mathbf{X} = \mathbf{X}(\Omega)$, i.e., the domain Ω_c is replaced in both function spaces by the smooth domain Ω.

The closed convex cone $\mathbf{K} \subset \mathbf{X}$ can be defined using the dual order in the Sobolev space $(H^{\frac{1}{2}}_{00}(\Gamma_c))'$ as

$$\mathbf{K} = \left\{\mathbf{q} \in \mathbf{X},\ [\mathbf{q}.\nu] = 0,\ \text{on}\, \Gamma_c,\ (\mathbf{q}.\nu)^{\pm} \le 0,\ \text{on}\, \Gamma_c^{\pm}\right\},$$

where $[.]$ denotes the jump across Γ_c and ν is the unit normal vector pointing to the exterior of Ω_1 (see Figure 1). More precisely, we can use the integral inequalities and the cone $\mathbb{C}(\Gamma_c)$ in order to define $\mathbf{K}$ in an equivalent way,

$$\mathbf{K} = \left\{\mathbf{q} \in \mathbf{X},\ \int_{\Omega_c} \mathbf{q} \cdot \nabla v + v \operatorname{div}\mathbf{q} \ge 0 \quad \forall v \in \mathbb{C}(\Gamma_c)\right\}.$$

Under our assumptions, functions in $H^1(\Omega_c)$ admit traces on the curve Σ, and therefore on the crack Γ_c. In order to characterize such traces as elements of fractional Sobolev spaces and introduce the dual order in the dual spaces, we need some notations. We introduce the space $H^{\frac{1}{2}}(\Sigma)$ equipped with the norm

$$\|\varphi\|^2_{H^{\frac{1}{2}}(\Sigma)} = \|\varphi\|^2_{L^2(\Sigma)} + \int_\Sigma \int_\Sigma \frac{|\varphi(x) - \varphi(y)|^2}{|x-y|^2}\, dx\, dy,$$

and we denote by $H^{-\frac{1}{2}}(\Sigma)$ its dual space. For $\mathbf{q} \in \mathbf{X}$ the traces $(\mathbf{q}.\nu)^{\pm}$ on $\Sigma^{\pm}$ can be defined as elements of $H^{-\frac{1}{2}}(\Sigma)$ and the trace operator is continuous from $\mathbf{X}$ into $H^{-\frac{1}{2}}(\Sigma)$. The space $H^{\frac{1}{2}}_{00}(\Gamma_c)$ is the subspace of $H^{\frac{1}{2}}(\Gamma_c)$ which can be identified [30] with the subspace of functions in $H^{\frac{1}{2}}(\Sigma)$ vanishing on the set $\Sigma \setminus \Gamma_c$. So, formally $H^{\frac{1}{2}}_{00}(\Gamma_c)$ includes the functions vanishing at the endpoints of Γ_c (see [30]). We can define the traces $(\mathbf{q}.\nu)^{\pm} \in (H^{\frac{1}{2}}_{00}(\Gamma_c))'$ and the constraints in the definition of $\mathbf{K}$ can be formulated using the duality, i.e., $[\mathbf{q}.\nu]=0$ means that

$$\langle [\mathbf{q}.\nu]\,,\varphi\rangle_{\frac{1}{2},\Gamma_c}=0 \quad \forall\varphi\in H_{00}^{\frac{1}{2}}(\Gamma_c),$$

and if the jump condition $[\mathbf{q}.\nu]=0$ is combined with the sign condition $(\mathbf{q}.\nu)^{\pm}\leq 0$ it is simply required that

$$\langle (\mathbf{q}.\nu)^{\pm},\varphi\rangle_{\frac{1}{2},\Gamma_c}\leq 0 \quad \forall\varphi\in H_{00}^{\frac{1}{2}}(\Gamma_c),\ \varphi\geq 0,\ \text{a.e. on } \Gamma_c,$$

where $\langle .,.\rangle_{\frac{1}{2},\Gamma_c}$ stands for the duality pairing between $H_{00}^{\frac{1}{2}}(\Gamma_c)$ and its dual $(H_{00}^{\frac{1}{2}}(\Gamma_c))'$.

We can consider the following equalities in the sense of distributions, i.e., in $\mathcal{D}'(\Omega_c)$,

$$\mathbf{p}=\mathbf{grad}\,u \quad \text{in } \Omega_c, \tag{5}$$

and then we have

$$-\mathrm{div}\,\mathbf{p}=f \quad \text{in } \Omega_c. \tag{6}$$

The mixed formulation of boundary value problem (1)–(4) can be written as follows. Find $(\mathbf{p},u)\in\mathbf{K}\times V$ such that

$$\left\{\begin{array}{l} \int_{\Omega_c}\mathbf{p}\,(\mathbf{q}-\mathbf{p})\,dx+\int_{\Omega_c}u\,(\mathrm{div}\,\mathbf{q}\,-\,\mathrm{div}\,\mathbf{p})\,dx\geq 0 \quad \forall\mathbf{q}\in\mathbf{K},\\ -\int_{\Omega_c}\mathrm{div}\,\mathbf{p}\,v\,dx=\int_{\Omega_c}f\,v\,dx \quad \forall v\in V. \end{array}\right. \tag{7}$$

Note that $\mathbf{p}=\mathbf{grad}u$ and u is the solution of problem (1)–(4).

Remark 2.2. The mixed formulation (7) can also be applied in the case of the set $\overline{\Gamma}_c$ crossing the external boundary Γ as well as in the case of Γ_c, which is less regular and belongs only to the class $C^{0,1}$ (see, e.g., [27]). In the case of Γ_c, which divides Ω into two disjoint Lipschitz subdomains Ω^1 and Ω^2, and for the inequality type boundary conditions (3)–(4) prescribed on Γ_c, the mixed formulation of the contact problem for two elastic bodies occupying Ω^1 and Ω^2 is obtained.

Remark 2.3. The smooth domain method can also be used for the modelling of a large class of crack problems with inequality type conditions prescribed on the crack including the most difficult, from a mathematical point of view, contact problem with Coulomb friction law. In particular, the field of applications includes the linear elastic bodies and the Kirchhoff plate models [25]. As an example of modelling in the framework of elasticity, we can consider the frictionless contact problem that takes the form of an equilibrium boundary value problem for the linear elastic body occupying the domain of reference Ω_c with the interior crack Γ_c. Such a problem can be formulated as follows.

Find $\mathbf{u}=(u_1,u_2)$ and $\sigma=(\sigma)_{ij}$, $i,j=1,2$, such that

$$-\mathbf{div}\,\sigma=\mathbf{f} \qquad \text{in } \Omega_c, \tag{8}$$

$$C\sigma-\varepsilon(\mathbf{u})=0 \qquad \text{in } \Omega_c, \tag{9}$$

$$\mathbf{u}=0 \qquad \text{on } \Gamma, \tag{10}$$

$$[\mathbf{u}]\,\nu\geq 0, \qquad [\sigma_\nu]=0, \qquad \sigma_\nu\,[\mathbf{u}]\cdot\nu=0 \qquad \text{on } \Gamma_c, \tag{11}$$

$$\sigma_\nu\leq 0, \qquad \sigma_\tau=0 \qquad \text{on } \Gamma_c^{\pm}. \tag{12}$$

Here

$$\sigma_\nu = \sigma_{ij}\nu_j\nu_i,\ \sigma_\tau = \sigma\nu - \sigma_\nu = \left\{\sigma_\tau^i\right\}_{i=1}^2,\ \sigma\nu = \left\{\sigma_{ij}\nu_j\right\}_{i=1}^2,$$
$$\varepsilon_{ij}(\mathbf{u}) = \frac{1}{2}(u_{i,j} + u_{j,i}),\ i,j = 1,2,\ \varepsilon(\mathbf{u}) = (\varepsilon_{ij})_{i,j=1}^2,$$
$$\left\{C\sigma\right\}_{ij} = c_{ijk\ell}\sigma_{k\ell},\ c_{ijk\ell} = c_{jik\ell} = c_{k\ell ij},\ c_{ijk\ell} \in L^\infty(\Omega).$$

The tensor C satisfies the ellipticity condition

$$c_{ijk\ell}\xi_{ji}\xi_{k\ell} \geq c_0|\xi|^2 \quad \forall\xi_{ji} = \xi_{ij},\ c_0 > 0, \tag{13}$$

and we have used the summation convention over repeated indices.

This problem can also be reformulated in the framework of the smooth domain method. Then the complete numerical analysis performed in the paper can be extended to the boundary value problem for frictionless contact conditions on the crack. The most challenging task is to extend the numerical results to the case of contact problems with friction.

Now we are in position to present the smooth domain method that allows us to solve numerically the crack problem in the smooth domain Ω. An application of the method means that the functions $\mathbf{p}$ and u are extended to the entire domain $\Omega = \Omega_c \cup \Gamma_c$, and it results in the closed problem formulation (14) obtained by replacing Ω_c with Ω in (7), with the obvious modification of the function spaces defined now in Ω, which are still denoted by $\mathbf{X} = \mathbf{X}(\Omega)$ and $V = V(\Omega)$,

$$\left\{\begin{array}{l} \int_\Omega \mathbf{p}\,(\mathbf{q} - \mathbf{p})\,dx + \int_\Omega u\,(\operatorname{div}\mathbf{q}\, -\, \operatorname{div}\mathbf{p})\,dx \geq 0 \quad \forall\mathbf{q} \in \mathbf{K}, \\ -\int_\Omega \operatorname{div}\mathbf{p}\,v\,dx = \int_\Omega f\,v\,dx \quad \forall v \in V. \end{array}\right. \tag{14}$$

$\mathbf{K} = \mathbf{K}(\Omega)$ denotes the closed convex set

$$\mathbf{K} = \left\{\mathbf{q} \in L^2(\Omega)^2,\ \operatorname{div}\mathbf{q} \in L^2(\Omega),\ \mathbf{q}.\nu \leq 0,\ \text{on}\ \ \Gamma_c\right\}.$$

The well-posedness of smooth domain formulation (14) is proved in [25] with arguments based on the regularization technique (a similar argument used in [33] yields the same result). We briefly recall the main idea of the regularization technique that we also use in the discretization of the problem. Actually, for the regularization parameter $\delta > 0$, we consider the equation

$$\delta u_\delta - \operatorname{div}\mathbf{p}_\delta = f \quad \text{in } \Omega, \tag{15}$$

which leads to the following regularized formulation: Find $(\mathbf{p}_\delta, u_\delta) \in \mathbf{K} \times V$ such that

$$\left\{\begin{array}{l} a_\delta(u_\delta, v_\delta) + b(v_\delta, \mathbf{p}_\delta) = (f, v_\delta) \quad \forall v_\delta \in V, \\ -b(u_\delta, \mathbf{q}_\delta - \mathbf{p}_\delta) + g(\mathbf{p}_\delta, \mathbf{q}_\delta - \mathbf{p}_\delta) \geq 0 \quad \forall\mathbf{q}_\delta \in \mathbf{K}, \end{array}\right. \tag{16}$$

where we have

$$a_\delta(u, v) = \delta\int_\Omega u\,v\,dx,$$

$$b(v, \mathbf{q}) = -\int_\Omega v\operatorname{div}\mathbf{q}\,dx,$$

and

$$g(\mathbf{p}, \mathbf{q}) = \int_\Omega \mathbf{p}\,\mathbf{q}\,dx.$$

The bilinear form $a_\delta(.,.)$ is continuous and V-elliptic, and $b(.,.)$ is continuous and satisfies the inf-sup condition. This yields the following result.

THEOREM 2.4. *Problem* (16) *admits a unique solution* $(u_\delta, \mathbf{p}_\delta)$ *for any* $f \in L^2(\Omega)$. *Moreover, we have the following stability estimate:*

$$\|u_\delta\|_V + \|\mathbf{p}_\delta\|_X \leq c\|f\|_{L^2(\Omega)}, \tag{17}$$

and the sequence of the regularized solutions $(u_\delta, \mathbf{p}_\delta)_\delta$ *converges to* $(u, \mathbf{p})$ *the solution of problem* (14) *when* δ *goes to zero.*

Remark 2.5. Note that the interpretation of problem (16) leads to

$$\mathbf{p}_\delta = \mathbf{grad}\, u_\delta,$$

and also it gives $u_\delta = 0$ on Γ; thus u_δ belongs to $H_0^1(\Omega)$. It follows also from (15) that if f is in $H^1(\Omega)$, then $\mathbf{p}_\delta$ belongs to the space

$$\mathbf{Z} = \left\{\mathbf{q} \in (H^1(\Omega))^2;\ \operatorname{div} \mathbf{q} \in H^1(\Omega)\right\}.$$

However, the convergence of u_δ to u is to be understood in the weak $H^1(\Omega)$-norm and the convergence of $\mathbf{p}_\delta$ holds in the weak $H(\operatorname{div}, \Omega)$-norm [25].

There are only very few results on the regularity of the solutions to crack problems with unilateral conditions. However, proceeding as for the unilateral contact problems [31], it can readily be checked that the unilateral conditions may also generate some singularities of solutions in the vicinity of the tips of Γ_c even for a regular datum f and the smooth exterior boundary $\partial\Omega$. For example, if $f \in H^1(\Omega)$, the solution u may not be of class H^3 in the vicinity of the crack Γ_c (see [31]). The reason for the lack of regularity can be explained in the following way. Let $\mathbf{m}$ be a point on Γ_c where the unilateral constraints change from binding to nonbinding; then the Dirichlet–Neumann singular function $S_\mathbf{m}(r, \vartheta) = r^{\frac{3}{2}} \sin(\frac{3}{2}\vartheta)\varphi(r)$ appears in the decomposition of the solution. Here (r, ϑ) are the polar coordinates with the origin at $\mathbf{m}$, and φ is a smooth function with the compact support, which equals 1 in the vicinity of $\mathbf{m}$. We refer the reader to [20] for the details on the decompositions of solutions to elliptic equations into singular and regular parts. The first Dirichlet–Neumann singular function $r^{\frac{1}{2}} \sin(\frac{1}{2}\vartheta)\psi(r)$ does not appear in the decomposition, since it fails to satisfy the required unilateral conditions—i.e., the nonnegativity of $S_\mathbf{m}$ and $\frac{\partial S_\mathbf{m}}{\partial n}$, simultaneously. Therefore, following [31] (see also [17]), we can apply the results derived for the Signorini problem and show that under appropriate symmetry conditions for f and Ω, it can be expected at most that $u \in H^\sigma(\mathcal{O}(\Gamma_c))$ with $\sigma < \frac{5}{2}$, where $\mathcal{O}(\Gamma_c)$ is an open set containing $\overline{\Gamma_c}$.

3. Discrete variational formulation.

3.1. The discrete regularized problem. We propose a discretization of the continuous variational formulation. First, we note that the bilinear form $g(.,.)$ is not elliptic on $\mathbf{X}$; therefore, the regularized problem (16) is considered for the approximation analysis. In fact, the ellipticity of $g(.,.)$ on the subspace of divergence free vector fields is a sufficient condition in order to apply the saddle-point theory. However, the regularization technique leads to a simple numerical method and, acting as a stabilized formulation, allows more flexibility in the choice of discretization spaces. In what follows, the regularization parameter $\delta > 0$ is omitted in our notation; e.g., we write u_h instead of $u_{\delta,h}$ for the sake of simplicity.

The finite element family that we have chosen in the discretization is based on the element called the Taylor–Hood mini element coming from the fluid dynamic. It consists of the approximation of the displacement u_h by piecewise affine polynomials and the pressure p_h by the P_1-bubble element. Other (more standard) choices, such as elements based on the Raviart–Thomas finite element, are currently considered in the implementation. The reason of our choice is that we expect the solutions of our problem to have the same regularity as those of the usual Signorini problem; thus, we choose an element that requires few degrees of freedom and provides “high” accuracy. In fact this element is an intermediary choice between RT0 and RT1.

We assume, to avoid curved elements, that Ω is polygonal and the crack Γ_c is a straight segment. We denote by $\mathcal{T}_h$ a triangulation of Ω. $\mathcal{T}_h$ is a family of elements which are triangles (or quadrilaterals), and the maximal size of elements is the parameter of approximation denoted by $h > 0$, in addition satisfying the usual admissibility assumptions. That is, the intersection of two different elements is either empty, a vertex, or a whole edge. Furthermore, $\mathcal{T}_h$ is assumed to be regular; i.e., the ratio of the diameter of any element $T \in \mathcal{T}_h$ to the diameter of its largest inscribed ball is bounded by a constant σ independent of T and h. We also assume that the endpoints of Γ_c are vertices of the triangulation. The nodes on Γ_c are denoted by $c_1 = x_0, x_1, \ldots, x_{I-1}, x_I = c_2$, and we set $t_i =]x_{i-1}, x_i[$ and $|t_i| = |x_i - x_{i-1}|$. We will assume for simplicity that the triangulation $\mathcal{T}_h$ is quasi-uniform, i.e., there is a constant $\tau > 0$ such that

$$\frac{\max_T \ h_T}{\min_T \ h_T} \leq \tau.$$

Remark 3.1. This assumption could be weakened. Indeed, if some general meshes are considered (for example in some adaptivity process), we can avoid such assumption and only assume that the 1D triangulation on Γ_c satisfies the following criterion (due to Crouzeix and Thomée [13]):

$$\frac{|t_i|}{|t_j|} \leq C\beta^{|i-j|} \quad \forall i, j \, (0 \leq i, j \leq I-1), \tag{18}$$

with $1 \leq \beta < 4$ and a constant C independent of h. In fact, this last condition is sufficient to prove the continuity property of the projection operators (for the appropriate norms), which is equivalent to the inf-sup conditions [11], [5]. In the case of quasi-uniform meshes, this continuity property results directly from inverse inequalities.

We introduce the following finite dimensional space for $h > 0$:

$$V_h = \left\{ v_h \in C(\overline{\Omega}), \ v_{h|T} \in P_1(T) \right\}.$$

For each element T in $\mathcal{T}_h$, the associated bubble function φ_T is defined by

$$\varphi_T(x) = \prod_{i=1}^{3} \lambda_i(x) \quad \forall x \in T,$$

where λ_i denotes the ith barycentric coordinate in T. $\mathcal{P}_1(T)$ stands for the space of the first-order polynomials over T, and $P_B(T) = P_1(T) \oplus \mathbb{R}\varphi_T$ is selected as the local approximation space for the vector fields in $\mathbf{X}$. Hence the global approximation space takes the form

$$\mathbf{X}_h = \left\{ \mathbf{q}_h \in C(\overline{\Omega})^2,\ \mathbf{q}_h \in P_B(T)^2 \right\},$$

and the following closed convex set is introduced for approximation of $\mathbf{K}$:

$$\mathbf{K}_h = \{ \mathbf{q}_h \in \mathbf{X}_h,\ \mathbf{q}_h.\nu \leq 0,\ \text{on}\, \Gamma_c \}.$$

Due to the lack of regularity for solutions of crack problems, we restrict ourselves to affine finite elements. The numerical simulations show in some cases an additional regularity of solutions, and therefore the use of higher order finite elements could be advantageous [2]. We point out that the choice of the discrete spaces V_h and $\mathbf{X}_h$ can be modified by choosing any other classical lower order finite elements spaces. Some possible choices, such as Raviart–Thomas elements, will be considered in a forthcoming paper. Note also that, for the choice presented in this paper, the discrete spaces satisfy the usual inf-sup condition that we recall now (see [8]): There exists $\gamma > 0$ independent of h such that

$$\forall v_h \in V_h,\ \sup_{\mathbf{q}_h \in \mathbf{X}_h} \frac{|b(v_h, \mathbf{q}_h)|}{\|\mathbf{q}_h\|_{\mathbf{X}}} \geq \gamma \|v_h\|_V. \tag{19}$$

By $V_h(\Omega^\ell)$ and $\mathbf{X}_h(\Omega^\ell)$, $\ell = 1, 2$, we denoted the finite dimensional spaces of functions of V_h and $\mathbf{X}_h$, respectively, restricted to the subdomains Ω^ℓ.

The discrete problem is defined in the following way.
Find $(u_h, \mathbf{p}_h) \in V_h \times \mathbf{K}_h$ such that

$$\left\{ \begin{array}{l} a_\delta(u_h, v_h) + b(v_h, \mathbf{p}_h) = (f, v_h) \quad \forall v_h \in V_h, \\ \\ -b(u_h, \mathbf{q}_h - \mathbf{p}_h) + g(\mathbf{p}_h, \mathbf{q}_h - \mathbf{p}_h) \geq 0 \quad \forall \mathbf{q}_h \in \mathbf{K}_h. \end{array} \right. \tag{20}$$

THEOREM 3.2. *Problem* (20) *admits a unique solution* $(u_h, \mathbf{p}_h)$ *for* $h > 0$. *Moreover, we have the following stability estimate, uniform with respect to h:*

$$\|u_h\|_V + \|\mathbf{p}_h\|_X \leq c \|f\|_{L^2(\Omega)}. \tag{21}$$

Proof. The proof in the discrete case is similar to the continuous problem (see [33, Theorem 2.3]). Indeed, the existence is based on a perturbation technique applied to the variational inequality obtained by summing the two lines of (20), then applying Stampacchia's theorem and, thanks to a uniform a priori estimate (with respect to h), passing to the limit.

It remains to prove the uniqueness of the solution of problem (20), which follows from direct computations. Assume there exist two solutions $(u_{hi}, \mathbf{p}_{hi})$, $i = 1, 2$. Choosing $\mathbf{q}_h = \mathbf{p}_{h2}$ in the second line of (20) with the first solution, respectively, $\mathbf{q}_h = \mathbf{p}_{h1}$ with the second solution, and summing the resulting inequalities yield

$$-b(u_{h2} - u_{h1}, \mathbf{p}_{h2} - \mathbf{p}_{h1}) + g(\mathbf{p}_{h2} - \mathbf{p}_{h1}, \mathbf{p}_{h2} - \mathbf{p}_{h1}) \leq 0.$$

Subtracting the first lines of problem (20),

$$\begin{array}{l} a(u_{h1}, v_h) + b(v_h, \mathbf{p}_{h1}) = (f, v_h), \\ a(u_{h2}, v_h) + b(v_h, \mathbf{p}_{h2}) = (f, v_h), \end{array}$$

and choosing $v_h = u_{h2} - u_{h1}$ lead to

$$-b(u_{h2} - u_{h1}, \mathbf{p}_{h2} - \mathbf{p}_{h1}) = a_\delta(u_{h2} - u_{h1}, u_{h2} - u_{h1}) \geq 0;$$

thus $g(\mathbf{p}_{h2} - \mathbf{p}_{h1}, \mathbf{p}_{h2} - \mathbf{p}_{h1}) \leq 0$, which implies $\mathbf{p}_{h1} = \mathbf{p}_{h2}$, and we deduce that $u_{h1} = u_{h2}$. □

For the convergence analysis and the numerical simulations we will introduce a new discrete formulation of problem (20) in the framework of the saddle-point approach.

3.2. New discrete formulation. The numerical analysis of mixed variational formulations for unilateral frictionless contact problems is performed, e.g., in [14], [29], [5], [33]. There are some similarities between modelling of contact problems and the smooth domain models of crack problems considered in this paper. Therefore, the same saddle-point framework, as in the case of contact problems, can be used for the convergence analysis of proposed finite element approximations for the smooth domain method.

First, the following energy functional is defined over the convex set $V \times \mathbf{K}$:

$$\mathcal{J}(v, \mathbf{q}) = \frac{1}{2} a_\delta(v, v) - (f, v) - b(v, \mathbf{q}) + \frac{1}{2} g(\mathbf{q}, \mathbf{q}).$$

Clearly, solution of problem (20) is equivalent to the minimization problem for $\mathcal{J}$,

$$\mathcal{J}(u, \mathbf{p}) = \min_{(v,\mathbf{q}) \in V \times \mathbf{K}} \mathcal{J}(v, \mathbf{q}). \tag{22}$$

The constraints in $\mathbf{K}$ can be defined by duality using the closed convex cone

$$M = \left\{ \mu \in H^{\frac{1}{2}}(\Gamma_c);\ \mu \geq 0 \right\};$$

thus, we can write equivalently problem (16) as follows: Find $(u, \mathbf{p}, \lambda) \in V \times \mathbf{X} \times M$ such that

$$\left\{ \begin{array}{l} a_\delta(u, v) + b(v, \mathbf{p}) = (f, v) \quad \forall v \in V, \\ \\ -b(u, \mathbf{q}) + g(\mathbf{p}, \mathbf{q}) + \langle \lambda, \mathbf{q}.\nu \rangle_{\frac{1}{2}, \Gamma_c} = 0 \quad \forall \mathbf{q} \in \mathbf{X}, \\ \\ \langle \mu - \lambda, \mathbf{p}.\nu \rangle_{\frac{1}{2}, \Gamma_c} \leq 0 \quad \forall \mu \in M, \end{array} \right. \tag{23}$$

where the elements $(u, \mathbf{p}, \lambda)$ are given by a saddle-point of the Lagrangian

$$\mathcal{L}(v, \mathbf{q}, \mu) = \mathcal{J}(v, \mathbf{q}) + \langle \mu, \mathbf{q}.\nu \rangle_{\frac{1}{2}, \Gamma_c},$$

defined over the product $V \times \mathbf{X} \times M$. Note that λ is the Lagrange multiplier associated to the inequality constraint $\mathbf{p}.\nu \leq 0$ on Γ_c.

PROPOSITION 3.3. *Problem* (23) *admits a unique solution* $(u, \mathbf{p}, \lambda) \in V \times \mathbf{X} \times M$ *for any* $\delta > 0$. *Moreover,*

$$\lambda = [u] \ \text{ on } \Gamma_c,$$

and $(u, \mathbf{p})$ *is the solution of problem* (16).

In order to define a finite dimensional approximation of problem (23) we need an approximation of the inequality constraints in $\mathbf{K}$. For this purpose, we introduce two finite dimensional spaces of scalar functions on Γ_c,

$$W_h^0(\Gamma_c) = \left\{\mu_h,\ \mu_{h|t_i} \in \mathbb{P}_0(t_i),\ 0 \le i \le I-1\right\},$$
$$W_h^1(\Gamma_c) = \left\{\mu_h \in C(\overline{\Gamma}_c),\ \exists \mathbf{q}_h \in \mathbf{X}_h,\ \text{such that } \mathbf{q}_h.\nu = \mu_h \text{ on } \Gamma_c\right\}.$$

Now, we are in position to define the finite dimensional approximations of the set M. The first set M_h^0 is an external approximation of M since piecewise constant functions are not elements of the fractional Sobolev space $H^{\frac{1}{2}}$. Thus, with the choice of the space $W_h^0(\Gamma_c)$ we have the definition

$$M_h^0 = \left\{\mu_h \in W_h^0(\Gamma_c),\ \mu_h \ge 0,\ \text{on } \Gamma_c\right\}, \tag{24}$$

and the choice of $W_h^1(\Gamma_c)$ leads to the following two approximation sets:

$$M_h^1 = \left\{\mu_h \in W_h^1(\Gamma_c),\ \mu_h \ge 0 \text{ on } \Gamma_c\right\} \tag{25}$$

and

$$M_h^{1,*} = \left\{\mu_h \in W_h^1(\Gamma_c),\ \int_{\Gamma_c} \mu_h \psi_h \, d\Gamma \ge 0 \,\forall \psi_h \in M_h^1\right\}. \tag{26}$$

We note that the set M_h^1 is well defined since μ_h is a continuous function, piecewise P_1 so that the nonnegativity condition can only be imposed at the nodes of the 1D mesh of Γ_c.

Remark 3.4. It can be expected that the choice of the set M_h^0, for the approximation of Lagrangian multipliers as elements of $H^{\frac{1}{2}}(\Gamma_c)$, leads to worse results compared to the two other possibilities listed above. This fact is confirmed by the convergence analysis, at least when we compare with the choice of $M_h^{1,*}$. We consider such an approximation (with M_h^0) for the sake of completeness (since it is sometimes used in computations in contact mechanics).

The solution $(u_h, \mathbf{p}_h, \lambda_h) \in V_h \times \mathbf{X}_h \times M_h$ of the finite dimensional mixed approximation of (23) satisfies the following discrete system of equations and inequalities:

$$\begin{cases} a_\delta(u_h, v_h) + b(v_h, \mathbf{p}_h) = (f, v_h) \quad \forall v_h \in V_h, \\ -b(u_h, \mathbf{q}_h) + g(\mathbf{p}_h, \mathbf{q}_h) + \int_{\Gamma_c} (\lambda_h)(\mathbf{q}_h.\nu)\, d\sigma = 0 \quad \forall \mathbf{q}_h \in \mathbf{X}_h, \\ \int_{\Gamma_c} (\mu_h - \lambda_h)(\mathbf{p}_h.\nu)\, d\sigma \le 0 \quad \forall \mu_h \in M_h, \end{cases} \tag{27}$$

where M_h is a specific multiplier set defined by (24), (25), or in (26).

NOTATION . *$d(.,.)$ is a bilinear form defined on $M \times (V \times \mathbf{X})$ by*

$$d(\mu, \mathbf{V}) = \langle (\mathbf{q}.\nu), \mu \rangle_{\frac{1}{2},\Gamma_c},$$

where $\mathbf{V} = (v, \mathbf{q}) \in V \times \mathbf{X}$.

The uniqueness of $(u_h, \mathbf{p}_h)$ as a solution of (27) follows directly from the uniqueness argument in the proof of Theorem 3.2.

Therefore, to prove the existence and uniqueness of a saddle-point in (27), it is sufficient to verify that

$$\{\mu_h \in M_h,\ d(\mu_h, \mathbf{V}) = 0 \quad \forall \mathbf{V} \in V_h \times \mathbf{X}_h\} = \{0\},$$

which is straightforward in the case $M_h = M_h^1$ or $M_h = M_h^{1,*}$ and which still holds for $M_h = M_h^0$ by the inf-sup condition (29) under condition (18). Thus, the following result is obtained.

PROPOSITION 3.5. *Assume that the set M_h is given by $M_h = M_h^0$, $M_h = M_h^1$, or $M_h = M_h^{1,*}$. For each of the choices, problem* (27) *admits a unique solution.*

In order to perform the convergence analysis of finite element methods, we first check the compatibility condition (inf-sup condition) between the spaces $W_h^1(\Gamma_c)$ and $V_h \times \mathbf{X}_h$, respectively, the compatibility condition between W_h^0 and $V_h \times \mathbf{X}_h$. These conditions are necessary to obtain optimal stability results.

The first inf-sup condition. This condition between W_h^0 and $V_h \times \mathbf{X}_h$ is obtained under the assumption (18) in [5, Lemma 6.3] with W_h^0 equipped with the $H^{-\frac{1}{2}}$-norm. For our purpose, we need the inf-sup condition in the mesh-dependent norm

$$\|\mu_h\|_L = \left(\sum_{i=1}^{I-1} h_{t_i} \|\mu_h\|^2_{L^2(t_i)} \right)^{\frac{1}{2}}.$$

We denote by $\|\mu_h\|_{L^{-1}} = \left(\sum_{i=1}^{I-1} h_{t_i}^{-1} \|\mu_h\|^2_{L^2(t_i)}\right)^{\frac{1}{2}}$ its dual norm. Therefore, it is standard [11] that the inf-sup condition follows from the stability with respect to the norm $\|.\|_{L^{-1}}$ of the L^2-projection operator $\pi_h^0 : L^2(\Gamma_c) \longrightarrow W_h^0$:

$$\int_{\Gamma_c} v\psi_h \, d\sigma = \int_{\Gamma_c} \pi_h^0(v)\psi_h \, d\sigma, \quad \psi_h \in W_h^0. \tag{28}$$

Noting that (28) is a linear system of the form $y = Dx$, with a diagonal (positive definite) matrix D, the stability property for π_h^0 follows by straightforward computations. Thus, we derive the following inf-sup condition.

PROPOSITION 3.6. *There exists $\beta_0 > 0$ such that*

$$\forall \mu_h \in W_h^0, \quad \sup_{\mathbf{V}_h \in V_h \times \mathbf{X}_h} \frac{d(\mu_h, \mathbf{V}_h)}{\|\mathbf{V}_h\|_{V\times\mathbf{X}}} \geq \gamma_0 \,\|\mu_h\|_L \geq \beta_0 \, h^{\frac{1}{2}} \|\mu_h\|_{L^2(\Gamma_c)}. \tag{29}$$

The operator π_h^0 satisfies the following estimates proved in [29]. Namely, for the functions $\varphi \in H^\nu(\Gamma_c)$ with $\nu = \frac{1}{2}$, or with $\nu = 1$, there exists a constant $c > 0$ independent of h such that

$$\|\varphi - \pi_h^0\varphi\|_{L^2(\Gamma_c)} \leq ch^\nu \|\varphi\|_{H^\nu(\Gamma_c)}. \tag{30}$$

Moreover, if $\varphi \in L^2(\Gamma_c)$, then

$$\|\varphi - \pi_h^0\varphi\|_{H^{-\frac{1}{2}}(\Gamma_c)} \leq ch^{\frac{1}{2}} \|\varphi - \pi_h^0\varphi\|_{L^2(\Gamma_c)}. \tag{31}$$

In addition, we have the following property of the operator: For $\varphi \geq 0$ it follows that $\pi_h^0\varphi \in M_h^0$.

The second inf-sup condition. The second condition is stated in Proposition 3.7 and requires us to introduce some additional tools. We define the projection operator $\pi_h^1 : L^2(\Gamma_c) \mapsto W_h^1(\Gamma_c)$, with respect to the scalar product in $L^2(\Gamma_c)$, which satisfies the following properties proved in [7].

Given $\mu \in [0,1]$ and $\nu \in \left]\frac{1}{2}, 2\right]$, there exists a constant $c > 0$ that is independent of h, such that for all functions $\varphi \in H^\nu(\Gamma_c)$,

$$\|\varphi - \pi_h^1\varphi\|_{H^{-\mu}(\Gamma_c)} + h^{\mu+\frac{1}{2}}\|\varphi - \pi_h^1\varphi\|_{H^{\frac{1}{2}}(\Gamma_c)} \leq ch^{\mu+\nu}\|\varphi\|_{H^\nu(\Gamma_c)}. \tag{32}$$

Proposition 3.7. *There exists $\beta > 0$, independent of h, such that the following inf-sup condition holds:*

$$\sup_{\mathbf{V}\in V_h\times\mathbf{X}_h} \frac{d(\mu_h, \mathbf{V})}{\|\mathbf{V}\|} \geq \beta\|\mu_h\|_{H^{\frac{1}{2}}(\Gamma_c)} \quad \forall \mu_h \in W_h^1. \tag{33}$$

Proof. Let $\mu_h \in W_h^1(\Gamma_c)$. We want to construct $\mathbf{q}_h \in \mathbf{X}_h$ such that

$$d(\mu_h, (0, \mathbf{q}_h)) \geq \|\mu_h\|^2_{H^{\frac{1}{2}}(\Gamma_c)} \quad \text{and} \quad \beta\|\mathbf{q}_h\|_{H^1(\Omega)^2} \leq \|\mu_h\|_{H^{\frac{1}{2}}(\Gamma_c)}. \tag{34}$$

Let us consider $\mathbf{q} \in H^1(\Omega)^2$ such that

$$\int_\Omega \mathbf{q}\cdot\mathbf{w}\,d\mathbf{x} + \int_\Omega (\mathbf{grad}\,\mathbf{q}) : (\mathbf{grad}\,\mathbf{w})\,d\mathbf{x} = d(\mu_h, (0, \mathbf{w})) \quad \forall \mathbf{w} \in H^1(\Omega)^2, \tag{35}$$

where

$$\mathbf{grad}\,\mathbf{q} : \mathbf{grad}\,\mathbf{w} = \sum_{i,j=1}^{2} \frac{\partial \mathbf{q}_j}{\partial x_i}\frac{\partial \mathbf{w}_j}{\partial x_i}.$$

The following stability inequalities hold:

$$c_1\|\mu_h\|_{H^{\frac{1}{2}}(\Gamma_c)} \leq \|\mathbf{q}\|_{H^1(\Omega)^2} \leq c_2\|\mu_h\|_{H^{\frac{1}{2}}(\Gamma_c)}. \tag{36}$$

Note that the first inequality comes from the continuous inf-sup condition of $d(.,.)$ and (35).

Then we set $\mathbf{q}_h \in \mathbf{X}_h$ such that $(\mathbf{q}_h.\nu)_{\Gamma_c} = \pi_h^1((\mathbf{q}.\nu)_{\Gamma_c})$ and

$$\|\mathbf{q}_h\|_{H^1(\Omega)^2} \leq c\|\pi_h^1(\mathbf{q}.\nu)\|_{H^{\frac{1}{2}}(\Gamma_c)} \leq c\|\mathbf{q}.\nu\|_{H^{\frac{1}{2}}(\Gamma_c)}. \tag{37}$$

Such $\mathbf{q}_h$ is built using a stable finite element extension operator studied in [6]. Next, observe that we have

$$d(\mu_h, (0, \mathbf{q}_h)) = d(\mu_h, (0, \mathbf{q})) = \|\mathbf{q}\|^2_{H^1(\Omega)^2} \geq c_1^2\|\mu_h\|^2_{H^{\frac{1}{2}}(\Gamma_c)},$$

which yields the first statement of (34). The second one is obtained from (36) and (37). □

4. Convergence analysis.

In this section we perform the convergence analysis and give the error estimates and the rates of convergence. Let us define a bilinear form $A(.,.)$ on the product space $V \times \mathbf{X}$ by

$$\begin{aligned} A(\mathbf{U} - \mathbf{U}_h, \mathbf{U} - \mathbf{V}_h) = {} & a_\delta(u - u_h, u - v_h) + b(u - v_h, \mathbf{p} - \mathbf{p}_h) \\ & -b(u - u_h, \mathbf{p} - \mathbf{q}_h) + g(\mathbf{p} - \mathbf{p}_h, \mathbf{p} - \mathbf{q}_h), \end{aligned}$$

where $\mathbf{U} = (u, \mathbf{p})$, $\mathbf{U}_h = (u_h, \mathbf{p}_h)$ and $\mathbf{V}_h = (v_h, \mathbf{q}_h)$. In the following lemma we establish an abstract error expression for the solution $(u, \mathbf{p})$ of problem (27); since the proof is rather long we give it in the appendix.

Lemma 4.1. *Let $(u, \mathbf{p})$ be the solution of problem* (16) *and $(u_h, \mathbf{p}_h)$ the solution of problem* (27)*; then the following estimate holds: For small $\delta > 0$, and for any $(\mathbf{V}_h, \mu_h) \in L^2(\Omega) \times \mathbf{X}_h \times M_h$,*

(38)
$$\|u-u_h\|_V^2+\|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2}^2 \le c\big(|A(\mathbf{U}-\mathbf{U}_h, \mathbf{U}-\mathbf{V}_h)|+|d(\mu_h-\lambda, \mathbf{p}-\mathbf{p}_h)+d(\lambda-\lambda_h, \mathbf{p}-\mathbf{q}_h) + d(\lambda-\mu_h, \mathbf{p}) + d(\lambda_h, \mathbf{p}) + d(\mu_h, \mathbf{p}_h)| + \inf_{v_h \in V_h} \|u-v_h\|_V^2 + \|\lambda-\lambda_h\|^2\big).$$

We also need some related results on the approximation by means of the Lagrange interpolation. We refer the reader to [12] for the proofs of the results. Denote by I_h^ℓ and i_h the Lagrange interpolation operators with values in the spaces $V_h(\Omega^\ell)$ and $W_h^1(\Gamma_c)$, respectively. Then, there exists a constant $C > 0$ such that for all $v^\ell \in H^2(\Omega^\ell)$ and $v \in H^{\frac{3}{2}}(\Gamma_c)$,

$$\|v^\ell - I_h^\ell v^\ell\|_{L^2(\Omega^\ell)} \le ch^2 \|v^\ell\|_{H^2(\Omega^\ell)}; \ \|v - i_h v\|_{L^2(\Gamma_c)} \le ch^{\frac{3}{2}} \|v\|_{H^{\frac{3}{2}}(\Gamma_c)}. \tag{39}$$

Let Π_h^ℓ be the projection operator from $\mathbf{X}(\Omega^\ell)$ into $(V_h(\Omega^\ell))^2$ introduced in [8]; then we have for $\mathbf{q} \in \mathbf{X}$ such that $\mathbf{q}^\ell = \mathbf{q}_{|\Omega^\ell} \in H^{s_\ell}(\Omega^\ell)$, $1 \le s_\ell \le 2$, $\ell = 1, 2$ [8, Theorem 3.4],

$$\|\mathbf{q}^\ell - \Pi_h^\ell \mathbf{q}^\ell\|_{L^2(\Omega^\ell)^2} \le ch^{s_\ell} \|\mathbf{q}^\ell\|_{(H^{s_\ell}(\Omega^\ell))^2}, \tag{40}$$

$$\|\operatorname{div} \mathbf{q}^\ell - \operatorname{div} \Pi_h^\ell \mathbf{q}^\ell\|_{L^2(\Omega^\ell)} \le ch^{s_\ell - 1} \|\mathbf{q}^\ell\|_{(H^{s_\ell - 1}(\Omega^\ell))^2}. \tag{41}$$

In order to simplify the error analysis we will assume that the solution $\mathbf{p}$ of problem (23) is such that

$$\operatorname{div} \mathbf{p}_\ell \in H^1(\Omega^\ell), \quad \ell = 1, 2. \tag{42}$$

It is readily checked that under assumption (42) the trace $\mathbf{p}.\nu$ belongs to $H^{\frac{3}{2}}(\Gamma_c)$. Note that assumption (42) is not stringent since it requires only local regularity in each subdomain (which holds in general—see the end of section 1). If we assume only $\mathbf{p}^\ell \in H^1(\Omega^\ell)$, we derive, similarly to the rest of this section, the complete error estimate (in this case the error behaves as $O(h^{\frac{1}{4}})$).

The following lemma states the first error estimates; for the convenience of the reader the proof is also given in the appendix.

Lemma 4.2. *Let $(\mathbf{U}, \lambda)$, with $\mathbf{U} = (u, \mathbf{p})$, be the solution of problem* (23). *Suppose that $u_{|\Omega^1} \in H^2(\Omega^1)$, $u_{|\Omega^2} \in H^2(\Omega^2)$, that also $\mathbf{p}_{|\Omega^1} \in H^1(\Omega^1)^2$, $\mathbf{p}_{|\Omega^2} \in H^1(\Omega^2)^2$, and that assumption* (42) *holds.*

(i) *Let $(\mathbf{U}_h, \lambda_h)$ be the solution of* (27) *with $M_h = M_h^0$; then the following estimate holds:*

(43)
$$\|u-u_h\|_V^2 + \|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2}^2 \le C(\delta, u, \mathbf{p})\big(h\|\lambda-\lambda_h\|_{L^2(\Gamma_c)} + \|\lambda-\lambda_h\|_{L^2(\Gamma_c)}^2 + h^{\frac{3}{2}}\big).$$

(ii) *In the case of $M_h = M_h^{1,*}$ the following estimate holds:*

(44)
$$\|u-u_h\|_V^2+\|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2}^2 \le C(\delta, u, \mathbf{p})\big(h^{\frac{3}{2}}\|\lambda-\lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)}+\|\lambda-\lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)}^2+h^{\frac{3}{2}}\big),$$

where the (generic) constant $C(\delta, u, \mathbf{p})$ *depends linearly on the norms* $\|u_{|\Omega^\ell}\|_{H^2(\Omega^\ell)}$, $\|\mathbf{p}_{|\Omega^\ell}\|_{H^1(\Omega^\ell)^2}$, *and* $\|\operatorname{div} \mathbf{p}_{|\Omega^\ell}\|_{H^1(\Omega^\ell)^2}$, $\ell = 1, 2$.

Proof. First, the result is established for $M_h = M_h^{1,*}$, and we denote by π_h the associated projection operator π_h^1 given in (32). The proof is divided into small steps.

Step 1. Recall the definition of $A(.,.)$:

$$\begin{aligned} A(\mathbf{U} - \mathbf{U}_h, \mathbf{U} - \mathbf{V}_h) = a_\delta(u - u_h, u - v_h) + b(u - v_h, \mathbf{p} - \mathbf{p}_h) \\ -b(u - u_h, \mathbf{p} - \mathbf{q}_h) + g(\mathbf{p} - \mathbf{p}_h, \mathbf{p} - \mathbf{q}_h). \end{aligned}$$

Then, for particular choices of the test functions as $v_h^\ell = I_h^\ell u^\ell$ and $\mathbf{q}_h^\ell = \Pi_h \mathbf{p}^\ell$, $\ell = 1, 2$, and using inequalities (39) and (40), we derive

$$|a_\delta(u - u_h, u - v_h)| \leq \delta c(u) h^2 \|u - u_h\|_V,$$

$$|b(u - v_h, \mathbf{p} - \mathbf{p}_h)| \leq c(u) h^2 \|\operatorname{div} \mathbf{p} - \operatorname{div} \mathbf{p}_h\|_{L^2(\Omega)},$$

$$|b(u - u_h, \mathbf{p} - \mathbf{q}_h)| \leq c(\mathbf{p}) h \|u - u_h\|_V,$$

$$|g(\mathbf{p} - \mathbf{p}_h, \mathbf{p} - \mathbf{q}_h)| \leq c(\mathbf{p}) h \|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)^2},$$

where the (generic) constants are linear with respect to the appropriate norms, i.e., with

$$c(u) \leq c \max\{\|u_{|\Omega^1}\|_{H^2(\Omega^1)}, \|u_{|\Omega^2}\|_{H^2(\Omega^2)}\},$$

and

$$c(\mathbf{p}) \leq c \max\{\|\mathbf{p}_{|\Omega^1}\|_{H^1(\Omega^1)^2}, \|\mathbf{p}_{|\Omega^2}\|_{H^1(\Omega^2)^2}, \|\operatorname{div} \mathbf{p}_{|\Omega^1}\|_{H^1(\Omega^1)}, \|\operatorname{div} \mathbf{p}_{|\Omega^2}\|_{H^1(\Omega^2)}\}.$$

Note that we have (see [8, Theorem 3.4 and condition (3.10)])

$$\begin{aligned} (45) \quad \|\operatorname{div}\mathbf{p} - \operatorname{div}\mathbf{p}_h\|_{L^2(\Omega)} &= \|\operatorname{div}\mathbf{p} - \operatorname{div}\mathbf{q}_h\|_{L^2(\Omega)} \\ &= \left(\sum_{T \in \mathcal{T}_h} \|\operatorname{div}\mathbf{p} - \operatorname{div}\mathbf{q}_h\|_{L^2(T)}^2 \right)^{\frac{1}{2}} \leq c \left(\sum_{T \in \mathcal{T}_h} h_T^2 \|\operatorname{div}\mathbf{p}\|_{H^1(T)}^2 \right)^{\frac{1}{2}} \leq c(\mathbf{p}) h. \end{aligned}$$

Thus we can write

$$|b(u - v_h, \mathbf{p} - \mathbf{p}_h)| \leq c(u, \mathbf{p}) h^3.$$

The above estimates yield

$$(46) \qquad A(\mathbf{U} - \mathbf{U}_h, \mathbf{U} - \mathbf{V}_h) \leq C(u, \mathbf{p}, \delta) \left\{ h(\|u - u_h\|_V + \|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)^2}) + h^3 \right\}.$$

Step 2. Taking $\mu_h = i_h(\lambda)$, by an application of the Cauchy–Schwarz inequality, combined with estimates (39), it follows that

$$\begin{aligned} d(\lambda - \mu_h, \mathbf{U}_h - \mathbf{U}) &\leq \|\lambda - \mu_h\|_{L^2(\Gamma_c)} \|(\mathbf{p}_h - \mathbf{p}) \cdot \nu\|_{L^2(\Gamma_c)} \\ &\leq c h^{\frac{3}{2}} \|\lambda\|_{H^{\frac{3}{2}}(\Gamma_c)} \|(\mathbf{p}_h - \mathbf{p}) . \nu\|_{L^2(\Gamma_c)}. \end{aligned}$$

By a scaling we derive, for each edge e of a triangle $T \in \mathcal{T}_h \cap \Gamma_c$, the following trace theorem:

$$\|(\mathbf{p}-\mathbf{p}_h)\cdot\nu\|_{L^2(e)} \le c\big(h_T^{-\frac{1}{2}}\|\mathbf{p}-\mathbf{p}_h\|_{L^2(T)^2} + h_T^{\frac{1}{2}}\|(\operatorname{div}\mathbf{p} - \operatorname{div}\mathbf{p}_h)\|_{L^2(T)}\big). \tag{47}$$

Applying this inequality and (45) yields

$$d(\lambda-\mu_h, \mathbf{U}_h-\mathbf{U}) \le C(u,\mathbf{p})\big(h\|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2} + h^2\big). \tag{48}$$

The term $d(\mu_h, \mathbf{p}_h)$ is bounded similarily and yields

$$d(\mu_h, \mathbf{U}_h-\mathbf{U}) \le C(u,\mathbf{p})\big(h\|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2} + h^2\big). \tag{49}$$

Step 3. For $\mathbf{q}_h.\nu = \pi_h(\mathbf{q}.\nu)$, an application of the Cauchy–Schwarz inequality combined with (32) leads to

$$\begin{aligned} d(\lambda-\lambda_h, \mathbf{U}-\mathbf{V}_h) &\le \|\lambda-\lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)}\|(\mathbf{p}-\mathbf{q}_h).\nu\|_{H^{-\frac{1}{2}}(\Gamma_c)} \\ &\le C(\mathbf{p})h^2\|\lambda-\lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)}. \end{aligned} \tag{50}$$

Step 4. We have

$$\begin{aligned} d(\lambda-\mu_h, \mathbf{U}) &= \int_{\Gamma_c}(\lambda-\mu_h)(\mathbf{p}.\nu)\,d\Gamma \\ &= \int_{\Gamma_c}(\lambda - i_h(\lambda))(\mathbf{p}.\nu - \pi_h(\mathbf{p}.\nu))\,d\Gamma \quad (\pi_h(i_h(\varphi)) = i_h(\varphi)) \\ &\le \|\lambda - i_h(\lambda)\|_{L^2(\Gamma_c)}\|\mathbf{p}.\nu - \pi_h(\mathbf{p}.\nu)\|_{L^2(\Gamma_c)}. \end{aligned}$$

Using (39) and the appropriate approximation property of the projection $\pi_h = \pi_h^1$ [7], we obtain

$$d(\lambda-\mu_h, \mathbf{U}) \le C(u,\mathbf{p})h^3. \tag{51}$$

Step 5. We establish an estimate for the last term in (38) in order to apply estimate (38). The term is rewritten as follows:

$$\begin{aligned} d(\lambda_h, \mathbf{U}) &= \int_{\Gamma_c}(\lambda_h)(\mathbf{p}.\nu)\,d\Gamma \\ &= \int_{\Gamma_c}(\lambda_h)(\mathbf{p}.\nu - i_h(\mathbf{p}.\nu))\,d\Gamma + \int_{\Gamma_c}\lambda_h i_h(\mathbf{p}.\nu)\,d\Gamma. \end{aligned}$$

Since $i_h(\mathbf{p}.\nu) \le 0$, and $\lambda_h \in M_h^{1,*}$, we have

$$\int_{\Gamma_c}\lambda_h i_h(\mathbf{p}.\nu)\,d\Gamma \le 0.$$

Therefore

$$\begin{aligned} d(\lambda_h, \mathbf{U}) &\le \int_{\Gamma_c}(\lambda_h)(\mathbf{p}.\nu - i_h(\mathbf{p}.\nu))\,d\Gamma \\ &\le \int_{\Gamma_c}(\lambda_h-\lambda)(\mathbf{p}.\nu - i_h(\mathbf{p}.\nu))\,d\Gamma \\ &\quad + \int_{\Gamma_c}(\lambda)(\mathbf{p}.\nu - i_h(\mathbf{p}.\nu))\,d\Gamma \\ &\le \|\lambda-\lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)}\|(\mathbf{p}.\nu - i_h(\mathbf{p}.\nu))\|_{L^2(\Gamma_c)} \\ &\quad + \|\lambda\|_{L^2(\Gamma_c)}\|(\mathbf{p}.\nu - i_h(\mathbf{p}.\nu))\|_{L^2(\Gamma_c)} \end{aligned}$$

and by (39)

$$d(\lambda_h, \mathbf{U}) \leq C(u, \mathbf{p}) h^{\frac{3}{2}} \|\lambda - \lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)} + C(u, \mathbf{p}) h^{\frac{3}{2}}. \tag{52}$$

Finally, assembling estimates (46)–(52) in the right-hand side of (38) yields

$$\begin{aligned}\|u - u_h\|_V^2 + \|\mathbf{p} - \mathbf{p}_h\|^2_{L^2(\Omega)^2} \leq C(\delta, u, \mathbf{p})\big(h(\|u - u_h\|_V + \|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)^2}) \\ + h^{\frac{3}{2}} \|\lambda - \lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)} + \|\lambda - \lambda_h\|^2_{H^{\frac{1}{2}}(\Gamma_c)} + h^{\frac{3}{2}}\big).\end{aligned}$$

Writing

$$\begin{aligned}&C(\delta, u, \mathbf{p}) h(\|u - u_h\|_V + \|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)^2}) \\ &\qquad \leq \ \gamma(\|u - u_h\|_V + \|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)^2})^2 + \frac{C(\delta, u, \mathbf{p})^2}{4\gamma} h^2\end{aligned}$$

with $\gamma > 0$ leads to the desired estimate for sufficiently small γ. This completes the proof for $M_h = M_h^{1,*}$.

The case of $M_h = M_h^0$ can be treated in the same way, with the projection π_h in Steps 3 and 4 replaced by the appropriate L^2-projection π_h^0 on M_h (see [29] for the properties of the projection operator), and in view of $d(\lambda_h, \mathbf{U}) \leq 0$, Step 5 can be neglected. We briefly list the results that can be obtained for the particular case of $M_h = M_h^0$; the details are left to the reader. Actually, in Step 3 the following estimate is established:

$$d(\lambda - \lambda_h, \mathbf{U} - \mathbf{V}_h) \leq \|\lambda - \lambda_h\|_{L^2(\Gamma_c)} \|(\mathbf{p} - \mathbf{q}_h).\nu\|_{L^2(\Gamma_c)} \leq C(\mathbf{p}) h \|\lambda - \lambda_h\|_{L^2(\Gamma_c)},$$

and accordingly, in Step 4 the resulting inequality takes the form

$$d(\lambda - \mu_h, \mathbf{U}) \leq C(u, \mathbf{p}) h^{\frac{5}{2}}. \qquad \square$$

Remark 4.3. The same rate of convergence as in Lemma 4.2 cannot be derived for the case of $M_h = M_h^1$. However, the same procedure as in [5] results in the convergence rate $O(h^{\frac{1}{2}})$.

Remark 4.4. Estimates (43) and (44) can be formulated in terms of the mesh-dependent norm $\|.\|_h$ on $\mathbf{X}$ defined by

$$\|\mathbf{q}\|_h = \left(\sum_{T \in \mathcal{T}_h} \|\mathbf{q}\|^2_{L^2(T)^2} + h_T^2 \|\operatorname{div} \mathbf{q}\|^2_{L^2(T)} \right)^{\frac{1}{2}}.$$

Lemma 4.5. *Let $(u, \mathbf{p}, \lambda)$ be the solution of problem* (23). *As usual we denote $\mathbf{U} = (u, \mathbf{p})$. Suppose that $u_{|\Omega^1} \in H^2(\Omega^1)$, $u_{|\Omega^2} \in H^2(\Omega^2)$ and also $\mathbf{p}_{|\Omega^1} \in H^1(\Omega^1)^2$, $\mathbf{p}_{|\Omega^2} \in H^1(\Omega^2)^2$, and assumption* (42) *holds. Let $(\mathbf{U}_h, \lambda_h)$ be the solution of* (27) *for $M_h = M_h^0$; then the following estimate holds:*

$$\|\lambda - \lambda_h\|_{L^2(\Gamma_c)} \leq C h^{-\frac{1}{2}} (\|u - u_h\|_V + \|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)^2}) + C(u) h^{\frac{1}{2}}. \tag{53}$$

If $M_h = M_h^{1,*}$, then the following estimate is obtained:

$$\|\lambda - \lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)} \leq C(\|u - u_h\|_V + \|\mathbf{p} - \mathbf{p}_h\|_{L^2(\Omega)^2} + C(u, \mathbf{p}) h), \tag{54}$$

where $C(u,\mathbf{p}) \leq c \max\{\|u_{|\Omega^\ell}\|_{H^2(\Omega^\ell)}, \|\mathbf{p}_{|\Omega^\ell}\|_{H^1(\Omega^\ell)^2}, \|\mathrm{div}\,\mathbf{p}_{|\Omega^\ell}\|_{H^1(\Omega^\ell)^2},\ \ell = 1,2\}$.

Proof. We set $\mathbf{q} = \mathbf{q}_h \in \mathbf{X}_h \subset \mathbf{X}$ in the second equation of (23) and subtract the resulting equation from the second equation in (27), which leads to

$$-b(u-u_h,\mathbf{q}_h) + g(\mathbf{p}-\mathbf{p}_h,\mathbf{q}_h) + d(\lambda - \lambda_h(0,\mathbf{q}_h)) = 0$$

and

$$\begin{aligned} d(\lambda_h - \pi_h(\lambda),(0,\mathbf{q}_h)) &= -b(u-u_h,\mathbf{q}_h) + g(\mathbf{p}-\mathbf{p}_h,\mathbf{q}_h) + d(\lambda - \pi_h(\lambda),(0,\mathbf{q}_h)) \\ &\leq C(\|u-u_h\|_V + \|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2} + C\|\lambda - \pi_h(\lambda)\|_{H^s(\Gamma_c)}\|\mathbf{q}_h\|_{\mathbf{X}}), \end{aligned}$$

where $s = 0$ or $\frac{1}{2}$. We consider separately two particular cases of projection operators and derive the resulting error estimates. Namely, $s = 0$ and $\pi_h := \pi_h^0$ in the first case of $M_h = M_h^0$; otherwise, $s = \frac{1}{2}$ and $\pi_h := \pi_h^1$ if $M_h = M_h^{1,*}$ in the second case.

Case of projection π_h^0 *in* M_h^0. In view of (30) we have

$$\|\lambda - \pi_h(\lambda)\|_{L^2(\Gamma_c)} \leq Ch\|\lambda\|_{H^{\frac{3}{2}}(\Gamma_c)}. \tag{55}$$

On the other hand, using (29) we derive the following estimate:

$$\begin{aligned} \|\lambda_h - \pi_h(\lambda)\|_{L^2(\Gamma_c)} &\leq \beta_0^{-1} h^{-\frac{1}{2}} \sup_{\mathbf{V}_h \in V_h \times \mathbf{X}_h} \frac{d(\lambda_h - \pi_h(\lambda_h),\mathbf{V}_h)}{\|\mathbf{V}_h\|_{V_h\times\mathbf{X}_h}} \\ &\leq Ch^{-\frac{1}{2}}(\|u-u_h\|_V + \|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2} + Ch\|\lambda\|_{H^{\frac{3}{2}}(\Gamma_c)}). \end{aligned} \tag{56}$$

Case of projection π_h^1 *in* $M_h^{1,*}$. Using (32), we obtain

$$\|\lambda - \pi_h(\lambda)\|_{H^{\frac{1}{2}}(\Gamma_c)} \leq Ch\|\lambda\|_{H^{\frac{3}{2}}(\Gamma_c)}, \tag{57}$$

which together with the inf-sup condition (33) leads to

$$\begin{aligned} \beta\|\lambda_h - \pi_h(\lambda)\|_{H^{\frac{1}{2}}(\Gamma_c)} &\leq \sup_{\mathbf{V}_h \in V_h \times \mathbf{X}_h} \frac{d(\lambda_h - \pi_h(\lambda_h),\mathbf{V}_h)}{\|\mathbf{V}_h\|_{V_h\times\mathbf{X}_h}} \\ &\leq C(\|u-u_h\|_V + \|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2} + Ch\|\lambda\|_{H^{\frac{3}{2}}(\Gamma_c)}). \end{aligned} \tag{58}$$

By the triangular inequality

$$\|\lambda - \lambda_h\|_{H^{\frac{1}{2}}(\Gamma_c)} \leq \|\lambda - \pi_h(\lambda)\|_{H^{\frac{1}{2}}(\Gamma_c)} + \|\lambda_h - \pi_h(\lambda)\|_{H^{\frac{1}{2}}(\Gamma_c)}$$

and the estimates (56) and (55) (respectively, (58) and (57)), we obtain the inequality (53) (respectively, (54)). □

Assembling all the estimates given in Lemmas 4.2 and 4.5, we obtain the main result on error estimates.

THEOREM 4.6. *Let* $(u,\mathbf{p},\lambda)$ *be the solution of problem* (23). *Suppose that* $u_{|\Omega^1} \in H^2(\Omega^1)$, $u_{|\Omega^2} \in H^2(\Omega^2)$ *and also* $\mathbf{p}_{|\Omega^1} \in H^1(\Omega^1)^2$, $\mathbf{p}_{|\Omega^2} \in H^1(\Omega^2)^2$, *and assumption* (42) *holds. Let* $(\mathbf{U}_h,\lambda_h)$ *be the solution of* (27) *with* $M_h = M_h^0$. *Then the following estimate holds:*

$$\|u-u_h\|_V + \|\mathbf{p}-\mathbf{p}_h\|_{L^2(\Omega)^2} + \|\lambda - \lambda_h\|_{L^2(\Gamma_c)} \leq C(\delta,u,\mathbf{p})h^{\frac{1}{2}}. \tag{59}$$

When $M_h = M_h^{1,*}$ *the following estimate holds:*
